

BALANCED REALIZATIONS FOR LINEAR SYSTEMS: A VARIATIONAL APPROACH*

U. HELMKE†

Abstract. This paper develops a new geometric approach to balanced realizations, which enables balanced realizations for arbitrary linear systems to be defined and studied. For an arbitrary (unitarily invariant) strictly plurisubharmonic function on the set of realizations of a given transfer function, the class of realizations is considered that minimizes the function. Based on results from invariant theory and complex analysis, a general theorem on the existence and uniqueness properties of such function-minimizing realizations is derived. If the function is the sum of the traces of the controllability and observability gramians, the usual class of balanced realizations is obtained. Other choices of functions yield different, new classes of function-minimizing realizations.

1. Introduction. Balanced realizations in the state space for asymptotically stable linear systems are introduced by Moore [16] and have quickly found widespread use in model reduction and approximation theory of linear systems. They are defined by the characterizing property that their controllability and observability gramians are equal and diagonal and an explicit construction is available based on the singular value decomposition (SVD) of the associated Hankel operators. In signal processing, balanced realizations and singular values already appear in the early work of Mullis and Roberts [17], Hwang [10]. For parametrizations of classes of linear systems by balanced realizations, we refer to Ober [21].

The current use of balanced realizations is mainly restricted to the class of asymptotically stable linear systems, while only few attempts have been made to widen the class of linear systems that can be balanced. Kenney and Hower [13] introduce balanced realizations for a certain generic class of transfer functions, which also contains unstable systems. A different type of (LQG) balanced realizations was introduced by Verriest [25] and further studied by Jonkheere and Silverman [11]. Their construction is based on the unique positive definite solution of the algebraic Riccati equation and thus works for arbitrary minimal systems (A, B, C) .

From a theoretical viewpoint, the problem of finding balanced realizations of linear systems is very similar to a classical problem in physics, namely, that of diagonalizing the inertia tensor of a rigid body; see Arnold [3]. It is therefore of interest to see whether it is also possible to analyze balanced realizations in the same way as physicists analyze momentum tensors, i.e., via coadjoint orbits and moment maps.

In this paper, we develop such a new geometric approach, which enables us to define and study balanced realizations for arbitrary, i.e., possibly unstable, transfer functions in a coherent and systematic framework. Our main tool is a recent result due to Kempf and Ness [12], who consider moment maps in the context of invariant theory. The starting point for our analysis are arbitrary (unitarily invariant) Hermitian norms on the set of realizations (A, B, C) of a given transfer function. All realizations that minimize a given norm are called *norm minimal*, and, based on the Kempf–Ness theorem, we derive a general existence and uniqueness theorem for such norm minimal realizations. The result is then generalized for the class of smooth, unitarily invariant,

strictly plurisubharmonic functions, a special case being the plurisubharmonic function defined as the sum of traces of the controllability and observability gramians. If the function is the sum of traces of the controllability and observability gramians, the class of balanced realizations introduced by Moore is obtained. Other choices of functions yield different, new classes of function-minimizing realizations.

In § 2 the Kempf–Ness theorem (Theorem 2.1) is reviewed, together with an application, which shows how the Kempf–Ness theorem can be used to derive the singular value decomposition of a finite-dimensional complex operator. A recent generalization of the Kempf–Ness theorem is given, which is due to Azad and Loeb [4]. It is this theorem that enables us to develop a unified approach to balanced realizations, for both the balanced realizations introduced by Moore, as well as the balanced realizations derived from the Kempf–Ness theorem. We then apply the preceding theory in § 3 to prove our main technical result (Theorem 3.2) on the existence and uniqueness properties of norm-minimizing realizations of an arbitrary transfer function $G(s)$. Moore’s balanced realizations for asymptotically stable systems are derived as a special case. The simplest norm to which our main Theorem 3.2 applies is the Euclidean norm, introduced in § 4. Realizations that minimize the Euclidean norm are characterized for arbitrary transfer functions, as well as for symmetric and Hamiltonian transfer functions.

There are some antecedents of our results and techniques in the control theoretic literature. We mention, in particular, the work of Mullis and Roberts [17], [18], Hwang [10], Williamson [27], and Verriest and Gray [24], where (Moore) balanced realizations for asymptotically stable systems are also treated as a minimization problem for a suitable performance measure. However, the techniques used by these authors are quite different than ours. Byrnes and Willems [6] use moment maps in a similar way as is done here to study a least squares estimation problem.

2. The Kempf–Ness theorem. The purpose of this section is to recall an important recent result from invariant theory, which is due to Kempf and Ness [12]. A recent generalization using several complex variable theory has been obtained by Azad and Loeb [4] and plays a central role in our approach to the balanced realization problem. For references on invariant theory, we refer to Dieudonné and Carrell [7], Kraft [14], and Mumford and Fogarty [19].

Recall that a linear algebraic group is called *reductive* if the radical, i.e., the maximal connected solvable normal subgroup, is a torus.

We consider an arbitrary complex reductive algebraic Lie group G with maximal compact subgroup K . Examples of such groups are

- (i) The general linear group $GL(n, \mathbb{C})$ of invertible complex $n \times n$ matrices with maximal compact subgroup $U(n, \mathbb{C})$, the subgroup of $n \times n$ unitary matrices;
- (ii) The special linear group $SL(n, \mathbb{C})$ of invertible complex $n \times n$ matrices with determinant 1. A maximal compact subgroup is $SU(n, \mathbb{C})$, defined by all unitary $n \times n$ matrices of determinant one;
- (iii) The complex orthogonal group $O(n, \mathbb{C})$ of all complex $n \times n$ matrices T satisfying $T \cdot T' = I_n$. A maximal compact subgroup is the orthogonal group $O(n, \mathbb{R})$ of real orthogonal $n \times n$ matrices.

Let

$$(2.1) \quad \begin{aligned} \alpha : G \times V &\rightarrow V, \\ (g, x) &\mapsto g \cdot x \end{aligned}$$

denote a linear algebraic action of G on a finite-dimensional complex vector space V .

Thus α is an algebraic map such that, for all $x \in V$ and $g, h \in G$,

$$(2.2a) \quad e \cdot x = x,$$

$$(2.2b) \quad (gh) \cdot x = g \cdot (h \cdot x),$$

$$(2.2c) \quad \text{the map } V \rightarrow V, x \mapsto g \cdot x, \text{ is } \mathbb{C}\text{-linear}$$

hold (where $e \in G$ denotes the identity element). Given an element $x \in V$, the subset of V

$$(2.3) \quad G \cdot x = \{g \cdot x \mid g \in G\}$$

is called an orbit of G . Since G is a complex manifold, each orbit $G \cdot x$ is a complex manifold that is biholomorphic to the complex homogeneous space G/H , where $H = \{g \in G \mid g \cdot x = x\}$ is the stabilizer group.

We are interested in the critical points of K -invariant smooth functions, defined on G -orbits of an algebraic group action α . Here a function $\varphi : G \cdot x \rightarrow \mathbb{R}$ on a G -orbit $G \cdot x$ is called *K-invariant* if, for all $g \in G$ and all $k \in K$,

$$(2.4) \quad \varphi(kg \cdot x) = \varphi(g \cdot x)$$

holds. A specific example of such a situation arises as follows.

A Hermitian inner product $\langle \cdot, \cdot \rangle$ on V is called *K-invariant* if $\langle k \cdot x, k \cdot y \rangle = \langle x, y \rangle$ holds for all $x, y \in V$ and $k \in K$. This induces a K -invariant Hermitian norm on V , defined by $\|x\|^2 := \langle x, x \rangle$. Fix any such K -invariant Hermitian norm on V . For any given $x \in V$, we consider the following (induced) *distance functions* on $G \cdot x$ and G :

$$(2.5a) \quad \phi_x : G \cdot x \rightarrow \mathbb{R}, \quad g \cdot x \mapsto \|g \cdot x\|^2$$

and

$$(2.5b) \quad \phi_x : G \rightarrow \mathbb{R}, \quad g \mapsto \|g \cdot x\|^2.$$

Note that $\phi_x(g)$ is the (square of the) distance of the transformed vector $g \cdot x$ to the origin.

Let

$$(2.6) \quad \mu(x) := D\phi_x(e)$$

denote the Fréchet derivative of ϕ_x at the identity element e of G . This defines a map

$$(2.7) \quad \mu : V \rightarrow \mathfrak{g}^*, \quad x \mapsto \mu(x)$$

from V to the dual of the Lie algebra \mathfrak{g} of G . Note that μ is K -equivariant with respect to the coadjoint action of K on \mathfrak{g}^* . μ is called the *moment map* for the action (2.1). Thus the zeros of the moment map (2.7) are precisely the critical points of the smooth function defined on the G -orbits $G \cdot x = \{g \cdot x \mid g \in G\}$, which gives the (square of the) distance of an element $y = g \cdot x$ to the origin.

We can now state the Kempf–Ness result. For a proof, we refer to [12], [19]. See [23] for a real version of the theorem.

THEOREM 2.1 (Kempf–Ness). *Let $\alpha : G \times V \rightarrow V$ be an algebraic action of a complex reductive group G on a finite-dimensional vectorspace V and let $\|\cdot\|$ be a K -invariant*

Hermitian norm on V . Then

- (i) *The induced norm function $\phi_x: G \rightarrow \mathbb{R}$ has a global minimum (i.e., $\|g_0 \cdot x\| = \inf_{g \in G} \|g \cdot x\|$ for some $g_0 \in G$) if and only if there exists a critical point of $\phi_x: G \rightarrow \mathbb{R}$, if and only if the G -orbit $G \cdot x$ is a closed subset of V ;*
- (ii) *Let $G \cdot x$ be a closed subset of V . Every critical point of ϕ_x is a global minimum, and the set of global minima of $\phi_x: G \cdot x \rightarrow \mathbb{R}$ is a single, uniquely determined K -orbit.*

The above result has been generalized by Azad and Loeb [4] for plurisubharmonic functions defined on complex homogeneous spaces. To state their result, we recall some basic facts and definitions from several complex variable theory concerning plurisubharmonic functions. A basic reference is [15].

Assume that $X \subset \mathbb{C}^n$ is an open and connected subset of \mathbb{C}^n . An upper semicontinuous function $f: X \rightarrow \mathbb{R} \cup \{-\infty\}$ is called *plurisubharmonic* (*plush*) if the restriction of f to any one-dimensional complex disc is subharmonic, i.e., if, for all $a, b \in \mathbb{C}^n$ and $z \in \mathbb{C}$ with $a + bz \in X$, the function

$$(2.8) \quad z \mapsto f(a + bz)$$

is subharmonic. The class of plurisubharmonic functions constitutes a natural extension of the class of convex functions: Any convex function on X is plurisubharmonic. We list a number of further properties of plurisubharmonic functions.

Properties. (i) Let $f: X \rightarrow \mathbb{C}$ be holomorphic. Then the functions $\log |f|$ and $|f|^p$, $p > 0$ real, are plurisubharmonic (plush).

(ii) Let $f: X \rightarrow \mathbb{R}$ be twice continuously differentiable. Then f is plush if and only if the *Levi form* of f

$$(2.9) \quad L(f) := \left(\frac{\partial^2 f}{\partial z_i \partial \bar{z}_j} \right)$$

is positive semidefinite on X . We say that $f: X \rightarrow \mathbb{R}$ is *strictly plush* if the Levi form $L(f)$ is positive definite, i.e., $L(f) > 0$, on X .

(iii) Let $f, g: X \rightarrow \mathbb{R}$ be plush, $a \geq 0$ real. Then the functions $f + g$ and $a \cdot f$ are plush.

(iv) Let $\varphi: X \rightarrow Y$ be holomorphic and $f: Y \rightarrow \mathbb{R}$ be plush. Then $f \circ \varphi: X \rightarrow \mathbb{R}$ is plush. By property (iv), the notion of plurisubharmonic functions can be extended to functions on any complex manifold (and even on any complex analytic subvariety of \mathbb{C}^n). We then have the next important property;

(v) Let $M \subset X$ be a complex submanifold and $f: X \rightarrow \mathbb{R}$ plush. Then the restriction $f|_M: M \rightarrow \mathbb{R}$ of f to M is plush. Any norm on \mathbb{C}^n is certainly a convex function of its arguments and, therefore, plush. More generally, we have by property (v) the final property;

(vi) Let $\|\cdot\|$ be any norm on \mathbb{C}^n and let X be a complex analytic subvariety of \mathbb{C}^n . Then, for every $a \in \mathbb{C}^n$, the distance function $\phi_a: X \rightarrow \mathbb{R}$, $\phi_a(x) = \|x - a\|$, is plurisubharmonic.

If $\|\cdot\|$ is the induced norm of an Hermitian inner product on \mathbb{C}^n and $X \subset \mathbb{C}^n$ is a complex analytic submanifold, then the distance functions $\phi_a: X \rightarrow \mathbb{R}$, $\phi_a(x) = \|x - a\|^2$, are strictly plurisubharmonic.

For a proof of the following result, we refer to [4].

THEOREM 2.2 (Azad-Loeb). *Let $\alpha: G \times V \rightarrow V$ be an algebraic action of a complex reductive group G on a finite-dimensional complex vectorspace V and let $\varphi: G \cdot x \rightarrow \mathbb{R}$ be a smooth unitarily invariant strictly plurisubharmonic function defined on a G -orbit $G \cdot x$. Suppose that a global minimum of φ exists on $G \cdot x$. Then every critical point of φ is a point where φ assumes its global minimum. The set of global minima is a single K -orbit.*

Since any norm function induced by a K -invariant Hermitian inner product on V is strictly plurisubharmonic on any G -orbit, part (ii) of the Kempf–Ness theorem follows immediately from the Azad–Loeb result.

To see how the above theorems can be applied in a concrete situation, we discuss the following example, which is closely related to the SVD of a finite-dimensional operator.

Example (Singular value decomposition (SVD)). Here $G = GL(n, \mathbb{C})$ and $V = \mathbb{C}^{M \times n} \times \mathbb{C}^{n \times N}$, $n \leq \min(M, N)$. $K = U_n(\mathbb{C})$ and a K -invariant Hermitian norm on V is $(A^* := \bar{A}')$

$$(2.10) \quad \|(X, Y)\|^2 := \text{tr}(X^*X + YY^*),$$

i.e., is given by the sum of the norm squares of the entries of X and Y . The action on V is

$$\begin{aligned} \alpha: GL(n, \mathbb{C}) \times (\mathbb{C}^{M \times n} \times \mathbb{C}^{n \times N}) &\rightarrow \mathbb{C}^{M \times n} \times \mathbb{C}^{n \times N}, \\ (S, (X, Y)) &\mapsto (XS^{-1}, SY). \end{aligned}$$

The induced distance function on $GL(n, \mathbb{C})$ is

$$\phi_{(X, Y)}: GL(n, \mathbb{C}) \rightarrow \mathbb{R}$$

with

$$(2.11) \quad \phi_{(X, Y)}(S) = \text{tr}((S^*)^{-1}X^*XS^{-1}) + \text{tr}(SY Y^*S^*),$$

from which the moment map is easily computed.

We find that

$$(2.12) \quad \mu(X, Y) = 2(YY^* - X^*X),$$

and thus the critical points are characterized by

$$(2.13) \quad \mu(X, Y) = 0 \Leftrightarrow X^*X = YY^*.$$

Let $GL(n, \mathbb{C}) \cdot (X, Y) = \{(XS^{-1}, SY) | S \in GL(n, \mathbb{C})\}$ be an orbit of the $GL(n, \mathbb{C})$ -action α . It is not difficult to show that $GL(n, \mathbb{C}) \cdot (X, Y)$ is a closed subset of $\mathbb{C}^{M \times n} \times \mathbb{C}^{n \times N}$ if and only if $\text{rk}X = \text{rk}Y = \text{rk}XY$; see Kraft [14].

Thus the Kempf–Ness theorem gives the following result.

COROLLARY 2.3. (i) *There exists $S_0 \in GL(n, \mathbb{C})$, which minimizes the distance function $\phi_{(X, Y)}$ defined by (2.11) if and only if $\text{rk}X = \text{rk}Y = \text{rk}XY$;*

(ii) *Let $\text{rk}X = \text{rk}Y = n$. Every critical point of $\phi_{(X, Y)}$ minimizes $\phi_{(X, Y)}$. There exists $S \in GL(n, \mathbb{C})$, unique up to a unitary left factor, such that $(\tilde{X}, \tilde{Y}) := (XS^{-1}, SY)$ satisfies*

$$(2.14) \quad \tilde{X}^* \tilde{X} = \tilde{Y} \tilde{Y}^*.$$

Using the well-known fact that every rank n matrix $A \in \mathbb{C}^{M \times N}$ has a full rank factorization $A = XY$ and that $\{XS^{-1}, SY | S \in GL(n, \mathbb{C})\}$ is the whole class of such factorizations, Corollary 2.3 immediately implies the following result, which is equivalent to the SVD.

COROLLARY 2.4 (SVD). (i) *Every $A \in \mathbb{C}^{M \times N}$ with rank $A = n$ has a factorization $A = XY$, where X and Y are $M \times n$ and $n \times N$ full rank matrices, with*

$$(2.15) \quad X^*X = YY^*;$$

(ii) *If $A = X_1 Y_1 = X_2 Y_2$ are factorizations as in (i), then*

$$X_2 = X_1 T^{-1}, \quad Y_2 = T Y_1$$

for a unique unitary transformation $T \in U(n, \mathbb{C})$.

Remark 2.4. (a) The singular values of an operator A are defined as the (nonnegative) square roots of the eigenvalues of AA^* . Thus the singular values of A coincide with the eigenvalues of the positive definite Hermitian matrix (2.15). It follows that, for $rkX = rkY = rkXY$, the minimal value of the distance function (2.11) is given by the $2 \times$ (sum of the singular values of XY).

(b) Part (i) of Corollary 2.3 is equivalent to a result of Flanders [8]. Flanders's proof, as well as those of Anderson and Olkin [2] and Wimmer [28], is, however, quite different and longer than the above proof.

3. Norm and function balanced realizations. Consider the complex vector space of triples (A, B, C)

$$(3.1) \quad L(n, m, p) := \{(A, B, C) \in \mathbb{C}^{n \times n} \times \mathbb{C}^{n \times m} \times \mathbb{C}^{p \times n}\}.$$

The reductive group $GL(n, \mathbb{C})$ of complex invertible $n \times n$ matrices S acts on $L(n, m, p)$ via the algebraic group action

$$(3.2) \quad \begin{aligned} \sigma: GL(n, \mathbb{C}) \times L(n, m, p) &\rightarrow L(n, m, p), \\ (S, (A, B, C)) &\mapsto (SAS^{-1}, SB, CS^{-1}). \end{aligned}$$

The orbits of σ

$$(3.3) \quad \mathcal{O}(A, B, C) = \{(SAS^{-1}, SB, CS^{-1}) \mid S \in GL(n, \mathbb{C})\}$$

are complex homogeneous spaces and thus complex submanifolds of $L(n, m, p)$.

A function $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$ is called *unitarily invariant* if, for all unitary matrices $S \in U(n, \mathbb{C})$, $SS^* = I_n$,

$$(3.4) \quad f(SAS^{-1}, SB, CS^{-1}) = f(A, B, C)$$

holds. We are interested in the critical point structure of smooth, unitarily invariant plurisubharmonic functions $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$ on $GL(n, \mathbb{C})$ -orbits $\mathcal{O}(A, B, C)$. A particular case of interest is where the function $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$ is induced from a suitable norm on $L(n, m, p)$.

Thus let $\langle \cdot, \cdot \rangle$ denote a Hermitian inner product on the \mathbb{C} -vector space $L(n, m, p)$. The induced Hermitian norm of (A, B, C) is defined by

$$(3.5) \quad \|(A, B, C)\|^2 = \langle (A, B, C), (A, B, C) \rangle.$$

A Hermitian norm (3.5) is called unitarily invariant if

$$(3.6) \quad \|(SAS^{-1}, SB, CS^{-1})\| = \|(A, B, C)\|$$

holds for all unitary transformations S , $SS^* = I_n$, and $(A, B, C) \in L(n, m, p)$. Any Hermitian norm (3.5) defines a smooth strictly plurisubharmonic function

$$(3.7) \quad \begin{aligned} \phi: \mathcal{O}(A, B, C) &\rightarrow \mathbb{R}, \\ (SAS^{-1}, SB, CS^{-1}) &\mapsto \|(SAS^{-1}, SB, CS^{-1})\|^2 \end{aligned}$$

on $\mathcal{O}(A, B, C)$.

In the following, we fix a strictly proper transfer function $G(s) \in \mathbb{C}^{p \times m}(s)$ of McMillan degree n , and we also fix an initial controllable and observable realization $(A, B, C) \in L(n, m, p)$ of $G(s)$ as follows:

$$(3.8) \quad G(s) = C(sI - A)^{-1}B.$$

Thus the $GL(n, \mathbb{C})$ -orbit $\mathcal{O}(A, B, C)$ parametrizes the set of all (minimal) realizations of $G(s)$.

Our goal is to study the variation of the norm $\|(SAS^{-1}, SB, CS^{-1})\|^2$ as S varies in $GL(n, \mathbb{C})$. In particular, we seek to obtain answers to the following questions:

1. Given a function $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$, does there exist a realization of $G(s)$ that minimizes f ?

2. How can we characterize the set of realizations of a transfer function that minimize $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$?

As we will see, the Kempf–Ness and Azad–Loeb theorems give a rather general solution to these questions. Let $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}$ be a smooth function on $\mathcal{O}(A, B, C)$ and let $\|\cdot\|$ denote a Hermitian norm defined on $L(n, m, p)$.

DEFINITION 3.1. A realization

$$(3.9a) \quad (F, G, H) = (S_0AS_0^{-1}, S_0B, CS_0^{-1})$$

of a transfer function $G(s) = C(sI - A)^{-1}B$ is called *norm balanced* and *function balanced*, respectively, if the function

$$(3.9b) \quad \begin{aligned} \phi: GL(n, \mathbb{C}) &\rightarrow \mathbb{R}, \\ S &\mapsto \|(SAS^{-1}, SB, CS^{-1})\|^2 \end{aligned}$$

or the function

$$(3.10) \quad \begin{aligned} \mathcal{F}: GL(n, \mathbb{C}) &\rightarrow \mathbb{R}, \\ S &\mapsto f(SAS^{-1}, SB, CS^{-1}), \end{aligned}$$

respectively, has a critical point at $S = S_0$; i.e., if the Fréchet derivative

$$(3.11) \quad D\phi|_{S_0} = 0,$$

respectively,

$$(3.12) \quad D\mathcal{F}|_{S_0} = 0$$

vanishes. (F, G, H) is called *norm minimal* or *function minimizing* if $\phi(S_0)$, respectively, $\mathcal{F}(S_0)$, is a global minimum for the function (3.9) or (3.10) on $GL(n, \mathbb{C})$. See Fig. 1.

We need the following characterization of controllable and observable realizations as the $GL(n, \mathbb{C})$ -stable points for the similarity action $(A, B, C) \mapsto (SAS^{-1}, SB, CS^{-1})$.

LEMMA 3.2. $(A, B, C) \in L(n, m, p)$ is controllable and observable if and only if the following conditions are satisfied:

FIG. 1. Norm minimality.

(i) *The similarity orbit $\mathcal{O}(A, B, C) := \{(SAS^{-1}, SB, CS^{-1}) | S \in GL(n, \mathbb{C})\}$ is a closed subset of $L(n, m, p)$;*

(ii) $\dim_{\mathbb{C}} \mathcal{O}(A, B, C) = n^2$.

Proof. The necessity of (ii) is obvious, since $GL(n, \mathbb{C})$ acts freely on controllable and observable triples via similarity. The necessity of (i) follows from realization theory, since $\mathcal{O}(A, B, C)$ is a fibre of the continuous map

$$(3.13) \quad \begin{aligned} \mathcal{H}: L(n, m, p) &\rightarrow \prod_{i=1}^{\infty} \mathbb{C}^{p \times m}, \\ (F, G, H) &\mapsto (HF^i G | i \in \mathbb{N}_0), \end{aligned}$$

where $\prod_{i=1}^{\infty} \mathbb{C}^{p \times m}$ is endowed with the product topology.

To prove the sufficiency, let us assume that, e.g., (A, B) is not controllable while conditions (i), (ii) are satisfied. Without loss of generality,

$$A = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \quad C = [C_1, C_2],$$

and (A_{11}, B_1) controllable, $A_{ii}n_i \times n_i$ for $i = 1, 2$. Consider the one-parameter group of transformations

$$S_t := \begin{bmatrix} I_{n_1} & 0 \\ 0 & t^{-1}I_{n_2} \end{bmatrix} \in GL(n, \mathbb{C})$$

for $t \neq 0$. Then $(A_t, B_t, C_t) := (S_t A S_t^{-1}, S_t B, C S_t^{-1}) \in \mathcal{O}(A, B, C)$ with

$$A_t = \begin{bmatrix} A_{11} & tA_{12} \\ 0 & A_{22} \end{bmatrix}, \quad B_t := \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \quad C_t := [C_1, tC_2].$$

Since $\mathcal{O}(A, B, C)$ is closed,

$$(A_0, B_0, C_0) = \left(\begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix}, \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, [C_1, 0] \right) \in \mathcal{O}(A, B, C),$$

which is stabilized by $S_t, t \in \mathbb{C}^*$. This is a contradiction to (ii). Thus (A, B) must be controllable, and, similarly, (A, C) must be observable. This proves Lemma 3.2. \square

The following theorems are the main results of this paper. They are immediate consequences of Lemma 3.2 and Theorem 2.2 (Azad-Loeb) and Theorem 2.1 (Kempf-Ness), respectively. Recall that a continuous function $f: X \rightarrow \mathbb{R}$ on a topological space X is called *proper* if the inverse image $f^{-1}([a, b])$ of any compact interval $[a, b] \subset \mathbb{R}$ is a compact subset of X . For every proper map $f: X \rightarrow \mathbb{R}$, the image $f(X)$ is a closed subset of \mathbb{R} .

THEOREM 3.3. *Let $G(s) = C(sI - A)^{-1}B \in \mathbb{C}^{p \times m}(s)$ be a strictly proper rational transfer function of McMillan degree n . Let $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}_+ (\mathbb{R}_+ = [0, \infty[)$ be a smooth, unitarily invariant, strictly plurisubharmonic function on $\mathcal{O}(A, B, C)$, which is proper. Then*

- (a) *There exists a global minimum of f in $\mathcal{O}(A, B, C)$;*
- (b) *A controllable and observable realization (A, B, C) of $G(s)$ is function minimal if and only if it is function balanced;*
- (c) *If $(A_1, B_1, C_1), (A_2, B_2, C_2) \in \mathcal{O}(A, B, C)$ are minima of f , then there exists a uniquely determined unitary transformation $S \in U(n, \mathbb{C})$ such that*

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1}).$$

THEOREM 3.4. Let $\|\cdot\|^2$ be a unitarily invariant Hermitian norm on $L(n, m, p)$ and let $G(s) \in \mathbb{C}^{p \times m}(s)$ denote a strictly proper rational transfer function of McMillan degree n . Then

- (a) There exists a norm minimal realization (A, B, C) of $G(s)$;
- (b) A controllable and observable realization $(A, B, C) \in L(n, m, p)$ of $G(s)$ is norm minimal if and only if it is norm balanced;
- (c) If $(A_1, B_1, C_1), (A_2, B_2, C_2) \in L(n, m, p)$ are controllable and observable norm minimal realizations of $G(s)$, then there exists a uniquely determined unitary transformation $S \in U(n, \mathbb{C})$ such that

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1}).$$

Remark 3.5. (1) Let $G(s) \in \mathbb{R}^{p \times m}(s)$ denote a strictly proper *real* rational transfer function of McMillan degree n and let $\|\cdot\|^2$ be a unitarily invariant Hermitian norm on the complex vector space $L(n, m, p)$ (or let $f: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}_+$ be a smooth, unitarily invariant, strictly plurisubharmonic function on the complex similarity orbit that is proper and invariant under complex conjugation: $f(\bar{F}, \bar{G}, \bar{H}) = f(F, G, H)$ for all $(F, G, H) \in \mathcal{O}(A, B, C)$). Then Theorems 3.3 and 3.4 remain valid if conditions (a)–(c) in Theorems 3.3 and 3.4 are replaced by their respective versions (a')–(c') as follows (when we use “norm minimal,” we are referring to Theorem 3.4; “function minimal” refers to Theorem 3.3):

- (a') A *real* controllable and observable realization $(A, B, C) \in L(n, m, p)$ of $G(s)$ is norm (function) minimal if and only if it is norm (function) balanced;
- (b') There exists a *real* norm (function) minimal realization (A, B, C) of $G(s)$;
- (c') If $(A_1, B_1, C_1), (A_2, B_2, C_2) \in L(n, m, p)$ are *real* controllable and observable norm (function) minimal realizations of $G(s)$, then there exists a uniquely determined *real orthogonal* transformation $S \in O(n, \mathbb{R})$ such that

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1}).$$

This follows from the easily established fact that any similarity transformation $S \in GL(n, \mathbb{C})$, which transforms a given real controllable and observable realization (A_1, B_1, C_1) into a real realization $(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$, is necessarily real, i.e., $S \in GL(n, \mathbb{R})$. Alternatively, the result follows immediately from Slodowy's real version of Theorem 2.1 [23].

(2) The norm balanced realizations were also considered by Verriest [26], where they are referred to as “optimally clustered.” Also, Verriest points out the invariance of the norm under orthogonal transformations but does not show global minimality of the norm balanced realizations. An example is given that shows not every similarity orbit $\mathcal{O}(A, B, C)$ allows a norm balanced realization. In fact, by Theorem 2.1 (Kempf–Ness) (i), there exists a norm balanced realization in $\mathcal{O}(A, B, C)$ if and only if $\mathcal{O}(A, B, C)$ is a closed subset of $L(n, m, p)$.

Balanced realizations for the class of asymptotically stable linear systems were first introduced by Moore [16] and are defined by the condition that the controllability and observability gramians are equal and diagonal. We will now show that these balanced realizations can be treated as a special case of our above theorems. For simplicity, we consider only the discrete-time case and complex systems (A, B, C) .

DEFINITION 3.5. A complex realization (A, B, C) is called *N-balanced* if and only if

$$(3.14) \quad \sum_{k=0}^N A^k B B^* (A^*)^k = \sum_{k=0}^N (A^*)^k C^* C A^k.$$

An asymptotically stable realization (A, B, C) (i.e., $\sigma(A) < 1$) is said to be *balanced*, or ∞ -balanced, if and only if

$$(3.15) \quad \sum_{k=0}^{\infty} A^k B B^* (A^*)^k = \sum_{k=0}^{\infty} (A^*)^k C^* C A^k.$$

Note that the above terminology differs slightly from the usual terminology in the sense that the controllability, respectively, observability, gramians are not required to be diagonal. Of course, this can always be achieved by an orthogonal change of basis in the state space. In Verriest and Gray [24], realizations (A, B, C) satisfying (3.14) or (3.15) are called essentially balanced.

To prove the existence of (N) -balanced realizations, we consider the minimization problem for the “ N -gramian norm” function

$$(3.16) \quad f_N(A, B, C) := \text{tr} \sum_{k=0}^N (A^k B B^* (A^*)^k + (A^*)^k C^* C A^k)$$

for $N \in \mathbb{N} \cup \{\infty\}$. Let $(A, B, C) \in L(n, m, p)$ be a controllable and observable realization with $N \geq n$. Consider the smooth unitarily invariant function on the $GL(n, \mathbb{C})$ -orbit

$$(3.17) \quad \begin{aligned} f_N: \mathcal{O}(A, B, C) &\rightarrow \mathbb{R}_+, \\ (SAS^{-1}, SB, CS^{-1}) &\mapsto f_N(SAS^{-1}, SB, CS^{-1}), \end{aligned}$$

where $f_N(SAS^{-1}, SB, CS^{-1})$ is defined by (3.16) for any $N \in \mathbb{N} \cup \{\infty\}$. It is not difficult to show that $f_N: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}_+$ is proper for $N \geq n$; see Perkins, Helmke, and Moore [22]. Using properties (i)–(v) for plurisubharmonic functions that follow Theorem 2.1, it is not difficult to show that f_N is strictly plurisubharmonic for any $N \in \mathbb{N} \cup \{\infty\}$, $N \geq n$.

Thus we can apply Theorem 3.3. To compute the critical points of $f_N: \mathcal{O}(A, B, C) \rightarrow \mathbb{R}_+$, we consider the induced function on $GL(n, \mathbb{C})$

$$(3.18) \quad \begin{aligned} F_N: GL(n, \mathbb{C}) &\rightarrow \mathbb{R}_+, \\ S &\mapsto F_N(SAS^{-1}, SB, CS^{-1}) \end{aligned}$$

for any $N \in \mathbb{N} \cup \{\infty\}$. A simple calculation of the gradient vector ∇F_N at $S = I_n$ shows that

$$(3.19) \quad \nabla F_N(I_n) = 2 \sum_{k=0}^N (A^k B B^* (A^*)^k - (A^*)^k C^* C A^k)$$

for any $N \in \mathbb{N} \cup \{\infty\}$. We conclude the following result.

COROLLARY 3.6. *Given a complex rational strictly proper transfer function $G(s)$ of McMillan degree n , then, for all finite $N \geq n$, there exists a realization (A_*, B_*, C_*) of $G(s)$ that is N -balanced. If (A_1, B_1, C_1) , (A_2, B_2, C_2) are N -balanced realizations of $G(s)$ of order n , $N \geq n$, then*

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$$

for a uniquely determined unitary transformation $S \in U(n, \mathbb{C})$. (A_1, B_1, C_1) is N -balanced if and only if it minimizes the N -gramian norm taken over all realizations of $G(s)$ of order n .

This also follows immediately from Corollary 2.3 and from the SVD (Corollary 2.4), applied to the factorization of the $N \times N$ -block Hankel $\mathcal{H}_N = O_N \cdot R_N$, where $R_N := (B, AB, \dots, A^N B)$, $O_N := (C', A'C', \dots, (A')^N C')'$.

For asymptotically stable linear systems, we obtain the following amplification of Moore's fundamental existence and uniqueness theorem for balanced realizations.

THEOREM 3.7. *Given a complex rational strictly proper transfer function $G(s)$ of McMillan degree n and with all poles in the open unit disc, there exists a balanced realization (A_1, B_1, C_1) of $G(s)$ of order n . If $(A_1, B_1, C_1), (A_2, B_2, C_2)$ are two balanced realizations of $G(s)$ of order n , then*

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$$

for a uniquely determined unitary transformation $S \in U(n, \mathbb{C})$. An n -dimensional realization (A_1, B_1, C_1) of $G(s)$ is balanced if and only if (A_1, B_1, C_1) minimizes the gramian norm (3.17) (for $N = \infty$), taken over all realizations of $G(s)$ of order n .

We consider a (discrete time) asymptotically stable transfer function $G(s) \in \mathbb{C}^{p \times m}(s)$ of McMillan degree n . Let $\sigma_1 \geq \dots \geq \sigma_n$ denote the singular values of the induced Hankel operator; see Moore [16], Glover [9]. For any $p \in \mathbb{N}$, let

$$(3.20) \quad S_p(G) := \left(\sum_{j=1}^n \sigma_j^p \right)^{1/p}$$

and, for any stable (A, B, C) , let

$$|(A, B, C)|_p := (\text{tr}(W_C^p + W_O^p))^{1/p},$$

where

$$W_C := \sum_{k=0}^{\infty} A^k B B^* (A^*)^k,$$

respectively,

$$W_O := \sum_{k=0}^{\infty} (A^*)^k C^* C A^k,$$

are the controllability, respectively, observability, gramians. The following result has been shown by Williamson [27], in the special case where $p = 1$. His proof is quite different than ours and is based on an inequality of Mullis and Roberts [17].

THEOREM 3.8. *Let (A, B, C) be a controllable and observable realization of the asymptotically stable transfer function $G(s)$. Then, for all $p \in \mathbb{N}$,*

$$|(A, B, C)|_p \geq 2^{1/p} \cdot S_p(G).$$

(A, B, C) is balanced if and only if, for one $p \in \mathbb{N}$ (and hence for all p),

$$(3.21) \quad |(A, B, C)|_p = 2^{1/p} \cdot S_p(G),$$

where $S_p(G)$ is defined by (3.20).

Proof. A straightforward computation of the gradient vector of the function $\phi: GL(n, \mathbb{C}) \rightarrow \mathbb{R}, S \mapsto |(SAS^{-1}, SB, CS^{-1})|_p^p$ at $S = I_n$ gives

$$(3.22) \quad \nabla \Phi(I_n) = 2p(W_C^p - W_O^p).$$

Thus (A, B, C) is function balanced for $||_p$ if and only if $W_C(A, B, C)^p = W_O(A, B, C)^p$, i.e., if and only if (A, B, C) is balanced. Thus the minimal value of $|(A, B, C)|_p$ is achieved (where (A, B, C) runs through all controllable and observable realizations of $G(s)$) if and only if (A, B, C) is balanced (this uses Theorem 3.7). In the balanced case,

$$|(A, B, C)|_p = 2^{1/p} \cdot (\text{tr } W_C^p)^{1/p}.$$

By Remark 2.4, $\text{tr } W_C = S_1(G)$ and, similarly, $\text{tr } W_C^p = [S_p(G)]^p$. The result follows. \square

4. New classes of balanced realizations. The simplest candidate of a unitarily invariant Hermitian norm on $L(n, m, p)$ is the *standard Euclidean norm*, defined by

$$(4.1) \quad \|(A, B, C)\|^2 := \operatorname{tr} AA^* + \operatorname{tr} BB^* + \operatorname{tr} C^*C,$$

where $X^* = \bar{X}'$ denotes Hermitian transpose. An application of Theorem 3.4 to this norm yields the following result, which describes a new class of norm minimal realizations.

THEOREM 4.1. *Let $G(s)$ be a real rational strictly proper transfer function of McMillan degree n . Then*

- (i) *There exists a (real) controllable and observable realization (A, B, C) of $G(s)$ with*

$$(*) \quad AA' + BB' = A'A + C'C.$$

- (ii) *If $(A_1, B_1, C_1), (A_2, B_2, C_2)$ are (real) controllable and observable realizations of $G(s)$ satisfying $(*)$, then there exists a unique orthogonal transformation $S \in O(n, \mathbb{R})$, with*

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1}).$$

- (iii) *An n -dimensional realization (A, B, C) of $G(s)$ satisfies $(*)$ if and only if it minimizes the Euclidean norm (4.1), taken over all possible n -dimensional realizations of $G(s)$.*

Proof. For any controllable and observable realization (A, B, C) of $G(s)$, consider the function $\phi: GL(n, \mathbb{R}) \rightarrow \mathbb{R}$ defined by the Euclidean norm

$$\phi(S) = \|(SAS^{-1}, SB, CS^{-1})\|^2.$$

Thus $\phi(S) = \operatorname{tr}(SAS^{-1}(S')^{-1}A'S') + \operatorname{tr}(SBB'S') + \operatorname{tr}((S')^{-1}C'CS^{-1})$. The gradient vector of ϕ at $S = I_n$ is

$$(4.2) \quad \nabla \phi(I_n) = 2(AA' - A'A + BB' - C'C),$$

and thus (A, B, C) is norm balanced for the Euclidean norm (4.1) if and only if

$$AA' - A'A + BB' - C'C = 0,$$

which is equivalent to $(*)$. The result now follows immediately from Theorem 3.2. \square

Similar results hold for symmetric or Hamiltonian transfer functions. Recall that a real rational $m \times m$ -transfer function $G(s)$ is called *symmetric*, respectively, *Hamiltonian*, if for all $s \in \mathbb{C}$

$$(4.3) \quad G(s) = G(s)',$$

respectively,

$$(4.4) \quad G(s) = G(-s)'$$

(where $'$ denotes transpose).

Every strictly proper symmetric transfer function $G(s)$ of McMillan degree n has a minimal *signature symmetric* realization (A, B, C) satisfying

$$(4.5) \quad (AI_{pq})' = AI_{pq}, \quad C' = I_{pq}B,$$

where $I_{pq} = \operatorname{diag}(\varepsilon_1, \dots, \varepsilon_n)$ with

$$(4.6) \quad \varepsilon_i = \begin{cases} 1 & i = 1, \dots, p, \\ -1 & i = p+1, \dots, p+q = n. \end{cases}$$

Here $p - q$ is the Cauchy–Maslov index of $G(s)$; cf. Anderson and Bitmead [1], Byrnes and Duncan [5]. Similarly, every strictly proper Hamiltonian transfer function $G(s) \in \mathbb{R}(s)^{m \times m}$ of McMillan degree $2n$ has a minimal Hamiltonian realization (A, B, C) satisfying

$$(4.7) \quad (AJ)' = AJ, \quad C' = JB,$$

where

$$(4.8) \quad J = \begin{bmatrix} 0 & -I_n \\ I_n & 0 \end{bmatrix}$$

is the standard complex structure. Let $O(p, q)$, respectively, $Sp(n, \mathbb{R})$, denote the (real) isotropy groups of I_{pq} , respectively, J , i.e.,

$$(4.9a) \quad T \in O(p, q) \Leftrightarrow T' I_{pq} T = I_{pq}, \quad T \in GL(n, \mathbb{R}),$$

$$(4.9b) \quad T \in Sp(n, \mathbb{R}) \Leftrightarrow T' J T = J, \quad T \in GL(2n, \mathbb{R}).$$

THEOREM 4.2. (i) *Every strictly proper symmetric transfer function $G(s) \in \mathbb{R}(s)^{m \times m}$ with McMillan degree n and Cauchy–Maslov index $p - q$ has a controllable and observable signature symmetric realization (A, B, C) satisfying*

$$(4.10a) \quad (A I_{pq})' = A I_{pq}, \quad C' = I_{pq} B,$$

$$(4.10b) \quad A A' + B B' = A' A + C' C.$$

(ii) *If $(A_1, B_1, C_1), (A_2, B_2, C_2)$ are two minimal realizations of $G(s)$ satisfying (4.10a) and (4.10b), then there exists a unique orthogonal transformation $S = \text{diag}(S_1, S_2) \in O(p) \times O(q) \subset O(n)$ with*

$$(A_2, B_2, C_2) = (S A_1 S^{-1}, S B_1, C_1 S^{-1}).$$

A similar result holds for Hamiltonian transfer functions.

THEOREM 4.3. (i) *Every strictly proper Hamiltonian transfer function $G(s) \in \mathbb{R}(s)^{m \times m}$ with McMillan degree $2n$ has a controllable and observable Hamiltonian realization (A, B, C) satisfying*

$$(4.11a) \quad (AJ)' = AJ, \quad C' = JB,$$

$$(4.11b) \quad A A' + B B' = A' A + C' C.$$

(ii) *If $(A_1, B_1, C_1), (A_2, B_2, C_2)$ are two minimal realizations of $G(s)$ satisfying (4.11a) and (4.11b), then there exists a unique symplectic transformation $S \in Sp(n, \mathbb{R}) \cap O(2n; \mathbb{R})$ with*

$$(A_2, B_2, C_2) = (S A_1 S^{-1}, S B_1, C S^{-1}).$$

Proofs. We first prove Theorem 4.3. Let $Sp(n, \mathbb{C})$ denote the complex symplectic group; i.e., $T \in Sp(n, \mathbb{C})$ if and only if $T \in GL(2n, \mathbb{C})$ and $T' J T = J$. $Sp(n, \mathbb{C})$ is a reductive Lie group with maximal compact subgroup $K = Sp(n; \mathbb{C}) \cap U_{2n}(\mathbb{C})$. Let V denote the complex vector space of all triples $(A, B, C) \in \mathbb{C}^{2n \times 2n} \times \mathbb{C}^{2n \times m} \times \mathbb{C}^{m \times 2n}$ satisfying $(AJ)' = AJ, JB = C'$. The Euclidean norm (4.1) defines a K -invariant Hermitian norm on V . By Lemma 3.3, the $Sp(n, \mathbb{C})$ -orbit of a point $(A, B, C) \in V$ is closed if (A, B, C) is controllable and observable. Theorem 4.3 now follows immediately from Theorem 2.2 (Kempf–Ness), once it is observed that Remark 3.4 remains in force (with the appropriate modification) and that $Sp(n, \mathbb{R}) \cap O(2; \mathbb{R})$ is the set of real points of K .

Unfortunately, the above direct proof does not work for Theorem 4.2, since $O(p, q)$ is not reductive. We therefore proceed in a different way. We first prove (i). By Theorem

4.1, there exists a minimal realization (A, B, C) of the symmetric transfer function $G(s)$, which satisfies (4.10b), and (A, B, C) is unique up to an orthogonal change of basis $S \in O(n; \mathbb{R})$. By the symmetry of $G(s)$, with (A, B, C) , (A', C', B') is also a realization of $G(s)$. Note that if (A, B, C) satisfies (4.10b), (A', C', B') also satisfies (4.10b). Thus, by the above uniqueness property (ii) of Theorem 4.1, there exists a unique $S \in O(n; \mathbb{R})$ with

$$(4.12) \quad (A', C', B') = (SAS', SB, CS').$$

By transposing (4.12), we also obtain that

$$(4.13) \quad (A, B, C) = (SA'S', SC', B'S')$$

or, equivalently,

$$(4.14) \quad (A', C', B') = (S'AS, S'B, CS).$$

Thus (by minimality of (A, B, C)) $S = S'$ is symmetric orthogonal. A straightforward argument (see Byrnes and Duncan [5] for details) shows that the signature of S is equal to the Cauchy–Maslov index $p - q$ of $G(s) = C(sI - A)^{-1}B$. Thus $S = T'I_{pq}T$ for $T \in O(n; \mathbb{R})$, and the new realization

$$(F, G, H) := (TAT', TB, CT')$$

satisfies (4.10a), (4.10b).

To prove part (ii) of Theorem 4.2, let

$$(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$$

be two realizations of $G(s)$ that satisfy (4.10a), (4.10b). Byrnes and Duncan [5, Thm. 4.1] show that (4.10a) implies that $S \in O(p, q)$. By Theorem 4.1(ii), also $S \in O(n, \mathbb{R})$. Since $O(p) \times O(q) = O(p, q) \cap O(n, \mathbb{R})$, the result follows. \square

Remark 4.4. (1) There is a formal analogy between norm minimal realizations (A, B, C) satisfying

$$(**) \quad AA' - A'A + BB' - C'C = 0$$

and balanced realizations obtained by the Riccati equation; see Jonkheere and Silverman [11]. Riccati balanced realizations are defined by the following result, whose proof is immediate, by letting T denote the positive definite square root of the uniquely determined positive definite stabilizing solution of the algebraic Riccati equation; see [25] and [11] for details.

PROPOSITION. *Given any controllable and observable n -dimensional realization $(\tilde{A}, \tilde{B}, \tilde{C})$, there exists a state space equivalent realization $(A, B, C) = (T\tilde{A}T^{-1}, T\tilde{B}, \tilde{C}T^{-1})$ satisfying*

$$(***) \quad A + A' + BB' - C'C = 0.$$

If (A_i, B_i, C_i) , $i = 1, 2$ are two such realizations, there exists a unique orthogonal transformation $S \in O(n, \mathbb{R})$ with $(A_2, B_2, C_2) = (SA_1S^{-1}, SB_1, C_1S^{-1})$.

Note the apparent similarity between formulas (**) and (***).

(2) Euclidean norm balanced realizations (**) of Theorem 4.1 were also considered by Verriest [26]. See part (2) of Remark 3.5.

Acknowledgments. The author thanks the two anonymous referees for their careful review of this paper.

EXISTENCE THEOREMS FOR POSITIVE SEMIDEFINITE AND SIGN INDEFINITE STABILIZING SOLUTIONS OF H_∞ RICCATI EQUATIONS*

GARY HEWER†

Abstract. The existence of both positive semidefinite and sign indefinite stabilizing solutions of H_∞ -type Riccati equations is determined via joint eigenvalue and Hamiltonian tests. These tests determine the inertia properties of the solutions. They are dependent on a formula—derived in this paper—that shows how the solution of game Riccati equations can be decomposed into a sum of two well-known Riccati equations, namely, the standard filter Riccati equation and the bounded real Riccati equation. Other properties of stabilizing solutions such as solution partial order, spectral radius monotonicity, and rank are also discussed.

Key words. H_∞ -optimal control, Riccati equations, bounded real system

1. Introduction. This paper presents a collection of results on the game Riccati equation

$$(1.1) \quad A^T X + XA + X \left(\frac{1}{\gamma^2} B_1 B_1^T - B_2 B_2^T \right) X + C^T C = 0.$$

The existence of a stabilizing positive definite or positive semidefinite solution $X(\gamma)$ of the game Riccati equation with real parameter γ defined on some infinite half-line $0 < \gamma \leq \infty$ is a prerequisite for an H_∞ -control problem to have a solution [4]. Here A , B_1 , B_2 , and C are real $n \times n$, $n \times p$, $n \times m$, and $q \times n$ real matrices, respectively, and A^T denotes the matrix transpose. It is the objective of this paper to show that many properties of $X(\gamma)$ can be connected to the standard filter algebraic Riccati equation (FARE)

$$(1.2) \quad AZ + ZA^T - ZC^T CZ + B_2 B_2^T = 0$$

and to the bounded real Riccati equation (BRRE)

$$(1.3) \quad (A - ZC^T C)W + W(A - C^T CZ)^T - WC^T CW - \frac{1}{\gamma^2} B_1 B_1^T = 0$$

by noting that any solution of the “dual” game Riccati equation

$$(1.4) \quad AY + YA^T - YC^T CY + B_2 B_2^T - \frac{1}{\gamma^2} B_1 B_1^T = 0$$

can be written as the sum of the appropriate solution of FARE and BRRE (provided they all exist). The technique of expressing the solution of the dual Riccati equation (1.4) as the sum of two terms, one a solution to a filter Riccati equation and one a solution of a bounded real Riccati equation, can be found within the proofs presented in Willems [25], with a subsequent appearance in Molinari [16].

While real symmetric stabilizing solutions of the control algebraic Riccati equation (CARE) are always positive semidefinite and maximal [13], there can exist sign indefinite stabilizing solutions of (1.1) and (1.4). Nevertheless, if they exist, the stabilizing solutions of these Riccati equations are always unique [19]. The following

† Code 39103, Naval Weapons Center, China Lake, California 93555.

variant of Theorem 3.3 unites all of these Riccati equations and provides an eigenvalue characterization of the nonsingular sign indefinite stabilizing solutions, as well as a test criterion that can be used to determine a lower bound for the γ semi-infinite interval of existence for $X(\gamma)$. A positive definite unique stabilizing solution of (1.1) exists on some γ half-line if and only if (i) an antistabilizing negative definite minimal solution Z_- of (1.2) exists, (ii) the negative semidefinite maximal antistabilizing solution $W_-(\gamma)$ of (1.3) exists on the same γ half-line, and (iii) the spectral radius of $-W_-(\gamma)Z_-^{-1}$ is less than unity. This spectral radius test criterion is apparently new and is one of the main results of this paper.

The results are more delicate for positive semidefinite stabilizing solutions $X(\gamma)$ of (1.1) defined on some half-line, since the antistabilizing solution of FARE need not exist [7]. Nevertheless, when $X(\gamma)$ exists, by a fundamental theorem about the regularity of solutions of (1.1) summarized in the Appendix, the “slightly” perturbed game Riccati equation for some sufficiently small positive real parameter ε

$$(1.5) \quad A^T X^\varepsilon + X^\varepsilon A + X^\varepsilon \left(\frac{1}{\gamma^2} B_1 B_1^T - B_2 B_2^T \right) X^\varepsilon + C^T C + \varepsilon I = 0$$

always has a positive definite stabilizing solution $X^\varepsilon(\gamma)$ defined on the same γ -half-line. Since the matrix norm of the difference between $X^\varepsilon(\gamma)$ and $X(\gamma)$ tends to zero as $\varepsilon \downarrow 0$, the spectral radius test in Theorem 3.3 is reformulated for the positive semidefinite stabilizing solution $X(\gamma)$ by utilizing the “nearby” solutions $X^\varepsilon(\gamma)$.

The game Riccati equations required for a full solution to the H_∞ -control problem are more general than (1.1) and (1.4), which are studied in the first two sections. However, all of the assumptions required in the main theorems and lemmas in those sections are weak enough such that they are directly applicable to the more general Riccati equations. Actually, a full solution to the H_∞ -control problem requires two Riccati equations, which are

$$(1.6) \quad \begin{aligned} & (A - B_2 E_1^{-1} D_{12}^T C_1)^T \hat{X} + \hat{X} (A - B_2 E_1^{-1} D_{12}^T C_1) \\ & + \hat{X} \left(\frac{1}{\gamma^2} B_1 B_1^T - B_2 E_1^{-1} B_2^T \right) \hat{X} \\ & + C_1^T (I - D_{12} E_1^{-1} D_{12}^T) C_1 = 0, \end{aligned}$$

$$(1.7) \quad \begin{aligned} & (A - B_1 D_{21}^T E_2^{-1} C_2) \hat{Y} + \hat{Y} (A - B_1 D_{21}^T E_2^{-1} C_2)^T \\ & + \hat{Y} \left(\frac{1}{\gamma^2} C_1^T C_1 - C_2^T E_2^{-1} C_2 \right) \hat{Y} \\ & + B_1 (I - D_{21}^T E_2^{-1} D_{21}) B_1^T = 0. \end{aligned}$$

Here the superscript -1 denotes the matrix inverse, and I is the $n \times n$ identity matrix. The matrices in these equations arise in a linear system of the form

$$\begin{aligned} \dot{x} &= Ax + B_1 w + B_2 u, \\ z &= C_1 x + D_{12} u, \\ y &= C_2 x + D_{21} w, \end{aligned}$$

where x is the $n \times 1$ state vector, w is the $n \times p$ disturbance input, u is the $n \times m$ control input, z is the $q \times n$ error output, and y is the $r \times n$ measured output. Related variants of these state equations are described in Safonov and Limebeer [22] and Zhou and Khargonekar [27]. To ensure that the H_∞ -control problem has a solution, Petersen,

Anderson, and Jonckheere [18] require that this system satisfy the following additional assumptions (see also Glover and Doyle [6] and Bernstein and Haddad [1]): $D_{12}^T D_{12} = E_1 > 0$, $D_{21} D_{21}^T = E_2 > 0$,

$$(1.8) \quad \text{rank} \begin{bmatrix} A - j\omega I & B_2 \\ C_1 & D_{12} \end{bmatrix} = n + m \quad \text{for all } \omega \geq 0,$$

$$(1.9) \quad \text{rank} \begin{bmatrix} A - j\omega I & B_1 \\ C_2 & D_{21} \end{bmatrix} = n + r \quad \text{for all } \omega \geq 0.$$

To qualify for the H_∞ -control problem, both game Riccati equations (1.6) and (1.7) must have positive semidefinite stabilizing solutions $X_\infty(\gamma)$ and $Y_\infty(\gamma)$ on a common γ interval of existence and satisfy the spectral inequality $\rho(X_\infty(\gamma)Y_\infty(\gamma)) < \gamma^2$ [6].

Throughout the paper, the γ -dependent monotonic ordering of the maximal and minimal solutions of the game Riccati equations on the γ -half-line is established. These monotonicity results are extended to give a monotonicity result for the spectral radius $\rho(X_\infty(\gamma)Y_\infty(\gamma))$. In the final section, a complete description of the rank of the stabilizing solution of the game Riccati equation is presented, including the fact that the rank is independent of γ . While neither of these apparently new results are unexpected, nevertheless, they do further characterize the γ partial ordering and γ -independent rank properties of these solutions.

2. Stabilizing and antistabilizing solutions of the dual game Riccati equation. In this section a formula is derived that expresses the maximal stabilizing solution of the dual game Riccati equation as the sum of the maximal stabilizing solution of the FARE and the minimal stabilizing solution of the BRRE. A complementary formula for the minimal antistabilizing solution of the dual game Riccati equation is also included. Using these formulas a simple eigenvalue test determines the inertia of either solution.

Before deriving these results, these additional concepts are introduced. The *inertia* of the matrix \hat{M} is the triple $\text{In}(\hat{M}) = (\nu(\hat{M}), \delta(\hat{M}), \pi(\hat{M}))$, where $\nu(\hat{M})$, $\delta(\hat{M})$, $\pi(\hat{M})$ are, respectively, the number of eigenvalues of \hat{M} counting multiplicities with negative, zero, and positive real parts [14]. The symmetric matrix \hat{M} is *nonsingular* if $\delta(\hat{M}) = 0$. An $n \times n$ symmetric matrix \hat{M} for $n \geq 2$ is *sign indefinite* if $\text{In}(\hat{M}) = (\nu(\hat{M}), 0, \pi(\hat{M}))$ with $\nu(\hat{M}) > 0$ and $\pi(\hat{M}) > 0$. Here and elsewhere, $X > P(X \geq P)$ denotes the usual partial order for symmetric matrices and means that $X - P$ is positive (semi)definite [10].

Recall that a real symmetric solution P of the algebraic Riccati equation

$$(2.1) \quad A^T P + PA - PMP + Q = 0$$

with real symmetric matrices M and Q , $M \geq 0$ is a *maximal (minimal)* [7], [21] solution if $P \geq \hat{P}$ ($P \leq \hat{P}$) for any other symmetric solution \hat{P} of (2.1). Whenever they exist, the *maximal and minimal* solutions will be denoted by P_+ and P_- , respectively. Independent of the inertia of M , a real symmetric matrix P that satisfies (1.5) is said to be *stabilizing* if $A - MP$ is stable. The matrix $A - MP$ is *stable* if the real part of each eigenvalue of $(A - MP)$ is less than zero (i.e., $\text{Re } \lambda_i(A - MP) < 0$, $i = 1, \dots, n$). If all of the eigenvalues of $A - MP$ satisfy the inequality $\text{Re } \lambda_i(A - MP) \leq 0$, then P is a *strong solution*. P is an *antistabilizing* solution if $-(A - MP)$ is stable. The spectral radius [10] of an $n \times n$ matrix M is the maximum modulus over the set of all eigenvalues $\rho(M) = \max_{1 \leq j \leq n} |\lambda_j(M)|$. The 2-norm of M is $\|M\|_2 = [\rho(M^T M)]^{1/2}$ and is the maximum singular value of M .

Associated with the algebraic Riccati equation (1.5) is the $2n \times 2n$ Hamiltonian matrix

$$(2.2) \quad H = \begin{pmatrix} A & -M \\ -Q & -A^T \end{pmatrix}.$$

If P is any solution of (2.1), then $(P, -I)H \begin{pmatrix} I \\ P \end{pmatrix} = 0$. The notation $\text{Ric}(P, H) = 0$ will symbolize this relation between a solution of the Riccati equation (2.1) and the Hamiltonian (2.2). The Hamiltonians for the game Riccati equation (1.1) and the filter algebraic Riccati equation are, respectively,

$$H_\infty(\gamma) = \begin{pmatrix} A & (1/\gamma^2)B_1B_1^T - B_2B_2^T \\ -C^TC & -A^T \end{pmatrix}, \quad H_2 = \begin{pmatrix} A^T & -C^TC \\ -B_2B_2^T & -A \end{pmatrix}.$$

Whenever the solutions Z_+ or Z_- for FARE exist, define the Hamiltonian for BRRE as

$$H(Z_\pm, \gamma) = \begin{pmatrix} (A - Z_\pm C^TC)^T & -C^TC \\ (1/\gamma^2)B_1B_1^T & -(A - Z_\pm C^TC) \end{pmatrix}.$$

An eigenvalue λ of A is (A, B) controllable if $\text{rank}[A - \lambda I, B] = n$. The pair (A, B) is stabilizable if and only if (A, B) has no uncontrollable eigenvalue in the closed right half plane. Observability and detectability follow by duality.

Recently, Petersen, Anderson, and Jonckheere [18] have proved the strict bounded real lemma for nonminimal realizations. For completeness, their lemma will be repeated here with an added statement and proof about the minimality of the stabilizing solution. Willems [25] has proved, again for A stable, that if the bounded real Riccati equation admits a real symmetric solution, then $\|G(s)\|_\infty < 1$.

LEMMA 2.1 (strict bounded real lemma). *The following are equivalent:*

- (i) A is stable and the transfer matrix $G(s) = C(sI - A)^{-1}B$ evaluated on the imaginary axis satisfies the inequality $\|G(s)\|_\infty = \max_{\omega \in \mathbb{R}} \|G(j\omega)\|_2 < 1$,
- (ii) The Riccati equation

$$(2.3) \quad A^TP + PA + PBB^TP + C^TC = 0$$

has a stabilizing solution $P_S \geq 0$. Moreover, the solution P_S is unique and minimal.

Proof. Suppose that P is any other real symmetric solution of (2.2). After solving (2.3) for C^TC , substitute its value in the Riccati equation for P_S . After arranging the two solutions, it follows that their difference satisfies the Lyapunov equation

$$(2.4) \quad \begin{aligned} & (A + BB^TP_S)(P_S - P) + (P_S - P)(A + BB^TP_S) \\ & - (P_S - P)BB^T(P_S - P) = 0 \end{aligned}$$

Since $A + BB^TP_S$ is stable, the conclusion follows by Lyapunov inertia theory [14, p. 447]. \square

Bounded real Riccati equations satisfy monotonicity and extension properties that are derivable from general theorems of this type in Ran and Vreugdenhil [21], or Gohberg, Lancaster, and Rodman [7] and for monotonicity Wimmer [26]. The following result is found in Petersen, Anderson, and Jonckheere [18].

THEOREM 2.2 (bounded real extension theorem). *Suppose that A is stable, \hat{Q} is a real symmetric matrix, and the Riccati equation $A^TP + PA + PBB^TP + \hat{Q} = 0$ has a real symmetric solution \hat{P} . Furthermore, suppose that $\hat{Q} \geq Q \geq 0$. Then the Riccati equation $A^TP + PA + PBB^TP + Q = 0$ will have a unique strong solution $P \geq 0$ such that $P \leq \hat{P}$.*

Another key result is the relationship given by Boyd, Balakrishnan, and Kabamba (BBK) [2] that connects the singular values of a stable transfer matrix $G(s) = C(sI - A)^{-1}B$ and the spectrum of the Hamiltonian matrix

$$H(\gamma) = \begin{pmatrix} A & (1/\gamma^2)BB^T \\ -C^TC & -A^T \end{pmatrix}.$$

Their theorem does not require any special observability or controllability conditions on the system $\{A, B, C\}$.

THEOREM 2.3 (BBK theorem). *Suppose that A is stable. $\|G(s)\|_\infty < \lambda$ if and only if $\delta(H(\gamma)) = 0$.*

The maximal stabilizing solution of FARE and the minimal or maximal stabilizing solution of BRRE—depending on whether (1.3) or (2.3) is solved—are now combined to define the maximal and minimal stabilizing solution of the dual game Riccati equation.

THEOREM 2.4. *If the stabilizing Z_+ of FARE exists and if $\delta(H(Z_+, \hat{\gamma})) = 0$ for some $\hat{\gamma}$, $0 < \hat{\gamma} < \infty$, then the unique maximal stabilizing solution $W_+(\gamma)$ of $\text{Ric}(W, H(Z_+, \gamma)) = 0$ exists for all γ , $0 < \hat{\gamma} \leq \gamma \leq \infty$. Furthermore, the stabilizing solution $Y_+(\gamma)$ of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ also exists on the same interval and $Y_+(\gamma) = Z_+ + W_+(\gamma)$, $0 < \hat{\gamma} \leq \gamma \leq \infty$. Moreover, if $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$, then $Y_+(\gamma_1) \leq Y_+(\gamma_2)$.*

Proof. Since $\delta(H(Z_+, \hat{\gamma})) = 0$ and $A - Z_+C^TC$ is stable, the transfer matrix $G_1(s)$ for the realization $(A - Z_+C^TC, B_1, C)$ satisfies the inequality $\|G_1(s)\|_\infty < \hat{\gamma}$ (Theorem 2.3). Let $W = -P$ in $\text{Ric}(W, H(Z_+, \gamma)) = 0$ and obtain the equation

$$(2.5) \quad (A - Z_+C^TC)P + P(A - Z_+C^TC)^T + PC^TCP + \frac{1}{\gamma^2} B_1 B_1^T = 0$$

By Lemma 2.1, the unique minimal solution $P_-(\hat{\gamma}) \geq 0$ of (2.5) exists.

The explicit Riccati equation for $\text{Ric}(W, H(Z_+, \gamma)) = 0$ is

$$(2.6) \quad (A - Z_+C^TC)W + W(A - Z_+C^TC)^T - WC^TCW - \frac{1}{\gamma^2} B_1 B_1^T = 0.$$

Transforming back the maximal stabilizing solution $W_+(\hat{\gamma}) = -P_-(\hat{\gamma}) \leq 0$ of (2.6) is obtained.

Next, we show that $W_+(\gamma)$ exists for any γ in the infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$ and satisfies the inequality

$$(2.7) \quad W_+(\hat{\gamma}) \leq W_+(\gamma), \quad 0 < \hat{\gamma} \leq \gamma \leq \infty.$$

Since $A - Z_+C^TC$ is stable for any γ and $(1/\gamma^2)B_1 B_1^T \leq (1/\hat{\gamma})B_1 B_1^T$, the strong solution $P_-(\gamma)$ of (2.5) exists and satisfies the partial order $0 \leq P_-(\hat{\gamma}) \leq P_-(\gamma)$ by Theorem 2.2. To show that $W_+(\gamma)$ is stabilizing, note that $(1/\gamma)\|G_1(s)\|_\infty \leq (1/\hat{\gamma})\|G_1(s)\|_\infty < 1$ and then apply Theorem 2.3 to show that $\delta(H(Z_+, \gamma)) = 0$ for all $\gamma \geq \hat{\gamma}$.

The next step is to show that the sum $Y_+(\gamma) = Z_+ + W_+(\gamma)$ is a solution of (1.4). First, substitute it into (1.4) and rearrange the equation to obtain the identity (the subscripts are unnecessary)

$$(2.8) \quad \begin{aligned} & A(Z + W(\gamma)) + (Z + W(\gamma))A^T - (Z + W(\gamma))C^TC(Z + W(\gamma)) \\ & \quad + B_2 B_2^T - \frac{1}{\gamma^2} B_1 B_1^T \\ & = (AZ + ZA^T - ZC^TCZ + B_2 B_2^T) + (A - ZC^TC)W(\gamma) \\ & \quad + W(\gamma)(A - ZC^TC)^T - W(\gamma)C^TCW(\gamma) - \frac{1}{\gamma^2} B_1 B_1^T = 0. \end{aligned}$$

Thus, the sum of any two such solutions is a solution of the dual game Riccati equation. Since $(A - Z_+ C^T C) + P_-(\gamma) C^T C$ is stable, the sum $Z_+ + W_+(\gamma)$ is stabilizing. The maximality of $Y_+(\gamma)$ can be established by the Lyapunov arguments used in the proof of Lemma 2.1. By (2.7), $Y_+(\gamma_1) - Y_+(\hat{\gamma}_2) = W_+(\gamma_1) - W_+(\hat{\gamma}_2) \geq 0$, which establishes the partial order of $Y_+(\gamma)$. \square

The properties of the dual minimal antistabilizing solution $Y_-(\gamma)$ will now be established by similar arguments applied to the Riccati equation $\text{Ric}(W, -H(Z_-, \gamma)) = 0$.

THEOREM 2.5. *If the antistabilizing Z_- of FARE exists and if $\delta(H(Z_-, \hat{\gamma})) = 0$ for some $\hat{\gamma}$, $0 < \hat{\gamma} < \infty$, then the unique minimal stabilizing solution $W_-(\gamma)$ of $\text{Ric}(W, -H(Z_-, \gamma)) = 0$ exists for all γ , $0 < \hat{\gamma} \leq \gamma \leq \infty$. Furthermore, the antistabilizing solution $Y_-(\gamma)$ of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ also exists on the same interval and the relation is valid $Y_-(\gamma) = Z_- + W_-(\gamma)$, $0 < \hat{\gamma} \leq \gamma \leq \infty$. Moreover, if $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$, then $Y_-(\gamma_2) \leq Y_-(\gamma_1)$.*

Proof. The congruence transformation

$$\begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix} H(Z_-, \hat{\gamma}) \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix} = -H^T(Z_-, \hat{\gamma})$$

implies by Sylvester's law of inertia [10] that $\delta(-H(Z_-, \hat{\gamma})) = \delta(-H^T(Z_-, \hat{\gamma})) = \delta(H(Z_-, \hat{\gamma})) = 0$.

Since $A - Z_- C^T C$ is antistable, the transfer matrix $\hat{G}(s)$ for the realization $-(A - Z_- C^T C), B_1, C$ satisfies the inequality $\|\hat{G}(s)\|_\infty < \hat{\gamma}$ by Theorem 2.3. Invoking the reasoning in Theorem 2.4, $\delta(-H^T(Z_-, \gamma)) = 0$ for all $\gamma \geq \hat{\gamma}$.

The explicit Riccati equation for $\text{Ric}(W, -H(Z_-, \gamma)) = 0$ is

$$(2.9) \quad [-(A - Z_- C^T C)]W + W[-(A - Z_- C^T C)]^T + WC^T C W + \frac{1}{\gamma^2} B_1 B_1^T = 0.$$

Again by Lemma 2.1 the stabilizing solution $W_-(\gamma)$ of (2.9) exists. The extension and solution monotonicity properties that are derived in Theorem 2.1 can be used to show that $W_-(\gamma)$ exists on the semi-infinite interval and satisfies the partial order

$$(2.10) \quad W_-(\gamma) \leq W_-(\hat{\gamma}), \quad 0 < \hat{\gamma} \leq \gamma \leq \infty.$$

The sum $Y_-(\gamma) = Z_- + W_-(\gamma)$ is a solution of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ because it satisfies (2.8). Since $-(A - Z_- C^T C) + W_-(\gamma) C^T C$ is stable, it follows that $W_-(\gamma)$ is antistabilizing and that the sum $Y_-(\gamma)$ is antistabilizing. By (2.10), $Y_-(\gamma) - Y_-(\hat{\gamma}) = W_-(\gamma) - W_-(\hat{\gamma}) \geq 0$, thus, the partial order of $Y_+(\gamma)$ is established. \square

Using the decomposition theorems just derived, the inertia properties of the antistabilizing and stabilizing solutions of (1.4) can be easily derived. Moreover, they clearly reveal how and why sign indefinite stabilizing solutions can occur. The existence of sign indefinite stabilizing solutions of game Riccati equations for $0 < \gamma < \infty$ highlights a fundamental difference between them and the stabilizing solutions of the standard control, filtering or the bounded real Riccati equations, which cannot be sign indefinite. Only the inertia properties of the stabilizing solutions will be proved.

Let $\text{Ker}(M)$ denote the null space or kernel of the matrix M and $\text{Im}(M)$ denote the range or image of M .

THEOREM 2.6. *If the nonzero solution Z_+ of $\text{Ric}(Z, H_2) = 0$ is nonsingular and $W_+(\gamma)$ of $\text{Ric}(W, H(Z_+, \gamma)) = 0$ exists for some $\hat{\gamma}$, $0 < \hat{\gamma} < \infty$, then the solution $Y_+(\gamma)$ of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ exists for all γ $0 < \hat{\gamma} \leq \gamma \leq \infty$ —by Theorem 2.4—and satisfies the following properties:*

$$(a) \quad \text{In}(Y_+(\gamma)) = \text{In}(I + W_+(\gamma)Z_+^{-1}),$$

- (b) $\delta(Y_+(\gamma)) = 0$ if and only if $\lambda_i(-W_+(\gamma)Z_+^{-1}) \neq 1$, $i = 1, \dots, n$,
(c) $Y_+(\gamma) > 0$ for all γ , $0 < \hat{\gamma} \leq \gamma \leq \infty$ if and only if $\rho(-W_+(\hat{\gamma})Z_+^{-1}) < 1$.

Proof. Since Z_+ is nonsingular by Sylvester's law of inertia $\text{In}(Y_+(\gamma)) = \text{In}(Y_+(\gamma)Z_+^{-1}) = \text{In}(I + W_+(\gamma)Z_+^{-1})$ and (a)–(b) follow from this identity. Since $Z_+ > 0$ and $W_+(\gamma) \leq 0$, the spectral radius test [10], is equivalent to the statement $Y_+(\hat{\gamma}) > 0$ if and only if $\rho(-W_+(\hat{\gamma})Z_+^{-1}) < 1$. The inverse square root $Z_+^{-1/2}$ exists, because $Z_+ > 0$. Now, by (2.7), $W_+(\hat{\gamma}) \geq W_+(\gamma)$ for $0 < \hat{\gamma} \leq \gamma \leq \infty$. The spectral sets for $-W_+(\gamma)Z_+^{-1}$ and $-Z_+^{-1/2}W_+(\gamma)Z_+^{-1/2}$ are identical and they only contain real nonnegative eigenvalues [10, p. 468]. Thus, for $0 < \hat{\gamma} \leq \gamma \leq \infty$,

$$\begin{aligned} \rho(-W_+(\gamma)Z_+^{-1}) &= \rho(-Z_+^{-1/2}W_+(\gamma)Z_+^{-1/2}) \\ &= \|(Z_+^{-1/2}W_+(\gamma)Z_+^{-1/2})\| \leq \|(Z_+^{-1/2}W_+(\hat{\gamma})Z_+^{-1/2})\| \\ &= \rho(-Z_+^{-1/2}W_+(\hat{\gamma})Z_+^{-1/2}) = \rho(-W_+(\hat{\gamma})Z_+^{-1}). \quad \square \end{aligned}$$

In fact, if $Y_+(\hat{\gamma})$ is sign indefinite for some $\hat{\gamma}$ and if $Y_+(\gamma)$ exists on the half-line $0 < \hat{\gamma} \leq \gamma \leq \infty$, then by the continuity of eigenvalues and by the monotone nondecreasing property of $Y_+(\gamma)$ as a function of γ , it will be singular for some finite value of γ because the $\text{In}(Y_+(\gamma))$ depends continuously on the eigenvalues of $Y_+(\gamma)$ and $Y_+(\infty) = Z_+$.

The following converse of Theorem 2.4 is now obtained.

THEOREM 2.7. *If there exists a maximal stabilizing solution $Y_+(\gamma)$ of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ on some γ semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$, then the following solutions exist on the same interval:*

- (i) *the stabilizing solution Z_+ of $\text{Ric}(Z, H_2) = 0$ exists and $\delta(H(Z_+, \gamma)) = 0$,*
(ii) *the stabilizing solution $W_+(\gamma)$ of $\text{Ric}(W, H(Z_+, \gamma)) = 0$ exists.*

Proof. Since $Y_+(\gamma)$ exists at $\gamma = \infty$, the solution $Z_+ = Y_+(\infty)$ clearly exists. Since Z_+ exists, the similarity transformation

$$(2.11) \quad \begin{pmatrix} I & 0 \\ -Z_+ & I \end{pmatrix} H_\infty^T(\gamma) \begin{pmatrix} I & 0 \\ Z_+ & I \end{pmatrix} = H(Z_+, \gamma).$$

shows that $\text{In}(H_\infty^T(\gamma)) = \text{In}(H(Z_+, \gamma))$. Thus, $\delta(H(Z_+, \gamma)) = 0$ because $Y_+(\gamma)$ is stabilizing now, the proof in Theorem 2.4 shows that $W_+(\gamma)$ exists on the same interval. \square

By combining the proof of Theorems 2.5 and 2.6, the following dual result for the antistabilizing solutions is obtained.

THEOREM 2.8. *If there exists a minimal antistabilizing solution $Y_-(\gamma)$ of $\text{Ric}(Y, H_\infty^T(\gamma)) = 0$ on some γ semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$, then on the same interval*

- (i) *the antistabilizing solution Z_- of $\text{Ric}(Z, H_2) = 0$,*
(ii) *the stabilizing solution $W_-(\gamma)$ of $\text{Ric}(W, -H(Z_-, \gamma)) = 0$ exists.*

Proof. Since $Y_-(\gamma)$ exists at $\gamma = \infty$, the solution $Z_- = Y_-(\infty)$ clearly exists. Since (2.11) is a similarity transformation $\text{In}(H_\infty^T(\gamma)) = \text{In}(H(Z_\pm, \gamma))$, which means that $\delta(H(Z_-, \gamma)) = 0$ because $Y_-(\gamma)$ is antistabilizing. Now the proof in Theorem 2.5 can be applied to show that $W_-(\gamma)$ exists. \square

3. Stabilizing solutions of the game Riccati equation. In this section, the stabilizing solution $X(\gamma)$ of the game Riccati control equation (1.1) is related via the separation formulas derived in the previous section to the antistabilizing solutions Z_- and $W_-(\gamma)$ that are factors of the dual game Riccati equation antistabilizing solution. When $\gamma = \infty$

and $X(\gamma)$ is nonsingular, then this relationship reduces to the familiar fact, namely, $Z_- = -X^{-1}(\infty)$ [11].

To keep the controllability and observability assumptions to a minimum in the subsequent theorems, some properties of the stabilizing solutions $X(\gamma)$ of (1.1) are deduced. However, before these deductions are discussed, a key lemma that avoids assuming that the pair (C, A) is observable is introduced. This is especially important for the Riccati equations described by (1.6) and (1.7). Then a preliminary theorem is proved that investigates the role of stabilizability and detectability, when $X(\gamma)$ is a stabilizing solution.

This decomposition is used in Petersen, Anderson, and Jonckheere [18] and Hinrichsen and Pritchard [9]. It is a consequence of two key facts. Namely, the linear subspaces determined by $\text{Im } X(\gamma)$ and $\text{Ker } X(\gamma)$ are orthogonal and $\text{Ker } X(\gamma)$ is an A -invariant subspace of $\text{Ker } C$.

LEMMA 3.1. *Let X be any real symmetric solution of $\text{Ric}(X, H_\infty(\gamma)) = 0$. The matrices A , B_1 , B_2 , and C with respect to any orthonormal basis compatible with the decomposition $R^n = \text{Im } X \oplus \text{Ker } X$ can be written as*

$$A = \begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix}, \quad C = [C_{11}, 0], \quad B_1 = \begin{bmatrix} B_{11} \\ B_{22} \end{bmatrix}, \quad B_2 = \begin{bmatrix} B_{21} \\ B_{22} \end{bmatrix}, \quad X = \begin{bmatrix} X_{11} & 0 \\ 0 & 0 \end{bmatrix}.$$

Moreover, if X is not identically zero, $\delta(X_{11}) = 0$ [9], and X_{11} satisfies the equation

$$(3.1) \quad A_{11}^T X_{11} + X_{11} A_{11} + X_{11} \left(\frac{1}{\gamma^2} B_{11} B_{11}^T - B_{21} B_{21}^T \right) X_{11} + C_{11}^T C_{11} = 0.$$

Some of the deductions in the next theorem are well known for $\text{Ric}(X, H_\infty(\infty)) = 0$, and (iii) would follow from the H infinity papers such as [4] or [18]. However, $\text{Ric}(X, H_\infty(\gamma)) = 0$ can have sign indefinite stabilizing solutions. Because local properties of stabilizing solutions are important for numerical studies [12], a proof is included. In fact, the next theorem, when combined with the result in the Appendix and with the metric topology introduced by Gahinet and Laub [5], can be used to justify the informal statement: the neighbourhoods defined by “small admissible perturbations” of $\text{Ric}(X, H_\infty(\gamma)) = 0$ will always contain unique stabilizing solutions, whenever the unperturbed equation has a stabilizing solution. Subsequently, a theorem will show that if a positive semidefinite stabilizing solution exists for a single γ , $0 < \gamma < \infty$ then it exists for any larger value of γ . This extension property and the minimal assumptions that guarantee it are apparently new.

Let $H_\infty^\varepsilon(\gamma)$ denote the $2n \times 2n$ Hamiltonian matrix for the slightly perturbed game equation (1.8) obtained from $H_\infty(\gamma)$ by perturbing the $(2, 1)$ block matrix $C^T C$ by εI for $\varepsilon > 0$ and $H^\varepsilon(Z_\pm, \gamma)$ is the $2n \times 2n$ matrix obtained from $H(Z_\pm, \gamma)$ by perturbing the $(1, 2)$ block matrix $C^T C$ by εI for $\varepsilon > 0$.

THEOREM 3.2. *Suppose (that $\text{Ric}(X, H_\infty(\gamma)) = 0$ has a nonzero stabilizing solution $X(\gamma)$ for some γ , $0 < \gamma < \infty$, then*

- (i) $\delta(H_2) = 0$, otherwise,
- (ii) if $X(\gamma) \geq 0$, then the pair (A, B_2) is stabilizable,
- (iii) if $X(\gamma) > 0$, then the pair $(C, -A)$ is detectable.

Proof. Since $X(\gamma)$ is stabilizing, the closed-loop matrix $A + ((1/\gamma^2)B_1 B_1^T - B_2 B_2^T)X(\gamma)$ is stable. Since the decomposition in Lemma 3.1 can be realized by a real orthogonal similarity transformation, the A_{22} block of the transformed closed loop matrix will be stable. Now the dimension of X_{11} equals the dimension of the block matrix A_{11} . The unstable eigenvalues (if any) of A_{11} are clearly $(A_{11}, (1/\gamma^2)B_1 B_1^T - B_2 B_2^T)$ -controllable. Since $X_{11}(\gamma)$ is nonsingular, (3.1) can be

rearranged to yield the equivalent equation

$$(3.2) \quad \begin{aligned} A_{11} + \left(\frac{1}{\gamma^2} B_{11} B_{11}^T - B_{21} B_{21}^T \right) X_{11}(\gamma) \\ = -X_{11}^{-1}(\gamma) (A_{11} + X_{11}^{-1}(\gamma) C_{11}^T C_{11})^T X_{11}(\gamma) \end{aligned}$$

Equation (3.2) clearly shows that $(A_{11} + X_{11}^{-1}(\gamma) C_{11}^T C_{11})$ is antistable, and so the stable or pure imaginary eigenvalue of A_{11} (if any) are clearly $(A_{11}, C_{11}^T C_{11})$ -observable. Equation (3.2) shows that the purely imaginary eigenvalues (if any) of A are (C, A) -observable.

By Theorem A in the Appendix, the perturbed Riccati equation $\text{Ric}(X^\varepsilon, H_\infty^\varepsilon(\gamma)) = 0$ will have a nonsingular stabilizing solution $X^\varepsilon(\gamma)$. Rearranging the equation, it becomes

$$(3.3) \quad \begin{aligned} (A - B_2 B_2^T X^\varepsilon(\gamma))^T X^\varepsilon(\gamma) + X^\varepsilon(\gamma) (A - B_2 B_2^T X^\varepsilon(\gamma)) \\ + X^\varepsilon(\gamma) \left(\frac{1}{\gamma^2} B_1 B_1^T + B_2 B_2^T \right) X^\varepsilon(\gamma) + C^T C + \varepsilon I = 0. \end{aligned}$$

Since $X^\varepsilon(\gamma)$ is nonsingular and $(\varepsilon I, A - B_2 B_2^T X^\varepsilon(\gamma))$ is observable, it follows by Lyapunov inertia theory [14, p. 448], that $\text{In}(A - B_2 B_2^T X^\varepsilon(\gamma)) = \text{In}(-X^\varepsilon(\gamma))$ and $\delta(A - B_2 B_2^T X^\varepsilon(\gamma)) = 0$. At the very least, all of the eigenvalues of A on the imaginary axis are (A, B_2) -controllable and so $\delta(H_2) = 0$ [13], [15], otherwise if $X(\gamma) \geq 0$, then $X^\varepsilon(\gamma) > 0$ (Appendix) and so (A, B_2) is stabilizable. The second claim follows by a similarity transformation identical to (3.2). \square

The following theorem establishes the existence of nonsingular stabilizing solutions of the control Riccati equation (1.1) by a Hamiltonian and spectral radius test over the parameter interval. These tests can be implemented by a Hamiltonian bisection search [9], [2] or by a gradient search on the spectral radius [17]. Moreover, these conditions completely characterize the nonsingular stabilizing solutions of (1.1), including the sign indefinite ones.

THEOREM 3.3. *The nonsingular stabilizing solution $X(\gamma)$ of $\text{Ric}(X, H_\infty(\gamma)) = 0$ exists on the semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$ if and only if*

- (i) *the equation $\text{Ric}(Z, H_2) = 0$ has a minimal antistabilizing solution $Z_- < 0$,*
- (ii) *the stabilizing solution $W_-(\gamma)$ of $\text{Ric}(W, -(H(Z_-, \gamma))) = 0$ exists on the same interval,*
- (iii) *the real eigenvalues of the matrix $W_-(\gamma) Z_1^{-1}$ satisfy the inequality $\lambda_i(-W_-(\gamma) Z_1^{-1}) \neq 1$ on the same interval.*

Furthermore, $\text{In}(X(\gamma)) = \text{In}(I + W_-(\gamma) Z_1^{-1})$ and $X(\gamma) > 0$ if and only if $\rho(W_-(\gamma)(-Z_1^{-1})) < 1$.

Proof. First, the sufficiency conditions are assumed. The matrix $Y_-(\gamma) = Z_- + W_-(\gamma)$ is an antistabilizing solution of the dual game Riccati equation by Theorem 2.5. Clearly, if the real eigenvalues of $W_-(\gamma) Z_1^{-1}$ satisfy (iii) then $Y_-(\gamma)$ is nonsingular by Theorem 2.6. If $Y_-(\gamma)$ is nonsingular, then its inverse will satisfy the game Riccati equation (1.1) and, by an obvious modification of (3.2), it will be the unique stabilizing solution of (1.1), too. Since the stabilizing solution of (1.1) is unique $X(\gamma) = -(Y_-(\gamma))^{-1}$ so $X(\gamma)$ has the asserted properties. Z_- is nonsingular by hypothesis and so by Theorem 2.6 $\text{In}(Y_-(\gamma)) = \text{In}(I + W_-(\gamma) Z_1^{-1})$.

If $X(\gamma)$ is the nonsingular stabilizing solution on $0 < \hat{\gamma} \leq \gamma \leq \infty$, then $-X^{-1}(\infty)$ is an antistabilizing solution of $\text{Ric}(Z, H_2) = 0$ and so (i) is satisfied. Again, by (3.2), for any γ in the interval $Y_-(\gamma) = -X^{-1}(\gamma)$ is an antistabilizing solution of $\text{Ric}(W, H_\infty^T(\gamma)) = 0$ on the same interval. By Theorems 2.5 and 2.8, (ii) and (iii) are satisfied. \square

When the stabilizing solution is semidefinite, then (i), (ii), and (iii) are satisfied by the perturbed Riccati equation $\text{Ric}(W, H_\infty^\varepsilon(\gamma)^T) = 0$ and, conversely, these conditions guarantee the existence of a strong solution. A strong solution of (1.1) will also be stabilizing if either the assumption $\delta(H_\infty(\gamma) = 0$ is satisfied on some semi-infinite interval or the less familiar assumption (1.8) is satisfied.

THEOREM 3.4. *If the stabilizing solution $X(\gamma) \geq 0$ of $\text{Ric}(X, H_\infty(\gamma)) = 0$ exists on the semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$, then for all sufficiently small $\varepsilon > 0$*

(i) *the equation $\text{Ric}(Z, (H_\infty^\varepsilon(\infty))^T) = 0$ has a minimal solution $Z_-^\varepsilon < 0$ on the same interval,*

(ii) *the stabilizing solution $W_-^\varepsilon(\gamma)$ of $\text{Ric}(W, -(H^\varepsilon(Z_-, \gamma))) = 0$ exists on the same interval,*

(iii) *the real eigenvalues of the matrix $W_-^\varepsilon(\gamma)Z_-^{\varepsilon-1}$ satisfy the inequality $\rho(-W_-^\varepsilon(\gamma)Z_-^{\varepsilon-1}) < 1$ on the same interval.*

Proof. Since $X(\gamma)$ is stabilizing and $X(\gamma) \geq 0$, Theorem A in the Appendix can be applied to $\text{Ric}(X^\varepsilon, H_\infty^\varepsilon(\gamma)) = 0$, which has a stabilizing solution $X^\varepsilon(\gamma) > 0$. The existence of Z_-^ε in (i) follows, because the pair $(C^T C + \varepsilon I, A)$ is observable, and by Theorem 3.2 the pair $(-A, B_2)$ is detectable. The other conditions are now immediate from Theorem 2.8.

Conditions (i), (ii), and (iii) and Theorem 3.3 guarantee that $\text{Ric}(X^\varepsilon, H_\infty^\varepsilon(\gamma)) = 0$ has a nonsingular stabilizing solution $X^\varepsilon(\gamma) > 0$. Theorem A in the Appendix then guarantees the existence of a strong solution, and the difference $X^\varepsilon(\gamma) - X(\gamma)$ can be made arbitrarily small as ε decreases. \square

The next theorem shows that if a positive semidefinite stabilizing solution of (1.1) exists, for a single value of γ , then it will exist for all larger values of γ ; in other words, its interval of existence is connected. This extension and connectivity property of the γ parameter can be extended to any perturbed equation that satisfies Theorem A. Thus both the game Riccati equation and “nearby” perturbed solutions will also exist over the entire gamma interval, which ensures that the regularity properties of stabilizing solutions are well defined.

THEOREM 3.5. *If a nonzero stabilizing solution $X(\hat{\gamma}) \geq 0$ of $\text{Ric}(X, H_\infty(\hat{\gamma})) = 0$ exists for some $\hat{\gamma}$, $0 < \hat{\gamma} < \infty$, then $X(\gamma) \geq 0$ exists and is stabilizing on the semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$ and obeys the partial order $X(\gamma_2) \leq X(\gamma_1)$ for $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$.*

Proof. Since $X(\hat{\gamma}) \geq 0$ is stabilizing, there exists by Lemma 3.1 a real orthogonal matrix S such that $X(\hat{\gamma})$ and A are transformed by the congruence transformation $S^T A S$ and $S^T X(\hat{\gamma}) S$ into the block form

$$\begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix}, \quad \begin{pmatrix} X_{11}(\hat{\gamma}) & 0 \\ 0 & 0 \end{pmatrix}.$$

The closed-loop matrix $A + ((1/\gamma^2)B_1 B_1^T - B_2 B_2^T)X(\gamma)$ is stable and thus the A_{22} block of the transformed closed-loop matrix will be stable. The unstable eigenvalues (if any) of A_{11} are clearly controllable. By Lemma 3.1, the dimension of $X_{11}(\hat{\gamma})$ equals that of A_{11} , and $X_{11}(\hat{\gamma}) > 0$ is a stabilizing solution of the reduced Riccati equation (3.1). By Theorems 2.6 and 2.7, the stabilizing solution $X_{11}(\gamma) > 0$ exists on the semi-infinite intervals $0 < \hat{\gamma} \leq \gamma \leq \infty$. The inertia relation $\text{In}(S^T X(\gamma) S) = \text{In}(0, \nu(0), \pi(X_{11}(\gamma)))$ and the uniqueness of stabilizing solutions of (1.1) guarantee that $X(\gamma) \geq 0$ exists on the semi-infinite interval.

By Theorem 3.4, the solution $Y_-^\varepsilon(\gamma) < 0$ exists on the same interval, and by Theorem 2.5, $Y_-^\varepsilon(\gamma_2) \leq Y_-^\varepsilon(\gamma_1)$ for $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$. Moreover, the proof of Theorem 3.3 shows that the solution $X^\varepsilon(\gamma)$ of $\text{Ric}(X^\varepsilon, H_\infty^\varepsilon(\gamma)) = 0$ exists and satisfies the equation $X^\varepsilon(\gamma) = -Y_-^\varepsilon(\gamma)^{-1}$, which implies that the partial order $X^\varepsilon(\gamma_2) \leq X^\varepsilon(\gamma_1)$ is valid. \square

4. Monotonicity of the spectral radius. Since the spectral radius is not a norm, its functional properties often require special considerations. Functional properties are especially important when the spectral radius is coupled with a computational algorithm. For example Pandey *et al.* [17] search over the γ interval for the optimal H_∞ -norm by a gradient method applied to the special radius $\rho(X_\infty(\gamma)Y_\infty(\gamma))$. The next theorem shows that the discontinuities (if any) of the spectral radius $\rho(X_\infty(\gamma)Y_\infty(\gamma))$ are jumps.

THEOREM 4.1. *If there exist maximal stabilizing solutions $X_\infty(\gamma) \geq 0$ and $Y_\infty(\gamma) \geq 0$ of the respective game Riccati equations (1.6) and (1.7) defined on the same semi-infinite interval $0 < \hat{\gamma} \leq \gamma \leq \infty$, then $\rho(X_\infty(\gamma_2)Y_\infty(\gamma_2)) \leq \rho(X_\infty(\gamma_1)Y_\infty(\gamma_1))$ for $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$.*

Proof. Throughout the proof, γ is confined to the interval $0 < \hat{\gamma} \leq \gamma \leq \infty$. Both solutions satisfy the same γ dependent partial order $X_\infty(\gamma_2) \leq X_\infty(\gamma_1)$, $Y_\infty(\gamma_2) \leq Y_\infty(\gamma_1)$, by an obvious modification of the proof of Theorem 2.1 for the first inequality and then by invoking duality for the second inequality.

Since both solutions $X_\infty(\gamma)$ and $Y_\infty(\gamma)$ are stabilizing, Theorem A in the Appendix can be applied to the “slightly” perturbed versions of the game Riccati equations (1.6) and (1.7), which are obtained from the original equations by adding the matrix εI with $\varepsilon > 0$ to the respective matrices $C_1^T(I - D_{12}E_1^{-1}D_{12}^T)C_1$ and $B_1(I - D_{21}E_2^{-1}D_{21}^T)B_1^T$. The perturbed solutions $X_\infty^\varepsilon(\gamma) > 0$ and $Y_\infty^\varepsilon(\gamma) > 0$ inherit the same γ dependent partial order as the original solutions.

For each $\varepsilon > 0$ and γ standard balancing results [11] can be invoked to show that there exists a similarity transformation T (the explicit dependency on ε and γ is omitted) such that $X_\infty^\varepsilon(\gamma)$ and Y_∞^ε can be simultaneously diagonalized

$$T^T X_\infty^\varepsilon(\gamma) T = \Sigma_\infty^\varepsilon(\gamma) = T^{-1} Y_\infty^\varepsilon(\gamma) T^{-T}.$$

The real diagonal elements $\sigma_\infty^\varepsilon(\gamma)_i$ of the diagonal matrix $\Sigma_\infty^\varepsilon(\gamma)$ are determined by

$$\sigma_\infty^\varepsilon(\gamma)_i = (\lambda_i(X_\infty^\varepsilon(\gamma)Y_\infty^\varepsilon(\gamma)))^{1/2}, \quad i = 1, \dots, n.$$

Since $\Sigma_\infty^\varepsilon(\gamma)$ is the common unique maximal stabilizing solution of the “slightly perturbed” game Riccati equations in the transformed state equations representation, it inherits the γ dependent partial order. Thus, the spectral radius ordering

$$\rho(X_\infty^\varepsilon(\gamma_2)Y_\infty^\varepsilon(\gamma_2)) \leq \rho(X_\infty^\varepsilon(\gamma_1)Y_\infty^\varepsilon(\gamma_1))$$

for $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$ is established for any ε .

The eigenvalues of $X_\infty^\varepsilon(\gamma)Y_\infty^\varepsilon(\gamma)$ are all positive or zero real numbers [10, p. 468]. Furthermore, the eigenvalues of the matrices $X_\infty^{1/2}(\gamma)(X_\infty^{1/2}(\gamma)Y_\infty(\gamma))$ and $X_\infty^{1/2}(\gamma)Y_\infty(\gamma)X_\infty^{1/2}(\gamma)$ are identical. Thus, the following chain of inequalities can be obtained:

$$\begin{aligned} \rho(X_\infty(\gamma_2)Y_\infty(\gamma_2)) &= \rho(X_\infty^{1/2}(\gamma_2)Y_\infty(\gamma_2)X_\infty^{1/2}(\gamma_2)) \\ &= \|X_\infty^{1/2}(\gamma_2)Y_\infty(\gamma_2)X_\infty^{1/2}(\gamma_2)\| \\ &\leq \|X_\infty^{1/2}(\gamma_2)Y_\infty(\gamma_2)X_\infty^{1/2}(\gamma_2) - X_\infty^\varepsilon(\gamma_2)^{1/2}Y_\infty^\varepsilon(\gamma_2)X_\infty^\varepsilon(\gamma_2)^{1/2}\| \\ &\quad + \|X_\infty^\varepsilon(\gamma_2)^{1/2}Y_\infty^\varepsilon(\gamma_2)X_\infty^\varepsilon(\gamma_2)^{1/2}\| \\ &\leq \|X_\infty^{1/2}(\gamma_2)Y_\infty(\gamma_2)X_\infty^{1/2}(\gamma_2) - X_\infty^\varepsilon(\gamma_2)^{1/2}Y_\infty^\varepsilon(\gamma_2)X_\infty^\varepsilon(\gamma_2)^{1/2}\| \\ &\quad + \|X_\infty^\varepsilon(\gamma_1)^{1/2}Y_\infty^\varepsilon(\gamma_1)(\gamma_1)^{1/2} - X_\infty^\varepsilon(\gamma_1)Y_\infty(\gamma_1)X_\infty^{1/2}(\gamma_1)\| \\ &\quad + \|X_\infty^{1/2}(\gamma_1)Y_\infty(\gamma_1)X_\infty^{1/2}(\gamma_1)\|. \end{aligned}$$

Since the obvious terms in the inequality chain tend to zero as $\varepsilon \rightarrow 0$, it follows that $\rho(X_\infty(\gamma_2)Y_\infty(\gamma_2)) \leq \rho(X_\infty(\gamma_1)Y_\infty(\gamma_1))$ for $0 < \hat{\gamma} \leq \gamma_1 \leq \gamma_2 \leq \infty$. \square

5. Rank. By Theorem 3.5, the rank of $X(\gamma)$ is a decreasing function of γ , because $X_+(\infty) \leq X(\gamma)$ for $0 < \gamma \leq \infty$. In fact, a more complete description of the rank is possible; namely, the rank of $X(\gamma)$ is a constant for all γ and it is determined by the eigenvalues of the dynamical system matrix A . According to Postlethwaite, Gu, and Young [20] the rank of $X_+(\infty)$ is determined by the unstable controllable eigenvalues and by the stable observable eigenvalues. Their descriptive and interesting eigenvalue characterization of the rank of $X_+(\infty)$ is also valid for $X(\gamma)$. The strategy of determining the rank of $X(\gamma)$ by using the direct sum decomposition of R^n derived in Lemma 3.1 is apparently new.

THEOREM 5.1. *If $X(\gamma)$ is a nonzero stabilizing solution of $\text{Ric}(X, H_\infty(\gamma)) = 0$ for some γ , $0 < \gamma \leq \infty$, then the rank of $X(\gamma)$ equals the number of unstable eigenvalues of A that are $(A, (1/\gamma^2)B_1B_1^T - B_2B_2^T)$ -controllable plus the number of stable eigenvalues of A that are (C, A) -observable. Moreover, if $X(\gamma)$ is stabilizing on some γ -interval $0 < \gamma_1 \leq \gamma \leq \gamma_2 \leq \infty$ then rank of $X(\gamma)$ is constant on the interval.*

Proof. By assumption, the closed-loop matrix $A + ((1/\gamma^2)B_1B_1^T - B_2B_2^T)X(\gamma)$ is stable. The decomposition in Lemma 3.1 can be realized by a real orthogonal similarity transformation. Since the eigenvalues of the A_{22} block are feedback invariants, the transformed closed loop matrix will be stable. Now, the dimension of $X_{11}(\gamma)$ equals the dimension of the block matrix A_{11} . The unstable eigenvalues (if any) of A_{11} are clearly controllable. Since $X_{11}(\gamma)$ is nonsingular, (3.1) can be rearranged to yield the equivalent equation

$$(5.1) \quad \begin{aligned} A_{11} + \left(\frac{1}{\gamma^2} B_{11}B_{11}^T - B_{21}B_{21}^T \right) X_{11}(\gamma) \\ = -X_{11}^{-1}(\gamma)(A_{11} + X_{11}^{-1}(\gamma)C_{11}^TC_{11})^TX_{11}(\gamma) \end{aligned}$$

Equation (5.1) clearly shows that $(A_{11} + X_{11}^{-1}(\gamma)C_{11}^TC_{11})$ is antistable, and so the stable eigenvalues of A_{11} (if any) are clearly observable, while the decomposition in Lemma 3.1 shows that the stable eigenvalues of A_{22} are clearly (C, A) -unobservable. Since these two types of eigenvalues exhaust the possibilities, the rank of $X(\gamma)$ must be as asserted.

Suppose that the rank of the stabilizing solutions $X(\gamma)$ is not constant on some open interval. Since the number of unstable eigenvalues of A are independent of γ , the rank of $X(\gamma)$ can only change on the stable eigenvalues. If an eigenvalue λ of A_{11} is (C_{11}, A_{11}) -observable, then it is also (C, A) -observable, because all right eigenvectors of A_{22} are members of the subspace $\text{Ker}(C)$ and all right eigenvectors of A_{11} are members of the subspace $\text{Im}(C)$, and the dimensions $\text{Im}(C)$, A_{11} and $\text{Im} X(\gamma)$ are equal. If the rank $X(\gamma_1)$ is different from the rank of $X(\gamma_2)$ on the interval $\gamma_1 \leq \hat{\gamma}_1 < \hat{\gamma}_2 \leq \gamma_2$, then, by using Lemma 3.1 again, there will exist a stable eigenvalue of A that is both (C, A) -observable and (C, A) -unobservable, which is impossible. \square

Appendix. The main theorem in this appendix is an amalgamation of separate theorems—some stated with more generality—that have been proved in recent publications. The theorem itself has not appeared in any of the separate publications and it will not be proved here. For completeness, each of the contributing results are referenced and they can be consulted for the relevant proofs.

THEOREM A. *Suppose that M and Q are real symmetric matrices with $Q \geq 0$ and ε is a nonnegative parameter.*

The matrix Riccati equation

$$(A.1) \quad A^T P + PA - PMP + Q = 0$$

has a unique stabilizing solution $P \geq 0$ if and only if

(i) *the Hamiltonian*

$$H = \begin{pmatrix} A & -M \\ -Q & -A^T \end{pmatrix}$$

has no imaginary eigenvalues, and

(ii) *the matrix Riccati equation for*

$$(A.2) \quad A^T P^\varepsilon + P^\varepsilon A - P^\varepsilon M P^\varepsilon + Q + \varepsilon I = 0$$

has a singular unique stabilizing solution $P^\varepsilon > 0$ for ε ($\varepsilon > 0$) sufficiently small that depends continuously on ε . Moreover, if P is stabilizing for $\text{Ric}(P, H)$ then the stabilizing solution P^ε for (A.2) will exist.

This fundamental result shows that the stabilizing solution of (A.1) will retain its property in the proximity of a perturbed Riccati equation. The solution depends continuously—at least locally—on the coefficient variation in the Riccati equation. By using a norm-induced metric space and the implicit function theorem, Gahinet and Laub [5] formulate the previous sentence in precise mathematical concepts. By a clever use of the implicit function theorem, they show in a neighborhood—induced by the metric norm—of the stabilizing solution set (P, A, M, Q) the matrix Riccati equation for the perturbed matrices $(A + \Delta A, M + \Delta M, Q + \Delta Q)$ will also have a stabilizing solution, provided that ΔA , ΔM , and ΔQ are real matrices, $\Delta M^T = \Delta M$, $\Delta Q^T = \Delta Q$ and that they are “sufficiently close” to the normal solution set. This local result does not require any other special system requirements such as stabilizability, observability, or inertia properties for ΔM or ΔQ . Another and earlier proof of the regularity of the stabilizing solution of the matrix Riccati equation using the implicit function theorem is found in [3].

Petersen, Anderson, and Jonckheere [18] prove that the existence of a positive semidefinite symmetric solution of (A.2) implies that (A.1) will have a positive semidefinite strong solution. Actually, the matrix $Q + \varepsilon I$ in (A.2) can be replaced by $\hat{Q} \geq Q$ with $\hat{Q} > 0$ in their theorem.

When $\varepsilon > 0$ $(A, \varepsilon I)$ is clearly controllable, and so by a well-known result of Shayman [23], every real symmetric solution of (A.2) is nonsingular. Finally, the statement “ $P \geq 0$ then $P^\varepsilon > 0$ ” in the theorem is proved in paper by Safonov, Limebeer, and Chiang [24]. Whenever (A.1) has a stabilizing solution P , then (A.2) for ε sufficiently small will have a stabilizing solution P^ε also, and both of these solutions will be unique by a theorem in Petersen [19].

Acknowledgments. The author thanks the anonymous referees for their helpful comments.

A GLOBALLY CONVERGENT STOCHASTIC APPROXIMATION*

SID YAKOWITZ†

Abstract. By combining a constrained Kiefer–Wolfowitz search with an automatic learning algorithm, it is shown that asymptotically normal convergence of an estimator to a global optimum under reasonably lenient assumptions can be attained. It is enough that the objective function be smooth and locally strictly convex at its minima. The central conclusion is that if θ_n is the estimate produced by the method shown at the n th decision epoch, then for some global minimizer θ^* , $n^{1/3}(\theta_n - \theta^*)$ is asymptotically normally distributed. This coincides with the conventional Kiefer–Wolfowitz convergence rate to a local optimum.

Whereas this study was motivated by needs of machine learning, the basic plan would seem applicable to root-finding tasks, and to other types of stochastic approximation algorithms.

Key words. stochastic approximation, random search, automatic learning

AMS(MOS) subject classifications. primary 62G05; secondary 62G99

1. An algorithm and statement of results. Many problems in automatic learning can be abstracted as a stochastic minimization problem, to wit: Let $f(\cdot)$ be an unknown function defined on a given domain D . On the basis of noisy observation pairs $\{(\theta_i, Y_i)\}_{i=1}^{n-1}$, with

$$(1.1) \quad Y_i = f(\theta_i) + Z(\theta_i),$$

choose θ_n in such a fashion that with respect to some criterion,

$$(1.2) \quad f(\theta_n) \rightarrow f_{\text{MIN}}.$$

Here f_{MIN} designates the global minimum of $f(\cdot)$ on D , and $Z(\theta_i)$ is a 0-mean random variable depending on the past only through the choice of θ_i .

A number of investigators, e.g., Devroye [1], [2], Gurin [3], and Yakowitz and Lugosi [14], have provided stochastic minimization algorithms that are globally consistent in various senses, and Yakowitz and Fisher [11] and Yakowitz and Lowe [13] have established rates of convergence. These works did not assume the objective function to be smooth, as will be required here. However, under our more stringent assumptions, a much more rapid convergence rate is assured. Computer experimentation on sequences of games, puzzles, and model queueing processes (some of which is reported in Yakowitz [10] and Yakowitz and Lowe [13]) have convinced the author that automatic learning holds promise as a practical methodology. A feature of the objective functions $f(\cdot)$ from these areas of applications is that they are multimodal, and local minima preclude the use of conventional methods.

Neural networks have become a popular facet of learning theory. We may readily confirm (Khanna [5, Chap. 5]) that standard neural network algorithms resemble stochastic approximation formulas. For that reason, the present study may have relevance because a common complaint about neural network learning is that the algorithms are attracted to suboptimal local minima.

The present paper is devoted to synthesizing an automatic learning procedure with Kiefer–Wolfowitz-type stochastic approximations (see Kiefer and Wolfowitz [6]) so as to take advantage of the rapid convergence properties of the latter technique

TABLE 1
A stochastic approximation learning algorithm.

The Components	
D , where D is convex, $D \subset \mathbb{R}^d$.	
$p(\cdot)$, a continuous probability density function (chosen by the user) with D as support.	
$\{N(i)\}$, with	
(1.3)	$N(i) = \text{integer part of } (C \exp(i)), \quad i = 1, 2, \dots$
In (1.3), C is an arbitrary positive constant. The $N(i)$'s are referred to as "new sample times."	
$\{a(i)\}$ and $\{c(i)\}$, are positive sequences, with	
	$a(i) = A/i \quad \text{and} \quad c(i) = C'/i^{1/6}.$
Here A and C' are positive constants, and the sequences are parameters of the K-W search.	
Initialization	
$n = 1, NP = 0$. (n is the decision time, NP is Number of test Points at time n .)	
The Procedure	
If $n \in \{N(i)\}$, then get new test point.	
1. Set $NP = NP + 1$.	
2. Choose a new test point $T_{NP}(n)$ at random according to the density $p(\cdot)$. Set $\theta_n = T_{NP}(n)$ and observe the noisy value	
(1.4)	$Y_n = f(\theta_n) + Z(\theta_n).$
3. Initialize a sample average, a resample counter, and a hypercube for the new test point by defining	
	$m_{NP}(n) = Y_n, \quad \text{and} \quad NS_{NP}(n) = 1,$
and define $H(NP)$ to be the hypercube centered at T_{NP} with sides of length $(1/NP)^{1/d}$. This hypercube is fixed for the rest of the process. (T_{NP} will be constrained to wander around inside of $H(NP)$ as the process evolves.)	
4. Select a good test point for resampling. If $NP > 1$, define MIN to be the index j that minimizes $m_j(n)$, $1 \leq j \leq NP(n)$. Designate as I^* the smallest index i such that	
(1.5)	$m_i \leq m_{\text{MIN}} + 2/\log(n).$
Go to 8.	
Else if $n \notin \{N(i)\}$ then take a K-W step at the (apparently) best point and update other points as needed.	
5. Make a K-W step at I^* : We describe the K-W for the one-dimensional domain case, but the extension to dimension d should be obvious. Set	
	$\theta_n = T_{I^*}$
	$NS = NS_{I^*}(n)$
	$a = a(NS)$
(1.6)	$c = c(NS)$
	$Y1 = f(\theta_n + c) + Z(\theta_n + c)$
	$Y2 = f(\theta_n - c) + Z(\theta_n - c)$
	$DY^*(\theta_n, c) = \frac{1}{2c} (Y1 - Y2).$
Set	
(1.7)	$T = T_{I^*} - a \times DY^*(\theta_n, c).$
The K-W step redefines T_{I^*} to be $T_{I^*} = T$ for $T \in H(I^*)$ or the closest point in $H(I^*)$ to T if $T \notin H(I^*)$.	
6. Update the sample mean and counter:	
(1.8)	$m_{I^*}(n) = 1/(NS + 1)[NSm_{I^*}(n-1) + (Y1 + Y2)/2]$
and	
	$NS = NS + 1.$
7. Update other test points if necessary: Do preceding step at any index i , $1 \leq i \leq NP$, such that $NS_i(n) < n^\gamma$. Here $\gamma \in (0.5, 1)$ is a number which is held fixed for the duration of the process.	
8. Set $n = n + 1$ and repeat the procedure.	

while preserving robust consistency characteristics of the former. It will suffice for our purposes that $f(\cdot)$ be smooth, at least piecewise, and locally strictly convex near its minima.

Table 1 gives a global Kiefer-Wolfowitz (K-W) rule based on the Yakowitz-Lugosi method. Basically, the (very conventional) idea is to occasionally explore the domain to find better points and to improve estimates of values at old but unpromising test points. However, at most decision times, we choose test points at which the performance, as measured by sample averages, is seemingly better. The purposes of this re-sampling are to (i) improve the estimate at these places and (ii) attain performance that is best with respect to the current state of knowledge.

The obvious but apparently new contribution we offer is to take K-W steps at these "resample" times. By this enhancement, we can hope that, as resampling proceeds, each test point "wanders" into the bottom of the valley in which it finds itself. By gradually acquiring new test points in the tradition of random search, eventually every valley will be explored.

The central result (§ 2) is that for the hybrid method, and θ^* some *global* minimizer of $f(\cdot)$,

$$(1.9) \quad n^{1/3}(\theta_n - \theta^*)$$

is asymptotically normal.

We close this section by presenting the globally convergent K-W algorithm and a simple illustration of its use.

An example. We close this introductory section by examining the experimental side. Figure 1 is a plot of

$$(1.10) \quad f(x) = x \sin(30x), \quad x \in D = [0, 2].$$

The noise is independent and identically distributed (i.i.d.) standard normal. Figure 2 gives the average observed performance $(1/n) \sum_{i=1}^n Y_i$ for a version of the K-W learning algorithm, and, for purposes of comparison, Fig. 3 was obtained from a code that is the same, except it does not take K-W steps, but keeps T_i constant at its original, randomly chosen value. That is, update (1.7) is omitted.

FIG. 1. The objective function.

FIG. 2. A search with K-W steps, $\bar{Y}(n) = 1/n \sum_{1 \leq i \leq n} Y(\theta(i))$.

FIG. 3. A search without K-W steps.

Rationale and variations of the algorithm. The goal of finding a global stochastic approximation rule having been set, there are many plausible routes to its accomplishment. Alternative learning schemes that also could be synthesized with the K-W step are briefly discussed in Yakowitz and Lugosi [14]. The author suspects that the algorithm would be convergent without the hypercube constraint construct. However, a demonstration does not readily dawn on him. In any event, there is no hope of attaining a faster asymptotic rate than the present algorithm, which has the rate of the pure K-W process.

We anticipate that readers with specific stochastic minimization problems at hand will take liberties with our algorithm. To get an acceptable level of performance early in the learning process, it is sensible to initially take a goodly number of new point samples relatively soon. Perhaps computation in an interactive mode is warranted. If our global stochastic approximation methodology takes root, it may be worthwhile to devise an adaptive variation which chooses “new point” and “resample” times adaptively according to the degree of observed success in the exploration of new points,

and the observed sample variability in the running means $m_i(n)$. Such data-driven extensions are akin to “automatic bandwidth selection” procedures of the nonparametric estimation literature. To the extent that the nonparametric estimation literature is a useful guide, we may anticipate that analytic prowess will be needed to assure that convergence rates are maintained.

2. Convergence analysis. Here it is shown that a particular set of assumptions can assure convergence, in distribution and mean square, of a global stochastic approximation (SA) minimizer at a stated asymptotic rate. However, the reader will see from the plan we follow that other standard rules and assumptions of the SA realm can likewise be merged with the learning algorithm to attain convergence, perhaps in other senses. The first part of these developments pertains to pure K-W steps, and to avoid confusion with the learning algorithm, the decision variable is x , in §§ 2.1–2.3. Thus we seek a minimizer of $f(x)$ on the basis of noisy observations $Y(x) = f(x) + Z(x)$, $x \in D$. In § 2.4, we synthesize the constrained SA results with the global learning algorithm to demonstrate asymptotic convergence to a global minimizer.

2.1. Process assumptions.

About the objective function.

F.1. The function $f(\cdot)$ to be minimized is defined and three times continuously differentiable on a convex Borel set $D \subset R^d$. The domain D is further presumed to have an open subset.

F.2. The set of global minima (minimizers) of $f(\cdot)$ is finite but not empty.

F.3. Let f_{LOC} denote the infimum of the local but not global minima of $f(\cdot)$. Then

$$f_{\text{LOC}} > f_{\text{MIN}}.$$

F.4. Assume $f(\cdot)$ is locally strictly convex at its global minima, and each such minimum is an interior point of D . Furthermore, hypothesize that not all third-order partial derivatives are 0 at the minima.

About the noise.

N.1. The random variables $Z(x)$ are indexed by $x \in D$. Presume that $\{X(n)\}$ is a sequence obtained by some deterministic operation on observations

$$(X(i), Y(X(i))), i < n.$$

The distribution of $Z(X(n))$ depends on the past history only through the value $X(n)$. That is, in distribution, the conditioned variable

$$(2.1) \quad Z(X(n)) | \{X(1), Y(X(1)), \dots, X(n)\} = Z(X(n)) | X(n).$$

N.2. For each $x \in D$, $E[Z(x)] = 0$.

We remark that a consequence of (2.1) and the 0-conditional expectation assumption is that $\{Z(X(n))\}$ is a martingale difference sequence with respect to the sigma field induced by the preceding X - Y values.

N.3. For some positive constant σ^2 and all $x \in D$, the conditional variance $\text{var}(Z(x)) \leq \sigma^2$. The variance $\text{var}(Z(x))$ is further hypothesized to be continuous in neighborhoods of minima of $f(\cdot)$.

N.4. For some positive number δ and all x , we have

$$(2.2) \quad E|Z(x)|^{2+\delta} \leq M < \infty.$$

About the Kiefer–Wolfowitz steps.

S.1. The sequences $\{a(n)\}$ and $\{c(n)\}$ are defined by

$$(2.3) \quad a(n) = A/(n+1), \quad c(n) = C/(n+1)^{1/6},$$

A and C being positive constants.

S.2. Fix some d -dimensional hypercube $H \subset D$, and suppose the initial value $x(1)$ is chosen arbitrarily from H . For any real function (random or otherwise) $q(\cdot)$ and number $c \neq 0$, we use the notation

$$(2.4) \quad Dq(x, c) = (q(x+c) - q(x-c))/2c.$$

If $q(\cdot)$ is defined on a higher-dimension space, then $Dq(x, c)$ is a vector of like dimension. The j th coordinate is given by

$$Dq_j(x, c) = (q(x + ce_j) - q(x - ce_j))/2c,$$

where e_j is the vector with 1 at the j th coordinate and 0's elsewhere. With these constructs, the constrained search proceeds as follows: For $n \geq 1$, recursively define

$$(2.5) \quad \tilde{X}(n+1) = X(n) - a(n)DY(X(n), c(n)).$$

If $\tilde{X}(n+1) \in H$ then $X(n+1) = \tilde{X}(n+1)$. Otherwise, $X(n+1)$ is the closest vector in H to $\tilde{X}(n+1)$.

2.2. Almost sure convergence. The theory for almost sure convergence for constrained stochastic approximation and asymptotic normality offered in Kushner and Clark [7, Chaps. 5 and 7, respectively] is the foundation for our developments. Hereafter, “KC” will denote this reference and precede its equation and theorem numbers. This section and the following are devoted to recasting KC results into our setting. Our approach to demonstrating asymptotic normality requires first obtaining almost sure convergence, and that is the topic of discourse now.

LEMMA 2.1. *Let $f(\cdot)$ satisfy the conditions F.1, F.2, the noise process satisfy N.1–N.3, and the search be as in S.1 and S.2. Presume that $f(\cdot)$ assumes a minimum at x^* at an interior point of hypercube H and is strictly convex. Then almost surely,*

$$(2.6) \quad X(n) \rightarrow x^*.$$

Furthermore, if the convexity assumption is dropped, but $X(i)$ visits every neighborhood of x^ infinitely often, then almost surely, (2.6) holds.*

Proof. We proceed by showing that the assumptions of Theorem 5.3.1 [KC, p. 191] are satisfied, and then state how the conclusion implies the lemma. To apply this theorem, which ostensibly is directed at the Robbins–Monro case, we set $h(x) = -\nabla f(x)$, as suggested by [KC, p. 190]. Then β_n , as in [KC, eq. 5.3.1], is

$$(2.7) \quad \beta_n = -h(X(n)) - Df(X(n), c(n))$$

and

$$(2.8) \quad \xi_n = -DZ(X(n), c(n)).$$

From standard results on numerical differentiation.

$$(2.9) \quad \beta_n = O(c(n)^2).$$

Thus condition [KC, A5.1.5] is satisfied.

The condition [KC, A5.3.1] that the constraint functions be continuously differentiable is satisfied by the hyperplanes forming the boundary of H . Condition [KC, A5.3.2]

is satisfied if the series

$$(2.10) \quad \sum_{i=1}^{\infty} (a(i)/c(i))Z(X(i))$$

is almost surely convergent. But by N.3 and S.1, we have

$$\sum [a(i)/c(i)]^2 \sigma^2 < \infty$$

which for such orthogonal series, is known to imply almost sure convergence of (2.10) (e.g., Loève [8]).

We have now established that all the conditions of Theorem KC 5.3.1 are satisfied. The conclusion of the theorem is that if the point x is the limit of any convergent subsequence of $\{X(n)\}$, then x is a Kuhn-Tucker (KT) point. By the strict convexity assumption of our lemma, x^* is the unique KT point, and since H is compact, there must be a convergent subsequence. Thus (2.6) must hold. If convexity is dropped, the second part of the lemma is assured by the second part of Theorem KC 5.3.1.

2.3. Asymptotic normality. Theorem KC 7.3.1 addresses asymptotic normality of the unconstrained K-W algorithm directly. Under the conditions of Lemma 2.1, we have almost sure convergence to the minimizer, which is an interior point, and so eventually the points $X(n)$ are all determined by the pure K-W formula (2.5), and thus results about the unconstrained case apply.

LEMMA 2.2. *Under the conditions of Lemma 2.1, including the strict convexity assumption, and also N.4,*

$$(2.11) \quad n^{1/3}(X(n) - x^*)$$

converges in distribution to a normal vector with 0 mean. Also, the variable in (2.11) converges in mean square.

Proof. In the multivariable case, by “square” we mean right multiplication of the $d \times 1$ vector by its transpose. We follow the developments of [KC, Case 1, Chap. 7]. The result holds if we can show that the conditions of [KC, Thm. 7.3.1] are satisfied. Our choice of the sequences $a(n)$ and $c(n)$ are in agreement with [KC, A7.2.4(a)]. Lemma 2.1 is condition [KC, A7.2.2], Condition F.1 is [KC, A7.2.3]. Our noise assumptions N.1 to N.3 are [KC, A7.2.5] to [KC, A7.2.7]. This completes the hypotheses, and the conclusion of Theorem KC 7.3.1 is the conclusion of the lemma. (The discussion in [KC, § 7.4] makes this connection transparent.)

An expression for the limiting covariance matrix is given in [KC, 7.4.2], but it involves terms and parameters which will not usually be available to the statistician.

2.4. Convergence of the learning algorithm. In what follows, we refer to the times at which Algorithm Step 5 is taken, at which we resample at I^* , as *resample* times. The main result of our study is the following theorem.

THEOREM 2.1. *If all the assumptions F.1 to F.4, N.1 to N.4, and S.1 are in force, and the search algorithm of Table 1 is applied, then during resample times n , for some minimizer θ^* of $f(\cdot)$,*

$$(2.12) \quad n^{1/3}(\theta_n - \theta^*)$$

converges asymptotically in distribution to a normal random vector with zero mean. Moreover, the variable (2.12) converges in mean square to a constant matrix, and θ_n converges almost surely to θ^ .*

Proof. The plan is the following: We let V (for “valleys”) designate the union of neighborhoods of the global minima on which $f(\cdot)$ is strictly convex, and on which $f(\cdot)$ takes values no greater than $f_{\text{MIN}} + \varepsilon/2$, with $\varepsilon = f_{\text{LOC}} - f_{\text{MIN}}$ as in F.3. We will

show that eventually there will be hypercubes, as in Step 2, which lie entirely in V and which contain the minima as interior points. Almost surely, for all but finitely many n , resampling will concentrate on but one of these convergent test-points. It is then a simple matter to call upon the lemmas to confirm the statements of the theorem.

Let θ^* be a global minimum of $f(\cdot)$ and B_1 a ball centered at θ^* and having radius r sufficiently small that $f(\cdot)$ is convex on B_1 and is bounded above by $f_{\text{MIN}} + \varepsilon/2$ on B_1 . To show that eventually there is some hypercube $H(k)$ containing θ^* , and such that $H(k) \subset B_1$, take $N > 2/r$, and let E be the event that for some $i \geq N$, $\theta^* \in H(i)$. If E occurs, we have the desired hypercube. Let E^c be the complement of E . Then

$$\begin{aligned} P[E^c] &= \lim_n \prod_{i=N}^n (1 - P[\theta^* \in H(i)]) \\ (2.13) \quad &= \lim_n \prod_{i=N}^n (1 - [p(\theta^*)((1/i) + o(1/i))]) \end{aligned}$$

and this above product converges to 0.

Now that we know that almost surely any test point will eventually fall within an arbitrarily small search hypercube, the next goal is to show that for all but finitely many resample times, test point index I^* , as in Algorithm Step 4, will be selected to be some fixed index of a K-W search in V .

Let $\bar{f}_i(n)$ denote the average of all the true function values made at index i , $1 \leq i \leq NP(n)$, up to decision time n . That is, letting $\tau_i(j)$ denote the time of the j th call to test point T_i ,

$$(2.14) \quad \bar{f}_i(n) = 1/NS_i(n) \sum_{j=1}^{NS_i(n)} (f(\theta_{\tau_i(j)} + c(j)) + f(\theta_{\tau_i(j)} - c(j)))/2.$$

The actual averaged observations at index i , is, of course, the quantity $m_i(n)$, in the algorithm. The observation error due to noise is

$$\begin{aligned} (2.15) \quad e_i(n) &= \bar{f}_i(n) - m_i(n) \\ &= \sum_{j=1}^{NS_i(n)} (1/NS_i(n)) [Z(\theta_{\tau_i(j)} + c(j)) + Z(\theta_{\tau_i(j)} - c(j))]/2. \end{aligned}$$

The objective now is to demonstrate that

$$(2.16) \quad P[|e_i(N(j))| > 1/\log(N(j)), \text{ for infinitely many } i, j] = 0.$$

Fix an index i and let $S_i(n) = NS_i(n) \cdot e_i(n)$. Note that since Kolmogorov's inequality holds for martingales [4, p. 14], for any positive C ,

$$(2.17) \quad P\left[\max_{k \leq N(j)} |S_i(k)| > C\right] \leq N(j)\sigma^2/C^2.$$

From Step 7,

$$NS_i(N(j)) \geq N(j)^\gamma.$$

From this, and after setting $C = N(j)^\gamma/\log(N(j))$, and recalling that $NP(n) = O(\log(n))$, conclude that for some constant C' ,

$$\begin{aligned} (2.18) \quad &P\left[\max_{i \leq NP(N(j))} \max_{N(j)^\gamma \leq k \leq N(j)} |e_i(k)| > 1/\log(N(j))\right] \\ &\leq C' \log^3(N(j))\sigma^2/N(j)^{2\gamma-1}. \end{aligned}$$

The reader will verify that in view of the exponential growth rate of $N(j)$ (recall (1.3)), the right side of (2.18) is summable in index j . The Borel–Cantelli lemma then gives us (2.16).

Since we are examining asymptotic behavior, without loss of generality and in view of (2.16), in discussions to follow we assume that for all new sample times $N(j)$ at which I^* is reassigned,

$$(2.19) \quad |m_i(N(j)) - \bar{f}_i(N(j))| < 1/\log(N(j)), \quad 1 \leq i \leq NP(n).$$

We have noted that every global minimizer is eventually an interior point of some Step 3 hypercube on which the conditions of Lemma 2.1 are satisfied. The conclusion of Lemma 2.1 implies that every global minimizer is the target of some (in fact, arbitrarily many!) K-W searches $T_i(n)$. Define \mathcal{G} to be the (random) set of indices i such that $T_i(n) \rightarrow \bar{\theta}$, for some $\bar{\theta}$ a global minimizer of $f(\cdot)$, and designate G to be the minimum index in \mathcal{G} . By the second part of the Lemma 2.1 and our hypothesis F.3 (which implies that every global minimum is an isolated Kuhn–Tucker point), we conclude that for $i < G$ almost surely $\liminf \bar{f}_i(n) > \bar{f}_G(n)$. Consequently, in view of (2.16), only finitely many times can such a value $i < G$ serve as I^* . That is, almost surely, for all retest times n sufficiently large,

$$I^*(n) \geq G.$$

Toward analyzing the convergence behavior of $\bar{f}_G(n)$, we appeal to a law of the iterated logarithm for the K-W process in Hall and Heyde [4, § 7.6]. Hall and Heyde’s (designated now as HH) conditions B1 through B4 are covered by our smoothness and convexity postulates F1 and F4, and the observation that eventually $T_G(n)$ is a pure K-W process converging to θ^* . The HH condition B5 is satisfied by our noise assumptions N1 through N4. The HH analysis assumes that the K-W domain is of dimension 1, but assuming dimension $d > 1$ has influence only in replacing scalars by vectors, and reading absolute as norms, in their analysis. An implication of HH Theorem 7.15 is that almost surely,

$$(2.20) \quad |T_G(\tau_G(j)) - \theta^*| < C\sqrt{\log(\log(\tau_G(j)))/j^\gamma}$$

for some positive constant C and all j sufficiently large. After summing j from 1 to n^γ , and using that $f(T_G(\tau_G(j))) - f_{\min} = o(T_G(\tau_G(j)) - \theta^*)$, we see that almost surely,

$$(2.21) \quad \bar{f}_G(n) - f_{\min} = o(1/n^{1/6}).$$

Relations (2.16) and (2.21) yield that for all $i > G$ and large j ,

$$(2.22) \quad \begin{aligned} m_i(N(j)) + 2/\log(N(j)) &> f_{\min} + 2/\log(N(j)) \\ &> \bar{f}_G(n) + 2/\log(N(j)) + o(1/N(j)^{1/6}) \\ &> m_G(N(j)). \end{aligned}$$

The preceding sequence implies that condition (1.6) for choosing I^* will be satisfied by G for all but finitely many $N(j)$. This gives that almost surely, at all retest times n sufficiently large, Lemmas 2.1 and 2.2 apply to the search $T_G(n)$. The conclusions of these lemmas imply the theorem. \square

Upon recognizing that Step 1 and Step 7 times grow as $o(n)$, we can readily modify the global SA to assure asymptotic normality without restriction on n by letting the $N(i)$ ’s be randomly chosen (independently of the search process) integers from the interval

$$[C(1 - \alpha) \exp(i), C(1 + \alpha) \exp(i)],$$

for α an arbitrary number in the open unit interval and C as before. It is evident that the asymptotic normality result and convergence rate will be unchanged, but, of course, the almost sure convergence is sacrificed. The modifications of the proof of the theorem to cover this alteration are fairly evident.

COROLLARY 2.1. *If the conditions and the global SA are as in the theorem, except that the $N(i)$'s are randomly chosen from the integers in*

$$[C(1 - \alpha) \exp(i), C(1 + \alpha) \exp(i)],$$

then we have that, regardless of n ,

$$(2.23) \quad n^{1/3}(\theta_n - \theta^*)$$

converges asymptotically in distribution to a normal random vector with zero mean. Moreover, if the search domain D is bounded, the variable (2.23) converges in mean square to a constant matrix.

3. Conclusions. To some, the orientation of this study, with its emphasis on the "stochastic minimization" problem, will appear misguided. The major contribution would seem to be to the stochastic approximation method, about which we find much more research interest than machine learning. The orientation here stems from the author's conviction that the machine learning problem is the more significant, and that stochastic approximation is but one important tool among many for machine learning.

On the pragmatic side, the author and his students have found the global stochastic approximation to be effective for artificial-intelligence and heuristic search problems with low-dimension variables. Our experience with problems in which the search domain D has dimension higher than 10, say, has not been encouraging. This appears to have more to do with the curse of dimensionality than our deviation from pure K-W rules. (This phenomenon casts a shadow on the neural network enterprise.)

At the beginning of § 2, it was noted that our analysis could apparently be modified to encompass other stochastic approximation rules or to obtain convergence in other senses. In that regard, a fine study by Polak and Tsybakov [9] offers a stochastic approximation idea based on kernel regression notions and shows how to achieve optimal rates with respect to the class of all data-based nonparametric algorithms, under certain standard assumptions about the smoothness and noise.

As a final point, it is to be noted that our technique can be employed for the original Robbins-Monro task of finding the root of a regression function. Thus we could seek roots for functions $f(\cdot)$ which only satisfy the standard conditions locally, without sacrificing asymptotic rates.

Acknowledgments. This research effort stemmed from discussions with Professor Luc Devroye, who graciously invited me to a two-week visit at McGill University. Also, I am deeply indebted to a reviewer who not only uncovered a defect in the original proof of Theorem 2.1, but provided details of a way to circumvent the trouble and strengthen the conclusion, so as to show that G is almost surely chosen from some time onward. My gratitude is especially heartfelt because this reviewer offered these developments with utmost courtesy and diplomacy.

OPTIMAL MUTUAL INFORMATION FOR CODERS AND JAMMERS IN MISMATCHED COMMUNICATION CHANNELS*

KENJIRO YANAGI†

Abstract. The mismatched communication channel with an infinite-dimensional real separable Hilbert space as input and output spaces is considered. To study communication in the presence of jamming, a two person zero sum game with mutual information of input source and output source as the payoff function can be formulated. The coder's goal is to make mutual information as large as possible, and the jammer's goal is to make mutual information as small as possible. The optimal mutual information under appropriate constraints of coders and jammers is obtained.

Key words. information theory, game theory, communications, jamming

AMS(MOS) subject classification. 94A

1. Introduction. The additive Gaussian channels can be considered in the following way. For the sake of simplicity, we consider both the input spaces and the output spaces to be a real separable Hilbert space H . Suppose that the noise source μ_Z is a Gaussian measure on H with mean 0 and covariance operator R_Z and the input source μ_X is a probability measure on H . Then the output source μ_Y is defined as

$$\mu_Y(A) = \mu_X \otimes \mu_Z\{(x, y); x + y \in A\}, \quad A \in \mathcal{B},$$

where $\mu_X \otimes \mu_Z$ is the usual product measure of μ_X and μ_Z and \mathcal{B} is the Borel σ -field of H . The compound source μ_{XY} derived from the input source μ_X and the noise source μ_Z is defined by

$$\mu_{XY}(B) = \mu_X \otimes \mu_Z\{(x, y); (x, x + y) \in B\}, \quad B \in \mathcal{B} \times \mathcal{B},$$

where $\mathcal{B} \times \mathcal{B}$ is the Borel σ -field of $H \times H$.

The mutual information $I(X, Y)$ of μ_{XY} with respect to $\mu_X \otimes \mu_Y$ is defined as follows: If $\mu_{XY} \ll \mu_X \otimes \mu_Y$,

$$I(X, Y) = \int_{H \times H} \log \frac{d\mu_{XY}}{d\mu_X \otimes \mu_Y}(x, y) d\mu_{XY}(x, y),$$

and otherwise $I(X, Y) = \infty$ (see [10], [11], [12], [17], [18]).

The information capacity is then $\sup \{I(X, Y); \mu_X \in \Phi\}$, where Φ is a set of admissible μ_X . Baker [1] defined mismatched Gaussian channels in the following way: Let μ_w be a Gaussian measure on H with mean 0 and covariance operator R_w satisfying

$$\text{range}(R_w^{1/2}) \subset \text{range}(R_Z^{1/2})$$

and

$$\overline{\text{range}(R_w)} = H.$$

Then there exists an unbounded densely defined selfadjoint operator S such that

$$R_Z = R_w^{1/2}(I + S)R_w^{1/2}.$$

An appropriate constraint is thus

$$\Phi = \left\{ \mu_X; \mu_X \text{ is a mean zero probability measure satisfying} \right. \\ \left. \int_H \|x\|_w^2 d\mu_X(x) \leq P(>0) \right\},$$

where $\|\cdot\|_w$ is the norm of reproducing kernel Hilbert space of μ_w . Then the capacity was obtained exactly.

McEliece and Stark [16] have modeled the conflict between coder and jammer when coding is used by a two-player zero-sum game with mutual information as the payoff function (see also [9], [19]). Recently, Hughes and Narayan [13], [14] obtained the interesting results for optimal coding. On the other hand, if the payoff function is instead taken as a quadratic distortion measure, it is known that Gaussian measures constitute saddle points for both finite and infinite-dimensional formulations (see [2], [3], [4], [5], [6], [7], [8]). But since we are interested in mutual information, we here adopt the viewpoint given in [9] that this is a game with two players. Player A, which we call the coder, controls the input source μ_X . Player B, which we call the jammer, controls the noise source μ_Z . The coder's goal is to make $I(X, Y)$ as large as possible, and the jammer's goal is to make it as small as possible. We call $I(X, Y)$ the game's payoff function in our game. This game will be meaningless and trivial unless we place restrictions on the players. We suppose that the coder's choice of μ_X must lie in a certain set Φ , the set of allowable inputs, and that μ_Z must lie in Ψ , the set of allowable noises. Then two programs are associated with this game.

$$\text{Coder's program:} \quad \alpha = \sup_{\mu_X \in \Phi} \inf_{\mu_Z \in \Psi} I(X, Y).$$

$$\text{Jammer's program:} \quad \beta = \inf_{\mu_Z \in \Psi} \sup_{\mu_X \in \Phi} I(X, Y).$$

A strategy μ_X^* such that

$$(1) \quad \inf_{\mu_Z \in \Psi} I(X^*, Y) = \alpha$$

is called an optimal strategy for the coder. The significance is that (1) implies

$$(2) \quad I(X^*, Y) \geq \alpha$$

for all allowable noises μ_Z . Hence, if the coder chooses the input μ_X^* , he is guaranteed a payoff of at least α , regardless of the jammer's strategy.

Similarly, an optimal strategy for the jammer is defined to be a strategy $\mu_Z^* \in \Psi$ such that

$$(3) \quad \sup_{\mu_X \in \Phi} I(X, Y^*) = \beta.$$

It follows that (3) implies

$$(4) \quad I(X, Y^*) \leq \beta$$

for all allowable input μ_X .

If it happens that $\alpha = \beta$, then combining (2) and (4), we have

$$(5) \quad I(X^*, Y^*) = \alpha = \beta$$

$$(6) \quad I(X, Y^*) \leq I(X^*, Y^*) \leq I(X^*, Y)$$

for every choice of allowable μ_X and μ_Z . If (5) holds, which is equivalent to (6), the common value is called the value of the game. The pair (μ_X^*, μ_Z^*) of optimal strategies is called a saddle point. In absence of other information, the coder will want to play strategy μ_X^* , and the jammer will want to play μ_Z^* .

2. Preliminaries. We assume that $\dim[H] = \infty$. We adopt the following Φ as a constraint of allowable coders:

$$\Phi = \left\{ \mu_X; \mu_X \text{ is a zero mean probability measure on } H \text{ satisfying} \right. \\ \left. \int_H \|x\|_W^2 d\mu_X(x) \leq P(>0) \right\}.$$

We also adopt the following Ψ as a constraint of allowable jammers:

$\Psi = \{\mu_Z; \mu_Z \text{ is a zero mean probability measure on } H \text{ with covariance operator } R_Z = R_W^{1/2}(I + S)R_W^{1/2}, \text{ where } S \text{ has } \theta \text{ (=the smallest limit point of the spectrum of } S) \text{ and } \{\lambda_n\}, \lambda_n \leq \lambda_{n+1} \text{ (=the set of eigenvalues of } S \text{ that are strictly less than } \theta), \text{ satisfying the following conditions:}$

$$\sum_n (\theta - \lambda_n) \geq P$$

and

$$\sum_n (1 + \lambda_n) \leq Q(>0)\}.$$

We remark that the limit points of the spectrum of S consist of all eigenvalues of infinite multiplicity, limit points of distinct eigenvalues, or points of the continuous spectrum. And we remark that $\#\{n; \lambda_n < \theta\} < \infty$, where $\#A$ denotes the number of elements of A . Then we set $L = \#\{n; \lambda_n < \theta\}$. The above Ψ in the infinite-dimensional channel is considered to be a naturally extended constraint of that which is stated in the finite-dimensional channel (Theorem 6). When μ_X is Gaussian with covariance operator

$$R_X = \sum_n \tau_n [R_Z^{1/2} u_n] \odot [R_Z^{1/2} u_n],$$

where $\tau_n \geq 0$ for $n \geq 1$, $\sum_n \tau_n < \infty$, $\{u_n; n \geq 1\}$ is a c.o.n. set and $(u \odot v)x = \langle x, v \rangle u$, and when μ_Z is also Gaussian, then we obtain

$$I(X, Y) = \frac{1}{2} \sum_n \log(1 + \tau_n).$$

Rewriting the condition of μ_X , we have

$$\sum_n \tau_n \|(I + S)^{1/2} U^* u_n\|^2 \leq P,$$

where U is a unitary operator. Setting $x_n^2 = \tau_n \|(I + S)^{1/2} U^* u_n\|^2$,

$$I(X, Y) = \frac{1}{2} \sum_n \log \left(1 + \frac{x_n^2}{1 + \lambda_n} \right)$$

where $\sum_n x_n^2 \leq P$, $\lambda_n = \langle S v_n, v_n \rangle$, $n \geq 1$, $\{v_n; n \geq 1\}$ is a c.o.n. set in the domain $\mathcal{D}(S)$ of S . We denote the direct sum by \oplus . Let R_n be the eigenspace of S relative to the eigenvalue λ_n . In order to make the value of game finite, we assume that

$$R_1 \oplus R_2 \oplus \cdots \oplus R_L \supset \text{linear supp}(\mu_X)$$

in Theorems 1-5 below, where $\text{linear supp}(\mu_X)$ means the linear support of μ_X .

When $\mu_Z \in \Psi$ is Gaussian, we at first obtain the following value:

$$C = \sup_{\mu_X \in \Phi} I(X, Y).$$

By the well-known results [1], [11], we obtain as follows:

1. If $\sum_{n=1}^L (\theta - \lambda_n) = P$, then

$$(7) \quad C = \frac{1}{2} \sum_{n=1}^L \log \frac{1+\theta}{1+\lambda_n} + \frac{1}{2} \frac{P + \sum_{n=1}^L (\lambda_n - \theta)}{1+\theta}.$$

2. If $\sum_{n=1}^L (\theta - \lambda_n) > P$, then the following hold:

(a) If $P + \sum_{n=1}^L \lambda_n > L\lambda_L$, then

$$(8) \quad C = \frac{1}{2} \sum_{n=1}^L \log \frac{\sum_{i=1}^L \lambda_i + P + L}{L(1+\lambda_n)}.$$

(b) If $K\lambda_{K+1} \geq P + \sum_{n=1}^K \lambda_n > K\lambda_K$ for some $K < L$,

$$(9) \quad C = \frac{1}{2} \sum_{n=1}^K \log \frac{\sum_{i=1}^K \lambda_i + P + K}{K(1+\lambda_n)}.$$

In both cases C is attained by Gaussian μ_X .

It is convenient to introduce the following notations:

$$\Phi^0 = \{\mu_X \in \Phi; \mu_X \text{ is Gaussian}\},$$

$$\Psi^0 = \{\mu_Z \in \Psi; \mu_Z \text{ is Gaussian}\},$$

$$\alpha_0 = \sup_{\mu_X \in \Phi^0} \inf_{\mu_Z \in \Psi^0} I(X, Y),$$

$$\beta_0 = \inf_{\mu_Z \in \Psi^0} \sup_{\mu_X \in \Phi^0} I(X, Y).$$

It is well known that we may show $\alpha_0 = \beta_0$ to show $\alpha = \beta$. And so, it is sufficient to show (6) for every $\mu_X \in \Phi^0$ and $\mu_Z \in \Psi^0$. That is, we can assume that both allowable coders and allowable jammers are Gaussian.

3. Statements and proofs. At first we state the following four theorems.

THEOREM 1. (L is fixed; θ and $\{\lambda_1, \lambda_2, \dots, \lambda_L\}$ are variable)

$$\alpha = \beta = \frac{L}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying $x_1^2 = x_2^2 = \dots = x_L^2 = P/L$, $\lambda_1 = \lambda_2 = \dots = \lambda_L = (Q - L)/L$, and $\theta > (P + Q)/L - 1$.

THEOREM 2. (L and θ are fixed; $\{\lambda_1, \lambda_2, \dots, \lambda_L\}$ are variable). Let $M = [(P + Q)/(1 + \theta)]$, when $[k]$ denotes the largest integer which is not larger than k .

1. If $L \leq M$, then

$$\alpha = \beta = \frac{L}{2} \log \frac{L(1+\theta)}{L(1+\theta) - P},$$

which is attained by Gaussian coder and Gaussian jammer satisfying $x_1^2 = x_2^2 = \dots = x_L^2 = P/L$, and $\lambda_1 = \dots = \lambda_L = \theta - P/L$.

2. If $L > M$, then

$$\alpha = \beta = \frac{L+1}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying $x_1^2 = x_2^2 = \dots = x_{L+1}^2 = P/(L+1)$, and $\lambda_1 = \lambda_2 = \dots = \lambda_{L+1} = Q/(L+1) - 1$.

THEOREM 3. (θ, L and $\{\lambda_1, \lambda_2, \dots, \lambda_L\}$ are all variable)

$$\alpha = \beta = \frac{1}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying

$$x_1 = P, \quad \lambda_1 = Q - 1, \quad \theta > P + Q - 1, \quad L = 1.$$

THEOREM 4. (θ is fixed; L and $\{\lambda_1, \lambda_2, \dots, \lambda_L\}$ are variable).

1. If $\theta > P + Q - 1$, then

$$\alpha = \beta = \frac{1}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying

$$x_1^2 = P, \quad \lambda_1 = Q - 1, \quad L = 1.$$

2. If $\theta \leq P + Q - 1$, then

$$\alpha = \beta = \frac{1}{2} \log \frac{\theta + 1}{\theta + 1 - P},$$

which is attained by Gaussian coder and Gaussian jammer satisfying

$$x_1^2 = P, \quad \lambda_1 = \theta - P, \quad L = 1.$$

Since the proofs of the above four theorems are similar, we only prove Theorem

2. Essentially, we need the following lemma.

LEMMA 1. The following inequalities hold.

1. If $x_i \geq 0 (1 \leq i \leq n)$, then

$$\log \left(1 + \frac{x_1}{a} \right) \left(1 + \frac{x_2}{a} \right) \dots \left(1 + \frac{x_n}{a} \right) \leq n \log \left(1 + \frac{x_1 + \dots + x_n}{na} \right).$$

The equality holds when $x_1 = x_2 = \dots = x_n$.

2. If $x_i > 0 (1 \leq i \leq n)$, then

$$n \log \left(1 + \frac{na}{x_1 + \dots + x_n} \right) \leq \log \left(1 + \frac{a}{x_1} \right) \left(1 + \frac{a}{x_2} \right) \dots \left(1 + \frac{a}{x_n} \right).$$

The equality holds when $x_1 = x_2 = \dots = x_n$.

Proof of Lemma 1.

1. Let $f(x) = 1 + x/a (x \geq 0)$ and $g(x) = \log f(x)$. Then $g''(x) = -1/(x+a)^2 < 0$. By Jensen's inequality,

$$g \left(\frac{x_1 + \dots + x_n}{n} \right) \geq \frac{1}{n} \{g(x_1) + \dots + g(x_n)\},$$

where the equality holds when $x_1 = x_2 = \dots = x_n$. Then we have

$$n \log \left(1 + \frac{x_1 + \dots + x_n}{na} \right) \geq \log \left(1 + \frac{x_1}{a} \right) \left(1 + \frac{x_2}{a} \right) \dots \left(1 + \frac{x_n}{a} \right).$$

2. Let $f(x) = 1 + a/x = (x+a)/x (x > 0)$ and $g(x) = \log f(x)$. Then $g''(x) = a(2x+a)/x^2(x+a)^2 > 0$. By Jensen's inequality,

$$g\left(\frac{x_1 + \cdots + x_n}{n}\right) \leq \frac{1}{n} \{g(x_1) + \cdots + g(x_n)\},$$

where the equality holds when $x_1 = x_2 = \cdots = x_n$. Then we have

$$n \log \left(1 + \frac{na}{x_1 + \cdots + x_n}\right) \leq \log \left(1 + \frac{a}{x_1}\right) \left(1 + \frac{a}{x_2}\right) \cdots \left(1 + \frac{a}{x_n}\right). \quad \square$$

Proof of Theorem 2.

1. We show the left-hand side of (6). We have to maximize the value

$$\frac{1}{2} \sum_{n=1}^L \log \left(1 + \frac{x_n^2}{1 + \theta - P/L}\right),$$

where $\sum_{n=1}^L x_n^2 \leq P$, $x_n^2 \geq 0 (1 \leq n \leq L)$. By part 1 of Lemma 1,

$$\begin{aligned} & \log \left(1 + \frac{x_1^2}{1 + \theta - P/L}\right) \left(1 + \frac{x_2^2}{1 + \theta - P/L}\right) \cdots \left(1 + \frac{x_L^2}{1 + \theta - P/L}\right) \\ & \leq L \log \left(1 + \frac{x_1^2 + x_2^2 + \cdots + x_L^2}{L(1 + \theta) - P}\right). \end{aligned}$$

(The equality holds when $x_1^2 = \cdots = x_L^2$)

$$\begin{aligned} & \leq L \log \left(1 + \frac{P}{L(1 + \theta) - P}\right) \\ & = L \log \frac{L(1 + \theta)}{L(1 + \theta) - P}. \end{aligned}$$

(The equality holds when $x_1^2 + \cdots + x_L^2 = P$)

Then the maximal value is

$$\frac{2}{L} \log \frac{L(1 + \theta)}{L(1 + \theta) - P},$$

which is attained by $x_1^2 = \cdots = x_L^2 = P/L$.

Next we show the right-hand side of (6). We have to minimize the value

$$(10) \quad \frac{1}{2} \sum_{n=1}^L \log \left(1 + \frac{P/L}{1 + \lambda_n}\right),$$

where

$$\sum_{n=1}^L (1 + \lambda_n) \leq Q, \quad \sum_{n=1}^L (\theta - \lambda_n) \geq P.$$

Since $L \leq M$, we have $L \leq (P+Q)/(1+\theta)$. Then $L(1+\theta) - P \leq Q$. Hence we may minimize the value (10) where

$$\sum_{n=1}^L (\theta - \lambda_n) \geq P.$$

That is equal to $\sum_{n=1}^L (1 + \lambda_n) \leq L(1 + \theta) - P$. By part 2 of Lemma 1,

$$\begin{aligned} & \log \left(1 + \frac{P/L}{1 + \lambda_1} \right) \left(1 + \frac{P/L}{1 + \lambda_2} \right) \cdots \left(1 + \frac{P/L}{1 + \lambda_L} \right) \\ & \geq L \log \left(1 + \frac{P}{L + \lambda_1 + \lambda_2 + \cdots + \lambda_L} \right). \end{aligned}$$

(The equality holds when $\lambda_1 = \cdots = \lambda_L$)

$$\begin{aligned} & \geq L \log \left(1 + \frac{P}{L(1 + \theta) - P} \right) \\ & = L \log \frac{L(1 + \theta)}{L(1 + \theta) - P}. \end{aligned}$$

(The equality holds when $L + \lambda_1 + \cdots + \lambda_L = L(1 + \theta) - P$.)

Then the minimal value is

$$\frac{L}{2} \log \frac{L(1 + \theta)}{L(1 + \theta) - P},$$

which is attained by $\lambda_1 = \cdots = \lambda_L = \theta - (P/L)$.

2. We show the left-hand side of (6). We have to maximize the value

$$\frac{1}{2} \sum_{n=1}^{L+1} \log \left(1 + \frac{x_n^2}{Q/(L+1)} \right),$$

where $\sum_{n=1}^{L+1} x_n^2 \leq P$, $x_n^2 \geq 0$ ($1 \leq n \leq L+1$). By part 1 of Lemma 1 and the same method of Theorem 1, it is obtained that the maximal value is

$$\frac{L+1}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by $x_1^2 = \cdots = x_{L+1}^2 = P/(L+1)$.

Next we show the right-hand side of (6). We must maximize the value

$$(11) \quad \frac{1}{2} \sum_{n=1}^{L+1} \log \left(1 + \frac{P/(L+1)}{1 + \lambda_n} \right),$$

where

$$\sum_{n=1}^{L+1} (1 + \lambda_n) \leq Q, \quad \sum_{n=1}^{L+1} (\theta - \lambda_n) \geq P.$$

Since $L > M$, we have $(P + Q)/(1 + \theta) < L$. Then $(L+1)(1 + \theta) - P > Q$. By part 2 of Lemma 1 and the same method of Theorem 1, it is obtained that the minimal value is

$$\frac{L+1}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by $\lambda_1 = \cdots = \lambda_{L+1} = Q/(L+1) - 1$. \square

The following is an example in which the optimal coders and the optimal jammers do not exist.

THEOREM 5. (L and $\{\lambda_1, \lambda_2, \cdots, \lambda_L\}$ are fixed; θ is only variable); $\alpha_0 = \beta_0$ does not necessarily hold.

Counterexample of Theorem 5. Let $L = 2$, $\lambda_1 < \lambda_2$, $P > \lambda_2 - \lambda_1$, and $Q \geq 2 + \lambda_1 + \lambda_2$. The condition of θ is that $\theta \geq (P + \lambda_1 + \lambda_2)/2$. Then

$$\begin{aligned} e^{2\alpha_0} &= \max_{0 \leq x \leq P} \left[\min \left\{ \left(1 + \frac{x}{1 + \lambda_1}\right) \left(1 + \frac{P-x}{1 + \lambda_2}\right) \right. \right. \\ &\quad \left. \left. \cdot \left(1 + \frac{P-x}{1 + \lambda_1}\right) \left(1 + \frac{x}{1 + \lambda_2}\right) \right\} \right] \\ &= \left(1 + \frac{P}{2(1 + \lambda_1)}\right) \left(1 + \frac{P}{2(1 + \lambda_2)}\right). \end{aligned}$$

On the other hand, by the result of Baker [1] (see (7), (8), (9)),

$$e^{2\beta_0} = \frac{(P + 2 + \lambda_1 + \lambda_2)^2}{4(1 + \lambda_1)(1 + \lambda_2)}.$$

Hence $\beta_0 > \alpha_0$.

Finally we assume that $\dim[H] = N < \infty$. We adopt the following Φ as a constraint of allowable coders:

$\Phi = \{\mu_X; \mu_X \text{ is a zero mean probability measure on } H \text{ with covariance operator } R_X \text{ satisfying } \text{Tr}[R_X] \leq P(>0)\}$.

Since we can take $R_W = I$ (= the identity), $R_Z = R_W^{1/2}(I + S)R_W^{1/2}$ becomes $R_Z = I + S$. Then we can take $\theta = \infty$ because S has at most N eigenvalues. And $\{\lambda_n\}$ are all eigenvalues of S and $\{\lambda_n\}$ always satisfy the following conditions:

$$\sum_n (\theta - \lambda_n) \geq P.$$

So we use a true power constraint. Then we adopt the following Ψ as a constraint of allowable jammers:

$\Psi = \{\mu_Z; \mu_Z \text{ is a zero mean nondegenerate probability measure on } H \text{ with covariance operator } R_Z \text{ satisfying } \text{Tr}[R_Z] \leq Q(>0)\}$.

Now we obtain the final theorem.

THEOREM 6. *We have*

$$\alpha = \beta = \frac{N}{2} \log \left(1 + \frac{P}{Q}\right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying $x_1^2 = x_2^2 = \dots = x_N^2 = P/N$ for eigenvalues of R_X and $r_1 = r_2 = \dots = r_N = Q/N$ for eigenvalues of R_Z .

Since we can prove this by the same method, we omit the proof.

4. Remarks.

1. To motivate the problem formulation, and to illustrate the main results, we give some specific examples of channels which would fit the infinite-dimensional Hilbert space set-up and satisfy the various assumptions made on the covariance operators associated with the input and noise signals.

The continuous time Gaussian channel is presented by

$$(12) \quad Y(t) = \int_0^t x(u) du + Z(t), \quad 0 \leq t \leq T,$$

where $x(\cdot)$, $Y(\cdot)$, and $Z(\cdot)$ are the channel input, the channel output, and the noise, respectively. The noise $Z(\cdot)$ is assumed to be a Gaussian process given by

$$Z(t) = B(t) + \int_0^t \int_0^s f(s, u) dB(u) ds,$$

where $B(\cdot)$ is a Brown motion and $f(s, u) \in L^2([0, T] \times [0, T])$ is a Volterra function (i.e., $f(s, u) = 0$ if $s < u$).

The white Gaussian channel is presented by

$$Y(t) = \int_0^t x(u) du + B(t), \quad 0 \leq t \leq T,$$

and is a special case of the Gaussian channel (12). We assume that an average power constraint

$$\int_0^T E[x(u)^2] du \leq PT$$

is imposed on the channel input, where $P > 0$ is a constant.

Let F and F^* be the integral operators on $L^2[0, T]$ with integral kernel $f(s, u)$ and $f^*(s, u) \equiv f(u, s)$, respectively, and define a selfadjoint operator S by

$$S = F + F^* + FF^*.$$

The S above works for jammers. Since S is a Hilbert-Schmidt operator, the smallest limit point of the spectrum of S is 0. Then we can assume that the negative eigenvalues $\{\lambda_n\}$, $\lambda_n \leq \lambda_{n+1}$, of S satisfy the following conditions:

$$\sum_n |\lambda_n| \geq P$$

and

$$\sum_n (1 + \lambda_n) \leq Q (> 0).$$

In Theorem 2, we assume that $\{\lambda_1, \dots, \lambda_L\}$ are variable and in Theorem 4, we assume that L and $\{\lambda_1, \dots, \lambda_L\}$ are variable.

2. We consider the problems that allow for the encoder to receive some feedback information from the output of the channel. In general, the following model for the discrete time Gaussian channel with feedback is considered:

$$Y_n = U_n + Z_n, \quad n = 1, 2, \dots, N,$$

where $Z = \{Z_n; n = 1, \dots, N\}$ is a nondegenerate, zero mean Gaussian process representing the noise and $U = \{U_n; n = 1, \dots, N\}$ and $Y = \{Y_n; n = 1, \dots, N\}$ are stochastic processes representing input signals and output signals, respectively. The channel is with noiseless feedback, so U_n is a function of a message X to be transmitted and the output signals Y_1, \dots, Y_{n-1} . We assume that a constraint, given in terms of the covariance matrix, is imposed on the input signals. Rigorously speaking, we assume the following constraints:

(A.1). A message X to be transmitted is a random variable, taking values in an arbitrary measurable space and independent of Z . However, we may regard messages $X = \{X_n; n = 1, \dots, N\}$ as stochastic processes.

(A.2). U_n is $\mathcal{F}(X) \vee \mathcal{F}_{n-1}(Y)$ -measurable, where $\mathcal{F}(X)$ and $\mathcal{F}_{n-1}(Y)$ are the σ -fields generated by X and $\{Y_k; k = 1, \dots, n-1\}$, respectively, and $\mathcal{A} \vee \mathcal{B}$ denotes the σ -field generated by σ -fields \mathcal{A} and \mathcal{B} .

(A.3). $\sum_{n=1}^N E[U_n^2] \leq P$.

Denote by Ω the class of all pairs (X, U) of a message X and an input signal U which satisfy the conditions (A.1)–(A.3). The mutual information quantity between a message X and the output signal $Y = \{Y_n; n = 1, \dots, N\}$ is denoted by $I(X, Y)$. Then the capacity C of the channel is defined as

$$C = \sup \{I(X, Y); (X, U) \in \Omega\}.$$

We denote $C_0(P)$ and $C_f(P)$ the capacities of Gaussian channels without and with feedback, respectively. In [15], [20], we obtained the necessary and sufficient conditions for the feedback capacity to increase.

Now we denote by $R_Z = \{z_{kl}\}$ the covariance matrix of Z with eigenvalues $0 < r_1 \leq r_2 \leq \dots \leq r_N$. We let $L_k = \{l(\neq k); z_{kl} \neq 0\}$. Then Z is said to be *white* when $L_k = \emptyset$ for any k , Z is said to be *blockwise white* when Z is not white and there exists k such that $L_k = \emptyset$, and Z is said to be *completely nonwhite* when $L_k \neq \emptyset$ for any k . When Z is blockwise white, we denote by \hat{R}_Z the submatrix of R_Z constructed by $\{k; L_k \neq \emptyset\}$.

The results are summarized in the following Proposition.

PROPOSITION 1. *The following results hold.*

- (a) *If Z is white, then $C_0(P) = C_f(P)$ for any P .*
- (b) *If Z is completely nonwhite, then $C_0(P) < C_f(P)$ for any P .*
- (c) *If Z is blockwise white, then:*
 - (i) *$P > P_0$ implies $C_0(P) < C_f(P)$,*
 - (ii) *$P \leq P_0$ implies $C_0(P) = C_f(P)$,*

where $P_0 = mr_m - (r_1 + \dots + r_m)$ and r_m is the smallest eigenvalues of \hat{R}_Z .

We apply our problems to the feedback case. We assume that $\dim[H] = N < \infty$. We denote the following Φ as a constraint of allowable coders:

$\Phi = \{(\mu_X, T); \mu_X \text{ is a zero mean probability measure on } H \text{ with covariance matrix } R_X, T \text{ is a Volterra matrix satisfying}$

$$\text{Tr}[(I + T)R_X(I + {}^tT) + TR_Z{}^tT] \leq P(>0)\},$$

where tT is the transposed matrix of T .

We adopt the following Ψ as a constraint of allowable jammers:

$$\Psi = \{\mu_Z; \mu_Z \text{ is a zero mean nondegenerate probability measure on } H \text{ with covariance matrix } R_Z \text{ satisfying } \text{Tr}[R_Z] \leq Q(>0)\}.$$

Using Proposition 1, it is not difficult to show the following result.

PROPOSITION 2.

$$\alpha = \beta = \frac{N}{2} \log \left(1 + \frac{P}{Q} \right),$$

which is attained by Gaussian coder and Gaussian jammer satisfying $x_1^2 = x_2^2 = \dots = x_N^2 = P/N$ for eigenvalues of R_X and $r_1 = r_2 = \dots = r_N = Q/N$ for eigenvalues of R_Z and $T = 0$.

Then we can see that feedback is not useful in our jamming channels.

Acknowledgments. The author would like to express his hearty thanks to the referee in the course of preparing this paper.

OPTIMAL CONTROL OF FAVORABLE GAMES WITH A TIME LIMIT*

MARTIN KULLDORFF†

Abstract. This paper shows how to optimally control a stochastic process if one seeks to reach a certain value before a fixed time without first hitting zero. The process has a drift in the favorable direction. Discrete time random walks, as well as continuous time diffusion processes, are considered. The controls available are such that zero variance means zero drift, and more variance means more drift. To be more precise, in the continuous time case it holds that $dX_t = \sigma(X_t, t)(\mu_t dt + dB_t)$, where σ is the control variable. As corollaries of the results, some interesting inequalities for stochastic processes are obtained.

Key words. stochastic control, gambling theory, red and black, limits of control problems, inequalities for stochastic processes, Brownian motion, random walk

1. Introduction. The problem of red and black, which has taken its name from the game of roulette, has been of interest to probabilists for quite some time. It reads as follows. Suppose that we visit a casino with only one game available. In this game, we bet an amount s . With probability $1 - w$, we lose the stake, and, with probability w , we win the amount s . $w \in (0, 1)$ is fixed by the casino. The stake can be any amount of our choice, as long as it does not exceed the fortune f at that moment. Negative bets are not permitted. Our goal is, with repeated bets, to maximize the probability of reaching some fixed fortune $c > f$. Without loss of generality, we put $c = 1$, which implies that $f \in [0, 1]$. The question is how we should bet, and, with that probability, we reach the goal if we use the optimal strategy.

Although this problem has taken its structure from the world of casinos, the interesting applications are found in areas that are less glamorous. One example is the control of dams in connection to hydroelectric power plants [7]. The applications are not dealt with in this paper.

The problem might be divided into four cases: the odds could be favorable ($w > \frac{1}{2}$) for unfavorable ($w < \frac{1}{2}$), and the playing time could be finite or infinite.

Dubins and Savage [2] solved the unfavorable infinite time problem. They gave all optimal betting strategies as well as $U(f)$, the probability of reaching 1 if the initial fortune is f and if an optimal strategy is used. Bold play, i.e., betting the minimum of f and $1 - f$, is one of the optimal strategies.

The unfavorable finite time problem was solved by Dvoretzky (see [2, p. 92]). Also, bold play is one of the optimal strategies here.

In the favorable infinite time case, there are many strategies that reach the goal with probability one. They share the fact that the bets are timid, so that the law of large numbers ensures that the goal is eventually reached. Kelly [5] studied a related problem, where he sought to maximize the expected growth rate of the fortune. He gave the optimal betting strategy for this objective, which is betting a fixed proportion of the fortune every time. The more favorable the game is, the larger this proportion should be. This strategy of betting is now called the “Kelly criterion” and is also one of the optimal strategies for the favorable infinite time case.

The fourth and last case remains, that of the favorable finite time problem. This is, together with some generalizations, its limits, and its continuous time version, the subject of this paper. Because of the favorability, bold play can no longer be expected to be optimal, and, because of the time limit, timid play cannot be optimal. The solution must lie somewhere in between. The problem was studied by Breiman [1]. He determined $U(f, t)$, the probability of reaching 1 with fortune f , and t times to play, if we play optimally. He also gave a method for finding one of the optimal strategies.

In practice, the Kelly criterion has often been used for these problems as well. The motivation for this has been based on intuition, a limit result of Breiman and the fact that nothing better has been available. Breiman [1] showed that $U(f, t) - K(f, t)$ converges to zero uniformly as $t \rightarrow \infty$. Here K is the probability of reaching 1 if we use the Kelly criterion. This result is not as strong as we would like. For $\varepsilon > 0$, consider the following strategy: First, we discard our entire fortune, except ε (if $f \leq \varepsilon$, discard nothing), and then we play according to the Kelly criterion. Let $K_\varepsilon(f, t)$ be the probability of reaching 1 if we use this strategy. It is clearly not a good strategy if ε is small, but $U(f, t) - K_\varepsilon(f, t)$ converges to zero uniformly for any $\varepsilon > 0$. To see this, note that $K(f, t) = K_\varepsilon(f, t)$ for $f \leq \varepsilon$ and that $K(\varepsilon, t) \rightarrow 1$ as $t \rightarrow \infty$.

In § 2.2 we give an alternative solution to that of Breiman. This gives us simple characteristics of $U(f, t)$ and of an entire family of optimal betting strategies, and it enables us to obtain their limits in § 2.6. Just as Dubins and Savage [2] extended their result to general primitive casinos, i.e., where we, instead of s , gain $((1-r)/r)s$, $r \in (0, 1)$ if we win, we do the same in § 2.4. In § 2.3 we replace the 0/1 utility of reaching or not reaching 1 with the utility function $u(f) = f$, $f \in [0, 1]$, where $u(f)$ is the value for us to have fortune f with no time left to play. Section 2.5 extends the results further to a family of utility functions.

More interesting than the discrete time problems, perhaps, are their continuous time counterparts. Heath et al. [4] solved the continuous time equivalent of Kelly's problem, and Sudderth and Weerasinghe [6] showed that bold play is optimal for unfavorable, continuous time, red and black when there is a time limit. In § 3 we solve the continuous time version of the favorable limited time problem, both for 0/1, $u(f) = f$ and some more general utility functions. The solutions prove to be the same as the limit of the discrete time problem.

Section 4 gives some inequalities for stochastic processes that follow as corollaries to the preceding results.

There is no dependence between §§ 2 and 3, so they can be read independently. The notational framework is that of Dubins and Savage [2].

2. Discrete time primitive casinos.

2.1. Description of problem. In the general discrete time problem, for a limited number of times, we place stakes $s(f, t)$. These might depend on f , the fortune, and t , the number of times left to play. Of course, $0 \leq s(f, t) \leq f$. With probability $1 - w$, we lose the stake, and, with probability w , we win the amount $((1-r)/r)s$. The numbers $w \in (0, 1)$ and $r \in (0, 1)$ are fixed to us. Since we are studying a favorable case, we have that $w > r$.

There is a utility function $u(f)$, describing the value of having fortune f when time is out. Our goal is to maximize the expected utility at the end of the game. We let $U(f, t)$ be the optimal expected utility at fortune f with t times left to play. Clearly, $U(f, 0) = u(f)$. We wish to find $U(f, t)$, as well as the strategy, i.e., sequence of stakes, that will give the optimal expected utility.

For readability, we use the following notation:

$$F(k|t, p) = \begin{cases} \sum_{i=0}^k \binom{t}{i} p^i (1-p)^{t-i} & \text{if } k \in \{0, 1, \dots, t\}, \\ 0 & \text{if } k < 0, \\ 1 & \text{if } k > t. \end{cases}$$

This is, of course, $P(X \leq k)$ when $X \sim \text{Binomial}(t, p)$.

DEFINITION. Let $q(f, t)$ and $k(f, t)$ be the unique numbers such that

$$f = F(k-1|t, 1-r) + q(f, t) \binom{t}{k} (1-r)^k r^{t-k} \quad \text{and} \quad 0 \leq q(f, t) < 1.$$

We often write k instead of $k(f, t)$. Understanding F , q , and k is important in the reading of the proofs.

2.2. Red and black. We first discuss the simplest case: red and black. We have that $u(f) = 0$ for $f < 1$, $u(1) = 1$, $r = \frac{1}{2}$, and $w > \frac{1}{2}$. The intuition we get from solving this problem enables us to do the general case in the next sections, as well as the limit problem. The proofs are only sketched or hinted at in this section, since these results follow from those in § 2.4. For an alternative approach to this problem, see Breiman [1]. He found U and gave a method for obtaining an optimal strategy.

DEFINITIONS. A fortune f is binary at time t , i.e., with t times left to play, if $f2^t$ is an integer.

A stake is binary at fortune f if we arrive at a binary fortune, regardless of whether we win or lose.

A strategy is binary if it only uses binary stakes.

By using a binary strategy, the player finishes at fortune 0 or 1. The pay-off from any optimal strategy has the following property.

PROPOSITION 1. *It holds that $U(f, t) = U(n/2^t, t)$, where n is the integer such that $n/2^t \leq f < (n+1)/2^t$.*

Proof. The proof follows by induction.

This means that $U(f, t)$ is a step function of f with jumps at the binary fortunes.

PROPOSITION 2. *If the initial fortune is binary, then every optimal strategy is binary.*

Proof. For the proof, use Proposition 1.

PROPOSITION 3. *If we play t times, there are 2^t possible outcomes of the gamble. If the initial fortune is binary with $f = n/2^t$ and the strategy is binary, then exactly n of the 2^t outcomes result in reaching 1, and the remaining $2^t - n$ outcomes result in reaching zero.*

Proof. We surely reach 0 or 1 if we use a binary strategy, and, if $w = \frac{1}{2}$, we get a martingale for the fortune, so $P(\text{reaching } 1) = U(n/2^t, t) = n/2^t$ for integers n . Since all specific outcomes have the same probability $1/2^t$, exactly n outcomes bring us to 1. Hence the proposition is true for $w = \frac{1}{2}$. Since the resulting fortune of an outcome does not depend on w , it is true for all w . \square

For $w > \frac{1}{2}$ we can get an upper bound on U by adding the n outcomes with the highest probabilities.

COROLLARY 1. *Let $k = k(n/2^t, t)$. If n is an integer, then*

$$U\left(\frac{n}{2^t}, t\right) \leq F(k-1|t, 1-w) + q\left(\frac{n}{2^t}, t\right) \binom{t}{k} (1-w)^k w^{t-k}.$$

The result is that this is not only an upper bound, but also the actual value of U . To show this, we must find a strategy that conserves U . In the following, including Proposition 4, note that we are not dealing with probabilities but only with outcomes (not being concerned about how likely they are), fortunes, and stakes.

With an initial fortune of $n/2^t$, we need all outcomes with at most $k(n/2^t, t) - 1 = k - 1$ losses to bring us to 1, and there can be no outcome with more than k losses that brings us there.

Suppose now that we win our first gamble. There are $F(k - 1 | t - 1, \frac{1}{2})2^{t-1}$ outcomes that start with a win and have at most $k - 1$ losses. Since all these must lead us to our goal, our new fortune in the case of a win must be at least $F(k - 1 | t - 1, \frac{1}{2})$. Likewise, the new fortune must be at most $F(k | t - 1, \frac{1}{2})$. So

$$F\left(k - 1 | t - 1, \frac{1}{2}\right) - \frac{n}{2^t} \leq s\left(\frac{n}{2^t}, t\right) \leq F\left(k | t - 1, \frac{1}{2}\right) - \frac{n}{2^t}.$$

If our first gamble is a loss instead, there are $F(k - 2 | t - 1, \frac{1}{2})2^{t-1}$ outcomes that start with a loss and have a total of at most $k - 1$ losses. This means that, in the case of a loss, we must finish with a fortune of at least $F(k - 2 | t - 1, \frac{1}{2})$. Likewise, our new fortune cannot exceed $F(k - 1 | t - 1, \frac{1}{2})$. So

$$\frac{n}{2^t} - F\left(k - 1 | t - 1, \frac{1}{2}\right) \leq s\left(\frac{n}{2^t}, t\right) \leq \frac{n}{2^t} - F\left(k - 2 | t - 1, \frac{1}{2}\right).$$

Putting these inequalities together, we get the following proposition.

PROPOSITION 4. *If f is a binary fortune with t times left to play, then $s(f, t)$ is an optimal stake if and only if*

- (i) $s(f, t)$ is binary,
- (ii) $s(f, t) \leq \min \{n/2^t - F(k - 2 | t - 1, \frac{1}{2}), F(k | t - 1, \frac{1}{2}) - n/2^t\}$,
- (iii) $s(f, t) \geq |F(k - 1 | t - 1, \frac{1}{2}) - n/2^t|$.

To verify that such a stake always exists, use the formula

$$F(k - 1 | t, \frac{1}{2}) = \frac{1}{2} F(k - 1 | t - 1, \frac{1}{2}) + \frac{1}{2} F(k - 2 | t - 1, \frac{1}{2})$$

and the fact that $F(k - 1 | t, \frac{1}{2}) \leq f \leq F(k | t, \frac{1}{2})$.

We also have the next proposition.

PROPOSITION 5 (see Breiman [1]). *It holds that*

$$U(f, t) = F(k - 1 | t, 1 - w) + q\left(\frac{n}{2^t}, t\right) \binom{t}{k} (1 - w)^k w^{t-k},$$

where n is the largest integer such that $f \geq n/2^t$.

2.3. Utility function $u(f) = f$. We now consider the general primitive casino, where r is not necessarily equal to $\frac{1}{2}$. In this section we will consider the case in which $u(f) = f$. We first need a simple combinatorial lemma.

LEMMA 1. *Let $k = k(f, t)$. If $F(k - 1 | t - 1, 1 - r) \leq f \leq F(k | t - 1, 1 - r)$ (i.e., $k/t \leq q(f, t) < 1$), then*

$$\begin{aligned} f &= F(k - 1 | t, 1 - r) + q(f, t) \binom{t}{k} (1 - r)^k r^{t-k} \\ &= F(k - 1 | t - 1, 1 - r) + r \frac{t}{t - k} \left(q(f, t) - \frac{k}{t} \right) \binom{t - 1}{k} (1 - r)^k r^{t-1-k}. \end{aligned}$$

If $F(k-1|t, 1-r) \leq f \leq F(k-1|t-1, 1-r)$ (i.e., $0 \leq q(f, t) < k/t$), then

$$\begin{aligned} f &= F(k-1|t, 1-r) + q(f, t) \binom{t}{k} (1-r)^k r^{t-k} \\ &= F(k-2|t-1, 1-r) + \left[r + \frac{t}{k} (1-r) q(f, t) \right] \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k}. \end{aligned}$$

Proof. It holds that

$$\begin{aligned} &F(k-1|t, 1-r) + q(f, t) \binom{t}{k} (1-r)^k r^{t-k} \\ &= rF(k-1|t-1, 1-r) + (1-r)F(k-2|t-1, 1-r) \\ &\quad + q(f, t) \binom{t}{k} (1-r)^k r^{t-k} \\ &= F(k-2|t-1, 1-r) + r \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k} \\ &\quad + \frac{t}{k} (1-r) q(f, t) \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k} \\ &= F(k-2|t-1, 1-r) + \left[r + \frac{t}{k} (1-r) q(f, t) \right] \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k}. \end{aligned}$$

If $q(f, t) \geq k/t$, then $r + (t/k)(1-r)q(f, t) \geq 1$; so the above is equal to

$$\begin{aligned} &F(k-2|t-1, 1-r) + \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k} + \left[\frac{t}{k} (1-r) q(f, t) + r - 1 \right] \binom{t-1}{k-1} \\ &\quad \cdot (1-r)^{k-1} r^{t-k} \\ &= F(k-1|t-1, 1-r) + (1-r) \left[\frac{t}{k} q(f, t) - 1 \right] r \frac{k}{t-k} \binom{t-1}{k} (1-r)^{k-1} r^{t-1-k} \\ &= F(k-1|t-1, 1-r) + r \frac{t}{t-k} \left[q(f, t) - \frac{k}{t} \right] \binom{t-1}{k} (1-r)^k r^{t-1-k}. \quad \square \end{aligned}$$

THEOREM 1. *Let*

$$\begin{aligned} Q(f, t) &= F(k-1|t, 1-w) + q(f, t) \binom{t}{k} (1-w)^k w^{t-k} \quad \text{and} \\ f &= F(k-1|t, 1-r) + q(f, t) \binom{t}{k} (1-r)^k r^{t-k}, \end{aligned}$$

where F , k , r , and q are defined as in § 2.1. If $w > r$, then

$$(i) \quad U(f, t) = Q(f, t),$$

(ii) $s(f, t)$ is an optimal stake at time t with fortune f if and only if

$$s(f, t) \geq \max \left\{ f - F(k-1 | t-1, 1-r), \frac{r}{1-r} (F(k-1 | t-1, 1-r) - f) \right\} \\ = \underline{s}(f, t) \quad (\text{minimum bet})$$

and

$$s(f, t) \leq \min \left\{ f - F(k-2 | t-1, 1-r), \frac{r}{1-r} (F(k | t-1, 1-r) - f) \right\} \\ = \bar{s}(f, t) \quad (\text{maximum bet}).$$

Remark. As an alternate formula,

$$Q(f, t) = F(k-1 | t, 1-w) + \frac{f - F(k-1 | t, 1-r)}{\binom{t}{k} (1-r)^k r^{t-k}} \binom{t}{k} (1-w)^k w^{t-k} \\ = F(k-1 | t, 1-w) + [f - F(k-1 | t, 1-r)] \left(\frac{1-w}{1-r} \right)^k \left(\frac{w}{r} \right)^{t-k}.$$

Remark. Note that the optimal stakes do not depend on w .

To graph $U(f, t)$, just draw straight lines through the points $(F(k | t, 1-r), F(k | t, 1-w))$ when k is increasing from 0 to t . See Fig. 1.

Proof of Theorem 1. The proof follows by induction. It is trivially true for $t=0$. Assume the result for $t-1$.

First, we show that Q is obtainable ($U \geq Q$); see Cases 1 and 2, below.

Case 1. Suppose that $q(f, t) \geq k/t$, i.e., $F(k-1 | t-1, 1-r) \leq f < F(k | t, 1-r)$.

FIG. 1. Example of $U(f, t)$ with $w = \frac{2}{3}$, $r = \frac{1}{3}$, and $t = 0, 1, 2, 3$, and 4.

This case corresponds to the fortunes in Fig. 2, where the minimum stake is increasing. Let $s(f, t) = f - F(k-1|t-1, 1-r) = \underline{s}(f, t)$, the minimum stake. According to Lemma 1, f can be written as

$$f = F(k-1|t-1, 1-r) + r \frac{t}{t-k} \left(q(f, t) - \frac{k}{t} \right) \binom{t-1}{k} (1-r)^k r^{t-1-k},$$

$$\begin{aligned} U(f, t) &\geq (1-w)U(f-s, t-1) + wU\left(f + \frac{1-r}{r}s, t-1\right) \\ &= (1-w)Q(f-s, t-1) + wQ\left(f + \frac{1-r}{r}s, t-1\right) \\ &= (1-w)Q(F(k-1|t-1, 1-r), t-1) \\ &\quad + wQ\left\{F(k-1|t-1, 1-r) + \frac{t}{t-k} \left(q(f, t) - \frac{k}{t} \right) \binom{t-1}{k} (1-r)^k r^{t-1-k}, t-1\right\} \\ &= (1-w)F(k-1|t-1, 1-w) \\ &\quad + w\left\{F(k-1|t-1, 1-w) + \frac{t}{t-k} \left(q(f, t) - \frac{k}{t} \right) \binom{t-1}{k} (1-w)^k w^{t-1-k}\right\} \\ &= F(k-1|t-1, 1-w) + w \frac{t}{t-k} \left(q(f, t) - \frac{k}{t} \right) \binom{t-1}{k} (1-w)^k w^{t-1-k} \\ &= F(k-1|t, 1-w) + q(f, t) \binom{t}{k} (1-w)^k w^{t-k} = Q(f, t). \end{aligned}$$

Case 2. Suppose instead that $q(f, t) < k/t$, i.e., $f < F(k-1|t-1, 1-r)$.

Let $s(f, t) = (r/(1-r))(F(k-1|t-1, 1-r) - f) = \underline{s}(f, t)$. According to Lemma 1, f can be written as

$$f = F(k-2|t-1, 1-r) + \left(r + q(f, t) \frac{t}{k} (1-r) \right) \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k},$$

FIG. 2. Optimal stakes $s(f, t)$ when $r = \frac{1}{3}$ and $t = 4$.

$$\begin{aligned}
U(f, t) &\geq (1-w)Q(f-s, t-1) + wQ\left(f + \frac{1-r}{r}s, t-1\right) \\
&= (1-w)Q\left\{F(k-2|t-1, 1-r) + \frac{t}{k}q(f, t)\binom{t-1}{k-1}(1-r)^{k-1}r^{t-k}, t-1\right\} \\
&\quad + wQ(F(k-1|t-1, 1-r), t-1) \\
&= (1-w)\left\{F(k-2|t-1, 1-w) + q(f, t)\binom{t}{k}(1-w)^{k-1}w^{t-k}\right\} \\
&\quad + wF(k-1|t-1, 1-w) \\
&= F(k-1|t, 1-w) + q(f, t)\binom{t}{k}(1-w)^kw^{t-k} = Q(f, t).
\end{aligned}$$

Hence Q is obtainable.

Now we show that we cannot do any better than Q ($U \leq Q$). See Fig. 1 throughout the rest of the proof.

Let

$$\begin{aligned}
E_s(f, t) &= (1-w)U(f-s, t-1) + wU\left(f + \frac{1-r}{r}s, t-1\right) \\
&= \text{constant} + w\frac{1-r}{r}s\left(\frac{1-w}{1-r}\right)^n\left(\frac{w}{r}\right)^{t-1-n} - (1-w)s\left(\frac{1-w}{1-r}\right)^m\left(\frac{w}{r}\right)^{t-1-m},
\end{aligned}$$

where m is such that $F(m-1|t-1, 1-r) \leq f-s < F(m|t-1, 1-r)$, and n is such that $F(n-1|t-1, 1-r) \leq f + ((1-r)/r)s < F(n|t-1, 1-r)$. m and n depend on s .

Note that $E_s(f, t)$ is continuous and almost everywhere differentiable with respect to s . We know that $U(f, t) = \max_s E_s(f, t)$ [2].

To prove that s is an optimal bet if and only if $\underline{s} \leq s \leq \bar{s}$ and that we cannot do any better than Q , we show that

$$\frac{d}{ds} E_s(f, t) \begin{cases} > 0 & \text{when } s < \underline{s}, \\ = 0 & \text{when } \underline{s} < s < \bar{s}, \\ < 0 & \text{when } s > \bar{s} \end{cases}$$

for all s , where E_s is differentiable.

If $s < \underline{s}$, then $m = n$; so

$$\frac{d}{ds} E_s(f, t) = w\left(\frac{1-w}{1-r}\right)^n\left(\frac{w}{r}\right)^{t-1-n}\left(\frac{1-r}{r} - \frac{1-w}{w}\right) > 0 \quad \text{since } w > r.$$

If $\underline{s} < s < \bar{s}$, then $m = n-1$;

$$\text{so } \frac{d}{ds} E_s(f, t) = \frac{(1-w)^nw^{t-n}}{(1-r)^{n-1}r^{t-n}} - \frac{(1-w)^nw^{t-n}}{(1-r)^{n-1}r^{t-n}} = 0.$$

If $s > \bar{s}$, then $m \leq n-2 = n-1-i$ for some positive integer i ; so

$$\begin{aligned}
\frac{d}{ds} E_s(f, t) &= \frac{(1-w)^{n-1}w^{t-n}}{(1-r)^{n-1}r^{t-n}} - \frac{(1-w)^{n-i}w^{t-n+i}}{(1-r)^{n-1-i}r^{t-n+i}} \\
&= \frac{(1-w)^{n-i}w^{t-n}}{(1-r)^{n-1-i}r^{t-n}} \left(\left(\frac{1-w}{1-r}\right)^i - \left(\frac{w}{r}\right)^i \right) < 0 \quad \text{since } w > r \text{ and } i \geq 1. \quad \square
\end{aligned}$$

2.4. A 0/1 utility function. In this section we consider the case where $u(f) = 0$ for $f < 1$ and $u(f) = 1$ for $f = 1$. $U(f, t)$ is, as previously defined, the probability of reaching 1 using an optimal strategy and starting at fortune f with t times left to play.

DEFINITION. A fortune f is binomial at time t if $q(f, t) \binom{t}{k}$ is an integer.

Examples. (i) The binomial fortunes when $t=2$ are 0, r^2 , $r^2 + r(1-r) = r$, $r^2 + 2r(1-r) = 1 - (1-r)^2$, and 1.

(ii) When $r = \frac{1}{2}$, then the binomial fortunes at time t are the integer multiples of $\frac{1}{2^t}$, i.e., the previously defined binary fortunes.

DEFINITION. A stake $s(f, t)$ is binomial if we arrive at a binomial fortune, regardless of whether we win or lose, i.e., if $f - s(f, t)$ and $f + ((1-r)/r)s(f, t)$ are binomial fortunes at time $t-1$.

THEOREM 2. If $w > r$ and f is binomial, then $U(f, t) = Q(f, t)$ (as in Theorem 1), and $s(f, t)$ is optimal if and only if

- (i) $s(f, t) \geq \max \{f - F(k-1 | t-1, 1-r), (r/(1-r))(F(k-1 | t-1, 1-r) - f)\} \triangleq \underline{s}(f, t),$
- (ii) $s(f, t) \leq \min \{f - F(k-2 | t-1, 1-r), (r/(1-r))(F(k | t-1, 1-r) - f)\} \triangleq \bar{s}(f, t),$
- (iii) $s(f, t)$ is a binomial stake.

Compare this with Proposition 4 and Theorem 1. It means that for binomial f we can do just as well for this case as for the case of § 2.3, despite $u(f)$ being smaller.

Proof. The proof follows by induction. It is trivially true for $t=0$. We only must show that there always exists a binomial stake fulfilling conditions (i) and (ii). The rest follows from Theorem 1.

Case 1. Suppose that $q(f, t) \geq k/t$. We want to show that $s(f, t) = f - F(k-1 | t-1, 1-r)$ ($= \underline{s}(f, t)$) is a binomial stake.

- (i) $f - s = F(k-1 | t-1, 1-r)$, which is binomial at time $t-1$,
- (ii)

$$\begin{aligned} f + \frac{1-r}{r}s &= F(k-1 | t-1, 1-r) + \frac{t}{t-k} \left(q(f, t) - \frac{k}{t} \right) \binom{t-1}{k} (1-r)^k r^{t-1-k} \\ &= F(k-1 | t-1, 1-r) + q(f, t) \binom{t}{k} (1-r)^k r^{t-1-k}, \end{aligned}$$

which is binomial at time $t-1$, since f being binomial at time t implies that $q(f, t) \binom{t}{k}$ is an integer.

Case 2. Suppose instead that $q(f, t) < k/t$. Now we want to show that $s(f, t) = (r/(1-r))(F(k-1 | t-1, 1-r) - f)$ ($= \bar{s}(f, t)$) is a binomial stake.

- (i) $f + ((1-r)/r)s = F(k-1 | t-1, 1-r)$, which is binomial at time $t-1$,
- (ii)

$$\begin{aligned} f - s + F(k-2 | t-1, 1-r) + \frac{t}{k} q(f, t) \binom{t-1}{k-1} (1-r)^{k-1} r^{t-k} \\ = F(k-2 | t-1, 1-r) + q(f, t) \binom{t}{k} (1-r)^{k-1} r^{t-k}, \end{aligned}$$

which is binomial at time $t-1$, since $q(f, t) \binom{t}{k}$ is integer-valued. \square

For nonbinomial f , we can use the fact that U is nondecreasing to obtain a lower bound for U , and we can use Theorem 1 to obtain an upper bound. Let $\tilde{Q}(f, t) = F(k-1 | t, 1-w) + [q(f, t) \binom{t}{k}] (1-w)^k w^{t-k}$, where $f = F(k-1 | t, 1-r) + q(f, t) \binom{t}{k} \cdot (1-r)^k r^{t-k}$ ($[x]$ is the integer part of x). This means that \tilde{Q} takes jumps of magnitudes $(1-w)^k w^{t-k}$ (k varies) at binomial fortunes, and is constant otherwise. For binomial fortunes, $\tilde{Q} = U$.

COROLLARY 2. It holds that $\tilde{Q}(f, t) \leq U(f, t) \leq Q(f, t)$.

Since $|Q(f, t) - \tilde{Q}(f, t)|$ converges to zero when $t \rightarrow \infty$, the bounds will be good for large t . For the case of $r \leq \frac{1}{2} \leq w$, the result is stronger.

THEOREM 3. *If $r \leq \frac{1}{2} \leq w$, then $U(f, t) = \tilde{Q}(f, t)$.*

It is easy to find a counterexample to this equality for general r and w . Just pick any r and w such that $r < w < \frac{1}{2}$ or $\frac{1}{2} < r < w$ and try it for sufficiently large t .

Proof. The proof follows by induction. It is trivially true for $t = 0$. Assume the result for $t - 1$. Let f_1, f_2, \dots and g_1, g_2, \dots be the binomial fortunes at time t and $t - 1$, respectively. We know that $g_i - g_{i-1} = (1 - r)^k r^{t-1-k}$ for some k and that $U(g_i, t - 1) - U(g_{i-1}, t - 1) = (1 - w)^k w^{t-1-k}$ for the same k .

Since U is nondecreasing, and since $\tilde{Q}(f, t)$ is a step function, it is enough to show that $U(f, t) = \tilde{Q}(f, t)$ at fortunes $f_j - \varepsilon$, where $\varepsilon > 0$ is arbitrarily small. To be more precise, we must show that $U(f_j - \varepsilon, t) = U(f_{j-1}, t)$ for all binomial fortunes f_j . It is clear that an optimal stake can be found among those of the form $f_j - \varepsilon - g_i \geq 0$. So

$$U(f_j - \varepsilon, t) = \max_i \left\{ (1 - w)U(g_i + \varepsilon, t - 1) + wU\left(f_j + \frac{1 - r}{r}(f_j - \varepsilon - g_i), t - 1\right) \right\} \triangleq \max_i U_i.$$

Let $g_x = f_j - \bar{s}$, $g_m = f_j - \underline{s}$, $g_{\bar{x}} = f_j + ((1 - r)/r)\bar{s}$, and $g_{\bar{m}} = f_j + ((1 - r)/r)\underline{s}$, where x and m are index variables.

Let us first try $g_x \leq g_i \leq g_m$, below:

$$U_i = (1 - w)U(g_i + \varepsilon, t - 1) + wU(g_{\bar{x}-(i-x)} - o(\varepsilon), t - 1),$$

so

$$\begin{aligned} U_i &= (1 - w)U(g_i, t - 1) + wU(g_{\bar{x}-(i-x)-1}, t - 1) \\ &= (1 - w)U(g_i, t - 1) + wU(g_{\bar{x}-(i-x)}, t - 1) - w(1 - w)^k w^{t-1-k} \\ &= U(f_j, t) - (1 - w)^k w^{t-k} = U(f_{j-1}, t). \end{aligned}$$

Now let us try $g_i < g_x$, below:

$$U_i = (1 - w)U(g_i + \varepsilon, t - 1) + wU(g, t - 1),$$

where $g < g_{\bar{x}+(x-i)}$ since $r \leq \frac{1}{2}$; so

$$\begin{aligned} U_i &\leq (1 - w)U(g_i, t - 1) + wU(g_{\bar{m}-(i-m)-1}, t - 1) \\ &\leq (1 - w)\{U(g_x, t - 1) - (x - i)(1 - w)^{k-1} w^{t-1-(k-1)}\} \\ &\quad + w\{U(g_{\bar{x}}, t - 1) + (x - i - 1)(1 - w)^{k+1} w^{t-1-(k+1)}\} \\ &= U(f_j, t) - (x - i - 1) \\ &\quad \cdot \{(1 - w)^k w^{t-k} - (1 - w)^{k+1} w^{t-(k+1)}\} - (1 - w)^k w^{t-k} \\ &\leq U(f_j, t) - (1 - w)^k w^{t-k} \text{ (since } w \geq \frac{1}{2}) = U(f_{j-1}, t). \end{aligned}$$

It remains to try $g_i > g_m$, below:

$$U_i = (1 - w)U(g_i, t - 1) + wU(g, t - 1),$$

where $g < g_{\bar{m}-(i-m)}$ since $r \leq \frac{1}{2}$; so

$$\begin{aligned} U_i &\leq (1 - w)U(g_i, t - 1) + wU(g_{\bar{m}-(i-m)-1}, t - 1) \\ &= (1 - w)\{U(g_m, t - 1) + (i - m)(1 - w)^k w^{t-1-k}\} \\ &\quad + w\{U(g_{\bar{m}}, t - 1) - (i - m - 1)(1 - w)^k w^{t-1-k}\} \\ &= U(f_j, t) - (i - m)\{(1 - w)^k w^{t-1-k}(w - (1 - w))\} - (1 - w)^k w^{t-k} \\ &\leq U(f_j, t) - (1 - w)^k w^{t-k} \text{ (since } w \geq \frac{1}{2}) = U(f_{j-1}, t). \end{aligned}$$

□

To know which bets are optimal ($r \leq \frac{1}{2} \leq w$), we divide our fortune f into two parts:

- (i) $f - \{q(f, t) \binom{t}{k} - [q(f, t) \binom{t}{k}]\}(1-w)^k w^{t-k}$, the valuable part;
- (ii) $\{q(f, t) \binom{t}{k} - [q(f, t) \binom{t}{k}]\}(1-w)^k w^{t-k}$, the worthless part.

If we use the valuable part and the money it generates during the course of the play, to bet, according to Theorem 2, we achieve optimum. This means that we can use the worthless part and the money it generates for bets whenever we want, and the strategy will not influence our chances to reach our goal. We could, of course, also use it, before we start playing, for some luck-bringing endeavor, such as throwing it in a fountain. The strategies described here are not the only optimal ones, except when the worthless part is zero (i.e., f is binomial).

2.5. Other utility functions. The results of this section follow immediately from the previous theorems. Let $S_1(f, t)$ and $S_3(f, t)$ be the sets of optimal stakes in Theorems 1 and 3, respectively.

COROLLARY 3. *If $u(f) = Q(f, s)$ (or $\tilde{Q}(f, s)$), then $U(f, t) = Q(f, s+t)$ (respectively, $\tilde{Q}(f, s+t)$), and $s(f, t)$ is optimal if it belongs to the set $S_1(f, s+t)(S_3(f, s+t))$.*

2.6. Limit results and approximation formulas. All limits in this section are the same for the cases of §§ 2.3 and 2.4, so we do not make a distinction. Φ denotes the cumulative distribution function of the standard normal distribution.

What happens to $U(f, t)$ when $t \rightarrow \infty$? It is easy to see that it converges to 1 pointwise. However, this is not the limit that we are interested in. We want to know the limit of $U(f, t)$ when w and r vary with t in such a way that $w - r \rightarrow 0$ as $t \rightarrow \infty$. This means that the bets get less favorable, but this is compensated by the number of bets allowed, which increase. We do this in such a way that $\sqrt{t}(w - r)$ equals a constant c for all t .

THEOREM 4. *If $\sqrt{t}(w - r) = c$ and $w \rightarrow w_0 \in (0, 1)$, then $\lim_{t \rightarrow \infty} U(f, t) = \Phi(\Phi^{-1}(f) + c/\sqrt{w_0(1-w_0)})$.*

We obtain this same function as U for similar continuous time problems in Theorems 6 and 7.

Proof. It holds that

$$\begin{aligned} f &< F(k(f, t) | t, 1-r) = P(S_t \leq k(f, t)) \\ &= P\left(\frac{S_t - t(1-r)}{\sqrt{tr(1-r)}} \leq \frac{k(f, t) - t(1-r)}{\sqrt{tr(1-r)}}\right) = \Phi\left(\frac{k(f, t) - t(1-r)}{\sqrt{tr(1-r)}}\right) + \Delta_t, \end{aligned}$$

where $S_t \sim \text{Bin}(t, 1-r)$ and where $\lim_{t \rightarrow \infty} \Delta_t = 0$, since $(k(f, t) - t(1-r))/\sqrt{tr(1-r)}$ converges. Hence $k(f, t) > \Phi^{-1}(f - \Delta_t)\sqrt{tr(1-r)} + t(1-r)$. Likewise,

$$f \geq F(k(f, t) - 1 | t, 1-r) = \Phi\left(\frac{k(f, t) - 1 - t(1-r)}{\sqrt{tr(1-r)}}\right) + \Delta'_t;$$

so $k(f, t) \leq \Phi^{-1}(f - \Delta'_t)\sqrt{tr(1-r)} + t(1-r) + 1$. Now

$$\begin{aligned} U(f, t) &< F(k(f, t) | t, 1-w) = P(R_t \leq k(f, t)) \\ &= P\left(\frac{R_t - t(1-w)}{\sqrt{tw(1-w)}} \leq \frac{k(f, t) - t(1-w)}{\sqrt{tw(1-w)}}\right) = \Phi\left(\frac{k(f, t) - t(1-w)}{\sqrt{tw(1-w)}}\right) + \varepsilon_t \\ &\leq \Phi\left(\frac{\Phi^{-1}(f - \Delta'_t)\sqrt{tr(1-r)} + t(1-r) + 1 - t(1-w)}{\sqrt{tw(1-w)}}\right) + \varepsilon_t \\ &= \Phi\left(\Phi^{-1}(f - \Delta'_t)\sqrt{\frac{r(1-r)}{w(1-w)}} + \frac{c}{\sqrt{w(1-w)}} + \frac{1}{\sqrt{tw(1-w)}}\right) + \varepsilon_t, \end{aligned}$$

where $R_t \sim \text{Bin}(t, 1-w)$ and where $\lim_{t \rightarrow \infty} \varepsilon_t = 0$. Likewise,

$$\begin{aligned} U(f, t) &\geq F(k(f, t) - 1 | t, 1-w) + \Phi\left(\frac{k(f, t) - 1 - t(1-w)}{\sqrt{tw(1-w)}}\right) + \varepsilon'_t \\ &> \Phi\left(\Phi^{-1}(f - \Delta_t) \sqrt{\frac{r(1-r)}{w(1-w)}} + \frac{c}{\sqrt{w(1-w)}} - \frac{1}{\sqrt{tw(1-w)}}\right) + \varepsilon'_t; \end{aligned}$$

so $\lim_{t \rightarrow \infty, w \rightarrow w_0} U(f, t) = \Phi(\Phi^{-1}(f) + c/\sqrt{w_0(1-w_0)})$. \square

If we want to use this result to provide approximate values for $U(f, t)$, we should perhaps use the following corollary instead, which follows from the proof of the theorem.

COROLLARY 4. *If t , $tw(1-w)$ and $tr(1-r)$ are all large, then*

$$U(f, t) \approx \Phi\left(\Phi^{-1}(f) \sqrt{\frac{r(1-r)}{w(1-w)}} + \frac{\sqrt{t(w-r)}}{\sqrt{w(1-w)}}\right).$$

We might also be interested in the limit of $s(f, t)$ as $t \rightarrow \infty$. It is not difficult to see that it converges to zero uniformly (also when $w-r \rightarrow 0$), but this does not relay anything about how fast or in what way it converges. Neither does it give us an approximation formula for the bet sizes. Betting zero all the time is gainless.

Instead, we consider the limit of $\sqrt{t} s(f, t)$ as $t \rightarrow \infty$. Since $s(f, t)$ is not unique, we can choose different sequences of $\sqrt{t} s(f, t)$, some of which may not converge. Which sequence should we choose? When $f = F(k | t, 1-r)$, the bet size is unique, so then the choice is obvious. For $F(k-1 | t, 1-r) < f < F(k | t, 1-r)$, we choose a bet such that $s(f, t)$ is between $s(F(k-1 | t, 1-r), t)$ and $s(F(k | t, 1-r), t)$. In the case of § 2.3, there is always such an optimal bet. That is also true for the case of § 2.4, with the exception of when $k = t/2$.

THEOREM 5. *It holds that $\lim_{t \rightarrow \infty} \sqrt{t} s(f, t) = \sqrt{(r/(1-r))} \phi(\Phi^{-1}(f))$, where ϕ is the density function of the standard normal distribution.*

Proof. It is enough to consider fortunes of the form $F(k-1 | t, 1-r)$. Let

$$\begin{aligned} f &= F(k-1 | t, 1-r) \text{ so } s(f, t) = F(k-1 | t, 1-r) - F(k-2 | t-1, 1-r) \\ &= (1-r)F(k-2 | t-1, 1-r) + rF(k-1 | t-1, 1-r) - F(k-2 | t-1, 1-r) \\ &= F(k-1 | t-1, 1-r) - F(k-2 | t-1, 1-r); \end{aligned}$$

$k(f, t) > \Phi^{-1}(f - \Delta_t) \sqrt{tr(1-r)} + t(1-r)$ and $k(f, t) \leq \Phi^{-1}(f - \Delta'_t) \sqrt{tr(1-r)} + t(1-r) + 1$; so $k(f, t) = \Phi^{-1}(f - \tilde{\Delta}_t) \sqrt{tr(1-r)} + t(1-r) + d$, where $d \in [0, 1]$. It holds that

$$\begin{aligned} \lim_{t \rightarrow \infty} \sqrt{t} s(f, t) &= \lim_{t \rightarrow \infty} \sqrt{t} r \{F(k-1 | t-1, 1-r) - F(k-2 | t-1, 1-r)\} \\ &= r \lim_{t \rightarrow \infty} \sqrt{t} P(S_{t-1} = k-1) \\ &= r \lim_{t \rightarrow \infty} \sqrt{t} \left(\frac{1}{\sqrt{tr(1-r)}} \phi\left(\frac{k(f, t) - 1 - t(1-r)}{\sqrt{tr(1-r)}}\right) + \varepsilon_t \right) \\ &= \sqrt{\frac{r}{1-r}} \lim_{t \rightarrow \infty} \phi\left(\Phi^{-1}(f + \tilde{\Delta}_t) + \frac{d-1}{\sqrt{tr(1-r)}}\right) + r \lim_{t \rightarrow \infty} \sqrt{t} \varepsilon_t \\ &= \sqrt{\frac{r}{1-r}} \phi(\Phi^{-1}(f)), \end{aligned}$$

since

$$\begin{aligned} \left| r \lim_{t \rightarrow \infty} \sqrt{t} \varepsilon_t \right| &\leq r \lim_{t \rightarrow \infty} \sqrt{t} \left| \frac{1}{\sqrt{tr(1-r)}} \left(\frac{A}{t} + \frac{B}{\sqrt{t}} \left(\frac{k-t(1-r)}{\sqrt{t} r(1-r)} \right)^2 \right) \right| \\ &= \sqrt{\frac{r}{1-r}} \lim_{t \rightarrow \infty} \left| \frac{A}{t} + \frac{B}{\sqrt{t}} \right| \left| \left(\Phi^{-1}(f - \tilde{\Delta}_t) + \frac{d}{\sqrt{tr(1-r)}} \right)^2 \right| = 0, \end{aligned}$$

where A and B are constants. For the bound on ε_t , see Feller [3, p. 170]. \square

COROLLARY 5. *If t and $tr(1-r)$ are large, then $s(f, t) \approx (1/\sqrt{t}) \cdot \sqrt{r/(1-r)} \phi(\Phi^{-1}(f))$.*

For $r = \frac{1}{2}$, this is similar to the optimal stake for the continuous time problem with constant drift μ_t (Theorems 6 and 7).

The variance of a single bet is $s(f, t)^2(w(1-w)/r^2)$. If we multiply the stake by $\sqrt{r/(1-r)}$, we get variance $(s(f, t) \sqrt{r/(1-r)})^2(w(1-w)/r^2) = s(f, t)^2(w(1-w)/r(1-r))$, which is equal to $s(f, t)^2$ in the limit, since $w-r \rightarrow 0$. This is the intuition behind the $\sqrt{r/(1-r)}$ part of the above formulas.

3. Continuous time problem. Consider the stochastic process X_t such that $dX_t = \sigma_t(\mu_t dt + dB_t)$, where B_t is the standard Brownian motion. In the gambling context, X_t represents the fortune at time t . The fortune space is of the form $[a, b]$, and without loss of generality, we assume it to be $[0, 1]$. μ_t is a fixed function and, for some constant M , $\mu_t \leq M$ for all t . Zero and 1 are absorbing states, so, if $X_t = 0$ or 1, then $\sigma_s = 0$ for all $s \geq t$. Otherwise, the control variable σ_t , which may only depend on what has happened up to time t , can be chosen to be any nonnegative value as long as

$$\int_t^{T-\varepsilon} |\sigma_s|^2 ds < \infty \quad \forall \varepsilon > 0 \quad \left(\text{which implies } \int_t^{T-\varepsilon} |\mu_s \sigma_s| ds < \infty \right).$$

T is a fixed stopping time, and our goal is to maximize the expected value of a utility function $u(f, T)$ which expresses the value of having fortune f at time T . In addition, we want to know $U(f, t)$; the expected utility at time t , given that we have fortune f at time t and that we use an optimal strategy.

With Φ we denote the cumulative distribution function of the standard normal distribution, and with ϕ its density function. Let $\sigma^*(f, t)$ be the optimal choice of σ_t if we have fortune f at time t .

Let $S = \{(f, t) : 0 \leq f \leq 1, 0 \leq t \leq T\}$ be the state space. Let $\mu_t^+ = \max\{0, \mu_t\}$.

DEFINITION. Let $m_t = \sqrt{\int_t^T (\mu_s^+)^2 ds}$, a measure of the remaining amount of “favorability.” Note that when $\mu_t = \mu$, for all t , then $m_t = \sqrt{T-t} \mu$.

Without loss of generality, we assume that $m_t > 0$ when $t < T$. This property can easily be obtained by a change of T , since $\sigma_t = 0$ is one of the optimal strategies when $m_t = 0$.

3.1. Utility function $u(f, T) = f$. We first study the problem with the utility function $u(f, T) = f$.

THEOREM 6. *If $u(f, T) = f$, then $U(f, t) = \tilde{U}(f, t) \triangleq \Phi(\Phi^{-1}(f) + m_t)$, $(f, t) \in S$ and $\sigma^*(f, t) = \tilde{\sigma}^*(f, t) \triangleq \phi(\Phi^{-1}(f))(\mu_t^+/m_t)$, $0 \leq f \leq 1$, $0 \leq t < T$.*

Remark. For $\mu_t = \mu$, for all t , and for $r = T-t$, the time left to play, we get the formulas

$$U(f, T-r) = \Phi(\Phi^{-1}(f) + \sqrt{r} \mu) \quad \text{and} \quad \sigma^*(f, T-r) = \frac{1}{\sqrt{r}} \phi(\Phi^{-1}(f)).$$

See Figs. 3 and 4.

FIG. 3. $U(f, t)$ when μ_t is a constant equal to 1 and there are one and two time units left to play ($m_t = 1$ and $\sqrt{2}$).

FIG. 4. $\sigma^*(f, t)$ when μ_t is a constant and there are one and two time units left to play ($\mu_t^+ / m_t = 1$ and $1/\sqrt{2}$).

Note that this result is the same as that for the limit of the discrete time problem of § 2.6. Note also that the bet size does not depend on μ in this special case. In the general case, the bet size only depends on μ_τ in relation to m_t . That is, for two functions μ_t and $\bar{\mu}_t$, the optimal control is the same if $\bar{\mu}_t = C\mu_t$, for all t and some positive constant C .

The main tool in proving the theorem is Ito's formula. Since the derivatives of U are not finite, we are not able to use the formula directly. Instead, we first must look at a problem where the state space is reduced to $S_\varepsilon = \{(f, t): \varepsilon \leq f \leq 1, 0 \leq t \leq T - \varepsilon\}$ and where $u(\varepsilon, t) = \tilde{U}(\varepsilon, t)$, $u(f, T - \varepsilon) = \tilde{U}(f, T - \varepsilon)$ and $u(f, t) = 0$, otherwise. $u(f, \tau)$ is the utility function at fortune f if we stop the process at time τ . Let U_ε and σ_ε^* be the U and σ^* functions of this modified problem.

LEMMA 2. It holds that

$$U_\varepsilon(f, t) = \tilde{U}(f, t) \quad \forall (f, t) \in S_\varepsilon \quad \text{and} \quad \sigma_\varepsilon^*(f, t) = \tilde{\sigma}^*(f, t) \quad \forall (f, t) \in \text{interior of } S_\varepsilon.$$

Proof. Let $U_\varepsilon^t(U_\varepsilon^f)$ be the derivative of U_ε with respect to time (fortune); let U_ε^{ff} be the second derivative of U_ε with respect to fortune; and let $I(\sigma) = U_\varepsilon^t(X_s, s) + U_\varepsilon^f(X_s, s)\sigma_s\mu_s + \frac{1}{2}U_\varepsilon^{ff}(X_s, s)\sigma_s^2$. By definition, $U_\varepsilon(f, t) = \tilde{U}(f, t)$ on the boundaries of S_ε . First, we must show that $\tilde{U}(X_t, t)$ is a martingale for the strategy σ_ε^* (\tilde{U} is obtainable). Then we must show that $\tilde{U}(X_t, t)$ is a supermartingale for all

strategies (\tilde{U} is excessive). Let τ be the stopping time when X_t hits the boundary of S_ε . We note that $U \in C^2$ on an open set containing S_ε and that

$$E\left(\int_t^{T-\varepsilon} |\mu_s \sigma_s^*| ds\right) \leq \int_t^{T-\varepsilon} M\sigma^*\left(\frac{1}{2}, T-\varepsilon\right) ds < \infty$$

and

$$E\left(\int_t^{T-\varepsilon} |\sigma_s^*|^2 ds\right) \leq \int_t^{T-\varepsilon} \left|\sigma^*\left(\frac{1}{2}, T-\varepsilon\right)\right|^2 ds < \infty.$$

Hence we can use Ito's formula as follows:

$$\begin{aligned} E[U_\varepsilon(x_\tau, \tau) | X(t)] &= E\left[U_\varepsilon(X_t, t) + \int_t^\tau I(\sigma) ds + \int_t^\tau U_\varepsilon^f(x_s, s) \sigma_s dB_s \middle| X_t\right] \\ &= U_\varepsilon(X_t, t) + E\left[\int_t^\tau I(\sigma) ds \middle| X_t\right] \\ &\begin{cases} = U_\varepsilon(X_t, t) \text{ if } I(\sigma) = 0, \text{ which makes } U_\varepsilon(X_t, t) \text{ a martingale,} \\ \leq U_\varepsilon(X_t, t) \text{ if } I(\sigma) \leq 0, \text{ which makes } U_\varepsilon(X_t, t) \text{ a supermartingale,} \end{cases} \end{aligned}$$

since the expected value of the integral with respect to B_s is zero. So it only remains to show that $I(\sigma^*) = 0$ and that $I(\sigma) \leq 0$ for all σ ; see the following equations:

$$\begin{aligned} I(\sigma^*) &= -\phi(\Phi^{-1}(f) + m_s) \frac{(\mu_s^+)^2}{2m_s} + \frac{\phi(\Phi^{-1}(f) + m_s)}{\phi(\Phi^{-1}(f))} \phi(\Phi^{-1}(f)) \frac{\mu_s^+}{m_s} \mu_s^+ \\ &\quad + \frac{1}{2} (-1) \frac{\phi(\Phi^{-1}(f)) m_s}{\phi(\Phi^{-1}(f))^2} \phi(\Phi^{-1}(f))^2 \frac{(\mu_s^+)^2}{m_s^2} \\ &= \phi(\Phi^{-1}(f) + m_s) \frac{(\mu_s^+)^2}{m_s} \left(-\frac{1}{2} + 1 - \frac{1}{2}\right) = 0; \\ 0 &= \frac{dI(\sigma)}{d\sigma} = U_\varepsilon^f(X_s, s) \mu_s^+ + U_\varepsilon^g(X_s, s) \sigma_s \\ &= \frac{\phi(\Phi^{-1}(f) + m_s)}{\phi(\Phi^{-1}(f))} \mu_s^+ + (-1) \frac{\phi(\Phi^{-1}(f) + m_s) m_s}{\phi(\Phi^{-1}(f))^2} \sigma_s \\ &= \frac{\phi(\Phi^{-1}(f) + m_s)}{\phi(\Phi^{-1}(f))} \left(\mu_s^+ - \frac{m_s \sigma_s}{\phi(\Phi^{-1}(f))^2}\right), \end{aligned}$$

which implies that $\sigma_s = \phi(\Phi^{-1}(f))(\mu_s^+/m_s) = \sigma_s^*$, which maximizes $I(\sigma)$, since

$$\frac{d^2 I(\sigma)}{d\sigma^2} = U_\varepsilon^g(X_s, s) = -\frac{\phi(\Phi^{-1}(f) + m_s)}{\phi(\Phi^{-1}(f))^2} m_s < 0. \quad \square$$

Proof of Theorem 6. Since $\tilde{U}(f, T) = U(f, T) = u(f, T)$ and $\tilde{U}(0, t) = U(0, t) = u(0, t)$, and since \tilde{U} and U are bounded continuous functions, there exists a $\delta_\varepsilon > 0$ for every $\varepsilon > 0$ such that

- (i) $\lim_{\varepsilon \rightarrow 0} \delta_\varepsilon = 0$;
- (ii) $|U(f, t) - u(0, t)| < \delta_\varepsilon$ and $|\tilde{U}(f, t) - u(0, t)| < \delta_\varepsilon$, for all $f \leq \varepsilon$;
- (iii) $|U(f, t) - u(f, T)| < \delta_\varepsilon$ and $|\tilde{U}(f, t) - u(f, T)| < \delta_\varepsilon$, for all $t \geq T - \varepsilon$.

Take any $(f, t) \in S$. We want to show that $U(f, t) = \tilde{U}(f, t)$. On the boundaries of S , it is true by definition. On the interior, we have that, for sufficiently small ε (Lemma 2),

$$\begin{aligned} U(f, t) - \tilde{U}(f, t) &= U(f, t) - U_\varepsilon(f, t) \\ &= \lim_{\varepsilon \rightarrow 0} (U(f, t) - U_\varepsilon(f, t)) \\ &\geq \lim_{\varepsilon \rightarrow 0} \left(E \int U(f_\tau, \tau) dv - E \int U_\varepsilon(f_\tau, \tau) dv \right) \\ &= \lim_{\varepsilon \rightarrow 0} E \left[\int U(f_\tau, \tau) - u_\varepsilon(f_\tau, \tau) dv \right] \geq \lim_{\varepsilon \rightarrow 0} E \left[\int -2\delta_\varepsilon dv \right] = 0, \end{aligned}$$

where τ is as before and v is the probability measure of (f_τ, t) under the strategy σ_ε^* . Likewise,

$$\begin{aligned} U(f, t) - \tilde{U}(f, t) &\leq \lim_{\varepsilon \rightarrow 0} E \int U(f_\tau, \tau) dw - E \int U_\varepsilon(f_\tau, \tau) dw \\ &= \lim_{\varepsilon \rightarrow 0} E \left[\int U(f_\tau, \tau) - U_\varepsilon(f_\tau, \tau) dw \right] \leq \lim_{\varepsilon \rightarrow 0} E \int 2\delta_\varepsilon dw = 0, \end{aligned}$$

where w is the probability measure of (f_τ, τ) under the strategy σ^* . Hence $U(f, t) = \tilde{U}(f, t)$ on the interior of S , which implies that $\sigma^* = \sigma_\varepsilon^*$ on the interior of S . \square

3.2. The 0/1 utility function. We now shift our attention to the utility function $u(f, T) = 0$ for $f < 1$ and $u(1, T) = 1$. This is the one for which Sudderth and Weerasinghe [6] solved the subfair case.

THEOREM 7. *If $u(f, T) = 0$ for $f < 1$ and $u(1, T) = 1$, then*

$$U(f, t) = \tilde{U}(f, t) \triangleq \Phi(\Phi^{-1}(f) + m_t), \quad (f, t) \in S$$

and

$$\sigma^*(f, t) = \tilde{\sigma}^*(f, t) \triangleq \phi(\Phi^{-1}(f))(\mu_t^+ / m_t), \quad 0 \leq f \leq 1, 0 \leq t < T.$$

Proof. Since, for all f , the utility function $u(f, T)$ is smaller than that in § 3.1, we know from Theorem 6 that $U(f, t) \leq \tilde{U}(f, t)$.

To show that $U(f, t) \geq \tilde{U}(f, t)$, we consider the following modified problem. Let $u'_t = \mu_{t+\varepsilon}$ for $t \leq T - \varepsilon$ and $u'_t = 0$ for $T - \varepsilon < t \leq T$. Consider the strategy $\sigma(f, t) = 1/(T - t)$ for $T \geq T - \varepsilon$. With it, we leave the interval $(0, 1)$ with probability 1 before time T , since $\int_{T-\varepsilon}^T |1/(T-s)|^2 ds = \infty$. The probability of leaving the interval at $f = 1$ is equal to the fortune at time $T - \varepsilon$, since there is no drift ($u'_t = 0$). Hence $U_\varepsilon(f, t) \geq f$ for $t \geq T - \varepsilon$, where U_ε is the “ U -function” of the modified problem.

From this and Theorem 6, we have that $U_\varepsilon(f, t) \geq \tilde{U}(f, t + \varepsilon)$. Now $U(f, t) \geq U_\varepsilon(f, t)$ for all ε , and hence $U(f, t) \geq \lim_{\varepsilon \rightarrow 0} U_\varepsilon(f, t) \geq \lim_{\varepsilon \rightarrow 0} \tilde{U}(f, t + \varepsilon) = \tilde{U}(f, t)$. $\sigma^*(f, t) = \tilde{\sigma}^*(f, t)$ now follows from Theorem 6. \square

Remark. In this paper we have fixed μ_t as a predetermined function, while the control variable $\sigma(f, t)$ can be chosen almost freely. If we also have μ_t as a control variable, i.e., we can choose from among various μ_t -functions, then it follows from Theorems 6 and 7, respectively, that we should pick the function that maximizes m_t , while $\sigma(f, t)$ is chosen as before. It is an open question regarding what happens if there is a restriction on the choice of $\sigma(f, t)$, such as an upper limit, or if the allowable controls depend on the present fortune.

3.3. Other utility functions.

COROLLARY 6 (to Theorem 6). *If $u(f, T) = \Phi(\Phi^{-1}(f) + m)$, $m \geq 0$, then*

$$U(f, t) = \Phi(\Phi^{-1}(f) + m + m_t) \quad \text{and} \quad \sigma^*(f, t) = \phi(\Phi^{-1}(f))\mu_t^+ / (m + m_t).$$

Remark. Note that the optimal strategy is no longer independent of μ when $\mu_t = \mu$ for all t . We assume that the intuition behind this is that $u(f, T)$ is no longer a convex function.

4. Inequalities for stochastic processes. In this section we reformulate the problems into stochastic processes, where σ (or s), which previously was a control variable, is now arbitrary and possibly unknown. We wish to establish some inequalities of the probability of hitting an upper bound u before some given time T and before hitting a lower bound l .

Consider the random walk $X_t = X_{t-1} + \sigma_{t-1} Y_{t-1}$, where Y_{t-1} has the two-point distribution $P(Y = -1) = 1 - w$ and $P(Y = (1 - r)/r) = w$, $w > r$ and where σ_{t-1} is arbitrary. Let F , k , and q be defined as in § 2.1 and let $\tau_u = \min \{t: X_t \geq u\}$ and $\tau_l = \min \{t: X_t \leq l\}$.

INEQUALITY 1. *If $w \geq \frac{1}{2} \geq r$ and $l < X_0 < u$, then*

$$\begin{aligned} P(\tau_u \leq T, \tau_u < \tau_l | X_0) &\leq F(k-1 | T, 1-w) + \left[q(f, T) \binom{T}{k} \right] (1-w)^k w^{T-k} \\ &< F(k | T, 1-w), \end{aligned}$$

where $f = (X_0 - l)/(u - l)$ and $[x]$ is the integer part of x .

Proof. The proof follows from Theorem 3, where we found the strategy σ^* that maximizes the above probability.

INEQUALITY 2. *For any $w > r$ and if $l < X_0 < u$, then*

$$P(\tau_u \leq T, \tau_u < \tau_l | X_0) \leq F(k-1 | T, 1-w) + q(f, T) \binom{T}{k} (1-w)^k w^{T-k} < F(k | T, 1-w).$$

Proof. The proof follows from Corollary 2.

Remark. Since $P(X_T \geq u, X_s > l \text{ for all } s < T | X_0) \leq P(\tau_u \leq T, \tau_u < \tau_l | X_0)$, we get inequalities for this probability, also.

We now turn to the continuous time process $dX_t = \sigma_t(\mu_t dt + dB_t)$, where B_t is the standard Brownian motion and where σ_t is arbitrary but nonnegative and fulfils the conditions stated in the beginning of § 3.

INEQUALITY 3. *If $l < X_0 < u$, then*

$$P(X_T \geq u, X_s > l \forall s < T | X_0) \leq P(\tau_u \leq T, \tau_u < \tau_l | X_0) \leq \Phi\left(\Phi^{-1}\left(\frac{X_0 - l}{u - l}\right) + m_t\right),$$

where m_t is defined as in § 3.

Proof. The proof follows from Theorem 7.

Remark. The inequality also holds for a process $dX_t = \sigma_t(\tilde{\mu}_t dt + dB_t)$, where $\sigma_t \tilde{\mu}_t \leq \sigma_t \mu_t$ for all t .

Acknowledgment. The author thanks David Heath for valuable discussions.

ON A CERTAIN ASYMPTOTIC BEHAVIOUR OF TIME-INVARIANT RICCATI MATRIX DIFFERENTIAL EQUATIONS*

WERNER KRATZ†

Abstract. The main result of this paper reads as follows: Given (real) $(n \times n)$ -matrices A , B , C , and C_0 such that B , C , and C_0 are symmetric, such that B and C_0 are nonnegative definite, such that the pair (A, B) is (completely) controllable (i.e., $\text{rank} [B, A, \dots, A^{n-1}B] = n$), and such that the triple (A, B, C_0) is strongly observable (i.e., $\dot{x} = Ax + Bu$, $C_0 x \equiv 0$ on some nondegenerate interval implies $x(t) \equiv 0$), then, for any $t_0 > 0$ and any symmetric matrix Q_0 , the solution $Q(t; \lambda)$ of the Riccati matrix differential equation

$$\dot{Q} + A^T Q + Q A + Q B Q - C + \lambda C_0 = 0, \quad Q(0) = Q_0$$

exists on $[0, t_0]$ if $\lambda \leq \lambda_0$, and it satisfies $\lim_{\lambda \rightarrow -\infty} Q(t_0; \lambda) = \infty$ (i.e., all eigenvalues of the symmetric matrix Q tend to ∞). The result is that the new notion of strong observability is even necessary for the assertion. This result on Riccati matrix equations is motivated by the following application. It is shown that

$$\min \left\{ \int_0^{t_0} [x^T C x + u^T B u] dt \middle/ \int_0^{t_0} x^T C_0 x dt, \text{ where } x(t) \neq 0, \text{ and } \dot{x} = Ax + Bu \text{ with } u \in C^s[0, t_0] \right\}$$

exists just under the same assumptions as above.

Key words. Riccati matrix differential equation, linear systems, controllability, observability, optimal linear regulator, Rayleigh quotient

1. Introduction. The main objective of this paper is a result on the asymptotic behaviour of certain Riccati matrix differential equations, which is discussed below. These investigations, however, were motivated mainly by the following optimization problem. Given a time-invariant linear system

$$\dot{x} = Ax + Bu, \quad y = C_0 x$$

with state x , input u , and output y , we ask whether the

$$(*) \quad \min \{R(x) \mid \dot{x} = Ax + Bu \text{ for some } u \in C^s[0, t_0], x \neq 0\}$$

exists, where the “Rayleigh quotient” $R(x)$ is given by

$$R(x) = \int_0^{t_0} \{x^T(t) C x(t) + u^T(t) B u(t)\} dt \middle/ \int_0^{t_0} x^T(t) C_0 x(t) dt,$$

where $C^s[0, t_0]$ denotes the *piecewise continuous* functions on $[0, t_0]$, where we assume naturally that C , B , C_0 are symmetric $(n \times n)$ -matrices, and where B and C_0 are nonnegative definite (observe that the nonnegative-definiteness of B corresponds to the Legendre condition in the calculus of variations). In this paper, we give conditions on the matrices involved that guarantee the existence of the minimum above. Of course, this problem is closely related to the linear optimal regulator, where only the quadratic functional in the numerator of $R(x)$ is considered, and its theory is well developed. Here, we seek to minimize the numerator relative to another quadratic functional (which can be interpreted as output-performance of the linear system). Moreover, the question of minimizing $R(x)$ is a classical problem in the calculus of variations (here $R(x)$ is the so-called Rayleigh quotient of corresponding eigenvalue problems; see,

e.g., [21–23]), and it is completely solved only for special cases, namely, quadratic functionals (where B and C_0 are regular) and for so-called Sturm–Liouville problems (where $\text{rank } B = \text{rank } C_0 = 1$) [3], [21]–[23]. Except in these two cases, there was always assumed some definiteness property (which reduces to the assumption that $R(x)$ is bounded from below; see, e.g., [23, p. 381, (\mathcal{H}_κ)], [4], [11], [18], [21], [22], [25], and others]) to prove that the above minimum exists (which corresponds to the existence of a (minimal) eigenvalue of the related eigenvalue problem).

As we see below, the problem of minimizing $R(x)$ is intimately connected with the asymptotic behaviour of a corresponding matrix differential equation, which plays also an important role for the linear optimal regulator [2], [7], [10], [17]. Our main result (Theorem 3, below) reads as follows:

Given (real) $(n \times n)$ -matrices A , B , C , and C_0 such that B , C , and C_0 are symmetric, such that B and C_0 are nonnegative definite, such that the pair (A, B) is *controllable* (i.e., $\text{rank } [B, A, \dots, A^{n-1}B] = n$), and such that the triple (A, B, C_0) is *strongly observable* (i.e., $\dot{x} = Ax + Bu$, $C_0 x \equiv 0$ on some nondegenerate interval implies that $x \equiv 0$). Then, for any $t_0 > 0$ and any symmetric matrix Q_0 , the solution $Q(t; \lambda)$ of the Riccati matrix differential equation

$$(\quad +) \quad \dot{Q} + A^T Q + QA + QBQ - C + \lambda C_0 = 0, \quad Q(0) = Q_0$$

exists on $[0, t_0]$ if $\lambda \leq \lambda_0$, and it satisfies

$$\lim_{\lambda \rightarrow -\infty} Q(t_0; \lambda) = \infty$$

(i.e., all eigenvalues of the symmetric matrix Q tend to ∞).

Using this result, we prove in Theorem 4 that the minimum (*) does exist just under the same assumptions. In Proposition 6, we show that the new notion of strong observability is also necessary for the assertion of Theorem 3 (i.e., the asymptotic behaviour of $Q(t; \lambda)$, above). This asymptotic behaviour is known (even in a more explicit form) when we deal with special cases coming from Sturm–Liouville problems [14], [15], [20] or from quadratic functionals [3], as mentioned above. Throughout this paper, we restrict ourselves to constant matrices, but inequalities related to Riccati equations (see, e.g., [24]) lead to corresponding results for time-dependent systems.

Now we summarize the setup of this paper. In § 2 we derive a normal form for controllable systems, which is related to the standard normal form used to show the theorem on pole assignment (see, e.g., [12], [19], [26]). In § 3 we prove a central inequality (Theorem 2), which is the key for the proof of our main result. This inequality (together with the normalization of § 2) leads to a form of C_0 , such that the general Riccati equation (+) separates into special equations, which are related to Sturm–Liouville problems where the asymptotic result is known (see Proposition 5, below). In § 4 we state the correspondence of (+) to certain linear systems in the sense that Q solves (+) if and only if

$$Q = UX^{-1}, \quad \text{where } \dot{X} = AX + BU, \quad \dot{U} = (C - \lambda C_0)X - A^T U,$$

and this is used to derive inequalities on Riccati equations (Proposition 3). While § 5 is devoted to the proof of our main result (Theorem 3), we apply this result in § 6 to show the existence of the minimum (*) (Theorem 4). This proof of Theorem 4 uses a standard technique known from the linear optimal regulator. Moreover, we prove the necessity of strong observability (Proposition 6) in § 6, as discussed above.

2. The normal form. In this section, we derive a canonical form of (completely) controllable systems, which is the basis for the main theorem in § 5. The first part

(Proposition 1) of this normal form is contained in [13, Prop. 1], where the transformation is constructed explicitly by induction], and it essentially equals the so-called Hessenberg form [26, eq. (5.186)]. Moreover, our final canonical form (Theorem 1) can be used to very easily derive the standard normal form for proving the theorem on pole assignment [1], [19], [27], [12, Satz 3.5 "Regelungsnormalform"] (see also [6], [9]). Hence our normal form (and its proof) can be used to give a rather simple alternative proof of pole assignment for controllable systems (either using Theorem 1 directly or by deriving first the standard normal form as in [1] or [12], [19]).

PROPOSITION 1. Assume that the pair (A, B) of (real) $(n \times n)$ -matrices A and B is controllable, i.e., $\text{rank}[B, AB, \dots, A^{r-1}B] = n$ for some (minimal) $r \in \{1, \dots, n\}$, and let $l_r = \text{rank } B$, $\sum_{\mu=r-k+1}^r l_\mu = \text{rank}[B, AB, \dots, A^{k-1}B]$ for $k=1, \dots, r$. Then $1 \leq l_1 \leq \dots \leq l_r$, $\sum_{\mu=1}^r l_\mu = n$, and then there exists an orthogonal matrix T such that

$$(i) \quad T^T B = \begin{pmatrix} 0 \\ -\frac{0}{B_0} \end{pmatrix}$$

with an $(l_r \times n)$ -matrix B_0 of rank l_r ; and

(ii) $T^T A T = (A_{\mu\nu})$, $\mu, \nu \in \{1, \dots, r\}$ with $(l_\mu \times l_\nu)$ -matrices $A_{\mu\nu}$, where $A_{\mu\nu} = 0$ for $\nu > \mu + 1$ and $\text{rank } A_\mu = l_\mu$ for $A_\mu = A_{\mu, \mu+1} \dots A_{\mu-1, r}$, $\mu = 1, \dots, r-1$ (see [13, Prop. 1], and observe that r is the so-called controllability index of the system $\dot{x} = Ax + Bu$, according to [19]).

Now we can derive our normal form.

THEOREM 1. Under the assumptions and with the notation of Proposition 1, there exists a regular matrix T such that

$$(i) \quad T^{-1} B = \begin{pmatrix} 0 \\ -\frac{0}{B_0} \end{pmatrix}$$

with an $(l_r \times n)$ -matrix B_0 of rank l_r as in Proposition 1; and

$$(ii) \quad T^{-1} A T = \begin{pmatrix} 0 & J_1 & \dots & 0 \\ & \ddots & & \vdots \\ 0 & & 0 & J_{r-1} \\ A_{r1} & \dots & & A_{rr} \end{pmatrix}$$

with $(l_\mu \times l_{\mu+1})$ matrices J_μ of the form $J_\mu = (I \mid 0)$, where $I = I_\mu$ is the $(l_\mu \times l_\mu)$ -identity matrix, and with certain $(l_r \times l_\mu)$ -matrices $A_{r\mu}$.

Proof. We may assume that

$$A = (A_{\mu\nu}^{(0)}), \quad B = \begin{pmatrix} 0 \\ -\frac{0}{B_0} \end{pmatrix}$$

are as in the statement of Proposition 1. First, let $T = \text{diag}(T_1, \dots, T_r)$ be a block-diagonal matrix with regular $(l_\mu \times l_\mu)$ -matrices T_μ and with $T_1 = I$. Then $T^{-1} A T = A^{(1)} = (A_{\mu\nu}^{(1)})$ with $A_{\mu\nu}^{(1)} = T_\mu^{-1} A_{\mu\nu}^{(0)} T_\nu$. Hence $A_{\mu\nu}^{(1)} = 0$ for $\nu > \mu + 1$, and, inductively, $J_\mu = A_{\mu, \mu+1}^{(1)} = T_\mu^{-1} A_{\mu, \mu+1} T_{\mu+1} = (I \mid 0)$ for $\mu = 1, \dots, r-1$ with suitable, regular matrices T_2, \dots, T_r , since $\text{rank } A_{\mu, \mu+1} = l_\mu$. Moreover, the form of B remains unchanged when multiplying with T^{-1} from the left. Next, let

$$T = \begin{pmatrix} I & 0 & 0 \\ \left(-A_{11}^{(1)} \right) & I & \vdots \\ 0 & & \ddots \\ \vdots & & & \vdots \\ 0 & \dots & & I \end{pmatrix}.$$

Then

$$T^{-1} = \begin{pmatrix} I & 0 & 0 \\ \begin{pmatrix} A_{11}^{(1)} \\ 0 \end{pmatrix} & I & \vdots \\ \vdots & & \ddots \\ 0 & \dots & I \end{pmatrix}$$

and

$$A^{(2)} = T^{-1}A^{(1)}T = \begin{pmatrix} 0 & J_1 & \dots & 0 \\ A_{21}^{(2)} & A_{22}^{(2)} & J_2 & 0 \\ & & \ddots & \\ A_{r1}^{(2)} & & & A_{rr}^{(2)} \end{pmatrix}.$$

After r steps these transformations lead to the final form, namely,

$$A^{(r)} = \begin{pmatrix} 0 & J_1 & \dots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & & & J_{r-1} \\ A_{r1}^{(r)} & \dots & & A_{rr}^{(r)} \end{pmatrix},$$

which is asserted in our theorem, while B remains unchanged. \square

In view of our application of this normal form, we can simplify this form further by dealing with inequalities instead of identities. This is motivated by the monotonicity behaviour of Riccati equations (as discussed below). We henceforth write $A \leq B$ for square-matrices A, B , if A and B are symmetric and if $B - A$ is nonnegative definite.

COROLLARY 1. *Under the assumptions and with the notation of Proposition 1 (respectively Theorem 1), suppose, moreover, that $B \geq 0$ and that C is another $(n \times n)$ -matrix, which is symmetric. Then there exists a regular matrix T and a real $\alpha > 0$ such that*

$$\begin{pmatrix} \tilde{C} & -\tilde{A}^T \\ -\tilde{A} & -\tilde{B} \end{pmatrix} \geq \begin{pmatrix} -\alpha I & -J^T \\ -J & -\mathcal{B} \end{pmatrix},$$

where $\tilde{A} = T^{-1}AT$, $\tilde{B} = T^{-1}B(T^{-1})^T$, $\tilde{C} = T^TCT$,

$$J = \begin{pmatrix} 0 & J_1 & \dots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & & & J_{r-1} \\ 0 & \dots & & 0 \end{pmatrix}$$

with $J_\mu = (I_\mu | 0)$ for $\mu = 1, \dots, r-1$ as in Theorem 1, and where $\mathcal{B} = \begin{pmatrix} 0 & 0 \\ 0 & I \end{pmatrix}$ with $(l_r \times l_r)$ -identity matrix I .

Proof. Suppose, first, that T is a regular matrix as in the statement of Theorem 1. Then

$$T^{-1}B(T^{-1})^T = \begin{pmatrix} 0 & 0 \\ 0 & B_0 \end{pmatrix}$$

with a positive definite $(l_r \times l_r)$ -matrix B_0 , since B is symmetric, nonnegative definite, and $\text{rank } B = \text{rank } B_0 = l_r$. Moreover, we may assume that $2B_0 \leq I$ (multiply T by some positive number, which does not change \tilde{A}). Now, given any vectors $c, d \in \mathbb{R}^n$, let

$c^T = (c_1^T, \dots, c_r^T)$, $d^T = (d_1^T, \dots, d_r^T)$ with $c_\nu, d_\nu \in \mathbb{R}^{l_\nu}$. Then

$$\begin{aligned} & c^T(\tilde{C} + \alpha I)c + d^T(\mathcal{B} - \tilde{B})d + 2d^T(J - \tilde{A})c \\ &= c^T(\tilde{C} + \alpha I)c + d_r^T(I - B_0)d_r - 2d_r^T \sum_{\nu=1}^r A_{r\nu}c_\nu \\ &\geq \frac{1}{2} \left| d_r - 2 \sum_{\nu=1}^r A_{r\nu}c_\nu \right|^2 + c^T(\tilde{C} + \alpha I - 2(\tilde{A} - J)(\tilde{A} - J)^T)c \geq 0, \end{aligned}$$

if $\alpha > 0$ is sufficiently large. \square

Next, we give those transformations T , under which the normal form of Corollary 1 is (essentially) invariant. To do this, we must refine the block-structure of A (respectively, J) as follows: Let l_1, \dots, l_r be given as before (i.e., as in Theorem 1 and elsewhere) such that $1 \leq l_1 \leq \dots \leq l_r$, $\sum_{\nu=1}^r l_\nu = n$. We subdivide the blocks of length l_ν , further, namely, into ν blocks of lengths $\Delta_\mu = l_\mu - l_{\mu-1} \geq 0$ (with $l_0 := 0$). Then $\sum_{\mu=1}^\nu \Delta_\mu = l_\nu$ for $\nu = 1, \dots, r$. Using this notation, we obtain the following result.

COROLLARY 2. Assume that J and \mathcal{B} are given as in Corollary 1, and let $\Delta_\mu = l_\mu - l_{\mu-1}$ for $\mu = 1, \dots, r$, $l_0 := 0$. Moreover, let $\nu \in \{1, \dots, r\}$, and suppose that T is a regular matrix of the following form: $T^{-1} = \text{diag}(T_1, \dots, T_r)$ is block-diagonal, where the blocks T_μ along the diagonal are $(l_\mu \times l_\mu)$ -matrices such that $T_\mu = I$ for $\mu = 1, \dots, \nu-1$,

$$T_\nu = \begin{pmatrix} I & 0 & \dots & 0 \\ \vdots & \ddots & & \vdots \\ 0 & & I & 0 \\ C_{\nu 1} & \dots & & C_{\nu \nu} \end{pmatrix}$$

with arbitrary $(\Delta_\nu \times \Delta_\mu)$ -matrices $C_{\nu\mu}$, where $C_{\nu\nu}$ is regular, and let

$$T_{\nu+1} = \begin{pmatrix} I & \dots & 0 \\ \vdots & \ddots & \vdots \\ C_{\nu 1} & \dots & C_{\nu \nu} \\ 0 & \dots & I \end{pmatrix}, \dots, T_r = \begin{pmatrix} I & \dots & 0 \\ \vdots & \ddots & \vdots \\ C_{\nu 1} & \dots & C_{\nu \nu} \\ 0 & \dots & I \end{pmatrix} \leftarrow \nu\text{th row.}$$

Then $T^{-1}JT = J$, $T^{-1}\mathcal{B}(T^{-1})^T = \begin{pmatrix} 0 & 0 \\ 0 & B_0 \end{pmatrix}$ with a positive definite $(l_r \times l_r)$ -matrix B_0 ($B_0 = T_r^T T_r$), and, of course, $T^T T \leq \alpha I$ for suitable $\alpha > 0$.

Proof. The statements of the corollary follow quite easily if we show that $T_\mu J_\mu T_{\mu+1}^{-1} = J_\mu$ for $\mu = 1, \dots, r-1$. This is trivial for $\mu = 1, \dots, \nu-2$, and, for $\mu = \nu-1$, we have that

$$T_{\nu-1} J_{\nu-1} T_\nu^{-1} = \left(I \begin{smallmatrix} 1 \\ \vdots \\ 1 \end{smallmatrix} \begin{smallmatrix} 0 \\ \vdots \\ 0 \end{smallmatrix} \right) \begin{pmatrix} I & 0 \\ * & * \end{pmatrix} = \left(I \begin{smallmatrix} 1 \\ \vdots \\ 1 \end{smallmatrix} \begin{smallmatrix} 0 \\ \vdots \\ 0 \end{smallmatrix} \right) = J_{\nu-1}.$$

Finally, for $\mu = \nu, \dots, r-1$, we obtain that

$$T_\mu J_\mu T_{\mu+1}^{-1} = T_\mu \left(I \begin{smallmatrix} 1 \\ \vdots \\ 1 \end{smallmatrix} \begin{smallmatrix} 0 \\ \vdots \\ 0 \end{smallmatrix} \right) \begin{pmatrix} T_\mu^{-1} & 0 \\ 0 & I \end{pmatrix} = J_\mu. \quad \square$$

DEFINITION 1. Transformations T , which are a (finite) product of matrices as described in Corollary 2 above, are called *invariant matrices*.

3. The central inequality. The result of this section is the key to the proof of our theorem on the asymptotic behaviour of Riccati equations. Before we can state the

inequality, however, we need some notion. Let (as in the preceding section)

$$\begin{aligned} n \in \mathbb{N}, \quad 1 \leq l_1 \leq \cdots \leq l_r \quad \text{with} \quad \sum_{\nu=1}^r l_\nu = n, \quad \text{and} \\ \Delta_\nu = l_\nu - l_{\nu-1}, \quad \nu = 1, \dots, r \quad \text{with} \quad l_0 := 0, \quad \text{such that} \\ l_\nu = \sum_{\mu=1}^{\nu} \Delta_\mu, \quad \text{in particular} \quad m := \sum_{\mu=1}^r \Delta_\mu = l_r; \end{aligned}$$

the $(n \times n)$ -matrices J and \mathcal{B} are defined as in Corollary 1. Then a function $x \in C_1(\mathcal{J})$ (on some interval $\mathcal{J} \subset \mathbb{R}$) satisfies

$$\dot{x} = Jx + \mathcal{B}u \quad \text{on } \mathcal{J} \text{ for some function } u(t) \in C^s(\mathcal{J})$$

if and only if $x(t)$ is of the following form:

$$(1) \quad \begin{aligned} x^T(t) &= (x_1^T(t), x_1''^T(t), x_2^T(t), x_1''^T(t), x_2'^T(t), x_3^T(t), \dots, x_r^T(t)) \\ &\quad \text{with } x_\nu(t) \in \mathbb{R}^{\Delta_\nu}, \in C_{r-\nu+1}^s(\mathcal{J}) \text{ for } \nu = 1, \dots, r. \end{aligned}$$

(By $x, x', x'', x^{(\nu)}$, and so forth, we denote the first, second, ν th, and other derivatives of x .)

DEFINITION 2. Functions $x(t)$ of the form (1) are called *admissible* on \mathcal{J} , and, for such functions, we define

$$\tilde{x}^T(t) := (x_1^T(t), \dots, x_r^T(t)) = (y_1(t), y_2(t), \dots, y_m(t)) \in \mathbb{R}^m.$$

Observe that $y_1(t), \dots, y_m(t)$ are just the “free” real-valued functions defining the corresponding admissible $x(t)$. Moreover, we want to mention that we allow, in particular, $\Delta_\nu = 0$ for $\nu \in \{2, \dots, r\}$, such that the corresponding $x_\nu(t)$ does not occur.

THEOREM 2. Let C be a symmetric and nonnegative definite $(n \times n)$ -matrix and $t_0 > 0$, such that (compare Definition 3 below)

$$f(x) := \int_0^{t_0} x^T(t) C x(t) dt > 0$$

for all admissible functions $x(t)$ on $[0, t_0]$, which do not vanish identically. Then there exist constants $\delta \geq 1$, $\varepsilon_0 > 0$ and an invariant transformation T such that the following holds:

$$(2) \quad \begin{aligned} f(Tx) &\geq \int_0^{t_0} \left\{ \sum_{\nu=1}^r \sum_{\mu=l_{\nu-1}+1}^{l_\nu} [\varepsilon_\mu |y_\mu|^2 - \delta \varepsilon_{\mu+1} (|y'_\mu|^2 + \dots + |y_\mu^{(r-\nu)}|^2)] \right\} dt \\ &= \int_0^{t_0} \{ \varepsilon_1 |y_1|^2 - \delta \varepsilon_2 (|y'_1|^2 + \dots + |y_1^{(r-1)}|^2) + \dots + \varepsilon_m |y_m|^2 \} dt \end{aligned}$$

for all admissible functions $x(t)$ on $[0, t_0]$ and for all $\varepsilon_1, \dots, \varepsilon_m$ with $0 < \varepsilon_\nu \leq \varepsilon_0$, $\delta \cdot \varepsilon_{\nu+1} \leq \varepsilon_\nu$ for $\nu = 1, \dots, m$ ($\varepsilon_{m+1} := 0$).

Proof. We proceed by induction with respect to $n \in \mathbb{N}$. First, if $n = 1$, then $r = m = \Delta_1 = 1$, and the assumption on $f(x)$ implies that $C > 0$. Hence

$$f(x) = \int_0^{t_0} C x^2(t) dt \geq \varepsilon_1 \int_0^{t_0} x^2(t) dt \quad \text{if } 0 < \varepsilon_1 \leq \varepsilon_0 := C,$$

which yields the induction hypothesis for $n = 1$. Next, let $n \geq 2$, and suppose throughout that $x(t)$ is admissible. We consider two cases.

Case 1. We have that $\Delta_r \geq 1$. Let $x_r^T(t) = (\bar{x}_r^T(t), y(t))$ with real-valued $y(t)$ (i.e., $\bar{x}_r(t)$ denotes the first $\Delta_r - 1$ coordinates of $x_r(t)$, and $\bar{x}_r^T(t)$ denotes its transpose).

Then $x^T(t) = (\bar{x}^T(t), y(t))$, where $\bar{x}(t)$ is admissible according to Definition 2, but $\bar{x}(t) \in \mathbb{R}^{n-1}$ instead of \mathbb{R}^n with corresponding “parameters” $\bar{l}_\nu = l_\nu$, $\bar{\Delta}_\nu = \Delta_\nu$ for $\nu = 1, \dots, r-1$ and $\bar{l}_r = l_r - 1$, $\bar{\Delta}_r = \Delta_r - 1 \geq 0$, $\bar{m} = m - 1$ such that the induction hypothesis may be applied to these $\bar{x}(t)$. We write

$$C = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}$$

such that C_{11} is an $((n-1) \times (n-1))$ -matrix, $C_{21}^T = C_{12} \in \mathbb{R}^n$, and such that $C_{22} \in \mathbb{R}$. Then

$$x^T C x = \bar{x}^T C_{11} \bar{x} + 2 \bar{x}^T C_{12} y + C_{22} y^2.$$

Here we see the main assumption, i.e., $f(x) = \int_0^{t_0} x^T C x dt > 0$ if $x(t) \neq 0$ (compare the notion of strong observability in Definition 3). It implies that $C_{22} > 0$, since otherwise we would have that $f(x) = 0$ (i.e., $x^T C x \equiv 0$ on $[0, t_0]$) for $\bar{x}_r(t) \equiv 0$ and arbitrary, nonvanishing $y(t) \in C^s[0, t_0]$, which yields an admissible $x(t) \neq 0$ by Definition 2. Hence

$$(3) \quad x^T C x = \bar{x}^T \bar{C} \bar{x} + C_{22} \left(y + \frac{1}{C_{22}} C_{12}^T \bar{x} \right)^2$$

with $\bar{C} = C_{11} - (1/C_{22}) C_{12} C_{12}^T$. Then \bar{C} is nonnegative definite (since C is nonnegative definite), and $\bar{f}(\bar{x}) := \int_0^{t_0} \bar{x}^T \bar{C} \bar{x}(t) dt > 0$ for all admissible $\bar{x}(t) \neq 0$ (put $y(t) = -(1/C_{22}) C_{12}^T \bar{x}(t)$ and use (3)). Thus we may apply the induction hypothesis, i.e., that there exist $\bar{\delta} \geq 1$, $\bar{\varepsilon}_0 > 0$, and in invariant transformation $\bar{T}_{(n-1) \times (n-1)}$ such that

$$(4) \quad \bar{f}(\bar{T} \bar{x}) \geq \int_0^{t_0} \left\{ \sum_{\nu=1}^r \sum_{\mu=\bar{l}_{\nu-1}+1}^{\bar{l}_\nu} [\varepsilon_\mu |\bar{y}_\mu|^2 - \bar{\delta} \varepsilon_{\mu+1} (|\bar{y}'_\mu|^2 + \dots + |\bar{y}_\mu^{(r-\nu)}|^2)] \right\} dt$$

for all admissible $\bar{x}(t)$ and all $\varepsilon_1, \dots, \varepsilon_{m-1}$, $\varepsilon_m := 0$ with $0 < \varepsilon_\nu \leq \bar{\varepsilon}_0$, $\bar{\delta} \varepsilon_{\nu+1} \leq \varepsilon_\nu$ for $\nu = 1, \dots, m-1$. Now, for $0 < \varepsilon_m \leq \frac{1}{2} C_{22}$, we obtain that

$$\begin{aligned} C_{22} \left(y + \frac{1}{C_{22}} C_{12}^T \bar{T} \bar{x} \right)^2 &= \varepsilon_m y^2 + (C_{22} - \varepsilon_m) \left(y + \frac{1}{C_{22} - \varepsilon_m} C_{12}^T \bar{T} \bar{x} \right)^2 \\ &\quad - \frac{\varepsilon_m}{C_{22}(C_{22} - \varepsilon_m)} (C_{12}^T \bar{T} \bar{x})^2 \geq \varepsilon_m y^2 - \delta^* \varepsilon_m |\bar{x}|^2 \\ &= \varepsilon_m y^2 - \delta^* \varepsilon_m \sum_{\nu=1}^r \sum_{\mu=\bar{l}_{\nu-1}+1}^{\bar{l}_\nu} [|\bar{y}_\mu|^2 + \dots + |\bar{y}_\mu^{(r-\nu)}|^2] \end{aligned}$$

if $\delta^* = \delta^*(C_{22}, C_{12}^T, \bar{T})$ is sufficiently large. Using (3) and (4), we obtain the induction hypothesis for some $\bar{\delta} \geq 2\bar{\delta} \geq 1$, $0 < \varepsilon_0 \leq \bar{\varepsilon}_0$ with

$$T = \begin{pmatrix} \bar{T} & 0 \\ 0 & 1 \end{pmatrix}_{n \times n}$$

(which is an invariant transformation, too).

Case 2. We have that $\Delta_r = 0$. Then $r \geq 2$, and the admissible functions $x(t)$ are of the form $x^T(t) = (x_1^T(t), x_1'^T(t), \dots, x_1^{(r-1)T}(t), \dots, x_{r-1}^T(t))$, so that $l := n - m \geq m$. We write

$$C = \left(\underbrace{\begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}}_l \right)_l^l \left(\underbrace{\quad}_m \right)_m^m,$$

and, according to this notion, we split this into two subcases.

Case 2.1. C_{22} is singular. This is the main case, where the invariant transformations of Corollary 2 are needed; actually, the whole degree of freedom of our normal form is exhausted. Since C_{22} is singular and symmetric, there exists a lower-triangular and regular $(m \times m)$ -matrix T_r and some $\rho \in \{1, \dots, m\}$ such that the ρ th column and the ρ th row of $\tilde{C}_{22} := (T_r^{-1})^T C_{22} T_r^{-1}$ are zero. Such a matrix T_r is obviously a product of matrices T_r , as occurring in Corollary 2; i.e.,

$$T_r = \begin{pmatrix} C_{11} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ C_{r1} & \cdots & C_{rr} \end{pmatrix} \quad \text{with } (\Delta_\nu \times \Delta_\mu)\text{-matrices } C_{\nu\mu}.$$

Moreover, by Corollary 2, if $T^{-1} = \text{diag}(T_1, \dots, T_r)$ with

$$T_\nu = \begin{pmatrix} C_{11} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ C_{\nu 1} & \cdots & C_{\nu \nu} \end{pmatrix} \quad \text{for } \nu = 1, \dots, r,$$

then T is an invariant matrix. We have that $f(Tx) = \int_0^{t_0} x^T(t) \bar{C}x(t) dt$, where

$$\bar{C} = T^T C T = \begin{pmatrix} \bar{C}_{11} & \bar{C}_{12} \\ \bar{C}_{21} & \bar{C}_{22} \end{pmatrix}.$$

Since the ρ th column and the ρ th row of \bar{C}_{22} are zero, and since C is nonnegative definite, it follows that the ρ th column of \bar{C}_{12} , respectively, the ρ th row of $\bar{C}_{21} = \bar{C}_{12}^T$, is zero (i.e., the whole corresponding column, respectively row, of \bar{C} is zero). This means that the highest derivative of the function y_ρ (where $\hat{x}^T = (y_1, \dots, y_m)$ as in Definition 2) does not occur in the quadratic form $x^T \bar{C} x$ at all. Hence the induction hypothesis for $n-1$ yields the assertion for n .

Case 2.2. C_{22} is regular. In this case, we prove a stronger assertion, namely, that there exists $\alpha > 0$ such that

$$(5) \quad f(x) \geq \alpha \int_0^{t_0} \{|y_1|^2 + \cdots + |y_m|^2\} dt$$

for all admissible $x(t)$.

In this case (i.e., $\Delta_r=0$ with regular C_{22}), our assertion can be reduced to a situation, where Corollary 3 to Theorem 4 below is applicable, as follows. For any admissible $x(t)$, write $x^T(t) = (\bar{x}^T(t), u^{*T}(t))$ with $\bar{x} \in \mathbb{R}^l$ and $u^* \in \mathbb{R}^m$ such that $u^* = (x_1^{(r-1)T}, \dots, x_{r-1}^{(r-1)T})$. Moreover, let

$$\begin{aligned} \bar{A}_{l \times l} &:= \left(\begin{array}{cccc} 0 & J_1 & \cdots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & \cdots & & J_{r-2} \\ & -C_{22}^{-1} & C_{21} & \end{array} \right) \left. \vphantom{\begin{pmatrix} 0 \\ \vdots \\ 0 \end{pmatrix}} \right\}^{l-m}_m, \quad \bar{B}_{l \times l} := \left(\begin{array}{cc} 0 & 0 \\ 0 & C_{22}^{-1} \end{array} \right) \left. \vphantom{\begin{pmatrix} 0 \\ 0 \end{pmatrix}} \right\}^{l-m}_m, \\ \bar{C}_{l \times l} &:= C_{11} - C_{21}^T C_{22}^{-1} C_{21}, \quad \bar{u}(t) := \begin{pmatrix} 0 \\ C_{22} u^*(t) + C_{21} \bar{x}(t) \end{pmatrix} \in \mathbb{R}^l. \end{aligned}$$

Then the pair (\bar{A}, \bar{B}) is controllable (even in normal form as in Theorem 1), $\dot{\bar{x}} = \bar{A}\bar{x} + \bar{B}\bar{u}$ (if and only if x is admissible), and $x^T C x = \bar{x}^T \bar{C}_1 \bar{x} + \bar{u}^T \bar{B} \bar{u}$. It follows that $f(x) = \int_0^t \{\bar{x}^T \bar{C}_1 \bar{x} + \bar{u}^T \bar{B} \bar{u}\} dt > 0$ for all admissible x , i.e., $\dot{\bar{x}} = \bar{A}\bar{x} + \bar{B}\bar{u}$ with $x \neq 0$. Now Corollary 3 below for dimension $l < n$ implies that there exists $\alpha > 0$ (depending on $\bar{C}_1, \bar{A}, \bar{B}$,

and also on t_0) such that

$$f(x) \cong \alpha \int_0^{t_0} |\bar{x}(t)|^2 dt \cong \alpha \int_0^{t_0} \{|y_1|^2 + \cdots + |y_m|^2\} dt$$

for all admissible $x(t)$ (choose the identity matrix as corresponding $l \times l$ -matrix C_0). This completes the proof of Theorem 2. \square

Remarks. (i) The foregoing proof shows that the matrix T and the constant $\delta \geq 1$ depend on the matrix C only, while the constant $\varepsilon_0 > 0$ depends additionally on t_0 (because of Case 2.2., where Corollary 3 to Theorem 4 is applied; observe the corresponding remark there).

(ii) Note, that $\Delta_\nu = 0$ for some $\nu \in \{2, \dots, r\}$ is explicitly allowed (while $\Delta_1 = l_1 \geq 1$). Then $l_{\nu-1} = l_\nu$, and $\sum_{\mu=l_{\nu-1}+1}^{l_\nu} \cdots$ is empty, i.e., $= 0$. Moreover, the sum $|y'_\mu|^2 + \cdots + |y^{(r-\nu)}_\mu|^2$ is also $= 0$, if $\nu = r$.

4. Auxiliary results on Riccati matrix differential equations. We need some statements on Riccati equations, which are essentially known, so we omit the proofs, except for Proposition 3, which differs substantially from the cited results. Throughout, we assume that A, B, C , and Q_0 are any (real) $(n \times n)$ -matrices, and we consider the initial value problem for the Riccati matrix differential equation

$$(6) \quad \dot{Q} + A^T Q + Q A + Q B Q - C = 0, \quad Q(t_0) = Q_0$$

on some interval \mathcal{I} of the real axis with $t_0 \in \mathcal{I}$. First, we have the well-known correspondence with a linear system, a so-called *Hamiltonian system* (see, e.g., [15], [16], [23], [24]).

PROPOSITION 2. *An $(n \times n)$ -matrix function $Q(t)$ is a solution of (6) on \mathcal{I} if and only if the following holds: $Q(t) = U(t)X^{-1}(t)$, where the $(n \times n)$ -matrices $X(t)$ and $U(t)$ solve the initial value problem*

$$(7) \quad \dot{X} = AX + BU, \quad \dot{U} = CX - A^T U, \quad X(t_0) = I, \quad U(t_0) = Q_0,$$

and where $X(t)$ is regular for $t \in \mathcal{I}$.

Next, we state the important comparison result, which is essentially contained in [15, Prop. 2] (see also [24, p. 118]).

PROPOSITION 3. *Assume that B, C , and Q_0 are symmetric, that $B \geq 0$ (i.e., nonnegative definite), and that $\mathcal{I} = [t_0, T)$ ($T > t_0$). Moreover, let $\tilde{A}, \tilde{B}, \tilde{C}$, and \tilde{Q}_0 be $(n \times n)$ -matrices that satisfy the fact that \tilde{B}, \tilde{C} , and \tilde{Q}_0 are symmetric such that $\tilde{Q}_0 \leq Q_0$ and such that*

$$(8) \quad \begin{pmatrix} C & -A^T \\ -A & -B \end{pmatrix} \geq \begin{pmatrix} \tilde{C} & -\tilde{A}^T \\ -\tilde{A} & -\tilde{B} \end{pmatrix}.$$

Then, if the solution $\tilde{Q}(t)$ of $\dot{\tilde{Q}} + \tilde{A}^T \tilde{Q} + \tilde{Q} \tilde{A} + \tilde{Q} \tilde{B} \tilde{Q} - \tilde{C} = 0$, $\tilde{Q}(t_0) = \tilde{Q}_0$ exists on \mathcal{I} , the solution $Q(t)$ of (6) exists on \mathcal{I} also, and it satisfies

$$(9) \quad Q(t) \geq \tilde{Q}(t) \text{ for } t \in \mathcal{I} = [t_0, T).$$

Proof. The proof is based on the correspondence to linear systems according to the previous Proposition 2 (so that $Q = UX^{-1}$, respectively, $\tilde{Q} = \tilde{U}\tilde{X}^{-1}$) and on the following identity, which follows from (7) directly (see [15, Prop. 2])

$$\begin{aligned} \frac{d}{dt} X^T (Q - \tilde{Q}) X &= (\tilde{Q} X - U)^T B (\tilde{Q} X - U) \\ &+ (X^T, X^T \tilde{Q}) \begin{pmatrix} C - \tilde{C} & \tilde{A}^T - A^T \\ \tilde{A} - A & \tilde{B} - B \end{pmatrix} \begin{pmatrix} X \\ \tilde{Q} X \end{pmatrix} \geq 0 \end{aligned}$$

since $B \geq 0$, and since (8) holds for all $t \in \mathcal{J}$, where $Q(t)$ exists (observe that $Q(t)$ and $\tilde{Q}(t)$ are symmetric for all t because Q_0 and \tilde{Q}_0 are symmetric). This inequality yields (9) using $Q_0 \geq \tilde{Q}_0$. To prove that $Q(t)$ exists on $[t_0, T)$ we proceed similarly to the proof of Proposition 4 in [15]. If $Q(t)$ does not exist on $[t_0, T)$ then there exists $t_1 \in (t_0, T)$ such that the following holds (use Proposition 2, above): $Q(t)$ exists on $[t_0, t_1)$, $X(t)$ is regular for $t \in [t_0, t_1)$, $X(t_1)$ is singular such that $X(t_1)c = 0$ for some $c \in \mathbb{C}^n \setminus \{0\}$, and $g(t) := c^T X^T(t) \{Q(t) - \tilde{Q}(t)\} X(t)c = c^T X^T(t) \{U(t) - \tilde{Q}(t)X(t)\}c \equiv 0$ on $[t_0, t_1]$ (since $g(t_0) \geq 0$, $g'(t) \geq 0$ on $[t_0, t_1]$, and $g(t_1) = 0$). Hence $(Q(t) - \tilde{Q}(t))X(t)c \equiv 0$ on $[t_0, t_1]$ (use that $Q(t) \geq \tilde{Q}(t)$), which implies that $\{U(t) - \tilde{Q}(t)X(t)\}c \equiv 0$. Thus $U(t_1)c = X(t_1)c = 0$, contradicting the fact that $\text{rank} \begin{pmatrix} U(t) \\ X(t) \end{pmatrix} \equiv n$. \square

Finally, we state the transformation behaviour of Riccati equations (see [24], p. 104).

PROPOSITION 4. *Given any regular matrix T ; then $Q(t)$ solves (6) on the interval \mathcal{J} if and only if $\tilde{Q}(t) := T^T Q(t) T$ is on \mathcal{J} a solution of $\tilde{Q} + \tilde{A}^T \tilde{Q} + \tilde{Q} \tilde{A} + \tilde{Q} \tilde{B} \tilde{Q} - \tilde{C} = 0$, $\tilde{Q}(t_0) = \tilde{Q}_0$, where $\tilde{A} = T^{-1} A T$, $\tilde{B} = T^{-1} B (T^{-1})^T$, $\tilde{C} = T^T C T$, and $\tilde{Q}_0 = T^T Q_0 T$.*

5. The main result. Before stating our main result, we need two notions, the well-known notion of “controllability” (see, e.g., [5, p. 80] and [2, p. 390]) and a new notion of “strong observability,” which is stronger than the well-known notion of observability [2], [5].

DEFINITION 3. Let be given $(n \times n)$ -matrices A , B , and C . Then we call (i) the pair (A, B) (completely) *controllable*, if $\text{rank} [B, AB, \dots, A^{n-1}B] = n$; and we call (ii) the triple (A, B, C) *strongly observable* if $\dot{x} = Ax + Bu$, $Cx \equiv 0$ on some nondegenerate interval \mathcal{J} , and $u \in C^s(\mathcal{J})$ always implies that $x \equiv 0$ on \mathcal{J} .

Remarks. (i) Obviously, strong observability of (A, B, C) implies that the pair (A, C) is (completely) observable (put $u \equiv 0$). This notion of strong observability seems to be new, and it is actually in a sense equivalent to the asymptotic behaviour of a corresponding Riccati equation (stated in our main result below). This “equivalence” is shown in the next section (Proposition 6). Observe, moreover, that both notions of Definition 3 are *invariant* under transformations according to Proposition 4, i.e., when replacing A, B, C by $\tilde{A} = T^{-1} A T$, $\tilde{B} = T^{-1} B (T^{-1})^T$, and $\tilde{C} = T^T A T$, where T is any regular matrix.

(ii) The assumption of *piecewise continuity* on u (i.e., $u \in C^s(\mathcal{J})$) in Definition 3 may be replaced by the assumption that u is an *entire function* (i.e., $u(t) = \sum_{k=0}^{\infty} u_k t^k$ for all $t \in \mathbb{R}$) without changing the notion of strong observability; we only need this weaker assumption.

Now we can state the main result of this paper.

THEOREM 3. *Let be given (real) $(n \times n)$ -matrices A, B, C, C_0 satisfying the assumptions: B, C , and C_0 are symmetric; B and C_0 are nonnegative definite; the pair (A, B) is controllable; and the triple (A, B, C_0) is strongly observable. Then, for any $t_0 > 0$ and for any symmetric matrix Q_0 , there exists $\lambda_0 = \lambda_0(t_0, Q_0; A, B, C, C_0)$ such that the solution $Q(t; \lambda)$ of the initial value problem*

$$(10) \quad \dot{Q} + A^T Q + Q A + Q B Q - C + \lambda C_0 = 0, \quad Q(0) = Q_0$$

exists on $[0, t_0]$ whenever $\lambda \leq \lambda_0$, and it satisfies

$$(11) \quad \lim_{\lambda \rightarrow -\infty} Q(t_0; \lambda) = \infty; \quad \text{i.e., all eigenvalues of the symmetric } (n \times n)\text{-matrix } Q(t_0; \lambda) \text{ tend to } \infty \text{ as } \lambda \rightarrow -\infty.$$

Proof. Using Corollary 1 and Proposition 3, we may assume that the system is transformed to “normal form.” More precisely, we may suppose that the matrices A ,

B , C , C_0 , and Q_0 have the following form (compare §§ 2 and 3):

$$A = J = \begin{pmatrix} 0 & J_1 & \dots & 0 \\ \vdots & & \ddots & \vdots \\ 0 & & & J_{r-1} \\ 0 & \dots & & 0 \end{pmatrix}$$

with $(l_\mu \times l_{\mu+1})$ -matrices $J_\mu = (I \mid 0)$ for $\mu = 1, \dots, r-1$, $B = \mathcal{B} = \begin{pmatrix} 0 & 0 \\ 0 & I \end{pmatrix}$ with the $(l_r \times l_r)$ -identity matrix I , where $1 \leq l_1 \leq \dots \leq l_r$ with $\sum_{\nu=1}^r l_\nu = n$, $C = -\alpha I$, and $Q_0 = -\beta I$ with sufficiently large positive constants α and β . Moreover, we use the notation of § 3: among others, the quantities $\Delta_\nu = l_\nu - l_{\nu-1}$, $m = \sum_{\nu=1}^r \Delta_\nu = l_r$, and the notion of admissible functions $x(t)$ according to Definition 2. Then the assumption of strong observability implies that

$$\int_0^{t_0} x^T(t) C_0 x(t) dt > 0 \quad \text{for all } t_1 > 0 \text{ and for all admissible functions } x(t)$$

(i.e., $\dot{x} = Ax + Bu$ for some function u) on $[0, t_1]$ with $x \not\equiv 0$. Hence Theorem 2 applies, where we may assume that the transformation matrix $T = I$ (using Corollary 2 and again Propositions 3 and 4 such that we can still assume that $A = J$, $B = \mathcal{B}$, $C = -\alpha I$, and $Q_0 = -\beta I$). Now Theorem 2 (noting additionally remark (i) to Theorem 2 and the remark to Corollary 3, below) yields the following: There exists $\delta \geq 1$, and, for a given $0 < \eta \leq t_0$, there exists $\varepsilon_0(\eta) > 0$ such that

$$\begin{aligned} (12) \quad & \int_0^{t_1} x^T(t) C_0 x(t) dt \\ & \geq \int_0^{t_1} \left\{ \sum_{\nu=1}^r \sum_{\mu=l_{\nu-1}+1}^{l_\nu} [\varepsilon_\mu |y_\mu|^2 - \delta \varepsilon_{\mu+1} (|y'_\mu|^2 + \dots + |y_\mu^{(r-\nu)}|)] \right\} dt \\ & = \int_0^{t_1} x^T(t) \tilde{C}_0 x(t) dt \quad \text{with the diagonal matrix} \\ & \tilde{C}_0 = \text{diag} \left(\underbrace{\Delta_1=l_1}_{\varepsilon_1, \dots, \varepsilon_{l_1}}, \underbrace{\Delta_1+\Delta_2=l_2}_{-\delta \varepsilon_2, \dots, -\delta \varepsilon_{l_1+1}, \varepsilon_{l_1+1}, \dots, \varepsilon_{l_2}}, \right. \\ & \quad \left. -\delta \varepsilon_2, \dots, -\delta \varepsilon_{l_2+1}, \varepsilon_{l_2+1}, \dots, \varepsilon_{l_3}, \dots, \right. \\ & \quad \left. \underbrace{-\delta \varepsilon_2, \dots, -\delta \varepsilon_{l_{r-1}+1}, \varepsilon_{l_{r-1}+1}, \dots, \varepsilon_{l_r}}_{\Delta_1+\dots+\Delta_r=l_r} \right) \end{aligned}$$

for all $\eta \leq t_1 \leq t_0$, $0 < \varepsilon_\nu \leq \varepsilon_0$, $\delta \varepsilon_{\nu+1} \leq \varepsilon_\nu$ ($\nu = 1, \dots, m = l_r$ with $\varepsilon_{m+1} := 0$), and for all admissible functions $x(t)$ on $[0, t_0]$. Using this inequality and notation, we obtain the following lemma, which is similar to Proposition 3.

LEMMA. Let $0 < \eta \leq t_0$ such that the solution $Q(t; 0)$ of (10) (with $\lambda = 0$) exists on $[0, \eta]$, and let $\lambda \leq 0$ be fixed. Moreover, assume that $\delta \geq 1$, $\varepsilon_0(\eta) > 0$, $0 < \varepsilon_\nu \leq \varepsilon_0$, $\delta \varepsilon_{\nu+1} \leq \varepsilon_\nu$ for $\nu = 1, \dots, m$, as above. Then, if the solution $\tilde{Q}(t) = \tilde{Q}(t; \lambda)$ of

$$(13) \quad \dot{\tilde{Q}} + A^T \tilde{Q} + \tilde{Q} A + \tilde{Q} B \tilde{Q} - C + \lambda \tilde{C}_0 = 0, \quad \tilde{Q}(0) = Q_0$$

exists on $[0, t_0]$, the solution $Q(t; \lambda)$ of (10) exists on $[0, t_0]$ also, and it satisfies

$$(14) \quad Q(t; \lambda) \geq \tilde{Q}(t; \lambda) \quad \text{for all } t \in [\eta, t_0].$$

Proof of the lemma. First, $Q(t; \lambda)$ exists on $[0, \eta]$ since $\lambda \leq 0$ and $C_0 \geq 0$ by Proposition 3 (with $\tilde{A} = A$, $\tilde{B} = B$, $\tilde{Q}(t) = Q(t; 0)$, $\tilde{C} = C$, and $C - \lambda C_0$ (which is $\geq C$))

instead of C). Then the existence of $Q(t; \lambda)$ on $[\eta, t_0]$ follows similarly as in the second part of the proof of Proposition 3, provided that we have shown (14) (assuming the existence). Now, by Proposition 2, we have that $Q(t) := Q(t; \lambda) = U(t)X^{-1}(t)$, where $X(t)$, $U(t)$ solve the linear system $\dot{X} = AX + BU$, $\dot{U} = (C - \lambda C_0)X - A^T U$ with $X(0) = I$, $U(0) = -\beta I$. The asserted inequality (14) follows, if we show that

$$c^T X^T(t) \{Q(t) - \tilde{Q}(t)\} X(t) c \geq 0 \quad \text{for all } t \in [\eta, t_0] \text{ and } c \in \mathbb{C}^n.$$

Therefore let $c \in \mathbb{C}^n$ and consider that $x(t) = X(t)c$. It follows that $\dot{x} = Ax + Bu$ with $u(t) = U(t)c = Q(t)X(t)c$, i.e., $x(t)$ is admissible, and

$$\frac{d}{dt} x^T(t) \{Q(t) - \tilde{Q}(t)\} x(t) = x^T(t) \{-\lambda(C_0 - \tilde{C}_0)\} x(t) + (\tilde{Q}(t)x(t) - u(t))^T;$$

$$B(\tilde{Q}(t)x(t) - u(t)) \geq x^T(t) \{-\lambda(C_0 - \tilde{C}_0)\} x(t)$$

(using $B \geq 0$, $\dot{x} = Ax + Bu$, and the Riccati equations satisfied by Q , respectively, \tilde{Q}). Hence inequality (12) implies that

$$x^T(t) \{Q(t) - \tilde{Q}(t)\} x(t) \geq (-\lambda) \int_0^t x^T(\tau) (C_0 - \tilde{C}_0) x(\tau) d\tau \geq 0$$

for $t \in [\eta, t_0]$, which yields (14). \square

Now we can continue the proof of Theorem 3. According to the preceding proof and the lemma, we may choose constants $\alpha > 0$, $\beta > 0$, $\eta \in (0, t_0]$, $\varepsilon_0 = \varepsilon_0(\eta) > 0$, and $\delta \geq 1$, and we can put $A = J$, $B = \mathcal{B}$, $C = -\alpha I$, and $Q_0 = -\beta I$. Then it suffices to prove that the solution $\tilde{Q}(t; \lambda)$ of (13) exists on $[0, t_0]$ for $\lambda \leq \lambda_0 < 0$ ($-\lambda_0$ sufficiently large) with $\lim_{\lambda \rightarrow -\infty} \tilde{Q}(t_0; \lambda) = \infty$, where the numbers ε_ν can be chosen as suitable functions of λ , satisfying $0 < \varepsilon_\nu(\lambda) \leq \varepsilon_0$, $\delta \varepsilon_{\nu+1}(\lambda) \leq \varepsilon_\nu(\lambda)$ for $\nu = 1, \dots, m = l_r$. We choose the $\varepsilon_\nu(\lambda)$ inductively as follows: $\varepsilon_1(\lambda) \equiv \varepsilon_0 > 0$ and $\rho_\nu(\lambda) = \sqrt[2r]{-\lambda \varepsilon_\nu}$, $-\lambda \varepsilon_{\nu+1}(\lambda) = \rho_\nu(\lambda)$ for $\nu = 1, \dots, m$. Then

$$(15) \quad \rho_\nu(\lambda) \rightarrow \infty, \quad -\lambda \varepsilon_{\nu+1}(\lambda) \rho_\nu^{-2} = 1/\rho_\nu(\lambda) \rightarrow 0 \quad \text{as } \lambda \rightarrow -\infty \text{ for } \nu = 1, \dots, m$$

such that the restrictions on the ε_ν are satisfied for $\lambda \leq \lambda_0 < 0$. Now we have, by Proposition 2 that $\tilde{Q}(t; \lambda) = U(t)X^{-1}(t)$, where the columns $x(t)$, respectively, $u(t)$, of the $(n \times n)$ -matrices $X(t)$, respectively, $U(t)$, solve the linear system

$$(16) \quad \dot{x} = Jx + \mathcal{B}u, \quad \dot{u} = (-\alpha I - \lambda \tilde{C}_0)x - J^T u.$$

This normal form of (7) is constructed in such a way that it separates into self-adjoint scalar differential equations (which correspond to Sturm-Liouville eigenvalue problems, where the asserted asymptotic behaviour (11) is known; see, e.g., [15, Thm. 11] and [14, Thm. 2]) as follows: Columns $x(t)$, $u(t)$ solve the differential system (15) if and only if $x(t)$ is admissible according to Definition 2 (i.e., $x^T(t) = (x_1^T(t), \dot{x}_1^T(t), \dots, x_r^T(t))$, and we put $\tilde{x}^T(t) = (x_1^T(t), \dots, x_r^T(t)) = (y_1(t), \dots, y_m(t)) \in \mathbb{R}^m$ as in Definition 2), if $u(t)$ is of the form (very abbreviated)

$$u^T(t) = \left((-1)^r y_1^{(2r-1)} + \sum_{\nu=2}^{r-1} (-1)^\nu (-\alpha + \lambda \cdot \delta \varepsilon_2) y_1^{(2\nu-2)}, \dots, y_1(t), \dots, y_m(t) \right),$$

and if the functions $y_1(t), \dots, y_m(t)$ solve the selfadjoint differential equations

$$(17) \quad (-1)^s y_\mu^{(2s)} + \sum_{\nu=1}^{s-1} (-1)^\nu (-\alpha + \lambda \delta \varepsilon_{\mu+1}) y_\mu^{(2\nu)} = (\lambda \varepsilon_\mu + \alpha) y_\mu$$

for $\mu \in \{1, \dots, m\}$, $s \in \{1, \dots, r\}$ with $l_{r-s} < \mu \leq l_{r+1-s}$.

Since the initial value matrix $Q_0 = -\beta I$ is diagonal, the matrices $X(t)$, $U(t)$ "separate completely," which means that $\tilde{Q} = UX^{-1}$ is given by $\tilde{Q}(t; \lambda) = P^T \text{diag}(Q_1(t; \lambda), \dots, Q_m(t; \lambda))P$ with some permutation matrix P , where the diagonal blocks $Q_\mu(t; \lambda)$ solve Riccati equations corresponding to (16). More precisely,

$$(18) \quad \dot{Q}_\mu + A_s^T Q_\mu + Q_\mu A_s + Q_\mu B_s Q_\mu - C_s + \lambda C_{0s} = 0, \quad Q_\mu(0) = -\beta I$$

for $\mu \in \{1, \dots, m\}$, $s \in \{1, \dots, r\}$, $l_{r-s} < \mu \leq l_{r+1-s}$, where the $(s \times s)$ -matrices A_s , B_s , C_s , C_{0s} are given by $C_s = -\alpha I$, $C_{0s} = \text{diag}(\varepsilon_\mu, -\delta\varepsilon_{\mu+1}, \dots, -\delta\varepsilon_{\mu+1})$, $B_s = \text{diag}(0, \dots, 0, 1)$, and the companion matrix

$$A_s = \begin{pmatrix} 0 & 1 & & 0 \\ \vdots & & \ddots & 1 \\ 0 & & & 0 \end{pmatrix}.$$

These solutions $Q_\mu(t; \lambda)$ are evaluated asymptotically in [15, Thm. 11], [14, Thm. 2], and the corresponding result needed here is stated in Proposition 5, below. Since $-\lambda\varepsilon_\mu = \rho_\mu^{2r}(\lambda) \geq \rho_\mu^{2s}(\lambda) \rightarrow \infty$ and $-\lambda\varepsilon_{\mu+1} = \rho_\mu$, Proposition 5 (with $\varepsilon(\rho_\mu) = 1/\rho_\mu$) implies that $Q_\mu(t; \lambda)$ exists on $[0, t_0]$ for $\lambda \leq \lambda_0$ and that $\lim_{\lambda \rightarrow \infty} Q_\mu(t_0; \lambda) = \infty$ for all $\mu = 1, \dots, m$, which yields the desired assertion. \square

PROPOSITION 5. *Assume that A is the $(s \times s)$ -companion matrix, that $B = \text{diag}(0, \dots, 0, 1)$ as above, and that $C_0 = \text{diag}(1, 0, \dots, 0)$, $C = \text{diag}(r_0(\rho), \dots, r_{s-1}(\rho))$ such that*

$$|r_\nu(\rho)|\rho^{2(\nu-s)} \leq \varepsilon(\rho) \rightarrow 0 \quad \text{as } \rho \rightarrow \infty \text{ for } \nu = 0, \dots, s-1.$$

Then, for any $t_0 > 0$ and for any symmetric matrix Q_0 , the solution $Q(t; \rho)$ of

$$\dot{Q} + A^T Q + Q A + Q B Q + C + \rho^{2s} C_0 = 0, \quad Q(0) = Q_0$$

exists on $[0, t_0]$ for $\rho > 0$ sufficiently large, and it satisfies

$$Q(t_0; \rho) = \rho \tilde{D}_\rho \{G + O(\varepsilon(\rho))\} \tilde{D}_\rho \rightarrow \infty \text{ as } \rho \rightarrow \infty,$$

where $\tilde{D}_\rho = \text{diag}(\rho^{s-1}, \dots, \rho, 1)$ and where G is a positive definite matrix (depending on s only).

Proof. The proof (and the assertion) of Theorem 2 in [14] uses the more restrictive assumption that $\varepsilon(\rho) = O(\rho^{-2})$ (which is needed there for Theorem 1). An inspection of the explicit calculations in that proof, however, immediately shows that Proposition 5, above (with $O(\varepsilon(\rho))$ instead of $O(\rho^{-2})$ in [14, Thm. 2]), is true. \square

6. Applications to the linear regulator in optimal control. In this section, we prove a consequence of Theorem 3 concerning the quotient of quadratic functionals

$$R(x) := \int_0^{t_0} \{x^T C x + u^T B u\} dt \Big/ \int_0^{t_0} x^T C_0 x dt,$$

where the denominator is positive for admissible $x(t) \not\equiv 0$. Then the quotient $R(x)$ is $\geq \lambda_0$ if and only if the quadratic functional

$$I(x; \lambda_0) := \int_0^{t_0} \{x^T C x + u^T B u\} dt - \lambda_0 \int_0^{t_0} x^T C_0 x dt$$

is ≥ 0 , which relates the minimization of $R(x)$ to the optimal linear regulator problem. Our result on the minimization of $R(x)$ is well known if $B = C_0 = I$ (see, e.g., [23, Chap. IV, Thm. 3.1] and [3, § 7.2]); in particular, the method of proof is normally used when dealing with the linear regulator in optimal control (see, e.g., [17, § 3.3]).

Moreover, Theorem 3 can be used to prove a far more general result (including general boundary conditions and also time-dependent systems) via Theorem 4 of [3]. This will be done in a forthcoming paper, where a general oscillation result (compare [3, Thm. 3]) will be derived. Here, however, we need a rather special case, which was already used in the inductive proof of the central inequality (2) in Theorem 2, above. Moreover, the proof below is rather easy (when Theorem 3 is known), and it makes this paper self-contained.

THEOREM 4. *Under the assumptions of Theorem 3, there exists*

$$\lambda_0 := \min \{R(x) \mid x(t) \text{ admissible and } \neq 0\},$$

where $x(t)$ is admissible if $\dot{x} = Ax + Bu$ for some $u \in C^s[0, t_0]$, and where

$$R(x) := \int_0^{t_0} \{x^T Cx + u^T Bu\} dt \Big/ \int_0^{t_0} x^T C_0 x dt.$$

Moreover, $\lambda_0 = R(z)$, where

$$\dot{z} = Az + Bv, \quad \dot{v} = (C - \lambda_0 C_0)z - A^T v \quad \text{on } [0, t_0], \quad v(0) = v(t_0) = 0.$$

Proof. Consider the solution $Q(t; \lambda)$ of the initial value problem (10) with $Q_0 = 0$. Then, by Proposition 2, we have that $Q(t; \lambda) = U(t; \lambda)X^{-1}(t; \lambda)$ where $\dot{X} = AX + BU$, $\dot{U} = (C - \lambda C_0)X - A^T U$ and $X(0) = I$, $U(0) = 0$. By Theorem 3 and [3, Thm. 1 with $S_{24} = I$, $S_{13} = 0$], there exists $\lambda_0 > -\infty$ such that the following holds: $Q(t; \lambda)$ exists (i.e., $X(t; \lambda)$ is regular) on $[0, t_0]$ for $\lambda \leq \lambda_0$, $Q(t_0; \lambda)$ is positive definite for $\lambda < \lambda_0$, and $Q(t_0; \lambda_0)$ is singular, i.e., $U(t_0; \lambda_0)c = 0$ for some $c \in \mathbb{R}^n \setminus \{0\}$ (observe that $\lambda_0 < \infty$ is an immediate consequence of inequality (19), below). Now assume that $x(t)$ is admissible, i.e., $\dot{x} = Ax + Bu$ with $u \in C^s[0, t_0]$. Then we obtain from Riccati's equation (10) that

$$(19) \quad \frac{d}{dt} x^T(t) Q(t; \lambda) x(t) = -(u - Qx)^T B(u - Qx) + u^T Bu + x^T (C - \lambda C_0) x$$

for $t \in [0, t_0]$ and $\lambda \leq \lambda_0$ (observe that formula (18) reduces to the so-called "Picone identity" [3, (6.1)] in this special case). Since B is nonnegative definite, $Q(0) = 0$, and, since $Q(t_0; \lambda)$ is positive definite for $\lambda < \lambda_0$, we obtain the inequality

$$(20) \quad \int_0^{t_0} \{x^T Cx + u^T Bu\} dt \geq \lambda \int_0^{t_0} x^T C_0 x dt \quad \text{for } \lambda < \lambda_0.$$

Hence $R(x) \geq \lambda_0$. Moreover, $\lambda_0 = R(z)$, where $z(t) = X(t; \lambda_0)c \neq 0$ satisfies $\dot{z} = Az + Bv$, $\dot{v} = (C - \lambda_0 C_0)z - A^T v$ for $v(t) = U(t; \lambda_0)c$ with $v(0) = v(t_0) = 0$, which completes the proof. \square

Remarks. (i) Observe that controllability and strong observability imply that the differential system $\dot{x} = Ax + Bu$, $\dot{u} = (C - \lambda C_0)x - A^T u$ is *normal* according to [3, (A2)], which is needed for the application of [3, Thm. 1], above. Moreover, if $C_0 = I$, then this notion of normality coincides with "identically normal" in [23, p. 313] and with condition $[C]$ in [8, pp. 36, 37].

(ii) Next, note that $C_0 \geq 0$ and strong observability is equivalent to $\int_0^{t_0} x^T C_0 x dt > 0$ for every admissible and not vanishing $x(t)$ and every $t_0 > 0$. Hence the denominator of the quotient $R(x)$ is never zero when taking the minimum as above.

(iii) A simple but nontrivial application of Theorem 4 (which is not covered by known results, to our knowledge) results from the following example.

Example. Let

$$C_0 = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and let C be any symmetric (4×4) -matrix, e.g., $C = -\alpha I$. Then (A, B) is controllable, and $x(t) = (x_i(t)) \in C_1^s[0, t_0]$ is admissible if and only if $\dot{x}_1 = x_3$ and $\dot{x}_2 = x_4$. Hence, $\int_0^{t_0} x^T C_0 x \, dt = \int_0^{t_0} \{x_2^2 + (x_1 + \dot{x}_2)^2\} \, dt > 0$ for all admissible $x(t) \neq 0$. This implies that (A, B, C_0) is strongly observable. For this example, the full strength of Theorem 2 (in particular, Case 2.1 of its proof) is needed for the proof of Theorem 3, which becomes, in this rather elementary case, by no means trivial (including Theorem 4).

An immediate consequence of Theorem 4 is the following result.

COROLLARY 3. *Under the assumptions of Theorem 3, suppose additionally that $\int_0^t \{x^T C x + u^T B u\} \, d\tau > 0$ for all $t > 0$ and all admissible $x(\tau)$ with $x(\tau) \neq 0$ (and $\dot{x} = Ax + Bu$). Then there exists (a maximal) $\alpha = \alpha(t) > 0$ such that*

$$\int_0^t \{x^T C x + u^T B u\} \, d\tau \geq \alpha \int_0^t x^T C_0 x \, d\tau$$

for all admissible $x(\tau) \in C_1^s[0, t]$.

Remark. Of course, $\alpha(t)$, above, depends on t in general; a rather elementary reasoning either directly with $R(x)$ or considering $\det U(t; \lambda)$ (according to the proof of Theorem 4) shows that $\alpha(t)$ is continuous on $(0, \infty)$. Hence, for $0 < \delta \leq t_0$, there exists $\varepsilon = \varepsilon(\delta, t_0) > 0$ such that $\alpha(t) \geq \varepsilon$ for all $t \in [\delta, t_0]$.

Finally, we prove that strong observability is necessary for the statement of Theorem 3 (and actually also of Theorem 4!).

PROPOSITION 6. *Let there be given (real) $(n \times n)$ -matrices A, B, C, C_0 , and Q_0 such that B, C, C_0 , and Q_0 are symmetric, and such that B is nonnegative definite. Assume that, for any $t_0 > 0$, the solution $Q(t; \lambda)$ of (10) exists on $[0, t_0]$ whenever $\lambda \leq \lambda_0(t_0)$ and satisfies (11). Then C_0 is nonnegative definite, and (A, B, C_0) is strongly observable.*

Proof. Let there be given $t_0 > 0$ and an admissible function $x(t)$ on $[0, t_0]$ with $x(t_0) \neq 0$ such that $\dot{x} = Ax + Bu$ for some $u \in C^s[0, t_0]$. Since B is nonnegative definite and since the solution $Q(t; \lambda)$ of (10) exists on $[0, t_0]$ for $\lambda \leq \lambda_0$, we obtain from (18) the inequality

$$\begin{aligned} (-\lambda) \int_0^{t_0} x^T C_0 x \, dt &\geq -x^T(0) Q_0 x(0) - \int_0^{t_0} \{u^T B u + x^T C x\} \, dt \\ &\quad + x^T(t_0) Q(t_0; \lambda) x(t_0) \quad \text{for all } \lambda \leq \lambda_0. \end{aligned}$$

Now $x^T(t_0) Q(t_0; \lambda) x(t_0) \rightarrow \infty$ as $\lambda \rightarrow -\infty$ by our assumption, and this implies that $\int_0^{t_0} x^T C_0 x \, dt > 0$. Hence C_0 is nonnegative definite, and (A, B, C_0) is strongly observable (compare remark (ii) after Theorem 4). \square

NONLINEAR OPTIMIZATION: ON CONNECTED COMPONENTS OF LEVEL SETS*

HUBERTUS TH. JONGEN† AND JAN RUECKMANN‡

Abstract. This paper is concerned with differentiable constrained optimization problems in finite dimensions. The constraint qualification used is of Mangasarian–Fromovitz type. This paper studies the connected component of the level set of the objective function containing a specific local minimizer, considering that component as a function of the objective level. Special attention is paid to compactness and continuity aspects, also in connection with the occurrence of stationary points. Moreover, a covering of such a compact connected component is presented with differentiable curves tending to the specific local minimizer along which the objective function monotonically decreases.

Key words. level sets, connected components, descent curves, Mangasarian–Fromovitz constraint qualification, stationary points, strongly stable stationary points, MFCQ

AMS(MOS) subject classification. 90C31

1. Introduction. Main results. Let R^n be the n -dimensional Euclidean space, and $C^k(R^n, R)$, $k \geq 0$, the space of real-valued, k -times continuously differentiable functions on R^n . If $f \in C^1(R^n, R)$, then $Df(x)$ represents the derivative (row vector) of f at x . We consider the following optimization problem in standard form:

$$(P) \quad \text{Minimize } f(x) \text{ subject to } M,$$

where the feasible set M is defined as

$$M = \{x \in R^n \mid h_i(x) = 0, i \in I, g_j(x) \leq 0, j \in J\}$$

and $I = \{1, \dots, m\}$, $J = \{1, \dots, s\}$ are two finite index sets with $m < n$. Furthermore, we assume that $f, h_i, g_j \in C^2(R^n, R)$, $i \in I$, and $j \in J$. For $x \in R^n$, we define the set of active inequality constraints

$$J_0(x) = \{j \in J \mid g_j(x) = 0\}.$$

We say that a point $\hat{x} \in M$ is a *stationary point* of (P) if there exist numbers u_i , $i \in I \cup J_0(\hat{x})$ satisfying the following system:

$$(1.1) \quad Df(\hat{x}) + \sum_{i \in I} u_i Dh_i(\hat{x}) + \sum_{j \in J_0(\hat{x})} u_j Dg_j(\hat{x}) = 0, \quad u_j \geq 0, j \in J_0(\hat{x}).$$

By $E(P)$, we denote the set of all stationary points of (P). If \bar{x} is a local minimizer and if, in addition, a certain constraint qualification is fulfilled at \bar{x} , then $\bar{x} \in E(P)$ (cf. [3]). In this study, we need two constraint qualifications, the well-known linear independence constraint qualification (LICQ) and the Mangasarian–Fromovitz constraint qualification (MFCQ) at a point \hat{x} . These are defined below.

* Received by the editors July 25, 1990; accepted for publication (in revised form) August 21, 1991.

† Aachen University of Technology, Department of Mathematics, Templergraben 55, W-5100 Aachen, Germany.

‡ Leipzig University of Technology, Department of Mathematics and Computer Science, P.O. Box 66, O-7030 Leipzig, Germany.

LICQ is said to hold at \hat{x} if the vectors $Dh_i(\hat{x}), i \in I, Dg_j(\hat{x}), j \in J_0(\hat{x})$ are linearly independent.

MFCQ is said to hold at \hat{x} if the following two conditions are satisfied:

- (i) The vectors $Dh_i(\hat{x}), i \in I$, are linearly independent; and
- (ii) There exists a vector $\xi \in R^n$ satisfying

$$Dh_i(\hat{x})\xi = 0, \quad i \in I; \quad Dg_j(\hat{x})\xi < 0, \quad j \in J_0(\hat{x}).$$

It is easily seen that LICQ implies MFCQ at \hat{x} . In recent years, many results belonging to stability or continuity analysis have been proved under the assumption that MFCQ is satisfied at certain points. Recall, for example, that MFCQ is satisfied at $\hat{x} \in E(P)$ if and only if the set of Lagrange multipliers, $u_i, i \in I \cup J_0(\hat{x})$ satisfying (1.1) is bounded [4]. Furthermore, we refer to Kojima's necessary and sufficient conditions for strong stability of stationary points under MFCQ [10]. In [6], [7], [11], one-parametric optimization problems are studied, and, in particular, the local structure of the one-dimensional set of stationary points. There it is shown that the failure of MFCQ gives rise to bifurcation points of the feasible sets under consideration and to boundary points of the set of stationary points. Under MFCQ, the (structural) stability and continuity of the set-valued mapping

$$(h_i, g_j, i \in I, j \in J) \mapsto \{x \in R^n \mid h_i(x) = 0, i \in I, g_j(x) \leq 0, j \in J\}$$

are studied in papers [5], [9]. Finally, we also refer to continuity aspects given in [13].

Many of these results are basic for the theoretical background and the development of concepts and algorithms in nonlinear optimization. In this paper, we study properties of a connected component of the level set of f depending on the level. Special attention is paid to compactness and continuity aspects, also in connection with the occurrence of stationary points. We call a subset $A \subset B$ a *connected component* of B if A is connected and if, for every connected subset C of B with $A \subset C$, it holds that $A = C$. A set A is called *path-connected* if, for any two points $x, y \in A$, there exists a continuous mapping $\omega: t \in [0, 1] \mapsto \omega(t) \in A$ with $\omega(0) = x$ and $\omega(1) = y$. In particular, the set $\{\omega(t) \mid t \in [0, 1]\}$ is called a *path*.

For $a \in R$, we define $M^a = \{x \in M \mid f(x) \leq a\}$, $M_0^a = \{x \in M \mid f(x) < a\}$ and, for $\bar{x} \in M$, $a \geq f(\bar{x})$ ($a > f(\bar{x})$), the set $M(\bar{x}, a)$ ($M_0(\bar{x}, a)$) as the connected component of M^a (M_0^a), which contains \bar{x} . To compute a stationary point of (P), we can use an algorithm that starts with a point x^0 and computes a sequence $\{x^i\}$ whose cluster points belong to $E(P)$. In many cases, this sequence $\{x^i\}_{i=0,1,2,\dots}$ belongs to (a neighbourhood of) exactly one connected component of M (or one path-connected component of M , if using trajectory methods), and the condition $f(x^{i+1}) \leq f(x^i) - \varepsilon^i$ ($\varepsilon^i > 0, \varepsilon^i \rightarrow 0$) is satisfied. Therefore we are interested in (topological) properties of the sets $M(\bar{x}, a)$ depending on a . We investigate properties of $M(\bar{x}, a)$, $a \in [f(\bar{x}), \bar{a}]$, and, throughout the paper, we assume the following two conditions:

- (V1) \bar{x} is an isolated local minimizer of (P) and \bar{a} is fixed with $\bar{a} > f(\bar{x})$; and
- (V2) MFCQ is satisfied at all points $x \in M(\bar{x}, \bar{a})$.

Before stating the first theorem, we return to Kojima's strong stability. In [10] the so-called stationary index (s.i. (\hat{x})) of a strongly stable stationary point \hat{x} , the appropriate generalization of the Morse index [12], is defined if MFCQ is satisfied at \hat{x} . In particular, if MFCQ holds at \hat{x} , but LICQ does not, then s.i. (\hat{x}) = 0.

The close relationship between the change of the topological structure of M^a when passing the level of a strongly stable stationary point \hat{x} , and the stationary index s.i. (\hat{x}) is investigated in [8] and [5, Thm. C]. A consequence of MFCQ and strong stability is the following theorem.

THEOREM 1. *Suppose that every point of $(M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}) \cap E(P)$ is strongly stable. Then $M(\bar{x}, \bar{a})$ is path-connected.*

The next theorem provides the existence of a covering of the set $M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$ with disjoint trajectories contained in $M(\bar{x}, \bar{a})$ and tending to \bar{x} along which f monotonically decreases.

THEOREM 2. *Let $M(\bar{x}, \bar{a})$ be compact and $M(\bar{x}, \bar{a}) \cap E(P) = \{\bar{x}\}$. Then for each $\hat{x} \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$, there exists a continuous function*

$$\Phi_{\hat{x}}: t \in [0, f(\hat{x}) - f(\bar{x})] \mapsto \Phi_{\hat{x}}(t) \in M(\bar{x}, \bar{a})$$

with the following properties:

- (i) $\Phi_{\hat{x}}|_{(0, f(\hat{x}) - f(\bar{x}))}$ is continuously differentiable;
- (ii) $\Phi_{\hat{x}}(0) = \hat{x}$, $\Phi_{\hat{x}}(f(\hat{x}) - f(\bar{x})) = \bar{x}$;
- (iii) $f(\Phi_{\hat{x}}(t)) = f(\hat{x}) - t$;
- (iv) Let $\tilde{x} \in M(\bar{x}, \bar{a})$ with $f(\tilde{x}) \geq f(\hat{x})$. Then either (a) for each $t \in [0, f(\hat{x}) - f(\tilde{x})]$, $\Phi_{\hat{x}}(t) = \Phi_{\tilde{x}}(f(\tilde{x}) - f(\hat{x}) + t)$, or (b) for each $t \in [0, f(\hat{x}) - f(\bar{x})]$, $\Phi_{\hat{x}}(t) \neq \Phi_{\tilde{x}}(f(\tilde{x}) - f(\hat{x}) + t)$.

For our purposes, we introduce the following assumption.

- (V3) The stationary points in $M(\bar{x}, \bar{a})$, other than \bar{x} itself, constitute a finite set, each element of which is strongly stable with stationary index strictly greater than 1 (in the sense of Kojima). If this set is nonempty, we denote it by $\{x^1, \dots, x^p\}$.

For our purposes, we define the cone $N_{\hat{x}}$ at $\hat{x} \in M$ as follows:

$$N_{\hat{x}} = \left\{ \sum_{i \in I} \lambda_i Dh_i(\hat{x}) - \sum_{j \in J_0(\hat{x})} \mu_j Dg_j(\hat{x}) \left| \begin{array}{l} \lambda_i \in \mathbb{R}, i \in I \\ \mu_j \in \mathbb{R}, j \in J_0(\hat{x}) \\ \mu_j \geq 0 \end{array} \right. \right\} \cup \{0\}.$$

Furthermore, let $\|\cdot\|$ denote the Euclidean norm and, for $\varepsilon > 0$, $A \subset \mathbb{R}^n$ and $\hat{x} \in \mathbb{R}^n$, put

$$d(\hat{x}, A) = \inf \{\|\hat{x} - x\| \mid x \in A\},$$

$$B_\varepsilon(\hat{x}) = \{x \in \mathbb{R}^n \mid \|x - \hat{x}\| < \varepsilon\} \quad \text{and}$$

$$B_\varepsilon(A) = \{x \in \mathbb{R}^n \mid d(x, A) < \varepsilon\}.$$

The condition defined below is an appropriate modification of the ("Palais-Smale") condition C^* in [5].

DEFINITION 1. Condition C^+ is fulfilled by the function $g \in C^1(\mathbb{R}^n, \mathbb{R})$ on a set $S \subset \mathbb{R}^n$ if

$$\inf \{d(Dg(x), N_x) \mid x \in S\} > 0.$$

If (V3) is fulfilled, then there exist open bounded neighbourhoods U_0 of \bar{x} and U_i of x^i , $i = 1, \dots, p$ such that

$$U_i \cap U_j = \emptyset, \quad i \neq j, \quad i, j = 0, \dots, p \quad \text{and}$$

$$(1.2) \quad \text{MFCQ is satisfied at all } x \in \bigcup_{i=0}^p U_i.$$

Henceforth, we sometimes use, under (V3), the following additional assumption:

- (V4) The function f fulfils condition C^+ on the set $M(\bar{x}, \bar{a}) \setminus \bigcup_{i=0}^p U_i$ for every choice of open bounded neighbourhoods U_0 of \bar{x} and U_i of x^i , $i = 1, \dots, p$ satisfying (1.2).

THEOREM 3. *Let conditions (V3) and (V4) be fulfilled. Then, for every $a \in [f(\bar{x}), \bar{a}]$,*

$$(1.3) \quad M(\bar{x}, \bar{a}) \cap M^a = M(\bar{x}, a).$$

In the following two theorems, we consider continuity properties of the point-to-set mapping

$$\Gamma: a \in [f(\bar{x}), \bar{a}] \mapsto \Gamma(a) = M(\bar{x}, a).$$

A well-detailed study of continuity aspects related to point-to-set mappings is given in [1]. Using the definitions from [1], the mapping Γ is said to be *continuous at $\hat{a} \in [f(\bar{x}), \bar{a}]$* if Γ is (i) lower semicontinuous in the sense of Berge (lsc-B) at \hat{a} , as well as (ii) upper semicontinuous in the sense of Hausdorff (usc-H) at \hat{a} . Γ is called lsc-B at \hat{a} if, for any open set $\Omega \subset \mathbb{R}^n$ with $\Omega \cap \Gamma(\hat{a}) \neq \emptyset$, there exists a neighbourhood $B_\varepsilon(\hat{a})$ such that $\Omega \cap \Gamma(a) \neq \emptyset$ for each $a \in B_\varepsilon(\hat{a})$. We say that Γ is usc-H at \hat{a} if, for each $\varepsilon > 0$, there exists a $\delta > 0$ such that $\Gamma(a) \subset B_\varepsilon(\Gamma(\hat{a}))$ for every $a \in B_\delta(\hat{a})$.

Before stating the next theorem, we remark that Theorem 4 is true without assuming (V2).

THEOREM 4. (i) *If Γ is lsc-B at \bar{a} , then*

$$(1.4) \quad \text{cl } M_0(\bar{x}, \bar{a}) = M(\bar{x}, \bar{a})$$

(where cl denotes the closure);

(ii) *Let $M_0(\bar{x}, \bar{a})$ be path-connected and let (1.4) be satisfied. Then Γ is lsc-B at \bar{a} ;*

(iii) *If $M(\bar{x}, \bar{a})$ is compact, then Γ is usc-H at \bar{a} .*

From the latter theorem, we obtain the following results for our special situation.

THEOREM 5. *Assume conditions (V3) and (V4). Then*

(i) $\text{cl } M_0(\bar{x}, a) = M(\bar{x}, a)$ for all $a \in (f(\bar{x}), \bar{a}]$;

(ii) $M(\bar{x}, a)$ is compact for all $a \in [f(\bar{x}), \bar{a}]$;

(iii) Γ is continuous at a for all $a \in [f(\bar{x}), \bar{a}]$.

In § 2 we present some basic lemmas used later. Then § 3 contains the proof of the Theorems 1–5 given above, as well as some additional remarks.

2. Lemmas, preliminary results. In [5, Thm. A] it is shown that M is a topological manifold with the boundary $\delta M = \{x \in \mathbb{R}^n \mid h_i(x) = 0, i \in I, \max_{j \in J} g_j(x) = 0\}$ if MFCQ is satisfied at all points of M . As a local consequence, we formulate the following lemma.

Lemma 1. *Let MFCQ be satisfied at a point $\tilde{x} \in M$. Then*

(a) *There exist open neighbourhoods $U(\tilde{x})$ of \tilde{x} and \tilde{U} of the origin in \mathbb{R}^{n-m} such that $U(\tilde{x}) \cap M$ is connected and homeomorphic to \tilde{U} if $J_0(\tilde{x}) = \emptyset$, and otherwise homeomorphic to $\tilde{U} \cap \mathbb{R}^{n-m-1} \times \mathbb{R}_+$, where $\mathbb{R}_+ = \{y \in \mathbb{R} \mid y \geq 0\}$;*

(b) *Let $U(\tilde{x})$ be chosen as in (a). Then $U(\tilde{x}) \cap M$ is path-connected.*

Proof. If $J_0(\tilde{x}) = \emptyset$, then MFCQ (i) implies that, locally around \tilde{x} , the set M is a C^2 -manifold and therefore homeomorphic to a (path-connected) neighbourhood \tilde{U} of the origin in \mathbb{R}^{n-m} . If $J_0(\tilde{x}) \neq \emptyset$, the desired homeomorphism is constructed in the proof of [5, Thm. A]. \square

Corollary 1. *Let A be a connected component of M , and let MFCQ be satisfied at all points of A . Then A is path-connected.*

Proof. The proof is immediate from the fact that A is connected and locally path-connected.

In the following lemma, let $\eta: \mathcal{O} \rightarrow \mathbb{R}^n$ be a vector field defined on the open subset $\mathcal{O} \subset \mathbb{R}^n$. The lemma is a well-known result from the theory of ordinary differential equations.

LEMMA 2. (a) If η is locally Lipschitzian, respectively, belongs to the class C^k ($k \geq 1$), then, for each $\tilde{x} \in \mathcal{O}$, there exist an open neighbourhood $U(\tilde{x})$ of \tilde{x} , a number $\varepsilon(\tilde{x}) > 0$, and a unique mapping $\Phi \in C^k(U(\tilde{x}) \times (-\varepsilon(\tilde{x}), \varepsilon(\tilde{x})), \mathcal{O})$ ($k = 0$, respectively, $k \geq 1$) such that

$$\frac{\partial \Phi}{\partial t}(x, t) = \eta(\Phi(x, t)), \quad \eta(x, 0) = x, \quad \text{and}$$

$$\Phi_{t_1+t_2}(x) = \Phi_{t_1} \circ \Phi_{t_2}(x)$$

for all $x \in U(\tilde{x})$, $\{t_1, t_2\} \subset (-\varepsilon(\tilde{x}), \varepsilon(\tilde{x}))$ satisfying $|t_1 + t_2| < \varepsilon(\tilde{x})$, where we put $\Phi_t(\cdot) = \Phi(\cdot, t)$.

(b) If $\mathcal{O} = R^n$, η locally Lipschitzian (or C^k ($k \geq 1$)), and bounded, then Φ is defined on $R^n \times R$; i.e., η is completely integrable, and $\Phi(\cdot, t)$ is a homeomorphism (or C^k -diffeomorphism) for each $t \in R$.

In the following lemma, we need condition C^+ introduced in § 1.

Lemma 3. Let \hat{M} be a closed subset of M and let MFCQ be satisfied at all points of \hat{M} . Suppose that f fulfils condition C^+ on \hat{M} . Then there exists a bounded vector field $\eta \in C^1(R^n, R^n)$ with the following properties:

(i) For all $x \in M$,

$$Df(x)\eta(x) \leq 0,$$

$$Dh_i(x)\eta(x) = 0, \quad i \in I,$$

$$Dg_j(x)\eta(x) \leq 0, \quad j \in J_0(x);$$

(ii) For all $x \in \hat{M}$,

$$Df(x)\eta(x) \leq -1;$$

(iii) The flow Φ of the vector field η satisfies the relation

$$\Phi(\cdot, t)[M(\bar{x}, a)] \subset M(\bar{x}, a)$$

for all $a \geq f(\bar{x})$ and all $t \geq 0$.

Proof. Lemma 3 can be proved in the same way as [5, Thm. C], substituting \hat{M} for the set M_a^b in the latter reference. In particular, condition C^+ yields the boundedness of the vector field η .

In the next lemma, let X be a topological Hausdorff space and denote by $H_q(X)$, $q = 0, 1, 2, \dots$ the q th singular homology space over the reals with respect to X . Roughly speaking, the dimension of $H_q(X)$ represents the number of “ $(q + 1)$ -dimensional holes” in X (see [8, Chap. 5]). The next lemma is well known (cf. [15]).

LEMMA 4. (a) The cardinality of path-connected components of X is equal to $\dim H_0(X)$ (where \dim denotes the dimension);

(b) Let X and Y be homotopy-equivalent Hausdorff spaces. Then, for all $q = 0, 1, 2, \dots$, $H_q(X) \cong H_q(Y)$.

3. Proofs of the theorems and remarks.

Proof of Theorem 1. The proof is given in two steps.

Step 1. First, we show that every nonempty connected component Z of $M(\bar{x}, \bar{a}) \setminus \{x \in E(P) | f(x) = \bar{a}\}$ is path-connected. Let $\tilde{x} \in Z$ and

$$A^0 = \{x \in Z | \text{there exists a path in } Z \text{ connecting } x \text{ and } \tilde{x}\}.$$

We know $\tilde{x} \in A^0$, and we prove that A^0 is open and closed in Z . Suppose that $\hat{x} \in A^0$.

Since $\hat{x} \notin \{x \in E(P) | f(x) = \bar{a}\}$, MFCQ is fulfilled at \hat{x} with respect to the set

$$M^{\bar{a}} = \left\{ x \in R^n \left| \begin{array}{l} h_i(x) = 0, i \in I \\ g_j(x) \leq 0, j \in J \\ f(x) \leq \bar{a} \end{array} \right. \right\}.$$

Now Lemma 1 implies the existence of an open neighbourhood $U(\hat{x})$ of \hat{x} such that $U(\hat{x}) \cap \{x \in E(P) | f(x) = \bar{a}\} = \emptyset$ and $U(\hat{x}) \cap M^{\bar{a}}$ is path-connected. The latter two facts imply that $U(\hat{x}) \cap M^{\bar{a}} \subset Z$ and $U(\hat{x}) \cap M^{\bar{a}} = U(\hat{x}) \cap Z$, as well as $U(\hat{x}) \cap Z \subset A^0$. Now let $\bar{x}^i \in A^0$, $\bar{x}^i \rightarrow x'$ and $x' \in Z$. From Lemma 1 and the fact that $x' \notin \{x \in E(P) | f(x) = \bar{a}\}$, we see that $\bar{x}^{i_0} \in U(x')$ for an appropriate index i_0 , and, consequently, there exists a path in Z connecting x' and \bar{x}^{i_0} .

Step 2. Now let $\tilde{x} \in M(\bar{x}, \bar{a}) \cap E(P)$ and $f(\tilde{x}) = \bar{a}$. From (V1), we know that $f(\bar{x}) < \bar{a}$, and hence $\tilde{x} \neq \bar{x}$. If the stationary index of \tilde{x} vanishes, then \tilde{x} is a strict local minimizer. It follows that there exists a neighbourhood U of \tilde{x} such that $M^{\bar{a}} \cap U = \{\tilde{x}\}$. Consequently, the connectedness of $M(\bar{x}, \bar{a})$ implies that $\tilde{x} \notin M(\bar{x}, \bar{a})$. So the stationary index of \tilde{x} must be greater than zero, and hence LICQ is satisfied at \tilde{x} (cf. [10, Thm. 7.2]). Consequently, there exists a vector $v \in R^n$ satisfying

$$Dh_i(\tilde{x})v = 0, \quad i \in I, \quad Dg_j(\tilde{x})v = 0, \quad j \in J_0(\tilde{x}), \quad v^T D^2 L(\tilde{x})v < 0.$$

Here $L = f + \sum_{i \in I} u_i h_i + \sum_{j \in J_0(\tilde{x})} u_j g_j$ is the corresponding Lagrange function (with unique numbers u_i, u_j such that (1.1) at \tilde{x} is satisfied). Furthermore, choose vectors $\xi_l \in R^n, l = 1, \dots, n - |I| - |J_0(\tilde{x})|$ such that $Dh_i(\tilde{x})^T, i \in I, Dg_j(\tilde{x})^T, j \in J_0(\tilde{x}), \xi_l, l = 1, \dots, n - |I| - |J_0(\tilde{x})|$ form a basis of R^n . So we can construct the local C^2 -coordinate transformation

$$\Omega(x) = \begin{pmatrix} h_i(x), i \in I \\ g_j(x), j \in J_0(\tilde{x}) \\ \xi_l^T(x - \tilde{x}), l = 1, \dots, n - |I| - |J_0(\tilde{x})| \end{pmatrix}$$

and the C^1 -vector field $v(x) = D\Omega^{-1}(\Omega(x))D\Omega(\tilde{x})v$, defined on an appropriate neighbourhood of \tilde{x} . It is easily seen that there exists a neighbourhood $\tilde{U}(0)$ of 0 such that the relations

$$\Phi(\tilde{x}, t) \in M \setminus E(P) \quad \text{and} \quad f(\Phi(\tilde{x}, t)) < \bar{a}$$

hold for all $t \in \tilde{U}(0) \setminus \{0\}$, where $\Phi(\tilde{x}, t)$ denotes the trajectory through \tilde{x} corresponding to the vector field $v(x)$.

Now Theorem Cb. in [5] implies that locally around \tilde{x} the set $M(\bar{x}, \bar{a}) \setminus \{\tilde{x}\}$ is connected if s.i. $(\tilde{x}) \geq 1$. In this case, the path $\{\Phi(\tilde{x}, t) | t \geq 0, t \in \tilde{U}(0)\}$ connects the points $\Phi(\tilde{x}, 0) = \tilde{x}$ and $\Phi(\tilde{x}, t) \in M(\bar{x}, \bar{a}) \setminus E(P), t > 0, t \in \tilde{U}(0)$. If s.i. $(\tilde{x}) = 1$, then, locally around \tilde{x} , the set $M(\bar{x}, \bar{a}) \setminus \{\tilde{x}\}$ consists of two connected components; a moment of reflection shows that the sets

$$\{\Phi(\tilde{x}, t) | t > 0, t \in \tilde{U}(0)\} \quad \text{and} \quad \{\Phi(\tilde{x}, t) | t < 0, t \in \tilde{U}(0)\}$$

do not belong to the same connected component.

The results given in Steps 1 and 2 imply that the set

$$\{x \in M(\bar{x}, \bar{a}) | \text{there exists a path in } M(\bar{x}, \bar{a}) \text{ connecting } \bar{x} \text{ and } x\}$$

is nonempty, open, and closed in $M(\bar{x}, \bar{a})$. Thus we are done. \square

Proof of Theorem 2. Let $\hat{x} \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$ be arbitrarily chosen and fixed. As a consequence of $\hat{x} \notin E(P)$, condition (V2), and the well-known Farkas lemma, we see

that the set

$$(3.1) \quad A(\hat{x}) = \left\{ v \in R^n \mid \begin{array}{l} Df(\hat{x})v < 0, Dh_i(\hat{x})v = 0, i \in I \\ Dg_j(\hat{x})v < 0, j \in J_0(\hat{x}) \end{array} \right\}$$

is nonempty. Now choose $\xi_l \in R^n, l = m+1, \dots, n$ in such a way that the vectors $Dh_i(\hat{x}), i \in I, \xi_l, l = m+1, \dots, n$ form a basis of R^n . Put $y = \Omega_{\hat{x}}(x)$, where $y_i = h_i(x), i \in I$ and $y_l = \xi_l(x - \hat{x}), l = m+1, \dots, n$. Obviously, or $v(\hat{x}) \in A(\hat{x})$, there exists an open neighbourhood $\mathcal{O}(\hat{x})$ of \hat{x} such that, for any $x \in \mathcal{O}(\hat{x})$, the Jacobian $D\Omega_{\hat{x}}(x)$ is regular and $J_0(x) \subset J_0(\hat{x})$, as well as $\hat{v}(x) \in A(x)$, where $\hat{v}(x) = D\Omega_{\hat{x}}^{-1}(\Omega_{\hat{x}}(x))D\Omega_{\hat{x}}(\hat{x})v(\hat{x})$ and $A(x)$ as in (3.1). Now we can define the open covering

$$\mathcal{O} = \bigcup_{\bar{x} \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}} \mathcal{O}(\hat{x})$$

of the set $M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$ with $\bar{x} \notin \mathcal{O}$.

By means of a C^1 -partition of unity subordinate to the covering $\{\mathcal{O}(\hat{x}), \hat{x} \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}\}$, selecting on each $\mathcal{O}(\hat{x})$ the vector field $\hat{v}(x)$, we get a C^1 -vector field $\tilde{F}(x)$ on \mathcal{O} satisfying $\tilde{F}(x) \in A(x)$ for every $x \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$. In particular, $Df(x)\tilde{F}(x) \neq 0, x \in \mathcal{O}$ and, therefore, we can define the C^1 -vector field

$$F(x) = \frac{\tilde{F}(x)}{\|Df(x)\tilde{F}(x)\|}$$

on \mathcal{O} satisfying $F(x) \in A(x)$ and $Df(x)F(x) = -1$ for every $x \in M(\bar{x}, \bar{a}) \setminus \{\bar{x}\}$. In virtue of Lemma 2, there exist an $\varepsilon(\hat{x}) > 0$ and an open neighbourhood $V(\hat{x}) \times (-\varepsilon(\hat{x}), \varepsilon(\hat{x}))$ of $(\hat{x}, 0)$, as well as a unique flow $\Phi(x, t) \in C^1$ of $F(x)$ on $V(\hat{x}) \times (-\varepsilon(\hat{x}), \varepsilon(\hat{x}))$ with $\Phi(x, 0) = x$ for $x \in V(\hat{x})$. Obviously, we have that

$$(3.2) \quad f(\Phi(x, t_1)) - f(\Phi(x, t_2)) = t_2 - t_1$$

for any $\{t_1, t_2\} \subset (-\varepsilon(\hat{x}), \varepsilon(\hat{x}))$ with $|t_1 + t_2| < \varepsilon(\bar{x})$ and $x \in V(\hat{x})$.

PROPOSITION. $\Phi(\hat{x}, \cdot)$ is defined for all $t \in [0, f(\hat{x}) - a]$ and every $a \in (f(\bar{x}), f(\hat{x}))$.

We proceed with the proof, assuming that the above proposition has already been proved. By $\{\Phi(\hat{x}, t) \mid t \in [0, f(\hat{x}) - f(\bar{x})]\} \subset M(\bar{x}, \bar{a})$ and the compactness of $M(\bar{x}, \bar{a})$, it follows that the set

$$\Phi(\hat{x}, f(\hat{x}) - f(\bar{x})) := \left\{ x \in M(\bar{x}, \bar{a}) \mid \begin{array}{l} \text{there exists a sequence } \{t^i\} \subset [0, f(\hat{x}) - f(\bar{x})] \\ \text{satisfying } \lim_{t^i \rightarrow f(\hat{x}) - f(\bar{x})} \Phi(\hat{x}, t^i) = x \end{array} \right\}$$

is nonempty and that it is $f(x) = f(\bar{x})$ for every $x \in [\Phi(\hat{x}, f(\hat{x}) - f(\bar{x}))]$. In view of $M(\bar{x}, \bar{a}) \cap M^{f(\bar{x})} = \{\bar{x}\}$, we obtain $\lim_{t \rightarrow f(\hat{x}) - f(\bar{x})} \Phi(\hat{x}, t) = \bar{x}$.

Finally, we must prove the above proposition.

Proof. Let $a \in (f(\bar{x}), f(\hat{x}))$ be arbitrarily chosen and fixed. Since the set $M(\bar{x}, a, \bar{a}) := \{x \in M(\bar{x}, \bar{a}) \mid f(x) \geq a\}$ is compact, there exists a finite covering $\{\tilde{V}(\bar{x}^i) \mid \bar{x}^i \in M(\bar{x}, a, \bar{a}), i \in \tilde{I}\}$ of $M(\bar{x}, a, \bar{a})$, where \tilde{I} is a finite index set and $\tilde{V}(\bar{x}^i)$ (as above) are open neighbourhoods of $\bar{x}^i, i \in \tilde{I}$. Put $\varepsilon = \min \{\varepsilon(\bar{x}^i) \mid i \in \tilde{I}\}$. Since $\Phi(x, t)$ is uniquely determined and well defined on $M(\bar{x}, a, \bar{a}) \times (-\varepsilon, \varepsilon)$, it can be uniquely extended at every reached point from $M(\bar{x}, a, \bar{a})$.

By (3.2) we obtain that

$$f(\Phi(\hat{x}, t)) = f(\hat{x}) - t, \quad t \in [0, f(x) - a],$$

and we achieve the desired result. \square

Remark 1. If we delete the compactness of $M(\bar{x}, \bar{a})$ in Theorem 2 without any substitute, then the trajectory $\Phi(\hat{x}, t), t \geq 0$, constructed in the proof of Theorem 2, need not tend to \bar{x} , and it might happen that $\lim_{t \rightarrow \bar{t}} \|\Phi(\hat{x}, t)\| = \infty$ for some \bar{t} .

In Fig. 1, such a situation is sketched for the case where $|I| = |J| = \emptyset$. Here the function f is represented by means of some level lines, and the dotted, boundary line is identified with the "point at infinity."

Remark 2. In the following, we occasionally use the expression: "We add locally at x^i a constant ε to the function f " ($i \in \{1, \dots, p\}$ and fixed). By this expression, we mean that we add to f a function $\varepsilon \cdot \xi \in C^2(R^n, R)$ having the following properties:

- (i) $0 \leq \xi(x) \leq 1$,
- (ii) $\xi(x) = 1$ in a neighbourhood of x^i ,
- (iii) There exists an open bounded neighbourhood \bar{U}^i of x^i with support $(\xi) \subset \bar{U}^i \cap U^i$, where U^i is defined as in (1.2), and x^i is the only stationary point of the resulting perturbed problem in \bar{U}^i and is strongly stable with stationary index s.i. (x^i) .

Proof of Theorem 3. Obviously, $M(\bar{x}, \bar{a}) \cap M^a = M(\bar{x}, \bar{a})$. Now suppose there exists an $a \in (f(\bar{x}), \bar{a})$ such that (1.3) is not satisfied. We add locally at every $x^i, i = 1, \dots, p$ with $f(x^i) = \bar{a}$ a constant $-\varepsilon_1 < 0$ and at every $x^i, i = 1, \dots, p$ with $f(x^i) = a$ a constant $\varepsilon_2 > 0$ to f . We denote this perturbed function by \tilde{f} . Furthermore, put $\tilde{M}^a = \{x \in M \mid \tilde{f}(x) \leq a\}$, and $\tilde{M}(\bar{x}, a)$ is the connected component of \tilde{M}^a containing \bar{x} .

It is easily seen that we can choose the perturbation functions and the constants ε_1 and ε_2 in such a way that the following properties are fulfilled:

- (a) $a + \varepsilon_2 < \bar{a} - \varepsilon_1$,
- (b) $\tilde{M}(\bar{x}, a) \subset M(\bar{x}, a)$, $M(\bar{x}, \bar{a}) \subset \tilde{M}(\bar{x}, \bar{a})$,
- (c) There exists a point $\hat{x} \in \{M(\bar{x}, \bar{a}) \cap M^a\} \setminus M(\bar{x}, a)$ with $\hat{x} \in \tilde{M}^a$,
- (d) $\tilde{M}(\bar{x}, \bar{a}) \subset M(\bar{x}, \bar{a}) \cup \bigcup_j \bar{U}^j$, where \bar{U}^j is defined as in Remark 2 and j varies in the set $\{j \in \{1, \dots, p\} \mid f(x^j) = \bar{a}\}$. By (V3) and $\tilde{f}(x^i) < \bar{a}, i = 1, \dots, p$, it follows that MFCQ is satisfied at all $x \in \tilde{M}(\bar{x}, \bar{a})$ with respect to the constraints $h_i(x) = 0, i \in I, g_j(x) \leq 0, j \in J$, and $\tilde{f}(x) \leq \bar{a}$.

Properties (a)–(c) imply that $\hat{x} \in (\tilde{M}(\bar{x}, \bar{a}) \cap \tilde{M}^a) \setminus \tilde{M}(\bar{x}, a)$, and hence

$$(3.3) \quad \tilde{M}(\bar{x}, \bar{a}) \cap \tilde{M}^a \neq \tilde{M}(\bar{x}, a).$$

By property (d) and Lemma 1, we see that $\tilde{M}(\bar{x}, \bar{a})$ is a topological manifold, and, consequently, there exists an open neighbourhood V of $\tilde{M}(\bar{x}, \bar{a})$ satisfying $V \cap \tilde{M}^a = \tilde{M}(\bar{x}, \bar{a})$. Then $\{V, R^n \setminus \tilde{M}(\bar{x}, \bar{a})\}$ is an open covering of R^n . Let $\Phi_i \in C^1(R^n, R), i = 1, 2$ be a partition of unity subordinate to this covering. In particular, we have that

$$\Phi_1|_{\tilde{M}(\bar{x}, \bar{a})} \equiv 1 \quad \text{and} \quad \Phi_2|_{R^n \setminus V} \equiv 1.$$

FIG. 1

Now we consider the following optimization problem. Minimize $\tilde{f}(x)$ subject to \hat{M} , where

$$\hat{M} = \left\{ x \in R^n \left| \begin{array}{l} h_i(x) = 0, i \in I \\ \Phi_1(x)g_j(x) + \Phi_2(x) \leq 0, j \in J \end{array} \right. \right\}.$$

Put $\hat{M}^a = \{x \in \hat{M} \mid \tilde{f}(x) \leq a\}$. Obviously, we have that

$$(3.4) \quad \hat{M}^{\bar{a}} = \tilde{M}(\bar{x}, \bar{a}), \quad \hat{M}^a = \tilde{M}(\bar{x}, \bar{a}) \cap \tilde{M}^a,$$

and the stationary points of this problem are \bar{x}, x^1, \dots, x^p . Also, x^i is strongly stable with the stationary index s.i. (x^i) , $i = 1, \dots, p$. Furthermore, by (d), MFCQ is satisfied at all $x \in \hat{M}^{\bar{a}}$, and (V4) is also satisfied (if we substitute f by \tilde{f} and $M(\bar{x}, \bar{a})$ by $\tilde{M}(\bar{x}, \bar{a})$). These facts remain true if we perturb \tilde{f} in such a way that $\tilde{f}(x^i) \neq \tilde{f}(x^j)$ for $i \neq j$, $i, j = 1, \dots, p$, and if \hat{M}^a and $\hat{M}^{\bar{a}}$ are not changed. Then, by Theorem Cb in [5] and Theorem 5.2.1 in [8], it is $\dim H_0(\hat{M}^a) = \dim H_0(\hat{M}^{\bar{a}}) (=1)$, and so, in view of Lemma 4(a), \hat{M}^a and $\hat{M}^{\bar{a}}$ have the same number of path-connected components. This, however, is in contradiction with (3.3), (3.4), and the definition of $\tilde{M}(\bar{x}, a)$. The validity of (1.3) at $a = f(\bar{x})$ is obvious, since we can essentially use a similar argument. \square

Remark 3. In the following two examples, $|I| = |J| = \emptyset$, and f is sketched by means of some level lines. These examples illustrate that (1.3) is, generally, not fulfilled if one of the conditions (V3), (V4) is violated. In Fig. 2, the connected set $M(\bar{x}, \bar{a})$ contains a stationary point with *stationary index* 1, and $M(\bar{x}, \bar{a}) \cap M^a$ consists of two connected components for $a < \bar{a}$ with a sufficiently near \bar{a} .

In Fig. 3, condition (V4) is not fulfilled, and, as in Fig. 1, the dotted boundary line is identified with the "point at infinity."

Proof of Theorem 4. Throughout this proof, the index i always varies in the whole set of natural numbers: $i = 1, 2, 3, \dots$

FIG. 2

FIG. 3

(i) Obviously, we have that $\text{cl } M_0(\bar{x}, \bar{a}) \subset M(\bar{x}, \bar{a})$, and, therefore, we suppose that there exists an \hat{x} satisfying

$$\hat{x} \in M(\bar{x}, \bar{a}) \setminus \text{cl } M_0(\bar{x}, \bar{a}).$$

Let $\{\varepsilon^i\}$ be a sequence with $\varepsilon^i \rightarrow 0$, $\varepsilon^i > 0$. Since $M(\bar{x}, \bar{a}) \cap B_{\varepsilon^i}(\hat{x}) \neq \emptyset$ and Γ is lsc-B at \bar{a} , there exists numbers $\delta^i > 0$ such that $M(\bar{x}, \bar{a}) \cap B_{\varepsilon^i}(x) \neq \emptyset$ for all $a \in B_{\delta^i}(\bar{a})$. Thus we have sequences $\{\bar{x}^i\}, \{a^i\}$ with $a^i < \bar{a}$, $\bar{x}^i \in M(\bar{x}, a^i) \cap B_{\varepsilon^i}(\hat{x})$, and, consequently, $\bar{x}^i \in M_0(\bar{x}, \bar{a})$ (since $M(\bar{x}, a^i)$ is connected, $\bar{x} \in M(\bar{x}, a^i)$, $M(\bar{x}, a^i) \subset M_0^{\bar{a}}$), $\bar{x}^i \rightarrow \hat{x}$, and $\hat{x} \in \text{cl } M_0(\bar{x}, \bar{a})$, a contradiction.

(ii) Suppose that there exists an open set \mathcal{O} with $M(\bar{x}, \bar{a}) \cap \mathcal{O} \neq \emptyset$ and a sequence $\{a^i\}$ such that $a^i \rightarrow \bar{a}$ and $M(\bar{x}, a^i) \cap \mathcal{O} = \emptyset$. Since $M(\bar{x}, a_1) \subset M(\bar{x}, a_2)$ whenever $a_1 \leq a_2$, it follows that $a^i < \bar{a}$ and

$$(3.5) \quad M(\bar{x}, a) \cap \mathcal{O} = \emptyset \quad \text{for all } a < \bar{a}.$$

By (3.5) and assumption (1.4), there is an $\hat{x} \in M_0(\bar{x}, \bar{a}) \cap \mathcal{O}$ with $f(\hat{x}) = \hat{a} \geq f(\bar{x})$ and $\hat{x} \notin M(\bar{x}, \hat{a})$. Now let $\tilde{x} \in M(\bar{x}, \hat{a})$ (note that $M(\bar{x}, \hat{a}) \neq \emptyset$ since $\bar{x} \in M(\bar{x}, \hat{a})$), and hence $\tilde{x} \in M_0(\bar{x}, \bar{a})$. In view of the path-connectedness of $M_0(\bar{x}, \bar{a})$, there exists a path \mathcal{C} in $M_0(\bar{x}, \bar{a})$ connecting \tilde{x} and \hat{x} , and therefore $\hat{a} \leq \max \{f(x) \mid x \in \mathcal{C}\} < \bar{a}$ and $\hat{x} \in M(\bar{x}, \max \{f(x) \mid x \in \mathcal{C}\}) \cap \mathcal{O}$, which contradicts (3.5).

(iii) Suppose that there exist a positive number $\bar{\varepsilon}$ and sequences $\{a^i\}, \{\bar{x}^i\}$ such that $a^i > \bar{a}$, $a^i \rightarrow \bar{a}$, $\bar{x}^i \in M(\bar{x}, a^i)$ and $\bar{x}^i \notin B_{\bar{\varepsilon}}(M(\bar{x}, \bar{a}))$. Furthermore, let $\varepsilon^i > 0$ and $\varepsilon^i \rightarrow 0$. Since $B_{\varepsilon^i}(M(\bar{x}, a^i))$ is open and connected and, therefore, path-connected, we have, for every i , a path \mathcal{C}^i in $B_{\varepsilon^i}(M(\bar{x}, a^i))$ connecting \bar{x}^i and \bar{x} . By $\tilde{\mathcal{C}}^i$ we denote the connected component of $\mathcal{C}^i \cap \text{cl } B_{\bar{\varepsilon}}(M(\bar{x}, \bar{a}))$, which contains \bar{x} . As a consequence of $\bar{x}^i \notin B_{\bar{\varepsilon}}(M(\bar{x}, \bar{a}))$, there is an $\hat{x}^i \in \tilde{\mathcal{C}}^i$ such that $d(\hat{x}^i, M(\bar{x}, \bar{a})) = \bar{\varepsilon}$, and the compactness of $M(\bar{x}, \bar{a})$ implies the existence of a cluster point \hat{x} of $\{\hat{x}^i\}$. We show that the set

$$A = \{y \mid \text{there exists a subsequence } \{y^{\nu_i}\}_{\{\nu_i\} \subset \{i\}} \text{ with } y^{\nu_i} \in \tilde{\mathcal{C}}^{\nu_i} \text{ and } y^{\nu_i} \rightarrow y\}$$

is connected. Then, by $\tilde{\mathcal{C}}^i \subset B_{\varepsilon^i}(M(\bar{x}, a^i))$ and $\bar{x} \in A$, we obtain that $d(y^{\nu_i}, M(\bar{x}, a^{\nu_i})) \rightarrow 0$, $f(y) \leq \bar{a}$ for $y \in A$, and, consequently, $A \subset M(\bar{x}, \bar{a})$. This, however, cannot be true in view of $\hat{x} \in A$ and $d(\hat{x}, M(\bar{x}, \bar{a})) = \bar{\varepsilon}$. If A were not connected, then there would exist open sets $\mathcal{O}_1, \mathcal{O}_2$ satisfying $\mathcal{O}_1 \cap \mathcal{O}_2 = \emptyset$, $\mathcal{O}_1 \cap A \neq \emptyset$, $\mathcal{O}_2 \cap A \neq \emptyset$ and $A \subset \mathcal{O}_1 \cup \mathcal{O}_2$. Now let $\bar{x} \in \mathcal{O}_1$ and $\tilde{x} \in A \cap \mathcal{O}_2$. Then there exists a sequence $\{\tilde{x}^{\nu_i}\}$ such that $\tilde{x}^{\nu_i} \rightarrow \tilde{x}$ and $\tilde{x}^{\nu_i} \in \tilde{\mathcal{C}}^{\nu_i} \cap \mathcal{O}_2$. By $\bar{x} \in \tilde{\mathcal{C}}^{\nu_i} \cap \mathcal{O}_1$ and since $\tilde{\mathcal{C}}^{\nu_i}$ is connected, it follows that $\tilde{\mathcal{C}}^{\nu_i} \not\subset \mathcal{O}_1 \cup \mathcal{O}_2$, and thus there is an $\hat{x}^{\nu_i} \in \tilde{\mathcal{C}}^{\nu_i} \setminus (\mathcal{O}_1 \cup \mathcal{O}_2)$. The compactness of $M(\bar{x}, \bar{a})$ implies that A contains a cluster point \hat{x} of $\{\hat{x}^{\nu_i}\}$ satisfying $\hat{x} \in A \setminus (\mathcal{O}_1 \cup \mathcal{O}_2)$, which contradicts $A \subset \mathcal{O}_1 \cup \mathcal{O}_2$. This completes the proof. \square

Remark 4. The proof of Theorem 4(ii) shows that the condition that $M_0(\bar{x}, \bar{a})$ is path-connected can be weakened. It is sufficient to assume that, for any point $\hat{x} \in M_0(\bar{x}, \bar{a}) \setminus \text{cl } \bigcup_{a < \bar{a}} M(\bar{x}, a)$, there exists a point $\tilde{x} \in \bigcup_{a < \bar{a}} M(\bar{x}, a)$ and a path in $M_0(\bar{x}, \bar{a})$ connecting \hat{x} and \tilde{x} .

The following example, however, illustrates that the path-connectedness of $M_0(\bar{x}, \bar{a})$ cannot be deleted without any substitute. In Fig. 4(a), f is sketched by means of some level lines, where \bar{a} is the maximum of f and the line $[x^1, x^2]$ connecting x^1 and x^2 is just $\{x \mid f(x) = \bar{a}\}$. Outside of the "boundary level lines," let f be constant with $f \equiv f(\tilde{x})$. The feasible set M is described by the inequalities $0 \leq x_1 \leq x_1^0, x_2^0 \leq x_2 \leq$

FIG. 4

x_2^1 , and $g(x) \leq 0$, where

$$\begin{aligned} \{x \mid g(x) \leq 0\} &= \{x \in \mathbb{R}^2 \mid x_2 \geq 0\} \cup \bigcup_{n \in \mathbb{N}} \left\{ \left(x_1, -\frac{1}{n} \right) \mid x_1 \in \mathbb{R} \right\} \\ &\quad \cup \bigcup_{k \in \mathbb{N}} \{x^1\} \times \left[-\frac{1}{2k-1}, -\frac{1}{2k} \right] \\ &\quad \cup \bigcup_{k \in \mathbb{N}} \{x^2\} \times \left[-\frac{1}{2k}, -\frac{1}{2k+1} \right] \end{aligned}$$

(cf. Fig. 4(b)). The existence of such a smooth function g follows from the fact that every nonempty closed subset A of \mathbb{R}^n can be represented as the zero set of a nonnegative function $h_A \in C^\infty(\mathbb{R}^n, \mathbb{R})$ (cf. [2]). (Recall that Theorem 4 is true without assuming (V2).)

The sets $M(\bar{x}, \bar{a})$ ($=M$) and $M_0(\bar{x}, \bar{a}) = M(\bar{x}, \bar{a}) \setminus [x^1, x^2]$ are connected, but *not path-connected*. For $a < \bar{a}$, the set $M(\bar{x}, a)$ contains only points with nonnegative x_2 -components and so we have that $\text{cl } M_0(\bar{x}, \bar{a}) = M(\bar{x}, \bar{a})$, but Γ is not lsc-B at \bar{a} .

Remark 5. In Theorem 4(iii), we proved that Γ is usc-H at \bar{a} if $M(\bar{x}, \bar{a})$ is compact. For the function f sketched in Fig. 3, it holds that

$$\text{cl } M_0(\bar{x}, \bar{a}) = M(\bar{x}, \bar{a}).$$

We see that $M(\bar{x}, \bar{a})$ is not compact and that Γ is not usc-H at \bar{a} .

Proof of Theorem 5. (i) Let $a \in (f(\bar{x}), \bar{a}]$ be arbitrarily chosen and fixed. We show the inclusion $M(\bar{x}, a) \subset \text{cl } M_0(\bar{x}, a)$, since $\text{cl } M_0(\bar{x}, a) \supset M(\bar{x}, a)$ is obvious. Let $x \in M(\bar{x}, a)$, and we distinguish two cases. If $x \notin E(P)$, then (V2) and Lemma 1 imply the existence of a sequence $\{\bar{x}^i\}$ (the index i is always varying in the whole set of natural numbers) such that $\bar{x}^i \rightarrow x$ and $\bar{x}^i \in M_0^a \cap M(\bar{x}, a)$. Then, in view of Theorem 3, we obtain that $\bar{x}^i \in M_0(\bar{x}, a)$. Now let $x \in E(P)$. If $x = \bar{x}$, we can put $\bar{x}^i = \bar{x}$, and it is $\bar{x}^i \in M_0(\bar{x}, a)$ and $\bar{x}^i \rightarrow x$. For $x \neq \bar{x}$, by Theorem 1 and (V3), there exists a sequence $\{\hat{x}^i\} \subset M(\bar{x}, a)$ satisfying $\hat{x}^i \rightarrow x$ and $\hat{x}^i \notin E(P)$. Using the argumentation of the first case ($x \notin E(P)$) for each \hat{x}^i , there exists, for every $\varepsilon > 0$ and every index i_0 , a point $\tilde{x}(i_0, \varepsilon) \in M_0(\bar{x}, a)$ such that $\|\tilde{x}(i_0, \varepsilon) - \hat{x}^{i_0}\| < \varepsilon$. Consequently, for a sequence $\{\varepsilon^i\}$ with $\varepsilon^i > 0$, $\varepsilon^i \rightarrow 0$, we can construct a sequence $\{\tilde{x}^i\} \subset M_0(\bar{x}, a)$ such that $\|\tilde{x}^i - x\| < \varepsilon^i$, and therefore $\tilde{x}^i \rightarrow x$.

(ii) The proof of (ii) is given in four steps, which are demonstrated below.

Step 1. In view of Lemma 2.2 in [14], there exists an $a^+ > f(\bar{x})$ such that $M(\bar{x}, a^+) \cap E(P) = \{\bar{x}\}$ and $M(\bar{x}, a)$ is compact for each $a \in [f(\bar{x}), a^+]$. By (V3) we can choose a discretization $f(\bar{x}) = a_0 < a^+ < a_1 < \dots < a_r = \bar{a}$ with $1 \leq r-1 \leq p$ such that, for each $i \in \{1, \dots, p\}$, there exists an index $j \in \{1, \dots, r\}$ satisfying $f(x^i) = a_j$.

Step 2. Choose an open bounded neighbourhood \hat{U}_0 of \bar{x} such that $f(x) < a^+$ for all $x \in \hat{U}_0 \cap M$. For any $\hat{a} \in (a^+, a^1)$, we put $\hat{M} = M(\bar{x}, \hat{a}) \setminus \hat{U}_0$, and, in virtue of (V4), Lemma 3, and Theorem 3, we obtain a C^1 -vector field η on R^n with the flow $\psi(x, t)$ satisfying

$$\psi(\cdot, \hat{a} - a^+)[\hat{M}] \subset M(\bar{x}, a^+).$$

Since $\psi(\cdot, a - a^+)$ is a homeomorphism and, according to Step 1, $M(\bar{x}, a^+)$ is compact, it follows that \hat{M} is compact, and, considering the boundedness of \hat{U}_0 , $M(\bar{x}, a)$ is compact for each $a \in [f(\bar{x}), a^1]$.

Step 3. Obviously, we can choose positive numbers γ, ε and the neighbourhoods $U_i, i = 0, \dots, p$ in (V4) in such a way that $\gamma + 3\varepsilon < \min\{a_k - a_{k-1} | k = 1, \dots, r\}$ and

$$(3.6) \quad f(x) - f(x^i) < \gamma \quad \text{for each } x \in U_i.$$

Without loss of generality, suppose that $\gamma = a^+ - f(\bar{x})$. In this step, let $k = 1, a_k < \bar{a}$. i is always varying in the set $A_k = \{i = 1, \dots, p | f(x_i) = a_k\}$. Now, we locally add at x^i the constant -3ε to f and define \hat{U}_i as an open bounded neighbourhood of x^i satisfying $\tilde{f}(x) < a_k - 2\varepsilon$ whenever $x \in \hat{U}_i$, where \tilde{f} is the so-perturbed function f . Furthermore, $\tilde{M}(\bar{x}, a)$ denotes, for $a \geq f(\bar{x})$, the connected component of $\{x \in M | f(x) \leq a\}$, which contains \bar{x} . Then, for each $a \in [f(\bar{x}), \bar{a}]$, it is $M(\bar{x}, a) \subset \tilde{M}(\bar{x}, a)$, and some consideration shows that, in view of (3.6) and Theorem 3, we also have that $M(\bar{x}, a) \subset M(\bar{x}, a) \cup \bigcup_{i \in A_k} U_i$. For $a \in [f(\bar{x}), \bar{a}]$, it follows that $M(\bar{x}, a)$ is compact if and only if $\tilde{M}(\bar{x}, a)$ is compact, and, in particular, Step 2 simplifies the compactness of $\tilde{M}(\bar{x}, a)$, $a \in [f(\bar{x}), a_1]$. For an arbitrarily chosen $\hat{a} \in [a_k, a_{k+1})$, we put

$$\hat{M} = \tilde{M}(\bar{x}, \hat{a}) \setminus \bigcup_{\{i=1, \dots, p | f(x_i) \leq a_k\} \cup \{0\}} \hat{U}_i,$$

and, by (V4), Lemma 3, and Theorem 3, we obtain a C^1 -vector field $\tilde{\eta}(x)$ with the flow $\tilde{\psi}(x, t)$. The above construction implies that

$$\tilde{\psi}(\cdot, \hat{a} - (a_k - \varepsilon))[\hat{M}] \subset \tilde{M}(\bar{x}, a_k - \varepsilon).$$

Since $\tilde{\psi}(\cdot, \hat{a} - (a_k - \varepsilon))$ is a homeomorphism and $\tilde{M}(\bar{x}, a_k - \varepsilon)$ is compact and

$$\bigcup_{\{i=1, \dots, p | f(x_i) \leq a_k\} \cup \{0\}} \hat{U}_i$$

is bounded, the compactness of the sets $\hat{M}, \tilde{M}(\bar{x}, \hat{a})$, and $M(\bar{x}, a)$ follows for each $a \in [f(\bar{x}), a_{k+1})$.

Step 4. In Steps 2 and 3, we proved the compactness of $M(\bar{x}, a)$ for $a \in [f(\bar{x}), a_1]$ and $a \in [a_1, a_2]$, respectively. We proceed by using the method of mathematical induction. In Step 3, let the index k run along the set $\{2, \dots, r-1\}$ in numerical order, where, at $k = k_0$, the compactness of $M(\bar{x}, a)$, $a \in [a_{k_0}, a_{k_0+1}]$ is proved by means of the above-shown compactness of $M(\bar{x}, a)$, $a \in [f(\bar{x}), a_{k_0}]$.

Finally, we must show the compactness of $M(\bar{x}, \bar{a})$. Let i always vary in the set A_r . We locally add at x^i a constant $\delta^i > 0$ to f , and we denote the resulting function by \hat{f} . Then the set $\hat{U} = \{x \in R^n | \hat{f}(x) > \bar{a}\}$ is open and $\hat{U} \cap M(\bar{x}, \bar{a})$ is bounded since (V3). Put

$$\hat{M} = M(\bar{x}, \bar{a}) \setminus \left\{ \hat{U} \cup \bigcup_{\{j \in \{1, \dots, p\} | f(x_j) \leq a_{r-1}\} \cup \{0\}} \hat{U}_j \right\}.$$

By (V4), Lemma 3, and Theorem 3, we obtain a C^1 -vector field $\hat{\eta}$ with the flow $\hat{\psi}(x, t)$ satisfying

$$\hat{\psi}(\cdot, \varepsilon)[\hat{M}] \subset M(\bar{x}, \bar{a} - \varepsilon).$$

Using the compactness of $M(\bar{x}, \bar{a} - \varepsilon)$ and an analogous argument as above, it follows that $M(\bar{x}, \bar{a})$ is compact. This completes the proof of (ii).

(iii) We show that Γ is usc-H and lsc-B at each $a \in [f(\bar{x}), \bar{a}]$. Obviously, Γ is lsc-B at $f(\bar{x})$, and, in view of Theorems 4 and 5 (i) (ii), it suffices to prove that $M_0(\bar{x}, a)$ is path-connected for each $a \in (f(\bar{x}), \bar{a}]$. Choose $\hat{a} \in (f(\bar{x}), \bar{a}]$ and $\{\hat{x}^1, \hat{x}^2\} \subset M_0(\bar{x}, \hat{a})$. By Theorem 3 and $M_0(\bar{x}, \hat{a}) \subset M(\bar{x}, \hat{a})$, we obtain that $\{\hat{x}^1, \hat{x}^2\} \subset M(\bar{x}, \max\{f(\hat{x}^1), f(\hat{x}^2)\}) \subset M_0(\bar{x}, \hat{a})$, and, in view of Theorem 1, we obtain the existence of a path in $M_0(\bar{x}, \hat{a})$ connecting \hat{x}^1 and \hat{x}^2 . \square

Remark 6. Theorem 5.2.1 in [8] and Lemma 4 (b) of this paper imply that $M(\bar{x}, a_1)$ and $M(\bar{x}, a_2)$, $a_1 < a_2 \leq \bar{a}$ need not be homotopy-equivalent, since, in the case where $(M_0(\bar{x}, a_2) \setminus M(\bar{x}, a_1)) \cap E(P) \neq \emptyset$, there might exist q such that $\dim H_q(M(\bar{x}, a_1)) \neq \dim H_q(M(\bar{x}, a_2))$. In particular, the continuity of Γ is not sufficient to guarantee homotopy-equivalence of the images of Γ .

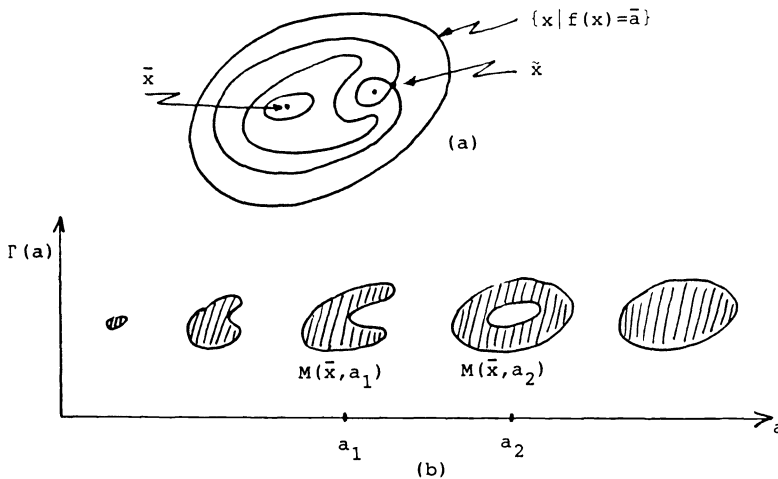

FIG. 5

Remark 7. It is easily seen that assertions (i)–(iii) of Theorem 5 remain true if we assume, instead of s.i. $(x^i) > 1$ in (V3), that (1.3) holds for all $a \in [f(\bar{x}), \bar{a}]$ and s.i. $(x^i) \geq 1$, $i = 1, \dots, p$. In Fig. 5(a), the function f is sketched by means of some level lines, and the three appearing stationary points are strongly stable, having stationary indices 0, 1, and 2. Moreover, it is $\dim H_0(M(\bar{x}, \bar{a}) \cap M^{a_1}) = \dim H_0(M(\bar{x}, a_1))$ and $\dim H_1(M(\bar{x}, a_2)) = \dim H_1(M(\bar{x}, a_1)) + 1$, where $f(\bar{x}) < a_1 < f(\tilde{x}) < a_2 < \bar{a}$, $\tilde{x} \in E(P) \cap M(\bar{x}, \bar{a})$ and s.i. $(\tilde{x}) = 1$ (see Fig. 5(b)).

Finally, we present a corollary in which (V2) is used in a modified form.

COROLLARY 2. *Let MFCQ be satisfied at all $x \in M_0(\bar{x}, \bar{a})$. Then*

(i) $M_0(\bar{x}, \bar{a}) = \bigcup_{a < \bar{a}} M(\bar{x}, a)$,

(ii) *If, in addition, Γ is lsc-B at \bar{a} , then $\text{cl} \bigcup_{a < \bar{a}} M(\bar{x}, a) = M(\bar{x}, \bar{a})$.*

Proof. (i) Obviously, $\bigcup_{a < \bar{a}} M(\bar{x}, a) \subset M_0(\bar{x}, \bar{a})$. Now suppose that $M_0(\bar{x}, \bar{a}) \setminus \bigcup_{a < \bar{a}} M(\bar{x}, a) \neq \emptyset$. Some consideration shows that there exists an $\hat{x} \in M_0(\bar{x}, \bar{a})$ such that, for each neighbourhood $U(\hat{x})$ of \hat{x} , we have that

$$(3.7) \quad U(\hat{x}) \cap \bigcup_{a < \bar{a}} M(\bar{x}, a) \neq \emptyset \quad \text{and}$$

$$(3.8) \quad U(\hat{x}) \cap \left\{ M_0(\bar{x}, \bar{a}) \setminus \bigcup_{a < \bar{a}} M(\bar{x}, a) \right\} \neq \emptyset.$$

By Lemma 1, we obtain a neighbourhood \hat{U} of \hat{x} such that $f(x) < \hat{a} < \bar{a}$ for all $x \in \hat{U}$ and $\hat{U} \cap M^{\hat{a}} = \hat{U} \cap M$ is path-connected. Formula (3.7) implies that $\hat{U} \cap M \subset \bigcup_{a < \bar{a}} M(\bar{x}, a)$, which contradicts (3.8). Assertion (ii) is a consequence of (i) and Theorem 4(i). \square

CONTROL OF A SECOND-ORDER INTEGRO-DIFFERENTIAL EQUATION*

JONG UHN KIM†

Abstract. Reachability for a second-order integro-differential equation is proved. The method is based upon a new kind of unique continuation property. The main significance of the result is that there is no restriction on the size of the memory kernel.

Key words. reachability, integro-differential equation, unique continuation property

AMS(MOS) subject classifications. 35L10, 49E99

Introduction. In this paper we discuss a reachability problem for a second-order integro-differential equation of the following form:

$$(0.1) \quad \begin{aligned} u_{tt}(x, t) - a(t)\Delta u(x, t) + b(t)u_t(x, t) + c(t)u(x, t) \\ - \Delta \int_0^t Q(t, \sigma)u(x, \sigma) d\sigma = 0 \text{ in } \Omega \times (0, T), \end{aligned}$$

$$(0.2) \quad u = g \quad \text{on } \partial\Omega \times (0, T),$$

$$(0.3) \quad u(x, 0) = 0, \quad u_t(x, 0) = 0 \quad \text{in } \Omega.$$

Here Ω is an open bounded subset of R^n with smooth boundary $\partial\Omega$. When $n = 1$, (0.1) reduces to a model equation in linear viscoelasticity. The question of reachability is posed as follows. For given (u_0, u_1) in Ω , is there a boundary control g that can drive the solution of (0.1)–(0.3) to the final state

$$(0.4) \quad u(x, T) = u_0(x), \quad u_t(x, T) = u_1(x) \quad \text{in } \Omega?$$

The purpose of this work is to present an affirmative answer without any size condition on the memory kernel $Q(t, \sigma)$; see Theorem 1.1 below. Let us first review some known results on analogous problems. A reachability problem for a plate equation with a memory was first resolved by Leugering [8]. His main tool was harmonic analysis under the assumption that the space domain is a rectangle and that the memory kernel is in the form of convolution. For a similar equation in a general domain, Lagnese and Lions [5] proved reachability by a different method. Their argument is valid for a general memory kernel including nonconvolution type, but under the assumption that the size of kernel is sufficiently small. Lasiecka [6] also obtained a similar result by a direct operator method with a more general memory kernel that depends both on time and space variables. For a general discussion of analogous problems, the reader is referred to Lions [9]. The common assumption was always that the size of kernel is sufficiently small except in the work of Leugering [8]. In fact, if the size of $Q(t, \sigma)$ in (0.1) is sufficiently small, the above problem can be resolved by the same argument as in [5] and [9]. Here we assume that the memory kernel is independent of space variables in contrast to [6]. By virtue of this assumption, we can employ a fairly simple, but different argument based on a new kind of unique continuation property, which is proved by adapting an idea of Bardos, Lebeau, and Rauch [1]. The technical details are given in the following sections.

1. Statement of the main result. We assume that

$$(1.1) \quad a(t) \in C^2([0, \infty)) \text{ and } a(t) \geq a_0, \text{ for all } t, \text{ for some positive constant } a_0,$$

$$(1.2) \quad b(t) \in C^1([0, \infty)),$$

$$(1.3) \quad c(t) \in C([0, \infty)),$$

$$(1.4) \quad Q(\sigma, t) \in C^2([0, \infty) \times [0, \infty)).$$

Let T_0 be a positive number such that

$$\int_0^{T_0} (a(\sigma))^{1/2} d\sigma = \text{diameter of } \Omega.$$

THEOREM 1.1. *Suppose that $T > T_0$. Then, for given $(u_0, u_1) \in L^2(\Omega) \times H^{-1}(\Omega)$, there is a control $g \in L^2(\partial\Omega \times (0, T))$ such that the solution of (0.1)–(0.3) satisfies (0.4).*

By means of a simple transformation of variables, we reduce the above problem to a simpler form.

Let us define $p(t)$ by

$$(1.5) \quad p(t) = \int_0^t (a(\sigma))^{1/2} d\sigma \quad \text{for } t \geq 0,$$

and set

$$(1.6) \quad s = p(t),$$

$$(1.7) \quad v(x, s) = u(x, q(s)),$$

where $q(\cdot)$ is the inverse of $p(\cdot)$, i.e., $t = q(s)$. It is easy to see that (0.1) is equivalent to

$$(1.8) \quad \begin{aligned} & v_{ss}(x, s) - \Delta v(x, s) + a(q(s))^{-1} \{ p''(q(s)) + b(q(s))p'(q(s)) \} v_s(x, s) \\ & + a(q(s))^{-1} c(q(s)) v(x, s) \\ & - \Delta \int_0^s a(q(s))^{-1} Q(q(s), q(\xi)) \frac{dq(\xi)}{d\xi} v(x, \xi) d\xi = 0 \quad \text{in } \Omega \times (0, p(T)), \end{aligned}$$

which can be rewritten as

$$(1.9) \quad \begin{aligned} & v_{ss}(x, s) - \Delta v(x, s) + b_1(s) v_s(x, s) + b_2(s) v(x, s) \\ & - \Delta \int_0^s Q_1(s, \xi) v(x, \xi) d\xi = 0 \quad \text{in } \Omega \times (0, p(T)). \end{aligned}$$

Next we set

$$(1.10) \quad w(x, s) = v(x, s) \exp \left(\int_0^s \frac{1}{2} b_1(\sigma) d\sigma \right).$$

Then (1.9) is equivalent to

$$(1.11) \quad \begin{aligned} & w_{ss}(x, s) - \Delta w(x, s) + \left(b_2(s) - \frac{1}{2} b_1'(s) - \frac{1}{4} b_1^2(s) \right) w(x, s) \\ & - \Delta \int_0^s Q_1(s, \xi) \exp \left(\frac{1}{2} \int_\xi^s b_1(\sigma) d\sigma \right) w(x, \xi) d\xi = 0 \quad \text{in } \Omega \times (0, p(T)), \end{aligned}$$

which we rewrite as

$$(1.12) \quad w_{ss}(x, s) - \Delta w(x, s) + b_3(s)w(x, s) - \Delta \int_0^s Q_2(s, \xi)w(x, \xi) d\xi = 0 \\ \text{in } \Omega \times (0, p(T)).$$

It follows from (1.1)–(1.4) that

$$(1.13) \quad b_3(s) \in C([0, \infty)),$$

$$(1.14) \quad Q_2(s, \xi) \in C^2([0, \infty) \times [0, \infty)).$$

Now we consider a reachability problem for the following equation.

$$(1.15) \quad u_{tt}(x, t) - \Delta u(x, t) + \alpha(t)u(x, t) - \Delta \int_0^t Q(t, \sigma)u(x, \sigma) d\sigma = 0 \quad \text{in } \Omega \times (0, T),$$

$$(1.16) \quad u = g \quad \text{on } \partial\Omega \times (0, T),$$

$$(1.17) \quad u(x, 0) = 0, \quad u_t(x, 0) = 0 \quad \text{in } \Omega,$$

where we assume that

$$(1.18) \quad \alpha(t) \in C([0, \infty)),$$

$$(1.19) \quad Q(t, \sigma) \in C^2([0, \infty) \times [0, \infty)).$$

Our claim is the following.

THEOREM 1.2. *Let T be greater than the diameter of Ω . Then, for given $(u_0, u_1) \in L^2(\Omega) \times H^{-1}(\Omega)$, there is a control $g \in L^2(\partial\Omega \times (0, T))$ that can drive the solution of (1.15)–(1.17) to the final state*

$$(1.20) \quad u(x, T) = u_0(x), \quad u_t(x, T) = u_1(x) \quad \text{in } \Omega.$$

Through the above transformation of variables, it is obvious that Theorem 1.2 implies Theorem 1.1.

The essence of the proof of this theorem is to establish a certain key estimate (Lemma 2.1) of the dual problem. For this, we reduce the dual equation to a simpler equation with a memory as a compact perturbation by solving an associated integral equation. Then, by means of the known estimates for solutions of a wave equation, the proof of the key estimate can be reduced to a unique continuation property of an integro-differential equation. Finally, we resolve this unique continuation property by adapting an idea in the proof of Proposition 6 in [1]. The details are presented in the following sections.

2. Proof of Theorem 1.2. Let us consider the dual problem.

$$(2.1) \quad \phi_{tt} - \Delta \phi + \alpha(t)\phi - \Delta \int_t^T Q(\sigma, t)\phi(x, \sigma) d\sigma = 0 \quad \text{in } \Omega \times (0, T),$$

$$(2.2) \quad \phi = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(2.3) \quad \phi(x, T) = \phi_0(x), \quad \phi_t(x, T) = \phi_1(x) \quad \text{in } \Omega.$$

The crux of the matter is to establish the following key estimate.

LEMMA 2.1. *Let T be greater than the diameter of Ω . For $(\phi_0, \phi_1) \in H_0^1(\Omega) \times L^2(\Omega)$, let ϕ be a unique solution of (2.1)–(2.3) in $C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$. Then, it holds that $\partial v / \partial \nu \in L^2(\partial\Omega \times (0, T))$ and*

$$(2.4) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial v}{\partial \nu} \right)^2 dx dt \geq M(\|\phi_0\|_{H_0^1(\Omega)}^2 + \|\phi_1\|_{L^2(\Omega)}^2),$$

where M denotes a positive constant independent of ϕ_0 and ϕ_1 , and v is defined by

$$(2.5) \quad v(x, t) = \phi(x, t) + \int_t^T Q(\sigma, t) \phi(x, \sigma) d\sigma.$$

Here $\partial/\partial\nu$ denotes the outward normal derivative on $\partial\Omega$.

We postpone the proof of this and proceed to prove Theorem 1.2. We define a mapping Λ on $H_0^1(\Omega) \times L^2(\Omega)$ as follows. For given $(\phi_0, \phi_1) \in H_0^1(\Omega) \times L^2(\Omega)$, let ϕ be a unique solution of (2.1)–(2.3) in $C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$. By choosing $g = \partial v/\partial\nu$, where v is defined by (2.5), we find a unique solution u of (1.15)–(1.17) according to Lemma 3.5 below. Now we define

$$(2.6) \quad \Lambda(\phi_0, \phi_1) = (-u_t(T), u(T)).$$

Then, Λ is a continuous linear mapping from $H_0^1(\Omega) \times L^2(\Omega)$ into $H^{-1}(\Omega) \times L^2(\Omega)$. The continuity of Λ will be obvious in the next section. On account of (2.4) and (3.26), we also have

$$(2.7) \quad \langle \Lambda(\phi_0, \phi_1), (\phi_0, \phi_1) \rangle \geq M(\|\phi_0\|_{H_0^1(\Omega)}^2 + \|\phi_1\|_{L^2(\Omega)}^2),$$

where \langle, \rangle stands for the duality pairing between $H_0^1(\Omega) \times L^2(\Omega)$ and $H^{-1}(\Omega) \times L^2(\Omega)$. Hence, Theorem 1.2 follows from the Lax–Milgram lemma. In the next section, we present some technical preliminaries for the proof of Lemma 2.1.

3. Preliminaries. We consider the following initial boundary value problem.

$$(3.1) \quad v_{tt} - \Delta v = h \quad \text{in } \Omega \times (0, T),$$

$$(3.2) \quad v = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(3.3) \quad v(x, 0) = v_0(x), \quad v_t(x, 0) = v_1(x) \quad \text{in } \Omega.$$

The following facts are well known.

LEMMA 3.1. For $(v_0, v_1) \in H_0^1(\Omega) \times L^2(\Omega)$ and $h \in L^1(0, T; L^2(\Omega))$, there is a unique solution v of (3.1)–(3.3) in $C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$. Furthermore, it holds that

$$(3.4) \quad \begin{aligned} & \|v\|_{C([0, T]; H_0^1(\Omega))}^2 + \|v_t\|_{C([0, T]; L^2(\Omega))}^2 + \int_0^T \int_{\partial\Omega} \left(\frac{\partial v}{\partial \nu} \right)^2 dx dt \\ & \leq M(\|v_0\|_{H_0^1(\Omega)}^2 + \|v_1\|_{L^2(\Omega)}^2 + \|h\|_{L^1(0, T; L^2(\Omega))}^2), \end{aligned}$$

where $\partial/\partial\nu$ denotes the outward normal derivative on $\partial\Omega$ and M is a constant independent of v_0 , v_1 , and h .

For the proof, see [9].

LEMMA 3.2. Let $h = 0$ and let T be greater than the diameter of Ω . Then, for $(v_0, v_1) \in H_0^1(\Omega) \times L^2(\Omega)$, it holds that

$$(3.5) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial v}{\partial \nu} \right)^2 dx dt \geq M(\|v_0\|_{H_0^1(\Omega)}^2 + \|v_1\|_{L^2(\Omega)}^2),$$

for a positive constant M independent of v_0 and v_1 .

This was originally due to Ho [2] and was later improved in the present form by Komornik [4]. The next lemma will be used to define a weak solution.

LEMMA 3.3. *Let u be a smooth solution of (1.15)–(1.17) with $g \in C_0^\infty(\partial\Omega \times (0, T))$. Then, it holds that*

$$(3.6) \quad \|u\|_{C([0,T];L^2(\Omega))} + \|u_t\|_{C([0,T];H^{-1}(\Omega))} \leq M \|g\|_{L^2(\partial\Omega \times (0,T))},$$

where M is a constant independent of g .

Proof. Fix any $0 < s \leq T$ and let ϕ be a smooth solution of the following dual problem.

$$(3.7) \quad \phi_{tt}(x, t) - \Delta \phi(x, t) + \alpha(t)\phi(x, t) - \Delta \int_t^s Q(\sigma, t)\phi(x, \sigma) d\sigma = 0 \quad \text{in } \Omega \times (0, s),$$

$$(3.8) \quad \phi = 0 \quad \text{on } \partial\Omega \times (0, s),$$

$$(3.9) \quad \phi(x, s) = \phi_0(x), \quad \phi_t(x, s) = \phi_1(x) \quad \text{in } \Omega,$$

where ϕ_0 and ϕ_1 belong to $C_0^\infty(\Omega)$. Multiplying (3.7) by u and integrating over $\Omega \times (0, s)$, we obtain

$$(3.10) \quad \langle \phi_1, u(s) \rangle - \langle \phi_0, u_t(s) \rangle = \int_0^s \int_{\partial\Omega} g \frac{\partial v}{\partial \nu} dx dt,$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product in $L^2(\Omega)$ and

$$(3.11) \quad v(x, t) = \phi(x, t) + \int_t^s Q(\sigma, t)\phi(x, \sigma) d\sigma.$$

This can be inverted to give

$$(3.12) \quad \phi(x, t) = v(x, t) + \int_t^s R(\sigma, t)v(x, \sigma) d\sigma,$$

where $R(\sigma, t)$ is determined from $Q(\sigma, t)$ and $R(\sigma, t) \in C^2([0, \infty) \times [0, \infty))$. It is apparent that v satisfies

$$(3.13) \quad v_0 = v(x, s) = \phi_0, \quad v_1 = v_t(x, s) = \phi_1 - Q(s, s)\phi_0,$$

$$(3.14) \quad v = 0 \quad \text{on } \partial\Omega \times (0, s),$$

$$(3.15) \quad \begin{aligned} &v_{tt}(x, t) - \Delta v(x, t) - R(t, t)v_t(x, t) + (\alpha(t) - 2R_t(t, t) - R_{\sigma\sigma}(t, t))v(x, t) \\ &+ \int_t^s \alpha(t)R(\sigma, t)v(x, \sigma) d\sigma + \int_t^s R_{tt}(\sigma, t)v(x, \sigma) d\sigma = 0 \quad \text{in } \Omega \times (0, s). \end{aligned}$$

It is well known that

$$(3.16) \quad \|v\|_{C([0,s];H_0^1(\Omega))} + \|v_t\|_{C([0,s];L^2(\Omega))} \leq M(\|v_0\|_{H_0^1(\Omega)} + \|v_1\|_{L^2(\Omega)}),$$

where M is a constant depending on T , but independent of v_0, v_1 , and $0 < s \leq T$. By writing (3.15) in the form of (3.1) and modifying the time interval in an obvious manner, we can use (3.4) to derive

$$(3.17) \quad \begin{aligned} \int_0^s \int_{\partial\Omega} \left(\frac{\partial v}{\partial \nu} \right)^2 dx dt &\leq M(\|v_0\|_{H_0^1(\Omega)}^2 + \|v_1\|_{L^2(\Omega)}^2) \\ &\leq M(\|\phi_0\|_{H_0^1(\Omega)}^2 + \|\phi_1\|_{L^2(\Omega)}^2), \end{aligned}$$

where M is independent of ϕ_0, ϕ_1 and $0 < s \leq T$. Now we consider (3.10). By setting $\phi_0 = 0$, we have

$$(3.18) \quad \begin{aligned} |\langle \phi_1, u(s) \rangle| &\leq \|g\|_{L^2(\partial\Omega \times (0,s))} \left\| \frac{\partial v}{\partial \nu} \right\|_{L^2(\partial\Omega \times (0,s))} \\ &\leq M \|g\|_{L^2(\partial\Omega \times (0,T))} \|\phi_1\|_{L^2(\Omega)}, \end{aligned}$$

where M is independent of ϕ_1 , g and $0 < s \leq T$, from which it follows that

$$(3.19) \quad \|u(s)\|_{L^2(\Omega)} \leq M \|g\|_{L^2(\partial\Omega \times (0, T))}$$

for all $0 \leq s \leq T$. Similarly, we set $\phi_1 = 0$ and use (3.17) to obtain

$$(3.20) \quad \|u_t(s)\|_{H^{-1}(\Omega)} \leq M \|g\|_{L^2(\partial\Omega \times (0, T))}$$

for all $0 \leq s \leq T$. The proof of (3.6) is now complete.

By the method of transposition, we can define a weak solution as in [5] and [9].

DEFINITION 3.4. For given $g \in L^2(\partial\Omega \times (0, T))$, a function $u \in C([0, T]; L^2(\Omega)) \cap C^1([0, T]; H^{-1}(\Omega))$ is called a solution of (1.15)–(1.17) if

$$(3.21) \quad \int_0^T \int_{\Omega} u h \, dx \, dt = - \int_0^T \int_{\partial\Omega} g \frac{\partial v}{\partial \nu} \, dx \, dt$$

for every $h \in C_0^\infty(\Omega \times (0, T))$, where

$$(3.22) \quad v(x, t) = \phi(x, t) + \int_t^T Q(\sigma, t) \phi(x, \sigma) \, d\sigma$$

and ϕ is a solution of

$$(3.23) \quad \phi_{tt} - \Delta \phi + \alpha(t) \phi - \Delta \int_t^T Q(\sigma, t) \phi(x, \sigma) \, d\sigma = h \quad \text{in } \Omega \times (0, T),$$

$$(3.24) \quad \phi = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(3.25) \quad \phi(x, T) = 0, \quad \phi_t(x, T) = 0 \quad \text{on } \Omega.$$

It is evident that a smooth solution is also a solution according to the above definition.

LEMMA 3.5. For given $g \in L^2(\partial\Omega \times (0, T))$, there is a unique solution of (1.15)–(1.17).

Proof. We can find a sequence $\{g^m\}_{m=1}^\infty$ in $C_0^\infty(\partial\Omega \times (0, T))$ such that g^m converges to g strongly in $L^2(\partial\Omega \times (0, T))$. For each g^m , there is a smooth solution u^m and $\{u^m\}_{m=1}^\infty$ is strongly convergent in $C([0, T]; L^2(\Omega)) \cap C^1([0, T]; H^{-1}(\Omega))$ by virtue of (3.6). The limit function u is obviously a solution of (1.15)–(1.17). Uniqueness is trivial.

Through a similar procedure, we can also prove the following identity, which was already used in the proof of Theorem 1.2.

LEMMA 3.6. For $g \in L^2(\partial\Omega \times (0, T))$, the above solution also satisfies

$$(3.26) \quad \langle \phi_1, u(T) \rangle - \langle \phi_0, u_t(T) \rangle = \int_0^T \int_{\partial\Omega} g \frac{\partial v}{\partial \nu} \, dx \, dt,$$

where v is defined by (2.5) in terms of $\phi \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$, which is a solution of (2.1)–(2.3). In (3.26), $\langle \cdot, \cdot \rangle$ denotes either the duality pairing between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$ or the inner product in $L^2(\Omega)$.

Finally, we present a certain regularity property of solution. Let us set

$$(3.27) \quad w(x, t) = v(x, t) \exp \left(\frac{1}{2} \int_t^T R(\sigma, \sigma) \, d\sigma \right),$$

where v is defined by (2.5) in terms of ϕ , which satisfies (2.1). Then, (3.15) with $s = T$ is equivalent to

$$(3.28) \quad w_{tt} - \Delta w + \gamma(t)w + \int_t^T G(\sigma, t)w(x, \sigma) \, d\sigma = 0 \quad \text{in } \Omega \times (0, T),$$

where $\gamma(t)$ and $G(\sigma, t)$ are expressed in terms of $\alpha(t)$ and $R(\sigma, t)$, and

$$(3.29) \quad \gamma(t) \in C([0, \infty)),$$

$$(3.30) \quad G(\sigma, t) \in C([0, \infty) \times [0, \infty)).$$

LEMMA 3.7. *Let T be greater than the diameter of Ω and let Ω_0 be an open subset of Ω such that $\bar{\Omega}_0 \subset \Omega$. Suppose that $w \in C([0, T]; L^2(\Omega)) \cap C^1([0, T]; H^{-1}(\Omega))$ satisfies (3.28) in the sense of distribution in $\Omega \times (0, T)$. If $w = 0$ in $(\Omega \setminus \Omega_0) \times (0, T)$, then $w \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$.*

Proof. Let $w^\varepsilon = w * \rho_\varepsilon$, where ρ_ε is the Friedrichs mollifier in R^n and the convolution is taken only in the space variables. We take ε so small that $\text{supp } w^\varepsilon \subset \Omega \times [0, T]$. Then, w^ε satisfies (3.28) in $\Omega \times (0, T)$ and $w^\varepsilon \in C^1([0, T]; H_0^2(\Omega))$. We then write

$$(3.31) \quad w^\varepsilon = \psi^\varepsilon + \zeta^\varepsilon,$$

where $\psi^\varepsilon \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ is a solution of

$$(3.32) \quad \psi_{tt}^\varepsilon - \Delta \psi^\varepsilon = -\gamma(t)w^\varepsilon - \int_t^T G(\sigma, t)w^\varepsilon(x, \sigma) d\sigma \quad \text{in } \Omega \times (0, T),$$

$$(3.33) \quad \psi^\varepsilon = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(3.34) \quad \psi^\varepsilon(x, T) = 0, \quad \psi_t^\varepsilon(x, T) = 0 \quad \text{in } \Omega,$$

and ζ^ε is a solution of

$$(3.35) \quad \zeta_{tt}^\varepsilon - \Delta \zeta^\varepsilon = 0 \quad \text{in } \Omega \times (0, T),$$

$$(3.36) \quad \zeta^\varepsilon = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(3.37) \quad \zeta^\varepsilon(x, T) = w^\varepsilon(x, T), \quad \zeta_t^\varepsilon(x, T) = w_t^\varepsilon(x, T) \quad \text{in } \Omega.$$

By virtue of Lemma 3.1 with time reversed, we find that

$$(3.38) \quad \|\psi^\varepsilon\|_{C([0, T]; H_0^1(\Omega))} + \|\psi_t^\varepsilon\|_{C([0, T]; L^2(\Omega))} \leq M \|w\|_{C([0, T]; L^2(\Omega))},$$

$$(3.39) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial \psi^\varepsilon}{\partial \nu} \right)^2 dx dt \leq M \|w\|_{C([0, T]; L^2(\Omega))}^2,$$

for a constant M independent of ε and w . In the mean time, since $\text{supp } w^\varepsilon \subset \Omega \times [0, T]$, we have

$$(3.40) \quad \frac{\partial \psi^\varepsilon}{\partial \nu} = -\frac{\partial \zeta^\varepsilon}{\partial \nu} \quad \text{on } \partial\Omega \times (0, T),$$

which, combined with Lemma 3.2 and (3.39), yields

$$(3.41) \quad \|w^\varepsilon(T)\|_{H_0^1(\Omega)}^2 + \|w_t^\varepsilon(T)\|_{L^2(\Omega)}^2 \leq M \|w\|_{C([0, T]; L^2(\Omega))}^2.$$

It now follows that

$$(3.42) \quad \|w^\varepsilon\|_{C([0, T]; H_0^1(\Omega))} + \|w_t^\varepsilon\|_{C([0, T]; L^2(\Omega))} \leq M \|w\|_{C([0, T]; L^2(\Omega))},$$

where M is independent of ε and w . This yields $w \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$.

4. Proof of Lemma 2.1. We shall first prove the following.

LEMMA 4.1. *Let T be greater than the diameter of Ω and let $w \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ be a solution of (3.28) in $\Omega \times (0, T)$ such that $\partial w / \partial \nu = 0$ on $\partial\Omega \times (0, T)$. Then, $w = 0$ in $\Omega \times (0, T)$.*

Proof. Let Ω_1 be a bounded open subset of R^n with smooth boundary such that $\bar{\Omega} \subset \Omega_1$ and let $T > \text{diameter of } \Omega_1 > \text{diameter of } \Omega$. We can extend w to $\Omega_1 \times (0, T)$ such that $w(x, t) = 0$ for $x \in \Omega_1 \setminus \Omega$. Since $w = \partial w / \partial \nu = 0$ on $\partial \Omega \times (0, T)$, $w \in C([0, T]; H_0^1(\Omega_1)) \cap C^1([0, T]; L^2(\Omega_1))$ and w satisfies

$$(4.1) \quad w_{tt} - \Delta w + \gamma(t)w + \int_t^T G(\sigma, t)w(x, \sigma) d\sigma = 0$$

in the sense of distribution in $\Omega_1 \times (0, T)$. We now set

$$(4.2) \quad \mathcal{S} = \{w \in C([0, T]; H_0^1(\Omega_1)) \cap C^1([0, T]; L^2(\Omega_1)) : w \text{ is a solution of (4.1) in } \Omega_1 \times (0, T) \text{ and } w = 0 \text{ in } (\Omega_1 \setminus \Omega) \times (0, T)\}.$$

It is easy to see that \mathcal{S} is a Banach space equipped with the norm of $C([0, T]; H_0^1(\Omega_1)) \cap C^1([0, T]; L^2(\Omega_1))$, which we shall denote by $\|\cdot\|_{\mathcal{S}}$. It will be shown that \mathcal{S} is of finite dimension. Let

$$(4.3) \quad \mathcal{X} = \{w \in \mathcal{S} : \|w\|_{\mathcal{S}} \leq 1\}.$$

If \mathcal{X} is compact, then \mathcal{S} is of finite dimension. For this, we will use the regularity result established in Lemma 3.7 as in [7]. Choose any $w \in \mathcal{X}$ and set

$$(4.4) \quad \eta_i = \frac{\partial w}{\partial x_i}, \quad i = 1, \dots, n.$$

Then, it is evident that Lemma 3.7 can be applied to each η_i . By virtue of (3.42), we find that $\eta_i \in \mathcal{S}$ and

$$(4.5) \quad \|\eta_i\|_{\mathcal{S}} \leq M,$$

where M is a positive constant independent of w , provided $w \in \mathcal{X}$. Hence, it follows that \mathcal{X} is bounded in $C([0, T]; H_0^1(\Omega_1) \cap H^2(\Omega_1)) \cap C^1([0, T]; H_0^1(\Omega_1))$. It is also bounded in $C^2([0, T]; L^2(\Omega_1))$ by (4.1). Therefore, \mathcal{X} is compact. Next choose any $w \in \mathcal{S}$. Since \mathcal{S} is of finite dimension and $\partial/\partial x_1$ is a linear operator from \mathcal{S} into \mathcal{S} , there is an integer $N \geq 1$ such that

$$(4.6) \quad \left(\frac{\partial}{\partial x_1}\right)^N w + \alpha_1 \left(\frac{\partial}{\partial x_1}\right)^{N-1} w + \dots + \alpha_N w = 0 \quad \text{in } \Omega_1 \times (0, T),$$

for some constants $\alpha_1, \dots, \alpha_N$; see [3, p. 191]. We show that $w = 0$ in $\Omega_1 \times (0, T)$. Let us use the notation

$$(4.7) \quad y = x_1 \in R,$$

$$(4.8) \quad z = (x_2, \dots, x_n, t) \in R^n,$$

so that $(x, t) = (y, z)$. Now we choose any $(y_0, z_0) \in \bar{\Omega} \times (0, T)$. Then, there is y_1 such that $(y_1, z_0) \in (\Omega_1 \setminus \bar{\Omega}) \times (0, T)$ and the line segment connecting (y_1, z_0) and (y_0, z_0) is contained in $\Omega_1 \times (0, T)$. There are also positive numbers δ_1 and δ_2 such that the cylinder $I_{\delta_1} \times B_{\delta_2}$ is contained in $\Omega_1 \times (0, T)$ where $I_{\delta_1} = (y_1 - \delta_1, y_0 + \delta_1)$ and $B_{\delta_2} = \{z \in R^n : |z - z_0| < \delta_2\}$. We can further require that $[y_1 - \delta_1, y_1] \times B_{\delta_2}$ is contained in $(\Omega_1 \setminus \bar{\Omega}) \times (0, T)$. Next we choose any $\phi \in C_0^\infty(B_{\delta_2})$ and set

$$(4.9) \quad \xi(y) = \int_{B_{\delta_2}} w \phi dz.$$

Then, $\xi(y) \in L^2(I_{\delta_1})$ and it holds that

$$(4.10) \quad \left(\frac{d}{dy}\right)^N \xi + \alpha_1 \left(\frac{d}{dy}\right)^{N-1} \xi + \dots + \alpha_N \xi = 0$$

in the sense of distribution in I_{δ_1} , which yields that $\xi \in C^\infty(I_{\delta_1})$. In the meantime, $\xi = 0$ in $(y_1 - \delta_1, y_1)$, since $w = 0$ in $(\Omega_1 \setminus \Omega) \times (0, T)$. This implies that $\xi = 0$ in I_{δ_1} . Consequently, $w = 0$ in a neighborhood of (y_0, z_0) . We finally conclude that $w = 0$ in $\Omega_1 \times (0, T)$. Now the proof is complete.

Proof of Lemma 2.1. First, (3.17) implies that $\partial v / \partial \nu \in L^2(\partial\Omega \times (0, T))$. We define w by (3.27). Then, (2.4) is equivalent to

$$(4.11) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial w}{\partial \nu} \right)^2 dx dt \cong M(\|w_0\|_{H_0^1(\Omega)}^2 + \|w_1\|_{L^2(\Omega)}^2),$$

where

$$(4.12) \quad w_0(x) = w(x, T), \quad w_1(x) = w_t(x, T) \quad \text{in } \Omega.$$

Assume that (4.11) is false. Then there is a sequence $\{(w_0^m, w_1^m)\}_{m=1}^\infty$ in $H_0^1(\Omega) \times L^2(\Omega)$ such that

$$(4.13) \quad \|w_0^m\|_{H_0^1(\Omega)}^2 + \|w_1^m\|_{L^2(\Omega)}^2 = 1 \quad \text{for all } m,$$

$$(4.14) \quad (w_0^m, w_1^m) \rightarrow (w_0^\infty, w_1^\infty) \text{ weakly in } H_0^1(\Omega) \times L^2(\Omega) \quad \text{as } m \rightarrow \infty,$$

$$(4.15) \quad (w^m, w_t^m) \rightarrow (w^\infty, w_t^\infty) \text{ weak* in } L^\infty(0, T; H_0^1(\Omega)) \\ \times L^\infty(0, T; L^2(\Omega)) \quad \text{as } m \rightarrow \infty$$

$$(4.16) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial w^m}{\partial \nu} \right)^2 dx dt \rightarrow 0 \quad \text{as } m \rightarrow \infty.$$

Here each w^m is a solution of (3.28) and

$$(4.17) \quad w^m = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(4.18) \quad w^m(x, T) = w_0^m(x), \quad w_t^m(x, T) = w_1^m(x) \quad \text{in } \Omega,$$

and w^∞ is a solution of (3.28), (4.17) and

$$(4.19) \quad w^\infty(x, T) = w_0^\infty(x), \quad w_t^\infty(x, T) = w_1^\infty(x) \quad \text{in } \Omega.$$

Since $\partial w^\infty / \partial \nu = 0$ on $\partial\Omega \times (0, T)$, which follows from (4.16), we find that $w^\infty = 0$ by virtue of Lemma 4.1. As before, we write

$$(4.20) \quad w^m = \psi^m + \zeta^m,$$

where $\psi^m \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ is a solution of

$$(4.21) \quad \psi_{tt}^m - \Delta \psi^m = -\gamma(t)w^m - \int_t^T G(\sigma, t)w^m(x, \sigma) d\sigma \quad \text{in } \Omega \times (0, T),$$

$$(4.22) \quad \psi^m = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(4.23) \quad \psi^m(x, T) = 0, \quad \psi_t^m(x, T) = 0 \quad \text{in } \Omega,$$

and $\zeta^m \in C([0, T]; H_0^1(\Omega)) \cap C^1([0, T]; L^2(\Omega))$ is a solution of

$$(4.24) \quad \zeta_{tt}^m - \Delta \zeta^m = 0 \quad \text{in } \Omega \times (0, T),$$

$$(4.25) \quad \zeta^m = 0 \quad \text{on } \partial\Omega \times (0, T),$$

$$(4.26) \quad \zeta^m(x, T) = w^m(x, T), \quad \zeta_t^m(x, T) = w_t^m(x, T) \quad \text{in } \Omega.$$

Since (4.15) implies that

$$(4.27) \quad w^m \rightarrow 0 \text{ strongly in } L^1(0, T; L^2(\Omega)),$$

it follows from Lemma 3.1 (with time reversed) that

$$(4.28) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial \psi^m}{\partial \nu} \right)^2 dx dt \rightarrow 0 \quad \text{as } m \rightarrow \infty.$$

Now we derive from (4.16), (4.20), and (4.28) that

$$(4.29) \quad \int_0^T \int_{\partial\Omega} \left(\frac{\partial \xi^m}{\partial \nu} \right)^2 dx dt \rightarrow 0 \quad \text{as } m \rightarrow \infty.$$

Thus, by Lemma 3.2, we have

$$(4.30) \quad \|w^m(x, T)\|_{H_0^1(\Omega)}^2 + \|w_t^m(x, T)\|_{L^2(\Omega)}^2 \rightarrow 0$$

as $m \rightarrow \infty$, which contradicts (4.13). Now the proof of (4.11) is complete.

Acknowledgments. I would like to acknowledge a very helpful discussion with E. Zuazua in Vorau, Austria. He suggested a transformation in the time variable to reduce the equation to a simpler form. I am also indebted to nice lectures given by V. Komornik at Virginia Tech.

METROPOLIS-TYPE ANNEALING ALGORITHMS FOR GLOBAL OPTIMIZATION IN \mathbb{R}^{d*}

SAUL B. GELFAND[†] AND SANJOY K. MITTER[‡]

Abstract. The convergence of a class of Metropolis-type Markov-chain annealing algorithms for global optimization of a smooth function $U(\cdot)$ on \mathbb{R}^d is established. No prior information is assumed as to what bounded region contains a global minimum. The analysis contained herein is based on writing the Metropolis-type algorithm in the form of a recursive stochastic algorithm $X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k$, where $\{W_k\}$ is a standard white Gaussian sequence, $\{\xi_k\}$ are random variables, and $a_k = A/k$, $b_k = \sqrt{B}/\sqrt{k \log \log k}$ for k large. Convergence results for $\{X_k\}$ are then applied from our previous work [*SIAM Journal on Control and Optimization*, 29 (1991), pp. 999–1018]. Since the analysis of $\{X_k\}$ is based on the asymptotic behavior of the related Langevin-type Markov diffusion annealing algorithm $dY(t) = -\nabla U(Y(t)) dt + c(t) dW(t)$, where $W(\cdot)$ is a standard Wiener process and $c(t) = \sqrt{C}/\sqrt{\log t}$ for t large, this work demonstrates and exploits the close relationship between the Markov chain and diffusion versions of simulated annealing.

Key words. global optimization, random optimization, simulated annealing, stochastic gradient algorithms, Markov chains

AMS(MOS) subject classifications. 65K10, 90C30, 60J60

1. Introduction. Let $U(\cdot)$ be a real-valued function on some set Σ . The global optimization problem is to find an element of the set $S^* = \{x: U(x) \leq U(y) \text{ for all } y \in \Sigma\}$ (assuming that $S^* \neq \emptyset$). Recently, there has been much interest in the simulated annealing method for global optimization. Annealing algorithms were initially proposed for finite optimization (Σ finite), and later developed for continuous optimization ($\Sigma = \mathbb{R}^d$). An annealing algorithm for finite optimization was first suggested in [17], [2] and is based on simulating a finite-state Metropolis-type Markov chain. The Metropolis algorithm and other related algorithms such as the “heat bath” algorithm, were originally developed as Markov chain sampling methods for sampling from a Gibbs distribution [1]. The asymptotic behavior of finite state Metropolis-type annealing algorithms has been extensively analyzed [3], [5], [9], [12], [14], [21], [24], [25].

A continuous-time annealing algorithm for continuous optimization was first suggested in [10], [13], and is based on simulating a Langevin-type Markov diffusion as follows:

$$(1.1) \quad dY(t) = -\nabla U(Y(t)) dt + c(t) dW(t).$$

Here $U(\cdot)$ is a smooth function on \mathbb{R}^d , $W(\cdot)$ is a standard d -dimensional Wiener process, and $c(\cdot)$ is a positive function with $c(t) \rightarrow 0$ as $t \rightarrow \infty$. In the terminology of simulated annealing algorithms, $U(x)$ is called the energy of state x , and $T(t) = c^2(t)/2$ is called the temperature at time t . Note that for a fixed temperature $T(t) = T$, the resulting Langevin diffusion, like the Metropolis chain, has a Gibbs distribution $\propto \exp(-U(x)/T)$ as its invariant measure. Now (1.1) can be viewed as adding decreasing white Gaussian noise to the continuous time gradient algorithm

$$(1.2) \quad \dot{z}(t) = -\nabla U(z(t)).$$

We use (1.1) instead of (1.2) for minimizing $U(\cdot)$ to avoid getting trapped in strictly local minima. The asymptotic behavior of $Y(t)$ as $t \rightarrow \infty$ has been studied in [4], [10], [11], [18]. In [10], [18] convergence results were obtained for a version of (1.1), which was modified to constrain the trajectories to lie in a fixed bounded set (and hence is only applicable to global optimization over a compact subset of \mathbb{R}^d); in [4], [11] results were obtained for global optimization over all of \mathbb{R}^d . Chiang, Hwang, and Sheu's main result from [4] can be roughly stated as follows: If $U(\cdot)$ is suitably behaved and $c^2(t) = C/\log t$ for t large with $C > C_0$ (a constant depending only on $U(\cdot)$), then $Y(t) \rightarrow S^*$ as $t \rightarrow \infty$ in probability.

A discrete-time annealing algorithm for continuous optimization was suggested in [8], [18] and is based on simulating a recursive stochastic algorithm

$$(1.3) \quad X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k.$$

Here $U(\cdot)$ is again a smooth function on \mathbb{R}^d , $\{\xi_k\}$ is a sequence of \mathbb{R}^d -valued random variables, $\{W_k\}$ is a sequence of independent standard d -dimensional Gaussian random variables, and $\{a_k\}, \{b_k\}$ are sequences of positive numbers with $a_k, b_k \rightarrow 0$ as $k \rightarrow \infty$. Algorithm (1.3) could arise from a discretization or numerical integration of the diffusion (1.1) so as to be suitable for implementation on a digital computer; in this case, ξ_k is due to the discretization error. Alternatively, algorithm (1.3) could arise by artificially adding decreasing white Gaussian noise (i.e., the $b_k W_k$ terms) to a stochastic gradient algorithm

$$(1.4) \quad Z_{k+1} = Z_k - a_k(\nabla U(Z_k) + \xi_k),$$

which arises in a variety of optimization problems including adaptive filtering, identification and control; in this case, ξ_k is due to noisy or imprecise measurements of $\nabla U(\cdot)$ (cf. [19]). We again use (1.3) instead of (1.4) for minimizing $U(\cdot)$ to avoid getting trapped in strictly local minima. In the following, we refer to (1.4) and (1.3) as standard and modified stochastic gradient algorithms, respectively. The asymptotic behavior of X_k as $k \rightarrow \infty$ has been studied in [8], [18]. In [18] convergence results were obtained for a version of (1.3), which was modified to constrain the trajectories to lie in a compact set (and hence is only applicable to global optimization over a compact subset of \mathbb{R}^d); in [8] results were obtained for global optimization over all of \mathbb{R}^d . Also, in [18] convergence is obtained essentially only for the case where $\xi_k = 0$; in [8] convergence is obtained for $\{\xi_k\}$ with unbounded variance. This latter fact has important implications when $\nabla U(\cdot)$ is not measured exactly. Our main result from [8] can be roughly stated as follows: If $U(\cdot)$ and $\{\xi_k\}$ are suitably behaved, $a_k = A/k$ and $b_k^2 = B/k \log \log k$ for k large with $B/A > C_0$ (the same C_0 as above), and $\{X_k\}$ is tight, then $X_k \rightarrow S^*$ as $k \rightarrow \infty$ in probability (conditions are also given in [8] for tightness of $\{X_k\}$). Our analysis in [8] of the asymptotic behavior of X_k as $k \rightarrow \infty$ is based on the behavior of the associated stochastic differential equation (SDE) (1.1). This is analogous to the well-known method of analyzing the asymptotic behavior of Z_k as $k \rightarrow \infty$ based on the behavior of the associated ordinary differential equation (ODE) (1.2) [19], [20].

It has also been suggested that continuous optimization might be performed by simulating a continuous-state Metropolis-type Markov chain [10]. This method has been applied to the restoration of noise corrupted images [16], [23]. In these works, Gaussian random field models are used so that the state space is unbounded. Although some numerical work has been performed with continuous-state Metropolis-type annealing algorithms, there has been very little theoretical analysis, and, furthermore,

the analysis of the continuous-state case does not follow from the finite-state case in a straightforward way (especially for an unbounded state space). The only analysis of which we know is in [16], where a certain asymptotic stability property is established for a related algorithm and a particular cost function that arises in a problem of image restoration.

In this paper, we demonstrate the convergence of a class of continuous-state Metropolis-type Markov-chain annealing algorithms for general cost functions. Our approach is to write such an algorithm in the form of a modified stochastic gradient algorithm (1.3) for suitable choice of ξ_k , and to apply results from [8]. A convergence result is obtained for global optimization over all of \mathbb{R}^d . Some care is necessary to formulate a Metropolis-type Markov chain with appropriate scaling. It turns out that writing the Metropolis-type annealing algorithm in the form (1.3) is more complicated than writing standard variations of gradient algorithms, which use some type of finite-difference estimate of $\nabla U(\cdot)$, in the form (1.4) (cf. [19]). Indeed, to the extent that the Metropolis-type annealing algorithm uses an estimate of $\nabla U(\cdot)$, it does so in a much more subtle manner than a finite-difference approximation, as is seen in the analysis.

Since our convergence results for the Metropolis-type Markov-chain annealing algorithm are ultimately based on the asymptotic behavior of the Langevin-type Markov diffusion annealing algorithm, this paper demonstrates and exploits the close relationship between the Markov chain and diffusion versions of simulated annealing, which is particularly interesting in view of the fact that the development and analysis of these methods has proceeded more or less independently. We note that similar convergence results for other annealing algorithms based on the continuous-state Markov-chain sampling method (such as the “heat bath” method) can be obtained by a procedure similar to that used in this paper.

It is important to note that, although we establish the convergence of the Metropolis-type Markov-chain annealing algorithm by effectively comparing it with the Langevin-type Markov diffusion annealing algorithm, the finite-time behavior of the algorithms may be quite different. Some indication of this arises in the analysis; see Remarks 1 and 2 in § 4.

The paper is organized as follows. In § 2 we discuss appropriately modified versions of tightness and convergence results for modified stochastic gradient algorithms, as given in [8]. In § 3 we present a class of continuous-state Metropolis-type annealing algorithms and state some convergence theorems. In § 4 we prove the convergence theorems of § 3, using the results of § 2.

2. Modified stochastic gradient algorithms. In this section, we give convergence and tightness results for modified stochastic gradient algorithms of the type described in § 1. The algorithms and theorems discussed below are a slight variation on the results of [8] and are appropriate for proving convergence and tightness for a class of continuous state Metropolis-type annealing algorithms (see §§ 3 and 4).

We use the following notation throughout the paper. Let $\nabla U(\cdot)$, $\Delta U(\cdot)$, and $HU(\cdot)$ denote the gradient, Laplacian, and Hessian matrix of $U(\cdot)$, respectively. Let $|\cdot|$, $\langle \cdot, \cdot \rangle$, and \otimes denote Euclidean norm, inner product, and outer product, respectively. For real numbers a and b , let $a \vee b = \text{maximum}\{a, b\}$, $a \wedge b = \text{minimum}\{a, b\}$, $[a]^+ = a \vee 0$, and $[a]^- = a \wedge 0$. For a process $\{X_k\}$ and a function $f(\cdot)$, let $E_{n,x}\{f(X_k)\}$ denote conditional expectation, given $X_n = x$, and let $E_{n_1, x_1; n_2, x_2}\{f(X_k)\}$ denote conditional expectation, given $X_{n_1} = x_1$ and $X_{n_2} = x_2$ (more precisely, these are suitably fixed versions of the conditional expectation). Also, for a measure $\mu(\cdot)$ and a function $f(\cdot)$, let

$\mu(f) = \int f d\mu$. Finally, let $N(m, R)(\cdot)$ denote normal measure with mean m and covariance matrix R , and let I denote the identity matrix.

2.1. Convergence. In this section, we consider the convergence of the discrete-time algorithm

$$(2.1) \quad X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k.$$

Here $U(\cdot)$ is a smooth real-valued function on \mathbb{R}^d , $\{\xi_k\}$ is a sequence of \mathbb{R}^d -valued random variables, $\{W_k\}$ is a sequence of independent standard d -dimensional Gaussian random variables, and

$$a_k = \frac{A}{k}, \quad b_k = \frac{\sqrt{B}}{\sqrt{k \log \log k}}, \quad k \text{ large},$$

where A, B are positive constants.

For $k = 0, 1, \dots$, let $\mathcal{F}_k = \sigma(X_0, W_0, \dots, W_{k-1}, \xi_0, \dots, \xi_{k-1})$. In the following, we consider the following conditions (α, β are constants whose values are specified later).

Condition 1. $U(\cdot)$ is a C^2 function from \mathbb{R}^d to $[0, \infty)$ such that

$$\begin{aligned} \lim_{|x| \rightarrow \infty} \frac{|\nabla U(x)|}{|x|} &> 0, \\ \lim_{|x| \rightarrow \infty} \left\langle \frac{\nabla U(x)}{|\nabla U(x)|}, \frac{x}{|x|} \right\rangle &= 1, \\ \inf_x (|\nabla U(x)|^2 - \Delta U(x)) &> -\infty. \end{aligned}$$

Condition 2. For $\varepsilon > 0$, let

$$d\pi^\varepsilon(x) = \frac{1}{Z^\varepsilon} \exp\left(-\frac{2U(x)}{\varepsilon^2}\right) dx, \quad Z^\varepsilon = \int \exp\left(-\frac{2U(x)}{\varepsilon^2}\right) dx < \infty.$$

π^ε has a weak limit π as $\varepsilon \rightarrow 0$.

Condition 3. Let K be a compact subset of \mathbb{R}^d . Then there exists $L, k_0 \geq 0$ such that, for every $k \geq k_0$,

$$(2.2a) \quad E\{|\xi_k|^2 | \mathcal{F}_k\} \leq L a_k^\alpha, \quad \forall X_k \in K, \quad \text{with probability one (w.p.1),}$$

$$(2.2b) \quad |E\{\xi_k | \mathcal{F}_k\}| \leq L a_k^\beta, \quad \forall X_k \in K, \quad \text{w.p.1.}$$

W_k is independent of \mathcal{F}_k .

We note that π concentrates on S^* , the global minima of $U(\cdot)$. The existence of π and a simple characterization in terms of $HU(\cdot)$ is discussed in [15].

In [4] and [8], it was shown that there exists a constant C_0 , which plays a critical role in the convergence of (1.1) and (1.3), respectively (in [4] C_0 was denoted by c_0). C_0 has an interpretation in terms of the action functional for the perturbed dynamical systems

$$(2.3) \quad dY^\varepsilon(t) = -\nabla U(Y^\varepsilon(t)) dt + \varepsilon dW(t).$$

Now, for $\phi(\cdot)$ an absolutely continuous function on \mathbb{R}^d , the (normalized) action functional for (2.3) is given by

$$I(t, x, y) = \inf_{\substack{\phi(0)=x \\ \phi(t)=y}} \frac{1}{2} \int_0^t |\dot{\phi}(s) + \nabla U(\phi(s))|^2 ds.$$

According to [4],

$$C_0 = \frac{3}{2} \sup_{x, y \in S_0} (V(x, y) - 2U(y)),$$

where $V(x, y) = \lim_{t \rightarrow \infty} I(t, x, y)$, and S_0 is the set of all the stationary points of $U(\cdot)$, i.e., $S_0 = \{x: \nabla U(x) = 0\}$; see [4] for a further discussion of C_0 , including some examples.

Let $K_1 \subset \mathbb{R}^d$, and let $\{X_k^x\}$ denote the solution of (2.1) with $X_0 = x$. We say that $\{X_k^x: k \geq 0, x \in K_1\}$ is tight if, given $\varepsilon > 0$, there exists a compact $K_2 \subset \mathbb{R}^d$ such that $P_{0,x}\{X_k \in K_2\} > 1 - \varepsilon$ for all $k \geq 0$ and $x \in K_1$. Below is our theorem on the convergence of X_k as $k \rightarrow \infty$.

THEOREM 1. *Assume that Conditions 1-3 hold with $\alpha > -1$ and $\beta > 0$. Let $\{X_k\}$ be given by (2.1), and assume that $\{X_k^x: k \geq 0, x \in K\}$ is tight for K a compact set. Then, for $B/A > C_0$ and any bounded continuous function $f(\cdot)$ on \mathbb{R}^d ,*

$$(2.4) \quad \lim_{k \rightarrow \infty} E_{0,x}\{f(X_k)\} = \pi(f)$$

uniformly for x in a compact set.

Note that since π concentrates on S^* , under the conditions of Theorem 1, we have that $X_k \rightarrow S^*$ as $k \rightarrow \infty$ in probability.

Theorem 1 is the same as [8, Thm. 2], except there we assumed that (2.2) was valid for all $k \geq 0$. However, examination of the proof of [8, Thm. 2] shows that we actually established that

$$(2.5) \quad \lim_{k \rightarrow \infty} E_{0,x;k_0,x_0}\{f(X_k)\} = \pi(f)$$

uniformly for x_0 in a compact set and all x , only assuming that (2.2) is valid for all $k \geq k_0$. It is easy to show that (2.4) follows from (2.5) and the assumption that $\{X_k^x: k \geq 0, x \in K\}$ is tight.

2.2. Tightness. In this section, we consider the tightness of the discrete-time algorithm

$$(2.6) \quad X_{k+1} = X_k - a_k(\psi_k(X_k) + \eta_k) + b_k \sigma_k(X_k) W_k.$$

Here $\{\psi_k(\cdot)\}$ are Borel functions from \mathbb{R}^d to \mathbb{R}^d , $\{\sigma_k(\cdot)\}$ are Borel functions from \mathbb{R}^d to \mathbb{R} , $\{\eta_k\}$ is a sequence of \mathbb{R}^d -valued random variables, and $\{W_k\}, \{a_k\}, \{b_k\}$ are as in § 2.1. Below, we give sufficient conditions for the tightness of $\{X_k^x: k \geq 0, x \in K\}$, where K is a compact subset of \mathbb{R}^d . Note that algorithm (2.6) is somewhat more general than algorithm (2.1). We consider this more general algorithm because it is sometimes convenient to write an algorithm in the form (2.6) (with $\psi_k(x) \neq \nabla U(x)$ for some x, k) to verify tightness, and then to write the algorithm in the form (2.1) to verify convergence. We give an example of this situation when we consider continuous-state Metropolis-type annealing algorithms in §§ 3 and 4.

Let $\mathcal{G}_k = \sigma(X_0, W_0, \dots, W_{k-1}, \eta_0, \dots, \eta_{k-1})$. We consider the following conditions ($\alpha, \beta, \gamma_1, \gamma_2$ are constants whose values are specified later).

Condition 4. Let K be a compact subset of \mathbb{R}^d . Then

$$\sup_{k; x \in K} |\psi_k(x)| < \infty,$$

$$\overline{\lim}_{k, |x| \rightarrow \infty} \frac{|\psi_k(x)|}{|x|} a_k^{\gamma_1} < \infty,$$

$$\lim_{k, |x| \rightarrow \infty} \frac{|\psi_k(x)|}{|x|} a_k^{\gamma_2} > 0,$$

$$\lim_{k, |x| \rightarrow \infty} \left\langle \frac{\psi_k(x)}{|\psi_k(x)|}, \frac{x}{|x|} \right\rangle > 0.$$

Condition 5. Let K be a compact subset of \mathbb{R}^d . Then

$$\sup_{k; x \in K} |\sigma_k(x)| < \infty, \quad \overline{\lim}_{k, |x| \rightarrow \infty} \frac{|\sigma_k(x)|}{|x|} < \infty.$$

Condition 6. There exists $L \geq 0$ such that

$$(2.7a) \quad E\{|\eta_k|^2 | \mathcal{G}_k\} \leq La_k^\alpha (|X_k|^2 + 1) \quad \text{w.p.1,}$$

$$(2.7b) \quad |E\{\eta_k | \mathcal{G}_k\}| \leq La_k^\beta (|X_k| + 1) \quad \text{w.p.1.}$$

W_k is independent of \mathcal{G}_k .

THEOREM 2. Assume that Conditions 4–6 hold with $\alpha > -1$, $\beta > 0$, and $0 \leq \gamma_2 \leq \gamma_1 < \frac{1}{2}$. Let $\{X_k\}$ be given by (2.6), and let K be a compact subset of \mathbb{R}^d . Then $\{X_k^x: k \geq 0, x \in K\}$ is a tight family of random variables.

Theorem 2 is proved similarly to [8, Thm. 3], where we assumed that $\sigma_k(\cdot) = 1$ and did not allow the bounds in (2.7) to be state-dependent. The extension to the present case is straightforward.

3. Metropolis-type annealing algorithms. In this section, we review the finite-state Metropolis-type Markov-chain annealing algorithm, generalize it to an arbitrary state space, and then specialize it to a class of algorithms for which the results in § 2 can be applied to establish convergence.

The finite-state Metropolis-type annealing algorithm may be described as follows [12]. Assume that the state space Σ is finite set. Let $U(\cdot)$ be a real-valued function on Σ (the “energy” function) and $\{T_k\}$ be a sequence of strictly positive numbers (the “temperature” sequence). Let $q(i, j)$ be a stationary transition probability from i to j , for $i, j \in \Sigma$. The one-step transition probability at time k for the finite-state Metropolis-type annealing chain $\{X_k\}$ is given by

$$(3.1) \quad P\{X_{k+1} = j | X_k = i\} = q(i, j) s_k(i, j), \quad j \neq i,$$

$$P\{X_{k+1} = i | X_k = i\} = 1 - \sum_{j \neq i} q(i, j) s_k(i, j),$$

where

$$(3.2) \quad s_k(i, j) = \exp \left(- \frac{[U(j) - U(i)]^+}{T_k} \right).$$

This nonstationary Markov chain may be interpreted (and simulated) in the following manner. Given the current state $X_k = i$, generate a candidate state $\tilde{X}_k = j$ with probability $q(i, j)$. Set the next state $X_{k+1} = j$ if $s_k(i, j) > \theta_k$, where θ_k is an independent random variable uniformly distributed on the interval $[0, 1]$; otherwise, set $X_{k+1} = i$. Suppose that the stochastic transition matrix $Q = [q(i, j)]$ is symmetric, i.e., $q(i, j) = q(j, i)$, and the temperature T_k is fixed at a constant $T > 0$. Then it is easy to show that the resulting stationary Markov chain has a Gibbs invariant measure with mass $\propto \exp(-U(i)/T)$. Furthermore, if the chain is recurrent, then the chain, in fact, has a unique Gibbs

invariant probability measure, and the transition probabilities converge to the Gibbs probabilities as $k \rightarrow \infty$ for all initial states. Of course, if a finite-state Markov chain is irreducible, then it is recurrent. There has been much work on the convergence and asymptotic behavior of the nonstationary annealing chain when $T_k \rightarrow 0$ [3], [5], [9], [12], [14], [21], [24], [25].

We next generalize the finite-state Metropolis-type annealing algorithm (3.1), (3.2) to a general state space. In the formulation and analysis of general state space Markov chains, it is usually assumed that the state space Σ is a σ -finite measure space, say (Σ, Λ, μ) (see [22, Chap. 1] for a thorough discussion of general state space Markov chains). Let $U(\cdot)$ be a real-valued measurable function on such a Σ , and let $\{T_k\}$ be as above. Let $q(x, y)$ be a stationary transition probability density with respect to μ from x to y , for $x, y \in \Sigma$. The one-step transition probability at time k for the general state Metropolis-type annealing chain $\{X_k\}$ is given by

$$(3.3) \quad P\{X_{k+1} \in A | X_k = x\} = \int_A q(x, y) s_k(x, y) d\mu(y) + r_k(x) 1_A(x),$$

where

$$(3.4) \quad s_k(x, y) = \exp\left(-\frac{[U(y) - U(x)]^+}{T_k}\right)$$

($r_k(x)$ gives the appropriate normalization, i.e., $r_k(x) = 1 - \int q(x, y) s_k(x, y) d\mu(y)$). Note that if μ does not have an atom at x , then $r_k(x)$ is the self transition probability starting at state x at time k . Also, note that (3.3), (3.4) reduces to (3.1), (3.2) when the state space is finite and μ is counting measure. The general state chain may be interpreted (and simulated) similarly to the finite-state chain: here $q(x, y)$ is a conditional probability density for generating a candidate state $\tilde{X}_k = y$, given the current state $X_k = x$. Suppose that the stochastic transition function $Q(x, A) = \int_A q(x, y) d\mu(y)$ is symmetric, i.e., $q(x, y) = q(y, x)$, and the temperature T_k is fixed at a constant $T > 0$. Then it is easy to show that the resulting stationary Markov chain has a Gibbs invariant measure with density (with respect to μ) $\propto \exp(-U(x)/T)$. Furthermore, if this measure is finite and the chain is μ -recurrent,¹ then the chain, in fact, has a unique Gibbs invariant probability measure, and the transition probability measure converges to the Gibbs measure (in the total variation norm) as $k \rightarrow \infty$ for all initial states [22, Thm. 7.1, p. 30]. It is known that if a chain is μ -irreducible² and satisfies a certain condition due to Doeblin [6, Hyp. (D), p. 192], then it is μ -recurrent. In [7, Chap. 3], we use this theory to give some sufficient conditions for the ergodicity of general state Metropolis-type Markov chains when Σ is a compact metric space and μ is a finite Borel measure. However, there has been almost no work on the convergence and asymptotic behavior of the nonstationary annealing chain when $T_k \rightarrow 0$, although, when Σ is a compact metric space, we would expect the behavior to be similar to when Σ is finite.

We next specialize the general state Metropolis-type annealing algorithm (3.3), (3.4) to a d -dimensional Euclidean state space. This is the most important case and the one that has seen application [16], [23]. Actually, the Metropolis-type annealing chain that we consider is not exactly a specialization of the general state chain described above. Motivated by our desire to show convergence of the chain by writing it in the

¹ If, for every $x \in \Sigma$ and $A \in \Lambda$ such that $\mu(A) > 0$, $P_{0,x} \bigcup_{k=1}^{\infty} \{X_k \in A\} = 1$, then $\{X_k^x\}$ is μ -recurrent.

² If, for every $x \in \Sigma$ and $A \in \Lambda$ such that $\mu(A) > 0$, $P_{0,x} \bigcup_{k=1}^{\infty} \{X_k \in A\} > 0$, then $\{X_k^x\}$ is μ -irreducible.

form of the modified stochastic gradient algorithm (2.1), we are led to choosing a nonstationary Gaussian transition density

$$(3.5) \quad q_k(x, y) = \frac{1}{(2\pi b_k^2 \sigma_k^2(x))^{d/2}} \exp\left(-\frac{1}{2} \frac{|y-x|^2}{b_k^2 \sigma_k^2(x)}\right),$$

and a state-dependent temperature sequence

$$(3.6) \quad T_k(x) = \frac{b_k^2 \sigma_k^2(x)}{2a_k} \left(= \frac{\text{const } \sigma_k^2(x)}{\log \log k} \right),$$

where

$$(3.7) \quad \sigma_k(x) = (\delta_k |x|) \vee 1, \quad \delta_k \downarrow 0.$$

To understand these choices, suppose that x lies in some fixed compact set. Then, for k large enough,

$$(3.8) \quad q_k(x, y) = \frac{1}{(2\pi b_k^2)^{d/2}} \exp\left(-\frac{1}{2} \frac{|y-x|^2}{b_k^2}\right)$$

and

$$(3.9) \quad T_k(x) = T_k = \frac{b_k^2}{2a_k}.$$

The choice of the transition density (3.8) is clear, given that we want to write the chain in the form (2.1). The choice of the temperature schedule (3.9) is also clear if we view (2.1) as a sampled version of the associated diffusion (1.1) with sampling intervals a_k and sampling times $t_k = \sum_{n=0}^{k-1} a_n$, since then we should have the corresponding sampled temperatures $T(t_k) = c^2(t_k)/2$. Indeed, it is straightforward to check that, if $C = B/A$, then

$$T_k = \frac{b_k^2}{2a_k} \sim \frac{c^2(t_k)}{2} = T(t_k) \quad \text{as } k \rightarrow \infty$$

(recall that $a_k = A/k$, $b_k^2 = B/k \log \log k$, and $c^2(t) = C/\log t$ for large k, t). Finally, the reason that the $|x|$ dependence is needed in $\sigma_k(x)$, and hence both (3.5), (3.6), is that to establish tightness of the annealing chain by writing the chain in the form of (2.6), we need a condition similar to the following:

$$|\psi_k(x)| \geq \text{const } |x|, \quad |x| \text{ large, } k \text{ fixed,}$$

for suitable choice of $\psi_k(\cdot)$. In other words, the annealing chain must generate a drift (toward the origin) at least proportional to the distance from the origin. This discussion leads us to the following continuous-state Metropolis-type Markov-chain annealing algorithm and convergence result. To establish convergence, we must assume, along with Conditions 1 and 2, the following condition.

Condition 7. It holds that

$$\inf_{\delta > 0} \overline{\lim}_{|x| \rightarrow \infty} \sup_{|y-x| < \delta |x|} |HU(y)| \frac{|x|^2}{U(x)} < \infty.$$

This condition is satisfied if, for example, $U(x) \sim \text{const } |x|^p$ and $HU(x) = O(|x|^{p-2})$ as $|x| \rightarrow \infty$, for some $p \geq 2$.

Metropolis-Type Annealing Algorithm 1. Let $\{X_k\}$ be a Markov chain with one-step transition probability at time k given by

$$(3.10) \quad P\{X_{k+1} \in A \mid X_k = x\} = \int_A s_k(x, y) dN(x, b_k^2 \sigma_k^2(x) I)(y) + r_k(x) 1_A(x),$$

where

$$(3.11) \quad \sigma_k(x) = (a_k^\gamma |x|) \vee 1,$$

$$(3.12) \quad s_k(x, y) = \exp \left(-\frac{2a_k [U(y) - U(x)]^+}{b_k^2 \sigma_k^2(x)} \right),$$

and $\gamma > 0$ ($r_k(x)$ gives the correct normalization).

THEOREM 3. Assume that Conditions 1, 2, and 7 hold, and also that

$$(3.13) \quad \overline{\lim}_{|x| \rightarrow \infty} \frac{|\nabla U(x)|}{|x|} < \infty.$$

Let $\{X_k\}$ be the Markov chain with transition probability given by (3.10)–(3.12) and with $0 < \gamma < \frac{1}{4}$. Then, for $B/A > C_0$ and any bounded continuous function $f(\cdot)$ on \mathbb{R}^d ,

$$(3.14) \quad \lim_{k \rightarrow \infty} E_{0,x}\{f(X_k)\} = \pi(f)$$

uniformly for x in a compact set.

The proof of Theorem 3 is in § 4.1. Observe that the conditions of Theorem 3 are satisfied if, for example, $\nabla U(x) \sim \text{const } x$ and $HU(x) = O(1)$ as $|x| \rightarrow \infty$. We can allow for faster growth in $\nabla U(x)$ by using a suitable modification of (3.12).

Metropolis-Type Annealing Algorithm 2. Let $\{X_k\}$ be a Markov chain with one-step transition probability at time k given by

$$(3.15) \quad P\{X_{k+1} \in A \mid X_k = x\} = \int_A s_k(x, y) dN(x, b_k^2 \sigma_k^2(x) I)(y) + r_k(x) 1_A(x),$$

where

$$(3.16) \quad \sigma_k(x) = (a_k^\gamma |x|) \vee 1,$$

$$(3.17) \quad s_k(x, y) = \exp \left(-\frac{2a_k [U(y) - U(x)]^+}{b_k^2 \sigma_k^2(x)} \right) \quad \text{if } U(x) \leq \frac{|x|^2 + 1}{a_k^\gamma}$$

$$= \exp \left(-\frac{2a_k [|y|^2 - |x|^2]^+}{b_k^2 \sigma_k^2(x)} \right) \quad \text{if } U(x) > \frac{|x|^2 + 1}{a_k^\gamma},$$

and $\gamma > 0$ ($r_k(x)$ gives the correct normalization). Note that if K is any fixed compact, $X_{k=x} \in K$, and k is very large, then (3.17) and (3.12) coincide. Note also that (3.17), like (3.12), only uses measurements of $U(\cdot)$ (and not $\nabla U(\cdot)$).

THEOREM 4. Assume that Conditions 1, 2, and 7 hold, and also that

$$(3.18) \quad \overline{\lim}_{|x| \rightarrow \infty} |\nabla U(x)| \frac{|x|}{U(x)} < \infty.$$

Let $\{X_k\}$ be the Markov chain with transition probability given by (3.15)–(3.17) and with $0 < \gamma < \frac{1}{8}$. Then, for $B/A > C_0$ and any bounded continuous function $f(\cdot)$ on \mathbb{R}^d ,

$$(3.19) \quad \lim_{k \rightarrow \infty} E_{0,x}\{f(X_k)\} = \pi(f)$$

uniformly for x in a compact set.

The proof of Theorem 4 is in § 4.2. Observe that the conditions of Theorem 4 are satisfied if, for example, $\nabla U(x) \sim \text{const } |x|^{p-2}x$ and $HU(x) = O(|x|^{p-2})$ as $|x| \rightarrow \infty$, for some $p \geq 2$.

4. Proofs of Theorems 3 and 4. In the following, c_1, c_2, \dots denotes positive constants whose value may change from proof to proof. We need the following lemma.

LEMMA 1. Assume that $V(\cdot)$ is a C^2 function from \mathbb{R}^d to \mathbb{R} . Let

$$s(x, y) = \exp(-\lambda[V(y) - V(x)]^+)$$

and

$$\hat{s}(x, y) = \exp(-\lambda[\langle \nabla V(x), y - x \rangle]^+),$$

where $\lambda > 0$. Then

$$|s(x, y) - \hat{s}(x, y)| \leq \lambda \sup_{\varepsilon \in (0,1)} |HV(x + \varepsilon(y - x))| |y - x|^2$$

for all $x, y \in \mathbb{R}^d$.

Proof. Let

$$f(x, y) = V(y) - V(x) - \langle \nabla V(x), y - x \rangle.$$

Then, by the second-order Taylor theorem,

$$(4.1) \quad |f(x, y)| \leq \sup_{\varepsilon \in (0,1)} |HV(x + \varepsilon(y - x))| |y - x|^2.$$

By separately considering the four cases corresponding to the possible signs of $V(y) - V(x)$ and $\langle \nabla V(x), y - x \rangle$, it can be shown that

$$(4.2) \quad |s(x, y) - \hat{s}(x, y)| \leq 1 - \exp(-\lambda|f(x, y)|) \leq \lambda|f(x, y)|.$$

Combining (4.1) and (4.2) completes the proof. \square

4.1. Proof of Theorem 3. We write

$$(4.3) \quad X_{k+1} = X_k - a_k(\nabla U(X_k) + \xi_k) + b_k W_k$$

(this defines ξ_k) and apply Theorem 1 to show that, if $\{X_k^x; k \geq 0, x \in K\}$ is tight for K compact, then (3.14) is true. We further let $\psi(x) = \nabla U(x)$, write

$$(4.4) \quad X_{k+1} = X_k - a_k(\psi(X_k) + \eta_k) + b_k \sigma_k(X_k) W_k$$

(this defines η_k), and apply Theorem 2 to show that $\{X_k^x; k \geq 0, x \in K\}$ is, in fact, tight for K compact, and that (3.14) is, in fact, true.

We first show that we can find a version of $\{X_k\}$ in the form

$$(4.5) \quad X_{k+1} = X_k + b_k \sigma_k(X_k) \zeta_k W_k.$$

To do this, we inductively define the sequence $\{W_k, \zeta_k\}$ of random variables as follows. Assume that $X_0, W_0, \dots, W_{k-1}, \zeta_0, \dots, \zeta_{k-1}$ have been defined. Let W_k be a standard d -dimensional Gaussian random variable independent of $X_0, W_0, \dots, W_{k-1}, \zeta_0, \dots, \zeta_{k-1}$, and let ζ_k be a $\{0, 1\}$ -valued random variable with

$$(4.6) \quad P\{\zeta_k = 1 | X_0, W_0, \dots, W_k, \zeta_0, \dots, \zeta_{k-1}\} = s_k(X_k, X_k + b_k \sigma_k(X_k) W_k).$$

Using (4.6), it is easy to check that (4.5) is a Markov chain that has transition probability given by (3.10)–(3.12). Hence (4.5) is indeed a version of $\{X_k\}$, and we henceforth always deal with this version.

Now, comparing (4.3) and (4.4) with (4.5), we have that

$$(4.7) \quad \xi_k = -\nabla U(X_k) + \frac{b_k}{a_k} (1 - \sigma_k(X_k) \zeta_k) W_k$$

and

$$(4.8) \quad \eta_k = -\psi(X_k) + \frac{b_k}{a_k} \sigma_k(X_k) (1 - \zeta_k) W_k.$$

Furthermore, it is easy to show that W_k is independent of \mathcal{F}_k and \mathcal{G}_k , and also that $P\{\xi_k \in \cdot \mid \mathcal{F}_k\} = P\{\xi_k \in \cdot \mid X_k\}$ and $P\{\eta_k \in \cdot \mid \mathcal{G}_k\} = P\{\eta_k \in \cdot \mid X_k\}$. We use these facts below.

The following lemmas give the crucial estimates for $E\{|\xi_k|^2 \mid \mathcal{F}_k\}$, $E\{\xi_k \mid \mathcal{F}_k\}$, $E\{|\eta_k|^2 \mid \mathcal{G}_k\}$, and $E\{\eta_k \mid \mathcal{G}_k\}$.

LEMMA 2. *Let K be a compact subset of \mathbb{R}^d . There exists $L, k_0 \geq 0$ such that, for every $k \geq k_0$,*

- (a) $|E\{\xi_k \mid \mathcal{F}_k\}| \leq L(a_k/b_k)$ for all $X_k \in K$, w.p.1;
- (b) $E\{|\xi_k|^2 \mid \mathcal{F}_k\} \leq L(b_k/a_k)$ for all $X_k \in K$, w.p.1.

LEMMA 3. *There exists $L \geq 0$ such that*

- (a) $|E\{\eta_k \mid \mathcal{G}_k\}| \leq L(a_k^{1-2\gamma}/b_k)(|X_k|+1)$ w.p.1;
- (b) $E\{|\eta_k|^2 \mid \mathcal{G}_k\} \leq L(b_k/a_k^{1+\gamma})(|X_k|^2+1)$ w.p.1.

Assume that Lemmas 2 and 3 are true. Then Condition 3 is satisfied with $\alpha = -\frac{1}{2} > -1$ and $0 < \beta < \frac{1}{2}$. Conditions 4–6 are satisfied for $\alpha = -\frac{1}{2} - \gamma > -1$, $0 < \beta < \frac{1}{2} - 2\gamma$, and $\gamma_1 = \gamma_2 = 0$ (recall that we assume that $0 < \gamma < \frac{1}{4}$). Hence Theorems 1 and 2 apply, and Theorem 3 follows. It remains to prove Lemmas 2 and 3. We use the following claim.

CLAIM. *Let $u \in \mathbb{R}^d$ with $|u| = 1$. Then*

- (a) $\int_{0 \leq \langle u, w \rangle \leq \delta} dN(0, I)(w) = O(\delta)$;
- (b) $\int_{0 \leq \langle u, w \rangle \leq \delta} w dN(0, I)(w) = O(\delta^2)$;
- (c) $\int_{0 \leq \langle u, w \rangle \leq \delta} w \otimes w dN(0, I)(w) = O(\delta)$.

Proof. Let $u_1 = u$, and extend u_1 to an orthonormal basis $\{u_1, \dots, u_d\}$ for \mathbb{R}^d . Then, by changing variables (rotation) and using the mean value theorem, we obtain that

$$\begin{aligned}
 (a) \quad & \int_{0 \leq \langle u, w \rangle \leq \delta} dN(0, I)(w) = \int_0^\delta \frac{1}{(2\pi)^{1/2}} \exp\left(-\frac{v^2}{2}\right) dv = O(\delta); \\
 (b) \quad & \int_{0 \leq \langle u, w \rangle \leq \delta} w dN(0, I)(w) = u_1 \int_0^\delta v \frac{1}{(2\pi)^{1/2}} \exp\left(-\frac{v^2}{2}\right) dv = O(\delta^2); \\
 (c) \quad & \int_{0 \leq \langle u, w \rangle \leq \delta} w \otimes w dN(0, I)(w) = u_1 \otimes u_1 \int_0^\delta v^2 \frac{1}{(2\pi)^{1/2}} \exp\left(-\frac{v^2}{2}\right) dv \\
 & \quad + \sum_{i=2}^d u_i \otimes u_i \int_0^\delta \frac{1}{(2\pi)^{1/2}} \exp\left(-\frac{v^2}{2}\right) dv = O(\delta).
 \end{aligned}$$

□

Proof of Lemma 2(a). Since K is compact and $a_k^\gamma \rightarrow 0$, we can choose k_0 such that $a_k^\gamma |X_k| \leq 1$ (and so $\sigma_k(X_k) = 1$) for all $X_k \in K$ and $k \geq k_0$. Hence, using (4.7) and the fact that $P\{\xi_k \in \cdot \mid \mathcal{F}_k\} = P\{\xi_k \in \cdot \mid X_k\}$ and W_k is independent of X_k , we have, for $k \geq k_0$ and $X_k \in K$ (w.p.1), that

$$\begin{aligned}
 (4.9) \quad & E\{\xi_k \mid \mathcal{F}_k\} = E\{\xi_k \mid X_k\} \\
 & = -\nabla U(X_k) + \frac{b_k}{a_k} E\{(1 - \zeta_k) W_k \mid X_k\} \\
 & = -\nabla U(X_k) - \frac{b_k}{a_k} E\{W_k E\{\zeta_k \mid X_k, W_k\} \mid X_k\} \\
 & = -\nabla U(X_k) - \frac{b_k}{a_k} E\{W_k P\{\zeta_k = 1 \mid X_k, W_k\} \mid X_k\} \\
 & = -\nabla U(X_k) - \frac{b_k}{a_k} E\{W_k P\{\zeta_k = 1 \mid X_k, W_k\}\}.
 \end{aligned}$$

Henceforth, we assume that $k \geq k_0$ and condition on $X_k = x \in K$. Then, using (4.6), we obtain that

$$(4.10) \quad E\{\xi_k | X_k = x\} = -\nabla U(x) - \frac{b_k}{a_k} \int w s_k(x, x + b_k w) dN(0, I)(w).$$

Let

$$(4.11) \quad \hat{s}_k(x, y) = \exp\left(-\frac{2a_k}{b_k^2} [\langle \nabla U(x), y - x \rangle]^+\right)$$

and $\tilde{s}_k(x, y) = s_k(x, y) - \hat{s}_k(x, y)$. Using the fact that $HU(\cdot) = O(1)$ on a compact, we obtain that, for any fixed $\delta > 0$,

$$\sup_{\varepsilon \in (0,1)} |HU(x + \varepsilon(y - x))| \leq c_1,$$

for all $|y - x| < \delta$. Hence, using Lemma 1,

$$(4.12) \quad |\tilde{s}_k(x, y)| \leq c_2 \frac{a_k}{b_k^2} |y - x|^2, \quad |y - x| < \delta.$$

Of course,

$$(4.13) \quad |\tilde{s}_k(x, y)| \leq 1.$$

Using (4.12), (4.13), and a standard estimate for the tail probability of a Gaussian random variable, we obtain, for $i \geq 0$, that

$$\begin{aligned} & \int |w|^i |\tilde{s}_k(x, x + b_k w)| dN(0, I)(w) \\ & \leq \int_{|w| \leq \delta/b_k} |w|^i |\tilde{s}_k(x, x + b_k w)| dN(0, I)(w) \\ (4.14) \quad & + \int_{|w| > \delta/b_k} |w|^i |\tilde{s}_k(x, x + b_k w)| dN(0, I)(w) \\ & \leq c_3 a_k + c_3 \exp\left(-\frac{c_4}{b_k^2}\right) \\ & = O(a_k). \end{aligned}$$

Now, expanding (4.10) and using (4.14) gives

$$\begin{aligned} E\{\xi_k | X_k = x\} &= -\nabla U(x) - \frac{b_k}{a_k} \int w \hat{s}_k(x, x + b_k w) dN(0, I)(w) \\ &\quad - \frac{b_k}{a_k} \int w \tilde{s}_k(x, x + b_k w) dN(0, I)(w) \\ (4.15) \quad &= -\nabla U(x) - \frac{b_k}{a_k} \int w \hat{s}_k(x, x + b_k w) dN(0, I)(w) \\ &\quad + O(b_k) \end{aligned}$$

$$\begin{aligned} (4.16) \quad &= -\nabla U(x) - \frac{b_k}{a_k} \int_{\langle \nabla U(x), w \rangle \leq 0} w dN(0, I)(w) \\ &\quad - \frac{b_k}{a_k} \int_{\langle \nabla U(x), w \rangle > 0} w \exp\left(-\frac{2a_k}{b_k} \langle \nabla U(x), w \rangle\right) dN(0, I)(w) \\ &\quad + O(b_k). \end{aligned}$$

Clearly,

$$(4.17) \quad E\{\xi_k | X_k = x\} = O(b_k)$$

for x such that $\nabla U(x) = 0$. Henceforth, we assume that $\nabla U(x) \neq 0$. Let $\nabla \hat{U}(x) = \nabla U(x)/|\nabla U(x)|$. Completing the square in the second integral in (4.16), we obtain that

$$(4.18) \quad \begin{aligned} E\{\xi_k | X_k = x\} &= -\nabla U(x) - \frac{b_k}{a_k} \int_{\langle \nabla \hat{U}(x), w \rangle \leq 0} w dN(0, I)(w) \\ &\quad - \frac{b_k}{a_k} \int_{\langle \nabla \hat{U}(x), w \rangle \geq 0} w \exp\left(2\left(\frac{a_k}{b_k}\right)^2 |\nabla U(x)|^2\right) dN\left(\frac{2a_k}{b_k} \nabla U(x), I\right)(w) \\ &\quad + O(b_k). \end{aligned}$$

Now $\nabla U(x) = O(1)$, and so

$$(4.19) \quad \exp\left(2\left(\frac{a_k}{b_k}\right)^2 |\nabla U(x)|^2\right) = 1 + O\left(\left(\frac{a_k}{b_k}\right)^2\right).$$

Substituting (4.19) into (4.18), using $\nabla U(x) = O(1)$ and $a_k/b_k = O(1)$, and changing variables from $w + 2(a_k/b_k)\nabla U(x)$ to w , gives

$$(4.20) \quad \begin{aligned} E\{\xi_k | X_k = x\} &= -\nabla U(x) - \frac{b_k}{a_k} \int_{\langle \nabla \hat{U}(x), w \rangle \leq 0} w dN(0, I)(w) \\ &\quad - \frac{b_k}{a_k} \int_{\langle \nabla \hat{U}(x), w \rangle \geq O(a_k/b_k)} w dN(0, I)(w) \\ &\quad + 2\nabla U(x) \int_{\langle \nabla \hat{U}(x), w \rangle \geq O(a_k/b_k)} dN(0, I)(w) \\ &\quad + O\left(\frac{a_k}{b_k}\right) + O(b_k) \\ &= \frac{b_k}{a_k} \int_{0 \leq \langle \nabla \hat{U}(x), w \rangle \leq O(a_k/b_k)} w dN(0, I)(w) \\ &\quad - 2\nabla U(x) \int_{0 \leq \langle \nabla \hat{U}(x), w \rangle \leq O(a_k/b_k)} dN(0, I)(w) \\ &\quad + O\left(\frac{a_k}{b_k}\right). \end{aligned}$$

Hence, by (a) and (b) of the claim, and by again using $\nabla U(x) = O(1)$, we have that

$$(4.21) \quad E\{\xi_k | X_k = x\} = O\left(\frac{a_k}{b_k}\right).$$

Combining (4.17) and (4.21) completes the proof of Lemma 2(a). \square

Proof of Lemma 2(b). As in the proof of Lemma 2(a), choose k_0 such that $a_k^\gamma |X_k| \leq 1$ (and so $\sigma_k(X_k) = 1$) for all $X_k \in K$ and $k \geq k_0$. Hence, using (4.7) and the fact that

$P\{\xi_k \in \cdot | \mathcal{F}_k\} = P\{\xi_k \in \cdot | X_k\}$, W_k is independent of X_k , and $\nabla U(\cdot) = O(1)$ on a compact, we have, for $k \geq k_0$ and $X_k \in K$ (w.p.1), that

$$\begin{aligned}
 E\{\xi_k \otimes \xi_k | \mathcal{F}_k\} &= E\{\xi_k \otimes \xi_k | X_k\} \\
 &= \left(\frac{b_k}{a_k}\right)^2 E\{((1 - \zeta_k) W_k) \otimes ((1 - \zeta_k) W_k) | X_k\} + e_k(X_k) \\
 (4.22) \quad &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 E\{W_k \otimes W_k E\{\zeta_k | X_k, W_k\} | X_k\} + e_k(X_k) \\
 &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 E\{W_k \otimes W_k P\{\zeta_k = 1 | X_k, W_k\} | X_k\} + e_k(X_k) \\
 &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 E_{W_k}\{W_k \otimes W_k P\{\zeta_k = 1 | X_k, W_k\}\} + e_k(X_k),
 \end{aligned}$$

where

$$\begin{aligned}
 e_k(X_k) &= O\left(\frac{b_k}{a_k} |\nabla U(X_k)| + |\nabla U(X_k)|^2\right) \\
 &= O\left(\frac{b_k}{a_k}\right).
 \end{aligned}$$

Henceforth, we assume that $k \geq k_0$ and condition on $X_k = x \in K$. Then, using (4.6), we obtain that

$$\begin{aligned}
 E\{\xi_k \otimes \xi_k | X_k = x\} &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int w \otimes w s_k(x, x + b_k w) dN(0, I)(w) \\
 (4.23) \quad &+ O\left(\frac{b_k}{a_k}\right).
 \end{aligned}$$

Let $\hat{s}_k(x, y)$ be given by (4.11) and $\tilde{s}_k(x, y) = s_k(x, y) - \hat{s}_k(x, y)$. Then, expanding (4.23) and using (4.14), gives

$$\begin{aligned}
 E\{\xi_k \otimes \xi_k | X_k = x\} &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int w \otimes w \hat{s}_k(x, x + b_k w) dN(0, I)(w) \\
 &\quad - \left(\frac{b_k}{a_k}\right)^2 \int w \otimes w \tilde{s}_k(x, x + b_k w) dN(0, I)(w) \\
 &\quad + O\left(\frac{b_k}{a_k}\right) \\
 (4.24) \quad &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int w \otimes w \hat{s}_k(x, x + b_k w) dN(0, I)(w) \\
 &\quad + O\left(\frac{b_k^2}{a_k}\right) + O\left(\frac{b_k}{a_k}\right)
 \end{aligned}$$

$$\begin{aligned}
 (4.25) \quad &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \nabla U(x), w \rangle \leq 0} w \otimes w dN(0, I)(w) \\
 &\quad - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \nabla U(x), w \rangle > 0} w \otimes w \\
 &\quad \cdot \exp\left(-\frac{2a_k}{b_k} \langle \nabla U(x), w \rangle\right) dN(0, I)(w) \\
 &\quad + O\left(\frac{b_k}{a_k}\right).
 \end{aligned}$$

Clearly,

$$(4.26) \quad E\{\xi_k \otimes \xi_k \mid X_k = x\} = O\left(\frac{b_k}{a_k}\right)$$

for x such that $\nabla U(x) = 0$. Henceforth, we assume that $\nabla U(x) \neq 0$. Let $\nabla \hat{U}(x) = \nabla U(x)/|\nabla U(x)|$. Completing the square in the second integral in (4.25), we obtain that

$$(4.27) \quad \begin{aligned} E\{\xi_k \otimes \xi_k \mid X_k = x\} &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \hat{U}(x), w \rangle \leq 0} w \otimes w dN(0, I)(w) \\ &\quad - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \nabla \hat{U}(x), w \rangle \geq 0} w \otimes w \\ &\quad \cdot \exp\left(2\left(\frac{a_k}{b_k}\right)^2 (|\nabla U(x)|)^2\right) dN\left(-\frac{2a_k}{b_k} \nabla U(x), I\right)(w) \\ &\quad + O\left(\frac{b_k}{a_k}\right). \end{aligned}$$

Substituting (4.19) into (4.27), using $\nabla U(x) = O(1)$ and $a_k/b_k = O(1)$, and changing variables from $w + 2(a_k/b_k)\nabla U(x)$ to w gives

$$(4.28) \quad \begin{aligned} E\{\xi_k \otimes \xi_k \mid X_k = x\} &= \left(\frac{b_k}{a_k}\right)^2 I - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \nabla \hat{U}(x), w \rangle \leq 0} w \otimes w dN(0, I)(w) \\ &\quad - \left(\frac{b_k}{a_k}\right)^2 \int_{\langle \nabla \hat{U}(x), w \rangle \geq O(a_k/b_k)} w \otimes w dN(0, I)(w) \\ &\quad + O(1) + O\left(\frac{b_k}{a_k}\right) \\ &= \left(\frac{b_k}{a_k}\right)^2 \int_{0 \leq \langle \nabla \hat{U}(x), w \rangle \leq O(a_k/b_k)} w \otimes w dN(0, I)(w) \\ &\quad + O\left(\frac{b_k}{a_k}\right). \end{aligned}$$

Hence, by part (c) of the Claim,

$$(4.29) \quad E\{\xi_k \otimes \xi_k \mid X_k = x\} = O\left(\frac{b_k}{a_k}\right).$$

Combining (4.26) and (4.29) and using $|\xi_k|^2 \leq |\xi_k \otimes \xi_k|$ completes the proof of Lemma 2(b). \square

Proof of Lemma 3. Using (4.8) and the fact that $P\{\eta_k \in \cdot \mid \mathcal{G}_k\} = P\{\eta_k \in \cdot \mid X_k\}$, W_k is independent of X_k , and $\psi(x) = \nabla U(x) = O(|x| + 1)$, we get, similarly to (4.9) and (4.22), that

$$E\{\eta_k \mid \mathcal{G}_k\} = -\psi(X_k) - \frac{b_k}{a_k} \sigma_k(X_k) E\{W_k P\{\zeta_k = 1 \mid X_k, W_k\}\}$$

and

$$E\{\eta_k \otimes \eta_k | \mathcal{G}_k\} = \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(X_k) I \\ - \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(X_k) E_{W_k} \{W_k \otimes W_k P\{\zeta_k = 1 | X_k, W_k\}\} + e_k(X_k),$$

where

$$e_k(X_k) = O\left(\frac{b_k}{a_k} \sigma_k(X_k) |\psi(X_k)| + |\psi(X_k)|^2\right) \\ = O\left(\frac{b_k}{a_k} \sigma_k(X_k) (|X_k| + 1) + |X_k|^2\right).$$

Henceforth, we condition on $X_k = x$ and assume, for simplicity, that $|x| \geq 1$ and $a_k \leq 1$.

Let

$$(4.30) \quad \hat{s}_k(x, y) = \exp\left(-\frac{2a_k [\langle \nabla U(x), y - x \rangle]^+}{b_k^2 \sigma_k^2(x)}\right)$$

and $\tilde{s}_k(x, y) = s_k(x, y) - \hat{s}_k(x, y)$. Using Condition 7, we obtain, for some $\delta > 0$, that

$$\sup_{\varepsilon \in (0, 1)} |HU(x + \varepsilon(y - x))| \leq c_1 \left(\frac{U(x)}{|x|^2} + 1\right)$$

for all $|y - x| < \delta|x|$. By assumption, however, $\nabla U(x) = O(|x|)$, and so, by the mean value theorem, $U(x) = O(|x|^2)$. Hence, using Lemma 1, we obtain that

$$|\tilde{s}_k(x, y)| \leq c_2 \frac{a_k}{b_k^2} \frac{|y - x|^2}{\sigma_k^2(x)}, \quad |y - x| < \delta \sigma_k(x),$$

and, similarly to the derivation of (4.14), we obtain that

$$(4.31) \quad \int |w|^i \tilde{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) = O(a_k).$$

Next, using (4.31), we obtain, similarly to the derivation of (4.15) and (4.24), that

$$E\{\eta_k | X_k = x\} = -\psi(x) - \frac{b_k}{a_k} \sigma_k(x) \int w \hat{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) \\ + O(b_k \sigma_k(x))$$

and

$$E\{\eta_k \otimes \eta_k | X_k = x\} = \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(x) I \\ - \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(x) \int w \otimes w \hat{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) \\ + O\left(\frac{b_k^2}{a_k} \sigma_k^2(x)\right) + O\left(\frac{b_k}{a_k} \sigma_k(x) |x| + |x|^2\right).$$

At this point, we separately consider the cases where $a_k^\gamma |x| \leq 1$ and > 1 ($\sigma_k(x) = 1$ and $a_k^\gamma |x|$, respectively). Proceeding as in the proof of Lemma 2 and using $\psi(x) = O(|x|)$ and $a_k^{1-\gamma}/b_k = O(1)$, we can show that

$$\begin{aligned} E\{\eta_k | X_k = x\} &= O\left(\frac{a_k^{1-2\gamma}}{b_k}\right), & a_k^\gamma |x| \leq 1, \\ &= O\left(\frac{a_k^{1-\gamma}}{b_k} |x|\right), & a_k^\gamma |x| > 1, \end{aligned}$$

and

$$\begin{aligned} E\{\eta_k \otimes \eta_k | X_k = x\} &= O\left(\frac{b_k}{a_k^{1+\gamma}}\right), & a_k^\gamma |x| \leq 1, \\ &= O\left(\frac{b_k}{a_k^{1-\gamma}} |x|^2\right), & a_k^\gamma |x| > 1. \end{aligned}$$

Combining the two cases completes the proof of the lemma. \square

Remark 1. In Fig. 1 we demonstrate the type of approximations used in the proof of Theorem 3. In Fig. 1(a) we show the transition density $p_k(x, y)$ for the Markov chain with transition probability given by (3.10)–(3.12); in Figure 1(b) we show the transition density $p'_k(x, y)$ for the same Markov chain but using $\hat{s}_k(x, y)$ (4.30) in place of $s_k(x, y)$ (3.12); and in Fig. 1(c) we show the transition density $p''_k(x, y)$ for the Markov chain of (2.1) with $\xi_k = 0$. Note that the densities in Figs. 1(a) and 1(b) contain impulsive components associated with the positive probability of no transition. All three densities are “close” for sufficiently large k and x in a compact set, and this is the basis of the proof. However, for small k , the transition densities can be quite different. In particular, it is seen that the Metropolis-type algorithm takes a less “local” point of view than the gradient-based algorithms.

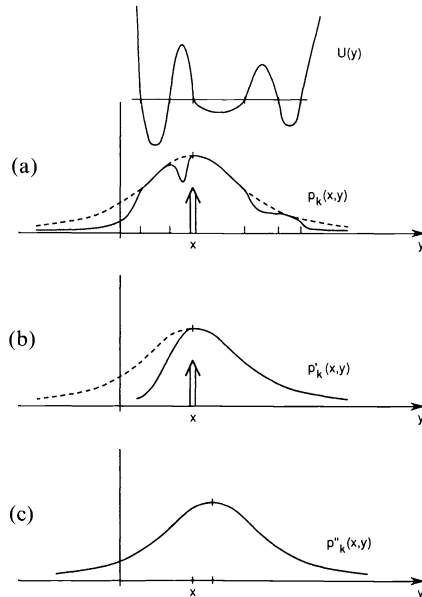

FIG. 1. Three transition probability densities.

Remark 2. The Metropolis-type Markov-chain annealing algorithms use only measurements of $U(\cdot)$ (and not $\nabla U(\cdot)$). Another class of algorithms that use only measurements of $U(\cdot)$ could be based on a finite-difference approximation $D_k U(\cdot)$ of $\nabla U(\cdot)$,

$$(4.32) \quad X_{k+1} = X_k - a_k D_k U(X_k) + b_k W_k.$$

Suppose that $D_k U(\cdot)$ is a random direction forward finite-difference approximation; i.e., suppose that θ_k is an independent random vector uniformly distributed on the d -one-dimensional unit sphere, and

$$D_k U(x) = \frac{U(x + h_k \theta_k) - U(x)}{h_k} \theta_k$$

($\{h_k\}$ is a sequence of nonzero numbers with $h_k \rightarrow 0$). If we write (4.32) in the form (2.1), then, by analysis similar to [19, pp. 58–60], it can be shown that ξ_k is *bounded* for X_k in a compact. However, when we write (3.10)–(3.12) in the form (2.1), the best estimate we can obtain suggests that ξ_k is *unbounded* for X_k in a compact (see Lemma 2(b), and note that $b_k/a_k \rightarrow \infty$). Hence the Metropolis-type approximation appears to be much farther away from an exact gradient-based algorithm than a finite-difference approximation.

4.2. Proof of Theorem 4. We write

$$X_{k+1} = X_k - a_k (\nabla U(X_k) + \xi_k) + b_k W_k$$

(this defines ξ_k) and apply Theorem 1 to show that, if $\{X_k^x: k \geq 0, x \in K\}$ is tight for K compact, then (3.19) is true. We further let

$$\begin{aligned} \psi_k(x) &= \nabla U(x) \quad \text{if } U(x) \leq \frac{|x|^2 + 1}{a_k^\gamma} \\ &= 2x \quad \text{if } U(x) > \frac{|x|^2 + 1}{a_k^\gamma}, \end{aligned}$$

write

$$X_{k+1} = X_k - a_k (\psi_k(X_k) + \eta_k) + b_k \sigma_k(X_k) W_k$$

(this defines η_k), and apply Theorem 2 to show that $\{X_k^x: k \geq 0, x \in K\}$ is, in fact, tight for K compact and (3.19) is, in fact, true.

The following lemmas give the crucial estimates for $E\{|\xi_k|^2 | \mathcal{F}_k\}$, $|E\{\xi_k | \mathcal{F}_k\}|$, $E\{|\eta_k|^2 | \mathcal{G}_k\}$, and $|E\{\eta_k | \mathcal{G}_k\}|$ (compare with Lemmas 2 and 3).

LEMMA 4. *Let K be a compact subset of \mathbb{R}^d . Then there exists $L, k_0 \geq 0$ such that, for every $k \geq k_0$,*

- (a) $|E\{\xi_k | \mathcal{F}_k\}| \leq L(a_k/b_k)$ for all $X_k \in K$, w.p.1;
- (b) $E\{|\xi_k|^2 | \mathcal{F}_k\} \leq L(b_k/a_k)$ for all $X_k \in K$, w.p.1.

LEMMA 5. *There exists $L \geq 0$ such that*

- (a) $|E\{\eta_k | \mathcal{G}_k\}| \leq L(a_k^{1-4\gamma}/b_k)(|X_k| + 1)$ w.p.1;
- (b) $E\{|\eta_k|^2 | \mathcal{G}_k\} \leq L(b_k/a_k^{1+2\gamma})(|X_k|^2 + 1)$ w.p.1.

Assume that Lemmas 4 and 5 are true. Then Condition 3 is satisfied with $\alpha = -\frac{1}{2} > -1$ and $0 < \beta < \frac{1}{2}$. Conditions 4–6 are satisfied with $\alpha = -\frac{1}{2} - 2\gamma > -1$, $0 < \beta < \frac{1}{2} - 4\gamma$, $\gamma_1 = \gamma$, and $\gamma_2 = 0$ (recall that we assume that $0 < \gamma < \frac{1}{8}$). We note that the second relation in Condition 4 is verified with $\gamma_1 = \gamma$ by considering the two cases where $U(x)$ is $<$ or $\geq (|x|^2 + 1)/a_k^\gamma$ and applying (3.18); in fact, we obtain that $\psi_k(x) = O(|x|/a_k^\gamma)$ as $|x| \rightarrow \infty$ uniformly for all k . Hence Theorems 1 and 2 apply, and Theorem 4 follows. It remains to prove Lemmas 4 and 5.

Proof of Lemma 4. Since K is compact and $a_k^\gamma \rightarrow 0$, we can choose k_0 such that $U(X_k) \leq (|X_k|^2 + 1)/a_k^\gamma$ for all $X_k \in K$ and $k \geq k_0$. Hence the proof of Lemma 4 is the same as that of Lemma 2. \square

Proof of Lemma 5. Using $\psi_k(x) = O(|x|/a_k^\gamma + 1)$ (see discussion following the statement of Lemmas 4 and 5), we get, similarly to the proof of Lemma 3, that

$$E\{\eta_k | \mathcal{G}_k\} = -\psi_k(X_k) - \frac{b_k}{a_k} \sigma_k(X_k) E_{W_k}\{W_k P\{\zeta_k = 1 | X_k, W_k\}\}$$

and

$$\begin{aligned} E\{\eta_k \otimes \eta_k | \mathcal{G}_k\} &= \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(X_k) I \\ &\quad - \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(X_k) E_{W_k}\{W_k \otimes W_k P\{\zeta_k = 1 | X_k, W_k\}\} + e_k(X_k), \end{aligned}$$

where

$$\begin{aligned} e_k(X_k) &= O\left(\frac{b_k}{a_k} \sigma_k(X_k) |\psi_k(X_k)| + |\psi_k(X_k)|^2\right) \\ &= O\left(\frac{b_k}{a_k} \sigma_k(X_k) \left(\frac{|X_k|}{a_k^\gamma} + 1\right) + \frac{|X_k|^2}{a_k^{2\gamma}}\right). \end{aligned}$$

Henceforth, we condition on $X_k = x$ and assume for simplicity that $|x| \geq 1$ and $a_k \leq 1$.

Let

$$\begin{aligned} \hat{s}_k(x, y) &= \exp\left(-\frac{2a_k}{b_k^2} \frac{[\langle \nabla U(x), y - x \rangle]^+}{\sigma_k^2(x)}\right) \quad \text{if } U(x) \leq \frac{|x|^2 + 1}{a_k^\gamma} \\ &= \exp\left(-\frac{2a_k}{b_k^2} \frac{[\langle 2x, y - x \rangle]^+}{\sigma_k^2(x)}\right) \quad \text{if } U(x) > \frac{|x|^2 + 1}{a_k^\gamma} \end{aligned}$$

and $\tilde{s}_k(x, y) = s_k(x, y) - \hat{s}_k(x, y)$. Now if a C^2 function $V(\cdot)$ satisfies Condition 7, then, for some $\delta > 0$,

$$\sup_{\varepsilon \in (0, 1)} |HV(x + \varepsilon(y - x))| \leq c_1 \left(\frac{V(x)}{|x|^2} + 1\right)$$

for all $|y - x| < \delta|x|$; so this inequality holds when $V(z) = U(z)$ and when $V(z) = |z|^2$. Hence, by considering the two cases when $U(x)$ is \leq or $>$ $(|x|^2 + 1)/a_k^\gamma$ and using Lemma 1, we obtain that

$$|\tilde{s}_k(x, y)| \leq c_2 \frac{a_k^{1-\gamma}}{b_k^2} \frac{|y - x|^2}{\sigma_k^2(x)}, \quad |y - x| < \delta \sigma_k(x),$$

and, similarly to the derivation of (4.14), we obtain that

$$(4.33) \quad \int |w|^i \tilde{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) = O(a_k^{1-\gamma}).$$

Next, using (4.33), we obtain, similarly to the derivation of (4.15) and (4.24), that

$$\begin{aligned} E\{\eta_k | X_k = x\} &= -\psi_k(x) - \frac{b_k}{a_k} \sigma_k(x) \int w \hat{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) \\ &\quad + O\left(\frac{b_k}{a_k^\gamma} \sigma_k(x)\right) \end{aligned}$$

and

$$\begin{aligned} E\{\eta_k \otimes \eta_k | X_k = x\} &= \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(x) I \\ &\quad - \left(\frac{b_k}{a_k}\right)^2 \sigma_k^2(x) \int w \otimes w \hat{s}_k(x, x + b_k \sigma_k(x) w) dN(0, I)(w) \\ &\quad + O\left(\frac{b_k^2}{a_k^{1+\gamma}} \sigma_k^2(x)\right) + O\left(\frac{b_k}{a_k^{1+\gamma}} \sigma_k(x) |x| + \frac{|x|^2}{a_k^{2\gamma}}\right). \end{aligned}$$

We now separately consider the cases where $a_k^\gamma |x| \leq 1$ and > 1 ($\sigma_k(x) = 1$ and $a_k^\gamma |x|$, respectively). Proceeding as in the proof of Lemma 2 and using $\psi_k(x) = O(|x|/a_k^\gamma)$ and $a_k^{1-2\gamma}/b_k = O(1)$, we can show that

$$\begin{aligned} E\{\eta_k | X_k = x\} &= O\left(\frac{a_k^{1-4\gamma}}{b_k}\right), & a_k^\gamma |x| \leq 1, \\ &= O\left(\frac{a_k^{1-3\gamma}}{b_k} |x|\right), & a_k^\gamma |x| > 1 \end{aligned}$$

and

$$\begin{aligned} E\{\eta_k \otimes \eta_k | X_k = x\} &= O\left(\frac{b_k}{a_k^{1+2\gamma}}\right), & a_k^\gamma |x| \leq 1, \\ &= O\left(\frac{b_k}{a_k} |x|^2\right), & a_k^\gamma |x| > 1. \end{aligned}$$

Combining the two cases completes the proof of the lemma. \square

SINGULAR PERTURBATIONS IN MANUFACTURING*

H. METE SONER†

Abstract. An asymptotic analysis for a large class of stochastic optimization problems arising in manufacturing is presented. A typical example of the problems considered in this paper is a production planning problem with random capacity and demand. In this example, it is assumed that the capacity of the system fluctuates faster than the other quantities. The general model considered here also has a fast controlled Markov process in its state description. By using the difference in the time scales of different quantities, the problem is simplified by “averaging” out the fast process. Then asymptotically optimal strategies are constructed from the optimal solutions of the limiting problems. The proofs of these results use the theory of viscosity solutions to dynamic programming equations. However, the formal construction of the asymptotically optimal strategies does not require knowledge of this theory.

Key words. dynamic programming, viscosity solutions, production planning, manufacturing, singular perturbations

1. Introduction. Most modern manufacturing systems are complex and large in scale, including several subsystems, a wide variety of equipment, and a number of different products. Moreover, operating policies of these systems must respond to discrete events that are quite different from one another, for example, machine setups, failure and repairs, demand changes, purchasing and building new facilities, etc. Because of the size of the systems, it is impossible to achieve optimal operating policies. The only practical strategies are the suboptimal ones, derived using the structure of a given system. Generally, these techniques amount to reduction of the complexity by decomposing the original system into simpler subsystems. We limit ourselves to systems that have hierarchical decomposition. Based on this structure we “average out” certain parameters, thus simplifying the optimization problems. Then suboptimal policies are obtained as solutions to these simplified problems. For further information on control of manufacturing systems, we refer the reader to Gershwin et al. [9]; on hierarchical production planning, see Gershwin [8] and Bitran and Tirupati [3].

Recently Lehoczy et al. [11] carried out the above procedure for a specific stochastic production planning problem. However, the scope of the mathematical tools used in [11] is not limited to the production planning problem. In this paper, we demonstrate the versatility of these techniques by introducing a general framework for asymptotic analysis of optimal stochastic control problems. This framework, in particular, includes the problem studied in [11] and its generalizations.

Typical of the problems we consider is a production planning problem subject to random changes in capacity and demand. We consider the case in which the capacity fluctuates faster than the other quantities, when the system is working. In other words, when there is production, the rate at which the capacity changes occur is much larger than the rate of fluctuation in demand, the rate of discounting, and other time scales. In this model the capacity process depends on the production rate. The model without this dependency is analyzed in [11] and a limiting problem is obtained by simply replacing the random capacity by its average value. However, for the general model,

† Department of Mathematics, Carnegie Mellon University, Pittsburgh, Pennsylvania 15213.

a straightforward averaging, as it was done in [11], is no longer valid. In fact, the “average” capacity is a function of the production rate and its computation is quite complicated. This dependency also implies that in general the diffusion approximation is not possible. Therefore, we are not able to use the elegant analysis of Kushner [10].

The mathematical analysis of this paper uses the dynamic programming principle and the viscosity solutions of the differential equations. Although our proofs are complicated at times, on the formal level the methodology is straightforward and we wish to emphasize this. An outline of the formal method is as follows: First derive the dynamic programming (Bellman) equation for the full problem. Then let the fluctuation rate of the faster process go to infinity in the equation. Obtain the formal limiting equation by assuming the regularity of the value function. Compute the optimal control problem related to the limiting equation and its optimal solution. This solution in turn generates an asymptotically optimal control for the original model. The asymptotic optimality of this control was recently proved by Zhang and Sethi [15] for the model considered in [11]. Finally, we note that our techniques are related to those in Bensoussan [2] and Saksena, O’Reilly, and Kokotovic [13].

The paper is organized as follows. The stochastic production planning problem is described in § 2. Using this problem as a model, we introduce the general framework in § 3. Section 4 is devoted to the proof of the convergence result. A suboptimal but asymptotically optimal control is constructed in § 5. Finally, a discussion of the convergence rate is given.

2. Production planning. Consider a manufacturing facility in which there are m identical machines that are equally capable of producing n distinct part types. The production must be scheduled to meet a demand that fluctuates randomly. However, we assume that the machines are subject to a Markovian breakdown and repair process. Thus the demand may not be met every time, and the production strategies should take this into account.

Akella and Kumar [1] studied the one-dimensional model ($n = m = 1$) with a constant demand rate. They explicitly computed the optimal production rate, which is a bang-bang control. They showed that there is a threshold level $\alpha^* \geq 0$ such that, when the only available machine is in working condition, the production rate is either zero or equal to the full capacity if the inventory is strictly greater than α^* or less than α^* . Of course, when the machine is down, the only possible production rate is zero.

The general model we are considering also admits an optimal control, which is bang-bang. However, for large n and m the computation of the threshold levels is complicated. Also the description of the production rate includes not only the threshold levels but the fractions of the capacity devoted to each part. We simplify this model by using its hierarchical structure. As discussed in the Introduction, we assume that the occurrence of machine breakdown and repair process is faster than the other time scales that are relevant to this problem.

We continue with the description of the model. Let an n -vector $x(t)$ denote the inventory at time $t \geq 0$. For a given production rate (control) $u(t)$, the inventory (state) satisfies the ordinary differential equation

$$(2.1) \quad \frac{d}{dt} x(t) = u(t) - d(t), \quad t > 0,$$

where $d(t) = (d_1(t), \dots, d_n(t))$ is the demand vector. The demand process is assumed to be Markov, taking values in a discrete set $D \subset (0, \infty)^n$. The components of the production rate are nonnegative and they are bounded from above by a constant related

to $\alpha^\varepsilon(t)$, the number of available machines at time t . We assume that $\alpha^\varepsilon(t) \in \{0, 1, \dots, m\}$ is a Markov chain with infinitesimal generator

$$(2.2) \quad \frac{1}{\varepsilon} Q^{u(t)} = \left(\frac{1}{\varepsilon} q_{ij}(u(t)) \right)_{i,j=0,1,\dots,m}.$$

Note that the generator of α^ε depends on the production rate $u(t)$. Since the machine failures are more likely when the production rate is high, this dependence is a natural one. However, in certain situations one may argue that it is negligible as it was assumed in [11].

The parameter $\varepsilon > 0$ appearing in the machine availability process is related to the hierarchy in the time scales. Indeed, the mean rate of change of $\alpha^\varepsilon(\cdot)$ is of order $1/\varepsilon$, while the rate of change of demand is bounded in ε . Hence, for small $\varepsilon > 0$, these two time scales are of different order.

The optimization problem is to *minimize*

$$(2.3) \quad J^\varepsilon(x, d, i; u) = E_{x,d,i} \int_0^\infty e^{-t} G(x(t), u(t)) dt$$

over all nonanticipative production processes, $u(t)$, satisfying the machine availability constraint

$$(2.4) \quad u(t) \in K(\alpha^\varepsilon(t)) \quad \forall t \geq 0,$$

where $E_{x,d,i}$ denotes the mathematical expectation with initial conditions $x(0) = x$, $d(0) = d$, and $\alpha^\varepsilon(0) = i$. The constraint set is given by

$$K(i) = \left\{ u \in [0, \infty)^n : \sum_{k=1}^n u_k \gamma_k \leq i \right\}, \quad i = 1, \dots, m,$$

with nonnegative constants γ_k .

Let $v^\varepsilon(x, d, i)$ be the value function

$$v^\varepsilon(x, d, i) = \inf_{u(\cdot)} J^\varepsilon(x, d, i; u), \quad x \in R^n, \quad d \in D, \quad i \in \{0, 1, \dots, m\}.$$

Then v^ε is a (viscosity) solution of

$$(2.5) \quad \begin{aligned} 0 = v^\varepsilon(x, d, i) + \sup_{u \in K(i)} & \left\{ -(u-d) \cdot D_x v^\varepsilon(x, d, i) - G(x, u) \right. \\ & - \frac{1}{\varepsilon} \sum_{j=0}^m q_{ij}(u) [v^\varepsilon(x, d, j) - v^\varepsilon(x, d, i)] \\ & \left. - \sum_{d' \in D} \bar{q}_{dd'} [v^\varepsilon(x, d', i) - v^\varepsilon(x, d, i)] \right\} \end{aligned}$$

for all $x \in R^n$, $d \in D$, $i \in \{0, 1, \dots, m\}$, where $\bar{Q} = (\bar{q}_{dd'})_{d,d' \in D}$ is the infinitesimal generator of $d(\cdot)$, and D_x denotes the gradient in the x -variable.

We close this section by rewriting (2.5) in a manner which is compatible with the notation of the next section. For $(x, d, i) \in R^n \times D \times \{0, 1, \dots, m\}$, and $p \in R^n$, $L \in R^{|D|}$, $\kappa \in R^{m+1}$, define $H(x, d, i; p, L, \kappa)$ by

$$(2.6) \quad \begin{aligned} H(x, d, i; p, L, \kappa) = \sup_{v \in K(i)} & \left\{ -(u-d) \cdot p - G(x, u) - \sum_{j=0}^m q_{ij}(u) [\kappa_j - \kappa_i] \right\} \\ & - \sum_{d' \in D} \bar{q}_{dd'} [L_{d'} - L_d]. \end{aligned}$$

Then (2.5) can be rewritten as

$$v^\varepsilon(x, d, i) + H\left(x, d, i; D_x v^\varepsilon(x, d, i), v^\varepsilon(x, \cdot, i), \frac{1}{\varepsilon} v^\varepsilon(x, d, \cdot)\right) = 0.$$

Finally, we note that the sum of the entries of each row of any infinitesimal generator is zero, i.e.,

$$\sum_{j=0}^m q_{ij}(u) = \sum_{d' \in D} \bar{q}_{dd'} = 0, \quad \forall i \in \{0, \dots, m\}, \quad d \in D.$$

This implies that

$$(2.7) \quad H(x, d, i; p, L + c_1, \kappa + c_2) = H(x, d, i; p, L, \kappa)$$

for any constants $c_1, c_2 \in (-\infty, \infty)$, and $L + c_1$ denotes the vector obtained by adding the constant c_1 to each component of L ; $\kappa + c_2$ is defined similarly.

3. General model. We consider a family of discounted, infinite horizon stochastic optimal control problems indexed by a parameter $\varepsilon > 0$, with a state space $\Sigma = R^n \times D \times Z$. We take both D and Z to be finite sets. For $(x, d, i) \in \Sigma$, let $v^\varepsilon(x, d, i)$ be the value function satisfying the dynamic programming equation

$$(3.1) \quad v^\varepsilon(x, d, i) + H\left(x, d, i; D_x v^\varepsilon(x, d, i), v^\varepsilon(x, \cdot, i), \frac{1}{\varepsilon} v^\varepsilon(x, d, \cdot)\right) = 0 \quad \forall (x, d, i) \in \Sigma,$$

where H is a real valued function of $\Sigma \times R^n \times R^{|D|} \times R^{|Z|}$. We will not describe the underlying stochastic model. But the function H is given in terms of the running cost and the dynamics of the state process. In particular H is *jointly convex in the last three variables and has the invariance property* (2.7). We now make a structural assumption. Fix $(x, d) \in R^n \times D$, $p \in R^n$, $L \in R^{|D|}$, and $\alpha \in R^{|Z|}$. Consider the nonlinear equation

$$(3.2) \quad \alpha_i + H(x, d, i; p, L, \kappa) = 0 \quad \forall i \in Z,$$

where $\kappa \in R^{|Z|}$ is the unknown. Due to the translation invariance (2.7), if κ is a solution of (3.2) then $\kappa + c$ is a solution for any constant c . So we should search for a unique solution in the quotient space which we call

$$(3.3) \quad \mathcal{P}_{|Z|} = \left\{ \kappa \in R^{|Z|} : \sum_{i \in Z} \kappa_i = 0 \right\}.$$

The translation invariance also yields that the range of the map $\kappa \mapsto \{H(x, d, i; p, L, \kappa)\}_{i \in Z}$ is not equal to $R^{|Z|}$. Hence we may only expect (3.2) to have a unique solution $\kappa \in \mathcal{P}_{|Z|}$ provided that the components of α satisfy a (possibly nonlinear) scalar equation. More precisely we assume that there are functions

$$(3.4i) \quad H_{av} : R^n \times D \times R^n \times R^{|D|} \times R^{|Z|} \rightarrow R,$$

and

$$(3.4ii) \quad A : \Sigma \times R^n \times R^{|D|} \times R^{|Z|} \rightarrow R$$

such that for all $(x, d, i) \in \Sigma$, $p \in R^n$, $L \in R^{|D|}$, and $\alpha \in R^{|Z|}$, we have $A(x, d, \cdot; p, L; \alpha) \in \mathcal{P}_{|Z|}$, and

$$(3.5) \quad \alpha_i + H(x, d, i; p, L, A(x, d, \cdot; p, L; \alpha)) = 0,$$

provided that $\alpha = \{\alpha_i\}_{i \in Z}$ satisfies

$$(3.6) \quad H_{av}(x, d; p, L; \alpha) = 0.$$

Clearly, the function H_{av} is not uniquely determined. However, under mild assumptions on the coefficients of the optimization problem, we can show that it is continuous and monotone in α . Then by multiplying it by (-1) if necessary, we may take it to be nondecreasing in α . So the following assumption is not restrictive:

(3.7) A, H_{av} are continuous and H_{av} is nondecreasing in α .

Note that (3.1) is similar to (3.2). However, in (3.2) variables p and L are assumed to be independent of i , and in (3.1) $p = D_x v^\varepsilon(x, d, i)$ and $L_{d'} = v^\varepsilon(x, d', i)$. However, we expect the dependence of v^ε on i to be averaged out in the limit $\varepsilon \rightarrow 0$. So suppose that $v^\varepsilon(x, d, i)$ converges to $v(x, d)$, and

$$\kappa^\varepsilon(x, d, j) = \frac{1}{\varepsilon} \left[v^\varepsilon(x, d, j) - \sum_{k \in Z} v^\varepsilon(x, d, k) \right]$$

converges to $\kappa(x, d, j)$. Due to the invariance (2.7), we may rewrite (3.1) as

$$v^\varepsilon(x, d, i) + H(x, d, i; D_x v^\varepsilon(x, d, i), v^\varepsilon(x, \cdot, i), \kappa^\varepsilon(x, d, \cdot)) = 0.$$

Now let ε go to zero. Formally, we obtain

$$v(x, d) + H(x, d, i; D_x v(x, d), v(x, \cdot), \kappa(x, d, \cdot)) = 0 \quad \forall i \in Z.$$

Note that the above equation is a special case of (3.2) with $p = D_x v(x, d)$ and $L_{d'} = v(x, d')$. Hence (3.6) yields

$$\bar{H}_{av}(x, d; D_x v(x, d), v(x, \cdot); v(x, d)) = 0,$$

where for $x \in R^n$, $d \in D$, $p \in R^n$, $L \in R^{|D|}$, and a scalar v ,

$$\bar{H}_{av}(x, d; p, L; v) = H_{av}(xd; p, L; \bar{v})$$

with $\bar{v} = (v, \dots, v) \in R^{|Z|}$.

In the next section, we will show that v^ε converges to a solution of the above equation. Since \bar{H}_{av} is convex in the last three variables, $\bar{H}_{av} = 0$ is the dynamic programming equation of an optimal control problem with state space $R^n \times D$. Therefore v is the value function of this problem. The connection between the equation $\bar{H}_{av} = 0$ and the optimal control problem will be clarified in Examples 3.1–3.3, below.

Our final assumption is a strong monotonicity condition on H_{av} . For each $i \in Z$, $\kappa^i \in R^{|Z|}$, set

$$\alpha_i = -H(x, d, i; p, L, \kappa^i), \quad i \in Z.$$

Since κ^i may depend on i , we can *not* conclude that (3.6) holds. However, we assume that

$$(3.8i) \quad H_{av}(x, d, i; p, L; \alpha) \leq 0 \quad (\text{or } \geq 0, \text{ respectively})$$

whenever there is $\kappa \in R^{|Z|}$ such that for all $i, j \in Z$,

$$(3.8ii) \quad \kappa_j^i \leq \kappa_j^i + [\kappa_i - \kappa_j] \quad (\text{or } \geq, \text{ respectively}).$$

We now give two examples to clarify the above hypothesis.

Example 3.1. Consider (2.5) with $n = m = 1$, $D = \{d_0\}$, and $q_{01}(u) = -q_{00} = \lambda > 0$, $q_{10}(u) = -q_{11}(u) = \mu(u) \geq 0$. Then $K(0) = \{0\}$, $K(1) = [0, 1/\gamma_1]$ and the Hamiltonian H

in (2.6) has the form

$$H(x, 0; p, \kappa) = d_0 p - G(x, 0) - \lambda[\kappa_1 - \kappa_0],$$

$$H(x, 1; p, \kappa) = \sup_{0 \leq u \leq 1/\gamma_1} \{-up - G(x, u) + \mu(u)[\kappa_1 - \kappa_0]\} + d_0 p.$$

Equation (3.2) is equivalent to

$$(3.9i) \quad \alpha_0 + d_0 p - G(x, 0) - \lambda[\kappa_1 - \kappa_0] = 0,$$

$$(3.9ii) \quad \alpha_1 + \sup_{0 \leq u \leq 1/\gamma_1} \{-(u - d_0)p - G(x, u) + \mu(u)[\kappa_1 - \kappa_0]\} = 0.$$

Suppose that for a given (α_0, α_1) we have a solution $(\kappa_0, \kappa_1) \in \mathcal{P}_2$ solves (3.9). Then (3.9i) yields

$$(3.10) \quad \kappa_1 - \kappa_0 = \frac{1}{\lambda} [\alpha_0 + d_0 p - G(x, 0)].$$

Since $(\kappa_0, \kappa_1) \in \mathcal{P}_2$, $\kappa_0 + \kappa_1 = 0$. Therefore,

$$\kappa_1 = A(x, 1; p, \alpha) = \frac{1}{2\lambda} [\alpha_0 + d_0 p - G(x, 0)],$$

$$\kappa_0 = A(x, 0; p, \alpha) = -\kappa_1.$$

Observe that we used only (3.9i) to obtain the above formula. The other equation, (3.9ii), will be used to compute H_{av} . Indeed, using (3.10) in (3.9ii), we arrive at

$$H_{av}(x; p; \alpha) = 0,$$

where

$$H_{av}(x; p; \alpha_0, \alpha_1) = \alpha_1 + \sup_{0 \leq u \leq 1/\gamma_1} \left\{ -(u - d_0)p - G(x, u) + \frac{\mu(u)}{2\lambda} [\alpha_0 + d_0 p - G(x, 0)] \right\}.$$

To verify (3.8), suppose that (3.9i) holds with $\kappa^0 = (\kappa_0^0, \kappa_1^0)$ and (3.9ii) holds with $\kappa^1 = (\kappa_0^1, \kappa_1^1)$. Then (3.10) holds with $\kappa_1^0 - \kappa_0^0$ on the left-hand side. Also suppose that (3.8ii) holds. Then

$$\kappa_1^0 - \kappa_0^0 \leq \kappa_1^1 - \kappa_0^1.$$

Using the above inequality and (3.10) in (3.9ii), we obtain $H_{av}(x, p; \alpha_0, \alpha_1) \leq 0$. Hence (3.8i) holds.

In this example, the optimal control problem related to the limiting equation $\bar{H}_{av} = 0$ is to minimize

$$\int_0^\infty \exp\left(-t - \int_0^t \frac{\mu(u(s))}{2\lambda} ds\right) \left[G(x(t), u(t)) + \frac{\mu(u(t))}{2\lambda} G(x(t), 0) \right] dt$$

subject to

$$\frac{d}{dt} x(t) = u(t) - \left(1 + \frac{\mu(u(t))}{2\lambda}\right) d_0, \quad t > 0$$

and $u(t) \in [0, 1/\gamma_1]$, $t \geq 0$.

Example 3.2. Again consider (2.5) with $n = 1$, $m = 2$, $D = \{d_0\}$, and

$$Q(u) = \begin{bmatrix} -\lambda_1 & \lambda_1 & 0 \\ \mu_1(u) & -[\mu_1(u) + \lambda_2] & \lambda_2 \\ 0 & \mu_2(u) & -\mu_2(u) \end{bmatrix}.$$

Then $K(0) = \{0\}$, $K(1) = [0, 1/\gamma_1]$, $K(2) = [0, 2/\gamma_1]$. Suppose that for a given $x, p, \alpha \in \mathbb{R}^3$, $K \in \mathcal{P}_3$ solves (8.2). Then a computation similar to the previous case yields

$$\begin{aligned}\kappa_1 - \kappa_0 &= \frac{1}{\lambda_1} [\alpha_0 + d_0 p - G(x, 0)], \\ \kappa_2 - \kappa_1 &= \frac{1}{\lambda_2} \left[\alpha_1 + \sup_{0 \leq u_1 \leq 1/\gamma_1} \{-(u_1 - d_0)p - G(x, u_1) + \mu_1(u_1)[\kappa_1 - \kappa_0]\} \right], \\ \alpha_2 + \sup_{0 \leq u_2 \leq 2/\gamma_1} \{-(u_2 - d_0)p - G(x, u_2) + \mu_2(u_2)[\kappa_2 - \kappa_1]\} &= 0.\end{aligned}$$

Hence

$$H_{av}(x; p; \alpha) = \sup_{\substack{0 \leq u_1 \leq 1/\gamma_1 \\ 0 \leq u_2 \leq 2/\gamma_1}} \left\{ -f(u_1, u_2)p - g(x, u_1, u_2) + \alpha_2 + \frac{\mu_2(u_2)}{\lambda_2} \left[\alpha_1 + \alpha_0 \frac{\mu_1(u_1)}{\lambda_1} \right] \right\},$$

where

$$\begin{aligned}f(u_1, u_2) &= (u_2 - d_0) + \frac{\mu_2(u_2)}{\lambda_2} \left[(u_1 - d_0) - \frac{\mu_1(u_1)}{\lambda_1} d_0 \right], \\ g(x, u_1, u_2) &= G(x, u_2) + \frac{\mu_2(u_2)}{\lambda_2} \left[G(x, u_1) + \frac{\mu_1(u_1)}{\lambda_1} G(x, 0) \right].\end{aligned}$$

The corresponding control problem is similar to that described in the Example 3.1.

Example 3.3. Again consider (2.5) with $n = 1$, $D = \{d_0\}$ and $Q(u) = Q$ is an irreducible $(m+1) \times (m+1)$ stochastic matrix. Then, (3.2) has the form

$$(3.11) \quad \alpha_i = - \sup_{0 \leq u \leq i/\gamma_i} \{-(u - d_0) \cdot p - G(x, u)\} + (Q\kappa)_i, \quad i \in \{0, 1, \dots, m\}.$$

Since Q is irreducible, there is a positive vector $\nu \in \mathbb{R}^{m+1}$ such that $\nu_i > 0$, $\sum_i \nu_i = 1$, and $(\nu Q)_i = 0$ for all i . Multiply the above equation by ν_i and sum over i to obtain

$$\sum_{i=0}^m \left[\alpha_i \nu_i + \sup_{0 \leq u_i \leq i/\gamma_i} \{ -\nu_i(u_i - d_0)p - \nu_i G(x, u_i) \} \right] = 0.$$

A straightforward algebraic manipulation gives

$$H_{av}(x, p; \alpha) = \sum_{i=0}^m \alpha_i \nu_i + \sup_{0 \leq u \leq \bar{v}} \{ -(u - d_0)p - \bar{G}(x, u) \},$$

where

$$\begin{aligned}\bar{v} &= \sum_{i=0}^m i \nu_i / \gamma_i, \\ \bar{G}(x, u) &= \inf \left\{ \sum_{i=0}^m \nu_i G(x, u_i) : u_j \in K(j) \text{ and } \sum_{i=0}^m \nu_i u_i = u \right\}.\end{aligned}$$

To verify (3.8), suppose that (3.11) holds with $\kappa^i \in \mathbb{R}^{m+1}$, and κ^i 's satisfy (3.8ii). Multiply (3.11) by ν_i , sum over i , and then use the formula for H_{av} to obtain

$$H_{av}(x, p; \alpha) = \sum_{i,j=0}^m \nu_i q_{ij} \kappa_j^i.$$

Now use (3.8ii) and the nonnegativity of q_{ij} for $i \neq j$, to obtain

$$\begin{aligned} \sum_{i,j=0}^m \nu_i q_{ij} \kappa_j^i &\leq \sum_{i,j=0}^m \nu_i q_{ij} [\kappa_j^j + (\kappa_j - \kappa_i)] \\ &= \sum_{j=0}^m (\kappa_j^j + \kappa_j) \left[\sum_{i=0}^m \nu_i q_{ij} \right] - \sum_{i=0}^m (\nu_i \kappa_i) \left[\sum_{j=0}^m q_{ij} \right] \\ &= 0. \end{aligned}$$

The corresponding optimal control problem is simple, and it is described in Example 5.1.

These examples can easily be generalized to obtain the following lemma.

LEMMA 3.1. *Suppose that H is as in (2.4) and $G(x, u)$ is convex in the u -variable, and either $\alpha^\varepsilon(t)$ is a birth-death process, i.e.,*

$$(3.12) \quad q_{ij}(u) = \begin{cases} \mu_i(u), & j = i - 1, \quad i = 1, \dots, m, \\ \lambda_i, & i = j - 1, \quad j = 1, \dots, m, \\ -[\lambda_i + \mu_i(u)], & \text{if } i = j = 0, \dots, m, \\ 0, & \text{otherwise,} \end{cases}$$

with $\mu_i(u) \geq 0$, $\lambda_i > 0$, or $Q(u) \equiv Q$ for all u and Q is irreducible. Then the assumptions (3.5), (3.6), and (3.8) are satisfied.

The convergence results under the second hypothesis is first obtained in [11]. These results are then improved in [15]. The asymptotic analysis of v^ε under the first set of assumptions, however, is not covered in the previous studies. In this case, the parameter λ_i is the machine repair rate when $i - 1$ machine are operating. It is natural to assume that λ_i is independent of the production rate. The quantity $\mu_i(u)$ is the machine failure rate when i machines are operating with a production rate of u , and, in general, μ_i is a function of the production rate.

4. Convergence. In this section we study the limiting behavior of v^ε as ε tends to zero. In whatever follows we always assume the structural assumptions (3.5)–(3.8). However, to obtain convergence results we need to impose some uniform estimates on v^ε . In this section we assume that there are $K, \nu \geq 0$, independent of ε , such that for all $\varepsilon \in (0, 1]$, $(x, d, i) \in \Sigma$,

$$(4.1i) \quad |v^\varepsilon(x, d, i)| \leq K(1 + |x|^\nu),$$

$$(4.1ii) \quad \frac{1}{|x - y|} |v^\varepsilon(x, d, i) - v^\varepsilon(y, d, i)| \leq K(1 + |x|^\nu), \quad 0 < |y - x| \leq 1,$$

$$(4.1iii) \quad |v^\varepsilon(x, d, i) - v^\varepsilon(x, d, j)| \leq \varepsilon K(1 + |x|^\nu), \quad j \in \mathbb{Z}.$$

The inequality (4.1ii) is a uniform Lipschitz estimate. If the function v^ε is continuously differentiable in the x -variable, then (4.1ii) is equivalent to the uniform boundedness of the gradient, i.e.,

$$(4.2) \quad \sup_{\varepsilon \in (0, 1]} |D_x v^\varepsilon(x, d, i)| \leq K(1 + |x|^\nu).$$

The estimate (4.1iii) is related to the scaling used in the equation (3.1). Notice that in (3.1) the vector $(1/\varepsilon)v^\varepsilon(x, d, \cdot)$ appears. So intuitively we expect the differences $|v^\varepsilon(x, d, i) - v^\varepsilon(x, d, j)|/\varepsilon$ to be locally bounded as assumed in (4.1iii). Note that the translation invariance (2.7) is the reason why we do not expect $v^\varepsilon/\varepsilon$ to be bounded.

In the production planning examples, these estimates are always satisfied. Indeed consider the cases discussed in Lemma 3.1 and assume that

$$(4.3) \quad |G(x, u)| + \frac{1}{|x - y|} |G(x, u) - G(y, u)| \leq K(1 + |x|^\nu)$$

for all $x, y, u \in R^n$, $0 < |x - y| \leq 1$. Then for the second case of Lemma 3.1, the estimates (4.1) are proved in [11]; see Lemma 2.1 in [11]. A very similar proof yields these estimates also in the first case of Lemma 3.1.

Using (4.1) and the Ascoli–Arzela theorem we construct a sequence, denoted by ε again, and locally Lipschitz continuous function $v(x, d)$ such that $v^\varepsilon(x, d, i)$ converges to $v(x, d)$ uniformly on compact subsets on Σ . As we discussed in § 3, formally v solves the limiting equation

$$(4.4) \quad \bar{H}_{av}(x, d; D_x v(x, d), v(x, \cdot); v(x, d)) = 0, \quad (x, d) \in R^n \times D.$$

Recall that for $(x, d; p, L) \in R^n \times D \times R^n \times R^{|D|}$ and a scalar v ,

$$\bar{H}_{av}(x, d; p, L; v) := H_{av}(x, d; p, L; \bar{v}),$$

with $\bar{v} = (v, v, \dots, v) \in R^{|Z|}$. We will show below that v indeed is a solution of (4.4).

In general, v is not differentiable and the equation (4.4) must be interpreted in the viscosity sense. We refer the reader to Crandall and Lions [5]; Crandall, Evans, and Lions [4]; Lions [12]; Soner [14]; Fleming, Sethi, and Soner [6]; and [11] for the definition and the properties of the viscosity solutions of (3.1) or (4.4).

THEOREM 4.1 (Stability). *Assume (4.1), and that v^ε is a viscosity solution of (3.1). Suppose that (4.4) has a unique viscosity solution v satisfying (4.1). Then v^ε converges to v uniformly on compact subsets of $R^n \times D$, as ε tends to zero.*

Proof. Let $\bar{v}(x, d)$ be the limit of $v^{\varepsilon_m}(x, d, i)$ for some sequence $\varepsilon_m \rightarrow 0$. Let $\psi(x, d)$ be a continuously differentiable function and for $d \in D$, let $x_0 \in R^n$ be the strict maximum of $\bar{v}(\cdot, d) - \psi(\cdot, d)$ on R^n . To show that \bar{v} is a viscosity subsolution of (4.4), we must verify the inequality

$$(4.5) \quad \bar{H}_{av}(x_0, d; D_x \psi(x_0, d), \bar{v}(x_0, \cdot); \bar{v}(x_0, d)) \leq 0.$$

Consider the map $x \mapsto v^{\varepsilon_m}(x, d, i) - \psi(x, d)$. Since x_0 is a strict maximizer, there are $x_m(i) \in R^n$ converging to x_0 and maximizing the above map locally in the x variable. Then the viscosity property of $v^m := v^{\varepsilon_m}$ yields

$$v^m(x_m(i), d, i) + H\left(x_m(i), d, i; D_x \psi(x_m(i), d), v^m(x_m(i), \cdot, i), \frac{1}{\varepsilon_m} v^m(x_m(i), d, \cdot)\right) \leq 0.$$

Since v^m converges to \bar{v} and $x_m(i)$ converges to x_0 , there is a sequence $K_m \rightarrow 0$ such that

$$(4.6) \quad \bar{v}(x_0, d) + H(x_0, d, i; p_0, \bar{v}(x_0, \cdot), \kappa^{m,i}) \leq K_m,$$

where $p_0 = D_x \psi(x_0, d)$ and

$$\kappa_j^{m,i} = \frac{1}{\varepsilon_m} v^m(x_m(i), d, j), \quad x \in R^n, \quad i, j \in Z.$$

Since $x_m(i)$ is a local maximizer of $v^m(\cdot, d, i) - \psi(\cdot, d)$, we have

$$v^m(x_m(j), d, j) - \psi(x_m(j), d) \geq v^m(x_m(i), d, j) - \psi(x_m(i), d)$$

for all $i, j \in Z$. Set $\kappa_j = \psi(x_m(j), d)$. Then

$$\kappa_j^{m,i} \leq \kappa_j^{m,j} + (\kappa_i - \kappa_j)$$

for every $i, j \in Z$. Hence, (3.8) implies that

$$H_{av}(x_0, d; p_0, \bar{v}(x_0, \cdot); \beta) \leq 0,$$

where

$$\beta(i) = -H(x_0, d, i; p_0, \bar{v}(x_0, \cdot), \kappa^{m,i}), \quad i \in Z.$$

Also (4.6) yields that $\beta(i) \geq \bar{v}(x_0, d) - K_m$ for every $i \in Z$. Hence, the monotonicity of H_{av} yields that

$$\bar{H}_{av}(x_0, d; p_0, \bar{v}(x_0, \cdot); \bar{v}(x_0, d) - K_m) \leq H_{av}(x_0, d; p_0, \bar{v}(x_0, \cdot); \beta) \leq 0 \quad \forall m.$$

Now let m go to infinity and use the fact that $K_m \rightarrow 0$ to obtain (4.5). Hence \bar{v} is a viscosity subsolution. Similarly we can show that it is also a viscosity supersolution, and therefore a solution. Since (4.4) has a unique viscosity solution v satisfying (4.1), $\bar{v} = v$. \square

COROLLARY 4.1. *Assume the hypothesis of Lemma 3.1, and (4.3). Then v^ε converges uniformly on compact subsets of Σ , as ε tends to zero.*

Proof. We have argued that (4.3) implies the estimates (4.1). Also the uniqueness of viscosity solutions of (4.4) satisfying (4.1) follows from the classical techniques of Crandall, Evans, Lions [4]. \square

5. Asymptotically optimal controls. In this section we outline a procedure of constructing suboptimal controls by using the limiting equation (4.4). We will show that under certain assumptions, the difference between the value function and the performance of the controls that we construct converges to zero in the limit $\varepsilon \rightarrow 0$. Before we describe the procedure for the general case, we discuss two examples.

Example 5.1. Consider the case described in Example 3.3. Let $v(x)$ be the unique viscosity solution of the limit equation,

$$\begin{aligned} 0 &= \bar{H}_{av}(x, D_x v(x), v(x)) \\ &= v(x) + \sup_{0 \leq u \leq \bar{v}} \{-(u - d_0)D_x v(x) - \bar{G}(x, u)\}. \end{aligned}$$

Then $v(x)$ is the value function of a deterministic optimal control problem. Indeed,

$$v(x) = \inf \int_0^\infty e^{-t} \bar{G}(x(t), u(t)) dt,$$

subject to constraints $x(0) = x$, (2.1) with $d(t) \equiv d_0$, and $0 \leq u(t) \leq \bar{v}$ for all $t \geq 0$. Suppose that v is differentiable. For each x , pick

$$u^*(x) \in \operatorname{argmax} \{-(u - d_0)D_x v(x) - \bar{G}(x, u) : 0 \leq u \leq \bar{v}\}.$$

If

$$(5.1) \quad \frac{d}{dt} x(t) = u^*(x(t)) - d_0, \quad t > 0,$$

has a solution, then it is elementary to show that $\tilde{u}(t) = u^*(x(t))$ is optimal. So suppose that this is the case. Then we construct a feedback control for the $\varepsilon > 0$ problem by setting

$$u^{*,\varepsilon}(x, i) = iu^*(x), \quad x \in (-\infty, \infty), \quad i = 0, 1, \dots, m.$$

Then we expect $u^{*,\varepsilon}$ to perform close to the optimal control. Indeed, Zhang and Sethi [15] have shown that

$$\lim_{\varepsilon \rightarrow 0} |J^\varepsilon(x, i; u^{*,\varepsilon}) - v^\varepsilon(x, i)| = 0,$$

provided that (5.1) has a unique solution.

Example 5.2. Now we return to Example 3.2. As in the previous example suppose that the solution v of the limit equation is differentiable, i.e.,

$$(5.2) \quad \sup_{\substack{0 \leq u_1 \leq 1/\gamma_1 \\ 0 \leq u_2 \leq 2/\gamma_2}} \{l(u_1, u_2)v(x) - f(u_1, u_2)D_x v(x) - g(x, u_1, u_2)\} = 0,$$

where f, g are as in Example 3.2, and

$$l(u_1, u_2) = 1 + \frac{\mu_2(u_2)}{\lambda_2} \left[1 + \frac{\mu_1(u_2)}{\lambda_1} \right].$$

Let $u_1^*(x), u_2^*(x)$ be a maximizer in (5.2). Clearly, the sequence $u^*(x, 0) = 0, u^*(x, 1) = u_1^*(x)$, and $u^*(x, 2) = u_2^*(x)$ satisfies the machine availability constraint and is a candidate for an asymptotically optimal control. We will show in Theorem 5.1 below that this is indeed the case, provided that u^* has certain properties.

To motivate the construction in the general framework, we will derive a property of u^* next. Set

$$p(x) = D_x v(x),$$

and

$$A(x, i) = A(x, i; p(x), \bar{v}(x)), \quad i = 0, 1, 2;$$

recall that $\bar{v}(x) = (v(x), v(x), v(x))$. Then by (3.5), we have

$$\begin{aligned} 0 &= v(x) + H(x, i; p(x), A(x, \cdot)) \\ &= v(x) + \sup_{0 \leq u \leq i/\gamma_1} \{- (u - d_0)p(x) - G(x, u) - (Q(u)A(x, \cdot))(i)\}, \quad i = 0, 1, 2. \end{aligned}$$

Then it is straightforward to show that $u^*(x, i)$ maximizes the expression in the above equation. We will use this description of u^* in the discussion of the general problem.

In general, the Hamiltonian H has the form

$$(5.3) \quad H(\xi; p, L, \kappa) = \sup_{u \in K(\xi)} \{-\mathcal{L}^{u,\xi}(p, L, \kappa) - G(\xi, u)\}$$

for $\xi \in \Sigma, p \in \mathbb{R}^n, L \in \mathbb{R}^{|D|}, \kappa \in \mathbb{R}^{|Z|}$, a set $K(\xi) \subset U$, a function G of $\Sigma \times U$, and a family of linear operators $\mathcal{L}^{u,\xi}(p, L, \kappa)$, which are invariant under scalar translations of L, κ . In the notation of § 2, for example, $U = [0, \infty)^n, K(\xi) = K(i)$,

$$(5.4) \quad \mathcal{L}^{u,\xi}(p, L, \kappa) = (u - d) \cdot p + (\bar{Q}L)(d) + (Q(u)\kappa)(i)$$

for $\xi = (x, d, i) \in \Sigma$. Assume that v is differentiable and set

$$p(x, d) = D_x v(x, d), \quad A(x, d, i) = A(x, d, i; p(x, d), v(x, \cdot); \bar{v}(x, d)).$$

Then choose $u^*(\xi) \in K(\xi)$ such that

$$\begin{aligned} (5.5) \quad & -\mathcal{L}^{u^*(\xi),\xi}(p(x, d), v(x, \cdot), A(x, d, \cdot)) - G(\xi, u^*(\xi)) \\ & = H(\xi; p(x, d), v(x, \cdot), A(x, d, \cdot)). \end{aligned}$$

It is known that not every feedback control yields a well-defined state process. However, we assume that u^* is indeed related to a well-defined state process. Let $J^{\varepsilon,*}(\xi)$ be the value of the pay-off functional. Then $J^{\varepsilon,*}$ formally solves

$$(5.6)^{\varepsilon} \quad J^{\varepsilon,*}(\xi) - \mathcal{L}^{u^*(\xi),\xi} \left(D_x J^{\varepsilon,*}(\xi), J^{\varepsilon,*}(x, \cdot, i), \frac{1}{\varepsilon} J^{\varepsilon,*}(x, d, \cdot) \right) - G(\xi, u^*(\xi)) = 0.$$

The definition of u^* implies that the formal limit of $(5.6)^{\varepsilon}$ is (4.4). So we expect $J^{\varepsilon,*}$ to converge to v ; the unique (viscosity) solution of (4.4). However the coefficients of $(5.6)^{\varepsilon}$ are not necessarily smooth, and the procedure of § 4 may not apply to this case. Still a convergence theorem holds if $(5.6)^{\varepsilon}$ has a comparison principle, which we define next.

DEFINITION 5.1. We say that $(5.6)^{\varepsilon}$ has a comparison principle if any viscosity subsolution w of $(5.6)^{\varepsilon}$ satisfying (4.1i) is less than or equal to any viscosity supersolution \tilde{w} of $(5.6)^{\varepsilon}$ satisfying (4.1i).

If, for example, $\mathcal{L}^{u^*,\xi}$ is as in (5.4), then $(5.6)^{\varepsilon}$ has a comparison principle for a large class of $u^*(\cdot)$. This class, in particular, includes the Lipschitz continuous functions.

We start our convergence proof with a lemma, which is due to Souganidis.

LEMMA 5.1. Suppose that the unique viscosity solutions v of (4.4) and v^{ε} of (3.1) are convex, continuously differentiable in the x -variable, and satisfy (4.1). Then $D_x v^{\varepsilon}(x, d, i)$ converges to $D_x v(x, d)$ uniformly on compact subsets of Σ , as $\varepsilon \rightarrow 0$.

Proof. Pick $\varepsilon_n \rightarrow 0$, $x_n \rightarrow x$ such that $p_n = D_x v^{\varepsilon_n}(x_n, d, i)$ converges to p . First, the convexity of $v^{\varepsilon_n}(\cdot, d, i)$ yields

$$v^{\varepsilon_n}(x_n + y, d, i) - v^{\varepsilon_n}(x_n, d, i) \geq p_n \cdot y, \quad \forall y.$$

Let n go to infinity to obtain

$$v(x + y, d) - v(x, d) \geq p \cdot y \quad \forall y.$$

Then the differentiability of v implies that $p = D_x v(x, d)$. \square

For $\xi = (x, d, i) \in \Sigma$, set

$$A^{\varepsilon}(\xi) = A(\xi; D_x v^{\varepsilon}(\xi), v^{\varepsilon}(x, \cdot, i); v^{\varepsilon}(x, d, \cdot)).$$

Equation (3.1) and the translation invariance (2.7) yield that

$$A^{\varepsilon}(\xi) = \frac{1}{\varepsilon} \left[v^{\varepsilon}(\xi) - \sum_{j \in Z} v^{\varepsilon}(x, d, j) \right].$$

Using the definition of A , we rewrite (3.1) as

$$(5.7) \quad v^{\varepsilon}(\xi) + H(\xi; D_x v^{\varepsilon}(\xi), v^{\varepsilon}(x, \cdot, i), A^{\varepsilon}(x, d, \cdot)) = 0.$$

Set

$$K^{\varepsilon}(\xi) = v^{\varepsilon}(\xi) - \mathcal{L}^{u^*(\xi),\xi}(D_x v^{\varepsilon}(\xi), v^{\varepsilon}(x, \cdot, i), A^{\varepsilon}(x, d, \cdot)) - G(\xi, u^*(\xi)).$$

In view of (5.3) and (5.7), $K^{\varepsilon}(\xi) \leq 0$.

LEMMA 5.2. Suppose that $(5.6)^{\varepsilon}$ has a comparison principle. Let J^{ε} be the viscosity solution of $(5.6)^{\varepsilon}$ satisfying (4.1). Then

$$(5.8) \quad v^{\varepsilon} \leq J^{\varepsilon}.$$

Proof. Since $K^{\varepsilon} \leq 0$, v^{ε} is a subsolution of $(5.6)^{\varepsilon}$. Therefore, the comparison principle yields $v^{\varepsilon} \leq J^{\varepsilon}$. \square

LEMMA 5.3. Assume the hypothesis of Theorem 4.1 and Lemma 5.1. Then K^ε converges to zero, as $\varepsilon \rightarrow 0$.

Proof. This follows from the continuity of A , (3.7), the convergence of v^ε and $D_x v^\varepsilon$, and the definition of \mathcal{L}^{u^*} . \square

The above result indicates that the difference $J^\varepsilon - v^\varepsilon$ should converge to zero. To prove this convergence, we assume that there are $\bar{K}, K, \nu, \bar{\nu} \geq 0$ such that for all $\xi \in \Sigma$,

$$(5.9) \quad |A(\xi; p, L; \alpha)| \leq \bar{K}(1 + |x|^{\bar{\nu}}) \quad \forall |p| + |L| + |\alpha| \leq K(1 + |x|^\nu),$$

and

$$(5.10) \quad \sup_{u \in K(\xi)} |\mathcal{L}^{u, \xi}(p, L, \kappa)| \leq \bar{K}(1 + |p| + |L| + |\kappa|) \quad \forall p \in R^n.$$

LEMMA 5.4. Assume (5.9), (5.10). Then for every $\tilde{K}, \tilde{\nu} \geq 0$ there is a continuously differentiable function $\eta(x) \geq 1$, such that

$$(5.11) \quad \frac{1}{2}\eta(x) - \mathcal{L}^{u, \xi}(D_x \eta(x), 0, 0) \geq 0 \quad \forall \xi \in \Sigma, \quad u \in K(\xi),$$

and

$$(5.12) \quad \eta(x) \geq \tilde{K}(1 + |x|^{\tilde{\nu}}).$$

Proof. Let $\eta(x) = C + \tilde{K}|x|^a$ for some $C \geq \tilde{K}$ and $a = \max\{2, \tilde{\nu}\}$. We will show that, for an appropriate choice of C , η satisfies (5.11) and (5.12). Indeed,

$$D_x \eta(x) = a\tilde{K}x|x|^{a-2},$$

and (5.10) yields

$$|\mathcal{L}^{u, \xi}(D_x \eta(x), 0, 0)| \leq \bar{K}(1 + [a\tilde{K}]|x|^{a-1}).$$

Therefore,

$$\frac{1}{2}\eta(x) - \mathcal{L}^{u, \xi}(D_x \eta(x), 0, 0) \geq (\frac{1}{2}C - \bar{K}) + \tilde{K}|x|^{a-1}(\frac{1}{2}|x| - a\bar{K}).$$

It is now elementary to show that the right-hand side of the above inequality is positive for every x if C is sufficiently large. \square

THEOREM 5.1. Assume the hypothesis of Theorem 4.1, Lemma 5.1, and (5.9), (5.10). Then $J^\varepsilon - v^\varepsilon$ converges to zero. In particular, u^* is asymptotically optimal.

Proof. Since v^ε satisfies (4.1), (5.9) implies that

$$|A^\varepsilon(\xi)| \leq \bar{K}(1 + |x|^{\bar{\nu}}).$$

In view of (5.10), the above estimate together with (4.1) yields

$$|K^\varepsilon(\xi)| \leq \tilde{K}(1 + |x|^{\tilde{\nu}-1})$$

for some $\tilde{K}, \tilde{\nu} \geq 1$. Let η be as in Lemma 5.4. Then (5.12) implies that $K^\varepsilon(\xi)/\eta(x)$ converges to zero uniformly on Σ , as $\varepsilon \rightarrow 0$. Set

$$k^\varepsilon = \inf \{|K^\varepsilon(\xi)/\eta(x)| : \xi \in \Sigma\}$$

and

$$w^\varepsilon(\xi) = v^\varepsilon(\xi) + 2k^\varepsilon \eta(x), \quad \xi = (x, d, i) \in \Sigma.$$

Then, the linearity of $\mathcal{L}^{u, \xi}$, the definition of K^ε , and (5.11) yield

$$\begin{aligned} w^\varepsilon(\xi) - \mathcal{L}^{u^*(\xi), \xi} \left(D_x w^\varepsilon(\xi), w^\varepsilon(x, \cdot, i), \frac{1}{\varepsilon} w^\varepsilon(x, d, \cdot) \right) - G(\xi, u^*(\xi)) \\ = K^\varepsilon(\xi) + 2k^\varepsilon [\eta(x) - \mathcal{L}^{u^*(\xi), \xi}(D_x \eta(x), 0, 0)] \\ \geq K^\varepsilon(\xi) + k^\varepsilon \eta(x) \geq 0. \end{aligned}$$

Hence w^ε is a supersolution of (5.6) ^{ε} . Consequently, the comparison principle implies that $J^\varepsilon \leq w^\varepsilon$. Now let ε go to zero and use the convergence of K^ε to zero together with (5.8) to obtain the convergence of J^ε to v . \square

Remark. If the operator $\mathcal{L}^{u^*(\xi),\xi}(p, L, k)$ is continuous in ξ , then $K^\varepsilon(\xi)$ converges to zero uniformly on compact subsets of Σ . Therefore w^ε , defined as in the above proof, converges to v uniformly on compact sets. Consequently, the conclusion of Theorem 5.1 holds uniformly on compact subsets of Σ .

Example 5.3. Consider the problem described in §2 with $n=2$, $m=1$, $D=\{(\delta, 1)\}$, $\gamma_1=\beta/K$, $\gamma_2=1/K$, $\mu_1(u)=\mu[\nu u_1+u_2]$, $\lambda_0=1$, and $G(x, y, u)=\alpha|x|+|y|$, where all the parameters are positive. Set

$$E = K\mu + 1,$$

$$\lambda = K\mu\nu + \beta.$$

Case 1. $\lambda \leq E\alpha$. In this case, the optimal feedback control is

$$u^*(x, y, 1) = \begin{cases} (0, 0) & \text{if } x > 0, y > 0, \\ (0, 1) & \text{if } x > 0, y = 0, \\ (0, K) & \text{if } x > 0, y < 0, \\ (E\delta, K - \lambda\delta)/[1 + \mu\delta(\beta - \nu)] & \text{if } x = 0, y < 0, \\ (K/\beta, 0) & \text{if } x < 0, \\ (\delta, 0) & \text{if } x = 0, y > 0, \\ (\delta, 1) & \text{if } x = 0, y = 0. \end{cases}$$

Case 2. $\lambda \geq E\alpha$. Then

$$u^*(x, y, 1) = \begin{cases} (0, 0) & \text{if } x > 0, y > 0, \\ (0, 1) & \text{if } x > 0, y = 0, \\ (0, K) & \text{if } y < 0, \\ (K - E, \lambda)/[\mu\nu + (1 - \mu)\beta] & \text{if } x < 0, y = 0, \\ (K/\beta, 0) & \text{if } x < 0, y > 0, \\ (\delta, 0) & \text{if } x = 0, y > 0, \\ (\delta, 1) & \text{if } x = 0, y = 0. \end{cases}$$

The value function is continuously differentiable in either case, and a comparison principle for (5.6) ^{ε} holds.

The above strategies differ only on the fourth quadrant. This is expected because in the other quadrants at most one of the products is in shortage, and then the optimal policy is to produce the product in shortage, if there is one, in full capacity. However, in the fourth quadrant of each of the products is in shortage, and therefore a priority rule is needed. The above calculations provide just this. In the first case, the optimal strategy is to produce x in full capacity. Hence in this case, the first product has priority over the second one. In the second case, this priority changes. So we may sum the above findings into the following rule:

If $\lambda \leq E\alpha$, produce the first product in full capacity if there is any shortage of it regardless the inventory level of the second product. If $\lambda \geq E\alpha$, reverse this rule.

6. Convergence rate. The exact rate at which $|v^\varepsilon - v|$ converges to zero is an interesting question. Recently Zhang and Sethi [15] obtained the rate $\varepsilon^{1/2}$ or $\varepsilon^{1/4}$ under different assumptions for the case described in Example 3.3. Also, they show, with an

explicit example, that in general $\varepsilon^{1/2}$ is the best rate. However, when the limit function is continuously differentiable we expect that the function $(v^\varepsilon(x, d, i) - v(x, d))/\varepsilon$ is uniformly bounded in ε on every compact subset of Σ . A similar result was proved in [7].

MAXIMUM LIKELIHOOD ESTIMATOR FOR TWO-POINT BOUNDARY VALUE PROCESS*

SHIN ICHI AIHARA† AND ARUNABHA BAGCHI‡

Abstract. The problem of identifying unknown parameters in two-point boundary value (TPBV) processes is studied. Using the explicit form of the likelihood functional, the consistency property of the maximum likelihood estimator is analyzed under a large number of independent experiments.

Key words. two-point boundary value (TPBV) process, maximum likelihood estimator, consistency, likelihood functional

AMS(MOS) subject classifications. 93E12, 60H99, 62M09

1. Introduction. The smoothing problem for boundary value (TPBV) processes has been extensively studied by Adams, Willsky, and Levy [1], [2]. These are random fields (processes) satisfying partial (ordinary) differential equations with noisy boundary conditions. A rigorous mathematical treatment of boundary value processes and the related smoothing and identification problems may be found in Bagchi and Aihara [3]. The likelihood functional derived in that paper is not given in terms of system parameters and is therefore not particularly suitable for identification purposes. In Bagchi and Westdijk [4], this likelihood formula has been further worked out for the one-parameter case, the so-called two-point boundary value (TPBV) processes, and expressed in terms of the system parameters. In this paper, we use this expression to study consistency of the maximum likelihood estimates of the unknown system parameters for TPBV processes.

TPBV processes are observed in a fixed-time interval; say $[0, T]$. Based on one realization of the observation process in this time interval, no statement can be made about the asymptotic properties of estimates of the unknown parameters. In this paper, we make n independent experiments. Based on the observations $y_t^1, y_t^2, \dots, y_t^n, 0 \leq t \leq T$, we obtain the maximum likelihood estimate of the unknown system parameters. Using the approach proposed by Borkar and Bagchi [5], we show the consistency of the maximum likelihood estimate obtained for TPBV processes.

2. Problem formulation and the likelihood functional. Suppose that $\{x_t, t \geq 0\}$ is an n -dimensional, real-valued, time-invariant, TPBV process satisfying

$$(2.1) \quad dx_t = A(\theta)x_t dt + B(\theta) dw_t$$

and the boundary condition

$$(2.2) \quad V^0 x_0 + V^T x_T = v,$$

where $\{w_t, t \geq 0\}$ is a p -dimensional standard Brownian motion. v is an n -dimensional Gaussian random vector, independent of $\{w_t, 0 \leq t \leq T\}$, with $Ev = 0$ and $Evv^* = \Sigma_v > 0$, with $(*)$ denoting transpose.

$A(\theta)$ is an $n \times n$ matrix and $B(\theta)$ is an $n \times p$ matrix. The components of $A(\theta)$ and $B(\theta)$ depend on the unknown parameter vector $\theta \in \Theta$, where Θ is a compact set in \mathbb{R}^k . V^0 and V^T are constant $n \times n$ matrices.

The measurement process $\{y_t, 0 \leq t \leq T\}$ is given by

$$(2.3) \quad dy_t = Cx_t dt + D dw_t, \quad y_0 = 0,$$

where y_t is an m -dimensional random vector and the matrices C and D are known. We assume that $BD^* = 0$ (the state and measurement noises are independent) and that DD^* is a positive definite matrix. Without loss of generality, we may take $DD^* = I$ (identity matrix).

Our problem is to determine an estimate for θ based on n independent experiments that give us a sample $y_t^1, \dots, y_t^n, 0 \leq t \leq T$ of n independent trajectories of the observation process $\{y_t, 0 \leq t \leq T\}$. Based on these samples, we determine the maximum likelihood estimate $\hat{\theta}_n$ of the unknown parameter θ by maximizing the likelihood functional for the problem. Our objective is to show consistency of the maximum likelihood estimator obtained for the unknown parameter vector θ .

We derive in this section the exact form of the likelihood functional for our problem. The detailed derivation may be found in [4] and is based on an important result of Shepp [6]. We present here only the broad outline of the results obtained in [4], which helps us also in setting the notations used throughout the paper. It is easy to solve (2.1), (2.2), and the solution is given by

$$(2.4) \quad x_t = \Phi(t)(V^0 + V^T \Phi(T))^{-1} \cdot \left\{ V^0 \int_0^t \Phi(u)^{-1} B dw_u - V^T \Phi(T) \int_t^T \Phi(u)^{-1} B dw_u + v \right\},$$

where the (fixed) parameter θ is not explicitly mentioned, the matrix $V^0 + V^T \Phi(T)$ is assumed to be invertible, and $\Phi(t) \equiv e^{At}$, the state transition matrix for the system. The signal process in (2.3) is then

$$(2.5) \quad Cx_t = V(t)v + \int_0^T h(t, u) dw_u, \quad 0 \leq t \leq T,$$

where

$$(2.6a) \quad V(t) = C\Phi(t)(V^0 + V^T \Phi(T))^{-1}$$

and

$$(2.6b) \quad h(t, u) = \begin{cases} V(t)V^0\Phi(u)^{-1}B, & 0 \leq u \leq t, \\ -V(t)V^T\Phi(T)\Phi(u)^{-1}B, & t < u \leq T. \end{cases}$$

Define

$$(2.7) \quad \begin{aligned} r(t, u) &\triangleq E\{(Cx_t)(Cx_u)^*\} \\ &= V(t)\Sigma_v V(u)^* + \int_0^T h(t, z)h(u, z)^* dz. \end{aligned}$$

Define the operator $R: L_2^m[0, T] \rightarrow L_2^m[0, T]$ by

$$(2.8) \quad (Rf)(t) = \int_0^T r(t, u)f(u) du.$$

The covariance operator R_y of the observation process is then given by

$$(2.9) \quad R_y = I + R.$$

Noting that the operator R is trace class, the Fredholm determinant is

$$(2.10) \quad d = \prod_j (1 + \lambda_j),$$

where λ_j 's are the eigenvalues of R . Furthermore, there exists a unique operator K such that

$$(2.11) \quad K = R(I + R)^{-1} = I - (I + R)^{-1}.$$

Let p_y denote the measure induced by the process y_t , $0 \leq t \leq T$ on the space $C([0, T]; \mathbb{R}^m)$ of \mathbb{R}^m -valued continuous functions on $[0, T]$ with p_w denoting the Wiener measure thereon. By a result of Shepp [6] mentioned above, p_y is absolutely continuous with respect to p_w , and the Radon-Nikodym derivative is given by

$$(2.12) \quad \frac{dp_y}{dp_w}(y) = d^{-1/2} \exp \left\{ \frac{1}{2} \int_0^T \left[\int_0^T k(t, s) dy_s, dy_t \right] \right\},$$

where $k(t, s)$ is the kernel of the operator K and the integral on the right-hand side of (2.12) is a *double Wiener integral* as defined in [6].

It may be possible to define this integral as a quasimartingale following Itô [7], but in that case a correction term would appear in the right-hand side of (2.12).

Using Krein factorization [8], we get

$$(2.13) \quad R_y^{-1} = (I + R)^{-1} = (I - L^*)(I - L),$$

where L is a Volterra operator with kernel $l(t, s)$ and, as is shown in [8, pp. 232-234],

$$(2.14) \quad \begin{aligned} \log d^{-1/2} &= \frac{1}{2} \text{Tr} \log (I + R)^{-1} = -\frac{1}{2} \text{Tr} (L + L^*) \\ &= -\frac{1}{2} \int_0^T \text{Tr} l(t, t) dt. \end{aligned}$$

It has been shown in [4] that

$$(2.15) \quad \int_0^T \text{Tr} l(t, t) dt = \int_0^T \text{Tr} [C \{F(t)^{-1}\}_{1,2} C^*] dt,$$

where $\{F(t)^{-1}\}_{1,2}$ is the $(1, 2)$ th block of the block matrix $F(t)^{-1}$ with

$$(2.16) \quad F(t) \triangleq W^0(t) e^{-\Delta t} + W^T(t).$$

Here is

$$(2.17) \quad W^0(t) \triangleq \begin{pmatrix} \Pi_0(t) & -I \\ \Pi_1(t)^* & 0 \end{pmatrix}, \quad W^T(t) \triangleq \begin{pmatrix} \Pi_1(t) & 0 \\ \Pi_2(t) & I \end{pmatrix}, \quad \Delta \triangleq \begin{pmatrix} A & BB^* \\ C^*C & -A^* \end{pmatrix},$$

and $\Pi_i(t)$, $i = 0, 1, 2$, satisfy the differential equations

$$(2.18a) \quad \dot{\Pi}_0(t) = \Pi_1(t) BB^* \Pi_1(t)^*, \quad \Pi_0(T) = V^0 \Sigma_v^{-1} V^0,$$

$$(2.18b) \quad \dot{\Pi}_1(t) = \Pi_1(t) BB^* \Pi_2(t) - \Pi_1(t) A, \quad \Pi_1(T) = V^{0*} \Sigma_v^{-1} V^T,$$

$$(2.18c) \quad \dot{\Pi}_2(t) = \Pi_2(t) BB^* \Pi_2(t) - \Pi_2(t) A - A^* \Pi_2(t), \quad \Pi_2(T) = V^{T*} \Sigma_v^{-1} V^T.$$

Furthermore, as shown in [4], with \mathcal{Y}_t denoting the smallest σ -algebra generated by y_s , $0 \leq s \leq t$,

$$(2.19) \quad C \hat{x}_t \triangleq CE[x_2 | \mathcal{Y}_T] = \int_0^T k(t, s) dy_s.$$

Therefore, we get

$$(2.20) \quad \log \frac{dp_y}{dp_w}(y) = \frac{1}{2} \int_0^T [C\hat{x}_t, dy_t] - \frac{1}{2} \int_0^T \text{Tr} [C\{F(t)^{-1}\}_{1,2}C^*] dt.$$

Suppose now that we make n independent experiments, yielding independent sample trajectories $y_t^1, y_t^2, \dots, y_t^n$. For $k = 1, 2, \dots, n$, let

$$(2.21) \quad dx_t^k(\theta) = A(\theta)x_t^k(\theta) dt + B(\theta) dw_t^k, \quad V^0 x_0^k + V^T x_T^k = v^k,$$

and

$$(2.22) \quad dy_t^k = Cx_t^k dt + D dw_t^k.$$

Let $\hat{x}_t^k \triangleq E[x_t^k | \mathcal{Y}_t^k]$.

Then the log likelihood functional is given by

$$(2.23) \quad \begin{aligned} L_n(y^1, \dots, y^n; \theta) &= \log \prod_{k=1}^n \frac{dp_y}{dp_w}(y^k) = \sum_{k=1}^n \log \frac{dp_y}{dp_w}(y^k) \\ &= \frac{1}{2} \sum_{k=1}^n \left(\int_0^T [C\hat{x}_t^k(\theta), dy_t^k] - \int_0^T \text{Tr} [C\{F(t; \theta)^{-1}\}_{1,2}C^*] dt \right). \end{aligned}$$

3. Sample properties of signal and observation processes. We begin with the strong laws for independent sample trajectories.

THEOREM 3.1 (strong law of large numbers). *It holds that*

$$(3.1) \quad \frac{1}{n} \sum_{k=1}^n Cx_t^k \rightarrow 0 \quad \text{as } n \rightarrow \infty \quad \forall t \in [0, T] \text{ a.s.}$$

and

$$(3.2) \quad \frac{1}{n} \sum_{k=1}^n (Cx_t^k)(Cx_t^k)^* \rightarrow E\{Cx_t(Cx_t)^*\} \quad \text{as } n \rightarrow \infty \quad \forall t \in [0, T] \text{ a.s.}$$

with $\{x_t, 0 \leq t \leq T\}$ given by (2.4).

Proof. From the strong law of large numbers in [9, p. 363], to prove (3.1), we only need to check that

$$E\{|Cx_t^k|^4\} \leq \text{Const independent of } k.$$

Noting that Cx_t^k is a Gaussian random process, we have

$$E\{|Cx_t^k|^4\} = 3(E\{|Cx_t^k|^2\})^2.$$

It follows from (2.5) that

$$\begin{aligned} E\{|Cx_t^k|^4\} &= 3 \left(\text{Tr} \{V(t)\Sigma_v V(t)^*\} + \int_0^T \text{Tr} \{h(t, u)h(t, u)^*\} du \right)^2 \\ &\leq \text{Const independent of } k. \end{aligned}$$

The proof of (3.2) is similar. \square

THEOREM 3.2. *It holds that*

$$(3.3) \quad \begin{aligned} &\frac{1}{n} \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s) dy_s^k, dy_t^k \right] \\ &= \frac{1}{n} \sum_{k=1}^n \int_0^T [C\hat{x}_t^k, dy_t^k] \\ &\rightarrow E \int_0^T [C\hat{x}_t, Cx_t] dt + \text{Tr } K \text{ a.s. as } n \rightarrow \infty. \end{aligned}$$

Proof. Let

$$(3.4) \quad I_n \triangleq \frac{1}{n} \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s) dy_s^k, dy_t^k \right].$$

Then

$$(3.5) \quad \begin{aligned} I_n &= \frac{1}{n} \left(\sum_{k=1}^n \int_0^T [C\hat{x}_t^k, Cx_t^k] dt + \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s) Cx_s^k ds, D dw_t^k \right] \right. \\ &\quad \left. + \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s) D dw_s^k, D dw_t^k \right] \right) \\ &= I_n^1 + I_n^2 + I_n^3, \end{aligned}$$

say. Using the same method used in Theorem 3.1, we have

$$(3.6) \quad I_n^2 \rightarrow E \int_0^T \left[\int_0^T k(t, s) Cx_s ds, D dw_t \right] = 0 \quad \text{a.s. as } n \rightarrow \infty,$$

and the independence of the signal and measurement noises implies that

$$(3.7) \quad \begin{aligned} I_n^1 &= \frac{1}{n} \sum_{k=1}^n \left(\int_0^T \left[\int_0^T k(t, s) Cx_s^k ds, Cx_t^k \right] dt \right. \\ &\quad \left. + \int_0^T \left[\int_0^T k(t, s) D dw_s^k, Cx_t^k \right] dt \right) \\ &\rightarrow E \int_0^T \int_0^T [k(t, s) Cx_s, Cx_t] ds dt \\ &= E \int_0^T [C\hat{x}_t, Cx_t] dt \quad \text{a.s. as } n \rightarrow \infty. \end{aligned}$$

All we must do now is to study the convergence of I_n^3 , which is defined in the sense of a double Wiener integral.

From Shepp [6], we have

$$E(I_n^3) = \frac{1}{n} \sum_{k=1}^n \int_0^T \text{Tr } k(t, t) dt = \text{Tr } K.$$

Let $J_k = \int_0^T [\int_0^T k(t, s) D dw_s^k, D dw_t^k] - \text{Tr } K$. Then $\{J_k\}$ is a sequence of mutually independent random vectors of zero mean, and, by the strong law of large numbers,

$$(3.8) \quad I_n^3 \rightarrow \text{Tr } K \quad \text{a.s. as } n \rightarrow \infty.$$

Combining (3.6)–(3.8), we get the desired result. \square

4. The identification problem. We have already obtained the likelihood functional $L(y^1, \dots, y^n; \theta)$ for our problem. Since Θ is a compact set, for each ω in the sample space, we can find an element $\hat{\theta}_n(\omega) \in \Theta$ such that

$$(4.1) \quad L(y^1, \dots, y^n; \hat{\theta}_n) \geq L(y^1, \dots, y^n; \theta') \quad \text{for all } \theta' \in \Theta;$$

that is,

$$\sum_{k=1}^n \log \frac{dp_y^\theta}{dp_w}(y^k) \big|_{\theta=\hat{\theta}_n} \geq \sum_{k=1}^n \log \frac{dp_y^{\theta'}}{dp_w}(y^k) \quad \text{for all } \theta' \in \Theta.$$

In particular, for $\theta' = \theta_0$ (the true value of the parameter, which is assumed to lie in Θ), we have

$$(4.2) \quad \sum_{k=1}^n \log \frac{dp_y^\theta}{dp_{y_0}^{\theta_0}}(y^k) \geq 0.$$

We call $\hat{\theta}_n$ the *maximum likelihood estimate* (MLE) of θ_0 based on n independent sample trajectories y^1, \dots, y^n .

To establish consistency of the MLE, we must check the continuity of $\hat{x}_t^k(\theta)$ with respect to θ . For this, we need the following assumption.

Assumption A1. There exists a constant C such that

$$\begin{aligned} \sup_{\theta \in \Theta} \|A(\theta)\| &\leq C, & \sup_{\theta \in \Theta} \|\nabla_\theta A(\theta)\| &\leq C, \\ \sup_{\theta \in \Theta} \|B(\theta)\| &\leq C, & \sup_{\theta \in \Theta} \|\nabla_\theta B(\theta)\| &\leq C. \end{aligned}$$

LEMMA 4.1. *It holds that*

$$(4.3) \quad \begin{aligned} \lim_{n \rightarrow \infty} \sup_{\theta \in \Theta} \frac{1}{n} \sum_{k=1}^n \int_0^T [C\hat{x}_t^k(\theta), D dw_t^k] \\ = \sup_{\theta \in \Theta} \int_0^T \text{Tr } k(t, t; \theta) dt \quad a.s. \end{aligned}$$

Proof. The main idea of this proof is to transform the double Wiener integral into the Itô type integral. Then we can directly apply the results proposed by Borkar and Bagchi [5] to our case. It is easy to show that

$$(4.4) \quad \begin{aligned} \frac{1}{n} \sum_{k=1}^n \int_0^T [C\hat{x}_t^k(\theta), D dw_t^k] &= \frac{1}{n} \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s; \theta) dy_s^k, D dw_t^k \right] \\ &= \frac{1}{n} \sum_{k=1}^n \int_0^T \left(\int_0^T k(t, s; \theta) Cx_t^k(\theta_0) ds \right)^* D dw_t^k \\ &\quad + \frac{1}{n} \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s; \theta) D dw_s^k, D dw_t^k \right], \end{aligned}$$

where the first term of the right-hand side of (4.4) is defined in the Itô sense [7] because Cx^k and Dw^k are independent, and we find that Dw_t^k is \mathcal{F}_t -martingale for $\mathcal{F}_t = \sigma\{Dw_s^k; 0 \leq s \leq T\}$. Using the integration by parts formula for the double Wiener integral, the second term of the right-hand side of (4.4) becomes

$$(4.5) \quad \begin{aligned} &\frac{1}{n} \sum_{k=1}^n \int_0^T \left[\int_0^T k(t, s; \theta) D dw_s^k, D dw_t^k \right] \\ &= -\frac{1}{n} \sum_{k=1}^n w_T^{k*} D^* k(T, T; \theta) D w_T^k \\ &\quad + \frac{1}{n} \sum_{k=1}^n w_T^{k*} D^* \int_0^T \{k(t, T; \theta) + k(T, t; \theta)\} D dw_t^k \\ &\quad + \frac{1}{n} \sum_{k=1}^n \int_0^T \int_0^T w_t^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D w_s^k ds dt \\ &= I_1^n + I_2^n + I_3^n, \end{aligned}$$

say. With the aid of Itô's formula and $DD^* = I$, we have

$$\begin{aligned} I_1^n &= -\frac{2}{n} \sum_{k=1}^n \int_0^T w_t^{k*} D^* k(T, T; \theta) D dw_t^k - \text{Tr} \{k(T, T; \theta)\} \cdot T, \\ I_2^n &= \frac{2}{n} \sum_{k=1}^n \int_0^T w_t^{k*} D^* (k(t, T; \theta) + k(T, t; \theta)) D dw_t^k \\ &\quad + \int_0^T \text{Tr} \{k(t, T; \theta) + k(T, t; \theta)\} dt, \end{aligned}$$

and, for the integrand of I_3^n term, setting $t > s$,

$$\begin{aligned} \frac{1}{n} \sum_{k=1}^n w_t^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D w_s^k &= \frac{1}{n} \sum_{k=1}^n w_s^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D w_s^k \\ &\quad + \frac{1}{n} \sum_{k=1}^n \int_s^T w_s^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D dw_t^k; \end{aligned}$$

applying the Itô formula to the first term, we have

$$\begin{aligned} &= \frac{1}{n} \sum_{k=1}^n \left\{ \int_0^s 2w_\tau^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D dw_\tau^k + \int_s^t w_s^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D dw_\tau^k \right\} \\ &\quad + \text{Tr} \left\{ \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} \right\}_s. \end{aligned}$$

Hence

$$\begin{aligned} I_3^n &= \frac{1}{n} \sum_{k=1}^n \int_0^T \int_0^T \left\{ \int_0^{s \wedge t} 2w_\tau^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D dw_\tau^k \right. \\ &\quad \left. + \int_{s \wedge t}^{s \vee t} w_s^{k*} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D dw_\tau^k \right\} dt ds \\ &\quad + \int_0^T \int_0^T \text{Tr} \left\{ \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} \right\} (t \wedge s) dt ds. \end{aligned}$$

Combining all estimates, we have

$$\begin{aligned} &\frac{1}{n} \sum_{k=1}^n \int_0^T [C\hat{x}_t^k(\theta), D dw_t^k] \\ &= \frac{1}{n} \sum_{k=1}^n \int_0^T f^k(t, w^k; \theta) dw_t^k \\ (4.6) \quad &+ \int_0^T \int_0^T \frac{1}{n} \sum_{k=1}^n \int_0^{s \vee t} g^k(t, s, \tau, w^k) dw_\tau^k ds dt \\ &- \text{Tr} \{k(T, T; \theta)\} + \int_0^T \text{Tr} \{k(t, T; \theta) + k(T, t; \theta)\} dt \\ &+ \int_0^T \int_0^T \text{Tr} \left\{ \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} \right\} (t \wedge s) dt ds, \end{aligned}$$

where

$$\begin{aligned} f^k(t, w^k; \theta) &= \int_0^T k(t, s; \theta) Cx_s^k(\theta_0) ds D - 2w_t^{k*} D^* k(T, T; \theta) D \\ &\quad + 2w_t^{k*} D^* (k(t, T; \theta) + k(T, t; \theta)) D \end{aligned}$$

and

$$g^k(t, s, \tau, w^k) = \{2\chi_{s < t} w_\tau^{k*} + (1 - \chi_{s < t}) w_s^{k*}\} D^* \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} D,$$

where

$$\chi_{s < t} = \begin{cases} 1 & \text{if } s < t, \\ 0 & \text{if } s > t. \end{cases}$$

Hence, we must prove that

$$(4.7) \quad \lim_{n \rightarrow \infty} \sup_{\theta \in \Theta} \left(\frac{1}{n} \sum_{k=1}^n \int_0^T f^k(t, w^k; \theta) dw_t^k \right) = 0 \quad \text{a.s.}$$

and

$$(4.8) \quad \lim_{n \rightarrow \infty} \sup_{\theta \in \Theta} \left(\frac{1}{n} \sum_{k=1}^n \int_0^{s \vee t} g^k(t, s, \tau; w^k) dw_\tau^k \right) = 0 \quad \text{a.s.}$$

To apply the results of Borkar and Bagchi [5], we define

$$\tilde{w}_t = [w_t^1, w_t^2, \dots, w_t^n]^*$$

and

$$\tilde{f}(t, \tilde{w}, \theta) = [f^1(t, w^1; \theta), f^2(t, w^2; \theta), \dots, f^n(t, w^n; \theta)]$$

so that

$$(4.9) \quad \frac{1}{n} \sum_{k=1}^n \int_0^T f^k(t, w^k; \theta) dw_t^k = \frac{1}{n} \int_0^T \tilde{f}(t, \tilde{w}, \theta) d\tilde{w}_t.$$

Hence, for every $\theta_1, \theta_2 \in \Theta$, $2m \geq p+1$ ($\Theta \subset R^p$), and $m \geq 2$, by using the same argument as Lemma 3.1 of [5, p. 196], we have

$$\begin{aligned} & E \left\{ \left(\frac{1}{n} \int_0^T (\tilde{f}(t, \tilde{w}; \theta_1) - \tilde{f}(t, \tilde{w}; \theta_2)) d\tilde{w}_t \right)^{2m} \right\} \\ & \leq (m(2m-1))^{m-1} T^{m-1} \frac{1}{n^{2m}} \int_0^T E \left\{ \left(\sum_{k=1}^n \|f^k(t, w^k; \theta_1) - f^k(t, w^k; \theta_2)\|^2 \right)^m \right\} dt \\ & \leq C(m) \frac{n \cdot m}{n^{2m}} \sum_{k=1}^n \int_0^T E \{ \|f^k(t, w^k; \theta_1) - f^k(t, w^k; \theta_2)\|^{2m} \} dt, \end{aligned}$$

where

$$\begin{aligned} C(m) &= (m(2m-1))^{m-1} T^{m-1} \\ & \leq C(m) m \frac{n}{n^{2m}} \sum_{k=1}^n \int_0^T E \left\{ \left\| \int_0^T (k(t, s; \theta_1) - k(t, s; \theta_2)) Cx_s^k(\theta_0) ds \right. \right. \\ & \quad - 2w_t^{k*} D^* (k(T, T; \theta_1) - k(T, T; \theta_2)) D \\ & \quad + 2w_t^{k*} D^* \{ (k(t, T; \theta_1) - k(t, T; \theta_2)) \\ & \quad \left. \left. + (k(T, t; \theta_1) - k(T, t; \theta_2)) \} D \right\|^{2m} \right\} dt. \end{aligned} \quad (4.10)$$

From Assumption A1, we can show that

$$\|k(t, s; \theta_1) - k(t, s; \theta_2)\| \leq C \|\theta_1 - \theta_2\| \quad \text{for } 0 \leq s, \quad t \leq T.$$

Furthermore,

$$E \left\{ \left(\int_0^T \|x_s^k(\theta_0)\| ds \right)^{2m} \right\} \leq \text{Const independent of } k$$

and

$$E \{ \|w_t^k\|^{2m} \} \leq \text{Const independent of } k.$$

Hence, (4.10) becomes

$$\begin{aligned} E \left\{ \left(\frac{1}{n} \int_0^T (\tilde{f}(t, \tilde{w}; \theta_1) - \tilde{f}(t, \tilde{w}; \theta_2)) d\tilde{w}_t \right)^{2m} \right\} \\ \leq \text{Const} \frac{n^2}{n^{2m}} \|\theta_1 - \theta_2\|^{2m}, \end{aligned}$$

noting that, from $m \geq 2$, there exists an $\alpha > 0$ such that

$$(4.11) \quad \leq \text{Const} \frac{\|\theta_1 - \theta_2\|^{2m}}{n^{1+\alpha}}.$$

This estimate is the same as Lemma 3.1 [5, p. 196]; hence (4.7) can be derived. Repeating the same argument as above, we can prove (4.8). Details are omitted.

From (4.6)–(4.8), we have

$$\begin{aligned} \lim_{n \rightarrow \infty} \sup_{\theta \in \Theta} \frac{1}{n} \int_0^T [C\hat{x}_t^k(\theta), D dw_s^k] \\ = \sup_{\theta \in \Theta} \left\{ -\text{Tr} \{k(T, T; \theta)\} + \int_0^T \text{Tr} \{k(t, T; \theta) + k(T, t; \theta)\} dt \right. \\ \left. + \int_0^T \int_0^T \text{Tr} \left\{ \frac{\partial^2 k(t, s; \theta)}{\partial t \partial s} \right\} (t \wedge s) dt ds \right\} \quad \text{a.s.} \end{aligned}$$

(integrating by parts)

$$= \sup_{\theta \in \Theta} \int_0^T \text{Tr} k(t, t; \theta) dt \quad \text{a.s.}$$

This is the desired result. \square

THEOREM 4.1. *Let \mathcal{M} be the set of measure zero outside of which Lemma 4.1 holds. For each $\omega \notin \mathcal{M}$, letting $\hat{\theta}_n$ be the maximum likelihood estimate of θ_0 , we have the following strong consistency property:*

$$(4.12) \quad \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{k=1}^n \int_0^T |C(\hat{x}_t^k(\hat{\theta}_n) - x_t^k(\theta_0))|^2 dt = \int_0^T \text{Tr} [CP(t; \theta_0)C^*] dt \quad \text{a.s.}$$

Proof. From (4.2), the MLE $\hat{\theta}_n$ satisfies

$$(4.13) \quad \left(\frac{d(1, \theta_0)}{d(1, \hat{\theta}_n)} \right)^{n/2} \exp \left\{ \frac{1}{2} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n) - \hat{x}_t^k(\theta_0)), dy_t^k] \right\} \geq 1.$$

From (2.14) and (2.15), we find that

$$\begin{aligned} \log \left(\frac{d(1, \theta_0)}{d(1, \hat{\theta}_n)} \right)^{n/2} &= \frac{n}{2} \{ \text{Tr} \{K(\theta_0) - K(\hat{\theta}_n)\} \} \\ &= \frac{n}{2} \int_0^T \text{Tr} \{CP(t; \theta_0)C^* - CP(t; \hat{\theta}_n)C^*\} dt. \end{aligned}$$

Hence, from (4.13),

$$(4.14) \quad \begin{aligned} & \frac{1}{2} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n) - \hat{x}_t^k(\theta_0)), dy_t^k] \\ & - \frac{n}{2} \left\{ \int_0^T \text{Tr}[CP(t; \hat{\theta}_n)C^* - CP(t; \theta_0)C^*] dt \right\} \geq 0. \end{aligned}$$

Dividing (4.14) by n , the first term of the above inequality becomes

$$\begin{aligned} & \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n) - \hat{x}_t^k(\theta_0)), dy_t^k] \\ & = \lim_{n \rightarrow \infty} \left\{ \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n) - \hat{x}_t^k(\theta_0)), Cx_t^k(\theta_0)] dt \right. \\ & \quad \left. + \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n) - \hat{x}_t^k(\theta_0)), D dw_t^k] \right\} \\ & = \lim_{n \rightarrow \infty} \{T_1^n + T_2^n\}, \end{aligned}$$

say. From Lemma 4.1 and (3.3), it follows that

$$(4.15) \quad \begin{aligned} \lim_{n \rightarrow \infty} T_2^n &= \lim_{n \rightarrow \infty} \frac{1}{2} \int_0^T \text{Tr}[k(t, t; \hat{\theta}_n) - k(t, t; \theta_0)] dt \\ &= \lim_{n \rightarrow \infty} \frac{1}{2} \int_0^T \text{Tr}[CP(t; \hat{\theta}_n)C^* - CP(t; \theta_0)C^*] dt \quad \text{a.s.} \end{aligned}$$

Hence, dividing (4.14) by n and using (4.15), we have

$$(4.16) \quad \lim_{n \rightarrow \infty} T_1^n \geq 0 \quad \text{a.s.}$$

This implies that

$$(4.17) \quad \begin{aligned} & \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [Cx_t^k(\hat{\theta}_n), Cx_t^k(\theta_0)] dt \\ & \geq \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C\hat{x}_t^k(\theta_0), Cx_t^k(\theta_0)] dt \\ & = E \left\{ \int_0^T [C\hat{x}_t(\theta_0), Cx_t(\theta_0)] dt \right\} \\ & = E \left\{ \int_0^T |C\hat{x}_t(\theta_0)|^2 dt \right\} \quad \text{a.s.} \end{aligned}$$

Hence, by using (4.17), the following inequality can be derived:

$$(4.18) \quad \begin{aligned} & \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(x_t^k(\theta_0) - C\hat{x}_t^k(\hat{\theta}_n)), Cx_t^k(\theta_0)] dt \\ & \leq \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T |C(x_t^k(\theta_0)|^2 dt - E \left\{ \int_0^T |C\hat{x}_t(\theta_0)|^2 dt \right\} \\ & = E \left\{ \int_0^T |Cx_t(\theta_0) - C\hat{x}_t(\theta_0)|^2 dt \right\} \\ & = \int_0^T \text{Tr}[CP(t; \theta_0)C^*] dt \quad \text{a.s.} \end{aligned}$$

On the other hand, from (4.18), we also have

$$\begin{aligned}
 & \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(x_t^k(\theta_0) - C\hat{x}_t^k(\hat{\theta}_n)), Cx_t^k(\theta_0)] dt \\
 &= \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \left\{ \int_0^T |Cx_t^k(\theta_0)|^2 dt - \int_0^T |C\hat{x}_t^k(\hat{\theta}_n)|^2 dt \right\} \\
 &+ \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n), C\hat{x}_t^k(\hat{\theta}_n) - Cx_t^k(\theta_0))] dt \\
 &\leq \int_0^T \text{Tr}[CP(t; \theta_0)C^*] dt \quad \text{a.s.}
 \end{aligned}$$

Then

$$\begin{aligned}
 & \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \int_0^T [C(\hat{x}_t^k(\hat{\theta}_n), C\hat{x}_t^k(\hat{\theta}_n) - Cx_t^k(\theta_0))] dt \\
 &\leq \int_0^T \text{Tr}[CP(t; \theta_0)C^*] dt \\
 &- \lim_{n \rightarrow \infty} \frac{1}{2n} \sum_{k=1}^n \left\{ \int_0^T |Cx_t^k(\theta_0)|^2 dt - \int_0^T |C\hat{x}_t^k(\hat{\theta}_n)|^2 dt \right\} \\
 (4.19) \quad &= \int_0^T \text{Tr}[CP(t; \theta_0)C^*] dt \\
 &- \lim_{n \rightarrow \infty} E \left\{ \int_0^T |Cx_t(\theta_0)|^2 dt - \int_0^T |C\hat{x}_t(\hat{\theta}_n)|^2 dt \right\} \\
 &\leq 0 \quad \text{a.s.},
 \end{aligned}$$

where we used the fact that $P(t; \theta_0)$ is an error covariance in the sense of minimum variance estimate, i.e.,

$$\text{Tr}\{P(t, \theta_0)\} - E\{|x_t(\theta)|^2 - |\hat{x}_t(\theta)|^2\} \leq 0 \quad \forall \theta \in \theta.$$

Then, summing (4.18) and (4.19), (4.12) can be derived. \square

COROLLARY. *It holds that*

$$\hat{\theta}_n \rightarrow \{\theta \mid P_{\theta_0}\{C\hat{x}_t^n(\theta) = C\hat{x}_t^n(\theta_0) \text{ a.e.t., } \forall n\} = 1\} \quad \text{a.s.}$$

Proof. The proof follows from the previous theorem and the fact that

$$\begin{aligned}
 & \frac{1}{n} \sum_{k=1}^n \int_0^T |C\hat{x}_t^k(\theta) - Cx_t^k(\theta_0)|^2 dt \rightarrow E \int_0^T |C\hat{x}_t(\theta) - C\hat{x}_t(\theta_0)|^2 dt \\
 &+ \int_0^T \text{Tr}(CP(t; \theta_0)C^*) dt,
 \end{aligned}$$

where the expectation is with respect to the stationary measure.

5. Conclusion. The remaining problem for parameter identification for the TPBV process is to derive the practical algorithm for generating the optimal MLE. Noting that explicit form of smoother for the TPVB process has been derived in [4] in a computable form, it is possible to show the explicit form of necessary condition for the optimal MLE. Then, by using the similar technique presented by Aihara and Bagchi [10], from the derived necessary condition, we can construct a practical algorithm for generating the optimal MLE.

A METHOD OF CENTERS BASED ON BARRIER FUNCTIONS FOR SOLVING OPTIMAL CONTROL PROBLEMS WITH CONTINUUM STATE AND CONTROL CONSTRAINTS*

E. POLAK†, T. H. YANG†, AND D. Q. MAYNE‡

Abstract. This paper describes a method of centers based on barrier functions for solving optimal control problems with continuum inequality constraints on the state and control. The method decomposes the original problem into a sequence of easily solved optimal control problems with control constraints only. The method requires only approximate solution of these problems.

Key words. optimal control algorithms, method of centers, barrier functions, state space, control constraints

AMS(MOS) subject classifications. 49N40, 49M39, 49M30

1. Introduction. The difficulty of an optimal control problem is very much a function of the constraints. In the realm of optimal control problems, optimal control problems with control constraints and inequality state-space constraints rank close to the top in terms of difficulty or, alternatively, close to the bottom in terms of tractability. In this paper, we use ideas contained in recent work on phase I-phase II methods of centers [20], methods of centers based on barrier functions [7], [16], [22], and barrier function methods for semi-infinite minimax problems [21] to construct a reasonably promising optimal control algorithm for solving optimal control problems with both control and inequality state-space constraints. An important feature of this algorithm is that it decomposes the original problem into an infinite sequence of highly tractable optimal control problems with integral cost and control constraints only, each of which need only to be solved approximately.

To help establish the extent to which this paper advances the state of the art, we now discuss some of the earlier results in this area. We recall that free-time problems can always be transcribed into fixed-time problems by means of an augmentation of the dynamics (see [26]), and hence we need only discuss fixed-time problems. First (see [2]), unconstrained optimal control problems and optimal control problems with inequality endpoint constraints (both without control constraints), with smooth dynamics, can be formulated as

$$(1.1a) \quad \min_{u \in C} f^0(u)$$

and

$$(1.1b) \quad \min_{u \in C} \{f^0(u) \mid f^j(u) \leq 0, j = 1, 2, \dots, q\},$$

respectively, with all the functions $f^j(\cdot)$ continuously Frechet differentiable on the pre-Hilbert space $L_{\infty,2} \triangleq \{L_{\infty}^m[0,1], \|\cdot\|_2\}$, where $\|\cdot\|_2$ denotes the norm $L_2^m[0,1]$. These problems can be solved by exact analogues of the Armijo gradient method [1] (see, e.g., [8], [27]) and of the method of centers (see [17], [18]), respectively.

Simple optimal control problems with control constraints only assume the form

$$(1.2a) \quad \min_{u \in U} f^0(u),$$

where $U \triangleq \{u \in L_{\infty,2} | u(t) \in U, t \in [0,1]\}$, with U a compact subset of \mathbb{R}^m , and $f^0(\cdot)$ as above. For simple sets U , these problems can be solved by analogues of the slow-to-converge Frank-Wolfe algorithm [5], the faster Goldstein-Levitin-Polyak gradient projection method (see [3]), and a multiplier method [6], as well as by two algorithms that are optimal control specific: the strong variations algorithm in [23] and the relaxed-control steepest-descent algorithm in [27]. The addition of control constraints to (1.1b) results in a problem of the form

$$(1.2b) \quad \min_{u \in U} \{f^0(u) | f^j(u) \leq 0, j = 1, 2, \dots, q\},$$

which can be solved by an extension (see [12]) of the method of centers [17], [18]. However, the control constraints result in a considerable increase in difficulty in the search-direction-finding problem. The addition of equality constraints to (1.2b) can be handled by means of exact penalty functions (see, e.g., [12]–[14]).

The most difficult optimal control problems have both control and state-space constraints and can assume the following abstract form:

$$(1.3) \quad \min_{u \in U} \left\{ f^0(u) | f^j(u) \leq 0, j = 1, 2, \dots, q, \max_{t \in [0,1]} \phi^k(u, t) \leq 0, k = 1, 2, \dots, r \right\},$$

where the functions $f^j(\cdot)$ and $\phi^k(\cdot, \cdot)$ are all continuously differentiable. We recognize these problems as generalizations of finite-dimensional semi-infinite programming problems (see [19]). The presence of the control constraints generates a major obstacle because it precludes the efficient use of minimax theorems in the solution of extremely difficult search-direction-finding problems (see [19] for their use in semi-infinite optimization).

Not counting nonlinear programming algorithms on discretized versions of optimal control problems or algorithms whose convergence has not been established (see, e.g., [9], [10], [15]), there appear to be only two algorithms in the literature for the solution of problems of the form (1.3). They are both extensions of the method in [17], [18]; the one in [28] is based on the use of relaxed controls, whereas the one in [12] is not. Both of these algorithms postulate extremely difficult search-direction computations.

The algorithm we present in this paper is much simpler in structure than either of the algorithms [28], [29] or [11], [12]; furthermore, it is easily implemented using existing methods (such as in [3], [8]). In § 2 we present our algorithm in a simplified (conceptual) form. In §§ 3 and 4 we give full details of two alternative versions of our new algorithm and prove their convergence to feasible stationary points. Computational results are reported in § 5 and show that the algorithm performs satisfactorily.

2. A conceptual phase I–phase II method of centers. We consider optimal control problems defined in the pre-Hilbert space $L_{\infty,2} \triangleq \{L_{\infty}^m[0,1], \|\cdot\|_2\}$, consisting of elements in $L_{\infty}^m[0,1]$ but endowed with the $L_2[0,1]$ scalar product $\langle \cdot, \cdot \rangle_2$ and corresponding norm $\|\cdot\|_2$. The problems are normalized, fixed-time problems with control and

state-space constraints, of the form

$$(2.1a) \quad \mathbf{P}: \min \left\{ f^0(u) \mid f^j(u) \leq 0, j = 1, 2, \dots, q_1, \right. \\ \left. \max_{t \in [0, 1]} \phi^k(u, t) \leq 0, k = 1, 2, \dots, q_2, u \in G \right\},$$

where

$$(2.1b) \quad G \triangleq \{u \in L_{\infty, 2} \mid u(t) \in U, \forall t \in [0, 1]\}$$

with $U \subset \mathbb{R}^m$. The cost function $f^0: L_{\infty, 2} \rightarrow \mathbb{R}$ and the endpoint constraint functions $f^j: L_{\infty, 2} \rightarrow \mathbb{R}, j = 1, 2, \dots, q_1$ are defined by

$$(2.2a) \quad f^j(u) \triangleq g^j(x^u(1));$$

whereas the state-space constraint functions $\phi^k: L_{\infty, 2} \times [0, 1] \rightarrow \mathbb{R}, k = 1, 2, \dots, q_2$, are defined by

$$(2.2b) \quad \phi^k(u, t) \triangleq g^k(x^u(t)),$$

where the functions $g^j, g^k: \mathbb{R}^n \rightarrow \mathbb{R}$ and $x^u(\cdot)$ is the solution of the differential equation

$$(2.3a) \quad \dot{x}(t) = h(x(t), u(t)), \quad t \in [0, 1],$$

$$(2.3b) \quad x(0) = x_0,$$

where $h: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$, and $x_0 \in \mathbb{R}^n$ is given.

We assume that the problem \mathbf{P} has a solution. In addition, we will require the following hypotheses, which ensure (see [2]) that (a) the solutions $x(\cdot)$ exist and are locally Lipschitz continuously differentiable, (b) the functions $f^j(\cdot)$ are locally Lipschitz continuously differentiable, and (c) the functions $\phi^j(\cdot, \cdot)$ are locally Lipschitz continuously differentiable in u and continuous in t .

Assumption 2.1. Let the following hold:

- (i) The set $U \subset \mathbb{R}^m$ is compact and convex;
- (ii) The functions $g^j, g^k: \mathbb{R}^n \rightarrow \mathbb{R}$ are locally Lipschitz continuously differentiable;
- (iii) The function $h: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ is locally Lipschitz continuously differentiable;
- (iv) There is a constant $M < \infty$ such that $\|h(x, u)\| \leq M(1 + \|x\|)$ for all $(x, u) \in X \times U$, where X is a sufficiently large but bounded subset of \mathbb{R}^n .

For the purpose of convergence analysis, it is useful to introduce the relaxed-controls closure of the set G .

We recall that a Radon probability measure μ on the Borel sets of U (in (2.1b)) is a positive measure such that $\mu(U) = 1$. The set of Radon probability measures will be denoted by $\text{rpm}(U)$. A relaxed control σ is a measurable function $\sigma: [0, 1] \rightarrow \text{rpm}(U)$. We define the relaxed-controls closure of the set G (in (2.1b)) by

$$(2.4a) \quad \bar{G} \triangleq \{\sigma: [0, 1] \rightarrow \text{rpm}(U) \mid \sigma \text{ is measurable}\}.$$

We use the weak* topology on $L^1([0, 1], C(U))^*$ to topologize \bar{G} . Consequently, $\{\sigma_i\} \subset \bar{G}$ converges to $\sigma \in \bar{G}$ if and only if

$$(2.4b) \quad \lim_{i \rightarrow \infty} \int_0^1 \int_U \phi(t, u) \sigma_i(t)(du) dt = \int_0^1 \int_U \phi(t, u) \sigma(t)(du) dt$$

$$\forall \phi \in L^1([0, 1], C(U)),$$

where $L^1([0, 1], C(U))$ denotes the space of absolutely integrable functions that map the interval $[0, 1]$ into $C(U)$, the space of real-valued continuous functions defined on U .

In this topology, \bar{G} is sequentially compact. We recall that there is an injection of the ordinary controls into the relaxed controls: With each ordinary control $u \in G$, we associate a relaxed control $\sigma \in \bar{G}$ such that $\sigma(t)(S) = \delta_{u(t)}(S)$ for all measurable sets $S \subset U$, where $\delta_u(S) = 1$ if $u \in S$ and $\delta_u(S) = 0$ otherwise.

Relaxed controls give rise to relaxed dynamics as follows:

$$(2.4c) \quad \dot{x}(t) = \int_U h(x(t), u) \sigma(t)(du), \quad t \in [0, 1],$$

$$(2.4d) \quad x(0) = x_0,$$

whose solutions we will denote by $\bar{x}^\sigma(t)$. We extend this notation also to the functions in (2.2a), (2.2b); thus $\bar{f}^j(\sigma) = g^j(\bar{x}^\sigma(1))$ and $\bar{\phi}^k(\sigma, t) = g^k(\bar{x}^\sigma(t))$.

Our exposition will be simpler if we assume a single form for both the state-space and endpoint constraints. This requires that the functions $f^j(\cdot)$ be replaced by functions of the form $\max_{t \in [0, 1]} \phi^j(u, t)$ with $\phi^j(u, t) \triangleq g^j(x^u(1))$ for all $t \in [0, 1]$. Then, if we let $q = q_1 + q_2$ and replace the indices k in (2.2b) by $j = q_1 + k$, problem (2.1a) becomes

$$(2.5a) \quad \mathbf{P}: \min \left\{ f^0(u) \mid \max_{t \in [0, 1]} \phi^j(u, t) \leq 0, j = 1, 2, \dots, q, u \in G \right\},$$

or, in the even more compact form,

$$(2.5b) \quad \mathbf{P}: \min \{ f^0(u) \mid \psi^j(u) \leq 0, j = 1, 2, \dots, q, u \in G \},$$

where $\psi^j(u) \triangleq \max_{t \in [0, 1]} \phi^j(u, t)$.

We can also state the relaxed control version of (2.5b), as follows:

$$(2.5c) \quad \bar{\mathbf{P}}: \min \{ \bar{f}^0(\sigma) \mid \bar{\psi}^j(\sigma) \leq 0, j = 1, 2, \dots, q, \sigma \in \bar{G} \}.$$

Since we have assumed that \mathbf{P} has a solution, the *minimum values* for \mathbf{P} and $\bar{\mathbf{P}}$ are the same. However, it is conceivable that $\bar{\mathbf{P}}$ has solutions that do not have counterparts in G .

For any $u \in L_{\infty, 2}$, let $\psi(u) \triangleq \max_{j \in q} \psi^j(u)$, where $q \triangleq \{1, 2, \dots, q\}$, and let $\psi(u)_+ \triangleq \max \{0, \psi(u)\}$. The phase I-phase II methods of centers that we present in this paper are based on the use of the *unifying* function $F: L_{\infty, 2} \times L_{\infty, 2} \rightarrow \mathbb{R}$, defined by¹

$$(2.6) \quad F(u \mid u') = \max_{j \in q} \{ f^0(u) - f^0(u') - 2\psi(u')_+, \psi^j(u) - \psi(u')_+ \}.$$

The following result is obvious.

PROPOSITION 2.1. (i) For all $u \in L_{\infty, 2}$, $F(u \mid u) = 0$. (ii) Suppose that $\hat{u} \in G$ is a local optimizer for problem (2.5b). Then $F(u \mid \hat{u}) \geq 0$ for all $u \in G$ near \hat{u} , i.e., \hat{u} is a local minimizer for the problem $\min_{u \in G} F(u \mid \hat{u})$.

Phase I-phase II methods of centers are based on the following geometric notion: Given a point $u_i \in G$, its successor u_{i+1} is chosen to be a “center” of the set

$$(2.7) \quad V(u_i) \triangleq \{u \in G \mid F(u \mid u_i) \leq 0\}.$$

For our methods of centers to work, we must introduce the following commonly used “constraint qualification” type of hypothesis, which is easily interpreted in terms of Proposition 2.1.

¹ The scale factor 2 in the term $2\psi(u')_+$ in (2.6) can be replaced by any other scale factor $\gamma > 1$.

Assumption 2.2. For every $\sigma \in \bar{G}$ that is not a solution of $\bar{\mathbf{P}}$, there exists a $u \in G$ such that $F(u|\sigma) < 0$.

The methods differ by the manner in which they define a “center.” The simplest, but not practical, definition of the “center” u_{i+1} is

$$(2.8) \quad u_{i+1} = \operatorname{argmin}_{u \in G} F(u|u_i).$$

Solving (2.8) for u_{i+1} is hardly easier than solving the original problem (2.5b). Hence, we will now introduce a much more tractable definition of a “center” based on the parametrized *barrier function* $p_\alpha : L_{\infty,2} \times L_{\infty,2} \rightarrow \mathbb{R}$ for the above sets $V(u')$, defined by, for $\alpha > 0$,

$$(2.9) \quad p_\alpha(u|u') \triangleq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} + \sum_{j=1}^q \int_0^1 \frac{1}{\alpha + \psi(u')_+ - \phi^j(u, t)} dt.$$

Because for $\alpha > 0$, $p_\alpha(u'|u') < \infty$, the parameter α makes it possible to use the point u' for initializing a descent method in solving $\min_{u \in V(u')} p_\alpha(u|u')$.

We begin by establishing that as $\alpha \rightarrow 0$, $p_\alpha(\cdot|u')$ becomes a barrier function for the set $V(u')$.

LEMMA 2.1. *There exists a constant $L > 0$, such that, for all $u' \in G$, $u \in V(u')$, and $\alpha > 0$,*

$$(2.10) \quad p_\alpha(u|u') \geq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} + \frac{1}{L} \log \left(1 + \frac{L}{(\alpha + \psi(u')_+ - \psi(u))} \right).$$

Proof. It follows from our assumptions that there exists a constant $L < \infty$, such that each $\phi^j(u, \cdot)$ is uniformly Lipschitz in t on $[0, 1]$ with the same Lipschitz constant L for all $u \in G$. Without loss of generality, we may assume that $L \geq \psi(u')_+ - \psi(u)$ for all $u, u' \in G$. Now, given $u' \in G$ and $u \in V(u')$, let $k \in \bar{q}$ and $\hat{t} \in [0, 1]$ be such that $\phi^k(u, \hat{t}) = \psi(u)$, and let $t \in [0, 1]$ be arbitrary. Then we have that

$$(2.11) \quad \phi^k(u, t) \geq \phi^k(u, \hat{t}) - L|t - \hat{t}| = \psi(u) - L|t - \hat{t}|.$$

Consequently, since $\psi(u')_+ - \psi(u) \geq 0$,

$$(2.12) \quad \begin{aligned} p_\alpha(u|u') &\geq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} + \int_0^1 \frac{1}{(\alpha + \psi(u')_+ - \phi^k(u, t))} dt \\ &\geq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} + \int_0^1 \frac{1}{(\alpha + \psi(u')_+ - \psi(u) + L|t - \hat{t}|)} dt \\ &\geq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} \\ &\quad + \frac{1}{L} \log \left(\frac{(\alpha + \psi(u')_+ - \psi(u) + L\hat{t})(\alpha + \psi(u')_+ - \psi(u) + L(1 - \hat{t}))}{(\alpha + \psi(u')_+ - \psi(u))^2} \right) \\ &\geq \frac{1}{\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)} + \frac{1}{L} \log \left(1 + \frac{L}{(\alpha + \psi(u')_+ - \psi(u))} \right), \end{aligned}$$

where the last line is obtained by minimizing the preceding line with respect to \hat{t} , which happens when $\hat{t} = 0$ or 1 . \square

It follows by inspection of (2.10) that when $u \rightarrow u'$ with $u \in V(u')$, then $p_0(u|u') \rightarrow \infty$, i.e., that $p_0(\cdot, u')$ is indeed a barrier function for $V(u')$.

Now consider the following conceptual algorithm for solving the problem **P** (2.5a).

Algorithm 2.1.

Data: $u_0 \in G$ and a sequence $\{\alpha_k\}_{k=0}^\infty$ such that $\alpha_k > 0$ for all $k \in \mathbb{N}$ and $\alpha_k \downarrow 0$ as $k \rightarrow \infty$.

Step 0: Set $i = 0$ and $k = 0$.

Step 1: Compute

$$(2.13) \quad u_{i+1} \in A(u_i) \triangleq \operatorname{argmin}_{u \in V(u_i)} p_{\alpha_k}(u|u_i).$$

Step 2: If $F(u_{i+1}|u_i) = 0$, replace k by $k+1$ and go to Step 1.

Step 3: Replace i by $i+1$ and k by $k+1$, and go to Step 1.

Note that (2.13) defines u_{i+1} as a solution of the simple optimal control problem, shown below:

$$(2.14) \quad \min_{u \in G} \left\{ \frac{1}{\alpha_{k_i} + 2\psi(u_i)_+ + g^0(x^{u_i}(1)) - g^0(x^u(1))} + \sum_{j=1}^q \int_0^1 \frac{1}{\alpha_{k_i} + \psi(u_i)_+ - g^j(x^u(t))} dt \right\},$$

where, as before, $x^u(t)$ is the solution of (2.4a), (2.4b). This problem has only control constraints; its cost is the endpoint-plus-integral form. Barring possible ill conditioning, such problems are tractable by algorithms such as the Goldstein-Levitin-Polyak gradient projection method (see [3]) or by the algorithm described in [2]. However, these methods require an *infinite* number of iterations to produce an accumulation point that can only be shown to be stationary (not necessarily optimal); hence Algorithm 2.1 is only conceptual.

THEOREM 2.1. (i) *Suppose that Algorithm 2.1 jams up in the loop between Steps 1 and 2 at the control u_{i_0} . Then u_{i_0} is a solution of **P**.* (ii) *Suppose that $\{u_i\}_{i=0}^\infty$ is a sequence of controls constructed by Algorithm 2.1. If this sequence has an accumulation point $\hat{u} \in G$, then \hat{u} is a solution of **P**.*

Proof. (i) For contradiction, suppose that u_{i_0} is not a solution of **P**. Since the algorithm is cycling in the loop between Steps 1 and 2, $k \rightarrow \infty$. Let $\hat{u}_k \triangleq \operatorname{argmin}_{u \in V(u_{i_0})} p_{\alpha_k}(u|u_{i_0})$. Then, since $\alpha_k \rightarrow 0$ as $k \rightarrow \infty$ and $F(\hat{u}_k|u_{i_0}) = 0$ for all k , we conclude that $p_{\alpha_k}(\hat{u}_k|u_{i_0}) \rightarrow \infty$ as $k \rightarrow \infty$. By Assumption 2.2, however, since u_{i_0} is not a solution of **P**, there exists a $\hat{u} \in V(u_{i_0})$ such that $F(\hat{u}|u_{i_0}) < 0$, which implies that $p_0(\hat{u}|u_{i_0}) < \infty$. Since $p_{\alpha_k}(\hat{u}|u_{i_0})$ is continuous in α , there exists a k_0 such that $p_{\alpha_k}(\hat{u}|u_{i_0}) \leq 2p_0(\hat{u}|u_{i_0})$ for all $k \geq k_0$. Because $p_{\alpha_k}(\hat{u}_k|u_{i_0}) \rightarrow \infty$, however, there exists a k_1 such that $p_{\alpha_k}(\hat{u}_k|u_{i_0}) > p_{\alpha_k}(\hat{u}|u_{i_0})$ for all $k \geq k_1 \geq k_0$, which contradicts the fact that \hat{u}_k is a minimizer.

(ii) Suppose that there exists an infinite subset $K \subset \mathbb{N}$ and a $\hat{u} \in G$ such that the subsequence $\{u_i\}_{i \in K}$ converges to \hat{u} ; we write this as $u_i \xrightarrow{K} \hat{u} \in G$ as $i \rightarrow \infty$. For contradiction, suppose that \hat{u} is not a solution of **P**.

Case 1. There exists an i_0 such that $\psi(u_{i_0}) \leq 0$, so that $\psi(u_{i_0})_+ = 0$. Since $F(u_{i_0+1}|u_{i_0}) < 0$, we have that

$$(2.15a) \quad f^0(u_{i_0+1}) - f^0(u_{i_0}) < 0,$$

$$(2.15b) \quad \psi(u_{i_0+1}) < 0.$$

It now follows by induction that, for all $i \geq i_0$,

$$(2.16a) \quad f^0(u_{i+1}) - f^0(u_i) < 0,$$

$$(2.16b) \quad \psi(u_i) < 0.$$

Hence, since the sequence $\{f^0(u_i)\}_{i=i_0}^\infty$ is monotone decreasing, and since $f^0(u_i) \xrightarrow{K} f^0(\hat{u})$ as $i \rightarrow \infty$, by continuity, it follows that $f^0(u_i) \rightarrow f^0(\hat{u})$ as $i \rightarrow \infty$; therefore, since

$$(2.17a) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) > \frac{1}{\alpha_{k_i} + f^0(u_i) - f^0(u_{i+1})},$$

and $\alpha_{k_i} \rightarrow 0$ as $i \rightarrow \infty$, we have that

$$(2.17b) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) \rightarrow \infty \quad \text{as } i \rightarrow \infty.$$

However, since \hat{u} is not a solution to **P**, by Assumption 2.2 there exists a $u^* \in V(\hat{u})$ such that $F(u^*|\hat{u}) < 0$ and therefore that $p_0(u^*|\hat{u}) < \infty$. Since, by construction, $V(\hat{u}) \subset V(u_i)$ for all $i \geq i_0$, it follows that

$$(2.18) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) \leq p_{\alpha_{k_i}}(u^*|u_i) \quad \forall i \geq i_0.$$

Furthermore, by continuity of $p_\alpha(u^*|u)$ in (α, u) , $p_{\alpha_{k_i}}(u^*|u_i) \xrightarrow{K} p_0(u^*|\hat{u}) < \infty$; hence, there exists an $i_1 \geq i_0$ such that, for all $i \in K$, $i \geq i_1$,

$$(2.19) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) \leq 2p_0(u^*|\hat{u}),$$

which is a contradiction of (2.17b).

Case 2. Suppose that $\psi(u_i) > 0$ for all $i \in \mathbb{N}$. Then, since $p_{\alpha_{k_i}}(u_{i+1}|u_i)$ for all $i \in \mathbb{N}$, it follows from (2.10) that $\psi(u_{i+1}) < \psi(u_i)$ for all $i \in \mathbb{N}$ and hence, since by continuity $\psi(u_i) \xrightarrow{K} \psi(\hat{u})$ as $i \rightarrow \infty$, that $\psi(u_i) \rightarrow \psi(\hat{u})$ as $i \rightarrow \infty$. Hence, since by (2.10)

$$(2.20a) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) > \frac{1}{L} \log \left(1 + \frac{L}{(\alpha_{k_i} + \psi(u_i)_+ - \psi(u_{i+1}))} \right)$$

and $\alpha_{k_i} \rightarrow 0$ as $i \rightarrow \infty$, we have that

$$(2.20b) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) \rightarrow \infty \quad \text{as } i \rightarrow \infty.$$

However, by Assumption 2.2, since \hat{u} is not a solution of **P**, there exists a $u^* \in V(\hat{u})$ such that $F(u^*|\hat{u}) < 0$, and hence $p_0(u^*|\hat{u}) < \infty$. By continuity of $F(u^*|\cdot)$, it now follows that there exists an i_2 such that $F(u^*|u_i) < 0$ for all $i \in K$, $i \geq i_2$, and hence we see that $u^* \in V(u_i)$ for all $i \in K$, $i \geq i_2$. Hence, again by continuity, there exists an $i_3 \geq i_2$ such that

$$(2.21) \quad p_{\alpha_{k_i}}(u_{i+1}|u_i) \leq p_{\alpha_{k_i}}(u^*|u_i) \leq 2p_0(u^*|\hat{u}) < \infty,$$

which contradicts (2.20b). \square

Since the set G is not compact, it is entirely possible that a sequence $\{u_i\}_{i=0}^\infty$ constructed by Algorithm 2.1 has no accumulation points in G . In that case, Theorem 2.1 is vacuous. However, the sequence $\{u_i\}_{i=0}^\infty$ must have accumulation points, in the sense of control measures, in the sequentially compact set \bar{G} . The following result follows directly from the arguments used to prove Theorem 2.1.

COROLLARY 2.1. *Suppose that $\{u_i\}_{i=0}^\infty$ is a sequence of controls constructed by Algorithm 2.1. If this sequence has an accumulation point $\hat{\sigma} \in \bar{G}$, then $\hat{\sigma}$ is a solution of $\bar{\mathbf{P}}$.*

3. An implementable phase I–phase II method of centers. The main objection to Algorithm 2.1 is that the update operation in (2.13) is not implementable. We will now develop an implementable algorithm that replaces (2.13) by an approximate stationarity condition and incorporates a feature that enables us to use the point u_i as a starting point in computing u_{i+1} by an algorithm such as Algorithm 5.14 in [2].

First, referring to [2], we see that the Frechet differentials (of the functions $f^0(\cdot)$, $\phi^k(\cdot, t)$ in (2.5a)) $df^0(u; u' - u)$, $d\phi^k(u, t; u' - u)$ exist and can be expressed in terms of scalar products with gradients $\nabla f^0(u)$ and $\nabla_u \phi^j(u, t)$, which are in $L_{\infty,2}$, i.e., $df^0(u; u' - u) = \langle \nabla f^0(u), u' - u \rangle_2$ and $d\phi^j(u, t; u' - u) = \langle \nabla_u \phi^j(u, t), u' - u \rangle_2$. Neither our proofs nor our algorithm require formulae for these gradients.

Next, we define an *optimality function* $\theta: G \rightarrow \mathbb{R}$ for the problem **P** (2.5a), which is a first-order convex approximation to the function $F(u|u)$, by

$$\begin{aligned} \theta(u) \triangleq \min_{u' \in G} \max \{ \frac{1}{2} \|u' - u\|_2^2 + \{-2\psi(u)_+ + df^0(u; u' - u), \\ (3.1) \quad \phi^j(u, t_j) - \psi(u)_+ + \langle \nabla_u \phi^j(u, t_j), u' - u \rangle_2, \\ t_j \in [0, 1], j \in q \} \}. \end{aligned}$$

At one point in our convergence proof, we will need to bring in the relaxed-controls topology. Hence, we need the relaxed-controls extension of $\theta(u)$. For this purpose, it is useful to recall that alternative formulae for $\langle \nabla f^0(u), u' - u \rangle_2$ and $\langle \nabla \phi^j(u, t), u' - u \rangle_2$ are given by

$$(3.2) \quad \langle \nabla f^0(u), u' - u \rangle_2 = \langle \nabla g^0(x^u(1)), \delta x^{u',u}(1) \rangle,$$

$$(3.3) \quad \langle \nabla \phi^j(u, t), u' - u \rangle_2 = \langle \nabla g^j(x^u(t)), \delta x^{u',u}(t) \rangle,$$

where $\delta x^{u',u}(t)$ is the solution of the first variational equation

$$\begin{aligned} (3.4) \quad \delta \dot{x}(t) = \left[\frac{\partial h(x^u(t), u(t))}{\partial x} \right] \delta x(t) \\ + \left[\frac{\partial h(x^u(t), u(t))}{\partial u} \right] [u'(t) - u(t)], \quad \delta x(0) = 0. \end{aligned}$$

As in [30] and [2], given a relaxed control $\sigma \in \bar{G}$ with corresponding solution $\bar{x}^\sigma(\cdot)$ of (2.4c), (2.4d) and a function $s: U \rightarrow L_{2,\infty}$, we define $\delta \bar{x}^{\sigma,s}(\cdot)$ to be the solution of

$$\begin{aligned} (3.5a) \quad \delta \dot{x}(t) = \int_U \left[\frac{\partial h(\bar{x}^\sigma(t), u)}{\partial x} \right] \sigma(t)(du) \delta x(t) \\ + \int_U \left[\frac{\partial h(x^\sigma(t), u)}{\partial u} \right] s(u)(t) \sigma(t)(du), \end{aligned}$$

$$(3.5b) \quad \delta x(0) = 0.$$

Next, we say that a *search direction function* $s: U \rightarrow L_{2,\infty}$ is *admissible* if, for all $u \in U$, $u + s(u)(t) \in U$ for almost all $t \in [0, 1]$. We define S to be the set of all admissible search direction functions. These definitions allow the relaxed-controls extension $\bar{\theta}: \bar{G} \rightarrow \mathbb{R}$ of $\theta(\cdot)$ to be defined by

$$\begin{aligned} \bar{\theta}(\sigma) \triangleq \min_{s \in S} \max \{ \frac{1}{2} \|s\|_2^2 + \{-2\bar{\psi}(\sigma)_+ + \langle \nabla g^0(\bar{x}^\sigma(1)), \delta \bar{x}^{\sigma,s}(1) \rangle, \\ (3.6) \quad \bar{\phi}^j(\sigma, t_j) - \bar{\psi}(\sigma)_+ + \langle \nabla g^j(\bar{x}^\sigma(t_j)), \delta \bar{x}^{\sigma,s}(t_j) \rangle, \\ t_j \in [0, 1], j \in q \} \}. \end{aligned}$$

The following result can be found in [2].

THEOREM 3.1. *We have the following conditions:*

- (i) *The optimality functions $\theta(\cdot)$ and $\bar{\theta}(\cdot)$ are well defined and continuous;*
- (ii) *If $\sigma \in \bar{G}$ corresponds to the ordinary control $u \in G$, then $\bar{\theta}(\sigma) = \theta(u)$;*
- (iii) *If $\hat{u} \in G$ is an optimal solution to the problem P , then $\theta(\hat{u}) = 0$;*
- (iv) *If $\hat{\sigma} \in \bar{G}$ is an optimal solution to the problem \bar{P} , then $\bar{\theta}(\hat{\sigma}) = 0$.*

In our proofs, we find it convenient to use an alternative formula for $\theta(u)$. Let the set of Radon probability measures on the interval $[0, 1]$ be denoted by $\text{rpm}([0, 1])$, let V denote the set of measurable functions $\nu: [0, 1] \rightarrow \text{rpm}([0, 1])$, and let

$$(3.7a) \quad W \triangleq \left\{ w = (w^0, w^1, \dots, w^q) \in \mathbb{R}^{q+1} \mid \sum_{i=0}^q w^i = 1, w^i \geq 0, i = 0, 1, \dots, q \right\}.$$

Finally, with $\text{rfm}([0, 1])$ denoting the space of Radon finite measures, let Σ be the set of measurable functions $\mu: [0, 1] \rightarrow [\text{rfm}([0, 1])]^{q+1}$ defined by

$$(3.7b) \quad \Sigma \triangleq \{ \mu \in [\text{rfm}([0, 1])]^{q+1} \mid \mu^j = w^j \nu, j = 0, 1, \dots, q, w \in W, \nu \in V \}.$$

Then it is obvious that

$$(3.7c) \quad \theta(u) \triangleq \min_{u' \in G} \max_{\mu \in \Sigma} \left\{ \frac{1}{2} \|u' - u\|_2^2 + \left\{ \int_{[0,1]} [-2\psi(u)_+ + df^0(u; u' - u)] \mu^0(t) (dt) \right. \right. \\ \left. \left. + \sum_{j=1}^q \int_{[0,1]} [\phi^j(u, t) - \psi(u)_+] \mu^j(t) (dt) \right. \right. \\ \left. \left. + \sum_{j=1}^q \left\langle \int_{[0,1]} \nabla_u \phi^j(u, t) \mu^j(t) (dt), u' - u \right\rangle_2 \right\} \right\}.$$

We will require the following assumption, which is usually required for methods of centers and feasible directions.

Assumption 3.1. (i) The \bar{G} -closure of the set $\{u \in G \mid \psi(u) \leq 0\}$ is equal to the \bar{G} -closure of its interior. (ii) For all $u \in G$ such that $\psi(u) > 0$, $\theta(u) < 0$.

Next, referring to definition (2.9), we conclude that

$$(3.8a) \quad \nabla_u p_\alpha(u \mid u') = \frac{\nabla f^0(u)}{[\alpha + 2\psi(u')_+ + f^0(u') - f^0(u)]^2} \\ + \sum_{j=1}^q \int_0^1 \frac{\nabla_u \phi^j(u, t)}{[\alpha + \psi(u')_+ - \phi^j(u, t)]^2} dt.$$

To evaluate $\nabla_u p_\alpha(u \mid u')$, we do not use the cumbersome formula (3.8a); rather, we use the following computationally efficient formula:

$$(3.8b) \quad \nabla_u p_\alpha(u \mid u')(t) = \left[\frac{\partial h(x^u(t), u(t))}{\partial u} \right]^T \lambda^{u'u}(t),$$

where $\lambda^{u'u}(t)$ is the solution of the following adjoint system:

$$(3.8c) \quad \dot{\lambda}(t) = - \left[\frac{\partial h(x^u(t), u(t))}{\partial x} \right]^T \lambda(t) \\ - \sum_{j=1}^q \frac{\nabla_x g^j(x^u(t))}{[\alpha + \psi(u')_+ - g^j(x^u(t))]^2}, \quad t \in [0, 1],$$

$$(3.8d) \quad \lambda(1) = \frac{1}{[\alpha + 2\psi(u')_+ + g^0(x^{u'}(1)) - g^0(x^u(1))]^2} \nabla g^0(x^u(1)).$$

Algorithm 2.1 now gives rise to the following implementable algorithm.

Algorithm 3.1.

Data: $u_0 \in G$, $\varepsilon > 0$, and $\{\alpha_k\}_{k=0}^\infty$ such that $\alpha_k > 0$ for all $k \in \mathbb{N}$ and $\alpha_k \downarrow 0$ as $k \rightarrow \infty$.

Step 0: Set $i = 0$ and $k = 0$.

Step 1: Use any descent algorithm to generate a $u_{i+1} \in V(u_i)$ such that

$$(3.9) \quad 0 \geq \min_{u \in G} \langle \nabla_u p_{\alpha_k}(u_{i+1} | u_i), u - u_{i+1} \rangle_2 + \frac{1}{2} \|u - u_{i+1}\|^2 \geq -\varepsilon.$$

Step 2: If $F(u_{i+1} | u_i) = 0$, replace k by $k + 1$ and go to Step 1.

Step 3: Replace i by $i + 1$ and k by $k + 1$, and go to Step 1.

The proof of convergence of Algorithm 3.1 depends on the following two lemmas.

LEMMA 3.1. *Suppose that Assumption 2.1 holds, that $\gamma > 0$, that $u' \in G$, and that $u \in V(u')$. For $j \in q$, let $T_\gamma^j(u) \subset [0, 1]$ be defined by*

$$(3.10a) \quad T_\gamma^j(u) = \{t \in [0, 1] \mid \phi^j(u, t) \geq \psi(u) - \gamma\}.$$

Then, for each $t \notin T_\gamma^j(u)$, with $t \in [0, 1]$ and $j \in q$,

$$(3.10b) \quad \frac{1}{(\psi(u')_+ - \phi^j(u, t))} \leq \frac{1}{\gamma}.$$

Proof. Because $t \notin T_\gamma^j(u)$, $\phi^j(u, t) < \psi(u) - \gamma$. Since $u \in V(u')$, we obtain that $\psi(u')_+ \geq \psi(u)$. Hence,

$$(3.11) \quad \psi(u')_+ - \phi^j(u, t) \geq \psi(u) - \phi^j(u, t) \geq \gamma,$$

and the desired inequality follows. \square

LEMMA 3.2. *Suppose that Assumption 2.1 holds. Then, for any $M_\alpha < \infty$, there exists a constant $\delta > 0$ such that, for any $0 < \alpha \leq M_\alpha$, for all $u' \in G$, and for all $u \in V(u')$,*

$$(3.12) \quad (\alpha + \psi(u')_+ - \psi(u)) \sum_{j \in q} \int_{[0, 1]} \frac{1}{(\alpha + \psi(u')_+ - \phi^j(u, t))^2} dt \geq \delta > 0.$$

Proof. Since G is bounded, it follows from Assumption 2.1 that there exists a Lipschitz constant $L < \infty$ such that each $\phi^j(u, \cdot)$ is uniformly Lipschitz in t on $[0, 1]$ for all $u \in G$. Without loss of generality, we may assume that $L \geq \psi(u')_+ - \psi(u)$ for all $u, u' \in G$. Let $j \in q$ be such that $T_0^j(u)$ is nonempty, let $t_u \in T_0^j(u)$ be given and let $t \in [0, 1]$. Then we have that

$$(3.13a) \quad \phi^j(u, t) \geq \phi^j(u, t_u) - L|t - t_u| = \psi(u) - L|t - t_u|.$$

Now suppose that $0 < \gamma \leq L + M_\alpha$. Then $\{t \in [0, 1] \mid |t - t_u| \leq \gamma/(L + M_\alpha)\} \subset T_\gamma^j(u)$, and hence $m(T_\gamma^j(u)) \geq \gamma/(L + M_\alpha)$, where $m(\cdot)$ denotes the Lebesgue measure on \mathbb{R} . Hence, we conclude that

$$(3.13b) \quad \begin{aligned} \sum_{j \in q} \int_{[0, 1]} \frac{\alpha + \psi(u')_+ - \psi(u)}{(\alpha + \psi(u')_+ - \phi^j(u, t))^2} dt &\geq \int_{T_\gamma^j(u)} \frac{\alpha + \psi(u')_+ - \psi(u)}{(\alpha + \psi(u')_+ - \phi^j(u, t))^2} dt \\ &\geq \frac{\gamma}{(L + M_\alpha)} \frac{\alpha + \psi(u')_+ - \psi(u)}{(\alpha + \psi(u')_+ - \psi(u) + \gamma)^2}. \end{aligned}$$

Setting $\gamma = \alpha + \psi(u')_+ - \psi(u) \leq M_\alpha + L$ and $\delta = \frac{1}{4}(L + M_\alpha)$, we obtain the desired result. \square

THEOREM 3.2. (i) *Suppose that Algorithm 3.1 jams up in the loop between Steps 1 and 2 at the control u_{i_0} . Then $\psi(u_{i_0}) \leq 0$ and $\theta(u_{i_0}) = 0$.* (ii) *Suppose that $\{u_i\}_{i=0}^\infty$ is a sequence of controls constructed by Algorithm 3.1. If this sequence has an accumulation point $\hat{u} \in G$, then $\psi(\hat{u}) \leq 0$ and $\theta(\hat{u}) = 0$.*

Proof. (i) The proof of this part is essentially the same as for (i) of Theorem 2.1 and hence is omitted. (ii) Since u_{i+1} is constructed from u_i by a descent method, it follows from $F(u_{i+1}|u_i) < 0$ that, if $\psi(u_i) \leq 0$, then $\psi(u_{i+1}) \leq 0$ also. Hence, our proof breaks down into the examination of two cases.

Case 1. Suppose that $u_i \xrightarrow{K} \hat{u} \in G$ as $i \rightarrow \infty$ and that there exists an i_0 such that $\psi(u_i) \leq 0$ for all $i \geq i_0$. Then, by construction, the sequence $\{f^0(u_i)\}_{i=i_0}^\infty$ is monotone decreasing, and, since it is bounded, it must converge to $f(\hat{u})$. The fact that $\psi(\hat{u}) \leq 0$ follows directly from the continuity of $\psi(\cdot)$.

Now, for $i \geq i_0$, $j \in q$, and $t \in [0, 1]$, let

$$(3.14a) \quad \rho_i^j(t) \triangleq \frac{[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2}{(\alpha_{k_i} - \phi^j(u_i, t))^2}.$$

Finally, let

$$(3.14b) \quad \nu_i \triangleq 1 + \sum_{j=1}^q \int_0^1 \rho_i^j(t) dt.$$

It now follows from (3.8a) and (3.9) that, for all $i \geq i_0$,

$$(3.15a) \quad \begin{aligned} 0 \geq \Theta'(u_i) &\triangleq \min_{u \in G} \frac{1}{\nu_i} \left\{ df^0(u_i; u - u_i) + \sum_{j=1}^q \int_0^1 \rho_i^j(t) d\phi^j(u_i, t; u - u_i) + \frac{1}{2} \|u - u_i\|_2^2 \right\} \\ &\geq -\varepsilon_i \triangleq -\varepsilon \frac{[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2}{\nu_i}. \end{aligned}$$

Since $\nu_i \geq 1$ for all $i \geq i_0$ and since $f^0(u_i) \rightarrow f^0(\hat{u})$ and $\alpha_{k_i} \rightarrow 0$ as $i \rightarrow \infty$, it follows that $\varepsilon_i \rightarrow 0$ as $i \rightarrow \infty$. Next, it follows from (3.7c) that, for all $i \geq i_0$,

$$(3.15b) \quad \begin{aligned} 0 \geq \theta(u_i) &\geq \Theta'(u_i) + \frac{1}{\nu_i} \sum_{j=1}^q \int_0^1 \rho_i^j(t) \phi^j(u_i, t) dt \\ &\geq -\varepsilon_i + \frac{1}{\nu_i} \sum_{j=1}^q \int_0^1 \rho_i^j(t) \phi^j(u_i, t) dt. \end{aligned}$$

Now, for any $\gamma > 0$, let $I_\gamma^j(u) \subset [0, 1]$ be defined by

$$(3.16a) \quad I_\gamma^j(u) \triangleq \{t \in [0, 1] \mid \phi^j(u, t) \geq -\gamma/2\}.$$

It now follows from (3.14a, b) and the relation

$$0 \geq \frac{\phi^j(u_i, t)}{(\alpha_{k_i} - \phi^j(u_i, t))^2} \geq \frac{\phi^j(u_i, t)}{(-\phi^j(u_i, t))^2}$$

that, for any $j \in q$, and any $\gamma > 0$,

$$(3.16b) \quad \begin{aligned} 0 &\geq \frac{1}{\nu_i} \int_0^1 \rho_i^j(t) \phi^j(u_i, t) dt \\ &= \frac{1}{\nu_i} \int_{t \in I_\gamma^j(u_i)} \rho_i^j(t) \phi^j(u_i, t) dt + \frac{1}{\nu_i} \int_{t \in I_\gamma^j(u_i)^c} \rho_i^j(t) \phi^j(u_i, t) dt \\ &\geq -\frac{\gamma}{2} + \frac{[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2}{\nu_i} \int_{t \in I_\gamma^j(u_i)^c} \frac{\phi^j(u_i, t)}{(\alpha_{k_i} - \phi^j(u_i, t))^2} dt \\ &\geq -\frac{\gamma}{2} + \frac{[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2}{\nu_i} \left\{ \int_{t \in I_\gamma^j(u_i)^c} \frac{1}{\phi^j(u_i, t)} dt \right\} \\ &\geq -\frac{\gamma}{2} - \left(\frac{[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2}{\nu_i} \right) \frac{2}{\gamma}. \end{aligned}$$

Since $[\alpha_{k_i} + f^0(u_{i-1}) - f^0(u_i)]^2 / \nu_i \rightarrow 0$ as $i \rightarrow \infty$, (3.16b) holds for any $\gamma > 0$ and, by Theorem 3.1, $\theta(\cdot)$ is continuous, it now follows that $\theta(\hat{u}) = 0$.

Case 2. We now suppose that $\psi(u_i) > 0$ for all $i \in \mathbb{N}$. Then we must have that the sequence $\{\psi(u_i)\}_{i=0}^\infty$ is monotonically decreasing, and hence it must converge to $\psi(\hat{u})$. We note that $\psi(u_i) = \psi(u_i)_+$ for all $i \in \mathbb{N}$. In this case, we define

$$(3.17a) \quad \rho_i^0(t) \triangleq \frac{\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i)}{(\alpha_{k_i} + 2\psi(u_{i-1}) + f^0(u_{i-1}) - f^0(u_i))^2},$$

$$(3.17b) \quad \rho_i^j(t) \triangleq \frac{\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i)}{(\alpha_{k_i} + \psi(u_{i-1}) - \phi^j(u_i, t))^2}, \quad j = 1, 2, \dots, q.$$

It now follows from Lemma 3.2 that

$$(3.18) \quad \nu_i \triangleq \sum_{j=0}^q \int_0^1 \rho_i^j(t) dt \geq \delta > 0$$

and from (3.9) that

$$(3.19) \quad \begin{aligned} 0 \geq \Theta''(u_i) &\triangleq \min_{u \in G} \frac{1}{\nu_i} \left\{ \int_0^1 \rho_i^0(t) df^0(u_i; u - u_i) dt \right. \\ &\quad \left. + \sum_{j=1}^q \int_0^1 \rho_i^j(t) d\phi^j(u_i, t; u - u_i) dt + \frac{1}{2} \|u - u_i\|_2^2 \right\} \\ &\geq -\varepsilon_i \triangleq -\varepsilon \frac{[\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i)]}{\nu_i}. \end{aligned}$$

Clearly, $\varepsilon_i \rightarrow 0$ as $i \rightarrow \infty$. Next, by the same argument as in (3.15b), we obtain that

$$(3.20) \quad \begin{aligned} 0 \geq \theta(u_i) &\geq \Theta''(u_i) + \frac{1}{\nu_i} \left\{ \int_0^1 -2\rho_i^0(t)\psi(u_{i-1}) dt \right. \\ &\quad \left. + \sum_{j=1}^q \int_0^1 \rho_i^j(t)[\phi^j(u_i, t) - \psi(u_{i-1})] dt \right\} \\ &\geq -\varepsilon_i + \frac{1}{\nu_i} \left\{ \int_0^1 -2\rho_i^0(t)\psi(u_{i-1}) dt \right. \\ &\quad \left. + \sum_{j=1}^q \int_0^1 \rho_i^j(t)[\phi^j(u_i, t) - \psi(u_{i-1})] dt \right\}. \end{aligned}$$

First, it follows from (3.18), the relation

$$0 \geq \frac{\phi^j(u_i, t) - \psi(u_{i-1})}{(\alpha_{k_i} + \psi(u_{i-1}) - \phi^j(u_i, t))^2} \geq \frac{1}{\phi^j(u_i, t) - \psi(u_{i-1})},$$

and Lemma 3.1 that, for all $j \in \underline{q}$ and for any $\gamma > 0$,

$$\begin{aligned} 0 &\geq \frac{1}{\nu_i} \int_0^1 \rho_i^j(t)[\phi^j(u_i, t) - \psi(u_{i-1})] dt \\ &= \frac{1}{\nu_i} \int_{t \in T_\gamma^j(u_i)} \rho_i^j(t)[\phi^j(u_i, t) - \psi(u_{i-1})] dt \end{aligned}$$

$$\begin{aligned}
(3.21) \quad & + \frac{(\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i))}{\nu_i} \left(\int_{t \in T_{\gamma}^j(u_i)^c} \frac{\phi^j(u_i, t) - \psi(u_{i-1})}{(\alpha_{k_i} + \psi(u_{i-1}) - \phi^j(u_i, t))^2} dt \right) \\
& \cong \psi(u_i) - \gamma - \psi(u_{i-1}) - \frac{(\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i))}{\nu_i} \\
& \quad \cdot \int_{t \in T_{\gamma}^j(u_i)^c} \frac{1}{\psi(u_{i-1}) - \phi^j(u_i, t)} dt \\
& \cong -\gamma + \psi(u_i) - \psi(u_{i-1}) - \frac{(\alpha_{k_i} + \psi(u_{i-1}) - \psi(u_i))}{\delta} \frac{1}{\gamma}.
\end{aligned}$$

Since $\psi(u_i) - \psi(u_{i-1}) \rightarrow 0$ and $\alpha_{k_i} \rightarrow 0$ as $i \rightarrow \infty$ and (3.21) is satisfied for any $\gamma > 0$, we obtain that

$$(3.22) \quad \frac{1}{\nu_i} \sum_{j=1}^q \int_0^1 \rho_i^j(t) [\phi^j(u_i, t) - \psi(u_{i-1})] dt \rightarrow 0, \quad \text{as } i \rightarrow \infty.$$

Hence, to complete our proof, we need only show that $\psi(u_i) \rightarrow 0$, as $i \rightarrow \infty$.

For contradiction, suppose that $\psi(\hat{u}) > 0$. We now have two possibilities. The first is that $2\psi(u_i) + f^0(u_{i-1}) - f^0(u_i) \rightarrow 0$ as $i \rightarrow \infty$, which implies that for all sufficiently large i , $f^0(u_i) \cong f^0(u_{i-1}) + \psi(\hat{u})$ and hence that $f^0(u_i) \rightarrow \infty$ as $i \rightarrow \infty$. Since the set G is bounded, this is clearly impossible. Hence, we consider the second possibility: There exists an infinite subset $K' \subset \mathbb{N}$ and a $\delta > 0$ such that $2\psi(u_i) + f^0(u_{i-1}) - f^0(u_i) \cong \delta$ for all $i \in K'$. In turn, this implies that $\int_0^1 \rho_i^0(t) dt \xrightarrow{K'} 0$ as $i \rightarrow \infty$. Furthermore, we may assume that $u_i \xrightarrow{K'} \sigma^* \in \bar{G}$, in the sense of control measures, as $i \rightarrow \infty$. Clearly, we must have $\bar{\psi}(\sigma^*) = \psi(\hat{u}) > 0$. In view of the above, (3.20), (3.21), and the continuity of $\bar{\theta}(\cdot)$, this implies that $\theta(\sigma^*) = 0$. However, this contradicts Assumption 3.1, and hence our proof is complete. \square

4. A special case. It is not at all uncommon for the set U in (2.1b) to be described in terms of convex inequalities, as follows:

$$(4.1) \quad U \triangleq \{z \in \mathbb{R}^m \mid s^l(z) \leq 0, l = 1, 2, \dots, q_3\},$$

where the $s^l: \mathbb{R}^m \rightarrow \mathbb{R}$ are all Lipschitz continuously differentiable convex functions.

If, for $j = q_1 + q_2 + 1, \dots, q_1 + q_2 + q_3$, we define the functions $\phi^j: L_{\infty,2} \times [0, 1] \rightarrow \mathbb{R}$ by

$$(4.2) \quad \phi^j(u, t) \triangleq s^{j-q_1-q_2}(u(t)),$$

we find that $\phi^j(\cdot, t)$ is differentiable on $L_{\infty,2}$, with $d_u \phi^j(u, t; u' - u) = \langle \nabla s^{j-q_1-q_2}(u(t)), u'(t) - u(t) \rangle$.

Now, let $q_4 \triangleq q_1 + q_2$ and $q_5 \triangleq q_1 + q_2 + q_3$; then (2.5a) becomes

$$(4.3a) \quad \mathbf{P}': \min \left\{ f^0(u) \mid \max_{t \in [0,1]} \phi^j(u, t) \leq 0, j = 1, 2, \dots, q_5, u \in L_{\infty,2} \right\},$$

or, in the even more compact form (see (2.5b)),

$$(4.3b) \quad \mathbf{P}': \min \{ f^0(u) \mid \psi^j(u) \leq 0, j = 1, 2, \dots, q_5, u \in L_{\infty,2} \},$$

where $\psi^j(u) \triangleq \max_{t \in [0,1]} \phi^j(u, t)$.

For problem \mathbf{P}' , letting $\psi(u) = \max \{ \psi^j(u), j = 1, \dots, q_5 \}$ and $\psi(u)_+ = \max \{ 0, \psi(u) \}$, we define the optimality function $\theta': L_{\infty,2} \rightarrow \mathbb{R}$ by

$$\begin{aligned}
(4.4) \quad & \theta'(u) \triangleq \min_{u' \in L_{\infty,2}} \left\{ \frac{1}{2} \|u' - u\|_2^2 + \max \{ df(u; u' - u) - 2\psi_+(u), \right. \\
& \quad \left. \phi^j(u, t) - \psi(u)_+ + d_u \phi^j(u, t; u' - u), \right. \\
& \quad \left. t \in [0, 1], j \in q_5 \} \right\}
\end{aligned}$$

which is a first-order convex approximation to the unifying function $F'(u'|u)$, defined by (2.6) with q and the functions $\phi^j(\cdot, \cdot)$ redefined as above.

We begin by establishing a relationship between the functions $\theta(\cdot)$ and $\theta'(\cdot)$.

THEOREM 4.1. *Suppose that*

$$(4.5) \quad \dot{U} \triangleq \{z \in U \mid s^j(z) < 0, j = 1, 2, \dots, q_3\},$$

where \dot{U} denotes the interior of U , and where \dot{U} is not empty. Then, for any $u \in G$, $\theta(u) = 0$ if and only if $\theta'(u) = 0$.

Proof. \Rightarrow Suppose that $\theta(\hat{u}) = 0$ but $\theta'(\hat{u}) < 0$. Since $\theta'(\hat{u}) < 0$, there exists a $\bar{u} \in L_{\infty,2}$ such that $F'(\bar{u}|\hat{u}) < 0$. If $\psi(\hat{u})_+ = 0$, then because of $F'(\bar{u}|\hat{u}) < 0$ we have that

$$(4.6a) \quad f^0(\bar{u}) - f^0(\hat{u}) - 2\psi(\hat{u})_+ = f^0(\bar{u}) - f^0(\hat{u}) < 0,$$

$$(4.6b) \quad \begin{aligned} \phi^j(\bar{u}, t) - \psi(\hat{u})_+ &= \phi^j(\bar{u}, t) < 0, \\ \forall t \in [0, 1], \text{ for } j &= 1, \dots, q_1 + q_2, \end{aligned}$$

$$(4.6c) \quad \begin{aligned} \phi^j(\bar{u}, t) - \psi(\hat{u})_+ &= \phi^j(\bar{u}, t) < 0, \\ \forall t \in [0, 1], \text{ for } j &= q_1 + q_2 + 1, \dots, q_1 + q_2 + q_3. \end{aligned}$$

By (4.6c) $\bar{u} \in G$. It now follows from (4.6a) and (4.6b) that $\theta(\hat{u}) < 0$, which contradicts our hypothesis.

Next, we need to prove that $\psi(\hat{u})_+ = 0$. Suppose that $\psi(\hat{u})_+ > 0$. Since $\hat{u} \in G$, $\phi^j(\hat{u}, t) \leq 0$ for all $j = q_5 \setminus q_4 \triangleq \{q_1 + q_2 + 1, \dots, q_1 + q_2 + q_3\}$ and for all $t \in [0, 1]$. Hence, $\psi(\hat{u})_+ > 0$ implies that there exist $j_0 \in q_4$ and $t_0 \in [0, 1]$ such that $\psi(\hat{u}) = \phi^{j_0}(\hat{u}, t_0) > 0$. However, in this case Assumption 3.1 ensures that $\theta(\hat{u}) < 0$, which is a contradiction, and therefore, $\psi(\hat{u})_+ = 0$.

Suppose that $\theta'(\hat{u}) = 0$. For the sake of contradiction, suppose that $\theta(\hat{u}) < 0$. Let $\xi(u|\hat{u})$ be defined by

$$(4.7a) \quad \begin{aligned} \xi(u|\hat{u}) &= \frac{1}{2}\|u - \hat{u}\|_2^2 + \max \{-2\psi(\hat{u})_+ + df^0(\hat{u}; u - \hat{u}), \\ &\quad \phi^j(\hat{u}, t) - \psi(\hat{u})_+ + d_u \phi^j(\hat{u}, t; u - \hat{u}), \\ &\quad t \in [0, 1], j = 1, \dots, q_1 + q_2\}. \end{aligned}$$

Since $\theta(\hat{u}) < 0$, there exists a $\bar{u} \in G$ such that

$$(4.7b) \quad \theta(\hat{u}) = \min_{u \in G} \xi(u|\hat{u}) = \xi(\bar{u}|\hat{u}) \triangleq -2\delta < 0.$$

For $\alpha \in (0, 1)$, let $u_\alpha \triangleq \hat{u} + \alpha(\bar{u} - \hat{u})$. Then $u_\alpha \in G$ for all $\alpha \in (0, 1)$ because the set G is convex. Since $-2\psi(\hat{u})_+ \leq 0$ and $\phi^j(\hat{u}, t) - \psi(\hat{u})_+ \leq 0$ for all j , we have that, for all $\alpha \in (0, 1)$,

$$(4.7c) \quad \xi(\bar{u}|\hat{u}) \leq \xi(u_\alpha|\hat{u}) \leq -2\alpha\delta < 0.$$

Let \tilde{u} be any control such that $\tilde{u}(t) \in \dot{U}$ for all $t \in [0, 1]$. Then, by (4.5), there exist $\bar{\delta}_j$ such that $\max_{t \in [0, 1]} \phi^j(\tilde{u}, t) = -\bar{\delta}_j < 0$ for all $j \in q_5 \setminus q_4$. Let $u'_{\alpha, \beta} \triangleq (1 - \alpha)\hat{u} + \alpha(\bar{u} + \beta(\tilde{u} - \bar{u})) = u_\alpha + \alpha\beta(\tilde{u} - \bar{u})$, where $\beta \in (0, 1)$. Obviously, $u'_{\alpha, \beta} \in G$. By the continuity of $\xi(\cdot|\hat{u})$, for any $\alpha \in (0, 1)$, there exists a $\beta_\alpha \in (0, 1)$ such that

$$(4.7d) \quad \theta(\hat{u}) \leq \xi(u'_{\alpha, \beta}|\hat{u}) \leq -\alpha\delta < 0, \quad \forall 0 < \beta \leq \beta_\alpha.$$

Since the functions $\phi^j(\cdot, t)$ are convex for all $j \in q_5 \setminus q_4$ and for all $t \in [0, 1]$, we conclude that, for all $j \in q_5 \setminus q_4$, for all $t \in [0, 1]$, for all $\alpha \in (0, 1)$, and for all $\beta \in (0, 1)$,

$$(4.8a) \quad \begin{aligned} \phi^j(u'_{\alpha, \beta}, t) &\leq (1 - \alpha)\phi^j(\hat{u}, t) + \alpha\phi^j(\bar{u} + \beta(\tilde{u} - \bar{u}), t) \\ &\leq (1 - \alpha)\phi^j(\hat{u}, t) + \alpha\{(1 - \beta)\phi^j(\bar{u}, t) + \beta\phi^j(\tilde{u}, t)\} \\ &\leq -\alpha\beta\bar{\delta}_j < 0. \end{aligned}$$

The last inequality is valid because $\phi^j(\hat{u}, t) \leq 0$, $\phi^j(\bar{u}, t) \leq 0$, and $\phi^j(\tilde{u}, t) \leq -\bar{\delta}_j < 0$. Also, because all the gradients $\nabla_u \phi^j(\cdot, t)$ are Lipschitz continuous,

$$\begin{aligned}
 \phi^j(u'_{\alpha,\beta}, t) &= \phi^j(\hat{u}, t) + \langle \nabla_u \phi^j(\hat{u}, t), u'_{\alpha,\beta}(t) - \hat{u}(t) \rangle \\
 &\quad + \int_0^1 \langle (\nabla_u \phi^j(\hat{u} + s(u'_{\alpha,\beta} - \hat{u}), t) - \nabla_u \phi^j(\hat{u}, t)), u'_{\alpha,\beta} - \hat{u} \rangle ds \\
 &\geq \phi^j(\hat{u}, t) + \langle \nabla_u \phi^j(\hat{u}, t), u'_{\alpha,\beta}(t) - \hat{u}(t) \rangle \\
 &\quad - L_j \alpha^2 / 2 (\|\bar{u}(t) - \hat{u}(t)\|^2 + \beta^2 \|\tilde{u}(t) - \bar{u}(t)\|^2),
 \end{aligned}
 \tag{4.8b}$$

where $L_j \triangleq \max_{t \in [0,1]} L_j(t)$ and $L_j(t)$ is a Lipschitz constant of $\nabla_u \phi^j(\cdot, t)$. Combining (4.8a) with (4.8b), we can conclude that there exist $\alpha_0, \beta_0 \in (0, 1)$ such that, for all $0 < \alpha \leq \alpha_0$, for all $0 < \beta \leq \beta_0$, for all $t \in [0, 1]$, and for all $j \in q_5 \setminus q_4$,

$$\begin{aligned}
 &\frac{1}{2} \|u'_{\alpha,\beta}(t) - \hat{u}(t)\|^2 + \phi^j(\hat{u}, t) + \langle \nabla \phi^j(\hat{u}, t), u'_{\alpha,\beta}(t) - \hat{u}(t) \rangle \\
 &\leq -\alpha \beta \bar{\delta}_j / 2 < 0.
 \end{aligned}
 \tag{4.8c}$$

Since (4.7d) and (4.8c) imply that, given $0 < \alpha \leq \alpha_0$, for all $0 < \beta \leq \min\{\beta_\alpha, \beta_0\}$,

$$\theta'(\hat{u}) \leq \max\{-\alpha \delta, -\alpha \beta \bar{\delta}_j / 2, j \in q_5 \setminus q_4\} < 0,
 \tag{4.8d}$$

we obtain a contradiction of our hypothesis, and hence our proof is complete. \square

Clearly, Algorithm 3.1 is applicable to \mathbf{P}' , and it may be initialized with a control that is not in G . However, we must amend Assumption 3.1 as follows. Since relaxed controls must be associated with bounded controls, we introduce an arbitrarily large compact set $U^* \subset \mathbb{R}^n$, and we define G^* by (2.1b) with U replaced by U^* . We denote the corresponding set of relaxed controls by \bar{G}^* .

Assumption 4.1. (i) The \bar{G}^* -closure of the set $\{u \in G^* \mid \psi(u) \leq 0\}$ is equal to the \bar{G}^* -closure of its interior. (ii) For all $u \in G^*$ such that $\psi(u) > 0$, $\theta'(u) < 0$.

At this point, the following result should be obvious.

THEOREM 4.2. (i) Suppose that Algorithm 3.1 is applied to problem \mathbf{P}' and jams up in the loop between Steps 1 and 2 at the control u_{i_0} . Then $\psi(u_{i_0}) \leq 0$ and $\theta'(u_{i_0}) = \theta(u_{i_0}) = 0$.

(ii) Suppose that $\{u_i\}_{i=0}^\infty$ is a sequence of controls constructed by Algorithm 3.1 in solving \mathbf{P}' . If this sequence has an accumulation point $\hat{u} \in L_{\infty,2}$, then $\psi(\hat{u}) \leq 0$ (so that $\hat{u} \in G$) and $\theta'(\hat{u}) = \theta(\hat{u}) = 0$.

There is considerable programming convenience in using the formulation \mathbf{P}' over \mathbf{P} when possible. Our computational results in the next section show that the use of the formulation \mathbf{P}' does not result in any penalty in terms of computing times.

5. Numerical results. We now present two examples that illustrate the performance of Algorithm 3.1. In our experiments, the computations in Step 1 of Algorithm 3.1 were carried out by using Algorithm A in [21], which is of the Gauss-Newton type. The sequence $\{\alpha_k\}_{k=0}^\infty$ was defined by $\alpha_{k+1} = \alpha_k / 1.1$ with $\alpha_0 = 0.005$. Our experiments suggest that larger values of α_0 result in an increase in the number of iterations needed to solve a problem.

Example 5.1. Our first problem is a minimum-time brachistochrone problem with a state-variable inequality constraint, described in [4]. We treat this problem in fixed-time scaled form, where the scale variable T corresponds to the actual final time.

$$\mathbf{P}: \min_{\gamma \in L_{\infty,2}} \left\{ \frac{1}{2} T^2 \mid \max_{t \in [0,1]} \phi^j(\gamma, t) \leq 0, j = 1, 2, \forall t \in [0, 1] \right\},
 \tag{5.1a}$$

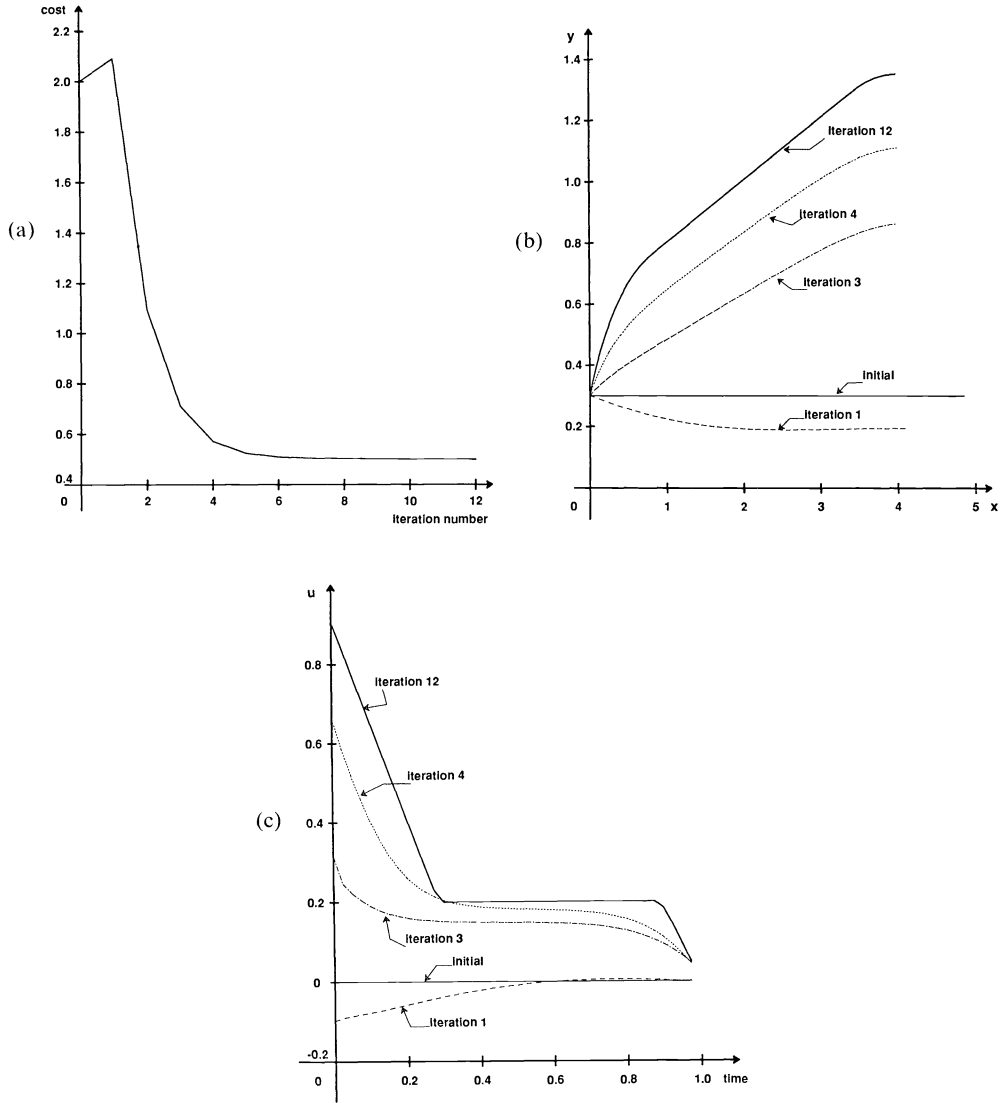

FIG 1. (a) Cost versus iteration number, (b) state-space trajectories, and (c) controls at various iterations for Example 5.1 with set (i) of initial conditions.

where

$$(5.1b) \quad \phi^1(\gamma, t) = y(t) - x(t) \tan \theta - h,$$

$$(5.1c) \quad \phi^2(\gamma, t) = \frac{1}{2}(x(1) - l)^2 - \xi,$$

where horizontal distance x and vertical distance y are defined by

$$(5.2a) \quad \dot{x}(t) = T\sqrt{2gy(t)} \cos \gamma(t),$$

$$(5.2b) \quad \dot{y}(t) = T\sqrt{2gy(t)} \sin \gamma(t),$$

where g is the acceleration due to gravity; γ is the path angle to the horizontal; θ and h are constants; and ξ is a small tolerance by which we are willing to relax the requirement $x(1) = l$.

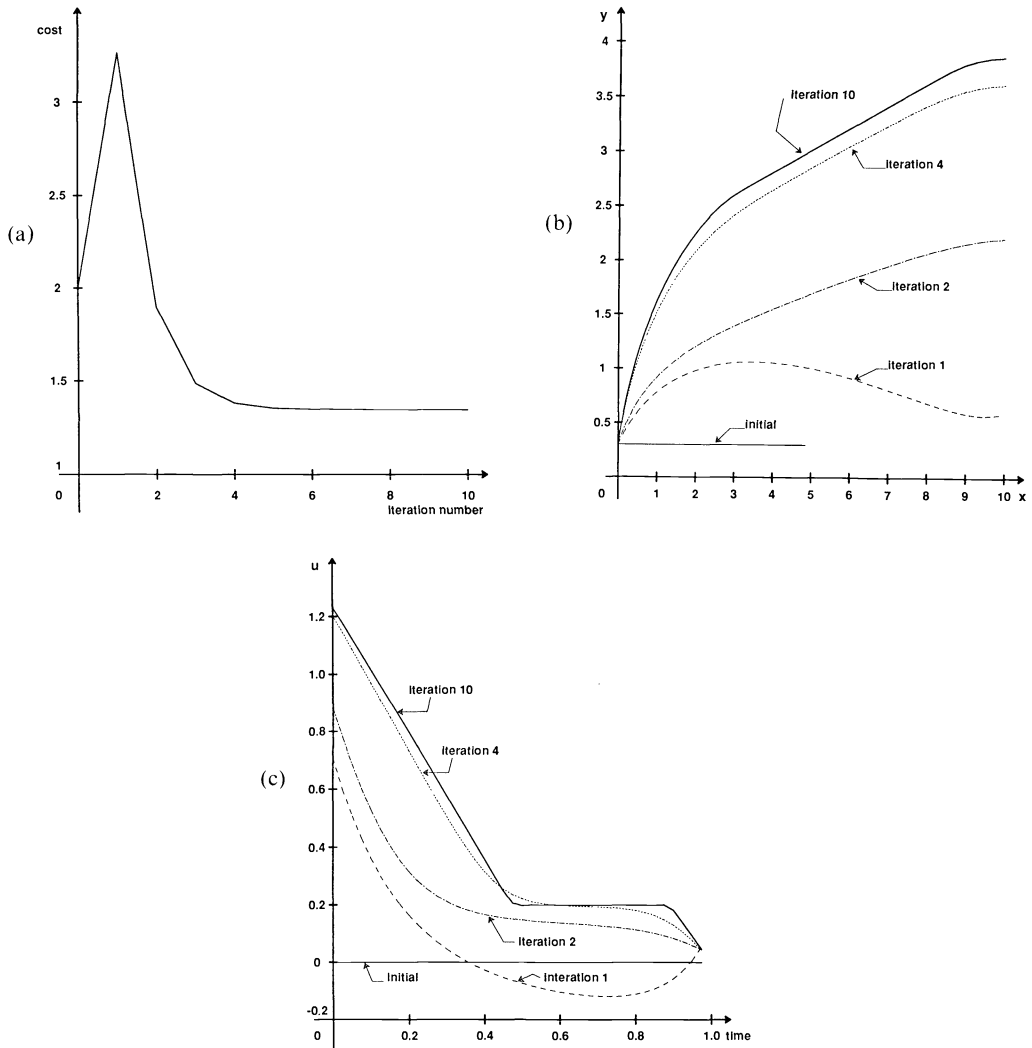

FIG. 2. (a) Cost versus iteration number, (b) state-space trajectories, and (c) controls at various iterations for Example 5.1 with set (ii) of initial conditions.

Since the system equations (5.2a) and (5.2b) cannot be integrated explicitly, we must use a numerical integration scheme, which discretizes the time interval $[0, 1]$. The discretization may be either fixed or variable. We used 40 uniformly spaced points in conjunction with the Runge-Kutta second-order method [25]. The gradients used were those corresponding to the discretized dynamics imposed by the integration scheme. The results that we obtained converge to the expected results, obtained analytically in [4, p. 120]. We stopped our computations when the constraints were satisfied and the difference in the cost values between successive iterations was less than 1×10^{-5} .

We used the following two sets of initial conditions: (i) $(x(0), y(0), T) = (0.0, 0.3, 2.0)$, $\theta = 0.2$, $h = 0.6$, $l = 4.0$, and $\xi = 0.0005$; and (ii) $(x(0), y(0), T) = (0.0, 1.0, 2.0)$, $\theta = 0.2$, $h = 2.0$, $l = 10.0$, and $\xi = 0.0005$.

Figure 1(a) presents a plot of the values $f^0(u_i)$ versus iteration number i . Figures 1(b) and 1(c) show state-space trajectories and inputs at various iterations, respectively,

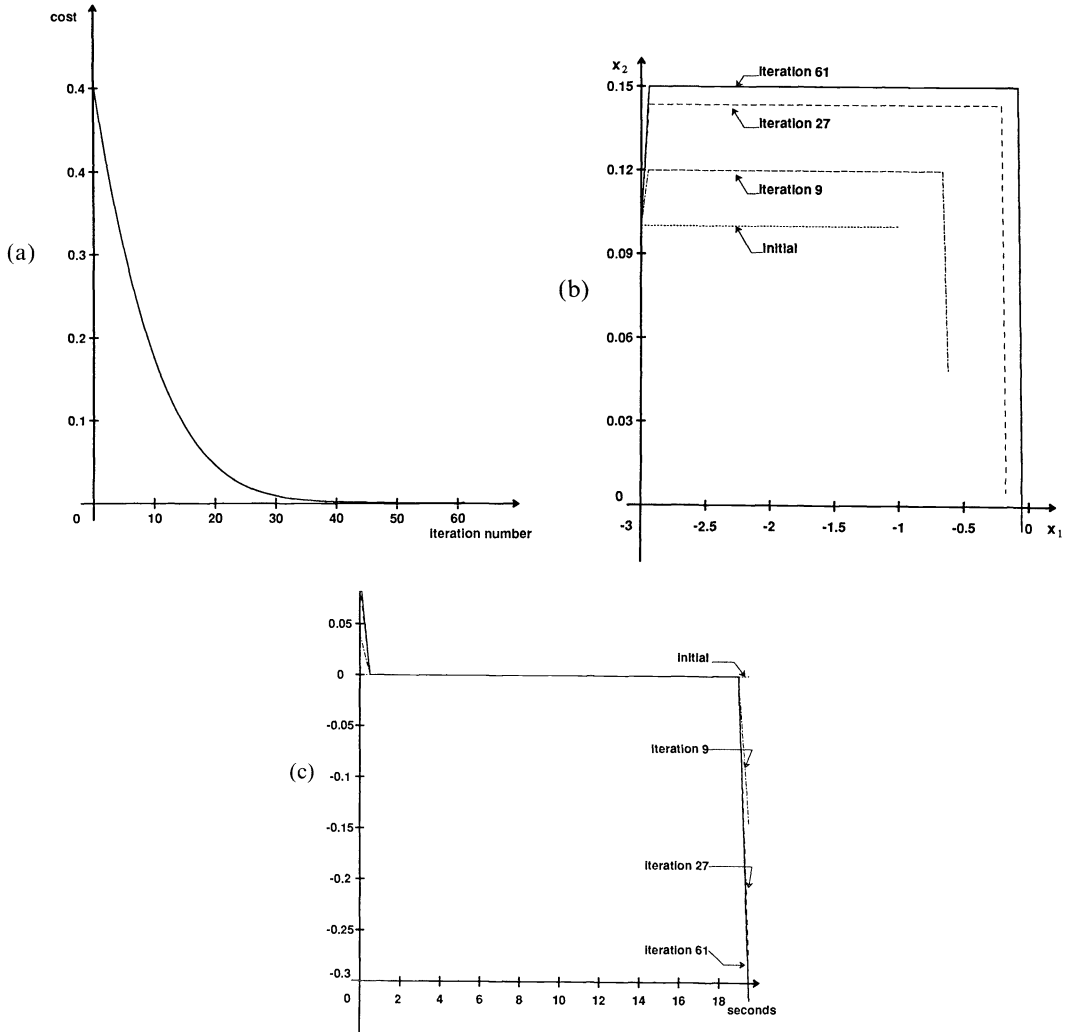

FIG. 3. (a) Cost versus iteration number, (b) state-space trajectories, and (c) controls at various iterations for Example 5.2 using penalized control.

obtained by using the first set of initial conditions. The value of $\frac{1}{2}T^2$ is determined to be 0.99971 after twelve iterations. The results of the computations using the second set of initial conditions are shown in Figs. 2(a)-2(c). The final value of $\frac{1}{2}T^2$, 1.63998 seconds, is obtained after ten iterations.

Example 5.2. Our second problem is a fixed-time minimum final error problem with a state-variable inequality constraint and bounds on the control

$$(5.3a) \quad \mathbf{P}: \min_{u \in G} \left\{ \frac{1}{2} \|x(1)\|^2 \mid x^2(t) - l \leq 0, \forall t \in [0, 1] \right\},$$

where the state is determined by the scaled differential equation

$$(5.3b) \quad \dot{x}(t) = \begin{pmatrix} \dot{x}^1(t) \\ \dot{x}^2(t) \end{pmatrix} = T \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} x(t) + T \begin{bmatrix} 0 \\ 1 \end{bmatrix} u(t),$$

with $T > 0$ the actual final time. The input $u(\cdot)$ is scalar-valued and $u \in G \triangleq \{u \in L_{\infty,2} \mid \|u\|_{\infty} \leq 1.0\}$. We use the initial state given by $x(0) = (-3.0, 0.1)^T$. We set $l = 0.15$

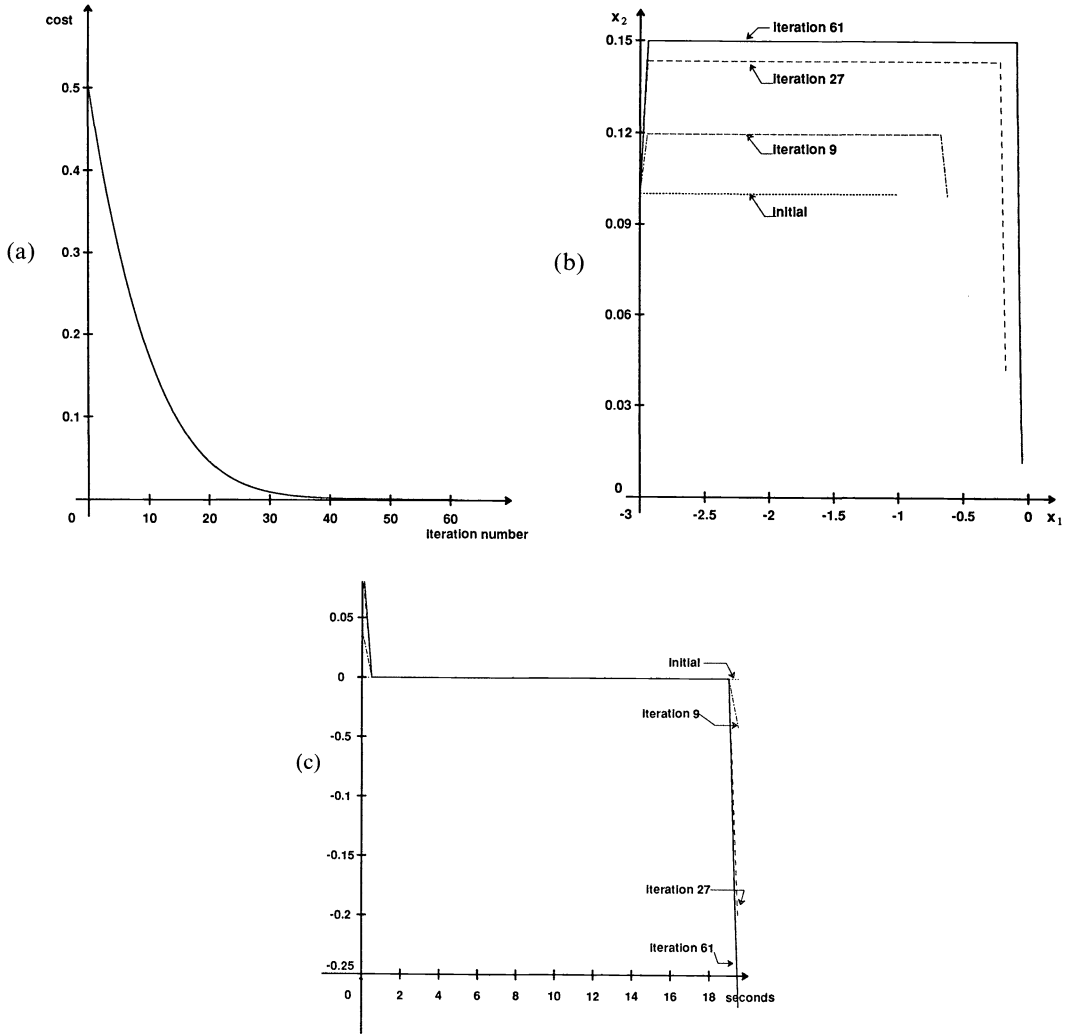

FIG. 4. (a) Cost versus iteration number, (b) state-space trajectories, and (c) controls at various iterations for Example 5.2 using nonpenalized control.

and $T = 20$. With $s(\cdot)$ defined by $s(t) = u(t)^2 - 1.0$, problem **P** (5.3a) becomes

$$(5.4a) \quad \mathbf{P}': \min_{u \in L_{\infty,2}} \left\{ \frac{1}{2} \|x(1)\|^2 \right\} \max_{t \in [0,1]} \phi^j(u, t) \leq 0, \quad j = 1, 2,$$

where

$$(5.4b) \quad \phi^1(u, t) = x^2(t) - l,$$

$$(5.4c) \quad \phi^2(u, t) = s(t).$$

We applied Algorithm 3.1 to both problems **P** and **P'**.

Figures 3(a)–3(c) present plots of the cost $f^0(u_i)$ versus iteration number i , as well as corresponding state-space trajectories and inputs at various iterations obtained by using formulation (2.1a). Similar results from using formulation (4.3b) are shown in Figs. 4(a)–4(c). As we can see, the results obtained are almost identical.

It is clear from our experimental results that Algorithm 3.1 is effective in solving optimal control problems with continuum state and control constraints. Also, when we have a special description of the set of controls, we can take advantage of it without any penalty.

6. Conclusion. We have presented two versions of a phase I-phase II method of centers algorithm for the solution of optimal-control problems with control and state-space constraints. The computational advantages of these algorithms derive from the fact that we used barrier functions for defining an approximate center to be computed at each iteration. Although, at first glance, the algorithms appear to have potential for failure due to ill conditioning, preliminary computational results show that this is not so and that, in fact, the algorithms are highly effective. This observation agrees with the numerical results reported in [21] for a related algorithm that solves semi-infinite minimax problems.

NEARLY OPTIMAL CONTROLS FOR STOCHASTIC ERGODIC PROBLEMS WITH PARTIAL OBSERVATION*

WOLFGANG J. RUNGGLADIER† AND ŁUKASZ STETTNER‡

Abstract. This paper considers the problem of constructing nearly optimal controls for discrete-time, infinite horizon, stochastic control problems under partial observations, with the average cost criterion.

Key words. stochastic control, partial observations, ergodic control, invariant measures, nearly optimal controls, approximation methods

AMS(MOS) subject classifications. primary 93E20; secondary 93E11, 93E25

1. Introduction. Stochastic control problems with partial observation have considerable importance in applications, and a large body of literature is available concerning this subject (see, e.g., [5] and references therein). Nevertheless, while many results are available concerning existence of optimal controls, little is known concerning the construction of an optimal, or at least nearly optimal, control. Here we address such a problem in the case of infinite horizon with the average cost criterion and partial observations of the state. The construction of nearly optimal controls is closely related to approximations of stochastic control problems, and in this area some pioneering work is due to Kushner (see [8]; see also the more recent survey [9]). In line with previous work [2] on using approximation methods to derive nearly optimal controls, in a first paper [12] we studied the case of infinite horizon with discounting and partial observations of the state. Here we again study the infinite horizon problem, but with the average cost criterion and partial observations of the state, which required a rather different approach and for which, to our knowledge, nothing has yet appeared in the literature (see [5], where, in the case of partially observed diffusions, open problem 6 is such a problem).

We consider a rather general setting of the problem, where the state process is Markov, characterized by its transition kernel, and evolves on a locally compact state space. On the other hand, we treat only the discrete-time case, but this case arises in many circumstances and is natural when the observations, and therefore also the controls, are taken at discrete-time points.

As admissible controls, we take those corresponding to the so-called separated problem, namely, those that depend on past and present observations only through the filter values. We do not address the problem of whether the optimal control for the separated problem is optimal also when the controls are simply adapted to the σ -field generated by the observations. Such a fact is true in many situations (see, e.g., [3]; see also [12] for a proof in the continuous-time, infinite horizon case with discounting, when, besides continuously acting controls, also impulsive control and stopping are allowed), and here we simply accept it, concentrating our efforts on the construction of a method to obtain a control that is nearly optimal with respect to

such a class of admissible controls. The class of controls that we consider, and the assumptions that we impose, are mainly motivated by the need to have a unique invariant measure for the controlled filtering process.

The method consists of two basic parts: The first part—essentially § 3—consists of a procedure to determine a nearly optimal control function that, when applied to the true filter values, yields nearly optimal controls. Since generally the true filter values cannot be computed in practice, in the second part—essentially § 4—we introduce a computable approximate filter and show that, when applying the nearly optimal control functions of the first part to the approximate filter values, we still obtain nearly optimal controls.

In § 1.1 we give a precise formulation of the problem. In § 1.2 we state and explain our assumptions. Section 1.3 is devoted to some preliminary results, including results on measure transformations that allow the problem to be cast in its proper frame. Section 2 contains some fundamental results for the rest of the paper, namely, on convergence of invariant measures that underlie many more specific results, as well as on approximations of controls. Section 3 describes the first part of our approximation method, namely, the construction of a control function that, when applied to the true filter values, yields nearly optimal controls for the original problem. Section 3.3 summarizes the algorithmic aspects of our (approximation) procedure. Finally, § 4 concerns the definition of a computable approximate filter process and the proof that, when evaluating the nearly optimal control function—constructed in § 3—at the approximating filter values, we still obtain nearly optimal controls for the original problem.

Concerning notation, we sometimes use $\mathcal{B}(A)$ to denote both the Borel sets in A as well as the (bounded) Borel functions on A ; the context should create no ambiguity.

1.1. Problem formulation. On a given probability space (Ω, \mathcal{F}, P) , consider a controlled Markov process (x_i) , $i = 1, 2, \dots$, with values in a locally compact separable state space E . Assume that (x_i) has initial law μ and denote by $P^{u_i}(x, d\eta)$ its transition kernel in the generic period i , where u_i represents the control that takes values in a set of control parameters $U \subset \mathcal{R}^k$, which is compact and such that $\{0\} \in U$. The process (x_i) is only partially observed through observations (y_i) , $y_i \in \mathcal{R}^d$, defined by

$$(1.1) \quad y_i = h(x_i) + w_i, \quad i = 1, 2, \dots,$$

where $h \in C(E, \mathcal{R}^d)$, the space of continuous bounded functions from E into \mathcal{R}^d , and (w_i) are independently and identically distributed d -dimensional standard Gaussian random variables, independent of x_k for $k \leq i$. We assume that each u_i is adapted to the observation σ -algebra $Y^i := \sigma\{y_1, \dots, y_i\}$. Given a bounded Borel function ϕ on E , now define a process $\pi_i^{\mu, u}(\cdot)$ with values in the space $\mathcal{P}(E)$ of probability measures on E , endowed with the topology of weak convergence, as follows:

$$(1.2) \quad \pi_0^{\mu, u}(\phi) = \mu(\phi), \quad \pi_i^{\mu, u}(\phi) = E_\mu\{\phi(x_i) | Y^i\},$$

where E_μ stands for the expectation, given the initial law μ for the process (x_i) that is controlled by a law u to be defined below and where we use $\pi(\phi)$ to denote the integral of a function $\phi(x)$ with respect to the measure $\pi(dx)$. We call $(\pi_i^{\mu, u})$ the filtering process corresponding to the controlled process (x_i) with observations (1.1). This process can easily be seen to be Markov; its transition kernel will be denoted (see (1.33) below) by $\Pi^u(\mu, \Lambda)$, with $\Lambda \in \mathcal{B}(\mathcal{P}(E))$ the σ -field of Borel subsets of $\mathcal{P}(E)$.

We are now more specific as to the sense in which we consider u_i to be Y^i -adapted: We define the class \mathcal{A} of admissible control functions as the class

$$\mathcal{A} = \{u : \mathcal{P}(E) \rightarrow U; u \text{ is continuous}\}.$$

By analogy to known results in the discounted infinite horizon case concerning the so-called separated problem (for a proof, see, e.g., [12, Thm. 3]), in the first part of the paper, more precisely in §§ 1–3, we then consider Y^i -adapted controls u_i of the form

$$(1.3) \quad u_i = u(\pi_i^{\mu, u}), \quad u \in \mathcal{A}.$$

Since generally the true filtering process cannot be computed, in the last part of the paper, essentially § 4, we consider Y^i -adapted controls of the form (1.3), where $\pi_i^{\mu, u}$ is replaced by a computable approximate filtering process.

Being interested in ergodic stochastic control, given a continuous and bounded function $c(x, v) : E \times U \rightarrow \mathcal{R}$, we consider as an objective function to be minimized the following functional:

$$(1.4) \quad J_\mu(u) = \limsup_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} E_\mu\{c(x_i, u(\pi_i^{\mu, u}))\}.$$

The minimization is over the class \mathcal{A} of admissible control functions. In §§ 2 and 3, we describe a feasible method for the construction of a nearly optimal control function $u(\cdot)$ for the cost functional (1.4) in the class \mathcal{A} as well as in restricted subclasses to be defined later.

Given a nearly optimal control function \hat{u} , we are still not able to apply the controls of the form (1.3) since the filtering process $(\pi_i^{\mu, u})$ cannot be computed explicitly. Therefore, in § 4 we define a computable approximating filtering process $(\pi_i^{m(\mu)})$ taking values in a finite-dimensional simplex S^m ; we also define a mapping $\tilde{\mathcal{J}}_m$ from \mathcal{A} into functions defined on S^m such that, given a nearly optimal control function $\hat{u} \in \mathcal{A}$, the controls

$$(1.5) \quad u_i = \tilde{\mathcal{J}}_m \hat{u}(\pi_i^{m(\mu)})$$

are nearly optimal, i.e.,

$$\limsup_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} E_\mu\{c(x_i, u_i)\} \leq \inf_{u \in \mathcal{A}} J_\mu(u) + \varepsilon,$$

thus completing the description of a feasible method for the construction of nearly optimal controls for our ergodic control problem.

1.2. Basic assumptions and their discussion. We make the following assumptions:

- (A1) For fixed $v \in U$, the transition kernel $P^v(x, \cdot)$ is Feller.
- (A2) If $U \ni v_m \rightarrow v$, then, letting \Rightarrow denote weak convergence, $P^{v_m}(x, \cdot) \Rightarrow P^v(x, \cdot)$ uniformly for x from compact subsets of E , i.e., for any $f \in C(E)$, $P^{v_m}f(x) \rightarrow P^vf(x)$, uniformly on compact subsets of E .
- (A3) For each open set $\mathcal{O} \subset E$, $v \in U$, $x \in E$, $P^v(x, \mathcal{O}) > 0$.
- (A4) There exists $\eta(\cdot) \in \mathcal{P}(E)$ such that for all $x \in E$ we have $P^v(x, \cdot) = \eta(\cdot)$ for $v = 0$.

Remark 1.2.1. Assumptions (A1) and (A2) guarantee (see Proposition 1.2(ii), below) the Feller property of the filtering process $(\pi_i^{\mu, u})$ and seem to be natural. Assumption (A3) corresponds to the nondegeneracy of the controlled transition kernel of the state process. Assumption (A4) might appear restrictive, but is satisfied in a

variety of applied models (see, e.g., [1]); more generally, it holds in the following example.

Example (EX). Let $E = \mathcal{R}^n$ and let x_i satisfy

$$(1.6) \quad x_{i+1} = f(x_i, u_i) + g(x_i, u_i)v_i, \quad x_0 = x$$

where $f(x, u)$, $g(x, u)$ are continuous functions such that for all $x \in E$ we have $f(x, 0) = \text{const}$, $g(x, 0) = c \cdot I$ ($c \neq 0$), and where (v_i) is an independently and identically distributed sequence of standard Gaussian random vectors, independent of (w_i) in (1.1).

Note that, for the example, (A1)–(A3) are also satisfied.

We now make further assumptions that depend on whether E is locally compact without being compact. In the case where E is locally compact, but noncompact, we make the following further assumptions.

(B1) There exists $j \in \{1, 2, \dots, d\}$ such that the j th component $h^j(x)$ of $h(x)$ has a limit at “ ∞ ” and attains at “ ∞ ” either its strong maximum or strong minimum. More precisely, letting

$$(1.7) \quad K_n = \{x \in E \mid \rho(x, \bar{x}) \leq n\},$$

where ρ is a metric on E compatible with the topology and \bar{x} is a fixed element of E , we either have

$$(1.8) \quad \sup_{x \in K_n} h^j(x) < \sup_{x \in E} h^j(x) \quad \text{for } n = 1, 2, \dots$$

or

$$(1.9) \quad \inf_{x \in K_n} h^j(x) > \inf_{x \in E} h^j(x).$$

(B2) For each $\varepsilon > 0$, there exists $u_\varepsilon \in \mathcal{A}$ and a unique invariant measure Φ^{u_ε} corresponding to the transition operator $\Pi^{u_\varepsilon}(\mu, \cdot)$, such that u_ε is ε -optimal in the sense that, for a given initial law μ of the state process (x_i) , we have

$$(1.10) \quad \int_{\mathcal{P}(E)} \int_E c(x, u_\varepsilon(v)) \nu(dx) \Phi^{u_\varepsilon}(d\nu) = J_\mu(u_\varepsilon) \leq \inf_{u \in \mathcal{A}} J_\mu(u) + \varepsilon.$$

(B3) There exists an initial law μ such that the family of Cesaro averages

$$\left\{ \frac{1}{t} \sum_{i=0}^{t-1} (\Pi^u)^i(\mu, \cdot), \quad u \in \mathcal{A}, \quad t = 1, 2, \dots \right\}$$

is tight.

(B4) For any compact set $K \subset E$, there exists $\alpha > 0$ such that

$$\inf_{v \in U} \inf_{x \in E} P^v(x, K^c) \geq \alpha.$$

Remark 1.2.2. Although assumption (B2) contains an usual requirement in ergodic control (see, e.g., [10; § 6]), its verification in general cases seems to be an open problem (in particular, concerning the existence of a unique invariant measure). This problem is studied in [6], but for a very particular partially observed model. On the other hand, if we restrict the class of admissible control functions \mathcal{A} to a subclass $\bar{\mathcal{A}} \subset \mathcal{A}$, then, given the other assumptions, we may hope to be able to obtain uniqueness of the invariant measure for $(\pi_i^{\mu, u})$. This is indeed the case and, to define the subclass $\bar{\mathcal{A}}$, let $r: [0, 1] \rightarrow [0, 1]$ be a continuous nondecreasing function such that, with $0 < b < c < 1$,

$$(1.11) \quad r(x) = \begin{cases} 0 & \text{for } x < b, \\ 1 & \text{for } x > c. \end{cases}$$

Furthermore, let $\psi_n(x) \in C(E)$ with values in $[0, 1]$ be a given function satisfying

$$(1.12) \quad \psi_n(x) = \begin{cases} 1 & \text{for } x \in K_{n-1}, \\ 0 & \text{for } x \in E \setminus K_n. \end{cases}$$

Now define

$$(1.13) \quad \bar{\mathcal{A}} = \bigcup_{n=1}^{\infty} \bar{\mathcal{A}}_n \quad \text{with } \bar{\mathcal{A}}_n = \{u \in \mathcal{A} \mid u(v) = \tilde{u}(v)r(v(\psi_n)) \text{ for } \tilde{u} \in \mathcal{A}\};$$

i.e., $\bar{\mathcal{A}}$ consists of control functions in \mathcal{A} that are equal to zero in a weak neighborhood of “ ∞ .” It follows from Corollary 2.4, below, that, given the other assumptions, (B2) is automatically satisfied for the class $\bar{\mathcal{A}}$ and that, if (B2) can be verified, the optimal minimal values of the cost functional $J_\mu(u)$ over $\bar{\mathcal{A}}$ and \mathcal{A} coincide. Note, furthermore, that Proposition 1.1 and its Corollary 1.1, below, provide sufficient conditions for (B3) to hold. It is easily seen that the condition of Corollary 1.1 holds for Example (EX), provided that $g(x, u)$ is bounded and $f(x, u)$ satisfies, for all $x \in X$, the growth condition

$$(1.14) \quad \sup_{v \in U} \|f(x, v)\|_e^2 \leq \gamma(\|x\|_e^2 + K),$$

where $\|\cdot\|$ denotes the Euclidean norm, $\gamma \in (0, 1)$, and $0 < K < \infty$. Adding to these conditions the requirement that there exists $a > 0$ such that for all $x \in \mathcal{R}^n$, $v \in U$, $z \in \mathcal{R}^n$,

$$(1.15) \quad (g(x, v)z, g(x, v)z) \geq a\|z\|^2,$$

it is easily seen that in (EX) we have, for sufficiently large m ,

$$(1.16) \quad P\{\|x_1\| \geq m\} \geq P\left\{\|w_0\| \geq \frac{3m}{\sqrt{a}}\right\} = \alpha > 0,$$

so that (EX) also satisfies (B4). Assuming finally that we add to the state equation (1.6) an observation equation with $h(\cdot)$ satisfying (B1), we have in (EX) a rather general example for which (A1)–(A4) and (B1)–(B4) are all satisfied, provided that the admissible controls are restricted to $\bar{\mathcal{A}}$. Concerning assumption (B4), note finally that it represents a nondegeneracy condition for the state process that is always satisfied for state evolution models with nondegenerate additive Gaussian noise.

To study the case where E is compact, we assume the following assumptions in addition to (A1)–(A4).

(C1) There exists $j \in \{1, 2, \dots, d\}$ and $\hat{x} \in E$ such that either

$$(1.17) \quad h^j(\hat{x}) > h^j(x) \quad \text{for any } x \in E, x \neq \hat{x}$$

or

$$(1.18) \quad h^j(\hat{x}) < h^j(x) \quad \text{for any } x \in E, x \neq \hat{x}.$$

also require the following assumption.

(C2) There exists n_0 and a sequence of positive α_n such that for all $n \geq n_0$ we have

$$\inf_{v \in U} \inf_{x \in E} P^v(x, B_n) \geq \alpha_n$$

with $B_n = \{x \in E \mid \rho(x, \hat{x}) \leq n^{-1}\}$.

Contrary to the case where E is locally compact, but noncompact, provided it is possible to verify assumption (B2), we do not necessarily have to restrict the original

class \mathcal{A} of admissible control functions to the subclass $\tilde{\mathcal{A}}$, here we are forced to consider a subclass that we denote by \mathcal{A}^r . Letting $\psi(x) \in C(E)$ with values in $[0, 1]$ be any function such that

$$(1.19) \quad \hat{x} \notin \text{closure } \{x \mid \psi(x) > 0\},$$

the class \mathcal{A}^r is given by

$$(1.20) \quad \mathcal{A}^r = \{u \in \mathcal{A} \mid u(\nu) = \tilde{u}(\nu)r(\nu(\psi)) \text{ for } \tilde{u} \in \mathcal{A}\};$$

i.e., \mathcal{A}^r consists of control functions in \mathcal{A} that are equal to zero in a weak neighborhood of the Dirac measure $\delta_{\hat{x}}$.

Remark 1.2.3. Also for this case where E is compact, it follows from results to be obtained below that, given assumptions (A1)–(A4), (C1), (C2), as well as (B3), assumption (B2) is automatically satisfied for the class \mathcal{A}^r . In fact, by Theorem 2.3(ii), (iv) below, for each $u \in \mathcal{A}^r$ there exists a unique invariant measure Φ^u for the filtering process. Furthermore, by (A1), (A2) (see Proposition 1.2(ii) below), the filtering process $(\pi_i^{\mu, u})$ is, for each $u \in \mathcal{A}^r$, a Markov–Feller process; if then the initial law μ is such that (B3) holds, the ensuing tightness of the Cesaro averages together with the Feller property of $(\pi_i^{\mu, u})$, giving (1.10).

In the course of the paper, we make two further assumptions (A5) and (A6), which are also satisfied by Example (EX) under additional mild assumptions on the coefficients, and where we further require that the cost function $c(x, v)$ can be uniformly approximated by step functions in x .

Remark 1.2.4. The strongest of all our assumptions appears to be (A4). We can, however, provide an alternative approach to our problem, based on an extended notion of control that includes compulsory shifts on the state, depending on the value of the filter, and for which assumption (A4) is not required. Details are in [14].

We conclude this section with Proposition 1.1 and its Corollary 1.1, giving sufficient conditions for (B3) to hold. We use the symbol P_μ^u to denote the probability measure induced either by the signal process (x_i) starting from the initial measure μ , or by the corresponding filtering process $(\pi_i^{\mu, u})$.

PROPOSITION 1.1. *Suppose that for any $\varepsilon > 0$ there exists an increasing sequence of compact sets $L_k \subset E$ such that for any $u \in \mathcal{A}$*

$$(1.21) \quad \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} \sum_{k=1}^{\infty} 2^k P_\mu^u \{x_i \in L_k^c\} \leq \varepsilon;$$

then the family $\{t^{-1} \sum_{i=0}^{t-1} (\Pi^u)^i(\mu, \cdot), u \in \mathcal{A}, t = 1, 2, \dots\}$ is tight.

Proof. Let $\Gamma(\varepsilon) = \{\nu \in \mathcal{P}(E) : \nu(L_k^c) \leq 2^{-k} \text{ for all } k = 1, 2, \dots\}$. Clearly, $\Gamma(\varepsilon)$ is a compact subset of $\mathcal{P}(E)$. Moreover,

$$(1.22) \quad \begin{aligned} (\Pi^u)^i(\mu, \Gamma(\varepsilon)) &= P_\mu^u \{\pi_i^{\mu, u} \in \Gamma(\varepsilon)\} = P_\mu^u \{\pi_i^{\mu, u}(L_k^c) \leq 2^{-k} \text{ for all } k\} \\ &= 1 - P_\mu^u \{\pi_i^{\mu, u}(L_k^c) > 2^{-k} \text{ for some } k\} \\ &\geq 1 - \sum_{k=1}^{\infty} 2^k P_\mu^u \{x_i \in L_k^c\}. \end{aligned}$$

Therefore, by (1.21)

$$(1.23) \quad \liminf_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} (\Pi^u)^i(\mu, \Gamma(\varepsilon)) \geq 1 - \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} \sum_{k=1}^{\infty} 2^k P_\mu^u \{x_i \in L_k^c\} \geq 1 - \varepsilon,$$

from which our claim follows.

COROLLARY 1.1. Assume that $E = \mathcal{R}^n$ with Euclidean norm $\|\cdot\|_e$ and let

$$(1.24) \quad b = \sup_{u \in \mathcal{A}} \sup_i E_\mu^u \{\|x_i\|_e\} < \infty;$$

then (1.21) holds.

Proof. We define $L_k = \{x: \|x\|_e \leq 2^{2k} \varepsilon^{-1} b\}$. Then by Chebyshev's inequality

$$P_\mu^u \{\|x_i\|_e > 2^{2k} \varepsilon^{-1} b\} \leq 2^{-2k} \varepsilon b^{-1} E_\mu^u \{\|x_i\|_e\} \leq \varepsilon 2^{-2k},$$

and (1.21) is obviously satisfied.

1.3. Preliminary results. Consider the process (\bar{L}_n) defined as follows:

$$(1.25) \quad \bar{L}_n = \prod_{i=1}^n \exp \left[-(w_i, h(x_i)) - \frac{1}{2} (h(x_i), h(x_i)) \right]; \quad \bar{L}_0 = 1$$

with (\cdot, \cdot) standing for the Euclidean scalar product in \mathcal{R}^d . Given the increasing family of σ -algebras

$$(1.26) \quad (XW)^n := \sigma\{x_0, \dots, x_n; w_1, \dots, w_n\},$$

the process (\bar{L}_n) becomes a $((XW)^n, P)$ -martingale. Therefore we can define a new probability measure P^0 by

$$(1.27) \quad P_{(XW)^n}^0 = \bar{L}_n P_{(XW)^n} \quad \text{for } n = 1, 2, \dots$$

The following lemma is known and can be easily proved (see, e.g., [13]).

LEMMA 1.1. Under P^0 , the y_i are independently and identically distributed standard Gaussian, independent of the process (x_i) , and (x_i) has the same initial law μ and the same transition kernel $P^{u(\pi_i^{\mu,n})}(x_i, d\eta)$ as under P . Moreover,

$$(1.28) \quad P_{(XW)^n} = L_n P_{(XW)^n}^0$$

with

$$(1.29) \quad L_n = (\bar{L}_n)^{-1} = \prod_{i=1}^n \exp \left[(y_i, h(x_i)) - \frac{1}{2} (h(x_i), h(x_i)) \right], \quad L_0 = 1.$$

Using the conditional Bayes rule, usually called the Kallianpur–Striebel formula, we may now write

$$(1.30) \quad \pi_i^{\mu,u}(\phi) = \frac{E_\mu^0[L_i \phi(x_i) | Y^i]}{E_\mu^0[L_i | Y^i]} := \frac{\sigma_i^{\mu,u}(\phi)}{\sigma_i^{\mu,u}(1)} \quad P_\mu\text{-a.s.},$$

where, for $i = 1, 2, \dots$,

$$(1.31) \quad \begin{aligned} \sigma_i^{\mu,u}(\phi) &= E_\mu^0 \left[L_{i-1} E_\mu^0 \left\{ \exp \left[(y_i, h(x_i)) - \frac{1}{2} (h(x_i), h(x_i)) \right] \phi(x_i) \mid X^{i-1} Y^i \right\} \mid Y^i \right] \\ &= E_\mu^0 \left[L_{i-1} \int_E \exp \left[(y_i, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) P^{u(\pi_{i-1}^{\mu,u})}(x_{i-1}, dz) \mid Y^i \right] \\ &= \int_E \int_E \exp \left[(y_i, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) P^{u(\pi_{i-1}^{\mu,u})}(x, dz) \sigma_{i-1}^{\mu,u}(dx) \end{aligned}$$

with $\sigma_0^\mu(\cdot) = \mu(\cdot)$, and where E_μ^0 denotes expectation under the measure P^0 , assuming that (x_i) has initial law μ . By (1.30) it follows that the filtering process $(\pi_i^{\mu,u})$, defined in (1.2), can be obtained recursively as

$$\begin{aligned}
 \pi_0^{\mu,u}(\phi) &= \mu(\phi), \\
 \pi_i^{\mu,u}(\phi) &= \int_E \int_E \exp \left[(y_i, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \\
 &\quad \cdot \phi(z) P^{u(\pi_{i-1}^{\mu,u})}(x, dz) \pi_{i-1}^{\mu,u}(dx) \\
 &\quad \cdot \left(\int_E \int_E \exp \left[(y_i, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \right. \\
 &\quad \cdot P^{u(\pi_{i-1}^{\mu,u})}(x, dz) \pi_{i-1}^{\mu,u}(dx) \Big)^{-1} \\
 &:= M^u(y_i, \pi_{i-1}^{\mu,u})(\phi),
 \end{aligned}
 \tag{1.32}$$

where we implicitly define the operator M^u . The following proposition can now be proved (see [13]).

PROPOSITION 1.2. *Let $u \in \mathcal{A}$ be given and assumptions (A1), (A2) hold. Then*

- (i) *The mapping $M^u(y, \nu): \mathcal{R}^d \times \mathcal{P}(E) \rightarrow \mathcal{P}(E)$ is continuous;*
- (ii) *The process $(\pi_i^{\mu,u})$ is, for the filtration (Y^i) and under the probability measure P , a Feller–Markov process on $\mathcal{P}(E)$ with transition kernel $\Pi^u(\mu, \Lambda)$ given by*

$$\begin{aligned}
 \Pi^u(\mu, \Lambda) &= (2\pi)^{-(d/2)} \\
 &\quad \cdot \int_E \int_{\mathcal{R}^d} \left(\int_E \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right. \\
 &\quad \cdot P^{u(\mu)}(x, d\eta) 1_\Lambda(M^u(y, \mu)) \Big) dy \mu(dx)
 \end{aligned}
 \tag{1.33}$$

for $\Lambda \in \mathcal{B}(\mathcal{P}(E))$, the σ -field of Borel subsets of $\mathcal{P}(E)$.

To have a Feller property for $(\pi_i^{\mu,u})$, i.e., to know that Π^u transforms $C(\mathcal{P}(E))$ into itself, is very important for various reasons. We can then show, for example, that the Cesaro averages $n^{-1} \sum_{k=0}^{n-1} (\Pi^u)^k$, provided that they are tight and converge weakly to an invariant measure Φ^u of Π^u . Consequently, the functional (1.4) may be rewritten as

$$\begin{aligned}
 J_\mu(u) &= \limsup_{n \rightarrow \infty} n^{-1} \sum_{i=0}^{n-1} E_\mu \left\{ \int_E c(z, u(\pi_i^{\mu,u})) \pi_i^{\mu,u}(dz) \right\} \\
 &= \int_{\mathcal{P}(E)} \int_E c(x, u(\nu)) \nu(dx) \Phi^u(d\nu)
 \end{aligned}
 \tag{1.34}$$

for Φ^u -almost all $\mu \in \mathcal{P}(E)$.

2. Fundamental results.

2.1. Convergence of invariant measures. In this section, we prove Theorems 2.1 and 2.2 on convergence of invariant measures, where in the first theorem the control functions belong to the class \mathcal{A} , while in the second we restrict them to the classes $\bar{\mathcal{A}}$ or \mathcal{A}^r .

For this purpose, given $v \in U$, consider the transition kernel $P^v(x, \cdot)$ governing the given Markov process (x_i) on E and let $P_m^v(x, \cdot)$ be a sequence of Markov transition kernels approximating $P^v(x, \cdot)$ in the sense that

$$\begin{aligned}
 &\text{if } U \ni v_m \rightarrow v, \text{ then } P_m^{v_m}(x, \cdot) \Rightarrow P^v(x, \cdot) \\
 &\text{uniformly in } x \text{ from compact subsets of } E.
 \end{aligned}
 \tag{2.1}$$

Furthermore, given $u \in \mathcal{A}$ (or $\bar{\mathcal{A}}$, \mathcal{A}^r), let u_m be a sequence of Borel maps from $\mathcal{P}(E)$

into U such that

$$(2.2) \quad u_m(\nu) \rightarrow u(\nu) \text{ uniformly in } \nu \text{ from compact subsets of } \mathcal{P}(E).$$

Finally, let $h_m(x)$ be a sequence of bounded Borel maps approximating $h(x)$ in (1.1) in the sense that

$$(2.3) \quad \sup_{x \in E} |h_m(x) - h(x)| \rightarrow 0 \quad \text{for } m \rightarrow \infty.$$

Recall now that, given $u \in \mathcal{A}$ (or $\bar{\mathcal{A}}, \mathcal{A}^r$), $(\pi_i^{\mu, u})$ denotes the filtering process corresponding to the state process (x_i) with initial distribution μ , transition kernel $P^u(x, \cdot)$, and observations (1.1); note also that $P^u(x, \cdot)$ stands for the transition kernel that, in the generic period i , is given by $P^{v_i}(x, \cdot)$ with $v_i = u(\pi_i^{\mu, u})$.

Analogously, given $u \in \mathcal{A}$ (or $\bar{\mathcal{A}}, \mathcal{A}^r$) and $P_m^v(x, \cdot)$ as well as $u_m(\nu)$ according to (2.1) and (2.2), respectively, let (π_i^{m, μ, u_m}) denote the filtering process corresponding to the state process (x_i^m) with initial distribution μ , transition kernel $P_m^{u_m}(x_i^m, \cdot)$, and observations $y_i = h_m(x_i^m) + w_i$; again, $P_m^{u_m}(x, \cdot)$ stands for the transition kernel that, in the generic period i , is given by $P_m^{v_i}(x_i^m, \cdot)$ with $v_i = u_m(\pi_i^{m, \mu, u_m})$.

Below, we use the following additional notation: By analogy to $M^u(y, \nu)$ and $\Pi^u(\mu, \cdot)$ in (1.32), (1.33), we let

$$(2.4) \quad M_m^{u_m}(y, \nu)(\phi) := \int_E \int_E \exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \phi(z) P_m^{u_m(\nu)}(x, dz) \nu(dx) \\ \cdot \left(\int_E \int_E \exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] P_m^{u_m(\nu)}(x, dz) \nu(dz) \right)^{-1}$$

for a bounded Borel function ϕ on E and use $\Pi_m^{u_m}(\mu, \cdot)$ to denote the transition kernel of the Markov process (π_i^{m, μ, u_m}) . Furthermore, by analogy to previous usage, we let $\Pi^u(\mu, F)$ and $\Pi_m^{u_m}(\mu, F)$ denote the integrals of a bounded Borel function $F(\nu) \in \mathcal{B}(\mathcal{P}(E))$ with respect to the measures $\Pi^u(\mu, d\nu)$ and $\Pi_m^{u_m}(\mu, d\nu)$, respectively.

We are now ready to state the first theorem.

THEOREM 2.1. *Given $u \in \mathcal{A}$, let (2.1)–(2.3) hold, as well as*

- (i) *Assumptions (A1), (A2);*
 - (ii) *$u \in \mathcal{A}$ is such that the corresponding filtering process $(\pi_i^{\mu, u})$ admits a unique invariant measure Φ^u ;*
 - (iii) *For each u_m satisfying (2.2), there exists an invariant measure $\Phi_m^{u_m}$ for the filtering process (π_i^{m, μ, u_m}) ;*
 - (iv) *The family $\{\Phi_m^{u_m}, m = 1, 2, \dots\}$ is tight.*
- Then $\Phi_m^{u_m} \Rightarrow \Phi^u$ for $m \rightarrow \infty$.*

THEOREM 2.2. *Let $u \in \bar{\mathcal{A}}$ or \mathcal{A}^r be given and (2.1)–(2.3) hold. Assume (A1)–(A4) as well as*

- (i) *For $u \in \bar{\mathcal{A}}$, assume furthermore (B1), (B4), with (B4) holding uniformly in m also for the sequences of kernels $P_m^v(x, \cdot)$ in (2.1);*
- (ii) *For $u \in \mathcal{A}^r$, assume furthermore (C1), (C2), with (C2) holding uniformly in m also for $P_m^v(x, \cdot)$.*

Then there exist unique invariant measures $\Phi_m^{u_m}, \Phi^u$ corresponding to the filtering processes $(\pi_i^{m, \mu, u_m}), (\pi_i^{\mu, u})$, respectively, and

$$\Phi_m^{u_m} \Rightarrow \Phi^u \quad \text{for } m \rightarrow \infty.$$

Furthermore, for any $F \in \mathcal{B}(\mathcal{P}(E))$, $\nu \in \mathcal{P}(E)$, any $u \in \bar{\mathcal{A}}$ or $u \in \mathcal{A}'$ satisfying the conditions in (i) and (ii), respectively, and for sufficiently large m ,

$$(2.5) \quad \lim_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} (\Pi_m^{u_m}(\nu, F))^i = \int_{\mathcal{P}(E)} F(\nu) \Phi_m^{u_m}(d\nu),$$

$$(2.6) \quad \lim_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} (\Pi^u(\nu, F))^i = \int_{\mathcal{P}(E)} F(\nu) \Phi^u(d\nu).$$

For the proof of the above theorems, the following proposition and its corollary will be crucial.

PROPOSITION 2.1. *Let (2.1)–(2.3) hold and assume (A1), (A2). If $F_m \in \mathcal{B}(\mathcal{P}(E))$ is a sequence of Borel functions with uniform bound b_F , i.e.,*

$$(2.7) \quad \|F_m\| \leq b_F$$

and satisfies

$$(2.8) \quad F_m \rightarrow F \in C(\mathcal{P}(E))$$

uniformly on compact subsets of $\mathcal{P}(E)$, then

$$(2.9) \quad \Pi_m^{u_m}(\nu, F_m) \rightarrow \Pi^u(\nu, F)$$

uniformly in ν from compact subsets of $\mathcal{P}(E)$.

Proof. See Appendix A.1.

Corollary 2.1 follows immediately.

COROLLARY 2.1. *Under the assumptions of Proposition 2.1, if $\nu_m \Rightarrow \nu$, then*

$$\Pi_m^{u_m}(\nu_m, F_m) \rightarrow \Pi^u(\nu, F) \quad \text{for } m \rightarrow \infty.$$

Proof of Theorem 2.1. By the tightness assumption (iv) of Theorem 2.1, we have that the family $\{\Phi_m^{u_m}, m = 1, 2, \dots\}$ has a compact closure [4, Thm. 6.1] and there exists a measure $\Phi \in \mathcal{P}(\mathcal{P}(E))$ and a subsequence of $\{m\}$, for simplicity also denoted by $\{m\}$, such that $\Phi_m^{u_m} \Rightarrow \Phi$. Then, for $F \in C(\mathcal{P}(E))$,

$$(2.10) \quad \begin{aligned} |\Phi(F) - \Phi(\Pi^u F)| &\leq |\Phi(F) - \Phi_m^{u_m}(F)| + |\Phi_m^{u_m}(F) - \Phi_m^{u_m}(\Pi_m^{u_m} F)| \\ &\quad + |\Phi_m^{u_m}(\Pi_m^{u_m} F) - \Phi_m^{u_m}(\Pi^u F)| + |\Phi_m^{u_m}(\Pi^u F) - \Phi(\Pi^u F)|. \end{aligned}$$

Since $\{\Phi_m^{u_m}, m = 1, 2, \dots\}$ is tight, for each $\varepsilon > 0$ there is a compact set $\Gamma \subset \mathcal{P}(E)$ such that

$$\Phi_m^{u_m}(\Gamma) \geq 1 - \varepsilon \quad \text{for } m = 1, 2, \dots$$

Hence

$$(2.11) \quad |\Phi_m^{u_m}(\Pi_m^{u_m} F) - \Phi_m^{u_m}(\Pi^u F)| \leq 2\|F\|\varepsilon + \sup_{\nu \in \Gamma} |\Pi_m^{u_m} F(\nu) - \Pi^u F(\nu)|.$$

By (A1), (A2), and Proposition 1.2, we know that $\Pi^u F \in C(\mathcal{P}(E))$. Therefore, letting $m \rightarrow \infty$ in (2.10), from Proposition 2.1 and (2.11), we obtain

$$(2.12) \quad |\Phi(F) - \Phi(\Pi^u F)| \leq 2\|F\|\varepsilon.$$

Thus, since ε can be chosen arbitrarily small, we obtain $\Phi(F) = \Phi(\Pi^u F)$ for any $F \in \mathcal{P}(E)$, and, by the uniqueness of the invariant measure of $(\pi_t^{\mu, u})$, we have $\Phi = \Phi^u$. \square

For the proof of Theorem 2.2, we need additional notation and further preliminary results. Concerning the notation, let $\bar{\psi}_n(x) \in C(E)$ with values in $[0, 1]$ be the same as

$\psi_n(x)$ in (1.12) if (B1), (B2) hold, while in case of (C1), (C2) it is given by

$$(2.13) \quad \bar{\psi}_n(x) = \begin{cases} 0 & \text{for } x \in \{z \in E \mid \rho(z, \hat{x}) \leq 1/n\}, \\ 1 & \text{for } x \in \{z \in E \mid \rho(z, \hat{x}) \geq 2/n\} \end{cases}$$

and is furthermore Lipschitz with Lipschitz constant n .

Consider now $u \in \mathcal{A}$; then (see (1.13)), for some n , $u \in \bar{\mathcal{A}}_n$. On the other hand, if $u \in \mathcal{A}'$, then (see (1.20)), for some n , $\{z \in E \mid \rho(z, \hat{x}) \leq 2/n\} \subset \{x \mid \psi(x) = 0\}$. Whether $u \in \bar{\mathcal{A}}$ or $u \in \mathcal{A}'$, let \tilde{n} be a positive integer with the properties just mentioned and define

$$(2.14) \quad \Gamma = \{\nu \in \mathcal{P}(E), \nu(\bar{\psi}_{\tilde{n}}) < b\},$$

where b is as in the definition of the function $r(\cdot)$ in (1.11). Consider then the stopping times

$$\begin{aligned} \tau^{\mu, u} &= \inf \{i > 0 \mid \pi_i^{\mu, u} \in \Gamma\} = \inf \{i > 0 \mid \pi_i^{\mu, u}(\bar{\psi}_{\tilde{n}}) < b\}, \\ \bar{\tau}^{\mu, u} &= \inf \{i \geq 0 \mid \pi_i^{\mu, u} \in \Gamma\} \\ \tau_{(m)}^{\mu, u_m} &= \inf \{i > 0 \mid \pi_i^{m, \mu, u_m} \in \Gamma\}, \\ \bar{\tau}_{(m)}^{\mu, u_m} &= \inf \{i \geq 0 \mid \pi_i^{m, \mu, u_m} \in \Gamma\} \end{aligned}$$

as well as the sequences

$$\begin{aligned} \tau_1^{\mu, u} &= \tau^{\mu, u}, & \tau_{n+1}^{\mu, u} &= \tau_n^{\mu, u} + \tau^{\mu, u} \Theta_{\tau_n^{\mu, u}}, \\ \tau_{1(m)}^{\mu, u_m} &= \tau_{(m)}^{\mu, u_m}, & \tau_{n+1(m)}^{\mu, u_m} &= \tau_{n(m)}^{\mu, u_m} + \tau_{(m)}^{\mu, u_m} \Theta_{\tau_{n(m)}^{\mu, u_m}}, \end{aligned}$$

where Θ_{τ_n} stands for the Markov shift operator of the corresponding filtering process. Finally, for given $y \in \mathcal{R}^d$, $\mu \in \mathcal{P}(E)$, define the measures $R(y, \mu)$, $R_m(y, \mu) \in \mathcal{P}(E)$ by ($K \in \mathcal{B}(E)$) as follows:

$$(2.15) \quad R(y, \mu)(K) = \frac{\int_K \exp[(y, h(z)) - \frac{1}{2}(h(z), h(z))] \mu(dz)}{\int_E \exp[(y, h(z)) - \frac{1}{2}(h(z), h(z))] \mu(dz)},$$

$$(2.16) \quad R_m(y, \mu)(K) = \frac{\int_K \exp[(y, h_m(z)) - \frac{1}{2}(h_m(z), h_m(z))] \mu(dz)}{\int_E \exp[(y, h_m(z)) - \frac{1}{2}(h_m(z), h_m(z))] \mu(dz)},$$

so that, letting

$$(2.17) \quad \zeta^u(\mu)(\cdot) = \int_E P^{u(\mu)}(x, \cdot) \mu(dx), \quad \zeta_{m^m}^{u_m}(\mu)(\cdot) = \int_E P^{u_m(\mu)}(x, \cdot) \mu(dx),$$

we have (see (1.32), (2.4))

$$(2.18) \quad M^u(y, \mu) = R(y, \zeta^u(\mu)), \quad M_{m^m}^{u_m}(y, \mu) = R_m(y, \zeta_{m^m}^{u_m}(\mu)).$$

LEMMA 2.1. Under (B1), (B4) or (C1), (C2), for any $\gamma \in (0, 1)$, $M > 0$, $n = 1, 2, \dots$, and any $u \in \mathcal{A}$ we can find y_0, m_0 such that, if $(y^j$ is the j th component of $y \in \mathcal{R}^d)$

$$(2.19) \quad y^j > y_0, \quad |y^i| \leq M \quad \text{when } i \neq j,$$

we have for any $\nu \in \mathcal{P}(E)$ and $m > m_0$

$$(2.20) \quad M^u(y, \nu)(K_n^c) \geq \gamma, \quad M_{m^m}^{u_m}(y, \nu)(K_n^c) \geq \gamma,$$

$$(2.21) \quad M^u(y, \nu)(B_n) \geq \gamma, \quad M_{m^m}^{u_m}(y, \nu)(B_n) \geq \gamma,$$

according to whether (B1), (B4) or (C1), (C2) are satisfied and where K_n is as in (1.7), and B_n as in (C2).

Proof. See Appendix A.1.

From Lemma 2.1 and the above definitions, we immediately have the following corollary.

COROLLARY 2.2. Under (B1), (B4) or (C1), (C2),

$$\inf_{u \in \mathcal{A}} \inf_{\nu \in \mathcal{P}(E)} \Pi^u(\nu, \Gamma) \geq \beta > 0,$$

$$\inf_{u \in \mathcal{A}} \inf_{\nu \in \mathcal{P}(E)} \inf_{m \geq m_0} \Pi_{m^m}^u(\nu, \Gamma) \geq \beta > 0,$$

Consequently, the following holds.

COROLLARY 2.3. Always under (B1), (B4) or (C1), (C2), for $k = 1, 2, \dots$, we have

$$\sup_{u \in \mathcal{A}} \sup_{\nu \in \mathcal{P}(E)} E_{\nu}^u(\tau^{\nu, u})^k < \infty,$$

$$\sup_{u \in \mathcal{A}} \sup_{\nu \in \mathcal{P}(E)} \sup_{m \geq m_0} E_{\nu}^{u_m}(\tau_{(m)}^{\nu, u_m})^k < \infty,$$

which implies the same statement also for $\bar{\tau}^{\nu, u}$ and $\bar{\tau}_{(m)}^{\nu, u_m}$.

We also have the following lemmas.

LEMMA 2.2. Under the assumptions of Theorem 2.2, the processes $(\pi_{\tau_n}^{\nu, u})$ and $(\pi_{\tau_{n(m)}}^{m, \mu, u_m})$ —where for simplicity of notation we identify τ_n with $\tau_n^{\nu, u}$ and $\tau_{n(m)}$ with $\tau_{n(m)}^{\nu, u}$ —have, for m greater than the m_0 in Lemma 2.1 and for $\nu \in \Gamma$, unique invariant measures $I^u(\cdot)$ and $I_m^{u_m}(\cdot)$, respectively. More precisely, we have for $B \in \mathcal{B}(\mathcal{P}(E))$

$$\begin{aligned} I^u(B) &= E_{\nu}^u\{\pi_{\tau_1}^{\nu, u} \in B\} \\ (2.22) \quad &= \int_E (2\pi)^{-d/2} \int_{\mathcal{R}^d} E_{R(y, \eta)}^u\{\pi_{\bar{\tau}}^{R, u} \in B\} \\ &\quad \cdot \exp\left[-\frac{1}{2}(y - h(z), y - h(z))\right] dy \eta(dz), \end{aligned}$$

$$\begin{aligned} I_m^{u_m}(B) &= E_{\nu}^{u_m}\{\pi_{\tau_{1(m)}}^{m, \nu, u_m} \in B\} \\ (2.23) \quad &= \int_E (2\pi)^{-d/2} \int_{\mathcal{R}^d} E_{R_m(y, \eta)}^{u_m}\{\pi_{\bar{\tau}(m)}^{m, R, u_m} \in B\} \\ &\quad \cdot \exp\left[-\frac{1}{2}(y - h(z), y - h(z))\right] dy \eta(dz), \end{aligned}$$

where $\eta(\cdot)$ is the measure corresponding to (A4) and E_{ν}^u denotes expectation under the control function u and initial distribution $\nu \in \mathcal{P}(E)$.

Proof. The proof uses the definition of the set Γ in (2.14) and of the stopping times below (2.14) as well as the properties of the controls $u \in \bar{\mathcal{A}}$ or $u \in \mathcal{A}^r$ mentioned above (2.14). \square

LEMMA 2.3. Under the assumptions of Theorem 2.2, for $m > m_0$ there exist unique invariant measures $\Phi^u, \Phi_m^{u_m}$ of the processes $\{\pi_i^{\mu, u}\}$ and $\{\pi_i^{m, \mu, u_m}\}$, respectively. Letting $B \in \mathcal{B}(\mathcal{P}(E))$, they are given by

$$\begin{aligned} \Phi^u(B) &= \int_E (2\pi)^{-d/2} \int_{\mathcal{R}^d} E_{R(y, \eta)}^u \left\{ \sum_{i=0}^{\bar{\tau}} \chi_B(\pi_i^{R, u}) \right\} \\ (2.24) \quad &\cdot \exp\left[-\frac{1}{2}(y - h(z), y - h(z))\right] dy \eta(dz) \\ &\cdot \left(\int_E (2\pi)^{-d/2} \int_{\mathcal{R}^d} E_{R(y, \eta)}^u \{\bar{\tau} + 1\} \right. \\ &\quad \left. \cdot \exp\left[-\frac{1}{2}(y - h(z), y - h(z))\right] dy \eta(dz) \right)^{-1}, \end{aligned}$$

$$\begin{aligned}
\Phi_m^{u_m}(B) = & \int_E (2\pi)^{-d/2} \int_{\mathbb{R}^d} E_{R_m(y,\eta)}^{u_m} \left\{ \sum_{i=0}^{\bar{\tau}_{(m)}} \chi_B(\pi_i^{m,R_m,u_m}) \right\} \\
& \cdot \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] dy \eta(dz) \\
(2.25) \quad & \cdot \left(\int_E (2\pi)^{-d/2} \int_{\mathbb{R}^d} E_{R_m(y,\eta)}^{u_m} \{ \bar{\tau}_{(m)} + 1 \} \right. \\
& \left. \cdot \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] dy \eta(dz) \right)^{-1}.
\end{aligned}$$

Proof. The proof uses the following intermediate result. Since by the previous lemma there exists a unique invariant measure I^u for $\pi_{\tau_n}^{\nu,u}$ with $\nu \in \Gamma$, by Corollary 2.3 there exists a unique invariant measure Φ^u also for $(\pi_i^{\mu,u})$ with $\nu \in \mathcal{P}(E)$ that is given by

$$\Phi^u(B) = \frac{\int_{\Gamma} E_{\nu}^u \{ \sum_{i=0}^{\tau-1} \chi_B(\pi_i^{R,u}) \} I^u(d\nu)}{\int_{\Gamma} E_{\nu}^u \{ \tau \} I^u(d\nu)}$$

and analogously for the process (π_i^{m,μ,u_m}) . From here, we then proceed by analogy to the proof of the previous lemma, exploiting the definition of the set Γ and the structure of the controls $u \in \tilde{\mathcal{A}}$ or $u \in \mathcal{A}^r$. \square

At this point, to prove Theorem 2.2 it suffices to show the convergence of the right-hand side in (2.25) to the right-hand side in (2.24). By Corollary 2.3, this, in turn, is equivalent to showing that

$$\begin{aligned}
(2.26) \quad & E_{R_m(y,\eta)}^{u_m} \{ \chi_{\Gamma^c}(\pi_1^{m,R_m,u_m}) \cdots \chi_{\Gamma^c}(\pi_{i-1}^{m,R_m,u_m}) F(\pi_i^{m,R_m,u_m}) \} \\
& \rightarrow E_{R(y,\eta)}^u \{ \chi_{\Gamma^c}(\pi_1^{R,u}) \cdots \chi_{\Gamma^c}(\pi_{i-1}^{R,u}) F(\pi_i^{R,u}) \}.
\end{aligned}$$

Because the function of $(\pi_1^{R,u}, \dots, \pi_i^{R,u})$ on the right-hand side of (2.26) is not continuous, we also need the following auxiliary result, whose proof is in Appendix A.1.

LEMMA 2.4. *Let $u \in \tilde{\mathcal{A}}(\mathcal{A}^r)$ and Z be a continuous \mathbb{R}^d -valued random variable; furthermore, let $\nu \in \mathcal{P}(E)$ be such that, if $\mathcal{O} \subset E$ is an open set, then $\nu(\mathcal{O}) > 0$. The following then hold:*

(i) *Under (B1), for any $\phi \in C(E)$ such that $\text{supp}(\phi) \subset K_n$ and any $b \in (0, 1)$, we have*

$$P\{M^u(Z, \nu)(\phi) = b\} = 0;$$

(ii) *Under (C1), for any $\phi \in C(E)$ such that $\text{supp}(\phi) \subset E \setminus B_n$ and any $b \in (0, 1)$, we have*

$$P\{M^u(Z, \nu)(\phi) = b\} = 0.$$

We finally also have Proposition 2.2, whose proof follows immediately from Lemma A.1.3 in Appendix A.1 and the fact that, for all $y \in \mathbb{R}^d$, $\nu \in \mathcal{P}(E)$,

$$(2.27) \quad R_m(y, \nu) \rightarrow R(y, \nu).$$

PROPOSITION 2.2. *Under the assumptions of Theorem 2.2, given a positive integer q and $F_1, \dots, F_q \in C(\mathcal{P}(E))$, we have, for all $(y, \nu) \in \mathbb{R}^d \times \mathcal{P}(E)$,*

$$\begin{aligned}
& E_{R_m(y,\eta)}^{u_m} \{ F_1(\pi_1^{m,R_m,u_m}) \cdots F_q(\pi_q^{m,R_m,u_m}) \} \\
& \rightarrow E_{R(y,\eta)}^u \{ F_1(\pi_1^{R,u}) \cdots F_q(\pi_q^{R,u}) \} \quad \text{for } m \rightarrow \infty.
\end{aligned}$$

We are now in a position to complete the following proof.

Proof of Theorem 2.2. The statement of Proposition 2.2 is equivalent to the weak convergence

$$(\pi_1^{m, R_m, u_m}, \dots, \pi_q^{m, R_m, u_m}) \Rightarrow (\pi_1^{R, u}, \dots, \pi_q^{R, u}).$$

By Lemma 2.4 we then obtain (2.26) from which we get the desired weak convergence of the invariant measure, noting that

$$\begin{aligned} E_{R_m(y, \eta)}^{u_m} \left\{ \sum_{i=0}^{\bar{\tau}(m)} \chi_B(\pi_i^{m, R_m, u_m}) \right\} \\ = \chi_B(R_m(y, \eta)) + \sum_{i=1}^{\infty} \chi_{\Gamma^c}(R_m(y, \eta)) \\ \cdot E_{R_m(y, \eta)}^{u_m} \{ \chi_{\Gamma^c}(\pi_1^{m, R_m, u_m}) \cdot \dots \cdot \chi_{\Gamma^c}(\pi_{i-1}^{m, R_m, u_m}) \chi_B(\pi_i^{m, R_m, u_m}) \}. \end{aligned}$$

The last statement of the theorem follows from the law of large numbers applied to the uniformly ergodic processes $(\pi_{\tau_n}^{v, u})$ and $(\pi_{\tau_n(m)}^{m, \mu, u_m})$ (see Lemma 2.2) and from Corollary 2.3 (details are similar to Proposition 3 in [7]). \square

2.2. Approximation of admissible control functions. For our approximation purpose, it is crucial to have not only a unique limiting invariant measure, but also control functions $u: \mathcal{P}(E) \rightarrow U$ of a possibly simple form. We therefore approximate the admissible control functions in the classes $\mathcal{A}, \bar{\mathcal{A}}, \mathcal{A}^r$ considered so far, by simpler control functions in corresponding families parametrized by two parameters $L > 0$ and $n = 1, 2, \dots$, in such a way that

(a) For all approximating control functions u , the controlled filtering process $(\pi_i^{\mu, u})$ admits a unique invariant measure Φ^u ;

(b) The infima of the objective function $J_\mu(u)$ over the classes $\mathcal{A}, \bar{\mathcal{A}}, \mathcal{A}^r$ and over the corresponding classes of approximating control functions can be made as close as possible by choosing the parameters L and n sufficiently large.

DEFINITION 2.1. If E is noncompact and (B1) holds, then, given $L > 0$ and integer $n > 0$, let

$$\mathcal{A}(L, n) := \{u \in \mathcal{A} \mid u(\nu) = \bar{u}(\nu(\phi_1), \dots, \nu(\phi_n))r(\nu(\psi_n))\},$$

where

- $\bar{u}: \mathcal{R}^n \rightarrow U$ is Lipschitz with Lipschitz constant L ,
- $\phi_1, \phi_2, \dots, \phi_n, \dots$ is a dense sequence in $C_0(E)$, the space of continuous functions vanishing at infinity, and
- $r(\cdot)$ and $\psi_n(\cdot)$ are fixed and given as in (1.11), (1.12).

Note that $\mathcal{A}(L, n)$ is a subclass not only of \mathcal{A} , but also of $\bar{\mathcal{A}}$.

DEFINITION 2.2. If (C1) holds, then, given $L > 0$ and integer $n > 0$, let

$$\mathcal{A}^r(L, n) := \{u \in \mathcal{A}^r \mid u(\nu) = \bar{u}(\nu(\phi_1), \dots, \nu(\phi_n))r(\nu(\psi \wedge \psi_n))\},$$

where \bar{u} and $r(\cdot)$ are, as in Definition 2.1,

- $\phi_1, \phi_2, \dots, \phi_n, \dots$ is a dense sequence in $C(E)$ or $C_0(E)$ according to whether E is compact or only locally compact,
- $\psi(\cdot)$ is any function as in (1.19) with the additional requirement of being Lipschitz with constant n , and
- $\psi_n(\cdot)$ are given Lipschitz functions with constant n , taking values in $[0, 1]$, and such that

$$\psi_n(x) = \begin{cases} 0 & \text{for } x \in \{z \in E: \rho(z, \hat{x}) < 1/n\} \cup E \setminus K_n, \\ 1 & \text{for } x \in K_{n-1} \setminus \{z \in E: \rho(z, \hat{x}) < 2/n\}, \end{cases}$$

where K_n is as in (1.7).

We now state Theorem 2.3, which will not only be of interest in itself, namely, to justify the choice of the classes $\mathcal{A}(L, n)$, $\mathcal{A}^r(L, n)$, but its setup will be useful also in various situations in the rest of the paper, where it is important to have a unique limiting invariant measure (see, e.g., Proposition 3.2 and Theorem 3.1 below).

THEOREM 2.3. *Assume (A1)–(A4). Then*

(i) *If (B1)–(B3) are satisfied, for each $\mu \in \mathcal{P}(E)$ for which (B3) holds, we have*

$$(2.28) \quad \lim_{L \rightarrow \infty, n \rightarrow \infty} \inf_{u \in \mathcal{A}(L, n)} J_\mu(u) = \inf_{u \in \mathcal{A}} J_\mu(u);$$

(ii) *If (B3), (C1) are satisfied, for each $\mu \in \mathcal{P}(E)$ for which (B3) holds, we have*

$$(2.29) \quad \lim_{L \rightarrow \infty, n \rightarrow \infty} \inf_{u \in \mathcal{A}^r(L, n)} J_\mu(u) = \inf_{u \in \mathcal{A}^r} J_\mu(u);$$

(iii) *If (B1), (B4) are satisfied, for any $\mu \in \mathcal{P}(E)$, we have*

$$(2.3) \quad \lim_{L \rightarrow \infty, n \rightarrow \infty} \inf_{u \in \mathcal{A}(L, n)} J_\mu(u) = \inf_{u \in \mathcal{A}} J_\mu(u);$$

(iv) *If (C1), (C2) are satisfied, for any $\mu \in \mathcal{P}(E)$, we have*

$$(2.31) \quad \lim_{L \rightarrow \infty, n \rightarrow \infty} \inf_{u \in \mathcal{A}^r(L, n)} J_\mu(u) = \inf_{u \in \mathcal{A}^r} J_\mu(u).$$

Moreover, the controlled filtering process $(\pi_i^{\mu, u})$ admits a unique invariant measure Φ^u in the following situations:

For $u \in \mathcal{A}(L, n)$ under the assumptions of case (i);

For $u \in \mathcal{A}^r$ under the assumptions of either case (ii) or (iv);

For $u \in \tilde{\mathcal{A}}$ under the assumptions of case (iii).

Proof. By the very definition of compact sets in $\mathcal{P}(E)$, for each compact set $\Lambda \in \mathcal{P}(E)$, and (ψ_n) as in (1.12), we have $r(\nu(\psi_n)) = 1$ for $\nu \in \Lambda$ and n sufficiently large. Moreover, for any $\psi \in C(E)$, for which $0 \leq \psi \leq 1$, $\hat{x} \notin \text{closure } \{x: \psi(x) > 0\}$ there is a sequence (g_n) of Lipschitz functions taking values in $[0, 1]$ and having Lipschitz constant n , such that, with (ψ_n) as in Definition 2.2, we have by the Stone–Weierstrass theorem (see, e.g., [11, Thm. 9.28])

$$(2.32) \quad \lim_{n \rightarrow \infty} \min \{\psi_n(x), g_n(x)\} = \psi(x)$$

uniformly on compact subsets of E , from which we obtain the convergence $r(\nu(\psi_n \wedge g_n)) \rightarrow r(\nu(\psi))$, for $n \rightarrow \infty$, uniformly in ν from compact subsets Λ of $\mathcal{P}(E)$. Furthermore, by a suitable version of the Stone–Weierstrass theorem (see [16, App.]), each $u \in C(\mathcal{P}(E), U)$ can be approximated uniformly on compact sets with the use of functions $\hat{u}(\nu) = \bar{u}(\nu(\phi_1), \dots, \nu(\phi_n))$, $n = 1, 2, \dots$, $\bar{u} \in C(\mathcal{R}^n, U)$. Therefore, each $u \in \mathcal{A}$, respectively \mathcal{A}^r , can be approximated uniformly on compact sets with the use of functions of the type $u(\nu)$ from the respective classes $\mathcal{A}(L, n)$, $\mathcal{A}^r(l, n)$, with L, n sufficiently large.

Starting with case (i), note that, for each $u_\varepsilon \in \mathcal{A}$ satisfying (B2), there exists a sequence L_m with $L_m \leq L_{m+1} \rightarrow \infty$, and a sequence $u_m \in \mathcal{A}(L_m, m)$, such that $u_m(\nu) \rightarrow u_\varepsilon(\nu)$ uniformly on compact subsets of $\mathcal{P}(E)$. Since by Proposition 1.2, under (A1)–(A2) each process (π_i^{μ, u_m}) is Feller, and by (B3) the family

$$\left\{ \frac{1}{t} \sum_{i=0}^{t-1} (\Pi^{u_m})^i(\mu, \cdot), t = 1, 2, \dots \right\}$$

is tight, any weak limit Φ^{u_m} of

$$\frac{1}{t} \sum_{i=0}^{t-1} (\Pi^{u_m})^i(\mu, \cdot) \quad \text{with } t \rightarrow \infty$$

is an invariant measure of Π^{u_m} . Moreover, by (B3) again, the family $\{\Phi^{u_m}, m = 1, 2, \dots\}$ is tight. Therefore, recalling that by (B2) we have a unique invariant measure Φ^{u^*} , the assumptions of Theorem 2.1. are satisfied, and we have $\Phi^{u_m} \Rightarrow \Phi^{u^*}$ for $m \rightarrow \infty$. Consequently, (2.28) holds.

To prove (2.29), let us for a moment assume the uniqueness of an invariant measure Φ^u of the controlled filtering process $\pi^{\mu, u}$ for $u \in \mathcal{A}^r$. Given this fact and a sequence $u_m \in \mathcal{A}^r(L_m, m)$ ($L_m, m \rightarrow \infty$) such that $u_m(\nu) \rightarrow u(\nu)$ uniformly on compact subsets of $\mathcal{P}(E)$, since by (B3) the family $\{\Phi^{u_m}, m = 1, 2, \dots\}$ is tight, all the assumptions of Theorem 2.1 are again fulfilled. Therefore $\Phi^{u_m} \Rightarrow \Phi^u$ for $m \rightarrow \infty$, and, taking into account that for each $\mu \in \mathcal{P}(E)$ for which (B3) holds and $u \in \mathcal{A}^r$

$$\frac{1}{t} \sum_{i=0}^{t-1} (\Pi^u)^i(\mu, \cdot) \Rightarrow \Phi^u, \quad \text{letting } t \rightarrow \infty,$$

we obtain (2.29).

The proofs for the cases (iii) and (iv) are based on Theorem 2.2 and follow almost immediately from (2.5) and (2.6).

It remains to show the second assertion of the theorem. By results of the proof of Theorem 1.21 and the remark following Theorem 1.4 in [15], the existence of a unique invariant set, i.e., the fact that there are no two disjoint invariant sets, ensures the existence of a unique invariant measure. Therefore we prove that there exists a unique invariant set for the process $\pi_i^{\mu, u}$, $\mu \in \mathcal{P}(E)$.

Let $u \in \mathcal{A}(L, n)$. For $i = 0, 1, 2, \dots$, define

$$(2.33) \quad \pi_{i+1}^{\mu, u}(\phi, y) = \int_E \exp \left[(y, h(\eta)) - \frac{1}{2} (h(\eta), h(\eta)) \right] \phi(\eta) \hat{\pi}_i^{\mu, u}(d\eta) \cdot \left(\int_E \exp \left[(y, h(\eta)) - \frac{1}{2} (h(\eta), h(\eta)) \right] \hat{\pi}_i^{\mu, u}(d\eta) \right)^{-1}$$

with

$$(2.34) \quad \hat{\pi}_i^{\mu, u}(d\eta) = \int_E P^{u(\pi_i^{\mu, u})}(x, d\eta) \pi_i^{\mu, u}(dx).$$

Clearly, $\pi_{i+1}^{\mu, u}(\phi) = \pi_{i+1}^{\mu, u}(\phi, y_{i+1})$. Assume that (1.8) is satisfied. Then

$$(2.35) \quad \pi_{i+1}^{\mu, u}(\psi_n, y) \rightarrow 0 \text{ for the } j\text{th coordinate } y^j \text{ of } y \text{ tending to } \infty.$$

In fact, let $\|h^j\|_n = \sup_{x \in K_n} |h^j(x)|$. By (1.8), $\|h^j\| > \|h^j\|_n$ and

$$(2.36) \quad \pi_{i+1}^{\mu, u}(\psi_n, y) = \frac{\int_{K_n} \psi_n(z) \exp[(y, h(z)) - \|h^j\|_n - \frac{1}{2}(h(z), h(z))] \hat{\pi}_i^{\mu, u}(dz)}{\int_E \exp[(y, h(z)) - \|h^j\|_n - \frac{1}{2}(h(z), h(z))] \hat{\pi}_i^{\mu, u}(dz)}.$$

From (A3) and (2.34), $\hat{\pi}_i^{\mu, u}(\mathcal{O}) > 0$ for some open set \mathcal{O} , implying (2.35).

Now, by (2.35) there are $d_j > 0$, $d > 0$, such that, for $y^j > d_j$ and $|y^k| \leq d$ with $k \neq j$, we have $\pi_{i+1}^{\mu, u}(\psi_n, y) < b$ with b as in (1.11). Therefore $r(\pi_{i+1}^{\mu, u}(\psi_n)) = 0$, and, consequently, $u(\pi_{i+1}^{\mu, u}) = 0$, all with a positive probability. Thus, on account of assumption (A4),

$$(2.37) \quad \pi_{i+2}^{\mu, u}(\phi, y_{i+2}) = \frac{\int_E \exp[(y_{i+2}, h(z)) - \frac{1}{2}(h(z), h(z))] \phi(z) \eta(dz)}{\int_E \exp[(y_{i+2}, h(z)) - \frac{1}{2}(h(z), h(z))] \eta(dz)}$$

with positive probability. Since for any other $\nu \in \mathcal{P}(E)$, again with positive probability, $\pi_{i+2}^{\nu, u}(\phi, y_{i+2})$ is equal to the right-hand side of (2.37), there is a unique invariant set for the filtering process $(\pi_i^{\mu, u})$. The proof of the uniqueness of the invariant measure Φ^u for $u \in \mathcal{A}(L, n)$ and under (1.8) is thus completed. The case where $u \in \mathcal{A}(L, n)$ and

under (1.9) can be shown analogously. The proof of the uniqueness of Φ^u for $u \in \mathcal{A}'$ and under (C1) consists of similar steps: namely, we show that $\pi_{i+1}^{\mu,u}(\psi, y) \rightarrow 0$ for $y^j \rightarrow \infty$ under (1.17) or for $y^j \rightarrow -\infty$ under (1.18), which by (A3) and (A4) implies that $r(\pi_{i+1}^{\mu,u}(\psi)) = 0$, and, consequently, $u(\pi_{i+1}^{\mu,u}) = 0$, with a positive probability. Therefore, for any $\nu \in \mathcal{P}(E)$, $\pi_{i+2}^{\mu,u}$ is equal with positive probability to the right-hand side of (2.37), which implies the uniqueness of the invariant set and, consequently, of the invariant measure. The cases of $u \in \mathcal{A}'$ under (C1), (C2) and of $u \in \bar{\mathcal{A}}$ under (B1), (B4) follow immediately from Theorem 2.2 and the definitions of the approximating control functions in the classes $\mathcal{A}(L, n)$, $\mathcal{A}'(L, n)$. \square

COROLLARY 2.4. *Under (A1)–(A4), (B1), (B4) for the class $\bar{\mathcal{A}}$ of admissible control functions defined in (1.13), we have that assumption (B2) is satisfied. If (B2) can be verified independently, we also have for any $\mu \in \mathcal{P}(E)$*

$$\inf_{u \in \bar{\mathcal{A}}} J_\mu(u) = \inf_{u \in \mathcal{A}} J_\mu(u).$$

3. Construction of a nearly optimal control function.

3.1. Approximation of the state process. So far, the admissible control functions have been reduced to those that are elements of $\mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$, but it will be difficult to determine an optimal or even only ε -optimal control for $J_\mu(u)$ in the classes $\mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$. We therefore need to further approximate the problem at hand; the first step in this direction is a discretization of the state process (x_i) , which will be seen to imply that the corresponding filtering process takes values in a finite-dimensional space. For this purpose, we start by partitioning the state space E as follows: For each positive integer m , we choose disjoint Borel sets B_k^m , $k = 1, 2, \dots, k_m$, such that

- (i) $\bigcup_{k=1}^{k_m} B_k^m = E$;
- (ii) B_k^m have nonempty interiors, the closures \bar{B}_k^m of B_k^m for $k < k_m$ are compact;
- (D_m) (iii) $\sup_{(k=1,2,\dots,k_m-1)} \text{diam}(B_k^m) \rightarrow 0$ as $m \rightarrow \infty$ where $\text{diam}(B)$ stands for the diameter of the set B ;
- (iv) $B_{k_m}^m \supset B_{k_m+1}^{m+1}$, $\bigcap_{m=1}^{\infty} B_{k_m}^m = \emptyset$;
- (v) for $k = 1, 2, \dots, k_m$, there are indices $r_1, \dots, r_{i(k)}$ such that

$$B_k^m = \bigcup_{p=1}^{i(k)} B_{r_p}^{m+1}.$$

Moreover, we assume that

(A5) Each $h^j(x)$, $j = 1, 2, \dots, d$, as well as the function $c(x, v)$ in the objective function (1.4) can be arbitrarily closely approximated in a uniform way by step functions $h_m^j(x)$ and $c_m(x, v)$ given, respectively, by

$$(3.1) \quad h_m^j(x) = \sum_{k=1}^{k_m} \chi_{B_k^m}(x) h_m^{k,j}$$

and

$$(3.2) \quad c_m(x, v) = \sum_{k=1}^{k_m} \chi_{B_k^m}(x) c_k^m(v) \quad \text{with } c_k^m \in C(U).$$

Next, for a given m , we choose a set of selectors $\{z_k^m, k = 1, 2, \dots, k_m\}$ of the partition (D_m) with the following properties:

$$(3.3) \quad \begin{aligned} z_k^m \in \text{int}(B_k^m), \quad \{z_k^m, k = 1, 2, \dots, k_m\} \subset \{z_k^{m+1}, k = 1, 2, \dots, k_{m+1}\}, \\ z_{k_m}^m \rightarrow \infty \quad \text{for } m \rightarrow \infty \end{aligned}$$

and consider the simplex S^m in \mathcal{R}^{k_m} given by

$$S^m = \left\{ (s_1, \dots, s_{k_m}), 0 \leq s_k \leq 1, k = 1, 2, \dots, k_m, \sum_{k=1}^{k_m} s_k = 1 \right\}.$$

By analogy to $\mathcal{A}(L, n)$, we let a corresponding class $\mathcal{A}_m(L, n)$ of controls $u: S^m \rightarrow U$ be defined by

$$(3.4) \quad \begin{aligned} \mathcal{A}_m(L, n) := \left\{ u \in C(S^m, U) \mid u(s) = \bar{u} \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \right. \\ \left. \cdot r \left(\sum_{k=1}^{k_m} \psi_n(z_k^m) s_k \right) \right\}, \end{aligned}$$

where \bar{u} , ϕ_i , r , and ψ_n are as in Definition 2.1. Similarly, we have

$$(3.5) \quad \begin{aligned} \mathcal{A}_m^r(L, n) := \left\{ u \in C(S^m, U) \mid u(s) = \bar{u} \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \right. \\ \left. \cdot r \left(\sum_{k=1}^{k_m} (\psi \wedge \psi_n)(z_k^m) s_k \right) \right\}, \end{aligned}$$

where \bar{u} , ϕ_i , r , ψ , and ψ_n are as in Definition 2.2.

Since we will have to pass from controls in one class to controls in another class, it is useful to consider the following mappings:

$$(3.6) \quad \mathcal{L}_m: \mathcal{P}(E) \ni \nu \rightarrow \sum_{k=1}^{k_m} \nu(B_k^m) \delta_{z_k^m} \in \mathcal{P}(E),$$

$$(3.7) \quad \bar{\mathcal{L}}_m: C(\mathcal{P}(E), U) \ni u \rightarrow \bar{\mathcal{L}}_m u \quad \text{with } \bar{\mathcal{L}}_m u(\nu) = u(\mathcal{L}_m \nu),$$

$$(3.8) \quad \tilde{\mathcal{L}}_m: \mathcal{A} \ni u \rightarrow \tilde{\mathcal{L}}_m u \in C(S^m, U) \quad \text{with } \tilde{\mathcal{L}}_m u(s) = u \left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m} \right).$$

It follows immediately that

$$(3.9) \quad \bar{\mathcal{L}}_m u(\nu) = u \left(\sum_{k=1}^{k_m} \nu(B_k^m) \delta_{z_k^m} \right) = \tilde{\mathcal{L}}_m u(\nu(B_1^m), \dots, \nu(B_{k_m}^m))$$

and, consequently,

$$(3.10) \quad \tilde{\mathcal{L}}_m \mathcal{A}(L, n) = \mathcal{A}_m(L, n), \quad \tilde{\mathcal{L}}_m \mathcal{A}^r(l, n) = \mathcal{A}_m^r(L, n).$$

LEMMA 3.1. *We have*

$$(3.11) \quad \mathcal{L}_m \nu \Rightarrow \nu \text{ as } m \rightarrow \infty, \text{ uniformly on compact subsets of } \mathcal{P}(E);$$

$$(3.12) \quad \text{For } u \in \mathcal{A}, \bar{\mathcal{L}}_m u(\nu) \rightarrow u(\nu) \text{ as } m \rightarrow \infty, \text{ uniformly on compact subsets of } \mathcal{P}(E);$$

$$(3.13) \quad \text{If } \mathcal{B}(\mathcal{P}(E), U) \ni u_m \rightarrow u \in C(\mathcal{P}(E), U) \text{ uniformly on } \mathcal{P}(E), \text{ then } \bar{\mathcal{L}}_m u_m(\nu) \rightarrow u(\nu), \text{ uniformly on compact subsets of } \mathcal{P}(E), \text{ as } m \rightarrow \infty.$$

Proof. If $\Gamma \subset \mathcal{P}(E)$ is compact, then for any $\varepsilon > 0$ there is a compact set K and integer $m_0 > 0$ such that $K \subset \bigcup_{k=1}^p B_k^{m_0}$, $p < k_{m_0}$, and $\nu(K) > 1 - \varepsilon$ for $\nu \in \Gamma$. Then, for $\phi \in C(\mathcal{P}(E))$, using (D_m) (iii),

$$\sup_{\nu \in \Gamma} |\nu(\phi) - \mathcal{L}_m \nu(\phi)| \leq 2\varepsilon \|\phi\| + \sup_{\nu \in \Gamma} \sum_{k=1}^{k_m} \int_{K \cap B_k^m} |\phi(x) - \phi(z_k^m)| \nu(dx) \\ \rightarrow 2\varepsilon \|\phi\|, \quad \text{as } m \rightarrow \infty,$$

and, since $\varepsilon > 0$ can be chosen arbitrarily small, we obtain (3.11).

Convergence (3.12) is an almost immediate implication of (3.11) and Lemma A.1.1.

For the proof of (3.13) let us note that, denoting by ρ_U a metric compatible with the topology of U , we have

$$\rho_U(\bar{\mathcal{L}}_m u_m(\nu), u(\nu)) \leq \rho_U(\bar{\mathcal{L}}_m u_m(\nu), \bar{\mathcal{L}}_m u(\nu)) + \rho_U(\bar{\mathcal{L}}_m u(\nu), u(\nu)).$$

By (3.12) and the definition of $\bar{\mathcal{L}}_m$ we then obtain $\bar{\mathcal{L}}_m u_m(\nu) \rightarrow u(\nu)$, uniformly on compact sets of $\mathcal{P}(E)$. \square

Now let $E_m = \{1, 2, \dots, k_m\}$, which, through the correspondence $k \leftrightarrow z_k^m$, we can identify with the set $\{z_1^m, \dots, z_{k_m}^m\}$ and consider the following two approximated transition kernels:

$$(3.14) \quad \bar{P}_m^{u(\nu)}(x, \cdot) = \sum_{k=1}^{k_m} \chi_{B_k^m}(x) P^{\bar{\mathcal{L}}_m u(\nu)}(z_k^m, \cdot),$$

defined on the original state space E , and

$$(3.15) \quad P_m^v(k, p) = P^v(z_k^m, B_p^m), \quad k, p \in E_m$$

for an embedded Markov chain on E_m .

We also henceforth assume that

(A6) The partition (D_m) as well as the choice of selectors $\{z_k^m, k = 1, 2, \dots, k_m\}$ is such that, for each $k, p = 1, 2, \dots, k_m$, $v \in U$,

$$P^v(z_k^m, \partial B_p^m) = 0.$$

Note that under (A2) and (A6) the mapping $U \ni v \rightarrow P^v(z_k^m, B_p^m)$ is continuous.

Consider then the two partially observed control systems, below:

(CS₁) The unobserved state process (\bar{x}_i^m) evolves on E according to the transition operator $\bar{P}_m^u(x, \cdot)$ with initial law $\mu \in \mathcal{P}(E)$; the observations (\bar{y}_i) are of the form

$$(3.16) \quad \bar{y}_i = h_m(\bar{x}_i^m) + \bar{w}_i, \quad i = 1, 2, \dots,$$

where \bar{w}_i is a sequence of independently and identically distributed d -dimensional standard Gaussian vectors, independent of \bar{x}_k^m , $k \leq i$. We denote by $(\bar{\pi}_i^{m, \mu, u}) \in \mathcal{P}(E)$ the corresponding controlled filtering process.

(CS₂) The unobserved state process (x_i^m) evolves on E_m according to the transition probability matrix $P_m^u(k, p)$ with initial law $\bar{\mu}$ given by

$$(3.17) \quad \bar{\mu} = (\mu(B_1^m), \dots, \mu(B_{k_m}^m)) \in S^m.$$

The observations (\bar{y}_i) satisfy

$$(3.18) \quad \bar{y}_i = \sum_{k=1}^{k_m} h_m(z_k^m) \delta_{\{k\}}(x_i^m) + \bar{w}_i,$$

where, again, (\bar{w}_i) are independently and identically distributed standard Gaussian vectors independent of (x_k^m) , $k \leq i$. We denote by $(\pi_i^{m,\bar{\mu},u})$ the corresponding controlled filtering process.

By analogy to (1.32), define now, for $u \in \mathcal{A}$, $\nu \in \mathcal{P}(E)$, $y \in \mathcal{R}^d$,

$$(3.19) \quad \begin{aligned} \bar{M}_m^u(y, \nu)(\phi) &:= \int_E \int_E \exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \phi(z) \bar{P}_m^{u(\nu)}(x, dz) \nu(dx) \\ &\cdot \left(\int_E \int_E \exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \bar{P}_m^{u(\nu)}(x, dz) \nu(dx) \right)^{-1} \end{aligned}$$

and, for $u \in \mathcal{A}_m(L, n)$ or $\mathcal{A}_m^r(L, n)$, $y \in \mathcal{R}^d$, $s = (s_1, \dots, s_{k_m}) \in S^m$, $k \in E_m$,

$$(3.20) \quad \begin{aligned} M_m^u(y, s_1, \dots, s_{k_m})(k) &:= \exp \left[(y, h_m^k) - \frac{1}{2} (h_m^k, h_m^k) \right] \sum_{q=1}^{k_m} P_m^{u(s)}(q, k) s_q \\ &\cdot \left(\sum_{i=1}^{k_m} \exp \left[(y, h_m^i) - \frac{1}{2} (h_m^i, h_m^i) \right] \sum_{q=1}^{k_m} P_m^{u(s)}(q, i) s_q \right)^{-1}. \end{aligned}$$

LEMMA 3.2. For $u \in \mathcal{A}$, $i = 1, 2, \dots$, $\phi \in \mathcal{B}(E)$, we have

$$(3.21) \quad \bar{\pi}_{i+1}^{m,\mu,u}(\phi) = \bar{M}_m^u(\bar{y}_{i+1}, \bar{\pi}_i^{m,\mu,u})(\phi)$$

and $(\bar{\pi}_i^{m,\mu,u})$ is a Markov process with transition operator $(\Lambda \in \mathcal{B}(\mathcal{P}(E)))$

$$(3.22) \quad \begin{aligned} \bar{\Pi}_m^u(\nu, \Lambda) &= (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \int_E \exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] \bar{P}_m^{u(\nu)}(\zeta, d\eta) \\ &\cdot 1_\Lambda(\bar{M}_m^u(y, \nu)) dy \nu(d\zeta). \end{aligned}$$

Furthermore, for $u \in \mathcal{A}_m(L, n)$ or $\mathcal{A}_m^r(L, n)$, $s \in S^m$, $i = 1, 2, \dots$,

$$(3.23) \quad \pi_{i+1}^{m,s,u}(k) = M_m^u(\bar{y}_{i+1}, \pi_i^{m,s,u})(k), \quad \pi_0^{m,s,u}(k) = s_k, \quad (k \in E_m)$$

and $(\pi_i^{m,s,u})$ is a Feller–Markov process with transition operator $(\Lambda \in \mathcal{B}(S))$

$$(3.24) \quad \begin{aligned} \Pi_m^u(s, \Lambda) &= (2\pi)^{-(d/2)} \sum_{k=1}^{k_m} \int_{\mathcal{R}^d} \left(\sum_{q=1}^{k_m} \exp \left[-\frac{1}{2} (y - h_m^q, y - h_m^q) \right] P_m^{u(s)}(k, q) \right) \\ &\cdot 1_\Lambda(M_m^{u(s)}(y, s)) dy s_k. \end{aligned}$$

Proof. The proof can be obtained by an adaptation of Lemma 1.1. and Proposition 1.2, using also the continuity assumption (A6) for the proof of the Feller property of $\Pi_m^u(s, F)$. \square

The actual process of interest is $(\pi_i^{m,\bar{\mu},u})$, which evolves on a finite-dimensional space; $(\bar{\pi}_i^{m,\mu,u})$ is an intermediate auxiliary process needed in the convergence proofs. To be able to state our main approximation result (namely, Theorem 3.1, below), we need some preliminary results on invariant measures for the processes $(\pi_i^{m,\bar{\mu},u})$ and $(\bar{\pi}_i^{m,\mu,u})$ that will allow us to formulate the approximating partially observable control problem on a finite-dimensional state space.

It can be easily seen that, for $u \in \mathcal{A}_m(L, n)$, the process $(\pi_i^{m, \bar{\mu}, u})$ is the Feller on the compact state space S^m ; therefore there exists an invariant measure Φ_m^u , and we have the following proposition, whose proof is given in Appendix A.2.

PROPOSITION 3.1. *Given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$, if $\Phi_m^{\tilde{\mathcal{L}}_m u}$ is an invariant measure of $(\pi_i^{m, \bar{\mu}, \tilde{\mathcal{L}}_m u})$, then*

$$(3.25) \quad \bar{\Phi}_m^u(A) \stackrel{\text{def}}{=} \int_{S^m} \bar{\Pi}_m^u \left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m}, A \right) \Phi_m^{\tilde{\mathcal{L}}_m u}(ds)$$

for $A \in \mathcal{B}(\mathcal{P}(E))$, is an invariant measure of $(\bar{\pi}_i^{m, \mu, u})$.

We now define the approximating control problem as the partially observable problem (CS₂) with cost function given, for $u \in \mathcal{A}_m(L, n)$ or $\mathcal{A}^r_m(L, n)$, by

$$(3.26) \quad \begin{aligned} J_\mu^m(u) &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_{\bar{\mu}}\{c_m(x_i^m, u(\pi_i^{m, \bar{\mu}, u}))\} \\ &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_{\bar{\mu}} \left(\sum_{k=1}^{k_m} c_k^m(u(\pi_i^{m, \bar{\mu}, u})) \pi_i^{m, \bar{\mu}, u}(k) \right), \end{aligned}$$

where, by the correspondence $k \leftrightarrow z_k^m$, we have identified $\sum_{k=1}^{k_m} z_k^m \delta_{\{k\}}(x_i^m)$ with x_i^m .

The following proposition can now be stated, whose proof is also in Appendix A.2.

PROPOSITION 3.2. *Assume (A1)–(A6) and either (B1) or (C1). Given an integer $n > 0$, let $m_0(n)$ be such that for $m > m_0(n)$ we have, in the case of assumption (B1), that $\rho(z_{k_m}^m, \bar{x}) > n$, and, more precisely, for (1.8) (respectively (1.9)),*

$$(3.27) \quad h_m^{k,j} < h_m^{k_m,j} \quad (h_m^{k,j} > h_m^{k_m,j}) \quad \text{with } k = 1, 2, \dots, k_m - 1,$$

while, in the case of (C1), there is a $q \in \{1, \dots, k_m\}$ such that $\hat{x} \in B_q^m$, $B_q^m \subset \{x: \rho(x, \hat{x}) < 1/n\}$, and, more precisely, for (1.17) (respectively, (1.18)),

$$(3.28) \quad h_m^{k,j} < h_m^{q,j} \quad (h_m^{k,j} > h_m^{q,j}) \quad \text{with } k \neq q.$$

Then, for any $u \in \mathcal{A}(L, n)$ or $u \in \mathcal{A}^r(L, n)$, according to whether (B1) or (C1) is satisfied, and $m \geq m_0(n)$ there exists a unique invariant measure Φ_m^u of $(\pi_i^{m, \bar{\mu}, u})$. Moreover, for any $u \in \mathcal{A}(L, n)$ ($\mathcal{A}^r(L, n)$), and initial law $\bar{\mu} \in S$,

$$(3.29) \quad \begin{aligned} J_\mu^m(\tilde{\mathcal{L}}_m u) &= \int_{S^m} \sum_{k=1}^{k_m} c_k^m(\tilde{\mathcal{L}}_m u(s)) s_k \Phi_m^{\tilde{\mathcal{L}}_m u}(ds) \\ &= \int_{\mathcal{P}(E)} \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) \bar{\Phi}_m^u(d\nu) \end{aligned}$$

with $\bar{\Phi}_m^u$ defined by (3.25).

We are now ready to prove the main state-approximation result.

THEOREM 3.1. *Assume (A1)–(A6) together with (B1), (B4), or (C1), (C2), or (C1) and the compactness of E . Then, under (B1), (B4),*

$$(3.30) \quad \lim_{m \rightarrow \infty} \inf_{u \in \mathcal{A}_m(L, n)} J_\mu^m(u) = \inf_{u \in \mathcal{A}(L, n)} J_\mu(u),$$

while under (C1), (C2), or (C1) and the compactness of E ,

$$(3.31) \quad \lim_{m \rightarrow \infty} \inf_{u \in \mathcal{A}_m^r(L, n)} J_\mu^m(u) = \inf_{u \in \mathcal{A}^r(L, n)} J_\mu(u)$$

for each $\mu \in \mathcal{P}(E)$. Moreover, if for $s \in S^m$, and $\varepsilon > 0$

$$(3.32) \quad \begin{aligned} \tilde{u}_m(s_1, \dots, s_{k_m}) &= \bar{u}_m \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \\ &\quad \cdot r \left(\sum_{k=1}^{k_m} \psi_n(z_k^m) s_k \right), \end{aligned}$$

$$(3.33) \quad \begin{aligned} \tilde{u}_m(s_1, \dots, s_{k_m}) &= \bar{u}_m \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \\ &\quad \cdot r \left(\sum_{k=1}^{k_m} (\psi^m \wedge \psi_n)(z_k^m) s_k \right) \end{aligned}$$

are for $m=1, 2, \dots$ sequences of ε -optimal control functions for $J_{\bar{\mu}}^m(u)$ over $\mathcal{A}_m(L, n)(\mathcal{A}'_m(L, n)$, respectively), then any uniform limit of

$$(3.34) \quad \hat{u}_m(v) = \bar{u}_m(v(\phi_1), \dots, v(\phi_n)) r(v(\psi_n)),$$

$$(3.35) \quad \hat{u}_m(v) = \bar{u}_m(v(\phi_1), \dots, v(\phi_n)) r(v(\psi^m \wedge \psi_n))$$

forms an ε -optimal control function for $J_{\bar{\mu}}(u)$ over $\mathcal{A}(L, n)(\mathcal{A}'(L, n)$, respectively).

Remark 3.1. In Theorem 3.1, we make assumptions (A1)–(A6) and one among the three alternative additional groups (B1), (B4), or (C1), (C2), or (C1) and the compactness of E . This setting will remain the same for the rest of the paper. We want to point out, however, that the results to follow can also be obtained under assumptions (B1), (B3) by imposing additional tightness conditions; this latter approach is taken in [13].

Proof of Theorem 3.1. We divide the proof into two steps.

Step 1. For a given strategy $u \in \mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$, we have

$$(3.36) \quad \lim_{m \rightarrow \infty} J_{\bar{\mu}}^m(\tilde{\mathcal{L}}_m u) = J_{\bar{\mu}}(u).$$

For this purpose, letting

$$(3.37) \quad \tilde{P}_m^\nu(x, \cdot) = \sum_{k=1}^{k_m} \chi_{B_k^m}(x) P^\nu(z_k^m, \cdot),$$

note that all assumptions of Theorem 2.1 or Theorem 2.2 are satisfied with $u_m = \tilde{\mathcal{L}}_m u$, $\Phi_m^{u_m} = \bar{\Phi}_m^u$, $\pi_i^{m, \mu, u_m} = \bar{\pi}_i^{m, \mu, u}$, $y_i = \bar{y}_i$, $P_m^{u_m} = \bar{P}_m^u$, $P_m^v = \tilde{P}_m^v$. In fact, under our assumptions, by the second part of Theorem 2.3, we have that, for each $u \in \mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$, there exists a unique invariant measure Φ^u of the filtering process $(\pi_i^{\mu, u})$. Furthermore, (2.1) follows from (3.38) below, (2.2) is a consequence of Lemma 3.1, (2.3) is guaranteed by (A.5), and (B4) holds, uniformly in m , for each $P_m^v(x, \cdot)$ by its definition. We next show that under our assumptions we have

$$(3.38) \quad \begin{aligned} &\text{if } U \ni v_m \rightarrow v, \text{ then} \\ &\tilde{P}_m^{v_m} \Rightarrow P^v(x, \cdot) \text{ uniformly in } x \text{ from compact subsets of } E. \end{aligned}$$

In fact, assume that $K \subset E$ is a compact set. By the construction of the partition (D_m) , for each m and $x \in K$, there exists an index $m(x)$ such that $x \in B_{m(x)}^m$ and, letting $m \rightarrow \infty$, $\sup_{x \in K} \rho(z_{m(x)}^m, x) \rightarrow 0$. Then, for $f \in C(E)$ we have from (A1) and (A2)

$$(3.39) \quad \begin{aligned} |\tilde{P}_m^{v_m} f(x) - P^v f(x)| &\leq |P_m^{v_m} f(z_{m(x)}^m) - P^v f(z_{m(x)}^m)| \\ &\quad + |P^v f(z_{m(x)}^m) - P^v f(x)| \rightarrow 0 \quad \text{for } m \rightarrow \infty, \end{aligned}$$

from which (3.38) follows. Applying Theorem 2.1 or Theorem 2.2, we then have

$$(3.40) \quad \bar{\Phi}_m^u \Rightarrow \Phi^u \quad \text{for } m \rightarrow \infty,$$

and for any $\varepsilon > 0$ there is a compact set $\Gamma(\varepsilon) \subset \mathcal{P}(E)$ such that for $m = 1, 2, \dots$

$$(3.41) \quad \bar{\Phi}_m^u(\Gamma(\varepsilon)) \geq 1 - \varepsilon, \quad \Phi^u(\Gamma(\varepsilon)) \geq 1 - \varepsilon.$$

Since $\Gamma(\varepsilon)$ is tight, there is a compact set $K(\varepsilon) \subset E$ such that

$$(3.42) \quad \nu(K(\varepsilon)) \geq 1 - \varepsilon \quad \text{for } \nu \in \Gamma(\varepsilon).$$

By the continuity of $c(x, v)$, given $\varepsilon > 0$, there is $\delta > 0$ such that

$$(3.43) \quad \rho_U(v, v') < \delta \quad \text{implies} \quad \sup_{x \in K(\varepsilon)} |c(x, v) - c(x, v')| < \varepsilon.$$

Finally, by Lemma 3.1, for $m > \bar{m}$

$$(3.44) \quad \sup_{\nu \in \Gamma(\varepsilon)} \rho_U(\bar{\mathcal{L}}_m u(\nu), u(\nu)) < \delta.$$

Now, applying (3.29), we have

$$(3.45) \quad \begin{aligned} |J_\mu(u) - J_\mu^m(\bar{\mathcal{L}}_m u)| &= \left| \int_{\mathcal{P}(E)} \int_E c(x, u(\nu)) \nu(dx) \Phi^u(d\nu) \right. \\ &\quad \left. - \int_{\mathcal{P}(E)} \int_E c_m(x, \bar{\mathcal{L}}_m(u(\nu))) \nu(dx) \bar{\Phi}_m^u(d\nu) \right| \\ &\leq \left| \int_{\mathcal{P}(E)} \int_E c(x, u(\nu)) \nu(dx) (\Phi^u(d\nu) - \bar{\Phi}_m^u(d\nu)) \right| \\ &\quad + \left| \int_{\mathcal{P}(E)} \int_E (c(x, u(\nu)) - c(x, \bar{\mathcal{L}}_m u(\nu))) \nu(dx) \bar{\Phi}_m^u(d\nu) \right| \\ &\quad + \left| \int_{\mathcal{P}(E)} \int_E (c(x, \bar{\mathcal{L}}_m u(\nu)) - c_m(x, \bar{\mathcal{L}}_m u(\nu))) \nu(dx) \bar{\Phi}_m^u(d\nu) \right| \\ &= \text{I}_m + \text{II}_m + \text{III}_m. \end{aligned}$$

Clearly, (3.40) implies that $\text{I}_m \rightarrow 0$, and from (A5) it follows that $\text{III}_m \rightarrow 0$. By (3.41)–(3.44) for $m > \bar{m}$,

$$(3.46) \quad \begin{aligned} \text{II}_m &\leq \int_{\Gamma(\varepsilon)} \int_{K(\varepsilon)} |c(x, u(\nu)) - c(x, \bar{\mathcal{L}}_m u(\nu))| \nu(dx) \bar{\Phi}_m^u(d\nu) + 4\|c\|\varepsilon \\ &\leq \varepsilon(1 + 4\|c\|). \end{aligned}$$

Thus (3.36) holds.

Step 2. From Step 1, we have

$$(3.47) \quad \limsup_{m \rightarrow \infty} \inf_{u \in \mathcal{A}'_m(L, n)} J_\mu^m(u) \leq \inf_{u \in \mathcal{A}'(L, n)} J_\mu(u)$$

or

$$(3.48) \quad \limsup_{m \rightarrow \infty} \inf_{u \in \mathcal{A}'_m(L, n)} J_\mu^m(u) \leq \inf_{u \in \mathcal{A}'(L, n)} J_\mu(u).$$

The inverse inequalities follow from the second assertion of the theorem, an assertion that we will prove next. Let \tilde{u}_m , given by (3.32) (respectively, (3.33)), be such that for $m = 1, 2, \dots$, they form a sequence of ε -optimal control functions for $J_\mu^m(u)$ over $\mathcal{A}_m(L, n)$ ($\mathcal{A}'_m(L, n)$, respectively). Since \tilde{u}_m are bounded and Lipschitz with Lipschitz

constant L , by Ascoli's theorem (see, e.g., [11, Thm. 9.33]), there is $\bar{u} \in C(R^n, U)$ and a subsequence $m_k \rightarrow \infty$ such that $\bar{u}_{m_k} \rightarrow \bar{u}$ uniformly on $[-\|\phi_1\|, \|\phi_1\|] \times \cdots \times [-\|\phi_n\|, \|\phi_n\|]$. Also, since ψ^m are Lipschitz with Lipschitz constant n and values from $[0, 1]$, we may assume that m_k is chosen in such a way that $\psi^{m_k}(x) \rightarrow \psi(x)$ uniformly in K_n . Let us now define

$$(3.49) \quad \hat{u}(\nu) = \bar{u}(\nu(\phi_1), \dots, \nu(\phi_n))r(\nu(\psi_n)) \in \mathcal{A}(L, n)$$

or

$$(3.50) \quad \hat{u}(\nu) = \bar{u}(\nu(\phi_1), \dots, \nu(\phi_n))r(\nu(\psi \wedge \psi_n)) \in \mathcal{A}^r(L, n).$$

Then, both in the case $\tilde{u}_{m_k} \in \mathcal{A}(L, n)$ and $\tilde{u}_{m_k} \in \mathcal{A}^r(L, n)$, we have

$$(3.51) \quad \hat{u}_{m_k}(\nu) \rightarrow \hat{u}(\nu) \quad \text{uniformly in } \nu \in \mathcal{P}(E)$$

with $\hat{u}(\nu)$ given by (3.49) or (3.50), accordingly. Hence, by (3.13), $\bar{\mathcal{L}}_{m_k} \hat{u}_{m_k}(\nu) \rightarrow \hat{u}(\nu)$ uniformly on compact subsets of $\mathcal{P}(E)$. Letting the subsequence m_k also be denoted by m for simplicity of notation, we again apply Theorem 2.2, this time with $u = \hat{u}$, $u_m = \bar{\mathcal{L}}_m \hat{u}_m$, $\Phi_m^u = \bar{\Phi}_m^{\hat{u}_m}$, $\pi_i^{m, \mu, u_m} = \bar{\pi}_i^{m, \mu, \hat{u}_m}$, $P_m^u = \bar{P}_m^u$, $P_m^v = \bar{P}_m^v$. Therefore

$$(3.52) \quad \bar{\Phi}_m^{\hat{u}_m} \Rightarrow \bar{\Phi}^{\hat{u}},$$

and, by analogy to (3.41)–(3.46), we obtain

$$(3.53) \quad \lim_{m \rightarrow \infty} J_{\bar{\mu}}^m(\bar{\mathcal{L}}_m \hat{u}_m) = J_{\mu}(\hat{u}).$$

Since $\tilde{u}_m = \bar{\mathcal{L}}_m \hat{u}_m$, as can easily be checked, and \tilde{u}_m is ε -optimal for $J_{\bar{\mu}}^m$ over $\mathcal{A}_m(L, n)$ ($\mathcal{A}_m^r(L, n)$, respectively) from (3.47) and (3.48), we have

$$(3.54) \quad J_{\mu}(\hat{u}) \leq \limsup_{m \rightarrow \infty} \inf_{u \in \mathcal{A}_m(L, n)} J_{\bar{\mu}}^m(u) + \varepsilon \leq \inf_{u \in \mathcal{A}(L, n)} J_{\mu}(u) + \varepsilon$$

and

$$(3.55) \quad J_{\mu}(\hat{u}) \leq \limsup_{m \rightarrow \infty} \inf_{u \in \mathcal{A}_m^r(L, n)} J_{\bar{\mu}}^m(u) + \varepsilon \leq \inf_{u \in \mathcal{A}^r(L, n)} J_{\mu}(u) + \varepsilon,$$

respectively. This means, however, that \hat{u} given by (3.49) (respectively, (3.50)) is ε -optimal for J_{μ} over $\mathcal{A}(L, n)$, ($\mathcal{A}^r(L, n)$, respectively), which is the claim of the second part of the theorem. In addition, since in (3.54), (3.55) ε can be chosen arbitrarily small, taking also (3.47) and (3.48) into account, we obtain (3.30) ((3.31), respectively). The proof of Theorem 3.1 is thus completed. \square

COROLLARY 3.1. *Under the assumptions of Theorem 3.1, if \tilde{u}_m given by (3.32) (respectively, (3.33)) are ε -optimal for $J_{\bar{\mu}}^m(u)$ over $\mathcal{A}_m(L, n)$ (respectively, $\mathcal{A}_m^r(L, n)$), then \hat{u}_m defined in (3.34) (respectively, (3.35)) are, for m sufficiently large, 2ε -optimal for $J_{\mu}(u)$ over $\mathcal{A}(L, n)$ (respectively, $\mathcal{A}^r(L, n)$).*

Proof. It is enough to show that

$$(3.56) \quad \limsup_{m \rightarrow \infty} J_{\mu}(\hat{u}_m) \leq \inf_{u \in \mathcal{A}(L, n)} J_{\mu}(u) + \varepsilon,$$

which follows from the fact that, for any subsequence \hat{u}_{m_k} converging uniformly to \hat{u} , again from Theorem 2.1 we have

$$(3.57) \quad J_{\mu}(\hat{u}_{m_k}) \rightarrow J_{\mu}(\hat{u}) \leq \inf_{u \in \mathcal{A}(L, n)} J_{\mu}(u) + \varepsilon. \quad \square$$

3.2. Finite set of control functions. By Theorem 3.1 and Corollary 3.1, we know that we can obtain a nearly optimal control function for our original problem in the classes $\mathcal{A}(L, n)$, $\mathcal{A}^r(L, n)$, provided that we are able to obtain, for sufficiently large m , an optimal or at least nearly optimal control function for $J_{\bar{\mu}}^m(u)$ in the classes

$\mathcal{A}_m(L, n)$ or $\mathcal{A}'_m(L, n)$, respectively. By Theorem 2.3, such control function is then nearly optimal also for $J_\mu(u)$ in the original classes \mathcal{A} or $\bar{\mathcal{A}}$ and \mathcal{A}' , respectively, if L and n are sufficiently large. The construction of an optimal control function in the classes $\mathcal{A}_m(L, n)$, $\mathcal{A}'_m(L, n)$ is still a formidable problem; on the other hand, we need only a nearly optimal control function, and this allows us to proceed with further approximations. For this purpose, note first that the sets of Lipschitz-continuous functions $C_L(H_n, U)$ from $H_n := [-\|\phi_1\|, \|\phi_1\|] \times \cdots \times [-\|\phi_n\|, \|\phi_n\|] \subset \mathcal{R}^n$ into the compact set $U \subset \mathcal{R}^k$, and $C_n(K_n, [0, 1])$ from $K_n = \{x: \rho(x, \bar{x}) \leq n\}$ into $[0, 1]$, are compact, so that for any $\delta > 0$ there exist finite δ -nets $C_L(\delta) \subset C_L(H_n, U)$ and $\tilde{C}_n(\delta) \subset C_n(K_n, [0, 1])$. Since the functions $\bar{u}: \mathcal{R}^n \rightarrow U$, used in the definitions of $\mathcal{A}_m(L, n)$ and $\mathcal{A}'_m(L, n)$, are Lipschitz with constant L and, for given ϕ_1, \dots, ϕ_n , they are actually defined on the compact set H_n , consider then the classes $\mathcal{A}_m^{\delta}(L, n) \subset \mathcal{A}_m(L, n)$, and $\mathcal{A}_m^{r, \delta}(L, n) \subset \mathcal{A}'_m(L, n)$ given by

$$(3.58) \quad \mathcal{A}_m^{\delta}(L, n) = \left\{ u \in C(S^m, U): \exists \bar{u} \in C_L(\delta) \text{ for which} \right. \\ \left. u(s) = \bar{u} \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \right. \\ \left. \cdot r \left(\sum_{k=1}^{k_m} \psi_n(z_k^m) s_k \right) \right\},$$

$$(3.59) \quad \mathcal{A}_m^{r, \delta}(L, n) = \left\{ u \in C(S^m, U): \exists \bar{u} \in C_L(\delta), \psi \in \tilde{C}_n(\delta) \text{ for which} \right. \\ \left. u(s) = \bar{u} \left(\sum_{k=1}^{k_m} \phi_1(z_k^m) s_k, \dots, \sum_{k=1}^{k_m} \phi_n(z_k^m) s_k \right) \right. \\ \left. \cdot r \left(\sum_{k=1}^{k_m} (\psi \wedge \psi_n)(z_k^m) s_k \right) \right\}$$

and note that such classes contain only a finite number of elements. In principle, it is then possible to evaluate $J_\mu^m(u)$ for each $u \in \mathcal{A}_m^{\delta}(L, n)$, $\mathcal{A}_m^{r, \delta}(L, n)$, compare the corresponding values, and thus determine an optimal control function u_δ^* for $J_\mu^m(u)$ in the classes $\mathcal{A}_m^{\delta}(L, n)$ and $\mathcal{A}_m^{r, \delta}(L, n)$, respectively. To evaluate $J_\mu^m(u)$, by Propositions 3.1 and 3.2, we must be able to compute the invariant measure Φ_m^u of the process $(\pi_i^{m, \bar{\mu}, u})$ on S^m for each $u \in \mathcal{A}_m^{\delta}(L, n)$ or $\mathcal{A}_m^{r, \delta}(L, n)$. Since S^m is infinite-valued, to make such computation feasible, we must introduce further approximations, so that instead of an optimal u_δ^* we will be able to compute only an ε -optimal control function u_δ^ε for $J_\mu^m(u)$ in $\mathcal{A}_m^{\delta}(L, n)$ and $\mathcal{A}_m^{r, \delta}(L, n)$, respectively. The details of such further approximations are fully described in [13]; here we limit ourselves to prove Theorem 3.2, which shows that, for $\delta > 0$ sufficiently small, the computation of u_δ^ε in the classes $\mathcal{A}_m^{\delta}(L, n)$ and $\mathcal{A}_m^{r, \delta}(L, n)$ is sufficient for our purposes; all we need, in fact, is a nearly optimal control function for $J_\mu^m(u)$ in the classes $\mathcal{A}_m(L, n)$ and $\mathcal{A}'_m(L, n)$, respectively.

THEOREM 3.2. *Assume (A1)–(A6) and either (B1) or (C1). For fixed L and positive integer n , we then have, for every $m > m_0(n)$, where $m_0(n)$ is given in Proposition 3.2, and any $\bar{\mu} \in S^m$,*

$$(3.60) \quad \lim_{\delta \rightarrow 0} \inf_{u \in \mathcal{A}_m^{\delta}(L, n)} J_\mu^m(u) = \inf_{u \in \mathcal{A}_m(L, n)} J_\mu^m(u)$$

for the case of (B1), and

$$(3.61) \quad \lim_{\delta \rightarrow 0} \inf_{u \in \mathcal{A}_m^{r, \delta}(L, n)} J_\mu^m(u) = \inf_{u \in \mathcal{A}_m^{r, \delta}(L, n)} J_\mu^m(u)$$

for the case of (C1).

Proof. With $E = E_m$, $\mathcal{P}(E) = S^m$, and since, furthermore, letting $\delta \rightarrow 0$, each $u \in \mathcal{A}_m(L, n)$ or $\mathcal{A}_m^r(L, n)$ can be uniformly approximated by $u_\delta \in \mathcal{A}_m^\delta(L, n)$ ($\mathcal{A}_m^{r,\delta}(L, n)$, respectively), all assumptions of Theorem 2.1 are satisfied. Therefore, by Theorem 2.1 we have $J_\mu^m(u) = \lim_{\delta \rightarrow 0} J_\mu^m(u_\delta)$, and consequently (3.60) and (3.61) hold. \square

3.3. Algorithmic structure of our procedure. Summarizing the results of § 3, we have a constructive method for determining a nearly optimal control function for the original problem. This control function is given by an ε -optimal control function u_δ^ε for $J_\mu^m(u)$ over $\mathcal{A}_m^\delta(L, n)$ and $\mathcal{A}_m^{r,\delta}(L, n)$, respectively, which, by the further approximations described in [13], can indeed be computed. In fact, by Theorem 3.2, such u_δ^ε is 2ε -optimal for J_μ^m over $\mathcal{A}_m(L, n)$ (respectively, $\mathcal{A}_m^r(L, n)$) if δ is sufficiently small. Combining this finally with the results of §§ 2.2 and 3.1, we have that, provided furthermore that L , n and m are sufficiently large, this u_δ^ε induces a nearly optimal control function $\hat{u}_\delta^\varepsilon \in \mathcal{A}(L, n)$ (respectively, $\mathcal{A}^r(L, n)$) for the original problem. To obtain from this control function $\hat{u}_\delta^\varepsilon$ the actual control values, it must be evaluated for the current filter values $(\pi_i^{\mu,u})$ of the original problem. Although such filter values cannot be computed in practice, we are nevertheless able to compute (see (4.6) below) an approximating filtering process $(\pi_i^{m(\bar{\mu})})$ over the simplex S^m . In § 4 we show that, by using $\hat{u}_\delta^\varepsilon$ with the approximate filter values $\pi_i^{m(\bar{\mu})}$, we indeed obtain (for L , n , m , sufficiently large and δ sufficiently small) nearly optimal controls for the original problem.

4. Filter approximation and near optimal control values. The purpose of this section is to show that (provided that the values of the parameters L , n in § 2.2, and m in § 3.1 are sufficiently large, while that of δ in § 3.2 is sufficiently small) the control function $\hat{u}_\delta^\varepsilon \in \mathcal{A}(L, n) \subset \mathcal{A}$ (or $\mathcal{A}^r(L, n) \subset \mathcal{A}^r$), determined according to the previous § 3, yields nearly optimal control values also if evaluated in correspondence of the computable approximate filter $(\pi_i^{m(\bar{\mu})}) \in S^m$ defined in (4.6) below for a generic initial measure $\bar{\nu} \in S^m$.

To obtain the desired result, we must also introduce, besides $(\pi_i^{m(\bar{\mu})})$, other auxiliary measure-valued processes. For this purpose, recall the measure $\zeta^u(\mu)(\cdot)$ defined in (2.17) and analogously let

$$(4.1) \quad \zeta^u(\mu, \nu)(\cdot) = \int_E P^{u(\nu)}(x, \cdot) \mu(dx)$$

for any $\mu, \nu \in \mathcal{P}(E)$ and $u \in \mathcal{A}$.

Given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$ and an arbitrary measure $\nu \in \mathcal{P}(E)$, first let $(\pi_i^{(\nu)})$ be a process in $\mathcal{P}(E)$ defined recursively by

$$(4.2) \quad \pi_0^{(\nu)}(\cdot) = \nu(\cdot), \quad \pi_{i+1}^{(\nu)}(\cdot) = R(y_{i+1}^{(\nu)}, \zeta^u(\pi_i^{(\nu)}))(\cdot),$$

where $R(\cdot, \cdot)$ is as defined in (2.15) and $(y_i^{(\nu)})$ are the observations given by (1.1) when (x_i) is governed by the transition function $P^{u(\pi_i^{(\nu)})}(\cdot, \cdot)$. Furthermore, given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$ and $\mu, \nu \in \mathcal{P}(E)$, let the process $(\pi_i^{(\mu, \nu)})$ in $\mathcal{P}(E)$ be defined by

$$(4.3) \quad \pi_0^{(\mu, \nu)}(\cdot) = \mu(\cdot), \quad \pi_{i+1}^{(\mu, \nu)}(\cdot) = R(y_{i+1}^{(\nu)}, \zeta^u(\pi_i^{(\mu, \nu)}, \pi_i^{(\nu)}))(\cdot),$$

where $(y_i^{(\nu)})$ are as above.

Note that, if the state process (x_i) is governed by the same transition function $P^{u(\pi_i^{(\nu)})}(\cdot, \cdot)$ as above, but starts with a given initial law μ , then by (1.30)–(1.32) we obtain that

$$(4.4) \quad E_\mu\{\phi(x_i) | Y^i\} = R(y_i^{(\nu)}, \zeta^u(\pi_{i-1}^{(\mu, \nu)}, \pi_{i-1}^{(\nu)}))(\phi) = \pi_i^{(\mu, \nu)}(\phi) \quad \text{for } i = 1, 2, \dots$$

Given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$, $\nu \in \mathcal{P}(E)$, $\bar{\nu} \in S^m$, with $\bar{\nu}(k) = \nu(B_k^m)$ for $k = 1, 2, \dots, k_m$, by analogy to (3.21), (3.23), we further introduce two approximating filtering processes $\bar{\pi}_i^{m(\nu)}$ in $\mathcal{P}(E)$ and $\pi_i^{m(\bar{\nu})}$ in S^m defined as follows:

$$(4.5) \quad \bar{\pi}_0^{m(\nu)}(\cdot) = \nu(\cdot), \quad \bar{\pi}_{i+1}^{m(\nu)}(\cdot) = \bar{M}_m^u(y_{i+1}^{(\nu)}, \bar{\pi}_i^{m(\nu)})(\cdot);$$

$$(4.6) \quad \pi_0^{m(\bar{\nu})}(k) = \bar{\nu}(k), \quad \pi_{i+1}^{m(\bar{\nu})}(k) = M_m^{\bar{\mathcal{F}}_m^u}(y_{i+1}^{(\nu)}, \pi_i^{m(\bar{\nu})})(k),$$

with $y_i^{(\nu)}$ now denoting the observations given by (1.1) when the state process (x_i) is governed by the transition function $P_m^u(\bar{\pi}_i^{m(\nu)})(\cdot, \cdot)$, which, due to (3.9) and the fact that $\bar{\pi}_i^{m(\nu)}(B_k^m) = \pi_i^{m(\bar{\nu})}(k)$ (cf. Lemma A.2.1), is equivalent to $P_m^{\bar{\mathcal{F}}_m^u}(\pi_i^{m(\bar{\nu})})(\cdot, \cdot)$. Note that the approximating filter process $(\pi_i^{m(\bar{\nu})}) \in S^m$ is explicitly computable; in fact, the observations $y_i^{(\nu)}$ correspond to our real observations since (x_i) is governed by the original transition kernel $P^v(\cdot, \cdot)$ with control values $v_i = \bar{\mathcal{L}}_m^u(\pi_i^{m(\bar{\nu})})$.

Finally, given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$ and $\mu, \nu \in \mathcal{P}(E)$, let, by analogy to (4.3), the process $(\pi_i^{m(\mu, \nu)})$ in $\mathcal{P}(E)$ be defined by

$$(4.7) \quad \begin{aligned} \pi_0^{m(\mu, \nu)}(\cdot) &= \mu(\cdot), \\ \pi_{i+1}^{m(\mu, \nu)}(\cdot) &= R(y_{i+1}^{(\nu)}, \zeta^{\bar{\mathcal{F}}_m^u}(\pi_i^{m(\mu, \nu)}, \pi_i^{m(\bar{\nu})}))(\cdot) \\ &= R(y_{i+1}^{(\nu)}, \zeta^{\bar{\mathcal{F}}_m^u}(\pi_i^{m(\mu, \nu)}, \bar{\pi}_i^{m(\nu)}))(\cdot), \end{aligned}$$

where $(y_i^{(\nu)})$ is as defined below (4.6) and where we have implicitly extended the definition of $\zeta^u(\cdot, \cdot)$, again using the fact that $\bar{\pi}_i^{m(\nu)}(B_k^m) = \pi_i^{m(\bar{\nu})}(k)$. Analogously to (4.4), note again that, if the state process (x_i) is governed by the transition function $P_m^{\bar{\mathcal{F}}_m^u}(\pi_i^{m(\nu)})(\cdot, \cdot) = P_m^{\bar{\mathcal{F}}_m^u}(\pi_i^{m(\nu)})(\cdot, \cdot)$ and starts with the given initial law μ , then by (1.30)–(1.32) we obtain that

$$(4.8) \quad E_\mu\{\phi(x_i) | Y^i\} = \pi_i^{m(\mu, \nu)}(\phi) \quad \text{for } i = 1, 2, \dots$$

Therefore, the process $\pi_i^{m(\mu, \nu)}$ depends on the measure ν through the values of $\bar{\nu} = (\nu(B_1^m), \dots, \nu(B_{k_m}^m))$ only. With abuse of notation, we write $\pi_i^{m(\mu, \nu)} = \pi_i^{m(\mu, \bar{\nu})}$ and define the process $\pi_i^{m(\mu, s)}$ with $s \in S^m$ as equal to $\pi_i^{m(\mu, \nu)}$ with $\bar{\nu} = s$. (For the relationship between ν and $\bar{\nu}$, we recall (3.17).) We are now in a position to consider the three pairs of processes $(\pi_i^{(\mu, \nu)}, \pi_i^{(\nu)})$, $(\pi_i^{m(\mu, \nu)}, \bar{\pi}_i^{m(\nu)})$, $(\pi_i^{m(\mu, \nu)}, \pi_i^{m(\bar{\nu})})$. By considerations similar to those in the proof of Proposition 1.2, we can show that these processes are Markov with transition operators T^u , \bar{T}_m^u , T_m^u defined, respectively, as follows: For $F \in \mathcal{B}(\mathcal{P}(E) \times \mathcal{P}(E))$ the set of bounded Borel functions on $\mathcal{P}(E) \times \mathcal{P}(E)$ and $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$, we have

$$(4.9) \quad \begin{aligned} T^u F(\mu, \nu) &= E_\mu\{F(\pi_1^{(\mu, \nu)}, \pi_1^{(\nu)})\} \\ &= \int_E \int_E \left(\int_{\mathcal{R}^d} (2\pi)^{-d/2} \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] \right) \\ &\quad \cdot F(R(y, \zeta^u(\mu, \nu)), R(y, \zeta^u(\nu))) dy P^{u(\nu)}(x, dz) \mu(dx), \end{aligned}$$

$$(4.10) \quad \begin{aligned} \bar{T}_m^u F(\mu, \nu) &= E_\mu\{F(\pi_1^{m(\mu, \nu)}, \bar{\pi}_1^{m(\nu)})\} \\ &= \int_E \int_E \left(\int_{\mathcal{R}^d} (2\pi)^{-d/2} \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] \right) \\ &\quad \cdot F(R(y, \zeta^{\bar{\mathcal{F}}_m^u}(\mu, \nu)), \bar{M}_m^u(y, \nu)) dy P^{\bar{\mathcal{F}}_m^u}(\nu)(x, dz) \mu(dx), \end{aligned}$$

while for $\bar{F} \in \mathcal{B}(\mathcal{P}(E) \times S^m)$

$$\begin{aligned}
 T_m^u \bar{F}(\mu, \bar{\nu}) &= E_\mu \{ \bar{F}(\pi_1^{m(\mu, \bar{\nu})}, \pi_1^{m(\bar{\nu})}) \} \\
 (4.11) \quad &= \int_E \int_E \left(\int_{\mathcal{R}^d} (2\pi)^{-d/2} \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] \right. \\
 &\quad \cdot \bar{F}(R(y, \zeta^{\tilde{\mathcal{F}}_m^u}(\mu, \bar{\nu})), M_m^{\tilde{\mathcal{F}}_m^u}(y, \bar{\nu})) dy \\
 &\quad \cdot P^{\tilde{\mathcal{F}}_m^u(\bar{\nu})}(x, dz) \mu(dx).
 \end{aligned}$$

Moreover, by a suitable adaptation of the proof of Proposition 1.2, we can show that under (A1), (A2) the operator T^u is Feller. Assuming, in addition, (A6), we obtain the Feller property of T_m^u as well.

The relationship between the operators \bar{T}_m^u and T_m^u is shown in Lemmas 4.1 and 4.2. By analogy to Lemma A.2.1, we first have Lemma 4.1, whose proof is completely similar to the second part of that of Lemma A.2.1.

LEMMA 4.1. *Let $F \in \mathcal{B}(\mathcal{P}(E) \times S^m)$, then, for $\mu, \nu \in \mathcal{P}(E)$,*

$$\begin{aligned}
 (4.12) \quad &\int_{\mathcal{P}(E)} \int_{\mathcal{P}(E)} F(\mu', \nu'(B_1^m), \dots, \nu'(B_{k_m}^m)) \bar{T}_m^u(\mu, \nu, d\mu' \times d\nu') \\
 &= \int_{\mathcal{P}(E)} \int_{S^m} F(\mu', s_1, \dots, s_{k_m}) T_m^u(\mu, \bar{\nu}, d\mu' \times ds).
 \end{aligned}$$

Corresponding to Proposition 3.1 and using Lemma 4.1, we immediately have Lemma 4.2 as well.

LEMMA 4.2. *If, for $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$ the measure Ψ_m^u is an invariant measure of the operator T_m^u , then with $A \in \mathcal{B}(\mathcal{P}(E) \times \mathcal{P}(E))$*

$$(4.13) \quad \bar{\Psi}_m^u(A) \stackrel{\text{def}}{=} \int_{\mathcal{P}(E) \times S^m} \bar{T}_m^u \left(\mu', \sum_{k=1}^{k_m} s_k \delta_{z_k^m}, A \right) \Psi_m^u(d\mu', ds)$$

is an invariant measure for the transition operator \bar{T}_m^u .

PROPOSITION 4.1. *Assume (A1)–(A4). Then*

- (i) *Under (B1), (B4), for each $u \in \mathcal{A}(L, n)$, there is a unique invariant measure Ψ^u of T^u ;*
- (ii) *Under (C1), (C2), for each $u \in \mathcal{A}^r(L, n)$, there is a unique invariant measure Ψ^u of T^u ;*
- (iii) *Under (A6) and (B1), (B2), for each $u \in \mathcal{A}(L, n)$ and $m > m_0(n)$ with $m_0(n)$ defined in Proposition 3.2, there is a unique invariant measure Ψ_m^u of T_m^u ;*
- (iv) *Under (A6) and (C1), (C2), for each $u \in \mathcal{A}^r(L, n)$, and $m > m_0(n)$, there is a unique invariant measure Ψ_m^u of T_m^u ;*
- (v) *Under (A6), (C1) and the compactness of E , for each $u \in \mathcal{A}^r(L, n)$ and $m > m_0(n)$, there exists a unique invariant measure Ψ^u of T^u and Ψ_m^u of T_m^u .*

Proof. For cases (i)–(iv), we use the arguments from the proof of Theorem 2.2; namely, letting

$$\begin{aligned}
 \bar{\Gamma} &= \{(\mu, \nu) \in \mathcal{P}(E) \times \mathcal{P}(E) \mid \nu(\bar{\psi}_n) < b\}, \\
 \tilde{\Gamma} &= \left\{ (\mu, s) \in \mathcal{P}(E) \times S^m \mid \sum_{k=1}^{k_m} s_k \psi_n(z_k^m) < b \right\},
 \end{aligned}$$

define

$$\begin{aligned}
 \tau &= \inf \{i > 0 \mid (\pi_i^{(\mu, \nu)}, \pi_i^{(\nu)}) \in \bar{\Gamma}\} && \text{in case of } T^u, \\
 \tau &= \inf \{i > 0 \mid (\pi_i^{m(\mu, \nu)}, \bar{\pi}_i^{m(\nu)}) \in \bar{\Gamma}\} && \text{in case of } \bar{T}_m^u, \\
 \tau &= \inf \{i > 0 \mid (\pi_i^{m(\mu, \nu)}, \pi_i^{m(\bar{\nu})}) \in \tilde{\Gamma}\} && \text{in case of } T_m^u
 \end{aligned}$$

and show suitable versions of Lemmas 2.1–2.3 and of Corollaries 2.2 and 2.3.

For case (v), we use the tightness and Feller property of T^u and T_m^u for the existence, while for the uniqueness we use the fact that with positive probability $r(\pi_i^{(\nu)}(\psi \wedge \psi_n))$ and $r(\pi_i^{m(\nu)}(\psi \wedge \psi_n))$ are equal zero, implying by (A3)–(A4) the uniqueness of the invariant set. The details are similar to those in the proofs of Theorem 2.3 and Proposition 3.2. \square

The next result is fundamental for our further approximations.

PROPOSITION 4.2. *Assume (A1)–(A6) together with (B1), (B4), or (C1), (C2), or (C1) and the compactness of E . Then, under (B1), (B4) for $u \in \mathcal{A}(L, n)$, and under (C1) for $u \in \mathcal{A}^r(L, n)$, we have*

$$(4.14) \quad \bar{\Psi}_m^u \Rightarrow \Psi^u \quad \text{for } m \rightarrow \infty.$$

Proof. For the case when (B1), (B4) or (C1), (C2) are satisfied, we follow the arguments of the proof of Theorem 2.2, in particular, Lemmas 2.3 and 2.4 and a suitable version of Proposition 2.2. Under (C1) and the compactness of E , by analogy to the first part of the proof of Theorem 2.1, it suffices to show that, for any $F \in C(\mathcal{P}(E) \times \mathcal{P}(E))$,

$$(4.15) \quad \bar{T}_m^u F(\mu, \nu) \rightarrow T^u F(\mu, \nu) \quad \text{for } m \rightarrow \infty$$

uniformly in $(\mu, \nu) \in \mathcal{P}(E) \times \mathcal{P}(E)$. We have

$$(4.16) \quad \begin{aligned} & |T^u F(\mu, \nu) - \bar{T}_m^u F(\mu, \nu)| \\ & \leq \int_E \int_E \int_{\mathcal{R}^d} (2\pi)^{-d/2} \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] \\ & \cdot |F(R(y, \zeta^u(\mu, \nu)), R(y, \zeta^u(\nu))) - F(R(y, \zeta^{\bar{\mathcal{P}}_m^u}(\mu, \nu)), \bar{M}_m^u(y, \nu))| dy \\ & \cdot P^{u(\nu)}(x, dz) \mu(dx) + \|F\| \int_E \int_{\mathcal{R}^d} \left| \int_E (2\pi)^{-d/2} \exp \left[-\frac{1}{2} (y - h(z), y - h(z)) \right] \right. \\ & \cdot (P^{u(\nu)}(x, dz) - P^{\bar{\mathcal{P}}_m^u(\nu)}(x, dz)) \left. dy \mu(dx) \right| = I_m + II_m. \end{aligned}$$

By a suitable version of Lemma A.1.2, we have that $\bar{M}_m^u(y, \nu) \Rightarrow R(y, \zeta^u(\nu))$, uniformly for $y \in B$, a compact subset of \mathcal{R}^d and $\nu \in \mathcal{P}(E)$. Moreover, by Lemma 3.1, $R(y, \zeta^{\bar{\mathcal{P}}_m^u}(\mu, \nu)) \Rightarrow R(y, \zeta^u(\mu, \nu))$ uniformly for $y \in B$, $(\nu, \mu) \in \mathcal{P}(E) \times \mathcal{P}(E)$. Therefore, repeating the considerations of the proof of Proposition 2.1, we conclude that $I_m + II_m \rightarrow 0$ uniformly in $(\nu, \mu) \in \mathcal{P}(E) \times \mathcal{P}(E)$. \square

Note that, if the state process (x_i) is governed by $P^{u(\pi_i^{(\mu)})}(\cdot, \cdot)$ with $\pi_i^{(\mu)}$ given by (4.2) for $\nu = \mu$ and starts with the initial law μ , then clearly the processes $\pi_i^{\mu, u}$ (see (1.32)), $\pi_i^{(\mu, \mu)}$ (see (4.3)) and $\pi_i^{(\mu)}$ (see (4.2)) all coincide. Given $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$, we then have, under the assumptions of Theorem 2.3,

$$(4.17) \quad \begin{aligned} J_\mu(u) &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu \{c(x_i, u(\pi_i^{(\mu)}))\} \\ &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu \left\{ \int_E c(z, u(\pi_i^{\mu, u})) \pi_i^{\mu, u}(dz) \right\} \\ &= \int_{\mathcal{P}(E)} \int_E c(z, u(\nu)) \nu(dz) \Phi^u(d\nu) \end{aligned}$$

valid for all μ for which (B3) holds in the cases (i) and (ii) specified in Theorem 2.3, and for all $\mu \in \mathcal{P}(E)$ in the remaining cases (iii) and (iv).

In what follows, given any sequence (η_i) of U -valued random variables, we consider the cost function $J_\mu((\eta_i))$ as given by

$$(4.18) \quad J_\mu((\eta_i)) = \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu\{c(x_i, \eta_i)\}.$$

LEMMA 4.3. Assume the state process (x_i) is governed by $P^{u(\pi_i^{(\nu)})}(\cdot, \cdot)$ with $u \in \mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$ for a generic $\nu \in \mathcal{P}(E)$, but starts with the given initial law μ . Let the assumptions of Proposition 4.1(i), (ii), or (v) hold. Then for all pairs $(\mu, \nu) \in \mathcal{P}(E) \times \mathcal{P}(E)$, we have with $u_i = u(\pi_i^{(\nu)})$

$$(4.19) \quad \begin{aligned} J_\mu((u_i)) &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu\{c(x_i, u(\pi_i^{(\nu)}))\} \\ &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu\left\{\int_E c(z, u(\pi_i^{(\nu)})) \pi_i^{(\mu, \nu)}(dz)\right\} \\ &= \int_{\mathcal{P}(E) \times \mathcal{P}(E)} \int_E c(z, u(\nu')) \mu'(dz) \Psi^u(d\mu' \times d\nu') \\ &= \int_{\mathcal{P}(E)} \int_E c(z, u(\nu')) \nu'(dz) \Phi^u(d\nu'). \end{aligned}$$

Proof. The first identity in (4.19) follows from (4.4). By a suitable version of the second part of Theorem 2.2 in the case of assumptions (i) and (ii) of Proposition 4.1, and by the weak convergence of the Cesaro averages, the Feller property of T^u and the uniqueness of its invariant measure Ψ^u in case of assumption (v), we obtain the second identity. Since the value of the integral

$$\int_{\mathcal{P}(E) \times \mathcal{P}(E)} c(z, u(\nu')) \mu'(dz) \Psi^u(d\mu' \times d\nu')$$

does not depend on μ or $\nu \in \mathcal{P}(E)$, this is also the limit for the case where $\nu = \mu$. Then via (4.17) we obtain the last identity. \square

We can now state the main result of this section contained in Theorem 4.1 and Corollary 4.1.

THEOREM 4.1. Let $u \in \mathcal{A}(L, n)$ or $\mathcal{A}'(L, n)$ be given and define a control $u_i^{m, \bar{\nu}}$ by

$$(4.20) \quad u_i^{m, \bar{\nu}} = \tilde{\mathcal{L}}_m u(\pi_i^{m(\bar{\nu})}),$$

where $(\pi_i^{m(\bar{\nu})})$ is the approximating filtering process on the simplex S^m given by (4.6) for an arbitrary initial measure $\nu \in \mathcal{P}(E)$. Under the assumptions of Proposition 4.2, if $m > m_0(n)$, for $(\mu, \bar{\nu}) \in \mathcal{P}(E) \times S$, we have

$$(4.21) \quad \begin{aligned} J_\mu((u_i^{m, \bar{\nu}})) &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu\{c(x_i, \tilde{\mathcal{L}}_m u(\pi_i^{m(\bar{\nu})}))\} \\ &= \limsup_{t \rightarrow \infty} t^{-1} \sum_{i=0}^{t-1} E_\mu\left\{\int_E c(z, \tilde{\mathcal{L}}_m u(\pi_i^{m(\bar{\nu})})) \pi_i^{(\mu, \nu)}(dz)\right\} \\ &= \int_{\mathcal{P}(E) \times S^m} \int_E c(z, \tilde{\mathcal{L}}_m u(s)) \mu'(dz) \Psi_m^u(d\mu' \times ds) \\ &= \int_{\mathcal{P}(E) \times \mathcal{P}(E)} \int_E c(z, \tilde{\mathcal{L}}_m u(\nu')) \mu'(dz) \bar{\Psi}_m^u(d\mu' \times d\nu'). \end{aligned}$$

Furthermore, we have

$$(4.22) \quad \lim_{m \rightarrow \infty} J_\mu((u_i^{m,\bar{v}})) = J_\mu((u_i)),$$

where $u_i = u(\pi_i^{\mu,u})$ is the control obtained from the given $u \in \mathcal{A}(L, n)$, evaluated at the original filtering process $(\pi_i^{\mu,u})$.

Proof. Up to the last identity, (4.21) follows from a suitable version of the second part of Theorem 2.2 in the case of assumptions (B1), (B4) or (C1), (C2), and by the weak convergence of the Cesaro averages, the Feller property of T_m^μ and the uniqueness of its invariant measure Ψ_m^μ in case of assumption (B1) and the compactness of E . The last identity in (4.21) is a consequence of Lemma 4.1 and definition (4.13) of $\tilde{\Psi}_m^\mu$. Finally, the convergence (4.22) follows from (4.21), Proposition 4.2, (4.19), and the convergence $\tilde{\mathcal{L}}_m u \rightarrow u$ for $m \rightarrow \infty$, which is uniform on compact subsets of $\mathcal{P}(E)$ (see Lemma 3.1). \square

COROLLARY 4.1. *Let u_δ^ε be the ε -optimal control function for $J_\mu^\delta(u)$ over $\mathcal{A}_m^\delta(L, n)$ or $\mathcal{A}_m^{\delta,r}(L, n)$ determined according to § 3. Let $(\pi_i^{m(\bar{\mu})})$ be the approximate filtering process on the simplex S^m , determined according to (4.6) for the given initial measure μ . Let u_i^* be the control defined by*

$$(4.23) \quad u_i^* = u_\delta^\varepsilon(\pi_i^{m(\bar{\mu})}).$$

Then, given $\varepsilon > 0$, if L, n, m are sufficiently large and δ sufficiently small, we have

$$(4.24) \quad J_\mu((u_i^*)) \leq \inf J_\mu(u) + \varepsilon,$$

where, depending on the formulation of the original problem, the infimum is taken over \mathcal{A} , $\tilde{\mathcal{A}}$, or \mathcal{A}^r ; i.e., (u_i^) is a nearly optimal control of the original problem.*

Proof. From the previous sections, we know that u_δ^ε induces a control function $\hat{u}_\delta^\varepsilon \in \mathcal{A}(L, n)$, $(\mathcal{A}^r(L, n))$ such that, defining

$$(4.25) \quad \hat{u}_i = \hat{u}_\delta^\varepsilon(\pi_i^{\mu,u}),$$

where $(\pi_i^{\mu,u})$ is the original filtering process given by (1.32), we have for sufficiently large L, n, m and small δ

$$(4.26) \quad J_\mu((\hat{u}_i)) \leq \inf J_\mu(u) + \frac{\varepsilon}{2},$$

where, again, depending on the formulation of the original problem, the infimum is taken over \mathcal{A} , $\tilde{\mathcal{A}}$, or \mathcal{A}^r . On the other hand, from Theorem 4.1, we know that, defining

$$(4.27) \quad \hat{u}_i^{m,\bar{\mu}} = \tilde{\mathcal{L}}_m \hat{u}_\delta^\varepsilon(\pi_i^{m(\bar{\mu})}),$$

where $(\pi_i^{m(\bar{\mu})})$ is the approximate filtering process on S^m obtained from (4.6) for the given initial measure μ , we have for sufficiently large m

$$(4.28) \quad J_\mu((\hat{u}_i^{m,\bar{\mu}})) \leq J_\mu((\hat{u}_i)) + \frac{\varepsilon}{2}.$$

Since

$$(4.29) \quad \tilde{\mathcal{L}}_m \hat{u}_\delta^\varepsilon = u_\delta^\varepsilon,$$

we have

$$(4.30) \quad u_i^* = \hat{u}_i^{m,\bar{\mu}},$$

and, combining (4.26), (4.28), and (4.30), we obtain the desired (4.24). \square

Appendix A.1 (Auxiliary results and proofs for § 2.1). We first recall without proof the following lemma.

LEMMA A.1.1. *Suppose that (M_1, ρ_1) , (M_2, ρ_2) are metric spaces, $F: (M_1, \rho_1) \rightarrow (M_2, \rho_2)$ is a continuous map and $K \subset M_1$ is a compact set. Moreover, $F_m: (M_1, \rho_1) \rightarrow (M_2, \rho_2)$ are measurable mappings that converge to F , uniformly on compact subsets of M_1 . Then, for any $\varepsilon > 0$, there exists $\delta > 0$ and m_0 such that for $m > m_0$*

$$(A.1.1) \quad \rho_1(x, x') < \delta \Rightarrow \rho_2(F(x), F_m(x')) < \varepsilon \quad \text{for all } x \in K, \quad x' \in M_1.$$

LEMMA A.1.2. *Under the assumptions of Theorem 2.1, we have*

$$(A.1.2) \quad M_m^{u_m}(y, \nu) \Rightarrow M^u(y, \nu) \quad \text{as } m \rightarrow \infty$$

uniformly for $y \in B$, $\nu \in \Gamma$, which are compact subsets of \mathcal{R}^d and $\mathcal{P}(E)$, respectively, and where $M^u(y, \nu)$ is given in (1.32).

Proof. Given $\phi \in C(E)$, we have

$$(A.1.3) \quad \begin{aligned} & \left| \int_E \int_E \exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \phi(z) P_m^{u_m(\nu)}(x, dz) \nu(dx) \right. \\ & \quad \left. - \int_E \int_E \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) P^{u(\nu)}(x, dz) \nu(dx) \right| \\ & \leq \left| \int_E \int_E \left(\exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \right. \right. \\ & \quad \left. \left. - \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \right) \phi(z) P_m^{u_m(\nu)}(x, dz) \nu(dx) \right| \\ & \quad + \left| \int_E \int_E \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) \right. \\ & \quad \left. \cdot (P_m^{u_m(\nu)}(x, dz) - P^{u(\nu)}(x, dz)) \nu(dx) \right| \\ & = I_m + II_m. \end{aligned}$$

Now

$$(A.1.4) \quad \begin{aligned} I_m & \leq \left(|y| \|h_m - h\| + \frac{1}{2} \|(h_m, h_m) - (h, h)\| \right) \\ & \quad \cdot \int_E \int_E \left(\exp \left[(y, h_m(z)) - \frac{1}{2} (h_m(z), h_m(z)) \right] \right. \\ & \quad \left. + \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \right) |\phi(z)| P_m^{u_m(\nu)}(x, dz) \nu(dx) \\ & \leq \left(|y| \|h_m - h\| + \frac{1}{2} \|(h_m, h_m) - (h, h)\| \right) (e^{|y| \|h_m\|} + e^{|y| \|h\|}) \|\phi\|, \end{aligned}$$

which by (2.3) tends to zero for $m \rightarrow \infty$, uniformly in $y \in B$.

Note now that by the Stone–Weierstrass theorem [11, Thm. 9.28 and Prob. 9.32], the function

$$(A.1.5) \quad B \times [-\|h\|, \|h\|]^d \ni (y, r) \rightarrow \exp[(y, r) - \frac{1}{2}(r, r)]$$

can be uniformly approximated with the use of functions $g_k(y, r) = \sum_{i=1}^k b_i(y) c_i(r)$,

where $b_i \in C(B)$, $c_i \in C([- \|h\|, \|h\|]^d)$; i.e., given $\varepsilon > 0$, there exists g_k such that

$$(A.1.6) \quad \sup_{y \in B} \sup_{r \in [- \|h\|, \|h\|]^d} \left| \exp \left[(y, r) - \frac{1}{2} (r, r) \right] - \sum_{i=1}^{i_k} b_i(y) c_i(r) \right| < \varepsilon.$$

Using this approximation and noting that from the compactness of Γ , for $\varepsilon > 0$ given, there is a compact set $K \subset E$ such that $\nu(K) \geq 1 - \varepsilon$ for $\nu \in \Gamma$. We then obtain

$$(A.1.7) \quad \begin{aligned} \Pi_m &\leq \left| \int_K \int_E \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) \right. \\ &\quad \cdot (P_m^{u_m(\nu)}(x, dz) - P^{u(\nu)}(x, dz)) \nu(dx) \Big| + 2\varepsilon \|\phi\| e^{|y| \|h\|} \\ &\leq \left| \int_K \int_E \sum_{i=1}^{i_k} b_i(y) c_i(h(z)) \phi(z) (P_m^{u_m(\nu)}(x, dz) - P^{u(\nu)}(x, dz)) \nu(dx) \right| \\ &\quad + 2\varepsilon \|\phi\| + 2\varepsilon \|\phi\| e^{|y| \|h\|} \\ &\leq \sum_{i=1}^{i_k} |b_i(y)| \sup_{x \in K} \left| \int_E c_i(h(z)) \phi(z) (P_m^{u_m(\nu)}(x, dz) - P^{u(\nu)}(x, dz)) \right| \\ &\quad + 2\varepsilon \|\phi\| (1 + e^{|y| \|h\|}). \end{aligned}$$

Letting $m \rightarrow \infty$, from (2.1) and (2.2) we get

$$(A.1.8) \quad \lim_{m \rightarrow \infty} \sup_{y \in B} \Pi_m \leq 2\varepsilon \|\phi\| \left(1 + \sup_{y \in B} e^{|y| \|h\|} \right).$$

From (A.1.3), (A.1.4), (A.1.7), and (A.1.8), letting $\varepsilon \rightarrow 0$, we finally obtain (A.1.2), which finishes the proof of Lemma A.1.2. \square

Proof of Proposition 2.1. For $F \in C(\mathcal{P}(E))$, we have

$$(A.1.9) \quad \begin{aligned} &|\Pi_m^{u_m}(\nu, F_m) - \Pi^u(\nu, F)| \\ &= \left| (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \left[\int_E \exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] \right. \right. \\ &\quad \cdot P_m^{u_m(\nu)}(\zeta, d\eta) F_m(M_m^{u_m}(y, \nu)) \\ &\quad \left. \left. - \int_E \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] P^{u(\nu)}(\zeta, d\eta) F(M^u(y, \nu)) \right] dy \nu(d\zeta) \right| \\ &\leq \left| (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \int_E \left(\exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] \right. \right. \\ &\quad \left. \left. - \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right) \right. \\ &\quad \cdot P_m^{u_m(\nu)}(\zeta, d\eta) F_m(M_m^{u_m}(y, \nu)) dy \nu(d\zeta) \Big| \\ &\quad + \left| (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \int_E \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right. \\ &\quad \cdot (P_m^{u_m(\nu)}(\zeta, d\eta) - P^{u(\nu)}(\zeta, d\eta)) F_m(M_m^{u_m}(y, \nu)) dy \nu(d\zeta) \Big| \\ &\quad + \left| (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \int_E \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] P^{u(\nu)}(\zeta, d\eta) \right. \\ &\quad \left. \cdot (F_m(M_m^{u_m}(y, \nu)) - F(M^u(y, \nu))) dy \nu(d\zeta) \right| = \text{I}_m + \text{II}_m + \text{III}_m. \end{aligned}$$

We now obtain

$$\begin{aligned}
 I_m &\leq (2\pi)^{-(d/2)} \int_E \int_{\mathcal{R}^d} \int_E (|y| \|h_m - h\| + \|(h_m, h_m) - (h, h)\|) \\
 &\quad \cdot \left(\exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] + \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right) \\
 &\quad \cdot b_F P_m^{u(\nu)}(\zeta, d\eta) dy \nu(d\zeta) \\
 &\leq \int_E \int_E \left\{ (2\pi)^{-(d/2)} \int_{\mathcal{R}^d} \left(\exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] \right. \right. \\
 (A.1.10) \quad &\quad \left. \left. + \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right) \|(h_m, h_m) - (h, h)\| dy \right. \\
 &\quad \left. + \left[\left((2\pi)^{-(d/2)} \int_{\mathcal{R}^d} (y, y) \exp \left[-\frac{1}{2} (y - h_m(\eta), y - h_m(\eta)) \right] dy \right)^{1/2} \right. \right. \\
 &\quad \left. \left. + \left((2\pi)^{-(d/2)} \int_{\mathcal{R}^d} (y, y) \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] dy \right)^{1/2} \right] \right. \\
 &\quad \left. \cdot \|h_m - h\| \right\} b_F P_m^{u(\nu)}(\zeta, d\eta) \nu(d\zeta) \\
 &\leq 2 \|(h_m, h_m) - (h, h)\| b_F + (2 + \|(h_m, h_m)\| + \|(h, h)\|) \|h_m - h\| b_F \rightarrow 0 \\
 &\quad \text{for } m \rightarrow \infty.
 \end{aligned}$$

To evaluate II_m and III_m , let $\Gamma \subset \mathcal{P}(E)$ be a compact set. For any $\varepsilon > 0$, there exist compact sets $K \subset E$, $B \subset \mathcal{R}^d$ such that for $\nu \in \Gamma$, $\nu(K) \geq 1 - \varepsilon$ and

$$(A.1.11) \quad (2\pi)^{-(d/2)} \inf_{\eta \in E} \int_B \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] dy \geq 1 - \varepsilon.$$

By Proposition 1.2(i), $M^u(B, \Gamma)$ is a compact subset of $\mathcal{P}(E)$. Applying Lemma A.1.1 to $(M_1, \rho_1) = (\mathcal{P}(E), \rho_w)$, $(M_2, \rho_2) = (\mathcal{R}, |\cdot|)$, $K = M(B, \Gamma)$, where ρ_w stands for the metric compatible with weak convergence on $\mathcal{P}(E)$, for a sufficiently large m , by Lemma A.1.2 we have

$$(A.1.12) \quad \sup_{y \in B} \sup_{\nu \in \Gamma} |F_m(M_m^{u_m}(y, \nu)) - F(M^u(y, \nu))| \leq \varepsilon.$$

Estimating II_m , we again use the approximation (A.1.6), obtaining

$$\begin{aligned}
 (A.1.13) \quad II_m &\leq \left| (2\pi)^{-(d/2)} \int_K \int_B \int_E \exp \left[-\frac{1}{2} (y - h(\eta), y - h(\eta)) \right] \right. \\
 &\quad \cdot (P_m^{u_m(\nu)}(\zeta, d\eta) - P^{u(\nu)}(\zeta, d\eta)) F_m(M_m^{u_m}(y, \nu)) dy \nu(d\zeta) \left. \right| + 2b_F \varepsilon + 2b_F \varepsilon \\
 &\leq 6b_F \varepsilon + (2\pi)^{-(d/2)} \int_K \int_B \exp \left[-\frac{1}{2} (y, y) \right] \sum_{i=1}^{i_k} |c_i(y)|
 \end{aligned}$$

$$\begin{aligned}
& \cdot \left| \int_E b_i(h(\eta))(P_m^{u_m(\nu)}(\zeta, d\eta) - P^{u(\nu)}(\zeta, d\eta)) \right| \cdot |F_m(M_m^u(y, \nu))| dy \nu(d\zeta) \\
& \leq 6b_F \varepsilon + b_F (2\pi)^{-(d/2)} \sum_{i=1}^{i_k} \int_B \exp \left[-\frac{1}{2}(y, y) \right] |c_i(y)| dy \\
& \cdot \sup_{\zeta \in K} \left| \int_E b_i(h(\eta))(P_m^{u_m(\nu)}(\zeta, d\eta) - P^{u(\nu)}(\zeta, d\eta)) \right|.
\end{aligned}$$

Then, using (2.1) and (2.2), we get for $\nu \in \Gamma$

$$(A.1.14) \quad \limsup_{m \rightarrow \infty} \Pi_m \leq 6b_F \varepsilon.$$

Finally, by (A.1.12) we have for sufficiently large m

$$\begin{aligned}
(A.1.15) \quad \text{III}_m & \leq (2\pi)^{-(d/2)} \int_K \int_B \int_E \exp \left[-\frac{1}{2}(y - h(\eta), y - h(\eta)) \right] P^{u(\nu)}(\zeta, d\eta) \\
& \cdot |F_m(M_m^u(y, \nu)) - F(M^u(y, \nu))| dy \nu(d\zeta) + 2b_F \varepsilon + 2b_F \varepsilon \\
& \leq \sup_{y \in B} \sup_{\nu \in \Gamma} |F_m(M_m^u(y, \nu)) - F(M^u(y, \nu))| \\
& \cdot (2\pi)^{-(d/2)} \int_K \int_E \int_B \exp \left[-\frac{1}{2}(y - h(\eta), y - h(\eta)) \right] \\
& \cdot dy P^{u(\nu)}(\zeta, d\eta) \nu(d\zeta) + 4b_F \varepsilon \\
& \leq \varepsilon(4b_F + 1).
\end{aligned}$$

In summary, from (A.1.9), (A.1.10), (A.1.14), (A.1.15),

$$(A.1.16) \quad \limsup_{m \rightarrow \infty} \sup_{\nu \in \Gamma} \left| \Pi_m^u(\nu, F) - \Pi^u(\nu, F) \right| \leq \varepsilon(10b_F + 1).$$

Letting $\varepsilon \rightarrow 0$, we obtain the proof of Proposition 2.1. \square

Proof of Lemma 2.1. Let us first consider the case (B1), (B4) and, to be specific, assume that alternative (1.8) holds. Given n , we can then find $n_1 > n$ such that $h^j(z) \geq \|h^j\|_n + \varepsilon$ for some $\varepsilon > 0$ and all $z \notin K_{n_1}$, where $\|h^j\|_n = \sup_{x \in K_n} |h^j(x)|$. Then, for $y^j > y_0 > 0$ and $|y^i| \leq M$, if $i \neq j$,

$$\begin{aligned}
R(y, \zeta^u(\nu))(K_{n_1}) & \leq e^{2\|h\|M} \\
& \cdot \left(\int_{K_{n_1}^c} \exp \left[(y, h(z) - \|h^j\|_n) - \frac{1}{2}(h(z), h(z)) \right] \zeta^u(\nu)(dz) \right)^{-1} \\
& \leq e^{2\|h\|M} e^{(1/2)\|h\|^2} e^{-\varepsilon y_0} e^{2\|h\|M} \frac{1}{\zeta^u(\nu)(K_{n_1}^c)} \\
& \leq e^{4\|h\|M} e^{(1/2)\|h\|^2} \frac{1}{\alpha} e^{-\varepsilon y_0} \leq 1 - \gamma.
\end{aligned}$$

By (2.18), this then implies the first statement. Similarly, we obtain $M_m^u(y, \nu)(K_n^c) \geq \gamma$ where m_0 is such that, for $m > m_0$, $h_m^j(z) \geq \|h_m^j\| + \varepsilon$. Analogously, we may study the case (C1), (C2). \square

Proof of Lemma 2.4. We prove case (i) of Lemma 2.4 for alternative (1.8). If $P\{M^u(Z, \nu)(\phi) = b\} > 0$, then by continuity (see Proposition 1.2), $M^u(Z, \nu)(\phi) = b$ for all y from some open subset G of \mathbb{R}^d . By (A3), it then follows that $b > 0$, since, for nonnegative $\phi(z) \neq 0$,

$$\int_E \int_E \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \phi(z) P^{u(\nu)}(x, dz) \nu(dx) > 0.$$

Note now that

$$\int_E \int_E \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] (\phi(z) - b) P^u(x, dz) \nu(dx) = 0$$

for $y \in G$. Differentiating m times with respect to y_j , we obtain

$$\int_E \int_E (h^j(z))^m \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] (\phi(z) - b) P^u(x, dz) \nu(dx) = 0$$

for $y \in G$, $m = 0, 1, 2, \dots$. Therefore, for any continuous function $c : [-\|h\|, \|h\|] \rightarrow \mathbb{R}$,

$$\int_E \int_E c(h^j(z)) \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] (\phi(z) - b) P^u(x, dz) \nu(dx) = 0$$

for $y \in G$. There exists a compact set K with $K_n \subset K$ such that

$$\sup_{z \in E} h^j(z) \geq \inf_{z \in K^c} h^j(z) = a_1 > \sup_{z \in K_n} h^j(z).$$

Let g_1 be a strictly increasing, continuous, and bounded function: $[-\|h\|, \|h\|] \rightarrow \mathbb{R}$ and set

$$g_2(a) = \begin{cases} g_1(a) & \text{for } a < a_1, \\ g_1(a_1) & \text{for } a > a_1. \end{cases}$$

Then, for $y \in G$,

$$\begin{aligned} & \int_E \int_E (g_1 - g_2)(h^j(z)) \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] \\ & \cdot (\phi(z) - b) P^u(x, dz) \nu(dx) = 0 \end{aligned}$$

and, consequently,

$$\int_E \int_{K_n^c} (g_1 - g_2)(h^j(z)) \exp \left[(y, h(z)) - \frac{1}{2} (h(z), h(z)) \right] (-b) P^u(x, dz) \nu(dx) = 0$$

for $y \in G$. However, $(g_1 - g_2)(h^j(z))$ is strictly positive on an open subset of K_n^c . Therefore, by (A3), $b = 0$, implying thus a contradiction.

Case (ii) can be shown in a similar way. \square

LEMMA A.1.3. *Consider the assumptions of Proposition 2.2 and suppose further that there exist uniformly bounded sequences $F_i^m \in \mathcal{B}(\mathcal{P}(E))$ ($i = 1, 2, \dots, q$) such that $F_i^m \rightarrow F_i$ for $m \rightarrow \infty$, uniformly on compact subsets of $\mathcal{P}(E)$. Then, if $\nu_m \Rightarrow \nu$, we have for each positive integer q*

$$\begin{aligned} (A.1.17) \quad & E_{\nu_m}^u \{ F_1^m(\pi_1^{m, \nu_m, u_m}) \cdot \dots \cdot F_q^m(\pi_q^{m, \nu_m, u_m}) \} \\ & \rightarrow E_{\nu}^u \{ F_1(\pi_1^{\nu, u}) \cdot \dots \cdot F_q(\pi_q^{\nu, u}) \}. \end{aligned}$$

Proof. We prove by induction. Step $q = 1$ follows from Corollary 2.1. Assume that (A.1.17) holds for q ; then for $q + 1$ we have

$$(A.1.18) \quad \begin{aligned} E_{\nu_m}^{u_m} \{ F_1^m(\pi_1^{m,\nu_m,u_m}) \cdots F_q^m(\pi_q^{m,\nu_m,u_m}) F_{q+1}^m(\pi_{q+1}^{m,\nu_m,u_m}) \} \\ = E_{\nu_m}^{u_m} \{ F_1^m(\pi_1^{m,\nu_m,u_m}) \cdots F_q^m(\pi_q^{m,\nu_m,u_m}) \Pi_m^u(\pi_q^{m,\nu_m,u_m}, F_{q+1}^m) \}. \end{aligned}$$

Recall now from Proposition 2.1 that

$$\Pi_m^u(\nu, F_{q+1}^m) \rightarrow \Pi^u(\nu, F_{q+1}) \quad \text{for } m \rightarrow \infty$$

uniformly on compact subsets of $\mathcal{P}(E)$. By the induction hypothesis, we then have the convergence of (A.1.18) to

$$\begin{aligned} E_{\nu}^u \{ F_1(\pi_1^{\nu,u}) \cdots F_q(\pi_q^{\nu,u}) \Pi^u(\pi_q^{\nu,u}, F_{q+1}) \} \\ = E_{\nu}^u \{ F_1(\pi_1^{\nu,u}) \cdots F_{q+1}(\pi_{q+1}^{\nu,u}) \}. \end{aligned} \quad \square$$

Appendix A.2 (Auxiliary results and proofs for § 3.1).

LEMMA A.2.1. *Let $u \in \mathcal{A}(L, n)$ or $\mathcal{A}^r(L, n)$. Given the partially observed system (CS_1) , let*

$$(A.2.1) \quad x_i^m = \sum_{k=1}^{k_m} k \chi_{B_k^m}(\bar{x}_i^m).$$

Then x_i^m is a particular version of the state process in the system (CS_2) corresponding to the transition matrix $P_m^{\tilde{\mathcal{L}}_m^u}(k, p)$. Furthermore, the observations \bar{y}_i in (3.16) and (3.18) coincide and

$$(A.2.2) \quad \bar{\pi}_i^{m,\mu,u}(B_k^m) = \pi_i^{m,\bar{\mu},\tilde{\mathcal{L}}_m^u}(k), \quad k = 1, 2, \dots, k_m;$$

i.e., $\pi_i^{m,\bar{\mu},\tilde{\mathcal{L}}_m^u}$ is a restriction of $\bar{\pi}_i^{m,\mu,u}$ to (S^m) . In addition, if $F: \mathcal{R}^{k_m} \rightarrow \mathcal{R}$ is bounded measurable, then

$$(A.2.3) \quad \begin{aligned} \int_{\mathcal{P}(E)} F(\nu(B_1^m), \dots, \nu(B_{k_m}^m)) \bar{\Pi}_m^u(\nu', d\nu) \\ = \int_{S^m} F(s_1, \dots, s_{k_m}) \Pi_m^{\tilde{\mathcal{L}}_m^u}(\nu'(B_1^m), \dots, \nu'(B_{k_m}^m), ds). \end{aligned}$$

Proof. By the definition of h_m in (3.1) and by (A.2.1), we clearly have that the observation processes \bar{y}_i of the types (3.16) and (3.18) coincide. Furthermore, the initial law for (x_i^m) is $\bar{\mu}$, which, by (3.14) and (3.15) as well as by (3.8), implies that the transition matrix for (x_i^m) at the initial stage $i = 0$ is $P_m^{\tilde{\mathcal{L}}_m^u(\bar{\mu})}(x_0^m, p)$. The fact that the transition law for x_i^m is $P_m^{\tilde{\mathcal{L}}_m^u}(k, p)$ for any period i follows then by induction using always (3.14), (3.15), and (3.8). Relation (A.2.2) now follows, again by induction, comparing the values of $\bar{M}_m^u(\bar{y}_{i+1}, \bar{\pi}_i^{m,\mu,u})$ and $\bar{M}_m^{\tilde{\mathcal{L}}_m^u}(\bar{y}_{i+1}, \pi_i^{m,\bar{\mu},\tilde{\mathcal{L}}_m^u})$.

Coming to the second part of the lemma, let $G \in \mathcal{B}(S)$ and $F = 1_G$. Then

$$\begin{aligned} \int_{\mathcal{P}(E)} 1_G(\nu(B_1^m), \dots, \nu(B_{k_m}^m)) \bar{\Pi}_m^u(\nu', d\nu) &= \bar{\Pi}_m^u(\nu', D) \\ &= \Pi_m^{\tilde{\mathcal{L}}_m^u}(\nu'(B_1^m), \dots, \nu'(B_{k_m}^m), G), \end{aligned}$$

where $D = \{\nu \in \mathcal{P}(E) \mid (\nu(B_1^m), \dots, \nu(B_{k_m}^m)) \in G\}$. Thus (A.2.3) is satisfied for simple functions and, consequently, by a standard procedure also for any bounded measurable function F . \square

Proof of Proposition 3.1. Given $A \in \mathcal{B}(\mathcal{P}(E))$, $u \in \mathcal{A}(L, n)$, or $\mathcal{A}^r(L, n)$, note from (3.14), (3.19), (3.22) that the value of $\bar{\Pi}_m^u(\nu, A)$ depends only on $(\nu(B_1^m), \dots, \nu(B_{k_m}^m))$, i.e., there is a measurable, bounded function F such that

$$(A.2.4) \quad \bar{\Pi}_m^u(\nu, A) = F(\nu(B_1^m), \dots, \nu(B_{k_m}^m)).$$

Therefore, using (3.25), (A.2.4), and (A.2.3), we obtain

$$(A.2.5) \quad \begin{aligned} & \int_{\mathcal{P}(E)} \bar{\Pi}_m^u(\nu, A) \bar{\Phi}_m^u(d\nu) \\ &= \int_{\mathcal{P}(E)} \bar{\Pi}_m^u(\nu, A) \int_{S^m} \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m}, d\nu\right) \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds) \\ &= \int_{S^m} \left(\int_{\mathcal{P}(E)} \bar{\Pi}_m^u(\nu, A) \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m}, d\nu\right) \right) \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds) \\ &= \int_{S^m} \int_{S^m} \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} a_k \delta_{z_k^m}, A\right) \Pi_m^{\tilde{\mathcal{L}}_m^u}(s_1, \dots, s_{k_m}, da) \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds) \\ &= \int_{S^m} \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} a_k \delta_{z_k^m}, A\right) \Phi_m^{\tilde{\mathcal{L}}_m^u}(da) = \bar{\Phi}_m^u(A) \end{aligned}$$

with $a = (a_1, \dots, a_{k_m}) \in S^m$, which is our claim. \square

Proof of Proposition 3.2. By the properties (D_m) and (A5), there exists, both under (B1) and (C1), an $m_0(n)$ with the properties formulated in the first part of Proposition 3.2. The proof of the uniqueness of the invariant measure Φ_m^u is based on arguments similar to those used in the proof of Theorem 2.3. Namely, proceeding analogously to (2.35)–(2.37), we show that there exists a unique invariant set for the controlled filtering process, which implies the uniqueness of the invariant measure Φ_m^u .

The first part of identity (3.29) now follows from the Feller property of $(\pi_i^{m, \bar{\mu}, \tilde{\mathcal{L}}_m^u})$ and the uniqueness of the invariant measure $\Phi_m^{\tilde{\mathcal{L}}_m^u}$. It remains to prove the second part of (3.29). By (3.25) we have

$$(A.2.6) \quad \begin{aligned} & \int_{\mathcal{P}(E)} \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) \bar{\Phi}_m^u(d\nu) \\ &= \int_{\mathcal{P}(E)} \int_{S^m} \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m}, d\nu\right) \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds) \\ &= \int_{S^m} \int_{\mathcal{P}(E)} \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) \bar{\Pi}_m^u\left(\sum_{k=1}^{k_m} s_k \delta_{z_k^m}, d\nu\right) \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds). \end{aligned}$$

By (A5) and the definition of $\tilde{\mathcal{L}}_m$,

$$(A.2.7) \quad \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) = \sum_{k=1}^{k_m} c_k^m\left(u\left(\sum_{p=1}^{k_m} \nu(B_p^m) \delta_{z_p^m}\right)\right) \nu(B_k^m)$$

is a function of $(\nu(B_1^m), \dots, \nu(B_{k_m}^m))$ only. Therefore, applying (A.2.3), we continue (A.2.6), obtaining

$$(A.2.8) \quad \begin{aligned} & \int_{\mathcal{P}(E)} \int_E c_m(x, \tilde{\mathcal{L}}_m u(\nu)) \nu(dx) \bar{\Phi}_m^u(d\nu) \\ &= \int_{S^m} \int_{S^m} \sum_{k=1}^{k_m} c_k^m\left(u\left(\sum_{p=1}^{k_m} s_p \delta_{z_p^m}\right)\right) s_k \Pi_m^{\tilde{\mathcal{L}}_m^u}(a_1, \dots, a_{k_m}, ds) \Phi_m^{\tilde{\mathcal{L}}_m^u}(da) \\ &= \int_{S^m} \sum_{k=1}^{k_m} c_k^m(\tilde{\mathcal{L}}_m u(s)) s_k \Phi_m^{\tilde{\mathcal{L}}_m^u}(ds), \end{aligned}$$

where the last identity follows from the fact that $\Phi_m^{\mathcal{F}_m^u}$ is an $\Pi_m^{\mathcal{F}_m^u}$ invariant measure. \square

A SUBSPACE DECOMPOSITION PRINCIPLE FOR SCALED GRADIENT PROJECTION METHODS: LOCAL THEORY*

J. C. DUNN†

Abstract. This paper is a sequel to an earlier work on a modification of the Gafni–Bertsekas scaled gradient projection method. Global convergence theorems proved in the first paper are complemented here by a local convergence analysis for the general SGP schemes and for special SGP algorithms with Newtonian scaling operators.

Key words. constrained minimization, gradient projection, Newtonian scaling, local convergence

AMS(MOS) subject classifications. 49D07, 65K10, 65B99

1. Introduction. The Goldstein–Levitin–Poljak unscaled gradient projection (GP) scheme [1], [2] inherits the basic convergence behavior of its steepest descent counterpart for unconstrained minimization [3]–[11], and costs little more to implement in the simple polyhedral and nonpolyhedral convex feasible sets commonly found in control problems, network flow problems, and other applications (e.g., Cartesian products of orthants, boxes, simplices, balls, cones, etc., [3], [5], [12]–[15]). For such problems, the GP method will compute well-conditioned nonsingular minimizers very efficiently. On the other hand, like steepest descent, the GP algorithm converges slowly to minimizers that are only moderately ill-conditioned, and some sort of Newtonian scaling of the objective function gradient is needed to restore acceptable rates of convergence in such cases. Bertsekas explains how this scaling might be done in orthants, boxes, and simplices [14], proves global and local convergence theorems in this setting, demonstrates the effectiveness of the scaled gradient projection (SGP) method for multistage bounded input optimal control problems, and proposes an extension of the scaling principle for general polyhedral feasible sets in \mathbb{R}^n . In [15], Gafni and Bertsekas describe a modified scaling principle that can be implemented in any closed convex set, prove a global convergence result at this level of generality, and show that in polyhedral sets in \mathbb{R}^n , any iterate sequence $\{u^i\}$ with a nondegenerate proper (i.e., strict) local minimizer \bar{u} in its limit point set must converge to \bar{u} , and converge superlinearly when \bar{u} is nonsingular and the objective function gradient is properly scaled.

While the global convergence theorem in [15] holds in arbitrary closed convex sets in a Hilbert space, the accompanying local superlinear convergence result is essentially limited to polyhedra since the scaling subspaces produced by the Gafni–Bertsekas dual cone decomposition in nonpolyhedral sets are too small to support Newtonian scaling operators likely to induce superlinear convergence [16]; moreover, the local result *assumes* that $\{u^i\}$ has a nonsingular minimizer \bar{u} in its limit point set, and is therefore weaker than the true local convergence theorems in [14] and [5], [8], [9] (which establish convergence of $\{u^i\}$ to *any* nonsingular local minimizer \bar{u} from all

sufficiently nearby starting points u^1). In addition, the local convergence proof in [15] is not valid in infinite-dimensional spaces. With these observations in mind, [13] and [17] consider a variant of the scaling principles in [14], [15] designed for closed convex feasible sets prescribed by finitely many smooth inequality constraints in a real Hilbert space. The new subspace decomposition and scaling principle preserves the descent and limit point stationarity properties of the algorithms in [14], [15], produces scaling subspaces that support the Newtonian scaling operators in [16], generates the same iterates as Bertsekas's original SGP algorithm near nondegenerate stationary points in orthants and boxes, is simpler than the Gafni–Bertsekas dual cone construction, and has some cost advantage over both of the earlier SGP schemes even in rudimentary polyhedral sets in \mathbb{R}^n (e.g., in a n -dimensional orthant, the derivative sign tests in [14] and cone projections in [15] can require $O(n)$ floating point comparisons beyond the $O(n)$ flops count for subspace decomposition).

The present article complements the global analysis in [17] by resolving several basic local convergence questions for the subspace decomposition principle in convex feasible sets prescribed by finitely many smooth inequality constraints, and for a generalization of the Gafni–Bertsekas dual cone decomposition principle in polyhedra; as in [17], the setting is a general real Hilbert space and the results obtained apply to finite- and infinite-dimensional nonlinear programs. For convenience, the SGP algorithms, constraint qualification, and several definitions from [8], [17] are fully described in §2, along with the Newtonian scaling operators in [16]. Section 3 then addresses the local convergence behavior of the SGP algorithms for general (i.e., not necessarily Newtonian) scaling operators that satisfy only minimal boundedness and coercivity conditions. It is first shown that the SGP sequences $\{u^i\}$ converge to a stationary point \bar{u} from all nearby starting points u^1 *only if* \bar{u} is a proper local minimizer and an isolated stationary point. A partial converse of this result is then proved for nondegenerate stationary points in \mathbb{R}^n , and several other partial converses are established in arbitrary real Hilbert spaces. The proof strategy employed here subsumes the local convergence proof in [14] and parallels the analysis in [8] and [9]. Nondegeneracy and local uniform growth conditions are imposed on the objective function near \bar{u} to insure that the iterates u^i will remain in any arbitrarily small neighborhood of \bar{u} in the feasible set if u^1 is sufficiently close to \bar{u} (i.e., to make \bar{u} a “stable” fixed point for the SGP algorithms). Additional local growth conditions on some measure of nonstationarity near \bar{u} can then be invoked to force convergence of $\{u^i\}$ to \bar{u} for all sequences $\{u^i\}$ confined to a sufficiently small neighborhood of \bar{u} (i.e., to make \bar{u} an “asymptotically stable” fixed point, or “stable local attractor”). In particular, if the required growth conditions hold and the objective and constraint function gradients are Lipschitz continuous near \bar{u} , then SGP iterates that begin near \bar{u} are shown to eventually enter and remain within the smooth manifold defined by the active inequality constraints at \bar{u} , and then converge to \bar{u} . All of the aforementioned nondegeneracy, growth, and continuity hypotheses are demonstrated for nonsingular local minimizers, and linear convergence rates are also proved in this special case; however, local asymptotic stability is established here for a much larger class of strict local minimizers, and the proof technique in [8] will yield a hierarchy of associated convergence rates for SGP processes in polyhedral sets. Thus, the analysis in §3 not only proves desirable generic local convergence properties for the new SGP subspace decomposition scheme in nonpolyhedral sets, but also substantially extends and strengthens the local convergence theorems of [14], [15] in polyhedra. In the concluding §4, the focus is narrowed to SGP algorithms that use the largest admissible scaling subspaces and the associated New-

tonian scaling operators in [16]. In this setting, the subspace decomposition scheme and the Gafni–Bertsekas dual cone decomposition scheme are shown to produce identical iterates near nondegenerate stationary points (and in particular near nonsingular minimizers) in polyhedra, and a new local superlinear convergence theorem is proved for the subspace decomposition principle in nonpolyhedral sets.

Several interesting questions are left unanswered in this investigation. For instance, while all of the SGP schemes considered here have the same basic descent and limit point stationarity properties and exhibit identical local convergence behavior near nondegenerate stationary points wherever they are jointly applicable, this does not rule out potentially significant differences in their global convergence properties (and hence their net computational costs) within specific problem classes; existing global convergence theories and published numerical experiments are simply not capable of resolving this issue at present. In addition, counterparts of the important quasi-Newton scaling operator recursions for unconstrained minimization have also received no explicit consideration here. It is easily seen that quasi-Newtonian versions of the subject SGP algorithms will retain the local superlinear convergence property if their scaling operator sequences obey asymptotic quasi-Newton conditions like (43) in the SGP framework. If the unconstrained quasi-Newton theory is a reliable guide here, then the general linear convergence rate estimate and active constraint identification results in Theorem 4 of §3 should supply the essential first steps in a demonstration of this sort.

2. SGP methods. Let Ω be a nonempty closed convex set in a real Hilbert space \mathcal{U} , and let J be a continuously Fréchet differentiable real function to be minimized over Ω . The SGP algorithms in [13]–[15], [17] generate successive feasible approximations $u^i \in \Omega$ recursively with

$$(1a) \quad u^{i+1} = P_{\Omega}(u^i + \sigma^i v^i)$$

where at each $u \in \Omega$,

$$(1b) \quad v = v_N + v_T,$$

$$(1c) \quad v_N = s_N P_N(-\nabla J(u)),$$

$$(1d) \quad v_T = P_T S_T P_{N^*}(-\nabla J(u)),$$

$$(1e) \quad N = \text{a closed convex cone containing } K(u),$$

$K(u)$ = the normal cone at u

$$(1f) \quad = \{w : \forall v \in \Omega, \langle w, v - u \rangle \leq 0\},$$

N^* = the dual cone for N

$$(1g) \quad = \{w^* : \forall w \in N, \langle w^*, w \rangle \leq 0\},$$

$$(1h) \quad T = \{v_N\}^{\perp} \cap N^*,$$

$$(1i) \quad [T] = \text{the closed linear hull of } T,$$

$$(1j) \quad \mu_3 \geq s_N \geq \mu_2 > 0,$$

S_T = a bounded linear map from $[T]$ into $[T]$ such that

$$(1k) \quad \langle P_{N^*}(-\nabla J(u)), S_T P_{N^*}(-\nabla J(u)) \rangle \geq \mu_0 \|P_{N^*}(-\nabla J(u))\|^2,$$

and

$$\begin{aligned}
 (11) \quad & \|S_T\| \leq \mu_1, \\
 & \sigma = \max s, \text{ subject to} \\
 & \frac{s}{\alpha} \in \{1, \beta, \beta^2, \dots\},
 \end{aligned}$$

and

$$\begin{aligned}
 (1m) \quad & J(u) - J(P_\Omega(u + sv)) \geq \delta \{(s_N s)^{-1} \|u + sv_T - P_\Omega(u + sv)\|^2 \\
 & + \langle P_{N^*}(-\nabla J(u)), v_T \rangle s\},
 \end{aligned}$$

and where δ and β are fixed real numbers in $(0, 1)$, α and μ_0, \dots, μ_3 are fixed positive real numbers, and P_A denotes projection into the set A .

Further restrictions are needed on the cones N in (1) to insure desirable global and local convergence behavior for the associated sequences $\{u^i\}$. The extended Gafni–Bertsekas construction treated in [17] begins with an explicit affine inequality representation

$$(2a) \quad \Omega = \{u \in \mathcal{U} : \forall j \in \mathcal{J}, \langle a^j, u \rangle - bj \leq 0\}$$

for the closed convex set Ω , where the index set \mathcal{J} is finite for polyhedral Ω , and infinite otherwise. Given an arbitrary but fixed positive number ϵ_o , we then put

$$\begin{aligned}
 (2b) \quad & d(u) = \|u - P_\Omega(u - \nabla J(u))\|, \\
 (2c) \quad & \epsilon(u) = \min\{\epsilon_o, d(u)\}, \\
 (2d) \quad & \mathcal{J}(u) = \{j \in \mathcal{J} : \langle a^j, u \rangle - bj \geq -\|a^j\|\epsilon(u)\}, \\
 (2e) \quad & C(u) = \{w : \forall j \in \mathcal{J}(u), \langle w, a^j \rangle \leq 0\},
 \end{aligned}$$

and require that

$$(2f) \quad N \supset C(u)^* = \{w^* : \forall w \in C(u), \langle w^*, w \rangle \leq 0\}$$

at each $u \in \Omega$. This restriction is weaker than the condition imposed in the original Gafni–Bertsekas scheme of [15], namely that

$$N = \hat{C}^*,$$

where

$$\hat{C} = \{w : \forall j \in \hat{\mathcal{J}}, \langle w, a^j \rangle \leq 0\}$$

and

$$\hat{\mathcal{J}} \supset \mathcal{J}(u).$$

In particular, the latter condition does not admit arbitrary closed subspaces $N \supset C(u)^*$.

When the cone N is a subspace, (1) reduces to

$$(3a) \quad u^{i+1} = P_\Omega(u^i + \sigma^i v^i)$$

with

$$\begin{aligned}
(3b) \quad & v = v_N + v_T, \\
(3c) \quad & v_N = -s_N P_N \nabla J(u), \\
(3d) \quad & v_T = -S_T P_T \nabla J(u), \\
(3e) \quad & N = \text{a closed subspace} \supset K(u), \\
(3f) \quad & K(u) = \{w : \forall v \in \Omega, \langle w, v - u \rangle \leq 0\}, \\
(3g) \quad & T = N^\perp, \\
(3h) \quad & \mu_3 \geq s_N \geq \mu_2 > 0, \\
& S_T = \text{a bounded linear map from } T \text{ into } T, \text{ such that} \\
(3i) \quad & \langle P_T \nabla J(u), S_T P_T \nabla J(u) \rangle \geq \mu_0 \|P_T \nabla J(u)\|^2,
\end{aligned}$$

and

$$(3j) \quad \|S_T\| \leq \mu_1,$$

$\sigma = \max s$, subject to

$$\frac{s}{\alpha} \in \{1, \beta, \beta^2, \dots\},$$

and

$$\begin{aligned}
(3k) \quad & J(u) - J(P_\Omega(u + sv)) \geq \delta \{(s_N s)^{-1} \|u + sv_T - P_\Omega(u + sv)\|^2 \\
& - \langle P_T \nabla J(u), v_T \rangle s\}.
\end{aligned}$$

As before, further restrictions on the subspaces N in (3) are dictated by global and local convergence considerations. The subspace decomposition and scaling procedure in [13], [17] applies to closed convex Ω with representations

$$(4a) \quad \Omega = \{u \in \mathcal{U} : g_i(u) \leq 0, j = 1, \dots, m\}.$$

With ϵ_0 and θ fixed in $(0, \infty)$ and $(1, \infty)$ respectively, put

$$\begin{aligned}
(4b) \quad & d(u) = \|u - P_\Omega(u - \nabla J(u))\|, \\
(4c) \quad & \epsilon(u) = \min\{\epsilon_0, d(u)\}, \\
(4d) \quad & \mathcal{J}_0(u) = \{j : g_j(u) = 0\}, \\
(4e) \quad & \mathcal{J}(u) = \{j : g_j(u) \geq -\theta \|\nabla g_j(u)\| \epsilon(u)\} \supset \mathcal{J}_0(u), \\
(4f) \quad & \mathcal{G}_0(u) = \{\nabla g_j(u)\}_{j \in \mathcal{J}_0(u)}, \\
(4g) \quad & \mathcal{G}(u) = \{\nabla g_j(u)\}_{j \in \mathcal{J}(u)} \supset \mathcal{G}_0(u), \\
(4h) \quad & N_0(u) = \text{span}[\mathcal{G}_0(u) \cup \{0\}], \\
(4i) \quad & N(u) = \text{span}[\mathcal{G}(u) \cup \{0\}] \supset N_0(u),
\end{aligned}$$

and require that

$$(4j) \quad N \supset N(u)$$

at each $u \in \Omega$ (note that the sets $\mathcal{J}_o(u)$, $\mathcal{J}(u)$, $\mathcal{G}_o(u)$, and $\mathcal{G}(u)$ may be empty at certain $u \in \Omega$).

The SGP scheme (3), (4) is designed to admit the convergence-accelerating Newtonian scaling operators of [16]. In this construction, we set

$$\begin{aligned} (5a) \quad & N = N(u), \\ (5b) \quad & T = T(u) = N(u)^\perp, \end{aligned}$$

and

$$(5c) \quad S_T = S_T(u) \triangleq E_T L_T^{-1}$$

with

$$\begin{aligned} (5d) \quad & E_T = P_T E|_T \\ (5e) \quad & L_T = P_T L|_T \\ (5f) \quad & E = I + s_N \Lambda \\ (5g) \quad & L = \nabla^2 J(u) + \Lambda \\ (5h) \quad & \Lambda = \sum_{j=1}^m \lambda_j(u) \nabla^2 g_j(u), \end{aligned}$$

where the $\lambda_j(u)$'s are obtained by solving the linear equations

$$\begin{aligned} (5i) \quad & \sum_{j=1}^m \lambda_j(u) \nabla g_j(u) = -P_N \nabla J(u), \\ (5j) \quad & \lambda_j(u) = 0, \quad j \notin \mathcal{J}(u). \end{aligned}$$

The associated full step Newtonian projection (NP) iteration in [16] sets $\sigma = 1$ in place of (3k), and implements (3a)–(3h), (4), and (5). Since the resulting NP sequences $\{u^i\}$ are locally superlinearly convergent to nonsingular minimizers when (4a) satisfies a standard constraint qualification (see below), it seems likely that a similar result can hold for Newtonian SGP processes (3), (4) employing the operators (5). This is shown in §4 when $\alpha = 1$, $\delta \in (0, 1/2)$ and the scaling paramter s_N satisfies the auxiliary rule

$$(6a) \quad s_N = s_N(u) \triangleq \begin{cases} 1, & \text{if } b(u) = 0 \\ \min \left\{ 1, \frac{a(u)}{b(u)} \right\}, & \text{if } b(u) \neq 0, \end{cases}$$

where

$$\begin{aligned} (6b) \quad & a(u) = (1 - 2\delta) \langle P_T \nabla J(u), L_T^{-1} P_T \nabla J(u) \rangle, \\ (6c) \quad & b(u) = \|\Lambda_T L_T^{-1} P_T \nabla J(u)\|^2 + |\langle P_T \nabla J(u), \Lambda_T L_T^{-1} P_T \nabla J(u) \rangle|. \end{aligned}$$

Under these circumstances, the construction (5) is compatible with (3h)–(3j) near nonsingular local minimizers \bar{u} , and the rule (3k) eventually produces unit steps $\sigma^i = 1$ for SGP sequences $\{u^i\}$ converging to \bar{u} , i.e., the Newtonian SGP scheme (3)–(6) eventually reduces to the NP iteration in [16].

In [17], [16] and in the following local convergence analysis, it is assumed that (4a) satisfies the following constraint qualifications.

CONSTRAINT QUALIFICATION Q. *Either*

(i) *the functions g_j in (4a) are affine, i.e.,*

$$g_j(u) = \langle a^j, u \rangle - b^j,$$

with $a^j \in \mathcal{U}$ and $b^j \in \mathbb{R}$, or else

(ii) *(4a) is a normal representation for Ω , i.e.,*

$$\forall u \in \Omega, \mathcal{G}_0(u) \text{ is linearly independent.}$$

In what follows, we will refer to this constraint qualification as Q.

As in [17], a point $\bar{u} \in \Omega$ is said to be *stationary* if and only if

$$-\nabla J(\bar{u}) \in K_\Omega(\bar{u}),$$

or, equivalently,

$$d(\bar{u}) = 0.$$

In convex sets Ω , every local minimizer of J is stationary. A stationary point $\bar{u} \in \Omega$ is said to be *nondegenerate* if and only if

$$-\nabla J(\bar{u}) \in \text{ri}K_\Omega(\bar{u}),$$

where ri denotes the interior of $K_\Omega(u)$ relative to its closed affine hull.

3. Local convergence theorems for general SGP methods. The descent property and fixed point characterization established by Lemma 3 and its corollary in [17] implies that J must be constant on the limit point set for any SGP sequence $\{u^i\}$ generated by (1), and that no local maximizer \bar{u} can be a limit point, except trivially when $u^i = \bar{u}$ for some i . Moreover, while the descent property does not rule out nontrivial subsequential limits at saddles or other spurious stationary points, such occurrences are atypical. These observations, together with the global convergence analysis in [17], and Theorem 1 and Lemma 1 below, suggest that SGP sequences produced by (1), (2) or (3), (4) either have no limit points or are likely to converge to some local minimizer. However, it has not yet been shown that convergence to any *particular* local minimizer \bar{u} must occur if u^i is eventually close enough to \bar{u} . This *asymptotic stability* question is addressed here for (1), (2) and (3), (4) in polyhedral convex Ω satisfying the constraint qualification Q(i), and for (3), (4) in closed convex Ω satisfying Q(ii). The principal results obtained for (1), (2) extend Proposition 3 in [15] in several directions, while the results for (3), (4) are entirely new.

The following development draws on the terminology and theorems in [8], [9].

DEFINITION 1. (i) A fixed point \bar{u} for the SGP iteration (1) is *stable* if and only if for each $\epsilon > 0$, there is a corresponding $\Delta \in (0, \epsilon]$ such that for all sequences $\{u^i\}$ generated by (1),

$$\|u^1 - \bar{u}\| \leq \Delta \Rightarrow \forall i, \quad \|u^i - \bar{u}\| \leq \epsilon.$$

(ii) A fixed point \bar{u} for the SGP iteration (1) is *asymptotically stable* if and only if \bar{u} is stable and there is a $\Delta > 0$ such that for all $\{u^i\}$ generated by (1),

$$\|u^1 - \bar{u}\| \leq \Delta \Rightarrow \lim_{i \rightarrow \infty} u^i = \bar{u}.$$

THEOREM 1. *If \bar{u} is an asymptotically stable fixed point for the SGP iteration (1), then \bar{u} is a proper (i.e., strict) local minimizer and an isolated stationary point for J in Ω .*

Proof. Since every stationary point is a fixed point of (1) [17], \bar{u} cannot be asymptotically stable if stationary points accumulate at \bar{u} . Therefore, suppose that \bar{u} is an isolated stationary point but is not a proper local minimizer. Then every neighborhood of \bar{u} in Ω contains a nonstationary point u^1 at which $J(u^1) \leq J(\bar{u})$. For any sequence $\{u^i\}$ that begins at u^1 and is generated by (1), the descent property insures that for all $i \geq 2$,

$$J(u^i) \leq J(u^2) < J(u^1) \leq J(\bar{u}).$$

Since J is continuous at \bar{u} , it follows that $\{u^i\}$ cannot converge to \bar{u} . Thus if \bar{u} is not an isolated stationary point or \bar{u} is not a proper local minimizer, then \bar{u} is not an asymptotically stable fixed point for (1). \square

Note 1. An example in [18] shows that asymptotically stable proper local minimizers can accumulate at a proper local minimizer \bar{u} ; for certain \bar{u} 's of this type, the sequences generated by (1) cannot converge to \bar{u} from *any* starting point $u^1 \neq \bar{u}$, i.e., \bar{u} cannot be computed with (1).

Our objective now is first to extend the convergence assertion in Proposition 3 of [15], and then to establish several stronger partial converses of Theorem 1 for SGP iterations (1), (2) and (3), (4).

Definition 2. (i) \bar{u} is a *uniformly proper local minimizer* for J in Ω if and only if $\bar{u} \in \Omega$ and there is a $\rho > 0$ and a nondecreasing positive-definite function $a : [0, \rho] \rightarrow [0, \infty]$ such that for all $u \in \Omega$

$$\|u - \bar{u}\| \leq \rho \Rightarrow J(u) - J(\bar{u}) \geq a(\|u - \bar{u}\|).$$

(ii) \bar{u} is a *uniformly isolated stationary point* for J in Ω if and only if $d(\bar{u}) \triangleq \|\bar{u} - P_\Omega(\bar{u} - \nabla J(\bar{u}))\| = 0$, and \bar{u} is a uniformly proper local minimizer of $d(u)$ in Ω . More generally, \bar{u} is a uniformly isolated zero of $f : \mathcal{U} \rightarrow [0, \infty)$ in a closed subset $\mathcal{A} \subset \Omega$ if and only if $\bar{u} \in \mathcal{A}$, $f(\bar{u}) = 0$ and \bar{u} is a uniformly proper local minimizer of f in \mathcal{A} .

Note 2. If $\dim \mathcal{U} < \infty$, then every proper local minimizer of a continuous function J is uniformly proper, every isolated stationary point of a continuously differentiable function J is uniformly isolated, and every isolated zero of a continuous function f is uniformly isolated [8].

LEMMA 1. *Let \bar{u} be a limit point for a sequence $\{u^i\}$ generated by an SGP iteration (1). If \bar{u} is a uniformly proper local minimizer of J in Ω , then $\{u^i\}$ must converge to \bar{u} .*

Proof. Let J , ρ , and $a(\cdot)$ meet the condition in part (i) of Definition 2. Suppose that $\{u^i\}$ does not converge to \bar{u} . Since $u^i - u^{i+1} \rightarrow 0$ (Lemma 4 in [17]), there is an $\epsilon > 0$ and an infinite set Z_1 of positive integers such that for all i

$$\begin{aligned} i \in Z_1 &\Rightarrow u^i \in \{u \in \Omega : \rho \geq \|u - \bar{u}\| \geq \epsilon\} \\ &\Rightarrow J(u^i) - J(\bar{u}) \geq a(\epsilon) > 0. \end{aligned}$$

On the other hand, the descent property insures that

$$\lim_{i \rightarrow \infty} J(u^i) = J(\bar{u}).$$

This contradiction proves that $\{u^i\}$ must converge to \bar{u} . \square

Note 3. The convergence assertion in Proposition 3 of [15] may be seen as a corollary of Lemma 1 (see Note 2).

The strongest local convergence theorems for unconstrained variable metric gradient methods in $\Omega = \mathcal{U}$ have been proved for a special type of uniformly proper local minimizer/uniformly isolated stationary point, namely, the so-called *nonsingular* local minimizer \bar{u} where ∇J vanishes and $\nabla^2 J$ is continuous and coercive; at such points, we have

$$(7a) \quad J(u) - J(\bar{u}) \geq c_1 \|u - \bar{u}\|^2$$

and

$$(7b) \quad \|\nabla J(u)\| \geq c_2 \|u - \bar{u}\|$$

for some $c_1 > 0$, $c_2 > 0$ and all u near \bar{u} [8]. This notion of nonsingularity has a natural extension in Definition 3 below, and once again occupies a central position in the local convergence theories for (1), (2) and (3), (4) in closed convex Ω with representations (4a) satisfying the constraint qualification Q. Observe first that if (4a) satisfies Q, then at each stationary point \bar{u} , there is a Karush–Kuhn–Tucker (KKT) multiplier vector $\bar{\lambda} \in \mathbb{R}^m$ such that

$$(8a) \quad -\nabla J(\bar{u}) = \sum_{j=1}^m \bar{\lambda}_j \nabla g_j(\bar{u}),$$

$$(8b) \quad \bar{\lambda}_j \geq 0, \quad j = 1, \dots, m,$$

$$(8c) \quad (\bar{\lambda}_j > 0 \Rightarrow j \in \mathcal{J}_0(\bar{u})), \quad j = 1, \dots, m$$

with $\mathcal{J}_0(u)$ defined in (4); moreover, it has been shown in [10] that

$$(9) \quad \begin{aligned} &\bar{u} \text{ is a nondegenerate stationary point} \Leftrightarrow \\ &\exists \bar{\lambda} \in \mathbb{R}^m, \bar{\lambda} \text{ satisfies (8) and } (j \in \mathcal{J}_0(\bar{u}) \Rightarrow \bar{\lambda}_j > 0), \quad j = 1, \dots, m. \end{aligned}$$

In particular, if Q(ii) holds, then $\bar{\lambda}$ is unique. At $u \in \Omega$, put

$$T_0(u) = N_0(u)^\perp$$

with $N_0(u)$ defined in (4). When J and the functions g_j in (4a) are twice Fréchet differentiable at u , put

$$(10) \quad L(u, \lambda) = \begin{cases} \nabla^2 J(u), & \text{if Q(i) holds} \\ \nabla^2 J(u) + \sum_{j=1}^m \lambda_j \nabla^2 g_j(u), & \text{if Q(ii) holds.} \end{cases}$$

DEFINITION 3. Assume that Ω is a closed convex set with a representation (4a) that satisfies the constraint qualification Q. A local minimizer (respectively, stationary point) \bar{u} for J in Ω is *nonsingular* if and only if \bar{u} is nondegenerate, J and the functions g_j in (4a) are twice continuously differentiable at \bar{u} , and the reduced Lagrangian Hessian,

$$P_{T_0(\bar{u})} L(\bar{u}, \bar{\lambda})|_{T_0(\bar{u})},$$

is coercive (respectively, bijective) for any KKT multiplier $\bar{\lambda}$ satisfying the right-hand side of (9). (Note that either $\bar{\lambda}$ is unique or $L(\bar{u}, \bar{\lambda})$ does not depend on the choice of $\bar{\lambda}$. Therefore, in all cases, $L(\bar{u}, \bar{\lambda})$ is uniquely prescribed at \bar{u} .)

LEMMA 2. *Suppose that \bar{u} is a nonsingular local minimizer for J in a closed convex set Ω with a representation (4a) that satisfies the constraint qualification Q, and let*

$$\mathcal{A}(\bar{u}) = \{u \in \Omega : \mathcal{J}_0(u) = \mathcal{J}_0(\bar{u})\}.$$

Then for some $\rho > 0$, $c_1 > 0$, and $c_2 > 0$, and all u ,

$$(11a) \quad u \in B(\bar{u}, \rho) \cap \Omega \Rightarrow J(u) - J(\bar{u}) \geq c_1 \|u - \bar{u}\|^2,$$

$$(11b) \quad u \in B(\bar{u}, \rho) \cap \mathcal{A}(\bar{u}) \Rightarrow \|P_{T_0(u)} \nabla J(u)\| \geq c_2 \|u - \bar{u}\|.$$

Proof. The estimate (11a) can be deduced with (9) and the general Banach space sufficiency proof technique in [19, pp. 191–192]. The estimate (11b) is established in [9] when Q(ii) holds. Suppose instead that (4a) satisfies Q(i). Observe that for all $u \in \mathcal{A}(\bar{u})$, one has $\mathcal{J}_0(u) = \mathcal{J}_0(\bar{u})$ and consequently $T_0(u) = T_0(\bar{u})$. Since $P_{T_0(\bar{u})} \nabla J(u)$ and $P_{T_0(\bar{u})} \nabla^2 J(u)|_{T_0(\bar{u})}$ can be seen as the gradient and Hessian of a translate of J restricted to the Hilbert space $T_0(\bar{u})$, assertion (11b) now follows from (7b) and the coercivity of $P_{T_0(\bar{u})} \nabla^2 J(\bar{u})|_{T_0(\bar{u})} = P_{T_0(\bar{u})} L(\bar{u}, \bar{\lambda})|_{T_0(\bar{u})}$.

Note 4. In view of (11), every nonsingular local minimizer is automatically a uniformly proper local minimizer and a uniformly isolated zero of the function $\|P_{T_0(u)} \nabla J(u)\|$ in $\mathcal{A}(\bar{u})$.

One additional property of nondegenerate stationary points is needed to establish a link with hypothesis (B) in the local convergence analysis of [15], and to develop an analogous local theory for (3), (4) in nonpolyhedral sets.

LEMMA 3. *Let \bar{u} be a nondegenerate stationary point for J in a closed convex set Ω with a representation (4a) satisfying the constraint qualification Q. Assume that the functions g_j in (4a) are continuously Fréchet differentiable at \bar{u} . Let α_1 and α_2 be fixed positive numbers, with $\alpha_1 < \alpha_2$. Then for some corresponding $\epsilon > 0$, and for all h and s ,*

$$(12) \quad \|h\| \leq \epsilon \quad \text{and} \quad s \in [\alpha_1, \alpha_2] \Rightarrow P_\Omega(\bar{u} - s \nabla J(\bar{u}) + sh) \in \mathcal{A}(\bar{u}).$$

Proof. Put $\bar{v} = -\nabla J(\bar{u}) \in \text{ri } K(\bar{u})$. Suppose that Q(i) holds. Then for some $\epsilon > 0$, and all h and s ,

$$\begin{aligned} \|h\| \leq \epsilon \quad \text{and} \quad s \in [\alpha_1, \alpha_2] &\Rightarrow (\bar{u} + s P_{T_0(\bar{u})} h) \in \mathcal{A}(\bar{u}) \quad \text{and} \quad s(\bar{v} + P_{N_0(\bar{u})} h) \in K(\bar{u}) \\ &\Rightarrow (\bar{u} + s P_{T_0(\bar{u})} h) \in \mathcal{A}(\bar{u}) \quad \text{and} \quad s(\bar{v} + P_{N_0(\bar{u})} h) \in K(\bar{u} + s P_{T_0(\bar{u})} h) \\ &\Rightarrow P_\Omega(\bar{u} + s \bar{v} + sh) = (\bar{u} + s P_{T_0(\bar{u})} h) \in \mathcal{A}(\bar{u}). \end{aligned}$$

On the other hand, if Q(ii) holds, then an argument similar to that used in the proof of Lemma 1 in [9] will show that $\mathcal{J}_0(P_\Omega(\bar{u} + s \bar{v} + sh)) = \mathcal{J}_0(\bar{u})$ for $s \in [\alpha_1, \alpha_2]$ and $\|h\|$ sufficiently small. Thus, note that since the g_j 's are continuous at \bar{u} , and since

$$\|P_\Omega(\bar{u} + s \bar{v} + sh) - \bar{u}\| = \|P_\Omega(\bar{u} + s \bar{v} + sh) - P_\Omega(\bar{u} + s \bar{v})\| \leq s \|h\|,$$

it follows that

$$\exists \epsilon > 0, \quad \forall s \in [\alpha_1, \alpha_2], \quad \forall h \in B(0, \epsilon_1), \quad \mathcal{J}_0(P_\Omega(\bar{u} + s \bar{v} + sh)) \subset \mathcal{J}_0(\bar{u}).$$

To prove the reverse inclusion, note that if $\mathcal{J}_0(\bar{u}) = \emptyset$ then trivially $\mathcal{J}_0(\bar{u}) \subset \mathcal{J}_0(P_\Omega(\bar{u} + s\bar{v} + sh))$ for all s, h . Therefore, suppose that $\mathcal{J}_0(\bar{u}) \neq \emptyset$. With reference to (9) there is a $\bar{\lambda} \in \mathbb{R}^m$ such that

$$(13a) \quad (j \notin \mathcal{J}_0(\bar{u}) \Rightarrow \bar{\lambda}_j = 0), \quad j = 1, \dots, m,$$

$$(13b) \quad b \triangleq \min_{j \in \mathcal{J}_0(\bar{u})} \bar{\lambda}_j > 0,$$

and

$$(13c) \quad \bar{v} = \sum_{j=1}^m \bar{\lambda}_j \nabla g_j(\bar{u}).$$

Furthermore, Q(ii) insures that for all s, h , there is a corresponding $\ell(s, h) \in \mathbb{R}^m$ such that

$$(14a) \quad \ell_j(s, h) \geq 0, \quad j = 1, \dots, m,$$

$$(14b) \quad (j \notin \mathcal{J}_0(P_\Omega(\bar{u} + s\bar{v} + sh)) \Rightarrow \ell_j(s, h) = 0), \quad j = 1, \dots, m,$$

and

$$(14c) \quad \bar{u} + s\bar{v} + sh - P_\Omega(\bar{u} + s\bar{v} + sh) = \sum_{j=1}^m \ell_j(s, h) \nabla g_j(P_\Omega(\bar{u} + s\bar{v} + sh));$$

therefore,

$$(14d) \quad \begin{aligned} & 2s\|h\| + \|\ell\|_2 \|\nabla g(P_\Omega(\bar{u} + s\bar{v} + sh)) - \nabla g(\bar{u})\|_2 \\ & \geq \left\| \sum_{j=1}^m (\ell_j(s, h) - s\bar{\lambda}_j) \nabla g_j(\bar{u}) \right\| \end{aligned}$$

with

$$\|\nabla g(P_\Omega(\bar{u} + s\bar{v} + sh)) - \nabla g(\bar{u})\|_2 \triangleq \left(\sum_{j=1}^m \|\nabla g_j(P_\Omega(\bar{u} + s\bar{v} + sh)) - \nabla g_j(\bar{u})\|^2 \right)^{1/2}.$$

For $s \in [\alpha_1, \alpha_2]$ and $\|h\|$ sufficiently small, it will now be shown that $\ell_j(s, h)$ must be positive for all $j \in \mathcal{J}_0(\bar{u})$, and hence that $\mathcal{J}_0(\bar{u}) \subset \mathcal{J}_0(P_\Omega(\bar{u} + s\bar{v} + sh))$. Observe first that Q(ii) and the continuity of the gradients $\nabla g_j(\cdot)$ at \bar{u} imply that

$$\exists \epsilon_2 \in [0, \epsilon_1], \quad \exists \gamma > 0, \quad \forall s \in [\alpha_1, \alpha_2], \quad \forall h \in B(0, \epsilon_2), \quad \forall c \in \mathbb{R}^m,$$

$$\gamma \left\| \sum_{j \in \mathcal{J}_0(\bar{u})} c_j \nabla g_j(P_\Omega(\bar{u} + s\bar{v} + sh)) \right\| \geq \left(\sum_{j \in \mathcal{J}_0(\bar{u})} c_j^2 \right)^{1/2}.$$

Therefore, in view of (14), there is an $\epsilon \in (0, \epsilon_2]$ such that for all s, h ,

$$\begin{aligned} \|h\| \leq \epsilon \quad \text{and} \quad s \in [\alpha_1, \alpha_2] & \Rightarrow \frac{1}{2} \gamma^{-1} s b \geq \gamma^{-1} \max_{j \in \mathcal{J}_0(\bar{u})} |\ell_j(s, h) - s\bar{\lambda}_j| \\ & \Rightarrow \forall j \in \mathcal{J}_0(\bar{u}), \quad \ell_j(s, h) \geq s \left(\bar{\lambda}_j - \frac{b}{2} \right) > 0 \\ & \Rightarrow \mathcal{J}_0(\bar{u}) \subset \mathcal{J}_0(P_\Omega(\bar{u} + s\bar{v} + sh)). \quad \square \end{aligned}$$

Note 5. Suppose that Ω is a polyhedral convex set with a representation (4a) satisfying Q(i) and let (12) hold with $\alpha_1 = \alpha_2 = 1$. Then for all h ,

$$\begin{aligned} h \in N_0(\bar{u}) \quad \text{and} \quad \|h\| \leq \epsilon &\Rightarrow P_\Omega(\bar{u} - \nabla J(\bar{u}) + h) \in \mathcal{A}(\bar{u}) \\ &\Rightarrow \exists \xi \in \mathcal{A}(\bar{u}), \quad (\bar{u} - \nabla J(\bar{u}) + h - \xi) \in K(\xi) \\ &\Rightarrow \exists \xi \in \mathcal{A}(\bar{u}), \quad [(\bar{u} - \xi) + (-\nabla J(\bar{u}) + h)] \in K(\bar{u}). \end{aligned}$$

Since $\bar{u} - \xi \in T_0(\bar{u}) = N_0(\bar{u})^\perp$ and $-\nabla J(\bar{u}) + h \in N_0(\bar{u}) \supset K(\bar{u})$, it now follows that for all h

$$h \in N_0(\bar{u}) \quad \text{and} \quad \|h\| \leq \epsilon \Rightarrow -\nabla J(\bar{u}) + h \in K(\bar{u}).$$

Thus, when Q(i) holds, the converse of Lemma 3 is also true, and the nondegeneracy condition $-\nabla J(\bar{u}) \in \text{ri } K(\bar{u})$ is *equivalent* to hypothesis (B) in [15]. This can also be shown by applying Theorem 2.8 in [10], after noting that $\mathcal{A}(\bar{u})$ is the relative interior of a quasipolyhedral face when Q(i) is satisfied. Similarly, when Q(ii) holds, it turns out that $\mathcal{A}(\bar{u})$ is an *open facet* \mathcal{F} in Ω [8], and for any such \mathcal{F} one can prove that

$$\text{int } P_\Omega^{-1}[\mathcal{F}] = \mathcal{F} + \text{ri } K(\mathcal{F}),$$

where $K(\mathcal{F}) = K(u)$ for all $u \in \mathcal{F}$; once again, Lemma 3 and its converse are corollaries of this more general result.

The following lemma leads immediately to a stability condition for fixed points of the SGP iterations (1), (2) and (3), (4).

LEMMA 4. *Let \bar{u} be a nondegenerate stationary point in a closed convex set Ω with a representation (4a) that satisfies the constraint qualification Q. Suppose that J and the functions g_j in (4a) are continuously Fréchet differentiable at \bar{u} . Then*

$$(15) \quad \exists \rho > 0, \quad \forall u \in B(\bar{u}, \rho) \cap \Omega, \quad [P_\Omega(u - \nabla J(u)) \in \mathcal{A}(\bar{u}) \quad \text{and} \quad \mathcal{J}(u) = \mathcal{J}(\bar{u})]$$

with $\mathcal{J}(u)$ defined by (4). Furthermore, if Q(i) is satisfied then (15) also holds with $\mathcal{J}(u)$ defined by (2).

Proof. Suppose that Q(ii) holds. Then, by Lemma 3 and the continuity of $\nabla J(\cdot)$ at \bar{u} ,

$$(16) \quad \exists \rho_1 > 0, \quad \forall u \in B(\bar{u}, \rho_1), \quad P_\Omega(u - \nabla J(u)) \in \mathcal{A}(\bar{u}).$$

The remaining portion of (15) is established by Lemma 3.5 in [16], whose proof bears repeating here. Observe first that $d(\cdot)$, $g_j(\cdot)$, and $\nabla g_j(\cdot)$ are continuous at \bar{u} , with $d(\bar{u}) = 0$. Hence for any fixed θ there is a $\rho_2 \in (0, \rho_1]$ and a $c < 0$ such that for all u ,

$$(17) \quad \begin{aligned} u \in B(\bar{u}, \rho_1) \cap \Omega &\Rightarrow \forall j \notin \mathcal{J}_0(\bar{u}), \quad g_j(u) \leq \frac{c}{2} \leq -\theta \|\nabla g_j(u)\| \epsilon(u) \\ &\Rightarrow \mathcal{J}(u) \subset \mathcal{J}_0(\bar{u}) \end{aligned}$$

with $\mathcal{J}(u)$ defined by (4). To prove the reverse inclusion, note that by (16) and the mean value theorem, we have, for all u ,

$$(18) \quad \begin{aligned} u \in B(\bar{u}, \rho_2) \cap \Omega &\Rightarrow \forall j \in \mathcal{J}_0(\bar{u}), \quad g_j(P_\Omega(u - \nabla J(u))) = 0 \\ &\Rightarrow \forall j \in \mathcal{J}_0(\bar{u}), \quad \exists \xi^j \in \Omega, \\ g_j(u) &\geq -(\|\nabla g_j(u)\| + \|\nabla g_j(\xi^j) - \nabla g_j(u)\|)d(u), \quad \text{and} \quad \|\xi^j - u\| \leq d(u). \end{aligned}$$

Furthermore, by Q(ii), $\|\nabla g_j(\bar{u})\| > 0$ for all $j \in \mathcal{J}_0(\bar{u})$. Consequently for any fixed $\theta > 1$, there is a $\rho \in (0, \rho_2]$ such that for all u ,

$$(19) \quad \begin{aligned} u \in B(\bar{u}, \rho) \cap \Omega &\Rightarrow \forall j \in \mathcal{J}_0(\bar{u}), \quad g_j(u) \geq -\theta \|\nabla g_j(u)\| \epsilon(u) \\ &\Rightarrow \mathcal{J}_0(\bar{u}) \subset \mathcal{J}(u) \end{aligned}$$

with $\mathcal{J}(u)$ defined by (4).

Now suppose that Q(i) holds. In this case, (16) follows from Lemma 3 as before, and (17) is therefore true once again for any fixed θ , and thus for $\mathcal{J}(u)$ defined by (2) or (4). Conversely, since affine g_j 's have constant gradients, $\nabla g_j = a^j$, the estimates in (16) establish (17) for any fixed $\theta \geq 1$ and hence for $\mathcal{J}(u)$ defined by (2) or (4). \square

Note 6. If τ is fixed in $(0, \infty)$ and $\epsilon(\cdot)$ is replaced in (2) and (4) by any continuous measure of nonstationarity satisfying

$$\epsilon(u) \geq \|u - P_\Omega(u - \tau \nabla J(u))\|$$

near nondegenerate stationary points \bar{u} , then the estimates in (15) continue to hold provided $P_\Omega(u - \nabla J(u))$ is replaced by $P_\Omega(u - \tau \nabla J(u))$. Since this alteration has no impact on the subsequent local convergence analyses, the function $\epsilon(\cdot)$ in (2) and (4) is merely the prototype for a large class of admissible nonstationarity measures for SGP iterations (1), (2) and (3), (4). In fact, we wonder whether the restriction $\theta > 1$ imposed in (4) is again superfluous, as it was in the global analyses of [17]. This would certainly be true if there is a $\theta > 1$ and sufficiently small positive numbers τ and ρ such that for all u ,

$$u \in B(\bar{u}, \rho) \cap \Omega \Rightarrow \theta \|u - P_\Omega(u - \tau \nabla J(u))\| \leq \|u - P_\Omega(u - \nabla J(u))\|.$$

Unfortunately, this proposition is generically false for nondegenerate stationary points in the relative boundary of sets (4a) satisfying Q. For example, in $\mathcal{U} = \mathbb{R}^2$ let Ω be the nonpositive orthant $\{(u_1, u_2) : u_1 \leq 0, u_2 \leq 0\}$ and let $J(u) = -u_1 - u_2$. Then Ω satisfies Q, and J has a nondegenerate stationary point (and global minimizer) at $\bar{u} = (0, 0)$. At boundary points $(u_1, 0)$ near \bar{u} in Ω , it can be seen that for all τ ,

$$\begin{aligned} \sqrt{|u_1|} &\leq \tau \leq 1 \Rightarrow P_\Omega(u - \tau \nabla J(u)) = \bar{u} \\ &\Rightarrow \|u - P_\Omega(u - \tau \nabla J(u))\| = \|u - P_\Omega(u - \nabla J(u))\|. \end{aligned}$$

Thus for any fixed $\theta > 1$ and $\tau \in (0, 1)$, every deleted neighborhood of \bar{u} in Ω contains points at which

$$\theta \|u - P_\Omega(u - \theta \nabla J(u))\| > \|u - P_\Omega(u - \nabla J(u))\|.$$

Since similar counterexamples are readily constructed in nonpolyhedral sets (4a), there seems to be no easy way around the restriction $\theta > 1$ in (4).

LEMMA 5. *Assume that Ω is a closed convex set with a representation (4a) satisfying the constraint qualification Q. Let \bar{u} be a uniformly proper local minimizer and a nondegenerate stationary point for J in Ω , and suppose that J and the functions g_j in (4a) are continuously Fréchet differentiable at \bar{u} . Then \bar{u} is a stable fixed point for the SGP iteration (3), (4). Furthermore, if Q(i) is satisfied then \bar{u} is also a stable fixed point for (1), (2).*

Proof. By Lemma 3 and its corollary in [17], \bar{u} is a fixed point of the SGP iterations in question, and stability will follow from the descent property and a Lyapunov

construction, provided the associated maps $u \rightarrow P_\Omega(u + \sigma v)$ are continuous at \bar{u} , uniformly in the parameters N, s_N and S_T admitted by (3), (4) or (1), (2), respectively.

For any map $u \rightarrow P_\Omega(u + \sigma v)$ satisfying (3), (4), we have

$$\begin{aligned}
 (20a) \quad \|P_\Omega(u + \sigma v) - \bar{u}\| &= \|P_\Omega(u + \sigma v) - P_\Omega(\bar{u} - \sigma s_N \nabla J(\bar{u}))\| \\
 &\leq \|u - \bar{u} + \sigma(v + s_N \nabla J(\bar{u}))\| \\
 &\leq \|u - \bar{u}\| + \alpha(\mu_1 + \mu_3)\|P_{T(u)}\nabla J(u)\| + \alpha\mu_3\|\nabla J(u) - \nabla J(\bar{u})\|
 \end{aligned}$$

since $N^\perp = T \subset T(u)$. If Q(ii) holds, then Lemma 3.2 and Theorem 3.1 in [15] establish that

$$(20b) \quad \lim_{\substack{u \rightarrow \bar{u} \\ u \in \Omega}} P_{T(u)}\nabla J(u) = 0.$$

Hence $u \rightarrow P_\Omega(u + \sigma v)$ is seen to be continuous at \bar{u} , uniformly in N, s_N and S_T when Q(ii) holds. Given any $\epsilon > 0$, it is now possible to construct a corresponding set $\mathcal{I}_\epsilon \subset B(\bar{u}, \epsilon) \cap \Omega$ such that \mathcal{I}_ϵ is invariant under every such map, and \bar{u} lies in the interior of \mathcal{I}_ϵ relative to Ω ; evidently, this construction will prove that \bar{u} is stable for (3), (4). With reference to Definition 2, choose $\rho > 0$ and $a(\cdot)$ so that for all u ,

$$u \in B(\bar{u}, \rho) \cap \Omega \Rightarrow J(u) - J(\bar{u}) \geq a(\|u - \bar{u}\|).$$

Fix ϵ in $(0, \rho]$. Then for some $r > 0$, and all u, N, T, s_N , and S_T ,

$$u \in B(\bar{u}, r) \cap \Omega \quad \text{and} \quad (3), (4) \Rightarrow \|P_\Omega(u + \sigma v) - \bar{u}\| \leq \epsilon.$$

Construct the corresponding set

$$\mathcal{I}_\epsilon = \{u \in \Omega : \|u - \bar{u}\| \leq \epsilon \text{ and } J(u) - J(\bar{u}) < a(r)\}.$$

By the descent property and the properties of $a(\cdot)$, it follows that for all u, N, T, s_N, S_T ,

$$\begin{aligned}
 u \in \mathcal{I}_\epsilon \text{ and } (3), (4) &\Rightarrow (a(\|u - \bar{u}\|) \leq J(u) - J(\bar{u}) < a(r)) \\
 &\quad \text{and } J(P_\Omega(u + \sigma v)) - J(\bar{u}) < a(r) \\
 &\Rightarrow (\|u - \bar{u}\| \leq r, \|P_\Omega(u + \sigma v) - \bar{u}\| \leq \epsilon, \\
 &\quad \text{and } J(P_\Omega(u + \sigma v)) - J(\bar{u}) < a(r)) \\
 &\Rightarrow P_\Omega(u + \sigma v) \in \mathcal{I}_\epsilon.
 \end{aligned}$$

Thus \mathcal{I}_ϵ is invariant under any map $u \rightarrow P_\Omega(u + \sigma v)$ satisfying (3), (4); moreover, since J is continuous at \bar{u} , there is a $\Delta \in (0, r]$ such that

$$B(\bar{u}, \Delta) \cap \Omega \subset \mathcal{I}_\epsilon \subset B(\bar{u}, \epsilon) \cap \Omega.$$

By construction, if $u^1 \in B(\bar{u}, \Delta) \cap \Omega$ and if $\{u^i\}$ is generated by (3), (4), then u^i must remain in \mathcal{I}_ϵ for $i \geq 1$.

Similarly, for any map $u \rightarrow P_\Omega(u + \sigma v)$ satisfying (1), (2), it can be seen that

$$\begin{aligned}
 (21a) \quad \|P_\Omega(u + \sigma v) - \bar{u}\| &\leq \|u - \bar{u}\| + \alpha(\mu_1 + \mu_3)\|P_{C(u)}(-\nabla J(u))\| + \alpha\mu_3\|\nabla J(u) - \nabla J(\bar{u})\|
 \end{aligned}$$

Furthermore, if Q(i) holds, then Lemma 4 implies that for u near \bar{u} in Ω ,

$$(21b) \quad C(u)^* = C(\bar{u})^* = K(\bar{u});$$

therefore,

$$(21c) \quad \begin{aligned} \|P_{C(u)}(-\nabla J(u))\| &= \|P_{C(\bar{u})}(-\nabla J(\bar{u})) + P_{C(\bar{u})}(-\nabla J(u)) - P_{C(\bar{u})}(-\nabla J(\bar{u}))\| \\ &\leq \|\nabla J(u) - \nabla J(\bar{u})\|. \end{aligned}$$

Hence, $u \rightarrow P_\Omega(u + \sigma v)$ is continuous at \bar{u} uniformly in N, s_N , and S_T , and a repetition of the foregoing argument proves that \bar{u} is stable for (1), (2), and hence for (3), (4) (see Note 1 in [17]). \square

Lemma 5 immediately yields a complete characterization of nondegenerate asymptotically stable fixed points for (3), (4) and (1), (2) in finite-dimensional spaces.

THEOREM 2. *Assume that $\dim \mathcal{U} < \infty$ and that Ω is a closed convex set with a representation (4a) satisfying the constraint qualification Q. Let \bar{u} be a nondegenerate stationary point for J in Ω and suppose that J and the functions g_j in (4a) are continuously Fréchet differentiable at \bar{u} . Then \bar{u} is an asymptotically stable fixed point for the SGP iteration (3), (4) if and only if \bar{u} is a proper local minimizer and an isolated stationary point for J in Ω . Furthermore, if Q(i) is satisfied, then the same conclusion holds for (1), (2).*

Proof. By Theorem 1, an asymptotically stable fixed point for any SGP iteration (1) must be a proper local minimizer and an isolated stationary point. Conversely, suppose that \bar{u} is a proper local minimizer. Since J is differentiable at \bar{u} and hence continuous near \bar{u} , it can be seen that \bar{u} is a uniformly proper local minimizer (see Note 2). Since \bar{u} is nondegenerate, Lemma 4 asserts that \bar{u} is stable for (3), (4). Now suppose that for some $\epsilon > 0$, \bar{u} is the only stationary point in $B(\bar{u}, \epsilon) \cap \Omega$. Choose $\Delta \in (0, \epsilon]$ so that every sequence that begins in $B(\bar{u}, \Delta) \cap \Omega$ and is generated by (3), (4) will remain in $B(\bar{u}, \epsilon) \cap \Omega$. All such sequences must converge to \bar{u} , in view of Theorem 2 in [17] and the compactness of $B(\bar{u}, \epsilon) \cap \Omega$. When Q(i) holds, the same argument applies to (1), (2). \square

Two variants of Theorem 2 will now be established in arbitrary real Hilbert spaces \mathcal{U} , with the aid of the following supplement to Lemmas 5–8 in [17].

LEMMA 6. *Let \bar{u} be a nondegenerate stationary point for J in a closed convex set Ω with a representation (4a) that satisfies the constraint qualification Q. Assume that J and the functions g_j in (4a) are continuously Fréchet differentiable at \bar{u} . If Q(ii) holds and v is determined by (3b)–(3j) and (4), then for some $\Delta > 0$, $\rho > 0$ and $\kappa > 0$, and all $\sigma \in (0, \Delta]$ and $u \in B(\bar{u}, \rho) \cap \Omega$,*

$$(22a) \quad \langle x, P_\Omega(u + \sigma v) - u \rangle \geq \langle x, v \rangle \sigma + \|x\| \eta(\sigma, u, v)$$

and

$$(22b) \quad \begin{aligned} \langle \nabla J(u), u - P_\Omega(u + \sigma v) \rangle &\geq [s_N^{-1} \sigma^{-2} \|u + \sigma v_T - P_\Omega(u + \sigma v)\|^2 - \langle P_T \nabla J(u), v_T \rangle] \sigma \\ &\quad + s_N^{-1} \|x\| \eta(\sigma, u, v) \end{aligned}$$

with

$$(22c) \quad x = (v_T - s_N P_T \nabla J(u)) \in T \subset T(u)$$

and

$$(22d) \quad \eta(\sigma, u, v) = -\kappa \|\nabla g(P_\Omega(u + \sigma v)) - \nabla g(u)\|_2 \sigma.$$

Furthermore if Q(i) holds and v is determined by (1b)–(1l) and (2), then for some $\Delta > 0$ and $\rho > 0$, and all $\sigma \in (0, \Delta]$ and $u \in B(\bar{u}, \rho) \cap \Omega$,

$$(23a) \quad \langle x, P_\Omega(u + \sigma v) - u \rangle \geq \langle x, v \rangle \sigma$$

and

$$(23b) \quad \langle \nabla J(u), u - P_\Omega(u + \sigma v) \rangle \geq (s_N \sigma)^{-1} \|u + \sigma v_T - P_\Omega(u + \sigma v)\|^2 + \langle P_{N^*}(-\nabla J(u)), v_T \rangle \sigma$$

with

$$(23c) \quad x = v_T + s_N P_{N^*}(-\nabla J(u)) \in T \subset C(u).$$

Proof. The estimates (22b) and (23b) derive from the inequality (8) in [17] and (22a) and (23a), as explained in the proof of Lemma 2 in [17]. The inequalities (22a) and (23a) are established as follows. Recall first that for all $\sigma \geq 0$, $u \in \Omega$, $v \in \mathcal{U}$,

$$(24a) \quad (u + \sigma v - P_\Omega(u + \sigma v)) \in K(P_\Omega(u + \sigma v))$$

and

$$(24b) \quad \|P_\Omega(u + \sigma v) - \bar{u}\| \leq \|u - \bar{u}\| + \|v\| \sigma$$

Now suppose that Q(ii) holds. An examination of the first part of the proof of Lemma 7 in [17] will show that for some $M > 0$, $\Delta_1 > 0$, $\rho_1 > 0$, $\kappa > 0$, and for all σ, u, v

$$(25) \quad u \in B(\bar{u}, \rho_1) \cap \Omega, \text{ (3b)–(3j), and (4)} \Rightarrow \|v\| \leq (\mu_1 + \mu_3) \|\nabla J(u)\| \leq M$$

and

$$\sigma \in (0, \Delta_1], \quad u \in B(\bar{u}, \rho_1) \cap \Omega, \text{ (3b)–(3j), and (4)} \Rightarrow$$

$$\forall x \in T(u), \langle x, P_\Omega(u + \sigma v) - u \rangle \geq \langle x, v \rangle \sigma + \|x\| \eta(\sigma, u, v) - \left| \langle x, \sum_{j=1}^m c_j \nabla g_j(u) \rangle \right|,$$

where c is a nonnegative vector in \mathbb{R}^m , depending on σ, u, v and satisfying

$$(j \notin \mathcal{J}(P_\Omega(u + \sigma v))) \Rightarrow c_j = 0, \quad j = 1, \dots, m.$$

This much is true for any $\bar{u} \in \Omega$. Moreover, if \bar{u} is a nondegenerate stationary point, then in view of (24b), (25), and Lemma 4, there are numbers $\Delta \in (0, \Delta_1]$ and $\rho \in (0, \rho_1]$, such that for all σ, u, v ,

$$\sigma \in (0, \Delta], \quad u \in B(\bar{u}, \rho) \cap \Omega, \text{ (3b)–(3j) and (4)} \Rightarrow \mathcal{J}(u) = \mathcal{J}_0(\bar{u}) = \mathcal{J}(P_\Omega(u + \sigma v))$$

$$\Rightarrow \sum_{j=1}^m c_j \nabla g_j(u) \in N(u)$$

$$\Rightarrow \forall x \in T(u), \langle x, P_\Omega(u + \sigma v) - u \rangle \geq \langle x, v \rangle \sigma + \|x\| \eta(\sigma, u, v)$$

On the other hand, suppose that Q(i) holds. Then according to Lemma 4 and (24), there are numbers $M > 0$, $\Delta > 0$ and $\rho > 0$ such that for all σ, u, v ,

$$u \in B(\bar{u}, \rho) \cap \Omega, (1B) - (1L), \text{ and } (2) \Rightarrow \|v\| \leq (\mu_1 + \mu_3) \|\nabla J(u)\| \leq M$$

and

$$\begin{aligned} \sigma \in (0, \Delta], u \in B(\bar{u}, \rho) \cap \Omega, (1B) - (1L) \text{ and } (2) &\Rightarrow C(u)^* = K(u) = C(P_\Omega(u + \sigma v))^* \\ &\Rightarrow (u + \sigma v - P_\Omega(u + \sigma v)) \in C(u)^* \\ &\Rightarrow \forall x \in C(u), \langle x, u + \sigma v - P_\Omega(u + \sigma v) \rangle \leq 0. \quad \square \end{aligned}$$

With Lemma 6, it is now possible to prove that the step lengths σ generated by (3), (4) and (1), (2) are bounded away from zero near nondegenerate stationary points \bar{u} , provided J and the constraint functions g_j have locally Lipschitz continuous gradients near \bar{u} . A bound of this sort is needed for the active constraint identification result in Proposition 3 of [15], and plays a similar part here in the proofs of Theorems 3 and 4 to follow.

LEMMA 7. *Let \bar{u} be a nondegenerate stationary point for J in a closed convex set Ω with a representation (4a) satisfying the constraint qualification Q. If Q(ii) holds and the gradients of J and the constraint functions g_j in (4a) are Lipschitz continuous near \bar{u} , then the step lengths σ generated by (3), (4) are bounded away from 0 near \bar{u} . Similarly, if Q(i) holds and the gradient of J is Lipschitz continuous near \bar{u} then the step lengths σ generated by (1), (2) are likewise bounded away from 0.*

Proof. Suppose that Q(ii) holds and σ is determined by (3), (4) at $u \in \Omega$. If u is stationary, then $\sigma = \alpha$. Assume that u is not stationary and that $\sigma \leq \alpha\beta$. Then (3k) implies that

$$(26) \quad \begin{aligned} J(u) - J(P_\Omega(u + \beta^{-1}\sigma v)) &< \delta\{(s_N\beta^{-1}\sigma)^{-1}\|u + \beta^{-1}\sigma v_T - P_\Omega(u + \beta^{-1}\sigma v)\|^2 \\ &\quad - \langle P_T \nabla J(u), v_T \rangle \beta^{-1}\sigma\} \end{aligned}$$

With reference to (10), observe that

$$(27a) \quad \begin{aligned} \|P_\Omega(u + \beta^{-1}\sigma v) - \bar{u}\| &\leq \|u - \bar{u}\| + \beta^{-1}\alpha(\mu_1 + \mu_3)\|P_{T(u)} \nabla J(u)\| \\ &\quad + \beta^{-1}\alpha\|\nabla J(u) - \nabla J(\bar{u})\| \end{aligned}$$

with

$$(27b) \quad \lim_{u \rightarrow \bar{u}} P_{T(u)} \nabla J(u) = 0.$$

Hence, there are numbers $\Delta > 0$, $\rho > 0$, $\kappa > 0$, and $\rho_1 \in (0, \rho]$ such that the estimates (20) hold, and for all $u \in B(\bar{u}, \rho_1) \cap \Omega$,

$$(28a) \quad P_\Omega(u + \beta^{-1}\sigma v) \in B(\bar{u}, \rho) \cap \Omega,$$

$$(28b) \quad J(u) - J(P_\Omega(u + \beta^{-1}\sigma v)) \geq \langle \nabla J(u), u - P_\Omega(u + \beta^{-1}\sigma v) \rangle - \frac{1}{2} L_J \|P_\Omega(u + \beta^{-1}\sigma v) - u\|^2,$$

and

$$(28c) \quad \|\nabla g(P_\Omega(u + \beta^{-1}\sigma v)) - \nabla g(u)\|_2 \leq L_g \|P_\Omega(u + \beta^{-1}\sigma v) - u\|,$$

where L_J and L_g are local Lipschitz constants for ∇J and ∇g . According to (22) and (28), it follows that for all $u \in B(\bar{u}, \rho_1) \cap \Omega$, either $\sigma > \beta \min\{\alpha, \Delta\}$, or

$$\begin{aligned}
 (29a) \quad & (1 + \beta^{-1}\alpha\kappa L_g)\|x\| \|P_\Omega(u + \beta^{-1}\sigma v) - u\| \geq (\|v_T\|^2 + \mu_0\mu_2\|P_T\nabla J(u)\|^2)\beta^{-1}\sigma \\
 & \geq \min\left\{1, \frac{\mu_0\mu_2}{2\mu_3(\mu_1 + \mu_3)}\right\} \|x\|^2\beta^{-1}\sigma \\
 & = \frac{\mu_0\mu_2}{2\mu_3(\mu_1 + \mu_3)} \|x\|^2\beta^{-1}\sigma
 \end{aligned}$$

and

$$\begin{aligned}
 (29b) \quad & \langle \nabla J(u), u - P_\Omega(u + \beta^{-1}\sigma v) \rangle \geq (s_N\beta^{-1}\sigma)^{-1} \|u + \beta^{-1}\sigma v_T - P_\Omega(u + \beta^{-1}\sigma v)\|^2 \\
 & - \langle P_T\nabla J(u), v_T \rangle \beta^{-1}\sigma - s_N^{-1}\kappa L_g\|x\| \|P_\Omega(u + \beta^{-1}\sigma v) - u\|\beta^{-1}\sigma.
 \end{aligned}$$

The estimates (26), (28), (29), and the parallelogram law imply that for all $u \in B(\bar{u}, \rho_1) \cap \Omega$, either $\sigma > \beta \min\{\alpha, \Delta\}$ or u is nonstationary and

$$\begin{aligned}
 (30a) \quad & c_1\|P_\Omega(u + \beta^{-1}\sigma v) - u\|^2\beta^{-1}\sigma \geq (1 - \delta)[\mu_3^{-1}\|u + \beta^{-1}\sigma v_T - P_\Omega(u + \beta^{-1}\sigma v)\|^2 \\
 & \quad + \mu_0\mu_1^{-2}\|v_T\|^2(\beta^{-1}\sigma)^2] \\
 & \geq c_2[\|u + \beta^{-1}\sigma v_T - P_\Omega(u + \beta^{-1}\sigma v)\|^2 + \|v_T\|^2(\beta^{-1}\sigma)^2] \\
 & \geq c_2\|P_\Omega(u + \beta^{-1}\sigma v) - u\|^2,
 \end{aligned}$$

where

$$(30b) \quad c_1 = \frac{1}{2}L_J + 2\mu_3\mu_0^{-1}\mu_2^{-2}(\mu_1 + \mu_3)\kappa L_g(1 + \beta^{-1}\alpha\kappa L_g)$$

and

$$(30c) \quad c_2 = \frac{1}{2}(1 - \delta)\min\{\mu_3^{-1}, \mu_0\mu_1^{-2}\}.$$

However, if u is nonstationary then Corollary 1 of Lemma 3 in [17] guarantees that $\|P_\Omega(u + \beta^{-1}\sigma v) - u\| > 0$ and thus

$$\sigma \geq \beta c_2 c_1^{-1} > 0.$$

Consequently, for all $u \in B(\bar{u}, \rho_1) \cap \Omega$,

$$\sigma \geq \min\{\alpha, \beta\Delta, \beta c_2 c_1^{-1}\} > 0.$$

A simpler but analogous argument applies when Q(i) is satisfied and σ is determined by (1), (2). As before, $\sigma = \alpha$ when u is stationary. If u is not stationary and $\sigma \leq \alpha\beta$ then (1m) implies a counterpart of (26) with $P_T\nabla J(u)$ replaced by $-P_{N^*}(-\nabla J(u))$. Moreover, with reference to (21), we obtain

$$\|P_\Omega(u + \beta^{-1}\sigma v) - \bar{u}\| \leq \|u - \bar{u}\| + \alpha(\mu_1 + \mu_3)\|P_{C(u)}(-\nabla J(u))\| + \alpha\mu_3\|\nabla J(u) - \nabla J(\bar{u})\|$$

with

$$\lim_{u \rightarrow \bar{u}} \|P_{C(u)}(-\nabla J(u))\| = 0$$

in place of (27). Hence there are numbers $\Delta > 0$, $\rho > 0$, and $\rho_1 \in (0, \rho]$ such that (42a), (42b) holds with (23). In view of (23), it can be seen that for all $u \in B(\bar{u}, \rho_1) \cap \Omega$, either $\sigma > \beta \min\{\alpha, \Delta\}$ or,

$$\begin{aligned} \langle \nabla J(u), u - P_\Omega(u + \beta^{-1}\sigma v) \rangle &\geq (s_N \beta^{-1}\sigma)^{-1} \|u + \beta^{-1}\sigma v_T - P_\Omega(u + \beta^{-1}\sigma v)\|^2 \\ &\quad + \langle P_{N^*}(-\nabla J(u)), v_T \rangle \beta^{-1}\sigma. \end{aligned}$$

Together, these estimates and the parallelogram law imply that for all $u \in B(\bar{u}, \rho_1) \cap \Omega$,

$$\sigma \geq \min\{\alpha, \beta\Delta, \beta c_2 c_1^{-1}\} > 0$$

with

$$c_1 = \frac{1}{2} L_J$$

and

$$c_2 = \frac{1}{2}(1 - \delta) \min\{\mu_3^{-1}, \mu_0 \mu_1^{-2}\}. \quad \square$$

THEOREM 3. *Assume that Ω is a closed convex set with a representation (4a) that satisfies the constraint qualification Q. Let \bar{u} be a nondegenerate stationary point and a uniformly proper local minimizer for J in Ω , and suppose that the gradients of J and the functions g_j in (4a) are Lipschitz continuous near \bar{u} in Ω . In addition, assume that \bar{u} is either a uniformly isolated stationary point, or more generally, a uniformly isolated zero of the nonstationarity measure $d(\cdot)$ in the active constraint manifold $\mathcal{A}(\bar{u})$. Then \bar{u} is an asymptotically stable fixed point for the SGP iteration (3), (4). Moreover, if Q(i) holds then \bar{u} is an asymptotically stable fixed point for (1), (2) as well. In either case, every associated SGP sequence $\{u^i\}$ that converges to \bar{u} is eventually confined to the active constraint manifold $\mathcal{A}(\bar{u})$.*

Proof. Suppose that Q(ii) holds. Then by Lemma 5, \bar{u} is a stable fixed point for (3), (4). Suppose that \bar{u} is a uniformly isolated zero of $d(\cdot)$ in $\mathcal{A}(\bar{u})$. Then for some $\rho_1 > 0$, some nondecreasing positive-definite real function $a(\cdot)$, and all u ,

$$(31) \quad u \in B(\bar{u}, \rho_1) \cap \mathcal{A}(\bar{u}) \Rightarrow d(u) \geq a(\|u - \bar{u}\|).$$

According to Lemma 7, there are numbers $\rho_2 \in (0, \rho_1]$, $\alpha_1 > 0$ and $\alpha_2 > 0$ such that for all u ,

$$u \in B(\bar{u}, \rho_2) \cap \Omega \text{ and } (3) - (4) \Rightarrow \alpha_2 \geq \sigma s_N \geq \alpha_1.$$

With reference to the proof of Lemma 5, note that for (3), (4),

$$(32a) \quad P_\Omega(u + \sigma v) = P_\Omega(\bar{u} - \sigma s_N \nabla J(\bar{u}) + h(u))$$

with

$$(32b) \quad \|h(u)\| \leq \|u - \bar{u}\| + \alpha(\mu_1 + \mu_3) \|P_{T(u)} \nabla J(u)\| + \alpha \mu_3 \|\nabla J(u) - \nabla J(\bar{u})\|;$$

therefore,

$$(32c) \quad \lim_{\substack{u \rightarrow \bar{u} \\ u \in \Omega}} h(u) = 0.$$

Hence by Lemma 3, there is a $\rho_3 \in (0, \rho_2]$ such that for all u ,

$$u \in B(\bar{u}, \rho_3) \cap \Omega \text{ and } (3) - (4) \Rightarrow P_\Omega(u + \sigma v) \in \mathcal{A}(\bar{u}).$$

Furthermore, since \bar{u} is stable, there is a $\rho_4 \in (0, \rho_3]$ such that if $u^1 \in B(\bar{u}, \rho_4) \cap \Omega$ and $\{u^i\}$ is generated by (3), (4), then $u^i \in B(\bar{u}, \rho_3) \cap \Omega$ for all $i \geq 1$; therefore $u^i \in B(\bar{u}, \rho_3) \cap \mathcal{A}(\bar{u})$ for all $i \geq 2$. For all such sequences $\{u^i\}$, the corresponding step lengths σ^i are bounded away from zero and Lemma 4 in [17] implies that

$$\lim_{i \rightarrow \infty} d(u^i) = 0;$$

therefore,

$$\lim_{i \rightarrow \infty} \|u^i - \bar{u}\| = 0$$

in view of (31).

Now suppose that Q(i) holds and \bar{u} is a uniformly isolated zero of $d(\cdot)$ in $\mathcal{A}(\bar{u}) = \bar{u} + K(\bar{u})^\perp$. For (1), (2), the estimate (32) is replaced by

$$P_\Omega(u + \sigma v) = P_\Omega(\bar{u} - \sigma s_N \nabla J(\bar{u}) + h(u))$$

with

$$\|h(u)\| \leq \|u - \bar{u}\| + \alpha(\mu_1 + \mu_3) \|P_{C(u)}(-\nabla J(u))\| + \alpha\mu_3 \|\nabla J(u) - \nabla J(\bar{u})\|;$$

therefore,

$$\lim_{u \rightarrow \bar{u}} h(u) = 0.$$

Lemmas 3, 5, and 7 are then used as before to show that \bar{u} is asymptotically stable for (1), (2) and hence (3), (4) (see Note 1 in [17]), and that every corresponding SGP sequence $\{u^i\}$ which converges to \bar{u} , eventually enters and remains in $\mathcal{A}(\bar{u})$. \square

THEOREM 4. *Assume that Ω is a closed convex set with a representation (4a) that satisfies the constraint qualification Q. Let \bar{u} be a nonsingular local minimizer for J in Ω . Then \bar{u} is an asymptotically stable fixed point for the SGP iteration (3), (4). Moreover, if Q(i) holds then \bar{u} is an asymptotically stable fixed point for (1), (2) as well. In either case, every associated SGP sequence $\{u^i\}$ that converges to \bar{u} is eventually confined to the active constraint manifold $\mathcal{A}(\bar{u})$. Furthermore, if $\{u^i\}$ converges to \bar{u} , and if $u^i \neq \bar{u}$ for all i , then for some $r \in [0, 1)$ and some positive real sequence $\{\rho_i\}$,*

$$(33a) \quad \limsup_{i \rightarrow \infty} \frac{J(u^{i+1}) - J(\bar{u})}{J(u^i) - J(\bar{u})} = r$$

and

$$(33b) \quad \|u^i - \bar{u}\|^2 \leq \rho_i, \quad i = 1, 2, \dots$$

with

$$(33c) \quad \limsup_{i \rightarrow \infty} \frac{\rho_{i+1}}{\rho_i} = r.$$

Proof. According to Definition 3 and the estimate (11a) in Lemma 2, \bar{u} is a nondegenerate stationary point and a uniformly proper local minimizer; moreover, the gradients of J and the functions g_j are Lipschitz continuous near \bar{u} in Ω . All of our claims except (33) will then follow from Theorem 3 if it can be shown that \bar{u} is also a uniformly isolated zero of $d(\cdot)$ in $\mathcal{A}(\bar{u})$. When Q(i) holds, this can be proved with Lemma 3.1 in [8], or more directly as follows. Note that by Lemma 4,

$$P_\Omega(u - \nabla J(u)) \in \mathcal{A}(\bar{u}) = \bar{u} + T_0(\bar{u});$$

therefore,

$$[u - \nabla J(u) - P_\Omega(u - \nabla J(u))] \in K(P_\Omega(u - \nabla J(u)) = K(\bar{u}) \subset T_0(\bar{u})^\perp$$

for u sufficiently near \bar{u} in Ω ; moreover, if u is also in $\mathcal{A}(\bar{u})$, then

$$u - P_\Omega(u - \nabla J(u)) \in T_0(\bar{u}).$$

Consequently, for u near \bar{u} in $\mathcal{A}(\bar{u})$ we have

$$(u - P_\Omega(u - \nabla J(u)) - P_{T_0(\bar{u})} \nabla J(u)) \in T_0(\bar{u}) \cap T_0(\bar{u})^\perp$$

and hence

$$u - P_\Omega(u - \nabla J(u)) - P_{T_0(\bar{u})} \nabla J(u) = 0;$$

therefore,

$$d(u) = \|P_{T_0(\bar{u})} \nabla J(u)\| = \|P_{T_0(u)} \nabla J(u)\|.$$

The estimate (11b) in Lemma 2 now implies that \bar{u} is a uniformly isolated zero of $d(\cdot)$ in $\mathcal{A}(\bar{u})$. Similarly, if Q(ii) holds, then Lemma 2 in [9] asserts that

$$d(u) \geq c \|P_{T_0(u)} \nabla J(u)\|$$

for some $c > 0$ and all u near \bar{u} in $\mathcal{A}(\bar{u})$, in which case (11b) insures once again that \bar{u} is a uniformly isolated zero of $d(\cdot)$ in $\mathcal{A}(\bar{u})$.

To prove (33) suppose first that Q(ii) holds. Then, according to Lemma 3 in [9],

$$(34) \quad \langle P_{T_0(u)} \nabla J(u), u - \bar{u} \rangle \geq J(u) - J(\bar{u})$$

for u sufficiently near \bar{u} in $\mathcal{A}(\bar{u})$. In view of (11a) this implies that

$$\|P_{T_0(u)} \nabla J(u)\|^2 \geq c_1 (J(u) - J(\bar{u}))$$

for u near \bar{u} in $\mathcal{A}(\bar{u})$. Hence if $\{u^i\}$ is generated by (3), (4) and converges to \bar{u} , the inequalities

$$J(u^i) - J(u^{i+1}) \geq \delta \mu_0 c_1 (J(u^i) - J(\bar{u}))$$

and

$$J(u^i) - J(\bar{u}) \geq c_1 \|u^i - \bar{u}\|^2$$

must hold eventually. This establishes (33) for (3), (4). On the other hand, suppose that Q(i) holds. Since \bar{u} is nonsingular, the restriction of J to $\mathcal{A}(\bar{u}) = \bar{u} + T_0(\bar{u})$ is convex near \bar{u} ; therefore, (34) is satisfied once again near \bar{u} in $\mathcal{A}(\bar{u})$. A repetition of the argument following (34) will prove (33) for (1), (2) and hence for (3), (4) (see Note 1 in [17]). \square

Note 7. When Q(i) holds, Theorem 2 and Lemma 3.2 in [8] can be used to establish sublinear convergence rate estimates for (1), (2) and (3), (4) near certain asymptotically stable singular minimizers \bar{u} .

4. Newtonian convergence acceleration. The linear convergence rate results in Theorem 4 are “worst case” estimates for general SGP iterations (1), (2) and (3), (4) near nonsingular minimizers; in particular, these estimates apply to the original unscaled Goldstein–Levitin–Polyak GP iteration obtained when $s_N = 1$ and $N = \mathcal{U}$ in (1). The analysis in this section now focuses more narrowly on SGP iterations (3), (4) that employ the smallest admissible subspaces $N = N(u)$, and hence the largest admissible scaling subspaces $T = T(u) = N(u)^\perp$. On the face of it, these algorithms offer the greatest latitude of choice for local convergence acceleration within the scheme (3), (4), and it is shown below that the special SGP iteration (3)–(6) is indeed locally superlinearly convergent to nonsingular minimizers in closed convex sets with representations (4a) satisfying Q. Moreover, when Q(i) holds, a variant of Proposition 3 in [15] is obtained by demonstrating that, near nondegenerate stationary points \bar{u} at which ∇J is continuous, every SGP iteration (1), (2) with $N = C(u)^*$ is locally equivalent to some SGP iteration (3), (4) with $N = N(u)$. This last result will be proved first.

LEMMA 8. *Assume that Ω is a polyhedral convex set with a representation (4a) that satisfies the constraint qualification Q(i). Let \bar{u} be a nondegenerate stationary point for J in Ω and suppose that J is continuously Fréchet differentiable at \bar{u} . Then there is a $\rho > 0$ such that in $B(\bar{u}, \rho) \cap \Omega$, every SGP map $u \rightarrow P_\Omega(u + \sigma v)$ satisfying (1), (2) with $N = C(u)^*$ coincides with some SGP map $u \rightarrow P_\Omega(u + \sigma v)$ satisfying (3), (4) with $N = N(u)$.*

Proof. For $u \in \Omega$, let

$$x(u) \triangleq P_{C(u)}(-\nabla J(u)), \quad y(u) \triangleq P_{C(u)^*}(-\nabla J(u)).$$

It suffices to show that for some $\rho > 0$ and all $u \in B(\bar{u}, \rho) \cap \Omega$,

$$(35a) \quad y(u)^\perp \cap C(u) = T(u),$$

$$(35b) \quad x(u) = -P_{T(u)}\nabla J(u),$$

$$(35c) \quad y(u) = -P_{N(u)}\nabla J(u).$$

According to Lemma 4, there is a $\rho_1 > 0$ such that for all $u \in B(\bar{u}, \rho_1) \cap \Omega$,

$$(36) \quad C(u)^* = K(\bar{u}) \quad \text{and} \quad N(u) = [K(\bar{u})].$$

Hence (35a) will follow if it can be shown that for some $\rho \in (0, \rho_1]$ and all $u \in B(\bar{u}, \rho) \cap \Omega$

$$y(u)^\perp \cap K(\bar{u})^* = K(\bar{u})^\perp.$$

Note that $K(\bar{u})^\perp \subset K(\bar{u})^*$. Furthermore, $y(u) \in K(\bar{u})$ for all $u \in B(\bar{u}, \rho_1) \cap \Omega$, in view of (36). Hence, for all $u \in B(\bar{u}, \rho_1) \cap \Omega$,

$$K(u)^\perp \subset y(u)^\perp \cap K(\bar{u})^*.$$

To prove that the reverse inclusion holds near \bar{u} in Ω , let

$$h(u) = P_{K(\bar{u})}(-\nabla J(u)) - P_{K(\bar{u})}(-\nabla J(\bar{u})) \in [K(\bar{u})]$$

and observe that

$$\|h(u)\| \leq \|\nabla J(u) - \nabla J(\bar{u})\|.$$

Since $-\nabla J(\bar{u}) \in \text{ri } K(\bar{u})$, and $\nabla J(\cdot)$ is continuous at \bar{u} , there is a $\rho \in (0, \rho_1]$ such that for all $u \in B(\bar{u}, \rho) \cap \Omega$

$$P_{K(\bar{u})}(-\nabla J(u)) \in \text{ri } K(\bar{u}),$$

i.e., for some $\epsilon > 0$ and all η ,

$$(37) \quad \eta \in [K(\bar{u})] \quad \text{and} \quad \|\eta\| \leq \epsilon \Rightarrow (P_{K(\bar{u})}(-\nabla J(u)) + \eta) \in K(\bar{u}).$$

Now suppose that $w \in y(u)^\perp \cap K(\bar{u})^*$. In view of (37) it can be seen that for all $u \in B(\bar{u}, \rho) \cap \Omega$ and all $\eta \in [K(\bar{u})] \cap B(0, \epsilon)$,

$$\langle \eta, w \rangle = \langle P_{K(\bar{u})}(-\nabla J(u)) + \eta, w \rangle \leq 0.$$

Since $[K(\bar{u})]$ is a subspace, it follows that $w \in K(\bar{u})^\perp$. Consequently, for all $u \in B(\bar{u}, \rho) \cap \Omega$,

$$y(u)^\perp \cap K(\bar{u})^* \subset K(u)^\perp.$$

This establishes (35a). Next, observe that

$$(38a) \quad -\nabla J(u) = x(u) + y(u)$$

and

$$(38b) \quad \langle x(u), y(u) \rangle = 0$$

(cf. [20, Lemma 2.2]). According to (35a) and (38b), we therefore have

$$x(u) \in T(u) = y(u)^\perp \cap C(u) \subset C(u)$$

for all $u \in B(\bar{u}, \rho) \cap \Omega$. This proves (35b). Finally, conditions (35b) and (38a) yield

$$\begin{aligned} y(u) &= -\nabla J(u) - x(u) \\ &= -\nabla J(u) + P_{T(u)} \nabla J(u) \\ &= -P_{N(u)} \nabla J(u) \end{aligned}$$

for all $u \in B(\bar{u}, \rho) \cap \Omega$.

THEOREM 5. *Let \bar{u} be a nonsingular local minimizer for J in a polyhedral convex set Ω with a representation (4a) satisfying the constraint qualification Q(i). Then there are positive numbers ρ and $\bar{\mu}_1 \geq \bar{\mu}_0$ such that for all $u \in B(\bar{u}, \rho) \cap \Omega$, the operators $P_{T(u)} \nabla^2 J(u)|_{T(u)}$ are bijective and the corresponding inverse operators,*

$$S_T(u) = (P_{T(u)} \nabla^2 J(u)|_{T(u)})^{-1},$$

in (5) satisfy the conditions

$$(39a) \quad \|S_T(u)\| \leq \bar{\mu}_1$$

and

$$(39b) \quad \inf_{w \in T(u)} \langle w, S_T(u)w \rangle \geq \bar{\mu}_0 \|w\|^2.$$

Furthermore, suppose that $\{u^i\}$ is generated by an SGP iteration (3), (4), with $\mu_1 \geq \bar{\mu}_1 \geq \bar{\mu}_0 \geq \mu_0$, $\delta \in (0, \frac{1}{2})$, and $\alpha = 1$, and assume that for all i ,

$$(40) \quad u^i \in B(\bar{u}, \rho) \cap \Omega \Rightarrow N^i = N(u^i) \quad \text{and} \quad S_T^i = S_T(u^i).$$

Then $\{u^i\}$ converges to \bar{u} , provided u^1 is sufficiently near \bar{u} in Ω ; moreover, if $\{u^i\}$ converges to \bar{u} , then eventually,

$$(41a) \quad u^i \in \mathcal{A}(\bar{u}) = \bar{u} + T_0(\bar{u}),$$

$$(41b) \quad u^{i+1} = u^i + \sigma^i v_T^i,$$

and

$$\sigma^i = \max s$$

subject to

$$s \in \{1, \beta, \beta^2, \dots\}$$

and

$$(41c) \quad J(u^i) - J(P_\Omega(u^i + s v_T^i)) \geq -\delta \langle P_{T_0(\bar{u})} \nabla J(u^i), v_T^i \rangle s,$$

where

$$(41d) \quad v_T^i = -(P_{T_0(\bar{u})} \nabla^2 J(u^i)|_{T_0(\bar{u})})^{-1} P_{T_0(\bar{u})} \nabla J(u^i).$$

Accordingly,

$$(42a) \quad \sigma^i = 1$$

for sufficiently large i , and $\{u^i\}$ converges q -superlinearly to \bar{u} , i.e., either $u^i = \bar{u}$ eventually, or

$$(42b) \quad \lim_{i \rightarrow \infty} \frac{\|u^{i+1} - \bar{u}\|}{\|u^i - \bar{u}\|} = 0.$$

Proof. By Definition 3, the reduced Hessian $P_{T_0(\bar{u})} \nabla^2 J(\bar{u})|_{T_0(\bar{u})}$ is self adjoint and coercive, and $\nabla^2 J(\cdot)$ is continuous at \bar{u} . By Lemma 4, $N(u) = N_0(\bar{u})$ and $T(u) = T_0(\bar{u})$ near \bar{u} in Ω . Hence the operators $P_{T(u)} \nabla^2 J(u)|_{T(u)}$ and their inverses are bounded and coercive uniformly near \bar{u} in Ω . By Theorem 4, all sequences $\{u^i\}$ generated by (3), (4) must converge to \bar{u} from nearby starting points u^1 in Ω , and must eventually enter and remain within $\mathcal{A}(\bar{u}) = \bar{u} + T_0(\bar{u})$, as stated in (41a). For large i , we therefore have

$$u^i - u^{i+1} \in T_0(\bar{u}), \quad [u^i + \sigma^i v^i - u^{i+1}] \in K(u^{i+1}) = K(\bar{u}) \subset N_0(\bar{u}).$$

Thus, (40) insures that for large i

$$(u^i - u^{i+1} + \sigma^i v_T^i) \in T_0(\bar{u}) \cap N_0(\bar{u}) = \{0\}.$$

This proves (41b) and hence (41c). The remaining assertions are obtained from Proposition 1.15 in [21], after noting that (41b), (41c) amounts to an unconstrained relaxed Newton iteration with Armijo steps. \square

Note 8. Assertions (41a)–(41c) and (42) continue to hold if the Newtonian scaling restriction in (40) is replaced by the weaker quasi-Newton condition

$$(43) \quad \lim_{i \rightarrow \infty} \frac{\|(S_T^i - S_T(u^i))P_{T(u^i)}\nabla J(u^i)\|}{\|P_{T(u^i)}\nabla J(u^i)\|} = 0.$$

(See Proposition 1.15 in [21].)

Note 9. An application of Lemma 8 yields a counterpart of Theorem 5 for SGP iterations (1), (2) satisfying $N^i = C(u^i)^*$ in place of $N^i = N(u^i)$; this result may be viewed as a supplement to the Newtonian convergence acceleration consequences of Proposition 3 in [15] (note that in [15], \bar{u} is *assumed* to be a subsequential limit of the sequence $\{u^i\}$).

In nonpolyhedral convex Ω , the normal scaling parameters s_N have a more important bearing on convergence acceleration than heretofore. Previously, the numbers s_N^i merely had to remain bounded away from 0 and ∞ , but now they must satisfy additional restrictions to insure that near nonsingular minimizers, the Newtonian scaling operators $S_T(u)$ in (5) satisfy conditions (3i), (3j), that the step length rule (3) admits $\sigma = 1$ when $\delta \in (0, \frac{1}{2})$ and $\alpha = 1$, and hence that (3)–(5) reduce to the superlinearly convergent NP iteration in [16]. All these requirements are met by the rule (6).

THEOREM 6. *Let \bar{u} be a nonsingular local minimizer for J in a closed convex set Ω with a representation (4a) satisfying the constraint qualification Q(ii). Then there are positive numbers ρ , $\bar{\mu}_3 \geq \bar{\mu}_2$, $\bar{\mu}_1 \geq \bar{\mu}_0$ such that for all $u \in B(\bar{u}, \rho) \cap \Omega$ the operators $P_{T(u)}\nabla^2 J(u)|_{T(u)}$ are bijective, and the corresponding operators $S_T(u)$ and scaling parameters $s_N(u)$ in (5), (6) are well defined and satisfy the conditions*

$$(44a) \quad \bar{\mu}_3 \geq s_N(u) \geq \bar{\mu}_2,$$

$$(44b) \quad \langle P_{T(u)}\nabla J(u), S_T(u)P_{T(u)}\nabla J(u) \rangle \geq \bar{\mu}_0 \|P_{T(u)}\nabla J(u)\|^2,$$

$$(44c) \quad \|S_T(u)\| \leq \bar{\mu}_1.$$

Furthermore, suppose that $\{u^i\}$ is generated by an SGP iteration (3), (4) with $\mu_1 \geq \bar{\mu}_1 \geq \bar{\mu}_0 \geq \mu_0$, $\mu_3 \geq \bar{\mu}_3 \geq \bar{\mu}_2 \geq \mu_2$, $\delta \in (0, \frac{1}{2})$, and $\alpha = 1$, and assume that for all i

$$(45) \quad u^i \in B(\bar{u}, \rho) \cap \Omega \Rightarrow N^i = N(u^i), \quad s_N^i = s_N(u^i) \quad \text{and} \quad S_T^i = S_T(u^i)$$

Then $\{u^i\}$ converges to \bar{u} provided u^1 is sufficiently close to \bar{u} ; moreover, if $\{u^i\}$ converges to \bar{u} , then eventually

$$(46a) \quad u^i \in \mathcal{A}(\bar{u}),$$

$$(46b) \quad \sigma^i = 1,$$

and hence $\{u^i\}$ converges q -superlinearly to \bar{u} .

Proof. It is shown in §§3 and 4 of [16] that the multiplier function $\lambda(\cdot)$ in (5) is continuous at \bar{u} , that the associated operators $L_T(u)$ and their inverses are uniformly bounded and coercive near \bar{u} , and that

$$(47) \quad \lim_{\substack{u \rightarrow \bar{u} \\ u \in \Omega}} P_{T(u)}\nabla J(u) = 0.$$

Since the operators $\Lambda_T(u)$ are also uniformly bounded near \bar{u} , it can be seen that conditions (5) and (6) uniquely define scale factors $s_N(u)$ and scaling operators $S_T(u)$

satisfying (44). By Theorem 4, all sequences $\{u^i\}$ generated by (3), (4) must converge to \bar{u} from nearby starting points u^1 , and eventually satisfy (46a). Condition (46b) will now follow from (3k) if it can be shown that for $u \in \mathcal{A}(\bar{u})$ sufficiently near \bar{u} ,

$$(48a) \quad J(u) - J(\phi(u, 1)) - \delta\{s_N(u)^{-1}\|u - S_T(u)P_{T(u)}\nabla J(u) - \phi(u, 1)\|^2 + \langle P_{T(u)}\nabla J(u), S_T(u)P_{T(u)}\nabla J(u) \rangle\} \geq 0,$$

where

$$(48b) \quad \phi(u, s) = P_\Omega(u - s s_N(u)P_{N(u)}\nabla J(u) - s S_T(u)P_{T(u)}\nabla J(u)).$$

With reference to (32), note that

$$\phi(u, 1) = P_\Omega(\bar{u} - s_N(u)\nabla J(\bar{u}) + h(u))$$

with $s_N(u)$ bounded away from 0 and ∞ near \bar{u} , and

$$\lim_{\substack{u \rightarrow \bar{u} \\ u \in \Omega}} h(u) = 0.$$

Therefore, for $u \in \Omega$ near \bar{u} ,

$$\phi(u, 1) \in \mathcal{A}(\bar{u}),$$

by Lemma 3. Consequently, for $u \in \mathcal{A}(\bar{u})$ near \bar{u} , and for all i ,

$$\mathcal{J}(u) = \mathcal{J}_0(u) = \mathcal{J}_0(\phi(u, 1)) = \mathcal{J}_0(\bar{u})$$

and

$$\begin{aligned} i \in \mathcal{J}(u) \Rightarrow 0 = g_i(u) - g_i(\phi(u, 1)) &= \langle \nabla g_i(u), u - \phi(u, 1) \rangle \\ &\quad - \frac{1}{2} \langle u - \phi(u, 1), \nabla^2 g_i(u)(u - \phi(u, 1)) \rangle \\ &\quad + o(\|u - \phi(u, 1)\|^2). \end{aligned}$$

In view of (5), this yields

$$0 = -\langle P_{N(u)}\nabla J(u), u - \phi(u, 1) \rangle - \frac{1}{2} \langle u - \phi(u, 1), \Lambda(u)(u - \phi(u, 1)) \rangle + o(\|u - \phi(u, 1)\|^2);$$

therefore,

$$(49) \quad \begin{aligned} J(u) - J(\phi(u, 1)) &= \langle P_{T(u)}\nabla J(u), u - \phi(u, 1) \rangle \\ &\quad - \frac{1}{2} \langle u - \phi(u, 1), L(u)(u - \phi(u, 1)) \rangle + o(\|u - \phi(u, 1)\|^2) \end{aligned}$$

as $u \rightarrow \bar{u}$ with $u \in \mathcal{A}(\bar{u})$. In addition, the analysis in §4 of [16] shows that for $u \in \mathcal{A}(\bar{u})$ near \bar{u} ,

$$(50a) \quad \phi(u, 1) - \bar{u} = o(\|u - \bar{u}\|),$$

$$(50b) \quad u - \bar{u} = P_{T(u)}(u - \bar{u}) + o(\|u - \bar{u}\|),$$

and

$$(50c) \quad P_{T(u)}\nabla J(u) = L_T(u)^{-1}P_{T(u)}(u - \bar{u}) + o(\|u - \bar{u}\|);$$

therefore,

$$(51) \quad u - \phi(u, 1) = L_T(u)^{-1} P_{T(u)} \nabla J(u) + o(\|P_{T(u)} \nabla J(u)\|)$$

as $u \rightarrow \bar{u}$ with $u \in \mathcal{A}(\bar{u})$. (In particular, see (4.13), (4.23), Lemma 4.2, Corollary 4.2.1, Lemma 4.3, and the remark concerning $s_N(u)$ at the beginning of §4 in [16].) In view of (49) and (51), it can now be seen that the left side of (48a) is bounded below by

$$\begin{aligned} & \left(\frac{1}{2} - \delta \right) \langle P_{T(u)} \nabla J(u), L_T(u)^{-1} P_{T(u)} \nabla J(u) \rangle - \delta s_N(u) \{ \|\Lambda_T(u) L_T(u)^{-1} P_{T(u)} \nabla J(u)\|^2 \\ & \quad + |\langle P_{T(u)}, \Lambda_T(u) L_T(u)^{-1} P_{T(u)} \nabla J(u) \rangle| \} + o(\|P_{T(u)} \nabla J(u)\|^2) \\ & \geq \frac{(1 - 2\delta)^2}{2} \langle P_{T(u)} \nabla J(u), L_T(u)^{-1} P_{T(u)} \nabla J(u) \rangle + o(\|P_{T(u)} \nabla J(u)\|^2) \geq 0 \end{aligned}$$

as $u \rightarrow \bar{u}$ with $u \in \mathcal{A}(\bar{u})$. This estimate and (46a) establish (46b), and q -superlinear convergence of $\{u^i\}$ then follows from (50a). \square

Note 10. If the Hessians of J and the functions g_j are Lipschitz continuous near a nonsingular minimizer \bar{u} , then the q -superlinear convergence rate estimate in Theorems 5 and 6 can be replaced with a sharper q -quadratic convergence rate estimate (see Note 4.2 in [16]).

Note 11. An examination of (4.13), (4.23) and the related analysis in §4 of [16] will show that the conclusions in Theorem 6 also remain valid if the Newtonian scaling restriction in (45) is replaced by the quasi-Newton condition (43).

TWO GENERALIZATIONS OF A THEOREM OF ARROW, BARANKIN, AND BLACKWELL*

RICHARD J. GALLAGHER[†] AND OSSAMA A. SALEH[‡]

Abstract. In 1953, Arrow, Barankin, and Blackwell proved that if R^n is equipped with its natural ordering and if A is a closed convex subset of R^n , then the set of points in A that can be supported by strictly positive linear functionals is dense in the set of all efficient (maximal) points of A . In this note two generalizations of this result are given. The first of these is in the setting of a dual system and requires relatively weak assumptions on the ordering cone but a rather strong compactness assumption on the set A . The second generalization, which is in the setting of a locally convex space, relaxes the compactness assumption on the set A but demands more stringent assumptions on the ordering cone. This second result was recently obtained by Petschke for normed spaces [M. Petschke, “On a theorem of Arrow, Barankin and Blackwell”, *SIAM J. Control Optim.*, 28 (1990), pp. 395–401]. The proof given here is substantially different from that given by Petschke.

Key words. vector optimization, scalarization, proper efficiency

1. Introduction. In 1953 Arrow, Barankin, and Blackwell [1] proved that if R^n is equipped with its natural ordering and if A is a closed convex subset of R^n , then the set of points in A that can be supported by strictly positive linear functionals is dense in the set of all efficient (maximal) points of A . (Here, a point $a_0 \in A$ is said to be supported by a linear functional f if $f(a_0) \geq f(a)$ for all $a \in A$.) This theorem has important implications in mathematical economics and multiple objective optimization. In particular, in mathematical economics a strictly positive linear functional p can be regarded as a pricing system, and a point $a_0 \in A$ supported by p represents an efficient allocation of resources that can be sustained by the pricing system p . Hence, the theorem states that under appropriate conditions, “nearly every” efficient allocation of resources can be sustained by a suitable pricing system. In the case of multiple objective optimization where one is interested in identifying the set of all efficient points of a given set A , the theorem implies that “nearly every” efficient point of A can be found as the solution of a suitable single-objective real-valued optimization problem.

Over the past 25 years, several authors have generalized the Arrow–Barankin–Blackwell theorem in various ways. Hartley [12] and Bitran and Magnanti [2] showed that the theorem remains valid if R^n is partially ordered by an arbitrary closed pointed convex cone. Three mathematical economists, Radner [24], Majumdar [19], and Peleg [21], obtained density results in the infinite dimensional normed vector lattices ℓ^∞ , L^∞ and ℓ^p , $1 \leq p \leq \infty$, respectively. Chichilnisky and Kalman [6] proved a density theorem in a Hilbert space setting; and Salz [26], Borwein [3], [4], Jahn [13], Dauer

and Gallagher [9], and Petschke [23] proved density results in general normed spaces. Three other papers that should be mentioned are those of Peleg [20], which includes a constructive proof of the original theorem of Arrow, Barankin, and Blackwell; and DaCunha and Polak [8] and Durier [10], which include related density theorems for constrained multiple objective problems having a finite number of objectives.

A brief examination of the various hypotheses used in [3], [4], [9], [13], [23], and [26] to obtain density results in general normed spaces, reveals that there is a trade-off between restrictions placed on the ordering cone and restrictions placed on the set A . That is, existing density results either require strong assumptions on the ordering cone and relatively weak assumptions on the set A , or relatively weak assumptions on the ordering cone and strong assumptions on the set A . However, no counterexamples appear in the literature that demonstrate that such trade-offs are necessary. Hence, further study is warranted.

It is the purpose of this paper to present two density theorems, in the most general settings known to the authors, which exemplify the above-mentioned trade-offs. It is hoped that the unified treatment given here will provide some insight and direction towards either obtaining density results with less restrictive hypotheses, or showing that the known results are, in some sense, the best that can be obtained.

The first theorem (Theorem 2.6) generalizes the density results in [3], [4], [9], and [24] to the setting of a dual system. Although the technique of proof relies on a standard argument, abstracting the problem to this setting emphasizes the precise properties that the ordering cone must satisfy in order for the argument to remain valid. More important, by Corollary 2.8 it follows that the density result of Borwein [3, Thm. 2] remains true without requiring the cone to have a weakly compact base. Indeed, the result only requires the cone to be closed and convex and to admit strictly positive continuous linear functionals. Borwein himself noted this in a later paper [4, Thm. 5], but made no comment on the proof. Since two recent papers [13], [23] quote only the former result, it seems that even in a normed space setting, Corollary 2.8 is not widely known.

The second density theorem presented in this paper (Theorem 3.1) extends a recent result of Petschke [23] to the setting of a locally convex space. Petschke has shown that in a normed space the Arrow–Barankin–Blackwell theorem holds provided the ordering cone has a closed bounded base and the set A is weakly compact and convex. The proof given by Petschke is somewhat lengthy and depends strongly on the norm structure. In Theorem 3.1 it is shown that the result is even true in a locally convex space. The proof given is quite short and relies only on standard separation arguments.

The paper is organized as follows. In §2 we introduce the notion of a D-cone, demonstrate that the properties of such a cone are relatively easy to satisfy in locally bounded spaces (in particular, in normed spaces), and establish Theorem 2.6 which assumes that the ordering is induced by a D-cone. In §3 we review the notion of a base for a cone, discuss the relationship between D-cones and cones with a closed bounded base, and establish Theorem 3.1 which assumes that the ordering is induced by a cone with a closed bounded base. In both §§2 and 3 several corollaries of the main results are given. Some concluding remarks and an open question are given in §4.

2. Density for a space ordered by a D-cone. We begin by reviewing the definition of a dual system. For a comprehensive treatment of this concept, the reader is referred to Schaefer [27].

Let \mathcal{X} and \mathcal{F} be vector spaces over R , and let $\langle \cdot, \cdot \rangle$ be a bilinear form on $\mathcal{X} \times \mathcal{F}$ satisfying the separation axioms (2.1) and (2.2) below.

$$(2.1) \quad \text{If } \langle x_0, f \rangle = 0 \text{ for all } f \in \mathcal{F}, \text{ then } x_0 = \theta.$$

$$(2.2) \quad \text{If } \langle x, f_0 \rangle = 0 \text{ for all } x \in \mathcal{X}, \text{ then } f_0 = \theta.$$

(The symbol θ denotes the zero vector in the appropriate space.) Then the triple $(\mathcal{X}, \mathcal{F}, \langle \cdot, \cdot \rangle)$ is called a *dual system* over R , and is usually denoted more briefly as $\langle \mathcal{X}, \mathcal{F} \rangle$. The prototype example of a dual system is the case when \mathcal{X} is a normed space and \mathcal{F} is the topological dual \mathcal{X}^* of \mathcal{X} . In this case the bilinear form $\langle x, f \rangle = f(x)$ defines a dual system.

A subset $K \subseteq \mathcal{X}$ is said to be a *pointed convex cone* if K is convex, $\lambda K \subseteq K$ for all $\lambda \geq 0$, and $K \cap (-K) = \{\theta\}$.

Throughout this section, let $\langle \mathcal{X}, \mathcal{F} \rangle$ denote a dual system over R , and suppose that \mathcal{X} is partially ordered by a pointed convex cone K . The *dual cone* K^+ and its *quasi-interior* K^{+i} are defined as

$$K^+ = \{f \in \mathcal{F} : \langle k, f \rangle \geq 0 \text{ for all } k \in K\}$$

and

$$K^{+i} = \{f \in \mathcal{F} : \langle k, f \rangle > 0 \text{ for all } k \in K \setminus \{\theta\}\}.$$

If the set K^{+i} is nonempty, we say that K admits strictly positive linear functionals. Throughout this work, it will be assumed that K^{+i} is nonempty. For general conditions under which such an assumption is valid, see [5, Prop. 2.7], [14, p. 58], [16, Thm. 2.7], [18, Thm. 2.8], and [22, pp. 26–27]. We mention specifically that the positive cones in the normed vector lattices R^n , $C[a, b]$, ℓ^p , and L^p all admit strictly positive linear functionals.

The following notions are fundamental in the study of vector optimization. Definition 2.1 is standard, and the terminology in Definition 2.2 for points that can be supported by strictly positive linear functionals was introduced in [9].

DEFINITION 2.1. Let \mathcal{X} be a vector space partially ordered by a pointed convex cone K , and let A be a nonempty subset of \mathcal{X} . A point $a \in A$ is said to be an *efficient* (*maximal*) *point* of A if $A \cap (\{a\} + K) = \{a\}$.

DEFINITION 2.2. Let $\langle \mathcal{X}, \mathcal{F} \rangle$ be a dual system over R , let A be a nonempty subset of \mathcal{X} , and suppose that \mathcal{X} is partially ordered by a pointed convex cone K . A point $a_0 \in A$ is said to be a *positive proper efficient point* of A if there exists $f \in K^{+i}$ such that $\langle a_0, f \rangle \geq \langle a, f \rangle$ for all $a \in A$.

We denote the set of efficient points of A by $E(A)$ and the set of positive proper efficient points of A by $\text{Pos}(A)$. In Lemma 2.3 some elementary observations regarding the sets $E(A)$ and $\text{Pos}(A)$ are given. The proof is left to the reader.

LEMMA 2.3. Let $\langle \mathcal{X}, \mathcal{F} \rangle$ be a dual system over R , and suppose that \mathcal{X} is partially ordered by a pointed convex cone K .

- (a) If $A \subseteq \mathcal{X}$, then $\text{Pos}(A) \subseteq E(A)$.
- (b) If A and C are nonempty subsets of \mathcal{X} satisfying $A \subseteq C \subseteq A - K$, then $E(A) = E(C)$ and $\text{Pos}(A) = \text{Pos}(C)$.
- (c) Suppose \mathcal{X} is equipped with a topology such that $\langle \cdot, f \rangle$ is continuous for all $f \in \mathcal{F}$, and suppose that K^{+i} is nonempty. If C is a compact subset of \mathcal{X} , then $\text{Pos}(C)$ is nonempty.

We next introduce the notion of a D-cone, the properties of which are fundamental to the proof of the density theorem (Theorem 2.6). The letter "D" in the name emphasizes the role that property (b) of the definition plays in the proof of the theorem; namely, to ensure that a set of saddle points which is constructed is indexed by a directed set ("D" for directed) so as to form a net.

If f and g are in \mathcal{F} , we use the notation $f \leq g$ to indicate that $g - f \in K^+$.

DEFINITION 2.4. Let $\langle \mathcal{X}, \mathcal{F} \rangle$ be a dual system over R , and let \mathcal{F} be equipped with the topology induced by \mathcal{X} . A pointed convex cone K in \mathcal{X} is said to be a *D-cone* if there exists a nonempty subset D of K^{+i} satisfying the following three conditions:

- (a) the set D is contained in a compact convex subset of \mathcal{F} ;
- (b) for every $f, g \in D$, there exists $h \in D$ such that $h \leq f$ and $h \leq g$; and
- (c) if $\langle x, f \rangle \geq 0$ for all $f \in D$, then $x \in K$.

We remark that even if the assumptions that K is pointed and convex are not explicitly mentioned in the above definition, they are implicitly implied by other assumptions. Indeed, the fact that K^{+i} is nonempty implies that K is pointed; and condition (c), together with the fact that D is a subset of K^{+i} , implies that

$$K = \bigcap_{f \in D} \{x \in \mathcal{X} : \langle x, f \rangle \geq 0\}.$$

Hence, K is convex. Moreover, if \mathcal{X} is equipped with a topology such that $\langle \cdot, f \rangle$ is continuous for all $f \in \mathcal{F}$, then K is closed.

In Lemma 2.5 sufficient conditions for a cone to be a D-cone are given. An important consequence of the lemma is that in a normed space any closed convex cone that admits strictly positive continuous linear functionals is a D-cone. Thus, in particular, the nonnegative orthants in R^n , $C[a, b]$, ℓ^p , and L^p , $1 \leq p \leq \infty$, are D-cones. It is also interesting to note that in addition to the above-mentioned normed spaces, the lemma also implies that the nonnegative orthants in the non-locally convex spaces ℓ^p , $0 < p < 1$ (e.g., see [25, p. 82]) are D-cones.

LEMMA 2.5. *Let \mathcal{X} be a locally bounded Hausdorff topological vector space such that \mathcal{X}^* separates points of \mathcal{X} , and let K be a weakly-closed convex cone in \mathcal{X} such that the set*

$$K^{+i} = \{f \in \mathcal{X}^* : f(k) > 0 \text{ for all } k \in K \setminus \{\theta\}\}$$

is nonempty. Then K is a D-cone.

Proof. Let V be a bounded neighborhood of the origin in \mathcal{X} . By the Banach-Alaoglu Theorem (e.g., see [25, Thm. 3.15]) the polar

$$V^\circ = \{f \in \mathcal{X}^* : |f(v)| \leq 1 \text{ for all } v \in V\}$$

of V is weak-star compact. Also, since V is bounded, it follows that $\sup\{|f(v)| : v \in V\}$ is finite for all $f \in \mathcal{X}^*$. Thus $K^{+i} \cap V^\circ$ is nonempty. Now, let $p \in K^{+i} \cap V^\circ$, and define

$$D = \bigcup_{n=1}^{\infty} (\{(1/n)p\} + K^+) \cap V^\circ.$$

Then D is a nonempty subset of K^{+i} contained in the weak-star compact set V° . It must be shown that conditions (b) and (c) of Definition 2.4 are satisfied.

Suppose $f, g \in D$. Then $f = (1/r)p + k_1^+$ and $g = (1/s)p + k_2^+$ for some positive integers r and s and some $k_1^+, k_2^+ \in K^+$. Choose $t = \max\{r, s\}$ and define $h = (1/t)p$. Then $h \in D$, $h \leq f$ and $h \leq g$. Hence, condition (b) is satisfied.

Suppose $x \notin K$. Since \mathcal{X}_w (\mathcal{X} with the weak topology) is a locally convex space, and since K is weakly closed and convex, there exists $q \in (\mathcal{X}_w)^*$ such that $q(x) < 0 \leq q(k)$ for all $k \in K$. The fact that \mathcal{X}^* separates points of \mathcal{X} implies that $\mathcal{X}^* = (\mathcal{X}_w)^*$ (e.g., see [25, pp. 62–63]) and hence, $q \in K^+$. Now, since V is bounded, we may assume that $\sup\{|q(v)| : v \in V\} < 1/2$. Then for n sufficiently large, we have $(1/n)p + q \in D$ and $((1/n)p + q)(x) < 0$. Hence, condition (c) is satisfied. \square

We now state and prove the main theorem of this section. The proof of the theorem uses essentially the same argument as the proofs of the density theorems given by Radner [24, p. 352], Borwein [3, Thm. 2], and Dauer and Gallagher [9, Thm. 4.5], which are all in the setting of normed spaces. (Radner's result is specifically stated for ℓ^∞ .) Proving the theorem in the more abstract setting of a dual system emphasizes that the essence of the argument is independent of any norm structure, and it clarifies the precise properties that the ordering cone must satisfy in order for the argument to remain valid; in particular, the cone must be a D-cone.

The notation $\text{cl}[S]$ is used to denote the closure of a subset S of a topological space.

THEOREM 2.6. *Let $\langle \mathcal{X}, \mathcal{F} \rangle$ be a dual system over R , let \mathcal{F} be equipped with the topology induced by \mathcal{X} , let \mathcal{X} be equipped with a topology such that $\langle \cdot, f \rangle$ is continuous for all $f \in \mathcal{F}$, and let \mathcal{X} be partially ordered by a D-cone K . If A is a subset of \mathcal{X} , and if there exists a compact convex subset C of \mathcal{X} such that $A \subseteq C \subseteq A - K$, then $E(A) \subseteq \text{cl}[\text{Pos}(A)]$.*

The following lemma will be used in the proof of Theorem 2.6; it is a corollary of a minimax theorem due to Fan [11, Thm. 1].

LEMMA 2.7. *Let A and B be compact convex sets, each in a topological vector space, and let Φ be a real-valued function defined on $A \times B$. Suppose that for each $b \in B$, $\Phi(a, b)$ is a continuous convex function on A , and for each $a \in A$, $\Phi(a, b)$ is a continuous concave function on B . Then there exists a pair $(a_0, b_0) \in A \times B$ satisfying*

$$\Phi(a_0, b) \leq \Phi(a_0, b_0) \leq \Phi(a, b_0)$$

for all $a \in A$ and all $b \in B$.

Proof of Theorem 2.6. Without loss of generality it will be shown that if $\theta \in E(A)$, then $\theta \in \text{cl}[\text{Pos}(A)]$. Since K is a D-cone, there exists a nonempty subset D of K^{+i} satisfying (a), (b), and (c) in Definition 2.4. Let B be the compact convex subset containing D , and for each $p \in D$ define

$$B(p) = \{f \in B : f \geq p\}.$$

Then $B(p)$ is a compact convex subset of \mathcal{F} . Since C is also compact and convex, Lemma 2.7 implies that there exists $c_p \in C$ and $f_p \in B(p)$ satisfying

$$(2.3) \quad \langle c, f_p \rangle \leq \langle c_p, f_p \rangle \leq \langle c_p, f \rangle$$

for all $c \in C$ and all $f \in B(p)$. Since $f_p \in K^{+i}$, it follows that $c_p \in \text{Pos}(C)$. Also, since $A \subseteq C \subseteq A - K$, it follows by Lemma 2.3 that $c_p \in \text{Pos}(A)$.

Since the set D satisfies condition (b) in Definition 2.4, the pair (D, \leq) is a directed set (e.g., see [7, p. 377]). Hence, the set $\{c_p : p \in D\}$ is a net in $\text{Pos}(A)$. Since C is compact, the net has a cluster point, say $\bar{c} \in C$. It follows that $\bar{c} \in \text{cl}[\text{Pos}(A)]$.

To finish the proof, we show that $\bar{c} = \theta$. Since $\theta \in E(A) = E(C)$, it suffices to show that $\bar{c} \in K$. Thus, by (c) in Definition 2.4, we need only show that $\langle \bar{c}, g \rangle \geq 0$ for all $g \in D$. To this end, let $g \in D$ and $\varepsilon > 0$ be given.

Since \bar{c} is a cluster point of $\{c_p : p \in D\}$ and since $\langle \cdot, g \rangle$ is continuous, there exists $r \in D$, $r \leq g$ such that

$$\langle \bar{c}, g \rangle > \langle c_r, g \rangle - \varepsilon.$$

Since $r \leq g$, we have $g \in B(r)$. Hence, since $\theta \in C$, inequality (2.3) implies that $\langle c_r, g \rangle \geq 0$. Thus, $\langle \bar{c}, g \rangle > -\varepsilon$. Since ε and g are arbitrary, it follows that $\langle \bar{c}, g \rangle \geq 0$ for all $g \in D$. Hence, $\bar{c} = \theta$. \square

As an immediate corollary of Theorem 2.6 and Lemma 2.5, we obtain the following generalization of a result of Borwein [4, Thm. 5]. As was mentioned in the Introduction, it seems that Borwein's result is not widely known.

COROLLARY 2.8. *Let \mathcal{X} be a locally bounded Hausdorff topological vector space such that \mathcal{X}^* separates points of \mathcal{X} , let K be a weakly closed convex cone in \mathcal{X} such that the set K^{+i} is nonempty, and let A be a subset of \mathcal{X} . If there exists a compact (respectively, weakly compact) convex subset C of \mathcal{X} such that $A \subseteq C \subseteq A - K$, then $E(A) \subseteq \text{cl}[\text{Pos}(A)]$ (respectively, $E(A) \subseteq \text{weak-cl}[\text{Pos}(A)]$).*

In Corollary 2.10 a local version of Corollary 2.8 is given for the case when \mathcal{X} is normed. The following elementary lemma is used in its proof.

LEMMA 2.9. *Let \mathcal{X} be a normed space and let A be a convex subset of \mathcal{X} . Let $\varepsilon > 0$ and $\bar{a} \in A$ be given, and define*

$$A(\varepsilon) = \{a \in A : \|\bar{a} - a\| < \varepsilon\}.$$

Let $f : A \rightarrow \mathbb{R}$ be a concave function, and suppose that there exists $a^ \in A(\varepsilon)$ satisfying*

$$f(a^*) \geq f(a) \quad \text{for all } a \in A(\varepsilon).$$

Then

$$f(a^*) \geq f(a) \quad \text{for all } a \in A.$$

Proof. If $a \in A$, there exists t , $0 \leq t < 1$, such that $ta^* + (1-t)a \in A(\varepsilon)$. It follows that $f(a^*) \geq f(a)$. \square

COROLLARY 2.10. *Let \mathcal{X} be a real normed space partially ordered by a closed convex cone K such that K^{+i} is nonempty, let A be a nonempty subset of \mathcal{X} , and let $\bar{a} \in A$ be an efficient point of A . If either*

- (a) *A is convex and the set $\bar{A}(t) = \{a \in A : \|a - \bar{a}\| \leq t\}$ is compact for some $t > 0$, or*
- (b) *$A - K$ is convex and the set $(\overline{A - K})(t) = \{x \in A - K : \|x - \bar{a}\| \leq t\}$ is compact for some $t > 0$,*

then $\bar{a} \in \text{cl}[\text{Pos}(A)]$.

Proof. (a) Let ε , $0 < \varepsilon \leq t$, be given; and define

$$A(\varepsilon) = \{a \in A : \|\bar{a} - a\| < \varepsilon\}.$$

Since $\bar{A}(t)$ is compact and convex, and since \bar{a} is an efficient point of $\bar{A}(t)$, Corollary 2.8 implies that $\bar{a} \in \text{cl}[\text{Pos}(\bar{A}(t))]$. Hence, there exists $a^* \in A(\varepsilon)$ and $f \in K^{+i}$ such that $f(a^*) \geq f(a)$ for all $a \in A(\varepsilon)$. By Lemma 2.9, it follows that $f(a^*) \geq f(a)$ for all $a \in A$; that is, $a^* \in \text{Pos}(A)$. Since ε is arbitrary, it follows that $\bar{a} \in \text{cl}[\text{Pos}(A)]$.

(b) This follows directly from part (a) and the set equalities $E(A) = E(A - K)$ and $\text{Pos}(A) = \text{Pos}(A - K)$. \square

3. Density for a space ordered by a cone with a bounded base. Throughout this section, \mathcal{X} will denote a (Hausdorff) locally convex topological vector space and K will denote a cone in \mathcal{X} . We say that a subset B of K is a *base* for K if B is convex, $\theta \notin \text{cl}[B]$, and

$$K = \text{cone}(B) \stackrel{\text{def}}{=} \{\lambda b : \lambda \geq 0, b \in B\}.$$

It is easily established that in a locally convex space, a based cone is convex and admits strictly positive continuous linear functionals (e.g., see [5, Prop. 2.7]). If, in addition, the base is closed and bounded, then K is closed [15, p. 121]. Hence, by Lemma 2.5, in a normed space, a cone with a closed bounded base is necessarily a D-cone. But in general, a D-cone need not have a bounded base. For example, the nonnegative orthants in $C[a, b]$, ℓ^p , and L^p , for $1 < p \leq \infty$, are D-cones but do not have bounded bases (e.g., see [9, Cors. 3.4 and 3.5] and [15, pp. 121–122 and 169]).

In this section we obtain density results similar to those given in the previous section, but are able to relax the hypotheses on the set A by assuming that the ordering cone has a closed bounded base. The primary examples of partially ordered locally convex spaces in which the ordering cones have closed bounded bases are R^n , ℓ^1 , and L^1 with their natural orderings and with either their norm or weak topologies. Other examples of closed and bounded based cones arise naturally in certain dual spaces. Indeed, if K is a cone in a locally convex space \mathcal{X} such that the interior of K is nonempty, then the dual cone $K^+ = \{f \in \mathcal{X}^* : f(k) \geq 0 \text{ for all } k \in K\}$ has a weak-star closed and bounded base (i.e., a weak-star compact base) [15, p. 23]. Thus, in particular, if K denotes the nonnegative orthant in $C[a, b]$, ℓ^∞ , or L^∞ , then the dual cone K^+ in the associated dual space has a weak-star closed bounded base. There is, of course, no shortage of closed and bounded based cones. Indeed, one can construct such cones from any closed, bounded convex set B not containing θ ; simply let $K = \text{cone}(B)$. For a thorough study of cones with bounded bases, see Jameson [15, pp. 120–126].

The main result of this section is Theorem 3.1, which is in the setting of a locally convex space. This result was recently obtained by Petschke [23] for normed spaces. It is important to note that the proof given here is substantially different from that given by Petschke. Indeed, Petschke shows that in a normed space $(\mathcal{X}, \|\cdot\|)$ a cone K with a closed bounded base is representable as a Bishop–Phelps cone; that is, there exists $f \in \mathcal{X}^*$ and a norm $p(\cdot)$ on \mathcal{X} which is equivalent to $\|\cdot\|$ such that

$$K = \{x \in \mathcal{X} : p(x) \leq f(x)\}.$$

Once this representation is established, the density result given in Jahn [13, Thm. 3.1], which requires the cone to be a Bishop–Phelps cone, is utilized. For completeness, we mention that the proof given by Jahn for his result involves an argument using weakly lower semicontinuous convex functions and subgradients to generate positive proper efficient points arbitrarily close to a prespecified efficient point. In contrast, the proof of Theorem 3.1 given below relies on standard separation theorems to generate such points.

THEOREM 3.1. *Let \mathcal{X} be a locally convex topological vector space partially ordered by a cone K with a closed bounded base, and let A be a subset of \mathcal{X} . If there exists a weakly compact convex subset C of \mathcal{X} such that $A \subseteq C \subseteq A - K$, then $E(A) \subseteq \text{cl}[\text{Pos}(A)]$.*

Proof. Without loss of generality, assume $\theta \in E(A)$. Let W be a convex open neighborhood of θ . We show that $W \cap \text{Pos}(A) \neq \emptyset$. Since \mathcal{X} is locally convex, there

exist convex open neighborhoods U and V of θ such that $\text{cl}[V] \subseteq W$ and $U + U \subseteq V$ (e.g., see [25, pp. 9–10]).

Let B denote a closed bounded base for K . Since B is bounded, we may assume that $B \subseteq U$. Since $\theta \in E(A) = E(C)$, we have $C \cap K = \{\theta\}$. Hence, $C \cap B = \emptyset$; and consequently, letting $\overline{C} := C \cap \text{cl}[V]$, we have $\overline{C} \cap B = \emptyset$. But \overline{C} is weakly compact and convex, and B is weakly closed and convex; so there exists $g \in \mathcal{X}^*$ and $\bar{c} \in \overline{C}$ such that

$$(3.1) \quad g(\bar{c}) = \max\{g(c) : c \in \overline{C}\} < \inf\{g(b) : b \in B\}$$

(e.g., see [25, Thm. 3.4(b)]).

To finish the proof, it suffices to show that $\bar{c} \in \text{Pos}(A)$. From (3.1), there exists a convex open neighborhood N of θ such that $N \subseteq U$ and

$$\widehat{B} := B + N \subseteq \{x \in \mathcal{X} : g(x) > g(\bar{c})\}.$$

Let $P = \text{cone}(\widehat{B})$. Then $K \setminus \{\theta\} \subseteq \text{int}[P]$ (the interior of P). We next show that $P \cap (C - \{\bar{c}\}) = \{\theta\}$. For the sake of contradiction, suppose there exists $\lambda > 0$ and $c \in C \setminus \{\bar{c}\}$ such that $c - \bar{c} = \lambda \hat{b}$ for some $\hat{b} \in \widehat{B}$. Since C is convex and since $\theta \in C$, the vector $z := (1 + \lambda)^{-1}c \in C$. Also $z \in \text{cl}[V]$ and $g(z) > g(\bar{c})$. But this contradicts (3.1); hence, $P \cap (C - \{\bar{c}\}) = \{\theta\}$. Consequently, $\text{int}[P] \cap (C - \{\bar{c}\}) = \emptyset$. Thus, there exists $f \in \mathcal{X}^*$, $f \neq 0$, such that

$$(3.2) \quad \sup\{f(x) : x \in (C - \{\bar{c}\})\} \leq 0 \leq \inf\{f(p) : p \in P\}.$$

Moreover, $f(p) > 0$ for all $p \in \text{int}[P]$ (e.g., see [25, Thm. 3.4(a)]). Since $K \setminus \{\theta\} \subseteq \text{int}[P]$, $f(k) > 0$ for all $k \in K \setminus \{\theta\}$. Also, it follows from (3.2) that $f(\bar{c}) \geq f(c)$ for all $c \in C$. Hence, $\bar{c} \in \text{Pos}(C) = \text{Pos}(A)$. \square

The following corollary provides a local version of Theorem 3.1 in a normed space setting. Its proof is nearly identical to the proof of Corollary 2.10 and is therefore omitted.

COROLLARY 3.2. *Let \mathcal{X} be a real normed space partially ordered by a cone K with a closed bounded base, let A be a nonempty subset of \mathcal{X} , and let $\bar{a} \in A$ be an efficient point of A . If either*

- (a) *A is convex and the set $\overline{A}(t) = \{a \in A : \|a - \bar{a}\| \leq t\}$ is weakly compact for some $t > 0$, or*
- (b) *$A - K$ is convex and the set $\overline{(A - K)}(t) = \{x \in A - K : \|x - \bar{a}\| \leq t\}$ is weakly compact for some $t > 0$,*

then $\bar{a} \in \text{cl}[\text{Pos}(A)]$.

The next corollary, in the setting of a reflexive normed space, generalizes the finite dimensional results of Hartley [12, Thm. 5.5] and Bitran and Magnanti [2, Cor. 3.1]. (Also, compare with [13, Cor. 3.4].)

COROLLARY 3.3. *Let \mathcal{X} be a reflexive Banach space partially ordered by a cone K with a closed bounded base, and let A be a subset of \mathcal{X} such that either A is closed and convex or $A - K$ is closed and convex. Then $\text{Pos}(A)$ is norm dense in $E(A)$.*

We conclude this section by mentioning that Theorem 3.1 can be applied to prove an important result of Klee, which states that the support points of a locally weakly compact convex subset A of a locally convex space are dense in the boundary of A [17, Thm. 9.11]. The authors will present this proof in a forthcoming paper.

4. Conclusion. As was mentioned in the introduction and as is revealed when comparing Corollary 2.8 with Theorem 3.1, if A is a subset of a normed space, then existing results giving sufficient conditions for the set $\text{Pos}(A)$ to be norm dense in the set $E(A)$ either require strong assumptions on the ordering cone and relatively weak assumptions on the set A , or relatively weak assumptions on the ordering cone and strong assumptions on the set A . It is not known whether such trade-offs are absolutely necessary. From the results presented here, an obvious question that arises is the following: Is it possible to show that $\text{Pos}(A)$ is norm dense in $E(A)$ if A is only assumed to be weakly compact and convex (as in Theorem 3.1) and the ordering cone is only assumed to be closed and convex and to admit strictly positive continuous linear functionals (as in Corollary 2.8)? It would seem that the method of proof or counterexample needed to answer this question would have important implications with regard to other functional analytic questions as well.

LOWER SEMICONTINUOUS SOLUTIONS OF HAMILTON–JACOBI–BELLMAN EQUATIONS*

HÉLÈNE FRANKOWSKA†

Abstract. The value function of Mayer’s problem arising in optimal control is investigated, and lower semicontinuous solutions of the associated Hamilton–Jacobi–Bellman equation are defined in three (equivalent) ways. Under quite weak assumptions about the control system, the value function is the unique solution. Moreover, it is stable with respect to perturbations of the control system and the cost. It coincides with the viscosity solution whenever it is continuous.

Key words. Hamilton–Jacobi equation, Mayer’s problem, viability theory, viscosity solution

AMS(MOS) subject classifications. 35B37, 49C20, 49J15, 49J45, 90C39

1. Introduction. Consider the following Hamilton–Jacobi–Bellman (HJB) equation:

$$(1) \quad -\frac{\partial V}{\partial t}(t, x) + H\left(t, x, -\frac{\partial V}{\partial x}(t, x)\right) = 0, \quad V(T, \cdot) = g(\cdot)$$

associated with the Mayer problem arising in control theory:

$$\text{minimize } \{ g(x(T)) \mid x(T) \in K \}$$

over all solutions of the control system

$$(2) \quad x' = f(t, x, u(t)), \quad u(t) \in U$$

satisfying the initial condition

$$(3) \quad x(0) = \xi_0,$$

where K is a given set (called target).

By a simple change of variables, the classical Bolza problem

$$\text{minimize } \left\{ g(x(T)) + \int_0^T L(t, x(t), u(t)) dt \mid x(T) \in K \right\}$$

over all state-control solutions (x, u) of (2), (3) may be reduced to the Mayer problem.

In (1) the Hamiltonian H is given by

$$H(t, x, p) = \sup_{u \in U} \langle p, f(t, x, u) \rangle.$$

The value function for Mayer’s problem is defined by

$$(4) \quad V(t_0, x_0) = \inf \{ g(x(T)) \mid x \text{ is a solution of (2), } x(t_0) = x_0, x(T) \in K \}$$

In general, V is merely lower semicontinuous and is equal to $+\infty$ at all points from which it is impossible to reach the target K . In fact, we can even avoid explicitly mentioning the target K in (4) by setting $g(x) = +\infty$ whenever $x \notin K$.

The value function allows us to single out optimal trajectories since it is nondecreasing along solutions of (2) and is constant along optimal solutions. These two properties and the final value $V(T, \cdot) = g(\cdot)$ characterize the value function.

When V is differentiable, it solves the partial differential equation (1). When it is merely lower semicontinuous, the solution of the HJB equation must be defined in such way that under quite general assumptions on H and g , V is the unique solution of (1).

In [12], [14] the notion of viscosity solution was introduced to deal with continuous solutions of the Hamilton–Jacobi equation. The basic idea consists in replacing the gradient by *superdifferential* and *subdifferential* and the equality in (1) by two inequalities. In [13] several results concerning uniqueness of solutions in the class of uniformly continuous functions is given.

A different approach, based on Dini derivatives, was developed in [25], [26] for Lipschitz solutions.

Since the value function is merely lower semicontinuous, an extension of viscosity solutions to semicontinuous functions is needed.

In [16]–[19] a study using contingent derivatives (which are extensions of Dini derivatives to semicontinuous functions and are defined in §2) was proposed. It was shown that a function V satisfying two contingent inequalities (called contingent solution of the HJB equation) has properties of the value function: it is nondecreasing along solutions of (2) and is constant along at least one solution. It is unique whenever the final value $V(T, \cdot)$ is fixed. Proofs are based on viability theory ([2]–[4]). Relationships with viscosity solutions were also discussed. Contingent derivatives have further applications in control theory. For instance, in some cases the optimal synthesis may be obtained using the directional derivatives of the value function (see [19], [10]).

Results obtained in [16]–[19] do not allow us to deal with arbitrary lower semicontinuous functions. Namely, one of the contingent inequalities

$$\forall (t, x) \in \text{Dom}(V), \quad t < T, \quad \sup_{u \in U} D_{\uparrow}(-V)(t, x)(1, f(t, x, u)) \leq 0,$$

which implies an invariance property of the epigraph of $-V$, allows us to deal only with upper semicontinuous V .

In this paper we replace it by a new inequality, specifically,

$$\forall (t, x) \in \text{Dom}(V), \quad t > 0, \quad \sup_{u \in U} D_{\uparrow}V(t, x)(-1, -f(t, x, u)) \leq 0,$$

which yields an invariance property of the epigraph of V . Such a modification leads to much stronger results. On one hand, it allows us to provide a characterization of the lower semicontinuous value function in terms of contingent derivatives and the final value $V(T, \cdot) = g(\cdot)$ (see §2 for the main result); on the other hand, every continuous contingent solution of the HJB equation turns out to be its viscosity solution (this is shown in §7). In particular, it implies uniqueness results for viscosity solutions of HJB equations with convex Hamiltonian $H(t, x, \cdot)$ under less restrictive assumptions than in [13].

Recently, in [8], [9], a modification of the concept of viscosity solutions for semicontinuous functions was proposed. The approach is based on a construction of “touching from one side” functions, which is usual for viscosity solutions theory. Such a modified definition of a solution states that a lower semicontinuous function V is a solution of (1) if for all $(p_t, p_x) \in \mathbf{R} \times \mathbf{R}^n$ in the subdifferential of V at $(t, x) \in]0, T[\times \mathbf{R}^n$,

$$-p_t + H(t, x, -p_x) = 0$$

and for all $\bar{x} \in \mathbf{R}^n$,

$$(5) \quad V(0, \bar{x}) = \liminf_{(t,x) \rightarrow (0+, \bar{x})} V(t, x) \ \& \ g(\bar{x}) = \liminf_{(t,x) \rightarrow (T-, \bar{x})} V(t, x).$$

We have uniqueness of lower semicontinuous solutions of (1), when H is, loosely speaking, Lipschitz and convex with respect to p . Furthermore, a continuous function V is a viscosity solution if and only if it satisfies the above properties. This result is improved in this paper by relaxing assumptions about the Hamiltonian H .

We discuss three equivalent definitions of lower semicontinuous solutions of HJB equation: the one from [8], a modified “contingent definition,” and the one with (5) replaced by the following: For all (p_t, p_x) in the subdifferential of V at $(0, \bar{x})$,

$$-p_t + H(0, x, -p_x) \geq 0,$$

and for all (p_t, p_x) in the subdifferential of V at (T, \bar{x}) ,

$$-p_t + H(T, x, -p_x) \leq 0.$$

As in [16], the modified “contingent definition” yields monotonicity. The approach we use is still based on viability theory. We describe the dynamics by differential inclusions since, by the well-known arguments, the control system (2) can be reduced to the differential inclusion

$$x' \in F(t, x) := f(t, x, U).$$

The outline of the paper is as follows: In §2 we state the main result. Section 3 is devoted to the monotone behavior of contingent solutions and §4 is devoted to solutions formulated in terms of subdifferentials. In §5 we address the definition of solution proposed in [8] using alternative boundary conditions. A comparison with continuous viscosity solutions is provided in §6. In §7 we associate with a Hamilton–Jacobi–Bellman equation (1) (with convex Hamiltonian) an optimal control problem whose value function is the only solution of the HJB equation. This leads to both existence and uniqueness results for (1). Finally, in §8 the stability of value function is investigated. In view of the results of §7, this allows us to study stability of solutions of the HJB equation under perturbations of H and g .

2. Main theorem. Consider $T > 0$, a set-valued map $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ and the associated differential inclusion

$$(6) \quad x'(t) \in F(t, x(t)) \text{ almost everywhere.}$$

We denote by $S_{[t_0, T]}(x_0)$ the set of absolutely continuous solutions of (6) defined on $[t_0, T]$ and satisfying the initial condition $x(t_0) = x_0$.

Let an extended function $g : \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ and $\xi_0 \in \mathbf{R}^n$ be given. Consider the following minimization problem (called *Mayer’s problem*):

$$(7) \quad \min \{g(x(T)) \mid x \text{ is a solution to (6), } x(0) = \xi_0\}.$$

The value function $\mathcal{V} : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{\pm\infty\}$ associated with it is defined by the following: for all $(t_0, x_0) \in [0, T] \times \mathbf{R}^n$,

$$(8) \quad \mathcal{V}(t_0, x_0) = \inf \{g(x(T)) \mid x \in S_{[t_0, T]}(x_0)\}.$$

Denote by $B_R(0)$ the closed ball of center zero and radius $R \geq 0$. We impose the following assumptions

- (a) F is continuous with nonempty convex compact images;
- (b) $\exists k \in L^1(0, T)$ such that for almost all $t \in [0, T]$, we have
- (9) $\forall x \in \mathbf{R}^n, \sup_{v \in F(t, x)} \|v\| \leq k(t)(1 + \|x\|);$
- (c) $\forall R > 0, \exists c_R \in L^1(0, T)$ such that for almost all $t \in [0, T]$
 $F(t, \cdot)$ is $c_R(t)$ -Lipschitz on $B_R(0)$.

PROPOSITION 2.1. *If (9) holds true, then \mathcal{V} is lower semicontinuous and*

$$(10) \quad \forall (t_0, x_0) \in [0, T] \times \mathbf{R}^n, \quad \mathcal{V}(t_0, x_0) = \min \{g(x(T)) \mid x \in S_{[t_0, T]}(x_0)\}.$$

Furthermore,

$$(11) \quad \forall \bar{x} \in \mathbf{R}^n, \quad g(\bar{x}) = \liminf_{t \rightarrow T-, x \rightarrow \bar{x}} \mathcal{V}(t, x), \quad \mathcal{V}(0, \bar{x}) = \liminf_{t \rightarrow 0+, x \rightarrow \bar{x}} \mathcal{V}(t, x).$$

Proof. The first statement results from the compactness of $S_{[t_0, T]}(x_0)$ in $\mathcal{C}(t_0, T; \mathbf{R}^n)$ (see, for instance, [4], [5, p. 273]). To prove (11), consider $\bar{x} \in \mathbf{R}^n$ and let $t_i \rightarrow T-, \bar{x}_i \rightarrow \bar{x}$ be such that

$$\lim_{i \rightarrow \infty} \mathcal{V}(t_i, \bar{x}_i) = \liminf_{t \rightarrow T-, x \rightarrow \bar{x}} \mathcal{V}(t, x).$$

Consider $y_i \in \mathbf{R}^n$ and $x_i \in S_{[t_i, T]}(y_i)$ such that $x_i(T) = \bar{x}$. Then, by (9), $y_i \rightarrow \bar{x}$. Since $\mathcal{V}(t_i, y_i) \leq g(x_i(T)) = g(\bar{x})$, we obtain

$$\lim_{i \rightarrow \infty} \mathcal{V}(t_i, \bar{x}_i) \leq \liminf_{i \rightarrow \infty} \mathcal{V}(t_i, y_i) \leq g(\bar{x}) = V(T, \bar{x})$$

and deduce the first equality in (11) using the lower semicontinuity of V .

Let $x \in S_{[0, T]}(\bar{x})$ be such that $\mathcal{V}(0, \bar{x}) = g(x(T))$. Then $\mathcal{V}(0, \bar{x}) \equiv \mathcal{V}(t, x(t))$ for all $t \in [0, T]$, and the result follows from the lower semicontinuity of \mathcal{V} . \square

DEFINITION 2.2. Consider an extended function $\varphi : \mathbf{R}^n \mapsto \mathbf{R} \cup \{\pm\infty\}$.

- (i) The domain of φ , $\text{Dom}(\varphi)$, is the set of all x_0 such that $\varphi(x_0) \neq \pm\infty$.
- (ii) The subdifferential of φ at $x_0 \in \text{Dom}(\varphi)$ is given by

$$\partial_- \varphi(x_0) = \left\{ p \in \mathbf{R}^n \mid \liminf_{x \rightarrow x_0} \frac{\varphi(x) - \varphi(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \geq 0 \right\}$$

(iii) The contingent epiderivative of φ at $x_0 \in \text{Dom}(\varphi)$ in the direction $u \in \mathbf{R}^n$ is given by

$$D_1 \varphi(x_0)(u) = \liminf_{h \rightarrow 0+, u' \rightarrow u} \frac{\varphi(x_0 + hu') - \varphi(x_0)}{h}.$$

Remark. The subdifferential was used in [12], [14] to define viscosity supersolutions of Hamilton–Jacobi equations. The contingent epiderivative was used in [1], [4] to investigate stability. See also [5, Chap. 6] for further properties.

Assume that F has nonempty compact images and define the Hamiltonian $H : [0, T] \times \mathbf{R}^n \times \mathbf{R}^n \mapsto \mathbf{R}$ by

$$(12) \quad H(t, x, p) = \max_{v \in F(t, x)} \langle p, v \rangle.$$

Then $H(t, x, \cdot)$ is convex and positively homogeneous. Furthermore, if F is upper semicontinuous (respectively, lower semicontinuous), then so is H .

Consider a function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$. We may always assume that V is defined on $\mathbf{R} \times \mathbf{R}^n$ by setting $V(t, x) = +\infty$, whenever $t \notin [0, T]$. In the theorem below we use Definition 2.2 with such an extension of V .

THEOREM 2.3. *Assume (9) and let $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ be an extended lower semicontinuous function.*

Then the following five statements are equivalent:

- (i) V is the value function, i.e., $V = \mathcal{V}$;
- (ii) $V(T, \cdot) = g(\cdot)$ and for all $(t_0, x_0) \in \text{Dom}(V)$ we have
 $\forall x \in S_{[t_0, T]}(x_0), \forall t \in [t_0, T], V(t, x(t)) \geq V(t_0, x_0)$
 $\exists \bar{x} \in S_{[t_0, T]}(x_0), \forall t \in [t_0, T], V(t, \bar{x}(t)) \leq V(t_0, x_0)$;
- (iii) $V(T, \cdot) = g(\cdot)$ and for all $(t, x) \in \text{Dom}(V)$,
 $0 \leq t < T \implies \inf_{v \in F(t, x)} D_{\uparrow} V(t, x)(1, v) \leq 0$
 $0 < t \leq T \implies \sup_{v \in F(t, x)} D_{\uparrow} V(t, x)(-1, -v) \leq 0$;
- (iv) $\forall (t, x) \in]0, T[\times \mathbf{R}^n, \forall (p_t, p_x) \in \partial_- V(t, x), -p_t + H(t, x, -p_x) = 0$
 $\forall (p_t, p_x) \in \partial_- V(0, x), -p_t + H(0, x, -p_x) \geq 0$
 $\forall (p_t, p_x) \in \partial_- V(T, x), -p_t + H(T, x, -p_x) \leq 0$ and $V(T, \cdot) = g(\cdot)$;
- (v) $\forall (t, x) \in]0, T[\times \mathbf{R}^n, \forall (p_t, p_x) \in \partial_- V(t, x), -p_t + H(t, x, -p_x) = 0$
 $\forall \bar{x} \in \mathbf{R}^n, V(0, \bar{x}) = \liminf_{t \rightarrow 0+, x \rightarrow \bar{x}} V(t, x)$
 $\forall \bar{x} \in \mathbf{R}^n, V(T, \bar{x}) = \liminf_{t \rightarrow T-, x \rightarrow \bar{x}} V(t, x)$, and $V(T, \cdot) = g(\cdot)$.

Finally, if $\text{Dom}(V)$ is closed and the restriction of V to its domain is continuous and if

$$(13) \quad ([0, T] \times \mathbf{R}^n) \cap \text{Dom}(V) \subset \overline{([0, T[\times \mathbf{R}^n) \cap \text{Dom}(V)}}$$

then the above statements are equivalent to the following:

V is a viscosity solution of the Hamilton–Jacobi equation

$$-\frac{\partial V}{\partial t}(t, x) + H\left(t, x, -\frac{\partial V}{\partial x}(t, x)\right) = 0, \quad V(T, \cdot) = g(\cdot)$$

on $\text{Dom}(V)$.

Remark. We recall the definition of viscosity solutions in §6.

The fact that (i) \iff (ii) is well known (see, for instance, [15, §3.3]). We prove all other equivalences in §§3–6.

3. Monotone behavior of contingent solutions. Theorems 3.2 and 3.3 proved below yield equivalence of (ii) and (iii) in Theorem 2.3. We need the following definition.

DEFINITION 3.1. Let $K \subset \mathbf{R}^n$ be a nonempty subset and $x_0 \in K$. The contingent cone to K at x_0 , $T_K(x_0)$, is defined by

$$v \in T_K(x_0) \iff \liminf_{h \rightarrow 0+} d\left(v, \frac{K - x_0}{h}\right) = 0.$$

This notion was introduced by Bouligand in the early 1930s. See, for instance, [5, Chap. 4] for many properties of tangent cones.

It was shown in [5, p. 226] that for $\varphi : \mathbf{R}^n \rightarrow \mathbf{R} \cup \{\pm\infty\}$ and $x_0 \in \text{Dom}(\varphi)$

$$(14) \quad \mathcal{E}p(D_{\uparrow}\varphi(x_0)) = T_{\mathcal{E}p(\varphi)}(x_0, \varphi(x_0)),$$

where $\mathcal{E}p$ denotes the epigraph. Consider $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$.

THEOREM 3.2. *Let $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ be an extended lower semicontinuous function. Assume that F is upper semicontinuous, that $F(t, x)$ is nonempty convex and compact for all $(t, x) \in \text{Dom}(V)$, and that for some integrable function $k : [0, T] \mapsto \mathbf{R}_+$,*

$$\forall (t, x) \in \text{Dom}(V), \quad \sup_{v \in F(t, x)} \|v\| \leq k(t)(1 + \|x\|).$$

Then the following two statements are equivalent

- (i) $\forall (t, x) \in \text{Dom}(V)$ with $t < T$, $\inf_{v \in F(t, x)} D_{\uparrow}V(t, x)(1, v) \leq 0$;
- (ii) $\forall (t_0, x_0) \in [0, T] \times \mathbf{R}^n$, $\exists \bar{x} \in S_{[t_0, T]}(x_0)$, $\forall t \in [t_0, T]$, $V(t, \bar{x}(t)) \leq V(t_0, x_0)$.

Proof. Assume that (i) holds true and fix $(t_0, x_0) \in \text{Dom}(V)$. Define the upper semicontinuous set-valued map $\hat{F} : \mathbf{R}_+ \times \mathbf{R}^n \times \mathbf{R} \rightsquigarrow \mathbf{R} \times \mathbf{R}^n \times \mathbf{R}$ by

$$\hat{F}(t, x, z) = \begin{cases} \{1\} \times F(t, x) \times \{0\} & \text{when } t < T \\ [0, 1] \times \overline{\text{co}}(F(T, x) \cup \{0\}) \times \{0\} & \text{when } t \geq T \end{cases}$$

and consider the viability problem

$$(15) \quad \begin{aligned} (t, x, z)' &\in \hat{F}(t, x, z), \\ (t, x, z)(t_0) &= (t_0, x_0, V(t_0, x_0)), \\ (t, x, z) &\in \mathcal{E}p(V), \end{aligned}$$

By (14), for all $(t, x, z) \in \mathcal{E}p(V)$ we have $\hat{F}(t, x, z) \cap T_{\mathcal{E}p(V)}(t, x, z) \neq \emptyset$.

The viability theorem [22] (see also [4, p. 180], [2], [3]) yields that problem (15) has a solution

$$[t_0, T] \ni t \mapsto (t, \bar{x}(t), z(t)) \in \mathcal{E}p(V).$$

Thus $V(t, \bar{x}(t)) \leq z(t) = V(t_0, x_0)$ for all $t \in [t_0, T]$ and (ii) follows.

Conversely, assume that (ii) is satisfied. Fix $(t_0, x_0) \in \text{Dom}(V)$ with $t_0 < T$ and let \bar{x} be as in (ii). Let $h_n \rightarrow 0+$ be such that $[\bar{x}(t_0 + h_n) - \bar{x}(t_0)]/h_n$ converge to some v . By the mean value theorem [4, p. 21], $v \in F(t_0, x_0)$, and by (ii),

$$D_{\uparrow}V(t_0, x_0)(1, v) \leq 0. \quad \square$$

THEOREM 3.3. *Let $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ be an extended lower semicontinuous function. Assume that F verifies (9).*

Then the following two statements are equivalent:

- (i) $\forall (t, x) \in \text{Dom}(V)$ with $t > 0$, $\sup_{v \in F(t, x)} D_{\uparrow}V(t, x)(-1, -v) \leq 0$;
- (ii) $\forall (t_0, x_0) \in [0, T] \times \mathbf{R}^n$, $\forall x \in S_{[t_0, T]}(x_0)$ and for all $t \in [t_0, T]$, $V(t_0, x_0) \leq V(t, x(t))$.

Proof. Assume (i) and fix $(t_0, x_0) \in [0, T] \times \mathbf{R}^n$, $x \in S_{[t_0, T]}(x_0)$. Since (i) does not involve T , it is sufficient to prove the inequality in (ii) for $t = T$ and it is enough to consider the case $V(T, x(T)) < \infty$.

Let U denote the closed unit ball in \mathbf{R}^n . From [5, p. 380] there exists a continuous function $f : [0, T] \times \mathbf{R}^n \times U \mapsto \mathbf{R}^n$ such that

$$\begin{aligned} \forall (t, x) \in [0, T] \times \mathbf{R}^n, \quad F(t, x) &= f(t, x, U), \\ \forall u \in U, \quad f(t, \cdot, u) &\text{ is } 5nc_R(t) - \text{Lipschitz on } B_R(0) \text{ for a.e. } t \in [0, T], \\ \forall u, v \in U, \quad \|f(t, x, u) - f(t, x, v)\| &\leq 5n(\sup_{y \in F(t, x)} \|y\|) \|u - v\|. \end{aligned}$$

By [5, p. 316] for a measurable $u : [t_0, T] \mapsto U$, $x'(t) = f(t, x(t), u(t))$ almost everywhere. Consider a sequence of continuous maps $u_k : [t_0, T] \mapsto U$ converging to u in $L^1(t_0, T; U)$ and let x_k denote the solution of

$$x'_k(t) = f(t, x_k(t), u_k(t)), \quad t \in [t_0, T], \quad x_k(T) = x(T).$$

The Gronwall lemma yields that $x_k(t_0)$ converge to x_0 . On the other hand, the map $t \mapsto (T - t, x_k(T - t), V(T, x(T)))$ is the only solution of

$$(16) \quad \begin{aligned} \gamma'(t) &= -1, \\ y'(t) &= -f(T - t, y(t), u_k(T - t)), \\ z'(t) &= 0, \\ \gamma(0) &= T, \quad y(0) = x(T), \quad z(0) = V(T, x(T)). \end{aligned}$$

By (14) and (i) we know that

$$\forall (\gamma, x, z) \in \mathcal{E}p(V), \quad (-1, -f(\gamma, x, u_k(\gamma)), 0) \in T_{\mathcal{E}p(V)}(\gamma, x, z).$$

The map $(t, x) \leadsto \{-f(T - t, x, u_k(T - t))\}$ being continuous, the viability theorem [22] yields that (16) has at least one solution

$$[0, T - t_0] \ni t \mapsto (\gamma(t), y(t), z(t)) \in \mathcal{E}p(V).$$

Consequently,

$$\forall 0 \leq t \leq T - t_0, \quad (T - t, x_k(T - t), V(T, x(T))) \in \mathcal{E}p(V);$$

therefore, for all $0 \leq t \leq T - t_0$, $V(T, x(T)) \geq V(T - t, x_k(T - t))$. In particular, $V(t_0, x_k(t_0)) \leq V(T, x(T))$. Taking the limit when $k \rightarrow \infty$ and using that V is lower semicontinuous, we deduce (ii) for $t = T$.

Conversely, assume that (ii) is verified. Let $(t_0, x_0) \in \text{Dom}(V)$ be such that $t_0 > 0$. Fix $v \in F(t_0, x_0)$. Filippov's theorem [4, p. 120] implies that for some $\bar{h} > 0$ there exist $y_0 \in \mathbf{R}^n$ and $y \in S_{[t_0 - \bar{h}, t_0]}(y_0)$ such that $y(t_0) = x_0$ and

$$\lim_{h \rightarrow 0+} \frac{y(t_0 - h) - x_0}{h} = -v.$$

On the other hand, by (ii), for all $h \in [0, \bar{h}]$, $V(t_0 - h, y(t_0 - h)) \leq V(t_0, x_0)$. Consequently $D_{\uparrow} V(t_0, x_0)(-1, -v) \leq 0$. Since $v \in F(t_0, x_0)$ is arbitrary, statement (i) follows. \square

4. Subgradient form of the HJB equation. The equivalence (iii) \iff (iv) of Theorem 2.3 follows from Lemmas 4.3 and 4.4 given in this section. From [19] (see also [5, pp. 249, 253]) we have the following result.

PROPOSITION 4.1. *Let $\varphi : \mathbf{R}^n \mapsto \mathbf{R} \cup \{\pm\infty\}$ and $x_0 \in \text{Dom}(\varphi)$. Then the following statements are equivalent:*

- (i) $p \in \partial_- \varphi(x_0)$;
- (ii) $\forall u \in \mathbf{R}^n, \langle p, u \rangle \leq D_{\uparrow} \varphi(x_0)(u)$;
- (iii) $(p, -1) \in [T_{\mathcal{E}_p(\varphi)}(x_0, \varphi(x_0))]^-$ (the negative polar cone).

The following result can be deduced from [24, Theorem 1] (see also [23]).

LEMMA 4.2. *Consider an extended lower semicontinuous function $\varphi : \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ and $x_0 \in \text{Dom}(\varphi)$. Let $(p, 0) \in [T_{\mathcal{E}_p(\varphi)}(x_0, \varphi(x_0))]^-$ be such that $p \neq 0$. Then for every $\varepsilon > 0$, there exist $x_\varepsilon, p_\varepsilon$ in \mathbf{R}^n and $q_\varepsilon < 0$ such that*

$$\|x_\varepsilon - x_0\| \leq \varepsilon, \quad \|p_\varepsilon - p\| \leq \varepsilon \quad \& \quad (p_\varepsilon, q_\varepsilon) \in [T_{\mathcal{E}_p(\varphi)}(x_\varepsilon, \varphi(x_\varepsilon))]^-.$$

Consider a set-valued map $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ with nonempty compact images and define the Hamiltonian H by (12).

LEMMA 4.3. *Consider an extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$. Assume that F is upper semicontinuous and has nonempty convex compact images on $\text{Dom}(V)$.*

Then the following four statements are equivalent:

- (i) $\forall (t, x) \in \text{Dom}(V)$ with $t < T$ and $\forall (p_t, p_x, q) \in [T_{\mathcal{E}_p(V)}(t, x, V(t, x))]^-$
- (17) $-p_t + H(t, x, -p_x) \geq 0$;
- (ii) For all $(t, x) \in \text{Dom}(V)$ with $t < T$ and for all $y \geq V(t, x)$
- $(\{1\} \times F(t, x) \times \{0\}) \cap T_{\mathcal{E}_p(V)}(t, x, y) \neq \emptyset$;
- (iii) For all $(t, x) \in \text{Dom}(V)$ with $t < T$

$$\min_{v \in F(t, x)} D_{\uparrow} V(t, x)(1, v) \leq 0;$$

- (iv) For all $(t, x) \in \text{Dom}(V)$ with $t < T$

$$\forall (p_t, p_x) \in \partial_- V(t, x), \quad -p_t + H(t, x, -p_x) \geq 0.$$

Proof. By (14), (ii) \iff (iii). Clearly (ii) \implies (i).

If (i) holds true, then, from the separation theorem,

$$(18) \quad (\{1\} \times F(t, x) \times \{0\}) \cap \overline{\text{co}}(T_{\mathcal{E}_p(V)}(t, x, y)) \neq \emptyset$$

for all $(t, x) \in \text{Dom}(V)$ with $t < T$ and $y \geq V(t, x)$. Finally, since F is upper semicontinuous and has convex compact images, by [21] (see also [6] for a better proof), (18) implies (ii).

By Proposition 4.1, (i) yields (iv). Assume next that (iv) is verified. Fix $(t, x) \in \text{Dom}(V)$ with $t < T$ and $(p_t, p_x, q) \in [T_{\mathcal{E}_p(V)}(t, x, V(t, x))]^-$. Then $q \leq 0$. If $q < 0$, then

$$\left(\frac{p_t}{|q|}, \frac{p_x}{|q|}, -1 \right) \in [T_{\mathcal{E}_p(V)}(t, x, V(t, x))]^-.$$

From Proposition 4.1 and (iv) we deduce (17). It remains to consider the case $q = 0$ and $(p_t, p_x) \neq 0$. For this purpose it is enough to apply Lemma 4.2 and to use the upper semicontinuity of H . \square

LEMMA 4.4. *Consider an extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ and assume that F is lower semicontinuous and has nonempty compact images on $\text{Dom}(V)$.*

Then the following four statements are equivalent:

(i) $\forall (t, x) \in \text{Dom}(V)$ with $t > 0$ and $\forall (p_t, p_x, q) \in [T_{\mathcal{E}p(V)}(t, x, V(t, x))]^-$

$$-p_t + H(t, x, -p_x) \leq 0;$$

(ii) For all $(t, x) \in \text{Dom}(V)$ with $t > 0$ and for all $y \geq V(t, x)$

$$\{-1\} \times (-F(t, x)) \times \{0\} \subset T_{\mathcal{E}p(V)}(t, x, y);$$

(iii) For all $(t, x) \in \text{Dom}(V)$ with $t > 0$

$$\sup_{v \in F(t, x)} D_{\uparrow} V(t, x)(-1, -v) \leq 0;$$

(iv) For all $(t, x) \in \text{Dom}(V)$ with $t > 0$

$$\forall (p_t, p_x) \in \partial_- V(t, x), \quad -p_t + H(t, x, -p_x) \leq 0.$$

Proof. We deduce from (14) that (ii) is equivalent to (iii). Clearly, (ii) \implies (i). The separation theorem and (i) yield

$$(19) \quad \{-1\} \times (-F(t, x)) \times \{0\} \subset \overline{\text{co}}(T_{\mathcal{E}p(V)}(t, x, y))$$

for all $(t, x) \in \text{Dom}(V)$ with $t > 0$ and $y \geq V(t, x)$.

Since F is lower semicontinuous, (19) and [5, p. 130] imply that for all $(t, x) \in \text{Dom}(V)$ with $t > 0$ and all $y \geq V(t, x)$,

$$\begin{aligned} \{-1\} \times (-F(t, x)) \times \{0\} &\subset \text{Liminf}_{(t', x', y') \rightarrow_{\mathcal{E}p(V)}(t, x, y)} \overline{\text{co}}(T_{\mathcal{E}p(V)}(t', x', y')) \\ &\subset T_{\mathcal{E}p(V)}(t, x, y), \end{aligned}$$

where Liminf denotes the *lower set limit* and $\rightarrow_{\mathcal{E}p(V)}$ the convergence in the epigraph of V . Hence (ii) follows from (i). Arguments similar to those of the proof of Lemma 4.3 yield (i) \iff (iv). \square

5. Alternative boundary conditions. We observe that in Theorem 2.3 (iv) \implies (v), thanks to the equivalence (iv) \iff (i) and in view of Proposition 2.1. In this section we prove that (v) yields (iii). Consider a set-valued map $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$.

THEOREM 5.1. *Assume (9). If an extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ satisfies*

$$\begin{aligned} \forall (t, x) \in]0, T[\times \mathbf{R}^n, \quad \forall (p_t, p_x) \in \partial_- V(t, x), \quad -p_t + H(t, x, -p_x) &= 0, \\ \forall \bar{x} \in \mathbf{R}^n, \quad V(0, \bar{x}) &= \liminf_{t \rightarrow 0+, x \rightarrow \bar{x}} V(t, x), \\ \forall \bar{x} \in \mathbf{R}^n, \quad V(T, \bar{x}) &= \liminf_{t \rightarrow T-, x \rightarrow \bar{x}} V(t, x) \end{aligned}$$

then for all $(t, x) \in \text{Dom}(V)$,

$$(20) \quad \begin{aligned} 0 < t \leq T &\implies \sup_{v \in F(t, x)} D_{\uparrow} V(t, x)(-1, -v) \leq 0, \\ 0 \leq t < T &\implies \inf_{v \in F(t, x)} D_{\uparrow} V(t, x)(1, v) \leq 0. \end{aligned}$$

Proof. From the proofs of Lemmas 4.3 and 4.4 we deduce that for all $(t, x) \in \text{Dom}(V)$ with $0 < t < T$ we have

$$\inf_{v \in F(t, x)} D_{\uparrow} V(t, x)(1, v) \leq 0, \quad \sup_{v \in F(t, x)} D_{\uparrow} V(t, x)(-1, -v) \leq 0.$$

This and Theorems 3.2 and 3.3 imply that for all $0 < t_1 \leq t_2 < T$

$$(21) \quad \forall x \in S_{[t_1, t_2]}(x_1), \quad V(t_1, x_1) \leq V(t_2, x(t_2))$$

and

$$(22) \quad \forall (t_1, x_1) \in \text{Dom}(V), \quad \exists x \in S_{[t_1, t_2]}(x_1) \quad \text{with} \quad V(t_1, x_1) = V(t_2, x(t_2)).$$

We show next that (21) holds true also for $t_2 = T$. Consider any $(t_0, x_0) \in \text{Dom}(V)$ and $x \in S_{[t_0, T]}(x_0)$. Let $x(T) = \bar{x}$ and $t_i \rightarrow T-$, $x_i \rightarrow \bar{x}$ be such that

$$\lim_{i \rightarrow \infty} V(t_i, x_i) = V(T, \bar{x}).$$

By Filippov's theorem [4, p. 120], there exist \bar{y}_i and $y_i \in S_{[0, T]}(\bar{y}_i)$ such that $y_i(t_i) = x_i$ and y_i converge to x uniformly on $[t_0, T]$. Then for all arbitrary but fixed $t_0 < t < T$ and all i large enough, $V(t, y_i(t)) \leq V(t_i, x_i)$. Since V is lower semicontinuous,

$$V(t, x(t)) \leq \liminf_{i \rightarrow \infty} V(t, y_i(t)) \leq \lim_{i \rightarrow \infty} V(t_i, x_i) = V(T, \bar{x}).$$

This, (21), and Theorem 3.3 yield the first inequality in (20).

To prove that (22) holds true also with $t_1 = 0$, fix $(0, \bar{x}) \in \text{Dom}(V)$ and consider $t_i \rightarrow 0+$, $\bar{x}_i \rightarrow \bar{x}$ satisfying

$$V(0, \bar{x}) = \lim_{i \rightarrow \infty} V(t_i, \bar{x}_i).$$

Let $\bar{y}_i \in \mathbf{R}^n$ and $x_i \in S_{[0, T]}(\bar{y}_i)$ be such that $x_i(t_i) = \bar{x}_i$ and

$$\forall t_i \leq t \leq T - \frac{1}{i}, \quad V(t_i, \bar{x}_i) = V(t, x_i(t)).$$

Taking a subsequence and keeping the same notation, by the convergence theorem [5, p. 273], we may assume that x_i converge uniformly to some $x \in S_{[0, T]}(\bar{x})$. Then for all $0 < t < T$,

$$V(0, \bar{x}) = \lim_{i \rightarrow \infty} V(t, x_i(t)) \geq V(t, x(t)).$$

This, (22), and Theorem 3.2 imply the second inequality in (20). \square

6. Comparisons with viscosity solutions. Let $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ be a set-valued map with nonempty compact images and H be given by (12). Consider the Hamilton–Jacobi–Bellman equation

$$(23) \quad -\frac{\partial V}{\partial t}(t, x) + H\left(t, x, -\frac{\partial V}{\partial x}(t, x)\right) = 0$$

An extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ is called a *viscosity supersolution* of (23) if for all $(t, x) \in \text{Dom}(V)$ with $t \in]0, T[$ we have

$$\forall (p_t, p_x) \in \partial_- V(t, x), \quad -p_t + H(t, x, -p_x) \geq 0.$$

Remark. We refer to [12], [14] for the continuous case and also underline that the interior of $\text{Dom}(V)$ may be empty. This leads to a slight difference with the usual definition of viscosity supersolutions, usually defined on the closure of an open set.

However, for optimal control problems with constraints it may happen that the domain of definition of the value function has an empty interior. For this reason it is more natural to deal with arbitrary lower semicontinuous solutions of HJB equations.

In particular, any V satisfying (v) of Theorem 2.3 is a viscosity supersolution.

THEOREM 6.1. *Let $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ be an extended lower semicontinuous function. Assume that F is upper semicontinuous and has nonempty convex compact images on $\text{Dom}(V)$.*

Then the following two statements are equivalent:

- (i) V is a viscosity supersolution of (23);
- (ii) For all $0 < t < T$ and $x \in \mathbf{R}^n$ such that $V(t, x) \neq +\infty$, we have

$$(24) \quad \inf_{v \in F(t, x)} D_{\uparrow} V(t, x)(1, v) \leq 0.$$

The proof follows by the same arguments as in the proof of Lemma 4.3.

Next we recall the notion of viscosity subsolution of (23).

DEFINITION 6.2. Consider an extended function $\varphi : \mathbf{R}^n \mapsto \mathbf{R} \cup \{\pm\infty\}$. The superdifferential of φ at $x_0 \in \text{Dom}(\varphi)$ is defined by

$$p \in \partial_+ \varphi(x_0) \iff \limsup_{x \rightarrow x_0} \frac{\varphi(x) - \varphi(x_0) - \langle p, x - x_0 \rangle}{\|x - x_0\|} \leq 0.$$

The contingent *hypoderivative* of φ at $x_0 \in \text{Dom}(\varphi)$ in the direction $u \in \mathbf{R}^n$ is defined by

$$D_{\downarrow} \varphi(x_0)(u) = \limsup_{h \rightarrow 0+, u' \rightarrow u} \frac{\varphi(x_0 + hu') - \varphi(x_0)}{h}.$$

Clearly,

$$\partial_+ \varphi(x_0) = -\partial_-(-\varphi)(x_0) \quad \text{and} \quad D_{\downarrow} \varphi(x_0)(u) = -D_{\uparrow}(-\varphi)(x_0)(u)$$

and

$$T_{\mathcal{Hyp}(\varphi)}(x_0, \varphi(x_0)) = \mathcal{Hyp}(D_{\downarrow} \varphi(x_0)),$$

where \mathcal{Hyp} states for the hypograph. In particular, $p \in \partial_+ \varphi(x_0)$ if and only if

$$(25) \quad \forall u \in \mathbf{R}^n, \quad D_{\downarrow} \varphi(x_0)(u) \leq \langle p, u \rangle.$$

Thus

$$(26) \quad p \in \partial_+ \varphi(x_0) \iff (-p, +1) \in (T_{\mathcal{Hyp}(\varphi)}(x_0, \varphi(x_0)))^-.$$

An extended upper semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{-\infty\}$ is called a *viscosity subsolution* of (23) if for all $(t, x) \in \text{Dom}(V)$ with $0 < t < T$ we have

$$\forall (p_t, p_x) \in \partial_+ V(t, x), \quad -p_t + H(t, x, -p_x) \leq 0.$$

In the above we set $V = -\infty$ on the complement of $[0, T] \times \mathbf{R}^n$ and define the superdifferential for such extended function.

THEOREM 6.3. *Let $V : [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R} \cup \{\pm\infty\}$ be an extended function whose domain is closed and such that the restriction of V to $\text{Dom}(V)$ is continuous. Assume that F satisfies (9). Then the following two statements are equivalent:*

- (i) V is a viscosity subsolution of (23);
- (ii) For all $0 < t < T$ and all $x \in \mathbf{R}^n$ with $(t, x) \in \text{Dom}(V)$,

$$\sup_{v \in F(t, x)} D_{\uparrow} V(t, x)(-1, -v) \leq 0.$$

Proof. Assume (ii) and set $V(t, x) = +\infty$ for all $(t, x) \notin \text{Dom}(V)$. Then V is lower semicontinuous. Fix $0 < t_0 < T$. By Theorem 3.3, for every $t_0 \leq t_1 < T$ and every $x \in S_{[t_0, t_1]}(x_0)$ the following holds true:

$$\forall t \in [t_0, t_1], \quad V(t_0, x_0) \leq V(t, x(t))$$

Fix $v \in F(t_0, x_0)$. From Filippov's theorem [4, p. 120], there exist $t_0 < t_1 < T$ and $x \in S_{[t_0, t_1]}(x_0)$ such that $x'(t_0) = v$. The above inequality yields $0 \leq D_{\downarrow} V(t_0, x_0)(1, v)$. Consequently,

$$\forall (p_t, p_x) \in \partial_+ V(t_0, x_0), \quad 0 \leq p_t + \langle p_x, v \rangle$$

Since $v \in F(t_0, x_0)$ is arbitrary, V is a viscosity subsolution.

Assume next that (i) is verified. We set $V(t, x) = -\infty$ for all $(t, x) \notin \text{Dom}(V)$. Then the hypograph $\mathcal{Hyp}(V)$ of V is closed. Exactly as at the end of the proof of Lemma 4.3 we show that for all $(t, x) \in \text{Dom}(V)$ with $0 < t < T$ and all $z \leq V(t, x)$

$$(27) \quad \forall (q_t, q_x, q) \in (T_{\mathcal{Hyp}(V)}(t, x, z))^{-}, \quad q_t + H(t, x, q_x) \leq 0.$$

We next deduce from (27) and the separation theorem that for all $(t, x) \in \text{Dom}(V)$ with $0 < t < T$ and all $z \leq V(t, x)$

$$\{1\} \times F(t, x) \times \{0\} \subset \overline{co}(T_{\mathcal{Hyp}(V)}(t, x, z)).$$

This, [5, p. 130], and lower semicontinuity of F imply that for all $(t, x) \in \text{Dom}(V)$ with $0 < t < T$

$$\begin{aligned} \{1\} \times F(t, x) \times \{0\} &\subset \liminf_{\substack{(t', x', z') \rightarrow (t, x, V(t, x)) \\ (t', x', z') \in \mathcal{Hyp}(V)}} \overline{co}(T_{\mathcal{Hyp}(V)}(t', x', z')), \\ &\subset T_{\mathcal{Hyp}(V)}(t, x, V(t, x)) = \mathcal{Hyp}(D_{\downarrow} V(t, x)). \end{aligned}$$

Thus for all $(t, x) \in \text{Dom}(V)$ satisfying $0 < t < T$,

$$\inf_{v \in F(t, x)} D_{\downarrow} V(t, x)(1, v) \geq 0.$$

Consider the extended lower semicontinuous $W : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ defined by $W(t, x) = -V(T - t, x)$. Then for all $(t, x) \in \text{Dom}(W)$ with $0 < t < T$ and all $v \in F(T - t, x)$, we have

$$D_{\uparrow} W(t, x)(-1, v) = -D_{\downarrow} V(T - t, x)(1, v) \leq 0.$$

Fix any $(t_0, x_0) \in \text{Dom}(V)$ with $0 < t_0 < T$, $v \in F(t_0, x_0)$ and consider a solution $y(\cdot)$ of the differential inclusion

$$\begin{aligned} y' &\in -F(T - t, y), \\ y(T - t_0) &= x_0, \quad y'(T - t_0) = -v. \end{aligned}$$

(It exists by [4, p. 120].) Then, applying Theorem 3.3 with W and the set-valued map $(t, x) \rightsquigarrow -F(T - t, x)$, we deduce that for all small $s > 0$,

$$W(T - t_0, x_0) \leq W(T - t_0 + s, y(T - t_0 + s))$$

and therefore for a sequence $v_s \rightarrow v$ we have $V(t_0 - s, x_0 - sv_s) \leq V(t_0, x_0)$. Thus $D_1 V(t_0, x_0)(-1, -v) \leq 0$. Since $v \in F(t_0, x_0)$ is arbitrary, (ii) follows. \square

Let $\text{Dom}(V) \subset [0, T] \times \mathbf{R}^n$ be a closed set such that (13) holds true and $V : \text{Dom}(V) \mapsto \mathbf{R}$ be a continuous *viscosity solution* of (23) (i.e., it is simultaneously super and subsolution in the viscosity sense). Then, using Theorems 6.1 and 6.3 and Proposition 4.1, we check that V verifies (v) of Theorem 2.3. Conversely, if V verifies (v), then (iii) holds true and from Theorems 6.1 and 6.3, V is a viscosity solution of (23).

The proof of Theorem 2.3 is completed.

7. Representation of solutions of Hamilton–Jacobi equations with convex Hamiltonians. Consider $H : [0, T] \times \mathbf{R}^n \times \mathbf{R}^n \mapsto \mathbf{R}$ and the Hamilton–Jacobi–Bellman equation

$$(28) \quad -\frac{\partial V}{\partial t}(t, x) + H\left(t, x, -\frac{\partial V}{\partial x}(t, x)\right) = 0.$$

We look for its solutions in the class of lower semicontinuous extended functions $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$.

In this section we impose the following assumptions:

- (i) H is continuous;
- (ii) $H(t, x, \cdot)$ is convex;
- (29) (iii) $\exists k \in L^1(0, T), \forall p \in B, \|H(t, x, p)\| \leq k(t)(1 + \|x\|)$;
- (iv) $\forall R > 0, \exists c_R \in L^1(0, T)$ such that for almost all $t \in [0, T]$
 $\forall p \in B, H(t, \cdot, p)$ is $c_R(t)$ –Lipschitz on $B_R(0)$;
- (v) $H(t, x, \cdot)$ is positively homogeneous,

where B denotes the closed unit ball in \mathbf{R}^n .

Remark. In all the results of this section we assume (29). However, assumption (v) may be replaced by the Lipschitz continuity of $H(t, x, \cdot)$ together with (modified with respect to p) conditions (iii), (iv). Then it is possible to study solutions of (28) via a Hamilton–Jacobi–Bellman equation with the new (conjugate) Hamiltonian meeting assumptions (29) (as was done, for instance, in [8]). We avoid a detailed discussion on such a more general case, because the optimal control problems give rise to positively homogeneous $H(t, x, \cdot)$.

Define $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ by

$$(30) \quad F(t, x) = \bigcap_{\|p\|=1} \{v \in \mathbf{R}^n \mid \langle p, v \rangle \leq H(t, x, p)\}$$

PROPOSITION 7.1. *If (29) holds true, then F verifies (9) and*

$$\forall p \in \mathbf{R}^n, \quad \sup_{v \in F(t, x)} \langle p, v \rangle = H(t, x, p).$$

Proof. By [11, p. 54] F has convex compact images and is continuous. Let $\bar{v} \in F(t, x)$ be such that $\|\bar{v}\| = \sup_{v \in F(t, x)} \|v\|$. Applying assumption (29) (iii) with $p = \bar{v} / \|\bar{v}\|$, we obtain (9) (b). Fix $t \in [0, T]$, $R > 0$ and let $x, y \in B_R(0)$, $z \in F(t, x)$. Observe that for every $p \in B$,

$$\langle p, z \rangle \leq H(t, x, p) \leq H(t, y, p) + c_R(t) \|x - y\|.$$

Hence, by the separation theorem, $z \in F(t, y) + c_R(t) \|x - y\| B$. Thus $F(t, x) \subset F(t, y) + c_R(t) \|x - y\| B$ and (9) (c) follows. The last statement is a well-known result of functional analysis. \square

THEOREM 7.2. *Assume (29) and consider an extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$.*

Then the following two statements are equivalent:

(i) *V satisfies the equation*

$$(31) \quad \forall (t, x) \in]0, T[\times \mathbf{R}^n, \quad \forall (p_t, p_x) \in \partial_- V(t, x), \quad -p_t + H(t, x, -p_x) = 0$$

and inequalities

$$\forall (p_t, p_x) \in \partial_- V(0, x), \quad -p_t + H(0, x, -p_x) \geq 0$$

$$\forall (p_t, p_x) \in \partial_- V(T, x), \quad -p_t + H(T, x, -p_x) \leq 0;$$

(ii) *V satisfies (31) and*

$$\forall \bar{x} \in \mathbf{R}^n, \quad V(0, \bar{x}) = \liminf_{(t, x) \rightarrow (0+, x)} V(t, x) \quad \text{and} \quad V(T, \bar{x}) = \liminf_{(t, x) \rightarrow (T-, x)} V(t, x).$$

Furthermore, define the extended lower semicontinuous function $g(\cdot) = V(T, \cdot)$ and let F be given by (30). Then the above statements are equivalent to

(iii) *For all $(t_0, x_0) \in [0, T] \times \mathbf{R}^n$,*

$$(32) \quad V(t_0, x_0) = \inf \{g(x(T)) \mid x \in S_{[t_0, T]}(x_0)\}.$$

Finally, if $\text{Dom}(V)$ is closed and the restriction of V to its domain is continuous and if

$$(\{0, T\} \times \mathbf{R}^n) \cap \text{Dom}(V) \subset \overline{[0, T[\times \mathbf{R}^n \cap \text{Dom}(V)},$$

then the above statements are equivalent to the following:

V is a viscosity solution of Hamilton–Jacobi equation (28) on $\text{Dom}(V)$.

The proof follows from Theorem 2.3 and Proposition 7.1.

COROLLARY 7.3 (maximum principle). *Assume (29) and let V_1, V_2 be extended lower semicontinuous functions from $[0, T] \times \mathbf{R}^n$ into $\mathbf{R} \cup \{+\infty\}$ satisfying (i) (or, equivalently, (ii)) of Theorem 7.2.*

If $V_1(T, \cdot) \geq V_2(T, \cdot)$, then $V_1 \geq V_2$.

Proof. By Theorem 7.2, V_i is given by (32) with $g = V_i(T, \cdot)$. \square

Remark. By the analogy with viscosity solutions, an extended lower semicontinuous function $V : [0, T] \times \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$ can be called a solution of (28) if it verifies (i) or (ii) of Theorem 7.2. In particular, in [8] (ii) is taken as a definition of solution.

8. Stability of value functions. In this section we show that the lower epilimit of value functions is still the value function of a Mayer problem. Definitions and properties of epilimits can be found, for instance, in [5, Chap. 7].

THEOREM 8.1. *Consider set-valued maps $F_i : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$, $i \geq 1$ satisfying (9) with $k(\cdot)$, $c_R(\cdot)$ independent of i , and extended lower semicontinuous functions $g_i : \mathbf{R}^n \mapsto \mathbf{R} \cup \{+\infty\}$. Assume that $\inf_{i \geq 1, x \in \mathbf{R}^n} g_i(x) > -\infty$.*

Let \mathcal{V}_i be defined by (32) with F and g replaced by F_i and g_i , respectively, and \mathcal{V} denote the lower epilimit of \mathcal{V}_i . Set $g(\cdot) = \mathcal{V}(T, \cdot)$.

If for a set-valued map $F : [0, T] \times \mathbf{R}^n \rightsquigarrow \mathbf{R}^n$ and for every $(t_0, x_0) \in [0, T] \times \mathbf{R}^n$

$$\lim_{i \rightarrow \infty, (t, x) \rightarrow (t_0, x_0)} F_i(t, x) = F(t_0, x_0),$$

then \mathcal{V} verifies (32).

Proof. We first claim that \mathcal{V} is nondecreasing along solutions of differential inclusion (6). Indeed fix $t_1 \in]t_0, T]$, $x \in S_{[t_0, T]}(x_0)$. Then for almost all $t \in [t_0, T]$,

$$\forall i \geq 1, \quad \text{dist} \left(x'(t), F_i(t, x(t)) \right) \leq \|x'(t)\| + k(t)(1 + \|x(t)\|)$$

$$\lim_{i \rightarrow \infty} \text{dist} \left(x'(t), F_i(t, x(t)) \right) = 0.$$

Let $(t_j, x_1^j) \rightarrow (t_1, x(t_1))$ be such that $\mathcal{V}(t_1, x(t_1)) = \lim_{j \rightarrow \infty} \mathcal{V}_{i_j}(t_j, x_1^j)$. From Filippov's theorem [4, p. 120] there exist solutions x_j of

$$\begin{aligned} x_j'(t) &\in F_{i_j}(t, x_j(t)), \quad t \in [t_0, T], \\ x_j(t_j) &= x_1^j \end{aligned}$$

such that $\lim_{j \rightarrow \infty} \sup_{t \in [t_0, T]} \|x_j(t) - x(t)\| = 0$. Thus, for all large j ,

$$\mathcal{V}_{i_j}(t_0, x_j(t_0)) \leq \mathcal{V}_{i_j}(t_j, x_j(t_j)) = \mathcal{V}_{i_j}(t_j, x_1^j)$$

and from the lower semicontinuity of \mathcal{V} we obtain

$$\mathcal{V}(t_0, x_0) \leq \lim_{j \rightarrow \infty} \mathcal{V}_{i_j}(t_j, x_1^j) = \mathcal{V}(t_1, x(t_1)).$$

We next show that for all $(t_0, x_0) \in [0, T] \times \mathbf{R}^n$, there exists $x \in S_{[t_0, T]}(x_0)$ such that $\mathcal{V}(t_0, x_0) \geq g(x(T))$. Indeed fix $(t_0, x_0) \in \text{Dom}(\mathcal{V})$ and let $(t_j, x_j) \rightarrow (t_0, x_0)$ be such that

$$\lim_{j \rightarrow \infty} \mathcal{V}_{i_j}(t_j, x_j) = \mathcal{V}(t_0, x_0).$$

Consider $\bar{x}_j \in S_{[t_j, T]}(x_j)$ such that $\mathcal{V}_{i_j}(t_j, x_j) = g_{i_j}(\bar{x}_j(T))$. Taking a subsequence and keeping the same notations we may assume that \bar{x}_j converge (pointwise) to some $\bar{x} \in S_{[t_0, T]}(x_0)$. Thus, by the lower semicontinuity of g ,

$$\mathcal{V}(t_0, x_0) = \lim_{j \rightarrow \infty} g_{i_j}(\bar{x}_j(T)) \geq g(\bar{x}(T)) = V(T, \bar{x}(T))$$

From the equivalence of i) and ii) in Theorem 2.3 we deduce that \mathcal{V} is the value function of problem (7). \square

Acknowledgments. I would like to thank P.-L. Lions, who brought my attention to [8], [9] while I was preparing this manuscript and the unknown referee for many constructive suggestions, which helped to improve the presentation of results.

A TRIBUTE TO WENDELL H. FLEMING

For forty years Wendell Fleming has advanced mathematics, sometimes in fundamental ways, in the areas of geometric measure theory, the calculus of variations, the theory of differential games, stochastic control theory, and population genetics. In addition, he has served as an educator, an administrator, and a national leader in policy matters affecting mathematics. His dedication to mathematics and his tireless support of mathematicians, especially young ones, has been a hallmark throughout his long, illustrious career. Those of us who have had the good fortune to know and work with Wendell have come to admire his wisdom, integrity, and kindness, and to cherish his friendship.

Wendell Fleming was born March 7, 1928, in Guthrie, Oklahoma, where his father was teaching temporarily. In 1929 the family returned to Indiana, where Fleming, who considers himself a native Hoosier, grew up on a farm near Sullivan. Upon graduation from Sullivan High School in 1945, he entered Purdue University, majoring in chemical engineering. There he met Flo Tatum, whom he married in 1948. At that time Purdue had (and still has) a course designed to give students insight into their future careers in engineering. After taking this course, Fleming decided to switch to mathematics. He attributes this decision to the discovery that he was “good at math.” One of his chemical engineering professors, upon learning of his decision, told him that mathematics was a stable subject—nothing had changed in 100 years and nothing would change in the next 100 years. After graduating from Purdue, Fleming attended the University of Wisconsin, where he wrote a thesis in surface area theory, under the direction of L. C. Young. He received his Ph.D. from Wisconsin in 1951.

For the next four years, Fleming was employed as a mathematician by the Rand Corporation. Returning to academic life in 1955, Fleming accepted a position as assistant professor at Purdue University. He moved to Brown University in 1958, and has remained on the Brown faculty. He served a term as chairman of the Department of Mathematics and is now in his third term as chairman of the Division of Applied Mathematics. Since joining Brown, he has spent a year at the University of Wisconsin, a year at Stanford University, a semester at the Massachusetts Institute of Technology, a semester at the Institute for Mathematics and its Applications at the University of Minnesota, and shorter periods of time at other institutions.

Fleming was granted a National Science Foundation Fellowship for the period 1968–1969 and was named a Guggenheim Fellow for 1976–1977. He was an invited plenary speaker at the 1983 International Congress of Mathematicians. In 1987 he was awarded the American Mathematical Society’s Steele Prize for his work with Herbert Federer on geometric measure theory. In 1991 Fleming was awarded the degree Doctor of Science, *Honoris Causa*, by Purdue University.

Wendell Fleming has authored or coauthored three books. His first, *Functions of Several Variables*, is a highly regarded undergraduate text. *Deterministic and Stochastic Optimal Control*, coauthored with Raymond Rishel, has been a standard reference in stochastic optimal control for fifteen years. The recent development of viscosity solutions of partial differential equations has inspired a new book on stochastic optimal control, entitled *Controlled Markov Processes and Viscosity Solutions*, written with Mete Soner.

Twenty students, including the third author of this tribute, have obtained Ph.D. degrees under Wendell Fleming’s supervision. Many of these students are active in

research, and work of two of them, Mete Soner and Thaleia Zariphopoulou, appears in this issue.

Good citizenship has been a high priority in Wendell Fleming's career. He has served on the editorial boards of eight journals, including the *SIAM Journal on Control and Optimization* from 1979–1990, and as an editor for two book series. He has served on numerous committees of the Conference Board of Mathematical Sciences and the American Mathematical Society, and for five years compiled reports on graduate education and employment for the *AMS Notices*. During 1981–1984 he was a member of the Board of Governors of the Institute for Mathematics and its Applications (IMA), and he helped organize the IMA programs for the years 1985–1986 and 1992–1993. From 1986–1988 he chaired the Air Force Review Panel for Mathematical Sciences and the Panel on Future Directions in Control Theory, from which emerged an influential report.

Wendell Fleming's research to date can be roughly divided into four areas: (a) the calculus of variations and geometric measure theory, (b) differential games, (c) stochastic control, and (d) population genetics. Each of these is discussed below.

(a) Beginning in the 1950s, Fleming played a major role in both the rapid development of the calculus of variations and the initiation of the new field of geometric measure theory. He made many significant and lasting contributions to these subjects, including some that were fundamental. L. C. Young, Fleming's Ph.D. supervisor, introduced the theory of generalized surfaces for the purpose of creating a general setting for problems in multi-dimensional calculus of variations. Both Fleming and Young made great strides in developing the theory of generalized surfaces and this work undoubtedly influenced Fleming's subsequent work with Federer.

In 1960, Fleming coauthored a seminal paper with Herbert Federer, "Normal and integral currents," *Ann. of Math.*, 72 (1960), pp. 458–520, which marked the beginning of geometric measure theory as it is known today. This paper introduced and developed the theory of integral currents, which, like generalized surfaces, provides a general framework for geometric problems in the calculus of variations. De Rham's concept of a k -dimensional current in R^n is used to identify a k -dimensional oriented manifold M with the operation of integrating a k -form over M . De Rham's currents are linear functionals on differential k -forms and become Schwartz distributions in the case $k = 0$. To be useful in applications, integral currents had to be general enough to allow integration of forms over sets that differed in small measure from oriented C^1 -manifolds, while at the same time they had to provide compactness properties needed for existence of solutions to geometric problems in the calculus of variations, such as the problem of least area (Plateau's Problem) in arbitrary dimension and codimension. In the 1930s, Douglas and Rado were the first to make substantial progress toward the resolution of Plateau's problem. Their work established the existence of a solution to the problem of finding a surface of least area of prescribed topological type bounded by a given curve in R^3 . However, their methods were not general enough to treat the phenomenon illustrated by Fleming in his paper "An example in the problem of least area," *Proc. Amer. Math. Soc.*, 7 (1956), pp. 1063–1074. Here he showed the existence of a simple closed rectifiable curve in R^3 such that the problem of least area with unrestricted topological type has no solution of finite topological type. The theory of integral currents is general enough to accommodate this pathology. It also supplies a powerful linkage between measure theory and algebraic topology and gives the existence of minimizing integral currents in integral homology classes. For their remarkable achievements, Federer and Fleming were awarded the Steele Prize, which carried with it the following citation: "The 1987 Steele Prize for a paper which has

proved to be of fundamental or lasting importance in its field is awarded to Herbert Federer and Wendell Fleming for their pioneering paper "Normal and integral currents".

Fleming used the theory of integral currents to investigate the regularity of solutions to the problem of least area in the paper "On the oriented Plateau problem," *Rend. Circ. Mat. Palermo*, 11 (1962), pp. 1-22. Previous attempts on the problem of least area, including those by Douglas and Rado mentioned earlier, did not completely resolve the question of the solution's regularity, allowing the possibility of branch points. Fleming settled the question in the case of a two-dimensional oriented minimizing current in R^3 by showing that, away from the boundary, it is a smooth minimal surface in the sense of classical differential geometry. Techniques developed in this paper have played a key role in subsequent work on regularity of minimal currents. In this paper Fleming also provided a completely new method of attacking the Bernstein conjecture, which states that a smooth function satisfying the minimal surface equation on R^{n-1} has the property that its graph is a hyperplane in R^n . At that time, proofs were known for the case $n = 3$, and most used methods of complex analysis. Fleming's proof did not. He showed that the Bernstein conjecture would follow from an interior regularity result for minimal integral currents with codimension one in R^n . His regularity theorem thus gave another proof of the Bernstein conjecture for $n = 3$. His discovery concerning regularity results for minimal currents and the Bernstein conjecture was used extensively in subsequent efforts by various authors that eventually led to a complete resolution of the conjecture.

(b) In the early 1960s Fleming published two papers that greatly influenced developments in differential game theory. The study of differential games was initiated in the mid 1950s by Isaacs, who treated many examples in a formal fashion. A mathematically satisfactory general treatment of the notion of strategy and of the question of the existence of value had, however, not been developed. The first major step in this direction was Fleming's 1961 paper, "The convergence problem for differential games," *J. Math. Anal. Appl.*, 3 (1961), pp. 102-116. Fleming discretized time and replaced the differential equation dynamics by difference equation dynamics. The integral payoff was also replaced by a discrete approximation. Decisions were made by each player at each of n discrete times, with full knowledge of the history of the game prior to, but not including, the current time. Fleming showed that the values $V_n(x, T)$ of the n th step discrete game tended to a limit $V(x, T)$ as $n \rightarrow \infty$. This limit he took to be the value of the game. To prove this result, Fleming introduced the discrete-time majorant (or upper) game and the discrete-time minorant (or lower) game, in which the maximizing and minimizing players, respectively, have information advantages. In this paper certain restrictive assumptions were made concerning the form of the dynamics and the payoff.

In his second paper, "The convergence problem for differential games II," in *Advances in Game Theory*, *Ann. of Math. Stud.*, Vol. 52, M. Dresher, L. S. Shapley, and A. W. Tucker, eds., Princeton University Press, 1964, Fleming removed the restrictions on the dynamics and on the integrand of the payoff. To achieve this, he introduced the novel device of considering the discrete game with a small noise term added at each decision time. He showed that if $\varepsilon > 0$ is the measure of the smallness of the noise and if $V_n^\varepsilon(x, T)$ denotes the value of the n th stage discrete game with noise term, then for each fixed $\varepsilon > 0$, $V_n^\varepsilon(x, T)$ tends to a function $V^\varepsilon(x, T)$ as $n \rightarrow \infty$. Here $V^\varepsilon(x, T)$ is the solution of the Isaacs equation with a term $(\varepsilon^2/2)\Delta V$ added, where Δ denotes the Laplacian. He also showed that if $V_n(x, T)$ is, as before, the value of the n th stage game without noise, then $|V_n^\varepsilon(x, T) - V_n(x, T)|$ is uniformly small. From

this it follows that $V_n(x, T)$ tends to a limit, which he again defined to be the value of the game. For the next 20 years the ideas introduced in these papers were taken up by many authors in their treatments of differential games. The partial differential equation considerations connected with small-noise games were precursors of the development of the theory of viscosity solutions, whose recent introduction has greatly simplified the theory and removed the need to study small-noise games.

(c) In the late 1960s, Wendell Fleming began pioneering work in the formulation and study of continuous-time, nonlinear, stochastic control models. He first provided conditions under which models with complete observations and models with partial observations were well-posed, raised and offered some resolution to the thorny problem of degeneracy of the underlying diffusion, and broached the issue of singular perturbation of deterministic problems by the addition of a small-noise term. This work was centered around the Hamilton–Jacob–Bellman equation, and relied on the author’s facility with nonlinear partial differential equations as well as stochastic analysis. With the publication of “Optimal control of partially observable diffusions,” *SIAM J. Control Optim.*, 6 (1968), pp. 194–214, Fleming initiated the study of continuous-time nonlinear problems with partial observations, providing a modeling framework and methods for the proof of existence of optimal controls. The paper “Duality and a priori estimates in Markovian optimization problems,” *J. Math. Anal. Appl.*, 16 (1966), pp. 254–279, introduces nonanticipative controls as a device to overcome the complications arising from the nonsmooth dependence of the control variable on the state variable. This paper also shows how to characterize the solution of a degenerate Hamilton–Jacobi–Bellman equation as the unique almost everywhere solution obtained as a limit of solutions to perturbed problems. Such equations typically have many almost everywhere solutions; Fleming’s method is now understood to yield the “viscosity solution,” which is the one of interest in control theory. In “Stochastic control for small noise intensities,” *SIAM J. Control Optim.*, 9 (1971), pp. 473–517, Fleming obtained an expansion of the value function in powers of a noise parameter. This kind of analysis, which contains a first glimmer of large deviation theory for diffusion processes, has been simplified and expanded through the use of viscosity solutions; Fleming has been intimately involved in these developments.

(d) In the 1970s, Wendell Fleming turned his considerable analytical skills to problems in population genetics. Learning the models and issues of population genetics, he contributed several highly regarded papers.

A central issue in population biology regards the existence and the character of equilibrium distributions of genetic types (alleles). Fleming’s first paper in the field, coauthored with Chau-Hsing Su, was “Some one-dimensional migration models in population genetics theory,” *Theoret. Population Biol.*, 5 (1974), pp. 431–449. Fleming and Su investigated mutation, random genetic drift (the stochastic fluctuation of gene frequencies in finite populations), and migration in a line segment. They formulated a boundary value problem for the covariance between the gene frequencies at two arbitrary points in the habitat, solved it at equilibrium, and found the eigenvalues and eigenfunctions that control convergence to equilibrium.

In “A selection-migration model in population genetics,” *J. Math. Biol.*, 2 (1975), pp. 219–233, Fleming analyzed a partial differential equation model for gene frequency in a bounded, one-dimensional habitat. Fleming’s model, a generalization of the classical Fisher model and closely tied to contemporaneous research activity, provides a sterling example of careful and complete analysis with genuine applied significance. Using Lyapunov function techniques to study the asymptotic behavior of the solution

to the equation at hand, Fleming identified both stable and unstable equilibria in different parameter regimes and discovered bifurcation of equilibria. Moreover, he showed in this general framework how extinction of one allele could occur, a somewhat surprising result.

In "Equilibrium distributions of continuous polygenic traits," *SIAM J. Appl. Math.*, 36 (1979), pp. 148–168, Fleming undertook to model the distribution of a continuous trait (such as size) influenced by a finite number of loci. The evolutionary processes involved were selection, mutation, and recombination (paternal and maternal genes mixing to form offspring). Again, one wants to know the equilibrium distribution. The existing models at the time either assumed independence of the distributions at different loci or else assumed a multivariate normal equilibrium distribution at the loci under consideration. Instead of making these kinds of restrictive assumptions, Fleming chose to exploit the fact that mutation and selection are weak influences, and to expand the equilibrium distribution in terms of these small parameters. The expansion of the equilibrium he obtained turned out to have the normal distribution as its leading term, but also nonnormal deviations introduced by higher-order terms.

Wendell Fleming's best-known work in population genetics is the fundamental paper "Some measure-valued Markov processes in population genetics theory," *Indiana Univ. Math. J.*, 28 (1979), pp. 817–843, with Michel Viot. Fleming and Viot constructed a measure-valued process to model populations subject to mutation, natural selection, and random genetic drift. Prior to the construction of this so-called *Fleming–Viot process*, population geneticists were restricted to models in which traits or "types" of individuals were discrete, so that the distribution of types in a population could be described as a finite-dimensional, or perhaps countably-infinite-dimensional, probability vector. Using approximation arguments and the martingale characterization of Markov processes, Fleming and Viot managed to build a process taking values in the set of measures on a locally compact space of types. Despite the generality of the Fleming–Viot process, its usefulness, even at the level of explicit computations, has been subsequently demonstrated by the work of many authors. The reader is referred to the survey paper "Fleming–Viot processes in population genetics," by T. Kurtz and S. Ethier, appearing in this issue.

On behalf of the numerous mathematicians and other scientists who have been inspired by the work and person of Wendell Fleming, we express to him our gratitude through the dedication of this special issue of the *SIAM Journal on Control and Optimization* on the occasion of Wendell's sixty-fifth birthday.

Editor's Note

The SIAM staff is indebted to everyone who made this issue possible. In particular, we would like to thank Steven Shreve, of Carnegie Mellon University, for serving as Editor-in-Chief for this issue. We would also like to thank the following editors for their efforts: Leonard Berkovitz (Purdue University); Thomas Kurtz (University of Wisconsin); Pierre-Louis Lions (Université du Paris-Dauphine); and Etienne Pardoux

(Université de Provence). Thanks are also due to Wendell Fleming for providing a list of his publications and the photo that accompanies this tribute.

DISCRETE-TIME CONTROLLED MARKOV PROCESSES WITH AVERAGE COST CRITERION: A SURVEY*

ARISTOTLE ARAPOSTATHIS[†], VIVEK S. BORKAR[‡], EMMANUEL
FERNÁNDEZ-GAUCHERAND[§], MRINAL K. GHOSH¹, AND STEVEN I. MARCUS²

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. This work is a survey of the average cost control problem for discrete-time Markov processes. The authors have attempted to put together a comprehensive account of the considerable research on this problem over the past three decades. The exposition ranges from finite to Borel state and action spaces and includes a variety of methodologies to find and characterize optimal policies. The authors have included a brief historical perspective of the research efforts in this area and have compiled a substantial yet not exhaustive bibliography. The authors have also identified several important questions that are still open to investigation.

Key words. controlled Markov processes, average cost, stationary policies, dynamic programming, optimal policies, ergodicity

AMS(MOS) subject classifications. 93E20, 60J70

1. Introduction. The average cost criterion (equivalently, the long-run average or ergodic cost) is a popular criterion for optimization of stochastic dynamical systems over an infinite time horizon. It is a reasonable criterion to use when the anticipated time interval for optimization (which in practice is finite) is long compared to other timescales involved, and there are no compelling reasons to prefer short-term optimization over long-term. Naturally, it is not favored in financial applications where money spent now is worth more than money spent later, but there are situations (communication networks being a prime example) where a “steady state” operation is expected over intervals that are long compared to the time constants of the system. Then it makes sense to minimize the limiting time-averaged cost, i.e., the “average cost.”

Mathematically, the criterion stands out as being much more difficult to analyze than the others; while other classical criteria lead to reasonably complete solutions, the average cost does not. The finite state and action problem is well understood, but there are numerous counterexamples in which infinite state or action problems do not have a nice solution. In fact, it appears not as a single problem but a collection of problems, some of which do not have a nice solution (cf. [150]). Thus, a variety of approaches have been developed to handle different situations. Not surprisingly,

this is one chapter of Markov decision theory that is anything but closed. At the same time, it has come of age, having been studied for over 30 years, with promises of significant advances on the horizon. This, in short, is the *raison d'être* for this survey; we have attempted to put together a coherent account of what has been done, with an indication of what future advances may be.

Any such project has obvious limitations. Space constraints dictate a certain amount of selection, and not every relevant work can be covered in significant detail. We have included proofs where we felt they were essential to understanding the results or contained potentially useful novel ideas. In all cases, a serious attempt at objectivity has been made. For complementary reading on the general subject of Markov decision theory, see [137], [181], [196], [207].

The paper is organized as follows: §2 describes the problem formulation in full detail. Section 3 gives a brief history. Sections 4–6 extensively treat the finite state, the countable state, and the Borel state space cases, respectively, under complete observations. Section 7 treats the problem under partial observations. Section 8 describes some recent results on multiobjective average cost control. Finally, we conclude with some relevant remarks.

2. Preliminaries and formulation of the problem. In this section, the model and basic results concerning controlled Markov processes are given in the most general form needed for our presentation. In some subsequent sections, we specialize our presentation to situations in which measure-theoretic aspects are of no essential concern, as in the case for models with countable state space, allowing for a more transparent exposition. Before presenting the model, we summarize our key notation as follows:

- \mathbb{R} : set of real numbers;
- \mathbb{N} : set of positive integers;
- \mathbb{N}_0 : set of nonnegative integers;
- $\mathcal{B}(\mathbf{W})$: Borel σ -algebra of a given topological space \mathbf{W} ;
- $\mathcal{P}(\mathbf{W})$: for a Borel space \mathbf{W} (see [15], [82]), the set of all probability measures on $\mathcal{B}(\mathbf{W})$ endowed with the topology of weak convergence (see [134]).

The following are function spaces on a topological space \mathbf{W} :

- $C_b(\mathbf{W}) := \{v : \mathbf{W} \rightarrow \mathbb{R} \mid v \text{ is continuous and bounded}\}$;
- $\mathcal{M}(\mathbf{W}) := \{v : \mathbf{W} \rightarrow \mathbb{R} \mid v \text{ is Borel measurable}\}$;
- $\mathcal{M}_b(\mathbf{W}) := \{v : \mathbf{W} \rightarrow \mathbb{R} \mid v \text{ is Borel measurable and bounded}\}$;
- $\mathcal{L}(\mathbf{W}) := \{v : \mathbf{W} \rightarrow \mathbb{R} \mid v \text{ is lower semicontinuous and bounded below}\}$;
- $\mathcal{L}_b(\mathbf{W}) := \mathcal{L}(\mathbf{W}) \cap \mathcal{M}_b(\mathbf{W})$.

For $v \in \mathcal{M}_b(\mathbf{W})$, we let

- $\|v\| := \sup_{w \in \mathbf{W}} \{|v(w)|\}$;
- $\text{span}(v) := \sup_{w, w' \in \mathbf{W}} \{v(w) - v(w')\}$;
- $v^+ := v - \inf_{w \in \mathbf{W}} \{v(w)\}$, $v^- := v - \sup_{w \in \mathbf{W}} \{v(w)\}$.

We refer to $\text{span}(v)$ as the *span seminorm* of v .

The following is a list of the abbreviations used in this paper (the section where each abbreviation is first introduced is indicated in parenthesis):

- AC average cost (§2.4);
- ACOE average cost optimality equation (§3);
- ACOI average cost optimality inequality (§5.2);
- CMP controlled Markov process (§2.1);

- CO completely observable (§3);
- DC discounted cost (§2.4);
- DCOE discounted cost optimality equation (§2.6);
- PO partially observable (§7.2);
- POCMP partially observable controlled Markov process (§3);
- TC total cost (§2.4).

2.1. The model. A discrete-time, stationary controlled Markov process (CMP), or Markov decision process, is a stochastic dynamical system specified by the five-tuple $(\mathbf{S}, \mathbf{A}, U, P, c)$, where

- (a) \mathbf{S} is a Borel space, called the *state space*, the elements of which are called *states*;
- (b) \mathbf{A} is a Borel space, called the *action* or *control* space;
- (c) $U : \mathbf{S} \rightarrow \mathcal{B}(\mathbf{A})$ is a strict, measurable, compact-valued multifunction (see the Appendix). $U(x)$ represents the set of admissible actions (or control inputs) when the system is in state $x \in \mathbf{S}$. Accordingly, the set of admissible state/action pairs is $\mathbf{K} := \{(x, a) : x \in \mathbf{S}, a \in U(x)\} = \text{Graph}(U)$, and we have that $\mathbf{K} \in \mathcal{B}(\mathbf{S} \times \mathbf{A})$. This set is endowed with the subspace topology corresponding to $\mathcal{B}(\mathbf{S} \times \mathbf{A})$;
- (d) P is a stochastic kernel on \mathbf{S} given \mathbf{K} , called the *transition kernel*. It is assumed to be Borel measurable, i.e., $P(D \mid \cdot) : \mathbf{K} \rightarrow [0, 1]$ is Borel measurable, for each $D \in \mathcal{B}(\mathbf{S})$;
- (e) $c : \mathbf{K} \rightarrow \mathbb{R}$ is the (measurable) one-stage cost function.

The evolution of the system is as follows. Let X_t denote the state at time $t \in \mathbb{N}_0$, and A_t the action chosen at that time. If $X_t = x \in \mathbf{S}$ and $A_t = a \in U(x)$, then (i) a cost $c(x, a)$ is incurred, and (ii) the system moves to the next state X_{t+1} , according to a probability distribution $P(\cdot \mid x, a)$. Once the transition into the next state has occurred, a new action is chosen, and the process is repeated.

The total period of time over which the system is to be observed is called the planning (or decision-making or control) horizon and is denoted by T . It can be a finite interval $\{0, \dots, N-1\}$, with $N \in \mathbb{N}$, or an infinite horizon, e.g., $T = \mathbb{N}_0$.

The (admissible) *history spaces* are defined as

$$\mathbf{H}_0 := \mathbf{S}, \quad \mathbf{H}_t := \mathbf{H}_{t-1} \times \mathbf{K}, \quad t \in \mathbb{N}_0,$$

and the canonical sample space is defined as $\mathbf{\Omega} := (\mathbf{S} \times \mathbf{A})^\infty$. These spaces are endowed with their respective product topologies and are therefore Borel spaces. A generic element $\omega \in \mathbf{\Omega}$ is of the form $\omega = (x_0, a_0, x_1, a_1, \dots)$, $x_i \in \mathbf{S}$, $a_i \in \mathbf{A}$; all random variables will be defined on the measurable space $(\mathbf{\Omega}, \mathcal{B}(\mathbf{\Omega}))$.

The state, action (or control), and information processes, denoted by $\{X_t\}_{t \in T}$, $\{A_t\}_{t \in T}$ and $\{H_t\}_{t \in T}$, respectively, are defined by the projections

$$X_t(\omega) := x_t, \quad A_t(\omega) := a_t, \quad H_t(\omega) := (x_0, \dots, a_{t-1}, x_t), \quad t \in T$$

for each realization $\omega = (x_0, \dots, a_{t-1}, x_t, a_t, \dots) \in \mathbf{\Omega}$. Since $\mathcal{B}(\mathbf{\Omega}) = (\mathcal{B}(\mathbf{S}) \times \mathcal{B}(\mathbf{A}))^\infty$, the above are well-defined random processes on $(\mathbf{\Omega}, \mathcal{B}(\mathbf{\Omega}))$. Note that $\mathcal{B}(\mathbf{\Omega}) = \bigvee_{t=0}^\infty \mathfrak{F}_t$, where $\mathfrak{F}_t = \sigma(H_t)$, the σ -algebra generated by H_t .

Example 2.1. Let \mathbf{S} , \mathbf{A} , \mathbf{W} be Borel spaces and $F : \mathbf{S} \times \mathbf{A} \times \mathbf{W} \rightarrow \mathbf{S}$ a Borel function. Consider a nonlinear stochastic system described by the system equation

$$X_{t+1} = F(X_t, A_t, W_t), \quad t \in T,$$

where the process $\{W_t\}$ is a sequence of independent and identically distributed (i.i.d.) \mathbf{W} -valued random variables, with common probability distribution \mathcal{P}_W , often referred to as a stochastic state disturbance, or noise; $\{W_t\}$ is assumed to be independent of X_0 . Suppose that a strict, measurable, compact-valued multifunction $U : \mathbf{S} \rightarrow \mathcal{B}(\mathbf{A})$ has been specified, giving the necessary constraints on the control actions, or that $U(x) = \mathbf{A}$, for all $x \in \mathbf{S}$, if there are no constraints. Then the evolution of the system is equivalently described in terms of the stochastic kernel P on \mathbf{S} given \mathbf{K} defined as

$$P(D \mid x, a) := \int_{\mathbf{W}} I\{F(x, a, w) \in D\} \mathcal{P}_W(dw), \quad (x, a) \in \mathbf{K}, \quad D \in \mathcal{B}(\mathbf{S}),$$

where $I\{A\}$ denotes the indicator function of the event A . The additional specification of a measurable cost function $c : \mathbf{K} \rightarrow \mathbb{R}$ would completely define a CMP $(\mathbf{S}, \mathbf{A}, U, P, c)$.

Example 2.2. Consider a countable set \mathbf{S} endowed with the discrete topology. With no loss in generality we can take $\mathbf{S} = \mathbb{N}_0$. Let \mathbf{A} be a Borel space and $U(x) = \mathbf{A}$, for all $x \in \mathbf{S}$. In this case, every stochastic kernel on \mathbb{N}_0 given $\mathbf{K} := \mathbb{N}_0 \times \mathbf{A}$ reduces to a collection of discrete probability distributions parameterized by $(i, a) \in \mathbf{K}$. These can also be represented by a collection of stochastic matrices $\{P(a) = [p_{ij}(a)]\}_{a \in \mathbf{A}}$; i.e., $P(a)$ is a state transition matrix, and $p_{ij}(a)$ is the probability that the state of the system makes a transition from i to j , under action a . Therefore, additionally specifying a cost function $c : \mathbb{N}_0 \times \mathbf{A} \rightarrow \mathbb{R}$ completely defines a CMP.

2.2. Policies and performance criteria. An *admissible control strategy*, or *policy*, is a sequence $\pi = \{\pi_t\}_{t \in T}$ of Borel measurable stochastic kernels on \mathbf{A} given \mathbf{H}_t , satisfying the constraint

$$\pi_t(U(x_t) \mid h_t) = 1, \quad x_t \in \mathbf{S}, \quad h_t \in \mathbf{H}_t.$$

The set of all admissible policies will be denoted by Π .

If $\mu \in \mathcal{P}(\mathbf{S})$ and $\pi \in \Pi$ are given, there exists a unique probability measure \mathcal{P}_μ^π on $(\Omega, \mathcal{B}(\Omega))$ satisfying the following [15, Prop. 7.28, pp. 140–144], [130, Prop. V.1.1, pp. 162–164], with $D \in \mathcal{B}(\mathbf{S})$ and $C \in \mathcal{B}(\mathbf{A})$:

$$(2.1) \quad \mathcal{P}_\mu^\pi(X_0 \in D) = \mu(D),$$

$$(2.2) \quad \mathcal{P}_\mu^\pi(A_t \in C \mid H_t) = \pi_t(C \mid H_t), \quad \mathcal{P}_\mu^\pi\text{-a.s.},$$

$$(2.3) \quad \mathcal{P}_\mu^\pi(X_{t+1} \in D \mid H_t, A_t) = P(D \mid X_t, A_t), \quad \mathcal{P}_\mu^\pi\text{-a.s.}$$

Therefore, if μ is the distribution of the initial state X_0 , and policy $\pi \in \Pi$ is used, the underlying probability space of all random variables of interest is $(\Omega, \mathcal{B}(\Omega), \mathcal{P}_\mu^\pi)$. The expectation operator with respect to \mathcal{P}_μ^π will be denoted by E_μ^π . Furthermore, if μ is a Dirac measure at $x \in \mathbf{S}$, we will simply write \mathcal{P}_x^π and E_x^π .

Certain classes of admissible policies are of special interest. A policy π is called a *Markov randomized policy* if there exists a sequence of measurable maps $\{f_t\}_{t \in T}$, called *randomized decision rules*, where $f_t : \mathbf{S} \rightarrow \mathcal{P}(\mathbf{A})$, for each $t \in T$, such that

$$\pi_t(\cdot \mid H_t) = f_t(X_t)(\cdot), \quad \mathcal{P}_\mu^\pi\text{-a.s.}$$

Conversely, every sequence of measurable maps $f_t : \mathbf{S} \rightarrow \mathcal{P}(\mathbf{A})$, $t \in T$, satisfying $f_t(x)(U(x)) = 1$, defines a Markov randomized policy in an obvious way; with some

abuse in notation, the sequence itself will be referred to as the policy. The set of all Markov randomized policies will be denoted by Π_M . A policy $\{f_t\}_{t \in T} \in \Pi_M$ is called a *stationary* randomized policy if there is a randomized decision rule f such that, for all $t \in T$, $f_t = f$. The set of all stationary randomized policies will be denoted by Π_{SR} . A *nonrandomized*, *deterministic*, or *pure* decision rule is a measurable map $f: \mathcal{S} \rightarrow \mathcal{A}$. A policy $\{f_t\}_{t \in T} \in \Pi_M$ is called a *nonrandomized*, *deterministic*, or *pure* Markov policy if each f_t is deterministic. Hence, in this case, $A_t = f_t(X_t)$ almost surely. The set of deterministic Markov policies will be denoted by Π_{MD} . Stationary deterministic policies are defined in the obvious way. The set of all stationary deterministic policies is denoted by Π_{SD} , and, for $\pi \in \Pi_{SD}$, $\pi(x)$ will denote the action chosen at $x \in \mathcal{S}$. Clearly $\Pi_{SD} \subseteq \Pi_{MD} \subseteq \Pi_M \subseteq \Pi$, and $\Pi_{SD} \subseteq \Pi_{SR} \subseteq \Pi_M$.

It is easily seen that, under a policy $\pi = \{f_t\}_{t \in T} \in \Pi_M$, the state process $\{X_t\}_{t \in T}$ is a Markov process. That is, for $D \in \mathcal{B}(\mathcal{S})$,

$$\begin{aligned} \mathcal{P}_\mu^\pi(X_{t+1} \in D \mid X_t, \dots, X_0) &= \mathcal{P}_\mu^\pi(X_{t+1} \in D \mid X_t) \\ &= \int_{\mathcal{A}} P(D \mid X_t, a) f_t(X_t)(da), \quad \mathcal{P}_\mu^\pi\text{-a.s.}, \end{aligned}$$

and, under a policy $\pi' \in \Pi_{SR}$, $\{X_t\}_{t \in T}$ is a Markov process with stationary transition probabilities.

Each policy $\pi \in \Pi$ incurs a stream of random costs, e.g., $\{c(X_t, f_t(X_t))\}_{t \in T}$, for $\{f_t\}_{t \in T} \in \Pi_{MD}$. Depending upon the problem requirements, several cost evaluation criteria are studied. The following criteria are frequently used.

Total cost (TC). The total cost incurred by the policy $\pi \in \Pi$ over the entire planning horizon is given by

$$J_T(\mu, \pi) := E_\mu^\pi \left[\sum_{t \in T} c(X_t, A_t) \right].$$

When the horizon is finite, i.e., $T = \{0, \dots, N-1\}$, $N \in \mathbb{N}_0$, we denote the above more explicitly as $J_N(\mu, \pi)$. Furthermore, given a *terminal cost* function $h \in \mathcal{M}_b(\mathcal{S})$, we define

$$J_N(\mu, \pi, h) := E_\mu^\pi \left[\sum_{t=0}^{N-1} c(X_t, A_t) + h(X_N) \right].$$

Discounted cost (DC). Let $0 < \beta < 1$, the *discount factor*, and $\pi \in \Pi$ be given. The total discounted cost incurred by π over the infinite planning horizon is given by

$$J_\beta(\mu, \pi) := E_\mu^\pi \left[\sum_{t=0}^{\infty} \beta^t c(X_t, A_t) \right].$$

Average cost (AC). The expected long-run average cost incurred by $\pi \in \Pi$ is given by

$$J(\mu, \pi) := \limsup_{N \rightarrow \infty} E_\mu^\pi \left[\frac{1}{N} \sum_{t=0}^{N-1} c(X_t, A_t) \right] = \limsup_{N \rightarrow \infty} \frac{1}{N} J_N(\mu, \pi).$$

Sample path average cost. This is a pathwise version of the AC, and, for $X_0 = x$, it is given by

$$J_S(x, \pi) := \limsup_{N \rightarrow \infty} \frac{1}{N} \sum_{t=0}^{N-1} c(X_t, A_t),$$

where $\{X_t\}$ and $\{A_t\}$ are the state and control process induced by $\pi \in \Pi$. Here, $J_S(x, \pi)$ is to be regarded as an extended real-valued random variable on the canonical sample space.

For the AC criterion, the limit of the expected average cost may not exist for some or all policies $\pi \in \Pi$, and thus the limit superior is used. This is always well defined and captures the *worst* possible asymptotic expected average performance under policy $\pi \in \Pi$; i.e., it gives a “pessimistic” measure of performance. On the other hand, the limit inferior could also be used, which would yield an “optimistic” measure of performance by capturing the *best* possible asymptotic expected average performance. The planning horizon for the TC criterion can be finite or infinite, whereas, for the other criteria above, it is always infinite. Under certain conditions, it can be shown that a problem with the DC criterion is equivalent to one with a TC criterion, with a random (finite) horizon; see [40, pp. 31–32]. Also, it can be shown that, for each $\pi \in \Pi$, a policy $\pi' \in \Pi_M$ can be found such that $E_\mu^\pi[c(X_t, A_t)] = E_\mu^{\pi'}[c(X_t, A_t)]$, for each $t \in \mathbb{N}_0$ and any initial distribution $\mu \in \mathcal{P}(\mathcal{S})$ [42], [51, §3.8]. Thus, for criteria that are determined by these expected costs, such as the AC, DC, and TC criteria, it suffices to consider policies in Π_M .

For an infinite planning horizon, $J_T(\mu, \pi)$ need not be well defined or may be infinite for all $\pi \in \Pi$, rendering this criterion useless for comparing the performance under different policies. Therefore, the DC or AC criteria are usually selected when the planning horizon is infinite. When the DC criterion is used, a rather complete theory is available for the corresponding dynamic programming formulation of the problem [14], [15], [51], [82], [103], [150], [200]. In this situation, future costs are discounted at a fixed rate $0 < \beta < 1$, and therefore, if β is not sufficiently close to 1, the asymptotic behavior of the state/cost process may not be important at all. Quite the opposite is the case with the AC criterion, under which all decision times are given equal weight, and we take the limit of time-averaged expected costs. The finite time evolution of the state/cost process is, in some sense, completely irrelevant in this case, and some sort of asymptotic stable behavior is desired, making this case mathematically much more involved than the previous one. Hence, the DC and AC can be seen as two opposite extremes in the spectrum of possible criteria that can be considered, in the sense that the first one captures primarily the performance of the process at the present and near future, and the second captures the performance at the distant future.

2.3. The optimal control problem. The *optimal control (or decision) problem* is that of selecting an admissible policy such that a given performance criterion is minimized over all admissible policies. For example, for the DC criterion, a policy $\pi^* \in \Pi$ is said to be (β) -discount ε -optimal for the initial distribution μ if

$$J_\beta(\mu, \pi^*) \leq J_\beta(\mu, \pi) + \varepsilon \quad \forall \pi \in \Pi,$$

where $\varepsilon > 0$. If a policy is discount ε -optimal for all distributions $\mu \in \mathcal{P}(\mathcal{S})$, then it is simply called discount ε -optimal. If a policy is discount ε -optimal *for all* $\varepsilon > 0$, then it is called *discount optimal*. The (optimal) value function is given by

$$(2.4) \quad J_\beta^*(\mu) := \inf_{\pi \in \Pi} J_\beta(\mu, \pi).$$

Also, if μ is concentrated at $x \in \mathcal{S}$, we denote the value function by $J_\beta^*(x)$. Similar definitions apply to other criteria; $J_T^*(\mu)$ and $J^*(\mu)$ will denote the optimal value functions for the TC and AC criteria, respectively. For sample path AC, we define an

optimal policy as follows: We say that a policy $\pi^* \in \Pi$ is *sample path AC optimal* (or *almost surely AC optimal*) if there exists a constant ρ^* such that, for any initial law μ ,

$$J_S^*(\mu, \pi^*) = \rho^*, \quad \mathcal{P}_\mu^{\pi^*}\text{-a.s.},$$

while, for any other policy $\pi \in \Pi$ and any initial law μ' ,

$$J_S^*(\mu', \pi) \geq \rho^*, \quad \mathcal{P}_{\mu'}^\pi\text{-a.s.}$$

The constant ρ^* is the sample path optimal average cost.

Having defined various optimality criteria and the set of admissible policies Π , the obvious question now is: Do there exist optimal policies? Without imposing further assumptions on our general model, the answer is no. One of the reasons behind this is that the Borel measurability assumption in the definition of admissible policies is too restrictive, in general, to be able to attain the infimum in (2.4). To circumvent this problem, either a broader sense of measurability is allowed, i.e., a larger set of admissible policies is used, or further assumptions are imposed. The first approach was taken by Shreve and Bertsekas [15], [164], [165], who considered *universally measurable* policies, a class properly containing the (Borel measurable) admissible policies defined previously; see also [51]. We will instead follow the second approach mentioned above and concentrate on the *semicontinuous model*, as studied in [15], [47], [51], [71], [88], [123], [152]–[154].

2.4. The semicontinuous model. In general, we consider the case when the one-stage cost function $c(\cdot, \cdot)$ is unbounded. Since, for the most part, the criteria considered in this paper are given by a sum of expected costs over the infinite horizon, then, to avoid indeterminate situations, the following conditions will be assumed to hold throughout the paper, unless otherwise indicated.

Assumption 2.1. $c(x, a) \geq 0$ for all $(x, a) \in \mathbf{K}$.

Assumption 2.2. The transition kernel $P(\cdot \mid x, a)$ is *weakly continuous* in (x, a) ; that is, $v(\cdot) \in C_b(\mathbf{S})$ implies that $\int_{\mathbf{S}} v(y)P(dy \mid \cdot, \cdot) \in C_b(\mathbf{K})$.

Assumption 2.3. (i) The multifunction $U(x)$ is upper semicontinuous; (ii) $c(\cdot, \cdot) \in \mathcal{L}(\mathbf{K})$.

Remark 2.1. Concerning Assumption 2.1, note that (for the AC and DC criteria) we must only assume that the cost is bounded below. The assumption that the cost is nonnegative is only made for convenience. Assumption 2.2 is equivalent to $\int v(y)P(dy \mid \cdot, \cdot) \in \mathcal{L}(\mathbf{K})$, for each $v(\cdot) \in \mathcal{L}(\mathbf{S})$ [51, p. 52]. This property is crucial in our development.

Example 2.3. For the nonlinear stochastic system in Example 2.1, assume further that

- (i) \mathbf{A} is compact,
- (ii) For each $x \in \mathbf{S}$, $U(x)$ is closed (and therefore compact), and
- (iii) The system function $F : \mathbf{K} \times \mathbf{W} \rightarrow \mathbf{S}$ is continuous.

If $c(\cdot, \cdot) \in \mathcal{L}(\mathbf{K})$, then, by Remark 2.1, Assumption 2.2 will hold. Furthermore, the assumption on the compactness of \mathbf{A} can be dispensed with if there are compact subsets $\mathbf{K}_1 \subseteq \mathbf{K}_2 \subseteq \cdots$ in $\mathbf{S} \times \mathbf{A}$, such that $\mathbf{K} = \bigcup_{n \in \mathbb{N}} \mathbf{K}_n$ and

$$\liminf_{n \rightarrow \infty} \{c(x, a) : (x, a) \in \mathbf{K}_n \setminus \mathbf{K}_{n-1}\} = +\infty,$$

since, in this case, \mathbf{A} can be conveniently compactified; cf. [15, Cor. 8.6.1, p. 210]. Also, the case in which $\mathbf{S} = \mathbb{R}^n$, $\mathbf{A} = \mathbb{R}^m$, and $c(x, a) = x'Qx + a'Ra$, where Q and

R are positive semidefinite and positive definite matrices, respectively, of appropriate dimensions can also be considered by a (one-point) compactification of \mathbf{A} [164, pp. 965–966].

Under Assumptions 2.1–2.3, the *undiscounted dynamic programming map* T given by

$$(2.5) \quad T(v)(x) := \inf_{a \in U(x)} \left\{ c(x, a) + \int_{\mathbf{S}} v(y) P(dy \mid x, a) \right\} \quad \forall x \in \mathbf{S}$$

maps $\mathcal{L}(\mathbf{S})$ into itself. Also, for $0 < \beta < 1$, the *discounted dynamic programming map* $T_\beta : \mathcal{L}(\mathbf{S}) \rightarrow \mathcal{L}(\mathbf{S})$ is given by

$$(2.6) \quad T_\beta(v) := T(\beta v).$$

The following properties are easily verified.

LEMMA 2.1. *Let $v, v' \in \mathcal{L}(\mathbf{S})$. Then (i) for all $k \in \mathbb{R}$, $T(v + k) = T(v) + k$; (ii) if $v \leq v'$, then $T(v) \leq T(v')$.*

Some key results for the stochastic control problem under a DC criterion are summarized in the following theorem.

THEOREM 2.1. *Under Assumptions 2.1–2.3*

(i) *The following equation, which is called the discounted cost optimality equation (DCOE), holds:*

$$(2.7) \quad J_\beta^*(x) = T_\beta(J_\beta^*)(x) = \inf_{a \in U(x)} \left\{ c(x, a) + \beta \int_{\mathbf{S}} J_\beta^*(y) P(dy \mid x, a) \right\}, \quad x \in \mathbf{S};$$

(ii) *A policy $\pi^* \in \Pi_{SD}$ is discount optimal if and only if $\pi^*(x)$ attains the infimum in (2.7), for all $x \in \mathbf{S}$;*

(iii) *A discount optimal policy $\pi^* \in \Pi_{SD}$ exists;*

(iv) *Define $T_\beta^0 : \mathcal{L}(\mathbf{S}) \rightarrow \mathcal{L}(\mathbf{S})$ as the identity operator and $T_\beta^k : \mathcal{L}(\mathbf{S}) \rightarrow \mathcal{L}(\mathbf{S})$, $k \in \mathbb{N}$, by $T_\beta^k(f) := T_\beta(T_\beta^{k-1}(f))$. Then, for any $f \in \mathcal{L}_b(\mathbf{S})$,*

$$T_\beta^k(f)(x) \xrightarrow[k \rightarrow \infty]{} J_\beta^*(x) \quad \text{for all } x \in \mathbf{S};$$

(v) *$J_\beta^*(\cdot)$ is nonnegative and lower semicontinuous.*

Remark 2.2. The above results are essentially contained in [15], [51]. The existence of a measurable selector that attains the infimum in (2.7), e.g., the result in (iii) of Theorem 2.1, follows from [15, Prop. 7.33, p. 153], [29], [47, pp. 35–38], [51, §2.6], [88], [139, Thm. 4.1, p. 9], [184, Thm. 9.1, p. 880]. The scheme used in (iv) of Theorem 2.1 to compute $J_\beta^*(\cdot)$ is called the *value iteration* (or successive approximations) algorithm. When the one-stage cost function is bounded, the usual approach is to prove the existence of a unique solution to the DCOE via a contraction mapping theorem [14], [82]. Otherwise, $J_\beta^*(\cdot)$ is not necessarily the only fixed point of T_β ; however, $J_\beta^*(\cdot)$ is the *minimal* fixed point of T_β among the class of nonnegative functions in $\mathcal{L}(\mathbf{S})$ [15, Chap. 5], [173].

3. A sketch of historical development. We now present a brief historical sketch of the development of CMP, with an emphasis on the average cost criterion. The roots of CMP can be traced back to the pioneering work of Wald [186], [187]

on sequential analysis and statistical decision functions. In the late 1940s and early 1950s, several investigators formulated the essential concepts of CMP, which are found in their work in sequential game models. A CMP can be viewed as a one-player game. Of particular interest is the work of Bellman and Blackwell [12], Bellman and LaSalle [13], and also Shapley, who formulated the essential mechanism of stochastic dynamic programming and used the theory of contraction mappings [160]. Using his famous heuristic “minimum cost to go,” Bellman showed how powerful the dynamic programming technique was by using it to solve problems in a myriad of settings [9]–[11]. Bellman studied mostly problems with a finite horizon, for which the backward induction approach of dynamic programming suffices to give a complete treatment. The situation is quite different in problems over an infinite horizon. Early work on CMP is also reported in econometrics [4], [49].

Howard [95] was apparently the first to study CMP with an average cost criterion. His *policy iteration* algorithm was the first major computational breakthrough, and his book helped establish CMP as an independent subject of investigation. For CMP with finite state and action spaces, Howard’s policy iteration scheme established the existence of a stationary deterministic policy, optimal in this class only. Derman [38] and Viskov and Shiryaev [183] independently showed that this policy was optimal among all admissible policies. Other computational methods were later proposed. Manne [125] gave a linear programming formulation for the AC criterion, and Wagner [185] later characterized extreme-point optima of the linear program as stationary deterministic policies. White [197] introduced the value iteration (or successive approximations) technique. Excellent accounts of these and other computational methods are given in [14, §5.2] and [137].

On the theoretical side, Blackwell’s seminal paper [18] gave considerable impetus to research in this area, motivating numerous other papers. In [18] Blackwell studied CMP with finite state and action spaces. He considered the DC criterion in great detail and established many important results. In the same paper, he initiated an approach for the AC case, which we will refer to as the *vanishing discount approach*: he treated the AC case as a limit of the DC case, when the discount factor goes to 1, i.e., the discounting effect vanishes. Blackwell established in [18] the existence of a stationary deterministic policy that is discount optimal, for all β sufficiently close to 1. This type of optimality is now called *Blackwell optimality* [14, pp. 336–341]. The relation between the discounted and average case also becomes apparent via Tauberian theorems [87, §4.6]. This fact seems to have been observed first by Gillette [79], who used Tauberian theorems to establish the existence of optimal stationary policies in a stochastic game problem with an AC criterion. Also, using Tauberian theorems, Derman [38] showed that the Blackwell optimal policy found in [18] was also optimal for the AC criterion. Average cost CMP with finite state and arbitrary action spaces were studied under various conditions in the works of [35], [57]–[59], [100].

Blackwell optimal policies do not necessarily exist when the state space is countably infinite [122]. In fact, average optimal policies need not exist in this situation [121], [150]. Similar nonexistence result holds when the state space is finite, but the action space is an arbitrary compact metric space [8]. For such models, the existence of an optimal policy has been proved by Bather [8], Martin-Löf [126], and Feinberg [58], under certain conditions. Derman [39] studied the problem with countable state space, finite action space, and bounded cost. He studied the following equation, which

became known as the *average cost optimality equation* (ACOE):

$$\rho + h(i) = \min_{a \in U(i)} \left\{ c(i, a) + \sum_{j \in S} P(j \mid i, a) h(j) \right\},$$

where ρ is a scalar, $h : S \rightarrow \mathbb{R}$, $S = \mathbb{N}_0$, and we write $P(j \mid \cdot, \cdot)$ for $P(\{j\} \mid \cdot, \cdot)$. He showed that, if the ACOE has a *bounded solution*, i.e., a solution (ρ, h) with $h(\cdot)$ a bounded function, then the stationary deterministic policy realizing the pointwise minimum on the right-hand side of the ACOE is average optimal, and ρ is the minimum average cost. Derman's paper, in conjunction with Derman and Veinott [43], showed that a sufficient condition for the existence of such a solution was that the expected hitting time of a fixed state under *any* stationary deterministic policy is bounded uniformly with respect to the choice of the policy and the initial state. Motivated by Blackwell's work, Taylor [177] extended the vanishing discount approach to obtain a bounded solution for a Markovian sequential replacement problem by studying the asymptotics of the *differential* discounted value function $h_\beta(\cdot) := J_\beta(\cdot) - J_\beta(0)$. Ross [147], [148] refined Taylor's procedure and showed that, under the Derman–Veinott [43] condition, $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$ was uniformly bounded in β . By letting $\beta \uparrow 1$, Ross established that the ACOE had a bounded solution. This made the vanishing discount approach very popular. In subsequent works, many variants of Derman–Veinott recurrence conditions appeared. See [52], [178] for a great variety of such conditions. These conditions are difficult to remove, and counterexamples abound [150]. Actually, it has been shown in [64], in a very general setting, that the uniform boundedness of $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$ in β is also a *necessary* condition for a bounded solution to the ACOE to exist. Cavazos-Cadena [30], [31], under some additional conditions, showed that the existence of bounded solutions to the ACOE necessarily impose a very strong recurrence structure on the model. Lippman [115] studied controlled semi-Markov processes with unbounded cost with both discounted and average cost criteria. Following the vanishing discount approach, he derived results for the average cost case under several restrictive assumptions. Federgruen, Hordijk, and Tijms [53] have explored the same approach.

Hordijk [91] extended many earlier results to countable state space and compact action spaces. He introduced the Lyapunov function method for CMP. He used this method to obtain a (possibly *unbounded*) solution to the ACOE, yielding an optimal policy. However, the Lyapunov function method necessarily imposes a blanket stability of the processes (in the sense of positive recurrence). Such stability is not always met in, e.g., many queueing model applications. In addition, he introduced some new concepts, particularly based on the relation of stochastic dynamic programming with Markov potential theory. There is a vast amount of literature devoted to CMP in several volumes of the Mathematisch Centrum tracts; see [181] and the references therein.

With Hordijk's work, it appeared that a shift away from the vanishing discount approach was necessary. Rosberg, Varaiya, and Walrand [144] treated the average cost criterion as the limiting case of the finite horizon problem, but details of their arguments depend heavily on the specifics of the problem they consider, viz., the control of two queues in tandem with a linear cost structure. Federgruen and Tijms [56] initiated a direct study of the ACOE by a span seminorm method, for bounded costs. This method allows us to obtain useful value iteration algorithms. Later, Federgruen, Schweitzer, and Tijms [55] treated the problem with countable state space

and unbounded costs. Assuming a recurrence condition on the model, they established the existence of a (possibly unbounded) solution to the ACOE, thereby establishing the existence of an optimal stationary deterministic policy.

In a series of papers [20]–[25], Borkar presented a convex analytic approach to treat the problem with countable state space, compact action space, and unbounded cost. This approach can be seen as an extension of the ideas in Manne [125] and Wagner [185]. Borkar stressed the existence of an optimal *stable* stationary deterministic policy, i.e., one that induces a positive recurrent process. While a blanket stability assumption (e.g., of Lyapunov type) may be too restrictive to cover many queueing applications, it nevertheless is desirable that the optimal policy be stable. Borkar showed that, to obtain an optimal stable stationary deterministic policy, either a blanket stability hypothesis or a condition on the cost that penalizes unstable behavior is necessary. He also emphasized the concept of almost sure optimality by a “pathwise” treatment of the problem. A comprehensive account of the convex analytic approach to CMP is given in [26].

After the extensive works of Hordijk, Federgruen et al., and Borkar, it seemed that the vanishing discount approach was not appropriate for many classes of problems with unbounded costs. However, this approach has been revived and generalized to a great extent in [17], [61], [63], [74], [76], [77], [83], [85], [155], [156], [167], [172], [190]. In some of these references, an *inequality* version of the ACOE is studied. In view of the results of [30], [31], and [64], it is clear that a bounded solution to the ACOE is too restrictive, in general. A natural candidate solution is one that is bounded below [28], [76], [85], [155], [156], [172], [190], or one having suitable growth properties [28] or satisfying other conditions [167]. Weber and Stidham [172], [190] studied the problem for queueing systems. Under a penalizing condition on the cost and some structural assumptions, they established the existence of a (possibly unbounded) solution to the ACOE and showed the existence of an optimal stationary deterministic policy. Sennott proceeded along similar lines. She identified very general conditions on the discounted value function so that the vanishing discount approach could successfully be pursued. We refer to [155]–[157], [172], [190] for many interesting examples of queueing systems and to [34] for a comparison of different sets of assumptions. Extensions of these techniques to semi-Markov decisions processes with applications to queueing systems have been reported in [157].

The first attempt to give a description of CMP with more general state and actions spaces was carried out by Karlin [98]. Blackwell [19], Maitra [123], and Strauch [173] studied CMP with a general state space and the discounted cost criterion. Their work was significantly extended by Shreve and Bertsekas in [15], [164], [165]. Feinberg [60] studied CMP with Borel state space and with arbitrary numerical criteria, which include TC, AC, and DC as particular cases. By establishing the convexity of the set of strategic measures (measures of the type \mathcal{P}_μ^π on the canonical space), he established the existence of an ε -optimal $f \in \Pi_{SD}$ for these criteria. De Leve [112]–[114] considered general state and action space CMP in continuous time with an AC criterion, with an emphasis on the ergodic behavior of the processes. Ross [148] used the vanishing discount approach to study CMP with an AC criterion, general state space, finite action space, and bounded cost function. He showed that, if the family of differential discounted value functions $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$ is equicontinuous and uniformly bounded, then the ACOE admits a bounded solution, yielding an optimal stationary deterministic policy. Ross also introduced the concept of minorant. He showed that,

if there exists a state $x_0 \in \mathcal{S}$ and $\alpha > 0$ such that

$$P(x_0 \mid x, a) > \alpha \quad \text{for all } a \in U(x), \quad x \in \mathcal{S},$$

then the average cost case could be reduced to a discounted one. This was greatly extended in the work of Gubenko and Statland [80] (see also [43]). They showed that, under similar minorant (or majorant) conditions, a contraction map, with respect to the sup norm, could be defined on $\mathcal{M}_b(\mathcal{S})$, which would yield a bounded solution to the ACOE. They also obtained bounded solutions to the ACOE under continuity and boundedness conditions, which guarantee that $\{h_{\beta_n}(\cdot)\}$, with $\beta_n \uparrow 1$, is uniformly bounded and equicontinuous; thus a similar approach as in [148] can be followed. Georgin [72], [73] also explored this approach, under some ergodicity conditions. Tijms [179] and Hübner [96] directly studied the ACOE, under some ergodicity assumptions, by showing that the undiscounted dynamic programming map is a contraction on $\mathcal{M}_b(\mathcal{S})$, with respect to the span seminorm. For an excellent presentation of these methods and the type of ergodicity conditions used, see [82, §3.3]. Wijngaard [201], [202] and Kumar [101] studied the problem under Doeblin's condition using an operator theoretic method. Under several conditions, Kurano [104] obtained solutions to the ACOE and also showed the existence of an average optimal stationary deterministic policy. Also, in [105]–[107], he obtained the existence of an optimal stationary deterministic policy under Doeblin's condition. For a comprehensive presentation of the different recurrence conditions used for the above purposes, see [86].

The study of *partially observable controlled Markov processes* (POCMP) was initiated independently by various authors [5], [46], [50], [161], [162]. The reduction to models with complete information (see §7) was exhibited for various cases in [5], [138], [151], [205]. The study of finite state space POCMP with an AC criterion was initiated by Sondik [170]. Transforming the problem into an equivalent *completely observable* (CO) problem with Borel state space, Sondik tried to cast the problem in the framework of Ross [148] but did not show equicontinuity of $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$. Ross [150], Wang [189], and White [191] showed this equicontinuity condition for specific scalar replacement problems. Ohnishi, Mine, and Kawai [132] studied a multistate replacement problem by using concavity properties of $h_\beta(\cdot)$. Platzman studied the general problem of finite state and action space POCMP, also by using concavity properties of the functions $h_\beta(\cdot)$. Under certain reachability conditions, he proved that the family $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$ is uniformly bounded. However, even though this family may not be equicontinuous with respect to the Euclidean metric, he showed that it is equi-Lipschitzian with respect to some other appropriate metric, thus putting the problem within the framework of Ross [148]. Fernández-Gauchera, Arapostathis, and Marcus [62], [63] followed a different approach to the problem, using the concepts of invariant sets of a CMP and controlled sub-Markov processes. This approach allows us to consider POCMP with countable state and observation spaces. Borkar [26] also studied the problem via his convex analytic approach.

4. Finite state space. In this section, we will consider models with a finite state space. Initially, we restrict our attention to the case when \mathcal{A} is a finite set; models with compact action space will be discussed at the end of the section.

4.1. Finite action spaces. Let $\mathcal{S} = \{1, \dots, k\}$. In this case, Π_{SD} is finite. This fact plays a crucial role in the analysis for the average cost problem. For a policy $\pi \in \Pi$, let $J_\beta(\pi)$ denote the vector $(J_\beta(1, \pi), \dots, J_\beta(k, \pi))^T$; similarly, we define $J_N(\pi)$, $J(\pi)$,

J_β^* , J^* , and J_N^* . For a stationary deterministic policy $f \in \Pi_{SD}$, let $P(f)$ denote the transition matrix of the corresponding process and

$$c(f) := (c(1, f(1)), \dots, c(k, f(k)))^T.$$

Also, the (i, j) th entry in the n th power of the transition matrix $P(f)$ will be denoted by $P_{ij}^n(f)$ or $P^n(f)(i, j)$. It is well known that

$$\lim_{N \rightarrow \infty} \frac{1}{N} \sum_{n=0}^{N-1} P^n(f) := P^*(f)$$

exists [18], [87, Chap. 4], [137], where $P^0(f) = I$ (the $k \times k$ identity matrix). Using the theory of stochastic matrices, the following results can be proved. For details, see [8], [18], [87], [137].

THEOREM 4.1. *For each $f \in \Pi_{SD}$,*

- (i) $J(f) = P^*(f)c(f)$;
- (ii) *The number of linearly independent equations in $(I - P(f))w = c(f) - J(f)$ is k minus the number of communicating classes in $P(f)$;*
- (iii) *The equations*

$$(4.1) \quad (I - P(f))w = c(f) - v,$$

$$(4.2) \quad P^*(f)w = 0$$

have solutions $v = J(f)$ and $w = w(f)$, where

$$w(f) := (I - P(f) + P^*(f))^{-1}(I - P^*(f))c(f);$$

- (iv) *$v = J(f)$ and $w = w(f)$ are the unique solutions to (4.1) and (4.2) for which $v(s) = v(s')$ if s and s' are in the same communicating class of $P(f)$, and $v(s) = J(s, f)$ if state s is transient in $P(f)$.*

Remark 4.1. (a) It is easily seen from the above theorem that if, under an $f \in \Pi_{SD}$, the process is irreducible or unichain (see [87]), then $J(\cdot, f)$ is constant.

- (b) The matrix

$$H(f) := (I - P(f) + P^*(f))^{-1}(I - P^*(f))$$

is called the *deviation matrix*. It plays a fundamental role in the analysis. For the discounted case, $J_\beta(f) = (I - \beta P(f))^{-1}c(f)$. Analogous results can be developed for the average cost case using $H(f)$. The following result, due to Miller and Veinott [127] and Lamond and Puterman [110], can be proved using the spectral theory of stochastic matrices.

THEOREM 4.2. *Let $\beta \in [0, 1)$ and $\lambda = (1 - \beta)\beta^{-1}$. Let $f \in \Pi_{SD}$ and ν be the eigenvalue of $P(f)$ less than one with largest modulus. If $0 \leq \lambda \leq 1 - |\nu|$, then*

$$(4.3) \quad (\lambda I + I - P)^{-1} = \lambda^{-1}P^*(f) + \sum_{n=0}^{\infty} (-\lambda)^n H^{n+1}(f)$$

and

$$(4.4) \quad J_\beta(f) = (1 + \lambda) \left[\lambda^{-1}P^*(f)c(f) + \sum_{n=0}^{\infty} (-\lambda)^n H^{n+1}(f)c(f) \right].$$

Remark 4.2. (a) The quantity $h(f) := H(f)c(f)$ plays a crucial role in the analysis of the problem. It is called the *bias* or *transient cost*. It can be easily seen from the Neumann series expansion of $(I - P(f) + P^*(f))^{-1}$ [137] that, for $s \in \mathcal{S}$,

$$h(f)(s) = E_s^f \left[\sum_{t=0}^{\infty} (c(X_t, f(X_t)) - J(X_t, f)) \right].$$

From the above representation, $h(f)$ can be interpreted as the expected total cost for a CMP with cost $c - J$. If $P(f)$ is aperiodic, the distribution of X_t converges to a limiting distribution, so eventually $c(X_t, f(X_t))$ and $J(X_t, f)$ will differ very little. Thus, $h(f)$ can be thought of as the expected total cost “until convergence” or the expected total cost during the “transient” phase of the evolution of the process [137].

(b) Howard [95] has shown that

$$J_N(f) = NJ(f) + h(f) + o(1).$$

Therefore, as N becomes large, for each $s \in \mathcal{S}$, $J_N(f)$ approaches a straight line with slope $J(f)$ and intercept $h(f)$. When $J(f)(s)$ is constant, $J_N(s) - J_N(s')$ approaches $h(f)(s) - h(f)(s')$, so that $h(f)$ is the asymptotic relative difference of starting the process in two states s and s' . That is why $h(f)$ is often referred to as the relative value. See [14, pp. 304–308], [36] for a good discussion of these matters.

(c) Expansion (4.4) extends Blackwell’s expansion [18].

(d) Using expansion (4.4), the following important result is immediate.

COROLLARY 4.1. For $f \in \Pi_{SD}$, $J(f) = \lim_{\beta \uparrow 1} (1 - \beta)J_\beta(f)$.

Following Blackwell [18] and Derman [40], we now prove the following existence results.

THEOREM 4.3. *There exists an $f \in \Pi_{SD}$ that is discount optimal for all β sufficiently close to 1 and is also optimal for the average cost criterion.*

Proof. For each $f \in \Pi_{SD}$ and $s \in \mathcal{S}$, $J_\beta(s, f)$ is obviously an analytic function of β . Let $\{\beta_n\}$, $0 < \beta_n < 1$ be a sequence such that $\beta_n \uparrow 1$. For a fixed n , let $f_n \in \Pi_{SD}$ be β_n -discount optimal (see Theorem 2.1). Since Π_{SD} is a finite set, the sequence $\{f_n\}$ must contain at least one $f^* \in \Pi_{SD}$ that occurs infinitely often. Let $\{\beta_{n_k}\}$ be a subsequence of $\{\beta_n\}$ such that $\beta_{n_k} \uparrow 1$ and $f^* = f_{n_1} = f_{n_2} = \dots$. Then, for every $g \in \Pi$, $J_{\beta_{n_k}}(f^*) \leq J_{\beta_{n_k}}(g)$. Since all coordinates of $J_\beta(f^*)$ and $J_\beta(g)$ are analytic functions of β , it follows that

$$J_\beta(f^*) \leq J_\beta(g)$$

for all β near 1. Since this holds for all $g \in \Pi$, it follows that f^* is β -discount optimal for all β near 1. We next show that f^* is average optimal. Let $\pi \in \Pi$. Then

$$(1 - \beta_{n_k})J_{\beta_{n_k}}(f^*) \leq (1 - \beta_{n_k})J_{\beta_{n_k}}(\pi), \quad k = 1, 2, \dots$$

Therefore, letting $k \rightarrow \infty$ and using Theorem 4.1 and a standard Tauberian theorem (Theorem A.2 in the Appendix), it follows that

$$\begin{aligned} J(f^*) &= \lim_{\beta \uparrow 1} (1 - \beta)J_\beta(f^*) \\ &= \lim_{k \rightarrow \infty} (1 - \beta_{n_k})J_{\beta_{n_k}}(f^*) \\ &\leq \limsup_{k \rightarrow \infty} (1 - \beta_{n_k})J_{\beta_{n_k}}(\pi) \leq J(\pi), \end{aligned}$$

and the proof is complete. \square

We now briefly mention three numerical approaches. For details, we refer to [14], [137], [180], among others. Our presentation follows [137].

Value iteration. We assume that, under any $f \in \Pi_{SR}$, the corresponding chain is unichain and aperiodic. For any positive integer N , the finite horizon value function J_N^* satisfies the equation

$$(4.5) \quad J_{N+1}^* = \min_{f \in \Pi_{SD}} \{c(f) + P(f)J_N^*\}.$$

Equation (4.5) can act as an iteration equation with $J_0^* \equiv 0$ as the initial condition. Let $f_{N+1}^* \in \Pi_{SD}$ realize the minimum in (4.5). We can treat $(1/N)J_N^*$ and f_N^* as our guesses for J^* and an average optimal policy. Then $J_N^* - NJ^*$ converges as $N \rightarrow \infty$. Also, there exists an integer N_0 such that, for any $N \geq N_0$, any $f \in \Pi_{SD}$ that attains the minimum in (4.5) is average optimal. However, this property does not yield an error estimate and hence fails to provide a stopping rule for the iteration scheme. To this end, with $h = (h(1), \dots, h(k))$, we let

$$L(h) := \min_{x \in \mathbf{S}} \{Th(x) - h(x)\}, \quad U(h) := \max_{x \in \mathbf{S}} \{Th(x) - h(x)\}.$$

It can be shown that [137]

$$\min_{x \in \mathbf{S}} \{J_N^*(x) - J_{N-1}^*(x)\} \leq J^* \leq \max_{x \in \mathbf{S}} \{J_N^*(x) - J_{N-1}^*(x)\}$$

and

$$L(J_{N-1}^*) \leq L(J_N^*) \leq J^* \leq U(J_N^*) \leq U(J_{N-1}^*).$$

Furthermore, $\lim_{N \rightarrow \infty} \{U(J_N^*) - L(J_N^*)\} = 0$. Thus, an average ε -optimal policy can be found by stopping the value iteration when

$$U(J_N^*) - L(J_N^*) < \varepsilon.$$

There are other variants of this approach; see [54], [56], and [96].

Linear programming. To simplify our presentation, we will assume that, under any $f \in \Pi_{SR}$, the corresponding process is irreducible. Let $P(f)$ denote the transition matrix of the process, and $\eta(f) \in \mathcal{P}(\mathbf{S})$ its invariant measure. Then, for any $s \in \mathbf{S}$, $J(s, f) = J(f)$, a constant, and

$$J(f) = \sum_{s \in \mathbf{S}} \sum_{a \in U(s)} c(s, a) f(s, a) \eta(f)(s).$$

Therefore, the average cost problem can be reduced to the following linear programming problem:

$$(4.6a) \quad \text{minimize} \quad \sum_{s \in \mathbf{S}} \sum_{a \in U(s)} c(s, a) x(s, a)$$

subject to

$$(4.6b) \quad x(s, a) \geq 0, \quad s \in \mathbf{S}, \quad a \in U(s),$$

$$(4.6c) \quad \sum_{s \in \mathbf{S}} \sum_{a \in U(s)} x(s, a) = 1,$$

$$(4.6d) \quad \sum_{a \in U(s)} x(s, a) = \sum_{s' \in \mathbf{S}} \sum_{a \in U(s')} x(s', a) P(s' | s, a).$$

Under the irreducibility assumption, the simplex method can be employed to find an optimal stationary deterministic policy. This formulation is due to Manne [125].

Policy improvement. We work under the irreducibility assumption. The dual to the linear program (4.6a)–(4.6d) is the problem of finding variables g and $h(s)$, $s \in \mathbf{S}$, to

$$(4.7a) \quad \text{maximize } g$$

subject to

$$(4.7b) \quad g + \sum_{s' \in \mathbf{S}} (\delta(s, s') - P(s' | s, a)) h(s) \leq c(s, a),$$

$(s, a) \in \mathbf{S} \times U(s)$, where $\delta(s, s')$ is the Kronecker delta.

The functional equation

$$(4.8) \quad g + h(s) = \min_{a \in U(s)} \left\{ c(s, a) + \sum_{s' \in \mathbf{S}} P(s' | s, a) h(s') \right\}$$

is equivalent to (4.7a), (4.7b) under the irreducibility assumption and is the average cost optimality equation [87]. We will discuss this equation in detail in the next section. It will be shown that an $f \in \Pi_{SD}$ is optimal if and only if f realizes the pointwise minimum in (4.8), and then g is the optimal average cost. This suggests the following iteration algorithm.

- (i) Let $n = 1$. Choose $f_n \in \Pi_{SD}$. Let $h_n(s) \equiv 0$ for all $s \in \mathbf{S}$.
- (ii) Find a solution g_n and $h_n(s)$ of the following equation:

$$g_n + h_n(s) = c(s, f_n(s)) + \sum_{s' \in \mathbf{S}} P(s' | s, f_n(s)) h_n(s').$$

- (iii) For each $s \in \mathbf{S}$, compute

$$\phi_n(s) = \min_{a \in U(s) \setminus \{f_n(s)\}} \left\{ c(s, a) + \sum_{s' \in \mathbf{S}} P(s' | s, a) h_n(s') \right\} - g_n - h_n(s).$$

If $\phi_n(s) \geq 0$ for all $s \in \mathbf{S}$, then f_n is average optimal and g_n is the optimal average cost. If $\phi_n(s) < 0$ for some $s \in \mathbf{S}$, then pick $a \in U(s)$ such that

$$c(s, a) + \sum_{s' \in \mathbf{S}} P(s' | s, a) h_n(s') - g_n - h_n(s) < 0.$$

Define $f_{n+1} \in \Pi_{SD}$ as $f_{n+1}(s) = a$ and $f_{n+1}(\cdot) = f_n(\cdot)$, otherwise. Then f_{n+1} yields a lower average cost. Since Π_{SD} is finite, the policy improvement scheme converges in a finite number of steps.

4.2. Compact action spaces. We now consider the problem where the action set \mathbf{A} is not finite but a compact metric space. In this situation, an optimal policy may not exist; see [51, p. 178, Ex. 1]. Note that here Π_{SD} is no longer finite. Under certain ergodicity assumptions, Martin-Löf [126] and Feinberg [57] have proved the existence of an optimal $f \in \Pi_{SD}$. We will discuss various ergodicity assumptions on a countable state space in detail in the next section. First, we focus on ε -optimal policies established by Chitashvili [35] and Feinberg [58]; see [51, Chap. 7].

THEOREM 4.4. *Under Assumptions 2.1–2.3, for every $\varepsilon > 0$, there exists an ε -optimal $f \in \Pi_{SD}$.*

Proof (Sketch). For $f \in \Pi_{SD}$, let $J(f)$ be as in Theorem 4.1. For $i \in \mathbf{S}$, let

$$(4.9) \quad \tilde{J}(i) = \inf_{f \in \Pi_{SD}} J(f)(i).$$

Clearly, $J^*(i) \leq \tilde{J}(i)$, for each $i \in \mathbf{S}$. Corresponding to $i \in \mathbf{S}$, select an $f_i \in \Pi_{SD}$ such that

$$(4.10) \quad J(f_i)(i) \leq \tilde{J}(i) + \varepsilon.$$

The set $\tilde{\mathbf{A}} = \{f_i(j) : i, j \in \mathbf{S}\}$ is obviously finite. Taking the action set to be $\tilde{\mathbf{A}}$, the preceding results can be applied to the finite CMP $(\mathbf{S}, \tilde{\mathbf{A}}, P, c)$. For this model, there exists a stationary deterministic policy, say f^* , which is average optimal. Thus

$$(4.11) \quad J(f^*)(i) \leq J(f_i)(i) \leq \tilde{J}(i) + \varepsilon \quad \text{for each } i \in \mathbf{S}.$$

Let

$$\rho^*(i) := \limsup_{\beta \uparrow 1} (1 - \beta)J_\beta^*(i).$$

Then, by Theorem A.2, in the Appendix,

$$(4.12) \quad \rho^*(i) \leq J^*(i) \quad \text{for each } i \in \mathbf{S}.$$

By (4.11), it suffices to show that $J^*(i) = \tilde{J}(i)$, for each $i \in \mathbf{S}$. From (4.12), it then suffices to show that $\rho^*(i) \geq \tilde{J}(i)$. For each $\beta \in (0, 1)$, let $f_\beta \in \Pi_{SD}$ be β -discount optimal. Let f be a limit point of f_β as $\beta \uparrow 1$. Then using (4.4) (which is valid in this case as well) and Assumptions 2.1–2.3, it can be shown that

$$\rho^*(i) \geq J(f)(i) \geq \tilde{J}(i). \quad \square$$

Concerning the existence of an optimal policy, we state the following result.

THEOREM 4.5. *Let Assumptions 2.1 and 2.2 hold and further assume that $c(\cdot)$ is continuous on Π_{SR} and that, under any $f \in \Pi_{SR}$, the corresponding chain is unichain. Then there exists an optimal policy in $f \in \Pi_{SD}$.*

The result is almost immediate from the fact that, under the unichain assumption, $P^*(\cdot)$, and therefore also $J(\cdot)$, is continuous on Π_{SR} [91, Lemma 10.2]. For further details, including the convergence of a policy improvement algorithm, see [94].

5. Countable state space. The average cost problem becomes much more complicated when the state space is countable. Maitra [121] has given a counterexample that shows that there need not exist an optimal policy. In [122] Maitra has studied a particular problem in which there does not exist any policy that is β -discount optimal for all β sufficiently close to 1. Flynn [68] has constructed a more dramatic counterexample. In his example, there exists an average optimal policy in Π_{SD} . Nevertheless he exhibits an $f \in \Pi_{SD}$ and a $\beta_0 \in (0, 1)$ such that f is β -discount optimal for all $\beta \in (\beta_0, 1)$, but it is not average optimal. Fisher and Ross [67] have presented a counterexample that shows that the optimal policy need not be stationary or deterministic. We refer to [150] for several other counterexamples. It is apparent that the average

cost problem is closely related to the ergodic behavior of the process, and it is well known that the ergodic theory of Markov processes on a countable state space is much more involved than on a finite state space; for example, a Markov process on a finite state space cannot be null recurrent. Another vital difference in this case is that the number of stationary deterministic policies is no longer finite. To study the ergodic theory, some recurrence conditions are necessary. There are many such conditions available in the literature [26], [52], [178]; we will survey a few representative ones.

In what follows, the state space $\mathbf{S} = \{0, 1, 2, \dots\}$. For each $i \in \mathbf{S}$, the action space $U(i)$ is a prescribed compact metric space. We will always assume that, for fixed $i, j \in \mathbf{S}$, $c(i, \cdot)$, $P(i | j, \cdot)$, are continuous. These conditions can be weakened or dropped in several places, as will be clear from the specific context.

Derman [38] studied the ACOE that, with ρ a scalar and $h : \mathbf{S} \rightarrow \mathbb{R}$, takes the following form:

$$(5.1) \quad \rho + h(i) = \min_{a \in U(i)} \left\{ c(i, a) + \sum_{j \in \mathbf{S}} P(j | i, a) h(j) \right\}.$$

A solution to (5.1) is a pair (ρ, h) satisfying it.

Suppose that $f \in \Pi_{SD}$ is a minimizing selector in (5.1). Then (5.1) becomes

$$(5.1') \quad \rho + h(i) = c(i, f(i)) + \sum_{j \in \mathbf{S}} P(j | i, f(i)) h(j).$$

Equation (5.1') asserts that, apart from ρ , the cost if the process stops now equals the expected cost if it continues under the policy f for just one more period. We can give a similar interpretation to (5.1). Hence, we may think that ρ is the average cost under f and that no other $f \in \Pi_{SD}$ has a smaller average cost. Thus, the function h in (5.1) is roughly a measure of how much we are prepared to pay to stop the process, though continuing to pay an average cost ρ in the future [141] (cf. Remark 4.2(a)). Therefore, the function h may be viewed as a cost potential. Also, by a stochastic representation of h , using (5.1) and (5.1'), h is indeed a potential. Hordijk [91] has pursued this line of thought in great detail, which we will discuss later.

We start with a characterization of optimal policies.

THEOREM 5.1. *If the ACOE has a solution (ρ, h) satisfying*

$$(5.2) \quad \lim_{t \rightarrow \infty} \frac{1}{t} E_i^\pi h(X_t) = 0 \quad \forall \pi \in \Pi_{SD}, \quad \forall i \in \mathbf{S},$$

then there exists an $f \in \Pi_{SD}$ such that

$$\rho = J(i, f) = J^*(i) \quad \forall i \in \mathbf{S}.$$

Moreover, an $f \in \Pi_{SD}$ is average optimal if, for each $i \in \mathbf{S}$,

$$(5.3) \quad c(i, f(i)) + \sum_{j \in \mathbf{S}} P(j | i, f(i)) h(j) = \min_{a \in U(i)} \left\{ c(i, a) + \sum_{j \in \mathbf{S}} P(j | i, a) h(j) \right\},$$

and, conversely, if an $f \in \Pi_{SD}$ is average optimal and the corresponding chain is irreducible and positive recurrent, then (5.3) holds.

Proof. Let $f \in \Pi_{SD}$ satisfy (5.3). Then, since

$$E_i^f [h(X_{t+1}) | \mathfrak{F}_t] = \sum_{j \in \mathbf{S}} P(j | X_t, f(X_t)) h(j),$$

it follows from (5.1) and (5.3) that

$$(5.4) \quad \rho + h(X_t) = c(X_t, f(X_t)) + E_i^f[h(X_{t+1}) \mid \mathfrak{F}_t].$$

Summing (5.4) from $t = 0$ to $N - 1$, dividing by N , and taking expectations, we obtain

$$\rho = \frac{1}{N} E_i^f \left[\sum_{t=0}^{N-1} c(X_t, f(X_t)) \right] + \frac{E_i^f[h(X_N)] - h(i)}{N}.$$

Next, letting $N \rightarrow \infty$ and using (5.2) yields

$$\rho = \lim_{N \rightarrow \infty} \frac{1}{N} E_i^f \left[\sum_{t=0}^{N-1} c(X_t, f(X_t)) \right].$$

On the other hand, if π is any other policy, we can show using the same arguments that

$$\rho \leq \limsup_{N \rightarrow \infty} \frac{1}{N} E_i^\pi \left[\sum_{t=0}^{N-1} c(X_t, A_t) \right].$$

Hence, f is average optimal. Conversely, let $f \in \Pi_{SD}$ be average optimal and suppose that the corresponding chain is irreducible and positive recurrent. If f does not satisfy (5.3), then there exist $i_0 \in \mathcal{S}$, $a_0 \in U(i_0)$ and $\delta > 0$ such that

$$(5.5) \quad \begin{aligned} c(i_0, f(i_0)) + \sum_{j \in \mathcal{S}} P(j \mid i_0, f(i_0)) h(j) \\ = c(i_0, a_0) + \sum_{j \in \mathcal{S}} P(j \mid i_0, a_0) h(j) + \delta. \end{aligned}$$

Let $f' \in \Pi_{SD}$ be defined as follows:

$$f'(i) = \begin{cases} f(i) & \text{if } i \neq i_0, \\ a_0 & \text{if } i = i_0. \end{cases}$$

Then, using (5.5) along with irreducibility and positive recurrence, it is easily seen that $J(i_0, f') < J(i_0, f)$, which contradicts the average optimality of f . \square

Remark 5.1. (a) We say that (5.1) admits a bounded solution if $h(\cdot)$ is bounded. If the ACOE has a bounded solution, then (5.2) is clearly satisfied; moreover, using the martingale stability theorem [117, p. 53], it can be shown that the $f \in \Pi_{SD}$ selecting the minimum in (5.3) is sample path average optimal [72].

(b) Various extensions of last assertion of Theorem 5.1 have been obtained by Sennott [158].

Derman and Veinott [43] have prescribed a certain recurrence condition that ensures that (5.1) admits a bounded solution. We will discuss it later in this section. The ACOE resembles the dynamic programming equation, and Theorem 5.1 is analogous to a dynamic programming characterization of an optimal policy. However, the dynamic programming heuristic does not lead directly to the ACOE. Taylor [177] developed a vanishing discount approach for a particular problem, which was extended for the general case by Ross [147]–[150]. Our presentation here follows Ross [150]. As noted earlier, the average case can in some sense be treated as the limiting case of

the discounted problem as the discount factor approaches 1. The discounted value function $J_\beta^*(\cdot)$ satisfies the DCOE (cf. Theorem 2.1)

$$J_\beta^*(i) = \min_{a \in U(i)} \left\{ c(i, a) + \beta \sum_{j \in \mathcal{S}} P(j | i, a) J_\beta^*(j) \right\},$$

and a β -discounted optimal policy selects a minimizing action. One possible way of finding an average optimal policy might be to choose the actions minimizing

$$\lim_{\beta \rightarrow 1} \left\{ c(i, a) + \beta \sum_{j \in \mathcal{S}} P(j | i, a) J_\beta^*(j) \right\}.$$

However, this limit need not exist and indeed would often be infinite for all actions. The situation can nevertheless be salvaged by considering a “differential” discounted value function, i.e., $h_\beta(i) := J_\beta^*(i) - J_\beta^*(0)$, where $0 \in \mathcal{S}$ is an arbitrary, fixed state. The function $h_\beta(\cdot)$ satisfies

$$(5.6) \quad (1 - \beta)J_\beta^*(0) + h_\beta(i) = \min_{a \in U(i)} \left\{ c(i, a) + \beta \sum_{j \in \mathcal{S}} P(j | i, a) h_\beta(j) \right\}.$$

From (5.6) it is now apparent that (5.1) can be derived under certain conditions by letting $\beta \rightarrow 1$. We state here a simple result [150], despite the fact that it also holds under weaker hypotheses (see Theorem 5.9).

THEOREM 5.2. *Suppose that there exists a constant $K > 0$ such that $|h_\beta(i)| \leq K$, for all $\beta \in (0, 1)$ and $i \in \mathcal{S}$. Then*

- (i) *The ACOE admits a bounded solution (ρ, h) ;*
- (ii) *For some sequence $\beta_n \rightarrow 1$, $h(i) = \lim_{n \rightarrow \infty} h_{\beta_n}(i)$, $i \in \mathcal{S}$;*
- (iii) *$\lim_{\beta \rightarrow 1} (1 - \beta)J_\beta^*(i) = \rho$ for any $i \in \mathcal{S}$.*

Proof. Let $\beta_n \uparrow 1$ be given. By the uniform boundedness of $h_\beta(\cdot)$, using a diagonalization procedure, we can find a subsequence, which for simplicity we also denote by β_n , such that $h_{\beta_n}(i) \rightarrow h(i)$ for each $i \in \mathcal{S}$, where $h(\cdot)$ is a bounded function. Again, since $(1 - \beta_n)J_{\beta_n}^*(0)$ is bounded, there is a further subsequence $\beta_{n_k} \uparrow 1$ such that

$$\lim_{k \rightarrow \infty} (1 - \beta_{n_k})J_{\beta_{n_k}}^*(0)$$

exists. Part (i) of the theorem then follows from (5.6) and an application of the dominated convergence theorem. Furthermore, by Theorem 5.1, ρ is the minimum average cost. Since the above results are independent of the sequence chosen, (iii) then follows. \square

Remark 5.2. It has been shown [64] that, if the ACOE has a bounded solution, then there exists a constant $K > 0$ such that $|h_\beta(i)| \leq K$ for all $\beta \in (0, 1)$, $i \in \mathcal{S}$.

5.1. Bounded costs. In this section, we assume that $c(\cdot, \cdot)$ is bounded. Ross [150] has proved that under a Derman–Veinott [43] type recurrence condition (see (5.7), below), the uniform boundedness hypothesis of Theorem 5.2 is satisfied.

THEOREM 5.3. *Let $f \in \Pi_{SD}$ and let $\{X_t\}$ be the corresponding state process. Let*

$$\tau = \min\{t \geq 1 : X_t = 0\}.$$

If there exists a $K > 0$ such that

$$(5.7) \quad E_i^f[\tau] < K$$

for all $f \in \Pi_{SD}$ and all $i \in \mathbf{S}$, then $h_\beta(i)$ is bounded uniformly in $\beta \in (0, 1)$ and $i \in \mathbf{S}$.

Proof. Let $\beta \in (0, 1)$ and $f_\beta \in \Pi_{SD}$ be β -discount optimal. We have

$$(5.8) \quad \begin{aligned} J_\beta^*(i) &= E_i^{f_\beta} \left[\sum_{t=0}^{\infty} \beta^t c(X_t, f_\beta(X_t)) \right] \\ &= E_i^{f_\beta} \left[\sum_{t=0}^{\tau-1} \beta^t c(X_t, f_\beta(X_t)) \right] + E_i^{f_\beta} \left[\sum_{t=\tau}^{\infty} \beta^t c(X_t, f_\beta(X_t)) \right] \\ &\leq M E_i^{f_\beta}[\tau] + J_\beta^*(0) E_i^{f_\beta}[\beta^\tau], \end{aligned}$$

where M is a bound on $c(\cdot, \cdot)$. From (5.7) and (5.8), it follows that

$$(5.9) \quad J_\beta^*(i) - \beta J_\beta^*(0) \leq MK.$$

Also, from (5.8) and applying Jensen's inequality, we obtain

$$J_\beta^*(i) \geq J_\beta^*(0) E_i^{f_\beta}[\beta^\tau] \geq J_\beta^*(0) \beta^K.$$

Therefore,

$$(5.10) \quad \begin{aligned} J_\beta^*(0) - J_\beta^*(i) &\leq (1 - \beta^K) J_\beta^*(0) \\ &\leq (1 - \beta^K) \frac{M}{1 - \beta} \leq MK. \end{aligned}$$

The desired result follows from (5.9) and (5.10). \square

After the work of Derman [38], Derman and Veinott [43], and Ross [147], [148], several recurrence conditions have appeared [178]. We explore a few representative ones.

Let $f \in \Pi_{SD}$. For a finite set $A \subset \mathbf{S}$, let

$$(5.11) \quad \tau_A = \min\{t \geq 1 : X_t \in A\}.$$

Assumption 5.1. There is a finite $A \subset \mathbf{S}$ and a constant $K > 0$ such that $E_i^f[\tau_A] < K$ for all $i \in \mathbf{S}$ and $f \in \Pi_{SD}$. Furthermore, for any $f \in \Pi_{SD}$ the corresponding process does not have two disjoint invariant sets.

Assumption 5.2. There exists a constant $K > 0$, and, for every $f \in \Pi_{SD}$, there is a state $j(f) \in \mathbf{S}$ such that

$$E_i^f[\tau_{\{j(f)\}}] < K \quad \forall i \in \mathbf{S}.$$

Assumption 5.3 (simultaneous Doeblin). There is a finite set A , an integer $n \geq 1$ and a scalar $\alpha > 0$ such that

$$\sum_{j \in A} P(j \mid i, f(i)) \geq \alpha$$

for all $i \in \mathbf{S}$ and all $f \in \Pi_{SD}$. Furthermore, for any $f \in \Pi_{SD}$, the corresponding process does not have two disjoint invariant sets.

Assumption 5.4 (scrambling). There is an integer $n \geq 1$ and a scalar $\alpha > 0$ such that, for any $f \in \Pi_{SD}$,

$$\sum_{j \in \mathbf{S}} \min\{P_{i_1,j}^n(f), P_{i_2,j}^n(f)\} \geq \alpha \quad \forall i_1, i_2 \in \mathbf{S}.$$

Assumption 5.5 (ergodicity). There is an integer $n \geq 1$ and a scalar $\rho > 0$ such that, for each $f \in \Pi_{SD}$, there exists an $\eta(f) \in \mathcal{P}(\mathbf{S})$ for which

$$\sum_j |P_{ij}^m(f) - \eta(f)(j)| \leq 2(1 - \rho)^{\lfloor m/n \rfloor}$$

for all $i \in \mathbf{S}$ and $m \geq 1$, where $\lfloor x \rfloor$ denotes the largest integer not exceeding x .

Remark 5.3. Clearly Assumptions 5.1 and 5.2 are generalizations of the Derman–Veinott condition. Hordijk [91] has proved the existence of a bounded solution to the ACOE using Assumption 5.1. Under Assumption 5.5, for each $f \in \Pi_{SD}$, $\eta(f)$ is the unique invariant measure of the corresponding process.

Federgruen, Hordijk, Tijms [52] have established the following theorem.

THEOREM 5.4. *Assumptions 5.1–5.3 are equivalent. Also, if for any $f \in \Pi_{SD}$ the corresponding process is aperiodic, then Assumptions 5.1–5.5 are equivalent.*

Remark 5.4. Under any one of Assumptions 5.1–5.5, Federgruen, Hordijk, and Tijms [52] have established the existence of a bounded solution to the ACOE by extending the vanishing discount approach of Taylor and Ross.

We have thus far seen several recurrence conditions which are sufficient for the ACOE to admit a bounded solution. Cavazos-Cadena [30], [31] has dealt with the converse question of what are the necessary recurrence conditions for the ACOE to have a bounded solution. He has obtained the following result. Consider the following assumption.

Assumption 5.6. There exists a constant $K > 0$ such that, for each bounded and measurable $c : \mathbf{S} \times \mathbf{A} \rightarrow \mathbb{R}$ and every collection $\{U(i) : i \in \mathbf{S}\}$, $U(i) \subset \mathbf{A}$, there exist $\rho \in \mathbb{R}$ and $h : \mathbf{S} \rightarrow \mathbb{R}$ bounded that solve (5.1) and satisfy $\|h\| \leq K\|c\|$, where $\|\cdot\|$ is the sup norm.

THEOREM 5.5. *Assumptions 5.2 and 5.6 are equivalent.*

The proof follows by an application of the uniform boundedness principle. For details and other variants, we refer to [30], [31]. Thus, an assumption on the existence of a bounded solution to the ACOE necessarily imposes a strong recurrence structure on the system. Also, note that Assumption 5.6 involves not just one CMP but a family of CMP (one for each c and $\{U(i)\}$). Since it is equivalent to Assumptions 5.1–5.3 and under aperiodicity conditions to Assumptions 5.1–5.5, it follows that Assumptions 5.1–5.5 are too strong for many important applications. In fact, there are interesting situations [20] in which these conditions are not satisfied, but for which we can find average optimal stationary deterministic policies.

Ross [148] has proved that, under the following recurrence condition, the AC can be reduced to an appropriate DC. Therefore, in view of Theorem 2.1, the problem can be resolved in this case.

THEOREM 5.6. *If there exists a constant $\alpha > 0$ such that*

$$P(0 \mid i, a) \geq \alpha > 0$$

for all $i \in \mathbf{S}$, $a \in U(i)$, then the AC can be reduced to an appropriate DC.

Proof. Let

$$\tilde{P}(j | i, \cdot) = \begin{cases} (1 - \alpha)^{-1} P(j | i, \cdot) & \text{for } j \neq 0, \\ (1 - \alpha)^{-1} (P(0 | i, \cdot) - \alpha) & \text{for } j = 0. \end{cases}$$

Let $\tilde{J}_\beta^*(\cdot)$ denote the β -discounted value function for the CMP with cost $c(\cdot, \cdot)$ and transition law $\tilde{P}(\cdot | \cdot, \cdot)$. Then it is easily verified that, for each $i \in \mathbf{S}$,

$$\alpha \tilde{J}_{1-\alpha}^*(0) + \tilde{J}_{1-\alpha}^*(i) = \min_{a \in U(i)} \left\{ c(i, a) + \sum_{j \in \mathbf{S}} P(j | i, a) \tilde{J}_{1-\alpha}^*(j) \right\}.$$

Let $f \in \Pi_{SD}$ be $(1 - \alpha)$ -discount optimal for the modified CMP. It follows from Theorem 5.1 that f is AC-optimal for the original CMP, and the optimal average cost is $\alpha \tilde{J}_{1-\alpha}^*(0)$. \square

Remark 5.5. Note that, if the ACOE has a bounded solution (ρ, h) , then ρ is the optimal average cost for any initial condition. Hence, the existence of a bounded solution to the ACOE suggests that some kind of “unchainedness” is in effect, since, for the multichain case, the average cost would, in general, depend on the initial condition. The multichain version of the ACOE is

$$(5.12a) \quad \min_{a \in U(i)} \sum_{j \in \mathbf{S}} P(j | i, a) \rho(j) = \rho(i),$$

$$(5.12b) \quad \rho(i) + h(i) = \min_{a \in U_1(i)} \left\{ c(i, a) + \sum_{j \in \mathbf{S}} P(j | i, a) h(j) \right\},$$

where

$$(5.12c) \quad U_1(i) = \left\{ a \in U(i) : \min_{a \in U(i)} \sum_{j \in \mathbf{S}} P(j | i, a) \rho(j) = \rho(i) \right\}.$$

This equation has been studied by Zijm [208] for countable state space. For more general state spaces, it was extensively studied much earlier by Yushkevich [204] (see also [51]); this work will be discussed in the next section.

If (5.12) has a bounded solution $\rho(i)$, $h(i)$, where both ρ and h are bounded functions, then we can show, as before, that $\rho(i)$ is the optimal average cost starting from state $i \in \mathbf{S}$ and a minimizing selector in (5.12) yields an average optimal stationary deterministic policy. Under a certain “geometric convergence condition,” Zijm [208] has established the existence of a bounded solution to (5.12). Under the additional assumptions that under any stationary deterministic policy the corresponding process has at most a finite number of ergodic classes, he has shown that the geometric convergence condition is equivalent to a number of recurrence conditions of the type Assumptions 5.1–5.5.

Hordijk [91] establishes the existence of an average optimal $f \in \Pi_{SD}$ without utilizing the ACOE. Let Π_{SD} be endowed with the product topology. Then Π_{SD} is compact and metrizable. Let us consider the following assumptions.

Assumption 5.7. For each $f \in \Pi_{SD}$ and $i \in \mathcal{S}$, there exists a measure $\eta_i(f) \in \mathcal{P}(\mathcal{S})$ such that $\eta_i(f)(j) = \lim_{N \rightarrow \infty} (1/N) \sum_{n=0}^{N-1} P^n(f)(i, j)$.

Assumption 5.8. $f \mapsto \eta_i(f)$ is continuous for any $i \in \mathcal{S}$.

Assumption 5.9. For each $i \in \mathcal{S}$, $\{\eta_i(f) : f \in \Pi_{SD}\}$ is tight (for a definition of tightness, see [134, Def. 3.1, p. 28]).

Assumption 5.10. For each $f \in \Pi_{SD}$, the corresponding process is recurrent.

Assumption 5.11. For each $f \in \Pi_{SD}$, the corresponding process does not have disjoint-invariant sets.

Assumption 5.12. $\{P(f)(i, \cdot) : i \in \mathcal{S}, f \in \Pi_{SD}\}$ is tight.

It is easy to see that Assumptions 5.7 and 5.8 imply that, for each $i \in \mathcal{S}$, $\{\eta_i(f) : f \in \Pi_{SD}\}$ is compact. Hence, in particular, Assumptions 5.7 and 5.8 imply Assumption 5.9. By definition, Assumption 5.9 implies Assumption 5.7. Also, it can easily be shown that Assumptions 5.9 and 5.11 imply Assumption 5.8, and that Assumption 5.12 implies 5.9. However, Assumption 5.12 may be easier to verify.

THEOREM 5.7. *Each of the following five combinations of assumptions is sufficient for the existence of an average optimal $f \in \Pi_{SD}$: (Assumption 5.7, Assumption 5.8), (Assumption 5.9, Assumption 5.10), (Assumption 5.9, Assumption 5.11), (Assumption 5.10, Assumption 5.12), (Assumption 5.11, Assumption 5.12).*

Remark 5.6. The main idea behind the proof of this theorem can be traced back to the proof of Theorem 4.3. We give the main points and skip the details. Let $\beta_n \in (0, 1)$ be a sequence such that $\beta_n \uparrow 1$, let $f_{\beta_n} \in \Pi_{SD}$ be β_n -discount optimal, and f_∞ be a limit point of $\{f_{\beta_n}\}$ in Π_{SD} . Suppose that $\rho^*(i)$ is a scalar satisfying $(1 - \beta_n)J_{\beta_n}^*(i) \rightarrow \rho^*(i)$, for each $i \in \mathcal{S}$ (along a suitable subsequence). Then, by using Tauberian and ergodic theorems, we deduce that $J^*(i) = \rho^*(i)$ and f_∞ is average optimal under (Assumption 5.7, Assumption 5.8). Under (Assumption 5.9, Assumption 5.10), f_∞ is average optimal for initial states $i \in \tilde{\mathcal{S}} := \bigcup_i \text{supp}(\eta_i(f_\infty))$, where “supp” denotes the support. Then by Assumption 5.10 there exists an \tilde{f} such that the corresponding process starting from any $i \in \mathcal{S} \setminus \tilde{\mathcal{S}}$ reaches $\tilde{\mathcal{S}}$. Set

$$\tilde{f}(i) = \begin{cases} \bar{f}(i) & \text{if } i \notin \tilde{\mathcal{S}}, \\ f_\infty(i) & \text{if } i \in \tilde{\mathcal{S}}. \end{cases}$$

It follows that \tilde{f} is average optimal. The other cases can be dealt with in a similar manner.

5.2. Unbounded costs. We have thus far considered bounded costs only. There are practical situations (e.g., in queueing systems) where the cost is typically unbounded. We assume that $c \geq 0$ (cf. Assumption 2.1). Let us now consider the ACOE for unbounded c . Note that the boundedness of c , did not play any role in the proof of Theorem 5.1. For unbounded c , the ACOE is unlikely to admit a bounded solution.

Lippman [115], [116] has studied controlled semi-Markov processes with unbounded costs. He has placed polynomial bounds on the movement of the process in one transition. He has made a further assumption that there exists an $f \in \Pi_{SD}$ such that both the mean first passage times and mean first passage costs from any state i to state zero under the policy are finite. Moreover, if $f \in \Pi_{SD}$ is close to β -discount optimal for a sequence of discount factors, then it is AC-optimal. Lippman has employed the vanishing discount approach of Taylor and Ross to establish the existence of a solution (ρ, h) to the ACOE with h satisfying (5.2), thereby establishing the existence of an

average optimal $f \in \Pi_{SD}$. He has also given some examples from queueing systems where his conditions are satisfied. However, his condition on the β -discounted value function appears to be very difficult to verify.

Hordijk [91] has used a Lyapunov stability condition to establish the existence of an average optimal $f \in \Pi_{SD}$.

Assumption 5.13 (Lyapunov condition). Let

$$\tilde{P}(f)(i, j) = \begin{cases} P(f)(i, j), & j \neq 0, \\ 0, & j = 0. \end{cases}$$

There exists a function $w : \mathbf{S} \rightarrow \mathbb{R}_+$ such that, for all $i \in \mathbf{S}$,

- (i) $c(i, f(i)) + 1 + \sum_j \tilde{P}(f)(i, j)w(j) \leq w(i)$, for all $f \in \Pi_{SD}$;
- (ii) $\sum_j P(f)(i, j)w(j)$ is continuous in f ;
- (iii) $\lim_{n \rightarrow \infty} \sum_j \tilde{P}^n(f)(i, j)w(j) = 0$.

THEOREM 5.8. *Under the above Lyapunov condition, there exists an AC-optimal $f \in \Pi_{SD}$.*

Proof (Sketch). Let $f \in \Pi_{SD}$. For $i \in \mathbf{S}$, we define $\tau_i = \min\{t \geq 1 : X_t = i\}$, where X_t is governed by f . Then, under Assumption 5.13, using the standard techniques of stochastic Lyapunov function method [91], [108], the following results can be proved:

$$(5.13) \quad E_i^f[\tau_0] \leq w(i),$$

$$(5.14) \quad E_i^f \left[\sum_{t=0}^{\tau_0-1} c(X_t, f(X_t)) \right] \leq w(i).$$

Indeed, with $n \in \mathbb{N}$ and $n > 1$,

$$\begin{aligned} E_i^f[w(X_{n \wedge \tau_0}) \mid \mathfrak{F}_{n \wedge \tau_0}] - w(i) &= -E_i^f \left[\sum_{t=0}^{n \wedge \tau_0-1} E_i^f[w(X_{t+1}) \mid X_t] - w(X_t) \right] \\ &\leq -E_i^f[n \wedge \tau_0], \end{aligned}$$

where the last inequality is due to Assumption 5.13. Hence, $E_i^f[n \wedge \tau_0] \leq w(i)$, and, letting $n \uparrow \infty$, (5.13) follows. Also, (5.14) can be proved along the same lines. By an ergodic theorem [133],

$$\begin{aligned} \lim_{N \rightarrow \infty} \frac{1}{N} E_0^f \left[\sum_{t=0}^{N-1} c(X_t, f(X_t)) \right] &= (E_0^f \tau_0)^{-1} E_0^f \left[\sum_{t=0}^{\tau_0-1} c(X_t, f(X_t)) \right] \\ &=: \rho(f). \end{aligned}$$

Let $\rho^* := \inf_{f \in \Pi_{SD}} \rho(f)$. Then $\rho^* \leq w(0)$. Define

$$h(i) = \inf_{f \in \Pi_{SD}} E_i^f \left[\sum_{t=0}^{\tau_0-1} (c(X_t, f(X_t)) - \rho^*) \right].$$

Then $h(0) = 0$. Using (5.13), (5.14), and Assumption 5.13(iii), it can be shown that (ρ^*, h) is a solution of the ACOE with h satisfying (5.2), and the desired result follows. \square

Remark 5.7. (a) Note that by Assumption 5.13(i) the cost function c does not grow faster than the Lyapunov function w . Thus, there is a restriction on the growth of c imposed by w . In CMP, $w(i) = i$, $w(i) = i^2$ are typical examples of Lyapunov functions [91]. In the latter case, for example, we can treat only those unbounded cost functions that do not grow faster than quadratic functions.

(b) Assumption 5.13(iii) is crucial in showing that the cost potential h satisfies $\lim_{t \rightarrow \infty} (1/t) E_i^f h(X_t) = 0$, for all $f \in \Pi_{SD}$, and $i \in \mathcal{S}$.

Federgruen, Hordijk, and Tijms [53] have extended Hordijk's results by replacing the single attracting point $\{0\}$ by a finite set $K \subset \mathcal{S}$. Their main assumption is the following: There exists a finite set $K \subset \mathcal{S}$ such that, for each initial state $i \in \mathcal{S}$, the suprema over the mean hitting time of K and mean hitting costs are finite. This, in turn, is equivalent to the existence of a Lyapunov function $w : \mathcal{S} \rightarrow \mathbb{R}_+$ satisfying Assumption 5.13(i), where now \tilde{P} is defined as

$$\tilde{P}(f)(i, j) = \begin{cases} P(f)(i, j), & j \notin K, f \in \Pi_{SD}, \\ 0, & j \in K. \end{cases}$$

Under the additional assumptions that Assumption 5.13(ii) and (iii) hold, and the “communication condition” that for any $f \in \Pi_{SD}$ the corresponding process has no two disjoint invariant sets, they have established the existence of a solution (ρ, h) to the ACOE by employing the vanishing discount approach and have shown that h satisfies (5.2). This work has been further extended by Federgruen, Schweitzer, and Tijms [55]. They have dropped the unchainedness assumption in [53]. Instead, they assume that any state can be reached from any other state via some policy. Under this and other conditions in [53], they have established the existence of a solution (ρ, h) to the ACOE, with h satisfying (5.2). They have deviated from the vanishing discount approach and have, instead, utilized Tychonoff's fixed point theorem in their analysis. We again note that, in all these investigations, a restrictive growth condition on the cost function is imposed, as noted in Remark 5.7.

The Lyapunov stability condition necessarily imposes a blanket stability (i.e., positive recurrence) of certain states (cf. (5.13)), which may be very restrictive. On the other hand, (5.2) is not easy to verify in general and, indeed, may not hold in the case of many queueing models [141]. Another generalization of the boundedness of the solution of the ACOE could be boundedness from below. This will be the case if the cost function has some “monotone” properties, which naturally arise in various queueing models. This line of thought has been pursued in various ways in [24], [28], [74], [76], [77], [141], [142], [155], [156], [172], [190].

Sennott [155], [156] has prescribed very general conditions in this direction. We will now briefly describe them. Consider the following assumptions.

Assumption 5.14. For every $i \in \mathcal{S}$ and every $\beta \in (0, 1)$, $J_\beta^*(i) < \infty$.

Assumption 5.15. There exists a nonnegative integer L such that

$$h_\beta(i) := J_\beta^*(i) - J_\beta^*(0) \geq -L.$$

Assumption 5.16. There exists a function $M : \mathcal{S} \rightarrow \mathbb{R}_+$ such that $h_\beta(i) \leq M(i)$ for all $i \in \mathcal{S}$ and any $\beta \in (0, 1)$. For every $i \in \mathcal{S}$, there exists an $a(i) \in U(i)$ such that

$$\sum_j P(j \mid i, a(i)) M(j) < \infty.$$

THEOREM 5.9. *Under Assumptions 5.14–5.16, there exists an AC-optimal $f \in \Pi_{SD}$.*

Proof. Let $\beta_n \in (0, 1)$ be such that $\beta_n \uparrow 1$. Let f_{β_n} be β_n -discount optimal. Let f be a limit point of f_{β_n} as $n \rightarrow \infty$. To simplify the notation, all subsequences of β_n will also be denoted by β_n . By Assumption 5.16 and a diagonal argument, there exists a function $h : \mathbf{S} \rightarrow \mathbb{R}$ such that $\lim_{n \rightarrow \infty} h_{\beta_n}(\cdot) = h(\cdot)$. By Assumption 5.15, $h(\cdot) \geq -L$. Let $\rho : \mathbf{S} \rightarrow \mathbb{R}_+$ be a function such that $\lim_{n \rightarrow \infty} (1 - \beta_n)J_{\beta_n}^*(i) = \rho(i)$. Using Assumption 5.16, it is easy to see that $\rho(i) = \rho^*$, a constant. Now, for $i \in \mathbf{S}$,

$$(5.15) \quad (1 - \beta_n)J_{\beta_n}^*(0) + h_{\beta_n}(i) = c(i, f_{\beta_n}(i)) + \beta_n \sum_{j \in \mathbf{S}} P(j \mid i, f_{\beta_n}(i)) h_{\beta_n}(j).$$

Fix an $i \in \mathbf{S}$. Add L to both sides to make $(h_{\beta_n}(i) + L) \geq 0$ and take “liminf” on both sides of (5.15). Then, by Fatou’s lemma and the assumption of continuity of $P(j \mid i, \cdot)$, we conclude that

$$\rho^* + h(i) \geq c(i, f(i)) + \sum_j P(j \mid i, f(i)) h(j).$$

Since $h(\cdot)$ is bounded below, the proof of Theorem 5.1 can be modified to show that $J(i, f) \leq \rho^*$. By Theorem A.2 in the Appendix, $J(i, \pi) \geq \rho^*$ for any $\pi \in \Pi$. Hence, $J(i, f) = J^*(i) = \rho^*$, and f is AC-optimal. \square

Remark 5.8. (a) From the above proof, it is clear that if ρ is a scalar, $h : \mathbf{S} \rightarrow \mathbb{R}$ is bounded below, and

$$(5.16) \quad \rho + h(i) \geq \min_{a \in U(i)} \left\{ c(i, a) + \sum_j P(j \mid i, a) h(j) \right\},$$

then ρ is the optimal average cost, and any $f \in \Pi_{SD}$ selecting the minimum on the right-hand side of (5.16) is AC-optimal. In this case, we may replace the ACOE by an *average cost optimality inequality* (ACOI), viz., (5.16).

(b) If, for each $i \in \mathbf{S}$, $U(i)$ is finite, then, in the above proof, $f_{\beta_n}(i) = f(i)$ for large n . Then we can write, for large n ,

$$\rho + h(i) = c(i, f(i)) + \beta_n \sum_j P(j \mid i, f(i)) h_{\beta_n}(j).$$

By Fatou’s lemma,

$$\rho + h(i) \geq c(i, f(i)) + \sum_j P(j \mid i, f(i)) h(j).$$

Consider the stronger assumption, below.

Assumption 5.17. Assumption 5.16 holds, and $\sum_j P(j \mid i, a) M(j) < \infty$, for all $a \in \mathbf{A}$ and $i \in \mathbf{S}$.

Under Assumption 5.17, using dominated convergence, it is easy to see that

$$\rho + h(i) = \min_{a \in U(i)} \left\{ c(i, a) + \sum_j P(j \mid i, a) h(j) \right\},$$

and we obtain the ACOE. If, for each $i \in \mathcal{S}$, there is a finite set $R_i \subset \mathcal{S}$ such that $P(j \mid i, \cdot) = 0$ for $j \notin R_i$, then Assumption 5.17 will obviously hold. Such a condition is satisfied for systems whose dynamics have a nearest-neighbour motion property [28].

(c) If there exists an $f \in \Pi_{SD}$, under which the process is ergodic, irreducible with an invariant measure $\eta(f) \in \mathcal{P}(\mathcal{S})$, and $\sum_i c(i, f(i))\eta(f)(i) < \infty$, then Assumptions 5.14 and 5.16 hold. Assumption 5.15 holds if $J_\beta^*(i)$ is increasing in i . Direct conditions implying Assumptions 5.14–5.17 can be found in [28], [32], [34], [76], [77], [155], [156], [172], [190]. See also [141], [142].

(d) Let $f \in \Pi_{SD}$ be a policy that attains the minimum on the right-hand side of (5.16). Fix an $i \in \mathcal{S}$. If the chain under f is positive recurrent at i , then we can show that equality holds at i in (5.16). However, the lack of positive recurrence at i may lead to strict inequality in (5.16). Cavazos-Cadena [33] had exhibited an example to demonstrate this. He has further shown in his example [33] that Assumptions 5.14–5.16 are satisfied, but the ACOE does not admit any solution.

5.3. The convex analytic approach. We will now describe Borkar's convex analytic approach for the average cost case [20]–[26]. The convex analytic approach to the AC-problem is a natural extension of the linear programming approach when the state/action spaces are no longer finite. In this approach, we view the control problem as the problem of minimizing a linear functional on the convex set of “ergodic occupation measures,” to be defined shortly [20]–[26]. This approach can also be used to treat other standard cost criteria, but it may be more involved for treating cases such as the DC criterion. On the other hand, it is more flexible and powerful for certain other purposes, e.g., pathwise average cost, constrained optimization problem, among others. Since the techniques involved here are entirely different from what we have thus far followed, we will embark on a more detailed discussion.

By replacing each $U(i)$ with $\prod_k U(k)$ and $P(j \mid i, \cdot)$ by its composition with the projection $\prod_k U(k) \rightarrow U(i)$, we may and will assume that the $U(i)$'s are replicas of a fixed compact metric space \mathbf{A} . We say that an $f \in \Pi_{SR}$ is *stable* if the corresponding process is positive recurrent. We will assume that, under an $f \in \Pi_{SR}$, the process has \mathcal{S} as its single communicating class. (This can be relaxed in some cases; see [26] for a discussion on this.) Therefore, f will have a unique invariant measure $\eta(f) \in \mathcal{P}(\mathcal{S})$ satisfying

$$\eta(f)P(f) = \eta(f).$$

Let Π_{SSR} denote the space of stable stationary policies. Π_{SSD} is defined analogously. For an $f \in \Pi_{SSR}$, denote by $\hat{\eta}(f) \in \mathcal{P}(\mathcal{S} \times \mathbf{A})$ the “ergodic occupation measure” defined by

$$\int_{\mathcal{S} \times \mathbf{A}} g d\hat{\eta}(f) = \sum_{i \in \mathcal{S}} \eta(f)(i) \int_{\mathbf{A}} g(i, a) f(i)(da)$$

for $g \in C_b(\mathcal{S} \times \mathbf{A})$. We will consider the sample path average cost optimality, which is stronger than the usual AC-optimality. Let

$$I_R = \{\hat{\eta}(f) : f \in \Pi_{SSR}\}, \quad I_D = \{\hat{\eta}(f) : f \in \Pi_{SSD}\}.$$

Note that $\hat{\eta}(f)$ can only be defined for an $f \in \Pi_{SSR}$. To consider optimality in Π , we will need to consider the following empirical processes. Let $\pi \in \Pi$ and let (X_t, A_t) be the corresponding processes with initial law $\mu \in \mathcal{P}(\mathcal{S})$. Define the $\mathcal{P}(\mathcal{S} \times \mathbf{A})$ -valued empirical process $\{\nu_t\}_{t \geq 1}$ by

$$(5.17) \quad \nu_t(C \times D) = \frac{1}{t} \sum_{s=0}^{t-1} I\{X_s \in C, A_s \in D\}, \quad t \geq 1,$$

for C, D Borel in \mathcal{S}, \mathcal{A} , respectively. Let $\overline{\mathcal{S}} = \mathcal{S} \cup \{\infty\}$ be the one-point compactification of \mathcal{S} . By abuse of notation, we may identify ν_t with the element of $\mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$ that restricts to it on $\mathcal{S} \times \mathcal{A}$. Since $\mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$ is compact, $\{\nu_t\}$, viewed as a sequence of $\mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$ -valued random variables, converges to a sample path dependent compact limit set in $\mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$. We characterize this set in Lemma 5.1, below, the statement of which calls for some new notation. Note that any element $\nu \in \mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$ can be decomposed as

$$(5.18) \quad \nu(B) = \delta_\nu \nu'(B \cap (\mathcal{S} \times \mathcal{A})) + (1 - \delta_\nu) \nu''(B \cap (\{\infty\} \times \mathcal{A}))$$

for B Borel in $\overline{\mathcal{S}} \times \mathcal{A}$, $\delta_\nu \in [0, 1]$ is uniquely specified and $\nu' \in \mathcal{P}(\mathcal{S} \times \mathcal{A})$ (respectively, $\nu'' \in \mathcal{P}(\{\infty\} \times \mathcal{A})$) is uniquely specified if $\delta_\nu > 0$ (respectively, $\delta_\nu < 1$). We may render ν', ν'' unique at all times by imposing an arbitrary fixed choice thereof when $\delta_\nu = 0$, respectively, 1.

LEMMA 5.1. *Outside a set of zero probability (with respect to \mathcal{P}_μ^π), the following holds: For any limit point ν of $\{\nu_t\}$ in $\mathcal{P}(\overline{\mathcal{S}} \times \mathcal{A})$ for which $\delta_\nu > 0$,*

$$\nu' = \hat{\eta}(f)$$

for some $f \in \Pi_{SSR}$.

Proof. By the martingale stability theorem [117, p. 53],

$$\begin{aligned} \lim_{t \rightarrow \infty} \frac{1}{t} \sum_{s=1}^t \left[I\{X_s = i\} - E_\mu^\pi \left[I\{X_s = i\} \mid \mathfrak{F}_{s-1} \right] \right] \\ = \lim_{t \rightarrow \infty} \frac{1}{t} \sum_{s=1}^t \left[I\{X_s = i\} - \sum_{j \in \mathcal{S}} P(i \mid j, A_{s-1}) I\{X_{s-1} = j\} \right] \\ = \lim_{t \rightarrow \infty} \left[\nu_t(\{i\} \times \mathcal{A}) - \int P(i \mid \cdot, \cdot) d\nu_t \right] \\ = 0 \quad \text{a.s.,} \end{aligned}$$

for each $i \in \mathcal{S}$. Consider a sample path outside the set of zero probability on which the above fails for any $i \in \mathcal{S}$. Then, for any ν as in the statement of the lemma, we must have

$$\nu'(\{i\} \times \mathcal{A}) \geq \int P(i \mid \cdot, \cdot) d\nu', \quad i \in \mathcal{S}.$$

Note that an inequality is obtained here, since the second term on the right-hand side of (5.18) is obviously nonnegative. Summing over $i \in \mathcal{S}$ on both sides, it follows that equality must hold. Decomposing ν' as $\nu'(i, da) = \bar{\nu}(i) f(i)(da)$, where $\bar{\nu} \in \mathcal{P}(\mathcal{S})$ is the marginal on \mathcal{S} and $i \mapsto f(i) \in \mathcal{P}(\mathcal{A})$ is a version of the regular conditional law that defines an element of Π_{SR} , we obtain

$$\bar{\nu}(i) = \sum_{j \in \mathcal{S}} \bar{\nu}(j) P(f)(i, j).$$

Hence, $\bar{\nu} = \eta(f)$, and the conclusion follows. \square

LEMMA 5.2. *The sets I_R and I_D are closed; also, I_R is convex and has its extreme points in I_D .*

Proof. Let $\hat{\eta}(f_n) \in I_R$ and $\hat{\eta}(f_n) \rightarrow \nu$ for some ν in $\mathcal{P}(\mathcal{S} \times \mathcal{A})$. Then, for all $i \in \mathcal{S}$,

$$\hat{\eta}(f_n)(\{i\} \times \mathcal{A}) = \int P(i \mid \cdot, \cdot) d\hat{\eta}(f_n), \quad n \geq 1.$$

Letting $n \rightarrow \infty$, $\nu(\{i\} \times \mathcal{A}) = \int P(i \mid \cdot, \cdot) d\nu$. Now argue as in the proof of the preceding lemma to conclude that $\nu = \hat{\eta}(f)$ for some $f \in \Pi_{SSR}$. This proves that I_R is closed. The proof that I_D is closed is similar. Let $f_1, f_2 \in \Pi_{SSR}$ and $0 \leq \lambda \leq 1$. Define $f \in \Pi_{SSR}$ as follows:

$$f(i) = \frac{\lambda \eta(f_1)(i) f_1(i) + (1 - \lambda) \eta(f_2)(i) f_2(i)}{\lambda \eta(f_1)(i) + (1 - \lambda) \eta(f_2)(i)}.$$

Then using the properties of invariant measures, it is not difficult to see that

$$\begin{aligned} \eta(f) &= \lambda \eta(f_1) + (1 - \lambda) \eta(f_2), \\ \hat{\eta}(f) &= \lambda \hat{\eta}(f_1) + (1 - \lambda) \hat{\eta}(f_2), \end{aligned}$$

showing that I_R is convex. Now let $f \in \Pi_{SSR}$ be such that, for some $i_0 \in \mathcal{S}$ and $0 < \lambda < 1$, there exist $\phi_1, \phi_2 \in \mathcal{P}(\mathcal{A})$ such that

$$\begin{aligned} \int P(\cdot \mid i_0, a) f(i_0)(da) &= \lambda \int P(\cdot \mid i_0, a) \phi_1(da) + (1 - \lambda) \int P(\cdot \mid i_0, a) \phi_2(da), \\ \int P(\cdot \mid i_0, a) \phi_1(da) &\neq \int P(\cdot \mid i_0, a) \phi_2(da). \end{aligned}$$

Define $f_1, f_2 \in \Pi_{SSR}$ as

$$f_i(j) = \begin{cases} f(j), & j \neq i_0, \\ \phi_i, & j = i_0. \end{cases}$$

Then it can be shown [24] that $f_1, f_2 \in \Pi_{SSR}$, and any two of $\eta(f)$, $\eta(f_1)$, $\eta(f_2)$ are distinct from each other. Let $b \in (0, 1)$ be such that

$$\lambda = b\eta(f_1)(i_0) / (b\eta(f_1)(i_0) + (1 - b)\eta(f_2)(i_0)).$$

Then we can argue as before to conclude that $\hat{\eta}(f) = b\hat{\eta}(f_1) + (1 - b)\hat{\eta}(f_2)$. Therefore $\hat{\eta}(f)$ is not an extreme point of I_R . This implies that, for $\hat{\eta}(f')$ to be an extreme point of I_R , $P(\cdot \mid i, a)$ must be constant over $a \in \text{supp}(f'(i))$, for each $i \in \mathcal{S}$. Hence, $P(f'') = P(f')$, for all $f'' \in \Pi_{SSR}$ such that $\text{supp}(f''(i)) \subset \text{supp}(f'(i))$, for each $i \in \mathcal{S}$. In this case, $\eta(f'') = \eta(f')$. Suppose that for some i , say $i = 1$, there exist $\alpha \in (0, 1)$ and $\phi'_1, \phi'_2 \in \mathcal{P}(\mathcal{A})$, $\phi'_1 \neq \phi'_2$, such that $f'(1) = \alpha\phi'_1 + (1 - \alpha)\phi'_2$. Define $f'_1, f'_2 \in \Pi_{SSR}$ by

$$f'_k = \begin{cases} \phi'_k & \text{if } i = 1, \\ f'(i) & \text{if } i \neq 1, \end{cases} \quad k = 1, 2.$$

It follows that $\eta(f') = \eta(f'_1) = \eta(f'_2)$. It is also easy to check that

$$\begin{aligned} \hat{\eta}(f') &= \alpha\hat{\eta}(f'_1) + (1 - \alpha)\hat{\eta}(f'_2), \\ \hat{\eta}(f'_1) &\neq \hat{\eta}(f'_2), \end{aligned}$$

which contradicts the extremality of $\hat{\eta}(f')$. Hence, $f'(1)$ must be a Dirac measure. Applying this argument to each $i \in \mathbf{S}$, we deduce that $f \in \Pi_{SSD}$. From this, it follows that the extreme points of I_R lie in I_D . \square

We now proceed to show the existence of a sample path average cost optimal $f \in \Pi_{SSD}$. It is clear that a blanket stability condition or some condition on the cost that penalizes unstable behavior is required to give the desired existence. For example, consider the case where $c(i, a) = \exp(-i)$, which rewards unstable behavior. Clearly, the cost for any $f \in \Pi_{SSR}$ is almost surely positive. On the other hand, provided that $\Pi_{SSR} \neq \Pi_{SR}$, there exists an unstable policy in Π_{SR} that results in an almost-sure zero cost and is, therefore, optimal (the hypothesis that under some $f \in \Pi_{SR}$ the process has \mathbf{S} as its single communicating class plays a crucial role in this assertion). We want to rule out this possibility, as stability is a very desirable property of a policy. We wish to find conditions under which our goal will be achieved. Let $f \in \Pi_{SSR}$. Define

$$\rho(f) := \int c d\hat{\eta}(f), \quad \rho^* := \inf_{f \in \Pi_{SSR}} \rho(f).$$

Note that, under $f \in \Pi_{SSR}$, $J(i, f) = \rho(f)$ for each $i \in \mathbf{S}$. We consider two sets of hypotheses.

Assumption 5.18 (the near-monotonicity condition). It holds that

$$\liminf_{i \rightarrow \infty} \min_{a \in \mathbf{A}} c(i, a) > \rho^*.$$

Intuitively, Assumption 5.18 penalizes the drift of the process away from some finite set, requiring the optimal policy to exert some kind of a “centripetal force” pushing the process back toward this finite set. Thus, the optimal policy gains the desired stability property. If $c(i, a) = k(i)$ for some $k : \mathbf{S} \rightarrow \mathbb{R}_+$ and $k(i)$ is increasing, then this condition will automatically be satisfied. Such penalizing conditions quite often occur in queueing applications (see [20], [155], [156], [172], [190]).

Assumption 5.19 (stability condition (cf. Assumptions 5.7–5.12)). $\Pi_{SR} = \Pi_{SSR}$ and I_R is compact.

Assumption 5.19'. Equivalent conditions to Assumption 5.19 are

- (i) $\Pi_{SD} = \Pi_{SSD}$ and I_D is compact;
- (ii) The mean return times to a prescribed state (say 0) are uniformly integrable over all $f \in \Pi_{SR}$;
- (iii) This is the same as (ii), but with Π_{SD} replacing Π_{SR} .

THEOREM 5.10. *Under Assumption 5.18 or Assumption 5.19, there exists an $f \in \Pi_{SSD}$, which is sample path average cost optimal in Π_{SR} .*

Proof. From Lemma 5.2, it can be shown by an application of Choquet’s theorem [25], [26] that, if $\nu \mapsto \int c d\nu$ attains its minimum on I_R , it will do so for an $f \in \Pi_{SD}$. Under Assumption 5.19, it can be shown that $f \mapsto \hat{\eta}(f)$ is continuous. Therefore, the desired result follows under Assumption 5.19. We next consider the case under Assumption 5.18. Let $f_n \in \Pi_{SR}$ be such that $\rho(f_n) \downarrow \rho^*$. By identifying $\hat{\eta}(f_n)$ with the element of $\mathcal{P}(\bar{\mathbf{S}} \times \mathbf{A})$ that restricts to it on $\mathbf{S} \times \mathbf{A}$ for each n and then dropping to a subsequence if necessary, we may assume that $\hat{\eta}(f_n) \rightarrow \nu$ in $\mathcal{P}(\bar{\mathbf{S}} \times \mathbf{A})$ for some ν . Let $n \rightarrow \infty$ in the equation

$$\hat{\eta}(f_n)(\{j\} \times \mathbf{A}) = \int P(j \mid \cdot, \cdot) d\hat{\eta}(f_n), \quad j \in \mathbf{S}$$

and argue as in Lemma 5.1 to conclude that, for ν' as in (5.18), $\delta_\nu > 0$ implies that

$$\nu'(\{j\} \times \mathbf{A}) = \int P(j \mid \cdot, \cdot) d\nu', \quad j \in \mathbf{S}.$$

Decomposing ν' as $\nu'(i, da) = \bar{\nu}(i)f(i)(da)$, $i \in \mathbf{S}$, we have $\bar{\nu} = \eta(f)$ and therefore $\nu' = \hat{\eta}(f)$. Let $c_m = c \wedge m$ for $m \geq 1$ and pick $\varepsilon > 0$ such that Assumption 5.18 continues to hold with $\rho^* + \varepsilon$ in place of ρ^* . Then

$$\begin{aligned} \rho^* &= \lim_{n \rightarrow \infty} \int c d\hat{\eta}(f_n) \\ &\geq \lim_{n \rightarrow \infty} \int c_m d\hat{\eta}(f_n) \\ &\geq \delta_\nu \int c_m d\hat{\eta}(f) + (1 - \delta_\nu)((\rho^* + \varepsilon) \wedge m). \end{aligned}$$

Letting $m \rightarrow \infty$,

$$\rho^* \geq \delta_\nu \rho^* + (1 - \delta_\nu)(\rho^* + \varepsilon).$$

This is possible only if $\delta_\nu = 1$ and $\int c d\hat{\eta}(f) = \rho^*$. \square

The above theorem, however, does not ensure optimality of the cost-minimizing policy in I_R with respect to arbitrary policies. For the near-monotone case, this can be resolved without any further assumptions, but, for the stable case, we need the following.

Assumption 5.20. If $\tau = \min\{t \geq 1 : X_t = 0\}$, then

$$\sup_{\pi \in \Pi} E_0^\pi[\tau^2] < \infty.$$

Remark 5.9. Assumption 5.20 clearly implies Assumption 5.19. The converse need not be true, as can be shown by an explicit example [24]. Some sufficient conditions for Assumption 5.20 are (i) a Lyapunov condition [28], which we will describe shortly (cf. Theorem 5.11), (ii) the strong uniform recurrence condition of Doeblin and its variants [178], and (iii) the condition that there exist an $N < \infty$ for which

$$\sup_{\pi \in \Pi} \sup_i \mathcal{P}_i^\pi(\tau \geq N) < 1,$$

where τ is as above.

THEOREM 5.11. *Under Assumption 5.18 or Assumption 5.20, there exists an $f \in \Pi_{SD}$, which is sample path average cost optimal.*

Proof. Under Assumption 5.20, it can be shown [26] that the processes ν_t as defined in (5.17) are tight over Π . Therefore, δ_ν as in the statement of Lemma 5.1 may be taken to be 1. This resolves the case under Assumption 5.20. Under (A5.18), let ν be a limit point of $\{\nu_t\}$ in $\mathcal{P}(\bar{\mathbf{S}} \times \mathbf{A})$ along some subsequence. Then, as in the proof of Theorem 5.9, it can be shown that

$$(5.19) \quad \liminf_{t \rightarrow \infty} \int c d\nu_t \geq \rho^*.$$

Since this is true for any limit point ν of $\{\nu_t\}$ in $\mathcal{P}(\bar{\mathbf{S}} \times \mathbf{A})$ and for all sample points outside a set of probability zero, the desired result follows in this case also. \square

Remark 5.10. Some open problems arising in this context are:

(i) Can Assumption 5.20 be replaced by Assumption 5.19 while retaining the desired optimality?

(ii) If $\Pi_{SR} = \Pi_{SSR}$, will Assumption 5.19 hold automatically?

Remark 5.11. The condition in (5.19) implies a much stronger optimality, which will be discussed in §6.

Now, after the existence result of Theorem 5.11, an alternative treatment of the ACOE is possible. We will present a brief description without proofs. For details, see [24], [26], [28]. Define $h : \mathbf{S} \rightarrow \mathbb{R}$ by

$$(5.20) \quad h(i) = E_i^{f_0} \left[\sum_{t=0}^{\tau-1} (c(X_t, f_0(X_t)) - \rho^*) \right], \quad i \in \mathbf{S},$$

where $\tau = \min\{t \geq 1 : X_t = 0\}$ and $f_0 \in \Pi_{SD}$ is any sample path average cost optimal policy. In [22], [24], it is shown that $(h(\cdot), \rho^*)$ satisfies the ACOE under the following additional hypothesis called stability under local perturbations.

Assumption 5.21. Given an $f \in \Pi_{SSD}$ with $\rho(f) < \infty$, any $f' \in \Pi_{SD}$ obtained from f by changing the actions at most finitely many states is also stable and $\rho(f') < \infty$.

A sufficient, though not necessary, condition for Assumption 5.21 to hold is that every state has at most finitely many neighbors; i.e., for each $i \in \mathbf{S}$, there is a finite set $R_i \subset \mathbf{S}$ such that $P(j | i, \cdot) = 0$ for $j \notin R_i$.

In many cases, the solution (ρ^*, h) of the ACOE can be characterized (Theorem 5.12, below). The usual characterization of AC-optimal $f \in \Pi_{SD}$ in terms of the ACOE can also be proved for the foregoing.

THEOREM 5.12. *Assume Assumption 5.18 and let f_0, h be defined as above (cf. (5.20)). Let*

$$H = \{(\rho, w) : (\rho, w) \text{ satisfies the ACOE}, w(0) = 0, \inf w(\cdot) > -\infty\}.$$

Then (ρ^, h) is the unique element of H corresponding to the minimum value of ρ (i.e., if (ρ', w') is another element of H , then $\rho' \geq \rho^*$ with equality if and only if $w' = h$). Now, instead of Assumption 5.18, suppose that c is bounded and the following Lyapunov condition holds: There exists an $w : \mathbf{S} \rightarrow \mathbb{R}_+$, a finite $A \subset \mathbf{S}$ and an $\varepsilon > 0$ such that*

(a) $0 \in A$ and the set $\{i \in A^c : P(j | i, a) > 0, \text{ for some } j \in A, a \in \mathbf{A}\}$ is finite;

(b) $\lim_{i \rightarrow \infty} w(i) = \infty$;

(c) Under any $\pi \in \Pi, \mu \in \mathcal{P}(\mathbf{S})$

$$E_\mu^\pi [(w(X_{t+1}) - w(X_t) + \varepsilon) I\{X_t \notin A\} | \mathfrak{F}_t] \leq 0, \quad a.s.;$$

(d) There exists a random variable Z and a scalar $\lambda > 0$ such that $E[\exp(\lambda Z)] < \infty$ and, for all $b \geq 0$,

$$\mathcal{P}_\mu^\pi (|w(X_{t+1}) - w(X_t)| > b | \mathfrak{F}_t) \leq P(Z > b).$$

Then (ρ^, h) is the unique solution of the ACOE in the class $\{(\rho, w) : w(0) = 0, \limsup_{i \rightarrow \infty} h(i)/w(i) < \infty\}$.*

Remark 5.12. An alternative “intrinsic” formulation of the ACOE is also possible. For any $f \in \Pi_{SSD}$, define $h_f : \mathbf{S} \rightarrow \mathbb{R}$ by

$$h_f(i) = E_i^f \left[\sum_{t=0}^{\tau-1} (c(X_t, f(X_t)) - \rho(f)) \right], \quad i \in \mathbf{S}.$$

We say that f is *locally AC-optimal* if it yields a lower cost than any other element of Π_{SD} obtainable from f by changing f in at most finitely many states. In addition to the foregoing hypotheses, assume that every locally AC-optimal f is AC-optimal (for bounded c , a sufficient condition for this is that $\Pi_{SD} = \Pi_{SSD}$ and $\{\eta(f) : f \in \Pi_{SSD}\}$ is tight). We then have that f is sample path average cost optimal if and only if, for $i \in \mathbf{S}$,

$$h_f(i) = \inf_a \left\{ \sum_j P(j | i, a) h_f(j) + c(i, a) - \rho(f) \right\}.$$

This statement is “intrinsic” in the sense that all quantities (i.e., $h_f, \rho(f)$) are computable in terms of f . An interesting open problem is to characterize the most general conditions under which local AC-optimality implies AC-optimality.

Remark 5.13. The Lyapunov condition in Theorem 5.12(ii) implies Assumption 5.20 and has many other implications [26], but condition (ii)(d) there is rather strong, and, due to this, it may be difficult to construct such a function in a given situation. A partial answer to this question is given in [74]. It would be interesting to investigate if the Lyapunov conditions studied by [55], [91] (cf. Assumption 5.13), which do not involve condition (ii)(d) above, imply Assumption 5.20.

6. Borel state and action spaces. We consider in this section the case in which \mathbf{S} and \mathbf{A} are general Borel spaces. This is a natural setting for many problems, e.g., control of stock in water reservoirs, allocation of a resource between production and consumption, control of biological populations, harvesting a natural resource; see [17], [51], [82], and references therein for several examples. Also, the equivalent formulation of POCMP in terms of the conditional distribution of the (unobservable) state leads to a problem with an uncountable Borel state space, as we see in §7.

In this more general context, the ACOE is written as

$$(6.1) \quad \begin{aligned} \rho(x) + h(x) &= \inf_{a \in U(x)} \left\{ c(x, a) + \int_{\mathbf{S}} h(y) P(dy | x, a) \right\} \\ &= T(h)(x), \quad x \in \mathbf{S}, \end{aligned}$$

where $\rho, h \in \mathcal{M}(\mathbf{S})$. As in §5, a pair of functions (ρ, h) as above is called a solution to the ACOE, and, if ρ and h are bounded, we will say that the solution is bounded. Also, as in Theorem 5.1, our aim is to relate the AC problem to the existence of solutions to the ACOE. We have the following theorem.

THEOREM 6.1. *Suppose that (ρ, h) is a solution to the ACOE and that, for each policy $\pi \in \Pi_M$, the following holds:*

$$(6.2) \quad \lim_{t \rightarrow \infty} E_x^\pi \left[\frac{h(X_t)}{t} \right] = 0 \quad \forall x \in \mathbf{S}.$$

Then we have the following:

(i) *There holds*

$$(6.3) \quad \limsup_{n \rightarrow \infty} \frac{1}{n+1} E_x^\pi \left[\sum_{t=0}^n \rho(X_t) \right] \leq J(x, \pi),$$

and if $\pi \in \Pi_{SD}$ is such that $\pi(x)$ attains the infimum in (6.1), then equality is attained in (6.3);

(ii) *If $\rho(x) = \rho^* \in \mathbb{R}$, for all $x \in \mathcal{S}$, then $J^*(x) = \rho^*$, for all $x \in \mathcal{S}$, and any $\pi^* \in \Pi_{SD}$ such that $\pi^*(x)$ attains the infimum in (6.1) is average optimal.*

The proof of Theorem 6.1 follows that of Theorem 5.1 and is essentially contained in [177], more explicitly in [80], [148]; see also [78, pp. 66–68], [82, pp. 53–55], [150, pp. 93–94]. Note that (i), above, says that if $\rho(\cdot)$ is taken as the cost function to define another CMP $(\mathcal{S}, \mathcal{A}, U, P, \rho)$ then, for any $\pi \in \Pi_M$, the average cost incurred under the cost function $\rho(\cdot)$ does not exceed that under cost function $c(\cdot, \cdot)$.

Given the results above, it is of interest to find conditions under which there exists a solution (ρ, h) to the ACOE, satisfying (6.2). If h is bounded, then (6.2) is satisfied trivially. Also, if the random variables $\{h(X_t)\}$ are uniformly integrable under \mathcal{P}_x^π , for $\pi \in \Pi_M$ and $x \in \mathcal{S}$, then there exists a constant $0 < K_x^\pi < \infty$ such that $E_x^\pi[|h(X_t)|] \leq K_x^\pi$. Hence, if such a uniform integrability condition holds under *every* $\pi \in \Pi_M$ and $x \in \mathcal{S}$, then (6.2) is also satisfied trivially. The latter approach has been used by Shwartz and Makowski for some queueing problems [166]–[168].

6.1. Bounded costs. We first assume that $c(\cdot, \cdot)$ is bounded. When there are bounded solutions (ρ, h) to the ACOE, then much stronger results than those in Theorem 6.1 (i) can be obtained. To state these, some definitions are needed.

Let R and H be bounded, measurable, real-valued functions on \mathcal{S} , i.e., $R, H \in \mathcal{M}_b(\mathcal{S})$ and let $\pi^* \in \Pi$. Following the terminology of Dynkin and Yushkevich [51], the triplet (R, H, π^*) is said to be *canonical* if

$$(6.4) \quad J_N(x, \pi^*, H) = J_N^*(x, H) = H(x) + NR(x) \quad \forall N \in \mathbb{N}_0, \quad x \in \mathcal{S},$$

and $\pi^* \in \Pi$ is said to be a *canonical policy* if it is an element of some canonical triplet. Note that, if (R, H, π^*) is a canonical triplet, then π^* is N -stage optimal, for all $N \in \mathbb{N}_0$, when H is taken as the terminal cost. This concept was introduced by Yushkevich [204]. For finite models, Denardo and Fox [37] used a similar approach.

A policy $\pi^* \in \Pi$ is said to be *strong average optimal* if

$$(6.5) \quad \limsup_{N \rightarrow \infty} \frac{1}{N} J_N(x, \pi^*) \leq \liminf_{N \rightarrow \infty} \frac{1}{N} J_N(x, \pi) \quad \forall x \in \mathcal{S}, \pi \in \Pi.$$

Alternate definitions of strong average optimality are given in [69], [70]. Clearly, a strong average optimal policy π^* is also average optimal, and the limit of the sequence $\{1/N J_N(x, \pi^*)\}$, as $N \rightarrow \infty$, exists. An interpretation of (6.5) is that the “most pessimistic” average performance under π^* is no worse than the most “optimistic” performance under any other policy. We have the following result.

THEOREM 6.2. *Let $\pi^* \in \Pi_{SD}$, let $\rho, h \in \mathcal{M}_b(\mathcal{S})$, and let $c \in \mathcal{M}_b(\mathcal{K})$. Then (ρ, h, π^*) is a canonical triplet if and only if*

$$(6.6) \quad \rho(x) = \inf_{a \in U(x)} \left\{ \int_{\mathcal{S}} \rho(y) P(dy \mid x, a) \right\}$$

and

$$(6.7) \quad \rho(x) + h(x) = \inf_{a \in U(x)} \left\{ c(x, a) + \int_{\mathcal{S}} h(y) P(dy \mid x, a) \right\}$$

and $\pi^*(x)$ attains the infimum in both (6.6) and (6.7), for all $x \in \mathcal{S}$.

Proof. Necessity. Let (ρ, h, π^*) be a canonical triplet. Then, by (6.4),

$$(6.8) \quad \begin{aligned} h(x) + \rho(x) + N\rho(x) &= J_{N+1}^*(x, h) \\ &= T(J_N^*)(x) \\ &= c(x, \pi^*(x)) + \int_{\mathcal{S}} J_N^*(y, h) P(dy \mid x, \pi^*(x)). \end{aligned}$$

Since $J_0(x, \pi^*, h) = J_0^*(x, h) = h(x)$, then (6.7) follows from (6.8) by letting $N = 0$. Furthermore, since $\rho(\cdot)$, $h(\cdot)$, and $c(\cdot, \cdot)$ are bounded, then dividing both sides of (6.8) by N and letting $N \rightarrow \infty$ yields (6.6).

Sufficiency. Let (ρ, h) satisfy (6.6) and (6.7) and let $\pi^*(x)$ attain the infimum in these expressions. We use induction to show that (ρ, h, π^*) is a canonical triplet. For $N = 0$, this is trivially satisfied. Suppose that $N \in \mathbb{N}_0$ is the first integer for which (6.4) fails; then

$$\begin{aligned} J_N^*(x, h) &= T(J_{N-1}^*)(x) \\ &= T(h + (N-1)\rho)(x) \\ &= \inf_{a \in U(x)} \left\{ c(x, a) + \int_{\mathcal{S}} h(y) P(dy \mid x, a) + (N-1) \int_{\mathcal{S}} \rho(y) P(dy \mid x, a) \right\} \\ &\geq T(h)(x) + (N-1) \inf_{a \in U(x)} \left\{ \int_{\mathcal{S}} \rho(y) P(dy \mid x, a) \right\} \\ &= T(h)(x) + (N-1)\rho(x) = h(x) + N\rho(x). \end{aligned}$$

On the other hand,

$$\begin{aligned} J_N^*(x, h) &\leq J_N(x, \pi^*, h) \\ &= c(x, \pi^*(x)) + \int_{\mathcal{S}} J_{N-1}^*(y, \pi^*, h) P(dy \mid x, \pi^*(x)) \\ &= c(x, \pi^*(x)) + \int_{\mathcal{S}} [h(y) + (N-1)\rho(y)] P(dy \mid x, \pi^*(x)) \\ &= T(h)(x) + (N-1)\rho(x) = h(x) + N\rho(x) \end{aligned}$$

contradicting our hypothesis. Therefore, (ρ, h, π^*) is a canonical triplet. \square

The results in Theorem 6.2 were obtained by Yushkevich [204]; see also [51]. Note that (6.7) is the ACOE and that (6.6) allows $\rho(\cdot)$ to be treated as a constant, with respect to the optimization problem. Of course, if $\rho(x) = \rho^*$ for all $x \in \mathcal{S}$, then (6.6) is satisfied trivially. The coupled equations (6.6) and (6.7) were apparently introduced by Howard [95, pp. 61–62], in the context of finite state CMP for which, under some policies, $\{X_t\}$ has several ergodic classes, i.e., the so-called multichain case. In this case, different ergodic classes may have different optimal average cost, and $\rho(\cdot)$ gives this cost, as will be shown.

From Theorem 6.2, we see that the canonical policy π^* is a measurable selector for both (6.6) and (6.7). However, Assumption 2.2 in §2 is not enough to guarantee the existence of selectors in either (6.6) or (6.7), since ρ and h are assumed to be bounded and measurable functions, but not necessarily lower semicontinuous. For this situation, the following condition is needed.

Assumption 6.1. The transition kernel $P(\cdot \mid x, a)$ is *strongly continuous* in (x, a) ; that is, $u \in \mathcal{M}_b(\mathbf{S})$ implies that $\int_{\mathbf{S}} u(y)P(dy \mid \cdot, \cdot) \in C_b(\mathbf{K})$.

It follows that under Assumptions 2.1, 2.3, 6.1, measurable selectors exist for each of (6.6) and (6.7), and $\pi^* \in \Pi_{SD}$ will be a canonical policy if and only if it is a selector for both (6.6) and (6.7). If (ρ, h, π^*) is a canonical triplet, then (ρ, h) solves the ACOE, and (6.2) is satisfied, since h is bounded. Consequently, the results of Theorem 6.1 follow. The next result presents other important implications.

THEOREM 6.3. *Let (ρ, h, π^*) be a canonical triplet, and let $c \in \mathcal{M}_b(\mathbf{K})$. Then, for each $x \in \mathbf{S}$,*

- (i) $J_N(x, \pi^*) \leq J_N(x, \pi) + \text{span}(h)$, for every $\pi \in \Pi$;
- (ii) π^* is strong average optimal;
- (iii) $J(x, \pi^*) = J^*(x) = \rho(x)$;
- (iv) $h^-(x) + \rho(x)/(1 - \beta) \leq J_\beta^*(x) \leq h^+(x) + \rho(x)/(1 - \beta)$;
- (v) If $\rho(x) = \rho^* \in \mathbb{R}$, for all $x \in \mathbf{S}$, then, for every $\pi \in \Pi$,

$$\limsup_{N \rightarrow \infty} \frac{1}{N} \sum_{t=0}^{N-1} c(X_t, A_t) \geq \rho^*, \quad \mathcal{P}_x^\pi\text{-a.s.},$$

when $X_0 = x$, and $\{A_t\}$ is generated using the policy π . Furthermore,

$$\lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=0}^{N-1} c(X_t, A_t) = \rho^*, \quad \mathcal{P}_x^\pi\text{-a.s.},$$

if and only if

$$\lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=0}^{N-1} \Phi(X_t, A_t) = 0, \quad \mathcal{P}_x^\pi\text{-a.s.},$$

where $\Phi : \mathbf{K} \rightarrow \mathbb{R}$ is given by

$$\Phi(x, a) := c(x, a) + \int h(y)P(dy \mid x, a) - \rho^* - h(x);$$

- (vi) π^* is sample path average cost optimal.

Proof. To prove (i), note that, for all $\pi \in \Pi$,

$$\begin{aligned} J_N(x, \pi^*, h) &= E_x^{\pi^*} \left[\sum_{t=0}^{N-1} c(X_t, A_t) + h(X_N) \right] \\ &\leq E_x^\pi \left[\sum_{t=0}^{N-1} c(X_t, A_t) + h(X_N) \right] = J_N(x, \pi, h). \end{aligned}$$

Hence,

$$\begin{aligned} J_N(x, \pi^*) &\leq J_N(x, \pi) + E_x^\pi[h(X_N)] - E_x^{\pi^*}[h(X_N)] \\ &\leq J_N(x, \pi) + \text{span}(h) \quad \forall \pi \in \Pi. \end{aligned}$$

By the boundedness of $h(\cdot)$, we have that

$$\lim_{N \rightarrow \infty} \frac{1}{N} J_N(x, \pi^*, h) = \lim_{N \rightarrow \infty} \left[\frac{h(x) + N\rho(x)}{N} \right] = \rho(x).$$

Furthermore, since $J_N(x, \pi^*, h) = J_N(x, \pi^*) + E_x^{\pi^*}[h(X_N)]$, then

$$\rho(x) = \lim_{N \rightarrow \infty} \frac{1}{N} J_N(x, \pi^*),$$

and (ii)–(iii) follows from (i).

Next, since (ρ, h) solve the ACOE, then (ρ, h^-) and (ρ, h^+) are also solutions to the ACOE. Since $h^-(\cdot) \leq 0 \leq h^+(\cdot)$, then by Lemma 2.1 we have that $T(h^-) \leq T(\beta h^-) = T_\beta(h^-)$, and $T(h^+) \geq T(\beta h^+) = T_\beta(h^+)$. Then, (iv) follows by induction, using Theorem 2.1 (iv); see [64].

Turning our attention to (v) and (vi), observe that, due to (6.7), $\Phi(x, a) \geq 0$ for all $(x, a) \in \mathbf{K}$. Also, by the (Markov) property (2.3) in §2, we have that, for any $\pi \in \Pi$,

$$\Phi(X_t, A_t) = E_x^\pi \left[c(X_t, A_t) + h(X_{t+1}) - \rho^* - h(X_t) \mid H_t, A_t \right], \quad \mathcal{P}_x^\pi\text{-a.s.}$$

Let

$$Z_t := c(X_t, A_t) + h(X_{t+1}) - h(X_t) - \rho^* - \Phi(X_t, A_t)$$

and

$$M_N := \sum_{t=0}^{N-1} Z_t = \sum_{t=0}^{N-1} c(X_t, A_t) - N\rho^* + h(X_N) - h(X_0) - \sum_{t=0}^{N-1} \Phi(X_t, A_t).$$

Note that $\{Z_t\}$ is a $(\mathfrak{G}_t, \mathcal{P}_x^\pi)$ martingale difference, where $\mathfrak{G}_t := \sigma(H_{t+1}, A_{t+1})$. Since $\{Z_t\}$ is bounded uniformly in t , by the martingale stability theorem

$$\lim_{N \rightarrow \infty} \frac{M_N}{N} = \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{t=0}^{N-1} Z_t = 0, \quad \mathcal{P}_x^\pi\text{-a.s.}$$

Therefore, by the boundedness of $h(\cdot)$,

$$\lim_{N \rightarrow \infty} \left[\frac{1}{N} \sum_{t=0}^{N-1} c(X_t, A_t) - \rho^* - \frac{1}{N} \sum_{t=0}^{N-1} \Phi(X_t, A_t) \right] = 0, \quad \mathcal{P}_x^\pi\text{-a.s.}$$

Finally, (v) and (vi) follow, since $\Phi(x, a) \geq 0$ for all $(x, a) \in \mathbf{K}$ and since, for a canonical policy π^* , $\Phi(X_t, A_t) = 0$, $\mathcal{P}_x^{\pi^*}$ -a.s. \square

The results in (i)–(iii) of Theorem 6.3 are essentially contained in [51, Chap. 7]; that in (iv) is motivated by similar results in [136] and [64]; (v) and (vi) are due to Georgin [72], see also [82, pp. 52–55]. Also, the function Φ defined in (v) was introduced by Mandl [124] and is often referred to as *Mandl's discrepancy function*.

In view of Theorem 6.3, it follows that a canonical triplet yields the desired results. We therefore look for conditions on the primary objects like the cost function c and transition kernel P , which imply the existence of a canonical triplet, so that the theory

can be used in a given practical situation. To this end, a standard procedure is to assume some ergodicity conditions that will ensure the existence of a bounded solution to the ACOE. We have already discussed several such conditions for the countable state case (cf. Assumptions 5.1–5.5). Analogues of such assumptions are also available in the literature, an extensive survey of which appears in [86]. We will focus on a particular ergodicity condition that not only subsumes many such conditions but also facilitates easily implementable numerical schemes. Our presentation here follows essentially that in [82, Chap. 3].

Assumption 6.2. There exists a number $\alpha < 1$ such that

$$\sup_{k, k' \in K} \|P(\cdot | k) - P(\cdot | k')\|_{TV} \leq 2\alpha,$$

where $\|\cdot\|_{TV}$ denotes the total variation norm.

Example 6.1. Let $\mathbf{S} = \mathbb{R}$, $\mathbf{A} \subset \mathbb{R}$, a compact set. Consider the system

$$X_{t+1} = F(X_t, A_t) + G(X_t)W_t, \quad X_0 = x,$$

where $F : \mathbb{R} \times \mathbf{A} \rightarrow \mathbb{R}$, $G : \mathbb{R} \rightarrow \mathbb{R}$ are bounded, continuous and $G(\cdot) > 0$, and $\{W_t\}$ is a sequence of independent $N(0, 1)$ random variables ($N(a, b)$ stands for the Gaussian distribution with mean a and variance b). In this case, the transition kernel is given by

$$P(\cdot | x, a) = N(F(x, a), G^2(x)).$$

Using the assumed conditions on F, G we can show that Assumption 6.2 holds. We omit the details. An important consequence of Assumption 6.2 is given below; for a proof and further discussion, see [82, Chap. 3].

LEMMA 6.1. *Suppose that Assumption 6.2 holds. Then, for any $f \in \Pi_{SD}$, the corresponding process $\{X_t\}$ has a unique invariant measure $\eta(f) \in \mathcal{P}(\mathbf{S})$ satisfying*

$$(6.9) \quad \|P^t(\cdot | x, f(x)) - \eta(f)(\cdot)\|_{TV} \leq 2\alpha^t, \quad t = 0, 1, \dots,$$

where $P^t(\cdot | x, f(x))$ denotes the t -step transition probability measure under f with $X_0 = x$.

Remark 6.1. (a) Lemma 6.1 also holds for any $f \in \Pi_{SR}$.

(b) It follows from (6.9) that, for any $f \in \Pi_{SD}$, $P^t(\cdot | x, f(x))$ converges to $\eta(f)$ in total variation norm, uniformly in x , and at a geometric rate.

(c) It is clear that, for any $f \in \Pi_{SD}$,

$$J(\mu, f) = \int_{\mathbf{S}} c(x, f(x))\eta(f)(dx)$$

for any initial law μ .

(d) Compare (6.9) with Assumption 5.5. In view of Theorem 5.4, Assumption 6.2 may be viewed as a representative counterpart of Assumptions 5.1–5.5 for the general state space case.

We now introduce the concept of span-contraction.

DEFINITION 6.1. Let $T : \mathcal{M}_b(\mathbf{S}) \rightarrow \mathcal{M}_b(\mathbf{S})$. T is said to be a *span-contraction* if, for some $\gamma \in [0, 1)$,

$$\text{span}(Tu - Tv) \leq \gamma \text{span}(u - v) \quad \text{for all } u, v \in \mathcal{M}_b(\mathbf{S}).$$

Let \sim be the equivalence relation on $\mathcal{M}_b(\mathbf{S})$ defined by $u \sim v$ if and only if there exists some constant C such that $u(x) - v(x) = C$ for all $x \in \mathbf{S}$. Let $\widetilde{\mathcal{M}}_b(\mathbf{S}) = \mathcal{M}_b(\mathbf{S}) / \sim$, the quotient space, endowed with the quotient norm induced by the span seminorm. For $v \in \mathcal{M}_b(\mathbf{S})$, let \tilde{v} denote the corresponding element of $\widetilde{\mathcal{M}}_b(\mathbf{S})$ and $\tilde{T} : \widetilde{\mathcal{M}}_b(\mathbf{S}) \rightarrow \widetilde{\mathcal{M}}_b(\mathbf{S})$ be the canonically induced map, i.e., $\tilde{T}\tilde{v} = \widetilde{Tv}$, $v \in \mathcal{M}_b(\mathbf{S})$. It is easily seen that, if T is a span-contraction on $\mathcal{M}_b(\mathbf{S})$, then \tilde{T} is a contraction on $\widetilde{\mathcal{M}}_b(\mathbf{S})$ and therefore has a unique fixed point. In turn, it follows that the map T has a span-fixed point; i.e., there exists a $v^* \in \mathcal{M}_b(\mathbf{S})$ such that $\text{span}(Tv^* - v^*) = 0$ or, equivalently, $Tv^* - v^*$ is a constant. It also follows that any two span-fixed points of T must differ by a constant.

We now replace Assumption 2.3 with the following

Assumption 6.3. (i) The multifunction $U(x)$ is continuous; (ii) $c(\cdot, \cdot) \in C_b(\mathbf{K})$.

We have the following result; for a proof, see [82, Lemma 3.5].

LEMMA 6.2. *Under Assumptions 2.2, 6.2, and 6.3, the operator T defined in (2.5) maps $C_b(\mathbf{S})$ to $C_b(\mathbf{S})$ and is a span-contraction.*

COROLLARY 6.1. *Under Assumptions 2.2, 6.2, and 6.3, the ACOE has a bounded solution $(\rho^*, h^*) \in \mathbb{R} \times C_b(\mathbf{S})$.*

Proof. This follows from the fact that there exists a $h^* \in C_b(\mathbf{S})$ such that $\text{span}(Th^* - h^*) = 0$. Hence, $Th^* = h^* + \rho^*$ for some constant ρ^* . \square

Remark 6.2. (a) Assume Assumptions 6.2 and 6.3. Let $(\rho^*, h^*) \in \mathbb{R} \times C_b(\mathbf{S})$ be a solution to the ACOE and fix $x_0 \in \mathbf{S}$. Define $h(\cdot) = h^*(\cdot) - h^*(x_0)$. Then (ρ^*, h) is also a solution to the ACOE. By the span-contraction property of T , it is the unique solution in $\mathbb{R} \times C_b(\mathbf{S})$ satisfying $h(x_0) = 0$; i.e., if $(\rho', h') \in \mathbb{R} \times C_b(\mathbf{S})$ is any other solution of the ACOE in $\mathbb{R} \times C_b(\mathbf{S})$ such that $h'(x_0) = 0$, then $\rho' = \rho$ and $h' = h$.

(b) In view of the span-contraction property of the operator T , the value iteration scheme described in §4 can be extended to this case; for details, we refer to [82, Chap. 3].

(c) Note that Corollary 6.1 asserts the existence of a canonical triplet.

Remark 6.3. In §4 we have identified the duality between the linear programming formulation and the ACOE under the irreducibility assumption. This has been extended by Yamada [203] to the case when the state space \mathbf{S} is a compact subset of \mathbb{R}^n and the transition law has a density that satisfies a certain “positivity” condition. Hernández-Lerma, Hennet, and Lasserre [84] have further extended this result to the Borel state space setting under Assumption 6.2.

Kurano [105]–[107] has studied the problem for compact state and action spaces, under the hypothesis of Doeblin. Doeblin’s condition for the general state space can be described as follows.

Assumption 6.4. There exists a nontrivial finite measure μ on $(\mathbf{S}, \mathcal{B}(\mathbf{S}))$, a positive integer ℓ , and an $\varepsilon > 0$ such that

$$P^\ell(A \mid x, f(x)) \geq 1 - \varepsilon \quad \text{if } \mu(A) \geq \varepsilon,$$

for all $f \in \Pi_{SD}$ and $x \in \mathbf{S}$.

THEOREM 6.4. *Let the state and action spaces be compact and Assumptions 6.3 and 6.4 hold. Then there exist an $f \in \Pi_{SD}$ and a set $A \in \mathcal{B}(\mathbf{S})$ with $\mu(A) > \varepsilon$ such that $P(A \mid x, f(x)) = 1$ for all $x \in \mathbf{S}$, and f is optimal, provided that the initial law is supported on the set A .*

Furthermore, assume the following.

Assumption 6.5 (reachability). For any $x \in \mathcal{S}$ and $D \in \mathcal{B}(\mathcal{S})$ with $\mu(D) > \varepsilon$ (μ and ε as in Assumption 6.4, there exists a $\pi \in \Pi$ such that

$$P_x^\pi \left(\bigcup_{t=0}^{\infty} \{X_t \in D\} \right) = 1.$$

Assumption 6.6. One of the following two conditions is satisfied:

- (i) $\mu(\partial D) = 0$ if $\mu(D) > 0$, where ∂D denotes the boundary of D ;
- (ii) For each $D \in \mathcal{B}(\mathcal{S})$ with $\mu(D) > \varepsilon$, $P(D \mid x, a)$ is continuous in (x, a) .

THEOREM 6.5. *Under Assumptions 6.3–6.6 there exists an $f \in \Pi_{SD}$, which is optimal.*

Remark 6.4. (a) The proof of Theorem 6.3 exploits the idea involved in Lemma 5.1 of extracting a stationary randomized policy from a limit point of empirical processes. A novel idea in [105] is to remove the randomization by using the ergodic decomposition of Markov processes under Assumption 6.4. The compactness is used to ensure the tightness of the empirical processes under any policy. This can be dropped if the cost function has a penalizing condition or if there is a blanket stability of Lyapunov type. The details closely mimic the development at the end of §5.

(b) Wijngaard [201] has also obtained the existence of an optimal $f \in \Pi_{SD}$ under Doeblin's condition using an operator theoretic method.

We will now discuss the vanishing discount approach to obtain a bounded solution to the ACOE. For a fixed $x_0 \in S$, let $h_\beta(\cdot) = J_\beta^*(\cdot) - J_\beta^*(x_0)$ denote the differential discounted value function. For a general state space, the usual diagonalization procedure used on a countable state space is not amenable. Nevertheless, if $h_\beta(\cdot)$ is uniformly bounded and equicontinuous, then we can use a more subtle diagonalization involving the Arzela–Ascoli theorem to take the required limits and obtain a bounded solution to the ACOE. This was studied by Ross [148]. Following [17], [72], [73], we will discuss some sufficient conditions to obtain the required uniform boundedness and equicontinuity of $h_\beta(\cdot)$.

Assumption 6.7. For each $\beta \in (\beta', 1)$, for some $0 < \beta' < 1$, and $f_\beta \in \Pi_{SD}$, the corresponding state process has a unique invariant probability measure $\eta(f_\beta)$ such that

$$(6.10) \quad \sup_{\substack{x \in S \\ \beta \in (\beta', 1)}} \sum_{t=1}^{\infty} \|P^t(\cdot \mid x, f_\beta(x)) - \eta(f_\beta)(\cdot)\|_{TV} < \infty.$$

The following result is now easy to establish.

LEMMA 6.3. *Under Assumptions 6.1, 6.3, and 6.7, $h_\beta(\cdot) := J_\beta^*(\cdot) - J_\beta^*(x_0)$, $x_0 \in S$ fixed, is uniformly bounded, and is equicontinuous for $\beta \in (\beta', 1)$.*

COROLLARY 6.2. *Under Assumptions 6.1, 6.3, and 6.7, the ACOE has a solution (ρ^*, h) such that $h \in C_b(S)$.*

Remark 6.5. If Assumption 6.4 is satisfied and we further impose the condition that, for every $f \in \Pi_{SD}$, the corresponding state process has a single ergodic class, then (6.10) holds. In particular, if $P(dy \mid x, a)$ has a density $p(y, x, a)$, with respect to some σ -finite measure μ , and there exists a nonnegative measurable function p_0 satisfying $\int p_0(y) \mu(dy) > 0$ and $p(y, x, a) \geq p_0(y)$, for all (x, a) , then Assumption 6.4 holds and (6.10) can be easily verified. If $(x, a) \rightarrow p(y, x, a)$ is continuous, then by Scheffe's theorem, $p(\cdot \mid x, a)$ is strongly continuous in (x, a) .

6.2. Unbounded costs. We now drop the boundedness condition on the cost function and discuss some recent developments involving refinements and extensions of the vanishing discount approach. Since for unbounded costs the uniform boundedness of the differential discounted value function $h_\beta(\cdot)$ is rather unnatural, we attempt to extend the procedure of [155], [156] to the present case. To this end, we make the following analogues of Assumptions 5.14–5.16.

Assumption 6.8. There exists a nonnegative function $b \in \mathcal{M}(\mathbf{S})$, a constant $M \geq 0$, and a sequence $\{\beta_n\} \subset (0, 1)$, $\beta_n \uparrow 1$, such that for all $x \in \mathbf{S}$, (i) $-M \leq h_{\beta_n}(x) \leq b(x)$, and (ii) $\int_{\mathbf{S}} b(y)P(dy | x, a) < \infty$, for all $a \in U(x)$.

Assumption 6.9. There exists a policy π and an initial state \hat{x} such that $J(\hat{x}, \pi) < \infty$.

Assumption 6.10. There exists $\beta' \in (0, 1)$ such that $\sup_{\beta \in (\beta', 1)} \tilde{h}_\beta(x) < \infty$, where $\tilde{h}_\beta(x) = J_\beta^*(x) - \inf_{x \in \mathbf{S}} J_\beta^*(x)$.

Assumption 6.11. The transition kernel $P(\cdot | x, a)$ is strongly continuous in a , for each $x \in \mathbf{S}$.

Under Assumptions 6.8 and 6.11, defining $h(x) = \liminf_{n \rightarrow \infty} h_{\beta_n}(x)$, $x \in \mathbf{S}$, and using Fatou's lemma, we can show that there exists a constant ρ^* such that

$$(6.11) \quad \lim_{n' \rightarrow \infty} (1 - \beta_{n'})J_{\beta_{n'}}^*(x) = \rho^* \quad \text{for all } x \in \mathbf{S},$$

where $\beta_{n'} \uparrow 1$ is a subsequence of $\{\beta_n\}$, and

$$(6.12) \quad \rho^* + h(x) \geq \min_{a \in U(x)} \left\{ c(x, a) + \int_{\mathbf{S}} h(y)P(dy | x, a) \right\}, \quad x \in \mathbf{S},$$

which is the ACOI (see (5.16)) for this case. Similarly, under Assumptions 6.9–6.11, we can find a constant ρ^* such that, along a suitable sequence $\beta_n \in (\beta', 1)$, $\beta_n \uparrow 1$, $\lim_{n \rightarrow \infty} (1 - \beta_n) \inf_{x \in \mathbf{S}} J_{\beta_n}^*(x) = \rho^*$. Then, defining $h(x) = \liminf_{n \rightarrow \infty} \tilde{h}_{\beta_n}(x)$, we can deduce (6.12). Thus, we have the following result.

THEOREM 6.6. *Under Assumptions 6.8 and 6.11 or under Assumption 6.9–6.11, there exists a constant ρ^* and a function h , which is bounded below and satisfies (6.12). Any policy $\pi \in \Pi_{SD}$ realizing the minimum on the right-hand side of (6.12) is average optimal and ρ^* is the minimum average cost.*

Remark 6.6. For details, we refer to [83], [85], [140]. In the case of a countable state space, a number of sufficient conditions on the transition kernel and the cost function that enable us to verify Assumptions 5.14–5.16 are available, as mentioned in §5. This does not seem to be the case for a general Borel state space model, although several interesting examples have been studied in [83], [85], and [140]. Also, Assumption 6.11 is a very strong condition and will not, in general, be satisfied for the transition kernel of the equivalent problem for a partially observable model. Thus, this case needs further investigation. Finally, note that Assumption 6.10 may in principle be easier to verify than Assumption 6.8.

Remark 6.7. We note that Theorem 6.6 provides only an ACOI, and not the ACOE. In many situations, the discounted value function is convex (e.g., in linear systems with quadratic cost [14]), or concave (e.g., the separated problem in partially observable models). This class of problems has been used in [61] to obtain the ACOE under Assumptions 6.8, 6.11, and some additional assumptions.

7. Partially observable controlled Markov processes. Thus far, we have assumed that the complete history of the process H_t is available to the decision-maker, at each stage $t \in T$. However, in many situations, some components of the state process may not be directly available to the controller since, e.g., it may be impossible or too costly to measure these. Furthermore, due to imprecisions in the measuring devices, only noisy observations of the state may be available. When these situations arise, the problem is said to be a partially observable controlled Markov process. Here, we study POCMP with finite or countably infinite state and observation spaces, and finite or compact action set. A major portion of our exposition concentrates on the vanishing discount method, where we see that the particular structure of the POCMP can be employed to yield stronger results than those available for general Borel spaces. We also review Borkar's convex analytic approach, specialized to the partially observable case [26].

7.1. Models with partial state information. The model for this problem is essentially that in [51, Chap. 8] and is as follows. The state process is described by a pair $\{X_t, Y_t\}_{t \in T}$ taking values in a product of Borel spaces $\mathbf{X} \times \mathbf{Y}$. Only the second component $\{Y_t\}_{t \in T}$ of the state process is available for decision-making, and, reflecting this, \mathbf{Y} is called the *observation* or *message space*, and Y_t the *observation process*. With \mathbf{A} denoting the action space, the evolution of the system is governed by a measurable stochastic kernel P on $\mathbf{X} \times \mathbf{Y}$ given $\mathbf{X} \times \mathbf{Y} \times \mathbf{A}$.

Let $\mu \in \mathcal{P}(\mathbf{X} \times \mathbf{Y})$ be an initial distribution of the state. Decomposing (disintegrating) the measure μ , we have

$$\mu(dx, dy) = \bar{Q}_0(dy) \psi_0(dx | y),$$

where \bar{Q}_0 is the marginal of μ on \mathbf{Y} and ψ_0 is a version of the regular conditional law, defined \bar{Q}_0 almost surely; we pick any version from this equivalence class and keep it fixed thereafter. Note that knowledge of μ , since the value of Y_0 is available to the controller, implies that an a posteriori distribution ψ_0 (given $Y_0 = y$) for the unobserved initial state is introduced. We include ψ_0 into the *observed history* by letting

$$\bar{H}_0 := \mathcal{P}(\mathbf{X}) \times \mathbf{Y}, \quad \bar{H}_t := \bar{H}_{t-1} \times \mathbf{Y} \times \mathbf{A}, \quad t \in \mathbb{N}_0.$$

The set of admissible actions is specified by a strict, measurable, compact-valued multifunction $U : \mathbf{Y} \rightarrow \mathcal{B}(\mathbf{A})$. Hence, in this context, an admissible policy is a sequence $\pi = \{\pi_t\}_{t \in T}$ of Borel measurable stochastic kernels π_t on \mathbf{A} given \bar{H}_t satisfying, for all $t \in T$, the constraint

$$\pi_t(U(y_t) | \bar{h}_t) = 1 \quad \forall \bar{h}_t \in \bar{H}_t.$$

The set of all admissible policies is again denoted by Π .

Remark 7.1. In general, decisions take into account past and present information, not just the last observation. Note that the constraints on the actions cannot depend on the unobservable component X_t of the state. If this type of constraint must be included in the model, then it must be provided to the controller as an additional observation. Similarly, if the cost process $\{c(X_t, Y_t, A_t)\}$ is available to the controller, then it should also be regarded as an additional component in the observation process [51, p. 201].

Remark 7.2. Quite often, μ is specified as

$$\mu(dx, dy) = Q_0(dy | x) \mu_0(dx),$$

where $\mu_0 \in \mathcal{P}(\mathbf{X})$ is an initial distribution for X_0 , and Q_0 is a stochastic kernel on \mathbf{Y} given \mathbf{X} [15, Chap. 10], [82, Chap. 4].

With $\mu \in \mathcal{P}(\mathbf{X} \times \mathbf{Y})$ and an admissible policy π specified, there exists a unique probability measure \mathcal{P}_μ^π on $(\Omega, \mathcal{B}(\Omega))$, where $\Omega := (\mathbf{X} \times \mathbf{Y} \times \mathbf{A})^\infty$, defined by

$$\begin{aligned} \mathcal{P}_\mu^\pi(dx_0, dy_0, da_0, \dots, da_{t-1}, dx_t, dy_t) \\ = \mu(dx_0, dy_0) \pi_0(da_0 \mid \psi_0, y_0) P(dx_1, dy_1 \mid x_0, y_0, a_0) \cdots \\ \pi_{t-1}(da_{t-1} \mid \psi_0, y_0, a_0, \dots, y_{t-1}) P(dx_t, dy_t \mid x_{t-1}, y_{t-1}, a_{t-1}). \end{aligned}$$

7.2. Transformation into a completely observable model. A common approach in the analysis of a partially observable (PO) model is to construct a completely observable (CO) model, equivalent to the original one in the sense that corresponding policies have equal costs. The advantages in doing this are obvious, since the theory of CO problems is much better developed. However, the price usually paid is that the dimensionality of the new state space is substantially larger than that of the original one.

Such an equivalent CO problem can be obtained in many ways. The main idea is to specify an *information state process* that summarizes, at each time, all relevant information for decision-making. Clearly, $\bar{H}_t = (\psi_0, Y_0, A_0, \dots, A_{t-1}, Y_t)$ can be used as an information state process, but this leads to a nonstationary CO model, in which “growing memory” difficulties arise; see [15, Chap. 10]. We present here the more standard approach where the inferential knowledge of X_t is summarized using its conditional probability distribution, given the entire observed history up to time t . We first present the construction of the equivalent CO model for general Borel state spaces and then specialize to models with countable state space. Also, the following assumption will be in effect throughout this section.

Assumption 7.1. The transition kernel $P(\cdot \mid x, y, a)$ and the cost function $c(x, y, a)$ do not depend on y , and $U(y) = \mathbf{A}$ for all $y \in \mathbf{Y}$.

7.2.1. Borel state space. Given a PO model $(\mathbf{X} \times \mathbf{Y}, \mathbf{A}, U, P, c)$ satisfying Assumption 7.1, we construct a CO model $(\mathcal{P}(\mathbf{X}), \mathbf{A}, \tilde{U}, \mathcal{K}, \tilde{c})$ as follows. Let $\{\Psi_t, Y_t\}_{t \in T}$ and $\{\tilde{H}_t\}_{t \in T}$ denote the state process and the history spaces, respectively. The set of admissible actions is selected by letting $\tilde{U}(\psi) = \mathbf{A}$ for all $\psi \in \mathcal{P}(\mathbf{X})$. We define the cost function \tilde{c} by

$$(7.1) \quad \tilde{c}(\psi, a) := \int_{\mathbf{X}} c(x, a) \psi(dx), \quad \psi \in \mathcal{P}(\mathbf{X}).$$

It remains to construct the transition kernel \mathcal{K} . Working on the canonical sample space $\tilde{\Omega} = (\mathcal{P}(\mathbf{X}) \times \mathbf{A})^\infty$, we first define a stochastic kernel q on $\mathbf{X} \times \mathbf{Y}$ given $\mathcal{P}(\mathbf{X}) \times \mathbf{A}$ by

$$(7.2) \quad q(dx, dy \mid \psi, a) := \int_{\mathbf{X}} P(dx, dy \mid x', a) \psi(dx'), \quad \psi \in \mathcal{P}(\mathbf{X}),$$

and, decomposing q , we obtain

$$(7.3) \quad q(dx, dy \mid \psi, a) = Q(dy \mid \psi, a) \Psi(dx \mid \psi, a, y).$$

Equation (7.3) is the *filtering equation*. For fixed (ψ, a) , the map $y \mapsto \Psi$, as defined implicitly in (7.3), is a measurable mapping from \mathbf{Y} to $\mathcal{P}(\mathbf{X})$. Consequently, along

with the distribution Q on \mathbf{Y} , it induces a distribution \mathcal{K} on $\mathcal{B}(\mathcal{P}(\mathbf{X}))$, which is a measurable function of (ψ, a) or, in other words, a stochastic kernel on $\mathcal{P}(\mathbf{X})$ given $\mathcal{P}(\mathbf{X}) \times \mathbf{A}$. It follows that the model $(\mathcal{P}(\mathbf{X}), \mathbf{A}, \mathcal{K}, \tilde{c})$, with state process $\{\Psi_t\}_{t \in T}$, forms a completely observable controlled Markov process, with transition kernel given by

$$(7.4) \quad \mathcal{K}(B \mid \psi, a) := \int_{\mathbf{Y}} I\{\Psi(\cdot \mid \psi, a, y) \in B\} Q(dy \mid \psi, a), \quad B \in \mathcal{B}(\mathcal{P}(\mathbf{X})).$$

The distribution $\tilde{\mu}_0$ of Ψ_0 , corresponding to an initial distribution μ of the PO model, is taken to be

$$(7.5) \quad \tilde{\mu}_0(B) := \int_{\mathbf{Y}} \mu(B, dy), \quad B \in \mathcal{B}(\mathcal{P}(\mathbf{X})).$$

Given a history $\bar{h}_t = (\psi_0, y_0, \dots, a_{t-1}, y_t) \in \bar{\mathbf{H}}_t$ in the PO model, we can construct ψ_1, ψ_2, \dots in a recursive manner by starting from ψ_0 and, having obtained ψ_{t-1} , solving for Ψ in (7.3), with $(\psi, a, y) = (\psi_{t-1}, a_{t-1}, y_t)$, and letting $\psi_t = \Psi$. In this manner, we obtain a corresponding history $\tilde{h}_t = (\psi_0, a_0, \dots, a_{t-1}, \psi_t) \in \tilde{\mathbf{H}}_t$ for the CO model; we denote this correspondence by the map $g_t : \bar{\mathbf{H}}_t \rightarrow \tilde{\mathbf{H}}_t$. We can then assign to each admissible policy $\tilde{\pi} \in \tilde{\Pi}$ in the CO model a corresponding policy $\pi = g^*(\tilde{\pi})$ in the PO model, defined by

$$(7.6) \quad \pi_t(\cdot \mid \bar{h}_t) := \tilde{\pi}_t(\cdot \mid g_t(\bar{h}_t)), \quad \bar{h}_t \in \bar{\mathbf{H}}_t.$$

Clearly, every policy $\pi \in \Pi$ can also be regarded as a policy in $\tilde{\Pi}$; in other words, the map g^* is onto. If $\mathcal{P}_{\tilde{\mu}}^{\tilde{\pi}}$ is the probability measure induced by the policy $\tilde{\pi}$ and the initial distribution $\tilde{\mu}$ (corresponding to μ) on the canonical sample space $\tilde{\Omega}$, then, for each $C \in \mathcal{B}(\mathbf{X})$,

$$(7.7) \quad \mathcal{P}_{\mu}^{g^*(\tilde{\pi})}(X_t \in C \mid \bar{H}_t = \bar{h}_t) = \Psi_t(C), \quad \mathcal{P}_{\tilde{\mu}}^{\tilde{\pi}}\text{-a.s.}$$

Utilizing (7.1), (7.4), and (7.5), it can be verified that

$$(7.8) \quad E_{\mu}^{g^*(\tilde{\pi})}[c(X_t, A_t)] = E_{\tilde{\mu}}^{\tilde{\pi}}[\tilde{c}(\Psi_t, A_t)] \quad \forall t \in T,$$

thus establishing that the two models are indeed equivalent as claimed. It follows that the process Ψ_t summarizes all information, relevant for control purposes, and is called for this purpose a *sufficient statistic* (see [50], [161], [162]). We define the set of *separated policies* Π_S as those policies $\pi \in \Pi$ for which there a Markov policy $\tilde{\pi}$ on the equivalent CO problem such that $\pi = g^*(\tilde{\pi})$, as defined in (7.6). In other words, with $\tilde{\pi} = \{f_t\}_{t \in T} \in \tilde{\Pi}_M$, $f_t : \mathcal{P}(\mathbf{X}) \rightarrow \mathcal{P}(\mathbf{A})$ and for each initial distribution $\mu \in \mathcal{P}(\mathbf{S})$,

$$\pi_t(\cdot \mid \bar{h}_t) = f_t(\Psi_t)(\cdot), \quad \mathcal{P}_{\mu_0}^{\tilde{\pi}}\text{-a.s.}$$

Thus, the actions taken using a separated policy only depend on \bar{H}_t through the conditional distribution of X_t . In other words, the following *separation principle* holds: If an optimal policy exists in Π , one exists in Π_S . Hence, the process can be controlled optimally by first estimating the state via the conditional distribution and

choosing control actions based solely on the latter. These and other results, in various degrees of generality, were independently obtained by various authors, e.g., [3], [5], [89], [138], [151], [163], [174], [175], [199], [205].

Example 7.1. A partially observable version of the stochastic nonlinear system in Example 2.1 is described by the equations

$$\begin{aligned} X_{t+1} &= F(X_t, A_t, W_t), \\ Y_t &= G(X_t, A_{t-1}, V_t), \\ Y_0 &= G_0(X_0, V_0), \end{aligned}$$

where G and G_0 are Borel measurable, and the disturbance $\{V_t\}_{t \in T}$ is an i.i.d. sequence of random variables taking values in a Borel space \mathbf{V} , with a common distribution \mathcal{P}_V ; furthermore, it is assumed that X_0 , $\{W_t\}$, and $\{V_t\}$ are mutually independent.

7.2.2. Countable state space. We now specialize to the case where the state space $\mathbf{X} \times \mathbf{Y}$ is a finite or countably infinite set, the action space \mathbf{A} is a finite or compact set and with Assumption 7.1 in effect. Thus, $U(y) = \mathbf{A}$ for all $y \in \mathbf{Y}$, and the kernel of the process takes the form $P(x', y' \mid x, a)$. We also assume that the cost c and the kernel P are continuous with respect to $a \in \mathbf{A}$. The space $\mathcal{P}(\mathbf{X})$ is identified with the set Δ of probability vectors, i.e.,

$$(7.9) \quad \Delta := \left\{ \psi \in [0, 1]^{\mathbf{X}} : \sum_{x \in \mathbf{X}} \psi(x) = 1 \right\}$$

endowed with the topology given by the metric

$$d(\psi_1, \psi_2) := \sum_{x \in \mathbf{X}} |\psi_1(x) - \psi_2(x)| = \|\psi_1 - \psi_2\|_1,$$

where $\|\cdot\|_1$ stands for the standard ℓ_1 -norm on $\mathbb{R}^{\mathbf{X}}$.

In general, the recursive (filtering) equation (7.3) used to compute ψ_{t+1} , is obtained via a decomposition of measures technique; see [15, Chap. 10], [51, Chap. 8], [82, Chap. 4], [205]. This is particularly simple to accomplish (using the Bayes rule) when \mathbf{X} and \mathbf{Y} are countable or when the system is described by a linear system function and the disturbances are Gaussian; see [5], [14], [103], [174], [175]. For this purpose, we need the following definitions (compare with (7.2), (7.3)):

$$(7.10) \quad q(x, y \mid \psi, a) := \sum_{x' \in \mathbf{X}} P(x, y \mid x', a) \psi(x'),$$

$$(7.11) \quad V(y, \psi, a) := \sum_{x \in \mathbf{X}} q(x, y \mid \psi, a),$$

$$(7.12) \quad T(y, \psi, a)(\cdot) := \begin{cases} \frac{q(\cdot, y \mid \psi, a)}{V(y, \psi, a)}, & \text{if } V(y, \psi, a) \neq 0, \\ 0, & \text{otherwise.} \end{cases}$$

Note that the map $\psi \rightarrow T(y, \psi, a)$ maps Δ into itself. In the countable case, ψ_t can be computed by letting $\psi_t = T(y_t, \psi_{t-1}, a_{t-1})$. Here, $V(y, \psi, a)$ is interpreted as the (one-step ahead) conditional probability of the observation being y given an a priori distribution ψ for the core state, under decision a . Likewise, $T(y, \psi, a)$ is interpreted

as the a posteriori conditional probability distribution of the core state, given that decision a was made, observation y obtained, and an a priori distribution ψ . Also, the kernel in (7.4) takes the form

$$(7.13) \quad \mathcal{K}(B \mid \psi, a) := \sum_{y \in Y} V(y, \psi, a) I\{T(y, \psi, a) \in B\}, \quad B \in \mathcal{B}(\Delta),$$

while the cost \tilde{c} is computed by

$$(7.14) \quad \tilde{c}(\psi, a) := \sum_{x \in X} c(x, a) \psi(x).$$

Remark 7.3. It is common to specify, instead of the kernel P , a transition kernel \bar{P} on X given $X \times A$, and an *observation kernel* \bar{Q} on Y given $X \times A$ [14], [63], [82], [128], [170]. Note that this is only a special case of our presentation, which happens when the kernel P admits the decomposition

$$P(x, y \mid x', a) = \bar{Q}(y \mid x, a) \bar{P}(x \mid x', a).$$

In this case, we can express (7.10)–(7.12) in a convenient vector form by viewing ψ as an element of \mathbb{R}^X and defining the transition matrix $[\bar{P}(a)]_{x, x'} := \bar{P}(x \mid x', a)$ and the observation matrix $Q_y(a) := \text{diag}\{Q(y \mid x, a) : x \in X\}$. Then, with \bar{q} denoting the vector in \mathbb{R}^X defined by $\bar{q}_x(y \mid \psi, a) := q(x, y \mid \psi, a)$ and $\mathbf{1}' = (1, \dots, 1)$, we have

$$(7.10') \quad \bar{q}(y \mid \psi, a) = \bar{Q}_y(a) \bar{P}(a) \psi,$$

$$(7.11') \quad V(y, \psi, a) = \mathbf{1}' \bar{Q}_y(a) \bar{P}(a) \psi$$

(analogously for (7.12)).

Note that a *nonrandomized* separated admissible policy can be viewed as a sequence of maps $\pi_t : \Delta \rightarrow A$. Then an equivalent, *completely observable*, discounted cost problem (DC') can be formulated as finding a separated admissible policy that minimizes

$$J_\beta(\psi, \pi) := E_{\psi_0}^\pi \left[\sum_{t=0}^{\infty} \beta^t \tilde{c}(\Psi_t, A_t) \right].$$

The average cost problem (AC') is analogously defined.

Note that the one-stage cost function $\tilde{c}(\psi, a)$ is linear in $\psi \in \Delta$. It is easy to show that the expectation operator corresponding to the kernel \mathcal{K} preserves concavity (convexity) [6], [50]. The following results complement those in Theorem 2.1.

THEOREM 7.1. *For a (DC') decision problem, $J_\beta^*(\cdot)$ is a concave function, for all $0 < \beta < 1$. The DCOE is given by*

$$(7.15) \quad J_\beta^*(\psi) = \min_{a \in A} \left\{ \tilde{c}(\psi, a) + \beta \sum_{y \in Y} V(y, \psi, a) J_\beta^*(T(y, \psi, a)) \right\},$$

and any (nonrandomized) separated stationary policy that attains the minimum above is optimal.

Remark 7.4. The optimality equation (7.15) is obtained from the general theory of CMP [15], [82]. For other results, see [5]–[7], [14], [50], [128], [161], [169], [170], [171]. Also, for a survey of relevant computational methods, see [119].

In this context, a pair (ρ, h) is said to be a solution to the ACOE if, for all $\psi \in \Delta$,

$$(7.16) \quad \rho + h(\psi) = \min_{a \in \mathbf{A}} \left\{ \tilde{c}(\psi, a) + \sum_{y \in \mathbf{Y}} V(y, \psi, a) h(T(y, \psi, a)) \right\}.$$

7.3. The vanishing discount approach. As shown in §5, for a countable state space CMP, boundedness conditions on the differential discounted value function were sufficient for solutions to the corresponding ACOE to exist. We consider here the following hypothesis.

Assumption 7.2. There exists a sequence $\beta_n \uparrow 1$, such that h_{β_n} is bounded.

Despite the fact that the model $(\Delta, \mathbf{A}, \mathcal{K}, \tilde{c})$ has a general Borel state space, it has two special features that simplify the analysis via the vanishing discount method. The first of these features is the concavity of the discounted value function, while the second is the fact that the kernel $\mathcal{K}(\cdot \mid \psi, a)$ vanishes on the complement of a countable set (for fixed ψ and a), and thus the integrals with respect to \mathcal{K} reduce to infinite sums.

For the finite state and action space case, the concavity of the discounted value function has been exploited by Platzman [136] and by Ohnishi, Mine, and Kawai [132]. These authors utilize the fact that a collection of concave functions, defined on some relatively open convex set C , which are finite and pointwise bounded, is uniformly bounded and equi-Lipschitzian relative to any closed subset of C [143, Thm. 10.6]. Thus, under Assumption 7.2, the finite dimensionality of Δ and the concavity of $h_\beta(\cdot)$ are used in [132], [136] to obtain a bounded solution (ρ^*, h) to the ACOE, via the vanishing discount approach. In particular, they partition Δ into its interior, its vertices, and its edges, i.e.,

$$\Delta = \bigcup_{j \in \mathcal{J}} \Delta_j.$$

Note that $|\mathcal{J}| = 2^{|\mathbf{X}|+1} - 1$ and that each set Δ_j is a relatively open convex set. Given a sequence $\beta_n \uparrow 1$, then the concavity of $h_\beta(\cdot)$ and Assumption 7.2 are used to obtain subsequences $\beta_n(j)$ such that $\{h_{\beta_n(j)}(\cdot)\}$ converges on Δ_j . Platzman [136] defines a metric on Δ that accomplishes this partition. Let

$$\begin{aligned} \mathcal{I}(\psi) &:= \{i \in \mathbf{X} : \psi(i) > 0\}, \quad \psi \in \Delta, \\ d(\psi_1, \psi_2) &:= 1 - \min \left\{ \frac{\psi_1(i)}{\psi_2(i)} : i \in \mathcal{I}(\psi_2) \right\}, \quad \psi_1, \psi_2 \in \Delta, \\ D(\psi_1, \psi_2) &:= \max \{d(\psi_1, \psi_2); d(\psi_2, \psi_1)\}. \end{aligned}$$

In [135, pp. 88–89], Platzman shows that $D(\cdot, \cdot)$ is a metric that leaves Δ disconnected and with components identical to the elements of the partition $\{\Delta_j\}_{j \in \mathcal{J}}$. The following is shown in [136, Lemma A.1].

LEMMA 7.1. *Let $f : \Delta \rightarrow \mathbb{R}$ be concave and bounded below; then*

$$|f(\psi_1) - f(\psi_2)| \leq \text{span}(f) D(\psi_1, \psi_2).$$

Hence, under Assumption 7.2, $\{h_\beta(\cdot)\}_{\beta \in (0,1)}$ is an equi-Lipschitzian family, with common Lipschitz constant given by the (smallest) uniform bound, and the Arzela–Ascoli theorem can be used as in [148] to obtain a bounded solution to the ACOE.

If the state space is infinite, the above method does not work, simply because the partition induced by the Platzman metric results in a nonseparable space. In this situation, the particular structure of the kernel has been employed in [63] to develop a theoretical framework based on the notion of *invariant* subsets (subprocesses) of a CMP, and sufficient conditions are given for the existence of solutions to the ACOE, in the case of a finite action space. The key point is to note that, if we let $B(\psi, a) := \{T(y, \psi, a) : y \in \mathbf{Y}\}$, which is a countable set since \mathbf{Y} is countable, then $\mathcal{K}(B(\psi, a) | \psi, a) = 1$. Thus, at any time $t \in \mathbb{N}_0$, the set of possible *next states* for Ψ_t is the set $\bigcup_{a \in \mathbf{A}} B(\Psi_t, a)$, which is countable, provided that \mathbf{A} is finite. This special structure has also been identified by other authors, e.g., [5, p. 187], [136, p. 369], [170, pp. 19–20].

We briefly summarize the work in [63]. The notions of *descendents*, *ancestors*, and *relatives* of a point $\psi \in \Delta$ are first introduced. The descendents of ψ are defined as the smallest subset of Δ containing ψ that is invariant under the action of the maps in the collection $\{T(y, \cdot, a) : y \in \mathbf{Y}, a \in \mathbf{A}\}$, while the ancestors of ψ are defined as all the points in Δ that reach ψ under the application a finite sequence of these maps. Finally, the relatives of a point ψ , denoted by $\mathcal{R}_\psi^{(1)}$, is the set formed by the union of its descendents and ancestors. Note that the definition of the descendents is an extension, to the present context, of Doob's concept of *consequent sets* [45, p. 206]. Subsequently, the *genealogical tree* GT_ψ of ψ is defined by

$$GT_\psi := \bigcup_{n \in \mathbb{N}} \mathcal{R}_\psi^{(n)},$$

where the sets $\mathcal{R}_\psi^{(n)}$ are defined recursively as

$$\mathcal{R}_\psi^{(n+1)} := \bigcup_{s \in \mathcal{R}_\psi^{(n)}} \mathcal{R}_s^{(1)}, \quad n \in \mathbb{N}.$$

The descendents of a point form a countable set, but the ancestors can, in general, be uncountably many. To guarantee that the relatives and hence the genealogical tree of a point is a countable set, the following condition is introduced.

Assumption 7.3. For all $y \in \mathbf{Y}$, $a \in \mathbf{A}$, and $\psi \in \Delta$, $T^{-1}(y, \psi, a)$ is a countable set.

Introduce the relation $\psi \sim \psi'$ if $GT_\psi = GT_{\psi'}$. It follows that “ \sim ” defines an *equivalence relation* on Δ resulting in a partition of Δ into equivalence classes that are precisely the sets GT_ψ . Under Assumptions 7.2 and 7.3, the standard diagonalization argument can be employed on each equivalence class GT_ψ to construct a pair (ρ^*, h_{GT_ψ}) that solves the ACOE on GT_ψ (the boundedness hypothesis (Assumption 7.2) can be weakened by letting the constant M depend on the equivalence class). Then, by defining $h(\psi) := h_{GT_\psi}(\psi)$ for all $\psi \in \Delta$, (ρ^*, h) clearly solves the ACOE on Δ . One peculiarity of this approach is that the resulting function h is not guaranteed to be measurable. This is not a major problem though, since an important consequence of the particular structure (with finite action space) is that the “measurability of various objects is of no essential concern” for the equivalent problem [15, p. xi]. The approach in [63] fails when the action space \mathbf{A} is not finite.

Since the vanishing discount method relies heavily on the boundedness of the differential discounted value function, the problem of finding sufficient conditions on the cost and the kernel of the process for this to hold becomes important. Platzman [136] has given (reachability and detectability) conditions for Assumption 7.2 to hold;

however, these conditions are difficult to verify. On the other hand, many models of interest possess special properties, which allow the verification of Assumption 7.2 very easily. We examine some of these properties next.

Suppose that a partial order “ \prec_{Δ} ” has been defined on Δ and let “ \prec_A ” denote a linear order on A ; we assume that A is finite. We also identify X with \mathbb{N}_0 and endow it with its natural ordering.

DEFINITION 7.1. Consider $((\Delta, \prec_{\Delta}), (A, \prec_A), \mathcal{K}, \tilde{c})$ and let $\psi_1, \psi_2 \in \Delta$. We state the following:

(i) The value functions are *monotone* if

$$\psi_1 \prec_{\Delta} \psi_2 \implies J_{\beta}^*(\psi_1) \leq J_{\beta}^*(\psi_2) \quad \text{for all } 0 < \beta < 1;$$

(ii) A (nonrandomized) stationary separated policy π is *monotone* if

$$\psi_1 \prec_{\Delta} \psi_2 \implies \pi(\psi_1) \prec_A \pi(\psi_2).$$

Two frequently used partial orders on Δ are the *stochastic dominance* \prec_{st} and the *monotone likelihood ratio* \prec_{lr} , defined below.

DEFINITION 7.2. Let $\psi_1, \psi_2 \in \Delta$; we state the following:

- (i) $\psi_1 \prec_{st} \psi_2$ if $\sum_{i \geq q} \psi_1(i) \leq \sum_{i \geq q} \psi_2(i)$, for all $q \in X$;
- (ii) $\psi_1 \prec_{lr} \psi_2$ if $\psi_1(j)\psi_2(i) \leq \psi_1(i)\psi_2(j)$, for all $i, j \in X$ such that $i \leq j$.

Let e^j denote the element of Δ with the j th component equal to 1, $j \in X$; thus, e.g., $e^0 = (1, 0, 0, \dots)$. The following is easily shown.

LEMMA 7.2. If $\psi_1, \psi_2 \in \Delta$ and $\psi_1 \prec_{lr} \psi_2$, then $\psi_1 \prec_{st} \psi_2$. Also, for all $\psi \in \Delta$, $e^0 \prec_{lr} \psi$.

DEFINITION 7.3. An action $a_j \in A$ is called a reset action if, for some $j \in X$, $T(y, \psi, a_j) = e^j$, for all $y \in Y$ and $\psi \in \Delta$.

A reset action a_j corresponds to the core state of the system being j , with probability one, at the next time epoch after action a_j has been taken. This type of action arises naturally in manufacturing systems subject to inspection, maintenance, and replacement. The following results derive from the work of Sondik [170]; see also [63].

LEMMA 7.3. If there exists a reset action $a_j \in A$, then

$$J_{\beta}^*(\psi) - J_{\beta}^*(e^j) \leq \tilde{c}(\psi, a_j) \quad \forall \psi \in \Delta.$$

If X is finite and for each $j \in X$ there is a corresponding reset action, then for each $\beta \in (0, 1)$ there exists $J \in X$ such that

$$0 \leq J_{\beta}^*(\psi) - J_{\beta}^*(e^J) \leq M \quad \forall \psi \in \Delta,$$

where $M := \max\{c(i, a) \mid i \in X, a \in A\}$.

Remark 7.5. Note that, if $J_{\beta}^*(\cdot)$ is monotone with respect to \prec_{lr} and if there is an action $a_0 \in A$ that resets the state to e^0 , then $0 \leq J_{\beta}^*(\psi) - J_{\beta}^*(e^0) \leq \tilde{c}(\psi, a_0)$ uniformly in $\beta \in (0, 1)$. Furthermore, note that when X is finite, a constant $M > 0$ exists such that $\tilde{c}(\psi, a_0) \leq M$, for all $\psi \in \Delta$, and thus Assumption 7.2 holds.

Models with a *replacement* action that resets the system to an “as new” state e^0 have been considered in [2], [118], [131], [132], [149], [188], [189], [191]–[195]. Related problems are those considered in [66], where a reset action to a most desirable state is available, and in [90], where (maintenance) reset actions a_j are available for all $j \neq 0$, with X a finite set.

7.4. The convex analytic method. We will now briefly describe Borkar's convex analytic approach. The action set \mathbf{A} is assumed to be any compact metric space. We also assume that c and P are continuous in a . We will consider the pathwise average cost. This cannot, in general, be written as an equivalent cost in terms of $\{\Psi_t\}$, but it is natural to propose that

$$(7.17) \quad \limsup_{T \rightarrow \infty} \frac{1}{T} \sum_{t=0}^{T-1} \tilde{c}(\Psi_t, A_t)$$

as a substitute. Any $\mu \in \mathcal{P}(\Delta \times \mathbf{A})$ can be decomposed as

$$(7.18) \quad \mu(d\psi, da) = \bar{\mu}(d\psi) \Phi(\psi)(da),$$

where $\bar{\mu}$ is the marginal of μ on Δ and Φ is the regular conditional law defined $\bar{\mu}$ almost surely. We always work with one arbitrary representative of this equivalence class. Define $\Gamma \subset \mathcal{P}(\Delta \times \mathbf{A})$ by

$$(7.19) \quad \begin{aligned} \Gamma &= \left\{ \mu \in \mathcal{P}(\Delta \times \mathbf{A}) \mid \begin{array}{l} \text{For } \bar{\mu}, \Phi \text{ as in (7.18), } \bar{\mu} \text{ is invariant under } \\ \text{the stationary randomized policy } \Phi \end{array} \right\} \\ &= \left\{ \mu \in \mathcal{P}(\Delta \times \mathbf{A}) \mid \iint f(\psi) \mathcal{K}(d\psi \mid \psi', a) \Phi(\psi')(da) \bar{\mu}(d\psi') \right. \\ &\quad \left. = \int f d\bar{\mu} \text{ for all } f \in C_b(\Delta) \right\}. \end{aligned}$$

From (7.19) we can easily check that Γ is closed. Note that the set of invariant probability measures for the process $\{\Psi_t\}$ controlled by a stationary randomized policy Φ , when nonempty, need not be a singleton. In general, it will form a closed convex set in $\mathcal{P}(\Delta)$, the extreme points of which correspond to ergodic measures. That is, the above process with one of these extreme measures (say, μ) as the initial condition will be ergodic. Then (7.17) will almost surely equal $\int \tilde{c} d\mu$. In view of the ergodic decomposition of a stationary Markov process, this will also be the case for other invariant measures (which will be a convex combination of the ergodic ones). Define

$$\rho^* = \inf_{\mu \in \Gamma} \int \tilde{c} d\mu.$$

We assume that $\rho^* < \infty$. We consider two alternative conditions under which the above infimum will be a minimum.

Assumption 7.4 (near-monotone case). c satisfies $\lim_{i \rightarrow \infty} \inf_a c(i, a) = \infty$.

Assumption 7.5 (stable case). Assumption 5.19' (ii) holds.

Observe that the “near-monotonicity” condition here is more restrictive than the one used in §5. We now state the following result; the proof is analogous to that of Theorem 5.10.

LEMMA 7.4. *Under either Assumption 7.4 or Assumption 7.5, the map $\mu \mapsto \int \tilde{c} d\mu$ attains its minimum on Γ .*

Define the $\mathcal{P}(\Delta \times \mathbf{A})$ -valued process $\{\eta_t\}$ by

$$\int f d\eta_t = \frac{1}{t} \sum_{m=0}^{t-1} f(\Psi_m, A_m), \quad t \geq 1, \quad f \in C_b(\Delta \times \mathbf{A}),$$

where $\{\Psi_t\}$ is governed by some policy. Again, we can prove the following analogue of Lemma 5.1.

LEMMA 7.5. *With probability 1, any limit point of $\{\eta_t\}$ in $\mathcal{P}(\Delta \times \mathbf{A})$ lies in Γ .*

Consider the near-monotone case. Suppose that, for a given sample path, a subsequence of $\{\eta_t\}$ has no limit point in $\mathcal{P}(\Delta \times \mathbf{A})$. Arguments similar to those in the proof of Theorem 5.1 can be used to show that the cost must go to $+\infty$ along this subsequence. In view of Lemma 7.5, this leads to

$$(7.20) \quad \liminf_{T \rightarrow \infty} \frac{1}{T} \sum_{t=0}^{T-1} \tilde{c}(\Psi_t, A_t) \geq \rho^* \quad \text{a.s.}$$

Along with Lemma 7.4, this would seem to lead to the existence of an optimal stationary randomized policy. There is, however, one catch. It is not a priori clear that any initial law for $\{\Psi_t\}$ would be in the domain of attraction of the element(s) of Γ that minimize the cost (or, for that matter, whether this domain of attraction can be reached in a finite random time from any initial law under some policy). Similar “reachability” problems surface when we try to extend the dynamic programming equations. These are circumvented under somewhat stringent conditions in [136], as we have already discussed.

Finally, we can prove the convexity of Γ . Again, it is unclear how (and whether) we can characterize the extreme points of Γ as those corresponding to stationary (nonrandomized) policies. As the ACOE is not available in this approach, the existence of an optimal stationary policy remains an open issue in general. In the stable case, it is not clear if (7.20) holds, and thus this case remains open to investigation. To sum up, the convex analytic approach to POCMP needs to be further studied.

8. Multiobjective and constrained models. An important success of the convex analytic approach discussed in §5 is in the domain of multiobjective problems, in which there is more than one cost (objective) function. We will first consider a multiobjective CMP with average cost criterion recast as a CMP with several constraints. CMP with one or multiple constraints have been studied in [1], [16], [26], [40], [41], [44], [92], [93], [97], [120], [129], [145], [146], [166]. Our presentation follows [25], [26].

We consider the case when $\mathbf{S} = \{0, 1, 2, \dots\}$; \mathbf{A} , the action space, is a prescribed compact metric space; and $P(j | i, a)$ is continuous in a for fixed i, j . Also, $U(i) = \mathbf{A}$ for all $i \in \mathbf{S}$. In the constrained CMP problem, we have, in addition to the cost function $c \in C_b(\mathbf{S} \times \mathbf{A})$, m additional “costs” $c_i \in C_b(\mathbf{S} \times \mathbf{A})$, $1 \leq i \leq m$ and are required to satisfy

$$(8.1) \quad a_i \leq \int c_i d\hat{\eta}(f) \leq b_i, \quad 1 \leq i \leq m$$

for prescribed numbers $b_i > a_i$, $f \in \Pi_{SD}$, and $\hat{\eta}(f) \in \mathcal{P}(\mathbf{S} \times \mathbf{A})$ is as in §5. (We are assuming all costs are bounded for simplicity. Also, we are confining our attention to Π_{SSR} ; this suffices under reasonable hypotheses, as we saw in §5.) We will assume Assumption 5.20 in §5.

Recall that $I_R = \{\hat{\eta}(f) : f \in \Pi_{SSR}\}$. Let \tilde{I}_R be the subset of I_R , where the constraints (8.1) are satisfied. Then \tilde{I}_R is closed and convex. We assume also that it is compact (this will be true under Assumption 5.20 in §5). Under this assumption, we can show, as in §5, that there exists an $f^* \in \Pi_{SR}$ that is optimal for this problem. We will now proceed to show that f^* requires randomization in at most m states.

Let $g \in C_b(\mathbf{S} \times \mathbf{A})$. For some $a \in \mathbb{R}$, let $H = I_R \cap \{\psi : \int g d\psi \leq a\}$, assumed to be nonempty. Clearly, H is closed and convex. Let $\hat{\eta}(f)$ be an extreme point of H .

Suppose that it is not an extreme point of I_R itself. Then there exist distinct measures $\hat{\eta}(f_{11})$, $\hat{\eta}(f_{12})$ such that at least one of them (say $\hat{\eta}(f_{11})$) is not in H , and $\hat{\eta}(f)$ is a convex combination of the two. Suppose that $\hat{\eta}(f_{21}) \in I_R \setminus H$, $\hat{\eta}(f_{22})$ is another such pair. Then it can be shown that $\hat{\eta}(f_{ij})$, $1 \leq i, j \leq 2$ are collinear (I_R , \tilde{I}_R , H , and so on are viewed as subsets of $\mathfrak{M}(\mathbf{S} \times \mathbf{A})$, the Banach space of finite signed measures on $\mathbf{S} \times \mathbf{A}$). Therefore, all pairs of points in I_R satisfying (a) at least one of them is not in H , and (b) $\hat{\eta}(f)$ is a convex combination thereof, lie on a single straight line in $\mathfrak{M}(\mathbf{S} \times \mathbf{A})$. Let Z denote the intersection of this line with I_R . Under our hypotheses on I_R , Z is a closed finite line segment. Let $\eta(f_1)$, $\eta(f_2)$ denote its endpoints. Then it can be shown that $\eta(f_i)$, $i = 1, 2$ are extreme points of I_R . By Lemma 5.2, $f_i \in \Pi_{SSD}$; also, f_1 and f_2 are distinct since $\hat{\eta}(f)$ is not an extreme point of I_R . Therefore, there exists an $a' \in (0, 1)$ such that

$$\hat{\eta}(f) = a'\hat{\eta}(f_1) + (1 - a')\hat{\eta}(f_2).$$

Arguing as in the proof of Lemma 5.2, it is clear that for each $i \in \mathbf{S}$ we may take $f(i)$ to be a convex combination of $f_1(i)$ and $f_2(i)$. Let $\tilde{f} \in \Pi_{SD}$ be such that, for each $i \in \mathbf{S}$, $\tilde{f}(i) =$ either $f_1(i)$ or $f_2(i)$. Then, under our hypotheses (Assumption 5.20 of §5), we can show that $\hat{\eta}(\tilde{f}) \in Z$. Now consider Z as a union of two closed line segments Z_1 and Z_2 , Z_1 being the line segment between $\hat{\eta}(f_1)$ and $\hat{\eta}(f)$, and Z_2 that between $\hat{\eta}(f_2)$ and $\hat{\eta}(f)$. Let $\{f'_n\}$ be a sequence in Π_{SD} , defined as follows: $f'_0 = f_1$, and

$$f'_n(i) = \begin{cases} f_2(i), & i \leq n, \\ f_1(i), & i > n. \end{cases}$$

Then, by the above considerations, $\hat{\eta}(f'_n) \in Z$. Since $f'_n \rightarrow f_2$ as $n \rightarrow \infty$, we conclude that $\hat{\eta}(f'_n) \rightarrow \hat{\eta}(f_2)$ (the map $f \mapsto \hat{\eta}(f)$ is continuous under Assumption 5.19). Thus, the sequence $\hat{\eta}(f'_n)$, $n \geq 0$ starts in Z_1 and eventually moves into Z_2 . Let n denote the first time this happens. Then either $\hat{\eta}(f'_n) = \hat{\eta}(f)$ or $\hat{\eta}(f)$ is a convex combination of $\hat{\eta}(f'_n)$ and $\hat{\eta}(f'_{n-1})$. Since $f'_n(i) = f'_{n-1}(i)$ for $i \neq n$, the arguments employed in Lemma 5.2 show that we may take $f(i) =$ the Dirac measure at $f'_n(i)$ for $i \neq n$ and $f(n) =$ a suitable convex combination of Dirac measures at $f_1(n)$ and $f_2(n)$. We have established the following result.

THEOREM 8.1. *Each extreme point of H corresponds to an $\hat{\eta}(f)$ such that $f \in \Pi_{SR}$ satisfies the following claim: For all but at most one i , $f(i)$ is a Dirac measure at some point of \mathbf{A} . For the single remaining i , if any, $f(i)$ is a convex combination of two such Dirac measures.*

A variant of the above theorem leads to the following result [27].

THEOREM 8.2. *The minimum of $\nu \mapsto \int c d\nu$ on \tilde{I}_R , is attained at an $\hat{\eta}(f) \in \tilde{I}_R$, where f is either deterministic or satisfies the following claim: There are states $i_1, \dots, i_k \in \mathbf{S}$ and positive integers $n_1, \dots, n_k > 1$ such that f requires randomization among n_j values at state i_j , $1 \leq j \leq k$; requires no randomization for the remaining states; and $\sum_{i=1}^k n_i \leq m$.*

Once this existence result is available, necessary conditions for optimality can be obtained from the standard Lagrange multiplier theory.

THEOREM 8.3. *There exist $\lambda_i, \beta_i \geq 0$, $1 \leq i \leq k$ such that $\hat{\eta}(f)$, as in Theorem 8.2, minimizes*

$$\eta \mapsto F(\eta, \{\lambda_i\}, \{\beta_i\}) := \int c d\eta - \sum_{i=1}^k \lambda_i (b_i - \int c_i d\eta) - \sum_{i=1}^k \beta_i (\int c_i d\eta - a_i)$$

on I_R . Furthermore, if \tilde{I}_R has nonempty interior, the following saddle-point property holds: For all $\bar{\lambda}_i, \bar{\beta}_i \geq 0$, $1 \leq i \leq k$, $\eta \in I_R$,

$$F(\hat{\eta}(f), \{\bar{\lambda}_i\}, \{\bar{\beta}_i\}) \leq F(\hat{\eta}(f), \{\lambda_i\}, \{\beta_i\}) \leq F(\eta, \{\lambda_i\}, \{\beta_i\}).$$

Remark 8.1. The result in Theorem 8.1 cannot be improved in general. Indeed, in [26] there is a counterexample to show the nonexistence of an optimal $f \in \Pi_{SD}$ for the CMP with one constraint.

Remark 8.2. We have discussed the stable case only. Analogous results can be obtained for the near-monotone case (conditions similar to Assumption 5.18). For details, we refer to [25].

Remark 8.3. When the action set \mathbf{A} is countable, analogous results are obtained in [1].

We next consider another multiobjective CMP with AC criterion. We have m cost functions $c_i \in C_b(\mathbf{S} \times \mathbf{A})$, $1 \leq i \leq m$. All cost functions are of equal importance, and, as a result, the optimality problem cannot be recast as a constrained one. Therefore, we directly deal with the optimality problem with a vector cost criterion. This has been studied in [48], [75].

Let I_R be compact. Consider the vector cost criterion

$$\left(\int c_1 d\hat{\eta}(f), \dots, \int c_m d\hat{\eta}(f) \right), \quad \hat{\eta}(f) \in I_R.$$

In general, there need not exist an $f \in \Pi_{SSR}$ that minimizes all of $\int c_i d\hat{\eta}(f)$ over I_R . This motivates the concept of Pareto optimality. An $f \in \Pi_{SSR}$ is said to be *Pareto optimal* if there does not exist any $\bar{f} \in \Pi_{SSR}$ for which $\int c_i d\hat{\eta}(\bar{f}) \leq \int c_i d\hat{\eta}(f)$, $1 \leq i \leq m$, with inequality being strict for at least one i . Pareto optimality is clearly the minimal requirement for any reasonable notion of an optimal solution for the multiobjective problem with no priority among objectives. The Pareto optimal solutions can be characterized as follows.

THEOREM 8.4. *Any $f \in \Pi_{SSR}$ that minimizes $\sum_{i=1}^m \lambda_i \int c_i d\hat{\eta}(f)$ for some $\lambda_i > 0$, $1 \leq i \leq m$ is Pareto optimal. Conversely, any Pareto optimal $\bar{f} \in \Pi_{SSR}$ minimizes the above functional for some choice of $\lambda_i \geq 0$, $1 \leq i \leq m$.*

Remark 8.4. Note that the converse is only partial, since we have $\lambda_i \geq 0$ instead of $\lambda_i > 0$. It becomes exact if \mathbf{S} and \mathbf{A} are finite.

We often reduce a vector cost criterion as above to a scalar one by introducing a “utility function.” One such case is that of finding the “shadow minimum” for the problem of minimizing the vector cost $\nu \mapsto [\int c_1 d\nu, \dots, \int c_m d\nu] \in \mathbb{R}^m$ on I_R . Letting L denote the range of this map, L can be shown to be closed and convex. Suppose that $y_i^* = \min\{\int c_i d\nu : \nu \in I_R\}$, $1 \leq i \leq m$. Let $y^* = (y_1^*, \dots, y_m^*)$. The point y^* is called the ideal (or utopian) point. The point $x^* \in L$ that is closest to y^* is called the *shadow minimum*. This point is unique and is characterized by

$$\langle y^* - x^*, z - x^* \rangle \leq 0, \quad z \in \mathbf{S}.$$

For finite \mathbf{S} and \mathbf{A} , a combined linear-quadratic program can find x^* explicitly [75]. The point x^* is easily seen to be Pareto optimal.

9. Conclusions. We hope this paper has provided a useful presentation of the problems and techniques in average cost control of Markov processes. As is amply

clear, there is not a globally applicable approach. Instead, we expect to build a library of special tricks, a collection of simple verifiable sufficient conditions under which the problem is accessible, possibly with different techniques. Going one step further, there are the more difficult, partially observable, and multiobjective problems. Though these have seen some significant results of late, there remains much more that eludes satisfactory analysis. A similar comment applies to computational aspects and adaptive control, two topics we have not touched upon here. For computational aspects, we refer to [81], [87], [137], [180] and, for adaptive control, [26], [82], [102]. Also, we have not dealt with the vast literature on *sensitive* optimality [137], [182], nor with some other criteria, such as overtaking [111], variance sensitive [198], and weighted cost [60], [65], [99]. Finally, the discrete-time models have interesting applications to continuous-time problems, for which we refer to [14, §6.7], [109], [159], [206].

Appendix. Multifunctions and measurable selectors. Let V and W denote nonempty Borel spaces and let 2^W denote the collection of all *nonempty* subsets of W . A *multifunction* (or set-valued function) Φ from V to W is a map $\Phi : V \rightarrow 2^W$. The subset $\text{Dom}(\Phi) := \{v \in V : \Phi(v) \neq \emptyset\}$ is called the *domain* of Φ . When $\text{Dom}(\Phi) = V$, we say that the map Φ is *strict*. In what follows, we assume that Φ is a strict multifunction. If, for each $v \in V$, $\Phi(v)$ is a compact (closed, measurable) subset of W , then Φ is said to be *compact (closed, measurable)-valued*. A *selector* (or selection) of Φ is a function $\varphi : V \rightarrow W$ such that $\varphi(v) \in \Phi(v)$, for all $v \in \text{Dom}(\Phi)$. The set of (Borel) measurable selectors of Φ will be denoted by $S(\Phi)$. The *graph* of Φ , denoted by $\text{Graph}(\Phi)$, is defined as

$$\text{Graph}(\Phi) := \{(v, w) : v \in V, w \in \Phi(v)\}.$$

For a set $W \in 2^W$, we define

$$\Phi^{-1}[W] := \{v \in V : \Phi(v) \cap W \neq \emptyset\},$$

and we say that Φ is (Borel) *measurable* if $\Phi^{-1}[B] \in \mathcal{B}(V)$, for each *closed* subset B of W . If Φ is *closed-valued*, then measurability of Φ implies that $\text{Graph}(\Phi) \in \mathcal{B}(V \times W)$; furthermore, if Φ is *compact-valued*, then the converse also holds [88], [184, Thm. 4.2]. The multifunction Φ is called *upper semicontinuous* if, for every $v \in V$ and every open set $G \supset \Phi(v)$, there exists a neighborhood N of v such that $\Phi(v') \subset G$, for all $v' \in N$; it is called *lower semicontinuous* if, for every $v \in V$ and every open set G such that $G \cap \Phi(v) \neq \emptyset$, $\Phi^{-1}(G)$ contains an open neighborhood of v . Also, Φ is said to be *continuous* if it is both upper and lower semicontinuous.

The following result, in different variations, has been shown by several authors [15, §7.5], [47, Lemma 6, p. 38], [51, Chap. 2], [88], [154] and also summarized in [82], [184, Thm. 9.1].

THEOREM A.1. *Let Φ be a compact-valued, measurable, strict multifunction from V to W . Let $f : \text{Graph}(\Phi) \rightarrow \mathbb{R}$ be a measurable function, such that, for each $v \in V$, $f(v, \cdot)$ is lower semicontinuous on $\Phi(v)$. Then there exists a measurable selector $\varphi^* \in S(\Phi)$ such that*

$$f(v, \varphi^*(v)) = \min_{w \in \Phi(v)} \{f(v, w)\} \quad \forall v \in V.$$

Let $f^ : V \rightarrow \mathbb{R}$, defined by $f^*(v) := f(v, \varphi^*(v))$. If Φ is upper semicontinuous and f is bounded below, then $f^* \in \mathcal{L}(V)$. Also, if Φ is continuous and $f \in C_b(V \times W)$, then $f^* \in C_b(V)$.*

A Tauberian theorem. The following Tauberian theorem plays a very important role in the analysis of the average cost criterion. For its proof, which is very difficult to locate in the literature in this particular format, we refer to [176].

THEOREM A.2. *Let $\{a_n\}$ be a sequence of nonnegative numbers and $\beta \in (0, 1)$. Then*

$$\begin{aligned} \liminf_{N \rightarrow \infty} \frac{1}{N} \sum_{m=0}^{N-1} a_m &\leq \liminf_{\beta \uparrow 1} (1 - \beta) \sum_{n=0}^{\infty} \beta^n a_n \\ &\leq \limsup_{\beta \uparrow 1} (1 - \beta) \sum_{n=0}^{\infty} \beta^n a_n \leq \limsup_{N \rightarrow \infty} \frac{1}{N} \sum_{m=0}^{N-1} a_m. \end{aligned}$$

Acknowledgments. The authors would like to thank the anonymous referee and Associate Editor Steven E. Shreve for their constructive criticism and comments, which helped to improve this paper. Our thanks also go to Prof. Linn I. Sennott for pointing out an error in the statement of Theorem 5.1, in an earlier draft of this manuscript. We were blessed by having an excellent typist, Joan Van Cleave, who rose above mere patience when faced with numerous revisions of our “final draft.” Finally, E. Fernández-Gaucherand wishes to thank Prof. O. Hernández-Lerma of CINVESTAV-IPN, México for useful discussions.

FLEMING–VIOT PROCESSES IN POPULATION GENETICS*

S. N. ETHIER[†] AND THOMAS G. KURTZ[‡]

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. Fleming and Viot [*Indiana Univ. Math. J.*, 28 (1979), pp. 817–843] introduced a class of probability-measure-valued diffusion processes that has attracted the interest of both pure and applied probabilists. This paper surveys the subject of Fleming–Viot processes as it relates to population genetics. Topics include:

1. Introduction.
2. Some measure-valued Markov chains.
- 2.1. A diploid model.
- 2.2. The Wright–Fisher model.
- 2.3. A Moran model.
3. The Fleming–Viot process: characterization.
4. Convergence.
5. Ergodicity.
6. An infinite particle system.
7. Bounded mutation operators.
8. Reversibility.
9. Examples.
- 9.1. Continuous-state stepwise-mutation model.
- 9.2. Infinitely-many-neutral-alleles model.
- 9.3. Infinitely-many-neutral-alleles model with ages.
- 9.4. Two-locus model with recombination.
- 9.5. n -locus model with gene conversion.
- 9.6. Infinitely-many-sites model without recombination.
- 9.7. Infinitely-many-neutral-alleles model with allelic genealogies.

Key words. measure-valued Markov chain, measure-valued diffusion process, martingale problem, convergence in distribution, ergodicity, infinite particle system, reversibility, infinitely-many-neutral-alleles model

AMS(MOS) subject classifications. 60G57, 60J60, 92D15

1. Introduction. The neutral diffusion model in population genetics, in which each individual is of some “type” and the set E of types is finite, has state space

$$(1.1) \quad \Delta_E = \left\{ (p_i)_{i \in E} \in [0, 1]^E : \sum_{i \in E} p_i = 1 \right\},$$

where p_i denotes the proportion of the population that is of type i . Its generator is

$$(1.2) \quad L = \frac{1}{2} \sum_{i, j \in E} p_i (\delta_{ij} - p_j) \frac{\partial^2}{\partial p_i \partial p_j} + \sum_{j \in E} \left(\sum_{i \in E} q_{ij} p_i \right) \frac{\partial}{\partial p_j},$$

where $(q_{ij})_{i, j \in E}$ is the infinitesimal matrix for a Markov process in E ; for $i \neq j$, q_{ij} is interpreted as the intensity of a mutation from type i to type j .

*Received by the editors January 3, 1992; accepted for publication (in revised form) July 7, 1992. This research was supported in part by National Science Foundation grants DMS-8901464 and DMS-9102925.

[‡]Department of Mathematics, University of Wisconsin–Madison, Madison, Wisconsin 53706.

Except for some technical requirements on $(q_{ij})_{i,j \in E}$, the same description is valid when E is countably infinite. One such example is Ohta and Kimura's (1973) stepwise-mutation model, in which $E = \mathbf{Z}$ and

$$(1.3) \quad q_{ij} = \begin{cases} \frac{1}{2}\theta & \text{if } j = i \pm 1 \\ -\theta & \text{if } j = i \\ 0 & \text{otherwise} \end{cases}$$

for some $\theta > 0$.

The case in which E is uncountably infinite, however, requires a different approach. The key idea, due to Fleming and Viot (1979), is to topologize E and replace Δ_E by $\mathcal{P}(E)$, the set of Borel probability measures on E with the topology of weak convergence. Then (1.2) becomes

$$(1.4) \quad (\mathcal{L}\varphi)(\mu) = \frac{1}{2} \int_E \int_E \mu(dx)(\delta_x(dy) - \mu(dy)) \frac{\delta^2 \varphi(\mu)}{\delta \mu(x) \delta \mu(y)} \\ + \int_E \mu(dx) A \left(\frac{\delta \varphi(\mu)}{\delta \mu(\cdot)} \right) (x),$$

where $\delta \varphi(\mu)/\delta \mu(x) = \lim_{\varepsilon \rightarrow 0+} \varepsilon^{-1} \{\varphi(\mu + \varepsilon \delta_x) - \varphi(\mu)\}$ and A is the generator for a Markov process in E . Here $\delta_x \in \mathcal{P}(E)$ denotes the unit mass at $x \in E$. The resulting probability-measure-valued diffusion process is referred to as a *Fleming-Viot process*. E is called the *type space* and A is known as the *mutation operator*. Terms corresponding to recombination and selection can also be included in (1.4); see (3.12) below.

It may reasonably be asked why an uncountable type space is needed. There are at least three reasons, and they are illustrated by the following three examples from population genetics, about which we will have more to say in §9.

(a) Continuous-state stepwise-mutation model (Ohta and Kimura (1973), Fleming and Viot (1979)). Here $E = \mathbf{R}$ and

$$(1.5) \quad (Af)(x) = \frac{1}{2}\theta f''(x),$$

which arises as a limit of the case $E = \mathbf{Z}$ and (1.3) after a suitable rescaling. The idea is that the type of an individual could be a quantitative characteristic measured on a continuum, thereby requiring an uncountable type space.

(b) Infinitely-many-neutral-alleles model (Kimura and Crow (1964), Watterson (1976), Ethier and Kurtz (1981), (1986), (1987)). Here E is arbitrary (except as noted below) and

$$(1.6) \quad (Af)(x) = \frac{1}{2}\theta \int_E (f(\xi) - f(x)) P(x, d\xi).$$

Mutations occur with intensity $\frac{1}{2}\theta$, and the type of a mutant offspring of a type x parent is distributed according to the one-step transition function $P(x, d\xi)$. The basic assumption of the model is that every mutant is of a new type, which requires that $P(x, \cdot)$ be nonatomic (i.e., have no atoms) for each $x \in E$. For this we need E uncountable.

(c) Infinitely-many-sites model without recombination (Kimura (1969), (1971), Watterson (1975), Ethier and Griffiths (1987)). Here $E = [0, 1]^{\mathbf{Z}_+}$ and

$$(1.7) \quad (Af)(\mathbf{x}) = \frac{1}{2}\theta \int_0^1 (f(\xi, \mathbf{x}) - f(\mathbf{x})) d\xi.$$

The interpretation is that $[0,1]$ is the set of sites on the chromosome, and an individual is of type $\mathbf{x} = (x_0, x_1, \dots) \in E$ if x_0, x_1, \dots is the sequence of sites at which mutations have occurred in the line of descent of that individual. Note that, even if $[0,1]$ were replaced by a finite set (with at least two elements), E would still be uncountable. The idea of using the type space to keep track of certain aspects of the history of the process is a very useful one.

As the work of Dawson, Dynkin, Le Gall, Perkins, Shiga, and others suggests, the subject of measure-valued diffusion processes has become an active and important branch of probability theory in recent years. The class of Fleming-Viot processes is surely one of the two most studied classes of measure-valued diffusions. It is our aim here to survey the subject of Fleming-Viot processes. Emphasis will be on results that relate to diffusion models in population genetics. This was, after all, the original motivation of Fleming and Viot (1979).

We assume throughout that (E, r) is a complete separable metric space. However, in most applications, E is compact or (as in example (a) above) locally compact. Of course, the locally compact case can be reduced to the compact case by a one-point compactification. Thus, we assume compactness of E whenever it is convenient to do so.

2. Some measure-valued Markov chains. The Fleming-Viot process arises most naturally as the limit in distribution of certain sequences of Markov chains occurring in population genetics. Here we describe three such models.

2.1. A diploid model. We define an equivalence relation \sim on $E^2 = E \times E$ as follows: $(x, y) \sim (z, w)$ if $(x, y) = (z, w)$ or $(x, y) = (w, z)$. The quotient set $E^{(2)}$ of all equivalence classes can be regarded as the set of all unordered pairs $\{x, y\}$ of elements of E . In a diploid population, chromosomes occur in pairs, and so an individual is described for our purposes by its genotype, which is an element of $E^{(2)}$. The formula

$$(2.1.1) \quad r^{(2)}(\{x, y\}, \{z, w\}) = (r(x, z) + r(y, w)) \wedge (r(x, w) + r(y, z))$$

defines a metric for $E^{(2)}$, and the quotient map $\rho : E^2 \mapsto E^{(2)}$ given by $\rho(x, y) = \{x, y\}$ is continuous. It can be shown that, if f is symmetric and Borel measurable on E^2 , then the function g on $E^{(2)}$ defined by $g(\{x, y\}) = f(x, y) = f(y, x)$ is Borel measurable.

Given $\mu \in \mathcal{P}(E^{(2)})$, we define its *symmetrization* $\hat{\mu} \in \mathcal{P}(E^2)$ by

$$(2.1.2) \quad \hat{\mu}(\Gamma) = \int_{E^{(2)}} \frac{1}{2} (\delta_{(x,y)}(\Gamma) + \delta_{(y,x)}(\Gamma)) \mu(d\{x, y\}).$$

For example, if $\mu = \delta_{\{x,y\}}$, then $\hat{\mu} = \frac{1}{2}(\delta_{(x,y)} + \delta_{(y,x)})$. Note that $\hat{\mu}\rho^{-1} = \mu$, so μ can be recovered from its symmetrization. We say that $\mu \in \mathcal{P}(E^{(2)})$ is in *Hardy-Weinberg form* if $\hat{\mu}$ is a product measure, that is, if $\hat{\mu} = \hat{\mu}\pi^{-1} \times \hat{\mu}\pi^{-1} = (\hat{\mu}\pi^{-1})^2$, where π is the projection of E^2 onto its first coordinate.

This model, as well as the other two, depends on certain “parameters,” which we introduce here for all three models. For each positive integer M , let w_M be a positive, symmetric, bounded, Borel function on E^2 , let $R_M((x, y), dx' \times dy')$ be a one-step transition function on $E^2 \times \mathcal{B}(E^2)$ satisfying

$$(2.1.3) \quad R_M((x, y), dx' \times dy') = R_M((y, x), dy' \times dx'),$$

and let $Q_M(x, dx')$ be a one-step transition function on $E \times \mathcal{B}(E)$. The functions w_M , R_M , and Q_M involve selection, recombination, and mutation, respectively.

Let $N \geq 1$ be the diploid population size. It will be convenient to define the mapping $\eta_N : (E^{(2)})^N \mapsto \mathcal{P}(E^{(2)})$ by letting $\eta_N(\{x_1, y_1\}, \dots, \{x_N, y_N\})$ be the empirical distribution determined by the (not necessarily distinct) points $\{x_1, y_1\}, \dots, \{x_N, y_N\} \in E^{(2)}$:

$$(2.1.4) \quad \eta_N(\{x_1, y_1\}, \dots, \{x_N, y_N\}) = N^{-1}(\delta_{\{x_1, y_1\}} + \dots + \delta_{\{x_N, y_N\}}).$$

The state space for the model is

$$(2.1.5) \quad \mathcal{P}_N(E^{(2)}) \equiv \eta_N((E^{(2)})^N) \subset \mathcal{P}(E^{(2)}).$$

Given $\mu \in \mathcal{P}(E^{(2)})$, we define $\mu_{2N}^*, \mu_{2N}^{**}, \mu_{2N}^{***} \in \mathcal{P}(E^{(2)})$ by

$$(2.1.6) \quad \hat{\mu}_{2N}^*(dx \times dy) = w_{2N}(x, y)(\hat{\mu}\pi^{-1})^2(dx \times dy) / \langle w_{2N}, (\hat{\mu}\pi^{-1})^2 \rangle,$$

$$(2.1.7) \quad \hat{\mu}_{2N}^{**}(dx' \times dy') = \int_{E^2} R_{2N}((x, y), dx' \times dy') \hat{\mu}_{2N}^*(dx \times dy),$$

$$(2.1.8) \quad \hat{\mu}_{2N}^{***}(dx' \times dy') = \int_{E^2} Q_{2N}(x, dx') Q_{2N}(y, dy') \hat{\mu}_{2N}^{**}(dx \times dy);$$

in general, $\langle f, \mu \rangle = \int_E f d\mu$ for $f \in B(E)$ and $\mu \in \mathcal{P}(E)$. (The condition (2.1.3) ensures that $\hat{\mu}_{2N}^*$ is the symmetrization of a measure in $\mathcal{P}(E^{(2)})$.) The Markov chain has one-step transition function $P_N(\mu, d\nu)$ on $\mathcal{P}_N(E^{(2)}) \times \mathcal{B}(\mathcal{P}_N(E^{(2)}))$ given by

$$(2.1.9) \quad P_N(\mu, \cdot) = \int_{(E^{(2)})^N} (\mu_{2N}^{***})^N(d\{x_1, y_1\} \times \dots \times d\{x_N, y_N\}) \delta_{\eta_N(\{x_1, y_1\}, \dots, \{x_N, y_N\})}(\cdot).$$

(A measure raised to the N th power denotes its N -fold product measure.) The model is a slight generalization of a model of Ethier and Kurtz (1987), which in turn generalizes a model of Ethier and Nagylaki (1980).

The interpretation is as follows. If $\mu \in \mathcal{P}_N(E^{(2)})$ is the empirical distribution of the N genotypes in the parent generation, then the empirical distribution of the N genotypes in the offspring generation is determined from μ in the four steps (2.1.6)–(2.1.9), corresponding, respectively, to reproduction and selection, recombination, mutation, and regulation (random sampling). In particular, (2.1.6) implicitly assumes that an infinite number of zygotes are produced in Hardy–Weinberg form as the initial step in the life cycle. See Nagylaki (1990) for a detailed discussion of the original formulation of the model.

2.2. The Wright–Fisher model. This model is mathematically simpler than the preceding one, but less reasonable biologically. In a diploid population of size N , there are $M = 2N$ gametes. Here we consider only the empirical distribution of the gametic types. It is unnecessary to require that M be even, so let M be a positive integer, and define $\eta_M : E^M \mapsto \mathcal{P}(E)$ as in (2.1.4):

$$(2.2.1) \quad \eta_M(x_1, \dots, x_M) = M^{-1}(\delta_{x_1} + \dots + \delta_{x_M}).$$

The state space for this model is

$$(2.2.2) \quad \mathcal{P}_M(E) \equiv \eta_M(E^M) \subset \mathcal{P}(E).$$

Given $\mu \in \mathcal{P}(E)$, we define $\mu_M^* \in \mathcal{P}(E^2)$ and $\mu_M^{**}, \mu_M^{***} \in \mathcal{P}(E)$ by

$$(2.2.3) \quad \mu_M^*(dx \times dy) = w_M(x, y) \mu^2(dx \times dy) / \langle w_M, \mu^2 \rangle,$$

$$(2.2.4) \quad \mu_M^{**}(dx') = \int_{E^2} R_M((x, y), dx' \times E) \mu_M^*(dx \times dy),$$

$$(2.2.5) \quad \mu_M^{***}(dx') = \int_E Q_M(x, dx') \mu_M^{**}(dx),$$

where w_M , R_M , and Q_M are as in §2.1. The Markov chain has one-step transition function $P_M(\mu, d\nu)$ on $\mathcal{P}_M(E) \times \mathcal{B}(\mathcal{P}_M(E))$ given by

$$(2.2.6) \quad P_M(\mu, \cdot) = \int_{E^M} (\mu_M^{***})^M(dx_1 \times \cdots \times dx_M) \delta_{\eta_M(x_1, \dots, x_M)}(\cdot).$$

For future reference, we note that $P_M(\mu, d\nu)$ can be extended to $\mathcal{P}(E) \times \mathcal{B}(\mathcal{P}_M(E))$.

The present formulation of the model is from Ethier and Kurtz (1993a), and the interpretation is similar to that in §2.1. The Wright–Fisher model has some characteristics of a diploid model (e.g., (2.2.3) and (2.2.4)) and some characteristics of a haploid model (e.g., (2.2.6)). It is, nevertheless, the most widely used discrete stochastic model in population genetics.

We note that, if we define $\gamma : \mathcal{P}(E^{(2)}) \mapsto \mathcal{P}(E)$ by $\gamma(\mu) = \hat{\mu}\pi^{-1}$, the image of the diploid model of §2.1 under γ is not generally the same as the Wright–Fisher model (with $M = 2N$). It is the same if the fitness function is multiplicative (i.e., $w_{2N}(x, y) = v_{2N}(x)v_{2N}(y)$) and recombination is absent (i.e., $R_M((x, y), \cdot) = \delta_{(x, y)}(\cdot)$), for then $\mu_{2N}^{***} \in \mathcal{P}(E^{(2)})$ is in Hardy–Weinberg form for all $\mu \in \mathcal{P}_{2N}(E^{(2)})$.

2.3. A Moran model. There are many variants of the model originated by Moran (1958). We describe a particularly simple one that allows us to use the notation introduced earlier. Unlike in the two preceding models, generations are overlapping. Transitions involve the death of an individual and the birth of another. Let $M \geq 1$ be the number of gametes in the population. The Markov chain has state space $\mathcal{P}_M(E)$ and one-step transition function $P_M(\mu, d\nu)$ on $\mathcal{P}_M(E) \times \mathcal{B}(\mathcal{P}_M(E))$ given by

$$(2.3.1) \quad P_M(\mu, \cdot) = \int_E \mu(dx) \int_E \mu_M^{***}(dx') \delta_{\mu - M^{-1}\delta_x + M^{-1}\delta_{x'}}(\cdot),$$

where $\mu_M^{***} \in \mathcal{P}(E)$ is defined in terms of $\mu \in \mathcal{P}(E)$ by (2.2.3)–(2.2.5). The interpretation is clear.

3. The Fleming–Viot process: characterization. Let $\{\nu_\tau^{(M)}, \tau \in \mathbf{Z}_+\}$ ($M = 1, 2, \dots$) be a sequence of Wright–Fisher models as described in §2.2. Under suitable conditions on E and the sequences $\{w_M\}$, $\{R_M\}$, and $\{Q_M\}$, and assuming weak convergence of initial distributions, it can be shown (see §4) that

$$(3.1) \quad \{\nu_{[Mt]}^{(M)}, t \geq 0\} \Rightarrow \{\mu_t, t \geq 0\} \quad \text{in } D_{\mathcal{P}(E)}[0, \infty) \quad \text{as } M \rightarrow \infty,$$

where $\{\mu_t, t \geq 0\}$ is a diffusion process in $\mathcal{P}(E)$. In this section we identify and characterize the limiting diffusion.

Let \mathcal{L}_M denote the discrete generator for the M th rescaled Markov chain:

$$(3.2) \quad (\mathcal{L}_M \varphi)(\mu) = M \int_{\mathcal{P}_M(E)} (\varphi(\nu) - \varphi(\mu)) P_M(\mu, d\nu),$$

where P_M is given by (2.2.6); we regard (3.2) as being defined on all of $\mathcal{P}(E)$, not just on $\mathcal{P}_M(E)$. We want to find sufficient conditions for the limit of (3.2) to exist as $M \rightarrow \infty$. We initially restrict our attention to test functions φ of the form

$$(3.3) \quad \varphi(\mu) = \langle f_1, \mu \rangle \cdots \langle f_k, \mu \rangle,$$

where $k \geq 1$ and $f_1, \dots, f_k \in B(E)$; recall that $\langle f, \mu \rangle = \int_E f d\mu$. By (2.2.6),

$$(3.4) \quad \begin{aligned} & (\mathcal{L}_M \varphi)(\mu) \\ &= M \int_{\mathcal{P}_M(E)} \left\{ \prod_{i=1}^k \langle f_i, \nu \rangle - \prod_{i=1}^k \langle f_i, \mu \rangle \right\} P_M(\mu, d\nu) \\ &= M \left\{ \int_{E^M} \prod_{i=1}^k \langle f_i, \eta_M(x_1, \dots, x_M) \rangle (\mu_M^{***})^M(dx_1 \times \cdots \times dx_M) - \prod_{i=1}^k \langle f_i, \mu \rangle \right\} \\ &= M \left\{ M^{-k} \int_{E^M} \sum_{j_1=1}^M \cdots \sum_{j_k=1}^M f_1(x_{j_1}) \cdots f_k(x_{j_k}) (\mu_M^{***})^M(dx_1 \times \cdots \times dx_M) \right. \\ & \quad \left. - \prod_{i=1}^k \langle f_i, \mu \rangle \right\} \\ &= M \left\{ O(M^{-2}) + M^{-k} \frac{M!}{(M-k+1)!} \sum_{1 \leq i < j \leq k} \langle f_i f_j, \mu_M^{***} \rangle \prod_{l: l \neq i, j} \langle f_l, \mu_M^{***} \rangle \right. \\ & \quad \left. + M^{-k} \frac{M!}{(M-k)!} \prod_{i=1}^k \langle f_i, \mu_M^{***} \rangle - \prod_{i=1}^k \langle f_i, \mu \rangle \right\} \\ &= \sum_{1 \leq i < j \leq k} (\langle f_i f_j, \mu_M^{***} \rangle - \langle f_i, \mu_M^{***} \rangle \langle f_j, \mu_M^{***} \rangle) \prod_{l: l \neq i, j} \langle f_l, \mu_M^{***} \rangle \\ & \quad + \sum_{i=1}^k M (\langle f_i, \mu_M^{***} \rangle - \langle f_i, \mu \rangle) \prod_{l: l < i} \langle f_l, \mu \rangle \prod_{l: l > i} \langle f_l, \mu_M^{***} \rangle + O(M^{-1}), \end{aligned}$$

uniformly in $\mu \in \mathcal{P}(E)$. This calculation is from Kurtz (1981).

To ensure that this converges, we assume the existence of $\sigma \in B_{\text{sym}}(E^2)$ (the *selection intensity function*), a bounded linear transformation B from $B(E)$ to $B(E^2)$ (the *recombination operator*) of the form

$$(3.5) \quad (Bf)(x, y) = \alpha \int_E (f(x') - f(x)) R((x, y), dx'),$$

where $\alpha \geq 0$ (the *recombination intensity*) and $R((x, y), dx')$ is a one-step transition function on $E^2 \times \mathcal{B}(E)$, and a possibly unbounded linear operator A on $B(E)$ (the *mutation operator*, defined only on a subspace $\mathcal{D}(A)$) such that

$$(3.6) \quad w_M(x, y) = 1 + M^{-1} \sigma(x, y) + o(M^{-1}),$$

$$(3.7) \quad \int_E f(x') R_M((x, y), dx' \times E) = f(x) + M^{-1} (Bf)(x, y) + o(M^{-1}),$$

$$(3.8) \quad \int_E f(x') Q_M(x, dx') = f(x) + M^{-1} (Af)(x) + o(M^{-1}),$$

for all $f \in B(E)$ and $f \in \mathcal{D}(A)$, respectively, uniformly in $x, y \in E$. This then implies that

$$\begin{aligned}
 (3.9) \quad & \langle f, \mu_M^{***} \rangle \\
 &= \langle f + M^{-1}Af, \mu_M^{**} \rangle + o(M^{-1}) \\
 &= \langle (f + M^{-1}Af) \circ \pi + M^{-1}B(f + M^{-1}Af), \mu_M^* \rangle + o(M^{-1}) \\
 &= \frac{\langle ((f + M^{-1}Af) \circ \pi + M^{-1}Bf)(1 + M^{-1}\sigma), \mu^2 \rangle}{\langle 1 + M^{-1}\sigma, \mu^2 \rangle} + o(M^{-1}) \\
 &= \langle f, \mu \rangle + M^{-1}\{\langle Af, \mu \rangle + \langle Bf, \mu^2 \rangle + \langle (f \circ \pi)\sigma, \mu^2 \rangle - \langle f, \mu \rangle \langle \sigma, \mu^2 \rangle\} + o(M^{-1})
 \end{aligned}$$

for all $f \in \mathcal{D}(A)$, uniformly in $\mu \in \mathcal{P}(E)$, where π is the projection of E^2 onto its first coordinate.

Thus, if for $\varphi \in B(\mathcal{P}(E))$ of the form (3.3) with $k \geq 1$ and $f_1, \dots, f_k \in \mathcal{D}(A)$ we define

$$\begin{aligned}
 (3.10) \quad (\mathcal{L}\varphi)(\mu) &= \sum_{1 \leq i < j \leq k} (\langle f_i f_j, \mu \rangle - \langle f_i, \mu \rangle \langle f_j, \mu \rangle) \prod_{l: l \neq i, j} \langle f_l, \mu \rangle \\
 &\quad + \sum_{i=1}^k \{\langle Af_i, \mu \rangle + \langle Bf_i, \mu^2 \rangle\} \prod_{l: l \neq i} \langle f_l, \mu \rangle \\
 &\quad + \sum_{i=1}^k \{\langle (f_i \circ \pi)\sigma, \mu^2 \rangle - \langle f_i, \mu \rangle \langle \sigma, \mu^2 \rangle\} \prod_{l: l \neq i} \langle f_l, \mu \rangle,
 \end{aligned}$$

then, assuming that $\overline{\mathcal{D}(A)}$ is an algebra, (3.4) and (3.9) imply that

$$(3.11) \quad (\mathcal{L}_M \varphi)(\mu) = (\mathcal{L}\varphi)(\mu) + o(1),$$

uniformly in $\mu \in \mathcal{P}(E)$. More generally, we define \mathcal{L} by

$$\begin{aligned}
 (3.12) \quad (\mathcal{L}\varphi)(\mu) &= \frac{1}{2} \int_E \int_E \mu(dx)(\delta_x(dy) - \mu(dy)) \frac{\delta^2 \varphi(\mu)}{\delta \mu(x) \delta \mu(y)} \\
 &\quad + \int_E \mu(dx) A\left(\frac{\delta \varphi(\mu)}{\delta \mu(\cdot)}\right)(x) + \int_E \int_E \mu(dx) \mu(dy) B\left(\frac{\delta \varphi(\mu)}{\delta \mu(\cdot)}\right)(x, y) \\
 &\quad + \int_E \int_E \mu(dx) \mu(dy) (\sigma(x, y) - \langle \sigma, \mu^2 \rangle) \frac{\delta \varphi(\mu)}{\delta \mu(x)},
 \end{aligned}$$

where $\delta \varphi(\mu) / \delta \mu(x) = \lim_{\varepsilon \rightarrow 0+} \varepsilon^{-1} \{\varphi(\mu + \varepsilon \delta_x) - \varphi(\mu)\}$, and we take $\mathcal{D}(\mathcal{L})$ to be the set of all $\varphi \in B(\mathcal{P}(E))$ of the form

$$(3.13) \quad \varphi(\mu) = F(\langle f_1, \mu \rangle, \dots, \langle f_k, \mu \rangle) = F(\langle \mathbf{f}, \mu \rangle),$$

where $k \geq 1$, $f_1, \dots, f_k \in \mathcal{D}(A)$, and $F \in C^2(\mathbf{R}^k)$. For such φ ,

$$\begin{aligned}
 (3.14) \quad (\mathcal{L}\varphi)(\mu) &= \frac{1}{2} \sum_{i,j=1}^k (\langle f_i f_j, \mu \rangle - \langle f_i, \mu \rangle \langle f_j, \mu \rangle) F_{z_i z_j}(\langle \mathbf{f}, \mu \rangle) \\
 &\quad + \sum_{i=1}^k \{\langle Af_i, \mu \rangle + \langle Bf_i, \mu^2 \rangle\} F_{z_i}(\langle \mathbf{f}, \mu \rangle) \\
 &\quad + \sum_{i=1}^k \{\langle (f_i \circ \pi)\sigma, \mu^2 \rangle - \langle f_i, \mu \rangle \langle \sigma, \mu^2 \rangle\} F_{z_i}(\langle \mathbf{f}, \mu \rangle).
 \end{aligned}$$

The formulation (3.14) is from Fleming and Viot (1979), whereas (3.12) is due to Dawson and Hochberg (1982).

Another choice for the domain of \mathcal{L} that is often useful is the set of all $\varphi \in B(\mathcal{P}(E))$ of the form $\varphi(\mu) = \langle f, \mu^k \rangle$, where $k \geq 1$ and $f \in B(E^k)$ satisfies certain conditions. To describe these conditions precisely, we need to be more specific about our assumptions on A . We assume that E is locally compact and that the closure of A generates a Feller semigroup $\{T(t)\}$ on $\hat{C}(E)$, the space of real continuous functions on E vanishing at infinity. (If E is compact, then $\hat{C}(E) = C(E)$.) Note that $\{T(t)\}$ is given by a transition function $P(t, x, d\xi)$, that is,

$$(3.15) \quad T(t)f(x) = \int_E f(\xi) P(t, x, d\xi).$$

For each $k \geq 1$, we define the semigroup $\{T_k(t)\}$ on $B(E^k)$ by

$$(3.16) \quad T_k(t)f(x_1, \dots, x_k) = \int_E \cdots \int_E f(\xi_1, \dots, \xi_k) P(t, x_1, d\xi_1) \cdots P(t, x_k, d\xi_k),$$

and we let $A^{(k)}$ denote its generator; note that $\mathcal{D}(A^{(k)})$ is a subspace of $B(E^k)$.

In addition, for each $k \geq 2$ and $1 \leq i < j \leq k$, we define $\Phi_{ij}^{(k)} : B(E^k) \mapsto B(E^{k-1})$ by letting $\Phi_{ij}^{(k)} f$ be the function obtained from f by replacing x_j by x_i and renumbering the variables:

$$(3.17) \quad (\Phi_{ij}^{(k)} f)(x_1, \dots, x_{k-1}) = f(x_1, \dots, x_{j-1}, x_i, x_j, \dots, x_{k-1}).$$

For each $k \geq 1$ and $1 \leq i \leq k$, we define $H_i^{(k)} : B(E^k) \mapsto B(E^{k+1})$ by

$$(3.18) \quad (H_i^{(k)} f)(x_1, \dots, x_{k+1}) = \int_E f(x_1, \dots, x_{i-1}, \xi, x_{i+1}, \dots, x_k) R((x_i, x_{k+1}), d\xi)$$

and $K_i^{(k)} : B(E^k) \mapsto B(E^{k+2})$ by

$$(3.19) \quad (K_i^{(k)} f)(x_1, \dots, x_{k+2}) = \frac{\bar{\sigma} + \sigma(x_i, x_{k+1}) - \sigma(x_{k+1}, x_{k+2})}{2\bar{\sigma}} f(x_1, \dots, x_k),$$

where $\bar{\sigma} = \sup_{x, y, z \in E} |\sigma(x, y) - \sigma(y, z)|$ and $0/0 = 0$.

For each $k \geq 1$ and $f \in \mathcal{D}(A^{(k)})$, we define $\varphi_f \in B(\mathcal{P}(E))$ by

$$(3.20) \quad \varphi_f(\mu) = \langle f, \mu^k \rangle,$$

and we note that (3.12) reduces (informally, at least) to

$$(3.21) \quad (\mathcal{L}\varphi_f)(\mu) = \sum_{1 \leq i < j \leq k} (\langle \Phi_{ij}^{(k)} f, \mu^{k-1} \rangle - \langle f, \mu^k \rangle) \\ + \langle A^{(k)} f, \mu^k \rangle + \alpha \sum_{i=1}^k (\langle H_i^{(k)} f, \mu^{k+1} \rangle - \langle f, \mu^k \rangle) \\ + 2\bar{\sigma} \sum_{i=1}^k (\langle K_i^{(k)} f, \mu^{k+2} \rangle - \langle f, \mu^k \rangle) + \bar{\sigma} k \langle f, \mu^k \rangle.$$

This leads immediately to the so-called *dual process*. For each $k \geq 1$, $f \in B(E^k)$, and $\mu \in \mathcal{P}(E)$, write

$$(3.22) \quad \varphi_f(\mu) = \varphi_\mu(f) = \langle f, \mu^k \rangle,$$

and consider the Markov process in $\cup_{k=1}^\infty B(E^k)$ with generator $\mathcal{L}^\#$ satisfying

$$(3.23) \quad (\mathcal{L}\varphi_f)(\mu) = (\mathcal{L}^\#\varphi_\mu)(f) + \bar{\sigma}k\varphi_\mu(f).$$

By (3.21), this is a process that jumps from $f \in B(E^k)$ to $\Phi_{ij}^{(k)} f \in B(E^{k-1})$ at rate 1 ($1 \leq i < j \leq k$), to $H_i^{(k)} f \in B(E^{k+1})$ at rate α ($1 \leq i \leq k$), and to $K_i^{(k)} f \in B(E^{k+2})$ at rate $2\bar{\sigma}$ ($1 \leq i \leq k$). Between jumps it moves from $f \in B(E^k)$ to $T_k(t)f \in B(E^k)$ in time t . The process was first described by Dawson and Hochberg (1982).

Let us be more explicit about the dual process. Let $M = \{M(t), t \geq 0\}$ be the pure-jump Markov process in \mathbf{N} , the set of positive integers, with transition intensities $q_{k,k-1} = k(k-1)/2$, $q_{k,k+1} = \alpha k$, and $q_{k,k+2} = 2\bar{\sigma}k$. Let $0 = \tau_0 < \tau_1 < \tau_2 < \dots$ be the jump times of M (this sequence will be finite if $\alpha = \bar{\sigma} = 0$), and given M , let $\Gamma_1, \Gamma_2, \dots$ be a sequence of conditionally independent random operators such that, if $n \geq 1$ and $M(\tau_{n-1}) = k$, then

$$(3.24) \quad \mathbf{P}\{\Gamma_n = \Phi_{ij}^{(k)} \mid M\} = \binom{k}{2}^{-1} \quad (1 \leq i < j \leq k) \quad \text{if } M(\tau_n) = k-1,$$

$$(3.25) \quad \mathbf{P}\{\Gamma_n = H_i^{(k)} \mid M\} = k^{-1} \quad (1 \leq i \leq k) \quad \text{if } M(\tau_n) = k+1,$$

$$(3.26) \quad \mathbf{P}\{\Gamma_n = K_i^{(k)} \mid M\} = k^{-1} \quad (1 \leq i \leq k) \quad \text{if } M(\tau_n) = k+2.$$

The dual process can then be written as

$$(3.27) \quad Y(t) = T_{M(\tau_k)}(t - \tau_k)\Gamma_k T_{M(\tau_{k-1})}(\tau_k - \tau_{k-1})\Gamma_{k-1} \dots \\ \Gamma_2 T_{M(\tau_1)}(\tau_2 - \tau_1)\Gamma_1 T_{M(0)}(\tau_1)Y(0) \quad \text{if } \tau_k \leq t < \tau_{k+1}, \quad k \geq 0,$$

where $Y(0) \in B(E^{M(0)})$. The next result is essentially from Ethier and Kurtz (1987).

THEOREM 3.1. *Let E be locally compact and suppose that the closure of A generates a Feller semigroup on $\hat{C}(E)$. Define B in terms of $\alpha \geq 0$ and a transition function $R((x, y), dx')$ on $E^2 \times \mathcal{B}(E)$ by (3.5), and let $\sigma \in B_{\text{sym}}(E^2)$. Then the martingale problems for \mathcal{L} defined by (3.3) and (3.10), by (3.13) and (3.14), and by (3.20) and (3.21) are equivalent. If $\{\mu_t, t \geq 0\}$ is a solution and if $\{Y(t), t \geq 0\}$ is defined as above and is independent of $\{\mu_t, t \geq 0\}$, then*

$$(3.28) \quad \mathbf{E}[\langle f, \mu_t^m \rangle] = \mathbf{E}\left[\langle Y(t), \mu_0^{M(t)} \rangle \exp\left\{\bar{\sigma} \int_0^t M(s) ds\right\}\right],$$

for all $m \geq 1$, $f \in B(E^m)$, and $t \geq 0$, where $Y(0) = f$ and $M(0) = m$.

A number of authors (Fleming and Viot (1979), Kurtz (1981), Ethier and Kurtz (1987), Donnelly and Kurtz (1993)) have given conditions under which the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} is well posed, thereby characterizing the diffusion process associated with \mathcal{L} . Because of Theorem 3.1, uniqueness of solutions (with specified initial distribution) is almost immediate. Existence, however, requires a relative compactness argument. The following conditions are essentially from Ethier and Kurtz (1987).

THEOREM 3.2. (a) *Under the assumptions of Theorem 3.1, uniqueness of solutions of the martingale problem for \mathcal{L} defined by (3.13) and (3.14) (with specified initial distribution) holds.*

(b) *Suppose in addition that either $B = 0$ or both E is compact and B maps $C(E)$ into $C(E^2)$. Then the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} is well posed.*

It is occasionally necessary to simultaneously generalize (3.14) and (3.21). For this purpose we consider the set of all $\varphi \in B(\mathcal{P}(E))$ of the form

$$(3.29) \quad \varphi(\mu) = F(\langle f_1, \mu^{n_1} \rangle, \dots, \langle f_k, \mu^{n_k} \rangle),$$

where $k \geq 1$, $n_1, \dots, n_k \geq 1$, $f_1 \in \mathcal{D}(A^{(n_1)})$, \dots , $f_k \in \mathcal{D}(A^{(n_k)})$, and $F \in C^2(\mathbf{R}^k)$. In this case (3.12) becomes (again, informally)

$$(3.30) \quad \begin{aligned} (\mathcal{L}\varphi)(\mu) &= \frac{1}{2} \sum_{i,j=1}^k \sum_{l=1}^{n_i} \sum_{m=1}^{n_j} (\langle \Psi_{lm}^{(n_i, n_j)}(f_i, f_j), \mu^{n_i+n_j-1} \rangle - \langle f_i, \mu^{n_i} \rangle \langle f_j, \mu^{n_j} \rangle) F_{z_i z_j} \\ &\quad + \sum_{i=1}^k (\mathcal{L}\varphi_{f_i})(\mu) F_{z_i}, \end{aligned}$$

where $\Psi_{lm}^{(n_i, n_j)}(f_i, f_j)$ is the function in $B(E^{n_i+n_j-1})$ obtained from $f_i(x)f_j(y)$ by replacing y_m by x_l and renumbering the variables, $\mathcal{L}\varphi_f$ is as in (3.21), and the partial derivatives of F have the same arguments as F in (3.29). Under the assumptions of Theorem 3.1, the martingale problem for \mathcal{L} defined by (3.29) and (3.30) is equivalent to those of the theorem.

Let $\{\mu_t, t \geq 0\}$ denote the canonical coordinate process on $\Omega = C_{\mathcal{P}(E)}[0, \infty)$. Let \mathcal{M} denote the Borel σ -field, and put $\mathcal{M}_t = \sigma\{\mu_s : 0 \leq s \leq t\}$ for each $t \geq 0$. We now state a result showing that the transformation from the neutral model (no selection) to the selective model is a Girsanov-type transformation. The result is essentially from Dawson (1978).

THEOREM 3.3. *Suppose, in addition to the assumptions of Theorem 3.1, that $\sigma \in B_{\text{sym}}(E^2) \cap \mathcal{D}(A^{(2)})$. Let $P \in \mathcal{P}(\Omega)$ be a solution of the Ω martingale problem for \mathcal{L}_0 defined by (3.20) and (3.21) with $\bar{\sigma} = 0$. Then*

$$(3.31) \quad R_t = \exp \left\{ \frac{1}{2} \varphi_\sigma(\mu_t) - \frac{1}{2} \varphi_\sigma(\mu_0) - \int_0^t (e^{-\varphi_\sigma/2} \mathcal{L}_0 e^{\varphi_\sigma/2})(\mu_s) ds \right\}$$

is a mean-one $\{\mathcal{M}_t\}$ -martingale on (Ω, \mathcal{M}, P) . Moreover, if we define $Q \in \mathcal{P}(\Omega)$ by $dQ/dP|_{\mathcal{M}_t} = R_t$ for all $t \geq 0$, then Q is a solution of the Ω martingale problem for \mathcal{L} defined by (3.20) and (3.21).

The first assertion follows from Lemma 4.3.2 of Ethier and Kurtz (1986). The fact that Q corresponds to \mathcal{L} is essentially a consequence of the calculation

$$(3.32) \quad \begin{aligned} &\frac{\mathcal{L}_0(\varphi_f e^{\varphi_\sigma/2}) - \varphi_f \mathcal{L}_0 e^{\varphi_\sigma/2}}{e^{\varphi_\sigma/2}} \\ &= \mathcal{L}_0 \varphi_f + \frac{\mathcal{L}_0(\varphi_f e^{\varphi_\sigma/2}) - \varphi_f \mathcal{L}_0 e^{\varphi_\sigma/2} - e^{\varphi_\sigma/2} \mathcal{L}_0 \varphi_f}{e^{\varphi_\sigma/2}} = \mathcal{L} \varphi_f, \end{aligned}$$

where the last step uses (3.30). Also by (3.30), the integrand in (3.31) reduces to

$$(3.33) \quad \begin{aligned} &(e^{-\varphi_\sigma/2} \mathcal{L}_0 e^{\varphi_\sigma/2})(\mu) \\ &= \frac{1}{2} (\langle \Phi_{12}^{(2)} \sigma, \mu \rangle + \langle A^{(2)} \sigma, \mu^2 \rangle + 2\alpha \langle H_1^{(2)} \sigma, \mu^3 \rangle + 2\bar{\sigma} \langle K_1^{(2)} \sigma, \mu^4 \rangle \\ &\quad - (1 + 2\alpha + \bar{\sigma}) \langle \sigma, \mu^2 \rangle). \end{aligned}$$

We consider separately the special case in which $B = 0$ and $\sigma \equiv 0$. The following result seems to be new.

THEOREM 3.4. *Let E be compact, and suppose that the closure of A generates a Feller semigroup on $C(E)$. Then the closure of the operator \mathcal{L} defined on*

$$(3.34) \quad \mathcal{D}(\mathcal{L}) = \{\varphi_f : f \in \mathcal{D}(A^{(k)}) \cap C(E^k), k \geq 1\}$$

by (3.21) with $\alpha = \bar{\sigma} = 0$ generates a Feller semigroup on $C(\mathcal{P}(E))$.

Proof. We apply the Hille–Yosida theorem. $\mathcal{D}(\mathcal{L})$ is dense in $C(\mathcal{P}(E))$ since $\mathcal{D}(A^{(k)}) \cap C(E^k)$ is dense in $C(E^k)$ for each $k \geq 1$. Dissipativity of \mathcal{L} follows by (3.11) and the fact that the closure of \mathcal{L} defined by (3.3), (3.10), and linearity extends \mathcal{L} defined by (3.34) and (3.21). Let $\lambda > 0$. We need to show that $\mathcal{R}(\lambda - \mathcal{L})$ is dense in $C(\mathcal{P}(E))$. Given $k \geq 1$ and $g \in C(E^k)$, define $f \in \mathcal{D}(A^{(k)}) \cap C(E^k)$ by

$$(3.35) \quad f = \sum_{n=0}^{\infty} \left[(\lambda + \binom{k}{2} - A^{(k)})^{-1} \sum_{1 \leq i < j \leq k} \Psi_{ij}^{(k)} \right]^n (\lambda + \binom{k}{2} - A^{(k)})^{-1} g,$$

where $\Psi_{ij}^{(k)} : C(E^k) \mapsto C(E^k)$ is defined by letting $\Psi_{ij}^{(k)} f$ be the function obtained from f by replacing x_j by x_i . Then

$$(3.36) \quad (\lambda + \binom{k}{2} - A^{(k)})f - \sum_{1 \leq i < j \leq k} \Psi_{ij}^{(k)} f = g,$$

so $(\lambda - \mathcal{L})\varphi_f = \varphi_g$, and the range condition follows. Thus, the closure of \mathcal{L} generates a strongly continuous conservative contraction semigroup $\{\mathcal{T}(t)\}$ on $C(\mathcal{P}(E))$. If $k \geq 1$, $f \in C(E^k)$, and $\varphi_f \geq 0$, then

$$(3.37) \quad \|\varphi_f\| - \mathcal{T}(t)\varphi_f(\mu) = \mathcal{T}(t)(\|\varphi_f\| - \varphi_f)(\mu) \leq \|\|\varphi_f\| - \varphi_f\| \leq \|\varphi_f\|$$

for all $\mu \in \mathcal{P}(E)$ and $t \geq 0$, so the positivity of $\{\mathcal{T}(t)\}$ follows. (Note that $\varphi_f \geq 0$ does not imply $f \geq 0$.) \square

4. Convergence. We begin by showing that, under suitable conditions, the Fleming–Viot process of §3 approximates the Markov chains of §2.

LEMMA 4.1. *For each $M \geq 1$, let $P_M(\mu, d\nu)$ be a one-step transition function on $\mathcal{P}_M(E) \times \mathcal{B}(\mathcal{P}_M(E))$ (see (2.2.2)) and let $\beta_M > 0$. Assume that $\lim_{M \rightarrow \infty} \beta_M = \infty$. Let $\mathcal{D} \subset B(E)$ and suppose that for each $f, g \in \mathcal{D}$ there exist $a_{f,g}, b_f \in B(\mathcal{P}(E))$ such that*

$$(4.1) \quad \beta_M \int (\langle f, \nu \rangle - \langle f, \mu \rangle) P_M(\mu, d\nu) = b_f(\mu) + o(1),$$

$$(4.2) \quad \beta_M \int (\langle f, \nu \rangle - \langle f, \mu \rangle)(\langle g, \nu \rangle - \langle g, \mu \rangle) P_M(\mu, d\nu) = a_{f,g}(\mu) + o(1),$$

$$(4.3) \quad \beta_M \int (\langle f, \nu \rangle - \langle f, \mu \rangle)^4 P_M(\mu, d\nu) = o(1),$$

as $M \rightarrow \infty$, uniformly in $\mu \in \mathcal{P}_M(E)$. Let $\varphi \in B(\mathcal{P}(E))$ have the form

$$(4.4) \quad \varphi(\mu) = F(\langle f_1, \mu \rangle, \dots, \langle f_k, \mu \rangle) = F(\langle \mathbf{f}, \mu \rangle),$$

where $k \geq 1$, $f_1, \dots, f_k \in \mathcal{D}$, and $F \in C^2(\mathbf{R}^k)$, and define

$$(4.5) \quad (\mathcal{L}_M \varphi)(\mu) = \beta_M \int (\varphi(\nu) - \varphi(\mu)) P_M(\mu, d\nu)$$

and

$$(4.6) \quad (\mathcal{L}_\infty \varphi)(\mu) = \frac{1}{2} \sum_{i,j=1}^k a_{f_i, f_j}(\mu) F_{z_i z_j}(\langle \mathbf{f}, \mu \rangle) + \sum_{i=1}^k b_{f_i}(\mu) F_{z_i}(\langle \mathbf{f}, \mu \rangle).$$

Then

$$(4.7) \quad (\mathcal{L}_M \varphi)(\mu) = (\mathcal{L}_\infty \varphi)(\mu) + o(1)$$

as $M \rightarrow \infty$, uniformly in $\mu \in \mathcal{P}_M(E)$.

Proof. The result is immediate from a second-order Taylor expansion. \square

Suppose that the assumptions of Theorem 3.2(b) hold, that the sequences $\{w_M\}$, $\{R_M\}$, and $\{Q_M\}$ satisfy (3.6)–(3.8), and that σ is continuous. Suppose also that $\{\mu_t, t \geq 0\}$ is a solution of the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for the operator \mathcal{L}_∞ defined by (4.4) and (4.6) with $\mathcal{D} = \mathcal{D}(A)$,

$$(4.8) \quad a_{f,g}(\mu) = \langle fg, \mu \rangle - \langle f, \mu \rangle \langle g, \mu \rangle,$$

and

$$(4.9) \quad b_f(\mu) = c\{\langle Af, \mu \rangle + \langle Bf, \mu^2 \rangle + \langle (f \circ \pi)\sigma, \mu^2 \rangle - \langle f, \mu \rangle \langle \sigma, \mu^2 \rangle\},$$

where c is a positive constant.

Let $\{\nu_\tau^{(N)}, \tau \in \mathbf{Z}_+\}$ ($N = 1, 2, \dots$) be a sequence of diploid models as described in §2.1, and suppose $c = 1$. If $\hat{\nu}_0^{(N)} \pi^{-1} \Rightarrow \mu_0$, then

$$(4.10) \quad \{\hat{\nu}_{[2Nt]}^{(N)} \pi^{-1}, t \geq 0\} \Rightarrow \{\mu_t, t \geq 0\}$$

in $D_{\mathcal{P}(E)}[0, \infty)$. This follows from a slight modification of Lemma 4.1 (or of (3.4)), together with Corollary 4.8.17 of Ethier and Kurtz (1986).

Let $\{\nu_\tau^{(M)}, \tau \in \mathbf{Z}_+\}$ ($M = 1, 2, \dots$) be a sequence of Wright–Fisher models as described in §2.2, and suppose $c = 1$. If $\nu_0^{(M)} \Rightarrow \mu_0$, then

$$(4.11) \quad \{\nu_{[Mt]}^{(M)}, t \geq 0\} \Rightarrow \{\mu_t, t \geq 0\}$$

in $D_{\mathcal{P}(E)}[0, \infty)$. This follows from Lemma 4.1 or (3.11), together with Corollary 4.8.17 of Ethier and Kurtz (1986).

Let $\{\nu_\tau^{(M)}, \tau \in \mathbf{Z}_+\}$ ($M = 1, 2, \dots$) be a sequence of Moran models as described in §2.3, and suppose $c = \frac{1}{2}$. If $\nu_0^{(M)} \Rightarrow \mu_0$, then

$$(4.12) \quad \{\nu_{[M^2 t/2]}^{(M)}, t \geq 0\} \Rightarrow \{\mu_t, t \geq 0\}$$

in $D_{\mathcal{P}(E)}[0, \infty)$. This follows from Lemma 4.1, together with Corollary 4.8.17 of Ethier and Kurtz (1986).

There are two problems with the above diffusion approximations. First, the topology of weak convergence is too weak for many applications. For example, we might be interested in functions φ on $\mathcal{P}(E)$ such as

$$(4.13) \quad \varphi(\mu) = \mu^2(D), \quad D = \{(x, y) \in E^2 : x = y\},$$

the population homozygosity. But this function is not continuous in the topology of weak convergence (unless D is open, as, e.g., when E is finite). Second, the assumption that the selection intensity function σ is continuous rules out a number of important examples, e.g.,

$$(4.14) \quad \sigma(x, y) = \sigma I_D(x, y),$$

where σ is a real constant and D is as in (4.13); this corresponds to the situation in which homozygotes have a selective advantage or disadvantage compared to heterozygotes. We treat these two issues separately.

A solution to the first problem is obtained by imposing a stronger topology on $\mathcal{P}(E)$. Here we assume that (E, r) is a complete separable metric space. Let ρ denote the Prohorov metric on $\mathcal{P}(E)$, which induces the topology of weak convergence. Define the metric ρ_a on $\mathcal{P}(E)$ by

$$(4.15) \quad \rho_a(\mu, \nu) = \rho(\mu, \nu) + \sup_{0 < \varepsilon \leq 1} \left| \int_E \int_E \left(1 - \frac{r(x, y)}{\varepsilon}\right)_+ \mu(dx) \mu(dy) - \int_E \int_E \left(1 - \frac{r(x, y)}{\varepsilon}\right)_+ \nu(dx) \nu(dy) \right|.$$

The topology on $\mathcal{P}(E)$ induced by ρ_a is called the *weak atomic topology* (Ethier and Kurtz (1993a)).

LEMMA 4.2. *Let $\{\mu_n\} \subset \mathcal{P}(E)$ and $\mu \in \mathcal{P}(E)$. The following are equivalent:*

(a) $\rho_a(\mu_n, \mu) \rightarrow 0$.

(b) $\rho(\mu_n, \mu) \rightarrow 0$ and $\sum_x \mu_n(\{x\})^2 \rightarrow \sum_x \mu(\{x\})^2$.

(c) $\rho(\mu_n, \mu) \rightarrow 0$ and the sizes and locations of the atoms of μ_n converge to the sizes and locations of the atoms of μ .

For example, if $x_n \rightarrow x$, $x_n \neq x$ for all n , and $\mu_n = \frac{1}{2}(\delta_{x_n} + \delta_x)$, then $\rho(\mu_n, \delta_x) \rightarrow 0$ but $\rho_a(\mu_n, \delta_x) \not\rightarrow 0$.

Let $k \geq 1$, $\mathbf{n} = (n_1, \dots, n_k) \in \mathbf{N}^k$, and $n = n_1 + \dots + n_k > 1$, and define $\Gamma_{\mathbf{n}} = \{(x_1, \dots, x_n) \in E^n : \text{there exist distinct } y_1, \dots, y_k \in E \text{ such that } |\{1 \leq i \leq n : x_i = y_j\}| = n_j \text{ for } j = 1, \dots, k\}$. Then the mapping $\varphi_{\mathbf{n}} : \mathcal{P}(E) \mapsto [0, 1]$ given by $\varphi_{\mathbf{n}}(\mu) = \mu^n(\Gamma_{\mathbf{n}})$ is continuous in the weak atomic topology but not typically in the topology of weak convergence. Of course, (4.13) is a special case. See §9.2 for the relevance of such functions.

The result we need in order to generalize the diffusion approximations discussed above is the following theorem.

THEOREM 4.3. *A sequence of processes $\{\mu_t^{(M)}, t \geq 0\}$ ($M = 1, 2, \dots$) with sample paths in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$ is relatively compact in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$ if and only if it is relatively compact in $D_{(\mathcal{P}(E), \rho)}[0, \infty)$ and for each $T > 0$ and $\delta > 0$ there exists $\varepsilon > 0$ such that*

$$(4.16) \quad \liminf_{M \rightarrow \infty} \mathbf{P}\left\{ \sup_{0 \leq t \leq T} (\mu_t^{(M)} \times \mu_t^{(M)})(\{(x, y) \in E^2 : 0 < r(x, y) < \varepsilon\}) \leq \delta \right\} \geq 1 - \delta.$$

To establish relative compactness in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$ for the three models of §2, additional assumptions are needed. For each $M \geq 1$, write

$$(4.17) \quad Q_M(x, \cdot) = \left(1 - \frac{\theta_M(x)}{2M}\right) \delta_x(\cdot) + \frac{\theta_M(x)}{2M} \lambda_M(x, \cdot),$$

where $\theta_M \in B(E)$ is nonnegative and λ_M is a one-step transition function on $E \times \mathcal{B}(E)$, and suppose that

$$(4.18) \quad \sup_M \sup_{x \in E} \theta_M(x) < \infty,$$

$$(4.19) \quad \lim_{\varepsilon \rightarrow 0} \limsup_{M \rightarrow \infty} \sup_{x, y \in E} \theta_M(x) \lambda_M(x, B_\varepsilon(y)) = 0,$$

and

$$(4.20) \quad \lim_{\varepsilon \rightarrow 0} \sup_{x, y, z \in E} R((x, y), B_\varepsilon(z)) = 0,$$

where $B_\varepsilon(y)$ is the ball of radius ε centered at y . These assumptions, in addition to the ones imposed previously, guarantee that (4.10)–(4.12) hold in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$; see Ethier and Kurtz (1993a).

We turn next to the problem of relaxing the continuity assumption on the selection intensity function σ . Let E be compact, let $\theta > 0$ and $\nu_0 \in \mathcal{P}(E)$, and put

$$(4.21) \quad (Af)(x) = \frac{1}{2} \theta \int_E (f(\xi) - f(x)) \nu_0(d\xi).$$

We assume all previously stated assumptions in this section except for the continuity of σ , and we assume in addition that A is given by (4.21) and $B = 0$. Define $\sigma_0 \in B(E)$ by $\sigma_0(x) = \sigma(x, x)$, and let $D_{\sigma_0} = \{x \in E : \sigma_0 \text{ is discontinuous at } x\}$ and $D_{\sigma}^- = \{(x, y) \in E^2 : \sigma \text{ is discontinuous at } (x, y) \text{ and } x \neq y\}$. Assume further that

$$(4.22) \quad \mathbf{P}\{(\mu_0 + \nu_0)(D_{\sigma_0}) = 0\} = 1$$

and

$$(4.23) \quad \mathbf{P}\{(\mu_0 + \nu_0)^2(D_{\sigma}^-) = 0\} = 1.$$

Then (4.10)–(4.12) hold in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$.

As for the proof, relative compactness in $D_{(\mathcal{P}(E), \rho_a)}[0, \infty)$ is established as before. The difficulty is in identifying the limiting process. The assumptions (4.22) and (4.23) ensure that $\mathcal{L}\varphi_f$ is continuous in the weak atomic topology almost surely with respect to the distribution of μ_t for each $f \in C(E^k)$, $k \geq 1$, and $t \geq 0$. This is proved using Theorem 3.3 above and Theorem 8.3 below, the latter explaining why (4.21) is assumed. But undoubtedly the conclusions hold in greater generality.

Finally, convergence in distribution of sequences of Fleming–Viot processes as well as weak convergence of stationary distributions can be established under similar conditions to the above. See Ethier and Kurtz (1993a). One technique we have not discussed here is the use of dual processes to prove convergence in distribution of

sequences of Fleming-Viot processes. In particular, this is well adapted to the case of discontinuous selection intensity functions. See Ethier and Kurtz (1987).

5. Ergodicity. The ergodic theorem for a measurable E -valued stationary process Z states that if f is a real-valued Borel function on E with $\mathbf{E}[|f(Z(0))|] < \infty$, then

$$(5.1) \quad \lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t f(Z(s)) ds = \mathbf{E}[f(Z(0)) \mid \mathcal{I}],$$

where \mathcal{I} is the σ -algebra of invariant events, that is, events of the form $\{Z(\cdot) \in \Gamma\}$, $\Gamma \in \mathcal{B}(E^{[0, \infty)})$, such that $\{Z(\cdot) \in \Gamma\} = \{Z(t + \cdot) \in \Gamma\}$ for all $t \geq 0$. If the events in \mathcal{I} are all of probability zero or one, then Z is said to be *ergodic* and the right-hand side of (5.1) is just $\mathbf{E}[f(Z(0))]$. (See, e.g., Durrett (1991, Chap. 6).)

If $P(t, x, d\xi)$ is the transition function for an E -valued Markov process and $\nu_0 \in \mathcal{P}(E)$ is a stationary distribution for $P(t, x, d\xi)$, that is,

$$(5.2) \quad \int_E P(t, x, \Gamma) \nu_0(dx) = \nu_0(\Gamma), \quad \Gamma \in \mathcal{B}(E),$$

then a sufficient condition for ergodicity of the stationary process obtained by taking ν_0 to be the initial distribution is that ν_0 be the unique probability measure satisfying (5.2). If the closure of A generates the semigroup corresponding to $P(t, x, d\xi)$ on a subspace of $B(E)$ that is separating, then (5.2) is equivalent to

$$(5.3) \quad \langle Af, \nu_0 \rangle = 0, \quad f \in \mathcal{D}(A).$$

The following is essentially a result of Dynkin (1989).

THEOREM 5.1. *Let E be compact, and suppose that the closure of A generates a Feller semigroup on $C(E)$. Suppose further that there exists a unique $\nu_0 \in \mathcal{P}(E)$ satisfying (5.3). Then there exists a unique stationary distribution for the Fleming-Viot process with type space E and mutation operator A (and no recombination or selection).*

Proof. Existence is automatic by virtue of the Feller property of the Fleming-Viot process. For uniqueness, we must show that there is a unique $\Pi \in \mathcal{P}(\mathcal{P}(E))$ satisfying

$$(5.4) \quad \langle \mathcal{L}\varphi_f, \Pi \rangle = 0$$

for all $k \geq 1$ and $f \in \mathcal{D}(A^{(k)}) \cap C(E^k)$, where $\mathcal{L}\varphi_f$ is as in (3.21) with $\alpha = \bar{\sigma} = 0$. For $k = 1$, (5.4) becomes

$$(5.5) \quad \int_{\mathcal{P}(E)} \langle Af, \mu \rangle \Pi(d\mu) = 0, \quad f \in \mathcal{D}(A),$$

which by the assumption on ν_0 implies that $\int_{\mathcal{P}(E)} \mu(\Gamma) \Pi(d\mu) = \nu_0(\Gamma)$ for all $\Gamma \in \mathcal{B}(E)$ and hence that

$$(5.6) \quad \int_{\mathcal{P}(E)} \langle f, \mu \rangle \Pi(d\mu) = \langle f, \nu_0 \rangle, \quad f \in C(E).$$

We proceed by induction. Given $k \geq 2$, suppose that $\int_{\mathcal{P}(E)} \langle f, \mu^{k-1} \rangle \Pi(d\mu)$ is determined for all $f \in C(E^{k-1})$. By (5.4),

$$(5.7) \quad \int_{\mathcal{P}(E)} \langle \binom{k}{2} f - A^{(k)} f, \mu^k \rangle \Pi(d\mu) = \int_{\mathcal{P}(E)} \sum_{1 \leq i < j \leq k} \langle \Phi_{ij}^{(k)} f, \mu^{k-1} \rangle \Pi(d\mu)$$

for all $f \in \mathcal{D}(A^{(k)}) \cap C(E^k)$, but since the range of $\lambda - A^{(k)}$ contains $C(E^k)$ for all $\lambda > 0$, (5.7) implies that

$$(5.8) \quad \int_{\mathcal{P}(E)} \langle f, \mu^k \rangle \Pi(d\mu) = \int_{\mathcal{P}(E)} \sum_{1 \leq i < j \leq k} \langle \Phi_{ij}^{(k)} R^{(k)} f, \mu^{k-1} \rangle \Pi(d\mu)$$

for all $f \in C(E^k)$, where

$$(5.9) \quad R^{(k)} f = (\binom{k}{2} - A^{(k)})^{-1} f = \int_0^\infty e^{-(\binom{k}{2})t} T_k(t) f dt.$$

Uniqueness of stationary distributions follows. \square

For a Markov process Z with transition function $P(t, x, d\xi)$ we are typically interested in statements stronger than just uniqueness of stationary distributions. In particular, we would like to know that for an arbitrary initial distribution, the process is, in some sense, asymptotically stationary. Two possible senses are

$$(5.10) \quad \lim_{t \rightarrow \infty} \mathbf{E}[f(Z(t))] = \langle f, \nu_0 \rangle, \quad f \in \overline{C}(E),$$

for every initial distribution, which we refer to as *weak ergodicity* (occasionally we may need to replace the limit in (5.10) by the corresponding Cesàro limit), and

$$(5.11) \quad \lim_{t \rightarrow \infty} \|P(t, x, \cdot) - \nu_0\|_{\text{var}} = 0, \quad x \in E,$$

which we refer to as *strong ergodicity*. Here $\|\nu_1 - \nu_2\|_{\text{var}} = \sup_{\Gamma \in \mathcal{B}(E)} |\nu_1(\Gamma) - \nu_2(\Gamma)|$. One important consequence of strong ergodicity is that

$$(5.12) \quad \lim_{t \rightarrow \infty} \frac{1}{t} \int_0^t f(Z(s)) ds = \langle f, \nu_0 \rangle \quad \text{a.s.}, \quad f \in B(E),$$

for every initial distribution.

Duality gives a simple proof of weak ergodicity in the absence of recombination and selection.

THEOREM 5.2. *Let E be compact, and suppose that the closure of A generates a Feller semigroup $\{T(t)\}$ on $C(E)$ corresponding to a weakly ergodic Markov process (equivalently, there exists $\nu_0 \in \mathcal{P}(E)$ such that $\lim_{t \rightarrow \infty} T(t)f(x) = \langle f, \nu_0 \rangle$ for all $f \in C(E)$ and $x \in E$). Then the Fleming–Viot process with type space E and mutation operator A is weakly ergodic.*

Proof. Note that without recombination or selection, the Markov jump process M in the definition of the dual process is a pure death process absorbing at 1. Let τ be the absorption time. Then by the duality identity (3.28) and the assumption of weak ergodicity, for each $m \geq 1$ and $f \in C(E^m)$ we have

$$(5.13) \quad \lim_{t \rightarrow \infty} \mathbf{E}[\langle f, \mu_t^m \rangle] = \lim_{t \rightarrow \infty} \mathbf{E}[\langle T(t - \tau)Y(\tau), \mu_0 \rangle; \tau \leq t] = \mathbf{E}[\langle Y(\tau), \nu_0 \rangle; \tau < \infty],$$

regardless of the distribution of μ_0 . Together with the Riesz representation theorem, this proves the theorem. \square

Coupling arguments provide one approach to strong ergodicity. The basic idea is to construct E -valued Markov processes Z_1 and Z_2 with transition function $P(t, x, d\xi)$ but with different initial distributions on the same probability space in such a way that there is a random time τ such that $Z_1(t) = Z_2(t)$ for all $t \geq \tau$. We then have the basic coupling inequality

$$(5.14) \quad \|\mathbf{P}\{Z_1(t) \in \cdot\} - \mathbf{P}\{Z_2(t) \in \cdot\}\|_{\text{var}} \leq \mathbf{P}\{\tau > t\}, \quad t \geq 0.$$

If $Z_1(0)$ has distribution δ_x and $Z_2(0)$ has distribution ν_0 (a stationary distribution), then

$$(5.15) \quad \|P(t, x, \cdot) - \nu_0\|_{\text{var}} \leq \mathbf{P}\{\tau > t\}, \quad t \geq 0.$$

We say that the coupling is *successful* if $\mathbf{P}\{\tau < \infty\} = 1$. We call the coupling a *Markov coupling* if the coupled pair is a Markov process in $E \times E$. See Griffeath (1978) for a general discussion of coupling. The following theorem is from Ethier and Kurtz (1993b).

THEOREM 5.3. *Let E be locally compact, and suppose that the closure of A generates a Feller semigroup on $\hat{C}(E)$. Let \tilde{A} be the generator for a Markov process in $E \times E$ giving a Markov coupling for A , that is, if (Z_1, Z_2) is a Markov process corresponding to \tilde{A} with initial distribution $\nu_1 \times \nu_2$, where $\nu_1, \nu_2 \in \mathcal{P}(E)$, then Z_i is a Markov process corresponding to A with initial distribution ν_i for $i = 1, 2$. Let $\{\tilde{\mu}_t, t \geq 0\}$ be a Fleming–Viot process with type space $E \times E$ and mutation operator \tilde{A} (and no recombination or selection). Then $\mu_t^{(1)}(\Gamma) = \tilde{\mu}_t(\Gamma \times E)$ and $\mu_t^{(2)}(\Gamma) = \tilde{\mu}_t(E \times \Gamma)$ define Fleming–Viot processes with type space E and mutation operator A . If the coupling given by \tilde{A} is successful, then there exists a random time $\tau < \infty$ a.s. such that $\tilde{\mu}_t\{(x, x) : x \in E\} = 1$ for all $t \geq \tau$. In particular, $\mu_t^{(1)} = \mu_t^{(2)}$ for all $t \geq \tau$, so the Fleming–Viot process with type space E and mutation operator A is strongly ergodic.*

The simplest example satisfying the hypotheses of the theorem is

$$(5.16) \quad (Af)(x) = \frac{1}{2}\theta \int_E (f(\xi) - f(x)) \nu_0(d\xi)$$

with

$$(5.17) \quad (\tilde{A}f)(x, y) = \frac{1}{2}\theta \int_E (f(\xi, \xi) - f(x, y)) \nu_0(d\xi),$$

where $\theta > 0$ and $\nu_0 \in \mathcal{P}(E)$. In this case the coupling inequality (5.15) gives the rate of convergence to equilibrium for the Fleming–Viot process; see (8.11) below.

Theorem 5.3 can be extended to models with recombination under a somewhat stronger assumption on the coupling \tilde{A} . See Ethier and Kurtz (1993b).

There does not seem to be a direct extension of Theorem 5.3 to models with selection. In particular, there does not seem to be a selection intensity function on the product space $E \times E$ for which both marginal processes are Fleming–Viot processes in $\mathcal{P}(E)$ with the desired mutation and selection. We can, however, define a selection intensity function on $E \times E$ for which one of the marginal processes has the desired properties. For $\sigma \in B_{\text{sym}}(E \times E)$, define $\tilde{\sigma}_i \in B_{\text{sym}}(E^2 \times E^2)$ for $i = 1, 2$ by $\tilde{\sigma}_i((x_1, x_2), (y_1, y_2)) = \sigma(x_i, y_i)$.

Let the coupled neutral model of Theorem 5.3 be defined on a probability space $(\Omega, \mathcal{F}, \mathbf{P})$, and let $\sigma \in B_{\text{sym}}(E \times E) \cap \mathcal{D}(A^{(2)})$. For $i = 1, 2$, define $\tilde{\sigma}_i$ as above, define \tilde{R}_t^i as in (3.31) using $\tilde{\sigma}_i$, and set $d\mathbf{Q}_i = \tilde{R}_t^i d\mathbf{P}$ on the σ -algebra generated by $\{\tilde{\mu}_s : 0 \leq s \leq t\}$. Since on any time interval $[0, t]$ the Radon–Nikodym derivatives are bounded below by a constant $\rho(t)$, we see that

$$(5.18) \quad \mathbf{Q}_i\{\mu_t^{(i)} \in \Gamma\} \geq \rho(t)\mathbf{P}\{\mu_t^{(i)} \in \Gamma\} \geq \rho(t)\mathbf{P}\{\mu_t^{(i)} \in \Gamma, \tau \leq t\}.$$

But the right-hand side of (5.18) does not depend on i , so if t is large enough that $\mathbf{P}\{\tau \leq t\} > 0$, we see that the distributions $\mathbf{Q}_1(\mu_t^{(1)})^{-1}$ and $\mathbf{Q}_2(\mu_t^{(2)})^{-1}$ cannot be mutually singular. It follows that the Fleming–Viot process with mutation operator A and selection intensity function σ can have at most one stationary distribution. If there exist $t > 0$ and $\varepsilon > 0$ such that $\mathbf{P}\{\tau \leq t\} \geq \varepsilon$ for all choices of the distribution of $\tilde{\mu}_0$, then a renewal argument gives the following theorem from Ethier and Kurtz (1993b).

THEOREM 5.4. *Suppose the assumptions of Theorem 5.3 hold. Let $\{\tilde{\mu}_t, t \geq 0\}$ be as in that theorem, and assume that there exist $t > 0$ and $\varepsilon > 0$ such that $\mathbf{P}\{\tau \leq t\} \geq \varepsilon$ for all choices of the initial distribution. Let $\sigma \in B_{\text{sym}}(E \times E) \cap \mathcal{D}(A^{(2)})$. Then the Fleming–Viot process with type space E , mutation operator A , and selection intensity function σ is strongly ergodic.*

6. An infinite particle system. Let E be compact. (Recall that if the desired type space is only locally compact, e.g., \mathbf{R}^d , then E can be taken to be its one-point compactification.) With reference to (3.21), observe that in the case of no recombination or selection,

$$(6.1) \quad (\mathcal{L}\varphi_f)(\mu) = \sum_{1 \leq i < j \leq n} (\langle \Phi_{ij}^{(n)} f, \mu^{n-1} \rangle - \langle f, \mu^n \rangle) + \langle A^{(n)} f, \mu^n \rangle = \langle Cf, \mu^n \rangle,$$

for all $f \in \mathcal{D}(A^{(n)})$, where

$$(6.2) \quad (Cf)(x_1, \dots, x_n) = \sum_{1 \leq i < j \leq n} \{f(\theta_{ij}(x_1, \dots, x_n)) - f(x_1, \dots, x_n)\} + (A^{(n)}f)(x_1, \dots, x_n),$$

$\theta_{ij}(x_1, \dots, x_n)$ being the element of E^n obtained from (x_1, \dots, x_n) by replacing the j th component by the i th.

We interpret C as an operator with domain in $B(E^\infty)$. It is clear that C is the generator for an E^∞ -valued process $X = (X_1, X_2, \dots)$ whose j th component (which we refer to as the particle at level j) evolves according to the mutation process until it “looks down” to level i for some $i < j$ and changes its value to the value on level i . This process was first considered by Dawson and Hochberg (1982), and it played a key role in their work on the support properties of the Fleming–Viot process with Brownian mutation. It was studied in depth in Donnelly and Kurtz (1993), and results from that paper are summarized here.

Let $\{S(t)\}$ denote the Feller semigroup defined on $C(E^\infty)$ corresponding to C . Then, viewing $C(E^n)$ as a closed subspace of $C(E^\infty)$, we note that $S(t) : C(E^n) \mapsto C(E^n)$ for all $t \geq 0$. The fact that (6.1) holds of course implies for each $\lambda > 0$ that

$$(6.3) \quad (\lambda - \mathcal{L})\varphi_f(\mu) = \langle (\lambda - C)f, \mu^n \rangle$$

for all $f \in \mathcal{D}(A^{(n)}) \cap C(E^n)$ and hence that

$$(6.4) \quad (\lambda - \mathcal{L})^{-1} \varphi_f(\mu) = \langle (\lambda - C)^{-1} f, \mu^n \rangle$$

for all $f \in C(E^n)$. This last identity ensures that

$$(6.5) \quad \mathbf{E}_\mu[\langle f, \mu_t^n \rangle] = \langle S(t)f, \mu^n \rangle = \mathbf{E}_{\mu^\infty}^X[f(X_1(t), \dots, X_n(t))]$$

for all $f \in C(E^n)$ and $t \geq 0$. Here \mathbf{E}_μ denotes the expectation for the Fleming–Viot process under the assumption that the initial state is μ , and $\mathbf{E}_{\mu^\infty}^X$ denotes the expectation for the particle system under the assumption that $X_1(0), X_2(0), \dots$ are i.i.d. with common distribution μ . Let $\nu \in \mathcal{P}(\mathcal{P}(E))$. By (6.5),

$$(6.6) \quad \int_{\mathcal{P}(E)} \mathbf{E}_\mu[\langle f, \mu_t^n \rangle] \nu(d\mu) = \int_{\mathcal{P}(E)} \mathbf{E}_{\mu^\infty}^X[f(X_1(t), \dots, X_n(t))] \nu(d\mu)$$

for all $f \in B(E^n)$ and $t \geq 0$. The left-hand side is just the expectation for a Fleming–Viot process with initial distribution ν , and the right-hand side is the expectation for the particle system under the assumption that $(X_1(0), X_2(0), \dots)$ is an exchangeable sequence with

$$(6.7) \quad \mathbf{P}\{X_1(0) \in \Gamma_1, \dots, X_n(0) \in \Gamma_n\} = \int_{\mathcal{P}(E)} \prod_{i=1}^n \mu(\Gamma_i) \nu(d\mu).$$

The identity (6.6) implies that

$$(6.8) \quad \mathbf{P}\{X_1(t) \in \Gamma_1, \dots, X_n(t) \in \Gamma_n\} = \int_{\mathcal{P}(E)} \prod_{i=1}^n \mu(\Gamma_i) \nu_t(d\mu)$$

for all $t \geq 0$, where ν_t is the distribution at time t of the Fleming–Viot process with initial distribution ν . Consequently, we see that if $(X_1(0), X_2(0), \dots)$ is an exchangeable sequence, then $(X_1(t), X_2(t), \dots)$ is an exchangeable sequence, and the corresponding de Finetti measure

$$(6.9) \quad \hat{\mu}_t = \lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n \delta_{X_i(t)}$$

has the same distribution as μ_t . In fact, as the next theorem states, the process $\{\hat{\mu}_t, t \geq 0\}$ is a version of the Fleming–Viot process.

THEOREM 6.1. *Let E be compact, and suppose that the closure of A generates a Feller semigroup on $C(E)$. Let $X = (X_1, X_2, \dots)$ be a Markov process in E^∞ with generator C and suppose that $(X_1(0), X_2(0), \dots)$ is exchangeable. Then, for each $t > 0$, $(X_1(t), X_2(t), \dots)$ is exchangeable, and the process given by the de Finetti measures (6.9) is a Fleming–Viot process with type space E and mutation operator A .*

Proof. Note that the process given by the first n components of X is itself a Markov process. In Donnelly and Kurtz (1993) it is shown that this E^n -valued process can be coupled to an E^n -valued process $Y^{(n)}$ with generator

$$(6.10) \quad \begin{aligned} &(\tilde{C}^n f)(x_1, \dots, x_n) \\ &= \frac{1}{2} \sum_{i \neq j} \{f(\theta_{ij}(x_1, \dots, x_n)) - f(x_1, \dots, x_n)\} + (A^{(n)} f)(x_1, \dots, x_n) \end{aligned}$$

in such a way that

$$(6.11) \quad \eta_t^{(n)} \equiv \frac{1}{n} \sum_{i=1}^n \delta_{Y_i^{(n)}(t)} = \frac{1}{n} \sum_{i=1}^n \delta_{X_i(t)}$$

for all $t \geq 0$. ($Y^{(n)}$ can be thought of as a variant of a Moran model in which mutation takes place continuously rather than only at birth/death events. Note that by the obvious symmetry of $Y^{(n)}$, this coupling also gives the exchangeability of $X(t)$.) It is easy to check that the sequence of empirical measure processes $\{\eta_t^{(n)}, t \geq 0\}$ converges to the Fleming–Viot process. \square

An explicit construction of the particle system can be given in terms of a collection of unit Poisson processes $\{N_{ij}, 1 \leq i < j < \infty\}$ where N_{ij} determines the times at which the j th level looks down to the i th level, and a collection of independent random mappings $U_{jk} : E \times [0, \infty) \mapsto E$ that determine the values at the j th level between the k th and $(k+1)$ th look-downs from the j th level. That is, for $x \in E$ and $j, k \geq 0$, $U_{jk}(x, \cdot)$ is a version of the mutation process starting from x , $X_1(t) = U_{10}(X_1(0), t)$ for all $t \geq 0$, $X_j(t) = U_{j0}(X_j(0), t)$ until the first look-down from level j , and if the k th look-down from the j th level occurs at time τ and the look-down is to level i , then up until the time of the $(k+1)$ th look-down from level j , $X_j(t) = U_{jk}(X_i(\tau), t - \tau)$.

If the mutation process is a diffusion, then the particle system can be obtained as the solution of an infinite system of stochastic differential equations. Let $\{N_{ij}\}$ be as above, and let $\{W_j\}$ be a sequence of independent Brownian motions which are independent of the sequence $\{N_{ij}\}$. Then we can take

$$(6.12) \quad \begin{aligned} X_j(t) = X_j(0) &+ \int_0^t \sigma(X_j(s)) dW_j(s) + \int_0^t b(X_j(s)) ds \\ &+ \sum_{1 \leq i < j} \int_0^t (X_i(s-) - X_j(s-)) dN_{ij}(s). \end{aligned}$$

Note that the solution of this system exists and is unique if, for example, σ and b are Lipschitz continuous.

If the mutation process has a stationary distribution, then we can assume that $X_1(t)$ is defined for all $-\infty < t < \infty$, and taking the processes N_{ij} to be unit Poisson point processes on $(-\infty, \infty)$ ($N_{ij}(a, b]$ will denote the number of points in the interval $(a, b]$), an analogue of the above construction can be carried out on the time interval $(-\infty, \infty)$ in which there is a look-down from level j to level i at each point in N_{ij} . Note that the resulting E^∞ -valued process will be stationary. If the stationary process X_1 is ergodic (in the sense that events defined in terms of X_1 that are invariant under a time shift must have probability zero or one), then X (and hence the corresponding Fleming–Viot process) is ergodic.

Assume that we are in the stationary setting described in the preceding paragraph. In this model, we can trace the ancestry of a particle by following the look-down process backward in time. For $s < t$, we define $a_j(s, t)$ to be the level of the ancestor at time s of the j th-level particle at time t . To be precise, for $s < t$, let $N_j(s, t] = \sum_{i:i < j} N_{ij}(s, t]$. Define $\gamma_j(t) = \sup\{u < t : N_j(u, t] > 0\}$ and let $\alpha_j(\gamma_j(t))$ be the index i such that $\gamma_j(t) \in N_{ij}$. Define $a_j(s, t) = j$ for $\gamma_j(t) \leq s < t$ and $a_j(s, t) = \alpha_j(\gamma_j(t))$ for $\gamma_{\alpha_j(\gamma_j(t))}(\gamma_j(t)) \leq s < \gamma_j(t)$, and extend the definition of $a_j(s, t)$ to all $s < t$ in the obvious manner.

Let $\Gamma_n(s, t) = \{a_j(s, t) : j = 1, \dots, n\}$ (allowing $n = \infty$). Then, letting $|\Gamma_n(s, t)|$ denote the cardinality of $\Gamma_n(s, t)$, it follows that for $s < t$, $|\Gamma_\infty(s, t)| < \infty$. In particular, $D_n(u) = |\Gamma_n(t - u, t)|$ is a pure death process with transition intensity $k(k - 1)/2$ from state k . If we define the equivalence relation R_u on $\{1, 2, \dots\}$ by setting $i \sim j$ if $a_i(t - u, t) = a_j(t - u, t)$, then $\{R_u, u \geq 0\}$ is Kingman's (1982b) coalescent.

For definiteness, fix $t = 0$ in the above construction. Define $\tau_1 = \inf\{u : D_\infty(u) = 1\}$. Then this construction determines an embedding of a tree in the particle system on the time interval $[-\tau_1, 0]$ whose branches are formed by the ancestral lines of the particles at time 0. The mutation processes determine the evolution of the types of the particles beginning with the type of the two particles at time $-\tau_1$ with descendants at time zero. (Note that one of the two particles will be X_1 .) This observation demonstrates that the genealogical tree with mutation considered by Donnelly and Tavaré (1987) can be embedded in the particle system.

This embedding of the genealogical tree in the particle system provides a powerful tool for studying Fleming-Viot processes. For example, Theorem 7.2 below can be proved by observing that, for pure-jump mutation operators, the genealogical structure implies that, except at points of discontinuity of a component X_i , $X_i = X_j$ for infinitely many j . This type of argument is also at the heart of the results of Dawson and Hochberg (1982) on the support properties of the Fleming-Viot process with Brownian mutation.

7. Bounded mutation operators. Here we consider Fleming-Viot processes with mutation operators A on $B(E)$ of the form

$$(7.1) \quad (Af)(x) = \frac{1}{2}\theta(x) \int_E (f(\xi) - f(x)) P(x, d\xi),$$

where $\theta \in B(E)$ is nonnegative and $P(x, d\xi)$ is a one-step transition function on $E \times B(E)$. (The factor $\frac{1}{2}$ is of course unnecessary but will be convenient later.)

THEOREM 7.1. *Let \mathcal{L} be the generator (3.20) and (3.21) for the Fleming-Viot process with type space E , mutation operator A as in (7.1), no recombination, and selection intensity function $\sigma \in B_{\text{sym}}(E^2)$.*

- (a) *Then the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} is well posed.*
- (b) *In the absence of selection, the closure of \mathcal{L} acting on*

$$(7.2) \quad \{\varphi_f \in B(\mathcal{P}(E)) : f \in B(E^n), n \geq 1\}$$

generates a strongly continuous positive conservative contraction semigroup on the closure of (7.2) in the sup norm on $B(\mathcal{P}(E))$.

- (c) *In the absence of selection, and assuming that E is compact, θ is continuous, and $P(x, d\xi)$ has the Feller property, the closure of \mathcal{L} restricted to*

$$(7.3) \quad \{\varphi_f \in C(\mathcal{P}(E)) : f \in C(E^n), n \geq 1\}$$

generates a Feller semigroup on $C(\mathcal{P}(E))$.

Proof. Part (c) follows from Theorem 3.4, and part (b) is proved similarly. This and the Girsanov transformation give existence in part (a), while uniqueness is a consequence of duality. \square

The main effect of assumption (7.1) is that the resulting Fleming-Viot process lives in $\mathcal{P}_a(E)$, the set of purely atomic Borel probability measures on E . This result

is due to Ethier and Kurtz (1986), (1987). It is also a consequence of the work of Shiga (1990).

THEOREM 7.2. *If $\{\mu_t, t \geq 0\}$ is a Fleming–Viot process as in Theorem 7.1, then*

$$(7.4) \quad \mathbf{P}\{\mu_t \in \mathcal{P}_a(E) \text{ for all } t > 0\} = 1.$$

If Π is a stationary distribution for such a Fleming–Viot process, then $\Pi(\mathcal{P}_a(E)) = 1$.

In fact this result also holds with recombination, but the simple proof of Ethier and Kurtz (1987) does not apply in that case. Donnelly and Kurtz (1993) have extended the theorem to general pure-jump mutation operators.

The next observation is frequently useful in applications. It is a consequence of Doob’s martingale inequality.

PROPOSITION 7.3. *Under the assumptions of Theorem 7.1, if $\{\mu_t, t \geq 0\}$ is a solution of the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} , then for each φ in (7.2),*

$$(7.5) \quad \varphi(\mu_t) - \int_0^t (\mathcal{L}\varphi)(\mu_s) ds$$

is a martingale with almost all sample paths continuous.

This shows that the sample paths of such a Fleming–Viot process are continuous in the weak atomic topology on $\mathcal{P}(E)$.

COROLLARY 7.4. *Under the assumptions of Theorem 7.1, if $\{\mu_t, t \geq 0\}$ is a solution of the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} , then almost all sample paths of $\{\mu_t, t \geq 0\}$ belong to $C_{(\mathcal{P}(E), \rho_a)}[0, \infty)$.*

Shiga (1990) strengthened this conclusion (except at time $t = 0$) considerably.

THEOREM 7.5. *Let E be locally compact, and assume the conditions of Theorem 7.1. If $\{\mu_t, t \geq 0\}$ is a solution of the $C_{\mathcal{P}(E)}[0, \infty)$ martingale problem for \mathcal{L} , then almost all sample paths of $\{\mu_t, t > 0\}$ are continuous in the total variation norm.*

Note that, if $\mu \in \mathcal{P}(E)$ is nonatomic and $\nu \in \mathcal{P}_a(E)$, then $\|\mu - \nu\|_{\text{var}} = 1$. This implies that continuity in the total variation norm cannot hold at time $t = 0$ unless $\mu_0 \in \mathcal{P}_a(E)$.

We conclude this section by discussing the stationary distribution of a Fleming–Viot process with a bounded mutation operator (and no recombination or selection). For simplicity, we assume that E is compact, θ in (7.1) is a positive constant, and $P(x, d\xi)$ has the Feller property. The following result is due to Ethier and Kurtz (1992) and has been used in the population genetics literature in connection with the model discussed in §9.5 below (Griffiths and Watterson (1990)).

THEOREM 7.6. *Let E be compact, let $\theta > 0$, and let $P(x, d\xi)$ be a one-step Feller transition function on $E \times \mathcal{B}(E)$ that is weakly ergodic in the sense that*

$$(7.6) \quad \lim_{t \rightarrow \infty} (e^{\theta(P-I)t/2} f)(x) = \langle f, \nu_0 \rangle, \quad f \in C(E), x \in E,$$

where $(Pf)(x) = \int_E f(\xi) P(x, d\xi)$ and $\nu_0 \in \mathcal{P}(E)$. Let $\Pi \in \mathcal{P}(\mathcal{P}(E))$ denote the unique stationary distribution of the Fleming–Viot process with type space E and mutation operator A defined by

$$(7.7) \quad (Af)(x) = \frac{1}{2}\theta \int_E (f(\xi) - f(x)) P(x, d\xi).$$

Define the Markov chain $\{X(\tau), \tau \in \mathbf{Z}_+\}$ in $E^2 \cup E^3 \cup \dots$ as follows. Let $X(0) = (\xi_0, \xi_0) \in E^2$, where ξ_0 is an E -valued random variable with distribution ν_0 . From

state $(x_1, \dots, x_n) \in E^n$, where $n \geq 2$, one of two types of transitions occurs. With probability $\theta/(n(n-1+\theta))$ a transition to state $(x_1, \dots, x_{i-1}, \xi_i, x_{i+1}, \dots, x_n) \in E^n$ occurs ($1 \leq i \leq n$), where ξ_i is distributed according to $P(x_i, d\xi)$. With probability $(n-1)/((n+1)n(n-1+\theta))$ a transition to state $(x_1, \dots, x_{j-1}, x_i, x_j, \dots, x_n) \in E^{n+1}$ occurs ($1 \leq i \leq n$, $1 \leq j \leq n+1$). Then, for each $n \geq 2$,

$$(7.8) \quad X(\tau_{n+1} - 1) \text{ has distribution } \int_{\mathcal{P}(E)} \mu^n(\cdot) \Pi(d\mu),$$

where τ_n denotes the hitting time of E^n . Moreover, the empirical measure determined by the n coordinates of $X(\tau_{n+1} - 1)$ converges almost surely as $n \rightarrow \infty$ to a $\mathcal{P}(E)$ -valued random variable with distribution Π .

The two types of transitions of X correspond to mutations and duplications, which is reminiscent of Hoppe's (1987) urn process. Equation (7.8) makes it very easy to simulate the n th moment measure of the stationary distribution Π , which can be interpreted as the distribution of a random sample of size n from μ , where the random measure μ is distributed according to Π . Except in the special case in which $P(x, d\xi)$ does not depend on x (treated in the next section), the explicit form of Π seems to be unknown. A continuous-time version of this Markov chain can be embedded in the particle system of §6, giving an extension of (7.8) to models with general mutation operators. See Donnelly and Kurtz (1993).

8. Reversibility. In this section we consider the special case of §7 in which the mutation operator A has the form

$$(8.1) \quad (Af)(x) = \frac{1}{2}\theta \int_E (f(\xi) - f(x)) \nu_0(d\xi),$$

where $\theta > 0$ and $\nu_0 \in \mathcal{P}(E)$. We assume for convenience that E is a compact metric space.

If we further assume that E is finite and the support of ν_0 is all of E , and if we identify $\mathcal{P}(E)$ with Δ_E (see (1.1)), then the resulting Fleming-Viot process has generator L as in (1.2), where

$$(8.2) \quad q_{ij} = \frac{1}{2}\theta_j \equiv \frac{1}{2}\theta\nu_0(\{j\}) > 0, \quad i, j \in E, \quad i \neq j.$$

In this case Wright (1949) discovered that there is a unique stationary distribution $\pi \in \mathcal{P}(\Delta_E)$, namely, the Dirichlet distribution with parameter $(\theta_i)_{i \in E}$, which has $(|E| - 1)$ -dimensional Lebesgue density proportional to $\prod_{i \in E} p_i^{\theta_i - 1}$. See Ethier and Kurtz (1981) for a proof.

To describe the stationary distribution (unique by Theorem 5.1) in general, we need to introduce Kingman's (1975) Poisson-Dirichlet distribution. Consider an inhomogeneous Poisson point process on $(0, \infty)$ with intensity function $\theta u^{-1}e^{-u}$ ($u > 0$). With probability 1, the points can be arranged in decreasing order $Z_1 > Z_2 > \dots$ and have a finite sum $Z = Z_1 + Z_2 + \dots$. We define the Poisson-Dirichlet distribution with parameter θ to be the distribution of $(Z_1/Z, Z_2/Z, \dots)$. In particular, it is concentrated on

$$(8.3) \quad \nabla_\infty = \left\{ p = (p_1, p_2, \dots) : p_1 \geq p_2 \geq \dots \geq 0, \sum_{i=1}^{\infty} p_i = 1 \right\},$$

which is topologized as a subset of the product space $[0, 1]^\infty$.

There is an alternative characterization that helps to explain the term “Poisson–Dirichlet” (Kingman (1975)). For each $n \geq 2$, let $(\rho_1^n, \dots, \rho_n^n)$ be $\Delta_{\{1, \dots, n\}}$ -valued with the symmetric Dirichlet distribution with parameter $p_n > 0$. Let $\rho_{(1)}^n \geq \dots \geq \rho_{(n)}^n$ denote the descending order statistics. If $n p_n \rightarrow \theta > 0$, then the distribution of $(\rho_{(1)}^n, \dots, \rho_{(n)}^n, 0, 0, \dots)$ converges weakly on ∇_∞ to the Poisson–Dirichlet distribution with parameter θ .

The following description of the stationary distribution is due to Ethier and Kurtz (1986, 1993a).

THEOREM 8.1. *The Fleming–Viot process with type space E and mutation operator A defined by (8.1) (where $\theta > 0$ and $\nu_0 \in \mathcal{P}(E)$), has a unique stationary distribution $\Pi_{\theta, \nu_0} \in \mathcal{P}(\mathcal{P}(E))$, which is given by*

$$(8.4) \quad \Pi_{\theta, \nu_0}(\cdot) = \mathbf{P} \left\{ \sum_{i=1}^{\infty} \rho_i \delta_{\xi_i} \in \cdot \right\},$$

where (ρ_1, ρ_2, \dots) has the Poisson–Dirichlet distribution with parameter θ , and ξ_1, ξ_2, \dots are i.i.d. ν_0 , independent of (ρ_1, ρ_2, \dots) .

Note that this conclusion is consistent with Theorem 7.2.

The following result of Shiga (1990) and Ethier (1990a) gives reversibility.

THEOREM 8.2. *The Fleming–Viot process of Theorem 8.1 is reversible with respect to Π_{θ, ν_0} . In other words, if $\{\mu_t, -\infty < t < \infty\}$ is a stationary Fleming–Viot process with type space and mutation operator as in Theorem 8.1, then*

$$(8.5) \quad \{\mu_t, -\infty < t < \infty\} \stackrel{\mathcal{D}}{=} \{\mu_{-t}, -\infty < t < \infty\}.$$

One might ask whether reversibility of Fleming–Viot processes holds more generally than for mutation operators A of the form (8.1) (assuming no recombination or selection). When E is finite, Shiga (personal communication) has shown that the answer to this question is negative. It seems reasonable to conjecture that the answer is negative in general.

We now state a recent result of Ethier and Griffiths (1993) giving the transition function for the Fleming–Viot process of Theorem 8.1. It generalizes the finite-dimensional results of Shimakura (1977, 1981) and Griffiths (1979). For each $n \geq 1$ define $\eta_n : E^n \mapsto \mathcal{P}(E)$ by

$$(8.6) \quad \eta_n(x_1, \dots, x_n) = n^{-1}(\delta_{x_1} + \dots + \delta_{x_n}).$$

Let $\{D_t, t \geq 0\}$ be the pure death process in $\mathbf{Z}_+ \cup \{\infty\}$ starting at ∞ with death rates

$$(8.7) \quad \lambda_n = n(n-1+\theta)/2, \quad n \geq 0,$$

(∞ is an entrance boundary) and define

$$(8.8) \quad d_n(t) = \mathbf{P}\{D_t = n\}, \quad n \geq 0, t > 0.$$

It can be shown (see Tavaré (1984)) that

$$(8.9) \quad d_n(t) = \begin{cases} 1 - \sum_{m=1}^{\infty} (2m-1+\theta)(m!)^{-1}(-1)^{m-1}\theta_{(m-1)}e^{-\lambda_m t} & \text{if } n = 0, \\ \sum_{m=n}^{\infty} (2m-1+\theta)(m!)^{-1}(-1)^{m-n}\binom{m}{n}(n+\theta)_{(m-1)}e^{-\lambda_m t} & \text{if } n \geq 1. \end{cases}$$

Here we use the notation $a_{(0)} = 1$ and $a_{(n)} = a(a+1)\cdots(a+n-1)$ for $n \geq 1$.

THEOREM 8.3. *The Fleming–Viot process of Theorem 8.1 has transition function $P(t, \mu, d\nu)$ given for each $t > 0$ and $\mu \in \mathcal{P}(E)$ by*

$$(8.10) \quad \begin{aligned} P(t, \mu, \cdot) &= d_0(t) \Pi_{\theta, \nu_0}(\cdot) \\ &\quad + \sum_{n=1}^{\infty} d_n(t) \int_{E^n} \mu^n(dx_1 \times \cdots \times dx_n) \Pi_{n+\theta, (n+\theta)^{-1}\{n\eta_n(x_1, \dots, x_n) + \theta\nu_0\}}(\cdot). \end{aligned}$$

In particular, the theorem shows that, for each $t > 0$ and $\mu \in \mathcal{P}(E)$, $P(t, \mu, \cdot)$ is a mixture of probability distributions of the form (8.4). This is of course consistent with Theorem 7.2.

Shiga (1990) proved strong ergodicity under these assumptions. The theorem allows one to say more.

COROLLARY 8.4. *Under the assumptions of Theorem 8.3 and for each $\mu \in \mathcal{P}(E)$,*

$$(8.11) \quad \|P(t, \mu, \cdot) - \Pi_{\theta, \nu_0}(\cdot)\|_{\text{var}} \leq 1 - d_0(t), \quad t > 0.$$

Moreover, equality holds in (8.11) if μ and ν_0 are mutually singular.

Tavaré (1984) has shown that $e^{-\lambda_1 t} \leq 1 - d_0(t) \leq (1 + \theta)e^{-\lambda_1 t}$ for all $t > 0$.

We conclude this section by considering the effect of selection on Theorems 8.1 and 8.2. These results are from Ethier and Kurtz (1993a), (1993b).

THEOREM 8.5. *Let $\sigma \in B_{\text{sym}}(E^2)$. Then $\Pi_{\theta, \nu_0}^\sigma \in \mathcal{P}(\mathcal{P}(E))$, defined for the appropriate constant C by*

$$(8.12) \quad \Pi_{\theta, \nu_0}^\sigma(d\mu) = C e^{\langle \sigma, \mu^2 \rangle} \Pi_{\theta, \nu_0}(d\mu),$$

is the unique stationary distribution for the Fleming–Viot process with type space E , mutation operator A defined by (8.1) (where $\theta > 0$ and $\nu_0 \in \mathcal{P}(E)$), and selection intensity function σ .

THEOREM 8.6. *The Fleming–Viot process of Theorem 8.5 is reversible with respect to $\Pi_{\theta, \nu_0}^\sigma$.*

The proof of reversibility is based on the reversibility-preserving transformation of Fukushima and Stroock (1986).

9. Examples. In this section we examine several Fleming–Viot processes of interest in population genetics. To provide a better understanding of the models, a number of proofs are included.

Handa (1990) and Vaillancourt (1990a), (1990b) have considered interacting systems of Fleming–Viot processes to study the effects of geographical structure. Although these processes do not strictly fit into the present framework and are therefore not discussed below, they are very much in the same spirit.

9.1. Continuous-state stepwise-mutation model. Here $E = \mathbf{R}^d$ and

$$(9.1.1) \quad A = \frac{1}{2} \theta \sum_{i=1}^d \frac{\partial^2}{\partial x_i^2}, \quad \mathcal{D}(A) = C_c^2(\mathbf{R}^d),$$

for some $\theta > 0$. The resulting Fleming–Viot process is the one originally studied by Fleming and Viot (1979) and extensively analyzed by Dawson and Hochberg (1982).

The discrete-state stepwise-mutation model (with $E = \mathbf{Z}^d$) is due to Ohta and Kimura (1973) and was studied by Shiga (1982).

We consider first the ergodic behavior of the process. The mutation process is d -dimensional Brownian motion (multiplied by a constant), so the ergodic theorems of §5 do not apply. Nevertheless, if we translate the random probability measure at time t by minus its empirical mean, convergence in distribution holds as $t \rightarrow \infty$. This extends a result of Dawson and Hochberg (1982) and is analogous to a result of Shiga (1982) for the discrete-state stepwise-mutation model. It has its origins in work of Moran (1975), (1976) and Kingman (1976).

The infinite particle system X discussed in §6 provides an alternative approach to this result. Centering each component of X by the first component X_1 instead of by the empirical mean, the resulting process $\tilde{X} = (0, X_2 - X_1, X_3 - X_1, \dots)$ is easily seen to be asymptotically stationary. See Donnelly and Kurtz (1993) for details.

To prove the theorem, we first need a lemma.

LEMMA 9.1.1. *Let $\{\nu_n\}$ be a sequence of $\mathcal{P}(\mathbf{R}^d)$ -valued random variables such that, for each $n \geq 1$ and $m \geq 1$, $\mathbf{E}[\int_{\mathbf{R}^d} |x|^m \nu_n(dx)] < \infty$. If*

$$(9.1.2) \quad \lim_{n \rightarrow \infty} \mathbf{E} \left[\int_{\mathbf{R}^d} x^{\alpha^1} \nu_n(dx) \cdots \int_{\mathbf{R}^d} x^{\alpha^k} \nu_n(dx) \right] \equiv r_k(\alpha^1, \dots, \alpha^k)$$

exists for all $k \geq 1$ and $\alpha^1, \dots, \alpha^k \in (\mathbf{Z}_+)^d$, where $x^\alpha = x_1^{\alpha^1} \cdots x_d^{\alpha^d}$, and if

$$(9.1.3) \quad \sup_{m \geq 1} \max_{1 \leq i \leq d} m^{-1} r_1(2m\varepsilon^i)^{1/(2m)} < \infty,$$

where $\varepsilon^i = (\delta_{i1}, \dots, \delta_{id})$, then there exists a $\mathcal{P}(\mathbf{R}^d)$ -valued random variable ν such that ν_n converges in distribution to ν as $n \rightarrow \infty$.

Proof. By (9.1.2) with $k = 1$, $\{\mathbf{E}[\nu_n(\cdot)]\}$ is tight, and hence tightness (and therefore relative compactness) of the sequence $\mathbf{P}\{\nu_n \in \cdot\}$ follows. Any limit point Π of this sequence has the property that its k th moment measure $\int_{(\mathbf{R}^d)^k} \mu^k(\cdot) \Pi(d\mu)$ has moments $r_k(\alpha^1, \dots, \alpha^k)$. By (9.1.3), these moment measures are uniquely determined, and consequently Π is uniquely determined. This implies that $\mathbf{P}\{\nu_n \in \cdot\} \Rightarrow \Pi$. \square

THEOREM 9.1.2. *Let $\{\mu_t, t \geq 0\}$ be a Fleming–Viot process with type space \mathbf{R}^d and mutation operator (9.1.1), and suppose that $\mathbf{E}[\int_{\mathbf{R}^d} |x|^m \mu_0(dx)] < \infty$ for each $m \geq 1$. Then*

$$(9.1.4) \quad \mathbf{E} \left[\sup_{0 \leq t \leq T} \int_{\mathbf{R}^d} |x|^m \mu_t(dx) \right] < \infty$$

for all $T > 0$ and $m \geq 1$, so, with probability 1, the empirical mean process

$$(9.1.5) \quad x(t) = \int_{\mathbf{R}^d} x \mu_t(dx), \quad t \geq 0,$$

exists and has continuous sample paths. Let $\{\mu_t^, t \geq 0\}$ denote the centered process, defined by*

$$(9.1.6) \quad \mu_t^*(\cdot) = \mu_t(\cdot + x(t)).$$

Then there exists $\Pi \in \mathcal{P}(\mathcal{P}(\mathbf{R}^d))$ not depending on μ_0 such that

$$(9.1.7) \quad \lim_{t \rightarrow \infty} \mathbf{E}[\varphi(\mu_t^*)] = \langle \varphi, \Pi \rangle, \quad \varphi \in \overline{C}(\mathcal{P}(\mathbf{R}^d)).$$

Proof. By Theorem 3.1 (with a slight change in notation),

$$(9.1.8) \quad \mathbf{E}[\langle f, \mu_t^l \rangle] = \mathbf{E}[\langle Y(t), \mu_0^{N(t)} \rangle]$$

for all $l \geq 1$, $f \in \overline{C}((\mathbf{R}^d)^l)$, and $t \geq 0$, where

$$(9.1.9) \quad Y(t) = T_k \left(t - \sum_{i=k+1}^l \Lambda_i \right) \Gamma_{k+1} \cdots \Gamma_{l-1} T_{l-1}(\Lambda_{l-1}) \Gamma_l T_l(\Lambda_l) f$$

and $N(t) = k \quad \text{if} \quad \sum_{i=k+1}^l \Lambda_i \leq t < \sum_{i=k}^l \Lambda_i, \quad 1 \leq k \leq l.$

Here $\Lambda_l, \dots, \Lambda_2$ are independent exponential random variables with $\mathbf{E}[\Lambda_k] = 1/\binom{k}{2}$ and $\Lambda_1 \equiv \infty$,

$$(9.1.10) \quad T_k(t)f(x) = (2\pi\theta t)^{-kd/2} \int_{(\mathbf{R}^d)^k} f(y) e^{-|y-x|^2/(2\theta t)} dy,$$

and $\Gamma_l, \dots, \Gamma_2$ are independent random operators with $\Gamma_k = \Phi_{ij}^{(k)}$ with probability $1/\binom{k}{2}$, $1 \leq i < j \leq k$. Furthermore, $\Lambda_l, \dots, \Lambda_2, \Gamma_l, \dots, \Gamma_2$, and μ_0 are independent.

In fact, we claim that (9.1.8) holds (with both sides finite) for all $l \geq 1$, $f \in C((\mathbf{R}^d)^l)$ with polynomial growth, and $t \geq 0$. Indeed, if we define $f_{m,k}$ on $(\mathbf{R}^d)^k$ for $m, k \geq 1$ by

$$(9.1.11) \quad f_{m,k}(x^1, \dots, x^k) = \left(1 + \sum_{i=1}^k |x^i|^2 \right)^m, \quad x^1, \dots, x^k \in \mathbf{R}^d,$$

then straightforward estimates give

$$(9.1.12) \quad T_k(t)f_{m,k} \leq C_{m,k}(t)f_{m,k} \quad \text{and} \quad \Gamma_k f_{m,k} \leq 2^m f_{m,k-1},$$

where $C_{m,k}(t) = 2^{2m-1}(1 + (kd\theta/2)^m(2m)!(m!)^{-1}t^m)$. Therefore,

$$(9.1.13) \quad |Y(t)| \leq 2^{(l-k)m} C_{m,l}(\Lambda_l) \cdots C_{m,k+1}(\Lambda_{k+1}) C_{m,k} \left(t - \sum_{i=k+1}^l \Lambda_i \right) f_{m,k}$$

if $|Y(0)| \leq f_{m,l}, \quad \sum_{i=k+1}^l \Lambda_i \leq t < \sum_{i=k}^l \Lambda_i, \quad 1 \leq k \leq l.$

Since exponential random variables have all moments finite, this implies the claimed assertion. Doob's martingale inequality applied to the continuous martingale

$$(9.1.14) \quad M_t^\varepsilon \equiv \langle f_{m,1}/(1 + \varepsilon f_{m,1}), \mu_t \rangle - \int_0^t \langle A[f_{m,1}/(1 + \varepsilon f_{m,1})], \mu_s \rangle ds,$$

leads to (9.1.4).

Now, given $\alpha \in (\mathbf{Z}_+)^d$, define $g_\alpha \in C((\mathbf{R}^d)^{|\alpha|+1})$ by

$$(9.1.15) \quad g_\alpha(y^0, y^1, \dots, y^{|\alpha|}) = \prod_{i=1}^d \prod_{j=\alpha_1+\dots+\alpha_{i-1}+1}^{\alpha_1+\dots+\alpha_i} (y_i^0 - y_i^j),$$

and note that g_α is translation invariant in the sense that

$$(9.1.16) \quad g_\alpha(y^0 + z, y^1 + z, \dots, y^{|\alpha|} + z) = g_\alpha(y^0, y^1, \dots, y^{|\alpha|})$$

for all $y^0, \dots, y^{|\alpha|}, z \in \mathbf{R}^d$. Since translation invariance is preserved by the semigroup (9.1.10) and by the operators $\Phi_{ij}^{(k)}$, the dual process $\{Y_\alpha(t), t \geq 0\}$ with $Y_\alpha(0) = g_\alpha$ is translation invariant valued. Let $\tau = \Lambda_{|\alpha|+1} + \dots + \Lambda_2$. Then $Y_\alpha(\tau)$ is a (random) translation invariant function of one variable ($x \in \mathbf{R}^d$), hence constant in x . Moreover,

$$(9.1.17) \quad \mathbf{E} \left[\int_{\mathbf{R}^d} x^\alpha \mu_t^*(dx) \right] = \mathbf{E}[\langle g_\alpha, \mu_t^{|\alpha|+1} \rangle] = \mathbf{E}[\langle Y_\alpha(t), \mu_0^{N(t)} \rangle] \\ \rightarrow \mathbf{E}[\langle Y_\alpha(\tau), \mu_0 \rangle] = \mathbf{E}[Y_\alpha(\tau)(0)]$$

as $t \rightarrow \infty$, where the limit is justified using (9.1.13). This gives (9.1.2) (with $\nu_n = \mu_{t_n}^*$) for $k = 1$, and the general case is similar. Since

$$(9.1.18) \quad \mathbf{E} \left[\int_{\mathbf{R}^d} x_i^{2m} \mu_t^*(dx) \right] = \mathbf{E} \left[\int_{\mathbf{R}^d} (x_i - x_i(t))^{2m} \mu_t(dx) \right] \\ \leq \mathbf{E} \left[\int_{\mathbf{R}^d} \int_{\mathbf{R}^d} (x_i - y_i)^{2m} \mu_t(dx) \mu_t(dy) \right] \\ = \mathbf{E}[\langle Y(t), \mu_0^{N(t)} \rangle] \\ \rightarrow \mathbf{E}[Y(\tau)(0)] \\ = \int_0^\infty e^{-t} \mathbf{E}[(B_1(t) - B_2(t))^{2m}] dt \\ = \theta^m (2m)!$$

for $i = 1, \dots, d$, where τ is exponential with parameter 1 and B_1 and B_2 are independent one-dimensional Brownian motions with variance parameter θ , (9.1.3) holds as well, and so the result follows from Lemma 9.1.1. \square

The most striking results about this process concern its sample path behavior. Here is a small part of what is known. The first conclusion is due to Konno and Shiga (1988) and Reimers (1989) and the second is due to Dawson and Hochberg (1982) and Reimers (1993); see also Shiga (1990).

THEOREM 9.1.3. *Let $\{\mu_t, t \geq 0\}$ be a Fleming–Viot process with type space \mathbf{R}^d and mutation operator (9.1.1).*

(a) *If $d = 1$, then, with probability 1, μ_t is absolutely continuous with respect to Lebesgue measure on \mathbf{R} for all $t > 0$ and its density is jointly continuous in t and x .*

(b) *If $d \geq 2$, then, with probability 1, μ_t is singular with respect to Lebesgue measure on \mathbf{R}^d for all $t > 0$.*

9.2. Infinitely-many-neutral-alleles model. Here $E = S$, which is assumed to be a compact metric space, and A is given by

$$(9.2.1) \quad (Af)(x) = \frac{1}{2}\theta \int_S (f(\xi) - f(x)) P(x, d\xi),$$

where $\theta > 0$ and $P(x, d\xi)$ is a one-step Feller transition function on $S \times \mathcal{B}(S)$ satisfying

$$(9.2.2) \quad P(x, \{\xi\}) = 0, \quad x, \xi \in S.$$

In other words, mutations occur at rate $\frac{1}{2}\theta$, and $P(x, \cdot)$ is the distribution of the allelic type of a mutant offspring of a type x parent. The condition (9.2.2) models the basic assumption that every mutant is of a new type.

The model is due to Kimura and Crow (1964); see Crow (1989) for a historical survey. Kingman's (1975) introduction of the Poisson-Dirichlet distribution led Waterson (1976) to formulate the model as the limit of a sequence of finite-dimensional diffusions. Ethier and Kurtz (1981) characterized the limiting process in

$$(9.2.3) \quad \bar{\nabla}_\infty = \left\{ p = (p_1, p_2, \dots) : p_1 \geq p_2 \geq \dots \geq 0, \sum_{i=1}^{\infty} p_i \leq 1 \right\}$$

and subsequently (Ethier and Kurtz (1986), (1987)) reformulated the model as a Fleming-Viot process.

The process in $\bar{\nabla}_\infty$ is characterized in terms of the generator

$$(9.2.4) \quad G = \frac{1}{2} \sum_{i,j=1}^{\infty} p_i (\delta_{ij} - p_j) \frac{\partial^2}{\partial p_i \partial p_j} - \frac{1}{2} \theta \sum_{i=1}^{\infty} p_i \frac{\partial}{\partial p_i}$$

acting on $\mathcal{D}(G) =$ subalgebra of $C(\bar{\nabla}_\infty)$ generated by $1, \varphi_2, \varphi_3, \dots$, where $\varphi_m \in C(\bar{\nabla}_\infty)$ is defined for $m \geq 2$ by $\varphi_m(p) = \sum_{i=1}^{\infty} p_i^m$. (Sums in (9.2.4) are evaluated on ∇_∞ (see (8.3)) and extended to $\bar{\nabla}_\infty$ by continuity.) It is known (Ethier and Kurtz (1981)) that this process has a unique stationary distribution, namely, the Poisson-Dirichlet distribution with parameter θ . (In fact, it has a transition density; see Griffiths (1979) and Ethier (1992b).)

Define $\gamma : \mathcal{P}(S) \mapsto \bar{\nabla}_\infty$ by letting $\gamma(\mu) = (p_1, p_2, \dots)$ if p_i is the size (or mass) of the i th largest atom of μ (or 0 if μ has fewer than i atoms) for each $i \geq 1$, and note that $\gamma(\mathcal{P}_a(S)) = \nabla_\infty$.

THEOREM 9.2.1. *Let $\{\mu_t, t \geq 0\}$ be a Fleming-Viot process with type space S and mutation operator A given by (9.2.1), where $\theta > 0$ and $P(x, d\xi)$ is a one-step Feller transition function on $S \times \mathcal{B}(S)$ satisfying (9.2.2). Then $\{\gamma(\mu_t), t \geq 0\}$ solves the $C_{\bar{\nabla}_\infty}[0, \infty)$ martingale problem for G .*

Proof. Let $k \geq 1$, $m_1, \dots, m_k \geq 2$, and $m = m_1 + \dots + m_k$. Define $f \in B(S^m)$ to be the indicator function of the set of $(x_1, \dots, x_m) \in S^m$ for which $x_1 = \dots = x_{m_1}$, $x_{m_1+1} = \dots = x_{m_1+m_2}$, \dots , $x_{m_1+\dots+m_{k-1}+1} = \dots = x_m$. Then

$$(9.2.5) \quad F(\mu) \equiv \langle f, \mu^m \rangle = \varphi_{m_1}(\gamma(\mu)) \cdots \varphi_{m_k}(\gamma(\mu))$$

and

$$(9.2.6) \quad \begin{aligned} (\mathcal{L}F)(\mu) &= \sum_{i=1}^k \binom{m_i}{2} \varphi_{m_i-1}(\gamma(\mu)) \prod_{l:l \neq i} \varphi_{m_l}(\gamma(\mu)) \\ &\quad + \sum_{1 \leq i < j \leq k} m_i m_j \varphi_{m_i+m_j-1}(\gamma(\mu)) \prod_{l:l \neq i,j} \varphi_{m_l}(\gamma(\mu)) \\ &\quad - \frac{1}{2} m(m-1+\theta) \varphi_{m_1}(\gamma(\mu)) \cdots \varphi_{m_k}(\gamma(\mu)) \\ &= G(\varphi_{m_1} \cdots \varphi_{m_k})(\gamma(\mu)) \end{aligned}$$

for all $\mu \in \mathcal{P}(S)$, where $\varphi_1 \equiv 1$, and the result follows using Proposition 7.3. \square

Both $\{\mu_t, t \geq 0\}$ and $\{\gamma(\mu_t), t \geq 0\}$ are referred to as the *infinitely-many-neutral-alleles diffusion model*; for obvious reasons, the former is sometimes called the *labeled model*, whereas the latter is known as the *unlabeled model*.

A related diffusion process assumes values in

$$(9.2.7) \quad \bar{\Delta}_\infty = \left\{ z = (z_1, z_2, \dots) : z_1 \geq 0, z_2 \geq 0, \dots, \sum_{i=1}^{\infty} z_i \leq 1 \right\}.$$

It was characterized by Ethier (1981) in terms of the generator

$$(9.2.8) \quad \Omega = \frac{1}{2} \sum_{i,j=1}^{\infty} z_i (\delta_{ij} - z_j) \frac{\partial^2}{\partial z_i \partial z_j} - \frac{1}{2} \theta \sum_{i=1}^{\infty} z_i \frac{\partial}{\partial z_i}$$

acting on $\mathcal{D}(\Omega) = \{f \in C^2(\bar{\Delta}_\infty) : f \text{ depends on only finitely many coordinates}\}$. To interpret this process, we define $\varphi : \mathcal{P}(S) \times \mathcal{P}(S) \mapsto \bar{\Delta}_\infty$ by letting $\varphi(\mu, \nu) = (z_1, z_2, \dots)$ if z_i is the mass given by μ to the i th largest atom of ν (or 0 if ν has fewer than i atoms) for each $i \geq 1$. (Technical note: There is an ambiguity in the definition if ν has two or more atoms of the same size. To overcome this, assume that S is totally ordered by $<$ and that $\{(x_1, x_2) \in S^2 : x_1 < x_2\}$ is a Borel set. The atoms of the same size can then be ordered according to $<$, and the mapping φ is Borel measurable.) The following result is a slight extension of a result of Ethier (1990a).

THEOREM 9.2.2. *With $\{\mu_t, t \geq 0\}$ as in Theorem 9.2.1, $\{\varphi(\mu_t, \mu_0), t \geq 0\}$ solves the $C_{\bar{\Delta}_\infty}[0, \infty)$ martingale problem for Ω .*

Note that the i th coordinate of $\varphi(\mu_t, \mu_0)$ is the frequency at time t of the allele that is i th most frequent at time 0. Thus, this process keeps track only of the frequencies of the alleles present at time 0 and ignores new mutants. In particular, $\mathbf{E}[\sum_{i=1}^{\infty} \varphi_i(\mu_t, \mu_0)] \leq e^{-\theta t/2} < 1$ for all $t > 0$.

Now let us define $P : C(S) \mapsto C(S)$ by $(Pf)(x) = \int_S f(\xi) P(x, d\xi)$ and assume that there exists $\nu_0 \in \mathcal{P}(S)$ such that

$$(9.2.9) \quad \lim_{t \rightarrow \infty} (e^{\theta(P-I)t/2} f)(x) = \langle f, \nu_0 \rangle, \quad f \in C(S), x \in S.$$

THEOREM 9.2.3. *The Fleming–Viot process with type space S and mutation operator A given by (9.2.1), where $\theta > 0$ and $P(x, d\xi)$ is a one-step Feller transition function on $S \times \mathcal{B}(S)$ satisfying (9.2.2) and (9.2.9), is weakly ergodic and has a unique stationary distribution $\Pi \in \mathcal{P}(\mathcal{P}(S))$. Moreover, the Π -distribution of γ is precisely the Poisson–Dirichlet distribution with parameter θ . Let $k \geq 1$, $\mathbf{n} = (n_1, \dots, n_k) \in \mathbf{N}^k$, and $n = n_1 + \dots + n_k$, and define*

$$(9.2.10) \quad \Gamma_{\mathbf{n}} = \{(x_1, \dots, x_n) \in S^n : \text{there exist distinct } y_1, \dots, y_k \in S \text{ such that } |\{1 \leq i \leq n : x_i = y_j\}| = n_j \text{ for } j = 1, \dots, k\}.$$

Then the Ewens (1972) sampling formula holds, that is,

$$(9.2.11) \quad \int_{\mathcal{P}(S)} \mu^n(\Gamma_{\mathbf{n}}) \Pi(d\mu) = \frac{n!}{n_1 \cdots n_k a_1! \cdots a_n!} \frac{\theta^{k-1}}{(1+\theta) \cdots (n-1+\theta)},$$

where $a_i = |\{1 \leq j \leq k : n_j = i\}|$ for $i = 1, \dots, n$.

Proof. The first assertion follows from Theorem 5.2. Let $k \geq 1$, $m_1, \dots, m_k \geq 2$, and $m = m_1 + \dots + m_k$, and define $F \in B(\mathcal{P}(S))$ as in (9.2.5). By (9.2.6),

$$(9.2.12) \quad 0 = \int_{\mathcal{P}(S)} (\mathcal{L}F)(\mu) \Pi(d\mu) = \int_{\overline{\nabla}_\infty} G(\varphi_{m_1} \cdots \varphi_{m_k}) d\Pi \gamma^{-1},$$

and this gives the second assertion. The last assertion is a property of the Poisson-Dirichlet distribution (see, e.g., Watterson (1976)). \square

We should emphasize that the results of this subsection rely on (9.2.2); the assumption (8.1) (and in particular reversibility) is not needed.

9.3. Infinitely-many-neutral-alleles diffusion model with ages. Here S , θ , and $P(x, d\xi)$ are as in §9.2, $E = S \times [0, \infty]$, and

$$(9.3.1) \quad (Af)(x, a) = \left(\frac{\partial}{\partial a} f \right)(x, a) + \frac{1}{2} \theta \int_S (f(\xi, 0) - f(x, a)) P(x, d\xi)$$

with $\mathcal{D}(A) = C^{0,1}(S \times [0, \infty])$. We associate an age with each allele represented in the population, and we take the type space E to be the set of all ordered pairs of alleles and ages. Again, mutations occur with intensity $\frac{1}{2}\theta$ and according to $P(x, d\xi)$, and new mutants initially have age 0. Ages increase deterministically with time at rate 1.

Ages of alleles have been studied by several authors, including Watterson and Guess (1977), Kelly (1979), Donnelly (1986), Donnelly and Tavaré (1986), (1987), and Hoppe (1987). The formulation as a Fleming-Viot process is from Ethier (1990a).

The mutation operator (9.3.1) is unbounded, so Theorem 7.2 does not apply. Nevertheless, its conclusion is valid here; in fact, we can say more. Let

$$(9.3.2) \quad \begin{aligned} \mathcal{P}_a^0(S \times [0, \infty]) = \{ \mu \in \mathcal{P}_a(S \times [0, \infty]) : \mu(S \times \{\infty\}) = 0, \\ \mu^2(\{((x_1, a_1), (x_2, a_2)) : (x_1 = x_2, a_1 \neq a_2) \text{ or } \\ (x_1 \neq x_2, a_1 = a_2)\}) = 0 \} \end{aligned}$$

The extra conditions mean that no allele has infinite age, each allele has only one age, and no two alleles have the same age.

LEMMA 9.3.1. *Let $\{\mu_t, t \geq 0\}$ be a Fleming-Viot process with type space $S \times [0, \infty]$ and mutation operator A given by (9.3.1), where $\theta > 0$ and $P(x, d\xi)$ is a Feller transition function satisfying (9.2.2), and suppose that $\mathbf{P}\{\mu_0 \in \mathcal{P}_a^0(S \times [0, \infty])\} = 1$. Then*

$$(9.3.3) \quad \mathbf{P}\{\mu_t \in \mathcal{P}_a^0(S \times [0, \infty]) \text{ for all } t \geq 0\} = 1.$$

We now assume a slightly stronger condition than (9.2.9), namely,

$$(9.3.4) \quad \lim_{n \rightarrow \infty} \int_S f(\xi) P^n(x, d\xi) = \langle f, \nu_0 \rangle, \quad f \in C(S), \quad x \in S,$$

LEMMA 9.3.2. *Assuming (9.3.4), the Fleming-Viot process of Lemma 9.3.1 is weakly ergodic and has a unique stationary distribution $\Pi \in \mathcal{P}(\mathcal{P}(S \times [0, \infty]))$. Also, $\Pi(\mathcal{P}_a^0(S \times [0, \infty])) = 1$.*

The Ewens sampling formula (9.2.12) was generalized to age-ordered samples by Donnelly and Tavaré (1986). Ethier (1990a) rederived the Donnelly-Tavaré sampling formula in the present framework.

THEOREM 9.3.3. *Let $k \geq 1$, $\mathbf{n} = (n_1, \dots, n_k) \in \mathbf{N}^k$, and $n = n_1 + \dots + n_k$, and define*

$$(9.3.5) \quad \Gamma_{\mathbf{n}}^* = \{((x_1, a_1), \dots, (x_n, a_n)) \in (S \times [0, \infty])^n : \\ \text{there exist distinct } y_1, \dots, y_k \in S \text{ and } 0 < \alpha_1 < \dots < \alpha_k < \infty \\ \text{such that } |\{1 \leq i \leq n : (x_i, a_i) = (y_j, \alpha_j)\}| = n_j \text{ for } j = 1, \dots, k\}.$$

Then, under the assumptions of Lemma 9.3.2,

$$(9.3.6) \quad \int_{\mathcal{P}(S \times [0, \infty])} \mu^n(\Gamma_{\mathbf{n}}^*) \Pi(d\mu) \\ = \frac{n!}{n_1(n_1 + n_2) \cdots (n_1 + \dots + n_k)} \frac{\theta^{k-1}}{(1 + \theta) \cdots (n - 1 + \theta)}.$$

Note that $\Gamma_{\mathbf{n}}^*$ is the set of all ordered samples of size n containing k alleles, of which the youngest has n_1 representatives, the second youngest has n_2 representatives, and so on.

We now consider a second way to study the ages of the alleles in the infinitely-many-neutral-alleles diffusion model. It is based on the sample paths of the Fleming–Viot process of §9.2, except that we require reversibility. The following lemma is from Ethier (1990a).

LEMMA 9.3.4. *Let $\{\mu_t, -\infty < t < \infty\}$ be a stationary Fleming–Viot process with type space S and mutation operator*

$$(9.3.7) \quad (Af)(x) = \frac{1}{2}\theta \int_S (f(\xi) - f(x)) \nu_0(d\xi),$$

where $\theta > 0$ and $\nu_0 \in \mathcal{P}(S)$ is nonatomic. Recall the notation in Theorem 9.2.2 and define

$$(9.3.8) \quad X^+(t) = \varphi(\mu_t, \mu_0) \quad \text{and} \quad X^-(t) = \varphi(\mu_{-t}, \mu_0), \quad t \geq 0.$$

Then almost all sample paths of X^+ and X^- belong to $C_{\overline{\Delta}_\infty}[0, \infty)$, and X^+ and X^- induce the same distribution on $C_{\overline{\Delta}_\infty}[0, \infty)$.

Theorem 9.2.2 shows how X^+ (and therefore X^-) evolves; and Theorem 9.2.3 implies that $X^+(0) \equiv X^-(0)$ has the Poisson–Dirichlet distribution with parameter θ . The proof of Lemma 9.3.4 is essentially immediate from the reversibility of $\{\mu_t, -\infty < t < \infty\}$ (Theorem 8.2).

For each $i \geq 1$, define $\tau_i : C_{\overline{\Delta}_\infty}[0, \infty) \mapsto [0, \infty]$ by $\tau_i(x) = \inf\{t \geq 0 : x_i(t) = 0\}$, where $\inf \emptyset = \infty$.

THEOREM 9.3.5. *Let X^- be as in Lemma 9.3.4 and let U be an independent uniform $[0, 1)$ random variable. Define the positive-integer-valued random variables α and β by*

$$(9.3.9) \quad \alpha = i \quad \text{if} \quad \tau_i(X^-) > \tau_j(X^-) \text{ for all } j \in \mathbf{N} - \{i\}$$

and

$$(9.3.10) \quad \beta = i \quad \text{if} \quad \sum_{j=1}^{i-1} X_j^-(0) \leq U < \sum_{j=1}^i X_j^-(0);$$

both are defined on an event of probability 1. Then

$$(9.3.11) \quad X_{\alpha}^{-}(0) \stackrel{\mathcal{D}}{=} X_{\beta}^{-}(0)$$

and the common distribution is the $\text{beta}(1, \theta)$ distribution.

Remark. (9.3.11) says that the frequency of the oldest allele at time 0 in the stationary infinitely-many-neutral-alleles diffusion model is distributed as the frequency of a randomly chosen allele at time 0.

Proof. The assertion (9.3.11) follows from the calculation

$$\begin{aligned} (9.3.12) \quad & \mathbf{P}\{\alpha = i \mid X^{-}(0)\} \\ &= \mathbf{P}\{\tau_i(X^{-}) \geq \sup_{j:j \neq i} \tau_j(X^{-}) \mid X^{-}(0)\} \\ &= \mathbf{P}\left\{\tau_1\left(X_i^{-}, \sum_{j:j \neq i} X_j^{-}, 0, 0, \dots\right) \geq \tau_2\left(X_i^{-}, \sum_{j:j \neq i} X_j^{-}, 0, 0, \dots\right) \mid X^{-}(0)\right\} \\ &= X_i^{-}(0) \\ &= \mathbf{P}\{\beta = i \mid X^{-}(0)\}, \end{aligned}$$

where the third equality uses Theorem 9.2.2, Lemma 9.3.4, and the observation that the function $z_1/(z_1 + z_2)$ is harmonic for Ω . Actually, this function has a singularity at $(0, 0, \dots)$, so to make the argument precise and to verify the first equality in (9.3.12), one must check that if Z is a solution of the $C_{\bar{\Delta}_{\infty}}^{-}[0, \infty)$ martingale problem for Ω starting at $z \in \bar{\Delta}_{\infty}$, and if $z_1 + z_2 > 0$, then $\mathbf{P}\{\tau_1(Z) = \tau_2(Z)\} = 0$. See Ethier (1990a) for details; alternatively, Shiga (personal communication) has pointed out that this follows from his representation (Shiga (1990)) of the neutral diffusion model in population genetics as a normalized time-changed continuous-state branching diffusion.

As for the distribution of (9.3.11), let V have the $\text{beta}(1, \theta)$ distribution. Then, for each $k \geq 1$,

$$\begin{aligned} (9.3.13) \quad \mathbf{E}[X_{\beta}^{-}(0)^k] &= \mathbf{E}\left[\sum_{i=1}^{\infty} X_i^{-}(0)^k \mathbf{P}\{\beta = i \mid X^{-}(0)\}\right] \\ &= \mathbf{E}\left[\sum_{i=1}^{\infty} X_i^{-}(0)^{k+1}\right] = \frac{k!}{(1 + \theta) \cdots (k + \theta)} = \mathbf{E}[V^k], \end{aligned}$$

where the third equality uses the Ewens sampling formula, and the result follows. \square

Theorem 9.3.5 is a special case of a result derived heuristically by Griffiths (unpublished) and subsequently established by Ethier (1990b) (see Sawyer (1977), Donnelly and Tavaré (1986), Hoppe (1987), and Donnelly and Joyce (1991) for closely related results). The general result says that the frequencies of the oldest, second-oldest, third-oldest, \dots alleles in the stationary infinitely-many-neutral-alleles diffusion model are distributed as the coordinates of the so-called size-biased Poisson–Dirichlet distribution with parameter θ , which in turn are distributed as $Z_1, (1 - Z_1)Z_2, (1 - Z_1)(1 - Z_2)Z_3, \dots$, where Z_1, Z_2, Z_3, \dots are independent $\text{beta}(1, \theta)$. This last distribution is now known as the GEM distribution with parameter θ . The equality of the size-biased Poisson–Dirichlet and the GEM is a result of Patil and Taillie (1977) (see Donnelly and Joyce (1989) for a proof). We remark that Theorem 9.3.5 (and the

generalization) can be proved in the generality of Theorem 9.3.3 (see Ethier (1990b), (1992a)), but the present argument using reversibility is more appealing.

9.4. The two-locus model with recombination. Here $E = E_1 \times E_2$, where E_1 and E_2 are for simplicity assumed to be compact metric spaces representing the sets of alleles (or types) at two particular loci. Mutation operates independently at the two loci in accordance with mutation operators A_1 and A_2 , which are assumed to generate Feller semigroups on $C(E_1)$ and $C(E_2)$, respectively. Thus, the mutation operator here is the closure \bar{A} of the linear operator A defined on $\mathcal{D}(A) = \text{span}\{f_1 \times f_2 : f_1 \in \mathcal{D}(A_1), f_2 \in \mathcal{D}(A_2)\}$ by

$$(9.4.1) \quad A(f_1 \times f_2) = A_1 f_1 \times f_2 + f_1 \times A_2 f_2,$$

where $(f_1 \times f_2)(x_1, x_2) = f_1(x_1)f_2(x_2)$.

The distinguishing feature of the model, however, is recombination. Assume that the transition function R_M in (2.1.7) and (2.2.4) has the form, for each $M \geq 1$,

$$(9.4.2) \quad R_M((x_1, x_2), (y_1, y_2), \cdot) = (1 - r_M)(\delta_{(x_1, x_2)} \times \delta_{(y_1, y_2)}) + r_M(\delta_{(x_1, y_2)} \times \delta_{(y_1, x_2)}),$$

where $0 \leq r_M \leq \frac{1}{2}$. The idea is that, with probability r_M , two chromosomes with respective types (x_1, x_2) and (y_1, y_2) split at some point between the two loci and recombine, yielding chromosomes with types (x_1, y_2) and (y_1, x_2) . If $\lim_{M \rightarrow \infty} M r_M = \alpha \in [0, \infty)$, then the recombination operator B in (3.5) has the form

$$(9.4.3) \quad (Bf)((x_1, x_2), (y_1, y_2)) = \alpha(f(x_1, y_2) - f(x_1, x_2)).$$

The resulting Fleming–Viot process has been studied by many authors in the finite-dimensional case and by Ethier and Griffiths (1990a), (1990b) and Hochberg (1991) in general.

Let us define π_1 and π_2 to be the projections of $E = E_1 \times E_2$ onto its two coordinates. If $\{\mu_t, t \geq 0\}$ is a Fleming–Viot process as above (type space E , mutation operator A , recombination operator B), it is immediate that $\{\mu_t \pi_1^{-1}, t \geq 0\}$ and $\{\mu_t \pi_2^{-1}, t \geq 0\}$ are Fleming–Viot processes with type spaces E_1 and E_2 and mutation operators A_1 and A_2 (and no recombination). Thus, the two-locus diffusion model can be regarded as a Markov coupling of two one-locus diffusion models, with the recombination parameter measuring in some sense the degree of independence between the marginal processes. The case $\alpha = 0$ is known as the case of complete linkage, whereas the case $\alpha \rightarrow \infty$ corresponds to no linkage, as the following theorem shows. The result is due to Littler (1972) and Ethier (1979) in the finite-dimensional case, and to Ethier and Griffiths (1990a) in general.

THEOREM 9.4.1. *Let E_1, E_2, E, A_1, A_2, A , and B be as above. Let $\{\mu_t^{(1)}, t \geq 0\}$ and $\{\mu_t^{(2)}, t \geq 0\}$ be independent Fleming–Viot processes with type spaces E_1 and E_2 and mutation operators A_1 and A_2 , and let $\{\mu_{\alpha, t}, t \geq 0\}$ be a Fleming–Viot process with type space E , mutation operator A , and recombination operator B , with the dependence on α made explicit. If $(\mu_{\alpha, 0} \pi_1^{-1}, \mu_{\alpha, 0} \pi_2^{-1}) \Rightarrow (\mu_0^{(1)}, \mu_0^{(2)})$ in $\mathcal{P}(E_1) \times \mathcal{P}(E_2)$ as $\alpha \rightarrow \infty$, then*

$$(9.4.4) \quad \{(\mu_{\alpha, t} \pi_1^{-1}, \mu_{\alpha, t} \pi_2^{-1}), t \geq 0\} \Rightarrow \{(\mu_t^{(1)}, \mu_t^{(2)}), t \geq 0\}$$

in $C_{\mathcal{P}(E_1) \times \mathcal{P}(E_2)}[0, \infty)$.

This result asserts asymptotic independence of the marginal processes as $\alpha \rightarrow \infty$. As might be expected, a similar conclusion holds for stationary distributions. Define $\zeta : \mathcal{P}(E_1) \times \mathcal{P}(E_2) \mapsto \mathcal{P}(E)$ by $\zeta(\mu_1, \mu_2) = \mu_1 \times \mu_2$.

THEOREM 9.4.2. *Assume, in addition to the assumptions of Theorem 9.4.1, that the Feller semigroups $\{T_1(t)\}$ and $\{T_2(t)\}$ generated by A_1 and A_2 are weakly ergodic, that is, there exist $\nu_1 \in \mathcal{P}(E_1)$ and $\nu_2 \in \mathcal{P}(E_2)$ such that*

$$(9.4.5) \quad \lim_{t \rightarrow \infty} T_i(t)f(x) = \langle f, \nu_i \rangle, \quad f \in C(E_i), \quad x \in E_i, \quad i = 1, 2.$$

Let $\Pi^{(1)} \in \mathcal{P}(\mathcal{P}(E_1))$ and $\Pi^{(2)} \in \mathcal{P}(\mathcal{P}(E_2))$ be the unique stationary distributions of the Fleming–Viot processes with type spaces E_1 and E_2 and mutation operators A_1 and A_2 , and let $\Pi_\alpha \in \mathcal{P}(\mathcal{P}(E))$ be a stationary distribution of the Fleming–Viot process with type space E , mutation operator A , and recombination operator B (unique by Ethier and Griffiths (1990a)). Then $\Pi_\alpha \Rightarrow (\Pi^{(1)} \times \Pi^{(2)})\zeta^{-1}$ on $\mathcal{P}(E)$ as $\alpha \rightarrow \infty$.

In particular, the limiting stationary distribution is concentrated on the set of product measures.

We conclude this subsection with a simple but useful observation. (We continue to assume that E_1, E_2, E, A_1, A_2, A , and B are as above.) Write the typical element of E^n as $((x_1^1, x_2^1), \dots, (x_1^n, x_2^n))$. Suppose $a, b, c \geq 0$ and $n = a + b + c \geq 1$. Denote by $C_{a,b,c}(E^n)$ the space of continuous functions f on E^n that do not depend on x_2^1, \dots, x_2^a or on $x_1^{a+1}, \dots, x_1^{a+b}$. Given such an f , let us say that the “monomial” $\varphi_f \in C(\mathcal{P}(E))$ defined by $\varphi_f(\mu) = \langle f, \mu^n \rangle$ has degree $a + b + 2c$. Then the generator \mathcal{L} of the Fleming–Viot process with type space E , mutation operator A , and recombination operator B preserves degree, that is, if the monomial φ_f belongs to $\mathcal{D}(\mathcal{L})$, then $\mathcal{L}\varphi_f$ is a linear combination of monomials, each of degree at most that of φ_f .

Here is an elementary application of this idea. For $i = 1, 2$, let A_i be defined by

$$(9.4.6) \quad (A_i f)(x) = \frac{1}{2} \theta_i \int_{E_i} (f(\xi) - f(x)) P_i(x, d\xi),$$

where $\theta_i > 0$ and $P_i(x, d\xi)$ is a one-step Feller transition function on $E_i \times \mathcal{B}(E_i)$ satisfying $P_i(x, \{\xi\}) = 0$ for all $x, \xi \in E_i$. The Fleming–Viot process with type space E , mutation operator A , and recombination operator B is the two-locus analogue of the infinitely-many-neutral-alleles diffusion model of §9.2. Assume that the Feller semigroups $\{T_1(t)\}$ on $C(E_1)$ and $\{T_2(t)\}$ on $C(E_2)$ generated by A_1 and A_2 satisfy (9.4.5), and let Π_α be as in Theorem 9.4.2 (with $0 \leq \alpha < \infty$). Then (see Strobeck and Morgan (1978), Griffiths (1981), and Ethier and Griffiths (1990b))

$$(9.4.7) \quad \int_{\mathcal{P}(E)} \mu^2(\{((x_1, x_2), (y_1, y_2)) \in E^2 : x_1 = y_1, x_2 = y_2\}) \Pi_\alpha(d\mu) \\ = \frac{(3 + \theta)(6 + \theta) + \alpha(2 + \theta + 2(6 + \theta)\kappa) + 2\alpha^2\kappa}{(1 + \theta)(3 + \theta)(6 + \theta) + \alpha(2 + \theta)(13 + 3\theta) + 2\alpha^2(2 + \theta)},$$

where $\theta = \theta_1 + \theta_2$ and $\kappa = (1 + \theta_1)^{-1} + (1 + \theta_2)^{-1}$. It seems clear that there is no explicit formula in the present context that is analogous to the Ewens sampling formula (9.2.11).

9.5. n -locus model with gene conversion. Fix $n \geq 2$. Here $E = [0, 1]^n$ and A is defined by

$$\begin{aligned}
 (9.5.1) \quad (Af)(x_1, \dots, x_n) \\
 = v \sum_{i=1}^n \left\{ \int_0^1 f(x_1, \dots, x_{i-1}, \xi, x_{i+1}, \dots, x_n) d\xi - f(x_1, \dots, x_n) \right\} \\
 + \lambda \sum_{i \neq j} \{ (\Psi_{ij}^{(n)} f)(x_1, \dots, x_n) - f(x_1, \dots, x_n) \},
 \end{aligned}$$

where $\Psi_{ij}^{(n)} : C([0, 1]^n) \mapsto C([0, 1]^n)$ is defined by letting $\Psi_{ij}^{(n)} f$ be the function obtained from f by replacing x_j by x_i ; here $v > 0$ is the mutation intensity at each locus, and $\lambda > 0$ is the rate at which the allele at locus j is converted to the allele at locus i ($i, j = 1, \dots, n$; $i \neq j$). The model is due to Ohta (1982), (1983), and the present formulation is that of Shimizu (1985), (1990).

LEMMA 9.5.1. *The pure-jump Markov process in $[0, 1]^n$ with generator A given by (9.5.1) is weakly ergodic and therefore has a unique stationary distribution. Consequently, the Fleming–Viot process with type space $[0, 1]^n$ and mutation operator A is weakly ergodic and therefore has a unique stationary distribution $\Pi \in \mathcal{P}(\mathcal{P}([0, 1]^n))$.*

Proof. By Theorem 5.2, we need only verify the first assertion. Let $\{(x_1(t), \dots, x_n(t)), t \geq 0\}$ denote the Markov process with generator A . The functions $f_{m_1, \dots, m_n}(x_1, \dots, x_n) = f_{x_1, \dots, x_n}(m_1, \dots, m_n) = x_1^{m_1} \cdots x_n^{m_n}$ give rise to a dual process $\{(m_1(t), \dots, m_n(t)), t \geq 0\}$ in $(\mathbf{Z}_+)^n$ with transitions

$$(9.5.2) \quad (m_1, \dots, m_n) \mapsto (m_1, \dots, m_{i-1}, 0, m_{i+1}, \dots, m_n)$$

with rate $v/(m_i + 1)$ for $i = 1, \dots, n$, and

$$(9.5.3) \quad (m_1, \dots, m_n) \mapsto (m_1, \dots, m_{i-1}, m_i + m_j, m_{i+1}, \dots, m_{j-1}, 0, m_{j+1}, \dots, m_n)$$

with rate λ for $i, j = 1, \dots, n$, $i \neq j$. This process absorbs at $(0, \dots, 0)$ in finite time with probability 1. Thus, as $t \rightarrow \infty$,

$$\begin{aligned}
 (9.5.4) \quad \mathbf{E}_{(x_1, \dots, x_n)} [x_1(t)^{m_1} \cdots x_n(t)^{m_n}] \\
 = \mathbf{E}_{(m_1, \dots, m_n)} \left[x_1^{m_1(t)} \cdots x_n^{m_n(t)} \exp \left\{ -v \int_0^t \sum_{i=1}^n \frac{m_i(s)}{m_i(s) + 1} ds \right\} \right] \\
 \rightarrow \mathbf{E}_{(m_1, \dots, m_n)} \left[\exp \left\{ -v \int_0^\infty \sum_{i=1}^n \frac{m_i(s)}{m_i(s) + 1} ds \right\} \right]
 \end{aligned}$$

for all $(x_1, \dots, x_n) \in [0, 1]^n$ and $(m_1, \dots, m_n) \in (\mathbf{Z}_+)^n$, and the weak ergodicity follows. \square

The following result is due to Shimizu (1987), (1990).

THEOREM 9.5.2. *Let Π be as in Lemma 9.5.1, and let Π_0 be the unique stationary distribution for the Fleming–Viot process with type space $[0, 1]$ and mutation operator A_0 given by*

$$(9.5.5) \quad (A_0 f)(x) = \frac{1}{2} \theta \int_0^1 (f(\xi) - f(x)) d\xi,$$

where $\theta = v/\lambda$. Then, for each $k \geq 1$ and $\mathbf{n} = (n_1, \dots, n_k) \in \mathbf{N}^k$,

$$(9.5.6) \quad \int_{\mathcal{P}([0, 1]^n)} \mu(\Gamma_{\mathbf{n}}) \Pi(d\mu) = \int_{\mathcal{P}([0, 1])} \nu^n(\Gamma_{\mathbf{n}}) \Pi_0(d\nu),$$

where $\Gamma_{\mathbf{n}}$ is as in (9.2.10) and $n = n_1 + \cdots + n_k$.

Remark. The right-hand side of (9.5.6) is given by the Ewens sampling formula (9.2.11). Several explanations have been proposed for this result (Watterson (1989a), (1989b), Shimizu (1990)), but it seems to us that (9.5.9) below is the key observation.

Proof. Define $\sigma, \eta \in \mathcal{P}([0, 1]^n)$ by

$$(9.5.7) \quad \sigma(\cdot) = \int_{\mathcal{P}([0, 1]^n)} \mu(\cdot) \Pi(d\mu), \quad \eta(\cdot) = \int_{\mathcal{P}([0, 1])} \nu^n(\cdot) \Pi_0(d\nu).$$

Then

$$(9.5.8) \quad 0 = \int_{\mathcal{P}([0, 1]^n)} \mathcal{L}[\langle f, \mu \rangle] \Pi(d\mu) = \int_{\mathcal{P}([0, 1]^n)} \langle Af, \mu \rangle \Pi(d\mu) = \int_{[0, 1]^n} Af \, d\sigma;$$

here $\mathcal{L}[\langle f, \mu \rangle]$ is short for $(\mathcal{L}\varphi)(\mu)$, where $\varphi(\mu) = \langle f, \mu \rangle$. Moreover, letting \mathcal{L}_0 denote the generator of the Fleming-Viot process with type space $[0, 1]$ and mutation operator A_0 , we note that

$$(9.5.9) \quad \mathcal{L}_0[\langle f, \nu^n \rangle] = (2\lambda)^{-1} \langle Af, \nu^n \rangle$$

and hence

$$(9.5.10) \quad \begin{aligned} 0 &= \int_{\mathcal{P}([0, 1])} \mathcal{L}_0[\langle f, \nu^n \rangle] \Pi_0(d\nu) \\ &= (2\lambda)^{-1} \int_{\mathcal{P}([0, 1])} \langle Af, \nu^n \rangle \Pi_0(d\nu) = (2\lambda)^{-1} \int_{[0, 1]^n} Af \, d\eta. \end{aligned}$$

We conclude from (9.5.8), (9.5.10), and Lemma 9.5.1 that $\sigma = \eta$, and hence that (9.5.6) holds. \square

9.6. Infinitely-many-sites model without recombination. Here $E = [0, 1]^{\mathbf{Z}_+}$ and

$$(9.6.1) \quad (Af)(\mathbf{x}) = \frac{1}{2}\theta \int_0^1 (f(\xi, \mathbf{x}) - f(\mathbf{x})) \, d\xi.$$

The interpretation is as follows. The set of sites on the chromosome is identified with $[0, 1]$. An individual is of type $\mathbf{x} = (x_0, x_1, \dots) \in E$ if x_0, x_1, \dots is the sequence of sites at which mutations have occurred in the line of descent of that individual. For example, x_0 is the site at which the most recent mutation occurred to the individual or any of its ancestors.

The infinitely-many-sites model is due to Kimura (1969), (1971), who included recombination as well. Watterson (1975) studied the model without recombination, and the present formulation is due to Ethier and Griffiths (1987).

If $n \geq 1$, we say that $(\mathbf{x}_1, \dots, \mathbf{x}_n) \in E^n$ is a *genealogical n -tree* if

- (a) the coordinates x_{ij} , $j \in \mathbf{Z}_+$, of \mathbf{x}_i are distinct for fixed $i \in \{1, \dots, n\}$;
- (b) whenever $i, i' \in \{1, \dots, n\}$, $j, j' \in \mathbf{Z}_+$, and $x_{ij} = x_{i'j'}$, we have $x_{i, j+l} = x_{i', j'+l}$ for all $l \geq 1$;
- (c) there exist $j_1, \dots, j_n \in \mathbf{Z}_+$ such that $x_{1j_1} = \cdots = x_{nj_n}$.

Informally, (a) means that mutations never occur more than once at the same site; (b) means that if two individuals have ancestors with the most recent mutations

in their respective lines of descent at the same site, then the ancestors are of the same type; and (c) means that every n individuals have a common ancestral type, hence a common ancestor.

For each $n \geq 1$, let $\mathcal{T}_n \subset E^n$ be the set of all genealogical n -trees, and let

$$(9.6.2) \quad \mathcal{P}_a^0(E) = \{\mu \in \mathcal{P}_a(E) : \mu^n(\mathcal{T}_n) = 1 \text{ for every } n \geq 1\}.$$

LEMMA 9.6.1. *The Fleming-Viot process with type space $E = [0, 1]^{\mathbb{Z}_+}$ and mutation operator A given by (9.6.1) has a unique stationary distribution Π , and $\Pi(\mathcal{P}_a^0(E)) = 1$. If $\{\mu_t, t \geq 0\}$ is a Fleming-Viot process with type space E and mutation operator A , and if $\mathbf{P}\{\mu_0 \in \mathcal{P}_a^0(E)\} = 1$, then $\mathbf{P}\{\mu_t \in \mathcal{P}_a^0(E) \text{ for all } t \geq 0\} = 1$.*

Given $n \geq 1$ and $(\mathbf{x}_1, \dots, \mathbf{x}_n) \in \mathcal{T}_n$, we say that $z \in [0, 1]$ is a *segregating site* of $(\mathbf{x}_1, \dots, \mathbf{x}_n)$ if z appears in at least one but not all of the sequences $\mathbf{x}_1, \dots, \mathbf{x}_n$. Watterson (1975) determined the distribution of the number of segregating sites in a random sample $\mathbf{x}_1, \dots, \mathbf{x}_n$ from μ , where μ is distributed according to Π . In the present setting, the result is due to Ethier and Griffiths (1987). For each $n \geq 1$ and $s \geq 0$, let $\mathcal{T}_{n,s} \subset E^n$ be the set of genealogical n -trees with s segregating sites.

THEOREM 9.6.2. *The stationary distribution Π of Lemma 9.6.1 satisfies*

$$(9.6.3) \quad \int_{\mathcal{P}(E)} \mu^n(\mathcal{T}_{n,s}) \Pi(d\mu) = \mathbf{P}\left\{\sum_{j=1}^{n-1} Y_j = s\right\},$$

for each $n \geq 2$ and $s \geq 0$, where Y_1, \dots, Y_{n-1} are independent with Y_j geometrically distributed on \mathbb{Z}_+ with parameter $j/(j + \theta)$.

Proof. For each $n \geq 1$ and $s \geq 0$, define $\varphi_{n,s} \in B(\mathcal{P}(E))$ by $\varphi_{n,s}(\mu) = \mu^n(\mathcal{T}_{n,s})$, and let $p_{n,s} = \int_{\mathcal{P}(E)} \varphi_{n,s}(\mu) \Pi(d\mu)$. Then, clearly $p_{1,s} = \delta_{s0}$, and the identity $\int_{\mathcal{P}(E)} (\mathcal{L}\varphi_{n,s})(\mu) \Pi(d\mu) = 0$ reduces (with some effort) to

$$(9.6.4) \quad \binom{n}{2} (p_{n-1,s} - p_{n,s}) + \frac{1}{2} n \theta (p_{n,s-1} - p_{n,s}) = 0, \quad n \geq 2, s \geq 0,$$

where $p_{n,-1} = 0$. Letting $q_n(z) = \sum_{s=0}^{\infty} p_{n,s} z^s$, we find from (9.6.4) that

$$(9.6.5) \quad (n-1)q_{n-1}(z) + \theta z q_n(z) = (n-1+\theta)q_n(z),$$

and hence

$$(9.6.6) \quad q_n(z) = \prod_{j=2}^n \frac{j-1}{j-1+\theta(1-z)},$$

as required. \square

9.7. Infinitely-many-neutral-alleles model with allelic genealogies.

Again, let S be a compact metric space. Here we define $E = S^{\mathbb{Z}_+} \times [0, \infty]^{\mathbb{Z}_+}$ and

$$(9.7.1) \quad (Af)(\mathbf{x}, \mathbf{a}) = \left(\frac{\partial}{\partial a_0} f\right)(\mathbf{x}, \mathbf{a}) + \frac{1}{2} \theta \int_S (f(\xi, \mathbf{x}, 0, \mathbf{a}) - f(\mathbf{x}, \mathbf{a})) P(x_0, d\xi),$$

where $\theta > 0$ and $P(x, d\xi)$ is a one-step Feller transition function on $S \times \mathcal{B}(S)$ satisfying (9.2.2); $\mathcal{D}(A)$ is defined in the obvious way (cf. (9.3.1)). An individual is of type $(\mathbf{x}, \mathbf{a}) = ((x_0, x_1, \dots), (a_0, a_1, \dots)) \in E$ if

x_0 = its allelic type,

a_0 = the age of x_0 ,

x_i = the allelic type of the individual that produced x_{i-1} by mutation, $i \geq 1$,

a_i = the age of x_i at the time x_{i-1} first appeared, $i \geq 1$.

This model is due to Ethier and Shiga (1993) and was motivated by the work of Takahata and Nei (1990) and Takahata (1991). It includes the processes of §§9.2, 9.3, and 9.6 as marginal processes. The stationary distribution is of primary interest.

LEMMA 9.7.1. *Assuming (9.2.2) and (9.3.4), the Fleming-Viot process with type space $E = S^{\mathbf{Z}_+} \times [0, \infty]^{\mathbf{Z}_+}$ and mutation operator A given by (9.7.1) has a unique stationary distribution $\Pi \in \mathcal{P}(E)$ and is weakly ergodic.*

As in §9.6, if $n \geq 1$, we say that $((\mathbf{x}_1, \mathbf{a}_1), \dots, (\mathbf{x}_n, \mathbf{a}_n)) \in E^n$ is a *genealogical n -tree* if

- (a) the coordinates x_{ij} , $j \in \mathbf{Z}_+$, of \mathbf{x}_i are distinct for fixed $i \in \{1, \dots, n\}$,
- (b) whenever $i, i' \in \{1, \dots, n\}$, $j, j' \in \mathbf{Z}_+$, and $x_{ij} = x_{i'j'}$, we have $(x_{i,j+l}, a_{i,j+l}) = (x_{i',j'+l}, a_{i',j'+l})$ for all $l \geq 1$ and $\sum_{l=0}^j a_{il} = \sum_{l=0}^{j'} a_{i'l}$,
- (c) there exist $j_1, \dots, j_n \in \mathbf{Z}_+$ such that $x_{1j_1} = \dots = x_{nj_n}$.

For each $n \geq 1$, let $\mathcal{T}_n \subset E^n$ denote the set of all genealogical n -trees, and define $\mathcal{P}_a^0(E)$ as in (9.6.2).

LEMMA 9.7.2. *Under the assumptions of Lemma 9.7.1, $\Pi(\mathcal{P}_a^0(E)) = 1$.*

We assume hereafter that

$$(9.7.2) \quad P(x, d\xi) \equiv \nu_0(d\xi),$$

where $\nu_0 \in \mathcal{P}(S)$ is nonatomic.

For $1 \leq k \leq n$, let $\pi(n, k)$ denote the set of partitions of $\{1, \dots, n\}$ into k nonempty subsets β_1, \dots, β_k , labeled so that $\min \beta_1 < \dots < \min \beta_k$. The *n -coalescent with mutation* (Kingman (1982a)) is a pure-jump Markov process with state space

$$(9.7.3) \quad \mathcal{E}_n(\mathbf{Z}_+) = \bigcup_{k=1}^n \{\pi(n, k) \times (\mathbf{Z}_+)^k\},$$

initial state $(\{1\}, \dots, \{n\}; 0, \dots, 0)$, and transitions from $(\beta_1, \dots, \beta_k; m_1, \dots, m_k)$ to

$$(9.7.4) \quad (\beta_1, \dots, \beta_{i-1}, \beta_i \cup \beta_j, \beta_{i+1}, \dots, \beta_{j-1}, \beta_{j+1}, \dots, \beta_k; 0, \dots, 0)$$

with rate 1, $1 \leq i < j \leq k$, and to

$$(9.7.5) \quad (\beta_1, \dots, \beta_k; m_1, \dots, m_{i-1}, m_i + 1, m_{i+1}, \dots, m_k)$$

with rate $\theta/2$, $1 \leq i \leq k$. When there are k sets in the partition, the jump rate is $k(k-1+\theta)/2$. Transitions to (9.7.4) represent coalescences, whereas transitions to (9.7.5) represent mutations. Thus, m_1, \dots, m_k count the numbers of mutations in the k lines since the most recent coalescence.

For $i = 1, \dots, n$, let $M_i(t) = m_j(t)$ if $i \in \beta_j(t)$, $\tau_{i0} = \inf\{t > 0 : M_i(t) - M_i(t-) = 1\}$, and $\tau_{il} = \inf\{t > \tau_{i,l-1} : M_i(t) - M_i(t-) = 1\}$ for each $l \geq 1$. Arrange the distinct

elements of $\{\tau_{il} : i = 1, \dots, n, l \in \mathbf{Z}_+\}$ in ascending order $\tau_{(0)} < \tau_{(1)} < \tau_{(2)} < \dots$. Let $\xi_0, \xi_1, \xi_2, \dots$ be i.i.d. ν_0 . For $i = 1, \dots, n$ and $l \in \mathbf{Z}_+$, let $x_{il} = \xi_j$ if $\tau_{il} = \tau_{(j)}$.

THEOREM 9.7.3. *Assume (9.7.2) and let Π be as in Lemma 9.7.1. Then $((x_{i0}, x_{i1}, x_{i2}, \dots), (\tau_{i0}, \tau_{i1} - \tau_{i0}, \tau_{i2} - \tau_{i1}, \dots))$ ($i = 1, \dots, n$) have joint distribution $\int_{\mathcal{P}(E)} \mu^n(\cdot) \Pi(d\mu)$.*

This shows that the n th moment measure of Π (which can be interpreted as the joint distribution of a random sample of size n from μ , where μ is distributed according to Π) can be expressed in terms of the n -coalescent with mutation and ν_0 . The correspondence is not one-to-one, however. In particular, the coalescence times have no interpretation in the allelic genealogy. See Ethier and Shiga (1993) for the proof and further discussion.

CURVATURE-DRIVEN FLOWS: A VARIATIONAL APPROACH*

FRED ALMGREN†, JEAN E. TAYLOR‡, AND LIHE WANG§

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. This paper introduces a new mathematical approach to the study of time evolutions of solids $K(t)$ in n -space whose boundaries move with velocity equal to the weighted mean curvature derived from the boundary surface energy $\Phi(\partial K(t))$. These “flat Φ curvature flows” are limits of sequences of solutions to variational problems in which a sum of surface and bulk energy is minimized. The construction works equally well for smooth elliptic Φ ’s, for nondifferentiable crystalline Φ ’s, and for anything in between. The flows agree with classical smooth flows when the data is smooth and elliptic in any dimension and coincide with motion by crystalline curvature for polyhedral curves in the plane.

Key words. curvature evolution, flat curvature flow, motion-by-mean curvature, weighted mean curvature, currents, calculus of variations, geometric measure theory

AMS(MOS) subject classifications. 35A15, 35K99, 49F22, 58E99

1. Introduction. This paper is a contribution to the study of time evolutions of solids $K(t)$ in space whose boundaries move with velocity equal to the weighted mean curvature derived from the boundary surface energy $\Phi(\partial K(t))$. By “weighted mean curvature” at boundary point p , we mean (intuitively) the rate at p at which surface energy decreases with unit rate of volume change. If $\partial K(t)$ is a smooth hypersurface and if the surface energy $\Phi(\partial K(t))$ is the surface area of $\partial K(t)$, such evolution is called “motion-by-mean curvature.” For other smooth surface energies, weighted mean curvature can be expressed as a weighted sum of principal curvatures. In this paper, we give a reasonable construction of such motion for general convex parametric surface energy functions Φ . Our estimates apply, in particular, to crystalline surface energies, which are not differentiable. (The paper [BSS] by Barles, Soner, and Souganidis reviews and unifies several approaches to a class of geometric flows including motion by mean curvature. The paper [TCH] of Taylor, Cahn, and Handwerker gives a general discussion of geometric models of crystal growth, including both metallurgical applications and even more formulations of motion by weighted mean curvature; it includes references to contributions by S. Angenent, K. Brakke, L. Bronsard, Y.-G. Chen, K. Ecker, L. C. Evans, M. Gage, Y. Giga, S. Goto, M. Grayson, R. Hamilton, G. Huisken, T. Ilmanen, R. V. Kohn, W. Mullins, S. Osher, J. A. Sethian, H. M. Soner, P. E. Souganidis, J. Spruck, J. E. Taylor, and many others.)

§ Department of Mathematics, Princeton University, Princeton, New Jersey 08544.

For a given initial solid $K(0)$ and parametric surface energy function Φ , we select a sequence of solid positions $K_j(t)$ associated with timesteps of size Δt_j . Compactness theorems for integral currents, invoked in Cantor's diagonal process, guarantee the existence of a subsequence $j(1), j(2), j(3), \dots$ of $1, 2, 3, \dots$ such that, for a dense set of times, the currents $[K_{j(i)}(t)]$ will converge to a limit current $[K(t)]$ as $i \rightarrow \infty$; this fact, in itself, does not preclude the possibility that the $[K(t)]$'s might vary in a wildly discontinuous way. As our pivotal result, we prove a priori estimates for the discrete evolutions K_j , which imply the Hölder continuity of the limit K in the appropriate metric (see § 4). We also show that, if the initial boundary lies outside a given Wulff shape, then the boundary later lies outside a suitably scaled Wulff shape, and, if the initial solid lies inside a given Wulff shape, then, it later lies inside a suitably scaled Wulff shape (see § 5). Additionally, we establish sufficient conditions, so that the evolution be smooth locally in space-time (see § 6). We further show (see § 7) that, if $\partial K(0)$ is a smooth hypersurface and Φ is smooth and elliptic, then there is a smooth Φ curvature flow beginning with $\partial K(0)$ and continuing for at least a short while. For smooth and elliptic Φ 's, flat Φ curvature flows coincide with smooth flows for as long as the latter remain smooth. In § 8 we give several examples.

In a related paper [AT], Almgren and Taylor show that, for polyhedral curves in the plane driven by a crystalline even Φ , the motion constructed in this paper typically coincides with motion by crystalline curvature produced by direct integration of ordinary differential equations.

The mathematics contained in this paper largely belongs to the field of geometric measure theory. Wendell Fleming made fundamental and pivotal contributions to the field during the 1950s and 1960s, part of which time the first author was a graduate student in mathematics at Brown University. (The 1960 paper [FF] laid many of the foundations of modern geometric measure theory; this paper was awarded the 1986 Steele Prize of the American Mathematical Society for a seminal contribution to Mathematics.)

2. Questions and answers about Φ curvature flows.

2.1. What are the ingredients of Φ curvature flows? The context in which we study curvature flows is the following.

2.1.1. Environment. The ambient space in which we study curvature flows is n -dimensional Euclidean space \mathbb{R}^n , which is measured by n -dimensional Lebesgue measure \mathcal{L}^n and $(n-1)$ -dimensional Hausdorff measure \mathcal{H}^{n-1} . When we write $A \subset_{n-1} B$, we mean $\mathcal{H}^{n-1}(A \sim B) = 0$. We set

$$\mathbb{B}^n(p, r) = \mathbb{R}^n \cap \{x: |x - p| \leq r\}, \quad \alpha(n) = \mathcal{L}^n(\mathbb{B}^n(0, 1)).$$

We denote by $\beta(n)$ the covering multiplicity constant of the Besicovitch covering theorem (denoted $2\zeta + 1$ in [F, § 2.8.14]). We additionally denote by \mathcal{C} the collection of all compact subsets of \mathbb{R}^n equipped with the Hausdorff distance function \mathbb{HD} , so that

$$\mathbb{HD}(A, B) = \sup \{ \inf \{|a - b|: a \in A\}: b \in B \} + \sup \{ \inf \{|a - b|: b \in B\}: a \in A \}$$

for $A, B \in \mathcal{C}$. There seem to be no particular obstacles to the study of curvature motions in other ambient manifolds.

2.1.2. Solids and their boundaries. By *solids*, we mean n -dimensional integral currents $[K] = \mathbb{E}^n \llcorner K$ in \mathbb{R}^n associated with bounded \mathcal{L}^n measurable subsets K of \mathbb{R}^n having finite perimeter. Currents seem the natural setting for our study, since, in particular, sets differing in measure zero are identified; various definitions and properties of currents are set forth in § 3.1, below. We denote by \mathcal{K} the space of such solids,

and, when we write $[K] \in \mathcal{K}$, we mean, in particular, that K is such a set of finite perimeter. Associated with each such K is the rectifiable set ∂K of points p in \mathbb{R}^n at which K has a well-defined unit exterior normal vector $\mathbf{n}_K(p)$. As currents, we can write $\partial[K] = \mathcal{H}^{n-1} \llcorner \partial K \wedge * \mathbf{n}_K$. We denote by $\partial\mathcal{K}$ the space of $(n-1)$ -dimensional integral currents $\partial[K]$ associated with $[K]$ s in \mathcal{K} . The metric we use on solids is given by the mass norm \mathbf{M} , which in this case can be written as

$$\mathbf{M}([K] - [L]) = \mathcal{L}^n(K \triangle L);$$

here

$$K \triangle L = ((K \sim L) \cup (L \sim K)) = K \cap (\mathbb{R}^n \sim L) \cup (\mathbb{R}^n \sim K) \cap L$$

denotes the symmetric difference between K and L . There is a corresponding \mathbb{G} norm on boundaries given by setting

$$\mathbb{G}(\partial[K] - \partial[L]) = \mathbf{M}([K] - [L]).$$

The norm \mathbb{G} is essentially equivalent to the flat norm on currents. The support $\text{spt } \partial[K]$ of each member $\partial[K]$ of $\partial\mathcal{K}$, of course, is a set belonging to \mathcal{C} .

2.1.3. Surface energy integrands and their integrals. We denote by

$$\Phi: \mathbb{R}^n \rightarrow \mathbb{R}^+$$

a fixed *parametric surface energy integrand*; this means that Φ is continuous and is positively homogeneous of degree one (i.e., $\Phi(\lambda v) = \lambda \Phi(v)$ if λ is nonnegative). We also assume that Φ is positive on \mathbb{R}^n except at the origin and that Φ is convex. (This assumption of convexity is not necessarily true for the surface energy functions of physical crystalline materials. When energies are not convex, it is customary to replace the actual energy by the smallest convex energy that is not less than the actual energy and then to understand surfaces to have tangent planes in the sense of varifold geometry. The Wulff shape of the convexified energy (see § 5) is the same as that of the original energy.) We call Φ *even*, provided that $\Phi(-v) = \Phi(v)$ for each v . We call Φ *smooth*, provided that the function Φ is three times Hölder continuously differentiable except at the origin. We call a smooth Φ *elliptic* provided that Φ is uniformly convex in the sense that the restriction of Φ to any arc length parametrized line in \mathbb{R}^n not containing the origin has strictly positive second derivatives. We further denote

$$0 < \Phi_0 =: \inf \{ \Phi(v) : |v| = 1 \} \leq \Phi^0 =: \sup \{ \Phi(v) : |v| = 1 \} < \infty$$

as lower and upper bounds for surface energy density on unit normal vectors. By the integral of Φ over $\partial[K]$, we mean the number

$$\Phi(\partial[K]) = \int_{p \in \partial K} \Phi(\mathbf{n}_K(p)) \, d\mathcal{H}^{n-1} p.$$

Similarly,

$$\Phi(-\partial[K]) = \int_{p \in \partial K} \Phi(-\mathbf{n}_K(p)) \, d\mathcal{H}^{n-1} p,$$

since $-\partial[K]$ is the boundary of $-[K]$, the current with negative orientation associated to K . The *mass integrand* \mathbf{M} is given by setting $\mathbf{M}(v) = |v|$ for each v , so that $\mathbf{M}(\partial[K]) = \mathcal{H}^{n-1}(\partial K)$.

2.2. In the smooth case, what is Φ curvature, and what is its relation with Φ ? Suppose S is a twice continuously differentiable closed submanifold of \mathbb{R}^n oriented by unit normal vector field \mathbf{n} . Associated with S is the smooth normal Φ curvature vector field

$$H = H_{\Phi, S}: S \rightarrow \mathbb{R}^n$$

given by setting for each $p \in S$,

$$H_{\Phi, S}(p) = \mathbf{n}(p) \operatorname{trace} (D^2\Phi(\mathbf{n}(p)) \circ D^2R(p)).$$

Here R is any twice continuously differentiable real-valued function defined in some neighborhood U of p in \mathbb{R}^n for which

$$S \cap U = R^{-1}\{0\} \quad \text{and} \quad \nabla R(p) = -\mathbf{n}(p).$$

Also, $D^2R(p)$ here denotes the $n \times n$ Hessian matrix of second derivatives of R evaluated at p , and $D^2\Phi(\mathbf{n}_K(p))$ denotes the $n \times n$ Hessian matrix of second derivatives of Φ evaluated at the unit normal vector $\mathbf{n}(p)$; R is defined on the ambient \mathbb{R}^n , while Φ is defined on the \mathbb{R}^n of normal vectors. (If S is the sphere of radius r in \mathbb{R}^n oriented as the boundary of a ball and $\Phi(v) = \mathbf{M}(v) = |v|$ (so that $\Phi(S) = \mathcal{H}^{n-1}(S)$ is the surface area of S), then we could take $R(x) = (2r)^{-1}(r^2 - |x|^2)$ and compute $H_{\Phi, S}(p) = -(n-1)p/r$ for each p in the sphere of radius r .)

If $G_t: \mathbb{R}^n \rightarrow \mathbb{R}^n$ ($t \in \mathbb{R}$) is a deformation of \mathbb{R}^n starting with the identity at time $t=0$ and having initial velocity vector field $g = (d/dt)G_t|_{t=0}$ (which vanishes on ∂S), then

$$\left. \frac{d}{dt} \Phi(G_t(S)) \right|_{t=0} = - \int_{p \in S} g(p) \cdot H_{\Phi, S}(p) d\mathcal{H}^{n-1}p.$$

If $S = \partial K$ for some $[K] \in \mathcal{K}$ and $\mathbf{n} = \mathbf{n}_K$, then we write $H = H_{\Phi, \partial K}$ and have, correspondingly,

$$\left. \frac{d}{dt} \Phi(G_t(\partial K)) \right|_{t=0} = - \int_{p \in \partial K} g(p) \cdot H_{\Phi, \partial K}(p) d\mathcal{H}^{n-1}p.$$

Since

$$\left. \frac{d}{dt} \mathcal{L}^n(G_t(K)) \right|_{t=0} = \int_{p \in \partial K} g(p) \cdot \mathbf{n}_K(p) d\mathcal{H}^{n-1}p,$$

we can intuitively regard $H_{\Phi, \partial K}(p)$ as the infinitesimal rate of change of surface energy with volume at p .

2.3. What is smooth Φ curvature flow? Suppose that Φ is smooth and that

$$[K(\cdot)]: (a, b) \rightarrow \mathcal{K}$$

is a time parametrized family of solids. We say that the $\partial[K(t)]$ s constitute a *smooth Φ curvature flow*, provided that the $\partial K(t)$ s are a smoothly varying family of hypersurfaces and that, for each $a < s < b$ and each $p \in \partial K(s)$, the normal velocity of the $\partial K(t)$ s at p at time s equals $H_{\Phi, \partial K(s)}(p)$. Obvious definitions apply for flows on closed and half open intervals of time. Also, the notion of smooth Φ curvature flows has an obvious localization in space.

2.4. Do smooth Φ curvature flows exist? If Φ is elliptic and $\partial K(0)$ is a three times Hölder continuously differentiable submanifold, then there will exist a smooth Φ curvature flow $\partial[K(t)]$ beginning with $\partial[K(0)]$ and defined for some interval of times t of positive length; see Theorem 7.1. Examples show that such flows can develop singularities in finite time.

2.5. What are nonparametric smooth Φ curvature flows? Suppose that Φ is elliptic. Suppose also that U is an open subset of $\mathbb{R}^{n-1} \times \mathbb{R}^+$ and $f: U \rightarrow \mathbb{R}$ is twice continuously differentiable. We say that f is a *nonparametric smooth Φ curvature flow*, provided that the hypersurfaces $\Sigma(t) = \mathbb{R}^n \cap \{(x, f(x, t)): (x, t) \in U\}$ are varying smoothly with normal velocities equal to $H_{\Phi, \Sigma(t)}$ for some continuous choice of normal vectors.

2.6. What is a flat Φ curvature flow? By a *flat Φ curvature flow*, we mean any function $\partial[K(\cdot)]: \mathbb{R}^+ \rightarrow \partial\mathcal{K}$ that is constructed by the following variational procedure. Whenever $[K] \in \mathcal{K}$ and $[L] \in \mathcal{K}$ and Δt is a positive number, we set

$$\mathcal{E}([K], [L], \Delta t) = \Phi(\partial[L]) + \frac{1}{\Delta t} \int_{p \in K \triangle L} \text{dist}(p, \partial K) d\mathcal{L}^n p.$$

Suppose then that $[K(0)] \in \mathcal{K}$ is a given initial solid position. For each fixed integer j , we set $\Delta t = 2^{-j}$ and choose

$$[K_j(\cdot)]: \mathbb{R}^+ \rightarrow \mathcal{K}$$

by the inductive requirements that

$$[K_j(0)] = [K(0)],$$

and, for each $k = 0, 1, 2, 3, \dots$, $[K_j(k\Delta t + \Delta t)]$ is chosen so that

$$\mathcal{E}([K_j(k\Delta t)], [K_j(k\Delta t + \Delta t)], \Delta t) = \mathcal{E}([K_j(k\Delta t)], [L], \Delta t)$$

and

$$K_j(k\Delta t + s) = K_j(k\Delta t + \Delta t)$$

for each $0 < s \leq \Delta t$. This defines *approximate flows* $\partial[K_j(t)]$ for $j = 1, 2, 3, \dots$ and all $t \geq 0$. A function $\partial[K(\cdot)]: \mathbb{R}^+ \rightarrow \partial\mathcal{K}$ is called a *flat Φ curvature flow*, provided that

$$\lim_{i \rightarrow \infty} \mathbb{G}(\partial[K(t)] - \partial[K_{j(i)}(t)]) = 0$$

locally uniformly in time t for some approximate flows $\partial[K_j(t)]$ and some subsequence $j(1), j(2), j(3), \dots$ of $1, 2, 3, \dots$.

2.7. Do flat Φ curvature flows exist? We show in § 4.4, below, that there are a priori \mathbb{G} Hölder continuity estimates for the approximate flows constructed above. These estimates imply the existence of the required convergent subsequences in § 4.5.

2.8. Are flat Φ curvature flows smooth? Suppose that Φ is smooth and elliptic and that the boundary of our initial solid is a three times Hölder continuously differentiable hypersurface. Then, at least for a short time, a smooth Φ curvature flow will exist, beginning with this hypersurface; see Theorem 7.1. For as long as this smooth flow does exist, it will coincide with any flat Φ curvature flow; see Theorem 7.4.

2.9. What are viscosity Φ curvature flows? Suppose that Φ is smooth and that $A: (a, b) \rightarrow \mathcal{C}$ is continuous in the $\mathbb{H}\mathbb{D}$ topology so that $\Sigma = \mathbb{R}^n \times (a, b) \cap \{(x, t): x \in A(t)\}$ is closed in $\mathbb{R}^n \times (a, b)$. Assume also that $\sigma: \mathbb{R}^n \times (a, b) \rightarrow \Sigma \rightarrow \{-1, 1\}$ is a continuous orientation function; σ is supposed to take value -1 in the crystal, and $+1$ otherwise. We say that A is a *viscosity Φ curvature flow* (with respect to σ), provided that the following condition holds: Suppose that $g: \mathbb{R}^n \times (a, b) \rightarrow \mathbb{R}$ is any twice continuously differentiable test function so that $\Gamma = \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) = 0\}$ is closed and $\Gamma^+ = \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) > 0\}$ is open. In the case where $\Sigma \cap \Gamma^+$ is empty and $\Sigma \cap \Gamma$ consists of a single point (p, s) at which $\nabla_x g(p, s) \neq 0$, we then require that

$$\frac{\partial g}{\partial t}(p, s) \geq \text{trace} \left(D^2 \Phi \left(\pm \frac{\nabla_x g}{|\nabla_x g|}(ps) \right) \circ D_x^2 g(p, s) \right);$$

here we take the $+$ sign if σ is positive in Γ_+ near (p, s) , and the $-$ sign otherwise. It is easy to check that an equivalent definition results if we replace the condition that $\Sigma \cap \Gamma$ consist of a single point (p, s) by the requirement that $(p, s) \in \Sigma \cap \Gamma$.

2.10. Do viscosity Φ curvature flows exist? Viscosity Φ curvature flows (as defined above) for smooth elliptic Φ are closely related to the viscosity solutions of the level set approach, which were initially shown to exist and be unique for any continuous initial data by [CGG] (for $\Phi = \mathbf{M}$, this was simultaneously shown by [ES1]). The current status of that and related approaches is given by [BSS]. In any of those contexts or in that of § 2.9 above, any smooth Φ curvature flow can be shown to be a viscosity Φ curvature flow. Now, suppose that $\partial[K(t)]$ is a flat Φ curvature flow constructed from approximating flows $\partial[K_j(t)]$. Let $A(t) = \text{spt } \partial[K(t)]$ and $A_j(t) = \text{spt } \partial[K_j(t)]$ for times t . In case $A(t)$ is continuous in the $\mathbb{H}\mathbb{D}$ topology for $a < t < b$ and $\mathbb{H}\mathbb{D}(A_j(t), A(t)) \rightarrow 0$ locally uniformly in t for $a < t < b$, then $A(t)$ is a viscosity Φ curvature flow (in § 2.9), as we show in § 6.2.

2.11. Are viscosity Φ curvature flows smooth? The most general information we know about this question is the following. Suppose that U is an open subset of $\mathbb{R}^{n-1} \times \mathbb{R}^+$ and that $f: U \rightarrow \mathbb{R}$ is a Lipschitz function. A necessary and sufficient condition that f be a nonparametric smooth Φ curvature flow is that the function $t \mapsto \{(x, f(x, t))\}$ be a viscosity Φ curvature flow. The Hölder continuous differentiability of f follows from the work [CW] of Caffarelli and Wang, while the twice Hölder continuous differentiability follows from work [W] of Wang.

2.12. Why is it reasonable to think of flat Φ curvature flows as curvature flows? Suppose that Φ is elliptic. We show in §§ 3.5–3.8 that the general surface regularity theory of [Bo] (or of [A1] in case Φ is even), together with higher differentiability estimates from the associated Euler-Lagrange partial differential equations (PDEs) guarantee that each $\partial K_j(t)$ ($t > \Delta t$) will \mathcal{H}^{n-1} almost everywhere be a smooth submanifold of \mathbb{R}^n and that, at each regular point p of $\partial K_j(t)$,

$$H_{\Phi, \partial K_j(t)}(p) = \frac{\text{dist}(p, \partial K_j(t - \Delta t))}{\Delta t} \mathbf{n}(p);$$

here $\Delta t = 2^{-j}$ is the timestep associated with the approximations $K_j(t)$, and $\mathbf{n}(p) = \mathbf{n}_\Omega(p)$ is the unit exterior normal vector to the symmetric difference $\Omega = K_j(t - \Delta t) \triangle K_j(t)$. In this sense, at each stage of the approximation, we have a reasonable approximation to a curvature flow if we accept

$$\frac{\text{dist}(p, \partial K_j(t - \Delta t))}{\Delta t}$$

as a reasonable approximation of interface speed and are willing to measure curvature at p in $\partial K_j(t)$ rather than, say, somewhere on $\partial K_j(t - \Delta t)$.

For smooth elliptic Φ and smooth initial data, flat Φ curvature flow coincides with smooth Φ curvature flow at least until singularities develop in the smooth flow, as shown in Theorem 7.4.

For polyhedral curves in the plane and a crystalline Φ , which is also even, flat Φ curvature flow typically coincides with motion by crystalline curvature computed by integration of ordinary differential equations, as shown in [AT].

For all other surface energy functions, the construction also appears to be a reasonable one and has strong a priori estimates.

2.13. What are reasons for interest in general flat Φ curvature flows? Our original interest in flat flows arose in the study of the changing geometry of a crystal as it evolves within its melt in a cold environment either by melting crystal or freezing melt [AW]; our interest is both theoretical and computational. In one model of such evolution, we intuitively consider the equation

$$v = M(\Omega + \text{wmc})$$

in which v denotes the surface normal velocity, Ω is the undercooling below the freezing temperature T_0 of a planar interface, wmc is the weighted mean curvature of the interface measuring the desire of the interface to decrease its surface energy, and M is the mobility of the interface measuring the response of the interface to the driving pressures of undercooling and surface tension. This model also applies to a wide range of other interface motion problems, involving chemical- as well as temperature-dependent bulk driving forces. In the freezing problem, we usually add a heat of fusion as new regions crystallize (or take heat away if melting occurs). This raises the temperature and slows the growth (since the amount of undercooling is decreased). One of the limiting factors in the rate of growth is thus the speed at which this added heat can diffuse away to the cold environment. The more subtle part of the problem, however, involves the curvature wmc , since this changes with changes in crystal shape. To focus on this difficulty, we can assume that the ambient temperature is T_0 and that heat diffuses infinitely fast; under this assumption, Ω is always zero. There seems little general theoretical or experimental knowledge about the form of the mobility function M (only its sign seems determined by classical thermodynamics [Gu]). To focus on the curvature difficulty, we also simply assume that the mobility M is identically equal to one. We are thus led to the study of our heuristic equation that

$$v_{\partial K(t)} = H_{\Phi, \partial K(t)},$$

to which we referred above. In this case, the only relevant driving force is that seeking to reduce surface energy so that any initial crystal will ultimately melt. By doing this, we are able to concentrate on the following central difficulties involved in making theoretical and computational sense of such flows:

(i) It is necessarily the case (by example) that such flows will develop singularities in finite time (such as necks pinching off or separate crystals shrinking to points at different times). Since we wish the flows to be defined for all time, it is necessary to find a construction or definition that enables us to continue the evolution even in the presence of singularities (including unbounded or undefined curvatures);

(ii) Generally, it is numerically difficult and unreliable to try to obtain curvature information from combinatorial representations of surfaces [U], [DS]. (Note that the crystalline curvature approach avoids this problem by using a natural parametrization derived from the Gauss map; see [T2] for the case of the motion of polyhedral curves in the plane);

(iii) Many naturally occurring surface energy functions for crystalline materials are not smooth and elliptic. Surface energies play a demonstrably important role in the geometry of the crystallization process for such surface energy functions, but their influence is not expressible in naively formulated notions of curvature, since the rate of change of surface energy with volume for faceted shapes or shapes with corners typically is either zero or infinite. We are thus led to find a process in which surface energy wants to be minimized but is constrained by a cost of adding or deleting from the solid region.

2.14. Is it possible to compute flat flows? Generally, it is difficult to perform the variational minimizations required by our procedure, but, when $n = 2$ or the variational problem can be legitimately confined to a finite-dimensional subspace, there has been substantial progress, including working codes and graphics. For crystalline surface energies, this reduction to a low-dimensional subspace has been shown to hold for $n = 2$ [AT], and the appropriate approximations for $n = 3$ seem to be in hand. These situations are illustrated in papers and videotapes by Taylor [T2]–[T4]. Also, for $n = 2$, computations including both curvature and bulk driving forces involving quantities that diffuse are illustrated in work of Roosen and Taylor [RT], [R]. In a related paper of Almgren [Al], the mobility M is taken to be infinite so that bulk driving force balances weighted mean curvature.

2.15. What are the main missing ingredients about Φ curvature flows in the flat sense? Perhaps the biggest missing estimate is one that would guarantee that $\mathcal{H}^{n-1}(\text{spt } \partial[K(t)] \sim \partial K(t)) = 0$ for times t . This does hold in the approximations to the flow as shown in § 3.4. However, (except when $\Phi = \mathbf{M}$) we know no way to preclude the possibility that approximations develop filigree structures that become increasingly elaborate as $\Delta t \downarrow 0$; if this does happen, it might well lead to limit currents with excessively large supports. Another missing estimate in the smooth case is one that would guarantee that, if $\partial K(t)$ were measure theoretically nearly a flat disk somewhere, then, a short time later, it would become a smooth nearly flat disk evolving smoothly. A third missing estimate is one that would guarantee that combining a flat flow from $t = 0$ to $t = T_1$ with one from $t = T_1$ to $t = T_2$ would yield a flat flow from $t = 0$ to $t = T_2$.

3. Existence and structure of \mathcal{E} minimizers. This section establishes existence and properties of \mathcal{E} minimizers including regularity in the case where surface energy is smooth and elliptic. We first set forth basic properties of currents needed in our analysis. The existence of \mathcal{E} minimizers is then a consequence of a compactness theorem for integral currents in the \mathbb{G} topology. We establish various properties of \mathcal{E} minimizers and show their relation to the (Φ, ω, δ) minimal currents of Bombieri and the (γ, δ) restricted sets and the $(\Phi, \varepsilon, \delta)$ minimal sets of Almgren; surface energy integrals over sets are defined only for even Φ . If our surface energy function Φ is smooth and elliptic, such minimality alone implies that the supports of \mathcal{E} minimizers are almost everywhere continuously differentiable submanifolds of \mathbb{R}^n . The particular form of our \mathcal{E} minimization, however, enables us to conclude higher differentiability. In particular, if K is a minimizer in $\mathcal{E}([K_0], [K], \Delta t)$ and ∂K_0 is a $C^{k,\alpha}$ submanifold, then those parts of ∂K near ∂K_0 will be a C^{k+2} submanifold almost everywhere. If $n = 2$ or 3 , there are no singularities in \mathcal{E} minimizers for elliptic Φ .

3.1. Integral currents and their properties. The present study of flat Φ curvature flows is set in the context of integral currents for several reasons. First, when sets are regarded as currents, the identifications we want are automatically made. Second, we are able to utilize constructions and estimates proved for currents rather than attempting to reprove them without the current structure. Some basic references for currents are Federer's treatise [F], the text [S] by Simon, and the introductory book [M1] by Morgan.

3.1.1. General currents. A general k (dimensional) *current* T in \mathbb{R}^n is a real-valued continuous linear functional on the real vector space of infinitely differentiable differential k forms in \mathbb{R}^n with compact support. If $k \geq 1$, then the boundary of T is the $k - 1$ current ∂T given by setting $\partial T(\omega) = T(d\omega)$ for differential $k - 1$ forms ω ; i.e., Stokes' theorem becomes a definition.

Associated with any infinitely differentiable proper mapping $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ and any k current T in \mathbb{R}^n is the k current $f_* T$ in \mathbb{R}^m defined by setting $f_* T(\omega) = T(f^* \omega)$ for differential k forms ω in \mathbb{R}^m . In particular, $\partial f_* T = f_* \partial T$.

3.1.2. Rectifiable sets and Lipschitz maps. A subset S of \mathbb{R}^n is called k rectifiable, provided that, for each $\varepsilon > 0$, there is a compact continuously differentiable k -dimensional submanifold with boundary M_ε for which $\mathcal{H}^k(S \Delta M_\varepsilon) < \varepsilon$. (Such sets are called (\mathcal{H}^k, k) rectifiable and \mathcal{H}^k measurable in [FF, § 3.2.14].) When R, S are k rectifiable subsets of \mathbb{R}^n and $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is Lipschitz, then the following is true [F, §§ 3.2.19, 3.2.20, 3.2.23, 3.2.29]:

(i) $R \cup S$ and $R \cap S$ are k rectifiable subsets of \mathbb{R}^n and $f(S)$ is a k rectifiable subset of \mathbb{R}^m in case $m \geq k$;

(ii) \mathcal{H}^k almost every p in S admits an (\mathcal{H}^k, k) approximate tangent plane $\tau_S(p) = \text{Tan}^k(\mathcal{H}^k \llcorner S, p)$, which is a k -dimensional linear subspace of \mathbb{R}^n , and f admits an (\mathcal{H}^k, k) approximate differential $\text{ap } Df(p): \tau_S(p) \rightarrow \mathbb{R}^m$ and an (\mathcal{H}^k, k) approximate Jacobian $\text{ap } J_k f(p) = \|\wedge_k \text{ap } Df(p)\|$;

(iii) If $m \geq k$ and $g: \mathbb{R}^m \rightarrow \mathbb{R}$, then

$$\int_S (g \circ f) \text{ap } J_k f d\mathcal{H}^k = \int_{z \in \mathbb{R}^m} g(z) N(f|S, z) d\mathcal{H}^k z;$$

here $N(f|S, z) = \text{Card}(S \cap f^{-1}\{z\})$ is the multiplicity with which $f|S$ assumes the value z ;

(iv) If $m < k$ and $g: S \rightarrow \mathbb{R}$ is $\mathcal{H}^{n-1} \llcorner S$ integrable, then $S \cap f^{-1}\{y\}$ is $k-m$ rectifiable for \mathcal{L}^m almost every $y \in \mathbb{R}^m$, and

$$\int_S g \cdot \text{ap } J_m f d\mathcal{H}^k = \int_{y \in \mathbb{R}^m} \int_{S \cap f^{-1}\{y\}} g d\mathcal{H}^{k-m} d\mathcal{L}^m y$$

(one form of Federer's coarea formula).

Suppose that S is an $n-1$ rectifiable subset of \mathbb{R}^n and that our surface energy integrand Φ is even, i.e. $\Phi(v) = \Phi(-v)$, for each v in accordance with § 2.1.3. In that case, we extend our notion of surface energy by setting

$$\Phi(S) = \int_{x \in S} \Phi(n_S(x)) d\mathcal{H}^{n-1} x,$$

where n_S is any $\mathcal{H}^{n-1} \llcorner S$ measurable unit vector-valued function for which $n_S(x)$ is perpendicular to $\tau_S(x)$ at almost every x .

3.1.3. Rectifiable and integral currents. (See [F, § 4.1.24].) A k current T in \mathbb{R}^n is called *rectifiable*, provided that it can be expressed as

$$T = \mathbf{t}(S, \theta, \sigma)$$

for some bounded k rectifiable set S , some positive integer-valued $\mathcal{H}^k \llcorner S$ summable density function $\theta: S \rightarrow \mathbb{Z}^+$, and some simple unit k vector-valued orientation function $\sigma: S \rightarrow \wedge_k \mathbb{R}^n$ that is compatible with the approximate tangent plane structure of S ; i.e., $\tau_S(p)$ is the linear subspace associated with $\sigma(p)$ for \mathcal{H}^k almost every p in S [F, § 4.1.28]. If ω is a smooth differential k form with compact support, then

$$T(\omega) = \mathbf{t}(S, \theta, \sigma)(\omega) =: \int_{x \in S} \langle \sigma(x), \omega(x) \rangle \theta(x) d\mathcal{H}^k x;$$

this definition also makes sense for unbounded S 's, provided that θ is locally summable. The *variation measure* $\|T\|$ associated with T is given by setting

$$\|T\| = \mathcal{H}^k \wedge \theta, \quad \text{i.e., } \|T\|(A) = \int_{S \cap A}^* \theta d\mathcal{H}^k$$

for each $A \subset \mathbb{R}^n$; here \int^* denotes the upper integral.

The *mass* of T [F, § 4.1.27] is the number

$$\mathbf{M}(T) = \|T\|\mathbb{R}^n = \int_S \theta d\mathcal{H}^k = \sup \{T(\omega) : \|\omega\| \leq 1\} = \sup \{T(\omega) : |\omega| \leq 1\},$$

while the *size* of T is the number

$$\mathbf{S}(T) = \int_S 1 d\mathcal{H}^k = \mathcal{H}^k(S).$$

We say that T is an *integral k current*, provided that T is a rectifiable k current, and, additionally in case $k \geq 1$, ∂T is a rectifiable $k-1$ current. (The term “integral” here refers to the fact that the density function θ takes positive integer values; real rectifiable currents have real-valued density functions.)

Associated in a natural way with any rectifiable k current $T = \mathbf{t}(S, \theta, \sigma)$ in \mathbb{R}^n and any Lipschitz mapping $f: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is the rectifiable k current $f_{\#}T$ in \mathbb{R}^m defined by setting

$$f_{\#}T(\omega) = \lim_{j \rightarrow \infty} T(g_j^* \omega)$$

for any sequence $\{g_j\}_j$ of infinitely differentiable mappings with uniformly bounded Lipschitz constants that converge uniformly to f [F, § 4.1.14]. Furthermore, the following hold:

(i) If

$$\xi(p) = \sum_{x \in S \cap f^{-1}\{p\} \cap \{z: \text{ap } J_k f(x) > 0\}} \theta(x) \frac{\langle \sigma(x), \wedge_k \text{ap } Df(x) \rangle}{|\langle \sigma(x), \wedge_k \text{ap } Df(x) \rangle|}$$

and $R = \mathbb{R}^m \cap \{p: \xi(p) \neq 0\}$ then [F, § 4.1.30]

$$f_{\#}T = \mathbf{t}\left(R, |\xi|, \frac{\xi}{|\xi|}\right).$$

In particular, $R \subset_{n-1} f(S)$ and, if $g: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is another Lipschitz mapping that agrees with f on S , then $g_{\#}T = f_{\#}T$;

(ii) If $k \geq 1$ and T is an integral k current, then $f_{\#}T$ is an integral current and $\partial f_{\#}T = f_{\#}\partial T$.

If $T = \mathbf{t}(S, \theta, \sigma)$ is a rectifiable k current it is often the case that the support $\text{spt } T$ of T will be considerably larger than S . It follows from [F, §§ 2.10.6, 2.10.17(4)] that one condition that is sufficient so that $\mathcal{H}^k(\text{spt } T \triangle S) = 0$ is that there exist continuous positive functions $a, b: \mathbb{R}^n \rightarrow \mathbb{R}^+$ such that the *density ratios*

$$\Theta^k(\|T\|, p, r) =: \frac{\|T\|\mathbb{B}^n(p, r)}{\alpha(k)r^k}$$

are not less than $a(p)$ whenever $p \in \text{spt } T$ and $0 < r < b(p)$. If such a and b exist, then it follows that

$$\Theta^{*k}(\|T\|, p) =: \limsup_{r \downarrow 0} \frac{\|T\|\mathbb{B}^n(p, r)}{\alpha(k)r^k} \geq a(p)$$

whenever $p \in \text{spt } (T)$; $\Theta^{*k}(\|T\|, p)$ is called the *upper k density of $\|T\|$ at p* .

We can extend the definitions above in obvious ways to define currents that are locally rectifiable or locally integral.

3.1.4. Integral currents of dimension n in \mathbb{R}^n . (See [FF, § 4.5].) The n -dimensional Euclidean current

$$\mathbb{E}^n = \mathbf{t}(\mathbb{R}^n, 1, \mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_n)$$

is a locally integral current with $\partial \mathbb{E}^n = 0$, which, when restricted to a bounded \mathcal{L}^n measurable subset K of \mathbb{R}^n , gives the rectifiable n current

$$[K] = \mathbb{E}^n \llcorner K = \mathbf{t}(K, 1, \mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_n).$$

If $[K]$ is an integral current, then $[K] \in \mathcal{H}$, and we can write

$$\partial[K] = \mathcal{H}^{n-1} \wedge * \mathbf{n}_K = \mathbf{t}(\partial K, 1, *\mathbf{n}_K)$$

[F, § 4.5.6], as indicated in § 2.1.2. General integral n currents T in \mathbb{R}^n can be represented uniquely as

$$T = \mathbf{t}(A, \theta, \sigma) = \sum_{i=1}^{\infty} [N_i] - \sum_{j=1}^{\infty} [L_j],$$

where

$$N_i = \{x: \sigma(x) = \mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_n \text{ and } \theta(x) \geq i\},$$

$$L_j = \{x: \sigma(x) = -\mathbf{e}_1 \wedge \cdots \wedge \mathbf{e}_n \text{ and } \theta(x) \geq j\}.$$

In particular, $N_1 \cap L_1 = \emptyset$, and $N_1 \supset N_2 \supset N_3 \dots$, and $L_1 \supset L_2 \supset L_3 \dots$. Furthermore [F, § 4.5.17],

$$\partial T = \sum_i \partial[N_i] - \sum_j \partial[L_j]$$

with

$$\|\partial T\| = \sum_i \|\partial[N_i]\| + \sum_j \|\partial[L_j]\|$$

so that

$$\mathbf{M}(\partial T) = \sum_i \mathbf{M}(\partial[N_i]) + \sum_j \mathbf{M}(\partial[L_j]).$$

For such T , we set in the obvious way

$$\Phi(\partial T) = \sum_i \Phi(\partial[N_i]) + \sum_j \Phi(-\partial[L_j]).$$

We note that whenever $[K], [L] \in \mathcal{H}$ then

$$[K] + [L] = [K \cup L] + [K \cap L], \quad \partial[K] + \partial[L] = \partial[K \cup L] + \partial[K \cap L],$$

and we confirm that

$$\partial(K \cup L) \cup \partial(K \cap L) \subset_{n-1} \partial K \cup \partial L$$

and

$$\Phi(\partial[K \cup L]) + \Phi(\partial[K \cap L]) \leq \Phi(\partial[K]) + \Phi(\partial[L]).$$

3.1.5. A compactness theorem for integral currents. (See [F, § 4.2.17], [A2, § 4.3].) There are various compactness theorems for integral and real rectifiable currents. One that is suitable for our purposes is the following. Suppose that T_1, T_2, T_3, \dots are

integral k currents in \mathbb{R}^n such that $\sup_i \mathbf{M}(T_i) < \infty$, $\sup_i \mathbf{M}(\partial T_i) < \infty$, and $\bigcup_i \text{spt}(T_i)$ is bounded. Then there is a subsequence $i(1), i(2), i(3), \dots$ of $1, 2, 3, \dots$ and an integral k current T such that $T_{i(j)} \rightarrow T$ weakly as $j \rightarrow \infty$, i.e., $T_{i(j)}(\omega) \rightarrow T(\omega)$ as $j \rightarrow \infty$ for each smooth differential k from ω . It follows that $\mathbf{M}(T) \leq \liminf_{j \rightarrow \infty} \mathbf{M}(T_{i(j)})$ and is also true that $\mathbf{S}(T) \leq \liminf_{j \rightarrow \infty} \mathbf{S}(T_{i(j)})$ [A2, § 2.10]. In case $k = n$, then $\mathbf{M}(T - T_{i(j)}) \rightarrow 0$; a consequence of this is that, if $T_i = [K_i] \in \mathcal{H}$ for each i , then $T = [K] \in \mathcal{H}$ for some K . In case $k = n - 1$, then $\mathbb{G}(T - T_{i(j)}) \rightarrow 0$ and $\Phi(T) \leq \liminf_{j \rightarrow \infty} \Phi(T_{i(j)})$. (A corresponding lower semicontinuity estimate holds for integrals of appropriate convex surface energy integrands for general dimensions k .)

3.1.6. The cone construction. (See [F, § 4.1.11].) Associated with any integral k , current T ($k \leq n - 1$), and point p in \mathbb{R}^n is the cone $[p] \times T$ over T with vertex p , which is an integral $k + 1$ current with

$$\partial([p] \times T) = T - [p] \times \partial T.$$

In case $\text{spt } T \subset \mathbb{B}^n(p, r)$, then $\text{spt}([p] \times T) \subset \mathbb{B}^n(p, r)$, and we can estimate

$$\mathbf{S}([p] \times T) \leq \mathbf{M}([p] \times T) \leq \frac{r}{k+1} \mathbf{M}(T).$$

As a consequence of the constancy theorem [F, § 4.1.7], together with the cone construction, we infer that, corresponding to each integral $n - 1$ current R with $\partial R = 0$, there is a unique n current $Q = [0] \times R$ with $\partial Q = R$.

3.1.7. Isoperimetric inequalities. (See [A3].) Whenever T is an integral k current (with $1 \leq k \leq n - 1$) with $\partial T = 0$, there is an integral $k + 1$ current Q with $\partial Q = T$, having support in the convex hull of T such that

$$\mathbf{M}(Q) \leq \gamma(k+1) \mathbf{M}(T) \mathbf{S}(T)^{1/k} \leq \gamma(k+1) \mathbf{M}(T)^{(k+1)/k},$$

here the isoperimetric constant $\gamma(k+1)$ is determined by the requirement that equality results if Q is a flat $k+1$ disk having a standard round k sphere T as boundary. As noted in § 3.1.5, Q will be uniquely determined by T in case $k = n - 1$. The left-hand inequality above also holds for real rectifiable currents.

3.1.8. Slicing integral currents by Lipschitz functions. (See [F, § 4.3].) There is a quite general theory of slicing for currents. The special case we need is the following. Suppose that $T = \mathbf{t}(S, \theta, \sigma)$ is an integral k current ($k \geq 1$) and $\rho: \mathbb{R}^n \rightarrow \mathbb{R}$ satisfies a Lipschitz condition with constant 1. We set $m(r) = \|T\|(\{x: \rho(x) < r\})$ for each r so that m is nondecreasing and hence differentiable for almost every r . Then, for almost every r , the following will hold:

- (i) $\|T\|(\{x: \rho(x) = r\}) = 0$;
- (ii) The restriction current $T \llcorner \{x: \rho(x) < r\}$ is an integral k current, while the restriction current $\partial T \llcorner \{x: \rho(x) < r\}$ is an integral $k - 1$ current;
- (iii) The slice current $\langle T, \rho, r \rangle = \mathbf{t}(S \cap \{x: \rho(x) = r\}, \theta, \tau)$, for the appropriate τ , is a well-defined integral $k - 1$ current with $\mathbf{M}(\langle T, \rho, r \rangle) \leq m'(r)$ and

$$\partial(T \llcorner \{x: \rho(x) < r\}) = \partial T \llcorner \{x: \rho(x) < r\} + \langle T, \rho, r \rangle;$$

- (iv) The slice current $\langle \partial T, \rho, r \rangle$ is a well-defined integral $k - 2$ current with

$$\langle \partial T, \rho, r \rangle = -\langle \partial T, \rho, r \rangle.$$

3.1.9. Half-space comparisons. Suppose that $[K] \in \mathcal{H}$ and $\lambda: \mathbb{R}^n \rightarrow \mathbb{R}$ is linear with $\|\lambda\| = 1$. Then, for every r in \mathbb{R} , $[K \cap \{x: \lambda(x) < r\}] \in \mathcal{H}$, and we can use Stokes' theorem and Jensen's inequality [F, § 2.4.19] to infer that

$$\mathbf{M}(\partial[K \cap \{x: \lambda(x) < r\}]) \leq \mathbf{M}(\partial[K])$$

and

$$\Phi(\partial[K \cap \{x: \lambda(x) < r\}]) \leq \Phi(\partial[K]).$$

3.2. Existence of \mathcal{E} minimizers. Suppose that $\Delta t > 0$, $[K_0] \in \mathcal{H}$ and $[L_1], [L_2], [L_3], \dots$ are currents in \mathcal{H} for which

$$\lim_{i \rightarrow \infty} \mathcal{E}([K_0], [L_i], \Delta t) = \inf \{ \mathcal{E}([K_0], [L], \Delta t) : [L] \in \mathcal{H} \}.$$

In view of § 3.1.9, we can modify our L_i 's if necessary so that $\cup_i L_i$ is bounded. Since $\Phi_0 > 0$ (§ 2.1.3), we infer that $\sup_i \mathbf{M}(\partial L_i) < \infty$. The compactness theorem indicated in § 3.1.5 and the lower semicontinuity of Φ integrals guarantee the existence of a subsequence $i(1), i(2), i(3), \dots$ of $1, 2, 3, \dots$ and $[K] \in \mathcal{H}$ such that

$$\lim_{j \rightarrow \infty} \mathbb{G}(\partial[L_{i(j)}] - \partial[K]) = \lim_{j \rightarrow \infty} \mathcal{L}^n(L_{i(j)} \triangle K) = 0$$

and

$$\mathcal{E}([K_0], [K], \Delta t) = \inf \{ \mathcal{E}([K_0], [L], \Delta t) : [L] \in \mathcal{H} \}.$$

We define such a $[K]$ to be an \mathcal{E} minimizer for $[K_0]$ over Δt . (If we say $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt , it is to be presumed that $[K_0]$ and $[K]$ are in \mathcal{H} and $\Delta t > 0$.) We infer from § 3.1.5 again that the support of any such \mathcal{E} minimizer $[K]$ must lie within the convex hull of the closure of ∂K_0 .

3.3. Properties of \mathcal{E} minimizers. Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt .

3.3.1. For $[L] \in \mathcal{H}$, we check

$$K_0 \triangle L \sim K_0 \triangle K \subset K \triangle L$$

and infer from the definition of \mathcal{E} that

$$\Phi(\partial[K]) \leq \Phi(\partial[L]) + \frac{1}{\Delta t} \int_{x \in K \triangle L} \text{dist}(x, \partial K_0) d\mathcal{L}^n x.$$

3.3.2. We assert that, whenever Q is an integral n current in \mathbb{R}^n , then

$$\Phi(\partial[K]) \leq \Phi(\partial[K] + \partial Q) + \mathbf{S}(Q) \sup \left\{ \frac{\text{dist}(x, \partial K_0)}{\Delta t} : x \in \text{spt } Q \right\}.$$

To see this, we write

$$Q = \sum_i [Q_i] - \sum_j [P_j], \quad [K] + Q = \sum_i [N_i] - \sum_j [J_j],$$

as in § 3.1.4. As a comparison region, we set $L = N_1 = (K \sim P_1) \cup Q_1$ so that

$$K \triangle L = (Q_1 \sim K) \cup (P_1 \cap K) \subset Q_1 \cup P_1.$$

Our assertion now follows from §§ 3.3.1 and 3.1.3.

3.3.3. Suppose that $\varphi: \mathbb{R}^n \rightarrow \mathbb{R}^n$ is Lipschitz and $W = \{x: \varphi(x) \neq x\}$ is bounded. We assert the following:

$$(i) \quad \Phi_0 \mathcal{H}^{n-1}(\partial K \cap W) \leq \Phi^0 \mathcal{H}^{n-1}(\varphi(\partial K \cap W)) + E,$$

and, in case Φ is even,

$$(ii) \quad \Phi(\partial K \cap W) \leq \Phi(\varphi(\partial K \cap W)) + E,$$

where

$$E = \frac{\text{diam}(W \cup \varphi(W))}{n} [\mathcal{H}^{n-1}(\partial K \cap W) + \mathcal{H}^{n-1}(\varphi(\partial K \cap W))] \sup_{x \in \text{spt } Q} \left\{ \frac{\text{dist}(x, \partial K_0)}{\Delta t} \right\}.$$

To see this, we write

$$\varphi_*[K] - [K] = \sum_i [N_i] - \sum_j [L_j]$$

as in § 3.1.4, and, as a comparison region, we take $J = N_1 \cup (K \sim L_1)$ so that (since $N_1 \cap L_1 = \emptyset$)

$$K \triangle J = (N_1 \sim K) \cup (K \cap L_1) \subset N_1 \cup L_1$$

with

$$\partial(N_1 \cup L_1) \subset_{n-1} \partial N_1 \cup \partial L_1 \subset_{n-1} \varphi(\partial K \cap W) \cup (\partial K \cap W).$$

We then infer from the cone construction with p in W that

$$\begin{aligned} \mathcal{L}^n(K \triangle J) &\leq \mathcal{L}^n(N_1 \cup L_1) \\ &= \mathbf{M}([p] \times \partial[N_1 \cup L_1]) \\ &\leq \frac{\text{diam}(W \cup \varphi W)}{n} [\mathcal{H}^{n-1}(\partial K \cap W) + \mathcal{H}^{n-1}(\varphi(\partial K \cap W))]. \end{aligned}$$

We write

$$\varphi_*[K] = [K] + \sum_i [N_i] - \sum_j [L_j] = [J] + \sum_{i \geq 2} [N_i^*] - \sum_j [L_j^*]$$

for appropriate N_i^* 's and L_j^* 's, and we use § 3.1.4 to conclude that

$$\partial J \subset_{n-1} \varphi(\partial K \cap W) \cup (\partial K \sim W).$$

Since $\varphi(x) = x$ for $x \in \partial K \sim W$, we infer from the formula in § 3.1.3(i) that $\mathbf{n}_J(p) = \mathbf{n}_K(p)$ for \mathcal{H}^{n-1} almost every point p in $\partial K \cap \partial J \sim \varphi(\partial K \cap W)$. *Caution:* Examples show that there can be a set of positive \mathcal{H}^{n-1} measure in $\partial K \cap \partial J \cap \varphi(\partial K \cap W)$ for which $\mathbf{n}_J(p) = -\mathbf{n}_K(p)$. We infer that

$$\begin{aligned} \Phi(\partial J) &= \Phi(\partial J \llcorner (\partial K \sim W)) + \Phi(\partial J \llcorner \varphi(\partial K \cap W)) \\ &= \Phi(\partial K \llcorner (\partial K \sim W)) + \Phi(\partial J \llcorner \varphi(\partial K \cap W)). \end{aligned}$$

In view of § 3.3.1, we estimate that

$$\begin{aligned} \Phi(\partial K \llcorner W) &= \Phi(\partial K) - \Phi(\partial K \llcorner (\partial K \sim W)) \\ &\leq \Phi(\partial J \llcorner \varphi(\partial K \cap W)) + \frac{1}{\Delta t} \int_{x \in K \triangle J} \text{dist}(x, \partial K_0) d\mathcal{L}^n x. \end{aligned}$$

The two assertions of § 3.3.3 follow.

3.4. \mathcal{E} minimizers have lower density ratio bounds. Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . Suppose also that the convex hull of K_0 has diameter no larger than $D-1$ (for some $D \geq 1$). We will show the existence of uniform lower bounds to the density ratios of the measures $\|\partial[K]\|$ at points p in \mathbb{R}^n for which $\Theta^{*n-1}(\|\partial[K]\|, p) > 0$. As noted in § 3.1.3, this will imply that $\mathcal{H}^{n-1}(\text{closure}(\partial K) \triangle \partial K) = 0$.

We abbreviate $T = \partial[K]$ and suppose that $p \in \mathbb{R}^n$ with $\Theta^{*n-1}(\|T\|, p) > 0$. We set $\rho(x) = |x - p|$ for $x \in \mathbb{R}^n$ and $T_r = T \llcorner \{x: \rho(x) < r\}$,

$$m(r) = \mathbf{M}(T_r) = \mathcal{H}^{n-1}(\partial K \cap \mathbb{B}^n(p, r))$$

for $r > 0$. We use § 3.1.8 to infer that for almost every $r > 0$, the slice $\langle T, \rho, r \rangle$ exists with $\partial T_r = \langle T, \rho, r \rangle$ and $\mathbf{M}(\partial T_r) \leq m'(r)$. We then use the isoperimetric inequality in § 3.1.7 to infer the existence of an integral $n-1$ current R having support in $\mathbb{B}^n(p, r)$ such that $\partial R = \partial T_r = \langle T, \rho, r \rangle$ and

$$\mathbf{M}(R) \leq \gamma(n-1)\mathbf{M}(\partial T_r)^{(n-1)/(n-2)} \leq \gamma(n-1)m'(r)^{(n-1)/(n-2)}.$$

Since $\partial(R - T_r) = 0$, we infer from § 3.1.6 that the cone $Q = [p] \rtimes (R - T_r)$ satisfies the conditions $\partial Q = R - T_r$ and

$$\mathbf{M}(Q) \leq \frac{r}{n} \mathbf{M}(R - T_r) \leq \frac{r}{n} (\gamma(n-1)m'(r)^{(n-1)/(n-2)} + m(r)).$$

We infer that

$$\Phi(T + \partial Q) - \Phi(T) = \Phi(R + (T - T_r)) - \Phi(T_r + (T - T_r)) = \Phi(R) - \Phi(T_r),$$

and we use § 3.3.2 (recalling that $T = \partial[K]$) to conclude that

$$\begin{aligned} \Phi_0 m(r) &\leq \Phi(T_r) \\ &\leq \Phi(R) + \mathbf{M}(Q) \sup \left\{ \frac{\text{dist}(x, \partial K_0)}{\Delta t} : x \in \mathbb{B}^n(p, r) \right\} \\ &\leq \Phi^0 \gamma(n-1)m'(r)^{(n-1)/(n-2)} \\ &\quad + \frac{r}{n} (\gamma(n-1)m'(r)^{(n-1)/(n-2)} + m(r)) \sup \left\{ \frac{\text{dist}(x, \partial K_0)}{\Delta t} : x \in \mathbb{B}^n(p, r) \right\}. \end{aligned}$$

We restrict r 's to not exceed 1, and we infer that

$$m(r) \leq \frac{\Phi^0}{\Phi_0} \gamma(n-1)m'(r)^{(n-1)/(n-2)} + r \frac{D}{n\Delta t \Phi_0} (\gamma(n-1)m'(r)^{(n-1)/(n-2)} + m(r)),$$

so that

$$m(r) \left(1 - r \left(\frac{D}{n\Delta t \Phi_0} \right) \right) \leq \left(\gamma(n-1) \frac{\Phi^0}{\Phi_0} m'(r)^{(n-1)/(n-2)} \right) \left(1 + r \left(\frac{D}{n\Delta t \Phi_0} \right) \right).$$

In case

$$r \leq r_0 = \left(\frac{n\Phi_0}{3D} \right) \Delta t \quad \text{and} \quad C^{(n-1)/(n-2)} = 2\gamma(n-1) \frac{\Phi^0}{\Phi_0},$$

then

$$m(r) \leq C^{(n-1)/(n-2)} m'(r)^{(n-1)/(n-2)},$$

which implies that

$$((n-1)m(r)^{1/(n-1)})' = \frac{m'(r)}{m(r)^{(n-2)/(n-1)}} \geq \frac{1}{C};$$

since $m(r)$ is nondecreasing in r , we conclude that

$$(n-1)m(r)^{1/(n-1)} \geq \frac{r}{C}, \quad m(r) \geq \left(\frac{1}{(n-1)C} \right)^{n-1} r^{n-1}.$$

If $r_0 \leq r \leq \Delta t$, we can conclude further that

$$\frac{m(r)}{r^{n-1}} \geq \frac{m(r_0)}{r_0^{n-1}} \left(\frac{r_0}{r} \right)^{n-1} \geq \left(\frac{1}{(n-1)C} \right)^{n-1} \left(\frac{n\Phi_0}{3D} \right)^{n-1}.$$

We set

$$\theta = \frac{1}{(n-1)^{n-1}} \left(\frac{\Phi_0}{2\gamma(n-1)\Phi^0} \right)^{(n-1)^2/(n-2)} \inf \left\{ 1, \frac{n\Phi_0}{3D} \right\},$$

and we conclude that

$$\frac{m(r)}{r^{n-1}} \geq \theta \quad \text{for } 0 < r \leq \Delta t.$$

3.5. \mathcal{E} minimizers are (Φ, ω, δ) minimal currents in the sense of Bombieri. (See [Bo, Def. 1].) Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt and $D-1 \geq \text{diam}(K_0)$ (for some $D > 1$). Suppose that X is any $n-1$ integral current with $\partial X = 0$ whose support lies in a compact set $C \in \mathcal{C}$ for which

$$\text{diam}(C) = r \leq \delta =: \frac{n\Phi_0}{3D} \Delta t.$$

We assert that

$$\Phi(\partial[K] \llcorner C) \leq \Phi(\partial[K] \llcorner C + X) + \omega(r) \mathbf{M}(\partial[K] \llcorner C + X),$$

where

$$\omega(r) = r \left(\frac{3D\Phi^0}{n\Phi_0\Delta t} \right).$$

This condition is what is required for the current $\partial[K]$ to be (Φ, ω, δ) *minimal* in the sense of Definition 1 of [Bo].

In case Φ is smooth and elliptic, we assert further the existence of an open subset U of \mathbb{R}^n such that $\mathcal{H}^{n-1}(\text{spt } \partial[K] \sim U) = 0$ and $\text{spt } \partial[K] \cap U$ is a continuously differentiable $(n-1)$ -dimensional submanifold of \mathbb{R}^n . In case $n=3$, then $\text{spt } \partial[K]$ is a compact continuously differentiable two-dimensional submanifold of \mathbb{R}^3 without boundary.

To see our first assertion, we pick p in C and set $Q = [p] \times X$ (see § 3.1.6) so that $\partial Q = X$ and

$$\mathbf{S}(Q) \leq \mathbf{M}(Q) \leq \frac{r}{n} \mathbf{M}(X) \leq \frac{r}{n} [\mathbf{M}(\partial[K] \llcorner C + X) + \mathbf{M}(\partial[K] \llcorner C)].$$

From § 3.3.2, we infer that $\Phi(\partial[K]) \leq \Phi(\partial[K] + X) + \mathbf{S}(Q)(D/\Delta t)$, so that

$$\Phi(\partial[K] \llcorner C) \leq \Phi(\partial[K] \llcorner C + X) + \frac{rD}{n\Delta t\Phi_0} [\Phi(\partial[K] \llcorner C + X) + \Phi(\partial[K] \llcorner C)].$$

In case $r \leq \delta$, we infer that

$$\frac{1 + \frac{rD}{n\Delta t\Phi_0}}{1 - \frac{rD}{n\Delta t\Phi_0}} \leq 1 + 3 \frac{rD}{n\Delta t\Phi_0},$$

and hence

$$\Phi(\partial[K] \llcorner C) \leq \Phi(\partial[K] \llcorner C + X) \left(1 + 3 \frac{rD}{n\Delta t\Phi_0} \right).$$

Our first assertion follows directly.

The almost everywhere regularity asserted above follows from the final remark in [Bo], together with the density ratio estimate of § 3.4. The everywhere regularity in the case where $n = 3$ similarly follows, with the additional observation that tangent cones to $\partial[K]$ are absolutely Φ minimizing, hence everywhere regular in accordance with [ASS].

3.6. The supports of \mathcal{E} minimizers are (γ, δ) restricted sets in the sense of Almgren. (See [A1, § II.1].) Suppose $\Delta t > 0$ and $[K_0], [K]$ are solids in \mathcal{K} with

$$\mathcal{E}([K_0], [K], \Delta t) = \inf \{ \mathcal{E}([K_0], [L], \Delta t) : [L] \in \mathcal{K} \}$$

and $D - 1 \geq \text{diam}(K_0)$ (for some $D > 1$). We set

$$S = \text{spt } \partial[K], \quad \gamma = 2 \frac{\Phi^0}{\Phi_0}, \quad \delta = \inf \left\{ 1, \frac{n\Phi_0}{D} \Delta t \right\},$$

and assert

- (i) $\mathcal{H}^{n-1}(S \triangle \partial K) = 0$;
- (ii) $\mathcal{H}^{n-1}(S \cap W) \leq \gamma \mathcal{H}^{n-1}(\varphi(S \cap W))$ whenever
 - (a) $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a Lipschitz mapping,
 - (b) $W = \{x : \varphi(x) \neq x\}$,
 - (c) $\text{diam}(W \cup \varphi(W)) < \delta$.

These conditions comprise the definition of S being (γ, δ) *restricted* with respect to the empty set in the sense of [A1, § II.1]. This implies that S has the various properties demonstrated in Theorem II.3 of [A1].

Assertion (i) follows from the lower density ratio bounds established in § 3.4, as noted in § 3.3.1. Assertion (ii) follows from assertion (i) and § 3.3.3(i); compare the estimates in § 3.4 and § 3.7, below.

3.7. The supports of \mathcal{E} minimizers are $(\Phi, \varepsilon, \delta)$ minimal sets in the sense of Almgren. (See [A1, § III.1].) Suppose that Φ is an even integrand, $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt , $D \geq 1 + \text{diam}(K_0)$, and $\lambda = 3D/n\Phi_0$. We set

$$S = \text{spt } \partial[K], \quad \varepsilon(r) = r \left(\frac{\lambda}{\Delta t} \right), \quad \delta = \inf \left\{ 1, \frac{\Delta t}{\lambda} \right\}$$

for $0 < r < \delta$ and assert

- (i) S is (γ, δ) restricted (for suitable $\gamma > 1$);
- (ii) $\Phi(S \cap W) \leq (1 + \varepsilon(r))\Phi(\varphi(S \cap W))$ whenever
 - (a) $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is a Lipschitz mapping,
 - (b) $W = \{x : \varphi(x) \neq x\}$,
 - (c) $\text{diam}(W \cup \varphi(W)) = r < \delta$.

These conditions comprise the definition of S being $(\Phi, \varepsilon, \delta)$ *minimal* with respect to the empty set in the sense of [A1, § III.1]. This implies that S has the various properties demonstrated in Theorem III.3 of [A1]; in particular, if Φ is smooth and elliptic, then there is an open subset U of \mathbb{R}^n such that $\mathcal{H}^{n-1}(S \sim U) = 0$ and $S \cap U$ is locally a Hölder continuously differentiable $(n-1)$ -dimensional submanifold of \mathbb{R}^n for each Hölder exponent less than $\frac{1}{2}$.

Assertion (i) follows from § 3.6. Assertion (ii) follows from § 3.3.3(ii). In particular, we estimate from assertion (i), above, and § 3.3.3(ii) that

$$\Phi(S \cap W) \leq \Phi(\varphi(S \cap W)) + \frac{r}{n\Phi_0} [\Phi(S \cap W) + \Phi(\varphi(S \cap W))] \frac{D}{\Delta t},$$

so that

$$\Phi(S \cap W) \left(1 - r \frac{\lambda}{3\Delta t}\right) \leq \Phi(\varphi(S \cap W)) \left(1 + r \frac{\lambda}{3\Delta t}\right).$$

We check that

$$\frac{\left(1 + r \frac{\lambda}{3\Delta t}\right)}{\left(1 - r \frac{\lambda}{3\Delta t}\right)} \leq \left(1 + r \frac{\lambda}{\Delta t}\right)$$

provided $r \leq \Delta t / \lambda$.

THEOREM 3.8 (higher regularity of \mathcal{E} minimizers). *Suppose that Φ is smooth and elliptic and that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . For each $p \in \mathbb{R}^n$, let $g(p) = \pm \text{dist}(p, \partial K_0)$, where we take the negative sign if $p \in K_0$, and take the positive sign otherwise.*

(1) *For \mathcal{H}^{n-1} almost every point p in $\text{spt } \partial[K]$, there is a Euclidean motion $L: \mathbb{R}^n \rightarrow \mathbb{R}^n$, together with positive numbers R and M and a continuously differentiable function $f: \mathbb{B}^{n-1}(0, 2R) \rightarrow (-M, M)$ for which*

$$L(K) \cap (\mathbb{B}^{n-1}(0, 2R) \times (-M, M)) = \{(x, y): x \in \mathbb{B}^{n-1}(0, 2R), -M < y < f(x)\}.$$

Furthermore, g is Lipschitz continuous with Lipschitz constant equal to 1, and $g(x, f(x))$ is Lipschitz as a function of x .

For simplicity of notation, we will hereafter assume that L is the identity mapping on \mathbb{R}^n and that R , M , and f are fixed.

(2) *f weakly satisfies*

$$(3.8.1) \quad \sum_{i=1}^{n-1} \frac{\partial}{\partial x_i} \left(\frac{\partial \Phi}{\partial v_i}(v) \right) \Big|_{v=(-\partial f / \partial x_1)(x), \dots, -(\partial f / \partial x_{n-1})(x), 1)} = \frac{g(x, f(x))}{\Delta t},$$

is thus twice Hölder continuously differentiable in $\mathbb{B}^{n-1}(0, R)$, and strongly satisfies

$$(3.8.2) \quad \begin{aligned} \frac{g(x, f(x))}{\Delta t} &= - \sum_{i,j=1}^{n-1} \frac{\partial^2 \Phi}{\partial v_i \partial v_j}(v) \Big|_{v=(-\partial f / \partial x_1)(x), \dots, -(\partial f / \partial x_{n-1})(x), 1)} \frac{\partial^2 f}{\partial x_i \partial x_j}(x) \\ &= H_{\Phi, \partial K}(x, f(x)) \cdot \mathbf{n}_K(x, f(x)). \end{aligned}$$

(3) f , in fact, satisfies the *a priori* estimates on second derivatives

$$\begin{aligned} & \sup \left\{ \left| \frac{\partial^2 f}{\partial x_i \partial x_j}(x) \right| : 1 \leq i \leq j \leq n-1, x \in \mathbb{B}^{n-1}(0, R) \right\} \\ & \leq C \left(\frac{1}{R} \sup \left\{ \left| \frac{\partial f}{\partial x_i}(x) \right| : 1 \leq i \leq n-1, x \in \mathbb{B}^{n-1}(0, 2R) \right\} \right. \\ & \quad \left. + \frac{R}{\Delta t} \sup \{ |\nabla g(x)| : x \in \mathbb{B}^{n-1}(0, 2R) \} \right); \end{aligned}$$

here C is a constant depending only on an upper bound for $|\nabla f|$.

(4) \mathcal{H}^{n-1} almost everywhere, $\text{spt } \partial[K]$ is a twice continuously differentiable submanifold of \mathbb{R}^n , with estimates on its principal curvatures analogous to those in (3) above.

(5) If $|g|$ is sufficiently small, g will be as differentiable as ∂K_0 is. If g is k times Hölder continuously differentiable with exponent α for some positive integer k and some $0 < \alpha < 1$, and if f is a Lipschitz solution to (3.8.1), then f is, in fact, $k+2$ times Hölder continuously differentiable with exponent α .

Proof. (1) We know from our analysis in § 3.5 or § 3.7, above, that $\text{spt } \partial[K]$ is almost everywhere a continuously differentiable submanifold of \mathbb{R}^n ; the distance function is always Lipschitz with Lipschitz constant 1 (by the triangle inequality), and the Lipschitz dependence on x follows from the fact that f is Lipschitz.

(2) Since $[K]$ is an \mathcal{E} minimizer, f must weakly satisfy the Euler–Lagrange equation for \mathcal{E} , which is (3.8.1). Since f is Lipschitz, (3.8.1) is uniformly elliptic; i.e.,

$$\sum_{i,j=1}^{n-1} \partial_{v_i}(\partial_{v_j} \Phi) \xi_i \xi_j \geq \nu |\xi|^2$$

for every ξ in \mathbb{R}^{n-1} and some $\nu = \nu(\|f\|_{\text{Lip}}) > 0$.

Using [LU, Chap. 6, Thm. 1.1, p. 339], we conclude that f is Hölder continuously differentiable with Hölder norm depending only on the sup norm of ∇f . However, we can differentiate (3.8.1) again and conclude that the first partial derivative of f with respect to x_k is itself a solution of the linear PDE

$$\frac{1}{\Delta t} \left(\frac{\partial g}{\partial x_k}(x, f(x)) + \frac{\partial g}{\partial y}(x, f(x)) \frac{\partial f}{\partial x_k}(x) \right) = \sum_{i,j=1}^{n-1} \frac{\partial}{\partial x_i} \left(a_{i,j}(x) \frac{\partial (f/\partial x_k)}{\partial x_j}(x) \right)$$

for

$$a_{i,j} = \frac{\partial^2 \Phi}{\partial v_i \partial v_j} \left(-\frac{\partial f}{\partial x_1}, \dots, -\frac{\partial f}{\partial x_{n-1}}, 1 \right),$$

which is Hölder continuous. Using [G, Chap. VII, Thm. 1.2, p. 219] (and the fact that g is Lipschitz), we conclude that $\partial f/\partial x_k$ is also Hölder continuously differentiable. Conclusion (3) now is a consequence of the fact that $\partial f/\partial x_k$ satisfies a linear PDE.

(3) This is essentially a restatement of (1)–(3).

(4) This follows from [KP] and [G] as before. \square

Comment. We do not use the estimates on the second derivatives in (3) in this paper, nor do we use the curvature estimates in (4) or the estimates in (5). These results are included here as essentially the maximum regularity that we know, in general, about \mathcal{E} minimizers (see § 7). We note that it is difficult to use (5) to conclude higher differentiability in the approximate flows $\partial[K_j(t)]$ constructed as in § 2.6, since any given $\Delta t = 2^{-j}$ may not be sufficiently small. Conclusions (1), (3), and (5) of Theorem 5.4 give our best general barrier estimates; see also the barriers constructed in 7.1.

THEOREM 3.9 (scaling of \mathcal{E} minimizers and tangent currents). *Suppose that our surface energy function Φ is smooth and elliptic and the $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . For each point p in \mathbb{R}^n (which we fix) and each scale factor $R > 0$, we set $f_{p,R}(x) = R(x - p)$ (a translation followed by a homothety) and $[K(R)] = [f_{p,R}K]$ and $[K_0(R)] = [f_{p,R}K_0]$.*

(1) *Each $[K(R)]$ is an \mathcal{E} minimizer for $[K_0(R)]$ over $R^2\Delta t$, i.e.,*

$$\begin{aligned} & \Phi(\partial[K(R)]) + \frac{1}{R^2\Delta t} \int_{x \in K(R) \triangle K_0(R)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x \\ &= \inf \left\{ \Phi(\partial[L]) + \frac{1}{R^2\Delta t} \int_{x \in L \triangle K_0(R)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x : [L] \in \mathcal{H} \right\}. \end{aligned}$$

(2) *Each increasing sequence $R(1), R(2), R(3), \dots$ of positive numbers that diverges to infinity has a subsequence $R(i(1)), R(i(2)), R(i(3)), \dots$ such that the currents $[K(R(i(j)))]$ converge, as $j \rightarrow \infty$, to a limit locally integral current $[J]$; such convergence means that, for each radius r , $\lim_{j \rightarrow \infty} \mathcal{L}^n(J \triangle K(R(i(j)))) = 0$. The boundary $\partial[J]$ of each such limit current $[J]$ is absolutely Φ minimizing, and the supports of the $\partial[K(R(i(j)))]$'s converge to the support of $\partial[J]$, as $j \rightarrow \infty$, locally uniformly in the Hausdorff distance topology.*

Notation. Any such current $\partial[J]$ is called a *tangent current* to $\partial[K]$ at p . Conclusion (2) asserts that any tangent current to any \mathcal{E} minimizer at any point is locally Φ minimizing. In general, it is an open question whether there can be more than one tangent current at a given point p .

Proof. With regard to the first assertion above, we compute that

$$\begin{aligned} \Phi(\partial[K_0(R)]) &= R^{n-1}\Phi(\partial[K]), \\ \frac{1}{\Delta t} \int_{x \in K(R) \triangle K_0(R)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x &= R^{n+1} \frac{1}{\Delta t} \int_{x \in K \triangle K_0} \text{dist}(x, \partial K_0) \, d\mathcal{L}^n x. \end{aligned}$$

The existence of the convergent sequence $\{K(R(i(j)))\}_j$ follows from general compactness theorems for locally integral currents such as [A2, § 4.4] (see also [F, § 4.2.17], [ASS, Thm. 1.1, p. 225], and §§ 3.1.5, 3.2, above). The bounds on mass necessary for applying such theorems follow from the observation that, for each q and r ,

$$\Phi(\partial[K(R)]) \leq \Phi(\partial[K^R \sim \mathbb{B}^n(q, r)]) + \frac{1}{R^2\Delta t} \int_{x \in \mathbb{B}^n(q, r)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x,$$

which implies that

$$\Phi(\partial[K(R)] \llcorner \mathbb{B}^n(q, r)) \leq \Phi^0 n \alpha(n) r^{n-1} + \frac{1}{R^2\Delta t} \int_{\mathbb{B}^n(q, r)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x,$$

since $\mathcal{H}^{n-1}(\partial \mathbb{B}^n(q, r)) = n \alpha(n) r^{n-1}$. For each fixed q and r , we can check that

$$\lim_{R \rightarrow \infty} \frac{1}{R^2\Delta t} \int_{\mathbb{B}^n(q, r)} \text{dist}(x, \partial K_0(R)) \, d\mathcal{L}^n x = 0.$$

This last fact, in addition to providing upper density ratio bounds, implies that the integrals over $K(R) \triangle K_0(R)$ matter less in the \mathcal{E} minimization as R becomes large. We use this fact to infer that any limit $\partial[J]$ is locally Φ minimizing.

The lower density ratio bounds established in § 3.4 are used to establish the convergence of the supports. \square

THEOREM 3.10 (elliptic \mathcal{E} minimizers are smooth near contact points with smooth barriers and in low dimensions). *Suppose that our surface energy function Φ is smooth and elliptic and that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt .*

(1) *If $\{p\} = \text{spt } \partial[K] \cap \mathbb{B}^n(q, r)$ for some points p and q in \mathbb{R}^n and $r = |q - p|$, then there is an open neighborhood U of p such that $\text{spt } (\partial[K]) \cap U$ is a twice continuously differentiable hypersurface in \mathbb{R}^n . In particular, $\text{spt } \partial[K] \cap U = \partial K \cap U$.*

(2) *If $n = 2$ (respectively, $n = 3$), then $\text{spt } \partial[K] = \partial K$ is everywhere a smooth curve in the plane (respectively, a smooth surface in space).*

Proof. The criterion that we use for regularity above is that the support of $\partial[K]$ within a small ball centered at p can, in fact, be contained in a very thin disk through p in that ball. Knowing this, we can then invoke the regularity construction of Bombieri to conclude C^1 regularity in a smaller ball; the higher regularity then follows from Theorem 3.8(2). The way in which we establish such a disk condition on the supports is by showing that there is a tangent current to $\partial[K]$ at p whose support is regular. This being the case, we also infer that there is a tangent current there having a hyperplane as support. The disk condition is then a consequence of the convergence of the supports given in conclusion (2) of Theorem 3.9.

Now consider the conditions assumed in assertion (1) of Theorem 3.10. We let $f_{p,R}$ be as in Theorem 3.9 (same p) and let $\partial[J]$ be any Φ minimizing tangent current as in Theorem 3.9(2). We infer that the support of $\partial[J]$ lies in the half-space $\{v: v \cdot (q - p) \geq 0\}$ and contains the origin. We now use Remark 1 about Φ minimizers following [ASS, Thm. 1.2, p. 227] to conclude that the origin is a regular point of $\text{spt } \partial[J]$. This then implies conclusion (1), above. The first assertion of conclusion (2) of the above theorem follows in a similar way, based on the one-dimensional regularity for Φ minimizers given in [F, § 5.3.20]. The second assertion of conclusion (2) similarly is based on the two-dimensional regularity of Φ minimizers given in [ASS, Cor. 3.2, p. 255]. \square

4. Existence and Hölder continuity of flat Φ curvature flows. The goal of this section is to establish modulus of continuity estimates on approximate Φ curvature flows that imply a priori Hölder continuity in the \mathbb{G} metric of any limit flat Φ curvature flow. Such a modulus of continuity estimate is a pivotal result in this paper in justifying the variational approach to curvature motion. It follows from our \mathcal{E} minimization construction that each $K_j(t)$ lies within the convex hull of the initial $K(0)$ with

$$\Phi_0 \mathbf{M}(\partial[K_j(t)]) \leq \Phi(\partial[K_j(t)]) \leq \Phi(\partial[K(0)]) \leq \Phi^0 \mathbf{M}(\partial[K(0)]).$$

We can thus use compactness theorems for integral currents (§ 3.1.5), together with Cantor's diagonal process, to infer the existence of a subsequence $j(1), j(2), j(3), \dots$ of $1, 2, 3, \dots$, so that, for a dense set of times, the currents $\partial[K_{j(i)}(t)]$ will converge to a limit current $\partial[K(t)]$ as $i \rightarrow \infty$. Since this fact, in itself, does not preclude the possibility that the $\partial[K(t)]$'s might vary in a wildly discontinuous way, some additional estimate is necessary to guarantee continuity, and the Hölder estimate does this.

Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . Since we can always take $K = K_0$ in minimizing $\mathcal{E}([K_0], [K], \Delta t)$, we will take a different K only if there is a reduction in surface energy at least equal to the cost

$$\frac{1}{\Delta t} \int_{p \in K_0 \Delta K} \text{dist}(p, \partial K_0) d\mathcal{L}^n p.$$

In Proposition 4.2 (based on Proposition 4.1), we are effectively able to dominate the volume of $K_0 \triangle K$ in terms of

$$\frac{\Delta t^{1/2}(\Phi(\partial[K_0]) - \Phi(\partial[K]))^{1/2}}{\theta},$$

where θ denotes a positive lower bound to the density ratios of $\|\partial[K_0]\|$; the necessary bounds were established in § 3.4. Theorem 4.4 is a formal statement of the a priori Hölder bound, and Theorem 4.5 is a formal statement of the existence of flat Φ curvature flows.

The lower density ratio bound θ for $\|\partial[K_0]\|$ depends on the assumption that $[K_0]$ itself is an \mathcal{E} minimizer. Without this assumption, $\partial[K_0]$ might contain filigree and nooks and crannies, and hence there may be a large volume within a short distance from ∂K_0 .

We note that the best general estimate we have on how far ∂K can be from ∂K_0 (with no minimizing assumption on K_0) is comparable to $\Delta t^{1/2}$ (which would not give a uniform modulus of continuity when summed over many Δt 's). One side of this bound will be obtained in conclusion (2) of Proposition 5.3; the other side of the bound follows if we reformulate our study in terms of complementary currents as noted in Step 3 of the proof of Theorem 5.4. See also conclusions (1) and (3) of Theorem 5.4.

PROPOSITION 4.1 (a volume-distance inequality). *Suppose that C is a closed subset of \mathbb{R}^n and $\rho(x) = \text{dist}(x, C)$ for each x . Suppose also that A is an \mathcal{L}^n measurable subset of \mathbb{R}^n and that Δt and E are positive numbers such that*

$$\frac{1}{\Delta t} \int_A \rho \, d\mathcal{L}^n \leq E.$$

Then, for each $0 < R < \infty$,

$$\mathcal{L}^n(A \sim C) \leq 2^{1/2} (\sup \{ \mathcal{H}^{n-1}(A \cap \rho^{-1}\{r\}) : 0 < r < R \})^{1/2} (\Delta t)^{1/2} + \frac{\Delta t}{R} E.$$

Proof of Proposition 4.1.

Step 1. For each function $f: [0, R] \rightarrow [0, S]$, we have

$$\int_0^R f \, dr \leq 2^{1/2} S^{1/2} \left(\int_0^R r f(r) \, dr \right)^{1/2}.$$

Proof. If f is not measurable, then neither side of the asserted inequality is defined. Suppose then that f is measurable and let $h: [0, S] \rightarrow [0, R]$ be the distribution function of f defined by requiring that

$$h(s) = \mathcal{L}^1\{r: f(r) > s\}$$

for each s . We denote by $g: [0, R] \rightarrow [0, S]$ the nonincreasing function having h as distribution function; g is called the decreasing rearrangement of f . Fubini's theorem implies that

$$\int_0^R f \, dr = \int_0^S h \, ds = \int_0^R g \, dr,$$

and it is obvious that

$$\int_0^R g \rho \, dr \leq \int_0^R f \rho \, dr$$

for every nondecreasing function $\rho : [0, R] \rightarrow \mathbb{R}^+$. We use this second fact, together with Fubini's theorem, to estimate

$$\begin{aligned} \int_0^R rf(r) dr &\geq \int_0^R rg(r) dr \\ &= \int_{r=0}^R \int_{s=0}^{g(r)} r ds dr \\ &= \int_{s=0}^S \int_{r=0}^{h(s)} r dr ds \\ &= \frac{1}{2} \int_{s=0}^S h^2(s) ds. \end{aligned}$$

We use the first fact, together with the extreme inequality above and Schwarz's inequality, to estimate

$$\begin{aligned} \int_{r=0}^R f(r) dr &= \int_{s=0}^S h(s) ds \\ &\leq S^{1/2} \left(\int_{s=0}^S h^2(s) ds \right)^{1/2} \\ &\leq 2^{1/2} S^{1/2} \left(\int_0^R rf(r) dr \right)^{1/2}, \end{aligned}$$

which establishes the assertion of Step 1.

Step 2. Suppose that $\mathcal{H}^{n-1}(\rho^{-1}\{r\} \cap A) \leq S < \infty$ for \mathcal{L}^1 almost every $0 < r < R$. Then

$$\mathcal{L}^n(A \cap \rho^{-1}(0, R)) \leq 2^{1/2} S^{1/2} \left(\int_{A \cap \rho^{-1}(0, R)} \rho d\mathcal{L}^n \right)^{1/2}.$$

Proof. For each $0 < r < R$, we set $f(r) = \mathcal{H}^{n-1}(A \cap \rho^{-1}\{r\})$ and use Federer's coarea formula (§ 3.1.2(iv)) to estimate

$$\mathcal{L}^n(A) = \int_A J_1 \rho d\mathcal{L}^n = \int_0^R f(r) dr$$

and

$$\int_A \rho d\mathcal{L}^n = \int_0^R rf(r) dr.$$

The assertion of Step 2 now follows from Step 1.

Step 3. For $0 < R < \infty$, we note that

$$\mathcal{L}^n(A \cap \rho^{-1}(0, R)) \leq 2^{1/2} (\sup \{ \mathcal{H}^{n-1}(A \cap \rho^{-1}\{r\}) : 0 < r < R \})^{1/2} (\Delta t)^{1/2} E^{1/2}$$

as a consequence of Step 2, while clearly

$$R \mathcal{L}^n(A \cap \rho^{-1}[R, \infty)) \leq \int_{A \cap \rho^{-1}[R, \infty)} \rho d\mathcal{L}^n$$

so that $\mathcal{L}^n(A \cap \rho^{-1}[R, \infty)) \leq (\Delta t/R)E$. The proposition follows. \square

PROPOSITION 4.2 (a volume-distance inequality when the zero set has density ratios bounded from below). *Suppose that C is a compact subset of \mathbb{R}^n and $\rho(x) = \text{dist}(x, C)$ for each x . Suppose also that A is an \mathcal{L}^n measurable subset of \mathbb{R}^n and that $\delta, \theta, \Delta t$, and E are positive numbers such that*

$$\frac{1}{\Delta t} \int_A \rho \, d\mathcal{L}^n \leq E$$

and

$$\mathcal{H}^{n-1}(C \cap \mathbb{B}^n(p, r)) \geq \theta r^{n-1}.$$

whenever p lies in C and $0 < r \leq \delta$. Then, for each $\delta < R < \infty$,

$$\mathcal{L}^n(A \sim C) \leq \left[2\Gamma \left(\frac{R}{\delta} \right)^{n-1} \mathcal{H}^{n-1}(C) \right]^{1/2} (\Delta t)^{1/2} E^{1/2} + \frac{\Delta t}{R} E.$$

Here

$$\Gamma = 2^{2n+1} n \alpha(n) \beta(n) / \theta,$$

$\alpha(n)$ is the volume of the unit n ball in \mathbb{R}^n , and $\beta(n)$ is the constant of the Besicovitch-Federer covering theorem in \mathbb{R}^n .

Proof of Proposition 4.2. Given Proposition 4.1, we prove this proposition by showing that

$$\sup_{0 < r < R} \mathcal{H}^{n-1}(\rho^{-1}\{r\}) \leq \Gamma \left(\frac{R}{\delta} \right)^{n-1} \mathcal{H}^{n-1}(C).$$

We prove this in three steps, shown below. In them, we use Σ rather than C , because sometimes we are dealing with only a portion of C or a scaled and translated portion of it. Similarly, we use σ rather than ρ to denote distance to Σ . (The proposition will be applied with $C = \text{spt } \partial[K_j(k\Delta t_j)]$ in Theorem 4.5.)

Step 1 (a divergence theorem estimate between level sets of a distance function). Suppose that σ is the distance function to some compact subset Σ of \mathbb{R}^n . Then, for almost every $0 < R < S < \infty$,

$$\mathcal{H}^{n-1}(\sigma^{-1}\{S\}) - \mathcal{H}^{n-1}(\sigma^{-1}\{R\}) \leq \frac{n-1}{R} \mathcal{L}^n(\sigma^{-1}(R, S)).$$

Proof. We would like to prove Step 1 via the intermediate relations

$$\int_{\sigma^{-1}\{S\}} \nabla \sigma \cdot \mathbf{n} \, d\mathcal{H}^{n-1} - \int_{\sigma^{-1}\{R\}} \nabla \sigma \cdot \mathbf{n} \, d\mathcal{H}^{n-1} = \int_{\sigma^{-1}(R, S)} \Delta \sigma \, d\mathcal{L}^n \leq \frac{n-1}{R} \int_{\sigma^{-1}(R, S)} 1 \, d\mathcal{L}^n$$

with the equality following from the divergence theorem (with $\mathbf{n} = \mathbf{n}_{\sigma^{-1}(R, S)}$), and the inequality arising from the facts that the Laplacian of the distance function from a point is $(n-1)/R$ and that the infimum of two functions has its Laplacian less than the supremum of the two Laplacians (with the Laplacian along the crease where the two functions are equal being $-\infty$). However, σ need not be smooth enough to do this directly (unless C consists of just a couple of points). We must therefore work harder.

Suppose that Ω is an open subset of \mathbb{R}^n , that $f, g : \Omega \rightarrow \mathbb{R}$ are infinitely smooth, and that $\nabla(f-g)$ does not vanish on the smooth submanifold $\Gamma = \{x; f(x) = g(x)\}$; we set $A = \Omega \cap \{x; f(x) < g(x)\}$. We check that the distribution Laplacian of the function $h = \inf\{f, g\}$ is associated with the measure

$$\mathcal{L}^n L\Omega \wedge \Delta h + \mathcal{H}^{n-1} \llcorner \Gamma \wedge (\mathbf{n}_A \cdot \nabla g - \mathbf{n}_A \cdot \nabla f)$$

and that $\mathbf{n}_A \cdot \nabla g - \mathbf{n}_A \cdot \nabla f$ is negative; here Δh is set equal to zero on Γ . By saying this,

we mean, in particular, that

$$\int_{\Omega} \Delta \varphi h \, d\mathcal{L}^n = \int_{\Omega} \varphi \Delta h \, d\mathcal{L}^n + \int_{\Gamma} \varphi (\mathbf{n}_A \cdot \nabla g - \mathbf{n}_A \cdot \nabla f) \, d\mathcal{H}^{n-1}$$

for every test function φ with compact support in Ω . It follows that, if M is positive and $\Delta f \leq M$ and $\Delta g \leq M$, then

$$\int_{\Omega} \Delta \varphi h \, d\mathcal{L}^n \leq M \int_{\Omega} \varphi \, d\mathcal{L}^n$$

for every nonnegative test function φ with compact support in Ω . More generally, if f and g are summable functions with

$$\int_{\Omega} \Delta \varphi f \, d\mathcal{L}^n \leq M \int_{\Omega} \varphi \, d\mathcal{L}^n \quad \text{and} \quad \int_{\Omega} \Delta \varphi g \, d\mathcal{L}^n \leq M \int_{\Omega} \varphi \, d\mathcal{L}^n$$

for every nonnegative test function φ with compact support in Ω , then

$$\int_{\Omega} \Delta \varphi \inf \{f, g\} \, d\mathcal{L}^n \leq M \int_{\Omega} \varphi \, d\mathcal{L}^n$$

for such φ . Indeed, regularization and the Morse–Sard–Federer theorem reduce the estimate to the case in which f and g are smooth as above. The Laplacian of the radius function r is computed to equal $(n-1)/r$ for $r \neq 0$. Since σ is the infimum of a countable set of nonnegative radius functions centered at points dense in Σ , we use Lebesgue’s dominated convergence theorem to conclude that, whenever $0 < R < S < \infty$ and $\Omega = \sigma^{-1}(R, S)$, then

$$\int_{\Omega} \Delta \varphi \sigma \, d\mathcal{L}^n \leq \frac{n-1}{R} \int_{\Omega} \varphi \, d\mathcal{L}^n$$

for every nonnegative test function φ with compact support in Ω . Suppose that Ψ_{ε} is a spherically symmetric smoothing function with support contained in $\mathbb{B}^n(0, \varepsilon)$ and $\sigma_{\varepsilon} = \sigma * \Psi_{\varepsilon}$ is a smoothing of σ and $\nabla \sigma_{\varepsilon}$ is the smoothing of $\nabla \sigma$, equivalently, the gradient of σ_{ε} . Then, as is well known, $\sigma_{\varepsilon} \rightarrow \sigma$ uniformly as $\varepsilon \downarrow 0$ and $\nabla \sigma_{\varepsilon} \rightarrow \nabla \sigma$ almost everywhere as $\varepsilon \downarrow 0$. We use Federer’s coarea formula (§ 3.1.2(iv)) to confirm that, for almost every R and S , our Ω will be a set having finite perimeter $\partial\Omega$, which is \mathcal{H}^{n-1} almost equal to $\sigma^{-1}\{S\} \cup \sigma^{-1}\{R\}$, while, for \mathcal{H}^{n-1} almost every p in $\sigma^{-1}\{S\}$, $\mathbf{n}_{\Omega}(p) = \nabla \sigma(p)$, and for \mathcal{H}^{n-1} almost every p in $\sigma^{-1}\{R\}$, $\mathbf{n}_{\Omega}(p) = -\nabla \sigma(p)$. Similarly, for almost every R and S ,

$$\int_{\partial\Omega} |\nabla \sigma_{\varepsilon} - \nabla \sigma| \, d\mathcal{H}^{n-1} \rightarrow 0 \quad \text{as } \varepsilon \downarrow 0.$$

For almost every R and S , we can let χ_{Ω} denote the characteristic function of Ω and use the divergence theorem to infer that

$$\begin{aligned} \int_{\Omega} \Delta \sigma_{\varepsilon} \, d\mathcal{L}^n &= \int_{\partial\Omega} \nabla \sigma_{\varepsilon} \cdot \mathbf{n}_{\Omega} \, d\mathcal{H}^{n-1} \\ &= \int_{\sigma^{-1}\{S\}} \nabla \sigma \cdot \nabla \sigma \, d\mathcal{H}^{n-1} + \int_{\sigma^{-1}\{S\}} (\nabla \sigma_{\varepsilon} - \nabla \sigma) \cdot \mathbf{n}_{\Omega} \, d\mathcal{H}^{n-1} \\ &\quad - \int_{\sigma^{-1}\{R\}} \nabla \sigma \cdot \nabla \sigma \, d\mathcal{H}^{n-1} - \int_{\sigma^{-1}\{R\}} (\nabla \sigma_{\varepsilon} - \nabla \sigma) \cdot \mathbf{n}_{\Omega} \, d\mathcal{H}^{n-1} \\ &= \mathcal{H}^{n-1}(\sigma^{-1}\{S\}) - \mathcal{H}^{n-1}(\sigma^{-1}\{R\}) \\ &\quad + \int_{\sigma^{-1}\{S\}} (\nabla \sigma_{\varepsilon} - \nabla \sigma) \cdot \mathbf{n}_{\Omega} \, d\mathcal{H}^{n-1} - \int_{\sigma^{-1}\{R\}} (\nabla \sigma_{\varepsilon} - \nabla \sigma) \cdot \mathbf{n}_{\Omega} \, d\mathcal{H}^{n-1}, \end{aligned}$$

while

$$\begin{aligned}
 \int_{\Omega} \Delta \sigma_{\varepsilon} d\mathcal{L}^n &= \lim_{\delta \downarrow 0} \int_{\mathbb{R}^n} (\chi_{\Omega} * \Phi_{\delta}) \Delta \sigma_{\varepsilon} d\mathcal{L}^n \\
 &= \lim_{\delta \downarrow 0} \int_{\mathbb{R}^n} \Delta(\chi_{\Omega} * \Phi_{\delta}) \sigma_{\varepsilon} d\mathcal{L}^n \\
 &= \lim_{\delta \downarrow 0} \int_{\mathbb{R}^n} \Delta(\chi_{\Omega} * \Phi_{\delta} * \Phi_{\varepsilon}) \sigma d\mathcal{L}^n \\
 &\leq \lim_{\delta \downarrow 0} \frac{n-1}{R-\delta-\varepsilon} \int_{\mathbb{R}^n} (\chi_{\Omega} * \Phi_{\delta} * \Phi_{\varepsilon}) d\mathcal{L}^n \\
 &= \frac{n-1}{R-\varepsilon} \int_{\mathbb{R}^n} (\chi_{\Omega} * \Phi_{\varepsilon}) d\mathcal{L}^n.
 \end{aligned}$$

Our asserted inequality follows by combining these two inequalities and letting $\varepsilon \downarrow 0$.

Step 2 (an estimate on the size of level sets of a distance function inside balls). Suppose that $\sigma: \mathbb{R}^n \rightarrow \mathbb{R}^+$ gives the distance to some closed subset Σ of \mathbb{R}^n . Then

$$\mathcal{H}^{n-1}(\sigma^{-1}\{1\} \cap \mathbb{B}^n(0, 2)) \leq 2^{2n+1} n\alpha(n).$$

Proof. Replacing Σ by $\Sigma \cap \mathbb{B}^n(0, 3)$, if necessary we assume without loss of generality that $\Sigma \subset \mathbb{B}^n(0, 3)$. Federer's coarea formula (§ 3.1.2(iv)) implies the existence of $\frac{1}{2} < R < 1$ such that $\mathcal{H}^{n-1}(\sigma^{-1}\{R\}) \leq 2\mathcal{L}^n(\sigma^{-1}(\frac{1}{2}, 1))$. Combining this with Step 1 we obtain

$$\begin{aligned}
 \mathcal{H}^{n-1}(\sigma^{-1}\{1\}) &\leq \mathcal{H}^{n-1}(\sigma^{-1}\{R\}) + 2(n-1)\mathcal{L}^n(\sigma^{-1}(R, 1)) \\
 &\leq 2n\mathcal{L}^n(\sigma^{-1}(\tfrac{1}{2}, 1)) \\
 &\leq 2n\mathcal{L}^n(\mathbb{B}^n(0, 4)) \\
 &= 2^{2n+1} n\alpha(n).
 \end{aligned}$$

Step 3. For almost every $0 < r < \infty$,

$$\mathcal{H}^{n-1}(\rho^{-1}\{r\}) \leq \begin{cases} \Gamma \mathcal{H}^{n-1}(C) & \text{in case } 0 < r < \delta, \\ \Gamma(r/\delta)^{n-1} \mathcal{H}^{n-1}(C) & \text{in case } \delta \leq r < \infty, \end{cases}$$

where $\Gamma = 2^{2n+1} n\alpha(n)\beta(n)/\theta$ as above.

Proof. Fix $0 < r < \infty$ and consider balls $\mathbb{B}^n(p, r)$ corresponding to all points p in C . Then, according to our hypothesis about density ratio, for each p and r we have

$$r^{n-1} \leq \frac{1}{\theta} \mathcal{H}^{n-1}(C \cap \mathbb{B}^n(p, r)) \quad \text{in case } 0 < r < \delta$$

and

$$r^{n-1} = \left(\frac{r}{\delta}\right)^{n-1} (\delta)^{n-1} \leq \left(\frac{r}{\delta}\right)^{n-1} \frac{1}{\theta} \mathcal{H}^{n-1}(C \cap \mathbb{B}^n(p, \delta)) \quad \text{for } \delta \leq r < \infty.$$

The Besicovitch-Federer covering theorem (or a direct argument in this case) guarantees the existence of points p_1, p_2, p_3, \dots in C such that C is contained in the union of the $\mathbb{B}^n(p_i, r)$'s and no point in \mathbb{R}^n is contained in more than $\beta(n)$ of the

$\mathbb{B}^n(p_i, r)$'s. Since C is bounded, the number of these balls is finite. Clearly, $\rho^{-1}\{r\}$ is contained in the union of the $\mathbb{B}^n(p_i, 2r)$'s, since each point in $\rho^{-1}\{r\}$ is distance r from some point in C and that point is contained in one of the $\mathbb{B}^n(p_i, r)$'s. Hence, we can scale Step 2, above, by the homothetic factor r in an obvious way to estimate

$$\mathcal{H}^{n-1}(\rho^{-1}\{r\}) \leq \sum_i \mathcal{H}^{n-1}(\rho^{-1}\{r\} \cap \mathbb{B}^n(p_i, 2r)) \leq \sum_i 2^{2n+1} n\alpha(n) r^{n-1}.$$

We abbreviate $\tau = 2^{2n+1} n\alpha(n)/\theta$. In case $0 < r < \delta$, we further estimate

$$\mathcal{H}^{n-1}(\rho^{-1}\{r\}) \leq \tau \sum_i \mathcal{H}^{n-1}(C \cap \mathbb{B}^n(p_i, r)) \leq \tau \beta(n) \mathcal{H}^{n-1}(C).$$

In case $\delta \leq r < \infty$, we similarly estimate

$$\mathcal{H}^{n-1}(\rho^{-1}\{r\}) \leq \tau \left(\frac{r}{\delta}\right)^{n-1} \sum_i \mathcal{H}^{n-1}(C \cap \mathbb{B}^n(p_i, \delta)) \leq \tau \left(\frac{r}{\delta}\right)^{n-1} \beta(n) \mathcal{H}^{n-1}(C).$$

The assertion of Step 3 follows.

The assertion of the proposition follows from Step 3 and Proposition 4.1, as noted initially. \square

PROPOSITION 4.3 (an inequality for sums). *Suppose that $A_i, E_i, \Delta t_i$ are positive numbers for $i = 1, \dots, N$ and*

$$A = \sum_{i=1}^N A_i, \quad E = \sum_{i=1}^N E_i, \quad \Delta t = \sum_{i=1}^N \Delta t_i \leq 1.$$

Suppose also that, for each $i = 1, \dots, N$ and each $R > \Delta t_i$,

$$A_i \leq \Gamma \left(\frac{R}{\Delta t_i}\right)^{(n-1)/2} (\Delta t_i)^{1/2} E_i^{1/2} + \frac{\Delta t_i}{R} E_i$$

for some positive constant Γ . Then

$$A \leq (\Gamma E^{1/2} + E)(\Delta t)^{1/(n+1)}.$$

Proof. For each i , set $R_i = \Delta t_i / \Delta t^{1/(n+1)}$ and use Schwarz's inequality to estimate

$$\begin{aligned} A &\leq \sum_{i=1}^N \Gamma \left(\frac{R_i}{\Delta t_i}\right)^{(n-1)/2} (\Delta t_i)^{1/2} E_i^{1/2} + \frac{\Delta t_i}{R_i} E_i \\ &= \sum_{i=1}^N \Gamma (\Delta t)^{(1-n)/2(n+1)} (\Delta t_i)^{1/2} E_i^{1/2} + (\Delta t)^{1/(n+1)} E_i \\ &\leq \Gamma (\Delta t)^{(1-n)/2(n+1)} (\Delta t)^{1/2} E^{1/2} + (\Delta t)^{1/(n+1)} E \\ &= (\Gamma E^{1/2} + E)(\Delta t)^{1/(n+1)}. \end{aligned}$$

\square

THEOREM 4.4 (a Hölder estimate for the discrete approximations to flat Φ curvature flows). *Assume*

- (a) $[K(0)]$ is an initial solid in \mathcal{K} ;
- (b) $\mathcal{L}^n(\text{spt } \partial[K(0)]) = 0$;
- (c) j is a fixed positive integer and $\Delta t_j = 2^{-j}$;
- (d) $K_j(0) = K(0)$;
- (e) For each nonnegative integer k , we choose $[K_j((k+1)\Delta t_j)] \in \mathcal{K}$ so that

$$\mathcal{E}([K_j(k\Delta t_j)], [K_j((k+1)\Delta t_j)], \Delta t_j) = \inf \{ \mathcal{E}([K_j(k\Delta t_j)], [L], \Delta t_j) : [L] \in \mathcal{K} \};$$

- (f) $\Delta t = N\Delta t_j$, with N a positive integer such that $\Delta t \leq 1$.

Then there is a $\Gamma < \infty$ (given explicitly in the proof) such that, for any nonnegative integer k ,

$$\mathbb{G}(\partial[K_j(k\Delta t_j)] - \partial[K_j((k+N)\Delta t_j)]) \leq \Gamma \Delta t^{1/(n+1)}.$$

Proof of Theorem 4.4. Let $D = \text{diam}(K(0)) + 1$ and $E = \Phi(\partial[K(0)])$. For each nonnegative integer k , let $E_k = \Phi(\partial[K_j(k\Delta t_j)]) - \Phi(\partial[K_j((k+1)\Delta t_j)])$.

Step 1. For each k ,

$$\frac{1}{\Delta t_j} \int_{x \in K_j(k\Delta t_j) \Delta K_j((k+1)\Delta t_j)} \text{dist}((x, \partial K_j(k\Delta t_j))) d\mathcal{L}^n x \leq E_k.$$

Proof. This is a statement of the fact that $[K_j(l\Delta t_j)]$ is among the candidates for $[K_j((l+1)\Delta t_j)]$ in the minimization, and $\mathcal{E}([K], [K], c) = \Phi(\partial[K])$ for any solid K and any $c > 0$.

Step 2. For each k , $\mathcal{H}^{n-1}(\partial K_j(k\Delta t_j)) \leq E/\Phi_0$.

Proof. The volume integral part of Step 1 cannot be negative, so $E_l \geq 0$, for each $0 \leq l$. For each k , we add these inequalities for $0 \leq l \leq k-1$ to conclude that $\Phi(\partial[K_j(0)]) - \Phi(\partial[K_j(k\Delta t_j)]) > 0$. Step 2 follows.

Step 3. Let $\Gamma_0 = (2^{2n+1} n \alpha(n) \beta(n)) / \theta$ and $\Gamma_1 = (2\Gamma_0 E / \Phi_0)$. Here θ is the lower bound to the density ratios of § 3.5, and $\alpha(n)$ and $\beta(n)$ are as in § 2.1.1. Then

$$\begin{aligned} & \mathbb{G}(\partial[K_j(k\Delta t_j)] - \partial[K_j((k+1)\Delta t_j)]) \\ &= \mathcal{L}^n(K_j(k\Delta t_j) \triangle K_j((k+1)\Delta t_j)) \\ &\leq \left[2\Gamma_0 \left(\frac{R}{\Delta t_j} \right)^{n-1} \mathcal{H}^{n-1}(\partial K_j(k\Delta t_j)) \right]^{1/2} (\Delta t_j)^{1/2} E_k^{1/2} \\ &\leq \Gamma_1 \left(\frac{R}{\Delta t_j} \right)^{(n-1)/2} (\Delta t_j)^{1/2} + \frac{\Delta t_j}{R} E_k \end{aligned}$$

for each R with $\Delta t_j < R < \infty$.

Proof. The equality is a definition. The first inequality follows by applying Proposition 4.2 with C, δ, θ, E, A replaced there by $\text{spt } \partial[K_j(k\Delta t_j)], \Delta t_j, \theta, E_k, K_j(k\Delta t_j) \triangle K_j((k+1)\Delta t_j)$, respectively. (The hypotheses of Proposition 4.2 are satisfied, according to Step 1 and § 3.5.) The second inequality follows from the definition of Γ_1 and Step 2.

Step 4. Let $\Gamma = \Gamma_1 E^{1/2} + E$. Then, for any nonnegative integer k ,

$$\mathbb{G}(\partial[K_j(k\Delta t_j)] - \partial[K_j((k+N)\Delta t_j)]) \leq \Gamma \Delta t^{1/(n+1)}.$$

Proof. By the triangle inequality,

$$\mathbb{G}(\partial[K_j(k\Delta t_j)] - \partial[K_j((k+N)\Delta t_j)]) \leq \sum_{i=1}^N \mathbb{G}(\partial[K_j(k-1+i\Delta t_j)] - \partial[K_j((k+i)\Delta t_j)]).$$

We now apply Proposition 4.3, with $A, A_i, E, E_i, \Delta t, \Delta t_i, R, \Gamma$ replaced there by $\mathbb{G}(\partial[K_j(k\Delta t_j)] - \partial[K_j(k\Delta t_j + \Delta t)]), \mathbb{G}(\partial[K_j(k-1+i\Delta t_j)] - \partial[K_j((k+i)\Delta t_j)]), E', E_i, \Delta t, \Delta t_j, R, \Gamma_1$, respectively, where $E' = \sum_i E_{k-1+i} \leq E$. The hypotheses of Proposition 4.3 are satisfied according to Step 3. \square

THEOREM 4.5 (existence and Hölder continuity of flat Φ curvature flows). *Let $[K(0)]$ be an initial solid in \mathcal{K} for which $\mathcal{L}^n(\text{spt } \partial[K(0)]) = 0$ and suppose that approximate flat Φ curvature flows $[K_j(\cdot)]: \mathbb{R}^+ \rightarrow \mathcal{K}$ have been constructed as in § 2.6. Then there is a subsequence $j(1), j(2), j(3), \dots$ of $1, 2, 3, \dots$ and a flat Φ curvature flow $[K(\cdot)]: \mathbb{R}^+ \rightarrow \mathcal{K}$ such that*

$$\mathbb{G}(\partial[K_{j(i)}(\cdot)] - \partial[K(\cdot)]) \rightarrow 0 \quad \text{as } i \rightarrow \infty$$

locally uniformly. Furthermore, whenever $0 \leq s < t \leq s+1 < \infty$, then

$$\mathbb{G}[\partial[K(s)] - \partial[K(t)]] \leq \Gamma \Phi[\partial[K(0)]] |s - t|^{1/(n+1)}$$

for any such limit; here

$$\Gamma = 1 + \frac{2\Gamma_0}{\Phi_0},$$

where Γ_0 is the constant of Theorem 4.4, depending on the dimension n , the upper and lower bounds Φ^0 , Φ_0 of the surface energy density, and the diameter of $K(0)$.

Proof of Theorem 4.5. As stated in the Introduction, we infer from the existence theorem for \mathcal{E} minimizers (§ 3.2) that all the $K_j(t)$'s lie within the convex hull of the closure of $K(0)$ and have boundaries with masses dominated by E/Φ_0 ; hence the compactness theorem for integral currents (§ 3.1.5), together with Cantor's diagonal process, guarantees the existence of a subsequence $j(1), j(2), j(3), \dots$ of $1, 2, 3, \dots$ and a function $[K_0(\cdot)]$ such that $[K_{j(i)}(t)] \rightarrow [K(t)]$ as $i \rightarrow \infty$ for each fixed positive dyadic fractional number t (i.e., each $t = k2^{-m}$ for some integers k, m). The above assertions, for all positive s, t , now follow readily from the uniform Hölder continuity estimate of Theorem 4.4. The continuity at zero follows from the observation that, if $\lim_{\Delta t \downarrow 0} \mathcal{L}^n(K(0) \triangle L_{\Delta t})$ were not zero, then the \mathcal{E} energies of the minimizers would go to infinity, which they do not, since K_0 itself is a candidate in each case. \square

Remark. Stefan Luckhaus told us on July 23, 1992 that, in a forthcoming preprint [LS], he and Sturzenhecker will give a different argument for showing the Hölder continuity of flat curvature flows for the area integrand. Their estimate has exponent $\frac{1}{2}$, in contrast with our exponent $1/(n+1)$, above.

Note added in proof. A suggestion by Thomas Ilmanen in August 1992 has led us to an argument showing Hölder exponent $\frac{1}{2}$ for all Φ .

5. Wulff shapes and \mathcal{E} minimizers.

5.1. Wulff shapes. The *Wulff shape* for our surface energy function Φ is the current $[\mathcal{W}]$ associated with the convex body

$$\mathcal{W} =: \mathbb{R}^n \cap \{x: x \cdot u \leq \Phi(u) \text{ for each unit vector } u \in \mathbb{R}^n\}$$

by giving it positive orientation. Also, we denote by \mathcal{W}^* the central inversion of \mathcal{W} ; when it is used as a current (e.g., in evaluating surface energy), it is typically given negative orientation and thus written $-\mathcal{W}^*$.

By a *scaled Wulff shape* for Φ , we mean a solid $[W_R]$ (for some positive R) that is a homothetic image of $[\mathcal{W}]$, the scale chosen so that the result has volume R^n . A basic property [T1] of any scaled Wulff shape $[W_R]$ is that

$$\Phi(\partial[W_R]) \leq \Phi(\partial[L])$$

whenever $[L] \in \mathcal{H}$ with $\mathcal{L}^n(L) = \mathcal{L}^n(W_R) = R^n$. In our constructions, we will use scaled Wulff shapes $[W_R]$ in constructing comparison currents in \mathcal{E} minimizations and use the underlying sets W_R in constructing barriers by set addition. Similarly, we will use *scaled inverted Wulff shapes* $-\mathcal{W}_R^*$, which have the property that

$$\Phi(-\partial[W_R^*]) \leq \Phi(-\partial[L])$$

whenever $[L] \in \mathcal{H}$ with $\mathcal{L}^n(L) = \mathcal{L}^n(W_R) = R^n$. Scaled Wulff shapes and scaled inverted Wulff shapes for our surface energy Φ are analogous to soap bubbles for surface area in the sense that, for the volume enclosed (appropriately positively or negatively oriented), the surface energy attains its minimum value. (We think of the Wulff shape

as being the equilibrium shape of a crystal within another substance or vapor and the inverted Wulff shape as being the equilibrium shape of a hole in the crystal filled with the other substance.)

This extremal property, together with the ability to adjust volumes by homothetic expansions or contractions, enables us to obtain useful estimates, in terms of volume differences, on the surface energy of a Wulff shape with a small piece added or removed. Since our flat Φ curvature flows are limits of minimizers of \mathcal{E} , there is the potential for useful estimates if distance to the previous boundary, say ∂K_0 , can be controlled. Such distance control is obtained if we assume either that ∂K_0 lies inside a larger Wulff shape or outside a smaller one. When things are sorted out, we can conclude that flat Φ curvature flows that start outside an appropriate initial Wulff shape will remain outside a suitably shrinking Wulff shape, while those starting inside an appropriate Wulff shape remain inside Wulff shapes shrinking at a somewhat different rate. We also use scaled inverted Wulff shapes when outside the crystal solid. *Caution:* All the assertions in this chapter are based on Wulff shapes shrinking from initial time $t = 0$ and are not known to hold when starting at a later time $t_0 > 0$ unless all the $\partial K_j(t_0)$'s ($j = 1, 2, 3, \dots$) satisfy the starting assumptions (and not only $\partial L(t_0)$).

We set

$$w_* =: \sup \{r: \mathbb{B}^n(0, r) \subset W_1\} \leq w^* =: \inf \{r: \mathbb{B}^n(0, r) \supset W_1\}.$$

If $0 < R < 1$, then the following statements hold:

- (i) Each point in $\mathbb{R}^n \sim W_1$ is distance at least $(1 - R)w_*$ from W_R ;
- (ii) Each point in W_1 is distance no more than $(1 - R)w^*$ from W_R .

To see (i), we note that the infimum of the distances between points in the closure of ∂W_1 and in the closure of ∂W_R is attained and necessarily the support planes to W_1 and W_R are unique and parallel. The homothety carrying W_1 to W_R carries one of these planes into the other. The infimum of distances between such planes is clearly $(1 - R)w_*$. If $p \in W_1$, then $Rp \in W_R$ with $|p - Rp| = (1 - R)|p| \leq (1 - R)w^*$; (ii) follows.

PROPOSITION 5.2 (estimates on perturbations of a Wulff shape). *Let $[W] \in \mathcal{H}$ be a scaled Wulff shape for Φ and suppose that $[U], [V]$ are also solids of positive mass in \mathcal{H} . Then*

- (1) $(\mathcal{L}^n(W)/\mathcal{L}^n(U))^{(n-1)/n} \Phi(\partial[U]) \geq \Phi(\partial[W])$;
- (2) *If $V \subset W$ with $2\mathcal{L}^n(V) \leq \mathcal{L}^n(W)$, then*

$$\begin{aligned} \Phi(\partial[W]) - \Phi(\partial[W \sim V]) &\leq \left(1 - \left[1 - \frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right]^{(n-1)/n}\right) \Phi(\partial[W]) \\ &\leq \Phi(\partial[W]) \left[\frac{n-1}{n} \left(\frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right) + \frac{2^{1/n}(n-1)}{n^2} \left(\frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right)^2 \right]; \end{aligned}$$

- (3) *If $V \subset \mathbb{R}^n \sim W$, then*

$$\begin{aligned} \Phi(\partial[W \cup V]) - \Phi(\partial[W]) &\geq \left(\left[1 + \frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right]^{(n-1)/n} - 1\right) \Phi(\partial[W]) \\ &\geq \Phi(\partial[W]) \left[\frac{n-1}{n} \left(\frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right) - \frac{n-1}{2n^2} \left(\frac{\mathcal{L}^n(V)}{\mathcal{L}^n(W)}\right)^2 \right]. \end{aligned}$$

Now, suppose additionally that $[K], [L]$ are solids of positive mass in \mathcal{H} ;

- (4) *If $L = K \cup W$ and $2\mathcal{L}^n(W \sim K) \leq \mathcal{L}^n(W)$, then*

$$\begin{aligned} \Phi(\partial[L]) - \Phi(\partial[K]) \\ \leq \Phi(\partial[W]) \left[\frac{n-1}{n} \left(\frac{\mathcal{L}^n(W \sim K)}{\mathcal{L}^n(W)}\right) + \frac{2^{1/n}(n-1)}{n^2} \left(\frac{\mathcal{L}^n(W \sim K)}{\mathcal{L}^n(W)}\right)^2 \right]; \end{aligned}$$

(5) If $L = K \cap W$, then

$$\begin{aligned} & \Phi(\partial[K]) - \Phi(\partial[L]) \\ & \geq \Phi(\partial[W]) \left[\frac{n-1}{n} \left(\frac{\mathcal{L}^n(K \sim W)}{\mathcal{L}^n(W)} \right) - \frac{n-1}{2n^2} \left(\frac{\mathcal{L}^n(K \sim W)}{\mathcal{L}^n(W)} \right)^2 \right]. \end{aligned}$$

Proof of Proposition 5.2. To establish the first assertion, we apply a homothetic transformation to U with scale factor $(\mathcal{L}^n(W)/\mathcal{L}^n(U))^{1/n}$ to adjust the volume of U to equal that of W . The Φ surface energy scales by factor $(\mathcal{L}^n(W)/\mathcal{L}^n(U))^{(n-1)/n}$. The left-hand inequalities of assertions (2) and (3) follow from (1). The right-hand inequalities of (2) and (3) respectively follow from the extended mean value theorem applied to the function $(1+x)^{(n-1)/n}$ in ranges $-\frac{1}{2} \leq x \leq 0$ and $0 \leq x < \infty$, respectively.

To establish (4), we set $V = W \sim K \subset W$ and use the last inequality in § 3.1.4 to check that

$$\begin{aligned} \Phi(\partial[L]) + \Phi(\partial[W \sim V]) &= \Phi(\partial[W \cup K]) + \Phi(\partial[W \cap K]) \\ &\leq \Phi(\partial[W]) + \Phi(\partial[K]); \end{aligned}$$

assertion (4) now follows from (2).

To establish (5), we set $V = K \sim W \subset \mathbb{R}^n \sim W$ and use the last inequality in § 3.1.4 to check that

$$\begin{aligned} \Phi(\partial[K]) + \Phi(\partial[W]) &\geq \Phi(\partial[K \cup W]) + \Phi(\partial[K \cap W]) \\ &= \Phi(\partial[W \cup V]) + \Phi(\partial[L]); \end{aligned}$$

assertion (5) now follows from (3). \square

PROPOSITION 5.3 (\mathcal{E} minimizers and Wulff shapes). *Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . Suppose also that $0 < R < S < \infty$.*

(1) If $W_S \subset K_0$ and $0 < 2\mathcal{L}^n(W_R \sim K) \leq R^n$, then

$$\frac{S-R}{\Delta t} R \leq \frac{n-1}{n} \frac{\Phi(\partial[W_1])}{w_*} + \frac{2^{1/n}(n-1)}{n^2} \frac{\Phi(\partial[W_1])}{w_*} \frac{\mathcal{L}^n(W_R \sim K)}{R^n};$$

(2) If

$$R = \frac{S}{2} = \Delta t^{1/2} \left(\frac{2\Phi(\partial[W_1])}{w_*} \right)^{1/2},$$

then

$$\mathbb{R}^n \sim K \subset (\mathbb{R}^n \sim K_0) + W_S^* \quad (\text{set addition}).$$

(3) If $K_0 \subset W_S$ and $\mathcal{L}^n(K \sim W_R) > 0$, then

$$\frac{S-R}{\Delta t} R \geq \frac{n-1}{n} \frac{\Phi(\partial[W_1])}{w^*} - \frac{n-1}{2n^2} \frac{\Phi(\partial[W_1])}{w^*} \frac{\mathcal{L}^n(K \sim W_R)}{R^n}.$$

Proof. Suppose that $W_S \subset K_0$ and $2\mathcal{L}^n(W_R \sim K) \leq R^n = \mathcal{L}^n(W_R)$. As a comparison surface to our minimizer K , we set $L = K \cup W_R = K \cup (W_R \sim K)$ and check that $K_0 \triangle L \subset K_0 \triangle K$ with $K_0 \triangle K \sim K_0 \triangle L = W_R \sim K$. Since K is an \mathcal{E} minimizer, we conclude using statement 5.1(i) that

$$\begin{aligned} \Phi(\partial[L]) - \Phi(\partial[K]) &\geq \frac{1}{\Delta t} \int_{x \in (K_0 \triangle K) \sim (K_0 \triangle L)} \text{dist}(x, \partial K_0) d\mathcal{L}^n x \\ &\geq \frac{1}{\Delta t} \mathcal{L}^n(W_R \sim K) S \left(1 - \frac{R}{S} \right) w_*. \end{aligned}$$

Assertion (1) follows from conclusion (4) of Proposition 5.2.

To verify assertion (2), we check that our assumption implies that

$$\frac{R^2}{\Delta t} > \frac{n-1}{n} \frac{\Phi(\partial[W_1])}{w_*} + \frac{2^{1/n}(n-1)}{n^2} \frac{\Phi(\partial[W_1])}{w_*} \frac{1}{2}.$$

If the asserted inclusion did not hold, then the set $(\mathbb{R}^n \sim K) \sim [(\mathbb{R}^n \sim K_0) + W_S^*]$ would contain some point p . Applying a translation, if necessary, we assume without loss of generality that p is the origin in \mathbb{R}^n and hence infer that $W_S \subset K_0$ and $\mathcal{L}^n(W_R \sim K) > 0$. In this case, we additionally assert that $\mathcal{L}^n(W_R \sim K) \leq R^n/2$. If this inequality did not hold, i.e., if $\mathcal{L}^n(W_R \sim K) > R^n/2$, we could construct a comparison set $L = K \cup W_R$ as above and, as in the above proof of (1), confirm that

$$\Phi(\partial[L]) - \Phi(\partial[K]) \geq \frac{1}{\Delta t} \mathcal{L}^n(W_R \sim K) S \left(1 - \frac{R}{S}\right) w_* > \frac{w_* R^{n+1}}{2\Delta t}.$$

We use the last inequality in § 3.1.4 to further estimate that

$$\Phi(\partial[L]) \leq \Phi(\partial[K \cup W_R]) + \Phi(\partial[K \cap W_R]) \leq \Phi(\partial[K]) + \Phi(\partial[W_R]),$$

so that

$$\Phi(\partial[L]) - \Phi(\partial[K]) \leq R^{n-1} \Phi(\partial[W_1]),$$

and hence

$$\frac{w_* R^{n+1}}{2\Delta t} < R^{n-1} \Phi(\partial[W_1]),$$

which is false by our definition of R . Under our original assumption that (2) fails, we conclude that the hypotheses of (1) are satisfied, from which we infer that

$$\frac{S-R}{\Delta t} R \leq \frac{n-1}{n} \frac{\Phi(\partial[W_1])}{w_*} + \frac{2^{1/n}(n-1)}{n^2} \frac{\Phi(\partial[W_1])}{w_*} \frac{1}{2},$$

which is also false by our assumptions on R . This completes the proof of (2).

To verify assertion (3), we assume that $K_0 \subset W_S$. As a comparison surface to our minimizer K , we set $L = K \cap W_R$ so that $K_0 \triangle L \sim K_0 \triangle K = K \sim W_R$. Since K is an \mathcal{E} minimizer, we conclude using statement 5.1(ii) that

$$\begin{aligned} \Phi(\partial[K]) - \Phi(\partial[L]) &\leq \frac{1}{\Delta t} \int_{x \in (K_0 \triangle L) \sim (K_0 \triangle K)} \text{dist}(x, \partial K_0) d\mathcal{L}^n x \\ &\leq \frac{1}{\Delta t} \mathcal{L}^n(K \sim W_R) S \left(1 - \frac{R}{S}\right) w^*. \end{aligned}$$

Assertion (3) follows from part (5) of Proposition 5.2. \square

THEOREM 5.4 (flat Φ curvature flows and shrinking Wulff sets). *Assuming that $0 < S < \infty$ is given, we set*

$$\begin{aligned} S_0(t) &= (S^2 - c_0 t)^{1/2} \quad \text{for } 0 \leq t \leq \frac{S^2}{c_0}, \\ S^0(t) &= (S^2 - c^0 t)^{1/2} \quad \text{for } 0 \leq t \leq \frac{S^2}{c^0}; \end{aligned}$$

here

$$c_0 = \frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*}, \quad c^0 = c_0 \frac{w_*}{w^*}.$$

For later use, we set

$$c_1 = \frac{w_*}{16\Phi(\partial[W_1])}.$$

Assume that $\partial[K_j(\cdot)]:\mathbb{R}^+ \rightarrow \partial\mathcal{H}$ are approximate flat Φ curvature flows for $j=1, 2, 3, \dots$ associated with timesteps $\Delta t_j = 2^{-j}$. Assume also that $\partial[K(\cdot)]:\mathbb{R}^+ \rightarrow \partial\mathcal{H}$ is a flat Φ curvature flow that is the limit of a subsequence of the $\partial[K_j(\cdot)]$'s and that p is a point in \mathbb{R}^n .

Then the following are true:

- (1) Suppose that $\{p\} + W_S \subset K_j(k_0\Delta t_j)$ for some j and k_0 . If j is large enough so that $\Delta t_j < c_1^2 S^2$ and k is small enough so that $(k-1)\Delta t_j \leq S/2$, then $\{p\} + W_{S-(2c_0/S)k\Delta t_j} \subset K_j((k_0+k)\Delta t_j)$;
- (2) If $\{p\} + W_S \subset K(0)$, then $\{p\} + W_{S_0(t)} \subset K(t)$ for each $0 \leq t \leq S^2/c_0$;
- (3) Suppose that $\{p\} + W_S^* \subset \mathbb{R}^n \sim K(k_0\Delta t_j)$ for some j and k_0 . If j is large enough so that $\Delta t_j < c_1^2 S^2$ and k is small enough so that $(k-1)\Delta t_j \leq S/2$, then $\{p\} + W_{S-(2c_0/S)k\Delta t_j}^* \subset \mathbb{R}^n \sim K_j((k_0+k)\Delta t_j)$;
- (4) If $\{p\} + W_S^* \subset \mathbb{R}^n \sim K(0)$, then $\{p\} + W_{S_0(t)}^* \subset \mathbb{R}^n \sim K(t)$ for each $0 \leq t \leq S^2/c_0$;
- (5) If $K_j(k_0\Delta t_j) \subset \{p\} + W_S$ for some j and k_0 , then, for each $k=1, 2, 3, \dots$,

$$K_j((k_0+k)\Delta t_j) \subset \{p\} + W_{\sup\{S/2, S-(2c^0/S)k\Delta t_j\}};$$

- (6) If $K(0) \subset \{p\} + W_S$, then $K(t) \subset \{p\} + W_{S^0(t)}$ for each $0 \leq t \leq S^2/c^0$.

Proof.

Step 1. Whenever $0 < R < S < \infty$, we check that

$$W_S = W_R + W_{S-R} \quad \text{and} \quad \mathbb{R}^n \sim W_R = (\mathbb{R}^n \sim W_S) + W_{S-R}^*.$$

Step 2. Suppose that $0 < S < \infty$ and $[K_0] \in \mathcal{H}$ with $W_S \subset K_0$. For each

$$0 < \Delta t < \frac{S^2}{16} \left(\frac{w_*}{2\Phi(\partial[W_1])} \right)^2,$$

we choose $[K_{\Delta t}] \in \mathcal{H}$ such that

$$\mathcal{E}([K_0], [K_{\Delta t}], \Delta t) = \inf \{ \mathcal{E}([K_0], [L], \Delta t) : [L] \in \mathcal{H} \}.$$

We infer from assertion (2) of Proposition 5.3 and Step 1 that $W_{S/2} \sim K_{\Delta t} = \emptyset$ and set

$$R(\Delta t) = \sup \{ r : W_r \sim W_{\Delta t} = \emptyset \} \geq \frac{S}{2}.$$

We then infer from assertion (1) of Proposition 5.3 that

$$\frac{S-R(\Delta t)}{\Delta t} R(\Delta t) \leq \frac{n-1}{n} \frac{\Phi(\partial[W_1])}{w_*} = \frac{c_0}{2},$$

which implies, in addition, that

$$S-R(\Delta t) \leq \Delta t \frac{2(n-1)}{nS} \frac{\Phi(\partial[W_1])}{w_*}.$$

We infer conclusion (1) of Theorem 5.4 from this last formula. Suppose then that $f:[0, \Delta t] \rightarrow \mathbb{R}^+$ is a smooth decreasing function with $f(0) = S$ and, for each $0 < c < \Delta t$,

$$-(f^2)'(c) \geq c_0 + \frac{\Delta t}{S^2} \left(\frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*} \right)^2.$$

Then, according to the mean value theorem, there is $0 < c_* < \Delta t$ such that

$$\begin{aligned} -(f^2)'(c_*) &= \frac{f^2(0) - f^2(\Delta t)}{\Delta t} \\ &\geq c_0 + \frac{\Delta t}{S^2} \left(\frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*} \right)^2 \\ &\geq 2 \frac{S - R(\Delta t)}{\Delta t} R(\Delta t) + \frac{\Delta t}{S^2} \left(\frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*} \right)^2, \end{aligned}$$

which implies that

$$\begin{aligned} S^2 - f^2(\Delta t) &\geq (S - R(\Delta t))((S + R(\Delta t)) - (S - R(\Delta t))) \\ &\quad + \left(\frac{\Delta t}{S} \right)^2 \left(\frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*} \right)^2 \end{aligned}$$

so that

$$R(\Delta t)^2 \geq f^2(\Delta t) - (S - R(\Delta t))^2 + \left(\frac{\Delta t}{S} \right)^2 \left(\frac{2(n-1)}{n} \frac{\Phi(\partial[W_1])}{w_*} \right)^2 \geq f^2(\Delta t).$$

Since $S_0(\cdot)$ satisfies the equation $-(S_0^2(\cdot))' = c_0$, we infer conclusion (2) of the theorem.

Step 3. In an entirely straightforward way, we can reformulate the study of flat Φ curvature flows $[K(\cdot)]$ in the language of the complementary currents

$$[\mathbb{R}^n \sim K(\cdot)] = \mathbb{E}^n - [K(\cdot)] = \mathbf{t}(\mathbb{R}^n \sim K(\cdot), 1, \mathbf{e}_1 \wedge \dots \wedge \mathbf{e}_n).$$

The main observation is that, whenever $[K], [L] \in \mathcal{H}$, then

$$\Phi(\partial[L]) + \frac{1}{\Delta t} \int_{x \in K \triangle L} \text{dist}(x, \partial K) d\mathcal{L}^n x$$

equals

$$\Phi(-\partial[\mathbb{R}^n \sim L]) + \frac{1}{\Delta t} \int_{x \in (\mathbb{R}^n \sim K) \triangle (\mathbb{R}^n \sim L)} \text{dist}(x, \partial(\mathbb{R}^n \sim K)) d\mathcal{L}^n x$$

so that the \mathcal{E} minimizations in constructing approximations would be formally the same (since $\mathbf{n}_{\mathbb{R}^n \sim L} = -\mathbf{n}_L$); we must just use negative orientations for the evaluation of surface energies. Since the constructions used in proving conclusions (1) and (2) of Proposition 5.3 are entirely local, they admit a straightforward reformation when the assumption $W_S \subset K_0$ is replaced by the assumption $W_S^* \subset \mathbb{R}^n \sim K_0$. The arguments above used to prove conclusions (1) and (2) of Theorem 5.4 translate into proofs of conclusions (3) and (4) of the theorem, respectively.

Step 4. The proof of conclusions (5) and (6), above, are based on estimate (3) of Proposition 5.3 and are similar (but easier) than the proofs of conclusions (1) and (2), above. We leave them to the reader. \square

6. Hausdorff distance convergence and viscosity solutions. One of the key components in our study of flat Φ curvature flows is establishing their relationship to smooth Φ curvature flows. This is a substantial task because the discrete approximating flows are possibly of varying topological types and, in higher dimensions, can be partially singular. Examples show that, in mean curvature flow of some surfaces in space, singularities must develop at times before the final disappearance. The main intermediate steps between flat flows and smooth flows are viscosity Φ curvature flows.

In this chapter, we show in Theorem 6.2 that, if the supports of the currents in a flat Φ curvature flow vary continuously in the Hausdorff distance topology and if they are the uniform limits of the supports of the approximating flows in the same topology, then the supports of the flat Φ curvature flow constitute a viscosity Φ curvature flow. The smoothness of such a viscosity flow is discussed in § 2.11. It should be noted, however, that although the existence of a limit flat Φ curvature flow is proved in Theorem 4.5 (regardless of whether Φ is smooth and elliptic) the $\mathbb{H}\mathbb{D}$ continuity is *not* known to hold in general.

LEMMA 6.1 (comparison of weighted mean curvatures). *Suppose that Φ is smooth and elliptic and that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt , so that $B = \text{spt } \partial[K]$ is smooth almost everywhere (by conclusion (4) of Theorem 3.8). Suppose further that $h: \mathbb{R}^n \rightarrow \mathbb{R}$ is a twice continuously differentiable test function so that $\Sigma = \mathbb{R}^n \cap \{x: h(x) = 0\}$ is closed and $\Sigma^+ = \mathbb{R}^n \cap \{x: h(x) > 0\}$ is open. Suppose finally that $B \cap \Sigma^+$ is empty and $B \cap \Sigma$ consists of a single point p at which $\nabla h(p) \neq 0$ so that Σ is a smooth hypersurface near p . Then p is a regular point of B with a well-defined unit exterior normal vector $\mathbf{n}_K(p)$. We orient Σ near p to have orienting normal vector $\mathbf{n}_K(p)$. Then*

$$H_{\Phi, \partial K}(p) \cdot \nabla h(p) \leq H_{\Phi, \Sigma}(p) \cdot \nabla h(p) = \mathbf{n}(p) \cdot \nabla h(p) \text{ trace } (D^2\Phi(\mathbf{n}(p)) \circ D^2h(p)).$$

Proof. The one-sided barrier offered by Σ_+ near p is enough to guarantee that p is a regular point in accordance with part (1) of Theorem 3.10. The final assertion now follows from the definitions, since the situation is entirely classical. \square

THEOREM 6.2 (uniform $\mathbb{H}\mathbb{D}$ limits of flat flows are viscosity flows). *Suppose that Φ is elliptic and smooth and that $\partial[K_j(t)]$ are approximate curvature flows for $j = 1, 2, 3, \dots$ and $0 < t < \infty$ constructed as in § 2.6. Suppose also that $j(1), j(2), j(3), \dots$ is a subsequence of $1, 2, 3, \dots$ and $\partial[K(t)]$ is a limit flat Φ curvature flow for which*

$$\lim_{i \rightarrow \infty} \mathbb{G}(\partial[K_{j(i)}(t)] - \partial[K(t)]) = 0.$$

We set

$$A_j, A: \mathbb{R}^+ \rightarrow \mathcal{C}, \quad A_j(t) = \text{spt } \partial[K_j(t)], \quad A(t) = \text{spt } \partial[K(t)].$$

If A is $\mathbb{H}\mathbb{D}$ continuous for $a < t < b$ (some a and b) and

$$\lim_{i \rightarrow \infty} \mathbb{H}\mathbb{D}(A_{j(i)}(t), A(t)) = 0$$

uniformly for $a < t < b$, then $A(t)$ is a viscosity Φ curvature flow in (a, b) with respect to the orientation function $\sigma(x, t) = -1$ if $x \in \text{spt } [K(t)] \sim A(t)$ and $\sigma(x, t) = +1$ if $x \notin \text{spt } [K(t)]$.

Proof. Since A is $\mathbb{H}\mathbb{D}$ continuous in (a, b) , the set $C = \mathbb{R}^n \times (a, b) \cap \{(x, t): x \in A(t)\}$ is closed in $\mathbb{R}^n \times (a, b)$. To show that A is a viscosity Φ curvature flow (with respect to σ , above), we suppose that $g: \mathbb{R}^n \times (a, b) \rightarrow \mathbb{R}$ is some twice continuously differentiable test function so that $\Gamma =: \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) = 0\}$ is closed and $\Gamma^+ =: \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) > 0\}$ is open. We also suppose that $C \cap \Gamma^+$ is empty and that $C \cap \Gamma$ consists of a single point (p, s) at which $\nabla_{x,g}(p, s) \neq 0$. We must show that

$$\frac{\partial g}{\partial t}(p, s) \geq \text{trace} \left(D^2\Phi \left(\pm \frac{\nabla_{x,g}}{|\nabla_{x,g}|}(p, s) \right) \circ D^2_x g(p, s) \right);$$

here we take the $+$ sign if σ is positive in Γ^+ near (p, s) , and the $-$ sign otherwise. We now define $A_j^*(t) = \lim_{r \downarrow t} A_j(t) \cup \lim_{r \uparrow t} A_j(t)$ (taking the limit in the $\mathbb{H}\mathbb{D}$ topology) and set $C_j = \mathbb{R}^n \times (a, b) \cap \{(x, t): x \in A_j^*(t)\}$ so that each C_j is closed in $\mathbb{R}^n \times (a, b)$. By our uniqueness assumption on (p, s) , there will exist points $(p_i, s_i) \in C_{j(i)}$ converging

to (p, s) such that $\Gamma_i =: \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) = g(p_i, s_i)\}$ is closed, $\Gamma_i^+ =: \mathbb{R}^n \times (a, b) \cap \{(x, t): g(x, t) > g(p_i, s_i)\}$ is open, $C_i \cap \Gamma_i^+$ is empty, $(p_i, s_i) \in C_{j(i)} \cap \Gamma_i$, and $\nabla_x g(p_i, s_i) \neq 0$. For each i , we set $\Delta t_i = 2^{-j(i)}$ and estimate

$$\begin{aligned} \mathbf{n}_{K_i}(p) \cdot H_{\Phi, \partial K_{j(i)}(s_i)}(p_i) &= \pm \frac{\text{dist}(p_i, \partial K_{j(i)}(s_i))}{\Delta t_i} \\ &\approx \frac{g(p_i, s_i) - g(p_i, s_i - \Delta t_i)}{|\nabla_x g(p_i, s_i)| \Delta t_i} \\ &\approx \frac{\partial g}{\partial t}(p_i, s_i) \frac{1}{|\nabla_x g(p_i, s_i)|}. \end{aligned}$$

The theorem now follows from Lemma 6.1. \square

PROPOSITION 6.3. *Assume that our surface energy function Φ is smooth and elliptic. Suppose that $[K(0)] \in \mathcal{K}$ is an initial solid such that $\partial K(0)$ is a two times continuously differentiable $(n-1)$ -dimensional submanifold of \mathbb{R}^n without boundary. Then, for each $M < \infty$, there exists $\delta_0 = \delta_0(M) > 0$ with the following property.*

For $0 \leq t < \infty$, let $\partial[K_1(t)], \partial[K_2(t)], \partial[K_3(t)], \dots \in \mathcal{K}$ constitute approximate flows as in § 2.6, all starting with $\partial[K(0)]$. Suppose also that $j(1), j(2), j(3), \dots$ is a subsequence of $1, 2, 3, \dots$ and that $\partial[K(t)] \in \mathcal{K}$ gives a flat Φ curvature flow for which $\partial[K(t)] = \lim_{i \rightarrow \infty} \partial[K_{j(i)}(t)]$.

Suppose that $0 < \delta \leq \delta_0$ and, for each $0 < t < \delta$ and all sufficiently large j 's, that the set $\partial K_j(t)$ is a twice differentiable $(n-1)$ -dimensional submanifold of \mathbb{R}^n without boundary and that no principal curvature of any $\partial K_j(t)$ exceeds M at any point. Then

(1) *For each $j = 1, 2, 3, \dots$ and each positive integer k such that $k2^{-j} < \delta$ the set $\partial K_j(t)$ is a $2(k-1)$ times continuously differentiable $(n-1)$ -dimensional submanifold of \mathbb{R}^n ;*

(2) *We have convergence*

$$\mathbb{H}\mathbb{D}(\partial K_{j(i)}(t), \partial K(t)) \rightarrow 0$$

uniformly for $0 \leq t < \delta$ as $i \rightarrow \infty$;

(3) *$\partial K(t)$ is continuous in the $\mathbb{H}\mathbb{D}$ topology for $0 \leq t < \delta$;*

(4) *For each $0 < t_0 < \delta$ and each $p_0 \in \partial K(t)$, there exists a rotation $\theta: \mathbb{R}^n \rightarrow \mathbb{R}^n$ and a Lipschitz function $f: \mathbb{R}^{n-1} \rightarrow \mathbb{R}$ and $r > 0$ such that the set*

$$\mathbb{B}^{n+1}((p_0, t_0), r) \cap [\{(x, f(x, t)), t: x \in \mathbb{R}^{n-1}, t \in \mathbb{R}\} \triangle \{(p, t): 0 < t < \delta, \theta(p) \in \partial K(t)\}]$$

is empty;

(5) *For $0 \leq t < \delta$, $\text{spt } \partial[K(t)] = \partial K(t)$ is a viscosity Φ curvature flow with respect to the natural orientation;*

(6) *For $0 \leq t < \delta$, $\partial[K(t)]$ is a smooth Φ curvature flow.*

Proof. According to [M2, Prop. 3.3], \mathcal{W} and \mathcal{W}^* (and hence W_R and W_R^* for any $R > 0$) are uniformly convex. Our assumption on the principal curvatures guarantees the existence of a single $S > 0$ such that, for all sufficiently large j 's, for each $0 \leq t < \delta$ and each $x \in \partial K_j(t)$, there are unique points $p \in K_j(t)$ and $q \in \mathbb{R}^n \sim K_j(t)$ such that

$$(\{p\} + W_S) \cap \partial K_j(t) = \{x\}, \quad (\{q\} + W_S^*) \cap \partial K_j(t) = \{x\}.$$

These estimates, together with assumptions (1) and (3) of Theorem 5.4, guarantee the existence of a constant $M_1 < \infty$ such that, for all sufficiently large j ,

$$\mathbb{H}\mathbb{D}(\partial K_j(t), \partial K_j(t + 2^{-j})) \leq M_1 \Delta t$$

whenever $0 \leq t < t + 2^{-j} < \delta$. Our assumption on principal curvatures implies that each of the $\partial K_j(t)$'s can be written locally as graph of a smooth function with very small first derivatives over a disk of fixed size. Our Hausdorff distance estimate implies that the coordinate systems used in the representation of $\partial K(0)$ as graphs can also be used for representing the $\partial K_j(t)$'s, provided that δ_0 is sufficiently small. Conclusion (1) of the proposition now follows from the higher regularity asserted in Theorem 3.8, since the signed distance to a C^k manifold is itself C^k near the manifold in accordance with [KP]. Our above remarks about coordinate system representations with small first derivatives together with our $\mathbb{H}\mathbb{D}$ estimate between hypersurfaces at different times, give the common Lipschitz bounds in space-time sufficient to imply conclusions (2)–(4). Conclusion (5) follows from conclusions (2) and (3), together with Theorem 6.2. Conclusion (6) follows from conclusion (4), together with [CW] and [W], as noted in § 2.11. \square

7. Existence and smoothness of flat Φ curvature flows. In this section, we establish the short time existence of classical Φ curvature flows, provided that our initial hypersurface is $C^{3+\alpha}$ and that Φ is smooth and elliptic. We also show that, for a normal velocity that is slightly faster or slightly slower than Φ curvature, we can similarly obtain flows for short times. The uniformity of these estimates implies that, if we assume a Φ curvature flow exists for a longer time, then there will also exist slightly faster or slower flows with nearby starting conditions for essentially the same time. These slightly perturbed flows then become barriers to flat Φ curvature flow and lead to a proof that flat Φ curvature flow coincides with smooth Φ curvature flow as long as the latter exists. If such a flow is written as a graph $x_n = f(x_1, x_2, \dots, x_{n-1}, t)$ then the various partial derivatives $\partial^2 f / \partial x_i \partial x_j$ and $\partial f / \partial t$ will be Hölder continuous and will satisfy our evolution equation in the ordinary way. We learned recently that Giga and Goto [GG] proved similar results for general curvature flows by a method similar to that used by Evans and Spruck [ES2, Chap 2]. Our proof is different from theirs.

THEOREM 7.1 (short time existence of smooth Φ curvature flows and flows with slightly perturbed velocities). *Suppose that our surface energy Φ is smooth and elliptic and that $[K(0)]$ is a solid in \mathcal{K} for which $\partial K(0)$ is a $C^{3+\alpha}$ hypersurface. Then there is a neighborhood U of $\partial K(0)$ in the $C^{2+\alpha}$ topology and a neighborhood V of zero in \mathbb{R} and a positive time T_0 such that, for each $\partial L(0)$ in U and each s in V , there is a smooth flow $\partial L(t)$ for $0 \leq t \leq T_0$ starting with $\partial L(0)$ such that the normal velocity of $\partial L(t)$ at point p in $\partial L(t)$ equals*

$$H_{\Phi, \partial L(t)}(p) + s \mathbf{n}_{L(t)}(p).$$

A more technical description of the statement of this result is developed during the course of the proof.

Proof. There are several parts of our proof.

(1) We introduce function space terminology with which to write evolving surfaces $\partial L(t)$ as graphs of real-valued functions $g(x, t)$ over $\mathcal{M} \times [0, T]$; here $\mathcal{M} = \partial K(0)$ is a fixed smooth domain manifold that is the boundary of a region $A = K(0)$ having unit exterior normal vector field $\mathbf{n} = \mathbf{n}_A : \mathcal{M} \rightarrow \mathbb{R}^n$ and $0 < T \leq 1$. At time t , we associate with the function $g(x, t)$ the surface

$$(7.1) \quad \{x + g(x, t)\mathbf{n}(x) : x \in \mathcal{M}\}.$$

We consider simultaneously Banach spaces of functions associated with all time intervals $[0, T]$, $0 < T \leq 1$ because we do not know in advance the interval of time for which we will be able to obtain solutions; in particular, the evolving surfaces might

quickly move out of the region in \mathbb{R}^n in which they can be represented smoothly in the form (7.1).

As a signed distance function defined for x in \mathbb{R}^n , we set $d(x) = \pm \text{dist}(x, \mathcal{M})$; here we take the negative sign if and only if x belongs to A .

(2) We will use the formula given in § 2.2 to derive the nonlinear parabolic PDE that a function $g(x, t)$ must satisfy for the surfaces given in (7.1) to constitute a smooth Φ curvature flow. This equation will be of the form

$$(7.2) \quad \frac{g_t}{|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|} = G(x, g, Dg, D^2g).$$

Associated with this equation is the nonlinear operator F between Banach spaces of functions given by setting

$$(7.3) \quad F[g] = \left(\frac{g_t}{|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|} - G(x, g, Dg, D^2g), g(\cdot, 0) \right).$$

Given f in $C^{2+\alpha}(M)$, finding a function $g(x, t)$ such that $F[g(x, t)] = (0, f(x))$ is equivalent to finding a smooth Φ curvature flow beginning with the surface

$$\{x + f(x)\mathbf{n}(x) : x \in \mathcal{M}\}.$$

Similarly, finding a function $g(x, t)$ such that $F[g(x, t)] = (s, f(x))$ is equivalent to finding a smooth flow beginning with the same surface but whose normal velocity equals the Φ curvature plus s times the unit normal vector to the surface at that time.

(3) We would like to apply the inverse function theorem [B, Thm. 3.15] to the function F to guarantee the existence of function $g(x, t)$ such that $F[g(x, t)] = (\varepsilon, f(x))$ for small ε and small initial function f . The hypotheses of this theorem involve the Fréchet derivatives

$$DF[g](h) = \lim_{s \rightarrow 0} \frac{F[g + sh] - F[g]}{s},$$

which, for each fixed g , gives a linear partial differential operator on the tangent (same) Banach space of functions h . We compute and exhibit these derivative $DF[g]$; by inspection, they depend continuously on g .

We must then show that each $DF[g]$ is an isomorphism. This is accomplished first by using the a priori estimates of [LSU, Thm. 10.1, Chap. 4] to obtain a mapping norm bound (using a stronger norm) on $DF[g]^{-1}$ in coordinate patches for those functions that are in the image. We use a maximum principle argument to infer that we can replace the stronger norm with the norm relevant for our problem.

We then show why the estimates on $DF[g]^{-1}$ are, in fact, independent of the time interval $[0, T]$ in our original problem, provided that $T \leq 1$.

Finally, we use the surjectivity criterion [GT, Thm. 5.2] that, in homotopies of bounded linear mappings between Banach spaces, either every map is surjective or none are. This reduces the surjectivity problem to finding a convenient linear parabolic operator, which we know to be surjective. We effectively choose a smooth metric on \mathcal{M} and use [LM, Thm. 5.2] to conclude that the heat operator in this new metric maps smooth functions surjectively onto smooth functions, and thus we can use the heat operator as that convenient linear parabolic operator.

(4) Knowing that the inverse mappings $DF[g]^{-1}$ are varying continuously and are uniformly bounded (for bounded g 's) regardless of the time interval in our domain, we must check that there is some $g_\delta(x, t)$ such that $F[g_\delta]$ is small. That being the case, the inverse function theorem implies that for all small (s, f) there will exist a unique

g such that $F[g] = (s, f)$ and that g depends continuously on s and f . The function $g_\delta(x, t)$ we take is constructed as follows. Let $G_\delta(x)$ be a slight smoothing of the function $G(x, 0, 0, 0)$ and set

$$g_\delta(x, t) = tG_\delta(x).$$

Provided that T is small enough, $F[g_\delta]$ will be close to $(0, 0)$ as required. This is the point at which we need the freedom to take our time interval $[0, T]$ to be short.

We now give more details.

Step 1 (Banach spaces of functions). Whenever U is a nonempty bounded open subset of \mathbb{R}^n or of \mathbb{R}^{n-1} and k is a positive integer and $0 < \alpha < 1$, we have Banach spaces $C^{k+\alpha}(U)$ of functions $f: U \rightarrow \mathbb{R}$ whose k th derivatives are Hölder continuous with exponent α . We denote the usual norms by $\|f\|_{C^{k+\alpha}}$. Similarly, on domains $\mathcal{M} \times [0, T]$ we have Banach spaces

$$C^{k+\alpha, (k+\alpha)/2}(U \times [0, T])$$

of functions $g: U \times [0, T] \rightarrow \mathbb{R}$ with norms denoted by $\|g\|_{C^{k+\alpha, (k+\alpha)/2}}$. These norms are those set forth by Ladyzhenskaya, Solonnikov, and Ural'ceva in [LSU, Chap. 1, § 1]; we more closely follow the terminology of Evans and Spruck [ES2, Chap. 2] (we should add the term $\langle Du \rangle_x^{(\alpha)}$ in the definition of $\|u\|_{C^{1+\alpha, (1+\alpha)/2}}$ there). In particular,

$$\begin{aligned} \|g\|_{C^{2+\alpha, (2+\alpha)/2}} = & \sup_{x,t} |g(x, t)| + \sup_{x,t} |Dg(x, t)| + \sup_{x,t} |D^2g(x, t)| + \sup_{x,t} |g_t(x, t)| \\ & + \sup \left\{ \frac{|Dg(x, s) - Dg(x, t)|}{|s - t|^{(1+\alpha)/2}} : (x, s), (x, t) \in W \times [0, T] \text{ with } s \neq t \right\} \\ & + \sup \left\{ \frac{|D^2g(x, t) - D^2g(y, t)|}{|x - y|^\alpha} : (x, t), (y, t) \in W \times [0, T] \text{ with } x \neq y \right\} \\ & + \sup \left\{ \frac{|g_t(x, t) - g_t(y, t)|}{|x - y|^\alpha} : (x, t), (y, t) \in W \times [0, T] \text{ with } x \neq y \right\} \\ & + \sup \left\{ \frac{|D^2g(x, s) - D^2g(x, t)|}{|s - t|^{\alpha/2}} : (x, s), (x, t) \in W \times [0, T] \text{ with } s \neq t \right\} \\ & + \sup \left\{ \frac{|g_t(x, s) - g_t(x, t)|}{|s - t|^{\alpha/2}} : (x, s), (x, t) \in W \times [0, T] \text{ with } s \neq t \right\}. \end{aligned}$$

As indicated above, we assume that \mathcal{M} is a compact smooth hypersurface of \mathbb{R}^n that is the boundary of a region A . By smooth, we mean that \mathcal{M} is everywhere locally the graph of a function (written in Cartesian coordinates) that is three times Hölder continuously differentiable with exponent α (some $0 < \alpha < 1$). We fix $w > 0$ sufficiently small such that, in the open set $W = \{x: |d(x)| < w\}$, the nearest point retraction mapping $\pi: W \rightarrow \mathcal{M}$ is twice Hölder continuously differentiable. Our signed distance function d is three times Hölder continuously differentiable in W .

For our purposes, on the domain \mathcal{M} , we use the Banach spaces $C^{k+\alpha}(\mathcal{M})$ of functions $f: \mathcal{M} \rightarrow \mathbb{R}$ for which $f \circ \pi \in C^{k+\alpha}(W)$ with corresponding norm given by

$$\|f\|_{C^{k+\alpha}} = \|f \circ \pi\|_{C^{k+\alpha}}.$$

Similarly, on domains $\mathcal{M} \times [0, T]$ we use the Banach spaces

$$C^{k+\alpha, (k+\alpha)/2}(\mathcal{M} \times [0, T])$$

of functions $g : \mathcal{M} \times [0, T] \rightarrow \mathbb{R}$ for which $g \circ \pi \times \mathbf{1} \in C^{k+\alpha, (k+\alpha)/2}(W \times [0, T])$ with corresponding norms given by

$$\|g\|_{C^{k+\alpha, (k+\alpha)/2}} = \|g \circ \pi \times \mathbf{1}\|_{C^{k+\alpha, (k+\alpha)/2}}.$$

Step 2 (the parabolic PDE). We assert that the nonlinear parabolic PDE that $g(x, t)$ must satisfy to correspond to a smooth Φ curvature flow is the following:

$$(7.4) \quad \begin{aligned} \frac{g_t}{|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|} &= \text{trace} ([D^2\Phi(\mathbf{n} - (I - gD^2d)^{-1}\nabla g)] \\ &\quad \circ [(I - gD^2d)^{-1} \circ D^2g \\ &\quad \circ (I - gD^2d)^{-1} - (I - gD^2d)^{-1} \circ D^2d]); \end{aligned}$$

here I denotes the $n \times n$ identity matrix, $\nabla g(x, t) =: \nabla(g(\cdot, t) \circ \pi)(x)$, $D^2g(x, t) =: D^2(g(\cdot, t) \circ \pi)(x)$. This equation is a translation to our coordinates x in \mathcal{M} of the formulas given in §2.2 based on the fact that, for each time t , the surface $\{x + g(x, t)\mathbf{n}(x) : x \in \mathcal{M}\}$ has defining equation

$$d = g(\cdot, t) \circ \pi$$

in \mathbb{R}^n . The asserted equation follows from this observation, together with the facts that

$$\nabla(g(\cdot, t) \circ \pi)(z) = (I - g(\pi z, t)D^2d(\pi z))^{-1}\nabla g(\cdot, t)(\pi z)$$

and

$$\begin{aligned} D^2(g(\cdot, t))(z) \\ = (I - g(\pi z, t)D^2d(\pi z))^{-1} \circ D^2(g(\cdot, t) \circ \pi)(\pi z) \circ (I - g(\pi z, t)D^2d(\pi z))^{-1}. \end{aligned}$$

As indicated in (7.2), we abbreviate the expression on the right-hand side of the equality in (7.4) as $G(x, g, Dg, D^2g)$ and define our functions

$$F : C^{2+\alpha, (2+\alpha)/2}(\mathcal{M} \times [0, T]) \cap \{g : \sup |g| < w\} \rightarrow C^{\alpha, \alpha/2}(\mathcal{M} \times [0, T]) \times C^{2+\alpha}(\mathcal{M})$$

by formula (7.3).

Step 3 (the Fréchet derivatives). Corresponding to fixed g , we then compute the linearized operator

$$(7.5) \quad \begin{aligned} DF[g] : C^{2+\alpha, (2+\alpha)/2}(\mathcal{M} \times [0, T]) &\rightarrow C^{\alpha, \alpha/2}(\mathcal{M} \times [0, T]) \times C^{2+\alpha}(\mathcal{M}), \\ DF[g](h) &= \left[\frac{h_t}{|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|} - \frac{1}{2} \frac{g_t}{|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|} (\mathbf{n} - (I - gD^2d)^{-1}\nabla g) \right. \\ &\quad \cdot [-(I - gD^2d)\nabla h - (I - gD^2d)^{-2}D^2d\nabla gh] \\ &\quad - \text{trace} ([D^2\Phi(\mathbf{n} - (I - gD^2d)^{-1}\nabla g)] \\ &\quad \quad \circ [(I - gD^2d)^{-1} \circ (D^2(h \circ \pi)) \circ (I - gD^2d)^{-1}]) \\ &\quad + \text{trace} ([D^2\Phi(\mathbf{n} - (I - gD^2d)^{-1}\nabla g)] \\ &\quad \quad \circ [(I - gD^2d)^{-2} \circ D^2d \circ D^2g \circ (I - gD^2d)^{-1}h] \\ &\quad \quad + [(I - gD^2d)^{-1} \circ D^2g \circ (I - gD^2d)^{-2}(D^2d)h] \\ &\quad \quad \left. - [(I - gD^2d)^{-2} \circ (D^2d)^2h] \right) \\ &\quad + \text{trace} ([D^3\Phi(\mathbf{n} - (I - gD^2d)^{-1}\nabla g) \\ &\quad \quad \circ [(I - gD^2d)^{-1}\nabla h + (I - gD^2d)^{-2}D^2d\nabla gh] \\ &\quad \quad \circ [(I - gD^2d)^{-1} \circ (D^2(g \circ \pi)) \circ (I - gD^2d)^{-1} \\ &\quad \quad \quad - (I - gD^2d)^{-1}D^2d]), h(\cdot, 0) \Big]. \end{aligned}$$

By inspection of (7.5), we see that the linear operator $DF[g]$ depends continuously on g .

Step 4 (a bound in local coordinates on the mapping norms of the inverses of the Fréchet derivatives). We localize the linear second-order PDEs (7.5) to regions in which for some orthonormal coordinate system \mathcal{M} can be written as the graph of a function $\varphi(x_1, x_2, \dots, x_{n-1})$ defined in some region U in \mathbb{R}^{n-1} and having Hölder continuous third derivatives. If we represent h in these local coordinates $(x_1, x_2, \dots, x_{n-1})$, then the restriction of $DF[g]$ to these coordinates has the form $h \mapsto (\mathcal{L}_U^*(h), h(\cdot, 0))$. We multiply this \mathcal{L}_U^* by

$$|\mathbf{n} - (I - gD^2d)^{-1}\nabla g|$$

(which does not vanish for g 's in our domain) to obtain a partial differential operator \mathcal{L}_U in the form

$$(7.6) \quad \mathcal{L}_U(h) = \left(\frac{\partial h}{\partial t}(x, t) - \sum_{i,j=1}^{n-1} a_{i,j}(x, t) \frac{\partial^2 h}{\partial x_i \partial x_j}(x, t) + \sum_{i=1}^{n-1} b_i(x, t) \frac{\partial h}{\partial x_i}(x, t) + c(x, t)h(x, t) \right).$$

We check that the coefficient functions $a_{i,j}(x, t)$, $b_i(x, t)$, $c(x, t)$ all belong to

$$C^{0+\alpha, (0+\alpha)/2}(U \times [0, T])$$

with uniformly bounded $\|\cdot\|_{C^{0+\alpha, (0+\alpha)/2}}$ norms, provided that our g 's, which belong to

$$C^{2+\alpha, (2+\alpha)/2}(U \times [0, T]) \cap \{g: |g(x, t)| < w\},$$

have $\|g\|_{C^{2+\alpha, (2+\alpha)/2}}$ uniformly bounded. By direct computation, we infer from the ellipticity of Φ that the $a_{i,j}(x, t)$'s satisfy the ellipticity condition

$$\sum_{i,j=1}^{n-1} a_{i,j}(x, t) \xi_i \xi_j \geq \nu |\xi|^2 \quad \text{for all } \xi \in \mathbb{R}^{n-1};$$

here the positive constant ν depends only on norm bounds for our g 's. Theorem 10.1 of [LSU, Chap. 4, p. 351] applies to linear partial differential operators of the form of \mathcal{L} in (7.6), and we infer from that theorem the existence of constants $C_{T,U}$, $B_{T,U}$ (depending only on T and our norm bounds on the coefficients, and hence only on T and the norm bounds for our g 's) such that, for each

$$h \in C^{2+\alpha, (2+\alpha)/2}(U \times [0, T]),$$

$$(7.7) \quad \|h\|_{C^{2+\alpha, (2+\alpha)/2}} \leq C_{T,U} \|\mathcal{L}(h)\|_{C^{0+\alpha, (0+\alpha)/2}} + C_{T,U} \|h(\cdot, 0)\|_{C^{2+\alpha, (2+\alpha)/2}} + B_{T,U} \|h\|_{L^\infty}.$$

Estimate (7.7) seems the best local estimate. It, however, has the unfortunate $\|h\|_{L^\infty}$ dependence.

Step 5 (a global bound on the mapping norms of the inverses of the Fréchet derivatives that depends on T). Since \mathcal{M} can be covered by finitely many local coordinates patches U , we infer that the local bounds given for the mapping norms of the $DG(g)$'s give global bounds. By analogy, we write $DF[g](h) = (\mathcal{L}^*(h), h(\cdot, 0))$ and define a global operator \mathcal{L} by requiring that its restrictions be the \mathcal{L}_U 's above. Our local estimates then guarantee, for each

$$h \in C^{2+\alpha, (2+\alpha)/2}(\mathcal{M} \times [0, T]),$$

that

$$(7.8) \quad \|h\|_{C^{2+\alpha, (2+\alpha)/2}} \leq C_T \|\mathcal{L}(h)\|_{C^{0+\alpha, (0+\alpha)/2}} + C_T \|h(\cdot, 0)\|_{C^{2+\alpha, (2+\alpha)/2}} + B_T \|h\|_{L^\infty}.$$

We claim that estimate (7.8) holds with the constant B_T set equal to zero, provided that we increase the size of C_T if necessary. To see this, we consider the function

$$h_C(x, t) = e^{-Ct}h(x, t) \quad \text{for large } C$$

and let (p_C, t_C) be a point in $\mathcal{M} \times [0, T]$ at which h_C assumes a maximum value. This point (p_C, t_C) corresponds to some point (x_C, t_C) in one of our coordinate patches U . In the coordinate patch U , we evaluate

$$\mathcal{L}_U(h_C) = -C e^{-Ct}h + e^{-Ct}\mathcal{L}_U(h).$$

Either $t_C = 0$ so that the maximum of h_C and hence of h is dominated by the sup norm of $h(\cdot, 0)$, or $t_C > 0$ and we can use the first and second derivative properties of function at their maximums to conclude that

$$0 \leq -c(x_C, t_C)h_C(x_C, t_C) - C e^{-Ct_C}h(x_C, t_C) + e^{-Ct_C}\mathcal{L}_U(h)(x_C, t_C),$$

in which case (since C was large and positive) the maximum of h_C and hence of h is dominated by $\mathcal{L}_U(h)$. We can replace h by $-h$ to obtain a corresponding estimate for the minimum of h . We conclude that

$$(7.9) \quad \|h\|_{C^{2+\alpha, (2+\alpha)/2}} \leq C_T \|\mathcal{L}(h)\|_{C^{0+\alpha, (0+\alpha)/2}} + C_T \|h(\cdot, 0)\|_{C^{2+\alpha, (2+\alpha)/2}}$$

for suitable C_T 's.

Step 6 (a global bound on the mapping norms of the inverses of the Fréchet derivatives that does not depend on T). We assert that

$$(7.10) \quad \|h\|_{C^{2+\alpha, (2+\alpha)/2}} \leq C \|\mathcal{L}(h)\|_{C^{0+\alpha, (0+\alpha)/2}} + C \|h(\cdot, 0)\|_{C^{2+\alpha, (2+\alpha)/2}},$$

provided that we take the constant C to be that corresponding to $T=1$ in (7.9). This is accomplished by the following device. To the operators \mathcal{L}_U for functions defined on domains $U \times [0, T]$ above, we associate new operators defined on $U \times [0, 1]$ by setting

$$a_{i,j}(x, t) = \begin{cases} a_{i,j}(x, t) & \text{if } 0 \leq t \leq T, \\ a_{i,j}(x, T) & \text{if } T \leq t \leq 1, \end{cases}$$

and so forth. The Hölder norms of the coefficients of the \mathcal{L}_U 's on the time interval $[0, 1]$ clearly remain bounded by the norms on $[0, T]$. Our assertion follows.

This completes our proof that the $DF[g]^{-1}$'s have bounded mapping norms on their images.

Step 7 (the operators $DF[g]$ are surjections). As mentioned above, we wish to show surjectivity by using the homotopy criterion of Theorem 5.2 of [GT]. We choose a new infinitely differentiable manifold \mathcal{N} , which is very close to \mathcal{M} , and we let ρ denote the nearest point retraction mapping of a neighborhood of \mathcal{N} (containing \mathcal{M}) onto \mathcal{N} . The restriction of ρ to \mathcal{M} gives a diffeomorphism of \mathcal{M} with \mathcal{N} , which is three times Hölder continuously differentiable. This produces an isomorphism of our various function spaces on \mathcal{M} with the corresponding spaces on \mathcal{N} . We denote by $\Delta_{\mathcal{N}}$ Laplace's differential operator on \mathcal{N} . It is well known that we can solve the usual heat equation

$$\frac{\partial g}{\partial t} - \Delta_{\mathcal{N}}g = \varphi$$

with initial condition $g(\cdot, 0) = \psi$ for all smooth φ 's and ψ 's. It is difficult, however, to find a statement of this fact useful for our purposes. However, in desperation, we can invoke Theorem 5.2 [LM, p. 30] (as used in the proof [LM, Thm. 5.3, p. 32]) to infer the existence of infinitely differentiable solutions to our equation, provided that

φ and ψ are both infinitely differentiable. The Hölder estimates on $DF[g]^{-1}$'s work equally well for the inverse of the operator $\partial/\partial t - \Delta_{\mathcal{N}}$. Since we know all infinitely differentiable functions are in the range of $\partial/\partial t - \Delta_{\mathcal{N}}$, we can use these Hölder estimates to conclude that Hölder continuous φ 's and ψ 's are also appropriately in the image. Our above diffeomorphism now translates the problem with the heat operator on \mathcal{N} to a uniformly parabolic problem on \mathcal{M} (actually just a change of coordinates). This new problem on \mathcal{M} then gives the desired surjectivity property, and we conclude that each of our $DF[g]$'s is onto.

We have now shown that the $DF[g]$'s are uniformly isomorphisms as required. The remainder of argument to prove the theorem was set forth above. \square

COROLLARY 7.2 (perturbations of smooth elliptic curvature flows). *Suppose that our surface energy function Φ is smooth and elliptic. Suppose also that $[L(t)]$ is a time-parametrized family of solids such that the $\partial L(t)$'s constitute a smooth Φ curvature flow for $0 \leq t < t_0$ (some t_0). Then, for each $0 < t_1 < t_0$ there exist the following:*

- (a) *A positive initial perturbation distance bound ρ ;*
- (b) *A positive perturbation velocity bound σ ;*
- (c) *Solids $L[r, s, t] \in \mathcal{K}$ for perturbation parameters $-\rho < r < \rho$ and $-\sigma < s < \sigma$, and times $0 \leq t \leq t_1$;*
- (d) *Associated signed distance functions $d[r, s, t]: \mathbb{R}^n \rightarrow \mathbb{R}$ for $-\rho < r < \rho$, $-\sigma < s < \sigma$, and $0 \leq t \leq t_1$, such that $d[r, s, t](x) = \pm \text{dist}(x, \partial L[r, s, t])$, where we take the minus sign for $x \in L[r, s, t]$;*

with the following properties

- (1) *For each $0 \leq t \leq t_1$, $L[0, 0, t] = L(t)$;*
- (2) *For each r and s , $L[r, s, 0] = \{x: d[0, 0, 0] < r\}$;*
- (3) *For each r, s , and t , $\partial L[r, s, t]$ is a smooth hypersurface in \mathbb{R}^n that varies smoothly in the parameters r, s , and t ;*
- (4) *For each fixed r and s the normal velocity of $L[r, s, t]$ at the point p in $\partial L[r, s, t]$ and time t equals the Φ curvature plus s times the exterior normal vector, i.e.,*

$$-\frac{\partial d[r, s, t]}{\partial t}(p) = H_{\Phi, \partial L[r, s, t]}(p) + s \mathbf{n}_{L[r, s, t]}(p);$$

- (5) *For each fixed positive s , there exists $\Delta t_0 > 0$ such that, whenever $0 < \Delta t < \Delta t_0$, $0 \leq t - \Delta t < t \leq t_1$, and $p \in \partial L[r, s, t]$ then*

$$\frac{d[r, s, t - \Delta t](p)}{\Delta t} \geq \mathbf{n}_{L[r, s, t]}(p) \cdot H_{\Phi, \partial L[r, s, t]}(p) + \frac{s}{2}.$$

A similar statement holds if s is negative, except in that case we obtain

$$\frac{d[r, s, t - \Delta t](p)}{\Delta t} \leq \mathbf{n}_{L[r, s, t]}(p) \cdot H_{\Phi, \partial L[r, s, t]}(p) + \frac{s}{2}.$$

Proof. We divide the time interval $[0, t_0]$ into short subintervals $0 < t_1 < t_2 < \cdots < t_N < t_0$ of equal length. For $t_k \leq t \leq t_{k+1}$, we represent time-varying surfaces that are close to $\partial L(t_k)$ as graphs of functions $g(x, t)$ defined for $x \in \partial L(t_k)$ and $t_k \leq t \leq t_{k+1}$; such a surface is thus of the form

$$\{x + g(x, t) \mathbf{n}_{L(t_k)}(x): x \in \partial L(t_k)\}.$$

Theorem 7.1 tells us that over each suitably short time interval $[t_k, t_{k+1}]$ we are

guaranteed the existence of slight perturbations of $\partial L(t_k)$ evolving by slight perturbations of smooth Φ curvature flow. We also infer from Theorem 7.1 and the fact that $\partial L(t)$'s are evolving by smooth Φ curvature flow that surfaces that start close to $\partial L(t_k)$ at time t_k will be close to $\partial L(t_{k+1})$ at time t_{k+1} . Since smooth Φ curvature flows are viscosity Φ curvature flows, we can use the regularity theory set forth in [W] to infer that each $\partial K(t_k)$ everywhere locally will be a graph of a $C^{3+\alpha}$ function when written in Cartesian coordinates. We are thus able to apply Theorem 7.1 repeatedly for the finite number of times required to establish the present corollary. \square

LEMMA 7.3 (inside and outside barriers for \mathcal{E} minimizers). *Suppose that our surface energy function Φ is smooth and elliptic and that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt . Suppose also that $[L_0]$ and $[L]$ belong to \mathcal{K} and that ∂L_0 and ∂L are smooth hypersurfaces. We specify the signed distance functions*

$$d(x) = \pm \text{dist}(x, \partial K_0), \quad [\text{respectively, } d_*(x) = \pm \text{dist}(x, \partial L_0)],$$

where we take the negative sign if $x \in K_0$ [respectively, if $x \in L_0$], and take the positive sign otherwise.

(1) If $K_0 \subset L_0$ and $K \subset L$ and

$$\frac{d_*(p)}{\Delta t} > \mathbf{n}_L(p) \cdot H_{\Phi, \partial L}(p)$$

for each $p \in \partial L$, then $\text{spt } \partial[K] \cap \partial L = \emptyset$.

(2) If $L_0 \subset K_0$ and $L \subset K$ and

$$\frac{d_*(p)}{\Delta t} < \mathbf{n}_L(p) \cdot H_{\Phi, \partial L}(p)$$

for each $p \in \partial L$, then $\text{spt } \partial[K] \cap \partial L = \emptyset$.

Proof. We will prove conclusion (1) of Lemma 7.3 by contradiction. Suppose then there is a point p in $\text{spt } \partial[K] \cap \partial L$. The assumption that $K \subset L$ means that L is a smooth, one-sided barrier to $\text{spt } \partial[K]$. We infer from conclusion (1) of Theorem 3.10 that p is a regular point of $\text{spt } \partial[K]$. We infer from assumption (2) of Theorem 3.8 that

$$\frac{d(p)}{\Delta t} = \mathbf{n}_K(p) \cdot H_{\Phi, \partial K}(p).$$

The inclusion $K_0 \subset L_0$ implies that $d_*(p) \leq d(p)$. The inclusion $K \subset L$ implies that

$$\mathbf{n}_K(p) \cdot H_{\Phi, \partial K}(p) \leq \mathbf{n}_L(p) \cdot H_{\Phi, \partial L}(p)$$

and that $\mathbf{n}_K(p) = \mathbf{n}_L(p)$. We combine these inequalities to obtain

$$\mathbf{n}_L(p) \cdot H_{\Phi, \partial L}(p) < \frac{d_*(p)}{\Delta t} \leq \frac{d(p)}{\Delta t} = \mathbf{n}_K(p) \cdot H_{\Phi, \partial K}(p) \leq \mathbf{n}_L(p) \cdot H_{\Phi, \partial L}(p),$$

which is false. This proves (1) of Lemma 7.3. Conclusion (2) of the lemma follows with a similar argument. \square

THEOREM 7.4 (smooth elliptic curvature flows are flat flows). *Suppose that our surface energy function Φ is smooth and elliptic. Suppose also that $[L(t)]$ is a time-parametrized family of solids such that the $\partial L(t)$'s constitute a smooth Φ curvature flow for $0 \leq t < t_0$ (some t_0). Let $\partial[K(t)]$ be any flat Φ curvature flow for which $K(0) = L(0)$. Then $K(t) = L(t)$ for each $0 \leq t < t_0$.*

Proof. For $L(t)$, t_0 as above, we let t_1 , ρ , σ , $L[r, s, t]$, $d[r, s, t]$ have the meaning given in (a)–(d) of Corollary 7.2. For $j = 1, 2, 3, \dots$ and $k = 0, 1, 2, \dots$, we set $\Delta t_j = 2^{-j}$

and denote by $[K_j(k\Delta t_j)] \in \mathcal{K}$ the approximators used in constructing flat Φ curvature flows as in § 2.6, starting with $[K(0)] = [L(0)]$.

Clearly, for any s ,

$$K(0) \subset \{x: d[0, 0, 0](x) < \rho/2\} = L[\rho/2, s, 0].$$

We assert the existence of $0 < t_2 \leq t_1$ and a positive integer j_0 such that, for any $-\sigma/2 \leq s \leq \sigma/2$ and any $0 \leq t \leq t_2$,

$$(7.11) \quad \begin{aligned} K_j(k\Delta t_j) &\subset \{x: d[0, 0, 0](x) < \rho/6\} \\ &\subset \{x: d[0, 0, 0](x) < \rho/3\} \subset L[\rho/2, s, t] \end{aligned}$$

for all $j \geq j_0$, provided that k is sufficiently small so that $k\Delta t_j \leq t_2$. The left-hand inclusion follows from conclusions (1) and (3) of Theorem 5.4, while the right-hand inclusion follows from the smooth dependence of the $L[r, s, t]$'s on r, s, t .

We temporarily fix $0 < s_0 \leq \sigma/2$ and use conclusion (5) of Corollary 7.2 to choose $j_1 \geq j_0$ such that, whenever $j \geq j_1$, $-\rho/2 \leq r \leq \rho/2$, $\Delta t_j \leq t \leq t_1$, then

$$(7.12) \quad \frac{d[r, s_0, t - \Delta t_j](p)}{\Delta t_j} \geq \mathbf{n}_{L[r, s_0, t]}(p) \cdot H_{\Phi, \partial L[r, s_0, t]}(p) + \frac{s_0}{2}.$$

We now fix $j_2 \geq j_1$ and let k_0 denote the largest integer for which $k_0\Delta t_{j_2} \leq t_2$. By our choice (7.11), above, each $K_{j_2}(k\Delta t_{j_2})$ lies strictly inside $L[\rho/2, s_0, k\Delta t_{j_2}]$ for $k = 0, \dots, k_0$. With s_0, j_2 fixed, and k restricted to $\{0, \dots, k_0\}$, we denote by $0 \leq r_1 < \rho$ the smallest nonnegative number such that $K_{j_2}(k\Delta t_{j_2})$ lies strictly inside $L[r, s_0, k\Delta t_{j_2}]$ for each $k \in \{0, \dots, k_0\}$ and all $r_1 < r \leq \rho/2$. We assert that $r_1 = 0$. If this were not the case, there would be $k_1 \in \{1, \dots, k_0\}$ (clearly, $k_1 \neq 0$) such that $[K_{j_2}(k_1\Delta t_{j_2})]$ is an \mathcal{E} minimizer for $[K_{j_2}((k_1 - 1)\Delta t_{j_2})]$ over Δt_{j_2} with

$$K_{j_2}((k_1 - 1)\Delta t_{j_2}) \subset L[r_1, s_0, (k_1 - 1)\Delta t_{j_2}], \quad K_{j_2}(k_1\Delta t_{j_2}) \subset L[r_1, s_0, k_1\Delta t_{j_2}]$$

and

$$\text{spt } \partial[K_{j_2}(k_1\Delta t_{j_2})] \cap \partial L[r_1, s_0, k_1\Delta t_{j_2}] \neq \emptyset$$

(since otherwise there would be a smaller r_1). In view of (7.12), this situation is incompatible with conclusion (1) of Lemma 7.3. We therefore infer that $r_1 = 0$. We further infer, for each fixed $0 < s \leq \sigma/2$, that $K_j(k\Delta t_j) \subset L[0, s, k\Delta t_j]$ for all sufficiently large j and all k for which $0 \leq k\Delta t_j \leq t_2$.

An analogous argument based on conclusion (2) of Lemma 7.3 implies that, for each fixed $-\sigma/2 < s < 0$, $K_j(k\Delta t_j) \supset L[0, s, k\Delta t_j]$ for all sufficiently large j and all k for which $0 \leq k\Delta t_j \leq t_2$.

We then infer from the smooth dependence of $L[r, s, t]$ on r, s, t and the definition of flat convergence that $K(t) = L[0, 0, t] = L(t)$ for each $0 \leq t \leq t_2$.

We now wish to remedy the difficulty that $K(t) = L(t)$ only for $0 \leq t \leq t_2$. This difficulty came from the requirement that $K_j(k\Delta t_j) \subset L[\rho/2, s_0, k\Delta t_j]$ for our times Δt_j , and initially we could infer such inclusion only for $k\Delta t_j$'s not exceeding our t_2 . We now know that $\partial K_j(k\Delta t_j)$ lies extremely close to $\partial L(t_2)$ for $k\Delta t_j$'s extremely close to t_2 and j extremely large. We can now use this fact, together with shrinking Wulff shape barrier estimates given in conclusions (1) and (3) of Theorem 5.4 to infer the existence of a time t_3 greater than t_2 such that $\partial K_j(k\Delta t_j)$ lies still quite close to $\partial L(t_2)$ for $k\Delta t_j$'s between t_2 and t_3 . For huge j 's and t_3 , which is not too much greater than t_2 , we conclude that $K_j(k\Delta t_j) \subset L[\rho/2, s_0, k\Delta t_j]$ for $k\Delta t_j$'s not exceeding our t_3 .

We then look at even larger j 's to extend the arguments to a t_4 greater than t_3 . This procedure works (since our estimates are effectively uniform out to time t_1) to push the time of coincidence out to time t_1 . Since t_1 was any number less than t_0 , we conclude that $K(t) = L(t)$ for $0 \leq t < t_0$. \square

8. Examples of flat curvature flows.

8.1. Circles moving by flat arc length flow. The unique flat arc length curvature flow of curves in the plane starting with $\partial[\mathbb{B}^2((0, 0), r_0)]$ is given by

$$\partial[K(t)](t) = \begin{cases} \partial[\mathbb{B}^2((0, 0), (r_0^2 - 2t)^{1/2})] & \text{for } 0 \leq t < \frac{r_0^2}{2} \\ 0 & \text{for } \frac{r_0^2}{2} \leq t < \infty. \end{cases}$$

To see this, we suppose that $n = 2$ so that the integrand $\Phi(v) = |v|$ is the arc length integrand. Using the terminology of § 5.1 and Theorem 5.4, that we check that $W_1 = \mathbb{B}^2((0, 0), \pi^{-1/2})$, $w_* = w^* = \pi^{-1/2}$, $\Phi(\partial[W_1]) = 2\pi^{1/2}$, $c_0 = c^0 = 2\pi$, $c_1 = (32\pi)^{-1}$, $S_0(t) = S^0(t) = (S^2 - 2\pi t)^{1/2}$, and

$$W_S = \mathbb{B}^2((0, 0), \pi^{-1/2}S) \quad \text{for each } S.$$

We infer from conclusions (2), (4), and (6) of Theorem 5.4 that, for each point p and each initial radius r_0 , the shrinking circles

$$\partial\mathbb{B}^2(p, (r_0^2 - 2t)^{1/2}) \quad \text{for } 0 \leq t < \frac{r_0^2}{2}$$

are barriers to any flat arc length curvature flow from both the outside and inside. Our original assertion above follows.

8.2. Nonuniqueness of flat arc length curvature flows for an initial curve resembling a figure-eight curve. We will construct an initial solid $[K(0)]$ whose boundary curve $C = \partial K(0)$ is a continuously differentiable immersion of a circle resembling a figure eight lying on its side. The crossing occurs at the origin and has tangent given by the lines $y = \pm x$. Corresponding to one subsequence of approximating flows, the crossing in the limit flat flow will split horizontally into two halves. Corresponding to another subsequence, the crossing will split vertically. The difference in splitting occurs because on the scale appropriate to the first subsequence of Δt 's the crossing seems to occur at an angle slightly less than 90° (which favors the horizontal split for approximators associated with such Δt 's), while, on the scale appropriate to the second subsequence of Δt 's, the crossing angle is slightly greater than 90° (favoring the vertical split). The construction and argument require several steps. To be specific, we assume that $K(0)$ contains the disks $\mathbb{B}^2((12, 0), 3)$ and $\mathbb{B}^2((-12, 0), 3)$ and is disjoint from the disks $\mathbb{B}^2((0, 12), 3)$ and $\mathbb{B}^2((0, -12), 3)$.

We denote by $\xi: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ reflection across the x axis and denote by $\eta: \mathbb{R}^2 \rightarrow \mathbb{R}^2$ reflection across the y axis in \mathbb{R}^2 .

PROPOSITION 8.2.1 (approximators can be chosen with ξ and η symmetry). *Suppose that $[K_0]$ is a solid in \mathcal{K} with $K_0 = \xi K_0 = \eta K_0$, and $0 < \Delta t < \infty$. Then at least one of the currents $[K]$, which is an \mathcal{E} minimizer for $[K_0]$ over Δt , has the symmetries $K = \xi K = \eta K$.*

Proof. For any minimizing, K_* , select the quadrant Q in which

$$\Phi(\partial K_* \llcorner Q) + \frac{1}{\Delta t} \int_{x \in Q \cap K_* \Delta K_0} \text{dist}(x, \partial K_0) d\mathcal{L}^2 x$$

is the smallest and replace K_* by $K = K_* \cup \xi(K_*) \cup \eta(K_* \cup \xi(K_*))$. The main observation in showing

$$\mathcal{E}([K_0], [K], \Delta t) \leq \mathcal{E}([K_0], [K_*], \Delta t)$$

is that, for each point p in \mathbb{R}^2 , some closest point in ∂K_0 to p lies in the quadrant to which p belongs. \square

We denote by $[K_j(k\Delta t_j)]$, $j = 1, 2, 3, \dots$, $k = 0, 1, 2, \dots$, approximators to flat arc length curvature flows $[K(t)]$ beginning with $[K(0)]$; here $\Delta t_j = 2^{-j}$ for each j . In view of Proposition 8.2.1, we require that $K_j(k\Delta t_j) = \xi K_j(k\Delta t_j) = \eta K_j(k\Delta t_j)$ for each j and k . We recall the scaling estimates set forth in conclusion (1) of Theorem 3.9 and define $K_j^*(k) = \Delta t_j^{-1/2} K_j(k\Delta t)$ for each j and k (homothetic expansion by factor $\Delta t_j^{-1/2}$); hence each $[K_j^*(k+1)]$ is an \mathcal{E} minimizer for $[K_j^*(k)]$ over 1 (i.e., the time step equals 1).

8.2.2. Dumbbell-shaped barriers. We want to consider regions consisting of two widely separated large disks joined by a narrow strip. With this in mind we set

$$A(l, r, s) = \mathbb{B}^2((0, l), r) \cup \mathbb{B}^2((0, -l), r) \cup [-s, s] \times [-l, l]$$

for numbers $l > r \gg s$. In our applications, we will take $l = 12$ and $1 \leq r \leq 3$ or $\Delta t_j^{-1/2}$ times these numbers.

PROPOSITION 8.2.3 (nonshrinking central strips in the dumbbell barriers). *Suppose that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt and that $l > r \gg s > 32\pi\Delta t^{1/2}$. If $A(l, r, s) \cap K_0 = \emptyset$, then $A(l, r - (4\pi/r)\Delta t, s) \cap K = \emptyset$.*

Proof. It follows from conclusion (3) of Theorem 5.3 that $A(l, r - (4\pi/r)\Delta t, s - (4\pi/s)\Delta t) \cap K_0 = \emptyset$. Verification of the larger avoidance is based on construction of comparison curves in the \mathcal{E} minimization; details are left to the reader. \square

Analogous statements hold for the image of $A(l, r, s)$ and K_0 under any Euclidean motion or if $A(l, r, s) \subset K_0$.

The presence of two large disks at the ends of the strip means that the strip does not have to shrink to remain a barrier and that the separation persists until the disks have shrunk.

Proposition 8.2.3, together with conclusion (2) of Theorem 5.4, imply that, if Δt_j is small and

$$K_j(k_0\Delta t_j) \cap A(12, 2, 33\pi\Delta t_j^{1/2}) = \emptyset,$$

then

$$K_j((k_0 + k)\Delta t_j) \cap A(12, 1, 33\pi\Delta t_j^{1/2}) = \emptyset,$$

provided that $2\pi k\Delta t_j \leq 1$. In other words, if, for some j , $K_j(k_0\Delta t_j)$ achieves a horizontal separation by amount $33\pi\Delta t_j^{1/2}$ and $k_0\Delta t_j$ is small enough so that $K_j(k_0\Delta t_j)$ is still disjoint from the disks $\mathbb{B}^2((0, 12), 2)$ and $\mathbb{B}^2((0, -12), 2)$, then the horizontal separation in the $K_j(k\Delta t_j)$'s will persist for additional time at least $1/2\pi$.

If the separation criterion is stated in terms of the sets $K_j^*(k)$, then horizontal separation of 33π is sufficient for the separation to persist for time $1/2\pi$.

8.2.4. Double-sector-shaped regions and retraction functions. We want to consider regions shaped like two symmetric pieces of pie having vertex angles slightly smaller or slightly larger than a right angle and also retractions of the plane less the y axis onto such regions. For this section only, we use polar coordinates r, θ for the plane. For a (large) radius R and a (small) perturbation angle $-\pi/8 < \omega < \pi/8$, we set

$$X(R, \omega) = \mathbb{B}^2((0, 0), R) \cap \{(r, \theta): \text{either } |\theta| \leq \pi/4 - \omega \text{ or } |\theta - \pi| \leq \pi/4 - \omega\}.$$

We define functions $F[\omega]: \mathbb{R}^2 \sim (y \text{ axis}) \rightarrow \mathbb{R}^2$, which retract each R disk (with the y axis removed) onto $X(R, \omega)$, by requiring for each r and θ that

$$F[\omega](r, \theta) = \begin{cases} (r, \theta) & \text{if } (r, \theta) \in X(R, \omega), \\ \left(r, \left[\frac{\pi}{4} - \omega \right] - \frac{\frac{\pi}{4} - \omega}{\frac{\pi}{4} + \omega} \left[\theta - \left(\frac{\pi}{4} - \omega \right) \right] \right) & \text{if } \frac{\pi}{4} - \omega < \theta < \frac{\pi}{2}, \\ \left(r, \left[\frac{-\pi}{4} + \omega \right] + \frac{\frac{\pi}{4} - \omega}{\frac{\pi}{4} + \omega} \left[\left(-\frac{\pi}{4} + \omega \right) - \theta \right] \right) & \text{if } \frac{-\pi}{2} < \theta < -\frac{\pi}{4} + \omega, \\ \left(r, \left[\frac{3\pi}{4} + \omega \right] + \frac{\frac{\pi}{4} - \omega}{\frac{\pi}{4} + \omega} \left[\left(\frac{3\pi}{4} + \omega \right) - \theta \right] \right) & \text{if } \frac{\pi}{2} < \theta < \frac{3\pi}{4} + \omega, \\ \left(r, \left[\frac{-3\pi}{4} - \omega \right] - \frac{\frac{\pi}{4} - \omega}{\frac{\pi}{4} + \omega} \left[\theta - \left(\frac{3\pi}{4} - \omega \right) \right] \right) & \text{if } \frac{-3\pi}{4} - \omega < \theta < -\frac{\pi}{2}. \end{cases}$$

When restricted to each of the half-spaces $-\pi < \theta < \pi$ and $\pi < \theta < 3\pi/2$, our mapping $F[\omega]$ clearly is length nonincreasing and is area nonincreasing in case $\omega > 0$.

We can use the $X(R, \omega)$'s and $F[\omega]$'s to obtain estimates necessary for our construction.

We denote by k_0 the smallest integer for which $(k_0 - 1)(4/67) > 33\pi$ for use in the following proposition and additionally below.

PROPOSITION 8.2.5 (small separations grow to big separations). *Suppose that $0 < \omega < \pi/8$ and*

$$K_j^*(k) \cap \mathbb{B}^2((0, 0), 100\pi) \subset X(100\pi, \omega) \sim \mathbb{B}^2((0, 0), R)$$

for some $0 < R < 1$ and for $k = 1, 2, \dots, k_0$. Then

$$\begin{aligned} K_j^*(k) \cap \mathbb{B}^2((0, 0), 67\pi) \\ \subset \mathbb{B}^2((67\pi, 0), 67\pi - \frac{4}{67}(k-1)) \cup \mathbb{B}^2((-67\pi, 0), 67\pi - \frac{4}{67}(k-1)) \end{aligned}$$

for each $k = 0, 1, \dots, k_0$. In particular,

$$K_j^*(k_0) \cap \mathbb{B}^2((0, 0), 100\pi) \cap [-33\pi, 33\pi] \times \mathbb{R} = \emptyset.$$

Proof. The comparison surface construction used in the proof of part (5) of Theorem 5.4 is local and applies to the present case.

Analogous statements hold with $\omega < 0$, provided that K_0 is replaced by $\mathbb{R}^2 \sim K_0$, K is replaced by $\mathbb{R}^2 \sim K$, $X(S + \Delta S, \omega)$ is replaced by $X(S + \Delta S, \omega) \sim K_0$, and so forth.

PROPOSITION 8.2.6 (a sufficient condition to keep \mathcal{E} minimizing K 's inside X 's). *Suppose that $0 < \omega < \pi/8$ and $0 < S < \infty$. Suppose also that $[K]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt with $K = \xi K = \eta K$. In case*

$$K_0 \cap \mathbb{B}^2((0, 0), 2S) \subset X(2S, \omega)$$

and

$$K \cap [\mathbb{B}^2((0, 0), 2S) \sim \mathbb{B}^2((0, 0), S)] \subset X(2S, \omega),$$

then $K \cap \mathbb{B}^2((0, 0), S) \subset X(S, \omega)$.

Proof. Suppose that $[K_*]$ is an \mathcal{E} minimizer for $[K_0]$ over Δt with $K_* = \xi K_* = \eta K_*$ and with $K_* \sim X(S + \Delta S, \omega) \pm \emptyset$. Consider as a comparison solid the current associated with a set $K_* \sim \mathbb{B}^2((0, 0), S) \cup N_1$; here N_1 is obtained as follows. Write

$$F[\omega]_*[K \cap \{(x, y): x > 0\}] + F[\omega]_*[K \cap \{(x, y): x < 0\}] = \sum_i [N_i] - \sum_j [L_j]$$

in accordance with § 3.1.4 and take that N_1 . We check that

$$\mathcal{E}([K_0], [K_1], \Delta t) < \mathcal{E}([K_0], [K_*], \Delta t),$$

contrary to assumption. \square

Analogous statements hold with $\omega > 0$, provided that K_0 is replaced by $\mathbb{R}^2 \sim K_0$, K is replaced by $\mathbb{R}^2 \sim K$, $X(S + \Delta S, \omega)$ is replaced by $X(S + \Delta S, \omega) \sim K_0$, and so forth.

PROPOSITION 8.2.7 (how to satisfy the hypotheses of Proposition 8.2.6). *Suppose that $0 < \omega < \pi/8$ is given and S is chosen sufficiently large so that*

$$S \geq 100\pi \quad \text{and} \quad \frac{4\pi}{S/2} (k_0 + 1) \leq \frac{\omega S}{2}.$$

Then there exists $0 < R < S$ with the following property. Suppose, for a particular choice of j , that we know that $K_j^(0) \cap [\mathbb{B}^2((0, 0), 5S) \sim \mathbb{B}^2((0, 0), R)] \subset X(5S, 2\omega)$. Then $K_j^*(k) \cap [\mathbb{B}^2((0, 0), 2S) \sim \mathbb{B}^2((0, 0), S)] \subset X(2S, \omega)$ for all $k = 0, 1, \dots, k_0$.*

Proof. For points p lying in $\partial X(5S, 2\omega) \cap [\mathbb{B}^2((0, 0), 2S) \sim \mathbb{B}^2((0, 0), S)]$, denote by $r(p)$ the radius for which the point $q(p) = r(p)\mathbf{n}_{X(5S, 2\omega)}$ lies in the y axis. Clearly, $S/2 < |r(p)| < 3S$. Since the balls $\mathbb{B}^2(q(p), r(p))$ now lie outside $X(5S, 2\omega) \cup \mathbb{B}^2((0, 0), R)$ (provided R is small), we can use conclusion (1) of Theorem 5.4 to let the balls shrink while remaining barriers to the $K_j^*(k)$'s. Our numbers above have been chosen so that the radii $r(p)$ need shrink by amount no more than $S\omega/2$. \square

PROPOSITION 8.2.8 (initial separation). *Suppose that $0 < \omega < \pi/8$ is given and S is the smallest number for which*

$$S \geq 100\pi \quad \text{and} \quad \frac{4\pi}{S/2} (k_0 + 1) \leq \frac{\omega S}{2}.$$

Then there exists $0 < R < S$ with the following property. Suppose that K_R is an \mathcal{E} minimizer for K_0 over 1 with $K_0 = \xi K_0 = \eta K_0$, $K_R = \xi K_R = \eta K_R$, and

$$K_0 \cap [B^2((0, 0), 5S) \sim \mathbb{B}^2((0, 0), R)] = X(5S, 2\omega) \sim \mathbb{B}^2((0, 0), R).$$

Then

$$K_R \cap \mathbb{B}^2((0, 0), S) \subset X(S, \omega).$$

Proof. Corresponding to $R = 0$, we use Propositions 8.2.6 and 8.2.7, together with part (5) of Theorem 5.4 (as in the proof of Proposition 8.2.5), to infer that, if K_* is an \mathcal{E} minimizer for K_0 over 1 with $K_* = \xi K_* = \eta K_*$ and $K_0 \cap B^2((0, 0), 5S) = X(5S, 2\omega)$, then $K_* \cap \mathbb{B}^2((0, 0), S) \subset X(S, \omega)$ and

$$K_* \cap \mathbb{B}^2((0, 0), 67\pi) \subset \mathbb{B}^2((67\pi, 0), 67\pi - 4/67) \cup \mathbb{B}^2((-67\pi, 0), 67\pi - 4/67).$$

Any sequence of R 's converging to zero must contain a subsequence such the $[K_R]$'s converge to a minimizing $[K_*]$. From the uniform lower density bound, we conclude the convergence of the ∂K_R 's to ∂K_* in Hausdorff distance. The remainder of the proof is left to the reader. \square

8.2.9. An example of nonuniqueness of flat Φ curvature flows. As indicated above, we will describe the construction a special initial solid $[K]$ for which there is more than one flat arc length curvature flow beginning with $\partial[K]$. The boundary curve $C = \partial K$ will resemble a figure-eight curve C lying on its side and passing through the origin tangent to the lines $y = \pm x$. C will also have the symmetries $C = \xi C = \eta C$. First, we specify small perturbation angles $\omega_i = (-1)^i 2^{-(100+i)}$ of alternating signs. They key to the construction of C near the origin is selection of special radii $S_1 > R_1 > S_2 > R_2 \dots$

converging to zero; the proposition below asserts that we can make a suitable selection. Having suitably selected such radii, we construct a symmetric C such that, for each i ,

$$\begin{aligned} C \cap [\mathbb{B}^2((0, 0), S_i) \sim \mathbb{B}^2((0, 0), R_i)] \\ = \partial X(S_i + 1, 2\omega_i) \cap [\mathbb{B}^2((0, 0), S_i) \sim \mathbb{B}^2((0, 0), R_i)], \end{aligned}$$

while

$$C \cap [\mathbb{B}^2((0, 0), R_i) \sim \mathbb{B}^2((0, 0), S_{i+1})]$$

is a reasonable interpolation curve. We then extend C outside $\mathbb{B}^2((0, 0), S_1)$ to be a smooth symmetric curve resembling a figure eight on its side so that, if $K(0)$ be the bounded region whose topological boundary is C , then $K(0)$ contains the disks $\mathbb{B}^2((12, 0), 3)$ and $\mathbb{B}^2((-12, 0), 3)$ and is disjoint from the disks $\mathbb{B}^2((0, 12), 3)$ and $\mathbb{B}^2((0, -12), 3)$.

Corresponding to a suitable choice of $j(1) < j(2) < j(3) < \cdots$, we let $\partial[K_{j(i)}(k\Delta t_{j(i)})]$ be any collection of approximate flat Φ curvature flows for which

$$K(k\Delta t_{j(i)}) = \xi K(k\Delta t_{j(i)}) = \eta K(k\Delta t_{j(i)}).$$

We then have the following proposition.

PROPOSITION 8.2.10 (nonuniqueness of flat arc length curvature flows). *It is possible to choose $j(i)$'s, S_i 's, and R_i 's with which to make the construction in § 8.2.9 so that the following conditions hold.*

(1) *For all sufficiently large i 's that are even, our approximating boundary curves $\partial[K_{j(i)}(k\Delta t_{j(i)})]$ can be chosen to split horizontally into two pieces, one in the right half plane and the other in the left half plane, and this type of horizontal split of the crossing will persist until the final disappearance of the evolving curves. Furthermore, if $\partial[K(t)]$ is a flat arc length curvature flow that is the limit of a subsequence of $K_{j(i)}(\cdot)$'s in which the i 's are even, and $C(t) = \partial K(t)$, then $C(t)$ instantly splits horizontally into at least two components, which remain separated until the final disappearance.*

(2) *For all sufficiently large i 's that are odd, our approximating boundary curves $\partial[K_{j(i)}(k\Delta t_{j(i)})]$ can be chosen to split vertically, and near the origin there will be part in the upper half plane and part in the lower half plane. This type of vertical split of the crossing will remain at least while $k\Delta t_{j(i)} \leq 1/2\pi$. Furthermore, if $\partial[K(t)]$ is a flat arc length curvature flow that is the limit of a subsequence of $K_{j(i)}(\cdot)$'s in which the i 's are odd, and $C(t) = \partial K(t)$, then $C(t)$ instantly splits vertically and, in small neighborhoods of the origin, $C(t)$ contain at least two components separated vertically. Vertical separation near the origin persists for time at least $1/2\pi$.*

Proof. We pick $j(1)$ and $0 < S_1 < 1$ such that, if $5S = \Delta t_{j(1)}^{-1/2} S_1$, then S is the smallest number for which

$$S \geq 100\pi \quad \text{and} \quad \frac{4\pi}{S/2} (k_0 + 1) \leq \frac{\omega_1 S}{2}.$$

Associated with this S and with $\omega = \omega_1$, we choose $R_1 < S_1$ so that the number $\Delta t_{j(1)}^{-1/2} R_1$ satisfies the requirements of the number R in Propositions 8.2.7 and 8.2.8. We then pick $j(2) \gg j(1)$ and $S_2 \gg R_1$ to satisfy the analogous conditions above. We then sequentially pick R_2, S_3, R_3 , and so forth. We use Propositions 8.2.5–8.2.8 to establish the asserted behavior for time at least $1/2\pi$. In the case of the horizontal split, we can additionally use large circle barriers to guarantee that rejoining does not occur. \square

8.3. How we might construct an initial surface for which there are a continuum of different flat surface area curvature flows. We take $n = 3$ so that $\Phi(v) = |v|$ is the surface

area integrand. We suggest how to construct an initial surface S for which there might be a continuum of different flat curvature flows. The basic idea is to take a figure-eight curve C as in § 8.2, translate it a substantial x distance away from the origin, and then rotate the image around the y axis to obtain a surface S of revolution. It seems that careful modification of S near its singular curve (inspired by the construction of § 8.2.9 and Proposition 8.2.10) would lead to flat surface area curvature flows, starting with S , in which there was initial horizontal separation for positive x and initial vertical separation for negative x . In particular, the type of separation changes from horizontal to vertical, or vice versa, as we cross the yz plane along the singular curve. This being the case, we apparently could further modify the behavior of S near its singular curve so that the plane at which type of separation changes could be any plane containing the z axis, provided that we used the right subsequence of approximations. Much more elaborate types of splitting patterns also seem to be possible.

Acknowledgments. The authors thank Andrew Roosen and Andrea Sufke for a careful reading of a large part of this manuscript and for their suggestions for the improvement of the exposition.

FRONT PROPAGATION AND PHASE FIELD THEORY*

G. BARLES[†], H. M. SONER[‡], AND P. E. SOUGANIDIS[§]

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. The connection between the weak theories for a class of geometric equations and the asymptotics of appropriately rescaled reaction-diffusion equations is rigorously established. Two different scalings are studied. In the first, the limiting geometric equation is a first-order equation; in the second, it is a generalization of the mean curvature equation. Intrinsic definitions for the geometric equations are obtained, and uniqueness under a geometric condition on the initial surface is proved. In particular, in the case of the mean curvature equation, this condition is satisfied by surfaces that are strictly starshaped, that have positive mean curvature, or that satisfy a condition that interpolates between the positive mean curvature and the starshape conditions.

Key words. viscosity solutions, mean curvature flow, front propagation, reaction-diffusion equations

Introduction. In this paper we study the connection between the *weak propagation of fronts* (closed hypersurfaces in \mathbb{R}^N , which propagate in the normal direction with the velocity depending on the position, the normal vector, and its gradient) and the *phase field theory*, as it applies to the study of the asymptotic behavior of reaction-diffusion equations. More specifically, we study the properties of the *signed distance function* to the front; we relate these properties to the level set formulation of moving fronts, and we present some new, general, and, in some cases, sharp results guaranteeing the uniqueness of the fronts (“no interior”). Finally, we develop a rigorous justification of the “phase field” theory.

The study of propagating fronts is very interesting from both the theoretical point of view as well as for applications (e.g., phase transitions in continuum mechanics, flame propagation, pattern formation, chemical kinetics, etc.). The strong geometrical formulation of the motion (which requires smoothness) faces the development of singularities; the motion can, therefore, be defined only locally in time, which is quite unsatisfactory for the applications. On the other hand, a weak geometrical formulation by Brakke [Br] for motion by mean curvature gave rise to nonuniqueness problems, but resulted in deep regularity results for the motion. More recently, two different approaches were introduced to deal with these issues, namely, the level set and the phase field approach. The level set approach, which was put forward by Evans and Spruck [ESp1] for motion by mean curvature and Chen, Giga, and Goto [CGG] for general motions, is based on considering the front as a level set (for definiteness the zero level set) of the solution of a degenerate parabolic partial differential equation (pde). The phase field approach, suggested by Bronsard and Kohn [BrK] and DeGiorgi

[D], defines the front as the boundary of the regions where the solutions of certain (scaled) reaction diffusion equations converge to the equilibria points of the associated vector field. Both approaches have their own advantages. The level set formulation provides a large number of analytical tools to study the motion because it allows for the use of very recent developments of the theory of nonlinear degenerate parabolic pde's. The phase field formulation is very indirect but also closely related to (and very natural for) the applications. A great deal of work in this paper is devoted to justifying the "phase field" formulation. One way to relate these two approaches is to study the properties of the distance function to the front; much of the work in this paper is devoted to this. In fact, we could propose an alternative way to study front propagation using the distance function. This was done by Soner [So] when the normal velocity of the front does not depend on its position. We chose not to do so in this paper, although given what we prove here for the distance function we can easily develop such an approach. A very intriguing mathematical question arising with the weak formulation of moving fronts is whether such fronts are uniquely determined by their initial position (if they are described using the distance function); this is closely related to whether the level set formulation gives rise to *fat* level sets. Two sections in this paper are devoted to studying these questions.

The paper is organized as follows: In § 1 we recall the level set formulation and slightly improve some of the known results. In § 2 we discuss the "nonempty interior" difficulty and give an equivalent characterization. Section 3 is devoted to deducing some important properties of the (signed) distance to the fronts. In § 4 we study the nonempty interior difficulty. We give some general sufficient conditions and present some counterexamples. Section 5 provides some uniqueness properties for the distance function, which will be used in § 10. In § 6 we discuss the asymptotic limits of reaction-diffusion equations and the phase field theory. Section 7 is devoted to a formal derivation of the results. In § 8 we briefly review the theory of traveling waves of reaction-diffusion equations and we formulate our main assumptions. The main results about the phase field theory are stated in § 9; their proofs are given in § 10. Finally, in § 11 we present some possible applications and state a few open problems.

1. Geometrical evolution of level sets and degenerate parabolic pde's. In this section we recall and slightly generalize the level set formulation presented in Chen, Giga, and Goto [CGG] (see also Evans and Spruck [ESp1] for motion by mean curvature and Giga et al. [GGIS]). As mentioned in the Introduction, the underlying idea is to think of the front as the zero-level set of the solution of a pde. This type of formulation first appeared in a theoretical work of Barles [Ba1] on fronts moving with constant normal velocity. Barles [Ba1] was motivated by the computational work of Sethian [Se1] for a simple model in flame propagation. Later, Osher and Sethian [OS] extensively used this type of idea to perform numerical computations for different types of motions and, in particular, motion by mean curvature. Evans and Spruck [ESp1] provided the mathematical foundation of the level set approach for motion by mean curvature and Chen, Giga, and Goto [CGG] independently studied motions in the generality described below.

To better explain the ideas involved, we first present a formal derivation: Let Γ_t be a smooth front at time $t > 0$ and assume that $\Gamma_t = \partial D_t$, where $D_t \subset \mathbb{R}^N$ is open. The outward normal velocity V of Γ_t at $x(\in \Gamma_t)$ is given by

$$(1.1) \quad V = v(x, t, n, Dn),$$

where v is a continuous function of its arguments, n is the exterior unit normal vector

to Γ_t , and Dn is its gradient. Furthermore, we assume that there exists a smooth function $u: \mathbb{R}^N \times [0, \infty) \mapsto \mathbb{R}$ such that

$$D_t = \{x \in \mathbb{R}^N: u(x, t) > 0\}, \quad \Gamma_t = \{x \in \mathbb{R}^N: u(\cdot, t) = 0\} \quad \text{and} \quad Du \neq 0 \text{ on } \Gamma_t.$$

A classical calculation yields

$$V = \frac{u_t}{|Du|}, \quad n = -\frac{Du}{|Du|} \quad \text{and} \quad Dn = -\frac{1}{|Du|} \left(I - \frac{Du \otimes Du}{|Du|^2} \right) D^2 u.$$

Inserting the above formulae in (1.1) we obtain

$$u_t + F(x, t, Du, D^2 u) = 0,$$

where F is related to v by

$$(1.2) \quad F(x, t, p, X) = -|p|v\left(x, t, -\frac{p}{|p|}, -\frac{1}{|p|} \left(I - \frac{p \otimes p}{|p|^2} \right) X\right)$$

for $p \in \mathbb{R}^N$ and $X \in S^N$, the space of $N \times N$ matrices. An immediate consequence of (1.2) is that, for all $(x, t) \in \mathbb{R}^N \times (0, \infty)$, $p \in \mathbb{R}^N$, and $X \in S^N$, F satisfies

$$(1.3) \quad F(x, t, \lambda p, \lambda X + \mu(p \otimes p)) = \lambda F(x, t, p, X) \quad (\lambda > 0, \mu \in \mathbb{R}).$$

Any F that satisfies (1.3) will be called *geometric*.

For (1.1) to be well-posed, it is also necessary to assume that it is parabolic, i.e., that v is nonincreasing in the Dn argument. This translates in terms of (1.2) to F being (*degenerate*) *elliptic*, i.e.,

$$(1.4) \quad F(x, t, p, X) \leq F(x, t, p, Y) \quad \text{if } X \geq Y,$$

for all $(x, t) \in \mathbb{R}^N \times (0, \infty)$, $p \in \mathbb{R}^N$, and $X, Y \in S^N$. The fact that F is degenerate (in fact at least in the $p \otimes p$ direction) follows from (1.3). Finally, we point out that F is as smooth as v with a possible discontinuity at $p = 0$.

The level set approach to front propagations can be described as follows. Given a closed set Γ_0 in \mathbb{R}^N (front at time $t = 0$), choose $u_0: \mathbb{R}^N \rightarrow \mathbb{R}$ such that

$$\Gamma_0 = \{x \in \mathbb{R}^N: u_0(x) = 0\},$$

solve (in the appropriate way) the pde

$$(1.5) \quad \begin{aligned} u_t + F(x, t, Du, D^2 u) &= 0 \quad \text{in } \mathbb{R}^N \times (0, \infty), \\ u(x, 0) &= u_0(x) \quad \text{on } \mathbb{R}^N, \end{aligned}$$

and, finally, define Γ_t (the front at time t) by

$$(1.6) \quad \Gamma_t = \{x \in \mathbb{R}^N: u(x, t) = 0\}.$$

The main issues associated with such a program are (i) whether (1.5) does have a global solution allowing to define Γ_t and (ii) whether Γ_t depends only on Γ_0 and not the form of u_0 outside Γ_0 .

The first issue is settled ([ESp1], [CGG]) by considering *viscosity solutions*. Viscosity solutions, which turn out to be the correct class of generalized solutions for first- and second-order fully nonlinear pde's, were introduced by Crandall and Lions [CL] (see also [CEL] and Lions [Li] for first- and second-order equations, respectively). For the precise definition and some of the most recent developments, as well as references, we refer to the "user's guide" by Crandall, Ishii, and Lions [CIL]. In what follows (unless otherwise stated) by solution we will always mean viscosity solution. To avoid

some technicalities we will denote by (F) a set of some general assumptions needed for the statement of the next theorem. We will state and discuss these assumptions at the end of this section. Finally, we will denote by $UC(\mathcal{O})$ the set of real-valued uniformly continuous functions defined on \mathcal{O} .

THEOREM 1.1. *Assume (F), (1.3), and (1.4). Then, for any $u_0 \in UC(\mathbb{R}^N)$, there exists a unique solution $u \in UC(\mathbb{R}^N \times [0, +\infty))$ of (1.5). Moreover, if u and v are, respectively, sub- and supersolutions of (1.5) in $UC(\mathbb{R}^N \times [0, +\infty))$, then*

$$(1.7) \quad u(\cdot, 0) \leq v(\cdot, 0) \text{ in } \mathbb{R}^N \Rightarrow u \leq v \text{ in } \mathbb{R}^N \times [0, +\infty).$$

Next we discuss the issue of whether Γ_t depends only on Γ_0 . This follows from (1.3), which yields that (1.5) is invariant by nondecreasing changes $u \mapsto \psi(u)$. (See [ESp1], [CGG]).

THEOREM 1.2. *Assume the hypotheses of Theorem 1.1 hold and let $u, v \in UC(\mathbb{R}^N \times [0, +\infty))$ be solutions of (1.5) such that*

$$\begin{aligned} \{x: u(x, 0) > 0\} &= \{x: v(x, 0) > 0\}, & \{x: u(x, 0) < 0\} &= \{x: v(x, 0) < 0\}, \\ \{x: u(x, 0) = 0\} &= \{x: v(x, 0) = 0\}, \end{aligned}$$

and

$$(1.8) \quad \lim_{|x| \rightarrow +\infty} |u(x, 0)|, \lim_{|x| \rightarrow +\infty} |v(x, 0)| > 0.$$

Then, for all $t > 0$,

$$\{x: u(x, t) > 0\} = \{x: v(x, t) > 0\}, \quad \{x: u(x, t) < 0\} = \{x: v(x, t) < 0\}$$

and

$$\{x: u(x, t) = 0\} = \{x: v(x, t) = 0\}$$

This result justifies the term *equation of geometric type* for (1.5), since it yields that the evolution of the level set $\Gamma_0 \rightarrow \Gamma_t$ depends only on F and on the “signs” of the initial datum in the different regions (which in turn give a sense to the expressions “inside Γ_0 ” and “outside Γ_0 ”) and not really on the choice of the initial datum. Such a result was first obtained by Evans and Souganidis [ES1] in the case where F is independent of D^2u using representation formulae from the theory of deterministic differential games. In the generality stated above the result was obtained in [CGG]. Next we present a slightly simplified proof.

Proof. Consider the functions ϕ and ψ given by

$$\phi(t) = \inf \{v(y, 0) | u(y, 0) \geq t\} \quad \text{and} \quad \psi(t) = \sup \{v(y, 0) | u(y, 0) \leq t\}.$$

It is immediate that ϕ and ψ are nondecreasing, lower- and upper-semicontinuous (lsc and usc), respectively, and

$$(1.9) \quad \phi(u(\cdot, 0)) \leq v(\cdot, 0) \leq \psi(u(\cdot, 0)) \text{ on } \mathbb{R}^N.$$

Moreover, the assumptions on $u(\cdot, 0)$ and $v(\cdot, 0)$ yield that ϕ and ψ are actually continuous at 0 with $\phi(0) = \psi(0) = 0$. Finally, standard regularization procedures imply the existence of two sequences of nondecreasing and nonincreasing, respectively, smooth functions $(\phi_n)_n$ and $(\psi_n)_n$ such that

$$(1.10) \quad \phi = \sup_n \phi_n \quad \text{and} \quad \psi = \inf_n \psi_n.$$

Since F is geometric, $\phi_n(u)$ and $\psi_n(u)$ are solutions of (1.5). Moreover, (1.9), (1.10), and Theorem 1.1 yield

$$\phi_n(u) \leq v \leq \psi_n(u) \quad \text{in } \mathbb{R}^N \times [0, +\infty).$$

Letting $n \rightarrow \infty$ we conclude easily, since, in view of the assumptions on $u(\cdot, 0)$ and $v(\cdot, 0)$ and the definition of ϕ and ψ , $\phi(t) > 0$ if $t > 0$ and $\psi(t) < 0$ if $t < 0$. \square

We continue by discussing some examples of motions and their related “geometrical” equations.

In the first example, the hypersurface is assumed to propagate in the normal direction with velocity $v(x, t, n)$. The geometric equation in this case is

$$(1.11) \quad u_t - v \left(x, t, \frac{Du}{|Du|} \right) |Du| = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

with $F(x, t, p, M) = -v(x, t, p/|p|)|p|$ satisfying (1.3). This type of propagation, when $v \equiv c$ constant, was introduced by Landau as a flame front propagation model and was studied both analytically and numerically by Sethian [Se1] using (1.11). Then Barles [Ba1] showed the connections between (1.11) and (1.3).

Another very interesting example, both theoretically and from the applications point of view, is the motion of a hypersurface with normal velocity equal to its mean curvature. Here (1.5) takes the form

$$(1.12) \quad u_t - \Delta u + \frac{(D^2 u Du | Du)}{|Du|^2} = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

where $(\cdot | \cdot)$ denotes the usual inner product in \mathbb{R}^N . In this case (1.3) holds for every $\lambda \in \mathbb{R}$ (not only $\lambda > 0$). This yields that the equation is invariant by any change! Equation (1.12) was studied first numerically by Osher and Sethian [OS] and then analytically by Evans and Spruck [ESp1]–[ESp4] (see also Chen, Giga, and Goto [CGG], Soner [So], etc.).

Another example of propagations that arise very naturally in the theory of phase transitions is the case of anisotropic motion where (1.5) is of the form

$$(1.13) \quad u_t - |Du| \operatorname{div} \left(H \left(\frac{Du}{|Du|} \right) \right) + |Du| \beta \left(\frac{Du}{|Du|} \right) = 0$$

for some smooth functions H and β , with H convex. Equation (1.13) is studied in [So] and [CGG]. There are some very interesting models of phase transitions that yield (1.13) but with H not convex. Following a *relaxation* process, these problems give rise to (1.3) but with F discontinuous (in addition to $p = 0$) at certain directions in the gradient space. This is the subject of Gurtin, Soner, and Souganidis [GSS].

We conclude this rather long overview of the level set approach by stating and discussing assumption (F), which was necessary for the comparison result of Theorem 1.1. Assumption (F) consists of several parts, namely,

$$(x, t, p, X) \mapsto F(x, t, p, X) \text{ is bounded for bounded } (p, X)$$

$$(F_1) \quad \text{and continuous for } x \in \mathbb{R}^N, \quad t \in [0, R], \quad p \in B(0, R) \setminus \{0\}$$

$$\text{and } \|X\| \leq R, \text{ for all } R > 0.$$

$$(F_2) \quad F_*(x, t, \alpha(x-y), X) - F^*(y, t, \alpha(x-y), Y) \geq -\omega(|x-y|(1+\alpha|x-y|)),$$

where $\omega(0^+) = 0$ and for all $x, y \in \mathbb{R}^N$, $t \in (0, +\infty)$, $\alpha \geq 0$ and matrices $X, Y \in S^N$ such that $\begin{pmatrix} X & 0 \\ 0 & -Y \end{pmatrix} \leq K\alpha \begin{pmatrix} I & \\ & -I \end{pmatrix}$ for some constant $K > 0$. Finally,

$$(F_3) \quad F_*(x, t, 0, 0) = F^*(x, t, 0, 0);$$

we recall that F^* and F_* denote the upper- and lower-semicontinuous envelopes of F , respectively.

The proof of Theorem 1.1 can be found in [CGG]. The arguments of [CGG] can be, however, slightly simplified by remarking that, since (1.5) is invariant under nondecreasing changes, it is enough to have a comparison result in $BUC(\mathbb{R}^N \times [0, \infty))$, the space of bounded, uniformly continuous functions. This leads to an easier treatment of the unboundedness of the domain. In fact, with these assumptions, Theorem 1.1 extends easily to the case where either the sub- or the supersolution to be compared is discontinuous. Since we will use this remark throughout the paper, we state it as a separate theorem. (For the definition of discontinuous sub- and supersolutions we refer to [Is].)

THEOREM 1.3. *Assume (F), (1.3), and (1.4). If $u \in UC(\mathbb{R}^N \times [0, \infty))$ is a subsolution of (1.5) and $v: \mathbb{R}^N \times [0, \infty)$ is a discontinuous supersolution, then $u(\cdot, 0) \leq v(\cdot, 0)$ on \mathbb{R}^N yields $u(\cdot, t) \leq v(\cdot, t)$ on \mathbb{R}^N for all $t > 0$. A similar result holds if u is a discontinuous subsolution and $v \in UC(\mathbb{R}^N \times [0, \infty))$ is a supersolution.*

The final remark of this section is that assumption (1.8) in Theorem 1.2 can be relaxed to handle the case of unbounded fronts: we only need to assume that for each $\alpha > 0$ there exists $\varepsilon > 0$ such that

$$|u(x, 0)|, |v(x, 0)| \geq \varepsilon > 0 \quad \text{if } d(x, \Gamma_0) \geq \alpha > 0.$$

2. The nonempty interior difficulty. The level set approach seems to avoid all the geometrical difficulties related to the onset of singularities, etc. The evolution $\Gamma_0 \rightarrow \Gamma_t$ is well defined and unique. Given this fact, the next natural questions are related to the regularity of Γ_t . When $N = 2$ this issue was completely resolved by Angenent [A1], [A2] (see also the references therein). For $N \geq 3$ the issue is more complicated. In addition to a local existence result by Hamilton [H] and Evans and Spruck [ESp2] for motion by mean curvature, there are only partial regularity results (only for motion by mean curvature) due to Evans and Spruck [ESp3], [ESp4] and Ilmanen [II1], [II2].

A more basic question is whether Γ_t has an empty interior for $t > 0$. In principle, we expect Γ_t to be a hypersurface in \mathbb{R}^N ; in view of this Γ_t having interior seems rather unreasonable. This is related to the nonuniqueness features for the motion of front described by the distance function, as we will explain in the next section. Before we continue discussing this difficulty, we give a more precise definition.

DEFINITION 2.1. Let Γ_t be the evolution of Γ_0 by the level set approach. We say that $\{\Gamma_t\}_{t \geq 0}$ is regular if

$$\begin{aligned} \text{cl} \{(x, t) : u(x, t) > 0\} &= \{(x, t) : u(x, t) \geq 0\} \quad \text{and} \\ \text{int} \{(x, t) : u(x, t) \geq 0\} &= \{(x, t) : u(x, t) > 0\}. \end{aligned}$$

Clearly if $\{\Gamma_t\}_{t \geq 0}$ is regular then $\bigcup_{t \geq 0} (\Gamma_t \times \{t\})$ has an empty interior in $\mathbb{R}^N \times [0, \infty)$. Moreover in most examples the later is equivalent to Γ_t having an empty interior for all $t \geq 0$. Indeed for motion with constant normal velocity, this follows from the finite speed of propagation. For motion by mean curvature, it can be shown using explicit solutions of the form $\psi(|x|^2 + (N-1)t)$ as barriers.

We continue with a new formulation of the no empty interior question in terms of whether (1.5) has unique discontinuous solutions, with initial datum $\mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c}$, where $\mathbb{1}_A$ denotes the characteristic function of the set A , and Ω_0 and Ω_0^c are the “inside of Γ_0 ” (i.e., the set where u_0 is negative) and “outside of Γ_0 ” (i.e., the set where u_0 is positive), respectively. (See the discussion after the statement of Theorem 1.2).

THEOREM 2.1. $\{\Gamma_t\}_{t \geq 0}$ is regular if and only if there exists a unique solution of (1.5) with initial datum $\mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c}$.

In the above statement by a uniqueness we mean that if v, w are two solutions of (1.5) with the same initial data, then $(v)^* = (w)^*$ and $(v)_* = (w)_*$.

Proof of Theorem 2.1. Let $u \in UC(\mathbb{R}^N \times [0, \infty))$ be the solution of (1.5) with initial datum $d(x, \Gamma_0)$, the signed distance to Γ_0 , which is normalized to be positive inside Γ_0 and negative outside. Recall that by Theorem 1.2, it suffices to use $d(x, \Gamma_0)$ as an initial datum to obtain Γ_t . For $\varepsilon > 0$, and a scalar α set

$$u^\varepsilon(x, t) = \tanh((u(x, t) + \alpha)/\varepsilon),$$

where $\tanh(\cdot)$ is the hyperbolic tangent function. u^ε is also a solution of (1.5) (by (1.3)). The stability results for discontinuous viscosity solutions (cf. Crandall, Ishii, and Lions [CIL]) yield that the limit $u_\infty^\alpha = \lim_{\varepsilon \rightarrow 0} u^\varepsilon$ is a viscosity solution of (1.5). Moreover, the properties of \tanh yield

$$u_\infty^\alpha(x, t) = \begin{cases} 1 & \text{if } u(x, t) > \alpha, \\ -1 & \text{if } u(x, t) < \alpha, \\ 0 & \text{if } (x, t) \in \text{Int}\{u = \alpha\}. \end{cases}$$

For the rest of the points, the value of $u_\infty(x, t)$ depends on the lsc or usc envelope we consider in the definition of the discontinuous viscosity solution. Now set

$$\bar{u}_\infty = \lim_{\alpha \uparrow 0} u_\infty^\alpha \quad \text{and} \quad \underline{u}_\infty = \lim_{\alpha \downarrow 0} u_\infty^\alpha.$$

The above limits are taken in the viscosity sense (cf. [CIL]). The functions \bar{u}_∞ and \underline{u}_∞ are again solutions of (1.5). Moreover,

$$\bar{u}_\infty(x, t) = \begin{cases} 1 & \text{if } u(x, t) \geq 0 \\ -1 & \text{if } u(x, t) < 0 \end{cases} \quad \text{and} \quad \underline{u}_\infty(x, t) = \begin{cases} 1 & \text{if } u(x, t) > 0 \\ -1 & \text{if } u(x, t) \leq 0. \end{cases}$$

If $\{\Gamma_t\}_{t \geq 0}$ is not regular, \bar{u}_∞ and \underline{u}_∞ are two different discontinuous solutions of (1.5) with initial datum $\mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c}$.

Conversely, if $\{\Gamma_t\}_{t \geq 0}$ is regular, let w be a solution of (1.5) with $w(\cdot, 0) = \mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c}$ and choose a sequence $(\phi_n)_n$ of smooth functions such that $\phi_n \equiv 1$ on $[0, +\infty)$, $\phi'_n \geq 0$ in \mathbb{R} , $\phi_n(\mathbb{R}) \subset [-1, 1]$ and $\inf_n \phi_n = -1$ on $(-\infty, 0)$. Since $w^*(x, 0) \leq \phi_n(d(x, \Gamma_0))$ in \mathbb{R}^N , (1.3) and Theorem 1.3 yield $w^* \leq \phi_n(u)$ in $\mathbb{R}^N \times (0, +\infty)$ and

$$w^*(x, t) \leq -1 = \inf_n \phi_n(u(x, t)) \text{ on } \{u < 0\}.$$

On the other hand, (F_3) gives

$$F^*(x, t, 0, 0) = F_*(x, t, 0, 0) = 0;$$

hence, $+1$ and -1 are, respectively, sub- and supersolutions of (1.5). Therefore,

$$-1 \leq w_* \leq w^* \leq 1$$

and, finally, $w^* = -1$ on $\{u < 0\}$. The same method shows that $w_* = 1$ on $\{u > 0\}$, which, in view of the assumption that $\{u = 0\}$ is regular, identifies w uniquely. \square

By examining the solutions \bar{u}_∞ and \underline{u}_∞ , both equal to u_∞ in the “empty interior” case, we see that we switched from the pde formulation of the motion to a “quasi-geometric” formulation, since the notions of sub- and supersolution are only relevant on the sets $\bar{\Gamma}_t = \partial\{\bar{u}_\infty(\cdot, t) = 1\}$ and $\underline{\Gamma}_t = \partial\{\underline{u}_\infty(\cdot, t) = 1\}$. This is related to the distance function formulation for the motion, which we explain in the next section.

3. The properties of the distance function to the moving front. In this section we study the properties of the (signed) distance $d(x, \Gamma_t)$ to a front Γ_t , whose evolution has been defined by the level set approach described in § 1. The results we present here extend the work of Soner [So], who actually used the properties of the distance function to define the evolution of fronts in the case where the velocity of the front is independent of the position. Although we could do the same here, we chose not to do so, since, once the correct definition is given, all the arguments will follow exactly as in [So]. Another motivation to study the properties of the distance function, in addition to the fact that this quantity intrinsically defines the front, is that the distance function plays a central role in studying the fronts generated by reaction-diffusion equations ("phase field theory"), as we will explain in §§ 6–10.

As usual we begin with a closed set Γ_0 in \mathbb{R}^N and assign to it a notion of inside and outside in terms of the sign of its distance function. Let $\Gamma_0 \rightarrow \Gamma_t$ be the evolution of Γ_0 defined by the level set formulation. To state the main result we define the extinction time $t^* \in (0, +\infty]$ for Γ_t by

$$t^* = \sup \{t > 0 \text{ such that } \Gamma_t \neq \emptyset\}.$$

Finally, we denote by d the signed distance function to the front Γ_t .

THEOREM 3.1. *Assume that $\{\Gamma_t\}_{t \geq 0}$ is regular. Then $\underline{d} = d \wedge 0$ and $\bar{d} = d \vee 0$ satisfy, respectively,*

$$(3.1) \quad \underline{d}_t + F(x - \underline{d} D \underline{d}, t, D \underline{d}, D^2 \underline{d}) \leq 0 \quad \text{in } \mathbb{R}^N \times (0, t^*)$$

and

$$(3.2) \quad \bar{d}_t + F(x - \bar{d} D \bar{d}, t, D \bar{d}, D^2 \bar{d}) \geq 0 \quad \text{in } \mathbb{R}^N \times (0, t^*).$$

Moreover,

$$(3.3) \quad -(D^2 \underline{d} D \underline{d} | D \underline{d}) \leq 0 \quad \text{in } \{\underline{d} < 0\}$$

and

$$(3.4) \quad -(D^2 \bar{d} D \bar{d} | D \bar{d}) \geq 0 \quad \text{in } \{\bar{d} > 0\}.$$

Remark 3.2. The assumption that Γ_t has empty interior was made only to simplify the presentation. In fact, when Γ_t is not regular we can show that (3.1)–(3.4) still hold when d is replaced with appropriate functions. Indeed let $\bar{\Gamma}_t = \partial\{x: \bar{u}_\infty(x, t) = 1\}$ and $\underline{\Gamma}_t = \partial\{x: u_\infty(x, t) = 1\}$, where u_∞ and \bar{u}_∞ are defined as in the proof of Theorem 2.1. Then (3.1), (3.3) and (3.2), (3.4) hold true for $d(x, \bar{\Gamma}_t)$ and $d(x, \underline{\Gamma}_t)$. This again is related to the connections between the nonempty difficulty and the nonuniqueness in the weak geometric and distance function formulations of motions. For a detailed discussion of these connections we refer to [So].

Remark 3.3. We can read the speed of the moving front from (3.1) and (3.2). Indeed, if we know a priori that the front moves along its normal direction and if d is assumed to be smooth, then

$$d_t + F(x, t, Dd, D^2 d) = 0 \quad \text{if } d = 0,$$

which, in view of (1.1), yields $V = v(x, t, n, Dn) = -F(x, t, n, Dn)$.

Remark 3.4. We cannot expect that d will solve a pde like (1.5) as it can be observed by a direct calculation if everything is smooth. The term $x - dDd$ in (3.1) and (3.2) has a geometric meaning. Indeed, if $x \notin \Gamma_t$, then $x - dDd \in \Gamma_t$.

Proof of Theorem 3.1. We only prove (3.1) and (3.3); (3.2) and (3.4) can be obtained by similar arguments. To this end, observe that for each $k > 0$ the functions

$$w_k(x, t) = \begin{cases} 0 & \text{if } u_\infty(x, t) = 1, \\ -k & \text{if } u_\infty(x, t) = -1, \end{cases}$$

are solutions of (1.5), where $u_\infty = u_\infty^0$ is defined in the proof of Theorem 2.1. We next introduce the function

$$\bar{w}_k(x, t) = \sup_{y \in \mathbb{R}^N} \{w_k(y, t) - |x - y|\}.$$

An easy calculation yields

$$\bar{w}_k(x, t) = \max(d(x, t), -k).$$

On the other hand, standard arguments from the theory of viscosity solutions (cf. Lasry and Lions [LL], Jensen, Lions, and Souganidis [JLS]) yield that \bar{w}_k is a subsolution of (1.5). The inequalities (3.1) and (3.3) then follow easily when $d \neq 0$. If $d = 0$, we must observe that $\bar{w}_k \geq w_k$ in $\mathbb{R}^N \times (0, \infty)$ and if $\bar{w}_k(x, t) = w_k(x, t)$ at some point (x, t) , then $D^{2,+} \bar{w}_k(x, t) \subset D^{2,+} w_k(x, t)$; the last inclusion being exactly what is needed at $d = 0$. Letting $k \rightarrow \infty$ completes the proof. \square

4. When is the empty interior condition fulfilled? We hope that it has become clear by now that settling the empty interior condition is of great importance, since it may lead to some rather unintuitive situations. Unfortunately, if no conditions are imposed on Γ_0 , interior may be created for $t > 0$. See, for example, Evans and Spruck [ESp1], Soner [So], and Ilmanen [Il1] for some simple examples in this direction for motion by mean curvature. However, it can be argued that the interior in the examples of [ESp1] and [So] is due mainly to the fact that the initial data are not smooth, which, in turn, yields that the normal direction is somehow not well defined. This, of course, raises the question of finding some necessary and sufficient conditions of Γ_0 so that no interior is created. We will address this question below for the case of first-order and second-order motions whose geometric pde's are of the form

$$(4.1) \quad u_t + \alpha(x, t)|Du| = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

and

$$(4.2) \quad u_t + F(Du, D^2u) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

with initial datum

$$(4.3) \quad u(x, 0) = d(x, \Gamma_0) \quad \text{in } \mathbb{R}^N.$$

Throughout this section we will assume that

$$(4.4) \quad \Gamma_0 = \partial\{x \in \mathbb{R}^N : d(x, \Gamma_0) < 0\} = \partial\{x \in \mathbb{R}^N : d(x, \Gamma_0) > 0\},$$

which, in particular, implies that Γ_0 has no interior.

THEOREM 4.1. *Assume (4.3), (4.4), $\alpha \in W^{1,\infty}(\mathbb{R}^N \times (0, T))$ ($\forall T > 0$), and that either (i) α does not change sign in $\mathbb{R}^N \times (0, +\infty)$ or (ii) α is independent of t . Then $\Gamma_t = \{x : u(x, t) = 0\}$ is regular, where $u \in UC(\mathbb{R}^N \times (0, \infty))$ is the solution of (4.1), (4.3). In particular Γ_t has empty interior.*

Theorem 4.1 is almost sharp. Indeed at the end of this section we will give an example of $\alpha(x, t)$ which changes sign and Γ_t develops interior. We do not, however, know whether interior is created if $\alpha \equiv \alpha(x, p/|p|)$ changes sign. (The case where $\alpha(x, p/|p|) > 0$ was treated in [Sor].)

Proof of Theorem 4.1. We present here the proof only in the case of (ii) since (i) is obtained by similar and even simpler arguments. In view of Theorem 2.1 and the discussion after Definition 2.1, it suffices to prove the uniqueness of discontinuous solutions of (4.1) with the initial datum

$$u(\cdot, 0) = \mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c} \quad \text{in } \mathbb{R}^N,$$

where $\Omega_0(x: d(x, \Gamma_0) > 0)$. To this end, we first claim that we can examine the situation separately in the sets

$$O_1 = \{x \in \mathbb{R}^N \mid \alpha(x) > 0\} \quad \text{and} \quad O_2 = \{x \in \mathbb{R}^N \mid \alpha(x) < 0\}.$$

A formal argument to understand why this claim is true consists in looking at the optimal control interpretation of (4.1) and in remarking that the paths of the dynamics starting from a point in O_1 (or O_2) can never reach the boundary of O_1 (or O_2). To justify this argument completely, we adapt some arguments introduced by Barron and Jensen [BJ1] (See also Barles [Ba2]).

Let u be a solution of (4.1) and consider the function $u^\varepsilon: O_1 \times [0, +\infty) \rightarrow \mathbb{R}$ given by

$$u^\varepsilon(x, t) = \inf_{y \in O_1} \left\{ u(y, t) + e^{-\gamma t} \frac{|x - y|^2}{\varepsilon \alpha(y)} \right\}.$$

Combining classical (in the context of viscosity solutions) computations with the arguments of [BJ1], we easily show that u^ε is an approximate subsolution of (4.1) in $O_1 \times (0, +\infty)$ for $\gamma > 0$ large enough. Moreover, u^ε is continuous and satisfies

$$u^\varepsilon(\cdot, 0) \leq \mathbb{1}_{\Omega_0} - \mathbb{1}_{\Omega_0^c} \quad \text{on } O_1.$$

If v is another solution of (4.1) and (4.3), we claim that, as $\varepsilon \rightarrow 0$,

$$u^\varepsilon \leq v_* + o(1) \quad \text{in } O_1 \times [0, +\infty).$$

Indeed, we perform the usual uniqueness arguments for viscosity solutions with a test function $\psi: (O_1 \times (0, +\infty)) \times (O_1 \times (0, +\infty)) \rightarrow \mathbb{R}$ given by

$$\psi(x, t, y, s) = u^\varepsilon(x, t) - v_*(y, s) - \frac{|x - y|^2}{\beta} - \theta \left(|x|^2 + |y|^2 + \frac{1}{\alpha(x)} + \frac{1}{\alpha(y)} \right),$$

where β and θ are small parameters. The only slight new point comes from the term

$$\left(\frac{1}{\alpha(x)} + \frac{1}{\alpha(y)} \right),$$

which takes care of the lack of boundary condition on $\partial O_1 \times (0, +\infty)$. We leave the rest of the routine but tedious details to the reader. \square

Remark 4.2. An alternative way to understand the comparison result in the proof of Theorem 4.1 is to say that (4.1) holds up to the boundary of $O_1 \times (0, +\infty)$. Indeed, let u be a usc subsolution of (4.1) and assume that $(x, t) \in \partial O_1 \times (0, +\infty)$ is a strict local maximum of $u - \phi$ for some smooth ϕ . The function

$$(y, s) \mapsto u(y, s) - \phi(y, s) - \frac{\theta}{\alpha(y)}$$

attains a maximum at $(y_\theta, s_\theta) \rightarrow (x, t)$ as $\theta \rightarrow 0$. Evaluating (4.1) at (y_θ, s_θ) and letting $\theta \rightarrow 0$ yields the result.

We next turn our attention to the case of the motion governed by (4.2); the typical example here being motion by mean curvature. We will be making the following additional assumption on F :

$$(4.5) \quad F(\mu Q'p, \mu^2 Q'XQ) = \mu^2 F(p, X)$$

for all $\mu > 0$, $p \in \mathbb{R}^n$, $X \in S^N$ and $Q \in \mathcal{O}(N)$, where Q' is the adjoint of Q and $\mathcal{O}(N)$ is the group of $N \times N$ orthogonal matrices ($Q' = Q^{-1}$).

THEOREM 4.3. *Assume that (1.3), (1.4), and (4.5) hold and that Γ_0 is of class C^2 . In addition, assume that there exist nonnegative constants c_i ($i = 1, 2, 3$), a skewsymmetric matrix H , and $x_0 \in \mathbb{R}^N$ such that*

$$(4.6) \quad c_1(x - x_0) \cdot Dd(x) + c_2 H(x - x_0) \cdot Dd(x) - c_3 F(Dd(x), D^2 s(x)) \neq 0 \text{ on } \Gamma_0,$$

where d is the signed distance to Γ_0 . Then the set $\bigcup_{t>0} (\Gamma_t \times \{t\})$ has empty interior in $\mathbb{R}^N \times (0, +\infty)$.

The left-hand side of (4.6) is the generator of rotation, dilations, and translations in (x, t) evaluated at $t = 0$ on Γ_0 . Condition (4.6) includes as special cases results of Ilmanen [Il1] and Soner [So] for motion by mean curvature. On the other hand, (4.6) is not necessary. Indeed, recent work of Soner and Souganidis [SS] (see also Altschuler, Angenent, and Giga [AAG]) for bodies of rotation moving by mean curvature shows that there exist smooth Γ_0 's which do not satisfy (4.6), but their evolution never develops interior. It follows, however, that (4.6) holds near the singularities of Γ_t [SS]. This is related to a conjecture of DeGiorgi [D]. A related observation is that if (4.6) holds at a later time, this again yields no interior. For the case of mean curvature, Evans and Spruck [ESp4] also showed that under some assumptions on Γ_0 , almost every level set of the solution of (1.12) does not develop interior. Finally, at the end of this section we give an example where interior is created if the velocity depends on t .

Proof of Theorem 4.3. Let $u \in UC(\mathbb{R}^N \times (0, \infty))$ be the unique solution of (4.2) and (4.3) and, for $h > 0$, define the function

$$u_h(x, t) = \Phi(u((1 + c_1 h) e^{c_2 h H}(x - x_0) + x_0, (1 + c_1 h)t + c_3 h)),$$

where Φ is some increasing smooth function with $\Phi(0) = 0$ to be chosen later. In view of (1.3) and (4.5), u_h is also a solution of (4.2), since H being skewsymmetric yields $Q = e^{c_2 h H} \in \mathcal{O}(N)$. Moreover, if h is small enough, there exists some $\eta > 0$ such that

$$(4.7) \quad |u(\cdot, 0) - u_h(\cdot, 0)| \geq \eta h \quad \text{on } \mathbb{R}^N.$$

Assuming for the moment (4.7), we observe that Theorem 1.1 yields either $u_h \leq u - \eta h$ or $u_h \leq u + \eta h$ in $\mathbb{R}^N \times (0, \infty)$. If $\bigcup_{t>0} (\Gamma_t \times \{t\})$ has interior, either of the above inequalities, however, yields a contradiction, for if $u = 0$ in some neighborhood of a point (x_0, t_0) , then so does u_h for h sufficiently small.

We return now to the proof of (4.7). We first observe that we may choose Φ so that we only need to check (4.7) in a small neighborhood of Γ_0 . But for a suitable choice of such a neighborhood u is smooth. We can therefore perform the expansion

$$\begin{aligned} u((1 + c_1 h) e^{c_2 h H}(x - x_0) + x_0, c_3 h) &= u(x, 0) + h(c_1(x - x_0) \cdot Du(x, 0) \\ &\quad + c_2 H(x - x_0) \cdot Du(x, 0) + c_3 u_t(x, 0)) + o(h). \end{aligned}$$

Using (4.6), that $u(x, 0) = d(x)$, and the fact that the equation holds for small $t > 0$ (since Γ_0 is smooth) we conclude the proof. \square

In fact, with a modification of the above proof, we can prove that Γ_t is regular. We leave this modification to the reader.

We continue with an example of interior for a motion governed by (4.1).

PROPOSITION 4.4. *Consider (4.1) in $\mathbb{R} \times (0, \infty)$ with $\alpha(x, t) = x - t$. There exists an interval $I = (\beta, \gamma)$ such that the evolution $\Gamma_0 \rightarrow \Gamma_t$ has nonempty interior at some $t_0 > 0$, where $\Gamma_0 = \partial I$.*

Proof. In view of Theorem 2.1, it suffices to show that there exists I such that the equation

$$(4.8) \quad \begin{cases} u_t + (x - t)|u_x| = 0 & \text{in } \mathbb{R} \times (0, \infty), \\ u(x, 0) = (\mathbb{1}_I - \mathbb{1}_{I^c})(x) & \text{on } \mathbb{R}, \end{cases}$$

has more than one solution. To this end, choose $x_0 > 0$, solve the forward and backward ordinary differential equations (ode's)

$$\dot{X}_{\pm}(t) = \pm \alpha(X_{\pm}(t), t) \quad \text{with } X_{\pm}(x_0) = x_0,$$

and set $\beta = X_+(0)$, $\eta = X_-(0)$, and $I = (\beta, \eta)$. We will compute the minimal and maximal solution of (4.8), using the control interpretation of this equation. Indeed, consider the dynamics given by

$$\dot{y}_x(s) = \alpha(y_x(s), s)v(s), \quad y_x(t) = x,$$

where $v(\cdot) \in L^\infty((0, +\infty), [-1, 1])$ is the control process. Following Barles and Perthame [BaP] or Barron and Jensen [BJ2], we can prove easily that the minimal and maximal solution of $u_t + (x - t)|u_x| = 0$ in $\Omega_1 = \{x > t\}$ are, respectively,

$$u_*(x, t) = \inf_{v(\cdot)} u_*(y_x(0), 0) \quad \text{and} \quad u^*(x, t) = \inf_{v(\cdot)} u^*(y_x(0), 0),$$

where $u(x, 0) = (\mathbb{1}_I - \mathbb{1}_{I^c})(x)$. It is easy to see from the above formulae that $u_* \equiv -1$ on $\{(x, t): x = t\}$, $u^* = -1$ on $\{(x, t): x = t\} \setminus \{(x_0, x_0)\}$ and $u^*(x_0, x_0) = 1$. We now turn our attention to $\Omega_2 = \{(x, t): x < t\}$. Here the maximal and minimal solutions are, given by, respectively,

$$\bar{u}(x, t) = \sup_{v(\cdot)} \{-\mathbb{1}_{\{\tau=t\}} + u^*(y_x(\tau), \tau)\mathbb{1}_{\{\tau>t\}}\}$$

and

$$\underline{u}(x, t) = \sup_{v(\cdot)} \{-\mathbb{1}_{\{\tau=t\}} + u_*(y_x(\tau), \tau)\mathbb{1}_{\{\tau>t\}}\},$$

where, for each $v(\cdot)$, τ is the exit time from Ω_2 . It follows that, while $\underline{u} \equiv -1$ in Ω_2 , \bar{u} equals 1 at each point $(x, t) \in \Omega$ for which the trajectory y_x may reach the point (x_0, x_0) . It is easy to check that the set of these points is exactly the region $\{(x, t) \in \Omega_2: X_+(t) \leq x \leq X_-(t)\}$ which has a nonempty interior.

Since (4.8) has a nonuniqueness feature, we conclude by Theorem 2.1. \square

The next example of nonuniqueness corresponds to volume preserving mean curvature flow. The derivation of this motion and its significance for applications is discussed in § 11.

Let Γ_0 be the union of three disjoint circles in \mathbb{R}^2 , i.e., $\Gamma_0 = \partial B(x_1, R_0) \cup \partial B(x_2, R_0) \cup \partial B(x_3, r_0)$, with $x_i \in \mathbb{R}^2 (i = 1, 2, 3)$ to be chosen later and $0 < r_0 < R_0$. We consider the motion of Γ_0 with normal velocity

$$V = -\operatorname{div}(Dn) + \alpha(t) \quad (t > 0),$$

where $\alpha(t) = 2\pi N(t)L^{-1}(t)$, $N(t)$ and $L(t)$ being the number of disjoint parts of Γ_t and its length, respectively. In view of this explicit formula, at least for small time,

$$\Gamma_t = \partial B(x_1, R_t) \cup \partial B(x_2, R_t) \cup \partial B(x_3, r_t),$$

where R_t, r_t satisfy the ode's

$$\dot{R}_t = -R_t^{-1} + \alpha(t) \quad \text{and} \quad \dot{r}_t = -r_t^{-1} + \alpha(t) \quad \text{with} \quad \alpha(t) = 3(2R_t + r_t)^{-1}.$$

Let $t_1 = \sup \{t > 0 \text{ such that } r_t > 0\}$. The form of Γ_t above is valid for all $t \in (0, t_1)$. Since t_1 is independent of the choice of the x_i 's we can choose x_1 and x_2 so that $|x_1 - x_2| = 2R_{t_1}$. In view of this choice,

$$\Gamma_{t_1} = \partial B(x_1, R_{t_1}) \cup \partial B(x_2, R_{t_1}),$$

with the two circles touching at a point. There are two possible evolutions for $t \geq t_1$ depending on whether we think of Γ_t as one set or two separate ones. In the first case Γ_t moves with $\alpha(t) = 2\pi (\text{length}(\Gamma_t))^{-1}$ and actually converges to $\partial B((x_1 + x_2)/2, R_\infty)$, as $t \rightarrow \infty$, where $R_\infty = (2R_0^2 + r_0^2)^{1/2}$. In the second case, Γ_t remains stationary (i.e., $\alpha(t) \equiv R_{t_1}^{-1}$ for $t > t_1$).

We conclude the discussion about the “nonempty interior” difficulty with a general comment for the t -dependent velocities. It appears that we cannot hope to have a general theorem guaranteeing no interior without making very severe restrictions on the t -dependence of the normal velocity. The reason for this claim is the following. In principle, all motions have some “pathological” situations, where interior develops. We can take any such motion, perturb its velocity by a time dependent forcing term so that to drive the front to the pathological situation, and then simply turn off the time.

5. Uniqueness results for the distance function formulation. As mentioned in § 3, we can have a weak formulation of the propagation of a front in terms of whether the signed distance to the front satisfies the inequalities (3.1) and (3.2). A natural question to ask is whether (3.1) and (3.2) are enough to identify the distance function uniquely, i.e., if z satisfies (3.1) and (3.2) and $z(x, 0) = d(x, \Gamma_0)$, is it true that $z \equiv d$? In addition to being a natural mathematical question to ask, having such information simplifies a lot some of the analysis of the “phase field” theory.

In the following, and only to considerably simplify the presentation, we will only consider the equation

$$(5.1) \quad u_t - \theta \left(\Delta u - \frac{(D^2 u Du | Du)}{|Du|^2} \right) + \alpha(x, t)|Du| = 0 \text{ in } \mathbb{R}^N \times (0, \infty)$$

with the initial datum

$$(5.2) \quad u(x, 0) = d(x, \Gamma_0) \quad \text{in } \mathbb{R}^N,$$

with $\theta \geq 0$ and $\alpha \in W^{1,\infty}(\mathbb{R}^N \times (0, \infty))$. (Some of the arguments and the conclusions below hold if $\theta = \theta(x, t)$ (under some assumptions) as well as for anisotropic motions. We will discuss these situations elsewhere.)

As before, we denote by $\Gamma_t = \{x: u(x, t) = 0\}$. Theorem 3.1 and the discussion following it say that the functions $d_1 = d(x, \bar{\Gamma}_t)$ and $d_2 = d(x, \underline{\Gamma}_t)$ (where $\bar{\Gamma}_t = \partial\{x: u(x, t) > 0\}$ and $\underline{\Gamma}_t = \partial\{x: u(x, t) \geq 0\}$) satisfy the inequalities

$$(5.3) \quad z_t - \theta \Delta z + \alpha(x - zDz, t) \leq 0, \quad 1 - |Dz| = 0 \text{ in } \{z < 0\}$$

and

$$(5.4) \quad z_t - \theta \Delta z + \alpha(x - zDz, t) \geq 0, \quad |Dz| - 1 = 0 \text{ in } \{z > 0\}.$$

Of course, if the no-interior condition holds for every $t > 0$, (5.3) and (5.4) are satisfied by $d = d(x, \Gamma_t)$. The inequalities in (5.3) and (5.4) are a combination of (3.1) and (3.3) and (3.2) and (3.4), respectively, as they apply to (5.1). On the other hand, the equalities in (5.3) and (5.4) follow from the differentiability properties of the distance function and the definition of viscosity solutions.

Next we look into the converse of Theorem 3.1, i.e., we are interested in whether (5.3) and (5.4) identify z as the distance function.

THEOREM 5.1. *If the usc (respectively lsc) function z satisfies (5.2) and (5.3) (respectively (5.2) and (5.4)), then*

$$(5.5) \quad z \leq d_2 \quad \text{in } \{z < 0\} \supset \{d_2 < 0\},$$

$$(5.6) \quad z \geq d_1 \quad \text{in } \{z > 0\} \supset \{d_1 > 0\},$$

respectively. If z satisfies (5.2)–(5.4) and $\{\Gamma_t\}_{t \geq 0}$ is regular, then

$$(5.7) \quad z(x, t) = d(x, \Gamma_t) \quad \text{in } \mathbb{R}^N \times [0, \infty).$$

Proof. The proof is based on the following two lemmas.

LEMMA 5.2. *If z is usc (respectively lsc) and satisfies (5.3) (respectively, (5.4)), then z is a subsolution (respectively supersolution) of*

$$(5.8) \quad z_t - \theta \left(\Delta z - \frac{(D^2 z D z | D z)}{|D z|^2} \right) + \alpha(x - z D z, t) |D z| = 0$$

in $\{z < 0\}$ (respectively, $\{z > 0\}$).

LEMMA 5.3. *If a usc (respectively lsc) function z satisfies (5.3) (respectively (5.4)), then for C large enough, $\underline{z} = e^{Ct}(z \wedge 0)$ (respectively $\bar{z} = e^{Ct}(z \vee 0)$) is a subsolution (respectively supersolution) of (5.1).*

We first conclude the proof of the theorem and then prove the lemmas. We proceed by proving (5.5), since (5.6) follows in a similar way. To this end, observe that, since \underline{z} (defined in Lemma 5.3) is a subsolution of (5.1), Theorem 1.2 yields $\underline{z} \leq u \wedge 0$ in $\mathbb{R}^N \times (0, \infty)$; recall that $u \wedge 0$ is still a solution of (5.1), since $\Phi(u) = u \wedge 0$ is an increasing change of u . So, if $u < 0$ (or, equivalently, if $d_2 < 0$), $z < 0$ and the proof of (5.5) is complete.

Finally, if $\{\Gamma_t\}_{t \geq 0}$ is regular, then $d_1 = d_2 = d$ and (5.5) and (5.6) yield

$$\{z < 0\} = \{d < 0\}, \quad \{z > 0\} = \{d > 0\} \quad \text{and} \quad \{z = 0\} = \{d = 0\};$$

therefore, $z = d$ by the uniqueness results for the equations $|Dz| - 1 = 0$ and $1 - |Dz| = 0$, respectively, in $\{z > 0\} = \{d > 0\}$ and $\{z < 0\} = \{d < 0\}$. \square

We now return to the proofs of the lemmas.

Proof of Lemma 5.2. We only treat the case of a usc z that satisfies (5.6); the other case is proved similarly. Since z is usc, the set $\Omega = \{z < 0\}$ is open. Moreover, z being a solution of $1 - |Dz| = 0$ in $\Omega_t = \{x: z(x, t) < 0\}$ for all $t > 0$, yields

$$z(x, t) = \sup \{z^*(y, t) - |x - y|: y \in \Omega_t\}, \quad \forall x \in \Omega_t,$$

where $z^*(y, t) = \limsup_{\Omega_t \ni y' \rightarrow y} z(y', t)$. This formula implies that z is locally semiconvex with respect to x , i.e. $\partial^2 z / \partial \chi^2 \geq -C$ in Ω , for all unit vectors $\chi \in \mathbb{R}^N$. Next we define the ε -supconvolution z^ε of z in Ω with respect to t by

$$z^\varepsilon(x, t) = \sup_{(x, s) \in \Omega} \left\{ z(x, s) - \frac{(t - s)^2}{\varepsilon} \right\}.$$

It follows easily that, for (x, t) belonging to compact subset V of Ω and $\varepsilon > 0$ small enough, the supremum is actually achieved in Ω (and not on $\partial\Omega$) and that z_ε satisfies

$$(5.9) \quad 1 - |Dz^\varepsilon| = 0 \quad \text{and} \quad z_t^\varepsilon - \theta \Delta z^\varepsilon + \alpha(x - z^\varepsilon Dz^\varepsilon, t) \leq C\varepsilon \quad \text{in } V,$$

where C depends only on the Lipschitz bound of α . Let $(x_0, t_0) \in \Omega$ be a strict local maximum of $z - \phi$ in Ω for smooth ϕ and take $V \Subset \Omega$ in (5.9) to be a neighborhood of (x_0, t_0) . Since $z^\varepsilon \rightarrow z$, there exists $(x_\varepsilon, t_\varepsilon) \in V$ maximum points of $z^\varepsilon - \phi$, such that $(x_\varepsilon, t_\varepsilon) \rightarrow (x_0, t_0)$ as $\varepsilon \rightarrow 0$. Now we use Alexandrov's Maximum Principle-type arguments, brought in the theory of viscosity solutions by Jensen [J]. More precisely, Lemma A.3 of [CIL] implies the existence of $X_\varepsilon \in S^N$ such that

$$(5.10) \quad (\phi_t(x_\varepsilon, t_\varepsilon), D\phi(x_\varepsilon, t_\varepsilon), X_\varepsilon) \in J^{2,+} z^\varepsilon(x_\varepsilon, t_\varepsilon) \quad \text{and} \quad -K \leq X_\varepsilon \leq D_{xx}^2 \phi(x_\varepsilon, t_\varepsilon),$$

for some constant K , which is related to semiconvexity constant of z and, therefore, of z^ε in V ; the upper bound on X_ε comes from the Maximum Principle. (We refer to [CIL] for the definition of $J^{2,+}$.) Also we claim that $X_\varepsilon D\phi(x_\varepsilon, t_\varepsilon) = 0$. Indeed, since $|Dz^\varepsilon| = 1$ almost everywhere, $D_{xx}^2 z^\varepsilon Dz^\varepsilon = 0$ at any point where z^ε is twice differentiable. On the other hand (cf. [CIL, Lemma A.3]), $X_\varepsilon D\phi(x_\varepsilon, t_\varepsilon)$ is obtained as a limit of $D_{xx}^2 z^\varepsilon Dz^\varepsilon$ evaluated at nearby points. Finally, recall that $D\phi(x_\varepsilon, t_\varepsilon) = Dz^\varepsilon(x_\varepsilon, t_\varepsilon)$, since z^ε is differentiable at maximum points of $z^\varepsilon - \phi$ (again due to the semiconvexity).

Inserting all the information in (5.9) we obtain

$$\begin{aligned} & \phi_t - \theta \left(\Delta \phi - \frac{(D^2 \phi D\phi | D\phi)}{|D\phi|^2} \right) + \alpha(x_\varepsilon - z^\varepsilon D\phi, t_\varepsilon) \\ & \leq \phi_t - \theta \left(\text{Tr}(X_\varepsilon) - \frac{(X_\varepsilon D\phi | D\phi)}{|D\phi|^2} \right) + \alpha(x_\varepsilon - z^\varepsilon D\phi, t_\varepsilon) \leq C\varepsilon, \end{aligned}$$

where in the two inequalities above, z^ε and ϕ and its derivatives are evaluated at $(x_\varepsilon, t_\varepsilon)$. Letting $\varepsilon \rightarrow 0$ we conclude, the proof. \square

Proof of Lemma 5.3. We again only present the proof in the case that z is a usc subsolution.

If c is larger than the Lipschitz constant of α , Lemma 5.2 implies that $e^{ct}z$ is a subsolution of (5.1), since $|Dz| = 1$ yields

$$\alpha(x - zDz, t) \geq \alpha(x, t) - cz = \alpha(x, t)|Dz| - cz.$$

To conclude let $(\psi_n)_n$ be a sequence of smooth functions such that $\psi_n(t) = 0$ if $t \geq -1/n$, $\psi_n' \geq 0$ and $\psi_n' \rightarrow 1$ uniformly on compact subsets of $(-\infty, 0]$. Using the preceding lemma, it is easy to check that $\psi_n(e^{ct}z)$ is a subsolution of (5.1). Letting $n \rightarrow \infty$ we conclude, since $\psi_n(e^{ct}z) \rightarrow e^{ct}(z \wedge 0)$. \square

6. Asymptotic limits of Reaction-Diffusion equations-Phase field theory. Reaction-diffusion equations of the form

$$(6.1) \quad \phi_t - \Delta \phi + f(x, t, \phi) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

arise naturally in many areas of applications, such as phase transitions, flame propagations, pattern formations, chemical kinetics, etc. In most of these applications, fronts develop for large times as the boundaries of the regions where the solution ϕ of (6.1) converges to the different equilibria of the vector field f (cf. Fife [Fi]). For a discussion of some cases where the solutions of (6.1) converge to the different equilibria of f we refer to Aronson, and Weinberger [ArW], Fife and McCleod [FiM], etc. The main issue is to identify the rate at which ϕ converges to the different equilibria. For this,

we must have a better understanding of the fronts and, in particular, the way they propagate. In the case $f(x, t, \phi) = f(\phi)$, formal results of Fife [Fi] and Caginalp [Ca1]–[Ca3] imply that the fronts propagate with normal velocity

$$(6.2) \quad V = \alpha + \frac{1}{t}\kappa + O\left(\frac{1}{t^2}\right) \quad (t \gg 1),$$

when κ denotes the curvature.

Our goal here is to justify (6.2) rigorously in the generality of (6.1). One way to do this is to scale ϕ so as to capture the different terms in the asymptotic expansion (6.2). To obtain the first term, the appropriate scaling is $(x/\varepsilon, t/\varepsilon)$. If $\alpha = 0$, we then go to the next scaling $(x/\varepsilon, t/\varepsilon^2)$. These considerations give rise to singular perturbation problems of the form

$$(6.3) \quad \phi_t^\varepsilon - \varepsilon \Delta \phi^\varepsilon + \frac{1}{\varepsilon} f^\varepsilon(x, t, \phi^\varepsilon) = 0 \quad \text{in } \mathbb{R}^N = (0, +\infty)$$

and

$$(6.4) \quad \phi_t^\varepsilon - \Delta \phi^\varepsilon + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \phi^\varepsilon) \times 0 \quad \text{in } \mathbb{R}^N \times (0, +\infty),$$

with initial data

$$(6.5) \quad \phi^\varepsilon(\cdot, 0) = \phi_0^\varepsilon(\cdot) \quad \text{on } \mathbb{R}^N.$$

Here ϕ_0^ε is a given function that initializes the front and f^ε is some approximation of f . Singular perturbation problems of the form (6.3) and (6.4) are of independent interest for they also arise in models with slow diffusion and fast reaction, in phase transitions, etc.

In the following we study the behavior, as $\varepsilon \rightarrow 0$, of (6.3) and (6.4) under the assumption that $\phi \mapsto f^\varepsilon(x, t, \phi)$ is a “cubic-type” nonlinearity, i.e., it has two stable and one unstable equilibria. Typical examples of f^ε are

$$(6.6) \quad f^\varepsilon(x, t, q) = 2(q - \varepsilon\mu(x, t))(q^2 - 1),$$

$$(6.7) \quad f^\varepsilon(x, t, q) = 2(q - \mu(x, t))(q^2 - 1),$$

and

$$(6.8) \quad f^\varepsilon(x, t, q) = 2(q - \mu)(q^2 - 1) + \varepsilon\theta^\varepsilon(x, t),$$

where $\theta^\varepsilon, \mu \in W^{1,\infty}(\mathbb{R}^n \times [0, +\infty))$ are given and μ takes values in $(-1, 1)$.

To simplify the presentation, we restrict ourselves to problems where the second-order operator is the Laplacian, although all the arguments can be modified to apply to more general elliptic operators (under, of course, suitable hypotheses). This will be addressed in the future. Finally, we remark that the case where f^ε is of “quadratic” type (i.e., f^ε has one stable and one unstable equilibria) has been studied by probabilistic methods by Freidlin [Fr] and, in greater generality, by pde-type techniques by Evans and Souganidis [ES2], [ES3] and Barles, Evans, and Souganidis [BaES]. The latter work actually studies a general system of reaction-diffusion equations.

We conclude this section with a brief discussion of the “phase field” approach to study propagating fronts. This consists of first studying the behavior of ϕ^ε as $\varepsilon \rightarrow 0$ in (6.3) and (6.4) and then defining the propagating front as the boundary of the regions where the ϕ^ε ’s converge to the different equilibria of the vector field. The advantage of this approach, which is rather indirect, is that it avoids any discussion

of the empty interior and the nonuniqueness difficulties at least at first glance provided of course that such a convergence can be proved. However, it will become apparent below that the convergence is closely related to the interior issue. Perhaps another advantage of the phase field approach is that it allows other numerical methods. This way to study motion by mean curvature was proposed by Bronsard and Kohn [BrK] and DeGiorgi [D]. A byproduct of our analysis in the following sections is that the phase field formulation is equivalent to the level set and distance function ones, taking into account the nonempty interior difficulty.

7. Formal discussion. In this section we discuss, in a formal way, the essential mathematical difficulties involved in the study of (6.3) and (6.4). To simplify the arguments, we consider the special case

$$(7.1) \quad f^\varepsilon(x, t, q) = f_0(q) - \varepsilon\theta = 2(q - \mu)(q^2 - 1) - \varepsilon\theta \quad (\theta \in \mathbb{R}).$$

We begin observing that, for sufficiently small $\varepsilon > 0$, there exists $h_-^\varepsilon(\theta) < h_0^\varepsilon(\theta) < h_+^\varepsilon(\theta)$ such that

$$f^\varepsilon(x, t, h_-^\varepsilon(\theta)) = f^\varepsilon(x, t, h_0^\varepsilon(\theta)) = f^\varepsilon(x, t, h_+^\varepsilon(\theta)) = 0.$$

Set

$$(7.2) \quad \begin{aligned} m^\varepsilon(\theta) &= h_+^\varepsilon(\theta) - h_-^\varepsilon(\theta), \\ q^\varepsilon(r, \theta) &= h_-^\varepsilon(\theta) + m^\varepsilon(\theta)(1 + \exp(-m^\varepsilon(\theta)[r + r^\varepsilon(\theta)]))^{-1} (r \in \mathbb{R}), \\ c^\varepsilon(\theta) &= 2h_0^\varepsilon(\theta) - h_+^\varepsilon(\theta) - h_-^\varepsilon(\theta), \end{aligned}$$

where $r^\varepsilon(\theta)$ is chosen so that $q^\varepsilon(0, \theta) = h_0^\varepsilon(\theta)$. A straightforward calculation yields

$$(7.3) \quad q_{rr}^\varepsilon + c^\varepsilon(\theta)q_r^\varepsilon = f_0(q^\varepsilon) - \varepsilon\theta$$

with

$$(7.4) \quad \lim_{r \rightarrow \pm\infty} q^\varepsilon(r, \theta) = h_\pm^\varepsilon(\theta);$$

in other words, q^ε is the *traveling wave* corresponding to the nonlinearity $f_0 - \varepsilon\theta$, which travels with speed $c^\varepsilon(\theta)$. Indeed, if we set

$$\Phi^\varepsilon(\xi, t) = q^\varepsilon(\xi - c^\varepsilon(\theta)t) \quad \text{in } \mathbb{R} \times (0, \infty),$$

then

$$\Phi_t - \Phi_{\xi\xi} = f_0(\Phi) - \varepsilon\theta \quad \text{in } \mathbb{R} \times (0, \infty).$$

In fact, for any “cubic-type” nonlinearity, there exists a unique pair of traveling wave and speed satisfying (7.3) and (7.4). A detailed discussion of this fact as well as references will be given in the next section.

We now return to (6.3) and write the solution ϕ^ε as

$$\phi^\varepsilon = q^\varepsilon\left(\frac{z^\varepsilon}{\varepsilon}, \theta\right) \quad \text{in } \mathbb{R}^N \times (0, \infty).$$

A simple calculation yields

$$\frac{1}{\varepsilon}q_r^\varepsilon[z_t^\varepsilon - \varepsilon\Delta z^\varepsilon + c^\varepsilon(\theta)] - \frac{1}{\varepsilon}q_{rr}^\varepsilon(|Dz^\varepsilon|^2 - 1) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

where q_r^ε and q_{rr}^ε are evaluated at $(z^\varepsilon/\varepsilon, \theta)$.

Analyzing the two terms in the above equation separately, as $\varepsilon \rightarrow 0$, we formally conclude that $|Dz^\varepsilon| \cong 1$ and, therefore,

$$z^\varepsilon(x, t) \cong \text{signed distance function of } x \text{ to } \Gamma_t,$$

where Γ_t is the interface, and

$$z_t^\varepsilon - \varepsilon \Delta z^\varepsilon + c^\varepsilon(\theta) \cong 0 \text{ on } \Gamma_t.$$

Since $h_0^\varepsilon(\theta) \cong \mu + \varepsilon \theta (f_0'(\mu))^{-1}$ and $h_\pm^\varepsilon(\theta) \cong \pm 1 + \varepsilon \theta (f_0'(\pm 1))^{-1}$, (7.2) yields

$$\lim_{\varepsilon \rightarrow 0} c^\varepsilon(\theta) = 2\mu.$$

Therefore, always formally, Γ_t moves with normal velocity $V = -2\mu$. The geometric pde that gives Γ_t as the zero level set of its solutions is

$$u_t + 2\mu|Du| = 0 \text{ in } \mathbb{R}^N \times (0, \infty).$$

In view of the discussion in § 6, to consider (6.4) with the vector field f^ε given by (7.1), we must assume $\mu = 0$, i.e.,

$$f^\varepsilon(x, t, q) = 2q(q^2 - 1) - \varepsilon\theta.$$

Proceeding as for (6.3) above, we write

$$\phi^\varepsilon = q\left(\frac{z^\varepsilon}{\varepsilon}, \theta\right) \text{ in } \mathbb{R}^N \times (0, \infty)$$

and find

$$\frac{1}{\varepsilon} q_r^\varepsilon [z_t^\varepsilon - \Delta z^\varepsilon + \varepsilon^{-1} c^\varepsilon(\theta)] - \frac{1}{\varepsilon^2} q_{rr}^\varepsilon (|Dz^\varepsilon|^2 - 1) = 0 \text{ in } \mathbb{R}^N \times (0, \infty),$$

where q_r^ε and q_{rr}^ε are evaluated at $(z^\varepsilon/\varepsilon, \theta)$. Arguing as before, we find (formally) that $z^\varepsilon(x, t) \cong \text{signed distance function from } x \text{ to } \Gamma_t$, where Γ_t is the interface, and

$$z_t^\varepsilon - \Delta z^\varepsilon + \varepsilon^{-1} c^\varepsilon(\theta) \cong 0 \text{ on } \Gamma_t.$$

Using the expressions for $h_0^\varepsilon(\theta)$, $h_\pm^\varepsilon(\theta)$ and (7.2) we find

$$\lim_{\varepsilon \rightarrow 0} \varepsilon^{-1} c^\varepsilon(\theta) = -\frac{3}{2}\theta.$$

Therefore, always formally, Γ_t moves with normal velocity

$$V = \text{mean curvature} + \frac{3}{2}\theta.$$

The corresponding geometric pde is

$$u_t - \left(\Delta u - \frac{(D^2 u Du | Du)}{|Du|^2} \right) - \frac{3}{2}\theta|Du| = 0 \text{ in } \mathbb{R}^N \times (0, \infty).$$

8. Traveling waves. Here we discuss the existence and the general properties of traveling waves for functions $u \mapsto f^\varepsilon(x, t, u)$, which have the property that, for a and ε small, the function $u \mapsto f^\varepsilon(x, t, u) - \varepsilon a$ behaves like a “cubic function” of u . More precisely, we assume that, for a and ε sufficiently small, the equation $f^\varepsilon(x, t, u) - \varepsilon a = 0$ has exactly three zeros: $h_-^\varepsilon(x, t, a) < h_0^\varepsilon(x, t, a) < h_+^\varepsilon(x, t, a)$. Moreover, we assume that

$$(8.1) \quad \begin{aligned} f^\varepsilon(x, t, \cdot) - \varepsilon a &> 0 && \text{in } (h_-^\varepsilon, h_0^\varepsilon) \cup (h_+^\varepsilon, +\infty), \\ f^\varepsilon(x, t, \cdot) - \varepsilon a &< 0 && \text{in } (-\infty, h_-^\varepsilon) \cup (h_0^\varepsilon, h_+^\varepsilon), \\ f_u^\varepsilon(x, t, h_\pm^\varepsilon) &\cong \gamma > 0, \end{aligned}$$

with γ independent of (x, t, a, ε) .

Since, for fixed (x, t, a, ε) , the function $u \mapsto f^\varepsilon(x, t, u) - \varepsilon a$ satisfies the hypotheses of Aronson and Weinberger [ArW] and Fife and McLeod [FiM], there exists a unique pair $(q^\varepsilon(r, x, t, a), c^\varepsilon(x, t, a))$ such that

$$(8.2) \quad q_{rr}^\varepsilon(r, x, t, a) + c^\varepsilon(x, t, a)q_r^\varepsilon(r, x, t, a) = f^\varepsilon(x, t, q^\varepsilon(r, x, t, a)) - \varepsilon a$$

and

$$(8.3) \quad \lim_{r \rightarrow \pm\infty} q^\varepsilon(r, x, t, a) = h_\pm^\varepsilon(x, t, a) \quad \text{and} \quad q^\varepsilon(0, x, t, a) = h_0^\varepsilon(x, t, a);$$

the second part of (8.3) is necessary to fix q^ε since (8.2) is invariant under translation in r .

We continue listing a set of technical assumptions that we will be making on $(q^\varepsilon, c^\varepsilon)$. We then verify these assumptions for a particular class of f^ε 's, which arise naturally in applications. To this end, we assume that, as $\varepsilon \rightarrow 0$,

$$(8.4) \quad q^\varepsilon \text{ and } c^\varepsilon \text{ depend smoothly on } (x, t, a),$$

$$(8.5) \quad h_\pm^\varepsilon(x, t, a) \rightarrow h_\pm(x, t, a), \quad h_0^\varepsilon(x, t, a) \rightarrow h_0(x, t, a),$$

and either

$$(8.6) \quad c^\varepsilon(x, t, a) \rightarrow \alpha(x, t, a)$$

or

$$(8.7) \quad -\varepsilon^{-1}c^\varepsilon(x, t, a) \rightarrow \alpha(x, t, a), \quad \text{if } c^\varepsilon(x, t, a) \rightarrow 0,$$

with all the limits local uniform in (x, t, a) . Moreover, if

$$\alpha(x, t) = \alpha(x, t, 0), \quad h_\pm(x, t) = h_\pm(x, t, 0), \quad \text{and} \quad h_0(x, t) = h_0(x, t, 0),$$

we assume that there exists $K > 0$, independent of (x, t) , such that, for ε and a small enough and all (x, t) ,

$$(8.8) \quad |\alpha(x, t) - \alpha(y, t)| \leq K|x - y|.$$

If (8.7) holds, we also assume

$$(8.9) \quad \begin{aligned} & \text{(i)} \quad |h_{\pm t} - \Delta h_\pm| \leq K \\ & \text{(ii)} \quad \lim_{\varepsilon \rightarrow 0} \sup_{(x, t, r, a)} [\varepsilon |q_t^\varepsilon| + \varepsilon |\Delta q^\varepsilon| + |Dq_r^\varepsilon|] = 0 \end{aligned}$$

$$\text{(iii)} \quad \frac{1}{\varepsilon} |q_{rr}^\varepsilon(r, x, t, a)| + \frac{1}{\varepsilon^2} |q_r^\varepsilon(r, x, t, a)| \leq K e^{-K\delta/\varepsilon} \quad \text{for all } |r| \geq \delta.$$

Finally, for all (x, t) and ε, a sufficiently small, we assume

$$(8.10) \quad q_r^\varepsilon \geq 0 \quad \text{and} \quad q_a^\varepsilon \geq 0.$$

Next we present an example where the above hypotheses hold true. Indeed, consider

$$(8.11) \quad f^\varepsilon(x, t, q) = 2(q - \mu^\varepsilon(x, t))(q^2 - 1) - \varepsilon \theta^\varepsilon(x, t),$$

where $\theta^\varepsilon: \mathbb{R}^N \times (0, \infty) \rightarrow \mathbb{R}$ is a given function. Let $h_0^\varepsilon, h_\pm^\varepsilon, q^\varepsilon$ and c^ε be as in § 7 for each (x, t) and define

$$\begin{aligned} h_0^\varepsilon(x, t, a) &= h_0^\varepsilon(\theta^\varepsilon(x, t) + a), & h_\pm^\varepsilon(x, t, a) &= h_\pm^\varepsilon(\theta^\varepsilon(x, t) + a), \\ q^\varepsilon(r, x, t, a) &= q^\varepsilon(r, \theta^\varepsilon(x, t) + a), \end{aligned}$$

and

$$c^\varepsilon(x, t, a) = c^\varepsilon(\theta^\varepsilon(x, t) + a).$$

It is immediate that (8.4) holds (if θ^ε is smooth) and that (8.5) holds with $h_\pm(x, t, a) = \pm 1$ and $h_0(x, t, a) = \mu$; (8.6) holds with $\alpha(x, t, a) = 2\mu(x, t)$ where $\mu = \lim_{\varepsilon \rightarrow 0} \mu^\varepsilon$. If $\mu(x, t) = 0$, then (8.7) yields $\alpha(x, t, a) = \frac{3}{2}(\theta(x, t) + a)$, provided that $\theta^\varepsilon(x, t) \rightarrow \theta(x, t)$ uniformly. In view of the above, (8.8) needs

$$(8.12) \quad |\theta(x, t) - \theta(y, t)| \leq K|x - y| \quad \text{or} \quad |\mu(x, t) - \mu(y, t)| \leq K|x - y|.$$

To conclude, using the explicit formulae in (7.2) we compute

$$D_t q^\varepsilon = q_\theta^\varepsilon \theta_t^\varepsilon, \quad D_x q^\varepsilon = q_\theta^\varepsilon D_x \theta^\varepsilon, \quad \Delta_x q^\varepsilon = q_\theta^\varepsilon \Delta_x \theta^\varepsilon + q_{\theta\theta}^\varepsilon |D_x \theta^\varepsilon|^2.$$

Since $|q_\theta| \leq \varepsilon K$ and $|q_{\theta\theta}| \leq \varepsilon^2 K$ for some $K > 0$, (8.9) (ii) holds if θ^ε is such that

$$(8.13) \quad \lim_{\varepsilon \rightarrow 0} \varepsilon [\sup_{(x,t)} (\varepsilon |\theta_t^\varepsilon| + \varepsilon |\Delta \theta^\varepsilon| + |D\theta^\varepsilon|)] = 0.$$

For (8.12) and (8.13) to hold, it suffices to assume that

$$(8.14) \quad (\theta^\varepsilon)_{\varepsilon > 0} \text{ is uniformly bounded in } C^{2,1}(\mathbb{R}^N \times [0, \infty)).$$

Finally, (8.9)(iii) and (8.11) hold provided $4\varepsilon|\theta^\varepsilon| \leq 1$, which follows from (8.14) for ε small.

We conclude this section observing that similar computations are possible for

$$(8.15) \quad f^\varepsilon(x, t, q) = 2(\theta^\varepsilon(x, t)q - \mu^\varepsilon(x, t))((\theta^\varepsilon(x, t)q)^2 - 1).$$

9. Asymptotic behavior of reaction-diffusion equations; the main results. We next state our main theorem about the behavior of the solution ϕ^ε of (6.3) and (6.4). To study (6.3) we consider f^ε 's that satisfy (8.1)–(8.6) and (8.8) and (8.10). For (6.4) we will consider f^ε 's such that (8.1)–(8.5) and (8.7)–(8.10) hold. In either case, we will denote by $(q^\varepsilon(r, x, t), c^\varepsilon(x, t))$ the pair of traveling wave and speed which corresponds to f^ε and we will assume

$$(9.1) \quad \alpha(x, t, a) \geq \alpha(x, t) \quad \text{for all } a > 0.$$

Throughout the discussion below we will be assuming that

$$(9.2) \quad \phi^\varepsilon(x, 0) = q^\varepsilon\left(\frac{d(x, \Gamma_0)}{\varepsilon}, x, 0\right) \quad \text{on } \mathbb{R}^N,$$

where Γ_0 is a closed set in \mathbb{R}^N . The last assumption can be weakened at the expense of rather lengthy arguments. We will address this issue elsewhere.

In view of the (formal) discussion in § 7 we expect that the limiting behavior of ϕ^ε will be governed by the geometric pde's

$$(9.3) \quad u_t - \alpha(x, t)|Du| = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

for (6.3) and

$$(9.4) \quad u_t - \left(\Delta u - \frac{(D^2 u Du | Du)}{|Du|^2} \right) - \alpha(x, t)|Du| = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

for (6.4), with (by (9.2)),

$$(9.5) \quad u(x, 0) = d(x, \Gamma_0) \quad \text{on } \mathbb{R}^N.$$

THEOREM 9.1. *Let ϕ^ε be the solution of (6.3), (9.2) with f^ε satisfying (8.1)–(8.6) and (8.8), (8.10), and (9.1). If u is the solution of (9.3), (9.5), then, as $\varepsilon \rightarrow 0$,*

$$(9.6) \quad \begin{aligned} \text{(i)} \quad & \phi^\varepsilon(x, t) \rightarrow h_+(x, t) \quad \text{if } u(x, t) > 0, \\ \text{(ii)} \quad & \phi^\varepsilon(x, t) \rightarrow h_-(x, t) \quad \text{if } u(x, t) < 0, \end{aligned}$$

with the limits locally uniform in $\{(x, t) : u(x, t) \neq 0\}$.

THEOREM 9.2. *Let ϕ^ε be the solution of (6.4), (9.2) with f^ε satisfying (8.1)–(8.5), (8.7)–(8.10), and (9.1). If u is the solution of (9.4), (9.5), then, locally uniformly in $\{(x, t) : u(x, t) \neq 0\}$, as $\varepsilon \rightarrow 0$*

$$(9.7) \quad \begin{aligned} & \text{(i)} \quad \phi^\varepsilon(x, t) \rightarrow h_+(x, t) \quad \text{if } u(x, t) > 0, \\ & \text{(ii)} \quad \phi^\varepsilon(x, t) \rightarrow h_-(x, t) \quad \text{if } u(x, t) < 0. \end{aligned}$$

In the special case where $f^\varepsilon(x, y, u) = 2(u - \mu)(1 - u^2)$, Barles, Bronsard, and Souganidis [BaBS] studied the limiting behavior of the solutions ϕ^ε of (6.3). Gärtner [G] also studied the same problem when $f^\varepsilon(x, t, u) = f(x, t, u)$ by a combination of probabilistic and analytic techniques. Evans, Soner, and Souganidis [ESS] studied the limiting behavior of ϕ^ε in (6.4) when $f(u) = 2u(1 - u^2)$; this problem was first studied in the context of radially symmetric functions by Bronsard and Kohn [BrK]. Finally, Chen [Ch] and DeMottoni and Shatzman [DS] obtained results similar to Theorems 9.1 and 9.2 (for special cases of f) assuming, however, that Γ_t is a smooth surface. No such assumption is made here.

We conclude this section by remarking that we can actually obtain more precise results than (9.6) and (9.7). Indeed, it is possible to obtain WKB-type expressions for ϕ^ε of the form

$$\phi^\varepsilon(x, t) = q^\varepsilon\left(\frac{d(x, \Gamma_t) + o(1)}{\varepsilon}, x, t\right).$$

This is done in § 10.1 for some simple cases. The arguments for the general case are, however, rather complicated and will be presented elsewhere.

10. Proofs. Instead of presenting a general proof for Theorems 9.1 and 9.2, we will first give some less general but more direct arguments utilizing the results of § 5. At the end we will turn to the general case. The reason for doing this is that in the less general cases it is possible to work directly at the $\varepsilon = 0$ level, as opposed to the general case where we need to build super- and subsolutions for $\varepsilon > 0$. The latter approach ties us down to cases where the maximum principle holds.

10.1 The (x, t) -independent case. Here we assume that f^ε (and therefore q^ε) is independent of (x, t) and is given by (6.6) for (6.4) and (6.7) for (6.3). In fact, the traveling wave in either case is $q(r) = \tanh(r)$ ($r \in \mathbb{R}$) and the speed $2\varepsilon\mu$ and 2μ for (6.6) and (6.7), respectively.

Following the discussion in § 7, if

$$(10.1) \quad \phi^\varepsilon = q\left(\frac{z^\varepsilon}{\varepsilon}\right) \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

then z^ε solves

$$(10.2) \quad z_t^\varepsilon - \varepsilon \Delta z^\varepsilon + 2q\left(\frac{z^\varepsilon}{\varepsilon}\right)(|Dz^\varepsilon|^2 - 1) + 2\mu = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

in the case of (6.3), and

$$(10.3) \quad z_t^\varepsilon - \Delta z^\varepsilon + \frac{2}{\varepsilon}q\left(\frac{z^\varepsilon}{\varepsilon}\right)(|Dz^\varepsilon|^2 - 1) + 2\mu = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

in the case of (6.4), with, in either case,

$$(10.4) \quad z^\varepsilon(x, 0) = d(x, \Gamma_0) \quad \text{on } \mathbb{R}^N.$$

We want to study the behavior of z^ε as $\varepsilon \rightarrow 0$. To this end, we assume for the moment that $(z^\varepsilon)_{\varepsilon > 0}$ is locally uniformly bounded in $\mathbb{R}^N \times (0, T)$ for some $T > 0$ and we proceed. Since (10.2) and (10.3) are translation invariant with respect to x , it is immediate that

$$(10.5) \quad |Dz^\varepsilon| \leq 1 \quad \text{in } \mathbb{R}^N \times (0, \infty).$$

On the other hand, the form of (10.2) and (10.3) makes any kind of estimate z_t^ε hopeless. To circumvent this difficulty we use the, by now classical, half-relaxed limit techniques described in Barles and Perthame [BaP] (see also [CIL]), i.e., we consider the functions

$$(10.6) \quad z^*(x, t) = \limsup_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} z^\varepsilon(x, s) \quad \text{and} \quad z_*(x, t) = \liminf_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} z^\varepsilon(x, s).$$

We begin with (10.3), which can be rewritten as

$$(10.7) \quad z_t^\varepsilon - \Delta z^\varepsilon + 2\mu = -\frac{2}{\varepsilon} q\left(\frac{z^\varepsilon}{\varepsilon}\right) (|Dz^\varepsilon|^2 - 1).$$

The form of q and (10.5) yield

$$-\frac{2}{\varepsilon} q\left(\frac{z^\varepsilon}{\varepsilon}\right) (|Dz^\varepsilon|^2 - 1) \geq 0 \quad \text{if } z^\varepsilon > 0$$

and

$$-\frac{2}{\varepsilon} q\left(\frac{z^\varepsilon}{\varepsilon}\right) (|Dz^\varepsilon|^2 - 1) \leq 0 \quad \text{if } z^\varepsilon < 0.$$

Using (10.5), (10.7), and the above inequalities we get that z^* is a usc subsolution of (5.3) with $\alpha = -2\mu$ and a solution of $1 - |Dz| = 0$ in $\{z < 0\}$ and that z_* is an lsc supersolution of (5.4) with $\alpha = -2\mu$ and a solution of $|Dz| - 1 = 0$ in $\{z > 0\}$. That z^* (respectively, z_*) is a subsolution (respectively, supersolution) of (5.3) in $\{z < 0\}$ (respectively, (5.4) in $\{z > 0\}$) follows from (10.7) and the above inequalities, that z^* (respectively, z_*) solves $1 - |Dz| = 0$ (respectively, $|Dz| - 1 = 0$) in $\{z < 0\}$ (respectively, $\{z > 0\}$) follows the passage to the limit in both (10.5) and (10.7).

Theorem 5.1 implies that $z^* \leq d_2$ in $\{z^* < 0\} \supset \{u < 0\}$ and $z_* \geq d_1$ in $\{z_* > 0\} \supset \{u > 0\}$, where u is the solution of (9.4) with $\alpha = -2\mu$. Moreover if the “empty interior” condition holds, Theorem 5.1 yields $z^*(\cdot, t) = z_*(\cdot, t) = d(\cdot, \Gamma_t)$; therefore we have the result.

In the case of (10.2), we rewrite the equation as

$$z_t^\varepsilon - \varepsilon \Delta z^\varepsilon + 2\mu |Dz^\varepsilon| = -(|Dz^\varepsilon| - 1) \left(2\mu + 2q\left(\frac{z^\varepsilon}{\varepsilon}\right) (|Dz^\varepsilon| + 1) \right)$$

and pass to the limit using sign-type arguments, similar to the first case but for the limiting equation. Indeed, since $\mu \in (-1, 1)$, we obtain

$$z_t + 2\mu |Dz| \leq 0 \quad \text{in } \{z < 0\} \quad \text{and} \quad z_t + 2\mu |Dz| \geq 0 \quad \text{in } \{z > 0\},$$

where above we have suppressed the z^* and z_* notation. The arguments of the proofs of Theorem 5.1 and Lemmas 5.2 and 5.3 yield

$$\{z^* < 0\} \supset \{u < 0\} \quad \text{and} \quad \{z_* > 0\} \supset \{u > 0\};$$

we conclude as before.

It remains to prove the uniform local bound on z^ε . Such a bound is easy for (10.2) and we leave it up to the reader; here we concentrate on (10.3). Let $\psi: \mathbb{R} \rightarrow \mathbb{R}$ be a C^2 function such that $\psi \equiv 0$ in $[0, +\infty)$ and $\psi(-\infty) = -1$ with $\psi' > 0$ in $(-\infty, 0)$ and ψ''

bounded and consider the function $\bar{\omega}_\varepsilon$ defined by $\bar{\omega}_\varepsilon = \psi(z^\varepsilon)$. In view of the choice of ψ , it is clear that $-1 \leq \bar{\omega}_\varepsilon \leq 0$, i.e., $\bar{\omega}_\varepsilon$ is bounded. Next we define

$$\bar{w}^*(x, t) = \limsup_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} \bar{\omega}_\varepsilon(x, s);$$

\bar{w}^* is well defined and $\bar{w}^* = -1$ if $z^* = -\infty$, $\bar{w}^* = \psi(z^*)$ if $z^* \in (-\infty, 0)$ and $\bar{w}^* = 0$ if $z^* \geq 0$. Combining the above with arguments from the proof of Theorem 5.1, it can be shown that \bar{w}^* is a subsolution of the two-sided variational inequality

$$\max \left(w, \min \left(w + 1, w_t - \left(\Delta w - \frac{(D^2 w D w | D w)}{|D w|^2} \right) + 2\mu |D w| \right) \right) = 0.$$

A direct modification of the usual comparison results yields

$$\bar{w}^* \leq \psi(u) \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

where u is the solution of (9.4) with $\alpha = -2\mu$. Arguing in exactly the same way with $w_\varepsilon = -\psi(-z_\varepsilon)$, we find

$$w_*(x, t) = \lim_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} w_\varepsilon(x, t) \geq -\psi(-u) \quad \text{in } \mathbb{R}^N \times (0, \infty).$$

We conclude as follows: Let $t^* = \sup \{t > 0: \text{there exists } x \in \mathbb{R}^N \text{ such that } u(x, t) > 0\}$. If $t < t^*$, the sets $\{u > 0\}$ and $\{u < 0\}$ and, therefore, $\{z^* < 0\}$ and $\{z_* < 0\}$ are nonempty. Then there exist points in a bounded region of \mathbb{R}^N (depending only on u) such that $z^* < 0$ and $z_* > 0$. The local uniform bound then follows from (10.5) for all $T < t^*$. If $t > t^*$, then $z^* < 0$ and therefore $\phi_\varepsilon \rightarrow -1$ at any such point. \square

10.2. The (x, t) -dependent case. We now study (6.3) and (6.4) in the case where f^ε is given by (6.6)–(6.8). We only give the proof for (6.4) for f^ε given by (6.6); the other cases can be treated similarly. First, we recall that the traveling wave q^ε associated with (6.6) is still $q^\varepsilon = q = \tanh$. As before we perform the change $\phi^\varepsilon = q(z^\varepsilon/\varepsilon)$ and find (10.7) takes the form

$$(10.7) \quad z_t^\varepsilon - \Delta z^\varepsilon + 2\mu(x, t) + \frac{2}{\varepsilon} q\left(\frac{z^\varepsilon}{\varepsilon}\right) (|Dz^\varepsilon|^2 - 1) = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty)$$

with

$$z^\varepsilon(x, 0) = d(x, \Gamma_0) \quad \text{on } \mathbb{R}^N.$$

The main difference between this case and the (x, t) -independent one is that (10.7) is no longer translation invariant with respect to x . Instead of (10.5) here we have

$$(10.8) \quad |Dz^\varepsilon| \leq e^{Ct} \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

where C is the Lipschitz constant of 2μ with respect to x .

Next we introduce the function $\underline{z}^\varepsilon$ defined by

$$\underline{z}^\varepsilon(x, t) = \inf_{y \in \mathbb{R}^N} (\eta(z^\varepsilon(y, t)) + |x - y|),$$

where $\eta \in C^2$ is such that: $\eta(0) = 0$, $\eta' > 1$ in $(0, \infty)$, $\eta' < 1$ in $(-\infty, 0)$ and $\beta > \eta'' > 0$ and $\eta \geq -\beta^{-1}$ on \mathbb{R} for some $\beta > 0$. Since η is bounded from below, it is clear that the infimum in the definition of $\underline{z}^\varepsilon$ is achieved for some $y^\varepsilon(x)$; y^ε also depends on t

but we suppress this here. We now perform the usual arguments for this type of inf-convolution. If $y^\varepsilon(x) \neq x$, then

$$Dz^\varepsilon(y^\varepsilon(x), t) = \frac{1}{\eta'(z^\varepsilon(y^\varepsilon(x), t))} \frac{x - y^\varepsilon(x)}{|x - y^\varepsilon(x)|},$$

hence

$$(10.9) \quad q\left(\frac{z^\varepsilon}{\varepsilon}\right)(|Dz^\varepsilon|^2 - 1) = q\left(\frac{z^\varepsilon}{\varepsilon}\right)\left(\frac{1}{\eta'(z^\varepsilon)^2} - 1\right) \leq 0 \text{ at } (y^\varepsilon(x), t).$$

On the other hand, if $y^\varepsilon(x) = x$ and $\underline{z}^\varepsilon(x, t) = z^\varepsilon(x, t) > 0$, then $|Dz^\varepsilon(x, t)| \leq 1$ and

$$(10.10) \quad q\left(\frac{z^\varepsilon}{\varepsilon}\right)(|Dz^\varepsilon|^2 - 1) \leq 0.$$

Combining the last two inequalities and (10.8) we obtain

$$(10.11) \quad \underline{z}_t^\varepsilon - \Delta \underline{z}^\varepsilon + \beta e^{2Ct} + 2\eta'(z^\varepsilon(y^\varepsilon(x), t))\mu(y^\varepsilon(x), t) \geq 0 \text{ in } \{\underline{z}^\varepsilon > 0\}.$$

As in the previous section we assume that the z^ε 's (and therefore the $\underline{z}^\varepsilon$'s) are locally uniformly bounded in $\mathbb{R}^N \times (0, \infty)$ and we consider

$$z_*(x, t) = \liminf_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} z^\varepsilon(x, s) \quad \text{and} \quad \underline{z}(x, t) = \liminf_{\substack{\varepsilon \rightarrow 0 \\ s \rightarrow t}} \underline{z}^\varepsilon(x, s).$$

Letting $\varepsilon \rightarrow 0$ in (10.7) we get

$$(10.12) \quad \text{sgn}(z_*)(|Dz_*| - 1) \geq 0 \text{ in } \mathbb{R}^N \times (0, \infty).$$

We also must send $\varepsilon \rightarrow 0$ in (10.11). To do so we assume that $y^\varepsilon(x) \rightarrow y(x)$ for some $y(x)$ as $\varepsilon \rightarrow 0$ (since the family $(y^\varepsilon(x))_\varepsilon$ is bounded, $y^{\varepsilon_n}(x) \rightarrow y(x)$ for some $y(x)$ at least along some subsequence); hence

$$\underline{z}_t - \Delta \underline{z} + \beta e^{2Ct} + 2\eta'(z_*(y(x), t))\mu(y(x), t) \geq 0 \text{ in } \{\underline{z} > 0\}.$$

Now we remark that

$$\underline{z}(x, t) = \eta(z_*(y(x), t)) + |x - y(x)|;$$

the definitions of z^ε and \underline{z} together with (10.9), (10.10), and (10.12) and the properties of η yield $z_*(y(x), t) = 0$ and, therefore, $\underline{z}(x, t) = d(x, \{z_* = 0\})$ and $\eta'(z_*(y(x), t)) = 1$. We conclude by combining the arguments of the previous section and the ones of the proof of Theorem 5.1 and letting $\beta \rightarrow 0$.

10.3. The general case. Unfortunately, we cannot prove Theorems 9.1 and 9.2 in the case of general f^ε by a direct passage to the limit; one of the main difficulties being the lack of an explicit formula for the traveling wave q^ε and its speed c^ε . Here we will proceed by constructing sub- and supersolutions for (6.3) and (6.4) following ideas introduced in Evans, Soner, and Souganidis [ESS]. As before, we will only present the proof of Theorem 9.2; Theorem 9.1 is proved in a similar way with some modifications noted below. We begin with some preliminary facts.

For fixed $\delta, a > 0$, let $u^{\delta, a}$ be the solution of

$$(10.13) \quad \begin{aligned} u_t^{\delta, a} + F(x, t, Du^{\delta, a}, D^2 u^{\delta, a}) &= (\alpha(x, t, a) - \alpha(x, t))|Du^{\delta, a}| \\ u^{\delta, a}(x, 0) &= d(x, \Gamma_0) + \delta \quad \text{on } \mathbb{R}^N \end{aligned}$$

where

$$F(x, t, p, X) = -\operatorname{tr}(X) + \frac{(Xp|p)}{|p|^2} - \alpha(x, t)|p|.$$

If

$$d^{\delta,a}(x, t) = d(x, \{y: u^{\delta,a}(y, t) = 0\}),$$

Theorem 3.1 yields that

$$(10.14) \quad d_t^{\delta,a} - \Delta d^{\delta,a} - \alpha(x - d^{\delta,a} Dd^{\delta,a}, t, a) \geq 0 \text{ in } \{d^{\delta,a} > 0\}.$$

Following the proof of Lemma 3.1 of [ESS], we define

$$(10.15) \quad w^{\delta,a}(x, t) = \eta_\delta(d^{\delta,a}(x, t)),$$

where, as in [ESS], $\eta_\delta: \mathbb{R} \rightarrow \mathbb{R}$ is a smooth function satisfying

$$(10.16) \quad \begin{aligned} \eta_\delta(z) &= -\delta \text{ if } z \leq -\frac{\delta}{4}, \\ \eta_\delta(z) &= z - \delta \text{ if } z \geq \frac{\delta}{2}, \\ \eta_\delta(z) &\leq -\frac{\delta}{2} \text{ if } z \leq \frac{\delta}{2}, \\ 0 &\leq \eta'_\delta \leq C \text{ and } |\eta''_\delta| \leq C\delta^{-1} \text{ on } \mathbb{R}, \end{aligned}$$

where $C > 0$ is independent of δ . A straightforward modification of Lemma 3.1 of [ESS] together with (10.15) yields the following lemma.

LEMMA 10.1. *There exists a constant C , independent of δ and a , such that*

$$(10.17i) \quad w_t^{\delta,a} - \Delta w^{\delta,a} - \alpha(x, t, a) |Dw^{\delta,a}| \geq -\frac{C}{\delta} \quad \text{in } \mathbb{R}^N \times [0, t^*),$$

$$(10.17ii) \quad w_t^{\delta,a} - \Delta w^{\delta,a} - \alpha(x - w^{\delta,a} Dw^{\delta,a}, t, a) \geq 0 \quad \text{on } \left\{d^{\delta,a} > \frac{\delta}{2}\right\},$$

and

$$(10.18) \quad |Dw^{\delta,a}| = 1 \text{ in } \left\{d^{\delta,a} > \frac{\delta}{2}\right\},$$

where t^* is the extinction time of $\{u^{\delta,a} = 0\}$.

Finally, we define

$$(10.19) \quad \Phi^\varepsilon(x, t) = q^\varepsilon\left(\frac{w^{\delta,a}(x, t)}{\varepsilon}, x, t, a\right) \quad \text{on } \mathbb{R}^N \times [0, \infty),$$

where, for notational simplicity, we do not exhibit the dependence of Φ^ε on δ and a .

PROPOSITION 10.2. *Assume that f^ε satisfies the hypotheses of Theorem 9.2. Then, for every $a > 0$, Φ^ε is a supersolution of (6.4), if $\varepsilon \leq \varepsilon_0(\delta, a)$ and $\delta \leq \delta_0(a)$.*

The proof of the proposition is similar to the proof of Theorem 3.2 of [ESS]. The form, however, of Φ^ε is different than the one used in [ESS]. As usual we will present the proof as if $w^{\delta,a}$ has actual derivatives, keeping in mind that everything actually has to be checked in the viscosity sense; we will leave it to the reader to do so.

Proof. We must show that

$$(10.20) \quad \Phi_t^\varepsilon - \Delta \Phi^\varepsilon + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \Phi^\varepsilon) \geq 0$$

for $\varepsilon \leq \varepsilon_0(\delta, a)$ and $\delta \leq \delta_0(a)$. Using the equation for $q^\varepsilon(\xi, x, t, a)$, we calculate

$$(10.21) \quad \begin{aligned} \Phi_t^\varepsilon - \Delta \Phi^\varepsilon + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \Phi^\varepsilon) &= J^\varepsilon - \frac{q_{rr}^\varepsilon}{\varepsilon^2} (|Dw^{\delta,a}|^2 - 1) \\ &\quad + \frac{1}{\varepsilon} q_r^\varepsilon \left(w_t^{\delta,a} - \Delta w^{\sigma,a} + \frac{c^\varepsilon}{\varepsilon} \right) + \frac{a}{\varepsilon}, \end{aligned}$$

where q_r^ε and q_{rr}^ε are evaluated at $(w^{\delta,a}/\varepsilon, x, t, a)$, with

$$(10.22) \quad J^\varepsilon(x, t) = \left(q_t^\varepsilon + \frac{2}{\varepsilon} Dq_r^\varepsilon Dw^{\delta,a} + \Delta q^\varepsilon \right) \left(\frac{w^{\delta,a}}{\varepsilon}, x, t, a \right).$$

In view of its definition, it is immediate that $|Dw^{\delta,a}| \leq C$ where C is as in (10.16). Therefore, by (8.9) (ii),

$$(10.23) \quad J^\varepsilon = \frac{o(1)}{\varepsilon} \text{ as } \varepsilon \rightarrow 0 \text{ uniformly in } (x, t, \delta, a).$$

We proceed by examining three cases.

Case 1. $\delta/2 < d^{\delta,a} < 2\delta$.

Using (10.18), the Lipschitz continuity of α with respect to x , the fact that $d^{\delta,a} < 2\delta$, and the form of η_δ , we get

$$w_t^{\delta,a} - \Delta w^{\delta,a} - \alpha(x, t, a) \geq -C\delta \quad \text{and} \quad |Dw^{\delta,a}| = 1.$$

Substituting in (10.22) and employing (10.23) we obtain

$$(10.24) \quad \Phi_t^\varepsilon - \Delta \Phi^\varepsilon + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \Phi^\varepsilon) \geq \frac{1}{\varepsilon} \left[q_r^\varepsilon \left(-C\delta + \frac{c^\varepsilon(x, t, a)}{\varepsilon} + \alpha(x, t, a) \right) + a + o(1) \right],$$

where again q_r^ε is evaluated at $(w^{\delta,a}/\varepsilon, x, t, a)$. Since $\varepsilon^{-1}c^\varepsilon(x, t, a) \rightarrow -\alpha(x, t, a)$ as $\varepsilon \rightarrow 0$, uniformly in (x, t, a) , we see that the right side of (10.24) is positive if ε and δ are sufficiently small.

Case 2. $d^{\delta,a} \leq \delta/2$.

In this case the choice of η_δ yields

$$w^{\delta,a} \leq -\delta/2.$$

Consequently, (8.9) (iii) yields that

$$\frac{1}{\varepsilon} \left| q_r^\varepsilon \left(\frac{w^{\delta,a}}{\varepsilon}, x, t, a \right) \right| + \frac{1}{\varepsilon^2} \left| q_{rr}^\varepsilon \left(\frac{w^{\delta,a}}{\varepsilon}, x, t, a \right) \right| \leq Ke^{-K\delta/\varepsilon}$$

for some appropriate constant K . Using that $|Dw^{\delta,a}| \leq C$ as well as (10.17) in (10.21)

we obtain

$$\Phi_t^\varepsilon - \Delta \Phi^\varepsilon + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \Phi^\varepsilon) \geq K e^{-K\delta/\varepsilon} \left[-\frac{c}{\delta} - c \right] + o(1) + \frac{a}{\varepsilon}, \quad \text{as } \varepsilon \rightarrow 0;$$

for ε small enough the right hand side of the above inequality is again positive.

Case 3. $d^{\delta,a} > 2\delta$.

In this case we have $w^{\delta,a} > \delta$. Using (10.17) and (8.9) (iii) we conclude as in the previous case. \square

We are now ready to give the proof of Theorem 9.2.

Proof of Theorem 9.2. Fix $(x_0, t_0) \in \mathbb{R}^N \times [0, t^*)$ such that $u(x_0, t_0) = -\beta < 0$. The stability of solutions of the geometric pde's yields that $u^{\delta,a} \rightarrow u$, as $\delta, a \rightarrow 0$, uniformly in (x, t) . We choose, therefore, sufficiently small a and δ so that

$$(10.25) \quad u^{\delta,a}(x_0, t_0) < -\frac{\beta}{2} < 0.$$

Let Φ^ε be given by (10.19). In addition to being a supersolution of (6.4) for sufficiently small $\varepsilon > 0$, Φ^ε satisfies

$$\Phi^\varepsilon(x, 0) \geq q^\varepsilon\left(\frac{d(x, \Gamma_0)}{\varepsilon}, x, 0\right) \quad \text{on } \mathbb{R}^N,$$

where the last inequality follows from the fact that

$$w^{\delta,a}(x, 0) = \eta_\delta(d(x, \Gamma_0) + \delta) \geq d(x, \Gamma_0).$$

It follows by the standard comparison theorem for viscosity solutions and (8.10) that

$$\Phi^\varepsilon \leq \phi^\varepsilon \quad \text{in } \mathbb{R}^N \times [0, t^*).$$

On the other hand, (10.25) yields $d^{\delta,a}(x_0, t_0) < 0$; hence

$$\limsup_{\varepsilon \rightarrow 0} \phi^\varepsilon(x_0, t_0) \leq \limsup_{\varepsilon \rightarrow 0} \Phi^\varepsilon(x_0, t_0) = h_-(x_0, t_0).$$

To prove the reverse inequality, we consider $\hat{\Phi}(x, t) = h_-(x, t) - \gamma$ for some $\gamma > 0$. Since $h_- \in C^{2,1}$,

$$\frac{\partial \hat{\Phi}}{\partial t} - \Delta \hat{\Phi} + \frac{1}{\varepsilon^2} f^\varepsilon(x, t, \hat{\Phi}) \leq K + \frac{1}{\varepsilon^2} [-\gamma f_q^\varepsilon(x, t, h_-(x, t)) + o(\gamma)].$$

By (8.1), the right-hand side is negative for small ε and γ . Hence by the maximum principle

$$\liminf_{\varepsilon \rightarrow 0} \phi^\varepsilon(x, t) \geq h_-(x, t) - \gamma \quad \text{for all } (x, t) \text{ and } \gamma > 0.$$

We conclude by letting $\gamma \rightarrow 0$. A simple modification of the above arguments yields that $\phi^\varepsilon \rightarrow h_-$ locally uniformly in $\{u < 0\}$.

The fact that $\phi^\varepsilon \rightarrow h_+$ in $\{u > 0\}$ follows in a similar way, provided we construct a subsolution of (6.4).

To prove Theorem 9.1 we must consider the traveling waves associated by $f^\varepsilon - a$ and argue about a lower bound on $-\varepsilon \Delta w^{a,\delta}$. The latter follows from the facts that $w^{a,\delta} \neq 0$ if and only if $d^{a,\delta} \geq \delta/4$ and $\Delta d^{a,\delta} \geq -C/d^{a,\delta}$ in $\{d^{a,\delta} > 0\}$. \square

11. Possible applications. In this section we briefly discuss two applications where (6.4) arises naturally, with f^ε of the form

$$(11.1) \quad f^\varepsilon(x, t, q) = 2q(q^2 - 1) - \varepsilon \theta^\varepsilon(x, t),$$

which, in view of the discussion in § 8, satisfies the desired properties, provided $(\theta^\varepsilon)_\varepsilon$ is bounded in $C^{2,1}$. On the other hand, we do not know whether $(\theta^\varepsilon)_\varepsilon$ satisfies this necessary condition.

Example 1 (volume constraint). Let Ω be a bounded domain in \mathbb{R}^N with an outward normal vector $n(x)$, $x \in \partial\Omega$ and consider the reaction-diffusion equation

$$(11.2) \quad \phi_t^\varepsilon - \Delta \phi^\varepsilon + \frac{2}{\varepsilon^2} \phi^\varepsilon ((\phi^\varepsilon)^2 - 1) = a^\varepsilon(t) \quad \text{in } \Omega,$$

$$\frac{\partial \phi^\varepsilon}{\partial n} = 0 \quad \text{on } \partial\Omega,$$

where

$$(11.3) \quad a^\varepsilon(t) = \lambda^\varepsilon(\phi^\varepsilon(\cdot, t)) = \frac{1}{\varepsilon^2} \frac{1}{\text{meas}(\Omega)} \int_{\Omega} 2\phi^\varepsilon((\phi^\varepsilon)^2 - 1) \, dx.$$

If we set

$$\theta^\varepsilon(x, t) = \varepsilon \lambda^\varepsilon(\phi^\varepsilon(\cdot, t)),$$

(8.13) reduces to

$$\lim_{\varepsilon \downarrow 0} \varepsilon^2 \sup_t |\theta_t^\varepsilon(t)| = 0.$$

We do not know whether this estimate holds. Formally the limiting equation is

$$(11.4) \quad V = \text{mean curvature} + \alpha(t) \quad \text{in } \Omega,$$

with Neumann boundary condition on $\partial\Omega$ (see Giga and Sato [GS]). If Γ_t is a solution of this equation, then

$$\text{Volume enclosed by } \Gamma_t = \int_{\{u(\cdot, t) > 0\}} dx = \frac{1}{2} \lim_{\varepsilon \downarrow 0} \int_{\Omega} [\phi^\varepsilon(x, t) + 1] \, dx.$$

Moreover,

$$\frac{d}{dt} \int_{\Omega} (\phi^\varepsilon + 1) \, dx = \int_{\Omega} \left[\Delta \phi^\varepsilon - \frac{1}{\varepsilon^2} f_0(\phi^\varepsilon) + \lambda^\varepsilon \right] \, dx = 0,$$

i.e., the volume of the region enclosed by Γ_t is constant in time. For a detailed formal analysis of this problem refer to Rubinstein and Sternberg [RS].

The pair $(\Gamma_t, \alpha(t))$ is called a volume preserving mean curvature flow. The associated geometric pde in \mathbb{R}^N is

$$u_t - \left(\Delta u - \frac{(D^2 u Du | Du)}{|Du|^2} \right) - \alpha(t) |Du| = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty).$$

When $N = 2$, Lagrange multiplier $\alpha(t)$ is given by the explicit formula

$$\alpha(t) = 2\pi N(t)/L(t),$$

where $N(t)$ is the number of disjoint of connected parts of $\Gamma(t)$ and $L(t)$ is the length of Γ_t . This formula indicates that the Lagrange multiplier may, in general, be discontinuous in time. If, however, we do not insist that Γ_t is the boundary of a region and replace $\alpha(t)$ by the above formula, then a complete theory is available. In this framework the solution may develop self-intersections, which are not desirable in a physical problem.

In § 4 we presented an example of nonuniqueness for the volume preserving flow by mean curvature.

Example 2 (supercooled Stefan problem). We consider the problem of a melting or growing crystal in a melt. Let $\theta(x, t)$ be the appropriately scaled temperature and $C(t) \subset \mathbb{R}^N$ be the region occupied by the crystal. Gurtin [Gu] derived the equation

$$(11.5) \quad \frac{\partial}{\partial t}[\theta(x, t) + l\mathbb{1}_{C(t)}(x)] = \Delta\theta(x, t) \quad \text{in } (0, \infty) \times \mathbb{R}^N,$$

with the free boundary condition

$$(11.6) \quad \text{normal velocity of } \Gamma_t = \text{curvature} - \theta(x, t) \text{ on } \Gamma_t,$$

where the latent heat $l > 0$ is a given quantity and $\mathbb{1}_{C(t)}$ is the characteristic function of the set $C(t)$. In general, anisotropic versions of the above equation are more appropriate and we refer to Gurtin and Sonner [GuS] for a discussion of the generalizations of (11.5), (11.6), as well as appropriate notion of solution and the underlying physics. Luckhaus [Lu] and Almgren and Wang [AlW] also studied a similar problem in which (11.6) is replaced by the Gibbs–Thompson relation

$$0 = \text{curvature} - \theta \text{ on } \Gamma_t.$$

The system (11.5) and (11.6) can be approximated by the reaction diffusion equations

$$(11.7) \quad \theta_t^\varepsilon + \frac{l}{2} \phi_t^\varepsilon = \Delta\theta^\varepsilon \quad \text{in } \mathbb{R}^N \times (0, \infty),$$

and

$$(11.8) \quad \phi_t^\varepsilon - \Delta\phi^\varepsilon + \frac{1}{\varepsilon^2} \left[f_0(\phi^\varepsilon) - \frac{2}{3} \varepsilon \theta^\varepsilon \right] = 0 \quad \text{in } \mathbb{R}^N \times (0, \infty).$$

The above approximation was first proposed by Caginalp [Ca1]–[Ca3]. The convergence of this system was proved by Caginalp and Chen [CC] in the radial case by a method based on knowing that the limiting motion is classical. Indeed, in the radial case the interface Γ_t is a sphere and (11.6) reduces to an ordinary differential equation. In general, we do not expect Γ_t to be a smooth, classical solution of (11.6). The convergence of the system (11.7)–(11.8) is an open problem.

EUROPEAN OPTION PRICING WITH TRANSACTION COSTS*

MARK H. A. DAVIS†, VASSILIOS G. PANAS‡, AND THALEIA ZARIPHPOULOU‡

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. The authors consider the problem of pricing European options in a market model similar to the Black–Scholes one, except that proportional transaction charges are levied on all sales and purchases of stock. “Perfect replication” is no longer possible, and holding an option involves an essential element of risk. A definition of the option writing price is obtained by comparing the maximum utilities available to the writer by trading in the market with and without the obligation to fulfill the terms of an option contract at the exercise time. This definition reduces to the Black–Scholes value when the transaction costs are removed. Computing the price involves solving two stochastic optimal control problems. This paper shows that the value functions of these problems are the unique viscosity solutions, with different boundary conditions, of a fully nonlinear quasi-variational inequality. This fact implies convergence of discretisation schemes based on the “binomial” approximation of the stock price. Computational results are given. In particular, the authors show that, for a long dated option, the writer must charge a premium over the Black–Scholes price that is just equal to the transaction charge for buying one share.

Key words. option pricing, Black–Scholes formula, transaction costs, utility maximisation, stochastic control, free boundary problem, quasi-variational inequality, viscosity solution, Markov chain approximation

1. Introduction. Option pricing has been a focus of mathematical research in finance since the publication of the Black–Scholes formula in 1973 [3]. Consult Cox and Rubinstein [5] for a full explanation of financial options and their uses. Black and Scholes gave a valuation for a *European call option*, a contract that confers on the holder the right to buy at the *exercise time* T one share of a specified stock at an agreed price E (known as the *strike price*). Let $S(t)$ denote the stock price at time t . Clearly, the option is worthless if $S(T) \leq E$ but has positive value to the holder, and will be exercised, if $S(T) > E$. The *writer* of the option thus has the obligation to deliver one share at time T for a cash payment of E if $S(T) > E$. The pricing problem is to determine what a buyer should be prepared to pay at some earlier time t to acquire such an option and how much the writer should charge for issuing it.¹ Since holding an option is certainly a speculative position, it seems at first that the answer to this question must depend on the buyer’s or writer’s attitude to risk and therefore that there can be no “universal” pricing formula. However, Black and Scholes showed that, in certain circumstances, such a universal formula is indeed possible. Specifically, they assumed that the stock price process $S(t)$ is a geometric Brownian motion (this is described in § 3, below), that a bank account, i.e., a riskless investment paying interest at a constant rate r , is available, and that funds may be transferred from bank to stock and vice versa without restrictions or costs. Then it turns out that *perfect hedging* is possible: we can form a (time-varying or *dynamic*), self-financing portfolio of holdings in bank and stock whose value at time T is, with probability one, equal to $(S(T) - E)^+$.

* Received by the authors February 18, 1992; accepted for publication (in revised form) May 4, 1992.

¹ These are in general two separate calculations, although ultimately the writer and the buyer must of course agree on the same price. The circumstances required for such agreement to be reached are not discussed in this paper, but see § 8 for some further remarks.

(This is the value of the option at time T in the absence of any transaction costs, since if $S(T) > E$ the option can be exercised and the stock immediately resold, yielding a profit of $S(T) - E$.) It follows that the value of the option at time $t < T$ is the cash value $w(t)$ of the hedging portfolio at that time. Indeed, suppose that the option is offered for $z < w(t)$; then an investor can proceed as follows. He takes a short position in the hedging portfolio, thus acquiring $w(t)$ at time t , of which z is used to purchase the option, the remainder $(w(t) - z)$ being invested in the bank. At time T the investment in the bank is worth $x := (w(t) - z) \exp(r(T - t))$ and by exercising the option and immediately reselling the stock if $S(T) > E$ the investor acquires $(S(T) - E)^+$. Since the latter is exactly the amount required to close the short position, a sure profit of x has been made. A similar *arbitrage opportunity* is available to the writer if he is able to command a higher price than $w(t)$. It is axiomatic that arbitrage opportunities cannot exist (they contravene any concept of market equilibrium), and therefore $w(t)$ is the unique fair price for the option, from either the buyer's or writer's point of view.

In fact, perfect hedging of very general European contingent claims (ECC) is possible in the Black-Scholes world: if ψ is any function of the stock price trajectory $\{S(u) : t \leq u \leq T\}$ whose expectation exists, then there is a dynamic portfolio whose value at time T is exactly ψ ; this is the *replicating portfolio*. The ability to replicate arbitrary contingent claims is described as *completeness* of the market. In the Black-Scholes world, completeness ultimately hinges on the *martingale representation property* of Brownian motion; see Karatzas [13] for a full explanation. By the same argument as above, the fair price for an ECC with payoff ψ is the initial endowment of the replicating portfolio.

There is a paradoxical element to the Black-Scholes approach, which has been called the "Catch-22 of option pricing theory": the claims that can be priced are just those that are redundant in that the investor could, in principle, simply take a position in the replicating portfolio rather than actually buy the option. Thus, apparently such options have no reason to exist. The fallacy here is that we do not live in a Black-Scholes world. In particular, the replicating portfolio cannot be implemented exactly, since it involves incessant rebalancing, which is impractical in the face of any form of market friction such as transaction costs. In this paper, we develop a theory of option pricing in which transaction costs are explicitly taken into account. Perfect hedging is no longer possible, and therefore *buying or writing options involves an unavoidable element of risk*. For this reason, a preference-independent valuation is no longer possible, and the investor's or writer's attitude toward risk must be considered.

In this paper, a new definition is given for the writing price of a European option, based on utility maximisation theory. This is a modification of the definition introduced by Hodges and Neuberger [11], using a very similar approach. It is also shown that, if a replicating portfolio exists and the class of trading strategies forms a linear space, then the new definition of the writing price coincides with the Black-Scholes price for the contingent claim; in § 3 the Black-Scholes model is stated as an example of a market model where these conditions hold. In § 4 this model is modified to account for transaction costs. We assume for mathematical tractability that investors trade only in the underlying security, although in the presence of transaction costs they might well wish to invest in other securities also. The new definition involves the value functions of two different stochastic control problems and in § 4 the nonlinear partial differential equation (p.d.e.), satisfied by these value functions, is derived using informal arguments. Then we prove that these value functions are the unique viscosity solutions (with the appropriate boundary conditions) of this nonlinear p.d.e. in § 5, and a discretisation scheme is outlined in § 6, together with the proof of convergence to the

unique solution. Finally, § 7 presents the results of this scheme for investors whose preferences are modeled by an exponential utility function (i.e., their index of risk aversion is independent of wealth).

An alternative approach to the pricing problem was outlined by Leland [16], where a hedging strategy is derived based on discrete time rebalancing under transaction costs, but this method is not optimal in any well-defined sense. Also, Bensaid et al. [2] and Edirisinghe, Naik, and Uppal [10] price options using the concept of super-replicating strategies in a discrete time (binomial) model. Our initial reaction is that this approach is unlikely to be viable in a continuous time setting, but this is a question that merits further investigation.

2. Option pricing via utility maximization. In this section, we give a general definition of option price based on utility maximization. This is a modification of work by Hodges and Neuberger [11], who introduced many of the key ideas. The definition can be stated in very general terms, not restricted to any particular market model. The main result of this section, which demonstrates that our approach is well founded, is Theorem 1, which shows that, if perfect replication is possible, then our price coincides with the Black–Scholes price. On the other hand, our definition is applicable in many situations where the Black–Scholes methodology fails.

We consider a time interval $[0, T]$ and a market, which consists of n stocks whose prices $\mathbf{S}(t) = (S_1(t), \dots, S_n(t))$ are assumed to be stochastic processes on a given probability space (Ω, \mathcal{F}, P) ; their natural filtration is $\mathcal{F}_t = \sigma\{S_1(u), \dots, S_n(u) : 0 \leq u \leq t\}$. Investors can also keep their funds in cash, i.e., a risk-free asset, denoted by B . We wish to give a price applicable at time zero for a European option with exercise time T on one of the stocks, say $S_1(t)$.

Let $\mathcal{T}(B)$ denote the set of *admissible trading strategies* available to an investor who starts at time zero with an amount B in cash and no holdings in stock. We identify an element $\pi \in \mathcal{T}(B)$ with a vector stochastic process $(\mathbf{B}^\pi(t), \mathbf{y}^\pi(t)) = (\mathbf{B}^\pi(t), \mathbf{y}_1^\pi(t), \dots, \mathbf{y}_n^\pi(t))$, $t \in [0, T]$, where $\mathbf{B}^\pi(t)$ denotes the amount held in cash and $\mathbf{y}_i^\pi(t)$ the *number of shares* of stock i held, $i = 1, \dots, n$, over $[0, T]$ (this may or may not be constrained to be an integral number). There may be costs associated with transactions. In particular, $c(\mathbf{y}, \mathbf{S})$ is the liquidated cash value of a portfolio vector \mathbf{y} ; i.e., the residual cash value when long positions ($y_i > 0$) are sold, and short positions ($y_i < 0$) closed. We assume that $c(\mathbf{0}, \mathbf{S}) = 0$.

An option on stock $S_1(t)$ is the right to buy one share at time T at a price E , which may be a constant (in the case of a simple call option), or, more generally, may be an \mathcal{F}_T -measurable random variable (allowing for more exotic things such as *look-back* options). We suppose that the option writer forms a portfolio in order to hedge the option and liquidates the portfolio at time T . Suppose that $(B, \mathbf{y}, \mathbf{S})$ denote the cash, stock holdings, and stock price vector at time T , respectively. If $S_1 \leq E$, the option is not exercised, and the cash value of the portfolio is $B + c(\mathbf{y}, \mathbf{S})$. If $S_1 > E$, then the buyer pays the writer E in cash, and the writer delivers one share to the buyer. The value of the writer's portfolio after this transaction is $B + E + c(\mathbf{y} - \mathbf{e}_1, \mathbf{S})$, where \mathbf{e}_1 denotes the vector $(1, 0, \dots, 0)$.

Let $\mathcal{U} : \mathbb{R} \rightarrow \mathbb{R}$, the writer's utility function, be a concave increasing function such that $\mathcal{U}(0) = 0$. It is important that $\mathcal{U}(x)$ is defined for both positive and negative x . Now define the following value function:

$$(2.1) \quad \begin{aligned} V_w(B) = \sup_{\pi \in \mathcal{T}(B)} \mathbb{E} \{ & \mathcal{U}(\mathbf{B}^\pi(T) + I_{(S_1(T) \leq E)} c(\mathbf{y}^\pi(T), \mathbf{S}(T)) \\ & + I_{(S_1(T) > E)} [c(\mathbf{y}^\pi(T) - \mathbf{e}_1, \mathbf{S}(T)) + E]) \}, \end{aligned}$$

where \mathbb{E} denotes expectation, and I_A is the indicator function of the event A . We assume that $V_w(B) < \infty$ for all $B \in \mathbb{R}$ and that $V_w(B)$ is a continuous and monotone-increasing function of B . Note that $V_w(B)$ is the maximum utility available to the writer at time T by liquidating his portfolio after his obligations to the buyer have been met, given an initial endowment B . Now define

$$(2.2) \quad B_w = \inf \{B: V_w(B) \geq 0\}.$$

The writer is thus indifferent between (a) doing nothing and (b) accepting B_w and writing the option. This is, however, not the correct comparison for determining a fair option price. Let

$$(2.3) \quad V_1(B) = \sup_{\pi \in \mathcal{T}(B)} \mathbb{E}\{\mathcal{U}(\mathbf{B}^\pi(T) + c(\underline{\mathbf{y}}^\pi(T), \underline{\mathbf{S}}(T)))\}$$

and define the initial endowment B_1 by

$$(2.4) \quad B_1 = \inf \{B: V_1(B) \geq 0\},$$

where $B_1 \leq 0$, since clearly $V_1(0) \geq 0$. Think of $(-B_1)$ as the “entry fee” that the writer is prepared to pay to get into the market. Our definition of the option writing price p_w is now

$$(2.5) \quad p_w = B_w - B_1.$$

At this price, the writer is indifferent between going into the market to hedge the option and going into the market strictly on his own account. Note that in hedging the option in this way the writer may well hold stocks other than the one on which the option is written.

A primary justification for this definition is that it reduces to the Black-Scholes valuation in cases where this is applicable. Given an option contract on S_1 , a *replicating portfolio* for the writer is an element $\hat{\pi} \in \mathcal{T}(\hat{B})$, for an initial endowment \hat{B} , such that $(\mathbf{B}^{\hat{\pi}}(T), \underline{\mathbf{y}}^{\hat{\pi}}(T)) = I_{(S_1(T) > E)}(-E, e_1)$.

THEOREM 1. *Suppose that the class \mathcal{T} is a linear space; i.e., that if $\pi_i \in \mathcal{T}(B_i)$, $i = 1, 2$ then $a\pi_1 + b\pi_2 \in \mathcal{T}(aB_1 + bB_2)$ for $a, b \in \mathbb{R}$, where $a\pi_1 + b\pi_2 = (a\mathbf{B}^{\pi_1}(t) + b\mathbf{B}^{\pi_2}(t), a\underline{\mathbf{y}}^{\pi_1}(t) + b\underline{\mathbf{y}}^{\pi_2}(t))$. Suppose also that both $V_w(B)$ and $V_1(B)$ are continuous and strictly increasing functions of B . Then $p_w = \hat{B}$ if a replicating portfolio $\hat{\pi} \in \mathcal{T}(\hat{B})$ exists.*

Proof. It follows from the linearity of \mathcal{T} that an arbitrary trading strategy $\pi \in \mathcal{T}(B)$ can always be written in the form $\pi = \hat{\pi} + \tilde{\pi}$, where $\hat{\pi} \in \mathcal{T}(\hat{B})$ and $\tilde{\pi} \in \mathcal{T}(\tilde{B})$ with $B = \hat{B} + \tilde{B}$. Thus, by the continuity and monotonicity assumptions,

$$\begin{aligned} 0 &= V_w(B_w) \\ &= \sup_{\pi \in \mathcal{T}(B_w)} \mathbb{E}\{\mathcal{U}(\mathbf{B}^\pi(T) + I_{(S_1(T) \leq E)}c(\underline{\mathbf{y}}^\pi(T), \underline{\mathbf{S}}(T))) \\ &\quad + I_{(S_1(T) > E)}[E + c(\underline{\mathbf{y}}^\pi(T) - \underline{e}_1, \underline{\mathbf{S}}(T))]\} \\ &= \sup_{\tilde{\pi} \in \mathcal{T}(B_w - \hat{B})} \mathbb{E}\{\mathcal{U}(\mathbf{B}^{\tilde{\pi}}(T) + \mathbf{B}^{\hat{\pi}}(T) + I_{(S_1(T) \leq E)}c(\underline{\mathbf{y}}^{\tilde{\pi}}(T) + \underline{\mathbf{y}}^{\hat{\pi}}(T), \underline{\mathbf{S}}(T))) \\ &\quad + I_{(S_1(T) > E)}[E + c(\underline{\mathbf{y}}^{\tilde{\pi}}(T) + \underline{\mathbf{y}}^{\hat{\pi}}(T) - \underline{e}_1, \underline{\mathbf{S}}(T))]\} \\ &= \sup_{\tilde{\pi} \in \mathcal{T}(B_w - \hat{B})} \mathbb{E}\{\mathcal{U}(\mathbf{B}^{\tilde{\pi}}(T) - EI_{(S_1(T) > E)} + I_{(S_1(T) \leq E)}c(\underline{\mathbf{y}}^{\tilde{\pi}}(T), \underline{\mathbf{S}}(T))) \\ &\quad + I_{(S_1(T) > E)}[E + c(\underline{\mathbf{y}}^{\tilde{\pi}}(T), \underline{\mathbf{S}}(T))]\} \\ &= \sup_{\tilde{\pi} \in \mathcal{T}(B_w - \hat{B})} \mathbb{E}\{\mathcal{U}(\mathbf{B}^{\tilde{\pi}}(T) + c(\underline{\mathbf{y}}^{\tilde{\pi}}(T), \underline{\mathbf{S}}(T)))\} \\ &= V_1(B_w - \hat{B}). \end{aligned}$$

It follows that $B_1 = \inf\{B: V_1(B) \geq 0\}$ is equal to $(B_w - \hat{B})$ and hence that $\hat{B} = B_w - B_1 = p_w$. \square

3. Option pricing without transaction costs. In this section, we show that the standard Black–Scholes model satisfies the conditions of Theorem 1. The stock price and the price of the amount in the bank are described by differential equations, and it is assumed that there are no transaction costs: $c(y, \underline{S}) = y^T \underline{S}$. Several assumptions are made on the admissible trading strategies, which imply that $\mathcal{T}(B)$ is a linear space. For a more detailed presentation of a similar market model, refer to Karatzas [13].

The price of a stock $S_i(t)$, $i = 1, \dots, n$, is modeled by the following Markov diffusion process:

$$(3.1) \quad dS_i(t) = S_i(t)(\alpha_i(t) dt + \sigma_i^T(t) d\mathbf{R}(t)),$$

and the price of the amount in the bank is modeled by the following ordinary differential equation (o.d.e.):

$$(3.2) \quad d\mathbf{B}(t) = \mathbf{r}(t)\mathbf{B}(t) dt,$$

where $\mathbf{R}(t)$ is an n -dimensional P -Brownian motion, which generates the filtration, \mathcal{F}_t , to which $S_i(t)$ is adapted, $\alpha_i(t)$ is the mean growth rate of $S_i(t)$, $\sigma_i^T(t)$ is the i th row of the $n \times n$ volatility matrix σ , and $\mathbf{r}(t)$ is the interest rate. All of these are stochastic processes adapted to \mathcal{F}_t . It is assumed that both $\alpha_i(t)$ and $\mathbf{r}(t)$ are uniformly bounded and that

$$(3.3) \quad \exists \varepsilon > 0 \quad \text{such that } \sigma(t)\sigma^T(t) > \varepsilon I \quad \forall t \in [0, T],$$

where I is the $n \times n$ identity matrix. This last condition is known as the nondegeneracy condition, and it implies that at least one of the n sources of uncertainty in the model affects the price of $S_i(t)$, for each $i = 1, \dots, n$. The set of admissible trading strategies $\mathcal{T}(B)$ consists of the $(n+1)$ -dimensional, right-continuous, measurable, adapted processes, $(\mathbf{B}^\pi(t), \mathbf{y}^\pi(t))$, such that the investor's wealth is bounded below by a nonpositive integrable random variable. The wealth $\mathbf{W}(t)$ obeys the following stochastic differential equation:

$$(3.4) \quad \begin{aligned} d\mathbf{W}(t) &= d\mathbf{B}(t) + \mathbf{y}^T(t) d\mathbf{S}(t) \\ &= \mathbf{r}(t)\mathbf{B}(t) dt + \sum_{i=1}^n \mathbf{y}_i(t) S_i(t) \alpha_i(t) dt + \sum_{i=1}^n \mathbf{y}_i(t) S_i(t) \sigma_i^T(t) d\mathbf{R}(t), \end{aligned}$$

which can also be written as

$$(3.5) \quad d\mathbf{W}(t) = \mathbf{r}(t)\mathbf{W}(t) dt + \sum_{i=1}^n \mathbf{y}_i(t) S_i(t) \sigma_i^T(t) d\tilde{\mathbf{R}}(t),$$

where $\tilde{\mathbf{R}}(t)$ is a Brownian motion with drift.

That $\mathcal{T}(B)$ is a linear space can be verified directly from (3.5). Also, all the value functions are concave and increasing functions of B , as the utility function is a concave and increasing function of the investor's wealth. It can then be easily derived that both value functions are continuous functions of B , and Theorem 1 holds for all the contingent claims, $\psi = (S_1(T) - E)^+$, such that $\mathbb{E}\{\psi^\nu\} < \infty$ for some $\nu > 1$.

Remark. The validity of our price definition may alternatively be proved by deriving expressions for the value functions, following the steps in Karatzas [13].

4. Transaction costs: The Bellman equation for the value functions. It is now assumed that investors must pay transaction costs, which are proportional to the amount

transferred from the stock to the bank. A market model, similar to that of Davis and Norman [8], is then developed, based on the model outlined in the previous section. The main purpose of this section is the derivation of the fully nonlinear p.d.e., actually a variational inequality, satisfied by all the value functions of the utility maximisation problems stated in § 2. Also, a special utility function is defined, the properties of which enable us to determine the dependence of the value functions on the initial endowment B , and thus reduce the dimensionality of the problem.

It is assumed that investors trade only in the underlying stock $S(t)$, on which the contingent claim is written, to further reduce the dimensionality of the problem. Note that, in general, investors may wish to trade in all the risky securities available in the market to maximise their performance criteria. The cash value of a number of shares $y(t)$ of the stock is

$$(4.1) \quad c(y(t), S(t)) = \begin{cases} (1 + \lambda)y(t)S(t), & \text{if } y(t) < 0, \\ (1 - \mu)y(t)S(t), & \text{if } y(t) \geq 0. \end{cases}$$

where λ and μ are the fraction of the traded amount in stock, which the investor pays in transaction costs when buying or selling stock, respectively. The time interval considered is $[0, T]$, and the market model equations are

$$(4.2) \quad d\mathbf{B}(t) = r\mathbf{B}(t) dt - (1 + \lambda)S(t) d\mathbf{L}(t) + (1 - \mu)S(t) d\mathbf{M}(t),$$

$$(4.3) \quad dy(t) = d\mathbf{L}(t) - d\mathbf{M}(t),$$

$$(4.4) \quad dS(t) = S(t)(\alpha dt + \sigma d\mathbf{R}(t)),$$

where $\mathbf{L}(t)$ and $\mathbf{M}(t)$ are the cumulative number of shares bought or sold, respectively, over $[0, T]$ by an investor, $\mathbf{R}(t)$ is a P -Brownian motion that represents the single source of uncertainty, and r , α , and σ are nonrandom constants. As before, \mathcal{F}_t denotes the natural filtration of $\mathbf{R}(t)$. This system of equations describes a degenerate diffusion in \mathbb{R}^3 .

DEFINITION 1. The set of trading strategies $\mathcal{T}(B)$ consists of all the two-dimensional, right-continuous, measurable processes $(\mathbf{B}^\pi(t), y^\pi(t))$, which are the solution of equations (4.2)–(4.4), corresponding to some pair of right-continuous, measurable, \mathcal{F}_t -adapted, increasing processes $(\mathbf{L}(t), \mathbf{M}(t))$, such that

$$(4.5) \quad (\mathbf{B}^\pi(t), y^\pi(t), S(t)) \in \mathcal{E}_K \quad \forall t \in [0, T],$$

where K is a constant, which may depend on the policy π , and

$$(4.6) \quad \mathcal{E}_K = \{(B, y, S) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^+: B + c(y, S) > -K\}.$$

By convention, $\mathbf{L}(0-) = \mathbf{M}(0-) = 0$.

Remark. Investors may start with any combination of the two assets at time $s \in [0, T]$ in the general utility maximisation problem, and in that case the class of admissible trading strategies depends on the time s and the initial portfolio, which is characterised by the initial amount in the bank B , an initial number of shares y , and the initial value of the stock S . The constraint (4.5) is required for technical reasons in § 5, and it only rules out strategies that are clearly nonoptimal, as the objective is the maximisation of the utility of final wealth. Also, either $\mathbf{L}(0)$ or $\mathbf{M}(0)$ may be positive; i.e., a jump at the initial time is possible. Finally, (4.2) and (4.3) imply that the trading strategies are self-financing.

Now define the following two functions of wealth at the final time:

$$(4.7) \quad \Phi_1(T, \mathbf{B}(T), y(T), S(T)) = \mathbf{B}(T) + c(y(T), S(T))$$

and

$$(4.8) \quad \Phi_w(T, \mathbf{B}(T), \mathbf{y}(T), \mathbf{S}(T)) = \mathbf{B}(T) + I_{(S_1(T) \leq E)} c(\mathbf{y}(T), \mathbf{S}(T)) \\ + I_{(S_1(T) > E)} [c(\mathbf{y}(T) - 1, \mathbf{S}(T)) + E]$$

and the following value functions:

$$(4.9) \quad V_j(s, B, y, S) = \sup_{\pi \in \mathcal{T}} \mathbb{E}\{\mathcal{U}(\Phi_j(T, \mathbf{B}^\pi(T), \mathbf{y}^\pi(T), \mathbf{S}^\pi(T)))\}$$

where $(s, B, y, S) \in [0, T] \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^+$, and the index j is 1 or w .

From these definitions, it is evident that the dynamic programming algorithm will yield the same p.d.e. for each value function, the terminal condition of which is determined by the utility of the two functions $\Phi_j(T, B, y, S)$, where j is 1 or w . In the following, we derive, at least formally, the Hamilton–Jacobi–Bellman equations, associated with the two stochastic control problems,² which prove to be variational inequalities with gradient constraints. Consider, temporarily, a smaller class of trading strategies \mathcal{T}' , such that $\mathbf{L}(t)$ and $\mathbf{M}(t)$ are absolutely continuous processes, given by

$$(4.10) \quad \mathbf{L}(t) = \int_s^t \mathbf{l}(\xi) d\xi \quad \text{and} \quad \mathbf{M}(t) = \int_s^t \mathbf{m}(\xi) d\xi,$$

where $\mathbf{l}(\xi)$ and $\mathbf{m}(\xi)$ are positive and uniformly bounded by $k < \infty$. Then (4.2)–(4.4) is a vector stochastic differential equation with controlled drift, and the Bellman equation for a value function denoted by V_j^k is

$$(4.11) \quad \max_{0 \leq l, m \leq k} \left\{ \left(\frac{\partial V_j^k}{\partial y} - (1 + \lambda) S \frac{\partial V_j^k}{\partial B} \right) l - \left(\frac{\partial V_j^k}{\partial y} - (1 - \mu) S \frac{\partial V_j^k}{\partial B} \right) m \right\} \\ + \frac{\partial V_j^k}{\partial s} + rB \frac{\partial V_j^k}{\partial B} + \alpha S \frac{\partial V_j^k}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 V_j^k}{\partial S^2} = 0$$

for $(s, B, y, S) \in [0, T] \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^+$. The optimal trading strategy is determined by considering the following three possible cases:

$$(4.12) \quad \frac{\partial V_j^k}{\partial y} - (1 + \lambda) S \frac{\partial V_j^k}{\partial B} \geq 0 \quad \text{and} \quad \frac{\partial V_j^k}{\partial y} - (1 - \mu) S \frac{\partial V_j^k}{\partial B} > 0,$$

where the maximum is achieved by $m = 0$ and buying at the maximum possible rate $l = k$;

$$(4.13) \quad \frac{\partial V_j^k}{\partial y} - (1 + \lambda) S \frac{\partial V_j^k}{\partial B} < 0 \quad \text{and} \quad \frac{\partial V_j^k}{\partial y} - (1 - \mu) S \frac{\partial V_j^k}{\partial B} \leq 0,$$

where the maximum is achieved by $l = 0$ and selling at the maximum possible rate $m = k$; and

$$(4.14) \quad \frac{\partial V_j^k}{\partial y} - (1 + \lambda) S \frac{\partial V_j^k}{\partial B} \leq 0 \quad \text{and} \quad \frac{\partial V_j^k}{\partial y} - (1 - \mu) S \frac{\partial V_j^k}{\partial B} \geq 0,$$

where the maximum is achieved by doing nothing; that is $m = 0$ and $l = 0$. (Note that in this case the process $(\mathbf{B}^\pi(t), \mathbf{y}^\pi(t), \mathbf{S}(t))$ becomes an uncontrolled diffusion, which drifts under the influence of the stock process only.) All the other permutations of inequalities are impossible, as all the value functions are increasing functions of B and y .

² The argument is very similar to that in Davis and Norman [8].

The above results suggest that the optimisation problem is a free boundary problem, where, if a value function is known in the four-dimensional space, defined by the state of the investor (s, B, y, S) , the optimal trading strategy is determined by the above inequalities. Also, the state space is divided into three regions, called the *buy*, *sell* and *no-transaction* regions, which are characterised by (4.12), (4.13), and (4.14), respectively. Clearly, the buy and sell regions do not intersect, as it is not optimal to buy and sell at the same time. The boundaries between the no-transaction region and the buy and sell regions are denoted by ∂B and ∂S .

As $k \rightarrow \infty$, the class of admissible trading strategies becomes the class defined at the beginning of this section. It is conjectured that the state space remains divided into a buy region, a sell region, and a no-transaction region, and the optimal trading strategy mandates an immediate transaction to ∂B or ∂S if the state is in the buy region or sell region, followed by transactions of "local time" type at ∂B and ∂S . Therefore, each of the value functions satisfies the following set of equations:

(i) In the buy region, the value function remains constant along the path of the state, dictated by the optimal trading strategy, and therefore

$$(4.15) \quad V_j(s, B, y, S) = V_j(s, B - (1 + \lambda)S \delta y_b, y + \delta y_b, S),$$

where δy_b (the number of shares bought by the investor) can take any positive value up to the number required to take the state to ∂B . Allowing $\delta y_b \rightarrow 0$, (4.15) becomes

$$(4.16) \quad \frac{\partial V_j}{\partial y} - (1 + \lambda)S \frac{\partial V_j}{\partial B} = 0.$$

(ii) Similarly, in the sell region, the value function obeys the following equation:

$$(4.17) \quad V_j(s, B, y, S) = V_j(s, B + (1 - \mu)S \delta y_s, y - \delta y_s, S),$$

where δy_s (the number of shares sold by the investor) can take any positive value up to the number required to take the state to ∂S . Allowing $\delta y_s \rightarrow 0$, (4.17) becomes

$$(4.18) \quad \frac{\partial V_j}{\partial y} - (1 - \mu)S \frac{\partial V_j}{\partial B} = 0.$$

(iii) In the no-transaction region, the value function obeys the same set of equations obtained for the class of absolutely continuous trading strategies, and therefore the value function is given by

$$(4.19) \quad \frac{\partial V_j}{\partial s} + rB \frac{\partial V_j}{\partial B} + \alpha S \frac{\partial V_j}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 V_j}{\partial S^2} = 0,$$

and the pair of inequalities, shown above in (4.14), also hold. Note that, due to the continuity of the value function, if it is known in the no-transaction region, it can be determined in both the buy and sell regions by (4.15) and (4.17), respectively.

In the buy region the left-hand side of (4.18) is negative, and, in the sell region, the left-hand side of (4.16) is positive. Also, from the two pairs of inequalities (4.12) and (4.13), it is conjectured that the left-hand side of (4.19) is negative in both the buy and sell regions. Therefore, the above set of equations is condensed into the following fully nonlinear p.d.e.:

$$(4.20) \quad \max \left\{ \frac{\partial V_j}{\partial y} - (1 + \lambda)S \frac{\partial V_j}{\partial B}, - \left(\frac{\partial V_j}{\partial y} - (1 - \mu)S \frac{\partial V_j}{\partial B} \right), \right. \\ \left. \frac{\partial V_j}{\partial s} + rB \frac{\partial V_j}{\partial B} + \alpha S \frac{\partial V_j}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 V_j}{\partial S^2} \right\} = 0$$

for $(s, B, y, S) \in [0, T] \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}^+$.

Now consider the exponential utility function given by

$$(4.21) \quad \mathcal{U}(x) = 1 - \exp(-\gamma x),$$

where the index of risk aversion is $-\mathcal{U}''(x)/\mathcal{U}'(x) = \gamma$, which is independent of the investor's wealth. The definition of the value functions (4.9) can be written as

$$(4.22) \quad V_j(s, B, y, S) = 1 - \inf_{\pi \in \mathcal{T}} \mathbb{E}\{\exp(-\gamma \mathbf{B}^\pi(T)) \exp(-\gamma \Psi_j(T, \mathbf{y}^\pi(T), \mathbf{S}^\pi(T)))\},$$

where $\Psi_j(T, \mathbf{y}^\pi(T), \mathbf{S}^\pi(T)) := \Phi_j(T, \mathbf{B}^\pi(T), \mathbf{y}^\pi(T), \mathbf{S}^\pi(T)) - \mathbf{B}^\pi(T)$, and the amount $\mathbf{B}^\pi(T)$ is given by the following integral version of the state equation (4.2):

$$(4.23) \quad \mathbf{B}(T) = \frac{B}{\delta(T, s)} - \int_s^T \frac{(1+\lambda)\mathbf{S}(t)}{\delta(T, t)} d\mathbf{L}(t) + \int_s^T \frac{(1-\mu)\mathbf{S}(t)}{\delta(T, t)} d\mathbf{M}(t),$$

where $\delta(T, t)$ is the discount factor, defined by

$$(4.24) \quad \delta(T, t) = \exp(-r(T-t))$$

for the constant interest rate r . Therefore,

$$(4.25) \quad V_j(s, B, y, S) = 1 - \exp\left(-\gamma \frac{B}{\delta(T, s)}\right) Q_j(s, y, S),$$

where $Q_j(s, y, S)$ is a convex nonincreasing continuous function in y and S , defined by $Q_j(s, y, S) = 1 - V_j(s, 0, y, S)$. This representation means that, at time s , the monetary amount invested in the risky asset is independent of the total wealth. It also entails two very important simplifications. First, the writing price is given by the following explicit function of $Q_1(s, 0, S)$ and $Q_w(s, 0, S)$:

$$(4.26) \quad p_w(s, S) = \frac{\delta(T, s)}{\gamma} \ln\left(\frac{Q_w(s, 0, S)}{Q_1(s, 0, S)}\right).$$

Second, (4.20) is transformed into the following p.d.e. for $Q_j(s, y, S)$:

$$(4.27) \quad \min \left\{ \frac{\partial Q_j}{\partial y} + \frac{\gamma(1+\lambda)S}{\delta(T, s)} Q_j, -\left(\frac{\partial Q_j}{\partial y} + \frac{\gamma(1-\mu)S}{\delta(T, s)} Q_j \right), \frac{\partial Q_j}{\partial s} + \alpha S \frac{\partial Q_j}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 Q_j}{\partial S^2} \right\} = 0$$

with boundary conditions, for $Q_1(s, 0, S)$ and $Q_w(s, 0, S)$, given by

$$(4.28) \quad Q_1(T, y, S) = \exp(-\gamma c(y, S))$$

and

$$(4.29) \quad Q_w(T, y, S) = \exp(-\gamma(I_{(S \leq E)} c(y, S) + I_{(S > E)}[c(y-1, S) + E])).$$

Note that the function $Q_j(s, y, S)$ is evaluated in the three-dimensional space $[0, T] \times \mathbb{R} \times \mathbb{R}^+$.

If y defines the vertical axis, the optimal trading strategy when there are no transaction costs is defined by a surface denoted $\mathcal{J}(s, S)$; investors must trade in such a way that $y = \mathcal{J}(s, S)$ at all times. For V_1 , this surface is given by

$$(4.30) \quad \mathcal{J}_1(s, S) = \frac{\delta(T, s)}{\gamma S} \frac{\alpha - r}{\sigma^2}$$

by using the results in Karatzas [13]. For V_w , this surface is given by

$$(4.31) \quad \mathcal{J}_w(s, S) = \frac{\partial \mathcal{C}(s, S)}{\partial S} + \frac{\delta(T, s)}{\gamma S} \frac{\alpha - r}{\sigma^2},$$

where $\mathcal{C}(s, S)$ is the price of the European contingent claim in a market with no transaction costs and the partial derivative with respect to S is the replicating portfolio. In the case with transaction costs, it is conjectured that ∂B and ∂S are two surfaces, $\beta_b(s, S)$ and $\beta_s(s, S)$, which lie strictly below and above $\mathcal{I}(s, S)$, and the no-transaction region is between them (the numerical results, obtained in later sections, support this assertion). If the state of the investor (s, y, S) is in the no-transaction region, then it drifts, under the influence of the diffusion that describes the stock price, on the plane defined by $y = \text{const}$. If the state is in the buy region or sell region, then the investor performs the minimum transaction required to take the state to $\beta_b(s, S)$ or $\beta_s(s, S)$ with an immediate purchase or sale of stock. As noted above, if the function $Q_j(s, y, S)$ is known in the no-transaction region, then (4.16), (4.18), and (4.22) are used to derive

$$(4.32) \quad Q_j(s, y, S) = Q_j(s, y_b, S) \exp\left(-\frac{\gamma(1+\lambda)S}{\delta(T, s)}(y - y_b)\right) \quad \forall y \leq y_b,$$

where $y_b \in \beta_b(s, S)$. A similar equation can be derived for $Q_j(s, y, S)$, for all $y \geq \beta_s(s, S)$.

5. Existence and uniqueness of the solutions of the p.d.e. In this section, we characterise the value functions V_j given by (4.9) as weak (viscosity) solutions of the variational inequality (4.20). Since the stochastic control problems, whose value functions are given by (4.9), are associated with the same Hamilton–Jacobi–Bellman equation, we only examine the problem with value function V_1 . We next show that this value function is a constrained viscosity solution of (4.20) on $[0, T] \times \bar{\mathcal{E}}_\kappa$, where \mathcal{E}_κ is defined by (4.6); the characterisation of V_1 as a constrained viscosity solution of (4.20) is natural due to the presence of the state constraints (4.5).

The notion of *viscosity solutions* was introduced by Crandall and Lions [6] for first-order equations, and by Lions [17] for second-order equations. For a general overview of the theory, we refer to the *user's guide* by Crandall, Ishii, and Lions [7]. Next, we recall the notion of constrained viscosity solutions, which was introduced by Soner [18] and Capuzzo–Dolcetta and Lions [4] for first-order equations (see also Ishii and Lions [12] and Katsoulakis [14]). To this end, we consider a nonlinear second-order p.d.e. of the form

$$(5.1) \quad F(X, W, DW, D^2W) = 0 \quad \text{in } [0, T] \times \mathcal{E},$$

where $\mathcal{E} \subseteq \mathbb{R}^3$, DW , and D^2W denote the gradient vector and the second derivative of W , and the function F is continuous in all its arguments and degenerate elliptic, meaning that

$$(5.2) \quad F(X, p, q, A + N) \leq F(X, p, q, A) \quad \text{if } N \geq 0.$$

DEFINITION 2. A continuous function $W: [0, T] \times \bar{\mathcal{E}} \rightarrow \mathbb{R}$ is a constrained viscosity solution of (5.1) if (i) W is a viscosity subsolution of (5.1) on $[0, T] \times \bar{\mathcal{E}}$; that is, if, for any $\phi \in C^{1,2}([0, T] \times \bar{\mathcal{E}})$ and any local maximum point $X_0 \in [0, T] \times \bar{\mathcal{E}}$ of $W - \phi$,

$$(5.3) \quad F(X_0, W(X_0), D\phi(X_0), D^2\phi(X_0)) \leq 0,$$

and (ii) W is a viscosity supersolution of (5.1) on $[0, T] \times \bar{\mathcal{E}}$; that is, if, for any $\phi \in C^{1,2}([0, T] \times \bar{\mathcal{E}})$ and any local minimum point $X_0 \in [0, T] \times \bar{\mathcal{E}}$ of $W - \phi$,

$$(5.4) \quad F(X_0, W(X_0), D\phi(X_0), D^2\phi(X_0)) \geq 0.$$

THEOREM 2. *The value function $V_1(s, B, y, S)$ is a constrained viscosity solution of*

$$(5.5) \quad \min \left\{ -\left(\frac{\partial W}{\partial y} - (1+\lambda)S \frac{\partial W}{\partial B} \right), \frac{\partial W}{\partial y} - (1-\mu)S \frac{\partial W}{\partial B}, \right. \\ \left. -\left(\frac{\partial W}{\partial s} + rB \frac{\partial W}{\partial B} + \alpha S \frac{\partial W}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 W}{\partial S^2} \right) \right\} = 0$$

on $[0, T] \times \bar{\mathcal{E}}_K$.

Proof. In our case, the state X is (s, x) , where $x = (B, y, S) \in \bar{\mathcal{E}}_K$. Also, (4.20) has been given the above form to turn it into an elliptic p.d.e., to which the uniqueness theorems are applicable. Let $X_0 = (s_0, B_0, y_0, S_0) \in [0, T] \times \bar{\mathcal{E}}_K$: it follows, from results of Zhu [19, Thm. iv.2.2], that there exists an optimal trading strategy, dictated by the pair of processes $(\mathbf{L}^*(t), \mathbf{M}^*(t))$, where $\mathbf{X}_0^*(t) = (t, \mathbf{B}_0^*(t), \mathbf{y}_0^*(t), \mathbf{S}_0^*(t))$ is the optimal trajectory, with $\mathbf{X}_0^*(s_0) = X_0$.

(i) First, we prove that V_1 is a viscosity subsolution of (5.5) on $[0, T] \times \bar{\mathcal{E}}_K$; for this, we must show that, for all smooth functions $\phi(X)$, such that $V_1(X) - \phi(X)$ has a local maximum at $X_0 \in [0, T] \times \bar{\mathcal{E}}_K$, the following inequality holds:

$$(5.6) \quad \min \left\{ -\left(\frac{\partial \phi(X_0)}{\partial y} - (1+\lambda)S_0 \frac{\partial \phi(X_0)}{\partial B} \right), \frac{\partial \phi(X_0)}{\partial y} - (1-\mu)S_0 \frac{\partial \phi(X_0)}{\partial B}, \right. \\ \left. -\left(\frac{\partial \phi(X_0)}{\partial s} + rB_0 \frac{\partial \phi(X_0)}{\partial B} + \alpha S_0 \frac{\partial \phi(X_0)}{\partial S} + \frac{1}{2} \sigma^2 S_0^2 \frac{\partial^2 \phi(X_0)}{\partial S^2} \right) \right\} \leq 0.$$

Without loss of generality, we assume that $V_1(X_0) = \phi(X_0)$ and $V_1 \leq \phi$ on $[0, T] \times \bar{\mathcal{E}}_K$. We argue by contradiction: if the arguments inside the minimum operator of (5.6) satisfy

$$(5.7) \quad \frac{\partial \phi(X_0)}{\partial y} - (1+\lambda)S_0 \frac{\partial \phi(X_0)}{\partial B} < 0,$$

$$(5.8) \quad \frac{\partial \phi(X_0)}{\partial y} - (1-\mu)S_0 \frac{\partial \phi(X_0)}{\partial B} > 0,$$

then there exists $\theta > 0$, such that

$$(5.9) \quad \frac{\partial \phi(X_0)}{\partial s} + rB_0 \frac{\partial \phi(X_0)}{\partial B} + \alpha S_0 \frac{\partial \phi(X_0)}{\partial S} + \frac{1}{2} \sigma^2 S_0^2 \frac{\partial^2 \phi(X_0)}{\partial S^2} < -\theta.$$

From the fact that ϕ is smooth, the above inequalities become

$$(5.10) \quad \frac{\partial \phi(X)}{\partial y} - (1+\lambda)S \frac{\partial \phi(X)}{\partial B} < 0,$$

$$(5.11) \quad \frac{\partial \phi(X)}{\partial y} - (1-\mu)S \frac{\partial \phi(X)}{\partial B} > 0,$$

and

$$(5.12) \quad \frac{\partial \phi(X)}{\partial s} + rB \frac{\partial \phi(X)}{\partial B} + \alpha S \frac{\partial \phi(X)}{\partial S} + \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 \phi(X)}{\partial S^2} < -\theta,$$

where $X = (s, B, y, S) \in \mathcal{B}(X_0)$, a neighborhood of X_0 . In Lemma 1 it is shown that $\mathbf{X}_0^*(t)$ has no jumps, P -a.s., at $X_0 = \mathbf{X}_0^*(s_0)$. Hence, $\tau(\omega)$, defined by

$$(5.13) \quad \tau(\omega) = \inf \{t \in [s_0, T]: \mathbf{X}_0^*(t) \notin \mathcal{B}(X_0)\},$$

is positive P -a.s., and therefore

$$\begin{aligned}
 -\theta \mathbb{E}\{\tau\} &\geq \mathbb{E} \int_{s_0}^{\tau} \left(\frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial y} - (1+\lambda) \mathbf{S}_0^*(t) \frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial B} \right) d\mathbf{L}^*(t) \\
 &\quad - \mathbb{E} \int_{s_0}^{\tau} \left(\frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial y} - (1-\mu) \mathbf{S}_0^*(t) \frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial B} \right) d\mathbf{M}^*(t) \\
 (5.14) \quad &\quad + \mathbb{E} \int_{s_0}^{\tau} \left(\frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial s} + r \mathbf{B}_0^*(t) \frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial B} \right. \\
 &\quad \left. + \alpha \mathbf{S}_0^*(t) \frac{\partial \phi(\mathbf{X}_0^*(t))}{\partial S} + \frac{1}{2} \sigma^2 (\mathbf{S}_0^*(t))^2 \frac{\partial^2 \phi(\mathbf{X}_0^*(t))}{\partial S^2} \right) dt \\
 &= \mathbb{E}\{I_1\} - \mathbb{E}\{I_2\} + \mathbb{E}\{I_3\},
 \end{aligned}$$

where $(\mathbf{L}^*(t), \mathbf{M}^*(t))$ is the optimal trading strategy at X_0 . Applying Itô's formula to $\phi(X)$, where the state dynamics are given by (4.2)–(4.4), we get

$$(5.15) \quad \mathbb{E}\{\phi(\mathbf{X}_0^*(\tau))\} = \phi(X_0) + \mathbb{E}\{I_1\} - \mathbb{E}\{I_2\} + \mathbb{E}\{I_3\}.$$

Since $V(X) \leq \phi(X)$, for all $X \in \mathcal{B}(X_0)$, and $V_1(X_0) = \phi(X_0)$, (5.14) and (5.15) yield

$$(5.16) \quad \mathbb{E}\{V_1(\mathbf{X}_0^*(\tau))\} \leq V_1(X_0) + (\mathbb{E}\{I_1\} - \mathbb{E}\{I_2\} + \mathbb{E}\{I_3\}) < V_1(X_0) - \theta \mathbb{E}\{\tau\},$$

which violates the dynamic programming principle, together with the optimality of $(\mathbf{L}^*(t), \mathbf{M}^*(t))$. Therefore, at least one of the arguments inside the minimum operator of (5.6) is nonpositive, and hence the value function is a viscosity subsolution of (5.5).

(ii) In the second part of the proof, we show that V_1 is a viscosity supersolution of (5.5) in $[0, T] \times \mathcal{E}_K$; for this we must show that, for all smooth functions $\phi(X)$, such that $V_1(X) - \phi(X)$ has a local minimum at $X_0 \in [0, T] \times \mathcal{E}_K$, the following inequality holds:

$$\begin{aligned}
 (5.17) \quad \min \left\{ - \left(\frac{\partial \phi(X_0)}{\partial y} - (1+\lambda) S_0 \frac{\partial \phi(X_0)}{\partial B} \right), \frac{\partial \phi(X_0)}{\partial y} - (1-\mu) S_0 \frac{\partial \phi(X_0)}{\partial B}, \right. \\
 \left. - \left(\frac{\partial \phi(X_0)}{\partial s} + r B_0 \frac{\partial \phi(X_0)}{\partial B} + \alpha S_0 \frac{\partial \phi(X_0)}{\partial S} + \frac{1}{2} \sigma^2 S_0^2 \frac{\partial^2 \phi(X_0)}{\partial S^2} \right) \right\} \geq 0,
 \end{aligned}$$

where, without loss of generality, $V_1(X_0) = \phi(X_0)$ and $V_1 \geq \phi$ on $[0, T] \times \bar{\mathcal{E}}_K$. In this case, we prove that each argument of the minimum operator of (5.17) is nonnegative.

Consider the trading strategy $\mathbf{L}(t) = L_0 > 0$, $s_0 \leq t \leq T$, and $\mathbf{M}(t) = 0$, $s_0 \leq t \leq T$. By the dynamic programming principle,

$$(5.18) \quad V_1(s_0, B_0, y_0, S_0) \geq V_1(s_0, B_0 - (1+\lambda) S_0 L_0, y_0 + L_0, S_0).$$

This inequality holds for $\phi(s, B, y, S)$ as well, and, by taking the left-hand side to the right-hand side, dividing by L_0 , and sending $L_0 \rightarrow 0$, we get

$$(5.19) \quad \frac{\partial \phi(X_0)}{\partial y} - (1+\lambda) S_0 \frac{\partial \phi(X_0)}{\partial B} \geq 0.$$

Similarly, by using the trading strategy $\mathbf{L}(t) = 0$, $s_0 \leq t \leq T$, and $\mathbf{M}(t) = M_0 > 0$, $s_0 \leq t \leq T$, the second argument inside the minimum operator is found to be nonnegative.

Finally, consider the case where no trading is applied. By the dynamic programming principle

$$(5.20) \quad \mathbb{E}\{V_1(\mathbf{X}_0^d(t))\} \leq V_1(s_0, B_0, y_0, S_0),$$

where $\mathbf{X}_0^d(t)$ is the state trajectory when $\mathbf{M}(t) = \mathbf{L}(t) = 0$, $s_0 \leq t \leq T$, given by (4.2)–(4.4) as

$$(5.21) \quad \mathbf{X}_0^d(t) = (t, B_0 \exp(r(t-s_0)), y_0, S_0 \exp((\alpha - \frac{1}{2}\sigma^2)(t-s_0) + \sigma(\mathbf{R}(t) - \mathbf{R}(s_0))))$$

and $\mathbf{X}_0^d(t) \in \mathcal{B}(X_0)$. Therefore, by applying Itô's rule on $\phi(s, B, y, S)$, inequality (5.20) yields

$$(5.22) \quad \mathbb{E} \left\{ \int_{s_0}^t \left(\frac{\partial \phi(\mathbf{X}_0^d(\xi))}{\partial s} + r \mathbf{B}_0^d(\xi) \frac{\partial \phi(\mathbf{X}_0^d(\xi))}{\partial B} + \alpha \mathbf{S}_0^d(\xi) \frac{\partial \phi(\mathbf{X}_0^d(\xi))}{\partial S} + \frac{1}{2} \sigma^2 (\mathbf{S}_0^d(\xi))^2 \frac{\partial^2 \phi(\mathbf{X}_0^d(\xi))}{\partial S^2} \right) d\xi \right\} \geq 0,$$

and, by sending $t \rightarrow s_0$, the third argument inside the minimum operator is found to be nonnegative (for detailed proof, see Lions [17]). This completes the proof. \square

LEMMA 1. Assume that inequality (5.7) holds and denote the event that the optimal trajectory $\mathbf{X}_0^*(t)$ has a jump of size ε , along the direction $(0, -(1+\lambda)S_0, 1, 0)$, by $A(\omega)$. Assume that the state (after the jump) is $(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0) \in \mathcal{B}(X_0)$. Then

$$(5.23) \quad \left(\frac{\partial \phi(X_0)}{\partial y} - (1+\lambda)S \frac{\partial \phi(X_0)}{\partial B} \right) P(A) \geq 0,$$

and therefore $P(A) = 0$. Similarly, if inequality (5.8) holds, then the optimal trajectory has no jumps along the direction $(0, (1-\mu)S_0, -1, 0)$, P -a.s. at X_0 .

Proof. By the principle of dynamic programming,

$$(5.24) \quad \begin{aligned} V_1(s_0, B_0, y_0, S_0) &= \mathbb{E}\{V_1(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0)\} \\ &= \int_{A(\omega)} V_1(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0) dP \\ &\quad + \int_{\Omega - A(\omega)} V_1(s_0, B_0, y_0, S_0) dP, \end{aligned}$$

and therefore

$$(5.25) \quad \int_{A(\omega)} (\phi(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0) - \phi(s_0, B_0, y_0, S_0)) dP \geq 0,$$

since $V_1(X) \leq \phi(X)$ for all $X \in \mathcal{B}(X_0)$ and $V_1(X_0) = \phi(X_0)$. Therefore,

$$(5.26) \quad \limsup_{\varepsilon \rightarrow 0} \left\{ \int_{A(\omega)} \frac{\phi(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0) - \phi(s_0, B_0, y_0, S_0)}{\varepsilon} dP \right\} \geq 0,$$

and, by Fatou's lemma,

$$(5.27) \quad \int_{A(\omega)} \limsup_{\varepsilon \rightarrow 0} \left\{ \frac{\phi(s_0, B_0 - (1+\lambda)S_0\varepsilon, y_0 + \varepsilon, S_0) - \phi(s_0, B_0, y_0, S_0)}{\varepsilon} \right\} dP \geq 0,$$

which implies (5.23). \square

This section is concluded by showing that the value function V_1 is the unique bounded constrained viscosity solution of (5.5). Since this uniqueness result will be used mainly for the convergence of the numerical scheme presented in the next section, we prove the theorem for the exponential utility function. For simplicity of exposition, we assume that the interest rate $r = 0$. The argument is the same but notationally more cumbersome when $r > 0$.

THEOREM 3. *Let u be a bounded upper semicontinuous viscosity subsolution of (5.5) on $[0, T] \times \bar{\mathcal{E}}_K$, and let v be a bounded from below lower semicontinuous viscosity supersolution of (5.5) in $[0, T] \times \mathcal{E}_K$, such that $u(T, x) \leq v(T, x)$, for all $x \in \bar{\mathcal{E}}_K$, and $u(t, B, y, 0) \leq v(t, B, y, 0)$, on $[0, T] \times \bar{\mathcal{E}}_K$, where $u(T, x) = 1 - \exp(-\gamma(B + c(y, S)))$ and $u(t, B, y, 0) = 1 - \exp(-\gamma B)$. Then $u \leq v$ on $[0, T] \times \bar{\mathcal{E}}_K$.*

Note. The proof relies on arguments used in § v of Ishii and Lions [12]; only the main steps are presented.

Proof. Sketch. We first construct a positive strict supersolution of (5.5) in $[0, T] \times \mathcal{E}_K$. To this end, let $h: [0, T] \times \mathcal{E}_K \rightarrow \mathbb{R}^+$ be given by $h(t, B, y, S) = 1 - \exp(-\gamma(B + kyS)) + C_1(T - t) + C_2$, where the constants k , C_1 , and C_2 satisfy

$$(5.28) \quad 1 + \lambda > k > 1 - \mu, \quad C_1 > \frac{\alpha^2}{2\sigma^2} \exp(\gamma K), \quad \text{and } C_2 > \exp(K) - 1.$$

Then

$$(5.29) \quad \begin{aligned} & H(X, h_t, Dh, D^2h) \\ &= \min \left\{ -\frac{\partial h}{\partial y} + (1 + \lambda)S \frac{\partial h}{\partial B}, \frac{\partial h}{\partial y} - (1 - \mu)S \frac{\partial h}{\partial B}, -\frac{\partial h}{\partial s} - \alpha S \frac{\partial h}{\partial S} - \frac{1}{2} \sigma^2 S^2 \frac{\partial^2 h}{\partial S^2} \right\} \\ &= \exp(-\gamma(B + kyS)) \\ &\quad \cdot \min \left\{ \gamma S(1 + \lambda - k), \gamma S(k - (1 - \mu)), \right. \\ &\quad \left. C_1 \exp(\gamma(B + kyS)) + \frac{1}{2} \gamma^2 k^2 \sigma^2 (yS)^2 - \alpha k \gamma (yS) \right\}. \end{aligned}$$

Using (5.28) and the fact that the minimum value of the quadratic $\mathcal{Q}(\xi) = \frac{1}{2} \gamma^2 k^2 \sigma^2 \xi^2 - \alpha \gamma k \xi$ is $-\alpha^2/2\sigma^2$, the above inequality yields

$$(5.30) \quad \begin{aligned} & H(X, h_t, Dh, D^2h) \\ &> \exp(-\gamma(B + kyS)) \min \{ \gamma S(1 + \lambda - k), \gamma S(k - (1 - \mu)), K' \} \end{aligned}$$

in $[0, T] \times \bar{\mathcal{E}}_K$, where $0 < K' < C_1 - (\alpha^2/2\sigma^2) \exp(\gamma K)$.

Therefore, h is a strict supersolution (5.5). The fact that $h > 0$ follows from the choice of the constant C_2 .

To conclude the proof of the theorem, we will need the following key lemma. Its proof follows along the lines of Theorem vi.5 in Ishii and Lions [12], and therefore it is omitted.

LEMMA 2. *Let u be a bounded lower semicontinuous viscosity subsolution of (5.5) on $[0, T] \times \bar{\mathcal{E}}_K$, and let v be a bounded from below uniformly continuous viscosity supersolution of (5.5) in $[0, T] \times \mathcal{E}_K$ of the equation $H(X, v_t, Dv, D^2v) - f(x) = 0$, where $f > 0$ in \mathcal{E}_K , $u(T, x) \leq v(T, x)$, for all $x \in \bar{\mathcal{E}}_K$, and $u(t, B, y, 0) \leq v(t, B, y, 0)$, on $[0, T] \times \bar{\mathcal{E}}_K$. Then $u \leq v$ on $[0, T] \times \bar{\mathcal{E}}_K$.*

We now conclude the proof of the theorem. To this end, we first observe that, because of the choice of k , C_1 and C_2 ,

$$(5.31) \quad h(T, B, y, S) > 1 - \exp(-\gamma(B + c(y, S))) \quad \text{and} \quad h(t, B, y, 0) > 1 - \exp(-\gamma B).$$

Next, we define the function $w^\theta = \theta v + (1 - \theta)h$, where $0 < \theta < 1$, and, using (5.31), we get

$$(5.32) \quad w^\theta(T, B, y, S) \geq u(T, B, y, S) \quad \text{and} \quad w^\theta(t, B, y, 0) \geq u(t, B, y, 0).$$

We also observe that w^θ is a viscosity supersolution of $H - g = 0$, in $[0, T] \times \bar{\mathcal{E}}_K$, where $g = (1 - \theta)f$. In fact, let $\psi \in C^{1,2}([0, T] \times \mathcal{E}_K)$ and assume that $w^\theta - \psi$ has a minimum at X_0 . Then $v - \phi$ also has a minimum at X_0 , where $\phi = (1/\theta) \times (\psi - (1 - \theta)h)$. Using the fact that v is a viscosity supersolution of $H = 0$ and (5.30) we get

$$(5.33) \quad \begin{aligned} &\theta H(X_0, \phi_t(X_0), D\phi(X_0), D^2\phi(X_0)) \\ &+ (1 - \theta)H(X_0, h_t(X_0), Dh(X_0), D^2h(X_0)) \geq (1 - \theta)f(X_0). \end{aligned}$$

As the Hamiltonian $H(x, p, q, A)$ is jointly concave with respect to (p, q, A) , (5.33) yields

$$(5.34) \quad H(X_0, \psi_t(X_0), D\psi(X_0), D^2\psi(X_0)) \geq (1 - \theta)f(X_0),$$

which in turn implies that w^θ is a viscosity supersolution of $H - g = 0$. Finally, applying Lemma 2 to u and w^θ , we get

$$(5.35) \quad u \leq w^\theta \quad \text{on } [0, T] \times \bar{\mathcal{E}}_K,$$

and sending $\theta \uparrow 1$ concludes the proof of the theorem. \square

6. Discretisation and solution of the problem. The solution of the p.d.e. (4.20) is obtained by turning the stochastic differential equations (4.2)–(4.4) into Markov chains to apply the discrete time dynamic programming algorithm. The method here closely follows the one given in Martins and Kushner [15]. The discrete state is $\mathbb{X} = (\iota, \mathbb{B}, \eta, \mathbb{S})$, whose elements denote time, amount in the bank, number of shares, and stock price in a discrete space. The value functions, denoted by \mathbb{V}_1 and \mathbb{V}_w , are given a value at the final time by using the boundary conditions for the continuous value functions over the discrete subspace $(\mathbb{B}, \eta, \mathbb{S})$, and then they are estimated by proceeding backward in time by using the discrete time algorithm. As in the continuous time case, this algorithm is the same for both value functions and is derived below for a value function denoted by $\mathbb{V}_j^\rho(\iota, \mathbb{B}, \eta, \mathbb{S})$, where ρ is a discretisation parameter, which depends on the discrete time interval δt . If δt and the resolution of the η axis $\delta\eta$ are sent to zero, then the above discrete value function converges to a viscosity subsolution and a viscosity supersolution of the p.d.e. (4.20). Therefore, all the discrete value functions converge to their continuous counterparts; this is due to the uniqueness of the viscosity solution.

The discrete time variable ι takes values in $\{0, \delta t, 2\delta t, \dots, N\delta t\}$, where δt is the discrete time interval and $T - s = N\delta t$. The Markov chain for the discrete stock price process $\mathbb{S}(\iota)$ is modeled by

$$(6.1) \quad \mathbb{S}(\iota + 1) = \begin{cases} \mathbb{S}(\iota) \times k_u & \text{with probability } \frac{1}{2}, \\ \mathbb{S}(\iota) \times k_d & \text{with probability } \frac{1}{2}, \end{cases}$$

where the values of k_u and k_d are determined by equating the first and second moments of the chain with those of the diffusion, which describes S , and therefore

$$(6.2) \quad k_u = \exp(\alpha \delta t + \sigma \sqrt{\delta t}) \quad \text{and} \quad k_d = \exp(\alpha \delta t - \sigma \sqrt{\delta t}).$$

The discretisation scheme and its convergence properties are more thoroughly explained in Chapter 5 of Cox and Rubinstein [5]. The discrete time equation for the amount in the bank $\mathbb{B}(\iota)$ is

$$(6.3) \quad \mathbb{B}(\iota + 1) = \mathbb{B}(\iota) \exp(r \delta t),$$

which is a deterministic difference equation.

The discrete time dynamic programming principle is invoked, and the following discretisation scheme is proposed for the p.d.e. (4.20):

$$(6.4) \quad \mathcal{J}(\rho) \mathbb{V}_j^\rho - \mathbb{V}_j^\rho = 0,$$

where $\mathcal{S}(\rho)$ is an operator given by

$$(6.5) \quad \mathcal{S}(\rho)\mathbb{V}_j^\rho = \max \{ \mathbb{V}_j^\rho(\iota, \mathbb{B} - (1 + \lambda)\mathbb{S}\kappa\rho, \eta + \kappa\rho, \mathbb{S}), \mathbb{V}_j^\rho(\iota, \mathbb{B} + (1 - \mu)\mathbb{S}\kappa\rho, \eta - \kappa\rho, \mathbb{S}), \\ \mathbb{E}\{ \mathbb{V}_j^\rho(\iota + \rho, \mathbb{B} \exp(r\rho), \eta, \mathbb{S} \exp(\alpha\rho + \theta\sigma\sqrt{\rho})) \} \},$$

where $\rho = \delta t$, κ is a real constant and θ is a random variable taking values ± 1 with probability $\frac{1}{2}$ each. This scheme is based on the principle that the investor's policy is the choice of the optimum transaction, that is, to buy or sell or do nothing for a particular state given the value function for all the states in the next time instant. We next show that, as the discretisation parameter $\rho \rightarrow 0$, the solution \mathbb{V}_j^ρ of (6.4) converges to the value function V , or, equivalently, to the unique constrained viscosity solution of (4.20). Although the proof of the theorem follows along the lines of Barles and Souganidis [Thm. 2.1, p. 1], it is presented here for completeness.

THEOREM 4. *The solution \mathbb{V}_j^ρ of (6.4) converges locally uniformly as $\rho \rightarrow 0$ to the unique continuous constrained viscosity solution of (4.20).*

Proof. Let

$$(6.6) \quad V_j^\rho(t, B, y, S) = \begin{cases} \mathbb{V}_j^\rho(\iota, \mathbb{S}, \eta, \mathbb{B}), & \text{if } t \in [\iota, \iota + \rho), y \in [\eta, \eta + \kappa\rho), \\ \Phi_j(\mathbb{B}, \eta, \mathbb{S}), & \text{if } t = T \end{cases},$$

and

$$(6.7) \quad \underline{V}_j(X) = \liminf_{Y \rightarrow X, \rho \rightarrow 0} \{ \mathbb{V}_j^\rho(Y) \} \quad \text{and} \quad \bar{V}_j(X) = \limsup_{Y \rightarrow X, \rho \rightarrow 0} \{ \mathbb{V}_j^\rho(Y) \},$$

where $X = (t, B, y, S)$. We will show that \underline{V}_j and \bar{V}_j are a viscosity supersolution and a viscosity subsolution of (4.20), respectively. Combining this with the uniqueness result of Theorem 3 yields $\underline{V}_j \geq \bar{V}_j$ on $[0, T] \times \mathcal{E}_K$. The opposite inequality is true by the definition of \underline{V}_j and \bar{V}_j , and therefore,

$$(6.8) \quad \underline{V}_j(X) = \bar{V}_j(X) = V_j(X),$$

which, together with (6.7), also implies the local uniform convergence of \mathbb{V}_j^ρ to V_j (see [1]).

We will only prove that \underline{V}_j is a viscosity supersolution of (4.20), since the arguments for \bar{V}_j are identical. Let X_0 be a local minimum of $\underline{V}_j - \phi$ on $[0, T] \times \mathcal{E}_K$, for $\phi \in C^{1,2}([0, T] \times \mathcal{E}_K)$. Without loss of generality, we may assume that X_0 is a strict local minimum, that $\underline{V}_j(X_0) = \phi(X_0)$, and that $\phi \leq -2 \times \sup_\rho \{ \|\mathbb{V}_j^\rho\|_\infty \}$ outside the ball $\mathcal{B}(X_0, R)$, $R > 0$, where $\underline{V}_j(X) - \phi(X) \geq 0$.

Then there exist sequences $\rho_n \in \mathbb{R}^+$ and $Y_n \in [0, T] \times \mathcal{E}_K$, such that

$$(6.9) \quad \rho_n \rightarrow 0, Y_n \rightarrow X_0, \mathbb{V}_j^{\rho_n}(Y_n) \rightarrow \underline{V}_j(X_0), Y_n \text{ is a global minimum point of } \mathbb{V}_j^{\rho_n} - \phi.$$

Let $h_n = \mathbb{V}_j^{\rho_n} - \phi$; then

$$(6.10) \quad h_n \rightarrow 0 \quad \text{and} \quad \mathbb{V}_j^{\rho_n}(X) \geq \phi(X) + h_n(X) \quad \forall X \in [0, T] \times \mathcal{E}_K.$$

To show that \underline{V}_j is a viscosity supersolution of (4.20), it suffices to show that

$$(6.11) \quad \min \left\{ - \left(\frac{\partial \phi(X_0)}{\partial y} - (1 + \lambda) S_0 \frac{\partial \phi(X_0)}{\partial B} \right), \left(\frac{\partial \phi(X_0)}{\partial y} - (1 - \mu) S_0 \frac{\partial \phi(X_0)}{\partial B} \right), \right. \\ \left. - \left(\frac{\partial \phi(X_0)}{\partial s} + r B_0 \frac{\partial \phi(X_0)}{\partial B} + \alpha S_0 \frac{\partial \phi(X_0)}{\partial S} + \frac{1}{2} \sigma^2 S_0^2 \frac{\partial^2 \phi(X_0)}{\partial S^2} \right) \right\} \geq 0.$$

Let $Y_n = (t_{\rho_n}, \mathbb{B}_{\rho_n}, y_{\rho_n}, \mathbb{S}_{\rho_n})$, where $t_{\rho_n} \in [\iota_{\rho_n}, \iota_{\rho_n} + \rho_n)$ and $y_{\rho_n} \in [\eta_{\rho_n}, \eta_{\rho_n} + \kappa\rho_n)$. Then

$$\begin{aligned}
 & \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, y_{\rho_n}, \mathbb{S}_{\rho_n}) \\
 &= \max \{ \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n} - (1+\lambda)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} + \kappa\rho_n, \mathbb{S}_{\rho_n}), \\
 (6.12) \quad & \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n} + (1-\mu)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} - \kappa\rho_n, \mathbb{S}_{\rho_n}), \\
 & \mathbb{E}\{\mathbb{V}_j^{\rho_n}(\iota_{\rho_n} + \rho_n, \mathbb{B}_{\rho_n} \exp(r\rho_n), \eta_{\rho_n}, \mathbb{S}_{\rho_n} \exp(\alpha\rho_n + \theta\sigma\sqrt{\rho_n}))\} \}.
 \end{aligned}$$

Now we look at the following three cases.

Case 1. It holds that

$$\mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) = \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n} - (1+\lambda)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} + \kappa\rho_n, \mathbb{S}_{\rho_n}).$$

Then (6.10) implies that

$$\begin{aligned}
 (6.13) \quad & \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) \geq \phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n} - (1+\lambda)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} + \kappa\rho_n, \mathbb{S}_{\rho_n}) \\
 & + \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) - \phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}),
 \end{aligned}$$

and therefore

$$\begin{aligned}
 0 & \geq \liminf_n \left\{ \frac{\phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n} - (1+\lambda)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} + \kappa\rho_n, \mathbb{S}_{\rho_n}) - \phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n})}{\rho_n} \right\} \\
 (6.14) \quad & \geq \liminf_{\rho \rightarrow 0} \left\{ \frac{\phi(t_0, B_0 - (1+\lambda)S_0\kappa\rho, y_0 + \kappa\rho, S_0) - \phi(t_0, B_0, y_0, S_0)}{\rho} \right\} \\
 & = \frac{\partial \phi(X_0)}{\partial y} - (1+\lambda)S_0 \frac{\partial \phi(X_0)}{\partial B}.
 \end{aligned}$$

Case 2. It holds that

$$\mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) = \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n} + (1-\mu)\mathbb{S}_{\rho_n}\kappa\rho_n, \eta_{\rho_n} - \kappa\rho_n, \mathbb{S}_{\rho_n}).$$

Working similarly to the above case, we get

$$(6.15) \quad 0 \geq - \left(\frac{\partial \phi(X_0)}{\partial y} - (1-\mu)S_0 \frac{\partial \phi(X_0)}{\partial B} \right).$$

Case 3. It holds that

$$\mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) = \mathbb{E}\{\mathbb{V}_j^{\rho_n}(\iota_{\rho_n} + \rho_n, \mathbb{B}_{\rho_n} \exp(r\rho_n), \eta_{\rho_n}, \mathbb{S}_{\rho_n} \exp(\alpha\rho_n + \theta\sigma\sqrt{\rho_n}))\}.$$

Then (6.10) implies that

$$\begin{aligned}
 (6.16) \quad & \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) \\
 & \geq \mathbb{E}\{\phi(\iota_{\rho_n} + \rho_n, \mathbb{B}_{\rho_n} \exp(r\rho_n), \eta_{\rho_n}, \mathbb{S}_{\rho_n} \exp(\alpha\rho_n + \theta\sigma\sqrt{\rho_n}))\} \\
 & + \mathbb{V}_j^{\rho_n}(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}) - \phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n}),
 \end{aligned}$$

and therefore

$$\begin{aligned}
 0 & \geq \liminf_n \left\{ \frac{\phi(\iota_{\rho_n} + \rho_n, \mathbb{B}_{\rho_n} \exp(r\rho_n), \eta_{\rho_n}, \mathbb{S}_{\rho_n} \exp(\alpha\rho_n + \theta\sigma\sqrt{\rho_n})) - \phi(\iota_{\rho_n}, \mathbb{B}_{\rho_n}, \eta_{\rho_n}, \mathbb{S}_{\rho_n})}{\rho_n} \right\} \\
 (6.17) \quad & \geq \liminf_{\rho \rightarrow 0} \left\{ \frac{\phi(t_0 + \rho, B_0 \exp(r\rho), y_0, S_0 \exp(\alpha\rho + \theta\sigma\sqrt{\rho})) - \phi(t_0, B_0, y_0, S_0)}{\rho} \right\} \\
 & = \frac{\partial \phi(X_0)}{\partial s} + rB_0 \frac{\partial \phi(X_0)}{\partial B} + \alpha S_0 \frac{\partial \phi(X_0)}{\partial S} + \frac{1}{2} \sigma^2 S_0^2 \frac{\partial^2 \phi(X_0)}{\partial S^2}.
 \end{aligned}$$

Combining (6.14), (6.15), and (6.17) yields (6.11), and the proof is complete. \square

In the discrete time framework, the exponential utility function, given by (4.21), has the same effect on the value function as before, and therefore (4.25) can be written as follows:

$$(6.18) \quad \mathbb{V}_j(\iota, \mathbb{B}, \eta, \mathbb{S}) = 1 - \exp\left(-\gamma \frac{\mathbb{B}}{\Delta(N, \iota)}\right) \mathbb{Q}_j(\iota, \eta, \mathbb{S}),$$

where $\Delta(\nu, \nu')$ is the discrete time discount factor, given by

$$(6.19) \quad \Delta(\nu, \nu') = \exp(-r(\nu - \nu')),$$

where ν and ν' take values in the same set with ι and $\nu \geq \nu'$. The discretisation scheme for the new functions $\mathbb{Q}_j(\iota, \eta, \mathbb{S}) := 1 - \mathbb{V}_j(\iota, 0, \eta, \mathbb{S})$ is derived from (6.4) and (6.18) to be

$$(6.20) \quad \begin{aligned} \mathbb{Q}_j(\iota, \eta, \mathbb{S}) = \min \{ & \mathbb{F}_b(\iota, \zeta, \mathbb{S}) \times \mathbb{Q}_j(\iota, \eta + \zeta, \mathbb{S}), \\ & \mathbb{F}_s(\iota, \zeta, \mathbb{S}) \times \mathbb{Q}_j(\iota, \eta - \zeta, \mathbb{S}), \mathbb{E}\{\mathbb{Q}_j(\iota + \zeta, \eta, \Theta \times \mathbb{S})\} \}, \end{aligned}$$

where

$$(6.21) \quad \mathbb{F}_b(\iota, \zeta, \mathbb{S}) = \exp\left(\gamma \frac{(1 + \lambda)\mathbb{S}\zeta}{\Delta(N, \iota)}\right)$$

and

$$(6.22) \quad \mathbb{F}_s(\iota, \zeta, \mathbb{S}) = \exp\left(-\gamma \frac{(1 - \mu)\mathbb{S}\zeta}{\Delta(N, \iota)}\right),$$

and the boundary conditions at $\iota = N$ are given by the discrete space versions of (4.28) and (4.29). As in the continuous time case, if the value functions are known in the no-transaction region, then they can be calculated in the buy and sell regions by using the discrete space versions of (4.15) and (4.17): Suppose that η_b^* is the value of η , at which it is optimal to buy ζ shares, whereas, at $\eta = \eta_b^* + \zeta$ it is optimal to perform no transaction at all; then the function $\mathbb{Q}_j(\iota, \eta, \mathbb{S})$ is determined by

$$(6.23) \quad \mathbb{Q}_j(\iota, \eta, \mathbb{S}) = \mathbb{F}_b(\iota, \eta_b^* - \eta, \mathbb{S}) \times \mathbb{Q}_j(\iota, \eta_b^*, \mathbb{S}) \quad \forall \eta < \eta_b^*,$$

and a similar equation can be derived for $\eta > \eta_s^*$, the value of η at which it is optimal to sell ζ shares by using $\mathbb{F}_s(\iota, \eta - \eta_s^*, \mathbb{S})$. Finally, the price of the European contingent claim is given by

$$(6.24) \quad \mathbb{P}_w(\iota, \mathbb{S}) = \frac{\Delta(N, t)}{\gamma} \ln\left(\frac{\mathbb{Q}_w(\iota, 0, \mathbb{S})}{\mathbb{Q}_1(\iota, 0, \mathbb{S})}\right),$$

which is the discrete time version of (4.26).

7. Numerical results. The algorithm developed in the previous section was implemented, and the writing price of a European call option was calculated for a writer with exponential utility function given by (4.21) and for constant model coefficients. For comparison, the Black-Scholes value was also calculated from

$$(7.1) \quad p_{bs}(s, S) = SN(\chi) - Ee^{-r(T-s)}N(\chi - \sigma\sqrt{T-s}),$$

where

$$(7.2) \quad \chi = \frac{\ln(S/Ee^{-r(T-s)})}{\sigma\sqrt{T-s}} + \frac{1}{2}\sigma\sqrt{T-s},$$

and $N(\cdot)$ denotes the normal distribution function with mean zero and variance 1. The number of stock units held in the hedging portfolio is simply $N(\chi)$. The boundary conditions for the value functions were set according to the analysis presented in § 1, and several values of proportional transaction costs were tried. The effects on p_w of the model parameters, the time to expiration, and the stock price at the time the option is written were in line with expectations and are outlined below. The parameters λ and μ were set equal to each other and are denoted by T.C. in the figures.

For both value functions, the boundaries ∂B and ∂S were found to lie below and above the optimal trading strategy without transaction costs, and the no-transaction region was observed to widen as the expiration date approached. (Note that we have not proved that the optimal transaction policies consist of reflection off these boundaries, although, of course, we believe this to be the case.) This shows that the investor is reluctant to transact toward the end of the trading interval, as he thinks that the stock price may not vary too much until the final time. (The cost of transactions is likely to reduce the utility of the final wealth more than the cost of providing one share at the final time.) Also, the boundary ∂B , for the value function $V_w(s, B, y, S)$, was virtually equal to the Black-Scholes trading strategy $N(\chi)$, indicating that the writer considers the cost of the obligation to provide one share of stock at the final time (if he does not already own it) as the most significant factor, affecting the trading strategy for this value function.

The most important result appears in Fig. 1, where the price difference $p_w - p_{bs}$ is plotted against time over a three-year period, with the parameter values for a one-year period shown in its title (p_{bs} is the Black-Scholes price, given by (7.1)). The expiration date is at the end of the third year, where both prices vanish, as the option is worthless. The price difference a long time before the expiration of the claim is equal to λS , which is the amount required to buy one share of the stock. The reason for this is revealed by observing $N(\chi)$ over the three time periods, plotted in Fig. 2 for the same parameter values. Although $S < E$, $N(\chi)$ increases as the time to expiration increases and dictates that the investor must own almost one share of the stock in a market with no transaction costs if the time to expiration is long enough. By that time, the extra price that the writer charges is the amount required to buy one share of the stock,

FIG 1. T.C. = 0.2 percent; $S = 19$; $E = 20$; $\gamma = 1.0$; $\sigma = 0.05$; $r = 8.5$ percent; $\alpha = 10$ percent.

FIG 2. $S = 19$; $E = 20$; $\sigma = 0.05$; $r = 8.5$ percent.

which is the “hedging” strategy of the option writer, who performs few transactions long before expiration because of the wide range of possible paths of the stock price until the final time. Also, as the final time approaches, the price difference shows a “hump,” which represents the period of active trading by the option writer. Finally, if $S > E$, the price difference is λS at the final time.

The variation of the peak of the price difference with the model parameters was investigated, and the following results were obtained. The “overshoot” ratio $((p_w - p_{b_s}) - \lambda S) / \lambda S$ was calculated, and it was observed that it is (i) a linear increasing function of the logarithm of the index of risk aversion γ (ii) a linear increasing function of the volatility σ , (iii) a decreasing function of the stock price S , (iv) a convex decreasing function of the proportional transaction charge $\lambda = \mu$, (v) a convex function of the interest rate r , and (vi) a linear decreasing function of the stock’s mean growth rate α . These results are illustrated in Figs. 3–8, where the relevant parameter values

FIG. 3. T.C. = 0.2 percent; $S = 9$; $E = 10$; $\sigma = 0.075$; $r = 7$ percent; $\alpha = 10$ percent.

FIG. 4. T.C. = 0.2 percent; $S = 29$; $E = 30$; $\gamma = 1.0$; $r = 7$ percent; $\alpha = 10$ percent.

FIG. 5. $S = 29$; $E = 30$; $\gamma = 2.0$; $\sigma = 0.075$; $r = 7$ percent; $\alpha = 10$ percent.

are shown in their titles. The results are interpreted as follows. As the writer becomes more risk averse, the boundaries ∂B and ∂S come closer to the optimal trading strategy without transaction costs, thus mandating more transactions and increasing the option price. The linearity with $\ln(\gamma)$ is probably due to the form of the utility function. As the volatility of the underlying risky security increases, the uncertainty facing the option writer is greater, and the option price increases, as is in the case without transaction costs. As the stock price increases over the exercise price, the price difference is λS ; at expiration, the Black-Scholes strategy $N(\chi)$ dictates holding one share of the stock until expiration, and the “hump” is small. As the transaction costs increase, λS increases; but the above ratio decreases as the writer tries to perform less transactions (the boundaries ∂B and ∂S move away from the optimal trading strategy without transaction costs). Finally, the mean growth rate α and the interest rate r have little effect on the above ratio as compared to other parameters.

FIG. 6. T.C. = 0.2 percent; $E = 60$; $\gamma = 1.0$; $\sigma = 0.075$; $r = 7$ percent; $\alpha = 10$ percent.

FIG. 7. T.C. = 0.2 percent; $S = 29$; $E = 30$; $\gamma = 1.0$; $\sigma = 0.075$; $\alpha = 10$ percent.

8. Concluding remarks. There are several directions in which our approach needs further investigation.

1. *Nonexponential utilities.* There is no issue of principle here, but only of a further increased computational load, since the reduction from four dimensions to three is no longer available. Since the risk averse writer's strategy is basically a hedging strategy, we believe that the form of the utility function is unimportant and that only its curvature at the origin plays any real role. If true, this would provide a justification for using the computationally simpler exponential function.

2. *Diversified portfolios.* As pointed out earlier, in our framework the writer may well wish to include other stocks (not just the one on which the option is written) in the hedging portfolio. Again, this simply increases the dimensionality of the problem. By allowing investment in other stocks we are enlarging the class of possible hedging strategies, and hence the option writing price will be reduced; we do not know, however, by how much.

FIG. 8. T.C. = 0.2 percent; $S = 29$; $E = 30$; $\gamma = 1.0$; $\sigma = 0.075$; $r = 5$ percent.

3. *American options.* Clearly, a similar approach could be taken to the pricing of American options. There is, however, a conceptual problem in that the buyer, not the writer, controls the exercise strategy, and the pricing problem must involve the solution of one more utility maximisation problem over all the exercising strategies available to the buyer. In particular, there seems no reason why the buyer should use the “frictionless exercise strategy” as described in § 6 of Karatzas [13]. The precise definition of the problem is currently under investigation.

4. *Equilibrium.* Under what circumstances will a writer and a buyer agree on a “deal,” i.e., a common price for an option contract in the framework we have described? This is a very important question; one that we do not claim to understand fully. It is possible to define a buying price in a way that mirrors our definition of the writing price, and this is what Hodges and Neuberger [11] do. In the notation of § 2, if the buyer forms a hedging portfolio whose composition at the exercise time T is (B, \underline{y}) then its cash value after exercise of the option is $B - E + c(\underline{y} + \underline{e}_1, \underline{S})$. Analogous to the definition (2.1) for V_w , we can therefore define

$$(8.1) \quad V_b(B) = \sup_{\pi \in \mathcal{T}(B)} \mathbb{E} \{ \mathcal{U}(\mathbf{B}^\pi(T) + I_{(S_1(T) \leq E)} c(\underline{y}^\pi(T), \underline{S}(T)) + I_{(S_1(T) > E)} [c(\underline{y}^\pi(T) + \underline{e}_1, \underline{S}(T)) - E] \}$$

and

$$(8.2) \quad B_b = \inf \{ B : V_b(B) \geq 0 \},$$

and the buying price p_b as

$$(8.3) \quad p_b = B_b - B_1,$$

where B_1 is given by (2.4). However, we do not believe this definition to be an appropriate one. The most obvious objection is that it is very hard to see how writer and buyer could ever agree on a price. Certainly $p_w \neq p_b$ if all parameters are the same for all calculations. One may hypothesise that writer and buyer agree on market parameters, but have different utility functions. This fails, however, because it is always the case that $p_w > p_{bs}$ and $p_b < p_{bs}$, where p_{bs} is the (preference-independent) Black-Scholes price. At a more fundamental level the above buying price seems inappropriate

because it fails to respect the essential asymmetry in an option contract, namely that buying an option is a form of insurance, whereas writing one is a gamble. This distinction disappears in the Black-Scholes world, as there is no essential element of risk on either side, but no general theory of option pricing can be satisfactory if this distinction is not taken into account. This is an interesting area for further research.

Acknowledgments. The starting point for this work was a preliminary version of the paper [11], presented by Stewart Hodges and Anthony Neuberger at a workshop organised by the Financial Options Research Centre of Warwick University in 1989. Readers of [11] will appreciate that several of the key ideas were introduced in that paper. Collaborative work on the present paper was initiated while the first and third authors were visiting the Graduate School of Business, Stanford University, December 1990. We would like to thank Darrell Duffie, Avi Mandelbaum and the Finance and Decision Sciences groups at the Graduate School of Business at Stanford University for this opportunity as well as for stimulating comments on the work in progress. We also appreciate some incisive comments by Lucien Foldes at the London School of Economics and Political Science and discussions with Helyette Geman, which clarified our thinking.

ESTIMATION OF THE QUADRATIC VARIATION OF NEARLY OBSERVED SEMIMARTINGALES WITH APPLICATION TO FILTERING*

JEAN PICARD†

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. Consider a filtering problem in which the available information is a noisy observation of a continuous semimartingale H_t . In the case of a high signal-to-noise ratio, it is proved that H_t and its quadratic variation can be jointly estimated by means of a finite-dimensional filter; moreover, for this result, the observation noise and H_t are not required to be independent. This problem can be viewed as a linear filtering problem with randomly time-varying parameters, and our filter is auto-adaptive with respect to changes of the parameters. These results are then applied to the nonlinear filtering of Markov diffusion processes when the observation function is not injective but satisfies a weaker detectability assumption. It appears that filtering such a system involves two timescales. The study is based on time discretization; the main tools are an averaging principle and an application of the asymptotic ordinary differential equation method for the study of stochastic algorithms.

Key words. nonlinear filtering, systems with small noise, linear filtering with unknown parameters, adaptive filtering, averaging principle, stochastic algorithms

AMS(MOS) subject classifications. 93E11, 60G35, 62F35

Introduction. The problem of nonlinear filtering consists in estimating some stochastic process that is not directly observed. Recently, many works were devoted to the case where the process is nearly observed; this is indeed an asymptotic framework in which several computable filters can be mathematically studied. More precisely, suppose that the observation is the d -dimensional process Y_t , which is given by

$$(0.1) \quad Y_t = \int_0^t H_s ds + \varepsilon B_t,$$

where H_t is an adapted continuous process, B_t is a standard Wiener process independent of H_t and ε is a nonnegative parameter. If $\varepsilon = 0$, then H_t is adapted to the filtration \mathcal{Y}_t generated by Y_t ; we will say that H_t is observable. Similarly, any process Z_t that is adapted to the filtration of H is observable. If ε is positive and small, we may expect that such a process is asymptotically observable; we can indeed prove with the method of [17] that, if Z_t is integrable, then its conditional mean, given \mathcal{Y}_t , denoted by \hat{Z}_t , converges to Z_t in L^1 as ε tends to zero. However, the exact computation of \hat{Z}_t generally requires us to solve an infinite-dimensional equation, so we look for a computable approximation. This means that we must find an observable process \bar{Z}_t , which is obtained by solving a finite-dimensional equation and such that $\|Z_t - \bar{Z}_t\|_1$ tends to zero as $\varepsilon \rightarrow 0$. Another problem consists in estimating $\hat{Z}_t - \bar{Z}_t$; it has at most the order of $Z_t - \bar{Z}_t$, but can be much smaller if the filter is efficient.

An important case is the filtering of diffusion processes; we suppose that $H_t = h(X_t)$, where X_t is a n -dimensional diffusion process given by

$$(0.2) \quad dX_t = f(X_t)dt + g(X_t)dW_t.$$

Assuming that the smooth coefficients (f, g, h) are such that X_t is adapted to the natural filtration of $h(X_t)$ (this is a detectability assumption), we want to design an efficient suboptimal filter. The easiest case is the case where h is injective; see [5], [12], [1] for the scalar case and [13], [14] for the multidimensional case. Under some additional conditions, it can be proved that the extended Kalman filter provides an observable process \bar{X}_t such that $X_t - \bar{X}_t$ and $\hat{X}_t - \bar{X}_t$ are, respectively, of order $\sqrt{\varepsilon}$ and ε ; this filter requires us to solve an equation of dimension $n(n+3)/2$, but we can also find a simplified filter of dimension n satisfying the same estimates. Moreover, a deviation in the filter at time t (caused, for instance, by an aberrant observation) is forgotten after time t with an exponential rate of order $1/\varepsilon$; we say that the memory length is of order ε (some formal definitions of the memory length are proposed in [10]). More recently, conditions that are more general than the injectivity of h have been considered; in these cases, we can again find approximate filters, but $X_t - \bar{X}_t$ is generally larger than $\sqrt{\varepsilon}$. A first example is the case where $h'g = 0$ and $x \mapsto (h(x), Lh(x))$ injective, where h' is the Jacobian matrix of h and L is the generator of x ; this means that H_t is absolutely continuous and that X_t is a function of (H_t, \bar{H}_t) . A class of systems entering into this framework is studied in [18] and [11, §3], and we find a filter \bar{X}_t such that $X_t - \bar{X}_t$ is of order $\varepsilon^{1/4}$, $h(X_t) - h(\bar{X}_t)$ is of order $\varepsilon^{3/4}$, and the memory length is of order $\sqrt{\varepsilon}$. Thus the components of X_t are observed with different precisions but in the same timescale.

A second example is the case where $x \mapsto (h(x), h'gg^*h'^*(x))$ injective; if we let $\langle H, H \rangle_t$ be the quadratic covariation matrix of the process H_t , this assumption means that X_t is a function of H_t and $d\langle H, H \rangle_t/dt$, so that X_t is again adapted to the filtration of H_t . Note that, contrary to previous examples, this case is purely nonlinear, in the sense that a linear system cannot satisfy this injectivity condition except when h itself is injective. First, suppose that, for any h_0 , the set $\{h(x) = h_0\}$ is finite. Since we have a good observation of $h(X_t)$, then, to find an observable approximation of X_t , we must only choose between a finite number of possible approximations. This can be achieved by one of the test procedures described in [3]. Our results can be applied to the design of such a test, but we instead concentrate on the case where the sets $\{h(x) = h_0\}$ are connected manifolds. Then the filtering problem can be decomposed into, first, an estimation \bar{H}_t of $h(X_t)$ and, second, an estimation \bar{X}_t of X_t on the manifold $\{h(x) = \bar{H}_t\}$; a particular example has already been studied in [15]. Here, we find a family of observable processes \bar{X}_t , which can be computed by solving finite-dimensional equations and which approximate X_t . Their infinitesimal increment $d\bar{X}_t$ is obtained by adding a component due to the variations of $h(X_t)$ and a component that is tangent to $\{h(x) = h(\bar{X}_t)\}$ and that is due to the variations of the other components of X_t . Roughly speaking, these filters look like Kalman filters, but their gain processes are obtained from stochastic differential equations rather than Riccati equations. It is proved that $X_t - \bar{X}_t$ and $h(X_t) - h(\bar{X}_t)$ are, respectively, of order $\varepsilon^{1/4}$ and $\sqrt{\varepsilon}$, that $h(\bar{X}_t) - \bar{H}_t$ is of order $\varepsilon^{3/4}$, and that the memory length is of order ε for the estimation of $h(X_t)$, but only of order $\sqrt{\varepsilon}$ for the other components. Thus, the filter has two timescales; for detectable almost linear systems, it was proved in [6] that multitimescale filters are involved when the noises have different levels on the various components of X_t and Y_t . Here, multitimescale properties are a consequence of the geometric structure of the system.

Until now, we have explained the nature of our results for the filtering of diffusion processes; however, we will first consider this problem in a non-Markovian setting. This situation is much more general with regard to the assumptions, but we consider it easier to understand because we have not taken into account the geometric structure of the diffusion process. We also allow the signal and observation noises to be correlated.

We suppose that (H_t, Y_t) is an $(\mathbb{R}^d \times \mathbb{R}^d)$ -valued Itô process of the form

$$(0.3) \quad H_t = H_0 + \int_0^t F_s ds + \int_0^t G_s dW_s,$$

$$(0.4) \quad Y_t = \int_0^t H_s ds + \varepsilon \int_0^t J_s dW_s$$

for a standard m -dimensional Wiener process W_t and adapted processes F_t , G_t , and J_t . The problem of estimating H_t can be viewed as a linear filtering problem with time-varying unknown parameters (F_t, G_t, J_t) . The process H_t can be estimated with an error of order $\sqrt{\varepsilon}$ and a memory length of order ε , and we want to know which part of the parameters can be estimated. The Markovian case described above is then obtained by putting some nonlinear constraints on H_t and the parameters. First, it is clear that, by computing the quadratic variation of Y_t , $J_t J_t^*$ can be estimated with an arbitrary precision. On the other hand, F_t cannot generally be estimated with a small error. Take, for instance, $J_t = 0$, $G_t = I$, and $F_t = F$; then we observe a Wiener process with drift F , but it is well known that the drift can be identified only after a large amount of time. In this paper, we prove that $G_t G_t^*$ can be estimated with an error of order $\varepsilon^{1/4}$ and a memory length of order $\sqrt{\varepsilon}$; concerning the correlation between the noises, it appears that the skew-symmetric part of $G_t J_t^*$ can be estimated in the same conditions, but its symmetric part is generally not asymptotically observable. These results are proved by discretizing the time with the step $\varepsilon^{3/4}$, which is intermediate between the two timescales; thus, with respect to the phenomena occurring in the timescale ε , we can prove an averaging principle, and, with respect to the phenomena occurring in the timescale $\sqrt{\varepsilon}$, the discretized problem looks like the long-time behaviour of a stochastic algorithm with a small slowly varying gain. There exists a wide literature about stochastic algorithms, see, for instance [2], but our exposition will be self-contained. The main idea is that the behaviour of these algorithms can be approximately described by an ordinary differential equation. This tool was already applied in [9] and [16] to the estimation of fixed parameters in a linear system; here, the parameters are not constant but vary slowly with respect to the memory length of the filter. Observe, in particular, that the limiting differential equation involves random coefficients.

The approximate knowledge of the parameters enables us to improve the estimation of \hat{H}_t , so the next step consists of designing an adaptive filter that jointly estimates \hat{H}_t and the parameters. This can be done under stronger conditions, and it appears that \hat{H}_t can be computed with an error of order $\varepsilon^{3/4}$, even if the parameters cannot be identified; we say that the filter is self-tuning. The next step, which is not dealt with here, would consist in comparing the efficiency of the different filters concerning the parameter estimation; for this purpose, we must observe that the filtering problem actually contains two periods: First, we must estimate quickly and roughly the system for small times; if we have no knowledge on the initial conditions, this requires uniformly stable filters. Then, starting with these rough estimates, we must track the system as it evolves; as long as we neglect large deviations phenomena, this requires only locally stable filters. If we want to optimize the filter with respect to its local tracking properties, we obtain a filter that is locally (but not necessarily uniformly) stable. Thus we sometimes must use two different filters for the two periods. In this paper, we describe a filter that can be proved uniformly stable, and we introduce a wider class of locally stable filters.

These algorithms are then applied to the local tracking of Markovian diffusions observed with a small correlated noise. We suppose that the n -dimensional signal X_t

and the d -dimensional observation $Y_t (d < n)$ satisfy

$$(0.5) \quad dX_t = f(X_t) dt + g(X_t) dW_t,$$

$$(0.6) \quad dY_t = h(X_t) dt + \varepsilon j(X_t) dW_t.$$

We also suppose that jj^* and $h'g(I-j^*j)g^*h'^*$ are elliptic; this last condition means that there is some nondegenerate noise in $h(X_t)$ that is independent of the observation noise. If it is not satisfied, the filtering error may be too small for our method to work. Under these assumptions, the linear system

$$(0.7) \quad dH_t = h'g(x) dW_t, \quad dY_t = H_t dt + j(x) dW_t,$$

obtained by freezing the coefficients at x and normalizing the noise, admits a stationary Kalman filter, and we denote by $p(x)$ its gain. Then our local detectability condition is that $x \mapsto (h(x), p(x))$ is locally injective; under this condition and if X_0 is known, we can find a good filter \bar{X}_t that tracks X_t . Under the additional assumption $jj^* = I$, which implies that the filtering problem is not singular, we prove that $h(\bar{X}_t)$ is a good approximation of the conditional expectation of $h(X_t)$ given \mathcal{Y}_t . Observe that if, moreover, the noises are independent (this means that $fg^* = 0$), we have $p = (h'gg^*h'^*)^{1/2}$.

Let us now briefly describe the contents of this work. In § 1 we first set our notation. In § 1.1 we describe filters that do not necessarily give the best results but that work in a quite general framework. In § 1.2, under some additional assumptions, we describe some adaptive filters, and in § 1.3 we consider the Markovian case. These results are respectively proved in §§ 2–4.

1. The results. Throughout this work, we fix a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ with a filtration \mathcal{F}_t , and we let W_t be a standard m -dimensional \mathcal{F}_t -Wiener process. We suppose that \mathcal{F}_0 is trivial; this condition is not a restriction (if it is not satisfied, we can apply our results by working conditionally on \mathcal{F}_0) and is only used for notational convenience. It means that the initial condition of our system is unknown but deterministic. We also have a filtration $\mathcal{Y}_t \subset \mathcal{F}_t$ generated by an observation process Y_t , and \mathcal{Y}_t -adapted processes are said to be observable.

Let us set some definitions. If Z_t is a family (indexed by ε) of stochastic processes and if z_t is a family of deterministic positive functions, we say that Z_t is (at most) of order z_t , and we write $Z_t = O(z_t)$ if, for any $1 \leq k < \infty$,

$$(1.1) \quad \limsup_{\varepsilon \rightarrow 0} \sup_t \frac{\|Z_t\|_k}{z_t} < \infty$$

for t in some bounded or unbounded time interval (which will be made precise in the statements). If U is a family of events, we say that Z_t is of order z_t on U if $Z_t 1_U$ is of order z_t . The statement $Z_t - Z_s = O(\varepsilon^\beta)$ for $|t-s| \leq \varepsilon^\alpha$ means that

$$(1.2) \quad \limsup_{\varepsilon \rightarrow 0} \sup \{ \varepsilon^{-\beta} \|Z_t - Z_s\|_k ; |t-s| \leq \varepsilon^\alpha \} < \infty$$

for any k . We sometimes use the weaker notion of domination in probability; we say that Z_t is of order z_t in probability if

$$(1.3) \quad \lim_{\lambda \rightarrow \infty} \limsup_{\varepsilon \rightarrow 0} \sup_t \mathbb{P}[|Z_t| > \lambda z_t] = 0.$$

In particular, if Z_t is $O(\varepsilon^k)$ on an event of probability tending to 1, then Z_t is of order ε^k in probability. The notation $O(\varepsilon^\infty)$ means of order ε^k for any k . The set M_d is the space of $d \times d$ matrices; it is a Euclidean space with the product $\text{trace}(AB^*)$. The

subset of matrices, the eigenvalues of which have positive real part, will be denoted by M_d^+ . For A in M_d^+ , we put

$$(1.4) \quad A^\dagger = 2 \int_0^\infty e^{-A^*s} e^{-As} ds.$$

Observe that, if A is symmetric, A^\dagger is its inverse. A family of processes Z_t is said to be of class \mathcal{J} if Z_t are Itô processes such that $Z_0 = O(1)$ and

$$(1.5) \quad dZ_t = O(1)dt + O(1)dW_t.$$

For $\alpha \in \mathbb{R}$, we say that a family of M_d -valued processes A_t is exponentially stable in the timescale ε^α if the solution of

$$(1.6) \quad Z_t = I + \varepsilon^{-\alpha} \int_0^t A_s Z_s ds$$

satisfies

$$(1.7) \quad |Z_t Z_s^{-1}| \leq C \exp \{-c\varepsilon^{-\alpha}(t-s)\}$$

for some positive c and C . Examples of such processes are $A_t = -P_t$, where P_t is symmetric and uniformly elliptic, or $A_t = -P$, where P is in a compact subset of M_d^+ ; in these two examples, A_t is exponentially stable in any timescale. Other conditions ensuring the exponential stability will be given in Lemma 1.

1.1. Estimation of the signal and its quadratic variation. Consider the process (H_t, Y_t) defined by (0.3), (0.4) for some adapted processes F_t, G_t, J_t , which may depend on ε . We want to find observable approximations of the processes H_t, G_t , and J_t , assuming the knowledge of $J_t J_t^*$. The filter for H_t is given by

$$(1.8) \quad d\bar{H}_t = \bar{F}_t dt + \frac{\bar{P}_t}{\varepsilon} (dY_t - \bar{H}_t dt)$$

for some drift \bar{F}_t , some gain process \bar{P}_t , and some initial condition \bar{H}_0 .

THEOREM 1. Assume that H_t is of class \mathcal{J} , that $\bar{F}_t = O(1)$, that $J_t = O(1)$, and that $-\bar{P}_t$ is bounded and exponentially stable in the timescale ε . Then

$$(1.9) \quad H_t - \bar{H}_t = O(\sqrt{\varepsilon} + |H_0 - \bar{H}_0| e^{-ct/\varepsilon})$$

for some $c > 0$.

As is often the case for systems with small observation noise, the value of \bar{F}_t is not important for the efficiency of the filter. However, the dependence of \bar{H}_t on the process \bar{P}_t is crucial; the estimation of the parameters G_t and J_t is based on differentiation with respect to \bar{P}_t . For $E \in M_d$, let $\Gamma_t^E = \nabla_E \bar{H}_t$ be the derivative of \bar{H}_t with respect to a perturbation of \bar{P}_t in the direction E . We have

$$(1.10) \quad d\Gamma_t^E = -\frac{\bar{P}_t}{\varepsilon} \Gamma_t^E dt + \frac{E}{\varepsilon} (dY_t - \bar{H}_t dt)$$

with $\Gamma_0^E = 0$. The map $E \mapsto \Gamma_t^E$ is linear from M_d into \mathbb{R}^d , and let us denote it by $\Gamma_t = \nabla \bar{H}_t$. In particular, its adjoint Γ_t^* is linear from \mathbb{R}^d into M_d , and we can consider the M_d -valued observable process $\int \Gamma_t^* (dY_t - \bar{H}_t dt)$. Note that

$$(1.11) \quad \int_s^t \Gamma_u^* (dY_u - \bar{H}_u du) \simeq \int_s^t \Gamma_u^* (H_u - \bar{H}_u) du = -\frac{1}{2} \nabla \int_s^t |H_u - \bar{H}_u|^2 du.$$

We now describe the asymptotic value of this process as $\varepsilon \rightarrow 0$. To this end, we need the following elementary results about linear systems.

For G, J in M_d and $\bar{P} \in M_d^+$, consider the linear system

$$(1.12) \quad dh_t = GdW_t, \quad dy_t = h_t dt + JdW_t, \quad d\bar{h}_t = \bar{P}(dy_t - \bar{h}_t dt),$$

and let $\Lambda(G, J, \bar{P})$ be the limit of $\mathbb{E}|h_t - \bar{h}_t|^2$ as $t \rightarrow \infty$; the function $\Lambda(G, J, \bar{P})$ is the trace of the matrix-valued function $\bar{Q} = \bar{Q}(G, J, \bar{P})$ defined by

$$(1.13) \quad \bar{P}\bar{Q} + \bar{Q}\bar{P}^* = (G - \bar{P}J)(G - \bar{P}J)^*.$$

By differentiating with respect to \bar{P} in the direction E , we obtain

$$(1.14) \quad \bar{P}\nabla_E \bar{Q} + \nabla_E \bar{Q}\bar{P}^* + E\bar{Q} + \bar{Q}E^* + EJ(G - \bar{P}J)^* + (G - \bar{P}J)J^*E^* = 0,$$

so

$$(1.15) \quad \nabla_E \bar{Q} = -\int_0^\infty e^{-\bar{P}s}(E\bar{Q} + \bar{Q}E^* + EJ(G - \bar{P}J)^* + (G - \bar{P}J)J^*E^*)e^{-\bar{P}^*s} ds.$$

By taking the trace, we obtain

$$(1.16) \quad \nabla_E \Lambda = -\text{trace}(\bar{P}^\dagger RE^*),$$

where \bar{P}^\dagger and $R = R(G, J, \bar{P})$ are defined by (1.4) and

$$(1.17) \quad R = \bar{Q} + GJ^* - \bar{P}JJ^*.$$

Thus,

$$(1.18) \quad \nabla \Lambda(G, J, \bar{P}) = -\bar{P}^\dagger R(G, J, \bar{P}).$$

Let us return to system (0.3), (0.4) with time-varying coefficients and to the filter (1.8). By means of an averaging principle and from the previous calculation, it will be proved in Lemma 2 that, for $t - s \gg \varepsilon$, under some conditions including $\bar{P}_t \in M_d^+$, we have

$$(1.19) \quad \int_s^t |H_u - \bar{H}_u|^2 du \simeq \varepsilon \int_s^t \Lambda(G_u, J_u, \bar{P}_u) du,$$

$$(1.20) \quad \nabla \int_s^t |H_u - \bar{H}_u|^2 du \simeq -\varepsilon \int_s^t \bar{P}_u^\dagger R_u du$$

with $R_t = R(G_t, J_t, \bar{P}_t)$, and therefore from (1.11)

$$(1.21) \quad \int_s^t \Gamma_u^*(dY_u - \bar{H}_u du) \simeq \frac{\varepsilon}{2} \int_s^t \bar{P}_u^\dagger R_u du.$$

Thus, we have an observable approximation of $\bar{P}_t^\dagger R_t$; since \bar{P}_t^\dagger is known, we can deduce approximations of R_t . If $K > 0$ and if \bar{R}_t is solution of

$$(1.22) \quad d\bar{R}_t = \frac{K}{\varepsilon^{3/2}} \left(\Gamma_t^*(dY_t - \bar{H}_t dt) - \frac{\varepsilon}{2} \bar{P}_t^\dagger \bar{R}_t dt \right),$$

it appears that $R_t - \bar{R}_t$ is of order $\varepsilon^{1/4}$ for $t \gg \sqrt{\varepsilon}$.

THEOREM 2. Assume the conditions of Theorem 1 and suppose, moreover, that $H_0 - \bar{H}_0$ is of order $\sqrt{\varepsilon}$, that G_t and J_t are of class \mathcal{F} , that \bar{P}_t takes its values in a compact subset of M_d^+ , and that

$$(1.23) \quad \bar{P}_t - \bar{P}_s = O(\varepsilon^{3/8}), \quad \mathbb{E}[\bar{P}_t - \bar{P}_s | \mathcal{F}_s] = O(\sqrt{\varepsilon})$$

for $|t-s| \leq \varepsilon^{3/4}$. For $K > 0$, let \bar{R}_t satisfy (1.22) with $K > 0$ and $\bar{R}_0 = O(1)$. Then

$$(1.24) \quad R_t - \bar{R}_t = O(\varepsilon^{1/4} + |R_0 - \bar{R}_0|e^{-ct/\sqrt{\varepsilon}})$$

uniformly for $t \geq 0$.

On the other hand, we check from (1.13) and (1.17) that

$$(1.25) \quad G_t G_t^* = \bar{P}_t R_t^* + R_t \bar{P}_t^* + \bar{P}_t J_t J_t^* \bar{P}_t^*$$

and

$$(1.26) \quad G_t J_t^* - J_t G_t^* = R_t - R_t^* + \bar{P}_t J_t J_t^* - J_t J_t^* \bar{P}_t^*.$$

Thus, by replacing R_t by \bar{R}_t in these expressions, we deduce approximations for the quadratic variation of H_t and the skew-symmetric part of the quadratic covariation of H_t and Y_t . If we choose $\bar{P}_t = K'I$ for some $K' > 0$, the estimates for $G_t G_t^*$ and $G_t J_t^* - J_t G_t^*$ depend, respectively, only on the symmetric and skew-symmetric parts of $\Gamma_t^* x$, $x \in \mathbb{R}^d$, so that the estimation of these two quantities can be separated. Each of them requires only the computation of Γ_t^E for E symmetric, respectively, for E skew-symmetric; in particular, if we know that $G_t J_t^* = 0$ (independent case), we limit ourselves to E symmetric.

In the case where $J_t = 0$, the above result may still be applied and provides an approximation of the quadratic variation of an observable process H_t ; however, in this case, ε can be chosen arbitrarily, so the precision of the approximation is also arbitrary. This remark can be applied to the estimation of $J_t J_t^*$.

The symmetric part of $G_t J_t^*$ generally cannot be identified, as can be seen, for instance, for linear systems with an unknown parameter. Suppose that W_t is two-dimensional; that H_t is real; that θ is some real random parameter; that the conditional law of H_0 given θ is Gaussian with mean 0, variance $1 - \sin \theta$; and that

$$(1.27) \quad dH_t = \cos \theta dW_t^1 + \sin \theta dW_t^2,$$

$$(1.28) \quad dY_t = H_t dt + \varepsilon dW_t^2.$$

If \mathcal{Y}_t^θ is the filtration generated by θ and Y_t and if \hat{H}_t^θ is the conditional mean of H_t given \mathcal{Y}_t^θ , then \hat{H}_t^θ is given by the Kalman filter

$$(1.29) \quad \hat{H}_0^\theta = 0, \quad d\hat{H}_t^\theta = \frac{1}{\varepsilon} (dY_t - \hat{H}_t^\theta dt).$$

In particular, \hat{H}_t^θ is a Lipschitz function of $(Y_s, s \leq t)$; if we put

$$(1.30) \quad Y_t = \int_0^t \hat{H}_s^\theta ds + \varepsilon \beta_t^\theta,$$

then β_t^θ is a \mathcal{Y}_t^θ Wiener process, and Y_t is adapted to the filtration of β_t^θ . Since β^θ and θ are independent, it appears that Y and θ are independent, so the knowledge of Y does not give any information on θ . In particular, we cannot decide whether the signal and the observation noise are independent ($\theta = 0$). More generally, for the stationary filtering of linear systems with unknown parameter (G, J) such that $JJ^* = I$, parameters yielding the same gain in the Kalman filter are indistinguishable; this is also approximately true for time-varying parameters. To conclude this discussion, we can say that the stationary gain of the Kalman filter of the frozen system $(G, J) = (G_t, J_t)$ is the only quantity that can be identified; in particular, the process R_t estimated in Theorem 2 is a function of this gain. We will now explain how to directly estimate this gain.

1.2. Adaptive filters. Consider again the linear system (1.12) with coefficients (G, J) , suppose that JJ^* is invertible, and let

$$(1.31) \quad S = S(J) = I - J^*(JJ^*)^{-1}J$$

be the orthogonal projection on $\ker J$. Assume that GSG^* is invertible (this condition means that there is some nondegenerate noise in the signal that is independent of the observation noise); then the linear system admits a stationary Kalman filter. Its gain $P = P(G, J)$ is obtained as the solution of $R(G, J, P) = 0$ and is given by

$$(1.32) \quad P = (Q + GJ^*)(JJ^*)^{-1}$$

with $Q = Q(G, J)$ solution of

$$(1.33) \quad Q(JJ^*)^{-1}Q + GJ^*(JJ^*)^{-1}Q + Q(JJ^*)^{-1}JG^* = GSG^*.$$

Let us now return to the time-varying system (0.3), (0.4) and to the filter (1.8), and let us consider which is the best choice of \bar{P}_t for the estimation of H_t . If $P_t = P(G_t, J_t)$ is observable, then we should use $\bar{P}_t = P_t$. However, in our situation, G_t and J_t are not observable, so we want \bar{P}_t to be an approximation of P_t , and, moreover, we want to jointly estimate (H_t, P_t) . To this end, let us take the following viewpoint: We want to make $\int |H_t - \bar{H}_t|^2 dt$ as small as possible, and from (1.11) we have a good observable approximation of its gradient with respect to \bar{P}_t . Thus, we can use a gradient algorithm; for $K > 0$, we let \bar{P}_t be solution of

$$(1.34) \quad d\bar{P}_t = \frac{K}{\varepsilon^{3/2}} \Gamma_t^*(dY_t - \bar{H}_t dt).$$

THEOREM 3. Assume that G_t, J_t , and H_t are of class \mathcal{S} ; that G_t and J_t are bounded; that $J_t J_t^*$ and $G_t S_t G_t^*$ are uniformly elliptic; that $\bar{F}_t = O(1)$, and that $H_0 - \bar{H}_0 = O(\sqrt{\varepsilon})$. Let $P_t = P(G_t, J_t)$ be defined by (1.32) and consider the filter (1.8), (1.10), (1.34) with \bar{P}_0 in a compact subset of M_d^+ . Then

$$(1.35) \quad H_t - \bar{H}_t = O(\sqrt{\varepsilon}) \quad \text{and} \quad P_t - \bar{P}_t = O(\varepsilon^{1/4} + |P_0 - \bar{P}_0|e^{-ct/\sqrt{\varepsilon}})$$

on bounded time intervals, except on an observable event of probability $O(\varepsilon^\infty)$.

Remark 1. The rare event on which we cannot make our estimation is the set where \bar{P}_t becomes too large, too unstable, or has variations that are too fast. Observe indeed that, from our assumptions, P_t stays in a compact subset of M_d^+ ; however, nothing prevents \bar{P}_t from leaving this subset. It may even leave M_d^+ , and, in this case, the system becomes unstable. This can probably be remedied by modifying (1.34) near the boundary of M_d^+ , so that \bar{P}_t is constrained to stay in the above compact subset; after time discretization, the modified filter should reduce to a projected stochastic algorithm as described in [7].

Remark 2. As in § 1.1, we deduce estimates for the quadratic variation and covariation of H and Y via the formulas

$$(1.36) \quad G_t G_t^* = P_t J_t J_t^* P_t^*,$$

$$(1.37) \quad G_t J_t^* - J_t G_t^* = P_t J_t J_t^* - J_t J_t^* P_t^*,$$

which are proved from (1.32) and (1.33).

The filter of Theorem 3 is uniformly stable for the estimation of P_t in the sense that it identifies P_t even if P_0 is badly known. A wider class of filters is obtained by replacing K by a process K_t , taking its values in the space $M_{d \times d}$ of endomorphisms of M_d . If we assume that $P_0 - \bar{P}_0$ is small, we only need local stability on the filter and

obtain the following result: for K in $M_{d \times d}$, U, V in M_d , we let $\rho(K, U, V)$ be the endomorphism of M_d defined by

$$(1.38) \quad \rho(K, U, V): p \mapsto K[UpV].$$

THEOREM 4. *Assume that the conditions of Theorem 3 are satisfied, that $P_0 - \bar{P}_0$ is of order $\varepsilon^{1/4}$, and that K_t is a bounded observable $M_{(d \times d)}$ -valued process such that $K_t - K_s$ is of order $\varepsilon^{1/4}$ for $|t - s| \leq \varepsilon^{3/4}$ (in the sense of (1.2)). Suppose also that, for any bounded symmetric uniformly elliptic processes U_t, V_t of M_d , the process $-\rho(K_t, U_t, V_t)$ is exponentially stable in the timescale $\sqrt{\varepsilon}$. Consider the filter defined by (1.8), (1.10), and*

$$(1.39) \quad d\bar{P}_t = \frac{K_t}{\varepsilon^{3/2}} [\Gamma_t^*(dY_t - \bar{H}_t dt)].$$

Then $H_t - \bar{H}_t$ and $P_t - \bar{P}_t$ are, respectively, of order $\sqrt{\varepsilon}$ and $\varepsilon^{1/4}$ on bounded time intervals, except on an observable event of probability $O(\varepsilon^\infty)$.

Let us now look at the conditional mean \hat{H}_t of H_t given \mathcal{Y}_t . The filters of Theorem 1 satisfy $H_t - \bar{H}_t = O(\sqrt{\varepsilon})$, so, by conditioning on \mathcal{Y}_t , $\hat{H}_t - \bar{H}_t$ is also $O(\sqrt{\varepsilon})$. We now see that adaptive filters are better for the estimation of \hat{H}_t . The following result can be applied to the filters of Theorems 3 and 4.

THEOREM 5. *On a time interval $[T_0, T_1]$, suppose that G_t and J_t are bounded, that G_t, J_t , and H_t are of class \mathcal{F} , that $G_t S_t G_t^*$ is uniformly elliptic, and that $J_t J_t^* = I$. Suppose also that, for each ε fixed, there exists some $\alpha_\varepsilon > 0$ such that*

$$(1.40) \quad \sup_{T_0 \leq t \leq T_1} \mathbb{E} \exp \alpha_\varepsilon |F_t|^2 < \infty.$$

Let \bar{F}_t and \bar{P}_t be observable processes and consider the associate filter (1.8). We suppose that $\bar{F}_t = O(1)$ and that, except on an event of probability $O(\varepsilon^\infty)$, $H_t - \bar{H}_t$ and $P_t - \bar{P}_t$ are, respectively, $O(\sqrt{\varepsilon})$ and $O(\varepsilon^{1/4})$ on $[T_0, T_1]$. Then, for any $T'_0 \in (T_0, T_1)$, the process $\bar{H}_t - \hat{H}_t$ is of order $\varepsilon^{3/4}$ in probability on the time interval $[T'_0, T_1]$.

Remark. This result is false without the assumption on $J_t J_t^*$; if indeed $J_t J_t^*$ is random, then H_t may be observable, for instance, when H_t is a function of $J_t J_t^*$. In such a case, \hat{H}_t is equal to H_t , but $H_t - \bar{H}_t$ is not of order $\varepsilon^{3/4}$.

The next step would consist in giving a more precise estimation of $P_t - \bar{P}_t$ and in comparing the efficiency of the filters obtained for various gains K_t .

1.3. Filtering of Markov diffusion processes. In the Markovian case described in the Introduction, the processes P_t, Q_t , and S_t defined by (1.31)–(1.33), respectively, are equal to $p(X_t), q(X_t)$, and $\sigma(X_t)$, where

$$(1.41) \quad p = (q + h' g j^*)(j j^*)^{-1}, \quad \sigma = I - j^*(j j^*)^{-1} j,$$

$$q(j j^*)^{-1} q + h' g j^*(j j^*)^{-1} q + q(j j^*)^{-1} j g^* h'^* = h' g \sigma g^* h'^*.$$

We also use the function p^\dagger obtained from p by (1.4). We follow previous results, but we also must consider the geometric structure of the process (X_t, Y_t) . We are only interested here in the local tracking of X_t , so we suppose that $X_0 - \bar{X}_0$ is small.

THEOREM 6. *Let f, g, j , and h be fixed Borel functions defined on \mathbb{R}^n . Assume that f has at most linear growth at infinity; that g, j , and h' are C_b^2 ; that $j j^*$ and $h' g \sigma g^* h'^*$ are uniformly elliptic; that X_0 is bounded; and that (X_t, Y_t) is the solution of (0.5), (0.6). Let ϕ and ψ be fixed C_b^2 and C_b^1 functions, respectively, defined on \mathbb{R}^n such that, for each x , $\phi(x)$ is a linear map from \mathbb{R}^d into \mathbb{R}^n , $\psi(x)$ is a linear map from M_d into \mathbb{R}^n ; we suppose that $h' \phi = p$, that $h' \psi = 0$ (so that the image of $\psi(x)$ lies in $\ker h'(x)$), and that the real parts of the eigenvalues of the maps*

$$(1.42) \quad \rho(x): \ker h'(x) \rightarrow \ker h'(x), \quad \mu \mapsto \psi(x)[p^\dagger(x) \nabla_\mu p(x) j j^*(x)]$$

are bounded below by a positive constant. Let \bar{X}_t be the solution of

$$(1.43) \quad d\bar{X}_t = \frac{1}{\varepsilon} \phi(\bar{X}_t)(dY_t - h(\bar{X}_t) dt) + \frac{1}{\varepsilon^{3/2}} \psi(\bar{X}_t)[\Gamma_t^*(dY_t - h(\bar{X}_t) dt)],$$

$$(1.44) \quad d\Gamma_t^E = -\frac{1}{\varepsilon} p(\bar{X}_t) \Gamma_t^E dt + \frac{E}{\varepsilon} (dY_t - h(\bar{X}_t) dt).$$

Suppose that $X_0 - \bar{X}_0$ is of order $\varepsilon^{1/4}$ and that $h(X_0) - h(\bar{X}_0)$ is of order $\sqrt{\varepsilon}$. Then

$$(1.45) \quad X_t - \bar{X}_t = O(\varepsilon^{1/4}), \quad h(X_t) - h(\bar{X}_t) = O(\sqrt{\varepsilon})$$

on bounded time intervals, except on an event of probability $O(\varepsilon^\infty)$. Moreover, if $jj^* = I$ and if \hat{H}_t is the conditional expectation of $h(X_t)$ given \mathcal{Y}_t , then $\hat{H}_t - h(\bar{X}_t)$ is of order $\varepsilon^{3/4}$ in probability on any fixed time interval $[T_0, T_1] \subset (0, \infty)$.

Remark 3. We do not claim in this result that the rare event on which we cannot make our estimation is observable.

Remark 4. The ellipticity and boundedness assumptions imply that p takes its values in a compact subset of M_d^+ , so p^\dagger is bounded and elliptic. If $gj^* = 0$ (independent noise) and $jj^* = I$, then $p = (h'gg^*h'^*)^{1/2}$ is symmetric and $p^\dagger = p^{-1}$.

Remark 5. As in Theorem 5, the estimation of \hat{H}_t requires an additional assumption on jj^* ; it is indeed well known (see [17]) that the optimal filter is singular if $jj^*(x)$ depends on x . Without the assumption $jj^* = I$, we can only say that $h(\bar{X}_t)$ is the best approximation of $h(X_t)$ among filters of type (1.43).

Remark 6. Our conditions are local, so we must assume that $X_0 - \bar{X}_0$ is small. To drop this condition, we may conjecture that the stability condition should be the following one: For any fixed x and any \bar{x}_0 in the manifold $\{h(\bar{x}) = h(x)\}$, the solution of

$$(1.46) \quad \dot{\bar{x}}_t = -\psi(\bar{x}_t) \nabla \Lambda(g(x), j(x), p(\bar{x}_t))$$

converges to x as $t \rightarrow \infty$. Roughly speaking, the condition about the eigenvalues of $\rho(x)$ means that this holds for \bar{x}_0 in a neighbourhood of x .

Remark 7. As before, the next step would consist in estimating more precisely $X_t - \bar{X}_t$ to compare the efficiency of the filters corresponding to various ϕ and ψ . In the particular example of [15], a precise estimation of \hat{X}_t was derived; we found a filter \bar{X}_t such that $\hat{X}_t - \bar{X}_t$ and $\hat{H}_t - h(\bar{X}_t)$ are, respectively, $O(\sqrt{\varepsilon})$ and $O(\varepsilon)$. However, this example is particular in the sense that it is partly linear, and we do not know how to prove similar properties in the general case.

Example. Let us describe a filter satisfying the conditions of the theorem. It follows from the assumptions on the coefficients that $h'h'^*$ is invertible, so we can use

$$(1.47) \quad \phi = h'^*(h'h'^*)^{-1}p.$$

We can also let $\psi(x)$ be defined by its adjoint

$$(1.48) \quad \ker h'(x) \rightarrow M_d, \quad \mu \mapsto p^\dagger(x) \nabla_\mu p(x).$$

Then, for μ and ν in $\ker h'(x)$, we have

$$\begin{aligned} (\rho(x)\mu)^*\nu &= \text{trace}((\rho(x)\mu)\nu^*) \\ (1.49) \quad &= \text{trace}(\psi(x)[p^\dagger(x)\nabla_\mu p(x)jj^*(x)]\nu^*) \\ &= \text{trace}(p^\dagger(x)\nabla_\mu p(x)jj^*(x)\nabla_\nu p(x)^*p^\dagger(x)^*). \end{aligned}$$

In particular, $\rho(x)$ is symmetric, so the assumption on its eigenvalues is satisfied as soon as it is uniformly elliptic; this holds under the condition

$$(1.50) \quad |\nabla_{\mu} p(x)| \geq c|\mu|$$

for any μ in $\ker h'(x)$. This condition means that $x \mapsto (h(x), p(x))$ is locally injective.

2. Proofs of Theorems 1 and 2.

2.1. Exponentially stable systems and Theorem 1. We first summarize the basic properties of exponentially stable processes, which will be used later. Some of these properties were proved in [14]; see also [4].

LEMMA 1. *Let A_t be a bounded family of matrix-valued adapted processes. Then*

(1) *The three following conditions are equivalent:*

- (i) *The process A_t is exponentially stable in the timescale ε^{α} ;*
- (ii) *The solution λ_t of*

$$(2.1) \quad \varepsilon^{\alpha} \dot{\lambda}_t = A_t \lambda_t + \lambda_t A_t^* + I, \quad \lambda_0 = I$$

is bounded;

- (iii) *There exists an absolutely continuous process λ_t with values in symmetric matrices, such that $\lambda_0 \geq I$, λ_t is bounded and*

$$(2.2) \quad \varepsilon^{\alpha} \dot{\lambda}_t - A_t \lambda_t - \lambda_t A_t^* \geq I.$$

(2) *If A_t is exponentially stable in some timescale, then there exists a constant $C > 0$ such that any \bar{A}_t satisfying $|\bar{A}_t - A_t| \leq C$ is exponentially stable in the same timescale.*

(3) *Suppose that the real parts of the eigenvalues of A_t are bounded above by a negative constant, and that, for $|t - s| \leq \varepsilon^{\alpha}$, we have*

$$(2.3) \quad |A_t - A_s| \leq C\varepsilon^{\beta}$$

for some positive β and C ; then A_t is exponentially stable in the timescale ε^{α} .

(4) *Suppose that A_t is exponentially stable in the timescale ε^{α} , that Z_t satisfies*

$$(2.4) \quad dZ_t = \frac{1}{\varepsilon^{\alpha}} A_t Z_t dt + \frac{1}{\varepsilon^{\alpha}} f_t dt + \frac{1}{\varepsilon^{\alpha/2}} g_t dW_t,$$

and that f_t and g_t are of order ε^{γ} uniformly for $t \geq 0$. Then

$$(2.5) \quad Z_t = O(\varepsilon^{\gamma} + |Z_0|e^{-ct/\varepsilon^{\alpha}})$$

for some $c > 0$, uniformly for $t \geq 0$.

Proof of part (1). To prove that (i) implies (ii), note that, if Z_t is solution of (1.6)

$$(2.6) \quad \lambda_t = Z_t Z_t^* + \varepsilon^{-\alpha} \int_0^t Z_s Z_s^{-1} (Z_s Z_s^{-1})^* ds$$

is bounded from (1.7). It is immediate that (ii) implies (iii). To prove that (iii) implies (i), we look at the equation satisfied by $(Z_t Z_s^{-1})^* \lambda_t^{-1} Z_t Z_s^{-1}$ for $t \geq s$, and, by means of the inequality $\lambda_t^{-2} \geq \lambda_t^{-1}/|\lambda_t|$, we deduce that it decreases exponentially fast.

Proof of part (2). In condition (iii), it is clear that, by multiplying λ_t by a positive constant, we can replace the condition “ $\geq I$ ” by the condition “uniformly elliptic.” Since λ_t is bounded, this property also holds for \bar{A}_t in a neighbourhood of A_t .

Proof of part (3). Consider the time subdivision $s_i = i\varepsilon^{\alpha}$; define λ_{s_i} by

$$(2.7) \quad A_{s_i} \lambda_{s_i} + \lambda_{s_i} A_{s_i}^* + \gamma I = 0,$$

where $\gamma > 1$ is such that $\lambda_0 \geq I$; and let λ_t be the affine interpolation of these values. Then λ_t is bounded; moreover, for $s_i < t < s_{i+1}$, we have

$$(2.8) \quad |\lambda_t - \lambda_{s_i}| \leq C\varepsilon^\beta, \quad |\dot{\lambda}_t| \leq C\varepsilon^{\beta-\alpha},$$

so

$$(2.9) \quad \varepsilon^\alpha \dot{\lambda}_t - A_t \lambda_t - \lambda_t A_t^* \geq (\gamma - C\varepsilon^\beta) I \geq I$$

for ε small enough. Therefore, the exponential stability of A_t is deduced from the characterization (iii).

Sketch of the proof of part (4). We do not give the whole proof of this result, which is easily deduced from Lemma 1.3.2 of [14]. We take a process λ_t satisfying (iii), and, by applying Ito's formula, we write the differential increment of $Z_t^* \lambda_t^{-1} Z_t$. From (iii), we deduce that the moments of this process satisfy differential inequations, and therefore, we obtain estimates on these moments. \square

Remark. By considering the trace of λ_t^{-1} , it can be checked that a process λ_t satisfying (2.2) is uniformly elliptic as soon as A_t is bounded.

Proof of Theorem 1. By putting $Z_t = H_t - \bar{H}_t$, we have

$$(2.10) \quad dZ_t = -\frac{\bar{P}_t}{\varepsilon} Z_t dt + (F_t - \bar{F}_t) dt + (G_t - \bar{P}_t J_t) dW_t,$$

so we must only apply part (4) of Lemma 1. \square

2.2. An averaging principle. Assume the conditions of Theorem 2. Observe that part (4) of Lemma 1 implies that Γ_t is of order $\sqrt{\varepsilon}$. Since the estimation problem involves two timescales, the idea is to use a discretization of the time with a meshsize intermediate between the two timescales, more precisely, $\varepsilon^{3/4}$. Thus we define $t_i = i\varepsilon^{3/4}$. The notation $O_i(\varepsilon^\gamma)$ will mean of order ε^γ with zero conditional mean given \mathcal{F}_{t_i} .

Lemma 2, below, is an averaging principle; it will be basic in the proof of all our results. In classical results such as [8], we consider a fast ergodic process ξ_t and a slow process, which is solution of a stochastic differential equation, the coefficients of which depend on ξ_t . Then we prove that the behaviour of the slow component can be approximated by taking the average of the coefficients with respect to the invariant measure of ξ_t . In the proof of the following result, the statistics of the fast component are allowed to vary slowly.

LEMMA 2. *In the assumptions of Theorem 2, relax condition (1.23) on the oscillations of \bar{P} in the following one. We suppose that $\bar{P}_t - \bar{P}_s$ is of order $\varepsilon^{1/4}$ for $|t - s| \leq \varepsilon^{3/4}$. Then, for $i \geq 0$, we have*

$$(2.11) \quad \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} \Gamma_u^* (dY_u - \bar{H}_u du) = \frac{1}{2} \bar{P}_{t_i}^* R_{t_i} + O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}).$$

Proof. By developing dY_u , observe that

$$(2.12) \quad \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} \Gamma_u^* (dY_u - \bar{H}_u du) = \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} \Gamma_u^* (H_u - \bar{H}_u) du + O_i(\varepsilon^{1/8}).$$

Moreover, since Γ_u^* is the adjoint of Γ_u , for any E in M_d , we have

$$(2.13) \quad \text{trace} \left(\int_{t_i}^{t_{i+1}} \Gamma_u^* (H_u - \bar{H}_u) du E^* \right) = \int_{t_i}^{t_{i+1}} (H_u - \bar{H}_u)^* \Gamma_u^E du,$$

so it is sufficient to estimate this quantity for E fixed and prove that

$$(2.14) \quad \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} (H_u - \bar{H}_u)^* \Gamma_u^E du = \frac{1}{2} \text{trace} (\bar{P}_{t_i}^* R_{t_i} E^*) + O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}).$$

For $t_i \leq t < t_{i+1}$, consider the process (η_t, ξ_t) , which is the solution of

$$(2.15) \quad d\eta_t = -\frac{\bar{P}_{t_i}}{\varepsilon} \eta_t dt + \frac{G_{t_i} - \bar{P}_{t_i} J_{t_i}}{\sqrt{\varepsilon}} dW_t,$$

$$(2.16) \quad d\xi_t = -\frac{\bar{P}_{t_i}}{\varepsilon} \xi_t dt + \frac{E}{\varepsilon} \eta_t dt + \frac{E J_{t_i}}{\sqrt{\varepsilon}} dW_t,$$

with $\eta_t = (H_t - \bar{H}_{t_i})/\sqrt{\varepsilon}$ and $\xi_t = \Gamma_{t_i}^E/\sqrt{\varepsilon}$; observe that $\xi_t = -\nabla_E \eta_t$. The variables \bar{P}_{t_i} are in a compact subset of M_d^+ , so we can deduce from part (4) of Lemma 1 that η_t and ξ_t are $O(1)$. We have assumed that G_t and J_t are of class \mathcal{J} , so their oscillations on $[t_i, t_{i+1}]$ are of order $\varepsilon^{3/8}$; we have also assumed that the oscillations of \bar{P}_t are of order $\varepsilon^{1/4}$. Thus, by comparing the above equations with the equations of $H_t - \bar{H}_{t_i}$ and Γ_t^E and by applying part (4) of Lemma 1, we obtain that

$$(2.17) \quad \eta_t = \frac{H_t - \bar{H}_{t_i}}{\sqrt{\varepsilon}} + O(\varepsilon^{1/4}) \quad \text{and} \quad \xi_t = \frac{\Gamma_t^E}{\sqrt{\varepsilon}} + O(\varepsilon^{1/4}).$$

Conditionally on \mathcal{F}_{t_i} , the process (η_t, ξ_t) , $t_i \leq t < t_{i+1}$ is Gaussian; moreover, since \bar{P}_{t_i} is in a compact subset of M_d^+ , for $t_i \leq s \leq t < t_{i+1}$, the conditional covariance of (η_s, ξ_s) and (η_t, ξ_t) is of order $\exp(-c(t-s)/\varepsilon)$. In particular, the conditional covariance of $\eta_s^* \xi_s$ and $\eta_t^* \xi_t$ satisfies an estimate of the same type, so the conditional variance of $\varepsilon^{-3/4} \int_{t_i}^{t_{i+1}} \eta_u^* \xi_u du$ is of order $\varepsilon^{1/4}$. Thus

$$(2.18) \quad \begin{aligned} \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} (H_u - \bar{H}_{t_i})^* \Gamma_u^E du &= \varepsilon^{-3/4} \int_{t_i}^{t_{i+1}} \eta_u^* \xi_u du + O(\varepsilon^{1/4}) \\ &= \varepsilon^{-3/4} \int_{t_i}^{t_{i+1}} \mathbb{E}[\eta_u^* \xi_u | \mathcal{F}_{t_i}] du + O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}). \end{aligned}$$

Then, for $t_i \leq t < t_{i+1}$, we write the equations satisfied by $\eta_t \eta_t^*$ and $\eta_t \xi_t^*$, and we compute their conditional expectations. We deduce that with an error of order $\exp(-c(t-t_i)/\varepsilon)$, the conditional expectation of $\eta_t \eta_t^*$ is the asymptotic covariance error for the linear system with coefficients (G_{t_i}, J_{t_i}) and gain \bar{P}_{t_i} . Thus

$$(2.19) \quad \mathbb{E}[\eta_t \eta_t^* | \mathcal{F}_{t_i}] = \bar{Q}(G_{t_i}, J_{t_i}, \bar{P}_{t_i}) + O(e^{-c(t-t_i)/\varepsilon}).$$

Similarly, for $\eta_t \xi_t^*$, we check that we can differentiate the previous estimate, and we obtain

$$(2.20) \quad \mathbb{E}[\eta_t \xi_t^* + \xi_t \eta_t^* | \mathcal{F}_{t_i}] = -\nabla_E \bar{Q}(G_{t_i}, J_{t_i}, \bar{P}_{t_i}) + O(e^{-c(t-t_i)/\varepsilon}).$$

By taking the trace and using (1.16),

$$(2.21) \quad \begin{aligned} \mathbb{E}[\eta_t^* \xi_t | \mathcal{F}_{t_i}] &= -\frac{1}{2} \nabla_E \Lambda(G_{t_i}, J_{t_i}, \bar{P}_{t_i}) + O(e^{-c(t-t_i)/\varepsilon}) \\ &= \frac{1}{2} \text{trace}(\bar{P}_{t_i}^* R_{t_i} E^*) + O(e^{-c(t-t_i)/\varepsilon}), \end{aligned}$$

so, by integrating on $[t_i, t_{i+1}]$ and applying (2.18), estimate (2.14), which was required, is proved. \square

2.3. Linear stochastic algorithms and Theorem 2.

LEMMA 3. Let Z_t be a nonnegative adapted step process for the subdivision $t_i = i\varepsilon^{3/4}$. Suppose that $Z_0 = 0$ and that

$$(2.22) \quad Z_{t_{i+1}} \leq Z_{t_i} - c\varepsilon^{1/4} Z_{t_i} + (1 + \sqrt{Z_{t_i}})(O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}))$$

for some $c > 0$. Then Z_t is $O(1)$.

Proof. Let $k \geq 2$ be an integer. From the inequality

$$(2.23) \quad |(a+b)^k - a^k - ka^{k-1}b| \leq Ca^{k-2}b^2 + Cb^k$$

applied with $a+b$, the right-hand side of (2.22), and $a = Z_{t_i}(1 - c\varepsilon^{1/4})$, we obtain

$$(2.34) \quad \begin{aligned} Z_{t_{i+1}}^k &\leq Z_{t_i}^k(1 - c\varepsilon^{1/4})^k + (Z_{t_i}^{k-1/2} + Z_{t_i}^{k-1})O_i(\varepsilon^{1/8}) \\ &\quad + (Z_{t_i}^{k-1/2} + Z_{t_i}^{k-2})O(\varepsilon^{1/4}) + (1 + Z_{t_i}^{k/2})O(\varepsilon^{k/8}). \end{aligned}$$

By taking the expectation,

$$(2.25) \quad \begin{aligned} \mathbb{E}[Z_{t_{i+1}}^k] &\leq \mathbb{E}[Z_{t_i}^k](1 - c\varepsilon^{1/4})^k + \mathbb{E}[Z_{t_i}^{k-1/2}O(\varepsilon^{1/4})] \\ &\quad + \mathbb{E}[Z_{t_i}^{k-2}O(\varepsilon^{1/4})] + \mathbb{E}[Z_{t_i}^{k/2}O(\varepsilon^{k/8})] + O(\varepsilon^{k/8}). \end{aligned}$$

Thus, if we let u_i be the k th moment of Z_{t_i} , by using Hölder's inequality in the last three expectations of previous formula and the estimate

$$(2.26) \quad (1 - c\varepsilon^{1/4})^k = 1 - ck\varepsilon^{1/4} + O(\sqrt{\varepsilon}),$$

we obtain

$$(2.27) \quad \begin{aligned} u_{i+1} &= u_i - ck\varepsilon^{1/4}u_i + u_iO(\sqrt{\varepsilon}) + u_i^{(2k-1)/(2k)}O(\varepsilon^{1/4}) \\ &\quad + u_i^{(k-2)/k}O(\varepsilon^{1/4}) + (1 + \sqrt{u_i})O(\varepsilon^{k/8}). \end{aligned}$$

There is some constant $\gamma > 0$ such that, for ε small enough, $u_{i+1} - u_i \leq 0$ for $u_i \geq \gamma$; moreover, for $u_i \leq \gamma$, $u_{i+1} - u_i$ is of order $\varepsilon^{1/4}$. Thus

$$(2.28) \quad u_i \leq \gamma + O(\varepsilon^{1/4}) = O(1). \quad \square$$

LEMMA 4. Let A_t be a bounded adapted matrix-valued process that is exponentially stable in the timescale $\sqrt{\varepsilon}$ and such that $A_t - A_s$ is of order $\varepsilon^{1/4}$ for $|t - s| \leq \varepsilon^{3/4}$. Let Z_t be an adapted vector-valued step process such that $Z_t = O(1)$ and

$$(2.29) \quad Z_{t_{i+1}} = Z_{t_i} + \varepsilon^{1/4}A_{t_i}Z_{t_i} + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

Let z_t be the solution of

$$(2.30) \quad \dot{z}_t = \frac{1}{\sqrt{\varepsilon}}A_t z_t, \quad z_0 = Z_0.$$

Then $Z_t - z_t$ is of order $\varepsilon^{1/4}$; in particular,

$$(2.31) \quad Z_t = O(\varepsilon^{1/4} + |Z_0|e^{-ct/\sqrt{\varepsilon}}).$$

Proof. This lemma can be viewed as a discrete-time analogue of part (4) of Lemma 1; the recursive expression (2.29) can be interpreted as a stochastic algorithm, and (2.30) is the limiting ordinary differential equation. Since z_t is of order $|Z_0|e^{-ct/\sqrt{\varepsilon}}$, note that we must only prove the estimate on $Z_t - z_t$, and (2.31) will follow; moreover, from our assumption on the oscillations of A_t ,

$$(2.32) \quad z_{t_{i+1}} = z_{t_i} + \varepsilon^{1/4}A_{t_i}z_{t_i} + O(\sqrt{\varepsilon}).$$

Thus Z_t and $Z_t - z_t$ satisfy the same recursive estimate (2.29), and the proof can be reduced to the case where $Z_0 = 0$. Let λ_t be a process satisfying the conditions of the characterization (iii) of Lemma 1 and put $V_t = \lambda_t^{-1}$, so that V_t is bounded, uniformly elliptic, and

$$(2.33) \quad \sqrt{\varepsilon} \dot{V}_t + V_t A_t + A_t^* V_t \leq -cV_t.$$

By integrating this inequality,

$$(2.34) \quad \varepsilon^{-1/4}(V_{t_{i+1}} - V_{t_i}) + V_{t_i}A_{t_i} + A_{t_i}^*V_{t_i} \leq -cV_{t_i} + O(\varepsilon^{1/4}).$$

On the other hand, by writing the recursive formula satisfied by $Z_{t_i}^* V_{t_i} Z_{t_i}$ and by applying the recursive estimate (2.29) of Z_{t_i} , we obtain

$$(2.35) \quad \begin{aligned} Z_{t_{i+1}}^* V_{t_{i+1}} Z_{t_{i+1}} &= Z_{t_i}^* V_{t_i} Z_{t_i} + Z_{t_i}^* (V_{t_{i+1}} - V_{t_i} + \varepsilon^{1/4} A_{t_i}^* V_{t_i} + \varepsilon^{1/4} V_{t_i} A_{t_i}) Z_{t_i} \\ &\quad + |Z_{t_i}|^2 O(\sqrt{\varepsilon}) + |Z_{t_i}| (O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon})) + O(\varepsilon^{3/4}). \end{aligned}$$

We have assumed that $Z_t = O(1)$, so

$$(2.36) \quad |Z_{t_i}|^2 O(\sqrt{\varepsilon}) = |Z_{t_i}| O(\sqrt{\varepsilon}).$$

By also applying (2.34), we obtain

$$(2.37) \quad \begin{aligned} Z_{t_{i+1}}^* V_{t_{i+1}} Z_{t_{i+1}} &\leq Z_{t_i}^* V_{t_i} Z_{t_i} (1 - c\varepsilon^{1/4}) + |Z_{t_i}| (O_i(\varepsilon^{3/8}) \\ &\quad + O(\sqrt{\varepsilon})) + O(\varepsilon^{3/4}). \end{aligned}$$

Thus $Z_t^* V_t Z_t / \sqrt{\varepsilon}$ satisfies the assumptions of Lemma 3, and so is $O(1)$. \square

Proof of Theorem 2. We have

$$(2.38) \quad d\bar{R}_t = \frac{K}{\sqrt{\varepsilon}} \left(O(1) dt + O(\sqrt{\varepsilon}) dW_t - \frac{1}{2} \bar{P}_t^+ \bar{R}_t dt \right).$$

On the other hand, since \bar{P}_t lies in a compact subset of M_d^+ , we deduce that \bar{P}_t^+ is bounded and uniformly elliptic; thus it is exponentially stable in all timescales, and we deduce from part (4) of Lemma 1 that $\bar{R}_t = O(1)$. By again applying (2.38), the oscillations of \bar{R}_t on intervals of length $\varepsilon^{3/4}$ are shown to be of order $\varepsilon^{1/4}$; \bar{P}_t^+ satisfies the same condition, so

$$(2.39) \quad \bar{R}_{t_{i+1}} - \bar{R}_{t_i} = \frac{K}{\varepsilon^{3/2}} \int_{t_i}^{t_{i+1}} \Gamma_t^*(dY_t - \bar{H}_t dt) - \frac{K}{2} \varepsilon^{1/4} \bar{P}_{t_i}^+ \bar{R}_{t_i} + O(\sqrt{\varepsilon})$$

and, from Lemma 2,

$$(2.40) \quad \bar{R}_{t_{i+1}} - \bar{R}_{t_i} = \frac{K}{2} \varepsilon^{1/4} \bar{P}_{t_i}^+ (R_{t_i} - \bar{R}_{t_i}) + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

On the other hand, $R_t = R(G_t, J_t, \bar{P}_t)$, and R is a smooth function; since G_t and J_t are of class \mathcal{F} and from assumption (1.23) about the oscillations of \bar{P}_t , we have

$$(2.41) \quad R_{t_{i+1}} - R_{t_i} = O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

Thus the step process Z_t defined by $Z_{t_i} = R_{t_i} - \bar{R}_{t_i}$ satisfies the assumptions of Lemma 4 and therefore is of order $\varepsilon^{1/4} + |Z_0| e^{-ct/\sqrt{\varepsilon}}$. \square

3. Proofs of Theorems 3–5.

3.1. Nonlinear stochastic algorithms.

LEMMA 5. *Let Z_t be a bounded adapted step process associated to the subdivision (t_i) , with values in a Euclidean space E . We suppose that*

$$(3.1) \quad Z_{t_{i+1}} = Z_{t_i} + \varepsilon^{1/4} b(\beta_{t_i}, Z_{t_i}) + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}),$$

where β_t is a process of class \mathcal{F} taking its values in a compact subset \mathcal{H}_0 of a Euclidean space, and b is a smooth function on $\mathcal{H}_0 \times E$; we denote $b' = \partial b / \partial z$. We also suppose that $b(\beta, 0) = 0$ for any β , that the real parts of the eigenvalues of $b'(\beta, 0)$ are bounded above by a negative constant, that $b'(\beta_t, 0)$ is exponentially stable in the timescale $\sqrt{\varepsilon}$, and that, for any β and z_0 , the solution of

$$(3.2) \quad \dot{z}_t^\beta = b(\beta, z_t^\beta), \quad z_0^\beta = z_0$$

converges to zero as $t \rightarrow +\infty$. Let z_t be the solution of

$$(3.3) \quad \dot{z}_t = \frac{1}{\sqrt{\varepsilon}} b(\beta_0, z_t), \quad z_0 = Z_0.$$

Then $Z_t - z_t$ is of order $\varepsilon^{1/4}$; in particular, Z_t is of order $\varepsilon^{1/4} + |Z_0|e^{-ct/\sqrt{\varepsilon}}$.

Remark 8. This result can be viewed as a nonlinear version of Lemma 4. The idea of the proof is to transform the differential equation into an almost linear one, so that we can apply Lemma 4.

Remark 9. The assumption about the solution of (3.2) implies that the real parts of the eigenvalues of $b'(\beta, 0)$ are nonpositive; thus the additional assumption about these eigenvalues simply means that they should not be on the imaginary axis.

Proof. From part (2) of Lemma 1, since $b'(\beta_t, 0)$ and $b'(\beta_0, 0)$ are bounded and exponentially stable, there exists a $\lambda > 0$ such that any A_t satisfying

$$(3.4) \quad |A_t - b'(\beta_t, 0)| \leq \lambda \quad \text{or} \quad |A_t - b'(\beta_0, 0)| \leq \lambda$$

is exponentially stable. On the other hand, there exists a matrix-valued smooth function a such that $b(\beta, z) = a(\beta, z)z$; let $\tilde{a}(\beta, z)$ and $\tilde{b}(\beta, z) = \tilde{a}(\beta, z)z$ be other smooth functions that coincide with a and b for z in a neighbourhood of zero such that

$$(3.5) \quad |\tilde{a}(\beta, z) - b'(\beta, 0)| \leq \lambda$$

and such that, for any β and \tilde{z}_0 , the solution of

$$(3.6) \quad \frac{d}{dt} \tilde{z}_t^\beta = \tilde{b}(\beta, \tilde{z}_t^\beta), \quad \tilde{z}_0^\beta = \tilde{z}_0$$

converges to zero as $t \rightarrow +\infty$. Then $\tilde{a}(\beta_t, e_t)$ and $\tilde{a}(\beta_0, e_t)$ are exponentially stable for any process e_t . Since b and \tilde{b} coincide on a neighbourhood of zero, for any β , there exists a smooth diffeomorphism $D(\beta, \cdot)$, which transforms the flow Φ_β of (3.2) into the flow $\tilde{\Phi}_\beta$ of (3.6); it is given by

$$(3.7) \quad D(\beta, z) = \tilde{\Phi}_\beta(-t, \Phi_\beta(t, z))$$

for t sufficiently large, so that $(\Phi_\beta(s, z), s \geq t)$ stays in the above neighbourhood of zero. Similarly, the inverse of D is given by

$$(3.8) \quad D^{-1}(\beta, z) = \Phi_\beta(-t, \tilde{\Phi}_\beta(t, z))$$

for t large enough. Moreover, D and D^{-1} are smooth. The property of transformation of flows can be translated as

$$(3.9) \quad \frac{\partial D}{\partial z}(\beta, z)b(\beta, z) = \tilde{b}(\beta, D(\beta, z)).$$

Put $\tilde{Z}_t = D(\beta_t, Z_t)$; then

$$(3.10) \quad \begin{aligned} \tilde{Z}_{t_{i+1}} = \tilde{Z}_t &+ \frac{\partial D}{\partial z}(\beta_t, Z_t)(Z_{t_{i+1}} - Z_t) + \frac{\partial D}{\partial \beta}(\beta_t, Z_t)(\beta_{t_{i+1}} - \beta_t) \\ &+ O(|Z_{t_{i+1}} - Z_t|^2) + O(|\beta_{t_{i+1}} - \beta_t|^2). \end{aligned}$$

By using the recursive expression (3.1) for Z_t and by applying (3.9), we obtain

$$(3.11) \quad \tilde{Z}_{t_{i+1}} = \tilde{Z}_t + \varepsilon^{1/4} \tilde{b}(\beta_t, \tilde{Z}_t) + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

The assumptions of Lemma 4 are satisfied with $A_t = \tilde{a}(\beta_t, \tilde{Z}_t)$; thus, if ζ_t is the solution of

$$(3.12) \quad \dot{\zeta}_t = \frac{1}{\sqrt{\varepsilon}} \tilde{a}(\beta_t, \tilde{Z}_t) \zeta_t, \quad \zeta_0 = \tilde{Z}_0,$$

then $\zeta_t - \tilde{Z}_t$ is of order $\varepsilon^{1/4}$. By using this estimate and

$$(3.13) \quad |\beta_t - \beta_0| \zeta_t = O(\sqrt{t} e^{-ct/\sqrt{\varepsilon}}) = O(\varepsilon^{1/4}),$$

we deduce that

$$(3.14) \quad \dot{\zeta}_t = \frac{1}{\sqrt{\varepsilon}} (\tilde{a}(\beta_0, \zeta_t) \zeta_t + O(\varepsilon^{1/4})).$$

Moreover, if \tilde{z}_t is the solution of

$$(3.15) \quad \frac{d}{dt} \tilde{z}_t = \frac{1}{\sqrt{\varepsilon}} \tilde{b}(\beta_0, \tilde{z}_t), \quad \tilde{z}_0 = \tilde{Z}_0,$$

then

$$(3.16) \quad \frac{d}{dt} \tilde{z}_t = \frac{1}{\sqrt{\varepsilon}} (\tilde{a}(\beta_0, \zeta_t) \tilde{z}_t + \gamma_t (\tilde{z}_t - \zeta_t)),$$

where γ_t is a process satisfying

$$(3.17) \quad |\gamma_t| \leq C |\tilde{z}_t| \leq C e^{-ct/\sqrt{\varepsilon}}.$$

Thus

$$(3.18) \quad \frac{d}{dt} (\zeta_t - \tilde{z}_t) = \frac{1}{\sqrt{\varepsilon}} (\tilde{a}(\beta_0, \zeta_t) + \gamma_t) (\zeta_t - \tilde{z}_t) + \frac{1}{\sqrt{\varepsilon}} O(\varepsilon^{1/4}).$$

The process $\tilde{a}(\beta_0, \zeta_t)$ is exponentially stable in the timescale $\sqrt{\varepsilon}$, and, from (3.17), a perturbation by γ_t does not destroy this stability. So $\zeta_t - \tilde{z}_t$ is $O(\varepsilon^{1/4})$, and therefore $\tilde{Z}_t - \tilde{z}_t$ is also $O(\varepsilon^{1/4})$. Now we apply

$$(3.19) \quad Z_t = D^{-1}(\beta_t, \tilde{Z}_t), \quad z_t = D^{-1}(\beta_0, \tilde{z}_t).$$

The function $D^{-1}(\beta, \cdot)$ is the identity on a neighbourhood of zero; if C is chosen large enough, for $t \geq C\sqrt{\varepsilon}$, \tilde{z}_t in this neighbourhood, so z_t is equal to $D^{-1}(\beta_t, \tilde{z}_t)$, and the Lipschitz property of D^{-1} with respect to z implies that $Z_t - z_t$ is $O(\varepsilon^{1/4})$. For $t < C\sqrt{\varepsilon}$, we use

$$(3.20) \quad |Z_t - z_t| \leq C |\beta_t - \beta_0| + C |\tilde{Z}_t - \tilde{z}_t|$$

to obtain the same estimate. \square

3.2. Uniformly stable filters and Theorem 3. Assume the conditions of Theorem 3; we first describe the observable event of probability $1 - O(\varepsilon^\infty)$ on which we will estimate $H_t - \bar{H}_t$ and $P_t - \bar{P}_t$. We have supposed that (G_t, J_t) takes its values in a compact subset \mathcal{H}_0 of the set of matrices (G, J) such that JJ^* and $GS(J)G^*$ are definite positive; we have also supposed that \bar{P}_0 is in some compact subset \mathcal{H}_1 of M_d^+ . On the other hand, $\Lambda(G, J, p)$ is uniformly bounded for $(G, J) \in \mathcal{H}_0$, $p \in \mathcal{H}_1$, and $\inf_{\mathcal{H}_0} \Lambda(G, J, p)$ converges to $+\infty$ as p tends to $\partial M_d^+ \cup \{\infty\}$. We deduce that there exists a compact subset \mathcal{H} of M_d^+ such that

$$(3.21) \quad \inf_{p \notin \mathcal{H}} \inf_{(G, J) \in \mathcal{H}_0} \Lambda(G, J, p) > \sup_{p \in \mathcal{H}_1} \sup_{(G, J) \in \mathcal{H}_0} \Lambda(G, J, p).$$

Consider the subdivision $s_i = i\varepsilon$ and let τ be the infimum of times $t \geq 0$ such that $\bar{P}_t \notin \mathcal{H}$ or $|\bar{P}_t - \bar{P}_{s_i}| \geq \varepsilon^{1/4}$ for $s_i \leq t < s_{i+1}$. In Lemma 6, we prove the estimates (1.35) on the random observable time interval $[0, \tau]$; this implies that, for T fixed, these estimates hold on the time interval $[0, T]$ except on the event $\{T < \tau\}$, so it is then sufficient to prove that the probability of this event is $O(\varepsilon^\infty)$.

LEMMA 6. *The estimates about $H_t - \bar{H}_t$ and $P_t - \bar{P}_t$ stated in Theorem 3 hold on $\{t \leq \tau\}$.*

Proof. We deduce from part (3) of Lemma 1 that $-\bar{P}_t$ is exponentially stable in the timescale ε up to time τ , so the estimate about $H_t - \bar{H}_t$ follows from Theorem 1. Moreover, from Lemma 2, we have

$$(3.22) \quad \bar{P}_{t_{i+1}} - \bar{P}_{t_i} = -\frac{K}{2} \varepsilon^{1/4} \nabla \Lambda(G_{t_i}, J_{t_i}, \bar{P}_{t_i}) + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

The function $\Lambda(G, J, p)$ is not defined for any matrix p , but we can extend it into a function $\Lambda_0(G, J, p)$ defined everywhere, which coincides with Λ for p in \mathcal{H} , tending to $+\infty$ at infinity, and such that $\nabla \Lambda_0$ is zero only at $p = P(G, J)$. Then $Z_t = \bar{P}_t - P_t$ satisfies the recursive condition (3.1) of Lemma 5 with $\beta_t = (G_t, J_t)$ and

$$(3.23) \quad b(G, J, z) = -\frac{K}{2} \nabla \Lambda_0(G, J, z + P(G, J)).$$

For any (G, J) , the flow defined by (3.2) is the flow of a gradient dynamical system with a globally attractive equilibrium, so, to apply Lemma 5, we must only check that the eigenvalues of $b'(G, J, 0)$ are not on the imaginary axis. Since $b'(G, J, 0)$ is symmetric, it is sufficient to prove that it is invertible. Thus, let us study the function $\Lambda(G, J, \bar{P})$ in the neighbourhood of $P(G, J)$; since $\nabla \bar{Q}(G, J, \bar{P})$ is zero for $\bar{P} = P(G, J)$, we have

$$(3.24) \quad \bar{Q}(G, J, \bar{P}) = Q(G, J) + O(|\bar{P} - P|^2).$$

From (1.17) and since $R(G, J, P) = 0$, we have

$$(3.25) \quad \begin{aligned} R(G, J, \bar{P}) &= Q(G, J) + GJ^* - \bar{P}JJ^* + O(|\bar{P} - P|^2) \\ &= (P - \bar{P})JJ^* + O(|\bar{P} - P|^2). \end{aligned}$$

From (1.18), we deduce that

$$(3.26) \quad \nabla \Lambda(G, J, \bar{P}) = -P^\dagger(P - \bar{P})JJ^* + O(|\bar{P} - P|^2),$$

so $b'(G, J, 0)$ is given by

$$(3.27) \quad b'(G, J, 0): z \mapsto -\frac{K}{2} P^\dagger zJJ^*.$$

In particular, it is invertible; so we can apply Lemma 5, and the estimate on $P_t - \bar{P}_t$ follows. \square

Proof of Theorem 3. As was stated previously, it is now sufficient to prove that, for any fixed T , the probability of $\{T > \tau\}$ is $O(\varepsilon^\infty)$; to this end, we must only prove that, for any i ,

$$(3.28) \quad \mathbb{P}[s_i \leq \tau < s_{i+1}] = O(\varepsilon^\infty)$$

uniformly in i . The estimation of $\mathbb{P}[T > \tau]$ then follows by adding this estimate over the $O(1/\varepsilon)$ possible values of i . On the event $\{s_i \leq \tau < s_{i+1}\}$, the variable $\bar{P}_\tau - \bar{P}_{s_i}$ is of order $\sqrt{\varepsilon}$, so

$$(3.29) \quad \begin{aligned} & \mathbb{P}[|\bar{P}_\tau - \bar{P}_{s_i}| \geq \varepsilon^{1/4}, s_i \leq \tau < s_{i+1}] \\ & \leq \varepsilon^{-k/4} \mathbb{E}[|\bar{P}_\tau - \bar{P}_{s_i}|^k, s_i \leq \tau < s_{i+1}] = O(\varepsilon^{k/4}) \end{aligned}$$

for any k and is therefore $O(\varepsilon^\infty)$. On the other hand, let p_t be the solution of

$$(3.30) \quad \dot{p}_t = -\frac{K}{2\sqrt{\varepsilon}} \nabla \Lambda(G_0, J_0, p_t), \quad p_0 = \bar{P}_0.$$

Since p_t is solution of a gradient equation, it follows that $\Lambda(G_0, J_0, p_t)$ is nonincreasing, so

$$(3.31) \quad \begin{aligned} \inf_{(G,J) \in \mathcal{H}_0} \Lambda(G, J, p_t) & \leq \Lambda(G_0, J_0, p_t) \leq \Lambda(G_0, J_0, \bar{P}_0) \\ & \leq \sup_{p \in \mathcal{H}_1} \sup_{(G,J) \in \mathcal{H}_0} \Lambda(G, J, p). \end{aligned}$$

Since P_t is the point that minimizes $\Lambda(G_t, J_t, \cdot)$, we also have

$$(3.32) \quad \begin{aligned} \inf_{(G,J) \in \mathcal{H}_0} \Lambda(G, J, P_t) & \leq \Lambda(G_t, J_t, P_t) \leq \Lambda(G_t, J_t, \bar{P}_0) \\ & \leq \sup_{p \in \mathcal{H}_1} \sup_{(G,J) \in \mathcal{H}_0} \Lambda(G, J, p). \end{aligned}$$

Thus it follows from condition (3.21) that, on $\{t \leq \tau\}$, P_t and p_t take their values in \mathcal{H} , and that the distance between these two processes and $\partial\mathcal{H}$ is bounded below by a positive constant c_0 . From the application of Lemma 5 used in Lemma 6, we have

$$(3.33) \quad \bar{P}_t = P_t - P_0 + p_t + O(\varepsilon^{1/4})$$

on $\{t \leq \tau\}$. It follows from (3.30) that p_t converges exponentially fast to P_0 ; thus, if $s_i \geq \varepsilon^{1/4}$, then $P_{s_i} - \bar{P}_{s_i}$ is of order $\varepsilon^{1/4}$ on $\{s_i \leq \tau\}$; so $P_\tau - \bar{P}_\tau$ is of order $\varepsilon^{1/4}$ on $\{s_i \leq \tau < s_{i+1}\}$, and therefore

$$(3.34) \quad \begin{aligned} & \mathbb{P}[\bar{P}_\tau \in \partial\mathcal{H}, s_i \leq \tau < s_{i+1}] \\ & \leq \mathbb{P}[|\bar{P}_\tau - P_\tau| \geq c_0, s_i \leq \tau < s_{i+1}] = O(\varepsilon^\infty). \end{aligned}$$

Similarly, if $s_i < \varepsilon^{1/4}$, then $P_{s_i} - P_0$ is $O(\varepsilon^{1/8})$; so $p_{s_i} - \bar{P}_{s_i}$ is of order $\varepsilon^{1/8}$ on $\{s_i \leq \tau\}$, and therefore we obtain the same estimate. The wanted estimate (3.28) is then obtained by adding the two probabilities (3.29) and (3.34). \square

3.3. Locally stable filters and Theorem 4. For the proof of Theorem 4, let \mathcal{H} be a compact subset of M_d^+ such that P_t takes its values in a compact subset of the interior of \mathcal{H} and let τ be (as before) the infimum of times t such that $\bar{P}_t \notin \mathcal{H}$ or $|\bar{P}_t - \bar{P}_{s_i}| \geq \varepsilon^{1/4}$ for $s_i \leq t < s_{i+1}$. Let τ_0 be the infimum of times $t \geq 0$ such that $|P_t - \bar{P}_t| \geq \varepsilon^{1/8}$ or $|\bar{P}_t - \bar{P}_{s_i}| \geq \varepsilon^{1/4}$ for $s_i \leq t < s_{i+1}$. Note that τ_0 is not observable and that $\tau_0 \leq \tau$ for ε small enough.

LEMMA 7. *Under the conditions of Theorem 4, $H_t - \bar{H}_t$ is $O(\sqrt{\varepsilon})$ on $\{t \leq \tau\}$ and $P_t - \bar{P}_t$ is $O(\varepsilon^{1/4})$ on $\{t \leq \tau_0\}$.*

Proof. From part (3) of Lemma 1, $-\bar{P}_t$ is exponentially stable up to time τ , so we can apply Theorem 1 and obtain the estimate on $H_t - \bar{H}_t$. By applying (3.26), it appears that

$$(3.35) \quad K_t[\nabla \Lambda(G_t, J_t, \bar{P}_t)] = \bar{\rho}_t[\bar{P}_t - P_t]$$

for some process $\bar{\rho}_t$ that is a smooth function of K_t, G_t, J_t, \bar{P}_t such that

$$(3.36) \quad |\bar{\rho}_t - \rho(K_t, \bar{P}_t^\dagger, J_t J_t^*)| \leq C|\bar{P}_t - P_t|.$$

The Lipschitz dependence of $\bar{\rho}_t$ implies that the oscillations of $\bar{\rho}_t$ are $O(\varepsilon^{1/4})$ on $[t_i, t_{i+1}]$, and we deduce from part (2) of Lemma 1 and (3.36) that $-\bar{\rho}_t$ is exponentially stable in the timescale $\sqrt{\varepsilon}$ up to time τ_0 . On the other hand, from Lemma 2 and (3.35),

$$(3.37) \quad \bar{P}_{t_{i+1}} = \bar{P}_{t_i} - \frac{\varepsilon^{1/4}}{2} \bar{\rho}_{t_i} [\bar{P}_{t_i} - P_{t_i}] + O_t(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

Therefore, we can apply Lemma 4 to $Z_t = P_t - \bar{P}_t$ and deduce that this process is of order $\varepsilon^{1/4}$ on $\{t \leq \tau_0\}$. \square

Proof of Theorem 4. Let us consider the event $\{s_i \leq \tau_0 < s_{i+1}\}$; we deduce from Lemma 7 that, on this event, $\bar{P}_{\tau_0} - P_{\tau_0}$ and $\bar{P}_{\tau_0} - \bar{P}_{s_i}$ are, respectively, of order $\varepsilon^{1/4}$ and $\sqrt{\varepsilon}$. Thus, by proceeding as in Theorem 3, the probability of this event is $O(\varepsilon^\infty)$. By summing over the $O(1/\varepsilon)$ possible values of i , we deduce that $\mathbb{P}[\tau_0 < T]$ is $O(\varepsilon^\infty)$. On the other hand, note that $P_t - \bar{P}_t$ is $O(1)$ on $\{t \leq \tau\}$, is $O(\varepsilon^{1/4})$ on $\{t \leq \tau_0\}$, and that the probability of $\{\tau_0 < t \leq \tau\}$ is $O(\varepsilon^\infty)$; we easily deduce that $P_t - \bar{P}_t$ is $O(\varepsilon^{1/4})$ on $\{t \leq \tau\}$. Moreover, since $\tau_0 \leq \tau$, the probability of $\{\tau < T\}$ is $O(\varepsilon^\infty)$, so we can conclude as in Theorem 3. \square

3.4. Linearization and Theorem 5. For the estimation of \hat{H}_t , the idea is to choose some time before t and to compare our system with the linear system obtained by freezing the parameters at that time. This comparison is based on a change of probability chosen, so that, under the new probability, Y_t becomes the observation process of a linear system.

Proof of Theorem 5. Put $t'_i = i\varepsilon^{8/9}$, let us fix some time t , and let i be the index such that $t'_{i+1} \leq t < t'_{i+2}$. Let τ be the infimum of times $s \geq t'_i$ such that $|H_s - \bar{H}_s| \geq 1$, $|P_s - \bar{P}_s| \geq 1$, $|G_s - G_{t'_i}| \geq \varepsilon^{1/9}$, or $|J_s - J_{t'_i}| \geq \varepsilon^{1/9}$. Then, for $t'_i \leq s \leq t$, $H_s - \bar{H}_s$ and $P_s - \bar{P}_s$ are, respectively, $O(\sqrt{\varepsilon})$ and $O(\varepsilon^{1/4})$ on $\{t \leq \tau\}$, and the probability of this event is $O(\varepsilon^\infty)$. Define

$$(3.38) \quad \bar{W}_s = \int_0^s (G_u S_u G_u^*)^{-1/2} G_u S_u dW_u, \quad B_s = \int_0^s J_u dW_u.$$

They are two independent standard Wiener processes with respective dimensions n and d , and the system for (H, Y) can be written as

$$(3.39) \quad dH_s = F_s ds + (G_s S_s G_s^*)^{1/2} d\bar{W}_s + G_s J_s^* dB_s,$$

$$(3.40) \quad dY_s = H_s ds + \varepsilon dB_s.$$

Now consider the processes $\tilde{H}_s, \tilde{B}_s, \tilde{W}_s$, which coincide with H_s, B_s, \bar{W}_s for $s \leq t'_i$ and which are solutions of

$$(3.41) \quad d\tilde{H}_s = (G_{t'_i} S_{t'_i} G_{t'_i}^*)^{1/2} d\tilde{W}_s + G_{t'_i} J_{t'_i}^* d\tilde{B}_s,$$

$$(3.42) \quad d\tilde{B}_s = dB_s + \frac{1}{\varepsilon} (H_s - \tilde{H}_s) ds,$$

$$(3.43) \quad d\tilde{W}_s = d\bar{W}_s + \frac{1}{\varepsilon} (G_s S_s G_s^*)^{-1/2} G_s J_s^* (\tilde{H}_s - H_s) ds$$

for $s \geq t'_i$; this is a linear equation in \tilde{H} , so, in particular, it has a unique solution. Note that, from (3.40) and (3.42), the observation is given by

$$(3.44) \quad dY_s = \tilde{H}_s ds + \varepsilon d\tilde{B}_s.$$

Consider also the local martingale given by $L_s = 1$ for $s \leq t'_i$ and

$$(3.45) \quad dL_s = \frac{L_s}{\varepsilon} (\tilde{H}_s - H_s)^* dB_s - \frac{L_s}{\varepsilon} (\tilde{H}_s - H_s)^* J_s G_s^* (G_s S_s G_s^*)^{-1/2} d\bar{W}_s$$

for $s \geq t'_i$. For ε fixed and s bounded, we deduce from (1.40) and

$$(3.46) \quad d(H_s - \tilde{H}_s) = F_s ds + \frac{1}{\varepsilon} ((G_{t'_i} S_{t'_i} G_{t'_i}^*)^{1/2} (G_s S_s G_s^*)^{-1/2} G_s J_s^* - G_{t'_i} J_{t'_i}^*) (H_s - \tilde{H}_s) ds \\ + ((G_s S_s G_s^*)^{1/2} - (G_{t'_i} S_{t'_i} G_{t'_i}^*)^{1/2}) d\bar{W}_s + (G_s J_s^* - G_{t'_i} J_{t'_i}^*) dB_s$$

that an exponential moment of $|H_s - \tilde{H}_s|^2$ is bounded, so it follows from classical results that L_s is actually a martingale. Thus we can consider the probability $\tilde{\mathbb{P}} = L_{t_i} \mathbb{P}$ on \mathcal{F}_{t_i} . Under this probability, \tilde{W}_s and \tilde{B}_s are independent Wiener processes. We now have two probabilities; note, however, that the notation $O(\varepsilon^k)$ is a relation of domination in the spaces $L^k(\mathbb{P})$, but not necessarily in $L^k(\tilde{\mathbb{P}})$. Consider the process

$$(3.47) \quad h_s = \tilde{\mathbb{E}}[\tilde{H}_s | \mathcal{F}_{t'_i} \vee \mathcal{Y}_s].$$

Under $\tilde{\mathbb{P}}$, after time t'_i , the filtering problem (3.41)–(3.44) is linear with coefficients $(G_{t'_i}, J_{t'_i})$, so the optimal filter is given by a Kalman filter

$$(3.48) \quad dh_s = \frac{p_s}{\varepsilon} (dY_s - h_s ds), \quad h_{t'_i} = H_{t'_i},$$

where the gain p_s is solution of some differential Riccati equation. The solution of this equation converges exponentially fast to the solution of the algebraic Riccati equation, which is $P_{t'_i}$. Since $P_s - \bar{P}_s$ is $O(\varepsilon^{1/4})$ up to time τ , we deduce that, for $t'_i \leq s \leq t$,

$$(3.49) \quad p_s = P_{t'_i} + O(e^{-c(s-t'_i)/\varepsilon}) = P_s + O(\varepsilon^{4/9} + e^{-c(s-t'_i)/\varepsilon}) \\ = \bar{P}_s + O(\varepsilon^{1/4} + e^{-c(s-t'_i)/\varepsilon})$$

on $\{t \leq \tau\}$. Moreover, the error covariance matrix for the linear filter (3.48) is εp_s ; so

$$(3.50) \quad \tilde{\mathbb{E}}[|\tilde{H}_s - h_s|^k | \mathcal{F}_{t'_i} \vee \mathcal{Y}_s]^{1/k} = \tilde{\mathbb{E}}[|\tilde{H}_s - h_s|^k]^{1/k} = O(\sqrt{\varepsilon})$$

for any k . By comparing the equations (3.48) of h_s and (1.8) of \tilde{H}_s , and by applying (3.49) and part (4) of Lemma 1, since $t - t'_i \geq \varepsilon^{8/9} \gg \varepsilon$, it appears that $h_t - \tilde{H}_t$ is $O(\varepsilon^{3/4})$ on $\{t \leq \tau\}$. On the other hand, note from (3.46) that $H_s - \tilde{H}_s$ is $O(\varepsilon^{8/9})$ on $\{t \leq \tau\}$, so $\ln L_{t_i}$ is $O(\varepsilon^{1/3})$. Thus the event

$$(3.51) \quad \Omega_0 = \{|L_t - 1| \leq \varepsilon^{2/7}\} \cap \{t \leq \tau\}$$

is of probability $1 - O(\varepsilon^\infty)$ under \mathbb{P} . We deduce that

$$(3.52) \quad \tilde{\mathbb{P}}[\Omega_0] = \mathbb{E}[L_t 1_{\Omega_0}] \geq (1 - \varepsilon^{2/7}) \mathbb{P}[\Omega_0] \geq 1 - O(\varepsilon^{2/7}),$$

so, for any event A ,

$$(3.53) \quad \tilde{\mathbb{P}}[A] = \tilde{\mathbb{P}}[A \cap \Omega_0] + \tilde{\mathbb{P}}[A \cap \Omega_0^c] = \mathbb{E}[L_t 1_{A \cap \Omega_0}] + O(\varepsilon^{2/7}) \\ = \mathbb{P}[A] + O(\varepsilon^{2/7})$$

uniformly in A . This implies that a process is of order ε^k in \mathbb{P} -probability in the sense of (1.3) if and only if it has the same property in $\tilde{\mathbb{P}}$ -probability, and we will use the notation $O_p(\varepsilon^k)$ for this relation of domination. We have already checked that $\tilde{H}_t - h_t$ and $H_t - \tilde{H}_t$ are, respectively, $O(\varepsilon^{3/4})$ and $O(\varepsilon^{8/9})$ on $\{t \leq \tau\}$, so we have

$$(3.54) \quad \hat{H}_t - \bar{H}_t = \mathbb{E}[H_t - \bar{H}_t | \mathcal{Y}_t] = \mathbb{E}[(\tilde{H}_t - h_t) 1_{\Omega_0} | \mathcal{Y}_t] + O_p(\varepsilon^{3/4}).$$

Let \mathbb{P}_0 be the probability \mathbb{P} conditioned on Ω_0 ; then

$$\begin{aligned} \mathbb{E}[(\tilde{H}_t - h_t)1_{\Omega_0}|\mathcal{Y}_t] &= \mathbb{E}_0[\tilde{H}_t - h_t|\mathcal{Y}_t]\mathbb{P}[\Omega_0|\mathcal{Y}_t] \\ (3.55) \qquad \qquad \qquad &= \mathbb{E}_0[\tilde{H}_t - h_t|\mathcal{Y}_t] + O_p(\varepsilon^\infty), \end{aligned}$$

so

$$\begin{aligned} \hat{H}_t - \bar{H}_t &= \mathbb{E}_0[\tilde{H}_t - h_t|\mathcal{Y}_t] + O_p(\varepsilon^{3/4}) \\ (3.56) \qquad \qquad \qquad &= \frac{\tilde{\mathbb{E}}[L_t^{-1}1_{\Omega_0}(\tilde{H}_t - h_t)|\mathcal{Y}_t]}{\tilde{E}[L_t^{-1}1_{\Omega_0}|\mathcal{Y}_t]} + O_p(\varepsilon^{3/4}). \end{aligned}$$

Note that

$$(3.57) \qquad \qquad \qquad |L_t^{-1}1_{\Omega_0} - 1| \leq \varepsilon^{2/7} + 1_{\Omega_0^c},$$

so, from (3.52),

$$(3.58) \qquad \qquad \qquad \tilde{\mathbb{E}}[|L_t^{-1}1_{\Omega_0} - 1|^{8/7}] \leq C\varepsilon^{2/7}.$$

From (3.50), we also verify that

$$(3.59) \qquad \qquad \qquad \tilde{\mathbb{E}}[|\tilde{H}_t - h_t|^8|\mathcal{Y}_t]^{1/8} = \tilde{\mathbb{E}}[|\tilde{H}_t - h_t|^8]^{1/8} = O(\sqrt{\varepsilon}),$$

so, from Hölder's inequality,

$$\begin{aligned} \tilde{\mathbb{E}}[\tilde{\mathbb{E}}[L_t^{-1}1_{\Omega_0}(\tilde{H}_t - h_t)|\mathcal{Y}_t]] &\leq \tilde{\mathbb{E}}[(L_t^{-1}1_{\Omega_0} - 1)(\tilde{H}_t - h_t)| \\ (3.60) \qquad \qquad \qquad &= O(\varepsilon^{1/4})O(\sqrt{\varepsilon}) = O(\varepsilon^{3/4}). \end{aligned}$$

Thus the numerator of (3.56) is $O_p(\varepsilon^{3/4})$; the denominator is $1 + O_p(\varepsilon^{2/7})$, so the quotient is $O_p(\varepsilon^{3/4})$. \square

4. Proof of Theorem 6. Consider the subdivision $s'_i = i\sqrt{\varepsilon}$ and let τ be the infimum of times $t \geq 0$ such that $|\bar{X}_t - \bar{X}_{s'_i}| \geq \varepsilon^{1/8}$ for $s'_i \leq t < s'_{i+1}$ or $|X_t - \bar{X}_t| \geq \varepsilon^{3/16}$.

LEMMA 8. *Under the conditions of Theorem 6, the estimates on $X_t - \bar{X}_t$ and $h(X_t) - h(\bar{X}_t)$ hold on $\{t \leq \tau\}$.*

Proof. First, we prove from part (3) of Lemma 1 that $-p(\bar{X}_t)$ is exponentially stable up to time τ in the timescale ε , so, by applying part (4) of Lemma 1 to $h(X_t) - h(\bar{X}_t)$, it appears that this process is $O(\sqrt{\varepsilon})$ on $\{t \leq \tau\}$. Define

$$(4.1) \qquad \qquad \qquad \gamma = I - \phi p^{-1}h'.$$

For each x , $\gamma(x)$ is the projection on $\ker h'(x)$ in the direction of the image of $\phi(x)$. Observe that

$$\begin{aligned} X_t - \bar{X}_t &= \gamma(\bar{X}_t)(X_t - \bar{X}_t) + \phi p^{-1}(\bar{X}_t)(h(X_t) - h(\bar{X}_t)) \\ (4.2) \qquad \qquad \qquad &- \phi p^{-1}(\bar{X}_t)(h(X_t) - h(\bar{X}_t) - h'(\bar{X}_t)(X_t - \bar{X}_t)), \end{aligned}$$

so if we define

$$(4.3) \qquad \qquad \qquad Z_t = \gamma(\bar{X}_t)(X_t - \bar{X}_t),$$

since $|X_t - \bar{X}_t|^2$ and $h(X_t) - h(\bar{X}_t)$ are, respectively, $O(\varepsilon^{3/8})$ and $O(\sqrt{\varepsilon})$, we obtain

$$(4.4) \qquad \qquad \qquad X_t - \bar{X}_t = Z_t + O(\varepsilon^{3/8})$$

on $\{t \leq \tau\}$. Therefore, we must prove that Z_t is $O(\varepsilon^{1/4})$ on $\{t \leq \tau\}$. From the definition of γ and the properties of ϕ and ψ , we have $\gamma\phi = 0$ and $\gamma\psi = \psi$, so, by applying Ito's formula to (4.3),

$$(4.5) \quad \begin{aligned} dZ_t &= \gamma(\bar{X}_t) dX_t + d\gamma(\bar{X}_t)(X_t - \bar{X}_t) + d\langle \gamma(\bar{X}), X - \bar{X} \rangle_t \\ &\quad - \frac{1}{\varepsilon^{3/2}} \psi(\bar{X}_t) [\Gamma_t^*(dY_t - h(\bar{X}_t)dt)]. \end{aligned}$$

Since

$$(4.6) \quad d\bar{X}_t = O(\varepsilon^{-1/2})dt + O(1)dW_t,$$

the oscillations of \bar{X}_t on $[t_i, t_{i+1}]$ are $O(\varepsilon^{1/4})$, so Lemma 2 shows that

$$(4.7) \quad \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} \Gamma_t^*(dY_t - h(\bar{X}_t)dt) = \frac{1}{2} p^+(\bar{X}_{t_i}) r(X_{t_i}, \bar{X}_{t_i}) + O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}),$$

where, from (3.25),

$$(4.8) \quad r(x, \bar{x}) = R(g(x), j(x), p(\bar{x})) = (p'(\bar{x})(x - \bar{x}))jj^*(\bar{x}) + O(|x - \bar{x}|^2).$$

Thus, from (4.4),

$$(4.9) \quad r(X_t, \bar{X}_t) = (p'(\bar{X}_t)Z_t)jj^*(\bar{X}_t) + O(\varepsilon^{3/8}),$$

and since the oscillations of $\psi(\bar{X}_t)$ are $O(\varepsilon^{1/4})$, we deduce from (4.7) and the definition (1.42) of ρ that

$$(4.10) \quad \varepsilon^{-7/4} \int_{t_i}^{t_{i+1}} \psi(\bar{X}_t) [\Gamma_t^*(dY_t - h(\bar{X}_t)dt)] = \frac{1}{2} \rho(\bar{X}_{t_i})Z_{t_i} + O_i(\varepsilon^{1/8}) + O(\varepsilon^{1/4}).$$

On the other hand, since the oscillations of $X_t - \bar{X}_t$ are $O(\varepsilon^{1/4})$,

$$(4.11) \quad \int_{t_i}^{t_{i+1}} d\gamma(\bar{X}_u)(X_u - \bar{X}_u) = (\gamma(\bar{X}_{t_{i+1}}) - \gamma(\bar{X}_{t_i}))(X_{t_i} - \bar{X}_{t_i}) + O(\sqrt{\varepsilon}),$$

so, from (4.5) and (4.10),

$$(4.12) \quad \begin{aligned} Z_{t_{i+1}} - Z_{t_i} &= -\frac{\varepsilon^{1/4}}{2} \rho(\bar{X}_{t_i})Z_{t_i} + (\gamma(\bar{X}_{t_{i+1}}) \\ &\quad - \gamma(\bar{X}_{t_i}))(X_{t_i} - \bar{X}_{t_i}) + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}). \end{aligned}$$

The variables Z_{t_i} , $\bar{X}_{t_{i+1}} - \bar{X}_{t_i}$, and $X_{t_i} - \bar{X}_{t_i}$ are, respectively, of order $\varepsilon^{3/16}$, $\varepsilon^{1/4}$ and $\varepsilon^{3/16}$ on $\{t \leq \tau\}$, so $Z_{t_{i+1}} - Z_{t_i}$ is of order $\varepsilon^{3/8}$, and, from (4.4), $\bar{X}_{t_{i+1}} - \bar{X}_{t_i}$ has the same order. This implies that the second term in the estimation (4.12) is actually $O(\varepsilon^{9/16})$. Thus

$$(4.13) \quad Z_{t_{i+1}} - Z_{t_i} = -\frac{\varepsilon^{1/4}}{2} \rho(\bar{X}_{t_i})Z_{t_i} + O_i(\varepsilon^{3/8}) + O(\sqrt{\varepsilon}).$$

Define

$$(4.14) \quad \bar{\rho} = \rho\gamma + \phi p^{-1}h'.$$

Then the linear map $\bar{\rho}(x)$ is equal to $\rho(x)$ on $\ker h'(x)$ and to I on the image of $\phi(x)$; thus we can replace ρ by $\bar{\rho}$ in the estimation (4.13), and the set of eigenvalues of $\bar{\rho}(x)$ is equal to the set of eigenvalues of $\rho(x)$ in $\ker h'(x)$, plus the value 1. In particular, the real parts of these eigenvalues are bounded below by a positive constant; moreover,

the oscillations of \bar{X}_t are controlled, so we can deduce from part (3) of Lemma 1 that $-\bar{\rho}(\bar{X}_t)$ is exponentially stable in the timescale $\sqrt{\varepsilon}$. Then it follows from Lemma 4 that Z_t is $O(\varepsilon^{1/4})$ on $\{t \leq \tau\}$, so $X_t - \bar{X}_t$ satisfies the same property. \square

Proof of Theorem 6. On $\{t \leq \tau\}$, $X_t - \bar{X}_t$ and

$$(4.15) \quad \bar{X}_t - \bar{X}_{s'_t} = (\bar{X}_t - X_t) - (\bar{X}_{s'_t} - X_{s'_t}) + (X_t - X_{s'_t})$$

are $O(\varepsilon^{1/4})$, so we verify as in Theorem 3 or Theorem 4 that the probability of $\{T > \tau\}$ is $O(\varepsilon^\infty)$. The estimate on \hat{H}_t follows from Theorem 5. \square

CONVEX DUALITY AND NONLINEAR OPTIMAL CONTROL*

RICHARD VINTER†

This paper is dedicated to Wendell Fleming on the occasion of his 65th birthday.

Abstract. Problems in nonlinear optimal control can be reformulated as convex optimization problems over a vector space of linear functionals. In this way, methods of convex analysis can be brought to bear on the task of characterizing solutions to such problems. The result is a necessary and sufficient condition of optimality that generalizes well-known sufficient conditions, referred to as verification theorems, in dynamic programming; as a byproduct, we obtain a representation of the minimum cost in terms of the upper envelope of subsolutions to the Hamilton–Jacobi equation. It is a striking illustration of the wide range of problems to which convex analysis, and, in particular, convex duality, is applicable. The approach, applied to parametric problems in the calculus of variations, was pioneered by L. C. Young [*Lectures on the Calculus of Variations and Optimal Control Theory*, W. B. Saunders, Philadelphia, PA, 1969]. As recent work has shown, however, it is equally fruitful when applied in optimal control. This paper, which is expository, offers a self-contained treatment of the application of methods of convex duality to general nonlinear problems in deterministic optimal control. At the same time, it provides extensions of previously published results in several directions. A simple proof is given of the main “convex closure” theorem relating generalized flows and relaxed arcs; this is based on mollification techniques recently developed by Fleming and Vermes [*SIAM J. Control Optim.*, 27 (1989), pp. 1136–1155] for constructing smooth subsolutions to the Hamilton–Jacobi equation.

Key words. optimal control, convex analysis, dynamic programming

AMS(MOS) subject classifications. 49C05, 49A55, 49A52, 90C25

Introduction. Convex analysis is widely acknowledged to have an important but specialized role in optimization. The class of convex optimization problems with which it is concerned is one for which global minimizers admit a simple and precise characterization. Excluding degenerate cases, we find that for such problems the usual multiplier rules are necessary and sufficient for global optimality, that multipliers can be interpreted as minimizers for dual maximization problems, and that the supremum of the cost for the dual problem provides a tight lower bound on the minimum cost for the original problem. These advantages are bought at a heavy price, however,—a theory for convex optimization problems casts aside at the outset the possible existence of local minima as well as other phenomena that are correctly associated with nonlinear systems.

In view of these associations, it comes as a surprise that convex analysis has a significant role in the study of *fully nonlinear* problems in the calculus of variations and optimal control. The marriage of special techniques and general problems is possible here because, even if an optimization problem with which we are initially presented involves a nonconvex cost and nonconvex constraints, there is scope for changing the linear structure on the underlying vector space (or embedding the domain in a new vector space, which is the same) to furnish a convex problem.

A way to harness methods of convex analysis for application to parametric problems in the calculus of variations is provided by L. C. Young’s theory of generalized flows, an expository version of which appears in [15]. Let us refer to our initial problem as the “strong” problem, and the convex problem with which we associate it as the “weak” problem. Setting up the weak problem involves embedding the class of arcs considered in the strong problem in a new vector space \mathcal{X} , some space of linear

* Received by the editors October 18, 1991; accepted for publication (in revised form) December 23, 1991.

† Department of Electrical and Electronic Engineering, Imperial College of Science, Technology and Medicine, Exhibition Road, London SW7 2BT, England.

functionals, and extending the cost function for the strong problem as a linear function over \mathcal{X} . The constraint set for the weak problem is a convex set, defined by a family of affine equality and inequality constraint functions, which contains the images of arcs for the original problem under the embedding. Conditions on a minimizer for the strong problem are then obtained by showing that it corresponds to a minimizer for the weak problem and by applying methods of convex analysis to this convex optimization problem.

Young's ideas were placed in a broader context by Ioffe [5], Levin and Milyutin [8], Klötzler [7], and Vinter [11] and extended to apply to nonlinear problems in optimal control. These papers typically establish existence, in some sense, of a subgradient of a certain convex function associated with the cost over some abstract vector space of boundaries. As shown by Vinter and Lewis [12], [13], connections between such results and other, more familiar ones in optimal control theory become apparent when methods of convex duality are applied to the weak problem. In this way, we obtain necessary and sufficient conditions of optimality, which improve on the familiar sufficient conditions passing under the name of "verification theorems" in the dynamic programming literature. A byproduct is a representation of the minimum cost in terms of the upper envelope of smooth subsolutions to the Hamilton–Jacobi equation. Recently, Fleming [3] and Fleming and Vermes [4] successfully adapted the approach to apply to a large class of optimal control problems, relating to both deterministic and stochastic systems, and they have simplified, by means of mollification techniques, proofs of the key intermediate steps relating the strong and the weak problems.

When we attempt to characterize minimizers in terms of the solutions to the Hamilton–Jacobi equation for general classes of optimal control problems, we encounter the difficulty that strict sense solutions (i.e., continuously differentiable ones) to the Hamilton–Jacobi equation may fail to exist. A number of remedies are available based on a variety of notions of generalized solution to the Hamilton–Jacobi equation (viscosity solutions [9], generalized solutions involving the Clarke generalized gradients [2], or lower Dini derivatives [14], among others). It is now apparent that the convex analysis approach provides another means of overcoming the difficulty—in place of strict sense solutions to the Hamilton–Jacobi equation, optimality conditions are given in terms of smooth subsolutions to the equation.

A distinguishing feature of the convex duality approach is that it may be applied to optimal control problems with general endpoint constraints, even in "degenerate" situations. Optimality conditions supplied in [2], which also treat endpoint constraints, are typical in requiring satisfaction of certain "calmness" or "normality" hypotheses. On the other hand, the viscosity solutions literature is primarily concerned with situations where the value function associated with perturbations of the initial time and state is defined on some suitably large domain, situations corresponding to no endpoint constraints, where nondegeneracy hypotheses of a "controllability" nature apply or where we place restrictions on the manner in which arcs may strike the target set. Such hypotheses play no part here.

Another feature is the mild nature of the hypotheses under which optimality conditions can be derived by means of convex duality. It is required that the cost be expressible in terms of lower semicontinuous functions and the multifunction, by means of which the dynamics are modelled, be upper semicontinuous. We are not limited, in particular, to treating problems for which the data is Lipschitz continuous in the state variable, as in [2], [14].

This paper is expository in nature; the arguments involved are direct, and the proofs are largely self-contained. The proof of the central "convex closure" theorem

is based on techniques of Fleming [3] and Fleming and Vermes [4] for constructing smooth subsolutions to the Hamilton–Jacobi equation, which take a particularly simple form for the deterministic problems considered here. At the same time, we provide extensions in several directions. As compared with [12], [13], a more general cost function is now permitted, requirements that the data is continuous are weakened, and the hypothesis implicit in [13] that all points in the target set be reachable is completely dispensed with. Changes, too, in the duality arguments arising in the analysis of the weak problem lead to improved optimality conditions, as indicated above, and, once again, simpler proofs. The differentiability and linear growth conditions on the data, implicit in the hypotheses of [4] (specialized to the deterministic case), are replaced by “semicontinuity” conditions and boundedness assumptions on the underlying domain.

1. Generalized flows. Our object here is to set up machinery for the application of methods of convex duality to nonlinear problems of optimal control. This involves abstracting the classical concept of an arc (“ordinary arcs”). Two levels of abstraction are involved. The first is to view it as a special case of a “relaxed arc.” This concept is a familiar one, and its role in existence theory is widely appreciated. The essential idea is to regard values of the velocity as linear functionals. The second level of abstraction is to interpret a relaxed arc itself as a linear functional, possessing certain arc-like properties, termed a generalized flow. It is this lesser-known concept that is the key to the reformulation of nonlinear optimal control problems as a convex optimization problems.

1.1. Relaxed arcs. A well-known phenomenon in the calculus of variations is where, if the cost integrand is not convex in the velocity variable, then minimizing sequences of arcs may have velocities that switch increasingly rapidly. To provide an existence theory covering such situations, we must attach meaning to “limits” of such sequences. For this purpose, Young introduced the concept of generalized curves, or “relaxed arcs” according to modern nomenclature. We give a brief review of the ideas involved, slanted toward the requirements of the following sections.

Take $[t_0, T]$ to be a fixed interval and $\Omega \subset \mathbb{R}^n$ a compact set containing the origin.

DEFINITION 1.1. An element (t_1, x, m) is a *relaxed arc* (with reference to the velocity set Ω) if $t_1 \in [t_0, T]$, $x(\cdot)$ is a Lipschitz continuous mapping from $[t_0, t_1]$ to \mathbb{R}^n , m (also written $t \rightarrow m_t$) maps $[t_0, t_1]$ into the space of regular Borel probability measures on Ω , and the following conditions are satisfied:

- (i) m is measurable in the sense that, for each $g \in C(\Omega)$, the scalar-valued function $t \rightarrow \int g(v)m_t(dv)$ is Lebesgue measurable;
- (ii) m is a “generalized velocity” of $x(t)$ in the sense that

$$\dot{x}(t) = \int vm_t(dv) \quad \text{a.e. } t \in [t_0, t_1].$$

The set of relaxed arcs can be regarded as an extension of the class of *ordinary arcs*, namely, elements (t_1, x) for which $t_1 \in [t_0, T]$, and x is a Lipschitz continuous \mathbb{R}^n -valued function on $[t_0, t_1]$ satisfying the velocity constraint “ $\dot{x}(t) \in \Omega$ almost everywhere.” To this end, we associate with an ordinary arc (t_1, x) the relaxed arc (t_1, x, m) for which

$$m_t := \delta_{\{\dot{x}(t)\}} \quad \text{a.e. } [t_0, t_1].$$

Here $\delta_{\{a\}}$ denotes the probability measure concentrated at the point $\{a\}$.

It is often convenient to regard the functions x and m , which constitute a relaxed arc (t_1, x, m) , as functions with domain all of $[t_0, T]$. For this purpose, we extend x

by constant extrapolation from its value at $t = t_1$; thus

$$x(t) := x(t_1) \quad \text{for } t \in (t_1, T],$$

and we extend m by setting

$$m_t := \delta_{\{0\}} \quad \text{for } t \in (t_1, T].$$

The following theorem is proved by methods of ([15, §67]). It refers to the set of integrands \mathcal{G}

$$\mathcal{G} := \{h : [t_0, T] \times \mathbb{R}^n \times \Omega \rightarrow \mathbb{R} : h(\cdot, y, v) \text{ is measurable, } h(t \cdot, \cdot) \text{ is continuous, and } t \rightarrow |h(t \cdot, \cdot)|_{C(B)} \text{ is integrable for any compact set } B \subset \mathbb{R}^{2n}\}.$$

THEOREM 1.2. *Let $\{(t_i, x_i, m^i)\}$ be a sequence of relaxed arcs such that the x_i 's are uniformly bounded in $C([t_0, T]; \mathbb{R}^n)$. Then there exists a subsequence (also written $\{(t_1^i, x_i, m^i)\}$) and a relaxed arc (t_1, x, m) such that*

$$t_1^i \rightarrow t_1,$$

$$x_i \rightarrow x \text{ uniformly on } [t_0, T],$$

$$\int_{t_0}^{t_1^i} \int h(t, x_i(t), v) dm_t^i(v) dt \rightarrow \int_{t_0}^{t_1} \int h(t, x(t), v) dm_t(v) dt \quad \text{as } i \rightarrow \infty,$$

for each $h \in \mathcal{G}$.

Given an integrand $h \in \mathcal{G}$, the integral functional

$$(1.1) \quad J(t_1, x) := \int_{t_0}^{t_1} h(t, x(t), \dot{x}(t)) dt$$

over ordinary arcs (t_1, x) extends to a functional J_r over relaxed arcs as follows:

$$(1.2) \quad J_r(t_1, x, m) := \int_{t_0}^{t_1} \int h(t, x(t), v) dm_t(v) dt$$

in a manner that is compatible with the way in which we identify the ordinary arcs with a subclass of the relaxed arcs.

Since no convexity conditions feature in the definition of the set \mathcal{G} , for any h drawn from \mathcal{G} we should not expect the problem

$$\text{“Minimize } J(t_1, x) \text{ over ordinary arcs } (t_1, x) \text{ for which } x \in R\text{”}$$

to have a solution. Here R is a closed bounded subset of $C([t_0, t_1]; \mathbb{R}^n)$, and J is the integral functional (1.1). (The constraint set R may incorporate a priori bounds that we are able to establish on candidates for a minimizer.) We can at least, however, ensure existence of solutions to the following problem in which the domain of J is extended to the relaxed arcs:

$$\text{“Minimize } J_r(t_1, x, m) \text{ over relaxed arcs } (t_1, x, m) \text{ for which } x \in R\text{.”}$$

Provided that the set of (t_1, x, m) 's satisfying $x \in R$ is nonempty, there exists a minimizing sequence $\{(t_1^i, x_i, m^i)\}$ of relaxed arcs for the minimization problem with extended domain. According to Theorem 1.2, we may extract a subsequence (also written $\{(t_1, x_i, m^i)\}$) and identify a relaxed arc (t_1, x, m) such that

$$\inf J_r = \lim_i J_r(t_1^i, x_i, m^i) = J_r(t_1, x, m)$$

and $x \in R$. Here $\inf J_r$ denotes the infimum cost for problem J_r . Evidently, (t, x, m) is a minimizer for the “relaxed” problem.

1.2. Generalized flows. The next step is to view relaxed arcs, themselves an extension of the notion of ordinary arc, as examples of “generalized flows.” Generalized flows are linear functions that capture certain significant properties of relaxed arcs.

Take a point $x_0 \in \mathbb{R}^n$ and an interval $[t_0, T]$. Let K and r be positive numbers that satisfy

$$(1.3) \quad |x_0| + r|T - t_0| \leq K.$$

We write

$$D = [t_0, T] \times (K\bar{B}) \quad \text{and} \quad \Omega = r\bar{B},$$

where \bar{B} denotes the closed unit ball. Consider now the following set of constraints:

$$(C) \quad \begin{aligned} t_1 &\in [t_0, T], \\ \dot{x}(t) &\in \Omega \quad \text{a.e. } t \in [t_0, t_1], \\ (t, x(t)) &\in D \quad \text{for all } t \in [t_0, t_1], \\ x(t_0) &= x_0. \end{aligned}$$

A relaxed arc (t_1, x, m) with velocity set Ω , which satisfies these constraints, will be called a *relaxed arc for system (C)*. (The second of these constraints is taken to indicate that Ω is the velocity set of the relaxed arc.) Evidently, the class of relaxed arcs for system (C) is nonempty.

A relaxed arc (t_1, x, m) for system (C) defines a linear functional (μ, γ) on $C(D \times \Omega) \times C(D)$ as follows:

$$(1.4) \quad \langle (\mu, \gamma), (\xi, \eta) \rangle = \int_{t_0}^{t_1} \int \xi(t, x(t), v) dm_t(v) dt + \eta(t_1, x(t_1))$$

for all $(\xi, \eta) \in C(D \times \Omega) \times C(D)$.

It is easy to see that (μ, γ) is, in fact, a bounded linear functional on $C(D \times \Omega) \times C(D)$ and hence defines an element in the vector space $C^*(D \times \Omega) \times C^*(D)$, which is isometrically isomorphic to the dual space $(C(D \times \Omega) \times C(D))^*$.

We denote by S the set of linear functionals that arise in this way. The symbol is chosen to indicate that they are associated with relaxed arcs (t_1, x) satisfying the constraints (C) in some “strong” sense as follows:

$$(1.5) \quad S := \{(\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D) : \text{there exists a relaxed arc for (C) satisfying (1.4)}\}.$$

The set S is nonempty; it contains the linear functional (μ, γ) associated with the ordinary arc $(T, x \equiv x_0)$, for example. S is obviously bounded with respect to the dual norm. It is also weak* compact. To see this, we first note that, by Theorem 1.2, S is sequentially weak* compact. S , however, is bounded in the dual norm, and $C(D \times \Omega) \times C(D)$ is separable. By Bishop’s theorem [16], the weak* topology on $C^* \times C^*$ relativized to a ball in $C^* \times C^*$ containing S is metrizable. It follows that S is weak* compact.

Let us now examine sufficient conditions for membership of S . Take $(\mu, \gamma) \in S$. It is evident from (1.4) that

$$(1.6) \quad \mu \geq 0, \quad \gamma \geq 0, \quad |\mu|_{C^*} \leq T - t_0, \quad \text{and} \quad |\gamma|_{C^*} \leq 1.$$

Here, positivity is understood in the sense that $\langle \mu, h \rangle \geq 0$ when h is nonnegative-valued. $|\cdot|_{C^*}$ denotes the dual norm.

A further property that reflects the fact that (μ, γ) is associated with a relaxed arc (t_1, x, m) issuing from the point $(t_0, x(t_0))$ in (t, x) -space and terminating at some point $(t_1, x(t_1)) \in D$ is

$$(1.7) \quad \langle \mu, \phi_t(t, x) + \phi_x(t, x) \cdot v \rangle = \int \phi \, d\gamma - \phi(t_0, x_0)$$

for all functions $\phi \in C^1(\mathbb{R}^{1+n})$. (In this relationship, (t, x, v) is to be regarded as a generic point in $D \times \Omega$.)

To see this, we calculate

$$\begin{aligned} \langle \mu, \phi_t + \phi_x \cdot v \rangle &= \int_{t_0}^{t_1} \left[\frac{\partial}{\partial t} \phi(t, x(t)) + \frac{\partial}{\partial x} \phi(t, x(t)) \cdot \int v \, dm_t(v) \right] dt \\ &= \int_{t_0}^{t_1} \left[\frac{\partial}{\partial t} \phi(t, x(t)) + \frac{\partial}{\partial x} \phi(t, x(t)) \cdot \dot{x}(t) \right] dt = \int_{t_0}^{t_1} \frac{d}{dt} \phi(t, x(t)) \, dt \\ &= \phi(t_1, x(t_1)) - \phi(t_0, x_0) = \int \phi \, d\gamma - \phi(t_0, x_0). \end{aligned}$$

We use these conditions to define a new set of linear functionals \mathcal{W} . In this case, the chosen symbol indicates that these functionals are associated with relaxed arcs for (C) in some “weak” sense as follows:

$$(1.8) \quad \mathcal{W} := \{(\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D) : (\mu, \gamma) \text{ satisfies (1.6) and (1.7)}\}.$$

Since the conditions defining membership of \mathcal{W} are necessary conditions for membership of S , we have $S \subset \mathcal{W}$. We note also that \mathcal{W} is a convex weak* compact subset of $C^* \times C^*$. Convexity is obvious. \mathcal{W} is weak* compact because it is bounded with respect to the dual norm and expressible as the intersection of a family of weak* closed subspaces and half-spaces.

Our preliminary findings concerning the two subsets S and \mathcal{W} of $C^*(D \times \Omega) \times C^*(D)$, and their interrelation may be summarized as follows: *S and \mathcal{W} are nonempty weak* compact subsets of $C^*(D \times \Omega) \times C^*(D)$, S is convex, and $S \subset \mathcal{W}$.*

1.3. The structure of generalized flows. Our goal is to derive optimality conditions for minimizing arcs by analysing the properties of the set \mathcal{W} of generalized flows. The feasibility of this approach hinges, of course, on our ability to establish a close relationship between the set S of relaxed arcs and the set \mathcal{W} . The two sets do not coincide. Indeed, if ν_1 and ν_2 are two distinct elements in S , the point $\nu \in C^* \times C^*$ defined by

$$\langle \nu, g \rangle = \frac{1}{2} \langle \nu_1, g \rangle + \frac{1}{2} \langle \nu_2, g \rangle$$

(for all $g \in C \times C$) defines an element in \mathcal{W} but not in S . It is the case, however, that the two sets are related through the operation of “convex closure.” The following theorem, which discusses the details of this relationship, has a crucial role in the theory.

THEOREM 1.3. *Let the sets $S, \mathcal{W} \subset C^*(D \times \Omega) \times C^*(D)$ be as defined in (1.5) and (1.8). Then \mathcal{W} is the weak* closed convex hull of S , i.e., \mathcal{W} is the intersection of all weak* closed convex sets containing S .*

A proof of this theorem is given in §1.4. It is similar to one of Fleming [3] and is, in essence, a specialization of arguments in [4].

As a corollary, we have that an arbitrary element in \mathcal{W} can be decomposed into a convex combination of elements in S ; the weightings assigned to individual elements in S are specified through a probability measure on the Borel sets of S . (Here we refer to the Borel sets generated by the dual norm topology on S , which coincide with those generated by the weak* topology.)

COROLLARY 1.4. *Let ν be an arbitrary element in \mathcal{W} . Then there exists a regular probability measure Λ on the Borel subsets of S such that*

$$(1.9) \quad \langle \nu, g \rangle = \int_S \langle \lambda, g \rangle d\Lambda(\lambda)$$

for all $g \in C(D \times \Omega) \times C(D)$.

Proof. Denote by Π the class of regular probability measures on S . For any $\Lambda \in \Pi$ and $g \in C(D \times \Omega) \times C(D)$, the function $\lambda \rightarrow \langle \lambda, g \rangle$ is weak* continuous on S and therefore Λ -integrable. It follows that the right side of (1.9) is well defined. For each $\Lambda \in \Pi$, the mapping

$$g \rightarrow \int_S \langle \gamma, g \rangle d\Lambda(\gamma)$$

is a bounded linear functional on $C(D \times \Omega) \times C(D)$ and hence defines an element in the dual space $C^* \times C^*$. Denote by \tilde{S} the subset of points in $C^* \times C^*$ generated in this way by allowing Λ to range over the set Π . It is straightforward to show that \tilde{S} is a convex set containing S . The set \tilde{S} is also weak* compact. To see this, take a weak* convergent sequence $\{\nu_i\}$ of measures with limit ν , expressible in terms of measures Λ_i , $i = 1, 2, \dots$ drawn from the set Π according to

$$\langle \mu_i, g \rangle = \int_S \langle \gamma, g \rangle d\Lambda_i(\gamma) \quad \text{for all } g \in C(D \times \Omega) \times C(D).$$

By limiting attention to a subsequence, if necessary, we can arrange that the Λ_i 's (or, strictly speaking, the bounded linear functionals associated with the Λ_i 's) converge weak* to some $\Lambda \in \Pi$. Passage to the limit now gives (1.9) for all $g \in C(D \times \Omega) \times C(D)$. In other words, $\mu \in \tilde{S}$. \tilde{S} is therefore sequentially weak* compact. Since it is bounded in the dual norm, it is weak* compact. Then, however, \tilde{S} must contain \mathcal{W} , which, according to Theorem 1.3, lies in the intersection of all weak* closed convex sets containing S . This is what the corollary asserts. \square

A minor refinement of this last result will be required. Recall that any positive bounded linear functional $\nu = (\mu, \gamma)$ on $C(D \times \Omega) \times C(D)$ has associated with it an element $(d\mu, d\gamma)$ comprising bounded, regular positive Borel measures $d\mu$ and $d\gamma$ on $D \times \Omega$ and D , respectively. These measures provide an extension of the linear functional ν , namely,

$$g \rightarrow \int_{D \times \Omega} g_1 d\mu + \int_D g_2 d\gamma,$$

to the class of “integrands” $g = (g_1, g_2)$ in which g_1 and g_2 are extended-value functions on $D \times \Omega$ and D , respectively, which are Borel measurable and bounded below. Of particular interest to us will be integrands in this class comprising pairs of lower semicontinuous functions.

COROLLARY 1.5. *Take any $\nu \in \mathcal{W}$ and let Λ be the measure of Corollary 1.4. Then, for any element $g = (g_1, g_2)$ comprising functions $g_1: D \times \Omega \rightarrow \mathbb{R} \cup \{+\infty\}$ and $g_2: D \rightarrow \mathbb{R} \cup \{+\infty\}$, which are lower semicontinuous functions, (1.9) remains valid when we interpret the functional evaluations $\langle \nu, g \rangle$ and $\langle \lambda, g \rangle$ in the extended sense described above.*

Proof. Let μ , Λ and $g = (g_1, g_2)$ be as in the statement of the corollary. Let $\{g_1^i\}$ and $\{g_2^i\}$ be sequences of uniformly bounded, continuous functions, minorizing g_1 and g_2 and converging everywhere to g_1 and g_2 , respectively. For $i = 1, 2, \dots$, (1.9) is valid when (g_1^i, g_2^i) is substituted for (g_1, g_2) . Such sequences exist [1, p. 212]. Corollary 1.4 is now proved by expressing the functional operations in terms of measures and passage to the limit with the help of the monotone convergence theorem. \square

1.4. Proof of Theorem 1.3. Suppose that the assertion is false. We may then choose an element $(\mu_0, \gamma_0) \in \mathcal{W} \setminus \overline{\text{co}} S$. Here $\overline{\text{co}} S$ denotes the weak* convex closure of S . Therefore, $\{(\mu_0, \gamma_0)\}$ and $\overline{\text{co}} S$ are strictly separated. This means that there exist a function $(l_0, g_0) \in C(D \times \Omega) \times C(D)$ and a number a such that

$$(1.10) \quad \langle \mu, l_0 \rangle + \langle \gamma, g_0 \rangle \geq a \quad \text{for all } (\mu, \gamma) \in S$$

and

$$(1.11) \quad \langle \mu_0, l_0 \rangle + \langle \gamma_0, g_0 \rangle < a.$$

Noting that continuous functions on $D \times \Omega$ and D can be uniformly approximated by Lipschitz continuous functions, we are justified in replacing l_0 and g_0 by new functions that are Lipschitz continuous and that (following possible adjustment of the number a) satisfy (1.10) and (1.11).

Now assume that l_0, g_0 have been extended to the whole of $\mathbb{R}^{1+2n}, \mathbb{R}^{1+n}$, respectively, as Lipschitz functions. (This can be done, for example, by constant extrapolation of values at the boundary of each of the sets $D \times \Omega, D$ along rays radiating from some fixed interior point.)

For each $(t, x) \in (-\infty, T] \times \mathbb{R}^n$, we define

$$(1.12) \quad \phi(t, x) := \inf \left\{ \int_t^{t_1} \int l_0(s, y(s), v) dm_s(v) ds + g_0(t_1, y(t_1)) \right\},$$

where the infimum is taken over elements $\{t_1, y, m\}$, which comprise a point $t_1 \in [t, T]$, a Lipschitz continuous function $y: [t, t_1] \rightarrow \mathbb{R}^n$, and a measurable function $s \rightarrow \mu_s$ mapping the interval $[t, t_1]$ into the space of regular probability measures on Ω , which satisfy

$$\begin{aligned} y(t) &= x, \\ \dot{y}(s) &= \int v dm_s(v) \quad \text{a.e. } s \in [t, t_1]. \end{aligned}$$

Routine modification of standard arguments (see [2]) gives us the following lemma.

LEMMA 1.6. *The function $\phi: (-\infty, t_1] \times \mathbb{R}^n \rightarrow \mathbb{R}$ is locally Lipschitz continuous.*

Inequality (1.10) can be expressed as

$$\int_{t_0}^{t_1} \int l_0(s, y(s), v) dm_s(v) dt + g_0(t_1, y(t_1)) \geq a$$

for all relaxed arcs (t_1, y, m) for system (C). Now, in view of (1.3), the constraint

$$“(s, y(s)) \in D \quad \text{for all } s \in [t, t_1]”$$

is inactive. By definition of ϕ , then,

$$(1.13) \quad \phi(t_0, x_0) \geq a.$$

LEMMA 1.7. *Let (t, x) be a point in $(-\infty, T) \times \mathbb{R}^n$ at which ϕ is differentiable. Then, for all $v \in \Omega$,*

$$\frac{\partial}{\partial t} \phi(t, x(t)) + \frac{\partial}{\partial x} \phi(t, x(t)) \cdot v + l_0(t, x, v) \geq 0.$$

Proof. For each $v \in \Omega$ and $\varepsilon \in (0, T - t)$, the “arc”

$$(t + \varepsilon, y(s) \equiv x + (s - t)v, \mu_s \equiv \delta_{\{v\}})$$

lies in the set of elements over which the infimum in (1.12) is taken. It follows that

$$\varepsilon^{-1} [g_0(t + \varepsilon, x + \varepsilon v) - \phi(t, x)] \geq -\varepsilon^{-1} \int_t^{t+\varepsilon} l_0(s, x + (s - t)v, v) ds.$$

The definition of ϕ also implies that

$$g_0(t + \varepsilon, x + \varepsilon v) \geq \phi(t + \varepsilon, x + \varepsilon v).$$

The assertions of the lemma are now proved by combining these inequalities and passing to the limit as $\varepsilon \downarrow 0$. (This is justified under the differentiability assumption and because the integrand is continuous.) \square

Consider now the mollifiers $\rho_i : (-\infty, 0] \times \mathbb{R}^n \rightarrow \mathbb{R}$, $i = 1, 2, \dots$ defined according to

$$\rho_i(t, x) = \begin{cases} i^{(n+1)} & \text{if } -i^{-1} \leq t \leq 0 \quad \text{and} \quad -i^{-1} \leq x_i \leq 0, \\ 0 & \text{otherwise.} \end{cases}$$

Given a locally integrable function h on \mathbb{R}^{1+n} , the function $h * \rho_i$ is assumed to be

$$(h * \rho_i)(t, x) := \iint_{\mathbb{R}^{n+1}} h(t + \tau, x + \xi) \rho_i(\tau, \xi) d\tau d\xi.$$

The following lemma lists properties of $h * \rho_i$.

LEMMA 1.8. *Let $h : \mathbb{R}^{n+1} \rightarrow \mathbb{R}$ be a locally Lipschitz continuous function and let ρ_i , $i = 1, 2, \dots$, be as defined above. Then*

- (i) $h * \rho_i \in C^1(\mathbb{R}^{1+n})$ for $i = 1, 2, \dots$;
- (ii) $\nabla(h * \rho_i) = \iint_{\mathbb{R} \times \mathbb{R}^n} \nabla h(t + \tau, x + \xi) \rho_i(\tau, \xi) d\tau d\xi$ for $i = 1, 2, \dots$;
- (iii) $(h * \rho_i)(t, x) \rightarrow h(t, x)$ uniformly on compact sets.

The mollifiers are now used to establish existence of smooth approximate subsolutions to the Hamilton-Jacobi equation.

LEMMA 1.9. *There exist a sequence $\{\phi^i\}$ in $C^1(\mathbb{R}^{n+1})$ and a sequence of numbers $\{\delta_i\}$, with $\delta_i \downarrow 0$, such that $\phi^i(t, x) \rightarrow \phi(t, x)$, uniformly on D , as $i \rightarrow \infty$, and*

$$(1.14) \quad \frac{\partial}{\partial t} \phi^i(t, x) + \frac{\partial}{\partial x} \phi^i(t, x) \cdot v + l_0(t, x, v) \geq -\delta_i \quad \text{for } (t, x) \in D, \quad v \in \Omega,$$

$$i = 1, 2, \dots$$

Proof. Extend ϕ to all of $\mathbb{R} \times \mathbb{R}^n$ as a locally Lipschitz continuous function and define $\phi^i := \phi * \rho_i$ for $i = 1, 2, \dots$. According to Lemma 1.8, each ϕ^i is a C^1 function and $\phi^i \rightarrow \phi$ uniformly on D . By the almost everywhere differentiability of locally Lipschitz functions and by Lemma 1.7, we know that, for all $v \in \Omega$ and almost every $(t, x) \in (-\infty, t_1] \times \mathbb{R}^n$,

$$0 \leq \frac{\partial}{\partial t} \phi(t, x) + \frac{\partial}{\partial x} \phi(t, x) \cdot v + l_0(t, x, v).$$

For each i , the mollifier ρ_i is nonnegative-valued. The inequality is therefore preserved on convolving both sides of the inequality with ρ_i . Writing $\phi^i := \phi * \rho_i$ and appealing to Lemma 1.8, we deduce that

$$0 \leq \phi_t^i(t, x) + \phi_x^i(t, x) \cdot v + (l_0 * \rho_i)(t, x, v) \quad \text{for all } (t, x, v) \in D\mathbf{x}\Omega.$$

Now set

$$\delta_i = |l_0 - l_0 * \rho_i|_{C(D)}, \quad i = 1, 2, \dots$$

According to Lemma 1.8, $\delta_i \downarrow 0$ as $i \rightarrow \infty$. Equation (1.14) is then valid for this choice of $\{\delta_i\}$. \square

We are now ready for completion of the proof of Theorem 1.3. Take $\{\phi^i\}$ and $\{\delta_i\}$ as in Lemma 1.9. By definition of the set \mathcal{W} of linear functionals, the element $(\mu_0, \gamma_0) \in \mathcal{W}$ satisfies

$$\langle \mu_0, \phi_t^i + \phi_x^i \cdot v \rangle = \langle \gamma_0, \phi^i \rangle - \phi^i(t_0, x_0) \quad \text{for } i = 1, 2, \dots$$

Then, by (1.14),

$$\begin{aligned} \phi^i(t_0, x_0) &= \langle \mu_0, -(\phi_t^i + \phi_x^i \cdot v) \rangle + \langle \gamma_0, \phi^i \rangle \\ &\leq \langle \mu_0, l_0 \rangle + \langle \gamma_0, \phi \rangle + \varepsilon_i, \end{aligned}$$

where $\varepsilon_i = \delta_i |\mu_0|_{C^*} + |\phi^i - \phi|_{C(D)}$. By Lemma 1.9, $\varepsilon_i \rightarrow 0$ and $\phi^i(t_0, x_0) \rightarrow \phi(t_0, x_0) \rightarrow \phi(t_0, x_0)$ as $i \rightarrow \infty$. It follows now from (1.11) and (1.13) that

$$a \leq \phi(t_0, x_0) = \lim_i \phi^i(t_0, x_0) \leq \langle \mu_0, l_0 \rangle + \langle \gamma_0, \phi \rangle < a.$$

We conclude from this contradiction that $\mathcal{W} = \overline{\text{co}} S$.

2. Optimality conditions. Our knowledge about generalized flows is now used, in the derivation of optimality conditions. We consider an optimal control problem (P) in which the terminal time t_1 is a choice variable (this is a “free time” problem), where a description of the dynamics is provided in terms of a differential inclusion and where constraints, expressed in terms of general set inclusions, are imposed on values of the state trajectory $x(\cdot)$, the terminal time t_1 , and the terminal in state $x(t_1)$. Problem (P) is as follows:

(P) Minimize $\int_{t_0}^{t_1} l(t, x(t), \dot{x}(t)) dt + g(t_1, x(t_1))$ over points $t_1 \in [t_0, T]$ and Lipschitz continuous functions $x: [t_0, t_1] \rightarrow \mathbb{R}^n$ that satisfy

$$(2.1) \quad \dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } t \in [t_0, t_1],$$

$$(2.2) \quad (t, x(t)) \in A \quad \text{for all } t \in [t_0, t_1],$$

$$(2.3) \quad x(t_0) = x_0, \quad (t_1, x(t_1)) \in C.$$

In problem (P), the interval $[t_0, T]$, the point $x_0 \in \mathbb{R}^n$, the extended-value functions $l: [t_0, T] \times \mathbb{R}^n \rightarrow \mathbb{R} \cup \{+\infty\}$ and $g: [t_0, T] \times \mathbb{R}^n \rightarrow \mathbb{R} \cup \{\infty\}$, the multifunction $F: [t_0, T] \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, and the set $A \subset [t_0, T] \times \mathbb{R}^n$ are given. We refer to elements (t_1, x) , in which $t_1 \in [t_0, T]$ and x is a Lipschitz continuous \mathbb{R}^n -valued function on $[t_0, t_1]$ satisfying (2.1)–(2.3), as *admissible trajectories* for problem (P).

The data for problem (P) satisfies the following hypotheses:

(H1) l and g are lower semicontinuous;

(H2) F takes values compact, convex sets, and the set

$$\{(v, (t, x)) \in \mathbb{R}^n \times ([t_0, T] \times \mathbb{R}^n): v \in F(t, x), (t, x) \in A\}$$

is compact;

(H3) A and C are compact sets;

(H4) There exists an admissible trajectory (\bar{t}_1, \bar{x}) for problem (P) for which

$$\int_{t_0}^{\bar{t}_1} l(t, \bar{x}(t), \dot{\bar{x}}(t)) dt + g(\bar{t}_1, \bar{x}(\bar{t}_1)) < \infty;$$

(H5) For each $(t, x) \in [t_0, T] \times \mathbb{R}^n$, the function $l(t, x, \cdot)$ restricted to the convex set $F(t, x)$ is a convex function.

2.1. The main results. We shall show in § 2.4 that our earlier analysis of the structure of generalized flows leads to the following dual representation of the minimum cost for problem (P).

THEOREM 2.1. *Under hypotheses (H1)–(H5), problem (P) has a solution. The infimum cost, $\inf P$, is*

$$\inf (P) = \sup \{ \phi(t_0, x_0) \},$$

where the supremum on the right is taken over functions ϕ in $C^1(\mathbb{R}^{1+n})$ that satisfy

$$\frac{\partial}{\partial t} \phi(t, x) + \frac{\partial}{\partial x} \phi(t, x) \cdot v + l(t, x, v) \geq 0 \quad \text{for all } (t, x) \in A, \quad v \in F(t, x)$$

and

$$\phi(t, x) \leq g(t, x) \quad \text{for all } (t, x) \in C.$$

The above theorem leads directly to the following optimality conditions.

THEOREM 2.2. *Let $(t_1^*, x^*(\cdot))$ be an admissible trajectory for problem (P). Assume that hypotheses (H1)–(H5) are satisfied. Then the following conditions hold.*

(i) Sufficient condition. Suppose that there exists a sequence of functions $\{\phi^i\}$ in $C^1(\mathbb{R}^{1+n})$ such that, for $i = 1, 2, \dots$,

$$(2.4) \quad \frac{\partial}{\partial t} \phi^i(t, x) + \frac{\partial}{\partial x} \phi^i(t, x) \cdot v + l(t, x, v) \geq 0 \quad \text{for all } (t, x) \in A, \quad v \in F(t, x),$$

$$(2.5) \quad \phi^i(t, x) \leq g(t, x) \quad \text{for all } (t, x) \in C,$$

and furthermore

$$(2.6) \quad \lim_i \phi^i(t_0, x_0) = \int_{t_0}^{t_1^*} l(t, x^*(t), \dot{x}^*(t)) dt + g(t_1^*, x^*(t_1)).$$

Then $(t_1^*, x^*(\cdot))$ is a minimizer.

(ii) Necessary condition. Suppose that $(t_1^*, x^*(\cdot))$ is a minimizer. Then there exists a sequence $\{\phi^i\}$ in $C^1(\mathbb{R}^{1+n})$ satisfying conditions (2.4)–(2.6).

Proof. (i) Let $\{\phi_i\}$ be a sequence with the stated properties and let $(t_1, x(\cdot))$ be an arbitrary admissible trajectory for (P). Since, for each i , the function $t \rightarrow \phi_i(t, x(t))$ is Lipschitz continuous, we may express it as the integral of its derivative. Thus

$$\phi_i(t_0, x_0) = - \int_{t_0}^{t_1} \frac{d}{dt} \phi_i(t, x(t)) dt + \phi_i(t_1, x(t_1)).$$

Using the chain rule to reduce the integrand and noting the boundary condition (2.5) on ϕ_i , we obtain

$$\phi_i(t_0, x_0) \leq - \int_{t_0}^{t_1} \left\{ \frac{\partial}{\partial t} \phi_i(t, x(t)) + \frac{\partial}{\partial x} \phi_i(t, x(t)) \cdot \dot{x}(t) \right\} dt + g(t_1, x(t_1)).$$

Since ϕ satisfies (2.4), we conclude that

$$\phi_i(t_0, x_0) \leq \int_{t_0}^{t_1} l(t, x(t), \dot{x}(t)) dt + g(t_1, x(t_1)).$$

In the limit $i \rightarrow \infty$, we obtain

$$\lim_{i \rightarrow \infty} \phi_i(t_0, x_0) \leq \int_{t_0}^{t_1} l(t, x(t), \dot{x}(t)) dt + g(t_1, x(t_1)).$$

This inequality combines with (2.6) to establish that $(t_1^*, x^*(\cdot))$ is a minimizer.

(ii) Now suppose that $(t_1^*, x^*(\cdot))$ is a minimizer. Let $\{\phi_i\}$ be a maximizing sequence associated with the supremum in the statement of Theorem 2.1. Then the ϕ_i 's automatically satisfy condition (2.4) and (2.5). The remaining condition (2.6) is also satisfied, since, by Theorem 2.1, the supremum coincides with the infimum cost for (P). \square

In problem (P), the model for the system dynamics is a differential inclusion. There is, however, considerable flexibility built into the formulation, since the cost integrand l is allowed to be a lower semicontinuous extended-valued function. Suppose, for example, that the differential inclusion was replaced by a differential equation with control as follows:

$$\dot{x}(t) = f(t, x(t), u(t)) \quad \text{a.e. } t \in [t_0, t_1], \quad u(t) \in U,$$

and the integral functional term in the cost were of the form $\int_{t_0}^{t_1} l'(t, x(t), u(t)) dt$. Minimization is now conducted over Lipschitz continuous functions x and measurable functions u satisfying the constraints. The problem assumes the guise of (P) when we choose the multifunction F and the extended-value cost integrand l to be

$$F(t, x) := f(t, x, U) \quad \text{and} \quad l(t, x, v) := \inf \{l'(t, x, u) : v = f(t, x, u)\},$$

respectively. (We interpret the infimum as $+\infty$ at points for which $v \notin f(t, x, U)$.) Under mild hypotheses, we arrive at an equivalent problem in this way (see [6]). The conditions on F and l in (H1) and (H2) are satisfied if, for example, l' and f are continuous functions, U is a compact set, and $f(t, x, U)$ is convex. Theorem 2.2 then provides optimality conditions for optimal control problems involving differential equations with control, via the reformulation.

2.2. A weak formulation. Our object here is to reformulate problem (P) as an optimization problem over a space of linear functionals. Choose positive numbers r , K such that

$$\begin{aligned} |v| &\leq r \quad \text{for all } v \in F(t, x), \quad (t, x) \in A, \\ C, A &\subset [t_0, T] \times (K\bar{B}), \\ (2.7) \quad |x_0| + |T - t_0|r &\leq K. \end{aligned}$$

Such choices are possible in view of hypotheses (H2) and (H3). We write $D = [t_0, T] \times (K\bar{B})$ and $\Omega = r\bar{B}$.

The optimization problem here of interest, denoted by (W), is as follows:

(W) Minimize $\int_{D \times \Omega} l d\mu + \int_D g d\gamma$ over elements $(\mu, \gamma) \in \mathcal{W}$ that satisfy

$$\langle \mu, d_{\tilde{F}(t,x)}(v) \rangle = 0, \quad \langle \mu, d_A(t, x) \rangle = 0, \quad \langle \gamma, d_C(t, x) \rangle = 0.$$

In these relationships, \tilde{F} is the multifunction

$$\tilde{F}(t, x) := \begin{cases} F(t, x) & \text{if } (t, x) \in A, \\ \mathbb{R}^n & \text{if } (t, x) \notin A, \end{cases}$$

and $d_Z(\cdot): \mathbb{R}^k \rightarrow \mathbb{R}$ denotes the Euclidean distance function associated with a set $Z \subset \mathbb{R}^k$. Generic elements in $C(D \times \Omega)$ and $C(D)$ are written as (t, x, v) and (t, x) , respectively.

Problem (W) requires some interpretation. Recall that \mathcal{W} is the subset of $C^*(D \times \Omega) \times C^*(D)$ comprising elements that satisfy

$$\mu \geq 0, \quad \gamma \geq 0, \quad |\mu|_{C^*} \leq T - t_0, \quad |\gamma|_{C^*} \leq 1,$$

and

$$\left\langle \mu, \left[\frac{\partial}{\partial t} \phi(t, x) + \frac{\partial}{\partial x} \phi(t, x) \cdot v \right] \right\rangle = \langle \gamma, \phi \rangle - \phi(t_0, x_0)$$

for every $\phi \in C^1(\mathbb{R}^{1+n})$.

Given $(\mu, \gamma) \in \mathcal{W}$, the cost function involves integration with respect to the regular Borel measures on $D \times \Omega$ and D , which represent μ and γ , respectively. The integrals are well defined, since the integrands l and g are lower semicontinuous (and therefore Borel measurable and bounded below on the compact domains $D \times \Omega$ and D).

It is easy to see that

$$(2.8) \quad \inf(P) \geq \inf(W).$$

This follows from the fact that, if the arc x satisfies the constraints of problem (P), then the element $(\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D)$ defined by

$$\langle \mu, \xi \rangle := \int_{t_0}^{t_1} \xi(t, x(t), \dot{x}(t)) dt \quad \text{and} \quad \langle \gamma, \eta \rangle = \eta(t_1, x(t_1))$$

for all $\xi \in C(D \times \Omega)$ and $\eta \in C(D)$ satisfies the constraints of problem (W), and the values of the costs are the same. We now use the machinery developed in §1 to obtain the converse inequality.

THEOREM 2.3. *Problems (P) and (W) have minimizers, and $\inf(P) = \inf(W)$.*

Proof. First, note that the set of elements satisfying the constraints in (W) is a weak* closed subset of the weak* compact set \mathcal{W} and, as such, is weak* compact. It is nonempty, since it contains the element associated with the admissible arc (\bar{t}, \bar{x}) of hypothesis (H4). The cost functional for (W) is weak* lower semicontinuous on $\{(\mu, \gamma) \in C^* \times C^*: \mu \geq 0, \gamma \geq 0\}$. To verify this, we must show that, for any $\alpha \in \mathbb{R}$, the set

$$S_\alpha = \left\{ (\mu, \gamma) \in C^* \times C^*: \int_{D \times \Omega} l d\mu + \int_D g d\gamma \leq \alpha \right\}$$

is weak* closed. It is easily deduced from the monotone convergence theorem that

$$S_\alpha = \bigcap_{i=1}^{\infty} S_\alpha^i,$$

where

$$S_\alpha^i := \left\{ (\mu, \gamma) \in C^* \times C^*: \int_{D \times \Omega} l_i d\mu + \int_D g_i d\gamma \leq \alpha \right\}.$$

In these definitions, $\{l_i\}$ is some sequence of continuous functions on $D \times \Omega$ minorizing l and converging everywhere to l , and $\{g_i\}$ is any sequence of continuous functions on D minorizing g and converging everywhere to g . The fact that S_α is weak* closed now follows from the weak* closedness of the S_α^i 's. Existence of a minimizer (μ_0, γ_0) is therefore assured.

We now demonstrate the existence of an admissible arc for (P), the value of whose cost coincides with that of (μ_0, γ_0) in problem (W); this fact combined with (2.8) will permit us to conclude that (P), too, has a minimizer and that $\inf(P) = \inf(W)$.

Since $(\mu_0, \gamma_0) \in \mathcal{W}$, we know from Corollary 1.4 of the existence of a regular Borel probability measure Λ on S such that

$$(2.9) \quad (\mu_0, \gamma_0) = \int_S (\mu, \gamma) d\Lambda(\mu, \gamma).$$

The fact that (μ_0, γ_0) is feasible for problem (W) implies that

$$\begin{aligned} \int_S \langle \mu, d_{F(t,x)}(v) \rangle d\Lambda &= 0, \\ \int_S \langle \mu, d_A(t, x) \rangle d\Lambda &= 0, \quad \text{and} \\ \int_S \langle \gamma, d_C(t, x) \rangle d\Lambda &= 0. \end{aligned}$$

Let S' be the weak* closed subset of points (μ, γ) in S such that

$$(2.10) \quad \langle \mu, d_{F(t,x)}(v) \rangle = \langle \mu, d_A(t, x) \rangle = \langle \gamma, d_C(x) \rangle = 0.$$

Since the integrands involved are nonnegative, we deduce that S' has full Λ -measure.

Turn now to consideration of the cost function for (W). Equation (2.9) and the fact that S' has full measure imply that

$$(2.11) \quad \int l d\mu_0 + \int g d\gamma_0 = \int_{S'} \left[\int l d\mu + \int g d\gamma \right] d\Lambda(\mu, \gamma).$$

Suppose that $\int l d\mu + \int g d\gamma > \int l d\mu_0 + \int g d\gamma_0$ for every $(\mu, \gamma) \in S'$. Then, since Λ restricted to the Borel subsets for S' is a probability measure, we have

$$\int_{S'} \left[\int l d\mu + \int g d\gamma \right] d\Lambda(\mu, \gamma) > \int l d\mu_0 + \int g d\gamma_0.$$

This contradicts (2.11). Hence there exists some element (μ, γ) in S' such that

$$\int l d\mu + \int g d\gamma = \int l d\mu_0 + \int g d\gamma_0.$$

Let (t_1, x, m) be the relaxed arc associated with (μ, γ) . We have

$$(2.12) \quad \int_{t_0}^{t_1} \int l(t, x(t), v) dm_t(v) dt + g(t_1, x(t_1)) = \int l d\mu_0 + \int g d\gamma_0.$$

It follows from (2.10) that

$$(2.13) \quad \int d_{\tilde{F}(t, x(t))}(v) dm_t(v) = 0 \quad \text{a.e. } [t_0, t_1],$$

$$(2.14) \quad d_A(t, x(t)) = 0 \quad \text{a.e. } [t_0, t_1],$$

and

$$(2.15) \quad d_C(t_1, x(t_1)) = 0.$$

Equations (2.14) and (2.15) show us that

$$(2.16) \quad \text{graph } \{x\} \subset A \quad \text{and} \quad (t_1, x(t_1)) \in C.$$

From (2.13) and (2.14) we deduce that

$$(2.17) \quad \text{support } \{m_t\} \subset F(t, x(t)) \quad \text{a.e.}$$

Define

$$(2.18) \quad c(t) := \int_{t_0}^t \left(\int l(t, x(t), v) dm_t(v) \right) dt.$$

Then

$$\begin{bmatrix} \dot{c}(t) \\ \dot{x}(t) \end{bmatrix} = \int \begin{bmatrix} l(t, x(t), v) \\ v \end{bmatrix} dm_t(v) \quad \text{a.e.}$$

This relationship, together with (2.17), imply that, for almost every t ,

$$\begin{aligned} \begin{bmatrix} \dot{c}(t) \\ \dot{x}(t) \end{bmatrix} &\in \overline{\text{co}} \left\{ \begin{bmatrix} l(t, x(t), v) \\ v \end{bmatrix} : v \in F(t, x(t)) \right\} \\ &\subset \{(\alpha, v) \in \mathbb{R} \times \mathbb{R}^n : \alpha \geq l(t, x(t), v) \text{ and } v \in F(t, x(t))\} \\ &\quad \text{a.e. } [t_0, t_1]. \end{aligned}$$

This follows from the fact that the restriction of $l(t, x(t), \cdot)$ to the convex set $F(t, x(t))$ is a lower semicontinuous, convex function. Then, however,

$$(2.19) \quad \dot{c}(t) \geq l(t, x(t), \dot{x}(t)) \quad \text{a.e. } [t_0, t_1]$$

and

$$(2.20) \quad \dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } [t_0, t_1].$$

From (2.12), (2.18), and (2.19), we deduce that

$$(2.21) \quad \int l d\mu_0 + \int g d\gamma_0 \geq \int_{t_0}^{t_1} l(t, x(t), \dot{x}(t)) dt + g(t_1, x(t_1)).$$

In view of (2.16) and (2.20), (t_1, x) is an admissible arc for (P), while (2.21) establishes that this arc has cost not greater than $\inf(W)$. The proof is complete. \square

2.3. Fenchel duality. This section provides a brief summary of aspects of convex analysis relevant to the analysis of the weak problem. It focusses on one procedure (Fenchel duality) for generating optimization problems “paired in duality.” For a fuller account, see [10].

Take \mathcal{Y} and \mathcal{Y}' to be locally convex topological vector spaces, in duality with respect to a bilinear form $\langle \cdot, \cdot \rangle : \mathcal{Y} \times \mathcal{Y}' \rightarrow \mathbb{R}$. This means that every continuous linear functional on \mathcal{Y} can be represented by $\langle \cdot, y' \rangle$ for some $y' \in \mathcal{Y}'$ and that every continuous linear functional on \mathcal{Y}' can be represented by $\langle y, \cdot \rangle$ for some $y \in \mathcal{Y}$.

DEFINITION 2.4. (i) Consider a function $p : \mathcal{Y} \rightarrow \bar{\mathbb{R}}$. The *convex conjugate* of p is the function $p' : \mathcal{Y}' \rightarrow \bar{\mathbb{R}}$, defined by

$$(2.22) \quad p'(y') := \sup \{ \langle y, y' \rangle - p(y) : y \in \mathcal{Y} \}.$$

(ii) Consider a function $q : \mathcal{Y} \rightarrow \bar{\mathbb{R}}$. The *concave conjugate* of q is the function $q' : \mathcal{Y}' \rightarrow \bar{\mathbb{R}}$, defined by

$$(2.23) \quad q'(y') := \inf \{ \langle y, y' \rangle - q(y) : y \in \mathcal{Y} \}.$$

It will always be evident from context whether a convex or concave conjugate is intended, and confusion should not arise from using the prime notation for both constructs.

Because the spaces \mathcal{Y} and \mathcal{Y}' are interchangeable, we can apply the operation of convex conjugation to functions on \mathcal{Y}' , thereby obtaining functions on \mathcal{Y} . In particular, if we start with a function $p: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$, we can construct the convex conjugate $p': \mathcal{Y}' \rightarrow \bar{\mathbb{R}}$ according to (2.22) and then the *second convex conjugate* $p'': \mathcal{Y} \rightarrow \bar{\mathbb{R}}$, namely,

$$p''(y) := \sup \{ \langle y, y' \rangle - p'(y') : y' \in \mathcal{Y}' \}.$$

Likewise, we can define the *second convex conjugate* $q'': \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ of a function $q: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$, namely,

$$q''(y) := \inf \{ \langle y, y' \rangle - q'(y') : y' \in \mathcal{Y}' \},$$

where q' is given by (2.23).

Of particular interest are the conjugates of *proper* functions, as shown in Definition 2.5.

DEFINITION 2.5. (i) A function $p: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ is said to be a *proper convex function* if p is a lower semicontinuous, convex function such that $p(y) > -\infty$ for all points $y \in \mathcal{Y}$ and $p(\bar{y}) < +\infty$ for some point $\bar{y} \in \mathcal{Y}$.

(ii) A function $q: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ is said to be a *proper concave function* if q is an upper semicontinuous, concave function such that $q(y) < +\infty$ for all points $y \in \mathcal{Y}$ and $q(\bar{y}) > -\infty$ for some point $\bar{y} \in \mathcal{Y}$.

In fact, there is a one-to-one relationship between proper convex functions and their convex conjugates; a proper convex function is recoverable from information about its convex conjugate by taking the second convex conjugate. Analogous results apply to proper concave functions.

PROPOSITION 2.6. (i) If a function $p: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ is a *proper convex function*, then its *convex conjugate* is a *proper convex function*. We have

$$p(y) = p''(y) \quad \text{for all } y \in \mathcal{Y},$$

where p'' is the *second convex conjugate* of p .

(ii) If a function $q: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ is a *proper concave function*, then its *concave conjugate* is a *proper concave function*. We have

$$q(y) = q''(y) \quad \text{for all } y \in \mathcal{Y},$$

where q'' is the *second concave conjugate* of q .

A Fenchel program is a convex optimization problem taking the form

$$(I) \quad \text{Minimize } p(y) - q(y) \quad \text{over } y \in \mathcal{Y},$$

in which $p: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ and $q: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ are proper convex and proper concave functions, respectively. We call this the *primal problem*.

Fenchel duality is concerned with relating it to the associated concave problem, the *dual problem*, namely,

$$(II) \quad \text{Maximize } q'(y') - p'(y') \quad \text{over } y' \in \mathcal{Y}',$$

in which p' and q' are the convex and concave conjugates of p and q , respectively.

By the definitions of the conjugate functionals, we have that, for any $y \in \mathcal{Y}$ and $y' \in \mathcal{Y}'$,

$$p(y) - q(y) = \{ \langle y, y' \rangle - q(y) \} - \{ \langle y, y' \rangle - p(y) \} \geq q'(y') - p'(y').$$

It follows that

$$\inf \{ p(y) - q(y) : y \in \mathcal{Y} \} \geq \sup \{ q'(y') - p'(y') : y' \in \mathcal{Y}' \}.$$

Interest centers on circumstances when inequality here can be replaced by equality; in such circumstances, the primal and dual problems are said to be in *strong duality*.

We use the following criterion for strong duality. The hypotheses involved also ensure that the primal problem has a solution.

PROPOSITION 2.7. Let $p: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ and $q: \mathcal{Y} \rightarrow \bar{\mathbb{R}}$ be proper convex and proper concave functions, respectively. Denote by p' and q' the convex and concave conjugate functions of p and q , respectively. We suppose that the following condition holds:

(H) There exists a point $y' \in \mathcal{Y}'$ such that p' is continuous in a neighborhood of y' and $q'(y') > -\infty$.

Then

$$(2.24) \quad \inf \{p(y) - q(y) : y \in \mathcal{Y}\} = \sup \{q'(y') - p'(y') : y' \in \mathcal{Y}'\}.$$

Furthermore, the infimum on the left is achieved. This is true even if the infimum is $+\infty$, in which case, any $y \in \mathcal{Y}$ is interpreted as a minimizer.

2.4. Proof of Theorem 2.1. The proof of Theorem 2.1 involves reformulating the weak problem (W) of §2.2 as a Fenchel program, namely,

$$\text{Minimize } p(y) - q(y) \quad \text{over } y \in \mathcal{Y}$$

and applying the theory of the preceding section.

In this application, the space \mathcal{Y} is chosen to be the space $C^*(D \times \Omega) \times C^*(D)$ with the product weak* topology, and \mathcal{Y}' is chosen to be the space $C(D \times \Omega) \times C(D)$ with the supremum norm topology. The bilinear form pairing these two spaces in duality is simply

$$\langle (\mu, \gamma), (\xi, \eta) \rangle := \langle \mu, \xi \rangle + \langle \gamma, \eta \rangle$$

for $(\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D)$ and $(\xi, \eta) \in C(D \times \Omega) \times C(D)$. The two terms on the right are intended to describe the action of bounded linear functionals μ and γ in the dual spaces $C^*(D \times \Omega)$ and $C^*(D)$ on points ξ and η in $C(D \times \Omega)$ and $C(D)$, respectively.

The reformulation (we use the label (W)') amounts to retaining the value of the cost function on points satisfying the constraints of problem (W) as originally formulated and replacing it by $+\infty$ on points where they are violated. It is as follows:

$$(W)' \quad \text{Minimize } p(\mu, \gamma) - q(\mu, \gamma) \quad \text{over } (\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D).$$

Here $p: C^* \times C^* \rightarrow \mathbb{R} \cup \{+\infty\}$ and $q: C^* \times C^* \rightarrow \mathbb{R} \cup \{-\infty\}$ are defined as follows:

$$p(\mu, \gamma) := \int_{D \times \Omega} l \, d\mu + \int_D g \, d\gamma + \chi_P(\mu, \gamma) \quad \text{and} \quad q(\mu, \gamma) := -\chi_Q(\mu, \gamma).$$

In these expressions, χ_A denotes the indicator function of a set A , below:

$$\chi_A(a) := \begin{cases} +\infty & \text{if } a \notin A, \\ 0 & \text{if } a \in A. \end{cases}$$

The sets P and Q are taken as

$$P := \{(\mu, \gamma) \in C^* \times C^* : \mu \geq 0, \gamma \geq 0, |\mu|_{C^*} \leq (T - t_0), |\gamma|_{C^*} \leq 1,$$

and (μ, γ) satisfies condition (i) below\}

and

$$Q := \{(\mu, \gamma) \in C^* \times C^* : (\mu, \gamma) \text{ satisfies condition (ii) below}\}:$$

- (i) $\langle \mu, d_{\tilde{F}(t, x)}(v) \rangle = 0$, $\langle \mu, d_A(t, x) \rangle = 0$, and $\langle \gamma, d_C(t, x) \rangle = 0$;
- (ii) $\langle \mu, \phi_t + \phi_x \cdot v \rangle = \langle \gamma, \phi \rangle - \phi(t_0, x_0)$ for all $\phi \in C^1(\mathbb{R}^{1+n})$.

The convex and concave conjugates of p and q are

$$(2.25) \quad p'(\xi, \eta) = \sup \{ \langle \mu, \xi \rangle + \langle \gamma, \eta \rangle - p(\mu, \gamma) : (\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D) \}$$

and

$$(2.26) \quad q'(\xi, \eta) = \inf \{ \langle \mu, \xi \rangle + \langle \gamma, \eta \rangle - q(\mu, \gamma) : (\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D) \},$$

respectively.

The information we require about p and q , and their conjugates, is embodied in the following proposition. Here we use the notation b^+ , below, to describe the “non-negative” part of a real-valued function b :

$$b^+(s) := \max \{0, b(s)\}.$$

LEMMA 2.8. *The functions p and q are proper convex and proper concave functions, respectively, with respect to the weak* topology. The convex and concave conjugates p' and q' of these functions are, respectively,*

$$p'(\xi, \eta) = \max_{(t, x, v) \in A \times \text{graph}\{F\}} (\xi - l)^+(t, x, v) \cdot (T - t_0) + \max_{(t, x) \in C} (\eta - g)^+(t, x)$$

and

$$q'(\xi, \eta) = \eta(t_0, x_0) - \chi_{\bar{\mathcal{T}}}(\mu, \gamma),$$

in which $\bar{\mathcal{T}}$ is the closure in the supremum norm topology of the set

$$\begin{aligned} \mathcal{T} &:= \{(\xi', \eta') \in C \times C : \xi'(t, x, v) \\ &= \phi_t(t, x) + \phi_x(t, x) \cdot v, \eta' = -\phi \text{ for some } \phi \in C^1(\mathbb{R}^{1+n})\}. \end{aligned}$$

Proof. The function p can be expressed as $p(\mu, \gamma) = r(\mu, \gamma) + \chi_P(\mu, \gamma)$, where

$$r(\mu, \gamma) := \int_{D \times \Omega} l \, d\mu + \int_D g \, d\gamma + \chi_{\{(\mu', \gamma') \in C^* \times C^* : \mu' \geq 0, \gamma' \geq 0\}}(\mu, \gamma).$$

The function r is finite-valued at the point associated with the admissible trajectory (\bar{l}, \bar{x}) of hypothesis (H3). r cannot take the value $-\infty$, since l and g are bounded below, and r is lower semicontinuous according to our earlier observations. r then is a proper convex function. The set P is expressible as the intersection of a family of weak* closed sets of the following form:

$$\{(\mu, \gamma) \in C^*(D \times \Omega) \times C^*(D) : \langle (\mu, \gamma), d \rangle \leq \alpha\}$$

for some $d \in C(D \times \Omega) \times C(D)$ and $\alpha \in \mathbb{R}$. P is nonempty since it contains the element $(\bar{\mu}, \bar{\gamma})$ corresponding to the admissible trajectory (\bar{l}_1, \bar{x}) . As such, P is a nonempty, convex, weak* closed set. Along similar lines, we show that the set Q is also nonempty, convex, and weak* closed. It follows that p and $-q$ are proper convex functions. (The indicator functions of nonempty, closed, convex sets are proper convex functions, and the class of lower semicontinuous, convex functions is closed under summation.) Then q ($= -(-q)$) also is a proper concave function.

We now compute the values of p' . Take any $(\xi, \eta) \in C(D \times \Omega) \times C(D)$. Evidently,

$$(2.27) \quad p'(\xi, \eta) = \sup \left\{ \int_{D \times \Omega} (\xi - l) \, d\mu : \mu \in P_1 \right\} + \sup \left\{ \int_D (\eta - g) \, d\gamma : \gamma \in P_2 \right\},$$

in which

$$\begin{aligned} P_1 &:= \left\{ \mu \in C^*(D \times \Omega) : \mu \geq 0, \int_{D \times \Omega} d_{F(t, x)}(v) \, d\mu = 0, \right. \\ &\quad \left. \int_{D \times \Omega} d_A(t, x) \, d\mu = 0 \text{ and } \int_{D \times \Omega} d\mu \leq (T - t_0) \right\} \end{aligned}$$

and

$$P_2 := \left\{ \gamma \in C^*(D): \gamma \geq 0, \int_D d_C d\gamma = 0 \quad \text{and} \quad \int_D d\gamma \leq 1 \right\}.$$

Consider the first supremum in (2.27). It is clear from the conditions defining set P_1 that the support of each μ in P_1 is contained in $\text{graph}\{F\} \cap A$. If $\eta - g$ is nonpositive-valued, the supremum is zero. Otherwise, the supremum is achieved by concentrating the measure at a point in the compact set $\text{graph}\{F\} \cap A$ where the upper semicontinuous function $\eta - g$ takes its maximum value. The supremum is

$$\max_{A \times \text{graph}\{F\}} (\xi - l)^+ \cdot (T - t_0).$$

The value of the second supremum in (2.9) is likewise shown to be $\max_C (\eta - g)^+$. This verifies the formula for the conjugate functional p' .

We now turn to the function q' . Consider first a point $(\xi, \eta) \notin \bar{\mathcal{T}}$. Since $\bar{\mathcal{T}}$ is a closed subspace, it follows from the separation theorem (strict form) that there exists $(\mu', \gamma') \in C^*(D \times \Omega) \times C^*(D)$ such that

$$(2.28) \quad \langle \mu', \xi \rangle + \langle \gamma', \eta \rangle < 0$$

and

$$(2.29) \quad \langle \mu', \phi_t(t, x) + \phi_x(t, x) \cdot v \rangle + \langle \gamma', -\phi \rangle = 0$$

for all $\phi \in C^1(\mathbb{R}^{1+n})$.

Now we know that the generalized flow $(\bar{\mu}, \bar{\gamma})$ corresponding to the admissible trajectory (\bar{t}_1, \bar{x}) satisfies

$$(2.30) \quad \langle \bar{\mu}, \phi_t(t, x) + \phi_x(t, x) \cdot v \rangle + \langle \bar{\gamma}, -\phi \rangle = -\phi(t_0, x_0)$$

for all $\phi \in C^1(\mathbb{R}^{1+n})$. Note that, by (2.29) and (2.30),

$$(\bar{\mu}, \bar{\gamma}) + \alpha(\mu', \gamma') \in \mathcal{T}$$

for every $\alpha \in \mathbb{R}$. It follows that

$$\begin{aligned} q'(\xi, \eta) &= \inf \{ \langle (\mu, \gamma), (\xi, \eta) \rangle : (\mu, \gamma) \in Q \} \\ &\leq \langle (\bar{\mu}, \bar{\gamma}), (\xi, \eta) \rangle + \inf_{\alpha \in \mathbb{R}} \langle (\mu', \gamma'), (\xi, \eta) \rangle \alpha \\ &= -\infty, \end{aligned}$$

by (2.28). We conclude that $q'(\xi, \eta) = -\infty$.

It remains to consider a point $(\xi, \gamma) \in \bar{\mathcal{T}}$. Since $\bar{\mathcal{T}}$ is the strong closure of \mathcal{T} , there exists a sequence of functions $\{\phi_i\}$ in $C^1(\mathbb{R}^{1+n})$ such that

$$(2.31) \quad \phi_i^i(t, x) + \phi_x^i(t, x) \cdot v \rightarrow \xi(t, x) \quad \text{and} \quad -\phi^i(t, x) \rightarrow \eta(t, x)$$

uniformly on $D \times \Omega$ and D , respectively.

For any $(\mu, \gamma) \in Q$, we have

$$\begin{aligned} \langle (\mu, \gamma), (\xi, \eta) \rangle &= \lim_i \langle (\mu, \gamma), (\phi_i^i(t, x) + \phi_x^i(t, x) \cdot v, -\phi^i(t, x)) \rangle \\ &= \lim_i -\phi^i(t_0, x_0) \\ &= \eta(t_0, x_0), \end{aligned}$$

by (2.31). It follows that

$$q'(\xi, \eta) = \inf \{ \langle (\mu, \gamma), (\xi, \eta) \rangle : (\mu, \gamma) \in Q \} = \eta(t_0, x_0).$$

q' therefore takes the form asserted in the lemma. \square

The formulae we have just derived for the conjugate functionals p' and q' lead to a simple characterization of the supremum cost for the dual problem.

LEMMA 2.9. *It holds that*

$$\sup \{ p'(\xi, \eta) - q'(\xi, \eta) : (\xi, \eta) \in C(D \times \Omega) \times C(D) \} = \sup \{ \phi(t_0, x_0) \},$$

where the supremum on the right is taken over elements $\phi \in C^1(\mathbb{R}^{1+n})$ that satisfy

$$\min_{v \in F(t, x)} \{ \phi_t(t, x) + \phi_x(t, x) \cdot v + l((t, x, v)) \} \geq 0 \quad \text{for } (t, x) \in A$$

and

$$\phi(t, x) \leq g(t, x) \quad \text{for all } (t, x) \in C.$$

Proof. By Lemma 2.8,

$$\sup \{ q'(\xi, \eta) - p'(\xi, \eta) : (\xi, \eta) \in C(D \times \Omega) \times C(D) \} = \sup \{ m(\xi, \eta) : (\xi, \eta) \in \bar{\mathcal{T}} \},$$

where m is the function

$$m(\xi, \eta) := \eta(t_0, x_0) - \max_{A \times \text{graph}\{F\}} (\xi - l)^+(T - t_0) - \max_C (\eta - g)^+,$$

and where $\bar{\mathcal{T}}$ is the closure of the set \mathcal{T} defined in Lemma 2.8. Since, however, m is a continuous function, the supremum on the right side is unaltered if we replace $\bar{\mathcal{T}}$ by \mathcal{T} . It follows that

$$\sup \{ q' - p' \} = \sup_{\phi \in C(\mathbb{R}^{1+n})} \tilde{m}(\phi),$$

where

$$\tilde{m}(\phi) := -\phi(t_0, x_0) - \max_{A \times \text{graph}\{F\}} (\phi_t + \phi_x \cdot v - l)^+(T - t_0) - \max_C (-\phi - g)^+.$$

For any $\phi \in C^1(\mathbb{R}^{1+n})$, define

$$c_1 := \max_{A \times \text{graph}\{F\}} (\phi_t + \phi_x \cdot v - l)^+ \quad \text{and} \quad c_2 := \max_C (-\phi - g)^+$$

and consider the C^1 function

$$\tilde{\phi}(t, x) := \phi(t, x) + c_2 - c_1(t - t_0).$$

We find that

$$\tilde{m}(\tilde{\phi}) \geq \tilde{m}(\phi),$$

$$\tilde{\phi}_t(t, x) + \tilde{\phi}_x(t, x) \cdot v - l(t, x, v) \leq 0 \quad \text{for all } (t, x, v) \in \text{graph}\{F\} \cap A,$$

and

$$-\tilde{\phi}(t, x) \leq g(t, x) \quad \text{for all } (t, x) \in C.$$

It follows that

$$\begin{aligned} & \sup \{ p' - q' \} \\ &= \sup \{ -\phi(t_0, x_0) : \phi \in C^1(\mathbb{R}^{1+n}), \phi_t + \phi_x \cdot v - l \leq 0 \\ & \quad \text{on } \text{graph}\{F\} \cap A, -\phi \leq g \text{ on } C \} \\ &= \sup \{ \phi(t_0, x_0) : \phi \in C^1(\mathbb{R}^{1+n}), \phi_t + \phi_x \cdot v + l \geq 0 \\ & \quad \text{on } \text{graph}\{F\} \cap A, \phi \leq g \text{ on } C \}. \quad \square \end{aligned}$$

We now return to the proof of Theorem 2.1. p' is a continuous function on $C(D \times \Omega) \times C(D)$, and q' is, of course, proper. By Proposition 2.7,

$$\inf \{W\} \quad (= \inf \{p - q\}) = \sup \{q' - p'\}.$$

Assembling this inequality with the assertions of Theorem 2.3 and Lemma 2.9 we see that (P) has a solution and

$$\inf \{P\} = \sup \{\phi(t_0, x_0)\},$$

where the supremum on the right is taken over functions $\phi \in C^1(\mathbb{R}^{1+n})$ satisfying the constraints listed in the statement of Theorem 2.1. This what we intended to prove.

INFINITE-DIMENSIONAL VOLTERRA-STIELTJES EVOLUTION EQUATIONS AND RELATED OPTIMAL CONTROL PROBLEMS*

JIONGMIN YONG†

Abstract. Due to impulse control problems, a controlled Volterra–Stieltjes system in some Banach space is studied. In the system, the vector measure appearing in the Stieltjes-type integral (called Young integral here) is taken as a part of control action. In this paper, a general theory for infinite-dimensional Volterra–Stieltjes evolution equations is presented, and, for an optimal control problem governed by such type controlled system with a general endpoint constraint, a Pontryagin-type maximum principle is proved.

Key words. Young integral, Volterra–Stieltjes integral equation, distributed parameter system, measure control, maximum principle, optimal control

AMS(MOS) subject classifications. 49B27, 93C25, 93C22, 34G20

1. Introduction. Let us first give a motivation of the optimal control problem studied in this paper. Let X be a Banach space and $A: \mathcal{D}(A) \subset X \rightarrow X$ be the infinitesimal generator of some C_0 -semigroup e^{At} on X . We consider a controlled evolution system

$$(1.1) \quad \begin{aligned} \dot{x}(t) &= Ax(t) + g(t, x(t), u(t)), & t \in [0, T], \\ x(0) &= x_0. \end{aligned}$$

The state of the system is usually understood as the mild solution of (1.1). Namely, the state $x(\cdot)$ of the system satisfies the following Volterra integral equation:

$$(1.2) \quad x(t) = e^{At}x_0 + \int_0^t e^{A(t-s)}g(s, x(s), u(s)) \, ds, \quad t \in [0, T].$$

Now suppose that we have another control action—an impulse control; i.e., at moment $t = \tau_i$, $i \geq 1$, we make an impulse ξ_i to the state $x(\tau_i - 0)$. We refer $\{(\tau_i, \xi_i) | i \geq 1\}$ as an “impulse control.” Thus we have that

$$x(\tau_i) = x(\tau_i - 0) + \xi_i, \quad i \geq 1.$$

Then the state $x(\cdot)$ formally satisfies the following evolution equation:

$$(1.3) \quad \begin{aligned} \dot{x}(t) &= Ax(t) + g(t, x(t), u(t)) + \sum_{i \geq 1} \xi_i \delta(t - \tau_i), & t \in [0, T], \\ x(0) &= x_0, \end{aligned}$$

where $\delta(\cdot)$ is the δ -function. Similar to (1.2), we understand the state $x(\cdot)$ of system (1.3) as the solution of the following integral equation:

$$(1.4) \quad \begin{aligned} x(t) &= e^{At}x_0 + \int_0^t e^{A(t-s)}g(s, x(s), u(s)) \, ds \\ &+ \sum_{i \geq 1} e^{A(t-\tau_i)}\xi_i \chi_{[\tau_i, \infty)}(t), & t \in [0, T]. \end{aligned}$$

† Department of Mathematics, Fudan University, Shanghai 200433, China.

It is more reasonable that, in general, the impulse ξ_i at time $t = \tau_i$ should also depend on the state $x(\tau_i - 0)$, which is the state of the system before making impulse ξ_i . Thus it is more natural to consider the following state equation (compare with (1.3)):

$$(1.5) \quad \begin{aligned} dx(t) &= (Ax(t) + g(t, x(t), u(t))) dt \\ &\quad + g_0(t, x(t-0), u(t)) d\xi(t), \quad t \in [0, T], \\ x(0) &= x_0, \end{aligned}$$

where $\xi(t) = \sum_{i \geq 1} \xi_i \chi_{[\tau_i, \infty)}(t)$, $t \in [0, \infty)$. If we let

$$G(t, x, u) = \begin{pmatrix} g(t, x, u) \\ g_0(t, x, u) \end{pmatrix}, \quad \eta(t) = \begin{pmatrix} t \\ 0 \end{pmatrix} + \begin{pmatrix} 0 \\ \xi(t) \end{pmatrix} = \begin{pmatrix} t \\ \xi(t) \end{pmatrix},$$

then (1.5) can be written as

$$(1.6) \quad \begin{aligned} dx(t) &= Ax(t) dt + G(t, x(t-0), u(t)) d\eta(t), \quad t \in [0, T], \\ x(0) &= x_0. \end{aligned}$$

From the above, we see that it is reasonable to consider the following controlled system (formally):

$$(1.7) \quad \begin{aligned} dx(t) &= Ax(t) dt + F(t, x(t-0), u(t)) d\mu(t), \quad t \in [0, T], \\ x(0) &= x_0, \end{aligned}$$

with some $\mathcal{L}(Z, X)$ -valued function F and some vector-valued measure $\mu(\cdot)$, which together with $u(\cdot)$ will be considered as control actions. We specify the meaning of (1.7) in § 2. Associated with (1.7), we are given a cost functional

$$(1.8) \quad J(x(\cdot), u(\cdot), \mu(\cdot)) = \int_0^T \langle f(t, x(t-0), u(t)), \mu(dt) \rangle.$$

Again, we give the precise meaning of the above later in the paper. Clearly, in the case where there is no impulse, (1.8) is reduced to the usual cost functional of Lagrange form. We should note, at this moment, that the functional (1.8) is adopted from [32]. It is not the most interesting case for the optimal impulse control problems since, in those problems, the cost functional is not necessarily linear in the impulse control variable $\mu(\cdot)$. For details, see [34] and [37] (see also [35] for the finite-dimensional case).

The control problem we study in this paper is minimizing functional (1.8) over some class of admissible controls, subject to the state equation (1.7) and an endpoint constraint for the state of the following type:

$$(1.9) \quad (x(0), x(T)) \in \Omega \subset X \times X.$$

In [31], [32], a similar problem in finite-dimensional spaces was studied. It is immediate that the first major difference between this paper and [31], [32] is the issue of whether the coefficient of $\mu(\cdot)$ depends on the state $x(\cdot)$. Second, we are in infinite-dimensional space, and we have a general endpoint constraint (1.9), which is different from the separated endpoint constraint case (see [23] for comments). On the other hand, we should note that the operator-valued function $F(t, x, u)$ must be assumed Fréchet differentiable in x , which is slightly more restrictive than [32] for the finite-dimensional case (in [32] only the Lipschitz continuity in x was assumed). The removal of this restriction, as well as the study of more general cost functionals, is expected in our future work. For some special cases, the idea of [36] might be useful (see also [4]). We refer to [12] for some relevant results.

Impulse control problems have frequently been discussed. We refer to [6], [7], [25] for finite-dimensional stochastic systems, to [5], [35] for finite-dimensional deterministic systems, and to [34], [37] for infinite-dimensional cases. We refer to [8]–[10], [30], [33] for some classical optimal control problems and to [1]–[4], [17], [22]–[24] for distributed parameter system cases.

The so-called Young integral for scalar functions was introduced by L. C. Young in 1914 [38]. We refer to [18], [19] for the theory of Volterra–Stieltjes integral equations involving the Young integral (for the scalar-valued case). Some relevant results concerning the Volterra–Stieltjes integral equations (involving some other types of integrals) can be found in [21], [26], [28]. We should note that the integrals involved in [31], [32] were of the Bochner (i.e., the Lebesgue) type. We adopt the Young integral because such an integral inherits the exact “discontinuity” of the measure with respect to which the integral is taken. This is the case for the impulse control problems. It seems that a similar property of the Bochner-type integral is not as good as the one of the Young integral (see Remark 3.1).

The main results of this paper consist of the study of the infinite-dimensional Volterra–Stieltjes integral equations and the Pontryagin-type maximum principle for the related optimal control problems. We organize the paper as follows. In § 2 we present a theory for the infinite-dimensional Volterra–Stieltjes integral equations. In § 3 we state the optimal control problem and the maximum principle. We give some auxiliary results in § 4. Section 5 is devoted to proving the maximum principle. Some relevant results concerning the vector measures and Young integrals are collected in the Appendix.

2. Volterra–Stieltjes integral equations. In this section, we present some basic results concerning the Volterra–Stieltjes equations involving the Young integral. We refer to the Appendix for relevant results concerning the Young integral. We let X and Z be Banach spaces, K be a subset of Z , and

$$\begin{aligned} \mu(\cdot) &\in BV_0([0, T]; K) \\ &\equiv \{v(\cdot) : [0, T] \rightarrow K \mid v(\cdot) \text{ is of bounded variation and } v(0) = 0\}. \end{aligned}$$

We denote the bounded variational vector measure associated with μ by $\bar{\mu}$. The total variations of μ and $\bar{\mu}$ are denoted by $|\mu|$ and $|\bar{\mu}|$, respectively. Let

$$\Delta = \{(t, \tau) \in [0, T] \times [0, T] \mid 0 \leq \tau < t \leq T\}$$

and let $\bar{\Delta}$ be the closure of Δ . We consider the following integral equation:

$$(2.1) \quad x(t) = \varphi(t) + \int_0^t G(t, \tau, x(\tau-0)) d\mu(\tau), \quad t \in [0, T].$$

Let us assume that the following statements are true.

Assumption 1. The function $\varphi(\cdot) \in C_\mu([0, T]; X)$ holds (see the Appendix).

Assumption 2. The function $G : \bar{\Delta} \times X \rightarrow \mathcal{L}(Z, X)$ satisfies the following conditions:

(i) There exists a constant L such that

$$(2.2) \quad \|G(t, \tau, x)\|_{\mathcal{L}(Z, X)} \leq L(1 + |x|) \quad \forall (t, \tau) \in \bar{\Delta}, \quad x \in X,$$

$$(2.3) \quad \|G(t, \tau, x) - G(t, \tau, \hat{x})\|_{\mathcal{L}(Z, X)} \leq L|x - \hat{x}| \quad \forall (t, \tau) \in \bar{\Delta}, \quad x, \hat{x} \in X;$$

(ii) For any $\tau \in [0, T]$ and $x \in X$, the map $G(\cdot, \tau, x)$ is continuous on $[\tau, T]$.

We have the following result.

THEOREM 2.1. Let $\mu(\cdot) \in BV_0([0, T]; K)$, and let Assumptions 1 and 2 hold. Then (2.1) has a unique solution $x(\cdot) \in C_\mu([0, T]; X)$.

To prove this theorem, we need the following lemma, the proof of which can be found in [18].

LEMMA 2.2. *Let $\lambda(\cdot) \in BV_0([0, T]; \mathbb{R})$ and $h_0 \in \mathbb{R}$. Then there exists a unique solution $h(\cdot) \in BV([0, T]; \mathbb{R})$ of the following integral equation:*

$$(2.4) \quad h(t) = h_0 + \int_0^t h(\tau - 0) d\lambda(\tau), \quad t \in [0, T].$$

Moreover, the solution $h(\cdot)$ can be written as

$$(2.5) \quad h(t) = h_0 e^{\lambda(t)} [1 + \lambda(t) - \lambda(t-0)] e^{-[\lambda(t) - \lambda(t-0)]} \cdot \prod_{0 \leq \tau < t} [1 + \lambda(\tau + 0) - \lambda(\tau - 0)] e^{-[\lambda(\tau + 0) - \lambda(\tau - 0)]}, \quad t \in [0, T].$$

COROLLARY 2.3. *Let $\lambda(\cdot) \in BV_0([0, T]; \mathbb{R})$ be increasing and $h_0 \geq 0$. Then the unique solution $h(\cdot)$ of (2.4) satisfies*

$$(2.6) \quad h_0 \leq h(t) \leq h_0 e^{\lambda(t)}, \quad t \in [0, T].$$

Proof. By (2.5), we see that (since $h_0 \geq 0$ and $\lambda(\cdot)$ is increasing)

$$(2.7) \quad h(t) \geq 0 \quad \forall t \in [0, T].$$

Thus by (2.4) we see that

$$(2.8) \quad h(t) \geq h_0 \quad \forall t \in [0, T].$$

On the other hand, since $(1+a)e^{-a} \leq 1$ for all $a \geq 0$, we obtain the other half of (2.6). \square

Proof of Theorem 2.1. First, by Lemma 2.2 we let $h(\cdot)$ be the unique solution of the following equation:

$$(2.9) \quad h(t) = 1 + 2L \int_0^t h(\tau - 0) d|\mu|(\tau), \quad t \in [0, T].$$

Then by Corollary 2.3 we know that

$$(2.10) \quad 1 \leq h(t) \leq e^{2L|\mu|(t)}, \quad t \in [0, T].$$

Next, we define

$$(2.11) \quad \|x(\cdot)\|_h = \sup_{t \in [0, T]} h(t)^{-1} |x(t)|.$$

By definition, we see that $C_\mu([0, T]; X)$ is complete under this norm. Then, for any $x(\cdot) \in C_\mu([0, T]; X)$, we define

$$(2.12) \quad (\mathcal{S}x)(t) = \varphi(t) + \int_0^t G(t, \tau, x(\tau - 0)) d\mu(\tau), \quad t \in [0, T].$$

Since $\varphi(\cdot) \in C_\mu([0, T]; X)$, by Proposition A.8 of the Appendix, we see that

$$(2.13) \quad \mathcal{S}: C_\mu([0, T]; X) \rightarrow C_\mu([0, T]; X).$$

On the other hand, for any $x(\cdot), \hat{x}(\cdot) \in C_\mu([0, T]; X)$, we have that

$$\begin{aligned} |(\mathcal{S}x)(t) - (\mathcal{S}\hat{x})(t)| &\leq L \int_0^t |x(\tau - 0) - \hat{x}(\tau - 0)| d|\mu|(\tau) \\ &\leq L \|x(\cdot) - \hat{x}(\cdot)\|_h \int_0^t h(\tau - 0) d|\mu|(\tau) \\ &= \frac{h(t) - 1}{2} \|x(\cdot) - \hat{x}(\cdot)\|_h \quad \forall t \in [0, T]. \end{aligned}$$

Hence $\|(\mathcal{S}x)(\cdot) - (\mathcal{S}\hat{x})(\cdot)\|_h \leq \frac{1}{2} \|x(\cdot) - \hat{x}(\cdot)\|_h$. Then, by the Banach fixed point theorem, there exists a unique solution $x(\cdot) \in C_\mu([0, T]; X)$ of (2.1). \square

The next results give some basic properties of the solution of (2.1). The proofs are simple.

PROPOSITION 2.4. *Let Assumption 2 hold and let $\varphi(\cdot), \hat{\varphi}(\cdot) \in C_\mu([0, T]; X)$. Let $x(\cdot)$ and $\hat{x}(\cdot)$ be the solutions of (2.1) corresponding to $\varphi(\cdot)$ and $\hat{\varphi}(\cdot)$, respectively. Then, for any $\beta > 1$,*

$$(2.14) \quad |x(t) - \hat{x}(t)| \leq \frac{\beta}{\beta - 1} \left[\sup_{0 \leq \tau \leq t} |\varphi(\tau) - \hat{\varphi}(\tau)| \right] e^{\beta L|\mu|(t)}, \quad t \in [0, T],$$

$$(2.15) \quad |x(t)| \leq \frac{\beta}{\beta - 1} \left[\sup_{0 \leq \tau \leq t} |\varphi(\tau)| + L|\mu|(t) \right] e^{\beta L|\mu|(t)}, \quad t \in [0, T].$$

Assumption 3. There exist functions $\omega_G: [0, T] \times \mathbb{R}^+ \rightarrow \mathbb{R}^+$ and $\theta: [0, T] \rightarrow \mathbb{R}^+$ with the properties that $\omega_G(0, r) = 0$, for all $r \in \mathbb{R}^+$, $\omega_G(t, \cdot)$ and $\omega_G(\cdot, r)$ are nondecreasing and $\theta(\cdot)$ is $|\bar{\mu}|$ -integrable, such that

$$(2.16) \quad \|G(t, \tau, x) - G(s, \tau, x)\|_{\mathcal{L}(Z, X)} \leq \omega_G(\rho_\mu(t, s), |x|) \theta(\tau) \\ \forall \tau \in [0, T], \quad t, s \in [\tau, T], \quad x \in X.$$

PROPOSITION 2.5. *Let Assumptions 1–3 hold. Then, for the unique solution $x(\cdot)$ of (2.1), we have that*

$$(2.17) \quad |x(t) - x(s)| \leq |\varphi(t) - \varphi(s)| + L \left(1 + \sup_{0 \leq \tau \leq t} |x(\tau)| \right) (|\mu|(t) - |\mu|(s)) \\ + \omega_G \left(\rho_\mu(t, s), \sup_{0 \leq \tau \leq t} |x(\tau)| \right) \int_0^s \theta(\tau) d|\mu|(\tau) \\ \forall 0 \leq s \leq t \leq T.$$

In particular, if $\varphi(\cdot) \in BV([0, T]; X)$ and

$$(2.18) \quad \omega_G(t, r) = t\bar{\omega}(r) \quad \forall (t, r) \in [0, T] \times \mathbb{R}^+,$$

for some nondecreasing function $\bar{\omega}: \mathbb{R}^+ \rightarrow \mathbb{R}^+$ with $\bar{\omega}(0) = 0$, then $x(\cdot) \in BV([0, T]; X)$.

We should note that, in the case we study, the function $\varphi(\cdot)$ is not necessarily bounded variational and that (2.18) does not hold (in general), either. Thus we are not expected to obtain bounded variational solutions (although they are μ -continuous). However, in the finite-dimensional case, we do have $x(\cdot) \in BV([0, T]; X)$, provided that (2.16) and (2.18) hold, which is not too restrictive. Also, we should note that Assumption 1 is just for simplicity. It can be replaced by

$$\varphi(\cdot) \in D([0, T]; X) = \{ \varphi: [0, T] \rightarrow X \mid \varphi(t+0) \text{ and } \varphi(t-0) \text{ exist} \\ \text{for all } t \in [0, T] \},$$

and we seek the solutions of (2.1) in $D([0, T]; X)$ instead. The results will be similar.

The remainder of this section is devoted to the study of the following linear equation:

$$(2.19) \quad x(t) = e^{At}x_0 + \int_0^t e^{A(t-\tau)} B(\tau, x(\tau-0), d\mu(\tau)) \\ + \int_0^t e^{A(t-\tau)} \bar{G}(\tau) d\nu(\tau), \quad t \in [0, T].$$

We make the following assumptions.

Assumption 4. The operator $A: \mathcal{D}(A) \subset X \rightarrow X$ generates a C_0 -semigroup e^{At} on X and, for some constants $M \geq 1$ and $\omega \in \mathbb{R}$,

$$(2.20) \quad \|e^{At}\|_{\mathcal{L}(X)} \leq M e^{\omega t}, \quad t \geq 0.$$

Assumption 5. Function $B: [0, T] \rightarrow \tilde{\mathcal{B}}(X \times Z; X)$ is uniformly Borel-measurable, with $\tilde{\mathcal{B}}(X \times Z; X)$ being the set of all bounded bilinear forms from $X \times Z$ to X (see the Appendix), and $\|B(\tau)\|_{\tilde{\mathcal{B}}}$ is bounded by L_0 .

Assumption 6. $\nu(\cdot) \in BV_0([0, T]; Y)$ and $\bar{G}(\cdot) \in B_\nu([0, T]; \mathcal{L}(Y, X))$, with Y being some Banach space.

Under Assumptions 4 and 5, we know that there exists a unique solution $x(\cdot)$ of (2.19). Our next goal is to give a variation of constants formula. To this end, let us define the evolution operators $\Phi, \Theta: \bar{\Delta} \rightarrow \mathcal{L}(X)$ as follows:

$$(2.21) \quad \begin{aligned} \Phi(t, s)x_0 &= e^{A(t-s)}x_0 + \int_s^t e^{A(t-\tau)}B(\tau, \Phi(\tau-0, s)x_0, d\mu(\tau)), \\ 0 \leq s \leq t \leq T, \quad x_0 \in X, \end{aligned}$$

$$\Phi(s-0, s) = I, \quad 0 \leq s \leq T;$$

$$(2.22) \quad \begin{aligned} \Theta(t, s)x_0 &= \int_s^t e^{A(t-\tau)}B(\tau, \Theta(\tau-0, s)x_0, d\mu(\tau)), \\ 0 \leq s \leq t \leq T, \quad x_0 \in X, \end{aligned}$$

$$\Theta(s-0, s) = -I, \quad 0 \leq s \leq T.$$

It is clear that the above operator-valued functions are well defined. Also, we see that

$$(2.23) \quad \Theta(s, s) = 0, \quad \Theta(s+0, s) = B(s, -I, \mu(s+0) - \mu(s)).$$

Thus, if $\mu(\cdot)$ is right-continuous at some point $s \in [0, T]$, then

$$(2.24) \quad \Theta(t, s) = 0 \quad \forall 0 \leq s \leq t \leq T.$$

THEOREM 2.6 (variation of constants formula). *The unique solution $x(\cdot)$ of (2.19) can be represented by*

$$(2.25) \quad x(t) = \Phi(t, 0)x_0 + \int_0^t (\Phi(t, s) + \Theta(t, s))\bar{G}(s) d\nu(s), \quad t \in [0, T].$$

Proof. For simplicity, we denote

$$(2.26) \quad \Psi(t, s) = \Phi(t, s) + \Theta(t, s), \quad 0 \leq s \leq t \leq T.$$

Then we have that

$$(2.27) \quad \begin{aligned} \Psi(t, s)x_0 &= e^{A(t-s)}x_0 + \int_s^t e^{A(t-\tau)}B(\tau, \Psi(\tau-0, s)x_0, d\mu(\tau)), \\ 0 \leq s \leq t \leq T, \quad x_0 \in X, \\ \Psi(s-0, s) &= 0, \quad 0 \leq s \leq T. \end{aligned}$$

Now we set

$$(2.28) \quad y(t) = \Phi(t, 0)x_0 + \int_0^t \Psi(t, s) \bar{G}(s) d\nu(s), \quad t \in [0, T].$$

Then we have that

$$(2.29) \quad y(\tau - 0) = \Phi(\tau - 0, 0)x_0 + \int_{[0, \tau)} \Psi(\tau - 0, s) \bar{G}(s) \bar{\nu}(ds), \quad \tau \in [0, T].$$

Let us observe the following:

$$\begin{aligned}
 & \int_0^t e^{A(t-\tau)} B(\tau, y(\tau - 0), d\mu(\tau)) \\
 &= \int_0^t e^{A(t-\tau)} B(\tau, \Phi(\tau - 0, 0)x_0, d\mu(\tau)) \\
 & \quad + \int_0^t e^{A(t-\tau)} B\left(\tau, \int_{[0, \tau)} \Psi(\tau - 0, s) \bar{G}(s) \bar{\nu}(ds), d\mu(\tau)\right) \\
 &= \Phi(t, 0)x_0 - e^{At}x_0 + \int_{[0, t)} e^{A(t-\tau)} B\left(\tau, \int_{[0, \tau)} \Psi(\tau - 0, s) \bar{G}(s) \bar{\nu}(ds), \bar{\mu}(d\tau)\right) \\
 & \quad + B\left(t, \int_{[0, t)} \Psi(t - 0, s) \bar{G}(s) \bar{\nu}(ds), \mu(t) - \mu(t - 0)\right) \\
 (2.30) \quad &= \Phi(t, 0)x_0 - e^{At}x_0 + \int_{[0, t)} \int_{(s, t)} e^{A(t-\tau)} B(\tau, \Psi(\tau - 0, s) \bar{G}(s) \bar{\nu}(ds), \bar{\mu}(d\tau)) \\
 & \quad + \int_{[0, t)} B(t, \Psi(t - 0, s) \bar{G}(s) \bar{\nu}(ds), \mu(t) - \mu(t - 0)) \\
 &= \Phi(t, 0)x_0 - e^{At}x_0 + \int_0^t \int_s^t e^{A(t-\tau)} B(\tau, \Psi(\tau - 0, s) \bar{G}(s) d\nu(s), d\mu(\tau)) \\
 &= \Phi(t, 0)x_0 - e^{At}x_0 + \int_0^t (\Psi(t, s) - e^{A(t-s)}) \bar{G}(s) d\nu(s) \\
 &= y(t) - e^{At}x_0 - \int_0^t e^{A(t-s)} \bar{G}(s) d\nu(s).
 \end{aligned}$$

Hence (2.25) follows from the uniqueness of the solutions of (2.19). \square

In the above, the crucial step is to use the Fubini-type theorem (Theorem A.9) to exchange the integral order. For the case where $\mu(\cdot) \in \mathcal{M}([0, T]; Z)$ and $\nu(\cdot) \in \mathcal{M}([0, T]; Y)$, the proof looks clearer.

LEMMA 2.7. *The operator-valued function $\Psi(\cdot, \cdot)$ also satisfies the following:*

$$(2.31) \quad \Psi(t, s)x_0 = e^{A(t-s)}x_0 + \int_s^t \Psi(t, \tau) B(\tau, e^{A(\tau-s)}x_0, d\mu(\tau)),$$

$$0 \leq s \leq t \leq T.$$

Proof. We let the right-hand side of (2.31) be $\Psi(t, s)$. Then, by noting Theorem A.9 and the fact that $\Psi(s-0, s) = 0$, we have that

$$\begin{aligned}
 & \int_s^t \Psi(t, \tau) B(\tau, e^{A(\tau-s)} x_0, d\mu(\tau)) \\
 &= \int_s^t e^{A(t-\tau)} B(\tau, e^{A(\tau-s)} x_0, d\mu(\tau)) \\
 & \quad + \int_s^t \int_\tau^t e^{A(t-\tau)} B(r, \Psi(r-0, \tau) B(\tau, e^{A(\tau-s)} x_0, d\mu(\tau)), d\mu(r)) \\
 &= \int_s^t e^{A(t-\tau)} B(\tau, e^{A(\tau-s)} x_0, d\mu(\tau)) \\
 (2.32) \quad & \quad + \int_s^t \int_s^\tau e^{A(t-\tau)} B(r, \Psi(r-0, \tau) B(\tau, e^{A(\tau-s)} x_0, d\mu(\tau)), d\mu(r)) \\
 &= \int_s^t e^{A(t-\tau)} B(\tau, e^{A(\tau-s)} x_0 \\
 & \quad + \int_s^\tau \Psi(\tau-0, r) B(r, e^{A(\tau-s)} x_0, d\mu(r)), d\mu(\tau)) \\
 &= \int_s^t e^{A(t-\tau)} B(\tau, \bar{\Psi}(\tau-0, s) x_0, d\mu(\tau)).
 \end{aligned}$$

By uniqueness, we obtain (2.31). \square

This result is very similar to that given in [11] for the case where $\mu(t) = t$ (see also [22]). This result will be used in deriving the adjoint system along the optimal pair in § 5.

3. Optimal control problem. In this section, based in the preliminary results of the previous section, we state our optimal control problem and the main results concerning the control problem of this paper. We let X and Z be two Banach spaces, K be a convex and closed cone in Z , and U be a metric space. We define

$$\mathcal{U} = \{u(\cdot) : [0, T] \rightarrow U \mid u(\cdot) \text{ is Borel-measurable}\}$$

and

$$\mathcal{M} = \{\mu_0(\cdot)\} + \mathcal{M}_0([0, T]; K),$$

where $\mathcal{M}_0([0, T]; K)$ is defined as in the Appendix, and $\mu_0(\cdot) \in BV_0([0, T]; Z)$. By Proposition A.1, we know that \mathcal{M} is convex. Next, let us make the following hypotheses.

Hypothesis 1. The dual X^* of X is strictly convex.

Hypothesis 2. This is identical to Assumption 4 (see § 2).

Hypothesis 3. The map $F : [0, T] \times X \times U \rightarrow \mathcal{L}(Z, X)$ satisfies the following conditions:

(i) For any $(x, u) \in X \times U$, the map $F(\cdot, x, u) : [0, T] \rightarrow \mathcal{L}(Z, X)$ is uniformly Borel-measurable. For any $(t, x) \in [0, T] \times U$, the map $F(t, \cdot, u) : X \rightarrow \mathcal{L}(Z, X)$ is continuously Fréchet differentiable. For any $(t, x) \in [0, T] \times X$, the map $F(t, x, \cdot) : U \rightarrow \mathcal{L}(Z, X)$ is continuous;

(ii) There exists a constant $L > 0$ such that

$$(3.1) \quad \|F(t, x, u)\|_{\mathcal{L}(Z, X)} \leq L(1 + |x|), \quad (t, x, u) \in [0, T] \times X \times U,$$

$$(3.2) \quad \|F(t, x, u) - F(t, \hat{x}, u)\|_{\mathcal{L}(Z, X)} \leq L|x - \hat{x}|, \quad (t, u) \in [0, T] \times U, \quad x, \hat{x} \in X.$$

Hypothesis 4. The map $f: [0, T] \times X \times U \rightarrow Z^*$ satisfies the following conditions. For any $(x, u) \in X \times U$, the map $f(\cdot, x, u): [0, T] \rightarrow Z^*$ is uniformly Borel-measurable. For any $(t, x) \in [0, T] \times X$, the map $f(t, \cdot, u): X \rightarrow Z^*$ is continuously Fréchet differentiable. For any $(t, x) \in [0, T] \times X$, the map $f(t, x, \cdot): U \rightarrow Z^*$ is continuous.

Hypothesis 5. The set Ω is convex and closed in $X \times X$.

Now, for any $x_0 \in X$ and a pair $(u(\cdot), \mu(\cdot)) \in \mathcal{U} \times \mathcal{M}$, the response of the controlled system is defined to be the unique solution of the following integral equation:

$$(3.3) \quad x(t) = e^{At}x_0 + \int_0^t e^{A(t-\tau)} F(\tau, x(\tau-0), u(\tau)) d\mu(\tau), \quad t \in [0, T].$$

From the theory we presented in § 2, we see that the above equation makes sense. Moreover, by Theorem 3.1, we know that, under Hypotheses 2 and 3, there exists a unique solution $x(\cdot) \in C_\mu([0, T]; X)$ of (3.3) corresponding to the triplet $(x_0, u(\cdot), \mu(\cdot))$. System (3.3) is a mild form of (1.7). Thus we sometimes refer to the solution $x(\cdot)$ of (3.3) as the mild solution (1.7). We call $x(t)$ the state of our system at time t ; $x(\cdot)$ the trajectory of the system, and x_0 , $u(\cdot)$, and $\mu(\cdot)$ the initial state, continuous control, and measure control, respectively. We see that the measure control is an extended notion of the so-called impulse control [6], [7], [34], [35]. Hypothesis 1 is technical for later purposes. For the case where X is reflexive or separable, we can always change the norm of X to another equivalent one so that Hypothesis 1 holds (see [23] for comments).

Remark 3.1. It is very important to note that, by using the Young-type integral in (3.3), the trajectory of the system inherits the discontinuity of the measure control $\mu(\cdot)$. In fact, if we let $x(\cdot)$ be the solution of (3.3) corresponding to $(x_0, u(\cdot), \mu(\cdot))$, then, by Proposition A.8, we have that

$$x(t) = x(t-0) + F(t, x(t-0), u(t))[\mu(t) - \mu(t-0)], \quad t \in (0, T]$$

and

$$x(t+0) = x(t) + F(t, x(t-0), u(t))[\mu(t+0) - \mu(t)], \quad t \in (0, T].$$

The Bochner-type integral does not have such a property! As in [32], the Bochner- (or Lebesgue-) type integral was used, and, as a result, the trajectories had to be restricted to right-continuous functions. In our case, the trajectories are only of elements in the space $D([0, T]; X)$.

The payoff of our control problem is the following (which is the same as (1.8)):

$$(3.4) \quad J(x(\cdot), u(\cdot), \mu(\cdot)) = \int_0^T \langle f(t, x(t-0), u(t)), d\mu(t) \rangle.$$

The meaning of the right-hand side of (3.4) is clear if we regard the map f as a $\mathcal{L}(Z, \mathbb{R})$ -valued function. Now we are ready to state our optimal control problem.

PROBLEM C. We minimize functional (3.4) over all $(u(\cdot), \mu(\cdot)) \in \mathcal{U} \times \mathcal{M}$, subject to system (3.3) and the endpoint constraint

$$(3.5) \quad (x(0), x(T)) \in \Omega.$$

Next, let $(x^\#(\cdot), u^\#(\cdot), \mu^\#(\cdot))$ be an optimal solution to Problem C. We define

$$(3.6) \quad \mathcal{U}^\# = \{u(\cdot) \in \mathcal{U} \mid u(\tau) = u^\#(\tau), \text{ if } \mu^\#(\cdot) \text{ jumps at } \tau\}.$$

Note that $F: [0, T] \times X \times U \rightarrow \mathcal{L}(Z, X)$. Thus the Fréchet derivative F_x of F is a map

from $[0, T] \times X \times U$ to $\tilde{B}(Z \times X; X)$. We let

$$(3.7) \quad \begin{aligned} B(\tau, \xi, z) &= F_x(\tau, x^\#(\tau-0), u^\#(\tau); \xi)z \\ &\equiv \lim_{\varepsilon \rightarrow 0} \frac{F(\tau, x^\#(\tau-0) + \varepsilon \xi, u^\#(\tau))z - F(\tau, x^\#(\tau-0), u^\#(\tau))z}{\varepsilon} \\ \forall(\tau, \xi, z) &\in [0, T] \times X \times Z. \end{aligned}$$

Then we may define $B(\cdot, \cdot)^*: [0, T] \times Z \rightarrow \mathcal{L}(X^*)$ as follows:

$$(3.8) \quad \langle B(\tau, z)^* x^*, \xi \rangle = \langle B(\tau, \xi, z), x^* \rangle \quad \forall(\tau, \xi, z, x^*) \in [0, T] \times X \times Z \times X^*.$$

As in § 2, we let $\Phi(\cdot, \cdot)$, $\Theta(\cdot, \cdot)$, and $\Psi(\cdot, \cdot)$ be the evolution operators associated with the operator A and the bilinear form-valued function $B(\tau, \xi, z)$ (see (2.21), (2.22), and (2.26)). Then we define

$$(3.9) \quad \begin{aligned} \mathcal{R} &= \left\{ \int_0^T \Psi(T, \tau) [F(\tau, x^*(\tau-0), u(\tau)) - F(\tau, x^\#(\tau-0), u^\#(\tau))] d\mu^\#(\tau) \right. \\ &\quad \left. + \int_0^T \Psi(T, \tau) F(\tau, x^\#(\tau-0), u^\#(\tau)) d(\mu(\tau) - \mu^\#(\tau)) \right. \\ &\quad \left. \left| (u(\cdot), \mu(\cdot)) \in \mathcal{U}^\# \times \mathcal{M} \right\} \end{aligned}$$

and

$$(3.10) \quad \mathcal{Q} = \{y_1 - \Phi(T, 0)y_0 \mid (y_0, y_1) \in \Omega\}.$$

We introduce the Hamiltonian

$$(3.11) \quad \begin{aligned} H(\tau, x, u, \psi^0, \psi) &= \psi^0 f(\tau, x, u) + F(\tau, x, u)^* \psi \\ \forall(\tau, x, u, \psi^0, \psi) &\in [0, T] \times X \times \mathbb{R} \times X^*. \end{aligned}$$

We note that the function $H(\tau, x, u, \psi^0, \psi)$ is Z^* -valued.

Now we are ready to state our main result for Problem C.

THEOREM 3.2 (maximum principle). *Let Hypotheses 1-5 hold. Let $(x^\#(\cdot), u^\#(\cdot), \mu^\#(\cdot))$ be an optimal solution to Problem C. Let the set*

$$\mathcal{R} - \mathcal{Q} = \{r - q \mid r \in \mathcal{R}, q \in \mathcal{Q}\}$$

be finite-codimensional in X [17], [22], [23]. Then there exists a pair $(\psi(\cdot), \psi^0) \in D([0, T]; X^) \times \mathbb{R}$, such that*

$$(3.12) \quad \begin{aligned} \psi(t) &= e^{A^*(T-t)} \psi(T) + \int_t^T e^{A^*(\tau-t)} B(\tau, d\mu^\#(\tau))^* \psi(\tau) \\ &\quad + \psi^0 \int_t^T e^{A^*(\tau-t)} f_x(\tau, x^\#(\tau-0), u^\#(\tau))^* d\mu^\#(\tau) \quad \forall t \in [0, T], \end{aligned}$$

$$(3.13) \quad \psi^0 \leq 0,$$

$$(3.14) \quad (\psi(\cdot), \psi^0) \neq 0,$$

$$(3.15) \quad \int_0^T \langle H(\tau, x^\#(\tau-0), u^\#(\tau), \psi^0, \psi(\tau)), d\mu^\#(\tau) \rangle$$

$$= \max_{\mu(\cdot) \in \mathcal{M}} \int_0^T \langle H(\tau, x^\#(\tau-0), u^\#(\tau), \psi^0, \psi(\tau)), d\mu(\tau) \rangle,$$

$$(3.16) \quad \int_0^T \langle H(\tau, x^\#(\tau-0), u^\#(\tau), \psi^0, \psi(\tau)), d\mu^\#(\tau) \rangle$$

$$= \max_{u(\cdot) \in \mathcal{U}^\#} \int_0^T \langle H(\tau, x^\#(\tau-0), u(\tau), \psi^0, \psi(\tau)), d\mu^\#(\tau) \rangle,$$

$$(3.17) \quad \langle \psi(0), y_0 - x^\#(0) \rangle - \langle \psi(T), y_1 - x^\#(T) \rangle$$

$$- \langle \psi(T), \Theta(T, 0)(y_0 - x^\#(0)) \rangle \leq 0, \quad (y_0, y_1) \in \Omega.$$

Remark 3.3. Condition (3.17) is the transversality condition for the optimal solution of our problem. The appearance of the term $\langle \psi(T), \Theta(T, 0)(y_0 - x^\#(0)) \rangle$ is unexpected. This is caused by a possible jump of the measure control $\mu(\cdot)$ at $t=0$. It is interesting to note that in the case where

$$(3.18) \quad \mu^\#(0+0) = \mu^\#(0)$$

(i.e., where no jump of $\mu^\#(\cdot)$ appeared at $t=0$), from (2.24), we see that

$$(3.19) \quad \Theta(t, 0) = 0 \quad \forall t \in [0, T].$$

Thus condition (3.17) is reduced to the familiar form

$$(3.20) \quad \langle \psi(0), y_0 - x^\#(0) \rangle - \langle \psi(T), y_1 - x^\#(T) \rangle \leq 0, \quad (y_0, y_1) \in \Omega.$$

4. Some lemmas. In this section, we present some lemmas which are necessary for the proof of the maximum principle in the next section.

LEMMA 4.1. *Let Assumptions 4 and 5 hold. Let $x(\cdot)$ and $\hat{x}(\cdot)$ be the unique solutions of (3.3) corresponding to $(x_0, u(\cdot), \mu(\cdot))$ and $(\hat{x}_0, \hat{u}(\cdot), \hat{\mu}(\cdot))$, respectively. Then there exists a constant C , depending on the bounds of $|x_0|$, $|\hat{x}_0|$, $|\mu|(T)$, $|\hat{\mu}|(T)$ and L , such that*

$$(4.1) \quad |x(t) - \hat{x}(t)| \leq C[|x_0 - \hat{x}_0| + |\mu - \hat{\mu}|(t)$$

$$+ |\bar{\mu}|(\{u \neq \hat{u}\}) \wedge |\bar{\mu}|(\{u \neq \hat{u}\})], \quad t \in [0, T].$$

Proof. First, from (3.3), we see that

$$(4.2) \quad |x(t)| \leq M e^{\omega t} |x_0| + ML \int_0^t e^{\omega(t-\tau)} (1 + |x(\tau-0)|) d|\mu|(\tau).$$

Thus

$$(4.3) \quad e^{-\omega t} |x(t)| \leq M |x_0| + ML \int_0^t e^{-\omega\tau} d|\mu|(\tau)$$

$$+ ML \int_0^t e^{-\omega\tau} |x(\tau-0)| d|\mu|(\tau).$$

Set $\sigma(t) = e^{-\omega t} |x(t)|$. Next, let $\beta > 1$ and $h_\beta(\cdot)$ be the unique solution of

$$(4.4) \quad h_\beta(t) = 1 + \beta ML \int_0^t h_\beta(\tau-0) d|\mu|(\tau), \quad t \in [0, T].$$

Then

$$\begin{aligned}
 \sigma(t) &\leq M|x_0| + ML \int_0^t e^{-\omega\tau} d|\mu|(\tau) + ML \int_0^t \sigma(\tau-0) d|\mu|(\tau) \\
 (4.5) \quad &\leq M|x_0| + ML \int_0^t e^{-\omega\tau} d|\mu|(\tau) + \sup_{0 \leq \tau \leq t} [\sigma(\tau)h_\beta(\tau)^{-1}] \frac{h_\beta(t)-1}{\beta}.
 \end{aligned}$$

By Corollary 2.3, we have that

$$\begin{aligned}
 \sup_{0 \leq \tau \leq t} [\sigma(\tau)h_\beta(\tau)^{-1}] &\leq M|x_0| + ML(1 \vee e^{-\omega t})|\mu|(t) \\
 (4.6) \quad &+ \frac{1}{\beta} \sup_{0 \leq \tau \leq t} [\sigma(\tau)h_\beta(\tau)^{-1}].
 \end{aligned}$$

Hence, again by Proposition 2.5, we obtain

$$(4.7) \quad |x(t)| \leq \frac{\beta}{\beta-1} (M|x_0| + ML(1 \vee e^{-\omega t})|\mu|(t)) e^{\omega t + \beta ML|\mu|(t)}, \quad t \in [0, T].$$

Similarly,

$$(4.8) \quad |\hat{x}(t)| \leq \frac{\beta}{\beta-1} (M|\hat{x}_0| + ML(1 \vee e^{-\omega t})|\hat{\mu}|(t)) e^{\omega t + \beta ML|\hat{\mu}|(t)}, \quad t \in [0, T].$$

Then we have that

$$\begin{aligned}
 |x(t) - \hat{x}(t)| &\leq M e^{\omega t} |x_0 - \hat{x}_0| \\
 (4.9) \quad &+ ML \int_0^t e^{\omega(t-\tau)} |x(\tau-0) - \hat{x}(\tau-0)| d|\mu|(\tau) \\
 &+ ML \int_0^t e^{\omega(t-\tau)} (1 + |\hat{x}(\tau-0)|) d|\mu - \hat{\mu}|(\tau) \\
 &+ 2ML \int_0^t e^{\omega(t-\tau)} (1 + |x(\tau-0)|) \chi_{\{u \neq \hat{u}\}}(\tau) d|\mu|(\tau).
 \end{aligned}$$

Thus, by Gronwall's inequality, we obtain

$$(4.10) \quad |x(t) - \hat{x}(t)| \leq C[|x_0 - \hat{x}_0| + |\mu - \hat{\mu}|(t) + |\bar{\mu}|(\{u \neq \hat{u}\})], \quad t \in [0, T].$$

Exchanging $(x_0, u(\cdot), \mu(\cdot))$ and $(\hat{x}_0, \hat{u}(\cdot), \hat{\mu}(\cdot))$, we obtain (4.1). \square

The above result gives the continuous dependence of the solution $x(\cdot)$ on the data $(x_0, u(\cdot), \mu(\cdot))$.

Now let us introduce the following:

$$\begin{aligned}
 \tilde{d}((x_0, u(\cdot), \mu(\cdot)), (y_0, v(\cdot), \nu(\cdot))) \\
 (4.11) \quad &= \{|x_0 - y_0|^2 + |\mu - \nu|(T)^2 + |\bar{\mu}|(\{u \neq v\})^2 + |\bar{\nu}|(\{u \neq v\})^2\}^{1/2} \\
 &\quad \forall (x_0, u(\cdot), \mu(\cdot)), (y_0, v(\cdot), \nu(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}.
 \end{aligned}$$

It is clear that \tilde{d} is a metric on the space $X \times \mathcal{U} \times \mathcal{M}$. We have the following lemma.

LEMMA 4.2. *The space $(X \times \mathcal{U} \times \mathcal{M}, \tilde{d})$ is a complete metric space.*

Proof. Let $\{(x_0^n, u^n(\cdot), \mu^n(\cdot))\}$ be a Cauchy sequence in $X \times \mathcal{U} \times \mathcal{M}$ under \tilde{d} . Then we see that

$$(4.12) \quad x_0^n \rightarrow x_0 \quad \text{in } X, \quad (n \rightarrow \infty),$$

for some $x_0 \in X$. Now we show that there exists a $\mu(\cdot) \in \mathcal{M}$ such that

$$(4.13) \quad |\mu^n - \mu|(T) \rightarrow 0, \quad n \rightarrow \infty.$$

In fact, there exists a $\mu(\cdot) \in BV_0([0, T]; K)$ such that (4.13) holds. Thus we must show that $\mu(\cdot) \in \mathcal{M}$. To this end, we let

$$(4.14) \quad \bar{\mu}^n(E) = \int_E \theta_n(\tau) |\bar{\mu}^n|(d\tau) \quad \forall \mathcal{B}([0, T]), \quad n \geq 1$$

and set

$$(4.15) \quad \bar{\nu}^n(E) = \int_E \theta_n(\tau) |\bar{\mu}|(d\tau) \quad \forall \mathcal{B}([0, T]), \quad n \geq 1.$$

Then, by (4.13), we see that

$$(4.16) \quad ||\bar{\mu}^n| - |\bar{\mu}|||(E) \leq |\mu^n - \mu|(T) \rightarrow 0 \quad \forall E \in \mathcal{B}([0, T]), \quad n \rightarrow \infty.$$

Thus, noting $|\theta_n(\tau)| \leq 1$, we obtain

$$(4.17) \quad \begin{aligned} |\bar{\nu}^n - \bar{\mu}|(E) &\leq |\bar{\mu}^n - \bar{\mu}|(E) + \int_E |\theta_n(\tau)| ||\bar{\mu}^n| - |\bar{\mu}|||(d\tau) \\ &\leq 2|\mu^n - \mu|(T) \rightarrow 0 \quad \forall E \in \mathcal{B}([0, T]), \quad n \rightarrow \infty. \end{aligned}$$

Hence we see that

$$(4.18) \quad \int_{[0, T]} |\theta_n(\tau) - \theta_m(\tau)| |\bar{\mu}|(d\tau) = |\bar{\nu}^n - \bar{\nu}^m|([0, T]) \rightarrow 0;$$

i.e., the sequence $\{\theta_n(\cdot)\}$ is Cauchy in $L^1_{|\bar{\mu}|}(0, T)$. Thus there exists a $\theta(\cdot) \in L^1_{|\bar{\mu}|}(0, T)$ such that

$$(4.19) \quad \int_{[0, T]} |\theta_n(\tau) - \theta(\tau)| |\bar{\mu}|(d\tau) \rightarrow 0, \quad n \rightarrow \infty.$$

Then, by (4.15) and (4.17), we obtain

$$(4.20) \quad \bar{\mu}(E) = \int_E \theta(\tau) |\bar{\mu}|(d\tau) \quad \forall E \in \mathcal{B}([0, T]).$$

Then it follows that $\mu(\cdot) \in \mathcal{M}$. Finally, from

$$(4.21) \quad |\bar{\mu}|(\{u^n \neq u^m\}) \leq |\bar{\mu}^n|(\{u^n \neq u^m\}) + |\bar{\mu} - \bar{\mu}^n|([0, T]) \rightarrow 0, \quad m, n \rightarrow \infty,$$

we know that there exists a $u(\cdot)$, such that

$$(4.22) \quad u^n(\cdot) \rightarrow u(\cdot), \quad n \rightarrow \infty, \quad |\bar{\mu}| \text{ a.e.}$$

It is clear that we may assume $u(\cdot)$ to be Borel-measurable. Thus $u(\cdot) \in \mathcal{U}$. Hence the lemma is proved. \square

We should note that in $(X \times \mathcal{U} \times \mathcal{M}, \tilde{d})$,

$$(x_0, u(\cdot), \mu(\cdot)) = (y_0, v(\cdot), \nu(\cdot)),$$

if and only if

$$\begin{aligned} x_0 &= y_0, \\ \mu(\cdot) &= \nu(\cdot), \\ u(t) &= v(t), \quad |\bar{\mu}| \text{ a.e.} \end{aligned}$$

Thus, by changing the values of $u(\cdot)$ on a set of $|\bar{\mu}|$ -measure zero, we have not changed the element $(x_0, u(\cdot), \mu(\cdot))$ in the space $(X \times \mathcal{U} \times \mathcal{M}, \tilde{d})$. On the other hand, from Lemma 4.1, we see that the map from the data $(x_0, u(\cdot), \mu(\cdot))$ to the solution $x(\cdot)$ of (3.3) is well defined from $(X \times \mathcal{U} \times \mathcal{M}, \tilde{d})$ to $D([0, T]; X)$.

LEMMA 4.3. *Let $\lambda(\cdot) \in BV_0([0, T]; \mathbb{R})$ be nondecreasing and $f: \bar{\Delta} \rightarrow X$ be such that, for some nondecreasing function $\omega_f(\cdot): [0, T] \rightarrow \mathbb{R}^+$ with $\omega_f(0) = 0$ and some $|\bar{\lambda}|$ -integrable function $\sigma(\cdot)$, we have that*

$$(4.23) \quad |f(t, \tau) - f(\hat{t}, \tau)| \leq \omega_f(|t - \hat{t}|) \sigma(\tau) \quad \forall (t, \tau), (\hat{t}, \tau) \in \bar{\Delta}.$$

Moreover,

$$(4.24) \quad f(t, \tau) = 0 \quad \text{if } \lambda(\cdot) \text{ jumps at } \tau.$$

Then, for any $\rho \in (0, 1)$, there exists a Borel-measurable set $E_\rho \subset [0, T]$ such that

$$(4.25) \quad \bar{\lambda}(E_\rho) = \rho \bar{\lambda}_c([0, T]) \leq \rho \bar{\lambda}([0, T]),$$

$$(4.26) \quad \rho \int_0^t f(t, \tau) d\lambda(\tau) = \int_0^t f(t, \tau) \chi_{E_\rho}(\tau) d\lambda(\tau) + o(\rho),$$

uniformly in $t \in [0, T]$.

Proof. By (4.24), we see that

$$(4.27) \quad \int_0^t f(t, \tau) d\lambda(\tau) = \int_{[0, T]} f(t, \tau) \bar{\lambda}_c(d\tau).$$

Then, by the arguments used to prove the similar result for $\bar{\lambda}_c(\cdot)$ being Lebesgue-measurable (see [22], [23]), we can obtain a Borel-measurable set $E_\rho \subset [0, T]$ such that

$$(4.28) \quad \bar{\lambda}_c(E_\rho) = \rho \bar{\lambda}_c([0, T]),$$

and (4.26) holds. Since the jump points of $\lambda(\cdot)$ is at most a countable set, we may change E_ρ somewhat so that

$$(4.29) \quad \bar{\lambda}_c(E_\rho) = \bar{\lambda}(E_\rho).$$

Hence (4.25) follows. \square

COROLLARY 4.4. *Let $\mu(\cdot) \in \mathcal{M}$ and $G(t, \tau): \bar{\Delta} \rightarrow \mathcal{L}(Z, X)$ be uniformly Borel-measurable satisfying the following:*

$$(4.30) \quad \|G(t, \tau)\|_{\mathcal{L}(Z, X)} \leq a(\tau) \quad \forall (t, \tau) \in \bar{\Delta},$$

$$(4.31) \quad \|G(t, \tau) - G(s, \tau)\|_{\mathcal{L}(Z, X)} \leq \omega_G(|t - s|) b(\tau) \quad \forall (t, \tau), (s, \tau) \in \bar{\Delta},$$

where $a(\cdot), b(\cdot) \in B_{|\bar{\mu}|}([0, T]; \mathbb{R})$, and $\omega_G(\cdot): [0, T] \rightarrow \mathbb{R}^+$ is a nondecreasing function with $\omega_G(0) = 0$. Moreover, we let

$$(4.32) \quad G(t, \tau) = 0 \quad \text{if } \mu(\cdot) \text{ jumps at } \tau.$$

Then, for any $\rho \in (0, 1)$, there exists a Borel-measurable set $E_\rho \subset [0, T]$ such that

$$(4.33) \quad |\bar{\mu}|(E_\rho) = \rho |\bar{\mu}_c|([0, T]) \leq \rho |\mu|(T),$$

$$(4.34) \quad \rho \int_0^t G(t, \tau) d\mu(\tau) = \int_0^t G(t, \tau) \chi_{E_\rho}(\tau) d\mu(\tau) + o(\rho),$$

uniformly in $t \in [0, T]$.

LEMMA 4.5. Let $(u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)), (u^\#(\cdot), \mu^\#(\cdot)) \in \mathcal{U} \times \mathcal{M}$ be such that

$$(4.35) \quad \lim_{\varepsilon \rightarrow 0} |\mu^\varepsilon - \mu^\#|(T) = 0,$$

$$(4.36) \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\#|(\{u^\varepsilon \neq u^\#\}) = 0, \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\varepsilon|(\{u^\varepsilon \neq u^\#\}) = 0.$$

Let

$$D_\varepsilon = \{\tau \in [0, T] \mid \mu^\varepsilon(\cdot) \text{ jumps at } \tau\},$$

$$D_\# = \{\tau \in [0, T] \mid \mu^\#(\cdot) \text{ jumps at } \tau\}.$$

For $u(\cdot) \in \mathcal{U}$, with

$$(4.37) \quad u(\tau) = u^\#(\tau), \quad \tau \in D_\#,$$

set

$$(4.38) \quad u_\varepsilon(\cdot) = u(\cdot)\chi_{[0, T] \setminus D_\varepsilon}(\cdot) + u^\varepsilon(\cdot)\chi_{D_\varepsilon}(\cdot).$$

Then

$$(4.39) \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\#|(\{u_\varepsilon \neq u\}) = 0, \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\varepsilon|(\{u^\varepsilon \neq u\}) = 0.$$

Proof. For $n \geq 1$, let

$$D_\varepsilon^n = \{\tau \in [0, T] \mid |\mu^\varepsilon(\tau+0) - \mu^\varepsilon(\tau)| \text{ or } |\mu^\varepsilon(\tau) - \mu^\varepsilon(\tau-0)| \geq 1/n\},$$

$$D_\#^n = \{\tau \in [0, T] \mid |\mu^\#(\tau+0) - \mu^\#(\tau)| \text{ or } |\mu^\#(\tau) - \mu^\#(\tau-0)| \geq 1/n\}.$$

Then, by (4.35), we see that, for any $n \geq 1$, there exists an $\varepsilon_n > 0$, such that, for all $\varepsilon \in (0, \varepsilon_n)$,

$$(4.40) \quad D_\varepsilon^n = D_\#^n.$$

Thus, by noting the fact that

$$D_\varepsilon = \bigcup_{n \geq 1} D_\varepsilon^n, \quad D_\# = \bigcup_{n \geq 1} D_\#^n,$$

we have that

$$(4.41) \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\varepsilon|(D_\varepsilon \setminus D_\#) = 0, \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\varepsilon|(D_\# \setminus D_\varepsilon) = 0,$$

$$\lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\#|(D_\varepsilon \setminus D_\#) = 0, \quad \lim_{\varepsilon \rightarrow 0} |\bar{\mu}^\#|(D_\# \setminus D_\varepsilon) = 0.$$

Next, by (4.37), we have that

$$(4.42) \quad u(\cdot) = u(\cdot)\chi_{[0, T] \setminus D_\#}(\cdot) + u^\#(\cdot)\chi_{D_\#}(\cdot).$$

Thus we obtain

$$(4.43) \quad \{u_\varepsilon \neq u\} \subseteq D_\varepsilon \cup D_\#,$$

while

$$D_\varepsilon \cup D_\# = (D_\varepsilon \setminus D_\#) \cup (D_\# \setminus D_\varepsilon) \cup (D_\varepsilon \cap D_\#)$$

and

$$(D_\varepsilon \cap D_\#) \cap \{u_\varepsilon \neq u\} \subseteq \{u^\varepsilon \neq u^\#\}.$$

Hence (4.39) follows from (4.36) and (4.41). \square

5. Proof of maximum principle. In this section, we give a proof of the maximum principle stated in § 3. As assumed in § 3, we let $(x^\#(\cdot), u^\#(\cdot), \mu^\#(\cdot))$ be an optimal solution of Problem C such that the condition of Theorem 3.2 concerning $\mathcal{R} - \mathcal{Q}$ holds. For any $(x_0, u(\cdot), \mu(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}$, we let $x(\cdot; x_0, u(\cdot), \mu(\cdot))$ be the corresponding solution of (3.3), and we define

$$(5.1) \quad x^0(t) = \int_0^t \langle f(\tau, x(\tau; x_0, u(\cdot), \mu(\cdot)), u(\tau)), d\mu(\tau) \rangle, \quad t \in [0, T].$$

Then we see that $x^0(T) = J(x(\cdot), u(\cdot), \mu(\cdot))$, the cost functional of Problem C. Now, for any $\varepsilon > 0$, we define

$$(5.2) \quad \begin{aligned} J_\varepsilon(x_0, u(\cdot), \mu(\cdot)) &= \{d_\Omega(x_0, x(T; x_0, u(\cdot), \mu(\cdot)))^2 \\ &\quad + d_{\Omega^0(\varepsilon)}(x^0(T; x_0, u(\cdot), \mu(\cdot)))^2\}^{1/2} \\ \forall(x_0, u(\cdot), \mu(\cdot)) &\in X \times \mathcal{U} \times \mathcal{M}, \end{aligned}$$

where

$$\begin{aligned} \Omega^0(\varepsilon) &= (-\infty, -\varepsilon + x^{\#0}(T)], \\ d_\Omega(x_0, x_1) &= \inf \{(|x_0 - y_0|^2 + |x_1 - y_1|^2)^{1/2} \mid (y_0, y_1) \in \Omega\}, \\ d_{\Omega^0(\varepsilon)}(x^0) &= \inf \{|x^0 - y^0| \mid y^0 \in \Omega^0(\varepsilon)\}. \end{aligned}$$

Then it is clear that

$$(5.3) \quad J_\varepsilon(x_0, u(\cdot), \mu(\cdot)) > 0 \quad \forall(x_0, u(\cdot), \mu(\cdot)) \in X \times \mathcal{U} \times \mathcal{M},$$

$$(5.4) \quad J_\varepsilon(x^\#(0), u^\#(\cdot), \mu^\#(\cdot)) = \varepsilon \leq \inf_{X \times \mathcal{U} \times \mathcal{M}} J_\varepsilon(x_0, u(\cdot), \mu(\cdot)) + \varepsilon.$$

Thus by Ekeland's variational principle [15], [16], we can find an $(x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}$, such that

$$(5.5) \quad \tilde{d}((x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)), (x^\#(0), u^\#(\cdot), \mu^\#(\cdot))) \leq \sqrt{\varepsilon},$$

$$(5.6) \quad J_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)) \leq J_\varepsilon(x^\#(0), u^\#(\cdot), \mu^\#(\cdot)),$$

$$(5.7) \quad \begin{aligned} J_\varepsilon(x_0, u(\cdot), \mu(\cdot)) &\geq J_\varepsilon(x^\varepsilon(0), u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)) \\ &\quad - \sqrt{\varepsilon} \tilde{d}((x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)), (x_0, u(\cdot), \mu(\cdot))) \\ &\quad \forall(x_0, u(\cdot), \mu(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}. \end{aligned}$$

We let $x^\varepsilon(\cdot)$ be the solution of (3.3) corresponding to $(x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot))$ and $x^{0,\varepsilon}(\cdot)$ be the corresponding function defined by (5.1). Next, we let $D_\#$ and D_ε be the same as those defined in § 4 and fix any $\rho \in (0, 1)$ and $(x_0, u(\cdot), \mu(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}$ with

$$(5.8) \quad u(\cdot) \in \mathcal{U}^\# \equiv \{u(\cdot) \in \mathcal{U} \mid u(\tau) = u^\#(\tau), \forall \tau \in D_\#\}.$$

Then let

$$(5.9) \quad u_\varepsilon(\tau) = u(\tau)\chi_{[0, T] \setminus D_\varepsilon}(\tau) + u^\varepsilon(\tau)\chi_{D_\varepsilon}(\tau), \quad \tau \in [0, T].$$

By Lemma 4.5, we have that

$$(5.10) \quad |\bar{\mu}^\#|(\{u_\varepsilon \neq u\}), \quad |\bar{\mu}^\varepsilon|(\{u_\varepsilon \neq u\}) \rightarrow 0, \quad \varepsilon \rightarrow 0.$$

Next, by Corollary 4.4, we can find a Borel-measurable set $E_\rho \subset [0, T]$ such that

$$(5.11) \quad |\bar{\mu}^\varepsilon|(E_\rho) = \rho |\bar{\mu}_0^\varepsilon|([0, T]) \leq \rho |\bar{\mu}^\varepsilon|([0, T])$$

and

$$(5.12) \quad \rho \int_0^t e^{A(t-\tau)} \Delta F^\varepsilon(\tau) d\mu^\varepsilon(\tau) = \int_0^t e^{A(t-\tau)} \Delta F^\varepsilon(\tau) \chi_{E_\rho}(\tau) d\mu^\varepsilon(\tau) + o(\rho),$$

uniformly in $t \in [0, T]$, where

$$\Delta F^\varepsilon(\tau) = F(\tau, x^\varepsilon(\tau-0), u_\varepsilon(\tau)) - F(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)), \quad \tau \in [0, T].$$

Then we define

$$(5.13) \quad \begin{aligned} x_{0,\rho}^\varepsilon &= x_0^\varepsilon + \rho x_0, \\ u_\rho^\varepsilon(\cdot) &= u^\varepsilon(\cdot) \chi_{[0,T] \setminus E_\rho}(\cdot) + u_\varepsilon(\cdot) \chi_{E_\rho}(\cdot), \\ \mu_\rho^\varepsilon(\cdot) &= \mu^\varepsilon(\cdot) + \rho(\mu(\cdot) - \mu^\varepsilon(\cdot)). \end{aligned}$$

It is clear that $(x_{0,\rho}^\varepsilon, u_\rho^\varepsilon(\cdot), \mu_\rho^\varepsilon(\cdot)) \in X \times \mathcal{U} \times \mathcal{M}$. Now let $x_\rho^\varepsilon(\cdot)$ be the unique solution of (3.3) corresponding to $(x_{0,\rho}^\varepsilon, u_\rho^\varepsilon(\cdot), \mu_\rho^\varepsilon(\cdot))$ and $x_\rho^{\varepsilon,0}(\cdot)$ be defined as in (5.1) correspondingly. We now would like to derive the variation equation associated with (3.3). We observe the following:

$$(5.14) \quad \begin{aligned} & \frac{1}{\rho} [x_\rho^\varepsilon(t) - x^\varepsilon(t)] \\ &= e^{At} x_0 + \int_0^t e^{A(t-\tau)} F(\tau, x_\rho^\varepsilon(\tau-0), u_\rho^\varepsilon(\tau)) d(\mu(\tau) - \mu^\varepsilon(\tau)) \\ & \quad + \frac{1}{\rho} \int_0^t e^{A(t-\tau)} [F(\tau, x_\rho^\varepsilon(\tau-0), u_\rho^\varepsilon(\tau)) - F(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau))] d\mu^\varepsilon(\tau) \\ & \quad + \frac{1}{\rho} \int_0^t e^{A(t-\tau)} [F(\tau, x^\varepsilon(\tau-0), u(\tau)) - F(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau))] \chi_{E_\rho}(\tau) d\mu^\varepsilon(\tau). \end{aligned}$$

By (5.13) and Lemma 4.1, we see that

$$(5.15) \quad \lim_{\rho \rightarrow 0} \sup_{0 \leq t \leq T} |x_\rho^\varepsilon(t) - x^\varepsilon(t)| = 0.$$

Hence a careful calculation shows that (see (5.12))

$$(5.16) \quad \begin{aligned} & \frac{1}{\rho} [x_\rho^\varepsilon(t) - x^\varepsilon(t)] \\ &= e^{At} x_0 + \int_0^t e^{A(t-\tau)} F(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)) (d\mu(\tau) - \mu^\varepsilon(\tau)) \\ & \quad + \int_0^t e^{A(t-\tau)} F_x \left(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau); \frac{x_\rho^\varepsilon(\tau-0) - x^\varepsilon(\tau-0)}{\rho} \right) d\mu^\varepsilon(\tau) \\ & \quad + \int_0^t e^{A(t-\tau)} \Delta F^\varepsilon(\tau) d\mu^\varepsilon(\tau) + o(1), \end{aligned}$$

uniformly in $t \in [0, T]$, where

$$(5.17) \quad F_x(\tau, x, u; \xi) = \lim_{h \rightarrow 0} \frac{F(\tau, x + h\xi, u) - F(\tau, x, u)}{h},$$

the Fréchet derivative of $F(\tau, x, u)$ in x in the direction ξ . Hence the limit

$$(5.18) \quad \lim_{\rho \rightarrow 0} \frac{x_\rho^\varepsilon(\tau) - x^\varepsilon(t)}{\rho} = \xi_\varepsilon(t), \quad t \in [0, T],$$

exists, and $\xi_\varepsilon(\cdot)$ satisfies

$$(5.19) \quad \begin{aligned} \xi_\varepsilon(t) = & e^{At}x_0 + \int_0^t e^{A(t-\tau)} F_x(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau); \xi_\varepsilon(\tau-0)) d\mu^\varepsilon(\tau) \\ & + \int_0^t e^{A(t-\tau)} F(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)) d(\mu(\tau) - \mu^\varepsilon(\tau)) \\ & + \int_0^t e^{A(t-\tau)} \Delta F^\varepsilon(\tau) d\mu^\varepsilon(\tau), \quad t \in [0, T]. \end{aligned}$$

Similarly, we have the existence of the limit

$$(5.20) \quad \lim_{\rho \rightarrow 0} \frac{x_\rho^{0,\varepsilon}(\tau) - x^{0,\varepsilon}(t)}{\rho} = \xi_\varepsilon^0(t), \quad t \in [0, T],$$

and $\xi_\varepsilon^0(\cdot)$ satisfies

$$(5.21) \quad \begin{aligned} \xi_\varepsilon^0(t) = & \int_0^t \langle f_x(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)) \xi_\varepsilon(\tau-0), d\mu^\varepsilon(\tau) \rangle \\ & + \int_0^t \langle f(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)), d(\mu(\tau) - \mu^\varepsilon(\tau)) \rangle \\ & + \int_0^t \langle \Delta f^\varepsilon(\tau), d\mu^\varepsilon(\tau) \rangle, \quad t \in [0, T], \end{aligned}$$

where

$$\Delta f^\varepsilon(\tau) = f(\tau, x^\varepsilon(\tau-0), u_\varepsilon(\tau)) - f(\tau, x^\varepsilon(\tau-0), u^\varepsilon(\tau)), \quad \tau \in [0, T].$$

Then, from (5.5), we know that

$$(5.22) \quad \begin{aligned} \lim_{\varepsilon \rightarrow 0} x^\varepsilon(t) &= x^\#(t), & \lim_{\varepsilon \rightarrow 0} x_\varepsilon^0(t) &= x^{\#,0}(t), & t \in [0, T], \\ \lim_{\varepsilon \rightarrow 0} \xi_\varepsilon(t) &= \xi(t), & \lim_{\varepsilon \rightarrow 0} \xi_\varepsilon^0(t) &= \xi^0(t), & t \in [0, T], \end{aligned}$$

with

$$(5.23) \quad \begin{aligned} \xi(t) = & e^{At}x_0 + \int_0^t e^{A(t-\tau)} F_x(\tau, x^\#(\tau-0), u^\#(\tau); \xi(\tau-0)) d\mu^\#(\tau) \\ & + \int_0^t e^{A(t-\tau)} F(\tau, x^\#(\tau-0), u^\#(\tau)) d(\mu(\tau) - \mu^\#(\tau)) \\ & + \int_0^t e^{A(t-\tau)} \Delta F^\#(\tau) d\mu^\#(\tau), \quad t \in [0, T]; \end{aligned}$$

$$(5.24) \quad \begin{aligned} \xi^0(t) = & \int_0^t \langle f_x(\tau, x^\#(\tau-0), u^\#(\tau)) \xi(\tau-0), d\mu^\#(\tau) \rangle \\ & + \int_0^t \langle f(\tau, x^\#(\tau-0), u^\#(\tau)), d(\mu(\tau) - \mu^\#(\tau)) \rangle \\ & + \int_0^t \langle \Delta f^\#(\tau), d\mu^\#(\tau) \rangle, \quad t \in [0, T], \end{aligned}$$

where

$$\begin{aligned}\Delta F^\#(\tau) &= F(\tau, x^\#(\tau-0), u(\tau)) - F(\tau, x^\#(\tau-0), u^\#(\tau)), & \tau \in [0, T], \\ \Delta f^\#(\tau) &= f(\tau, x^\#(\tau-0), u(\tau)) - f(\tau, x^\#(\tau-0), u^\#(\tau)), & \tau \in [0, T].\end{aligned}$$

Next, by (5.7), we have that

$$\begin{aligned}(5.25) \quad & -\sqrt{\varepsilon} \tilde{d}((x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)), (x_{0,\rho}^\varepsilon, u_\rho^\varepsilon(\cdot), \mu_\rho^\varepsilon(\cdot))) \\ & \leq J_\varepsilon(x_{0,\rho}^\varepsilon, u_\rho^\varepsilon(\cdot), \mu_\rho^\varepsilon(\cdot)) - J_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot)).\end{aligned}$$

Then, by (5.11), (5.13), and (5.15)–(5.21), after dividing ρ and sending $\rho \rightarrow 0$ (similar to [23]), we have that

$$\begin{aligned}(5.26) \quad & -\sqrt{\varepsilon} \{ |x_0|^2 + |\mu^\varepsilon|(T)^2 + [|\mu^\varepsilon|(T) + |\mu|(T)]^2 \}^{1/2} \\ & \leq \frac{1}{J_\varepsilon(x_0^\varepsilon, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot))} \{ d_\Omega^0((x_0^\varepsilon, x^\varepsilon(T)); (x_0, \xi_\varepsilon(T))) d_\Omega(x_0^\varepsilon, x^\varepsilon(T)) \\ & \quad + d_{\Omega^0(\varepsilon)}^0(x^{0,\varepsilon}(T); \xi_\varepsilon^0(T)) d_{\Omega^0(\varepsilon)}(x^{0,\varepsilon}(T)) \} \\ & = \langle \bar{\varphi}_\varepsilon, x_0 \rangle + \langle \bar{\psi}_\varepsilon, \xi_\varepsilon(T) \rangle + \bar{\psi}_\varepsilon^0 \xi_\varepsilon^0(T),\end{aligned}$$

where

$$(5.27) \quad \bar{\varphi}_\varepsilon = \frac{d_\Omega(x_0^\varepsilon, x^\varepsilon(T)) a_\varepsilon}{J_\varepsilon(x_0, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot))},$$

$$(5.28) \quad \bar{\psi}_\varepsilon = \frac{d_\Omega(x_0^\varepsilon, x^\varepsilon(T)) b_\varepsilon}{J_\varepsilon(x_0, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot))},$$

$$(5.29) \quad \bar{\psi}_\varepsilon^0 = \frac{d_{\Omega^0(\varepsilon)}(x^{0,\varepsilon}(T))}{J_\varepsilon(x_0, u^\varepsilon(\cdot), \mu^\varepsilon(\cdot))},$$

with

$$(5.30) \quad \{(a_\varepsilon, b_\varepsilon)\} = \partial d_\Omega(x_0^\varepsilon, x^\varepsilon(T)).$$

Here the notations of Clarke's generalized directional derivative and gradient of functions d_Ω and $d_{\Omega^0(\varepsilon)}$ are adopted (see [10] for details). By Hypothesis 1, as in [23], we know that $\partial d_\Omega(x_0^\varepsilon, x^\varepsilon(T))$ is a singleton. Also, we have that (see [23])

$$(5.31) \quad |\bar{\varphi}_\varepsilon|_{X^*}^2 + |\bar{\psi}_\varepsilon|_{X^*}^2 + (\bar{\psi}_\varepsilon^0)^2 = 1 \quad \forall \varepsilon > 0.$$

Since Ω is convex, by (5.30), we have that

$$(5.32) \quad \langle a_\varepsilon, y_0 - x_0^\varepsilon \rangle + \langle b_\varepsilon, y_1 - x^\varepsilon(T) \rangle \leq 0 \quad \forall (y_0, y_1) \in \Omega.$$

Thus

$$\begin{aligned}(5.33) \quad & \langle \bar{\varphi}_\varepsilon, y_0 - x^\#(0) \rangle + \langle \bar{\psi}_\varepsilon, y_1 - x^\#(T) \rangle \\ & \leq \{ |x_0^\varepsilon - x_0^\#|^2 + |x^\varepsilon(T) - x^\#(T)|^2 \}^{1/2} \equiv \delta_\varepsilon \rightarrow 0, \quad (\varepsilon \rightarrow 0).\end{aligned}$$

Then, by (5.22) and (5.26), we obtain

$$\begin{aligned}(5.34) \quad & \langle \bar{\varphi}_\varepsilon, x_0 - (y_0 - x^\#(0)) \rangle + \langle \bar{\psi}_\varepsilon, \xi(T) - (y_1 - x^\#(T)) \rangle + \bar{\psi}_\varepsilon^0 \xi_\varepsilon^0(T) \geq -\hat{\delta}_\varepsilon \\ & \quad \forall (y_0, y_1) \in \Omega,\end{aligned}$$

with

$$(5.35) \quad \lim_{\varepsilon \rightarrow 0} \hat{\delta}_\varepsilon = 0,$$

uniformly in $(x_0, u(\cdot), \mu(\cdot))$ in bounded sets of $X \times \mathcal{U} \times \mathcal{M}$. Next, let (see (3.7))

$$(5.36) \quad B(\tau, \xi, z) = F_x(\tau, x^\#(\tau-0), u^\#(\tau); \xi)z \quad \forall (\tau, \xi, z) \in [0, T] \times X \times Z,$$

$$(5.37) \quad \nu(\tau) = \begin{pmatrix} \mu(\tau) \\ \mu^\#(\tau) \end{pmatrix} \quad \forall \tau \in [0, T],$$

and

$$(5.38) \quad \bar{G}(\tau) = (F(\tau, x^\#(\tau-0), u^\#(\tau)), \Delta F^\#(\tau)) \quad \forall \tau \in [0, T].$$

Then (5.23) reads

$$(5.39) \quad \begin{aligned} \xi(t) = & e^{A't}x_0 + \int_0^t e^{A(t-\tau)} B(\tau, \xi(\tau-0), d\mu^\#(\tau)) \\ & + \int_0^t e^{A(t-\tau)} \bar{G}(\tau) d\nu(\tau) \quad \forall t \in [0, T]. \end{aligned}$$

Similarly, (5.24) can be written as

$$(5.40) \quad \xi^0(t) = \int_0^t \langle f_x(\tau) \xi(\tau-0), d\mu^\#(\tau) \rangle + \int_0^t \langle \bar{f}(\tau), d\nu(\tau) \rangle \quad \forall t \in [0, T],$$

with

$$\begin{aligned} f_x(\tau) &= f_x(\tau, x^\#(\tau-0), u^\#(\tau)), \quad \tau \in [0, T], \\ \bar{f}(\tau) &= (f(\tau, x^\#(\tau-0), u^\#(\tau)), \Delta f^\#(\tau)), \quad \tau \in [0, T]. \end{aligned}$$

By Theorem 2.6, we obtain

$$(5.41) \quad \xi(t) = \Phi(t, 0)x_0 + \int_0^t \Psi(t, \tau) \bar{G}(\tau) d\nu(\tau), \quad t \in [0, T].$$

Then we see that

$$(5.42) \quad \mathcal{R} = \left\{ \int_0^t \Psi(t, \tau) \bar{G}(\tau) d\nu(\tau) \mid (u(\cdot), \mu(\cdot)) \in \mathcal{U}^\# \times \mathcal{M} \right\}.$$

Since we assume that $\mathcal{R} - \mathcal{Q}$ is finite-codimensional in X , it is easy to see that (see [23]) the set

$$\left\{ \left(\Phi(T, 0)x_0 + \xi \right) \mid \xi \in \mathcal{R}, \eta \in X \right\} - \Omega$$

is finite-codimensional in $X \times X$. Thus, as [17], [23], from (5.31) and (5.34), we can find a subsequence $\varepsilon \downarrow 0$, such that

$$(5.43) \quad (\bar{\varphi}_\varepsilon, \bar{\psi}_\varepsilon, \bar{\psi}_\varepsilon^0) \xrightarrow{*} (\bar{\varphi}, \bar{\psi}, \bar{\psi}^0) \neq 0.$$

Then, from (5.22), (5.26), and (5.29), we have that

$$(5.44) \quad \langle \bar{\varphi}, x_0 \rangle + \langle \bar{\psi}, \xi(T) \rangle + \bar{\psi}^0 \xi^0(T) \geq 0,$$

$$(5.45) \quad \bar{\psi}^0 \geq 0.$$

From (5.32), we have that

$$(5.46) \quad \langle \bar{\varphi}, y_0 - x_0^\# \rangle + \langle \bar{\psi}, y_1 - x^\#(T) \rangle \leq 0 \quad \forall (y_0, y_1) \in \Omega.$$

Next, we define

$$(5.47) \quad \psi^0 = -\bar{\psi}^0 \leq 0$$

and

$$(5.48) \quad \begin{aligned} \psi(t) &= \Psi(T, t)^* \psi(T) + \psi^0 \int_t^T \Psi(\tau - 0, t)^* f_x(\tau)^* d\mu^\#(\tau), \quad t \in [0, T], \\ \psi(T) &= -\bar{\psi}. \end{aligned}$$

Then we have that

$$(5.49) \quad \begin{aligned} 0 &\geq \langle \psi(T), \xi(T) \rangle - \langle \psi(0), \xi(0) \rangle + \psi^0 \xi^0(T) + \langle \psi(0) - \bar{\varphi}, x_0 \rangle \\ &= \left\langle \psi(T), \Phi(T, 0)x_0 + \int_0^T \Psi(T, \tau) \bar{G}(\tau) d\nu(\tau) \right\rangle \\ &\quad - \left\langle \Psi(T, 0)^* \psi(T) + \psi^0 \int_0^T \Psi(\tau - 0, 0)^* f_x(\tau)^* d\mu^\#(\tau), x_0 \right\rangle \\ &\quad + \psi^0 \int_0^T \left\langle f_x(\tau) \left[\Phi(\tau - 0, 0)x_0 + \int_{[0, \tau)} \Psi(\tau - 0, s) \bar{G}(s) \bar{\nu}(ds) \right], d\mu^\#(\tau) \right\rangle \\ &\quad + \psi^0 \int_0^T \langle \bar{f}(\tau), d\nu(\tau) \rangle + \langle \psi(0) - \bar{\varphi}, x_0 \rangle \\ &= \int_0^T \langle \Psi(T, \tau)^* \psi(T), \bar{G}(\tau) d\nu(\tau) \rangle - \langle \Theta(T, 0)^* \psi(T), x_0 \rangle \\ &\quad + \psi^0 \int_0^T \int_0^\tau \langle \Psi(\tau - 0, s)^* f_x(\tau)^* d\mu^\#(\tau), \bar{G}(s) d\nu(s) \rangle \\ &\quad + \psi^0 \int_0^T \langle \bar{f}(\tau), d\nu(\tau) \rangle + \langle \psi(0) - \bar{\varphi}, x_0 \rangle \\ &= \int_0^T \langle \psi(\tau), \bar{G}(\tau) d\nu(\tau) \rangle + \int_0^T \langle \psi^0 \bar{f}(\tau), d\nu(\tau) \rangle \\ &\quad + \langle \psi(0) - \bar{\varphi} - \Theta(T, 0)^* \psi(T), x_0 \rangle. \end{aligned}$$

The above holds for all $(x_0, u(\cdot), \mu(\cdot)) \in X \times \mathcal{U}^\# \times \mathcal{M}$. Thus, by taking $x_0 = 0$, we obtain

$$(5.50) \quad \int_0^T \langle \psi(\tau), \bar{G}(\tau) d\nu(\tau) \rangle + \int_0^T \langle \psi^0 \bar{f}(\tau), d\nu(\tau) \rangle \leq 0,$$

i.e.,

$$(5.51) \quad \begin{aligned} 0 &\geq \int_0^T \langle H(\tau, x^\#(\tau - 0), u^\#(\tau), \psi^0, \psi(\tau)), d(\mu(\tau) - \mu^\#(\tau)) \rangle \\ &\quad + \int_0^T \langle H(\tau, x^\#(\tau - 0), u(\tau), \psi^0, \psi(\tau)) \\ &\quad \quad - H(\tau, x^\#(\tau - 0), u^\#(\tau), \psi^0, \psi(\tau)), d\mu^\#(\tau) \rangle \end{aligned}$$

$$\forall (u(\cdot), \mu(\cdot)) \in \mathcal{U}^\# \times \mathcal{M}.$$

Hence (3.15) and (3.16) follow. Now, by taking $(u(\cdot), \mu(\cdot)) = (u^\#(\cdot), 0)$ in (5.49), we obtain

$$(5.52) \quad \langle \psi(0) - \bar{\varphi} - \Theta(T, 0)^* \psi(T), x_0 \rangle \leq 0 \quad \forall x_0 \in X.$$

Thus

$$(5.53) \quad \bar{\varphi} = \psi(0) - \Theta(T, 0)^* \psi(T).$$

Then (5.46) reads

$$(5.54) \quad \langle \psi(0) - \Theta(T, 0)^* \psi(T), y_0 - x_0^\# \rangle - \langle \psi(T), y_1 - x^\#(T) \rangle \leq 0 \quad \forall (y_0, y_1) \in \Omega.$$

This gives the transversality condition (3.17). By (5.43), (5.47), (5.48), and (5.53), we see that

$$(5.55) \quad (\psi(\cdot), \psi^0) \neq 0.$$

Finally, by (5.48) and Lemma 2.7, we have that

$$(5.56) \quad \begin{aligned} \psi(t) &= e^{A^*(T-t)} \psi(T) + \int_t^T e^{A^*(\tau-t)} B(\tau, d\mu^\#(\tau))^* \Psi(T, \tau)^* \psi(T) \\ &\quad + \int_t^T \psi^0 e^{A^*(\tau-t)} f_x(\tau)^* d\mu^\#(\tau) \\ &\quad + \int_t^T \psi^0 \int_t^\tau e^{A^*(s-t)} B(s, d\mu^\#(s))^* \Psi(\tau - 0, s)^* f_x(\tau)^* d\mu^\#(\tau) \\ &= e^{A^*(T-t)} \psi(T) + \int_t^T e^{A^*(\tau-t)} B(\tau, d\mu^\#(\tau))^* \psi(T) \\ &\quad + \int_t^T e^{A^*(\tau-t)} \psi^0 f_x(\tau)^* d\mu^\#(\tau). \end{aligned}$$

Thus, the function $\psi(\cdot)$ defined by (5.48) is the solution of (3.12). Hence we have completed the proof of Theorem 3.2. \square

Appendix. In this appendix, we present some relevant results concerning the Young integral and the vector measures, among others.

First, we let $T > 0$ be a constant, Z be a Banach space, and K be a subset of Z . We define

$$BV([0, T]; K) = \{\mu(\cdot) : [0, T] \rightarrow K \mid \mu(\cdot) \text{ is of bounded variation}\},$$

$$BV_0([0, T]; K) = \{\mu(\cdot) \in BV([0, T]; K) \mid \mu(0) = 0\}.$$

For convenience, we take the convention that, for any $\mu(\cdot) \in BV([0, T]; K)$,

$$(A.1) \quad \mu(0 - 0) = \mu(0), \quad \mu(T + 0) = \mu(T).$$

Next, for any $\mu(\cdot) \in BV([0, T]; K)$, we define

$$(A.2) \quad \begin{aligned} \bar{\mu}([0, t]) &= \mu(t + 0) - \mu(0), & 0 \leq t \leq T, \\ \bar{\mu}((s, t]) &= \mu(t + 0) - \mu(s + 0), & 0 \leq s \leq t \leq T. \end{aligned}$$

Extending this vector-valued set function to $\mathcal{B}([0, T])$, the Borel σ -field of $[0, T]$, we obtain a vector measure $\bar{\mu}(\cdot)$, which is of bounded variation. We refer to $\bar{\mu}(\cdot)$ as the

vector measure induced by $\mu(\cdot)$. For $\mu(\cdot) \in BV([0, T]; K)$, we let $|\mu|(\cdot) \in BV([0, T]; \mathbb{R}^+)$ be the variation of $\mu(\cdot)$; i.e., $|\mu|(t)$ is the total variation of $\mu(\cdot)$ on the interval $[0, t]$. It is clear that

$$(A.3) \quad \begin{cases} |\bar{\mu}|([0, t]) = |\mu|(t+0), \\ |\bar{\mu}|([0, t)) = |\mu|(t-0), \end{cases} \quad \forall 0 \leq t \leq T,$$

where $|\bar{\mu}|(\cdot)$ is the variation of the vector measure $\bar{\mu}(\cdot)$ (see [13]). Next, by noting that any $\mu(\cdot) \in BV([0, T]; K)$ has at most countably many discontinuity points, we may define

$$(A.4) \quad \begin{aligned} \mu_b(t) &= \sum_{0 \leq \tau < t} [\mu(\tau+0) - \mu(\tau-0)] + \mu(t) - \mu(t-0) \quad \forall t \in [0, T], \\ \mu_c(t) &= \mu(t) - \mu_b(t) \quad \forall t \in [0, T]. \end{aligned}$$

Then, it is easy to show (mimic the proof for the scalar-valued case; see [27]) that $\mu_c(\cdot) \in BV([0, T]; Z) \cap C([0, T]; Z)$ and

$$(A.5) \quad |\mu|(t) = |\mu_b|(t) + |\mu_c|(t) \quad \forall t \in [0, T].$$

Now we let $\bar{\mu}_b(\cdot)$ and $\bar{\mu}_c(\cdot)$ be the vector measures induced by $\mu_b(\cdot)$ and $\mu_c(\cdot)$, respectively. Then we have that

$$(A.6) \quad |\bar{\mu}|(E) = |\bar{\mu}_b|(E) + |\bar{\mu}_c|(E) \quad \forall E \in \mathcal{B}([0, T]).$$

Next, if Z has the RNP (Radon-Nikodym property [13]) with respect to $|\bar{\mu}|$, then there exists a $|\bar{\mu}|$ -integrable function $\theta(\cdot): [0, T] \rightarrow Z$ such that

$$(A.7) \quad \bar{\mu}(E) = \int_E \theta(\tau) |\bar{\mu}|(d\tau) \quad \forall E \in \mathcal{B}([0, T]),$$

$$(A.8) \quad |\bar{\mu}|(E) = \int_E |\theta(\tau)|_Z |\bar{\mu}|(d\tau) \quad \forall E \in \mathcal{B}([0, T])$$

(see [13] for a proof). Thus

$$(A.9) \quad |\theta(\tau)|_Z = 1, \quad |\bar{\mu}| \text{ a.e. } \tau \in [0, T].$$

Let us set

$$(A.10) \quad \begin{aligned} \mathcal{M}_0([0, T]; K) &= \left\{ \mu(\cdot) \in BV_0([0, T]; K) \mid \bar{\mu}(E) = \int_E \theta(\tau) |\bar{\mu}|(d\tau), \right. \\ &\quad \left. \forall E \in \mathcal{B}([0, T]), \text{ for some } \theta(\cdot), \text{ with } |\theta(\tau)|_Z = 1, |\bar{\mu}| \text{ a.e.} \right\}. \end{aligned}$$

PROPOSITION A.1. *Let K be a convex cone in Z . Then $\mathcal{M}_0 \equiv \mathcal{M}_0([0, T]; K)$ is a convex cone.*

The proof is straightforward.

Now let X be another Banach space. An operator-valued function $F(\cdot): [0, T] \rightarrow \mathcal{L}(Z, X)$ is said to be uniformly Borel-measurable if there exists a sequence of Borel-measurable simple functions $F_n(\cdot): [0, T] \rightarrow \mathcal{L}(X, Z)$ such that

$$(A.11) \quad \lim_{n \rightarrow \infty} \|F_n(t) - F(t)\|_{\mathcal{L}(Z, X)} = 0 \quad \forall t \in [0, T].$$

It is easy for us to define the Bochner integral for the operator-valued function $F(\cdot):[0, T] \rightarrow \mathcal{L}(Z, X)$ with respect to the vector measure $\bar{\mu}$ induced by $\mu \in BV_0([0, T]; Z)$. We denote

$$B_\mu([0, T]; \mathcal{L}(Z, X)) = \{F:[0, T] \rightarrow \mathcal{L}(Z, X) \mid F(\cdot) \text{ is } \bar{\mu}\text{-Bochner-integrable}\}.$$

Next, we would like to introduce the Young integral.

DEFINITION A.2. Let $\mu(\cdot) \in BV_0([0, T]; K)$ and $F(\cdot):[0, T] \rightarrow \mathcal{L}(Z, X)$ be uniformly Borel-measurable. We say that $F(\cdot)$ is μ -Young-integrable if $F(\cdot)$ is $\bar{\mu}_c$ -Bochner-integrable and

$$(A.12) \quad \sum_{0 \leq \tau \leq T} \|F(\tau)\|_{\mathcal{L}(Z, X)} |\mu(\tau+0) - \mu(\tau-0)| < \infty.$$

In this case, we define the Young integral of $F(\cdot)$ with respect to $\mu(\cdot)$ by the following:

$$(A.13) \quad \begin{aligned} \int_s^t F(\tau) d\mu(\tau) &= \int_{[s, t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{s < \tau < t} F(\tau) [\mu(\tau+0) - \mu(\tau-0)] \\ &\quad + F(s) [\mu(s+0) - \mu(s)] + F(t) [\mu(t) - \mu(t-0)], \\ &\quad \forall 0 \leq s < t \leq T, \end{aligned}$$

$$\int_t^t F(\tau) d\mu(\tau) = 0 \quad \forall t \in [0, T].$$

We let

$$Y_\mu([0, T]; \mathcal{L}(Z, X)) = \{F:[0, T] \rightarrow \mathcal{L}(Z, X) \mid F(\cdot) \text{ is } \mu\text{-Young-integrable}\}.$$

Then we have the following result concerning the relation between Bochner and Young integrals.

PROPOSITION A.3. Let $\mu(\cdot) \in BV_0([0, T]; K)$. Then

$$(A.14) \quad Y_\mu([0, T]; \mathcal{L}(Z, X)) = B_\mu([0, T]; \mathcal{L}(Z, X)),$$

and, for any $F(\cdot) \in B_\mu([0, T]; \mathcal{L}(Z, X))$, we have that

$$(A.15) \quad \begin{aligned} \int_s^t F(\tau) d\mu(\tau) &= \int_{[s, t]} F(\tau) \bar{\mu}(d\tau) - F(s) [\mu(s) - \mu(s-0)] \\ &\quad - F(t) [\mu(t+0) - \mu(t)] \\ &= \int_{(s, t)} F(\tau) \bar{\mu}(d\tau) + F(s) [\mu(s+0) \\ &\quad - \mu(s)] + F(t) [\mu(t) - \mu(t-0)], \\ &\quad \forall 0 \leq s < t \leq T. \end{aligned}$$

In particular,

$$(A.16) \quad \int_0^T F(\tau) d\mu(\tau) = \int_{[0, T]} F(\tau) \bar{\mu}(d\tau).$$

A similar result for the case where $F(\cdot)$ and $\mu(\cdot)$ are scalar-valued can be found in [18]. Since, in our optimal control problem, the vector measure $\bar{\mu}(\cdot)$ (or the BV function $\mu(\cdot)$) will be a part of control, we need the following notion.

DEFINITION A.4. A function $F(\cdot):[0, T] \rightarrow \mathcal{L}(Z, X)$ is said to be $BV_0([0, T]; K)$ -integrable if for any $\mu(\cdot) \in BV_0([0, T]; K)$, $F(\cdot)$ is $\bar{\mu}$ -Bochner-integrable, or, equivalently, μ -Young-integrable.

PROPOSITION A.5. Let $F(\cdot):[0, T] \rightarrow \mathcal{L}(Z, X)$ be uniformly Borel-measurable. Then $F(\cdot)$ is $BV_0([0, T]; Z)$ -integrable if and only if

$$(A.17) \quad \|F(\tau)\|_{\mathcal{L}(Z, X)} \leq C, \quad \tau \in [0, T].$$

Proof. The sufficiency is obvious. To prove the necessity, we suppose the contrary. Then there exist sequences $\tau_i \in [0, T]$ and $z_i \in Z$ with $|z_i| = 1/i^2$ ($i \geq 1$) such that

$$(A.18) \quad |F(\tau_i)z_i| \geq 1 \quad \forall i \geq 1.$$

Then let

$$\mu(t) = \sum_{i \geq 1} z_i \chi_{[\tau_i, \infty)}(t), \quad t \in [0, T].$$

We see that this $\mu(\cdot) \in BV_0([0, T]; Z)$ and $F(\cdot)$ is not $\bar{\mu}$ -Bochner-integrable. \square

Next, we introduce the μ -continuity. Let $\mu(\cdot) \in BV_0([0, T]; K)$. We introduce a metric on $[0, T]$, which is related to $\mu(\cdot)$ and is stronger than the usual Euclidean metric, as follows:

$$(A.19) \quad \rho_\mu(s, t) = |s - t| + \|\mu|(s) - \mu|(t)\| \quad \forall s, t \in [0, T].$$

Then, for any metric space V , we define

$$(A.20) \quad C_\mu([0, T]; V) = \{v(\cdot): [0, T] \rightarrow V \mid v(\cdot) \text{ is uniformly continuous from } [0, T] \text{ with metric } \rho_\mu(\cdot) \text{ to } V\}.$$

We should note that, in general, $[0, T]$ is not necessarily compact under metric $\rho_\mu(\cdot)$ (see [18] for relevant remarks on the scalar-valued case). Thus, in (A.20), we require $v(\cdot)$ to be uniformly continuous, instead of just continuous.

PROPOSITION A.6. Let $\mu \in BV_0([0, T]; K)$. Then

$$(A.21) \quad \mu(\cdot) \in C_\mu([0, T]; K),$$

and, if $v(\cdot) \in C_\mu([0, T]; V)$, then

$$(A.22) \quad \{t \in [0, T] \mid v(t-0) \neq v(t)\} \subseteq \{t \in [0, T] \mid \mu(t-0) \neq \mu(t)\},$$

$$(A.23) \quad \{t \in [0, T] \mid v(t+0) \neq v(t)\} \subseteq \{t \in [0, T] \mid \mu(t+0) \neq \mu(t)\}.$$

In particular,

$$(A.24) \quad C([0, T]; V) \subseteq C_\mu([0, T]; V) \quad \forall \mu(\cdot) \in BV_0([0, T]; K),$$

$$(A.25) \quad C([0, T]; V) = C_\mu([0, T]; V) \quad \forall \mu(\cdot) \in BV_0([0, T]; K) \cap C([0, T]; K).$$

Proof. By (A.19), we see that

$$(A.26) \quad |\mu(t) - \mu(s)| \leq \rho_\mu(t, s) \quad \forall t, s \in [0, T].$$

Thus (A.21) follows. Now we let $v(\cdot) \in C_\mu([0, T]; V)$ and d be the metric of V . Then there exists a modulus of continuity $\omega(\cdot)$ such that

$$(A.27) \quad d(v(s), v(t)) \leq \omega(\rho_\mu(s, t)) \quad \forall s, t \in [0, T].$$

Thus, if $t \in (0, T]$ with the property $\mu(t-0) = \mu(t)$, then

$$(A.28) \quad \begin{aligned} d(v(t), v(t-\varepsilon)) &\leq \omega(\rho_\mu(t, t-\varepsilon)) \\ &\leq \omega(\varepsilon + |\mu|(t) - |\mu|(t-\varepsilon)) \rightarrow 0 \quad (\varepsilon \rightarrow 0). \end{aligned}$$

Thus (A.22) follows. Similarly, we can obtain (A.23). Then (A.24) follows easily. To obtain (A.25), we let $\mu(\cdot) \in BV_0([0, T]; K) \cap C([0, T]; K)$. Then $|\mu|(\cdot) \in C([0, T]; \mathbb{R})$. Thus, for some modulus of continuity $\omega(\cdot)$, we have that

$$(A.29) \quad ||\mu|(s) - |\mu|(t)| \leq \omega(|s - t|) \quad \forall s, t \in [0, T].$$

Hence, if $v(\cdot) \in C_\mu([0, T]; V)$, then, for some modulus of continuity $\hat{\omega}(\cdot)$, we have that

$$(A.30) \quad d(v(s), v(t)) \leq \hat{\omega}(\rho_\mu(s, t)) \leq \hat{\omega}(|s - t| + \omega(|s - t|)).$$

Hence (A.25) follows. \square

Any function $v(\cdot) \in C_\mu([0, T]; V)$ is said to be μ -continuous. The main features of the μ -continuous functions are that they at most jump at the points where $\mu(\cdot)$ jumps, and at every point $t \in [0, T]$, the left and the right limits exist. We should note, however, that these functions are not necessarily of bounded variation.

Next, we consider the indefinite integral of the Young type. To this end, let $\mu(\cdot) \in BV_0([0, T]; K)$ and $F(\cdot) \in Y_\mu([0, T]; \mathcal{L}(Z, X))$. Then, for any $t \in [0, T]$, we have that

$$(A.31) \quad \int_0^t F(\tau) d\mu(\tau) = \int_{[0, t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{0 < \tau < t} F(\tau) [\mu(\tau + 0) - \mu(\tau - 0)] \\ + F(0) [\mu(0 + 0) - \mu(0)] + F(t) [\mu(t) - \mu(t - 0)].$$

We refer to the above indefinite Young integral.

PROPOSITION A.7. Let $\mu(\cdot) \in BV_0([0, T]; K)$ and $F(\cdot) \in Y_\mu([0, T]; \mathcal{L}(Z, X))$. Let

$$(A.32) \quad f(t) = \int_0^t F(\tau) d\mu(\tau) \quad \forall t \in [0, T].$$

Then $f(\cdot) \in C_\mu([0, T]; X) \cap BV([0, T]; X)$, and

$$(A.33) \quad f(t + 0) = f(t) + F(t) [\mu(t + 0) - \mu(t)], \quad t \in [0, T],$$

$$(A.34) \quad f(t - 0) = f(t) - F(t) [\mu(t) - \mu(t - 0)], \quad t \in (0, T],$$

$$(A.35) \quad |f|(t) \leq \int_0^t \|F(\tau)\|_{\mathcal{L}(Z, X)} d|\mu|(\tau), \quad t \in [0, T].$$

We let $\Delta = \{(t, \tau) \in [0, T] \times [0, T] \mid t \geq \tau\}$ and $\bar{\Delta}$ be its closure. Let $G(\cdot, \cdot): \bar{\Delta} \rightarrow \mathcal{L}(Z, X)$, and consider the following integral:

$$(A.36) \quad g(t) = \int_0^t G(t, \tau) d\mu(\tau), \quad t \in [0, T].$$

We have the following result, the proof of which is straightforward.

PROPOSITION A.8. Let $\mu(\cdot) \in BV_0([0, T]; K)$ and $G(\cdot, \cdot): \bar{\Delta} \rightarrow \mathcal{L}(Z, X)$. We assume the following:

(i) $G(\cdot, \cdot)$ is uniformly Borel-measurable. There exists a $|\bar{\mu}|$ -integrable function $a(\cdot): [0, T] \rightarrow \mathbb{R}$ such that

$$(A.37) \quad \|G(t, \tau)\|_{\mathcal{L}(Z, X)} \leq a(\tau) \quad \forall (t, \tau) \in \bar{\Delta}.$$

(ii) There exist functions $\omega_G: \mathbb{R}^+ \rightarrow \mathbb{R}^+$ and $\theta: [0, T] \rightarrow \mathbb{R}^+$, with the properties that ω_G is nondecreasing, $\omega_G(0) = 0$, and $\theta(\cdot)$ is $|\bar{\mu}|$ -integrable, such that

$$(A.38) \quad \|G(t, \tau) - G(s, \tau)\|_{\mathcal{L}(Z, X)} \leq \omega_G(\rho_\mu(t, s))\theta(\tau) \quad \forall (t, \tau), (s, \tau) \in \bar{\Delta}.$$

Then the function $g(\cdot)$ defined by (A.36) is μ -continuous and

$$(A.39) \quad \begin{aligned} g(t+0) &= \int_0^t G(t+0, \tau) d\mu(\tau) + G(t+0, t)[\mu(t+0) - \mu(t)], \\ g(t-0) &= \int_0^t G(t-0, \tau) d\mu(\tau) - G(t-0, t)[\mu(t) - \mu(t-0)], \end{aligned} \quad t \in [0, T],$$

where

$$(A.40) \quad G(t-0, t) \equiv G(t, t), \quad t \in [0, T], \quad G(T+0, T) = G(T, T).$$

In particular, if there exists a constant C such that

$$(A.41) \quad \omega_G(r) = Cr \quad \forall r \in \mathbb{R},$$

then $g(\cdot) \in BV_0([0, T]; X)$.

Next, we consider a Young-type multiple integral and the corresponding Fubini theorem. We let X , Y , and Z be a Banach space and let $T, S > 0$ be constants. Let $\mu(\cdot) \in BV_0([0, T]; Z)$ and $\nu(\cdot) \in BV_0([0, S]; Y)$. We let

$$(A.42) \quad \begin{aligned} \tilde{\mathcal{B}}(Y \times Z; X) &= \left\{ B: Y \times Z \rightarrow X \mid B \text{ is bilinear and} \right. \\ &\quad \left. \|B\| \equiv \sup_{|y|_X, |z|_Z \leq 1} |B(y, z)|_X < \infty \right\}. \end{aligned}$$

It is easy to see that $\tilde{\mathcal{B}}(Y \times Z; X)$ is a Banach space. Thus we may define the uniform Borel measurability for $\tilde{\mathcal{B}}(Y \times Z; X)$ -valued functions and the multiple Bochner-type integral of such functions with respect the vector measures $\bar{\mu}$ and $\bar{\nu}$. Then we can introduce the $(\mu \times \nu)$ -Young integral, which is defined in the following way: Let $\Psi: [0, T] \times [0, S] \rightarrow \tilde{\mathcal{B}}(Y \times Z; X)$ be uniformly Borel-measurable and

$$(A.43) \quad \int_{[0, T] \times [0, S]} \|\Psi(t, s)\| |\bar{\mu}|(dt) |\bar{\nu}|(ds) < \infty.$$

Then, for $0 \leq t_0 \leq t_1 \leq T$ and $0 \leq s_0 \leq s_1 \leq S$, we define

$$(A.44) \quad \begin{aligned} \int_{t_0}^{t_1} \int_{s_0}^{s_1} \Psi(t, s, d\mu(t), d\nu(s)) &= \int_{t_0}^{t_1} \int_{[s_0, s_1]} \Psi(t, s, d\mu(t), \bar{\nu}(ds)) \\ &\quad - \int_{t_0}^{t_1} \Psi(t, s_0, d\mu(t), \nu(s_0) - \nu(s_0 - 0)) \\ &\quad - \int_{t_0}^{t_1} \Psi(t, s_1, d\mu(t), \nu(s_1 + 0) - \nu(s_1)). \end{aligned}$$

The meaning of the right-hand side of (A.44) is clear ($\int d\mu(t)$ always means the Young integral, and $\int \bar{\nu}(ds)$ means the Bochner integral). In the case where the above Young integral can be defined, we say that the function Ψ is $(\mu \times \nu)$ -Young-integrable. From our definition, the $(\bar{\mu} \times \bar{\nu})$ -Bochner integrability and the $(\mu \times \nu)$ -Young integrability are the same. Thus, hereafter, we simply refer to these two integrabilities as the $(\mu \times \nu)$ -integrability. Next, let us introduce the following notation (compare (A.13)):

$$(A.45) \quad \begin{aligned} \int_s^t F(\tau) d\mu(\tau) &= \int_{[s, t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{s < \tau < t} F(\tau)[\mu(\tau+0) - \mu(\tau-0)] \\ &\quad + F(t)[\mu(t) - \mu(t-0)], \end{aligned}$$

$$(A.46) \quad \int_s^t F(\tau) d\mu(\tau) = \int_{[s,t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{s \leq \tau < t} F(\tau) [\mu(\tau+0) - \mu(\tau-0)] \\ + F(t) [\mu(t) - \mu(t-0)],$$

$$(A.47) \quad \int_s^{(t)} F(\tau) d\mu(\tau) = \int_{[s,t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{s < \tau < t} F(\tau) [\mu(\tau+0) - \mu(\tau-0)] \\ + F(s) [\mu(s+0) - \mu(s)],$$

$$(A.48) \quad \int_s^{[t]} F(\tau) d\mu(\tau) = \int_{[s,t]} F(\tau) \bar{\mu}_c(d\tau) + \sum_{s < \tau \leq t} F(\tau) [\mu(\tau+0) - \mu(\tau-0)] \\ + F(s) [\mu(s+0) - \mu(s)].$$

Similarly, we can define $\int_s^{(t)} F(\tau) d\mu(\tau)$, $\int_{[s,t]} F(\tau) d\mu(\tau)$, $\int_s^{[t]} F(\tau) d\mu(\tau)$ and $\int_{[s,t]} F(\tau) d\mu(\tau)$. It is easy to see that

$$(A.49) \quad \int_{(s)}^{(t)} F(\tau) d\mu(\tau) = \int_{(s,t)} F(\tau) \bar{\mu}(d\tau), \quad \int_{[s]}^{(t)} F(\tau) d\mu(\tau) = \int_{[s,t)} F(\tau) \bar{\mu}(d\tau), \\ \int_{(s)}^{[t]} F(\tau) d\mu(\tau) = \int_{(s,t]} F(\tau) \bar{\mu}(d\tau), \quad \int_{[s]}^{[t]} F(\tau) d\mu(\tau) = \int_{[s,t]} F(\tau) \bar{\mu}(d\tau).$$

The following result is a kind of Fubini theorem for the $(\mu \times \nu)$ -Young integral. The result has its own interest. To our knowledge, even for the scalar case of the Young integral, such a result is new. In deriving the adjoint system along the optimal triplet in § 5, it played an important role.

THEOREM A.9 (the Fubini theorem). *Let $\mu(\cdot) \in BV([0, T]; Z)$, $\nu(\cdot) \in BV([0, T]; Y)$ and $B(\cdot, \cdot): [0, T] \times [0, S] \rightarrow \mathcal{B}(Y \times Z; X)$ be $(\mu \times \nu)$ -integrable. Then*

$$(A.50) \quad \int_s^t \int_\tau^t B(r, \tau) d\mu(r) d\nu(\tau) - \int_s^t \int_s^\tau B(r, \tau) d\nu(\tau) d\mu(r) \\ = \int_s^{(t)} B(\tau, \tau) [\mu(\tau+0) - \mu(\tau)] d\nu(\tau) \\ - \int_{(s)}^t B(r, r) [\nu(r) - \nu(r-0)] d\mu(r)$$

$$\forall 0 \leq s < \tau < t \leq T.$$

In particular, if

$$(A.51) \quad B(\tau, \tau) = 0 \quad \forall 0 \leq \tau \leq T,$$

then

$$(A.52) \quad \int_s^t \int_\tau^t B(r, \tau) d\mu(r) d\nu(\tau) = \int_s^t \int_s^\tau B(r, \tau) d\nu(\tau) d\mu(r).$$

In the above, we have taken the convention that

$$B(t, s)yz = B(t, s)zy \quad \forall (y, z) \in Y \times Z.$$

This will not cause any confusion from the context. The proof of the above result consists of some direct computations. We see that in the case where (A.51) fails, the

right-hand side of (A.50) is not necessarily zero. Thus, when changing the order of Young integrals, we must be somewhat careful.

LIPSCHITZIAN STABILITY IN NONLINEAR CONTROL AND OPTIMIZATION*

ASEN L. DONTCHEV† AND WILLIAM W. HAGER‡

Abstract. This paper studies Lipschitz properties, relative to the parameter p , of the set of solutions to problems of the form

$$\text{Find } z \in \Omega_p \text{ such that } T_p(z) \in F_p(z).$$

As applications, various problems in control and optimization are examined, focusing in particular on the stability of the feasible set of a control problem, and the stability of solutions of infinite-dimensional mathematical programs and optimal control problems. In another application, an estimate is obtained for the error in the Euler approximation to an optimal control problem.

Key words. stability, sensitivity, feasible set, optimal set, discrete approximations, Euler approximation, sufficient optimality conditions

AMS(MOS) subject classifications. 49K40, 49M25, 90C31, 93B05

1. Introduction. This paper presents a general framework for analyzing Lipschitz stability in control and optimization. As applications of the theory, we study the dependence on a parameter of the set of controls and states that satisfies given inequality constraints. We also study the dependence on a parameter of the optimal solutions of various problems in nonlinear control and optimization.

The paper begins by studying (in § 2) the following problem:

$$(1) \quad \text{Find } z \in \Omega_p \text{ such that } T_p(z) \in F_p(z),$$

where p is a parameter, T_p maps Ω_p to Y_p , Y_p is a normed linear space, and $F_p(z)$ is a subset of Y_p for each $z \in \Omega_p$. Loosely speaking, we proceed in the following way: Along with (1), we consider an *auxiliary problem*

$$(2) \quad \text{Find } z \in \Omega_p \text{ such that } L_p(z) + y \in F_p(z),$$

where $y \in Y$ is treated as a new parameter. It turns out that if L_p approximates T_p in a suitable sense, and if the set of solutions of (2) possesses certain Lipschitz properties with respect to y , uniformly in p , then the set of solutions of (1) will have analogous properties with respect to p . In particular, if T_p is smooth, then L_p can be its linearization. For a nonsmooth T_p , we should choose a nonsmooth L_p .

Our abstract approach is based on a refinement of the set-valued contracting mapping principle (Lemma 1). An existence result given in Theorem 1, leads to various stability results. In particular, Corollary 1 obtains an estimate for the distance from a reference point to the set of solutions of (1). In Corollary 2, we assume that Ω , F , and L are independent of p , obtaining an implicit function theorem: If the solution set of (2) is pseudo-Lipschitz with respect to y around some given point, and if L strongly approximates T_p , then the set of solutions of (1) is pseudo-Lipschitz as well. Corollary 3 obtains a result related to metric regularity of the map $T - F$.

Generalized equations of the form (1) have been considered by Robinson in a series of papers [35]–[38] with Ω and F independent of p . Our analysis contains some of his results. While the theory of [35]–[38] is applied to finite-dimensional mathematical programming problems, our focus here is infinite-dimensional optimization, primarily optimal control. Our analysis is more in the spirit of [19] and [20].

Recently, a different approach to sensitivity based on nonsmooth analysis and the differentiability properties of set-valued maps was developed by Aubin [4], Aubin and Frankowska [6], Rockafellar [39] and [41], King and Rockafellar [24], Mordukhovich [32], and others. In [16] this approach is applied to various control problems. A motivation for the nonsmooth approach to Lipschitz stability is given by Rockafellar in [40].

An outline of our paper follows, while detailed comments connecting specific results in our paper to related literature appear throughout the paper. Section 3 examines the feasible set for a nonlinear control system with inequality state and control constraints that depend on a parameter. We show that if the functions defining the constraints are sufficiently smooth, and if an interior point condition holds for a linearized system, then the feasible set is pseudo-Lipschitz. Moreover, the interior point condition holds if the gradients of the active constraints satisfy an independence condition, the same condition that appeared in Hager's analysis [18] of Lipschitz continuity in time for an optimal control. At the end of § 3, we present an example of a nonsmooth control system with state and control constraints, and we demonstrate a method for proving local controllability.

Section 4 considers a quadratic minimum problem in a reflexive Banach space with linear cone constraints. We show that a coercivity condition together with surjectivity of the gradients of the (active) constraints guarantee local Lipschitz continuity of the solution relative to the data. In § 5 we apply this result to a nonlinear optimization problem, and a quadratic program plays the role of an auxiliary problem.

In § 6 we consider a nonlinear control problem with convex control constraints. The treatment of the control problem requires special care due to the discrepancy between the function spaces needed for coercivity and for differentiability. An example shows that the method of analysis can still be applied, even when the coercivity condition is violated.

Finally, in § 7 we obtain error estimates for Euler's approximation to a nonlinear optimal control problem with convex control constraints. In this case, the parameter p in (1) corresponds to the mesh spacing. The key step in the analysis is to show that the solution of a perturbed discrete linear-quadratic problem, related to the auxiliary problem (2), depends Lipschitz continuously on a parameter, uniformly in the mesh spacing. Our method makes use of the so-called averaged modulus of smoothness, introduced by Sendov and Popov [42]. When the optimal control has bounded variation, the error in the discrete control is on the order of the mesh spacing.

2. Abstract theory. Let Z be a Banach space, let Ω be a closed subset of Z , let Y be a normed vector space, and let 2^Y denote the collection of subsets of Y . Given a map $T: \Omega \rightarrow Y$ and a map $F: \Omega \rightarrow 2^Y$, we consider the following problem:

$$(3) \quad \text{Find } z \in \Omega \text{ such that } T(z) \in F(z).$$

Of course, for appropriate choices of Ω , T , and F , (3) may represent an equation, an inclusion, or a variational inequality. In this section, conditions are formulated that guarantee a solution to (3). This existence theorem applied to perturbations of (3) yields stability results. Throughout this paper, $\|\cdot\|$ denotes a norm in the appropriate

space. Given subsets P and $Q \subset Z$, the one-sided distance from P to Q (or excess function), denoted $\|P - Q\|$, is defined by

$$\|P - Q\| = \sup_{p \in P} \inf_{q \in Q} \|p - q\|.$$

If Q is empty, we set $\|P - Q\| = \infty$. Given $z \in Z$, let $B_r(z)$ denote the closed ball with center z and radius r .

We will use a contraction mapping principle for set-valued maps to obtain an existence result for (3). The proof that follows is similar to the usual proofs for the existence of a fixed point (see [22, p. 31] or [34]); however, since our Lipschitz assumption (b) below is weaker than the usual Lipschitz assumption, we include a proof for completeness. Although this fixed point result is stated for a Banach space, it holds in any complete metric space.

LEMMA 1. Let $\Phi: \Omega \rightarrow 2^\Omega$ with $\Phi(z)$ closed for every $z \in \Omega$. Suppose that there exist real numbers r and λ , and $z_0 \in \Omega$ with the following properties:

$$(a) \quad 0 \leq \lambda < 1 \quad \text{and} \quad \frac{\|z_0 - \Phi(z_0)\|}{1 - \lambda} < r,$$

$$(b) \quad \|\Phi(y) \cap B_r(z_0) - \Phi(z)\| \leq \lambda \|y - z\| \text{ for every } y \text{ and } z \in B_r(z_0) \cap \Omega.$$

Then there exists $z \in B_r(z_0) \cap \Omega$ such that $z \in \Phi(z)$. If Φ is single-valued, then assumption (a) can be replaced by

$$(a') \quad 0 \leq \lambda < 1 \quad \text{and} \quad \frac{\|z_0 - \Phi(z_0)\|}{1 - \lambda} \leq r,$$

and there exists a unique $z \in B_r(z_0) \cap \Omega$ with $z = \Phi(z)$.

Proof. By assumption (a), there exists $z_1 \in \Phi(z_0)$ such that $\|z_1 - z_0\| < r(1 - \lambda)$. Proceeding by induction, suppose that there exists $z_{k+1} \in \Phi(z_k) \cap B_r(z_0)$ for $k = 1, 2, \dots, n-1$ with $\|z_{k+1} - z_k\| < r(1 - \lambda)\lambda^k$. By assumption (b) and the induction hypothesis, we have

$$\|z_n - \Phi(z_n)\| \leq \|\Phi(z_{n-1}) \cap B_r(z_0) - \Phi(z_n)\| \leq \lambda \|z_n - z_{n-1}\| < r(1 - \lambda)\lambda^n.$$

Hence, there exists $z_{n+1} \in \Phi(z_n)$ such that $\|z_{n+1} - z_n\| < r(1 - \lambda)\lambda^n$. By the triangle inequality,

$$\|z_{n+1} - z_0\| \leq \sum_{k=0}^n \|z_{k+1} - z_k\| < r(1 - \lambda) \sum_{k=0}^n \lambda^k < r,$$

so that $z_{n+1} \in B_r(z_0)$. This completes the induction step.

By the triangle inequality and for $n > m$, we have

$$\|z_n - z_m\| \leq \sum_{k=m}^{n-1} \|z_{k+1} - z_k\| \leq r(1 - \lambda) \sum_{k=m}^{n-1} \lambda^k < r\lambda^m.$$

Thus the z_k form a Cauchy sequence that converges to some limit $z \in B_r(z_0) \cap \Omega$. By assumption (b),

$$\|z_k - \Phi(z)\| \leq \|\Phi(z_{k-1}) \cap B_r(z_0) - \Phi(z)\| \leq \lambda \|z_{k-1} - z\|.$$

Again, by the triangle inequality,

$$\|z - \Phi(z)\| \leq \|z - z_k\| + \|z_k - \Phi(z)\| \leq \|z - z_k\| + \lambda \|z_{k-1} - z\|,$$

which approaches zero as k increases. Since $\Phi(z)$ is closed, it follows that $z \in \Phi(z)$. If Φ is single-valued, then by (b), z is the unique element in $B_r(z_0) \cap \Omega$ for which $z = \Phi(z)$. \square

Given $y \in Y$ and a mapping L from Z to Y , consider the *auxiliary problem*

$$(4) \quad \text{Find } z \in \Omega \text{ such that } L(z) + y \in F(z).$$

Note that the set of solutions to (4) is closed if L is continuous and the graph of F is closed. Given $z_0 \in Z$ and $y_0 \in Y$, define the parameters D_r and δ by

$$D_r = \sup_{\substack{y, z \in B_r(z_0) \cap \Omega \\ y \neq z}} \frac{\|T(z) - T(y) - L(z) + L(y)\|}{\|z - y\|} \quad \text{and} \quad \delta = \|T(z_0) - L(z_0) - y_0\|.$$

If L is a bounded, linear operator, and z_0 lies in the interior of Ω , then $D_r \rightarrow 0$ when $r \rightarrow 0$ if and only if T is strictly (Fréchet) differentiable at z_0 (see [5, p. 16]). We have the following generalization of [20, Thm. 1].

THEOREM 1. *Let γ and r be real numbers that satisfy the relations*

$$(5) \quad 0 \leq \gamma D_r < 1 \quad \text{and} \quad r > \frac{\gamma \delta}{1 - \gamma D_r}.$$

Defining the set

$$\Delta_r = \bigcup_{z \in B_r(z_0) \cap \Omega} \{T(z) - L(z)\},$$

let Ψ denote a map from Δ_r to 2^Ω with the following properties: $z_0 \in \Psi(y_0)$, $\Psi(y)$ is a closed, nonempty subset of the solutions to (4) for each $y \in \Delta_r$, and

$$(6) \quad \|\Psi(y_1) \cap B_r(z_0) - \Psi(y_2)\| \leq \gamma \|y_1 - y_2\| \text{ for every } y_1 \text{ and } y_2 \in \Delta_r \cup \{y_0\}.$$

Then (3) has a solution $z \in B_r(z_0)$. If in addition there is only one solution of (4) for every $y \in \Delta_r$, then z is the unique solution of (3) in $B_r(z_0)$, and the second condition in (5) can be weakened to $r \geq \gamma \delta / (1 - \gamma D_r)$.

Proof. We apply Lemma 1 with $\Phi(z) = \Psi(T(z) - L(z))$. Thus z is a solution to (3) if $z \in \Phi(z)$. By (6), we have

$$\|\Phi(z) \cap B_r(z_0) - \Phi(y)\| \leq \gamma \|T(z) - T(y) - L(z) + L(y)\| \leq \gamma D_r \|z - y\|$$

whenever y and $z \in B_r(z_0) \cap \Omega$. Hence, Φ satisfies (b) of Lemma 1 with constant $\lambda = \gamma D_r$. Since $z_0 \in \Psi(y_0)$, it follows that

$$\begin{aligned} \|z_0 - \Phi(z_0)\| &\leq \|\Psi(y_0) \cap B_r(z_0) - \Psi(T(z_0) - L(z_0))\| \\ &\leq \gamma \|y_0 + L(z_0) - T(z_0)\| = \gamma \delta. \end{aligned}$$

Dividing this inequality by $1 - \lambda$, we see that $r > \|z_0 - \Phi(z_0)\| / (1 - \lambda)$. Since the contraction property of Lemma 1 holds on $B_r(z_0) \cap \Omega$, there exists $z \in B_r(z_0)$ with $z \in \Phi(z)$. If the solution of (4) is unique for every $y \in \Delta_r$, then Φ is single-valued on $B_r(z_0) \cap \Omega$. By Lemma 1, there exists a unique $z \in B_r(z_0) \cap \Omega$ with $z = \Phi(z)$. Hence, there is a unique solution to (3) in $B_r(z_0)$. \square

Remark 1. Note that if $\sigma \geq r D_r + \delta$, then $\Delta_r \subset B_\sigma(y_0)$. To prove this, we take the norm of the identity

$$T(z) - L(z) - y_0 = [T(z) - T(z_0) - L(z) + L(z_0)] + [T(z_0) - L(z_0) - y_0],$$

where $z \in B_r(z_0) \cap \Omega$, and we apply the triangle inequality to obtain the relation

$$\|T(z) - L(z) - y_0\| \leq r D_r + \delta \leq \sigma.$$

Now we consider a family of equations, each equation depending on a parameter p contained in a metric space P . Associated with each $p \in P$, there is a closed subset Ω_p of a Banach space Z_p , a normed vector space Y_p , and a pair of maps $T_p: \Omega_p \rightarrow Y_p$ and $F_p: \Omega_p \rightarrow 2^{Y_p}$. Analogous to (3), we study the following problem:

$$(7) \quad \text{Find } z \in \Omega_p \text{ such that } T_p(z) \in F_p(z).$$

Let 0 be a fixed element of P . Using Theorem 1, we will study the continuity of the map $p \rightarrow \Sigma(p)$, where $\Sigma(p)$ is the set of solutions of (7), making use of the following auxiliary problem:

$$(8) \quad \text{Find } z \in \Omega_p \text{ such that } L_p(z) + y \in F_p(z),$$

where $L_p: Z_p \rightarrow Y_p$, and $y \in Y_p$. We give three specific results assuming the maps appearing in (7) and (8) satisfy certain conditions near a reference point. The parameters D_r , Δ_r , and δ of Theorem 1 now depend on p as follows:

$$D_r(p) = \sup_{\substack{y, z \in B_r(z_p) \cap \Omega_p \\ y \neq z}} \frac{\|T_p(z) - T_p(y) - L_p(z) + L_p(y)\|}{\|z - y\|},$$

$$\Delta_r(p) = \Delta_r(p, z_p), \quad \text{where } \Delta_r(p, x) = \bigcup_{z \in B_r(x) \cap \Omega_p} \{T_p(z) - L_p(z)\}, \quad \text{and}$$

$$\delta(p) = \|T_p(z_p) - L_p(z_p) - y_p\|.$$

(Although the norms above may depend on p , this dependence is not indicated explicitly. In § 5 we consider a finite-dimensional discretization of an optimal control problem, in which case the norms depend on the mesh spacing.)

COROLLARY 1. *Let Ψ_p denote a map from a neighborhood of y_p to 2^{Ω_p} with the following properties: $z_p \in \Psi_p(y_p)$, $\Psi_p(y)$ is a closed, nonempty subset of the solutions to (8) for each $y \in \Delta_\sigma(p)$, where $\sigma > 0$, and for some γ and $\alpha > 0$, we have*

$$(9) \quad \|\Psi_p(y_1) \cap B_\alpha(z_p) - \Psi_p(y_2)\| \leq \gamma \|y_1 - y_2\| \text{ for every } y_1 \text{ and } y_2 \in \Delta_\sigma(p) \cup \{y_p\}.$$

If $D_r(p)$ and $\delta(p)$ tend to zero as r and p tend to zero, then for each $\gamma^+ > \gamma$ and for each p sufficiently close to zero, (7) has a solution z such that

$$(10) \quad \|z_p - z\| \leq \gamma^+ \|T_p(z_p) - L_p(z_p) - y_p\|.$$

If there is only one solution to (8) for every $y \in \Delta_\sigma(p)$, then z , satisfying (10), is the unique solution of (7) in a neighborhood of z_p .

Proof. Apply Theorem 1 with $\delta = \delta(p)$ and $r = \gamma^+ \delta(p)$. If $\delta = 0$, then z_p is a solution of (7), and (10) holds with $z = z_p$. If $\delta > 0$, then choose p sufficiently close to 0 that

$$\sigma \geq r, \quad \gamma D_r(p) < 1, \quad \alpha \geq r, \quad \text{and} \quad \gamma^+ > \frac{\gamma}{1 - \gamma D_r(p)}.$$

Hence, Theorem 1 yields (10). \square

Now we wish to start with a given solution z_0 of (7) associated with $p = 0$ and show that for small perturbations in the parameter, we can solve the equation, and in some sense, the solution is "well behaved." In this analysis, we allow T to depend on p , while Ω and F are independent of p . That is, the following problem is considered:

$$(11) \quad \text{Find } z \in \Omega \text{ such that } T_p(z) \in F(z).$$

To study the continuity of the solution map, we work with the fixed auxiliary problem (4) (L is independent of p).

We define an analogue $E_r(p)$ of D_r in which T is replaced by T_p , below:

$$(12) \quad E_r(p) = \sup_{\substack{y, z \in B_r(z_0) \cap \Omega \\ y \neq z}} \frac{\|T_p(z) - T_p(y) - L(z) + L(y)\|}{\|z - y\|}.$$

Following the terminology of Robinson [38], we say that $L(z)$ strongly approximates $T_p(z)$ at $z = z_0$ and $p = 0$ if and only if $E_r(p) \rightarrow 0$ as p and r tend to zero. Note that L does not need to be smooth. For example, if $T_p(z) = f_p(g(z))$, where f_p is Fréchet differentiable and g is Lipschitz, but not necessarily differentiable, then $L(z) = f'_0[g(z_0)]g(z)$ strongly approximates $T_p(z)$ at $z = z_0$ and $p = 0$ under appropriate continuity assumptions (see [38]).

In the following corollary, we take $z_p = z_0$ and $y_p = y_0$, and we replace assumption (9) by pseudo-Lipschitz continuity. Recall (see [4]) that the map Ψ is pseudo-Lipschitz with modulus γ , around a point (y_0, z_0) in the graph of Ψ , if there exist neighborhoods V of y_0 and U of z_0 such that

$$\|\Psi(y_1) \cap U - \Psi(y_2)\| \leq \gamma \|y_1 - y_2\|$$

whenever y_1 and $y_2 \in V$. Letting $\Sigma_r(p) = \Sigma(p) \cap B_r(z_0)$ denote the restriction of $\Sigma(p)$ to $B_r(z_0)$, we have the following corollary.

COROLLARY 2. *Given $z_0 \in \Sigma(0)$, define $y_0 = T_0(z_0) - L(z_0)$, and let $\Psi(y)$ denote the set of solutions to (4). We assume that Ψ is closed and nonempty-valued near y_0 , that Ψ is pseudo-Lipschitz with modulus γ around (y_0, z_0) , and that L strongly approximates $T_p(z)$ at $p = 0$ and $z = z_0$. If $T_p(z)$ is continuous in p at $p = 0$, uniformly in a neighborhood of $z = z_0$, then for each $\gamma^+ > \gamma$ and for r sufficiently small, there exists $s > 0$ such that $\Sigma_r(p)$ is nonempty for every $p \in B_s(0)$; moreover, for each p and $q \in B_s(0)$ and for each $z_p \in \Sigma_r(p)$, there exists $z_q \in \Sigma(q)$ such that*

$$(13) \quad \|z_p - z_q\| \leq \gamma^+ \|T_q(z_p) - T_p(z_p)\|.$$

If there is only one solution to (4) for every y near y_0 , then the solution of (11) is unique in $B_r(z_0)$ for every $p \in B_s(0)$. Moreover, the $z_q \in \Sigma(q)$ satisfying (13) also lies in $B_r(z_0)$.

Proof. Define the parameters

$$d(a, s) = \sup_{\substack{p, q \in B_s(0) \\ z \in B_a(z_0)}} \|T_p(z) - T_q(z)\| \quad \text{and} \quad \bar{D}_\rho = \sup_{p \in B_\rho(0)} E_\rho(p).$$

Let U and V be the neighborhoods of z_0 and y_0 appearing in the definition of pseudo-Lipschitz continuity. Choose σ sufficiently small that $B_\sigma(y_0) \subset V$. Choose ρ sufficiently small that $B_\rho(z_0) \subset U$

$$(14) \quad \sigma > \rho \bar{D}_\rho \quad \text{and} \quad \gamma < \gamma^+(1 - \gamma \bar{D}_\rho).$$

Choose a and s sufficiently small that

$$(15) \quad \rho \geq 2a, \quad \rho \geq s, \quad a > \gamma^+ d(a, s), \quad \text{and} \quad \sigma \geq \rho \bar{D}_\rho + d(a, s).$$

Let $p \in B_s(0)$. Referring to Remark 1, we see that $\Delta_a(p, z_0) \subset B_\sigma(y_0)$. Theorem 1 with T replaced by T_p and with $r = a$ implies that $\Sigma_a(p)$ is nonempty.

Given p and $q \in B_s(0)$ and $z_p \in \Sigma_a(p)$, let us apply Theorem 1 with z_0, y_0 , and T in the theorem replaced by $z_p, y_p = T_p(z_p) - L(z_p)$, and T_q , respectively. In Theorem 1, we take

$$r = \gamma^+ \delta, \quad \text{where} \quad \delta = \|T_q(z_p) - T_p(z_p)\| \leq d(a, s).$$

If $\delta = 0$, then (13) holds trivially by taking $z_q = z_p$. If $\delta > 0$, then by (15) we have

$$r > \frac{\gamma\delta}{1 - \gamma D_\rho},$$

where $D_\rho = E_\rho(q) \leq \bar{D}_\rho$. Since $B_r(z_p) \subset B_\rho(z_0)$, we have $\Delta_r(p, z_p) \subset \Delta_\rho(p, z_0) \subset B_\sigma(y_0)$. Hence, condition (6) of Theorem 1 holds, and (13) is established.

If the map Ψ is single-valued, then there exists a unique solution of (11) in $B_r(z_0)$ for every $p \in B_s(0)$. Similar to the proof of Theorem 1, the map $\Phi_p(z) = \Psi(T_p(z) - L(z))$ is a contraction on the ball $B_a(z_0)$ with contraction constant $\lambda = \gamma\bar{D}_\rho$ for each $p \in B_s(0)$. The distance from z_p to z_q is estimated by the following sequence of inequalities:

$$\begin{aligned} \|z_p - z_q\| &= \|\Phi_p(z_p) - \Phi_q(z_q)\| \leq \|\Phi_p(z_p) - \Phi_q(z_p)\| + \|\Phi_q(z_p) - \Phi_q(z_q)\| \\ &\leq \lambda \|z_p - z_q\| + \gamma \|T_p(z_p) - T_q(z_p)\|, \end{aligned}$$

which yields (13). \square

Observe that if there exists a constant κ such that T_p satisfies the Lipschitz condition

$$\|T_p(z) - T_q(z)\| \leq \kappa \text{ distance } \{p, q\}$$

for every z in a neighborhood of z_0 , then (13) implies that for every $z_p \in \Sigma_a(p)$, there exists $z_q \in \Sigma(q)$ such that

$$\|z_p - z_q\| \leq \gamma^+ \kappa \text{ distance } \{p, q\};$$

that is, the map Σ is pseudo-Lipschitz around $p = 0$ and $z = z_0$. Thus we conclude that if the auxiliary problem strongly approximates the original problem, and if the solution map of the auxiliary problem is pseudo-Lipschitz, then the solution map of the original problem is pseudo-Lipschitz as well.

Remark 2. Corollary 2 is a generalization of Theorem 2.1 in [37] and of Theorem 3.2 in [38]. In [37] Ω is a closed convex set, $F(z)$ is the normal cone to Ω at z , $T_p(z)$ is Fréchet differentiable with respect to z around $z = z_0$ and $p = 0$, and both $T_p(z)$ and its derivative $T'_p(z)$ are continuous with respect to z and p at $z = z_0$ and $p = 0$. Furthermore, it is assumed that (4) with

$$L(z) = T_0(z_0) + T'_0(z_0)(z - z_0)$$

has a unique solution that is Lipschitz near $y_0 = 0$. In [38] $F(z) = 0$, $L(z)$ strongly approximates $T_p(z)$ at $z = z_0$ and $p = 0$, and the assumptions for $L(z)$ are equivalent to the condition that L^{-1} is single-valued and Lipschitz near 0.

Corollary 2 is an implicit function theorem in which we avoid the surjectivity (interiority) condition, for a suitably defined derivative, that is usually present in a Graves-type theorem (see [7, p. 95]). For example, given a closed-valued map $F: Z \rightarrow 2^Y$ and given (z_0, y_0) in the graph of F , let $f: Z \rightarrow Y$ be a continuous function that is strictly Fréchet differentiable at z_0 . Let us apply Corollary 2 with $L(z) = -f'(z_0)(z - z_0)$, $p = y \in Y$, $T_p(z) = p - f(z)$, and Ψ defined by

$$\Psi(y) = \{z \in Z: y - f'(z_0)(z - z_0) \in F(z)\}.$$

By Corollary 2, Ψ is pseudo-Lipschitz around (y_0, z_0) if and only if the map $[F + f]^{-1}$ is pseudo-Lipschitz around $(y_0 + f(z_0), z_0)$.

In the remainder of the paper, we also make use of the following result.

COROLLARY 3. *If the assumptions of Corollary 2 hold, then for each $\gamma^+ > \gamma$, there exist positive constants a, ρ , and ε with the following properties: For every $z \in B_a(z_0)$, $p \in B_\rho(0)$, and $w_p \in F(z)$ with $\|T_p(z) - w_p\| \leq \varepsilon$, there exists $z_p \in \Sigma(p)$ such that*

$$(16) \quad \|z - z_p\| \leq \gamma^+ \|T_p(z) - w_p\|.$$

Proof. Choose σ and ρ as in the proof of Corollary 2 to satisfy (14). Let a and $\varepsilon > 0$ be small enough that

$$(17) \quad \frac{\rho}{2} \geq a \geq \gamma^+ \varepsilon \quad \text{and} \quad \sigma \geq \rho \bar{D}_\rho + \varepsilon.$$

Given $p \in B_\rho(0)$, $z \in B_a(z_0)$, and $w_p \in F(z)$ with $\|T_p(z) - w_p\| \leq \varepsilon$, let us define $y_p = w_p - L(z)$. We apply Theorem 1 with y_0 , z_0 , and T replaced by y_p , z , and T_p , and with $\delta = \|T_p(z) - w_p\|$. If $\delta = 0$, then $z \in \Sigma(p)$, and (16) holds. If $\delta > 0$, we take $r = \gamma^+ \delta$. Since $\delta \leq \varepsilon$, it follows from (14) and (17) that

$$\frac{\gamma \delta}{1 - \gamma E_\rho(p)} < r = \gamma^+ \delta \leq \gamma^+ \varepsilon \leq a \leq \frac{\rho}{2} < \rho.$$

Hence, $B_r(z) \subset B_\rho(z_0)$, which implies that $\Delta_r(p, z) \subset \Delta_\rho(p, z_0)$. By Remark 1 and (17), we have $\Delta_\rho(p, z_0) \subset B_\sigma(y_0)$ so that assumption (6) of Theorem 1 holds. By Theorem 1, there exists a solution $z_p \in B_r(z)$ to (11), where $r = \gamma^+ \delta$, which establishes (16). \square

Remark 3. Relation (16) implies that

$$\|z - \Sigma(p)\| \leq \gamma^+ \|T_p(z) - w_p\|.$$

Since the left-hand side of this inequality does not depend on w_p , it follows from Corollary 3 that when $\|T_p(z) - F(z)\|$ is sufficiently small, we have

$$(18) \quad \|z - \Sigma(p)\| \leq \gamma^+ \|T_p(z) - F(z)\|.$$

In particular, if $T_p(z) = T(z) + p$, we conclude that the map $T - F$ is *metrically regular* around $(z_0, 0)$. It turns out that metric regularity is equivalent to the pseudo-Lipschitz property (see Penot [33]). For a discussion of related results, see Cominetti [10], and the references therein.

Corollary 3 is a generalization of Theorem 1 in [36] where the estimate (18) is obtained under the following conditions: F is a closed, convex cone, independent of z ; $T_p(z)$ is continuously Fréchet differentiable; and interior point regularity holds. This regularity condition implies, via the celebrated Robinson-Ursescu theorem (see [36] and [43]), that the solution map of the linearized (auxiliary) problem is pseudo-Lipschitz.

3. Feasibility and controllability. As a first application of the abstract theory, we study the continuity of the map “parameter \rightarrow feasible set” of a nonlinear control system with constraints. The following model problem is analyzed: Given an interval $I = [0, 1]$, the state x is a map from I to R^n , while the control u is a map from I to R^m . Given θ between 1 and ∞ , let $L^\theta(R^m)$ denote the space of functions $u: I \rightarrow R^m$ with $|u(t)|^\theta$ integrable where $|\cdot|$ is the Euclidean norm. Let $W^{1,\theta}(R^n)$ denote the space of functions $x: I \rightarrow R^n$ with both x and its derivative in $L^\theta(R^n)$. We often omit the argument R^n or R^m when the context is clear. Of course, when θ is ∞ , these spaces are modified in the standard fashion: L^∞ is the space of essentially bounded functions, and $W^{1,\infty}$ is the space of Lipschitz continuous functions (or, equivalently, the space of essentially bounded functions with essentially bounded derivatives). Given functions

$$f_p: R^{n+m} \times I \rightarrow R^n, \quad K_p: R^m \times I \rightarrow R^\mu, \quad \text{and} \quad S_p: R^n \times I \rightarrow R^\nu,$$

where p is a parameter, and, given a starting condition $a \in R^n$, the feasible set $\Sigma(p)$ consists of the set of $u \in L^\infty$ and $x \in W^{1,\theta}$ that satisfy the relations

$$(19) \quad \begin{aligned} \dot{x}(t) &= f_p(x(t), u(t), t) \quad \text{and} \quad K_p(u(t), t) \leq 0 \quad \text{a.e. } t \in I, \\ x(0) &= a, \quad S_p(x(t), t) \leq 0 \quad \text{for every } t \in I. \end{aligned}$$

Using the notation of (11), the feasible set in the control problem consists of those $z \in \Omega$ such that $T_p(z) \in F(z)$, where

$$\Omega = \{z = (x, u): x \in W^{1,\theta}, u \in L^\infty, x(0) = a\},$$

$$T_p(x, u) = \begin{bmatrix} f_p(x, u) - \dot{x} \\ K_p(u) \\ S_p(x) \end{bmatrix}, \quad \text{and} \quad F(x, u) = \begin{bmatrix} 0 \\ L_-^\infty \\ L_-^\infty \end{bmatrix}.$$

Here L_-^∞ denotes the nonpositive functions in L^∞ .

Given a pair $z_0 = (x_0, u_0)$ that is feasible for (19) when $p = 0$, we wish to study the behavior of $\Sigma(p)$ for p near zero. Throughout this section, we make the following assumption: There exists a closed set $\Delta \subset R^n \times R^m \times I$ and a $\delta > 0$ such that $(x_0(t), u_0(t), t)$ lies in Δ for almost every $t \in I$, the distance from $(x_0(t), u_0(t), t)$ to the boundary of Δ in the hyperplane $R^n \times R^m \times \{t\}$ is at least δ for almost every $t \in I$, the derivatives of $f_p(x, u, t)$, $K_p(u, t)$, and $S_p(x, t)$ with respect to x and u exist on Δ , and these derivatives along with the function values are continuous with respect to $(x, u, t) \in \Delta$ and p near zero. From the development in § 2, Lipschitz properties of the solution map for the nonlinear problem are related to Lipschitz properties of the solution map for an auxiliary problem (4) when y is in a neighborhood of $T_0(z_0)$. We consider the following linearization of (19):

$$\begin{aligned} \dot{x}(t) - \dot{x}_0(t) &= A(t)(x(t) - x_0(t)) + B(t)(u(t) - u_0(t)) + y_1(t), \\ (20) \quad K(t)(u(t) - u_0(t)) + y_2(t) &\leq 0, \\ S(t)(x(t) - x_0(t)) + y_3(t) &\leq 0, \end{aligned}$$

where $y_1 \in L^\theta$, y_2 and $y_3 \in L^\infty$, and

$$A(t) = \nabla_x f_0(x_0(t), u_0(t), t),$$

$$B(t) = \nabla_u f_0(x_0(t), u_0(t), t),$$

$$K(t) = \nabla_u K_0(u_0(t), t),$$

$$S(t) = \nabla_x S_0(x_0(t), t).$$

Above any equality or inequality involving measurable functions is interpreted in the sense "almost everywhere."

From the development of § 2, we see that pseudo-Lipschitz continuity of the feasible map can be deduced from the following three conditions:

- (i) Lipschitz continuity of $T_p(z)$ with respect to p ,
- (ii) \bar{D}_ρ is sufficiently small,

(iii) The solution map associated with the linearized system is pseudo-Lipschitz. With regard to condition (i), Lipschitz continuity of $T_p(z)$ with respect to p is equivalent to Lipschitz continuity of $f_p(z)$, $K_p(z)$, and $S_p(z)$ with respect to p . Also, \bar{D}_ρ tends to zero as ρ tends to zero under our smoothness assumptions. In the following two lemmas, we study the Lipschitz continuity of the solution map for the linearized system.

LEMMA 2. *Let $z_0 = (x_0, u_0) \in \Omega$ be feasible in (19) when $p = 0$, let $\Lambda(y)$ denote the set of solutions $(x, u) \in W^{1,\theta} \times L^\infty$ to (20), and define $y_0 = T_0(z_0)$. If there exist $\alpha > 0$,*

$w \in W^{1,\theta}$, and $v \in L^\infty$ such that

$$(21) \quad \begin{aligned} \dot{w}(t) &= A(t)w(t) + B(t)v(t), & w(0) &= 0, \\ (K(t)v(t) + K_0(u_0(t), t))_i &\leq -\alpha, & i &= 1, 2, \dots, \mu, \\ (S(t)w(t) + S_0(x_0(t), t))_i &\leq -\alpha, & i &= 1, 2, \dots, \nu, \end{aligned}$$

then Λ is pseudo-Lipschitz around (y_0, z_0) .

Proof. This result follows from the Robinson-Ursescu theorem (see [36] and [43]) as stated (for example) by Aubin and Ekeland in [5, p. 132] or Clarke [9, p. 236]. That is, if there exists $r > 0$ such that for each y in a neighborhood of y_0 , we can find $z \in B_r(z_0)$ with $z \in \Lambda(y)$, then the map $y \rightarrow \Lambda(y) \cap B_r(z_0)$ is Lipschitz continuous, from which it follows that Λ is pseudo-Lipschitz around (y_0, z_0) . The proof of the lemma proceeds as follows: Given $y \in Y$ and a pair (w, v) satisfying (21), let x denote the solution to the differential equation in (20) corresponding to the control $u = v + u_0$ and the starting condition $x(0) = a$. Observe that x can be expressed as

$$x = w + x_0 + My_1,$$

where M is a bounded linear map from L^θ to $W^{1,\theta}$. Hence, we have

$$S(x - x_0) + y_3 = S(w + My_1) + y_3 \leq -\alpha + SM y_1 + y_3 - S_0(x_0).$$

Similarly, putting $u = v + u_0$ into the control constraint of (20) gives

$$K(u - u_0) + y_2 \leq -\alpha + y_2 - K_0(u_0).$$

Thus there exists $\sigma > 0$ such that x and u satisfy the constraints in (20) whenever $y \in B_\sigma(y_0)$, where

$$y_0 = T_0(z_0) = \begin{bmatrix} 0 \\ K_0(u_0) \\ S_0(x_0) \end{bmatrix}.$$

By the triangle inequality, we have

$$\|u - u_0\| + \|x - x_0\| \leq \|v\| + \|w\| + \|My_1\| \leq \|v\| + \|w\| + \sigma \|M\|$$

for every $y \in B_\sigma(y_0)$. Setting $r = \|v\| + \|w\| + \sigma \|M\|$, it follows that $B_r(z_0) \cap \Lambda(y)$ is nonempty whenever $y \in B_\sigma(y_0)$. This completes the proof. \square

The proof of Lemma 2 provides a way to construct a single-valued Ψ : For each $y \in Y$, x is the solution of the differential equation (20) corresponding to $u = v + u_0$. Now we present a condition that yields the existence of a state and control satisfying the interior point condition of Lemma 2. This condition is the same one that appeared in the study [18] of Lipschitz continuous solutions in optimal control. First, we provide some terminology. We say that a function g is piecewise continuous if there exists a finite sequence $\{t_i\}$ with

$$0 = t_0 < t_1 < t_2 < \dots < t_N = 1,$$

such that g is continuous on the open interval (t_i, t_{i+1}) for each i , and one-sided limits exist at each t_i . A function is piecewise continuously differentiable if it is continuous and its derivative is piecewise continuous. If $K(t)$ is the coefficient matrix for u in (20), then $K^B(t)$ and $K^N(t)$ denote the submatrices of $K(t)$ consisting of rows associated with those indices i for which either

$$K_0(u_0(t), t)_i = 0 \quad \text{or} \quad K_0(u_0(t), t)_i < 0, \quad \text{respectively.}$$

In other words, $K^B(t)$ and $K^N(t)$ are the submatrices corresponding to the binding and the nonbinding constraints at time t . The submatrices S^B and S^N of S are defined in a similar fashion. Basically, we will show that if the columns of $K^B(t)^T$ and

$B(t)^T S^B(t)^T$ are uniformly linearly independent, then the interior point condition of Lemma 2 is satisfied.

LEMMA 3. Let $z_0 = (x_0, u_0) \in \Omega$ be a point feasible for (19) when $p = 0$, and suppose that $S_0(a, 0) < 0$, $S_0(x_0)$ is piecewise continuously differentiable, both $K_0(u_0)$ and the matrices K and B are piecewise continuous, and at each t where these piecewise continuous functions are continuous, the following independence condition holds: There exists $\beta > 0$ such that

$$|K^B(t)^T b + B(t)^T S^B(t)^T c| \geq \beta(|b| + |c|)$$

for every b and c . Moreover, at a time t of discontinuity, this independence condition also holds, but with t replaced by both t^+ and t^- , and with the binding constraint set replaced by those of $K_0(u_0(t^+))$ and $K_0(u_0(t^-))$, respectively. Then there exist $w \in W^{1,\infty}$ and $v \in L^\infty$ that satisfy hypothesis (21) of Lemma 2 for some $\alpha > 0$.

Proof. Before considering the state constraints, we give a proof in the case of no state constraints. We first show that there exist a scalar $\delta > 0$ and sequences $\{t_i\}$ and $\{\tau_i\}$ such that

$$(22) \quad t_i \leq \tau_i \leq t_{i+1} \quad \text{for } 0 \leq i \leq N, \quad \tau_0 = t_0 = 0, \quad \tau_N = t_{N+1} = 1,$$

$$K_0^{N_i}(u_0(t), t) \leq -\delta \quad \text{for each } t_i \leq t \leq t_{i+1},$$

$$(23) \quad |K^{B_i}(t)^T b| \geq \delta |b| \quad \text{for each } t_i \leq t \leq t_{i+1}, \quad \text{for every } b,$$

where the B_i superscript means those rows (or components) associated with the binding constraints at τ_i , while the N_i superscript means those rows (or components) associated with nonbinding constraints at τ_i . The right-hand side of the inequality $K_0^{N_i}(u_0(t), t) \leq -\delta$ is interpreted as a vector with every component equal to $-\delta$.

To prove (22) and (23), we verify that they are satisfied on the closure of each open interval J where K and $K_0(u_0)$ are continuous. Let us define the parameter $\varepsilon(t)$ by

$$\varepsilon(t) = \text{minimum}_{1 \leq i \leq \mu} \{-K_0(u_0(t), t)_i : K_0(u_0(t), t)_i \neq 0\}.$$

If all the constraints are binding at t , then we set $\varepsilon(t) = +\infty$. The value of $K_0(u_0)$ at an endpoint of J is taken to be its limit at that point. By the continuity assumptions, it follows that for each $t \in J$, there exists an open ball O_t , containing t , such that

$$K_0^{N_i}(u_0(s)) \leq -\frac{\varepsilon(t)}{2} \quad \text{for every } s \in O_t$$

and

$$|K^{B_i}(s)^T b| \geq \frac{\beta}{2} |b| \quad \text{for every } s \in O_t,$$

where the superscript B_i stands for rows binding at t , while the superscript N_i stands for components nonbinding at t . If t is an endpoint of J , then the open ball is replaced by a half-open ball. By compactness, this cover of J has a finite subcover. In (22) and (23), the τ_i are the centers of the balls in the subcover, while the t_i are arbitrary points in the overlap region between adjacent balls. The parameter δ is given by

$$\delta = \frac{1}{2} \text{minimum} \{\varepsilon(\tau_0), \varepsilon(\tau_1), \dots, \varepsilon(\tau_N), \beta\}.$$

The control v that satisfies the interior point condition of Lemma 2 can be constructed in the following way: Given $\sigma > 0$ and t between t_i and t_{i+1} , $v(t)$ is the minimum norm solution of the equation $K^{B_i}(t)v(t) = -\sigma$ (if there are no binding constraints, set $v(t) = 0$). Since $K_0(u_0(t), t)$ is nonpositive, we have

$$(24) \quad K^{B_i}(t)v(t) + K_0^{B_i}(u_0(t), t) \leq -\sigma.$$

By (23), the smallest singular value of $K^{B_i}(t)$ is bounded from below by δ . It follows that $v(t)$ has the following bound in the Euclidean norm:

$$|v(t)| \leq \frac{\sigma \sqrt{\mu}}{\delta},$$

where μ is the number of component of K_0 . Hence, by (22) v also satisfies the inequality

$$(25) \quad K^{N_i}(t)v(t) + K_0^{N_i}(u_0(t), t) \leq \frac{\sigma \sqrt{\mu}}{\delta} |K^{N_i}(t)| - \delta.$$

Relations (24) and (25) imply that v satisfies the interior point condition (21) for σ sufficiently small.

When state constraints are present, this proof must be modified in several ways. By incorporating the state constraints in the definition of $\varepsilon(t)$, we can choose δ to satisfy the additional relation

$$S_0^{N_i}(x_0(t), t) \leq -\delta \quad \text{for each } t_i \leq t \leq t_{i+1}.$$

In addition, the independence condition (23) generalizes to the form

$$(26) \quad |K^{B_i}(t)^T b + B(t)^T S^{B_i}(t)^T c| \geq \delta(|b| + |c|).$$

Similar to the control constrained case, we wish to construct a control v_σ and a state w_σ such that $K^{B_i}v_\sigma(t) = -\sigma$ and $S^{B_i}w_\sigma(t) = -\sigma$ for t between t_i and t_{i+1} , and both v_σ and w_σ are bounded pointwise by a constant times σ . This construction is complicated by the fact that v_σ and w_σ must satisfy the linear differential equation in (21).

The proof proceeds by induction, interval by interval, from left to right. Suppose that on the interval $[t_0, t_k]$ we can construct a control v_σ and a corresponding state w_σ such that for each σ sufficiently small, we have

$$|w_\sigma(t_k)| \leq c\sigma, \quad S^{B_{k-1}}w_\sigma(t_k) = -\sigma,$$

where c is independent of σ , and with $\alpha = \sigma$, the control $v = v_\sigma$ and the state $w = w_\sigma$ satisfy the relations (21) on the interval $[0, t_k]$. We now show that this construction can be continued on the interval $[t_k, t_{k+1}]$. The control v and the state w on the new interval are chosen to satisfy the relations

$$(27) \quad \begin{aligned} K^{B_k}(t)v(t) &= -\sigma, \quad \text{for } t_k < t \leq t_{k+1}, \\ (S^{B_k}(t)w(t))_i &= (S^{B_k}(t_k)w_\sigma(t_k))_i + \gamma_i(t - t_k) \quad \text{for } t_k < t \leq t_k + \varepsilon, \\ S^{B_k}(t)w(t) &= -\sigma \quad \text{for } t_k + \varepsilon < t \leq t_{k+1}. \end{aligned}$$

The parameters γ_i and ε are selected so that $(S^{B_k}(t_k + \varepsilon)w(t_k + \varepsilon))_i = -\sigma$, or equivalently, so that

$$\gamma_i = -\frac{(S^{B_k}(t_k)w_\sigma(t_k))_i + \sigma}{\varepsilon}.$$

Since $w_\sigma(t_k)$ tends to zero as σ tends to zero, it follows that for any ε , γ_i tends to zero as σ tends to zero.

To obtain a control that satisfies (27), we differentiate the second and third equations in (27) and we substitute from the state equation $\dot{w} = Aw + Bv$ to obtain

$$(28) \quad \begin{aligned} S^{B_k}(t)B(t)v(t) &= \gamma_i - \frac{dS^{B_k}(t)}{dt} w(t) - S^{B_k}(t)A(t)w(t) \quad \text{for } t_k < t \leq t_k + \varepsilon, \\ S^{B_k}(t)B(t)v(t) &= -\frac{dS^{B_k}(t)}{dt} w(t) - S^{B_k}(t)A(t)w(t) \quad \text{for } t_k + \varepsilon < t \leq t_{k+1}. \end{aligned}$$

By the independence condition (26), the minimum norm control $v(t)$ that satisfies the equation $K^{B_k}(t)v(t) = -\sigma$ along with (28), where w is the solution to

$$\dot{w}(t) = A(t)w(t) + B(t)v(t), \quad w(t_k) = w_\sigma(t_k),$$

is bounded pointwise by a constant times σ . If the i th state constraint is binding at both τ_{k-1} and τ_k , then by the construction of w , we have

$$(S(t)w(t))_i = -\sigma \quad \text{for } t_k \leq t \leq t_{k+1},$$

which implies that

$$(S(t)w(t) + S_0(x_0(t), t))_i \leq -\sigma \quad \text{for } t_k \leq t \leq t_{k+1}.$$

If the i th state constraint is nonbinding at either τ_{k-1} or τ_k , then $S_0(x_0(t_k), t_k)_i \leq -\delta$. Hence, for ε sufficiently small, $S_0(x_0(t), t)_i \leq -\delta/2$ for t between t_k and $t_k + \varepsilon$. Taking σ sufficiently small yields

$$(S(t)w(t) + S_0(x_0(t), t))_i \leq -\delta/4 \quad \text{for } t_k \leq t \leq t_k + \varepsilon.$$

Now consider t in the interval $[t_k + \varepsilon, t_{k+1}]$. If the i th constraint is binding at τ_k , then

$$(S(t)w(t) + S_0(x_0(t), t))_i \leq -\sigma.$$

If the i th constraint is nonbinding at τ_k , then

$$(S(t)w(t) + S_0(x_0(t), t))_i \leq |S(t)w(t)| - \delta.$$

Since w is bounded by a constant times σ , the induction step is complete. \square

To conclude, we state a specific sensitivity result for the feasibility problem (19) based on Corollary 3.

THEOREM 2. *If (x_0, u_0) is feasible in (19) when $p = 0$, and there exist $\alpha > 0$, $w \in W^{1,\theta}$, and $v \in L^\infty$ satisfying (21), then for each p in a neighborhood of 0 and for each (x, u) in a neighborhood of $z_0 = (x_0, u_0)$, there exists x_p and u_p that are feasible in (19), and we have*

$$(29) \quad \|x_p - x\|_{W^{1,\theta}} + \|u_p - u\|_{L^\infty} \leq c(\|f_p(x, u) - \dot{x}\|_{L^\theta} + \|K_p(u)_+\|_{L^\infty} + \|S_p(x)_+\|_{L^\infty}),$$

where the “+” subscript stands for the positive part and c is independent of p .

Proof. Relation (29) follows from Corollary 3 and Lemma 2, where we identify the z of Corollary 3 with the pair (x, u) , while w_p is identified with the triple $(0, K_p(u)_-, S_p(x)_-)$. Here the subscript “-” stands for the negative part. \square

Remark 4. Using generalized derivatives of set-valued maps, a result related to Theorem 2 is established in [16, Thm. 10.1] for a problem with final state constraints. A linear system with convex state and control constraints is studied in [14].

We can use the same approach to study local controllability. The following simple example illustrates the basic ideas. Let us consider the nonsmooth control system

$$(30) \quad \dot{x}(t) = |x(t)| + x(t)^5 u(t) + u(t) \quad \text{a.e. } t \in I,$$

with the constraints

$$x(0) = 0, \quad x(t) \geq t - 1 \quad \text{for every } t \in I, \quad -1 \leq u(t) \leq 1 \quad \text{a.e. } t \in I, \quad x \in W^{1,\infty}, \quad u \in L^\infty.$$

A control system is *locally controllable* around 0 at $t = 1$ if for each a near zero that satisfies the state constraints at $t = 1$, there exists a feasible trajectory with $x(1) = a$. We will apply Corollary 1 with the following identifications:

$$\Omega = \{(x, u) \in W^{1,\infty} \times L^\infty : x(0) = 0, x(t) \geq t - 1 \text{ for every } t \in I, -1 \leq u(t) \leq 1 \text{ a.e. } t \in I\},$$

$$T_p(x, u) = \begin{bmatrix} \dot{x} - |x| - x^5 u - u \\ x(1) - p \end{bmatrix}, \quad \text{and} \quad F_p(x, u) = 0.$$

Local controllability is equivalent to existence of a solution to (7) for every $p \geq 0$, p sufficiently small.

In applying Corollary 1, we take $P = R_+$, the nonnegative real numbers, $z_p = z_0 = (x_0, u_0) = 0$, $y_0 = 0$, and

$$L_p(z) = \begin{bmatrix} \dot{x} - |x| - u \\ x(1) \end{bmatrix}.$$

With this definition, the auxiliary problem becomes the following:

$$(31) \quad \text{Find } (x, u) \in \Omega \text{ such that} \\ \dot{x}(t) - |x(t)| - u(t) + y_1(t) = 0, \quad x(1) + y_2 = 0.$$

Hypothesis (9) of Corollary 1 is satisfied if there exists a single-valued map Ψ from $L^\infty \times R$ to $W^{1,\infty} \times L^\infty$, with $\Psi(0) = 0$, with $(x, u) = \Psi(y_1, y_2)$ a solution of (31), and with Ψ Lipschitz continuous on the set $\Delta_\sigma(p)$ of Corollary 1. It can be verified that the following choice for Ψ has the desired properties:

$$\Psi(y) = \begin{bmatrix} \frac{1-e'}{e-1} y_2 \\ \frac{y_2}{1-e} - y_1(t) \end{bmatrix}.$$

(Note that if $(y_1, y_2) \in \Delta_\sigma(p)$, then $y_2 \leq 0$ since $p \geq 0$.) Hence, the control system (30) is locally controllable around 0 at $t = 1$.

4. Quadratic programs. In applying the results of § 2 to problems in optimal control and mathematical programming, we must derive Lipschitz results for the auxiliary problem. This section collects properties of quadratic programs that are relevant to the analysis.

LEMMA 4. *Let X denote a reflexive Banach space, let $\Lambda \subset X$ be a nonempty closed, convex subset, and consider the problem*

$$(32) \quad \text{minimize } \frac{1}{2} \langle Ax, x \rangle + \langle \phi, x \rangle \quad \text{over } x \in \Lambda,$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between X and the dual space X^* , $\phi \in X^*$, $A: X \rightarrow X^*$ is a continuous linear operator, and $\langle Ax, y \rangle = \langle Ay, x \rangle$ for every x and $y \in X$. If there exists a constant $\alpha > 0$ such that

$$(33) \quad \langle A(x_1 - x_2), x_1 - x_2 \rangle \geq \alpha \|x_1 - x_2\|^2 \quad \text{for every } x_1 \text{ and } x_2 \in \Lambda,$$

then there is a unique solution \bar{x} to (32), and \bar{x} is the unique solution to the following variational inequality:

$$(34) \quad \text{Find } \bar{x} \in \Lambda \text{ such that } \langle A\bar{x} + \phi, x - \bar{x} \rangle \geq 0 \quad \text{for every } x \in \Lambda.$$

If x_1 and x_2 denote the solutions of (32) corresponding to $\phi = \phi_1$ and $\phi = \phi_2$, then we have

$$(35) \quad \|x_1 - x_2\| \leq \|\phi_1 - \phi_2\| / \alpha.$$

Proof. In a Hilbert space, the existence of a solution \bar{x} to (32) and the correspondence between a solution to (32) and a solution to (34) is found for example, in [26, Chap. 1]. The Lipschitz result (35) is found in [20, Lemma 1] for a Hilbert space. These Hilbert space proofs are also valid in a reflexive Banach space. \square

The usual second-order sufficient condition for (32) has the form

$$(36) \quad \langle A(x - \bar{x}), x - \bar{x} \rangle \geq \alpha \|x - \bar{x}\|^2 \quad \text{for every } x \in \Lambda,$$

where $\alpha > 0$. Hence, condition (33) is stronger than the second-order sufficient condition. An important difference between (33) and (36) is that after small perturbations in A , (33) still holds for some $\alpha > 0$; after small perturbations in A and \bar{x} , (36) may not hold for any $\alpha > 0$.

Under the hypotheses of Lemma 4, let us consider the constraint set

$$(37) \quad \Lambda = \{x \in X: Bx + \psi \in K\},$$

where $B: X \rightarrow W$ is a continuous, linear operator; W is a Banach space; $\psi \in W$; and $K \subset W$ is a closed, convex cone with vertex at the origin. In this case, (32) takes the form

$$(38) \quad \text{minimize } \frac{1}{2}\langle Ax, x \rangle + \langle \phi, x \rangle \quad \text{subject to } Bx + \psi \in K.$$

Given x_1 and $x_2 \in \Lambda$, observe that $v = x_1 - x_2$ has the property that $Bv \in K - K$. Hence, when Λ is given by (37), (33) holds if

$$(39) \quad \langle Av, v \rangle \geq \alpha \|v\|^2 \quad \text{whenever } Bv \in K - K.$$

Conversely, if B is surjective and (33) holds, then (39) holds. Hence, (39) and (33) are equivalent when B is surjective.

Letting K^+ denote the polar cone defined by

$$K^+ = \{\lambda \in W^*: \langle \lambda, k \rangle \geq 0 \text{ for every } k \in K\},$$

suppose that there exists $\lambda \in K^+$ and $\bar{x} \in X$ satisfying

$$(40) \quad A\bar{x} - B^*\lambda + \phi = 0 \quad \text{and} \quad \langle \lambda, B\bar{x} + \psi \rangle = 0, \quad \text{where } B\bar{x} + \psi \in K.$$

It follows that

$$0 = \langle A\bar{x} + \phi, x - \bar{x} \rangle - \langle \lambda, Bx + \psi \rangle \leq \langle A\bar{x} + \phi, x - \bar{x} \rangle$$

for every $x \in X$ with $Bx + \psi \in K$. By Lemma 4, \bar{x} is the unique solution to (32). Note that the conditions $\langle \lambda, B\bar{x} + \psi \rangle = 0$ and $B\bar{x} + \psi \in K$ of (40) are often written in the compact form

$$B\bar{x} + \psi \in \partial K^+(\lambda),$$

where $\partial K^+(\lambda) = \{w \in W^{**}: \langle w, \mu - \lambda \rangle \geq 0 \text{ for each } \mu \in K^+\}$ is the normal cone at λ to the set K^+ .

If \bar{x} is a solution to (38) and B is surjective, it is known (see Kurcyusz [25]) that there exists a unique Lagrange multiplier $\lambda \in K^+$ satisfying (40). Assuming that B is surjective and (33) holds, let us study the dependence of the solution and the multiplier associated with (38) on the parameters ϕ and ψ . Given $\phi = \phi_i \in X^*$ and $\psi = \psi_i \in W$ for $i = 1$ and 2 , let \bar{x}_i be the corresponding solutions to (38), and let λ_i be the associated multipliers satisfying (40). If $x = \tilde{x}_1$ is any solution to $Bx = -\psi_1$, then by the open mapping principle (see [7, p. 57]), B^{-1} is Lipschitz continuous, and there exists a solution $x = \tilde{x}_2$ to $Bx = -\psi_2$ such that

$$\|\tilde{x}_1 - \tilde{x}_2\| \leq c \|\psi_1 - \psi_2\|,$$

where c is independent of ψ_1 and ψ_2 . Making the change of variables $\bar{x}_i = w_i + \tilde{x}_i$ in (40), we obtain

$$(41) \quad Aw_i - B^*\lambda_i + A\tilde{x}_i + \phi_i = 0, \quad Bw_i \in K, \quad \text{and} \quad \langle \lambda_i, Bw_i \rangle = 0.$$

Hence, $w = w_i$ is the solution to the problem

$$\begin{aligned} &\text{minimize} \quad \frac{1}{2}\langle Aw, w \rangle + \langle A\tilde{x}_i + \phi_i, w \rangle \\ &\text{subject to} \quad Bw \in K. \end{aligned}$$

By Lemma 4, inequality (35), we have

$$\alpha \|w_1 - w_2\| \leq \|\phi_1 - \phi_2\| + \|A\| \|\tilde{x}_1 - \tilde{x}_2\| \leq \|\phi_1 - \phi_2\| + c \|A\| \|\psi_1 - \psi_2\|.$$

Taking the norm of the identity $x_1 - x_2 = w_1 - w_2 + \tilde{x}_1 - \tilde{x}_2$, and applying the triangle inequality, we obtain

$$\|x_1 - x_2\| \leq c \|\phi_1 - \phi_2\| + c \|\psi_1 - \psi_2\|,$$

where c is independent of the ϕ_i and the ψ_i . Moreover, since B^* is one-to-one and $(B^*)^{-1}$ is a continuous linear operator, (40) implies that $\|\lambda_1 - \lambda_2\|$ has a similar bound. These observations are summarized in the following lemma.

LEMMA 5. *Suppose that B is surjective and (33) holds. If x_i and λ_i are the solutions to (40) corresponding to $\phi = \phi_i$ and $\psi = \psi_i$, $i = 1$ and 2 , then there exists a constant c , depending only on A and B , such that*

$$\|x_1 - x_2\| + \|\lambda_1 - \lambda_2\| \leq c \|\phi_1 - \phi_2\| + c \|\psi_1 - \psi_2\|.$$

Clearly, the coercivity condition (33) is preserved after small perturbations in A . In the context of (38) with B surjective, we now show that the coercivity condition (33) is preserved after small perturbations in B , and after arbitrary perturbations in ψ . Since B is surjective, we observed earlier that (33) is equivalent to (39). Since ψ does not appear in (39), coercivity is preserved after any perturbation in ψ . Now let us consider the effect of changes in B . Given a bounded linear operator $\bar{B}: X \rightarrow W$, the open mapping principle implies that there exists a constant c , depending only on B , with the following property: If $\bar{B}\bar{v} \in K - K$, we can find $v \in X$ with $Bv = \bar{B}\bar{v} \in K - K$ and

$$(42) \quad \|v - \bar{v}\| \leq c \|B - \bar{B}\| \|\bar{v}\|.$$

By the triangle inequality, we have

$$(43) \quad (1 - c \|B - \bar{B}\|) \|\bar{v}\| \leq \|v\| \leq (1 + c \|B - \bar{B}\|) \|\bar{v}\|.$$

Defining $\delta v = v - \bar{v}$ and applying (33) yields

$$(44) \quad \langle A\bar{v}, \bar{v} \rangle \geq \alpha \|v\|^2 - 2\langle Av, \delta v \rangle + \langle A\delta v, \delta v \rangle.$$

Utilizing the inequality $2ab \leq \rho a^2 + b^2/\rho$, where ρ is an arbitrary scalar, we have

$$|\langle Av, \delta v \rangle| \leq \|A\| \|v\| \|\delta v\| \leq \frac{\alpha}{4} \|v\|^2 + \frac{\|A\|^2}{\alpha} \|\delta v\|^2.$$

This inequality, coupled with relations (42)–(44), yields the following result.

LEMMA 6. *If the coercivity condition (39) holds and B is surjective, then for \bar{A} in a neighborhood of A and for \bar{B} in a neighborhood of B , there exists $\alpha > 0$ such that*

$$\langle \bar{A}v, v \rangle \geq \alpha \|v\|^2 \text{ whenever } \bar{B}v \in K - K.$$

We observe that in certain cases, the coercivity condition (33) holds for the set Λ if it holds on a subset $\Lambda \cap \Gamma$.

LEMMA 7. *Let Γ and Λ be convex subsets of X , and suppose that there exists $\alpha > 0$ such that*

$$(45) \quad \langle A(x_1 - x_2), x_1 - x_2 \rangle \geq \alpha \|x_1 - x_2\|^2 \text{ for every } x_1 \text{ and } x_2 \in \Lambda \cap \Gamma.$$

If $\text{int } \Gamma$, the interior of Γ , intersects Λ , then (33) holds.

Proof. Given $v_i \in \Lambda$, $i = 1$ and 2 , and $v \in \text{int } \Gamma \cap \Lambda$, define $v_i(\beta)$ by

$$v_i(\beta) = \beta v_i + (1 - \beta)v.$$

Since Λ is convex, $v_i(\beta) \in \Lambda$ for $i = 1$ and 2 , whenever $\beta \in [0, 1]$. Since $v_i(\beta) \rightarrow v$ as $\beta \rightarrow 0$, we can choose $\beta > 0$ small enough that $v_i(\beta) \in \Gamma$ for $i = 1$ and 2 . Applying (45) with $x_i = v_i(\beta)$, we obtain (33). \square

Remark 5. Suppose that $B = (B_1, B_2)$, $\psi = (\psi_1, \psi_2)$, and $K = K_1 \times K_2$, where B_1 is surjective, and where there exists $v \in X$ with $B_1 v + \psi_1 \in K_1$ and $B_2 v + \psi_2 \in \text{int } K_2$. Combining Lemmas 6 and 7, we see that if the coercivity condition (33) holds, then for \bar{A} and \bar{B}_1 near A and B_1 respectively, there exists $\alpha > 0$ such that

$$\langle \bar{A}v, v \rangle \geq \alpha \|v\|^2 \quad \text{whenever } \bar{B}_1 v \in K_1 - K_1.$$

5. Optimal solutions. In this section, we use Corollaries 1 and 2 to study an optimal solution of the problem

$$(46) \quad \text{minimize } C_p(x) \quad \text{over } x \in \Omega_p,$$

where p is a parameter in a metric space P , Ω_p is a closed, convex nonempty subset of a reflexive Banach space X , and $C_p: X \rightarrow \mathbb{R}$. Given a local minimizer x_0 of (46) corresponding to $p = 0$, we assume that for each $p \in P$, the functional $C_p(x)$ is twice Fréchet differentiable with respect to x in a neighborhood of x_0 , the derivatives $C'_p(x)$ and $C''_p(x)$ with respect to x are continuous in p and x in a neighborhood of $p = 0$ and $x = x_0$, and there exists $\alpha > 0$ such that

$$(47) \quad \langle C''_0(x_0)(x_1 - x_2), x_1 - x_2 \rangle \geq \alpha \|x_1 - x_2\|^2 \quad \text{for every } x_1, x_2 \in \bigcup_{p \in P} \Omega_p.$$

In addition, we assume that $\lim_{p \rightarrow 0} |\Omega_p - \Omega_0| = 0$, where $|A - B| = \|A - B\| + \|B - A\|$ is equivalent to the Hausdorff distance between the sets A and B .

THEOREM 3. For each $\beta > 1/\alpha$ and $\gamma > \|C'_0(x_0)\|$, there exists $s > 0$ with the following property: For each $p \in B_s(0)$, we can find a strict local minimizer x_p of (46) such that

$$(48) \quad \|x_p - x_0\| \leq \beta \|C'_p(x_0) - C'_0(x_0)\| + \sqrt{\gamma/\alpha} |\Omega_p - \Omega_0|^{1/2}.$$

If $C'_0(x_0) = 0$, then we require $\gamma > \|C''_0(x_0)\|$, and we replace the exponent $\frac{1}{2}$ in (48) by 1.

Proof. Since x_0 is a local minimizer of (46) and Ω_0 is convex, we have

$$(49) \quad \langle C'_0(x_0), x - x_0 \rangle \geq 0 \quad \text{for every } x \in \Omega_0.$$

Given $p \in P$, (47) and Lemma 4 imply that there exists a unique $\xi_p \in \Omega_p$ satisfying the relation

$$(50) \quad \langle C'_0(x_0) + L(\xi_p - x_0), x - \xi_p \rangle \geq 0 \quad \text{for every } x \in \Omega_p,$$

where $L = C''_0(x_0)$. Adding (49) with $x = z_0$ and (50) with $x = z_p$ to inequality (47) with $x_1 = \xi_p$ and $x_2 = x_0$, we get

$$\alpha \|\xi_p - x_0\|^2 \leq \langle L(\xi_p - x_0), z_p - x_0 \rangle + \langle C'_0(x_0), z_0 - \xi_p + z_p - x_0 \rangle$$

for every $z_0 \in \Omega_0$ and $z_p \in \Omega_p$. From this, it follows that

$$\alpha \|\xi_p - x_0\|^2 \leq \|L\| \|\xi_p - x_0\| \|x_0 - \Omega_p\| + \|C'_0(x_0)\| (\|x_0 - \Omega_p\| + \|\xi_p - \Omega_0\|).$$

Consequently, $\xi_p \rightarrow x_0$ as $p \rightarrow 0$, and we have

$$(51) \quad \alpha \|\xi_p - x_0\|^2 \leq (\|L\| \|\xi_p - x_0\| + \|C'_0(x_0)\|) |\Omega_p - \Omega_0|.$$

Now let us consider the following problem:

$$(52) \quad \text{Find } x_p \in \Omega_p \text{ such that } \langle C'_p(x_p), x - x_p \rangle \geq 0 \quad \text{for every } x \in \Omega_p.$$

We apply Corollary 1 to this problem, making the following identifications:

$$z = x, \quad T_p = C'_p, \quad y_p = C'_0(x_0) - L(x_0), \quad \text{and} \quad F_p(x) = \partial\Omega_p(x).$$

The auxiliary problem is the following:

$$(53) \quad \text{Find } x \in \Omega_p \text{ such that } \langle L(x) + y, w - x \rangle \geq 0 \quad \text{for every } w \in \Omega_p.$$

By Lemma 4, there exists a unique solution of (53) for each $y \in X^*$, and this solution is a Lipschitz continuous function of y with Lipschitz constant $1/\alpha$, independent of p . By Corollary 1 and for any constant $\beta > 1/\alpha$, there exists a solution x_p to (52) for p near zero, and we have

$$(54) \quad \|x_p - \xi_p\| \leq \beta \|C'_p(\xi_p) - L(\xi_p) - y_p\|.$$

By the definition of y_p , it follows that

$$\|C'_p(\xi_p) - L(\xi_p) - y_p\| = \|C'_p(\xi_p) - C'_0(x_0) - L(\xi_p - x_0)\|.$$

By the continuous differentiability assumptions, it follows that for any $\varepsilon > 0$, there exists an $s > 0$ such that

$$\|C'_0(\xi_p) - C'_0(x_0) - L(\xi_p - x_0)\| \leq \varepsilon \|\xi_p - x_0\| \quad \text{for every } p \in B_s(0)$$

and

$$\|C'_p(\xi_p) - C'_0(\xi_p)\| \leq \|C'_p(x_0) - C'_0(x_0)\| + \varepsilon \|\xi_p - x_0\| \quad \text{for every } p \in B_s(0).$$

These inequalities, combined with (51), (54), and the triangle inequality, yield (48).

By (47), x_p is a strict local minimizer of (46) for p near 0. \square

Remark 6. In general, the exponent $\frac{1}{2}$ in (48) is sharp (see [13, p. 13]). Theorem 3 is a generalization of Proposition 1.2 in [13].

Typically, Theorem 3 yields a Hölder-type estimate for $x_p - x_0$. However, when the constraint set is described by equalities and inequalities that possess certain regularity properties, a Lipschitz estimate can be established. We consider the following problem:

$$(55) \quad \text{minimize } C_p(x) \quad \text{subject to } G_p(x) \in K,$$

where $G_p: X \rightarrow W$, W is a Banach space, and $K \subset W$ is a closed, convex cone with vertex at the origin. Letting x_0 denote a local minimizer of (55) corresponding to $p = 0$, we assume henceforth in this section that C_p and G_p possess the following smoothness properties: $C_p(x)$ and $G_p(x)$ are twice Fréchet differentiable in x in a neighborhood of $p = 0$ and $x = x_0$, and these derivatives are continuous in p and x at $p = 0$ and $x = x_0$. The functions $G_p(x)$, $C'_p(x)$, and $G'_p(x)$ are Lipschitz in $p \in P$, uniformly in x near x_0 . Let H_p denote the Lagrangian defined by

$$H_p(x, \lambda) = C_p(x) - \langle \lambda, G_p(x) \rangle,$$

where $\lambda \in W^*$. The first-order necessary conditions associated with a solution to (55) can be expressed in the following way:

$$(56) \quad \nabla_x H_p(x_p, \lambda_p) = 0 \quad \text{and} \quad G_p(x_p) \in \partial K^+(\lambda_p), \quad \text{where } x_p \in X \quad \text{and} \quad \lambda_p \in K^+.$$

It is well known (see [25]) that if $G'_0(x_0)$ is surjective, then there exists λ_0 satisfying (56) for $p = 0$. Our Lipschitz result is based on the following coercivity condition: There exists $\alpha > 0$ such that

$$(57) \quad \begin{aligned} & \langle \nabla_{xx}^2 H_0(x_0, \lambda_0)(x_2 - x_1), x_2 - x_1 \rangle \geq \alpha \|x_2 - x_1\|^2 \\ & \text{whenever } G_0(x_0) + G'_0(x_0)(x_i - x_0) \in K, \quad \text{for } i = 1, 2. \end{aligned}$$

THEOREM 4. *If $G'_0(x_0)$ is surjective and the coercivity condition (57) holds, then there exists $s > 0$ such that (55) has a strict local minimizer x_p for each $p \in B_s(0)$, and both x_p , and the associated (unique) multiplier $\lambda_p \in K^+$ satisfying the first-order necessary condition (56), are Lipschitz continuous functions of $p \in B_s(0)$.*

Proof. We apply Corollary 2 with the following identifications: $z = (x, \lambda)$, $Z = X \times X^*$, $\Omega = X \times K^+$,

$$T_p(x, \lambda) = \begin{bmatrix} \nabla_x H_p(x, \lambda) \\ G_p(x) \end{bmatrix}, \quad \text{and} \quad F(x, \lambda) = \begin{bmatrix} 0 \\ \partial K^+(\lambda) \end{bmatrix}.$$

Hence, the problem "Find $z \in \Omega$ such that $T_p(z) \in F(z)$ " is the same as finding x and λ satisfying the first-order necessary condition for (55). In the auxiliary problem, we take $L = T'_0(z_0)$. Hence, the auxiliary problem is equivalent to the following: Given $\phi \in X^*$ and $\psi \in W$, find $x \in X$ and $\lambda \in K^+$ such that

$$(58) \quad \begin{aligned} Ax - B^*\lambda + \phi &= 0 \quad \text{and} \quad Bx + \psi \in \partial K^+(\lambda), \\ \text{where } A &= \nabla_{xx}^2 H_0(x_0, \lambda_0) \quad \text{and} \quad B = G'_0(x_0). \end{aligned}$$

By Lemma 5, the solution to (58) is a Lipschitz continuous function of ϕ and ψ . By Corollary 2, there exists a solution $z_p = (x_p, \lambda_p)$ to (56), which is a Lipschitz continuous function of p for p near 0. By Lemma 6, the coercivity condition (57) holds when the zeros are replaced by p near 0. Hence, the second-order sufficiency condition holds (see Maurer and Zowe [30]), and x_p is a strict local minimizer of (55) for p near 0. \square

Theorem 4 yields Lipschitz continuity without assuming strict complementary slackness. For an illustration, suppose that $G_p = (g_p, h_p)$ and $K = K_g \times K_h$, where K_g and K_h are closed convex cones with vertices at the origin of the associated Banach spaces. In this cases, the optimization problem (55) takes the form

$$(59) \quad \begin{aligned} &\text{minimize} \quad C_p(x) \\ &\text{subject to} \quad g_p(x) \in K_g, \quad h_p(x) \in K_h. \end{aligned}$$

The Lagrangian H_p is given by

$$H_p(x, \mu, \nu) = C_p(x) - \langle \mu, g_p(x) \rangle - \langle \nu, h_p(x) \rangle,$$

where $\lambda = (\mu, \nu)$ is the multiplier in the dual space. Again, if x_0 is a local minimizer of (59) and $G'_0(x_0)$ is surjective, then there exists a multiplier $\lambda_0 = (\mu_0, \nu_0)$ satisfying (56) for $p = 0$. Let us assume that $h_0(x_0) = 0$ and $\nu_0 \in \text{int } K_h^+$. In finite dimensions, h_p corresponds to the part of the inequality constraints that are active at $p = 0$ with associated multipliers that are strictly positive. We make the following coercivity assumption:

$$(60) \quad \begin{aligned} &\langle \nabla_{xx}^2 H_0(x_0, \mu_0, \nu_0)(x_2 - x_1), x_2 - x_1 \rangle \geq \alpha \|x_2 - x_1\|^2 \\ &\text{whenever } g_0(x_0) + g'_0(x_0)(x_i - x_0) \in K_g, \quad h'_0(x_0)(x_i - x_0) = 0, \quad \text{for } i = 1, 2. \end{aligned}$$

By Theorem 4, the following optimization problem has a local minimizer for p near 0 that depends Lipschitz continuously on p :

$$(61) \quad \begin{aligned} &\text{minimize} \quad C_p(x) \\ &\text{subject to} \quad g_p(x) \in K_g, \quad h_p(x) = 0. \end{aligned}$$

Observe that this problem differs from (59) since the constraint $h_p(x) \in K_h$ associated with (59) has been replaced by $h_p(x) = 0$. Exploiting the assumption that v_0 lies in the interior of K_h^+ , we show that this local minimizer for (61) is also a local minimizer of (59).

COROLLARY 4. *If $(g'_0(x_0), h'_0(x_0))$ is surjective, the coercivity condition (60) holds, and v_0 lies in the interior of K_h^+ , then there exists $s > 0$ such that (59) has a strict local minimizer x_p for each $p \in B_s(0)$, and both x_p , and the associated multipliers $\mu_p \in K_g^+$ and $\nu_p \in K_h^+$ satisfying the first-order necessary condition, are Lipschitz continuous functions of $p \in B_s(0)$.*

Proof. We apply the proof given for Theorem 4 to problem (61) replacing K by $K_g \times \{0\}$ and replacing the coercivity condition (57) by (60). It follows that there exists a solution x_p of (61) and associated Lagrange multipliers μ_p and ν_p that are Lipschitz continuous functions of p near 0 and that satisfy the first-order necessary conditions for (61). Since $\nu_p \in \text{int } K_h^+$ for p near zero, the first-order necessary conditions for (59) hold. By Lemma 8 of Appendix 1, x_p is a strict local minimizer of (61). \square

Finally, let us suppose that $G_p = (f_p, g_p, h_p)$ and $K = K_f \times K_g \times K_h$, where K_f , K_g , and K_h are closed convex cones with vertices at the origin of the associated Banach spaces. Hence, the optimization problem (55) takes the form

$$(62) \quad \begin{array}{ll} \text{minimize} & C_p(x) \\ \text{subject to} & f_p(x) \in K_f, \quad g_p(x) \in K_g, \quad h_p(x) \in K_h. \end{array}$$

If $f_0(x_0) \in \text{int } K_f$, then under the hypotheses of Corollary 4, the solution x_p of (59) is a Lipschitz continuous function of p and $f_p(x_p) \in K_f$ for p near 0. Hence, the local minimizer x_p of (59) is a local minimizer of (62).

Remark 7. Theorem 4 and Corollary 4 yield Lipschitz continuity of a local minimizer in a neighborhood of a reference point, without assuming strict complementary slackness. In finite dimensions, this problem was studied by Hager in [18] and by Robinson in [37]. Note that the coercivity assumption (60) is slightly weaker, in the infinite-dimensional context, than the coercivity assumption used in earlier work (see [18], [23], [37]) since (60) only requires coercivity relative to those x_i satisfying the constraint $g_0(x_0) + g'_0(x_0)(x_i - x_0) \in K_g$.

In comparing Corollary 4 to the recent paper [23] of Ito and Kunisch, note that in [23] the infinite-dimensional constraints are linear inequalities, the problem is formulated in a Hilbert space, and the nonlinear constraints for which the associated dual multiplier can vanish are finite-dimensional. Alt presents in [1] and [3] a stability analysis that is related to ours, but different. In [1] he considers a cone constrained problem, under the assumption that any neighborhood of the reference point contains a solution of the perturbed problem. In [3] he studies Lipschitz continuity of the solution of a problem with nonlinear cone constraints and with equality constraints under a weaker constraint qualification (Robinson's constraint regularity condition), but a stronger coercivity—(60) is required to hold on the kernel of the gradients of the equality constraints; moreover, he assumes that the variation of the Lagrange multipliers for the perturbed problem can be estimated in terms of the variation in the solution and the variation in the parameter (under our surjectivity condition, this hypothesis is satisfied). Recently, Malanowski [28] has obtained a Lipschitz continuity result in a Hilbert space setting that parallels the analysis of Ito and Kunisch [23], using a regularity condition for the constraints that is weaker than surjectivity.

6. Optimal control. Let us consider a nonlinear optimal control problem with control constraints

$$(63) \quad \begin{aligned} & \text{minimize} \quad \int_I g_p(x(t), u(t)) dt \\ & \text{subject to} \quad \dot{x}(t) = f_p(x(t), u(t)) \quad \text{and} \quad u(t) \in U \quad \text{a.e. } t \in I, \\ & \quad \quad \quad x(0) = a, \quad x \in W^{1,\theta}, \quad u \in L^\infty, \end{aligned}$$

where $f_p: R^{n+m} \rightarrow R^n$, $g_p: R^{n+m} \rightarrow R$, $U \subset R^m$ is nonempty, closed, and convex, a is the given starting condition, and $\theta \in [1, \infty]$. We assume that there exists a solution (x_0, u_0) to (63) corresponding to $p = 0$, and we wish to show that there exists a nearby solution for p in a neighborhood of zero. To this end, suppose that there exists a closed set $\Delta \subset R^n \times R^m$ and a $\delta > 0$ such that $(x_0(t), u_0(t))$ lies in Δ for almost every $t \in I$, the distance from $(x_0(t), u_0(t))$ to the boundary of Δ is at least δ for almost every $t \in I$, and the first two derivatives of $f_p(x, u)$ and $g_p(x, u)$ with respect to x and u exist on Δ , and these derivatives, along with the function value $f_p(x, u)$, are continuous with respect to $(x, u) \in \Delta$ and p near zero.

Let H_p denote the Hamiltonian defined by

$$H_p(x, u, \lambda) = g_p(x, u) + \lambda^T f_p(x, u).$$

If (x_p, u_p) is a solution of (63), then the minimum principle [22, p. 134] implies the following:

$$\nabla_u H_p(x_p(t), u_p(t), \lambda_p(t))^T (v - u_p(t)) \geq 0 \quad \text{a.e. } t \in I \text{ and for every } v \in U,$$

where $\lambda = \lambda_p$ is the solution of the adjoint equation

$$\dot{\lambda}(t) = -\nabla_x H_p(x(t), u(t), \lambda(t)) \quad \text{a.e. } t \in I, \quad \lambda(1) = 0,$$

associated with $x = x_p$ and $u = u_p$. Let $f_0^*(t)$ and $H_0^*(t)$ stand for $f_0(x_0(t), u_0(t))$ and $H_0(x_0(t), u_0(t), \lambda_0(t))$, and define the matrices

$$\begin{aligned} A(t) &= \nabla_x f_0^*(t), \quad B(t) = \nabla_u f_0^*(t), \quad Q(t) = \nabla_{xx}^2 H_0^*(t), \\ R(t) &= \nabla_{uu}^2 H_0^*(t), \quad S(t) = \nabla_{xu}^2 H_0^*(t). \end{aligned}$$

The following coercivity assumption will be utilized: There exists $\alpha > 0$ such that

$$(64) \quad \int_I (x(t)^T Q(t)x(t) + u(t)^T R(t)u(t) + 2x(t)^T S(t)u(t)) dt \geq \alpha \int_I |u(t)|^2 dt$$

whenever $x \in W^{1,2}$, $x(0) = 0$, $u \in L^2$, $\dot{x} = Ax + Bu$, $u = v - w$ for some v and $w \in L^2$ with $v(t)$ and $w(t) \in U$ for almost every $t \in I$. By taking $v = w$ except on a small interval, it can be shown, below, that a pointwise coercivity condition holds (see the recent paper [15]):

$$(65) \quad u^T R(t)u \geq \alpha |u|^2 \quad \text{a.e. } t \in I \text{ whenever } u = v - w \text{ with } v \text{ and } w \in U.$$

THEOREM 5. *If the coercivity condition (64) holds, then there exists positive constants κ , r , and s such that for each $p \in B_s(0)$, (63) has a strict local minimizer $(x_p, u_p) \in B_r(x_0, u_0)$ and the relation*

$$\begin{aligned} & \|x_p - x_q\|_{W^{1,\theta}} + \|u_p - u_q\|_{L^\infty} + \|\lambda_p - \lambda_q\|_{W^{1,\theta}} \\ & \leq \kappa (\|f_q(x_p, u_p) - f_p(x_p, u_p)\|_{L^\theta} \\ & \quad + \|\nabla_u H_q(x_p, u_p, \lambda_p) - \nabla_u H_p(x_p, u_p, \lambda_p)\|_{L^\infty} \\ & \quad + \|\nabla_x H_q(x_p, u_p, \lambda_p) - \nabla_x H_p(x_p, u_p, \lambda_p)\|_{L^\theta}) \end{aligned}$$

holds whenever p and $q \in B_s(0)$.

Proof. We apply Corollary 2 where the z of Corollary 2 is identified with (x, u, λ) , while Ω , T_p , and F are defined in the following way:

$$\Omega = \{(x, u, \lambda): x \in W^{1,\theta}, u \in L^\infty, \lambda \in W^{1,\theta}, x(0) = a, \\ \lambda(1) = 0, u(t) \in U \text{ a.e. } t \in I\},$$

$$T_p(x, u, \lambda) = \begin{bmatrix} \nabla_x H_p(x, u, \lambda) + \dot{\lambda} \\ \nabla_u H_p(x, u, \lambda) \\ f_p(x, u) - \dot{x} \end{bmatrix}, \quad \text{and} \quad F(x, u, \lambda) = \begin{bmatrix} 0 \\ \partial U(u) \\ 0 \end{bmatrix}.$$

The space Y containing the range of T_p is $L^\theta \times L^\infty \times L^\theta$. We make the following choice for the operator L of Corollary 2: $L(z) = M(z - z_0)$, where

$$M(x, u, \lambda) = \begin{bmatrix} A^T \lambda + Qx + Su + \dot{\lambda} \\ Ru + S^T x + B^T \lambda \\ Ax + Bu - \dot{x} \end{bmatrix}.$$

It can be verified that under the smoothness assumptions, $E_r(p) \rightarrow 0$ as p and r tend to zero, where $E_r(p)$ is defined in (12).

Given q_i and s_i in L^θ and r_i in L^∞ for $i = 1$ and 2 , let us consider the following problem:

$$(66) \quad \text{Find } (x, u, \lambda) \in \Omega \text{ such that } L(x, u, \lambda) + \begin{bmatrix} q_i \\ r_i \\ s_i \end{bmatrix} \in F(x, u, \lambda).$$

In [20, Lemma 3], we show that when the coercivity assumptions (64) and (65) hold, (66) has a unique solution (x_i, u_i, λ_i) , and the following Lipschitz property holds:

$$\|x_2 - x_1\|_{W^{1,\theta}} + \|u_2 - u_1\|_{L^\infty} + \|\lambda_2 - \lambda_1\|_{W^{1,\theta}} \\ \leq \gamma[\|q_2 - q_1\|_{L^\theta} + \|r_2 - r_1\|_{L^\infty} + \|s_2 - s_1\|_{L^\theta}].$$

Hence, Ψ is Lipschitz, and by Corollary 2, problem (11) has a locally unique solution that satisfies the conclusion of Theorem 5. Since the estimate of Theorem 5 yields an L^∞ perturbation in both state and the control, and since the coercivity assumption (64) is preserved after small perturbations in Q , R , S , A , and B , it follows from Corollary 5 in Appendix 1 that the solution of (11) provided by Corollary 2 is a strict local minimizer for the optimal control problem (63) when p is near zero. \square

We show by an example that Lipschitz continuity can be obtained without the coercivity condition (64). Consider the following problem:

$$(67) \quad \begin{aligned} &\text{minimize} \quad x_1(1) + x_2(1) \\ &\text{subject to} \quad \dot{x}_1 = px_1 \sin x_2 + u_1, \quad \dot{x}_2 = u_2, \quad x_1(0) = 1, \quad x_2(0) = 1, \\ &\quad \quad \quad u_1^2 + u_2^2 \leq 2, \end{aligned}$$

where p is a real parameter. For $p = 0$, the optimal solution is $u_0 = (-1, -1)$ and $x_0 = (1 - t, 1 - t)$, and the corresponding adjoint variable is $\lambda_0 = (-1, -1)$. The auxiliary problem has the form

$$\begin{aligned} \dot{x}_i &= u_i + s_i, \quad x_i(0) = 1, \quad \dot{\lambda}_i = q_i, \quad \lambda_i(1) = -1, \quad \text{for } i = 1, 2, \\ (\lambda + r)^T(v - u) &\geq 0 \quad \text{whenever } v_1^2 + v_2^2 \leq 2. \end{aligned}$$

The control solving the auxiliary problem is

$$u = \sqrt{2} w/|w|, \quad \text{where } w_i(t) = r_i(t) - 1 + \int_1^t q(s) ds.$$

Hence, the solution of the auxiliary problem is unique and Lipschitz continuous, with respect to $y = (s, r, q)$ around 0, as a function from L^∞ to $W^{1,\infty} \times L^\infty$. By Corollary 2 and for p near zero, there exists a solution (x_p, u_p, λ_p) of the first-order necessary conditions associated with (67), which is unique in a neighborhood of (x_0, u_0, λ_0) and which is a Lipschitz continuous function of p near 0. Using the uniqueness of (x_0, u_0) , it can be shown that (x_p, u_p) is the unique solution of (67). In this example, we use the strong convexity of the constraining set instead of the coercivity condition to ensure Lipschitz continuity.

Remark 8. Lipschitz results for problems with convex cost, linear dynamics, and linear inequality state and control constraints are obtained by Dontchev [13, Chap. 2] using duality theory and the regularity of the optimal control established by Hager [18]. Later, Malanowski [27] studied a problem with a quadratic cost functional, linear inequality state and control constraints, and system dynamics that are linear with respect to the control. A similar problem without state constraints, but with convex control constraints, is considered by Alt in [3] using Robinson's strong regularity condition. In [2] Alt considered a nonlinear problem with inequality control constraints. He obtains an estimate for the optimal control, assuming existence of a solution to the perturbed problem in a neighborhood of the reference point (see Remark 7).

7. Euler's method. Again, let us consider a nonlinear control problem with control constraints, below:

$$(68) \quad \begin{aligned} & \text{minimize} \quad \int_I g(x(t), u(t)) \, dt \\ & \text{subject to} \quad \dot{x}(t) = f(x(t), u(t)) \quad \text{and} \quad u(t) \in U \quad \text{a.e. } t \in I, \\ & \quad \quad \quad x(0) = a, \quad x \in W^{1,\infty}, \quad u \in L^\infty, \end{aligned}$$

where $f: R^{n+m} \rightarrow R^n$, $g: R^{n+m} \rightarrow R$, $U \subset R^m$ is nonempty, closed, and convex, and a is the given starting condition. We assume that there exists a solution (x^*, u^*) to (68) with u^* Riemann integrable, that there exists a closed set $\Delta \subset R^{n+m}$ where both f and g are twice continuously differentiable, and that there exists $\delta > 0$ such that $(x^*(t), u^*(t)) \in \Delta$ and the distance from $(x^*(t), u^*(t))$ to the boundary of Δ is at least δ for every $t \in I$. When we write \dot{x}^* , we mean a function whose values on I coincide with those of $f(x^*, u^*)$.

Let H denote the Hamiltonian defined by

$$H(x, u, \lambda) = g(x, u) + \lambda^T f(x, u),$$

and let $\lambda = \lambda^*$ be the solution of the adjoint equation

$$(69) \quad \dot{\lambda}(t) = -\nabla_x H(x(t), u(t), \lambda(t)) \quad \text{a.e. } t \in I, \lambda(1) = 0,$$

associated with $x = x^*$ and $u = u^*$. By the minimum principle [22, p. 134], we have

$$(70) \quad \nabla_u H(x^*(t), u^*(t), \lambda^*(t))^T (v - u^*(t)) \geq 0 \quad \text{a.e. } t \in I \text{ and for every } v \in U.$$

Given a natural number N , let $h = 1/N$ be the mesh spacing, and let x_i and u_i denote approximations to $x(t)$ and $u(t)$ at $t = t_i = ih$. We consider the Euler discretization of (68) given by

$$(71) \quad \begin{aligned} & \text{minimize} \quad \sum_{i=0}^{N-1} hg(x_i, u_i) \\ & \text{subject to} \quad x_{i+1} = x_i + hf(x_i, u_i) \quad \text{and} \\ & \quad \quad \quad u_i \in U, i = 0, 1, \dots, N-1, x_0 = a. \end{aligned}$$

If (x^h, u^h) denotes a solution to (71), let $\lambda = \lambda^h$ denote the solution of the discrete adjoint equation

$$(72) \quad \lambda_i = \lambda_{i+1} + h \nabla_x H(x_i, u_i, \lambda_{i+1}), \quad i = N-1, N-2, \dots, 0, \lambda_N = 0,$$

associated with $x = x^h$ and $u = u^h$. By the discrete minimum principle [22, p. 280], we have

$$(73) \quad \nabla_u H(x_i^h, u_i^h, \lambda_{i+1}^h)^T (v - u_i^h) \geq 0 \quad \text{for all } v \in U, \quad i = 0, 1, \dots, N-1.$$

To estimate the distance between (x^*, u^*) and (x^h, u^h) , we need a coercivity-type assumption for the discrete problem. Define the following matrices:

$$A(t) = \nabla_{xx} f^*(t), \quad B(t) = \nabla_{xu} f^*(t), \quad Q(t) = \nabla_{xx}^2 H^*(t),$$

$$R(t) = \nabla_{uu}^2 H^*(t), \quad S(t) = \nabla_{xu}^2 H^*(t).$$

Here $f^*(t)$ and $H^*(t)$ stand for $f(x^*(t), u^*(t))$ and $H(x^*(t), u^*(t), \lambda^*(t))$, respectively. Letting A_i, B_i, Q_i, S_i , and R_i denote the corresponding time-varying matrices evaluated at $t = t_i$, we assume that there exists a scalar $\alpha > 0$, α independent of N , such that

$$(74) \quad u^T R_i u \geq \alpha |u|^2, \quad 0 \leq i \leq N-1 \quad \text{whenever } u = v - w \text{ with } v \text{ and } w \in U,$$

$$(75) \quad \sum_{i=0}^{N-1} x_i^T Q_i x_i + u_i^T R_i u_i + 2x_i^T S_i u_i \geq \alpha \sum_{i=0}^{N-1} |u_i|^2$$

whenever $u_i = v_i - w_i$ for some v_i and $w_i \in U$, and

$$(76) \quad x_{i+1} = x_i + h A_i x_i + h B_i u_i, \quad i = 0, 1, \dots, N-1, \quad x_0 = 0.$$

Obviously, the discrete condition (74) holds if there exists $\alpha > 0$ such that

$$u^T R(t) u \geq \alpha |u|^2 \quad \text{for every } t \in I \text{ and for each } u = v - w \text{ with } v \text{ and } w \in U.$$

In Appendix 2, we show that assumption (75) for the discrete problem can be deduced from an analogous assumption for the continuous problem. In analyzing the discrete problem (71), we utilize a discrete L^p norm defined by

$$(\|u\|_{L^p})^p = \sum_{i=0}^{N-1} h |u_i|^p, \quad 1 \leq p < \infty, \quad \text{and} \quad \|u\|_{L^\infty} = \max_{0 \leq i < N} |u_i|.$$

If ϕ and v satisfy the finite difference system

$$\phi_{i+1} = \phi_i + h A_i \phi_i + h v_i, \quad i = 0, 1, \dots, N-1, \quad \phi_0 = 0,$$

then there exists a constant c , independent of h , such that

$$(77) \quad |\phi_j| \leq c \|v\|_{L^1} \leq c \|v\|_{L^2} \quad \text{for each } j = 0, 1, \dots, N.$$

Squaring this inequality, multiplying by h , and summing over j yields

$$\|\phi\|_{L^2}^2 \leq c \|v\|_{L^2}^2.$$

Hence, if the coercivity condition (75) holds relative to the control, then the following joint state-control coercivity condition holds: There exists $\alpha > 0$ such that

$$h \sum_{i=0}^{N-1} x_i^T Q_i x_i + u_i^T R_i u_i + 2x_i^T S_i u_i \geq \alpha (\|x\|_{L^2}^2 + \|u\|_{L^2}^2)$$

whenever $u_i = v_i - w_i$ for some v_i and $w_i \in U$, and

$$x_{i+1} = x_i + h A_i x_i + h B_i u_i, \quad i = 0, 1, \dots, N-1, \quad x_0 = 0.$$

Our convergence result for the discrete problem is expressed in terms of a modulus of smoothness introduced by Sendov and Popov [42]. The local modulus of continuity $\omega(u; t, h)$ of the function u is defined by

$$\omega(u; t, h) = \sup \{|u(a) - u(b)| : a, b \in [t - h/2, t + h/2] \cap I\},$$

while the average modulus of smoothness τ is given by

$$\tau(u; h) = \int_I \omega(u; t, h) dt.$$

In [42, pp. 8–11] it is shown that $\tau(u; h) \rightarrow 0$ as $h \rightarrow 0$ if and only if the bounded function u is Riemann integrable on I ; moreover, $\tau(u; h) = O(h)$ if and only if u has bounded variation on I . The main result in this section is the following theorem.

THEOREM 6. *If u^* is Riemann integrable and the coercivity assumptions (74) and (75) hold, then for all N sufficiently large, there exists a local minimizer (x^h, u^h) of (71) such that*

$$\max_{0 \leq i \leq N-1} |u^*(t_i) - u_i^h| = O(h + \tau(u^*; h)),$$

$$\max_{0 \leq i \leq N} |x^*(t_i) - x_i^h| = O(h + \tau(u^*; h)),$$

$$\max_{0 \leq i \leq N} |\lambda^*(t_i) - \lambda_i^h| = O(h + \tau(u^*; h)),$$

$$\max_{0 \leq i \leq N-1} \left| \dot{x}^*(t_i) - \frac{x_{i+1}^h - x_i^h}{h} \right| = O(h + \tau(u^*; h)).$$

Hence, if u^* has bounded variation, then each of these error estimates is of order h .

Proof. We apply Corollary 1 to the necessary conditions associated with the discrete problem (71). The parameter p of Corollary 1 is identified with the mesh spacing h the set Ω_p consists of discrete triples (x, u, λ) , where $u_i \in U$ for each i . Component i , $0 \leq i \leq N-1$, of the operators T_p and F_p , denoted T_i^h and F_i^h , respectively, is the following:

$$T_i^h(x, u, \lambda) = \begin{bmatrix} \nabla_x H(x_i, u_i, \lambda_{i+1}) + (\lambda_{i+1} - \lambda_i)/h \\ \nabla_u H(x_i, u_i, \lambda_{i+1}) \\ f(x_i, u_i) - (x_{i+1} - x_i)/h \end{bmatrix} \quad \text{and} \quad F_i^h(x, u, \lambda) = \begin{bmatrix} 0 \\ \partial U(u_i) \\ 0 \end{bmatrix}.$$

Given $z = (x, u, \lambda)$ in the discrete space Z_p associated with Ω_p , we use the L^∞ norm for each of the three components x , u , and λ of z . In the discrete space Y_p associated with the range of T_p , we use the L^1 norm for the first and last component, and the L^∞ norm for the middle component. That is, if $y = (a, b, c) \in Y_p$, then

$$\|y\|_p = \|a\|_{L^1} + \|b\|_{L^\infty} + \|c\|_{L^1}.$$

The point z_p of Corollary 1 is given by $z_p = (x^I, u^I, \lambda^I)$, where

$$x_i^I = x^*(t_i), \quad u_i^I = u^*(t_i), \quad \lambda_i^I = \lambda^*(t_i).$$

Also, in Corollary 1, component i of the point y_p , denoted y_i^h , is the triple

$$y_i^h = \begin{bmatrix} 0 \\ \nabla_u H(x_i^I, u_i^I, \lambda_i^I) \\ 0 \end{bmatrix}.$$

Observe that with this choice for y_p , we have $y_p \in F(z_p)$. We define a linear operator M^h that acts on a discrete triple (x, u, λ) to produce a vector whose i th component is

$$M_i^h(x, u, \lambda) = \begin{bmatrix} A_i^T \lambda_{i+1} + Q_i x_i + S_i u_i + (\lambda_{i+1} - \lambda_i)/h \\ R_i u_i + S_i^T x_i + B_i^T \lambda_{i+1} \\ A_i x_i + B_i u_i - (x_{i+1} - x_i)/h \end{bmatrix}.$$

Taking $L_p(z) = M^h(x, u, \lambda) - M^h(x^l, u^l, \lambda^l)$, observe that $L_p(z_p) = 0$.

It can be verified that under the smoothness assumptions and for ρ smaller than δ , we have $D_\rho(h) \rightarrow 0$ as $h \rightarrow 0$. Now consider the term

$$(78) \quad (T_p(z_p) - y_p)_i = \begin{bmatrix} \nabla_x H(x_i^l, u_i^l, \lambda_{i+1}^l) + (\lambda_{i+1}^l - \lambda_i^l)/h \\ \nabla_u H(x_i^l, u_i^l, \lambda_{i+1}^l) - \nabla_u H(x_i^l, u_i^l, \lambda_i^l) \\ f(x_i^l, u_i^l) - (x_{i+1}^l - x_i^l)/h \end{bmatrix}.$$

The middle component of this vector is $O(h)$ since λ^* is Lipschitz continuous. Since the analysis of the first and last component in (78) is similar, we only focus on the last component

$$(79) \quad \left| f(x_i^l, u_i^l) - \frac{x_{i+1}^l - x_i^l}{h} \right| \leq \frac{1}{h} \int_{t_i}^{t_{i+1}} |f(x_i^l, u_i^l) - \dot{x}^*(t)| dt \\ \leq \frac{1}{h} \int_{t_i}^{t_{i+1}} |f(x_i^l, u_i^l) - f(x^*(t), u^*(t))| dt \leq \frac{c}{h} \int_{t_i}^{t_{i+1}} [h + \omega(u^*; t, 2h)] dt,$$

where c denotes a generic constant, independent of h . Multiplying (79) by h , summing over i , and exploiting the inequality $\tau(u; kh) \leq k\tau(u; h)$ for each natural number k (see [42, p. 11]), it follows that

$$\|T_p(z_p) - y_p\|_p = O(h + \tau(u^*; h)).$$

Next, we must analyze the auxiliary problem and establish the existence of a constant γ satisfying (9). The analysis essentially parallels that of [20] except that continuous norms are replaced by their discrete analogues. We must examine how the solution to the following system depends on the perturbations q_i , r_i , and s_i :

$$(80) \quad \begin{aligned} A_i^T \lambda_{i+1} + Q_i x_i + S_i u_i + \frac{\lambda_{i+1} - \lambda_i}{h} + q_i &= 0, & \lambda_N &= 0, \\ (R_i u_i + S_i^T x_i + B_i^T \lambda_{i+1} + r_i)(v - u_i) &\geq 0 & \text{for every } v &\in U, \\ A_i x_i + B_i u_i - \frac{x_{i+1} - x_i}{h} + s_i &= 0, & x_0 &= a, \end{aligned}$$

$i = 0, 1, \dots, N-1$. Note that system (80) constitutes the first-order necessary conditions (see [22, p. 280]) associated with the following quadratic program:

$$(81) \quad \begin{aligned} \text{minimize} \quad & h \sum_{i=0}^{N-1} \frac{1}{2} x_i^T Q_i x_i + \frac{1}{2} u_i^T R_i u_i + x_i^T S_i u_i + q_i^T x_i + r_i^T u_i \\ \text{subject to} \quad & x_{i+1} = x_i + hA_i x_i + hB_i u_i + hs_i \quad \text{and} \\ & u_i \in U, \quad 0 \leq i \leq N-1, \quad x_0 = a. \end{aligned}$$

By Lemma 4 and the discussion that follows it, there is a one-to-one correspondence between a solution to (81) and a solution to (80) when (75) holds.

Now consider the perturbations (q^i, r^i, s^i) for $i = 1$ and 2 . Let (x^i, u^i, λ^i) denote the associated solutions to (80). Referring to Lemma 4 (see [20, § 2] for more details), we have

$$\|u^1 - u^2\|_{L^2} \leq c(\|q^1 - q^2\|_{L^1} + \|r^1 - r^2\|_{L^2} + \|s^1 - s^2\|_{L^1}),$$

where c is a constant independent of h . Utilizing (77), we also conclude that

$$(82) \quad \|x^1 - x^2\|_{L^\infty} + \|\lambda^1 - \lambda^2\|_{L^\infty} \leq c(\|q^1 - q^2\|_{L^1} + \|r^1 - r^2\|_{L^2} + \|s^1 - s^2\|_{L^1}).$$

Finally, by (74) and Lemma 4, we have

$$\|u^1 - u^2\|_{L^\infty} \leq c(\|r^1 - r^2\|_{L^\infty} + \|x^1 - x^2\|_{L^\infty} + \|\lambda^1 - \lambda^2\|_{L^\infty}).$$

Combining this with (82) yields

$$\begin{aligned} & \|x^1 - x^2\|_{L^\infty} + \|u^1 - u^2\|_{L^\infty} + \|\lambda^1 - \lambda^2\|_{L^\infty} \\ & \leq c(\|q^1 - q^2\|_{L^1} + \|r^1 - r^2\|_{L^\infty} + \|s^1 - s^2\|_{L^1}). \end{aligned}$$

Hence, there exists a constant γ such that (9) holds with $\sigma = \infty$.

By Corollary 1, there exists a solution to the discrete necessary conditions (72) and (73) associated with (71) that satisfies the first three estimates of Theorem 6. The discrete and continuous state equations, along with the previously established error estimates, imply that

$$\left| x^*(t_i) - \frac{x_{i+1}^h - x_i^h}{h} \right| = |f(x^*(t_i), u^*(t_i)) - f(x_i^h, u_i^h)| = O(h + \tau(u^*; h)),$$

which gives the last estimate of Theorem 6. The fact that x^h and u^h are local minimizers for (71) follows from Corollary 6 in Appendix 1, the coercivity condition (75), and the fact that coercivity condition (75) is preserved after small perturbations in Q_i , R_i , S_i , A_i , and B_i . \square

Remark 9. Note that the coercivity assumptions (74) and (75) do not necessarily imply that an optimal control is either unique or continuous. For example, if $g(x, u) = (u^2 - 1)^2$, $f = 0$, and $U = R^1$, then for each measurable set $M \subset 1$, the function defined by

$$u(t) = 1 \quad \text{for } t \in M \quad \text{and} \quad u(t) = -1 \quad \text{for } t \notin M$$

is an optimal control that satisfies (74) and (75).

Remark 10. Results most closely related to Theorem 6 include the papers of Budak, Berkovich, and Solov'eva [8] and Cullum [11] in which convergence of the optimal value associated with discrete approximations to state and control constrained problems is established. Mordukhovich [31] shows that the discrete optimal cost converges to the true optimal cost if and only if a relaxation of the control problem is stable. Estimates for the error in the optimal control associated with higher-order discretizations of unconstrained nonlinear problems are derived by Hager [17]. Dontchev [12] obtains an error estimate for Euler's approximation applied to an optimal control problem with convex cost, linear system dynamics, and linear inequality state and control constraints.

Appendix 1: Sufficient optimality conditions. We begin by establishing the sufficient optimality result needed for Corollary 4. Let us consider the following optimization problem:

$$(83) \quad \begin{aligned} & \text{minimize} && C(z) \\ & \text{subject to} && g(z) \in K_g, \quad h(z) \in K_h, \end{aligned}$$

where $g: Z \rightarrow W_g$ and $h: Z \rightarrow W_h$, W_g and W_h are Banach spaces, and K_g and K_h are closed, convex cones with vertices at the origin of their respective spaces. The Lagrangian H associated with (83) is given by

$$H(z, \mu, \nu) = C(z) - \langle \mu, g(z) \rangle - \langle \nu, h(z) \rangle,$$

where $\mu \in W_g^*$ and $\nu \in W_h^*$. Letting z^* be a point that is feasible in (83), we assume that C , g , and h are twice Fréchet differentiable at z^* . The first-order necessary conditions associated with (83) have the following form: There exists $\mu \in K_g^+$ and $\nu \in K_h^+$ such that

$$(84) \quad \nabla_z H(z^*, \mu, \nu) = 0, \quad \langle \mu, g(z^*) \rangle = 0, \quad \langle \nu, h(z^*) \rangle = 0.$$

Although the following lemma makes the same surjectivity assumption that appears in Corollary 4, this assumption can be replaced by any condition that ensures regularity of the linearized system (see Robinson [35] or Maurer and Zowe [30]).

LEMMA 8. *Suppose that z^* is feasible in (83), $\mu \in K_g^+$, $\nu \in \text{int } K_h^+$, the first-order necessary conditions (84) hold, the operator*

$$\begin{bmatrix} h'(z^*) \\ g'(z^*) \end{bmatrix}$$

is surjective, and there exists $\alpha > 0$ such that

$$\begin{aligned} &\langle \nabla_{zz}^2 H(z^*, \mu, \nu)(z - z^*), z - z^* \rangle \geq \alpha \|z - z^*\|^2 \\ &\text{whenever } g(z^*) + g'(z^*)(z - z^*) \in K_g \quad \text{and} \quad h'(z^*)(z - z^*) = 0. \end{aligned}$$

Then z^ is a strict local minimizer for (83).*

In comparing this result to Maurer and Zowe's classic sufficient optimality result [30], observe that the constraint $h'(z^*)(z - z^*) = 0$ in the coercivity condition above corresponds to a constraint of the form $h'(z^*)(z - z^*) \in K_h$ in [30]. In this respect, the coercivity condition of Lemma 8 is weaker than that of [30]. On the other hand, Lemma 8 assumes that $\nu \in \text{int } K_h^+$, while [30] only assumes that $\nu \in K_h^+$.

Proof. Throughout this proof, we let ε denote a generic positive constant that can be made arbitrarily small for z sufficiently close to z^* , we let α denote a generic positive constant that is uniformly bounded away from zero for z near z^* , and we let β denote a generic constant that is uniformly bounded from above for z near z^* . Expanding $H(z, \mu, \nu)$ in a Taylor series about $z = z^*$, we have

$$\begin{aligned} H(z, \mu, \nu) &= H(z^*, \mu, \nu) + \nabla_z H(z^*, \mu, \nu)(z - z^*) \\ &\quad + \frac{1}{2} \nabla_{zz}^2 H(z^*, \mu, \nu)(z - z^*, z - z^*) + R(z), \end{aligned}$$

where $R(z) \leq \varepsilon \|z - z^*\|^2$. By the first-order necessary conditions, $H(z^*, \mu, \nu) = C(z^*)$ and $\nabla_z H(z^*, \mu, \nu) = 0$. Hence, it follows that

$$C(z) = C(z^*) + M(z) + R(z),$$

$$\text{where } M(z) = \langle \mu, g(z) \rangle + \langle \nu, h(z) \rangle + \frac{1}{2} \nabla_{zz}^2 H(z^*, \mu, \nu)(z - z^*, z - z^*).$$

If z is feasible in (83), then since $\nu \in \text{int } K_h^+$, we have $\langle \nu, h(z) \rangle \geq \alpha \|h(z)\|$. Thus we have

$$\langle \mu, g(z) \rangle + \langle \nu, h(z) \rangle \geq \alpha \|h(z)\|.$$

By the complementary slackness condition, $h(z^*) = 0$, and by the differentiability assumption,

$$h(z) = h'(z^*)(z - z^*) + o(\|z - z^*\|) \quad \text{and} \quad g(z) = g(z^*) + g'(z^*)(z - z^*) + o(\|z - z^*\|).$$

Referring to [35, Thm. 1], the surjectivity assumption implies that for each z near z^* , there exists an associated $y \in Z$ such that $h'(z^*)(y - z^*) = 0$, $g(z^*) + g'(z^*)(y - z^*) \in K_g$, and

$$\|y - z\| \leq \beta \|h'(z^*)(z - z^*)\| + \beta \inf \{\|g(z^*) + g'(z^*)(z - z^*) - k\| : k \in K_g\}.$$

This bound, combined with the Taylor expansions of g and h , implies that for each z near z^* , with z feasible in (83), there exists an associated $y \in Z$ such that $h'(z^*)(y - z^*) = 0$, $g(z^*) + g'(z^*)(y - z^*) \in K_g$, and $\|y - z\| \leq \beta \|h(z)\| + \varepsilon \|z - z^*\|$. Applying the triangle inequality yields

$$\|y - z\| \leq \beta \|h(z)\| + \varepsilon \|y - z^*\|.$$

By the coercivity assumption,

$$\nabla_{zz}^2 H(z^*, \mu, \nu)(z - z^*, z - z^*) \geq \alpha \|y - z^*\|^2 - \beta \|y - z^*\| \|y - z\| - \beta \|y - z\|^2.$$

These inequalities, along with the relation $h(z^*) = 0$, imply that for z near z^* with z feasible in (83), we have

$$M(z) \geq \alpha \|h(z)\| + \alpha \|y - z^*\|^2.$$

Recall that the remainder term R has the bound $R(z) \leq \varepsilon \|z - z^*\|^2$. By the triangle inequality,

$$\|z - z^*\| \leq \|z - y\| + \|y - z^*\| \leq (1 + \varepsilon) \|y - z^*\| + \beta \|h(z)\|,$$

from which it follows that

$$\|z - z^*\|^2 \leq \beta \|y - z^*\|^2 + \beta \|h(z)\|^2.$$

Hence, for z near z^* with z feasible in (83), we have

$$\begin{aligned} C(z) - C(z^*) &= M(z) + R(z) \geq \alpha \|h(z)\| + \alpha \|y - z^*\|^2 - \varepsilon \|z - z^*\|^2 \\ &\geq \alpha \|h(z)\| + \alpha \|z - z^*\|^2 - \beta \|h(z)\|^2 \geq \alpha \|z - z^*\|^2, \end{aligned}$$

which completes the proof. \square

Next, we obtain sufficient optimality conditions that are applicable to optimal control problems. A number of relevant sufficient optimality conditions have appeared in the literature; for example, see Ioffe [21] and, in particular, the results of Maurer [29]. Although the basic strategy for obtaining sufficient optimality results in the optimal control setting is developed nicely by Maurer in [29], the precise results that we need in §§ 6 and 7 are not stated in his paper. For completeness, we give a brief, self-contained treatment of the results needed in our paper. We begin with the abstract problem

$$(85) \quad \begin{aligned} &\text{minimize} && C(z) \\ &\text{subject to} && z \in \Lambda, \end{aligned}$$

where Λ is a subset of a normed vector space Z , and C is a real-valued function. As in [29], we assume that there are two different norms, denoted by $\|\cdot\|$ and $\|\cdot\|$, associated with Z .

LEMMA 9. *Suppose that z^* satisfies the constraints of (85) and that there exists a functional M and a scalar $\alpha > 0$ with the following property:*

$$(86) \quad M(z) \geq \alpha \|z - z^*\|^2 \quad \text{for each } z \in \Lambda \text{ with } \|z - z^*\| \text{ sufficiently small}$$

and

$$(87) \quad \frac{C(z) - C(z^*) - M(z)}{\|z - z^*\|^2} \rightarrow 0 \quad \text{as } \|z - z^*\| \rightarrow 0 \quad \text{with } z \in \Lambda.$$

Then z^* is a strict local minimizer for (85).

Proof. By the hypotheses above, we have

$$C(z) - C(z^*) \geq \alpha \|z - z^*\|^2 + o(\|z - z^*\|^2)$$

as $\|z - z^*\| \rightarrow 0$ with $z \in \Lambda$, which implies that z^* is a strict local minimizer for (85). \square

In the application of Lemma 9, the following observation is helpful.

LEMMA 10. Suppose that there exists a scalar $\alpha > 0$, a bilinear form b that is bounded relative to the norm $\|\cdot\|$, and a set T such that

$$b(z - z^*, z - z^*) \geq \alpha \|z - z^*\|^2 \quad \text{for every } z \in T.$$

If for each $z \in \Lambda$, there exists $y \in T$ such that $\|z - y\| = o(\|z - z^*\|)$, then for each $\beta < \alpha$, we have

$$b(z - z^*, z - z^*) \geq \beta \|z - z^*\|^2 \quad \text{for all } z \in \Lambda \text{ with } \|z - z^*\| \text{ sufficiently small.}$$

Proof. Given $z \in \Lambda$, let $y \in T$ be the hypothesized point for which $\|z - y\| = o(\|z - z^*\|)$. Since the bilinear form b is bounded, there exists a constant c such that

$$b(z - z^*, z - z^*) \geq \alpha \|y - z^*\|^2 - c \|z - y\|^2 - c \|z - y\| \|y - z^*\|.$$

The inequality

$$\|y - z^*\| \geq \|z - z^*\| - \|z - y\| = \|z - z^*\| - o(\|z - z^*\|)$$

completes the proof. \square

We now apply Lemmas 9 and 10 to optimal control problems. Note that in the following result, we neither assume an interior point nor controllability.

COROLLARY 5. Suppose that x^* and u^* are feasible for the optimal control problem (68), that f and g satisfy the differentiability conditions given below (68), that $\lambda = \lambda^*$ is the solution to the adjoint equation (69) associated with $x = x^*$ and $u = u^*$, and that the minimum principle (70) holds. If there exists $\alpha > 0$ such that

$$(88) \quad \int_I (x(t)^T Q(t)x(t) + u(t)^T R(t)u(t) + 2x(t)^T S(t)u(t)) dt \geq \alpha \int_I |u(t)|^2 dt$$

whenever $x \in W^{1,2}$, $x(0) = 0$, $u \in L^2$, $\dot{x} = Ax + Bu$, $u = v - u^*$ for some $v \in L^2$ with $v(t) \in U$ for almost every $t \in I$, then u^* is a strict local minimizer for (68).

Proof. We apply Lemmas 9 and 10 with the following identifications: The z of Lemma 9 is the pair (x, u) , the space Z is $W^{1,\infty} \times L^\infty$, the norm $\|\cdot\|$ associated with Z is the L^2 inner product norm, $C(z)$ is the integral cost function in (68), and Λ consists of those (x, u) in a convex neighborhood of (x^*, u^*) that satisfy the constraints

$$F(z) = 0, \quad \text{where } F(z) = f(x, u) - \dot{x}, \quad u(t) \in U \quad \text{a.e. } t \in I, \quad \text{and } x(0) = a.$$

The functional M is defined by

$$M(z) = \langle \nabla_u H(x^*, u^*, \lambda^*), u - u^* \rangle + b(z - z^*, z - z^*), \quad z = (x, u),$$

where

$$b(\delta z, \delta z) = \int_I (\delta x(t)^T Q(t) \delta x(t) + \delta u(t)^T R(t) \delta u(t) + 2 \delta x(t)^T S(t) \delta u(t)) dt,$$

$$\delta z = (\delta x, \delta u).$$

The set T of Lemma 10 is given by

$$T = \{z = (x, u) \in Z: F'(z^*)(z - z^*) = 0, x(0) = a, u(t) \in U \text{ a.e. } t \in I\}.$$

To verify identity (87), first note that for $z \in \Lambda$, we have

$$C(z) = \int_I g(z) + F(z)^T \lambda^* dt.$$

Hence, after an integration by parts and a Taylor expansion, we obtain (87). By the minimum principle (70), $M(z) \geq b(z - z^*, z - z^*)$. By the coercivity condition (88) and the fact that coercivity with respect to the control implies coercivity with respect to the state (see [20]), we have

$$b(z - z^*, z - z^*) \geq \alpha \|z - z^*\|^2 \quad \text{for some } \alpha > 0.$$

Thus (86) follows from Lemma 10 if, for each $z = (x, u) \in \Lambda$, we can establish the existence of $y \in T$ with $\|z - y\| = o(\|z - z^*\|)$. We construct y in the following way: Let w be the solution to

$$(89) \quad \dot{w} = \nabla_x f(x^*, u^*)w - F'(z^*)(z - z^*), \quad w(0) = 0,$$

and define $y = (w + x, u)$. Observe that $y \in T$. Also, by (89) we have

$$\|w\|_{L^2} \leq c \|F'(z^*)(z - z^*)\|_{L^2},$$

where c is a generic constant. From the relation

$$\|F'(z^*)(z - z^*)\|_{L^2} = \|F(z) - F(z^*) - F'(z^*)(z - z^*)\|_{L^2} = o(\|z - z^*\|_{L^2}),$$

we conclude that $\|z - y\|_{L^2} = \|w\|_{L^2} = o(\|z - z^*\|_{L^2})$, which completes the proof. \square

Now let us consider the finite-dimensional optimization problem

$$(90) \quad \begin{aligned} &\text{minimize} && C(x, u) \\ &\text{subject to} && F(x, u) = 0, \quad u \in \Omega \subset R^m, \quad x \in R^n, \end{aligned}$$

where Ω is convex and F maps R^{m+n} to R^n . Let z denote the pair (x, u) , and for $\lambda \in R^n$, let H be the Lagrangian defined by

$$H(z, \lambda) = C(z) + \lambda^T F(z).$$

COROLLARY 6. *Suppose that x^* and u^* are feasible for (90), that F and C are twice differentiable at $z^* = (x^*, u^*)$, and that $\nabla_x F(x^*, u^*)$ is nonsingular. If there exists a multiplier $\lambda^* \in R^n$ such that*

$$\nabla_x H(x^*, u^*, \lambda^*) = 0 \quad \text{and} \quad \nabla_u H(x^*, u^*, \lambda^*)^T (u - u^*) \geq 0 \quad \text{for every } u \in \Omega$$

and

$$(z - z^*)^T \nabla_{zz}^2 H(z^*, \lambda^*) (z - z^*) \geq \alpha |z - z^*|^2$$

whenever $F'(z^*)(z - z^*) = 0$ for some $z = (x, u)$ with $u \in \Omega$, then z^* is a local minimizer for (90).

Proof. We apply Lemma 9 with

$$M(z) = \nabla_z H(z^*, \lambda^*) (z - z^*) + \frac{1}{2} (z - z^*)^T \nabla_{zz}^2 H(z^*, \lambda^*) (z - z^*).$$

The set T of Lemma 10 is given by

$$T = \{z = (x, u) \in R^{m+n}: F'(z^*)(z - z^*) = 0, u \in \Omega\}.$$

The y of Lemma 10 is constructed in the following way: Given $z = (x, u)$ with $u \in \Omega$, $y = (x + w, u)$, where w is the solution to

$$\nabla_x F(x^*, u^*) w = -F'(z^*)(z - z^*).$$

Observe that $y \in T$. If $F(z) = 0$, then

$$|F'(z^*)(z - z^*)| = |F(z) - F(z^*) - F'(z^*)(z - z^*)| = o(|z - z^*|).$$

Since $\nabla_x F(x^*, u^*)$ is nonsingular, we have

$$|z - y| = |w| \leq c|F'(z^*)(z - z^*)| = o(|z - z^*|). \quad \square$$

Appendix 2: The coercivity condition. Here we show that the discrete coercivity condition (75) of § 7 can be deduced from an analogous continuous condition.

LEMMA 11. *Suppose that the matrices A , B , Q , R , and S of § 7 are continuous and that there exists $\beta > 0$ such that*

$$(91) \quad \int_I (x(t)^T Q(t)x(t) + u(t)^T R(t)u(t) + 2x(t)^T S(t)u(t)) dt \geq \beta \int_I |u(t)|^2 dt$$

whenever $x \in W^{1,2}$, $x(0) = 0$, $u \in L^2$, $\dot{x} = Ax + Bu$, $u = v - w$ for some v and $w \in L^2$ with $v(t)$ and $w(t) \in U$ for almost every $t \in I$. Then there exists $\alpha > 0$ satisfying the discrete coercivity condition (75).

Proof. Given sequences $\{x_i\}$ and $\{u_i\}$ that satisfy the linear equation (76) where $u_i = v_i - w_i$ for some v_i and $w_i \in U$, let u^h denote the piecewise constant extension of the u_i defined by

$$u^h(t) = u_i, \quad t_i \leq t < t_{i+1}, \quad i = 0, 1, \dots, N-1,$$

and let x^h be the solution of

$$\dot{x}^h = Ax^h + Bu^h, \quad x^h(0) = 0.$$

Define $y_i = x^h(t_i)$ and let y^h be the piecewise constant extension of the y_i . Since u^h is piecewise constant,

$$\int_I |u^h(t)|^2 dt = h \sum_{i=0}^{N-1} |u_i|^2.$$

We will show that, for $x = x^h$ and $u = u^h$,

$$(92) \quad |\text{left side of (91)} - \text{left side of (75)}| \leq h\epsilon^h \sum_{i=0}^{N-1} |u_i|^2,$$

where ϵ^h denotes a generic constant that tends to zero as h tends to zero. Hence, (75) follows from (91) when h is sufficiently small.

Let us begin with the quadratic control terms in (75) and (91). Since u^h is equal to u_i on the interval $[t_i, t_{i+1}]$, it follows that

$$h \sum_{i=0}^{N-1} u_i^T R_i u_i - \int_I u^h(t)^T R(t) u^h(t) dt = h \sum_{i=0}^{N-1} u_i^T \delta R_i u_i,$$

where

$$(93) \quad \delta R_i = R_i - \frac{1}{h} \int_{t_i}^{t_{i+1}} R(t) dt.$$

Since $R(t)$ is continuous in t , (93) approaches zero, uniformly in i , as $N \rightarrow \infty$. Hence, we have

$$\left| h \sum_{i=0}^{N-1} u_i^T R_i u_i - \int_I u^h(t)^T R(t) u^h(t) dt \right| \leq h \varepsilon^h \sum_{i=0}^{N-1} |u_i|^2.$$

Now let us consider the quadratic state terms in (75) and (91). As with the quadratic control term, we have

$$(94) \quad \left| h \sum_{i=0}^{N-1} y_i^T Q_i y_i - \int_I y^h(t)^T Q(t) y^h(t) dt \right| \leq h \varepsilon^h \sum_{i=0}^{N-1} |y_i|^2.$$

From the differential equation satisfied by x^h , we have

$$(95) \quad \|y^h\|_{L^2}^2 \leq \|y^h\|_{L^\infty}^2 \leq \|x^h\|_{L^\infty}^2 \leq c \|u^h\|_{L^2}^2 = ch \sum_{i=0}^{N-1} |u_i|^2,$$

where c denotes a generic constant that is independent of h for h sufficiently small. Combining (94) and (95) yields

$$(96) \quad \left| h \sum_{i=0}^{N-1} y_i^T Q_i y_i - \int_I y^h(t)^T Q(t) y^h(t) dt \right| \leq h \varepsilon^h \sum_{i=0}^{N-1} |u_i|^2.$$

Since y^h is the piecewise constant extension of x^h , it follows from the equation for x^h that

$$\|y^h - x^h\|_{L^2} \leq h \|\dot{x}^h\|_{L^2} \leq ch \|u^h\|_{L^2}.$$

This estimate, along with (95), implies that

$$(97) \quad \left| \int_I y^h(t)^T Q(t) y^h(t) - x^h(t)^T Q(t) x^h(t) dt \right| \leq ch \|u^h\|_{L^2}^2 = h \varepsilon^h \sum_{i=0}^{N-1} |u_i|^2.$$

Finally, let us consider the difference

$$\sum_{i=0}^{N-1} y_i^T Q_i y_i - x_i^T Q_i x_i.$$

Integrating the differential equation for x^h over the interval $[t_i, t_{i+1}]$ gives

$$(98) \quad y_{i+1} = y_i + h A_i y_i + h B_i u_i + e_i,$$

where

$$e_i = -h \delta B_i u_i - h \delta A_i y_i + \int_{t_i}^{t_{i+1}} A(t) (x^h(t) - y_i) dt.$$

The factors δA_i and δB_i are defined by

$$\delta A_i = A_i - \frac{1}{h} \int_{t_i}^{t_{i+1}} A(t) dt \quad \text{and} \quad \delta B_i = B_i - \frac{1}{h} \int_{t_i}^{t_{i+1}} B(t) dt.$$

Subtracting the finite difference equation (76) from (98) gives

$$|y_j - x_j| \leq c \sum_{i=0}^{N-1} |e_i|.$$

From the definition of e_i , we have

$$|e_i| \leq h \varepsilon^h (|u_i| + |y_i|).$$

It follows that

$$|y_j - x_j| \leq h \varepsilon^h \sum_{i=0}^{N-1} |u_i| + |y_i| \leq \varepsilon^h \|u^h\|_{L^2}.$$

Summing over j yields

$$h \sum_{j=0}^{N-1} |y_j - x_j|^2 \leq \varepsilon^h \|u^h\|_{L^2}^2.$$

Hence, we have

$$(99) \quad \left| h \sum_{i=0}^{N-1} y_i^T Q_i y_i - x_i^T Q_i x_i \right| \leq \varepsilon^h \|u^h\|_{L^2}^2.$$

The triangle inequality, along with (96), (97), and (99), gives

$$\left| h \sum_{i=0}^{N-1} x_i^T Q_i x_i - \int_I x^h(t)^T Q(t) x^h(t) dt \right| \leq h \varepsilon^h \sum_{i=0}^{N-1} |u_i|^2.$$

Since the cross-product term $x_i^T S_i u_i$ can be analyzed in a similar manner, the proof of (92) is complete. \square

PURSUIT-EVASION PROBLEMS AND VISCOSITY SOLUTIONS OF ISAACS EQUATIONS*

PIERPAOLO SORAVIA†

Abstract. The Dirichlet problem for first-order Hamilton–Jacobi equations arising in differential games of pursuit and evasion is studied. Local and global sub- and superoptimality principles are stated for, respectively, viscosity sub- and supersolutions. These results are applied to obtain a general existence theorem and to prove the existence of the value of the game. The main application concerns the problem of stability (terminability) of a dynamical system with two competitive controls and the opposite one of evadability from a general closed set. The approach used in this paper allows Lyapunov functions satisfying the usual condition in the weak sense of viscosity solutions.

Key words. viscosity solutions, comparison theorems, dynamical systems, stability, differential games

AMS(MOS) subject classifications. 35B37, 49L25, 90D25

Introduction. In a previous work of Bardi and the author [BS1], we studied the Dirichlet problem for a Hamilton–Jacobi equation

$$(0.1) \quad \begin{aligned} H(x, DU) &= 0 && \text{in } \Omega \setminus \mathcal{T}, \\ U &= g && \text{on } \partial\mathcal{T}, \\ U(x) &\rightarrow +\infty && \text{as } x \rightarrow x_0 \in \partial\Omega, \end{aligned}$$

where the Hamiltonian can be written in the following way:

$$(0.2) \quad H(x, p) := \inf_{b \in B} \sup_{a \in A} \{-f(x, a, b) \cdot p - h(x, a, b)\}, \quad \text{for all } x, p \in \mathbf{R}^N,$$

where A, B are compact, \mathcal{T} is closed, and f, g, h are sufficiently smooth but mainly $h(x, a, b) \geq h_0 > 0$. In this framework, we proved a free boundary uniqueness result: There exists at most one pair (U, Ω) where $\Omega \supset \mathcal{T}$ is open and U is continuous in $(\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T}$, is bounded below, and is a viscosity solution of (0.1). In particular, the solution of (0.1) is the value function V of a differential game whose dynamics have vector field f , running cost h , terminal set \mathcal{T} , and final cost g , without any regularity assumption on V .

Our first purpose here is to revisit that result and state it as a free-boundary comparison theorem: We assume that U satisfies the differential equation that appears in (0.1) and the boundary condition on $\partial\mathcal{T}$ as a viscosity subsolution or supersolution, and we state, respectively, that $U \leq V$ or $U \geq V$ in $\Omega \setminus \mathcal{T}$. We also prove the corresponding inequalities between the sets Ω and $\{x: V(x) < +\infty\}$. This result can, in fact, be viewed as a sub- or superoptimality principle, respectively, in the sense of Lions–Souganidis [LSO]. If g is bounded, we also allow more general boundary conditions on $\partial\Omega$, such as $U \equiv c$, where $c > \sup_{\partial\mathcal{T}} g$. Moreover, we prove that the same results also hold if the Hamiltonian can be written as

$$(0.3) \quad \tilde{H}(x, p) := \sup_{a \in A} \inf_{b \in B} \{-f(x, a, b) \cdot p - h(x, a, b)\},$$

i.e., when sup and inf have been interchanged. The proof in this case has some relevant differences with respect to the one in the other case. This is mainly due to the fact that

the two representations of the Hamiltonian arise in the context of survival differential games, but (0.2) refers to a pursuit problem in which the minimizing player (or pursuer) is the leader of the game, whereas (0.3) applies to the evasion problem in which the leader is the maximizing player. In fact, it is well known that, in general (if $H \neq \tilde{H}$), there is not a good definition of value function. A lower value V and an upper value \tilde{V} are introduced, and they provide some advantage to the minimizing or, respectively, the maximizing player (evader) (we will give the precise definitions in the next section; for more remarks about the notion of value for differential games, we also refer to [EK1], [Fl], [Fr], and [S2]).

Our comparison theorems have several applications in the theory of controls and differential games. In particular, we can prove rather general relaxation theorems (weak bang-bang principles), give sufficient conditions for the existence of the value, and prove the equivalence among different concepts of value; see also [BS1] and [S2].

We state as a comparison theorem a local uniqueness result in [BS1], which generalizes a previous one from Evans and James [EJ], for the Dirichlet problem

$$(0.4) \quad \begin{aligned} H(x, DU) &= 0 \quad \text{in } B(x_0, r) \setminus \mathcal{T}; \\ U &= g \quad \text{on } \partial\mathcal{T}. \end{aligned}$$

As a consequence of this last result, we then prove that, if (0.4) has continuous viscosity sub- and supersolutions for all $x_0 \in \partial\mathcal{T}$ and some choice of r , possibly depending on x_0 , then (0.1) has a solution pair (Ω, U) , with U continuous in $(\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T}$. This formulation of an existence theorem for a Dirichlet problem associated with a Hamilton–Jacobi equation is new. In fact, in the literature on existence of solutions for such problems, the existence of global viscosity sub- and supersolutions is usually assumed (see [Ba], [CL], [L1], [L2], and [I1]). Finally, for an understanding of the Dirichlet problems for Hamilton–Jacobi equations, we also refer to Soner [Sn], Ishii [I2], and Bardi and Soravia [BS2], and to the references therein.

The second part of this work is devoted to other consequences of the previous uniqueness results. In some papers (see Yong [Y1] and the works cited therein), the notions of local and local asymptotic terminability are introduced for pursuit games, generalizing the usual ones for dynamical systems. These notions are also related to the much-studied problem of stabilization of control systems (see Brockett [Br]). The opposite problems of evadability and strict evadability have also been studied for evasion games (see Yong [Y2] and the references therein). In the present work, we give sufficient conditions for terminability and evadability of systems, which generalize many of the results in [Y1] and [Y2] in two ways. It is well known that the classical sufficient condition for the local asymptotic stability of a dynamical system without any control $y' = f(y)$, where $f(0) = 0$ (here $\mathcal{T} = \{0\}$), prescribes the existence of a Lyapunov function U that satisfies the differential inequality

$$-f(x) \cdot DU(x) > 0$$

in a neighborhood of the origin. In a first result, we show that it is enough to assume that U is continuous and verifies the previous condition in the viscosity sense, and we prove that this result extends to the more general context of differential games, which requires a natural generalization of the classical differential inequality. However, known results for systems without controls (see, e.g., Bhatia, Szego, and Yorke [BSY] and Yorke [Yo]) involve Lyapunov functions that are just semicontinuous by means of certain weak derivatives (for more about weak conditions on U , see also Lakshmikantham and Leela [LL]). These stronger results could, in fact, be obtained in the classical case, also in the context of viscosity solutions, by a result due to Crandall and Lions

[CL]. Some related questions regarding semicontinuous Lyapunov functions and differential inclusions, and therefore control problems, can be found in Aubin [A], Aubin and Cellina [AC], and Aubin and Frankowska [AF].

In a second result, we give explicit conditions on the direction of the vector field f at the points of the boundary of the terminal set. We are able to manage general closed sets, not just closed convex sets in particular subspaces, as in the previous literature. There are two reasons for this. First, we need to construct a Lyapunov function that satisfies the differential inequality in the weak sense of viscosity solutions. Moreover, we employ a generalization of the concept of a normal vector, usually introduced for convex or smooth sets, which seems to be suitable in our framework. We apply a definition of an exterior normal vector to a general closed set \mathcal{T} , which, to our knowledge, was first used by Bony [B]. Roughly, a vector is said to be exterior normal to \mathcal{T} if, in that direction, we can construct a tangent exterior ball to \mathcal{T} . We adopt this definition instead of others that are perhaps more used in the literature because such vectors provide a nice representation of the viscosity sub- and super-differentials of the distance function to \mathcal{T} . More comments about this will follow in Remark 3.8. One of the referees pointed out to us that this definition has been used by Crandall and Newcomb [CN] and Souganidis [So] in the theory of viscosity solutions.

In the last part of § 3 we will develop similar techniques and results for the evasion problem.

1. Preliminaries. In this section, we describe the framework of the problem and the main assumptions that will hold throughout the paper. We consider a dynamical system controlled by two players

$$(1.1) \quad y' = f(y, a, b), \quad y(0) = x \in \mathbf{R}^N,$$

where the vector field $f: \mathbf{R}^N \times A \times B \rightarrow \mathbf{R}^N$ is continuous and satisfies a uniform Lipschitz condition in the state variable

$$|f(x, a, b) - f(z, a, b)| \leq L|x - z| \quad \text{for all } x, z, a, b.$$

We suppose that the control sets A, B are compact subsets of \mathbf{R}^M and that the controls a and b belong, respectively, to the following sets of admissible controls:

$$\mathcal{A} := \{a: \mathbf{R}_+ \rightarrow A \text{ measurable}\}, \quad \mathcal{B} := \{b: \mathbf{R}_+ \rightarrow B \text{ measurable}\}.$$

We denote by $y_x(\cdot; a, b)$, or simply by $y_x(\cdot)$, $y(\cdot)$, a solution of system (1.1) corresponding to a choice of a and b . We are also given a closed target (or terminal set) $\mathcal{T} \in \mathbf{R}^N$ and the two following functions: a running cost $h: \mathbf{R}^N \times A \times B \rightarrow \mathbf{R}$, which we suppose to be continuous and strictly positive, i.e.,

$$(1.2) \quad h(x, a, b) \geq h_0 > 0 \quad \text{for all } x, a, b,$$

and a final cost $g: \mathcal{T} \rightarrow [G; +\infty[$, which will be bounded below ($G > -\infty$) and continuous. For simplicity of notation, we assume that, in (1.2), $h_0 = 1$. This condition on the sign of h can be weakened in some cases, as will be stated in Remark 3.12.

For each choice of a and b , the game starts at the point x at time 0 and ends at the first time the trajectory hits the target, i.e., at the time

$$(1.3) \quad t_x = t_x(a, b) := \inf \{t: y(t) \in \mathcal{T}\} \leq +\infty,$$

where $t_x = +\infty$ if $y_x(\cdot)$ never reaches the target. The payoff of such a trajectory is defined to be

$$(1.4) \quad P(x, a, b) := \int_0^{t_x} h(y_x(t), a(t), b(t)) dt + g(y_x(t_x)).$$

We introduce the set of admissible strategies for the first player by following the ideas of various authors, i.e., Varaiya [V], Roxin [R], and Elliott and Kalton [EK1] (henceforth denoted VREK)

$$\Delta := \{\alpha: \mathcal{B} \rightarrow \mathcal{A}: b(t) = b'(t) \text{ for a.e. } t \leq t'\}$$

$$\text{implies } \alpha[b](t) = \alpha[b'](t) \text{ for a.e. } t \leq t',$$

and we indicate by Γ the corresponding set of strategies for the second player. The lower VREK value is defined by

$$V(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} P(x, \alpha[b], b),$$

and, in the same way, $\tilde{V}(x) = \sup_{\beta \in \Gamma} \inf_{a \in \mathcal{A}} P(x, a, \beta[a])$ is the upper VREK value. In the particular case of $h \equiv 1$ and $g \equiv 0$, we indicate with T and \tilde{T} the lower and the upper value functions; they are usually called the lower and upper capture time, respectively. The next definitions and results of this section deal with the lower value V , but everything can be translated, with obvious changes, in terms of \tilde{V} .

We also introduce the (lower) capturability set, namely, the set of starting points of the game such that the first player can choose a strategy that forces the system into the target in time less than some positive constant, no matter which control is selected by the second; i.e.,

$$\mathcal{R} := \{x: V(x) < +\infty\}.$$

$\tilde{\mathcal{R}}$ indicates the corresponding set for the upper value. It is not difficult to prove (see [BS1, Lemma 1.1]) that \mathcal{R} is independent of the choice of h and g . More generally, if $C > 0$, we set $\mathcal{R}(C) := \{x: V(x) < C\}$.

We now introduce the following change of variables, or Kruzkov transformation, which is crucial in the remainder of the paper:

$$(1.5) \quad \psi(r) = 1 - \exp(-r).$$

Consider the function defined by $v(x) := \psi(V(x))$ if $x \in \mathcal{R}$ and extended by $v(x) := 1$ if $x \in \mathcal{R}^c$. It is important to note that v is bounded and is itself the (lower) value function of a differential game. In fact, it is easily seen that

$$v(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \psi(P(x, \alpha[b], b)) \quad \text{for all } x \in \mathbf{R}^N \setminus \mathcal{T},$$

where the payoff in this case is

$$(1.6) \quad \begin{aligned} \psi(P(x, a, b)) = & \int_0^{t_x} h(y_x(t), a(t), b(t)) \exp\left(-\int_0^t h(y_x(s), a(s), b(s)) ds\right) dt \\ & + \exp\left(-\int_0^{t_x} h(y_x(s), a(s), b(s)) ds\right) \psi(g(y_x(t_x))). \end{aligned}$$

We now briefly recall the definition of a discontinuous viscosity solution of a Hamilton-Jacobi equation as introduced by Ishii [I1], which generalizes the original definition given by Crandall and Lions [CL]. Let $\Omega \in \mathbf{R}^N$ be an open set, and $F: \Omega \times \mathbf{R} \times \mathbf{R}^N \rightarrow \mathbf{R}$ be a continuous function. $u_1, u_2: \Omega \rightarrow \mathbf{R}$ are, respectively, a viscosity subsolution and supersolution of $F(x, u, Du) = 0$ in Ω if u_1 is upper semicontinuous, u_2 is lower semicontinuous, and for all $\varphi \in C^1(\Omega)$ such that $u_1 - \varphi$ attains a local maximum point at y (respectively, $u_2 - \varphi$ attains a local minimum point at y) we have $F(y, u_1(y), D\varphi(y)) \leq 0$ (respectively, $F(y, u_2(y), D\varphi(y)) \geq 0$). The set of these vectors $D\varphi(y)$ is called the superdifferential of u_1 at y and is denoted by $D^+u_1(y)$ (respectively, the subdifferential $D^-u_2(y)$). For an equivalent and more explicit definition of viscosity sub- and superdifferentials, see Crandall, Evans, and Lions [CEL].

A function $u: \Omega \rightarrow \mathbf{R}$ is a viscosity solution of $F(x, u, Du) = 0$ in Ω if the upper and lower semicontinuous envelopes of u

$$u^*(x) := \limsup_{y \rightarrow x} u(y), \quad u_*(x) := \liminf_{y \rightarrow x} u(y)$$

are, respectively, a subsolution and a supersolution.

We denote the relevant Hamiltonians for our problem,

$$(1.7) \quad H(x, p) := \min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot p - h(x, a, b)\},$$

$$(1.8) \quad \mathcal{H}(x, r, p) := \min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot p - h(x, a, b) + (h(x, a, b) - 1)r\},$$

and also define \tilde{H} and $\tilde{\mathcal{H}}$ by interchanging min and max in (1.7) and (1.8).

DEFINITION 1.1. A function $\sigma: \mathcal{A} \times \mathcal{B} \rightarrow \mathbf{R}_+$ is nonanticipating if $a(t) = a'(t)$ and $b(t) = b'(t)$ for almost every $0 \leq t \leq \sigma(a, b)$ imply that $\sigma(a, b) = \sigma(a', b')$.

The following general formulation of the dynamic-programming principle, which holds for differential games, is well known (see Evans and Ishii [EI] and Elliott and Kalton [EK2]).

PROPOSITION 1.2. Let $x \in \mathbf{R}^N \setminus \mathcal{T}$ and σ be a nonanticipating function such that $\sigma(a, b) \leq t_x(a, b)$ for all a, b . Then

$$V(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \left\{ \int_0^\sigma h(y_x(t), \alpha[b](t), b(t)) dt + V(y_x(\sigma(\alpha[b], b))) \right\}.$$

The next result is based on the dynamic-programming principle and relates the value functions V , v , and the Hamiltonians in (1.7) and (1.8). It is proved by combining the arguments in [ES] and [I2]. The corresponding statement for the upper value \tilde{V} uses the Hamiltonians \tilde{H} and $\tilde{\mathcal{H}}$.

PROPOSITION 1.3. (i) If \mathcal{R} is open and V is locally bounded, then V is a viscosity solution of

$$(1.9) \quad H(x, DV) = 0 \quad \text{in } \mathcal{R} \setminus \mathcal{T};$$

(ii) v is a viscosity solution of

$$(1.10) \quad v(x) + \mathcal{H}(x, v(x), Dv(x)) = 0 \quad \text{in } \mathbf{R}^N \setminus \mathcal{T}.$$

We recall that (1.9) and (1.10) are usually called the Isaacs equations of the lower games with payoff given in (1.4) and (1.6), respectively, and that the upper value functions satisfy the above equations with \tilde{H} and $\tilde{\mathcal{H}}$ in place of H and \mathcal{H} .

We now introduce another notation: Let $\Omega \in \mathbf{R}^N$ be an open set and let $x \in \Omega$. For any nonanticipating function $\sigma(a, b) \leq \tau_x(a, b)$, where $\tau_x(a, b)$ denotes the first exit time from Ω , i.e., $\tau_x(a, b) = \inf \{t \geq 0 : y_x(t) \in \Omega^c\}$, and for all $a \in \mathcal{A}$, $b \in \mathcal{B}$, $u: \partial\Omega \rightarrow \mathbf{R}$, we denote

$$(1.11) \quad \begin{aligned} Q(\sigma, x, a, b, u) &:= \int_0^\sigma h(y_x(t), a(t), b(t)) \exp \left(- \int_0^t h(y_x(s), a(s), b(s)) ds \right) dt \\ &+ \exp \left(- \int_0^\sigma h(y_x(s), a(s), b(s)) ds \right) u(y_x(\sigma)) \\ &= 1 - \exp \left(- \int_0^\sigma h(y_x(t), a(t), b(t)) dt \right) (1 - u(y_x(\sigma))). \end{aligned}$$

The next result is a modification of Proposition 2.3 in [BS1] and generalizes similar statements in Evans and Ishii [EI] and in Lions and Souganidis [LSO].

PROPOSITION 1.4. Let $\Omega \subset \mathbf{R}^N$ be an open set, and let $\tau_x(a, b)$ denote the first exit time from Ω . If $u \in C(\Omega)$ is a bounded viscosity subsolution (respectively, supersolution) of

$$u(x) + \mathcal{H}(x, u(x), Du(x)) = 0 \quad \text{in } \Omega$$

then $u(x) \leq$ (respectively, \geq) $\inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} Q(\tau_x, x, \alpha[b], b, u)$. (Note that only values of u on $\partial\Omega$ appear in the right-hand side of the inequality.)

Proof. Assume that u is a subsolution. Given $\varepsilon > 0$, we consider the open set

$$\Omega_\varepsilon^\wedge := \{x \in \Omega: \text{dist}(x, \partial\Omega) > \varepsilon, |x| < 1/\varepsilon\}.$$

It is well known (largely through Sard's lemma) that, for each $\varepsilon > 0$, there exists, as $\varepsilon \rightarrow 0$, an increasing family of sets $\Omega_\varepsilon, \Omega_{\varepsilon/2}^\wedge \in \Omega_\varepsilon^\wedge$ such that $\partial\Omega_\varepsilon$ is a smooth manifold. Now we define the function

$$u^\varepsilon(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} Q(\tau_x^\varepsilon, x, \alpha[b], b, u),$$

where τ_x^ε is the first exit time from Ω_ε . By Ishii [I2] (see also Proposition 1.3), it follows that u^ε satisfies in the viscosity sense

$$v(x) + \mathcal{H}(x, v(x), Dv(x)) = 0 \quad \text{in } \Omega_\varepsilon,$$

$$v = u \quad \text{or} \quad v(x) + \mathcal{H}(x, v(x), Dv(x)) = 0 \quad \text{on } \partial\Omega_\varepsilon.$$

By the comparison Theorem 1.1 in [BS3], we can deduce that

$$u \leq (u^\varepsilon)_* \leq u^\varepsilon \quad \text{in } \Omega_\varepsilon.$$

Now the proof follows the arguments of Theorem 4.1 in [E1], to pass to the limit as $\varepsilon \rightarrow 0$ and reach the conclusion. \square

We introduce more notation: Let $r > 0$; then $B(x, r) := \{y \in \mathbf{R}^N: |x - y| < r\}$, and for $x \in \mathbf{R}^N$, $B(X, r) := \{x: \text{dist}(x, X) < r\}$.

DEFINITION 1.5. Let $\mathcal{T} \subset \mathbf{R}^N$ be a closed set. A vector $\nu \in \mathbf{R}^N$, $|\nu| = 1$ is said to be exterior normal to \mathcal{T} at $x \in \partial\mathcal{T}$ if there exists $\varepsilon > 0$ such that

$$B(x + \varepsilon\nu, \varepsilon) \cap \mathcal{T} = \emptyset.$$

We also denote $d(x) := \text{dist}(x, \mathcal{T})$, the distance function from the target. It is possible to compute explicitly the viscosity sub- and superdifferentials of the function d . This result is contained in the next proposition and will also motivate Definition 1.5.

PROPOSITION 1.6. Let $x \in \mathbf{R}^N \setminus \mathcal{T}$.

(i) Assume that there exists a unique $z \in \partial\mathcal{T}$ such that $d(x) = |x - z|$, then $D^-d(x) = \{(x - z)/|x - z|\}$. Otherwise $D^-d(x)$ is empty;

(ii) $D^+d(x) = \text{co} \{(x - z)/|x - z|: z \in \partial\mathcal{T}, d(x) = |x - z|\}$.

In particular, the set $\{z \in \partial\mathcal{T}: |x - z| = d(x)\}$ consists of just one point \bar{z} if and only if d is differentiable at x . In this case, we have $Dd(x) = (x - \bar{z})/|x - \bar{z}|$.

Proof. Statement (i) substantially follows from the fact that d is a viscosity solution of $|Dd(x)| = 1$ in $\mathbf{R}^N \setminus \mathcal{T}$. Statement (ii) is a consequence of Proposition 1 in Souganidis [So], Theorem 3I in Rockafellar [Ro], and Theorem 2.1 in Clarke [C]. \square

In the following, C will indicate a generic positive constant.

2. Comparison results for the free-boundary problem. This section concerns several comparison results, in local or global form, between the value functions of the differential game introduced in § 1 and continuous viscosity sub- or supersolutions of the corresponding Isaacs equations, assuming that they satisfy suitable boundary conditions. As a consequence of one of these results, we prove the existence of a continuous

viscosity solution to the Dirichlet problem (0.1), assuming the existence of only local sub- and supersolutions.

DEFINITION 2.0. Given an open set $\Omega \supset \mathcal{T}$ and a constant $U_0 \in \mathbf{R} \cup \{+\infty\}$, we say that a function $U \in C((\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T})$ satisfies the boundary condition (BC) if $U(x) < U_0$ in $(\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T}$ and

$$U(x) \rightarrow U_0 \quad \text{as } x \rightarrow x_0 \in \partial \Omega.$$

The first result concerns the upper value function.

THEOREM 2.1. Let $\Omega \supset \mathcal{T}$ be an open set and $U \in C((\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T})$ be bounded below, satisfying (BC) and

$$\tilde{H}(x, DU) \geq 0 \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U \geq g \quad \text{on } \partial \mathcal{T}$$

in the viscosity sense. Then $U \geq \tilde{V}$ in $(\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T}$ and $\Omega \subset \tilde{\mathcal{R}}(U_0)$.

Proof. Let $u(x) := \psi(U(x))$; then we can extend its definition so that $u \in C(\overline{\Omega \setminus \mathcal{T}})$, is bounded and satisfies in the viscosity sense the following inequality:

$$u(x) + \tilde{\mathcal{H}}(x, u(x), Du(x)) \geq 0 \quad \text{in } \Omega \setminus \mathcal{T}.$$

Therefore, by Proposition 1.4 applied to the upper Isaacs equation, it follows that

$$(2.0) \quad u(x) \geq \sup_{\beta \in \mathbf{I}^+} \inf_{a \in \mathcal{A}} Q(\tau_x, x, \alpha[b], b, u),$$

where τ_x is the first exit time from $\Omega \setminus \mathcal{T}$. Let $x \in \Omega$, then $u(x) < \psi(U_0)$, and we can choose $\varepsilon > 0$ satisfying the inequality $2\varepsilon < \psi(U_0) - u(x)$. Thus, by (2.0), for all β , we can select a_β such that

$$(2.1) \quad 1 > \psi(U_0) - \varepsilon \geq u(x) + \varepsilon \geq Q(\tau_x, x, a_\beta, \beta[a_\beta], u).$$

Inequality (2.1) implies that $\tau_x = t_x$ because, if $\tau_x(a, b) = +\infty$, then the right-hand side of (2.1) is equal to unity. On the other hand, if $y_x(\tau_x) \in \partial \Omega$ then we easily obtain

$$\psi(U_0) - \varepsilon \geq \psi\left(\int_0^{\tau_x} h \, dt + U_0\right) \geq \psi(\tau_x + U_0),$$

which is a contradiction. Thus, since $u(z) \geq \psi(g(z))$ at $z \in \partial \mathcal{T}$, by (2.1) we get $u(x) + \varepsilon \geq \psi(P(x, a_\beta, \beta[a_\beta]))$ and then $u(x) \geq \tilde{v}(x)$, which implies both the conclusions. \square

The proof of the counterpart of Theorem 2.1 for subsolutions is not so easy. We need first to prove the following lemma, which roughly states that for a fixed $x \in \mathbf{R}^N \setminus \mathcal{T}$, if we are given two nonanticipating functions such that $\sigma(a, b) \leq \tau(a, b)$, a strategy β_1 , and a control a_1 that are almost optimal for the value function \tilde{v} up to time σ , then we can modify the definitions of β_1 and a_1 in the interval $[\sigma, +\infty[$ so that they become almost optimal up to time τ .

LEMMA 2.2. Let $x \in \mathbf{R}^N \setminus \mathcal{T}$ and let σ_x, τ_x be nonanticipating functions such that $\sigma_x(a, b) \leq \tau_x(a, b)$ for all a, b . Assume that for all β_1 there exists a_1 , which verifies

$$(2.2) \quad Q(\sigma_x, x, a_1, \beta_1[a_1], \tilde{v}) < C.$$

If, for a given β_2 we define

$$\beta[a](t) = \begin{cases} \beta_1[a](t) & \text{if } t \in [0, \sigma(a, \beta_1[a])], \\ \beta_2[a(\cdot - \sigma)](t - \sigma) & \text{elsewhere,} \end{cases}$$

then there exists $a_\beta, a_\beta = a_1$ for $t \leq \sigma(a_1, \beta_1[a_1])$ such that $Q(\tau_x, x, a_\beta, \beta[a_\beta], \tilde{v}) < C$.

Proof. We apply the dynamic programming principle to $\tilde{v}(y_x(\sigma_x))$ in (2.2) with respect to the nonanticipating function $\rho(a, b) := \tau_x(a', b') - \sigma_x(a_1, b_1)$, where $b_1 = \beta_1[a_1]$ and $a'(t) = a_1(t)$, $b'(t) = b_1(t)$ if $t \leq \sigma_x(a_1, b_1)$, $a'(t) = a(t-s)$, $b'(t) = b(t-s)$ elsewhere. Then, for all β_2 , there exists a_2 such that (we drop the x in σ_x)

$$\int_0^\sigma h \exp\left(-\int_0^t h ds\right) dt + \exp\left(-\int_0^\sigma h dt\right) Q(\rho, y(\sigma), a_1, \beta_1[a_1], \tilde{v}) < C.$$

It is now sufficient to define

$$a_\beta(t) = \begin{cases} a_1(t) & \text{if } t \in [0, \sigma(a_1, \beta_1[a_1])], \\ a_2(t-\sigma) & \text{elsewhere} \end{cases}$$

and to apply an easy change of variables to obtain the result. \square

We now want to prove the comparison theorem.

THEOREM 2.3. *Let $\Omega \supset \mathcal{T}$ be an open set and $U \in C((\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T})$ be bounded below, satisfying (BC) and*

$$\begin{aligned} \tilde{H}(x, DU) &\leq 0 \quad \text{in } \Omega \setminus \mathcal{T}, \\ U &\leq g \quad \text{on } \partial \mathcal{T} \end{aligned}$$

in the viscosity sense. Then $U \leq \tilde{V}$ in $(\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T}$ and $\Omega \supset \tilde{\mathcal{R}}(U_0)$.

Proof. First step. We prove that $\tilde{\mathcal{R}}(U_0) \cap \partial \Omega = \emptyset$. To this end, we assume by contradiction that there exists $x \in \tilde{\mathcal{R}}(U_0) \cap \partial \Omega$. Fix $\varepsilon > 0$ such that $\tilde{v}(x) < \psi(U_0) - \varepsilon$, and observe that, if $\psi(P(x, a, b)) < \psi(U_0) - \varepsilon$, then by (1.2) and $g \geq G$, we can choose a constant $C_1 > 0$, independent of the choice of a and b such that $t_x(a, b) \leq C_1$, which implies by Gronwall's lemma that we can find $R > 0$ such that

$$|y_x(t)| \leq R \quad \text{for all } t \leq t_x.$$

Let $C_2 := \sup_{B(0, R) \times A \times B} |f(z, a, b)|$, $\|\psi(g)\|_R := \sup\{|\psi(g(x))|; x \in \partial \mathcal{T} \cap B(0, R)\}$, $0 < \eta < \min\{\varepsilon, \psi(U_0) - \|\psi(g)\|_R\}$. We now choose $\delta > 0$ such that $\text{dist}(z, \partial \Omega) \leq \delta$ and $z \in \Omega \cap B(0, R)$ imply

$$(2.3) \quad u(z) := \psi(U(z)) > \psi(U_0) - \eta > \|\psi(g)\|_R$$

and then $z \notin \partial \mathcal{T}$.

We now define $\sigma_x(a, b)$ as the first exit time of $y_x(\cdot; a, b)$ from $\mathbf{R}^N \setminus \Omega_\delta$, where $\Omega_\delta := \{x \in \Omega; \text{dist}(x, \partial \Omega) \geq \delta\}$. By the dynamic programming principle (Proposition 1.2), we get

$$\tilde{v}(x) = \sup_{\beta \in \Gamma} \inf_{a \in \mathcal{A}} \{Q(\sigma_x, x, a, \beta[a], \tilde{v})\},$$

and then, by the choice of ε , for all β_1 , we can find a_1 such that

$$(2.4) \quad Q(\sigma_x, x, a_1, \beta_1[a_1], \tilde{v}) < \psi(U_0) - \varepsilon$$

and, as a consequence,

$$\begin{aligned} \tilde{v}(y(\sigma)) &\leq 1 - \exp\left(-\int_0^\sigma h ds\right) (1 - \tilde{v}(y(\sigma))) \\ (2.5) \quad &= Q(\sigma_x, x, a_1, \beta_1[a_1], \tilde{v}) < \psi(U_0) - \varepsilon. \end{aligned}$$

We fix β_1 and observe that $z := y(\sigma) \in \partial\Omega_\delta$ and $\text{dist}(z, \partial\Omega) = \delta$. We again apply the dynamic programming principle to $\tilde{v}(z)$ with the nonanticipating function $\tau_z(a, b)$, indicating the first exit time from $\Omega \setminus \mathcal{T}$, and get

$$\hat{v}(z) = \sup_{\beta \in \Gamma} \inf_{a \in \mathcal{A}} \{Q(\tau_z, z, a, \beta[a], \tilde{v})\}.$$

By the previous formula, Lemma 2.2, and (2.4), we deduce that for all β_2 there exists a_2 such that, if we construct β and a_β as in the lemma (in which $\sigma_x + \tau_z$ plays the part of τ), then

$$(2.6) \quad Q(\sigma_x + \tau_z, x, a_\beta, \beta[a_\beta], \tilde{v}) < \psi(U_0) - \varepsilon$$

and, thus, since the running cost is positive,

$$(2.7) \quad Q(\tau_z, z, a_2, \beta_2[a_2], \tilde{v}) < \psi(U_0) - \varepsilon,$$

$$(2.8) \quad \psi(P(x, a_{\beta'}, \beta'[a_{\beta'}], u)) < \psi(U_0) - \varepsilon$$

for a suitable strategy β' and control $a_{\beta'}$ constructed modifying β, a_β in $[\sigma_x + \tau_x, +\infty[$, as in Lemma 2.2, where, in this case, t_x plays the part of τ and $\sigma_x + \tau_x$ plays the part of σ .

Observe now that the function u defined in (2.3) is bounded, can be extended to a continuous function in $\overline{\Omega \setminus \mathcal{T}}$, and satisfies in the viscosity sense

$$u(x') + \tilde{\mathcal{H}}(x', u(x'), Du(x')) \leq 0 \quad \text{in } \Omega \setminus \mathcal{T}.$$

Therefore, by Proposition 1.4 we have that

$$u(x') \leq \sup_{\beta \in \Gamma} \inf_{a \in \mathcal{A}} \{Q(\tau_{x'}, x', a, \beta[a], u)\} \quad \text{in } \Omega \setminus \mathcal{T},$$

where $\tau_{x'}(a, b)$ is the first exit time from $\Omega \setminus \mathcal{T}$. Now (2.3) and the previous formula imply that there exists $\tilde{\beta}$ such that

$$Q(\tau_z, z, a, \tilde{\beta}[a], u) > \psi(U_0) - \eta \quad \text{for all } a \in \mathcal{A}.$$

If $t_z(a, \tilde{\beta}[a]) = \tau_z(a, \tilde{\beta}[a])$ for some a , since $u \leq \psi(g)$ on $\partial\mathcal{T}$, we obtain

$$(2.9) \quad \psi(P(z, a, \tilde{\beta}[a])) > \psi(U_0) - \eta.$$

If instead $t_z > \tau_z$, then

$$(2.10) \quad \begin{aligned} Q(\tau_z, z, a, \tilde{\beta}[a], u) &= 1 - \exp\left(-\int_0^{\tau_z} h \, ds\right) (1 - u(y(\tau_z))) \\ &= \psi\left(\int_0^{\tau_z} h \, dt + U(y_x(\tau_z))\right) \geq \psi(\tau_z + U_0). \end{aligned}$$

Now we specialize $\beta_2 = \tilde{\beta}$, $a = a_2$, and observe that (2.7) contradicts (2.9). Therefore, we obtain $\tau_z < t_z$. By (2.7) and (2.10), we now obtain

$$(2.11) \quad \begin{aligned} \psi(U_0) - \tilde{v}(y(\tau_z)) &= u(y(\tau_z)) - \tilde{v}(y(\tau_z)) \\ &\geq \exp\left(-\int_0^{\tau_z} h \, ds\right) \left(u(y(\tau_z)) - \tilde{v}(y(\tau_z))\right) \\ &= Q(\tau_z, z, a_2, \tilde{\beta}[a_2], u) - Q(\tau_z, z, a_2, \tilde{\beta}[a_2], \tilde{v}) \\ &\geq \psi(\tau_z + U_0) - \psi(U_0) + \varepsilon. \end{aligned}$$

By (2.8) we also have $\delta \leq |y(\tau_z) - z| \leq \int_0^{\tau_z} |f| ds \leq C_2 \tau_z$ and then $\tau_z \geq \delta / C_2$, which, in view of (2.11), implies

$$\tilde{v}(y(\tau_z)) \leq \psi(U_0) - \varepsilon - (\psi(\delta / C_2 + U_0) - \psi(U_0)).$$

Therefore the point $x_1 := y_z(\tau_z) = y_x(\sigma_x + \tau_z) \in \partial\Omega \cap \tilde{\mathcal{R}}(U_0)$, lies in $B(0, R)$ by (2.8), and $\tilde{v}(x_1) < \psi(U_0) - \varepsilon - \rho$, where the positive constant ρ depends on δ .

We now repeat the procedure above, starting from $x_1 = y_x(\sigma_x + \tau_z)$, and use Lemma 2.2 and the fact that the trajectory leading from x to x_1 can be extended to a trajectory leading to the target whose payoff is $\leq \psi(U_0) - \varepsilon$ (i.e., $t_x \leq C_1$) by (2.6) and (2.10). Then we can find another point $x_2 \in \partial\Omega \cap \tilde{\mathcal{R}}(U_0)$ on a trajectory performing the same property, which is therefore completely contained in the ball $B(0, R)$. Thus, the value δ does not change, the decrement ρ is constant, and $\tilde{v}(x_2) < \psi(U_0) - \varepsilon - 2\rho$. We proceed in this way, but since \tilde{v} is bounded, after a finite number of steps we find the required contradiction.

Second step. Let $x \in \tilde{\mathcal{R}}(U_0)$; we apply the dynamic-programming principle and get

$$\tilde{v}(x) = \sup_{\beta \in \Gamma} \inf_{a \in \mathcal{A}} \{Q(\tau_x, x, a, \beta[a], \tilde{v})\},$$

where τ_x is the first exit time from $\Omega \setminus \mathcal{T}$ if $x \in \Omega \setminus \mathcal{T}$ or the exit time from $\mathbf{R}^N \setminus \bar{\Omega}$ if $x \in \mathbf{R}^N \setminus \bar{\Omega}$.

We choose $\varepsilon > 0$ such that $\tilde{v}(x) + \varepsilon < \psi(U_0) \leq 1$; then, for all β , there exists a_β such that

$$Q(\tau_x, x, a_\beta, \beta[a_\beta], \tilde{v}) < \tilde{v}(x) + \varepsilon,$$

and therefore we conclude that $\tau_x \neq +\infty$ and then, since $\tilde{v}(y_x(\tau_x)) \leq Q(\tau_x, x, a_\beta, \beta[a_\beta], \tilde{v})$, that $y(\tau_x) \in \tilde{\mathcal{R}}(U_0)$ which implies $y(\tau_x) \notin \partial\Omega$. This gives a contradiction for $x \in \mathbf{R}^N \setminus \bar{\Omega}$ and then $\tilde{\mathcal{R}}(U_0) \subset \Omega$. For $x \in \Omega$, we instead obtain $\tau_x = t_x$. Therefore, since $u \leq \psi(g)$ on $\partial\mathcal{T}$, we get $Q(\tau_x, x, a_\beta, \beta[a_\beta], u) < \tilde{v}(x) + \varepsilon$, which implies, by Proposition 1.4, that $u \leq \tilde{v}$ in $\tilde{\mathcal{R}}(U_0)$. Now it is obvious by the definitions that the same inequality holds in $\Omega \setminus \mathcal{T}$. \square

The next uniqueness result is a consequence of both Theorems 2.1 and 2.3.

COROLLARY 2.4 (uniqueness for the free-boundary problem). *Assume that there exists one pair (Ω, U) such that $\Omega \supset \mathcal{T}$ is open, $U \in C((\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T})$ is bounded below, satisfying*

$$\tilde{H}(x, DU) = 0 \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U = g \quad \text{on } \partial\mathcal{T}$$

in the viscosity sense and (BC). Then $\Omega = \tilde{\mathcal{R}}(U_0)$ and $U = \tilde{V}$ in $(\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T}$.

We now complete the framework by stating the corresponding propositions for the lower value.

THEOREM 2.5. *Let $\Omega \supset \mathcal{T}$ be an open set and $U \in C((\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T})$ be bounded below, satisfying*

$$H(x, DU) \geq 0 \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U \geq g \quad \text{on } \partial\mathcal{T}$$

in the viscosity sense and (BC). Then $U \geq V$ in $(\Omega \setminus \mathcal{T}) \cup \partial\mathcal{T}$ and $\Omega \subset \mathcal{R}(U_0)$.

The proof of the previous result follows that of Theorem 2.1. The proof of the next theorem instead presents some relevant differences from the proof of Theorem 2.3 and is the same as the proof of Theorem 3.1 in [BS1].

THEOREM 2.6. *Let $\Omega \supset \mathcal{T}$ be an open set and $U \in C((\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T})$ be bounded below, satisfying*

$$H(x, DU) \leq 0 \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U \leq g \quad \text{on } \partial \mathcal{T}$$

in the viscosity sense and (BC). Then $U \leq V$ in $(\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T}$ and $\Omega \supset \mathcal{R}(U_0)$.

COROLLARY 2.7. *Assume that there exists one pair (Ω, U) such that $\Omega \supset \mathcal{T}$ is open, $U \in C((\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T})$ is bounded below, satisfying*

$$H(x, DU) = 0 \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U = g \quad \text{on } \partial \mathcal{T}$$

in the viscosity sense and (BC). Then $\Omega = \mathcal{R}(U_0)$ and $U = V$ in $(\Omega \setminus \mathcal{T}) \cup \partial \mathcal{T}$.

COROLLARY 2.8 (comparison of value functions and existence of value). *Assume that either V or \tilde{V} is continuous at the points of $\partial \mathcal{T}$. Then $\tilde{\mathcal{R}} \subset \mathcal{R}$ and $V(x) \leq \tilde{V}(x)$ for all $x \in \tilde{\mathcal{R}}$. If, moreover, $H = \tilde{H}$, then $\tilde{\mathcal{R}} = \mathcal{R}$ and $V = \tilde{V}$.*

Proof. We first observe that $H \geq \tilde{H}$. Moreover, by Theorem 6.1 in [BS1], if V is continuous at the points of $\partial \mathcal{T}$, then it is continuous in \mathcal{R} , \mathcal{R} is open, and the pair (\mathcal{R}, V) satisfies the boundary-value problem (0.1). The corresponding result holds for the upper value \tilde{V} . Therefore, it is sufficient to apply Theorem 2.3 or Theorem 2.5, respectively, if V or \tilde{V} is continuous at the points of $\partial \mathcal{T}$. If, moreover, $H = \tilde{H}$, we can apply Corollary 2.4 or Corollary 2.7, respectively. \square

We now turn to local uniqueness results. We give here the following statement, whose proof is the same as the proof of Theorem 4.1 in [BS1], but uses Proposition 1.4 instead of Proposition 2.3 in [BS2] and also holds for the upper Isaacs equation with obvious changes.

THEOREM 2.9. *Let $x_0 \in \partial \mathcal{T}$, $r > 0$, and $g \equiv 0$. If $U \in C(\overline{B(x_0, r) \setminus \mathcal{T}})$ is a nonnegative viscosity subsolution (respectively, supersolution) of*

$$H(x, DU) = 0 \quad \text{in } B(x_0, r) \setminus \mathcal{T}$$

and $U = 0$ on $\partial \mathcal{T} \cap B(x_0, r)$, then there exists $r' \leq r$ such that $U(x) \leq V(x)$ (respectively, $U(x) \geq V(x)$) for all $x \in B(x_0, r') \setminus \mathcal{T}$.

Remark 2.10. The previous result still holds if we have a general final cost g on $\partial \mathcal{T}$. In this case, we need to assume, instead of requiring U to be nonnegative, the following conditions:

$$(2.12) \quad U(x_0) < r/M_r + \min_{\partial(B(x_0, r) \setminus \mathcal{T})} U,$$

where $M_r := \max \{|f(x, a, b)| : x \in B(x_0, r), a \in A, b \in B\}$, and, if U is subsolution,

$$(2.13) \quad g(x) \geq \min_{\partial(B(x_0, r) \setminus \mathcal{T})} U \quad \text{for all } x \in \partial \mathcal{T}.$$

A different formulation of local comparison theorems can be found in Theorem 3.5. It is now easy to prove the following existence result for problem (0.1), which we state for only the lower Isaacs equation.

THEOREM 2.11. *Assume that for all $x_0 \in \partial\mathcal{T}$ there exist $r > 0$ and two functions $U_1, U_2 \in C(\overline{B(x_0, r)} \setminus \mathcal{T})$, respectively, viscosity super- and subsolutions of the Dirichlet problem*

$$\begin{aligned} H(x, DU) &= 0 \quad \text{in } B(x_0, r) \setminus \mathcal{T}, \\ U &= g \quad \text{on } \partial\mathcal{T} \cap B(x_0, r). \end{aligned}$$

If, moreover, U_1, U_2 satisfy (2.12), U_2 also verifies (2.13) and $U_1(x_0) = U_2(x_0) = g(x_0)$, then V is continuous in $(\mathcal{R} \setminus \mathcal{T}) \cup \partial\mathcal{T}$, and the pair (\mathcal{R}, V) solves the free-boundary problem (0.1).

Proof. By Theorem 2.9 and Remark 2.10, it follows that, for all $x_0 \in \partial\mathcal{T}$ and for some $r'(x_0) > 0$,

$$U_2(x) \leq V(x) \leq U_1(x) \quad \text{in } B(x_0, r') \setminus \mathcal{T}.$$

Then V is continuous at $x_0 \in \partial\mathcal{T}$. By Theorem 6.1 in [BS1], this is enough to conclude the proof. \square

3. Pursuit and evasion problems. In this section, we study the problems of terminability and evadability for a dynamical system with two competitive controls. We first introduce the following definitions.

DEFINITION 3.0. The differential game is stable if for all neighborhoods \mathcal{U} of \mathcal{T} we can find a neighborhood \mathcal{V} of \mathcal{T} which verifies the following condition: For all $x \in \mathcal{V}$, there is $\alpha \in \Delta$ such that $y_x(t) \in \mathcal{U}$ for all $b \in \mathcal{B}$ and $t \in [0, t_x]$.

DEFINITION 3.1. The differential game is locally asymptotically terminable if there exists an open set $\Omega \supset \mathcal{T}$ such that, for all $x \in \Omega \setminus \mathcal{T}$, there is $\alpha \in \Delta$ that verifies $t_x(\alpha[b], b) < +\infty$ or $\lim_{t \rightarrow +\infty} d(y_x(t)) = 0$ for all $b \in \mathcal{B}$.

DEFINITION 3.2. The differential game is locally terminable if there exists an open set $\Omega \supset \mathcal{T}$ such that $\Omega \subset \mathcal{R}$, i.e., for all $x \in \Omega \setminus \mathcal{T}$, there are $C > 0$ and $\alpha \in \Delta$ that satisfy $t_x(\alpha[b], b) \leq C$ for all $b \in \mathcal{B}$.

The previous notions generalize the usual ones for dynamical systems and have been used in control theory and in differential games by previous authors (see, e.g., Lee and Markus [LM], Yong [Y1], and the references therein). We note that, in the case of control systems, the asymptotical terminability (controllability) is, in general, only a necessary condition for the stabilization of the system, whose definition requires the existence of a feedback control. For the relationships between the two approaches, we refer to Brockett [Br]. If, in the definitions above, the set Ω is all of \mathbf{R}^N , we say that the game is globally asymptotically terminable or, respectively, globally terminable. This problem is obviously related to the properties of the function T and its Hamiltonian H .

We also want to study the counterpart of the terminability problem, that is, the evadability of a differential game from a closed set \mathcal{T} . This is a much-studied topic in the literature (see Yong [Y2] and the references therein). We introduce the following two definitions.

DEFINITION 3.3. The game is evadable if, for all $x \in \mathbf{R}^N \setminus \mathcal{T}$, there exists $\beta \in \Gamma$ such that $d(y_x(t; a, \beta[a])) > 0$ for all $a \in \mathcal{A}$ and $t \geq 0$.

DEFINITION 3.4. The game is strictly evadable if, for all $x \in \mathbf{R}^N \setminus \mathcal{T}$, there exist $\delta > 0$ and $\beta \in \Gamma$ such that $d(y_x(t; a, \beta[a])) \geq \delta$ for all $a \in \mathcal{A}$ and $t \geq 0$.

This problem is related to the properties of the function \tilde{T} and its Hamiltonian \tilde{H} . For example, it is clear that a necessary, but not sufficient, condition for the evadability is $\tilde{\mathcal{R}} = \mathcal{T}$ or, similarly, $\tilde{T}(x) = +\infty$ for all $x \in \mathbf{R}^N \setminus \mathcal{T}$. To escape from this apparent problem in the study of the evasion game by dynamic-programming methods, we need the change of variables in (1.5).

3.1. Pursuit problem. We start providing sufficient conditions for terminability by assuming the existence of a suitable Lyapunov function. This function will be assumed continuous, and the proofs will use the comparison theorems for viscosity solutions of the Isaacs equations proved in § 2.

THEOREM 3.5. *Let $\Omega \supset \mathcal{T}$ be an open set. Assume that there exist $\delta > 0$ and $U \in C(\overline{\Omega \setminus \mathcal{T}})$, bounded below, that satisfy in the viscosity sense*

$$\min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot DU(x)\} \geq \delta \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U = 0 \quad \text{on } \partial \mathcal{T},$$

and such that $\inf_{\partial \Omega} U > 0$. Consider the open set $\Omega' := \{x: U(x) < \inf_{\partial \Omega} U\}$; then the game is terminable in Ω' , and, moreover, we have the estimate $T(x) \leq U(x)/\delta$ for all $x \in \Omega' \setminus \mathcal{T}$. Thus the game is stable.

Proof. Define $W(x) := U(x)/\delta$; then W satisfies in the viscosity sense the following problem:

$$H(x, DW(x)) \geq 0 \quad \text{in } \Omega' \setminus \mathcal{T},$$

$$W = 0 \quad \text{on } \partial \mathcal{T},$$

$$W(x) = \inf_{\partial \Omega} W \quad \text{on } \partial \Omega',$$

where H is defined in (1.7) with $h \equiv 1$ and $W(x) < \inf_{\partial \Omega} W$ for $x \in \Omega'$. If we now apply Theorem 2.5, we get the local terminability. The estimate $T(x) \leq U(x)/\delta$ implies that T is continuous on $\partial \mathcal{T}$ if $U = 0$ on $\partial \mathcal{T}$ and immediately gives the stability of the game. In fact, given an open neighborhood \mathcal{U} of \mathcal{T} , let $x_0 \in \partial \mathcal{T}$, $r > 0$ such that $B(x_0, r) \in \mathcal{U}$ and $M := \max_{B(x_0, r) \times A \times B} |f(x, a, b)|$. We select $0 < \varepsilon \leq r/2M$ and r' such that $r' \leq r/2$ and $T(x) < \varepsilon$ for all $x \in B(x_0, r')$. By definition, given $x \in B(x_0, r')$, there is $\alpha \in \Delta$ such that, for all $b \in \mathcal{B}$, we have $t_x < \varepsilon$ and then

$$|y_x(t) - x_0| \leq tM \leq r/2 \quad \text{for all } t \in (0, t_x);$$

that is, $y_x(t) \in B(x_0, r)$ for $t \in (0, t_x)$. \square

In view of Theorem 2.9, by using a similar proof, we can also give a local version of the previous theorem.

THEOREM 3.6. *Let $x_0 \in \partial \mathcal{T}$, $r > 0$ and $U \in C(\overline{B(x_0, r) \setminus \mathcal{T}})$ be a nonnegative function that satisfies in the viscosity sense*

$$\min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot DU(x)\} \geq \delta \quad \text{in } B(x_0, r) \setminus \mathcal{T},$$

$$U = 0 \quad \text{on } \partial \mathcal{T};$$

then there exists $r' \leq r$ such that $T(x) \leq U(x)/\delta$ for all $x \in B(x_0, r') \setminus \mathcal{T}$. Therefore, the game is stable and terminable in $B(x_0, r') \setminus \mathcal{T}$.

We now want to specialize the above results by giving explicit conditions on the vector field f at the points of the boundary of the target \mathcal{T} , which, we recall, is a general closed set, and we want to prove that, under such conditions, the distance function $d(\cdot)$ is the required Lyapunov function.

COROLLARY 3.7. *Let $x_0 \in \partial \mathcal{T}$. Assume that the following condition holds: There exist $\delta, r > 0$ such that*

$$(3.1) \quad F(x, \nu) := \max_{b \in B} \min_{a \in A} \{f(x_0, a, b) \cdot \nu\} \leq -\delta$$

for all exterior normal vectors ν at $x \in B(x_0, r) \cap \partial\mathcal{T}$. Then, for $\eta < \delta$, there exists $\varepsilon > 0$ such that $T(x) \leq d(x)/\eta$ for all $x \in B(x_0, \varepsilon) \setminus \mathcal{T}$. Moreover, T is locally Lipschitz continuous in a neighborhood of x_0 .

Proof. Let $\eta < \delta$. We define the set $S := \text{cl} \{ \nu : \nu \text{ is exterior normal at } x \in B(x_0, r) \cap \partial\mathcal{T} \}$, which is compact. Then, for all $\nu \in S$, we have $F(x_0, \nu) < -\eta$. We can therefore find $\varepsilon(\nu) > 0$ such that

$$(3.2) \quad F(x, \mu) < -\eta$$

for all $x \in B(x_0, \varepsilon(\nu))$ and $\mu \in S \cap B(\nu, \varepsilon(\nu))$. Then, if we extract a finite subcovering of S from the open covering $\{B(\nu, \varepsilon(\nu)) : \nu \in S\}$, determined by ν_1, \dots, ν_h , and we set $2\varepsilon := \min \{\varepsilon(\nu_i)\} \wedge r$, then (3.2) holds for all $x \in B(x_0, 2\varepsilon)$ and $\mu \in S$. Now let $x \in B(x_0, \varepsilon) \setminus \mathcal{T}$ and $p \in D^-d(x)$; by Proposition 1.6, $p = (x - z)/|x - z|$, where $z \in \partial\mathcal{T}$ is the unique point in \mathcal{T} such that $d(x) = |x - z|$ and thus $p \in S$. Therefore, we obtain

$$\min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot Dd(x)\} \geq \eta \quad \text{in } B(x_0, \varepsilon) \setminus \mathcal{T}$$

in the viscosity sense. If we now apply Theorem 3.6 to the function d , we obtain the requested estimate. As for the Lipschitz continuity of T , this is a standard result whenever the estimate with the distance function holds (see, e.g., [BS1] or [S1]). \square

Remark 3.8. Condition (3.1) is established for a general closed set \mathcal{T} . It is not difficult to verify that if \mathcal{T} is a closed C^2 manifold, then the set of exterior normal vectors at x_0 in the sense of Definition 1.5 coincides with the set of unit vectors of the normal space to \mathcal{T} at x_0 , which we indicate by $N_{x_0}(\mathcal{T})$. In this case, by the regularity of \mathcal{T} condition (3.1) is equivalent to

$$F(x_0, n) < 0 \quad \text{for all } n \in N_{x_0}(\mathcal{T}).$$

An analogous statement holds if \mathcal{T} is a C^2 manifold with boundary, but, in this case, if $x_0 \in \partial_{\text{rel}}(\mathcal{T})$, the set to be taken into account is $\{n \in N_{x_0}(\partial_{\text{rel}}(\mathcal{T})) : n \cdot n(x_0) \leq 0\}$, where $n(x_0)$ is the inner normal vector to \mathcal{T} at x_0 in the sense of manifolds.

If \mathcal{T} is a C^1 manifold (with boundary), the previous condition still gives the requested regularity of T , but, in this case, according to Definition 1.5, we could find points $x \in \partial\mathcal{T}$ at which the set of exterior normal vectors is empty; therefore, in general, we can only state that it is contained in the set of unit vectors of $N_{x_0}(\mathcal{T})$ (respectively of $\{n \in N_{x_0}(\partial_{\text{rel}}(\mathcal{T})) : n \cdot n(x_0) \leq 0\}$ if $x_0 \in \partial_{\text{rel}}(\mathcal{T})$). Corollary 3.7 generalizes to differential games and to general closed targets a result of local Lipschitz continuity of the minimum time function in control theory, which was proved by the author in [S1] by using different techniques for the case where \mathcal{T} is a C^1 manifold with boundary and the classical result of Petrov [P], in which $\mathcal{T} = \{0\}$. We should also note that (3.1) is a very general sufficient condition for the local Lipschitz continuity of T around x_0 . In fact, if \mathcal{T} is the closure of an open set, (3.1) is also necessary (see [BS1]).

In the theory of geometric local controllability, many sufficient conditions for the local Lipschitz and Hölder continuity of the minimum time function have been studied for the case where $\mathcal{T} = \{0\}$ or is a smooth manifold (see [S1], Stefani [St], and the references therein). Such conditions usually concern the Lie algebra generated by the vector field f on $\partial\mathcal{T}$. The next result gives a sufficient condition for local Hölder continuity of T in differential games, uses partial differential equation methods, and requires an assumption that concerns the field f in a neighborhood of \mathcal{T} . At the present time, we do not know which are the precise relationships between the two different approaches.

COROLLARY 3.9. *Let $x_0 \in \partial\mathcal{T}$, and assume that there exist $0 < \alpha < 1$, $C, r > 0$ such that*

$$(3.3) \quad \min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot Dd(x)\} \geq Cd^{1-\alpha}(x) \quad \text{in } B(x_0, r) \setminus \mathcal{T}$$

in the viscosity sense. Then there exists $r' \leq r$ such that $T(x) \leq d^\alpha(x)/(C\alpha)$ for all $x \in B(x_0, r') \setminus \mathcal{T}$. Moreover, T is locally Hölder continuous with exponent α in a neighborhood of x_0 .

Proof. We first note that condition (3.3) can be rewritten as was done in Corollary 3.7, as a condition on the exterior normal vectors at points in $B(x_0, 2r) \cap \partial\mathcal{T}$ because of the representation of the subdifferential of $d(\cdot)$ given in Proposition 1.6. We now observe that, by means of an easy calculation and the definition of subdifferential, we can recover the following equality between sets:

$$D^-d^\alpha(x) = \alpha d^{\alpha-1}(x) D^-d(x).$$

This fact and (3.3) immediately give that the function $U(x) := d^\alpha(x)/(\alpha C)$ satisfies the conditions of Theorem 2.9, from which we obtain the conclusion. \square

We now turn to the study of stability and local asymptotical terminability of a pursuit game and first prove a lemma that relates the problem of stability to the study of particular level sets.

LEMMA 3.10. *Let $h: \mathbf{R}^N \setminus \mathcal{T} \rightarrow \mathbf{R}$ be a positive continuous function and*

$$W(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \int_0^{t_x} h(y_x(t)) dt,$$

then, for $x \in \mathbf{R}^N \setminus \mathcal{T}$ each $\varepsilon > 0$, there is $\alpha \in \Delta$ such that, for all $b \in \mathcal{B}$, we have $y_x(t) \in \{z: W(z) < W(x) + \varepsilon\}$ for all $t \in [0, t_x]$.

Proof. Let $\varepsilon > 0$, then by definition we can choose $\alpha \in \Delta$ such that

$$\int_0^{t_x} h(y_x(s)) ds < W(x) + \varepsilon \quad \text{for all } b \in \mathcal{B}.$$

Let $\bar{b} \in \mathcal{B}$ and $t \in (0, t_x)$, then, with obvious definitions of controls and strategies,

$$\int_0^t h(y_x(s)) ds + \int_0^{t_{y_x(t)}} h(y_{y_x(t)}(s)) ds < W(x) + \varepsilon$$

and then immediately $W(y_x(t)) < W(x) + \varepsilon$. \square

THEOREM 3.11. *Let $r > 0$ and $\Omega \supset B(\mathcal{T}, r)$ be an open set. Suppose that there exists a function $U \in C(\overline{\Omega \setminus \mathcal{T}})$, bounded below, which satisfies in the viscosity sense*

$$\min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot DU(x)\} \geq \mu(d(x)) \quad \text{in } \Omega \setminus \mathcal{T},$$

$$U = U_0 \quad \text{on } \partial\Omega,$$

where μ is a continuous, nonnegative real function, $\mu(t) = 0$ only if $t = 0$, and $\liminf_{t \rightarrow +\infty} \mu(t) > 0$. Assume that $U(x) < U_0$ if $x \in \Omega \setminus \mathcal{T}$ and that $|f| \leq M$ in $\partial\mathcal{T} \times A \times B$, then the game is locally asymptotically terminable. If, moreover, the level sets $\{x: U(x) < \varepsilon\}$ are a basis of the neighborhoods of \mathcal{T} (therefore, U is constant on $\partial\mathcal{T}$), then the game is also stable.

Proof. First, we assume that $U \geq 0$; otherwise, we will consider the function $U - \inf_{\Omega \setminus \mathcal{T}} U$. Let $x_0 \in \Omega \setminus \mathcal{T}$ and $\varepsilon < d(x_0) \wedge r$ such that $\Omega \supset B(\mathcal{T}, \varepsilon)$. We define t_x^ε as

the first exit time from $\mathbf{R}^N \setminus \overline{B(\mathcal{T}, \varepsilon)}$. Then U satisfies in the viscosity sense the following Dirichlet problem, where g_ε denotes the restriction of U on $\partial B(\mathcal{T}, \varepsilon)$:

$$\min_{b \in B} \max_{a \in A} \{-f(x, a, b) \cdot DU(x) - \mu(d(x))\} \geq 0 \quad \text{in } \Omega \setminus B(\mathcal{T}, \varepsilon),$$

$$U = g_\varepsilon \quad \text{on } \partial B(\mathcal{T}, \varepsilon),$$

$$U = U_0 \quad \text{on } \partial \Omega.$$

The usual solution of the previous problem is the value function

$$V_\varepsilon(x) := \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \left\{ \int_0^{t_x^\varepsilon} \mu(d(y_x(t))) dt + g_\varepsilon(y_x(t_x^\varepsilon)) \right\}.$$

Therefore, since $\mu(d(x)) \geq \inf_{t \geq \varepsilon} \mu(t) > 0$ in $\Omega \setminus B(\mathcal{T}, \varepsilon)$, we can apply Theorem 2.5 and state that $V_\varepsilon(x) \leq U(x)$ for all $x \in \Omega \setminus B(\mathcal{T}, \varepsilon)$.

Now we set $\varepsilon_j := \varepsilon/2^j$, $E_0 := \Omega \setminus B(\mathcal{T}, \varepsilon)$ and $E_j := \overline{B(\mathcal{T}, \varepsilon_{j-1})} \setminus B(\mathcal{T}, \varepsilon_j)$ for $j \in \mathbf{N}$. Let $\eta > 0$ and observe that, by the definition of V_{ε_j} and the inequality $V_{\varepsilon_j} \leq U$, for all $x \in E_j$ there exists $\alpha_x \in \Delta$ such that

$$\int_0^{t_x^{\varepsilon_j}} \mu(d(y(t))) dt + U(y_x(t_x^{\varepsilon_j})) \leq U(x) + \eta/2^{j+1} \quad \text{for all } b \in \mathcal{B}.$$

We observe that this implies that $t_x^{\varepsilon_j} < +\infty$. Therefore, we choose $\bar{b} \in \mathcal{B}$ and denote $\alpha_0 = \alpha_{x_0}$, $b_0 = \bar{b}$, $x_1 = y(t_0)$, $t_0 = t_{x_0}^\varepsilon$. Then we have

$$\int_0^{t_0} \mu(d(y_{x_0}(t))) dt + U(x_1) \leq U(x_0) + \eta/2, \quad x_1 \in E_1.$$

In the general case, let $\sigma_{j-1} = t_0 + \dots, t_{j-1}$, $\alpha_j = \alpha_{x_j}$, $b_j(t) = \bar{b}(t + \sigma_{j-1})$, $t_j = t_{x_j}^{\varepsilon_j}$; then

$$(3.4) \quad \int_0^{t_j} \mu(d(y_{x_j}(t))) dt + U(x_{j+1}) \leq U(x_j) + \eta/2^{j+1}, \quad x_{j+1} \in E_{j+1}.$$

Thus, if we define

$$\bar{a}(t) := \begin{cases} \alpha_0[b_0](t) & \text{if } t \in [0, \sigma_0], \\ \alpha_1[b_1](t - \sigma_0) & \text{if } t \in [\sigma_0, \sigma_1] \\ \dots \end{cases}$$

and the nonanticipating strategy $\bar{\alpha}: \mathcal{B} \rightarrow \mathcal{A}$ by means of the position $\bar{\alpha}[\bar{b}] = \bar{a}$, then, by applying recursively (3.4) and since U is nonnegative, we have that, for such $\bar{\alpha}$ and all $b \in \mathcal{B}$,

$$\liminf_{t \rightarrow t_{x_0}(\bar{\alpha}[b], b)} d(y(t)) = 0 \quad \text{and} \quad \int_0^{t_{x_0}} \mu(d(y(t))) dt \leq U(x_0) + \eta.$$

This implies, on the one hand, the estimate

$$(3.5) \quad \inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \int_0^{t_{x_0}} \mu(d(y(t))) dt \leq U(x_0) \quad \text{for all } x_0 \in \Omega \setminus \mathcal{T}$$

and, on the other hand, that the game is locally asymptotically terminable. In fact, if $t_{x_0} = +\infty$ and

$$\limsup_{t \rightarrow t_{x_0}(\bar{\alpha}[b], b)} d(y(t)) = \gamma > 0,$$

then, by using the notations above, for $\varepsilon_j < \gamma$ we can find an increasing sequence of positive real numbers $\{s_n: n \in \mathbb{N}\}$, such that, setting $y_n = y(s_n)$, we have $d(y_{2n}) = \varepsilon_j$, $d(y_{2n+1}) = \varepsilon_{j+1}$, and $\varepsilon_{j+1} < d(y(t)) < \varepsilon_j$ for $t \in (s_{2n}, s_{2n+1})$. Therefore, by the assumptions on the vector field, we obtain

$$\varepsilon_{j+1} \leq |y_{2n} - y_{2n+1}| \leq \int_{s_{2n}}^{s_{2n+1}} |f(y)| dt \leq (M + L\varepsilon_{j+1})|s_{2n} - s_{2n+1}|$$

and then

$$\begin{aligned} U(x_0) + \eta &\geq \int_0^{t_{x_0}} \mu(d(x)) dx \geq \sum_n \int_{s_{2n}}^{s_{2n+1}} \mu(d(y)) dt \\ &\geq \sum_n \inf_{t \geq \varepsilon_{j+1}} \mu(t)|s_{2n} - s_{2n+1}| \geq \sum_n \inf_{t \geq \varepsilon_{j+1}} \mu(t)\varepsilon_{j+1}/(M + L) = +\infty, \end{aligned}$$

which gives a contradiction. The last claim is a consequence of (3.5) and Lemma 3.10. \square

Remark 3.12. Note that inequality (3.5) in the proof of Theorem 3.11 holds without the supplementary assumption on the vector field. Now we extend to differential games the definition of L^p stability, which was introduced by Strauss [Sr] for dynamical systems and we state that a game is locally L^p terminable if there exists an open set $\Omega \in \mathcal{T}$ such that

$$\inf_{\alpha \in \Delta} \sup_{b \in \mathcal{B}} \int_0^{t_x} d^p(y_x(t; \alpha[b], b)) dt < +\infty \quad \text{for all } x \in \Omega \setminus \mathcal{T}.$$

By (3.5) we therefore obtain that, if $\mu(s) = cs^p$ for $c, p > 0$, then the game is L^p terminable.

Estimate (3.5) also holds independent interest. It can be seen as a comparison result between the value function of a generalized pursuit-evasion game whose running cost becomes zero on the target and a supersolution of the corresponding Isaacs equation. In fact, if the supersolution U also satisfies $U = 0$ on $\partial\mathcal{T}$, then (3.4) implies (3.5) if either U is nonnegative or it takes up the boundary data on $\partial\mathcal{T}$ uniformly. It is easy to verify that, in the general case of § 2, we need the following assumption on the sign of the running cost:

$$h(x, a, b) \geq C_\varepsilon > 0 \quad \text{for all } \varepsilon > 0, x \in \mathbf{R}^N \setminus B(\mathcal{T}, \varepsilon), a, b.$$

The corresponding statement holds for subsolutions as well.

Remark 3.13. All the previous results also provide sufficient conditions of global and global asymptotic terminability when $\Omega = \mathbf{R}^N$. In this case, the conditions at the points of $\partial\Omega$ obviously disappear. We finally observe that the choice of the distance function in the statement is only for simplicity.

3.2. Evasion problem. We now apply a similar method to the study of the counterpart of the pursuit problem.

THEOREM 3.14. *Let $\Omega \supset \mathcal{T}$ be an open set. Assume that there exists $U \in C(\overline{\Omega \setminus \mathcal{T}})$, which satisfies in the viscosity sense*

$$\max_{a \in A} \min_{b \in B} \{-f(x, a, b) \cdot DU(x)\} \leq 0 \quad \text{in } \Omega \setminus \mathcal{T}.$$

If, moreover, $U(x) = 0$ for $x \in \partial\mathcal{T}$, $U > 0$ in $\Omega \setminus \mathcal{T}$, and $c := \inf_{\partial\Omega} U > 0$, then the game is evadable.

Proof. We consider the set $\Omega' := \{x \in \Omega : U(x) < c\}$ and observe that $U(x) = c$ for all $x \in \partial\Omega'$. We first consider the case where $x_0 \in \Omega'$, therefore, we can choose suitable ε, σ such that $0 \leq \varepsilon < U(x_0) < \sigma \leq c$, and prove that the game is evadable at x_0 . We define $\tilde{U} := U - \varepsilon$ and observe that if we set, for $\eta > 0$, $\Omega_\eta := \{x \in \Omega : U(x) < \eta\}$, then \tilde{U} satisfies in the viscosity sense

$$(3.6) \quad \begin{aligned} \max_{a \in A} \min_{b \in B} \{-f(x, a, b) \cdot D\tilde{U}(x)\} &\leq 0 \quad \text{in } \Omega_\sigma \setminus \Omega_\varepsilon, \\ \tilde{U} &= 0 \quad \text{on } \partial\Omega_\varepsilon, \quad \tilde{U}(x) = \sigma - \varepsilon \quad \text{on } \partial\Omega_\sigma, \end{aligned}$$

and $\tilde{U} < \sigma - \varepsilon$ in $\Omega_\sigma \setminus \Omega_\varepsilon$. By a simple calculation, it is easy to verify that the differential inequality in system (3.6) is also satisfied by $\tilde{u} = \psi(\tilde{U})$ (ψ is defined in (1.5)) with boundary conditions $\tilde{u} = 0$ on $\partial\Omega_\varepsilon$, $\tilde{u}(x) = \psi(\sigma - \varepsilon)$ on $\partial\Omega_\sigma$. To this end, it is enough to observe that, if $\tilde{U} - \varphi$ attains a maximum point at y and $\tilde{U}(y) = \varphi(y)$, since

$$\psi(\tilde{U} - \varphi) = \exp(\varphi)(\psi(\tilde{U}) - \psi(\varphi)),$$

then also $\tilde{u} - \psi(\varphi)$ attains a maximum point at y and, moreover, $D\varphi = \exp(\varphi)D\psi(\varphi)$.

Now we set $u(x) := \tilde{u}(x)/\psi(\sigma - \varepsilon)$ and observe that $u < 1$ in $\Omega_\sigma \setminus \Omega_\varepsilon$; therefore, by (3.6) u satisfies the following Dirichlet problem in the viscosity sense:

$$\begin{aligned} u(x) + \mathcal{H}(x, u(x), Du(x)) &= u(x) - 1 + \max_{a \in A} \min_{b \in B} \{-f(x, a, b) \cdot Du(x)\} \leq 0 \quad \text{in } \Omega_\sigma \setminus \Omega_\varepsilon, \\ u &= 0 \quad \text{on } \partial\Omega_\varepsilon, \quad u = 1 \quad \text{on } \partial\Omega_\sigma. \end{aligned}$$

Therefore, if $t_x^\varepsilon(a, b)$ denotes the first exit time from $\mathbf{R}^N \setminus \overline{\Omega_\varepsilon}$, \tilde{T}_ε is the corresponding upper capture time, and $\tilde{v}_\varepsilon := \psi(\tilde{T}_\varepsilon)$, then, by the proof of Theorem 2.3, we deduce that

$$(3.7) \quad \psi(U(x) - \varepsilon)/\psi(\sigma - \varepsilon) = u(x) \leq \tilde{v}_\varepsilon(x) \quad \text{in } \Omega_\sigma \setminus \Omega_\varepsilon.$$

If we compute (3.7) at x_0 and let $\sigma \rightarrow U(x_0)$ from above, since $\sigma > U(x_0)$ were arbitrary, then we obtain $\tilde{T}_\varepsilon(x_0) = +\infty$ (note that the limit and the statement do not depend on the choice of $\varepsilon < U(x_0)$). This is not enough to conclude, but with a construction similar to the one in the proof of Theorem 3.11 it is easy to define a strategy $\bar{\beta} : \mathcal{A} \rightarrow \mathcal{B}$ such that

$$t_{x_0}(\bar{a}, \bar{\beta}[\bar{a}]) = +\infty \quad \text{for each choice of } \bar{a},$$

which means that $y_x(t; \bar{a}, \bar{\beta}[\bar{a}]) \in \mathbf{R}^N \setminus \mathcal{T}$ for all $t \geq 0$, and thus the game is evadable at x_0 . In fact, β can be chosen in such a way that the trajectory $y(t; \bar{a}, \bar{\beta}[\bar{a}])$ remains outside Ω_ρ for all fixed $\rho < U(x_0)$, and this will be used in the next result. With the same technique, it is now easy to treat the case where $x_0 \in \mathbf{R}^N \setminus \Omega'$. \square

As a consequence of the last remark in the previous proof, we state the following result.

COROLLARY 3.15. *In the framework of the previous theorem, assume, moreover, that there exists a strictly increasing function $\mu : \mathbf{R}_+ \rightarrow \mathbf{R}_+$ such that $\mu(t) = 0$ only if $t = 0$ and satisfies*

$$U(x) \leq \mu(d(x)) \quad \text{for all } x \in \Omega \setminus \mathcal{T}.$$

Then the game is strictly evadable.

Proof. We need only observe that, for $\varepsilon > 0$, we have $B(\mathcal{T}, \mu^{-1}(\varepsilon)) \subset \Omega_\varepsilon$, and we apply the proof of Theorem 3.14, in particular, the last remark. \square

As in the pursuit problem, the first candidate function to fulfill the hypotheses of Theorem 3.14 is the distance function. In view of the characterization of the super-differential of $d(\cdot)$ in Proposition 1.6, we state the following.

COROLLARY 3.16. *Assume one of the three following conditions:*

(i) *There exists $r > 0$ such that*

$$\tilde{F}(x, \nu) := \min_{a \in A} \max_{b \in B} \{f(x, a, b) \cdot \nu\} \geq 0 \quad \text{for all } x \in B(\mathcal{T}, r) \setminus \mathcal{T}$$

and for all vectors $\nu \in \text{co} \{(x - z)/|x - z| : z \in \partial\mathcal{T}, d(x) = |x - z|\}$ (co X indicates the convex hull of the set X).

(ii) *There exist $\delta, r > 0$ such that $d(\cdot)$ is differentiable in $B(\mathcal{T}, r) \setminus \mathcal{T}$ and $\tilde{F}(x_0, \nu) > \delta$, for all $x_0 \in \partial\mathcal{T}$ and all the exterior normal vectors ν at $x \in B(x_0, r) \cap \partial\mathcal{T}$.*

(iii) *Let $\partial\mathcal{T}$ be bounded and, for all $x_0 \in \partial\mathcal{T}$, there exists $r_0(x_0) > 0$ such that $\tilde{F}(x_0, \nu) > 0$ for all the exterior normal vectors ν at $x \in B(x_0, r_0) \cap \partial\mathcal{T}$.*

Then the game is strictly evadable.

Proof. Assumption (i) implies that $d(\cdot)$ satisfies the differential inequality

$$\max_{a \in A} \min_{b \in B} \{-f(x, a, b) \cdot Dd(x)\} \leq 0 \quad \text{for all } x \in B(\mathcal{T}, r) \setminus \mathcal{T}$$

in the viscosity sense. Now it is enough to apply Corollary 3.15.

Cases (ii) and (iii) are just modifications, using, in particular, the compactness arguments of the proof of Corollary 3.7. \square
