AN OPTIMAL CONTROL PROBLEM WITH A MIXED COST FUNCTION*

V. I. KOROBOV†, V. I. KRUTIN†, AND G. M. SKLYAR†

Abstract. The main objective of this paper is to find an optimal positional control in feedback form for a linear autonomous system with a mixed cost functional. The method of controllability functions is used. The relationship between this problem and an optimal stabilizability problem is also investigated, and several examples are presented.

Key words. linear system, mixed cost function, optimal positional control, controllability function, Riccati equation

AMS(MOS) subject classifications. 49C20, 34H05

Introduction. Consider the optimal control problem of the system

$$(0.1) \quad \dot{x} = Ax + Bu, \quad x \in \mathbb{R}^n, \quad u \in \mathbb{R}^r, \quad \text{rg}(B, AB, \dots, A^{n-1}B) = n,$$

$$(0.2) \quad x(0) = x_0, \quad x(T) = 0, \quad T \text{ arbitrary},$$

for which it is desired to minimize the functional

$$(0.3) \quad J(u) = k^2 T + \int_0^T [(Wx, x) + (Uu, u)] dt, \quad k > 0,$$

where W, U are symmetric matrices with $W \geq 0, U > 0$.

We refer to this functional as a mixed cost function. The main goal of our work is to find an optimal positional control for the formulated problem, i.e., to find the function $u = u(x)$, which depends only on the state variable x such that

(i) for any $x_0 \in \mathbb{R}^n$, the solution $x(t)$ of the Cauchy problem

$$(0.4) \quad \dot{x} = Ax + Bu(x), \quad x(0) = x_0$$

exists on some interval $[0, T(x_0))$ and is unique;

(ii) $x(t) \rightarrow 0$ as $t \rightarrow T(x_0)$;

(iii) the pair $(x(t), u(x(t)))$ is the solution of the optimal control problem (0.1)–(0.3).

In § 1 we consider the relationship between the optimal positional control problem and a traditional problem of finding the optimal control for (0.1)–(0.3) in the nonstationary linear feedback form. A form of the positional control $u(x)$ is given. It is shown that this control is not linear, as compared to the well-known case when $k = 0$ [1]–[3].

Therefore the investigation of the existence and uniqueness of the Cauchy problem (0.4) solution (§ 2) as defined in this article comprises an essential part of this work.

Property (ii) is obtained by the method of the controllability function, proposed in [4], on the basis of which different problems of nonoptimal admissible positional synthesis were solved; see, for example, [4], [5].

In § 3 optimality of the Cauchy problem (0.4) solution is proved (property (iii)). The case where $W = 0$ is considered separately, where we can also find a form of the optimal trajectories.

In the concluding sections, the relationship with the solution of the optimal stabilizability problem is established, i.e., with finding $u = u(x)$ such that $x(T) = 0$ and

$$(0.5) \quad \int_0^T [(Wx, x) + (Uu, u)] dt \rightarrow \inf.$$

It is shown that, when $k \rightarrow 0$ and $W > 0$, we have that $u_k(x) \rightarrow u(x)$, where $u_k(x)$ is the optimal positional control in problem (0.1)–(0.3) and $u(x)$ is the optimal positional control in problem (0.1), (0.5). This limited transition is also investigated in detail when $W = 0$.

1. Finding the positional control $u(x)$. It is a well-known fact that the solution of problem (0.1)–(0.3) for a fixed $T > 0$ exists and can be found in a nonstationary feedback form

$$(1.1) \quad u(x, t) = -U^{-1}B^*N^{-1}(T-t)x,$$

where $N(t)$ is the solution of the Cauchy problem for the matrix Riccati equation

$$(1.2) \quad \dot{N} = -AN - NA^* + BU^{-1}B^* - NWN, \quad N(0) = 0.$$

This will be helpful to us throughout the paper.

The optimal value of the functional (0.3) here is

$$J^*(T) = k^2T + (N^{-1}(T)x_0, x_0).$$

It is essential here that the Cauchy problem (1.2) has its only solution in the class of positive definite matrices for $t > 0$ [6]–[8] and is an analytic function of $t > 0$, according to the Kovalevskaya theorem.

In the case when T is not fixed, we let

$$J^* = \inf_{T>0} J_T^* = \inf_{T>0} [k^2T + (N^{-1}(T)x_0, x_0)].$$

Let us designate, for $T > 0$ and $x \in \mathbb{R}^n$, that

$$(1.3) \quad \psi(T, x) = k^2T + (N^{-1}(T)x, x),$$

$$(1.4) \quad \begin{aligned} \Phi(T, x) &= \psi'_T(T, x) \\ &= k^2 + ([N^{-1}(T)A + A^*N^{-1}(T) - N^{-1}(T)BU^{-1}B^*N^{-1}(T) + W]x, x). \end{aligned}$$

Remark 1.1. At each $x \in \mathbb{R}^n \setminus \{0\}$, the function $\psi(T, x)$ achieves its minimum. In fact, the function $\psi(T, x)$ is continuous (moreover, this function is analytic on $(0, \infty) \times \mathbb{R}^n$). Since $\|N(T)\|^{-1}\|x\| < (N^{-1}(T)x, x)$ and $\lim_{T \rightarrow +0} \|N(T)\| = 0$, it follows that $\lim_{T \rightarrow +0} \psi(T, x) = +\infty$.

On the other hand, it is also clear that $\lim_{T \rightarrow +\infty} \psi(T, x) = +\infty$; so the statement is verified.

Let $I_x = \{T > 0: \psi(T, x) \leq \psi(t, x) \text{ for every } t > 0\}$, $x \in \mathbb{R}^n \setminus \{0\}$. It follows from Remark 1.1 that the set $I_x \neq \emptyset$, and it follows from analyticity of the function $\psi(t, x)$ that this set consists of a finite number of points. Moreover, if $T \in I_x$, then $\Phi(T, x) = 0$.

Thus we have the following remark.

Remark 1.2. Problem (0.1)–(0.3) has a solution for every $x_0 \in \mathbb{R}^n \setminus \{0\}$. Moreover, the set of optimal controls has the form (1.1), where $T \in I_{x_0}$.

Remark 1.2 gives the solution of problem (0.1)–(0.3) in a nonstationary linear feedback form.

Next, we proceed to the choice of the optimal positional control $u(x)$. According to the required property (iii) of $u(x)$, at each $x_0 \in \mathbb{R}^n \setminus \{0\}$, $u(x_0)$ must coincide with the value of some optimal control of the form (1.1) when $t = 0$; i.e.,

$$(1.5) \quad u(x_0) \in \mathbb{Q}_{x_0} = \{u_0; u_0 = -U^{-1}B^*N^{-1}(T)x_0, T \in I_{x_0}\}.$$

If at each x_0 the set \mathbb{Q}_{x_0} had precisely one point, then the choice of the positional control $u(x)$ is trivial. This control would evidently satisfy properties (i)–(iii), with the possible exception of the uniqueness of the solution of problem (0.4). Such a situation takes place, for example, in the case when $k = 0$ (linear-quadratic problem) or in the time optimal problem [9], where the programmed optimal control for each initial point is uniquely defined. However, in the problem considered here, for some x , the set I_x may contain more than one point (for an example, see § 4). Therefore the choice of the unique control $u(x) \in \mathbb{Q}_x$, $x \in \mathbb{R}^n \setminus \{0\}$ having properties (i)–(iii), presents serious difficulties. Moreover, for any such choice, the control $u(x)$ will be discontinuous.

Later in this paper, it is shown that the control $u(x)$ defined by

$$(1.6) \quad u(x) = -U^{-1}B^*N^{-1}(\theta(x))x, \quad x \neq 0,$$

$$(1.7) \quad \theta(x) = \min I_x,$$

is the optimal positional control.

We refer to the function that is defined for $x \neq 0$ by equality (1.6) and defined for $x = 0$ by (1.6) with $\theta(0) = 0$ as the controllability function. At each $x \neq 0$, the value of this function coincides with the minimal positive root of the equation $\Phi(\theta, x) = 0$, at which the function $\psi(\theta, x)$ attains its global minimum.

We conclude this section by establishing some properties of the controllability function.

Property 1. From $\theta(x) \rightarrow 0$, it follows that $x \rightarrow 0$.

In fact,

$$(1.8) \quad \|N(\theta(x))\|^{-1}\|x\|^2 \leq \psi(\theta(x), x) = k^2\theta + (N^{-1}(\theta(x))x, x).$$

On the other hand,

$$(1.9) \quad \psi(\theta, x) \leq \psi(1, x) = k^2 + (N^{-1}(1)x, x) \leq k^2 + \|N^{-1}(1)\|\|x\|^2.$$

From (1.8) and (1.9), we obtain that

$$(1.10) \quad \|x\|^2(\|N(\theta(x))\|^{-1} - \|N^{-1}(1)\|) \leq k^2.$$

Let ε be any positive number such that

$$(1.11) \quad 1 - \|N^{-1}(1)\|\varepsilon > 0.$$

Choose $\delta > 0$ such that, if $0 < \theta(x) < \delta$, then $\|N(\theta(x))\| < \varepsilon$; that is, $\|N(\theta(x))\|^{-1} > 1/\varepsilon$. Then, when $0 < \theta(x) < \delta$, because of (1.10) and (1.11),

$$\|x\|^2(1/\varepsilon - \|N^{-1}(1)\|) \leq k^2, \quad \|x\|^2 \leq \varepsilon k^2 / (1 - \|N^{-1}(1)\|\varepsilon)$$

are fulfilled; hence Property 1 is obtained.

Property 2. When $\theta(x) \rightarrow 0$, then $\psi(\theta(x), x) \rightarrow 0$.

Let ε be any positive number and choose $\varepsilon > \delta > 0$ so small that when $\theta(x) < \delta$, $(N^{-1}(\varepsilon)x, x) < \varepsilon$ (this is possible because of Property 1). Then $\psi(\theta(x), x) \leq \psi(\varepsilon, x) = (k^2 + 1)\varepsilon$, which proves Property 2.

2. Existence and uniqueness of the Cauchy problem solution.

DEFINITION 2.1. We call the function $x(t)$ that satisfies almost everywhere the relationship

$$(2.1) \quad \dot{x} = Ax - BU^{-1}B^*N^{-1}(\theta(x))x$$

and is such that the function $\theta(x(t))$ is absolutely continuous on t , as the solution of the differential equation (0.1) with control (1.6). As is seen from the definition, the solution $x(t)$ is a continuously differentiable function.

Remark 2.1. Consider the system

$$(2.2) \quad \begin{aligned} \dot{x} &= Ax - BU^{-1}B^*N^{-1}(\sigma)x, \\ \dot{\sigma} &= f(t), \quad x(0) = x_0, \quad \sigma(0) = \theta(x_0). \end{aligned}$$

As is seen from Definition 2.1, the function $x(t)$ is the solution of (2.1) if and only if there exists $f(t)$ from the class of locally summable functions such that the pair $(x(t), \sigma(t))$ of the solutions of system (2.2) satisfies the equation

$$(2.3) \quad \begin{aligned} \Phi(\sigma(t), x(t)) &= k^2 + ([N^{-1}(\sigma(t))A + A^*N^{-1}(\sigma(t)) \\ &\quad - N^{-1}(\sigma(t))BU^{-1}B^*N^{-1}(\sigma(t)) + W]x(t), x(t)) = 0, \end{aligned}$$

and, for every t , $\sigma(t) = \theta(x(t))$.

THEOREM 2.1. For any initial condition $x_0 \in \mathbb{R}^n$, the solution $x(t)$ of (2.1), in the sense of Definition 2.1, exists and is unique on the interval $[0, \theta(x_0))$, and $\dot{\theta}(x(t)) = -1$ for every $t \in [0, \theta(x_0))$.

The proof uses the following lemma.

LEMMA 2.1. The function $\Phi(\theta, x)$ determined by (1.4) satisfies the equation

$$(2.4) \quad \Phi_\theta = (\Phi_x, Ax - BU^{-1}B^*N^{-1}(\theta)x).$$

(Here and elsewhere, a subscript variable signifies the corresponding partial derivative.)

Proof. Equation (1.4) gives

$$\Phi(\theta, x) = k^2 + 2(Ax, N^{-1}(\theta)x) - (N^{-1}(\theta)x, BU^{-1}B^*N^{-1}(\theta)x) + (Wx, x).$$

Since $N(\theta)$ satisfies the differential equation (1.2), the inverse matrix satisfies the equation

$$(2.5) \quad N_\theta^{-1} = N^{-1}A + A^*N^{-1} - N^{-1}BU^{-1}B^*N^{-1} + W.$$

By using (2.5), we obtain that

$$\begin{aligned} \Phi_\theta &= 2(Ax, [N^{-1}(\theta)A + A^*N^{-1}(\theta) - N^{-1}(\theta)BU^{-1}B^*N^{-1}(\theta) + W]x) \\ &\quad - 2([N^{-1}(\theta)A + A^*N^{-1}(\theta) - N^{-1}(\theta)BU^{-1}B^*N^{-1}(\theta) + W] \\ &\quad \cdot x, BU^{-1}B^*N^{-1}(\theta)x) \\ &= -(2[N^{-1}(\theta)A + A^*N^{-1}(\theta) - N^{-1}(\theta)BU^{-1}B^*N^{-1}(\theta) + W] \\ &\quad \cdot x, Ax - BU^{-1}B^*N^{-1}(\theta)x) \\ &= (\Phi_x, Ax - BU^{-1}B^*N^{-1}(\theta)x), \end{aligned}$$

which proves the lemma.

Proof of Theorem 2.1. We first prove existence of a solution of (2.1).

Assume that in (2.2)

$$(2.6) \quad f(t) = -1, \quad t \in [0, \theta(x_0)).$$

Let $(x(t), \sigma(t))$ be the solution of (2.2), with $f(t)$ given by (2.6). Then, according to Lemma 2.1,

$$\frac{d}{dt} \Phi(\sigma(t), x(t)) = -\Phi_\theta + (\Phi_x, Ax(t) - BU^{-1}B^*N^{-1}(\sigma(t)), x(t)) = 0.$$

Since, at the initial instant $\sigma(0) = \theta(x_0)$, it follows that

$$\Phi(\sigma(t), x(t)) \equiv 0 \quad \text{for every } t \in [0, \theta(x_0)).$$

We claim that, for every $t \in [0, \theta(x_0))$, $\sigma(t) = \theta(x(t))$, where $\sigma(t)$ is the minimal root of the equation

$$(2.7) \quad \Phi(\theta, x(t)) = 0,$$

at which $\psi(\theta, x(t))$ attains its global minimum.

To see this, consider the function of two variables

$$G(\theta, t) = \psi(\theta, x(t)), \quad t \in [0, \theta(x_0)).$$

LEMMA 2.2. *For every fixed $\theta_1 > 0$, it holds that*

$$\dot{G}(\theta_1 - t, t) \geq \dot{G}(\theta(x_0) - t, t) = G(\sigma(t), t), \quad t \in [0, \min(\theta_1, \theta(x_0))].$$

Proof. By using (1.4), (2.5), and (2.6), we have that

$$(2.8) \quad \begin{aligned} \dot{G}(\sigma(t), t) &= (N^{-1}(\sigma(t))x(t), Ax(t) - BU^{-1}B^*N^{-1}(\sigma(t))x(t)) \\ &\quad + (Ax(t) - BU^{-1}B^*N^{-1}(\sigma(t))x(t), N^{-1}(\sigma(t))x(t)) - \Phi(\sigma(t), x(t)) \\ &= -k^2 - (Wx(t), x(t)) - (N^{-1}(\sigma(t))BU^{-1}B^*N^{-1}(\sigma(t))x(t), x(t)), \end{aligned}$$

as well as

$$(2.9) \quad \begin{aligned} \dot{G}(\theta_1 - t, t) &= -(N^{-1}(\sigma(t))BU^{-1}B^*N^{-1}(\theta_1 - t)x(t), x(t)) - k^2 \\ &\quad - ([N^{-1}(\theta_1 - t)A + A^*N^{-1}(\theta_1 - t) \\ &\quad - N^{-1}(\theta_1 - t)BU^{-1}B^*N^{-1}(\theta_1 - t) + W]x(t), x(t)) \\ &\quad + (A^*N^{-1}(\theta_1 - t)x(t), x(t)) - (N^{-1}(\theta_1 - t)Ax(t), x(t)) \\ &\quad - (N^{-1}(\theta_1 - t)BU^{-1}B^*N^{-1}(\sigma(t))x(t), x(t)). \end{aligned}$$

By subtracting (2.8) from (2.9), we obtain that

$$\begin{aligned} \dot{G}(\theta_1 - t, t) - \dot{G}(\sigma(t), t) &= (N^{-1}(\sigma(t))BU^{-1}B^*N^{-1}(\sigma(t))x(t), x(t)) \\ &\quad + (N^{-1}(\theta_1 - t)BU^{-1}B^*N^{-1}(\theta_1 - t)x(t), x(t)) \\ &\quad - (N^{-1}(\theta_1 - t)BU^{-1}B^*N^{-1}(\sigma(t))x(t), x(t)) \\ &\quad - (N^{-1}(\sigma(t))BU^{-1}B^*N^{-1}(\theta_1 - t)x(t), x(t)) \\ &= \|U^{-1/2}B^*(N^{-1}(\theta_1 - t) - N^{-1}(\sigma(t)))x(t)\|^2 \\ &\geq 0; \end{aligned}$$

so the lemma is proved.

Continuing with the proof of Theorem 2.1, we let $t_1 \in [0, \theta(x_0))$ and $y \in (0, +\infty)$. Then, by denoting $\theta_1 = y + t_1$, we obtain the following inequality from Lemma 2.2:

$$\dot{G}(\theta_1 - t, t) \geq \dot{G}(\sigma(t), t) \quad \text{for every } t \in [0, \min(\theta_1, \theta(x_0))].$$

Integration of this inequality from 0 to t_1 yields

$$G(\theta_1 - t_1, t_1) - G(\theta_1, 0) \geq G(\sigma(t_1), t_1) - G(\theta(x_0), 0),$$

which implies that

$$\begin{aligned} G(\theta_1 - t_1, t_1) - G(\sigma(t_1), t_1) &= \psi(y, x(t_1)) - \psi(\sigma(t_1), x(t_1)) \\ &\geq G(\theta_1, 0) - G(\theta(x_0), 0) \\ &= \psi(\theta_1, x_0) - G\psi(\theta(x_0), x_0) \\ &\geq 0. \end{aligned}$$

If $y < \sigma(t_1)$, then $\theta_1 < \theta(x_0)$ and $\psi(\theta_1, x_0) - \psi(\theta(x_0), x_0) > 0$ because $\theta(x_0)$ is the smallest value of θ for which the function $\psi(\theta, x_0)$ achieves its minimum. Therefore $\psi(y, x(t_1)) - \psi(\sigma(t_1), t_1) > 0$.

We infer that $\sigma(t)$ is the minimal root of (2.3), at which $\psi(\theta, x(t))$ attains its global minimum for every $t \in [0, \theta(x_0)]$; that is, $\sigma(t) = \theta(x(t))$. Consequently, the existence of the solution of (2.1) with control (1.6), in the sense of Definition 2.1, is proved.

Next, we show the uniqueness of the solution of (2.1). Partition $\mathbb{R}^n \setminus \{0\}$ as follows: $\mathbb{R}^n \setminus \{0\} = \mathbb{M}_1 \cup \mathbb{M}_2$, where

$$\mathbb{M}_1 = \{x \in \mathbb{R}^n \setminus \{0\} : \Phi'_\theta(\theta(x), x) \neq 0\}, \quad \mathbb{M}_2 = \{x \in \mathbb{R}^n \setminus \{0\} : \Phi'_\theta(\theta(x), x) = 0\}.$$

We consider separately the cases where $x_0 \in \mathbb{M}_1$ and $x_0 \in \mathbb{M}_2$, where x_0 is the initial condition.

Let $x_0 \in \mathbb{M}_1$. Then the equality $\Phi(\theta(x_0), x_0) = 0$ holds at the point x_0 , and $\Phi'_\theta(\theta(x_0), x_0) \neq 0$. Let $x(t)$ be an arbitrary solution of (2.1) with initial condition $x(0) = x_0$, in the sense of Definition 2.1, and consider the function $g(\theta, t) = \Phi(\theta, x(t))$. Then g is continuous and has continuous partial derivatives in θ and t in a certain neighbourhood of the point $(\theta(x_0), 0)$. Since $g_\theta(\theta(x_0), 0) \neq 0$, the implicit function theorem implies that there exists a unique absolutely continuous function $\sigma(t)$ such that $g(\sigma(t), t) = \Phi(\sigma(t), x(t)) = 0$, and, according to (2.4),

$$(2.10) \quad \dot{\sigma} = -(\Phi_x, Ax(t) - BU^{-1}B^*N^{-1}(\theta(x(t)))x(t))\Phi_\theta = -1.$$

Therefore $x(t)$ is the solution of system (2.2) when $f(t) = 1$, which proves uniqueness for any point $x_0 \in \mathbb{M}_1$.

The case where $x_0 \in \mathbb{M}_2$ requires a more delicate argument. By the definition of the function $\theta(x)$ and the analyticity of $\psi(\theta, x)$ in its first argument, there exists the finite number $n = 2k$, $k > 1$ such that

$$\frac{\partial^i \Phi(\theta(x_0), x_0)}{\partial \theta^i} = 0, \quad i = 1, \dots, n; \quad \frac{\partial^{n+1} \Phi(\theta(x_0), x_0)}{\partial \theta^{n+1}} \neq 0.$$

Let $x(t)$ be an arbitrary solution (2.1) with the initial condition $x(0) = x_0$ in the sense of Definition 2.1. Then there exists an interval $[0, \tau(x_0)]$, $\tau(x_0) > 0$ such that

$$(2.11) \quad \frac{\partial^{n+1} \Phi(\theta(x(t)), x(t))}{\partial \theta^{n+1}} \neq 0, \quad t \in [0, \tau(x_0)].$$

We next claim that $\dot{\theta}(x(t)) = -1$ almost everywhere on the segment $[0, \tau(x_0)]$. To do this, we argue by contradiction. Since from (2.10) it follows that $\dot{\theta}(x(t)) = -1$ when $x(t) \in \mathbb{M}_1$, our assumption means that $\mu\mathbb{Q} > 0$, where $\mathbb{Q} = \{t \in [0, \tau(x_0)] : x(t) \in \mathbb{M}_2, \dot{\theta}(x(t)) \neq -1\}$. Thus there exists a closed set $\mathbb{Q}^1 \subset \mathbb{Q}$, $\mu\mathbb{Q}^1 > 0$, which can be presented in the form of the union $\mathbb{Q}^1 = \mathbb{Q}_1 \cup \mathbb{Q}_2$, where \mathbb{Q}_1 is perfect and \mathbb{Q}_2 is at most countable.

LEMMA 2.3. *For every point (θ, x) , we have that*

$$(2.12) \quad \begin{aligned} & \Phi_{\theta}^{(m)}(\theta, x) - ([\Phi_x(\theta, x)]_{\theta}^{(m-1)}, Ax - BU^{-1}B^*N^{-1}(\theta)x) \\ &= \sum_{j=1}^{m-1} c_j^m (U^{-1/2}B^*[\Phi_x(\theta, x)]_{\theta}^{(m-j-1)}, U^{-1/2}[\Phi_x(\theta, x)]_{\theta}^{(j-1)}), \end{aligned}$$

where $c_j^m < 0$ ($j = 1, \dots, m-1$, $m = 2, 3, \dots$) is true.

Proof. Note first that, because of (2.5),

$$(2.13) \quad 2(Ax - BU^{-1}B^*N^{-1}(\theta)x)_{\theta} = -BU^{-1}B^*\Phi_x.$$

Then, from (2.4), we obtain that

$$\Phi_{\theta\theta} = (\Phi_{x\theta}, Ax - BU^{-1}B^*N^{-1}(\theta)x) - \frac{1}{2}(\Phi_x, BU^{-1}B^*\Phi_x),$$

which proves the validity of (2.12) in the case where $m = 2$. Let $m = k$ and assume that

$$\begin{aligned} & \Phi_{\theta}^{(k)} - ([\Phi_x]_{\theta}^{(k-1)}, Ax - BU^{-1}B^*N^{-1}(\theta)x) \\ &= \sum_{j=1}^{k-1} c_j^k (U^{-1/2}B^*[\Phi_x]_{\theta}^{(k-j-1)}, U^{-1/2}B^*[\Phi_x]_{\theta}^{(j-1)}), \end{aligned}$$

where $c_j^k < 0$, $j = 1, \dots, k-1$. Differentiating this relationship on θ and using (2.13), we obtain that

$$\begin{aligned} & \Phi_{\theta}^{(k+1)} - ([\Phi_x]_{\theta}^{(k)}Ax - BU^{-1}B^*N^{-1}(\theta)x) \\ &= \sum_{j=1}^k c_j^{k+1} (U^{-1/2}B^*[\Phi_x]_{\theta}^{(k-j)}, U^{-1/2}B^*[\Phi_x]_{\theta}^{(j-1)}), \end{aligned}$$

where $c_1^{k+1} = c_1^k - \frac{1}{2} < 0$, $c_j^{k+1} = c_{j-1}^k + c_j^k < 0$, $j = 2, \dots, k-1$, and $c_k^{k+1} = c_{k-1}^k < 0$. This proves the lemma by induction on m .

We return to the proof of the uniqueness of the solution of (2.1) when $x_0 \in \mathbb{M}_2$. For every $t \in \mathbb{Q}_1$, the definition of \mathbb{M}_2 yields

$$(2.14) \quad \Phi_{\theta}(\theta(x(t)), x(t)) = 0,$$

and, moreover,

$$(2.15) \quad \Phi_{\theta\theta}(\theta(x(t)), x(t)) = 0,$$

because $\theta(x(t))$ is the point where the function $\psi(\theta, x(t))$ achieves its global minimum. By differentiating identity (2.14) with respect to t at the points of the perfect set \mathbb{Q}_1 , we see that, for $t \in \mathbb{Q}_1$,

$$(\Phi_{\theta x}(\theta(x(t)), x(t)), Ax(t)BU^{-1}B^*N^{-1}(\theta(x(t)))x(t)) + \Phi_{\theta\theta}(\theta(x(t)), x(t))\dot{\theta} = 0.$$

Considering (2.15), we obtain that

$$(2.16) \quad (\Phi_{\theta x}(\theta(x(t)), x(t)), Ax(t) - BU^{-1}B^*N^{-1}(\theta(x(t)))x(t)) = 0, \quad t \in \mathbb{Q}_1.$$

Therefore Lemma 2.3 with $m = 2$, and (2.15), (2.16) imply that

$$B^*\Phi_x(\theta(x(t)), x(t)) = 0, \quad t \in \mathbb{Q}_1.$$

The next claim is that, for $n = 2k$, the inductive assumptions

$$(2.17) \quad \Phi_{\theta}(\theta(x(t)), x(t)) = \Phi_{\theta\theta}(\theta(x(t)), x(t)) = \dots = \Phi_{\theta}^{(n)}(\theta(x(t)), x(t)) = 0$$

and

$$(2.18) \quad B^*[\Phi_x(\theta(x(t)), x(t))]_{\theta}^{(i)} = 0, \quad i = 0, \dots, k-1, \quad t \in \mathbb{Q}_1$$

imply that

$$\Phi_{\theta}^{(n+1)}(\theta(x(t)), x(t)) = \Phi_{\theta}^{(n+2)}(\theta(x(t)), x(t)) = 0$$

and

$$B^*[\Phi_x(\theta(x(t)), x(t))]_{\theta}^{(k)} = 0, \quad t \in \mathbb{Q}_1.$$

To see this, use Lemma 2.3 with $m = n + 1$ and apply (2.18) to obtain that

$$\begin{aligned} & -([\Phi_x(\theta(x(t)), x(t))]_{\theta}^{(n)}, Ax(t) - BU^{-1}B^*N^{-1}(\theta(x(t)))x(t)) \\ & + \Phi_{\theta}^{(n+1)}(\theta(x(t)), x(t)) = 0, \quad t \in \mathbb{Q}_1. \end{aligned}$$

On the other hand, by differentiating (2.17) with respect to t , $t \in \mathbb{Q}_1$, we have that

$$\begin{aligned} & \Phi_{\theta}^{(n+1)}(\theta(x(t)), x(t))\dot{\theta}(x(t)) \\ & + ([\Phi_x(\theta(x(t)), x(t))]_{\theta}^{(n)}Ax(t) - BU^{-1}B^*N^{-1}(\theta(x(t)))x(t)) = 0. \end{aligned}$$

Adding the previous two equalities and considering that $\dot{\theta}(x(t)) \neq -1$, $t \in \mathbb{Q}_1$, we infer that

$$(2.19) \quad \Phi_{\theta}^{(n+1)}(\theta(x(t)), x(t)) = 0, \quad t \in \mathbb{Q}_1.$$

By (2.17), (2.19), and the fact that $\psi(\theta, x(t))$ has global minimum at the point $\theta(x(t))$, we also infer that

$$(2.20) \quad \Phi_{\theta}^{(n+2)}(\theta(x(t)), x(t)) = 0, \quad t \in \mathbb{Q}_1.$$

Furthermore, Lemma 2.3, with $m = n + 2$ and (2.18)–(2.20), yields

$$B^*[\Phi_x(\theta(x(t)), x(t))]_{\theta}^{(k)} = 0, \quad t \in \mathbb{Q}_1.$$

Thus we have proved by induction that, for every integer $n > 0$,

$$\Phi_{\theta}^{(n)}(\theta(x(t)), x(t)) = 0, \quad t \in \mathbb{Q}_1.$$

However, this clearly contradicts (2.11).

It follows that almost everywhere on the segment $[0, \tau(x_0)]$ we must have that $\dot{\theta}(x(t)) = -1$, and, because of absolute continuity, $\dot{\theta}(x(t)) = -1$ for every $t \in [0, \tau(x_0)]$. Therefore $x(t)$ is the solution of system (2.2) when $f(t) = -1$, which proves uniqueness for every $x_0 \in \mathbb{M}_2$, and completes the proof of Theorem 2.1.

3. Optimality of positional control. In this section, we will verify that the control $u(x)$, given by formula (1.6), also has properties (ii) and (iii) stated in the Introduction.

THEOREM 3.1. *Consider the optimal control problem (0.1)–(0.3). Let $\theta(x)$ be the controllability function and suppose that the control $u(x)$ is given by (1.6). Then, for every $x_0 \in \mathbb{R}^n$, we have that $\lim_{t \rightarrow \theta(x_0)} x(t) \rightarrow 0$, where $x(t)$ is the solution of the closed-loop system (0.4), and functional (0.3) achieves its minimum at this control $u(x(t))$.*

Proof. The fact that $\lim_{t \rightarrow \theta(x_0)} x(t) \rightarrow 0$ follows from

$$\lim_{t \rightarrow \theta(x_0)} \theta(x) = \lim_{t \rightarrow \theta(x_0)} (\theta(x_0) - t) = 0.$$

Consider the value of the cost functional (0.3) at the control $u(x)$ and the solution $x(t)$ corresponding to it. Using (2.5) and (2.6), we have that

$$\begin{aligned}
 J(u(x)) &= \lim_{\varepsilon \rightarrow +0} \int_0^{\theta(x_0) - \varepsilon} [(Uu(x(t)), u(x(t))) + (Wx(t), x(t))] dt + k^2 \theta(x_0) \\
 &= \lim_{\varepsilon \rightarrow +0} \int_0^{\theta(x_0) - \varepsilon} -\dot{\psi}(\theta(x(t)), x(t)) dt \\
 &= -\lim_{\varepsilon \rightarrow +0} \psi(\theta(x(\theta(x_0) - \varepsilon)), x(\theta(x_0) - \varepsilon)) + \psi(\theta(x_0), x_0) \\
 &= \psi(\theta(x_0), x_0) \\
 &= k^2 \theta(x_0) + (N^{-1}(\theta(x_0))x_0, x_0) \\
 &= \min_{\theta > 0} [k^2 \theta + (N^{-1}(\theta)x_0, x_0)].
 \end{aligned}$$

This completes the proof.

Example 3.1. Consider the optimal control problem

$$\dot{x} = u, \quad x(0) = x_0, \quad x(T) = 0, \quad J(u) = k^2 T + \int_0^T (x^2 + u^2) dt.$$

In this case, $N(t)$ is found as the solution of the Riccati equation

$$\dot{N} = 1 - N^2, \quad N(0) = 0,$$

and a simple computation yields

$$N(t) = \frac{e^{2t} - 1}{e^{2t} + 1}.$$

The functions ψ and Φ are given by

$$\psi(\theta, x) = k^2 \theta + \frac{e^{2\theta} + 1}{e^{2\theta} - 1} x^2, \quad \Phi(\theta, x) = k^2 - \frac{4 e^{2\theta}}{(e^{2\theta} - 1)^2} x^2.$$

The controllability function $\theta(x)$ is the solution of the equation

$$\frac{4 e^{2\theta} x^2}{(e^{2\theta} - 1) x^2} = k^2.$$

Solving this equation for θ , we obtain that

$$\theta = \frac{1}{2} \ln \frac{2x^2 + k^2 + 2\sqrt{x^4 + x^2 k^2}}{k^2}$$

(note that the other root satisfies $(2x^2 + k^2 - 2\sqrt{x^4 + x^2 k^2})/k^2 < 1$, and so discarded). Thus the optimal control is given by the formula

$$u(x) = -\frac{e^{2\theta(x)} + 1}{e^{2\theta(x)} - 1} x = -\frac{x^2 + k^2 + \sqrt{x^4 + x^2 k^2}}{x^2 + \sqrt{x^4 + k^2 x^2}} x.$$

4. Solution of the problem with the mixed cost function in the case where $W = 0$. In the case considered in the previous two sections, the solution of the differential Riccati equation (1.2), as well as the solution of the differential equation (0.4) in the sense of

Definition 2.1, are not presented in the explicit form. If, however, we restrict our attention to the case where $W = 0$, then explicit forms of the solutions can be obtained. The Riccati equation (1.2) in this case has the form

$$(4.1) \quad \dot{N} = -AN - NA^* + BU^{-1}B^*,$$

and its solution for the initial condition $N(0) = 0$ is given by

$$(4.2) \quad N(t) = \int_0^t e^{-A\tau} BU^{-1}B^* e^{-A^*\tau} d\tau.$$

Hence it follows that this matrix is positive definite for $t > 0$ and satisfies

$$(4.3) \quad \begin{aligned} AN(t) + N(t)A^* &= A \int_0^t e^{-A\tau} BU^{-1}B^* e^{-A^*\tau} d\tau + \int_0^t e^{-A\tau} BU^{-1}B^* e^{-A^*\tau} d\tau A^* \\ &= - \int_0^t dI(t) = BU^{-1}B^* - I(t), \end{aligned}$$

where

$$(4.4) \quad I(t) = e^{-At} BU^{-1}B^* e^{-A^*t}.$$

The inverse matrix is readily seen to satisfy the equation

$$(4.5) \quad N^{-1}(t)A + A^*N^{-1}(t) = N^{-1}(t)BU^{-1}B^*N^{-1}(t) - N^{-1}(t)I(t)N^{-1}(t),$$

and the functions ψ and Φ take the form

$$(4.6) \quad \Phi(\theta, x) = k^2 - (I(\theta)N^{-1}(\theta)x, N^{-1}(\theta)x),$$

$$(4.7) \quad \psi(\theta, x) = k^2\theta + (N^{-1}(\theta)x, x), \quad k \neq 0.$$

Using these expressions to help in defining the controllability function $\theta(x)$, and using the control $u(x) = -U^{-1}B^*N^{-1}(\theta(x))x$, we can easily obtain the explicit form of the solution of (2.1) in the sense of Definition 2.1.

In fact, considering that on the trajectories of (2.1) the function $\theta(x)$ satisfies the equation $\dot{\theta}(x(t)) = -1$, and substituting $y(t) = N^{-1}(\theta(x(t)))x(t)$, we have that

$$\begin{aligned} \dot{y} &= [N^{-1}(\theta(x(t)))A + N^{-1}(\theta(x(t)))I(\theta(x(t)))N^{-1}(\theta(x(t))) \\ &\quad - N^{-1}(\theta(x(t)))BU^{-1}B^*N^{-1}(\theta(x(t)))]x(t). \end{aligned}$$

Because of identity (4.5) we obtain that $\dot{y}(t) = -A^*y(t)$. Hence

$$y(t) = e^{-A^*t} N^{-1}(\theta(x_0))x_0$$

and

$$x(t) = N(\theta(x(t))) e^{-A^*t} N^{-1}(\theta(x_0))x_0 = N(\theta(x_0) - t) e^{-A^*t} N^{-1}(\theta(x_0))x_0.$$

Thus $x(t) \rightarrow 0$ when $t \rightarrow \theta(x_0)$ because $N(\theta(x_0) - t) \rightarrow 0$ as $t \rightarrow \theta(x_0)$.

Example 4.1. Consider the optimal control problem

$$\begin{aligned} \dot{x}_1 &= x_2, & \dot{x}_2 &= u, \\ J(u) &= k^2 T + \int_0^T u^2 dt; \end{aligned}$$

that is, $\dot{x} = Ax + Bu$, where

$$\begin{aligned} x \in \mathbb{R}^2, \quad u \in \mathbb{R}^1, \quad A = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \\ I(\theta) = e^{-A\theta} B B^* e^{-A^*\theta} = \begin{pmatrix} \theta^2 & -\theta \\ -\theta & 1 \end{pmatrix}, \\ N(\theta) = \int_0^\theta e^{-A t} B B^* e^{-A^* t} dt = \begin{pmatrix} \theta^3/3 & -\theta^2/2 \\ -\theta^2/2 & \theta \end{pmatrix}, \\ N^{-1}(\theta) = \frac{12}{\theta^4} \begin{pmatrix} \theta & \theta^2/2 \\ \theta^2/2 & \theta^3/3 \end{pmatrix}. \end{aligned}$$

A direct computation yields, for $\theta > 0$, that

$$\begin{aligned} \psi(\theta, x) &= (N^{-1}(\theta)x, x) + k^2\theta = \frac{12x_1^2}{\theta^3} + \frac{12x_1x_2}{\theta^2} + \frac{4x_2^2}{\theta} + k^2\theta, \quad k > 0, \\ \Phi(\theta, x) &= k^2 - (N^{-1}(\theta)J(\theta)N^{-1}(\theta)x, x) \\ &= k^2 - \frac{36x_1^2}{\theta^4} - \frac{24x_1x_2}{\theta^3} - \frac{4x_2^2}{\theta^2} \\ &= k^2 - \left(6\frac{x_1}{\theta^2} + 2\frac{x_2}{\theta}\right)^2, \quad k > 0. \end{aligned}$$

The function $\theta = \theta(x)$ is found as the minimal solution of the equation

$$(4.8) \quad k^2\theta = 36x_1^2 + 24x_1x_2\theta + 4x_2^2\theta^2,$$

at which the function

$$(4.9) \quad \psi(\theta, x) = \frac{12x_1^2}{\theta^3} + \frac{12x_1x_2}{\theta^2} + \frac{4x_2^2}{\theta} + k^2\theta$$

assumes into its global minimum.

Consider the parabola defined by the equation

$$(4.10) \quad x_1 = -\alpha_0 x_2 |x_2|,$$

where α_0 is the unique root of the equation

$$(4.11) \quad \begin{aligned} G(\alpha) &= k^2[b_1 - b_2] + 4\left[\frac{1}{b_1} - \frac{1}{b_2}\right] - 12\alpha\left[\frac{1}{b_1^2} - \frac{1}{b_2^2}\right] + 12\alpha^2\left[\frac{1}{b_1^3} - \frac{1}{b_2^3}\right] = 0, \\ b_1 &= \frac{1}{k}[\sqrt{1-6k\alpha} - 1], \quad b_2 = \frac{1}{k}[\sqrt{1-6k\alpha} + 1], \end{aligned}$$

chosen so that $0 < \alpha_0 < 1/6k$. To see that such a root exists, observe that if $\alpha \ll 1$, then $G(\alpha) \approx 4/9\alpha > 0$, while if $\alpha = 1/6k$, then $G(\alpha) = \frac{4}{3}[2\sqrt{2} - 3] < 0$. To show that the root α_0 is unique, we calculate

$$\begin{aligned} G'(\alpha) &= \frac{2\alpha - b_1}{b_1^3} - \frac{2\alpha - b_2}{b_2^3} \\ &= \frac{2\alpha}{k^2} [2(\sqrt{1+6k\alpha} - \sqrt{1-6k\alpha} + \sqrt{1-36k^2\alpha^2} - 3)] \\ &= \frac{2\alpha}{k^2} P(\alpha). \end{aligned}$$

It is evident that

$$P(0) = -3, \quad P\left(\frac{1}{6k}\right) = 2\sqrt{2} - 3 < 0,$$

and

$$P'(\alpha) = \frac{6k}{\sqrt{1+6k\alpha}\sqrt{1-6k\alpha}} [\sqrt{1+6k\alpha} + \sqrt{1-6k\alpha} - 6k\alpha] > 0$$

for every $\alpha \in (0, 1/6k)$. Therefore $P(\alpha) < 0$ for every $\alpha \in (0, 1/6k)$; that is, $G'(\alpha) < 0$, for every $\alpha \in (0, 1/6k)$, so (4.11) has a unique root in the interval $(0, 1/6k)$.

Let

$$\begin{aligned} S_1 &= \{x \in \mathbb{R}^2: x_1 = -\alpha_0 x_2 |x_2|, x_1 > 0\}, \\ S_2 &= \{x \in \mathbb{R}^2: x_1 = -\alpha_0 x_2 |x_2|, x_1 < 0\}, \\ S^+ &= \{x \in \mathbb{R}^2: x_1 > -\alpha_0 x_2 |x_2|\}, \quad S_- = \{x \in \mathbb{R}^2: x_1 < -\alpha_0 x_2 |x_2|\}, \\ (4.12) \quad \theta(x) &= \begin{cases} 1/k(x_2 + \sqrt{x_2^2 + 6kx_1}), & (x_1, x_2) \in S^+ \cup S_1, \\ 1/k(-x_2 + \sqrt{x_2^2 - 6kx_1}), & (x_1, x_2) \in S^- \cup S_2. \end{cases} \end{aligned}$$

The function $\theta(x)$ has a discontinuity at the point of the set $S_1 \cup S_2$ because

$$\begin{aligned} \frac{1}{k}(x_2 + \sqrt{x_2^2 + 6kx_1}) &> \frac{1}{k}(-x_2 + \sqrt{x_2^2 - 6kx_1}), \quad (x_1, x_2) \in S_2, \\ \frac{1}{k}(-x_2 + \sqrt{x_2^2 - 6kx_1}) &> \frac{1}{k}(x_2 + \sqrt{x_2^2 + 6kx_1}), \quad (x_1, x_2) \in S_1. \end{aligned}$$

It is evident that, in this case, the set

$$\mathbb{M}_2 = \{x \in \mathbb{R}^2 \setminus \{0\}: \Phi'_\theta(\theta(x), x) = 0\}$$

introduced in § 2 is empty. The control $u(x)$ transferring an arbitrary space point \mathbb{R}^2 to the origin is given explicitly by

$$(4.13) \quad u(x) = -B^* N^{-1}(\theta(x))x = -\frac{6}{\theta^2(x)} x_1 - \frac{4}{\theta(x)} x_2;$$

that is,

$$(4.14) \quad u(x) = \begin{cases} \frac{x_2^2 - x_2 \sqrt{x_2^2 + 6kx_1}}{3x_1} - k, & (x_1, x_2) \in S^+ \cup S_1, \\ \frac{x_2^2 + x_2 \sqrt{x_2^2 - 6kx_1}}{3x_1} + k, & (x_1, x_2) \in S^- \cup S_2. \end{cases}$$

The solution of the system

$$(4.15) \quad \dot{x}_1 = x_2, \quad \dot{x}_2 = u(x),$$

in the sense of Definition 2.1, where $u(x)$ is given by (4.14), is given by formulas

$$\begin{aligned} x_1(t) &= c_1(\theta(x_0) - t)^2 + c_2(\theta(x_0) - t)^3, \\ x_2(t) &= -2c_1(\theta(x_0) - t) - 3c_2(\theta(x_0) - t)^2, \end{aligned}$$

where c_1, c_2 are found from initial conditions.

We note that if the point $x_0 = (x_{10}, x_{20}) \in S_1 \cup S_2$, then there exist two trajectories satisfying system (4.15) for every t and leading to 0; namely,

$$(4.16) \quad x_1(t) = c_1(a_1 - t)^2 + c_2(a_1 - t)^3, \quad x_2(t) = -2c_1(a_1 - t) - 3c_2(a_1 - t)^2,$$

where

$$a_1 = \frac{1}{k} (x_{20} + \sqrt{x_{20}^2 + 6kx_{10}}), \quad c_1 = \frac{a_1 x_{20} - 3\alpha_0 x_{20} |x_{20}|}{a_1^2},$$

$$c_2 = \frac{-a_1 x_{20} + 2\alpha_0 x_{20} |x_{20}|}{a_1^3},$$

and

$$(4.17) \quad x_1(t) = \tilde{c}_1(a_2 - t)^2 + \tilde{c}_2(a_2 - t)^3, \quad x_2(t) = -2\tilde{c}_1(a_2 - t) - 3\tilde{c}_2(a_2 - t)^2,$$

where

$$a_2 = \frac{1}{k} (-x_{20} + \sqrt{x_{20}^2 - 6kx_{10}}), \quad \tilde{c}_1 = \frac{a_2 x_{20} - 3\alpha_0 x_{20} |x_{20}|}{a_2^2},$$

$$\tilde{c}_2 = \frac{-a_2 x_{20} + 2\alpha_0 x_{20} |x_{20}|}{a_2^3}.$$

Furthermore, it is easy to see that when $x_0 \in S_1$, trajectory (4.16) satisfies Definition 2.1. On trajectory (4.17), the function $\theta(x(t))$ is not absolutely discontinuous, although the equality $\dot{\theta}(x(t)) = -1$ is satisfied for every t . For $x_0 \in S_2$, the only trajectory that satisfies Definition 2.1 is trajectory (4.17). The constructed synthesis gives the optimal solution of the problem

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = u,$$

$$(4.18) \quad J(u) = k^2 T + \int_0^T u^2 dt \rightarrow \inf.$$

The optimal value of the cost function is

$$J_{x_0}^* = \frac{12x_{10}^2}{\theta^3(x_0)} + \frac{12x_{10}x_{20}}{\theta^2(x_0)} + \frac{4x_{20}^2}{\theta(x_0)} + k^2\theta(x_0),$$

where $\theta(x)$ is given by (4.12). From (4.11), it follows that, for $x_0 \in S_1 \cup S_2$, both trajectories (4.16) and (4.17) are solutions of problem (4.18).

We conclude this section by noting that the forms of (4.8) for the definition of the controllability function and of control (4.13) are fully analogous with the forms of the equation for the function θ and for the control $u(x)$ of a corresponding example from the work [4], while solving the problem of finding possible nonoptimal positional control.

5. Finding the positional control in the optimal stabilizability problem. In this section, the connection between the solution of the problem with the mixed cost function (0.1)–(0.3) and the optimal stabilizability problem is investigated.

THEOREM 5.1. *Let $W > 0$. Then, for every $x_0 \in \mathbb{R}^n$, the optimal control $u_k(x)$ for problem (0.1)–(0.3) tends to the optimal control $u_0(x)$ for the optimal stabilizability problem when $k \rightarrow 0$.*

Proof. Let $N(t)$ be the solution of the Cauchy problem (1.2) and let N_1 be a positive definite matrix solution of the algebraic Riccati equation

$$(5.1) \quad AN_1 + N_1A^* - BU^{-1}B^* + N_1WN_1 = 0.$$

The matrix G given by

$$(5.2) \quad G = N_1 - N(t)$$

is the solution of the Cauchy problem

$$(5.3) \quad \dot{G} = -(A + N_1 W)G - G(A^* + WN_1) + G W G, \quad G(0) = N_1.$$

In addition to (5.3), we consider the Cauchy problem

$$(5.4) \quad \dot{P} = P(A + N_1 W) + (A^* + WN_1)P - W, \quad P(0) = N_1^{-1}.$$

As is well known, the solution of this problem is

$$(5.5) \quad P(t) = e^{(A^* + WN_1)t} N_1^{-1} e^{(A + N_1 W)t} - \int_0^t e^{(A^* + WN_1)\tau} W e^{(A + N_1 W)\tau} d\tau.$$

It will be convenient to introduce the function

$$(5.6) \quad \begin{aligned} \dot{f}_x(t) = (P(t)x, x) &= (N_1^{-1} e^{(A + N_1 W)t} x, e^{(A + N_1 W)t} x) \\ &- \int_0^t (W e^{(A + N_1 W)\tau} x, e^{(A + N_1 W)\tau} x) d\tau \end{aligned}$$

for $x \neq 0$ and $t \geq 0$.

We structure the remainder of the proof as a sequence of lemmas.

LEMMA 5.1. *For every fixed $x \neq 0$, we have that $\dot{f}_x(t) \geq 0$, for every $t \geq 0$, and, for every $t_1 > 0$, $\dot{f}_x(t)$ does not vanish identically on the interval $[0, t_1]$.*

Proof. We first calculate

$$\dot{f}_x(t) = (N_1^{-1}(A + N_1 W)y, y) + (N_1^{-1}y, (A + N_1 W)y) - (Wy, y),$$

where $y = e^{(A + N_1 W)t} x$. Then, because of (5.1),

$$(5.7) \quad \begin{aligned} \dot{f}_x(t) &= ([N_1^{-1}A + W + A^*N_1^{-1} + W - W]y, y) \\ &= (N_1^{-1}BU^{-1}B^*N_1^{-1}y, y) \\ &= \|U^{-1/2}B^*N_1^{-1}e^{(A + N_1 W)t}x\|^2 \\ &\geq 0. \end{aligned}$$

Suppose that $x \neq 0$ and $t_1 > 0$ are such that

$$(5.8) \quad B^*N_1^{-1}e^{(A + N_1 W)t}x = 0 \quad \text{for every } t \in [0, t_1].$$

Using (5.1), repeatedly differentiating (5.8), and setting $t = 0$, we obtain that

$$\begin{aligned} B^*(N_1^{-1}A + W)x &= B^*(A^*N_1^{-1} - N_1^{-1}BU^{-1}B^*N_1^{-1})x \\ &= B^*(A^* - N_1^{-1}BU^{-1}B^*)N_1^{-1}x = 0, \\ B^*(A^* - N_1^{-1}BU^{-1}B^*)^2N_1^{-1}x &= 0, \\ &\vdots \\ B^*(A^* - N_1^{-1}BU^{-1}B^*)^{m-1}N_1^{-1}x &= 0. \end{aligned}$$

Hence, because of complete controllability of the pair $((A - BU^{-1}B^*)N_1^{-1}, B)$, it follows that $N_1^{-1}x = 0$, $x \neq 0$, which contradicts to positive definiteness of N_1 . This completes the proof of Lemma 5.1.

COROLLARY 5.1. *At every fixed $x \neq 0$, the function $(P(t)x, x)$ is strictly increasing for $t > 0$; i.e., $t_2 > t_1$ implies that $(P(t_2)x, x) > (P(t_1)x, x)$.*

COROLLARY 5.2. *It holds that $N(t) \rightarrow N_1$ as $t \rightarrow +\infty$.*

To prove the corollaries, note that, because of the continuity of $\dot{f}_x(t)$ for each fixed x , there exists for every $T > 0$ an interval $[\alpha, \beta] \subset [0, T]$ on which $\dot{f}_x(t) > 0$. Consequently,

$$(5.9) \quad \int_0^T \dot{f}_x(t) dt > 0 \quad \text{for every } x \neq 0, T > 0.$$

If we designate

$$(5.10) \quad M(t) = \int_0^t e^{(A^* + WN_1)\tau} BU^{-1} B^* e^{(A + N_1 W)\tau} d\tau,$$

then, from (5.9), it follows that $M(t)$ is positive definite for $t > 0$. Choose a constant $c > 0$ such that, for every $x \in \mathbb{R}^n$,

$$(5.11) \quad (M(1)x, x) = \left(\int_0^1 e^{(A^* + WN_1)\tau} BU^{-1} B^* e^{(A + N_1 W)\tau} d\tau x, x \right) \geq c \|x\|^2.$$

We claim that $(M(t)x, x) \rightarrow +\infty$ as $t \rightarrow +\infty$. In fact,

$$(5.12) \quad \begin{aligned} (M(t)x, x) &= \sum_{k=0}^{[t]} \left(\int_0^1 e^{(A^* + WN_1)\tau} BU^{-1} B^* e^{(A + N_1 W)\tau} d\tau x, x \right) \\ &\quad + \left(\int_{[t]}^t e^{(A^* + WN_1)\tau} BU^{-1} B^* e^{(A + N_1 W)\tau} d\tau x, x \right) \\ &= \sum_{k=0}^{[t]} \left(\int_0^1 e^{(A^* + WN_1)\sigma} BU^{-1} B^* e^{(A + N_1 W)\sigma} d\sigma e^{(A + N_1 W)k} x, e^{(A + N_1 W)k} x \right) \\ &\quad + \left(\int_{[t]}^t e^{(A^* + WN_1)\tau} BU^{-1} B^* e^{(A + N_1 W)\tau} d\tau x, x \right). \end{aligned}$$

It is known [10] that $A - BU^{-1} B^* N_1^{-1}$ is a stable matrix; therefore, from (5.1), it follows that $-A^* - WN_1$ is also stable. Thus there exists a constant $c_1 > 0$ such that $\|e^{(A + N_1 W)k} x\| \leq c_1 \|x\|$ for every $k > 0$ and for every x . From (5.11) and (5.12), it follows that $(M(t)x, x) \geq [t]cc_1^2 \|x\|^2$.

Considering relationship (5.6), we have, for $t > 1$, that

$$(P(t)x, x) = \int_0^t \dot{f}_x(\tau) d\tau = (M(t)x, x) + (N_1^{-1}x, x) \geq [t]cc_1^2 \|x\|^2.$$

Thus, for the inverse matrix $G(t) = P(t)^{-1}$, we have that

$$(G(t)x, x) \leq \|x\|^2 / ([t]cc_1^2),$$

which immediately yields that $(G(t)x, x) \rightarrow 0$ as $t \rightarrow \infty$. The conclusion of the corollary follows from relationship (5.2).

LEMMA 5.2. *Let $Q(t)$ be a positive definite matrix for $t > 0$ and suppose that, for each $x \neq 0$, the function $(Q(t)x, x)$ is strictly increasing for $t > 0$. Then, for each $x \neq 0$, the function $(Q^{-1}(t)x, x)$ is strictly decreasing for $t > 0$.*

Proof. A direct computation yields that

$$\frac{d}{dt} (Q^{-1}(t)x, x) = -(Q^{-1} \dot{Q} Q^{-1} x, x) = -(\dot{Q}(t) Q^{-1}(t)x, Q^{-1}(t)x) = -(\dot{Q}(t)y, y) \leq 0,$$

where $y = Q^{-1}(t)x$; thus the function $(Q^{-1}(t)x, x)$ is nonincreasing.

To show that this function is strictly decreasing, suppose, to the contrary, that there exist t_1 and t_2 , $t_1 > t_2$ such that $(Q^{-1}(t_2)x, x) = (Q^{-1}(t_1)x, x)$ for some $x \neq 0$; i.e., $([Q^{-1}(t_2) - Q^{-1}(t_1)]x, x) = 0$. Since $Q^{-1}(t_2) - Q^{-1}(t_1)$ is negative semidefinite, it follows that $Q^{-1}(t_2)x = Q^{-1}(t_1)x$. Designating $Q^{-1}(t_1)x = y$, we obtain that $x = Q(t_2)y = Q(t_1)y$ and $(Q(t_2)y, y) = (Q(t_1)y, y)$, which contradicts the lemma's supposition. This completes the proof.

COROLLARY 5.3. *For every fixed $x \neq 0$, the function $(N^{-1}(t)x, x)$ is strictly decreasing for $t > 0$.*

In fact, from Corollary 5.1, we have that $(P(t)x, x)$ is strictly increasing. Since $P(t)$ is positive definite for $t = 0$, it follows that $P(t)$ is positive definite for $t > 0$. Thus the inverse matrix $P^{-1}(t)$ is positive definite, and, according to (5.2) and (5.3), coincides with $G(t)$. Considering relationship (5.2) and applying Lemma 5.2, we twice obtain the corollary.

LEMMA 5.3. *For x fixed, the controllability function $\theta_k(x)$ tends to $+\infty$ as $k \rightarrow 0$.*

Proof. For $T > 0$ and $\theta \in [0, T]$, we have that

$$\psi(\theta, x) = k^2\theta + (N^{-1}(\theta)x, x) \geq (N^{-1}(\theta)x, x) \geq (N^{-1}(T)x, x).$$

In accordance with Corollary 5.3, $(N^{-1}(T)x, x) > (N^{-1}(2T)x, x)$, so there exists $k > 0$ such that

$$k^2T + (N^{-1}(2T)x, x) < (N^{-1}(T)x, x) \leq \psi(\theta, x) \quad \text{for every } \theta \in [0, T].$$

Thus $\psi(\theta, x)$ cannot attain its global minimum on the interval $[0, T]$. The statement of lemma follows because $T > 0$ is arbitrary.

Theorem 5.1 follows from Lemma 5.3 and Corollary 5.2, since

$$J(u) \rightarrow \int_0^T [(Wx, x) + (Uu, u)] dt \quad \text{as } k \rightarrow 0,$$

and, because of (1.6), the control $u(x) \rightarrow -U^{-1}B^*N_1x$ as $k \rightarrow 0$.

If we drop the assumption that $W > 0$, then the matrix equation (5.1) may have no solution. Nevertheless, the limit of the matrix $N^{-1}(\theta)$ can exist, and, moreover, the control $u = -U^{-1}B^*Mx$, where $M = \lim_{\theta \rightarrow \infty} N^{-1}(\theta)$, can be optimal for the linear quadratic problem; that is, the form of Theorem 5.1 can occur when positive definiteness of the matrix W is no longer assumed.

We will consider the case when $W = 0$ and will obtain the exact answer to the question about the validity limits of Theorem 5.1 in terms of the matrix spectrum. With this purpose we consider the matrix

$$N(\theta) = \int_0^\theta e^{-A\tau} B U^{-1} B^* e^{-A^*\tau} d\tau$$

as the solution for the differential equation (4.1), satisfying identity (4.5).

We claim that $\lim_{\theta \rightarrow \infty} N^{-1}(\theta) = M$ exists and that this limit is the solution of the equation

$$(5.13) \quad MA + A^*M = MBU^{-1}B^*M.$$

LEMMA 5.4. *The function $N^{-1}(\theta)$ has a limit $M \in \mathbb{R}^{n^2}$ as $\theta \rightarrow \infty$, and M satisfies (5.13).*

Proof. Note that the function $(N^{-1}(\theta)x, x)$ is decreasing in θ for every fixed $x \in \mathbb{R}^n$ because, due to (4.4), its derivative $-(N^{-1}(\theta)I(\theta)N^{-1}(\theta)x, x)$ is nonpositive. Since

the function $(N^{-1}(\theta)x, x)$ is also bounded from below, the matrix $N^{-1}(\theta)$ has a limit M when $\theta \rightarrow \infty$.

Let us further consider identity (4.5). Letting $\theta \rightarrow \infty$ in (4.5), we know that the matrix $N^{-1}(\theta)I(\theta)N^{-1}(\theta)$ has a limit, and therefore the function $-(N^{-1}(\theta)I(\theta)N^{-1}(\theta)x, x)$ also has some limit. Since the latter is the derivative of the function $(N^{-1}(\theta)x, x)$, which has a finite limit, it follows that

$$\lim_{\theta \rightarrow \infty} (N^{-1}(\theta)I(\theta)N^{-1}(\theta)x, x) = 0$$

for every $x \in \mathbb{R}^n$; hence

$$\lim_{\theta \rightarrow \infty} (N^{-1}(\theta)I(\theta)N^{-1}(\theta) = 0.$$

Therefore the matrix M satisfies (5.13), and Lemma 5.4 is proved.

Let $\tilde{A} = A - BU^{-1}B^*M$. The root subspaces of an $n \times n$ matrix C corresponding to the eigenvalues with the positive, negative, and zero real parts are denoted by $L_+(C)$, $L_-(C)$, and $L_0(C)$, respectively.

LEMMA 5.5. *It holds that $L_+(\tilde{A}) \cap \text{Ker } M = \{0\}$; $L_+(A) \cap \text{Ker } M = \{0\}$.*

Proof. We argue by contradiction. Let x be an eigenvector of the matrix A , or \tilde{A} , corresponding to an eigenvalue λ with $\text{Re } \lambda > 0$, and suppose that $Mx = 0$. Then $\tilde{A}x = Ax = \lambda x$. Choose a control $u(t)$, $t \in [0, T]$ that transfers the point $x \in \mathbb{R}^n$ to the origin during the time interval $[0, T]$. We have that $-x = \int_0^T e^{-A^*t} Bu(t) dt$. Let y be a root vector of the matrix A^* corresponding to the eigenvalue λ such that $(x, y) \neq 0$. Then there exists a certain vector polynomial $q(t)$ such that

$$\begin{aligned} |(x, y)| &= \left| \int_0^T (e^{-A^*t} Bu(t), y) dt \right| = \left| \int_0^T (u(t), B^* e^{-\bar{\lambda}t} q(t)) dt \right| \\ (5.14) \quad &\leq \left(\int_0^T (Uu(t), u(t)) dt \right)^{1/2} \left(\int_0^\infty \|B^* e^{-\bar{\lambda}t} q(t)\|^2 dt \right)^{1/2} \\ &\leq c \left(\int_0^T (Uu(t), u(t)) dt \right)^{1/2}, \end{aligned}$$

where $c = \left(\int_0^\infty \|B^* e^{-\bar{\lambda}t} q(t)\|^2 dt \right)^{1/2}$.

Specifically, let us choose $u(t)$ in the form of $u(t) = -U^{-1}B^* e^{-A^*t} N^{-1}(T)x$. It is clear that this control transfers the point x to the origin. Then, from (5.14), we have that

$$\begin{aligned} \frac{1}{c} |(x, y)| &\leq \left(\int_0^T (Uu(t), u(t)) dt \right)^{1/2} \\ &= \left(\int_0^T (B^* e^{-A^*t} N^{-1}(T)x, U^{-1}B^* e^{-A^*t} N^{-1}(T)x) dt \right)^{1/2} \\ &= (N(T)N^{-1}(T)x, N^{-1}(T)x)^{1/2} = (N^{-1}(T)x, x)^{1/2}; \end{aligned}$$

hence

$$(5.15) \quad (Mx, x) \geq \frac{1}{c^2} |(x, y)|^2 > 0.$$

Inequality (5.15) contradicts the assumption that $Mx = 0$, and the lemma is proved.

LEMMA 5.6. *It is true that $L_0(\tilde{A}) + L_+(\tilde{A}) \subset \text{Ker } M$.*

Proof. Let x be an arbitrary eigenvector of the matrix \tilde{A} corresponding to an eigenvalue λ with $\text{Re } \lambda \geq 0$. We will show that $Mx = 0$.

We argue by contradiction. Let $Mx \neq 0$. Then, from relationship (5.13), it follows that

$$(5.16) \quad A^*Mx = -\lambda Mx.$$

Taking the inner product of the equality $Ax - BU^{-1}B^*Mx = \lambda x$ with Mx and using (5.16), we have that

$$(5.17) \quad (Ax, Mx) - (BU^{-1}B^*Mx, Mx) = -\bar{\lambda}(Mx, x) = -\|U^{-1/2}B^*Mx\|^2.$$

Because of (5.17), $B^*Mx = 0$. Since $Mx \neq 0$ is an eigenvector of the matrix A^* , it follows that $B^*(A^*)^i Mx = 0$, $i = 1, 2, 3, \dots$, which contradicts the complete controllability of the system. Therefore $Mx = 0$.

The remainder of the proof will be performed by induction. Suppose it has been proved that, for all root vectors x of height r of the matrix \tilde{A} located in $L_0(\tilde{A}) + L_+(\tilde{A})$, $Mx = 0$ is fulfilled. We will prove that $My = 0$, where $y \in L_0(\tilde{A}) + L_+(\tilde{A})$ is an arbitrary root vector of height $r+1$. Again, we argue by contradiction. Let $My \neq 0$. Then, from relationship (5.13) and from the assumption of induction, we have that

$$(5.18) \quad -(A^* + \lambda I)My = M(\tilde{A} - \lambda I)y = 0;$$

that is, My is an eigenvector of A^* corresponding to the value eigenvalue λ .

As shown before, from the equality $Ay - BU^{-1}B^*My = \lambda y + x$, where x is a root vector of height r , and using (5.18), we obtain that

$$\begin{aligned} (Ay, My) - (BU^{-1}B^*My, My) &= -\bar{\lambda}(My, y) - \|U^{-1/2}B^*My\|^2 \\ &= \lambda(My, y) + (x, My) = \lambda(My, y), \end{aligned}$$

for $(x, My) = (Mx, y) = 0$ because of the induction assumption. Hence

$$0 \leq (\bar{\lambda} + \lambda)(My, y) = \|U^{-1/2}B^*My\|^2,$$

which contradicts the complete controllability of the system. This proves the lemma.

LEMMA 5.7. *It holds that $\text{Im } M \subset L_+(A^*)$.*

Proof. Let y_1, \dots, y_n be a basis of \mathbb{R}^n that consists of the proper and root vectors of the matrix \tilde{A} . Then

$$\text{Im } M = \text{Span}(My_1, \dots, My_n).$$

Suppose, for some i , $1 \leq i \leq n$, that $My_i \neq 0$ and let λ_i be the eigenvalue corresponding to the root vector y_i . Because of Lemma 5.6, $\text{Re } \lambda_i < 0$. We have, using relation (5.13), that

$$\begin{aligned} (A^* + \lambda I)My_i &= (A^* + \lambda I)My_i^0 = My_i^1, \\ &\vdots \\ (A^* + \lambda I)My_i^{r-1} &= 0, \end{aligned}$$

where r is the height of the root vector y_i . Then $(A^* + \lambda I)^r My_i = 0$, and therefore $My_i \in L_+(A^*)$.

Because of the arbitrariness of i , $1 \leq i \leq n$, the lemma is proved.

THEOREM 5.2. *The spectrum of the matrix $\tilde{A} = A - BU^{-1}B^*M$ is contained in the closed left half plane; that is, the state space \mathbb{R}^n can be represented in form of direct sum $\mathbb{R}^n = L_-(\tilde{A}) + L_0(\tilde{A})$, where $L_0(\tilde{A}) = L_0(A)$, $L_-(\tilde{A}) \supset L_-(A)$.*

Proof. From Lemmas 5.5 and 5.6, it directly follows that $L_+(\tilde{A}) = \{0\}$, so that $\mathbb{R}^n = L_-(\tilde{A}) + L_0(\tilde{A})$. From Lemma 5.6, it also follows that $L_0(\tilde{A}) \subset \text{Ker } M$, which leads to the inclusion

$$(5.19) \quad L_0(\tilde{A}) \subseteq L_0(A).$$

In fact, $\tilde{A}x = Ax$ for every $x \in L_0(\tilde{A})$, which yields that

$$\tilde{A}^2x = A^2x + BU^{-1}B^*MAx = A^2x + BU^{-1}B^*M\tilde{A}x = A^2x.$$

Similarly, $\tilde{A}^nx = A^nx$, for every $n = 3, 4, \dots$, so the given inclusion (5.19) is proved.

Furthermore, from Lemma 5.5, it follows that

$$\dim L_+(A) = \dim L_+(A^*) \leq \dim \text{Im } M.$$

However, from Lemma 5.7, we conclude that $\text{Im } M = L_+(A^*)$. Hence $\text{Ker } M = L_-(A) + L_0(A)$, and, as we saw before,

$$(5.20) \quad L_0(A) \subseteq L_0(\tilde{A}),$$

$$(5.21) \quad L_-(A) \subseteq L_-(\tilde{A}).$$

The assertion of the theorem follows from the inclusions (5.19)–(5.21).

THEOREM 5.3 (concerning the solution of the optimal stabilizability problem when $W = 0$). 1. *For any initial data $x_0 \in L_-(A)$, the control $u = u(x) = -U^{-1}B^*Mx$ gives the solution of the optimal stabilizability problem.*

2. *If $x_0 \notin L_-(A)$, an optimal solution does not exist.*

Proof. Let us denote $m(x) = \inf_{u(t) \in \Omega} J(u)$, where $J(u) = \int_0^\infty (Uu(t), u(t)) dt$ and Ω is the set of bounded measurable controls that transfer the initial state x_0 asymptotically to the origin as $t \rightarrow \infty$.

We claim that $m(x_0) = (Mx_0, x_0)$. To see this, let

$$(5.22) \quad u_k(t) = \begin{cases} -U^{-1}B^*e^{-A^*t}N^{-1}(k)x_0, & t \in [0, k], \\ 0, & t \in (k, \infty), \end{cases}$$

for $k = 1, 2, \dots$. Then $J(u_k) = (N^{-1}(k)x_0, x_0)$, $k = 1, 2, \dots$, and hence

$$(5.23) \quad m(x_0) \leq (Mx_0, x_0).$$

Suppose that $m(x_0) < (Mx_0, x_0)$. Then there exist $\varepsilon > 0$ and a control $\bar{u}(t)$ transferring the point x_0 asymptotically to the origin such that

$$(5.24) \quad m(x_0) \leq \int_0^\infty (U\bar{u}(t), \bar{u}(t)) dt < (Mx_0, x_0) - \varepsilon.$$

Let $\bar{x}(t)$ be the solution of the equation $\dot{\bar{x}}(t) = A\bar{x}(t) + B\bar{u}(t)$ with initial condition x_0 . Since $\bar{x}(t) \rightarrow 0$ as $t \rightarrow \infty$, then there exists $T > 0$ such that

$$(5.25) \quad (N^{-1}(1)\bar{x}(T), \bar{x}(T)) < \varepsilon.$$

Let the control $\bar{\bar{u}}(t)$ be defined on the segment $[0, T+1]$ by the formula

$$\bar{\bar{u}}(t) = \begin{cases} \bar{u}(t), & t \in [0, T], \\ -U^{-1}B^*e^{-A^*(t-T)}N^{-1}(1)\bar{x}(T), & t \in [T, T+1]. \end{cases}$$

It is clear that the control $\bar{\bar{u}}(t)$ transfers the point x_0 to the origin on the time interval $[0, T+1]$, and, because of (5.23) and (5.24), we have that

$$(5.26) \quad \int_0^{T+1} (U\bar{\bar{u}}(t), \bar{\bar{u}}(t)) dt < (Mx_0, x_0).$$

On the other hand, it is known that, for any control $\tilde{u}(t)$ transferring the point x_0 to the point 0 on the time interval $[0, T+1]$, the inequality

$$(5.27) \quad \int_0^{T+1} (U\tilde{u}(t), \tilde{u}(t)) dt \geq (N^{-1}(T+1)x_0, x_0) \geq (Mx_0, x_0)$$

is fulfilled.

The contradiction between (5.25) and (5.26) shows that $m(x_0) \geq (Mx_0, x_0)$. Considering (5.23), we infer that $m(x_0) = (Mx_0, x_0)$.

We now can prove assertion 1 of Theorem 5.3.

Let $x_0 \in L_-(\tilde{A})$ and let $x(t)$ be the solution of the equation with the control $u(x) = -U^{-1}B^*Mx$. Then $x(t) \rightarrow 0$ as $t \rightarrow \infty$. On the other hand, because of (5.13), we have that

$$(5.28) \quad \begin{aligned} \frac{d}{dt} (Mx(t), x(t)) &= (A^*Mx(t), x(t)) - 2(MBU^{-1}B^*Mx(t), x(t)) + (MAx(t), x(t)) \\ &= -(MBU^{-1}B^*Mx(t), x(t)) \\ &= -(Uu(x(t)), u(x(t))). \end{aligned}$$

Integrating (5.27) from 0 to T , we obtain that

$$\begin{aligned} \int_0^T (Uu(x(t)), u(x(t))) dt &= - \int_0^T \frac{d}{dt} (Mx(t), x(t)) dt \\ &= (Mx_0, x_0) - (Mx(T), x(T)) \rightarrow (Mx_0, x_0) \\ &= m(x_0) \quad \text{as } T \rightarrow \infty, \end{aligned}$$

which proves assertion 1 of Theorem 5.3.

Next, we turn to the proof of assertion 2 of the theorem. Suppose first that $x_0 \in L_0(\tilde{A}) = L_0(A)$ (recall Theorem 5.2). Because of Lemma 5.6, $L_0(A) \subset \text{Ker } M$, so that $m(x_0) = 0$. Since the control $u \equiv 0$ does not transfer the point x_0 to the point 0, assertion 2 is proved in this case.

Next, suppose that $x_0 \notin L_-(\tilde{A})$. Then, from Theorem 5.2, it follows that $x_0 = y_0 + z_0$, where $y_0 \in L_-(\tilde{A})$ and $z_0 \in L_0(\tilde{A})$. Let $v(t)$ be any control transferring the point x_0 to the point 0 asymptotically as $t \rightarrow \infty$ and let $x(t)$ be the solution of the equation corresponding to this control such that

$$J(v) = \int_0^\infty (Uv(t), v(t)) dt \geq m(x_0).$$

Denote by $y(t)$ the solution of (0.1) with initial condition y_0 and control $u(y) = -U^{-1}B^*My$. Because of the linearity of (0.1), it is clear that the control $w(t) = v(t) - u(y(t))$ transfers the point z_0 to the origin of coordinates asymptotically. A direct computation yields that

$$\begin{aligned} \frac{d}{dt} (My(t), x(t)) &= (M\tilde{A}y(t), x(t)) + (My(t), Ax(t) + Bv(t)) \\ &= ([MA - MBU^{-1}B^*M + A^*M]y(t), y(t)) + (My(t), Bv(t)). \end{aligned}$$

Because of (5.2), we obtain that

$$(5.29) \quad \begin{aligned} \frac{d}{dt} (My(t), x(t)) &= (My(t), Bv(t)) = (UU^{-1}B^*My(t), v(t)) \\ &= (Uu(y(t)), v(t)). \end{aligned}$$

Hence, for every $T > 0$, because of (5.27), we have that

$$\begin{aligned}
 & \int_0^T (Uw(t), w(t)) dt \\
 &= \int_0^T (Uv(t), v(t)) dt - 2 \int_0^T (Uv(t), u(y(t))) dt \\
 (5.30) \quad &+ \int_0^T (Uu(y(t)), u(y(t))) dt \\
 &= \int_0^T (Uv(t), v(t)) dt + 2(My(T), y(T)) \\
 &\quad - 2(My_0, x_0) + (My_0, y_0) - (My(T), y(T)) \\
 &\rightarrow (Mx_0, x_0) - 2(My_0, x_0) + (My_0, y_0) \quad \text{as } T \rightarrow \infty
 \end{aligned}$$

because $x(T)$, $y(T)$ tend to zero as $T \rightarrow \infty$. Theorem 5.2 implies that $Mx_0 = My_0$, so, from (5.29), we obtain that

$$J(w) = (My_0, x_0) - 2(My_0, x_0) + (Mx_0, y_0) = -(My_0, x_0) + (Mx_0, y_0) = 0$$

because $(Mx_0, y_0) = (My_0, x_0)$ is a real number. It follows that $W(t)$ must be identically equal to zero. However, as we have seen before, the zero control does not transfer the point z_0 to the point 0, so this contradiction proves assertion 2.

COROLLARY 5.4. *If the spectrum of the matrix A is disjoint from the imaginary axis, then, for every initial state $x_0 \in \mathbb{R}^n$, the control $u(x) = -U^{-1}B^*Mx$ gives the solution of the optimal stabilizability problem.*

Example. Let the controlled process be described by the system

$$\dot{x}_1 = -11x_1 + 6x_2, \quad \dot{x}_2 = -20x_1 + 11x_2 + u,$$

$$J(u) = \int_0^\infty u^2 dt,$$

$$A = \begin{pmatrix} -11 & 6 \\ -20 & 11 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Straightforward computations yield

$$\begin{aligned}
 N(\theta) &= \begin{pmatrix} \frac{9}{2}e^{2\theta} - \frac{9}{2}e^{-2\theta} - 18\theta & \frac{15}{2}e^{2\theta} - 9e^{-2\theta} - 33\theta + \frac{3}{2} \\ \frac{15}{2}e^{2\theta} - 9e^{-2\theta} - 33\theta + \frac{3}{2} & \frac{25}{2}e^{2\theta} - 18e^{-2\theta} - 60\theta + \frac{11}{2} \end{pmatrix}; \\
 N^{-1}(\theta) &= \begin{pmatrix} \frac{25}{2}e^{2\theta} - 18e^{-2\theta} - 60\theta + \frac{11}{2} & -\frac{15}{2}e^{2\theta} + \frac{9}{2}e^{-2\theta} + 33\theta - \frac{3}{2} \\ -\frac{15}{2}e^{2\theta} + \frac{9}{2}e^{-2\theta} + 33\theta - \frac{3}{2} & \frac{9}{2}e^{2\theta} - \frac{9}{2}e^{-2\theta} - 18\theta \end{pmatrix} \frac{1}{\frac{9}{4}e^{2\theta} + \frac{9}{4}e^{-2\theta} - 9\theta^2 - \frac{18}{4}}; \\
 M &= \begin{pmatrix} \frac{50}{9} & -\frac{10}{3} \\ -\frac{10}{3} & 2 \end{pmatrix}; \\
 u(x) &= -B^*Mx = \frac{10}{3}x_1 - 2x_2.
 \end{aligned}$$

With the control $u(x)$, the system takes the following form:

$$\begin{aligned}
 \dot{x}_1 &= -11x_1 + 6x_2, \quad \dot{x}_2 = -\frac{50}{3}x_1 + 9x_2. \\
 (\lambda_1 = \lambda_2 = -1).
 \end{aligned}$$

The optimal value of the cost function for the initial state $x = (x_1, x_2)$ is given by $m(x) = \frac{50}{9}x_1^2 + 2x_2^2 - \frac{20}{3}x_1x_2$.

OPTIMALITY CONDITIONS VIA NORM SCALARIZATION IN VECTOR OPTIMIZATION*

PHAN QUOC KHANH†

Dedicated to Professor Stefan Rolewicz on his 60th birthday.

Abstract. An orthogonality concept in normed spaces is defined and used to obtain sufficient and necessary conditions for efficiency, weak efficiency, and proper efficiency via norm scalarization for the case of general (nonpointed) cones. As an application, a control approximation problem with a nonpointed ordering cone is considered.

Key words. norm scalarization, efficient points, weakly efficient points, properly efficient points, approximation

AMS(MOS) subject classifications. 90C31, 90C30, 90B50

1. Introduction. Scalarization means the replacement of the problem of finding an efficient (or weakly efficient, properly efficient) point of a subset S of the objective space X by a scalar problem of minimizing and/or maximizing a suitable functional f on X . If this functional is a norm, we have a norm scalarization. Perhaps this type of scalarization together with linear scalarization are of the most importance, because norms and linear functionals are in a sense simplest and best to handle. Furthermore, norm scalarization gives close relations between vector optimization and approximation theory.

Scalarization by the Euclidean norm was considered in [15], [21] among others, and by Chebyshev norm in [3]. For a complete review of various aspects of scalarization, including norm scalarization, in \mathbb{R}^n , the reader is referred to [19]. In particular, the weighted l_p norm, the weighted Chebyshev norm, and a composite norm were investigated there. Moreover, the mentioned scalarizing functional f is usually considered depending also on a vector parameter α , sometimes called a controlling parameter, since the decision maker can specify the values of α . A scalarizing functional f should desirably have certain properties. For instance, roughly speaking, we say that f is complete if and only if $(\hat{x}, \hat{\alpha})$ being a minimum of f (for some $\hat{\alpha}$, and on a suitable set of (x, α) related to S) is a necessary and sufficient condition for \hat{x} to be an efficient point of S . The completeness and various aspects of constructiveness of scalarization such as local controllability, robust computability, simplicity, and so on are considered in [19] for finite dimensions. Some of them are examined for differential games in [20].

The present paper concerns only one aspect: sufficient conditions and necessary conditions for efficient, weakly efficient, and properly efficient points via norm scalarization without a controlling parameter.

In [17] Wierzbicki proved the following sufficient condition. Assume that the ordering cone C of a Hilbert space X is such that

$$(1) \quad C \subseteq C^* := \{x^* \in X^* / \langle x^*, x \rangle \geq 0, \forall x \in C\}.$$

If \bar{x} is a unique minimum of $\|x - \hat{x}\|$ on S (or a unique maximum of it on a certain part of S), for a suitable reference point \hat{x} , then \bar{x} is an efficient point of S .

Rolewicz [14] extended this result to normed spaces under the condition

$$(2) \quad C \cap (x - C) \subseteq B(O, \|x\|) \cup \{x\} \quad \text{for all } x \in X,$$

where $B(O, r)$ stands for the open ball of radius r and centered at O , and proved that if X is a Hilbert space, (1) and (2) are equivalent. In [7]–[9], Jahn explained (2) as the condition that the norm in X is strongly increasing and generalized the result to the case of general strongly increasing functionals, which need not be the norm of X . He proved various necessary conditions and sufficient conditions for efficient points, weakly efficient points, and properly efficient points in terms of norms additionally defined on X . Moreover, these scalarization results proved to have interesting applications in approximation theory [10]. However, all the mentioned conditions are much more restrictive than pointedness. In fact, (1) means that the angle between any two vectors of C must not be greater than $\pi/2$. In practice, ordering cones not satisfying this condition or even nonpointed are often met. For example, the lexicographic order does not fulfill (1), nor does any ordering cone, which is strictly greater than \mathbb{R}_+^n in the Euclidean space. But this situation is quite frequently faced because the preference of the decision maker may be “looser” than that defined by \mathbb{R}_+^n . For an example with nonpointed cone, see § 6.

In this paper, we extend these results to normed spaces ordered by general ordering cones. We prefer to consider scalarization without additional norms because this says more about the geometric structure of X , in addition to possible applications in approximation theory.

In § 2 we recall the definitions of the needed optimality notions in vector optimization and introduce an orthogonality concept in normed spaces. Section 3 is devoted to sufficient conditions under assumptions weaker than (1) and (2). We also explain how to apply the results. In the next section, similar results are proved for weak and proper efficiency. Section 5 deals with necessary conditions for efficiency and weak efficiency via norm scalarization. Finally, an application to a control approximation problem with a nonpointed ordering cone is examined in § 6.

2. Definitions. First recall some notions. Let S be a subset of a normed space X ordered by a convex cone C . A point $\bar{x} \in S$ is said to be an efficient point of S if there are no points $x \in S$ such that $x \in (\bar{x} - C) \setminus (\bar{x} + C)$. If the relative interior riC is nonempty and there is no $x \in S$ such that $x \in \bar{x} - riC$, \bar{x} is called a weakly efficient point of S . There are various notions of proper efficiency given by Kuhn and Tucker [13], Hurwicz [6], Geoffrion [4], Borwein [2], Benson [1], and Henig [5]. In the simplest case, where $X = \mathbb{R}^n$, $C = \mathbb{R}_+^n$, and S is convex, all these notions coincide. For a consideration and comparison of these notions in \mathbb{R}^n , see [16], and in infinite-dimensional spaces, see [11].

In the present paper, we use the following definition of Borwein. A point $\bar{x} \in S$ is said to be a properly efficient point of S if O is an efficient point of the tangent cone $T(S + C, \bar{x})$ of $S + C$ at \bar{x} . In the following, we will use the notation $E(S, C)$, $WE(S, C)$, and $PE(S, C)$ for the sets of all efficient points, weakly efficient points, and properly efficient points, respectively, of S (with respect to the ordering cone C).

We define an orthogonality in a normed space X as follows. Assume that X is a direct sum $X = L \oplus L^\perp$ of two closed subspaces, with $\text{codim } L > 1$. Then we say that L^\perp is orthogonal to L if the following monotonicity of the canonical projection $p: X \rightarrow L^\perp$ holds: $d(x_1, L) < d(x_2, L)$ implies $\|p(x_1)\| < \|p(x_2)\|$. Observe that if L^\perp is orthogonal to L , then $d(x_1, L) = d(x_2, L)$ implies $\|p(x_1)\| = \|p(x_2)\|$. Indeed, $d(tx_1, L) < d(x_2, L)$ for $t \in (0, 1)$. Hence, $\|p(tx_1)\| < \|p(x_2)\|$. Taking the limit as $t \rightarrow 1$, we obtain $\|p(x_1)\| \leq \|p(x_2)\|$. Similarly, $\|p(x_2)\| \leq \|p(x_1)\|$.

Note that if $\text{codim } L = 1$, the above monotonicity always holds and then does not specify an orthogonality.

PROPOSITION 2.1. *Let X be a Hilbert space and L be a closed subspace. Then the orthogonal complement L^\perp (in the usual sense) is orthogonal to L . Conversely, if L^\perp is orthogonal to L and $L^+ \cap L^\perp = \{0\}$, then $L^+ = L^\perp$.*

Proof. L^\perp is clearly orthogonal to L . Now let L^+ be orthogonal to L and $L^+ \cap L^\perp \neq \{0\}$. Suppose $x_1 \in L^+ \setminus L^\perp$ exists. Then $d(x_1, L) < \|x_1\|$. We find $l \in L$ satisfying $d(x_1, L) < \|x_1 - l\| < \|x_1\|$. In $L^+ \cap L^\perp \neq \{0\}$, there exists x_2 with $\|x_2\| = \|x_1 - l\|$. Hence, $d(x_2, L) = \|x_2\| > d(x_1, L)$, which contradicts the fact that $\|p(x_2)\| = \|x_2\| < \|x_1\| = \|p(x_1)\|$. So, $L^+ \subseteq L^\perp$. If L^+ was a proper subset of L^\perp , there would exist $0 \neq x \in L^\perp$ such that $\langle x, l \rangle = 0$ for all $l \in L^+$. This and the fact that $\langle x, l \rangle = 0$ for all $l' \in L$ together imply that $\langle x, y \rangle = 0$ for all $y \in L \oplus L^+ = X$. This contradiction shows that $L^+ = L^\perp$. \square

Note that if X is not a Hilbert space, there may not exist L^+ orthogonal to a given closed subspace L . The following example shows that our orthogonality assumption imposed in the subsequent theorems is weaker than the usual orthogonality if X is a Hilbert space. It also ensures that the assumption $L^+ \cap L^\perp \neq \{0\}$ in Proposition 2.1 is essential.

Example 2.2 (Penot, private communication). Let X be the Euclidean space \mathbb{R}^4 , $L = \{(0, x_2, x_3, 0) \in X / x_2, x_3 \in \mathbb{R}\}$. Then, both $L^\perp = \{(x_1, 0, 0, x_4) \in X / x_1, x_4 \in \mathbb{R}\}$ and $L^+ = \{x \in X / x_1 = x_2, x_3 = x_4\}$ are orthogonal to L . Note that $L^+ \cap L^\perp = \{0\}$.

In what follows, for a set $A \subset X$, by A^+ we denote the projection $p(A)$ on L^+ .

3. Sufficient conditions for efficiency. Throughout this paper, let X be a normed space ordered by a convex cone C with $\text{cl } C \neq X$ and let S be a nonempty subset of X .

THEOREM 3.1. *Assume that $X = L \oplus L^+$, where L^+ is orthogonal to L if $\text{codim } L > 1$. Assume further that, for all $x_1, x_2 \in C^+$,*

$$(3) \quad \|\alpha x_1 + \beta x_2\| \leq \|x_1 + x_2\|$$

whenever $\alpha, \beta \in [0, 1]$. Then the following assertions hold:

(a) *If $S \subseteq \hat{x} + C$ for some $\hat{x} \in X$, then any point $\bar{x} \in X$ satisfying*

$$(4) \quad d(\bar{x}, \hat{x} + L) < d(x, \hat{x} + L) \quad \text{for all } x \in S \setminus \{\bar{x}\}$$

is an efficient point of S ;

(b) *Every point $\bar{x} \in (\tilde{x} - C) \cap S$, for some $\tilde{x} \in S$, satisfying*

$$(5) \quad d(\bar{x}, \tilde{x} + L) > d(x, \tilde{x} + L) \quad \text{for all } x \in ((\tilde{x} - C) \cap S) \setminus \{\bar{x}\}$$

is an efficient point of S .

Proof. (a) We first show that $p(\bar{x}) \in E(S^+, C^+)$. Since $S \subseteq \hat{x} + C$, $S^+ \subseteq p(\hat{x}) + C^+$. Then $(p(\bar{x}) - C^+) \cap S^+ = (p(\bar{x}) - C^+) \cap S^+ \cap (p(\hat{x}) + C^+)$. Let z be any point in the latter set. Then $z - p(\hat{x}) \in C^+$ and $p(\bar{x}) - p(\hat{x}) - (z - p(\hat{x})) \in C^+$. Therefore by (3),

$$\|z - p(\hat{x})\| \leq \|p(\bar{x}) - p(\hat{x})\|.$$

Since L^+ is orthogonal to L , (4) implies that

$$\|p(\bar{x}) - p(\hat{x})\| < \|z - p(\hat{x})\| \quad \text{for all } z \in S^+ \setminus \{p(\bar{x})\}.$$

Thus $(p(\bar{x}) - C^+) \cap S^+ = \{p(\bar{x})\}$, i.e., $p(\bar{x}) \in E(S^+, C^+)$.

Now suppose $\bar{x} \notin E(S, C)$, i.e., there exists $x \in S$ such that $x \in (\bar{x} - C) \setminus (\bar{x} + C)$. Then, $p(x) \in p(\bar{x}) - C^+$. Assertion (a) will be proved if we show that $p(x) \notin p(\bar{x}) + C^+$, because this contradicts the efficiency of $p(\bar{x})$. Note that (3) implies that C^+ is pointed, for if there exists $x_1 \in C^+ \setminus \{0\}$ such that $x_2 = -x_1 \in C^+$, then, taking $\alpha = 1, \beta = 0$, we arrive at a contradiction $\|x_1\| \leq 0$. So if $p(x) \in p(\bar{x}) + C^+$, we have $p(x) = p(\bar{x})$. Then by the orthogonality, $d(x, \hat{x} + L) = d(\bar{x}, \hat{x} + L)$, contradicting (4).

(b) Since \bar{x} is the center of the straight interval $(2\bar{x} - \tilde{x}, \tilde{x})$, by (5) and by the symmetry of the balls in X we have, for all $x \in ((\tilde{x} - C) \cap S) \setminus \{\bar{x}\}$,

$$d(\bar{x}, 2\bar{x} - \tilde{x} + L) < d(x, 2\bar{x} - \tilde{x} + L).$$

Observing that $\bar{x} \in (\tilde{x} - C) \cap S \cap (2\bar{x} - \tilde{x} + C) \subseteq 2\bar{x} - \tilde{x} + C$, we can apply assertion (a) to see that $\bar{x} \in E((\tilde{x} - C) \cap S \cap (2\bar{x} - \tilde{x} + C), C)$. We claim that $\bar{x} \in E((\tilde{x} - C) \cap S, C)$. Indeed, suppose there exists $x' \in (\tilde{x} - C) \cap S \cap ((\bar{x} - C) \setminus (\bar{x} + C))$. Then $p(\bar{x}) - p(x') \in C^+$. Since $p(\tilde{x}) - p(\bar{x}) \in C^+$, by (3),

$$\|p(\tilde{x}) - p(\bar{x})\| \leq \|p(\tilde{x}) - p(\bar{x}) + p(\bar{x}) - p(x')\| = \|p(\tilde{x}) - p(x')\|.$$

This and (5) together show that $x' = \bar{x}$, which is a contradiction. Thus $\bar{x} \in E((\tilde{x} - C) \cap S, C)$, i.e., $(\bar{x} - C) \cap (\tilde{x} - C) \cap S \subseteq \bar{x} + C$.

Finally, as $\bar{x} - C \subseteq \tilde{x} - C$, the last inclusion implies

$$(\bar{x} - C) \cap S = (\bar{x} - C) \cap (\tilde{x} - C) \cap S \subseteq \bar{x} + C,$$

i.e., $\bar{x} \in E(S, C)$. \square

Note that it is rather restrictive to assume that $S \subseteq \hat{x} + C$. Therefore, assertion (b), being true without this assumption, is important. Moreover we can ask the natural question of whether the theorem remains true if we strengthen (3) to the strict inequality and at the same time weaken (4) and (5), allowing nonstrict inequalities to hold. This is indeed the case, but under an additional assumption as follows.

THEOREM 3.1'. *Under the additional assumption that $L = \text{cl } C \cap (-\text{cl } C)$, Theorem 3.1 is still true if (3) is replaced by*

$$(3') \quad \|\alpha x_1 + \beta x_2\| < \|x_1 + x_2\|$$

for all $x_1, x_2 \in C^+$ such that $x_1 + x_2 \neq 0$ and all $\alpha, \beta \in [0, 1]$ with $\alpha + \beta < 2$, and if (4) and (5) are replaced by the nonstrict inequalities.

Proof. (a) Similarly as above, we have $p(\bar{x}) \in E(S^+, C^+)$. Suppose $\bar{x} \notin E(S, C)$, i.e., there exists $x \in S$ such that $x \in (\bar{x} - C) \setminus (\bar{x} + C)$. As before, if $p(x) \in (p(\bar{x}) - C^+) \cap (p(\bar{x}) + C^+)$, then $p(x) = p(\bar{x})$. Since $L = \text{cl } C \cap (-\text{cl } C)$, $x \in (\bar{x} - \text{cl } C) \cap (\bar{x} + \text{cl } C)$. This contradicts the fact that $x \notin \bar{x} + C$.

(b) This assertion is proved by applying (a) as for Theorem 3.1. \square

The following examples confirm that the assumptions of the theorems are essential.

Example 3.2 (the orthogonality is essential). Let X be the Euclidean space \mathbb{R}^3 . Assume, for Fig. 1, that $|\overline{ob}| = |\overline{oc}|$ and $|\overline{ab}| = |\overline{ac}|$ (by $|\cdot|$ we denote the length of a straight interval), and that $\angle oab = \angle oac = (\pi/2)$. Let the cone C be the part of \mathbb{R}^3 , defined by two planes oab and oac , corresponding to the angle bac . Let $\overline{de} \parallel \overline{ac}$. Let d be so near to b that $|\overline{ad}| > |\overline{ae}|$ and that $\angle aed > (\pi/2)$ (since $\angle bac > \pi/2$, see Fig. 1(b)). Let S be the interval \overline{de} . Let L be the plane oxy , which is not orthogonal to $L = C \cap (-C)$. Then all other assumptions of Theorems 3.1(a) and 3.1'(a) are satisfied with $\bar{x} = e$, since

$$d(e, L) < d(u, L) \quad \text{for all } u \in \overline{de}, u \neq e,$$

but $e \notin E(S, C)$ (d is the unique efficient point of S).

Similarly, we can show that the orthogonality is essential for assertion (b) (for instance, we can easily construct a similar counterexample in \mathbb{R}^3 with the ordering cone being $-C$, where C is defined in Example 3.2).

Example 3.3 (assumption that $L = \text{cl } C \cap (-\text{cl } C)$ is essential). Let X be the Euclidean space \mathbb{R}^3 ordered by \mathbb{R}_+^3 . Let $S = \{(0, 0, z) \mid z \in (0, 1]\}$. Then $E(S, C) = \emptyset$. Let L be the straight line \overline{oz} and L^+ be the plane oxy . Then, except for the assumption that $L = \text{cl } C \cap (-\text{cl } C)$, all assumptions of Theorem 3.1' are satisfied for every point of S , although none are efficient.

FIG. 1

The following lemma assures us that Theorems 3.1 and 3.1' are extensions of the corresponding results of Wierzbicki, Rolewicz, and Jahn.

LEMMA 3.4. *The following conditions are equivalent in pairs, (i)–(i') and (ii)–(ii'):*

- (i) Condition (3) holds;
- (ii) Condition (3') holds;
- (i') $C^+ \cap (x - C^+) \subseteq L^+ \cap \text{cl } B(0, \|x\|)$ for all $x \in L^+$;
- (ii') $C^+ \cap (x - C^+) \subseteq L^+ \cap B(0, \|x\|) \cup \{x\}$ for all $x \in L^+$.

Proof. We prove only the equivalence of (ii) and (ii'). The equivalence of (i) and (i') is proved similarly. Suppose there exist $x_1, x_2 \in C^+$ and $\alpha, \beta \in [0, 1]$ with $\alpha + \beta < 2$ such that $\|\alpha x_1 + \beta x_2\| \geq \|x_1 + x_2\|$. Put $x = x_1 + x_2$ and $z = \alpha x_1 + \beta x_2$. Then $z \in C^+ \cap (x - C^+)$, but $z \notin L^+ \cap B(0, \|x\|) \cup \{x\}$.

Conversely, if $z \in C^+ \cap (x - C^+)$, then $x - z \in C^+$. By (ii), if $x - z \neq 0$, we have

$$\|z\| < \|z + x - z\| = \|x\|.$$

Thus, (ii') holds. \square

Of course, we can restate (i) and (ii) in terms of increasing norms following Jahn to see clearer the relations between the above theorems and the corresponding results of Jahn [7], [9]. Note also that sometimes a statement of the form (i') and (ii') is more convenient than (i) and (ii), as in the case of Theorem 4.1 below. Furthermore, it may be interesting that in the case of Hilbert spaces, (i) and (ii) are equivalent although in general (ii) is stronger than (i). To prove this, we can show that (i') implies that $C^+ \subseteq (C^+)^*$, where the conjugation is considered on L^+ , in the same way as in Theorem 3 of [14].

We should point out the following important fact concerning possibilities of applying Theorems 3.1 and 3.1'. Both conditions (i) and (ii) are satisfied when L^+ is one-dimensional. So assertions (a) and (b) of these theorems always hold if L is any closed hyperplane of the normed space X if C is contained in a closed half-space defined by P . Moreover, since $\text{cl } C \neq X$ and C is a convex cone, such a P always

exists. In general, there may be many subspaces L satisfying the assumptions of these theorems. However, since $d(\bar{x}, \hat{x} + L) = \inf_{l \in L} \|\bar{x} - \hat{x} + l\|$, the bigger is L , the more difficult is the problem of finding \bar{x} . The following propositions are helpful in looking for a space L as small as possible.

PROPOSITION 3.5. *Let X be a Hilbert space. Let an orthogonal sum $L = L_1 \oplus L_2$ be a subspace of X . Let p_1 be the orthogonal projection of X onto L_1 . Assume that L satisfies (3) and that $\langle x, x' \rangle \geq 0$ for all $x, x' \in p_1(C)$. Then L_1 should satisfy (3) as well.*

Proof. Let p and \tilde{p} be the orthogonal projections of X onto L^\perp and L_2^\perp , respectively. Then for arbitrary c, c' in C we have

$$\begin{aligned} \langle \tilde{p}(c), \tilde{p}(c') \rangle &= \langle p(c) + p_1(c), p(c') + p_1(c') \rangle \\ &= \langle p(c), p(c') \rangle + \langle p_1(c), p_1(c') \rangle. \end{aligned}$$

Since L satisfies (3), $p(C) \subseteq (p(C))^*$, where the conjugation is considered in L^\perp . Hence $\langle p(c), p(c') \rangle \geq 0$. Thus $\langle \tilde{p}(c), \tilde{p}(c') \rangle \geq 0$, i.e., L_2 fulfils (3). \square

Note further that each subspace L satisfying (3) should contain $L_0 = \text{cl } C \cap (-\text{cl } C)$. Therefore a question may arise: can we extend L_0 to a subspace L satisfying (3)? The following simple result gives an answer.

PROPOSITION 3.6. *Let X be a Hilbert space. Let $L_0 = \text{cl } C \cap (-\text{cl } C)$. Let H be a set of all possible h in L_0^\perp meeting the following conditions:*

- (i) *All points of H are orthogonal in pairs;*
 - (ii) *For each $h \in H$, there exist $c, c' \in C$ such that $h = p(c)$ and $\langle p(c), p(c') \rangle < 0$, where p is the orthogonal projection of X onto $(L_0 \oplus (H \setminus \{h\}))^\perp$.*
- Then, the subspace $L = L_0 \oplus H$ satisfies (3).*

Proof. Suppose, to the contrary, that there exist $c_1, c_2 \in C$ such that $\langle \bar{p}(c_1), \bar{p}(c_2) \rangle < 0$, where \bar{p} stands for the orthogonal projections of X onto $L_0 \oplus H$. Then $H_1 = H \cup \{\bar{p}(c_1)\}$ also satisfies (i) and (ii). This contradicts the definition of H . \square

In practice, especially when X is a Euclidean space, we can expect that by applying Proposition 3.6 a possibly small subspace L meeting condition (3) may be constructed, starting with L_0 as follows. Let p be the orthogonal projection onto L_0^\perp . If $\langle p(c), p(c') \rangle \geq 0$ for all $c, c' \in C$, L_0 clearly satisfies (3). If there are $c_1, c_2 \in C$ with $\langle p(c_1), p(c_2) \rangle < 0$, we put $h_1 = p(c_1)$. It is added here that, since $L_0 = \text{cl } C \cap (-\text{cl } C)$, $p(\text{cl } C) = L_0^\perp \cap \text{cl } C$. Hence, checking the negativity of the above inner products is rather simple. Next, denoting by p_1 the orthogonal projection of X onto $(L_0 + \{\gamma h_1 : \gamma \in \mathbb{R}\})^\perp$, we check whether there are $c'_1, c'_2 \in C$ such that $\langle p_1(c'_1), p_1(c'_2) \rangle < 0$. If there are no such c'_1 and c'_2 , $L_0 + \{\gamma h_1 : \gamma \in \mathbb{R}\}$ is a desired subspace L . If otherwise, we continue to do similarly.

After this thorough discussion of the significance of Theorems 3.1 and 3.1' for efficiency, we are convinced that similar results for weak and proper efficiency are important. Such results are the content of the next section.

4. Sufficient conditions for weak and proper efficiency.

THEOREM 4.1. *Assume that $X = L \oplus L^+$, where L^+ is orthogonal to L if $\text{codim } L > 1$, and that $\text{ri } C \neq \emptyset$. Assume further that*

$$(6) \quad C^+ \cap (u - \text{ri } C^+) \subseteq L^+ \cap B(O, \|u\|) \quad \text{for all } u \in L^+.$$

Then the following assertions hold:

- (a) *If $S \subseteq \hat{x} + C$ for some $\hat{x} \in X$, then any point $\bar{x} \in S$ satisfying*

$$(7) \quad d(\bar{x}, \hat{x} + L) \leq d(x, \hat{x} + L) \quad \text{for all } x \in S$$

is a weakly efficient point of S ;

(b) Every point $\bar{x} \in (\tilde{x} - C) \cap S$, for some $\tilde{x} \in S$, satisfying

$$(8) \quad d(\bar{x}, \tilde{x} + L) \geq d(x, \tilde{x} + L) \quad \text{for all } x \in (\tilde{x} - C) \cap S$$

is a weakly efficient point of S .

Proof. (a) It follows from (6) that

$$(p(\hat{x}) + C^+) \cap (p(\bar{x}) - \text{ri } C^+) \subseteq L^+ \cap B(p(\hat{x}), \|p(\bar{x}) - p(\hat{x})\|).$$

On the other hand, the orthogonality and (7) together imply that

$$\|p(\bar{x}) - p(\hat{x})\| \leq \|p(x) - p(\bar{x})\| \quad \text{for all } x \in S.$$

Consequently, since $S^+ \subset p(\hat{x}) + C^+$, $S^+ \cap (p(\bar{x}) - \text{ri } C^+)$ is empty, i.e., $p(\bar{x}) \in WE(S^+, C^+)$.

To show that $\bar{x} \in WE(S, C)$, suppose there exists $x \in S \cap (\bar{x} - \text{ri } C)$. Then, $p(x) \in (S \cap (\bar{x} - \text{ri } C))^+ \subset S^+ \cap (p(\bar{x}) - \text{ri } C^+)$. This contraposition completes the proof of (a).

(b) By the same argument as in the proof of Theorem 3.1, we obtain that $\bar{x} \in WE((\tilde{x} - C) \cap S \cap (2\bar{x} - \tilde{x} + C), C)$. Furthermore, $\bar{x} \in WE((\tilde{x} - C) \cap S, C)$. For, if there exists $x' \in (\tilde{x} - C) \cap S \cap (\bar{x} - \text{ri } C)$, then $p(x') \in ((\tilde{x} - C) \cap S)^+ \cap (p(\bar{x}) - \text{ri } C^+)$. By (6) and by the symmetry of the balls in L^+ , $\|p(x') - p(\hat{x})\| > \|p(\bar{x}) - p(\tilde{x})\|$. This together with the orthogonality imply that $d(x', \tilde{x} + L) > d(\bar{x}, \tilde{x} + L)$. So $x' \notin (\tilde{x} - C) \cap S$ in view of (8). This contradiction confirms that $\bar{x} \in WE((\tilde{x} - C) \cap S, C)$. Now, observing that

$$(\bar{x} - \text{ri } C) \subseteq \bar{x} - C \subseteq \tilde{x} - C,$$

we obtain

$$(\bar{x} - \text{ri } C) \cap S = (\bar{x} - \text{ri } C) \cap S \cap (\tilde{x} - C) = \emptyset,$$

which allows us to conclude that $\bar{x} \in WE(S, C)$ \square

Remark 4.2. If $\text{ri } C^+ \neq \emptyset$, it is not hard to see the following connections between condition (6) and conditions (3), (3'): (3') \Rightarrow (6) \Rightarrow (3). If X is a Hilbert space, all these conditions are equivalent. But in the case of normed spaces, we can easily find examples showing that the converse implications are not true. Theorem 4.1(a) is an extension of the corresponding result of Jahn [7].

In the following, by $\text{reco } C$ ($\text{cor } C$) we denote the relative algebraic interior of C (the algebraic interior of C , respectively).

THEOREM 4.3. Let $X = L \oplus L^+$, where L^+ is orthogonal to L if $\text{codim } L > 1$. Assume that

$$(9) \quad C^+ \cap (x - C^+) \subseteq L^+ \cap B(O, \|x\|) \cup \{x\} \quad \text{for all } x \in L^+.$$

Then the following assertions hold:

(a) If $\text{reco } C \neq \emptyset$ and if $S \subseteq \hat{x} + C$ for some $\hat{x} \in X$, then any point $\bar{x} \in \hat{x} + \text{reco } C$ such that

$$(10) \quad d(\bar{x}, \hat{x} + L) \leq d(x, \hat{x} + L) \quad \text{for all } x \in S$$

is a properly efficient point of S ;

(b) If $\text{int } C \neq \emptyset$, then every point $\bar{x} \in (\tilde{x} - \text{int } C) \cap S$ for some $\tilde{x} \in S$ such that

$$(11) \quad d(\bar{x}, \tilde{x} + L) \geq d(x, \tilde{x} + L) \quad \text{for all } x \in (\tilde{x} - \text{int } C) \cap S$$

is a properly efficient point of S .

Proof. (a) First, we claim that

$$(12) \quad d(\bar{x}, \hat{x} + L) \leq d(x, \hat{x} + L) \quad \text{for all } x \in S + C.$$

Indeed, suppose there exist $x_1 \in S$ and $c_1 \in C$ such that

$$d(x_1 + c_1, \hat{x} + L) < d(\bar{x}, \hat{x} + L).$$

Then

$$\|p(x_1) + p(c_1) - p(\hat{x})\| < \|p(\bar{x}) - p(\hat{x})\|.$$

Since $p(c_1) \in C^+$ and $p(x_1) - p(\hat{x}) \in C^+$, we have

$$p(x_1) - p(\hat{x}) \in C^+ \cap (p(x_1) - p(\hat{x}) + p(c_1) - C^+).$$

Hence by (9),

$$\|p(x_1) - p(\hat{x})\| \leq \|p(x_1) + p(c_1) - p(\hat{x})\| < \|p(\bar{x}) - p(\hat{x})\|,$$

which contradicts (10). Thus (12) holds.

It is easy to verify that $d(\cdot, \hat{x} + L)$ is convex and continuous. Therefore (12) implies (see, e.g., [12, p. 156])

$$(13) \quad d(\bar{x}, \hat{x} + L) \leq d(\bar{x} + h, \hat{x} + L) \quad \text{for all } h \in T(S + C, \bar{x}).$$

Clearly, (13) also holds for all $h \in (\hat{x} - \bar{x} + C) \cap T(S + C, \bar{x})$. As $h \in \hat{x} - \bar{x} + C$, i.e., $\bar{x} + h \in \hat{x} + C$, we can apply Theorem 3.1' to obtain that

$$(14) \quad O \in E((\hat{x} - \bar{x} + C) \cap T(S + C, \bar{x}), C).$$

Suppose now that $\bar{x} \notin PE(S, C)$, i.e., $O \notin E(T(S + C, \bar{x}), C)$. Then there exists a nonzero vector $x \in ((-C) \setminus (C)) \cap T(S + C, \bar{x})$. Since $\bar{x} \in \hat{x} + \text{recor } C$, for sufficiently small $\gamma > 0$ we have $\bar{x} + \gamma x \in x + C$. Therefore

$$\gamma x \in (\hat{x} - \bar{x} + C) \cap ((-C) \setminus (C)) \cap T(S + C, \bar{x}).$$

This contradiction to (14) leads to assertion (a).

(b) The symmetry and (11) together imply that

$$d(\bar{x}, 2\bar{x} - \tilde{x} + L) \leq d(x, 2\bar{x} - \tilde{x} + L)$$

for all $x \in (\tilde{x} - \text{int } C) \cap S \cap (2\bar{x} - \tilde{x} + C) \subseteq 2\bar{x} - \tilde{x} + C$. Since $\bar{x} \in \tilde{x} - \text{int } C$, $\bar{x} \in 2\bar{x} - \tilde{x} + \text{int } C$ by the symmetry. According to assertion (a), $\bar{x} \in PE((\tilde{x} - \text{int } C) \cap S \cap (2\bar{x} - \tilde{x} + C), C)$, or, what is the same, $O \in E(T((\tilde{x} - \text{int } C) \cap S \cap (2\bar{x} - \tilde{x} + C) + C, \bar{x}), C)$. Now assertion (b) will follow immediately if we show that

$$(15) \quad T((\tilde{x} - \text{int } C) \cap S \cap (2\bar{x} - \tilde{x} + C) + C, \bar{x}) = T(S + C, \bar{x}).$$

Noting that $\bar{x} \in \text{int}((\tilde{x} - \text{int } C) \cap (2\bar{x} - \tilde{x} + C))$ we find a neighbourhood $N(\bar{x}) \subseteq (\tilde{x} - \text{int } C) \cap (2\bar{x} - \tilde{x} + C)$. Then

$$N(\bar{x}) \cap ((\tilde{x} - \text{int } C) \cap S \cap (2\bar{x} - \tilde{x} + C) + C) = N(\bar{x}) \cap (S + C).$$

Observing that the tangent cone of a set at a point depends only on the points of the set in a neighborhood of the given point, we arrive at (15). \square

Remark 4.4. Assertion (a) is an extension of Theorem 2.2 in [8], which corresponds to the case $L^+ = X$, $L = \{0\}$, $\text{cor } C \neq \emptyset$ and $S \subseteq \hat{x} + \text{cor } C$. In that theorem it is assumed that some conditions, which are more restrictive than (9) and (10), are satisfied for an additional norm in X . This norm is assumed to be not stronger than the norm of X . The concluded properness of \bar{x} is stated with respect to the original norm. However, we observe that the tangent cone corresponding to the additional norm $T^{\text{ad}}(S + C, \bar{x})$ contains $T(S + C, \bar{x})$. Hence $O \in E(T^{\text{ad}}(S + C, \bar{x}), C)$ implies $O \in E(T(S + C, \bar{x}), C)$. Thus using an additional norm does not make the theorem stronger.

5. Necessary conditions for efficiency and weak efficiency. In general, the above-formulated sufficient conditions are not necessary conditions, as we can easily find counterexamples. However, we have the following related necessary conditions.

THEOREM 5.1. *Let X be a normed space ordered by a closed convex cone C . Assume that $X = L \oplus L^+$, where $L = C \cap (-C)$ and L^+ is orthogonal to L if $\text{codim } L > 1$. Assume further that $\text{cor } C^+$ is nonempty. Then the following assertions hold.*

(a) *Each efficient point \bar{x} of an arbitrary set S satisfies the following condition: For a given \hat{x} such that $p(\hat{x}) \in p(\bar{x}) - \text{cor } C^+$,*

$$d(\bar{x}, \hat{x} + L) \leq d(x, \hat{x} + L)$$

and

$$\|p(\bar{x}) - p(\hat{x})\| < \|p(x) - p(\hat{x})\|$$

whenever $p(x) \neq p(\bar{x})$, for all $x \in S$ if and only if the norm (of X) considered on L^+ is the Minkowski functional corresponding to the order interval $[p(\hat{x}) - p(\bar{x}), p(\bar{x}) - p(\hat{x})]$, i.e.,

$$(16) \quad L^+ \cap \text{cl } B(O, \|p(\bar{x}) - p(\hat{x})\|) = (p(\hat{x}) - p(\bar{x}) + C^+) \cap (p(\bar{x}) - p(\hat{x}) - C^+).$$

(b) *Each efficient point \bar{x} of an arbitrary set S satisfies the condition: For a given \tilde{x} such that $p(\tilde{x}) \in p(\bar{x}) + \text{cor } C^+$,*

$$(17) \quad d(\bar{x}, \tilde{x} + L) \geq d(x, \tilde{x} + L)$$

and

$$(18) \quad \|p(\bar{x}) - p(\tilde{x})\| > \|p(x) - p(\tilde{x})\|$$

whenever $p(x) \neq p(\tilde{x})$, for all $x \in (\tilde{x} - C) \cap S$, if and only if the norm considered on L^+ is the Minkowski functional corresponding to the order interval $[p(\bar{x}) - p(\tilde{x}), p(\tilde{x}) - p(\bar{x})]$.

Proof. (a) Assume that (16) holds. Arguing by contradiction, suppose there exists $x' \in S$ with $\|p(x') - p(\hat{x})\| \leq \|p(\bar{x}) - p(\hat{x})\|$. Then $p(x') \in [2p(\hat{x}) - p(\bar{x}), p(\bar{x})]$. Hence $p(x') \in p(\bar{x}) - C^+$. If $p(x') \in p(\bar{x}) + C^+$, we have, by the pointedness of C^+ , $p(\bar{x}) = p(x')$. If $p(x') \notin p(\bar{x}) + C^+$, i.e.,

$$(19) \quad p(x') \in (p(\bar{x}) - C^+) \setminus (p(\bar{x}) + C^+),$$

then $x' \notin \bar{x} + C$. Moreover, $x' \in x - C$. Indeed, suppose $x' \in \bar{x} - C$. Then, since $L = C \cap (-C)$, $(x' + L) \cap (\bar{x} - C) = \emptyset$, for if $x' + l \in \bar{x} - C$ for some $l \in L$ we would have $x' = x' + l - l \in \bar{x} - C - l \subset \bar{x} - C$. Therefore, observing that $p(C) = C \cap L^+$, $p(x' + L) = p(x')$, we derive that $\{p(x')\} \cap (p(\bar{x}) - C^+) = \emptyset$. This contradiction to (19) asserts that $x' \in \bar{x} - C$. This in turn is impossible due to the efficiency of \bar{x} .

Now suppose there exists $x' \in S$ with $d(x', \hat{x} + L) < d(\bar{x}, \hat{x} + L)$. Then $\|p(x') - p(\hat{x})\| < \|p(\bar{x}) - p(\hat{x})\|$. As in the preceding part of the proof, this leads to a contradiction.

Conversely suppose (16) does not hold. Then at least one of the following two possibilities must occur.

(i) There exists $u \in L^+$ satisfying

$$\|u - p(\hat{x})\| < \|p(\bar{x}) - p(\hat{x})\|, \quad u \notin p(\bar{x}) - C^+.$$

Then the set S consisting of \bar{x} and any point x of $p^{-1}(u)$ has \bar{x} as an efficient point, but $d(x, \hat{x} + L) < d(\bar{x}, \hat{x} + L)$.

(ii) There exists $u \in L^+$ satisfying

$$\|p(\bar{x}) - p(\hat{x})\| < \|u - p(\hat{x})\|, \quad u \in (p(\bar{x}) - C^+) \setminus (p(\bar{x}) + C^+).$$

Then for the set S consisting of \bar{x} and any point x of $p^{-1}(u)$ we have $x \in E(S, C)$, but $d(\bar{x}, \hat{x} + L) < d(x, \hat{x} + L)$.

(b) We observe that $p(2\bar{x} - \tilde{x}) \in p(\bar{x}) - \text{cor } C^+$ and that

$$[p(\bar{x}) - p(\tilde{x}), p(\tilde{x}) - p(\bar{x})] = [p(2\bar{x} - \tilde{x}) - p(\bar{x}), p(\bar{x}) - p(2\bar{x} - \tilde{x})].$$

Furthermore, $\bar{x} \in E((\tilde{x} - C) \cap S, C)$ whenever $\bar{x} \in E(S, C)$.

These facts allow us to apply assertion (a) to obtain that

$$d(\bar{x}, 2\bar{x} - \tilde{x} + L) \leq d(x, 2\bar{x} - \tilde{x} + L)$$

and

$$\|p(\bar{x}) - p(2\bar{x} - \tilde{x})\| < \|p(x) - p(2\bar{x} - \tilde{x})\|$$

whenever $p(x) \neq p(\bar{x})$, for all $x \in (\tilde{x} - C) \cap S$. This, by virtue of the symmetry of the balls, implies that

$$d(\bar{x}, \tilde{x} + L) \geq d(x, \tilde{x} + L), \quad \|p(\bar{x}) - p(\tilde{x})\| > \|p(x) - p(\tilde{x})\|$$

whenever $p(x) \neq p(\bar{x})$, for all $x \in (\tilde{x} + C) \cap S$.

Conversely, if (17) and (18) hold, then by the symmetry of the balls we have

$$d(\bar{x}, 2\bar{x} - \tilde{x} + L) \leq d(x, 2\bar{x} - \tilde{x} + L)$$

and

$$\|p(\bar{x}) - p(2\bar{x} - \tilde{x})\| < \|p(x) - p(2\bar{x} - \tilde{x})\|$$

whenever $p(x) \neq p(\bar{x})$, for all $x \in (\tilde{x} - C) \cap S$. So, we can apply assertion (a) to see that the norm on L^+ is the Minkowski functional corresponding to the order interval

$$[p(2\bar{x} - \tilde{x}) - p(\bar{x}), p(\bar{x}) - p(2\bar{x} - \tilde{x})] = [p(\bar{x}) - p(\tilde{x}), p(\tilde{x}) - p(\bar{x})].$$

Theorem 5.1(a) extends Theorem 3.6 of [7]. The following example explains why the assumption that $L = C \cap (-C)$ is essential.

Example 5.2. Let $X = \mathbb{R}^3$ with the norm defined as follows

$$\|(x, y, z)\| = ((\max\{|x|, |y|\})^2 + |z|^2)^{1/2}.$$

Let $C = \{(x, y, 0) \mid x \geq 0, y \geq 0\}$. Let L be the subspace $\{(0, 0, z) \mid z \in \mathbb{R}\}$. Let $S = \{(1, 1, 1); (0, 0, 2)\} := \{\bar{x}, x'\}$. Let $\hat{x} = (0, 0, 0)$. Then, $\bar{x} \in E(S, C)$, but

$$d(\bar{x}, \hat{x} + L) = \sqrt{2} > 0 = d(x', \hat{x} + L).$$

A similar proof gives us the following result for weakly efficient points.

THEOREM 5.3. *Let X , C and L satisfy the assumptions of Theorem 5.1. Then the following assertions hold.*

(a) *Each weakly efficient point \bar{x} of an arbitrary set S fulfills the following condition: for a given \hat{x} such that $p(\hat{x}) \in p(\bar{x}) - \text{cor } C^+$,*

$$d(\bar{x}, \hat{x} + L) \leq d(x, \hat{x} + L) \quad \text{for all } x \in S$$

if and only if the norm considered on L^+ is the Minkowski functional corresponding to the order interval $[p(\hat{x}) - p(\bar{x}), p(\bar{x}) - p(\hat{x})]$.

(b) Each weakly efficient point of an arbitrary set S satisfies the following condition: for a given \tilde{x} such that $p(\tilde{x}) \in p(\bar{x}) + \text{cor } C^+$,

$$d(\bar{x}, \tilde{x} + L) \geq d(x, \tilde{x} + L) \quad \text{for all } x \in (\tilde{x} - C) \cap S$$

if and only if the norm considered on L^+ is the Minkowski functional corresponding to the order interval $[p(\bar{x}) - p(\tilde{x}), p(\tilde{x}) - p(\bar{x})]$.

Theorem 5.3(a) extends Theorem 3.2 of [7].

Remark 5.4. Using norm scalarization to obtain for proper efficiency, necessary conditions similar to Theorems 5.1 and 5.3 seem to be so complicated that they have no practical meaning. Using a penalty scalarizing functional, which is closely related to the norm, is much more convenient (see [18]).

6. Application: A control approximation problem. We investigate the following control approximation problem, which is similar to the control approximation problem considered in [10], but with a nonpointed ordering cone.

Let a control system

$$(20) \quad \dot{x}(t) = f(x(t), u(t)) \quad \text{almost everywhere on } [t_0, t_1],$$

$$(21) \quad x(t_0) = x_0,$$

$$(22) \quad u(\cdot) \in U$$

be given; where $F: \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ is a given mapping; $x_0 \in \mathbb{R}^n$ and $[t_0, t_1] \subset \mathbb{R}$ are given; and $U \subset L_\infty^m[t_0, t_1]$ are also given. Assume that for each control $u(\cdot) \in U$, the system (20)–(22) has a unique solution $x(\cdot, u) \in W_{1\infty}^n[t_0, t_1] := \{x: [t_0, t_1] \rightarrow \mathbb{R}^n \mid x \text{ is absolutely continuous and } \dot{x} \in L_\infty^n[t_0, t_1]\}$.

Let $z(\cdot) \in C^n[t_0, t_1]$ be given, where $C^n[t_0, t_1]$ is equipped with the norm

$$\|x(\cdot)\| = \max_{\substack{i \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t)|,$$

and ordered by the cone

$$C = \{x \in C^n[t_0, t_1] \mid x_i(t) \geq 0 \text{ for } i = 2, \dots, n \text{ and } t \in [t_0, t_1]\}.$$

We recall that a supremal point of a subset A of a linear ordered space X , denoted by $\sup A$, is a point $\bar{a} \in X$ such that $a \leq \bar{a}$ for all $a \in A$ and $\bar{a} \leq b$ for all b satisfying $a \leq b$ for all $a \in A$. An infimal point is similarly defined. If each pair of points of X has a supremal and an infimal point, X is called a linear lattice. A point $|x|^{or} := \sup \{x, -x\}$ is called an order absolute value of x . It is known that $C^n[t_0, t_1]$ ordered by the above C is a linear lattice.

Following [10], we say that $\bar{u}(\cdot) \in U$ is an optimal control (or weakly optimal control) if $|x(\cdot, \bar{u}) - z(\cdot)|^{or}$ is an efficient point (or weakly efficient point, respectively) of the set

$$S := \{|x(\cdot, u) - z(\cdot)|^{or} \mid u \in U\}.$$

The problem of finding an optimal control or a weakly optimal control is called a control approximation problem. Clearly, this problem corresponds to the vector optimization problem of finding an efficient point or a weakly efficient point of S .

In this case, we set $X = C^n[t_0, t_1]$,

$$L = C \cap (-C) = \{x \in X \mid x = (x^1, 0, \dots, 0)\},$$

$$L^+ = \{x \in X \mid x = (0, x^2, \dots, x^n)\}.$$

Then L^+ is orthogonal to L . Moreover $S \subseteq C$ and both (3) and (6) are satisfied. Observe also that, for $x \in C^n[t_0, t_1]$,

$$d(x, L) = \|p(x)\| = \|(O, x^2, \dots, x^n)\|,$$

$$\| |p(x)|^{or} \| = \max_{\substack{2 \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t)| = \|p(x)\|.$$

By virtue of Theorems 3.1 and 4.1 we obtain the following result. The proof is a direct calculation and then omitted.

COROLLARY 6.1. (a) A control $\bar{u} \in U$ is optimal if

$$\max_{\substack{2 \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t, \bar{u}) - z^i(t)| < \max_{\substack{2 \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t, u) - z^i(t)|$$

for all $u \in U$ with $|x(\cdot, u) - z(\cdot)|^{or} \neq |x(\cdot, \bar{u}) - z(\cdot)|^{or}$.

(b) A control $\bar{u} \in U$ is optimal if

$$\max_{\substack{2 \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t, \bar{u}) - z^i(t)| \leq \max_{\substack{2 \leq i \leq n \\ t_0 \leq t \leq t_1}} |x^i(t, u) - z^i(t)|$$

for all $u \in U$.

Acknowledgments. I would like to thank the referees and Professor J. P. Penot for many valuable remarks and suggestions.

CONTROLLABILITY AND STABILIZABILITY OF THE THIRD-ORDER LINEAR DISPERSION EQUATION ON A PERIODIC DOMAIN*

D. L. RUSSELL† AND B. Y. ZHANG‡

Abstract. In this paper, solutions of the third-order linear dispersion equations

$$\frac{\partial w}{\partial t} + \frac{\partial^3 w}{\partial x^3} = f(x, t) \quad \text{and} \quad \frac{\partial w}{\partial t} + \frac{\partial^3 w}{\partial x^3} = 0$$

are studied for $t \geq 0, 0 \leq x \leq 2\pi$. In the first case, periodic boundary conditions are imposed at 0 and 2π and the distributed control f , which may, however, have support smaller than $[0, 2\pi]$, is assumed to be generated by a linear feedback law conserving the "volume" $\int_0^{2\pi} w(x, t) dx$ while monotonically reducing $\int_0^{2\pi} w(x, t)^2 dx$. For the second equation, a feedback boundary control having the same properties is applied. In both cases, uniform exponential decay to a constant state is obtained. Related exact controllability questions are also studied, and affirmative results are obtained.

1. Introduction. In [8], [11], and in the doctoral thesis [16] of Zhang a certain control problem has been introduced for the forced Korteweg-de Vries equation

$$(1.1) \quad \frac{\partial w}{\partial t} + w \frac{\partial w}{\partial x} + \frac{\partial^3 w}{\partial x^3} = f(x, t)$$

on the domain $t \geq 0, 0 \leq x \leq 2\pi$, with periodic boundary conditions

$$(1.2) \quad \frac{\partial^k w}{\partial x^k}(0, t) = \frac{\partial^k w}{\partial x^k}(2\pi, t), \quad k = 0, 1, 2,$$

so that the process is periodic with period 2π in the variable x . Issues arising in [11] and [16] have made it clear that further progress requires a very thorough knowledge of the control theory for the related linear third-order equation

$$(1.3) \quad \frac{\partial w}{\partial t} + \frac{\partial^3 w}{\partial x^3} = f(x, t)$$

on the same domain with the same boundary conditions. Such a study is the theme of the present paper.

Let A denote the operator

$$(1.4) \quad Aw = -w'''$$

on the domain $\mathcal{D}(A) \subset L^2(0, 2\pi)$ consisting of functions in $H^3(0, 2\pi)$ satisfying boundary conditions of the form (1.2). It is immediately clear that A generates a strongly continuous unitary group on $L^2(0, 2\pi)$; the eigenfunctions are simply the orthogonal Fourier basis functions in $L^2(0, 2\pi)$,

$$\varphi_k(x) = (2\pi)^{-1/2} e^{ikx}, \quad k = 0, \pm 1, \pm 2, \dots,$$

and the corresponding exponential solutions take the form

$$(1.5) \quad w_k(x, t) = e^{i(k^3 t + kx)}$$

for the same values of k . The formula (1.5) shows immediately that the speed of propagation of sinusoidal waveforms is proportional to the cube of the spatial frequency (inversely proportional to the cube of the wavelength), resulting in rapid dispersion properties of solutions. For $f \in L^2_{\text{loc}}((0, \infty), L^2(0, 2\pi))$ and in initial state $w_0 \in L^2(0, 2\pi)$ the variation-of-parameters formula

$$(1.6) \quad w(\cdot, t) = e^{At}w_0 + \int_0^t e^{A(t-s)}f(\cdot, s) ds$$

applies to yield a strongly continuous “generalized solution” of the inhomogeneous system (1.3). As the work progresses, we will consider more specialized controls as required.

In [11] and [16] we have provided an application-oriented motivation for considering only controls that conserve the quantity

$$(1.7) \quad [w(\cdot, t)] \equiv \int_0^{2\pi} w(x, t) dx.$$

In the applications in question, this corresponds to a fluid “volume.” For appropriately smooth solutions of (1.2), (1.3), we have

$$(1.8) \quad \begin{aligned} \frac{d}{dt} \int_0^{2\pi} w(x, t) dx &= \int_0^{2\pi} \frac{\partial w}{\partial t}(x, t) dx = \int_0^{2\pi} \left(f(x, t) - \frac{\partial^3 w}{\partial x^3}(x, t) \right) dx \\ &= \int_0^{2\pi} f(x, t) dx - \frac{\partial^2 w}{\partial x^2}(x, t) \Big|_{x=0}^{x=2\pi} \end{aligned}$$

and we conclude, using the equation corresponding to $k=2$ in (1.2), that $[w(\cdot, t)]$ is conserved just in the case where

$$(1.9) \quad [f(\cdot, t)] \equiv \int_0^{2\pi} f(x, t) dx = 0$$

for almost all t . Since we are primarily interested in the linear equation (1.3) as a background for studies of the more relevant nonlinear equation (1.1), we will continue to impose this side condition on the applied controls in the linear case.

The exact controllability problem concerns the use of controls, as described, to transfer the system (1.2), (1.3) between given initial and terminal states

$$w(\cdot, 0) = w_0 \in L^2(0, 2\pi), \quad w(\cdot, T) = w_T \in L^2(0, 2\pi)$$

during the interval $[0, T]$, $T > 0$. One might also refer to this as the *open-loop* control problem.

Closed-loop control generally refers to control synthesis by state feedback of some sort and is predominantly concerned with achieving asymptotic stability of an equilibrium state or invariant set. Within the context (1.9) the appropriate invariant set is the set of constant states

$$(1.10) \quad w(x, t) \equiv c,$$

where $c = [w(\cdot, 0)]$. Since it is easy to show (see, e.g., [11]) that, among all $w \in L^2(0, 2\pi)$ such that $[w] = d$ (see (1.7) for the definition of $[w]$), for a given real d the constant state $w(x) \equiv c = d/2\pi$ has least norm in $L^2(0, 2\pi)$, we may hope to approach such a constant state c by incrementally reducing $\|w(\cdot, t)\|_{L^2(0, 2\pi)}$ with application of an appropriate control f , maintaining (1.9) so that (1.10) is true for all t . For $w(x, t)$ an

appropriately smooth solution of (1.3), we easily obtain, with two applications of integration by parts,

$$\begin{aligned}
 \frac{d}{dt} \left(\frac{1}{2} \int_0^{2\pi} w(x, t)^2 dx \right) &= \int_0^{2\pi} w(x, t) \left(f(x, t) - \frac{\partial^3 w}{\partial x^3}(x, t) \right) dx \\
 (1.11) \qquad &= \int_0^{2\pi} w(x, t) f(x, t) dx \\
 &\quad + \left(\frac{1}{2} \left(\frac{\partial w}{\partial x}(x, t) \right)^2 - w(x, t) \frac{\partial^2 w}{\partial x^2}(x, t) \right) \Big|_{x=0}^{x=2\pi}.
 \end{aligned}$$

If periodic boundary conditions (1.2) apply, we have

$$(1.12) \qquad \frac{d}{dt} \left(\frac{1}{2} \int_0^{2\pi} w(x, t)^2 dx \right) = \int_0^{2\pi} w(x, t) f(x, t) dx.$$

With $\mathcal{H} > 0$ and

$$(1.13) \qquad f(x, t) = -\mathcal{H} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right),$$

it is evident that (1.9) is satisfied, so that $[w(\cdot, t)]$ is constant and we may proceed further to compute

$$\begin{aligned}
 &\frac{d}{dt} \left\{ \frac{1}{2} \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} \\
 &= \frac{d}{dt} \left\{ \frac{1}{2} \int_0^{2\pi} w(x, t)^2 dx - \frac{1}{2\pi} [w(\cdot, t)]^2 \right\} \\
 (1.14) \qquad &= \int_0^{2\pi} w(x, t) \frac{\partial w}{\partial t}(x, t) dx \\
 &= -\mathcal{H} \int_0^{2\pi} w(x, t) \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right) dx \\
 &= -\mathcal{H} \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx,
 \end{aligned}$$

where we have used (1.7), (1.12), and (1.13) together with the mutual orthogonality of $[w(\cdot, t)]$ and $w(\cdot, t) - [w(\cdot, t)]/2\pi$. It follows that

$$(1.15) \qquad \left\| w(\cdot, t) - \frac{1}{2\pi} [w(\cdot, t)] \right\|_{L^2(0, 2\pi)}$$

decays to zero exponentially as t tends to infinity, i.e., $w(x, t)$ approaches the constant state $(2\pi)^{-1} [w(\cdot, t)]$ exponentially in the $L^2(0, 2\pi)$ norm.

A more interesting case is obtained if some *a priori* restrictions are imposed on the applied control $f(x, t)$. Let us suppose that $g(x)$ is a piecewise-continuous non-negative function defined for x in $[0, 2\pi]$ such that

$$(1.16) \qquad [g] = \int_0^{2\pi} g(x) dx = 1,$$

and let us restrict attention to controls of the form

$$(1.17) \qquad f(x, t) = g(x) \varphi(x, t), \quad \varphi \in L^2_{\text{loc}}((0, \infty); L^2(0, 2\pi)),$$

so that φ is, in effect, the applied control. If $[a, b]$ is a subinterval of $[0, 2\pi]$, setting $g(x) = (b - a)^{-1} \chi_{[a, b]}$ corresponds to restriction of the support of the control f .

We will study controllability of the system (1.3) by controls (1.17) in § 2. For the moment, we continue to discuss volume-conserving controls given in feedback form. With f of the form (1.13) and \mathcal{K} a positive constant, let us suppose φ to be generated by

$$(1.18) \quad \varphi(x, t) = -\mathcal{K} \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right), \quad \mathcal{K} > 0.$$

Using (1.16) we verify readily that (1.9) holds, so that $[w(\cdot, t)]$ is constant. Then, as in (1.12) and (1.14), we may compute

$$(1.19) \quad \begin{aligned} & \frac{d}{dt} \left\{ \frac{1}{2} \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} \\ &= \int_0^{2\pi} w(x, t) \frac{\partial w}{\partial t}(x, t) dx \\ &= -\mathcal{K} \int_0^{2\pi} w(x, t) g(x) \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right) dx. \end{aligned}$$

Using (1.16) we see that

$$\begin{aligned} & \int_0^{2\pi} g(x) \int_0^{2\pi} g(s) w(s, t) ds \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right) dx \\ &= \left(1 - \int_0^{2\pi} g(x) dx \right) \left(\int_0^{2\pi} g(s) w(s, t) ds \right)^2 = 0, \end{aligned}$$

so that (1.19) yields

$$(1.20) \quad \begin{aligned} & \frac{d}{dt} \left\{ \frac{1}{2} \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} \\ &= -\mathcal{K} \int_0^{2\pi} g(x) \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right)^2 dx \leq 0 \end{aligned}$$

and it is reasonable to suppose, again, that $w(\cdot, t)$ converges, in an appropriate sense, to the constant state $[w(\cdot, t)]$ as $t \rightarrow \infty$. With some further assumptions, we will establish this rigorously in § 2; we there show that with appropriate assumptions on g we have exponential decay to the constant state, uniform with respect to the norm in $L^2(0, 2\pi)$.

It is also possible to pose a volume-conserving open-loop boundary control problem for this system. Let us take $f(x, t) \equiv 0$ and apply the boundary conditions (1.2) for $k = 0$ and $k = 2$ but not for $k = 1$. Then we have

$$(1.21) \quad \frac{\partial w}{\partial t} + \frac{\partial^3 w}{\partial x^3} = 0$$

and (1.8) shows that $[w(\cdot, t)]$ is constant. Again proceeding as in (1.11) and (1.14), we have

$$(1.22) \quad \frac{d}{dt} \left\{ \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} = \left(\frac{\partial w}{\partial x}(x, t) \right)^2 \Big|_{x=0}^{x=2\pi}.$$

If we suppose that the boundary control mechanism takes the form

$$(1.23) \quad \frac{\partial w}{\partial x}(2\pi, t) - \frac{\partial w}{\partial x}(0, t) = h(t),$$

which, since 2π and 0 are identified in this context, is the same as

$$\frac{\partial w}{\partial x}(0^-, t) - \frac{\partial w}{\partial x}(0^+, t) = h(t),$$

then (1.21) becomes

$$\frac{d}{dt} \left\{ \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} = \left(\frac{\partial w}{\partial x}(2\pi, t) + \frac{\partial w}{\partial x}(0, t) \right) h(t).$$

An appropriate feedback mechanism is then

$$(1.24) \quad h(t) = -\mathcal{K} \left(\frac{\partial w}{\partial x}(2\pi, t) + \frac{\partial w}{\partial x}(0, t) \right), \quad \mathcal{K} > 0,$$

resulting in

$$(1.25) \quad \frac{d}{dt} \left\{ \frac{1}{2} \int_0^{2\pi} \left(w(x, t) - \frac{1}{2\pi} [w(\cdot, t)] \right)^2 dx \right\} = -\mathcal{K} \left(\frac{\partial w}{\partial x}(2\pi, t) + \frac{\partial w}{\partial x}(0, t) \right)^2 \leq 0.$$

Again we suspect that $w(\cdot, t)$ tends to the constant state $[w(\cdot, t)]$ as $t \rightarrow \infty$; we study this question in § 3 and show that, in fact, such decay does hold and is uniformly exponential with respect to the norm in $L^2(0, 2\pi)$. Concluding that section, we note that the uniform exponential decay to the constant state obtained for (1.23) and (1.24) implies exact controllability between initial and terminal states w_0 and $w_T \in L^2(0, 2\pi)$ for T appropriately large but independent of these states, provided only that $[w_0] = [w_T]$.

It is not difficult to see that the control mechanism (1.23) corresponds to the application of a dipole of strength $h(t)$ at the point 0 or, equivalently, 2π . One may proceed further to show that control processes of the form (1.17) can be regarded as spatial convolutions of the process (1.23) by using appropriate convolution kernels. We will not pursue these matters further here.

2. Exponential decay rates with distributed controls of restricted form. If we define the operator A as in (1.4), then the system (1.3) with $f(x, t)$ given by (1.17) and (1.18) can be expressed in the form

$$(2.1) \quad \dot{w} = (A - \mathcal{K}G)w$$

(where the dot signifies d/dt), with

$$(2.2) \quad (Gw)(x) = g(x) \left(w(x) - \int_0^{2\pi} g(s)w(s) ds \right), \quad w \in L^2(0, 2\pi).$$

Since A generates a strongly continuous semigroup $S(t)$ of bounded operators in $L^2(0, 2\pi)$ and G is a bounded \cdot operator, $A - \mathcal{K}G$ also generates a strongly continuous

semigroup $S_{\mathcal{K}}(t)$ on that space (see [6]). Thus, given an initial state $w_0 \in L^2(0, 2\pi)$, we have a unique solution $w(t)$, continuous with respect to the norm in that space for $t \geq 0$, given by

$$(2.3) \quad w(t) = S_{\mathcal{K}}(t)w_0.$$

Further results from the standard semigroup theory show that if $w_0 \in H_p^3(0, 2\pi)$, the domain of A and hence of $A - \mathcal{K}G$, the resulting solution w lies in $C((0, \infty); H_p^3(0, 2\pi)) \cap C^1((0, \infty); L^2(0, 2\pi))$.

From the work of § 1 we know that $[w(\cdot, t)]$ is constant and therefore equal to $[w_0]$ for all $t \geq 0$. Then (1.19) leads us to suspect that $w(\cdot, t)$ converges to the constant state $[w_0] \equiv [w(\cdot, t)]$ as $t \rightarrow \infty$. We will show that this is the case and that, in fact, the decay to the constant state takes place at a uniform exponential rate.

From the general plan outlined in [12], [14], [15], the first step in obtaining exponential decay for the system (1.3), (1.17), (1.18) is to obtain an exact controllability result for the related system

$$(2.4) \quad \frac{\partial v}{\partial t} + \frac{\partial^3 v}{\partial x^3} = Gf,$$

with v subject to the boundary conditions (1.2) and with the operator G as in (2.2). We may state this result as the following theorem.

THEOREM 1. *Let $T > 0$ be given, and let it be assumed that the function g associated with G is of class C^0 on $[0, 2\pi]$ (is of class $C_p^3(g, g', \text{ and } g'' \text{ periodic})$ on $[0, 2\pi]$). Given any final state $v_T \in L^2(0, 2\pi)$ ($v_1 \in H_p^3(0, 2\pi)$) with (see (1.7)) $[v_T] = 0$, there exists a control $f \in L^2((0, T); L^2(0, 2\pi))$ ($f \in L^2((0, T); H_p^3(0, 2\pi))$) such that the solution v of (1.2) and (2.4) with*

$$(2.5) \quad v(\cdot, 0) = 0 \quad \text{in } L^2(0, 2\pi) \ (H_p^3(0, 2\pi))$$

satisfies the terminal condition

$$(2.6) \quad v(\cdot, T) = v_T \quad \text{in } L^2(0, 2\pi) \ (H_p^3(0, 2\pi)).$$

Moreover, there is a positive number C , independent of v_T , such that

$$\|v\|_{L^2((0, T); L^2(0, 2\pi))} \leq C \|v_T\|_{L^2(0, 2\pi)} \quad (\|v\|_{L^2((0, T); H_p^3(0, 2\pi))} \leq C \|v_T\|_{H_p^3(0, 2\pi)}).$$

Proof. It is well known that the operator A as defined in (1.4) has eigenvalues $\lambda_k = -ik^3$ corresponding to eigenfunctions

$$\varphi_k(x) = e^{ikx}, \quad -\infty < k < \infty.$$

Relative to this basis, the terminal state v_T has the expansion, convergent in $L^2(0, 2\pi)$,

$$(2.7) \quad v_T = \sum_{k=-\infty}^{\infty} v_k \varphi_k, \quad v_k = \frac{1}{2\pi} \int_0^{2\pi} v_T(x) \overline{\varphi_k(x)} dx.$$

The homogeneous equation

$$(2.8) \quad \frac{\partial u}{\partial t} + \frac{\partial^3 u}{\partial x^3} = 0,$$

with periodic boundary conditions (1.2) has corresponding solutions

$$(2.9) \quad u_k(\cdot, t) = e^{\lambda_k t} \varphi_k.$$

For smooth f , periodic on $[0, 2\pi]$, we readily compute, using integration by parts with v satisfying (2.4) and (1.2), that

$$\frac{d}{dt} \int_0^{2\pi} v(x, t) \overline{u_k(x, t)} dx = \int_0^{2\pi} (Gf)(x, t) \overline{u_k(x, t)} dx.$$

Integrating with respect to t , we have

$$(2.10) \quad \begin{aligned} & \int_0^{2\pi} v(x, T) \overline{u_k(x, T)} dx - \int_0^{2\pi} v(x, 0) \overline{u_k(x, 0)} dx \\ &= \int_0^T \int_0^{2\pi} (Gf)(x, t) \overline{u_k(x, t)} dx dt. \end{aligned}$$

Continuity considerations then show that (2.10) continues to be valid for $f \in L^2((0, T); L^2(0, 2\pi))$.

Evaluation of the integrals in (2.10) with

$$\tilde{v}_k = \frac{1}{2\pi} \int_0^{2\pi} v(x, T) \overline{\varphi_k(x)} dx$$

and u_k as in (2.9) shows that

$$(2.11) \quad 2\pi \tilde{v}_k = \int_0^T e^{\lambda_k(T-t)} \int_0^{2\pi} (Gf)(x, t) \overline{\varphi_k(x)} dx dt, \quad -\infty < k < \infty.$$

By defining $p_k(t) = e^{\lambda_k t}$, $\mathcal{P} \equiv \{p_k \mid -\infty < k < \infty\}$ may be seen, from the results in [5], to form a Riesz basis for its closed span, P_T , in $L^2(0, T)$. We let $\mathcal{Q} \equiv \{q_k \mid -\infty < k < \infty\}$ be the unique dual Riesz basis for \mathcal{P} in P_T , i.e., the functions in \mathcal{Q} are the unique elements of P_T such that

$$(2.12) \quad \int_0^T q_j(t) \overline{p_k(t)} dt = \delta_{kj}, \quad -\infty < j, k < \infty.$$

We take the control f in (2.4) to have the form

$$(2.13) \quad f(x, t) = \sum_{j=-\infty}^{\infty} f_j q_j(t) (G\varphi_j)(x),$$

where the coefficients f_j are to be determined so that, among other things, the series (2.13) is appropriately convergent. Substituting (2.13) into (2.11) yields, by using the biorthogonality (2.12),

$$(2.14) \quad \begin{aligned} 2\pi \tilde{v}_k &= e^{\lambda_k T} \sum_{j=-\infty}^{\infty} f_j \int_0^T \overline{e^{\lambda_k t}} q_j(t) \int_0^{2\pi} G(G\varphi_j)(x) \overline{\varphi_k(x)} dx dt \\ &= f_k e^{\lambda_k T} \int_0^{2\pi} G(G\varphi_k)(x) \overline{\varphi_k(x)} dx, \quad -\infty < k < \infty. \end{aligned}$$

We verify easily that G is a selfadjoint operator on $L^2(0, 2\pi)$, so that

$$\int_0^{2\pi} G(G\varphi_k)(x) \overline{\varphi_k(x)} dx = (\|G\varphi_k\|_{L^2(0, 2\pi)})^2, \quad -\infty < k < \infty.$$

Since $|\varphi_k(x)| \equiv 1$, for $-\infty < k < \infty$ we have

$$\begin{aligned} (\|G\varphi_k\|_{L^2(0, 2\pi)})^2 &= \int_0^{2\pi} \left| g(x) \left(\varphi_k(x) - \int_0^{2\pi} g(s) \varphi_k(s) ds \right) \right|^2 dx \\ &= \int_0^{2\pi} g(x)^2 dx - 2 \left| \int_0^{2\pi} g(x) \varphi_k(x) dx \right|^2 \end{aligned}$$

$$+ \int_0^{2\pi} g(x)^2 dx \left| \int_0^{2\pi} g(x) \varphi_k(x) dx \right|^2 \equiv g_k.$$

Since $\varphi_0(x) \equiv 1$ it is easy to see, by using (1.16), that $g_0 = 0$. For $k \neq 0$ the fact that $g(x)$ is real valued shows that $g(x)\varphi_k(x)$ cannot be constant on any interval, so that $g_k \neq 0$. The familiar Lebesgue lemma shows that

$$(2.15) \quad \lim_{k \rightarrow \infty} g_k = \int_0^{2\pi} g(x)^2 dx \neq 0.$$

Clearly, \tilde{v}_0 must be zero since $g_0 = 0$. From (2.15) and the fact that $g_k \neq 0$ for $k \neq 0$, it follows that there is a positive δ such that $|g_k| > \delta^2$ for $k \neq 0$. If we set $f_0 = 0$ and

$$(2.16) \quad f_k = \frac{2\pi e^{-\lambda_k T} v_k}{g_k}, \quad -\infty < k < \infty, \quad k \neq 0.$$

Equation (2.14) implies $\tilde{v}_k = v_k$, where v_k is given by (2.7). Since the v_k are square summable and the g_k are bounded below, the f_k are also square summable and (2.16) gives

$$\begin{aligned} (\|f\|_{L^2((0,T);L^2(0,2\pi))})^2 &= \int_0^T \int_0^{2\pi} |f(x,t)|^2 dx dt \\ &= \int_0^{2\pi} \int_0^T \left| \sum_{k=-\infty}^{\infty} f_k q_k(t) (G\varphi_k)(x) \right|^2 dt dx \\ &\leq 2\pi\gamma^2 \int_0^T \left| \sum_{k=-\infty}^{\infty} f_k q_k(t) \right|^2 dt \\ (2.17) \quad &\leq 2\pi\gamma^2 C^2 \sum_{k=-\infty}^{\infty} |f_k|^2 \\ &\leq (2\pi)^3 \frac{\gamma^2}{\delta^2} C^2 |v_k|^2 \\ &= 4\pi^2 \frac{\gamma^2}{\delta^2} C^2 (\|v_T\|_{L^2(0,2\pi)})^2, \end{aligned}$$

where the constant C comes from the Riesz basis property of \mathcal{Q} in P_T , δ^2 is the lower bound for the g_k referred to previously, and

$$\gamma = \sup_{\substack{x \in [0, 2\pi] \\ -\infty < k < \infty}} |(G\varphi_k)(x)| < \infty.$$

A similar computation using only terms corresponding to $|k| > K$ from the series (2.13) shows that the series converges in $L^2((0, T); (0, 2\pi))$. We conclude that f , represented by (2.13), is an element of the space $L^2((0, T); L^2(0, 2\pi))$ bounded in terms of v_T as indicated in (2.17).

With A as defined in (1.4), the solution $v(\cdot, t)$ corresponding to the control $f(\cdot, t)$ just constructed has the form

$$(2.18) \quad v(\cdot, t) = \int_0^t e^{-A(t-s)} Gf(\cdot, s) ds.$$

Since G is a bounded operator and for $t \in [0, T]$

$$\|f\|_{L^1((0,t);L^2(0,2\pi))} \leq t^{1/2} \|f\|_{L^2((0,T);L^2(0,2\pi))},$$

we conclude that (2.18) converges for each such t and, using (2.17), we can see that there is a positive number B such that

$$(2.19) \quad \|v(\cdot, t)\|_{L^2(0, 2\pi)} \leq B \|v_T\|_{L^2(0, 2\pi)}, \quad t \in [0, T].$$

An argument similar to that found in [3] shows that $v(\cdot, t)$ is continuous, as a function of t , relative to the norm in $L^2(0, 2\pi)$. The identity (2.10) with the indicated u_k and our choice of f shows that $v(\cdot, T) = v_T$.

Now suppose $g(x)$ has a piecewise-continuous third derivative and that $v_T \in H_p^3(0, 2\pi)$. The coefficients v_k in (2.7) will have the form

$$v_k = (|k| + 1)^{-3} \hat{v}_k,$$

where the \hat{v}_k are square summable. Then, from (2.16) we have

$$f_k = (|k| + 1)^{-3} \hat{f}_k,$$

where the \hat{f}_k are square summable. Since $g(x)$ has a piecewise-continuous third derivative, it is a simple matter to verify, just as for the original series (2.13), that the series

$$\frac{\partial^3 f}{\partial x^3}(x, t) = \sum_{k=-\infty}^{\infty} \hat{f}_k q_k(t) (|k| + 1)^{-3} (G\varphi_k)'''(x)$$

converges in $L^2((0, T); L^2(0, 2\pi))$. Noting that (2.4) can be written

$$\frac{\partial v}{\partial t} + \frac{\partial^3 v}{\partial x^3} = g(x) \left(f(x, t) - \int_0^{2\pi} g(\xi) f(\xi, t) d\xi \right)$$

and differentiating three times with respect to x , we obtain an equation of the form

$$\frac{\partial}{\partial t} \left(\frac{\partial^3 v}{\partial x^3} \right) + \frac{\partial^3}{\partial x^3} \left(\frac{\partial^3 v}{\partial x^3} \right) = \hat{f}(x, t),$$

with \hat{f} in $L^2((0, T); L^2(0, 2\pi))$, which, together with the periodic boundary conditions and the initial state

$$\frac{\partial^3 v}{\partial x^3}(x, 0) \equiv 0,$$

allows us to replace the estimate (2.19) by an estimate

$$(2.20) \quad \|v(\cdot, t)\|_{H_p^3(0, 2\pi)} \leq B \|v_T\|_{H_p^3(0, 2\pi)}, \quad t \in [0, T].$$

With this the proof of Theorem 1 is complete. \square

We are now in a position to obtain an exponential decay result for the system (2.1), (2.2).

THEOREM 2. *There exist $\alpha, \beta > 0$ such that, for any $w_0 \in L^2(0, 2\pi)$ the unique solution $w(\cdot, t)$ of (1.3), (1.17), (1.18), equivalently (2.1), (2.2), satisfies*

$$(2.21) \quad \|w(\cdot, t) - [w_0]\|_{L^2(0, 2\pi)} \leq \beta e^{-\alpha t} \|w_0 - [w_0]\|_{L^2(0, 2\pi)}, \quad t \geq 0.$$

Proof. We assume without loss of generality that since $w(\cdot, t) - [w_0]$ is a solution of our system, then $[w_0] = 0$. Furthermore, we consider only real solutions here and dispense with the conjugate notation used in the inner products of the preceding theorem, where complex solutions were necessarily discussed.

Let $T > 0$, and let $w(\cdot, t)$ be as described. Then $w(\cdot, T) \in L^2(0, 2\pi)$, and if $w_0 \in H_p^3(0, 2\pi) = \mathcal{D}(A_G)$, then $w(\cdot, t) \in H_p^3(0, 2\pi)$ for all $t \geq 0$, in particular, for $t = T$. From Theorem 1 we see that we can find $f(\cdot, t) \in L^2(0, 2\pi)$, $t \in [0, T]$, such that the resulting solution $v(\cdot, t)$ of (2.4), (2.5), (1.2) satisfies

$$v(\cdot, T) = w(\cdot, T)$$

and from (2.17) and (2.19) there are positive numbers B and D such that

$$(2.22) \quad \|f\|_{L^2((0,T);L^2(0,2\pi))} \leq D \|w(\cdot, T)\|_{L^2(0,2\pi)}, \quad t \in [0, T],$$

$$(2.23) \quad \|v(\cdot, t)\|_{L^2(0,2\pi)} \leq B \|w(\cdot, T)\|_{L^2(0,2\pi)}, \quad t \in [0, T].$$

Furthermore, if w_0 , and hence $w(\cdot, T)$, lies in $H_p^3(0, 2\pi)$, then (2.22) and (2.23) remain true with $L^2(0, 2\pi)$ replaced by $H_p^3(0, 2\pi)$ where ever it occurs. As we have seen in § 1 the computations carried out there are immediately valid for $w_0 \in H_p^3(0, 2\pi)$ and follow from continuity considerations if $w_0 \in L^2(0, 2\pi)$,

$$(2.24) \quad \begin{aligned} & \int_0^{2\pi} w(x, T)^2 dx - \int_0^{2\pi} w_0(x)^2 dx \\ &= -\mathcal{H} \int_0^T \int_0^{2\pi} g(x) \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right)^2 dx dt. \end{aligned}$$

An analogous computation using (1.3), (1.2), and (2.4) yields

$$(2.25) \quad \begin{aligned} \int_0^{2\pi} w(x, T)^2 dx &= \int_0^{2\pi} w(x, T) v(x, T) dx - \int_0^{2\pi} w(x, 0) v(x, 0) dx \\ &= \int_0^T \int_0^{2\pi} w(x, t) (Gf)(x, t) dx dt - \mathcal{H} \int_0^T \int_0^{2\pi} (Gw)(x, t) v(x, t) dx dt \\ &= \int_0^T \int_0^{2\pi} (Gw)(x, t) (f(x, t) - \mathcal{H}v(x, t)) dx dt \\ &\leq \|Gw\|_{L^2((0,T);(0,2\pi))} \|f - \mathcal{H}v\|_{L^2((0,T);(0,2\pi))} \\ &\leq \left[\hat{g} \int_0^T \int_0^{2\pi} g(x) \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right)^2 dx dt \right]^{1/2} \\ &\quad \cdot \|f - \mathcal{H}v\|_{L^2((0,T);(0,2\pi))}, \end{aligned}$$

where $\hat{g} > 0$ is the least upper bound for $g(x)$ in the interval $[0, 2\pi]$. Combining (2.22) with (2.23), we can see that there is a positive number E such that

$$(2.26) \quad \|f - \mathcal{H}v\|_{L^2((0,T);(0,2\pi))}^2 \leq E \|w(\cdot, T)\|_{L^2(0,2\pi)}^2.$$

Substituting (2.26) into (2.25), we have

$$\int_0^T \int_0^{2\pi} g(x) \left(w(x, t) - \int_0^{2\pi} g(s) w(s, t) ds \right)^2 dx dt \leq (E\hat{g})^{-1} \|w(\cdot, T)\|_{L^2(0,2\pi)}^2.$$

Substituting this, in turn, into (2.24), we have

$$\int_0^{2\pi} w(x, T)^2 dx - \int_0^{2\pi} w_0(x)^2 dx \leq -\mathcal{H} (E\hat{g})^{-1} \|w(\cdot, T)\|_{L^2(0,2\pi)}^2,$$

so that

$$\|w(\cdot, T)\|_{L^2(0,2\pi)}^2 \leq \frac{E\hat{g}}{E\hat{g} + \mathcal{H}} \|w_0\|_{L^2(0,2\pi)}^2.$$

Repeating this estimate on successive intervals $[(k-1)T, kT]$ with w_0 and $w(\cdot, T)$ replaced by $w(\cdot, (k-1)T)$ and $w(\cdot, kT)$, respectively, and using the monotonicity of $\|w(\cdot, t)\|_{L^2(0, 2\pi)}$, we readily obtain the estimate (2.21) (recalling that we have taken, without loss of generality, $[w_0] = 0$).

Exponential decay in $H_p^3(0, 2\pi)$ for w_0 in that space is obtained quite directly; $(A - \mathcal{H}G)w_0$ lies in $L^2(0, 2\pi)$ under these circumstances, and the solution with this initial state, $(A - \mathcal{H}G)w$, by the result just established, decays exponentially in $L^2(0, 2\pi)$ to the constant state $[(A - \mathcal{H}G)w_0] = 0$. Denoting by $L_0^2(0, 2\pi)$ the orthogonal complement of the constant states in $L^2(0, 2\pi)$, we may see that $(A - \mathcal{H}G): H_p^3(0, 2\pi) \rightarrow L_0^2(0, 2\pi)$ is bounded and boundedly invertible, from which the desired result follows immediately. \square

3. Exponential decay for the equation with boundary dissipation. The question to be considered here has been developed in § 1. Thus we consider the system (1.3), (1.23), and (1.24), the last two of which result in the closed-loop boundary condition

$$(3.1) \quad \frac{\partial w}{\partial x}(2\pi, t) = \alpha \frac{\partial w}{\partial x}(0, t),$$

where $\alpha = (1 - \mathcal{H})/(1 + \mathcal{H})$ has absolute value less than unity as a consequence of the assumed positivity of \mathcal{H} .

THEOREM 3. *The operator $A_{\mathcal{H}}$ defined by $A_{\mathcal{H}}w = -w'''$, with domain consisting of functions in $H^3(0, 2\pi)$ satisfying (3.1) and (1.2) for $k=0, 2$, generates a strongly continuous semigroup $\hat{S}_{\mathcal{H}}(t)$, $t \geq 0$, of bounded operators on $L^2(0, 2\pi)$. Letting P denote the projection on $L^2(0, 2\pi)$ defined (see (1.7)) by $Pw = [w]$, we have*

$$(3.2) \quad P\hat{S}_{\mathcal{H}}(t) = \hat{S}_{\mathcal{H}}(t)P = P, \quad t \geq 0,$$

are there are positive numbers M and γ such that

$$(3.3) \quad \|\hat{S}_{\mathcal{H}}(t) - P\| \leq Me^{-\gamma t}, \quad t \geq 0.$$

Proof. The formula (1.22) shows that for $w \in \mathcal{D}(A_{\mathcal{H}})$ we have

$$(3.4) \quad (w, A_{\mathcal{H}}w) + (A_{\mathcal{H}}w, w) = |w'(x)|^2 \Big|_{x=0}^{x=2\pi} = (\alpha^2 - 1)|w'(0)|^2 \leq 0.$$

Then, for $\lambda > 0$ and $w \in \mathcal{D}(A_{\mathcal{H}})$

$$(3.5) \quad \|(\lambda I - A_{\mathcal{H}})w\|^2 = \lambda^2\|w\|^2 - \lambda((w, A_{\mathcal{H}}w) + (A_{\mathcal{H}}w, w)) + \|A_{\mathcal{H}}w\|^2 \geq \lambda^2\|w\|^2,$$

so that, with $R(\lambda, A_{\mathcal{H}})$ denoting the resolvent of $A_{\mathcal{H}}$, we have

$$\|R(\lambda, A_{\mathcal{H}})\| \leq \lambda^{-1}, \quad \lambda > 0.$$

By the Lumer-Phillips theorem [9] or the Hille-Yosida theorem [2], $A_{\mathcal{H}}$ generates a strongly continuous semigroup on $L^2(0, 2\pi)$ if the range of $\lambda I - A_{\mathcal{H}}$ is all of $L^2(0, 2\pi)$ for $\lambda > 0$. The uniform exponential decay may then be obtained from the result of Huang [4] by demonstrating the uniform boundedness of $R(\lambda, A_{\mathcal{H}})$ for λ on the imaginary axis of the complex plane. We will carry out these two tasks by explicit construction of the resolvent operator. To that end we consider the equation

$$(3.6) \quad w''' + \lambda w = f, \quad f \in L^2(0, 2\pi).$$

For $\lambda \neq 0$ we denote the three cube roots of $-\lambda$ by μ_0, μ_1 , and μ_2 ; later we will specify which root corresponds to each symbol μ_j . We define $w' = u$, $w'' = v$, and we have

$$(3.7) \quad W' \equiv \begin{pmatrix} w' \\ u' \\ v' \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -\lambda & 0 & 0 \end{pmatrix} \begin{pmatrix} w \\ u \\ v \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ f \end{pmatrix} \equiv F(\lambda)W + \varphi.$$

We diagonalize the system with the transformation $(\mu = (\mu_0, \mu_1, \mu_2))$

$$(3.8) \quad W \equiv \begin{pmatrix} w \\ u \\ v \end{pmatrix} = \begin{pmatrix} 1 & 1 & 1 \\ \mu_0 & \mu_1 & \mu_2 \\ \mu_0^2 & \mu_1^2 & \mu_2^2 \end{pmatrix} \begin{pmatrix} \xi \\ \eta \\ \zeta \end{pmatrix} \equiv V(\mu) \Xi.$$

Then we have

$$(3.9) \quad \Xi' = D(\mu) \Xi + \psi,$$

where $D(\mu) = \text{diag}(\mu_0, \mu_1, \mu_2)$ and $\psi = V(\mu)^{-1} \varphi$, so that for $0 \leq x \leq 2\pi$

$$(3.10) \quad \Xi(x) = e^{x D(\mu)} \Xi(0) + \int_0^x e^{(x-\xi) D(\mu)} \psi(\xi) d\xi.$$

Now, with $B(\alpha) = \text{diag}(1, \alpha, 1)$ the boundary conditions take the form

$$W(2\pi) = B(\alpha) W(0); \quad \text{i.e., } \Xi(2\pi) = V(\mu)^{-1} B(\alpha) V(\mu) \Xi(0)$$

and, for $x = 2\pi$, (3.10) assumes the form

$$(3.11) \quad (B(\alpha) V(\mu) - V(\mu) e^{2\pi D(\mu)}) \Xi(0) = V(\mu) \int_0^{2\pi} e^{(2\pi-x) D(\mu)} \psi(x) dx.$$

Let

$$(3.12) \quad U(\mu, \alpha) = (B(\alpha) V(\mu) - V(\mu) e^{2\pi D(\mu)}),$$

$$(3.13) \quad \Delta(\mu, \alpha) = \det(B(\alpha) V(\mu) - V(\mu) e^{2\pi D(\mu)}).$$

If $\Delta(\mu, \alpha) = 0$, any nonzero solution $\Xi(0)$ of $U(\mu, \alpha) \Xi(0) = 0$ yields an eigenfunction

$$(3.14) \quad \Xi(\mu, \alpha, x) = e^{x D(\mu)} \Xi(0)$$

of $A_{\mathcal{H}}$ corresponding to the value of λ associated with μ by $-\lambda = \mu_j^3$, $j = 0, 1, 2$. On the other hand, if $\Delta(\mu, \alpha) \neq 0$ we can solve (3.11) for $\Xi(0)$,

$$(3.15) \quad \Xi(0) = U(\mu, \alpha)^{-1} V(\mu) \int_0^{2\pi} e^{(2\pi-s) D(\mu)} \psi(s) ds,$$

and then substitute in (3.10) to obtain

$$(3.6) \quad \begin{aligned} \Xi(\mu, \alpha, \psi, x) &= e^{x D(\mu)} U(\mu, \alpha)^{-1} V(\mu) \int_0^{2\pi} e^{(2\pi-s) D(\mu)} \psi(s) ds \\ &\quad + \int_0^x e^{(x-s) D(\mu)} \psi(s) ds. \end{aligned}$$

The corresponding linear map from f to $w(\lambda, \alpha, f, \cdot)$ defines $R(\lambda, A_{\mathcal{H}})$ as a bounded linear operator on $L^2(0, 2\pi)$ for those μ such that $\Delta(\mu, \alpha) \neq 0$. There can be no positive λ such that $\Delta(\mu, \alpha) = 0$; if that were the case, the $w(\lambda, \alpha, x)$ corresponding to $\Xi(\mu, \alpha, x)$ in (3.16) would violate (3.5). We conclude therefore that $R(\lambda, A_{\mathcal{H}})$ is defined as a bounded linear operator on $L^2(0, 2\pi)$ for $\lambda > 0$, so that $A_{\mathcal{H}}$ generates a strongly continuous semigroup on $L^2(0, 2\pi)$.

There remains the question of the uniform exponential decay result (3.3). For this, as we have indicated, we must estimate $R(\lambda, A_{\mathcal{H}})$ for λ on the imaginary axis. More accurately, as already indicated in (3.3), we want to demonstrate the exponential decay of $\hat{S}_{\mathcal{H}}(t)$ to the orthogonal projection P . Since P commutes with $A_{\mathcal{H}}$ (this is just the “volume” conservation (1.8) of § 1 with $f \equiv 0$), what is needed is a demonstration of the uniform boundedness of $R(\lambda, A_{\mathcal{H}})(I - P)$ for λ on the imaginary axis.

We argue first that the only point on the imaginary axis where $R(\lambda, A_{\mathcal{H}})$ fails to exist as a bounded linear operator on $L^2(0, 2\pi)$ is the point $\lambda = 0$. If there were a point $\lambda = i\omega$, $\omega \neq 0$, such that $R(i\omega, A_{\mathcal{H}})$ should fail to be so defined, our previous arguments show that with μ_ρ , the corresponding vector whose components are the cube roots of $-i\omega$, we should have an eigenvector $w(i\omega, \alpha, x)$ of $A_{\mathcal{H}}$ corresponding to the eigenvalue $i\omega$. It is then easy to see from (3.4) that $w'(i\omega, \alpha, 0) = w'(i\omega, \alpha, 2\pi) = 0$. But then $w(i\omega, \alpha, x)$ is also an eigenfunction of A_0 , the third-order operator with periodic boundary conditions, corresponding to the eigenvalue $i\omega$. Since all such eigenfunctions are known to be nontrivial exponential functions unless $\omega = 0$, $w'(i\omega, \alpha, 0) = 0$ is impossible unless $\omega = 0$, and we see that the resolvent $R(\lambda, A_{\mathcal{H}})$ is indeed defined as a bounded linear operator on $L^2(0, 2\pi)$ for $\lambda \neq 0$ on the imaginary axis.

That being the case, to complete the proof of (3.3) by means of Huang's cited result, it is sufficient to show (i) that $R(\lambda, A_{\mathcal{H}})$ is uniformly bounded for large λ on the imaginary axis and (ii) that $R(\lambda, A_{\mathcal{H}})(I - P)$ remains bounded as $\lambda \rightarrow 0$. We will prove (i)—indeed, we will prove an even stronger result—in Lemma 4 to follow. In anticipation of that result, the proof of Theorem 3 requires only the demonstration of (ii).

The Hilbert space $L^2(0, 2\pi)$ has the orthogonal decomposition

$$L^2(0, 2\pi) = L_0^2(0, 2\pi) + [L^2](0, 2\pi),$$

where $L_0^2(0, 2\pi)$ denotes those $f \in L^2(0, 2\pi)$ for which $[f] = 0$ and $[L^2]$ is the subspace of constant functions in $L^2(0, 2\pi)$. Then P (see text preceding (3.2)) and $Q = I - P$ are the orthogonal projections on these subspaces. The space $[L^2]$, interpreted as a subspace of $H_p^3(0, 2\pi)$, is the null space of $A_{\mathcal{H}}$, and $L_0^2(0, 2\pi) \cap H_p^3(0, 2\pi)$ is a closed invariant subspace for $A_{\mathcal{H}}$ (this is implied by the computation (1.8)). The identities (3.2) follow directly from these observations, and (3.3) follows if we can show that the semigroup $\tilde{S}_{\mathcal{H}}(t)$ generated on $L^2(0, 2\pi)$ by the restriction $\tilde{A}_{\mathcal{H}}$ of $A_{\mathcal{H}}$ to $L_0^2(0, 2\pi)$ decays exponentially. The bounds on $R(\lambda, A_{\mathcal{H}})$ for λ on the imaginary axis bounded away from zero (to be proved in Lemma 4, below) continue to apply to $R(\lambda, \tilde{A}_{\mathcal{H}})$ there. To apply the cited theorem of Huang to $\tilde{S}_{\mathcal{H}}(t)$, it is therefore only necessary to show that we can obtain a bound

$$(3.17) \quad \|R(\lambda, \tilde{A}_{\mathcal{H}})f\|_{L_0^2(0, 2\pi)} = \|R(\lambda, A_{\mathcal{H}})f\| \leq K \|f\|_{L^2(0, 2\pi)}, \quad f \in L_0^2(0, 2\pi),$$

for some positive K independent of f , for λ near zero.

From (3.7) and (3.16), we have

$$(3.18) \quad \begin{aligned} W(\lambda, \alpha, f, x) &= V(\mu) e^{xD(\mu)} U(\mu, \alpha)^{-1} V(\mu) \int_0^{2\pi} e^{(2\pi-s)D(\mu)} V(\mu)^{-1} \varphi(s) ds \\ &\quad + V(\mu) \int_0^x e^{(x-s)D(\mu)} V(\mu)^{-1} \varphi(s) ds \\ &= e^{xF(\lambda)} T(\lambda, \alpha)^{-1} \int_0^{2\pi} e^{(2\pi-s)F(\lambda)} \varphi(s) ds + \int_0^x e^{(x-s)F(\lambda)} \varphi(s) ds, \end{aligned}$$

where (see (3.7) and (3.10))

$$T(\lambda, \alpha) = B(\alpha) - e^{2\pi F(\lambda)}.$$

The boundedness of the last term in (3.18) for λ in a neighborhood of zero is clearly no problem. For the first term after the last equality we note that $e^{xF(\lambda)}$ is bounded, and integrating by parts and using $[f] = 0, f \in L_0^2(0, 2\pi)$, we have

$$T(\lambda, \alpha)^{-1} \int_0^{2\pi} e^{(2\pi-s)F(\lambda)} \varphi(s) ds = T(\lambda, \alpha)^{-1} \hat{F}(\lambda) \int_0^{2\pi} e^{(2\pi-s)F(\lambda)} \Phi(s) ds,$$

wherein $\hat{F}(\lambda) = 2\pi F(\lambda)$ and

$$\Phi(s) = \int_0^s \varphi(\sigma) d\sigma.$$

Clearly then, it is sufficient to show that the matrix $T(\lambda, \alpha)^{-1} \hat{F}(\lambda)$ remains bounded in a neighborhood of $\lambda = 0$. From the easily verified property $F(\lambda)^3 = -\lambda I$, where I is now the 3×3 identity matrix, and from the power series expansion of $e^{F(\lambda)}$ it is clear that

$$(3.19) \quad \hat{F}(\lambda)^3 = -8\pi^3 \lambda I, \quad \hat{F}(\lambda)^{-1} = -\frac{1}{8\pi^3 \lambda} \hat{F}(\lambda)^2.$$

Using the Taylor expansion of $e^{2\pi F(\lambda)} = e^{\hat{F}(\lambda)}$,

$$e^{\hat{F}(\lambda)} = I + \hat{F}(\lambda) + \frac{1}{2} \hat{F}(\lambda)^2 + \frac{1}{6} \hat{F}(\lambda)^3 + \hat{F}(\lambda)^4 G(\lambda),$$

where $G(\lambda)$ is bounded in a neighborhood of $\lambda = 0$, we obtain

$$\begin{aligned} T(\lambda, \alpha)^{-1} \hat{F}(\lambda) &= (B(\alpha) - I - \hat{F}(\lambda) - \frac{1}{2} \hat{F}(\lambda)^2 - \frac{1}{6} \hat{F}(\lambda)^3 - \hat{F}(\lambda)^4 G(\lambda))^{-1} \hat{F}(\lambda) \\ &= (\hat{F}(\lambda)^{-1} (B(\alpha) - I - \hat{F}(\lambda) - \frac{1}{2} \hat{F}(\lambda)^2 - \frac{1}{6} \hat{F}(\lambda)^3 - \hat{F}(\lambda)^4 G(\lambda)))^{-1} \\ &= \left(\frac{1}{8\pi^3 \lambda} \hat{F}(\lambda)^2 (I + \hat{F}(\lambda) + \frac{1}{2} \hat{F}(\lambda)^2 + \frac{1}{6} \hat{F}(\lambda)^3 + \hat{F}(\lambda)^4 G(\lambda) - B(\alpha)) \right)^{-1}, \\ (3.20) \quad &= \left(\frac{1}{8\pi^3 \lambda} \hat{F}(\lambda)^2 (I - B(\alpha) - \frac{4}{3} \pi^3 \lambda I) - I - \frac{1}{2} \hat{F}(\lambda) + 8\pi^3 \lambda G(\lambda) \right)^{-1} \\ &= 2\pi (\lambda^{-1} F(\lambda)^2 (I - B(\alpha) - \frac{4}{3} \pi^3 \lambda I) - 2\pi I - 2\pi^2 F(\lambda) + \mathcal{O}(|\lambda|))^{-1} \\ &= \left(\begin{pmatrix} -1 & -\pi & -\frac{2}{3} \pi^2 \\ \frac{2}{3} \pi^2 \lambda & -1 & -\pi \\ \pi \lambda & \frac{2}{3} \pi^2 \lambda + (\alpha - 1)/2\pi & -1 \end{pmatrix} + \mathcal{O}(|\lambda|) \right)^{-1} \\ &= \left(\begin{pmatrix} -1 & -\pi & -\frac{2}{3} \pi^2 \\ 0 & -1 & -\pi \\ 0 & (\alpha - 1)/2\pi & -1 \end{pmatrix} + \mathcal{O}(|\lambda|) \right)^{-1}, \quad \lambda \rightarrow 0. \end{aligned}$$

Since the indicated constant matrix has determinant $-(1 + \alpha)/2 \neq 0$, we conclude that the matrix (3.20) is uniformly bounded in a neighborhood of $\lambda = 0$ and hence, as developed earlier, that (3.17) is valid and $R(\lambda, \tilde{A}_{\mathcal{H}})$ is, consequently, bounded on the imaginary axis. Applying Huang's cited result and Lemma 4 below, we conclude that the restricted semigroup $\tilde{S}_{\mathcal{H}}(t)$ has the property

$$\|\tilde{S}_{\mathcal{H}}(t)\| \leq M e^{-\gamma t}, \quad t \geq 0,$$

for some positive M and γ , which is equivalent to (3.3). With this the proof of Theorem is complete. \square

LEMMA 4. *We have the estimate*

$$\|R(i\omega, A_{\mathcal{H}})\| = \mathcal{O}(\omega^{-2/3}). \quad |\omega| \rightarrow \infty.$$

Proof. It is clear that w can be expressed in terms of f by using (3.8) and (3.16). It is computationally convenient to recall that this relationship has the form

$$(3.22) \quad w(\lambda, \alpha, x) = \int_0^{2\pi} G(\lambda, x, \xi) f(\xi) d\xi,$$

where for each $\xi \in [0, 2\pi]$ and λ such that (see (3.13)) $\Delta(\mu, \alpha) \neq 0$, $G(\lambda, x, \xi)$ satisfies, for $x \in (0, 2\pi)$,

$$(3.22) \quad G'''(\lambda, x, \xi) + \lambda G(\lambda, x, \xi) = \delta(x - \xi),$$

$$(3.24) \quad G(\lambda, 2\pi, \xi) = G(\lambda, 0, \xi),$$

$$(3.25) \quad G'(\lambda, 2\pi, \xi) = \alpha G'(\lambda, 0, \xi),$$

$$(3.26) \quad G''(\lambda, 2\pi, \xi) = G''(\lambda, 0, \xi),$$

the prime notation now representing d/dx . With μ_0, μ_1, μ_2 as defined earlier, we readily see that $G(\lambda, x, \xi)$ has the form, for coefficients c_0, c_1, c_2 to be determined,

$$(3.27) \quad \begin{aligned} G(\lambda, x, \xi) = & c_0 e^{\mu_0(x-\xi)} + c_1 e^{\mu_1(x-\xi)} + c_2 e^{\mu_2(x-\xi)} \\ & + H(x - \xi)(\hat{c}_0 e^{\mu_0(x-\xi)} + \hat{c}_1 e^{\mu_1(x-\xi)} + \hat{c}_2 e^{\mu_2(x-\xi)}), \end{aligned}$$

where $H(x - \xi)$ is the Heaviside function

$$H(x - \xi) = \begin{cases} 1, & x > \xi, \\ 0, & x \leq \xi, \end{cases}$$

and, corresponding to satisfaction of (3.23),

$$(3.28) \quad \begin{aligned} \hat{c}_0 + \hat{c}_1 + \hat{c}_2 &= 0, \\ \hat{c}_0 \mu_0 + \hat{c}_1 \mu_1 + \hat{c}_2 \mu_2 &= 0, \\ \hat{c}_0 \mu_0^2 + \hat{c}_1 \mu_1^2 + \hat{c}_2 \mu_2^2 &= 1. \end{aligned}$$

One easily computes

$$(3.29) \quad \hat{c}_0 = \frac{1}{(\mu_1 - \mu_0)(\mu_2 - \mu_0)}, \quad \hat{c}_1 = \frac{1}{(\mu_0 - \mu_1)(\mu_2 - \mu_1)}, \quad \hat{c}_2 = \frac{1}{(\mu_0 - \mu_2)(\mu_1 - \mu_2)}.$$

The coefficients c_0, c_1, c_2 are then to be chosen so that (3.24)–(3.26) are satisfied. If the three-dimensional vector whose components are c_k , $k = 0, 1, 2$, and the 3×3 matrix whose diagonal elements are $e^{\mu_k x}$, $k = 0, 1, 2$, are represented by c and $e^{\mu x}$, respectively, these equations take the form (see (3.8) and (3.12))

$$U(\mu, \alpha) e^{-\mu \xi} c = a(\mu, \xi) \equiv V(\mu) e^{\mu(2\pi - \xi)} \hat{c}(\mu),$$

$\hat{c}(\mu)$ being the vector whose components appear in (3.29). Here $U(\mu, \alpha)$ has the form

$$(3.31) \quad U(\mu, \alpha) = \begin{pmatrix} 1 - e^{2\pi \mu_0} & 1 - e^{2\pi \mu_1} & 1 - e^{2\pi \mu_2} \\ \mu_0(\alpha - e^{2\pi \mu_0}) & \mu_1(\alpha - e^{2\pi \mu_1}) & \mu_2(\alpha - e^{2\pi \mu_2}) \\ \mu_0^2(1 - e^{2\pi \mu_0}) & \mu_1^2(1 - e^{2\pi \mu_1}) & \mu_2^2(1 - e^{2\pi \mu_2}) \end{pmatrix}.$$

Solving (3.30), we have

$$(3.32) \quad e^{-\mu \xi} c = \Delta(\mu, \alpha)^{-1} b(\mu, \xi) \equiv \hat{a}(\mu, \xi),$$

where, according to Cramer's rule, $b(\mu, \xi)$ is the three-dimensional vector whose components $b_k(\mu, \xi)$, $k = 0, 1, 2$, are the determinants of the matrices obtained from $U(\mu, \alpha)$ by replacing the k th column of the matrix by $a(\mu, \xi)$. Letting ε be the three-dimensional vector whose components are all equal to 1 and ε^* its (row vector) transpose, we have

$$(3.33) \quad \begin{aligned} G(\lambda, x, \xi) &= \varepsilon^*(e^{\mu(x-\xi)} c + H(x - \xi) e^{\mu(x-\xi)} \hat{c}(\mu)) \\ &= \varepsilon^*(e^{\mu x} \hat{a}(\mu, \xi) + H(x - \xi) e^{\mu(x-\xi)} \hat{c}(\mu)). \end{aligned}$$

Let us take $\omega = \rho^3$, $\rho > 0$. Then the cube roots of $-\lambda = -i\rho^3$ can be taken to be $\mu_0 = i\rho$, $\mu_1 = \rho e^{i7\pi/6}$, $\mu_2 = \rho e^{-i\pi/6}$, which we abbreviate as ρe_0 , ρe_1 , ρe_2 , respectively. As $\rho \rightarrow \infty$, (3.30) yields the asymptotic relationship

$$(3.34) \quad a_k(\mu, \xi) \approx \mu_2^k \hat{c}_2(\mu) e^{\mu_2(2\pi - \xi)}, \quad k = 0, 1, 2.$$

From the form (3.31) of $U(\mu, \alpha)$ it is clear that $\Delta(\mu, \alpha)$, its determinant, has the asymptotic form, again as $\rho \rightarrow \infty$,

$$(3.35) \quad \Delta(\mu, \alpha) \approx -e^{2\pi\mu_2} D(\mu),$$

where

$$\begin{aligned} (3.36) \quad D(\mu) &= \det \begin{pmatrix} 1 - e^{2\pi\mu_0} & 1 & 1 \\ \mu_0(\alpha - e^{2\pi\mu_0}) & \alpha\mu_1 & \mu_2 \\ \mu_0^2(1 - e^{2\pi\mu_0}) & \mu_1^2 & \mu_2^2 \end{pmatrix} \\ &= -\rho^3 \{ (e_0(e_2^2 - e_1^2))(\alpha - e^{2\pi\mu_0}) - \alpha(e_1(e_2^2 - e_0^2))(1 - e^{2\pi\mu_0}) \\ &\quad + (e_2(e_1^2 - e_0^2))(1 - e^{2\pi\mu_0}) \} \\ &= -\rho^3 \{ (e_2 - e_1)((\alpha - 1) + 1 - e^{2\pi\mu_0}) + \alpha(e_2 - e_1)(1 - e^{2\pi\mu_0}) + (e_2 - e_1)(1 - e^{2\pi\mu_0}) \} \\ &= \sqrt{3}\rho^3 \{ (1 - \alpha) - (2 + \alpha)(1 - e^{2\pi\mu_0}) \}. \end{aligned}$$

A simple geometric argument then shows that

$$(3.37) \quad \Delta(\mu, \alpha) \approx \sqrt{3}\rho^3 e^{2\pi\mu_2} \delta(\mu_0, \alpha),$$

where $|\delta(\mu_0, \alpha)| \geq 1 - \alpha > 0$ for all values of ρ in $\mu_0 = \rho i$. In particular, this confirms for large ρ our earlier conclusion that $\Delta(\mu, \alpha)$ does not vanish when λ lies on the imaginary axis.

From the description of $b(\mu, \xi)$ following (3.32) and from (3.34), we further see that, asymptotically as $\rho \rightarrow \infty$,

$$b_k(\mu, \xi) \approx \hat{c}_2(\mu) e^{\mu_2(2\pi - \xi)} H_k(\mu), \quad k = 0, 1, 2,$$

where

$$(3.38) \quad H_0(\mu) = \det \begin{pmatrix} 1 & 1 & 2\pi\mu_2 \\ \mu_2 & \alpha\mu_1 & (\alpha - e^{2\pi\mu_2})\mu_2 \\ \mu_2^2 & \mu_1^2 & (1 - e^{2\pi\mu_2})\mu_2^2 \end{pmatrix} = \det \begin{pmatrix} 1 & 1 & 1 \\ \mu_2 & \alpha\mu_1 & \alpha\mu_2 \\ \mu_2^2 & \mu_1^2 & \mu_2^2 \end{pmatrix},$$

$$(3.39) \quad H_1(\mu) = \det \begin{pmatrix} 1 - e^{2\pi\mu_0} & 1 & 1 - e^{2\pi\mu_2} \\ \mu_0(\alpha - e^{2\pi\mu_0}) & \mu_2 & (\alpha - e^{2\pi\mu_2})\mu_2 \\ \mu_0^2(1 - e^{2\pi\mu_0}) & \mu_2^2 & (1 - e^{2\pi\mu_2})\mu_2^2 \end{pmatrix}$$

$$= \det \begin{pmatrix} 1 - e^{2\pi\mu_0} & 1 & 1 \\ \mu_0(\alpha - e^{2\pi\mu_0}) & \mu_2 & \alpha\mu_2 \\ \mu_0^2(1 - e^{2\pi\mu_0}) & \mu_2^2 & \mu_2^2 \end{pmatrix}.$$

$$(3.40) \quad H_2(\mu) = \det \begin{pmatrix} 1 - e^{2\pi\mu_0} & 1 & 1 \\ \mu_0(\alpha - e^{2\pi\mu_0}) & \alpha\mu_1 & \mu_2 \\ \mu_0^2(1 - e^{2\pi\mu_0}) & \mu_1^2 & \mu_2^2 \end{pmatrix} = D(\mu) \quad (\text{see (3.36)}).$$

Thus we find that as $\rho \rightarrow \infty$

$$\begin{aligned} b_0(\mu, \xi) &\approx \hat{c}_2(\mu) e^{\mu_2(2\pi-\xi)} H_0(\mu), \\ b_1(\mu, \xi) &\approx \hat{c}_2(\mu) e^{\mu_2(2\pi-\xi)} H_1(\mu), \\ b_2(\mu, \xi) &\approx \hat{c}_2(\mu) e^{\mu_2(2\pi-\xi)} D(\mu), \end{aligned} \quad (3.41)$$

so that from (3.32)

$$\hat{a}(\mu, \xi) \approx -\hat{c}_2(\mu) e^{-\mu_2 \xi} \begin{pmatrix} H_0(\mu)/D(\mu) \\ H_1(\mu)/D(\mu) \\ 1 \end{pmatrix} \equiv -\hat{c}_2(\mu) e^{-\mu_2 \xi} h(\mu). \quad (3.42)$$

Therefore, using (3.32) and (3.33), we see that for $f \in L^2(0, 2\pi)$

$$\begin{aligned} G(\lambda, x, \xi) &= \varepsilon^*(e^{\mu(x-\xi)} c + H(x-\xi) e^{\mu(x-\xi)} \hat{c}(\mu)) \\ &= \varepsilon^*(e^{\mu x} \hat{a}(\mu, \xi) + H(x-\xi) e^{\mu(x-\xi)} \hat{c}(\mu)). \end{aligned} \quad (3.43)$$

Since $e^{\mu x} e^{-\mu_2 \xi}$ is uniformly bounded for $x \leq \xi$, the ratios $H_0(\mu)/D(\mu)$ and $H_1(\mu)/D(\mu)$ are bounded as $\rho \rightarrow \infty$ and, as may be clearly seen from (3.29), $|\hat{c}_k(\mu)| \approx \rho^{-2}$ as $\rho \rightarrow \infty$, we conclude that given any $r > 0$ there is a constant \hat{M}_r , independent of ρ , such that for $x \leq \xi$

$$|\varepsilon^* e^{\mu x} \hat{a}(\mu, \xi)| \leq \hat{M}_r \rho^{-2}, \quad \rho > r. \quad (3.44)$$

For $x > \xi$, (3.43) has the asymptotic form

$$G(\lambda, x, \xi) \approx \varepsilon^* e^{\mu(x-\xi)} \hat{c}(\mu) - e^{\mu x} e^{-\mu_2 \xi} \hat{c}_2(\mu) h(\mu).$$

The first two components of this vector involve $e^{\mu_k(x-\xi)}$, $k=0, 1$, and $e^{\mu_k x - \mu_2 \xi}$, $k=0, 1$, all of which are uniformly bounded for $x > \xi$. The third component reduces to zero, as we see from (3.42). We consequently may extend (3.44) to the inequality

$$|G(\lambda, x, \xi)| \leq M_r \rho^{-2}, \quad \rho > r.$$

An entirely similar result is valid for $\lambda = -\rho^3$. Using this and (3.22), we have the result (3.21) and the proof of lemma 4 is complete. \square

COROLLARY 5. *The semigroup $\hat{S}_{\mathcal{H}}(t)$ generated by the operator $A_{\mathcal{H}}$ is a C^∞ semigroup on $L^2(0, 2\pi)$.*

Proof. This result follows immediately from (3.21) and [10, Cor. 4.10]. \square

If we interchange the roles of 2π and 0 in (3.1), equivalently, if we require $\alpha > 1$ in that equation as it stands, the same arguments used above show that the resulting system has uniform exponential decay to the constant state as $t \rightarrow -\infty$. Applying the principle that uniform stabilizability of a time-reversible linear system in both t directions implies exact controllability (see [12], [14], [15]), we conclude that (1.2), (1.3), (1.23) is exactly controllable in $L^2_0(0, 2\pi)$, i.e., controllable between initial and terminal states w_0 and w_T , respectively, for which $[w_T - w_0] = 0$, provided T is large enough so that (see (3.3)) $Me^{-\gamma T} < 1$, using controls $h \in L^2(0, T)$ and keeping the intermediate states $w(\cdot, t)$, $0 \leq t \leq T$, in $L^2(0, 2\pi)$, the norm of h and the maximum norm of $w(\cdot, t)$, $0 \leq t \leq T$, being uniformly bounded in terms of $\|w_0\|_{L^2(0, 2\pi)} + \|w_T\|_{L^2(0, 2\pi)}$; here we effectively reverse the procedure by which we obtained uniform exponential decay in § 2. Harmonic-analysis treatment of the control problem for (1.2), (1.3), (1.23), in much the same manner as for distributed control in § 2, indicates that

we should be able to take $T > 0$ but arbitrarily small. The argument is incomplete, however, because it is apparently not possible to establish that the $L^2(0, T)$ controls $h(t)$ obtained by that route leave the intermediate states $w(\cdot, t)$ in the state space $L^2(0, 2\pi)$ in general—the same difficulty encountered originally in treatment of boundary-value control of the wave equation in more than one space dimension [13], a problem also subsequently overcome by obtaining uniform exponential stabilization rates for the corresponding system with boundary-damping mechanisms [1], [7].

DYNAMIC OPTIMIZATION PROBLEMS WITH FREE-TIME AND ACTIVE STATE CONSTRAINTS*

J. D. L. ROWLAND† AND R. B. VINTER†

Abstract. Free-time dynamic optimization problems are treated with state constraints in which the data is permitted to be measurable with respect to the time variable. Necessary conditions for such problems have previously been derived only under the assumption that the state constraint is inactive at the optimal endtimes. A more detailed analysis than has yet been undertaken of the interaction between the optimal free endtimes and the state constraint permits the removal of this assumption. An example clarifies the nature of the new necessary condition.

Key words. necessary conditions, nonsmooth analysis, state constraints, free time

AMS(MOS) subject classifications. 49K15, 49K24

1. Introduction. In recent years, interest has been focused on necessary conditions of optimality for free-time dynamic optimization problems with state constraints, when the data is assumed to be merely measurable (and therefore possibly discontinuous), with respect to the time variable. It has arisen out of the awareness that a variety of threshold phenomena (associated, say, with abrupt changes in a tariff or rate of return on investment at prespecified times) give rise to such problems yet are beyond the scope of traditional necessary condition proof techniques. Our purpose here is to provide a more thorough analysis than has previously been undertaken of the interaction between optimal free endtimes and the state constraint in the “measurable” case. Necessary conditions are thereby provided under significantly weaker hypotheses than have yet been required.

We will soon address a more general problem, but, for the purposes of this introductory discussion, we now trace the development of necessary conditions for the following problem:

$$\begin{aligned}
 &\text{Minimize } g(x(b)) \\
 &\text{over times } b > 0 \text{ and arcs } x(\cdot) \in AC([0, b]; \mathbb{R}^n), \text{ satisfying} \\
 (\mathcal{P}) \quad &\dot{x}(t) \in F(t, x(t)), \quad \text{a.e. } [0, b], \\
 &h(x(t)) \leq 0, \quad \text{for all } t \in [0, b], \\
 &x(0) = x_0.
 \end{aligned}$$

Here $g, h: \mathbb{R}^n \rightarrow \mathbb{R}$ are given functions, $F: \mathbb{R}^{1+n} \rightrightarrows \mathbb{R}^n$ is a given multifunction, and x_0 is a given n -vector.

Necessary conditions for state constrained problems involving a differential inclusion were first obtained for fixed-time problems (problems to which the constraint “ $b = \beta$ ” has been appended, for some fixed $\beta > 0$; see [2]). They lead more or less directly to necessary conditions for free-time problems (\mathcal{P}) via a transformation of the independent variable, which reduces (\mathcal{P}) to a fixed-time problem (see, e.g., [2] or [9]). The following conditions on a minimizer $(\beta, \xi(\cdot))$ are thereby obtained: There

* Received by the editors March 25, 1991; accepted for publication (in revised form) September 16, 1991.

† Department of Electrical Engineering, Imperial College, Exhibition Road, London, SW7 2BT England.

exists an arc $p(\cdot) \in AC([0, b]; \mathbb{R}^n)$, a constant $\lambda \geq 0$, and a nonnegative measure $\mu \in C^*([0, \beta]; \mathbb{R})$, not all zero, satisfying

$$(1.1) \quad (-\dot{p}(t), \dot{\xi}(t)) \in \partial_{x,p} H\left(t, \xi(t), p(t) + \int_{[0,t)} \nabla h(\xi(t)) \mu(dt)\right), \quad \text{a.e. } [0, \beta],$$

$$(1.2) \quad -p(\beta) - \int_{[0,\beta]} \nabla h(\xi(t)) \mu(dt) \in \lambda \nabla g(\xi(\beta)),$$

$$(1.3) \quad \text{supp } \mu \subset \{t: h(\xi(t)) = 0\},$$

$$(1.4) \quad 0 = H\left(\beta, \xi(\beta), p(\beta) + \int_{[0,\beta]} \nabla h(\xi(t)) \mu(dt) - \nabla h(\xi(\beta)) \mu(\{\beta\})\right),$$

where the Hamiltonian $H: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \rightarrow \mathbb{R}$ is defined by

$$H(t, x, p) = \sup \{ \langle p, e \rangle : e \in F(t, x) \},$$

and $\partial_{x,p} H$ denotes the (Clarke) generalized gradient of $H(t, \cdot, \cdot)$. For simplicity, we have assumed that the functions $h(\cdot)$ and $g(\cdot)$ are continuously differentiable. Conditions (1.1)–(1.3) will be recognized as the standard fixed-time necessary conditions. Condition (1.4) supplies the extra information associated with the free terminal time.

Unfortunately, this approach is limited to problems where the data is at least Lipschitz continuous with respect to both the time and state variables. The reason is that, under the transformation, the original time variable becomes a component of the state vector, and the fixed-time necessary conditions we would like to apply are valid only for data Lipschitz with respect to the state variable. For problems without state constraints, a more refined analysis generates necessary conditions for free-time problems when the dynamics are continuous in the time variable; see [1], [12], or [13].

When treating problems with data measurable in time, a difficulty arises with the very *interpretation* of the free-time condition (1.4), let alone its proof. In the general setting, it is necessary to specify the data as regards time dependence only in an “almost everywhere” sense, and pointwise evaluation of $t \rightarrow H(t, \xi(t), p(t))$ at $t = \beta$ is meaningless. In [5] this difficulty is overcome, at least for problems without state constraints, by the introduction of the notion of (*convex*) *essential value* of a function.

DEFINITION 1.1. Let $A \subset \mathbb{R}$ be an open set and $h(\cdot): A \rightarrow \mathbb{R}$ be an essentially bounded, measurable function. Take $t \in A$. The (*convex*) *essential value* of $h(\cdot)$ at t , written $\text{co ess}_{s \rightarrow t} h(s)$, is the closed interval with left- and right-hand endpoints

$$\lim_{\epsilon \downarrow 0} \{ \text{ess inf } \{ h(s) : s \in [t - \epsilon, t + \epsilon] \} \}, \quad \lim_{\epsilon \downarrow 0} \{ \text{ess sup } \{ h(s) : s \in [t - \epsilon, t + \epsilon] \} \},$$

respectively. (The definition of the convex essential value coincides with the convex hull of the *essential value* introduced in [5].) It will be clear that adjustments of a function on a null set leave the convex essential value unchanged. Thus the notion of convex essential value is a natural one in the context of necessary conditions. The necessary conditions provided in [5], valid for problems with measurably time-dependent data and when the state constraint is inactive, replace condition (1.4) with the following “essential value” inclusion:

$$0 \in \text{co ess}_{t \rightarrow \beta} H(t, \xi(\beta), p(\beta)).$$

(Note that, when the state constraint is inactive, the measure μ is the zero measure by condition (1.3) and so may be dropped from the conditions.)

Subsequent developments were aimed at providing necessary conditions when the state constraints are active. This was achieved in [4], [15], and [16], but only under the “noninteraction” hypothesis that the state constraints are inactive at the optimal free endtime, or, in other words, only when

$$(1.5) \quad h(\xi(\beta)) < 0.$$

The necessity of investigating the nature of the interaction between the state constraint and the optimal free endtime β is thereby avoided. However, the noninteraction hypothesis (1.5) is unwelcome since it excludes consideration of a frequently encountered phenomenon in these problems, namely, that of a minimizing trajectory evolving on the boundary of the constraint set and terminating at a discontinuity in the dynamics or tariff.

This paper provides an answer to the question of what necessary conditions are valid when the noninteraction hypothesis is dropped. Our necessary conditions retain the flavour of the “Lipschitz case” conditions (1.1)–(1.4) with the exception that the boundary condition on the Hamiltonian (1.4) is replaced by

$$(1.4') \quad 0 = \operatorname{co\,ess}_{t \rightarrow \beta} H\left(t, \xi(\beta), p(\beta) + \int_{[0, \beta]} \nabla h(\xi(t)) \mu(dt) - \kappa \nabla h(\xi(\beta)) \mu(\{\beta\})\right),$$

for some $\kappa \in [0, 1]$. The significant respect in which (1.4') diverges from (1.4) is in the presence of the parameter κ . Its appearance is explained because our proof techniques (in common with those employed in recent research in dynamic optimization) involve extracting “multipliers” $p(\cdot)$, λ , and $\mu(\cdot)$ as limits of multipliers associated with a sequence of perturbed problems. In particular, the measure μ will arise as a limit point in the weak star topology on $\{\mu \in C^*: \mu \geq 0\}$, and so, even if (1.4') is satisfied along the sequence with $\kappa = 1$, we must allow $\kappa \in [0, 1]$ in the limit, due to the fact that the mapping $\mu \rightarrow \mu(\{\beta\})$ is merely weak star upper semicontinuous on the positive cone in C^* .

It is natural to ask whether, when we pass to more general problems than the Lipschitz ones, the need to express the necessary conditions in terms of the parameter κ in the range $0 \leq \kappa \leq 1$ results from a deficient analysis or whether, on the contrary, it represents an essential difference between “Lipschitz” and “non-Lipschitz” problems. The issue is settled by the following example of problem (\mathcal{P}) in which the necessary conditions can be satisfied only if the parameter κ is chosen to lie in $[0, 1]$.

Example 1.2. We consider the following problem involving a two-dimensional state space; state vectors are written (x_1, x_2) , and so forth:

$$\text{Minimize } x_1(b) - x_2(b)$$

over times $b > 0$ and arcs $(x_1(\cdot), x_2(\cdot)) \in AC([0, b]; \mathbb{R}^2)$, satisfying

$$(\dot{x}_1(t), \dot{x}_2(t)) \in \begin{cases} [-1, 1] \times \{1\}, & 0 \leq t \leq 2, \\ \{\eta\} \times \{1\}, & 2 < t, \end{cases} \quad \text{a.e. } t \in [0, b],$$

$$-x_1(t) \leq 0 \quad \text{for all } t \in [0, b],$$

$$(x_1(0), x_2(0)) = (1, 0).$$

Evidently, this is an example of (\mathcal{P}) in which

$$F(t, (x_1, x_2)) = \begin{cases} [-1, 1] \times \{1\}, & 0 \leq t \leq 2, \\ \{\eta\} \times \{1\}, & t > 2 \end{cases},$$

$$h(x_1, x_2) = -x_1,$$

$$g(x_1, x_2) = x_1 - x_2,$$

and the initial state vector is $(1, 0)$. The positive number η is a fixed parameter.

It is obvious that for $\eta < 1$ the example has unbounded cost. On the other hand, if $\eta \geq 1$, the cost is bounded below by -2 . Let us examine the process $(\beta, \xi(\cdot) = (\xi_1(\cdot), \xi_2(\cdot)))$, where $\beta = 2$ and

$$(\xi_1(t), \xi_2(t)) = \begin{cases} (1-t, t), & 0 \leq t \leq 1, \\ (0, t), & 1 \leq t \leq 2. \end{cases}$$

This process has cost -2 . It is a minimizing process if $\eta \geq 1$, but not if $\eta < 1$. We now ask the following question: For what choices of $\lambda \geq 0$, $p(\cdot) = (p_1(\cdot), p_2(\cdot)) \in AC([0, 2]; \mathbb{R}^2)$, and nonnegative measure $\mu \in C^*([0, 2]; \mathbb{R})$, with $\lambda + |p(\cdot)|_\infty + |\mu| > 0$ and $\kappa \in [0, 1]$ are conditions (1.1)–(1.3) and (1.4') satisfied in relation to $(\beta, \xi(\cdot))$?

For this problem, the Hamiltonian function is

$$H(t, (x_1, x_2), (p_1, p_2)) = \begin{cases} |p_1| + p_2, & 0 \leq t \leq 2, \\ p_1 \eta + p_2, & 2 < t. \end{cases}$$

The implications of the Hamiltonian inclusion (1.1) are first explored. Since H is independent of (x_1, x_2) , this condition implies that both $p_1(\cdot)$ and $p_2(\cdot)$ are constant functions. We write

$$p_1(\cdot) = p_1 \quad \text{and} \quad p_2(\cdot) = p_2.$$

Another consequence of (1.1) is that

$$\left\langle p(t) + \int_{[0,t)} \nabla h(\xi(s)) d\mu(s), \dot{\xi}(t) \right\rangle = H\left(t, \xi(t), p(t) + \int_{[0,t)} \nabla h(\xi(s)) d\mu(s)\right), \text{ a.e. } [0, 2].$$

Since $\text{support } \{\mu\} \subset \{h(\xi(t)) = 0\}$, by (1.3), it follows that, for almost every $t \in [0, 1]$,

$$-p_1 + p_2 = |p_1| + p_2.$$

This is only possible if $p_1 \leq 0$. It follows also that, for almost every $t \in [1, 2]$,

$$p_2 = \left| p_1 + \int_{[0,t)} (-1) d\mu(s) \right| + p_2.$$

Since $p_1 \leq 0$ and μ is a nonnegative measure, we conclude that

$$(1.6) \quad p_1 \equiv 0 \quad \text{and} \quad \text{support } \{\mu\} \subset \{2\}.$$

We next study the information embodied in the transversality condition (1.2) and the essential value inclusion (1.4'). In view of (1.6), they assert that

$$(-(-1)\mu(\{2\}), -p_2) = \lambda(1, -1) \quad \text{and} \quad 0 \in \{p_2\} + (1 - \kappa)\mu(\{2\})[-\eta, 1].$$

These combine to tell us that

$$\mu(\{2\}) = p_2 = \lambda \quad \text{and} \quad \lambda \in -\lambda(1 - \kappa)[- \eta, 1].$$

Now we are not permitted to choose $\lambda = 0$, for otherwise these conditions would imply that λ, p_1, p_2 , and μ were all zero, in violation of the requirement that $\lambda + |p(\cdot)|_\infty + |\mu| > 0$. Knowing that $\lambda > 0$, however, we arrive at

$$-(1 - \kappa) \leq 1 \leq (1 - \kappa)\eta.$$

Thus a choice of κ is compatible with (1.1)–(1.3) and (1.4') only if $\kappa \leq 1 - \eta^{-1}$. Evidently, the set of all possible multipliers is

$$\mathcal{M} = \{\lambda > 0, p_1(\cdot) \equiv 0, p_2(\cdot) \equiv \lambda, \mu(\cdot) = \lambda \delta_{\{2\}}(\cdot), \kappa: 0 \leq \kappa \leq 1 - \eta^{-1}\}.$$

Let us now draw conclusions from our characterization of the multiplier set \mathcal{M} . Note first that \mathcal{M} is nonempty if and only if $\eta \geq 1$. Bearing in mind that $(\beta, \xi(\cdot))$ is a minimizing process if and only if $\eta \geq 1$, we see that testing the process $(\beta, \xi(\cdot))$ against the necessary conditions precisely identifies the range of the parameter values η for which $(\beta, \xi(\cdot))$ is a minimizing process. This provides some evidence of the strength of the new necessary conditions. Our second observation is that, in the case where $\eta \geq 1$, when $(\beta, \xi(\cdot))$ is a minimizer, it is not possible to satisfy the necessary conditions with $\kappa = 1$. In fact, if $\eta = 1$, the only choice is $\kappa = 0$! This is consistent with the facts that the differential inclusion is discontinuous in time and that the state constraint is active at the optimal endtime, circumstances when condition (1.4) (the strengthened version of (1.4')) need not apply.

Our discussion has thus far been directed at necessary conditions in the form of a Hamiltonian inclusion for problems having a differential inclusion formulation. However, our methods also provide Pontryagin-type necessary conditions for differential inclusion problems (see § 4) and a general Pontryagin maximum principle for optimal control problems (see § 5). The novelty of these results is, as before, that they apply to problems in which the dynamic constraint is allowed to be merely measurable with respect to the time variable while allowing the state constraint to be active at the optimal endtimes.

We conclude the Introduction by setting our notation for normal cones and generalized differentiation concepts employed in the paper.

DEFINITION 1.3 (normal cones). Let $C \subset \mathbb{R}^n$ be a given closed set and take $x \in C$.

(a) The *proximal normal cone* to C at x , written $\text{PN}_C(x)$, is

$$\text{PN}_C(x) = \{\xi \in \mathbb{R}^n: \text{for some } M > 0, 0 \leq \langle -\xi, c - x \rangle + M|c - x|^2 \quad \forall c \in C\}.$$

(b) The *limiting normal cone*, to C at x , denoted $\text{LN}_C(x)$, is obtained by closing the graph of the multifunction $x \mapsto \text{PN}_C(x)$,

$$\text{LN}_C(x) = \{\xi: \xi_i \rightarrow \xi, x_i \rightarrow x, \xi_i \in \text{PN}_C(x_i), x_i \in C \text{ for all } i\}.$$

Both the proximal and limiting normal cone are subsets of the Clarke normal cone $N_C(x)$, [2]. In fact, the limiting normal cone and Clarke normal cone are related according to

$$N_C(x) = \overline{\text{co}} \text{LN}_C(x).$$

DEFINITION 1.4 (subgradients). Let $\psi: \mathbb{R}^n \rightarrow \mathbb{R}$ be lower semicontinuous near $x \in \mathbb{R}^n$.

(a) The *Clarke generalized gradient* of ψ at x , written $\partial\psi(x)$, is

$$\partial\psi(x) = \{\xi \in \mathbb{R}^n: (\xi, -1) \in N_{\text{epi } \psi}(x, \psi(x))\}.$$

(b) The *limiting subgradient* of ψ at x , written $L\partial\psi(x)$, is

$$L\partial\psi(x) = \{\xi \in \mathbb{R}^n: (\xi, -1) \in \text{LN}_{\text{epi } \psi}(x, \psi(x))\}.$$

For locally Lipschitz functions, the Clarke subgradient and limiting subgradient are related according to the formula $\partial\psi(x) = \text{co } L\partial\psi(x)$.

DEFINITION 1.5 (generalized Jacobians). Let $\psi: \mathbb{R}^n \rightarrow \mathbb{R}^d$ be Lipschitz continuous near $x \in \mathbb{R}^n$. The *generalized Jacobian* of ψ , at x , written $\partial\psi(x)$, is

$$\partial\psi(x) = \left\{ \lim_i \nabla\psi(x_i): x_i \rightarrow x, \psi \text{ is differentiable at } x_i \text{ and } \lim_i \nabla\psi(x_i) \text{ exists} \right\}.$$

There is no ambiguity of notation here since, if $d = 1$ in Definition 1.5 and ψ is Lipschitz continuous near x , the generalized Jacobian and the Clarke generalized gradient coincide.

2. Hamiltonian inclusion necessary conditions. In this section, we supply the main results of the paper. These are necessary conditions of “local” optimality for a generalization (P) of the earlier problem (\mathcal{P}), in which both endtimes are choice variables, namely,

$$(2.1) \quad \begin{aligned} &\text{Minimize } g(a, x(a), b, x(b)) \\ &\text{over intervals } [a, b] \subset \mathbb{R} \text{ and arcs } x(\cdot) \in AC([a, b]; \mathbb{R}^n), \text{ which satisfy} \\ (P) \quad &\dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } [a, b], \\ &h(t, x(t)) \leq 0 \quad \text{for all } t \in [a, b], \\ &(a, x(a), b, x(b)) \in S. \end{aligned}$$

Here $g: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$ and $h: \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$ are given functions, $F: \mathbb{R} \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is a given multifunction, and $S \subset \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n$ is a given set.

An *admissible process* for (P) is a triple $(a, b, x(\cdot))$, comprising left and right endpoints, a and b , respectively, of an interval, and a function $x(\cdot) \in AC([a, b]; \mathbb{R}^n)$, which satisfy the constraints of problem (P). It is convenient to regard the function $x(\cdot)$ in an admissible process $(a, b, x(\cdot))$ as having domain all of \mathbb{R} ; in this event, we extend $x(\cdot)$ to all of \mathbb{R} by constant extrapolation; i.e., we get

$$x(t) = x(a) \quad \text{for all } t < a \quad \text{and} \quad x(t) = x(b) \quad \text{for all } t > b.$$

We also require the concept of an “ ε -neighbourhood” about a given admissible process $(\alpha, \beta, \xi(\cdot))$. Given $\varepsilon > 0$, an admissible process $(a, b, x(\cdot))$ is said to lie in the ε -neighbourhood of $(\alpha, \beta, \xi(\cdot))$, provided that $|x(t) - \xi(t)| < \varepsilon$ for all $t \in \mathbb{R}$, $|a - \alpha| < \varepsilon$, and $|b - \beta| < \varepsilon$. (We employ our extrapolation convention to make sense of this definition.)

An admissible process $(\alpha, \beta, \xi(\cdot))$ is said to be a *local minimizer* for (P) if it achieves the minimum of the functional (2.1) over all admissible processes lying in an ε -neighbourhood of $(\alpha, \beta, \xi(\cdot))$ for some $\varepsilon > 0$. Properties of local minimizers are of interest here, and, consequently, it suffices to invoke hypotheses on the data relating merely to their properties “near” the local minimizer $(\alpha, \beta, \xi(\cdot))$ in question. “Nearness” is quantified by a parameter $\omega \in (0, (\beta - \alpha)/2)$. We employ the notation B for the open unit ball in Euclidean space and denote by $T_\omega(\alpha, \beta, \xi(\cdot))$ the tube

$$T_\omega(\alpha, \beta, \xi(\cdot)) = \{(\tau, \zeta): \tau \in (\alpha - \omega, \beta + \omega), |\zeta - \xi(\tau)| < \omega\}.$$

- (H1) g is Lipschitz continuous on $(\alpha, \xi(\alpha), \beta, \xi(\beta)) + \omega B$.
 (H2) h is continuous on $T_\omega(\alpha, \beta, \xi(\cdot))$; there exists a nonnegative number k_h such that

$$|h(t, x) - h(t, y)| \leq k_h |x - y| \quad \text{for all } (t, x), (t, y) \in T_\omega(\alpha, \beta, \xi(\cdot)).$$

- (H3) $F(\cdot, \cdot)$ is $\mathcal{L} \times \mathcal{B}$ -measurable; $F(t, x)$ is nonempty, compact, and convex-valued on $T_\omega(\alpha, \beta, \xi(\cdot))$; and there exists a nonnegative function $k_F(\cdot) \in L^1$, which is essentially bounded on $(\alpha - \omega, \alpha + \omega) \cup (\beta - \omega, \beta + \omega)$ such that

$$F(t, x) \subset k_F(t)B \quad \text{for all } (t, x) \in T_\omega(\alpha, \beta, \xi(\cdot))$$

and

$$F(t, x) \subset F(t, y) + k_F(t)|x - y|B \quad \text{for all } (t, x), (t, y) \in T_\omega(\alpha, \beta, \xi(\cdot)).$$

(H4) The set S is closed.

The statement of the necessary conditions involves the following notation:

$$\partial_x^+ h(x, t) = \text{co} \left\{ \lim_{i \rightarrow \infty} \gamma_i: \gamma_i \in \partial_x h(t_i, x_i), (t_i, x_i) \rightarrow (t, x), \text{ and } h(t_i, x_i) > 0 \text{ for all } i \right\}.$$

Note that $\partial_x^+ h(t, x) = \emptyset$ at points in $T_\omega(\alpha, \beta, \xi(\cdot))$, where $h(t, x) < 0$, since h is continuous there. If h is smooth and there exist points arbitrarily close to (t, x) at which h is positive, then

$$\partial_x^+ h(t, x) = \nabla_x h(t, x).$$

THEOREM 2.1. *Let $(\alpha, \beta, \xi(\cdot))$ be a local minimizer for (P). Suppose that, for some $\omega > 0$, hypotheses (H1)–(H4) hold. Then there exists an arc $p(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$; numbers k_1 and k_2 ; nonnegative numbers $\lambda \geq 0$, $\rho \geq 0$, and $\sigma \geq 0$; a nonnegative measure $\mu \in C^*([\alpha, \beta]; \mathbb{R})$; and a μ -integrable function $\gamma(\cdot): [\alpha, \beta] \rightarrow \mathbb{R}^n$ such that $\lambda + \|p(\cdot)\|_\infty + \rho + \sigma + \mu([\alpha, \beta]) = 1$ and*

$$(2.2) \quad (-\dot{p}(t), \dot{\xi}(t)) \in \partial_{x,p} H \left(t, \xi(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds) \right) \quad \text{a.e. } [\alpha, \beta],$$

$$(2.3) \quad \begin{aligned} \left(-k_1, p(\alpha), k_2, -p(\beta) - \int_{[\alpha, \beta]} \gamma(t) \mu(dt) \right) &\in \text{LN}_S(\alpha, \xi(\alpha), \beta, \xi(\beta)) \\ &+ \lambda L \partial g(\alpha, \xi(\alpha), \beta, \xi(\beta)) \\ &+ \rho L \partial h(\alpha, \xi(\alpha)) \times \sigma L \partial h(\beta, \xi(\beta)), \end{aligned}$$

$$(2.4) \quad k_1 \in \text{co} \operatorname{ess}_{t \rightarrow \alpha} H(t, \xi(\alpha), p(\alpha)),$$

$$(2.5) \quad k_2 \in \text{co} \operatorname{ess}_{t \rightarrow \beta} H \left(t, \xi(\beta), p(\beta) + \int_{[\alpha, \beta]} \gamma(t) \mu(dt) \right),$$

$$(2.6) \quad \gamma(t) \in \partial_x^+ h(t, \xi(t)) \quad \mu\text{-a.e.},$$

$$(2.7) \quad \text{Supp } \mu \subset \{t \in [\alpha, \beta]: \partial_x^+ h(t, \xi(t)) \neq \emptyset\},$$

$$(2.8) \quad \rho = 0 \quad \text{if } h(\alpha, \xi(\alpha)) < 0, \quad \sigma = 0 \quad \text{if } h(\beta, \xi(\beta)) < 0.$$

The conditions simplify when the constraint “ $h(t, x(t)) \leq 0$ ” is dropped from the formulation of problem (P). This situation can be regarded as an instance of a problem with formulation (P) where $h(\cdot, \cdot) \equiv -1$. (With this choice of function, the state constraint is satisfied by any admissible process.)

THEOREM 2.2. *Let $(\alpha, \beta, \xi(\cdot))$ be a local minimizer for (P). Suppose that, for some $\omega > 0$, hypotheses (H1)–(H4) hold. Suppose further that $h(\cdot, \cdot) \equiv -1$. Then there exists an arc $p(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$, numbers k_1 and k_2 , and a nonnegative number $\lambda \geq 0$ such that $\lambda + \|p(\cdot)\|_\infty = 1$ and*

$$\begin{aligned} &(-\dot{p}(t), \dot{\xi}(t)) \in \partial_{x,p} H(t, \xi(t), p(t)) \quad \text{a.e. } [\alpha, \beta], \\ &(-k_1, p(\alpha), k_2, -p(\beta)) \in \text{LN}_S(\alpha, \xi(\alpha), \beta, \xi(\beta)) + \lambda L \partial g(\alpha, \xi(\alpha), \beta, \xi(\beta)), \\ &k_1 \in \text{co} \operatorname{ess}_{t \rightarrow \alpha} H(t, \xi(\alpha), p(\alpha)), \\ &k_2 \in \text{co} \operatorname{ess}_{t \rightarrow \beta} H(t, \xi(\beta), p(\beta)). \end{aligned}$$

Theorem 2.2 is a straightforward refinement of [3, Cor. 2.2]. It differs only in the respect that here the transversality conditions are expressed in terms of limiting normal cones and limiting subgradients. To accommodate the changes, we must merely note that a transversality condition involving limiting normal cones is actually proved in [4], in the case that $g(a, x, b, y) = \langle \eta, y \rangle$ for some η (although the conclusions are not explicitly stated in this form). The restriction on g is then lifted by means of a state augmentation technique involving the epigraph of g along the lines of that in [4], with the exception that we now exploit the interpretation of subgradients of g in terms of elements in the limiting normal cone to $\text{epi } \{g\}$; see [14].

We stress that a proof of Theorem 2.2 is already available, with the qualifications outlined above, to justify using Theorem 2.2 as a building block in our proof of Theorem 2.1. However, Theorem 2.2 can be regarded as a simple corollary of Theorem 2.1. Indeed, if $h \equiv -1$, then by (2.7) the “state constraint multiplier” μ is the zero measure and so drops out of the conditions; the assertions of Theorem 2.2 follow.

The idea of sharpening the transversality conditions by expressing them in terms of limiting normal cones and subgradients is due to Mordukhovich [11] (although it was not originally proposed in connection with free-time problems with data measurable in t).

Finally, we clarify the relationship between the results of this section and the discussion in the Introduction. Making various simplifying assumptions about the data for problem (P), applying Theorem 2.1, and modifying the state constraint multiplier if necessary by addition of an atom at the right endtime, we obtain the following optimality conditions.

COROLLARY 2.3. *Suppose that the constraint set S is of the form*

$$S = \{0\} \times C \times \mathbb{R} \times \mathbb{R}^n,$$

and that the cost function g and state constraint function h are of the form

$$g(a, x, b, y) = \tilde{g}(y), \quad h(t, x) = \tilde{h}(x),$$

for some set $C \subset \mathbb{R}^n$ and functions $\tilde{g}: \mathbb{R}^n \rightarrow \mathbb{R}$ and $\tilde{h}: \mathbb{R}^n \rightarrow \mathbb{R}$. Let $(\beta, \xi(\cdot))$ be a local minimizer for (P). Suppose that, for some $\omega > 0$, hypotheses (H1)–(H4) hold. In addition, assume that $\tilde{h}(\cdot)$ is continuously differentiable. Then there exist numbers $\lambda \geq 0$, $\kappa \in [0, 1]$, an arc $p(\cdot) \in AC([0, \beta]; \mathbb{R}^n)$, and a nonnegative measure $\mu \in C^([0, \beta]; \mathbb{R}^n)$ such that $\lambda + \|p(\cdot)\|_\infty + \mu([0, \beta]) = 1$,*

$$(-\dot{p}(t), \dot{\xi}(t)) \in \partial_{x,p} H\left(t, \xi(t), p(t) + \int_{[0,t)} \nabla \tilde{h}(\xi(s)) \mu(ds)\right), \quad \text{a.e. } [0, \beta],$$

$$p(0) \in \text{LN}_C(\xi(0)),$$

$$-p(\beta) - \int_{[\alpha, \beta]} \nabla \tilde{h}(\xi(t)) \mu(dt) \in \lambda \text{L}\partial \tilde{g}(\xi(\beta)),$$

$$\text{Supp } \mu \subset \{t \in [0, \beta]: \tilde{h}(\xi(t)) = 0\},$$

$$0 \in \text{co } \text{ess}_{t \rightarrow \beta} H\left(t, \xi(\beta), p(\beta) + \int_{[0, \beta]} \nabla \tilde{h}(\xi(t)) \mu(dt) - \kappa \mu(\{\beta\}) \nabla \tilde{h}(\xi(\beta))\right).$$

3. Proof of Theorem 2.1. Let $(\alpha, \beta, \xi(\cdot))$ and $\omega > 0$ be as stated in the theorem. Define $h^+: \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$ by $h^+(t, x) = \max\{0, h(t, x)\}$. Since $(\alpha, \beta, \xi(\cdot))$ is a local

minimizer, we may choose some $\delta \in (0, \omega/2)$ such that $(\alpha, \beta, \xi(\cdot))$ is a minimizer for problem $Q(0)$, below

$$\begin{aligned}
 & \text{Minimize } g(a, x(a), b, x(b)) \\
 & \text{over intervals } [a, b] \subset \mathbb{R} \text{ and arcs } x(\cdot) \in AC([a, b]; \mathbb{R}^n), \text{ which satisfy} \\
 & \dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } [a, b], \\
 Q(0) \quad & \int_a^b h^+(t, x(t)) dt \leq 0, \\
 & h(a, x(a)) \leq 0, \quad h(b, x(b)) \leq 0, \\
 & (a, x(a), b, x(b)) \in S, \\
 & |x(\cdot) - \xi(\cdot)|_\infty \leq \delta, \quad |a - \alpha| \leq \delta, \quad |b - \beta| \leq \delta.
 \end{aligned}$$

This is a modification of problem (P), in which candidate arcs are required to lie close to $(\alpha, \beta, \xi(\cdot))$ and in which the original “pointwise” state constraint has been replaced with an equivalent formulation involving a combination of integral and pointwise constraints.

For now, we impose the following additional hypothesis on the data:

(HU) $(\alpha, \beta, \xi(\cdot))$ is the unique minimizer for problem $Q(0)$.

Problem $Q(0)$ is embedded in the family of problems $\{Q(r): r \leq 0\}$, shown below:

$$\begin{aligned}
 & \text{Minimize } g(a, x(a), b, x(b)) \\
 & \text{over intervals } [a, b] \subset \mathbb{R} \text{ and arcs } x(\cdot) \in AC([a, b]; \mathbb{R}^n), \text{ which satisfy} \\
 & \dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } [a, b], \\
 Q(r) \quad & \int_a^b h^+(t, x(t)) dt + r \leq 0, \\
 & h(a, x(a)) \leq 0, \quad h(b, x(b)) \leq 0, \\
 & (a, x(a), b, x(b)) \in S, \\
 & |x(\cdot) - \xi(\cdot)|_\infty \leq \delta, \quad |a - \alpha| \leq \delta, \quad |b - \beta| \leq \delta.
 \end{aligned}$$

Denote by V the value function associated with this family of problems; i.e., $V(r) = \inf Q(r)$ for $r \leq 0$. We adopt the convention of assigning V the value $+\infty$ if the “feasible set” for $Q(r)$ is empty. Sequential compactness arguments such as those employed in the proof of [1, Thm. 3.1.7] permit us to conclude the following lemma.

LEMMA 3.1. Assume hypotheses (H1)–(H4) and (HU).

(a) V is a lower semicontinuous function, and, if $V(r) < +\infty$, then $Q(r)$ has a solution.

(b) Let $\{r_i\}$ be any sequence of numbers increasing to zero such that $V(r_i) < +\infty$ for each i . Let $(a_i, b_i, x_i(\cdot))$ be a minimizer for $Q(r_i)$, $i = 1, 2, \dots$. Then

$$|x_i(\cdot) - \xi(\cdot)|_\infty \rightarrow 0, \quad |a_i - \alpha| \rightarrow 0, \quad |b_i - \beta| \rightarrow 0, \quad \text{as } i \rightarrow \infty.$$

The next step is to give conditions on admissible processes associated with a point in $\text{epi } V$ at which the proximal normal cone is nonempty.

LEMMA 3.2. Let $(v', -\varepsilon')$ be a proximal normal to $\text{epi } V$ at a point (r', e') with $\varepsilon' > 0$. Let $(a', b', x'(\cdot))$ be a minimizer for $Q(r')$ such that

$$|x'(\cdot) - \xi(\cdot)|_\infty \leq \omega', \quad |a' - \alpha| \leq \omega', \quad |b' - \beta| \leq \omega',$$

for some number $\omega' \in (0, \delta)$. Then there exist numbers k'_1 and k'_2 ; nonnegative numbers λ' , ρ' , σ' , and ζ' ; an arc $p'(\cdot) \in AC([a', b']; \mathbb{R}^n)$; and measurable functions $\gamma'(\cdot): [a', b'] \rightarrow \mathbb{R}^n$ and $m'(\cdot): [a', b'] \rightarrow [0, 1]$ such that $\lambda' + \rho' + \sigma' + \|p'(\cdot)\|_\infty + \|m'(\cdot)\|_1 > 0$ and

$$\begin{aligned} (-\dot{p}'(t), \dot{x}'(t)) &\in \partial_{x,p} H\left(t, x'(t), p'(t) + \int_{a'}^t \gamma'(s) \zeta' m'(s) ds\right) \quad \text{a.e. } [a', b'], \\ (-k'_1, p'(a'), k'_2, -p'(b')) &\in \lambda' L \partial g(a', x'(a'), b', x'(b')) + L N_S(a', x'(a'), b', x'(b')) \\ &\quad + \rho' L \partial h(a', x'(a')) \times \sigma' L \partial h(b', x'(b')), \\ k'_1 &\in \text{co ess}_{t \rightarrow a'} H(t, x'(a'), p'(a')), \\ k'_2 &\in \text{co ess}_{t \rightarrow b'} H(t, x'(b'), p'(b')), \\ \gamma'(t) &\in \partial_x^+ h(t, x'(t)) \quad \text{a.e. } \{t \in [a', b']: \partial_x^+ h(t, x'(t)) \neq \emptyset\}, \\ \{t \in [a', b']: m'(t) > 0\} &\subset \{t \in [a', b']: \partial_x^+ h(t, x'(t)) \neq \emptyset\}, \\ \rho' = 0 &\quad \text{if } h(a', x'(a')) < 0, \quad \sigma' = 0 \quad \text{if } h(b', x'(b')) < 0. \end{aligned}$$

Proof. Since the component $-\varepsilon'$ of the proximal normal $(v', -\varepsilon')$ is strictly negative, it must be that the point (r', e') in $\text{epi } V$ takes the form

$$(r', e') = \left(-\int_{a'}^{b'} h^+(t, x'(t)) dt, g(a', x'(a'), b', x'(b')) \right).$$

By definition of the proximal normal $(v', -\varepsilon')$, there exists $M > 0$ such that

$$(3.1) \quad \langle -(v', -\varepsilon'), (r', e') - (r, e) \rangle \leq M |(r, e) - (r', e')|^2$$

for all $(r, e) \in \text{epi } V$.

Take any element $(a, b, x(\cdot))$ that satisfies the constraints of problem $Q(0)$, with the possible exception of the state constraint $\int_{[a,b]} h^+(t, x(t)) dt \leq 0$. Then

$$(r, e) = \left(-\int_a^b h^+(t, x(t)) dt, g(a, x(a), b, x(b)) \right)$$

lies in $\text{epi } V$. Note that, if $r \leq r'$, then the point $(r, e') \in \text{epi } V$. It follows from (3.1) that $\langle -v', r' - r \rangle \leq M |r' - r|^2$ for all $r \leq r'$, whence $v' \geq 0$. In general, we interpret (3.1) as follows: $(a', b', (x'(\cdot), y'(\cdot) \equiv 0))$ is a minimizer for the problem

$$\begin{aligned} &\text{Minimize Max } \{ \mathcal{G}(a, x(a), b, x(b), y(b)), h(a, x(a)), h(b, x(b)) \} \\ &\text{over intervals } [a, b] \subset \mathbb{R} \text{ and arcs } (x(\cdot), y(\cdot)) \in AC([a, b]; \mathbb{R}^{n+1}), \text{ satisfying} \\ &\dot{x}(t) \in F(t, x(t)) \quad \text{a.e. } [a, b], \\ &\dot{y}(t) = h^+(t, x(t)) - h^+(t, x'(t)) \chi_{[a', b']}(t) \quad \text{a.e. } [a, b], \\ &(a, x(a), y(a), b, x(b), y(b)) \\ &\quad \in \{(s_1, s_2, 0, s_4, s_5, s_6): (s_1, s_2, s_4, s_5, s_6) \in S \times \mathbb{R}\}, \\ &|x'(\cdot) - x(\cdot)|_\infty \leq \omega', \quad |a' - a| \leq \omega', \quad |b' - b| \leq \omega'. \end{aligned}$$

Here $\chi_A(t)$ is the indicator function of the set A , and $\mathcal{G}: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$ is the function

$$\begin{aligned} \mathcal{G}(x_1, x_2, x_3, x_4, x_5) &= \varepsilon'(g(x_1, x_2, x_3, x_4) - g(a', x'(a'), b', x'(b'))) + v'(x_5 + m(a, b)) \\ &\quad + |g(x_1, x_2, x_3, x_4) - g(a', x'(a'), b', x'(b'))|^2 + (x_5 + m(a, b))^2, \end{aligned}$$

in which

$$m(a, b) = \int_{a'}^{a' \vee a} h^+(t, x'(t)) dt + \int_b^{b' \vee b} h^+(t, x'(t)) dt.$$

Note that this minimization problem is a dynamic optimization problem without state constraints, and the hypotheses are satisfied under which Theorem 2.2 is applicable. Using the fact that $m(a', b') = 0$ and the rules

$$L\partial(f_1(x) + f_2(x)) \subset L\partial f_1(x) + L\partial f_2(x)$$

and

$$L\partial(f_1(x) \vee f_2(x) \vee f_3(x)) \\ \subset \left\{ \sum_i \alpha_i L\partial f_i(x) : \sum_i \alpha_i = 1, \alpha_i \geq 0, \alpha_i = 0 \text{ if } f_i(x) < (f_1(x) \vee f_2(x) \vee f_3(x)) \right\}$$

governing the calculation of limiting subgradients for locally Lipschitz functions (see, e.g. [11]–[13]), we deduce that there exist nonnegative numbers $\alpha_1, \alpha_2, \alpha_3$, and λ ; numbers h' and k' ; and an arc $q(\cdot) \in AC([a', b']; \mathbb{R}^n)$, such that

$$(3.2) \quad \alpha_1 + \alpha_2 + \alpha_3 = 1, \quad \lambda + |q(\cdot)|_\infty \neq 0,$$

$$\alpha_2 = 0 \quad \text{if } h(a', x'(a')) < 0, \quad \alpha_3 = 0 \quad \text{if } h(b', x'(b')) < 0,$$

$$(3.3) \quad (-\dot{q}(t), \dot{x}'(t)) \in \partial_{x,p} H(t, x'(t), q(t)) - \lambda \alpha_1 v' \partial_x h^+(t, x'(t)) \quad \text{a.e. } [a', b'],$$

$$(3.4) \quad \begin{aligned} (-k'_1, q(a'), k'_2, -q(b')) &\in \lambda \alpha_1 \varepsilon' L\partial g(a', x'(a'), b', x'(b')) + L N_S(a', x'(a'), b', x'(b')) \\ &+ \lambda \alpha_2 L\partial h(a', x'(a')) \times \lambda \alpha_3 L\partial h(b', x'(b')), \end{aligned}$$

$$(3.5) \quad k'_1 \in \text{co ess}_{t \rightarrow a'} H(t, x'(a'), q(a')), \quad k'_2 \in \text{co ess}_{t \rightarrow b'} H(t, x'(b'), q(b')).$$

Define $\lambda' = \lambda \alpha_1 \varepsilon'$, $\rho' = \lambda \alpha_2$, $\sigma' = \lambda \sigma_3$, and $\zeta' = \lambda \alpha_1 v'$. Then λ', ρ', σ' , and $\zeta' \geq 0$, and

$$(3.6) \quad \lambda' + \rho' + \sigma' + |q(\cdot)|_\infty \neq 0,$$

$$(3.7) \quad \rho' = 0 \quad \text{if } h(a', x'(a')) < 0, \quad \sigma' = 0 \quad \text{if } h(b', x'(b')) < 0.$$

Now, arguing as in [4], we deduce from (3.3) existence of measurable functions $\gamma'(\cdot): [a', b'] \rightarrow \mathbb{R}^n$ and $m'(\cdot): [a', b'] \rightarrow [0, 1]$ such that

$$(3.8) \quad (-\dot{q}(t), \dot{x}'(t)) \in \partial_{x,p} H(t, x'(t), q(t)) - \zeta' m'(t) \gamma'(t) \times \{0\} \quad \text{a.e. } [a', b'],$$

$$(3.9) \quad \gamma'(t) \in \partial_x^+ h(t, x'(t)) \quad \text{a.e. } \{t \in [a', b']: \partial_x^+ h(t, x'(t)) \neq \emptyset\},$$

$$(3.10) \quad \{t \in [a', b']: m'(t) > 0\} \subset \{t \in [a', b']: \partial_x^+ h(t, x'(t)) \neq \emptyset\}.$$

Define $p'(\cdot) \in AC([a', b']; \mathbb{R}^n)$ by

$$(3.11) \quad p'(t) = q(t) - \int_{a'}^t \zeta' m'(s) \gamma'(s) ds.$$

It follows from (3.6) and (3.11) that

$$\lambda' + \rho' + \sigma' + |p'(\cdot)|_\infty + |m'(\cdot)|_1 \neq 0.$$

Substituting $(\lambda', \rho', \sigma', p'(\cdot))$ for $(\lambda \alpha_1 \varepsilon', \lambda \alpha_2, \lambda \alpha_3, q(\cdot))$, we arrive at the assertions of the lemma. \square

To conclude the proof of Theorem 2.1 (under the extra hypothesis (HU)), we use the fact that there exist sequences of proximal normals to $\text{epi } V$ and of corresponding base points in $\text{epi } V$, with general terms $(v_i, -\varepsilon_i)$ and (r_i, e_i) , respectively, such that $\varepsilon_i > 0$ along the sequence and $r_i \downarrow 0$. This follows from the lower semicontinuity of V (see [14]). Since $V(r_i) < +\infty$, there exists a minimizer $(a_i, b_i, x_i(\cdot))$ for $Q(r_i)$. By Lemma 3.1,

$$|x_i(\cdot) - \xi(\cdot)|_\infty \rightarrow 0, \quad |a_i - \alpha| \rightarrow 0, \quad |b_i - \beta| \rightarrow 0.$$

By discarding initial terms in the sequences, if necessary, we can arrange that

$$|x_i(\cdot) - \xi(\cdot)|_\infty \leq \bar{\omega}, \quad |a_i - \alpha| \leq \bar{\omega}, \quad |b_i - \beta| \leq \bar{\omega},$$

where $\bar{\omega} \in (0, \delta)$ is a number common to all points along the sequence. Now apply Lemma 3.2. We deduce conditions resembling those in Theorem 2.1, in all respects except that $(a_i, b_i, x_i(\cdot))$ replaces $(\alpha, \beta, \xi(\cdot))$, $(\lambda_i, \rho_i, \sigma_i, p_i(\cdot))$ replaces $(\lambda, \rho, \delta, p(\cdot))$, and $\mu_i(\cdot)$ is defined by

$$\mu_i(dt) = \zeta_i m_i(t) dt$$

replaces μ . We have $\eta_i > 0$, where

$$\eta_i := \lambda_i + \rho_i + \sigma_i + |p_i(\cdot)|_\infty + \mu_i([a_i, b_i]).$$

Scaling the multipliers by η_i^{-1} , we ensure that

$$\lambda_i + \rho_i + \sigma_i + |p_i(\cdot)|_\infty + \mu_i([a_i, b_i]) = 1.$$

Extracting subsequences, we obtain $\lambda, k_1, k_2, \rho, \sigma, p(\cdot)$, and $\mu(\cdot)$ such that $\lambda_i \rightarrow \lambda$, $k_{1i} \rightarrow k_1$, $k_{2i} \rightarrow k_2$, $\rho_i \rightarrow \rho$, $\sigma_i \rightarrow \sigma$, $|p_i(\cdot) - p(\cdot)|_\infty \rightarrow 0$, $\mu_i(\cdot) \xrightarrow{*} \mu(\cdot)$, and

$$\lambda + \rho + \sigma + |p(\cdot)|_\infty + \mu([a, b]) = 1.$$

The assertions of the theorem are proved by passage to the limit, with the help of a convergence analysis along the lines of that in [4] (which uses, in particular, the compactness of solutions to the multifunction F [1, Thm. 3.1.7], upper-semicontinuity properties of the convex essential value [3, Lem. 1.2], and the convergence results of [17]).

It remains to dispose of the extra hypothesis (HU). In circumstances when (HU) is violated, we replace the problem (P) with the problem (\tilde{P}) having cost function

$$g(a, x(a), b, x(b)) + \int_a^b |x(t) - \xi(t)|^2 dt + |b - \beta|^2 + |a - \alpha|^2.$$

The data for problem (\tilde{P}) satisfies the extra hypothesis (H5). Applying the special case of Theorem 2.1 to (\tilde{P}), we deduce the necessary conditions for (P). \square

4. Pontryagin-type conditions. In [8] Kaskosz and Lojasiewicz proved an optimality condition involving a *Carathéodory selection* $f(\cdot, \cdot)$ of the multifunction $F(\cdot, \cdot)$ (defined below) for the fixed-time, state constraint, free version of (P). In their necessary condition, the Hamiltonian inclusion is replaced by a separated adjoint equation and maximum condition reminiscent of the Pontryagin maximum principle. Subsequently, Pontryagin-type conditions were proved by a number of authors in a variety of settings (see [7], [10], [16], and [18]). Pontryagin-type conditions do not subsume Hamiltonian inclusion conditions but supply an independent test of optimality for putative minimizers. (The distinctive features of the two sets of conditions are illustrated by the example in [8].)

Pontryagin-type necessary conditions for problem (P) follow easily from Theorem 2.1, as we demonstrate in this section (cf. [10]).

DEFINITION 4.1. A mapping $f: \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}^n$ is called a Carathéodory selection of the multifunction $F: \mathbb{R} \times \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ if the single-valued multifunction $\tilde{F}(\cdot, \cdot) := \{f(\cdot, \cdot)\}$ obeys the hypothesis (H3) (with a possibly different Lipschitz constant) and satisfies $f(t, x) \in F(t, x)$ for all $(t, x) \in \mathbb{R} \times \mathbb{R}^n$.

Suppose that the arc $x(\cdot) \in AC([a, b]; \mathbb{R}^n)$ satisfies $\dot{x}(t) \in F(t, x(t))$, almost everywhere $t \in [a, b]$. It is shown in [8] that there always exists a Carathéodory selection f of the multifunction F such that $\dot{x}(t) = f(t, x(t))$, almost everywhere $t \in [a, b]$.

THEOREM 4.2. Let $(\alpha, \beta, \xi(\cdot))$ be a local minimizer for (P). Suppose that, for some $\omega > 0$, hypotheses (H1)–(H4) hold. Pick any Carathéodory selection f of F with the property that

$$\dot{\xi}(t) = f(t, \xi(t)) \quad \text{a.e. } [\alpha, \beta].$$

Then there exists an arc $p(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$; numbers k_1 and k_2 ; nonnegative numbers $\lambda \geq 0$, $\rho \geq 0$, and $\sigma \geq 0$; a nonnegative measure $\mu \in C^*([\alpha, \beta]; \mathbb{R})$; and a μ -integrable function $\gamma(\cdot): [\alpha, \beta] \rightarrow \mathbb{R}^n$ such that $\lambda + \|p(\cdot)\|_\infty + \rho + \sigma + \mu([\alpha, \beta]) = 1$ and

$$\begin{aligned} -\dot{p}(t) &\in \left\langle p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds), \partial_x f(t, \xi(t)) \right\rangle \quad \text{a.e. } [\alpha, \beta], \\ H(t, \xi(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds)) &= \left\langle p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds), \xi(t) \right\rangle \quad \text{a.e. } [\alpha, \beta], \\ \left(-k_1, p(\alpha), k_2, -p(\beta) - \int_{[\alpha, \beta]} \gamma(t) \mu(dt) \right) &\in \text{LN}_S(\alpha, \xi(\alpha), \beta, \xi(\beta)) \\ &\quad + \lambda L \partial g(\alpha, \xi(\alpha), \beta, \xi(\beta)) + \rho L \partial h(\alpha, \xi(\alpha)) \\ &\quad \times \sigma L \partial h(\beta, \xi(\beta)), \\ k_1 &\in \text{co} \operatorname{ess}_{t \rightarrow \alpha} H(t, \xi(\alpha), p(\alpha)), \\ k_2 &\in \text{co} \operatorname{ess}_{t \rightarrow \beta} H(t, \xi(\beta), p(\beta) + \int_{[\alpha, \beta]} \gamma(t) \mu(dt)), \\ \gamma(t) &\in \partial_x^+ h(t, \xi(t)) \quad \mu\text{-a.e.}, \\ \operatorname{Supp} \mu &\subset \{t \in [\alpha, \beta]: \partial_x^+ h(t, \xi(t)) \neq \emptyset\}, \\ \rho = 0 &\quad \text{if } h(\alpha, \xi(\alpha)) < 0, \quad \sigma = 0 \quad \text{if } h(\beta, \xi(\beta)) < 0. \end{aligned}$$

Proof. Take $f(\cdot, \cdot)$ as in the theorem statement. For each $i \in N$, consider the multifunction

$$F_i(t, x) = f(t, x) + i^{-1} \{F(t, x) - f(t, x)\}$$

and the optimization problem (P_i) , obtained from (P) by replacing F with F_i . Note that F_i inherits from F and f the hypotheses (H1)–(H4) for a suitably modified function $k_F(t)$ in (H3). In view of the convexity of $F(t, x)$ and since $f(\cdot, \cdot)$ is a selector of $F(\cdot, \cdot)$, we have $F_i(t, x) \subset F(t, x)$. Now consider the optimization problem (P_i) , obtained from (P) by replacing F with F_i . Since $F_i \subset F$, arcs admissible for (P_i) are also admissible for (P). In view of the fact that $(\alpha, \beta, \xi(\cdot))$ is a local minimizer for (P) and admissible for (P_i) , we deduce that $(\alpha, \beta, \xi(\cdot))$ is also a local minimizer for (P_i) , $i = 1, 2, 3, \dots$. An application of Theorem 2.1 to (P_i) , with reference to $(\alpha, \beta, \xi(\cdot))$,

gives the following information: There exists an arc $p_i(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$; numbers k_1 , and k_{2i} ; nonnegative numbers $\lambda_i \geq 0$, $\rho_i \geq 0$, and $\sigma_i \geq 0$; a nonnegative measure $\mu_i \in C^*([\alpha, \beta]; \mathbb{R})$; and a μ_i -integrable function $\gamma_i(\cdot): [\alpha, \beta] \rightarrow \mathbb{R}^n$ such that $\lambda_i + \|p_i(\cdot)\|_\infty + \rho_i + \sigma_i + \mu_i([\alpha, \beta]) = 1$ and

$$(4.1) \quad (-\dot{p}_i(t), \dot{\xi}(t)) \in \partial_{x,p} H_i\left(t, \xi(t), p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt)\right) \quad \text{a.e. } [\alpha, \beta],$$

$$(4.2) \quad \left(-k_{1i}, p_i(\alpha), k_{2i}, -p_i(\beta) - \int_{[\alpha, \beta]} \gamma_i(t) \mu_i(dt)\right) \in \text{LN}_S(\alpha, \xi(\alpha), \beta, \xi(\beta))$$

$$+ \lambda_i L \partial g(\alpha, \xi(\alpha), \beta, \xi(\beta))$$

$$+ \rho_i L \partial h(\alpha, \xi(\alpha))$$

$$\times \sigma_i L \partial h(\beta, \xi(\beta)),$$

$$(4.3) \quad k_{1i} \in \text{co ess}_{t \rightarrow \alpha} H_i(t, \xi(\alpha), p_i(\alpha)),$$

$$(4.4) \quad k_{2i} \in \text{co ess}_{t \rightarrow \beta} H_i\left(t, \xi(\beta), p_i(\beta) + \int_{[\alpha, \beta]} \gamma_i(t) \mu_i(dt)\right),$$

$$(4.5) \quad \gamma_i(t) \in \partial_x^+ h(t, \xi(t)) \quad \mu_i\text{-a.e.},$$

$$(4.6) \quad \text{Supp } \mu_i \subset \{t \in [\alpha, \beta]: \partial_x^+ h(t, \xi(t)) \neq \emptyset\},$$

$$(4.7) \quad \rho_i = 0 \quad \text{if } h(\alpha, \xi(\alpha)) < 0, \quad \sigma_i = 0 \quad \text{if } h(\beta, \xi(\beta)) < 0,$$

where $H_i(t, x, p) := (1 - i^{-1})\langle p, f(t, x) \rangle + i^{-1}H(t, x, p)$. Expanding (4.1), we obtain

$$(4.8) \quad (-\dot{p}_i(t), \dot{\xi}(t)) \in (1 - i^{-1}) \left[\left\langle p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt), \partial_x f(t, \xi(t)) \right\rangle \times \{f[t, \xi(t)]\} \right]$$

$$+ i^{-1} \partial_{x,p} H\left(t, \xi(t), p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt)\right) \quad \text{a.e. } [\alpha, \beta].$$

Now apply [1, Prop. 3.2.4] to the second component of (4.8) to obtain

$$i^{-1} f(t, \xi(t)) = \dot{\xi}(t) - (1 - i^{-1}) f(t, \xi(t))$$

$$\in i^{-1} \partial_p H\left(t, \xi(t), p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt)\right).$$

It follows that

$$(4.8) \quad H\left(t, \xi(t), p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt)\right)$$

$$= \left\langle p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt), \dot{\xi}(t) \right\rangle \quad \text{a.e. } [\alpha, \beta].$$

Applying the same proposition to the first component of (4.8), we deduce

$$(4.10) \quad -\dot{p}_i(t) \in (1 - i^{-1}) \left\langle p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt), \partial_x f(t, \xi(t)) \right\rangle$$

$$+ i^{-1} \left| p_i(t) + \int_{[\alpha, t)} \gamma_i(t) \mu_i(dt) \right| k_f(t) \bar{B}.$$

Relationships (4.2)–(4.7) and (4.9)–(4.10) are perturbed versions of the assertions of the theorem. Now let $i \rightarrow \infty$. A convergence analysis properties along the lines of that in [4] or [16] completes the proof. \square

5. Optimal control problems. This final section provides necessary conditions for free-time state-constrained dynamic optimization problems having a Pontryagin formulation; i.e., the dynamics are expressed in terms of a differential equation with control term. The novel aspect of these necessary conditions is that, once again, they apply to problems with data merely measurable in the time variable and that they allow the state constraints to be active at the optimal endtimes.

As is customary, the first step is to provide conditions on boundary points of a reachable set. The control system (C) of interest is specified by the following differential equation and constraint:

$$(5.1) \quad (C) \quad \dot{x}(t) = \phi(t, x(t), u(t)), \quad u(t) \in U_t \quad \text{a.e. } [a, b],$$

$$(5.2) \quad h(t, x(t)) \leq 0 \quad \text{for all } t \in [a, b],$$

Here $\phi: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ and $h: \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$ are given functions, and $U \subset \mathbb{R} \times \mathbb{R}^m$ is a given set. For $t \in \mathbb{R}$, define $U_t := \{u: (t, u) \in U\}$.

We term *control process* for (C) an element $(a, b, x(\cdot), u(\cdot))$ comprising left and right endpoints, a and b , respectively, of an interval, a function $x(\cdot) \in AC([a, b]; \mathbb{R}^n)$, and a measurable function $u(\cdot): [a, b] \rightarrow \mathbb{R}^m$, which satisfy constraints (5.1) and (5.2). As with inclusion processes, it is convenient to extend the domain of the absolutely continuous function $x(\cdot)$ in a control process to the whole of \mathbb{R} by constant extrapolation. The hypotheses we invoke are of a local nature; they relate to a nominal control process $(\alpha, \beta, \xi(\cdot), v(\cdot))$ and a parameter $\omega > 0$. Let $\varepsilon > 0$ and define the ε -tube of the control process $(\alpha, \beta, \xi(\cdot), v(\cdot))$ by

$$T_\varepsilon(\alpha, \beta, \xi(\cdot), v(\cdot)) = \{(\tau, \eta): \tau \in [\alpha - \varepsilon, \beta + \varepsilon], |\eta - \xi(\tau)| < \varepsilon\}.$$

(HC1) $h(\cdot, \cdot)$ is continuous on $T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot))$; there exists a nonnegative number k_h such that

$$|h(t, x) - h(t, y)| \leq k_h |x - y| \quad \text{for all } (t, x), (t, y) \in T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot)).$$

(HC2) $\phi(\cdot, \cdot)$ is $(\mathcal{L} \times \mathcal{B})$ -measurable for each $x \in \{\eta: (\tau, \eta) \in T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot))\}$. U is $\mathcal{L} \times \mathcal{B}$ -measurable. There exists a nonnegative function $k_\phi(\cdot) \in L^1$, which is essentially bounded on $(\alpha - \omega, \alpha + \omega) \cup (\beta - \omega, \beta + \omega)$ such that

$$|\phi(t, x, u)| \leq k_\phi(t) \quad \text{for all } (t, x) \in T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot)), u \in U_t$$

and

$$|\phi(t, x, u) - \phi(t, y, u)| \leq k_\phi(t) |x - y| B,$$

for all $(t, x), (t, y) \in T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot))$ and $u \in U_t$.

We employ the *unmaximized Hamiltonian* function $\mathcal{H}: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \rightarrow \mathbb{R}$, defined by

$$\mathcal{H}(t, x, u, p) = \langle p, \phi(t, x, u) \rangle.$$

THEOREM 5.1. *Let $(\alpha, \beta, \xi(\cdot), v(\cdot))$ be a control process for the control system (C) and suppose that hypotheses (HC1) and (HC2) are satisfied with respect to some number $\omega > 0$. Let $C \subset \mathbb{R}^{1+n+1}$ be a closed set and $\psi: \mathbb{R}^n \rightarrow \mathbb{R}^d$ be a function that is Lipschitz*

continuous on a neighbourhood of $(\alpha, \xi(\alpha), \beta)$. Suppose that $(\alpha, \xi(\alpha), \beta) \in C$ and $\psi(\xi(\beta))$ is a boundary point of the reachable set $\mathcal{R}_{\psi, c}^\omega$, defined by

$\mathcal{R}_{\psi, c}^\omega := \{\psi(x(b)): (a, b, x(\cdot), u(\cdot)) \text{ is a control process lying in } T_\omega(\alpha, \beta, \xi(\cdot), v(\cdot))\}$.

Then there exists a function $p(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$; numbers k_1 and k_2 ; nonnegative numbers $\rho \geq 0$ and $\sigma \geq 0$; a vector $\theta \in \mathbb{R}^d$; a nonnegative measure $\mu \in C^*([\alpha, \beta]; \mathbb{R})$; and a μ -integrable function $\gamma(\cdot): [\alpha, \beta] \rightarrow \mathbb{R}^n$ such that $|\theta| + |p(\cdot)|_\infty + \rho + \sigma + \mu([\alpha, \beta]) = 1$ and

$$\begin{aligned} -\dot{p}(t) &\in \partial_x \mathcal{H}\left(t, \xi(t), v(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds)\right) \quad \text{a.e. } [a, b], \\ \mathcal{H}\left(t, \xi(t), v(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds)\right) \\ &= \sup \left\{ \mathcal{H}\left(t, \xi(t), u, p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds)\right) : u \in U_t \right\} \quad \text{a.e. } [a, b], \\ \left(-k_1, p(\alpha), k_2, -p(\beta) - \int_{[\alpha, \beta]} \gamma(t) \mu(dt) \right) &\in \text{LN}_C(\alpha, \xi(\alpha), \beta) \times \partial \psi(\xi(\beta)) \theta \\ &\quad + \rho L \partial h(\alpha, \xi(\alpha)) \times \sigma L \partial h(\beta, \xi(\beta)), \\ k_1 &\in \text{co ess sup}_{t \rightarrow \alpha} \{ \mathcal{H}(t, \xi(\alpha), u, p(\alpha)) : u \in U_t \}, \\ k_2 &\in \text{co ess sup}_{t \rightarrow \beta} \left\{ \mathcal{H}\left(t, \xi(\beta), u, p(\beta) + \int_{[\alpha, \beta]} \gamma(t) \mu(dt)\right) : u \in U_t \right\}, \\ \gamma(t) &\in \partial_x^+ h(t, \xi(t)) \quad \mu\text{-a.e.}, \\ \text{Supp } \mu &\subset \{t \in [\alpha, \beta] : \partial_x^+ h(t, \xi(t)) \neq \emptyset\}, \\ \rho = 0 \quad &\text{if } h(\alpha, \xi(\alpha)) < 0, \quad \sigma = 0 \quad \text{if } h(\beta, \xi(\beta)) < 0. \end{aligned}$$

Consider now the optimal control problem (PC), below:

$$\begin{aligned} &\text{Minimize } \left(g(a, x(a), b, x(b)) + \int_a^b L(t, x(t), u(t)) dt \right) \\ &\text{over intervals } [a, b] \subset \mathbb{R} \text{ and arcs } x(\cdot) \in AC([a, b]; \mathbb{R}^n), \text{ which satisfy} \\ \text{(PC)} \quad &\dot{x}(t) = \phi(t, x(t), u(t)), \quad u(t) \in U_t \quad \text{a.e. } [a, b], \\ &h(t, x(t)) \leq 0 \quad \text{for all } t \in [a, b], \\ &(a, x(a), b, x(b)) \in S, \end{aligned}$$

which is expressed in terms of the control system (C), together with a given set $S \subset \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n$ and given functions $g: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$ and $L: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}$. Minimization is conducted over control processes $(a, b, x(\cdot), u(\cdot))$ for system (C) that satisfy the endpoint constraint $(a, x(a), b, x(b)) \in S$. A control process $(a, b, x(\cdot), u(\cdot))$ is said to lie in the ε -neighbourhood of the control process $(a, b, x(\cdot), u(\cdot))$, provided that

$$|a - a| < \varepsilon, \quad |b - b| < \varepsilon, \quad |x(t) - x(t)| < \varepsilon \quad \text{for all } t \in \mathbb{R}.$$

The control process $(a, b, x(\cdot), u(\cdot))$ is a *local minimizer* for (PC) if it achieves the minimum cost over the set of control processes lying in an ε -neighbourhood of

$(a, b, x(\cdot), u(\cdot))$ that satisfy the endpoint constraint. For this “integral cost” problem, the appropriate *unmaximized Hamiltonian* function $\mathcal{H}^\lambda: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^n \rightarrow \mathbb{R}$ is

$$\mathcal{H}^\lambda(t, x, u, p) = \langle p, \phi(t, x, u) \rangle - \lambda L(t, x, u).$$

THEOREM 5.2. *Let $(\alpha, \beta, \xi(\cdot), v(\cdot))$ be a local minimizer for (PC). Take $\omega > 0$. Suppose that S is a closed set, $g(\cdot, \cdot, \cdot, \cdot)$ is Lipschitz continuous on a neighbourhood of $(\alpha, \xi(\alpha), \beta, \xi(\beta))$, $h(\cdot, \cdot)$ satisfies hypothesis (HC1), and $\tilde{\phi} (:= \text{column} [\phi, L])$ and U satisfy hypothesis (HC2). Then there exists an arc $p(\cdot) \in AC([\alpha, \beta]; \mathbb{R}^n)$; numbers k_1 and k_2 ; nonnegative numbers $\lambda \geq 0$, $\rho \geq 0$, and $\sigma \geq 0$; a nonnegative measure $\mu \in C^*([\alpha, \beta]; \mathbb{R})$; and a μ -integrable function $\gamma(\cdot); [\alpha, \beta] \rightarrow \mathbb{R}^n$ such that $\lambda + |p(\cdot)|_\infty + \rho + \sigma + \mu([\alpha, \beta]) = 1$ and*

$$\begin{aligned} & -\dot{p}(t) \in \partial_x \mathcal{H}^\lambda \left(t, \xi(t), v(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds) \right) \quad \text{a.e. } [a, b], \\ & \mathcal{H}^\lambda \left(t, \xi(t), v(t), p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds) \right) \\ & = \sup \left\{ \mathcal{H}^\lambda(t, \xi(t), u, p(t) + \int_{[\alpha, t)} \gamma(s) \mu(ds)) : u \in U_t \right\} \quad \text{a.e. } [a, b], \\ & (-k_1, p(\alpha), k_2, -p(\beta) - \int_{[\alpha, \beta]} \gamma(t) \mu(dt)) \in \text{LN}_S(\alpha, \xi(\alpha), \beta, \xi(\beta)) \\ & \quad + \lambda L \partial g(\alpha, \xi(\alpha), \beta, \xi(\beta)) + \rho L \partial h(\alpha, \xi(\alpha)) \\ & \quad \times \sigma L \partial h(\beta, \xi(\beta)), \\ & k_1 \in \text{co ess sup}_{t \rightarrow \alpha} \{ \mathcal{H}^\lambda(t, \xi(\alpha), u, p(\alpha)) : u \in U_t \}, \\ & k_2 \in \text{co ess sup}_{t \rightarrow \beta} \left\{ \mathcal{H}^\lambda(t, \xi(\beta), u, p(\beta) + \int_{[\alpha, \beta]} \gamma(t) \mu(dt)) : u \in U_t \right\}, \\ & \gamma(t) \in \partial_x^+ h(t, \xi(t)) \quad \mu\text{-a.e.}, \\ & \text{Supp } \mu \subset \{t \in [\alpha, \beta] : \partial_x^+ h(t, \xi(t)) \neq \emptyset\}, \\ & \rho = 0 \quad \text{if } h(\alpha, \xi(\alpha)) < 0, \quad \sigma = 0 \quad \text{if } h(\beta, \xi(\beta)) < 0. \end{aligned}$$

Proof of Theorem 5.2. Let $(\alpha, \beta, \xi(\cdot), v(\cdot))$ solve problem (PC). Consider control processes $(a, b, x_1(\cdot), x_2(\cdot), x_3(\cdot), x_4(\cdot), x_5(\cdot), u(\cdot))$, where the state $(x_1(\cdot), x_2(\cdot), x_3(\cdot), x_4(\cdot), x_5(\cdot)) \in AC([a, b]; \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R})$ satisfies dynamical equations

$$(\dot{x}_1(t), \dot{x}_2(t), \dot{x}_3(t), \dot{x}_4(t), \dot{x}_5(t)) = (\phi(t, x(t), u(t)), L(t, x(t), u(t)), 0, 0, 0) \quad \text{a.e. } [a, b],$$

$$u(t) \in U_t \quad \text{a.e. } [a, b],$$

$$h(t, x_1(t)) \leq 0 \quad \text{all for } t \in [a, b].$$

Define the Lipschitz continuous function $\psi: \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}$ by

$$\psi(x_1, x_2, x_3, x_4, x_5) = (x_1 - x_3, x_2 - x_4, x_5),$$

the function $G: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \rightarrow \mathbb{R}$ by

$$G(a, x_1, b, x_3, x_4) = g(a, x_1, b, x_3) + x_4,$$

and the closed set $C \subset \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$ by

$$C = \{(a, x_1, x_2, x_3, x_4, b) : (a, x_1, b, x_3) \in S, \quad x_2 = 0, (a, x_1, b, x_3, x_4, x_5) \in \text{epi } G\}.$$

Note that

$$(a, b, x_1(\cdot), x_2(\cdot), x_3(\cdot), x_4(\cdot), x_5(\cdot), u(\cdot)) \\ = \left(\alpha, \beta, \xi(\cdot), \int_{\alpha}^{(\cdot)} L(t, \xi(t), v(t)) dt, \xi(\beta), \int_{\alpha}^{\beta} L(t, \xi(t), v(t)) dt, g(\alpha, \xi(\alpha), \beta, \xi(\beta)) \right. \\ \left. + \int_{\alpha}^{\beta} L(t, \xi(t), v(t)) dt, v(\cdot) \right)$$

is a control process for the five-state control system just defined. Furthermore,

$$(\alpha, x_1(\alpha), x_2(\alpha), x_3(\alpha), x_4(\alpha), x_5(\alpha), \beta) \in C,$$

and, by means of simple contradiction argument, we deduce that, for some $\omega > 0$,

$$\psi(x_1(\beta), x_2(\beta), x_3(\beta), x_4(\beta), x_5(\beta)) \in \text{boundary } \{\mathcal{R}_{\psi, c}^{\omega}\},$$

where $\mathcal{R}_{\psi, c}^{\omega}$ is the reachable set for the five-state control system. We apply Theorem 5.1, and the result follows. \square

Proof of Theorem 5.1. Let $(\alpha, \beta, \xi(\cdot), v(\cdot))$ and ω be as stated in the theorem. The theorem is proved first under the supplementary hypothesis (HCF), below:

(HCF) For each t , the set U_t contains finitely many points.

Take $\delta \in (0, \omega/2)$. Let M be the set of control processes $(a, b, x(\cdot), u(\cdot))$, satisfying

$$|\alpha - a| \leq \delta, \quad |\beta - b| \leq \delta, \quad |\xi(\gamma) - x(\tau)| \leq \delta \quad \text{for } \tau \in [\alpha - \delta, \beta + \delta].$$

Let $a \vee b$ and $a \wedge b$ be the maximum and minimum of a and b , respectively, and consider the metric d on M defined by

$$d((a, b, x(\cdot), u(\cdot)), (a', b', x'(\cdot), u'(\cdot))) = |a - a'| + |b - b'| + |x(0) - x'(0)| \\ + \mathcal{L}\text{-meas } \{t \in [a \vee a', b \wedge b'] : u(t) \neq u'(t)\}.$$

It is a straightforward matter (see [1, Lem. 1, p. 202]) to show that

- (i) M is closed with respect to this metric, and
- (ii) If $(a_i, b_i, x_i(\cdot), u_i(\cdot)) \rightarrow (a, b, x(\cdot), u(\cdot))$ in (M, d) , then

$$\lim_i |x_i(\cdot) - x(\cdot)|_{\infty} = 0, \quad \lim_i a_i = a, \quad \text{and} \quad \lim_i b_i = b.$$

Let $i \in \mathbb{N}$ and let ζ_i be a point in $\psi(\xi(\beta)) + i^{-2}B$ such that $\zeta_i \notin \mathcal{R}_{\psi, c}^{\omega}$. Define the function $\mathcal{G}_i: (M, d) \rightarrow \mathbb{R}$ to be

$$\mathcal{G}_i(a, b, x(\cdot), u(\cdot)) = |\zeta_i - \psi(x(b))|.$$

For each i , \mathcal{G}_i is continuous, and

$$\mathcal{G}_i(\alpha, \beta, \xi(\cdot), v(\cdot)) \leq \inf_{e \in M} \mathcal{G}_i(e) + i^{-2}.$$

By Ekeland's theorem [6], there exists a point $e_i = (a_i, b_i, x_i(\cdot), u_i(\cdot))$ in M such that, writing $\tilde{e} = (\alpha, \beta, \xi(\cdot), v(\cdot))$,

$$d(e_i, \tilde{e}) \leq i^{-1}$$

and

$$\mathcal{G}_i(e_i) \leq \mathcal{G}_i(e) + i^{-1}d(e, e_i) \quad \text{for all } e \in M.$$

By taking i sufficiently large, we can ensure that

$$|\alpha - a_i| < \delta, \quad |\beta - b_i| < \delta, \quad |\xi(\tau) - x_i(\tau)| < \delta \quad \text{for } \tau \in [\alpha - \delta, \beta + \delta].$$

This inequality can then be interpreted as stating that $(a_i, b_i, x_i(\cdot), y_i(\cdot) = \int_{a_i}^{(\cdot)} \Phi_i(t, u_i(t)) dt, u_i(\cdot))$ is a local minimizer for the following optimal control problem:

$$(5.3) \quad \text{Minimize } |\zeta_i - \psi(x(b))| + i^{-1}\{|a - a_i| + |b - b_i| + |x_i(a_i) - x(a)| + y(b)\}$$

over intervals $[a, b] \subset \mathbb{R}$ and arcs $(x(\cdot), y(\cdot)) \in AC([a, b]; \mathbb{R}^{n+1})$, which satisfy

$$(5.4) \quad \dot{x}(t) = \phi(t, x(t), u(t)),$$

$$(5.5) \quad \dot{y}(t) = \Phi_i(t, u(t)), \quad u(t) \in U_i \quad \text{a.e. } [a, b],$$

$$(5.6) \quad h(t, x(t)) \leq 0 \quad \text{for all } t \in [a, b],$$

$$(5.7) \quad (a, x(a), b, y(b)) \in C \times \{0\}.$$

Here $\Phi_i: \mathbb{R} \times \mathbb{R}^m \rightarrow \mathbb{R}$ is defined by

$$\Phi_i(t, u) = \begin{cases} 1, & \text{if } t \notin [a_i, b_i], \text{ or } u \neq u_i(t), \\ 0, & \text{otherwise.} \end{cases}$$

Next, we introduce the multifunction $F: \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R} \rightrightarrows \mathbb{R}^n \times \mathbb{R}$, defined by

$$F(t, x, y) = \{(\phi(t, x, u), \Phi_i(t, u)): u \in U_i\}.$$

Under the hypotheses imposed, the multifunction F obeys hypothesis (H3). (The supplementary hypothesis (HCF) is crucial at this point.) Since the right endpoint is unconstrained, it follows that $(a_i, b_i, x_i(\cdot), y_i(\cdot) = \int_{a_i}^{(\cdot)} \Phi_i(t, u_i(t)) dt, u_i(\cdot))$ remains a local minimizer when the dynamic constraints (5.4) and (5.5) are replaced by the constraint

$$(\dot{x}(t), \dot{y}(t)) \in \text{co } F(t, x(t), y(t)) \quad \text{a.e. } [a, b].$$

We have arrived at a differential inclusion problem of a kind to which the Pontryagin-type necessary conditions are applicable. It follows that, for i sufficiently large, there exists a function $(p_i(\cdot), q_i(\cdot)) \in AC([\alpha - \delta, \beta + \delta]; \mathbb{R}^{n+1})$ (with the family $\{p_i(\cdot)\}$ uniformly bounded and equicontinuous), numbers k_{1i} and k_{2i} , nonnegative numbers $\lambda_i \geq 0$, $\rho_i \geq 0$, and $\sigma_i \geq 0$, a nonnegative measure $\mu_i \in C^*([\alpha - \delta, \beta + \delta]; \mathbb{R})$, a μ_i -integrable function $\gamma_i: [\alpha - \delta, \beta + \delta] \rightarrow \mathbb{R}^n$, and a measurable set $A_i \subset [\alpha - \delta, \beta + \delta]$ such that $\lambda_i + \|(q_i(\cdot), p_i(\cdot))\|_\infty + \rho_i + \sigma_i + \mu_i([\alpha - \delta, \beta + \delta]) = 1$, and we have

$$\mathcal{L}\text{-meas } \{A_i\} \rightarrow \beta - \alpha \quad \text{as } i \rightarrow \infty,$$

for all $t \in A_i$,

$$(5.8) \quad \begin{aligned} -\dot{p}_i(t) &\in \partial_x \mathcal{H}\left(t, x_i(t), u_i(t), p_i(t) + \int_{[a_i, t]} \gamma_i(s) d\mu_i(s)\right), \\ -\dot{q}(t) &= 0, \end{aligned}$$

$$(5.9) \quad \begin{aligned} &\mathcal{H}\left(t, x_i(t), u_i(t), p_i(t) + \int_{[a_i, t]} \gamma_i(s) d\mu_i(s)\right) \\ &\geq \sup_{u \in U_i} \mathcal{H}\left(t, x_i(t), u, p_i(t) + \int_{[a_i, t]} \gamma_i(s) d\mu_i(s)\right) - i^{-1}, \end{aligned}$$

and

$$(5.10) \quad \left(-k_{1i}, p_i(a_i), k_{2i}, -p_i(b_i) - \int_{[a_i, b_i]} \gamma_i(t) d\mu_i(t) \right) \in \text{LN}_C(a_i, x_i(a_i), b_i) \times \partial\psi(x_i(b_i))\theta_i \\ + \rho_i L \partial h(a_i, x_i(a_i)) \\ \times \sigma_i L \partial h(b_i, x_i(b_i)) + i^{-1} B, \\ -q_i(b_i) \in i^{-1} B,$$

$$(5.11) \quad k_{1i} \in \text{co ess} \left\{ \max_{t \rightarrow a_i} \left\{ \max_{u \in U_i} \mathcal{H}(t, x_i, (a_i), u, p_i(a_i)) \right\} \right\} + i^{-1} B,$$

$$(5.12) \quad k_{2i} \in \text{co ess} \left\{ \max_{t \rightarrow b_i} \left\{ \max_{u \in U_i} \left(\mathcal{H}(t, x_i(b_i), u, p_i(b_i)) + \int_{[a_i, b_i]} \gamma_i(s) d\mu_i(s) \right) \right\} \right\} + i^{-1} B,$$

$$(5.13) \quad \gamma_i(t) \in \partial_x^+ h(t, x_i(t)) \quad \mu_i\text{-a.e.},$$

$$(5.14) \quad \text{Supp} \{ \mu_i \} \subset \{ t \in [\alpha - \delta, \beta + \delta] : \partial_x^+ h(t, x_i(t)) \neq \emptyset \},$$

where

$$\theta_i := \lambda_i \frac{\zeta_i - \psi(x_i(b_i))}{|\zeta_i - \psi(x_i(b_i))|},$$

so that

$$(5.15) \quad |\theta_i| + |p_i(\cdot)|_\infty + \rho_i + \sigma_i + \mu_i([\alpha - \delta, \beta + \delta]) \in [1 - i^{-1}, 1 + i^{-1}].$$

Conditions (5.8)–(5.15) will be recognized as perturbed versions of the relations whose validity is asserted in Theorem 5.2. The theorem is proved by subsequence extraction and passage to the limit. Finally, hypothesis (HCF) is removed by application of the technique on p. 207 of [2].

OPTIMIZATION OF QUEUES USING AN INFINITESIMAL PERTURBATION ANALYSIS-BASED STOCHASTIC ALGORITHM WITH GENERAL UPDATE TIMES*

EDWIN K. P. CHONG[†] AND PETER J. RAMADGE[‡]

Abstract. Convergence (with probability one) of a stochastic optimization algorithm for a single server queue is proved. The parameter to be optimized is updated using an infinitesimal perturbation analysis estimate of the gradient of the performance measure, and the updates are performed at general times. First, an algorithm in which the parameter is updated before each customer begins service is considered. Then it is shown how this analysis can be extended to an algorithm that updates at certain stopping times. The analysis suggests that the sample path behavior of the algorithm is similar to that of an algorithm that updates at the start of every busy period.

Key words. perturbation analysis, stochastic approximation, queueing

AMS(MOS) subject classifications. 93, 60

1. Introduction. We provide a proof of the convergence of a simple stochastic optimization algorithm based on infinitesimal perturbation analysis (IPA) applied to a single-server queue. Of particular note is that the algorithm can perform a parameter update before each customer starts service. Our convergence proof thus resolves an open problem that has been of interest for some time.

Our results are set in the following framework. Consider a GI/G/1 queue with a performance measure $J(\theta)$, where θ is a control parameter on which the service time distribution depends. Our objective is to find θ^* so that $J(\theta^*)$ is the global minimum value of J . We assume that J has just one local minimum, and this is at θ^* . To achieve our objective we observe a single sample path of the system and use an IPA-based estimate of $dJ/d\theta$ together with a stochastic approximation algorithm to recursively update the value of θ so that $J(\theta)$ is asymptotically minimized. Specifically, we set $\theta_{n+1} = \theta_n - a_n \hat{h}_{n+1}$, where $\{\theta_n\}$ is the sequence of control parameter values, $\{a_n\}$ is a gain sequence, and \hat{h}_{n+1} is an IPA-based estimate of $dJ/d\theta(\theta_n)$. In general, the index of the parameter sequence will be different from the index of the customers in the system, since the parameter updating can be performed less frequently than customers begin service. We assume that the parameter is updated each time a prespecified criterion is met (i.e., according to some stopping time). The key theoretical issue is to prove almost sure convergence of the parameter sequence θ_n to the optimizing value θ^* .

Several authors have examined algorithms within the above framework, e.g., [1]–[8]. In [5] Wardi presented a proof of convergence of an algorithm for the GI/G/1 queue. The task was to minimize $J(\theta) = f(W(\theta))$, where $W(\theta)$ is the mean waiting time, and f is a continuously differentiable function. The algorithm required increasingly larger numbers of customers between parameter updates, and used a nonstandard definition of convergence. In [7] Fu used an ordinary differential equation (ode) analysis to prove the almost sure convergence of an IPA-based algorithm

applied to a GI/G/1 queue with the performance measure $J(\theta) = T(\theta) + C(\theta)$, where $T(\theta)$ is the steady-state mean system time, and $C(\theta)$ is a deterministic cost function on θ . In Fu's algorithm the parameter is updated after every busy period of the queue. In [8] Chong and Ramadge used a martingale-based analysis to prove the almost sure convergence of an IPA-based algorithm applied to an M/G/1 queue with $J(\theta)$ as defined above. This algorithm also updates at the end of each busy period of the queue. These convergence proofs represent a significant step forward. However, the fact that the algorithms require a complete busy period before each update is felt to be unsatisfactory. If the load is high, the busy periods will be very long, and parameter updates will be very infrequent.

Suri and Leung [6] have examined an IPA-based algorithm for an M/M/1 queue in which the parameter updates are performed every time a fixed number of customers have been served. They considered the performance measure $J(\theta) = T(\theta) + c_1/\theta$, where $T(\theta)$ is the mean system time and c_1 is a constant. Their simulation study showed that the algorithm converged in the cases considered, with a relatively fast rate of convergence, corroborating the results in several previous studies (e.g., [2], [4]). Vázquez-Abad [9] has examined a similar scheme for adaptive routing in networks. This form of updating overcomes the restriction of waiting a complete busy period before updating the parameter. Although simulation studies indicate that such algorithms converge, a proof of almost sure convergence has been lacking.

Ideally, we would like to derive expressions for the convergence rates of algorithms involving durations between updates, and thereby be able to compare the convergence rate of an algorithm which updates before the service of each customer with that of one which updates before every busy period. However, this seems to be a difficult task. A necessary first step is to prove the convergence of these algorithms, and this is the focus of our paper. Our main result is a proof of the almost sure convergence of an IPA-based algorithm that updates the parameter at a general sequence of stopping times.¹ However, our approach gives insight not only into why the algorithms converge, but also (intuitively) how fast they should do so in practice. Specifically, our proof indicates a certain similarity of the sample paths of our algorithm with an algorithm that updates at the start of each busy period. This in turn suggests that the rates of convergence of these two algorithms may be very similar.

Our proof relies only on a simple convergence result for stochastic approximation algorithms (Lemma 3.9), rather than building on analogous results in a more sophisticated framework, such as algorithms for Markov chains with transition probabilities that depend on a parameter (see, for example, [11]). As a result our proof introduces some technical arguments that might otherwise have been avoided. We pay this penalty to provide the insight into the sample path behavior of our algorithm as discussed above. The basic method in the proof, however, is fairly simple and easily understood. To aid in the presentation, we focus first on an algorithm that updates the parameter before each customer begins service. Then we extend our analysis to an algorithm that performs parameter updates at certain specified stopping times. For simplicity, we restrict our attention to the performance measure $J(\theta) = T(\theta) + C(\theta)$, where $T(\theta)$ is the mean system time and $C(\theta)$ is a deterministic cost on θ . This choice of J is restrictive, but it simplifies the presentation. We indicate how the analysis can be extended to alternative performance measures in §5.

To prove our main result, it is necessary to impose certain assumptions on our

¹ We are grateful to a reviewer for pointing out that work similar in nature to the problem considered here has recently appeared in [10].

GI/G/1 queue. These are detailed in §3.1. Roughly speaking, the main assumptions are that the service time distribution has finite moments up to a sufficiently high order (at least 6), and that the interarrival time distribution has a bounded hazard rate. We view these assumptions as rather mild. They are satisfied, for example, by exponential, deterministic, and uniform service time distributions, and exponential, Erlang, and hyperexponential interarrival time distributions. Note, however, that our assumption on the interarrival time distribution precludes the uniform distribution.

Although the main contribution of the paper is a proof of convergence of a class of optimization algorithms for certain GI/G/1 queues, we believe our analysis is important in a larger context. To date, all theoretical analyses of IPA-based stochastic optimization of queueing systems have been limited to single-server systems. We believe that the tools and methods of analysis used in our work give additional insight into the behavior of these on-line optimization schemes, and we expect that these methods will be useful in the analysis of optimization algorithms for genuine multiparameter multiqueue systems.

The remainder of this paper is organized as follows. In §2 we describe the probability space over which our system is defined. We also discuss the optimization problem and formulate an IPA-based stochastic optimization algorithm that updates the parameter before the service of each customer. In §3 we prove the almost sure convergence of the algorithm. Extensions of our analysis to more general updating schemes are discussed in §4. In §5 we indicate how our results can be applied to more general performance measures. Section 6 concludes with a discussion of open problems and future work.

2. Problem formulation.

2.1. Model for a controlled GI/G/1 queue. Consider a GI/G/1 queue with service times that depend on a control parameter θ . We index the customers that arrive at the queue by $n = 1, 2, \dots$. For convenience, we assume that the first customer arrives to find the queue empty. We will use the symbol A_n for the duration of time from the arrival of the n th customer to that of the $(n+1)$ th customer, θ_n for the value of the control parameter for the n th customer, and $X_n(\theta_n)$ for the service time of the n th customer. The queue generates a sequence of alternating *busy periods* (BPs) and *idle periods*. We index the BPs by $k = 1, 2, \dots$, and the customers within each BP by $m = 1, 2, \dots$.

The probability space and corresponding sample path to model the queue can be set up in many ways. Here we will use a particular construction that is convenient for our purposes. We assume that the underlying probability space (Ω, \mathcal{F}, P) is equipped with the following random variables: for each $k \in \mathbb{N}$ (where $\mathbb{N} \triangleq \{1, 2, \dots\}$), sequences $\{A_m^k\}_{m=1}^\infty$ and $\{X_m^k\}_{m=1}^\infty$. The A_m^k are independent over m and k . Each X_m^k is a random positive function $X_m^k : \mathbb{R} \rightarrow \mathbb{R}_+$, and the X_m^k are independent over both m and k , and are also independent of the A_m^k . We write $X_m^k(\theta)$ for the value of the function X_m^k at the argument θ . For every m, k and θ , $X_m^k(\theta)$ is a positive random variable with distribution function $F(x, \theta)$.

We use the random variables defined on (Ω, \mathcal{F}, P) to model our controlled GI/G/1 queue as follows. For each BP k ,

- A_m^k gives the duration between the times of arrival of the m th and $(m+1)$ th customer; and
- $X_m^k(\theta)$ gives the service time of the m th customer in BP k , when the value of the control parameter is θ .

FIG. 1. The k th busy period of the queue.

It remains to specify the control parameter sequence $\{\theta_n\}$. However, once this is done the controlled GI/G/1 queue is completely determined. To see this, let \bar{N}_k denote the number of customers served in the k th BP, and let θ_m^k denote the value of the control parameter for the m th customer in the k th BP. The sequences $\{\bar{N}_k\}$ and $\{\theta_m^k\}$ can be determined recursively from the requirement that \bar{N}_k is the smallest positive integer satisfying

$$\sum_{i=1}^{\bar{N}_k} X_i^k(\theta_i^k) < \sum_{i=1}^{\bar{N}_k} A_i^k.$$

Then the sequence $\{A_n\}$ of interarrival times is given by

$$A_1^1, A_2^1, \dots, A_{\bar{N}_1}^1, A_1^2, A_2^2, \dots$$

and the sequence $\{X_n(\theta_n)\}$ of service times can be written as

$$X_1^1(\theta_1), X_2^1(\theta_2), \dots, X_{\bar{N}_1}^1(\theta_{\bar{N}_1}), X_1^2(\theta_{\bar{N}_1+1}), X_2^2(\theta_{\bar{N}_1+2}), \dots$$

Figure 1 shows a typical BP of the queue.

In contrast to a conventional GI/G/1 queue, the sequence $\{\bar{N}_k\}$ need not be independent nor identically distributed, since the θ values from one BP to the next may be dependent. Indeed, the value of the control parameter θ may differ from customer to customer, so that in contrast to a standard GI/G/1 queue the customer service times will not be identically distributed. In addition, the θ values for different customers will in general be dependent random variables, so the customer service times will also be dependent.

A situation of particular interest is when the control parameter is held constant at a value θ throughout the entire k th BP. In this case the BP is that of a conventional GI/G/1 queue, with the service times independent and identically distributed. Let $N_k(\theta)$ be the number of customers served in the k th BP, assuming that the control parameter is fixed at the value θ throughout this BP. Because of the way we have set up our model we can state that $N_k(\theta)$ is the smallest positive integer satisfying

$$\sum_{i=1}^{N_k(\theta)} X_i^k(\theta) < \sum_{i=1}^{N_k(\theta)} A_i^k.$$

2.2. Stochastic optimization. Our objective is to select the control parameter θ to minimize the performance measure $J(\theta) = T(\theta) + C(\theta)$ with $T(\theta)$ the steady-state mean system time, and $C(\theta)$ a cost function on θ . For example, θ may be the mean service time, and C a decreasing function of θ . To do so we use IPA derivative estimates for $dT(\theta)/d\theta$ together with a stochastic optimization algorithm to recursively update the value of θ .

Since θ will be updated recursively it is important to be precise about what information can be used to perform the updating. For this we introduce the following filtration. Let² $\mathcal{F}_1 = \sigma(\theta_1)$, and for $n > 1$, $\mathcal{F}_n = \sigma(\mathcal{F}_{n-1}, A_{n-1}, X_{n-1}(\theta_{n-1}))$. \mathcal{F}_n represents the information available just before the service of the n th customer. In particular, the service times of all prior customers are known, and the arrival times up to and including the n th customer are known, i.e., these random variables are \mathcal{F}_n -measurable. Note that if $\{f_n\}$ is the random sequence defined by

$$(1) \quad f_n = \begin{cases} 1, & \text{if the } n\text{th customer is the first in a BP,} \\ 0, & \text{otherwise,} \end{cases}$$

then f_n is \mathcal{F}_n -measurable. So, whether a particular customer is the first in a BP is information that can be incorporated into the mechanism for updating θ .

The control parameter sequence is generated by a stochastic optimization algorithm of the form $\theta_{n+1} = \theta_n - a_n \hat{h}_{n+1}$, where θ_n is the control parameter for the service time of customer n , a_n is a step-size, and \hat{h}_{n+1} is an \mathcal{F}_{n+1} -measurable estimate of $dJ/d\theta$. Note in particular that this algorithm updates the control parameter before the service of every customer (general update times are considered in §4).

In general, the control parameter θ_n is subject to some additional constraints. For example, if θ is the mean of the service time, then for stability of the queue, we must have that $0 \leq \theta < E(A_1^1)$. We assume that the parameter values $\{\theta_n\}$ are required to lie in a constraint set D and that D is a compact interval of the real line. To ensure the invariance of D , we modify the update equation to include a *projection*—if $\theta_n \in D$ but $\theta_n - a_n \hat{h}_{n+1} \notin D$, then we set $\theta_{n+1} = \theta_n$ (other forms of projections are also possible). We assume that θ_1 is a random variable taking values in D independent of A_m^k and X_m^k for all m and k (it may indeed be a fixed value). The algorithm is then of the form

$$(2) \quad \theta_{n+1} = \pi_{n+1}[\theta_n - a_n \hat{h}_{n+1}],$$

where $\pi_{n+1}[\cdot]$ is defined by

$$(3) \quad \pi_{n+1}[x] = \begin{cases} \theta_n, & \text{if } x \notin D, \\ x, & \text{otherwise.} \end{cases}$$

It remains to discuss the details of the derivative estimate \hat{h}_{n+1} . This will be done in the next section.

2.3. IPA estimate of $dJ/d\theta$. We begin with some assumptions on $X_m^k(\theta)$ and A_m^k .

Assumptions on $X_m^k(\theta)$ and A_m^k .

(P1) There exists a constant $\theta_{\max} \in D$ such that for all m, k and $\theta \in D$, $X_m^k(\theta) \leq X_m^k(\theta_{\max})$ almost surely;

² We use the notation $\sigma(Y)$ to denote the σ -algebra generated by Y , where Y may be random variable, a σ -algebra, or a combination of both.

(P2) $E(X_1^1(\theta_{\max})) < E(A_1^1)$;

(P3) $X_m^k(\theta)$ is almost surely differentiable with respect to θ on D , and for each $\theta \in D$, there exists a Borel measurable function ψ_θ such that $dX_m^k/d\theta(\theta) = \psi_\theta(X_m^k(\theta))$;

(P4) $E(\sup_{\theta \in D} dX_1^1(\theta)/d\theta)^2 < \infty$;

(P5) $E(X_1^1(\theta_{\max}))^2 < \infty$.

Assumption (P1) ensures that the number of customers served in BP k is bounded above by the random variable $N_k(\theta_{\max})$. For simplicity, we have assumed θ_{\max} to be a constant. This can be relaxed to allow θ_{\max} to be a random variable independent of θ_1 , X_m^k and A_m^k for all m and k . Assumption (P2) ensures that the system is stable for any fixed parameter value $\theta \in D$. Assumptions (P3) and (P4) are standard assumptions (see, for example, [4], [12]), to ensure that the IPA derivative estimates have certain desirable properties. They are generally easy to check. For example, if θ is a so-called scale parameter of $X_m^k(\theta)$, then $X_m^k(\theta) = \theta Y_m^k$ where Y_m^k is a random variable (that does not depend on θ). In this case X_m^k is differentiable, and (P3) holds since $dX_m^k(\theta)/d\theta = Y_m^k = X_m^k(\theta)/\theta$. Moreover, if $E(Y_m^k)^2 < \infty$, then assumption (P4) holds. Assumption (P5) ensures that the number of customers served in a BP has bounded second moments.

The above assumptions allow us to prove the following result.

LEMMA 2.1. *Suppose conditions (P1)–(P5) hold. Then the steady-state mean system time $T(\theta)$ is differentiable on D , and if $T'(\theta) \triangleq dT(\theta)/d\theta$, then for every $k \in \mathbb{N}$,*

$$T'(\theta) = \frac{E(\beta_k(\theta))}{E(N_k(\theta))},$$

where

$$(4) \quad \beta_k(\theta) = \sum_{i=1}^{N_k(\theta)} \sum_{j=1}^i \psi_\theta(X_j^k(\theta)).$$

Proof. This is a special case of a result in [12]. For completeness we provide a proof in Appendix A, based on the method of [12]. \square

Motivated by Lemma 2.1 we formulate an IPA estimate \hat{g}_{n+1} of $T'(\theta_n)$ as follows. Let $\phi_n(\theta_n) = dX_n(\theta_n)/d\theta$. Using (P3), this can be written as $\phi_n(\theta_n) = \psi_{\theta_n}(X_n(\theta_n))$. Define $\{\hat{g}_{n+1}\}$ by

$$(5) \quad \hat{g}_{n+1} = \begin{cases} \phi_n(\theta_n), & \text{if } f_n = 1, \\ \hat{g}_n + \phi_n(\theta_n), & \text{otherwise.} \end{cases}$$

Since $X_n(\theta_n)$ is \mathcal{F}_{n+1} -measurable, and f_n is \mathcal{F}_n -measurable, \hat{g}_{n+1} is \mathcal{F}_{n+1} -measurable.

Let S_k be the random variable defined by $S_1 \triangleq 0$, and for $k > 1$, $S_k \triangleq \sum_{i=1}^{k-1} \bar{N}_i$. S_k is the total number of customers served just prior to the k th BP. So, the m th customer in BP k is the $(S_k + m)$ th customer in the queue. Note that for each k , and each n such that $S_k + 1 \leq n \leq S_k + \bar{N}_k$,

$$(6) \quad \hat{g}_{n+1} = \sum_{i=S_k+1}^n \phi_i(\theta_i) = \sum_{i=S_k+1}^n \psi_{\theta_n}(X_n(\theta_n)),$$

which is similar to the inner sum of (4). Readers familiar with IPA will recognize this expression as the sample derivative of the system time for customer n .

A natural estimate of $dJ(\theta_n)/d\theta$ would be $\hat{g}_{n+1} + dC(\theta_n)/d\theta$. Our actual estimate \hat{h}_{n+1} of $dJ(\theta_n)/d\theta$ is defined recursively, together with a random sequence $\{p_n\}$, as follows: $p_1 = 0$, and for $n > 1$,

$$(7) \quad \hat{h}_{n+1} = \begin{cases} \hat{g}_{n+1} + \frac{dC}{d\theta}(\theta_n), & \text{if } p_n = 0 \text{ or } f_n = 1 \\ \hat{g}_{n+1} + \frac{dC}{d\theta}(\theta_n) + \hat{h}_n, & \text{otherwise} \end{cases}$$

$$(8) \quad p_{n+1} = \begin{cases} 1, & \text{if } \theta_n - a_n \hat{h}_{n+1} \notin D \\ 0, & \text{otherwise.} \end{cases}$$

The sequence $\{p_n\}$ simply indicates if a projection was used in the determination of θ_n . If no projection was involved in determining θ_n , i.e., $p_n = 0$, then we set $\hat{h}_{n+1} = \hat{g}_{n+1} + dC(\theta_n)/d\theta$, as expected. The same is true, regardless of the value of p_n , if the n th customer (the previous customer) was the first in a BP. However, in the case of all other projections, we adjust the value of \hat{h}_{n+1} so that it also incorporates the value of \hat{h}_n . Effectively, a sequence of projections results in an accumulation of the corresponding \hat{h}_n , subject to the above proviso that this accumulation process is “reset” after the first customer in a BP.

The reason for this seemingly complicated formulation of the estimate will become clear as the development proceeds. Suffice it to say at this point that as indicated above the “nominal” estimate is indeed $\hat{g}_{n+1} + dC(\theta_n)/d\theta$. The accumulation of the estimate over sequences of projections is technically advantageous in our proof and is used to extend the algorithm to deal with more general update times in §4. The resetting of the accumulations after the first customer in each BP is related to our basic method of analysis. Neither of these complications may be necessary in practice. For example, in the algorithm used by Suri and Leung [6], the projection method does not use the accumulation mechanism described above. This is essentially the only difference between our algorithm and the one in [6].

3. Convergence of the algorithm. To analyze the convergence of the algorithm described in the previous section it is necessary to introduce additional assumptions. We begin with a list and brief discussion of these assumptions.

3.1. Assumptions.

Assumptions on $\{a_n\}$.

(G1) $\{a_n\}$ is a sequence of positive random variables adapted to the filtration $\{\mathcal{F}_n\}$;

(G2) $\{a_n\}$ is nonincreasing, i.e., for all n , $a_{n+1} \leq a_n$ almost surely;

(G3) There exist a constant δ , $\frac{1}{2} < \delta \leq 1$, and constants $\bar{A} < \infty$, $\underline{A} > 0$ such that for each n , $\underline{A}n^{-\delta} \leq a_n \leq \bar{A}n^{-\delta}$ almost surely;

(G4) There exists a finite constant B_a such that for all n , $(1/a_{n+1}) - (1/a_n) \leq B_a$ almost surely.

The above assumptions are fairly standard and are generally easy to verify. Note that we require a_n to be \mathcal{F}_n -measurable.

We next place additional assumptions on the $X_m^k(\theta)$ and A_m^k . For this, let $0 < d < 1$ be such that

$$(9) \quad \sum_{n=1}^{\infty} a_n^{1+d} < \infty \quad \text{a.s.}$$

Such a d always exists; any d with $1/\delta - 1 < d < 1$ will do, e.g., $d = 1/(2\delta)$. Then let

$$p = \min\{n \in \mathbb{N} : n \geq 2(1+d)(3+d)/(1-d)\}.$$

Note that $p \geq 6$. In the following, it does not matter which m and k we are referring to, since for fixed θ , the $X_m^k(\theta)$ are identically distributed, and likewise the A_m^k .

Assumptions on $X_m^k(\theta)$.

(S1) $E(X_m^k(\theta_{\max}))^p < \infty$;

(S2) Let $\phi_m^k(\theta)$ denote the random variable $dX_m^k(\theta)/d\theta (= \psi_\theta(X_m^k(\theta)))$, and let $\bar{\phi}_m^k = \sup_{\theta \in D} \phi_m^k(\theta)$. Then, $E(\bar{\phi}_1^1)^p < \infty$;

(S3) For all m, k , there exists a measurable function $F_K : \mathbb{R}^D \rightarrow \mathbb{R}$ such that if $K_m^k = F_K(X_m^k)$, then for all $\theta_1, \theta_2 \in D$, $|\phi_m^k(\theta_2) - \phi_m^k(\theta_1)| \leq K_m^k |\theta_2 - \theta_1|$ and $E(K_1^1)^2 < \infty$;

(S4) The distribution of A_m^k has a bounded hazard rate $\mu(t)$, i.e., there exists a constant $\mu > 0$ such that $\mu(t) \leq \mu$ for all $t \geq 0$.

Assumption (S1), together with assumption (P2), is used to ensure that the p th moment of the number served in a BP for a fixed $\theta \in D$ is bounded (see Lemma 3.3, §3.3). Note that (S1) implies (P5). Assumption (S2) is used to ensure boundedness of the moments of the sample gradient ϕ_m^k , and it also ensures that moments of the random variables $\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k$ are bounded (see Lemma 3.4, §3.3). Note that assumption (S2) implies (P4). Assumption (S3) is a Lipschitz condition on the derivative $dX_m^k/d\theta (= \phi_m^k)$, and we assume that the Lipschitz constant K_m^k has finite second moment.

The *hazard rate* of the distribution $F_A(x)$ of A_m^k is a positive function $\mu(t)$ satisfying $F_A(x) = 1 - \exp(-\int_0^x \mu(t)dt)$. If $F_A(x)$ has a density, $f_A(x)$, then it has a hazard rate given by $\mu(t) = f_A(t)/(1 - F_A(t))$. Assumption (S4) is used to ensure that the idle periods are not too short, in the sense that if \bar{I} is the duration of the idle period, then $E(\bar{I}^{-q}) < \infty$ for all $q < 1$ (see Lemma 3.6). This assumption holds for many distributions of interest, including the exponential, Erlang and hyperexponential distributions.

Assumptions (S1) and (S2) are generally easy to check. For example, suppose, as before, that θ is a scale parameter of $X_m^k(\theta)$, i.e., $X_m^k = \theta Y_m^k$. Let $D = [\theta_a, \theta_b]$, and $\theta_{\max} = \theta_b$. If $E(Y_m^k)^p < \infty$, then assumptions (S1) and (S2) hold. In fact, in this case (S3) can also be seen to hold, since $\phi_m^k = Y_m^k$ is independent of θ . In general, however, (S3) may not be easy to check directly. The following proposition gives easily checked conditions which imply (S3).

PROPOSITION 3.1. *Suppose (S2) holds. Suppose that for all $x \geq 0$ and all $\theta_1, \theta_2 \in D$, $|\psi_{\theta_2}(x) - \psi_{\theta_1}(x)| \leq K_1(x)|\theta_2 - \theta_1|$ and for all $\theta \in D$ and all $x_1, x_2 \geq 0$, $|\psi_\theta(x_2) - \psi_\theta(x_1)| \leq K_2(\theta)|x_2 - x_1|$. Let $\bar{K}_m^k \triangleq \sup_{\theta \in D} K_1(X_m^k(\theta))$ and $\bar{L} \triangleq \sup_{\theta \in D} K_2(\theta)$. If $E(\bar{K}_m^k)^2 < \infty$ and $\bar{L} < \infty$, then condition (S3) holds.*

Proof. For the proof, see Appendix B. \square

Finally, we make certain assumptions on the cost function C , which appears in the performance measure J .

Assumptions on $C(\theta)$.

(C1) $C(\theta)$ is differentiable with respect to θ on D ;

(C2) Let $C'(\theta) \triangleq dC(\theta)/d\theta$. Then $C'(\cdot)$ is Lipschitz continuous on D , i.e., there exists a constant $C_M'' < \infty$ such that for all $\theta_1, \theta_2 \in D$, $|C'(\theta_2) - C'(\theta_1)| \leq C_M'' |\theta_2 - \theta_1|$;

(C3) $dJ(\theta_n)/d\theta = 0$ only if $\theta = \theta^*$ for some unique $\theta^* \in \overset{\circ}{D}$ (where $\overset{\circ}{D}$ denotes the interior of D), and θ^* minimizes J on D .

Assumptions (C1)–(C3) are natural assumptions to impose on $C(\theta)$. Assumptions (C1) and (C2) are used to ensure that J is sufficiently smooth, while (C3) ensures the uniqueness of the point θ^* that minimizes J . In fact, (C1) and (C2) together with Lemma 2.1 imply that the objective function J is continuously differentiable on D . Assumption (C3) is strong and can be weakened; however, we adopt it here for simplicity of presentation.

3.2. Main result. We are now ready to state our main result.

THEOREM 3.2. *Suppose that (P1)–(P3), (G1)–(G4), (S1)–(S4), and (C1)–(C3) are satisfied. Then, for the sequence $\{\theta_n\}$ defined by (2), (5), (7), and (8), we have that $\theta_n \rightarrow \theta^*$ as $n \rightarrow \infty$ with probability one.*

The proof of the theorem involves several steps and requires a variety of upper bounds. We present these bounds as a sequence of auxiliary lemmas, then proceed to the main steps in the proof.

3.3. Auxiliary lemmas. Throughout the remainder of the paper, we will use the notation $E_X(Y)$ to denote the conditional expectation of the random variable Y given X (where X may be a σ -algebra or a random variable).

We use assumptions (P2) and (S1) to show that the moments up to order p of N_k are bounded.

LEMMA 3.3. *Suppose that (P2) and (S1) hold. Then there exists a finite constant B_N such that for all $k \in \mathbb{N}$, and $r \leq p$, $E(N_k(\theta_{\max}))^r \leq B_N$.*

Proof. This is a special case of [13, Thm. 1(a)]. The result can also be proved using [14, Thm. 3.1(i); p. 78]. \square

Next we use assumption (S2) to show boundedness of the moments of the random variables $\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k$.

LEMMA 3.4. *Suppose (S2) holds. Then there exists a finite constant B_ϕ such that for all $k \in \mathbb{N}$, $\theta \in D$, and $r \leq p$,*

$$E \left(\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k \right)^r \leq B_\phi.$$

Proof. For the proof, see Appendix C. \square

Note that since C' is continuous (by (C2)), and D is compact, then C' is bounded on D . Let $C'_M \triangleq \sup_{\theta \in D} |C'(\theta)| < \infty$. Then by Lemma 3.4 there exists a finite constant B'_ϕ such that for all k , $\theta \in D$, and $r \leq p$,

$$(10) \quad E \left(\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k + C'_M \right)^r \leq B'_\phi.$$

We next use the assumption on the finiteness of the second moment of the Lipschitz constant K_m^k to show that the sum $\sum_{i=1}^{N_k(\theta)} K_i^k$ has a finite second moment.

LEMMA 3.5. *Suppose (S3) holds. Then there exists a finite constant B_K such that for all $k \in \mathbb{N}$ and $\theta \in D$,*

$$E \left(\sum_{i=1}^{N_k(\theta)} K_i^k \right)^2 \leq B_K.$$

Proof. For the proof, see Appendix D. \square

Finally we use assumption (S4) to show that the idle periods have the required property described in §3.1.

LEMMA 3.6. *Suppose (S4) holds. Let $\{\theta_n\}$ be a sequence of random variables adapted to $\{\mathcal{F}_n\}$, taking values in D . Let*

$$\bar{I} = \sum_{i=1}^{\bar{N}_1} A_i^1 - \sum_{i=1}^{\bar{N}_1} X_i^1(\theta_i^1).$$

Then for each $0 \leq q < 1$ there exists a constant B_I such that $E_{\theta_1}(\bar{I}^{-q}) \leq B_I$.

Proof. We may write $\bar{I} = A_{\bar{N}_1}^1 - L$, where $L = \sum_{i=1}^{\bar{N}_1} X_i^1(\theta_i^1) - \sum_{i=1}^{\bar{N}_1-1} A_i^1$. Note that $0 < L < A_{\bar{N}_1}^1$ almost surely. Now, the conditional distribution of \bar{I} given L is $F_{I|L}(x) = 1 - \exp(-\int_0^x \mu(t+L)dt)$, with a density $f_{I|L}(x) = \mu(x+L) \exp(-\int_0^x \mu(t+L)dt)$. By (S4), there exists a constant $\mu > 0$ such that for all $t \geq 0$, $\mu(t) \leq \mu$. Therefore, $f_{I|L}(x) \leq \mu$. Hence,

$$\begin{aligned} E_{\theta_1}(\bar{I})^{-q} &= E_{\theta_1} \left(\int_0^\infty x^{-q} f_{I|L}(x) dx \right) \\ &= E_{\theta_1} \left(\int_0^1 x^{-q} f_{I|L}(x) dx + \int_1^\infty x^{-q} f_{I|L}(x) dx \right) \\ &\leq E_{\theta_1} \left(\int_0^1 x^{-q} \mu dx + \int_1^\infty f_{I|L}(x) dx \right) \\ &\leq \frac{\mu}{1-q} + 1, \end{aligned}$$

which completes the proof. \square

3.4. A technical lemma. In the proof of Theorem 3.2, it will be convenient to relate the terms of the sequence $\{\theta_n\}$ for different customers within the same BP. To this end we define, for each BP k , the random sequence $\{\hat{a}_n^k : S_k + 1 \leq n < \infty\}$ *sample-pathwise* as follows: For $n \geq S_k(\omega) + \bar{N}_k(\omega)$, $\hat{a}_n^k(\omega) = a_{S_k + \bar{N}_k}(\omega)$, and for $S_k(\omega) + 1 \leq n < S_k(\omega) + \bar{N}_k(\omega)$,

$$(11) \quad \hat{a}_n^k(\omega) = \begin{cases} a_n(\omega), & \text{if } p_{n+1}(\omega) = 0, \\ \hat{a}_{n+1}^k(\omega), & \text{otherwise.} \end{cases}$$

Recall that S_k is the total number of customers served just prior to the k th BP. For $n \geq S_k(\omega) + \bar{N}_k(\omega)$, the value of $\hat{a}_n^k(\omega)$ is $\hat{a}_{S_k + \bar{N}_k}(\omega)$, i.e., the value of $a_n(\omega)$ used to update the first customer in the next BP. For $S_k(\omega) + 1 \leq n < S_k(\omega) + \bar{N}_k(\omega)$, the $\hat{a}_n^k(\omega)$ are defined recursively by moving backward through the BP. For $n = S_k(\omega) + \bar{N}_k(\omega) - 1$, the value of $\hat{a}_n^k(\omega)$ is $a_n(\omega)$ if $\theta_{n+1}(\omega)$ is computed without a projection, i.e., $p_{n+1}(\omega) = 0$; otherwise $\hat{a}_n^k(\omega)$ assumes the value of $\hat{a}_{n+1}^k(\omega)$. The value of $\hat{a}_n^k(\omega)$, for $n = S_k(\omega) + \bar{N}_k(\omega) - 2$, is then determined from the values of $a_n(\omega)$, $\hat{a}_{n+1}^k(\omega)$, and $p_{n+1}(\omega)$, and so on. Figure 2 gives an illustration of how the sample paths of $\{\hat{a}_n^k\}$ and $\{a_n\}$ are related. It is clear that \hat{a}_n^k is not \mathcal{F}_n -measurable. However, this will not be of importance in what follows.

By the construction of $\{\hat{a}_n^k\}$ it is easy to see that $\{\hat{a}_n^k\}$ is nonincreasing and that for every k and almost all $\omega \in \Omega$:

- (1) $\hat{a}_n^k(\omega) \geq a_{S_k + \bar{N}_k}(\omega)$;
- (2) For $S_k(\omega) + 1 \leq n \leq S_k(\omega) + \bar{N}_k(\omega)$, $\hat{a}_n^k(\omega) \leq a_n(\omega)$;

FIG. 2. Sample paths of $\{\hat{a}_n^k\}$ and $\{a_n\}$.

(3) If $n = S_k(\omega) + \bar{N}_k(\omega)$, then $\hat{a}_n^k(\omega) = a_n(\omega)$.

The sequence $\{\hat{a}_n^k\}$ allows us to relate terms of the sequence $\{\theta_n\}$ for different customers in a BP without explicitly having to deal with projections. Whenever a projection occurs, say in computing θ_{n+1} , the value of a_n used in that iteration is “lost.” However, the value of \hat{h}_{n+1} may be added to the estimate for the next customer, and if so is retained. This occurs whenever the previous customer was not the first in a BP—hence there is no accumulation from one BP to the next. So within each BP the algorithm behaves like one in which there are no projections, but with updates occurring only when a prespecified criterion is met, namely, no projection is required, and with a derivative estimate that is an accumulation of the derivative estimates for each of the customers encompassed in the current interupdate interval. Note that in this interpretation the criterion for updating is $\theta_n - a_n \hat{h}_{n+1} \in D$, which is an \mathcal{F}_{n+1} -measurable event, and the random sequence $\{1 - p_{n+1}\}$ indicates precisely the occurrence of these events. We will have more to say about this in §4.

We are now ready to state and prove our lemma.

LEMMA 3.7. For each k and every m, n such that $S_k + 1 \leq m \leq n \leq S_k + \bar{N}_k$,

$$(12) \quad \theta_n - \hat{a}_n^k \hat{h}_{n+1} = \theta_m - \hat{a}_m^k \hat{h}_{m+1} - \sum_{i=m+1}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i))$$

and

$$(13) \quad \theta_n - \theta_m = -\hat{a}_m^k \hat{h}_{m+1} - \sum_{i=m+1}^{l_n-1} \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)),$$

where $l_n = \max\{l \in \mathbb{N} : l \leq n, p_l = 0\}$.

Proof. To show (12), it suffices to show that for $S_k + 1 < n \leq S_k + \bar{N}_k$,

$$\theta_n - \hat{a}_n^k \hat{h}_{n+1} = \theta_{n-1} - \hat{a}_{n-1}^k \hat{h}_n - \hat{a}_n^k (\hat{g}_{n+1} + C'(\theta_n)).$$

To see this, suppose first that $p_n = 0$. Then, $a_{n-1} = \hat{a}_{n-1}^k$, $\hat{h}_{n+1} = \hat{g}_{n+1} + C'(\theta_n)$, and $\theta_n = \theta_{n-1} - a_{n-1} \hat{h}_n$. Therefore, combining these three equations, we get

$$\theta_n - \hat{a}_n^k \hat{h}_{n+1} = \theta_{n-1} - \hat{a}_{n-1}^k \hat{h}_n - \hat{a}_n^k (\hat{g}_{n+1} + C'(\theta_n)).$$

Suppose now that $p_n = 1$. Then, $\hat{a}_n^k = \hat{a}_{n-1}^k$, $\hat{h}_{n+1} = \hat{g}_{n+1} + C'(\theta_n) + \hat{h}_n$, and $\theta_n = \theta_{n-1}$. Again, combining these three equations, we get

$$\theta_n - \hat{a}_n^k \hat{h}_{n+1} = \theta_{n-1} - \hat{a}_{n-1}^k \hat{h}_n - \hat{a}_n^k (\hat{g}_{n+1} + C'(\theta_n)).$$

To show (13), we rewrite (12) as

$$\begin{aligned} \theta_n - \theta_m &= -\hat{a}_m^k \hat{h}_{m+1} - \sum_{i=m+1}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)) + \hat{a}_n^k \hat{h}_{n+1} \\ &= -\hat{a}_m^k \hat{h}_{m+1} - \sum_{i=m+1}^{l_n-1} \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)) + \hat{a}_n^k \hat{h}_{n+1} - \sum_{i=l_n}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)). \end{aligned}$$

Now, by definition of l_n , $p_{l_n+1} = \dots = p_n = 1$. Therefore, by (11), $\hat{a}_{l_n}^k = \dots = \hat{a}_n^k$, and by (7), $\hat{h}_{n+1} = \sum_{i=l_n}^n (\hat{g}_{i+1} + C'(\theta_i))$. Hence,

$$\hat{a}_n^k \hat{h}_{n+1} = \sum_{i=l_n}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i))$$

and thus (13) holds, which completes the proof. \square

The following special case of (12) will be used frequently. When $m = S_k + 1$, $\hat{h}_{S_k+2} = \hat{g}_{S_k+2} + C'(\theta_{S_k+1})$, and (12) becomes

$$\theta_n - \hat{a}_n^k \hat{h}_{n+1} = \theta_m - \sum_{i=m}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)).$$

3.5. Proof of main result. The proof is lengthy, but the basic approach is very simple. The key feature is to first analyze the subsequence of $\{\theta_n\}$ at the start of the BPs. We show that this subsequence behaves like one obtained from an algorithm that updates at the start of BPs, driven by derivative estimates that are asymptotically unbiased. Then, using a standard convergence result for stochastic approximations, convergence of this subsequence is established. Finally, the convergence of the whole sequence $\{\theta_n\}$ is proved by showing that the θ_n values within each BP are “close” to the values at the beginning of the BPs. The main steps of the proof can be summarized as:

(M1) Showing that the subsequence of $\{\theta_n\}$ consisting of the values of θ at the start of every BP (denoted by $\{\tilde{\theta}_k\}$) satisfies the recursion

$$\tilde{\theta}_{k+1} = \tilde{\pi}_{k+1} [\tilde{\theta}_k - \tilde{b}_k \tilde{h}_{k+1}],$$

where $\{\tilde{b}_k\}$ is not summable almost surely, but is square summable, $\tilde{h}_{k+1} = dJ(\tilde{\theta}_k)/d\theta + \tilde{\varepsilon}_{k+1}$, where $\{\tilde{\varepsilon}_{k+1}\}$ asymptotically vanishes (in a sense to be defined later), and $\{\tilde{\pi}_{k+1}\}$ is the subsequence of $\{\pi_{n+1}\}$ taken at the start of each BP;

(M2) Showing that $\tilde{\theta}_k \rightarrow \theta^*$ almost surely; and

(M3) Showing that the whole sequence $\{\theta_n\}$ converges to θ^* almost surely.

To begin, let $\mathbf{X}^k = \{X_m^k : m \in \mathbb{N}\}$ and $\mathbf{A}^k = \{A_m^k : m \in \mathbb{N}\}$, and define a filtration $\{\tilde{\mathcal{F}}_k\}$ as follows: $\tilde{\mathcal{F}}_1 = \sigma(\theta_1)$ and for $k > 1$, $\tilde{\mathcal{F}}_k = \sigma(\tilde{\mathcal{F}}_{k-1}, \mathbf{X}^{k-1}, \mathbf{A}^{k-1})$. Then let $\tilde{\theta}_k = \theta_{S_k+1}$, $\tilde{a}_k = a_{S_k+1}$, and $\tilde{\pi}_k[\cdot] = \pi_{S_k+1}[\cdot]$, i.e.,

$$\tilde{\pi}_{k+1}[x] = \begin{cases} x, & \text{if } x \in D, \\ \theta_{S_k+\bar{N}_k}, & \text{otherwise.} \end{cases}$$

The sequences $\{\tilde{\theta}_k\}$, $\{\tilde{\pi}_k\}$ and $\{\tilde{a}_k\}$ are subsequences of $\{\theta_n\}$, $\{\pi_n\}$, and $\{a_n\}$, respectively, taken at the start of every BP. Note that $\tilde{\theta}_k$ and \tilde{a}_k are $\tilde{\mathcal{F}}_k$ -measurable.

Step (M1) of the proof is the subject of the following lemma.

LEMMA 3.8. *Suppose the assumptions of Theorem 3.2 are satisfied. Then there exist sequences $\{\tilde{h}_k\}$ and $\{\tilde{b}_k\}$ of random variables adapted to $\{\tilde{\mathcal{F}}_k\}$ such that*

(a) $\{\tilde{\theta}_k\}$ satisfies the recursion

$$(14) \quad \tilde{\theta}_{k+1} = \tilde{\pi}_{k+1}[\tilde{\theta}_k - \tilde{b}_k \tilde{h}_{k+1}].$$

(b) For all $k \in \mathbb{N}$, $\tilde{a}_k \leq \tilde{b}_k \leq B_N \tilde{a}_k$.

Moreover, if we let $\tilde{\varepsilon}_{k+1} = \tilde{h}_{k+1} - dJ(\tilde{\theta}_k)/d\theta$, then

(c) $|E_{\tilde{\mathcal{F}}_k}(\tilde{\varepsilon}_{k+1})| \leq B \tilde{a}_k + B_d \tilde{a}_k^d$ for constants $B, B_d < \infty$, and

(d) $E_{\tilde{\mathcal{F}}_k}(\tilde{\varepsilon}_{k+1}^2) \leq \sigma^2$ for a constant $\sigma^2 < \infty$.

Proof. Without loss of generality, we may let $k = 1$ (this greatly simplifies the notation). Note that $S_1 = 0$, $\tilde{\theta}_1 = \theta_1$, $\tilde{a}_1 = a_1$, and $\tilde{\mathcal{F}}_1 = \mathcal{F}_1$. To further simplify the notation, let $N = N_1(\theta_1)$, $\bar{N} = \bar{N}_1$, $\bar{\phi}_n = \bar{\phi}_n^1$, and $K_n = K_n^1$.

Define the sequence $\{\theta_n^1\}$ by the following: For $1 \leq n \leq \bar{N}$, $\theta_n^1 = \theta_n$, and for $n > \bar{N}$, $\theta_n^1 = \theta_{\bar{N}}$. So, $\{\theta_n^1\}$ is simply an extension of $\{\theta_n : 1 \leq n \leq \bar{N}\}$, the parameter sequence within the first BP, obtained by repeating the last value $\theta_{\bar{N}}$ indefinitely.

We first prove (a) and (b). Now, by using the definitions of $\tilde{\theta}_2$ and $\tilde{\pi}_2$, and property (3) of $\{\hat{a}_n^1\}$, we have

$$\tilde{\theta}_2 = \theta_{\bar{N}+1} = \pi_{\bar{N}+1}[\theta_{\bar{N}} - a_{\bar{N}} \hat{h}_{\bar{N}+1}] = \tilde{\pi}_2[\theta_{\bar{N}} - \hat{a}_{\bar{N}}^1 \hat{h}_{\bar{N}+1}]$$

and then using Lemma 3.7 with $m = 1$ and $n = \bar{N}$, we obtain

$$\tilde{\theta}_2 = \tilde{\pi}_2 \left[\theta_1 - \sum_{i=1}^{\bar{N}} \hat{a}_i^1 (\hat{g}_{i+1} + C'(\theta_i)) \right].$$

Now, by (6),

$$\begin{aligned} & \sum_{i=1}^{\bar{N}} \hat{a}_i^1 (\hat{g}_{i+1} + C'(\theta_i)) \\ &= \sum_{i=1}^{\bar{N}} \hat{a}_i^1 \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right) \\ &= a_1 E_{\theta_1}(N) \sum_{i=1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right) \frac{1}{E_{\theta_1}(N)} \\ &= \tilde{a}_1 E_{\theta_1}(N) \left(\frac{1}{E_{\theta_1}(N)} \sum_{i=1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} \sum_{j=1}^i \phi_j^1(\theta_j^1) + \frac{1}{E_{\theta_1}(N)} \sum_{i=1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} C'(\theta_i^1) \right) \\ &= \tilde{a}_1 E_{\theta_1}(N) (\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3), \end{aligned}$$

where \tilde{c}_1 , \tilde{c}_2 , and \tilde{c}_3 are defined as follows:

$$\tilde{c}_1 = \frac{1}{E_{\theta_1}(N)} \sum_{i=1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} \sum_{j=1}^i \phi_j^1(\theta_j^1),$$

$$\tilde{c}_2 = \frac{1}{E_{\theta_1}(N)} \sum_{i=1}^N \frac{\hat{a}_i^1}{a_1} C'(\theta_i^1),$$

$$\tilde{c}_3 = \begin{cases} \frac{1}{E_{\theta_1}(N)} \sum_{i=\bar{N}+1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right), & \text{if } \bar{N} > N, \\ 0, & \text{if } \bar{N} = N, \\ -\frac{1}{E_{\theta_1}(N)} \sum_{i=\bar{N}+1}^N \frac{\hat{a}_i^1}{a_1} \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right), & \text{if } \bar{N} < N. \end{cases}$$

Let $\tilde{h}_2 = \tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3$, and $\tilde{b}_1 = E_{\theta_1}(N)\tilde{a}_1$. Then, we may write $\tilde{\theta}_2 = \tilde{\pi}_2[\tilde{\theta}_1 - \tilde{b}_1\tilde{h}_2]$. It is easy to check that \tilde{h}_2 is $\tilde{\mathcal{F}}_2$ -measurable. Since $E_{\theta_1}(N)$ and \tilde{a}_1 are $\tilde{\mathcal{F}}_1$ -measurable, then so is \tilde{b}_1 . This proves (a).

It is clear that $E_{\theta_1}(N) \geq 1$. Also, using Lemma 3.3, $E_{\theta_1}(N) \leq E_{\theta_1}(N_1(\theta_{\max})) = E(N_1(\theta_{\max})) \leq B_N$. Therefore, $\tilde{a}_1 \leq \tilde{b}_1 \leq B_N\tilde{a}_1$. This proves (b).

We now show (c). We can write $\tilde{\varepsilon}_2$ as

$$(15) \quad \begin{aligned} \tilde{\varepsilon}_2 &= \tilde{h}_2 - (T'(\theta_1) + C'(\theta_1)) \\ &= (\tilde{c}_1 - T'(\theta_1)) + (\tilde{c}_2 - C'(\theta_1)) + \tilde{c}_3 \end{aligned}$$

and hence

$$(16) \quad |E_{\mathcal{F}_1}(\tilde{\varepsilon}_2)| \leq |E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1))| + |E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1))| + |E_{\mathcal{F}_1}(\tilde{c}_3)|.$$

Since $\tilde{\mathcal{F}}_1 = \mathcal{F}_1$, to show that $|E_{\tilde{\mathcal{F}}_1}(\tilde{\varepsilon}_2)| \leq B\tilde{a}_1 + B_d\tilde{a}_1^d$, it suffices to show that $|E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1))| \leq B_1a_1$, $|E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1))| \leq B_2a_1$, and $|E_{\mathcal{F}_1}(\tilde{c}_3)| \leq B_3a_1^d$, where $B_1, B_2, B_3 < \infty$. This will proceed in several steps.

Step 1. Show that $|E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1))| \leq B_1a_1$.

Now, since θ_1 is \mathcal{F}_1 -measurable, then $E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1)) = E_{\mathcal{F}_1}(\tilde{c}_1) - T'(\theta_1)$. By Lemma 2.1 and the fact that θ_1 is independent of \mathbf{A}^1 and \mathbf{X}^1 we may write

$$\begin{aligned} T'(\theta_1) &= \frac{1}{E_{\theta_1}(N)} E_{\theta_1} \left(\sum_{i=1}^N \sum_{j=1}^i \phi_j^1(\theta_1) \right) \\ &= \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \sum_{j=1}^i \phi_j^1(\theta_1) \right), \end{aligned}$$

where the last line holds because the random variable inside the conditional expectation operator depends on \mathcal{F}_1 only through θ_1 . Thus, we may write

$$\begin{aligned} E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1)) &= \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \frac{\hat{a}_i^1}{a_1} \sum_{j=1}^i \phi_j^1(\theta_j^1) \right) - \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \sum_{j=1}^i \phi_j^1(\theta_1) \right) \\ &= \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left(\frac{\hat{a}_i^1}{a_1} - 1 \right) \sum_{j=1}^i \phi_j^1(\theta_j^1) + \sum_{i=1}^N \sum_{j=1}^i \phi_j^1(\theta_j^1) - \phi_j^1(\theta_1) \right), \end{aligned}$$

and, since $E_{\theta_1}(N) \geq 1$,

$$(17) \quad |E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1))| \leq E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| \sum_{j=1}^i |\phi_j^1(\theta_j^1)| + \sum_{i=1}^N \sum_{j=1}^i |\phi_j^1(\theta_j^1) - \phi_j^1(\theta_1)| \right).$$

Now, using the properties of the sequence $\{\hat{a}_i^1\}$, and assumptions (G2) and (G4),

$$\begin{aligned}
 \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| &= \hat{a}_i^1 \left(\frac{1}{\hat{a}_i^1} - \frac{1}{a_1} \right) \\
 &\leq a_1 \left(\frac{1}{a_{\bar{N}}} - \frac{1}{a_1} \right) \\
 (18) \quad &= a_1 \left(\frac{1}{a_{\bar{N}}} - \frac{1}{a_{\bar{N}-1}} + \frac{1}{a_{\bar{N}-1}} - \frac{1}{a_{\bar{N}-2}} + \cdots - \frac{1}{a_1} \right) \\
 &\leq a_1 \bar{N} B_a.
 \end{aligned}$$

Also, by assumption (S2),

$$(19) \quad \sum_{j=1}^i |\phi_j^1(\theta_j^1)| \leq \sum_{j=1}^i \bar{\phi}_j \leq \sum_{j=1}^N \bar{\phi}_j.$$

For each k , let $N_{\max}^k \triangleq N_k(\theta_{\max})$. By Lemma 3.3, $E(N_{\max}^k)^r \leq B_N$ for all $r \leq p$. It is clear by the construction of the BP that $\bar{N}_k \leq N_{\max}^k$. For brevity, write $N_{\max} = N_{\max}^1$.

Combining (18) and (19) yields

$$\begin{aligned}
 E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| \sum_{j=1}^i |\phi_j^1(\theta_j^1)| \right) &\leq E_{\mathcal{F}_1} \left(a_1 N \bar{N} B_a \sum_{j=1}^N \bar{\phi}_j \right) \\
 &\leq a_1 B_a E_{\mathcal{F}_1} \left(N_{\max}^2 \sum_{j=1}^{N_{\max}} \bar{\phi}_j \right).
 \end{aligned}$$

Using Schwarz's inequality, the fact that N_{\max} is independent of \mathcal{F}_1 , and Lemmas 3.3 and 3.4, we then obtain

$$\begin{aligned}
 E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| \sum_{j=1}^i |\phi_j^1(\theta_j^1)| \right) &\leq a_1 B_a \sqrt{E(N_{\max}^4)} \sqrt{E \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j \right)^2} \\
 (20) \quad &\leq a_1 B_a \sqrt{B_N} \sqrt{B_{\phi}}.
 \end{aligned}$$

Next, by assumption (S3),

$$(21) \quad \sum_{j=1}^i |\phi_j^1(\theta_j^1) - \phi_j^1(\theta_1)| \leq \sum_{j=1}^i K_j |\theta_j^1 - \theta_1|.$$

By Lemma 3.7,

$$\theta_j^1 - \theta_1 = - \sum_{i=1}^{k_j} \hat{a}_i^1 (\hat{g}_{i+1} + C'(\theta_i^1)),$$

where $k_j = \max\{k \in \mathbb{N} : k \leq j, p_k = 0\}$, and using (S2) and the fact that C' is bounded we obtain

$$|\theta_j^1 - \theta_1| \leq a_1 \sum_{i=1}^{\bar{N}} (|\hat{g}_{i+1}| + |C'(\theta_i^1)|)$$

$$\begin{aligned}
 (22) \quad & \leq a_1 \sum_{i=1}^{\bar{N}} \left(\sum_{k=1}^i |\phi_k^1(\theta_k^1)| + |C'(\theta_i^1)| \right) \\
 & \leq a_1 \bar{N} \left(\sum_{k=1}^{\bar{N}} \bar{\phi}_k + C'_M \right).
 \end{aligned}$$

Thus, from (21) and (22) we have

$$\begin{aligned}
 \sum_{i=1}^N \sum_{j=1}^i |\phi_j^1(\theta_j^1) - \phi_j^1(\theta_1)| & \leq \sum_{i=1}^N \sum_{j=1}^N a_1 K_j \bar{N} \left(\sum_{k=1}^{\bar{N}} \bar{\phi}_k + C'_M \right) \\
 & \leq a_1 N_{\max}^2 \left(\sum_{j=1}^N K_j \right) \left(\sum_{k=1}^{N_{\max}} \bar{\phi}_k + C'_M \right).
 \end{aligned}$$

Taking conditional expectations with respect to \mathcal{F}_1 , using Schwarz's inequality, (10), and Lemmas 3.3 and 3.5, yields

$$\begin{aligned}
 (23) \quad E_{\mathcal{F}_1} \left(\sum_{i=1}^N \sum_{j=1}^i |\phi_j^1(\theta_j^1) - \phi_j^1(\theta_1)| \right) & \leq a_1 E_{\mathcal{F}_1} \left(N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} K_j \right) \left(\sum_{k=1}^{N_{\max}} \bar{\phi}_k + C'_M \right) \right) \\
 & \leq a_1 \sqrt{B_K} \sqrt{\sqrt{B_N} \sqrt{B'_\phi}}.
 \end{aligned}$$

Finally, combining (20) and (23) with (17), we get

$$|E_{\mathcal{F}_1}(\tilde{c}_1 - T'(\theta_1))| \leq a_1 B_a \sqrt{B_N} \sqrt{B_\phi} + a_1 \sqrt{B_K} \sqrt{\sqrt{B_N} \sqrt{B'_\phi}} \leq B_1 a_1,$$

where $B_1 = B_a \sqrt{B_N} \sqrt{B_\phi} + \sqrt{B_K} \sqrt{\sqrt{B_N} \sqrt{B'_\phi}} < \infty$.

Step 2. Show that $|E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1))| \leq B_2 a_1$.

Now,

$$\begin{aligned}
 E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1)) & = \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \frac{\hat{a}_i^1}{a_1} C'(\theta_i^1) - \sum_{i=1}^N C'(\theta_1) \right) \\
 & = \frac{1}{E_{\theta_1}(N)} E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left(\frac{\hat{a}_i^1}{a_1} - 1 \right) C'(\theta_i^1) + \sum_{i=1}^N C'(\theta_i^1) - C'(\theta_1) \right),
 \end{aligned}$$

and therefore

$$(24) \quad |E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1))| \leq E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| |C'(\theta_i^1)| + \sum_{i=1}^N |C'(\theta_i^1) - C'(\theta_1)| \right).$$

By (18), the fact that C' is bounded, and Lemma 3.3, we have that

$$\begin{aligned}
 (25) \quad E_{\mathcal{F}_1} \left(\sum_{i=1}^N \left| \frac{\hat{a}_i^1}{a_1} - 1 \right| |C'(\theta_i^1)| \right) & \leq E_{\mathcal{F}_1} \left(\sum_{i=1}^N a_1 \bar{N} B_a C'_M \right) \\
 & \leq a_1 C'_M B_a E(N_{\max}^2) \\
 & \leq a_1 C'_M B_a B_N.
 \end{aligned}$$

Also, by assumption (C2), and (22),

$$\begin{aligned} \sum_{i=1}^N |C'(\theta_i^1) - C'(\theta_1)| &\leq \sum_{i=1}^N C''_M |\theta_i^1 - \theta_1| \\ &\leq \sum_{i=1}^N C''_M a_1 \bar{N} \left(\sum_{j=1}^{\bar{N}} \bar{\phi}_j + C'_M \right) \\ &\leq a_1 C''_M N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right). \end{aligned}$$

Taking conditional expectations with respect to \mathcal{F}_1 , using Schwarz's inequality, (10), and Lemma 3.3 yields

$$\begin{aligned} E_{\mathcal{F}_1} \left(\sum_{i=1}^N |C'(\theta_i^1) - C'(\theta_1)| \right) &\leq a_1 C''_M E_{\mathcal{F}_1} \left(N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right) \right) \\ (26) \qquad \qquad \qquad &\leq a_1 C''_M \sqrt{B_N} \sqrt{B'_\phi}. \end{aligned}$$

Finally, combining (26) and (26) with (24), we get

$$|E_{\mathcal{F}_1}(\tilde{c}_2 - C'(\theta_1))| \leq a_1 C'_M B_a B_N + a_1 C''_M \sqrt{B_N} \sqrt{B'_\phi} \leq B_2 a_1,$$

where $B_2 = C'_M B_a B_N + C''_M \sqrt{B_N} \sqrt{B'_\phi} < \infty$.

Step 3. Show that $|E_{\mathcal{F}_1}(\tilde{c}_3)| \leq B_3 a_1^d$.

Let 1_A denote the indicator function of the set A . Then, by definition of \tilde{c}_3 , we can write

$$\begin{aligned} \tilde{c}_3 &= 1_{\{\bar{N} > N\}} \frac{1}{E_{\theta_1}(N)} \sum_{i=N+1}^{\bar{N}} \frac{\hat{a}_i^1}{a_1} \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right) \\ &\quad - 1_{\{\bar{N} < N\}} \frac{1}{E_{\theta_1}(N)} \sum_{i=\bar{N}+1}^N \frac{\hat{a}_i^1}{a_1} \left(\sum_{j=1}^i \phi_j^1(\theta_j^1) + C'(\theta_i^1) \right), \end{aligned}$$

and thus

$$\begin{aligned} |\tilde{c}_3| &\leq (1_{\{\bar{N} > N\}} + 1_{\{\bar{N} < N\}}) \frac{1}{E_{\theta_1}(N)} \sum_{i=1}^{N_{\max}} \left(\sum_{j=1}^i \bar{\phi}_j + C'_M \right) \\ (27) \qquad \qquad \qquad &\leq 1_{\{\bar{N} \neq N\}} N_{\max} \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right). \end{aligned}$$

Let $p_1 = (1+d)/2d$ and $q_1 = (1+d)/(1-d)$. Note that p_1 and q_1 are conjugate exponents, i.e., $1/p_1 + 1/q_1 = 1$ and $p_1, q_1 > 1$. Then, by Hölder's inequality, and

Schwarz's inequality,

$$\begin{aligned} |E_{\mathcal{F}_1}(\tilde{c}_3)| &\leq E_{\mathcal{F}_1}(|\tilde{c}_3|) \\ &\leq (E_{\mathcal{F}_1}(1_{\{\bar{N} \neq N\}})^{p_1})^{1/p_1} \left(E_{\mathcal{F}_1} \left(N_{\max} \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right) \right)^{q_1} \right)^{1/q_1} \\ &\leq (E_{\mathcal{F}_1}(1_{\{\bar{N} \neq N\}}))^{1/p_1} \hat{B}_1, \end{aligned}$$

where the last line follows from (10) and Lemma 3.3 with $\hat{B}_1 = (\sqrt{B_N} \sqrt{B'_\phi})^{1/q_1} < \infty$.

Now, $E_{\mathcal{F}_1}(1_{\{\bar{N} \neq N\}}) = P_{\mathcal{F}_1}\{\bar{N} \neq N\} = P_{\mathcal{F}_1}\{\bar{N} > N\} + P_{\mathcal{F}_1}\{\bar{N} < N\}$. Therefore, to show that $|E_{\mathcal{F}_1}(\tilde{c}_3)| \leq B_3 a_1^d$, it suffices to show that $P_{\mathcal{F}_1}\{\bar{N} > N\} \leq \hat{B}_2 a_1^{(1+d)/2}$ and $P_{\mathcal{F}_1}\{\bar{N} < N\} \leq \hat{B}_3 a_1^{(1+d)/2}$ where $\hat{B}_2, \hat{B}_3 < \infty$.

Step 3(a). Show that $P_{\mathcal{F}_1}\{\bar{N} > N\} \leq \hat{B}_2 a_1^{(1+d)/2}$.

By definition, N is the smallest positive integer satisfying

$$\sum_{i=1}^N X_i^1(\theta_1) < \sum_{i=1}^N A_i^1.$$

The positive random variable $I_1 = \sum_{i=1}^N A_i^1 - \sum_{i=1}^N X_i^1(\theta_1)$ is the duration of the idle period following the first BP assuming the control parameter is given by θ_1 throughout the BP. Similarly, \bar{N} is the smallest positive integer satisfying

$$\sum_{i=1}^{\bar{N}} X_i^1(\theta_1^1) < \sum_{i=1}^{\bar{N}} A_i^1.$$

The positive random variable $\bar{I}_1 = \sum_{i=1}^{\bar{N}} A_i^1 - \sum_{i=1}^{\bar{N}} X_i^1(\theta_1^1)$ is the duration of the *actual* idle period following the first actual BP. We have that

$$\begin{aligned} \bar{N} > N &\Rightarrow \sum_{i=1}^N X_i^1(\theta_1^1) \geq \sum_{i=1}^N A_i^1 \\ &\Rightarrow \sum_{i=1}^N (X_i^1(\theta_1^1) - X_i^1(\theta_1)) \geq \sum_{i=1}^N (A_i^1 - X_i^1(\theta_1)) = I_1 \\ &\Rightarrow \sum_{i=1}^N |X_i^1(\theta_1^1) - X_i^1(\theta_1)| \geq I_1. \end{aligned}$$

Thus,

$$P_{\mathcal{F}_1}\{\bar{N} > N\} \leq P_{\mathcal{F}_1} \left\{ \sum_{i=1}^N |X_i^1(\theta_1^1) - X_i^1(\theta_1)| \geq I_1 \right\}.$$

Let E_I be the event $\left\{ \sum_{i=1}^N |X_i^1(\theta_1^1) - X_i^1(\theta_1)| \geq I_1 \right\}$. It is clear that

$$1_{E_I} \leq \frac{1}{I_1^{(1+d)/2}} \left(\sum_{i=1}^N |X_i^1(\theta_1^1) - X_i^1(\theta_1)| \right)^{(1+d)/2}.$$

Therefore,

$$P_{\mathcal{F}_1}\{\bar{N} > N\} \leq E_{\mathcal{F}_1} \left(\frac{1}{I_1^{(1+d)/2}} \left(\sum_{i=1}^N |X_i^1(\theta_i^1) - X_i^1(\theta_1)| \right)^{(1+d)/2} \right).$$

Let $p_2 = (3+d)/(2(1+d))$ and $q_2 = (3+d)/(1-d)$. Then p_2 and q_2 are conjugate exponents, and by Hölder's inequality,

$$P_{\mathcal{F}_1}\{\bar{N} > N\} \leq \left(E_{\mathcal{F}_1} \left(\frac{1}{I_1^{(1+d)/2}} \right)^{p_2} \right)^{1/p_2} \left(E_{\mathcal{F}_1} \left(\sum_{i=1}^N |X_i^1(\theta_i^1) - X_i^1(\theta_1)| \right)^{q_2(1+d)/2} \right)^{1/q_2}.$$

Let $p_3 = p_2(1+d)/2 = (3+d)/4 < 1$, and $q_3 = q_2(1+d)/2 = (1+d)(3+d)/(2(1-d))$. Then, we have that

$$(28) \quad P_{\mathcal{F}_1}\{\bar{N} > N\} \leq \left(E_{\mathcal{F}_1} \left(\frac{1}{I_1^{p_3}} \right) \right)^{1/p_2} \left(E_{\mathcal{F}_1} \left(\sum_{i=1}^N |X_i^1(\theta_i^1) - X_i^1(\theta_1)| \right)^{q_3} \right)^{1/q_2}.$$

Now, by the Mean Value Theorem, assumption (S2), and (22),

$$\begin{aligned} \sum_{i=1}^N |X_i^1(\theta_i^1) - X_i^1(\theta_1)| &\leq \sum_{i=1}^N \bar{\phi}_i |\theta_i^1 - \theta_1| \\ &\leq \sum_{i=1}^N \bar{\phi}_i a_1 \bar{N} \left(\sum_{j=1}^{\bar{N}} \bar{\phi}_j + C'_M \right) \\ &\leq a_1 N_{\max} \left(\sum_{i=1}^N \bar{\phi}_i \right) \left(\sum_{j=1}^{\bar{N}} \bar{\phi}_j + C'_M \right), \end{aligned}$$

and thus using Schwarz's inequality and our known bounds,

$$\begin{aligned} (29) \quad &E_{\mathcal{F}_1} \left(\sum_{i=1}^N |X_i^1(\theta_i^1) - X_i^1(\theta_1)| \right)^{q_3} \\ &\leq E_{\mathcal{F}_1} \left(a_1 N_{\max} \left(\sum_{i=1}^N \bar{\phi}_i \right) \left(\sum_{j=1}^{\bar{N}} \bar{\phi}_j + C'_M \right) \right)^{q_3} \\ &\leq a_1^{q_3} \sqrt{\sqrt{B_N} \sqrt{B_\phi} \sqrt{B'_\phi}}. \end{aligned}$$

Combining (29) with (28), we get

$$P_{\mathcal{F}_1}\{\bar{N} > N\} \leq \left(E_{\theta_1} \left(\frac{1}{I_1^{p_3}} \right) \right)^{1/p_2} \left(a_1^{q_3} \sqrt{\sqrt{B_N} \sqrt{B_\phi} \sqrt{B'_\phi}} \right)^{1/q_2}.$$

Since $p_3 < 1$, then by Lemma 3.6, we have

$$P_{\mathcal{F}_1}\{\bar{N} > N\} \leq a_1^{(1+d)/2} \hat{B}_2,$$

where $\hat{B}_2 = (B_I)^{1/p_2} \left(\sqrt{\sqrt{B_N} \sqrt{B_\phi} \sqrt{B'_\phi}} \right)^{1/q_2} < \infty$.

Step 3(b). Show that $P_{\mathcal{F}_1}\{\bar{N} < N\} \leq \hat{B}_3 a_1^{(1+d)/2}$.

As before, we may write

$$\begin{aligned} \bar{N} < N &\Rightarrow \sum_{i=1}^{\bar{N}} X_i^1(\theta_1) \geq \sum_{i=1}^{\bar{N}} A_i^1 \\ &\Rightarrow \sum_{i=1}^{\bar{N}} X_i^1(\theta_1) - X_i^1(\theta_i^1) \geq \sum_{i=1}^{\bar{N}} A_i^1 - X_i^1(\theta_i^1) = \bar{I}_1 \\ &\Rightarrow \sum_{i=1}^{\bar{N}} |X_i^1(\theta_1) - X_i^1(\theta_i^1)| \geq \bar{I}_1. \end{aligned}$$

Thus,

$$P_{\mathcal{F}_1}\{\bar{N} < N\} \leq P_{\mathcal{F}_1}\left\{\sum_{i=1}^{\bar{N}} |X_i^1(\theta_1) - X_i^1(\theta_i^1)| \geq \bar{I}_1\right\}.$$

Proceeding in a similar fashion as in Step 3(a) (replacing all occurrences of N with \bar{N} , and I_1 with \bar{I}_1), we get that $P_{\mathcal{F}_1}\{\bar{N} < N\} \leq \hat{B}_3 a_1^{(1+d)/2}$ where $\hat{B}_3 < \infty$, which proves the result of Step 3(b).

Using Steps 3(a) and 3(b), we may write

$$\begin{aligned} |E_{\mathcal{F}_1}(\tilde{c}_3)| &\leq \left(a_1^{(1+d)/2}(\hat{B}_2 + \hat{B}_3)\right)^{\frac{1}{p_1}} \hat{B}_1 \\ (30) \quad &= a_1^{(1+d)/(2p_1)}(\hat{B}_2 + \hat{B}_3)^{\frac{1}{p_1}} \hat{B}_1 \\ &= a_1^d B_3, \end{aligned}$$

where $B_3 = (\hat{B}_2 + \hat{B}_3)^{1/p_1} \hat{B}_1 < \infty$. This completes Step 3.

Step 4. Show that $|E_{\tilde{\mathcal{F}}_n}(\tilde{\varepsilon}_{n+1})| \leq B\tilde{a}_n + B_d \tilde{a}_n^d$.

Using (16) and Steps 1–3, we have that

$$|E_{\tilde{\mathcal{F}}_n}(\tilde{\varepsilon}_2)| \leq B_1 a_1 + B_2 a_1 + B_3 a_1^d = B\tilde{a}_1 + B_d \tilde{a}_1^d,$$

where $B = (B_1 + B_2) < \infty$ and $B_d = B_3 < \infty$. Thus we have shown (c).

We now show (d). From (15),

$$\begin{aligned} \tilde{\varepsilon}_2^2 &= (\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3 - T'(\theta_1) - C'(\theta_1))^2 \\ (31) \quad &\leq (|\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3| + T'_M + C'_M)^2 \\ &\leq 2(\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3)^2 + 2(T'_M + C'_M)^2, \end{aligned}$$

where $T'_M \triangleq \sup_{\theta \in D} |T'(\theta)|$. By Lemma 2.1, T' is continuous, and since D is compact, $T'_M < \infty$. Taking conditional expectations with respect to \mathcal{F}_1 ,

$$(32) \quad E_{\mathcal{F}_1}(\tilde{\varepsilon}_2^2) \leq 2E_{\mathcal{F}_1}(\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3)^2 + 2(T'_M + C'_M)^2.$$

Now,

$$\begin{aligned} (33) \quad E_{\mathcal{F}_1}(\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3)^2 &\leq 4E_{\mathcal{F}_1}(\tilde{c}_1^2 + \tilde{c}_2^2 + \tilde{c}_3^2) \\ &= 4E_{\mathcal{F}_1}(\tilde{c}_1^2) + 4E_{\mathcal{F}_1}(\tilde{c}_2^2) + 4E_{\mathcal{F}_1}(\tilde{c}_3^2). \end{aligned}$$

Therefore, it will suffice to show that $E_{\mathcal{F}_1}(\tilde{c}_1^2) \leq \sigma_1^2$, $E_{\mathcal{F}_1}(\tilde{c}_2^2) \leq \sigma_2^2$, and $E_{\mathcal{F}_1}(\tilde{c}_3^2) \leq \sigma_3^2$, where $\sigma_1^2, \sigma_2^2, \sigma_3^2 < \infty$.

First,

$$\tilde{c}_1^2 = \frac{1}{(E_{\theta_1}(N))^2} \left(\sum_{i=1}^N \frac{\hat{a}_i^1}{a_1} \sum_{j=1}^i \phi_j^1(\theta_j^1) \right)^2 \leq \left(N_{\max} \sum_{j=1}^{N_{\max}} \bar{\phi}_j \right)^2.$$

Therefore, using Schwarz's inequality and Lemmas 3.3 and 3.4,

$$(34) \quad E_{\mathcal{F}_1}(\tilde{c}_1^2) \leq E_{\mathcal{F}_1} \left(N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j \right)^2 \right) \leq \sigma_1^2,$$

where $\sigma_1^2 = \sqrt{B_N} \sqrt{B_\phi} < \infty$.

Next,

$$\tilde{c}_2^2 = \frac{1}{(E_{\theta_1}(N))^2} \left(\sum_{i=1}^N C'(\theta_i^1) \right)^2 \leq N^2 (C'_M)^2.$$

Hence by Lemma 3.3, $E_{\mathcal{F}_1}(\tilde{c}_2^2) \leq E_{\theta_1}(N^2 (C'_M)^2) \leq \sigma_2^2$, where $\sigma_2^2 = (C'_M)^2 B_N < \infty$.

Finally, by (27), we have

$$\tilde{c}_3^2 \leq N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right)^2,$$

and hence using Schwarz's inequality, (10), and Lemma 3.3,

$$(35) \quad E_{\mathcal{F}_1}(\tilde{c}_3^2) \leq E_{\mathcal{F}_1} \left(N_{\max}^2 \left(\sum_{j=1}^{N_{\max}} \bar{\phi}_j + C'_M \right)^2 \right) \leq \sigma_3^2,$$

where $\sigma_3^2 = \sqrt{B_N} \sqrt{B'_\phi} < \infty$.

Let $\hat{\sigma}^2 = 4\sigma_1^2 + 4\sigma_2^2 + 4\sigma_3^2 < \infty$. Then, from (33), $E_{\mathcal{F}_1}(\tilde{c}_1 + \tilde{c}_2 + \tilde{c}_3)^2 \leq \hat{\sigma}^2$. Combining the above with (32), we get $E_{\mathcal{F}_1}(\tilde{\varepsilon}_2^2) \leq \sigma^2$, where $\sigma^2 = 2\hat{\sigma}^2 + 2(T'_M + C'_M)^2 < \infty$. Note that σ^2 is independent of θ_1 , and of the fact that $k = 1$. \square

Having proven step (M1), step (M2) can be shown with the aid of the following lemma.

LEMMA 3.9. *Suppose conditions (P1)–(P5), (S3) and (C1)–(C3) hold. Let $\{\tilde{\theta}_k\}$ satisfy (14). Suppose $\{\tilde{b}_k\}$ satisfies:*

(A1) $\sum_{k=1}^{\infty} \tilde{b}_k = \infty$ almost surely;

(A2) $\sum_{k=1}^{\infty} \tilde{b}_k^2 < \infty$ almost surely;

and $\{\tilde{\varepsilon}_k\}$ satisfies:

(E1) $\sum_{k=1}^{\infty} \tilde{b}_k |E_{\tilde{\mathcal{F}}_k}(\tilde{\varepsilon}_{k+1})| < \infty$ almost surely;

(E2) For all k , $E_{\tilde{\mathcal{F}}_k}(\tilde{\varepsilon}_{k+1}^2) \leq \sigma^2$, where σ^2 is a finite constant.

Then, $\tilde{\theta}_k \rightarrow \theta^*$ as $k \rightarrow \infty$ with probability one.

Proof. The proof is a variation of a standard result on the convergence of stochastic approximation algorithms. A detailed proof based on martingale convergence arguments is available in [8]. \square

Step (M2) is the result of the following lemma.

LEMMA 3.10. *Suppose the assumptions of Theorem 3.2 hold. Then, $\tilde{\theta}_k \rightarrow \theta^*$ as $k \rightarrow \infty$ with probability one.*

Proof. We prove this result by appealing to Lemma 3.9. To do so, we need only verify that $\{\tilde{b}_k\}$ satisfies conditions (A1) and (A2), and that $\{\tilde{\varepsilon}_k\}$ satisfies (E1) and (E2), since all the other assumptions of Lemma 3.9 already hold.

We first claim that for each k , $\tilde{a}_k \geq A_l a_k$ where A_l is a random variable such that $A_l > 0$ almost surely. To see this, we write

$$\frac{\tilde{a}_k}{a_k} = \frac{a_{S_{k+1}}}{a_k} \geq \frac{a_{S_{n+1}}}{a_k}.$$

Then by assumption (G3),

$$(36) \quad \frac{\tilde{a}_k}{a_k} \geq \frac{A}{\bar{A}} \left(\frac{S_{n+1}}{k} \right)^{-\delta}.$$

Now,

$$\frac{S_{n+1}}{k} = \frac{1}{k} \sum_{i=1}^k \tilde{N}_i \leq \frac{1}{k} \sum_{i=1}^k N_{\max}^i.$$

Since $\{N_{\max}^i\}$ is independent, identically distributed, and integrable, then by the Strong Law of Large Numbers, $1/k \sum_{i=1}^k N_{\max}^i$ is bounded by an almost surely finite random variable. Therefore, the sequence $\{S_{n+1}/k\}$ is bounded by an almost surely finite random variable, say B_s , and from (36) we can write

$$\frac{\tilde{a}_k}{a_k} \geq \frac{A}{\bar{A}} (B_s)^{-\delta}.$$

Letting $A_l = A/(\bar{A}B_s^\delta)$, we have that $\tilde{a}_k \geq A_l a_k$, with $A_l > 0$ almost surely.

Using (b) of Lemma 3.8 and the above result we find

$$\sum_{k=1}^{\infty} \tilde{b}_k \geq \sum_{k=1}^{\infty} A_l a_k \geq A_l A \sum_{k=1}^{\infty} k^{-\delta} = \infty \quad \text{a.s.}$$

This verifies condition (A1).

Similarly, using (b) of Lemma 3.8 and the fact that $\tilde{a}_k \leq a_k$ we have

$$\sum_{k=1}^{\infty} \tilde{b}_k^2 \leq \sum_{k=1}^{\infty} B_N^2 \tilde{a}_k^2 \leq B_N^2 \sum_{k=1}^{\infty} a_k^2 \leq B_N^2 \bar{A}^2 \sum_{k=1}^{\infty} k^{-2\delta} < \infty.$$

This verifies condition (A2).

To show that (E1) is satisfied, we use (b) and (c) of Lemma 3.8, the fact that $\tilde{a}_k \leq a_k$, and (G3) to write

$$(37) \quad \begin{aligned} \sum_{k=1}^{\infty} \tilde{b}_k |E_{\tilde{\mathcal{F}}_k}(\tilde{\varepsilon}_{k+1})| &\leq B_N \sum_{k=1}^{\infty} \tilde{a}_k (B \tilde{a}_k + B_d \tilde{a}_k^d) \\ &\leq B_N \left(B \sum_{k=1}^{\infty} a_k^2 + B_d \sum_{k=1}^{\infty} a_k^{1+d} \right) \\ &\leq B_N B \bar{A}^2 \sum_{k=1}^{\infty} k^{-2\delta} + B_N B_d \sum_{k=1}^{\infty} a_k^{1+d}. \end{aligned}$$

The first term is finite since $\frac{1}{2} < \delta \leq 1$, and the second term is finite by (9). Thus, (37) is almost surely finite. This verifies condition (E1).

That condition (E2) is satisfied is a direct consequence of part (d) of Lemma 3.8.

All the conditions of Lemma 3.9 now hold, and the result follows. \square

We are now ready for step (M3), which provides the proof of Theorem 3.2.

Proof of Theorem 3.2. Fix $\epsilon > 0$. We wish to show that there exists an almost surely finite random variable M such that for all $n \geq M(\omega)$, $|\theta_n(\omega) - \theta^*| < \epsilon$.

For each $n \in \mathbb{N}$, let k_n be the index of the BP containing the n th customer. Let $F_n = S_{k_n} + 1$ and $G_n = S_{k_n+1} + 1$. So, F_n is the index of the first customer in the BP containing the n th customer, and G_n is the index of the first customer in the BP just after the one containing the n th customer. Clearly $G_n - F_n = \bar{N}_{k_n}$.

By Lemma 3.10, there exists an almost surely finite random variable M_1 such that if $k \geq M_1(\omega)$, then $|\theta_{S_k+1}(\omega) - \theta^*| < \epsilon/2$. Let $M_2 = S_{M_1} + 1$. Clearly, $M_2 < \infty$ almost surely. Then, for all $n \geq M_2(\omega)$, $k_n(\omega) \geq M_1(\omega)$ and so $|\theta_{F_n}(\omega) - \theta^*| < \epsilon/2$.

Now, by (13) in Lemma 3.7,

$$\begin{aligned} |\theta_n - \theta_{F_n}| &\leq \left| \sum_{i=F_n}^n \hat{a}_i^k (\hat{g}_{i+1} + C'(\theta_i)) \right| \\ &\leq \hat{a}_n^k \sum_{i=F_n}^{G_n-1} \frac{\hat{a}_i^k}{\hat{a}_n^k} (|\hat{g}_{i+1}| + |C'(\theta_i)|). \end{aligned}$$

For simplicity of notation, let $\bar{\phi}_j = \bar{\phi}_j^{k_n}$, $j \in \mathbb{N}$. Then, by properties (1) and (2) of $\{\hat{a}_n^k\}$, and equation (6),

$$\begin{aligned} |\theta_n - \theta_{F_n}| &\leq a_n \sum_{i=F_n}^{G_n-1} \frac{a_{F_n}}{a_{G_n-1}} \left(\sum_{j=1}^{i-F_n+1} \bar{\phi}_j + C'_M \right) \\ &\leq \bar{A} n^{-\delta} \sum_{i=F_n}^{G_n-1} \frac{\bar{A}}{\underline{A}} \left(\frac{F_n}{G_n-1} \right)^{-\delta} \sum_{j=1}^{\bar{N}_k} \bar{\phi}_j + C'_M \\ &= n^{-\delta} \frac{\bar{A}^2}{\underline{A}} \bar{N}_k \left(\sum_{j=1}^{\bar{N}_k} \bar{\phi}_j + C'_M \right) \left(\frac{G_n-1}{F_n} \right)^\delta. \end{aligned}$$

Now,

$$\frac{G_n-1}{F_n} = \frac{F_n + \bar{N}_k - 1}{F_n} \leq 1 + \frac{\bar{N}_k}{F_n} \leq 1 + \bar{N}_k \leq 2\bar{N}_k.$$

Thus,

$$\begin{aligned} |\theta_n - \theta_{F_n}| &\leq n^{-\delta} \frac{\bar{A}^2}{\underline{A}} \bar{N}_k \left(\sum_{j=1}^{\bar{N}_k} \bar{\phi}_j + C'_M \right) (2\bar{N}_k)^\delta \\ &\leq n^{-\delta} \frac{\bar{A}^2}{\underline{A}} \left(\sum_{j=1}^{N_{\max}^k} \bar{\phi}_j + C'_M \right) N_{\max}^k (2N_{\max}^k)^\delta. \end{aligned}$$

So, squaring and using Hölder's inequality and our known bounds, we obtain

$$\begin{aligned}
 E(\theta_n - \theta_{F_n})^2 &\leq n^{-2\delta} \frac{\bar{A}^4}{\underline{A}^2} E \left(\left(\sum_{j=1}^{N_{\max}^k} \bar{\phi}_j + C'_M \right)^2 (N_{\max}^k)^2 (2N_{\max}^k)^{2\delta} \right) \\
 (38) \quad &\leq n^{-2\delta} \frac{\bar{A}^4}{\underline{A}^2} \left(E \left(\sum_{j=1}^{N_{\max}^k} \bar{\phi}_j + C'_M \right)^6 \right)^{1/3} \left(E \left((N_{\max}^k)^3 (2N_{\max}^k)^{3\delta} \right) \right)^{2/3} \\
 &\leq n^{-2\delta} \frac{\bar{A}^4}{\underline{A}^2} (B'_\phi)^{1/3} (8B_N)^{2/3}.
 \end{aligned}$$

Now, by Markov's inequality,

$$(39) \quad P\{|\theta_n - \theta_{F_n}| \geq \epsilon/2\} \leq \frac{E(\theta_n - \theta_{F_n})^2}{(\epsilon/2)^2}.$$

Combining (38) with (39), we obtain

$$P\{|\theta_n - \theta_{F_n}| \geq \epsilon/2\} \leq n^{-2\delta} \hat{B}_\epsilon,$$

where

$$\hat{B}_\epsilon = \frac{\bar{A}^4}{\underline{A}^2} (B'_\phi)^{1/3} (8B_N)^{2/3} \frac{1}{(\epsilon/2)^2} < \infty.$$

Thus,

$$\sum_{n=1}^{\infty} P\{|\theta_n - \theta_{F_n}| \geq \epsilon/2\} \leq \hat{B}_\epsilon \sum_{n=1}^{\infty} n^{-2\delta} < \infty.$$

Hence, by the Borel–Cantelli lemma, $|\theta_n - \theta_{F_n}| < \epsilon/2$ except possibly for an almost surely finite (random) number of n , i.e., there exists an almost surely finite random variable M_3 such that for all $n \geq M_3(\omega)$, $|\theta_n(\omega) - \theta_{F_n}(\omega)| < \epsilon/2$.

Let $M = \max(M_2, M_3)$. Then, for all $n \geq M(\omega)$,

$$|\theta_n(\omega) - \theta^*| \leq |\theta_n(\omega) - \theta_{F_n}(\omega)| + |\theta_{F_n}(\omega) - \theta^*| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon,$$

which proves the result of Theorem 3.2. \square

Observe that step (M1) basically shows that the sequence $\{\tilde{\theta}_n\}$ behaves like an algorithm in which θ is updated after every BP, and step (M2) (via Lemma 3.9) is a convergence result for such an algorithm. This suggests that the rate of convergence of our algorithm is essentially that of one which updates after every BP. To be more specific, observe that from the proof of Lemma 3.8, the quantity \tilde{h}_{n+1} is “close” (differing only by $\tilde{\epsilon}_{n+1}$) to a quantity of the form

$$(40) \quad \frac{1}{E_{\tilde{\theta}_n}(N_n)} \sum_{i=1}^{N_n} \sum_{j=1}^i \phi_j^n(\tilde{\theta}_n) + C'(\tilde{\theta}_n).$$

The quantity in (40) is in fact an unbiased estimate of the derivative of J at $\tilde{\theta}_n$ (by Lemma 2.1), and can be used in an algorithm that updates θ after each BP (see

[8]). We may consider \tilde{h}_{n+1} to be an estimate of $dJ(\tilde{\theta}_n)/d\theta$, and the expression $\theta_{n+1} = \tilde{\pi}_{n+1}[\tilde{\theta}_n - \tilde{b}_n \tilde{h}_{n+1}]$ to be an algorithm which updates after every BP. If we replace \tilde{h}_{n+1} by the quantity in (40), then the resulting algorithm (which updates after every BP) should behave sample-pathwise similar to the subsequence $\{\tilde{\theta}_n\}$ of our original algorithm.

4. Extension to general update times. We now show how our algorithm can be extended so that parameter updates occur only at selected customers. For example, we may wish to update the parameter every time a fixed number of customers have been served, or, more generally, after the service of some random number of customers, determined by a prespecified criterion.

To model this situation let $H_\tau = \{\tau_1, \tau_2, \dots\}$ be a sequence of integer-valued random variables such that $\tau_1 < \tau_2 < \dots$ almost surely. The random variables τ_j will indicate for which customer the j th update will be performed. We think of H_τ as the (random) set of update indices, i.e., $n \in H_\tau$ means that we update before the service of the n th customer. For convenience we set $\tau_1 = 1$, so that θ_1 is set just before serving the first customer. Naturally, we require that $\{\tau_j = n\} \in \mathcal{F}_n$, i.e., that each τ_j is a stopping time with respect to $\{\mathcal{F}_n\}$.

For simplicity and convenience of analysis we will also make the following two assumptions:

(T1) There exists a positive integer B_τ such that for every j , $\tau_{j+1} - \tau_j \leq B_\tau$ almost surely; and

(T2) For almost all $\omega \in \Omega$, if $f_n(\omega) = 1$ (where f_n is defined by (1)), then there exists $j \in \mathbb{N}$ such that $\tau_j(\omega) = n$;

The first assumption simply ensures that updates are not too far apart. In practice this is a very mild restriction, since B_τ can be arbitrarily large. The second assumption ensures that a parameter update is always performed for the first customer in each BP. Since f_{n+1} is \mathcal{F}_{n+1} -measurable, i.e., whether the next customer to be served is the first in a BP is known, it is always possible to modify the sequence $\{\tau_j\}$, if necessary, so that this assumption is satisfied. At the cost of some further complication in the analysis the assumption can be weakened to the following condition:

(T2') There exists an integer t such that $f_{tn} = 1$ only if there exists $j \in \mathbb{N}$ such that $\tau_j = tn$ almost surely,

i.e., a parameter update is performed for the first customer in every t th BP. In this form, the assumption is very mild, since t can be arbitrarily large. However, for brevity we restrict our attention to assumption (T2) in our analysis.

Our modified algorithm can be summarized as follows. Between updates, the control parameter remains fixed, i.e., for each $j \in \mathbb{N}$, $\theta_{\tau_j} = \theta_{\tau_j+1} = \dots = \theta_{\tau_{j+1}-1}$. Let $\beta_j = \theta_{\tau_j}$ be the control parameter at the j th iteration of the algorithm. Then the sequence $\{\beta_j\}$ is generated by the recursion

$$(41) \quad \beta_{j+1} = \pi'_{j+1}[\beta_j - b_j \hat{f}_{j+1}],$$

where $\{b_j\}$ is the step-size sequence, $\pi'_{j+1}[\cdot]$ is a projection defined by

$$(42) \quad \pi'_{j+1}[x] = \begin{cases} \beta_j, & \text{if } x \notin D, \\ x, & \text{otherwise,} \end{cases}$$

and \hat{f}_{j+1} is an estimate of $dJ(\beta_j)/d\theta$ defined by

$$(43) \quad \hat{f}_{j+1} = \begin{cases} \sum_{n=\tau_j}^{\tau_{j+1}-1} (\hat{g}_{n+1} + C'(\theta_n)), & \text{if } \beta_{j-1} - b_{j-1} \hat{f}_j \in D \text{ or } f_{\tau_j} = 1; \\ \sum_{n=\tau_j}^{\tau_{j+1}-1} (\hat{g}_{n+1} + C'(\theta_n)) + \hat{f}_j, & \text{otherwise.} \end{cases}$$

At the j th iteration, our estimate of $dJ(\beta_j)/d\theta$ is simply the sum of the estimates obtained for each customer during the iteration. As before, in the event that a projection is required we add our derivative estimate to the next estimate, subject to resetting this accumulation after the start of the next BP.

The above algorithm encompasses a variety of interesting special cases. For example, by setting $\tau_j = j$ we obtain our original “one customer updating” algorithm. By setting $\tau_j = lj \wedge \min\{n : l(j-1) < n \leq lj \text{ \& } f_n = 1\}$, for some positive integer l , we obtain an algorithm that updates each time l customers are served, or a new BP is started. More generally, we may wish to update only after the derivative estimate meets some criterion, e.g., is deemed to be of sufficient accuracy or of the correct sign, subject to also satisfying (T1). As pointed out before, the original “one customer updating” algorithm can also be viewed as an algorithm that updates after a prespecified criterion is met, namely that $\theta_n - a_n \hat{h}_{n+1} \in D$ or that the next customer is the first in a BP.

Define the filtration $\{\mathcal{F}_j^\tau\}$ by $\mathcal{F}_j^\tau = \mathcal{F}_{\tau_j}$ (the natural filtration associated with the stopping times $\{\tau_j\}$). Let assumptions (G1')–(G4') be (G1)–(G4) with a_n , $\{\mathcal{F}_n\}$, \bar{A} and \underline{A} replaced by b_n , $\{\mathcal{F}_n^\tau\}$, \bar{B} and \underline{B} , respectively. Then, for the generalized algorithm above we have the following result.

THEOREM 4.1. *Suppose that $\{b_j\}$ satisfies (G1')–(G4'), and that (P1)–(P3), (S1)–(S4), and (C1)–(C3) are satisfied. Then, for the sequence $\{\beta_j\}$ defined by (41), (5), and (43), we have that $\beta_j \rightarrow \theta^*$ as $j \rightarrow \infty$ with probability one.*

Proof. To prove this result, we show that the θ_n are related via an algorithm that updates every customer, and that satisfies the conditions of Theorem 3.2. To this end, we first define the projection $\pi_{n+1}[\cdot]$ as follows:

$$(44) \quad \pi_{n+1}[x] = \begin{cases} \theta_n, & \text{if } x \notin D \text{ or } n \notin H_\tau, \\ x, & \text{otherwise.} \end{cases}$$

Correspondingly, we define the projection indicator sequence $\{p_n\}$ by

$$(45) \quad p_{n+1} = \begin{cases} 1, & \text{if } n+1 \notin H_\tau \text{ or } \theta_n - a_n \hat{h}_{n+1} \notin D, \\ 0, & \text{otherwise.} \end{cases}$$

Then define the sequence $\{a_n\}$ by $a_{\tau_j} = a_{\tau_j+1} = \cdots = a_{\tau_{j+1}-1} = b_j$, $j \in \mathbb{N}$. It is now easy to see that the θ_n satisfy the recursion

$$\theta_{n+1} = \pi_{n+1}[\theta_n - a_n \hat{h}_{n+1}],$$

where $\{\hat{h}_{n+1}\}$ is defined by (7) with the sequence $\{p_n\}$ defined above.

Now, the proof of Theorem 3.2 does not depend on the sequence $\{p_n\}$, except through Lemma 3.7. Note, however, that Lemma 3.7 is a purely algebraic result and holds for an arbitrary sequence $\{p_n\}$. Therefore, provided the assumptions of Theorem 3.2 hold, our result follows. Since assumptions (P1)–(P3), (S1)–(S4), and (C1)–(C3) are already assumed to hold, then it remains only to show that $\{a_n\}$ satisfies (G1)–(G4).

Assumptions (G1) and (G2) clearly hold for $\{a_n\}$. To verify (G3), for each n define $\sigma_n \triangleq \max\{j : n \geq \tau_j\}$, so that $a_n = b_{\sigma_n}$. By assumption, $j \leq \tau_j \leq jB_\tau$, and therefore $\sigma'_n \leq \sigma_n \leq n$, where $\sigma'_n = \max(1, (n/B_\tau) - 1)$. By (G2'), we may write $b_n \leq a_n \leq b_{\sigma'_n}$. By (G3'), we have

$$\underline{B}n^{-\delta} \leq a_n \leq \bar{B}(\sigma'_n)^{-\delta}.$$

Since $\sigma'_n \geq n/(2B_\tau)$, then

$$\underline{B}n^{-\delta} \leq a_n \leq \bar{B} \left(\frac{n}{2B_\tau} \right)^{-\delta}.$$

Set $\underline{A} = \underline{B}$ and $\bar{A} = \bar{B}(2B_\tau)^\delta$. Then (G3) is satisfied. To see that (G4) holds, we note that for $n+1 \in H_\tau$, $a_n = b_{\sigma_n}$ and $a_{n+1} = b_{\sigma_{n+1}}$, so that by (G4'),

$$\frac{1}{a_{n+1}} - \frac{1}{a_n} \leq B_a.$$

For $n+1 \notin H_\tau$, $a_{n+1} = a_n$, and so the above inequality remains true. Hence (G4) holds.

Therefore, by Theorem 3.2, $\theta_n \rightarrow \theta^*$ almost surely. Since $\{\beta_j\}$ is a subsequence of $\{a_n\}$, we also have $\beta_j \rightarrow \theta^*$ almost surely, which completes the proof. \square

5. More general performance measures. The proof of our main result can be extended to more general performance measures. For example, consider performance measures of the type $J(\theta) = E(F(t(\theta), \theta))$, where $F: \mathbb{R}_+ \times D \rightarrow \mathbb{R}$ is a given “nice” function and $t(\theta)$ is a random variable that has the distribution of the steady-state system time. By a “nice” function we mean that F has partial derivatives $\partial_t F$ and $\partial_\theta F$ that are bounded and Lipschitz continuous on $\mathbb{R}_+ \times D$. In Appendix A we have shown that

$$\frac{d}{d\theta} J(\theta) = \frac{1}{E(N_1(\theta))} E \left(\sum_{i=1}^{N_1(\theta)} \partial_t F(t_i(\theta), \theta) \sum_{j=1}^i \psi_\theta(X_j(\theta)) + \partial_\theta F(t_i(\theta), \theta) \right),$$

where $\{t_n(\theta)\}$ is the sequence of system times of customers, defined recursively by

$$t_n = \begin{cases} X_n(\theta) - A_{n-1}, & \text{if } f_n = 1, \\ t_{n-1} + X_n(\theta) - A_{n-1}, & \text{otherwise,} \end{cases}$$

with $A_0 = 0$. Correspondingly, we define the sequence of derivative estimates $\{\hat{h}_n\}$ by

$$(46) \quad \hat{h}_{n+1} = \begin{cases} \partial_t F(\hat{t}_{i+1}, \theta_n) \hat{g}_{n+1} + \partial_\theta F(\hat{t}_{i+1}, \theta_n), & \text{if } p_n = 0 \text{ or } f_n = 1, \\ \partial_t F(\hat{t}_{i+1}, \theta_n) \hat{g}_{n+1} + \partial_\theta F(\hat{t}_{i+1}, \theta_n) + \hat{h}_n, & \text{otherwise,} \end{cases}$$

where $\{\hat{t}_n\}$ is defined recursively by

$$(47) \quad \hat{t}_{n+1} = \begin{cases} X_n(\theta_n) - A_{n-1}, & \text{if } f_n = 1, \\ \hat{t}_n + X_n(\theta_n) - A_{n-1}, & \text{otherwise.} \end{cases}$$

Under suitable assumptions, the approach of §3.5 can be used to show that the algorithm defined by (2), (5), (8), (46), and (47) converges almost surely. The proof involves replacing all occurrences of terms such as $\hat{g}_{n+1} + C'(\theta_n)$ by $\partial_t F(\hat{t}_{i+1}, \theta_n) \hat{g}_{n+1} + \partial_\theta F(\hat{t}_{i+1}, \theta_n)$ in the proofs of Lemma 3.8 and Theorem 3.2, and reestablishing the bounds obtained in these proofs.

6. Conclusions. We have proved convergence of a stochastic optimization algorithm using IPA for a GI/G/1 queue with general update times. Simulation plots of our algorithm have been presented in [15]. Our proof made use of certain assumptions on the GI/G/1 queue—roughly, that the service-time distribution has finite moments up to a sufficiently high order, and that the interarrival-time distribution has a bounded hazard rate. We view the latter as the more restrictive of the two main assumptions. This assumption was used only to prove Lemma 3.6. It could be relaxed if an alternative proof for Lemma 3.6 can be found.

Our approach may provide a fruitful line of investigation into the convergence of algorithms applied to networks of queues. Of course, there are many more technical complexities in this setting. This is a difficult but important practical problem.

Appendix A. Proof of Lemma 2.1. We will prove a general result, of which Lemma 2.1 is a special case. For this, let $F : \mathbb{R}_+ \times D \rightarrow \mathbb{R}$ be a function with partial derivatives $\partial_t F$ and $\partial_\theta F$ that are bounded on $\mathbb{R}_+ \times D \rightarrow \mathbb{R}$, and let $t(\theta)$ be a random variable that has the distribution of the steady-state system time. We will show that under the assumptions of Lemma 2.1,

(48)

$$\frac{d}{d\theta} E(F(t(\theta), \theta)) = \frac{1}{E(N_1(\theta))} E \left(\sum_{i=1}^{N_1(\theta)} \partial_t F(t_i(\theta), \theta) \sum_{j=1}^i \psi_\theta(X_j(\theta)) + \partial_\theta F(t_i(\theta), \theta) \right).$$

If we let F be the function $(t, \theta) \mapsto t$, then $\partial_t F = 1$, $\partial_\theta F = 0$, and (48) reduces to the case of Lemma 2.1.

For each $\theta \in D$, define a sequence $\{R_k(\theta)\}$ by $R_k(\theta) = \sum_{i=1}^k N_i(\theta)$, $k \geq 1$, and $R_0(\theta) = 0$. So $R_{k-1} + 1$ is simply the index of the first customer in the k th BP. Define a filtration $\{\mathcal{G}_n\}$ by $\mathcal{G}_1 = \sigma(A_1, \mathbf{X}_1)$, and for $n > 1$, $\mathcal{G}_n = \sigma(\mathcal{G}_{n-1}, A_n, \mathbf{X}_n)$. It can be shown that for each θ and k , $R_k(\theta)$ is a stopping time with respect to $\{\mathcal{G}_n\}$.

Note that for each $k \in \mathbb{N}$, $R_k(\theta)$ is simply the smallest positive integer satisfying

$$(49) \quad \sum_{i=R_{k-1}(\theta)+1}^{R_k(\theta)} X_i(\theta) < \sum_{i=R_{k-1}(\theta)+1}^{R_k(\theta)} A_i.$$

Let $N_{\max}^k = N_k(\theta_{\max})$. For each n , let $t_n(\theta)$ be the system time of the n th customer (with control parameter value θ). Specifically, if the n th customer is within the k th BP, then $t_n(\theta)$ is given by

$$t_n(\theta) = \sum_{i=R_{k-1}(\theta)+1}^n X_i(\theta) - \sum_{i=R_{k-1}(\theta)+1}^{n-1} A_i.$$

It is easy to see that the stopping time $R_k(\theta)$ are regeneration points for the process $\{t_n(\theta)\}$ (see [16]). Now, from the previous argument, the $R_k(\theta_{\max})$ are stopping times with respect to $\{\mathcal{G}_n\}$. We claim that the $R_k(\theta_{\max})$ are also regeneration points for the process $\{t_n(\theta)\}$. To see this, it suffices to show that for each k , there exists a random variable K_k such that $R_k(\theta_{\max}) = R_{K_k}(\theta)$, i.e., $\{R_k(\theta_{\max})\}$ is a subsequence of $\{R_k(\theta)\}$. It will suffice for us to show that there exists K_1 such that $R_1(\theta_{\max}) = R_{K_1}(\theta)$ (note that $R_1(\theta_{\max}) = N_{\max}^1$). To this end, let $K_1 = 1 + \max\{j \in \mathbb{N} : R_j(\theta) <$

$N_{\max}^1\}$. Now, $R_{K_1-1}(\theta) < N_{\max}^1$, and therefore

$$(50) \quad \sum_{i=1}^{R_{K_1-1}(\theta)} X_i(\theta_{\max}) \geq \sum_{i=1}^{R_{K_1-1}(\theta)} A_i.$$

Also, we note that N_{\max}^1 is the smallest positive integer satisfying

$$(51) \quad \sum_{i=1}^{N_{\max}^1} X_i(\theta_{\max}) < \sum_{i=1}^{N_{\max}^1} A_i.$$

Subtracting (50) from (51), we get that

$$\sum_{i=R_{K_1-1}(\theta)+1}^{N_{\max}^1} X_i(\theta_{\max}) < \sum_{i=R_{K_1-1}(\theta)+1}^{N_{\max}^1} A_i.$$

Since for all i , $X_i(\theta) \leq X_i(\theta_{\max})$, then we also have that

$$\sum_{i=R_{K_1-1}(\theta)+1}^{N_{\max}^1} X_i(\theta) < \sum_{i=R_{K_1-1}(\theta)+1}^{N_{\max}^1} A_i.$$

Since $R_{K_1}(\theta)$ is the smallest positive integer satisfying (49), then $R_k(\theta) \leq N_{\max}^1$. But by definition of K_1 , $R_{K_1}(\theta) \geq N_{\max}^1$. Hence, $R_{K_1}(\theta) = N_{\max}^1$.

Now, since the stopping times $R_k(\theta_{\max})$ are regeneration points for the process $\{t_n(\theta)\}$ (and hence also $\{F(t_n(\theta), \theta)\}$), then from the theory of regenerative systems (e.g., see [16]),

$$(52) \quad E(F(t(\theta), \theta)) = \frac{1}{E(N_{\max}^1)} E \left(\sum_{i=1}^{N_{\max}^1} F(t_i(\theta), \theta) \right).$$

Since each X_n is differentiable with respect to θ on D , then we claim that $F(t_n, \cdot)$ is also differentiable with respect to θ on D . It suffices to show that t_n is differentiable on D . To see this, first fix $\omega \in \Omega$. For each k , there exists an open interval $I_k(\omega)$ containing θ such that $N_k(\omega)$ is constant over $I_k(\omega)$. Therefore, there exists an open interval $I(\omega)$ containing θ such that for all $k \leq K_1(\omega)$, $R_k(\omega)$ is constant over $I(\omega)$. Consider the n th customer, where $n \leq N_{\max}^1(\omega)$. Suppose it is within the $k_n(\omega)$ th BP. Then clearly $k_n(\omega) \leq N_{\max}^1(\omega)$. Since (henceforth dropping the argument ω)

$$t_n(\theta) = \sum_{i=R_{k_n-1}+1}^n X_i(\theta) - \sum_{i=R_{k_n-1}+1}^{n-1} A_i,$$

then

$$\begin{aligned} \frac{dt_n}{d\theta}(\theta) = \lim_{\delta \rightarrow 0} \frac{1}{\delta} & \left(\sum_{i=R_{k_n-1}(\theta+\delta)+1}^n X_i(\theta+\delta) - \sum_{i=R_{k_n-1}(\theta)+1}^{n-1} X_i(\theta) \right. \\ & \left. - \sum_{i=R_{k_n-1}(\theta+\delta)+1}^{n-1} A_i + \sum_{i=R_{k_n-1}(\theta)+1}^{n-1} A_i \right). \end{aligned}$$

For all δ small enough such that $\theta + \delta \in I$, $R_{k_n-1}(\theta + \delta) = R_{k_n-1}(\theta)$ and hence

$$\sum_{i=R_{k_n-1}(\theta+\delta)+1}^n X_i(\theta + \delta) - \sum_{i=R_{k_n-1}(\theta)+1}^n X_i(\theta) = \sum_{i=R_{k_n-1}(\theta)+1}^n X_i(\theta + \delta) - X_i(\theta),$$

and, similarly,

$$\sum_{i=R_{k_n-1}(\theta+\delta)+1}^{n-1} A_i - \sum_{i=R_{k_n-1}(\theta)+1}^{n-1} A_i = 0.$$

Therefore,

$$\begin{aligned} \frac{dt_n}{d\theta}(\theta) &= \lim_{\delta \rightarrow 0} \sum_{i=R_{k_n-1}(\theta)+1}^n \frac{X_i(\theta + \delta) - X_i(\theta)}{\delta} \\ &= \sum_{i=R_{k_n-1}(\theta)+1}^n \lim_{\delta \rightarrow 0} \frac{X_i(\theta + \delta) - X_i(\theta)}{\delta} \\ &= \sum_{i=R_{k_n-1}+1}^n \frac{dX_i}{d\theta}(\theta). \end{aligned}$$

Since by assumption (P4), $dX_i(\theta)/d\theta = \psi_\theta(X_i(\theta))$, then we may write

$$\frac{dt_n}{d\theta}(\theta) = \sum_{i=R_{k_n-1}+1}^n \psi_\theta(X_i(\theta)).$$

Fix $\theta \in D$. We now claim that

$$\frac{d}{d\theta} E \left(\sum_{i=1}^{N_{\max}^1} F(t_i(\theta), \theta) \right) = E \left(\sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right).$$

To show this, we first define, for each $j \in \mathbb{N}$, $\bar{\phi}_j \triangleq \sup_{\theta \in D} (dX_j/d\theta)(\theta)$. Since $\partial_t F$ and $\partial_\theta F$ are both bounded, then there exists a finite constant B_F such that $\partial_t F, \partial_\theta F \leq B_F$. Let

$$Y = \sum_{i=1}^{N_{\max}^1} B_F \left(1 + \sum_{j=1}^i \bar{\phi}_j \right).$$

It is clear, by assumption (P3), that for each $i \leq N_{\max}$,

$$\left| \frac{dt_i}{d\theta}(\theta) \right| \leq \sum_{j=1}^i |\psi_\theta(X_j(\theta))|.$$

Therefore, we have that for all $\theta \in D$,

$$\begin{aligned} \left| \sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right| &= \left| \sum_{i=1}^{N_{\max}^1} \partial_t F(t_i(\theta), \theta) \frac{dt_i}{d\theta}(\theta) + \partial_\theta F(t_i(\theta), \theta) \right| \\ &\leq \sum_{i=1}^{N_{\max}^1} \left(B_F \sum_{j=1}^i |\psi_\theta(X_j(\theta))| + B_F \right) \leq \sum_{i=1}^{N_{\max}^1} B_F \left(1 + \sum_{j=1}^i \bar{\phi}_j \right) = Y. \end{aligned}$$

Now, we can write

$$\begin{aligned} |Y| &\leq \sum_{i=1}^{N_{\max}^1} B_F \left(1 + \sum_{j=1}^{N_{\max}^1} \bar{\phi}_j \right) \\ &= B_F N_{\max}^1 + B_F N_{\max}^1 \sum_{j=1}^{N_{\max}^1} (\bar{\phi}_j - E(\bar{\phi}_1)) + B_F (N_{\max}^1)^2 E(\bar{\phi}_1). \end{aligned}$$

By one of Wald's identities (see [17, p. 460]) and assumption (P4)

$$E \left(\sum_{j=1}^{N_{\max}^1} \bar{\phi}_j - E(\bar{\phi}_1) \right)^2 = E(N_{\max}^1) \text{Var}(\bar{\phi}_1) < \infty.$$

From assumption (P2) and Lemma 3.3, we have that

$$\begin{aligned} E(|Y|) &\leq B_F E(N_{\max}^1) + B_F \sqrt{E(N_{\max}^1)^2 E \left(\sum_{j=1}^{N_{\max}^1} \bar{\phi}_j - E(\bar{\phi}_1) \right)^2} \\ &\quad + B_F E(N_{\max}^1)^2 E(\bar{\phi}_1) \\ &< \infty, \end{aligned}$$

which shows that Y is integrable. Therefore, by continuity of $\sum_{i=1}^{N_{\max}^1} F(t_i(\cdot), \cdot)$ and [18, p. 46], we have that

$$(53) \quad \frac{d}{d\theta} E \left(\sum_{i=1}^{N_{\max}^1} F(t_i(\theta), \theta) \right) = E \left(\sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right).$$

Therefore, combining (53) with (52) we have that

$$(54) \quad \frac{d}{d\theta} F(t(\theta), \theta) = \frac{1}{E(N_{\max}^1)} E \left(\sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right).$$

Recall the definition for the sequence $\{R_k(\theta)\}$, where θ is the value previously fixed (we will hereafter drop the argument θ and simply write $\{R_k\}$). Since $\{R_k\}$ is a sequence of stopping times relative to $\{\mathcal{G}_n\}$, we may define a sequence of σ -algebras $\{\mathcal{H}_k\}$ by $\mathcal{H}_k = \mathcal{G}_{R_k}$, where $\mathcal{G}_{R_k} \triangleq \{A \in \mathcal{G} : A \cap \{R_k = i\} \in \mathcal{G}_i \text{ for all } i \in \mathbb{N}\}$ (see, e.g., [17, p. 449]). As $R_k \leq R_{k+1}$ almost surely for all $k \in \mathbb{N}$, then $\{\mathcal{H}_k\}$ is a filtration (see, e.g., [17, p. 455]), and $\{R_k\}$ is adapted to $\{\mathcal{H}_k\}$. It can be shown that K_1 is a stopping time with respect to $\{\mathcal{H}_k\}$.

Consider (54). Now, we may write

$$N_{\max}^1 = R_{K_1} = \sum_{k=1}^{K_1} N_k.$$

Therefore,

$$E(N_{\max}^1) = E \left(\sum_{k=1}^{K_1} N_k \right).$$

Since $\{N_k\}$ is an independent and identically distributed sequence adapted to $\{\mathcal{H}_k\}$, and K_1 is a stopping time with respect to $\{\mathcal{H}_k\}$, then by one of Wald's identities (see [17, p. 460]), we may write

$$(55) \quad E \left(\sum_{k=1}^{K_1} N_k \right) = E(K_1)E(N_1).$$

Similarly, we may write

$$\sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) = \sum_{i=1}^{R_{K_1}} \frac{d}{d\theta} F(t_i(\theta), \theta) = \sum_{k=1}^{K_1} \sum_{i=R_{k-1}+1}^{R_k} \frac{d}{d\theta} F(t_i(\theta), \theta).$$

We now note that the sequence of random variables

$$\left\{ \sum_{i=R_{k-1}+1}^{R_k} \frac{d}{d\theta} F(t_i(\theta), \theta) \right\}_{k \in \mathbb{N}}$$

is an independent and identically distributed sequence adapted to $\{\mathcal{H}_k\}$, and again by one of Wald's identities, we may write

$$(56) \quad E \left(\sum_{i=1}^{N_{\max}^1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right) = E(K_1)E \left(\sum_{i=1}^{N_1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right).$$

Combining (55) and (56) with (54) we obtain

$$\begin{aligned} \frac{d}{d\theta} F(t(\theta), \theta) &= \frac{1}{E(N_1)} E \left(\sum_{i=1}^{N_1} \frac{d}{d\theta} F(t_i(\theta), \theta) \right) \\ &= \frac{1}{E(N_1)} E \left(\sum_{i=1}^{N_1} \partial_t F(t_i(\theta), \theta) \sum_{j=1}^i \psi_{\theta}(X_j(\theta)) + \partial_{\theta} F(t_i(\theta), \theta) \right) \end{aligned}$$

which completes the proof. \square

Appendix B. Proof of Proposition 3.1. For simplicity of notation, let $X(\theta) = X_m^k(\theta)$, $K = K_m^k$, $\bar{K} = \bar{K}_m^k$, $\phi = \phi_m^k$, and $\bar{\phi} = \bar{\phi}_m^k$. Let $\theta_1, \theta_2 \in D$. Then

$$\begin{aligned} |\phi(\theta_2) - \phi(\theta_1)| &= |\psi_{\theta_2}(X(\theta_2)) - \psi_{\theta_1}(X(\theta_1))| \\ &= |\psi_{\theta_2}(X(\theta_2)) - \psi_{\theta_1}(X(\theta_2)) + \psi_{\theta_1}(X(\theta_2)) - \psi_{\theta_1}(X(\theta_1))| \\ &\leq K_1(X(\theta_2))|\theta_2 - \theta_1| + K_2(\theta_1)|X(\theta_2) - X(\theta_1)|. \end{aligned}$$

By the Mean Value Theorem,

$$\begin{aligned} |X(\theta_2) - X(\theta_1)| &= \left| \frac{\partial X}{\partial \theta}(\tilde{\theta}) \right| |\theta_2 - \theta_1| \\ &= |\psi_{\tilde{\theta}}(X(\tilde{\theta}))| |\theta_2 - \theta_1| \\ &= |\phi(\tilde{\theta})| |\theta_2 - \theta_1| \\ &\leq \bar{\phi} |\theta_2 - \theta_1|, \end{aligned}$$

where $\tilde{\theta} = \theta_1 + \xi(\theta_2 - \theta_1)$ with $0 \leq \xi \leq 1$. So,

$$\begin{aligned} |\phi(\theta_2) - \phi(\theta_1)| &\leq K_1(X(\theta_2))|\theta_2 - \theta_1| + \bar{L}\bar{\phi}|\theta_2 - \theta_1| \\ &\leq (\bar{K} + \bar{L}\bar{\phi})|\theta_2 - \theta_1| \\ &= K|\theta_2 - \theta_1|, \end{aligned}$$

where $K \triangleq \bar{K} + \bar{L}\bar{\phi}$. Now,

$$\begin{aligned} E(K^2) &= E(\bar{K}^2) + 2\bar{L}E(\bar{K}\bar{\phi}) + \bar{L}^2E(\bar{\phi}^2) \\ &\leq E(\bar{K}^2) + 2\bar{L}\sqrt{E(\bar{K}^2)}\sqrt{E(\bar{\phi}^2)} + \bar{L}^2E(\bar{\phi}^2) < \infty \end{aligned}$$

which completes the proof. \square

Appendix C. Proof of Lemma 3.4. It suffices to prove the result for $r = p$. Fix $k \in \mathbb{N}$ and $\theta \in D$. Define a filtration $\{\mathcal{F}_m^k\}$ by $\mathcal{F}_m^k = \sigma(X_i^k, A_i^k, i = 1, \dots, m)$. Then, $N_k(\theta)$ is a stopping time with respect to $\{\mathcal{F}_m^k\}$, since

$$\{N_k(\theta) = m\} = \left(\bigcap_{j=1}^{m-1} \left\{ \sum_{i=1}^{j-1} (X_i^k(\theta) - A_i^k) \geq 0 \right\} \right) \cap \left\{ \sum_{i=1}^m (X_i^k(\theta) - A_i^k) < 0 \right\}$$

and the sets on the right-hand side are in \mathcal{F}_m^k . Now, since $\bar{\phi}_m^k$ is a function of X_m^k , then it is clearly \mathcal{F}_m^k -measurable and independent of \mathcal{F}_{m-1}^k . Therefore, by [14, Thm. 5.2, p. 22],

$$E \left(\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k \right)^r \leq B_r' E(\bar{\phi}_1^1)^r E(N_k(\theta))^r,$$

where B_r' is a numerical constant depending only on r . Therefore, if we let $B_\phi = B_r' E(\bar{\phi}_1^1)^r B_N$ then by Lemma 3.3, we may write

$$E \left(\sum_{i=1}^{N_k(\theta)} \bar{\phi}_i^k \right)^r \leq B_\phi.$$

This completes the proof. \square

Appendix D. Proof of Lemma 3.5. Fix k and $\theta \in D$. Since $E(N_1(\theta)) < \infty$ and $E(K_1^1)^2 < \infty$, then by one of Wald's identities (see [17, p. 460]),

$$(57) \quad E \left(\sum_{i=1}^{N_k(\theta)} K_i^k - E(K_i^k) \right)^2 = E(K_1^1 - E(K_1^1))^2 E(N_1(\theta)).$$

Now,

$$\begin{aligned} &E \left(\sum_{i=1}^{N_k(\theta)} K_i^k \right)^2 \\ &= E \left(\sum_{i=1}^{N_k(\theta)} K_i^k - E(K_i^k) \right)^2 + 2E \left(N_k(\theta) \sum_{i=1}^{N_k(\theta)} K_i^k - E(K_i^k) \right) E(K_1^1) \end{aligned}$$

$$\begin{aligned}
& + (E(K_1^1))^2 E(N_1(\theta))^2 \\
& \leq E \left(\sum_{i=1}^{N_k(\theta)} K_i^k - E(K_i^k) \right)^2 + 2E(K_1^1) \sqrt{E(N_k(\theta))^2} \sqrt{E \left(\sum_{i=1}^{N_k(\theta)} K_i^k - E(K_i^k) \right)^2} \\
& \quad + (E(K_1^1))^2 E(N_1(\theta))^2.
\end{aligned}$$

Therefore, by (57) and using Lemma 3.3,

$$\begin{aligned}
& E \left(\sum_{i=1}^{N_k(\theta)} K_i^k \right)^2 \\
& \leq E(K_1^1 - E(K_1^1))^2 E(N_1(\theta)) + 2E(K_1^1) \sqrt{B_N} \sqrt{E(K_1^1 - E(K_1^1))^2 E(N_1(\theta))} \\
& \quad + (E(K_1^1))^2 B_N \\
& \leq B_K,
\end{aligned}$$

where

$$B_K = E(K_1^1 - E(K_1^1))^2 B_N + 2E(K_1^1) \sqrt{B_N} \sqrt{E(K_1^1 - E(K_1^1))^2 B_N} + (E(K_1^1))^2 B_N < \infty,$$

which concludes the proof. \square

A SET INDUCED NORM APPROACH TO THE ROBUST CONTROL OF CONSTRAINED SYSTEMS*

MARIO SZNAIER[†]

Abstract. Most realistic control problems involve both some type of time-domain constraints and model uncertainty. However, the majority of controller design procedures currently available focus only on one aspect of the problem, with only a handful of methods capable of simultaneously addressing both issues. Recently, it has been proposed to address this class of problems by using a “constrained robustness measure,” generated by a constraint-set induced operator norm, to assess the stability properties of a family of systems. In this paper the properties of this constrained-robustness measure are explored and the theoretical framework is extended to include control as well as state constraints. These results are applied to the problem of designing fixed-order stabilizing feedback controllers for systems subject to structured parametric model uncertainty and time-domain constraints.

Key words. constrained systems, discrete time systems, robust design techniques, robust stability

AMS(MOS) subject classifications. 93, 93B35, 93B51, 93C55, 93D09

1. Introduction. A substantial number of control problems can be summarized as the problem of designing a controller capable of achieving acceptable performance under system uncertainty and design constraints. This statement looks deceptively simple, but even in the case where the system under consideration is linear, the problem is far from solved. Several methods have been proposed recently to deal with constrained control problems under the assumption of exact knowledge of the model (see [1] and references therein). However, such an assumption can be too restrictive, ruling out cases where good qualitative models of the plant are available but the numerical values of various parameters are unknown or even change during operation.

On the other hand, during the last decade a considerable amount of time has been spent analyzing the question of whether some relevant properties of a system (most notably asymptotic stability) are preserved under the presence of unknown perturbations. This research effort has led to procedures for designing “robust” controllers, capable of achieving desirable properties under various classes of plant perturbations while, at the same time, satisfying frequency-domain constraints. However, most of these design procedures cannot accommodate directly time-domain constraints (which precludes their use in cases where there exist physically motivated “hard” bounds on the states or control effort), although some progress has been recently made in this direction [2]–[5].

In [6], [7] we proposed to approach time-domain constrained systems using an operator norm-theoretic approach. We introduced a simple robustness measure that indicated how well the family of systems under consideration satisfied a given set of time-domain constraints and we proposed a design method yielding controllers that maximized this robustness measure. In this paper we extend our formalism to include

control as well as a more general description of state constraints, and we explore the properties of the resulting constrained robustness measure. These theoretical results are applied to the problem of designing stabilizing controllers for systems subject to structured parametric model uncertainty and time-domain constraints. We show that in cases of practical interest the synthesis problem can be reduced to a convex, albeit in general nondifferentiable, optimization problem. We believe that the results presented here will provide a useful new approach for addressing more realistic control design problems.

The paper is organized as follows: In §2 we introduce the concepts of *constrained stability* and *robust constrained stability* and we use these concepts to give a formal definition of the *robust constrained stability analysis* and *robust constrained stability design* problems. The *analysis* problem is studied in §3 where we give necessary and sufficient conditions for constrained stability. We use these results to define a constrained robustness measure and we show that, under mild assumptions, this measure is a continuous, concave function of the dynamics of the system. In §4 we apply the results of §3 to the *design* problem and we show that in cases of practical interest our approach yields a well-behaved optimization problem. Finally, in §5 we summarize our results and indicate directions for future research.

2. Definitions and background results. In this section we give a formal definition of the robust constrained control problem. We begin by introducing several required concepts and preliminary results.

2.1. Preliminary definitions.

DEFINITION 1. Consider the linear, time invariant, discrete time, autonomous system modeled by the difference equation

$$(S^a) \quad \underline{x}_{k+1} = A\underline{x}_k, \quad k = 0, 1, \dots$$

subject to the constraint

$$(1) \quad \underline{x} \in \mathcal{G} \subset R^n$$

where $A \in R^{n \times n}$ and where \underline{x} indicates x is a vector quantity. The system (S^a) is *constrained stable* if for any point $\underline{\tilde{x}} \in \mathcal{G}$, the trajectory $\underline{x}_k(\underline{\tilde{x}})$ originating in $\underline{\tilde{x}}$ remains in \mathcal{G} for all k .

Remark 1. A nonempty subset $\mathcal{S} \subset R^n$ is a *positively invariant set* of the system (S^a) if for any initial state $\underline{x}_o \in \mathcal{S}$, the trajectory $\underline{x}_k(\underline{x}_o) \in \mathcal{S}$ for all k , or equivalently [8] if and only if $\underline{x} \in \mathcal{S}$ implies $A\underline{x} \in \mathcal{S}$. Therefore, it follows that the system (S^a) is constrained stable if and only if it has the set \mathcal{G} as a positively invariant set.

Next, we take into account parametric model uncertainty by extending the concept of constrained stability to a family of systems.

DEFINITION 2. Consider the family of linear discrete-time systems modeled by the difference equation

$$(S^a_{\Delta}) \quad \underline{x}_{k+1} = (A + \Delta)\underline{x}_k$$

where Δ belongs to some perturbation set $\mathcal{D} \subseteq R^{n \times n}$. The system (S^a) is *robustly constrained stable* with respect to the set \mathcal{D} if (S^a_{Δ}) is constrained stable for all perturbation matrices $\Delta \in \mathcal{D}$.

We now restrict the class of constraints allowed in our problem. As it will become apparent later, the introduction of this restriction, termed the *constraint qualification*

hypothesis, while not affecting significantly the number of real-world problems that can be handled by our formalism, introduces more structure into the problem. This additional structure plays a key role in §3 where we derive necessary and sufficient conditions for constrained stability.

2.2. Constraint qualification hypothesis. In this paper, we will limit ourselves to constraints of the form

$$(2) \quad \underline{x} \in \mathcal{G} \subset R^n$$

where \mathcal{G} is a convex, compact, balanced set (i.e., a convex compact set such that $\underline{x} \in \mathcal{G} \Rightarrow \lambda \underline{x} \in \mathcal{G}$ for $|\lambda| \leq 1$ [9]) containing the origin in its interior.

DEFINITION 3. [9]. The *Minkowsky functional* (or gauge) p of a balanced convex set \mathcal{G} containing the origin in its interior is defined by

$$(3) \quad p(\underline{x}) = \inf_{r>0} \left\{ r: \frac{\underline{x}}{r} \in \mathcal{G} \right\}.$$

A well-known result in functional analysis (see, for instance, [9]) establishes that p defines a seminorm in R^n . Furthermore, when \mathcal{G} is compact, this seminorm becomes a norm. In the sequel, we will denote this norm as

$$\|\underline{x}\|_{\mathcal{G}} \triangleq p(\underline{x}).$$

Remark 2. The set \mathcal{G} can be characterized as the unity ball in $\|\cdot\|_{\mathcal{G}}$, i.e., $\mathcal{G} = \{\underline{x}: \|\underline{x}\|_{\mathcal{G}} \leq 1\}$.

With the concepts introduced in this section, we are now ready to give a formal definition to our problem.

2.3. Statement of the problem. Consider the LTI system represented by the following state-space realization:

$$(S) \quad \underline{x}_{k+1} = A\underline{x}_k + B\underline{u}_k$$

subject to the constraint

$$\underline{x}_k \in \mathcal{G} \subset R^n$$

where $\underline{x} \in R^n$ represents the state and $\underline{u} \in R^m$ represents the control input. Then, the basic problems that we address in this paper are the following.

Robust constrained stability analysis problem. Given the nominal system (S) and a linear feedback control law $\underline{u}_k = F\underline{x}_k$, determine if the resulting closed-loop system is constrained stable. If the nominal closed-loop system is constrained stable, determine the maximum allowable level of model uncertainty (in the sense of some previously defined norm) such that the constraints are satisfied for any initial condition $\underline{x} \in \mathcal{G}$.

Linear robust constrained control synthesis problem. Given the system (S), find a *linear* controller such that the resulting closed-loop system is constrained stable and satisfies some additional specifications such as:

- (i) maximum robustness against structured model uncertainty of the form $A = A_o + \Delta$, $\Delta \in \mathcal{D}$;
- (ii) bounds on the control effort of the form $\underline{u}_k \in \Omega \subset R^m$, where Ω is a compact, convex, balanced set containing the origin in its interior.

3. Constrained stability analysis. Consider the system (S^a) and let $\|\cdot\|_{\mathcal{G}}$ denote the operator norm induced in $R^{n \times n}$ by \mathcal{G} , (i.e., $\|A\|_{\mathcal{G}} \triangleq \sup_{\|x\|_{\mathcal{G}}=1} \|Ax\|_{\mathcal{G}}$). From Definition 1 it follows that (S^a) is constrained stable if and only if $\|A\|_{\mathcal{G}} \leq 1$. Moreover, (S^a) is robustly constrained stable with respect to a given set \mathcal{D} if and only if $\|A + \Delta\|_{\mathcal{G}} \leq 1$ for all $\Delta \in \mathcal{D}$. This observation can be used to define a robustness measure in terms of the size of the smallest destabilizing perturbation as follows.

DEFINITION 4. Consider the system (S^a) . The *constrained stability measure* $\varrho_{\mathcal{G}}^{\mathcal{N}}$ is defined as

$$\varrho_{\mathcal{G}}^{\mathcal{N}} \triangleq \begin{cases} 0 & \text{if } \|A\|_{\mathcal{G}} > 1; \\ \max_{\Delta \in \mathcal{D}} \|\Delta\|_{\mathcal{N}} & \text{if } \|A + \Delta\|_{\mathcal{G}} < 1 \ \forall \Delta \in \mathcal{D}; \\ \min_{\Delta \in \mathcal{D}} \{\|\Delta\|_{\mathcal{N}} : \|A + \Delta\|_{\mathcal{G}} = 1\} & \text{otherwise} \end{cases}$$

where $\|\cdot\|_{\mathcal{N}}$ denotes a suitable operator norm defined in \mathcal{D} . In the special case where the induced operator norm $\|\cdot\|_{\mathcal{G}}$ is used in the set \mathcal{D} , we will denote the constrained stability measure as $\varrho_{\mathcal{G}}$.

Remark 3. Let the set $\mathcal{B}\Delta^{\mathcal{N}}$ be the intersection of \mathcal{D} with the origin centered ball of radius $\varrho_{\mathcal{G}}^{\mathcal{N}}$, i.e.,

$$\mathcal{B}\Delta^{\mathcal{N}} = \{\Delta \in \mathcal{D} : \|\Delta\|_{\mathcal{N}} \leq \varrho_{\mathcal{G}}^{\mathcal{N}}\}.$$

Then, from Definition 4 it follows that the family (S_{Δ}^a) is constrained stable for all perturbations $\Delta \in \mathcal{B}\Delta^{\mathcal{N}}$.

Remark 4. Definition 4 is quite general since in principle no conditions are imposed over the set \mathcal{D} . However, in the general case nothing can be stated about the properties of $\varrho_{\mathcal{G}}^{\mathcal{N}}$ which could conceivably be a *noncontinuous* function of A . In the sequel we will show that, under some assumptions that are commonly verified in practice, $\varrho_{\mathcal{G}}^{\mathcal{N}}$ is a *continuous, concave* function of the dynamics matrix A .

THEOREM 1. Assume that the perturbation set \mathcal{D} is a closed cone with vertex at the origin [10], (i.e., $\Delta^o \in \mathcal{D} \iff \alpha \Delta^o \in \mathcal{D}$ for all $0 \leq \alpha$). Then $\varrho_{\mathcal{G}}^{\mathcal{N}}$ is a continuous, concave function of A .

Proof. The proof of the theorem is given in Appendix A.

Remark 5. Note that the class of sets considered in this theorem includes, as a particular case, sets of the form:

$$(4) \quad \mathcal{D} = \left\{ \Delta : \Delta = \sum_1^m \mu_i E_i; \ \mu_i \geq 0, \ E_i \text{ given} \right\}$$

which has been the object of much interest lately ([11]–[13] and references therein).

In the next lemma we introduce a *lower bound* of the constrained stability measure and we show that for *unstructured* perturbations (i.e., the case where $\mathcal{D} \equiv R^{n \times n}$) this lower bound is saturated.

LEMMA 1.

$$(5) \quad \varrho_{\mathcal{G}} \geq 1 - \|A\|_{\mathcal{G}}.$$

Furthermore, for the unstructured perturbation case, i.e., the case where $\mathcal{D} \equiv R^{n \times n}$, condition (5) is saturated.

Proof. The first part of the lemma can be easily proved from Definition 4 and the triangle inequality. The second part follows by noting that for $\Delta^o \triangleq ((1 - \|A\|_{\mathcal{G}})A / \|A\|_{\mathcal{G}})$ (5) is saturated. \square

Remark 6. Note that the results of Lemma 1 can be used to find a lower bound for the constrained robustness measure in the general case when an operator norm different from $\|\cdot\|_{\mathcal{G}}$ is used in the set \mathcal{D} . Since all finite-dimensional matrix norms are equivalent [14], it follows that, given any norm \mathcal{N} in the set \mathcal{D} , there exist a constant c such that $\|\cdot\|_{\mathcal{G}} \leq c\|\cdot\|_{\mathcal{N}}$. Hence $\varrho_{\mathcal{G}}^{\mathcal{N}} \leq (\varrho_{\mathcal{G}}/c)$.

3.1. Quadratic constraints case. In this section we particularize our theoretical results for the special case where the constraint region is an hyperellipsoid. In this case, without loss of generality, we have

$$\mathcal{G} = \{\underline{x}: \underline{x}'P\underline{x} \leq 1, P \in R^{n \times n} \text{ positive definite}\}.$$

Hence

$$\begin{aligned} \|\underline{x}\|_{\mathcal{G}}^2 &= \underline{x}'P\underline{x} \\ \|A\|_{\mathcal{G}}^2 &= \max_{\underline{x}} \left\{ \frac{\underline{x}'A'PA\underline{x}}{\underline{x}'P\underline{x}} \right\} \\ (6) \quad &= \max_{\underline{x}} \left\{ \frac{\underline{x}'L'L^{-1}A'L'LAL^{-1}L\underline{x}}{\underline{x}'L'L\underline{x}} \right\} \\ &= \max_{\|\underline{y}\|_2=1} \|LAL^{-1}\underline{y}\|_2^2 \\ &= \|LAL^{-1}\|_2^2 = \|\tilde{A}\|_2^2 \end{aligned}$$

where $L'L = P$ and $\tilde{A} = LAL^{-1}$. We will show that in this case our approach yields a generalization of the well-known technique of estimating the robustness measure by using quadratic based Lyapunov functions, (see [15] and references therein) by obtaining robustness bounds previously derived in this context.

Example 1 (multilinearly correlated perturbations). In the case of quadratic constraints and multilinearly correlated uncertainty, the lower bound on ϱ given by (5) can be tightened as follows. Assume that the set \mathcal{D} is given by

$$(7) \quad \mathcal{D} = \left\{ \Delta \in R^{n \times n}: L\Delta L^{-1} = U \begin{pmatrix} \tilde{\Delta} \\ 0 \end{pmatrix}, \tilde{\Delta} \in R^{m \times n}, U'U = I_n, L'L = P \right\}.$$

Since the euclidian norm is invariant under multiplications by a unitary matrix, we have

$$\begin{aligned} \|A + \Delta\|_{\mathcal{G}} &= \|L(A + \Delta)L^{-1}\|_2 \\ (8) \quad &= \left\| \tilde{A} + U \begin{pmatrix} \tilde{\Delta} \\ 0 \end{pmatrix} \right\|_2 = \left\| \begin{pmatrix} A_1 \\ A_2 \end{pmatrix} + \begin{pmatrix} \tilde{\Delta} \\ 0 \end{pmatrix} \right\|_2 \\ &= \left\| \begin{pmatrix} A_1 + \tilde{\Delta} \\ A_2 \end{pmatrix} \right\|_2. \end{aligned}$$

A well-known result on matrix dilations establishes [16] that

$$\left\| \begin{pmatrix} X \\ A_2 \end{pmatrix} \right\|_2 \leq 1 \iff \|A_2\|_2 \leq 1 \quad \text{and} \quad X = Y(I - A_2'A_2)^{1/2}, \quad \|Y\|_2 \leq 1;$$

hence it follows that

$$(9) \quad \|A + \Delta\|_{\mathcal{G}} = 1 \iff \|(A_1 + \tilde{\Delta})N\|_2 = 1$$

where:

$$N \triangleq (I - A_2' A_2)^{-1/2}.$$

Finally, by defining $\|\Delta\|_{\mathcal{N}} \triangleq \|\tilde{\Delta}N\|_2$ and using the results of Lemma 1, we get

$$(10) \quad \varrho_{\mathcal{G}}^{\mathcal{N}} = 1 - \|A_1 N\|_2.$$

Remark 7. Note that when $A_2 = 0$ we recover the results of Lemma 1, since in this case $\varrho = 1 - \|A_1\|_2 = 1 - \|A\|_{L'L}$.

Example 2. (unstructured perturbation). In this case, Theorem 2 yields $\varrho_{\mathcal{G}} = 1 - \|A\|_{\mathcal{G}}$ where

$$(11) \quad \|A\|_{\mathcal{G}}^2 = \|A\|_P^2 = \max_{\underline{x}} \left(\frac{\underline{x}' A' P A \underline{x}}{\underline{x}' P \underline{x}} \right).$$

Now consider the case where $\varrho_{\mathcal{G}} > 0$. Then there exists Q positive definite such that

$$(12) \quad A' P A - P = -Q$$

and

$$(13) \quad \|A\|_{\mathcal{G}}^2 = \max_{\underline{x}} \left(1 - \frac{\underline{x}' Q \underline{x}}{\underline{x}' P \underline{x}} \right) \leq 1 - \frac{\sigma_{\min}(Q)}{\sigma_{\max}(P)}.$$

Hence

$$(14) \quad \varrho_{\mathcal{G}} = 1 - \|A\|_{\mathcal{G}} \geq 1 - \left(1 - \frac{\sigma_{\min}(Q)}{\sigma_{\max}(P)} \right)^{1/2}$$

A common technique in state space robust analysis is to obtain robustness bounds from equation (12) [17], [18]. This case can be accommodated by our formalism by recognizing the fact that once P is selected, the system becomes effectively constrained to remain within an hyperellipsoidal region. It has been suggested [17], [18] that good robustness bounds can be obtained from (12) when P is selected such that $Q = I$. In this case our approach yields

$$(15) \quad \varrho_{\mathcal{G}} = 1 - \|A\|_{\mathcal{G}} = 1 - \left(1 - \frac{1}{\sigma_{\max}(P)} \right)^{1/2}$$

which coincides with the robustness bound found by Sezer and Siljak [18].

Example 3 (unstructured perturbation, A semisimple). Consider the case where A is semisimple, i.e.,

$$(16) \quad \begin{aligned} A &= L^{-1} \Lambda L \\ \Lambda &= \text{diag} \left\{ \begin{pmatrix} \sigma_1 & \omega_1 \\ -\omega_1 & \sigma_1 \end{pmatrix}, \dots, \begin{pmatrix} \sigma_p & \omega_p \\ -\omega_p & \sigma_p \end{pmatrix}, \sigma_{p+1}, \dots, \sigma_n \right\}. \end{aligned}$$

Then, the maximum of the stability measure, $\varrho_{\mathcal{G}}$, over all possible positive definite matrices P , is achieved for $P = L'L$.

Proof. The proof follows by noting that $\|A\|_{L'L} = \rho(A)$ where $\rho(\cdot)$ denotes the spectral radius, which is a lower bound for any matrix norm [14]. \square

3.2. Polyhedral constraints. Consider now the case where the region \mathcal{G} is polyhedral, i.e., the case where

$$(17) \quad \mathcal{G} = \{\underline{x}: |G\underline{x}| \leq \underline{\omega}\}$$

where $G \in R^{p \times n}$, $\text{rank}(G) = n$, $\underline{\omega} \in R^p$, $\omega_i > 0$ and the $|\cdot|$ should be interpreted on a component by component sense. Although this case is of practical importance, up to now a technique to estimate the robustness of such systems was unavailable, except perhaps to fit an hyperellipsoidal region within the admissible region and then use some of the bounds available for the quadratic case. Such a technique is clearly inappropriate since it guarantees robust stability *only* in a certain subregion of the region of interest. In this section we show that polyhedral regions fit naturally within our formalism and that in this case $\varrho_{\mathcal{G}}^{\mathcal{N}}$ can be efficiently computed as the minimum of the solution of p linear programming problems.

THEOREM 2. Let $\varrho_i^{\mathcal{N}}$ be the solution of the following optimization problem:

$$(18) \quad \varrho_i^{\mathcal{N}} = \min_{\Delta \in \mathcal{D}} \{\|\Delta\|_{\mathcal{N}}: \|H + \Delta H\|_1^{(i)} \geq 1\}$$

where

$$\begin{aligned} W &= \text{diag}\{w_i\} \\ H &\triangleq W^{-1}GA(G'G)^{-1}G'W \\ \Delta H &\triangleq W^{-1}G\Delta(G'G)^{-1}G'W \end{aligned}$$

and where $\|M\|_1^{(i)}$ indicates the l_1 norm of the i th row of the matrix M . Then

$$(19) \quad \varrho_{\mathcal{G}}^{\mathcal{N}} = \min_{1 \leq i \leq p} \{\varrho_i^{\mathcal{N}}\}.$$

Proof. It is easily shown that

$$(20) \quad \|\underline{x}\|_{\mathcal{G}} = \max_{1 \leq i \leq p} \left\{ \frac{|G\underline{x}|_i}{\omega_i} \right\} = \|W^{-1}G\underline{x}\|_{\infty}.$$

From the definition of H we have that $W^{-1}GA = HW^{-1}G$. Hence

$$\|A\underline{x}\|_{\mathcal{G}} = \|W^{-1}GA\underline{x}\|_{\infty} = \|HW^{-1}G\underline{x}\|_{\infty}$$

and

$$\|A\|_{\mathcal{G}} = \sup_{\|W^{-1}G\underline{x}\|_{\infty}=1} \|A\underline{x}\|_{\mathcal{G}} = \sup_{\|\underline{y}\|_{\infty}=1} \|H\underline{y}\|_{\infty} = \|H\|_{\infty}.$$

Assume that the lemma is false and that there exist $\tilde{\varrho}$ and $\tilde{\Delta}$ such that

$$(21) \quad \|A + \tilde{\Delta}\|_{\mathcal{G}} = 1; \quad \|\tilde{\Delta}\|_{\mathcal{N}} = \tilde{\varrho} < \varrho_{\mathcal{G}}^{\mathcal{N}}.$$

Since $\|A + \tilde{\Delta}\|_{\mathcal{G}} = 1$ there exists i^o such that $\|H + \tilde{\Delta}H\|_1^{(i^o)} = 1$, $\|H + \tilde{\Delta}H\|_1^{(j)} \leq 1$, $j \neq i^o$, but this implies (equation (18)) that $\varrho_{i^o}^{\mathcal{N}} \leq \tilde{\varrho}$, which contradicts (21). \square

Example 4 (unstructured perturbation). Consider the following case:

$$(22) \quad A = \begin{pmatrix} 0.8 & 0.5 \\ -0.0208 & 0.5083 \end{pmatrix} \quad G = \begin{pmatrix} 1.0 & 2.0 \\ -1.5 & 2.0 \end{pmatrix} \quad \underline{\omega} = \begin{pmatrix} 5.0 \\ 10.0 \end{pmatrix}.$$

Then, from the definition of H , we have that

$$(23) \quad H = \begin{pmatrix} 0.7583 & 0.0 \\ -0.2083 & 0.55 \end{pmatrix}, \quad \|A\|_{\mathcal{G}} = 0.7583$$

and, from Theorem 2,

$$(24) \quad \varrho_i = \min_{\|\Delta\|_{\mathcal{G}}} \left\{ \|\Delta\|_{\mathcal{G}} : \sum_{j=1}^2 |H + \Delta|_{ij} = 1 \right\} \quad i = 1, 2.$$

Casting the problems (24) into a linear programming form and solving we have that

$$\varrho_1 = 0.2417, \quad \varrho_2 = 0.2417 \quad \text{and} \quad \varrho_{\mathcal{G}} = \min_{1 \leq i \leq 2} \varrho_i = 0.2417.$$

Note that, in this case, $\varrho_{\mathcal{G}} = 1 - \|A\|_{\mathcal{G}} = 0.2417$ as shown in Lemma 1.

4. Application to robust controllers design. Consider the *linear robust constrained control synthesis problem* introduced in §2.3. Let $p_{\Omega}(u)$ be the Minkowsky gauge for the set Ω and denote by $\|\cdot\|_{\Omega}$ the corresponding norm induced in R^m . It follows that, given a feedback control law of the form $u_k = Fx_k$, the control bounds are satisfied if and only if

$$\|F\|_{\mathcal{G}, \Omega} \triangleq \sup_{\|x\|_{\mathcal{G}} \leq 1} \|Fx\|_{\Omega} \leq 1.$$

Hence, a full state feedback matrix F that solves the synthesis problem can be found solving the following optimization problem:

$$(25) \quad \max_F \{ \varrho_{\mathcal{G}}^{\mathcal{N}}(F) \}$$

subject to

$$(26) \quad \begin{aligned} \varrho_{\mathcal{G}}^{\mathcal{N}}(F) &\triangleq \min_{\Delta \in \mathcal{D}} \{ \|\Delta\|_{\mathcal{N}} : \|A + BF + \Delta\|_{\mathcal{G}} = 1 \} \\ \|F\|_{\mathcal{G}, \Omega} &\leq 1. \end{aligned}$$

Since from Theorem 1, $\varrho_{\mathcal{G}}^{\mathcal{N}}(F)$ is a concave function, and since $\|F\|_{\mathcal{G}, \Omega} \leq 1$ is a convex constraint, it follows that (25) has a global optimum. Hence, the problem of finding the *maximally* robust controller leads to convex, albeit nondifferentiable, optimization problems, which can be solved using a number of techniques [19]. In the remainder of this section, we give several design examples using the proposed technique.

Example 5. Consider the following system:

$$(27) \quad \begin{aligned} A &= \begin{pmatrix} 0 & 1 \\ 0.505 & -0.51 \end{pmatrix} \quad B = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ \mathcal{G} &= \{x : \|x\|_2 \leq 1\}. \end{aligned}$$

The open-loop system has poles at $s_1 = 0.5$ and $s_2 = -1.01$. Assume that the perturbation set is such that it changes the position of the poles while maintaining constant their sum, i.e.,

$$(28) \quad \mathcal{D} = \left\{ \Delta : \Delta = \mu E, \quad E \triangleq \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}, \quad \mu \in \mathbb{R} \right\}.$$

Note that $\|E\|_2 = 1$; hence $\|\Delta\|_2 = |\mu|$.

In this case, the solution to the unconstrained maximally robust control problem can be computed by solving a matrix dilation problem [16]. Rewrite the dynamics matrix as

$$A = \begin{pmatrix} x_1 & x_2 \\ a_1 & a_2 \end{pmatrix},$$

where x_i denote elements that can be modified using state feedback. Since matrix dilations are norm increasing we have that

$$(29) \quad \begin{aligned} \|A + \mu E\|_2 &\geq \max \{ \| \begin{pmatrix} a_1 & a_2 + \mu \end{pmatrix} \|_2 \} \\ &= \sqrt{a_1^2 + (a_2 + \mu)^2}. \end{aligned}$$

Now define:

$$(30) \quad \begin{aligned} \mu^0 &= \operatorname{argmin} \{ |\mu|, \mu \in \mathbb{R}: a_1^2 + (a_2 + \mu)^2 = 1 \} \\ &= \sqrt{(1 - a_1^2)} - |a_2|. \end{aligned}$$

From (29) and (30) it follows that $\|A + \mu^0 E\|_2 \geq 1$ which implies that $\varrho_2(F) \leq \mu^0$ for all F . Furthermore, from the definition of μ^0 it follows that if F is selected such that $x_1 = x_2 = 0$, then $\varrho_2(F) = \mu^0$. Hence, this choice of F yields the solution to the unconstrained problem. In this particular example we have

$$(31) \quad F^o = \begin{pmatrix} 0 & 1 \end{pmatrix}, \quad \varrho_2 = 0.3531.$$

Now consider a feedback matrix F and let A_{cl} be the corresponding *closed-loop* matrix, i.e.,

$$(32) \quad A_{cl} = A + BF = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} + \mu \end{pmatrix}.$$

The corresponding value of the robustness measure can be computed using standard results on matrix dilations [16] as follows: The set Υ of numbers μ such that $\|A_{cl}\|_2 \leq 1$ can be parametrized as

$$(33) \quad \Upsilon = \{ \mu: \mu = -a_{22} - ya_{11}z + (1 - y^2)^{1/2}w(1 - z^2)^{1/2} \}$$

where

$$(34) \quad \begin{aligned} y &= \frac{a_{21}}{(1 - a_{11}^2)^{1/2}} \\ z &= \frac{a_{12}}{(1 - a_{11}^2)^{1/2}} \\ w &\in \mathbb{R}, |w| \leq 1. \end{aligned}$$

From (33) it follows that the constrained stability margin of A_{cl} is given by

$$\varrho_2(F) = |a_{22} + ya_{11}z - (1 - y^2)^{1/2}(1 - z^2)^{1/2}\operatorname{sign}(a_{22} + ya_{11}z)|.$$

FIG 1. Robustness vs. control effort for Example 5.

Figure 1 shows $\rho_2(F)$ versus $\|F\|_2$, the norm of the solution to (25). For $\|F\|_2 = 1$, we recover the unconstrained solution, for $\|F\|_2 = 0.1850$, we get the minimum control effort capable of stabilizing (in the constrained sense) the nominal system. Note the trade-off between control effort and robustness. In particular, there exist a region where the curve is flat, i.e., the control effort can be reduced while essentially maintaining the same robustness obtained with a “maximum robustness” type design.

Example 6 (polyhedral constraints, unstructured perturbation). Consider the following system:

$$\begin{aligned}
 A &= \begin{pmatrix} 0.8 & 0.5 \\ -0.4 & 1.2 \end{pmatrix} & B &= \begin{pmatrix} 0 \\ 1 \end{pmatrix} \\
 G &= \begin{pmatrix} 1.0 & 2.0 \\ -1.5 & 2.0 \end{pmatrix} & \underline{\omega} &= \begin{pmatrix} 5.0 \\ 10.0 \end{pmatrix} & \Omega &= \{u: |u| \leq \gamma\}.
 \end{aligned}
 \tag{35}$$

Since the constraint sets \mathcal{G} and Ω are polyhedral, the synthesis problem can be cast in the following format:

$$\min_F \epsilon$$

subject to

$$\begin{aligned}
 \|A + BF\|_{\mathcal{G}} &\leq \epsilon \\
 \|F\|_{\mathcal{G}, \Omega} &\leq 1,
 \end{aligned}$$

which can be transformed into an LP problem and solved using the simplex method. Note that a similar design algorithm was proposed by Vassilaki, Hennet, and Bitsoris [20], although in their case the goal was to find admissible linear controllers for systems under polyhedral constraints without taking into account robustness considerations. Figure 2 shows the constrained robustness measure versus γ , the bound on the control effort. Note that the minimum control effort required to stabilize the system is $\gamma = 2.6$.

5. Conclusions. Most realistic control problems involve both some type of time-domain constraints and a certain degree of model uncertainty. However, the majority

FIG 2. Robustness vs. control effort for example 6.

of control design methods currently available focus only on one aspect of the problem. Following the spirit of [6], [7], in this paper we proposed to approach time-domain constraints using an operator norm induced by the constraints to assess the stability properties of a family of systems. Specifically, in §2 we introduced a robustness measure that indicates how well the family of systems under consideration satisfies a given set of constraints. In §3 we explored the properties of this robustness measure for the case of additive parametric model uncertainty and we showed that our formalism provides a generalization of the well-known technique of estimating robustness bounds from the solution of a Lyapunov equation. We then proposed, in §4, a synthesis procedure for fixed-order controllers, based upon maximization of the robustness measure subject to additional performance constraints such as bounds on the control effort. There we showed that the proposed design procedure leads to a convex optimization problem. We believe that the results presented here will provide a valuable new approach to the problems of robust controllers analysis and design for linear systems. Furthermore, since our approach is based purely upon time-domain analysis, we have reason to believe the theory could be extended to encompass nonlinear systems in a much more direct fashion than other currently used techniques.

Perhaps the more severe limitation of the theory in its present form arises from the fact that the incorporation of additional performance constraints, of the form of a bound on the norm of a relevant transfer function, results in nonconvex optimization problems. We are currently looking into a solution to this problem by using an observer-based parametrization of all stabilizing controllers. It is expected that this formulation will be able to handle more general performance constraints as well as dynamic uncertainty, at the price of resulting in higher-order controllers.

Appendix A. Proof of Theorem 1. We begin by introducing two preliminary results.

LEMMA 2. Consider the system (S^a) . Assume that the perturbation set \mathcal{D} is a closed cone with vertex at the origin [10], i.e., $\Delta^o \in \mathcal{D} \iff \alpha \Delta^o \in \mathcal{D}$ for all $0 \leq \alpha$ and that (S^a) is constraint stable (i.e., $\|A\|_G < 1$). Let

$$(A1) \quad \Delta^o = \operatorname{argmin}_{\Delta \in \mathcal{D}} \{ \|\Delta\|_{\mathcal{N}} : \|A + \Delta\|_G = 1 \}$$

and consider a sequence $A^i \rightarrow A$ such that $\|A^i\|_G < 1$. Finally, define the sequence λ^i

as

$$(A2) \quad \lambda^i = \min_{\lambda \in \mathbb{R}^+} \{ \lambda : \|A^i + \lambda \Delta^o\|_{\mathcal{G}} = 1 \}.$$

Then the sequence λ^i has an accumulation point at one.

Proof. Since $\|A^i\|_{\mathcal{G}} < 1$ and since \mathcal{D} is a closed cone, it follows that λ^i is well defined. Furthermore, from (A2) it follows that

$$(A3) \quad \lambda^i \leq \frac{1 + \|A^i\|_{\mathcal{G}}}{\|\Delta^o\|_{\mathcal{G}}} \leq \frac{2}{\|\Delta^o\|_{\mathcal{G}}}.$$

Hence, from Bolzano–Weierstrass’ theorem [21] it follows that λ^i has an accumulation point $\tilde{\lambda}$ and that there exists a subsequence $\tilde{\lambda}^i \rightarrow \tilde{\lambda}$. Hence

$$\|A^i + \tilde{\lambda}^i \Delta^o\|_{\mathcal{G}} = 1,$$

and since $A^i \rightarrow A$ then

$$(A4) \quad \|A + \tilde{\lambda} \Delta^o\|_{\mathcal{G}} = 1.$$

Assume that $\tilde{\lambda} < 1$ and let $\hat{\Delta} \triangleq \tilde{\lambda} \Delta^o$. Then $\|\hat{\Delta}\|_{\mathcal{N}} < \|\Delta^o\|_{\mathcal{N}}$, $\|A + \hat{\Delta}\|_{\mathcal{G}} = 1$, and $\hat{\Delta} \in \mathcal{D}$ (since \mathcal{D} is a cone) which contradicts (A1). Now assume that $\tilde{\lambda} > 1$. Then, for i large enough, $\tilde{\lambda}^i > 1$, which together with (A2) implies that

$$(A5) \quad \|A^i + \Delta^o\|_{\mathcal{G}} < 1$$

and hence:

$$(A6) \quad \|A + \Delta^o\|_{\mathcal{G}} < 1,$$

which contradicts (A1). Therefore $\tilde{\lambda} = 1$. \square

LEMMA 3. Let $\rho_1 > 0, \rho_2 > 0$ and $0 \leq \lambda \leq 1$ be given numbers and assume that \mathcal{D} is a cone with vertex at the origin. Consider the following sets:

$$(A7) \quad \begin{aligned} \rho_1 B\Delta &= \{\Delta \in \mathcal{D} : \|\Delta\|_{\mathcal{N}} \leq \rho_1\} \\ \rho_2 B\Delta &= \{\Delta \in \mathcal{D} : \|\Delta\|_{\mathcal{N}} \leq \rho_2\} \\ \rho B\Delta &= \{\Delta \in \mathcal{D} : \|\Delta\|_{\mathcal{N}} \leq \rho \triangleq \lambda \rho_1 + (1 - \lambda) \rho_2\}. \end{aligned}$$

Then

$$\rho B\Delta \subseteq \lambda \rho_1 B\Delta + (1 - \lambda) \rho_2 B\Delta.$$

Proof. Consider any $\Delta^o \in \rho B\Delta$. Then

$$(A8) \quad \begin{aligned} \Delta^o &= \frac{\|\Delta^o\|_{\mathcal{N}}}{\rho} \left[\frac{\rho \Delta^o}{\|\Delta^o\|_{\mathcal{N}}} \right] \\ &= \frac{\|\Delta^o\|_{\mathcal{N}}}{\rho} \left[\lambda \rho_1 \frac{\Delta^o}{\|\Delta^o\|_{\mathcal{N}}} + (1 - \lambda) \rho_2 \frac{\Delta^o}{\|\Delta^o\|_{\mathcal{N}}} \right] \\ &= [\lambda \Delta_1 + (1 - \lambda) \Delta_2] \end{aligned}$$

where

$$\begin{aligned}
 \Delta_1 &= \alpha \rho_1 \frac{\Delta^o}{\|\Delta^o\|_{\mathcal{N}}} \\
 \Delta_2 &= \alpha \rho_2 \frac{\Delta^o}{\|\Delta^o\|_{\mathcal{N}}} \\
 \alpha &= \frac{\|\Delta^o\|_{\mathcal{N}}}{\rho} \leq 1.
 \end{aligned}
 \tag{A9}$$

The proof is completed by noting that from (A9) and the hypothesis it follows that $\Delta_1 \in \rho_1 B\Delta$ and $\Delta_2 \in \rho_2 B\Delta$. \square

Proof of Theorem 1. Assume that $\varrho_{\mathcal{G}}^{\mathcal{N}}$ is not continuous. Then, given $\epsilon > 0$, for every $\delta > 0$ there exist A_δ such that $\|A_\delta - A\|_{\mathcal{G}} \leq \delta$ and $|\varrho_{\mathcal{G}}^{\mathcal{N}}(A_\delta) - \varrho_{\mathcal{G}}^{\mathcal{N}}| > \epsilon$. Hence there exist a sequence $A^i \rightarrow A$ such that $\varrho_{\mathcal{G}}^{\mathcal{N}^i} \not\rightarrow \varrho_{\mathcal{G}}^{\mathcal{N}}$. Furthermore, it is easily seen that the sequence $\varrho_{\mathcal{G}}^{\mathcal{N}^i}$ is bounded and therefore it contains a convergent subsequence. It follows that there exists a sequence $A^i \rightarrow A$ such that $\varrho_{\mathcal{G}}^{\mathcal{N}^i} \rightarrow \tilde{\varrho} \neq \varrho_{\mathcal{G}}^{\mathcal{N}}$. Let

$$\Delta^i = \operatorname{argmin}_{\Delta \in \mathcal{D}} \{\|\Delta\|_{\mathcal{N}} : \|A^i + \Delta\|_{\mathcal{G}} = 1\}.
 \tag{A10}$$

From (A10) it follows that $\|\Delta^i\|_{\mathcal{G}} \leq 1 + \|A^i\|_{\mathcal{G}}$. It follows then that the sequence Δ^i is bounded and therefore, since $R^{n \times n}$ with a finite-dimensional matrix norm is complete and since \mathcal{D} is a closed set, it has an accumulation point $\tilde{\Delta}$ (Bolzano–Weierstrass) and a convergent subsequence $\tilde{\Delta}^i \rightarrow \tilde{\Delta}$ such that $\|A + \tilde{\Delta}\|_{\mathcal{G}} = 1$. Furthermore, from the definition of Δ^o it follows that

$$\tilde{\varrho} = \|\tilde{\Delta}\|_{\mathcal{N}} > \|\Delta^o\|_{\mathcal{N}} = \varrho_{\mathcal{G}}^{\mathcal{N}}.
 \tag{A11}$$

Hence, for i large enough,

$$\|\tilde{\Delta}^i\|_{\mathcal{N}} > \|\Delta^o\|_{\mathcal{N}}.
 \tag{A12}$$

Applying Lemma 3, we have that there exists a sequence $\lambda^i \rightarrow 1$ such that

$$\lambda^i = \min_{\lambda \in \mathbb{R}^+} \{\lambda : \|A^i + \lambda \Delta^o\|_{\mathcal{G}} = 1\}.
 \tag{A13}$$

From (A12), and since $\lambda^i \rightarrow 1$, it follows that for i large enough

$$\begin{aligned}
 \|\lambda^i \Delta^o\|_{\mathcal{N}} &< \|\tilde{\Delta}^i\|_{\mathcal{N}} \\
 \|A^i + \lambda^i \Delta^o\|_{\mathcal{G}} &= 1
 \end{aligned}
 \tag{A14}$$

and, since \mathcal{D} is a cone, $\lambda^i \Delta^o \in \mathcal{D}$, which contradicts (A10). The proof is completed by noting that since all finite-dimensional matrix norms are equivalent [14]; then continuity in the $\|\cdot\|_{\mathcal{G}}$ norm implies continuity in any other norm defined over $R^{n \times n}$. \square

To prove concavity, start by considering a convex linear combination $A = \lambda A_1 + (1 - \lambda)A_2$, $\lambda \leq 1$ of given matrices A_1 and A_2 . Then, from Lemma 4 it follows that

$$\begin{aligned}
 \max_{\Delta \in \rho B\Delta} \|A + \Delta\|_{\mathcal{G}} &\leq \max_{\substack{\Delta_1 \in \rho_1 B\Delta \\ \Delta_2 \in \rho_2 B\Delta}} \|\lambda(A_1 + \Delta_1) + (1 - \lambda)(A_2 + \Delta_2)\|_{\mathcal{G}} \\
 &\leq \lambda \max_{\Delta_1 \in \rho_1 B\Delta} \|A_1 + \Delta_1\|_{\mathcal{G}} + (1 - \lambda) \max_{\Delta_2 \in \rho_2 B\Delta} \|A_2 + \Delta_2\|_{\mathcal{G}}.
 \end{aligned}
 \tag{A15}$$

Now consider the case where $\rho_1 = \varrho_G^N(A_1)$ and $\rho_2 = \varrho_G^N(A_2)$. Then it follows from the definition of ϱ_G^N that both maximizations in the right-hand side of (A15) yield one and therefore:

$$(A16) \quad \max_{\Delta \in \rho B \Delta} \|A + \Delta\|_G \leq 1.$$

Hence, from the definition of ϱ_G^N ,

$$\varrho_G^N[\lambda A_1 + (1 - \lambda)A_2] \geq \varrho = \lambda \varrho_G^N(A_1) + (1 - \lambda) \varrho_G^N(A_2). \quad \square$$

THE FOUR-BLOCK MODEL MATCHING PROBLEM IN l^1 AND INFINITE-DIMENSIONAL LINEAR PROGRAMMING*

OLOF J. STAFFANS†

Abstract. The purpose of this work is fourfold. First the reader is introduced to the present state of the theory behind the solution of the general model matching problem in l^1 . This solution is based on the fact that the model matching problem can be recast as an infinite-dimensional linear programming problem. However, the transformation into linear programming form is highly nonunique, which leads to the second question of discussion, namely, how to find a “good” linear programming formulation. It is shown that the presently available formulations contain some redundancies that limit the applicability of the theory and lead to linear programming systems containing unnecessary degeneracies. The third object of this work is to study problems related to the computational complexity of two different approximation methods for the solution of the infinite-dimensional linear programming systems. Both of these methods are needed in order to get two-sided error bounds on the cutoff error. One complication is that even after the extra redundancies that were mentioned above have been removed, there are certain multi-output problems that contain a massive intrinsic degeneracy. Finally, the convergence properties of the two solution schemes are investigated, and it is explained which properties of the original linear programming formulation are needed for different types of convergence.

Key words. infinite-dimensional linear programming, l^1 -optimal control

1. Introduction. The standard discrete model matching problem in control theory can be formulated as follows: Three different sequences of matrices with real entries, $\{H(k)\}_{k=0}^\infty$, $\{U(k)\}_{k=0}^\infty$, and $\{V(k)\}_{k=0}^\infty$ are given. The dimensions of H , U , and V are $m \times n$, $m \times p$, and $q \times n$, respectively. The problem is to find a sequence of matrices $\{Q(k)\}_{k=0}^\infty$, of dimension $p \times q$, in such a way that the norm of

$$(1) \quad \Phi = H - K = H - U * Q * V$$

is as small as possible. Here $K = U * Q * V$ is the convolution of U , Q , and V , given by

$$(U * Q * V)(k) = \sum_{i=0}^k U(k-i) \sum_{j=0}^i Q(i-j)V(j), \quad k \geq 0.$$

This problem arises in several different situations; see, e.g., the discussion in [6].

The norm of Φ that we want to minimize is the operator norm of Φ , regarded as an operator from one space to another. Let X be the space of sequences of n -dimensional vectors $\{x(k)\}_{k=0}^\infty$, and let Y be the space of sequences of m -dimensional vectors $\{y(k)\}_{k=0}^\infty$. Then Φ induces a convolution operator from X into Y defined by

$$y(k) = (\Phi * x)(k) = \sum_{i=0}^k \Phi(k-i)x(i).$$

If we give both X and Y the l^2 -norm (the energy norm), then the operator norm of Φ , i.e., the norm

$$\|\Phi\| = \sup_{\|x\| \leq 1} \|\Phi * x\|,$$

is given by the H^∞ norm of Φ , and in this case the problem is referred to as the H^∞ minimization problem. If we instead give both X and Y the l^∞ -norm (the supremum norm), then the norm of $\Phi = \{\Phi_{ij}(k)\}_{k=0}^\infty$ is given by

$$(2) \quad \|\Phi\|_{l^1} = \max_{i \in \{1, \dots, m\}} \sum_{j=1}^n \sum_{k=0}^\infty |\Phi_{ij}(k)|.$$

This case is usually referred to as the l^1 -minimization problem, and this is the one that we shall consider here. The standard assumptions on H , U , and V are that they belong to l^1 , i.e., their l^1 -norms defined as in (2) (with m and n replaced by the appropriate dimensions) are finite. Also the free parameter Q is required to belong to l^1 . Thus, we want to solve the following problem:

$$(OPT) \quad \begin{array}{l} \text{minimize } \|\Phi\|_{l^1} \text{ over all } \Phi \text{ of the form } \Phi = H - U * Q * V \text{ where } Q \in l^1 \\ \text{and } \|\Phi\|_{l^1} \text{ is given by (2).} \end{array}$$

For any l^1 -function Φ we define the \mathcal{Z} -transform $\hat{\Phi}$ of Φ by

$$\hat{\Phi}(z) = \sum_{k=0}^\infty \Phi(k) z^k.$$

Throughout we denote \mathcal{Z} -transforms as above, i.e., a hat on a symbol representing a sequence in l^1 stands for the \mathcal{Z} -transform of this sequence. The \mathcal{Z} -transforms are analytic in the open unit disk D , and continuous on the closed unit disk \overline{D} . Moreover, the \mathcal{Z} -transform converts convolutions into pointwise multiplications. Thus, the \mathcal{Z} -transform applied to (1) gives

$$(3) \quad \hat{\Phi}(z) = \hat{H}(z) - \hat{K}(z) = \hat{H}(z) - \hat{U}(z)\hat{Q}(z)\hat{V}(z), \quad z \in \overline{D}.$$

Frequently we assume that the matrix functions \hat{H} , \hat{U} , and \hat{V} are (stable) rational functions. In the approach that we use this is not important; it is enough to assume that they belong to l^1 , i.e., they are \mathcal{Z} -transforms of l^1 -sequences. Observe, however, that our \mathcal{Z} -transforms have entries that are real for real z .

Throughout we shall make the following assumption.

Assumption 1.1. The rank of the matrices $\hat{U}(z)$ and $\hat{V}(z)$ are constant on the unit circle $|z| = 1$.

It is known that without this assumption the problem that we consider here does not, in general, have a minimizer Φ ; some examples with boundary zeros where no minimizers exist are given in [17].

The outline of this paper is as follows. In §2 we show that we may, without loss of generality, assume that $\hat{U}(z)$ has full column rank and $\hat{V}(z)$ has full row rank for all but finitely many $z \in D$. Let us assume that this is the case. Then

$$m \geq p \quad \text{and} \quad n \geq q.$$

If $m = p$ and $n = q$ then the problem is called a *one-block problem*. If one of the inequalities above is strict but not the other it is called a *two-block problem*. If both inequalities are strict it is a *four-block problem*. We use the common name *multiblock problem* for the two-block and four-block problems.

In §§3 and 4 we describe the set of all functions $\hat{K} \in \hat{l}^1$ that are of the form $\hat{K} = \hat{U}\hat{Q}\hat{V}$ for some $\hat{Q} \in \hat{l}^1$, i.e., we give a frequency domain description of the range of the operator $\hat{Q} \mapsto \hat{U}\hat{Q}\hat{V}$. Our formulation differs from the one in [10] in two respects: we have removed the redundancies appearing in the equations in [10], as well as one extra nonstandard hypothesis that limits the applicability of the results of [10] to the four-block case. In particular, in the one-block case we are able to identify the exact number of equations that are needed to describe the problem.

In §§5 and 6 we construct an operator whose null-space equals the range of the mapping $Q \mapsto U * Q * V$, and show how we may reformulate the problem as an infinite-dimensional linear programming problem in l^1 . We also present the corresponding dual infinite-dimensional linear programming problems in l^∞ and c^0 . These formulations are quite different in the one-block case and in the multiblock case. In the one-block case only finitely many constraints are needed, and the problem is semifinite (infinitely many variables, but only finitely many constraints). In the multiblock case there are infinitely many variables and infinitely many constraints.

In §7 we describe the standard alignment conditions between an optimal solution of the primal system and an optimal solution of the dual system.

Two different methods to solve the infinite-dimensional linear programming problems are described in §8. The solution of the one-block problem is quite simple compared to the solution of the multiblock problem. In [5] and [10] a solution method for the general case is described, which is based on an iterative procedure where we restrict the number of variables that is allowed to be nonzero, and gradually increase this number. An alternative approach was presented in [3], and independently in [14], where we instead ignore all but finitely many of the constraints, and gradually add more and more constraints. For the one-block problem the two methods are equivalent, and they both give the optimal solution in a finite number of iterations. However, when they are applied to the multiblock problem they give different results, one of them giving upper bounds on the optimum and the other giving lower bounds. As it was pointed out in [3] and [14], when the two methods are combined we get both upper and lower bounds, and we can compute the solution to within any specified accuracy.

The next three sections are devoted to a study of some computational aspects of the two solution methods, and to their convergence properties. The alternative approach mentioned above is especially interesting because it seems to work quite well in many cases, but there is a problem related to the computational complexity of this method. This problem is discussed in §9, and some solutions are proposed.

For the solutions mentioned to work it is crucial that the solution methods have certain convergence properties; it is not enough that the optima of the truncated problems converge to the optimum of the full problem. In addition some of the variables used in the formulation of the problem must converge. We take a closer look at the convergence properties of the two different solution methods in §§10 and 11.

The alternative approach has another drawback: it does not directly produce suboptimal solutions of the original problem. Still, as we show in §12, it is, in general, also possible to find suboptimal solutions in this case.

We shall use the following notation (some of this notation was already introduced

and is similar to that in, e.g., [10]).

$\langle x, x^* \rangle$	The value of the bounded functional x^* evaluated at x .
X^*	The dual of the Banach space X , with norm $\ x^*\ = \sup_{\ x\ \leq 1} \langle x, x^* \rangle$.
S^\perp	The (right) annihilator of $S \subset X$; $S^\perp = \{x^* \in X^* \mid \langle x, x^* \rangle = 0 \text{ for all } x \in S\}$. This set is weak* closed in X^* . Note that $S^\perp \subset X^*$.
${}^\perp S$	The (left) annihilator of $S \subset X^*$; ${}^\perp S = \{x \in X \mid \langle x, x^* \rangle = 0 \text{ for all } x^* \in S\}$. This set is (weakly and strongly) closed in X . Note that ${}^\perp S \subset X$.
$l_{m \times n}^1$	The set of summable $m \times n$ matrix valued sequences H , with norm $\ H\ _{l^1} = \max_{i \in \{1, \dots, m\}} \sum_{j=1}^n \sum_{k=0}^\infty H_{ij}(k) $. This is the dual of $c_{m \times n}^0$, with duality mapping $\langle x, x^* \rangle = \sum_{i,j,k} x_{ij}(k) x_{ij}^*(k)$.
$l_{m \times n}^\infty$	The set of bounded $m \times n$ matrix valued sequences H , with norm $\ H\ _{l^\infty} = \sum_{i=1}^m \sup_{1 \leq j \leq n, k \geq 0} H_{ij}(k) $. This is the dual of $l_{m \times n}^1$, with duality mapping $\langle x, x^* \rangle = \sum_{i,j,k} x_{ij}(k) x_{ij}^*(k)$.
$c_{m \times n}^0$	The closed subset of $l_{m \times n}^\infty$ of sequences H satisfying $ H(k) \rightarrow 0$ as $k \rightarrow \infty$.
D, \overline{D}	The open and closed unit disks in the complex plane, respectively.
\hat{H}	The \mathcal{Z} -transform of a function $H \in l_{m \times n}^1$; $\hat{H}(z) = \sum_{k=0}^\infty H(k) z^k$. It is analytic in D and continuous on \overline{D} .
$\hat{l}_{m \times n}^1$	The space of all \mathcal{Z} -transforms of functions in $l_{m \times n}^1$.
A^*	The adjoint of a continuous operator A mapping X into Y ; it maps Y^* into X^* .
$\mathcal{D}(A)$	Domain of the operator A .
$\mathcal{R}(A)$	Range of the operator A .

Recall that $\mathcal{N}(A) = {}^\perp \mathcal{R}(A^*)$, that $\mathcal{N}(A^*) = \mathcal{R}(A)^\perp$, that $\mathcal{N}(A)^\perp$ is the weak* closure of $\mathcal{R}(A^*)$, and that ${}^\perp \mathcal{N}(A^*)$ is the closure of $\mathcal{R}(A)$; see, e.g., [12, pp. 90–94].

2. Reduction of the dimension of the free parameter. We claim that it is almost always possible to assume, without loss of generality, that $\hat{U}(z)$ has full column rank and $\hat{V}(z)$ has full row rank for all but finitely many $z \in D$. To show this we decompose \hat{U} and \hat{V} into their Smith forms

$$(4) \quad \hat{U}(z) = \hat{L}_U(z) \hat{M}_U(z) \hat{R}_U(z), \quad \hat{V}(z) = \hat{L}_V(z) \hat{M}_V(z) \hat{R}_V(z).$$

Here \hat{L}_U , \hat{R}_U , \hat{L}_V , and \hat{R}_V are square matrices of the appropriate dimensions, belonging to \hat{l}^1 , and they have inverses that belong to \hat{l}^1 , also. The matrices \hat{M}_U and \hat{M}_V have the same dimensions as \hat{U} and \hat{V} , respectively, and they are of the form

$$(5) \quad \hat{M}_U = \begin{pmatrix} \hat{N}_U & 0 \\ 0 & 0 \end{pmatrix}, \quad \hat{M}_V = \begin{pmatrix} \hat{N}_V & 0 \\ 0 & 0 \end{pmatrix},$$

where the bordering zero matrices may be absent depending on the ranks of \hat{U} and \hat{V} , and \hat{N}_U and \hat{N}_V are diagonal matrices whose ranks at each point are the same as the ranks of the matrices \hat{U} and \hat{V} . In particular, by Assumption 1.1, the rank of $\hat{N}_U(z)$ and $\hat{N}_V(z)$ are constant on the unit circle $|z| = 1$. That such a decomposition exists for stable real rational matrices is well known, (see, e.g., [16, Thm. 29, p. 404]),

and in this case all the matrices will be stable real rational. It is also true in the case where \widehat{U} and \widehat{V} are analytic in a neighborhood of \overline{D} . However, it does not seem to be known whether the corresponding result for arbitrary ℓ^1 -valued matrices satisfying Assumption 1.1 is true. It is true if \widehat{U} and \widehat{V} have either full row rank or full column rank; this can be proved by modifying the argument in [8]. Therefore, in the case where \widehat{U} and \widehat{V} are ℓ^1 -valued we shall simply assume that the following assumption holds (we conjecture that this assumption is redundant).

Assumption 2.1. The matrices $\widehat{U}(z)$ and $\widehat{V}(z)$ have Smith factorizations of the form (4).

Let us proceed, taking Assumption 2.1 for granted. Since \widehat{R}_U and \widehat{L}_V are invertible ℓ^1 square matrices, they can be absorbed into \widehat{Q} (there is a one-to-one correspondence between \widehat{Q} and $\widehat{R}_U \widehat{Q} \widehat{L}_V$ in ℓ^1), and hence we may, without loss of generality, assume that \widehat{K} is of the form

$$(6) \quad \widehat{K} = \widehat{L}_U \widehat{M}_U \widehat{Q} \widehat{M}_V \widehat{R}_V.$$

If we partition \widehat{L}_U , \widehat{Q} , and \widehat{R}_V conformally with the partitions of \widehat{M}_U and \widehat{M}_V given above into

$$(7) \quad \widehat{L}_U = \begin{pmatrix} \widehat{L}_{U,1} & \widehat{L}_{U,2} \end{pmatrix}, \quad \widehat{Q} = \begin{pmatrix} \widehat{Q}_{11} & \widehat{Q}_{12} \\ \widehat{Q}_{21} & \widehat{Q}_{22} \end{pmatrix}, \quad \widehat{R}_V = \begin{pmatrix} \widehat{R}_{V,1} \\ \widehat{R}_{V,2} \end{pmatrix},$$

then we can write \widehat{K} in the form

$$(8) \quad \begin{aligned} \widehat{K} &= \begin{pmatrix} \widehat{L}_{U,1} & \widehat{L}_{U,2} \end{pmatrix} \begin{pmatrix} \widehat{N}_U & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \widehat{Q}_{11} & \widehat{Q}_{12} \\ \widehat{Q}_{21} & \widehat{Q}_{22} \end{pmatrix} \begin{pmatrix} \widehat{N}_V & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \widehat{R}_{V,1} \\ \widehat{R}_{V,2} \end{pmatrix} \\ &= \widehat{L}_{U,1} \widehat{N}_U \widehat{Q}_{1,1} \widehat{N}_V \widehat{R}_{V,1}. \end{aligned}$$

In this new representation the left multiplier $\widehat{L}_{U,1} \widehat{N}_U$ has full column rank and the right multiplier $\widehat{N}_V \widehat{R}_{V,1}$ has full row rank on the unit circle $|z| = 1$. Since they are analytic in the open unit disk D , it must be true that $\widehat{L}_{U,1} \widehat{N}_U$ has full column rank and $\widehat{N}_V \widehat{R}_{V,1}$ has full row rank in all but finitely many points in D . This proves our claim that we may almost, without loss of generality, assume that \widehat{U} has full column rank and that \widehat{V} has full row rank for all but finitely many $z \in \overline{D}$, and that none of the exceptional points lie on the unit circle $|z| = 1$. In particular, (5) becomes

$$(9) \quad \widehat{M}_U = \begin{pmatrix} \widehat{N}_U \\ 0 \end{pmatrix}, \quad \widehat{M}_V = \begin{pmatrix} \widehat{N}_V & 0 \end{pmatrix}.$$

As we shall see in (15), after the reduction of the dimension of Q described above has been carried out, Q is uniquely determined by K . This fact is important in the formulation of the model matching problem as an infinite-dimensional linear programming problem, and especially so in the multiblock case. In the general case we can solve Q , using the formulas above, as a unique function of K , $Q_{1,2}$, $Q_{2,1}$ and $Q_{2,2}$, where the last three are free parameters.

The reduction that we have described above is not always carried out in the one-block case; see, e.g., the discussion of the one-block case in [10].

3. Frequency domain formulation: Interpolation constraints. The model matching problem described can be formulated as a linear programming problem in

l^1 . The first step in this formulation is to construct a set of conditions that describe the class of all possible \mathcal{Z} -transforms \hat{K} in \hat{l}^1 that we get when Q varies over l^1 . Such descriptions are given in [4], [5], and [10]. However, since there are some redundancies in these descriptions, and since these redundancies have some nontrivial consequences for the main results of this paper, we prefer to give a slightly different formulation. Our formulation is an extension to the full multivariable case of the formulations in [14] and [15].

There is a set of necessary and sufficient conditions on a function $\hat{K} \in \hat{l}^1$ in order for it to be of the form $\hat{K} = \hat{U}\hat{Q}\hat{V}$ for some $\hat{Q} \in \hat{l}^1$. This set of conditions is simpler in the one-block case (the case where $n = p$ and $q = m$) than in the multiblock case. In the one-block case they consist of a finite number of “interpolation constraints,” and in the multiblock case we need both interpolation constraints and “convolution constraints.” We begin with a description of the former type of constraints. In the one-block case our description will be the same as one of the two alternative descriptions given in [10]. It is based on the Smith decompositions of \hat{U} and \hat{V} .

We begin our construction by partitioning the inverses of \hat{L}_U and \hat{R}_V into

$$(10) \quad \hat{L}_U^{-1} = \begin{pmatrix} \hat{U}_0 \\ \hat{U}_1 \end{pmatrix}, \quad \hat{R}_V^{-1} = \begin{pmatrix} \hat{V}_0 & \hat{V}_1 \end{pmatrix},$$

where the size of the different matrices correspond to the sizes of the matrices in (9), i.e., the dimensions of \hat{U}_0 and \hat{V}_0 are $p \times m$ and $n \times q$, respectively. Observe that the matrices \hat{U}_1 and \hat{V}_1 are absent in the one-block case, i.e., in this case $\hat{U}_0 = \hat{L}_U^{-1}$ and $\hat{V}_0 = \hat{R}_V^{-1}$. Multiply the identity $\hat{K} = \hat{L}_U \hat{M}_U \hat{R}_U \hat{Q} \hat{L}_V \hat{M}_V \hat{R}_V$ from the left by \hat{U}_0 and from the right by \hat{V}_0 to get (see (9))

$$(11) \quad \hat{U}_0 \hat{K} \hat{V}_0 = \hat{N}_U \hat{R}_U \hat{Q} \hat{L}_V \hat{N}_V.$$

This equation can be further analyzed as follows. Recall that \hat{N}_U and \hat{N}_V are diagonal matrices, i.e., $\hat{N}_U = \text{diag}(\hat{d}_{U,1}, \dots, \hat{d}_{U,m})$ and $\hat{N}_V = \text{diag}(\hat{d}_{V,1}, \dots, \hat{d}_{V,n})$. Partition \hat{U}_0 and \hat{V}_0 into sets of m row vectors and n column vectors, respectively, as

$$\hat{U}_0 = \begin{pmatrix} \hat{\alpha}_1 \\ \vdots \\ \hat{\alpha}_m \end{pmatrix} \quad \hat{V}_0 = \begin{pmatrix} \hat{\beta}_1 & \dots & \hat{\beta}_n \end{pmatrix}.$$

Then (11) becomes

$$(12) \quad \hat{\alpha}_i \hat{K} \hat{\beta}_j = \hat{d}_{U,i} \hat{q}_{i,j} \hat{d}_{V,j}, \quad i \in \{1, \dots, m\}, \quad j \in \{1, \dots, n\},$$

where $\hat{q}_{i,j}$ is the ij th element of $\hat{R}_U \hat{Q} \hat{L}_V$. Denote the set of all zeros of all different functions $\hat{d}_{U,i}$ and $\hat{d}_{V,j}$ in D by \mathcal{Z}_{UV} , and for each $z_0 \in \mathcal{Z}_{UV}$, let $\sigma_{U,i}(z_0)$ and $\sigma_{V,j}(z_0)$ denote the order of the zero of $\hat{d}_{U,i}$ and $\hat{d}_{V,j}$ at z_0 , respectively (we define $\sigma_{U,i}(z_0) = 0$ if $\hat{d}_{U,i}(z_0) \neq 0$, and $\sigma_{V,j}(z_0) = 0$ if $\hat{d}_{V,j}(z_0) \neq 0$).

From formula (12), together with the notations that we introduced, the following theorem follows more or less immediately (apart from the uniqueness and continuity claims, this is [10, Lem. 1]; these claims are not valid in [10, Lem. 1] due to the fact that there the reduction of §2 was not carried out).

THEOREM 3.1. *Given \hat{K} , \hat{U} , and \hat{V} in \hat{l}^1 of the type described above (i.e., we are in the one-block case, the dimensions are $m \times n$, $m \times m$, and $n \times n$, respectively,*

Assumption 1.1 is satisfied, and \widehat{U} and \widehat{V} have full rank in all but finitely many points in D), there is a unique function $\widehat{Q} \in \hat{l}^1$ such that $\widehat{K} = \widehat{U}\widehat{Q}\widehat{V}$ if and only if for all $z_0 \in \mathcal{Z}_{UV}$, all $i \in \{1, \dots, m\}$, and all $j \in \{1, \dots, n\}$

$$(13) \quad (\hat{\alpha}_i \widehat{K} \hat{\beta}_j)^{(r)}(z_0) = 0, \quad r \in \{0, \dots, \sigma_{U,i}(z_0) + \sigma_{V,j}(z_0) - 1\}.$$

Moreover, both the mapping $\widehat{Q} \mapsto \widehat{K} = \widehat{U}\widehat{Q}\widehat{V}$ and its inverse $\widehat{K} \mapsto \widehat{Q} = [\widehat{U}]^{-1}\widehat{K}[\widehat{V}]^{-1}$ are continuous.

Here (13) is considered to be vacuously satisfied if $\sigma_{U,i}(z_0) = \sigma_{V,j}(z_0) = 0$, i.e., if $\hat{d}_{U,i}(z_0) \neq 0$ and $\hat{d}_{V,j}(z_0) \neq 0$.

Proof. That (13) is a necessary condition is obvious from (12), and that it is sufficient follows from the discrete version of [7, Prop. 2.3].

Clearly, the operator that takes $Q \in l_{m \times n}^1$ into $U * Q * V \in l_{m \times n}^1$ is continuous. We have just characterized its range as the set of all functions in $l_{m \times n}^1$ that satisfy (13). This set of functions is closed in l^1 ; hence the range of the operator mentioned above is closed. By the open mapping theorem, the inverse of this operator, defined on its range, is continuous. \square

The total number σ_{UV} of conditions in (13) is

$$\sigma_{UV} = \sum_{z_0, i, j} (\sigma_{U,i}(z_0) + \sigma_{V,j}(z_0)) = \sigma_U n + \sigma_V m,$$

where σ_U and σ_V are the total multiplicities of the zeros of $\det \widehat{U}$ and $\det \widehat{V}$ in D , respectively, i.e.,

$$\sigma_U = \sum_{z_0 \in \mathcal{Z}_{UV}} \sum_{i \in \{1, \dots, m\}} \sigma_{U,i}(z_0), \quad \sigma_V = \sum_{z_0 \in \mathcal{Z}_{UV}} \sum_{j \in \{1, \dots, n\}} \sigma_{V,j}(z_0).$$

Furthermore, the conditions in (13) are linearly independent (one way to see this is to transfer the conditions back to the time domain, as is done in §5, and to observe that the resulting time domain conditions are linearly independent). Thus, the set of all possible elements of the form \widehat{K} is a closed subspace in \hat{l}^1 of finite codimension $\sigma_{UV} = \sigma_U n + \sigma_V m$.

If we replace \widehat{K} in (13) by $\widehat{H} - \widehat{\Phi}$, then we get

$$(14) \quad (\hat{\alpha}_i \widehat{\Phi} \hat{\beta}_j)^{(r)}(z_0) = (\hat{\alpha}_i \widehat{H} \hat{\beta}_j)^{(r)}(z_0), \quad r \in \{0, \dots, \sigma_{U,i}(z_0) + \sigma_{V,j}(z_0) - 1\}.$$

This equation can be interpreted as a requirement that $\widehat{\Phi}$ interpolates \widehat{H} in certain directions at each point $z_0 \in \mathcal{Z}_{UV}$. For this reason we shall refer to (13) and (14) as the *interpolation constraints*. In the H^∞ literature they are known as the two-sided Lagrange–Sylvester interpolation conditions ([1, §16.8]) or as the *discrete* interpolation conditions [2].

The definition of $\hat{\alpha}_i$ and $\hat{\beta}_j$ was based on the global Smith factorizations of \widehat{U} and \widehat{V} . For actual computations it is more convenient to use different functions $\hat{\alpha}_i$ and $\hat{\beta}_j$ at each different point $z_0 \in \mathcal{Z}_{UV}$, i.e., we use several *local* Smith factorizations, one at each point, rather than one global Smith factorization. This is possible because, at each z_0 , (14) depends only on the derivatives of $\hat{\alpha}_i$ and $\hat{\beta}_j$ of order at most $\sigma_{U,i}(z_0) + \sigma_{V,j}(z_0) - 1$. Thus, it is not necessary to use the same functions at all points $z_0 \in \mathcal{Z}_{UV}$, and we may always, without loss of generality, assume that at the point $z_0 \in \mathcal{Z}_{UV}$, the functions $\hat{\alpha}_i$ and $\hat{\beta}_j$ are constants if $\sigma_{U,i}(z_0) \leq 1$ and $\sigma_{V,j}(z_0) \leq 1$, respectively, and

that they are polynomials of order at most $\sigma_{U,i}(z_0) - 1$ and $\sigma_{V,j}(z_0) - 1$ otherwise. This simplifies the linear programming formulation of the problem to be discussed in §5.

Theorem 3.1 immediately gives us the following corollary.

COROLLARY 3.2. *In the one-block case, if \mathcal{Z}_{UV} is empty, or more generally, if for all $z_0 \in \mathcal{Z}_{UV}$, all $i \in \{1, \dots, m\}$, and all $j \in \{1, \dots, n\}$*

$$(\hat{\alpha}_i \hat{H} \hat{\beta}_j)^{(r)}(z_0) = 0, \quad r \in \{0, \dots, \sigma_{U,i}(z_0) + \sigma_{V,j}(z_0) - 1\}$$

then the optimal solution of (OPT) is $\Phi = 0$.

When this corollary is applied to the standard sensitivity minimization problem we recover the well-known fact that there are no restrictions on the achievable sensitivity for a minimum phase plant.

As proposed to us by one of the referees, let us end this section by pointing out a minor error in the discussion in [10] on the interpolation constraints. McDonald and Pearson present two different sets of interpolation constraints, one set in [10, Def. 2] and [10, Thm. 3], and another set in [10, Lem. 1]. The latter set is the one that we use in Theorem 3.1 and, as we have seen, it is linearly independent. This contradicts a claim made in [10], where it is stated that the first set of constraints is linearly independent, whereas the second set of constraints is not, and there it is recommended that we use the first set of constraints. To see that this claim must be false it suffices to compute the total number of scalar conditions contained in (13) on one hand, and in [10, Def. 2] on the other hand. As we have seen, the total number of scalar conditions in (13) is $\sigma_U n + \sigma_V m$. A similar computation shows that the number of scalar conditions in each of the parts (i), (ii), (iiia), and (iiib) of [10, Def. 2] are $\sigma_U n$, $\sigma_V m$, $\sigma_U n$, and $\sigma_V m$, respectively. When these numbers are added, we get either $2\sigma_U n + \sigma_V m$ or $\sigma_U n + 2\sigma_V m$, depending on which of the two alternative versions of (iii) that we use (if we use different versions of (iii) at different points, then we get some other number between these two). If \hat{U} and \hat{V} have no common zeros, then the two sets of constraints become equivalent (provided we use the trivially satisfied part of (iii); that is, at each point we use either (i) or (ii) and ignore all the remaining conditions), and it does not matter which set is used. However, the conditions listed [10, Def. 2] become redundant whenever \hat{U} and \hat{V} contain common zeros. One problem is that (i) and (ii) of [10, Def. 2] overlap in this case; to see this, note that they are equivalent to the requirement that for all $z_0 \in \mathcal{Z}_{UV}$, all $i \in \{1, \dots, m\}$, and all $j \in \{1, \dots, n\}$,

$$(\hat{\alpha}_i \hat{K})^{(r)}(z_0) \hat{\beta}_j(z_0) = 0, \quad r \in \{0, \dots, \sigma_{U,i}(z_0) - 1\}$$

and

$$\hat{\alpha}_i(z_0) (\hat{K} \hat{\beta}_j)^{(r)}(z_0) = 0, \quad r \in \{0, \dots, \sigma_{V,j}(z_0) - 1\},$$

respectively, and these conditions overlap already for $r = 0$ whenever both $\sigma_{U,i}(z_0)$ and $\sigma_{V,j}(z_0)$ are nonzero.

4. Frequency domain formulation: Convolution constraints. To see that the frequency domain conditions must be quite different in the multiblock case (i.e., two-block and four-block cases) compared to the single-block case, it suffices to look at a very simple example. Suppose that \hat{U} contains two identical rows. Then the corresponding rows of \hat{K} must also be identical. Clearly, the interpolation constraints

(13) that we described, and that completely characterize the one-block case, cannot force two rows of \hat{K} to be identical. Thus, we need some additional conditions for the multiblock case. In the previous example, there was a new constraint on \hat{K} of the following type: there is some vector $\alpha \in \mathbf{R}^m$ such that $\alpha\hat{K}$ vanishes identically. The general conditions that we shall use are generalizations of this simple condition, and they describe linear dependencies between the rows of \hat{U} and between the columns of \hat{V} .

Suppose that at least one of the two inequalities $p \leq m$ and $q \leq n$ is strict. Choose some arbitrary matrices \hat{U}_0 and \hat{V}_0 of dimension $p \times m$ and $n \times q$, respectively, such that $\hat{U}_0\hat{U}$ and $\hat{V}\hat{V}_0$ have rank p and q , respectively, in at least one point of D (if $p = n$ then we may choose $\hat{U}_0 = I$, and if $q = m$ then we may choose $\hat{V}_0 = I$). For example, one possible choice is to take U_0 and V_0 as in (10). This means that $\hat{U}_0\hat{U}$ and $\hat{V}\hat{V}_0$ are invertible in at least one point of D . Multiply the identity $\hat{K} = \hat{U}\hat{Q}\hat{V}$ from the left by $[\hat{U}_0\hat{U}]^{-1}\hat{U}_0$ and from the right by $\hat{V}_0[\hat{V}\hat{V}_0]^{-1}$ to get

$$(15) \quad \hat{Q} = [\hat{U}_0\hat{U}]^{-1}\hat{U}_0\hat{K}\hat{V}_0[\hat{V}\hat{V}_0]^{-1}.$$

The functions on the right-hand side are matrices with values in the quotient field of \hat{l}^1 (each element is a quotient of two elements of \hat{l}^1), and they determine \hat{Q} uniquely. Substituting this back into the equation $\hat{K} = \hat{U}\hat{Q}\hat{V}$ we get the following necessary condition that \hat{K} must satisfy:

$$(16) \quad \hat{K} = \hat{U}[\hat{U}_0\hat{U}]^{-1}\hat{U}_0\hat{K}\hat{V}_0[\hat{V}\hat{V}_0]^{-1}\hat{V}.$$

Formally, the matrix equation above contains mn different equations, one for each component of the matrix \hat{K} , but some of these equations are redundant. This redundancy is due to the fact that (16) has been constructed in such a way that the equation that we get by multiplying (16) from the left by \hat{U}_0 and from the right by \hat{V}_0 is always satisfied, independently of the choice of \hat{K} . We can remove this redundancy in the following way. Let \hat{U}_1 and \hat{V}_1 be matrices in \hat{l}^1 of dimensions $m - p$ and $n - q$, respectively, that complement \hat{U}_0 and \hat{V}_0 in the sense that the two matrices $\begin{pmatrix} \hat{U}_0 \\ \hat{U}_1 \end{pmatrix}$ and $\begin{pmatrix} \hat{V}_0 \\ \hat{V}_1 \end{pmatrix}$ are invertible in at least one point of D (one possible choice is the one in (10)). Then (16) is equivalent to the equation that we get when we multiply (16) from the left by $\begin{pmatrix} \hat{U}_0 \\ \hat{U}_1 \end{pmatrix}$ and from the right by $\begin{pmatrix} \hat{V}_0 \\ \hat{V}_1 \end{pmatrix}$. When this is done, we get the equivalent system

$$(17) \quad \begin{pmatrix} \hat{U}_0\hat{K}\hat{V}_0 & \hat{U}_0\hat{K}\hat{V}_1 \\ \hat{U}_1\hat{K}\hat{V}_0 & \hat{U}_1\hat{K}\hat{V}_1 \end{pmatrix} - \begin{pmatrix} \hat{U}_0\hat{K}\hat{V}_0 & (\hat{U}_0\hat{K}\hat{V}_0)[\hat{V}\hat{V}_0]^{-1}\hat{V}\hat{V}_1 \\ \hat{U}_1\hat{U}[\hat{U}_0\hat{U}]^{-1}(\hat{U}_0\hat{K}\hat{V}_0) & \hat{U}_1\hat{U}[\hat{U}_0\hat{U}]^{-1}(\hat{U}_0\hat{K}\hat{V}_0)[\hat{V}\hat{V}_0]^{-1}\hat{V}\hat{V}_1 \end{pmatrix} = 0,$$

which expresses $\hat{U}_0\hat{K}\hat{V}_1$, $\hat{U}_1\hat{K}\hat{V}_0$, and $\hat{U}_1\hat{K}\hat{V}_1$ as functions of $\hat{U}_0\hat{K}\hat{V}_0$. From this equation it is evident that the number of independent equations is $mn - pq$. (In the one-block case $mn - pq = 0$, and no extra conditions are needed).

We can turn (17) into an equation where all the factors belong to \hat{l}^1 (instead of to the quotient field of \hat{l}^1) by multiplying the equations by, e.g., the determinants of $\hat{U}_0\hat{U}$ and $\hat{V}\hat{V}_0$. Usually a better choice is to choose some other $p \times p$ and $q \times q$ -dimensional matrix functions \hat{W}_0 and \hat{W}_1 , respectively, with full rank at almost all points of D ,

in such a way that $\widehat{W}_0 \widehat{U}_1 \widehat{U} [\widehat{U}_0 \widehat{U}]^{-1}$ and $[\widehat{V} \widehat{V}_0]^{-1} \widehat{V} \widehat{V}_1 \widehat{W}_1$ have no singularities, and to multiply (17) from the left by $\begin{pmatrix} I & 0 \\ 0 & \widehat{W}_0 \end{pmatrix}$ and from the right by $\begin{pmatrix} I & 0 \\ 0 & \widehat{W}_1 \end{pmatrix}$. However, this leads to a system of the same type as (17); the only difference is that \widehat{U}_1 has been replaced by $\widehat{W}_0 \widehat{U}_1$ and that \widehat{V}_1 has been replaced by $\widehat{V}_1 \widehat{W}_1$. Thus, this discussion shows that it is possible to choose \widehat{U}_1 and \widehat{V}_1 in (17) in such a way that all the factors multiplying \widehat{K} belong to \hat{l}^1 . Throughout in the sequel we assume that this has been done. (For further comments on the choice of multipliers, see the discussion at the end of this section, as well as Lemma 6.4.)

If we transform (17) back into the time domain, then we get $mn - pq$ linearly independent convolution equations. For this reason we shall refer to the equations (16) and (17) as the *convolution constraints*. (In the H^∞ -literature these are called *continuous* interpolation conditions; see [2].) In the linear programming approach that is presented later we employ (17), but for simplicity we shall base the rest of the discussion in this section on (16).

An important observation is that the convolution constraints (16) are independent of \widehat{U}_0 and \widehat{V}_0 in the sense that if they are satisfied for one pair of functions \widehat{U}_0 and \widehat{V}_0 , then they are satisfied for every other pair of functions \widehat{U}_0 and \widehat{V}_0 , also, as long as $\widehat{U}_0 \widehat{U}$ and $\widehat{V} \widehat{V}_0$ are invertible in at least one point of D . To see this, multiply (16) from the left by $[\widehat{U}_0 \widehat{U}]^{-1} \widehat{U}_0$ and from the right by $\widehat{V}_0 [\widehat{V} \widehat{V}_0]^{-1}$ to get

$$(18) \quad [\widehat{U}_0 \widehat{U}]^{-1} \widehat{U}_0 \widehat{K} \widehat{V}_0 [\widehat{V} \widehat{V}_0]^{-1} = [\widehat{U}_0 \widehat{U}]^{-1} \widehat{U}_0 \widehat{K} \widehat{V}_0 [\widehat{V} \widehat{V}_0]^{-1}.$$

This implies two things. First, (16) is valid with \widehat{U}_0 and \widehat{V}_0 replaced by \widehat{U}_0 and \widehat{V}_0 , and second, if we use (15) as a definition of \widehat{Q} , then \widehat{Q} is independent of the particular choice of \widehat{U}_0 and \widehat{V}_0 .

Let us collect this argument into the following lemma.

LEMMA 4.1. *Let \widehat{U} , and \widehat{V} be matrices of dimension $m \times p$, and $q \times n$, respectively, with values in \hat{l}^1 , and suppose that \widehat{U} has full column rank and that \widehat{V} has full row rank.*

(i) *If \widehat{K} is a matrix of the form $\widehat{K} = \widehat{U} \widehat{Q} \widehat{V}$ for some $p \times q$ -dimensional matrix \widehat{Q} with values in \hat{l}^1 , then \widehat{K} satisfies the convolution constraints (16) for all matrices \widehat{U}_0 and \widehat{V}_0 of dimensions $p \times m$ and $n \times q$, respectively, with values in \hat{l}^1 , such that $\widehat{U}_0 \widehat{U}$ and $\widehat{V} \widehat{V}_0$ are invertible in at least one point of D .*

(ii) *Conversely, suppose that \widehat{K} is an $m \times n$ -dimensional matrix with values in \hat{l}^1 that satisfies the convolution constraints (16) for one pair of functions \widehat{U}_0 and \widehat{V}_0 of the type mentioned in (i). Then it satisfies the same constraints for all other possible choices of \widehat{U}_0 and \widehat{V}_0 , also, and it determines a function \widehat{Q} uniquely through the equations (15), where the choice of \widehat{U}_0 and \widehat{V}_0 is irrelevant in the sense that \widehat{Q} is independent of the particular choice of \widehat{U}_0 and \widehat{V}_0 . Each element of the function \widehat{Q} is the quotient of two functions belonging to \hat{l}^1 .*

As we mentioned previously, it is possible to choose U_0 , U_1 , V_0 , and V_1 as in (10). In this case

$$(19) \quad [\widehat{U}_0 \widehat{U}]^{-1} = [\widehat{R}_U]^{-1} [\widehat{N}_U]^{-1}, \quad [\widehat{V} \widehat{V}_0]^{-1} = [\widehat{N}_V]^{-1} [\widehat{L}_V]^{-1},$$

and (16) becomes (cf. (7))

$$(20) \quad \widehat{K} = \widehat{L}_{U,1} \widehat{U}_0 \widehat{K} \widehat{V}_0 \widehat{R}_{V,1}.$$

From this version of (16) it is easy to prove the following result.

LEMMA 4.2. *A function $\hat{K} \in \hat{\mathbb{I}}_{m \times n}^1$ satisfies (16) if and only if it is of the form $\hat{K} = \hat{L}_{U,1} \hat{S} \hat{R}_{V,1}$ for some $\hat{S} \in \hat{\mathbb{I}}_{p \times q}^1$. Moreover, both the mapping $\hat{S} \mapsto \hat{K} = \hat{L}_{U,1} \hat{S} \hat{R}_{V,1}$ and its inverse $\hat{K} \mapsto \hat{S} = \hat{U}_0 \hat{K} \hat{V}_0$, where \hat{U}_0 and \hat{V}_0 satisfy (10), is continuous.*

Proof. By (20), the condition $\hat{K} = \hat{L}_{U,1} \hat{S} \hat{R}_{V,1}$ is necessary (choose \hat{S} to be $\hat{S} = \hat{U}_0 \hat{K} \hat{V}_0$). Conversely, if \hat{S} is of this type, then we can multiply the identity $\hat{K} = \hat{L}_{U,1} \hat{S} \hat{R}_{V,1}$ from the left by \hat{U}_0 and from the right by \hat{V}_0 to get $\hat{S} = \hat{U}_0 \hat{K} \hat{V}_0$. This, substituted back into the equation $\hat{K} = \hat{L}_{U,1} \hat{S} \hat{R}_{V,1}$ shows that \hat{K} satisfies (20). The final continuity claim is obvious. \square

Let us return to the interpolation constraints that we found in §3. For later use, let us record the fact that the set of all the solutions of (13) can be parametrized in a way similar to the parametrization presented in Lemma 4.2.

LEMMA 4.3. *A function $\hat{K} \in \hat{\mathbb{I}}_{m \times n}^1$ satisfies (13) if and only if it is of the form*

$$(21) \quad \hat{K} = (\hat{L}_{U,1} \quad \hat{L}_{U,2}) \begin{pmatrix} \hat{N}_U \hat{T}_{11} \hat{N}_V & \hat{T}_{12} \\ \hat{T}_{21} & \hat{T}_{22} \end{pmatrix} \begin{pmatrix} \hat{R}_{V,1} \\ \hat{R}_{V,2} \end{pmatrix}$$

for some matrices $\hat{T}_{ij} \in \hat{\mathbb{I}}^1$ of appropriate dimensions. The mapping that takes $\begin{pmatrix} \hat{T}_{11} & \hat{T}_{12} \\ \hat{T}_{21} & \hat{T}_{22} \end{pmatrix}$ into K is continuous.

Proof. Let K satisfy (21). Multiply (21) from the left by \hat{U}_0 and from the right by \hat{V}_0 , where \hat{U}_0 and \hat{V}_0 satisfy (10), to get

$$\hat{U}_0 \hat{K} \hat{V}_0 = \hat{N}_U \hat{T}_{11} \hat{N}_V.$$

Clearly, this implies that K satisfies (13).

Conversely, if K satisfies (13), then the function \hat{T}_{11} defined by

$$\hat{T}_{11} = [\hat{N}_U]^{-1} \hat{U}_0 \hat{K} \hat{V}_0 [\hat{N}_V]^{-1}$$

belongs to $\hat{\mathbb{I}}^1$. Define

$$\hat{T}_{12} = \hat{U}_0 \hat{K} \hat{V}_1, \quad \hat{T}_{21} = \hat{U}_1 \hat{K} \hat{V}_0, \quad \hat{T}_{22} = \hat{U}_1 \hat{K} \hat{V}_1,$$

to get the desired representation. \square

By combining the preceding lemmas we get the following theorem.

THEOREM 4.4. *Given \hat{K} , \hat{U} , and \hat{V} in $\hat{\mathbb{I}}^1$ of the type described above (i.e., we are in the multiblock case, the dimensions are $m \times n$, $m \times p$, and $q \times n$, respectively, Assumption 1.1 is satisfied, and \hat{U} and \hat{V} have full column rank and row rank, respectively, in all but finitely many points in D), there is a unique function $\hat{Q} \in \hat{\mathbb{I}}^1$ such that $\hat{K} = \hat{U} \hat{Q} \hat{V}$ if and only if \hat{K} satisfies the convolution constraints (16) as explained in Lemma 4.1 and, in addition, for all $z_0 \in Z_{UV}$, all $i \in \{1, \dots, m\}$, and all $j \in \{1, \dots, n\}$, (13) holds. Moreover, both the mapping $\hat{Q} \mapsto \hat{K} = \hat{U} \hat{Q} \hat{V}$ and its inverse (defined on the range) are continuous. The inverse mapping has the representation (15). In particular, if \hat{U}_0 and \hat{V}_0 are chosen according to the decomposition (10), then this inverse mapping can be written in the form*

$$\hat{K} \mapsto \hat{Q} = [\hat{R}_U]^{-1} [\hat{N}_U]^{-1} \hat{U}_0 \hat{K} \hat{V}_0 [\hat{N}_V]^{-1} [\hat{L}_V]^{-1}.$$

The proof of this theorem is similar to the earlier proofs, and we leave it to the reader.

The comments at the end of §3 on the freedom of choice of the vectors $\hat{\alpha}_i$ and $\hat{\beta}_j$ also apply here. In particular, at each point $z \in \mathcal{Z}_{UV}$ we only need to know the particular local zero structure at that point, and α_i and β_j may be chosen to be polynomials, different at each point $z \in \mathcal{Z}_{UV}$. There is also a large freedom in the choice of the particular \hat{U}_0 and \hat{V}_0 to be used in Lemma 4.1. One choice that seems to be particularly attractive is to take \hat{U}_0 , \hat{U}_1 , \hat{V}_0 , and \hat{V}_1 to be determined from the Smith factorization of \hat{U} and \hat{V} , as in (10). Then

$$\hat{U}_0 \hat{U} = \hat{N}_U \hat{R}_U, \quad \hat{U}_1 \hat{U} = 0, \quad \hat{V} \hat{V}_0 = \hat{L}_V \hat{N}_V, \quad \hat{V} \hat{V}_1 = 0,$$

and (17) simplifies into

$$(22) \quad \begin{pmatrix} 0 & \hat{U}_0 \hat{K} \hat{V}_1 \\ \hat{U}_1 \hat{K} \hat{V}_0 & \hat{U}_1 \hat{K} \hat{V}_1 \end{pmatrix} = 0.$$

Another somewhat more flexible approach is to choose \hat{U}_0 and \hat{V}_0 in such a way that the factors $\hat{U}[\hat{U}_0 \hat{U}]^{-1}$ and $[\hat{V} \hat{V}_0]^{-1} \hat{V}$ appearing in (17) belong to \hat{l}^1 . Observe that we can rewrite these factors, using the Smith factorizations of \hat{U} and \hat{V} , into the form

$$(23) \quad \hat{U}[\hat{U}_0 \hat{U}]^{-1} = \hat{L}_{U,1}[\hat{U}_0 \hat{L}_{U,1}]^{-1}, \quad [\hat{V} \hat{V}_0]^{-1} \hat{V} = [\hat{R}_{V,1} \hat{V}_0]^{-1} \hat{R}_{V,1}.$$

If (10) holds, then $\hat{U}[\hat{U}_0 \hat{U}]^{-1} = \hat{L}_{U,1}$ and $[\hat{V} \hat{V}_0]^{-1} \hat{V} = \hat{R}_{V,1}$. However, it really suffices to choose \hat{U}_0 and \hat{V}_0 in such a way that $\hat{U}_0 \hat{L}_{U,1}$ and $\hat{R}_{V,1} \hat{V}_0$ are invertible. If this is done, then it is possible to choose the matrices \hat{U}_1 and \hat{V}_1 in such a way that $\begin{pmatrix} \hat{U}_0 \\ \hat{U}_1 \end{pmatrix}$ and $\begin{pmatrix} \hat{V}_0 & \hat{V}_1 \end{pmatrix}$ are invertible in all of \overline{D} . This condition becomes important in §11.

The theorem above should be compared to the corresponding Theorem 6 in [10]. The conditions (i) and (ii) used in [10, Thm. 6] are a special case of our equation (16). To get those conditions we choose the pair \hat{U}_0 and \hat{V}_0 in a special way, namely, they are chosen to be matrices that pick out p linearly independent rows from \hat{U} and q linearly independent columns from \hat{V} , respectively. The same choice of \hat{U}_0 and \hat{V}_0 are present in McDonald and Pearson's definition of the interpolation constraints for the multiblock case, also: instead of using the Smith factorizations of the full matrices \hat{U} and \hat{V} as we do they use the Smith factorizations of $\hat{U}_0 \hat{U}$ and $\hat{V} \hat{V}_0$ to define the vector functions $\hat{\alpha}_i$ and $\hat{\beta}_j$ that appear in (13). This leads to a result that differs significantly from ours, even if we ignore the redundancy in [10] due to the use of an alternative set of interpolation constraints (see the discussion at the end of the previous section). For one thing, the approach in [10] necessitates one extra nonstandard assumption, namely that there are p rows of \hat{U} and q columns of \hat{V} that are independent for all z on the unit circle (see Assumption 3 in [10]). This assumption is stronger than our Assumption 1.1. Moreover, since those specifically chosen rows of \hat{U} and columns of \hat{V} may lose rank at additional points in D , not belonging to the set \mathcal{Z}_{UV} determined by the zero structure of the full matrices \hat{U} and \hat{V} , in McDonald and Pearson's formulation there are usually additional points $z \in D$ that do not belong to \mathcal{Z}_{UV} , but that have to be included among the points z_0 in (13). It may also be the case that, at a particular point $z \in \mathcal{Z}_{UV}$, the determinants of the chosen rows and columns vanish to a higher order than the true total multiplicity of that point, and this leads to a greater number of derivatives in (13) than is needed in our formulation. In other words, the conditions listed in [10, Thm. 6] are, not in general, linearly independent. As reported in [14] and [15], such linear dependencies

may cause numerical instabilities in the solution schemes and, as we shall see in §11, it leads to nonuniqueness of the dual solutions. Moreover, with this choice of \widehat{U}_0 and \widehat{V}_0 it is not in general possible to choose \widehat{U}_1 and \widehat{V}_1 in such a way that $\begin{pmatrix} \widehat{U}_0 \\ \widehat{U}_1 \end{pmatrix}$ and $\begin{pmatrix} \widehat{V}_0 \\ \widehat{V}_1 \end{pmatrix}$ are invertible in all of \overline{D} ; this property seems to be highly desirable (see §11).

There is one case in particular where the difference between the method presented here and the one in [10] becomes profound. For a certain type of problems Z_{UV} is empty, whereas the corresponding set in McDonald and Pearson's formulation may be nonempty; see [13]. This has a great influence on the resulting linear programming system that we shall introduce in §6. Moreover, in this case, with our formulation the resulting FME method (see §§8 and 9) becomes very easy to implement since the critical computation of the value of N drops out.

5. Linear programming formulation: One-block case. The frequency domain descriptions that we have given can be transformed back into the time domain. The time domain formulation contains infinitely many variables, i.e., the elements $\Phi_{ij}(k)$ of the matrix sequence $\Phi = H - K = H - U * Q * V$. In the one-block case it contains finitely many equations, more precisely, σ_{UV} equations, and in the multiblock case it contains infinitely many equations. By now this transformation is standard, and it has been used in, e.g., [4], [5], [10], [11], [14], and [15]. However, none of these references contains all the different aspects of the time domain formulation that we shall need here. The paper [4] contains a nice description of the one-block case, including both the primal and the dual problems, but there only simple zeros are allowed, and the multiblock case is missing. In the multiblock papers the descriptions of the primal problems are satisfactory, but some of the aspects of the formulation of the dual problem are missing. Therefore, for the convenience of the reader we have included a short description of this transformation. For more details, especially for the primal formulation, we refer the reader to the references listed. In this section we give a description of the one-block case (similar to the description in [4]), and defer the discussion of the two-block case to the next section.

First we transform the interpolation constraints (14) back into the time domain and get (to simplify the notations we have replaced α_i by α and β_j by β , and use i and j as summation indices)

$$\sum_{j=0}^{\infty} j^r z_0^j \sum_{i=0}^j \alpha(j-i) \sum_{k=0}^i (\Phi(k) - H(k)) \beta(i-k) = 0$$

for all relevant α , β , z_0 , and r . After a change of the order of summation this becomes

$$(24) \quad \sum_{k=0}^{\infty} \sum_{i=k}^{\infty} \sum_{j=i}^{\infty} j^r z_0^j \alpha(j-i) (\Phi(k) - H(k)) \beta(i-k) = 0.$$

The left-hand side of this equation is a continuous affine mapping from the set of $m \times n$ -dimensional sequences Φ in l^1 into \mathbb{C} . Let us denote the coefficient of $\Phi(k)$ by $A(k)$, where $A(k)$ is a second-order tensor of dimensions $m \times n$. Then (24) becomes

$$(25) \quad \sum_{k=0}^{\infty} A(k) \Phi(k) = \sum_{k=0}^{\infty} A(k) H(k),$$

where the products $A(k)\Phi(k)$ and $A(k)H(k)$ are the usual tensor products

$$A(k)\Phi(k) = \sum_{ij} A_{ij}(k) \Phi_{ij}(k), \quad A(k)H(k) = \sum_{ij} A_{ij}(k) H_{ij}(k).$$

The coefficients $A(k)$ have one crucial property, namely, they satisfy $|A(k)| \rightarrow 0$ as $k \rightarrow \infty$; this follows directly from (24) and the fact that $|z_0| < 1$.

Above we discussed the inversion of (14) for one particular choice of α , β , z_0 , and r . The complete set of conditions (14) contains σ_{UV} different conditions. When they all are inverted, we can write the result in the form

$$(26) \quad \sum_{k=0}^{\infty} A(k) \Phi(k) = a,$$

where each $A(k)$ is a third-order tensor, mapping the space of $m \times n$ -dimensional matrices into a complex σ_{UV} -dimensional vector, and $a = \sum_{k=0}^{\infty} A(k) H(k)$ is an σ_{UV} -dimensional vector with complex entries. Observe that, since we start out with real-valued data, if $z_0 \in \mathcal{Z}_{UV}$, then $\bar{z}_0 \in \mathcal{Z}_{UV}$. This means that if the set of equations above is not real, then the nonreal equations appear in complex conjugate pairs. By replacing each such pair by the real part and the imaginary part of one of the two equations we may assume that the entries of A and a are real.

Let us record the preceding argument into the following lemma.

LEMMA 5.1. *The interpolation constraints (14) are equivalent to an equation of the form (26), where each $A(k)$ is a third-order tensor of dimension $\sigma_{UV} \times (m \times n)$ satisfying $|A(k)| \rightarrow 0$ as $k \rightarrow \infty$, $a = \sum_{k=0}^{\infty} A(k) H(k)$ is a σ_{UV} -dimensional vector with real entries, and the products of $A(k)$ with $\Phi(k)$ and $H(k)$ are interpreted as $(A(k) \Phi(k))_{\ell} = \sum_{ij} A_{\ell ij}(k) \Phi_{ij}(k)$ and $(A(k) H(k))_{\ell} = \sum_{ij} A_{\ell ij}(k) H_{ij}(k)$.*

As a byproduct of this result we get the following corollary (the same result could have been deduced directly from Theorem 3.1, with \hat{K} replaced by $\hat{H} - \hat{\Phi}$).

COROLLARY 5.2. *Under Assumption 1.1, in the one-block case we may, without loss of generality, assume that \hat{H} , \hat{U} , and \hat{V} are polynomials in the sense that the original problem with data in \hat{l}^1 is equivalent to a problem with polynomial data.*

To prove this it suffices to observe that we get the same equations (26) if we, instead of using the original \hat{H} , \hat{U} , and \hat{V} in the formulation of (26), use polynomial functions \hat{U} and \hat{V} that have the same left and right zero structure, respectively, as the original functions \hat{U} and \hat{V} have, and use a polynomial \hat{H} that interpolates the original \hat{H} to a sufficiently high degree at each point of \mathcal{Z}_{UV} .

To complete the formulation of (OPT) in the one-block case as a linear programming problem in l^1 we must supplement (26) with a set of inequalities describing the norm (2) that is suppose to be minimized. Clearly, this minimization is equivalent to the minimization of μ under the m constraints $\mu \geq \sum_{j,k} |\Phi_{ij}(k)|$, $i \in \{1, \dots, m\}$. Split each Φ into $\Phi^+ - \Phi^-$, where all the elements of Φ^+ and Φ^- are nonnegative. (A natural additional requirement would be that for each i , j , and k , either $\Phi_{ij}^+(k) = 0$ or $\Phi_{ij}^-(k) = 0$, but that requirement is difficult to incorporate in the formulation due to its nonlinearity.) Then the constraints related to the new cost variable μ can be written in the form

$$\mathbf{1}\mu \geq E(\Phi^+ + \Phi^-),$$

where $\mathbf{1}$ represents an m -dimensional column vector with all elements equal to one, and E is the tensor mapping Φ into a vector whose i th element is $\sum_{j,k} \Phi_{ij}(k)$. Observe that the coefficients of $\Phi^+(k)$ and $\Phi^-(k)$ in this sum are independent of k ; in particular they do not tend to zero as $k \rightarrow \infty$, as opposed to those in (26).

Collecting the different pieces, we get the following formulation of (OPT) in the one-block case:

$$\begin{aligned}
 (\text{PRIM}_1) \quad & \text{minimize } \mu, \\
 & \mathbf{1}\mu - E(\Phi^+ + \Phi^-) \geq 0, \\
 & A(\Phi^+ - \Phi^-) = a, \\
 & \Phi^+, \Phi^- \geq 0,
 \end{aligned}$$

where the unknown Φ^+ and Φ^- are $m \times n$ -dimensional matrices in l^1 , E is an operator from this space into \mathbf{R}^m , A is an operator from the same space into $\mathbf{R}^{\sigma_{UV}}$, and $a = AH \in \mathbf{R}^{\sigma_{UV}}$.

We claim that the dual of the preceding problem is another linear programming problem which is posed in l^∞ . We can get this dual problem from the problem above by proceeding formally in the same way as we would do in the finite-dimensional case, but is easier to justify the derivation of the dual problem if we proceed in a different way, i.e., in the same way as in [4]. Observe that the problem that we have posed above is equivalent to finding the distance of the sequence $H \in l^1$ to $\mathcal{N}(A)$; the null space of A (recall that $\Phi = H - K$, where H is fixed and $K \in \mathcal{N}(A)$). The standard dual problem is then the following (see, e.g., [9, Thm. 1, p. 119]):

$$\begin{aligned}
 & \text{maximize } \nu = \langle H, \delta \rangle, \\
 & \|\delta\|_{l^\infty} \leq 1, \\
 & \delta \in \mathcal{N}(A)^\perp.
 \end{aligned}$$

Here

$$\|\delta\|_{l^\infty} \stackrel{\text{def}}{=} \sum_{i=1}^m \left(\sup_{1 \leq j \leq n, k \geq 0} |\delta_{ij}(k)| \right) \leq 1$$

is the norm in l^∞ that is dual to the norm $\|\cdot\|_{l^1}$ defined earlier in (2).

To write the norm constraint on δ into linear programming form we may introduce new variables τ_i , $i \in \{1, \dots, m\}$, and require that

$$(27) \quad -\tau_i \leq \delta_{ij}(k) \leq \tau_i, \quad i = 1, \dots, m, \quad j = 1, \dots, n, \quad k = 0, 1, 2, \dots,$$

and that

$$(28) \quad \sum_{i=1}^m \tau_i = 1.$$

If we further observe that $\sum_{i=1}^m \tau_i = \mathbf{1}^* \tau$, and that $(E^* \tau)_{ij} = \tau_i$, then we arrive at an intermediate form

$$\begin{aligned}
 (\text{DUAL}'_1) \quad & \text{maximize } \nu = \langle H, \delta \rangle, \\
 & \mathbf{1}^* \tau = 1, \\
 & -E^* \tau \leq \delta \leq E^* \tau, \\
 & \delta \in \mathcal{N}(A)^\perp
 \end{aligned}$$

of the dual problem.

The preceding form is not yet the one that we would like to have. However, before we can proceed any further we must prove the following claim.

LEMMA 5.3. *Define A as above, and let $A^* : \mathbf{R}^{\sigma_{UV}} \rightarrow l_{m \times n}^\infty$ be the adjoint of A . Then $\mathcal{R}(A^*) \subset c_{m \times n}^0$ is finite-dimensional, hence closed in c^0 and weak* closed in l^∞ , A is the adjoint of A^* , and $\mathcal{N}(A)$ is weak*-closed in l^1 . In particular, $\mathcal{R}(A^*) = \mathcal{N}(A)^\perp = {}^\perp \mathcal{N}(A)$, and $\mathcal{N}(A) = {}^\perp \mathcal{R}(A^*) = \mathcal{R}(A^*)^\perp$.*

Parts of this lemma are found implicitly in some of the proofs given in [4], [5], and [10]. To understand the statement of Lemma 5.3 is important to keep in mind that l^∞ is the dual of l^1 which is the dual of c^0 . In particular, $\mathcal{N}(A)^\perp$ and ${}^\perp \mathcal{R}(A^*)$ are interpreted within the duality of l^1 and l^∞ , whereas ${}^\perp \mathcal{N}(A)$ and $\mathcal{R}(A^*)^\perp$ are interpreted within the duality of c^0 and l^1 .

Proof. Each element in the range of A^* is of the form $H_{ij}(k) = \sum_{r=1}^{\sigma_{UV}} \eta_r A_{rij}(k)$ for some $\eta \in \mathbf{R}^{\sigma_{UV}}$. Recall that for all r, i , and j , $|A_{rij}(k)| \rightarrow 0$ as $k \rightarrow \infty$. This implies that $\mathcal{R}(A^*) \subset c^0$, as claimed. Thus, A is the adjoint of A^* . Moreover, $\mathcal{R}(A^*)$ is finite-dimensional; hence it is closed in c^0 and weak*-closed in l^∞ . This implies that $\mathcal{R}(A^*) = \mathcal{N}(A)^\perp = {}^\perp \mathcal{N}(A)$, and that $\mathcal{N}(A) = {}^\perp \mathcal{R}(A^*) = \mathcal{R}(A^*)^\perp$. \square

Since, according to Lemma 5.3, $\mathcal{N}(A)^\perp = \mathcal{R}(A^*)$, we may replace $\delta \in \mathcal{N}(A)^\perp$ in (DUAL₁) by $A^*\eta$, and let η range over $\mathbf{R}^{\sigma_{UV}}$. This leads to our final version of the dual problem (recall that we have denoted AH by a):

$$\begin{aligned} \text{maximize } \nu &= \langle a, \eta \rangle, \\ \text{(DUAL}_1\text{)} \quad \mathbf{1}^* \tau &= 1, \\ -E^* \tau &\leq A^* \eta \leq E^* \tau. \end{aligned}$$

Observe that this problem is again in linear programming form. We urge every reader familiar with duality in finite-dimensional linear programming to check that, in a finite-dimensional setting, this is exactly the problem that we would get from (PRIM₁) by formally converting it to the dual problem according to the standard duality rules of linear programming.

We have posed the dual problems (DUAL₁') and (DUAL₁) in l^∞ , and considered them to be the dual of the problem (PRIM₁), posed in l^1 . If we instead posed (DUAL₁') and (DUAL₁) in c^0 , and compute their dual problem in l^1 , then we get back the problem (PRIM₁); to see this, revert the preceding computations and use Lemma 5.3. Since dual distance problems always have optimal solutions (see [9, Thm. 1, p. 119 and Thm. 2, p. 121]), we have the following result of the existence of solutions in the one-block case.

THEOREM 5.4. *In the situation described in Theorem 3.1, (the one-block case) problem (OPT) is equivalent to the infinite-dimensional linear programming problem (PRIM₁), and it has a minimizer $\Phi \in l^1$. The minimum is equal to the distance in l^1 of H to the weak*-closed null space of A , which is of finite codimension σ_{UV} . To compute this distance we may instead solve the dual problem (DUAL₁), which has a maximizer $\eta \in \mathbf{R}^{\sigma_{UV}}$.*

This is essentially the same result as [4, Thm. 4] and [10, Thm. 4]. The main difference of Theorem 5.4 compared to [10, Thm. 4] is that, since we use a linearly independent set of conditions in (13), we are able to identify the precise codimension of the null space of A , i.e., we are able to use a dual variable η of smallest possible dimension σ_{UV} . (See the discussion at the end of §3.)

6. Linear programming formulation: Multiblock case. In the multiblock case we have the same equations that we had above, but in addition we have an

infinite number of equations that we get by inverting (17). This leads to an additional equation of the form (again replace \widehat{K} by $\widehat{H} - \widehat{\Phi}$)

$$B * \Phi = b,$$

where $(B * \Phi)(\ell) = \sum_{k=0}^{\ell} B(\ell - k)\Phi(k)$, $b(\ell) = (B * H)(\ell) = \sum_{k=0}^{\ell} B(\ell - k)H(k)$, and each $B(\ell)$ is a third-order tensor mapping the space of $m \times n$ -dimensional matrices into \mathbf{R}^{mn-pq} (for a more detailed description of this operator, see the proof of Lemma 6.4). The important fact about B is that $B \in l^1$. When this equation is added to (PRIM₁), we get the linear programming formulation for the multiblock case:

$$\begin{aligned} & \text{minimize } \mu, \\ & \mathbf{1}\mu - E(\Phi^+ + \Phi^-) \geq 0, \\ (\text{PRIM}) \quad & A(\Phi^+ - \Phi^-) = a, \\ & B * (\Phi^+ - \Phi^-) = b, \\ & \Phi^+, \Phi^- \geq 0, \end{aligned}$$

where the meanings of Φ^+ , Φ^- , E , A , and a are the same as before, the operator $B*$ is a convolution operator mapping $m \times n$ -dimensional l^1 into $(mn - pq)$ -dimensional l^1 , and $b = B * H$ belongs to the range of $B*$.

We can make a computation similar to the one that we made in the one-block case to get a dual linear programming problem. Denote the operator that maps Φ into the pair $[A\Phi, B * \Phi]$ by $[A, B*]$. Then the equations in (PRIM) involving A and B say that $\Phi - H \in \mathcal{N}([A, B*])$. Thus, the standard dual problem is

$$\begin{aligned} & \text{maximize } \nu = \langle H, \delta \rangle, \\ & \mathbf{1}^* \tau = 1, \\ (\text{DUAL}') \quad & -E^* \tau \leq \delta \leq E^* \tau, \\ & \delta \in \mathcal{N}([A, B*])^\perp \end{aligned}$$

where we have replaced the condition $\|\delta\|_{l^\infty} \leq 1$ by the same inequalities as in (DUAL'₁). The adjoint $[A, B*]^*$ of the operator $[A, B*]$ is the operator that maps $(\eta, \gamma) \in \mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^\infty$ into $A^* \eta + B^* * \gamma \in l_{m \times n}^\infty$, where the adjoint $B^* *$ of $B*$ is the operator

$$(29) \quad (B^* * \gamma)(k) = \sum_{\ell=k}^{\infty} B^*(\ell - k)\gamma(\ell).$$

Thus, if we would know the range of $[A, B*]^*$ to be weak* closed, then we could proceed as in the one-block case and write (DUAL') in the form (replace δ by $A^* \eta + B^* * \gamma$, and recall that $AH = a$ and $B * H = b$):

$$\begin{aligned} & \text{maximize } \nu = \langle a, \eta \rangle + \langle b, \gamma \rangle, \\ (\text{DUAL}) \quad & \mathbf{1}^* \tau = 1, \\ & -E^* \tau \leq A^* \eta + B^* * \gamma \leq E^* \tau. \end{aligned}$$

Indeed, as we shall prove in the following, if the matrices $\begin{pmatrix} \widehat{U}_0 \\ \widehat{U}_1 \end{pmatrix}$ and $\begin{pmatrix} \widehat{V}_0 & \widehat{V}_1 \end{pmatrix}$ have full rank on the unit circle, then the range of $[A, B*]^*$ will be weak* closed, but there

seems to be no reason to believe that the range of $[A, B^*]^*$ will be weak* closed in general. Still, even if the range of $[A, B^*]^*$ is not weak* closed, much of Lemma 5.3 and Theorem 5.4 remains true for the multiblock case.

We first prove a weakened analogue of Lemma 5.3.

LEMMA 6.1. *Define A , B , $[A, B^*]$, and $[A, B^*]^*$ as before. Then $[A, B^*]^*$ maps $\mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$ continuously into $c_{m \times n}^0$, and $[A, B^*]$ is the adjoint of the operator $[A, B^*]^*$ restricted to $\mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$. In particular, $\mathcal{N}([A, B^*])$ is weak* closed in $l_{m \times n}^1$, and (PRIM) is the dual of the problem (DUAL) posed in $\mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$.*

Proof. That $[A, B^*]^*$, which is equal to the operator $(\eta, \gamma) \mapsto A^*\eta + B^*\gamma$, maps $\mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$ continuously into $c_{m \times n}^0$ follows from the fact that A^* maps $\mathbf{R}^{\sigma_{UV}}$ into $c_{m \times n}^0$ and that B^* maps $c_{(mn-pq)}^0$ into $c_{m \times n}^0$ since $B \in l^1$. All other claims in Lemma 6.1 then follow immediately. \square

The preceding considerations can be collected into the following result.

THEOREM 6.2. *In the situation described in Theorem 4.4 (the multiblock case) problem (OPT) is equivalent to the infinite-dimensional linear programming problem (PRIM), and it has a minimizer $\Phi \in l^1$. The minimum is equal to the distance in l^1 of H to the weak*-closed null space of $[A, B^*]$. To compute this distance we may instead solve the dual problem (DUAL'), which has a maximizer $\delta \in l_{m \times n}^\infty$, or we may solve the problem (DUAL) in $\mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$, which need not have a maximizing solution, but for which the supremum of the objective function $\langle a, \eta \rangle + \langle b, \gamma \rangle$ over the set of all feasible solutions $(\eta, \gamma) \in \mathbf{R}^{\sigma_{UV}} \times c_{(mn-pq)}^0$ equals the optimal value of (PRIM). If, in addition, $\mathcal{R}([A, B^*])$ is closed in $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^1$, then (DUAL) has a maximizing solution in $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^\infty$.*

Here the final statement makes use of the closed range theorem, which says that the range of the dual of an operator is weak* closed if and only if the range of the operator itself is closed; see [12, Thm. 4.14, p. 96]. Theorem 6.2 extends the corresponding ones in [5] and [10], where the existence of a maximizer of the dual problem in l^∞ is never addressed.

For later reference, let us mention the following result, related to Lemme 6.1.

LEMMA 6.3. *Let Assumption 1.1 hold. Then the mapping that takes $Q \in l_{p \times q}^1$ into $K = U * Q * V$ and its inverse are both norm-continuous and weak* continuous.*

Proof. We know that these mappings are norm-continuous; see Theorem 4.4. The weak* continuity is a consequence of the fact that the mapping $Q \mapsto U * Q * V$ is the adjoint of a continuous operator mapping $c_{m \times n}^0$ into $c_{p \times q}^0$. \square

The additional condition on the range of $[A, B^*]$ in Theorem 6.2 is satisfied in the following case.

LEMMA 6.4. *If the matrices $(\hat{U}_0 \ \hat{U}_1)$ and $(\hat{V}_0 \ \hat{V}_1)$ have full rank on the unit circle, then the range of the operator $[A, B^*]$ is closed in $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^1$.*

Proof. Recall that, by the closed range theorem [12, Thm. 4.14], $\mathcal{R}([A, B^*])$ is closed in $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^1$ if and only if $\mathcal{R}([A, B^*]^*)$ is closed in $l_{m \times n}^\infty$. The range of the latter operator is the sum of the ranges of A^* and B^* . Since the range of A is finite-dimensional, to prove that $\mathcal{R}([A, B^*]^*)$ is closed, it suffices to prove that $\mathcal{R}(B^*)$ is closed. However, again by the closed range theorem, this is true if and only if $\mathcal{R}(B)$ is closed in $l_{(mn-pq)}^1$. Thus, we have reduced the proof to a proof of the fact that $\mathcal{R}(B)$ is closed in $l_{(mn-pq)}^1$.

To prove that $\mathcal{R}(B)$ is closed we shall decompose B into three operators, $B = PDC$, where C has a closed range, and D and P have the property that the images

of closed subspaces under these operators are closed. Clearly, this implies that $\mathcal{R}(B^*)$ is closed. This decomposition is based on the fact that it is possible to rewrite (17) into the form

$$(30) \quad \begin{pmatrix} \widehat{U}_0 \\ \widehat{U}_1 \end{pmatrix} K \begin{pmatrix} \widehat{V}_0 & \widehat{V}_1 \end{pmatrix} - \begin{pmatrix} I & 0 \\ \widehat{U}_1 \widehat{U} [\widehat{U}_0 \widehat{U}]^{-1} & 0 \end{pmatrix} \begin{pmatrix} \widehat{U}_0 \\ \widehat{U}_1 \end{pmatrix} K \begin{pmatrix} \widehat{V}_0 & \widehat{V}_1 \end{pmatrix} \begin{pmatrix} I & [\widehat{V} \widehat{V}_0]^{-1} \widehat{V} \widehat{V}_1 \\ 0 & 0 \end{pmatrix} = 0.$$

We define the operator C to be the operator that maps $K \in l_{m \times n}^\infty$ into

$$CK = \begin{pmatrix} U_0 \\ U_1 \end{pmatrix} * K * \begin{pmatrix} V_0 & V_1 \end{pmatrix} = \begin{pmatrix} U_0 * K * V_0 & U_0 * K * V_1 \\ U_1 * K * V_0 & U_1 * K * V_1 \end{pmatrix}.$$

Then, by Theorem 3.1, Lemma 5.1, and Lemma 5.3, this operator has closed range (of finite codimension).

To define the remaining operators D and P we have to partition $K \in l_{m \times n}^1$ into $K = \begin{pmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{pmatrix}$ conformally with the partition above. Recall that \widehat{U}_0 , \widehat{U}_1 , \widehat{V}_0 , and \widehat{V}_1 have been chosen in such a way that the functions $\widehat{U}_1 \widehat{U} [\widehat{U}_0 \widehat{U}]^{-1}$ and $[\widehat{V} \widehat{V}_0]^{-1} \widehat{V} \widehat{V}_1$ in (17) belong to \hat{l}^1 . This means that they are \mathcal{Z} -transforms of some functions in l^1 . Let us denote these l^1 -functions by X_0 and X_1 , respectively. Then B^* can be written in the form $B^* = PDC$, where C is the operator defined above, and D and P are the operators

$$DK = \begin{pmatrix} K_{11} & K_{12} - K_{11} * X_1 \\ K_{21} - X_0 * K_{11} & K_{22} - X_0 * K_{11} * X_1 \end{pmatrix}, \quad PK = \begin{pmatrix} 0 & K_{12} \\ K_{21} & K_{22} \end{pmatrix}.$$

The operator D has a continuous inverse, which we get from the preceding formula for D by changing all minus signs to plus signs. The operator P is a continuous projection operator. Both of these operators have the property that the image of a closed subspace is closed. Thus, $B^* = PDC$ has a closed range, as claimed. \square

7. Alignment conditions. Later we shall need the following well-known connections between the primal and the dual problems. For simplicity we formulate this only for the multiblock case with the dual problem expressed in the form (DUAL'), and we leave the one-block case and the case where the dual problem has been phrased in the form (DUAL) to the reader.

THEOREM 7.1. (i) If (μ, Φ^+, Φ^-) is a feasible solution of (PRIM) and (ν, τ, δ) is a feasible solution of (DUAL') (i.e., the constraints are satisfied, but not necessarily the minimality or maximality condition), then $\mu \geq \nu$.

(ii) If, in addition, $\mu = \nu$, then both solutions are optimal for their respective problem (i.e., the minimality and maximality conditions are satisfied).

(iii) In the optimal case the following alignment conditions are satisfied:

(a) if for some $i \in \{1, \dots, m\}$, $\sum_{jk} (\Phi_{ij}^+(k) + \Phi_{ij}^-(k)) < \mu$, then $\tau_i = 0$;

(b) if $\Phi_{ij}^+(k) > 0$ for some $i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$, and $k \in \{0, 1, \dots\}$, then $\delta_{ij}(k) = \tau_i$;

(c) if $\Phi_{ij}^-(k) > 0$ for some $i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$, and $k \in \{0, 1, \dots\}$, then $\delta_{ij}(k) = -\tau_i$;

(d) if for some $i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$, and $k \in \{0, 1, \dots\}$, both $\Phi_{ij}^+(k) > 0$ and $\Phi_{ij}^-(k) > 0$, then $\tau_i = 0$.

Proof. Using the feasibility of the primal and dual solutions we get

$$\begin{aligned}
 \nu &= \langle H, \delta \rangle \\
 &= \langle \Phi^+ - \Phi^- - (\Phi^+ - \Phi^- - H), \delta \rangle \\
 &= \langle \Phi^+, \delta \rangle - \langle \Phi^-, \delta \rangle \\
 (31) \quad &\leq \langle \Phi^+, E^* \tau \rangle + \langle \Phi^-, E^* \tau \rangle \\
 &= \langle E(\Phi^+ + \Phi^-), \tau \rangle \\
 &\leq \mu \langle \mathbf{1}, \tau \rangle \\
 &= \mu.
 \end{aligned}$$

This proves part (i). Part (ii) is a direct consequence of part (i). Finally, by inspecting the inequalities in the computation above, and checking when they reduce to equalities, we get (iii). \square

If $\tau_i = 0$ for some $i \in \{1, \dots, m\}$, then the corresponding double inequalities in (DUAL) and (DUAL') collapse into equalities. This means that there is an extensive degeneracy in the dual problem, and that we can expect an infinite-dimensional nonuniqueness in the primal problem. It follows from (a) and (d) in Theorem 7.1 that this happens whenever the optimal primal solution contains a row i satisfying $\sum_{jk} |\Phi_{ij}(k)| < \mu$. Of course, if $m = 1$, i.e. U contains only one row, then this problem never shows up, since in that case $\tau_1 = 1$. For more details, see the discussion in §§8 and 9.

8. Solution methods. In [5] Dahleh and Pearson introduced a method for solving the linear programming version of (OPT), and the same method was used in [10]. In this method we restrict the number of nonzero variables $\Phi(k)$ in the primal problem, i.e., we solve a sequence of truncated problems

$$\begin{aligned}
 &\text{minimize } \mu, \\
 &1\mu - E(\Phi^+ + \Phi^-) \geq 0, \\
 &A(\Phi^+ - \Phi^-) = a, \\
 (\text{PRIM})_N \quad &B * (\Phi^+ - \Phi^-) = b, \\
 &(\Phi^+)(k) = (\Phi^-)(k) = 0, \quad k > N, \\
 &\Phi^+, \Phi^- \geq 0,
 \end{aligned}$$

where $N \rightarrow \infty$. The dual of this problem is

$$\begin{aligned}
 &\text{maximize } \nu = \langle a, \eta \rangle + \langle b, \gamma \rangle, \\
 (\text{DUAL})_N \quad &1^* \tau = 1, \\
 &-E^* \tau \leq (A^* \eta + B^* * \gamma)(k) \leq E^* \tau, \quad k \in \{0, 1, \dots, N\}.
 \end{aligned}$$

Clearly, since $(\text{PRIM})_N$ contains additional restrictions compared to (PRIM), and since the number of these additional restrictions decrease for increasing N , the optima μ_N of the truncated problems form a nonincreasing sequence, bounded from below by the optimum μ of (PRIM). Moreover, since the set of sequences with finite support is dense in l^1 , it is clear that $\mu_N \rightarrow \mu$ as $N \rightarrow \infty$. We shall refer to this method as the FMV method (finitely many variables in the primal problem).

As it was pointed out in [5] and [10], the FMV method has two drawbacks. One of them is that it cannot always be applied, due to the fact that the systems $(\text{PRIM})_N$

need not have any feasible solutions, i.e., there are cases where (PRIM) has no feasible solution Φ with finite support. A precise description of this class of problems where the FMV method fails was given in [10]; in particular, it requires \widehat{H} , \widehat{U} , and \widehat{V} to be rational functions. Another serious drawback is that there is no way of telling how close the optimum μ_N of the truncated problem (PRIM) $_N$ is to the optimum μ of the full problem, i.e., there is no way of knowing how good the solution of the truncated problem is.

The drawbacks mentioned previously prompted the author to propose another method in [14] for the solution of (PRIM); the same method was proposed independently by Dahleh in [3]. In this approach we drop all but finitely many equations, i.e., we solve the problem

$$\begin{aligned}
 & \text{minimize } \mu, \\
 (\text{PRIM})_M \quad & \mathbf{1}\mu - E(\Phi^+ + \Phi^-) \geq 0, \\
 & A(\Phi^+ - \Phi^-) = a, \\
 & (B * (\Phi^+ - \Phi^-))(\ell) = b(\ell), \quad \ell \in \{0, 1, \dots, M\}, \\
 & \Phi^+, \Phi^- \geq 0,
 \end{aligned}$$

where the constraints $(B * \Phi)(\ell) = b(\ell)$ have been ignored for $\ell > M$ for some number M , and let $M \rightarrow \infty$. The dual of a primal problem truncated in this way is a truncated version of (DUAL),

$$\begin{aligned}
 & \text{maximize } \nu = \langle a, \eta \rangle + \langle b, \gamma \rangle, \\
 (\text{DUAL})_M \quad & \mathbf{1}^* \tau = 1, \\
 & -E^* \tau \leq (A^* \eta + B^* * \gamma) \leq E^* \tau, \\
 & \gamma(\ell) = 0, \quad \ell > M,
 \end{aligned}$$

where we impose the extra condition $\gamma(\ell) = 0$ for $\ell > M$. Since (DUAL) $_M$ contains additional restrictions compared to (DUAL), and since the number of these additional restrictions decrease for increasing M , it is clear that the optima of the truncated problems form a nondecreasing sequence, bounded from above by the supremum of (DUAL) posed in $\mathbf{R}^{\sigma_{UV}} \times c^0_{(mn-pq)}$. Moreover, since the set of sequences with finite support is dense in c^0 , the optima of the truncated dual problem tend to the supremum of (DUAL) in $\mathbf{R}^{\sigma_{UV}} \times c^0_{(mn-pq)}$ as $M \rightarrow \infty$. We shall refer to this method as the FME method (finitely many equations in the primal problem).

Since the optimum of (PRIM) is equal to the supremum of (DUAL) in $\mathbf{R}^{\sigma_{UV}} \times c^0_{(mn-pq)}$, the limits of the optima obtained from the FMV method and the FME method are the same. Thus, by applying both these methods at the same time we get both upper bounds and lower bounds on the true optimum, and we may compute the optimum of the full problem to within any given tolerance.

Although it is clear in principle what we should do, one major obstacle remains: How do we solve the truncated problems?

Let us first discuss the solution of the truncated problems in the FMV method. For this method to be applicable we have to assume that the tensor sequence B and the vector sequence b have finite support. Then, if we require $\Phi(k) = 0$ for $k > N$, then both $(B * \Phi)(\ell)$ and $b(\ell)$ vanish for sufficiently large ℓ . This means that, although the problem formally is infinite dimensional, all but finitely many equations are satisfied trivially. Thus, instead of having an infinite-dimensional linear

programming system we have a finite-dimensional one, to which we may apply any standard linear programming solution method. (It may be the case that this finite-dimensional system has no feasible solution for any N , and in this case the FMV method fails; however, in a fair number of cases feasible solutions do exist; cf. [10].)

The situation is more complicated in the FME case, because there it is not obvious that each truncated system can be reduced to a finite-dimensional one. (As we shall see in a moment, this is indeed the case.) However, there is one simple case where everything is very straightforward, namely, the case where \mathcal{Z}_{UV} is empty. In this case the operator A is not present in (PRIM) and (DUAL). If we force $\gamma(\ell) = 0$ for $\ell > M$, then, by (29), $B^* \cdot \gamma(k) = 0$ for $k > M$. Thus, there are only a finite number of inequalities in (DUAL) that are not satisfied trivially (recall that $(E^* \tau)_{ij} = \tau_i \geq 0$). This means that we are again left with a finite-dimensional linear programming problem that can be solved with standard methods. This special case seems to be of substantial interest as many real world problems can be formulate in this way; see [13].

The argument above does not apply to a typical one-block case or multiblock case where A is present (if A is absent in the one-block case then the optimal solution is 0; the solution of the multiblock case may be nontrivial even if A is zero). To understand the multiblock case it is crucial that we understand how the one-block case may be handled; therefore let us first discuss the one-block case, where the convolution operators B^* and B^{**} are absent. That case was solved in [4] in the special case where only the zero-order derivatives are needed in (14). The solution of the general case is based on the following lemma (cf. [4, Thm. 5]).

LEMMA 8.1. *Let C be an operator from \mathbf{R}^r to one-dimensional real c^0 . Then there is some $N \geq 0$ such that $\sup_{k > N} |(C\eta)(k)| \leq \max_{k \leq N} |(C\eta)(k)|$ for every $\eta \in \mathbf{R}^r$, and the inequality is strict whenever $C\eta \neq 0$.*

Proof. For each k , we may write $(C\eta)(k)$ in the form $(C\eta)(k) = \sum_{j=1}^r c_{kj}\eta_j$. Thus we may regard C as an $\infty \times r$ -dimensional matrix. The assumption that C maps \mathbf{R}^r into c^0 means that $c_{kj} \rightarrow 0$ as $k \rightarrow \infty$.

Without loss of generality, we may suppose that the rank of C is r (otherwise the column rank of C will be less than r , and we may drop some of the columns of C without affecting the range of C , and decrease r). We may further assume that the mapping which takes η into the first r components of $C\eta$ has rank r (otherwise permute some of the rows of C). Let x represent the first r components of $C\eta$, and let D be the matrix of rank r that maps η into x (D consist of the first r rows of C). Then $\eta = D^{-1}x$.

For each k we have $|(C\eta)(k)| \leq \sum_{j=1}^r |c_{kj}\eta_j| \leq \|C_k\|_1 \|\eta\|_\infty$, where $\|C_k\|_1 = \sum_j |c_{kj}|$ and $\|\eta\|_\infty = \max_j |\eta_j|$. Replacing η by $D^{-1}x$, we get $|(C\eta)(k)| \leq \|C_k\|_1 \|D^{-1}\| \|x\|_\infty$, where $\|D^{-1}\|$ is the operator norm of D^{-1} as an operator from \mathbf{R}^r with the l^∞ -norm to itself. Thus, if we choose N so large that $\|C_k\|_1 \|D^{-1}\| < 1$ for all $k > N$, then

$$\sup_{k > N} |(C\eta)(k)| \leq \|C_k\|_1 \|D^{-1}\| \|x\|_\infty \leq \|x\|_\infty = \max_{k \leq r} |(C\eta)(k)| \leq \max_{k \leq N} |(C\eta)(k)|,$$

and the inequality is strict whenever $x \neq 0$, i.e., $C\eta \neq 0$. \square

By using Lemma 8.1 it is easy to prove the following theorem for the one-block case.

THEOREM 8.2. *In the one-block case the dual problem (DUAL₁) is equivalent to a problem with finitely many constraints, i.e., there is some $N > 0$ such that it is*

equivalent to the problem

$$\begin{aligned}
 & \text{maximize } \nu = \langle a, \eta \rangle, \\
 (\text{DUAL}_1)_N \quad & \mathbf{1}^* \tau = 1, \\
 & -E^* \tau \leq (A^* \eta)(k) \leq E^* \tau \quad k \in \{0, 1, \dots, N\}.
 \end{aligned}$$

This number N depends only on the zero structures of \widehat{U} and \widehat{V} ; in particular, it is independent of H .

Proof. For each i , let D_i be the operator that maps $\eta \in \mathbf{R}^{\sigma_{UV}}$ into $(A^* \eta)_{ij}(k)$. As it was pointed out when the operator A was first introduced, $A(k) \rightarrow 0$ as $k \rightarrow \infty$; hence D_i maps $\mathbf{R}^{\sigma_{UV}}$ into c^0 . Apply Lemma 8.1 to conclude that there is some number N_i such that $\sup_{1 \leq j \leq n, k > N} |(A^* \eta)_{ij}(k)| \leq \max_{1 \leq j \leq n, k \leq N} |(A^* \eta)_{ij}(k)|$ for every $\eta \in \mathbf{R}^{\sigma_{UV}}$. Choose $N = \max\{N_i\}$ to get the conclusion of Theorem 8.2. \square

COROLLARY 8.3. *In the one-block case the primal problem (PRIM_1) has a solution Φ that satisfies $\Phi(k) = 0$ for $k > N$, where N is the number given by Theorem 8.2. Moreover, it is possible to choose Φ in such a way that at most $\sigma_{UV} + m - 1$ of the components $\Phi_{ij}(k)$ are nonzero.*

The first claim follows from the fact that the dual problem of $(\text{DUAL}_1)_N$ is equal to (PRIM_1) with the additional restriction $\Phi^+(k) = \Phi^-(k) = 0$ for $k > N$, and the second claim is a standard result saying that in a system with $\sigma_{UV} + m$ inequalities we can find a solution with at most $\sigma_{UV} + m$ nonzero components, and one of these nonzero components is the variable μ . This corollary is closely related to [10, Thm. 5], although the proof given here is quite different from the one in [10].

The same argument can be applied to problem $(\text{DUAL})_M$, since (29) implies that $B^* * \gamma(k) \rightarrow 0$ as $k \rightarrow \infty$ whenever γ has finite support. Thus, the following theorem is true.

THEOREM 8.4. *In the multiblock case the problem $(\text{DUAL})_M$ is equivalent to a problem with finitely many constraints, i.e., there is some $N > 0$ such that it is equivalent to the problem*

$$\begin{aligned}
 & \text{maximize } \nu = \langle a, \eta \rangle + \langle b, \gamma \rangle, \\
 (\text{DUAL})_{MN} \quad & \mathbf{1}^* \tau = 1, \\
 & -E^* \tau \leq (A^* \eta + B^* * \gamma)(k) \leq E^* \tau, \quad k \in \{0, 1, \dots, N\}, \\
 & \gamma(\ell) = 0, \quad \ell > M.
 \end{aligned}$$

This number N is independent of H .

This means that the FME method also amounts to the solution of a sequence of finite-dimensional linear programming problems.

The problem $(\text{DUAL})_{MN}$ can be considered as the dual of the following problem:

$$\begin{aligned}
 & \text{minimize } \mu, \\
 (\text{PRIM})_{MN} \quad & \mathbf{1}\mu - E(\Phi^+ + \Phi^-) \geq 0, \\
 & A(\Phi^+ - \Phi^-) = a, \\
 & (B * (\Phi^+ - \Phi^-))(\ell) = b(\ell), \quad \ell \in \{0, 1, \dots, M\}, \\
 & (\Phi^+)(k) = (\Phi^-)(k) = 0, \quad k > N, \\
 & \Phi^+, \Phi^- \geq 0.
 \end{aligned}$$

Observe that this is exactly the same problem that we solve in the FMV method, except for the fact that in the FMV method M is large compared to N , whereas

in the FME method N is large compared to M . Since all standard programs for solving finite-dimensional linear programming systems produce the solution to both the primal problem and the dual problem at the same time, it does not really matter which one of the two problems $(\text{PRIM})_{MN}$ or $(\text{DUAL})_{MN}$ that we solve. This means that the only essential difference in the two methods is the difference in the sizes of M and N .

9. Determining the size of a truncated problem. According to the discussion in the preceding section, the FME method can always be applied, even when the functions \hat{H} , \hat{U} , and \hat{V} are not rational, and the sequence of optima that we get for the truncated problems converges to the optimum of the original problem. However, this is not the whole truth. Theorem 8.4 does not give any explicit formula for the calculation of the number N . A very crude estimate can be obtained from the proofs of Lemmas 8.1 and 8.2: At each step (i.e., for each M) we invert m different square matrices of size $(\sigma_{UV} + (mn - pq)(M + 1))^2$ (one for each i), and compute the l^∞ operator norms of these matrices. (We believe that it is possible to get a much better estimate based on the replacement of the l^∞ matrix norm by the l^2 matrix norm, but even the computation of this improved estimate requires a fair amount of work.) In the one-block this phase appears only once, and it can be afforded, but in the multiblock case this produces becomes rather expensive in terms of computation time. In addition, there is no guarantee that the problems do not become numerically ill behaved with increasing M . For this reason it would be very desirable to have some alternative method of estimating the number N corresponding to the number M in the FME method. (The upper bound on M that corresponds to a given N in the FMV method is of the type $M = N + \text{constant}$, so the computation of M in the FMV method presents no problems.)

In the case $m = 1$ there is a simple and effective solution to this problem. Recall that when $m = 1$, we have $\tau_1 = 1$. Moreover, recall that $(B^* * \gamma)(k) = 0$ for $k > M$. Thus, the problem is to determine, for each M and η , a bound $N > M$ such that

$$\left| \sum_{r=1}^{\sigma_{UV}} \eta_r A_{r1j}(k) \right| \leq 1, \quad k > N.$$

However, this is easy. If we use a standard Simplex type solution method, then at each stage of the computation we have explicit access to the vector η that currently is considered, and it suffices to choose $N > M$ so large that

$$\sup_r |\eta_r| \sum_{r=1}^{\sigma_{UV}} |A_{r1j}(k)| \leq 1, \quad k > N.$$

Thus, it is possible to determine during each step of the solution process exactly how large values of k need to be considered at that moment, and we can avoid the costly computation of the a priori upper bounds on N . If necessary, it is not difficult to increase the size of N during the solution process, since the matrix A has a form that makes it easy to compute additional coefficients from the original zero structures of \hat{U} and \hat{V} .

The case where $m > 1$ is more problematic. The same method that we just mentioned works in the case where each $\tau_i > 0$; the only difference is that we have to take $N > M$ so large that, for all $i \in \{1, \dots, m\}$ and all $j \in \{1, \dots, n\}$,

$$\sup_r |\eta_r| \sum_{r=1}^{\sigma_{UV}} |A_{rij}(k)| \leq \tau_i, \quad k > N.$$

If the optimal solution of (DUAL) is such that $\tau_i > 0$ for all i , then we expect the intermediate problems to have the same property for large enough M , and the computations can be carried out in an efficient way. (For further comments on this, see §§10 and 11.) If, however, at some stage of the computation one or more of the variables τ_i become zero, then we must use some alternative method, such as the one outlined in the beginning of this section.

The problem of having one or more of the variables $\tau_i = 0$ is more severe than it might appear at first glance, because it is quite common that the optimal solution has some of the variables τ_i equal to zero. See the discussion following Theorem 7.1. One possible solution to this problem is based on the following theorem that was proved in [15, Thm. 5.2] (that theorem is stated in a slightly different context, but the same proof applies without change).

THEOREM 9.1. *The matrix sequence that we get from an optimal solution Φ of the primal problem by dropping those rows i for which*

$$\sum_{j,k} |\Phi_{ij}(k)| < \max_i \sum_{j,k} |\Phi_{ij}(k)|$$

is optimal for the corresponding reduced problem, i.e., the problem that we get by dropping the corresponding rows of H and U . Moreover, the optimal values of the full problem and the reduced problem are the same.

Thus, if it appears that there are rows i in the optimal solution for which

$$\sum_{j,k} |\Phi_{ij}(k)| < \max_i \sum_{j,k} |\Phi_{ij}(k)|,$$

then one possibility is to simply drop these rows, and to solve a smaller problem.

There is a very interesting open question related to this approach: Is it always true that the smaller problem has the same rank as the original problem, and that it satisfies Assumption 1.1? (We conjecture that the answer is yes, at least generically.) If this is the case, then it is possible to construct a continuous, one-to-one mapping between all the feasible solutions of the smaller problem and the feasible solutions of the full problem.

LEMMA 9.2. *Let $I \subset \{1, \dots, m\}$ be an index set, and let $(\text{OPT})_I$ be the problem that we get from (OPT) by dropping all those rows i of H and U for which $i \notin I$. Suppose that the new matrix U has the same rank p as the original matrix has (in particular, I contains at least p indices; hence $m > p$, and we are in the multiblock case), and that the new matrix U satisfies Assumption 1.1. Then there is a bicontinuous one-to-one correspondence between the feasible solutions of $(\text{OPT})_I$ and the feasible solutions of (OPT).*

Proof. Let P_I be the $m \times m$ -dimensional projection matrix

$$(32) \quad P_I = \text{diag}(d(i)), \text{ where } d(i) = \begin{cases} 1, & \text{if } i \in I, \\ 0, & \text{if } i \notin I. \end{cases}$$

Then the reduced problem $(\text{OPT})_I$ can be written in the form

$$(\text{OPT})_I \quad \text{minimize } \|\Phi_I\|_{l^1} \text{ over all } \Phi_I \text{ of the form } \Phi_I = P_I H - P_I U * Q * V \text{ where } Q \in l^1 \text{ and } \|\Phi_I\|_{l^1} \text{ is given by (2).}$$

Clearly, each feasible solution Φ of (OPT) induces a feasible solution $\Phi_I = P_I \Phi$ of $(\text{OPT})_I$, and the mapping from Φ to Φ_I is continuous.

Conversely, suppose that $P_I U$ has rank p , and that Assumption 1.1 holds with \hat{U} replaced by $P_I \hat{U}$. Let Φ_I be a feasible solution of $(\text{OPT})_I$. By Lemma 6.3, there is a continuous map from Φ_I onto the free parameter Q in $(\text{OPT})_I$. Let Φ be the function that we get from Φ_I by first mapping $\Phi_I = P_I H - P_I U * Q * V$ onto Q , and then mapping Q onto $\Phi = H - U * Q * V$. Then Φ depends continuously on Φ_I , Φ is a feasible solution of (OPT) , and $\Phi_I = P_I \Phi$, as required. \square

Another possibility in the degenerate case is to perturb the original problem so that, instead of using the pure operator-norm $\|\Phi\|_{l^1}$ of Φ given by (2), we use the norm

$$(33) \quad \|\Phi\|_\epsilon = \max_{i \in \{1, \dots, m\}} \sum_{j=1}^n \sum_{k=0}^{\infty} |\Phi_{ij}(k)| + \epsilon \sum_{i=1}^m \sum_{j=1}^n \sum_{k=0}^{\infty} |\Phi_{ij}(k)|,$$

where ϵ is some small positive constant. When this change is incorporated in (DUAL) , then the crucial bound (9) is relaxed to

$$(34) \quad \sup_r |\eta_r| \sum_{r=1}^{\sigma_{UV}} |A_{rij}(k)| \leq \tau_i + \epsilon, \quad k > N.$$

Here the right-hand side cannot be zero, and the method described above works.

10. Convergence of primal and dual variables: FMV scheme. So far we have discussed only the convergence of the optima of the truncated problems to the true optimum. Two other interesting questions are whether the full solutions of the truncated primal problems converge to a full solution of the original primal problem, and whether the full solutions of the truncated dual problems tend to a full solution of the original dual problem. Apart from their theoretical interest, these questions have some practical consequences. One major issue on the dual side is that if the determination of the cutoff number N in the FME scheme is carried out as proposed in §9 then, for computational reasons, it is vital that the weights τ_i corresponding to the optimal solutions of the truncated dual problems behave in a consistent way. More specifically, they should stay bounded away from zero except in the case where the corresponding row is redundant in the optimal solution. In the latter case they should tend to zero. Another possible issue on the primal side, the importance of which is difficult to judge at this time due to the immature state of the theory, is the following. A typical approximate solution produced by the linear programming method is of very high order, and the order is growing without bound as we approach the true optimum. In many case the order of the approximate solution is so high that it does not make sense to implement this particular solution in a design. However, as some evidence presented in [14] and [15] indicates, an optimal solution may often be significantly “simpler,” e.g., of much lower order, than the approximate solutions. Suppose, indeed, that we can prove that the approximate solutions are “close” to a true optimal solution. Then it should be possible to use some order reduction scheme to recover a low order near optimal solution.

In this section we look first at the problem of the convergence of the complete solution of the truncated linear programming problems in the FMV scheme. The same question for the FME scheme is discussed in §11.

We begin with the question of the convergence of the primal variables in the FMV scheme.

THEOREM 10.1. (i) *For the FMV scheme, each subsequence of a sequence Φ_N of optimal solutions to the problem $(\text{PRIM})_N$ contains a subsequence that converges*

weak* in $l^1_{m \times n}$ to an optimal solution Φ of (PRIM). If, moreover, the optimal solution of (PRIM) is unique, then the whole sequence Φ_N tends to the optimal solution Φ of (PRIM) weak* in $l^1_{m \times n}$.

(ii) Let Φ be a optimal solution of (PRIM) that is a weak* limit of some subsequence Φ_{N_ℓ} of optimal solutions Φ_N of (PRIM) $_N$, as described in (i). Let I denote the set of indices $i \in \{1, \dots, m\}$ for which $\sum_{jk} |\Phi_{ij}(k)| = \mu = \sup_i \sum_{jk} |\Phi_{ij}(k)|$, and define the projection matrix P_I as in (32). Then $P_I \Phi_{N_\ell}$ tends to $P_I \Phi$ in the norm of $l^1_{m \times n}$. In other words, if we delete those rows of Φ_{N_ℓ} for which $\sum_{jk} |\Phi_{ij}(k)| < \mu = \sup_i \sum_{jk} |\Phi_{ij}(k)|$, then the remaining part of Φ_{N_ℓ} tends to the corresponding part of Φ in the norm of $l^1_{m \times n}$.

(iii) Let P_I be the projection operator defined in (ii). Suppose that $P_I U$ has the same rank as U , and that Assumption 1.1 holds with \hat{U} replaced by $P_I \hat{U}$. Then the subsequence Φ_{N_ℓ} in (ii) tends to Φ in the norm of $l^1_{m \times n}$.

Compare part (ii) of this theorem to Theorem 9.1. In both places the set of exceptional indices is the same.

Proof. (i) Since the norms $\mu_N = \|\Phi_N\|_{l^1}$ form a bounded (monotonically non-increasing) sequence, the sequence Φ_N is bounded in l^1 . Bounded subsets of l^1 are weak*-sequentially compact; hence each subsequence contains a subsequence that tends weak* to some limit Φ . The limit Φ must satisfy $\Phi - H \in \mathcal{N}([A, B*])$, since this null space is weak* closed, and since $\Phi_N - H \in \mathcal{N}([A, B*])$ for all N . Thus, Φ is an optimal solution of (PRIM). The final conclusion in (i) follows from the fact that if every subsequence has a subsequence that converges to the same limit, then the whole sequence must converge to this limit.

(ii) To simplify the notations slightly, let us replace the subsequence Φ_{N_ℓ} by the original sequence Φ_N . By Fatou's lemma, we have for all $i \in \{1, \dots, m\}$,

$$\sum_{jk} |\Phi_{ij}(k)| \leq \liminf_{N \rightarrow \infty} \sum_{jk} |(\Phi_N)_{ij}(k)|.$$

On the other hand, since $\lim_{N \rightarrow \infty} \|\Phi_N\|_{l^1} = \lim_{N \rightarrow \infty} \mu_N = \mu = \|\Phi\|_{l^1}$, where μ is the optimal value of (PRIM), the reverse inequality holds for all $i \in I$ with \liminf replaced by \limsup . Thus

$$\sum_{jk} |\Phi_{ij}(k)| = \lim_{N \rightarrow \infty} \sum_{jk} |(\Phi_N)_{ij}(k)|, \quad i \in I.$$

However, weak* convergence together with convergence of the norm implies norm convergence in one-dimensional l^1 (the norm in one-dimensional c^0 has the Kadec-Klee property), and we conclude that $P_I \Phi_N$ tends to $P_I \Phi$ in the norm of l^1 , as claimed.

(iii) This follows from (ii) and Lemma 9.2. \square

A partial answer to the uniqueness problem for (PRIM) is given in the following theorem.

THEOREM 10.2. *Let (ν, τ, δ) be an optimal solution of (DUAL'), and define the sets I and I' of indices $i \in \{1, \dots, m\}$ and the sets J , J^+ , and J^- of indices*

$i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$, and $k \in \{0, 1, \dots\}$ as follows:

$$\begin{aligned} I &= \{i \mid \tau_i > 0\}, \\ I' &= \{i \mid \tau_i = 0\}, \\ J &= \{(i, j, k) \mid -\tau_i < \delta_{ij}(k) < \tau_i\}, \\ J^+ &= \{(i, j, k) \mid \delta_{ij}(k) = \tau_i > 0\}, \\ J^- &= \{(i, j, k) \mid \delta_{ij}(k) = -\tau_i < 0\}. \end{aligned}$$

Then the optimal solution (μ, Φ) of (PRIM) is unique (under the additional normalizing assumption that for all i, j , and k , either $\Phi_{ij}^+(k) = 0$ or $\Phi_{ij}^-(k) = 0$) if and only if the following conditions determine $\mu \in \mathbf{R}$ and $\Phi \in l_{m \times n}^1$ uniquely:

$$\begin{aligned} A\Phi &= a, \\ B * \Phi &= b, \\ \sum_{jk} |\Phi_{ij}(k)| &= \mu, & i \in I, \\ \sum_{jk} |\Phi_{ij}(k)| &\leq \mu, & i \in I', \\ \Phi_{ij}(k) &= 0, & (i, j, k) \in J, \\ \Phi_{ij}(k) &\geq 0, & (i, j, k) \in J^+, \\ \Phi_{ij}(k) &\leq 0, & (i, j, k) \in J^-. \end{aligned} \tag{35}$$

Without the normalizing assumption that for all i, j , and k , either $\Phi_{ij}^+(k) = 0$ or $\Phi_{ij}^-(k) = 0$, the solution will not, in general, be unique. This relationship will be satisfied for all indices $i \in I$, but not necessarily for all $i \in I'$.

Proof. By Theorem 7.1, an optimal solution Φ must satisfy (35). Conversely, if Φ satisfies (35), then it is feasible, and checking the computation (31) we find that Φ must be optimal. Thus, every optimal solution satisfies (35), and every solution of (35) is optimal. \square

One interesting fact about Theorem 10.2 is that the conditions (35) do not refer to the dual solution directly; it only refers to the index sets I, I', J, J^+ , and J^- . This fact made it possible to construct the exact solutions of some two-block problems in [14]–[15]. In these cases it was possible to conjecture from the computer printouts what the correct index sets ought to be, and subsequently it was possible to use the equations in (35) (the inequalities in (35) turned out to be redundant) to construct exact optimal solutions. A proof of the optimality was also given, based on the construction of dual solutions corresponding to these index sets.

At this time it is not clear to what extent we may expect the dual solutions of $(\text{DUAL})_N$ to converge to a dual solution of (DUAL). If they stay bounded, then some subsequence must converge weak*, but we do not know what type of conditions that we would have to impose to guarantee the boundedness of a sequence of dual solutions.

11. Convergence of primal and dual variables: FME scheme. Much of Theorem 10.1 remains true for the FME scheme.

THEOREM 11.1. (i) *For the FME scheme, each subsequence of a sequence Φ_M of optimal solutions to the problem $(\text{PRIM})_M$ contains a subsequence that converges*

weak* in $l_{m \times n}^1$ to an optimal solution Φ of (PRIM). If, moreover, the optimal solution of (PRIM) is unique, then the whole sequence Φ_M tends to the optimal solution Φ of (PRIM) weak* in $l_{m \times n}^1$.

(ii) Let Φ be an optimal solution of (PRIM) that is a weak* limit of some subsequence Φ_{M_ℓ} of optimal solutions Φ_M of (PRIM) $_M$, as described in (i). Let I denote the set of indices $i \in \{1, \dots, m\}$ for which $\sum_{jk} |\Phi_{ij}(k)| = \mu = \sup_i \sum_{jk} |\Phi_{ij}(k)|$, and define the projection matrix P_I as in (32). Then $P_I \Phi_{M_\ell}$ tends to $P_I \Phi$ in the norm of $l_{m \times n}^1$. In other words, if we delete those rows of Φ_{M_ℓ} for which $\sum_{jk} |\Phi_{ij}(k)| < \mu = \sup_i \sum_{jk} |\Phi_{ij}(k)|$, then the remaining part of Φ_{M_ℓ} tends to the corresponding part of Φ in the norm of $l_{m \times n}^1$.

The proof of this theorem is essentially the same as the proof of Theorem 10.1.

There is one part missing in Theorem 11.1 compared to Theorem 10.1, namely, part (iii). Part (iii) does not carry over because the solutions of (PRIM) $_M$ are not feasible for the full problem (PRIM); hence, Lemma 9.2 cannot be applied.

The question of the convergence of the dual solutions is much easier for the FME scheme than for the FMV scheme.

THEOREM 11.2. (i) For the FME scheme, every subsequence of a sequence $(\nu_M, \tau_M, \eta_M, \gamma_M)$ of optimal solutions of the problem (DUAL) $_M$ contains a subsequence that tends to an optimal solution (ν, τ, δ) of (DUAL') in the sense that $\nu_{M_\ell} \rightarrow \nu$, $\tau_{M_\ell} \rightarrow \tau$ in \mathbf{R}^m , and $A^* \eta_{M_\ell} + B^* \gamma_{M_\ell} \rightarrow \delta$ weak* in $l_{m \times n}^\infty$. If, moreover, the solution of (DUAL') is unique, then the whole sequence $(\nu_M, \tau_M, \eta_M, \gamma_M)$ tends to (ν, τ, δ) in the sense described above.

(ii) If the matrices $\begin{pmatrix} \hat{V}_0 \\ \hat{V}_1 \end{pmatrix}$ and $\begin{pmatrix} \hat{V}_0 & \hat{V}_1 \end{pmatrix}$ have full rank on the unit circle, then there exists a bounded sequence $(\nu_M, \tau_M, \eta_M, \gamma_M)$ of optimal solutions of (DUAL) $_M$, and each subsequence of such a bounded sequence has a subsequence that tends to an optimal solution $(\nu, \tau, \eta, \gamma)$ of (DUAL) in the sense that $\nu_{M_\ell} \rightarrow \nu$, $\tau_{M_\ell} \rightarrow \tau$ in \mathbf{R}^m , $\eta_{M_\ell} \rightarrow \eta$ in $\mathbf{R}^{\sigma_{UV}}$, and $\gamma_{M_\ell} \rightarrow \gamma$ weak* in $l_{(mn-pq)}^\infty$.

(iii) If the matrices $\begin{pmatrix} \hat{V}_0 \\ \hat{V}_1 \end{pmatrix}$ and $\begin{pmatrix} \hat{V}_0 & \hat{V}_1 \end{pmatrix}$ have full rank everywhere in closed the unit disk \overline{D} , then the operator $[A, B]^*$ is one-to-one, and every sequence of optimal solutions $(\nu_M, \tau_M, \eta_M, \gamma_M)$ of (DUAL) $_M$ is bounded. Thus, in this case (ii) applies to all possible sequences of optimal solutions of (DUAL) $_M$.

(iv) The solution of (DUAL) is unique if and only if the operator $[A, B]^*$ is one-to-one and the solution of (DUAL') is unique. In this case every sequence of solutions $(\nu_M, \tau_M, \eta_M, \gamma_M)$ in (ii) is bounded and tends to the optimal solution $(\nu, \tau, \eta, \gamma)$ of (DUAL) in the sense described in (ii).

Proof. (i) By the restrictions $\mathbf{1}^* \tau_M = 1$ and $-E^* \tau_M \leq A^* \eta_M + B^* \gamma_M \leq E^* \tau_M$ in (DUAL) $_M$, the sequence $A^* \eta_M + B^* \gamma_M$ stays in the unit ball of $l_{m \times n}^\infty$; hence every subsequence of $(\nu_M, \tau_M, \eta_M, \gamma_M)$ contains a subsequence that converges in the sense described in (i) to a limit (ν, τ, δ) . We know from before that $\nu = \lim_{M \rightarrow \infty} \nu_M$ is the optimal value of (DUAL'). Clearly, the limit satisfies $\nu = \langle H, \delta \rangle$, $\mathbf{1}^* \tau = 1$ and $-E^* \tau \leq \delta \leq E^* \tau$. Moreover, $\delta \in \mathcal{N}([A, B]^*)^\perp$ since $A^* \eta_M + B^* \gamma_M \in \mathcal{N}([A, B]^*)^\perp$ for all M , and $\mathcal{N}([A, B]^*)^\perp$ is weak* closed. Thus, the limit is an optimal solution of (DUAL').

(ii) By Lemma 6.4 and the closed range theorem, the range of $[A, B]^*$ is closed. By the open mapping theorem, the mapping $[A, B]^*$ is open from $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^\infty$ onto its range. Thus, there is a bounded subset of $\mathbf{R}^{\sigma_{UV}} \times l_{(mn-pq)}^\infty$ that gets mapped onto the intersection of the unit ball in $l_{m \times n}^\infty$ with $\mathcal{R}([A, B]^*)$. Since $A^* \eta + B^* \gamma$ stays in this intersection whenever (η, γ) is part of a solution of (DUAL) $_M$, it is possible to

choose (η_M, γ_M) to belong to this bounded set. Thus, it is possible to find a bounded sequence of optimal solutions $(\nu_M, \tau_M, \eta_M, \gamma_M)$ of $(\text{DUAL})_M$. The rest of the proof is similar to the proof of (i).

(iii) The claim that $[A, B^*]^*$ is one-to-one is equivalent to the claim that $[A, B^*]$ is surjective (since the range of $[A, B^*]$ is closed). This claim is equivalent to the claim that B^* is surjective, and that A maps $\mathcal{N}(B^*)$ onto $\mathbf{R}^{\sigma_{UV}}$.

Since we assume that the matrices $\begin{pmatrix} \widehat{U}_0 \\ \widehat{U}_1 \end{pmatrix}$ and $\begin{pmatrix} \widehat{V}_0 & \widehat{V}_1 \end{pmatrix}$ have full rank everywhere in closed the unit disk \overline{D} , the operator C defined in the proof of Lemma 6.4 is surjective. The operators D and P defined in the same proof are also surjective. Thus, $B^* = PDC$ is surjective.

The null space of B^* consists of all functions that satisfy (16). By Lemma 4.2, it can be parametrized as the set of all functions K that satisfy $\widehat{K} = \widehat{L}_{U,1} \widehat{S} \widehat{R}_{V,1}$ for some $\widehat{Q} \in \widehat{l}_{p \times q}^1$. The free parameter \widehat{S} satisfies $\widehat{S} = \widehat{U}_0 \widehat{K} \widehat{V}_0$, if \widehat{U}_0 and \widehat{V}_0 are chosen as in (10). The operator A has been defined in such a way that it evaluates certain derivatives of components of $\widehat{S} = \widehat{U}_0 \widehat{K} \widehat{V}_0$ at certain points of D , and since \widehat{S} is a free parameter, this evaluation operator is surjective. Thus, $[A, B^*]$ is surjective, and $[A, B^*]^*$ is one-to-one.

The proof of (iv) is immediate. \square

There is a uniqueness result for the solution of (DUAL') similar to Theorem 10.2.

THEOREM 11.3. *Let (μ, Φ^+, Φ^-) be an optimal solution of (PRIM). Define $\Phi = \Phi^+ - \Phi^-$, and define the sets I and I' of indices $i \in \{1, \dots, m\}$ and the sets J , J^+ , and J^- , of indices $i \in \{1, \dots, m\}$, $j \in \{1, \dots, n\}$, and $k \in \{0, 1, \dots\}$ as follows:*

$$\begin{aligned} I &= \{i \mid \sum_{jk} |\Phi_{ij}(k)| = \mu\}, \\ I' &= \{i \mid \sum_{jk} |\Phi_{ij}(k)| < \mu\}, \\ J &= \{(i, j, k) \mid \Phi_{ij}(k) = 0\}, \\ J^+ &= \{(i, j, k) \mid \Phi_{ij}(k) > 0\}, \\ J^- &= \{(i, j, k) \mid \Phi_{ij}(k) < 0\}. \end{aligned}$$

Then the optimal solution (ν, τ, δ) of (DUAL) is unique if and only if the following conditions determine $\nu \in \mathbf{R}$, $\tau \in \mathbf{R}^m$, and $\eta \in l_{m \times n}^\infty$ uniquely:

$$\begin{aligned} \nu &= \langle H, \delta \rangle, \\ \sum_{i=1}^m \tau_i &= 1, \\ \delta &\in \mathcal{N}([A, B^*])^\perp, \\ \tau_i &\geq 0, \quad i \in I, \\ \tau_i &= 0, \quad i \in I', \\ -\tau_i &\leq \delta_{ij}(k) \leq \tau_i, \quad (i, j, k) \in J, \\ \delta_{ij}(k) &= \tau_i, \quad (i, j, k) \in J^+, \\ \delta_{ij}(k) &= -\tau_i, \quad (i, j, k) \in J^-. \end{aligned} \tag{36}$$

The easy proof of this theorem is left to the reader. As in the case of Theorem 10.2, conditions (36) do not refer to the primal solution directly, but only to the index sets.

12. Computation of suboptimal solutions in the FME scheme. The FMV method has one definite advantage over the FME method: at each step we have access to a suboptimal solution Φ_N of the full problem. Whenever we are ready to decide that the suboptimal value μ_N is sufficiently close to the optimal value μ , no further computations are needed. This should be contrasted to the fact that in the FME method, the functions Φ_M that we get are not feasible for the full problem, and although the FME method produces information about the optimal value μ , it does not directly produce a suboptimal solution whose norm is close to this value.

There is one possibility to bypass this problem. Recall that in the FME method, all the suboptimal solutions satisfy $A(H - \Phi_M) = 0$, i.e., $H - \Phi_M \in \mathcal{N}(A)$. By (11), with \hat{K} replaced by $\hat{H} - \hat{\Phi}_M$, this means that there is some function $Q_M \in l_{p \times q}^1$ such that $\hat{U}_0(\hat{H} - \hat{\Phi}_M)\hat{V}_0 = \hat{N}_U \hat{R}_U \hat{Q}_M \hat{L}_V \hat{N}_V$, where \hat{U}_0 and \hat{V}_0 are the matrices in (10). Solve this for \hat{Q}_M to get

$$(37) \quad \hat{Q}_M = [\hat{R}_U]^{-1}[\hat{N}_U]^{-1}\hat{U}_0(\hat{H} - \hat{\Phi}_M)\hat{V}_0[\hat{N}_V]^{-1}[\hat{L}_V]^{-1}.$$

Observe that, by Theorem 4.4, this would be the correct formula for the computation of \hat{Q} in case $\hat{\Phi}_M$ would be a feasible solution of (PRIM). Define the function Ψ_M by

$$(38) \quad \hat{\Psi}_M = \hat{H} - \hat{U}\hat{Q}_M\hat{V}.$$

Then $\hat{\Psi}_M$ can also be written in the form

$$(39) \quad \hat{\Psi}_M = \hat{H} - \hat{L}_{U,1}\hat{U}_0(\hat{H} - \hat{\Phi}_M)\hat{V}_0\hat{R}_{V,1}.$$

Clearly, by (38) this function Ψ_M is a feasible solution of (PRIM).

THEOREM 12.1. *Let $\{\Phi_{M_\ell}\}$ be a subsequence of solutions obtained from the FME scheme converging weak* to an optimal solution Φ of (PRIM), and define Ψ_{M_ℓ} as in (39), where \hat{U}_0 and \hat{V}_0 are chosen to satisfy (10). Then each Ψ_{M_ℓ} is a suboptimal solution of (PRIM), and $\Psi_{M_\ell} \rightarrow \Phi$ weak*. Moreover, if Φ_{M_ℓ} tends to Φ in the norm of $l_{m \times n}^1$, then so does Ψ_{M_ℓ} . In particular, if we define $\mu_{M_\ell} = \|\Psi_{M_\ell}\|_{l^1}$, then $\nu_{M_\ell} \leq \mu \leq \mu_{M_\ell}$, and, whenever we have norm convergence, $\mu_{M_\ell} - \nu_{M_\ell} \rightarrow 0$.*

In particular, observe that if we have norm convergence, then it is possible to get a converging upper bound on μ without the use of the FMV scheme. If we do not have norm convergence, then it may still be true that we have norm convergence for some reduced problem; see Theorems 9.1 and 11.1(ii).

Proof. The operator defined in (37) that maps $K = H - \Phi_M$ to Q_M is both norm continuous and weak* continuous from $\mathcal{N}(A)$ into $l_{p \times q}^\infty$. Thus, Q_{M_ℓ} tends to the function Q corresponding to the optimal solution Φ , either weak* or in norm, depending on the type of convergence of Φ_{N_ℓ} to Φ . By the same continuity argument, $\Psi_{M_\ell} = H - U * Q_{M_\ell} * V$ tends to $H - U * Q * V = \Phi$. The final claim is obvious. \square

13. About degeneracy. The major part of this paper deals with the two questions of how we should reformulate the model matching problem in l^1 as a linear programming problem in such a way that we avoid unnecessary redundancies, and how different formulations of the problem affect the behavior of the solutions of the two approximation schemes. In other words, we do our best to avoid degeneracies and describe how different degeneracies affect the solutions.

It is quite common to have degeneracies in finite-dimensional linear programming problems, and all standard solvers are required to cope with these in one way or another. In general, if the dimension of the problem is small, then possible degeneracies

do not cause serious trouble. If, however, the dimension of the problem is large, then degeneracies may complicate the solution process and may lead to problems that are quite hard to solve.

In our case the system is infinite-dimensional. The author has solved a number of different problems numerically, and the one thing that has caused the most trouble is the existence of a different type of degeneracies. Some of these problems caused by degeneracies are described in [14] and [15].

One way to characterize the nondegeneracy of the pair of finite-dimensional approximate problems $(\text{PRIM})_{MN}$ and $(\text{DUAL})_{MN}$ is the following. Since these problems are finite dimensional, they have optimal solutions. The pair of problems is nondegenerate if the two optimal solutions are unique, and if, in addition, the following conditions hold for all relevant values of i , j , and k (cf. Theorems 10.2 and 11.3):

$$\begin{aligned}\sum_{jk} |\Phi_{ij}(k)| &= \mu \iff \tau_i > 0, \\ \Phi_{ij}(k) > 0 &\iff (A^* \eta + B^* * \gamma)_{ij}(k) = \tau_i, \\ \Phi_{ij}(k) < 0 &\iff (A^* \eta + B^* * \gamma)_{ij}(k) = -\tau_i.\end{aligned}$$

Note that these conditions, together with the inequalities given in the original problems, imply that

$$\begin{aligned}\sum_{jk} |\Phi_{ij}(k)| < \mu &\iff \tau_i = 0, \\ \Phi_{ij}(k) = 0 &\iff -\tau_i < (A^* \eta + B^* * \gamma)_{ij}(k) < \tau_i.\end{aligned}$$

In particular (as already seen in §7), we must have $\sum_{jk} |\Phi_{ij}(k)| = \mu$ and $\tau_i > 0$ for all i .

In the infinite-dimensional case we could still use the same definition of degeneracy, provided both the primal and dual problems have optimal solutions. As we saw in Theorem 6.2, this is indeed the case whenever the range of $[A, B^*]$ is closed—a problem that we studied in Lemma 6.4. Uniqueness of the optimal dual solution requires the operator $[A, B^*]$ to have a dense range. If the range is closed, then this is equivalent to $[A, B^*]$ being surjective. A condition for this to be the case is given in Theorem 11.3(iii). The numerical problems described on pp. 179–180 of [14] are due to the fact that there the operator $[A, B^*]$ did not have this property.

The properties just described, which can be summarized as the property that $[A, B^*]$ should be surjective, is the only nondegeneracy property that it seems to be possible to build into the system without any a priori knowledge of optimal primal and dual solutions. In particular, since the property of having one or more rows i in the problem where an optimal solution Φ satisfies $\sum_{j,k} |\Phi_{ij}(k)| < \mu = \max_i \sum_{j,k} |\Phi_{ij}(k)|$ is not dependent on the particular linear programming formulation, but only on the original data, this situation cannot be avoided by a different choice of the operators A and B^* . Recall that this means massive nonuniqueness of the primal solution in the sense that in those rows the decomposition of $\Phi_{ij}(k)$ into $\Phi_{ij}(k) = \Phi_{ij}^+(k) - \Phi_{ij}^-(k)$ is no longer unique. However, in some cases this need not be a serious problem, because of the fact that although the decomposition need not be unique, the primal variable Φ itself may be unique; cf. Theorem 9.1, Lemma 9.2, and Theorem 10.1(iii).

CONTROL OF PLANAR NETWORKS OF TIMOSHENKO BEAMS*

J. E. LAGNESE[†], G. LEUGERING[‡], AND E. J. P. G. SCHMIDT[§]

Abstract. The present study is concerned with the questions of controllability and stabilizability of planar networks of vibrating beams consisting of several Timoshenko beams connected to each other by rigid joints at all interior nodes of the system. Some of the exterior nodes are either clamped or free; controls may be applied at the remaining exterior nodes and/or at interior joints in the form of forces and/or bending moments. For a given configuration, is it at all possible to drive all vibrations to the rest configuration in a given finite time interval by means of controls acting at some or all of the available (nonclamped) nodes of the network and, if so, where should such controls be placed? Alternatively, a control objective is to construct energy absorbing boundary-feedback controls that will guarantee uniform energy decay. It is demonstrated that if such a network does not contain closed loops and if at most one of the exterior nodes is clamped, exact controllability and uniform stabilizability of the network is indeed possible by means of controls placed at the free exterior nodes of the system. On the other hand, examples are presented to demonstrate that when a closed loop is present in the network or if the network has more than one clamped exterior node, it may happen that approximate control of the network to its rest configuration is not possible even if controls are placed at every available node of the system.

Key words. control of networks, Timoshenko beams, exact controllability, uniform stabilizability

AMS(MOS) subject classifications. 93C20, 93D15, 35B45

1. Introduction. In this paper are considered the questions of exact controllability and uniform stabilizability of a planar network of Timoshenko beams. Such a system is a particular case of a very general model of three-dimensional beam networks derived in [3] and to which we refer the reader for justification of the joint conditions given below.

The basic assumptions in our model are, first, that each beam of the network is adequately modeled by the Timoshenko beam system as far as transverse displacement and shear angle are concerned, and regarding longitudinal motion by the equation for the small axial deformations of a thin rod. In a system so described, the deformation of each beam is determined solely by the deformation of its centerline. The second assumption is that the deformed centerlines of the collection of beams together form a connected planar graph throughout the deformation process. This is a requirement of planar motion and also of *continuity* of the network at the interior *joints* (where two or more beams meet). The third assumption is that the interior joints are *rigid*. For the system considered here, this means that the rotation angles at a joint of each pair of beams meeting at that joint are the same throughout the deformation process; see [3] for justification of this definition. Obviously, there are other types of joint interactions that could equally well be considered and which will be the subject of subsequent studies.

The requirements of continuity and rigidity of the joints will be referred to as *geometric joint conditions*. In addition, there are *dynamic joint conditions*, repre-

senting balances of forces and moments at each joint. These may be obtained by direct analysis of the forces and moments acting on a joint or, more simply, from the variational formulation of the boundary value problem associated with the beam network, keeping in mind that the variation must be taken with respect to displacements that satisfy the geometric joint conditions described above, in addition to the usual geometric conditions at “simple nodes” (i.e., a node where only one beam begins or ends). Controls are introduced into the structure at the free exterior nodes through appropriate forces and moments and/or at the interior joints through the dynamic joint conditions. The control objective is to bring the entire system to its equilibrium configuration in a finite time, independent of the initial state of the system (exact null controllability). Alternatively, through the application of appropriate energy absorbing type feedback controls, we seek to damp out the vibrations in the structure at a uniform rate (uniform stabilization). We will find that structures for which at most one exterior node is clamped and which do not contain closed loops are both exactly controllable and uniformly stabilizable using controls at only the free exterior nodes of the network. On the other hand, examples will be given that demonstrate that in situations where either of these two conditions is violated, there may exist periodic waves propagating within the structure that cannot be influenced by means of nodal controls; this will be seen to be a highly “nongeneric” situation, however.

To the authors’ knowledge, to date very little research has been done on the problem of controllability, or stabilizability, of multiple-link structures from the point of view of distributed parameter systems. Closest to the spirit of the present paper is the work of Schmidt [9] dealing with exact controllability of a network of vibrating strings, and that of Leugering and Schmidt [6], where exact controllability of a network of rigidly connected Euler–Bernoulli beams was considered using so-called “slide and turn” controls (controls acting in the geometric boundary conditions, rather than through forces and moments, at exterior nodes). However, in [6] exact controllability was established only for a “bundle” of beams, i.e., a collection of beams, all of which emanate from a single multiple joint, with controls applied at all of the exterior nodes. The controllability results of the present paper are much more general in the sense that they apply to a richer class of beam configurations. We should also mention the paper of Chen et al., [1], where the issue of uniform stabilization of a *serially connected* network of Euler–Bernoulli beams was studied, and the work of Lions on exact controllability of “problems of transmission”; see [7, Chap. VI].

2. Description of the model. The network is comprised of n Timoshenko beams, labeled with indices $[1, 2, \dots, n]$. The equilibrium state of the centerline of the i th beam is a straight line segment of length ℓ_i , parametrized by x , $0 \leq x \leq \ell_i$, and is described parametrically by

$$\mathbf{p}_{0i} + x\mathbf{e}_i, \quad 0 \leq x \leq \ell_i,$$

where \mathbf{p}_{0i} is a fixed position vector in \mathbb{R}^3 and \mathbf{e}_i a unit vector in \mathbb{R}^3 directed along the centerline of the i th beam. The \mathbf{e}_i ’s are assumed to be coplanar, and the collection of reference lines is supposed to form a connected set. (We have tacitly assumed that the beam is not subject to tensile loading.) Let \mathbf{e}_i^\perp be a unit vector in the plane containing all of the direction vectors that is orthogonal to \mathbf{e}_i . In Timoshenko beam theory the vector pointing to the deformed material point originally located along the filament

$$\mathbf{p}_{0i} + x\mathbf{e}_i + z\mathbf{e}_i^\perp, \quad |z| \leq h/2,$$

is given by

$$\begin{aligned}\mathbf{R}_i(x, z, t) &:= \mathbf{p}_{0i} + (x + u_i(x, t) + z\psi_i(x, t))\mathbf{e}_i + (z + w_i(x, t))\mathbf{e}_i^\perp \\ &= (\mathbf{p}_{0i} + x\mathbf{e}_i + z\mathbf{e}_i^\perp) + \mathbf{r}_i(x, t) + z\psi_i(x, t)\mathbf{e}_i, \quad i = 1, \dots, n,\end{aligned}$$

where $\mathbf{r}_i = u_i\mathbf{e}_i + w_i\mathbf{e}_i^\perp$, u_i, w_i denote longitudinal and transverse displacements, respectively, of the point originally situated at $\mathbf{p}_{0i} + x\mathbf{e}_i$, and ψ_i is the rotation angle of the filament ($\phi_i = \psi_i + w'_i$ is the *shear angle*).

With this notation, the dynamic equations of motion of the i th beam (in the absence of body forces) are

$$\begin{aligned}(2.1) \quad & \rho_i \ddot{u}_i - E_i A_i u''_i = 0, \\ & \rho_i \ddot{w}_i - K_i (\psi_i + w'_i)' = 0, \\ & I_{\rho_i} \ddot{\psi}_i - E_i I_i \psi''_i + K_i (\psi_i + w'_i) = 0, \quad 0 < x < \ell_i, \quad t > 0.\end{aligned}$$

We have used $\dot{}$ and $'$ to denote time and spatial differentiation, respectively. The physical constants appearing in the above system are ρ_i , the mass density per unit of reference length; A_i , the area of a cross section in the reference configuration; E_i , Young's modulus of elasticity; I_i , the second moment of inertia of a cross section; I_{ρ_i} , the polar moment of inertia of a cross section; and K_i , the shear modulus. Although u_i is uncoupled from the other dependent variables in the above system, it is coupled to them through joint conditions, which we now describe.

A *node* of the beam network is a point in the plane where a beam begins or ends, i.e., an endpoint of a centerline. (We identify a beam with its reference line.) The nodes consist of *simple nodes*, where only one beam begins or ends, and *multiple nodes* (or *joints*), where two or more beams join. Suppose there are a total of m nodes, and label them with indices $[1, 2, \dots, m] := I$. We set $I = I_S \cup I_M$, where

$$\begin{aligned}I_S &= \{i \in I \mid i \text{ belongs to a simple node}\}, \\ I_M &= \{i \in I \mid i \text{ belongs to a multiple node}\}.\end{aligned}$$

We further partition $I_S = I_S^D \cup I_S^N$, $I_M = I_M^D \cup I_M^N$, where

$$\begin{aligned}I_S^D &= \{i \in I_S \mid i \text{ belongs to a clamped simple node}\}, \\ I_S^N &= \{i \in I_S \mid i \text{ belongs to a free simple node}\}, \\ I_M^D &= \{i \in I_S \mid i \text{ belongs to a clamped multiple node}\}, \\ I_M^N &= \{i \in I_S \mid i \text{ belongs to a free multiple node}\}.\end{aligned}$$

(Here we are tacitly assuming that each node belongs to one of these four classes.) To simplify the notation slightly, if $I_S^N \neq \emptyset$ we assume that the beams and nodes have been labeled so that $I_S^N = [1, \dots, p]$ for some $p < m$, and that the beam ending at node N_i ($i=1, \dots, p$) is beam i .

To describe the boundary conditions, it is convenient to introduce the following notation. Let N_k be a node corresponding to an index $k \in I$. Following Schmidt [9] we set

$$\mathcal{E}_k = \{i \in [1, 2, \dots, n] \mid N_k \text{ is an endpoint of beam } i\}.$$

Thus \mathcal{E}_k is a singleton if N_k is a simple node. For each $i \in \mathcal{E}_k$ we set

$$\varepsilon_{ik} = \begin{cases} -1 & \text{if } N_k \text{ corresponds to } x = 0, \\ +1 & \text{if } N_k \text{ corresponds to } x = \ell_i. \end{cases}$$

Then the outward pointing spatial derivative at the i th beam and at node N_k may be written $\varepsilon_{ik}(\partial/\partial x)$. The set of signs of the ε_{ik} at a multiple node is called the *sign arrangement* at N_k . We adopt the convention that

$$\varepsilon_{ik} = \begin{cases} -1 & \text{if } N_k \text{ is associated to an index } i \in I_S^D, \\ +1 & \text{if } N_k \text{ is associated to an index } i \in I_S^N. \end{cases}$$

Thus $x = 0$ at each clamped simple node, while $x = \ell_i$ at a free simple node.

Set $I^D = I_S^D \cup I_M^D$, which contains the indices of the clamped nodes. At such a node the boundary conditions are

$$(2.2) \quad u_i(N_k, t) = w_i(N_k, t) = \psi_i(N_k, t) = 0, \quad \forall i \in \mathcal{E}_k, \quad k \in I^D.$$

At a free simple node the boundary conditions are

$$(2.3) \quad E_i A_i u'_i(N_i, t) = K_i(\psi_i + w'_i)(N_i, t) = E_i I_i \psi'_i(N_i, t) = 0, \quad i = 1, \dots, p.$$

The geometric and dynamic conditions at a free multiple mode are, respectively,

$$(2.4) \quad \mathbf{r}_i(N_k, t) = \mathbf{r}_j(N_k, t), \quad \psi_i(N_k, t) = \psi_j(N_k, t), \quad \forall i, j \in \mathcal{E}_k, \quad \forall k \in I_M^N,$$

and

$$\begin{cases} \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} E_i I_i \psi'_i(N_k, t) = 0, \\ \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} [E_i A_i u'_i \mathbf{e}_i + K_i(\psi_i + w'_i) \mathbf{e}_i^\perp](N_k, t) = 0, \quad \forall k \in I_M^N. \end{cases}$$

Introducing the vector $\mathbf{n} := \mathbf{e}_i \times \mathbf{e}_i^\perp$ (which is independent of i) allows the last set of equations to be written

$$(2.5) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} [E_i A_i u'_i \mathbf{e}_i + K_i(\psi_i + w'_i) \mathbf{e}_i^\perp + E_i I_i \psi'_i \mathbf{n}](N_k, t) = 0, \quad \forall k \in I_M^N.$$

The dynamic joint conditions in their present forms assert that the resultant of bending moments and resultant of forces at each free multiple joint are zero. There is a slight abuse of notation in (2.4), (2.5); for instance, $\mathbf{r}_i(N_k, t)$ stands for $\mathbf{r}_i(0, t)$ or $\mathbf{r}_i(\ell_i, t)$, depending on whether N_k corresponds to $x = 0$ or to $x = \ell_i$.

The dynamic description of the network is completed by prescribing its initial state:

$$(2.6) \quad \mathbf{r}_i(0) = \mathbf{r}_i^0, \quad \dot{\mathbf{r}}_i(0) = \mathbf{r}_i^1, \quad \psi_i(0) = \psi_i^0, \quad \dot{\psi}_i(0) = \psi_i^1, \quad i = 1, 2, \dots, n,$$

with the usual notational convention: $\mathbf{r}_i(0)$ stands for $\mathbf{r}_i(x, 0)$, $0 \leq x \leq \ell_i$, etc.

Example 2.1. Consider the case of the “carpenter’s square” in \mathbb{R}^2 that is free at each simple node, as shown in Fig. 1.

Here we may choose $\mathbf{e}_1 = (1, 0)$, $\mathbf{e}_2 = (0, 1)$, so that $\mathbf{e}_1^\perp = \mathbf{e}_2$ and $\mathbf{e}_2^\perp = -\mathbf{e}_1$. The geometric node conditions at N_1 are therefore

$$u_1(0, t) = -w_2(0, t), \quad u_2(0, t) = w_1(0, t), \quad \psi_1(0, t) = \psi_2(0, t),$$

FIG. 1. *Carpenter's square configuration.*

while the dynamic node conditions there are

$$\begin{aligned} E_1 A_1 u'_1(0, t) - K_2(\psi_2 + w'_2)(0, t) &= 0, \\ E_2 A_2 u'_2(0, t) + K_1(\psi_1 + w'_1)(0, t) &= 0, \\ E_1 I_1 \psi'_1(0, t) + E_2 I_2 \psi'_2(0, t) &= 0. \end{aligned}$$

If N_2 is clamped rather than free, then $\mathbf{e}_2 = (0, -1)$, $\mathbf{e}_1^\perp = -\mathbf{e}_2$ and $\mathbf{e}_2^\perp = \mathbf{e}_1$, so that the geometric and dynamic node conditions then become

$$u_1(0, t) = w_2(\ell_2, t), \quad u_2(\ell_2, t) = -w_1(0, t), \quad \psi_1(0, t) = \psi_2(\ell_2, t),$$

and

$$\begin{aligned} E_1 A_1 u'_1(0, t) - K_2(\psi_2 + w'_2)(\ell_2, t) &= 0, \\ E_2 A_2 u'_2(\ell_2, t) + K_1(\psi_1 + w'_1)(0, t) &= 0, \\ E_1 I_1 \psi'_1(0, t) - E_2 I_2 \psi'_2(\ell_2, t) &= 0, \end{aligned}$$

respectively.

3. Controllability estimates for the Timoshenko network. In this section the a priori estimates that are needed in the study of exact controllability and uniform stabilizability of the Timoshenko network will be established.

The *total energy* of the network is given by

$$\mathcal{Q}(t) = \frac{1}{2} \sum_{i=1}^n \left\{ \int_0^{\ell_i} [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2] dx + \int_0^{\ell_i} [E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w_i')^2] dx \right\}.$$

The sum of the first integrals represents the kinetic energy and the sum of the second the strain energy of the network. Denote by $Q_i(x, t)$ the energy densities:

$$\mathcal{Q}(t) = \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} Q_i(x, t) dx.$$

If u, w, ψ is a sufficiently regular solution of (2.1), the time rate of change of the corresponding energy functional is given by

$$(3.1) \quad \dot{\mathcal{Q}}(t) = \frac{1}{2} \sum_{i=1}^n \int_0^{\ell_i} \dot{Q}_i(x, t) dx$$

$$= \sum_{i=1}^n [E_i A_i u'_i \dot{u}_i + E_i I_i \psi'_i \dot{\psi}_i + K_i (\psi_i + w'_i) \dot{w}_i] \Big|_0^{\ell_i}.$$

At each free simple node and at each clamped node the corresponding terms in the right-hand sum vanish. The rest of the sum may be written

$$(3.2) \quad \sum_{k \in I_M^N} \left(\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} [E_i A_i u'_i \mathbf{e}_i + K_i (\psi_i + w'_i) \mathbf{e}_i^\perp] (N_k, t) \right) \cdot \dot{\mathbf{r}}_{i_k} \\ + \sum_{k \in I_M^N} \left(\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} E_i I_i \psi'_i (N_k, t) \right) \dot{\psi}_{i_k} = 0$$

in view of (2.4) and (2.5), where the index i_k in (3.2) stands for any fixed index in \mathcal{E}_k , for example, $i_k = \min\{i \in \mathcal{E}_k\}$. Therefore, *the total energy of the system (2.1)–(2.5) is time invariant.*

Before proceeding to the derivation of energy estimates, we must say a little bit about existence and regularity of solutions of (2.1)–(2.6). We set

$$H = \prod_{i=1}^n L^2((0, \ell_i); \mathbb{R}^3) \\ = \prod_{i=1}^n L^2(0, \ell_i; [\mathbf{e}_i]) \oplus L^2(0, \ell_i; [\mathbf{e}_i^\perp]) \oplus L^2(0, \ell_i; [\mathbf{n}]),$$

where $[\mathbf{e}]$ denotes the linear span of a unit vector \mathbf{e} . If $\mathbf{R} \in H$ we write

$$\mathbf{R} = (\mathbf{R}_1, \mathbf{R}_2, \dots, \mathbf{R}_n), \quad \mathbf{R}_i = u_i \mathbf{e}_i + w_i \mathbf{e}_i^\perp + \psi_i \mathbf{n} = \mathbf{r}_i + \psi_i \mathbf{n}.$$

The norm on H is taken to be

$$\|\mathbf{R}\|_H = \left[\sum_{i=1}^n \int_0^{\ell_i} (\rho_i |\mathbf{r}_i|^2 + I_{\rho_i} \psi_i^2) dx \right]^{1/2}.$$

We also define

$$V = \left\{ \mathbf{R} \in \prod_{i=1}^n H^1((0, \ell_i); \mathbb{R}^3) \mid \mathbf{R} \text{ satisfies (2.2) and (2.4)} \right\}.$$

If $I^D \neq \emptyset$, the following defines a norm on V equivalent to the norm induced on V by $\prod_{i=1}^n H^1((0, \ell_i); \mathbb{R}^3)$ with its standard topology:

$$\|\mathbf{R}\|_V = \left\{ \sum_{i=1}^n \int_0^{\ell_i} [E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w_i')^2] dx \right\}^{1/2}.$$

If $I^D = \emptyset$, V may be defined as a quotient space modulo the rigid motions $\mathbf{R}_i = a_i \mathbf{e}_i + (c_i - b_i x) \mathbf{e}_i^\perp + b_i \mathbf{n}$ that satisfy (2.4). We note that

$$\mathcal{Q}(t) = \frac{1}{2} \left(\|\dot{\mathbf{R}}(t)\|_H^2 + \|\mathbf{R}(t)\|_V^2 \right).$$

The system (2.1)–(2.5) may be written as a variational equation as follows. Let \mathbf{R} be a solution of (2.1)–(2.5) and $\hat{\mathbf{R}} \in V$ be a test function. Form the $L^2((0, \ell_i); \mathbb{R}^3)$ scalar product of (2.1) with $\hat{\mathbf{R}}_i$ and sum over i from 1 to n . We obtain, with the aid of (2.2)–(2.5), the variational equation

$$(\ddot{\mathbf{R}}, \hat{\mathbf{R}})_H + (\mathbf{R}, \hat{\mathbf{R}})_V = 0, \quad \forall \hat{\mathbf{R}} \in V$$

or, equivalently,

$$(3.3) \quad \ddot{\mathbf{R}} + A\mathbf{R} = 0 \quad \text{in } V',$$

where V' denotes the dual space of V with respect to H and A is the Riesz isomorphism of V onto V' . The initial conditions (2.6) are written

$$(3.4) \quad \mathbf{R}(0) = \mathbf{R}^0, \quad \dot{\mathbf{R}}(0) = \mathbf{R}^1.$$

It follows from standard theory that if $(\mathbf{R}^0, \mathbf{R}^1) \in H \times V'$, then (3.3), (3.4) has a unique solution with $(\mathbf{R}, \dot{\mathbf{R}}) \in C([0, \infty); H \times V')$, called a *weak solution*; if $(\mathbf{R}^0, \mathbf{R}^1) \in V \times H$, then $(\mathbf{R}, \dot{\mathbf{R}})$ has the regularity $C([0, \infty); V \times H)$, and we then call the solution a *finite energy solution*; and if $(\mathbf{R}^0, \mathbf{R}^1) \in D_A \times V$ then $(\mathbf{R}, \dot{\mathbf{R}})$ belongs to $C([0, \infty); D_A \times V)$ and the solution called a *classical solution*, where

$$D_A = \{\mathbf{R} \in V \mid A\mathbf{R} \in H\}, \quad \|\mathbf{R}\|_{D_A} = \|A\mathbf{R}\|_H.$$

It is not difficult to verify that

$$\mathbf{R} \in D_A \iff \mathbf{R}_i \in H^2((0, \ell_i); \mathbb{R}^3) \text{ and satisfies (2.2)–(2.5), } i = 1, \dots, n.$$

An energy identity that is the basis for the a priori estimates to follow will now be derived.

PROPOSITION 3.1. *The following identity holds for each $T > 0$ and each classical solution of (2.1):*

$$(3.5) \quad f(T) - f(0) + \frac{1}{2} \sum_{i=1}^n \int_0^T \int_0^{\ell_i} [\alpha'_i Q_i - 2\alpha_i \rho_i \dot{w}_i \dot{\psi}_i + 2\alpha_i K_i \psi'_i (\psi_i + w'_i)] dx dt \\ = \frac{1}{2} \sum_{k=1}^m \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \int_0^T Q_i(N_k, t) dt,$$

where α_i is any $C^1([0, \ell_i])$ function and where

$$f(t) = \sum_{i=1}^n \int_0^{\ell_i} \alpha_i [\rho_i \dot{u}_i u'_i + \rho_i \dot{w}_i (\psi_i + w'_i) + I_{\rho_i} \dot{\psi}_i \psi'_i] dx.$$

A corollary of (3.5) is the following energy estimate.

COROLLARY 3.2. *Let*

$$k_i = \max \left(\sqrt{\frac{\rho_i}{I_{\rho_i}}}, \sqrt{\frac{K_i}{E_i I_i}} \right),$$

and let α_i be a positive, strictly increasing C^1 function on $[0, \ell_i]$ such that $\alpha'_i/\alpha_i > k_i$, $i = 1, 2, \dots, n$. For each $T > 0$ and each finite energy solution of (2.1)–(2.5) there are positive constants c_0, T_0 such that

$$(3.6) \quad c_0(T - T_0)\mathcal{Q}(0) \leq \frac{1}{2} \sum_{i=1}^p \alpha_i(N_i) \int_0^T [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2](N_i, t) dt \\ + \frac{1}{2} \sum_{k \in I_M} \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \int_0^T Q_i(N_k, t) dt.$$

Proof of Proposition 3.1. Identity (3.5) is proved by the use of multipliers and integrations by parts in the standard way. We multiply the three equations in (2.1) by $\alpha_i u'_i$, $\alpha_i w'_i$, and $\alpha_i \psi'_i$, respectively, add the three products, and apply $\int_0^T \int_0^{\ell_i}$ to the sum. (We might, of course, try different multipliers for each equation or even multiply (2.1) by $\mathcal{M}_i(x)(u'_i \ w'_i \ \psi'_i)^*$ using a 3×3 matrix \mathcal{M}_i of multipliers. But to obtain something useful we are forced in the end to choose \mathcal{M}_i diagonal and, moreover, nothing extra is gained by choosing distinct diagonal elements.) We obtain after an integration by parts

$$(3.7) \quad f_{1i}(T) - f_{1i}(0) + \frac{1}{2} \int_0^T \int_0^{\ell_i} \alpha'_i [\rho_i (\dot{u}_i^2 + \dot{w}_i^2) + I_{\rho_i} \dot{\psi}_i^2] dx dt \\ - \frac{1}{2} \int_0^T \alpha_i [\rho_i (\dot{u}_i^2 + \dot{w}_i^2) + I_{\rho_i} \dot{\psi}_i^2] \Big|_0^{\ell_i} dt \\ - \int_0^T \int_0^{\ell_i} \alpha_i [E_i A_i u''_i u'_i + K_i (\psi_i + w'_i)' w'_i \\ + E_i I_i \psi''_i \psi'_i - K_i (\psi_i + w'_i) \psi'_i] dx dt = 0,$$

where

$$(3.8) \quad f_{1i}(t) = \int_0^{\ell_i} \alpha_i [\rho_i (\dot{u}_i u'_i + \dot{w}_i w'_i) + I_{\rho_i} \dot{\psi}_i \psi'_i] dx.$$

We have

$$(3.9) \quad - \int_0^T \int_0^{\ell_i} \alpha_i [E_i A_i u''_i u'_i + K_i (\psi_i + w'_i)' w'_i + E_i I_i \psi''_i \psi'_i - K_i (\psi_i + w'_i) \psi'_i] dx dt \\ = - \frac{1}{2} \int_0^T [\alpha_i (E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w'_i)^2)] \Big|_0^{\ell_i} dt \\ + \frac{1}{2} \int_0^T \int_0^{\ell_i} \alpha'_i [E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w'_i)^2] dx dt \\ + \int_0^T \int_0^{\ell_i} \alpha_i K_i [\psi_i (\psi_i + w'_i)' + (\psi_i + w'_i) \psi'_i] dx dt.$$

Substitution of (3.9) into (3.7) yields

$$(3.10) \quad f_{1i}(T) - f_{1i}(0) + \int_0^T \int_0^{\ell_i} \alpha_i K_i [\psi_i (\psi_i + w'_i)' + (\psi_i + w'_i) \psi'_i] dx dt \\ + \frac{1}{2} \int_0^T \int_0^{\ell_i} \alpha'_i(x) Q_i(x, t) dx dt - \frac{1}{2} \int_0^T \alpha_i(x) Q_i(x, t) \Big|_{x=0}^{\ell_i} dt = 0.$$

From (2.1) we have

$$(3.11) \quad \int_0^T \int_0^{\ell_i} \alpha_i K_i \psi_i (\psi_i + w'_i)' dx dt = \int_0^T \int_0^{\ell_i} \alpha_i \rho_i \psi_i \ddot{w}_i dx dt \\ = f_{2i}(T) - f_{2i}(0) - \int_0^T \int_0^{\ell_i} \alpha_i \rho_i \dot{\psi}_i \dot{w}_i dx dt,$$

where

$$f_{2i}(t) = \int_0^{\ell_i} \alpha_i \rho_i \psi_i \dot{w}_i dx.$$

It follows from (3.10) and (3.11) that

$$(3.12) \quad f_i(T) - f_i(0) + \frac{1}{2} \int_0^T \int_0^{\ell_i} [\alpha'_i Q_i - 2\alpha_i \rho_i \dot{w}_i \dot{\psi}_i + 2\alpha_i K_i \psi'_i (\psi_i + w'_i)] dx dt \\ = \frac{1}{2} \int_0^T \alpha_i Q_i \Big|_{x=0}^{\ell_i} dt,$$

where $f_i = f_{1i} + f_{2i}$. Proposition 3.1 now follows upon summing (3.12) over i from 1 to n . \square

Proof of Corollary 3.2. We have

$$\alpha'_i Q_i - 2\alpha_i \rho_i \dot{w}_i \dot{\psi}_i + 2\alpha_i K_i \psi'_i (\psi_i + w'_i) \geq c_0 Q_i$$

for some $c_0 > 0$ if and only if $\alpha'_i > 0$ and

$$(\alpha_i \rho_i)^2 - \alpha_i'^2 \rho_i I_{\rho_i} < 0 \quad \text{and} \quad (\alpha_i K_i)^2 - \alpha_i'^2 K_i (E_i I_i) < 0$$

for $0 \leq x \leq \ell_i$. If also $\alpha_i > 0$, these are the same as

$$\frac{\alpha'_i}{\alpha_i} > \sqrt{\frac{\rho_i}{I_{\rho_i}}} \quad \text{and} \quad \frac{\alpha'_i}{\alpha_i} > \sqrt{\frac{K_i}{E_i I_i}}.$$

Also, since the total energy is time invariant for each solution of (2.1)–(2.5),

$$\sum_{i=1}^n \int_0^T \int_0^{\ell_i} Q_i dx dt = T \mathcal{Q}(0),$$

and

$$|f(t)| \leq C \mathcal{Q}(0)$$

for some $C > 0$ depending on the elastic parameters and on $\max_i \max_x \alpha_i(x)$. If we further use the boundary conditions (2.2), (2.3) in the right-hand side of (3.5) we obtain (3.6) with $T_0 = 2C/c_0$. This proves the corollary for classical solutions. On the other hand, for finite energy solutions of (2.1)–(2.5) we always have the inequality

$$(3.13) \quad \sum_{k=1}^m \sum_{i \in \mathcal{E}_k} \int_0^T Q_i(N_k, t) dt \leq C(T+1) \mathcal{Q}(0)$$

for some constant C . Indeed, in (3.5) it is only necessary to choose α_i so that $\varepsilon_{ik}\alpha_i(N_k) > 0$, since the left member of (3.5) is bounded above in absolute value by $C(T+1)\mathcal{Q}(0)$, which proves (3.13) for classical solutions and then, by approximation, for finite energy solutions. Thus the right-hand side of (3.6) is finite for all finite energy solutions of (2.1)–(2.5). \square

Remark 3.1. Inequality (3.6) may be written

$$(3.14) \quad c_0(T - T_0)(\|\mathbf{R}^0\|_V^2 + \|\mathbf{R}^1\|_H^2) \leq \sum_{i=1}^p \alpha_i(N_i) \int_0^T [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2](N_i, t) dt \\ + \sum_{k \in I_M} \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \int_0^T Q_i(N_k, t) dt,$$

where $(\mathbf{R}^0, \mathbf{R}^1) \in V \times H$ is the initial data of the solution. Suppose now that \mathbf{R} is only a weak solution, so that $(\mathbf{R}^0, \mathbf{R}^1) \in H \times V'$, and define $\tilde{\mathbf{R}} = -A^{-1}\dot{\mathbf{R}}$. Then $\dot{\tilde{\mathbf{R}}} = \mathbf{R}$ and $\tilde{\mathbf{R}} + A\tilde{\mathbf{R}} = 0$, so that $\tilde{\mathbf{R}}$ is a finite energy solution of (3.3) with initial data $(\tilde{\mathbf{R}}(0), \dot{\tilde{\mathbf{R}}}(0)) = (-A^{-1}\mathbf{R}^1, \mathbf{R}^0)$. Upon applying (3.14) to $\tilde{\mathbf{R}}$ we obtain the estimate

$$(3.15) \quad c_0(T - T_0)(\|\mathbf{R}^0\|_H^2 + \|\mathbf{R}^1\|_{V'}^2) \leq \sum_{i=1}^p \alpha_i(N_i) \int_0^T [\rho_i |\mathbf{r}_i|^2 + I_{\rho_i} \psi_i^2](N_i, t) dt \\ + \sum_{k \in I_M} \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \int_0^T \tilde{Q}_i(N_k, t) dt,$$

where \tilde{Q} denotes the energy density of the solution $\tilde{\mathbf{R}}$. Likewise, corresponding to (3.13) we have

$$\sum_{k=1}^m \sum_{i \in \mathcal{E}_k} \int_0^T \tilde{Q}_i(N_k, t) dt \leq C(T+1)(\|\mathbf{R}^0\|_H^2 + \|\mathbf{R}^1\|_{V'}^2),$$

from which follows, in particular, that

$$(3.16) \quad \sum_{i=1}^p \int_0^T [\rho_i |\mathbf{r}_i|^2 + I_{\rho_i} \psi_i^2](N_i, t) dt \leq C(T+1)(\|\mathbf{R}^0\|_H^2 + \|\mathbf{R}^1\|_{V'}^2).$$

3.1. Estimating the multiple node terms. We now wish to investigate under what conditions the energy estimate (3.6) can be strengthened to

$$(3.17) \quad c_0(T - T_0)(\|\mathbf{R}^0\|_V^2 + \|\mathbf{R}^1\|_H^2) \leq \sum_{i=1}^p \alpha_i(N_i) \int_0^T [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2](N_i, t) dt.$$

Inequality (3.17) is the type of controllability estimate that is needed in situations where controls are constrained to act at the free simple nodes only. To obtain it we will investigate under what conditions on the sign arrangements ε_{ik} and on the multipliers $\alpha_i(N_k)$ it is true that the multiple node conditions imply the inequality

$$(3.18) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) Q_i(N_k, t) \leq 0$$

at each multiple node.

It is clear that (3.18) can hold (with positive multipliers) at a clamped multiple node, i.e., for indices $k \in I_M^D$, if and only if $\varepsilon_{ik} = -1$ for all $i \in \mathcal{E}_k$. While the same sign arrangement is obviously sufficient to assure that (3.18) holds also at a free multiple node, there are other sign arrangements for which (3.18) may be verified with appropriately chosen positive values of $\alpha_i(N_k)$. While it should not be surprising that given an arbitrary sign arrangement at N_k it is not, in general, possible to choose positive values of $\alpha_i(N_k)$ such that (3.18) holds at a free multiple node, we will nevertheless find interesting configurations for which (3.18) can be established.

Writing things out, we have

$$(3.19) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) Q_i(N_k, t) = \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) (\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2)(N_k, t) \\ + \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) [E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w_i')^2](N_k, t).$$

The geometric joint conditions imply that

$$(3.20) \quad \dot{\psi}_i^2(N_k, t) = \dot{\psi}_j^2(N_k, t), \quad |\dot{\mathbf{r}}_i(N_k, t)|^2 = |\dot{\mathbf{r}}_j(N_k, t)|^2, \quad \forall i, j \in \mathcal{E}_k.$$

Therefore

$$(3.21) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2](N_k, t) \\ = \left(\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \rho_i \right) |\dot{\mathbf{r}}_{i_k}(N_k, t)|^2 + \left(\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) I_{\rho_i} \right) \dot{\psi}_{i_k}^2(N_k, t),$$

where the index i_k stands for any index in \mathcal{E}_k , in accordance with the conditions (3.20). Therefore (3.21) is nonpositive if and only if

$$(3.22) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) \rho_i \leq 0 \quad \text{and} \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) I_{\rho_i} \leq 0.$$

In particular, if the sign arrangement at N_k is $(+ \ - \ - \ \dots \ -)$, i.e., if $\varepsilon_{qk} = +1$ and $\varepsilon_{ik} = -1$ for some $q \in \mathcal{E}_k$ and all $i \neq q$ in \mathcal{E}_k , then (3.22) will be satisfied if every $\alpha_j(N_k) > 0$ and if $\alpha_q(N_k)$ is sufficiently small relative to the other values $\alpha_i(N_k)$, $i \neq q$. Lemma 3.3 below demonstrates that the same relative choices of nodal values of the multipliers will also make the second sum on the right-hand side of (3.19) nonpositive when the linear constraints (2.5) are imposed.

Let

$$X_i = \sqrt{E_i A_i} u_i' \mathbf{e}_i + \sqrt{K_i} (\psi_i + w_i') \mathbf{e}_i^\perp + \sqrt{E_i I_i} \psi_i' \mathbf{n}, \\ Y_i = E_i A_i u_i' \mathbf{e}_i + K_i (\psi_i + w_i') \mathbf{e}_i^\perp + E_i I_i \psi_i' \mathbf{n}.$$

LEMMA 3.3. *Suppose that $\varepsilon_{qk} = +1$ and $\varepsilon_{ik} = -1$ for some $q \in \mathcal{E}_k$ and all $i \neq q$ in \mathcal{E}_k . If the $\alpha_j(N_k) > 0$ are chosen so that $\alpha_q(N_k)$ is sufficiently small relative to the values of $\alpha_i(N_k)$, $i \neq q$, then*

$$\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} Y_i = 0 \implies \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) |X_i|^2 \leq 0.$$

FIG. 2. Although the sign arrangements are in accord with Corollary 3.4, inequality (3.18) cannot hold simultaneously at every multiple node if the multipliers are required to be increasing functions.

Proof. There are positive constants c, C such that

$$c|Y_i|^2 \leq |X_i|^2 \leq C|Y_i|^2, \quad \forall i \in \mathcal{E}_k.$$

We write $\sum_{i \neq q}$ for the sum over indices $i \in \mathcal{E}_k$ with $i \neq q$. We have

$$\begin{aligned} \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} \alpha_i(N_k) |X_i|^2 &= \alpha_q(N_k) |X_q|^2 - \sum_{i \neq q} \alpha_i(N_k) |X_i|^2 \\ &\leq C \alpha_q(N_k) |Y_q|^2 - c \sum_{i \neq q} \alpha_i(N_k) |Y_i|^2 \\ &\leq C \alpha_q(N_k) \sum_{i \neq q} |Y_i|^2 - c \sum_{i \neq q} \alpha_i(N_k) |Y_i|^2. \end{aligned}$$

The last right-hand side will be nonpositive if α_q is chosen sufficiently small relative to the other α_i 's. \square

As a consequence of Lemma 3.3 and the discussion preceeding it, we have the following result.

COROLLARY 3.4. *If N_k is a clamped multiple node with sign arrangement $(- \dots -)$, or if N_k is a free multiple node with a sign arrangement of either $(- \dots -)$ or $(+ \dots -)$, then positive values of $\alpha_i(N_k)$ may be chosen so that the estimate (3.18) will hold.*

It should be recalled that the parametrization of the network is not completely arbitrary, but rather is constrained by sign restrictions on the ε_{ik} 's at the simple nodes.

Remark 3.2. It is not difficult to show that the sign arrangements delineated in the last corollary are, in fact, *necessary* for the validity of (3.18) (with positive multipliers) at each multiple node. In addition, if a beam network contains a *closed loop*, it is not possible to choose positive, *increasing*, multipliers for the beams in the loop (as is required in Corollary 3.2) in such a way that (3.18) holds at each joint in the loop, even when the sign arrangements are selected in accordance with Corollary 3.4 (see Fig. 2). This is because the nodal values of the multipliers must increase in the directions of the vectors \mathbf{e}_i emanating from a particular node. In problems of control of beam networks, the failure of (3.18) to hold at a nonserial joint indicates that it is necessary to introduce controls at that joint if we hope to control the motion of the entire network. This issue will be discussed further in the next section.

4. Controllability of beam networks. In this section the estimates of §3 are applied to the study of exact controllability of the beam network in situations where the controls act through forces and bending moments applied at the joints of the system.

The controlled system is modeled by the system of equations

$$\begin{aligned}
 (4.1) \quad & \rho_i \ddot{u}_i - E_i A_i u_i'' = 0, \\
 & \rho_i \ddot{w}_i - K_i(\psi_i + w_i')' = 0, \\
 & I_{\rho_i} \ddot{\psi}_i - E_i I_i \psi_i'' + K_i(\psi_i + w_i') = 0, \quad 0 < x < \ell_i, \quad t > 0,
 \end{aligned}$$

$$(4.2) \quad u_i(N_k, t) = w_i(N_k, t) = \psi_i(N_k, t) = 0, \quad \forall i \in \mathcal{E}_k, \quad k \in I^D.$$

$$\begin{aligned}
 (4.3) \quad & E_i A_i u_i'(N_i, t) = f_{1i}(t), \\
 & K_i(\psi_i + w_i')(N_i, t) = f_{2i}(t), \\
 & E_i I_i \psi_i'(N_i, t) = f_{3i}(t), \quad i = 1, \dots, p,
 \end{aligned}$$

$$(4.4) \quad \mathbf{r}_i(N_k, t) = \mathbf{r}_j(N_k, t), \quad \psi_i(N_k, t) = \psi_j(N_k, t), \quad \forall i, j \in \mathcal{E}_k, \quad \forall k \in I_M^N,$$

and

$$(4.5) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} [E_i A_i u_i' \mathbf{e}_i + K_i(\psi_i + w_i') \mathbf{e}_i^\perp + E_i I_i \psi_i' \mathbf{n}](N_k, t) = \mathbf{F}_k, \quad \forall k \in I_M.$$

The controls are

$$\begin{aligned}
 \mathbf{f}_i &= f_{1i} \mathbf{e}_i + f_{2i} \mathbf{e}_i^\perp + f_{3i} \mathbf{n}, \quad i = 1, \dots, p, \\
 \mathbf{F}_k &= (\mathbf{F}_k \cdot \mathbf{e}_i) \mathbf{e}_i + (\mathbf{F}_k \cdot \mathbf{e}_i^\perp) \mathbf{e}_i^\perp + (\mathbf{F}_k \cdot \mathbf{n}) \mathbf{n}, \quad k \in I_M^N
 \end{aligned}$$

(the latter are independent of i for $i \in \mathcal{E}_k$). The components of the controls in the $\mathbf{e}_i, \mathbf{e}_i^\perp$ plane represent forces acting at the corresponding joints, while the components along \mathbf{n} represent bending moments (torques) at the corresponding joints. Some of these controls may be inactive, i.e., equal to zero for $t > 0$. We denote by \mathbf{u} the vector of active controls. Then, for example, if the controls at the free multiple joints are inactive,

$$\mathbf{u}(t) = \bigotimes_{i=1}^p \mathbf{f}_i(t) \in U, \quad t > 0,$$

where

$$(4.6) \quad U = \prod_{i=1}^p U_i, \quad U_i = [\mathbf{e}_i] \bigoplus [\mathbf{e}_i^\perp] \bigoplus [\mathbf{n}].$$

Remark 4.1. In (4.3) and (4.5) the masses of the joints have not been taken into account. Accounting for the masses of the free multiple joints, in particular, would require adding $M_k \ddot{\mathbf{r}}_{i_k} + I_k \ddot{\psi}_{i_k} \mathbf{n}$ to the right-hand member in (4.5), where M_k denotes the mass of the k th joint and I_k its principal moment of inertia.

As is well known, the exact controllability problem for (4.1)–(4.5) may be formulated in terms of the *reachability problem*: for vanishing initial data

$$(4.7) \quad \mathbf{R}(0) = \dot{\mathbf{R}}(0) = 0,$$

determine the reachable states

$$\mathcal{R}_T = \{(\mathbf{R}(T), \dot{\mathbf{R}}(T)) | \mathbf{u} \in \mathcal{C}\},$$

where \mathcal{C} is the space of controls. In this work, \mathcal{C} will be taken to be

$$(4.8) \quad \mathcal{C} = L^2_{\text{loc}}(0, \infty; \mathbb{R}^q),$$

where q is the number of active (scalar) controls.

With \mathcal{C} given by (4.8), existence and uniqueness of solutions of (4.1)–(4.7) can easily be proved within a variational framework. To simplify the discussion a little, we assume that $I_S^D \neq \emptyset$, but this is inessential. Proceeding along the lines of §3, let $\hat{\mathbf{R}} \in V$ be a test function, form the $L^2(0, \ell_i; \mathbb{R}^3)$ scalar product of $\hat{\mathbf{R}}_i$ with (4.1) and sum over i . After some integrations by parts we obtain the variational equation

$$(4.9) \quad (\ddot{\mathbf{R}}, \hat{\mathbf{R}})_H + (\mathbf{R}, \hat{\mathbf{R}})_V = \sum_{i=1}^p \mathbf{f}_i \cdot \hat{\mathbf{R}}_i(N_i) + \sum_{k \in I_M^N} \mathbf{F}_k \cdot \hat{\mathbf{R}}_{i_k}(N_k)$$

where, as usual, i_k denotes any index in \mathcal{E}_k in accordance with the geometric node conditions.

Set

$$\mathbf{u} = \left(\bigotimes_{i=1}^p \mathbf{f}_i \right) \otimes \left(\bigotimes_{k \in I_M^N} \mathbf{F}_k \right) \in U,$$

where

$$U = \left(\prod_{i=1}^p U_i \right) \times \left(\prod_{k \in I_M^N} U_{i_k} \right)$$

and U_i is defined in (4.6). We have

$$\left| \sum_{i=1}^p \mathbf{f}_i \cdot \hat{\mathbf{R}}_i(N_i) + \sum_{k \in I_M^N} \mathbf{F}_k \cdot \hat{\mathbf{R}}_{i_k}(N_k) \right| \leq C \|\mathbf{u}\|_U \|\hat{\mathbf{R}}\|_V.$$

Therefore we may define $B \in \mathcal{L}(U, V')$ by

$$(4.10) \quad \langle B\mathbf{u}, \hat{\mathbf{R}} \rangle_V = \sum_{i=1}^p \mathbf{f}_i \cdot \hat{\mathbf{R}}_i(N_i) + \sum_{k \in I_M^N} \mathbf{F}_k \cdot \hat{\mathbf{R}}_{i_k}(N_k), \quad \forall \hat{\mathbf{R}} \in V,$$

where $\langle \cdot, \cdot \rangle_V$ denotes the V', V duality pairing. Let us note that, defining $B' \in \mathcal{L}(V, U)$ through $\langle B\mathbf{u}, \hat{\mathbf{R}} \rangle_V = \langle \mathbf{u}, B'\hat{\mathbf{R}} \rangle_U$, we have

$$B'\hat{\mathbf{R}} = \left(\bigotimes_{i=1}^p \hat{\mathbf{R}}_i(N_i) \right) \otimes \left(\bigotimes_{k \in I_M^N} \hat{\mathbf{R}}_{i_k}(N_k) \right).$$

From (4.9) and (4.10) we obtain the variational equation

$$(4.11) \quad \ddot{\mathbf{R}} + A\mathbf{R} = B\mathbf{u} \quad \text{in } V', \quad \mathbf{u} \in L^2_{\text{loc}}(0, \infty; U).$$

It follows from standard theory that (4.11), with initial data (4.7), has a unique solution with $(\mathbf{R}, \dot{\mathbf{R}}) \in C([0, T]; H \times V')$ for every $T > 0$. In fact, we may prove that $(\mathbf{R}, \dot{\mathbf{R}}) \in C([0, T]; V \times H)$. To do so, and to introduce some notation for later, we write (4.11) as a system in $H \times V'$ by introducing

$$\Phi = \begin{pmatrix} \mathbf{R} \\ \dot{\mathbf{R}} \end{pmatrix}, \quad \mathcal{A} = \begin{pmatrix} 0 & I \\ -A & 0 \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} 0 \\ B \end{pmatrix}.$$

We obtain

$$(4.12) \quad \dot{\Phi} = \mathcal{A}\Phi + \mathcal{B}\mathbf{u}, \quad \Phi(0) = 0.$$

The operator \mathcal{A} is skew-adjoint as an operator in $H \times V'$ with domain $V \times H$, and $\mathcal{B} \in \mathcal{L}(U, H \times V')$. The dual \mathcal{A}' of \mathcal{A} is the operator in $H \times V$ given by

$$\mathcal{A}' = \begin{pmatrix} 0 & A \\ -I & 0 \end{pmatrix}, \quad \text{Dom}(\mathcal{A}') = V \times D_A.$$

For each $u \in L^2(0, T; U) := \mathcal{U}$, the unique solution of (4.12) is given by

$$(\mathcal{S}_T \mathbf{u})(t) := \Phi(t) = \int_0^t e^{(t-s)\mathcal{A}} \mathcal{B}\mathbf{u}(s) ds, \quad 0 \leq t \leq T,$$

where $e^{t\mathcal{A}}, t \geq 0$, is the unitary group on $H \times V'$ generated by \mathcal{A} . We have that \mathcal{S}_T is a bounded linear map from \mathcal{U} into $C([0, T]; H \times V')$. In fact, \mathcal{S}_T is bounded from \mathcal{U} into $C([0, T]; V \times H)$. To prove this, let $\hat{\Phi}^0 \in H \times V$ and form

$$(4.13) \quad \left\langle \int_0^\tau e^{(\tau-s)\mathcal{A}} \mathcal{B}\mathbf{u}(s) ds, \hat{\Phi}^0 \right\rangle_{H \times V} = \int_0^\tau (\mathbf{u}(s), \mathcal{B}' e^{(\tau-s)\mathcal{A}'} \hat{\Phi}^0)_U ds, \quad 0 \leq \tau \leq T,$$

where

$$\mathcal{B}' = \begin{pmatrix} 0 \\ B' \end{pmatrix} \in \mathcal{L}(H \times V, U).$$

Set $\hat{\Phi}(t) = e^{(\tau-t)\mathcal{A}'} \hat{\Phi}^0$. Then

$$(4.14) \quad \dot{\hat{\Phi}}(t) = -\mathcal{A}'\hat{\Phi}(t), \quad 0 \leq t < \tau, \quad \hat{\Phi}(\tau) = \hat{\Phi}^0.$$

Writing $\hat{\Phi} = (\hat{\mathbf{R}}_1, \hat{\mathbf{R}})$, $\hat{\Phi}^0 = (\hat{\mathbf{R}}^1, \hat{\mathbf{R}}^0)$, (4.14) signifies that

$$\ddot{\hat{\mathbf{R}}} + A\hat{\mathbf{R}} = 0, \quad \hat{\mathbf{R}}_1 = \dot{\hat{\mathbf{R}}},$$

$$\hat{\mathbf{R}}(\tau) = \hat{\mathbf{R}}^0, \quad \dot{\hat{\mathbf{R}}}(\tau) = \hat{\mathbf{R}}^1.$$

From the inequality (3.16), applied to $\hat{\mathbf{R}}$, we have

$$\int_0^\tau |\mathcal{B}'\hat{\Phi}(t)|_U^2 dt = \int_0^\tau |B'\hat{\mathbf{R}}(t)|_U^2 dt \leq C(\tau+1)(\|\hat{\mathbf{R}}^0\|_H^2 + \|\hat{\mathbf{R}}^1\|_{V'}^2) = C(\tau+1)\|\hat{\Phi}^0\|_{V' \times H}^2.$$

Use of this inequality in the right-hand side of (4.13) allows us to conclude that

$$\sup_{0 \leq \tau \leq T} \left| \left\langle \int_0^\tau e^{(\tau-s)\mathcal{A}} \mathbf{B} \mathbf{u}(s) ds, \hat{\Phi}^0 \right\rangle_{H \times V} \right| \leq C \sqrt{T+1} \|\mathbf{u}\|_{\mathcal{U}} \|\hat{\Phi}^0\|_{V' \times H}, \quad \forall \hat{\Phi}^0 \in H \times V.$$

It follows that

$$\Phi = S_T \mathbf{u} = (\mathbf{R}, \dot{\mathbf{R}}) \in L^\infty(0, T; V \times H).$$

We may then pass from L^∞ to C by a standard argument. We have proved the following proposition.

PROPOSITION 4.1. *For an arbitrary control $\mathbf{u} \in L^2_{loc}(0, \infty; \mathbb{R}^{3m})$, the system (4.1)–(4.7) has a unique finite energy solution.*

We now know that $(\mathbf{R}(T), \dot{\mathbf{R}}(T)) \in V \times H$ for every $T > 0$, whenever $\mathbf{u} \in \mathcal{C}$. We want to determine under what conditions it is true that *every element* in $V \times H$ is also in \mathcal{R}_T , i.e., S_T maps \mathcal{U} onto $H \times V$, where $S_T \mathbf{u} := (S_T \mathbf{u})(T)$. The validity of the statement $\mathcal{R}_T = V \times H$ depends on the number and placements of the active controls and these, in turn, depend on the particular beam configuration.

4.1. Controllability from the simple nodes. We begin by considering the case where the active controls are placed only at simple free nodes. Here we have U defined by (4.6) and the control operator $B \in \mathcal{L}(U, V')$ and its dual B' in this situation are defined, respectively, by

$$\langle B \mathbf{u}, \hat{\mathbf{R}} \rangle_V = \sum_{i=1}^p \mathbf{f}_i \cdot \hat{\mathbf{R}}_i(N_i), \quad \forall \hat{\mathbf{R}} \in V,$$

$$B' \hat{\mathbf{R}} = \bigotimes_{i=1}^p \hat{\mathbf{R}}_i(N_i), \quad \forall \hat{\mathbf{R}} \in V.$$

Let $S'_T \in \mathcal{L}(V' \times H, \mathcal{U})$ denote the dual of S_T ; it is defined by

$$\langle \hat{\Phi}^0, S_T \mathbf{u} \rangle_{V \times H} = (S'_T \hat{\Phi}^0, \mathbf{u})_{\mathcal{U}}, \quad \forall \hat{\Phi}^0 \in V' \times H, \forall \mathbf{u} \in \mathcal{U}.$$

Since

$$\langle \hat{\Phi}^0, S_T \mathbf{u} \rangle_{V \times H} = \int_0^T (\mathbf{u}(s), B' e^{(T-s)\mathcal{A}'} \hat{\Phi}^0)_U ds,$$

we have

$$(S'_T \hat{\Phi}^0)(s) = B' e^{(T-s)\mathcal{A}'} \hat{\Phi}^0.$$

The assertion $\text{Range}(S_T) = V \times H$ is equivalent to

$$\|S'_T \hat{\Phi}^0\|_{\mathcal{U}} \geq c_T \|\hat{\Phi}^0\|_{V' \times H}, \quad \forall \hat{\Phi}^0 \in V' \times H,$$

for some constant $c_T > 0$, that is,

$$(4.15) \quad \int_0^T |B' \hat{\mathbf{R}}(t)|_{\mathcal{U}}^2 dt \geq c_T (\|\hat{\mathbf{R}}^0\|_H^2 + \|\hat{\mathbf{R}}^1\|_{V'}^2), \quad \forall (\hat{\mathbf{R}}^0, \hat{\mathbf{R}}^1) \in H \times V',$$

FIG. 3. An example of an exactly controllable network. Beam n is clamped at its simple node and controls are applied at the free node of beam 1.

FIG. 4. An example of an exactly controllable network. Beam n is clamped at its simple node and controls are applied at all other simple nodes.

where $\hat{\mathbf{R}}$ is the solution of

$$(4.16) \quad \ddot{\hat{\mathbf{R}}} + A\hat{\mathbf{R}} = 0, \quad 0 \leq t < T, \quad \hat{\mathbf{R}}(T) = \hat{\mathbf{R}}^0, \quad \dot{\hat{\mathbf{R}}}(T) = \hat{\mathbf{R}}^1.$$

Sufficient conditions for the validity of (4.15) were given in §3. When (4.15) holds, the control \mathbf{u}_0 of minimum norm in \mathcal{U} that drives the initial data (4.7) to a prescribed state $(\mathbf{R}^0, \mathbf{R}^1) \in V \times H$ at time T is given by $\mathbf{u}_0 = B'\hat{\mathbf{R}}$, where $\hat{\mathbf{R}}$ is the solution of (4.16) with final data $(\hat{\mathbf{R}}^1, \hat{\mathbf{R}}^0) = (S_T S_T')^{-1}(\mathbf{R}^0, \mathbf{R}^1)$.

Example 4.1. Consider the following beam network shown in Fig. 3. In this figure, beam n is clamped at its simple node, a control \mathbf{f}_1 is applied at the simple node of beam 1 and the multiple nodes of the system are free. The angle between successive beams (determined by $\mathbf{e}_i \cdot \mathbf{e}_{i+1}$) may be chosen arbitrarily in the interval $[0, \pi]$. Based on the discussion of §3, the network exhibited in Fig. 3 is exactly controllable, i.e., $\mathcal{R}_T = V \times H$ if T is sufficiently large. This result may be compared to a result of Chen et al. [1], where uniform stabilization in finite energy space of a network of *serially* connected (i.e., $\mathbf{e}_i = \mathbf{e}_1$ for all i) Euler–Bernoulli beams was established (equivalent to $\mathcal{R}_T = V \times H$ for T sufficiently large), but only under a monotonicity requirement on the stiffnesses of successive beams.

Example 4.2. Another exactly controllable beam network is the H-shaped configuration shown in Fig. 4. Beam n is clamped at its simple node, controls (indicated by solid circles) are applied at all other simple nodes and the multiple nodes are free.

The angle of $\pi/2$ between horizontal and vertical beams is drawn only for convenience; any angle in $(0, \pi)$ is admissible.

Example 4.3. Figure 2 is an example of a network that we cannot prove is exactly controllable when controls act only at the simple nodes. In fact, the discussion of the next subsection shows that the network in Fig. 2 may not be even approximately controllable in all cases, even when controls are active at each node of the network.

4.2. Controllability with controls at the multiple nodes. In this subsection we wish to consider the question of controllability in situations where the network may not be exactly controllable by means of controls acting only at the free simple nodes. Such will be the case, for example, when $I_S^N = \emptyset$; or if the network contains a closed loop, as in Fig. 2. Although we are unable at the present time to give a definitive controllability analysis in these situations, we will indicate, through examples, some of the anomalies that can occur. What these examples show is that there are certain beam configurations (such as in Fig. 2) that may support nontrivial time periodic wave motions that cannot be controlled through controls placed at the available nodes of the system. On the other hand, such situations are certainly “nongeneric”; they occur only when the elastic parameters and beam lengths are related in very specific ways.

Only *approximate controllability* will be considered in what follows. The system (4.11) is approximately controllable at time T if $\bar{\mathcal{R}}_T = V \times H$ or, equivalently, if the range of S_T is dense in $V \times H$. The latter is the same as the assertion that the kernel of S'_T contains only the zero element of $V' \times H$. From the definition of S'_T , this is the same as saying that the only finite energy solution of the problem

$$(4.17) \quad \ddot{\mathbf{R}}(t) + A\mathbf{R}(t) = 0, \quad B'\mathbf{R}(t) = 0, \quad 0 < t < T,$$

is $\mathbf{R}(t) \equiv 0$.

From the definition of the control operator B , the condition $B'\mathbf{R} = 0$ means that

$$\mathbf{R}_i = u_i \mathbf{e}_i + w_i \mathbf{e}_i^\perp + \psi_i \mathbf{n} = 0,$$

at each simple, free node N_i and at each free multiple node N_k (for all $i \in \mathcal{E}_k$) where B has a nonzero component. Our main objective in what follows is to demonstrate that for certain beam networks, (4.17) admits nontrivial periodic solutions.

In order that the computations not obscure the main ideas, we will first consider networks of vibrating *strings*. Modeling and controllability of such networks have been studied by Schmidt [9] and we adopt the following model directly from [9]. With the same notation as above, the controlled model is

$$(4.18) \quad \ddot{\mathbf{r}}_i - K_i \mathbf{r}_i'' = 0, \quad i = 1, \dots, n,$$

where K_i is a 2×2 diagonal matrix with respect to the $\mathbf{e}_i, \mathbf{e}_i^\perp$ basis having real entries p_i^2, q_i^2 on the diagonal;

$$(4.19) \quad \mathbf{r}_i(N_i, t) = 0, \quad i \in I_S^D;$$

$$(4.20) \quad K_i \mathbf{r}_i'(N_i, t) = \mathbf{f}_i, \quad i = 1, \dots, p;$$

$$(4.21) \quad \mathbf{r}_i(N_k, t) = \mathbf{r}_j(N_k, t), \quad \forall i, j \in \mathcal{E}_k, \quad k \in I_M,$$

FIG. 5. Beams 1 and n are clamped at their simple nodes and controls are applied at all multiple nodes. Such a network is not approximately controllable, in general.

which are the geometric node conditions; and

$$(4.22) \quad \sum_{i \in \mathcal{E}_k} \varepsilon_{ik} (p_i^2 u'_i \mathbf{e}_i + q_i^2 w'_i \mathbf{e}_i^\perp)(N_k, t) = \mathbf{F}_k, \quad k \in I_M,$$

which are the dynamic node conditions. The dependent variables u_i, w_i represent longitudinal and transverse displacements respectively, along the i th string.

For the above string network, (4.17) consists of (4.18)–(4.22) with $\mathbf{f}_i = 0$, $\mathbf{F}_k = 0$, together with

$$(4.23) \quad \mathbf{r}_i = 0$$

at each simple free node N_i and at each multiple node N_k , for all $i \in \mathcal{E}_k$, where a control is active, i.e., where the control operator has a nonzero component. We want to look for eigenvalues of this system, so we set

$$\mathbf{r}_i(x, t) = e^{\sqrt{-1}\lambda t} \mathbf{r}_i(x), \quad i = 1, \dots, n,$$

and consider

$$(4.24) \quad K_i \mathbf{r}_i'' + \lambda^2 \mathbf{r}_i = 0, \quad i = 1, \dots, n,$$

$$\mathbf{r}_i(N_i) = 0, \quad i \in I_S^D, \quad K_i \mathbf{r}_i'(N_i) = 0, \quad i = 1, \dots, p,$$

$$\mathbf{r}_i(N_k) = \mathbf{r}_j(N_k), \quad i, j \in \mathcal{E}_k, \quad k \in I_M,$$

$$\sum_{i \in \mathcal{E}_k} \varepsilon_{ik} (p_i^2 u'_i \mathbf{e}_i + q_i^2 w'_i \mathbf{e}_i^\perp)(N_k) = 0, \quad k \in I_M.$$

In addition, (4.23) must hold at appropriate nodes, as described above.

The following two examples illustrate situations where the above eigenvalue problem has nontrivial solutions.

Example 4.4. Consider the network of Example 4.1, but with both simple nodes clamped and all multiple nodes controlled, as illustrated in Fig. 5. The eigenvalue

problem in this case consists of (4.24) together with

$$(4.25) \quad \mathbf{r}_i(0) = \mathbf{r}_i(\ell_i) = 0, \quad i = 1, \dots, n,$$

$$(4.26) \quad p_i^2 u'_i(\ell_i) \mathbf{e}_i + q_i^2 w'_i(\ell_i) \mathbf{e}_i^\perp = p_{i+1}^2 u'_{i+1}(0) \mathbf{e}_{i+1} + q_{i+1}^2 w'_{i+1}(0) \mathbf{e}_{i+1}^\perp, \\ i = 1, \dots, n-2,$$

$$(4.27) \quad p_{n-1}^2 u'_{n-1}(\ell_{n-1}) \mathbf{e}_{n-1} + q_{n-1}^2 w'_{n-1}(\ell_{n-1}) \mathbf{e}_{n-1}^\perp \\ = -[p_n^2 u'_n(\ell_n) \mathbf{e}_n + q_n^2 w'_n(\ell_n) \mathbf{e}_n^\perp].$$

From (4.24), (4.25) we must have

$$u_i(x) = u_i^0 \sin(\lambda/p_i)x, \quad w_i(x) = w_i^0 \sin(\lambda/q_i)x,$$

where

$$(4.28) \quad \sin(\lambda/p_i)\ell_i = \sin(\lambda/q_i)\ell_i = 0, \quad i = 1, \dots, n.$$

Equations (4.28) admit an infinite sequence of solutions $\lambda^{(j)} \rightarrow \infty$ provided the numbers $\ell_i/p_i, \ell_i/q_i$, $i = 1, \dots, n$, are comeasurable, i.e., their ratios are rational. In particular, p_i and q_i must then be comeasurable for each i .

Let λ be a nonzero solution of (4.28) such that

$$\cos(\lambda/p_i)\ell_i = \cos(\lambda/q_i)\ell_i = 1, \quad i = i, \dots, n.$$

Conditions (4.26), (4.27) require that

$$p_i u_i^0 \mathbf{e}_i + q_i w_i^0 \mathbf{e}_i^\perp = p_{i+1} u_{i+1}^0 \mathbf{e}_{i+1} + q_{i+1} w_{i+1}^0 \mathbf{e}_{i+1}^\perp, \quad i = 1, \dots, n-2, \\ p_{n-1} u_{n-1}^0 \mathbf{e}_{n-1} + q_{n-1} w_{n-1}^0 \mathbf{e}_{n-1}^\perp = -(p_n u_n^0 \mathbf{e}_n + q_n w_n^0 \mathbf{e}_n^\perp).$$

With $\mathbf{r}_1^0 = u_1^0 \mathbf{e}_1 + w_1^0 \mathbf{e}_1^\perp$ arbitrarily given, this last system uniquely determines \mathbf{r}_i^0 for $i = 2, \dots, n$. Therefore the network of Fig. 5 is not approximately controllable when the above conditions on the relative lengths and wave speeds of the various strings are met. On the other hand, in general (4.28) will admit only the trivial solution $\lambda = 0$. One may prove (although we shall not do so here) that the network is then approximately controllable, but we do not know if it is exactly controllable in such cases.

A similar phenomenon may occur in a network of strings containing a closed loop.

Example 4.5. Consider a closed loop consisting of n strings and n nodes, with controls at each node (see Fig. 6). Existence of periodic solutions $e^{\sqrt{-1}\lambda t} \mathbf{r}_i(x)$ of (4.17) for such a network requires that (4.25) hold, that

$$(4.29) \quad p_i^2 u'_i(\ell_i) \mathbf{e}_i + q_i^2 w'_i(\ell_i) \mathbf{e}_i^\perp = p_{i+1}^2 u'_{i+1}(0) \mathbf{e}_{i+1} + q_{i+1}^2 w'_{i+1}(0) \mathbf{e}_{i+1}^\perp, \\ i = 1, \dots, n-1,$$

and that

$$(4.30) \quad p_n^2 u'_n(\ell_n) \mathbf{e}_n + q_n^2 w'_n(\ell_n) \mathbf{e}_n^\perp = p_1^2 u'_1(0) \mathbf{e}_1 + q_1^2 w'_1(0) \mathbf{e}_1^\perp.$$

Assume that p_i, q_i, ℓ_i are such that (4.28) admits a nontrivial solution λ with

$$\cos(\lambda/p_i)\ell_i = \cos(\lambda/q_i)\ell_i = 1.$$

FIG. 6. Networks containing closed loops are not approximately controllable from their nodes, in general, regardless of the number of controlled nodes.

Given \mathbf{r}_1^0 , equations (4.29) then uniquely determine \mathbf{r}_i^0 , $i = 2, \dots, n$, in terms of \mathbf{r}_1^0 . The additional “compatibility condition” (4.30) requires that

$$p_1 u_1^0 \mathbf{e}_1 + q_1 w_1^0 \mathbf{e}_1^\perp = p_n u_n^0 \mathbf{e}_n + q_n w_n^0 \mathbf{e}_n^\perp,$$

which is easily seen to be a consequence of (4.29). Thus, under the above special conditions on string lengths and wave speeds, Fig. 6 is not an approximately controllable configuration. The same will be true even if Fig. 6 has other strings attached to it, as in Fig. 2. If all nodes in Fig. 2 are controlled, there can still be nontrivial periodic solutions; these will consist of a periodic wave traveling around the closed loop, as above, with the solution being identically zero in the appendages.

Now let us consider the configurations of Examples 4.4 and 4.5 in the context of Timoshenko beams. As is seen from the string examples, the main issue is whether the different beams of the network, subject to clamped boundary conditions, can have a common eigenvalue and, if so, whether corresponding eigenfunctions can be chosen to satisfy the given node conditions of the problem.

Consider first the configuration of Fig. 5. We are looking for periodic solutions of (4.17) of the form $\mathbf{r}_i(x, t) = e^{\sqrt{-1}\lambda t} \mathbf{r}_i(x)$, $\psi_i(x, t) = e^{\sqrt{-1}\mu t} \psi_i(x)$, which reflects the possibility of different wave speeds for elastic and shear waves. The triple u_i, w_i, ψ_i , $0 \leq x \leq \ell_i$, must then satisfy

$$\begin{aligned} (4.31) \quad & u_i'' + s_i^2 \lambda^2 u_i = 0, \quad s_i^2 = \rho_i / E_i A_i, \\ & (\psi_i + w_i')' + p_i^2 \lambda^2 w_i = 0, \quad p_i^2 = \rho_i / K_i, \\ & \psi_i'' + q_i^2 \mu^2 \psi_i - r_i^2 (\psi_i + w_i') = 0, \quad q_i^2 = I_{\rho_i} / E_i I_i, \quad r_i^2 = K_i / E_i I_i; \end{aligned}$$

$$(4.32) \quad u_i(0) = u_i(\ell_i) = w_i(0) = w_i(\ell_i) = \psi_i(0) = \psi_i(\ell_i) = 0, \quad i = 1, \dots, n;$$

$$(4.33) \quad \begin{aligned} E_i I_i \psi_i'(\ell_i) &= E_{i+1} I_{i+1} \psi_{i+1}'(0), \quad i = 1, \dots, n-2, \\ E_{n-1} I_{n-1} \psi_{n-1}'(\ell_{n-1}) &= E_n I_n \psi_n'(\ell_n); \end{aligned}$$

$$(4.34) \quad \begin{aligned} E_i A_i u_i'(\ell_i) \mathbf{e}_i + K_i w_i'(\ell_i) \mathbf{e}_i^\perp &= E_{i+1} A_{i+1} u_{i+1}'(0) \mathbf{e}_{i+1} + K_{i+1} w_{i+1}'(0) \mathbf{e}_{i+1}^\perp, \\ &\quad i = 1, \dots, n-2, \\ E_{n-1} A_{n-1} u_{n-1}'(\ell_{n-1}) \mathbf{e}_{n-1} + K_{n-1} w_{n-1}'(\ell_{n-1}) \mathbf{e}_{n-1}^\perp \\ &= E_n A_n u_n'(\ell_n) \mathbf{e}_n + K_n w_n'(\ell_n) \mathbf{e}_n^\perp \end{aligned}$$

From the first equation in (4.31) and (4.32) we must have

$$(4.35) \quad u_i(x) = u_i^0 \sin \lambda s_i x$$

with

$$(4.36) \quad \sin \lambda s_i \ell_i = 0, \quad i = 1, \dots, n.$$

The equations in w_i and ψ_i in (4.31) may be uncoupled as follows. We have

$$0 = w_i''' + \psi_i'' + p_i^2 \lambda^2 w_i' = w_i''' + r_i^2 (\psi_i + w_i') - q_i^2 \mu^2 \psi_i + p_i^2 \lambda^2 w_i'$$

which yields, upon differentiation,

$$\begin{aligned} 0 &= w_i'''' + r_i^2 (\psi_i + w_i')' - q_i^2 \mu^2 \psi_i' + p_i^2 \lambda^2 w_i'' \\ &= w_i'''' - r_i^2 p_i^2 \lambda^2 w_i - q_i^2 \mu^2 (-p_i^2 \lambda^2 w_i - w_i'') + p_i^2 \lambda^2 w_i'', \end{aligned}$$

that is,

$$(4.37) \quad w_i'''' + (p_i^2 \lambda^2 + q_i^2 \mu^2) w_i'' + p_i^2 \lambda^2 (q_i^2 \mu^2 - r_i^2) w_i = 0.$$

We define

$$\sigma_i^\pm(\lambda, \mu) = \frac{1}{2} \left\{ p_i^2 \lambda^2 + q_i^2 \mu^2 \pm [(p_i^2 \lambda^2 - q_i^2 \mu^2)^2 + 4p_i^2 r_i^2 \lambda^2]^{1/2} \right\},$$

and note that $\sigma_i^\pm(\lambda, \mu) > 0$ if $q_i^2 \mu^2 > r_i^2$, which we shall assume. The roots of the characteristic equation of (4.37) are $\pm \sqrt{-1} [\sigma_i^\pm(\lambda, \mu)]^{1/2}$, so that the general solution of (4.37) is

$$(4.38) \quad w_i(x) = a_i \sin x \sqrt{\sigma_i^+} + b_i \cos x \sqrt{\sigma_i^+} + c_i \sin x \sqrt{\sigma_i^-} + d_i \cos x \sqrt{\sigma_i^-}.$$

Upon setting $\psi_i' = -w_i'' - p_i^2 \lambda^2 w_i$ and integrating, we find that

$$(4.39) \quad \begin{aligned} \psi_i(x) &= \psi_i^0 + \frac{\sigma_i^+ - p_i^2 \lambda^2}{\sqrt{\sigma_i^+}} \left(b_i \sin x \sqrt{\sigma_i^+} - a_i \cos x \sqrt{\sigma_i^+} \right) \\ &\quad + \frac{\sigma_i^- - p_i^2 \lambda^2}{\sqrt{\sigma_i^-}} \left(d_i \sin x \sqrt{\sigma_i^-} - c_i \cos x \sqrt{\sigma_i^-} \right). \end{aligned}$$

Since then

$$\psi_i'' + (q_i^2 \mu^2 - r_i^2) \psi_i - r_i^2 w_i' = (q_i^2 \mu^2 - r_i^2) \psi_i^0,$$

to satisfy the third equation in (4.31) we must set $\psi_i^0 = 0$.

The boundary conditions $w_i(0) = \psi_i(0) = 0$ require that

$$b_i = -d_i, \quad c_i = -a_i \frac{\sqrt{\sigma_i^-} (\sigma_i^+ - p_i^2 \lambda^2)}{\sqrt{\sigma_i^+} (\sigma_i^- - p_i^2 \lambda^2)},$$

and therefore

$$w_i(x) = a_i \left(\sin x \sqrt{\sigma_i^+} - \frac{\sqrt{\sigma_i^-} (\sigma_i^+ - p_i^2 \lambda^2)}{\sqrt{\sigma_i^+} (\sigma_i^- - p_i^2 \lambda^2)} \sin x \sqrt{\sigma_i^-} \right) + b_i \left(\cos x \sqrt{\sigma_i^+} - \cos x \sqrt{\sigma_i^-} \right),$$

$$\begin{aligned} \psi_i(x) = & b_i \frac{\sigma_i^+ - p_i^2 \lambda^2}{\sqrt{\sigma_i^+}} \left(\sin x \sqrt{\sigma_i^+} - \frac{\sqrt{\sigma_i^+}(\sigma_i^- - p_i^2 \lambda^2)}{\sqrt{\sigma_i^-}(\sigma_i^+ - p_i^2 \lambda^2)} \sin x \sqrt{\sigma_i^-} \right) \\ & - a_i \frac{\sigma_i^+ - p_i^2 \lambda^2}{\sqrt{\sigma_i^+}} \left(\cos x \sqrt{\sigma_i^+} - \cos x \sqrt{\sigma_i^-} \right). \end{aligned}$$

The conditions $w_i(\ell_i) = \psi_i(\ell_i) = 0$ will yield nontrivial solution a_i, b_i if and only if the matrix

$$(4.40) \quad \begin{pmatrix} \sin \ell_i \sqrt{\sigma_i^+} - \frac{\sqrt{\sigma_i^-}(\sigma_i^+ - p_i^2 \lambda^2)}{\sqrt{\sigma_i^+}(\sigma_i^- - p_i^2 \lambda^2)} \sin \ell_i \sqrt{\sigma_i^-} & \cos \ell_i \sqrt{\sigma_i^+} - \cos \ell_i \sqrt{\sigma_i^-} \\ \cos \ell_i \sqrt{\sigma_i^-} - \cos \ell_i \sqrt{\sigma_i^+} & \sin \ell_i \sqrt{\sigma_i^+} - \frac{\sqrt{\sigma_i^+}(\sigma_i^- - p_i^2 \lambda^2)}{\sqrt{\sigma_i^-}(\sigma_i^+ - p_i^2 \lambda^2)} \sin \ell_i \sqrt{\sigma_i^-} \end{pmatrix}$$

is rank deficient, that is, if and only if

$$(4.41) \quad \begin{aligned} & \frac{\sigma_i^- (\sigma_i^+ - p_i^2 \lambda^2)^2 + \sigma_i^+ (\sigma_i^- - p_i^2 \lambda^2)^2}{\sqrt{\sigma_i^+ \sigma_i^-} (\sigma_i^+ - p_i^2 \lambda^2) (\sigma_i^- - p_i^2 \lambda^2)} \sin \ell_i \sqrt{\sigma_i^+} \sin \ell_i \sqrt{\sigma_i^-} \\ & - 2 \cos \ell_i \sqrt{\sigma_i^+} \cos \ell_i \sqrt{\sigma_i^-} + 2 = 0, \quad i = 1, \dots, n. \end{aligned}$$

Therefore, the spectrum of (4.31), (4.32) is determined by (4.36) and (4.41).

In analogy with string networks considered above, we expect that if (4.36), (4.41) admit a nontrivial solution $\bar{\lambda}, \bar{\mu}$, then nontrivial values of a_i, b_i, u_i^0 , $i = 1, \dots, n$, can be chosen so that the dynamic node conditions (4.33), (4.34) are satisfied. However, this will not be the case, in general. For suppose the above matrix has rank one. Then the parameter a_i will be uniquely determined in terms of b_i , $i = 1, \dots, n$. The parameters u_i^0, b_1 must be completely free (since the problem is homogeneous). Once u_i^0, b_i are known, (4.33) and (4.34) yield *three* linear equations for the *two* parameters u_{i+1}^0, b_{i+1} . This overdetermined system will not, in general, have a solution, unless all u_i^0, b_i are zero.

Therefore, to obtain a nontrivial solution of (4.31)–(4.34), we assume that the matrix above has rank zero, i.e.,

$$(4.42) \quad \cos \ell_i \sqrt{\sigma_i^+} = \cos \ell_i \sqrt{\sigma_i^-},$$

$$(4.43) \quad \begin{aligned} \sin \ell_i \sqrt{\sigma_i^+} &= \frac{\sqrt{\sigma_i^-}(\sigma_i^+ - p_i^2 \lambda^2)}{\sqrt{\sigma_i^+}(\sigma_i^- - p_i^2 \lambda^2)} \sin \ell_i \sqrt{\sigma_i^-} \\ &= \frac{\sqrt{\sigma_i^+}(\sigma_i^- - p_i^2 \lambda^2)}{\sqrt{\sigma_i^-}(\sigma_i^+ - p_i^2 \lambda^2)} \sin \ell_i \sqrt{\sigma_i^-}. \end{aligned}$$

Both (4.42) and (4.43) will be satisfied for some λ, μ if

$$(4.44) \quad \ell_i^2 \sigma_i^+ (\lambda, \mu) = 4M_i^2 \pi^2, \quad \ell_i^2 \sigma_i^- (\lambda, \mu) = 4m_i^2 \pi^2$$

for integers M_i, m_i with $M_i > m_i$. From (4.44) we have

$$(4.45) \quad \begin{aligned} p_i^2 \lambda^2 + q_i^2 \mu^2 &= \sigma_i^+(\lambda, \mu) + \sigma_i^-(\lambda, \mu) = \frac{4(M_i^2 + m_i^2)\pi^2}{\ell_i^2}, \\ p_i^2 \lambda^2 (q_i^2 \mu^2 - r_i^2) &= \sigma_i^+(\lambda, \mu) \sigma_i^-(\lambda, \mu) = \frac{16m_i^2 M_i^2 \pi^4}{\ell_i^4}, \quad i = 1, \dots, n. \end{aligned}$$

Thus a spectral point λ, μ must satisfy (4.36) and (4.45).

If the numbers $\ell_i s_i$ are comeasurable, (4.36) has a sequence of solutions $\lambda^{(j)} \rightarrow \infty$. We select these so that $\cos \lambda^{(j)} s_i \ell_i = 1$ for $i = 1, \dots, n$. Then $\lambda^{(j)}$ may be expressed as

$$(4.46) \quad \lambda^{(j)} = 2j\pi \frac{n_i}{\ell_i s_i}$$

for some integer n_i . (We have $n_i = \ell_i s_i$ if $\ell_i s_i$ is an integer.) Substitution of $\lambda^{(j)}$ into (4.45) leads to $2n$ equations for μ , namely,

$$(4.47) \quad \mu^2 = \frac{4\pi^2}{\ell_i^2 q_i^2} \left[(M_i^2 + m_i^2) - \frac{j^2 n_i^2 p_i^2}{s_i^2} \right],$$

$$(4.48) \quad \mu^2 = \frac{1}{q_i^2} \left[\frac{4\pi^2 m_i^2 M_i^2 s_i^2}{j^2 \ell_i^2 n_i^2 p_i^2} + r_i^2 \right], \quad i = 1, \dots, n.$$

Therefore, existence of a spectral point requires the right-hand sides of (4.47) and (4.48) to be equal and independent of $i \in [1, \dots, n]$ for some choices of the integers m_i, M_i, j . These requirements restrict the quantities $p_i^2, q_i^2, r_i^2, s_i^2$. They correspond to the restriction in the string network case that the wave speeds p_i, q_i be comeasurable for each i . In particular, if all the beams are identical, the condition for the existence of a spectral point is (dropping the subscripts i)

$$(4.49) \quad \frac{4\pi^2}{\ell^2} \left(M^2 + m^2 - \frac{j^2 n^2 p^2}{s^2} \right) = \frac{4\pi^2 m^2 M^2 s^2}{j^2 \ell^2 n^2 p^2} + r^2$$

for some positive integers j, m, M . In this case there are no restrictions on q^2 . If also ℓs is an integer (so that $n = \ell s$), then (4.49) is a restriction only between p^2 and r^2 .

When the above conditions for the existence of a spectral point are met, the parameters a_i, b_i, u_i^0 are completely free. Equations (4.33) and (4.34) then uniquely determine $a_{i+1}, b_{i+1}, u_{i+1}^0$ in terms of a_i, b_i, u_i^0 . In fact, we find that (4.33) is

$$(4.50) \quad \frac{E_i I_i (M_i^2 - m_i^2)}{\ell_i^2} b_i = \frac{E_{i+1} I_{i+1} k_{i+1} (M_{i+1}^2 - m_{i+1}^2)}{\ell_{i+1}^2} b_{i+1}, \quad i = 1, \dots, n-1,$$

and (4.34) is

$$(4.51) \quad \begin{aligned} s_i \bar{\lambda} E_i A_i u_i^0 \mathbf{e}_i + \frac{2K_i (m_i + M_i) \pi}{\ell_i} a_i \mathbf{e}_i^\perp &= s_{i+1} \bar{\lambda} E_{i+1} A_{i+1} u_{i+1}^0 \mathbf{e}_{i+1} \\ &+ \frac{2K_{i+1} (m_{i+1} + M_{i+1}) \pi}{\ell_{i+1}} a_{i+1} \mathbf{e}_{i+1}^\perp, \quad i = 1, \dots, n-1. \end{aligned}$$

The a_i, b_i, u_i^0 will all be nonzero if a_1, b_1, u_1^0 are nonzero. It follows that, in the special circumstances described above, the Timoshenko beam network of Fig. 5 is not approximately controllable. However, this is obviously an anomalous situation.

A similar analysis may be applied to a closed-loop beam network such as that illustrated in Fig. 6. The only difference is that the node conditions (4.33)–(i) and (4.34)–(i) must hold for $i = 1, \dots, n-1$, and the “compatibility conditions”

$$\begin{aligned} E_n I_n \psi'_n(\ell_n) &= E_1 I_1 \psi'_1(0), \\ E_n A_n u'_n(\ell_n) \mathbf{e}_n + K_n w'_n(\ell_n) \mathbf{e}_n^\perp &= E_1 A_1 u'_1(0) \mathbf{e}_1 + K_1 w'_1(0) \mathbf{e}_1^\perp, \end{aligned}$$

must be satisfied. The former uniquely determine a_i, b_i, u_i^0 , $i = 2, \dots, n$, in terms of a_1, b_1, u_1^0 when the conditions described above are met; these values are given by (4.50) and (4.51). The compatibility conditions are

$$\begin{aligned} \frac{E_n I_n (M_n^2 - m_n^2)}{\ell_n^2} b_n &= \frac{E_1 I_1 (M_1^2 - m_1^2)}{\ell_1^2} b_1, \\ s_n \bar{\lambda} E_n A_n u_n^0 \mathbf{e}_n + \frac{2K_n (m_n + M_n) \pi}{\ell_n} a_n \mathbf{e}_n^\perp &= s_1 \bar{\lambda} E_1 A_1 u_1^0 \mathbf{e}_1 + \frac{2K_1 (m_1 + M_1) \pi}{\ell_1} a_1 \mathbf{e}_1^\perp, \end{aligned}$$

which are easily seen to be consequences of (4.50) and (4.51).

5. Asymptotic stability of beam networks. In this section we consider the asymptotic stability of the control system (4.10) under (possibly nonlinear) feedback controls of the form

$$(5.1) \quad \mathbf{u} = -\mathbf{f}(B'\dot{\mathbf{R}}),$$

where $\mathbf{f} : U \mapsto U$ is continuous, monotone as a graph, and satisfies $\mathbf{f}(0) = 0$. The closed-loop system is then

$$(5.2) \quad \ddot{\mathbf{R}} + B\mathbf{f}(B'\dot{\mathbf{R}}) + A\mathbf{R} = 0.$$

It follows immediately from (5.2) that, at least formally,

$$(5.3) \quad \dot{Q}(t) = \frac{1}{2} \frac{d}{dt} [\|\dot{\mathbf{R}}(t)\|_H^2 + \|\mathbf{R}(t)\|_V^2] = -(\mathbf{f}(B'\dot{\mathbf{R}}), B'\dot{\mathbf{R}}(t))_U \leq 0.$$

We are interested in determining those configurations for which a rate of decay for $Q(t)$ exists and, for such networks, in specifying the decay rate in terms of properties of the function \mathbf{f} .

It is well known that there is a close connection between exact controllability of the open-loop controlled system and the existence of a decay rate for the closed-loop system (5.2), so it should not be surprising that we can establish a decay rate only in those cases where exact controllability can be proved. In other situations, such as those considered in §4.2, we cannot obtain uniform decay estimates and, in fact, such estimates are generally not possible. To illustrate this last point, consider the linear feedback system

$$\ddot{\mathbf{R}}(t) + A\mathbf{R}(t) = B\mathbf{u}(t), \quad \mathbf{u}(t) = -B'\dot{\mathbf{R}}(t)$$

or, equivalently (cf. (4.11)),

$$(5.4) \quad \dot{\Phi}(t) = \mathcal{A}\Phi(t), \quad \mathcal{A} = \begin{pmatrix} 0 & I \\ -A & -BB' \end{pmatrix},$$

where

$$\text{Dom}(\mathcal{A}) = \{(\mathbf{R}^0, \mathbf{R}^1) | \mathbf{R}^0 \in V, \mathbf{R}^1 \in V, A\mathbf{R}^0 + B B' \mathbf{R}^1 \in H\}.$$

It is standard theory that solutions of (5.4) are given by a contraction semigroup on $V \times H$. From (5.3) we have

$$(5.5) \quad \|e^{t\mathcal{A}}\Phi^0\|_{V \times H} = \|\Phi^0\|_{V \times H} - \int_0^t \|B'\Phi(s)\|_U^2 ds.$$

Let

$$\mathcal{W} = \{\Phi^0 \in V \times H | e^{t\mathcal{A}}\Phi^0 \rightarrow 0 \text{ weakly in } V \times H \text{ as } t \rightarrow \infty\}.$$

According to a decomposition theorem due to Foguel [2], $e^{t\mathcal{A}}\mathcal{W} \subset \mathcal{W}$ for every $t \geq 0$ and $e^{t\mathcal{A}}$ is reduced to a unitary group on \mathcal{W}^\perp . By (5.5), \mathcal{W}^\perp is characterized by those Φ^0 for which $B'\Phi(s) = 0$, $s \geq 0$. This means that $\mathcal{W} = V \times H$ if and only if

$$(5.6) \quad \ddot{\mathbf{R}}(t) + A\mathbf{R}(t) = 0, \quad B'\dot{\mathbf{R}}(t) = 0, \quad t \geq 0,$$

implies $\mathbf{R}(t) \equiv 0$. However, if \mathbf{R} satisfies (5.6) then $\dot{\mathbf{R}}$ satisfies (4.16) of §4.2. The examples of that section demonstrate that for beam networks having more than one clamped node or containing a closed loop, (5.6) may admit nontrivial time periodic solutions. Such configurations therefore may not be even weakly stable under the linear feedback $\mathbf{u} = -B'\dot{\mathbf{R}}$.

On the other hand, networks that are exactly controllable to $V \times H$ are uniformly asymptotically stable in $V \times H$ under *some* linear feedback $\mathbf{u} = C\mathbf{R} + D\dot{\mathbf{R}}$, where $C \in \mathcal{L}(V, U)$ and $D \in \mathcal{L}(H, U)$ (and conversely). This may be proved via the linear quadratic regulator (LQR) framework

$$J := \min_{\mathbf{u} \in \mathcal{U}} \left(\int_0^\infty \|\Phi(t)\|_{V \times H}^2 dt + C^2 \int_0^\infty \|\mathbf{u}(t)\|_U^2 dt \right).$$

The existence of a control for which $\Phi(t) = 0$ for $t > T$ for some $T > 0$ assures that J is finite. The minimum is achieved at a unique $\mathbf{u}_0 \in \mathcal{U}$ which is given as a feedback $\mathbf{u}_0(t) = \mathcal{R}\Phi(t)$ for an appropriate Riccati operator $\mathcal{R} \in \mathcal{L}(V \times H, U)$ which, in turn, is determined through a certain algebraic operator equation. We will not pursue further the LQR approach to stabilization of beam networks in this paper. The reader is referred to the comprehensive work of Lasiecka and Triggiani [5] on the subject of Riccati equation and LQR problems for boundary/point control problems for partial differential equations.

Instead, we shall consider feedback controls of the form (5.1) in situations where it is known that the network is exactly controllable. More specifically, we consider only situations where the nonzero components of B are in the free simple nodes, in analogy with §4.1. The control space is then $\mathcal{U} = L^2(0, T, U)$ where U is defined in (4.6), and we may write

$$\mathbf{u} = - \bigotimes_{i=1}^p \mathbf{f}_i(B'\dot{\mathbf{R}}) = - \bigotimes_{i=1}^p \mathbf{f}_i(\dot{\mathbf{R}}_1(N_1), \dots, \dot{\mathbf{R}}_p(N_p)),$$

where $\mathbf{f}_i = f_{1i}\mathbf{e}_i + f_{2i}\mathbf{e}_i^\perp + f_{3i}\mathbf{n}$. In terms of components, the closed-loop system is described by (4.1)–(4.5) with $f_{ij} = f_{ij}(\dot{\mathbf{R}}_1(N_1, t), \dots, \dot{\mathbf{R}}_p(N_p, t))$ and with $\mathbf{F}_k = 0$.

The following result shows that the closed-loop system is well posed in $V \times H$.

PROPOSITION 5.1. *Let \mathcal{A} be the (nonlinear) operator in $V \times H$ defined by*

$$\mathcal{A} = \begin{pmatrix} 0 & I \\ -A & -B\mathbf{f}(B'\cdot) \end{pmatrix},$$

$$\text{Dom}(\mathcal{A}) = \{(\mathbf{R}^0, \mathbf{R}^1) \mid \mathbf{R}^0 \in V, \mathbf{R}^1 \in V, A\mathbf{R}^0 + B\mathbf{f}(B'\mathbf{R}^1) \in H\}.$$

Then \mathcal{A} is densely defined and maximal dissipative.

Proof. The monotonicity of $-\mathcal{A}$ follows immediately from that of \mathbf{f} . The statement $\text{Rg}(\lambda I - \mathcal{A}) = V \times H$ is equivalent to $\text{Rg}(A + \lambda B\mathbf{f}(B'\cdot) + \lambda^2 I) = V'$. The latter follows from the coercivity of A , the continuity and monotonicity of \mathbf{f} and $\mathbf{f}(0) = 0$. Therefore, $-\mathcal{A}$ is maximal monotone. The density of $\text{Dom}(\mathcal{A})$ in $V \times H$ follows by noting that

$$(5.7) \quad \text{Dom}(\mathcal{A}) \supset D_A \times V_0,$$

where

$$V_0 = \{\mathbf{R} \in V : R_i(N_i) = 0, i = 1, \dots, p\}.$$

Then $D_A \times V_0$ is dense in $V \times H$ and $\mathbf{f}(B'\mathbf{R}^1) = 0$ if $\mathbf{R}^1 \in V_0$, hence (5.7) holds. \square

It follows from Proposition 5.1 that given initial data $(\mathbf{R}^0, \mathbf{R}^1) \in V \times H$, (5.2) has a unique solution with $(\mathbf{R}, \dot{\mathbf{R}}) \in C([0, T]; V \times H)$ for every $T > 0$. We refer to such a solution as a finite energy solution. To study the behavior of such solutions as $t \rightarrow \infty$, we assume that the network is such that the following a priori estimate holds: for each classical solution of (4.1),

$$(5.8) \quad \int_0^T \mathcal{Q}(t) dt \leq C \left[\sup_{0 \leq t \leq T} \mathcal{Q}(t) + \sum_{i=1}^p \int_0^T Q_i(N_i, t) dt \right]$$

for some constant C independent of T .

Remark 5.1. The estimate (5.8) follows from Proposition 3.1 when the inequality (3.18) is satisfied (cf. Corollary 3.2). Sufficient conditions for (3.18) to hold were discussed in §3.1. In particular, (5.8) is valid for the networks considered in Examples 4.1 and 4.2.

When (5.8) is valid for classical solutions of (4.1) it will hold a fortiori for finite energy solutions of the closed-loop system (5.2). In fact, for such solution we have $\mathcal{Q}(t) \leq \mathcal{Q}(0)$ so that the estimate (3.13) holds. Therefore, the right-hand side of (5.8) is finite for finite energy solutions of (5.2). Moreover, from (5.3) we have

$$\sup_{0 \leq t \leq T} \mathcal{Q}(t) = \mathcal{Q}(0) = \mathcal{Q}(T) + \int_0^T (\mathbf{f}(B'\dot{\mathbf{R}}(t)), B'\dot{\mathbf{R}}(t))_U dt,$$

so that from (5.8) we obtain the estimate

$$(5.9) \quad \int_0^T \mathcal{Q}(t) dt \leq C \left[\mathcal{Q}(T) + \int_0^T (\mathbf{f}(B'\dot{\mathbf{R}}(t)), B'\dot{\mathbf{R}}(t))_U dt + \sum_{i=1}^p \int_0^T Q_i(N_i, t) dt \right]$$

for finite energy solutions of (5.2).

Decay estimates for (5.2) will be deduced from (5.9). To do so, we shall employ a proof technique introduced by Lasiecka and Tartarù [4], which they used to obtain decay rates for solutions of a class of nonlinear, dissipative wave equations. We make the following assumptions regarding \mathbf{f} .

(H1) $\mathbf{f} : U \mapsto U$ is continuous, monotone as a graph and $\mathbf{f}(0) = 0$.

(H2) For all $\mathbf{u} \in U$ with $|\mathbf{u}| \geq 1$,

$$M_1|\mathbf{u}|^2 \leq \mathbf{u} \cdot \mathbf{f}(\mathbf{u}), \quad |\mathbf{f}(\mathbf{u})| \leq M_2|\mathbf{u}|,$$

where $M_1 > 0$.

(H3) There is a concave, strictly increasing continuous function $g : \mathbb{R}^+ \mapsto \mathbb{R}$ with $g(0) = 0$ such that for all $\mathbf{u} \in U$ with $|\mathbf{u}| \leq 1$,

$$|\mathbf{u}|^{2\alpha} + |\mathbf{f}(\mathbf{u})|^2 \leq g(\mathbf{u} \cdot \mathbf{f}(\mathbf{u}))$$

for some $\alpha \in (0, 1]$.

We set

$$g_T(\xi) = g\left(\frac{\xi}{T}\right), \quad \tilde{h}_T(\xi) = (I + g_T)^{-1}(\xi/\tilde{C}), \quad \xi \geq 0, \quad T > 0,$$

where \tilde{C} is a positive constant to be specified later, and

$$h_T(\xi) = \xi - (I + \tilde{h}_T)^{-1}(\xi), \quad \xi \geq 0.$$

Note that h_T is positive and strictly increasing since \tilde{h}_T has these properties. Define $S(t)\eta$ to be the solution of the nonlinear differential equation

$$(5.10) \quad \dot{X}(t) + h_T(X(t)) = 0, \quad X(0) = \eta > 0.$$

Of course, S depends also on T . Since h_T is increasing, $S(t)$, $t \geq 0$, is a (nonlinear) contraction semigroup on \mathbb{R}^+ . The main result of this section is as follows.

THEOREM 5.2. *Assume that \mathbf{f} satisfies (H1)–(H3). Let $(\mathbf{R}, \dot{\mathbf{R}})$ be a finite energy solution of (5.2). Then there is a $T > 0$ such that*

$$\mathcal{Q}(t) \leq S(t/T - 1)\mathcal{Q}(0), \quad t \geq T,$$

where $S(t)\eta$ is the solution of (5.10).

COROLLARY 5.3. *Let \mathbf{f} satisfy (H1), (H2) and*

$$(5.11) \quad \mathbf{u} \cdot \mathbf{f}(\mathbf{u}) \geq c_0|\mathbf{u}|^{q+1}, \quad |\mathbf{f}(\mathbf{u})| \leq C_0|\mathbf{u}|^\alpha$$

for all $\mathbf{u} \in U$ with $|\mathbf{u}| \leq 1$, where $c_0 > 0$, $0 < \alpha \leq 1$, and $q \geq \alpha$. Then as $t \rightarrow \infty$,

$$\mathcal{Q}(t) = O(e^{-\omega t}) \quad \text{if } p = \alpha = 1,$$

where $\omega > 0$;

$$\mathcal{Q}(t) = O(t^{-2\alpha/(q+1-2\alpha)}) \quad \text{if } q+1 > 2\alpha.$$

Proof of Corollary 5.3. We first exhibit a function g satisfying (H3). For $|\mathbf{u}| \leq 1$ we have from (5.11)

$$\begin{aligned} |\mathbf{u}|^{2\alpha} + |\mathbf{f}(\mathbf{u})|^2 &\leq c_0^{-2\alpha/(q+1)} (\mathbf{u} \cdot \mathbf{f}(\mathbf{u}))^{2\alpha/(q+1)} + C_0^2 |\mathbf{u}|^{2\alpha} \\ &\leq c_0^{-2\alpha/(q+1)} (1 + C_0^2) (\mathbf{u} \cdot \mathbf{f}(\mathbf{u}))^{2\alpha/(q+1)}. \end{aligned}$$

Therefore (H3) is satisfied if we choose

$$g(\xi) = c_0^{-2\alpha/(q+1)} (1 + C_0^2) \xi^{2\alpha/(q+1)}.$$

Case (i). $q = \alpha = 1$. Then

$$g(\xi) = \frac{1 + C_0^2}{c_0} \xi, \quad \tilde{h}_T(\xi) = \frac{\xi}{\tilde{C}(1 + C_T)}, \quad h_T(\xi) = \frac{\xi}{1 + \tilde{C}(1 + C_T)} := \mu\xi,$$

where $C_T = (1 + C_0^2)/(c_0 T)$. Thus $S(t)\eta = e^{-\mu t}\eta$.

Case (ii). $q + 1 > 2\alpha$. We write

$$g(\xi) = \frac{1 + C_0^2}{c_0^\beta} \xi^\beta, \quad \beta = \frac{2\alpha}{q+1} < 1.$$

The function \tilde{h}_T is determined through

$$\tilde{h}_T(\tilde{C}(\xi + C_T^\beta \xi^\beta)) = \xi, \quad C_T = \frac{(1 + C_0^2)^{1/\beta}}{c_0 T}.$$

Thus asymptotically we have

$$\tilde{h}_T(\xi) \sim \frac{\xi^{1/\beta}}{C_T \tilde{C}^{1/\beta}}, \quad (\xi \rightarrow 0).$$

Furthermore, h_T satisfies

$$h_T(\xi + \tilde{h}_T(\xi)) = \tilde{h}_T(\xi),$$

so that $h_T(\xi)$ must have the same asymptotic behavior as $\tilde{h}_T(\xi)$ as $\xi \rightarrow 0$. If we define

$$H(\xi) = \int_\xi^\infty \frac{dy}{h_T(y)}, \quad \xi > 0,$$

then H is a decreasing function and $H(\eta) = 0$, $H(0+) = +\infty$. Thus \mathbb{R}^+ is in the range of H and the solution of (5.10) is given by

$$X(t) = H^{-1}(t), \quad t \geq 0.$$

Since $H(0+) = +\infty$,

$$\lim_{t \rightarrow \infty} X(t) = \lim_{t \rightarrow \infty} H^{-1}(t) = 0.$$

Let $\varepsilon > 0$, $\varepsilon < 1$. There exists $\delta(\varepsilon) > 0$ such that if $0 < \xi < \delta$,

$$|h_T(\xi) - \omega \xi^{1/\beta}| < \varepsilon \omega \xi^{1/\beta}, \quad \omega = \frac{1}{C_T \tilde{C}^{1/\beta}}.$$

Also, there exists $t_0(\varepsilon) > 0$ such that $t \geq t_0$ implies $0 < X(t) < \delta$. Therefore, if $t \geq t_0$ we have

$$-h_T(X(t)) \leq \omega(\varepsilon - 1)(X(t))^{1/\beta},$$

hence

$$\dot{X}(t) + \omega(1 - \varepsilon)(X(t))^{1/\beta} \leq 0, \quad t \geq t_0.$$

It follows that

$$X(t) = O(t^{\beta/(\beta-1)}) \quad \text{as } t \rightarrow \infty. \quad \square$$

Proof of Theorem 5.2. Since $\mathcal{Q}(t)$ is nonincreasing we have

$$\int_0^T \mathcal{Q}(t) dt \geq T\mathcal{Q}(T).$$

Substitution of this estimate into (5.9) yields, for $T > C$,

$$(5.12) \quad \mathcal{Q}(T) \leq \frac{C}{T-C} \left[\int_0^T (\mathbf{f}(B'\dot{\mathbf{R}}(t)), B'\dot{\mathbf{R}}(t))_U dt + \sum_{i=1}^p \int_0^T Q_i(N_i, t) dt \right].$$

To simplify the notation, we write

$$\mathbf{v} = B'\dot{\mathbf{R}}, \quad (\mathbf{f}(B'\dot{\mathbf{R}}), B'\dot{\mathbf{R}})_U = \mathbf{v} \cdot \mathbf{f}(\mathbf{v}).$$

We have

$$(5.13) \quad \begin{aligned} \sum_{i=1}^p \int_0^T Q_i(N_i, t) dt &= \sum_{i=1}^p \int_0^T [\rho_i |\dot{\mathbf{r}}_i|^2 + I_{\rho_i} \dot{\psi}_i^2 \\ &\quad + E_i A_i u_i'^2 + E_i I_i \psi_i'^2 + K_i (\psi_i + w_i')^2] (N_i, t) dt \\ &\leq C_1 \sum_{i=1}^p \int_0^T [|\dot{\mathbf{R}}_i(N_i, t)|^2 + |\mathbf{f}_i(\mathbf{v}(t))|^2] dt \\ &\leq C_1 \int_0^T [|\mathbf{v}(t)|^2 + |\mathbf{f}(\mathbf{v}(t))|^2] dt \end{aligned}$$

for some constant C_1 . Use of (5.13) in (5.12) gives, for $T > C$,

$$(5.14) \quad \mathcal{Q}(T) \leq \frac{C}{T-C} \left(\int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt + C_1 \int_0^T [|\mathbf{v}(t)|^2 + |\mathbf{f}(\mathbf{v}(t))|^2] dt \right).$$

Set

$$J_1 = \{t \in [0, T] : |\mathbf{v}(t)| \geq 1\}, \quad J_2 = [0, T] - J_1.$$

Hypothesis (H2) implies

$$\int_{J_1} [|\mathbf{v}(t)|^2 + |\mathbf{f}(\mathbf{v}(t))|^2] dt \leq M_1^{-2}(1 + M_2^2) \int_0^T \mathbf{v} \cdot \mathbf{f}(\mathbf{v}(t)) dt.$$

In addition, with hypotheses (H1) and (H3) we obtain

$$\begin{aligned} \int_{J_2} [|\mathbf{v}(t)|^2 + |\mathbf{f}(\mathbf{v}(t))|^2] dt &\leq \int_{J_2} [|\mathbf{v}(t)|^{2\alpha} + |\mathbf{f}(\mathbf{v}(t))|^2] dt \\ &\leq \int_{J_2} g(\mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t))) dt \\ &\leq \int_0^T g(\mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t))) dt. \end{aligned}$$

We apply Jensen's inequality [8, p. 359] to the last integral to the effect that

$$\begin{aligned} \int_0^T g(\mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t))) dt &\leq Tg \left(\frac{1}{T} \int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt \right) \\ &\leq Tg_T \left(\int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt \right). \end{aligned}$$

Therefore

$$(5.15) \quad \begin{aligned} \int_0^T [|\mathbf{v}(t)|^2 + |\mathbf{f}(\mathbf{v}(t))|^2] dt &\leq M_1^{-2}(1 + M_2^2) \int_0^T \mathbf{v} \cdot \mathbf{f}(\mathbf{v}(t)) dt \\ &\quad + Tg_T \left(\int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt \right). \end{aligned}$$

Insertion of (5.15) into (5.14) yields, for some constant C_2 , the estimate

$$(5.16) \quad \begin{aligned} \mathcal{Q}(T) &\leq \frac{C_2 T}{T - C} \left[\int_0^T \mathbf{v} \cdot \mathbf{f}(\mathbf{v}(t)) dt + g_T \left(\int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt \right) \right] \\ &\leq \tilde{C} \left[\int_0^T \mathbf{v} \cdot \mathbf{f}(\mathbf{v}(t)) dt + g_T \left(\int_0^T \mathbf{v}(t) \cdot \mathbf{f}(\mathbf{v}(t)) dt \right) \right] \end{aligned}$$

for $T \geq 2C$, since $T/(T - C)$ is decreasing for $T > C$, where $\tilde{C} = 2C_2$. It follows from (5.16) that

$$\tilde{h}_T(\mathcal{Q}(T)) \leq \int_0^T \mathbf{v} \cdot \mathbf{f}(\mathbf{v}(t)) dt = \mathcal{Q}(0) - \mathcal{Q}(T),$$

that is,

$$(5.17) \quad \tilde{h}_T(\mathcal{Q}(T)) + \mathcal{Q}(T) \leq \mathcal{Q}(0), \quad T \geq T_0 = 2C.$$

Now fix $T \geq T_0$. Instead of the interval $[0, T]$ we could just as well work on the interval $[mT, (m+1)T]$, $m = 1, 2, \dots$. Then (5.17) would read

$$(5.18) \quad \tilde{h}_T(\mathcal{Q}((m+1)T)) + \mathcal{Q}((m+1)T) \leq \mathcal{Q}(mT),$$

with the same function \tilde{h}_T as in (5.17). We now apply the following lemma from [4].

LEMMA 5.4 (see [4]). *Let \tilde{h} be a positive, increasing function such that $\tilde{h}(0) = 0$, and set $h(\xi) = \xi - (I + \tilde{h})^{-1}(\xi)$. Let $\{s_m\}_{m=0}^\infty$ be a sequence of positive numbers such that*

$$\tilde{h}(s_{m+1}) + s_{m+1} \leq s_m, \quad m \geq 0.$$

Then $s_m \leq S(m)s_0$ where $S(t)\eta$ is the solution of

$$\dot{X}(t) + h(X(t)) = 0, \quad X(0) = \eta \geq 0.$$

It follows from (5.18) and Lemma 5.4, applied to the sequence $s_m = Q(mT)$, that

$$Q(mT) \leq S(m)Q(0), \quad m = 0, 1, \dots$$

For any $t > 0$ we may write $t = mT + \tau$ for some integer $m \geq 0$ and $\tau \in [0, T)$. Since both $Q(t)$ and $S(t)\eta$ are nonincreasing, we have

$$Q(t) \leq Q(mT) \leq S((t - \tau)/T)Q(0) \leq S(t/T - 1)Q(0), \quad t \geq T. \quad \square$$

THE STANDARD H_∞ PROBLEM AND THE MAXIMUM PRINCIPLE: THE GENERAL LINEAR CASE*

GILEAD TADMOR†

Abstract. The classical, relatively simple ideas of linear quadratic (LQ) optimization are used in a time domain treatment of the *standard H_∞ problem*. Given the power of time domain analysis, the problem can be solved in the general framework of linear time varying, possibly infinite-dimensional, finite as well as infinite horizon systems, under no structural restrictions (such as block dimensions, zero blocks in the D operator, etc.). In the spirit of recent finite-dimensional linear time invariant (LTI) results, the solution is given in terms of two coupled Riccati equations; it includes a criterion for suboptimality and a parametrization of all suboptimal compensators. Results pertinent to LTI, periodic, and asymptotic systems are obtained as corollaries.

Key words. the standard H_∞ problem, time varying and distributed systems, LQ variational methods, differential min-max games

1. Introduction. The celebrated H_∞ control theory has evolved in the 1980s as a *frequency domain* methodology par excellence. The theory's quintessential motivating examples—the *weighted sensitivity minimization* and the *model matching* problems—were cast in *frequency domain* terms; they have been analyzed and solved by sophisticated *frequency domain* techniques, relying mostly on factorization theory and operator interpolation (cf. [10] for an overview and references).

Yet it has recently been observed that important H_∞ results (e.g., in [3], [4], [9], [12], [13], [15], [16], [19], [22], [38], and [40]) bear considerable resemblance to, by now classical, linear quadratic Gaussian (LQG) observations. And while optimal control problems have been treated from algebraic perspectives, the inherent logic of the field stems from studies of system dynamics, i.e., from *time domain* analysis. Dynamic programming and the maximum principle are perhaps the two most fundamental observations in that respect.

It has also been observed [10] that H_∞ problems (and for that matter, a wide range of worst-case design issues) can be cast in the transform-invariant terms of input-output (I/O) operator norms. That is, these problems are equally meaningful over the *time domain* as over the *frequency domain*.

Motivated by these observations, we develop here an interpretation of the generic *standard problem* as a competition between disturbances and controls, with a quadratic cost objective. We are thus able to effectively invoke the powerful yet relatively simple LQ maximum principle as a main tool to obtain our version of the recent *two Riccati equations* result. It includes a suboptimality criterion and a parametrization of all suboptimal solutions. We do so in a general setting of linear systems, making no structural restrictions and allowing any time horizon, time varying systems, and infinite dimensionality.

A summary of the present discussion and some follow-ups are given in [36] and [37]. This note extends and complements our preliminary investigation of the same issue in [30] and [31] (where our LQ approach was first presented) and of I/O norms in linear systems in [32]. Its main results (Theorems I and II) are intended as a

theoretical backdrop to some further studies, both theoretical and applied, in robust control. A hint on examples of subclasses of linear time varying (LTV) systems where they can be feasibly implemented is given in the corollary, while some further developments stemming from them are presented in [33]–[35]. It is noted that similar and related approaches have been taken recently by several other authors (e.g., in [2], [17], [25]–[27], [29], and [39]).

In dealing with the present level of generality it seems essential to stick to a purely dynamic line of arguments, excluding many shortcuts we usually make in the LTI case (e.g., using linear algebraic techniques) or even differentiation (as the finite-dimensional case allows). Most of those arguments are fairly simple, drawn from a standard inventory of LQ optimization and linear dynamic systems tools. Yet their accumulation is felt in this note's length and notation burden; and while some of the resulting encumbrance is certainly due to the author's shortcomings, it seems that most of it is an inevitable consequence of the undertaking. We shall try to ease readability by occasional footnotes.

The paper is organized as follows: Preliminaries and the statement of main results are given in § 2. Proofs are given in § 3. For the sake of clarity, these results and proofs are made under certain simplifying assumptions on the system's structure. In § 4 we discuss the general case, where the simplifying structural assumptions are dropped.

2. Preliminaries. We consider a linear system \mathcal{S} of the form

$$(1) \quad \begin{aligned} \dot{x} &= Ax + B_1 w + B_2 u, \\ z &= C_1 x + D_{11} w + D_{12} u, \\ y &= C_2 x + D_{21} w + D_{22} u \end{aligned}$$

over a time interval (t_0, t_1) , $-\infty \leq t_0 < t_1 \leq +\infty$. In this setting x , u , w , y , and z are interpreted as the state, control, disturbance, observation, and the output signals, respectively. These signals take values in the Hilbert spaces \mathbf{X} , \mathbf{U} , \mathbf{W} , \mathbf{Y} , and \mathbf{Z} . The coefficients A , B_i , C_i , and D_{ij} are allowed to vary in time (e.g., $A = A(t)$). The input and output coefficients B_i , C_i , and D_{ij} are assumed to be L_∞ bounded-operator-valued functions. The operator A is assumed to generate a uniformly exponentially bounded evolution system $\Phi(t, s)$ on \mathbf{X} . That is, there exist real constants α and β such that¹

$$(2) \quad \|\Phi(t, s)\| \leq \alpha e^{\beta(t-s)}$$

for $t \geq s$.

Note. The reader who prefers to focus on the finite-dimensional case may substitute “transition matrix” for “evolution system” and assume that A is an L_∞ matrix-valued function. In the infinite-dimensional LTI case, “ c_0 -semigroup” should substitute for “evolution system” and exponential boundedness is guaranteed by definition. Details and precise definitions pertinent to evolution systems and their generators, as well as examples of conditions that assure that an operator generates an evolution system, can be found in [5]–[8], [11], [14], and [20].

For the benefit of those who wish to focus only on the finite-dimensional case, we chose to stick to the differential equation formalism, as in (1), and use the terms “generator” (and thereby “generates,” “generated,” etc.) also in reference to bounded perturbations of true generators. *It is stressed that these conventions do not adhere to*

¹ We use the same notation $\|\cdot\|$ in reference to the norm of a Hilbert space vector, a time function, and an operator's induced norm. The meaning will be clear from the context. When in doubt, we use subscript in reference to the underlying space, e.g. $\|\xi\|_X$. We also use subscript to denote the weight of a weighted Hilbert space norm, e.g. $\|\varphi\|_\Omega^2 = \langle \varphi, \Omega \varphi \rangle$. The reader will be alerted of the latter notation when it is used.

standard definitions and are made solely for the purpose of simplicity in notation and terminology. A brief discussion of the appropriate interpretation of (1) and of our (ab)use of the term “generator” and its derivatives, is provided in the remark on infinite dimensionality and in Lemmas 2.1 and 2.2 at the end of this section. Those readers who are interested in the distributed case may wish to consult that remark at this point.

Restrictions of (1) to subintervals $[t, t_1)$, $t \in (t_0, t_1)$ will be considered. Associated with each such restriction are the linear (bounded, in the finite horizon case) mappings from the initial state and the inputs u and w to the state, observation and output trajectories. Those will be denoted, respectively, by

$$\chi(t): (x(t), u, w) \rightarrow x: X \times L_2(t, t_1) \times L_2(t, t_1) \rightarrow \times L_2(t, t_1),$$

$$\mathcal{Y}(t): (x(t), u, w) \rightarrow y: X \times L_2(t, t_1) \times L_2(t, t_1) \rightarrow \times L_2(t, t_1),$$

and

$$\mathcal{X}(t): (x(t), u, w) \rightarrow z: X \times L_2(t, t_1) \times L_2(t, t_1) \rightarrow \times L_2(t, t_1).$$

As the discussion unfolds we introduce and use variants of these notations, in reference to the mappings associated with feedback control or the result of certain optimization problems. Those variants will be distinguished by super- and subscript notation, as will be explained in due time.

An *admissible feedback operator* $u = \mathcal{K}y$ in (1) is defined in terms of a linear time varying system

$$(3) \quad \dot{p} = Mp + Ny, \quad u = Qp + Ry,$$

where p takes values in a Hilbert space \mathbf{P} and where the assumptions on the coefficients in (3) are analogous to those made in (1). The closed-loop system, depicted in Fig. 1, should be well defined under our feedback. That is guaranteed by the condition that $I - RD_{22}$ (or equivalently, $I - D_{22}R$) be invertible. In the present time-varying setting, we require that admissible compensators maintain uniform invertibility; i.e., $(I - RD_{22})^{-1}$, $(I - D_{22}R)^{-1} \in L_\infty$. It is important to remember that since the feed-through component R is invariant under the choice of a particular realization of a compensator, so is the uniform invertibility condition.

The free motion in the closed-loop system is governed by this next operator:

$$(4) \quad \mathcal{A} = \begin{bmatrix} A + B_2(I - RD_{22})^{-1}RC_2 & B_2(I - RD_{22})^{-1}Q \\ N(I - D_{22}R)^{-1}C_2 & M + ND_{22}(I - RD_{22})^{-1}Q \end{bmatrix}.$$

Our admissible feedback is *internally stabilizing* if the operator \mathcal{A} is exponentially stable; i.e., such that “ β ” in the closed-loop counterpart of (2) is negative.

It is noted that in the case of a static feedback, $u = Ry$ the state space \mathbf{P} becomes trivial and (4) reduces to

$$(5) \quad \mathcal{A} = A + B_2(I - RD_{22})^{-1}RC_2.$$

FIG. 1. The closed-loop system.

Given an internally stabilizing feedback \mathcal{K} we denote by $\mathcal{T}_{\mathcal{K}}(s)$ the closed-loop mapping $w \rightarrow z = \mathcal{Z}(s)(0, u = \mathcal{K}y, w): L_2(s, t_1) \rightarrow L_2(s, t_1)$, $s \in (t_0, t_1)$. These operators are bounded, uniformly for all choice of s . Obviously, $\|\mathcal{T}_{\mathcal{K}}(t_0)\| = \max_s \|\mathcal{T}_{\mathcal{K}}(s)\|$. The optimal value in (1) is

$$(6) \quad \gamma_0 = \inf \{ \|\mathcal{T}_{\mathcal{K}}(t_0)\| : \mathcal{K} \text{ is internally stabilizing} \}.$$

In the context of the *standard problem* we want (i) to characterize *suboptimal values* $\gamma > \gamma_0$, and (ii) given a suboptimal γ , to parametrize all internally stabilizing compensators that assure $\|\mathcal{T}_{\mathcal{K}}(t_0)\| < \gamma$.

The following assumptions on the structure of \mathcal{S} result in considerable notational simplification of our main results and their proofs, and will be made throughout the remainder of this section and in § 3. In § 4 we will discuss the mathematically simple but notationally awkward steps that may be taken in removing all these assumptions.

$$(7) \quad \begin{aligned} D_{11} &= 0, & D'_{12}C_1 &= 0, & D'_{12}D_{12} &= I, & C'_1C_1 &\geq \varepsilon I, \\ D_{22} &= 0, & D_{21}B'_1 &= 0, & D_{21}D'_{21} &= I, & B_1B'_1 &\geq \varepsilon I. \end{aligned}$$

Subject to (7), the following are our main results.

THEOREM I. (a) $\gamma > \gamma_0$ if and only if there exist negative-definite, operator-valued functions $\Pi_1, \Pi_2 \in L_\infty(t_0, t_1)$, $(\Pi_i(t): X \rightarrow X)$ such that

(i) The operators $A_1 = A + (B_2B'_2 - (1/\gamma^2)B_1B'_1)\Pi_1$ and $A_2 = A - (1/\gamma^2)B_1B'_1\Pi_1 + \Pi_2(C'_2C_2 - (1/\gamma^2)\Pi_1B_2B'_2\Pi_1)$ generate exponentially stable evolution systems, Φ_1 and Φ_2 , respectively.

(ii) Π_1 and Π_2 satisfy these next Riccati integral equations:

$$(8) \quad \Pi_1(s)\xi = - \int_s^{t_1} \Phi'_1(t, s) \left[C'_1C_1 + \Pi_1 \left(B_2B'_2 - \frac{1}{\gamma^2} B_1B'_1 \right) \Pi_1 \right] (t) \Phi_1(t, s) \xi dt$$

and

$$(9) \quad \Pi_2(t)\xi = - \int_{t_0}^t \Phi_2(t, s) \left[B_1B'_1 + \Pi_2 \left(C'_2C_2 - \frac{1}{\gamma^2} \Pi_1B_2B'_2\Pi_1 \right) \Pi_2 \right] \cdot (s) \Phi'_2(t, s) \xi ds.$$

(b) Suppose that $\gamma > \gamma_0$. Then the following is a parametrization of all internally stabilizing compensators for (1) that assure $\|\mathcal{T}_{\mathcal{K}}(t_0)\| < \gamma$:

$$(10) \quad \begin{aligned} \dot{p} &= (A_1 + \Pi_2C'_2C_2)p + \Pi_2C'_2y - \left(I + \frac{1}{\gamma^2} \Pi_2\Pi_1 \right) B_2v, \\ q &= C_2p + y, & v &= \mathcal{K}_0q, \\ u &= -B'_2\Pi_1p + v. \end{aligned}$$

The free design parameter \mathcal{K}_0 may be any admissible compensator in (10), realized by a stable system and satisfying $\|\mathcal{K}_0\| < \gamma$.

THEOREM II. Assume state feedback is allowed (that is, substitute in (7) $C_2 = I$, $D_{21} = 0$). Then the following holds:

(c) $\gamma > \gamma_0$ if and only if Π_1 exists, as specified in part (a).

(d) Assume $\gamma > \gamma_0$. Then $u = B'_2\Pi_1x$ is an internally stabilizing compensator that assures $\|\mathcal{T}_{\mathcal{K}}(t_0)\| < \gamma$.

COROLLARY. (e) Assume that A is an L_∞ , bounded-matrix-valued function. Then, when existing, the solutions to the Riccati equations (8), (9) are absolutely continuous, and satisfy the differential counterparts of these equations:

$$(11) \quad \dot{\Pi}_1 = C'_1C_1 - \Pi_1A - A'\Pi_1 - \Pi_1 \left(B_2B'_2 - \frac{1}{\gamma^2} B_1B'_1 \right) \Pi_1$$

and

$$(12) \quad \begin{aligned} \dot{\Pi}_2 = & -B_1 B_1' + \Pi_2 \left(A - \frac{1}{\gamma^2} B_1 B_1' \Pi_1 \right)' + \left(A - \frac{1}{\gamma^2} B_1 B_1' \Pi_1 \right) \Pi_2 \\ & + \Pi_2 \left(C_2' C_2 - \frac{1}{\gamma^2} \Pi_1 B_2 B_2' \Pi_1 \right) \Pi_2, \end{aligned}$$

so that (i) if $t_1 < +\infty$ then $\Pi_1(t_1) = 0$; else $\Pi_1^{-1} \in L_\infty$; and (ii) if $t_0 > -\infty$ then $\Pi_2(t_0) = 0$; else $\Pi_2^{-1} \in L_\infty$.

(f) If the system is defined over the entire real line $((t_0, t_1) = (-\infty, +\infty))$ and its coefficients are periodic, then so are the solutions of the Riccati equations (8), (9) (or (11), (12)).

(g) If (1) is time invariant and defined over an infinite interval then Π_1 and Π_2 are constant operators and algebraic Riccati equations substitute for their differential counterparts in part (e).

(h) Suppose that $t_0 = -\infty$ and $t_1 = +\infty$, and that there exist $A^+, B_i^+, C_i^+, D_{ij}^+, A^-, B_i^-, C_i^-$, and D_{ij}^- such that the coefficients in (1) tend (in operator norm) to their “+” counterparts as $t \rightarrow +\infty$ and to their “-” counterparts as $t \rightarrow -\infty$. (e.g., $\|A(t) - A^+\| \rightarrow 0$ as $t \rightarrow +\infty$). Then $\Pi_i(t) \rightarrow \Pi_i^\pm$ as $t \rightarrow \pm\infty$, where Π_i^\pm are the solutions of the \pm limiting, time-invariant Riccati equations. In particular, if γ is strictly suboptimal in (1), so it is in the limiting systems. A γ -suboptimal, internally stabilizing compensator in the “+” system, say \mathcal{K}^+ , is internally stabilizing in (1), and it guarantees that eventually $\|\mathcal{T}_{\mathcal{K}^+}(t)\| < \gamma$.

Remark on handling infinite dimensionality. Our main purpose in this note is to adapt the relatively intuitive and simple arguments of time-domain LQ optimization, so that they could be utilized in solving the *standard H_∞ problem*, in as general a linear setup as may be reasonably desired. Since our aim is *not* the study of infinite-dimensional systems per se, we thus make the easily understood, simply stated assumption that “*A generates an exponentially bounded evolution system*,” rather than get into the detail of specific conditions on A that guarantee that that assumption holds. For such detail we refer the interested reader to the extensive literature on infinite-dimensional systems and, in particular, the citations made above. In line with the same philosophy, and to keep the presentation digestible for those who would rather focus on the finite-dimensional case, we further use certain formal simplifications.

First, as we have already noted above, we stick to the differential equation formalism, as in (1). Since mild evolutions might not be differentiable in the distributed case, all systems should then be interpreted in terms of the associated integral “variation of parameters” formulae, as done, e.g., in [11]. It is stressed that none of the developments in this paper requires state differentiation, and all of them could be made in the framework of specified integral “variation of parameters” input-output mappings.

Second, since we nonetheless use the differential equation form and the term “generator,” it is noted that even when an operator adheres to the requirements of a proper definition of a generator, the same is not necessarily true for bounded perturbations of that operator. Yet such bounded perturbations play an important role in this discussion (especially \mathcal{A} and A_i , $i = 1, 2$, above). As mentioned above, for the sake of simplicity we use the term “generator” also in reference to boundedly perturbed “true” generators. Those should be interpreted in terms of the following well-known lemma.

LEMMA 2.1 [6]. Suppose that E generates an exponentially bounded evolution system Ψ over the Hilbert space \mathbf{H} , and that F is an L_∞ bounded-operator-valued function. Then there exists a unique exponentially bounded evolution system $\tilde{\Psi}$ satisfying the following

integral equation:

$$(13) \quad \tilde{\Psi}(t, s)h = \Psi(t, s)h + \int_s^t \Psi(t, r)F(r)\tilde{\Psi}(r, s)h \, dr$$

for all $h \in \mathbf{H}$.

For the purpose of this discussion we deviate from standard terminology and refer to $\tilde{\Psi}$ as *the evolution generated by the perturbed generator $E + F$* (equivalently, we shall say that $E + F$ generates $\tilde{\Psi}$). Manipulations of the underlying differential equation model of a system, such as the introduction of feedback, can always be interpreted in terms of appropriate manipulations of the associated integral representations, in line with the lemma. The infinite-dimensional expert will be able to easily fill in the details, and thus we mostly omit them. Exceptions will be made and details provided in less obvious cases.

Outline of the proof. The usual: It easily follows from the exponential growth bound

$$(14) \quad \|\Psi(t, s)\| \leq \alpha e^{\beta(t-s)}, \quad t \geq s$$

that the successive approximations

$$(15) \quad \begin{aligned} \Psi_0 &= \Psi, \\ \Psi_{i+1}(t, s)h &= \Psi(t, s)h + \int_s^t \Psi(t, r)F(r)\Psi_i(r, s)h \, dr, \quad i = 0, 1, 2, \dots \end{aligned}$$

converge, uniformly for all h in the unit ball, and that the limit, which is a solution of (13), satisfies the growth condition

$$(16) \quad \|\tilde{\Psi}(t, s)\| \leq \alpha e^{(\beta + \alpha \|F\|_\infty)(t-s)}, \quad t \geq s;$$

hence *existence*.

Given any exponentially bounded solution, a successive substitution of the entire right-hand side of (13) for $\tilde{\Psi}$ in the integral term of that equation, shows that that solution must indeed be the limit of the successive approximations (15). Hence *uniqueness*. \square

Finally, the following result provides a very useful tool, to be used in stability analysis of distributed systems.

LEMMA 2.2 [8]. *Let E and F be as above and assume that E is exponentially stable; that is, that β in (14) is negative. Suppose also that the following inequality holds for some fixed η and all $t_0 < s < t_1$:*

$$(17) \quad \int_s^{t_1} \|\tilde{\Psi}(r, s)h\|^2 \, dr \leq \eta \|h\|^2.$$

Then the perturbed generator $E + F$ is also exponentially stable.

Note. The significance of this lemma is in either of the cases $t_0 = -\infty$ or $t_1 = +\infty$.

Proof. It suffices to focus only on the integral term on the right-hand side of (13). We first observe that that term is uniformly bounded over all choice of $t_1 > t \geq s > t_0$. Indeed,

$$(18) \quad \begin{aligned} \left\| \int_s^t \Psi(t, r)F(r)\tilde{\Psi}(r, s)h \, dr \right\|^2 &\leq \int_s^t \|\Psi(t, r)\|^2 \, dr \|F\|_\infty^2 \int_s^{t_1} \|\tilde{\Psi}(r, s)h\|^2 \, dr \\ &\leq \alpha^2 \frac{(e^{2\beta(t-s)} - 1)}{2\beta} \|F\|_\infty^2 \eta \|h\|^2 \\ &\leq \frac{\alpha^2}{2|\beta|} \|F\|_\infty^2 \eta \|h\|^2 < \infty. \end{aligned}$$

Next we show that the bound (17) can be improved to the following:

$$(19) \quad \int_p^{t_1} \|\tilde{\Psi}(r, s)h\|^2 dr \leq \eta \|h\|^2 e^{(s-p)/\eta}, \quad p \geq s.$$

Indeed, invoking (17) we see that the function

$$(20) \quad f(p) \triangleq \int_p^{t_1} \|\tilde{\Psi}(r, s)h\|^2 dr, \quad p \geq s$$

satisfies the differential and initial value inequalities

$$(21) \quad \begin{aligned} f(p) &= \int_p^{t_1} \|\tilde{\Psi}(r, s)h\|^2 dr = \int_p^{t_1} \|\tilde{\Psi}(r, p)\tilde{\Psi}(p, s)h\|^2 dr \\ &\leq \eta \|\tilde{\Psi}(p, s)h\|^2 = \eta(-\dot{f}(p)), \quad p \geq s, \end{aligned}$$

and

$$f(s) = \int_s^{t_1} \|\tilde{\Psi}(r, s)h\|^2 dr \leq \eta \|h\|^2,$$

which entails (19).

Now we split the integral term in (13) into two:

$$(22) \quad \int_s^{(t+s)/2} \Psi(t, r)F(r)\tilde{\Psi}(r, s)h dr + \int_{(t+s)/2}^t \Psi(t, r)F(r)\tilde{\Psi}(r, s)h dr.$$

In view of (18), the first term in (22) satisfies

$$(23) \quad \begin{aligned} &\left\| \int_s^{(t+s)/2} \Psi(t, r)F(r)\tilde{\Psi}(r, s)h dr \right\|^2 \\ &\leq \left\| \Psi\left(t, \frac{t+s}{2}\right) \right\|^2 \left\| \int_s^{(t+s)/2} \Psi\left(\frac{t+s}{2}, r\right)F(r)\tilde{\Psi}(r, s)h dr \right\|^2 \\ &\leq \alpha^2 e^{\beta(t-s)} \frac{\alpha^2}{2|\beta|} \|F\|_\infty^2 \eta \|h\|^2, \end{aligned}$$

where by (19), the second term obeys the bound

$$(24) \quad \begin{aligned} &\left\| \int_{(t+s)/2}^t \Psi(t, r)F(r)\tilde{\Psi}(r, s)h dr \right\|^2 \\ &\leq \int_{(t+s)/2}^t \|\Psi(t, r)\|^2 dr \|F\|_\infty^2 \int_{(t+s)/2}^{t_1} \|\tilde{\Psi}(r, s)h\|^2 dr \\ &\leq \alpha^2 \frac{(e^{2\beta(t-s)/2} - 1)}{2\beta} \|F\|_\infty^2 \eta e^{(s-t)/2\eta} \|h\|^2 \\ &\leq \frac{\alpha^2}{2|\beta|} \|F\|_\infty^2 \eta e^{(s-t)/2\eta} \|h\|^2. \end{aligned}$$

Both of these bounds indicate exponential decay, which completes the proof. \square

3. Proofs. The underlying idea is simple. It is based on the following straightforward observation.

OBSERVATION 3.0.1. $\gamma > \gamma_0$ if and only if there exist an internally stabilizing compensator \mathcal{K} and a constant $\delta > 0$ such that the following inequality holds for all w in L_2 :

$$(25) \quad \gamma^2 \|w\|^2 - \|\mathcal{T}_{\mathcal{K}}(t_0)w\|^2 \geq \delta^2 \|w\|^2.$$

With this observation in mind we define the family of quadratic cost indexes (parametrized by $s \in (t_0, t_1)$)

$$(26) \quad J(s; x(s), u, w) \triangleq \gamma^2 \|w\|_{L_2(s, t_1)}^2 - \|z\|_{L_2(s, t_1)}^2$$

where z is the system output along (s, t_1) , given the initial state $x(s)$ and the input functions u, w . We shall explore the following min-max problems:

$$(27) \quad \min_{w \in L_2} \max_{u \in L_2} J(s; \xi, u, w).$$

As stated, (27) is an open-loop problem; but following the example of other LQ optimization problems, we may well expect the solution to be given in closed loop. Therefore, we interpret the goal of the maximizing control as maintaining (25), whereas the minimizing disturbance tries to violate it.

Remark. A great deal of our efforts in what follows will be devoted to establishing stability and related boundedness properties. These parts of the discussion make sense, of course, and should be understood only in the context of systems that are defined over an infinite time interval. The finite horizon proof is considerably simpler, and we leave it to the reader to trim the redundancies for that case.

3.1. The LQ optimization problem. We start with the solution of the max part of (27). Throughout this section we assume that (1) is internally stabilizable; that is, that there exists an internally stabilizing compensator \mathcal{K} (of the form (3)) in (1). This assumption holds whenever the *optimal value* in (1), γ_0 , is finite. We then define²

$$(28) \quad c(s; \xi, u^0, w) \triangleq \|\mathcal{Z}(s)(\xi, u, w)\|^2 = \|C_1 \mathcal{X}(s)(\xi, u, w)\|^2 + \|u\|^2$$

and look for the control u^0 that satisfies

$$(29) \quad c(s; \xi, u^0, w) = c^0(s; \xi, w) \triangleq \inf_u c(s)(\xi, u, w).$$

In view of (7), $c(s)$ is a positive quadratic cost functional, and is nonsingular with respect to both state and control. That is, there holds

$$(30) \quad c(s; \xi, u, w) \geq \|u\|^2, \quad c(s; \xi, u, w) \geq \varepsilon \|\chi(s)(\xi, u, w)\|^2.$$

The solution to (29), which we bring for completeness and for reference in later parts of the proof, will follow the usual optimal control line (see, e.g., [1] and [18]): First we establish existence and uniqueness of u^0 . Then we shall characterize it in terms of a Hamilton–Jacobi boundary-value problem. Finally, the state and co-state of the latter will be related by the solution of a Riccati equation.

PROPOSITION 3.1.1. *If an internally stabilizing compensator exists in (1) then there is $\theta > 0$ such that for all $s \in (t_0, t_1)$ there holds*

$$(31) \quad c^0(s; \xi, w) < \theta^2 \|(\xi, w)\|^2.$$

Proof. Obviously, there holds

$$(32) \quad c^0(s; \xi, w) \leq \|\mathcal{Z}_{\mathcal{K}}(s)(\xi, w)\|^2 \leq \|\mathcal{Z}_{\mathcal{K}}(s)\|^2 \|(\xi, w)\|^2,$$

² The second equality in (28) is due to (7).

where \mathcal{K} is some stabilizing compensator, and where $\mathcal{L}_{\mathcal{K}}(s)(\xi, w) \triangleq \mathcal{L}(s)(\xi, u = \mathcal{K}y, w)$ defines the associated bounded, closed-loop output operator. Set $\theta = \|\mathcal{L}_{\mathcal{K}}(t_0)\|$. \square

PROPOSITION 3.1.2. *Assume (1) is internally stabilizable. Then, given s , ξ , and w , there exists a unique optimal control $u^0 = \mathcal{U}^0(s)(\xi, w)$ that attains the minimum in (29). Moreover, the operators $\mathcal{U}^0(s)$ are bounded uniformly for all choices of s .*

Proof. Given s , ξ , w , u_1 and u_2 such that all the following terms are finite, there holds

$$\begin{aligned} (7, i) \Rightarrow \|u_1 - u_2\|^2 &\leq \|\mathcal{L}(s)(0, u_1 - u_2, 0)\|^2 \\ &= 2(\|\mathcal{L}(s)(\xi, u_1, w)\|^2 + \|\mathcal{L}(s)(\xi, u_2, w)\|^2 \\ &\quad - 2\|\mathcal{L}(s)(\xi, \frac{1}{2}(u_1 + u_2), w)\|^2) \\ &\leq 2(\|\mathcal{L}(s)(\xi, u_1, w)\|^2 + \|\mathcal{L}(s)(\xi, u_2, w)\|^2 - 2c^0(s; \xi, w)). \end{aligned} \quad (33)$$

Therefore, if $\{u_\alpha\}$ is a minimizing sequence (i.e., $c^0(s; \xi, w) = \lim J(s; \xi, u_\alpha, w)$), it is a Cauchy sequence in L_2 , tending to a limit u^0 . Moreover, the limit is unique. Since $u \rightarrow c(s)(\xi, u, w)$ is a close mapping, u^0 satisfies (29). By (30) and (31) we have

$$\|\mathcal{U}^0(s)\| \leq \theta, \quad (34)$$

which completes the proof. \square

Having the proposition we introduce notation for the optimal state and output mappings $\mathcal{X}^0(x_s)(\xi, w) \triangleq \mathcal{X}(s)(\xi, u^0, w)$, $\mathcal{Z}^0(s)(\xi, w) \triangleq \mathcal{Z}(s)(\xi, u^0, w)$. It follows from (30) and (31) that these too are bounded operators, uniformly for all choice of s .

PROPOSITION 3.1.3. *Assume (1) is internally stabilizable. Then, given s , ξ , and w , as above, there exists a unique solution to the following inhomogeneous Hamilton–Jacobi boundary value problem:³*

$$\begin{aligned} \dot{x} &= Ax + B_2 B_2' e + B_1 w, & x(s) &= \xi, \\ \dot{e} &= C_1' C_1 x - A' e, & e(t_1) &= 0. \end{aligned} \quad (35)$$

Moreover, let (x, e) be the solution. Then $x = \mathcal{X}^0(s)(\xi, w)$ and $\mathcal{U}^0(s)(\xi, w) = B_2' e$. Denote $e = \mathcal{E}^0(s)(\xi, w)$. Then the linear mappings $\mathcal{E}^0(s)$ are bounded, uniformly for all choice of s .

Proof. Since we can only deal with the integrated form of (35), it will simplify matters if we assume for the moment that there exists an internally stabilizing state feedback compensator $u = Kx$ in (1), defined by an operator-valued function $K \in L_\infty$ with $K(t) : X \rightarrow U$. Indeed, it is established in [23] that dynamic feedback stabilizability (which is the current underlying hypothesis) implies the existence of a stabilizing static feedback, so this assumption causes no restriction of generality. For completeness we state and establish this fact in Lemma 3.1.6. Let

$$A_K \triangleq A + B_2 K \quad (36)$$

be the closed-loop exponentially stable generator, as in (5), and let Φ_K be the evolution system generated by A_K . Using the change of variables

$$u = Kx + v \quad (37)$$

the first and third equations in (1) read

$$\dot{x} = A_K x + B_2 v + B_1 w, \quad z = (C_1 + D_{12} K)x + D_{12} v, \quad (38)$$

³ In case $t_1 = +\infty$ the terminal constraint should be interpreted as follows: $\exists \lim_{t \rightarrow +\infty} e(t) = 0$.

which defines a stable system, and where the optimization variable is v .⁴ We denote by $\mathcal{Z}_K(s)(\xi, v, w)$ the output mapping in (38).

The following is an outline of a standard calculus of variations reasoning. Let s , ξ , and w be given and fix v^+ , $v \in L_2$. Then

$$(39) \quad \begin{aligned} \|\mathcal{Z}_K(s)(\xi, v^+ + v, w)\|^2 &= \|\mathcal{Z}_K(s)(\xi, v^+, w)\|^2 \\ &+ 2\langle \mathcal{Z}_K(s)(\xi, v^+, w), \mathcal{Z}_K(s)(0, v, 0) \rangle \\ &+ \|\mathcal{Z}_K(s)(0, v, 0)\|^2. \end{aligned}$$

Since the last term on the right-hand side of (39) is nonnegative, v^+ is optimal (i.e., it minimizes the norm of $\mathcal{Z}_K(\xi, v^+, w)$) if and only if

$$(40) \quad \langle \mathcal{Z}_K(s)(\xi, v^+, w), \mathcal{Z}_K(s)(0, v, 0) \rangle = 0$$

for all $v \in L_2$. Explicitly, this condition reads

$$(41) \quad u^+ = B_2' e^+,$$

where u^+ corresponds to v^+ via (37), and where e^+ is defined by⁵

$$(42) \quad e^+(t) = - \int_t^{t_1} \Phi_K'(s, t) (C_1' C_1 x^+ + K' u^+)(s) ds.$$

Finally, formal differentiation⁶ shows that the system comprising the first equation in (38) and equations (41) and (42) is equivalent to the Hamilton–Jacobi system (35), when restricted to L_2 trajectories.

Since there does exist an optimal control in (1), solving (29), this establishes the existence of a solution to (35).

Conversely, by the arguments above, any solution to (35) and the relation (41) define the unique optimal state and control in (29). If t_1 is finite, the co-state is completely determined by (42), which establishes uniqueness of the solution to (35). It remains to establish uniqueness in the case $t_1 = +\infty$. To that end we show that even when $t_1 = +\infty$ it is impossible to have a nonzero function e satisfying (35) and (41) with $x=0$, $u=0$ and $w=0$. The proof, as in the finite-dimensional case, relies on the assumption that (1) is stabilizable.

Indeed, suppose such $e(t)$ did exist. Then the stability of Φ_K and the assumptions $e(s) = \Phi(t, s)' e(t)$, $\lim_{t \rightarrow +\infty} e(t) = 0$, and $u = B_2' e = 0$ imply that for every $s < t$ and $\xi \in X$ there holds

$$(43) \quad \begin{aligned} 0 &= \int_s^t \langle B_2'(r) e(r), K(r) \Phi_K(r, s) \xi \rangle dr \\ &= \left\langle e(t), \int_s^t \Phi(t, r) B_2(r) K(r) \Phi_K(r, s) \xi dr \right\rangle \\ &= \langle e(t), \Phi_K(t, s) \xi \rangle - \langle e(t), \Phi(t, s) \xi \rangle \\ &= \langle e(t), \Phi_K(t, s) \xi \rangle - \langle e(s), \xi \rangle \xrightarrow{t \rightarrow +\infty} -\langle e(s), \xi \rangle \end{aligned}$$

whereby $e=0$, as claimed.

⁴ It is obvious that both u and x are L_2 functions if and only if the function v belongs to L_2 . Hence optimization over v is equivalent to optimization over u .

⁵ Our conversion of the system to a stable one, via (37), was made with the purpose that (42) be well defined. That is a usual trick. Once its role in establishing this proposition is done, (37) will be replaced by more advantageous feedback.

⁶ We recall that differentiation is generally not allowed in an infinite-dimensional setting, which is why we added the adjective “formal.” With little work the equivalence can be established in terms of the integral equation of Lemma 2.1 and the definition of boundedly perturbed generators that follows that lemma.

Now we can substitute x^0 , u^0 , and e^0 for x^+ , u^+ , and e^+ in (42), and get an expression for $\mathcal{E}^0(s)$ in terms of $\mathcal{U}^0(s)$ and of $\mathcal{X}^0(s)$. Uniform boundedness of $\mathcal{E}^0(s)$ is the result of the uniform boundedness of $\mathcal{U}^0(s)$ and of $\mathcal{X}^0(s)$, and from the exponential stability of A_K . This completes the proof. \square

Denote

$$(44) \quad \Lambda(s)\xi \triangleq (\mathcal{E}^0(s)(\xi, 0))(s).$$

By the previous proposition (in particular, as follows from (42)), these are uniformly bounded operators. Set

$$(45) \quad A_0 \triangleq A + B_2 B_2' \Lambda.$$

PROPOSITION 3.1.4. A_0 is an exponentially stable generator.

Proof. Let Φ_0 be the evolution generated by A_0 . By Proposition 3.1.3 there holds

$$(46) \quad \Phi_0(t, s)\xi = (\chi^0(s)(\xi, 0))(t).$$

Following from the L_2 uniform boundedness of $\mathcal{X}^0(s)$ there must exist η such that

$$(47) \quad \forall \xi, \quad \int_s^{t_1} \|\Phi_0(t, s)\xi\|^2 ds < \eta \|\xi\|^2$$

for all s . The proposition thus follows from Lemma 2.2, substituting A_K for E and $B_2' \Lambda - K$ for F . \square

PROPOSITION 3.1.5. $\Xi = \Lambda$ is the unique uniformly-bounded, negative-definite strong solution of the following integral Riccati equation.⁷

$$(48) \quad \Xi(s)\xi = - \int_s^{t_1} \Psi(r, s)' (C_1' C_1 + \Xi B_2 B_2' \Xi)(r) \Psi(r, s) \xi dr,$$

such that Ψ is the exponentially stable evolution generated by $A_\Xi \triangleq A + B_2 B_2' \Xi$.

Proof. Using the definition (44) for Λ , $w=0$ implies $e^0 = \Lambda x^0$ in (35). That Hamilton–Jacobi system then reads

$$(49) \quad \begin{aligned} \dot{x}^0 &= A_0 x^0, & x^0(s) &= \xi, \\ \dot{e}^0 &= (C_1' C_1 + \Lambda' B_2 B_2' \Lambda) x^0 - A_0' e^0, & e^0(t_1) &= 0. \end{aligned}$$

Consequently, with that definition there holds

$$(50) \quad \Lambda(s)\xi = e^0(s) = - \int_s^{t_1} \Phi_0(r, s)' (C_1' C_1 + \Lambda' B_2 B_2' \Lambda)(r) \Phi_0(r, s) \xi dr,$$

which, together with (7), shows that Λ is a negative-definite solution of (48).

Conversely, take any uniformly-bounded, negative-definite Ξ that satisfies (48) and such that the associated A_Ξ is exponentially stable. Substitute X for Λ and A_Ξ for A_0 in (49); then the L_2 solution of (49) defines an L_2 solution to (35) with $w=0$. The uniqueness of the solution to the latter implies that Ξ too is defined by (44). That is, our solution of (48) is unique. \square

⁷ Since a priori we do not know that (48) has a solution, nor that the solution is unique, neither that it is equal to Λ , as already defined above, we need to use an independent notation for the unknown in (48) (Ξ vis Λ) and for the evolution generated by the perturbed generator (Ψ vis Φ_0). Indeed, the observation that $\Xi = \Lambda$ and $\Psi = \Phi_0$ form the unique solution to (48) is the content of our proposition. The same policy applies to the notation used in (84).

We still owe the following. (Again, we note that a similar statement is established in [23].)

LEMMA 3.1.6. *If (1) is stabilizable then it is stabilizable by a zero-order state feedback.*

Proof. Our assumption is that there exists a dynamic compensator of the form (3) such that \mathcal{A} , as defined in (4), is an exponentially stable generator. We can rewrite (4) as

$$(51) \quad \mathcal{A} = \tilde{A} + \tilde{B}_2 \tilde{K}$$

(which is of the form of A_K) where

$$(52) \quad \tilde{A} \triangleq \begin{bmatrix} A & 0 \\ 0 & M \end{bmatrix}, \quad \tilde{B}_2 \triangleq \begin{bmatrix} B_2 & 0 \\ 0 & N \end{bmatrix}, \quad \tilde{K} \triangleq \begin{bmatrix} RC_2 & Q \\ C_2 & 0 \end{bmatrix}.$$

Denote also

$$(53) \quad \tilde{C}_1 \triangleq \begin{bmatrix} C_1 & 0 \\ 0 & I_P \\ 0 & 0 \end{bmatrix}, \quad \tilde{D}_{12} \triangleq \begin{bmatrix} D_{12} & 0 \\ 0 & 0 \\ 0 & I_Y \end{bmatrix}, \quad \tilde{x} \triangleq \begin{pmatrix} x \\ p \end{pmatrix}, \quad \tilde{u} \triangleq \begin{pmatrix} u \\ y \end{pmatrix}.$$

Substituting the $(\tilde{A}, \tilde{B}_2, \tilde{C}_1, \tilde{D}_{12})$ operators for their counterparts in the discussion above, we return to a setting of a system with a stabilizing state feedback. It involves a process in the product state space $X \times P$ with input from the product space $U \times Y$. Invoking Propositions 3.1.3–3.1.5, we thus conclude that the associated quadratic optimization problem $(\min_{\tilde{u}} \|\tilde{z} \triangleq \tilde{C}_1 \tilde{x} + \tilde{D}_{12} \tilde{u}\|_2)$ has a unique solution. Adding “~” to the various coefficients in the Hamilton–Jacobi system (35) and in the integral Riccati equation (48), we obtain a characterization of the optimal “control” in the augmented system, as described above. In particular, let us denote the solution of the augmented Riccati equation by $\tilde{\Lambda}$.

Now (save for the stabilizing feedback \tilde{K}) the augmented system coefficients are all block diagonal. In the case $w = 0$ we are thus actually dealing with two optimization problems, involving two noninteracting systems: The first involves a process in X , as described by the first and third equations in (1), while the other takes place in P . The solutions of the two problems are independent of each other: The optimal solution in X component is independent of the initial value of the P state, and vice versa. Using the equality (57), below (which as the reader will soon observe, must be satisfied in the augmented system), this implies that the $X \times P$ and $P \times X$ blocks of $\tilde{\Lambda}$ must vanish. That is $\tilde{\Lambda}$ is of the block diagonal form $\tilde{\Lambda} = \text{diag}(\Lambda, \Theta)$, where $\Lambda(t)$, $t \in (t_0, t_1)$ are negative-definite, uniformly bounded operators over X .

Moreover, as this implies that $\tilde{A}_0 \triangleq \tilde{A} - \tilde{B}_2 \tilde{B}_2' \tilde{\Lambda}$ is block diagonal, so is the evolution $\tilde{\Phi}_0$ that it generates. Substituting all those in the augmented version of (48) we find out that the X component of its solution, Λ , is a solution of (48) in its original form (i.e., with the “~” removed). Similarly, A_0 , which is the X component of \tilde{A}_0 , is stable. In particular, (1) is zero order stabilizable. \square

From now on we can take $K = B_2' \Lambda$ as our zero order stabilizing state feedback, and may substitute (37) by the control variable change

$$(54) \quad u = B_2' \Lambda x + v,$$

A_K by A_0 and Φ_K by Φ_0 , in the discussion above.

Suppose now that $w = 0$. Given any control input $u \in L_2$ that results in an L_2 state trajectory, let

$$(55) \quad u^\nabla \triangleq u - B_2' \Lambda x$$

be its momentary deviation from the optimal value (i.e., $u^\nabla = v$). The following is a standard, very useful observation.

PROPOSITION 3.1.7. *Given $t \geq s$, an initial state ξ , and an L_2 control u that result in a stable L_2 state trajectory,⁸ there holds*

$$(56) \quad \|\mathcal{Z}(s)(\xi, u, p)\|_{L_2[s,t]}^2 = \langle x(t), \Lambda(t)x(t) \rangle - \langle \xi, \Lambda(s)\xi \rangle + \|u^\nabla\|_{L_2[s,t]}^2.$$

In particular,

$$(57) \quad c^0(s; \xi, 0) = -\langle \xi, \Lambda(s)\xi \rangle.$$

Proof. In the finite dimensional case the simpler proof uses integration by parts. Differentiation is not allowed in the present context, whereby some toil is necessary.

We provide detail only for the case $t = t_1$. That is justified as follows: If $t_1 = \infty$ it is assumed that x is an L_2 function and that the limit $x(t_1) = 0$ exists. When $t_1 < \infty$ we recall that $\Pi_1(t_1) = 0$. Thus, in either case, the inner product term evaluated at $t = t_1$ vanishes from (56). The general form of (56), for any choice of t , is obtained by subtracting this equation's value over $[t, t_1]$ from its value over $[s, t_1]$.

We are interested in the quantities involved in

$$(58) \quad \begin{aligned} \|z\|^2 &= \|C_1 x\|^2 + \|u\|^2 \\ &= \|C_1 x\|^2 + \|u^\nabla\|^2 + 2\langle u^\nabla, B_2' \Lambda x \rangle + \|B_2' \Lambda x\|^2. \end{aligned}$$

Let us compute these quantities one by one. First, we have

$$(59) \quad \begin{aligned} &\|C_1 x\|_{L_2[s,t]}^2 \\ &= \int_s^t \left\langle C_1(r) \left(\Phi_0(r, s)\xi + \int_s^r \Phi_0(r, p)B_2(p)u^\nabla(p) dp \right), \right. \\ &\quad \left. C_1(r) \left(\Phi_0(r, s)\xi + \int_s^r \Phi_0(r, q)B_2(q)u^\nabla(q) dq \right) \right\rangle dr \\ &= \int_s^t \langle C_1(r)\Phi_0(r, s)\xi, C_1(r)\Phi_0(r, s)\xi \rangle dr \\ &\quad + 2 \int_s^t \left\langle C_1(r)\Phi_0(r, s)\xi, C_1(r) \int_s^r \Phi_0(r, q)B_2(q)u^\nabla(q) dq \right\rangle dr \\ &\quad + \int_s^t \left\langle C_1(r) \int_s^r \Phi_0(r, p)B_2(p)u^\nabla(p) dp, \right. \\ &\quad \left. C_1(r) \int_s^r \Phi_0(r, q)B_2(q)u^\nabla(q) dq \right\rangle dr \\ &= \left\langle \xi, \int_s^t \Phi_0'(r, s)C_1'(r)C_1(r)\Phi_0(r, s) dr \xi \right\rangle \\ &\quad + 2 \int_s^t \left\langle B_2'(q) \int_q^t \Phi_0'(r, q)C_1'(r)C_1(r)\Phi_0(r, q) dr \Phi_0(q, s)\xi, u^\nabla(q) \right\rangle dq \\ &\quad + 2 \int_s^t \left\langle B_2'(q) \int_q^t \Phi_0'(r, q)C_1'(r)C_1(r)\Phi_0(r, q) dr \right. \\ &\quad \left. \cdot \int_s^q \Phi_0(q, p)B_2(p)u^\nabla(p) dp, u^\nabla(q) \right\rangle dq \end{aligned}$$

⁸ That is, if $t_1 = +\infty$ then $\exists \lim_{t \rightarrow +\infty} x(t) = 0$.

$$= \left\langle \xi, \int_s^t \Phi'_0(r, s) C'_1(r) C_1(r) \Phi_0(r, s) dr \xi \right\rangle \\ + 2 \int_s^t \left\langle B'_2(q) \int_q^t \Phi'_0(r, q) C'_1(r) C_1(r) \Phi_0(r, q) dr x(q), u^\nabla(q) \right\rangle dq.$$

Similarly,

$$\|B'_2 \Lambda x\|^2 = \left\langle \xi, \int_s^{t_1} \Phi'_0(r, s) (\Lambda B_2 B'_2 \Lambda)(r) \Phi_0(r, s) dr \xi \right\rangle \\ (60) \quad + 2 \int_s^{t_1} \left\langle B'_2(q) \int_q^{t_1} \Phi'_0(r, q) (\Lambda B_2 B'_2 \Lambda)(r) \Phi_0(r, q) dr x(q), u^\nabla(q) \right\rangle dq.$$

Adding (59) and (60) we get

$$(61) \quad \|C_1 x\|^2 + \|B'_2 \Lambda x\|^2 = -\langle \xi, \Lambda(s) \xi \rangle - 2 \int_s^{t_1} \langle B'_2(q) \Lambda(q) x(q), u^\nabla(q) \rangle dq.$$

Substituting (61) into (58) we get (56) (without the inner product term in $t = t_1$, which vanishes as explained above). \square

3.2. The min in (27). Throughout this section we assume that $\gamma > \gamma_0$ (where γ_0 is equal to the optimal value in (1)). We denote

$$(62) \quad J^0(s; \xi, w) \triangleq J(s; \xi, \mathcal{U}^0(s)(\xi, w), w) \\ = \gamma^2 \|w\|^2 - \|\mathcal{L}^0(s)(\xi, w)\|^2$$

and search for w^* such that

$$(63) \quad J^0(s; \xi, w^*) = J^*(s; \xi) \triangleq \inf_w J^0(s; \xi, w).$$

The solution of this problem will follow, proposition by proposition, the analysis from § 3.1, with J^0 substituting for c as the quadratic cost, and where w substitutes u as the optimization variable. Some modifications will be needed, of course, due to the fact that c were positive definite whereas J^0 is not. These modifications are possible exactly when γ is strictly suboptimal, as assumed here.

PROPOSITION 3.2.1. Assume that $\gamma > \gamma_0$. Then (i) for all s and w

$$(64) \quad J^0(s; 0, w) \geq \delta^2 \|w\|^2$$

(where δ is as in (25)). (ii) There exists $\mu > 0$ such that

$$(65) \quad J^0(s; \xi, w) \geq -\mu \|\xi\|^2$$

for all s , w , and ξ . In particular,

$$(66) \quad J^*(s; 0) = 0$$

and

$$(67) \quad 0 > J^*(s; 0) > -\mu \|\xi\|^2$$

for $\xi \neq 0$.

Proof. (i) By Observation 3.0.1. there exists an internally stabilizing compensator \mathcal{K} such that (25) holds:

$$(68) \quad \gamma^2 \|w\|^2 - \|\mathcal{T}_{\mathcal{K}}(s)w\|^2 \geq \delta^2 \|w\|^2.$$

By definition,

$$(69) \quad J^0(s; 0, w) \geq \gamma^2 \|w\|^2 - \|\mathcal{T}_{\mathcal{K}}(s)w\|^2.$$

Hence this part of the proposition.

(ii) There holds

$$\begin{aligned}
 J^0(s; \xi, w) &= \gamma^2 \|w\|^2 - \|\mathcal{Z}^0(s)(\xi, w)\|^2 \\
 &= \gamma^2 \|w\|^2 - \|\mathcal{Z}^0(s)(\xi, 0) + \mathcal{Z}^0(0, w)\|^2 \\
 &\geq \gamma^2 \|w\|^2 - (\|\mathcal{Z}^0(s)(\xi, 0)\| + \|\mathcal{Z}^0(0, w)\|)^2 \\
 &= \gamma^2 \|w\|^2 - \|\mathcal{Z}^0(s)(0, w)\|^2 \\
 &\quad - 2\|\mathcal{Z}^0(s)(\xi, 0)\| \|\mathcal{Z}^0(0, w)\| - \|\mathcal{Z}^0(s)(\xi, 0)\|^2 \\
 &\geq \delta^2 \|w\|^2 - 2\|\mathcal{Z}^0(s)(\xi, 0)\| \|\mathcal{Z}^0(0, w)\| - \|\mathcal{Z}^0(s)(\xi, 0)\|^2 \\
 &\geq \delta^2 \|w\|^2 - \|\mathcal{Z}^0(s)\|^2 (2\|\xi\| \|w\| + \|\xi\|^2) \\
 &\geq \delta^2 \|w\|^2 - \theta^2 (2\|\xi\| \|w\| + \|\xi\|^2),
 \end{aligned}
 \tag{70}$$

where θ is as in Proposition 3.1.1. The right-most term in (70) is a quadratic form in $\|w\|$ which minimum is $-\theta^2(\theta^2/\delta^2 + 1)\|\xi\|^2$. So $\mu = \theta^2(\theta^2/\delta^2 + 1)$ satisfies the claim.

Substituting $w=0$ in (62) we see that $\inf_w J_0(s; \xi, w)$ is nonpositive; in fact, due to (7), the infimum is negative unless $\xi=0$. This completes the proof. \square

PROPOSITION 3.2.2. *Assume that $\gamma > \gamma_0$. Then, given ξ , there exists a unique disturbance $w^* = \mathcal{W}^*(s)(\xi)$ that attains the minimum in (63). Moreover, the operators $\mathcal{W}^*(s)$ are uniformly bounded for all choices of s .*

Proof. By (67) the infimum is finite. Moreover, it follows from that inequality together with (70) that disturbances that make J^0 approach its infimum are uniformly norm bounded; indeed, (70) coupled with the requirement $J^0 \leq 0$ implies that w satisfies

$$\|w\| \leq \frac{\theta(\theta + \sqrt{\theta^2 + \delta^2})}{\delta^2} \|\xi\|.
 \tag{71}$$

By (64) there holds

$$\begin{aligned}
 \|w_1 - w_2\|^2 &\leq \frac{1}{\delta^2} J^0(s; 0, w_1 - w_2) \\
 &= \frac{2}{\delta^2} \left(J^0(s; \xi, w_1) + J^0(s; \xi, w_2) - 2J^0\left(s; \xi, \frac{1}{2}(w_1 + w_2)\right) \right) \\
 &\leq \frac{2}{\delta^2} (J^0(s; \xi, w_1) + J^0(s; \xi, w_2) - 2J^*(s; \xi)).
 \end{aligned}
 \tag{72}$$

As in the proof of Proposition 3.1.2, (71) and (72) imply existence and uniqueness of w^* . Equation (71) also assures uniform boundedness of $\mathcal{W}^*(s)$. \square

We denote $\mathcal{U}^*(s)(\xi) \triangleq \mathcal{U}^0(s)(\xi, \mathcal{W}^*(s)(\xi))$, $\mathcal{X}^*(s)(\xi) \triangleq \mathcal{X}^0(s)(\xi, \mathcal{W}^*(s)(\xi))$, $\mathcal{E}^*(s)(\xi) \triangleq \mathcal{E}^0(s)(\xi, \mathcal{W}^*(s)(\xi))$ and $\mathcal{Z}^*(s)(\xi) \triangleq \mathcal{Z}^0(s)(\xi, \mathcal{W}^*(s)(\xi))$. It immediately follows that all these mappings define uniformly bounded operators.

PROPOSITION 3.2.3. *Assume that $\gamma > \gamma_0$. Then there exists a unique L_2 solution to the following Hamilton-Jacobi boundary-value problem:⁹*

$$\begin{aligned}
 \dot{x} &= Ax + \left(B_2 B_2' - \frac{1}{\gamma^2} B_1 B_1' \right) e, & x(s) &= \xi, \\
 \dot{e} &= C_1' C_1 x - A' e, & e(t_1) &= 0.
 \end{aligned}
 \tag{73}$$

That solution is given by $x^ = \mathcal{X}^*(s)(\xi)$, $e^* = \mathcal{E}^*(s)(\xi)$. In particular, the latter are bounded linear operators.*

⁹ Recall that when $t_1 = +\infty$ the terminal condition reads $\exists \lim_{t \rightarrow +\infty} e(t) = 0$.

Proof. As in the proof of Proposition 3.1.3, we first convert (1) to a stable system by use of a zero-order compensator. That is done by introducing the control change of variables

$$(74) \quad u = B'_2 \Lambda x + v.$$

In terms of (74), the first and last equations in (1) read

$$(75) \quad \dot{x} = A_0 x + B_1 w + B_2 v, \quad z = (C_1 + D_{12} B'_2 \Lambda) x + D_{12} v.$$

We denote by $v^0 = \mathcal{V}^0(s)(\xi, w)$ the value of v associated via (74) with the optimal control, and by abuse of notation, with $z = \mathcal{Z}(s)(\xi, v, w)$ and $z^0 = \mathcal{Z}^0(s)(\xi, w)$ the output and optimal output mappings in (75).

Given any two L_2 disturbances, w^+ and w , there holds

$$(76) \quad \begin{aligned} J^0(s; \xi, w^+ + w) &= J^0(s; \xi, w^+) + 2(\gamma^2 \langle w^+, w \rangle - \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}^0(s)(0, w) \rangle) \\ &\quad + J^0(s; 0, w) \end{aligned}$$

Since the last term on the right-hand side is nonnegative (by (64)), w^+ is minimizing if and only if the inner product term vanishes for all choices of w .

Expanding on that term we have

$$(77) \quad \begin{aligned} &\gamma^2 \langle w^+, w \rangle - \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}^0(s)(0, w) \rangle \\ &= \gamma^2 \langle w^+, w \rangle - \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}(s)(0, \mathcal{V}^0(s)(0, w), w) \rangle \\ &= \gamma^2 \langle w^+, w \rangle - \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}(s)(0, 0, w) \rangle \\ &\quad - \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}(s)(0, \mathcal{V}^0(s)(0, w), 0) \rangle. \end{aligned}$$

As shown in the proof of Proposition 3.1.3, the last term on the right-hand side of (77) vanishes. (Indeed, since $\mathcal{Z}^0(s)(\xi, w^+)$ is the output associated with the optimal value v^0 of v for the disturbance choice $w = w^+$, we concluded from (39) that (40) holds; in the present notation this means that

$$(78) \quad \langle \mathcal{Z}^0(s)(\xi, w^+), \mathcal{Z}(s)(0, v, 0) \rangle = 0$$

for all choices of v .)

Straightforward computation shows that the rest of the right-hand side of (77) vanishes for all choices of $w \in L_2$ if and only if

$$(79) \quad w^+ = -\frac{1}{\gamma^2} B'_1 e^+,$$

where

$$(80) \quad e^+(t) = - \int_t^{t_1} \Phi'_0(r, t) (C'_1 C_1 x^+ + \Lambda B_2 u^+)(r) dr$$

and

$$(81) \quad x^+ = \mathcal{X}^0(s)(\xi, w^+), \quad u^+ = \mathcal{U}^0(s)(\xi, w^+).$$

Substituting (74) for (37) as the definition of the zero-order stabilizing feedback, (80) is equal to the explicit expression in (42) for \mathcal{E}^0 ; namely, it reads $e^+ = \mathcal{E}^0(s)(\xi, w^+)$. This establishes existence of a solution to (73).

Moreover, we have shown that any solution of (73) defines the unique solution to the min-max problem (27) via (41) and (79). Thus, even if the solution to (73) were not unique, the functions x , $B_1'e$, and $B_2'e$ it creates are uniquely determined. It thus remains to be shown that when all the latter vanish then $e=0$ as well, which we established in the proof of Proposition 3.1.3. \square

Denote

$$(82) \quad \Pi_1(t)\xi \triangleq (\mathcal{E}^*(t)(\xi))(t)$$

(following from (80), these too are uniformly bounded linear operators) and let

$$(83) \quad A_1 = A + \left(B_2 B_2' - \frac{1}{\gamma^2} B_1 B_1' \right) \pi_1$$

as defined in Theorem I.

PROPOSITION 3.2.4. A_1 is exponentially stable.

The proof is completely analogous to the proof of Proposition 3.1.4, and is thus left out.

PROPOSITION 3.2.5. $\Xi = \Pi_1$ is the unique L_∞ bounded-operator-valued, negative-definite solution of the integral Riccati equation (8)

$$(84) \quad \Xi(s) = - \int_s^{t_1} \Psi(t, s)' \left[C_1' C_1 + \Xi \left(B_2 B_2' - \frac{1}{\gamma^2} B_1 B_1' \right) \Xi \right] (t) \Psi(t, s) ds,$$

where Ψ is the exponentially stable evolution generated by $A_\Xi \triangleq A + (B_2 B_2' - \frac{1}{\gamma^2} B_1 B_1') \Xi$.

Proof. The proof that Π_1 is the unique selfadjoint solution to our Riccati equation is essentially the same as its counterpart in the proof Proposition 3.1.5. Since the integrand in (84) contains both positive and negative parts, it remains to be established that Π_1 is negative definite.

Indeed, by Proposition 3.2.3 and the definition (82) there holds $e^* = \Pi_1 x^*$, whereby the optimal min-max inputs satisfy $u^* = B_2' \Pi_1 x^*$ and $w^* = -(1/\gamma^2) B_1' \Pi_1 x^*$. Substituting the entire right-hand side of (84) for $\Pi_1(s)$, the following equality is then obtained:

$$(85) \quad J^*(s; \xi) = \langle \xi, \Pi_1(s) \xi \rangle.$$

By Proposition 3.2.1, the left-hand side of (85) is a negative expression in ξ , which completes the proof. \square

We denote by

$$(86) \quad u^\Delta \triangleq u - B_2' \Pi_1 x, \quad w^\Delta \triangleq w + \frac{1}{\gamma^2} B_1' \Pi_1 x$$

the momentary deviations of the control and disturbance in (1) from their min-max optimal values. The following is a direct counterpart of Proposition 3.1.7, where the guideline of the proof can be found.

PROPOSITION 3.2.6. Given an initial time s and an initial state ξ and $t \geq s$, if u , w , and x in (1) are all L_2 functions then

$$(87) \quad \gamma^2 \|w\|_{L_2[s,t]}^2 - \|z\|_{L_2[s,t]}^2 = \langle \xi, \Pi_1(s) \xi \rangle - \langle x(t), \Pi_1(t) x(t) \rangle + \gamma^2 \|w^\Delta\|_{L_2[s,t]}^2 - \|u^\Delta\|_{L_2[s,t]}^2.$$

3.3. Completion of the proof of (c).

PROPOSITION 3.3.1. Assume that $\gamma > \gamma_0$. Then the zero-order state feedback $u = B_2' \Pi_1 x$ is internally stabilizing, and it guarantees strict γ -suboptimality; namely, $\|\mathcal{T}_x(t_0)\| < \gamma$. Conversely, if there exists a solution to the Riccati equation (8) with the properties described in part (a) of Theorem I, then $\gamma > \gamma_0$.

Proof. Assume that $\gamma > \gamma_0$. Then there exists Π_1 , satisfying the requirement in part (a) of Theorem I; in particular, such that A_1 is stable. The remainder of the proof depends only on the existence of such Π_1 . Set

$$(88) \quad A_3 \triangleq A + B_2 B_1' \Pi_1$$

and let Φ_3 be the evolution generated by A_3 . In the case $t_1 = +\infty$ we must establish exponential stability of Φ_3 . Indeed, plugging $w = 0$ and our feedback control into (87), and invoking assumption (7) (via (30)) we get

$$(89) \quad \begin{aligned} \varepsilon \|x\|_{L_2[s, t]}^2 &\leq \|z\|_{L_2[s, t]}^2 \\ &= -\langle \xi, \Pi_1(s)\xi \rangle + \langle x(t), \Pi_1(t)x(t) \rangle - \gamma^2 \|w^\Delta\|_{L_2[s, t]}^2 \\ &\leq -\langle \xi, \Pi_1(s)\xi \rangle \leq \|\Pi_1\|_\infty \|\xi\|^2 \end{aligned}$$

for all $t \geq s$ in the closed-loop system. Therefore

$$(90) \quad \forall \xi, \quad \int_s^{t_1} \|\Phi_3(r, s)\xi\|^2 dr \leq \frac{\|\Pi_1\|_\infty}{\varepsilon} \|\xi\|^2$$

for all s . Stability follows now from Lemma 2.2.

Allowing $w \neq 0$ with $\xi = 0$ and $t = t_1$, our state feedback turns (87) into

$$(91) \quad \gamma^2 \|w\|^2 - \|z\|^2 = \gamma^2 \|w^\Delta\|^2.$$

The closed-loop mapping $w^\Delta \rightarrow w$ is governed by a stable system

$$(92) \quad \dot{x} = A_1 x + B_1 w^\Delta, \quad w = w^\Delta - \frac{1}{\gamma^2} B_1 B_1' x.$$

In particular, that mapping is bounded. There exists thereby some $\delta \neq 0$ such that

$$(93) \quad \gamma^2 \|w^\Delta\|^2 \geq \delta^2 \|w\|^2.$$

Couple (91) with (93) to get

$$(94) \quad \gamma^2 \|w\|^2 - \|z\|^2 \geq \delta^2 \|w\|^2.$$

By Observation 3.0.1 the desired inequality $\|\mathcal{T}_{\mathcal{K}}(t_0)\| < \gamma$ follows. \square

3.4. Conjugation. Let a stabilizing feedback $u = \mathcal{K}y$ be given. Taking $t = t_1$ and $\xi = 0$, equation (87) suggests that the closed-loop mapping $\mathcal{T}_{\mathcal{K}}: w \rightarrow z$ has norm smaller than γ if and only if the mapping $\mathcal{T}_{\mathcal{K}}^\Delta: w^\Delta \rightarrow u^\Delta$ is so bounded. Keeping a cap on the latter is an estimation problem: we want the closed-loop observation-based control to be as good an estimate as possible of the state feedback $u = B_2' \Pi_1 x$.

The following system¹⁰ governs the mapping $\mathcal{T}_{\mathcal{K}}^\Delta: w^\Delta \rightarrow u^\Delta$:

$$(95) \quad \begin{aligned} \dot{x} &= \left(A - \frac{1}{\gamma^2} B_1 B_1' \Pi_1 \right) x + B_1 w^\Delta + B_2 u, \\ u^\Delta &= -B_2' \Pi_1 x + u, \\ y &= C_2 x + D_{21} w^\Delta, \quad u = \mathcal{K}y. \end{aligned}$$

It does not adhere with the first line of assumption (7), but its conjugate does. We thus obtain a second Riccati equation as a necessary condition, in terms of the conjugate

¹⁰ Note that by assumption (7) there holds $D_{21} w = D_{21} w^\Delta$, an equality we use in the observation term, in (94).

system. That will follow the tradition of converting optimal estimation problems into optimal input problems in a conjugate setting.

As a first and crucial step, we need the following proposition.

PROPOSITION 3.4.1. *Let Π_1 , be as stated in Theorem I, and let u^Δ and w^Δ be defined by (86) in terms of that Π_1 . Then the observation feedback $u = \mathcal{K}y$ is internally stabilizing and strictly γ -suboptimal in (1) if and only if it is so in (95).*

Proof. As a first step assume that the observation-feedback $u = \mathcal{K}y$ is internally stabilizing in both (1) and (95). It is easy to show that $u = \mathcal{K}y$ is then strictly γ -suboptimal in (1) if and only if it is so in (95). Indeed, under the stability assumption both the closed-loop mappings $w \leftrightarrow w^\Delta$ are continuous. Given the zero initial state we then have

$$(96) \quad \alpha \|w\|^2 \leq \|w^\Delta\|^2 \leq \beta \|w\|^2$$

for some positive α and β . Consider now (87) with $s = t_0$, $t = t_1$, and $\xi = 0$. Invoking Observation 3.0.1, $u = \mathcal{K}y$ is strictly γ -suboptimal in (1) if and only if the left-hand side of (87) is bounded below by $\delta^2 \|w\|^2$, which, by (96), is true if and only if the right-hand side of (87) is bounded below by $\eta^2 \|w^\Delta\|^2$ (for some appropriate positive δ and η), and, in turn, if and only if $u = \mathcal{K}y$ is strictly γ -suboptimal in (95).

For the main part of the proof, assume that the observation-feedback $u = \mathcal{K}y$ is internally stabilizing and strictly γ -suboptimal in (1). We then show that $u = \mathcal{K}y$ is stabilizing in (95) as well. (The proof of the converse proposition, going from stability and γ -suboptimality in (95) to stability in (1) is completely similar.) The main idea in the proof is the following. If the disturbance is such that $w^\Delta = 0$ then, by (87), the term $\gamma^2 \|w\|_{L_2[s, t_1]}^2 - \|z\|_{L_2[s, t_1]}^2$ is nonpositive in the closed-loop system. Under the assumption that the claim fails and \mathcal{K} is not internally stabilizing in (95) we shall find such a disturbance that makes the term positive; a contradiction. It will require some work.

Let (3) be a realization of \mathcal{K}

$$(97) \quad \dot{p} = Mp + Ny, \quad u = Qp + Ry,$$

let the exponentially stable closed-loop generator be as in (4)

$$(98) \quad \mathcal{A} = \begin{bmatrix} A + B_2 RC_2 & B_2 Q \\ NC_2 & M \end{bmatrix},$$

and let Φ be the evolution generated by \mathcal{A} over $\mathbf{X} \times \mathbf{P}$. We denote also

$$\mathcal{B} \triangleq \begin{bmatrix} B_1 + B_2 RD_{21} \\ ND_{21} \end{bmatrix}, \quad \mathcal{A}_0 \triangleq \mathcal{A} + \mathcal{B} \begin{bmatrix} -\frac{1}{\gamma^2} B_1' \Pi_1 & 0 \end{bmatrix}.$$

The claim is that the evolution Φ_0 , generated by \mathcal{A}_0 , is exponentially stable.

The equation

$$(99) \quad \dot{\tilde{x}} = \mathcal{A}_0 \tilde{x}$$

is equivalent to

$$(100) \quad \dot{\tilde{x}} = \mathcal{A} \tilde{x} + \mathcal{B} w$$

subject to the feedback

$$(101) \quad w = -\frac{1}{\gamma^2} B_1' \Pi_1 x,$$

where $\tilde{x} = [\tilde{x}_p]$. By Lemma 2.2, if the current proposition is false then the ratios

$$(102) \quad \frac{\|\tilde{x}\|_{L_2[s,t]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \tilde{x}(s) \in \mathbf{X} \times \mathbf{P}, \quad t_0 < s < t < t_1,$$

as governed by (99), are not uniformly bounded.

Suppose therefore that our proposition is false, and that (99) is not an exponentially stable equation. If the ratios

$$(103) \quad \frac{\|x\|_{L_2[s,t]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \tilde{x}(s) \in \mathbf{X} \times \mathbf{P}, \quad t_0 < s < t < t_1$$

were uniformly bounded, then by (101) so would be the ratios

$$(104) \quad \frac{\|w\|_{L_2[s,t]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \tilde{x}(s) \in \mathbf{X} \times \mathbf{P}, \quad t_0 < s < t < t_1.$$

Consequently, the stability of \mathcal{A} in (100) will impose a uniform bound on (102), in contrast to our assumption. Thus, if \mathcal{H} is not internally stabilizing in (95) then (103) is unbounded. We continue on that premise.

Let now $t_0 < s < t < t_1$ and $\tilde{x}(s)$ be given; then let \tilde{x} be the associated trajectory of (99) and denote $w \triangleq -(1/\gamma^2)B_1^*\Pi_1x$, $u \triangleq [RC_2 \quad Q]\tilde{x}$, and $z \triangleq C_1x + D_{12}u$. All these functions are thus far defined along $[s, t]$. Along the following interval $[t, t_1]$ we consider the optimization problem

$$(105) \quad \min_{w \in L_2} (\gamma^2 \|w\|^2 - \|z\|^2),$$

subject to (99) and the initial state $\tilde{x}(t)$, as already determined. Here again, the control and output are defined in terms of the realization of $\mathcal{H}: u \triangleq [RC_2 \quad Q]\tilde{x} + RD_{21}w$ and $z \triangleq C_1x + D_{12}u$. By arguments that are completely similar to those used in §§ 3.1 and 3.2 it follows that a unique solution to (105) exists, which we denote simply by w .

Now w is defined along the entire interval $[s, t_1]$, associated with a state trajectory \tilde{x} , a control u , and an output z . The observation that the ratios (102), (103), and (104) are unbounded implies that so are the ratios

$$(106) \quad \frac{\|\tilde{x}\|_{L_2[s,t_1]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \frac{\|x\|_{L_2[s,t_1]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \frac{\|w\|_{L_2[s,t_1]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \frac{\|z\|_{L_2[s,t_1]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}},$$

$$\tilde{x}(s) \in \mathbf{X} \times \mathbf{P}, \quad t_0 < s < t_1,$$

as derived by the procedure above.

We are going to construct yet two more sets of trajectories. Given the initial state $\tilde{x}(s)$, let \tilde{x}_σ be the following free motion of (100) (i.e., $\tilde{x}_\sigma(t) = \Phi(t, s)\tilde{x}(s)$), set $u_\sigma \triangleq [RC_2 \quad Q]\tilde{x}_\sigma$ and $z_\sigma \triangleq C_1x_\sigma + D_{12}u_\sigma$. Then set $\tilde{x}_\nu \triangleq \tilde{x} - \tilde{x}_\sigma$, $u_\nu \triangleq u - u_\sigma$, and $z_\nu \triangleq z - z_\sigma$.

Since Φ is exponentially stable, the ratios

$$(107) \quad \frac{\|z_\sigma\|_{L_2[s,t_1]}}{\|\tilde{x}(s)\|_{\mathbf{X} \times \mathbf{P}}}, \quad \tilde{x}(s) \in \mathbf{X} \times \mathbf{P}, \quad t_0 < s < t_1,$$

are uniformly bounded. It is therefore possible to select our parameters so that z_ν be increasingly the dominant part of z . That is, we can select s , t , and $\tilde{x}(s)$ so that

$$(108) \quad (1 - \lambda^2)\|z_\nu\|^2 \leq \|z\|^2 \leq (1 + \lambda^2)\|z_\nu\|^2$$

with arbitrarily small λ .

Let us carefully examine the trajectory x_ν . As follows from the definition above, we have

$$\begin{bmatrix} x_\nu(s) \\ p_\nu(s) \end{bmatrix} = \tilde{x}_\nu(s) = 0.$$

Thus, u_ν is just the feedback control $u_\nu = \mathcal{K}y_\nu$ ($\triangleq \mathcal{K}(C_2x_\nu + D_{21}w)$) and $z_\nu = \mathcal{Z}_{\mathcal{K}}(s)(0, u_\nu, w)$ (equal to the output associated with the disturbance w , the zero initial state, and the closed-loop control law $u = \mathcal{K}y$). Since we assume that \mathcal{K} is strictly γ -suboptimal, Observation 3.0.1. tells us that there holds

$$(109) \quad \gamma^2 \|w\|^2 - \|z_\nu\|^2 \geq \delta^2 \|w\|^2$$

with some nonzero δ that can be selected independent of our present constructions.

Combining (108) and (109) we get

$$(110) \quad \gamma^2 \|w\|^2 - \|z\|^2 \geq \gamma^2 \|w\|^2 - (1 + \lambda^2) \|z_\nu\|^2 \geq (\delta^2 - \lambda^2 \gamma^2) \|w\|^2.$$

As γ and δ are fixed and λ can be chosen arbitrarily small, we can select our parameters so that the right-hand side of (110) be positive; indeed, we can make it arbitrarily large.

Our next move is to show that a positive left-hand side in (110) is impossible. For that purpose we define $x^* \triangleq x$, $u^* \triangleq u$, and $z^* \triangleq z$ along $[s, t]$. Then we extend these trajectories via $x^*(\cdot) \triangleq \Phi_1(\cdot, t)x^*(t)$, $u^* \triangleq B_2' \Pi_1 x^*$, and $w^* \triangleq -(1/\gamma^2) B_1' \Pi_1 x^*$ along $[t, t_1]$. Since Φ_1 is exponentially stable, all these are L_2 trajectories. Moreover, the associated $w^{*\Delta}$ vanishes throughout. In particular, by (87) there holds

$$(111) \quad \gamma^2 \|w^*\|_{L_2[s, t_1]}^2 - \|z^*\|_{L_2[s, t_1]}^2 \leq 0.$$

As established in §§ 3.1 and 3.2, along $[t, t_1]$ we have

$$\begin{aligned} & \gamma^2 \|w^*\|_{L_2[t, t_1]}^2 - \|z^*\|_{L_2[t, t_1]}^2 \\ &= \min_{f \in L_2} \max_{g \in L_2} (\gamma^2 \|f\|_{L_2[t, t_1]}^2 - \|\mathcal{Z}(t)(x(t), g, f)\|_{L_2[t, t_1]}^2) \\ (112) \quad & \geq \min_{f \in L_2} (\gamma^2 \|f\|_{L_2[t, t_1]}^2 - \|\mathcal{Z}(t)(x(t), g = [RC_1 \quad Q]\tilde{x} + RD_{21}f, f)\|_{L_2[t, t_1]}^2) \\ &= \gamma^2 \|w\|_{L_2[t, t_1]}^2 - \|z\|_{L_2[t, t_1]}^2. \end{aligned}$$

We recall that, by definition, $w^* = w$ and $z^* = z$ along $[s, t]$. Thus the inequality between the right-most and the left-most terms in (112) can be extended to the entire interval $[s, t_1]$. Joining this inequality with (110) and (111), the contradiction

$$\begin{aligned} & 0 \geq \gamma^2 \|w^*\|_{L_2[s, t_1]}^2 - \|z^*\|_{L_2[s, t_1]}^2 \\ (113) \quad & \geq \gamma^2 \|w\|_{L_2[s, t_1]}^2 - \|z\|_{L_2[s, t_1]}^2 \\ & > (\delta^2 - \lambda^2 \gamma^2) \|w\|_{L_2[s, t_1]}^2 > 0 \end{aligned}$$

follows. This completes the proof. \square

Now we are almost ready to conjugate (95). As a matter of convenience (and personal preference)¹¹ we introduce the following notion of conjugation. Let Ω be the time reversal operator, applied to functions over \Re : $(\Omega f)(t) \triangleq f(-t)$. Given an operator $\mathcal{E}: L_2(t_0, t_1) \rightarrow L_2(t_0, t_1)$ we define its *conjugate* by $\mathcal{E}^\# = \Omega \mathcal{E}' \Omega: L_2(-t_1, -t_0) \rightarrow L_2(-t_1, -t_0)$ (where \mathcal{E}' is the usual adjoint). Obviously $\mathcal{E}^{\#\#} = \mathcal{E}$ and $\|\mathcal{E}\| = \|\mathcal{E}^\#\|$, and

¹¹ This way the conjugate system will be causal, instead of anticausal, and we will be able to directly draw on the results of the previous sections.

if \mathcal{E} is a multiplication operator (i.e., $(\mathcal{E}f)(t) = E(t)f(t)$, $t \in (t_0, t_1)$, for some operator valued function $E(t): \mathbb{F} \rightarrow \mathbb{F}$) then $(\mathcal{E}^\# g)(t) = E'(-t)g(t)$, $t \in (-t_1, -t_0)$. Finally, if E generates an exponentially stable evolution, $\Psi(t, s)$, $t_1 > t \geq s > t_0$, then $E^\#$ generates the exponentially stable evolution $\Psi'(-s, -t)$, $-t_0 > t \geq s > -t_1$.

Let $\mathcal{T}_{\mathcal{K}}^{\Delta\#}$ be the input-output operator defined via the realization (95), as above. Then its conjugate, $\mathcal{T}_{\mathcal{K}^\#}^{\Delta\#}$, is realized by

$$\begin{aligned} \dot{\hat{x}} &= \left(A - \frac{1}{\gamma^2} B_1 B_1' \Pi_1 \right)^\# \hat{x} - \Pi_1^\# B_2^\# \hat{w} + C_2^\# \hat{u}, \\ \hat{z} &= B_1^\# \hat{x} + D_{21}^\# \hat{u}, \\ \hat{y} &= B_2^\# \hat{x} + \hat{w}, \quad \hat{u} = \mathcal{K}^\# \hat{y} \end{aligned} \quad (114)$$

where $\mathcal{K}^\#$ has the realization

$$\dot{\hat{p}} = M^\# \hat{p} + Q^\# \hat{y}, \quad \hat{u} = N^\# \hat{p} + R^\# \hat{y}. \quad (115)$$

The following is an immediate result of Proposition 3.4.1.

COROLLARY 3.4.2. *The feedback $u = \mathcal{K}y$ is internally stabilizing and strictly γ -suboptimal in (1) if and only if $\hat{u} = \mathcal{K}^\# \hat{y}$ as in (114).*

Applying the analysis of §§ 3.1 and 3.2 to (114) we thus get the following corollary.

COROLLARY 3.4.3. *If $\gamma > \gamma_0$ in (1) and Π_1 is as described above then there exists also Π_2 , a solution to the Riccati equation (9), as stated in Theorem I.*

Proof. All it takes is to note that, due to the assumptions in the second line of (7), the open-loop part of (114) satisfies assumptions in the first line of (7), which we used in § 3.1, and that the role of the conjugated equation (9) in (114) is exactly that of (8) in (1). \square

This completes the proof of necessity in part (a) of Theorem I.

3.5. The parametrization of γ -suboptimal compensators.

PROPOSITION 3.5.1. *Every internally stabilizing, strictly γ -suboptimal compensator admits a realization of the form (10):*

$$\begin{aligned} \dot{p} &= (A_1 + \Pi_2 C_2' C_2) p + \Pi_2 C_2' y - \left(I + \frac{1}{\gamma^2} \Pi_2 \Pi_1 \right) B_2 v, \\ u &= -B_2' \Pi_1 p + v, \\ q &= C_2 p + y, \quad v = \mathcal{K}_0 q, \end{aligned} \quad (116)$$

where \mathcal{K}_0 has an exponentially stable realization and $\|\mathcal{K}_0\| < \gamma$.

Proof. Suppose that \mathcal{K} is an internally stabilizing, strictly γ -suboptimal compensator in (1). We define \hat{u}^Δ and \hat{w}^Δ in (114) following the same logic used in the analysis of (1). Here the appropriate definitions are

$$\hat{u}^\Delta = \hat{u} - C_2^\# \Pi_2^\# \hat{x}, \quad \hat{w}^\Delta = \hat{w} - \frac{1}{\gamma^2} B_2^\# \Pi_1^\# \Pi_2^\# \hat{x}. \quad (117)$$

Let then $\mathcal{K}_0^\#$ stand for the closed-loop mapping $\hat{w}^\Delta \rightarrow \hat{u}^\Delta: L_2(-t_1, -t_0) \rightarrow L_2(-t_1, -t_0)$. Following from Proposition 3.4.1 (applied to (114)), this mapping admits an exponentially stable realization and its norm is strictly smaller than γ .

Consider the following compensator $\mathcal{K}_1^\#$ as an alternative to $\mathcal{K}^\#$ in (114):

$$(118) \quad \begin{aligned} \dot{\hat{p}} &= (A_1 + \Pi_2 C_2' C_2)^\# \hat{p} - \Pi_1^\# B_2^\# \hat{y} + C_2^\# \hat{v}, \\ \hat{u} &= C_2^\# \Pi_2^\# \hat{p} + \hat{v}, \\ \hat{q} &= -B_2^\# \left(I + \frac{1}{\gamma^2} \Pi_2 \Pi_1 \right)^\# \hat{p} + \hat{y}, \quad \hat{v} = \mathcal{H}_0^\# \hat{q}. \end{aligned}$$

Setting $\hat{e} \triangleq \hat{x} - \hat{p}$ it easily follows that \hat{e} satisfies a homogeneous ordinary differential equation (ODE). In particular, if both the initial states in (114) and in (118) are zero then $\hat{x} = \hat{p}$. Consequently, then¹² $\hat{q} = \hat{w}^\Delta$ and finally $\hat{u} = C_2^\# \Pi_2^\# \hat{x} + \mathcal{H}_0^\# \hat{w}^\Delta$. Following from the definition of \mathcal{H}_0 this means that then $\hat{u} = \mathcal{K}^\# \hat{y}$.

In short, $\mathcal{K}^\#$ and $\mathcal{K}_1^\#$ coincide over the range of the closed-loop mapping $\hat{w} \rightarrow \hat{y}$. Yet when the initial state in (114) is zero, that mapping defines a Volterra operator of the second type, and is therefore invertible over any finite time span [24]. That is, $\mathcal{K}^\#$ and $\mathcal{K}_1^\#$ agree when restricted to the entire $L_2[s, t]$, for any finite s and t . Causality thus implies that $\mathcal{K}^\#$ and $\mathcal{K}_1^\#$ coincide throughout.

The proof is complete with the observation that (118) is just the conjugate of (116). \square

Proposition 3.5.2. *Suppose that Π_1 and Π_2 are as described in part (a) of Theorem 1, and that \mathcal{K} has a realization of the form (10). Then this compensator is internally stabilizing and strictly γ -suboptimal in (1). In particular, then $\gamma > \gamma_0$.*

Proof. The proof back-tracks the proof of necessity. We start by establishing that $\mathcal{K}^\#$, as given by (118), is internally stabilizing in the conjugate system (114).

Let the following be an exponentially stable realization of $\mathcal{H}_0^\#$:

$$(119) \quad \dot{\hat{r}} = M_0^\# \hat{r} + Q_0^\# \hat{q}, \quad \hat{v} = N_0^\# \hat{r} + R_0^\# \hat{q}.$$

We must show that when $\hat{w} = 0$ the combined closed-loop state of (114), (118), and (119),

$$\begin{bmatrix} \hat{x} \\ \hat{p} \\ \hat{r} \end{bmatrix},$$

satisfies an exponentially stable homogeneous ODE.

Obviously we can substitute $\hat{e} = \hat{x} - \hat{p}$ for \hat{p} in the extended state. As noted above, \hat{e} satisfies a homogeneous ODE; specifically,

$$(120) \quad \dot{\hat{e}} = A_1^\# \hat{e}.$$

Since A_1 is exponentially stable there is no loss of generality in taking $\hat{e} = 0$. We assume that to be the case, and focus on $\begin{bmatrix} \hat{x} \\ \hat{r} \end{bmatrix}$.

Our plan is to use Lemma 2.2. It thus must be checked (i) that the evolution of $\begin{bmatrix} \hat{x} \\ \hat{r} \end{bmatrix}$ is governed by a bounded perturbation of an exponentially stable generator, and (ii) that the norms

$$\left\| \begin{bmatrix} \hat{x} \\ \hat{r} \end{bmatrix} \right\|_{L_2[s, -t_0]}$$

are uniformly bounded in terms of the initial state $\begin{bmatrix} \hat{x}(s) \\ \hat{r}(s) \end{bmatrix}$.

We recall the observation made in the previous proof, that when $\hat{e} = 0$ and $\hat{w} = 0$ then $\hat{w}^\Delta = \hat{q}$. Thus (i) is easy. Our evolution is generated by

$$(121) \quad \begin{bmatrix} (A - (1/\gamma^2) B_1 B_1' \Pi_1 + \Pi_2 C_2' C_2)^\# - (1/\gamma^2) C_2^\# R_0^\# B_2^\# \Pi_1^\# \Pi_2^\# & C_2^\# N_0^\# \\ -(1/\gamma^2) Q_0^\# B_2^\# \Pi_1^\# \Pi_2^\# & M_0^\# \end{bmatrix}$$

¹² The objective of getting this equality was, in fact, the starting point in the derivation of (118) from (114).

By Proposition 3.3.1 (applied to (114)) the generator $(A - (1/\gamma^2)B_2B_2'\Pi_1 + \Pi_2C_1'C_1)^\#$ is exponentially stable. By assumption, so is $M_0^\#$. Thus our generator is indeed a bounded perturbation of an exponentially stable generator in the product space.

The following is the counterpart of (87) in the framework of (114)

$$(122) \quad \gamma^2 \|\hat{w}\|_{L_2[s,t]}^2 - \|\hat{z}\|_{L_2[s,t]}^2 = \langle \hat{x}(s), \Pi_2^\#(s)\hat{x}(s) \rangle - \langle \hat{x}(t), \Pi_2^\#(t)\hat{x}(t) \rangle \\ + \gamma^2 \|\hat{w}^\Delta\|_{L_2[s,t]}^2 - \|\hat{u}^\Delta\|_{L_2[s,t]}^2.$$

Taking $\hat{w} = 0$ and $t = -t_0$ (which is the maximal value for t in the conjugate system) and invoking assumption (7), equation (122) yields

$$(123) \quad \varepsilon \|\hat{x}\|_{L_2[s,-t_0]}^2 \leq \|\hat{z}\|_{L_2[s,-t_0]}^2 \\ = -\langle \hat{x}(s), \Pi_2^\#(s)\hat{x}(s) \rangle - \gamma^2 \|\hat{w}^\Delta\|_{L_2[s,-t_0]}^2 + \|\hat{u}^\Delta\|_{L_2[s,-t_0]}^2.$$

In adherence with previous notations pertinent to (1), we denote by $\hat{\mathcal{H}}(s): (r(s), y) \rightarrow r: R \times L_2(s, -t_0) \rightarrow L_2(s, -t_0)$ the mappings from the initial state and the input to the output in (119). (Thus $\mathcal{H}_0^\#|_{L_2(s,-t_0)} = \hat{\mathcal{H}}(s)|_{r(s)=0}$.) Due to the assumption that (119) is stable, these mappings are uniformly bounded. Let λ be a finite uniform bound on the induced norms $\|\hat{\mathcal{H}}(s)\|$. Set $\hat{e} = 0$ and $\hat{w} = 0$. Then there holds:

$$(124) \quad \|\hat{u}^\Delta\|_{L_2(s,-t_0)}^2 = \|\hat{\mathcal{H}}(s)(\hat{r}(s), \hat{w}^\Delta)\|_{L_2(s,-t_0)}^2 \\ = \|\hat{\mathcal{H}}(s)(0, \hat{w}^\Delta) + \hat{\mathcal{H}}(s)(\hat{r}(s), 0)\|_{L_2(s,-t_0)}^2 \\ \leq (\|\mathcal{H}_0^\# \hat{w}^\Delta\|_{L_2(s,-t_0)} + \|\hat{\mathcal{H}}(s)(\hat{r}(s), 0)\|_{L_2(s,-t_0)})^2 \\ \leq \gamma^2 \|\hat{w}^\Delta\|_{L_2(s,-t_0)}^2 + 2\gamma\lambda \|\hat{w}^\Delta\|_{L_2(s,-t_0)} \|\hat{r}(s)\| + \lambda^2 \|\hat{r}(s)\|^2.$$

Combining (123) and (124) we get

$$(125) \quad \varepsilon \|\hat{x}\|_{L_2[s,-t_0]}^2 \leq \|\Pi_2^\#\|_\infty \|\hat{x}(s)\|^2 + 2\gamma\lambda \|\hat{w}^\Delta\|_{L_2[s,-t_0]} \|\hat{r}(s)\| + \lambda^2 \|\hat{r}(s)\|^2 \\ = \|\Pi_2^\#\|_\infty \|\hat{x}(s)\|^2 + 2\frac{\lambda}{\gamma} \|B_1^{\#'} \Pi_1^\# \Pi_2^\# \hat{x}\|_{L_2[s,-t_0]} \|\hat{r}(s)\| + \lambda^2 \|\hat{r}(s)\|^2 \\ \leq \|\Pi_2^\#\|_\infty \|\hat{x}(s)\|^2 + 2\frac{\lambda}{\gamma} \|B_1^{\#'} \Pi_1^\# \Pi_2^\#\|_\infty \|\hat{x}\|_{L_2[s,-t_0]} \|\hat{r}(s)\| + \lambda^2 \|\hat{r}(s)\|^2,$$

which can be rewritten in the form

$$(126) \quad \varepsilon \|\hat{x}\|_{L_2[s,-t_0]}^2 - \eta \|\hat{x}\|_{L_2[s,-t_0]} \|\hat{r}(s)\| - \kappa \|\hat{x}(s)\|^2 - \lambda^2 \|\hat{r}(s)\|^2 \leq 0.$$

This last inequality provides a uniform bound of the form

$$(127) \quad \|\hat{x}\|_{L_2[s,-t_0]} \leq \alpha \|\hat{x}(s)\| + \beta \|\hat{r}(s)\|.$$

In turn, internal stability of (119) and the inequality (127) provide this next bound:

$$(128) \quad \|\hat{r}\|_{L_2[s,-t_0]} \leq \mu \|\hat{w}^\Delta\| - \frac{1}{\gamma^2} B_2^{\#'} \Pi_1^\# \Pi_2^\# \hat{x}\|_{L_2[s,-t_0]} + \nu \|\hat{r}(s)\| \\ \vdots \\ \leq \theta \|\hat{x}(s)\| + \tau \|\hat{r}(s)\|$$

for appropriate constants μ , ν , θ , and τ .

Relying on (127) and (128), we are now able to invoke Lemma 2.2 and deduce that, indeed, the evolution of $[\hat{x}_f^\#]$ is exponentially stable. Consequently, $\mathcal{H}^\#$ is internally stabilizing in (114); hence so is \mathcal{H} in (95).

Next we have to establish that $\mathcal{K}^\#$ is strictly γ -suboptimal in (114). Substituting $t = -t_0$ and $\hat{x}(s) = 0$ in (122), and invoking our assumption $\|\mathcal{H}_0\| < \gamma$, we get

$$(129) \quad \gamma^2 \|\hat{w}\|_{L_2[s, -t_0]}^2 - \|\hat{z}\|_{L_2[s, -t_0]}^2 > \delta^2 \|\hat{w}^\Delta\|$$

for some appropriate $\delta \neq 0$. With the initial values $\hat{x}(s) = \hat{p}(s) = 0$, the closed-loop mapping $\hat{w}^\Delta \rightarrow \hat{w}$ is realized by a stable system,

$$(130) \quad \begin{aligned} \dot{\hat{x}} &= A_2^\# \hat{x} - \Pi_1^\# B_2^{\#'} \hat{w}^\Delta + C_2^\# \hat{u}^\Delta \\ &= A_2^\# \hat{x} + (C_2^\# \mathcal{H}_0^\# - \Pi_1^\# B_2^{\#'}) \hat{w}^\Delta, \\ \hat{w} &= \frac{1}{\gamma^2} B_2^\# \Pi_1^\# \Pi_2^\# \hat{x} + \hat{w}^\Delta. \end{aligned}$$

In particular, it is bounded, and the inequality in (129) holds also when $\delta^2 \|\hat{w}^\Delta\|$ is replaced by $\theta^2 \|\hat{w}\|$ for some suitable $\theta \neq 0$. By Observation 3.0.1 the feedback $\mathcal{K}^\#$ is strictly γ -suboptimal in (114). By Corollary 3.4.2, \mathcal{K} is internally stabilizing and strictly γ -suboptimal in (1). \square

Remark. The trick by which (118), hence (10), was derived from (114) is simple: we first substitute \hat{u}^Δ for \hat{u} as the control input. That is done by appropriate modification of the state equation. Using the third equation in (114), we can substitute a term in \hat{x} and \hat{y} for the term in \hat{w} , in the modified state equation. Substituting \hat{p} and \hat{v} for \hat{x} and \hat{u}^Δ , the state equation in (118) is obtained. Using once more the third equation in (114), we get an expression for \hat{w}^Δ in terms of \hat{x} and \hat{y} . Substituting \hat{p} for \hat{x} , the third equation in (118) is obtained. The relation $\hat{v} = \mathcal{H}_0^\# \hat{q}$ then follows from the definition of \mathcal{H}_0 . The output formula in (118) comes directly from (117).

This completes the proof of Theorem I.

3.6. The corollary: Outline of proofs.

3.6.1. Part (e). If $A \in L_\infty$ then all the evolutions discussed heretofore are strongly differentiable [20, p. 129]. The Riccati differential equations (11) and (12) are obtained by differentiating (8) and (9).

Let $A_0 \triangleq A + B_2 B_2' \Lambda$, and let Φ_0 be the evolution it generates, as above. By the present assumption there holds

$$(131) \quad \|\Phi_0(t, s)\xi\| \geq e^{\|A_0\|_\infty(s-t)} \|\xi\|, \quad t \geq s.$$

Thus, when $t_1 = +\infty$ we have

$$(132) \quad \begin{aligned} J^0(s; \xi, 0) &= - \int_s^{+\infty} \langle \Phi_0(t, s)\xi, (C_1' C_1 + \Lambda B_2 B_2' \Lambda)(s) \Phi_0(t, s)\xi \rangle dt \\ &\leq -\varepsilon \int_s^{+\infty} \|\Phi_0(t, s)\xi\|^2 dt \\ &\leq -\frac{\varepsilon_1}{2\|A_0\|_\infty} \|\xi\|^2. \end{aligned}$$

Since

$$(133) \quad J^0(s; \xi, 0) \geq J^*(s; \xi) = \langle \xi, \Pi_1(s)\xi \rangle,$$

we conclude that Π_1 is uniformly negative. When $t_0 = -\infty$ the same reasoning assures uniform negativity of Π_2 .

3.6.2. Periodic and time invariant systems. When $t_1 = +\infty$, periodicity of the system coefficients implies periodicity of the min-max problem (27), and hence of its unique solution. In particular, then Π_1 is periodic. When we also have $t_0 = -\infty$, the same holds for Π_2 . When the system is time invariant, the assumption that the induced norm bound $\|\mathcal{T}_{\mathcal{H}}\| < \gamma$ can be achieved in stable closed-loop over some infinite ray, say $[t, +\infty)$ or $(-\infty, t]$, implies that it can be achieved for *any* such ray (i.e., for any choice of t). Consequently, then γ is strictly suboptimal over the entire real line. The result on periodic systems then implies that time invariant solutions to the two Riccati equations exist; in (8), (9) these solutions are defined with $t_0 = -\infty$ and $t_1 = +\infty$.

3.6.3. The asymptotic system. Our assumption here is that $t_0 = -\infty$, $t_1 = +\infty$, and that there exist A^+ , B_i^+ , C_i^+ , D_{ij}^+ , A^- , B_i^- , C_i^- , and D_{ij}^- such that the coefficients in (1) tend (in operator norm) to their “+” counterparts as $t \rightarrow +\infty$ and to their “-” counterparts as $t \rightarrow -\infty$. (e.g., $\|A(t) - A^+\| \rightarrow 0$ as $t \rightarrow +\infty$).

It follows from standard *small gain* arguments¹³ [16, Thm. 3] that \mathcal{H} is internally stabilizing in (1) if and only if so it is in the “+” and “-” asymptotic systems. Continuous dependence of the operator norms on the system parameters implies that strict γ -suboptimality of \mathcal{H} in the asymptotic systems is equivalent to strict γ -suboptimality of \mathcal{H} in (1) over intervals $(-\infty, s)$ and $(t, +\infty)$ for s small enough and t large enough. Therefore if solutions exist to the Riccati equations (8) and (9), as described in the theorem, then such solutions exist also in the asymptotic systems. Moreover, since the optimal min-max value $J^*(s; \xi) = \langle \xi, \Pi_1(s)\xi \rangle$ converges uniformly to its “+” counterpart as $s \rightarrow +\infty$, the convergence $\|\Pi_1(s) - \Pi_1^+\| \rightarrow 0$ follows. Similarly, we conclude that $\|\Pi_2(s) - \Pi_2^-\| \rightarrow 0$ as $s \rightarrow -\infty$. \square

4. Getting rid of removable assumptions. The technical discussion heretofore was carried under the assumptions of (7) on the structure of our system. The sole purpose of these hypotheses was to simplify notation, and *they are made without any loss of generality*. For completeness we verify this point now, and review a straightforward procedure for the removal of these assumptions. It is noted that there are several simple and more elegant ways to relax parts of (7); e.g., uniform positivity of $C_1' C_1$ can be substituted by uniform observability of $[A, C_1]$. Several authors (e.g., [16], [25], [27]–[29]) explored such ways, especially for the finite-dimensional, LTI case; their papers provide interesting and insightful analysis, and bear potential advantages. Since (given more awkward notation and definitions) the logic of the proofs remains exactly as in the previous section, proofs will be omitted. We shall be content with highlights of the modifications in formulae, statements of main results, and of those few arguments that have to be added.

The hypotheses of (7) can be divided into subgroups: the separation assumptions $D_{12}' C_1 = 0$ and $D_{21} B_1' = 0$, the normalized input-nonsingularity assumptions $D_{12}' D_{12} = I$ and $D_{21} D_{21}' = I$, the state-nonsingularity assumptions $C_1' C_1 > \varepsilon I$ and $B_1 B_1' > \varepsilon I$, the zero-tracking objective assumption $D_{11} = 0$, and the strict closed-loop causality assumption $D_{22} = 0$. Other than the last two, these assumptions came in pairs: one applies to the optimal state-feedback problem, while the other applies to the conjugate, estimation problem. We shall focus mostly on the state-feedback part; the conjugate system is to be treated in complete analogy.

The first Riccati equation. The following simple statement will be used to overcome singularity with respect to the state and/or control.

¹³ These arguments state that small perturbations do not destroy exponential stability.

PROPOSITION 4.1. *Let γ_0 be the optimal value in (1). Then $\gamma > \gamma_0$ if and only if γ is a strictly suboptimal value when the system's output is modified to¹⁴*

$$(134) \quad z_n \triangleq \begin{bmatrix} z \\ \varepsilon_0 x \\ \varepsilon_0 u \end{bmatrix}$$

for some $\varepsilon_0 > 0$. In particular, once such γ and ε_0 are fixed, the same holds when ε_0 is substituted by any $\varepsilon \in [0, \varepsilon_0]$.

Proof. Suppose $\gamma > \gamma_0$ in (1). Then there exist $\delta \neq 0$ and an admissible internally stabilizing feedback compensator, $u = \mathcal{K}y$, so that

$$(135) \quad \|z\|^2 \leq (\gamma^2 - \delta^2) \|w\|^2$$

in closed-loop. Since the closed-loop mappings $w \rightarrow x, u$ are continuous, we can choose ε_0 small enough to guarantee the closed-loop inequality

$$(136) \quad \varepsilon_0^2 (\|x\|^2 + \|u\|^2) \leq \frac{1}{2} \delta^2 \|w\|^2$$

whereby

$$(137) \quad \|z_n\|^2 \leq (\gamma^2 - \frac{1}{2} \delta^2) \|w\|^2.$$

Thus γ is strictly suboptimal in the modified system. The converse claim is obvious. \square

In view of the observation we substitute z by z_n . The modified output satisfies $\|z_n\|^2 \geq \varepsilon^2 \|x\|^2, \varepsilon^2 \|u\|^2$.

The purpose of the next set of modifications is to rewrite $\|z_n\|$ in the form

$$(138) \quad \|z_n\|^2 = \|C_{n1}(\varepsilon)(x + E_0(\varepsilon)w)\|^2 + \|E_1(\varepsilon)w\|^2 \\ + \|D_{n12}(\varepsilon)(u_n + E_2(\varepsilon)w)\|^2.$$

That can be done, setting

$$(139) \quad \begin{aligned} L(\varepsilon) &\triangleq -(D'_{12}D_{12} + \varepsilon^2 I_U)^{-1} D'_{12} C_1, \\ u_n &\triangleq u - L(\varepsilon)x, \\ D_{n12}(\varepsilon) &\triangleq \begin{bmatrix} D_{12} \\ 0_X \\ \varepsilon I_U \end{bmatrix}, \\ C_{n1}(\varepsilon) &\triangleq \begin{bmatrix} C_1 + D_{12}L(\varepsilon) \\ \varepsilon I_X \\ \varepsilon L \end{bmatrix}, \\ E_0(\varepsilon) &\triangleq (C'_{n1}(\varepsilon)C_{n1}(\varepsilon))^{-1} C'_{n1}(\varepsilon) \begin{bmatrix} D_{11} \\ 0_X \\ 0_U \end{bmatrix}, \\ E_2(\varepsilon) &\triangleq (D'_{n12}(\varepsilon)D_{n12}(\varepsilon))^{-1} D'_{n12}(\varepsilon) \begin{bmatrix} D_{11} \\ 0_X \\ 0_U \end{bmatrix}, \\ E_1(\varepsilon) &\triangleq \begin{bmatrix} D_{11} \\ 0_X \\ 0_U \end{bmatrix} - C_{n1}(\varepsilon)E_0(\varepsilon) - D_{n12}(\varepsilon)E_2(\varepsilon). \end{aligned}$$

¹⁴ In what follows the subscript n stands for "new," where variables or coefficients will be modified.

For brevity we shall suppress the notation of ε , bearing in mind the dependence of the *new* variables on that constant.

Consider now the modified version of the min-max problem (27):

$$(140) \quad \min_{w \in L_2} \max_{u \in L_2} \{ \gamma^2 \|w\|^2 - \|z_n\|^2 \}.$$

Once admissible controls are restricted to be only those that result in L_2 output (hence L_2 -state trajectories), the class of admissible u 's stands in 1:1 correspondence to the class of admissible u_n 's. We thus can, and henceforth shall, substitute u_n for u in (140), which thereby becomes

$$(141) \quad \min_{w \in L_2} \left\{ (\gamma^2 \|w\|^2 - \|E_1 w\|^2) - \min_{u_n \in L_2} \{ \|C_{n1}(x + E_0 w)\|^2 + \|D_{n12}(u_n + E_2 w)\|^2 \} \right\}.$$

It is a tracking problem, where the target trajectories for both x and u_n are determined by w .

The solution of the modified min-max problem goes exactly as developed in §§ 3.1 and 3.2 (given the cumbersome burden of more complicated variables and coefficients). In particular, the nonsingularity of the cost functional and strict suboptimality of γ guarantee existence, uniqueness, and continuous dependence on the initial data of a solution to the following Hamilton-Jacobi system:

$$(142) \quad \begin{aligned} \dot{x} &= (A + (B_1 - B_2 E_2)(S_1 - E'_0 S_0 E_0)^{-1} E'_0 S_0 + B_2 L)x \\ &\quad + (B_2 S_2^{-1} B'_2 - (B_1 - B_2 E_2)(S_1 - E'_0 S_0 E_0)^{-1} (B_1 - B_2 E_2)') e \\ \dot{e} &= (S_0 + S_0 E_0 (S_1 - E'_0 S_0 E_0)^{-1} E'_0 S_0) x \\ &\quad - (A + (B_1 - B_2 E_2)(S_1 - E'_0 S_0 E_0)^{-1} E'_0 S_0 + B_2 L)' e, \end{aligned}$$

where we use the abbreviations

$$(143) \quad \begin{aligned} S_0 &\triangleq C'_{n1} C_{n1}, \\ S_1 &\triangleq \gamma^2 I - E'_1 E_1, \\ S_2 &\triangleq D'_{n12} D_{n12}. \end{aligned}$$

When considered over an interval (s, t_1) , this system is subject to the boundary conditions $x(s) = \xi$ and $e(t_1) = 0$ (or $\lim_{t \rightarrow +\infty} e(t) = 0$ when $t_1 = +\infty$). The min-max inputs are the given by

$$(144) \quad \begin{aligned} w^* &= (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 x^* - (B_1 - B_2 E_2)' e^*), \\ u^* &= Lx^* + S_2^{-1} B'_2 e^* - E_2 w^*. \end{aligned}$$

Exactly as in the proof of uniqueness of the solution of the Hamilton-Jacobi systems (35) and (73), by (43), we use the following facts in establishing uniqueness of the solution of (143): (i) A solution to (143) defines an optimal solution to the min-max problem (142); (ii) the optimal state and input trajectories in the latter are unique; (iii) when we set $x^* = 0$, $u^* = 0$, and $w^* = 0$ then the e component of the solution satisfies a homogeneous ODE, now $\dot{e} = -(A + B_2 L)' e$, the zero terminal condition, and $B'_2 e = 0$; finally, (iv) the pair $[A, B_2]$, and hence $[A + B_2 L, B_2]$, is stabilizable.

The associated Riccati equation is

$$(145) \quad \begin{aligned} \Pi_1(t) = & - \int_t^{t_1} \Phi_1(s, t)' ((S_0 + S_0 E_0 (S_1 - E_0' S_0 E_0)^{-1} E_0' S_0) \\ & + \Pi_1(B_2 S_2^{-1} B_2' - (B_1 - B_2 E_2)(S_1 - E_0' S_0 E_0)^{-1} \\ & \cdot (B_1 - B_2 E_2)' \Pi_1)(s) \Phi_1(s, t) ds, \end{aligned}$$

where Φ_1 is the evolution generated by

$$(146) \quad \begin{aligned} A_1 \triangleq & A + (B_1 - B_2 E_2)(S_1 - E_0' S_0 E_0)^{-1} E_0' S_0 + B_2 L \\ & + (B_2 S_2^{-1} B_2' - (B_1 - B_2 E_2)(S_1 - E_0' S_0 E_0)^{-1} (B_1 - B_2 E_2)') \Pi_1. \end{aligned}$$

(We easily see that when (7) holds and $\varepsilon = 0$, this equation and generator retain their form from the previous sections.)

The appropriate counterpart of the complete-observation result, Theorem II, is given in terms of this Riccati equation as follows.

THEOREM 4.2. *Suppose that both the state x and (for small ε) the control-target trajectory $E_2 w$ are available. Then γ is strictly suboptimal if and only if the operator $S_1 - E_0' S_0 E_0$ is uniformly positive and there exists a uniformly bounded, negative-definite solution to the Riccati equation (145) with the associated A_1 being an exponentially stable generator, for some choice of small, nonzero ε . Moreover, if indeed such a solution exists for one choice of ε , it also exists for any smaller ε , the state-feedback control $u = (L + (D_{n12}' D_{n12})^{-1} B_2')x$ is internally stabilizing, and the feedback-feedforward control $u = (L + (D_{n12}' D_{n12})^{-1} B_2')x - E_2 w$ guarantees the closed-loop norm bound $\|\mathcal{T}_{\mathcal{K}}\| < \gamma$.*

The proof of sufficiency is essentially the same as in Theorem II. The following justifies the added constraint in the necessary part, the uniform positivity of $S_1 - E_0' S_0 E_0$.

PROPOSITION 4.3. *If (137) holds in stable closed-loop (for some positive ε and δ) then $S_1 - E_0' S_0 E_0$ is uniformly positive definite.*

Outline of the proof. The stable closed-loop mapping $w \rightarrow x$ is strictly causal. Thus, over short periods of time, its induced norm can be made arbitrarily small. The inequality (137) should hold over any time interval, and if the interval is sufficiently short, it thus implies

$$(147) \quad \begin{aligned} \frac{1}{4} \delta^2 \|w\|_{L_2[s, t]}^2 & \leq \gamma^2 \|w\|_{L_2[s, t]}^2 - \|C_{n1} E_0 w\|_{L_2[s, t]}^2 - \|E_1 w\|_{L_2[s, t]}^2 \\ & \quad - \|D_{n12}(u + E_2 w)\|_{L_2[s, t]}^2 \\ & \leq \gamma^2 \|w\|_{L_2[s, t]}^2 - \|C_{n1} E_0 w\|_{L_2[s, t]}^2 - \|E_1 w\|_{L_2[s, t]}^2 \\ & = \langle w, (S_1 - E_0' S_0 E_0) w \rangle_{L_2[s, t]}. \end{aligned}$$

Consequently,

$$(148) \quad \frac{1}{4} \delta^2 \|w(t)\|_{\mathbf{W}}^2 \leq \langle w(t), (\gamma^2 I - E_0' C_{n1}' C_{n1} E_0 - E_1' E_1)(t) w(t) \rangle_{\mathbf{W}}$$

almost everywhere. \square

Conjugation and the second Riccati equation. As in the case where (7) holds, the proof of Theorem 4.2 and the entire ensuing analysis, rely heavily on the following modified version of (87):¹⁵

$$(149) \quad \begin{aligned} & \|w\|_{S_1}^2 - \|x + E_0 w\|_{S_0}^2 - \|u - E_2 w\|_{S_2}^2 \\ & = \|\xi\|_{\Pi_1}^2 + \|w^\Delta\|_{(S_1 - E_0' S_0 E_0)}^2 - \|u^\Delta\|_{S_2}^2 \end{aligned}$$

¹⁵ Here the norm-notation form $\|\bullet\|_{\Theta}$ stands for the Hilbert-space norm weighted by Θ : $\|\psi\|_{\Theta}^2 \triangleq \langle \psi, \Theta \psi \rangle$.

where we use the modified definitions for the momentary deviations from optimality

$$\begin{aligned}
 w^\Delta &\triangleq w - (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1)_x \\
 u^\Delta &\triangleq u + E_2 w - (L + S_2^{-1} B_2' \Pi_1) x \\
 &= u + E_2 w^\Delta - (L + S_2^{-1} B_2' \Pi_1 - E_2 (S_1 - E'_0 S_0 E_0)^{-1} \\
 &\quad \cdot (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1)) x.
 \end{aligned}
 \tag{150}$$

The estimation problem is based on the conjugate of the closed-loop mapping $w^\Delta \rightarrow u^\Delta$. Given in (1) an admissible, internally stabilizing feedback control $u = \mathcal{K}y$ that maintains (137), that mapping is realized by the following system:

$$\begin{aligned}
 \dot{x} &= (A + B_1 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1)) x \\
 &\quad + B_1 w^\Delta + B_2 u \\
 u^\Delta &= -(L + S_2^{-1} B_2' \Pi_1 - E_2 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1)) x \\
 &\quad + E_2 w^\Delta + u \\
 y &= (C_2 + D_{21} (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1)) x \\
 &\quad + D_{21} w^\Delta + D_{22} u
 \end{aligned}
 \tag{151}$$

subject to $\hat{u} = \mathcal{H}y$; by Proposition 3.4.1, that feedback is internally stabilizing and strictly γ -suboptimal in (151). The conjugate mapping is thus realized by the well-defined, internally stable, closed-loop system

$$\begin{aligned}
 \dot{\hat{x}} &= (A + B_1 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# \hat{x} \\
 &\quad - (L + S_2^{-1} B_2' \Pi_1 - E_2 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# \hat{w} \\
 &\quad + (C_2 + D_{21} (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# \hat{u} \\
 \hat{z} &= B_1^\# \hat{x} + E_2^\# \hat{w} + D_{21}^\# \hat{u}, \\
 \hat{y} &= B_2^\# \hat{x} + \hat{w} + D_{22}^\# \hat{u}, \quad \hat{u} = \mathcal{H}^\# \hat{y}.
 \end{aligned}
 \tag{152}$$

Now we repeat our previous constructions: Provided that ε is small enough, we can substitute the output of (152) by \hat{z}_n such that $\|\hat{z}_n\|^2 = \|\hat{z}\|^2 + \varepsilon^2 (\|\hat{x}\|^2 + \|\hat{u}\|^2)$, without affecting the strict γ -suboptimality of the compensator. Then just as before, we introduce a control change of variable $\hat{u}_n \triangleq \hat{u} - M^\# \hat{x}$, and new and modified coefficients $B_{n1}^\#(\varepsilon)$, $D_{n21}^\#(\varepsilon)$, $F_0^\#(\varepsilon)$, $F_1^\#(\varepsilon)$, and $F_2^\#(\varepsilon)$, in terms of which we further denote $T_0^\# \triangleq B_{n1}^\# B_{n1}^\#$, $T_1^\# \triangleq \gamma^2 I - F_1^\# F_1^\#$, and $T_2^\# \triangleq D_{n21}^\# D_{n21}^\#$, so that

$$\|\hat{z}_n\|^2 = \|B_{n1}^\# (\hat{x} + F_0^\# \hat{w})\|^2 + \|F_1^\# \hat{w}\|^2 + \|D_{n21}^\# (\hat{u}_n + F_2^\# \hat{w})\|^2
 \tag{153}$$

and

$$\gamma^2 \|\hat{w}\|^2 - \|\hat{z}_n\|^2 = \|\hat{w}\|_{T_0^\#}^2 - \|(\hat{x} + F_0^\# \hat{w})\|_{T_0^\#}^2 (\hat{u}_n + F_2^\# \hat{w})\|_{T_2^\#}^2.
 \tag{154}$$

In order that the estimation Riccati equation, which involves more terms than its control counterpart, (145), be written in a readable way, we make three more abbreviations:

$$\begin{aligned}
 \tilde{A}^\# &\triangleq (A + B_1 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# \\
 G_1^\# &\triangleq -(L + S_2^{-1} B_2' \Pi_1 - E_2 (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# \\
 &\quad - (C_2 + D_{21} (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\# F_2^\#, \\
 G_2^\# &\triangleq (C_2 + D_{21} (S_1 - E'_0 S_0 E_0)^{-1} (E'_0 S_0 - (B_1 - B_2 E_2)' \Pi_1))^\#.
 \end{aligned}
 \tag{155}$$

In these terms, the second Riccati equation is

$$(156) \quad \begin{aligned} \Pi_2(s) = & - \int_{t_0}^s \Phi_2(s, t) ((T_0 + T_0 F'_0 (T_1 - F_0 T_0 F'_0)^{-1} F_0 T_0) \\ & + \Pi_2(G'_2 T_2^{-1} G_2 - G'_1 (T_1 - F_0 T_0 F'_0)^{-1} G_1) \Pi_2)(t) \Phi_2(s, t)' dt \end{aligned}$$

where Φ_2 is generated by

$$(157) \quad \begin{aligned} A_2 \triangleq & \tilde{A} + M G_2 + T_0 F'_0 (T_1 - F_0 T_0 F'_0)^{-1} G_2 \\ & + \Pi_2(G'_2 T_2^{-1} G_2 - G'_1 (T_1 - F_0 T_0 F'_0)^{-1} G_1). \end{aligned}$$

The conclusion at this point is, as expected, the following proposition.

Proposition 4.4. *If γ is strictly suboptimal in (1) then there exist uniformly bounded, negative-definite solutions to the two Riccati equations (145) and (156), with A_1 and A_2 being exponentially stable generators, for some choice of ε . Moreover, if such solutions exist for $\varepsilon = \varepsilon_0$ then the same holds for all $\varepsilon \in (0, \varepsilon_0)$.*

Parametrization of all compensators. We start with the case of $D_{22} = 0$. The momentary deviation of the control and the disturbance of (153) from their optimal values are given by

$$(158) \quad \begin{aligned} \hat{w}^\Delta & \triangleq \hat{w} - (T_1 - F_0 T_0 F'_0)^{\#-1} (T_0 F'_0 - \Pi_2 G'_1)^{\#} \hat{x}, \\ \hat{u}^\Delta & \triangleq \hat{u} + F_2^{\#} \hat{w} - (M + \Pi_2 G'_2 T_2^{-1})^{\#} \hat{x}. \end{aligned}$$

Following the directions in the remark at the end of § 3.5 (adapted from (114) to (152) with $D_{22} = 0$), we use these definitions to obtain this next representation for $\mathcal{K}^{\#}$:

$$(159) \quad \begin{aligned} \dot{\hat{p}} & = (\tilde{A} - B_2 G_1 + (M + \Pi_2 G'_2 T_2^{-1} + B_2 F_2) G_2)^{\#} \hat{p} + G_1^{\#} \hat{y} + G_2^{\#} \hat{v}, \\ \hat{u} & = (M + \Pi_2 G'_2 T_2^{-1} + B_2 F_2)^{\#} \hat{p} - F_2^{\#} \hat{y} + \hat{v}, \\ \hat{q} & = -(B^2 + (T_0 F'_0 - \Pi_2 G'_1)(T_1 - F_0 T_0 F'_0)^{-1})^{\#} \hat{p} + \hat{y}, \\ \hat{v} & = \mathcal{K}_0^{\#} \hat{q}. \end{aligned}$$

This system's conjugate provides the parametrization of compensators in (1), as follows.

Proposition 4.5. *Suppose that $D_{22} = 0$. Then (a) γ is strictly suboptimal in (1) if and only if for some small ε there exist uniformly bounded, negative-definite solutions to the Riccati equations (145) and (156), such that the associated generators A_1 and A_2 are exponentially stable. Moreover, if such solutions exist for $\varepsilon = \varepsilon_0$ then the same holds for all $\varepsilon \in (0, \varepsilon_0)$. (b) If γ is strictly suboptimal in (1) then admissible, internally stabilizing, strictly γ -suboptimal compensators in (1) are those having realizations of the following form:*

$$(160) \quad \begin{aligned} \dot{p} & = (\tilde{A} - B_2 G_1 + (M + \Pi_2 G'_2 T_2^{-1} + B_2 F_2) G_2) p \\ & + (M + \Pi_2 G'_2 T_2^{-1} + B_2 F_2) y \\ & - (B_2 + (T_0 F'_0 - \Pi_2 G'_1)(T_1 - F_0 T_0 F'_0)^{-1}) v \\ u & = G_1 p - F_2 y + v \\ q & = G_2 p + y, \quad v = \mathcal{K}_0 q \end{aligned}$$

where \mathcal{K}_0 is the input-output mapping in an exponentially stable system, $\|\mathcal{K}_0\| < \gamma$, and the solutions to the Riccati equations are derived for some small enough ε .

The arguments in the proofs of Propositions 3.5.1 and 3.5.2, which are needed in order to complete the proof of the current statement (beyond Proposition 4.4), adapt with none but notational changes to the current situation.

When treating the general case, $D_{22} \neq 0$, we recall the following simple fact.

OBSERVATION 4.6. *Let*

$$(161) \quad \dot{x} = Ax + Bu, \quad y = Cs + Du$$

be a given system, satisfying our standard assumptions. Then the following is an internally stabilizing compensator when we set $D = 0$,

$$(162) \quad \dot{p} = Mp + Ny, \quad u = Qp + Ry,$$

and $(I + RD)^{-1} \in L_\infty$, if and only if this next compensator is admissible and internally stabilizing in the original setting.

$$(163) \quad \begin{aligned} \dot{p} &= (M - N(I + DR)^{-1}DQ)p + N(I + DR)^{-1}y, \\ u &= (I + RD)^{-1}Qp + (I + RD)^{-1}Ry. \end{aligned}$$

Outline of the proof. One easily notes that, provided $(I + RD)^{-1} \in L_\infty$, the substitution of $y - Du$ for y in (162) yields (163). That is, the same closed-loop state $\begin{pmatrix} x \\ p \end{pmatrix}$ will satisfy both (161), (162) and (161), (163) for the two alternative output functions. In particular, (162) is internally stabilizing when $D = 0$ if and only if (163) is internally stabilizing in the original setting. The equality $(I - (I + RD)^{-1}RD)^{-1} = (I + RD)^{-1}$ shows that, indeed, $(I + RD)^{-1} \in L_\infty$ is the appropriate admissibility condition. \square

Direct application of this observation to proposition 4.5 yields the following general result.

THEOREM 4.7. (a) γ is strictly suboptimal in (1) if and only if for some ε small enough the operator $S_1 - E'_0 S_0 E_0$ is uniformly positive, there exists a uniformly bounded, negative-definite solution to the Riccati equation (145) such that A_1 is exponentially stable, the operator $T_1 - F_0 T_0 F'_0$ is uniformly positive, and the Riccati equation (156) possesses a uniformly bounded, negative-definite solution such that the associated generators and A_2 is exponentially stable. Moreover, if such solutions exist for $\varepsilon = \varepsilon_0$ then the same holds for all $\varepsilon \in (0, \varepsilon_0)$. (b) If γ is strictly suboptimal in (1) then admissible, internally stabilizing, strictly γ -suboptimal compensators in (1) are those having realizations as follows: the design-free parameter is a stable linear system \mathcal{H}_0 ,

$$(164) \quad \dot{\phi} = M_0 \phi + N_0 y, \quad \psi = Q_0 \phi + R_0 y$$

with the properties (i) $\|\mathcal{H}_0\| < \gamma$ and (ii) $(I + (R_0 - F_2)D_{22})^{-1} \in L_\infty$; the compensator associated with \mathcal{H}_0 is then of the form

$$(165) \quad \begin{aligned} \begin{pmatrix} \dot{p} \\ r \end{pmatrix} &= \left(\begin{bmatrix} \Gamma_{11} & \Gamma_{12} \\ \Gamma_{21} & \Gamma_{22} \end{bmatrix} - \begin{bmatrix} \Delta_1 \\ \Delta_2 \end{bmatrix} (I + D_{22}(R_0 - F_2))^{-1} [\Theta_1 & \Theta_2] \right) \begin{pmatrix} p \\ r \end{pmatrix} \\ &+ \begin{bmatrix} \Delta_1 \\ \Delta_2 \end{bmatrix} (I + D_{22}(R_0 - F_2))^{-1} y, \\ u &= (I + (R_0 - F_2)D_{22})^{-1} [\Theta_1 & \Theta_2] \begin{pmatrix} p \\ r \end{pmatrix} + (r_0 - F_2)y \end{aligned}$$

where

$$\begin{aligned} \Gamma_{11} &\triangleq (\tilde{A} - B_2 G_1 + (M + \Pi_2 G'_2 T_2^{-1} + B_2 F_2) G_2) \\ &\quad - (B_2 + (T_0 F'_0 - \Pi_2 G'_1)(T_1 - F_0 T_0 F'_0)^{-1}) R_0 G_2 \\ \Gamma_{12} &\triangleq -(B_2 + (T_0 F'_0 - \Pi_2 G'_1)(T_1 - F_0 T_0 F'_0)^{-1}) Q_0 \\ \Gamma_{21} &\triangleq N_0 G_2 \end{aligned}$$

$$\begin{aligned}
 (166) \quad & \Gamma_{22} \triangleq M_0 \\
 & \Delta_1 \triangleq (M + \Pi_2 G_2' T_2^{-1} + B_2 F_2) \\
 & \quad - (B_2 + (T_0 F_0' - \Pi_2 G_1')(T_1 - F_0 T_0 F_0')^{-1}) R_0 \\
 & \Delta_2 \triangleq N_0 \\
 & \Theta_1 \triangleq G_1 + R_0 G_2 \\
 & \Theta_2 \triangleq Q_0
 \end{aligned}$$

and where the solutions to the Riccati equations are derived for some small ϵ .

APPROXIMATION OF THE ALGEBRAIC RICCATI EQUATION IN THE HILBERT SPACE OF HILBERT–SCHMIDT OPERATORS*

A. DE SANTIS†, A. GERMANI‡, AND L. JETTO§

Abstract. This paper deals with the problem of approximating the infinite-dimensional algebraic Riccati equation, considered as an abstract equation in the Hilbert space of Hilbert–Schmidt operators. Two kinds of approximating schemes are proposed. The first scheme exploits the already established approximability of the corresponding dynamical Riccati equation together with its time convergence toward the steady state. The second method considers a particular sequence of finite-dimensional linear equations whose solutions are proved to converge toward the exact steady-state solution of the original problem.

Key words. infinite-dimensional systems, Galerkin approximation, algebraic Riccati equation

AMS subject classifications. Q3C25, Q3E11, 41A65, 65L60

1. Introduction. Both linear quadratic (LQ) optimal control and optimal linear filtering problems for linear systems evolving in Hilbert spaces lead to an infinite-dimensional Riccati equation. This has motivated the wide interest that, for at least two decades, has been devoted to establishing conditions for the existence and uniqueness of the solution of this equation [6], [9], [10], [12]. This problem has also been considered in [8], [15], [16], [20], [26], and [32] with particular reference to the LQ optimal control, in [6], [7], [19], [29], and [36] with reference to the optimal linear filtering, and in [10] and [11] with reference to both cases. In the above papers the topic is treated in different settings according to the different forms that the infinite-dimensional Riccati equation can take, depending on the structure assumed for the system dynamics.

Because of the infinite dimensionality, this Riccati equation cannot be instrumented by the standard computation techniques used in the classical finite-dimensional case and requires various approximation methods and truncation techniques. A large number of papers have been devoted to this problem. See, for instance, [4], [14], [22], [24], [25], [27], and [28]. The methods described in these papers work by projecting the infinite-dimensional Riccati equation onto a sequence of finite-dimensional subspaces of the original Hilbert space. The exact solution of the actual Riccati equation is so approximated by a sequence of solutions of finite-dimensional approximate Riccati equations.

Particularly important is the so-called *infinite-horizon problem*, which arises when the Riccati equation admits a steady-state solution. The corresponding nondynamical equation is referred to as the *algebraic Riccati equation* (ARE) [11], [18], [20], and [38]. Unfortunately, in this case the approximation problem tends to be much more difficult than the finite-horizon problem, for which significant results are available. Such a problem was discussed in [3], [21], and [22] with reference to the LQ optimal control, under the hypothesis that both the approximate semigroups and their adjoints

converge in the Trotter-Kato sense. Moreover, these papers also assumed uniform stability of the approximating semigroups.

The finite-dimensional approximation of the ARE in the space of Hilbert-Schmidt (H.S.) operators has recently been investigated in [33] and [34] under the hypothesis that the generator of the semigroup governing the system is strongly coercive.

In the present paper the approximation problem of the ARE in Hilbert spaces is considered with reference to the optimal-linear-filtering problem. As it is well acknowledged (see, e.g., [1], [6], and [7]), such a problem can be formally stated as follows.

Let us consider the following linear infinite-dimensional system on the Hilbert space H :

$$(1.1) \quad \begin{aligned} \dot{x}(t) &= Ax(t) + B\omega(t), & x(0) &= x_0, \\ y(t) &= Cx(t) + G\omega(t), \end{aligned}$$

where the following hold:

(a) A is the infinitesimal generator of a strongly continuous semigroup $\{T(t)\}$ on H such that $\|T(t)\| \leq Me^{\gamma t}$;

(b) $\omega \in L^2(0, T; H_n)$, where H_n is the Hilbert space where the noise takes values;

(c) $B: H_n \rightarrow H$, $C: H \rightarrow H_0$ (where H_0 is the observation Hilbert space) and $G: H_n \rightarrow H_0$ are bounded linear operators, with B H.S., such that $GB^* = 0$, $GG^* = I_{H_0}$.

The precise meaning of (1.1) is

$$x(t) = T(t)x_0 + \int_0^t T(t-s)B\omega(s) ds.$$

If $L^2(0, T; H_n)$ is equipped with the standard Gauss cylinder measure (which corresponds to model ω as a white-noise process) and x_0 is a Gaussian random variable with mean vector m_0 and nuclear covariance P_0 , the filtering problem consists of finding the best linear estimate $\hat{x}(t)$ of $x(t)$, given $\{y(s); 0 \leq s \leq t\}$. It evolves according to the equation

$$\dot{\hat{x}}(t) = A\hat{x}(t) + P(t)C^*(y(t) - C\hat{x}(t)), \quad \hat{x}(0) = m_0,$$

where $P(t)$ is the unique self-adjoint, nonnegative-definite, strongly continuous solution of the following Riccati equation:

$$(1.2) \quad P(t)x = T(t)P_0T^*(t)x + \int_0^t T(t-s)(BB^* - P(s)C^*CP(s))T^*(t-s)x ds,$$

$x \in H$. If (1.2) admits a steady-state solution P_∞ , namely,

$$(1.3) \quad P_\infty x = T(t)P_\infty T^*(t)x + \int_0^t T(t-s)(BB^* - P_\infty C^*CP_\infty)T^*(t-s)x ds,$$

then P_∞ is the solution of the following ARE:

$$(1.4) \quad AP_\infty + P_\infty A^* - P_\infty C^*CP_\infty + BB^* = 0.$$

By arguing as in [20], equation (1.4) can be derived from (1.3) only for $x \in D(A^*)$, but (1.4) is justified because $AP_\infty + P_\infty A^*$ admits the unique bounded extension $P_\infty C^*CP_\infty - BB^*$ to all of H .

The H.S. property of B has been assumed because it corresponds to the physically meaningful assumption of a spatially smoothed input noise. This hypothesis implies that the covariance operator of $B\omega(t)$ is the nuclear operator BB^* . On the other hand, also in the Ito formulation of the filtering problem, the distributed Wiener process is

defined with an incremental nuclear covariance operator. Regarding the observation noise, the white-noise approach has the advantage that the covariance operator is not required to be nuclear.

If the operator B is assumed to be nuclear, the ARE can be considered as an abstract equation in the Hilbert space of H.S. operators. Therefore, the smoothness property of its solution permits us to prove the convergence of the two approximating schemes here proposed toward the exact solution, under the unique assumption that the approximating semigroups converge in the Trotter–Kato sense. If the strong-smoothness action of H.S. operators [19, pp. 1289–1290] is exploited, no hypothesis on the finite-dimensional approximability of the adjoint semigroups is required. This makes such a class of approximation schemes much more feasible, because the choice of the approximating subspaces is crucial when the domain of the infinitesimal generator of the semigroup governing the system and the domain of its adjoint have a nondense intersection. This is the case, for instance, for hereditary systems [14], [17], [22], and [24]. In these cases the choice of approximating subspaces appears to be a nontrivial issue, because the simplest way of projecting the evolution equation on a finite-dimensional subspace does not give a convergent sequence for the corresponding solutions [14], [17], [22], and [24].

In this regard, it has recently been proved [5] that the spline scheme developed in [2] is such that the strong convergence property of the adjoint semigroups does not hold. A modified version of these splines was proposed in [24], where the optimal-control approximation problem was concerned. With reference to the same problem, the averaging approximation scheme was used in [22], where the trace-norm convergence of the solution of the resulting Riccati equation was obtained. However, in the above paper the approximation problem was dealt with on the basis of a conjecture; it assumed that the approximating systems are uniformly exponentially stable for sufficiently large dimensions if the original system is exponentially stable. This conjecture was shown to be correct for the averaging projection scheme in [35, §4.2].

The present paper is organized as follows. The discussion of the ARE in the Hilbert space of H.S. operators is given in §2. Existence and uniqueness of its solution are established together with a convergent sequence approximating the solution itself. Two kinds of finite-dimensional approximation schemes for the solution are given in §3. On the basis of recent results [19] concerning finite-dimensional approximability for the finite-horizon dynamical Riccati equation, the first method reduces the approximation problem to finding a large enough horizon time for approximating the steady-state solution. It constitutes an extension of the results in [19] and provides relaxed conditions for the approximability of the solution of the ARE. The second method computes the approximate solution by means of only algebraic linear operations, which can be easily implemented. It requires the assumption concerning the exponential stability of the perturbed semigroup. Section 4 contains a numerical example concerning the filtering problem for a delay system with approximating subspaces generated by first-order splines.

2. The algebraic Riccati equation in the space of Hilbert–Schmidt operators. Let H be a real, separable Hilbert space. An H.S. operator S on H is a bounded linear operator such that

$$\sum_{i=1}^{\infty} \|Se_i\|^2 := \|S\|_{\text{H.S.}}^2 < +\infty,$$

where $\{e_i\}$ is any orthonormal basis. The space $N(H)$ of all H.S. operators on H is a

Hilbert space with the inner product

$$[S, U]_{\text{H.S.}} = \sum_{i=1}^{\infty} (Se_i, Ue_i)$$

that is independent of the basis $\{e_i\}$ [1, p. 106]. The space of self-adjoint H.S. operators is a subspace of $N(H)$, which will be denoted by $N_s(H)$. The cone of nonnegative-definite operators in $N_s(H)$ will be denoted by $N_s^+(H)$. In the following, explicit reference to the space H will be omitted when this is clear from the context.

Let us recall that N is a (left and right) ideal [23, p. 148] of the space $L(H)$ of linear bounded operators on H such that

$$(2.1) \quad \|SL\|_{\text{H.S.}} \leq \|S\|_{\text{H.S.}} \|L\|, \quad S \in N, \quad L \in L(H),$$

and, furthermore,

$$(2.2) \quad \|S\|_{\text{H.S.}} = \|S^*\|_{\text{H.S.}}, \quad S \in N.$$

In this section the following ARE will be proved to have a unique solution in N_s^+ :

$$(2.3) \quad AP + PA^* - P\Sigma P + \Lambda = 0,$$

where

(H1) A is the infinitesimal generator of a strongly continuous semigroup of operators on H , $\{T(t), t \geq 0\}$, such that $\|T(t)\| \leq Me^{\lambda t}$;

(H2) Λ is trace-class operator in N_s^+ , and Σ is a bounded self-adjoint nonnegative-definite operator (not necessarily H.S.).

The hypotheses H1 and H2 will be referred to throughout the paper, and the next theorem provides a result that will be used later.

LEMMA 2.1. *Let $\{U(t), t \geq 0\}$ be a strongly continuous semigroup of operators on H , and let*

$$(2.4) \quad S(t)X = U(t)XU^*(t), \quad X \in N.$$

Then $\{S(t), t \geq 0\}$ is a strongly continuous semigroup on N .

Proof. Only the strong continuity needs to be shown. Let K be such that for h sufficiently small

$$(2.5) \quad \|U(h)\| \leq K,$$

and it follows by (2.1), (2.2), and (2.5) that

$$(2.6) \quad \begin{aligned} \|U(h)XU^*(h) - X\|_{\text{H.S.}}^2 &= \|U(h)X(U^*(h) - I) + (U(h) - I)X\|_{\text{H.S.}}^2 \\ &\leq 2K\|(U(h) - I)X^*\|_{\text{H.S.}}^2 + 2\|(U(h) - I)X\|_{\text{H.S.}}^2. \end{aligned}$$

Consider the first term of the last inequality in (2.6).

$$\begin{aligned} \|(U(h) - I)X^*\|_{\text{H.S.}}^2 &= \sum_{i=1}^{N_r} \|(U(h) - I)X^*\phi_i\|^2 + \sum_{i=N_r+1}^{\infty} \|(U(h) - I)X^*\phi_i\|^2 \\ &\leq \sum_{i=1}^{N_r} \|(U(h) - I)X^*\phi_i\|^2 + (1+K)^2 \sum_{i=N_r+1}^{\infty} \|X^*\phi_i\|^2 \\ &\leq \varepsilon, \end{aligned}$$

provided that N_r is chosen large enough that the second term is not greater than $\varepsilon/2$, whereas the first term can be made as small as needed by choosing h sufficiently small, because of the strong continuity of $U(h)$. The proof is completed by using the same arguments for the second term of (2.6). \square

LEMMA 2.2. *Let A be the infinitesimal generator of the strongly continuous uniformly bounded semigroup $\{U(t), t \geq 0\}$. Then the unique solution of the algebraic equation in N*

$$(2.7) \quad AX + XA^* + G = 0, \quad G \in N$$

admits a unique continuous extension on H given by

$$(2.8) \quad X = \int_0^\infty S(t)G \, dt,$$

where $S(t)$ is defined as in (2.4) provided that the integral (2.8) exists.

Proof. First of all, let us observe that $S(t)$ has the associate generator \mathcal{A} on N given by

$$(2.9) \quad \mathcal{A}X = AX + XA^*,$$

with

$$D(\mathcal{A}) \subseteq \{X \in N : R(X) \subset D(A)\},$$

which is dense because of the strong continuity of $\{S(t), t \geq 0\}$. Let us consider the equation in $C(0, \infty; N)$

$$(2.10) \quad \dot{X}(t) = \mathcal{A}X(t) + G, \quad X(0) \in N$$

that admits the mild solution [11, p. 41]

$$(2.11) \quad X(t) = S(t)X(0) + \int_0^t S(t-\tau)G \, d\tau, \quad t \geq 0.$$

Moreover,

$$X = \lim_{t \rightarrow \infty} X(t) = \int_0^\infty S(\tau)G \, d\tau$$

satisfies equation (2.7), as can be readily verified. \square

The existence theorem for the solution of equation (2.3) will be proved by constructing a sequence in N_s whose limit satisfies the ARE (2.3). For this we will use the following result concerning linear perturbed equations.

THEOREM 2.1. *Let $P \in N_s^+$, and let hypotheses $H1$ and $H2$ be satisfied. Moreover, let us assume that*

(i) *$(A - P\Sigma)$ is the infinitesimal generator of an asymptotically stable C_0 -semigroup $\{T_p(t), t \geq 0\}$ such that*

$$\int_0^\infty (T_p(t)(\Lambda + P\Sigma P)T_p^*(t)z, z) \, dt < \infty, \quad \forall z \in H.$$

(ii) *$(A, \Lambda^{1/2})$ is a controllable pair (in the sense specified in [10, p. 60]). Then the equation*

$$(2.12) \quad AX + XA^* - P\Sigma X - X\Sigma P + P\Sigma P + \Lambda = 0$$

admits a unique mild solution $X \in N_s^+$ such that

(a) *X is positive definite and*

(b) *$(A - X\Sigma)$ generates an asymptotically stable C_0 -semigroup $T_x(t)$ such that*

$$(2.13) \quad \int_0^\infty (T_x(t)(\Lambda + X\Sigma X)T_x^*(t)z, z) \, dt \leq (Xz, z).$$

Proof. Equation (2.12) can be rewritten as

$$(A - P\Sigma)X + X(A - P\Sigma)^* + P\Sigma P + \Lambda = 0,$$

which is of the kind (2.7), with $G = P\Sigma P + \Lambda \in N_S$. Hence from assumption (i) on the perturbed operator and by Lemma 2.1 it follows that the unique mild solution of equation (2.12) is

$$(2.14) \quad X = \int_0^\infty T_p(t)(\Lambda + P\Sigma P)T_p^*(t) dt, \quad X \in N_S.$$

The H.S. property of X is immediate. To prove the positive definiteness, let us assume the existence of a $z \in H$, $z \neq 0$, such that

$$\begin{aligned} 0 &= (Xz, z) = \int_0^\infty (T_p(t)(\Lambda + P\Sigma P)T_p^*(t)z, z) dt \\ &= \int_0^\infty \|\Lambda^{1/2}T_p^*(t)z\|^2 dt + \int_0^\infty \|\Sigma^{1/2}PT_p^*(t)z\|^2 dt, \end{aligned}$$

from which

$$(2.15) \quad \Lambda^{1/2}T_p^*(t)z = 0, \quad t \in [0, \infty],$$

$$(2.16) \quad \Sigma^{1/2}PT_p^*(t)z = 0, \quad t \in [0, \infty].$$

Moreover, by a well-known perturbation formula for semigroups [13, p. 69], $T_p^*(t)$ satisfies the following equation:

$$T_p^*(t)z = T^*(t)z - \int_0^t T^*(t-\tau)\Sigma PT_p^*(\tau)z d\tau.$$

Premultiplying both sides by $\Lambda^{1/2}$ and taking into account (2.15) and (2.16), we have

$$(2.17) \quad \Lambda^{1/2}T^*(t)z = 0,$$

against the hypothesis of approximate controllability [11, p. 60].

To prove assertion (b), let us consider the adjoint C_o -semigroup $\{T_x^*(t), t \geq 0\}$ generated by $(A - X\Sigma)^*$. Let $y(t) = T_x^*(t)z$, $z \in H$, and consider the following Lyapunov-like function:

$$(2.18) \quad V(y) = (Xy, y).$$

We have

$$\begin{aligned} \dot{V}(y) &= (X(A - X\Sigma)^*T_x^*(t)z, T_x^*(t)z) + (XT_x^*(t)z, (A - X\Sigma)^*T_x^*(t)z) \\ &= (T_x(t)(XA^* - X\Sigma X + AX - X\Sigma X)T_x^*(t)z, z), \end{aligned}$$

and by using (2.12) we obtain

$$\begin{aligned} \dot{V}(y) &= -(T_x(t)((P - X)\Sigma(P - X) + \Lambda + X\Sigma X)T_x^*(t)z, z) \\ (2.19) \quad &\leq -(\|\Lambda^{1/2}T_x^*(t)z\|^2 + \|\Sigma^{1/2}XT_x^*(t)z\|^2) \leq 0. \end{aligned}$$

To obtain inequality (2.13), let us write

$$0 \leq V(y(t)) = V(y(0)) + \int_0^t \dot{V}(y(\tau)) d\tau.$$

By (2.18) and (2.19) it follows that

$$0 \leq (Xz, z) - \int_0^t (T_x(\tau)(\Lambda + X\Sigma X)T_x^*(\tau)z, z) d\tau, \quad \forall t \geq 0,$$

which gives (2.13) by taking the limit for t going to infinity. \square

Now we can prove the uniqueness theorem for the steady-state solution of the ARE. For this purpose we need to state in advance the following lemma.

LEMMA 2.3. *Let $\{P_n\}$ be a sequence of nonnegative definite self-adjoint H.S. operators such that $P_n \leq P_0$. Then by denoting γ the maximum eigenvalue of P_0 we have*

$$P_n^2 \leq \gamma P_0.$$

Proof. It is enough to observe that for any $x \in H$

$$\begin{aligned} (P_n^2 x, x) &= (P_n P_n^{1/2} x, P_n^{1/2} x) \leq (P_0 P_n^{1/2} x, P_n^{1/2} x) \\ &\leq \gamma (P_n^{1/2} x, P_n^{1/2} x) = \gamma (P_n x, x) \\ &\leq \gamma (P_0 x, x). \end{aligned} \quad \square$$

THEOREM 2.2. *Assume that hypotheses H_1 and H_2 are verified. For a given $P_0 \in N_S^+$ let $(A - P_0 \Sigma)$ be the infinitesimal generator of a C_0 -semigroup $\{T_0(t), t \geq 0\}$ such that*

$$(2.20) \quad \int_0^\infty (T_0(t)(\Lambda + P_0 \Sigma P_0)T_0^*(t)z, z) dt = (P_1 z, z) < \infty, \quad \forall z \in H.$$

Then the sequence $\{P_n\}$ defined by

$$(2.21) \quad P_{n+1} = \int_0^\infty T_n(t)(\Lambda + P_n \Sigma P_n)T_n^*(t) dt, \quad n = 0, 1, \dots,$$

where $T_n(t)$ is generated by $(A - P_n \Sigma)$, converges in the H.S. norm toward the H.S. operator P_∞ , provided that $(A, \Lambda^{1/2})$ is a controllable pair. Moreover, if P_1 is a trace-class operator, so is P_∞ .

Proof. Equation (2.21) is well defined for $n = 0$. Moreover, by Theorem 2.1, $P_n, n \neq 0$, is such that

$$(P_n z, z) = \int_0^\infty (T_{n-1}(t)(\Lambda + P_{n-1} \Sigma P_{n-1})T_{n-1}^*(t)z, z) dt < \infty.$$

Hence (2.21) is well defined for each n , and the sequence $Q_n \in N_S^+$ given by

$$(2.22) \quad Q_n = P_n - P_{n+1}$$

can be defined. Now let us write (2.12) for $P = P_n$ and $X = P_{n+1}$ (respectively, $P = P_{n+1}$ and $X = P_{n+2}$). Then, let us subtract the second equation so obtained from the first. By defining $Q_{n+1} = P_{n+1} - P_{n+2}$, after simple calculations we get

$$AQ_{n+1} + Q_{n+1}A^* + Q_n \Sigma Q_n - P_{n+1} \Sigma Q_{n+1} - Q_{n+1} \Sigma P_{n+1} = 0,$$

which is again of the kind (2.12). Hence from (2.14)

$$(2.23) \quad Q_{n+1} = \int_0^\infty T_{n+1}(t)Q_n \Sigma Q_n T_{n+1}^*(t) dt,$$

where the integral exists, because from (2.18) and (2.19) we have

$$(Q_{n+1}z, z) \leq - \int_0^\infty \dot{V}(y) dt \leq (P_{n+1}z, z) < \infty, \quad \forall z \in H.$$

Moreover, (2.23) implies $Q_n \geq 0$, $n = 1, 2, \dots$, so that $P_n \geq P_{n+1}$. Let us define

$$(2.24) \quad P_\infty = P_0 - \sum_{i=0}^{\infty} Q_i.$$

Now it will be shown that $P_n \downarrow P_\infty$ in the H.S. norm. First one proves that $\|P_n\|_{\text{H.S.}} \downarrow \|P_\infty\|_{\text{H.S.}}$. Now let us recall that $A \geq B$, $A, B \in N_S$ implies that $\|A\|_{\text{H.S.}} \geq \|B\|_{\text{H.S.}}$, so we get

$$(2.25) \quad \|P_1\|_{\text{H.S.}} \geq \|P_n\|_{\text{H.S.}} \geq \|P_\infty\|_{\text{H.S.}}$$

and

$$(2.26) \quad \lim_{n \rightarrow \infty} \|P_n\|_{\text{H.S.}} = p \geq \|P_\infty\|_{\text{H.S.}}$$

On the other hand, we have

$$\begin{aligned} p^2 &= \lim_{n \rightarrow \infty} \sum_{i=1}^{\infty} (P_n \phi_i, P_n \phi_i) = \lim_{n \rightarrow \infty} \sum_{i=1}^{\infty} (P_n^2 \phi_i, \phi_i) \\ &= \lim_{n \rightarrow \infty} \sum_{i=1}^{N_\varepsilon} (P_n^2 \phi_i, \phi_i) + \lim_{n \rightarrow \infty} \sum_{i=N_\varepsilon+1}^{\infty} (P_n^2 \phi_i, \phi_i) \\ &\leq \lim_{n \rightarrow \infty} \sum_{i=1}^{N_\varepsilon} (P_n^2 \phi_i, \phi_i) + \sum_{i=N_\varepsilon+1}^{\infty} \gamma(P_0 \phi_i, \phi_i), \end{aligned}$$

where the last inequality follows from Lemma 2.3.

By the H.S. property of P_n we have that for a suitable choice of N_ε

$$\begin{aligned} p^2 &\leq \lim_{n \rightarrow \infty} \sum_{i=1}^{N_\varepsilon} (P_n^2 \phi_i, \phi_i) + \frac{\varepsilon}{2} = \sum_{i=1}^{N_\varepsilon} \lim_{n \rightarrow \infty} \|P_n \phi_i\|^2 + \frac{\varepsilon}{2} \\ &\leq \sum_{i=1}^{N_\varepsilon} \|P_\infty \phi_i\|^2 + \frac{\varepsilon}{2}, \end{aligned}$$

and therefore

$$(2.27) \quad p^2 < \|P_\infty\|_{\text{H.S.}}^2 + \varepsilon.$$

Since ε is arbitrary, from (2.26) and (2.27) it follows that

$$(2.28) \quad \lim_{n \rightarrow \infty} \|P_n\|_{\text{H.S.}} = p = \|P_\infty\|_{\text{H.S.}}$$

Now, from the parallelogram law, namely, $\|X - Y\|^2 + \|X + Y\|^2 = 2\|X\|^2 + 2\|Y\|^2$, by choosing $X = P_n$ and $Y = P_\infty$ we can write

$$\begin{aligned} (2.29) \quad \|P_n - P_\infty\|_{\text{H.S.}}^2 &= 2\|P_n\|_{\text{H.S.}}^2 + 2\|P_\infty\|_{\text{H.S.}}^2 - \|P_n + P_\infty\|_{\text{H.S.}}^2 \\ &= 2\|P_n\|_{\text{H.S.}}^2 - 2\|P_\infty\|_{\text{H.S.}}^2 + \|2P_\infty\|_{\text{H.S.}}^2 - \|P_n + P_\infty\|_{\text{H.S.}}^2. \end{aligned}$$

Moreover, $P_n + P_\infty \geq 2P_\infty$, so that

$$(2.30) \quad \|P_n + P_\infty\|_{\text{H.S.}} \geq \|2P_\infty\|_{\text{H.S.}}$$

Consequently, from (2.29) and (2.30) we have

$$\|P_n - P_\infty\|_{\text{H.S.}}^2 \leq 2(\|P_n\|_{\text{H.S.}}^2 - \|P_\infty\|_{\text{H.S.}}^2),$$

which by (2.28) implies that a large enough n can be found such that

$$\|P_n - P_\infty\|_{\text{H.S.}}^2 < \varepsilon. \quad \square$$

The nuclearity of P_∞ follows from the fact that $P_\infty \leq P_1$.

Remark 2.1. Note that Theorem 2.2 does not imply that $P_1 \leq P_0$, so if $P_0 = 0$ satisfies (2.20), it can be well assumed to start the iteration.

Remark 2.2. Inequality (2.20) is not equivalent to assuming that $T_0(t)$ is exponentially stable. This stronger property is guaranteed if it is also assumed that the pair $(A, \Lambda^{1/2})$ is exponentially stabilizable [1 p. 246]. In this case the nuclearity of P_1 is also guaranteed by the nuclearity of Λ . In the following we shall assume that P_1 is trace class.

To prove that P_∞ is the unique solution of the ARE, we need to state some preliminary results.

LEMMA 2.4 [11, Thm. 2.31]. *Let Ω be the infinitesimal generator of a C_0 -semigroup $\{\Gamma(t), t \geq 0\}$ on the Banach space B such that*

$$\|\Gamma(t)\| \leq Me^{\gamma t}, \quad \gamma \neq 0, t \geq 0,$$

and let P be a bounded linear operator on B . Then $(\Omega + P)$ is the infinitesimal generator of a C_0 -semigroup $\{\Gamma_p(t), t \geq 0\}$ such that

$$\|\Gamma_p(t)\| \leq Me^{(\gamma + \|P\|)t}, \quad t \geq 0.$$

LEMMA 2.5. *The following hold:*

$$(2.31) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|T_n(t) - T_\infty(t)\|_{\text{H.S.}}^2 = 0,$$

$$(2.32) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|T_n^*(t) - T_\infty^*(t)\|_{\text{H.S.}}^2 = 0,$$

where $T_n(t)$ is defined as in Theorem 2.2 and $T_\infty(t)$ is the semigroup generated by $A - P_\infty \Sigma$.

Proof. By Lemma (2.4) we have

$$(2.33) \quad \|T_n(t)\| \leq Me^{(\lambda + \|P_n \Sigma\|)t} \leq Me^{(\lambda + \|P_1\|_{\text{H.S.}} \|\Sigma\|)t} = Me^{\alpha t},$$

where $\alpha = \lambda + \|P_1\|_{\text{H.S.}} \|\Sigma\|$. The same bound (2.33) holds for $\|T_\infty(t)\|$. From the semigroup perturbation formula [13, p. 69] we have

$$T_\infty(t)x = T_n(t)x + \int_0^t T_n(t-\tau)(P_n - P_\infty)\Sigma T_\infty(\tau)x d\tau,$$

from which, after some calculations, it follows that

$$\|T_\infty(t) - T_n(t)\|_{\text{H.S.}}^2 \leq M^2 e^{2\alpha t} T^2 \|P_\infty - P_n\|_{\text{H.S.}}^2,$$

which proves (2.31) and (2.32) in light of Theorem 2.2 and equation (2.2). \square

LEMMA 2.6. *The operator P_∞ of Theorem 2.2 satisfies the following equation:*

$$(2.34) \quad P_\infty = \int_0^T T_\infty(t)(\Lambda + P_\infty \Sigma P_\infty) T_\infty^*(t) dt + T_\infty(T) P_\infty T_\infty^*(T), \quad T > 0.$$

Moreover, the operators in N_s^+ , $\mathcal{V} = \int_0^\infty T_\infty(t)(\Lambda + P_\infty \Sigma P_\infty) T_\infty^*(t) dt$, and P_∞ are positive definite.

Proof. From

$$P_{n+1} = \int_0^T T_n(t)(\Lambda + P_n \Sigma P_n) T_n^*(t) dt + \int_T^\infty T_n(t)(\Lambda + P_n \Sigma P_n) T_n^*(t) dt$$

we easily obtain

$$\begin{aligned} P_{n+1} &= \int_0^T T_n(t)(\Lambda + P_n \Sigma P_n) T_n^*(t) dt + T_n(T) \left\{ \int_0^\infty T_n(t)(\Lambda + P_n \Sigma P_n) T_n^*(t) dt \right\} T_n^*(T) \\ &= \int_0^T T_n(t)(\Lambda + P_n \Sigma P_n) T_n^*(t) dt + T_n(T) P_{n+1} T_n^*(T), \end{aligned}$$

which gives (2.34) by taking the limit for t going to infinity. From (2.34) it follows that \mathcal{V} is well defined because necessarily $\mathcal{V} \leq P_\infty \leq P_1$. By arguing as in (2.15)–(2.17) the positive definiteness of \mathcal{V} follows from the assumed approximate controllability of $(A, \Lambda^{1/2})$. This in turn implies the positive definiteness of P_∞ . \square

LEMMA 2.7. Let $Q(\tau) \in N_s^+$ be defined as

$$(2.35) \quad Q(\tau) = T_\infty(\tau)(\Lambda + P_\infty \Sigma P_\infty) T_\infty^*(\tau),$$

with P_∞ and $T_\infty(t)$ as in Theorem 2.2 and Lemma 2.5, respectively. Then \mathcal{V} is positive definite if and only if

$$(2.36) \quad \forall x \in H, \quad \exists \tau \geq 0: (Q(\tau)x, x) > 0.$$

Proof. If $\mathcal{V} > 0$, then $\forall x \in H$

$$0 < (\mathcal{V}x, x) = \int_0^\infty (Q(\tau)x, x) d\tau,$$

which implies (2.36). On the other hand, if (2.36) is satisfied for a $\bar{\tau} > 0$, then by the strong continuity of the semigroup there exists a $\sigma > 0$ such that $(Q(\bar{\tau} + \varepsilon)x, x) > 0$, $\forall \varepsilon \in [0, \sigma]$, which guarantees the positive definiteness of \mathcal{V} . \square

Since $Q(\tau) \in N_s^+$, $\forall \tau > 0$, $\forall x \in H$, it admits the representation

$$(2.37) \quad Q(\tau)x = \sum_{i=1}^\infty \lambda_i(\tau)(x, u_i^{(\tau)})u_i^{(\tau)},$$

with

$$\sum_i \lambda_i^2(\tau) < \infty, \quad \lambda_i(\tau) \geq 0 \quad i = 1, \dots,$$

where $\{u_i^{(\tau)}\}$ is a complete orthonormal eigenfunctions system.

Denoting the set of nonnegative rationals by Z^+ , we state the following lemma.

LEMMA 2.8. With the usual notations,

$$(2.38) \quad \text{span}\{u_i^r, i = 1, 2, \dots, r \in Z^+ : \lambda_i(r) > 0\} \equiv H$$

provided that the pair $(A, \Lambda^{1/2})$ is a controllable pair.

Proof. Let us suppose there exists a nonnull $h \in H$ such that

$$(2.39) \quad (h, u_i^r) = 0, \quad i = 1, 2, \dots \quad \forall r \in Z^+, \quad \lambda_i(r) > 0.$$

Hence by (2.38) and (2.39)

$$\begin{aligned}\sum_i (h, \sqrt{\lambda_i(r)} u_i^r)^2 &= \sum_i (h, Q^{1/2}(r) u_i^r)^2 \\ &= \|Q^{1/2}(r)h\|^2 = (Q(r)h, h) = 0.\end{aligned}$$

This implies $(Q(r)h, h) = 0 \forall r \in \mathbb{R}^+$ because Z^+ is dense in \mathbb{R}^+ , and hence $(\mathcal{V}h, h) = 0$, against the hypothesis of controllability by Lemma 2.6. \square

THEOREM 2.3. *Let $\{T_\infty(t), t \geq 0\}$ be the semigroup generated by $A_\infty = A - P_\infty \Sigma$. Then there exists an orthonormal basis $\{u_i\}$ on H such that*

$$(2.40) \quad \lim_{t \rightarrow \infty} \|T(t)u_i\| = 0.$$

Proof. First, let us prove that

$$(2.41) \quad \lim_{t \rightarrow \infty} \|T_\infty(t)u_i^r\| = 0 \quad \forall u_i^r: \lambda_i(r) > 0.$$

We have

$$\begin{aligned}(P_\infty x, x) &\geq \int_r^\infty (T_\infty(t-r)Q(r)T_\infty^*(t-r)x, x) dt \\ &= \int_r^\infty (Q(r)T_\infty^*(t-r)x, T_\infty^*(t-r)x) dt \\ &= \int_r^\infty \sum_i \lambda_i(r) (T_\infty^*(t-r)x, u_i^r)^2 dt.\end{aligned}$$

Now, for any orthonormal sequence $\{\phi_l\}$ on H we have

$$\begin{aligned}\text{tr } P_\infty &\geq \sum_l (P_\infty \phi_l, \phi_l) = \sum_l \int_r^\infty \sum_i \lambda_i(r) (T_\infty^*(t-r)\phi_l, u_i^r)^2 dt \\ &= \sum_i \lambda_i(r) \int_r^\infty \|T_\infty^*(t-r)u_i^r\|^2 dt.\end{aligned}$$

Since it must be that $\text{tr } P_\infty < \infty$, (2.41) is easily seen to hold.

Let us denote by $\{\tilde{u}_i, i = 1, 2, \dots\}$ a suitable renumbering of $\{u_i^r, i = 1, 2, \dots; r \in Z^+: \lambda_i(r) > 0\}$. Finally, by denoting by $\{u_l, l = 1, 2, \dots\}$ a basis on H obtained by the Gram-Schmidt orthogonalization procedure applied to $\{\tilde{u}_i, i = 1, 2, \dots\}$, equation (2.40) follows. \square

At this point the main theorem can be proved.

THEOREM 2.4. *Let $\{T_\infty(t), t \geq 0\}$ be defined as before, and suppose there exists $M_1 < \infty$ such that $\|T_\infty(t)\| \leq M_1$. Then for any operator $\Theta \in N_S^+$ the following equation holds:*

$$(2.42) \quad \lim_{t \rightarrow \infty} \|T_\infty(t)\Theta\|_{\text{H.S.}}^2 = 0.$$

Proof. By definition of H.S. norm one has

$$\|T_\infty(t)\Theta\|_{\text{H.S.}}^2 = \sum_i \|T_\infty(t)\Theta\phi_i\|^2 = \sum_i (T_\infty(t)\Theta\phi_i, T_\infty(t)\Theta\phi_i).$$

For $\{u_l\}$ defined as in Theorem 2.3 we have

$$\Theta\phi_i = \sum_l (\Theta\phi_i, u_l)u_l,$$

and substituting in the above expression we obtain

$$\begin{aligned}
 \|T_\infty(t)\Theta\|_{\text{H.S.}}^2 &= \sum_i \sum_l (\Theta\phi_i, u_l)(T_\infty(t)u_l, T_\infty(t)\Theta\phi_i) \\
 &= \sum_i \sum_{l=1}^{\bar{N}} (\Theta\phi_i, u_l)(T_\infty(t)u_l, T_\infty(t)\Theta\phi_i) \\
 &\quad + \sum_i \sum_{l=\bar{N}+1}^{\infty} (\Theta\phi_i, u_l)(T_\infty(t)u_l, T_\infty(t)\Theta\phi_i) \\
 &\leq \sum_{l=1}^{\bar{N}} \sum_i |(\Theta\phi_i, u_l)| \cdot |(\Theta T_\infty^*(t)T_\infty(t)u_l, \phi_i)| \\
 (2.43) \quad &\quad + \left(\sum_i \sum_{l=\bar{N}+1}^{\infty} (\Theta\phi_i, u_l)^2 \right)^{1/2} \left(\sum_i \sum_{l=\bar{N}+1}^{\infty} (\Theta T_\infty^*(t)T_\infty(t)u_l, \phi_i)^2 \right)^{1/2} \\
 &\leq \sum_{l=1}^{\bar{N}} \|\Theta u_l\| \cdot \|\Theta T_\infty^*(t)T_\infty(t)u_l\| \\
 &\quad + \left(\sum_{l=\bar{N}+1}^{\infty} \|\Theta u_l\|^2 \right)^{1/2} \left(\sum_{l=\bar{N}+1}^{\infty} \|\Theta T_\infty^*(t)T_\infty(t)u_l\|^2 \right)^{1/2} \\
 &\leq \|\Theta\|^2 \cdot M_1 \cdot \sum_{l=1}^{\bar{N}} \|T_\infty(t)u_l\| + \|\Theta\|_{\text{H.S.}} \cdot M_1^2 \cdot \left(\sum_{l=\bar{N}+1}^{\infty} \|\Theta u_l\|^2 \right)^{1/2}.
 \end{aligned}$$

Since Θ is an H.S. operator, we can choose \bar{N}_ε such that

$$\|\Theta\|_{\text{H.S.}} \cdot M_1^2 \cdot \left(\sum_{l=\bar{N}_\varepsilon+1}^{\infty} \|\Theta u_l\|^2 \right)^{1/2} < \frac{\varepsilon}{2},$$

and as a consequence of Theorem 2.3 we can find T_ε in order to obtain

$$\|\Theta\|^2 \cdot M_1 \cdot \sum_{l=1}^{\bar{N}_\varepsilon} \|T_\infty(t)u_l\| < \frac{\varepsilon}{2} \quad \forall t > T_\varepsilon,$$

so that from (2.43)

$$\|T_\infty(t)\Theta\|_{\text{H.S.}}^2 < \varepsilon \quad \forall t > T_\varepsilon,$$

which proves the theorem. \square

COROLLARY 2.1. *The semigroup $T_\infty(t)$, $t \geq 0$, is strongly stable.*

Proof. For each $z \in H$, $z \neq 0$, let Θ_z be the H.S. projection operator defined as $\Theta_z x = (x, z)z$, and let us choose an orthonormal basis $\{\phi_i\}$ on H such that $\phi_1 = z/\|z\|$. We have

$$\|T_\infty(t)\Theta_z\|_{\text{H.S.}}^2 = \sum_{i=0}^{\infty} \|T_\infty(t)\Theta_z\phi_i\|^2 = \|T_\infty(t)z\|^2,$$

which proves the strong stability of $T_\infty(t)$. \square

At this point the main theorem of this section can be stated.

THEOREM 2.5. *Let P_n be as in Theorem 2.2, and let P_1 be trace class. Then the trace-class operator P_∞ given by (2.34) is the unique solution of the ARE.*

$$AP_\infty + P_\infty A^* - P_\infty \Sigma P_\infty + \Lambda = 0.$$

Proof. By (2.34) we have

$$\left\| P_\infty - \int_0^T T_\infty(t)(\Lambda + P_\infty \Sigma P_\infty) T_\infty^*(t) dt \right\|_{\text{H.S.}} = \|T_\infty(\tau)P_\infty^{1/2}\|_{\text{H.S.}}^2,$$

where the right-hand side goes to zero for T going to infinity by Theorem 2.4 because $P_\infty^{1/2} \in N$. Hence

$$(2.44) \quad P_\infty = \int_0^\infty T_\infty(t)(\Lambda + P_\infty \Sigma P_\infty) T_\infty^*(t) dt.$$

Now, following the reasoning of [22, pp. 557–558], where the dual control problem is considered, one has that P_∞ maps the domain of A^* into the domain of A . Hence, by differentiating (2.44) we obtain

$$(2.45) \quad 0 = T_\infty(t)[AP_\infty + P_\infty A^* + \Lambda - P_\infty \Sigma P_\infty] T_\infty^*(t) \quad \forall t \geq 0.$$

Equation (2.45) implies that P_∞ is a solution of the ARE.

For the uniqueness let P and S be two such solutions, and let $\{T_q(t), t \geq 0\}$ and $\{T_p(t), t \geq 0\}$ be the semigroups generated by $(A - Q\Sigma)$ and $(A - P\Sigma)$, respectively. We find that the operator $E = P - Q$ satisfies

$$(A - Q\Sigma)E + E(A - Q\Sigma)^* - E\Sigma E = 0,$$

from which

$$(2.46) \quad E = - \int_0^\infty T_q(t) E \Sigma E T_q^*(t) dt.$$

Considering now the operator $F = Q - P$ and arguing as before, we readily obtain

$$(2.47) \quad F = - \int_0^\infty T_p(t) F \Sigma F T_p^*(t) dt.$$

From (2.46) and (2.47) it follows that $E = P - Q < 0$ and $F = Q - P < 0$. Hence it must be that $P = Q$. \square

3. Approximation methods.

3.1. Dynamic approximation. This approximation method is based on hypotheses H1 and H2 of § 2 and the trace-class property of the operator P_1 defined in Theorem 2.2. Moreover, it is assumed that $\forall x \in H$

$$(3.1) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|\Pi_n T(t)x - T_n(t)\Pi_n x\| = 0,$$

where

(i) Π_n is a projection operator on the finite-dimensional subspace $H_n \subset H$ such that $R(\Pi_n^*) \subset D(A)$ and $\Pi_n^* \Pi_n$ is strongly convergent to the identity on H . Therefore, $\|\Pi_n\| \leq M < \infty \forall n$ and for a suitably chosen M .

(ii) $T_n(t)$ is the semigroup generated by $\Pi_n A \Pi_n^*$.

Necessary and sufficient conditions for (3.1) to hold are established in the Trotter-Kato theorem (see, e.g., [31, p. 87]).

To state the convergence results for this approximation method we need to recall some results concerning the finite-horizon approximation of the Riccati equation.

Let $P(t)$ be the solution of the Riccati equation in $C(0, T; N_s^+(H))$,

$$(3.2) \quad P(t) = T(t)P(0)T^*(t) + \int_0^t T(t-s)[\Lambda - P(s)\Sigma P(s)]T(t-s)^* ds,$$

where Λ and Σ are as in hypothesis H2, $P(0)$ is trace class, and $P^{[n]}(t)$ is the solution

on $C(0, T; N_s^+(H_n))$ of

$$(3.3) \quad \begin{aligned} P^{[n]}(t) &= T_n(t) \Pi_n P(0) \Pi_n^* T_n^*(t) \\ &+ \int_0^t T_n(t-s) [\Pi_n A \Pi_n^* - P^{[n]}(s) \Pi_n \Sigma \Pi_n^* P^{[n]}(s)] T_n^*(t-s) ds. \end{aligned}$$

Then the following theorem holds [19]:

THEOREM 3.1. *Under hypothesis (3.1), for any $T > 0$*

$$(3.4) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|P^{[n]}(t) - \Pi_n P(t) \Pi_n^*\|_{\text{H.S.}} = 0.$$

This allows us to prove the following theorem:

THEOREM 3.2. *For each $\varepsilon > 0$ there exists a T_ε such that for any $T > T_\varepsilon$ an integer n_T exists such that for any $n > n_T$ the following holds:*

$$(3.5) \quad \|P^{[n]}(T) - \Pi_n P_\infty \Pi_n^*\|_{\text{H.S.}} < \varepsilon,$$

where $P^{[n]}(T)$ is the solution of (3.3) and P_∞ is the solution of the ARE.

Proof.

$$(3.6) \quad \|P^{[n]}(T) - \Pi_n P_\infty \Pi_n^*\|_{\text{H.S.}} \leq \|P^{[n]}(T) - \Pi_n P(T) \Pi_n^*\|_{\text{H.S.}} + M^2 \|P(T) - P_\infty\|_{\text{H.S.}}.$$

As in [19, p. 1299], the duality with the infinite-horizon control problem allows us to exploit the results stated in [22, Thm. 4.3] to prove that the following inequality holds:

$$(3.7) \quad 0 \leq P(t, \theta) - P_\infty \leq T_\infty(t) \theta T_\infty^*(t), \quad t > 0,$$

where $P(t, \theta)$ is the solution of (3.2) with $\theta = P(0)$, $\theta > P_\infty$ and is trace class, and $T_\infty(t)$ is the semigroup generated by $(A - P_\infty \Sigma)$. By (3.7) and Theorem 2.5 a sufficiently large T_ε can be found such that $\forall T > T_\varepsilon$

$$(3.8) \quad \|P(T, \theta) - P_\infty\|_{\text{H.S.}} < \varepsilon/2M^2.$$

By Theorem 3.1 it follows that $\forall T > T_\varepsilon$ there exists a n_T such that $\forall n > n_T$

$$\|P^{[n]}(T) - \Pi_n P(T) \Pi_n^*\|_{\text{H.S.}} < \varepsilon/2,$$

which, together with (3.8), implies (3.5). \square

Remark 3.1. Theorem 3.2 represents an extension of [19, Thm. 5] because of the quite restrictive hypothesis about the semigroup $T(t)$ generated by the operator A assumed there, i.e.,

$$\|T(t)\| \leq e^{-\omega t}, \quad \omega > \|A^{1/2}\| \|\Sigma^{1/2}\|$$

is now removed. In fact, any $\omega > 0$ is sufficient to guarantee that P_1 is trace class, so that Theorem 3.2 applies.

3.2. Algebraic approximation. This second approximation method is again based on hypotheses H1 and H2 of § 2, on the nuclearity of P_1 , and on the Trotter-Kato convergence of the approximating semigroup (3.1). Moreover, it is assumed that the semigroup $T_\infty(t)$ generated by $(A - P_\infty \Sigma)$ is exponentially stable, i.e.,

$$(3.9) \quad \|T_\infty(t)\| \leq e^{-\sigma t}, \quad \sigma > 0, \quad t \geq 0.$$

By the perturbation formula of semigroups (see Lemma 2.4) it can be shown that (3.9) implies that a constant λ exists such that

$$(3.10) \quad \|T(t)\| \leq e^{\lambda T}, \quad T \geq 0,$$

which is equivalent to the dissipativity of $A - \lambda I$. Inequality (3.10) implies that the semigroup $T_n(t)$ generated by $\Pi_n A \Pi_n^*$ is such that $\|T_n(t)\| \leq e^{\lambda t}$, $t \geq 0$, $n = 1, 2, \dots$ [37]. Let $\{P_n\}$ be the sequence of H.S. operators, decreasing to P_∞ , already computed in Theorem 2.2, and assume that P_0 is close enough to P_∞ to verify

$$\|P_0 - P_\infty\|_{\text{H.S.}} \cdot \|\Sigma\| < \sigma.$$

By the monotonicity of $\{P_n\}$ it follows that

$$(3.11) \quad \|P_n - P_\infty\|_{\text{H.S.}} \cdot \|\Sigma\| \leq \|P_0 - P_\infty\|_{\text{H.S.}} \cdot \|\Sigma\| < \sigma.$$

Note that such a choice of P_0 is always possible by assuming as P_0 the n th term of the sequence $\{P_n\}$ for a suitable n .

LEMMA 3.1. *The sequence of semigroups $\{T_k(t)$, $t \geq 0\}$ generated by the operators $(A - P_k)\Sigma$, $k = 0, 1, \dots$, satisfies the following inequality:*

$$(3.12) \quad \|T_k(t)\| \leq e^{-2\mu t}, \quad t \geq 0, \quad k = 0, 1, \dots,$$

where μ is a positive constant defined by

$$\mu = \frac{1}{2}(\sigma - \|(P_0 - P_\infty)\| \|\Sigma\|) > 0.$$

Proof. The proof is easily achieved with Lemma 2.4 by setting $\Omega = A - P_\infty \Sigma$ and $P = (P_\infty - P_k)\Sigma$ and by considering (3.11). \square

Now let $\{\Pi_n\}$ be a sequence of finite-dimensional orthoprojectors on H such that $\Pi_n H = H_n \subset D(A)$ strongly converges to the identity, and define

$$(3.13) \quad \Sigma_n = \Pi_n \Sigma \Pi_n, \quad A_n = \Pi_n A \Pi_n, \quad P_k^{(n)} = \Pi_n P_k \Pi_n.$$

Moreover, let Λ_n be such that

- (i) $\Lambda_n = \Lambda_n^T$;
- (ii) $\Lambda_n = \Pi_n \Lambda_n \Pi_n$;
- (iii) $\|\Lambda_n - \Lambda\|_{\text{H.S.}} \rightarrow 0$ as $n \rightarrow \infty$;
- (iv) $(A_n, \Lambda_n^{1/2})$ is a controllable couple $\forall n$.

A possible choice of Λ_n satisfying (i)–(iv) is

$$\Lambda_n = \Pi_n (\Lambda + E_n) \Pi_n,$$

where

$$E_n x = \frac{1}{n} \sum_{i=1}^{\infty} \frac{(x, \phi_i)}{2^i} \phi_i, \quad x \in H$$

for any orthonormal basis $\{\phi_i\}$ on H . In fact, E_n is a full-rank operator whose H.S. norm is $1/n$.

For each n let $\{\bar{P}_k^{(n)}\}$ be a sequence of positive-definite self-adjoint finite-rank operators converging to $\bar{P}^{(n)}$ defined by

$$(3.14) \quad \bar{P}_{k+1}^{(n)} = \int_0^\infty \bar{T}_k^{(n)}(t) [\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) dt, \quad k = 0, 1, \dots,$$

$$\bar{P}_0^{(n)} = P_0^{(n)},$$

where $\{\bar{T}_k^{(n)}(t)$, $t \geq 0\}$ is the semigroup generated by the operator $(A_n - \bar{P}_k^{(n)} \Sigma_n)$. The positive definiteness of $\bar{P}_k^{(n)}$ follows from (iv) as in Lemma 2.6. By Theorem 2.2 it follows that if $\bar{P}_k^{(n)}$ is well defined, then the same is true for $\bar{P}_{k+1}^{(n)}$ and we have

$$(3.15) \quad \bar{P}_{k+1}^{(n)} \leq \bar{P}_k^{(n)}.$$

Let $\{T_k^{(n)}(t), t \geq 0\}$ and $\{\hat{T}_k^{(n)}(t), t \geq 0\}$ be the semigroups generated by $(A_n - P_k^{(n)}\Sigma_n)$ and $(A_n - \Pi_n P_k \Sigma \Pi_n)$, respectively. By considering (3.14) we see that

$$(3.16) \quad \bar{T}_0^{(n)}(t) = T_0^{(n)}(t).$$

Note that condition (3.12) implies [37] the following uniform-growth condition on $\hat{T}_k^{(n)}(t)$:

$$\|\hat{T}_k^{(n)}(t)\| \leq e^{-2\mu t}, \quad t \geq 0.$$

So by Lemma 2.4

$$(3.17) \quad \|T_k^{(n)}(t)\| \leq e^{(-2\mu t)} \cdot e^{(\|\Pi_n P_k \Sigma \Pi_n - P_k^{(n)}\Sigma_n\| t)}$$

provided that we set $\Omega = A_n - \Pi_n P_k \Sigma \Pi_n$ and $P = \Pi_n P_k \Sigma \Pi_n - P_k^{(n)}\Sigma_n$. Now we can prove the following lemmas.

LEMMA 3.2. *Let P_k be defined as in Theorem 2.2, and let $P_k^{(n)}$ and Σ_n be defined as in (3.13). Then for each $\varepsilon > 0$ a n_ε exists such that*

$$(3.18) \quad \|P_k^{(n)} - P_k\|_{\text{H.S.}} < \varepsilon \quad \forall n > n_\varepsilon$$

uniformly with respect to $k = 1, 2, \dots$,

$$(3.19) \quad \|P_k \Sigma (I - \Pi_n)\|_{\text{H.S.}} < \varepsilon \quad \forall n > n_\varepsilon$$

uniformly with respect to $n = 1, 2, \dots$,

$$(3.20) \quad \|\Pi_n P_k \Sigma \Pi_n - P_k^{(n)}\Sigma_n\|_{\text{H.S.}} < \varepsilon \quad \forall n > n_\varepsilon$$

uniformly with respect to $k = 1, 2, \dots$.

Proof. After choosing an orthonormal basis $\{\varphi_i\}$ on H such that $\{\varphi_i, i = 1, \dots, n\}$ is a basis on H_n , by simple calculations one obtains

$$(3.21) \quad \begin{aligned} \|\Pi_n P_k \Pi_n - P_k\|_{\text{H.S.}} &\leq 2\|P_k(\Pi_n - I)\|_{\text{H.S.}} \\ &= 2\left(\sum_{i=n+1}^{\infty} \|P_k \varphi_i\|^2\right)^{1/2} = 2\left(\sum_{i=n+1}^{\infty} (P_k^2 \varphi_i, \varphi_i)\right)^{1/2}. \end{aligned}$$

Taking into account Lemma 2.3 and that $P_k \leq P_1$ by Theorem 2.2, one has that the right-hand side of (3.21) is bounded by $2(\gamma \Sigma_{i=n+1}^{\infty} (P_1 \varphi_i, \varphi_i))^{1/2}$, where γ is the maximum eigenvalue of P_1 , so from the trace-class property of P_1 it follows that a n'_ε can be found such that (3.18) is satisfied.

Analogously, we have

$$\begin{aligned} \|P_k \Sigma (I - \Pi_n)\|_{\text{H.S.}} &= \left(\sum_{i=n+1}^{\infty} \|P_k \Sigma \varphi_i\|^2\right)^{1/2} \\ &= \left(\sum_{i=n+1}^{\infty} (P_k^2 \Sigma \varphi_i, \Sigma \varphi_i)\right)^{1/2} \leq \left(\gamma \sum_{i=n+1}^{\infty} (\Sigma^* P_1 \Sigma \varphi_i, \varphi_i)\right)^{1/2}, \end{aligned}$$

which is less than ε for $n > n''_\varepsilon$, because $\Sigma^* P_1 \Sigma$ is trace class.

For (3.20) it is enough to observe that

$$\|\Pi_n P_k \Sigma \Pi_n - P_k^{(n)}\Sigma_n\|_{\text{H.S.}} \leq \|P_k(I - \Pi_n)\|_{\text{H.S.}} \|\Sigma\|,$$

which is less than ε for $n > n'''_\varepsilon$ as in (3.21). By defining $n_\varepsilon = \max\{n'_\varepsilon, n''_\varepsilon, n'''_\varepsilon\}$ the proof is achieved. \square

LEMMA 3.3. Let $\Gamma(t)$ and $\Gamma^{(n)}(t)$ be two semigroups on H and H_n , respectively, such that $\|\Gamma(t)\| \leq e^{\alpha t}$, $t \geq 0$, and $\|\Gamma_n(t)\| \leq e^{\alpha t}$, $t \geq 0$, and satisfying the Trotter-Kato convergence theorem:

$$(3.22) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|\Pi_n \Gamma(t)x - \Gamma_n(t)\Pi_n x\| = 0 \quad \forall x \in H.$$

Moreover, let P_k be defined as in Theorem 2.2, and let L be a linear operator $\in N(H)$. Then

$$(3.23) \quad \sup_{t \in [0, T]} \|(\Pi_n \Gamma(t) - \Gamma(t)\Pi_n)P_k\|_{\text{H.S.}} < \varepsilon \quad \forall n > n_\varepsilon$$

uniformly with respect to $k = 1, 2, \dots$,

$$(3.24) \quad \sup_{t \in [0, T]} \|(\Pi_n \Gamma(t) - \Gamma_n(t)\Pi_n)L\|_{\text{H.S.}} < \varepsilon \quad \forall n > m(\varepsilon, L).$$

Proof. For each P_k , by definition of H.S. norm we have

$$(3.25) \quad \begin{aligned} \|(\Pi_n \Gamma(t) - \Gamma_n(t)\Pi_n)P_k\|_{\text{H.S.}}^2 &= \sum_{i=1}^{N_{\varepsilon, k}} \|(\Pi_n \Gamma(t) - \Gamma_n(t)\Pi_n)P_k \varphi_i\|^2 \\ &+ \sum_{i=N_{\varepsilon, k}+1}^{\infty} \|(\Pi_n \Gamma(t) - \Gamma_n(t)\Pi_n)P_k \varphi_i\|^2, \end{aligned}$$

where φ_i is an orthonormal sequence on H . Let us choose $N_{\varepsilon, k}$ such that

$$\sum_{i=N_{\varepsilon, k}+1}^{\infty} \|P_k \varphi_i\|^2 < \frac{\varepsilon^2}{8} e^{-2\alpha t}.$$

So the second term on the right-hand side of (3.25) is less than $\varepsilon^2/4$. By (3.22) the finite summation in (3.25) can be made less than $\varepsilon^2/4$ by choosing n greater than a suitable integer $m(\varepsilon, P_k)$. Hence for each P_k we have

$$(3.26) \quad \sup_{t \in [0, T]} \|(\Pi_n \Gamma(t) - \Gamma^{(n)}(t)\Pi_n)P_k\|_{\text{H.S.}} \leq \varepsilon$$

for $n > m(\varepsilon, P_k)$.

Now, let K_ε be such that for any $K > K_\varepsilon$, $\|P_k - P_\infty\| < (\varepsilon/4)e^{-\alpha T}$. Then, for $K > K_\varepsilon$

$$\begin{aligned} &\|(\Pi_n \Gamma(t) - \Gamma^{(n)}(t)\Pi_n)P_k\|_{\text{H.S.}} \\ &\leq \|(\Pi_n \Gamma(t) - \Gamma^{(n)}(t)\Pi_n)(P_k - P_\infty)\|_{\text{H.S.}} + \|(\Pi_n \Gamma(t) - \Gamma^{(n)}(t)\Pi_n)P_\infty\|_{\text{H.S.}} \\ &\leq 2e^{\alpha T} \|P_k - P_\infty\|_{\text{H.S.}} + \|(\Pi_n \Gamma(t) - \Gamma^{(n)}(t)\Pi_n)P_\infty\|_{\text{H.S.}} \\ &< \varepsilon \quad \forall n > m(\varepsilon/2, P_\infty). \end{aligned}$$

By choosing $n_\varepsilon = \max\{m(\varepsilon, P_1), \dots, m(\varepsilon, P_{k_\varepsilon}), m(\varepsilon/2, P_\infty)\}$, (3.23) is achieved. Inequality (3.24) is a straightforward consequence of (3.26). \square

LEMMA 3.4. Let $\{T_k^{(n)}(t), t \geq 0\}$ and $\{T_k(t), t \geq 0\}$ be defined as before. Then an n_0 exists such that

$$(3.27) \quad \|T_k^{(n)}(t)\| \leq e^{-\mu t} \quad \forall n > n_0, \quad \forall k.$$

Moreover,

$$(3.28) \quad \sup_{t \in [0, T]} \|\Pi_n T_k(t)x - T_k^{(n)}(t)\Pi_n x\| \leq \varepsilon \quad \forall n > n_1$$

uniformly with respect to $k = 1, 2, \dots$.

Proof. Inequality (3.27) follows from (3.17) if we take into account (3.20) and choose $\varepsilon \leq \mu$. As far as (3.28) is concerned, by the perturbation formula we have $\forall x \in H$

$$\begin{aligned} T_k^{(n)}(t)\Pi_n x &= T^{(n)}(t)\Pi_n x - \int_0^t T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n) T_k^{(n)}(\tau)\Pi_n x \, d\tau, \\ T_k(t)x &= T(t)x - \int_0^t T(t-\tau)P_k \Sigma T_k(\tau)x \, d\tau, \end{aligned}$$

from which

$$\begin{aligned} & \|(\Pi_n T_k(t) - T_k^{(n)}(t)\Pi_n)x\| \\ & \leq \|(\Pi_n T(t) - T^{(n)}(t)\Pi_n)x\| \\ & \quad + \int_0^t \|(\Pi_n T(t-\tau)P_k \Sigma T_k(\tau) - T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n) T_k^{(n)}(\tau)\Pi_n)x\| \, d\tau \\ (3.29) \quad & = \|(\Pi_n T(t) - T^{(n)}(t)\Pi_n)x\| \\ & \quad + \int_0^t \|(\Pi_n T(t-\tau)P_k \Sigma - T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n)) T_k(\tau)x\| \, d\tau \\ & \quad + \int_0^t \|T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n)(\Pi_n T_k(\tau) - T_k^{(n)}(\tau)\Pi_n)x\| \, d\tau. \end{aligned}$$

The first term on the right-hand side of (3.29) is less than $\varepsilon_1 \, \forall n > n_{\varepsilon_1}$, by (3.1). For the second term we have

$$\begin{aligned} & \int_0^t \|(\Pi_n T(t-\tau)P_k \Sigma - T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n)) T_k(\tau)x\| \, d\tau \\ & \leq \int_0^t \|\Pi_n T(t-\tau)P_k - T^{(n)}(t-\tau)\Pi_n P_k\|_{\text{H.S.}} \cdot \|\Sigma \Pi_n\| \|T_k(\tau)x\| \, d\tau \\ & \quad + \int_0^t \|\Pi_n T(t-\tau)P_k \Sigma (I - \Pi_n)\|_{\text{H.S.}} \|T_k(\tau)x\| \, d\tau \\ & \leq \|\Sigma\| \cdot T \sup_{t \in [0, T]} \|(\Pi_n T(t) - T^{(n)}(t)\Pi_n)P_k\|_{\text{H.S.}} \|x\| \\ & \quad + T e^{\lambda T} \|x\| \|P_k \Sigma (I - \Pi_n)\|_{\text{H.S.}} < \varepsilon_1 \quad \forall n > n'_{\varepsilon_1} \end{aligned}$$

uniformly with respect to $k = 1, 2, \dots$, by (3.19) and (3.23) when we take into account that $T(t)$ and $T_n(t)$ satisfy the condition of Lemma 3.3.

For the third term of right-hand side of (3.29) we have, taking into account that $\|P_k\|_{\text{H.S.}} \leq \|P_0\|_{\text{H.S.}}$,

$$\begin{aligned} & \int_0^t \|T^{(n)}(t-\tau)(\Pi_n P_k \Sigma \Pi_n)(\Pi_n T_k(\tau) - T_k^{(n)}(\tau)\Pi_n)x\| \, d\tau \\ & \leq e^{\lambda T} \|P_0\|_{\text{H.S.}} \|\Sigma\| \int_0^T \|(\Pi_n T_k(\tau) - T_k^{(n)}(\tau)\Pi_n)x\| \, d\tau. \end{aligned}$$

So it follows that $\forall n > \max\{n_{\varepsilon_1}, n'_{\varepsilon_1}\}$

$$\begin{aligned} & \|(\Pi_n T_k(t) - T_k^{(n)}(t)\Pi_n)x\| \leq 2\bar{\varepsilon} + e^{\lambda T} \|P_0\|_{\text{H.S.}} \cdot \|\Sigma\| \\ & \quad \cdot \int_0^T \|(\Pi_n T_k(\tau) - T_k^{(n)}(\tau)\Pi_n)x\| \, d\tau. \end{aligned}$$

Finally, (3.28) follows from the Gronwall inequality if we choose ε_1 such that

$$\varepsilon = 2 \exp\{e^{\lambda T} \|P_0\|_{\text{H.S.}} \|\Sigma\| T\} \cdot \varepsilon_1. \quad \square$$

Before proving the final convergence results, we observe that from $\|P_k\|_{\text{H.S.}} \leq \|P_0\|_{\text{H.S.}}$ and by definition of $P_k^{(n)}$ and Σ_n it follows that inequality (3.17) implies

$$(3.30) \quad \|T_k^{(n)}(t)\| \leq e^{\alpha t}, \quad t \geq 0, \quad \alpha = 2(-\mu + \|P_0\|_{\text{H.S.}} \|\Sigma\|),$$

so by (3.12) it is also true that

$$(3.31) \quad \|T_k(t)\| \leq e^{\alpha t}, \quad t \geq 0.$$

Moreover, if we set $\Omega = A_n - P_k^{(n)} \Sigma_n$ and $P = (P_k^{(n)} - \bar{P}_k^{(n)}) \Sigma_n$, Lemma 2.4 and inequality (3.17) give

$$(3.32) \quad \bar{T}_k^{(n)}(t) \leq e^{(-2\mu + \|\Pi_n P_k \Sigma \Pi_n - P_k^{(n)} \Sigma_n\| + \|P_k^{(n)} - \bar{P}_k^{(n)}\| \Sigma_n) t},$$

which, after we take into account that $\bar{P}_k^{(n)} \leq \bar{P}_0^{(n)} = P_0^{(n)}$, implies

$$(3.33) \quad \bar{T}_k^{(n)}(t) \leq e^{-\beta t}, \quad t \geq 0, \quad \beta = -2(\mu + 2\|P_0\| \cdot \|\Sigma\|),$$

LEMMA 3.5. Assume that for a given k

$$(3.34) \quad \lim_{n \rightarrow \infty} \|\bar{P}_k^{(n)} - P_k^{(n)}\|_{\text{H.S.}} = 0.$$

Then

$$(3.35) \quad \lim_{n \rightarrow \infty} \sup_{t \in [0, T]} \|\bar{T}_k^{(n)}(t) - T_k^{(n)}(t)\| = 0.$$

Proof. Again, using the perturbation formula yields

$$\begin{aligned} \|\bar{T}_k^{(n)}(t) - T_k^{(n)}(t)\| &= \left\| \int_0^t T_k^{(n)}(t-\tau) [(\bar{P}_k^{(n)} - P_k^{(n)}) \Sigma_n] \bar{T}_k^{(n)}(\tau) d\tau \right\| \\ &\leq \int_0^t \|T_k^{(n)}(t-\tau)\| \cdot \|\bar{T}_k^{(n)}(\tau)\| \cdot \|(\bar{P}_k^{(n)} - P_k^{(n)}) \Sigma_n\| d\tau. \end{aligned}$$

Moreover, from (3.34), for n large enough

$$\|(\bar{P}_k^{(n)} - P_k^{(n)}) \Sigma_n\| \leq \hat{\varepsilon} \quad \forall n > n_{\varepsilon, k}.$$

By (3.33) there exists a constant $M > 0$ such that

$$\sup_{t \in [0, T]} \|\bar{T}_k^{(n)}(t)\| = M.$$

Moreover, by (3.27) and (3.34) it follows that

$$\sup_{t \in [0, T]} \|\bar{T}_k^{(n)}(t) - T_k^{(n)}(t)\| \leq \sup_{t \in [0, T]} \hat{\varepsilon} M \int_0^t e^{-\mu(t-\tau)} d\tau < \frac{\hat{\varepsilon} M}{\mu},$$

which proves (3.35). \square

THEOREM 3.3. Let $P_k^{(n)}$ and $\bar{P}_k^{(n)}$ be defined by (3.13) and (3.14), respectively. Then for any k

$$(3.36) \quad \lim_{n \rightarrow \infty} \|P_k^{(n)} - \bar{P}_k^{(n)}\|_{\text{H.S.}} = 0 \quad \forall k.$$

Proof. From (3.14) and (3.16) we have

$$\begin{aligned}
 & \|\bar{P}_1^{(n)} - P_1^{(n)}\|_{\text{H.S.}} \\
 &= \left\| \int_0^\infty T_0^{(n)}(t)[\Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}]T_0^{(n)*}(t) dt \right. \\
 &\quad \left. - \Pi_n \int_0^\infty T_0(t)[\Lambda + P_0\Sigma P_0]T_0^*(t) dt \Pi_n \right\|_{\text{H.S.}} \\
 &\leq \left\| \int_0^{T_\varepsilon} (T_0^{(n)}(t)[\Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}]T_0^{(n)*}(t) - \Pi_n T_0(t)[\Lambda + P_0\Sigma P_0]T_0^*(t)\Pi_n) dt \right\|_{\text{H.S.}} \\
 &\quad + \left\| \int_{T_\varepsilon}^\infty T_0^{(n)}(t)[\Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}]T_0^{(n)*}(t) dt \right\|_{\text{H.S.}} \\
 &\quad + \left\| \int_{T_\varepsilon}^\infty \Pi_n T_0(t)[\Lambda + P_0\Sigma P_0]T_0^*(t)\Pi_n dt \right\|_{\text{H.S.}}.
 \end{aligned}$$

From (3.12) and (3.27) we may choose an $n > n_0$ such that the above expression is less than or equal to

$$\begin{aligned}
 (3.37) \quad & \left\| \int_0^{T_\varepsilon} (T_0^{(n)}(t)[\Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}]T_0^{(n)*}(t) - \Pi_n T_0(t)[\Lambda + P_0\Sigma P_0]T_0^*(t)\Pi_n) dt \right\|_{\text{H.S.}} \\
 & + \int_{T_\varepsilon}^\infty e^{-2\mu t}(\|\Lambda_n\|_{\text{H.S.}} + \|P_0^{(n)}\|_{\text{H.S.}}^2\|\Sigma_n\|) dt + \int_{T_\varepsilon}^\infty e^{-4\mu t}(\|\Lambda\|_{\text{H.S.}} + \|P_0\|_{\text{H.S.}}^2\|\Sigma\|) dt.
 \end{aligned}$$

Let us choose T_ε such that

$$\begin{aligned}
 & \|P_1^{(n)} - \bar{P}_1^{(n)}\|_{\text{H.S.}} \leq \frac{\varepsilon}{2} + \left\| \int_0^{T_\varepsilon} (T_0^{(n)}(t)[\Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}]T_0^{(n)*}(t) \right. \\
 &\quad \left. - \Pi_n T_0(t)[\Lambda + P_0\Sigma P_0]T_0^*(t)\Pi_n) dt \right\|_{\text{H.S.}} \\
 &\leq \frac{\varepsilon}{2} + \int_0^{T_\varepsilon} \|T_0^{(n)}\Pi_n L_n \Pi_n T_0^{(n)*}(t) \\
 &\quad - \Pi_n T_0(t)L T_0^*(t)\Pi_n\|_{\text{H.S.}} dt,
 \end{aligned}$$

where

$$L = \Lambda + P_0\Sigma P_0, \quad L_n = \Lambda_n + P_0^{(n)}\Sigma_n P_0^{(n)}.$$

Note that

$$(3.38) \quad \lim_{n \rightarrow \infty} \|L - L_n\|_{\text{H.S.}} = 0$$

by the H.S. property of P_0 and by definition of Λ_n and $P_0^{(n)}$.

Hence by simple calculation we have

$$\begin{aligned}
 & \|P_1^{(n)} - \bar{P}_1^{(n)}\|_{\text{H.S.}} \leq \frac{\varepsilon}{2} + \int_0^{T_\varepsilon} (\|T_0^{(n)}(t)\| \|T_0^{(n)*}(t)\| \|L_n - L\|_{\text{H.S.}} \\
 &\quad + \|(T_0^{(n)}(t)\Pi_n - \Pi_n T_0(t))L\|_{\text{H.S.}} \cdot \|T_0^{(n)*}(t)\| \\
 &\quad + \|T_0(t)\| \|L(\Pi_n T_0^{(n)*}(t) - T_0^*(t)\Pi_n)\|_{\text{H.S.}}) dt.
 \end{aligned}$$

Now let us observe that because of (3.28), (3.30), and (3.31) the semigroups $T_k(t)$ and $T_k^{(n)}(t)$ satisfy the condition of Lemma 3.3, so by (3.24), property (2.2) of H.S. operators, and (3.38) it follows that the integral on the right-hand side of the last inequality is less than $\varepsilon/2$ for $n > n_\varepsilon$. Hence, given $\varepsilon > 0$, there exists a $n_\varepsilon > n_1$ such that $\forall n > n_\varepsilon$

$$(3.39) \quad \|P_1^{(n)} - \bar{P}_1^{(n)}\|_{\text{H.S.}} < \varepsilon.$$

Now let us suppose that property (3.36) holds for a given k . We will show the same is true for $k+1$. We have

$$\begin{aligned} & \|\bar{P}_{k+1}^{(n)} - P_{k+1}^{(n)}\|_{\text{H.S.}} \\ &= \left\| \int_0^\infty \bar{T}_k^{(n)}(t) [\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) dt \right. \\ & \quad \left. - \Pi_n \int_0^\infty T_k(t) [\Lambda + P_k \Sigma P_k] T_k^*(t) dt \Pi_n \right\|_{\text{H.S.}} \\ &\leq \left\| \int_0^{T_\varepsilon} (\bar{T}_k^{(n)}(t) [\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) - \Pi_n T_k(t) [\Lambda + P_k \Sigma P_k] T_k^*(t) \Pi_n) dt \right\|_{\text{H.S.}} \\ & \quad + \left\| \int_{T_\varepsilon}^\infty \bar{T}_k^{(n)}(t) [\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) dt \right\|_{\text{H.S.}} \\ & \quad + \left\| \int_{T_\varepsilon}^\infty \Pi_n T_k(t) [\Lambda + P_k \Sigma P_k] T_k^*(t) \Pi_n dt \right\|_{\text{H.S.}}. \end{aligned}$$

By (3.32), taking into account (3.20), the assumption on the k th step, and the uniform boundedness of Σ_n , for n large enough we obtain

$$\|\bar{T}_k^{(n)}(t)\| \leq e^{(-2\mu+2\varepsilon)t} = e^{-\mu't}, \quad 0 < \mu' = 2\mu - 2\varepsilon.$$

Now, by taking the norm in the above integral expression, it follows that

$$\begin{aligned} \|\bar{P}_{k+1}^{(n)} - P_{k+1}^{(n)}\|_{\text{H.S.}} &\leq \left\| \int_0^{T_\varepsilon} (\bar{T}_k^{(n)}(t) [\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) \right. \\ & \quad \left. - \Pi_n T_k(t) [\Lambda + P_k \Sigma P_k] T_k^*(t) \Pi_n) dt \right\|_{\text{H.S.}} \\ & \quad + \int_{T_\varepsilon}^\infty e^{-2\mu't} \|\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}\|_{\text{H.S.}} dt \\ & \quad + \int_{T_\varepsilon}^\infty e^{-4\mu't} (\|\Lambda\|_{\text{H.S.}} + \|P_0\|_{\text{H.S.}}^2 \|\Sigma\|) dt. \end{aligned}$$

Taking into account that $\bar{P}_k^{(n)} \leq \bar{P}_1^{(n)}$, we can find a suitable constant q such that $\forall n$ we have

$$\begin{aligned} \|\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}\|_{\text{H.S.}} &\leq \|\Lambda_n - \Lambda\|_{\text{H.S.}} + \|\Lambda\|_{\text{H.S.}} + \|\bar{P}_k^{(n)}\|_{\text{H.S.}}^2 \|\Sigma_n\| \\ &\leq \|\Lambda_n - \Lambda\|_{\text{H.S.}} + \|\Lambda\|_{\text{H.S.}} + (\|\bar{P}_1^{(n)} - P_1^{(n)}\|_{\text{H.S.}} + \|P_1^{(n)}\|_{\text{H.S.}})^2 \|\Sigma\| \leq q \end{aligned}$$

because Λ_n is uniformly converging to Λ in the H.S. norm and by (3.39). Hence a T_ε exists such that

$$(3.40) \quad \|\bar{P}_{k+1}^{(n)} - P_{k+1}^{(n)}\|_{\text{H.S.}} \leq \frac{\varepsilon}{2} + \left\| \int_0^{T_\varepsilon} (\bar{T}_k^{(n)}(t)[\Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)}] \bar{T}_k^{(n)*}(t) - \Pi_n T_k(t)[\Lambda + P_k \Sigma P_k] T_k^*(t) \Pi_n) dt \right\|_{\text{H.S.}}.$$

By defining

$$L_{n,k} = \Lambda_n + \bar{P}_k^{(n)} \Sigma_n \bar{P}_k^{(n)},$$

$$L_k = \Lambda + P_k \Sigma P_k,$$

we have

$$(3.41) \quad \lim_{n \rightarrow \infty} \|L_{n,k} - L_k\|_{\text{H.S.}} = 0.$$

To prove (3.41) it is enough to observe that

$$\|L_{n,k} - L_k\|_{\text{H.S.}} \leq \|\Lambda - \Lambda_n\|_{\text{H.S.}} + \|\bar{P}_k^{(n)} - P_k^{(n)}\|_{\text{H.S.}} + \|P_k^{(n)} - P_k\|_{\text{H.S.}}$$

and to take into account the convergence of Λ_n to Λ in the H.S. norm, the assumption on the k th step, and (3.18). Hence by arguing as in the derivation of (3.39) we have that

$$(3.42) \quad \begin{aligned} \|\bar{P}_{k+1}^{(n)} - P_{k+1}^{(n)}\|_{\text{H.S.}} &\leq \frac{\varepsilon}{2} + \int_0^{T_\varepsilon} (\|\bar{T}_k^{(n)}(t)\| \|\bar{T}_k^{(n)*}(t)\| \|L_{n,k} - L_k\|_{\text{H.S.}} \\ &\quad + \|(\bar{T}_k^{(n)}(t) \Pi_n - \Pi_n T_k(t)) L_k\|_{\text{H.S.}} \cdot \|\bar{T}_k^{(n)*}(t)\| \\ &\quad + \|T_k(t)\| \|L_k(\Pi_n \bar{T}_k^{(n)*}(t) - T_k^*(t) \Pi_n)\|_{\text{H.S.}}) dt. \end{aligned}$$

Moreover,

$$(3.43) \quad \begin{aligned} \|(\bar{T}_k^{(n)}(t) \Pi_n - \Pi_n T_k(t)) L_k\|_{\text{H.S.}} &\leq \|(\bar{T}_k^{(n)}(t) \Pi_n - T_k^{(n)}(t) \Pi_n) L_k\|_{\text{H.S.}} \\ &\quad + \|(T_k^{(n)}(t) \Pi_n - \Pi_n T_k(t)) L_k\|_{\text{H.S.}}. \end{aligned}$$

By (3.30), (3.33), and (3.35) the semigroups $\bar{T}_k^{(n)}(t)$ and $T_k^{(n)}(t)$ satisfy the condition of Lemma 3.3. Because the same is true for $T_k^{(n)}(t)$ and $T_k(t)$, it follows by (3.24) that the right-hand side of (3.43) is less than $\varepsilon/2 T_\varepsilon$ for $n > m(\varepsilon, L_k)$. So by taking into account property (2.2) of H.S. operators and (3.41), an $n_{\varepsilon,k}$ can be found such that the integral of (3.42) is less than $\varepsilon/2$ for $n > n_{\varepsilon,k}$.

So far we have shown that if property (3.36) holds at the k th step, it still holds at the $(k+1)$ th step. Consequently, by (3.39) the theorem is proved by induction. \square

THEOREM 3.4. *Let P_∞ be the solution of the ARE, and let $\bar{P}_k^{(n)}$ be defined by (3.14). Then, given $\varepsilon > 0$, we can choose k and n in order to obtain*

$$\|P_\infty - \bar{P}_k^{(n)}\| \leq \varepsilon.$$

Proof. By noting that

$$\begin{aligned} \|P_\infty - \bar{P}_k^{(n)}\|_{\text{H.S.}} &= \|P_\infty - P_k + P_k - P_k^{(n)} + P_k^{(n)} - \bar{P}_k^{(n)}\|_{\text{H.S.}} \\ &\leq \|P_\infty - P_k\|_{\text{H.S.}} + \|P_k - P_k^{(n)}\|_{\text{H.S.}} + \|P_k^{(n)} - \bar{P}_k^{(n)}\|_{\text{H.S.}} \end{aligned}$$

we see that the proof follows immediately if we exploit Theorem 2.2 for the first term, property (3.18) for the second term, and Theorem 3.3 for the last term. \square

4. Numerical results. As an example of application of the approximation techniques described in § 3, let us consider the filtering problem for linear hereditary systems, defined by the following equations:

$$(4.1) \quad \dot{z}(t) = \sum_{i=0}^d A_i z(t-h_i) + \int_{-r}^0 A_{01}(s) z(t+s) ds + B_0 \omega_1(t),$$

$$t \in [0, T], \quad z(0) = z_0, \quad z(s) = z_1(s), \quad -r \leq s < 0,$$

$$(4.2) \quad y(t) = C_0 z(t) + G_0 \omega_2(t),$$

where $0 = h_0 < \dots < h_d = r$, $z(t) \in \mathbb{R}^n$, $A_i \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n)$, $i = 1, \dots, d$, $A_{01} \in L^2(-r, 0; \mathcal{L}(\mathbb{R}^n, \mathbb{R}^n))$, $B_0 \in \mathcal{L}(\mathbb{R}^p, \mathbb{R}^n)$, $C_0 \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^q)$, $G_0 \in \mathcal{L}(\mathbb{R}^r, \mathbb{R}^q)$, and ω_1 and ω_2 are assumed to be standard \mathbb{R}^p -valued and \mathbb{R}^r -valued independent white-noise processes, respectively.

We consider the Hilbert space $M^2 = \mathbb{R}^n \times L_2(-r, 0; \mathbb{R}^n)$ with inner product

$$[(v_0, v_1), (u_0, u_1)] = v_0^T u_0 + \int_{-r}^0 v_1^T(s) u_1(s) g(s) ds,$$

where $g(s)$ is a step weighting function such that

$$g(s) = i \quad \text{for } -h_{d-i+1} \leq s < -h_{d-i}, \quad i = 1, \dots, d,$$

and we define the operator $A: \mathcal{D}(A) \rightarrow M^2$ by

$$\mathcal{D}(A) = \{z = (z_0, z_1) \in M^2 : z_1 \in H^1(-r, 0; \mathbb{R}^n), z_0 = z_1(0)\},$$

$$Az = \left(A_0 z_0 + \sum_{i=1}^d A_i z_1(-h_i) + \int_{-r}^0 A_{01}(s) z_1(s) ds, z_1 \right).$$

Then the operator $(A - \lambda I)$ is dissipative in M^2 , i.e., $[Az, z]_{M^2} \leq \lambda \|z\|_{M^2}^2$, $z \in \mathcal{D}(A)$, and generates a strongly continuous semigroup $T(t)$ on M^2 such that $\|T(t)z\|_{M^2} \leq e^{\lambda t} \|z\|_{M^2}$ [2]. Moreover, if $T^{(n)}(t)$ is an approximating semigroup, a constant $\bar{\gamma}$ exists such that $\|T^{(n)}(t)\| \leq \exp\{\bar{\gamma}t\}$.

By setting

$$B = \begin{bmatrix} B_0 & 0 \\ 0 & 0 \end{bmatrix}, \quad \omega^T = [\omega_1 \quad \omega_2]^T \in L_2(0, T; \mathbb{R}^{p+r}), \quad x^T = (z_0, z_1)^T,$$

$$C = [C_0 \quad 0], \quad G = [0 \quad G_0],$$

equations (4.1) and (4.2) can be rewritten as

$$(4.3) \quad x(t) = T(t)x_0 + \int_0^t T(t-s)B\omega(s) ds, \quad t \in [0, T],$$

$$(4.4) \quad y(t) = Cx(t) + G\omega(t),$$

and the solution of (4.1) is given by the first component of (4.3). Without any loss of generality we can always assume that $G_0 G_0^T = I$; moreover, B is H.S. because of the finite-dimensionality of its range.

Now, given the mean vector and the covariance operator of the initial state x_0 , the best linear estimate of $x(t)$, and consequently of $z(t)$, can be obtained by the infinite-dimensional Kalman filter.

For each n let Π_n be the projection operator on the subspace V_n generated by the following piecewise linear splines:

$$\begin{aligned} v_{i,0}^{(n)}(t) &= 1_{[-r/n,0]}(t)\{1 + (nt/r)\}e_i, \\ v_{i,m}^{(n)}(t) &= -1_{[-mr/n, -(m-1)r/n]}(t)\{m-1 + (nt)/r\} \\ &\quad \cdot 1_{[-(m+1)r/n, -mr/n]}(t)\{m+1 + (nt)/r\}e_i, \quad m = 1, \dots, 2^n - 1, \\ v_{i,n}^{(t)} &= -1_{[-1, -1+r/n]}(t)\{n-1 + (nt)/r\}e_i, \quad i = 1, 2, \dots, n, \end{aligned}$$

where e_i , $i = 1, 2, \dots, n$, is the canonical basis of \mathbb{R}^n , and we are considering $\mathcal{D}(A) \equiv H^1(-r, 0; \mathbb{R}^n)$. For such a scheme, the convergence of the approximate semigroup toward the actual one holds [2].

It is worth recalling that, as shown in [5], the above scheme does not satisfy the strong convergence property for the adjoint semigroups. Nevertheless, it can be used in the present filtering problem because both of the approximating methods proposed here do not require the fulfillment of such a property.

For the matrix representation, with respect to the selected basis, of all the operators to be used in the implementation of both the approximation methods, we refer to [2] and [19]. The numerical example proposed consists of the state estimation for the system described by the following equations:

$$(4.5) \quad \dot{x}(t) = a_0 x(t) + a_1 x(t-1) + bw(t),$$

$$(4.6) \quad y(t) = cx(t) + gv(t),$$

with initial conditions $x(s) = -50s + 50$, $-1 \leq s < 0$, and with $w(t)$ and $v(t)$ being independent standard white-noise processes.

To satisfy all the hypotheses that make the approximation theorems of § 3 hold, we imposed the stability condition $a_0 + |a_1| < 0$ [30] by choosing $a_0 = -3$, $a_1 = 2$. Moreover, we set $b = 3.5$ and $d = 2$. The system dynamic was simulated according to the following difference equations:

$$\begin{aligned} x((k+1)\Delta) &= e^{a_0\Delta}x(k\Delta) + \frac{\Delta}{2}[a_1x((k+1)\Delta - 1) + e^{a_0\Delta}a_1x(k\Delta - 1)] + w_k, \\ y(k\Delta) &= x(k\Delta) + v_k, \end{aligned}$$

where $\Delta = 0.025$, $k = 0, 1, \dots, 80$, and $\{w_k\}$ and $\{v_k\}$ are independent zero-mean Gaussian white sequences, with covariances $b^2 \int_0^\Delta \exp\{2a_0 t\} dt$ and d^2 , respectively, which were generated by using NAG FORTRAN subroutine G05DDF.

The filter was initialized with $\hat{x}_n(0) = y(0)$. The estimate $\hat{x}_n(t)$ was determined at each time instant by using the gain operator obtained off-line from the approximate solution $P_\infty^{(n)}$ of the ARE. It was computed by exploiting the two methods proposed in § 3, for $n = 3, 5, 7$. We will refer first to the method of obtaining $P_\infty^{(n)}$ through the dynamical Riccati equation evolving toward the steady state; the second method is for computing $P_\infty^{(n)}$ by algebraic linear operations.

The numerical values $\hat{x}_n(t)$, $t = k(2\Delta)$, $k = 1, 2, \dots, 40$, have been computed by integrating the approximate filter equation by means of the NAG FORTRAN subroutine D02EAF, which uses a variable-order, variable-step Gear method. The same subroutine has been also used to integrate the approximate dynamical Riccati equation and to compute the integral in equation (3.14) with null initial condition at each iteration. For both the approximation methods the achievement of numerical stability has been tested within the tolerance limit of 10^{-5} for 10 successive iterations.

For each experiment the filter performance was evaluated by computing the error statistics

$$\sigma_p^2 = \frac{1}{40} \sum_{k=1}^{40} [x(k\Delta) - \hat{x}(k\Delta)]^2$$

and by defining the signal-to-noise ratio improvement (SNRI) as

$$\text{SNRI} := 10 \log_{10}(\text{variance of observation noise} / \sigma_p^2).$$

For the first method we obtained SNRI = 1.606, 4.153, 4.382 for $n = 3, 5, 7$, respectively, and for the second method we obtained SNRI = 1.609, 4.150, 4.378 for the same respective values of n .

The whole numerical example was carried out on a VAX 780 computer. The simulation results are reported in Figs. 1, 2, and 3, corresponding to schemes of order $n = 3, 5$, and 7 , respectively. In each figure plots (a) and (b) represent the behavior of the filter built according to the first and second method, respectively. The good agreement between the two approximation methods is also evident from a comparison of the numerical values reported in Table 1.

5. Concluding remarks. The problem of approximating the infinite-dimensional algebraic Riccati equation, as an abstract equation in the Hilbert space of H.S. operators, has been considered. Two methods have been proposed. The first one is based on the results established in a previous paper, where, by exploiting the approximability of the corresponding dynamical Riccati equation and its time convergence toward the steady state, the problem was reduced to finding a large enough time horizon to approximate the steady-state solution. Here this approximation scheme has been shown to converge under more general conditions than those in the previous setting, relaxing, in particular, the strong hypothesis concerning the exponential stability of the unperturbed semigroup.

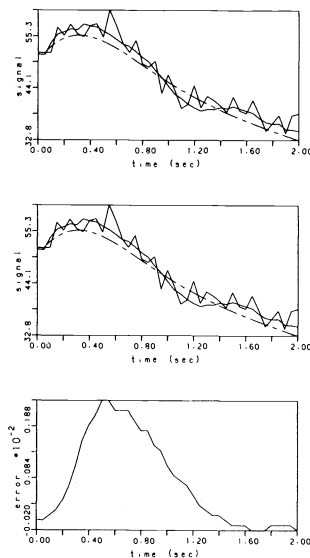

FIG. 1. Time plots of the noisy-state observation (continuous ragged line), true-state evolution (continuous smooth line), and approximate-Kalman-state estimation (dashed line) obtained with the (a) first and (b) second method with $n = 3$. (c) Time plot of the difference between the estimate values.

FIG. 2. Time plots of the noisy-state observation (continuous ragged line), true-state evolution (continuous smooth line), and approximate-Kalman-state estimation (dashed line) obtained with the (a) first and (b) second method with $n = 5$. (c) Time plot of difference between the estimate values.

FIG. 3. Time plots of the noisy-state observation (continuous ragged line), true-state evolution (continuous smooth line), and approximate-Kalman-state estimation (dashed line) obtained with the (a) first and (b) second method with $n = 7$. (c) Time plot of the difference between the estimate values.

The second method provides a scheme for computing the approximate solution by means of only algebraic linear operations under the exponential-stability assumption for the perturbed semigroup. In fact, the solutions of a sequence of finite-dimensional linear equations have been proved to converge to the exact steady-state solution of the original problem.

TABLE 1

Approximate steady-state solution of the algebraic Riccati equation $P_\infty^{(n)}$ computed by using the first and second methods with schemes of order $n = 3, 5, 7$.

	0.0159 0.0202 0.0163 0.0117 0.0093 0.0082 0.0089	0.0144 0.0186 0.0148 0.0101 0.0075 0.0064 0.0069
	0.0117 0.0163 0.0198 0.0165 0.0120 0.0094 0.0087	0.0102 0.0148 0.0182 0.0149 0.0103 0.0076 0.0067
	0.0096 0.0117 0.0165 0.0195 0.0165 0.0115 0.0095	0.0081 0.0101 0.0149 0.0177 0.0147 0.0096 0.0074
	0.0084 0.0093 0.0120 0.0165 0.0200 0.0165 0.0119	0.0068 0.0075 0.0103 0.0147 0.180 0.0144 0.0097
	0.0091 0.0082 0.0094 0.0115 0.0165 0.0194 0.0170	0.0074 0.0064 0.0076 0.0096 0.0144 0.0171 0.0146
	0.0102 0.0089 0.0087 0.0095 0.0119 0.0170 0.0182	0.0083 0.0069 0.0067 0.0074 0.0097 0.0146 0.01157

Both the solving methods work under quite general conditions that, on the other hand, do not allow for a uniform convergence of the approximate solution toward the actual one.

Finally, we wish to point out that no assumption on the finite-dimensional approximability of the adjoint semigroup is made. Such a hypothesis, which is generally requested in the literature, is often difficult to verify when $D(A) \cap D(A^*)$ is not dense. This is the case, for instance, in hereditary systems.

INTERIOR DUAL LEAST 2-NORM ALGORITHM FOR LINEAR PROGRAMS*

RUDY SETIONO†

Abstract. An interior algorithm is proposed for solving the dual of the least 2-norm formulation of a linear program. This is a convex quadratic problem with nonnegativity constraints only. Sixty-six test problems, including 63 NETLIB problems, were solved very accurately. The total time speedup of the algorithm for all 66 problems over MINOS 5.3 is 2.10. Linear convergence of the algorithm is also established.

Key words. linear programming, interior point method, Newton step

AMS subject classifications. 90C05, 90C25

1. Introduction. It is well known [16], [18] that a linear program

$$(1) \quad \min_x cx \quad \text{s.t. } Ax \geq b, \quad x \geq 0$$

is solvable if and only if the quadratic program

$$(2) \quad \min_x cx + \frac{\varepsilon}{2} xx \quad \text{s.t. } Ax \geq b, \quad x \geq 0$$

is solvable by the same \bar{x} for all $\varepsilon \in (0, \bar{\varepsilon}]$ for some $\bar{\varepsilon} > 0$. If $x(\varepsilon)$ solves the quadratic problem (2), then it is the solution of the linear program (1) that is closest to the origin in the 2-norm. The dual of the above quadratic program [14] is

$$(3) \quad \max_{x, u, v} -\frac{\varepsilon}{2} xx + bu$$

subject to

$$(4) \quad \varepsilon x - A'u - v + c = 0,$$

$$(5) \quad u, v \geq 0.$$

Elimination of x from the dual problem by using the constraint relation

$$x = \frac{1}{\varepsilon} (A'u + v - c)$$

leads to the following exterior penalty function with penalty parameter ε associated with the dual of linear program (1):

$$(6) \quad \min_{u, v} \frac{1}{2} \|A'u + v - c\|^2 - \varepsilon bu \quad \text{s.t. } u, v \geq 0.$$

The Karush–Kuhn–Tucker optimality conditions for the quadratic problem (6) can be expressed as a symmetric linear complementarity problem

$$(7) \quad Mz + q \geq 0, \quad z \geq 0, \quad z(Mz + q) = 0$$

after the following identifications have been made:

$$(8) \quad M := \begin{pmatrix} AA' & A \\ A' & I \end{pmatrix}, \quad q := \begin{pmatrix} -Ac - \varepsilon b \\ -c \end{pmatrix}, \quad z := \begin{pmatrix} u \\ v \end{pmatrix}.$$

Iterative successive overrelaxation methods have been proposed for solving the symmetric linear complementarity problems [15]. A successive overrelaxation method that preserves the sparsity structure of the problem has been implemented to solve very large linear programs [3], [19]. These large linear programs with up to 125,000 constraints and 500,000 variables are impossible to solve by using a direct method such as the simplex.

Our approach to finding the least 2-norm solution of a linear program is to use an interior penalty function. Since the only constraints present in the dual problem (6) are nonnegativity constraints, an initial starting point for the algorithm can be obtained trivially. The interiority of the iterates are easy to maintain by taking an appropriate step size. These facts constitute the motivation behind our dual interior penalty method.

We now briefly outline the contents of the paper. In § 2 we describe the algorithm, and in § 3 we establish its linear convergence. In § 4 we give computational results. In § 5 we summarize the paper.

2. Interior dual least 2-norm (IDLN) algorithm. We consider the linear program given in the standard form

$$(9) \quad \min_x cx \quad \text{s.t.} \quad Ax = b, \quad x \geq 0$$

and its dual

$$(10) \quad \max_{u,v} bu \quad \text{s.t.} \quad A'u + v = c, \quad v \geq 0,$$

where A is an $m \times n$ matrix; c , x , v are n -vectors; and b , u are m -vectors. We make the following assumption throughout regarding this linear program.

Assumption 1. The dual feasible region is nonempty and bounded. That is, the set $\mathcal{V} := \{(u, v) | A'u + v = c, v \geq 0\}$ is nonempty and bounded.

We note immediately that the following is a trivial consequence of the above assumption:

$$(11) \quad \mathcal{S} := \{(u, v) | A'u + v = 0, v \geq 0, (u, v) \neq 0\} = \emptyset.$$

By using a theorem of the alternative [17, Thm. 1], we have that the following is implied by (11) and hence is a consequence of Assumption 1.

LEMMA 2. Suppose that Assumption 1 holds. Then (i) the matrix A has full row rank and (ii) the set $\mathcal{X} := \{x | Ax = b, x > 0\} \neq \emptyset$.

The primal and dual least 2-norm formulations for the linear program (9) are

$$(12) \quad \min_x cx + \frac{\varepsilon}{2} xx \quad \text{s.t.} \quad Ax = b, x \geq 0$$

and

$$(13) \quad \min_{u,v} \frac{1}{2} \|A'u + v - c\|^2 - \varepsilon bu \quad \text{s.t.} \quad v \geq 0,$$

respectively, for some $\varepsilon > 0$.

If $x(\varepsilon)$ solves the primal problem (12) and $(u(\varepsilon), v(\varepsilon))$ solves the dual problem (13), then the following relation holds:

$$(14) \quad x(\varepsilon) = \frac{1}{\varepsilon} (A'u(\varepsilon) + v(\varepsilon) - c).$$

To solve problem (13) by the interior-penalty method, we solve a sequence of unconstrained subproblems

$$(15) \quad \min_{u,v} \frac{1}{2} \|A'u + v - c\|^2 - \varepsilon bu - \gamma^i \sum_{j=1}^n \log v_j,$$

where $\{\gamma^i\}$ is a sequence of decreasing positive parameters. However, for the algorithm that we are proposing here, subproblem (15) is not solved exactly. For each penalty parameter γ^i , one Newton step is taken.

Define the function $F(u, v)$ as follows:

$$F(u, v) := \frac{1}{2} \|A'u + v - c\|^2 - \varepsilon bu - \gamma^i \sum_{j=1}^n \log v_j.$$

Then its gradient and Hessian are

$$\begin{aligned} \nabla F(u, v) &= \begin{pmatrix} \nabla_u F(u, v) \\ \nabla_v F(u, v) \end{pmatrix} = \begin{pmatrix} A(A'u + v - c) - \varepsilon b \\ A'u + v - c - \gamma^i V^{-1}e \end{pmatrix}, \\ \nabla^2 F(u, v) &= \begin{pmatrix} AA' & A \\ A' & I + \gamma^i V^{-2} \end{pmatrix}, \end{aligned}$$

where $V := \text{diag}(v)$.

The Newton direction can then be obtained by solving the linear system

$$\nabla^2 F(u^i, v^i) \begin{pmatrix} u - u^i \\ v - v^i \end{pmatrix} + \nabla F(u^i, v^i) = 0$$

for u and v .

Since it is not known a priori how small ε needs be for a solution of (13) to yield the least 2-norm solution of the linear program (9), we start the algorithm with an arbitrary $\varepsilon^0 > 0$ and decrease its value as we iterate. We now state the complete algorithm.

ALGORITHM IDLN

- Initialization
 1. Choose initial points $u^0 \in \mathbb{R}^m$ and $v^0 \in \mathbb{R}_{++}^n$. Set $i = 0$.
 2. Choose initial parameters $\gamma^0 > 0$ and $\varepsilon^0 > 0$.
(A precise way to obtain these initial points and parameters is described in § 3.)
- Iteration
 1. Solve the linear system

$$(16) \quad \nabla^2 F(u^i, v^i) \begin{pmatrix} u - u^i \\ v - v^i \end{pmatrix} + \nabla F(u^i, v^i) = 0.$$

- Let (u^{i+1}, v^{i+1}) be the solution of the above linear system.
2. Set

$$(17) \quad x^{i+1} := \frac{1}{\varepsilon^i} (A'u^{i+1} + v^{i+1} - c).$$

- Termination

If the duality gap $|cx^{i+1} - bu^{i+1}|$ is sufficiently small, then stop.

Else

1. Set $i := i + 1$.

2. If $\gamma^i > \gamma_{\min}$, then $\gamma^{i+1} = \alpha\gamma^i$ for some $\alpha \in (0, 1)$.

If $\varepsilon^i > \varepsilon_{\min}$, then $\varepsilon^{i+1} = \rho\varepsilon^i$ for some $\rho \in (0, 1)$.

(The values of the attenuation factors α and ρ are given in § 3.)

3. Go to Iteration.

Remark 3. Choosing an interior point to start this algorithm is trivial, since the dual problem (13) has only nonnegativity constraints. This is the main advantage of this algorithm over the primal algorithm implemented in [10], the dual affine algorithm implemented in [23], and the primal-dual affine algorithm implemented in [13], [22], in which a Phase I is needed to start the algorithms.

Remark 4. The solution of the $m + n$ linear system (16) in the $m + n$ variables (u, v) can be achieved by first solving the m linear equations in m unknowns

$$(18) \quad \begin{aligned} & A[I - (I + \gamma(V^i)^{-2})^{-1}]A'(u - u^i) \\ & = A(I + \gamma(V^i)^{-2})^{-1}\nabla_v F(u^i, v^i) - \nabla_u F(u^i, v^i) \end{aligned}$$

for u and then computing

$$v - v^i = -(I + \gamma(V^i)^{-2})^{-1}(\nabla_v F(u^i, v^i) + A'(u - u^i)).$$

The Yale Sparse Matrix Package [6], [7] was used to solve the system of linear equations (18) for all the numerical results reported in this paper.

3. Convergence of IDLN. The logarithmic-penalty minimization problem associated with the dual problem (13) with penalty parameters $\varepsilon^i > 0$ and $\gamma^i > 0$ that we are considering is

$$(19) \quad \min_{u, v} F(u, v) := \frac{1}{2} \|A'u + v - c\|^2 - \varepsilon^i bu - \gamma^i \sum_{j=1}^n \log v_j.$$

The optimality condition for the above unconstrained problem is

$$(20) \quad A(A'u + v - c) - \varepsilon^i b = 0,$$

$$(21) \quad \gamma^i e - V(A'u + v - c) = 0,$$

where $V := \text{diag}(v)$. The Newton direction can then be obtained by solving the linear system

$$(22) \quad \begin{aligned} & \begin{pmatrix} AA' & A \\ A' & I \end{pmatrix} \begin{pmatrix} u^i \\ v^i \end{pmatrix} + \begin{pmatrix} -\varepsilon^i b - Ac \\ -c \end{pmatrix} - \begin{pmatrix} 0 \\ \gamma^i(V^i)^{-1}e \end{pmatrix} \\ & + \begin{pmatrix} AA' & A \\ A' & I + \gamma^i(V^i)^{-2} \end{pmatrix} \begin{pmatrix} u - u^i \\ v - v^i \end{pmatrix} = 0 \end{aligned}$$

or, equivalently,

$$(23) \quad A(A'u + v - c) - \varepsilon^i b = 0,$$

$$(24) \quad A'u + v - c - \gamma^i(V^i)^{-1}e + \gamma^i(V^i)^{-2}(v - v^i) = 0,$$

where $u^i \in \mathbb{R}^m$ and $v^i \in \mathbb{R}_{++}^n$. We denote the solution of the above system of linear equations by (u^{i+1}, v^{i+1}) .

Define the descent directions

$$y^i = u^{i+1} - u^i, \quad z^i = v^{i+1} - v^i,$$

and let

$$d^i = (V^i)^{-1}(v^{i+1} - v^i).$$

Premultiplying equation (24) by V^i gives

$$(25) \quad \begin{aligned} V^i(A'u^{i+1} + v^{i+1} - c) &= \gamma^i e - \gamma^i (V^i)^{-1}(v^{i+1} - v^i) \\ &= \gamma^i (e - d^i). \end{aligned}$$

Premultiplying the Newton equation (22) by the diagonal matrix

$$\begin{pmatrix} I & 0 \\ 0 & V^i \end{pmatrix}$$

gives the equation

$$\begin{aligned} &\begin{pmatrix} I & 0 \\ 0 & V^i \end{pmatrix} \begin{pmatrix} A(A'u^i + v^i - c) - \varepsilon^i b \\ A'u^i + v^i - c - \gamma^i (V^i)^{-1}e \end{pmatrix} \\ &+ \begin{pmatrix} I & 0 \\ 0 & V^i \end{pmatrix} \begin{pmatrix} AA^t & A \\ A^t & I + \gamma^i (V^i)^{-2} \end{pmatrix} \begin{pmatrix} u^{i+1} - u^i \\ v^{i+1} - v^i \end{pmatrix} = 0, \end{aligned}$$

which is equivalent to

$$(26) \quad \begin{pmatrix} A(A'u^i + v^i - c) - \varepsilon^i b \\ V^i(A'u^i + v^i - c) - \gamma^i e \end{pmatrix} + \begin{pmatrix} AA^t & AV^i \\ V^i A^t & \gamma^i I + (V^i)^2 \end{pmatrix} \begin{pmatrix} y^i \\ d^i \end{pmatrix} = 0.$$

Define the matrix M^i

$$(27) \quad M^i := \begin{pmatrix} AA^t & AV^i \\ V^i A^t & \gamma^i I + (V^i)^2 \end{pmatrix}$$

and the residual vector (p^i, r^i)

$$(28) \quad \begin{pmatrix} p^i \\ r^i \end{pmatrix} := \begin{pmatrix} \varepsilon^i b - A(A'u^i + v^i - c) \\ \gamma^i e - V^i(A'u^i + v^i - c) \end{pmatrix}.$$

Premultiplying equation (26) by (y^i, d^i) gives

$$(29) \quad \left\langle \begin{pmatrix} y^i \\ d^i \end{pmatrix}, M^i \begin{pmatrix} y^i \\ d^i \end{pmatrix} \right\rangle = \left\langle \begin{pmatrix} p^i \\ r^i \end{pmatrix}, (M^i)^{-1} \begin{pmatrix} p^i \\ r^i \end{pmatrix} \right\rangle.$$

The basic idea for the proof is as follows. Suppose that the residual vectors p^i and r^i are bounded at iteration i ; then the Newton solution (u^{i+1}, v^{i+1}) and the vector $x^{i+1} := (1/\varepsilon^i)(A'u^{i+1} + v^{i+1} - c)$ are shown to be primal-dual feasible. Moreover, by careful updating of the parameters ε and γ , the boundedness of the residual vectors p^{i+1} and r^{i+1} is guaranteed. This proof is based on the convergence proof given in [28] for the solution of a convex quadratic problem using the logarithmic-penalty method. The linear convergence of the algorithm is also established by using results given in [21]. Tseng [29] has also established the linear convergence for this algorithm.

We begin by stating the following lemmas regarding matrix M^i .

LEMMA 5. *Let M be a symmetric real $n \times n$ matrix such that, for all $x \in \mathbb{R}^n$, $\langle x, Mx \rangle \geq \gamma \|x\|^2$ for some $\gamma > 0$; then $\langle x, M^{-1}x \rangle \leq (1/\gamma) \|x\|^2$ for all $x \in \mathbb{R}^n$.*

LEMMA 6. *Let*

$$N = \begin{pmatrix} A & B \\ B^t & C \end{pmatrix}$$

be a symmetric invertible matrix. If A^{-1} and $(C - B'A^{-1}B)^{-1}$ exist, then

$$N^{-1} := \begin{pmatrix} A^{-1} + A^{-1}B(C - B'A^{-1}B)^{-1}B'A^{-1} & -A^{-1}B(C - B'A^{-1}B)^{-1} \\ -(C - B'A^{-1}B)^{-1}B'A^{-1} & (C - B'A^{-1}B)^{-1} \end{pmatrix}.$$

LEMMA 7. Let

$$M := \begin{pmatrix} AA' & AV \\ VA' & \gamma I + V^2 \end{pmatrix},$$

where A is an $m \times n$ real matrix with independent rows, V is an $n \times n$ positive diagonal matrix, and $\gamma > 0$; then, for all $(u, v) \in \mathbb{R}^{m+n}$,

(i)

$$(30) \quad \left\langle \begin{pmatrix} u \\ v \end{pmatrix}, M \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle \geq \gamma \|v\|^2;$$

(ii)

$$(31) \quad \left\langle \begin{pmatrix} 0 \\ v \end{pmatrix}, M^{-1} \begin{pmatrix} 0 \\ v \end{pmatrix} \right\rangle \leq \frac{1}{\gamma} \|v\|^2.$$

Proof. (i) We have that

$$\left\langle \begin{pmatrix} u \\ v \end{pmatrix}, \begin{pmatrix} AA' & AV \\ VA' & \gamma I + V^2 \end{pmatrix} \begin{pmatrix} u \\ v \end{pmatrix} \right\rangle = \|A'u + Vv\|^2 + \gamma \|v\|^2 \geq \gamma \|v\|^2.$$

(ii) By Lemma 6, we have that

$$\left\langle \begin{pmatrix} 0 \\ v \end{pmatrix}, M^{-1} \begin{pmatrix} 0 \\ v \end{pmatrix} \right\rangle = \langle v, N^{-1}v \rangle,$$

where

$$N^{-1} = (\gamma I + V^2 - VA'(AA')^{-1}AV)^{-1}$$

or

$$N = \gamma I + V(I - A'(AA')^{-1}A)V.$$

Define $P := (I - A'(AA')^{-1}A)$; then $P = P^2$, and we have the following:

$$\langle v, Nv \rangle = \gamma \|v\|^2 + \|PVv\|^2 \geq \gamma \|v\|^2.$$

Hence from Lemma 5 it follows that $\langle v, N^{-1}v \rangle \leq (1/\gamma)\|v\|^2$. \square

In a fashion similar to that of [12], we define the error function $E_\gamma: \mathbb{R}^m \times \mathbb{R}_+^n \rightarrow \mathbb{R}$ as

$$(32) \quad E_\gamma(u, v) := \|\gamma e - V(A'u + v - c)\|$$

to measure the error in satisfying the optimality condition (21) by the solution of the Newton equation (22). It is clear that $E_{\gamma^i}(u^{i+1}, v^{i+1}) = 0$ and $\varepsilon^i b - A(A'u^{i+1} + v^{i+1} - c) = 0$ if and only if (u^{i+1}, v^{i+1}) solves problem (19).

The next lemma gives bound to the error function E_{γ^i} at (u^{i+1}, v^{i+1}) .

LEMMA 8. Define the residual vectors p^i and r^i

$$p^i := \varepsilon^i b - A(A'u^i + v^i - c),$$

$$r^i := \gamma^i e - V^i(A'u^i + v^i - c);$$

the matrices

$$\begin{aligned} P &:= I - A'(AA')^{-1}A, \\ E^i &:= (I + (AA')^{-1}AV^i(\gamma^i I + V^i P V^i)^{-1}V^i A')(AA')^{-1}, \\ F^i &:= -(AA')^{-1}AV^i(\gamma^i I + V^i P V^i)^{-1}; \end{aligned}$$

and the scalar η^i

$$(33) \quad \eta^i := \|E^i\| \|p^i\|^2 + 2\|F^i\| \|p^i\| \|r^i\|.$$

Let (u^{i+1}, v^{i+1}) be the solution of the Newton equation (22). Then

$$E_{\gamma^i}(u^{i+1}, v^{i+1}) \leq \eta^i + \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle.$$

Proof. Recall that

$$v^{i+1} = v^i + z^i = v^i + V^i d^i.$$

Since $V^{i+1} = \text{diag}(v^{i+1})$, then $V^{i+1} = V^i + V^i D^i$. We have the following:

$$\begin{aligned} E_{\gamma^i}(u^{i+1}, v^{i+1}) &= \|\gamma^i e - V^{i+1}(A'u^{i+1} + v^{i+1} - c)\|_2 \\ &= \|\gamma^i e - (V^i + V^i D^i)(A'u^{i+1} + v^{i+1} - c)\|_2 \\ &= \|\gamma^i e - V^i(A'u^{i+1} + v^{i+1} - c) - D^i V^i(A'u^{i+1} + v^{i+1} - c)\|_2 \\ &= \|\gamma^i e - \gamma^i e + \gamma^i d^i - D^i(\gamma^i e - \gamma^i d^i)\|_2 \quad (\text{by (25)}) \\ &= \gamma^i \|D^i d^i\|_2 \\ &\leq \gamma^i \|D^i d^i\|_1 \\ (34) \quad &= \gamma^i \|d^i\|_2^2 \\ &\leq \left\langle \begin{pmatrix} y^i \\ d^i \end{pmatrix}, M^i \begin{pmatrix} y^i \\ d^i \end{pmatrix} \right\rangle \quad (\text{by Lemma 7}) \\ &= \left\langle \begin{pmatrix} p^i \\ r^i \end{pmatrix}, (M^i)^{-1} \begin{pmatrix} p^i \\ r^i \end{pmatrix} \right\rangle \quad (\text{by (29)}) \\ &= \langle p^i, E^i p^i \rangle + 2\langle p^i, F^i r^i \rangle + \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle \quad (\text{by Lemma 6}) \\ (35) \quad &\leq \eta^i + \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle. \end{aligned}$$

This completes the proof. \square

For the next iteration, we update the penalty parameter

$$(36) \quad \gamma^{i+1} = \alpha \gamma^i,$$

where

$$\alpha := \frac{0.375 + \sqrt{n}}{0.5 + \sqrt{n}}.$$

We are now ready to state the following important lemma.

LEMMA 9. Let γ^{i+1} be defined as in (36) and $V^i := \text{diag}(v^i)$, where $v^i \in \mathbb{R}_{++}^n$. Define the matrix M^{i+1} and the vector r^{i+1} as

$$(37) \quad \begin{aligned} M^{i+1} &:= \begin{pmatrix} AA^t & AV^{i+1} \\ V^{i+1}A^t & \gamma^{i+1}I + (V^{i+1})^2 \end{pmatrix}, \\ r^{i+1} &:= \gamma^{i+1}e - V^{i+1}(A^t u^{i+1} + v^{i+1} - c), \end{aligned}$$

where (u^{i+1}, v^{i+1}) is the solution of the Newton equation (22). Suppose that

$$(38) \quad \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle \leq 0.25 \gamma^i$$

and that η^i as defined in (33) satisfies

$$(39) \quad \eta^i \leq 0.125 \gamma^i.$$

Then

(i) The point (u^{i+1}, v^{i+1}) is feasible for the dual problem (13), $v^{i+1} > 0$, $x^{i+1} := (1/\varepsilon^i)(A^t u^{i+1} + v^{i+1} - c)$ is feasible for the primal problem (12) with $\varepsilon = \varepsilon^i$, and the following holds:

$$(40) \quad \varepsilon^i x_j^{i+1} v_j^{i+1} \leq \gamma^i \quad \forall j = 1, 2, \dots, n.$$

(ii) The vector r^{i+1} is bounded as follows:

$$\langle r^{i+1}, (\gamma^{i+1} I + V^{i+1} P V^{i+1})^{-1} r^{i+1} \rangle \leq 0.25 \gamma^{i+1}.$$

Proof. (i) We will first show that under the above conditions $\|d^i\| < 1$, where $d^i = (V^i)^{-1}(v^{i+1} - v^i)$. By (34) and (35) of the proof of Lemma 8, we have

$$\begin{aligned} \|d^i\|^2 &\leq \frac{1}{\gamma^i} (\eta^i + \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle) \\ &< 1. \end{aligned}$$

The fact that $\|d^i\| < 1$ and $v^i > 0$ implies that $v^{i+1} > 0$ and hence the dual feasibility of (u^{i+1}, v^{i+1}) . From (25) and the definition of x^{i+1} , we have

$$\begin{aligned} \varepsilon^i x^{i+1} &= A^t u^{i+1} + v^{i+1} - c \\ &= \gamma^i (V^i)^{-1} (e - d^i) > 0. \end{aligned}$$

The equality constraint $Ax^{i+1} = b$ follows from the definition of x^{i+1} and the Newton equation (23). To establish relation (40), note that from the definition $d^i = (V^i)^{-1}(v^{i+1} - v^i)$ we have

$$\begin{aligned} \varepsilon^i x^{i+1} &= \gamma^i (V^i)^{-1} (e - d^i) \\ &= \gamma^i (V^{i+1})^{-1} (D^i + I) (e - d^i) \\ &= \gamma^i (V^{i+1})^{-1} (e - D^i d^i) \\ &\leq \gamma^i (V^{i+1})^{-1} e. \end{aligned}$$

Upon premultiplying the last relation by V^{i+1} , we get $\varepsilon^i x_j^{i+1} v_j^{i+1} \leq \gamma^i$ for all $j = 1, 2, \dots, n$.

(ii) The proof of the second part of Lemma 9 is as follows:

$$\begin{aligned}
 & \left[\frac{1}{\gamma^{i+1}} \langle r^{i+1}, (\gamma^{i+1}I + V^{i+1}PV^{i+1})^{-1}r^{i+1} \rangle \right]^{1/2} \\
 &= \left[\frac{1}{\gamma^{i+1}} \left\langle \begin{pmatrix} 0 \\ r^{i+1} \end{pmatrix}, (M^{i+1})^{-1} \begin{pmatrix} 0 \\ r^{i+1} \end{pmatrix} \right\rangle \right]^{1/2} \\
 &\leq \frac{1}{\gamma^{i+1}} \|r^{i+1}\| \quad (\text{by Lemma 7}) \\
 &= \frac{1}{\gamma^{i+1}} \|\gamma^{i+1}e - V^{i+1}(A^t u^{i+1} + v^{i+1} - c)\| \\
 &= \frac{1}{\alpha \gamma^i} \|\alpha \gamma^i e - V^{i+1}(A^t u^{i+1} + v^{i+1} - c)\| \quad (\text{definition of } \gamma^{i+1}) \\
 &\leq \frac{1}{\alpha \gamma^i} (E_{\gamma^i}(u^{i+1}, v^{i+1}) + (1 - \alpha)\gamma^i \|e\|) \\
 &\leq \frac{1}{\alpha \gamma^i} (\eta^i + \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle) + \frac{1 - \alpha}{\alpha} \|e\| \quad (\text{by Lemma 8}) \\
 &\leq \frac{1}{\alpha} (0.125 + 0.25 + \sqrt{n}) - \sqrt{n} \\
 &\leq 0.5. \quad \square
 \end{aligned}$$

The next two lemmas establish the boundedness of u^{i+1} , v^{i+1} , and x^{i+1} under Assumption 1. We will show that, if the conditions (38) and (39) of Lemma 9 are satisfied, then x^{i+1} is bounded. The proof is similar to that of Polyak in [26] for the gradient-projection algorithm. The boundedness of x^{i+1} and the assumption that the dual feasible set is bounded establish the boundedness of (u^{i+1}, v^{i+1}) .

LEMMA 10. *Suppose that the conditions (38) and (39) of Lemma 9 are satisfied by $(u^i, v^i) \in \mathbb{R}^m \times \mathbb{R}_{++}^n$. Let (u^{i+1}, v^{i+1}) be the solution of the Newton equation (22), and let x^* be a solution of the linear program (9). If the parameters γ^i and ε^i are such that $\gamma^i \leq (\varepsilon^i)^2$, then*

$$(41) \quad \|x^{i+1} - x^*\|^2 \leq 2n + \|x^*\|^2,$$

where $x^{i+1} = (1/\varepsilon^i)(A^t u^{i+1} + v^{i+1} - c)$.

Proof. From the Newton equation (23), we have

$$A(A^t u^{i+1} + v^{i+1} - c) = \varepsilon^i b,$$

which gives

$$u^{i+1} = (AA^t)^{-1}(\varepsilon^i b - A(v^{i+1} - c)).$$

Hence

$$\begin{aligned}
 (42) \quad x^{i+1} &= (I - A'(AA^t)^{-1}A) \left(\frac{1}{\varepsilon^i} (v^{i+1} - c) \right) + A'(AA^t)^{-1}b \\
 &= P_Q \left(\frac{1}{\varepsilon^i} (v^{i+1} - c) \right),
 \end{aligned}$$

where $P_Q(x)$ is the projection of x onto the set $Q := \{z \mid Az = b\}$. By the minimum principle [26, p. 121] applied to the above projection problem (42), we have

$$(43) \quad 0 \geq \left\langle \frac{1}{\varepsilon^i} (v^{i+1} - c) - x^{i+1}, x^* - x^{i+1} \right\rangle$$

or, equivalently,

$$(44) \quad \begin{aligned} 0 &\geq \langle v^{i+1} - c - \varepsilon^i x^{i+1}, x^* - x^{i+1} \rangle \\ &= -\langle c, x^* - x^{i+1} \rangle + \langle v^{i+1}, x^* \rangle - \langle v^{i+1}, x^{i+1} \rangle - \varepsilon^i \langle x^{i+1}, x^* - x^{i+1} \rangle \\ &\geq \varepsilon^i \langle -x^{i+1}, x^* - x^{i+1} \rangle - n \frac{\gamma^i}{\varepsilon^i} \\ &= \frac{1}{2} \varepsilon^i (\|x^{i+1}\|^2 + \|x^{i+1} - x^*\|^2 - \|x^*\|^2) - n \frac{\gamma^i}{\varepsilon^i}. \end{aligned}$$

The second inequality in (44) follows from the fact that $cx^* \leq cx^{i+1}$, $\langle v^{i+1}, x^* \rangle \geq 0$, and $\varepsilon^i x_j^{i+1} v_j^{i+1} \leq \gamma^i$ for all $j = 1, 2, \dots, n$. Rearranging the terms in (44) and multiplying by $2/\varepsilon^i$ gives

$$\begin{aligned} \|x^{i+1} - x^*\|^2 &\leq 2n \frac{\gamma^i}{(\varepsilon^i)^2} + \|x^*\|^2 - \|x^{i+1}\|^2 \\ &\leq 2n + \|x^*\|^2. \end{aligned}$$

Hence the proof is complete. \square

In the next lemma, we establish the boundedness of (u^{i+1}, v^{i+1}) .

LEMMA 11. *Suppose that the point $(u^i, v^i) \in \mathbb{R}^m \times \mathbb{R}_{++}^n$ satisfies the conditions (38) and (39) of Lemma 9. Let (u^{i+1}, v^{i+1}) be the solution of the Newton equation (22) and $\gamma^i \leq (\varepsilon^i)^2$. Furthermore, suppose that the set $\mathcal{V} := \{(u, v) \mid A'u + v = c, v \geq 0\}$ is bounded. Then there exists a constant $\tau < \infty$ depending only on the matrix A and vectors b and c of the linear program (9) such that*

$$(45) \quad \|u^{i+1}, v^{i+1}\| \leq \tau.$$

Proof. Define the set \mathcal{V}^i as follows:

$$(46) \quad \mathcal{V}^i := \{(u, v) \mid A'u + v = c + \varepsilon^i x^{i+1}, v \geq 0\}.$$

Note that \mathcal{V}^i is nonempty by the construction of $x^{i+1} = (1/\varepsilon^i)(A'u^{i+1} + v^{i+1} - c)$. We claim that the set \mathcal{V}^i is bounded. In Lemma 10 it was shown that x^{i+1} is bounded. Hence, if the set \mathcal{V}^i is unbounded, then there exists (\bar{u}, \bar{v}) such that

$$A'\bar{u} + \bar{v} = 0, \quad \bar{v} \geq 0, \quad (\bar{u}, \bar{v}) \neq 0.$$

Then for any point $(w, z) \in \mathcal{V}$ we have that $(w + \lambda \bar{u}, z + \lambda \bar{v}) \in \mathcal{V}$ for any $\lambda \geq 0$, which contradicts the assumption that the set \mathcal{V} is bounded. Hence \mathcal{V}^i is bounded.

Consider now the following nonconvex problem:

$$(47) \quad \max_{u, v} \|(u, v)\| \quad \text{s.t. } A'u + v = c + \varepsilon^i x^{i+1}, v \geq 0.$$

This problem has a solution, since we have just shown that its feasible set is bounded. By the generalized theorem of the existence of a basic feasible solution [20], it follows that there must exist a basic solution. Let the basis matrix B^i denote the $n \times n$

nonsingular submatrix of $[A' \ I]$ corresponding to the basic solution (\tilde{u}, \tilde{v}) of problem (47). We have

$$\begin{aligned}\|\tilde{u}, \tilde{v}\| &= \|(B^i)^{-1}(c + \varepsilon^i x^{i+1})\| \\ &\leq \|(B^i)^{-1}\| \|c + \varepsilon^i x^{i+1}\|.\end{aligned}$$

Since there are only a finite number of basis matrices in $[A' \ I]$ and since both ε^i and x^{i+1} are bounded, we conclude that there must exist $\tau < \infty$ such that

$$\|u^{i+1}, v^{i+1}\| \leq \|\tilde{u}, \tilde{v}\| \leq \tau,$$

and this completes the proof. \square

From Lemma 11 we have that both $\max_v \|AV\|$ and $\max_v \|VA'\|$ such that $v \in \mathcal{V}^i$ and $V := \text{diag}(v)$ are finite, where \mathcal{V}^i is the set defined by (46).

The next lemma shows that, if the attenuation factor $\rho \in (0, 1)$ for decreasing ε^i is chosen carefully, then the assumption (39) of Lemma 9 holds at iteration $i+1$.

LEMMA 12. Let (u^{i+1}, v^{i+1}) be the solution of the Newton equation (22) and $x^{i+1} = (1/\varepsilon^{i+1})(A'u^{i+1} + v^{i+1} - c)$. Suppose that $(u^i, v^i) \in \mathbb{R}^m \times \mathbb{R}_{++}^n$ satisfy the conditions (38) and (39) of Lemma 9 and that the sequences $\{\gamma^k\}$ and $\{\varepsilon^k\}$ are such that

$$(48) \quad 0 < \{\gamma^k\} \leq \gamma_{\max}$$

and

$$(49) \quad 0 < \{\varepsilon^k\} \leq \varepsilon_{\max}.$$

Define the constants

$$K_1 = \|(AA')^{-1}\|,$$

$$K_2^i = \max \left\{ \max_v \|AV\|, \max_v \|VA'\| \right\} \quad \text{s.t. } A'u + v = c + \varepsilon^i x^{i+1}, v \geq 0,$$

$$C_1^i = (\gamma_{\max} + K_1(K_2^i)^2)K_1\varepsilon_{\max}^2 \|b\|^2 / \gamma^{i+1},$$

$$C_2^i = (4/\alpha)\varepsilon_{\max}\sqrt{n} \|b\| K_1 K_2^i,$$

where $\alpha = (0.375 + \sqrt{n})/(0.5 + \sqrt{n})$ and $\gamma^{i+1} = \alpha\gamma^i$. If

$$\varepsilon^{i+1} = \rho^i \varepsilon^i,$$

where

$$(50) \quad 1 > \rho^i \geq 1 - \delta^i$$

and

$$(51) \quad 0 < \delta^i \leq (-C_2^i + \sqrt{(C_2^i)^2 + 0.5\gamma^{i+1}C_1^i})/2C_1^i,$$

then we have

$$\eta^{i+1} \leq 0.125\gamma^{i+1},$$

where

$$\eta^{i+1} := \|E^{i+1}\| \|p^{i+1}\|^2 + 2\|F^{i+1}\| \|p^{i+1}\| \|r^{i+1}\|,$$

$$p^{i+1} := \varepsilon^{i+1}b - A(A'u^{i+1} + v^{i+1} - c),$$

$$r^{i+1} := \gamma^{i+1}e - V^{i+1}(A'u^{i+1} + v^{i+1} - c),$$

$$E^{i+1} := (I + (AA')^{-1}AV^{i+1}(\gamma^{i+1}I + V^{i+1}PV^{i+1})^{-1}V^{i+1}A')(AA')^{-1},$$

$$F^{i+1} := -(AA')^{-1}AV^{i+1}(\gamma^{i+1}I + V^{i+1}PV^{i+1})^{-1}.$$

Proof. We will first compute the bounds on the norms of the residual vectors p^{i+1} and r^{i+1} as follows:

(i)

$$\begin{aligned}\|p^{i+1}\| &= \|\varepsilon^{i+1}b - A(A'u^{i+1} + v^{i+1} - c)\| \\ &= \|\varepsilon^i b - A(A'u^{i+1} + v^{i+1} - c) + \varepsilon^{i+1}b - \varepsilon^i b\| \\ &= (1 - \rho^i)\varepsilon^i \|b\| \quad (\text{by (23)}),\end{aligned}$$

(ii)

$$\begin{aligned}\|r^{i+1}\| &= \|\gamma^{i+1}e - V^{i+1}(A'u^{i+1} + v^{i+1} - c)\| \\ &\leq \gamma^{i+1}\sqrt{n} + \|\varepsilon^i V^{i+1}x^{i+1}\| \\ &\leq 2\gamma^i\sqrt{n} \quad (\text{by (40)}).\end{aligned}$$

Next we compute the bounds on the norm of the matrices E^{i+1} and F^{i+1} as follows:

(i)

$$\begin{aligned}\|E^{i+1}\| &= \|(I + (AA')^{-1}AV^{i+1}(\gamma^{i+1}I + V^{i+1}PV^{i+1})^{-1}V^{i+1}A')(AA')^{-1}\| \\ &\leq \left(1 + \frac{1}{\gamma^{i+1}}K_1(K_2^i)^2\right)K_1,\end{aligned}$$

(ii)

$$\begin{aligned}\|F^{i+1}\| &= \|-(AA')^{-1}AV^{i+1}(\gamma^{i+1}I + V^{i+1}PV^{i+1})^{-1}\| \\ &\leq \frac{1}{\gamma^{i+1}}K_1K_2^i.\end{aligned}$$

Hence we have

$$\begin{aligned}\eta^{i+1} &= \|E^{i+1}\| \|p^{i+1}\|^2 + 2\|F^{i+1}\| \|p^{i+1}\| \|r^{i+1}\| \\ &\leq \frac{1}{\gamma^{i+1}}(\gamma^{i+1} + K_1(K_2^i)^2)K_1(1 - \rho^i)^2(\varepsilon^i)^2\|b\|^2 + 2\frac{1}{\gamma^{i+1}}K_1K_2^i(1 - \rho^i)\varepsilon^i\|b\|2\gamma^i\sqrt{n} \\ &\leq \varepsilon_{\max}^2(\gamma_{\max} + K_1(K_2^i)^2)K_1\|b\|^2(1 - \rho^i)^2/\gamma^{i+1} + (4/\alpha)\varepsilon_{\max}K_1K_2^i\|b\|\sqrt{n}(1 - \rho^i) \\ &\leq C_1^i(1 - \rho^i)^2 + C_2^i(1 - \rho^i) \\ &\leq C_1^i(\delta^i)^2 + C_2^i(\delta^i) \quad (\text{by (50)}) \\ &\leq 0.125\gamma^{i+1} \quad (\text{by (51)}).\end{aligned}$$

This completes the proof of the lemma. \square

By using the results from the Lemmas 9–12, we can now establish the following theorem regarding Algorithm IDLN.

THEOREM 13. Let $(u^i, v^i) \in \mathbb{R}^m \times \mathbb{R}_{++}^n$ be the i th iterate of Algorithm IDLN with parameter $\varepsilon = \varepsilon^i$ and $\gamma = \gamma^i$, $\gamma^i \leq (\varepsilon^i)^2$ such that the following two conditions are satisfied:

$$(52) \quad \langle r^i, (\gamma^i I + V^i P V^i)^{-1} r^i \rangle \leq 0.25\gamma^i$$

and

$$(53) \quad \eta^i \leq 0.125\gamma^i,$$

where r^i is the residual vector defined by (28) and η^i is the real number defined by (33) in Lemma 8. Suppose that (u^{i+1}, v^{i+1}) is the solution of the Newton equation (22). If we let

$$x^{i+1} = \frac{1}{\varepsilon^i} (A^t u^{i+1} + v^{i+1} - c),$$

$$\gamma^{i+1} = \alpha \gamma^i,$$

$$\varepsilon^{i+1} = \rho^i \varepsilon^i,$$

where $\alpha = (0.375 + \sqrt{n}) / (0.5 + \sqrt{n})$ and $\rho^i \in (0, 1)$, satisfying condition (50) in Lemma 12, then

(i) The triple $(x^{i+1}, u^{i+1}, v^{i+1})$ is bounded and is feasible for the primal-dual problems (12), (13) with $\varepsilon = \varepsilon^i$, $v^{i+1} > 0$, and

$$\varepsilon^i x_j^{i+1} v_j^{i+1} \leq \gamma^i \quad \forall j = 1, 2, \dots, n$$

holds, and

(ii) The bounds

$$\eta^{i+1} \leq 0.125 \gamma^{i+1}$$

and

$$\langle r^{i+1}, (\gamma^{i+1} + V^{i+1} P V^{i+1})^{-1} r^{i+1} \rangle \leq 0.25 \gamma^{i+1}$$

are satisfied for (u^{i+1}, v^{i+1}) .

The idea for the linear convergence proof of IDLN comes from a proof given by Mangasarian and De Leone [21] for the least 2-norm solution of linear programs, in which they give error bounds for a class of more general problems. The problem they consider is

$$(54) \quad \min_x f(x) \quad \text{s.t. } x \in S := \{x \mid x \geq 0, g(x) \leq 0\}.$$

We begin by restating their main result.

THEOREM 14 (see [21, Thm. 2.2]). *Let $f: \mathbb{R}^n \rightarrow \mathbb{R}$, $g: \mathbb{R}^n \rightarrow \mathbb{R}^m$ be differentiable on \mathbb{R}^n , let f be strongly convex on \mathbb{R}^n with positive constant k , and let g be convex on \mathbb{R}^n . Let g be linear and $S \neq \emptyset$ or let g satisfy the Slater constraint qualification, that is,*

$$g(\hat{x}) < 0, \quad \hat{x} > 0,$$

for some $\hat{x} \in \mathbb{R}^n$. Then for any $(x, u) \in \mathbb{R}^n \times \mathbb{R}_+^m$ the distance $\|x - \bar{x}\|$ to the unique solution \bar{x} of (54) is bounded by

$$\begin{aligned} k^{1/2} \|x - \bar{x}\| &\leq [x \nabla_x L(x, u) - u g(x) + \alpha \|(-\nabla_x L(x, u))_+\|_1 \\ &\quad + \beta \|g(x)_+\|_\infty + \gamma \|(-x)_+\|_\infty]^{1/2}, \end{aligned}$$

where

$$L(x, u) := f(x) + u g(x),$$

$$\alpha := \min_{x \in S} (\|x\|_\infty + \|\nabla f(x)\|_1 / k),$$

$$\beta := \min_{(u, v) \in W} \|u\|_1,$$

$$\gamma := \min_{(u, v) \in W} \|v\|_1,$$

where $W \subset \mathbb{R}_+^{m+n}$ is the nonempty closed convex polyhedral set of optimal multipliers (u, v) of the convex program (54) associated with the constraints $g(x) \leq 0$, $x \geq 0$.

By using Theorem 14 we will show that if we impose a stronger condition on the parameter ε^{i+1} , then IDLN Algorithm is linearly convergent.

THEOREM 15. *Let $(u^{i+1}, v^{i+1}, x^{i+1})$, α , and ρ^i be as in Theorem 13. Suppose that all the conditions in Theorem 13 are satisfied, and suppose that the parameter ε is decreased as*

$$(55) \quad \varepsilon^{i+1} = \bar{\rho}^i \varepsilon^i,$$

where $1 > \bar{\rho}^i := \max\{\alpha^{1/4}, \rho^i\}$, ρ^i as defined by (50), and that γ is decreased as

$$(56) \quad \gamma^{i+1} = \alpha \gamma^i,$$

where $\alpha = (0.375 + \sqrt{n}) / (0.5 + \sqrt{n})$. Then the sequence $\{x^i\}$ converges to \bar{x} , the unique least 2-norm solution of (9) with the linear root rate [25]

$$(57) \quad \|x^{i+1} - \bar{x}\| \leq \delta(\alpha^{1/4})^{i+1} \quad \text{for } i \geq \bar{i}$$

for some constant δ and some integer \bar{i} .

Proof. Let $L(x, u) = cx + (\varepsilon^i/2)xx - u'(Ax - b)$. Then

$$\nabla_x L(x^{i+1}, u^{i+1}) = c + \varepsilon^i x^{i+1} - A^t u^{i+1} = v^{i+1} > 0.$$

By Theorem 13 we have that

$$\begin{aligned} v^{i+1} &\geq 0, \\ x^{i+1} &\geq 0, \\ \varepsilon^i x_j^{i+1} v_j^{i+1} &\leq \gamma^i \quad \forall j = 1, 2, \dots, n, \\ Ax^{i+1} &= b. \end{aligned}$$

Let $\bar{x}(\varepsilon^i)$ be the solution of the quadratic problem (12) with $\varepsilon = \varepsilon^i$. It follows from Theorem 14 that

$$\begin{aligned} \|x^{i+1} - \bar{x}(\varepsilon^i)\| &= \frac{1}{\sqrt{\varepsilon^i}} \langle x^{i+1}, v^{i+1} \rangle^{1/2} \\ &\leq \frac{1}{\sqrt{\varepsilon^i}} (n\gamma^i / \varepsilon^i)^{1/2} \\ &= (n\gamma^i)^{1/2} / \varepsilon^i \\ &\leq (n(\alpha)^i \gamma^0)^{1/2} / (\alpha^{1/4})^i \varepsilon^0 \\ &= \delta(\alpha^{1/4})^{i+1}, \end{aligned}$$

where $\delta = \sqrt{n\gamma^0} / (\varepsilon^0 \alpha^{1/4})$. Now let \bar{i} be the smallest integer such that $\varepsilon^{\bar{i}} \leq \bar{\varepsilon}$, where $\bar{\varepsilon}$ is that defined below (2). Combining the last result and the fact that $\bar{x} = \bar{x}(\varepsilon^i)$ for $i \geq \bar{i}$, we have

$$\begin{aligned} \|x^{i+1} - \bar{x}\| &\leq \|x^{i+1} - \bar{x}(\varepsilon^i)\| + \|\bar{x}(\varepsilon^i) - \bar{x}\| \\ &= \|x^{i+1} - \bar{x}(\varepsilon^i)\| \\ &\leq \delta(\alpha^{1/4})^{i+1}. \end{aligned}$$

This establishes the linear convergence of the iterates. \square

Remark 16. The condition $\gamma^i \leq (\varepsilon^i)^2$ required in Theorem 13 will be satisfied for all i if we let $\gamma^0 = (\varepsilon^0)^2$ and if $\{\varepsilon^i\}$ and $\{\gamma^i\}$ are decreased according to (55) and (56).

Remark 17. The parameter ε^k in (49) need not go to zero. Let \bar{i} be the smallest integer such that $\varepsilon^{\bar{i}} \leq \bar{\varepsilon}$, where $\bar{\varepsilon}$ is defined below expression (2). If for all $k > \bar{i}$ we fix $\varepsilon^k = \bar{\varepsilon}$, then the linear convergence of the algorithm still holds.

Remark 18. Suppose that constraint matrix A and the right-hand-side vector b of the linear program (9) have the form

$$A = \begin{pmatrix} \bar{A} \\ e' \end{pmatrix}, \quad b = \begin{pmatrix} 0 \\ n \end{pmatrix},$$

where \bar{A} is some $(m-1) \times n$ matrix (see [4] for details on how to transform the constraints of a general linear program into this form). It is also assumed that the point e satisfies $Ae = b$. We claim that an initial feasible point satisfying the conditions (52) and (53) of Theorem 13 can be found immediately. To see this, define $\gamma^0 = (\varepsilon^0)^2$ for some positive ε^0 such that $\|(I - A'(AA')^{-1}A)c\| \leq 0.5\varepsilon^0$. Let $u^0 = (AA')^{-1}Ac$ and let $v^0 = \varepsilon^0 e$. We have

4. Numerical results. Algorithm IDLN was implemented in FORTRAN and run on a DECstation 3100 under the Ultrix V4.0 Operating System. The source code was compiled by using the “-O” option. All floating-point operations were done in double precision. All times reported here were obtained by calling the system subroutine *etime*().

It is not practical to convert the constraints of a linear program to be solved to the form described in Remark 18. We have implemented the algorithm to solve the linear program in standard form (9), where A is a general $m \times n$ matrix. For all test problems, we set the initial values of ε and γ to

$$\varepsilon^0 = 10^{-3}, \quad \gamma^0 = 10^{-6}.$$

The initial value of the dual variable u is

$$u^0 = 0.0.$$

For most of the problems solved, the initial value of the dual variable v is

$$v^0 = 60.0.$$

These initial values, together with the following updating schemes for the parameters γ and ϵ , produced the best computational results that we could obtain. The parameters are updated as follows. If $\epsilon^i > \epsilon_{\min} = 10^{-12}$, then

$$\epsilon^{i+1} = \epsilon^i / 4.0,$$

and, if $\gamma^i > \gamma_{\min} = 10^{-19}$, then

$$\gamma^{i+1} = \begin{cases} \gamma^i / 1.2 & \text{if } \|x^{i+1} - x^i\|^2 > 100,000, \\ \gamma^i / 2.0 & \text{if } \|x^{i+1} - x^i\|^2 > 1,000, \\ \gamma^i / 3.0 & \text{if } \|x^{i+1} - x^i\|^2 > 10, \\ \gamma^i / 3.5 & \text{if } \|x^{i+1} - x^i\|^2 > 0.1, \\ \gamma^i / 4.0 & \text{otherwise.} \end{cases}$$

The new iterate (u^{i+1}, v^{i+1}) is obtained as follows:

$$\begin{aligned} u^{i+1} &:= \bar{u}^i, \\ v^{i+1} &:= v^i + 0.98\lambda(\bar{v}^i - v^i), \end{aligned}$$

where (\bar{u}^i, \bar{v}^i) is the solution of the linear system (16) and the step size λ is defined as

$$(58) \quad \lambda := \begin{cases} 1 & \text{if } \bar{v}^i \geq 0, \\ \min_{j \in J} (v_j^i / (v_j^i - \bar{v}_j^i)) & \text{otherwise,} \end{cases}$$

where $J := \{j \mid v_j^i - \bar{v}_j^i > 0\}$.

Finally, the program is terminated if one of the following conditions is satisfied:

$$|(cx^i - cx^{i-1}) / cx^{i-1}| \leq 5 \times 10^{-8} \quad \text{and} \quad \|(-x)_+\| / \|x_+\| \leq 10^{-7}$$

or

$$|(cx^i - cx^{i-1}) / cx^{i-1}| \leq 10^{-8} \quad \text{and} \quad |(bu^i - bu^{i-1}) / bu^{i-1}| \leq 10^{-8}.$$

At the termination of Algorithm IDLN, an iterative scheme described in [9] is implemented to improve the accuracy of the solution of the linear program.

We tested the algorithm on 66 linear test problems, 63 of which were from the NETLIB collection [5], [8]. Problem Rabo came from the mortgage division of Rabo Bank of the Netherlands, and the problems Cre-a and Cre-c were made available by J. Kennington [2]. The dimensions of these 66 problems are given in Tables 1 and 2. In columns 3–5 of these tables, we list the number of rows (including the objective row), columns, and nonzeros of matrix A of the linear program in its original MPS format. Columns 6–8 show the size of the linear programs after the data is preprocessed so that these linear programs can be written in standard format (9).

For comparison, we solved these problems by using MINOS 5.3 [24], which is a linear-programming package based on the simplex method. MINOS was run with the default settings for all parameters except *log frequency* 200, *summary frequency* 200, and *solution no.* The results that we obtained on the 66 test problems are listed in Tables 3–8.

In Tables 3 and 4, we list

$$\text{Primal Infeasibility} = \max\left(\frac{\|Ax - b\|}{\|b\|}, \|(-x)_+\|\right),$$

$$\text{Dual Infeasibility} = \frac{\|(A'u - c)_+\|}{\|(-c)_+\| + 1.0},$$

$$\text{Duality Gap} = \left| \frac{cx - bu}{cx + bu} \right|,$$

$$\text{Complementarity} = \frac{\|X(c - A'u)\|}{\|x\| \|u\|},$$

where $X := \text{diag}(x)$.

Tables 5 and 6 show the objective values obtained by MINOS and IDLN. Column 5 of these tables gives the relative accuracy of IDLN objective value

$$\text{Relative Error} := \left| \frac{cx - cx^*}{cx^*} \right|,$$

where cx^* is the optimal objective value reported by MINOS.

Tables 7 and 8 compare the execution times for MINOS and IDLN. The total number of iterations for IDLN to solve each problem is shown in column 3, where the number in parentheses indicates the number of refinement iterations.

We note that, for most problems, IDLN solutions have better primal feasibility than do the solutions obtained by the IPP algorithm described in [27]. In the primal algorithm, a Newton direction is computed in the primal space, i.e., the descent direction p is such that $Ap = 0$ and the primal variable is updated $x^{i+1} = x^i + \alpha p$. As i increases, the error $\|Ax^i - b\|$ accumulates, and this leads to a deterioration in the feasibility of the primal solution. In contrast, because Algorithm IDLN takes the Newton step in the dual space, its primal feasibility $Ax^i = b$ depends only on the accuracy of the current Newton direction.

The results obtained from these 66 linear programs can be summarized as follows. After relatively few refinement iterations (< 3 for most problems), solutions with very good primal and dual feasibilities were obtained. For most problems solved, the IDLN objective value agreed with the MINOS objective value at least in the first eight digits. IDLN solved 34 of the 66 problems faster than did MINOS. Similar to other interior-point algorithms, the relative speedup of IDLN over MINOS increases as the problem dimension grows. The total time taken by IDLN to solve all the test problems was 5,589 seconds, whereas the total time for MINOS 5.3 to solve these problems was 11,754 seconds, which is 2.10 times as long as for IDLN.

The number of iterations for Algorithm IDLN is slightly more than that for the two-phase affine scaling algorithm of Adler, Resende, and Veiga [1], but it is very comparable to the number for the single-phase dual-barrier method of Gill, Murray, and Saunders [11]. To solve 31 NETLIB test problems, a total of 1005 iterations, 271 of which are Phase I iterations, are needed by the affine scaling algorithm. The total number of iterations for IDLN to solve these 31 problems is 1172. The corresponding total number of iterations for the single-phase dual-barrier method is 1097.

5. Summary. We have described a new algorithm for finding the least 2-norm solution of a linear program. The logarithmic-penalty approach is applied to the dual reformulation of the problem to find this solution. The dual problem has only nonnegativity constraints on some of the variables; hence finding an initial point for the algorithm and maintaining positivity of these variables is trivial. When the algorithm is started with an appropriate initial point and parameters, and if the parameters are updated at each iteration in a certain prescribed way, the algorithm is shown to converge globally and linearly locally.

Our numerical results indicate that the algorithm is competitive with other interior-point algorithms, such as the affine algorithm [1], [23] and the single-phase dual-barrier method [11].

CONTROLLABILITY ALONG A TRAJECTORY: A VARIATIONAL APPROACH*

ROSA MARIA BIANCHINI† AND GIANNA STEFANI‡

Abstract. This paper unifies and improves most sufficient conditions of local controllability both along a trajectory and at a point. This is accomplished by defining high-order variations that can be continuously summed. The peculiar property of these variations is that they may be generated by thin conditions as relations in the Lie algebra associated with a control system. This property leads to a variational interpretation of Sussmann-type sufficient conditions of local controllability (neutralization of obstructions), and it allows the use of different weights for neutralization.

Key words. local controllability at a point, local controllability along a trajectory, high-order variations, C^1 control systems, C^∞ affine control systems, graded approximations

AMS subject classifications. 49E15, 93B05, 93C10, 93C45

Introduction. The aim of this paper is to give high-order conditions for a point of a reference trajectory to be interior to the reachable set. This property is linked to the minimum-time problem by the fact that if \hat{x} is an optimal trajectory on $[0, T]$, then, for each $t \in [0, T)$, $\hat{x}(t)$ belongs to the boundary of $R(\xi_0, t)$, i.e., the reachable set at time t from the initial point $\xi_0 = \hat{x}(0)$ of the optimal trajectory. Therefore, each sufficient condition for $\hat{x}(t)$ to belong to the interior of $R(\xi_0, t)$ yields a necessary condition for \hat{x} to be time optimal. The high-order conditions are of particular interest in the case of nonlinear systems for which the Pontryagin maximum principle may not be sufficient to single out a unique candidate and singular trajectories may appear.

The original motivation for the paper was to give a unified setting to most of the results on local controllability, both at a point and along a reference trajectory. For the controllability at a point ξ_0 of systems with bounded controls, a quite general sufficient condition was obtained by the same authors in [1] by means of an open mapping theorem based on the properties of the cone of tangent directions to the reachable set at ξ_0 given in [7]. For controllability along a possibly nonstationary trajectory, the idea is to use some known conditions based on the relations at a point in the Lie algebra associated with the system in order to construct high-order variations of the trajectory.

Variational cones \mathcal{H} have been introduced to state high-order maximum principles [5], [8], [13], [14], etc., for optimal-control problems in a fixed interval of time $[0, T]$. If there are constraints on the final point, then it is usually required that the elements of \mathcal{H} have a continuous sum property (see [5], [14]). Roughly speaking, the property can be stated as follows: if v_1, \dots, v_k belong to \mathcal{H} , then for all sufficiently small positive numbers c_1, \dots, c_k there are control variations depending continuously on the data that produce a curve in the reachable set $R(\xi_0, T)$ whose tangent vector is given by $c_1 v_1 + c_2 v_2 + \dots + c_k v_k$. The continuous-sum property ensures that if \mathcal{H} is the whole tangent space, then the final point $\hat{x}(T)$ is interior to $R(\xi_0, T)$.

Control variations, possibly distributed along the trajectory, are defined in [5]. The result is that a variation of high order can be summed only with variations of order one. In [13], [14], instantaneous control variations are considered, i.e., the control

variation takes place in a small interval of time $[\tau, \tau + \varepsilon]$. For this kind of variation the main difficulties in proving the continuous sum property arise for tangent vectors generated by control variations that occur at the same time τ . In [13] and [14] these difficulties are overcome by requiring that a variation can be obtained continuously on a small arc of trajectory, so that the variations can be thought of as being produced at different times. This implies that the variations are not of local nature, so that they cannot be produced by thin conditions, such as those based on the relations that the Lie algebra associated with the system satisfies at a point on the trajectory; see Example 3.10. In [8] a high-order maximum principle is stated for unconstrained optimization problems. The variations defined therein have a local nature, but they do not have the continuous-sum property.

In this paper we define variations of a reference trajectory that satisfy the continuous-sum property and have a local nature. This is achieved by requiring that control variations of time duration ε and starting at times $\tau + \gamma\varepsilon$ (γ is a new “small” parameter) produce basically the same tangent vector to the reachable sets. This variational approach improves and unifies most of the known sufficient conditions for both local controllability at a point and local controllability along a reference trajectory [1], [3], [9], [12], [17], [18]. In particular, we prove that the Sussmann-type controllability conditions give rise to variations. As a consequence, we use different weights in neutralizing different obstructions. Our techniques can be used for both bounded and unbounded controls. Therefore, the results in [1] are also improved; in fact, the open mapping theorem described therein applies only to bounded controls. For a preliminary version of the results contained in this paper, see [2]. The paper is organized as follows: In § 1 we define the variational cone and state its main properties. In § 2 we study further properties of the variations for C^∞ systems, and we introduce the notion of weak local controllability. In §§ 3, 4, and 5, C^∞ control systems that are affine with respect to the control are considered. More precisely, in § 3 we prove that the variations depend on the “germ” of the system (Proposition 3.1), and we state the main result (Theorem 3.5) concerning the possibility of producing variations by means of the relations in the Lie algebra associated with the system. Many examples are given. In § 4 we study the variations of the trajectory relative to the drift term by using an approximating system we defined in [3]. In § 5 we give the applications to local controllability along a reference trajectory, Theorem 5.4. This theorem points out that controllability at a point and controllability along a trajectory can be seen in a unified setting.

1. The variational cone. Let M be an n -dimensional, paracompact connected C^q manifold, $q \geq 2$. We use the following notation: If $h: M \rightarrow M$ is a diffeomorphism, $h_*: TM \rightarrow TM$ is the tangent map of h . $o(\cdot)$ denotes a continuous map such that $\lim_{\varepsilon \rightarrow 0} o(\varepsilon)/\varepsilon = 0$, and $O(\cdot)$ denotes a continuous map such that $\lim_{\varepsilon \rightarrow 0} O(\varepsilon) = 0$. Let $\eta: [0, \bar{\varepsilon}] \rightarrow M$ be a continuous map such that $\eta(0) = \xi$, and let $v \in T_\xi M$. We write

$$\eta(\varepsilon) = \xi + \varepsilon^k v + o(\varepsilon^k)$$

if the equality holds in a chart (and hence in any chart). A time-dependent vector field $g: \mathbb{R} \times M \rightarrow TM$ is said to be a C^r Caratheodory vector field [10] if $q \geq r + 1$ and the following conditions are fulfilled:

(a) $\forall t \in \mathbb{R}$, $g(t, \cdot)$ is C^r .

(b) In any chart, g and all its derivatives with respect to $x \in M$ up to order r are measurable in t . To be more precise, if $D_x^j g$ denotes the j th derivative of g with respect to $x \in M$, then $D_x^j g(\cdot, x)$ is measurable $\forall x \in M$, $j = 0, 1, \dots, r$.

(c) In each chart, $D_2^j g, j = 0, 1, \dots, r$, is locally L^1 -bounded, i.e., for each compact K contained in the chart and for each $j = 1, \dots, r$ there exists a locally integrable map ϕ_j such that

$$\|D_2^j g(t, x)\| \leq \phi_j(t).$$

Let us consider a multi-input control system on the manifold M , i.e., a differential equation Σ on M :

$$\dot{x} = f(t, x, u),$$

depending on the control map $u \in \mathcal{U}$. \mathcal{U} will be called the set of admissible controls. We assume the following:

(A1) Each control map u is a measurable map defined on a compact interval I_u with values in \mathbb{R}^m .

(A2) $f: \mathbb{R} \times M \times \mathbb{R}^m \rightarrow TM$ is such that for each fixed $(t, \omega) \in \mathbb{R} \times \mathbb{R}^m$, $f(t, \cdot, \omega)$ is a C^1 map and for each $u \in \mathcal{U}$, $(t, x) \mapsto f(t, x, u(t))$ is a C^1 Caratheodory vector field.

(A3) If u belongs to \mathcal{U} , then each restriction of u to a subinterval of I_u belongs to \mathcal{U} . We shall denote both the control and its restriction by the same symbol.

(A4) If u, v belong to \mathcal{U} and $I_u = [a, b]$, $I_v = [b, c]$, then the concatenation $u \# v: [a, c] \rightarrow \mathbb{R}^m$ defined by

$$u \# v(t) = \begin{cases} u(t), & t \in [a, b], \\ v(t), & t \in [b, c], \end{cases}$$

belongs to \mathcal{U} .

Under these assumptions for each $u \in \mathcal{U}$, each $\xi \in M$, and each $t_0 \in I_u$, there is a unique maximal solution $t \mapsto S(t, t_0, \xi, u)$ of Σ such that $S(t_0, t_0, \xi, u) = \xi$. The map S defined on a suitable subset of $\mathbb{R} \times \mathbb{R} \times M \times \mathcal{U}$ by $(t, t_0, \xi, u) \mapsto S(t, t_0, \xi, u)$ is called the flow of the control system. For each fixed u , S is a continuous map that is C^1 with respect to ξ . We endow \mathcal{U} with a topology Π for which the flow and its derivative with respect to ξ , $(t, t_0, \xi, u) \mapsto (S(t, t_0, \cdot, u))_*$ are continuous. The possible choices of the topology Π depend on f and on the properties of the admissible controls [5], [10], [11]. If \mathcal{U} is immersed in $L^\infty(\mathbb{R})$, then we can choose Π equal to the L^∞ topology [10]. If f is affine in u , then the L^1 topology can be chosen as Π also; see [5].

Let us fix a reference control \hat{u} , and without loss of generality let us suppose $I_{\hat{u}} = [0, T]$. The reference control \hat{u} defines a reference flow

$$(t, \tau, \xi) \mapsto S(t, \tau, \xi, \hat{u}) \equiv \hat{S}(t, \tau, \xi).$$

Let us fix also the initial point ξ_0 , so that the reference trajectory $t \mapsto \hat{x}(t) \equiv \hat{S}(t, 0, \xi_0)$ is completely determined.

Definition 1.1. The control system is said to be locally controllable along \hat{x} (or, if the system can be understood, \hat{x} is locally controllable) if and only if for each $t \in (0, T]$

$$\hat{x}(t) \in \text{int } R(\xi_0, t) = \text{int}\{S(t, 0, \xi_0, u): u \in \mathcal{U}\}.$$

In this section we define the variational cone relative to the reference couple (\hat{x}, \hat{u}) , and we state its main properties. As a consequence, we will get conditions for the point $\hat{x}(t)$ to be interior to the reachable set and hence for the reference trajectory to be locally controllable. Since the proofs of the theorems are rather technical, we provide them at the end of the section.

We start by defining a variation of a reference trajectory at a given time t . Roughly speaking, we consider the principal part with respect to ε of the curve obtained by first applying a control variation starting at t for an interval of time length ε and then

transporting the obtained final point back to time t by means of the reference flow. Therefore, a control variation results in a tangent vector at $\hat{x}(t)$. We require that the same principal part can be obtained if the starting point of the control variation is shifted by $\varepsilon\gamma$, where γ is a small parameter that is independent of ε . It is this last property that allows us to sum the simultaneous variations (see the proofs of Lemma 1.15 and Theorem 1.7).

DEFINITION 1.2. A vector $v \in T_{\hat{x}(t)}M$ is a *right variation* of order α of (\hat{x}, \hat{u}) at time $t \in [0, T)$ if there are (a) positive numbers $\bar{\gamma}, \bar{c}, \bar{\varepsilon}$ and (b) a map $\eta: [0, \bar{\gamma}] \times [0, \bar{c}] \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ continuous in the Π topology of \mathcal{U} such that

$$(1.1) \quad \hat{S}(t, t + \varepsilon\gamma + \varepsilon, S(t + \varepsilon\gamma + \varepsilon, t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \eta(\gamma, c, \varepsilon))) = \hat{x}(t) + \varepsilon^\alpha cv + o(\varepsilon^\alpha)$$

uniformly with respect to γ and c . The vector v is a *left variation* at time $t \in (0, T]$ if

$$(1.2) \quad \hat{S}(t, t - \varepsilon\gamma, S(t - \varepsilon\gamma, t - \varepsilon\gamma - \varepsilon, \hat{x}(t - \varepsilon\gamma - \varepsilon), \eta(\gamma, c, \varepsilon))) = \hat{x}(t) + \varepsilon^\alpha cv + o(\varepsilon^\alpha).$$

The variation will be called *regular* if the map $o(\varepsilon^\alpha)$ that occurs in (1.1) or (1.2) is an $o(\varepsilon^\beta)$ for some $\beta > \alpha$.

Example 1.3. If the constant map $u(t) \equiv \omega$ is an admissible control, then

$$f(t, \hat{x}(t), \omega) - f(t, \hat{x}(t), \hat{u}(t))$$

is a right (left) variation of (\hat{x}, \hat{u}) at each t in which \hat{u} is right (left) continuous.

Remark 1.4. In a chart at $\hat{x}(t)$ equation (1.1) can also be written

$$S(t + \varepsilon\gamma + \varepsilon, t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \eta(\gamma, c, \varepsilon)) = \hat{x}(t + \varepsilon\gamma + \varepsilon) + \varepsilon^\alpha cv + o(\varepsilon^\alpha).$$

Remark 1.5. There are no left variations at $t = 0$ and no right variations at $t = T$.

Remark 1.6. A variation depends only on the reference trajectory and does not depend on the reference control. Namely, if the controls \hat{u} and $\hat{\hat{u}}$ give rise to the same trajectory \hat{x} in a neighborhood of t , then the set of variations at t is the same if either \hat{u} or $\hat{\hat{u}}$ is used.

By definition, the set of variations at t is a cone with vertex at the origin that is not in general a convex set. However, the subset of variations of the same order is a convex set (see Lemma 1.15). Moreover, the simultaneous variations can be summed in the following sense:

THEOREM 1.7. If v_1, \dots, v_r are variations of (\hat{x}, \hat{u}) at time t , then there exist

- (i) a positive number $\bar{\varepsilon}$,
- (ii) a neighborhood V of 0 in $(\mathbb{R}^+)^r$,
- (iii) a continuous map $\nu: V \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$, and
- (iv) two continuous maps $\Theta, \Phi: [0, \bar{\varepsilon}] \rightarrow \mathbb{R}^+$ that go to zero with ε such that

$$\hat{S}(t, t + \Theta(\varepsilon), S(t + \Theta(\varepsilon), t - \Phi(\varepsilon), \hat{x}(t - \Phi(\varepsilon)), \nu(c, \varepsilon))) = \hat{x}(t) + \varepsilon \sum_{i=1}^r c_i v_i + o(\varepsilon).$$

Notice that Theorem 1.7 implies that the transport along the reference flow of the convex hull of the set of variations at t defines a set of directions tangent to the reachable set. Hence the variations that occur at any time $\tau \in [0, t]$ provide information on the geometry of $R(\xi_0, t)$ at $\hat{x}(t)$. For this reason we define the variational cone at a time t as the convex hull of the transport of the variations obtained at each previous time. Contrary to the variations, the variational cone depends on the choice of the reference control except for $t = 0$.

Definition 1.8. Let $t \in [0, T]$. The variational cone $\mathcal{K}(t)$ of (\hat{x}, \hat{u}) at time t is given by

$$\mathcal{K}(t) = \begin{cases} \text{convex hull } \{v : v \text{ is a right variation at } 0\} & \text{if } t = 0. \\ \text{convex hull } \left\{ \bigcup_{\tau \in [0, t]} (\hat{S}(t, \tau, \cdot))_* v : v \text{ is a variation at } \tau \right\} & \text{if } t \neq 0. \end{cases}$$

Here only right (left) variations have to be considered at 0 (at t).

The vectors of $\mathcal{K}(t)$, $t > 0$, define directions tangent to $R(\xi_0, t)$ at $\hat{x}(t)$. In fact, the following property holds.

THEOREM 1.9. Let $w_1, \dots, w_s \in \mathcal{K}(t)$, $t > 0$; there is a neighborhood V of 0 in $(\mathbb{R}^+)^s$ and a continuous map $\eta : V \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ such that

$$(1.3) \quad S(t, 0, \xi_0, \eta(c, \varepsilon)) = \hat{x}(t) + \varepsilon \sum_{i=1}^s c_i w_i + o(\varepsilon).$$

The above theorem and degree theory provide in an obvious way the following sufficient condition for $\hat{x}(t)$ to be interior to the reachable set at time t .

THEOREM 1.10. If for some $t > 0$, $\mathcal{K}(t) = T_{\hat{x}(t)}M$, then $\hat{x}(t) \in \text{int } R(\xi_0, t)$.

By definition, it follows that if $\mathcal{K}(0) = T_{\xi_0}M$, then $\mathcal{K}(t) = T_{\hat{x}(t)}M$, $\forall t \in [0, T]$. Therefore, Theorem 1.10 implies the following:

COROLLARY 1.11. If $\mathcal{K}(0) = T_{\xi_0}M$, then the system is locally controllable along \hat{x} .

Example 1.12. Let

$$\dot{x} = Ax + bu, \quad \mathcal{U} = L^\infty(\mathbb{R}, [0, 1])$$

be a linear control system in \mathbb{R}^2 such that A has complex nonreal eigenvalues and $\text{rank}(b, Ab) = 2$. Let $\hat{u} \equiv 0$ be the reference control, and let $\hat{x} : t \mapsto e^{tA}\xi_0$ be the associated reference trajectory. b is a variation at each $s \in [0, t]$, and $(e^{A(t-s)}b)$ is the transport of b from time s up to time t . Therefore, the variational cone $\mathcal{K}(t)$ contains $e^{A\tau}b$ for all τ in $[0, t]$. Let $\alpha \pm i\beta$ be the eigenvalues of A ; if $t > \pi/\beta$, then the set $\{e^{A\tau}b : \tau \in [0, t]\}$ contains a positive basis of \mathbb{R}^2 . Hence $\hat{x}(t)$ is an interior point of $R(\xi_0, t)$ for each t greater than π/β .

The same ideas can be used to compute the time interval in which a single-input, linear, autonomous control system in \mathbb{R}^n is globally controllable with positive controls, if all the eigenvalues of A are simple and complex.

Notice that if $\text{int } R(\xi_0, t)$ is empty, Theorem 1.10 provides no information on $\hat{x}(t)$. Nevertheless, for a large class of control systems $R(\xi_0, t)$ is contained in a possibly lower-dimensional submanifold $N(\xi_0, t)$ and the interior of $R(\xi_0, t)$ relative to $N(\xi_0, t)$ is not empty [4]. In these cases the variational cone can be used to test whether $\hat{x}(t)$ is a relatively interior point (see § 2).

THEOREM 1.13. If $R(\xi_0, t)$ is contained in a submanifold N and $\mathcal{K}(t) = T_{\hat{x}(t)}N$, then $\hat{x}(t)$ is interior to $R(\xi_0, t)$ with respect to N .

Proof. The proof can be obtained easily by noting that if $R(\xi_0, t)$ is contained in a submanifold N , the definition of $\mathcal{K}(t)$ implies that $\mathcal{K}(t)$ is contained in the tangent space of N at $\hat{x}(t)$. \square

Remark 1.14. If all the constant maps with values in a subset Ω of \mathbb{R}^m are admissible controls, then Theorem 1.10 can also be put in a variational setting. In fact, it states that if $\hat{x}(t) \in \partial R(\xi_0, t)$, then there exists a nontrivial covector $\bar{\lambda}$ at $\hat{x}(t)$ such that $\langle \bar{\lambda}, w \rangle \leq 0$ for each $w \in \mathcal{K}(t)$. Hence in our hypothesis the definition of variational cone implies that the solution $\lambda : [0, t] \rightarrow T^*M$ of the adjoint equation, which in local

coordinates is given by

$$\dot{\lambda}(s) = -\lambda(s) \frac{\partial}{\partial x} f(s, \hat{x}(s), \hat{u}(s)), \quad \lambda(t) = \bar{\lambda},$$

is such that

$$(1.4) \quad \langle \lambda(s), f(s, \hat{x}(s), \omega) \rangle \leq \langle \lambda(s), f(s, \hat{x}(s), \hat{u}(s)) \rangle, \quad \forall \omega \in \Omega \text{ a.e. } s \in [0, t],$$

and

$$(1.5) \quad \langle \lambda(s), v \rangle \leq 0, \quad \forall v \in \mathcal{H}(s), \quad \forall s \in [0, t].$$

We end this section with the proofs of Theorems 1.7 and 1.9. To prove Theorem 1.7 we need the following two lemmas.

LEMMA 1.15. *Let v_1, \dots, v_s be right (left) variations of order k of (\hat{x}, \hat{u}) at time t ; there exist (i) positive numbers $\bar{\gamma}, \bar{\varepsilon}, \bar{t}$, (ii) a neighborhood V of 0 in $(\mathbb{R}^+)^s$, and (iii) a continuous map $\mu: [0, \bar{\gamma}] \times V \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ such that*

$$\begin{aligned} \hat{S}(t, t + \varepsilon\gamma + \varepsilon\bar{t}, S(t + \varepsilon\gamma + \varepsilon\bar{t}, t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \mu(\gamma, c, \varepsilon))) &= \hat{x}(t) + \varepsilon^k \sum_{i=1}^s c_i v_i + o(\varepsilon^k), \\ \left(\hat{S}(t, t - \varepsilon\gamma, S(t - \varepsilon\gamma, t - \varepsilon\gamma - \varepsilon\bar{t}, \hat{x}(t - \varepsilon\gamma - \varepsilon\bar{t}), \mu(\gamma, c, \varepsilon))) &= \hat{x}(t) + \varepsilon^k \sum_{i=1}^s c_i v_i + o(\varepsilon^k) \right). \end{aligned}$$

In other words, the convex set generated by v_1, \dots, v_s is a set of variations of order k .

Proof. We give the proof for right variations; the proof for left variations is analogous. Let us fix a chart at $\hat{x}(t)$ so that we can suppose $M = \mathbb{R}^n$. From Definition 1.2 it follows that there are $\bar{\gamma}_i, \bar{\varepsilon}_i, \bar{c}_i$ and continuous maps $\eta_i: [0, \bar{\gamma}_i] \times [0, \bar{c}_i] \times [0, \bar{\varepsilon}_i] \rightarrow \mathcal{U}$ such that

$$(1.6) \quad S(t + \varepsilon_i \gamma_i + \varepsilon_i, t + \varepsilon_i \gamma_i, \hat{x}(t + \varepsilon_i \gamma_i), \eta_i(\gamma_i, c_i, \varepsilon_i)) = \hat{x}(t + \varepsilon_i \gamma_i + \varepsilon_i) + \varepsilon_i^k c_i v_i + o(\varepsilon_i^k).$$

If $\varepsilon_1, \dots, \varepsilon_s$ are such that

$$(1.7) \quad \varepsilon_1(\bar{\gamma}_1 + 1) \leq \varepsilon_2 \bar{\gamma}_2, \varepsilon_1(\bar{\gamma}_1 + 1) + \varepsilon_2 \leq \varepsilon_3 \bar{\gamma}_3, \dots, \varepsilon_1(\bar{\gamma}_1 + 1) + \varepsilon_2 + \dots + \varepsilon_{s-1} \leq \varepsilon_s \bar{\gamma}_s,$$

then

$$\eta_i \left(\frac{\varepsilon_1(\gamma + 1) + \varepsilon_2 + \dots + \varepsilon_{i-1}}{\varepsilon_i}, c_i, \varepsilon_i \right)$$

is defined for $i = 2, \dots, s$, $\gamma \in [0, \bar{\gamma}_1]$, $c_i \in [0, \bar{c}_i]$, $\varepsilon_i \in [0, \bar{\varepsilon}_i]$. Let H_2, \dots, H_s be the positive numbers defined by

$$\bar{\gamma}_1 + 1 = H_2 \bar{\gamma}_2, H_2(\bar{\gamma}_2 + 1) = H_3 \bar{\gamma}_3, \dots, H_{s-1}(\bar{\gamma}_{s-1} + 1) = H_s \bar{\gamma}_s.$$

If $\varepsilon_1 = \varepsilon$, $\varepsilon_i = \varepsilon H_i$, $i = 2, \dots, s$, then the inequalities (1.7) are satisfied. Let

$$\bar{\gamma} = \bar{\gamma}_1, \quad \gamma_i = \gamma_i(\gamma) = (\gamma + 1 + H_2 + \dots + H_{i-1})/H_i,$$

$$\bar{\varepsilon} = \min \{1, \varepsilon_1, \bar{\varepsilon}_2/H_2, \dots, \bar{\varepsilon}_s/H_s\},$$

$$c = (c_1, \dots, c_s), \quad V_s = [0, \bar{c}_1] \times [0, \bar{c}_2 H_2^k] \times \dots \times [0, \bar{c}_s H_s^k].$$

The map $\mu: [0, \bar{\gamma}] \times V_s \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ given by

$$\mu(\gamma, c, \varepsilon) = \eta_1(\gamma, c_1, \varepsilon) \# \eta_2(\gamma_2, c_2/H_2^k, \varepsilon H_2) \# \dots \# \eta_s(\gamma_s, c_s/H_s^k, \varepsilon H_s)$$

is continuous. Moreover,

$$\begin{aligned} S(t + \varepsilon(\gamma + 1), t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \mu(\gamma, c, \varepsilon)) \\ = S(t + \varepsilon(\gamma + 1), t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \eta_1(\gamma, c_1, \varepsilon)) \\ = \hat{x}(t + \varepsilon\gamma + \varepsilon) + \varepsilon^k c_1 v_1 + o(\varepsilon^k), \end{aligned}$$

$$\begin{aligned}
& S(t + \varepsilon(\gamma + 1 + H_2), t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \mu(\gamma, \mathbf{c}, \varepsilon)) \\
&= S(t + \varepsilon(\gamma + 1 + H_2), t + \varepsilon(\gamma + 1), \hat{x}(t + \varepsilon(\gamma + 1))) \\
&\quad + \varepsilon^k c_1 v_1 + o(\varepsilon^k), \eta_2(\gamma_2, c_2/H_2^k, \varepsilon H_2)).
\end{aligned}$$

By the definition of Π the derivative of the flow with respect to the initial state is continuous, so that

$$\begin{aligned}
& S(t + \varepsilon(\gamma + 1 + H_2), t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \mu(\gamma, \mathbf{c}, \varepsilon)) \\
&= S(t + \varepsilon(\gamma + 1 + H_2), t + \varepsilon(\gamma + 1), \hat{x}(t + \varepsilon(\gamma + 1)), \eta_2(\gamma_2, c_2/H_2^k, \varepsilon H_2)) \\
&\quad + \left[\frac{\partial}{\partial \xi} S(t, t, \hat{x}(t), \eta_2(\gamma_2, c_2/H_2^k, 0)) + O(\varepsilon) \right] (\varepsilon^k c_1 v_1 + o(\varepsilon^k)) \\
&= \hat{x}(t + \varepsilon(\gamma + 1 + H_2)) + \varepsilon^k (c_1 v_1 + c_2 v_2) + o(\varepsilon^k).
\end{aligned}$$

By similar arguments if $\bar{t} = 1 + H_2 + \dots + H_s = H_s(\gamma_s + 1) - \gamma$, then

$$\begin{aligned}
& S(t + \varepsilon(\gamma + \bar{t}), t + \varepsilon\gamma, \hat{x}(t + \varepsilon\gamma), \mu(\gamma, \mathbf{c}, \varepsilon)) \\
&= S(t + \varepsilon H_s(\gamma_s + 1), t + \varepsilon H_s \gamma_s, \hat{x}(t + \varepsilon H_s \gamma_s) + \varepsilon^k (c_1 v_1 + \dots + c_{s-1} v_{s-1}) \\
&\quad + o(\varepsilon^k), \eta_s(\gamma_s, c_1/H_s^k, \varepsilon H_s)) \\
&= \hat{x}(t + \varepsilon\gamma + \varepsilon \bar{t}) + \varepsilon^k (c_1 v_1 + \dots + c_s v_s) + o(\varepsilon^k),
\end{aligned}$$

so that the lemma is proved. \square

LEMMA 1.16. Let v_1, \dots, v_r be right (left) variations of (\hat{x}, \hat{u}) at time t ; there exist (i) a positive number $\bar{\varepsilon}$, (ii) a neighborhood V of 0 in $(\mathbb{R}^+)^r$, (iii) a continuous map $\nu: V \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$, and (iv) a continuous map $\Theta: [0, \bar{\varepsilon}] \rightarrow \mathbb{R}^+$ that goes to zero with ε such that

$$\begin{aligned}
& \hat{S}(t, t + \Theta(\varepsilon), S(t + \Theta(\varepsilon), t, \hat{x}(t), \nu(c, \varepsilon))) = \hat{x}(t) + \varepsilon \sum_{i=1}^r c_i v_i + o(\varepsilon), \\
& \left(S(t, t - \Theta(\varepsilon), \hat{x}(t - \Theta(\varepsilon)), \nu(c, \varepsilon)) = \hat{x}(t) + \varepsilon \sum_{i=1}^r c_i v_i + o(\varepsilon) \right).
\end{aligned}$$

Proof. Let $k_1 < k_2 < \dots < k_p$ be the orders of the variations v_i 's. We denote by w_{i1}, \dots, w_{is_i} the variation of order k_i . Let $h_i = 1/k_i$; then $h_1 > h_2 > \dots > h_p$. By Lemma 1.15, for each i there are $\tilde{\gamma}_i, \tilde{\varepsilon}_i, \tilde{t}_i, V_i$ and $\mu_i: [0, \tilde{\gamma}_i] \times V_i \times [0, \tilde{\varepsilon}_i] \rightarrow \mathcal{U}$ such that in a chart at $\hat{x}(t)$

$$\begin{aligned}
& S(t + \varepsilon^{h_i} \gamma + \varepsilon^{h_i} \tilde{t}_i, t + \varepsilon^{h_i} \gamma, \hat{x}(t + \varepsilon^{h_i} \gamma), \mu_i(\gamma, d^i, \varepsilon^{h_i})) \\
&= \hat{x}(t + \varepsilon^{h_i} \gamma + \varepsilon^{h_i} \tilde{t}_i) + \varepsilon \sum_{j=1}^{s_i} d_j^i w_{ij} + o(\varepsilon).
\end{aligned}$$

Hence if ε is sufficiently small, say, $\varepsilon \in [0, \varepsilon']$, and if $d^i \in V_i$, then $\nu_i: (\varepsilon, d^i) \mapsto \mu_i(\varepsilon^{h_i} \tilde{t}_1 + \dots + \varepsilon^{h_{i-1}} \tilde{t}_{i-1}, d^i, \varepsilon^{h_i})$ is defined and continuous. Set $\Theta(\varepsilon) = \varepsilon^{h_1} \tilde{t}_1 + \dots + \varepsilon^{h_p} \tilde{t}_p$, $c \in \bigoplus_{i=1}^p V_i$, and $\nu(\varepsilon, c) = \nu_1(\varepsilon, d^1) \# \dots \# \nu_p(\varepsilon, d^p)$. With the same arguments used in the proof of Lemma 1.15 we get

$$S(t + \Theta(\varepsilon), t, \hat{x}(t), \nu(c, \varepsilon)) = \hat{x}(t + \Theta(\varepsilon)) + \varepsilon \sum_{j=1}^r c_j v_j + o(\varepsilon).$$

The proof is analogous for the left variations. \square

Proof of Theorem 1.7. Let v_1, \dots, v_r be variations of (\hat{x}, \hat{u}) at time t , and let us suppose that v_j is a left variation for $j \leq s$ and that it is a right variation for $j > s$. The control variation defined in Lemma 1.16 is a variation of the reference control \hat{u} before the time t for left variations and after time t for right variations. Therefore, by concatenating the two control variations we get the desired property. \square

Proof of Theorem 1.9. Let $\{w_1, \dots, w_s\} \subset \mathcal{H}(t)$; there exists $t_0 < t_1 < \dots < t_p$, $v_{1i}, \dots, v_{ri} \in T_{\hat{x}(t_i)}M$ such that v_{ji} is a variation at time t_i and $\{(S(t, \tau, \cdot, \hat{u}))_* v_{ji}, i = 1, \dots, p, j = 1, \dots, r_i\} = \{w_1, \dots, w_s\}$. For each i let $\bar{\varepsilon}_i, V_i, \Theta_i, \Phi_i$, and ν_i be as in Theorem 1.7; hence in a chart at $\hat{x}(t_i)$

$$(1.8) \quad \begin{aligned} & S(t_i + \Theta_i(\varepsilon), t_i - \Phi_i(\varepsilon), \hat{x}(t_i - \Phi_i(\varepsilon)), \nu_i(c^i, \varepsilon)) \\ &= \hat{x}(t_i + \Theta_i(\varepsilon)) + \varepsilon \sum_{j=1}^{r_i} c_j^i v_{ji} + o(\varepsilon). \end{aligned}$$

Let $\bar{\varepsilon} < \min \{\bar{\varepsilon}_i\}$ be such that $\sup_{\varepsilon \in [0, \bar{\varepsilon}]} \{t_i + \Theta_i(\varepsilon)\} < \inf_{\varepsilon \in [0, \bar{\varepsilon}]} \{t_{i+1} - \Phi_{i+1}(\varepsilon)\}$. Let $V = V_1 \times V_2 \times \dots \times V_p$; V is neighborhood of 0 in $(\mathbb{R}^+)^s$. We define $\mu: V \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ by

$$\mu(c, \varepsilon)(t) = \begin{cases} \nu_i(c^i, \varepsilon)(t), & t \in [t_i - \Phi_i(\varepsilon), t_i + \Theta_i(\varepsilon)], \\ \hat{u}(t), & \text{otherwise.} \end{cases}$$

Let us prove by induction that

$$(1.9) \quad \begin{aligned} & S(t_i + \Theta_i(\varepsilon), t_0, \xi_0, \mu(c, \varepsilon)) = \hat{x}(t_i + \Theta_i(\varepsilon)) \\ &+ \varepsilon \sum_{j=1}^i \sum_{s=1}^{r_j} c_s^j (\hat{S}(t_i + \Theta_i(\varepsilon), t_j, \cdot))_* v_{sj} + o(\varepsilon). \end{aligned}$$

For $i = 1$, (1.9) is proved by (1.8). Let $a_i(\varepsilon) = t_i + \Theta_i(\varepsilon)$ and $b_i(\varepsilon) = t_i - \Phi_i(\varepsilon)$. Then

$$\begin{aligned} & S(a_{i+1}(\varepsilon), t_0, \xi_0, \mu(c, \varepsilon)) = S(a_{i+1}(\varepsilon), b_{i+1}(\varepsilon), \\ & \quad \hat{S}(b_{i+1}(\varepsilon), a_i(\varepsilon), S(a_i(\varepsilon), t_0, \xi_0, \mu(c, \varepsilon))), \mu(c, \varepsilon)) \\ &= S\left(a_{i+1}(\varepsilon), b_{i+1}(\varepsilon), \hat{S}\left(b_{i+1}(\varepsilon), a_i(\varepsilon), \hat{x}(a_i(\varepsilon))\right.\right. \\ & \quad \left.\left.+ \varepsilon \left[\sum_{j=1}^i \sum_{s=1}^{r_j} c_s^j (\hat{S}(a_i(\varepsilon), t_j, \cdot))_* v_{sj} \right] + o(\varepsilon) \right), \nu_{i+1}(c^{i+1}, \varepsilon)\right) \\ &= S\left(a_{i+1}(\varepsilon), b_{i+1}(\varepsilon), \hat{x}(b_{i+1}(\varepsilon))\right. \\ & \quad \left.+ \varepsilon \left[\sum_{j=1}^i \sum_{s=1}^{r_j} c_s^j (\hat{S}(b_{i+1}(\varepsilon), t_j, \cdot))_* v_{sj} \right] \right. \\ & \quad \left.+ o(\varepsilon), \nu_{i+1}(c^{i+1}, \varepsilon)\right) \\ &= S(a_{i+1}(\varepsilon), b_{i+1}(\varepsilon), \hat{x}(b_{i+1}(\varepsilon)), \nu_{i+1}(c^{i+1}, \varepsilon)) \\ & \quad + \varepsilon \left[\sum_{j=1}^i \sum_{s=1}^{r_j} c_s^j (\hat{S}(a_{i+1}(\varepsilon), t_j, \cdot))_* v_{sj} \right] + o(\varepsilon) \\ &= \hat{x}(t_{i+1} + \Theta_{i+1}(\varepsilon)) + \varepsilon \left[\sum_{j=1}^{i+1} \sum_{s=1}^{r_j} c_s^j (\hat{S}(a_{i+1}(\varepsilon), t_j, \cdot))_* v_{sj} \right] + o(\varepsilon). \end{aligned}$$

If $t_p = T$, then $\Theta_p(\varepsilon) = 0$ since there are no right variations at T ; hence (1.9) proves the theorem for $i = p$. Otherwise, if $t_p < T$, we set $t_{p+1} = T$, $\Theta_{p+1}(\varepsilon) \equiv \Phi_{p+1}(\varepsilon) \equiv 0$, and (1.9) proves the theorem for $i = p + 1$. \square

2. C^∞ time-independent control systems. In this section we study the properties of the variational cone in the case of C^∞ time-independent control systems. Note that

any control system Σ can be considered to be time independent by considering the time as another state variable. Hence the results of this section can be adapted to the time-dependent systems that are C^∞ with respect to both time and state. For the C^∞ manifolds we use the following notations: $\mathcal{V}(M)$ is the Lie algebra of C^∞ vector fields on M . If $f \in \mathcal{V}(M)$, $(t, \xi) \mapsto \exp tf \cdot \xi$ denotes the local flow of f and $ad_f: \mathcal{V}(M) \rightarrow \mathcal{V}(M)$, $g \mapsto ad_f g \equiv [f, g]$ denotes the Lie derivation in $\mathcal{V}(M)$ with respect to f . If F is a subset of $\mathcal{V}(M)$, $\text{Lie}(F)$ denotes the Lie subalgebra of $\mathcal{V}(M)$ generated by F and $(\text{Lie}(F))'$ denotes the derived algebra of $\text{Lie}(F)$ defined by

$$(\text{Lie}(F))' = \text{span} \{[X, Y]: X, Y \in \text{Lie}(F)\}.$$

We consider the control system Σ :

$$\dot{x} = f(x, u).$$

In addition to the hypotheses of § 1, we assume the following:

(A5) The manifold M is C^∞ .

(A6) $f: M \times \mathbb{R}^m \rightarrow TM$ is such that for each $\omega \in \mathbb{R}^m$, $f(\cdot, \omega)$ is a C^∞ vector field.

(A7) If $u: [a, b] \rightarrow \mathbb{R}^m$ belongs to \mathcal{U} , then $\forall \tau$ the control map $u_\tau: [a + \tau, b + \tau] \rightarrow \mathbb{R}^m$, defined by $u_\tau(t) = u(t - \tau)$, belongs to \mathcal{U} .

Assumption (A7) ensures that if one has an admissible control, then one can use it at any time, so that the trajectories of Σ can always be thought of as trajectories with initial time equal to 0. For this reason from now on we will not specify the initial time. For example, $S(t, \xi, u)$ will denote the value at time t of the solution of Σ relative to the control u starting at ξ . Notice that because Σ is time independent, u_τ fulfills assumption (A2) if and only if u does.

Let Ω be the set of all the values taken by the control maps, i.e., $\Omega = \{u(t) \in \mathbb{R}^m: u \in \mathcal{U}, t \in I_u\}$. We associate with Σ the family $F = \{f(\cdot, \omega): \omega \in \Omega\} \subseteq \mathcal{V}(M)$. The trajectories of Σ relative to the piecewise-constant controls are contained in the orbits of F . The local flows of the vector fields in F generate a pseudogroup of local omeomorphisms:

$$G = \{\exp t_1 g_1 \cdots \exp t_k g_k: t_i \in \mathbb{R}, g_i \in F\}.$$

It is known that $N(\xi_0) = \{\phi(\xi_0): \phi \in G\}$ is a C^∞ immersed, connected submanifold of M [19]. $N(\xi_0)$ is the set of points that can be reached from ξ_0 by means of the orbits of F . Let $N(\xi_0, t)$ be the subset of $N(\xi_0)$ defined by

$$N(\xi_0, t) = \left\{ \phi(\xi_0): \phi \in G, \sum_{i=1}^k t_i = t \right\}.$$

$N(\xi_0, t)$ is a possibly disconnected, integral manifold of the distribution

$$\Delta^0 = \{g_* \phi \circ g^{-1} - h_* \chi \circ h^{-1}: g, h \in G, \phi, \chi \in F\}.$$

Δ^0 always contains the distribution

$$J^0(F) = \text{span} \left\{ \sum a_i X_i + Z: X_i \in F, a_i \in \mathbb{R}, \sum a_i = 0, Z \in (\text{Lie}(F))' \right\},$$

and Δ^0 coincides with J^0 if either $J^0(F)$ has constant dimension or the family F is analytic; see [4], [6] and the references therein.

In [4] it is proved that, whatever \mathcal{U} is with the properties A_1, \dots, A_7 , the reachable set $R(\xi_0, t)$ is contained in $N(\xi_0, t)$.

DEFINITION 2.1. The relative interior, $\text{int}_{\text{rel}} R(\xi_0, t)$, of $R(\xi_0, t)$ is the set of interior points of $R(\xi_0, t)$ in the topology of $N(\xi_0, t)$.

Remark 2.2. If \mathcal{U} contains the set of piecewise-constant controls with values in Ω and $R(\xi_0, t) \neq \emptyset$, then $\text{int}_{\text{rel}} R(\xi_0, t)$ is not empty if either F is analytic or $J^0(F)$ has constant dimension [20].

DEFINITION 2.3. The control system is *weakly locally controllable* along a trajectory \hat{x} (or, if the system can be understood, \hat{x} is weakly locally controllable) if and only if for each $t \in (0, T]$

$$\hat{x}(t) \in \text{int}_{\text{rel}} R(\xi_0, t).$$

By Theorem 1.10, if for each t positive $\mathcal{K}(t) = \Delta^0(\hat{x}(t))$, then \hat{x} is weakly locally controllable. For example, this is the case if $\mathcal{K}(0) = \Delta^0(\xi_0)$.

A variation at t or, more generally, an element $w \in \mathcal{K}(t)$ can be thought of as the value at $\hat{x}(t)$ of a vector field Y that is not uniquely determined. We will say that a vector field $Y \in \mathcal{V}(M)$ defines a variation at time t (an element of $\mathcal{K}(t)$) if and only if $Y(\hat{x}(t))$ is a variation at t (is an element of the variational cone at time t). In this sense we can say that a subset of $\mathcal{V}(M)$ is either a set of variations at t or a subset of the variational cone at t .

The subspaces contained in the variational cone are particularly interesting. As a matter of fact, if \hat{x} is time optimal, then the adjoint covector given by the Pontryagin maximum principle must be orthogonal to them. The subspaces of $\mathcal{V}(M)$ contained in the variational cone for each t in an interval give rise to further tangent directions. Namely, as a consequence of the properties of the transport along the reference flow, we have

THEOREM 2.4. *Let us suppose that the reference control is constant in $(t_0, t_1]$, i.e., $\hat{u}(t) = \omega \forall t \in (t_0, t_1]$, and let $f_0 = f(\cdot, \omega)$. If \mathcal{D} is a subspace of $\mathcal{V}(M)$ such that*

$$(2.1) \quad Z(\hat{x}(t)) \in \mathcal{K}(t) \quad \forall Z \in \mathcal{D} \text{ and } \forall t \in (t_0, t_1],$$

then for all $Z \in \mathcal{D}$

$$ad_{f_0}^i Z(\hat{x}(t)) \in \mathcal{K}(t) \quad \forall i \in \mathbb{N} \text{ and } \forall t \in (t_0, t_1].$$

Proof. Let $t_0 < t \leq t_1$; by definition $(\exp \tau f_0)_* Z(\hat{x}(t - \tau)) \in \mathcal{K}(t)$, $\forall \tau \in [0, t - t_0]$. Hence the subspace $H = \text{co} \{(\exp \tau f_0)_* Z(\hat{x}(t - \tau)) : Z \in \mathcal{D}, \tau \in [0, t - t_0]\}$ is contained in $\mathcal{K}(t)$. The C^∞ curve $\tau \mapsto (\exp \tau f_0)_* Z(\hat{x}(t - \tau))$ belongs to H , so that its derivatives at $\tau = 0$ belong to H and hence to $\mathcal{K}(t)$. However, the i th derivative at $\tau = 0$ is $ad_{f_0}^i Z(\hat{x}(t))$, so that the statement is proved. \square

Hypothesis (A7) implies that if the reference trajectory is stationary, then the set of variations at t does not depend on t , so that the variational cone is increasing with t . Hence in this case the maximal subspace contained in the variational cone at any positive time must be invariant under the Lie derivative with respect to f_0 . The variations, and hence the variational cone, of a stationary trajectory have further specific properties that are consequences of the fact that the control variation of Definition 1.2 can be chosen independently on γ . The properties we are going to prove are properties of variations of a stationary trajectory of a time-independent control system that satisfy hypothesis (A7), and they also hold if the control system is only C^1 . For variations of a stationary trajectory there is no distinction between right and left variations, and any variations can be thought of as a variation at any time. For this reason we omit the time at which a variation occurs and we consider each variation as a right variation.

PROPOSITION 2.5. *If v is a variation of order α relative to a stationary trajectory, it is a variation of any order greater than α .*

Proof. By Definition 1.2 there exists a continuous control variation $\eta(c, \varepsilon)$ such that in a chart at ξ_0

$$S(\varepsilon, \xi_0, \eta(c, \varepsilon)) = \xi_0 + \varepsilon^\alpha cv + o(\varepsilon^\alpha).$$

Let $\beta > 1$; ε^β is smaller than ε for $0 < \varepsilon < 1$. If $\bar{\eta}(c, \varepsilon)$ coincides with the control $\eta(c, \varepsilon^\beta)$ in the interval $[0, \varepsilon^\beta]$ and with the reference control in the interval $[\varepsilon^\beta, \varepsilon]$, then

$$S(\varepsilon, \xi_0, \bar{\eta}(c, \varepsilon)) = \xi_0 + \varepsilon^{\alpha\beta} cv + o(\varepsilon^{\alpha\beta}),$$

so that the proposition is proved. \square

Notice that for a nonstationary trajectory the variation's order cannot be enlarged in an analogous way. In fact, it may not be possible to enlarge the length $\varepsilon\gamma$ of the interval of possible starting times of control variations.

Lemma 1.15 implies the following:

COROLLARY 2.6. *The set of variations relative to a stationary trajectory is convex.*

3. Affine control systems. In this section we study the properties of the variational cone when the control system is a C^∞ system affine with respect to the control and the reference control is constant. Without loss of generality we can suppose that $\hat{u}(t) \equiv 0$. The results obtained can also be used when the reference control is a piecewise-constant one. In fact, if we restrict the reference couple to a subinterval, we obtain a variational cone that is contained in the original one.

Let Ω be an assigned subset of \mathbb{R}^m such that $0 \in \Omega$ and $\text{span } \Omega = \mathbb{R}^m$. To each family $\mathbf{f} = (f_0, f_1, \dots, f_m)$ of C^∞ vector fields on a manifold M we associate the affine control process $(\Sigma_{\mathbf{f}}, \Omega)$ on M , where $\Sigma_{\mathbf{f}}$ is defined by

$$\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$$

and the control u belongs to the class of the piecewise-constant maps with values in Ω . We will deal with controls defined on subintervals of a given interval $[0, T]$, so that we will take as admissible controls the set \mathcal{U} of piecewise-constant maps from the subintervals of $[0, T]$ to Ω . The set \mathcal{U} can be immersed in $L^1([0, T], \mathbb{R}^m)$ by extending each $u \in \mathcal{U}$ with the zero value. We choose Π equal to the topology induced on \mathcal{U} by the L^1 topology.

$(\Sigma_{\mathbf{f}}, \Omega)$ belongs to the class of systems considered in the previous sections. We will attach the subscript \mathbf{f} to any object defined in §§ 1 and 2 for a general system when it is referred to the system $\Sigma_{\mathbf{f}}$. For example, $S_{\mathbf{f}}(t, \xi, u)$ will denote the value at time t of the solution of $\Sigma_{\mathbf{f}}$ relative to the control u , starting at ξ . For this class of systems the distribution $J_{\mathbf{f}}^0$ defined in § 2 coincides with the distribution

$$\mathcal{S}_{\mathbf{f}} = \text{Lie} \{ad_{f_0}^i f_i, i = 1, \dots, m, j = 0, 1, \dots, \}.$$

Let $\hat{u} \equiv 0$ be the reference control, and let $\hat{x}_{\mathbf{f}}(t) = S_{\mathbf{f}}(t, \xi_0, 0)$, $t \in [0, T]$ be the reference trajectory; $\mathcal{K}_{\mathbf{f}}(t)$ is the variational cone of the reference couple $(\hat{x}_{\mathbf{f}}, 0)$. A vector v is a right variation of order α at t if there exists a continuous map $(\gamma, c, \varepsilon) \mapsto \eta(\gamma, c, \varepsilon)$ such that

$$\exp(-\varepsilon\gamma - \varepsilon)f_0 \cdot S_{\mathbf{f}}(\varepsilon, \hat{x}_{\mathbf{f}}(t + \varepsilon\gamma), \eta(\gamma, c, \varepsilon)) = \hat{x}_{\mathbf{f}}(t) + \varepsilon^\alpha cv + o(\varepsilon^\alpha).$$

Note that because η is continuous, its L^1 norm $\|\eta(\gamma, c, \varepsilon)\|_{L^1}$ goes to 0 with ε . In fact, we can suppose that the support of the map $\eta(\gamma, c, \varepsilon)$ is contained in the interval

$[0, \varepsilon]$; this implies that

$$\begin{aligned} \|\eta(\gamma, c, \varepsilon)\|_{L^1} &= \int_0^\varepsilon \|\eta(\gamma, c, \varepsilon)(s)\| ds \leq \int_0^\varepsilon \|\eta(\gamma, c, \varepsilon)(s) - \eta(\gamma, c, 0)(s)\| ds \\ &\quad + \int_0^\varepsilon \|\eta(\gamma, c, 0)(s)\| ds \\ &\leq \|\eta(\gamma, c, \varepsilon) - \eta(\gamma, c, 0)\|_{L^1} + \int_0^\varepsilon \|\eta(\gamma, c, 0)(s)\| ds. \end{aligned}$$

The flow of the control system S_t , as a map from a subset of $[0, T] \times M \times L_1([0, T], \mathbb{R}^m)$ to M , is continuous. Therefore, the variations at τ can be studied in any chart at $\hat{x}_t(\tau)$. In other words, the trajectory's variations are contained in a prescribed chart for ε small.

The following approximation result shows that the variations at τ depend in general on only the germs of the f_i 's at $\hat{x}_t(\tau)$. Without loss of generality set $\tau = 0$. Let us choose a coordinate system at $\xi_0 \in M$, and let us use the same notation for the system Σ_t and for its coordinate representation. The following property holds:

PROPOSITION 3.1. *Let Σ_Φ denote the affine control system obtained by substituting in the system Σ_t at each vector field f_i its Taylor approximation at ξ_0 of order k , and let $\alpha < k + 1$. If $\eta : [0, \bar{\gamma}] \times [0, \bar{c}] \times [0, \bar{\varepsilon}] \rightarrow \mathcal{U}$ is a continuous map such that*

$$(3.1) \quad (\|\eta(\gamma, c, \varepsilon)\|_{L^1})^{k+1} = o(\varepsilon^\alpha),$$

then

$$S_t(\varepsilon, \hat{x}_t(\varepsilon\gamma), \eta(\gamma, c, \varepsilon)) = \hat{x}_t(\varepsilon\gamma + \varepsilon) + \varepsilon^\alpha cv + o(\varepsilon^\alpha)$$

if and only if

$$S_\Phi(\varepsilon, \hat{x}_\Phi(\varepsilon\gamma), \eta(\gamma, c, \varepsilon)) = \hat{x}_\Phi(\varepsilon\gamma + \varepsilon) + \varepsilon^\alpha cv + o(\varepsilon^\alpha).$$

Proof. Let I be a compact interval containing 0 such that $\hat{x}_\Phi(t)$ is defined $\forall t \in I$. The Gronwall's lemma implies that there exist two positive constants H, C such that if $\|u\|_{L^1} < H$, then

$$(3.2) \quad \|S_\Phi(t, \xi_0, u)\| \leq \|\hat{x}_\Phi(t)\| + C\|u\|_{L^1} \quad \forall t \in I.$$

Let $G(x)$ denote the $(m+1) \times n$ matrix whose columns are the vector fields $f_i(x)$, $i = 0, 1, \dots, m$, and let $G_k(x)$ be its Taylor approximation of order k . Let $u \in \mathcal{U}$, $\|u\|_{L^1} < H$; we set $v(t)$ equal to the transpose of $(1, u_1(t), \dots, u_m(t))$.

$$\begin{aligned} \|S_t(t, \xi_0, u) - S_\Phi(t, \xi_0, u)\| &= \left\| \int_0^t (G(S_t(\tau, \xi_0, u)) - G_k(S_\Phi(\tau, \xi_0, u))) \cdot v(\tau) d\tau \right\| \\ &= \left\| \int_0^t (G(S_t(\tau, \xi_0, u)) - G(S_\Phi(\tau, \xi_0, u)) + G(S_\Phi(\tau, \xi_0, u)) \right. \\ &\quad \left. - G_k(S_\Phi(\tau, \xi_0, u))) \cdot v(\tau) d\tau \right\| \\ &\leq \int_0^t L\|v(\tau)\| \|S_t(\tau, \xi_0, u) - S_\Phi(\tau, \xi_0, u)\| d\tau \\ &\quad + \int_0^t N\|v(\tau)\| \|(S_\Phi(\tau, \xi_0, u))^{(k+1)}\| d\tau \\ &\leq \int_0^t L\|v(\tau)\| \|S_t(\tau, \xi_0, u) - S_\Phi(\tau, \xi_0, u)\| d\tau \\ &\quad + N(t+H) \left(\sup_{\tau \in [0, t]} \|S_\Phi(\tau, \xi_0, u)\|^{k+1} \right) \end{aligned}$$

for some positive constants N, L . Gronwall's inequality implies

$$\|S_t(t, \xi_0, u) - S_\Phi(t, \xi_0, u)\| \leq B \left(\sup_{\tau \in [0, t]} \|S_\Phi(\tau, \xi_0, u)\|^{k+1} \right).$$

By (3.1) if ε is sufficiently small, $\|\eta\|_{L^1} < H$. Let $\bar{\eta}(\gamma, c, \varepsilon)$ be the control map defined by

$$\bar{\eta}(\gamma, c, \varepsilon)(t) = \begin{cases} 0, & t \in [0, \varepsilon\gamma], \\ \eta(\gamma, c, \varepsilon)(t), & t \in (\varepsilon\gamma, \varepsilon + \varepsilon\gamma], \end{cases}$$

$\|\eta\|_{L^1} = \|\bar{\eta}\|_{L^1}$, and

$$\begin{aligned} & \|S_\Phi(\varepsilon, \hat{x}_\Phi(\varepsilon\gamma), \eta(\gamma, c, \varepsilon)) - \hat{x}_\Phi(\varepsilon\gamma + \varepsilon) - S_t(\varepsilon, \hat{x}_t(\varepsilon\gamma), \eta(\gamma, c, \varepsilon)) + \hat{x}_t(\varepsilon\gamma + \varepsilon)\| \\ & \leq \|\hat{x}_\Phi(\varepsilon\gamma + \varepsilon) - \hat{x}_t(\varepsilon\gamma + \varepsilon)\| + \|S_t(\varepsilon\gamma + \varepsilon, \xi_0, \bar{\eta}(\gamma, c, \varepsilon)) \\ & \quad - S_\Phi(\varepsilon\gamma + \varepsilon, \xi_0, \bar{\eta}(\gamma, c, \varepsilon))\| \\ & \leq B \left(\sup_{\tau \in [0, 2\varepsilon]} \|\hat{x}_\Phi(\tau)\|^{k+1} + \sup_{\tau \in [0, 2\varepsilon]} \|S_\Phi(\tau, \xi_0, \bar{\eta})\|^{k+1} \right). \end{aligned}$$

$\|\hat{x}_\Phi(\tau)\|$ goes to zero at least as τ , so that $\sup_{\tau \in [0, 2\varepsilon]} \|\hat{x}_\Phi(\tau)\|^{k+1} = o(\varepsilon^\alpha)$; moreover, by (3.1) and (3.2) we get $\sup_{\tau \in [0, 2\varepsilon]} \|S_\Phi(\tau, 0, \bar{\eta})\|^{k+1} = o(\varepsilon^\alpha)$, and the statement is proved. \square

Remark 3.2. Let v be a variation of order α such that the L^1 -norm of its control variation goes to 0 as ε^r . v remains a variation of order α if the vector fields f_i 's are perturbed with terms of order greater than $\max\{\alpha, \alpha/r\}$.

Notice that if Ω is bounded, then $\|\eta(\gamma, c, \varepsilon)\|_{L^1} \leq L\varepsilon$ for some constant L , so that the following corollary holds.

COROLLARY 3.3. *If Ω is bounded, v is a variation of order α for $(\hat{x}_t, 0)$ at time 0 if and only if it is a variation of order α at time 0 for $(\hat{x}_\Phi, 0)$ for each $k > \alpha - 1$.*

A way to compare variations that occur at different times is to bring each variation back to time 0 by using the reference flow, that is, $v \in T_{\hat{x}_t(t)}M$ is a variation at time t if and only if

$$\exp(-t - \varepsilon\gamma - \varepsilon)f_0 \cdot S_t(\varepsilon, \hat{x}_t(t + \varepsilon\gamma), \eta(\gamma, c, \varepsilon)) = \xi_0 + \varepsilon^\alpha c \exp(-tf_0)_* v + o(\varepsilon^\alpha).$$

This point of view is better understood by looking at the pullback system introduced in [3]. This system describes the behavior of the trajectories of Σ_t that lie near the reference trajectory relative to the reference trajectory itself. Hence it can be considered to be the “right” system for studying the variations of the reference couple. Let us recall from [3] the definition of a pullback system.

By the properties of differential equations it follows that there is a neighborhood U of ξ_0 and a neighborhood I of 0 in \mathbb{R} containing $[0, T]$ such that $\exp tf_0 \cdot \xi$ is defined for each t in I and each ξ in U . Therefore, we can define for any $f \in \mathcal{V}(M)$ the time-dependent vector field

$$f^*: I \times U \rightarrow TU \subset TM, \quad f^*(t, \xi) \equiv f^*(t)(\xi) = \exp(-tf_0)_* \cdot f(\exp tf_0 \cdot \xi).$$

If u belongs to a sufficiently small neighborhood of 0 in $L^1([0, T], \Omega)$, the map

$$t \mapsto y(t, \xi_0, u) \equiv \exp(-tf_0) \cdot S_t(t, \xi_0, u)$$

is defined and it satisfies the time-dependent control system on U :

$$\dot{y}(t) = \sum_{i=1}^m u_i(t) f_i^*(t, y(t)), \quad y(0) = \xi_0.$$

The time-dependent vector field f_i^* may be viewed as a C^∞ vector field on $M^* = I \times U$. If we set $\mathbf{f}^* = \{\partial/\partial t, f_1^*, \dots, f_m^*\}$, the pullback system of the system Σ_r is the system Σ_{r^*} on M^* given by

$$\dot{y}^* = \frac{\partial}{\partial t} + \sum_{i=1}^m u_i f_i^*(y^*).$$

Notice that there is an isomorphism between the solutions of Σ_{r^*} and the ones of the restriction of Σ_r to the neighborhood $V = \{\exp tf_0 \cdot \xi : \xi \in U, t \in I\}$ of the reference trajectory. The solutions of the two systems are linked by the relation

$$(3.3) \quad S_{r^*}(t, (\tau, \xi_0), u) = (t + \tau, \exp(-(t + \tau)f_0) \cdot S_r(t, \exp \tau f_0 \cdot \xi_0, u)).$$

In what follows we shall identify U with $\{0\} \times U$, so that $\xi_0 \equiv (0, \xi_0)$, $N_{r^*}(\xi_0, 0)$ is contained in $N_r(\xi_0, 0)$, $N_{r^*}(\xi_0, t) = \{t\} \times N_{r^*}(\xi_0, 0)$ and $\Delta_{r^*}^0(\hat{x}_{r^*}(t)) = \Delta_{r^*}^0(\xi_0)$. Notice that Σ_{r^*} evolves on $I \times N_{r^*}(\xi_0, 0)$ and that the reference flow is a translation. In some sense Σ_{r^*} transforms an open neighborhood of the reference trajectory in the product $I \times U$.

Since Σ_{r^*} reproduces only the trajectories of Σ_r lying near the reference trajectory, $N_{r^*}(\xi_0, 0)$ may be not open in $N_r(\xi_0, 0)$, but it is if $\Delta_{r^*}^0(\xi_0) = \Delta_r^0(\xi_0)$. In particular, this is the case if $\mathcal{S}_r(\xi_0) = \Delta_r^0(\xi_0)$; in fact, $\mathcal{S}_{r^*} = \{h^* : h \in \mathcal{S}_r\}$. In any case the variations are generated by small (with respect to the L^1 norm) controls, so that from (3.3) it follows that a vector field h is such that $h(\hat{x}_r(t))$ is a variation at t for $(\hat{x}_r, 0)$ if and only if $h^*(t, \xi_0)$ is a variation at t for $(\hat{x}_{r^*}, 0)$. In particular, $v \in \mathcal{H}_r(0)$ if and only if $v \in \mathcal{H}_{r^*}(0)$. In terms of pullback the vector $v \in \Delta_r^0(\xi_0)$ is a right variation of order α at t if there exists a continuous map $(\gamma, c, \varepsilon) \mapsto \eta(\gamma, c, \varepsilon)$ such that

$$S_{r^*}(\varepsilon, (t + \varepsilon\gamma, \xi_0), \eta(\gamma, c, \varepsilon)) = (t + \varepsilon\gamma + \varepsilon, \xi_0 + \varepsilon^\alpha cv + o(\varepsilon^\alpha)).$$

Each f_i , $i = 1, \dots, m$, provides a variation of order 1 at each time (see Example 1.3). Moreover, the Campbell–Hausdorff formula gives any trajectory of Σ_{r^*} relative to a piecewise-constant control as the trajectory of a vector field whose asymptotic expansion (modulo $\partial/\partial t$) is an element of \mathcal{S}_{r^*} . Noting that $\mathcal{S}_{r^*}(\xi_0) = \mathcal{S}_r(\xi_0)$, we shall keep the elements of $\mathcal{S}_r(\xi_0)$ as candidates to be variations at 0.

The main result in [3] provides a sufficient condition for (Σ_r, Ω) to be weakly locally controllable along \hat{x}_r when Ω is a neighborhood of the origin in \mathbb{R}^m . Namely, some elements of \mathcal{S}_r are pointed out as possible obstructions, and some conditions are given to neutralize them. In this paper we use the same ideas to construct variations at 0. The result is that different types of neutralization can be used for the same system; see Example 5.2. To make the above ideas more precise and to state the main result we need the notations introduced in [3], [18].

Let $\text{Lie } \mathbf{X}$ be the free Lie algebra on \mathbb{R} generated by the noncommutative indeterminates $\mathbf{X} = \{X_0, \dots, X_m\}$. \mathcal{S} will denote the ideal of $\text{Lie } \mathbf{X}$ generated by X_1, \dots, X_m . Substituting f_i for X_i in any element $\chi \in \text{Lie } \mathbf{X}$, we obtain a vector field that will be denoted by χ_r . For any subset A of $\text{Lie } \mathbf{X}$, A_r will denote the subset of $\text{Lie } \mathbf{f}$ given by $A_r = \{\chi_r : \chi \in A\}$. By means of a set $\mathbf{l} = (l_0, \dots, l_m)$ of integers we define a weight on $\text{Lie } \mathbf{X}$ that will induce a weight on $\text{Lie } \mathbf{f}$. Let Λ be a bracket in \mathcal{S} . We denote the length of Λ with respect to X_i (i.e., the number of times that X_i appears in Λ) by $|\Lambda|_i$. The weight of Λ is defined by

$$\|\Lambda\|_{\mathbf{l}} = \sum_{i=0}^m l_i |\Lambda|_i, \quad \|0\|_{\mathbf{l}} = 0,$$

and the subspace of \mathcal{S}_r of the elements of weight not greater than i is given by

$$V_i^r = \text{span} \{\Lambda_r : \Lambda \in \mathcal{S}, \|\Lambda\|_{\mathbf{l}} \leq i\}.$$

An element $\chi \in \mathcal{S}$ is called *l-homogeneous* if it is a linear combination of brackets with the same weight, which will be called the *weight* of χ . Following H. J. Sussmann, we say that an l-homogeneous element $\chi \in \mathcal{S}$ is *l-neutralized* for Σ_r at ξ_0 if χ_r is a linear combination at ξ_0 of brackets with less weight. In other words, χ is l-neutralized if there is an $i < \|\chi\|_1$ such that $\chi_r(\xi_0) \in V_i^1(\xi_0)$. For more details and examples see [3], [18].

To identify the elements of $\text{Lie } \mathfrak{f}$ that give rise to variations, we introduce the set of obstructions relative to a weight **l**; see [3]. Let

$$\mathcal{B} = \text{span} \{ \Lambda \in \mathcal{S} : |\Lambda|_0 \text{ is odd, } |\Lambda|_i \text{ is even, } i = 1, \dots, m \},$$

$$\mathcal{B}_S^1 = \{ \chi \in \mathcal{B} : \chi \text{ is symmetric w.r.t. those } X_i \text{'s that have the same weight, } i \neq 0 \}.$$

In other words, the elements of \mathcal{B}_S^1 are the fixed elements of the automorphisms of \mathcal{B} generated by $\mu_{ij} : X_i \mapsto X_j, \forall i, j$ such that $l_i = l_j$. For example, if $m = 3, l_0 = 0, l_1 = l_2 = 1, l_3 = 3$, then $ad_{X_1}^2 X_0 + ad_{X_2}^2 X_0$ and $ad_{X_3}^2 X_0$ belong to \mathcal{B}_S^1 , but $ad_{X_1}^2 X_0$ does not.

The set of obstructions relative to the weight **l** is the set

$$\mathcal{B}_l^* = \text{Lie}(X_0, \mathcal{B}_S^1) \cap \mathcal{S}.$$

DEFINITION 3.4. A set **l** = (l_0, \dots, l_m) of integers will be called a *set of admissible weights* for Ω if and only if for each $\omega = (\omega_1, \dots, \omega_m) \in \Omega$ and each $\varepsilon \in (0, 1)$

$$(3.4) \quad (\varepsilon^{l_1 - l_0} \omega_1, \dots, \varepsilon^{l_m - l_0} \omega_m) \in \Omega.$$

Notice that if Ω is a polydisk $H_p = \{(\omega_1, \dots, \omega_m) \in \mathbb{R}^m : |\omega_i| \leq \rho_i, i = 1, \dots, m\}$, possibly some $\rho_i = +\infty$, then (3.4) is equivalent to requiring that if ρ_i is finite, then $l_i \geq l_0$.

The following result states that an element of \mathcal{S}_r defines a variation at time zero if every obstruction with lower or equal weight is neutralized at ξ_0 by means of a set of admissible weights.

THEOREM 3.5. Let Ω be the polydisk $H_p = \{(\omega_1, \dots, \omega_m) \in \mathbb{R}^m : |\omega_i| \leq \rho_i, i = 1, \dots, m\}$, possibly some $\rho_i = +\infty$, and let Φ be a bracket in \mathcal{S} . If there exists a set of admissible nonnegative weights, **l** = (l_0, \dots, l_m) , such that

$$(3.5) \quad \text{each } \Lambda \in \mathcal{B}_l^* \text{ s.t. } \|\Lambda\|_1 \leq \|\Phi\|_1 \text{ is l-neutralized at } \xi_0$$

(i.e., Λ_r is a linear combination at ξ_0 of elements in \mathcal{S}_r with lower weight), then $\Phi_r(\xi_0)$ is a regular variation for the pair $(\hat{x}_r, 0)$. Moreover, if all the l_i 's are positive, then the order of the variation is $\|\Phi\|_1 / l_0$.

The proof of the theorem is based on the properties of suitable graded approximating systems introduced in [3]. In § 4 we shall investigate the links between the variations of the system and those of the approximating system, and we will provide the proof of the theorem. Notice that the approximation result in § 4 is different from the one stated in Proposition 3.1. In fact, the result in Proposition 3.1 links the order of a single variation to the order of the Taylor approximation of the fields. In § 4 we state that suitable subspaces of the set of variations of a first-order graded approximating system are also variations of the original system.

Theorem 3.5 provides subspaces contained in $\mathcal{K}_r(0)$; in fact, if a bracket $\Phi \in \mathcal{S}$ satisfies the hypotheses of the theorem, the same is true for each bracket with the same **l**-weight. Hence it can be used to derive by means of Corollary 1.11 and Remark 1.14 either sufficient conditions of weak local controllability or necessary conditions for the couple $(\hat{x}_r, 0)$ to be optimal. The applications to the local controllability property will be described in details in § 5. Here we limit ourselves to constructing subspaces of variations.

PROPOSITION 3.6. If Ω is a polydisk, the distributions

$$H_1 = \text{span} \{ f_j : j = 1, \dots, m \},$$

$$H_2 = \text{span} \{ [f_i, f_j] : i, j = 1, \dots, m \}$$

define two subspaces of regular variations at any time. If, moreover, $\Omega = \mathbb{R}^m$, then $\text{Lie}\{f_1, \dots, f_m\}$ defines a subspace of regular variations at any time.

Proof. Let $\mathbf{l} = (1, 1, \dots, 1)$: $\Lambda \in \mathcal{B}_1^*$ implies $\|\Lambda\|_1 \geq 3$. Hence if $\Phi \in \mathcal{S}$ is a bracket of length no greater than two, then (3.4) is fulfilled. This implies that for $i = 1, \dots, m$, $\pm f_i(\hat{x}(t))$ are regular variations of order 1 and $\pm[f_i, f_j](\hat{x}(t))$ are regular variations of order 2. If $\Omega = \mathbb{R}^m$, we can choose $\mathbf{l} = (1, 0, \dots, 0)$. $\Phi \in \text{Lie}\{f_1, \dots, f_m\}$ implies $\|\Phi\|_1 = 0$, meanwhile, $\Lambda \in \mathcal{B}_1^*$ implies $\|\Lambda\|_1 \geq 1$. Therefore, Φ satisfies the hypotheses of Theorem 3.5, and the proof is complete. \square

The above proposition and Theorem 2.4 lead to the following two corollaries.

COROLLARY 3.7. *For each positive t , the distribution*

$$\mathcal{C} = \text{span}\{ad_{f_0}^h f_i, ad_{f_0}^k [f_i, f_j]: h, k \geq 0, i, j \in (1, \dots, m)\}$$

defines a subspace contained in $\mathcal{H}_t(t)$.

COROLLARY 3.8. *If $\Omega = \mathbb{R}^m$, for each positive t the distribution*

$$\mathcal{Y} = \text{span}(ad_{f_0}^h Y: h \geq 0, Y \in \text{Lie}\{f_1, \dots, f_m\})$$

defines a subspace contained in $\mathcal{H}_t(t)$.

It is known that if $\hat{x}: [0, T] \rightarrow M$ is a time-optimal trajectory, then $\hat{x}(t) \in \partial R(\hat{x}(0), t)$ for each $t \in [0, T]$. Corollaries 3.7 and 3.8 and Remark 1.14 imply the following result:

PROPOSITION 3.9. *If the trajectory $t \mapsto \hat{x}_t(t) = \exp t f_0 \cdot \xi_0$ is time optimal in $[0, T]$, then $\mathcal{C}(\hat{x}_t(t)) \neq T_{\hat{x}_t(t)} M$ for each $t \in [0, T]$. Moreover, the adjoint covector $\lambda(t)$ of Remark 1.14 is orthogonal to $\mathcal{C}(\hat{x}_t(t))$. If $\Omega = \mathbb{R}^m$, then $\mathcal{Y}(\hat{x}_t(t)) \neq T_{\hat{x}_t(t)} M$ and the adjoint covector $\lambda(t)$ is orthogonal to $\mathcal{Y}(\hat{x}_t(t))$.*

Up to now we have given examples of subsets of $\text{Lie}\{f_0, \dots, f_m\}$ that define variations along the whole trajectory. Note that if $v = \Phi(x_t(t))$ is one of these variations, then in a chart at $x_t(t)$ there exist vectors near v that are variations at time near t . We will now provide an example of a vector field that defines a variation v at $t = 0$, but the set of variations at positive times is separated from v . This fact underlines once again the local nature of this kind of variation.

Example 3.10. Let us consider the following system on \mathbb{R}^3 :

$$\dot{x} = 1 + u, \quad \dot{y} = ux, \quad \dot{z} = u(x^3 y + y^2),$$

where $\xi_0 = (0, 0, 0)$ and $|u| \leq \frac{1}{2}$. The reference trajectory is given by $\hat{x}_t(t) = (t, 0, 0)$. Let $\chi = [ad_{f_0}^2 f_1, ad_{f_1}^2 f_0] = (2 - 6x)(\partial/\partial z) \pm \chi$ define variations at 0. In fact, they satisfy the hypotheses of Theorem 3.5 with $\mathbf{l} = (2, 3)$ (for details see [3]). To see that both $\pm\chi$ cannot define variations at positive times, consider $\bar{\xi} = \hat{x}_t(\bar{t})$, $\bar{t} \in (0, \frac{1}{3})$. If $\pm\chi$ were variations at \bar{t} , then they would be variations at 0 for the trajectory \hat{y}_t defined by $t \mapsto \exp t f_0 \cdot \bar{\xi}$. Since $\mathcal{C}(\bar{\xi}) = \text{span}\{\partial/\partial x, \partial/\partial y\}$ and $\chi(\bar{\xi}) = (2 - 6\bar{t})(\partial/\partial z)$, by Corollary 1.11 \hat{y}_t would be locally controllable. However, $ad_{f_1}^2 f_0 = -(2x^3 + 6xy - 2y)(\partial/\partial z)$, so that $ad_{f_1}^2 f_0(\hat{x}_t(\bar{t})) = -2\bar{t}^3(\partial/\partial z)$ does not belong to $\mathcal{C}(\hat{x}_t(\bar{t}))$. The results in [15] imply that for each $t > 0$ sufficiently small, $\hat{y}_t(t) = \exp t f_0 \cdot \bar{\xi}$ belongs to the boundary of $R(\bar{\xi}, t)$, a contradiction.

Slightly modifying the above example, we can show that if a vector field does not provide variations on an arc of trajectory, then its adjoint with respect to the reference field may not define an element of $\mathcal{H}_t(t)$. This shows that hypothesis (2.1) in Theorem 2.4 cannot be dropped.

Example 3.11. Let us consider the following system on \mathbb{R}^4 :

$$\dot{x} = 1 + u, \quad \dot{y} = ux, \quad \dot{z} = u(x^3 y + y^2), \quad \dot{w} = z + ux^3 y,$$

where $\xi_0 = (0, 0, 0, 0)$ and $|u| \leq \frac{1}{3}$. The reference trajectory is given by $\hat{x}_t(t) = (t, 0, 0, 0)$. Let $\chi = [ad_{f_0}^2 f_1, ad_{f_1}^2 f_0] = (2 - 6x)(\partial/\partial z) + (3x^2 - 4x)(\partial/\partial w)$. χ satisfies the hypothesis of

Theorem 3.5 at 0 with $\mathbf{l} = (2, 3)$, so that $\pm\chi$ define variations at 0. Hence for each positive t , $\mathcal{H}_t(t)$ contains $\pm(\exp tf_0)_*\chi(\xi_0) = \pm(2\partial/\partial z + 2t\partial/\partial w)$ and $\mathcal{C}(\hat{x}_t(t)) = \text{span}\{(\partial)/(\partial x), (\partial)/(\partial y)\}$. If $\pm ad_{f_0}\chi = \pm(6\partial/\partial z + (6-12x)(\partial/\partial w))$ defined an element of $\mathcal{H}_t(t)$, $\mathcal{H}_t(t)$ would be \mathbb{R}^4 for each positive t , so that the reference trajectory would be locally controllable. We shall show that points of type $(t, 0, 0, a^2)$ cannot be reached if t is sufficiently small.

Let us suppose that the control u is such that

$$x(t) = x(S_t(t, \xi_0, u)) = t, \quad y(t) = y(S_t(t, \xi_0, u)) = 0, \quad z(t) = z(S_t(t, \xi_0, u)) = 0.$$

We obtain

$$\begin{aligned} \int_0^\tau u(s)x^3(s)y(s) \, ds &= \frac{x^2(\tau)y^2(\tau)}{2} - \int_0^\tau y^2(s)x(s)(1+u(s)) \, ds \\ &= \frac{x^2(\tau)y^2(\tau)}{2} - \frac{y^3(\tau)}{3} - \int_0^\tau y^2(s)x(s) \, ds, \end{aligned}$$

so that

$$z(\tau) = \frac{x^2(\tau)y^2(\tau)}{2} - \frac{y^3(\tau)}{3} - \int_0^\tau y^2(s)x(s) \, ds + \int_0^\tau y^2(s)u(s) \, ds.$$

$y(t) = z(t) = 0$ implies

$$(3.6) \quad \int_0^t y^2(s)(x(s) - u(s)) \, ds = 0.$$

As a consequence, we obtain

$$\begin{aligned} w(t) = w(S_t(t, \xi_0, u)) &= \int_0^t z(s) \, ds - \int_0^t x(s)y^2(s) \, ds \\ &= \int_0^t \left(\frac{y^2(s)x^2(s)}{2} - \frac{y^3(s)}{3} \right) ds + \int_0^t \int_0^s y^2(\tau)(u(\tau) - x(\tau)) \, d\tau \, ds - \int_0^t x(s)y^2(s) \, ds \\ &= \int_0^t \left(\frac{y^2(s)x^2(s)}{2} - \frac{y^3(s)}{3} \right) ds + \int_0^t (t-s)y^2(s)(u(s) - x(s)) \, ds - \int_0^t x(s)y^2(s) \, ds \\ &= \int_0^t \left(\frac{y^2(s)x^2(s)}{2} - \frac{y^3(s)}{3} - sy^2(s)(u(s) - x(s)) - x(s)y^2(s) \right) ds, \end{aligned}$$

where the last equality is by (3.6). Since $\frac{2}{3}s \leq x(s) \leq \frac{4}{3}s$ and $-\frac{2}{9}s^2 \leq y(s) \leq \frac{2}{9}s^2$,

$$w(t) \leq \int_0^t \frac{y^2(s)}{2} \left(s^2 + s^2 + \frac{s}{3} + \frac{4}{3}s^2 - \frac{2}{3}s \right) ds \leq 0 \quad \text{for sufficiently small } t.$$

4. Graded approximating systems and variations. This section is essentially devoted to constructing subspaces of variations for the reference couple $(\hat{x}_t, 0)$ from the properties of graded approximating systems defined in [3]. As a consequence, we will derive the proof of Theorem 3.5. For the exact definition of a graded structure and its properties with respect to control systems, see [3] and the references therein. Here we give only a short summary of this topic.

Let $\mathbf{x} = (x^1, \dots, x^n)$ be a chart on a neighborhood U of $\xi_0 \in M$ such that $\mathbf{x}(\xi_0) = 0$ and $\mathbf{x}(U)$ is a ball centered at 0, and let $\mathbf{w} = (w^1, \dots, w^n)$ be a set of positive integers. The couple (\mathbf{x}, \mathbf{w}) defines a graded structure on U that will be called a *local graded structure* at ξ_0 and will be denoted by $(\mathbf{x}, U, \mathbf{w})$.

The graded structure is given by the dilations, i.e., maps δ_ε on U with values in U defined by

$$x^i \circ \delta_\varepsilon = \varepsilon^{w^i} x^i, \quad i = 1, \dots, n, \quad |\varepsilon| < 1.$$

In other words, we give the weight w^i to x^i . As a consequence, for each multi-index $\alpha = (\alpha_1, \dots, \alpha_n)$ the weight of the monomial $x^\alpha \equiv (x^1)^{\alpha_1} \dots (x^n)^{\alpha_n}$ is defined by $\mathcal{W}(x^\alpha) = \sum_{i=1}^n w^i \alpha_i$.

The *weight of a polynomial* (i.e., an element of the subalgebra \mathcal{D} of the algebra of C^∞ function on U generated by the coordinate functions x^1, \dots, x^n) is the greatest weight of the monomials contained in it. A polynomial is homogeneous if it is a sum of monomials of the same weight.

A vector field f is called *homogeneous of weight j* if for each homogeneous polynomial φ , $f \cdot \varphi$ is a homogeneous polynomial of weight $\mathcal{W}(\varphi) - j$ (the polynomials of negative weights are understood to be equal to 0). Roughly speaking, if the weight of f is j , then f "subtracts" weight j from the functions. In terms of components in the chart \mathbf{x} , f is homogeneous of weight j if and only if its i th component, f^i , is a homogeneous polynomial of weight $w^i - j$.

The *graded order* $\mathcal{O}(\varphi)$ of a function φ is defined as the *minimum weight* of the monomials contained in its Taylor asymptotic expansion at ξ_0 in the chart \mathbf{x} .

The *graded order* $\mathcal{O}(f)$ of a vector field f is defined as the *maximum weight* of the homogeneous vector fields appearing in its Taylor asymptotic expansion at ξ_0 in the chart \mathbf{x} . In other words $\mathcal{O}(f) = j$ if and only if $\mathcal{O}(f^i) \equiv w^i - j$, $i = 1, \dots, n$, with equality for some i .

The graded structure on M at ξ_0 can be extended to the manifold M^* on which the pullback system Σ_{r^*} is defined; see § 3. Without loss of generality we can suppose that $M^* = I \times U$. Denoting by $x^0: M^* \rightarrow \mathbb{R}$ the first canonical projection, we set $\mathbf{x}^* = (x^0, \mathbf{x})$ and $\mathbf{w}^* = (w^0, \mathbf{w})$, where $w^0 \equiv \mathcal{O}(f_0)$. In the chart \mathbf{x}^* the vector field $\partial/\partial t$ is $\partial/\partial x^0$ and $(\mathbf{x}^*, M^*, \mathbf{w}^*)$ defines a local graded structure on M^* at ξ_0 . By noting that

$$f^*(x^0, \xi) = \sum_{i \geq 0} \frac{(x^0)^i}{i!} \text{ad}_{f_0}^i f(\xi),$$

it is easy to see that for each $f \in \mathcal{V}(M)$, $\mathcal{O}(f^*) = \mathcal{O}(f)$, where \mathcal{O} denotes both the graded orders induced by the above graded structures on M and M^* . Moreover, f is homogeneous of weight r if and only if f^* is also (see [3, § 4]).

The systems defined by homogeneous vector fields of positive weight will be called *positively homogeneous systems*. Notice that the definition of local graded structure implies that it makes sense to consider homogeneous systems only if we restrict the system to U . To be more precise, let f_i be homogeneous of weight $l_i > 0$, $i = 0, \dots, m$. In this case, f_i^j is a homogeneous polynomial of weight $w^j - l_i$, so that it does not depend on the x^k 's with $w^k \equiv w^j$. In other words, the system Σ_r is a cascade of integrators. Since the Lie product of two homogeneous vector fields is homogeneous and its weight is the sum of the weights of the two factors, then \mathcal{S}_r is a nilpotent Lie algebra spanned by homogeneous vector fields. Moreover, the f_i 's in the chart (\mathbf{x}, U) are polynomial, so that $N_r(\xi_0, t)$ is an integral submanifold of \mathcal{S}_r . Other properties of positively homogeneous systems can be analyzed by means of a one-parameter family of variations of the null control associated with the set of integers $\mathbf{l} = (l_0, \dots, l_m)$.

Namely, the continuous map

$$\delta : [-1, 1] \times L^1([0, T], \mathbb{R}^m) \rightarrow L^1(\mathbb{R}, \mathbb{R}^m)$$

defined by

$$\delta(\varepsilon, u) \equiv \delta_\varepsilon u \equiv u_\varepsilon : t \mapsto \begin{cases} (\varepsilon^{l_1-l_0} u_1(t/\varepsilon^{l_0}), \dots, \varepsilon^{l_m-l_0} u_m(t/\varepsilon^{l_0})) & \text{if } t \in [0, \varepsilon^{l_0} T] \\ 0 & \text{otherwise.} \end{cases},$$

($\delta(0, u)$ is understood to be identically equal to 0.) The definition of $\delta_\varepsilon u$ implies that if $\alpha = \min \{l_i, i = 1, \dots, m\}$, then

$$(4.1) \quad \|\delta_\varepsilon u\|_{L^1} = \int_0^T \sum_{i=1}^m \varepsilon^{l_i} |u_i(s)| ds \leq \varepsilon^\alpha \|u\|_{L^1}.$$

Moreover, standard calculations imply that $\delta : [-1, 1] \times \mathcal{U} \rightarrow \mathcal{U}$ is continuous. Note that δ_ε maps \mathcal{U} into \mathcal{U} if and only if $\mathbf{l} = (l_0, \dots, l_m)$ is a set of admissible weight for Ω , see Definition 3.4.

The map δ has the following property (see [3, Thm. 2.1b]): if $\Sigma_\mathbf{f}$ is a homogeneous system and $S_\mathbf{f}(t, \xi, u)$ is defined, then

$$(4.2) \quad S_\mathbf{f}(\varepsilon^{l_0} t, \delta_\varepsilon \xi, u_\varepsilon) = \delta_\varepsilon S_\mathbf{f}(t, \xi, u).$$

Therefore, $\forall t \in \mathbb{R}, \forall \omega \in \Omega$, $\delta_\varepsilon \exp t(f_0 + \sum_{i=1}^m \omega_i f_i) \cdot \xi = \exp \varepsilon^{l_0} t(f_0 + \sum_{i=1}^m \varepsilon^{l_i-l_0} \omega_i f_i) \cdot \delta_\varepsilon \xi$. This implies that δ_ε maps $N_\mathbf{f}(\xi_0, t)$ in $N_\mathbf{f}(\xi_0, \varepsilon^{l_0} t)$. The two manifolds have the same dimension and δ_ε is an open map; hence $\delta_\varepsilon \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, t) \subseteq \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, \varepsilon^{l_0} t)$. Therefore, if \mathbf{l} is a set of admissible positive weights, then there is t such that

$$\hat{x}_\mathbf{f}(t) \in \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, t)$$

if and only if $(\Sigma_\mathbf{f}, \Omega)$ is weakly locally controllable along $\hat{x}_\mathbf{f}$. In fact, if such a t exists, then $\hat{x}_\mathbf{f}(\varepsilon^{l_0} t) = \delta_\varepsilon \hat{x}_\mathbf{f}(t) \in \delta_\varepsilon \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, t) \subseteq \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, \varepsilon^{l_0} t)$.

For the positively homogeneous systems, the following inverse of Theorem 1.10 holds.

THEOREM 4.1. *Let us suppose that (i) f_i is homogeneous of weight $l_i > 0$, $i = 0, \dots, m$, (ii) $\mathbf{l} = (l_0, \dots, l_m)$ is a set of admissible weights, and (iii) there is $t > 0$ such that $\hat{x}_\mathbf{f}(t) \in \text{int}_{\text{rel}} R_\mathbf{f}(\xi_0, t)$. If $h \in \mathcal{S}_\mathbf{f}$ is a homogeneous vector field of weight r such that $h(\xi_0) \neq 0$, then $h(\xi_0)$ is a regular variation at 0 of order r/l_0 .*

Proof. $h \in \mathcal{S}_\mathbf{f}$ is homogeneous of weight r if and only if $h^* \in \mathcal{S}_{\mathbf{f}^*}$ is and $h(\xi_0) = h^*(\xi_0)$. Therefore, we can prove the theorem for the pullback system. Let h_1, \dots, h_s be homogeneous vector fields that span $\mathcal{S}_{\mathbf{f}^*}$ at ξ_0 , and let r_1, \dots, r_s be their weights. The local inverse of the map

$$(d_1, \dots, d_s) \mapsto \exp d_1 h_1 \cdots \exp d_s h_s \cdot \xi_0$$

defines a chart (\mathbf{y}, W) of $N_{\mathbf{f}^*}(\xi_0, 0)$ at ξ_0 . Set $\mathbf{y}(W) = V$. Lemma A in the appendix of [3] implies, possibly restricting W , that there is a k -tuple $(\omega^1, \dots, \omega^k) \subseteq \Omega$ and an analytic map $\tau : V \rightarrow \{(t_1, \dots, t_k) : t_i \geq 0, t_1 + \dots + t_k = t\}$ such that

$$S_{\mathbf{f}^*}(t, \xi_0, u(\mathbf{d})) = (t, \mathbf{y}^{-1}(\mathbf{d})),$$

where $u(\mathbf{d})$ is the piecewise-constant control with values $\omega^1, \dots, \omega^k$ and switching times $\tau_1(\mathbf{d}), \dots, \tau_k(\mathbf{d})$. Denoting the canonical projection by $p : M^* \rightarrow U$, we obtain

$$\mathbf{y}(p(S_{\mathbf{f}^*}(t, \xi_0, u(\mathbf{d})))) = \mathbf{d}.$$

By (4.2) it follows that

$$\delta_\varepsilon^{-1} S_{\mathbf{f}^*}(\varepsilon^l t, (\varepsilon^l \gamma, \xi_0), \delta_\varepsilon u(\mathbf{d})) = S_{\mathbf{f}^*}(t, (\gamma, \xi_0), u(\mathbf{d})).$$

As a consequence, the map

$$(\gamma, \varepsilon, \mathbf{d}) \mapsto (\gamma, \varepsilon, \mathbf{y}(p(\delta_\varepsilon^{-1} S_{\mathbf{f}^*}(\varepsilon^l t, (\varepsilon^l \gamma, \xi_0), \delta_\varepsilon u(\mathbf{d}))))))$$

is defined in a neighborhood of $(0, 0, 0) \in \mathbb{R} \times \mathbb{R} \times \mathbb{R}^s$, it is analytic, and it has maximum rank at $(0, 0, 0)$. Therefore, it has a local analytic inverse (id, id, ν) . Set $\mathbf{e}_i = (1, 0, \dots, 0)$, and define $\eta(c, \gamma, \varepsilon) = \delta_\varepsilon u(\nu(\gamma, \varepsilon, c\mathbf{e}_i))$. The control η is a continuous function of its arguments, and we obtain

$$\begin{aligned} S_{\mathbf{f}^*}(\varepsilon^l t, \hat{\mathbf{x}}_{\mathbf{f}^*}(\varepsilon^l \gamma), \eta(c, \gamma, \varepsilon)) &= \delta_\varepsilon(t + \gamma, \mathbf{y}^{-1}(c\mathbf{e}_i)) \\ &= (\varepsilon^l(t + \gamma), \delta_\varepsilon \exp ch_1 \cdot \xi_0) = (\varepsilon^l(t + \gamma), \exp \varepsilon^{r_1} ch_1 \cdot \xi_0) \\ &= \hat{\mathbf{x}}_{\mathbf{f}^*}(\varepsilon^l(t + \gamma)) + \varepsilon^{r_1} ch_1(\xi_0) + o(\varepsilon^{r_1+a}) \quad \forall a < r_1. \end{aligned}$$

Setting $\varepsilon' = \varepsilon^l t$, we see that $h_1(\xi_0)$ is a regular variation of order r_1/l_0 . The statement follows because each homogeneous vector field that does not vanish at ξ_0 can be chosen as h_1 . \square

COROLLARY 4.2. *A positively homogeneous system $\Sigma_{\mathbf{f}}$ is weakly locally controllable along the trajectory relative to the null control if and only if $\mathcal{H}_{\mathbf{f}}(0) = \Delta_{\mathbf{f}}^0(\xi_0)$.*

We want to use graded structures at $\hat{\mathbf{x}}_{\mathbf{f}}(t)$ to construct variations at t of the reference couple. Without loss of generality we can suppose $t=0$. The vector fields $f_i \in \mathcal{V}(M)$ can be approximated at ξ_0 by means of vector fields homogeneous with respect to a graded structure $(\mathbf{x}, U, \mathbf{w})$ in the following sense (see [3]). Let $\mathcal{O}(f_i)$ be the graded order of the vector field f_i with respect to $(\mathbf{x}, U, \mathbf{w})$, and let $\mathbf{l} = (l_0, \dots, l_m)$ be a set of positive integers such that $l_i \geq \mathcal{O}(f_i)$. The graded approximation of weight l_i of f_i , say, \hat{f}_i , is the sum of the homogeneous vector fields of weight greater than or equal to l_i in the Taylor asymptotic expansion of f_i at ξ_0 in the chart \mathbf{x} . \hat{f}_i is homogeneous of weight l_i , $i = 0, \dots, m$, and $\hat{f}_i = 0$ if and only if $l_i > \mathcal{O}(f_i)$. Set $\hat{\mathbf{f}} = \{\hat{f}_0, \dots, \hat{f}_m\}$.

DEFINITION 4.3. The system $\Sigma_{\hat{\mathbf{f}}}$ defined on U is called a *graded approximation* at ξ_0 of the system $\Sigma_{\mathbf{f}}$. It is the graded approximation relative to $(\mathbf{x}, U, \mathbf{w})$ induced by \mathbf{l} .

The solutions of a system $\Sigma_{\mathbf{f}}$ and the ones of its graded approximation $\Sigma_{\hat{\mathbf{f}}}$ are related by the dilations of both state and control defined previously (see [3, Thm. 2.1]). In the rest of this paper we will also use the following result:

PROPOSITION 4.4. *Let $\bar{t} \in [0, T]$, $\bar{\xi} \in U$, $\omega = (\omega_1, \dots, \omega_m) \in \Omega$ be such that if $u \equiv \omega$, then $S_{\mathbf{f}}(\cdot, \bar{\xi}, u)$ is defined in $[0, \bar{t}]$. There exists a neighborhood $V(\bar{\xi})$ of $\bar{\xi}$ in U , a neighborhood $V(\bar{t})$ of \bar{t} in \mathbb{R} , an $\bar{\varepsilon} > 0$ such that $\forall \xi \in V(\bar{\xi}), \forall t \in V(\bar{t})$, and $\forall \varepsilon \in (-\bar{\varepsilon}, \bar{\varepsilon})$, $\varepsilon \neq 0$, $\delta_\varepsilon^{-1} S_{\mathbf{f}}(\cdot, \delta_\varepsilon \xi, u_\varepsilon)$ is defined in $[0, \varepsilon^l t]$ (on $[\varepsilon^l t, 0]$ if $\varepsilon^l < 0$). Moreover, the map $H: V(\bar{\xi}) \times V(\bar{t}) \times (-\bar{\varepsilon}, \bar{\varepsilon}) \rightarrow U$ defined by*

$$H(\xi, t, \varepsilon) = \begin{cases} \delta_\varepsilon^{-1} S_{\mathbf{f}}(\varepsilon^l t, \delta_\varepsilon \xi, u_\varepsilon), & \varepsilon \neq 0, \\ S_{\hat{\mathbf{f}}}(t, \xi, u), & \varepsilon = 0, \end{cases}$$

is a C^∞ map.

Proof. It is not restrictive to assume that U is an open neighborhood of 0 in \mathbb{R}^n . Let $\varepsilon \neq 0$, $\xi \in U$; the map $t \mapsto \delta_\varepsilon^{-1} S_{\mathbf{f}}(\varepsilon^l t, \delta_\varepsilon \xi, u_\varepsilon)$ is the solution of the differential equation on U

$$\dot{x} = F_0(\varepsilon, x) + \sum_{i=1}^m \omega_i F_i(\varepsilon, x), \quad x(0) = \xi,$$

where the F_i 's are defined by

$$F_i(\varepsilon, x) = \begin{cases} \varepsilon^{l_i} (\delta_\varepsilon^{-1})_* f_i(\delta_\varepsilon x), & \varepsilon \neq 0, \\ \hat{f}_i(x), & \varepsilon = 0. \end{cases}$$

The F_i 's are C^∞ vector fields on $(-1, 1) \times U$ (see [3, property P5]). The statement follows by the properties of differential equations. \square

COROLLARY 4.5. *Let $u = u(\tau_1, \dots, \tau_k)$ be the piecewise-constant control with values $\omega^1, \dots, \omega^k$ and switching times τ_1, \dots, τ_k . Let $t(\tau) = \sum_{i=1}^k \tau_i$; the map*

$$(\varepsilon, \xi, \tau_1, \dots, \tau_k) \mapsto \begin{cases} \delta_\varepsilon^{-1} S_f(\varepsilon^{l_0} t(\tau), \delta_\varepsilon \xi, u_\varepsilon), & \varepsilon \neq 0 \\ S_f(t, \xi u), & \varepsilon = 0 \end{cases}$$

is C^∞ .

Under suitable assumptions the local controllability of an approximating system along \hat{x}_f implies that all the vector fields in \mathcal{S}_f give rise to variations.

THEOREM 4.6. *Let us suppose that (i) $\mathbf{l} = (l_0, \dots, l_m)$ is a set of admissible positive weights such that $l_i \geq \mathcal{O}(f_i)$, $i = 0, \dots, m$, (ii) $\dim N_f(\xi_0, \cdot) = \dim N_f(\xi_0, 0) = s$, and (iii) there is $t > 0$ such that $\hat{x}_f(t) \in \text{int}_{\text{rel}} R_f(\xi_0, t)$. If $\chi \in \mathcal{S}$ is a bracket of \mathbf{l} -weight r such that $\chi_f(\xi_0) \neq 0$, then $\chi_f(\xi_0)$ is a regular variation at 0 of order r/l_0 for the reference couple of the original system.*

Proof. It is easily seen that starting from a system we obtain the same result if either (a) we first consider its graded approximation relative to $(\mathbf{x}, U, \mathbf{w})$ and \mathbf{l} and then the pullback or (b) first we consider the pullback and then the graded approximation relative to $(\mathbf{x}^*, M^*, \mathbf{w}^*)$ and \mathbf{l} . Therefore, we can prove the theorem for the pullback system. If $f \in \mathcal{V}(M)$, \hat{f}^* will denote the graded approximation of f^* that is equal to $(\hat{f})^*$. Assumption (ii) and [3, Lemma 2.1] imply that there are $h_1, \dots, h_s \in \mathcal{S}_{f^*}$ such that (a) $h_1 = \chi_{f^*}$ and $\text{span}\{h_1(\xi_0), \dots, h_s(\xi_0)\} = \mathcal{S}_{f^*}(\xi_0)$ and (b) $\text{span}\{\hat{h}_1(\xi_0), \dots, \hat{h}_s(\xi_0)\} = \mathcal{S}_{f^*}(\xi_0)$. By possibly restricting U it is also possible to assume that $N_{f^*}(\xi_0, 0)$ (which by (ii) is an integral manifold of \mathcal{S}_{f^*}) is embedded in M^* . Let r_i be the weight of h_i , and define the map $G: (-1, 1) \times (-1, 1)^s \rightarrow \mathbb{R} \times M^*$ locally by

$$(\varepsilon, d_1, \dots, d_s) \mapsto \begin{cases} \delta_\varepsilon^{-1} \exp \varepsilon^{r_1} d_1 h_1 \cdots \exp \varepsilon^{r_s} d_s h_s \cdot \xi_0, & \varepsilon \neq 0, \\ \exp d_1 \hat{h}_1 \cdots \exp d_s \hat{h}_s \cdot \xi_0, & \varepsilon = 0. \end{cases}$$

Corollary 4.5 implies that G is C^∞ . Moreover, $\tilde{G}: (\varepsilon, \mathbf{d}) \mapsto (\varepsilon, G(\varepsilon, \mathbf{d}))$ has maximum rank at $(0, 0)$; therefore, there is a neighborhood \mathcal{W} of $(0, 0)$ in $\mathbb{R} \times \mathbb{R}^s$ such that \tilde{G} is a C^∞ homeomorphism of \mathcal{W} onto $\tilde{G}(\mathcal{W})$. Denote by G_ε the restriction of G to $\mathcal{W}_\varepsilon \equiv \mathcal{W} \cap (\{\varepsilon\} \times \mathbb{R}^s)$. It is clear that $G_\varepsilon(\mathcal{W}_\varepsilon)$ is contained in $\delta_\varepsilon^{-1} N_{f^*}(\xi_0, 0) \subseteq \delta_\varepsilon^{-1} U$ (recall that δ_ε^{-1} is defined only on $\delta_\varepsilon U$). We claim that \mathcal{W} can be chosen so that there is a neighborhood U' of ξ_0 in U such that

$$(4.3) \quad G_\varepsilon(\mathcal{W}_\varepsilon) = \delta_\varepsilon^{-1} N_{f^*}(\xi_0, 0) \cap U'.$$

To prove this, notice that by [3, Lemma 2.1] it is possible to choose homogeneous vector fields k_{s+1}, \dots, k_n , of weights r_{s+1}, \dots, r_n such that

$$\begin{aligned} & \text{span}\{\hat{h}_1(\xi_0), \dots, \hat{h}_s(\xi_0), k_{s+1}(\xi_0), \dots, k_n(\xi_0)\} \\ &= \text{span}\{h_1(\xi_0), \dots, h_s(\xi_0), k_{s+1}(\xi_0), \dots, k_n(\xi_0)\} = T_{\xi_0} U. \end{aligned}$$

Moreover, by possibly restricting U the k_i 's can be chosen in such a way that

$$\exp d_n k_n \cdots \exp d_{s+1} k_{s+1} \cdot \xi \notin N_{f^*}(\xi_0, 0) \quad \text{if } \xi \in N_{f^*}(\xi_0, 0) \text{ and } |d_i| < 1.$$

Define $\Phi: (-1, 1) \times (-1, 1)^s \times (-1, 1)^{n-s} \rightarrow (-1, 1) \times U$ locally by

$$(\varepsilon, d_1, \dots, d_n) \mapsto (\varepsilon, \exp d_n k_n \cdots \exp d_{s+1} k_{s+1} \cdot G_\varepsilon(d_1, \dots, d_s)).$$

Φ is C^∞ , and it has maximum rank at $(0, 0, 0)$, so that there is a neighborhood \mathcal{V} of $(0, 0, 0)$ in $\mathbb{R} \times \mathbb{R}^s \times \mathbb{R}^{n-s}$, $\bar{\varepsilon} > 0$ and a neighborhood U' of ξ_0 in U such that Φ is a homeomorphism of \mathcal{V} onto $(-\bar{\varepsilon}, \bar{\varepsilon}) \times U'$. Since the k_i 's are homogeneous vector fields, we have that

$$\delta_\varepsilon U' = \{\exp \varepsilon^{r_n} d_n k_n \cdots \exp \varepsilon^{r_{s+1}} d_{s+1} k_{s+1} \cdot \delta_\varepsilon G_\varepsilon(d_1, \dots, d_s): (\varepsilon, \mathbf{d}) \in \mathcal{V}\}.$$

Therefore,

$$\delta_\varepsilon U' \cap N_{\mathbf{f}^*}(\xi_0, 0) = \{\delta_\varepsilon G_\varepsilon(d_1, \dots, d_s): (\varepsilon, \mathbf{d}) \in \mathcal{V}\}$$

and

$$U' \cap \delta_\varepsilon^{-1} N_{\mathbf{f}^*}(\xi_0, 0) = U' \cap \delta_\varepsilon^{-1} (N_{\mathbf{f}^*}(\xi_0, 0) \cap \delta_\varepsilon U') = \{G_\varepsilon(d_1, \dots, d_s): (\varepsilon, \mathbf{d}) \in \mathcal{V}\}.$$

If we set

$$\mathcal{W} = \mathcal{V} \cap (\mathbb{R} \times \mathbb{R}^s \times \{0\}),$$

we obtain (4.3).

Lemma A in the appendix of [3] implies, possibly restricting \mathcal{W}_0 , that there is a k -tuple $(\omega^1, \dots, \omega^k) \subseteq \Omega$ and an analytic map $\tau: \mathcal{W}_0 \rightarrow \{(t_1, \dots, t_k): t_i \geq 0, t_1 + \dots + t_k = t\}$ such that

$$S_{\mathbf{f}^*}(t, \xi_0, u(\mathbf{d})) = (t, G_0(\mathbf{d})),$$

where $u(\mathbf{d})$ is the piecewise-constant control with values $\omega^1, \dots, \omega^k$ and switching times $\tau_1(\mathbf{d}), \dots, \tau_k(\mathbf{d})$. Denoting the canonical projection by $p: M^* \rightarrow U$, we obtain

$$G_0^{-1}(p(S_{\mathbf{f}^*}(t, \xi_0, u(\mathbf{d})))) = \mathbf{d}.$$

By Corollary 4.5 the map

$$H: (\gamma, \varepsilon, \mathbf{d}) \mapsto \begin{cases} p(\delta_\varepsilon^{-1} S_{\mathbf{f}^*}(\varepsilon^{l_0} t, (\varepsilon^{l_0} \gamma, \xi_0), \delta_\varepsilon u(\mathbf{d}))), & \varepsilon \neq 0, \\ p(S_{\mathbf{f}^*}(t, \xi_0, u(\mathbf{d}))), & \varepsilon = 0, \end{cases}$$

is defined in a neighborhood \mathcal{W}' of $(0, 0, 0)$ and it is C^∞ . Possibly restricting \mathcal{W}' , $H(\mathcal{W}')$ is contained in U' , so that the map

$$(\gamma, \varepsilon, \mathbf{d}) \mapsto \begin{cases} (\gamma, \varepsilon, G_\varepsilon^{-1}(p(\delta_\varepsilon^{-1} S_{\mathbf{f}^*}(\varepsilon^{l_0} t, (\varepsilon^{l_0} \gamma, \xi_0), \delta_\varepsilon u(\mathbf{d}))))), & \varepsilon \neq 0, \\ (\gamma, 0, G_0^{-1}(p(S_{\mathbf{f}^*}(t, (\gamma, \xi_0), u(\mathbf{d}))))), & \varepsilon = 0, \end{cases}$$

is defined in a neighborhood of $(0, 0, 0)$, it is C^∞ , and its derivative has maximum rank at $(0, 0, 0)$. Therefore, it has a local analytic inverse (id, id, ν) . Set $\mathbf{e}_1 = (1, 0, \dots, 0)$, and define $\eta(c, \gamma, \varepsilon) = \delta_\varepsilon u(\nu(\gamma, \varepsilon, c\mathbf{e}_1))$. The control η is a continuous function of its arguments and so we obtain

$$\begin{aligned} S_{\mathbf{f}^*}(\varepsilon^{l_0} t, (\varepsilon^{l_0} \gamma, \xi_0), \eta(c, \gamma, \varepsilon)) &= (\varepsilon^{l_0}(t + \gamma), \exp \varepsilon^{r_1} c h_1 \cdot \xi_0) \\ &= (\varepsilon^{l_0}(t + \gamma), \xi_0) + \varepsilon^{r_1} c \chi_{\mathbf{f}^*}(\xi_0) + o(\varepsilon^{r_1+a}) \quad \forall a < r_1. \end{aligned}$$

Setting $\varepsilon' = \varepsilon^{l_0} t$, we obtain that $\chi_{\mathbf{f}^*}(\xi_0)$ is a regular variation of order r_1/l_0 . \square

Up to now we have used a graded structure on M^* induced by the graded structure $(\mathbf{x}, U, \mathbf{w})$ on M . This choice of graded structure on M^* allows us to deduce the properties of the graded approximation of the pullback system starting from the properties of the original system. On the other hand, one can choose any graded structure on M^*

and consider directly the properties of the graded approximation of Σ_{r^*} induced by this graded structure. Notice that in this case the properties of $\Sigma_{\hat{r}^*}$ may have no links with the properties of $\Sigma_{\hat{r}}$. Nevertheless, additional results may be obtained by this method. For example, the following result holds true.

COROLLARY 4.7. *Let $(\mathbf{x}^*, M^*, \mathbf{w}^*)$ be any graded structure on M^* at ξ_0 , and let $\Sigma_{\hat{r}^*}$ be the graded approximation of Σ_{r^*} induced by a set of admissible weights $\mathbf{l} = (l_0, \dots, l_m)$ such that $l_0 \geq w^0$, $l_i \geq \mathcal{O}(f_i^*)$, $i = 1, \dots, m$. If (i) $\dim N_{r^*}(\xi_0, 0) = \dim N_{\hat{r}^*}(\xi_0, 0)$, (ii) there is $t > 0$ such that $\hat{x}_{\hat{r}^*}(t) \in \text{int}_{\text{rel}} R_{\hat{r}^*}(\xi_0, t)$, and (iii) $\chi \in \mathcal{S}$ is a bracket of \mathbf{l} -weight r such that $\chi_{\hat{r}^*}(\xi_0) \neq 0$, then $\chi_{\hat{r}}(\xi_0)$ is a regular variation at 0 of order r/l_0 for the reference couple of the original system.*

Proof. By Theorem 4.6 $\chi_{r^*}(\xi_0)$ is a variation of Σ_{r^*} . The statement follows if we take into account that the variations of $\Sigma_{\hat{r}}$ and of Σ_{r^*} coincide and that $\chi_{r^*}(\xi_0) = \chi_{\hat{r}}(\xi_0)$. \square

Up to now we have constructed variations under the hypothesis that an approximating system is locally controllable along its reference trajectory. On the other hand, $\Sigma_{\hat{r}^*}$ is a cascade of integrators, so that some subsystem can be locally controllable along its reference trajectory. If this is the case, we obtain a subspace of $\mathcal{S}_{\hat{r}}(\xi_0)$ as a space of variations. To this aim we choose a suitable graded structure on M^* and we consider suitable subsystems of $\Sigma_{\hat{r}^*}$.

Let $(\mathbf{x}, U, \mathbf{w})$ be a graded structure on M at ξ_0 . Define on M^* the graded structure $\mathbf{w}^* = (w^0, \mathbf{w})$, where w^0 is any positive integer. Let $\mathbf{l} = (l_0, \dots, l_m)$ be a set of positive integers such that $l_0 = w^0$ and $l_i \geq \mathcal{O}(f_i^*)$, $i = 1, \dots, m$. As above, we can consider the graded approximation $\hat{\mathbf{f}}^* = \{\partial/\partial x^0, \hat{f}_1^*, \dots, \hat{f}_m^*\}$ of the family \mathbf{f}^* induced by \mathbf{l} and \mathbf{w}^* .

Let s be an integer less than or equal to $\max\{w^1, \dots, w^n\}$, and let the manifold $N \subseteq U$ be defined by

$$\{\xi \in U: x^j(\xi) = 0 \text{ if } w^j > s\}.$$

Let $N^* = I \times N$, and let $i: N^* \rightarrow M^*$ be the injection map. The chart \mathbf{x}^* induces a projection $\pi: M^* \rightarrow N^*$. For each $f^* \in \mathcal{V}(M^*)$, ϕ will denote the vector field on N^* given by $\phi = \pi_*(f^* \circ i)$, that is, the projection on TN^* of f^* restricted to N^* .

Let Σ_ϕ be the control system associated with the family $\Phi = \{\partial/\partial x^0, \phi_1, \dots, \phi_m\}$, and let $\Sigma_{\hat{\phi}}$ be the approximating system defined by $(\mathbf{x}^*, M^*, \mathbf{w}^*)$ and \mathbf{l} . The main result in this section is that if for some choice of the positive numbers s and w^0 the system $(\Sigma_{\hat{\phi}}, \Omega)$ is weakly locally controllable along $t \mapsto (t, \xi_0)$, then $T_{\xi_0}N$ is a subspace of $\mathcal{H}_{\hat{r}}(0)$. More precisely the following result holds.

THEOREM 4.8. *Let us suppose that (i) $\mathbf{l} = (l_0, \dots, l_m)$ is a set of admissible positive weights such that $l_0 = w^0$ and $l_i \geq \mathcal{O}(\phi_i)$, $i = 1, \dots, m$ and (ii) there exists $t > 0$ such that (t, ξ_0) is interior to $R_{\hat{\phi}}(\xi_0, t)$ relative to $\{t\} \times N$. If $\chi \in \mathcal{S}$ is a bracket of \mathbf{l} -weight r such that $\chi_{\hat{\phi}}(\xi_0) \neq 0$, then $\chi_{\hat{\phi}}(\xi_0)$ is a regular variation at 0 of order r/l_0 for the reference couple of the original system.*

Proof. Applying Theorem 4.6 to the system Σ_ϕ , we obtain that $\chi_\phi(\xi_0)$ is a regular variation of order r/l_0 for $(\hat{x}_\phi, 0)$. Let $\eta(c, \gamma, \varepsilon) = \delta_\varepsilon u(\gamma, \varepsilon, c)$ be the control constructed in that theorem with the property

$$(4.4) \quad S_\phi(\varepsilon^b t, (\varepsilon^b \gamma, \xi_0), \eta(c, \gamma, \varepsilon)) = (\varepsilon^b(\gamma + t), \varepsilon^r \chi_\phi(\xi_0) + o(\varepsilon^{r+a})).$$

Since $\Sigma_{\hat{r}^*}$ is a cascade of integrators and $\|u(\gamma, \varepsilon, c)\|_{L^1}$ is uniformly bounded, there is $\sigma > 0$ such that $S_{\hat{r}^*}(\sigma^b \tau, (\sigma^b \gamma, \xi_0), \delta_\sigma u(\gamma, \varepsilon, c))$ is defined and belongs to M^* for $\tau \in [0, t]$. Therefore, [3, Thm. 2.1] applies, so that we obtain that $S_{r^*}(\varepsilon^b t, (\varepsilon^b \gamma, \xi_0), \eta(c, \gamma, \varepsilon))$ is defined for ε smaller than σ . Moreover, for each j we have

$$(4.5) \quad \varepsilon^{-w^j} x^j(S_{r^*}(\varepsilon^b t, (\varepsilon^b \gamma, \xi_0), \eta(c, \gamma, \varepsilon))) \quad \text{uniformly bounded.}$$

Set $u_\varepsilon = \eta(c, \gamma, \varepsilon)$; to end the proof of the statement it is sufficient to show that

$$\|S_{f^*}(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon) - S_\Phi(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon)\| = o(\varepsilon^{s+\alpha}) \quad \forall \alpha < 1$$

uniformly on γ and c . By the definition and by (4.5) we have

$$\begin{aligned} & \|S_{f^*}(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon) - S_\Phi(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon)\| \\ & \leq \|\pi S_{f^*}(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon) - S_\Phi(\varepsilon^b t, (\varepsilon^b \gamma, 0), u_\varepsilon)\| + o(\varepsilon^{s+\alpha}) \\ & \leq \int_0^{\varepsilon^b t} \sum_{i=1}^m |(u_\varepsilon(\tau))_i| \|\pi_* f_i^*(S_{f^*}(\tau, (\varepsilon^b \gamma, 0), u_\varepsilon)) \\ & \quad - \pi_* f_i^*(S_\Phi(\tau, (\varepsilon^b \gamma, 0), u_\varepsilon))\| d\tau + o(\varepsilon^{s+\alpha}) \\ & \leq \int_0^{\varepsilon^b t} \sum_{i=1}^m |(u_\varepsilon(\tau))_i| L_i \|S_{f^*}(\tau, (\varepsilon^b \gamma, 0), u_\varepsilon) - S_\Phi(\tau, (\varepsilon^b \gamma, 0), u_\varepsilon)\| d\tau + O(\varepsilon^{s+\alpha}), \end{aligned}$$

where L_i are local Lipschitz constants of the f_i 's. The L_1 -norm of u_ε is uniformly bounded, so that Gronwall's lemma completes the proof. \square

Proof of Theorem 3.5. The proof of the theorem is based on the results in [3]. Notice that the proof given in [3] is for the case in which Ω is a hypercube, i.e., $\rho_1 = \dots = \rho_m$; however, it is easy to see that the proofs do not change if Ω is a polydisk. We can suppose that \mathbf{l} is a set of *positive* weights. In fact, if this is not the case, we can construct a new set of admissible positive weights for which hypothesis (3.5) of the theorem is fulfilled (see [3, Lemma 4.2]). Moreover, a bracket Λ is \mathbf{l} -neutralized for Σ_f if and only if it is \mathbf{l} -neutralized for Σ_{f^*} (see [3, Lemma 4.1]). Therefore, it is sufficient to prove the theorem for the pullback system Σ_{f^*} when \mathbf{l} is a set of *positive* weights. \mathbf{l}^* defines a filtration $\mathcal{N} = \{N_i\}_{i \geq 0}$ of \mathcal{S}_f , where $N_i = \text{span} \{\Lambda_f : \Lambda_f \in \mathcal{S}, \|\Lambda_f\|_1 \leq i\}$. Let $(\mathbf{x}, U, \mathbf{w})$ be a graded structure induced by \mathcal{N} at ξ_0 up to weight $p = \min\{i : N_i(\xi_0) = \mathcal{S}_f(\xi_0)\}$ (see [3, §§ 3, 4]). We set $\mathbf{x}^* = (x^0, \mathbf{x})$ and $\mathbf{w}^* = (l_0, \mathbf{w})$. $(\mathbf{x}^*, M^*, \mathbf{w}^*)$ is such that for each $f \in \mathcal{S}_f$, $\mathcal{O}(f^*) = \mathcal{O}(f)$, where \mathcal{O} denotes both the graded orders induced by the above graded structures on M and M^* (see [3, Lemma 4.3]). We define the submanifold $N \subseteq U$ by $x^j|_N = 0$ if $w^j > s = \|\Phi\|_1$, and we consider the system Σ_Φ on N^* as defined previously. By the definition of the graded structure induced by \mathbf{l}

$$T_{\xi_0} N = \{\Lambda_f(\xi_0) : \|\Lambda_f\|_1 \leq s\}.$$

Moreover, if h is a vector field whose graded order is equal to r , then each component h^j has graded order greater than or equal to $w^j - r$. Therefore, if Λ is a bracket in \mathcal{S} such that $\|\Lambda\|_1 = r$, we obtain (i) if $r \leq s$, then $\Lambda_f(\xi_0) = \Lambda_{f^*}(\xi_0) = \Lambda_\Phi(\xi_0)$, and (ii) if $r > s$, then $\Lambda_\Phi \equiv 0$. If $r \leq s$, [3, Prop. 3.1] implies that $\Lambda_\Phi(\xi_0) = \Lambda_\Phi(\xi_0) \pmod{V_{r-1}^1}$. As a consequence, we obtain

$$\chi_\Phi(\xi_0) = 0 \quad \forall \chi \in \mathcal{B}_1^* \text{ and } \mathcal{S}_\Phi(\xi_0) = T_{\xi_0} N.$$

Applying [3, Thm. 1.1], we obtain that (t, ξ_0) is interior to $R_\Phi(\xi_0, t)$ relative to $\{t\} \times N$ for each t . Theorem 4.8 completes the proof. \square

Remark 4.9. Let $\Phi \in \mathcal{S}$ satisfy the hypotheses of Theorem 3.5 for a set of weights \mathbf{l} that can be chosen to be positive (see [3, Lemma 4.2]). Φ defines a variation of order $\alpha = \|\Phi\|_1/l_0$. The L^1 norm of its control variation η is an $o(\varepsilon^b)$ for each $b < \min\{l_1, \dots, l_m\}/l_0$. Remark 3.2 implies that Φ defines a variation of order α also if the vector fields f_i 's are perturbed with terms of order greater than $k = \|\Phi\|_1/\min\{l_0, \dots, l_m\}$.

The result is not surprising since k is at least as large as the length of each bracket involved in the assumptions.

5. Applications to local controllability along a trajectory. This section is devoted to deriving from Theorem 3.5 sufficient conditions of weak local controllability along a trajectory. We will show that the variational approach we propose unifies most of the known sufficient conditions of local controllability.

By means of Theorem 3.5 we can construct for each admissible set of weights \mathbf{l} a space $V_r^{\mathbf{l}}$ of variations at time 0 as the maximal \mathbf{l} -neutralized subspace of \mathcal{S}_r . If the sum of such spaces over all the set of admissible weights is equal to $\Delta_r^0(\xi_0)$, then by Theorem 1.13 \hat{x}_r is weakly locally controllable. As a consequence, we obtain that different sets of weights can be used to neutralize the obstructions in the sense of the following result.

PROPOSITION 5.1. *Let Ω be a polydisk (possibly unbounded). For each set \mathbf{l} of nonnegative admissible weights let us define $r(\mathbf{l})$ as the maximum integer r for which each $\chi \in \mathcal{B}_1^*$ such that $\|\chi\|_1 \leq r$ is \mathbf{l} -neutralized at ξ_0 . If*

$$\mathcal{W} = \sum_{\mathbf{l}} \text{span} \{h(\xi_0) : h \in V_{r(\mathbf{l})}^{\mathbf{l}}\} = \Delta_r^0(\xi_0),$$

then (Σ_r, Ω) is weakly locally controllable along \hat{x}_r .

Proposition 5.1 contains [3, Thm. 1.1] as a particular case in which only one admissible set of weights is considered for neutralizing the obstructions. We recall that such a result generalizes those in [12] and [18] (see [3, Lemma 1.2] and subsequent paragraphs). The following example shows that more than one set of weights may be necessary to prove the local controllability of a trajectory.

Example 5.2. Let $M = \mathbb{R}^9$, $m = 1$, $\Omega = [-1, 1]$,

$$f_0(x_1, \dots, x_9) = x_1 \frac{\partial}{\partial x_2} + \dots + x_6 \frac{\partial}{\partial x_7} + (x_7 + x_1^4) \frac{\partial}{\partial x_8} + (x_2^2 + x_1^3) \frac{\partial}{\partial x_9},$$

$$f_1(x_1, \dots, x_9) = \frac{\partial}{\partial x_1}.$$

Σ_r is locally controllable at 0. In fact, $\mathbf{l} = (0, 1)$ and $\bar{\mathbf{l}} = (1, 1)$ are sets of admissible weights. $r(\mathbf{l}) = 1$, $r(\bar{\mathbf{l}}) = 4$, and

$$V_1^{\mathbf{l}} = \text{span} \left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_8} \right) \quad \text{and} \quad V_4^{\bar{\mathbf{l}}} = \text{span} \left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_4}, \frac{\partial}{\partial x_9} \right).$$

The nonzero obstructions are

$$ad_{f_1}^4 f_0 = 4! \frac{\partial}{\partial x_8} \quad \text{and} \quad ad_{[f_1, f_0]}^2 f_0 = 2 \frac{\partial}{\partial x_9}.$$

$ad_{f_1}^4 f_0$ can be neutralized at 0 only by $ad_{f_0}^7 f_1 = \partial / \partial x_8$; $ad_{[f_1, f_0]}^2 f_0$ can be neutralized only by $ad_{f_1}^3 f_0 = 24x_1(\partial / \partial x_8) + 3!(\partial / \partial x_9)$. Suppose that there is a set of weights for which both of the above obstructions are neutralized. In this case, $4l_1 + l_0 > 7l_0 + l_1$ and $2l_1 + 3l_0 > 3l_1 + 3l_0$, i.e., $l_1 > 2l_0$ and $l_1 < 2l_0$, a contradiction.

Remark 5.3. We point out that for applying Proposition 5.1 it is not sufficient that each obstruction be neutralized by a set of admissible weights. For example, consider the system in \mathbb{R}^5 , with $m = 1$, $\Omega = [-1, 1]$,

$$f_0(x_1, \dots, x_5) = x_1 \frac{\partial}{\partial x_2} + (x_2^2 + x_1^3) \frac{\partial}{\partial x_3} + x_3 \frac{\partial}{\partial x_4} + (x_1^4 + x_4) \frac{\partial}{\partial x_5},$$

$$f_1(x_1, \dots, x_5) = \frac{\partial}{\partial x_1}.$$

The nonvanishing obstructions are

$$\Lambda_1 = ad_{[f_0, f_1]}^2 f_0 = 2 \frac{\partial}{\partial x_3} \quad \text{and} \quad \Lambda_2 = ad_{f_1}^4 f_0 = 4! \frac{\partial}{\partial x_5}.$$

They can be neutralized, respectively, by $ad_{f_1}^3 f_0 = 3! \partial / \partial x_3$ and $ad_{f_0}^2 ad_{f_1}^3 f_0 = 3! \partial / \partial x_5$, so that Λ_1 is \mathbf{l} -neutralized if and only if $l_1 < 2l_0$ and Λ_2 is \mathbf{l} -neutralized if and only if $l_1 > 2l_0$. Both Λ_1 and Λ_2 can be neutralized at 0; nevertheless, if $l_1 > 2l_0$, Λ_1 cannot be neutralized and its weight is smaller than that of Λ_2 . Therefore $\partial / \partial x_5$ does not belong to \mathcal{W} and Proposition 5.1 does not apply.

If all the obstructions in $V_s^{\mathbf{l}}$ are neutralized along the trajectory, Theorem 2.4 implies that for each $h \in V_s^{\mathbf{l}}$, $ad_{f_0}^i h(\hat{x}(t))$ is an element of $\mathcal{H}_t(t)$ for each $i \geq 0$ and each $t > 0$. Notice that $ad_{f_0}^i h(\xi_0)$ need not be a variation at 0; nevertheless, it defines directions that can be used to prove controllability. All of the above arguments leads to the following summarizing result.

THEOREM 5.4. *Let Ω be a polydisk (possibly unbounded). For each set \mathbf{l} of nonnegative admissible weights let us define (i) $r(\mathbf{l})$ as the maximum integer r for which each $\chi \in \mathcal{B}_t^*$ such that $\|\chi\|_1 \leq r$ is \mathbf{l} -neutralized at ξ_0 and (ii) $s(\mathbf{l})$ as the maximum integer s for which each $\chi \in \mathcal{B}_s^*$ such that $\|\chi\|_1 \leq s$ is \mathbf{l} -neutralized at $\hat{x}_t(t)$ for all $t \in (0, \tau)$. If*

$$\mathcal{V} = \sum_{\mathbf{l}} \text{span} \{ \{h(\xi_0) : h \in V_{r(\mathbf{l})}^{\mathbf{l}}\} \cup \{ad_{f_0}^i g(\xi_0) : g \in V_{s(\mathbf{l})}^{\mathbf{l}}, i \geq 0\} \} = \Delta_r^0(\xi_0),$$

then (Σ_r, Ω) is weakly locally controllable along \hat{x}_t .

Proof. Lemma 3.1 in [16] states that if each \mathbf{l} -homogeneous element $\chi \in \mathcal{B}_s^{\mathbf{l}} \cap V_s^{\mathbf{l}}$ is \mathbf{l} -neutralized at any point $\hat{x}(t)$ and t belongs to a nondegenerate interval $[0, \tau)$, then each element $\chi \in \mathcal{B}_t^* \cap V_s^{\mathbf{l}}$ is \mathbf{l} -neutralized at the same points. Therefore, each $g \in V_{s(\mathbf{l})}^{\mathbf{l}}$ defines a variation at each $t \in (0, \tau)$. Let

$$\{h_1(\xi_0), \dots, h_k(\xi_0), ad_{f_0}^{i_1} g_1(\xi_0), \dots, ad_{f_0}^{i_j} g_j(\xi_0)\}$$

be a base of $\Delta_r^0(\xi_0)$. By continuity, if t is sufficiently small, the vectors

$$\{(\exp tf_0)_* h_1(\xi_0), \dots, (\exp tf_0)_* h_k(\xi_0), ad_{f_0}^{i_1} g_1(\exp tf_0 \cdot \xi_0), \dots, ad_{f_0}^{i_j} g_j(\exp tf_0 \cdot \xi_0)\}$$

are linearly independent. Since Δ_r^0 has constant dimension on \hat{x}_t , they are a base of $\Delta_r^0(\hat{x}_t(t))$ for t sufficiently small. By the definition of the variational cone and by Theorem 2.4 the vector space they span is contained in $\mathcal{H}_t(t)$. Hence for each $t > 0$ sufficiently small $\mathcal{H}_t(t) = \Delta_r^0(\hat{x}_t(t))$, and Theorem 1.10 completes the proof. \square

Remark 5.5. Theorem 5.4 points out that \hat{x}_t may be weakly locally controllable even if some obstructions are not neutralized by any set of weights. For example, let $M = \mathbb{R}^5$, $m = 1$,

$$f_0(x_1, \dots, x_5) = x_1 \frac{\partial}{\partial x_2} + x_1^3 \frac{\partial}{\partial x_3} + x_3 \frac{\partial}{\partial x_4} + (x_2^2 + x_4) \frac{\partial}{\partial x_5},$$

$$f_1(x_1, \dots, x_5) = \frac{\partial}{\partial x_1}.$$

In this example the obstruction $[[f_0, f_1], [[f_0, f_1], f_0]](0)$ belongs only to

$$\text{span} \{ad_{f_0}^2 [f_1 [f_1 [f_1, f_0]]](0)\},$$

so that it cannot be neutralized by any set of weights. However, setting $\mathbf{l} = (1, 1)$, we obtain $V_{s(\mathbf{l})}^{\mathbf{l}} = \text{span} \{\partial / \partial x_1, \partial / \partial x_2, \partial / \partial x_3\}$ and $\mathcal{V} = \mathbb{R}^5$, so that by Theorem 5.4 Σ_r is locally controllable at 0.

Neutralization with respect to different weights in the case of a stationary trajectory and bounded controls, has been considered by the present authors in [1]. Let us now analyze the case of unbounded controls. Corollary 3.8 implies that if

$$\mathcal{Y}(\xi_0) = \text{span} \{ad_{f_0}^h Y(\xi_0) : Y \in \text{Lie}\{f_1, \dots, f_m\}, h \geq 0\} = \Delta_r^0(\xi_0),$$

then the trajectory \hat{x}_r is weakly locally controllable. Otherwise, it is sufficient to look for a subspace transversal to $\mathcal{Y}(\xi_0)$ in \mathcal{W} . A sufficient condition of weak local controllability involving the brackets that contain f_0 only once is given in [3]. The result is obtained by giving a sufficiently large weight to f_0 and by giving a weight of unity to the controlled vector fields. The same arguments can be used to find subspace of variations. Namely, let

$$W_r = \text{span} \{\chi_r, \chi \text{ contains one } X_0 \text{ and its length is } r+1\}.$$

If s is such that

$$W_{2r}(\xi_0) \subseteq W_{2r-1}(\xi_0) \cup \text{Lie}\{f_1, \dots, f_m\}(\xi_0) \quad \forall 2r \leq s,$$

then $W_s(\xi_0)$ is a subspace of variation at 0. In [9] the author introduces the subspaces $W_r^i = \text{span} \{ad_{f_i}^j f_0, j \leq r\}$ in order to give conditions of local controllability at ξ_0 . The same type of conditions define W_r^i as subspaces of variations. This can be done by grading the weights of the f_i 's in a suitable way and by taking l_0 sufficiently large. Summarizing, we obtain

THEOREM 5.6. *Let $\Omega = \mathbb{R}^m$. Define $J = \text{Lie}(f_1, \dots, f_m)$, $\mathcal{Y} = \text{span} \{ad_{f_0}^h Z, Z \in J\}$, $W_r^i = \text{span} \{ad_{f_i}^j f_0, j \leq r\}$, $s(i)$ the maximum of the integers σ such that $W_{2r}^i(\xi_0) \subseteq W_{2r-1}^i(\xi_0) \cup J(\xi_0) \quad \forall 2r \leq \sigma$, $W_r = \text{span}(\chi_r, \chi \text{ contains one } X_0 \text{ and its length is } r+1)$, and s the maximum integer k with the property that $W_{2r}(\xi_0) \subseteq W_{2r-1}(\xi_0) \cup J(\xi_0) \quad \forall 2r \leq k$. If*

$$\mathcal{Y}(\xi_0) + W_{s(1)}^1(\xi_0) + \dots + W_{s(m)}^m(\xi_0) + W_s(\xi_0) = \Delta_r^0(\xi_0),$$

then (Σ_r, Ω) is weakly locally controllable along \hat{x}_r .

Proof. What we have said previously proves that $\mathcal{Y}(\xi_0) \subseteq \mathcal{W}$. Let $\chi^1, \dots, \chi^r \in \text{Lie}(X_1, \dots, X_m)$ be such that $\chi_r^1(\xi_0), \dots, \chi_r^r(\xi_0)$ is a basis of $J(\xi_0)$, and let h be the maximum length of the χ^i 's. Let $\mathbf{l} = (hs(i), s(i), \dots, 1, \dots, s(i))$ (1 in the i th position). $\Phi_r \in W_{s(i)}^i$ implies $\|\Phi\|_1 \leq (h+1)s(i) = k$. Let $\psi \in \mathcal{B}_1^*$; if ψ contains more than one X_0 , $\|\psi\|_1 > 2hs(i) > k$; if ψ contains any X_j with $j \neq i$, then $\|\psi\|_1 > (h+2)s(i) > k$. Hence the only obstructions with weight less than k belong to $\text{Lie}(X_0, X_i)$, contain X_0 once, and contain X_i no more than $s(i)$ times. The hypotheses imply that these obstructions are neutralized, since $\|\chi^j\|_1 \leq hs(i), j = 1, \dots, r$. Hence $W_{s(i)}^i \subseteq \mathcal{W}$. Let $\mathbf{m} = (hs, 1, \dots, 1)$ (h is the integer defined above). $\Phi_r \in W_s$ implies $\|\Phi\|_m \leq (h+1)s = \bar{k}$. The only obstructions with weight less than \bar{k} contain one X_0 and at most s indeterminates with indices different from 0. By the hypotheses these obstructions are neutralized, since $\|\chi^j\|_m \leq h < hs$. Hence $W_s \subseteq \mathcal{W}$, and the proof is complete. \square

VERSIONS OF SONTAG'S "INPUT TO STATE STABILITY CONDITION" AND THE GLOBAL STABILIZABILITY PROBLEM*

JOHN TSINIAS†

Abstract. This paper deals with the global feedback stabilizability problem for interconnected nonlinear systems that are affine in the control. The corresponding feedback stabilizers are supposed to be almost smooth real mappings. The results of this paper extend those developed in recent works of the author [*SIAM J. Control Optim.*, 29 (1991), pp. 457-473], [*Systems Control Lett.*, 15 (1990), pp. 441-448], [*SIAM J. Control Optim.*, 30 (1992), pp. 879-893] concerning the local stabilizability problem. The main sufficient conditions presented are of Lyapunov type, and the main idea of the paper is based on the input to state stability condition introduced by Sontag [*IEEE Trans. Automat. Control*, 35 (1990), pp. 473-477].

Key words. global stabilization, input to state stability condition, control Lyapunov function

AMS subject classification. 93D15

1. Introduction. In the last few years, there has been an increasing interest in the problem of local and global stabilization of nonlinear control systems by feedback (see, for instance, [1]-[12], [14]-[18], [20]-[36], and [38]).

In particular, in [8], [18], [21], [25], and [29], it was proved that if a smooth nonlinear system is globally smoothly stabilizable at its equilibrium, then adding an integrator does not change this property.

Generalizations of the previous result are also given in [25], [31], and [33]. Further progress was provided in [18] by Kokotovic and Sussmann, where sufficient conditions are established for global stabilization for interconnected systems of the form

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} f_1(x_1, x_2) \\ Ax_2 \end{pmatrix} + \begin{pmatrix} 0 \\ Bu \end{pmatrix},$$

where A and B are constant matrices.

Our purpose is to provide sufficient conditions for global stabilization for the case of systems

$$(1.1a) \quad \dot{x} = F(x) + G(x)u, \quad (x, u) \in \mathbb{R}^n \times \mathbb{R}^m,$$

$$(1.1b) \quad F(x) = \begin{pmatrix} f_1(x_1, x_2) \\ f_2(x_1, x_2) \end{pmatrix}, \quad G(x) = \begin{pmatrix} 0 \\ g(x_1, x_2) \end{pmatrix}, \quad x = (x'_1, x'_2)' \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2},$$

or, equivalently,

$$(1.2) \quad \begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} f_1(x_1, x_2) \\ f_2(x_1, x_2) \end{pmatrix} + \begin{pmatrix} 0 \\ g(x_1, x_2)u \end{pmatrix}.$$

The stabilization approach we present is based on a version of the *input to state stability condition* introduced by Sontag in [25] and also on some ideas from our recent works [32], [33].

We assume that the mappings $f_1: \mathbb{R}^n \rightarrow \mathbb{R}^{n_1}$, $f_2: \mathbb{R}^n \rightarrow \mathbb{R}^{n_2}$, and $g: \mathbb{R}^n \rightarrow \mathbb{R}^{n_2}$ are continuous and that the origin $O \in \mathbb{R}^n$ is an equilibrium for the uncontrolled term F (i.e., $F(0) = 0$).

* Received by the editors December 17, 1990; accepted for publication (in revised form) October 11, 1991.

We say that (1.1a) is *globally stabilizable (at the origin)* (G.S.) if there exists a map $r: \mathbb{R}^n \rightarrow \mathbb{R}^m$ such that, for every initial state $x_0 \in \mathbb{R}^n$, the solution $x(t, x_0)$ of the closed-loop system

$$(1.3) \quad \dot{x} = F(x) + G(x)r(x)$$

starting at x_0 , is defined—not necessarily uniquely—for all $t \geq 0$, tending to zero as $t \rightarrow +\infty$ or reaching zero at a finite time and, furthermore, zero is stable with respect to (1.3).

We say that a real function $\Phi: \mathbb{R}^n \rightarrow \mathbb{R}^+$ is a *global control Lyapunov function* (G.C.L.F.) of the origin $O \in \mathbb{R}^n$ with respect to (1.1a) if it is positive definite (namely, $\Phi(0) = 0$ and $\Phi(x) > 0$ otherwise), is continuous on \mathbb{R}^n and at least continuously differentiable on $\mathbb{R}^n \setminus \{0\}$, and, furthermore, (i) Φ is uniformly unbounded on \mathbb{R}^n (namely, $\Phi(x) \rightarrow +\infty$ as $\|x\| \rightarrow +\infty$); and (ii) the following property is satisfied:

$$(1.4) \quad (D\Phi G)(x) \stackrel{\text{def}}{=} ((D\Phi G_1)(x), \dots, (D\Phi G_m)(x)) = 0, \quad x \neq 0 \Rightarrow (D\Phi F)(x) < 0.$$

Artstein's theorem [3] asserts that system (1.1a) admits a G.C.L.F. at zero if and only if it is G.S. by means of a feedback law r that is smooth on $\mathbb{R}^n \setminus \{0\}$. To be more precise, $O \in \mathbb{R}^n$ will be globally asymptotically stable with respect to the resulting system (1.3), where, for each x_0 , the solution $x(t, x_0)$ of (1.3) starting at x_0 is uniquely defined for all positive t .

Further generalizations of the previous theorem are provided in [2], [12], [24], [29]–[31], [35]. In particular, Sontag in [24] offers an explicit formula for the stabilizing feedback law.

Given a continuous map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$, we say that the function $W: \mathbb{R}^n \rightarrow \mathbb{R}^+$ is a G.C.L.F. of the set

$$M_\phi \stackrel{\text{def}}{=} \{x = (x'_1, x'_2)' \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}: x_2 = \phi(x_1)\}$$

with respect to (1.2) if W is continuously differentiable on \mathbb{R}^n ; furthermore,

(i) There exist real functions a_i , $i = 1, 2$, of class \mathcal{K}_∞ (namely, a_i is continuous, strictly increasing and satisfies $a_i(0) = 0$ and $a_i(s) \rightarrow +\infty$ as $s \rightarrow +\infty$) such that

$$(1.5) \quad a_1(\|x_2 - \phi(x_1)\|) \leq W(x) \leq a_2(\|x_2 - \phi(x_1)\|)$$

for all $x = (x'_1, x'_2)' \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$;

(ii) There exists a real function a_3 of class \mathcal{K} (namely, a_3 is continuous, strictly increasing with $a_3(0) = 0$) such that the following holds:

$$(1.6) \quad (DWG)(x) = 0, \quad x \notin M_\phi \Rightarrow (DWF)(x) < -a_3(\|x_2 - \phi(x_1)\|).$$

We say that the function W , above, satisfies the *continuity property* (C.P.) if, furthermore, there exists a map $d: \mathbb{R}^n \rightarrow \mathbb{R}^+$ with $d(x) \rightarrow 0$ as $\text{dist}(x, M_\phi) \rightarrow 0$ such that, for any $x \neq 0$, a vector $u \in \mathbb{R}^m$ can be found satisfying the following inequalities:

$$(DWF)(x) + (DWG)(x)u < -a_3(\|x_2 - \phi(x_1)\|), \quad \|G(x)u\| \leq d(x).$$

Note that the above definition generalizes the notion of the *small control property* (see [3], [24], and [29]).

Finally, we say that the system

$$(1.7) \quad \dot{x}_1 = f(x_1, v), \quad (x_1, v) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$$

satisfies the *input to state stability condition* (I.S.S.C.) if there exist a continuously differentiable Lyapunov function $V: \mathbb{R}^n \rightarrow \mathbb{R}^+$ with respect to $\dot{x}_1 = f(x_1, 0)$ (namely,

$V(0) = 0$; $V(x_1) > 0$ and $DV(x_1)f(x_1, 0) < 0$ for $x_1 \neq 0$), which is uniformly unbounded on \mathbb{R}^n , and positive constants σ and ξ such that the following holds:

$$(1.8) \quad \|x_1\| > \xi, \quad \|v\| < \sigma \Rightarrow DV(x_1)f(x_1, v) < 0,$$

and, furthermore, for any measurable essentially bounded input v , system (1.7) is complete.

Note that the above property weakens a well-known Lyapunov-like condition provided by Sontag, which guarantees input to state stabilization (see condition (16) and Theorem 1 in [25]). We also note that (1.8) is satisfied if, for instance, we assume that zero $O \in \mathbb{R}^{n_1}$ is globally exponentially stable with respect to $\dot{x}_1 = f(x_1, 0)$, and, furthermore, the map $f(x_1, v)$ is Lipschitz continuous with respect to v uniformly on x_1 [37].

Consider now the simplest case of system (1.2), where $m = n_2$ and g is the unit matrix of dimension $m \times m$. Suppose that there exists a continuously differentiable map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^m$ such that $O \in \mathbb{R}^{n_1}$ is globally asymptotically stable with respect to

$$(1.9) \quad \dot{x}_1 = f_1(x_1, \phi(x_1))$$

and let $V(x_1)$ be a uniformly unbounded smooth Lyapunov function of $O \in \mathbb{R}^{n_1}$ with respect to (1.9). Then the function $\Phi(x) = V(x_1) + W(x)$, where $W(x) = \frac{1}{2}\|x_2 - \phi(x_1)\|^2$ is a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2), and so the overall system (1.2) is G.S. by means of a feedback law, which is smooth for $x \neq 0$ and continuous at zero (see [29], [31], and [33]).

Our purpose is to extend the previous result to the general nonlinear case (1.2). In particular, in Theorem 2.2, we establish that if there exists a continuous map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$ such that the set M_ϕ is positively invariant with respect to $\dot{x} = F(x)$, the system

$$(1.10) \quad \dot{x}_1 = f_1(x_1, \phi(x_1) + v), \quad (x_1, v) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}$$

satisfies the I.S.S.C.; furthermore, if (1.2) admits a G.C.L.F. with respect to M_ϕ , then system (1.2) is G.S. by means of an “almost smooth” feedback law $u = r(x)$. In particular, the map r will be smooth on $\mathbb{R}^n \setminus M_\phi$. In Theorem 2.4, we specialize the previous result to homogeneous nonlinear control systems.

If certain additional assumptions for subsystem (1.10) are imposed, then, in Theorems 3.1 and 3.5, we establish that there exists a G.C.L.F. of zero $O \in \mathbb{R}^n$, and so system (1.2) is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus \{0\}$. In particular, in Theorem 3.1 we show that, if, in addition to the hypothesis of Theorem 2.2, we assume that W satisfies the C.P., then system (1.2) admits a G.C.L.F. at the origin. So, according to Artstein’s theorem, system (1.2) is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus \{0\}$. In Theorem 3.5, we strengthen the input to state stability condition (1.8) for the subsystem $\dot{x}_1 = f_1(x_1, x_2)$ as follows: “There is a constant $c > 0$ such that, for any x with $W(x) < cV(x_1)$, we have $DV(x_1)f_1(x) < 0$, where W is a G.C.L.F. of the set M_ϕ with respect to (1.2).”

Under the previous assumption, we show that there exist a positive definite function $\tilde{V}(x_1)$ and a positive constant k so that the function

$$\Phi(x) = \tilde{V}(x_1) + kW(x)$$

is a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2). Finally, we apply Theorem 3.5 to recover a result from [33].

We note that a different approach is used in [33] to investigate the global stabilizability problem for system (1.2). The sufficient conditions we propose in [33]

are also based on the existence of a G.C.L.F. of the set M_ϕ and on a suitable Lyapunov function of $O \in \mathbb{R}^{n_1}$ with respect to (1.9). The corresponding result (Theorem 3.2 in [33]) is a generalization of Artstein's theorem.

2. Almost smooth feedback stabilizers. We state a technical lemma first. The proof is similar to those given in [2] and [35], and we leave it to the reader. This lemma will be used in the proofs of the main results in this section.

LEMMA 2.1. *Suppose that there exists a continuous map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$ and a G.C.L.F. W of the set $M_\phi = \{x \in \mathbb{R}^n: x_2 = \phi(x_1)\}$ with respect to (1.2). Then*

(a) *There exists a smooth map $r: \mathbb{R}^n \setminus M_\phi \rightarrow \mathbb{R}^m$, which satisfies the following inequality:*

$$(DWF + DWGr)(x) < -a_3(\|x_2 - \phi(x_1)\|) \quad \forall x \notin M_\phi;$$

(b) *Furthermore, the resulting map $F + Gr$ will be continuous on \mathbb{R}^n with $(Gr)(x) = 0$ for every $x \in M_\phi$, provided that W satisfies the C.P.*

THEOREM 2.2. *In addition to the hypothesis of Lemma 2.1(a), assume that*

- (i) *The set M_ϕ is positively invariant with respect to $\dot{x} = F(x)$; and*
- (ii) *System (1.10) satisfies the I.S.S.C.*

Then system (1.2) is G.S. by means of a feedback law $u = r(x)$, which is smooth on the region $\mathbb{R}^n \setminus M_\phi$.

Proof. According to Lemma 2.1(a), there exists a map $r: \mathbb{R}^n \rightarrow \mathbb{R}^m$, which is smooth for $x \notin M_\phi$, $r(x) = 0$ for $x \in M_\phi$. Furthermore, the following holds:

$$(2.1) \quad E(x) \stackrel{\text{def}}{=} -(DWF + DWGr)(x) > a_3(\|x_2 - \phi(x_1)\|) \geq a_3(\text{dist}(x, M_\phi)) > 0,$$

for every $x \notin M_\phi$. Next, we establish that the map $u = r(x)$ globally stabilizes system (1.2) at $0 \in \mathbb{R}^n$.

Since system (1.10) satisfies the I.S.S.C., there exists a Lyapunov function $V(x_1)$, which is at least continuously differentiable and uniformly unbounded on \mathbb{R}^{n_1} and which satisfies (1.8) with $f(x_1, v) \stackrel{\text{def}}{=} f_1(x_1, \phi(x_1) + v)$; namely, there exist positive constants σ and ξ such that

$$(2.2) \quad \|x_1\| > \xi, \quad \|v\| < \sigma \Rightarrow DV(x_1)f_1(x_1, \phi(x_1) + v) < 0.$$

Let c be a positive constant satisfying $a_1^{-1}(c) < \sigma$, where the function a_1 is defined in (1.5) and let

$$M_c \stackrel{\text{def}}{=} \{x \in \mathbb{R}^n: W(x) \leq c\},$$

$$K_c \stackrel{\text{def}}{=} M_c \cap \{x \in \mathbb{R}^n: \|x_1\| > \xi\}.$$

Then it is not difficult to see that the following holds:

$$(2.3) \quad DV(x_1)f_1(x_1, x_2) < 0 \quad \forall x \in K_c.$$

Indeed, by (1.5),

$$\|x_2 - \phi(x_1)\| < a_1^{-1}(c) \quad \forall x \in K_c,$$

which, by (2.2) and the fact that $a_1^{-1}(c) < \sigma$, yields $DV(x_1)f_1(x_1, x_2) < 0$. We also define

$$M \stackrel{\text{def}}{=} \{x \in M_c: DV(x_1)f_1(x_1, x_2) \geq 0\}.$$

For each nonzero x_1 such that $\|x_1\| \leq \xi$, consider a closed sphere $S_{p_{x_1}}$ of radius $p_{x_1} > 0$ centered at $(x_1, \phi(x_1))$, which is contained in $M_c \setminus M$, and let

$$\theta_1(x_1) \stackrel{\text{def}}{=} \sup \{|DV(x_1)f_1(x_1, x_2)|, (x'_1, x'_2)' \in M_c\},$$

$$\theta_2(x_1) \stackrel{\text{def}}{=} \inf \left\{ a_3(\|x_2 - \phi(x_1)\|), (x'_1, x'_2)' \notin \bigcup_{\|x_1\| < \xi} S_{(1/2)p_{x_1}} \right\}.$$

Obviously, by (1.5), the set $M_c \cap \{x_1 \in \mathbb{R}^{n_1}: \|x_1\| \leq \xi\}$ is compact; therefore, θ_1 is upper semicontinuous and nonnegative on the region $\{x_1 \in \mathbb{R}^{n_1}: 0 < \|x_1\| \leq \xi\}$. Moreover, θ_2 is lower semicontinuous and strictly positive on this region. Therefore, there exists a real function $b: \mathbb{R}^+ \rightarrow \mathbb{R}^+$ of class \mathcal{K} such that

$$(2.4) \quad \theta_1(x_1)b(\|x_1\|) < \theta_2(x_1) \quad \forall x_1 \neq 0: \|x_1\| \leq \xi.$$

Let ψ be any real function of class \mathcal{K}_∞ satisfying

$$(2.5) \quad V(x_1) \leq \psi(\|x_1\|) \quad \forall x_1 \in \mathbb{R}^{n_1}.$$

Finally, we define

$$(2.6) \quad \tilde{V}(x_1) = \int_0^{V(x_1)} b(\psi^{-1}(r)) dr.$$

Then, similar to [33, Thm. 3.2], we can easily establish that \tilde{V} is continuously differentiable, positive definite, and uniformly unbounded on \mathbb{R}^{n_1} . Moreover, by (2.3), we obtain

$$(2.7) \quad D\tilde{V}(x_1)f_1(x_1, x_2) = b(\psi^{-1}(V(x_1)))DV(x_1)f_1(x_1, x_2) < 0 \quad \forall x \in K_c.$$

Furthermore, it can be shown (see [33]) that the function

$$(2.8) \quad \Phi(x) = \tilde{V}(x_1) + W(x)$$

is positive definite and uniformly unbounded on \mathbb{R}^n , whereas its Lie derivative $\dot{\Phi}$ along the direction of $F + Gr$ is strictly negative on the region M_c . Indeed, for each nonzero $x \in M$ with $x_1 \neq 0$, it follows by (2.3) that $\|x_1\| < \xi$, and so, by (2.4)–(2.8), we have

$$(2.9) \quad \begin{aligned} (D\Phi(F + Gr))(x) &= b(\psi^{-1}(V(x_1)))DV(x_1)f_1(x_1, x_2) - E(x_1, x_2) \\ &\leq b(\|x_1\|)\theta_1(x_1) - \theta_2(x_1) < 0. \end{aligned}$$

For $x \in M_c \setminus M$, we have

$$DV(x_1)f(x) < 0, \quad E(x) \geq 0,$$

and so

$$(2.10) \quad (D\Phi(F + Gr))(x) = b(\psi^{-1}(V(x_1)))DV(x_1)f_1(x_1, x_2) - E(x_1, x_2) < 0.$$

Finally, from Lemma 2.1 for each nonzero $x \in M_c$ with $x_1 \neq 0$, we have

$$(2.11) \quad (D\Phi(F + Gr))(x) = -E(0, x_2) < 0.$$

From (2.9)–(2.11), it follows that there exists a function $d: \mathbb{R}^+ \rightarrow \mathbb{R}^+$ with $d(0) = 0$ and $d(s) > 0$ for $s > 0$ such that

$$(2.12) \quad \dot{\Phi}(x) = (D\Phi(F + Gr))(x) < -d(\|x\|) \quad \forall x \in M_c \setminus \{0\}.$$

We are now in a position to prove that the map $u = v(x)$ globally stabilizes system (1.2) at $O \in \mathbb{R}^n$. First, note that the set M_c is positively invariant with respect to (1.3), where each solution $x(t, x_0)$, $x_0 \in M_c$ of (1.3) is defined (not necessarily uniquely) for all $t \geq 0$. Indeed, for each $x_0 \in M_c \setminus M_\phi$, it follows by (2.1) that $W(x(t, x_0)) \leq W(x_0) \leq c$ as long as $x(t, x_0)$ remains in $M_c \setminus M_\phi$. We distinguish two cases. The first is $x(t, x_0) \in M_c \setminus M_\phi$, and so trajectory $x(t, x_0)$ remains in M_c for every positive t , with $\|x(t, x_0)\| < +\infty$. The other case is $x(t, x_0) \in M_c \setminus M_\phi$ for any $t \in [0, T)$, where $x(T, x_0) \in M_\phi$ for some positive T . Since M_ϕ is positively invariant, for every $w \in M_\phi$, there is a trajectory $\bar{x}(t, w)$, $t \geq 0$ of the system $\dot{x} = (F + Gr)(x) = F(x)$ remaining in M_ϕ for all $t \geq 0$. Therefore, the map $\hat{x}(t, x_0) \stackrel{\text{def}}{=} \bar{x}(t - T, x(T, x_0))$ for $t \geq T$ and $\hat{x}(t, x_0) \stackrel{\text{def}}{=} x(t, x_0)$ for

$t < T$ is a solution of (1.3) starting at x_0 , which remains in M_c provided that $\|x(t, x_0)\| < +\infty$, for $t \in [0, T]$. Repeating the same discussion for any other possible solution $x(t, w)$, $w \in M_\phi$, which is defined for every positive t and does not remain in M_ϕ , we conclude that M_c is indeed a positively invariant set. Furthermore, by (1.5), (2.1), the completeness of (1.10), the continuity of ϕ , and standard Lyapunov based arguments, it can be shown that, for each $x_0 \in \mathbb{R}^n \setminus M_c$, the corresponding trajectory $x(t, x_0)$ of (1.3) enters M_c after some time $T = T(x_0)$ and remains in this region thereafter, namely,

$$(2.13) \quad x(t, x_0) \in M_c \quad \forall t \geq T.$$

(We note that, because of (1.5), (2.1) and the continuity of ϕ , the map $v(t) \doteq x_2(t, x_0) - \phi(x_1(t, x_0))$ is defined for all $t \geq 0$ with $\|x_1(t, x_0)\| < +\infty$. The latter in conjunction with the completeness of (1.10) implies that $x_1(t, x_0)$ and therefore $x(t, x_0) = (x_1'(t, x_0), x_2'(t, x_0))'$ are defined for every $t \geq 0$). Finally, by (2.12), the positively invariance of M_c , and the fact that Φ is uniformly unbounded on \mathbb{R}^n , it follows that $O \in \mathbb{R}^n$ is stable with respect to (1.3) and

$$(2.14) \quad x(t, x_0) \rightarrow 0 \quad \text{as } t \rightarrow +\infty \quad \forall x_0 \in M_c$$

for each trajectory $x(t, x_0)$ of (1.3) starting at x_0 . From (2.13) and (2.14), we conclude that $x(t, x_0) \rightarrow 0$ as $t \rightarrow +\infty$ for all $x_0 \in \mathbb{R}^n$, and so the proof is completed. \square

Example 2.3. Consider the planar case ($n = 2$) where $n_1 = n_2 = m = 1$ and

$$\begin{aligned} f_1(x_1, x_2) &= -x_1 + (x_1^2 - x_2)^2, \\ (f_2 + ug)(x_1, x_2) &= x_2 - 3x_1^2 + u(x_1^2 - x_2)^2. \end{aligned}$$

We define $\phi(x_1) = x_1^2$. Then, obviously, the system $\dot{x}_1 = f_1(x_1, \phi(x_1) + v)$ satisfies the I.S.S.C. with $V(x_1) = \frac{1}{2}x_1^2$, $\xi = 1$, and $\sigma = 1/\sqrt{2}$. Furthermore, the function $W(x_1, x_2) = \frac{1}{2}(x_2 - \phi(x_1))^2$ is a G.C.L.F. of the set $M_\phi = \{x \in \mathbb{R}^2: x_2 = \phi(x_1)\}$. In particular, $(DWG)(x) \neq 0$ for any $x = (x_1, x_2)' \notin M_\phi$. Finally, note that M_ϕ is positively invariant with respect to $\dot{x} = F(x)$. Therefore, according to Theorem 2.2, the above system is G.S. by means of an almost smooth feedback stabilizer. Finally, note that, since the linearization of the system at $O \in \mathbb{R}^2$ is completely uncontrollable and contains a strictly positive eigenvalue, stabilization via smooth feedback is impossible.

An interesting consequence of Theorem 2.2 is the following result.

THEOREM 2.4. *Suppose that there exists a G.C.L.F. W of the set*

$$M_0 \stackrel{\text{def}}{=} \{x \in \mathbb{R}^n: x_2 = 0\}$$

with respect to (1.2), and $f_2(x_1, 0) = 0$ for all $x_1 \in \mathbb{R}^{n_1}$. Furthermore, assume that there exists a smooth map $\hat{f}_1: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$ such that

(i) *The map $\hat{f}_1(x_1)$ is homogeneous of degree $k \geq 1$, namely,*

$$\hat{f}_1(cx_1) = c^k \hat{f}_1(x_1) \text{ for all } c > 0 \text{ and } x_1 \in \mathbb{R}^{n_1};$$

(ii) *The origin $O \in \mathbb{R}^{n_1}$ is globally asymptotically stable with respect to*

$$(2.15) \quad \dot{x}_1 = \hat{f}_1(x_1);$$

(iii) *There is a positive constant ξ such that*

$$d(x_1, x_2) \stackrel{\text{def}}{=} \frac{|f_1(x_1, x_2) - \hat{f}_1(x_1)|}{\|x_1\|^k} \rightarrow 0, \quad \text{as } x_2 \rightarrow 0$$

uniformly on $x_1 \in \{x_1 \in \mathbb{R}^{n_1}: \|x_1\| > \xi\}$.

Then system (1.2) is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus M_0$, provided that $\dot{x}_1 = \hat{f}_1(x_1, v)$ is complete.

Proof. Assume first that $k > 1$. Then a well-known stability result [13] asserts that conditions (i) and (ii) imply the existence of a continuously differentiable Lyapunov function $V(x_1)$ of $O \in \mathbb{R}^{n_1}$ with respect to (2.16), which is homogeneous of degree $(m-1)(k-1)$, $m > 2$. Furthermore, there are positive constants c_1 and c_2 such that the following conditions are satisfied:

$$(2.16) \quad \|DV(x_1)\| \leq c_1 \|x_1\|^{(m-1)(k-1)-1},$$

$$(2.17) \quad DV(x_1)\hat{f}_1(x_1) \leq -c_2 \|x_1\|^{m(k-1)} \quad \forall x_1 \in \mathbb{R}^{n_1}.$$

According to assumption (iii), there is a positive constant σ such that

$$(2.18) \quad d(x_1, x_2) < \frac{3}{4} \frac{c_2}{c_1}$$

for every (x_1, x_2) with $\|x_2\| < \sigma$ and $\|x_1\| > \xi$. From (2.16)-(2.18), it follows that

$$\begin{aligned} DV(x_1)f_1(x_1, x_2) &\leq |DV(x_1)f_1(x_1, x_2) - DV(x_1)\hat{f}_1(x_1)| + DV\hat{f}_1(x_1) \\ &\leq \|x_1\|^{m(k-1)}(c_1 d(x_1, x_2) - c_2) \\ &\leq -\frac{c_2}{4} \|x_1\|^{m(k-1)} < 0 \quad \forall x_1, x_2: \|x_1\| > \xi, \|x_2\| < \sigma. \end{aligned}$$

Therefore, system (1.10) satisfies the I.S.S.C. with $\phi \equiv 0$, and M_0 is positively invariant with respect to $\dot{x} = F(x)$. We conclude that the assumptions of Theorem 2.2 are satisfied, and, consequently, system (1.2) is G.S. at the origin. Finally, for $k = 1$, zero $O \in \mathbb{R}^{n_1}$ is globally exponentially stable, and so there exist a continuously differentiable real function $V(x_1)$ of $O \in \mathbb{R}^{n_1}$ with respect to (2.15) and positive constants \hat{c}_1 and \hat{c}_2 such that $\|DV(x_1)\| \leq \hat{c}_1 \|x_1\|$; $DV(x_1)\hat{f}_1(x_1) \leq -\hat{c}_2 \|x_1\|^2$ for all $x_1 \in \mathbb{R}^{n_1}$. The rest of the proof follows by using exactly the same arguments as before. \square

Example 2.5. Consider the system

$$(2.19a) \quad \dot{x}_1 = -x_1^3 + x_1^3 \theta(x_2)$$

$$(2.19b) \quad \dot{x}_2 = f_2(x_2) + u g(x_2), \quad (x_1, x_2)' \in \mathbb{R} \times \mathbb{R}^{n_2}, \quad u \in \mathbb{R},$$

where θ is continuous with $\theta(0) = 0$ and $|\theta(x_2)| \leq 1$ for all x_2 and $f_2(0) = 0$. Furthermore, assume that there exists a G.C.L.F. $W: \mathbb{R}^{n_2} \rightarrow \mathbb{R}^+$ of $O \in \mathbb{R}^{n_2}$ with respect to (2.19b). Then we can easily justify that the function $\hat{f}_1(x_1) = -x_1^3$ satisfies the assumptions of Theorem 2.4, system (2.19a) is complete, and W is a G.C.L.F. of the set M_0 with respect to (2.19). Furthermore, note that, since (2.19b) admits a G.C.L.F. at $O \in \mathbb{R}^{n_2}$, this subsystem is G.S. by means of a feedback law $u = r(x_2)$, which is smooth on $\mathbb{R}^{n_2} \setminus \{0\}$ and depends only on x_2 . This law also globally stabilizes the overall system (2.19) at $O \in \mathbb{R}^n$.

3. Existence of global control Lyapunov functions. In this section, we give sufficient conditions for the existence of global control Lyapunov functions of the origin guaranteeing stabilization by means of feedback stabilizers that are smooth on $\mathbb{R}^n \setminus \{0\}$. The following theorem generalizes Theorem 2.2 of § 2.

THEOREM 3.1. *In addition to the assumptions of Theorem 2.2, assume that the function W satisfies the C.P. Then there exists a G.C.L.F. of the origin $O \in \mathbb{R}^n$ with respect to (1.2), and so the system is G.S. by means of a feedback law $u = r(x)$, which is smooth on $\mathbb{R}^n \setminus \{0\}$.*

Proof. We proceed exactly as in the proof of Theorem 2.2. Furthermore, by Lemma 2.1(b), there exists a map $r: \mathbb{R}^n \rightarrow \mathbb{R}^m$ such that $F + Gr$ is continuous on \mathbb{R}^n . Then,

similar to the proof of Theorem 2.2, we can establish that $O \in \mathbb{R}^n$ is globally asymptotically stable with respect to (1.3). Therefore, by Kurzweil's theorem [19], system (1.3) admits a smooth Lyapunov function $\hat{\Phi}$ at zero, which is uniformly unbounded on \mathbb{R}^n . It is not difficult to see that $\hat{\Phi}$ is a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2), and so, by Artstein's theorem, the system is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus \{0\}$. \square

EXAMPLE 3.2. Consider system (1.2) with $n_1 = 1$, $n_2 = 2$, $m = 1$, $x_1 = w_1 \in \mathbb{R}$, $x_2 = (w_2, w_3)' \in \mathbb{R}^2$, and

$$(3.1a) \quad f_1(x) = -w_1 - (w_2^k + w_3^l), \quad k, l \text{ integers,}$$

$$(3.1b) \quad f_2(x_2) + ug(x_2) = (-w_2, w_3 + uw_3^2)'.$$

Obviously, the system $\dot{x}_1 = f_1(x_1, 0)$ satisfies the I.S.S.C. with $V(x_1) = \frac{1}{2}x_1^2$, $\xi = 1$, and $\sigma = \frac{1}{4}$. Furthermore, the set $M_0 = \{x \in \mathbb{R}^3: x_2 = 0\}$ is positively invariant, and the function $W(x_2) = \frac{1}{2}\|x_2\|^2$ is a G.C.L.F. of M_0 with respect to the above system, which, in addition, satisfies the C.P. In particular, if we define

$$r(x_2) = \begin{cases} 0 & \text{for } w_3 = 0, \\ -2/w_3 & \text{otherwise,} \end{cases}$$

then $(DWF + rDWG)(x_2) = -w_2^2 - w_3^2$ for all $x_2 = (w_2, w_3)' \in \mathbb{R}^2$. Moreover, the resulting map rg equals $(0, -w_3)'$ for $w_3 \neq 0$ and $(0, 0)$ for $w_3 = 0$; hence it is continuous on \mathbb{R}^2 . Therefore, according to Theorem 3.1, the system is G.S. by means of a feedback law that is smooth on $\mathbb{R}^3 \setminus \{0\}$. Note that, according to our methodology, to determine the feedback stabilizer, we must first evaluate a control Lyapunov function Φ for the system $\dot{x} = F + Gr$. From a practical point of view, this is a very difficult problem. However, in our case, we can directly justify that the function

$$\Phi(x) = \frac{1}{2} w_1^2 + \frac{1}{2k} w_2^{2k} + \frac{1}{2} w_3^2$$

is a G.C.L.F. of $O \in \mathbb{R}^3$ with respect to (1.2) with dynamics given by (3.1). Therefore, we can apply Sontag's formula [24] to determine a feedback stabilizer. Indeed, Theorem 1 in [24] asserts that the feedback law

$$r(x) = \begin{cases} 0 & \text{for } x = 0, \\ -\sigma(a(x), b(x)), & \end{cases}$$

where

$$\sigma(a, b) = \begin{cases} 0 & \text{for } b = 0 \text{ and } a < 0, \\ \frac{a + \sqrt{a^2 + b^2}}{b} & \text{otherwise} \end{cases}$$

and

$$a(x) = (D\Phi F)(x) = -w_1^2 - w_1(w_2^k + w_3^l) - w_2^{2k} + w_3^2,$$

$$b(x) = (D\Phi G)(x) = w_3^3$$

is smooth on $x \in \mathbb{R}^3 \setminus \{0\}$ and globally asymptotically stabilizes the system at $O \in \mathbb{R}^3$.

An interesting consequence of Theorems 2.4 and 3.1 is the following result.

COROLLARY 3.3. *In addition to assumptions (i)–(iii) of Theorem 2.4, suppose that the mappings f_2 and g_i , $i = 1, \dots, m$, are homogeneous vector fields of degree k_0 and*

$k_i, i = 1, \dots, m$, respectively, with $k_0 > k_i$ and that they are independent of x_1 . Furthermore, there exists a positive definite matrix P_2 of dimension $n_2 \times n_2$ such that the following holds:

$$x_2' P_2 g(x_2) = 0, \quad x_2 \neq 0 \Rightarrow x_2' P_2 f_2(x_2) < 0.$$

Then there exists a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to the overall system (1.2), provided that $\dot{x}_1 = f_1(x_1, v)$ is complete.

Proof. The previous assumptions in conjunction with Theorem 2 in [34] assert that the function $W(x_2) = \frac{1}{2} x_2' P_2 x_2$ is a G.C.L.F. of the set $M_0 = \{x \in \mathbb{R}^n : x_2 = 0\}$ with respect to (1.2), which, in addition, satisfies the C.P. The rest of the proof is an immediate consequence of Theorems 2.4 and 3.1. \square

Remark 3.4. Corollary 3.3 generalizes a well-known result from linear control theory concerning systems of the form

$$\begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} + \begin{pmatrix} 0 \\ B \end{pmatrix} u,$$

which states that the above system is (globally) stabilizable at $O \in \mathbb{R}^n$, provided that the matrix A_{11} is Hurwitz and that the pair (A_{22}, B) is stabilizable at $O \in \mathbb{R}^{n_2}$.

Next, we establish that, if the input to state stability condition (1.8) is strengthened, it is possible to construct a G.C.L.F. of the origin with respect to (1.2). The construction of this function is based on some ideas from [32].

THEOREM 3.5. Suppose that there exist a continuous map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$; a positive constant c ; a positive definite, continuously differentiable, real function $V: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^+$, which is uniformly unbounded on \mathbb{R}^{n_1} ; and a G.C.L.F. W of M_ϕ with respect to (1.2) satisfying the following property:

$$(3.2) \quad DV(x_1) f_1(x_1, x_2) < 0 \quad \forall x = (x_1', x_2')': W(x) < cV(x_1).$$

Then there exists a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2), and so (1.2) is G.S. by means of a feedback law $u = r(x)$, which is smooth on $\mathbb{R}^n \setminus \{0\}$.

Remark 3.5. Note that the positively invariant assumption for the set M_ϕ as well as the completeness assumption for (1.10) are not required.

Proof. We establish that there exists a positive real function $s(x)$, which is smooth on $\mathbb{R}^n \setminus \{0\}$, and a positive constant k such that the function

$$(3.3) \quad \Phi(x) = s(x) V(x_1) + kW(x)$$

is a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2).

We consider a smooth real function $\psi: \mathbb{R}^+ \rightarrow \mathbb{R}^+$, which is strictly decreasing on the interval $[0, 1]$ and $\psi(s) = 0$ for all $s > 1$. Furthermore, assume that its first derivative $\psi^{(1)}(s)$ is uniformly bounded on \mathbb{R}^+ , and $\psi^{(l)}(+0) = 0$ for all $l = 1, 2, \dots$. Let k be a positive real constant such that

$$(3.4) \quad k > \frac{1}{c} \sup \left\{ \left| \psi^{(1)}(s) \right|, s \in \mathbb{R}^+ \right\}$$

and define

$$s(x) \stackrel{\text{def}}{=} \begin{cases} \psi\left(\frac{1}{c} \frac{W(x)}{V(x_1)}\right) & \text{for } x_1 \neq 0, \\ 0 & \text{for } x_1 = 0. \end{cases}$$

Then the function s is smooth for $x \neq 0$ and uniformly bounded on \mathbb{R}^n . The result is that Φ is positive definite and continuous on \mathbb{R}^n and, in addition, is continuously

differentiable on $\mathbb{R}^n \setminus \{0\}$. Next, we show that Φ is uniformly unbounded on \mathbb{R}^n . Consider any sequence

$$x_n = (x'_{1n}, x'_{2n})', \quad \|x_n\| \rightarrow +\infty.$$

Without any loss of generality, we may assume that there exist subsequences $\{y_n\}$ and $\{z_n\}$ such that

$$\{x_n\} = \{y_n\} \cup \{z_n\},$$

where

$$(3.5a) \quad \|y_{2n} - \phi(y_{1n})\| \rightarrow +\infty$$

and

$$(3.5b) \quad \|z_{2n} - \phi(z_{1n})\| \leq M \quad \forall n = 1, 2, \dots$$

for some positive constant M . Then, according to (1.5), it follows that $W(y_n) \rightarrow +\infty$, and so

$$(3.6) \quad \Phi(y_n) \rightarrow +\infty \quad \text{as } \|y_n\| \rightarrow +\infty.$$

Next, consider the subsequence $\{z_n\}$. Then, since $\|z_n\| \rightarrow +\infty$ and ϕ is continuous, condition (3.5b) implies that $\|z_{1n}\| \rightarrow +\infty$. The latter, in conjunction with the fact that V is uniformly unbounded on \mathbb{R}^n , implies that $V(z_{1n}) \rightarrow +\infty$. Moreover, by (1.5) and (3.5b), we have

$$W(z_n) \leq a_2(\|z_{2n} - \phi(z_{1n})\|) \leq a_2(M) \quad \forall n = 1, 2, \dots$$

Consequently,

$$\frac{W(z_n)}{V(z_{1n})} \rightarrow 0 \quad \text{and} \quad s(z_n) = \psi\left(\frac{1}{c} \frac{W(z_n)}{V(z_{1n})}\right) \rightarrow \psi(0) > 0;$$

therefore $s(z_n)V(z_{1n}) \rightarrow +\infty$, and so

$$(3.7) \quad \Phi(z_n) = s(z_n)V(z_{1n}) + W(z_n) \rightarrow +\infty.$$

By (3.6) and (3.7), it follows that $\Phi(x_n) \rightarrow +\infty$ as $\|x_n\| \rightarrow +\infty$, which means that Φ is uniformly unbounded on \mathbb{R}^n . To complete the proof, it suffices to show that condition (1.4) is fulfilled. Indeed, consider any nonzero \hat{x} such that $(D\Phi G)(\hat{x}) = 0$. Equivalently,

$$(D\Phi G)(\hat{x}) = \left(\frac{1}{c} \psi^{(1)}\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) + k \right) (DWG)(\hat{x}) = 0,$$

and so, by (3.4), we obtain $(DWG)(\hat{x}) = 0$. Therefore, by (1.6) and (3.2), it follows that the expression

$$(3.8) \quad \begin{aligned} (D\Phi F)(\hat{x}) &= (DVf_1)(\hat{x}) \left(\psi\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) - \frac{1}{c} \psi^{(1)}\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) \frac{W(\hat{x})}{V(\hat{x}_1)} \right) \\ &\quad + (DWF)(\hat{x}) \left(\frac{1}{c} \psi^{(1)}\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) + k \right) \end{aligned}$$

is strictly negative. Indeed, for \hat{x} such that $W(\hat{x}) \geq cV(\hat{x}_1)$, we have

$$\psi\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) = \psi^{(1)}\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) = 0;$$

therefore, by (1.6) and (3.8),

$$(D\Phi F)(\hat{x}) = k(DWF)(\hat{x}) < 0.$$

Finally, for \hat{x} such that $(W(\hat{x})/V(\hat{x}_1)) < c$, it follows by (3.2) and (1.6) that $DV(\hat{x}_1)f_1(\hat{x}) < 0$ and $(DWF)(\hat{x}) \leq 0$. Furthermore, since ψ is positive and strictly decreasing on the interval $[0, 1]$, it follows that $\psi^{(1)}(s) \leq 0$ for $s \in [0, 1]$, and so

$$\psi\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) - \frac{1}{c} \psi^{(1)}\left(\frac{1}{c} \frac{W(\hat{x})}{V(\hat{x}_1)}\right) \frac{W(\hat{x})}{V(\hat{x}_1)} > 0;$$

hence by (3.8) we obtain $(D\Phi F)(\hat{x}) < 0$. Therefore, (1.4) is fulfilled, and the map Φ as defined in (3.3) is a G.C.L.F. of $O \in \mathbb{R}^n$ with respect to (1.2). Hence, according to Artstein's theorem, system (1.2) is G.S. by means of a feedback law $u = r(x)$, which is smooth on $\mathbb{R}^n \setminus \{0\}$. \square

Example 3.6. Consider the planar case

$$(3.9) \quad \begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix} = \begin{pmatrix} -x_1^7 + (x_1^2 - x_2)x_1^6 \\ x_2 - x_1^2 + 2x_1^9 \end{pmatrix} + u \begin{pmatrix} 0 \\ r(x_1 + x_2) \end{pmatrix},$$

where r is a continuous function such that $r(s) = 0$ if and only if $s = 0$. We show that system (3.9) satisfies the assumptions of Theorem 3.5, and so it is G.S. at $0 \in \mathbb{R}^2$ by means of a feedback law that is smooth on $\mathbb{R}^2 \setminus \{0\}$. Let

$$f_1(x_1, x_2) = -x_1^7 + (x_1^2 - x_2)x_1^6, \quad f_2(x_1, x_2) = x_2 - x_1^2 + 2x_1^9, \quad g(x_1, x_2) = r(x_1 + x_2)$$

and define

$$\phi(x_1) = x_1^2, \quad V(x_1) = \frac{1}{2}x_1^2, \quad W(x_1, x_2) = \frac{1}{2}(x_1^2 - x_2)^2, \quad c = \frac{1}{2}.$$

Then, for any $x \in \mathbb{R}^2$ with $W(x_1, x_2) < cV(x_1)$, it holds that $|x_1^2 - x_2| < \frac{1}{2}|x_1|$, and so

$$DV(x_1)f_1(x_1, x_2) = -\frac{1}{2}x_1^8 < 0;$$

therefore (3.2) is fulfilled. Next, we show that the map W defined as above is a G.C.L.F. of the set

$$M_\phi = \{x = (x_1, x_2)' \in \mathbb{R}^2 : x_2 = x_1^2\}$$

with respect to (3.9). Indeed, for any $x \notin M_\phi$ such that $((\partial W / \partial x_2)r)(x) = 0$, we have $x_2 = -x_1$, and so

$$(DWF)(x) = -(x_1^2 + x_1)^2 < 0.$$

Therefore, according to Theorem 3.5, there exists a G.C.L.F. of $O \in \mathbb{R}^2$ with respect to (3.9).

Example 3.7. Consider the system

$$(3.10) \quad \begin{aligned} \dot{x}_1 &= -x_1^k + \theta(x), \\ \dot{x}_2 &= A_{22}x_2 + Bu, \quad x = (x_1, x_2)' \in \mathbb{R} \times \mathbb{R}^{n_2}, \end{aligned}$$

where k is odd, the function θ is continuous, and there exists a constant $M > 0$ satisfying

$$|\theta(x)| < M\|x_2\|^k \quad \forall x \in \mathbb{R} \times \mathbb{R}^{n_2}.$$

Furthermore, assume that the pair (A_{22}, B) is stabilizable. We show that system (3.10) satisfies the assumptions of Theorem 3.5; hence it admits a G.C.L.F. Indeed, since the pair (A_{22}, B) is stabilizable, there exists a positive definite matrix P_2 of dimension $n_2 \times n_2$ such that the following holds:

$$x_2'P_2B = 0 \Rightarrow x_2'P_2A_{22}x_2 < 0$$

(see [2] and [30]). Then, obviously, the function $W(x_2) = \frac{1}{2}x_2'P_2x_2$ is G.C.L.F. of the set $M_0 = \{(x_1, x_2') \in \mathbb{R} \times \mathbb{R}^{n_2}: x_2 = 0\}$ with respect to (3.10). Let p be a positive constant satisfying $x_2'Px_2 \leq p\|x_2\|^2$ for all $x_2 \in \mathbb{R}^{n_2}$. Let also $V(x_1) = \frac{1}{2}x_1^2$ and c be a positive constant with $c < 2pM^{-2/k}$. Then, for any $x = (x_1, x_2')'$ such that

$$p\|x_2\|^2 < \frac{c}{2}|x_1|^2,$$

we obtain

$$DV(x_1)(-x_1^k + \theta(x)) \leq -x_1^{k+1} + M\left(\frac{c}{2p}\right)^{2/k} x_1^{k+1} < 0,$$

and therefore (3.2) is fulfilled.

Finally, we apply Theorem 3.5 to recover an interesting result from [33].

PROPOSITION 3.8. *Suppose that there exist a continuous map $\phi: \mathbb{R}^{n_1} \rightarrow \mathbb{R}^{n_2}$, a continuously differentiable Lyapunov function V of $0 \in \mathbb{R}^{n_1}$ with respect to (1.9), a G.C.L.F. $W: \mathbb{R}^n \rightarrow \mathbb{R}^+$ of M_ϕ with respect to (1.2), and positive constants c_i , $i = 1, \dots, 5$, such that*

$$(3.11) \quad V(x_1) \geq c_1\|x_1\|^2,$$

$$(3.12) \quad DV(x_1)f_1(x_1, \phi(x_1)) \leq -c_2\|x_1\|^2,$$

$$(3.13) \quad \|DV(x_1)\| \leq c_3\|x_1\|,$$

$$(3.14) \quad \|f_1(x_1, x_2) - f_1(x_1, \hat{x}_2)\| \leq c_4\|x_2 - \hat{x}_2\|,$$

$$(3.15) \quad a_2(s) \leq c_5s^2$$

for any $x_1 \in \mathbb{R}^{n_1}$, $x_2, \hat{x}_2 \in \mathbb{R}^{n_2}$, and $s \geq 0$, where a_2 is defined in (1.5). Then there exists a constant $c > 0$ such that the input to state stability condition (3.2) of Theorem 3.5 is satisfied, and so system (1.2) is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus \{0\}$.

Proof. By (1.5), (3.11), and (3.15), it suffices to show that, for any $x = (x_1', x_2')' \in \mathbb{R}^n$ with

$$(3.16) \quad c_5\|x_2 - \phi(x_1)\|^2 < cc_1\|x_1\|^2,$$

it holds that

$$DV(x_1)f_1(x_1, x_2) < 0,$$

provided that

$$(3.17) \quad 0 < c \leq \frac{c_5}{c_1} \left(\frac{c_2}{c_3c_4} \right)^2.$$

Indeed, by (3.12)–(3.14), we evaluate

$$\begin{aligned} DV(x_1)f_1(x_1, x_2) &\leq |DV(x_1)f_1(x_1, x_2) - DV(x_1)f_1(x_1, \phi(x_1))| + DV(x_1)f_1(x_1, \phi(x_1)) \\ &\leq c_3c_4\|x_1\|\|x_2 - \phi(x_1)\| - c_2\|x_1\|^2. \end{aligned}$$

Therefore, by (3.16) and (3.17), we obtain

$$DV(x_1)f_1(x_1, x_2) \leq \left(c_3c_4 \sqrt{\frac{cc_1}{c_5}} - c_2 \right) \|x_1\|^2 < 0$$

for all $x \in \mathbb{R}^n$ satisfying inequality (3.16). The rest of the proof is a consequence of Theorem 3.5. \square

Example 3.9. Consider the system

$$(3.18a) \quad \dot{x}_1 = A_{11}x_1 + A_{12}x_2,$$

$$(3.18b) \quad \dot{x}_2 = f_2(x_2) + g(x_2)u, \quad (x'_1, x'_2) \in \mathbb{R}^{n_1} \times \mathbb{R}^{n_2}, \quad u \in \mathbb{R}^m,$$

where A_{11} and A_{12} are constant real matrices of dimension $n_1 \times n_1$ and $n_1 \times n_2$, respectively. Assume that

(H1) The matrix A_{11} is Hurwitz;

(H2) There is a positive definite matrix P_2 of dimension $n_2 \times n_2$ such that the function $W(x_2) = \frac{1}{2}x'_2 P_2 x_2$ is a G.C.L.F. of $O \in \mathbb{R}^{n_2}$ with respect to (3.18).

Then the assumptions of Proposition 3.8 are satisfied with $\phi = 0$, and so system (3.1) is G.S. by means of a feedback law that is smooth on $\mathbb{R}^n \setminus \{0\}$. Indeed, according to assumption (H1), there exists a positive definite matrix P_1 of dimension $n_1 \times n_1$ such that $P_1 A_{11} + A'_{11} P_1 = -I$, where I is the unit matrix of dimension $n_1 \times n_1$. Let $V(x_1) = \frac{1}{2}x'_1 P_1 x_1$. Then we can easily check that conditions (3.11)–(3.15) of Proposition 3.8 are fulfilled with V , as before, and W , as defined in (H2).

Remark 3.10. Similar to Remark 3.4, we can easily justify that Proposition 3.8 and Example 3.9 constitute generalizations of the linear case.

KALMAN FILTERING WITH RANDOM COEFFICIENTS AND CONTRACTIONS*

PHILIPPE BOUGEROL†

Abstract. The Riccati transformation of linear filtering/control theory is shown to be a contraction on the space of positive symmetric matrices. This is used to describe the asymptotic behavior of the filter for systems with stochastic stationary parameters.

Key words. Kalman filter, stochastic parameters, Riccati equation, stationary process

AMS subject classifications. 93C05, 93E11, 60G35, 34F05

Introduction. In this paper we study the asymptotic properties of the Kalman filter in a random stationary environment, under weak controllability and observability conditions. We show that the covariance matrix of the conditional error converges in law and that the filter is exponentially stable. This is a direct generalization of Kalman's classical results.

Our main tool is the following. Consider the classical Riccati transformation that associates the error covariance matrix at time $n+1$ to the error covariance matrix at time n . We show that this transformation is a contraction with respect to the Riemannian metric on the set of positive symmetric matrices. This important fact does not seem to have been noticed before. For instance, it leads to a straightforward proof of Kalman's results on the asymptotic behavior of the filter. It can also be useful in other parts of filtering or control theory.

For the convenience of the reader who is not interested in random environment, we present our results in three parts. Section 1 is devoted to the study of the above-mentioned contraction property in the classical set-up. Filtering with random parameters is considered in §2. Section 3 is an appendix that proves the general results on iteration of random Lipschitz contractions (needed in §2).

Let us describe the main results of this paper. We consider the linear system

$$(1) \quad \begin{aligned} X_n &= A_n X_{n-1} + F_n \varepsilon_n, & n \geq 1, \\ Y_n &= C_n X_n + \eta_n, \end{aligned}$$

where $X_n \in \mathbb{R}^d$, $\varepsilon_n \in \mathbb{R}^p$, $\eta_n, Y_n \in \mathbb{R}^q$. In §1, the parameters A_n, F_n , and C_n are *deterministic* matrices with size $d \times d$, $d \times p$ and $q \times d$, respectively. The random vectors $\{(\varepsilon_n, \eta_n), n \in \mathbb{N}\}$ are independent; they have the same Gaussian law with mean 0 and covariance matrix equal to the identity. We assume that X_0 has a Gaussian law with mean \hat{X}_0 and covariance matrix P_0 . We always suppose that the matrices A_n are nonsingular (our approach does not apply in the singular case).

For any $n \geq 1$, let \mathcal{F}_n be the sigma-algebra generated by the random vectors Y_1, Y_2, \dots, Y_n , and

$$(2) \quad \hat{X}_n := \mathbb{E}(X_n / \mathcal{F}_n),$$

$$(3) \quad P_n := \mathbb{E}((X_n - \hat{X}_n)(X_n - \hat{X}_n)^* / \mathcal{F}_n).$$

* Received by the editors January 2, 1991; accepted for publication (in revised form) November 1, 1991.

† Laboratoire de Probabilités, Université Paris VI, 4, Place Jussieu, 75252 Paris Cedex 05, France.

When \mathcal{F}_n is known, \hat{X}_n is the best estimate of X_n , and P_n is the conditional error covariance matrix. Let \mathcal{P} (respectively, \mathcal{P}_0) denote the set of $d \times d$ nonnegative (respectively, positive) symmetric matrices. For any n in \mathbb{N} and $P \in \mathcal{P}$, we set

$$(4) \quad \Phi_n(P) = (A_n P A_n^* + S_n)(I + R_n S_n + R_n A_n P A_n^*)^{-1},$$

where $R_n = C_n^* C_n$ and $S_n = F_n F_n^*$; then $\Phi_n(P) \in \mathcal{P}$, and Φ_n maps \mathcal{P}_0 in \mathcal{P}_0 . The classical Kalman's recursive equations can be written as

$$(5) \quad P_n = \Phi_n(P_{n-1})$$

$$(6) \quad \hat{X}_n = (A_n - P_n R_n A_n) \hat{X}_{n-1} + P_n C_n^* Y_n$$

(see, e.g., Balakrishnan [3, Relations 4-1-19, -27, -31, -34]). The main result of § 1 is that the maps Φ_n are contractions on \mathcal{P}_0 , if we equip this set with the Riemannian metric δ , which is invariant under conjugacy (see Theorem 1.7). Moreover, the fact that these contractions are strict and/or uniform depends on the observability and the controllability properties of the linear system (1). These results are proved in their natural context, namely, by looking at the symplectic matrices that act on the set of symmetric matrices by preserving \mathcal{P}_0 . In that setting, they can be seen as generalizations of the Perron–Frobenius theorem. We also could have considered the recursion associated with $\mathbb{E}(X_n/\mathcal{F}_{n-1})$ for which analogous results hold true (see [8]).

Section 2 is devoted to filtering in a random stationary environment. We consider again the linear equation (1), but we now suppose that the parameters A_n , F_n , and C_n are *stochastic* and that $\{(A_n, F_n, C_n), n \geq 1\}$ is a stationary ergodic process. Under suitable hypotheses (see Hypothesis in § 2), system (1) is conditionally Gaussian, and \hat{X}_n and P_n are also given by the recursive equations (5) and (6) of Kalman. These hypotheses hold, for instance, when the parameters are independent of the noises. We first describe in § 2.1 some actual situations that can be described by such systems. Then, in § 2.2 we introduce weak controllability and observability assumptions (in contrast with the uniform conditions of Kalman). These conditions can hold for systems that are usually neither controllable nor observable. Fault-tolerant systems usually have this property. Under these assumptions, we describe the asymptotic behavior of the conditional error covariance matrices P_n . Our main result is Theorem 2.4. We show that there exists a stationary \mathcal{P}_0 -valued process $\{\bar{P}_n, n \in \mathbb{N}\}$ with the following universal property: “Almost surely, for any solution P_n of (5), $\|P_n - \bar{P}_n\|$ converges to 0 as $n \rightarrow +\infty$.” In particular, P_n converges in law. In § 2.3 we prove that the filter (6) is exponentially stable. These results are deduced from properties of processes that are defined by iterations under stationary Lipschitz maps (Relation (5) and Theorem 1.7 show that the process P_n is of this type). These properties are interesting for their own sake; they are established in § 3.

This paper is self-contained and in some sense elementary. Some of its ideas are already in the literature. The trick of studying the filtering of Riccati's equation through the action of symplectic matrices is, of course, well known (see, e.g., Hermann [15], Shayman [24], and their references). Our semigroup \mathcal{H} has been introduced already by Wojtkowski [31], [32] in a different context. The contraction property of the Riccati transformation is a generalization of the contraction property of matrices with nonnegative elements for the Hilbert metric, due to G. Birkhoff [5]. It's also related with the contraction properties of product of random matrices on boundaries. In Bougerol [7] we recover some of the results obtained here by making use of the Osseledets theorem and the Lyapunov exponents of the associated Hamiltonian matrices.

All our results can be generalized easily to the continuous-time case, either by a direct study or by a reduction to discrete-time.

1. Contraction properties of Riccati equation.

1.1. The semigroup of Hamiltonian matrices. We consider the classical linear system (1) with deterministic parameters (A_n, F_n, C_n) , $n \geq 1$,

$$X_n = A_n X_{n-1} + F_n \varepsilon_n,$$

$$Y_n = C_n X_n + \eta_n,$$

defined in the Introduction. We always suppose that the matrices A_n are invertible. We associate to this system the so-called Hamiltonian matrices M_n of order $2d$ written in block form as

$$(7) \quad M_n = \begin{pmatrix} A_n & S_n A_n^{*-1} \\ R_n A_n & (I + R_n S_n) A_n^{*-1} \end{pmatrix},$$

where $R_n = C_n^* C_n$ and $S_n = F_n F_n^*$. These matrices are in the symplectic group $\text{Sp}(d, \mathbb{R})$. This group is defined as the set of all the matrices M of order $2d$ such that $M^* J M = J$, where $J = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}$, (I is the identity matrix of order d and M^* is the transpose of M). This relation can be written as $M^{-1} = J M^* J$, thus we see that M^* is also in $\text{Sp}(d, \mathbb{R})$. If we write

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

where the entries are $d \times d$ matrices, then BA^* and A^*C are symmetric and $A^*D - C^*B = I$.

Let \mathcal{P} (respectively, \mathcal{P}_0) be the set of $d \times d$ nonnegative (respectively, positive) symmetric matrices (we recall that a matrix M is nonnegative, respectively, positive, when for all $x \neq 0$, $x^* M x \geq 0$, respectively, > 0). The set of all Hamiltonian matrices is

$$\mathcal{H} = \left\{ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \text{Sp}(d, \mathbb{R}); A \text{ is invertible, } BA^* \in \mathcal{P}, A^*C \in \mathcal{P} \right\}.$$

Indeed, every matrix M_n defined previously is in \mathcal{H} , and every matrix $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ in \mathcal{H} is the Hamiltonian matrix of the linear system (1) with the constant parameters $A_n = A$, $F_n = \sqrt{BA^*}$, $C_n = \sqrt{CA^{-1}}$, and dimensions $p = q = d$. We define three subsets \mathcal{H}_1 , \mathcal{H}_2 , and \mathcal{H}_0 of \mathcal{H} by

$$\mathcal{H}_1 = \left\{ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \mathcal{H}; BA^* \in \mathcal{P}, A^*C \in \mathcal{P}_0 \right\},$$

$$\mathcal{H}_2 = \left\{ \begin{pmatrix} A & B \\ C & D \end{pmatrix} \in \mathcal{H}; BA^* \in \mathcal{P}_0, A^*C \in \mathcal{P} \right\},$$

$$\mathcal{H}_0 = \mathcal{H}_1 \cap \mathcal{H}_2.$$

We remark that \mathcal{H}_2 is the dual of \mathcal{H}_1 (in the sense that $M \in \mathcal{H}_1$ if and only if $M^* \in \mathcal{H}_2$). The following semigroup property of \mathcal{H} already appeared in a different context, implicitly in Ol'shanskii [22] and explicitly in Wojtkowski [31] and [32].

PROPOSITION 1.1. *The product of matrices in \mathcal{H} is in \mathcal{H} . The product of a matrix in \mathcal{H} with a matrix in \mathcal{H}_1 (respectively, \mathcal{H}_2 , \mathcal{H}_0) is in \mathcal{H}_1 (respectively, \mathcal{H}_2 , \mathcal{H}_0). In other words, \mathcal{H} is a semigroup of matrices, and \mathcal{H}_1 , \mathcal{H}_2 , and \mathcal{H}_0 are two-sided ideals of \mathcal{H} .*

We will need the following well-known lemma.

LEMMA 1.2. *When P and Q are in \mathcal{P} , then $I + PQ$ is invertible.*

Proof. If P is positive, we can find an invertible matrix M such that $P^{-1} = M^*M$ and $Q = M^*DM$, where D is diagonal with nonnegative entries. Then $I + PQ = M^{-1}(I + D)M$. Thus, the eigenvalues of $I + PQ$ are greater than one. By density, this remains true even if P is only nonnegative. \square

Proof of Proposition 1.1. Let M_1 and M_2 be two matrices in \mathcal{H} , and $M_3 = M_2M_1$. For $i = 1, 2$, or 3 we write $M_i = \begin{pmatrix} A_i & B_i \\ C_i & D_i \end{pmatrix}$, and we set $Q_1 = C_1A_1^{-1}$ and $P_2 = A_2^{-1}B_2$. Since $M_1 \in \mathcal{H}$, the matrix $A_1^*C_1$ is in \mathcal{P} and the fact that $Q_1 = A_1^{*-1}(A_1^*C_1)A_1^{-1}$ yields that Q_1 is in \mathcal{P} . Similarly, P_2 is also in \mathcal{P} . We have

$$A_3 = A_2A_1 + B_2C_1 = A_2(I + A_2^{-1}B_2C_1A_1^{-1})A_1 = A_2(I + P_2Q_1)A_1.$$

Hence, it follows from the previous lemma that A_3 is invertible. We will make use of the relation

$$A_2^*D_2 = C_2^*B_2 + I = C_2^*A_2P_2 + I = A_2^*C_2P_2 + I$$

in the next computation. Since $C_3 = C_2A_1 + D_2C_1$, one has

$$\begin{aligned} A_3^*C_3 &= A_1^*(I + Q_1P_2)A_2^*(C_2A_1 + D_2C_1) \\ &= A_1^*(I + Q_1P_2)(A_2^*C_2A_1 + A_2^*C_2P_2C_1 + C_1) \\ (8) \quad &= A_1^*(I + Q_1P_2)A_2^*C_2(A_1 + P_2C_1) + A_1^*C_1 + C_1^*P_2C_1 \\ &= A_1^*(I + Q_1P_2)A_2^*C_2(I + P_2Q_1)A_1 + A_1^*C_1 + C_1^*P_2C_1. \end{aligned}$$

This shows that $A_3^*C_3$ is a nonnegative symmetric matrix. Similarly (or using transpositions) we see that $A_3B_3^*$ is also nonnegative. This proves that M_3 is in \mathcal{H} . Thus, \mathcal{H} is a semigroup. If, moreover, $A_2^*C_2$ or $A_1^*C_1$ is invertible, then (8) shows that $A_3^*C_3$ is positive definite. Hence, \mathcal{H}_2 is an ideal of \mathcal{H} . Similarly, \mathcal{H}_1 , and thus \mathcal{H}_0 , is also an ideal of \mathcal{H} .

The following result will be useful later to link the fact that a linear system is observable or controllable with the fact that the associated Hamiltonian matrices are in \mathcal{H}_1 or in \mathcal{H}_2 .

PROPOSITION 1.3. *Let $M_n = \begin{pmatrix} A_n & B_n \\ C_n & D_n \end{pmatrix}$, $n \in \mathbb{N}$, be matrices in \mathcal{H} . Then $M_nM_{n-1} \dots M_1$ is in \mathcal{H}_1 if and only if*

$$\text{Det}(A_1^*C_1 + A_1^*A_2^*C_2A_1 + \dots + A_1^* \dots A_{n-1}^*A_n^*C_nA_{n-1} \dots A_1) \neq 0,$$

and $M_nM_{n-1} \dots M_1$ is in \mathcal{H}_2 if and only if

$$\text{Det}(B_nA_n^* + A_nB_{n-1}^*A_{n-1}^*A_n^* + \dots + A_n \dots A_2B_1A_1^*A_2^* \dots A_n^*) \neq 0.$$

Proof. For any $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ in \mathcal{H} , let $\xi(M) = A^*C$ and $\alpha(M) = A$. We first show that, if M_1 and M_2 are in \mathcal{H} , then for any x in \mathbb{R}^d ,

$$(9) \quad \xi(M_2M_1)x = 0$$

if and only if

$$(10) \quad \xi(M_1)x = 0 \quad \text{and} \quad \xi(M_2)A_1x = 0.$$

We use the following two properties:

- (i) When $P, Q \in \mathcal{P}$ and $(P + Q)x = 0$, then $Px = Qx = 0$;
- (ii) For any matrix M , if $P \in \mathcal{P}$ and $M^*PMx = 0$, then $PMx = 0$.

We know by (8) that if $Q_1 = C_1A_1^{-1}$ and $P_2 = A_2^{-1}B_2$, then

$$(11) \quad \xi(M_2M_1) = A_1^*(I + Q_1P_2)A_2^*C_2(I + P_2Q_1)A_1 + A_1^*C_1 + C_1^*P_2C_1.$$

The right-hand side is a sum of nonnegative symmetric matrices. Therefore, we see that if (9) holds, then $A_1^* C_1 x = 0$ and $A_2^* C_2 (I + P_2 Q_1) A_1 x = 0$. This implies that $C_1 x = 0$ (since A_1 is invertible) and $A_2^* C_2 A_1 x = 0$ (since $Q_1 A_1 x = C_1 x = 0$); thus, (10) holds. The converse also follows easily from (11). Using the equivalence between (9) and (10) we see that the following statements are equivalent:

$$\begin{aligned} & \xi(M_n \dots M_2 M_1) x = 0, \\ \Leftrightarrow & \xi(M_1) x = 0 \quad \text{and} \quad \xi(M_n \dots M_2) \alpha(M_1) x = 0, \\ \Leftrightarrow & \dots, \\ \Leftrightarrow & \xi(M_1) x = 0 \quad \text{and} \quad \xi(M_2) \alpha(M_1) x = 0, \dots, \\ \text{and} & \quad \xi(M_n) \alpha(M_{n-1}) \dots \alpha(M_1) x = 0. \end{aligned}$$

Since the matrices $\xi(M_n)$ are nonnegative and $\alpha(M_n)$ invertible, this is also equivalent to

$$\begin{aligned} & \{ \xi(M_1) + \alpha(M_1)^* \xi(M_2) \alpha(M_1) + \dots + \alpha(M_1)^* \dots \alpha(M_{n-1})^* \xi(M_n) \\ & \cdot \alpha(M_{n-1}) \dots \alpha(M_1) \} x = 0. \end{aligned}$$

This proves the first claim. The second claim is obtained by duality.

1.2. Contraction property. For any matrix $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ in \mathcal{H} we define a map $\Phi_M : \mathcal{P}_0 \rightarrow \mathcal{P}_0$ by

$$(12) \quad \Phi_M(T) = (AT + B)(CT + D)^{-1}, \quad T \in \mathcal{P}_0.$$

The fact that the right-hand side is a well-defined element of \mathcal{P}_0 will be shown in Proposition 1.5. A straightforward computation shows that the map $M \rightarrow \Phi_M$ defines an action of the semigroup \mathcal{H} on \mathcal{P}_0 , in the sense that, for any M, N in \mathcal{H} ,

$$(13) \quad \Phi_{MN} = \Phi_M \circ \Phi_N$$

(in fact this action is induced by the linear action of symplectic matrices on d -dimensional linear subspaces of \mathbb{R}^{2d}). We remark that the relation (4), which defines the maps Φ_n , can be written as

$$\Phi_n(P) = (A_n P + S_n A_n^{*-1})(R_n A_n P + (I + R_n S_n) A_n^{*-1})^{-1}.$$

This shows that $\Phi_n = \Phi_{M_n}$. Therefore, by (5), the error covariance matrix P_n satisfies

$$(14) \quad P_n = \Phi_{M_n}(P_{n-1}).$$

This equation is called the *discrete Riccati equation*. The classical continuous matrix Riccati equation on \mathcal{P}_0 is similar. Indeed, under some mild regularity and boundedness assumptions, if P_t , $t \in \mathbb{R}^+$, is the solution of the matrix-valued differential equation

$$\dot{P}_t = A_t P_t + P_t A_t^* - P_t R_t P_t + S_t, \quad P_0 \in \mathcal{P}_0,$$

where R_t , S_t , $t \geq 0$, are in \mathcal{P} , then there exists a family N_t , $t \geq 0$, of matrices in \mathcal{H} such that $P_t = \Phi_{N_t}(P_0)$ (cf., Hermann [15]).

DEFINITION 1.4. The Riemannian distance δ on \mathcal{P}_0 is defined by: for any $P, Q \in \mathcal{P}_0$,

$$\delta(P, Q) = \left\{ \sum_{i=1}^d \text{Log}^2 \lambda_i \right\}^{1/2},$$

where $\lambda_1, \dots, \lambda_d$ are the eigenvalues of the matrix PQ^{-1} .

It is shown in Maass [19, Thm. p. 27] (see also Terras [27]), that δ is the usual Riemannian distance on \mathcal{P}_0 when this set is considered as the Riemannian symmetric

space $\text{Gl}(d, \mathbb{R})/O(d)$ (this metric is associated to the arc length $ds^2 = \text{tr} \{(P^{-1} dP)^2\}$, which is invariant under conjugacy and coincides with the Euclidean arc length on the logarithms of the diagonal matrices in \mathcal{P}_0). In particular, (\mathcal{P}_0, δ) is complete and δ induces the usual topology. The main property of this distance is its invariance under conjugacy and under inversion. For any invertible matrix A and for all P, Q in \mathcal{P}_0 ,

$$\delta(APA^*, AQA^*) = \delta(P, Q) = \delta(P^{-1}, Q^{-1}).$$

We next prove that the transformations Φ_M are contractions of (\mathcal{P}_0, δ) when $M \in \mathcal{H}$.

PROPOSITION 1.5. *Let $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ be a matrix in \mathcal{H} . Then*

(i) *For any T in \mathcal{P} (respectively, \mathcal{P}_0), $CT + D$ is invertible and $(AT + B)(CT + D)^{-1}$ is in \mathcal{P} (respectively, \mathcal{P}_0).*

(ii) *If $M \in \mathcal{H}_2$, then for any T in \mathcal{P} , $(AT + B)(CT + D)^{-1}$ is in \mathcal{P}_0 .*

Proof. Let $T \in \mathcal{P}$. The matrices $P = A^{-1}B$, $Q = CA^{-1}$, and $S = A(T + P)A^*$ are in \mathcal{P} . Since

$$CT + D = QAT + QAP + A^{*-1} = (QS + I)A^{*-1},$$

it follows from Lemma 1.2 that $CT + D$ is invertible. Now, the relation

$$(AT + B)(CT + D)^{-1} = (AT + AP)A^*(QS + I)^{-1} = S(QS + I)^{-1}$$

easily implies the proposition (we note that this is equal to $(S^{-1} + Q)^{-1}$ when S is invertible). \square

We always use the Euclidean norm on \mathbb{R}^d and the associated operator norm on the set of matrices: if M is a matrix of order d , we let $\|M\| = \text{Sup}\{\|Mx\|; x \in \mathbb{R}^d, \|x\| = 1\}$.

PROPOSITION 1.6. *Let T, S be matrices in \mathcal{P}_0 and $\alpha = \text{Max}(\|T\|, \|S\|)$. Then for all $P \in \mathcal{P}$,*

$$\delta(T + P, S + P) \leq \frac{\alpha}{\alpha + \beta} \delta(T, S)$$

where $\beta = \text{Inf}\{\langle Px, x \rangle; \|x\| = 1\}$.

Proof. The mean value theorem yields that, when $0 < a, b \leq m$ and $r > 0$, then

$$(15) \quad \text{Log} \frac{a+r}{b+r} \leq \frac{m}{m+r} \text{Log}^+ \frac{a}{b}$$

(where $\text{Log}^+ x = \text{Max}(\text{Log} x, 0)$). It is known and not difficult to prove (see Gantmacher [14, Ch. 10, § 7]) that the eigenvalues of TS^{-1} are real, positive, and that they have the following Min-Max representation. Let

$$\lambda_1(T, S) \leq \lambda_2(T, S) \leq \dots \leq \lambda_d(T, S)$$

be the eigenvalues of TS^{-1} written in ascending order. Then

$$\lambda_k(T, S) = \text{Min} \left\{ \text{Max} \left\{ \frac{\langle Tx, x \rangle}{\langle Sx, x \rangle}; x \in V \right\}; V \in \Gamma(k) \right\},$$

where $\Gamma(k)$ is the set of k -dimensional linear subspaces of \mathbb{R}^d . We prove that

$$(16) \quad |\text{Log} \lambda_k(T + P, S + P)| \leq \frac{\alpha}{\alpha + \beta} |\text{Log} \lambda_k(T, S)|,$$

for any $1 \leq k \leq d$. We first suppose that $\lambda_k(T + P, S + P) > 1$. Relation (15) entails that

$$\text{Log} \frac{\langle Tx, x \rangle + \langle Px, x \rangle}{\langle Sx, x \rangle + \langle Px, x \rangle} \leq \frac{\alpha}{\alpha + \beta} \text{Log}^+ \frac{\langle Tx, x \rangle}{\langle Sx, x \rangle}.$$

Thus,

$$\begin{aligned}
 |\operatorname{Log} \lambda_k(T+P, S+P)| &= \operatorname{Log} \lambda_k(T+P, S+P) \\
 &= \operatorname{Log} \operatorname{Min} \left\{ \operatorname{Max} \left\{ \frac{\langle (T+P)x, x \rangle}{\langle (S+P)x, x \rangle}; x \in V \right\}; V \in \Gamma(k) \right\} \\
 &= \operatorname{Min} \left\{ \operatorname{Max} \left\{ \operatorname{Log} \frac{\langle Tx, x \rangle + \langle Px, x \rangle}{\langle Sx, x \rangle + \langle Px, x \rangle}; x \in V \right\}; V \in \Gamma(k) \right\} \\
 &\leq \frac{\alpha}{\alpha + \beta} \operatorname{Min} \left\{ \operatorname{Max} \left\{ \operatorname{Log}^+ \frac{\langle Tx, x \rangle}{\langle Sx, x \rangle}; x \in V \right\}; V \in \Gamma(k) \right\} \\
 &\leq \frac{\alpha}{\alpha + \beta} \operatorname{Log}^+ \lambda_k(T, S).
 \end{aligned}$$

Since the left-hand term is positive, this first gives that $\operatorname{Log}^+ \lambda_k(T, S) = |\operatorname{Log} \lambda_k(T, S)|$, and then that (16) holds. When $\lambda_k(T+P, S+P) = 1$, (16) is obvious. When $\lambda_k(T+P, S+P) < 1$, we use the relation $\lambda_k(T+P, S+P) = 1/\lambda_{d-k+1}(S+P, T+P)$, and we apply (16) to $\lambda_{d-k+1}(S+P, T+P)$. Finally, (16) implies immediately the proposition. \square

THEOREM 1.7. *The following properties hold:*

(i) *For any M in \mathcal{H} , and T, S in \mathcal{P}_0 ,*

$$\delta(\Phi_M(T), \Phi_M(S)) \leq \delta(T, S).$$

(ii) *For any M in \mathcal{H}_1 or in \mathcal{H}_2 , and T, S in \mathcal{P}_0 ,*

$$\delta(\Phi_M(T), \Phi_M(S)) < \delta(T, S).$$

(iii) *For any M in \mathcal{H}_0 , there exists $\rho(M)$, $0 < \rho(M) < 1$, such that, for all T, S in \mathcal{P}_0 ,*

$$\delta(\Phi_M(T), \Phi_M(S)) \leq \rho(M) \delta(T, S).$$

Proof. Let $M = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ be a matrix in \mathcal{H} . The matrices $P = A^{-1}B$ and $Q = CA^{-1}$ are in \mathcal{P} and

$$M = \begin{pmatrix} I & 0 \\ Q & I \end{pmatrix} \begin{pmatrix} A & 0 \\ 0 & A^{*-1} \end{pmatrix} \begin{pmatrix} I & P \\ 0 & I \end{pmatrix}.$$

We consider the transformations $\tau_P(T) = T + P$, $\tau_Q(T) = T + Q$, $\gamma_A(T) = ATA^*$ and $\sigma(T) = T^{-1}$ defined on \mathcal{P}_0 . By making use of (13) we obtain

$$(17) \quad \Phi_M(T) = (\sigma \circ \tau_Q \circ \sigma \circ \gamma_A \circ \tau_P)(T).$$

We have already noticed that γ_A and σ are isometries of the metric space (\mathcal{P}_0, δ) . It follows from Proposition 1.6 that τ_P and τ_Q are contractions. This and (17) prove (i). If M is in \mathcal{H}_1 , then Q is invertible. Hence, τ_Q is a strict contraction by Proposition 1.6. Similarly, when M is in \mathcal{H}_2 , P is invertible and τ_P is a strict contraction. Thus, (ii) follows from (17). Let us prove (iii). We consider an M in \mathcal{H}_0 . Then both P and Q are invertible. Moreover, for any T in \mathcal{P}_0 , $\tau_P(T) \geq P$ (in the sense that $\tau_P(T) - P \in \mathcal{P}$), which implies that $(\gamma_A \circ \tau_P)(T) \geq APA^*$, and thus,

$$(\sigma \circ \gamma_A \circ \tau_P)(T) \leq (APA^*)^{-1}.$$

Let $\zeta = \|(APA^*)^{-1}\|$ and $\varepsilon = \inf \{\langle Qx, x \rangle; \|x\| = 1\}$. It follows from Proposition 1.6 that

for all T_1 and T_2 in \mathcal{P}_0 ,

$$\begin{aligned} & \delta(\tau_Q[(\sigma \circ \gamma_A \circ \tau_P)(T_1)], \tau_Q[(\sigma \circ \gamma_A \circ \tau_P)(T_2)]) \\ & \leq \frac{\zeta}{\zeta + \varepsilon} \delta((\sigma \circ \gamma_A \circ \tau_P)(T_1), (\sigma \circ \gamma_A \circ \tau_P)(T_2)) \\ & \leq \frac{\zeta}{\zeta + \varepsilon} \delta(T_1, T_2). \end{aligned}$$

Since σ is an isometry, this relation and (16) yield that (iii) holds with $\rho(M) = \zeta/(\zeta + \varepsilon)$. \square

As an application, let us outline a short proof of a classical result of Kalman. We suppose that the linear system with constant coefficients

$$X_n = AX_{n-1} + F\varepsilon_n, \quad Y_n = CX_n + \eta_n,$$

is controllable and observable. Let M be the Hamiltonian matrix (here independent of n) defined by (7). It follows from Proposition 1.3 that there is an integer $p > 0$ such that M^p is in \mathcal{H}_0 . Therefore, by Theorem 1.7, Φ_M has a power that is a uniform contraction. This implies by the fixed point theorem that there exists a matrix P in \mathcal{P}_0 such that all the solutions P_n of (5) converge to P when $n \rightarrow +\infty$, as soon as P_0 is in \mathcal{P}_0 .

2. Filtering with random parameters. We now study the asymptotic behavior of linear filtering in a random environment. We consider the case where the parameters A_n , F_n , C_n of the linear equation (1) are stochastic. More precisely, we suppose that the following hypothesis holds.

Hypothesis H. For all $n \geq 1$, the quantities A_n , F_n , C_n , ε_n , η_n are random variables defined on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and $\{(A_n, F_n, C_n), n \geq 1\}$ is a strictly stationary ergodic process. There is a σ -algebra \mathcal{F}_0 contained in \mathcal{F} such that, if $\mathcal{F}_n = \sigma(\mathcal{F}_0, Y_1, \dots, Y_n)$ is the σ -algebra generated by \mathcal{F}_0 and by Y_1, Y_2, \dots, Y_n , then for all $n \geq 1$,

- (i) A_n , F_n , and C_n are \mathcal{F}_{n-1} measurable.
- (ii) The random vector (ε_n, η_n) has a Gaussian law with mean zero and covariance matrix equal to the identity matrix. It is independent of X_{n-1} and \mathcal{F}_{n-1} .
- (iii) Conditionally on \mathcal{F}_0 , the random vector X_0 has a Gaussian law with mean \hat{X}_0 and covariance matrix P_0 .

This set-up is called *conditionally Gaussian*. The conditional expectations $\hat{X}_n = \mathbb{E}(X_n / \mathcal{F}_n)$ and the conditional error covariance matrices $P_n = \mathbb{E}((X_n - \hat{X}_n)(X_n - \hat{X}_n)^* / \mathcal{F}_n)$ are given by the recursions (5) and (6) (see, e.g., Whittle [29, p. 260]). Work on such systems with stochastic parameters goes back to Kalman [17], [18]. A recent reference is De Koning [12] (see also Nahi [21]). An important example is the following: suppose that $\{(\varepsilon_n, \eta_n), n \geq 1\}$ is a sequence of independent normalized Gaussian random vectors, independent of a stationary ergodic process $(A_n, F_n, C_n), n \geq 1$. Then, if $\mathcal{F}_0 = \sigma\{(A_n, F_n, C_n), n \geq 1\}$, the hypothesis (H) holds.

In § 2.1, we present some examples of real situations that can be modeled by these equations. In § 2.2, we describe the asymptotic behavior of P_n as $n \rightarrow +\infty$. The exponential stability of the filter is proved in § 2.3. We will always suppose that the matrices A_n are nonsingular. Without loss of generality, we can and will suppose that the stationary process (A_n, F_n, C_n) is defined on $(\Omega, \mathcal{F}, \mathbb{P})$ for all $n \in \mathbb{Z}$.

2.1. Examples.

2.1.1. Filter with periodic parameters. We suppose that there exist functions A , B , C on $\Omega_1 = \mathbb{Z}/p\mathbb{Z}$ such that, for all $\omega \in \Omega_1$,

$$(A_n(\omega), B_n(\omega), C_n(\omega)) = (A(\omega + n), B(\omega + n), C(\omega + n)),$$

where $\omega + n$ is the sum modulo p . Let \mathcal{F}_1 be the set of all the subsets of Ω_1 , and let \mathbb{P}_1 be the uniform measure on Ω_1 . We also consider a sequence of noises (ε_n, η_n) , $n \geq 1$, defined on some $(\Omega_2, \mathcal{F}_2, \mathbb{P}_2)$. Then these coefficients define a linear system on the probability space $\Omega = \Omega_1 \times \Omega_2$, $\mathcal{F} = \mathcal{F}_1 \otimes \mathcal{F}_2$, $\mathbb{P} = \mathbb{P}_1 \otimes \mathbb{P}_2$, for which (H) holds. These systems with periodic parameters have been studied recently, for instance, by De Souza and Goodwin [13], and Bittanti, Colaneri, and Di Nicolao [6].

2.1.2. Random sampling. In several situations, a linear system can be observed only at random times $T_0 < T_1 < \dots$. This so-called stochastic sampling phenomenon can occur because of technical imperfections in the instrumentation. It may also be applied intentionally, for instance, when a digital computer is time shared in a stochastic manner as suggested by Kalman [17]. In Snyder and Fishman [25], the tracking of fireflies, which can be observed only by their flashes, is studied (we can easily imagine some more realistic examples); see also Chang [11]. These systems are used in modeling of ARMA processes with missing data.

The basic model is the usual time-invariant system

$$(18) \quad X_n = AX_{n-1} + F\varepsilon_n, \quad Y_n = CX_n + \eta_n.$$

We suppose that the state is observed only at random times T_n , $n \geq 0$, independent of this system, and that $\{T_{n+1} - T_n, n \geq 0\}$ is a stationary ergodic process with values in \mathbb{N}^* . If we let $Z_n = X_{T_n}$ and $W_n = Y_{T_n}$ then

$$Z_n = A^{T_n - T_{n-1}} Z_{n-1} + \sum_{k=0}^{T_n - T_{n-1} - 1} A^k F \varepsilon_{T_n - k}, \quad W_n = CZ_n + \eta_{T_n}.$$

For each $n \geq 1$, let $A_n = A^{T_n - T_{n-1}}$ and let F_n be a symmetric matrix such that

$$F_n^2 = \sum_{k=0}^{T_n - T_{n-1} - 1} A^k F F^* A^{*k}.$$

Using if necessary a generalized inverse of F_n , it is easy to see that there exists a sequence of independent Gaussian random variables $\alpha_n \in \mathbb{R}^p$, $\beta_n \in \mathbb{R}^q$, with mean 0 and covariance matrix equal to the identity, independent of the sequence $\{(A_n, F_n), n \geq 1\}$, such that

$$\sum_{k=0}^{T_n - T_{n-1} - 1} A^k F \varepsilon_{T_n - k} = F_n \alpha_n, \quad \eta_{T_n} = \beta_n.$$

We obtain that

$$(19) \quad Z_n = A_n Z_{n-1} + F_n \alpha_n, \quad W_n = CZ_n + \beta_n.$$

This is a system with stochastic parameters for which (H) holds. In this setting, the asymptotic properties of the filter have been studied by Viano [28] under the additional assumption that the matrix A is stable and that C^*C is invertible. We are able to treat the case where the system (18) is only controllable and observable. We remark that no uniform controllability property of (19) can be expected when the T_n 's are not bounded. When the random variables $T_{n+1} - T_n$ are independent and identically distributed, the error covariance P_n , $n \in \mathbb{N}$, is a Markov chain on \mathcal{P}_0 . But this process is singular (it does not satisfy the Harris irreducibility condition). Even in that case, it does not seem easy to study its asymptotic behavior without recourse to contractions properties.

2.1.3. Fault-tolerant filtering. Consider a failure-prone linear system. It can be, for instance, a manufacturing plant or a space-station under the bombardment of

meteorites. We can assume that the plant state has two equations: at time n , either $X_n = MX_{n-1} + \varepsilon_n$ if the system is operational, or $X_n = NX_{n-1} + \varepsilon_n$ if the system is in a state of failure and undergoing repair. The failure/repair process may be modeled by a stationary sequence A_n , $n \geq 1$, of random matrices such that $A_n \in \{M, N\}$. Such systems are considered, for instance, in Akella and Kumar [1] and in Mariton [20] (see also Willems and Willems [30]). If $Y_n = CX_n + \eta_n$, the associated filtering system will satisfy (H).

We may also consider a filtering system with a failure-prone observation process. This can be due to the instrumentation or to the fact that at some unexpected times, the state cannot be determined. For instance, we can think of the tracking of a plane, which is sometimes hidden by clouds. A model for this situation can be

$$X_n = AX_{n-1} + F\varepsilon_n, \quad Y_n = C_nX_n + \eta_n,$$

where C_n is equal to some matrix C when the observation process is operational and some other matrix D , otherwise. Notice that it is natural to assume that under failure, i.e., when $C_n = D$, the system is not observable.

It follows from the results of the next section that the filter has very good asymptotic properties. This shows that in some sense, Kalman's filtering is fault tolerant. Of course, users are already aware of this fact.

2.1.4. Estimation of AR processes with AR parameters. Suppose that we observe an univariate autoregressive (AR) process $Z_n = \rho_n Z_{n-1} + \eta_n$, where the parameters ρ_n satisfy $\rho_n = a\rho_{n-1} + \varepsilon_n$. Here, $\{(\varepsilon_n, \eta_n), n \geq 1\}$ is a sequence of independent normalized Gaussian random variables. These models occur, for instance, in stochastic adaptive control (see, e.g., Caines and Meyn [10]). If we want to estimate the parameter a , it is useful to compute the conditional law of ρ_n , once Z_1, \dots, Z_n are observed. Let $X_n = \rho_n$, $Y_n = Z_n$, $A_n = a$, $F_n = 1$, and $C_n = Z_{n-1}$. This system can be written as (1). If $a \in (-1, 1)$, then the parameter sequence is stationary and Hypothesis (H) holds.

2.2. Asymptotic properties of the error covariance matrix. We consider a linear system (1) with random parameters for which (H) holds. In particular, the process (A_n, F_n, C_n) is stationary and ergodic. In the sequel, δ is the distance on \mathcal{P}_0 introduced in Definition 1.4. We recall that $R_n = C_n^* C_n$ and $S_n = F_n^* F_n$. For any $n \geq 1$, let

$$\Omega_n = \{\omega \in \Omega; \text{Det}(A_1^* R_1 A_1 + A_1^* A_2^* R_2 A_2 A_1 + \dots + A_1^* \dots A_n^* R_n A_n \dots A_1) \neq 0\},$$

and

$$\Xi_n = \{\omega \in \Omega; \text{Det}(S_n + A_n S_{n-1} A_n^* + \dots + A_n \dots A_2 S_1 A_2^* \dots A_n^*) \neq 0\}.$$

DEFINITION 2.1. The system (1) is called *weakly observable* if for some $n > 0$, $\mathbb{P}(\Omega_n) > 0$; it is called *weakly controllable* if for some $n > 0$, $\mathbb{P}(\Xi_n) > 0$.

When the parameters are deterministic, we recover the usual observability and controllability conditions. But these notions are much weaker than the one commonly used in the study of time-dependent systems (see, e.g., Jazwinski [16], Anderson and Moore [2]). In some of the examples given in § 2.1, only these weak conditions were natural. We will need the following lemmas.

LEMMA 2.2. Let M_n , $n \in \mathbb{N}$, be the sequence of Hamiltonian matrices associated with a linear system (1) satisfying (H). If the system is weakly observable (respectively, weakly controllable), then, almost surely, $M_n \dots M_1$ is in \mathcal{H}_1 (respectively, \mathcal{H}_2) for all $n \in \mathbb{N}$ large enough.

Proof. If the system is weakly observable, then $\mathbb{P}(\Omega_k) > 0$ for some $k \geq 1$. Proposition 1.3 yields that $M_k(\omega)M_{k-1}(\omega) \dots M_1(\omega)$ is in \mathcal{H}_1 when $\omega \in \Omega_k$. Thus, $\mathbb{P}(M_k \dots M_1 \in \mathcal{H}_1) > 0$. It follows from the ergodic theorem that for almost all $\omega \in \Omega$ there exists an integer p , depending on ω , such that $M_{p+k}(\omega) \dots M_{p+1}(\omega) \in \mathcal{H}_1$. Since \mathcal{H}_1 is an ideal in \mathcal{H} (cf. Proposition 1.1) this shows that, almost surely, for n large enough, $M_n \dots M_1 \in \mathcal{H}_1$. When the system is weakly controllable, the proof is similar. \square

LEMMA 2.3. *For any $Q \in \mathcal{P}_0$,*

$$(20) \quad \text{Max} (\text{Log}^2 \|Q\|, \text{Log}^2 \|Q^{-1}\|) \leq \delta(Q, I)^2 \leq d \text{Max} (\text{Log}^2 \|Q\|, \text{Log}^2 \|Q^{-1}\|).$$

Proof. If $\lambda_1 \leq \dots \leq \lambda_d$ are the eigenvalues of Q , then $\lambda_1 = 1/\|Q^{-1}\|$ and $\lambda_d = \|Q\|$. Since $\delta(Q, I)^2 = \sum_{i=1}^d \text{Log}^2 \lambda_i$, the conclusion of the lemma is clear. \square

Our main result is the following theorem. It implies that:

(i) The filtering process is successful, since the conditional error covariance matrix P_n does not explode. This error is asymptotically stationary. For instance, it converges in law (see Corollary 3.3).

(ii) Even for a fixed $\omega \in \Omega$ (outside an exceptional subset of measure 0), there is no optimal choice of the initial condition P_0 , since all the sequences P_n have the same asymptotic behavior. An analogous result for the usual distance on \mathcal{P} is shown in Proposition 2.5.

THEOREM 2.4. *We consider a linear system (1) with stochastic parameters for which*

(a) *Condition (H) holds.*

(b) *The system is weakly observable and weakly controllable.*

(c) *The random variables $\text{LogLog}^+ \|A_1\|$, $\text{LogLog}^+ \|A_1^{-1}\|$, $\text{LogLog}^+ \|C_1\|$, $\text{LogLog}^+ \|F_1\|$ are integrable.*

Then, there exists an ergodic stationary \mathcal{P}_0 -valued process $\{\bar{P}_n, n \in \mathbb{Z}\}$, that is solution of (5). Furthermore, there is a negative real number $\alpha < 0$ such that, almost surely, for any solution P_n of (5) for which $P_0 \in \mathcal{P}_0$,

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} \delta(P_n, \bar{P}_n) \leq \alpha < 0.$$

Proof. We are going to apply Theorem 3.1, proved in the Appendix, to the sequence $\{\Phi_n, n \in \mathbb{Z}\}$ of random contractions of the metric space (\mathcal{P}_0, δ) defined by (4). We first check the condition (C1) of this theorem, namely that for some P in \mathcal{P}_0 , $\mathbb{E}[\text{Log} \delta(\Phi_1(P), P)]$ is finite. Actually, we choose P equal to the identity matrix I . Let $T = A_1 A_1^* + S_1$. We get $\Phi_1(I) = T(I + R_1 T)^{-1} = (T^{-1} + R_1)^{-1}$. Since $T - (T^{-1} + R_1)^{-1}$ is a nonnegative matrix, we have

$$\|\Phi_1(I)\| \leq \|(T^{-1} + R_1)^{-1}\| \leq \|T\| \leq \|A_1 A_1^*\| + \|S_1\| \leq \|A_1\|^2 + \|F_1\|^2$$

and

$$\|\Phi_1(I)^{-1}\| \leq \|T^{-1} + R_1\| \leq \|T^{-1}\| + \|R_1\| \leq \|(A_1 A_1^*)^{-1}\| + \|R_1\| \leq \|A_1^{-1}\|^2 + \|C_1\|^2.$$

By Lemma 2.3,

$$(21) \quad \delta(\Phi_1(I), I)^2 \leq d \text{Max} (\text{Log}^2 \|\Phi_1(I)\|, \text{Log}^2 \|\Phi_1(I)^{-1}\|).$$

Using these inequalities and hypothesis (c) from Theorem 2.4, we see that $\mathbb{E}[\text{Log} \delta(\Phi_1(I), I)]$ is finite. Now we check that Condition (C2) holds. By Theorem 1.7, Φ_n is a contraction. Thus, it suffices to show that the coefficient of contraction $\rho(\Phi_p \circ \dots \circ \Phi_1)$ is smaller than 1 for some $p > 0$, with positive probability. Let M_n , $n \in \mathbb{N}$, be the Hamiltonian matrices associated to (1). It follows from Lemma 2.2 that, almost surely, for all $p \in \mathbb{N}$ large enough, $M_p \dots M_1$ is both in \mathcal{H}_1 and in \mathcal{H}_2 . Since

$\mathcal{H}_0 = \mathcal{H}_1 \cap \mathcal{H}_2$, this yields that for some p , $\mathbb{P}(M_p \dots M_1 \in \mathcal{H}_0) \neq 0$. By (12), $\Phi_p \circ \dots \circ \Phi_1 = \Phi_{M_p \dots M_1}$, and therefore, $\mathbb{P}(\rho(\Phi_p \circ \dots \circ \Phi_1) < 1) \neq 0$ by Theorem 1.7 (iii). Thus, Condition (C2) of Theorem 3.1 holds. This theorem implies the result. \square

PROPOSITION 2.5. *We suppose that the hypotheses of Theorem 2.4 hold and that $\text{Log}^+ \|A_1\|$, $\text{Log}^+ \|A_1^{-1}\|$, $\text{Log}^+ \|C_1\|$, and $\text{Log}^+ \|F_1\|$ are integrable. Then, almost surely, for any solution P_n of (5) for which $P_0 \in \mathcal{P}_0$,*

$$(22) \quad \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} \|P_n - \bar{P}_n\| \leq \alpha < 0.$$

Proof. Since P_n and \bar{P}_n are symmetric positive matrices, we can find matrices K_n and D_n such that $\bar{P}_n = K_n^* K_n$, $P_n = K_n^* D_n K_n$, and such that D_n is a diagonal matrix with positive entries $\lambda_1^{(n)}, \dots, \lambda_d^{(n)}$. We have $\delta(P_n, \bar{P}_n) = \{\sum_{i=1}^d \text{Log}^2 \lambda_i^{(n)}\}^{1/2}$. It follows from Theorem 2.4 that

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} |\text{Log} \lambda_i^{(n)}| \leq \alpha,$$

for $i = 1, \dots, d$. This implies that

$$(23) \quad \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} |1 - \lambda_i^{(n)}| \leq \alpha.$$

As in the proof above, we see that $\mathbb{E}[\delta(\Phi_1(I), I)]$ is finite by (21). Moreover, by Lemma 2.3, $\text{Log} \|\bar{P}_n\| \leq \delta(I, \bar{P}_n)$. Thus, it follows from Proposition 3.4 that, almost surely,

$$(24) \quad \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} \|\bar{P}_n\| \leq 0.$$

For each $x \in \mathbb{R}^d$, $\|K_n x\|^2 = \langle K_n^* K_n x, x \rangle \leq \|\bar{P}_n x\|$, so that $\|K_n\|^2 \leq \|\bar{P}_n\|$. This yields that

$$\|P_n - \bar{P}_n\| \leq \|K_n^* (D_n - I) K_n\| \leq \|K_n\|^2 \|D_n - I\| \leq \|\bar{P}_n\|^2 \max_{1 \leq i \leq d} |1 - \lambda_i^{(n)}|.$$

It is clear that (22) is a consequence of (23), (24), and of this inequality. \square

Remark. It is not difficult to see that the conclusion of the theorem also holds when P_0 is only in \mathcal{P} . (The main point is to note that since the system is weakly controllable, there is almost surely an integer k such that $M_k \dots M_1$ is in \mathcal{H}_2 , by Lemma 2.2, which implies that $P_k = \Phi_{M_k \dots M_1}(P_0)$ is in \mathcal{P}_0 , by Proposition 1.5 (ii).)

2.3. Stability of the filter. We show that the linear equation (6) of the filter is exponentially stable. We make use of the classical method of Lyapunov, as in Anderson and Moore [2], for instance.

THEOREM 2.6. *We consider a system (1) with stochastic parameters for which:*

- (i) *Hypothesis (H) holds.*
- (ii) *The system is weakly observable and weakly controllable.*
- (iii) *The random variables $\text{Log}^+ \|A_1\|$, $\text{Log}^+ \|A_1^{-1}\|$, $\text{Log}^+ \|C_1\|$, $\text{Log}^+ \|F_1\|$ are integrable. Then the equation (6) of the filter is exponentially stable: namely, there is a real number $\gamma > 0$ such that, almost surely,*

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log} \|(A_n - P_n R_n A_n) \dots (A_1 - P_1 R_1 A_1)\| \leq -\gamma < 0,$$

for any solution $\{P_n, n \in \mathbb{N}\}$ of (5) such that $P_0 \in \mathcal{P}_0$.

We need the following classical lemma. It is an immediate consequence of the relation

$$\hat{X}_n - X_n = (A_n - P_n R_n A_n)(\hat{X}_{n-1} - X_{n-1}) + P_n C_n^* \eta_n + (P_n R_n - I) F_n \varepsilon_n,$$

which itself results from (1) and (6).

LEMMA 2.7. Let $B_n = A_n - P_n R_n A_n$ and $T_n = P_n R_n P_n + (I - P_n R_n) S_n (I - P_n R_n)^*$. Then, $P_n = B_n P_{n-1} B_n^* + T_n$.

LEMMA 2.8. Let $G_n = T_n + B_n T_{n-1} B_n^* + \dots + B_n \dots B_2 T_1 B_2^* \dots B_n^*$. Under the hypotheses of Theorem 2.6, there exists $n \in \mathbb{N}$ such that $\mathbb{P}(\text{Det}(G_n) \neq 0) > 0$.

Proof. We follow an argument in Anderson and Moore [2], where a similar result is proved. For each integer $i \geq 1$, let $K_i = P_i C_i^*$ and $H_i = (I - P_i R_i)$. We consider the two $d \times (p+q)n$ matrices

$$W_n = (K_n, F_n, A_n K_{n-1}, A_n F_{n-1}, \dots, A_n A_{n-1} \dots A_2 K_1, A_n A_{n-1} \dots A_2 F_1)$$

$$V_n = (K_n, H_n F_n, B_n K_{n-1}, B_n H_{n-1} F_{n-1}, \dots, B_n B_{n-1} \dots B_2 K_1, B_n B_{n-1} \dots B_2 H_1 F_1).$$

It is easy to see by straightforward manipulations that there exists a $(p+q)n \times (p+q)n$ upper triangular matrix U_n , with all diagonal terms equal to 1, such that $V_n = W_n U_n$. We remark that

$$W_n W_n^* \geq S_n + A_n S_{n-1} A_n^* + \dots + A_n \dots A_2 S_1 A_2^* \dots A_n^*.$$

Since the system is weakly controllable, there exists a positive integer n such that the subset Ξ_n , where the right-hand side is invertible, is of positive measure. On Ξ_n , the rank of W_n is d . The same property holds for V_n since $V_n = W_n U_n$ and since U_n is invertible. Then the lemma results from the fact that $G_n = V_n V_n^*$. \square

Proof of Theorem 2.6. For notational simplicity we suppose that $\mathbb{P}(\text{Det}(G_1) \neq 0) > 0$. The general case is treated in the same way (by looking at the sequence P_{nk} , $k \in \mathbb{N}$, where n is given by Lemma 2.8). For any $n \in \mathbb{N}$, let $\lambda_n = \|T_n^{-1}\|^{-1}$, $\sigma_n = \|P_n\|$, $\alpha = \|P_0^{-1}\|$, with the convention that $\lambda_n = 0$, if T_n is not invertible. Let p be a positive integer. For a fixed $x_p \in \mathbb{R}^d$, we define a finite sequence x_0, x_1, \dots, x_p , by the backward recursion $x_n = B_{n+1}^* x_{n+1}$. Let $V_n = x_n^* P_n x_n$. We have

$$V_{n+1} - V_n = x_{n+1}^* T_{n+1} x_{n+1} \geq \lambda_{n+1} \|x_{n+1}\|^2 \geq \frac{\lambda_{n+1}}{\sigma_{n+1}} V_{n+1}$$

so that, if $\tau_n = (1 - \lambda_n / \sigma_n)$, then $V_n \leq \tau_{n+1} V_{n+1}$. Therefore,

$$\|x_0\|^2 \leq \|P_0^{-1}\| V_0 \leq \|P_0^{-1}\| \tau_1 \dots \tau_p V_p \leq \|P_0^{-1}\| \tau_1 \dots \tau_p \|P_p\| \|x_p\|^2.$$

Since $x_0 = B_1^* \dots B_p^* x_p$, this implies that

$$\|B_p \dots B_1\|^2 \leq \alpha \tau_1 \dots \tau_p \sigma_p$$

and

$$\frac{1}{p} \text{Log} \|B_p \dots B_1\|^2 \leq \frac{1}{p} \text{Log} \alpha + \frac{1}{p} \text{Log} \sigma_p + \frac{1}{p} \sum_{i=1}^p \text{Log} \tau_i.$$

As in the proof of (24) we can apply Proposition 3.4 to see that, almost surely,

$$\overline{\lim}_{p \rightarrow +\infty} \frac{1}{p} \text{Log} \sigma_p \leq 0.$$

Therefore, it follows from Birkhoff's ergodic theorem (see the proof of Corollary 3.2) that, almost surely,

$$\overline{\lim}_{p \rightarrow +\infty} \frac{1}{p} \text{Log} \|B_p \dots B_1\|^2 \leq \mathbb{E}(\text{Log } \tau_1).$$

Since we have supposed that $\mathbb{P}(\text{Det}(G_1) \neq 0) > 0$, we know that $\mathbb{E}(\text{Log } \tau_1) < 0$. \square

Remark 1. The exponential rate γ can be chosen to be equal to the smallest positive Lyapunov exponent of the associated Hamiltonian matrices. This is shown in Bougerol [7]. 2. It is not difficult to see that the theorem also holds if we only suppose that $P_0 \in \mathcal{P}$.

3. Appendix. Iteration of stationary Lipschitz functions. In this appendix, we establish some general properties of the processes that are obtained by iteration of random Lipschitz functions. At least in particular cases, similar results are already known. But we think that our set-up and formulation can be useful in several situations; we applied them in § 2.

Let (E, δ) be a complete separable metric space. A Lipschitz map $\phi: E \rightarrow E$ is a map for which

$$\rho(\phi) := \text{Sup} \left\{ \frac{\delta(\phi(x), \phi(y))}{\delta(x, y)}; x, y \in E, x \neq y \right\}$$

is finite. If ϕ and φ are such Lipschitz maps, then

$$(25) \quad \rho(\phi \circ \varphi) \leq \rho(\phi)\rho(\varphi).$$

When $\rho(\phi) \leq 1$, the map ϕ is called a *contraction*. It is called a *uniform contraction* when $\rho(\phi) < 1$. We consider a stationary ergodic process $\{\phi_n, n \in \mathbb{Z}\}$ defined on a probability space $(\Omega, \mathcal{A}, \mathbb{P})$, where each $\phi_n: E \rightarrow E$ is a random Lipschitz map (we suppose that the maps $(\omega, x) \in \Omega \times E \rightarrow \phi_n''(x) \in E$ are measurable when E is equipped with its Borel σ -algebra; for notational convenience, we do not write ω explicitly). We consider the processes $X_n, n \in \mathbb{N}$, on E for which the following difference equation holds:

$$(26) \quad X_n = \phi_n(X_{n-1}).$$

The following theorem is more or less known. It generalizes results of Sunyach [26], Brandt [9], and Barnsley and Elton [4]. We recall that $\text{Log}^+ x = \text{Max}(\text{Log } x, 0)$. If E' is a countable dense subset of E , then $\rho(\phi_1)$ is the supremum of the countable set $\{\delta(\phi_1(x), \phi_1(y))/\delta(x, y); x, y \in E', x \neq y\}$; thus, $\rho(\phi_1)$ is measurable.

THEOREM 3.1. *Let $\{\phi_n, n \in \mathbb{Z}\}$ be a stationary ergodic sequence of Lipschitz maps from E into E . We suppose that the following conditions hold:*

(C1) *For some x in E , $\mathbb{E}[\text{Log}^+ \delta(\phi_1(x), x)]$ is finite.*

(C2) *The random variable $\text{Log}^+ \rho(\phi_1)$ is integrable, and for some integer $p > 0$, the real number*

$$\alpha = \frac{1}{p} \mathbb{E}[\text{Log } \rho(\phi_p \circ \phi_{p-1} \circ \dots \circ \phi_1)]$$

is strictly negative.

Then there exists an ergodic stationary process $\{\tilde{X}_n, n \in \mathbb{Z}\}$ with values in E , solution of (26), such that, almost surely,

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log } \delta(X_n, \tilde{X}_n) \leq \alpha < 0$$

for any process $\{X_n, n \geq 0\}$, such that $X_n = \phi_n(X_{n-1})$ for all $n > 0$.

Proof. Let us first show that, almost surely,

$$(27) \quad \overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \rho(\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k}) \leq \alpha.$$

By (25),

$$\overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \rho(\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k}) \leq \overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \rho(\phi_{-1} \circ \cdots \circ \phi_{-k}),$$

thus, the left-hand side of (27) is a subinvariant function. By ergodicity, it is constant, almost surely. Let β be this constant. We know that for any nonnegative integrable random variable Z , $\sum_{k=0}^{+\infty} \mathbb{P}(Z > k)$ is finite. Therefore, the integrability condition in (C2) entails that, for any $\varepsilon > 0$, $\sum_{k=0}^{+\infty} \mathbb{P}(\operatorname{Log}^+ \rho(\phi_1) > k\varepsilon) < +\infty$. Since all the ϕ_n 's have the same law, this entails that $\sum_{k=0}^{+\infty} \mathbb{P}(\operatorname{Log}^+ \rho(\phi_{-k}) > k\varepsilon) < +\infty$, so that by the Borel-Cantelli lemma, almost surely,

$$\overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \rho(\phi_{-k}) \leq 0.$$

By making use of this inequality, and of the fact that if $k = mp + r$, where r is an integer in $[0, p)$,

$$\begin{aligned} \operatorname{Log} \rho(\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k}) &\leq \left\{ \sum_{i=0}^{m-1} \operatorname{Log} \rho(\phi_{-ip} \circ \phi_{-ip-1} \circ \cdots \circ \phi_{-(i+1)p+1}) \right\} \\ &\quad + \operatorname{Log} \rho(\phi_{-mp} \circ \cdots \circ \phi_{-k}), \end{aligned}$$

we see that

$$\beta \leq \overline{\lim}_{k \rightarrow +\infty} \frac{1}{mp} \sum_{i=0}^{m-1} \operatorname{Log} \rho(\phi_{-ip} \circ \phi_{-ip-1} \circ \cdots \circ \phi_{-(i+1)p+1}).$$

It follows from Birkhoff's ergodic theorem that the expectation of the right-hand side is equal to α , proving (27). On the other hand, it follows as above from the integrability condition (C1) and from the Borel-Cantelli lemma that for some fixed x in E , almost surely,

$$(28) \quad \overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \delta(\phi_{-k}(x), x) \leq 0.$$

Now

$$\begin{aligned} &\delta((\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k})(x), (\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k} \circ \phi_{-k-1})(x)) \\ &\leq \rho(\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k}) \delta(x, \phi_{-k-1}(x)), \end{aligned}$$

thus, (27) and (28) imply that, almost surely,

$$\overline{\lim}_{k \rightarrow +\infty} \frac{1}{k} \operatorname{Log} \delta((\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k})(x), (\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k} \circ \phi_{-k-1})(x)) \leq \alpha.$$

Since $\alpha < 0$, this shows that $\{(\phi_0 \circ \phi_{-1} \circ \cdots \circ \phi_{-k})(x), k \in \mathbb{N}\}$ is a Cauchy sequence for almost all $\omega \in \Omega$. We suppose that E is complete, thus, this sequence converges. In the same way, we see that $(\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_{n-k})(x)$ converges, almost surely, for each fixed $n \in \mathbb{Z}$, when $k \rightarrow +\infty$. Let

$$(29) \quad \tilde{X}_n = \lim_{k \rightarrow +\infty} (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_{n-k})(x).$$

Since $\{\phi_k, k \in \mathbb{Z}\}$ is a stationary ergodic process, and since we can write $\tilde{X}_n = F(\phi_k, k \leq n)$ for some measurable function F independent of $n \in \mathbb{Z}$, we see that \tilde{X}_n is itself a stationary ergodic process. It is clear that it is a solution of (26). Finally, let $\{X_n, n \geq 0\}$ be any process satisfying (26). Since

$$\begin{aligned} \delta(X_n, \tilde{X}_n) &= \delta((\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(X_0), (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(\tilde{X}_0)) \\ &\leq \rho(\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1) \delta(X_0, \tilde{X}_0), \end{aligned}$$

we see that, almost surely,

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \text{Log } \delta(X_n, \tilde{X}_n) \leq \frac{1}{p} \mathbb{E}(\text{Log } \rho(\phi_p \circ \phi_{p-1} \circ \cdots \circ \phi_1)) = \alpha.$$

This concludes the proof of the theorem. \square

Remark. Suppose that $\text{Log}^+ \rho(\phi_1)$ is integrable, then if $\mathbb{E}\{\text{Log } \delta(\phi_1(x_0), x_0)\}$ is finite for some x_0 in E , then it is finite for all $x \in E$ since

$$\begin{aligned} \delta(\phi_1(x), x) &\leq \delta(\phi_1(x), \phi_1(x_0)) + \delta(\phi_1(x_0), x_0) + \delta(x_0, x) \\ &\leq \delta(\phi_1(x_0), x_0) + (\rho(\phi_1) + 1) \delta(x_0, x). \end{aligned}$$

COROLLARY 3.2. *Let π be the common law of the \tilde{X}_n 's. Under the hypotheses above, almost surely, for any sequence X_n satisfying (26), and for any bounded continuous function $f: E \rightarrow \mathbb{R}$,*

$$\lim_{n \rightarrow +\infty} \frac{1}{n} \sum_{i=1}^n f(X_i) = \int f d\pi.$$

Proof. The hypotheses on E imply that there exists a countable set D of bounded continuous functions on E such that any sequence of probability measures μ_n on E converges weakly to a probability measure μ if and only if $\int f d\mu_n \rightarrow \int f d\mu$ for any f in D (see, e.g., Parthasarathy [23, Thm. II.6.6]). Let $\Omega(f)$ be the subset of Ω , where $1/n \sum_{i=1}^n f(\tilde{X}_i)$ converges to $\int f d\pi$. Since (\tilde{X}_n) is stationary and ergodic, $\mathbb{P}(\Omega(f)) = 1$ by Birkhoff's ergodic theorem. Let Ω_0 be the intersection of the set, where $\delta(X_n, \tilde{X}_n)$ converges to 0 and of all the sets $\Omega(f)$, $f \in D$. It follows from Theorem 3.1 that $\mathbb{P}(\Omega_0) = 1$. We fix an ω in Ω_0 . Let m_n be the empirical measure of the sequence $\{\tilde{X}_n(\omega), n \geq 1\}$, defined by $\int f dm_n = 1/n \sum_{i=1}^n f(\tilde{X}_i(\omega))$, when $f: E \rightarrow \mathbb{R}$ is bounded and continuous. The sequence $\{m_n, n \geq 1\}$ converges weakly to π . Moreover, since $\delta(X_n(\omega), \tilde{X}_n(\omega)) \rightarrow 0$,

$$(30) \quad \lim_{n \rightarrow +\infty} \frac{1}{n} \sum_{i=1}^n f(X_i(\omega)) = \lim_{n \rightarrow +\infty} \frac{1}{n} \sum_{i=1}^n f(\tilde{X}_i(\omega)) = \int f d\pi$$

when f is uniformly continuous. This, in turn, yields that the empirical measure of the sequence $\{X_n(\omega), n \geq 1\}$ converges weakly to π , i.e., that (30) holds for any function f that is bounded and continuous (see Parthasarathy [23, Thm. II.6.1]). \square

COROLLARY 3.3. *Under the hypotheses of the previous theorem, all the solutions X_n of (26) converge in law to the same limit π .*

This corollary is an immediate consequence of the theorem. The following technical proposition has been used in § 2.

PROPOSITION 3.4. *Suppose that the random maps ϕ_n are contractions, that $\mathbb{E}[\delta(\phi_1(x), x)]$ is finite for some x in E , and that for some $p > 0$, $\mathbb{E}[\text{Log } (\rho(\phi_p \circ \cdots \circ \phi_1))] < 0$. Then, almost surely,*

$$\lim_{n \rightarrow +\infty} \frac{1}{n} \delta(x, X_n) = 0$$

for any sequence $\{X_n, n \geq 0\}$ for which (26) holds.

Proof. For any $n \geq 1$,

$$\begin{aligned} \delta(x, (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(x)) &\leq \delta(x, (\phi_n \circ \cdots \circ \phi_2)(x)) \\ &\quad + \delta((\phi_n \circ \cdots \circ \phi_2)(x), (\phi_n \circ \cdots \circ \phi_1)(x)) \\ &\leq \delta(x, (\phi_n \circ \cdots \circ \phi_2)(x)) + \rho(\phi_n \circ \cdots \circ \phi_2) \delta(x, \phi_1(x)). \end{aligned}$$

So that, by induction,

$$(31) \quad \delta(x, (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(x)) \leq \sum_{i=1}^n \rho(\phi_n \circ \cdots \circ \phi_{i+1}) \delta(x, \phi_i(x)).$$

Since the ϕ_n 's are contractions, this implies in particular, using (25), that

$$\delta(x, (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(x)) \leq \delta(x, \phi_n(x)) + \sum_{i=1}^{n-1} \rho(\phi_{i+1}) \delta(x, \phi_i(x)).$$

Thus, by Birkhoff's ergodic theorem, almost surely,

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \delta(x, (\phi_n \circ \cdots \circ \phi_1)(x)) \leq \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \sum_{i=1}^{n-1} \rho(\phi_{i+1}) \delta(x, \phi_i(x)) \leq \mathbb{E}[\rho(\phi_1) \delta(x, \phi_0(x))].$$

Similarly, for any fixed k in \mathbb{N} , we obtain from (31) that, when $n > k$,

$$\begin{aligned} \delta(x, (\phi_n \circ \cdots \circ \phi_1)(x)) &\leq \sum_{i=n-k+1}^n \rho(\phi_n \circ \cdots \circ \phi_{i+1}) \delta(x, \phi_i(x)) \\ &\quad + \sum_{i=1}^{n-k} \rho(\phi_{i+k} \circ \cdots \circ \phi_{i+1}) \delta(x, \phi_i(x)) \end{aligned}$$

and by the ergodic theorem,

$$(32) \quad \begin{aligned} \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \delta(x, (\phi_n \circ \cdots \circ \phi_1)(x)) &\leq \overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \sum_{i=1}^{n-1} \rho(\phi_{i+k} \circ \cdots \circ \phi_{i+1}) \delta(x, \phi_i(x)) \\ &\leq \mathbb{E}[\rho(\phi_k \circ \cdots \circ \phi_1) \delta(x, \phi_0(x))]. \end{aligned}$$

Now, $\rho(\phi_k \circ \cdots \circ \phi_1) \delta(x, \phi_0(x))$ converges, almost surely, to 0 as $k \rightarrow +\infty$ and is dominated by the integrable function $\delta(x, \phi_0(x))$. Thus, its expectation goes to 0 by Lebesgue's theorem; from (32) we obtain

$$\overline{\lim}_{n \rightarrow +\infty} \frac{1}{n} \delta(x, (\phi_n \circ \phi_{n-1} \circ \cdots \circ \phi_1)(x)) = 0$$

almost surely. Finally, since $X_n = (\phi_n \circ \cdots \circ \phi_1)(X_0)$, we see that

$$\begin{aligned} \delta(x, X_n) &\leq \delta(x, (\phi_n \circ \cdots \circ \phi_1)(x)) + \delta((\phi_n \circ \cdots \circ \phi_1)(x), (\phi_n \circ \cdots \circ \phi_1)(X_0)) \\ &\leq \delta(x, (\phi_n \circ \cdots \circ \phi_1)(x)) + \delta(x, X_0), \end{aligned}$$

so that

$$\delta(x, X_n)/n \rightarrow 0 \quad \text{as} \quad n \rightarrow +\infty. \quad \square$$

Remark. When the random maps ϕ_n are independent and identically distributed, then $\mathbb{E}(\delta(\tilde{X}_n, x))$ is finite under the hypothesis of this proposition. In that case, its conclusion follows directly from the Borel-Cantelli lemma.

A STATE-SPACE ALGORITHM FOR THE SUPEROPTIMAL HANKEL-NORM APPROXIMATION PROBLEM*

G. D. HALIKIAS†, D. J. N. LIMEBEER‡, AND K. GLOVER§

Abstract. It has been demonstrated by N. T. Young [NATO ASI Series F34, Springer-Verlag, Berlin, New York, 1987] that given a stable matrix-valued function $G_0(s)$ and a nonnegative integer k , there exists a unique superoptimal approximation $\Phi(s)$ with no more than k poles in the left half plane that minimizes the sequence $(s_1^\infty(G_0 + \Phi), s_2^\infty(G_0 + \Phi), \dots)$, with respect to lexicographic ordering, where $s_i^\infty(G_0 + \Phi) := \sup_\omega [s_i(G_0 + \Phi)(j\omega)]$ and $s_i(\cdot)$ are the singular values in descending order of magnitude. This paper presents a constructive state-space algorithm that evaluates the superoptimal approximating matrix function. The procedure recursively minimizes each frequency-dependent singular value with the aid of all-pass transformations constructed from the k th Schmidt pairs of a sequence of Hankel operators. The algorithm may be stopped after an arbitrary number of, say, $l \leq \min(m, p)$ steps. The representation formula at the l th stage will characterize all matrix functions that have $\leq k$ poles in the left half plane and that minimize $s_1^\infty(G_0 + \Phi), \dots, s_l^\infty(G_0 + \Phi)$.

Key words. model reduction, superoptimality, Hankel norm, Schmidt vectors

AMS subject classifications. 93B28, 93B40, 93B36

1. Introduction. There are many occasions on which engineers require reliable low-order approximations to high-order models. For this reason the model-order-reduction problem has been the subject of numerous theoretical investigations, and several different approaches have been developed. A technique that has received much recent attention is the optimal Hankel-norm approach [4], which offers good guaranteed performance characteristics that are close to verifiable lower bounds.

For matrix-valued problems the optimal Hankel-norm approach typically has a continuum of solutions. The question then arises as to which solution (if there is one) is best. A partial answer to this question is implicit in [4], in that \mathcal{L}^∞ -error bounds are available for only certain optimal Hankel-norm reduced-order models. Young discusses an alternative approach to the uniqueness question [16]. His suggestion is to seek to minimize the sequence $s^\infty(E) = (s_1^\infty(E), s_2^\infty(E), \dots)$ rather than just $s_1^\infty(E)$, where $s_i^\infty(E) := \sup_\omega [s_i(E)(j\omega)]$, $E(s)$ is the modeling error, and $s_i(\cdot)$ is the i th singular value (numbered in descending order of magnitude). The reduced-order model that minimizes $s^\infty(\times E)$ has been shown to exist and to be unique [16]. In model-reduction applications it is possible to reduce the \mathcal{L}^∞ -norm of the error system by using the superoptimal Hankel-norm approximation rather than some other approximation, but we have no proof of this. For diagonal problems the superoptimal solution is the most natural choice because it is the diagonal matrix of optimal solutions.

The idea behind superoptimality is easily illustrated by way of a simple 2×2 example. Suppose

$$(1.1) \quad G(s) = \begin{bmatrix} \frac{2}{s+1} & 0 \\ 0 & \frac{1}{s+1} \end{bmatrix} = \text{diag} \{g_1(s), g_2(s)\},$$

‡ Department of Electrical Engineering, Imperial College, Exhibition Road, London, United Kingdom.

§ Department of Engineering, Trumpington Street, Cambridge, United Kingdom.

in which $\sigma_i(G) = 1, \frac{1}{2}$. Suppose also that a reduced-order approximation in $\mathcal{H}_-^\infty(1)$ is required. Any solution of the form

$$(1.2) \quad F(s) = \text{diag} \{f_1(s), -\tfrac{1}{2}\}$$

is an optimal approximation to $G(s)$, provided that $f_1(s)$ is chosen to be in $\mathcal{H}_-^\infty(1)$ such that

$$(1.3) \quad \left\| \frac{2}{s+1} + f_1 \right\|_\infty \leq \tfrac{1}{2}.$$

For example, the solution

$$(1.4) \quad F_{ap}(s) := \text{diag} \left\{ -\frac{s+3}{2(s+1)}, -\frac{1}{2} \right\}$$

results in the all-pass error system

$$(1.5) \quad (G + F_{ap})(s) = \begin{bmatrix} -\frac{1}{2} \left(\frac{s-1}{s+1} \right) & 0 \\ 0 & -\frac{1}{2} \left(\frac{s-1}{s+1} \right) \end{bmatrix},$$

and in this case $(s_1^\infty(G + F_{ap}), s_2^\infty(G + F_{ap})) = (\frac{1}{2}, \frac{1}{2})$. It is clear, however, that we can do better than this. Suppose we use our one stable pole to cancel $g_1(s)$. This gives

$$(1.6) \quad F_{so}(s) = \begin{bmatrix} -\frac{2}{s+1} & 0 \\ 0 & -\frac{1}{2} \end{bmatrix},$$

resulting in an error system

$$(1.7) \quad (G + F_{so})(s) = \begin{bmatrix} 0 & 0 \\ 0 & -\frac{1}{2} \left(\frac{s-1}{s+1} \right) \end{bmatrix},$$

for which $(s_1^\infty(G + F_{so}), s_2^\infty(G + F_{so})) = (\frac{1}{2}, 0)$. This is the superoptimal approximation to $G(s)$. If the $(1, 2)$ and $(2, 1)$ elements of $G(s)$ are nonzero, the situation is more complicated and a formal algorithmic procedure is required.

This paper recasts Young's algorithm in a concrete state-space framework that can be implemented on a digital computer that can tackle any rotational superoptimal approximation problem. Section 2 contains the notation to be used and a standard Hankel-norm approximation result. Section 3 contains the main results of the paper: Theorem 3.1 is standard and describes a key property of the Schmidt pairs of Hankel operators. Lemma 3.2 is a modified version of a result in [9], and Lemmas 3.3 and 3.4 are generalizations of parallel results in [9]. The main results of the paper are Theorems 3.6 and 3.6', and Algorithm 3.1, which are believed to be new. The main conclusions of our work are given in § 4.

2. Notation and preliminaries.

2.1. Notation.

$\mathbb{R}, \mathbb{R}_+, \mathbb{C}$	real, nonnegative, and complex numbers
$\mathbb{R}(s)$	field of rational functions in s with real coefficients
$\mathbb{C}_+, \bar{\mathbb{C}}_+$	open (respectively, closed) right half plane
$\mathbb{C}_-, \bar{\mathbb{C}}_-$	open (respectively, closed) left half plane
$\lambda(A), \lambda_{\max}(A)$	spectrum of a square matrix A , largest eigenvalue of A
A^*	complex conjugate transpose of $A \in \mathbb{C}^{p \times m}$
$A \geq 0, A > 0$	A is positive semidefinite (respectively, positive definite)
$A \leq 0, A < 0$	A is negative semidefinite (respectively, negative definite)
$A^\#$	generalized inverse of matrix A
$\mathcal{L}^{\infty, (p \times m)}$	space of $p \times m$ matrix functions with entries that are bounded on the $j\omega$ axis (including the point at ∞)
$\ \cdot\ _\infty$	\mathcal{L}^∞ -norm of matrices in \mathcal{L}^∞
$\mathcal{H}_+^{\infty, (p \times m)}$	subspace of \mathcal{L}^∞ ; $p \times m$ matrix functions that are analytic and bounded in \mathbb{C}_+
$\mathcal{H}_-^{\infty, (p \times m)}$	subspace of \mathcal{L}^∞ ; $p \times m$ matrix functions that are analytic and bounded in \mathbb{C}_-
$\mathcal{H}_2, \mathcal{H}_2^\perp$	the sets of functions f analytic in \mathbb{C}_+ (respectively, \mathbb{C}_-) such that $\sup_{\xi > 0} \int_{-\infty}^{\infty} \ f(\xi + j\omega)\ _2^2 d\omega < \infty$ $(\sup_{\xi < 0} \int_{-\infty}^{\infty} \ f(\xi + j\omega)\ _2^2 d\omega < \infty)$
$\mathbb{R}\mathcal{H}_2, \mathbb{R}\mathcal{H}_2^\perp$	same as $\mathcal{H}_2, \mathcal{H}_2^\perp$ except that elements are taken from $\mathbb{R}^{(p \times m)}(s)$
$\mathcal{H}_\pm^{\infty, (p \times m)}(k)$	the set of $p \times m$ matrix functions in \mathcal{L}^∞ with no more than k poles in \mathbb{C}_\pm
$\mathcal{BH}_-^\infty, \mathcal{BH}_+^\infty$	unit balls in $\mathcal{H}_-^\infty: \{f \in \mathcal{H}_-^\infty: \ f\ _\infty \leq 1\}, \{f \in \mathcal{H}_+^\infty: \ f\ _\infty \leq 1\}$
$\mathbb{R}\mathcal{L}^{\infty, (p \times m)}$	same as $\mathcal{L}^{\infty, (p \times m)}$ except that elements are taken from $\mathbb{R}^{(p \times m)}(s)$
$\mathbb{R}\mathcal{H}_\pm^{\infty, (p \times m)}(k)$	same as $\mathcal{H}_\pm^{\infty, (p \times m)}(k)$ except that elements are taken from $\mathbb{R}^{(p \times m)}(s)$
Γ_G	Hankel operator with symbol $G(s) \in \mathcal{H}_+^\infty$
$\sigma_i(G(s))$	i th Hankel singular value of $G(s)$ (i.e., of Γ_G) in decreasing order of magnitude
$[F]_+$	the stable projection of F if F is decomposed as $F := [F]_+ + [F]_-$ in which $[F]_+ \in \mathcal{H}_+^\infty$ and $[F]_- \in \mathcal{H}_-^\infty$
$s_i(A)$	i th singular value of a matrix A with the numbering in descending order (if A is a function of frequency (i.e., $A(j\omega)$), then $s_i(\cdot)$ will be a function of frequency also)
$\prod_{i=0}^n A_i$	(right) matrix product $A_0 A_1 \cdots A_n$ ($\prod_{i=0}^0 A_i := A_0$)
$\ G(s)\ _H$	$\sigma_1(G(s))$, the Hankel-norm of $G(s)$
$G^*(s)$	$G(-\bar{s})^*$, the para-Hermitian conjugate of $G(s)$
$C(A, B), \bar{C}(A, B)$	controllable and uncontrollable modes of the pair (A, B)
$O(A, C), \bar{O}(A, C)$	observable and unobservable modes of the pair (A, C)
$A \oplus B$	direct sum given by

$$\begin{bmatrix} A & 0 \\ 0 & B \end{bmatrix}$$

Associated with a transfer function matrix $G_0(s) \in \mathbb{R}(s)^{p \times m}$ of MacMillan degree n is a state-space realization

$$G_0(s) = D + C(sI - A)^{-1}B, \quad (2.1)$$

where $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{p \times n}$, and $D \in \mathbb{R}^{p \times m}$. We will use the alternative notation $G_0(s) \triangleq (A, B, C, D)$ or

$$(2.2) \quad G_0(s) \triangleq \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

for realizations of $G_0(s)$. The rank of $G_0(s)$ is taken to be its rank for any s that is not a zero of $G_0(s)$.

In the above notation we have $G_0^*(s) \triangleq (-A^*, C^*, -B^*, D^*)$, and if D is nonsingular, we have $G_0^{-1}(s) \triangleq (A - BD^{-1}C, BD^{-1}, -D^{-1}C, D^{-1})$. If $G^{-1}(s) = G^*(s)$, then $G(s)$ is called *all-pass*. $G_0(s)$ is called *stable* if it has no poles in $\bar{\mathbb{C}}_+$. If $G_0(s)$ is both stable and all-pass, it is called *inner*.

We will talk about *basis changes* T in the state space of $G_0(s)$; we will take a basis change to mean $G_0(s) \triangleq (A, B, C, D) \xrightarrow{T} G_0(s) \triangleq (TAT^{-1}, TB, CT^{-1}, D)$. The *MacMillan degree* of $G_0(s)$ will be written $\deg(G_0)$, and the set of poles (zeros) of $G_0(s)$ will be denoted $\{\text{poles of } G_0\}(\{\text{zeros of } G_0\})$.

Let $P(s)$ be a partitioned matrix with a state-space realization given by

$$(2.3) \quad P(s) = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}(s) \triangleq \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{21} \end{array} \right].$$

Then

$$(2.4) \quad P_{ij}(s) = C_i(sI - A)^{-1}B_j + D_{ij}$$

is a state-space realization of $P_{ij}(s)$. A *linear fractional transformation* for the partitioned matrix P and a matrix K is defined as

$$(2.5) \quad \mathcal{F}_l(P, K) = P_{11} + P_{12}K(I - P_{22}K)^{-1}P_{21},$$

where K is of dimension $l \times m$ if P_{22} has dimension $m \times l$.

2.2. Preliminaries. This section provides a description of all k th-order approximations of a rational transfer function $G_0(s) \in \mathbb{R}\mathcal{H}_+^{\infty, (p \times m)}$. The description is in terms of a balanced realization of $G_0(s)$ and is based on [4, Thm. 8.7]. If $G_0(s) \triangleq (A, B, C, D)$ is balanced and minimal, the following Lyapunov equations are satisfied:

$$(2.6) \quad AP + PA^* + BB^* = 0,$$

$$(2.7) \quad A^*Q + QA + C^*C = 0,$$

in which

$$(2.8) \quad P = Q = \text{diag}(\Sigma, \sigma_{k+1}),$$

where

$$(2.9) \quad \Sigma = \text{diag}(\sigma_1, \dots, \sigma_k, \sigma_{k+2}, \dots, \sigma_n).$$

Remark 2.1. In the interests of a clear presentation, it is assumed that the $(k+1)$ th Hankel singular value is nonrepeated. Matrices A , B , and C are partitioned conformally with P and Q in (2.8) as

$$(2.10) \quad A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}, \quad C = [C_1 \ C_2].$$

In a further attempt to keep the notation simple, it will be assumed that $G_0(s)$ has been scaled to give $C_2^* C_2 = B_2 B_2^* = 1$.

Lemma 2.1 parameterizes the family of all optimal Hankel-norm approximations and their corresponding extensions in terms of an (arbitrary) unstable contraction [4].

LEMMA 2.1. *Let the transfer function $G_0(s) \in \mathbb{R}\mathcal{H}_+^{\infty, (p \times m)}$ have a stable, minimal, and balanced realisation $G_0(s) \triangleq (A, B, C, D)$ with Hankel singular values $\sigma_1 \geq \dots \geq \sigma_k > \sigma_{k+1} > \sigma_{k+2} \geq \dots \geq \sigma_n > 0$, and define*

$$(2.11) \quad \Gamma = \Sigma^2 - \sigma_{k+1}^2 I_{n-1}.$$

Then all error systems $\mathcal{E}(s) = G_0(s) + \mathcal{F}(s)$ with

$$(2.12) \quad \|\mathcal{E}(s)\|_\infty = \sigma_{k+1} := \sigma$$

and $\mathcal{F}(s) \in \mathcal{H}_-^\infty(k)$ are generated by

$$(2.13) \quad \mathcal{E}(s) = \mathcal{F}_l \left(H(s), \frac{1}{\sigma} \Theta(s) \right), \quad \Theta(s) \in \mathcal{B}\mathcal{H}_-^\infty,$$

in which $H(s)H^*(s) = \sigma^2 I$ and

$$(2.14) \quad H(s) = \begin{bmatrix} G_0 + F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix},$$

where

$$(2.15) \quad F(s) = \left[\begin{array}{c|cc} \Gamma^{-1}(\sigma^2 A_{11}^* + \Sigma A_{11} \Sigma - \sigma C_1^* U B_1^*) & \Gamma^{-1}(\Sigma B_1 + \sigma C_1^* U) & -\sigma \Gamma^{-1} C_1^* C_\perp^* \\ \hline -(C_1 \Sigma + \sigma U B_1^*) & \sigma U & -\sigma C_\perp^* \\ -\sigma B_\perp B_1^* & \sigma B_\perp & 0 \end{array} \right].$$

Also, $F(s) \in \mathbb{R}\mathcal{H}_-^{\infty, (p+m-1) \times (p+m-1)}(k)$. The matrices B_\perp and C_\perp are chosen to make $[C_2 \ C_\perp^*]$ and $[B_2^* \ B_\perp^*]$ orthogonal, and U is given by $U := -C_2 B_2$. In the single-input or single-output case B_\perp or C_\perp or both will be zero and the resulting error system will be unique.

Remark 2.2. It is interesting that the construction of the superoptimal approximation is particularly simple in the special case $k = n - 1$, for which the approximation can be obtained directly from Lemma 2.1. To see this we begin by noting that all error systems are given by

$$(2.16) \quad \mathcal{E}(s) = G + F_{11} + \frac{1}{\sigma_n} F_{12} \Theta \left(I - \frac{1}{\sigma_n} F_{22} \Theta \right)^{-1} F_{21},$$

in which $F(s)$ is stable. Suppose that we set $\Theta := (1/\sigma_n) F_{12}^*(s)$, which we note has the characteristic $\|\Theta\|_\infty < 1$ by the all-pass property $H(s)H^*(s) = \sigma_n^2 I$ and since $\det(F_{12}^* F_{12}(j\omega)) \neq 0$ for all real ω . In addition, F_{22}^* is completely unstable. By exploiting the all-pass character of (2.14), the expression for the error system may be rearranged as

$$(2.17) \quad \begin{aligned} \mathcal{E}(s) &= G + F_{11} + \frac{1}{\sigma_n^2} F_{12} F_{22}^* \left(I - \frac{1}{\sigma_n^2} F_{22} F_{22}^* \right)^{-1} F_{21} \\ &= G + F_{11} + F_{12} F_{22}^* (F_{21} F_{21}^*)^{-1} F_{21} \\ &= G + F_{11} - (G + F_{11}) F_{21}^* (F_{21} F_{21}^*)^{-1} F_{21} \\ &= (G + F_{11}) (I_m - F_{21}^* (F_{21} F_{21}^*)^{-1} F_{21}). \end{aligned}$$

Since $F_{21}(j\omega)$ has rank $m-1$, the error system has rank 1 and satisfies $\|\mathcal{E}\|_\infty = \sigma_n$, which is clearly superoptimal.

To show that the error system in (2.17) is unique, we suppose there are two superoptimal approximations Φ_{so1} and Φ_{so2} . It follows from Lemma 3.4 and the unity-rank property of $\mathcal{E}(s)$ in (2.17) that there exists an all-pass matrix $W(s) = [w(s) \quad W_\perp(s)]$ such that

$$(G + \Phi_{so1})W(s) = [\sigma_n a(s)v(s) \quad 0],$$

$$(G + \Phi_{so2})W(s) = [\sigma_n a(s)v(s) \quad 0].$$

Subtracting these expressions gives

$$(\Phi_{so1} - \Phi_{so2})W(s) = 0 \Rightarrow \Phi_{so1} - \Phi_{so2}.$$

3. Main results. In this section we present the main algorithm for calculating superoptimal approximations. Following the work of Young [15], [16], the procedure is based on an inductive dimension-peeling argument. At each step of the algorithm the rank of the problem is reduced by one. Since the original problem is assumed to be of finite rank, the algorithm terminates after a finite number of steps.

The Hankel operator induced by $G_0(s)$ is defined by $\Gamma_{G_0}: \mathcal{H}_2^\perp \rightarrow \mathcal{H}_2$, $\Gamma_{G_0}g = \Pi_+ M_{G_0}g$, where Π_+ denotes the projection $\mathcal{L}_2 \rightarrow \mathcal{H}_2$ and M_{G_0} is the multiplication operator. Note that Γ_{G_0} is determined by the stable component of $G_0(s)$. We begin our development by briefly mentioning some elementary properties of the Schmidt vectors of Γ_{G_0} . The interested reader is referred to [1], [13] for a more detailed exposition. Suppose that σ_{k+1} is a singular value of Γ_{G_0} . Then there exist Schmidt vectors $f_{k+1} \in \mathcal{H}_2$ and $g_{k+1} \in \mathcal{H}_2^\perp$ that satisfy

$$(3.1) \quad \Gamma_{G_0}g_{k+1} = \sigma_{k+1}f_{k+1}$$

and

$$(3.2) \quad \Gamma_{G_0}^*f_{k+1} = \sigma_{k+1}g_{k+1},$$

and consequently

$$(3.3) \quad \Gamma_{G_0}^* \Gamma_{G_0}g_{k+1} = \sigma_{k+1}^2 g_{k+1}.$$

The next result is standard (see, e.g., [13]) and demonstrates that any Schmidt pair of Γ_{G_0} has singular-vector-type properties for the error system $(G_0 + F)$. If $F(s) \in \mathcal{H}_-^\infty(k)$ is any optimal approximation of $G_0(s) \in \mathcal{H}_+^\infty$, then

$$(3.4) \quad (G_0 + F)g_{k+1}(s) = \sigma_{k+1}f_{k+1}(s), \quad (G_0 + F)^*f_{k+1}(s) = \sigma_{k+1}g_{k+1}(s).$$

Thus by modulo scaling $f_{k+1}(s)$ and $g_{k+1}(s)$ are singular vectors of the error system $E(s) = (G_0 + F)(s)$ at each frequency $s = j\omega$ corresponding to the largest singular value of $E(j\omega)$.

THEOREM 3.1. Every $F(s) \in \mathcal{H}_-^\infty(k)$ that achieves the infimum

$$(3.5) \quad \inf_{F(s) \in \mathcal{H}_-^\infty(k)} \|G_0 + F\|_\infty = \sigma_{k+1}(G_0) < \sigma_k(G_0)$$

satisfies

$$(3.6) \quad (G_0 + F)g_{k+1}(s) = \Gamma_{G_0}g_{k+1}(s) = \sigma_{k+1}(G_0)f_{k+1}(s),$$

where (g_{k+1}, f_{k+1}) is a Schmidt pair of Γ_{G_0} corresponding to the $(k+1)$ th singular value of Γ_{G_0} .

Proof. Let $F(s)$ be any (matrix) function that achieves the infimum in (3.5), and let Γ_F be the Hankel operator that it induces. Since $F(s) \in \mathcal{H}_-^\infty(k)$, $\text{rank}(\Gamma_F) \leq k$.

Suppose (g_i, f_i) , $(i = 1, 2, \dots)$, are the Schmidt pairs of Γ_{G_0} associated with σ_i , and define P to be the orthogonal projection onto $\text{Span}(f_1, f_2, \dots, f_{k+1})$. Then $\|\Gamma_{G_0} + \Gamma_F\| = \sigma_{k+1}(G_0)$ implies that

$$(3.7) \quad \|P(\Gamma_{G_0} + \Gamma_F)\| \leq \sigma_{k+1}(G_0).$$

The operator $P\Gamma_F$ mapping $\text{Span}(g_1, g_2, \dots, g_{k+1}) \rightarrow \text{Span}(f_1, f_2, \dots, f_{k+1})$ has rank at most k , and therefore there exists a function of norm equal to one such that

$$(3.8) \quad x = \sum_{i=1}^{k+1} \alpha_i g_i \in \text{Ker}(P\Gamma_F).$$

Consequently,

$$(3.9) \quad \|P(\Gamma_{G_0} + \Gamma_F)x\|_2 = \|P\Gamma_{G_0}x\|_2 \leq \sigma_{k+1}(G_0).$$

Also,

$$(3.10) \quad \begin{aligned} \left\| P\Gamma_{G_0} \left(\sum_{i=1}^{k+1} \alpha_i g_i \right) \right\|_2 &= \left\| P \left(\sum_{i=1}^{k+1} \alpha_i \Gamma_{G_0} g_i \right) \right\|_2 = \left\| P \sum_{i=1}^{k+1} \sigma_i \alpha_i f_i \right\|_2 \\ &= \left\| \sum_{i=1}^{k+1} \sigma_i \alpha_i f_i \right\|_2 \\ &= \sqrt{\sum_{i=1}^{k+1} \sigma_i^2 |\alpha_i|^2} \end{aligned}$$

since the f_i 's are orthonormal. This implies that $\sum_{i=1}^{k+1} \sigma_i^2 |\alpha_i|^2 \leq \sigma_{k+1}^2$, and since $\sigma_{k+1} < \sigma_k \leq \dots \leq \sigma_1$ and $\sum_{i=1}^{k+1} |\alpha_i|^2 = 1$, we conclude that $\alpha_i = 0$ for $i = 1, 2, \dots, k$, so that x must be a multiple of g_{k+1} , say, $x = \beta g_{k+1}$ with $|\beta| = 1$. Now, since $x \in \text{Ker}(P\Gamma_F)$, we have that $\Gamma_F x \perp \text{Span}(f_1, f_2, \dots, f_{k+1})$ and, in particular, $\langle \Gamma_F x, f_{k+1} \rangle_2 = 0$. Consequently,

$$(3.11) \quad \begin{aligned} \|\Gamma_{G_0}x + \Gamma_Fx\|_2^2 &= \|\beta \Gamma_{G_0}g_{k+1} + \Gamma_Fx\|_2^2 \\ &= \|\sigma_{k+1}f_{k+1}\|_2^2 + \|\Gamma_Fx\|_2^2 \\ &= \sigma_{k+1}^2 + \|\Gamma_Fx\|_2^2. \end{aligned}$$

However, since $\|\Gamma_{G_0}x + \Gamma_Fx\|_2^2 \leq \|\Gamma_{G_0} + \Gamma_F\|^2 \|x\|_2^2 = \sigma_{k+1}^2$, we conclude that

$$(3.12) \quad \sigma_{k+1}^2 + \|\Gamma_Fx\|_2^2 \leq \sigma_{k+1}^2 \Rightarrow \Gamma_Fx = 0 \Rightarrow \Gamma_Fg_{k+1} = 0,$$

so that

$$(3.13) \quad (\Gamma_{G_0} + \Gamma_F)g_{k+1} = \sigma_{k+1}f_{k+1}.$$

Also, if we define Π_+ to be the stable projection operator,

$$(3.14) \quad \begin{aligned} \sigma_{k+1} &= \|\sigma_{k+1}f_{k+1}\|_2 = \|\Pi_+(G_0 + F)g_{k+1}\|_2 \\ &\leq \|(G_0 + F)g_{k+1}\|_2 \\ &\leq \|G_0 + F\|_\infty \|g_{k+1}\|_2 \\ &= \|G_0 + F\|_\infty = \sigma_{k+1}, \end{aligned}$$

since $F(s)$ achieves the infimum in (3.5). This shows that $\Pi_+(G_0 + F)g_{k+1} = (G_0 + F)g_{k+1} = \sigma_{k+1}f_{k+1}$, as required. \square

In our application we use $f_{k+1}(s)$ and $g_{k+1}(s)$ as a basis for constructing two all-pass transformations to be used in a diagonalization procedure. Lemma 3.1 represents the first step in a two-stage scaling process. The aim is to find vectors $\xi_{k+1}(s)$ and $\psi_{k+1}(s)$ that have full rank at infinity but that retain the singular vector properties of the Schmidt pair [13, Lemmas 6, 9].

LEMMA 3.1. Let $G_0(s) \triangleq (A, B, C, D)$ be the minimal and balanced realization referred to in (2.6)–(2.8). Then

$$(3.15a) \quad f_{k+1}(s) \triangleq (A, e_n, C, 0),$$

$$(3.15b) \quad g_{k+1}(s) \triangleq (-A^*, e_n, B^*, 0)$$

are a Schmidt pair for the Hankel operator Γ_{G_0} corresponding to the singular value σ_{k+1} , where $e_n = [0 \ 0 \ \cdots \ 1]^T$. Also,

$$(3.16a) \quad f_{k+1}(s) = \phi_{k+1}(s)\xi_{k+1}(s),$$

$$(3.16b) \quad g_{k+1}(s) = \phi_{k+1}^*(s)\psi_{k+1}(s),$$

in which

$$(3.17a) \quad \xi_{k+1}(s) \triangleq \left[\begin{array}{c|c} A_{11} & A_{12} \\ \hline C_1 & C_2 \end{array} \right], \quad \xi_{k+1}(j\omega) \neq 0, \quad \omega \in \mathbb{R} \cup \{\infty\},$$

$$(3.17b) \quad \psi_{k+1}(s) \triangleq \left[\begin{array}{c|c} -A_{11}^* & -A_{21}^* \\ \hline B_1^* & B_2^* \end{array} \right], \quad \psi_{k+1}(j\omega) \neq 0, \quad \omega \in \mathbb{R} \cup \{\infty\},$$

$$(3.18) \quad \phi_{k+1}(s) = \det(sI - A_{11}) / \det(sI - A).$$

Proof. For realizations (3.15a, b) see [3, p. 69]. Equations (3.16a, b) follow by invoking a result on partitioned determinants [7, p. 656]. See [9] for details.

To scale $\xi_{k+1}(s)$ to be of unit length, note that the scalar function $\xi_{k+1}^*(s)\xi_{k+1}(s)$ is positive on the imaginary axis (by 3.17a), and hence it can be spectrally factored. In particular, let $\xi_{k+1} = nd^{-1}$ be a coprime factorization over the polynomials, with $\xi_{k+1}^*\xi_{k+1} = d^{-*}n^*nd^{-1}$. Factoring $n^*n = \tilde{n}^*\tilde{n}$, where \tilde{n} is scalar with its zeros in \mathbb{C}_+ , we obtain

$$(3.19) \quad v := \xi_{k+1}(\tilde{n}d^{-1})^{-1} = n\tilde{n}^{-1} \in \mathbb{R}\mathcal{H}_-^{\infty, p \times 1},$$

with $v^*v = 1$. It is always possible to find $V_{\perp}(s)$ such that $V = [v \ V_{\perp}](s)$ is all-pass and such that $\deg(v) = \deg([v \ V_{\perp}])$. A similar argument may be used to derive a $w(s)$ from ψ_{k+1} such that $w^*w = 1$. We summarize our progress so far.

LEMMA 3.2. Given $f \in \mathbb{R}\mathcal{H}_2$ and $g \in \mathbb{R}\mathcal{H}_2^{\perp}$, there exist all-pass matrices $V \in \mathbb{R}\mathcal{H}_-^{\infty, p \times p}$ and $W \in \mathbb{R}\mathcal{H}_+^{\infty, m \times m}$ given by

$$(3.20) \quad V = [v \ V_{\perp}](s)$$

and

$$(3.21) \quad W = [w \ W_{\perp}](s),$$

in which v and w are given by (3.19) and its dual. Furthermore, minimal realizations of $V(s)$ and $W(s)$ are controllable from the first input.

Next, we give a concrete state-space construction of the vectors $v(s)$ and $w(s)$ along with their all-pass completions that are derived from standard spectral factorization theory.

Scaling $\xi(s) = C_2 + C_1(sI - A_{11})^{-1}A_{12}$ to unit length as $v(s) = \xi(s)m^{-1}(s)$ requires the solution of the spectral factorization problem $\xi^*(s)\xi(s) = m^*(s)m(s)$. Since $v(s)$ is required to be completely unstable (for reasons that will become apparent later), the spectral factor $m(s)$ must be nonminimum phase. This is achieved by choosing the appropriate solution to the corresponding Riccati equation [2]. The construction of the all-pass completion $V_{\perp}(s)$ may be achieved with no increase in degree. This accounts for the fact that minimal realizations of $V(s)$ and $W(s)$ are controllable from the first input. The construction is summarized in the following steps:

(i) If (A_{11}, A_{12}) is not completely controllable, perform a transformation T_1 in the state space of (3.17a),

$$(3.22) \quad \xi(s) \triangleq \left[\begin{array}{c|c} \frac{A_{11}}{C_1} & \frac{A_{12}}{C_2} \end{array} \right] \xrightarrow{T_1} \left[\begin{array}{c|c} \tilde{A}_{11} & \tilde{A}_{12} \\ 0 & \tilde{A}_{22} \\ \hline \tilde{C}_1 & \tilde{C}_2 \end{array} \middle| \begin{array}{c} \tilde{A}_{13} \\ 0 \\ C_2 \end{array} \right],$$

in which $(\tilde{A}_{11}, \tilde{A}_{13})$ is controllable.

(ii) Choose Ω_r as the destabilizing solution to the Riccati equation

$$(3.23) \quad \Omega_r(\tilde{A}_{11} - \tilde{A}_{13}C_2^*\tilde{C}_1) + (\tilde{A}_{11} - \tilde{A}_{13}C_2^*\tilde{C}_1)^*\Omega_r + \Omega_r\tilde{A}_{13}\tilde{A}_{13}^*\Omega_r - \tilde{C}_1^*C_\perp^*C_\perp\tilde{C}_1 = 0.$$

Since $(\tilde{A}_{11}, \tilde{A}_{13})$ is controllable by construction and since the corresponding Hamiltonian is free of $j\omega$ -axis eigenvalues ($\xi_{k+1}(j\omega)$ is full rank $\forall \omega \in \mathbb{R}$), $\Omega_r \geq 0$ is guaranteed to exist; see [8] for more details.

(iii) $V(s)$ is given by

$$(3.24) \quad V(s) = [v | V_\perp] \triangleq \left[\begin{array}{c|c} \frac{\tilde{A}_{11} + \tilde{A}_{13}(\tilde{A}_{13}^*\Omega_r - C_2^*\tilde{C}_1)}{C_\perp^*C_\perp\tilde{C}_1 + C_2\tilde{A}_{13}^*\Omega_r} & \frac{\tilde{A}_{13}}{C_2} \\ \hline \Omega_r^\# \tilde{C}_1^* C_\perp^* & C_\perp^* \end{array} \right].$$

Note that $[v | V_\perp]$ may also be described by the (nonminimal) realization

$$(3.25) \quad V(s) = [v | V_\perp] \triangleq \left[\begin{array}{c|c} \frac{A_{11} + A_{12}(A_{12}^*\Omega - C_2^*C_1)}{C_\perp^*C_\perp C_1 + C_2 A_{12}^*\Omega} & \frac{A_{12}}{C_2} \\ \hline \Omega^\# C_1^* C_\perp^* & C_\perp^* \end{array} \right],$$

in which

$$(3.26) \quad \Omega := T_1^* \begin{bmatrix} \Omega_r & 0 \\ 0 & 0 \end{bmatrix} T_1.$$

Similarly,

$$(3.27) \quad W(s) = [w | W_\perp] \triangleq \left[\begin{array}{c|c} \frac{-\bar{A}_{11}^* - \bar{A}_{31}^*(\bar{A}_{31}\tilde{\Omega}_r - B_2\bar{B}_1^*)}{B_\perp^*B_\perp\bar{B}_1^* + B_2^*\bar{A}_{31}\tilde{\Omega}_r} & \frac{-\bar{A}_{21}^*}{B_2^*} \\ \hline -\tilde{\Omega}^\# \bar{B}_1 B_\perp^* & B_\perp^* \end{array} \right],$$

where $\tilde{\Omega}_r$ denotes the destabilizing solution of

$$(3.28) \quad \tilde{\Omega}_r(\bar{A}_{11} - \bar{B}_1 B_2^* \bar{A}_{31})^* + (\bar{A}_{11} - \bar{B}_1 B_2^* \bar{A}_{31})\tilde{\Omega}_r + \tilde{\Omega}_r \bar{A}_{31}^* \bar{A}_{31} \tilde{\Omega}_r - \bar{B}_1 B_\perp^* B_\perp \bar{B}_1^* = 0$$

and the various blocks of (3.27) and (3.28) are defined by

$$(3.29) \quad \psi(s) \triangleq \left[\begin{array}{c|c} -A_{11}^* & -A_{21}^* \\ \hline B_1^* & B_2^* \end{array} \right] \xrightarrow{\tilde{T}_1} \left[\begin{array}{c|c} -\bar{A}_{11}^* & -\bar{A}_{21}^* \\ 0 & -\bar{A}_{22}^* \\ \hline \bar{B}_1^* & \bar{B}_2^* \end{array} \middle| \begin{array}{c} -\bar{A}_{31}^* \\ 0 \\ B_2^* \end{array} \right],$$

in which $(\bar{A}_{11}, \bar{A}_{31})$ is an observable pair. It is also convenient to define

$$(3.30) \quad \tilde{\Omega} = \tilde{T}_1^* \begin{bmatrix} \tilde{\Omega}_r & 0 \\ 0 & 0 \end{bmatrix} \tilde{T}_1$$

in the case that (A_{11}, A_{21}) is not completely observable.

The construction of Lemma 3.2 together with Theorem 3.1 and Lemma 3.1 imply that $V(s)$ and $W(s)$ will block-diagonalize all the optimal error systems $(G_0 + F)(s)$. Moreover, the augmented system

$$(3.31) \quad G_a(s) = \begin{bmatrix} G_0(s) & 0 \\ 0 & 0 \end{bmatrix} \in \mathbb{R}^{\mathcal{H}_-^{\infty, (p+m-1) \times (p+m-1)}}$$

will have Schmidt vectors $[f_{k+1}^T(s) \ 0]^T$ and $[g_{k+1}^T(s) \ 0]^T$ and hence will be block-diagonalized by

$$(3.32) \quad V_a(s) := \begin{bmatrix} V(s) & 0 \\ 0 & I_{m-1} \end{bmatrix}, \quad W_a(s) := \begin{bmatrix} W(s) & 0 \\ 0 & I_{p-1} \end{bmatrix}.$$

The next result establishes the required decomposition of the family of all optimal error systems.

LEMMA 3.3. *The generator of all k th-order optimal error systems $G_a + F(s)$ can be diagonalized as*

$$(3.33) \quad V_a^*(G_a + F)W_a(s) = \begin{bmatrix} \sigma_{k+1}a(s) & 0 & 0 \\ 0 & G_1 + Q_{11} & Q_{12} \\ 0 & Q_{21} & Q_{22} \end{bmatrix},$$

in which

- (i) $a(s)$ is all-pass (in fact, inner),
- (ii) $G_1(s) \in \mathcal{H}_+^\infty$ and $Q(s) \in \mathcal{H}_-^\infty(k)$,
- (iii) and

$$(3.34) \quad \frac{1}{\sigma_{k+1}(G_0)} \begin{bmatrix} G_1 + Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix}$$

is all-pass.

Proof. The augmented system $G_a(s)$ has Schmidt vectors $[f_{k+1}^T(s) \ 0]^T$ and $[g_{k+1}^T(s) \ 0]^T$ corresponding to the $(k+1)$ th Hankel singular value of $G_0(s)$ and is therefore block-diagonalized by $V_a(s)$ and $W_a(s)$. The fact that $V_a(s)$, $W_a(s)$, and $(G_a + F)(s)$ are all-pass implies that

$$(3.35) \quad \frac{1}{\sigma_{k+1}(G_0)} \begin{bmatrix} G_1 + Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix}$$

and $a(s)$ are all-pass.

To show that $a(s)$ is inner, one need only show that all the poles of F_{11} (which is defined in (2.14) and (2.15)) cancel when forming $v^*(G + F_{11})w(s)$. Since we never exploit the inner character of $a(s)$ we omit the proof.

Finally, to show that the decomposition in (ii) is valid, assume that $V_a^*(s)$, $W_a(s)$, and $F(s)$ have minimal realizations

$$(3.36) \quad V_a^*(s) = \begin{bmatrix} v^* \\ V_\perp^* \\ I_{m-1} \end{bmatrix} \triangleq \left[\begin{array}{c|cc} A_v & B_v & 0 \\ C_{1v} & d_{1v} & 0 \\ C_{2v} & D_{2v} & 0 \\ 0 & 0 & I_{m-1} \end{array} \right],$$

$$(3.37) \quad W_a(s) = \begin{bmatrix} w & W_\perp \\ I_{p-1} \end{bmatrix} \triangleq \left[\begin{array}{c|cc} A_w & B_{1w} & B_{2w} & 0 \\ C_w & d_{1w} & D_{2w} & 0 \\ 0 & 0 & 0 & I_{p-1} \end{array} \right],$$

and

$$(3.38) \quad F(s) \triangleq \left[\begin{array}{c|cc} A_f & B_{1f} & B_{2f} \\ C_{1f} & D_{11f} & D_{12f} \\ C_{2f} & D_{21f} & 0 \end{array} \right]$$

with $V_a^*(s)$, $W_a(s) \in \mathbb{R}\mathcal{H}_+^\infty$, and $F(s) \in \mathbb{R}\mathcal{H}_-^\infty(k)$. Next, let $F_{12}(s)$ admit a right coprime factorization

$$(3.39) \quad F_{12}(s) := NM^{-1}(s) \stackrel{s}{=} \left[\begin{array}{c|c} A_f + B_{2f}K & B_{2f} \\ \hline C_{1f} + D_{12f}K & D_{12f} \end{array} \right] \left[\begin{array}{c|c} A_f + B_{2f}K & B_{2f} \\ \hline K & I \end{array} \right]^{-1},$$

in which K is chosen so that $\lambda(A_f + B_{2f}K) \cap \lambda(A_v) = \emptyset$; Lemma A.1 in Appendix A shows that this is always possible. Next, $v^*F_{12}(s) = 0 \Rightarrow v^*N(s) = 0$, and we may write

$$(3.40) \quad \begin{aligned} 0 &\stackrel{s}{=} \left[\begin{array}{c|c} A_v & B_v \\ \hline C_{1v} & d_{1v} \end{array} \right] \left[\begin{array}{c|c} A_f + B_{2f}K & B_{2f} \\ \hline C_{1f} + D_{12f}K & D_{12f} \end{array} \right] \\ &\stackrel{s}{=} \left[\begin{array}{cc|c} A_v & B_v(C_{1f} + D_{12f}K) & B_vD_{12f} \\ 0 & A_f + B_{2f}K & B_{2f} \\ \hline C_{1v} & d_{1v}(C_{1f} + D_{12f}K) & d_{1v}D_{12f} \end{array} \right]. \end{aligned}$$

Now let X be the (unique) solution to the linear matrix equation

$$(3.41) \quad X(A_f + B_{2f}K) - A_vX + B_v(C_{1f} + D_{12f}K) = 0.$$

Since $V_a^*(s)$ is observable through its first output, the basis change

$$(3.42) \quad T = \begin{bmatrix} I & X \\ 0 & I \end{bmatrix}$$

in (3.40) establishes that

$$(3.43) \quad B_vD_{12f} + XB_{2f} = 0,$$

which when substituted back into (3.41) gives

$$(3.44) \quad XA_f - A_vX + B_vC_{1f} = 0.$$

A similar argument based on $F_{21}w(s) = 0$ will establish the existence of a matrix Y such that

$$(3.45) \quad YA_w - A_fY + B_{1f}C_w = 0$$

and

$$(3.46) \quad D_{21f}C_w - C_{2f}Y = 0.$$

Forming the product

$$(3.47) \quad \begin{aligned} &\begin{bmatrix} V_\perp^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} G + F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix} \begin{bmatrix} W_\perp & 0 \\ 0 & I \end{bmatrix} \\ &\stackrel{s}{=} \left[\begin{array}{cccc|cc} A_v & B_vC & B_vC_{1f} & B_vD_{11f}C_w & B_vD_{11f}D_{2w} & B_vD_{12f} \\ 0 & A & 0 & BC_w & BD_{2w} & 0 \\ 0 & 0 & A_f & B_{1f}C_w & B_{1f}D_{2w} & B_{2f} \\ 0 & 0 & 0 & A_w & B_{2w} & 0 \\ \hline C_{2v} & D_{2v}C & D_{2v}C_{1f} & D_{2v}D_{11f}C_w & D_{2v}D_{11f}D_{2w} & D_{2v}D_{12f} \\ 0 & 0 & C_{2f} & D_{21f}C_w & D_{21f}D_{2w} & 0 \end{array} \right] \end{aligned}$$

and introducing the state-space transformations

$$(3.48) \quad T_1 = \begin{bmatrix} I & 0 & X & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & I \end{bmatrix}, \quad T_2 = \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & I & Y \\ 0 & 0 & 0 & I \end{bmatrix}$$

together with equations (3.43)–(3.46) establishes the decomposition

$$(3.49) \quad \begin{bmatrix} V_{\perp}^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} G + F_{11} & F_{12} \\ F_{21} & F_{22} \end{bmatrix} \begin{bmatrix} W_{\perp} & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} G_1 & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix},$$

in which $G_1(s) \in \mathbb{R}\mathcal{H}_+^{\infty}$ and

$$(3.50) \quad Q(s) = \left[\begin{array}{c|cc} A_f & B_{1f}D_{2w} + YB_{2w} & B_{2f} \\ \hline D_{2v}C_{1f} - C_{2v}X & 0 & D_{2v}D_{12f} \\ C_{2f} & D_{21f}D_{2w} & 0 \end{array} \right] \in \mathbb{R}\mathcal{H}_-^{\infty}(k).$$

This proves the result. \square

Remark 3.1. A direct calculation from the state-space formula for the scaled Schmidt vectors gives the following concrete realization for $Q(s)$ in terms of Ω and $\tilde{\Omega}$ defined in (3.26) and (3.30):

$$(3.51) \quad Q(s) = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix} \triangleq \left[\begin{array}{c|cc} \hat{A} & \hat{B}_1 & \hat{B}_2 \\ \hline \hat{C}_1 & 0 & -\sigma I \\ \hat{C}_2 & \sigma I & 0 \end{array} \right] \\ = \left[\begin{array}{c|cc} \Gamma^{-1}(\sigma^2 A_{11}^* + \Sigma A_{11} \Sigma - \sigma C_1^* U B_1^*) & (\tilde{\Omega}^{\#} + \Gamma^{-1} \Sigma) B_1 B_{\perp}^* & -\sigma \Gamma^{-1} C_1^* C_{\perp}^* \\ \hline -C_{\perp} C_1 (\Sigma + \Omega^{\#} \Gamma) & 0 & -\sigma I \\ -\sigma B_{\perp} B_1^* & \sigma I & 0 \end{array} \right].$$

Before we state and prove the main theorem of the section a technical result that gives certain properties of the zeros of the off-diagonal blocks of $Q(s)$ defined in (3.51) is required.

LEMMA 3.4. *Let $Q(s)$ be defined as in (3.51). Then*

- (i) *all MacMillan zeros of $Q_{21}(s)$ and $Q_{12}(s)$ lie in the open right half plane;*
- (ii) *if λ is a stable eigenvalue of $\hat{A} - \sigma^{-1} \hat{B}_2 \hat{C}_1$, then it is an uncontrollable mode of (\hat{A}, \hat{B}_2) , and $-\bar{\lambda}$ is a MacMillan zero of $\xi_{k+1}(s)$;*
- (iii) *if λ is a stable eigenvalue of $\hat{A} + \sigma^{-1} \hat{B}_1 \hat{C}_2$, then it is an unobservable mode of (\hat{A}, \hat{C}_2) , and λ is a MacMillan zero of $\psi_{k+1}(s)$.*

Proof. The position of the eigenvalues of $\hat{A} - \sigma^{-1} \hat{B}_2 \hat{C}_1$ will be established directly from (3.51), from which it is clear that they are located at the eigenvalues of

$$(3.52) \quad \Phi = \hat{A} + \Gamma^{-1} C_1^* C_{\perp}^* C_{\perp} C_1 (\Sigma + \Omega^{\#} \Gamma).$$

Next, we substitute (A.2) into (3.52) and make the transformation T_1 in (3.22) to obtain

$$(3.53) \quad T_1^{-*} \Gamma \Phi \Gamma^{-1} T_1^* = T_1^{-*} [C_1^* C_{\perp}^* C_{\perp} C_1 \Omega^{\#} - A_{11}^* + C_1^* C_2 A_{12}^*] T_1^* \\ = \left[\begin{array}{cc} \tilde{C}_1^* C_{\perp}^* C_{\perp} \tilde{C}_1 \Omega_r^{\#} - \tilde{A}_{11}^* + \tilde{C}_1^* C_2 \tilde{A}_{13}^* & 0 \\ * & -\tilde{A}_{22}^* \end{array} \right],$$

in which $-\tilde{A}_{22}^*$ is completely unstable and Ω_r is the appropriate solution to the reduced-dimension Riccati equation (3.23). Suppose that $\exists \xi \neq 0$ and $s_0 \in \mathbb{C}_-$ such that

$$(3.54) \quad \xi^* (\tilde{C}_1^* C_{\perp}^* C_{\perp} \tilde{C}_1 \Omega_r^{\#} - \tilde{A}_{11}^* + \tilde{C}_1^* C_2 \tilde{A}_{13}^*) = s_0 \xi^*.$$

Then the product of ξ^* , the left-hand side of (3.23), and ξ can be shown to imply that

$$(3.55) \quad (\tilde{A}_{11} - \tilde{A}_{13} C_2^* \tilde{C}_1) \xi = -s_0 \xi$$

and

$$(3.56) \quad C_{\perp} \tilde{C}_1 \xi = 0.$$

Substituting from (A.2) gives

$$(3.57) \quad \xi^*[\bar{s}_0 I + \Gamma \hat{A} \Gamma^{-1} | C_1^* C_\perp^*] = 0,$$

so that

$$(3.58) \quad (\xi^* \Gamma)[- \bar{s}_0 I - \hat{A} | \hat{B}_2] = 0.$$

This shows that $-\bar{s}_0$ is an uncontrollable mode of (\hat{A}, \hat{B}_2) . Inspecting the realization of $Q_{12}(s)$ given in (3.51), we conclude that

- (i) all the MacMillan zeros of $Q_{12}(s)$ lie in the open right half plane, and
- (ii) every eigenvalue of $\hat{A} - \sigma^{-1} \hat{B}_2 \hat{C}_1$ that lies in the left half plane is an uncontrollable mode of $[\hat{A}, \hat{B}_2]$.

Since s_0 is an unstable unobservable mode of $[\tilde{A}_{11} - \tilde{A}_{13} C_2^* \tilde{C}_1, C_\perp \tilde{C}_1]$, it is zero of

$$(3.59) \quad \begin{bmatrix} sI - \tilde{A}_{11} & -\tilde{A}_{13} \\ \tilde{C}_1 & C_2 \end{bmatrix}$$

by [12, Lemma 4.3]. Since $[\tilde{A}_{11}, \tilde{A}_{13}, \tilde{C}_1, C_2]$ is minimal, s_0 is also a MacMillan zero of $\xi(s)$.

A dual argument will establish the position of the zeros of $Q_{21}(s)$. \square

We are now in a position to present a preliminary version of the main algorithm. In this case we make a simplifying assumption about the position of the zeros of the Schmidt vectors; this restriction is removed later in Theorem 3.2'.

THEOREM 3.2. *Assume that the Schmidt vectors $\xi_{k+1}(s)$ and $\psi_{k+1}^*(s)$ given in (3.17) are free of right-half-plane MacMillan zeros. Then the family $\tilde{\mathcal{F}}(s)$ of all approximations $F \in \mathcal{H}^\infty(k)$ that minimize the pair*

$$(3.60) \quad (s_1^\infty(G_0 + F), s_2^\infty(G_0 + F))$$

lexicographically is parameterized by

$$(3.61) \quad \tilde{\mathcal{F}}(s) = F_{11} + V_\perp(-Q_{11} + \tilde{\mathcal{F}}_1)W_\perp^*(s),$$

in which $\tilde{\mathcal{F}}_1$ denotes the family of all optimal k th-order approximations of $G_1(s)$, that is, every $F_1(s) \in \mathcal{H}^\infty(k)$ that satisfies $\|G_1 + F_1\|_\infty = \sigma_{k+1}(G_1)$.

Proof. By using the results of Lemma 3.3, the family of all optimal error systems (with respect to $s_1^\infty(\cdot)$) may be parameterized by

$$(3.62) \quad G_0 + \mathcal{F}(s) = \left\{ V(s)[(\sigma_{k+1}(G_0)a(s)) \oplus (G_1 + \mathcal{F}_l(Q, \Theta))]W^*(s) \mid \Theta(s) \in \frac{1}{\sigma_{k+1}(G_0)} \mathcal{B}\mathcal{H}_-^\infty \right\}.$$

Since $V(s)$, $W^*(s)$, and $a(s)$ are all-pass, the family of all approximations that minimize $s_2(G_0 + \mathcal{F})$ are generated by

$$(3.63) \quad \inf_{\Theta \in 1/\sigma_{k+1}(G_0)\mathcal{B}\mathcal{H}_-^\infty} \|G_1 + \mathcal{F}_l(Q, \Theta)\|_\infty = s_2^\infty(G_0 + \mathcal{F}).$$

It will now be shown that if $\xi_{k+1}(s)$ and $\psi_{k+1}^*(s)$ have no MacMillan zeros in the right half plane, the minimization problem in (3.63) is equivalent to the unconstrained problem

$$(3.64) \quad \inf_{\tilde{F} \in \mathcal{H}_-^\infty(l)} \|G_1 + \tilde{F}\|_\infty = \sigma_{l+1}(G_1),$$

where l is the MacMillan degree of the stable part of $Q(s)$. Since $Q(s) \in \mathcal{H}_-^\infty(l)$ and $\|Q_{22}\Theta\|_\infty < 1$, a small-gain argument [6], [11] shows that $\mathcal{F}_l(Q, \Theta) \in \mathcal{H}_-^\infty(l)$ for all $\Theta(s) \in 1/\sigma_{k+1}(G_0)\mathcal{B}\mathcal{H}_-^\infty$. By comparing (3.63) and (3.64) we may write

$$(3.65) \quad \inf_{\Theta(s) \in 1/\sigma_{k+1}(G_0)\mathcal{B}\mathcal{H}_-^\infty} \|G_1 + \mathcal{F}_l(Q, \Theta)\|_\infty \geq \inf_{\tilde{F} \in \mathcal{H}_-^\infty(l)} \|G_1 + \tilde{F}\|_\infty = \sigma_{l+1}(G_1).$$

It will be shown that every $\tilde{F} \in \mathcal{H}_-^\infty(I)$ that achieves the minimum in (3.64) is generated by some $\Theta(s) \in 1/\sigma_{k+1}(G_0)\mathcal{B}\mathcal{H}_-^\infty$ through $\mathcal{F}_l(Q, \Theta)$. This is based on an argument given in [5].

Since all the MacMillan zeros of $Q_{12}(s)$ lie in the open right half plane (Lemma 3.4), $Q_{12}(j\omega)$ is nonsingular for every $\omega \in \mathbb{R}$. This and the all-pass character of

$$(3.66) \quad \frac{1}{\sigma_{k+1}(G_0)} \begin{bmatrix} G_1 + Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix}$$

give

$$(3.67) \quad \|G_1 + Q_{11}\|_\infty < \sigma_{k+1}(G_0).$$

Furthermore,

$$(3.68) \quad \sigma_{l+1}(G_1) \leq \|G_1 + Q_{11}\|_\infty,$$

so that

$$(3.69) \quad \sigma_{l+1}(G_1) < \sigma_{k+1}(G_0).$$

In addition, we will demonstrate that

$$(3.70) \quad \{\mathcal{F}_l(Q, \Theta): \|\Theta(s)\|_\infty < 1/\sigma_{k+1}, \Theta \in \mathcal{H}_-^\infty\}$$

generates every $\tilde{F}(s) \in \mathcal{H}_-^\infty(I)$ with the property $\|G_1 + \tilde{F}\|_\infty < \sigma_{k+1}(G_0)$. Suppose that some $\tilde{F}(s)$ satisfies $\|G_1 + \tilde{F}\|_\infty < \sigma_{k+1}(G_0)$. Then

$$(3.71) \quad \tilde{\Theta}(s) = \mathcal{F}_l\left(\frac{1}{\sigma_{k+1}^2(G_0)} \begin{bmatrix} Q_{22}^* & Q_{12}^* \\ Q_{21}^* & G_1^* + Q_{11}^* \end{bmatrix}, G_1 + \tilde{F}(s)\right)$$

gives

$$(3.72) \quad \tilde{F}(s) = \mathcal{F}_l\left(\begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix}, \tilde{\Theta}(s)\right).$$

Since $\|G_1 + Q_{11}\|_\infty < \sigma_{k+1}(G_0)$ and $\|G_1 + \tilde{F}\|_\infty < \sigma_{k+1}(G_0)$, the linear fractional map defining $\tilde{\Theta}(s)$ is well posed and, furthermore, $\|\tilde{\Theta}(s)\|_\infty < \sigma_{k+1}^{-1}(G_0)$. It remains to be shown that $\tilde{\Theta}(s) \in \mathcal{H}_-^\infty$. Suppose, contrary to what will be proved, that $\tilde{\Theta}(s)$ has r poles in the left plane. This implies that the A -matrix for $\mathcal{F}_l(Q, \tilde{\Theta})$ has $l+r$ eigenvalues in the left half plane by a Nyquist-type argument [6], [14]. Since $\tilde{F} \in \mathcal{H}_-^\infty(I)$ by assumption, there must be at least r cancellations in the closed loop. Since any cancellation is constrained to occur at a zero of (3.52a) or (3.52b) (by [10, Thm. 4.3]), we obtain the required contradiction, since the zero of (3.52a) and (3.52b) are all in the open right half plane by Lemma 3.4 and the theorem's hypothesis.

It follows, therefore, that all optimal l th order approximations of $G_1(s)$ are generated through $\mathcal{F}_l(Q, \Theta)$, as claimed. As a consequence, the set of all $F(s)$'s that minimize $(s_1^\infty(G_0 + F), s_2^\infty(G_0 + F))$ lexicographically is parameterized by

$$(3.73) \quad \begin{aligned} \tilde{\mathcal{F}}(s) &= -G_0 + V \begin{bmatrix} \sigma_{k+1}(G_0)a(s) & 0 \\ 0 & G_1(s) + \mathcal{F}(s) \end{bmatrix} W^* \\ &= -G_0 + V \begin{bmatrix} \sigma_{k+1}(G_0)a(s) & 0 \\ 0 & G_1 + Q_{11} \end{bmatrix} W^* + V \begin{bmatrix} 0 & 0 \\ 0 & \mathcal{F}_1 - Q_{11} \end{bmatrix} W^* \\ &= \mathcal{F}_l(F, 0) + V_\perp(\tilde{\mathcal{F}}_1 - Q_{11}) W_\perp^* = F_{11}(s) + V_\perp(\tilde{\mathcal{F}}_1 - Q_{11}) W_\perp^*(s), \end{aligned}$$

where $\tilde{\mathcal{F}}_1(s)$ denotes the family of all l th-order optimal approximations of $G_1(s)$. Finally, by Lemma 3.4 and the theorem's hypothesis, all stable modes of \hat{A} are

controllable through \hat{B}_2 and observable through \hat{C}_2 , and so $l = \deg(Q_+) = \deg([F_{22}]_+) = k$. This completes the proof of the theorem. \square

Remark 3.2. Theorem 3.2 establishes that all solutions that minimize $s_2^\infty(G_0 + F)$ can be parameterized in terms of all solutions that minimize $s_1^\infty(G_1 + F_1)$, which is a problem of dimension $(p-1) \times (m-1)$. The procedure can now be continued until a single-input or single-output problem is encountered (or until $\deg(G_{i+1}) \leq \deg[(Q_{i+1})_+]$). At this point there is a unique optimal approximation and the process stops.

If the assumptions on the MacMillan zeros of the Schmidt vectors $\xi_{k+1}(s)$ and $\psi_{k+1}^*(s)$ in Theorem 3.2 are relaxed, the construction of Theorem 3.2' will generate the family of superoptimal approximations with respect to the first two singular values.

THEOREM 3.2'. (i) Let $Q(s)$ be defined as in (3.51). Then its off-diagonal blocks $Q_{12}(s)$ and $Q_{21}(s)$ may be factored as $Q_{12}(s) = \mathcal{B}(s)\bar{Q}_{12}(s)$ and $Q_{21}(s) = \bar{Q}_{21}(s)\mathcal{A}(s)$, where $\mathcal{B}(s)$ and $\mathcal{A}(s)$ are inner and have degrees equal to the number of modes in $\bar{O}(\hat{A}, \hat{C}_2) \cap C(\hat{A}, \hat{B}_2) \cap \mathbb{C}_-$ and $\bar{O}(\hat{A}, \hat{C}_2) \cap \bar{C}(\hat{A}, \hat{B}_2) \cap \mathbb{C}_-$, respectively.

(ii) The family $\tilde{\mathcal{F}}(s)$ of all approximations $F \in \mathcal{H}_-^\infty(k)$ that minimize the pair

$$(3.74) \quad (s_1^\infty(G_0 + F), s_2^\infty(G_0 + F))$$

lexicographically is parameterized by

$$(3.75) \quad \tilde{\mathcal{F}}(s) = F_{11} + V_\perp \mathcal{B}(\mathcal{F}_1 - [\bar{Q}_{11}]_+ - [\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^*]_-)\mathcal{A}W_\perp^*(s),$$

in which \mathcal{F}_1 denotes the family of all optimal l th-order Hankel-norm approximations to $[\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+$, where $l = \deg([F_{22}]_+) \leq k$ and $\bar{Q}_{11} \in \mathcal{H}_-^\infty(l)$ is defined in the proof.

Proof. We begin by putting $(\hat{A}, \hat{B}_2, \hat{C}_2)$ (defined in (3.51)) into the Kalman canonical form

$$(3.76) \quad \begin{bmatrix} \hat{A} & \hat{B}_2 \\ \hat{C}_2 & 0 \end{bmatrix} = \left[\begin{array}{cccc|c} \hat{A}_{11} & 0 & \hat{A}_{13} & 0 & \hat{B}_{12} \\ \hat{A}_{21} & \hat{A}_{22} & \hat{A}_{23} & \hat{A}_{24} & \hat{B}_{22} \\ 0 & 0 & \hat{A}_{33} & 0 & 0 \\ 0 & 0 & \hat{A}_{43} & \hat{A}_{44} & 0 \\ \hline \hat{C}_{21} & 0 & \hat{C}_{23} & 0 & 0 \end{array} \right],$$

so that

$$(3.77) \quad Q(s) \triangleq \left[\begin{array}{cccc|cc} \hat{A}_{11} & 0 & \hat{A}_{13} & 0 & \hat{B}_{11} & \hat{B}_{12} \\ \hat{A}_{21} & \hat{A}_{22} & \hat{A}_{23} & \hat{A}_{24} & \hat{B}_{21} & \hat{B}_{22} \\ 0 & 0 & \hat{A}_{33} & 0 & \hat{B}_{31} & 0 \\ 0 & 0 & \hat{A}_{43} & \hat{A}_{44} & \hat{B}_{41} & 0 \\ \hline \hat{C}_{11} & \hat{C}_{12} & \hat{C}_{13} & \hat{C}_{14} & 0 & -\sigma I \\ \hat{C}_{21} & 0 & \hat{C}_{23} & 0 & \sigma I & 0 \end{array} \right].$$

Next, we transform the controllable realization $(\hat{A}_{22}, [\hat{B}_{21} \ \hat{B}_{22}], \hat{C}_{12})$ into

$$(3.78) \quad \left[\begin{array}{c|cc} \hat{A}_{22} & \hat{B}_{21} & \hat{B}_{22} \\ \hline \hat{C}_{12} & 0 & 0 \end{array} \right] \triangleq \left[\begin{array}{ccc|cc} \hat{A}_{22}^{11} & \hat{A}_{22}^{12} & \hat{A}_{22}^{13} & \hat{B}_{21}^1 & \hat{B}_{22}^1 \\ 0 & \hat{A}_{22}^u & 0 & \hat{B}_{21}^2 & \hat{B}_{22}^2 \\ 0 & \hat{A}_{22}^{32} & \hat{A}_{22}^s & \hat{B}_{21}^3 & \hat{B}_{22}^3 \\ \hline 0 & \hat{C}_{12}^2 & \hat{C}_{12}^3 & 0 & 0 \end{array} \right],$$

where the three partitions correspond to the unobservable modes (\hat{A}_{22}^{11}) and the stable and unstable unobservable modes (\hat{A}_{22}^s and \hat{A}_{22}^u , respectively). We also note that \hat{A}_{22}^{11} is completely unstable by Lemma 3.4. A similar transformation is carried out on $(\hat{A}_{33}, \hat{B}_{31}, [\hat{C}_{13}^T \ \hat{C}_{23}^T]^T)$. Combining these gives

$$(3.79) \quad Q(s) \triangleq \left[\begin{array}{cccc|cccc|cc} \hat{A}_{11} & 0 & 0 & 0 & \hat{A}_{13}^1 & \hat{A}_{13}^2 & \hat{A}_{13}^3 & 0 & \hat{B}_{11} & \hat{B}_{12} \\ \hat{A}_{21}^1 & \hat{A}_{22}^{11} & \hat{A}_{22}^{12} & \hat{A}_{22}^{13} & \hat{A}_{23}^{11} & \hat{A}_{23}^{12} & \hat{A}_{23}^{13} & \hat{A}_{24}^1 & \hat{B}_{21}^1 & \hat{B}_{22}^1 \\ \hat{A}_{21}^2 & 0 & \hat{A}_{22}^u & 0 & \hat{A}_{23}^{21} & \hat{A}_{23}^{22} & \hat{A}_{23}^{23} & \hat{A}_{24}^2 & \hat{B}_{21}^2 & \hat{B}_{22}^2 \\ \hat{A}_{21}^3 & 0 & \hat{A}_{22}^{32} & \hat{A}_{22}^s & \hat{A}_{23}^{31} & \hat{A}_{23}^{32} & \hat{A}_{23}^{33} & \hat{A}_{24}^3 & \hat{B}_{21}^3 & \hat{B}_{22}^3 \\ 0 & 0 & 0 & 0 & \hat{A}_{33}^{11} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \hat{A}_{33}^{21} & \hat{A}_{33}^u & \hat{A}_{33}^{23} & 0 & \hat{B}_{31}^2 & 0 \\ 0 & 0 & 0 & 0 & \hat{A}_{33}^{31} & 0 & \hat{A}_{33}^s & 0 & \hat{B}_{31}^3 & 0 \\ 0 & 0 & 0 & 0 & \hat{A}_{43}^1 & \hat{A}_{43}^2 & \hat{A}_{43}^3 & \hat{A}_{44} & \hat{B}_{41} & 0 \\ \hline \hat{C}_{11} & 0 & \hat{C}_{12}^2 & \hat{C}_{12}^3 & \hat{C}_{13}^1 & \hat{C}_{13}^2 & \hat{C}_{13}^3 & \hat{C}_{14} & 0 & -\sigma I \\ \hat{C}_{21} & 0 & 0 & 0 & \hat{C}_{23}^1 & \hat{C}_{23}^2 & \hat{C}_{23}^3 & 0 & \sigma I & 0 \end{array} \right].$$

Next, we consider the minimal realization

$$(3.80) \quad [Q_{21} | Q_{22}] \triangleq \left[\begin{array}{ccc|cc} \hat{A}_{11} & \hat{A}_{13}^2 & \hat{A}_{13}^3 & \hat{B}_{11} & \hat{B}_{12} \\ 0 & \hat{A}_{33}^u & \hat{A}_{33}^{23} & \hat{B}_{31}^2 & 0 \\ 0 & 0 & \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \hat{C}_{21} & \hat{C}_{23}^2 & \hat{C}_{23}^3 & \sigma I & 0 \end{array} \right].$$

Since $\sigma^{-1}[Q_{21} \ Q_{22}]$ is part of an all-pass matrix by part (iii) of Lemma 3.3, (3.80) may be factored as

$$(3.81) \quad [Q_{21} | Q_{22}] = [\bar{Q}_{21} | Q_{22}] \begin{bmatrix} \mathcal{A} & 0 \\ 0 & I \end{bmatrix} \triangleq \left[\begin{array}{cc|cc} \hat{A}_{11} & \hat{A}_{13}^2 & \hat{B}_{11} & \hat{B}_{12} \\ 0 & \hat{A}_{33}^u & \hat{B}_{31}^2 & 0 \\ \hline \hat{C}_{21} & \hat{C}_{23}^2 & \sigma I & 0 \end{array} \right] * \left[\begin{array}{c|cc} \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \sigma^{-1} \hat{C}_{23}^3 & I & 0 \\ 0 & 0 & I \end{array} \right],$$

in which we may assume without loss of generality (by possibly redefining \hat{A}_{13}^3 , \hat{A}_{33}^{23} , \hat{C}_{23}^3 , \hat{B}_{11} , and \hat{B}_{31}^2) that $\mathcal{A}(s)$ is inner; details of this factorization appear in Appendix B. Similarly, a (left) inner factor $\mathcal{B}(s)$ may be extracted from $Q_{12} = \mathcal{B}(s)\bar{Q}_{12}$, leading to a realization

$$(3.82) \quad \left[\begin{array}{c} \bar{Q}_{12} \\ Q_{22} \end{array} \right] \triangleq \left[\begin{array}{cc|cc} \hat{A}_{11} & 0 & \hat{B}_{12} \\ \hat{A}_{21}^1 & \hat{A}_{22}^u & \hat{B}_{22}^2 \\ \hline \hat{C}_{11} & \hat{C}_{12}^2 & -\sigma I \\ \hat{C}_{21} & 0 & 0 \end{array} \right],$$

in which \hat{A}_{21}^1 , \hat{B}_{22}^2 , and \hat{C}_{11} may have been redefined. Next, we define

$$(3.83) \quad \bar{Q}(s) = \left[\begin{array}{cc} \bar{Q}_{11} & \bar{Q}_{12} \\ \bar{Q}_{21} & Q_{22} \end{array} \right] \triangleq \left[\begin{array}{ccc|cc} \hat{A}_{11} & 0 & \hat{A}_{13}^2 & \hat{B}_{11} & \hat{B}_{12} \\ \hat{A}_{21}^1 & \hat{A}_{22}^u & 0 & 0 & \hat{B}_{22}^2 \\ 0 & 0 & \hat{A}_{33}^u & \hat{B}_{31}^2 & 0 \\ \hline \hat{C}_{11} & \hat{C}_{12}^2 & 0 & 0 & -\sigma I \\ \hat{C}_{21} & 0 & \hat{C}_{23}^2 & \sigma I & 0 \end{array} \right].$$

Now,

$$\{\text{OHLP system zeros of the realization of } Q_{21} \text{ in (3.79)}\} \subseteq \lambda(\hat{A}_{22}^s) \cup \lambda(\hat{A}_{44}),$$

where OLHP denotes the open left half plane, implies that

$$\{\text{System zeros of the realization of } Q_{21} \text{ in (3.80)}\} \subseteq \mathbb{C}_+.$$

As a result of the all-pass factorization (3.81),

$$\begin{aligned} & \{\text{System zeros of the realization of } \bar{Q}_{21} \text{ in (3.83)}\} \\ & \subseteq \{\text{System zeros of the realization of } Q_{12}(s) \text{ in (3.80)}\} \cup \lambda(\hat{A}_{22}^u). \end{aligned}$$

We conclude that

$$\{\text{System zeros of the realization of } \bar{Q}_{21} \text{ in (3.83)}\} \subseteq \mathbb{C}_+.$$

A dual argument shows that the system zeros of the realization of \bar{Q}_{12} in (3.83) also lie in the open right half plane. Thus for any $\sigma\Theta \in \mathcal{BH}_-^\infty$

$$\begin{aligned} (3.84) \quad s_2^\infty(G_0 + \mathcal{F}) &= \|G_1 + \mathcal{F}_l(Q, \Theta)\|_\infty \\ &= \|G_1 + Q_{11} + Q_{12}\Theta(I - Q_{22}\Theta)^{-1}Q_{21}\|_\infty \\ &= \|G_1 + Q_{11} + \mathcal{B}\bar{Q}_{12}\Theta(I - Q_{22}\Theta)^{-1}\bar{Q}_{21}\mathcal{A}\|_\infty \\ &= \|\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11} + \mathcal{F}_l(\bar{Q}, \Theta)\|_\infty \\ &= \left\| [\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+ + \mathcal{F}_l\left(\begin{bmatrix} J & 0 \\ 0 & 0 \end{bmatrix} + \bar{Q}, \Theta\right) \right\|_\infty \\ &\cong \sigma_{l+1}\{[\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+\}, \end{aligned}$$

in which $J(s) := [\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_-$. We may now use the arguments of Theorem 3.2 to show that

$$\mathcal{F}_l\left(\begin{bmatrix} J & 0 \\ 0 & 0 \end{bmatrix} + \bar{Q}, \Theta\right)$$

generates all σ_{k+1} -suboptimal approximations of $[\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+$ in $\mathcal{H}_-^\infty(l)$. To do this we note the following:

(i) The matrix

$$(3.85) \quad \frac{1}{\sigma} \left\{ \begin{bmatrix} \mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11} & 0 \\ 0 & 0 \end{bmatrix} + \bar{Q} \right\}$$

is all-pass.

(ii) $\|\bar{Q}_{22}\|_\infty = \|F_{22}\|_\infty < \sigma$ and the system zeros of the off-diagonal blocks of

$$(3.86) \quad \begin{bmatrix} J & 0 \\ 0 & 0 \end{bmatrix} + \bar{Q}$$

lie in the open right halfplane. This follows from the fact that $J(s)$ is completely unstable.

(iii)

$$(3.87) \quad \bar{Q} \in \mathcal{H}_-^\infty(l), \quad \text{where } l = \deg([F_{22}]_+).$$

It follows that

$$(3.88) \quad \inf_{\omega \in \mathbb{R}} \{s_2^\infty(G_0 + \mathcal{F})\} = \sigma_{l+1}([\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+).$$

Finally, the family of all approximations in $\mathcal{H}_-^\infty(k)$ that minimize the first two singular values is obtained by back substitution as

$$(3.89) \quad \tilde{\mathcal{F}}(s) = F_{11} + V_\perp \mathcal{B}(\mathcal{F}_1 - [\bar{Q}_{11}]_+ - [\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^*]_-) \mathcal{A} W_\perp^*(s),$$

where \mathcal{F}_1 denotes the family of all optimal l th-order Hankel-norm approximations to $[\mathcal{B}^*(G_1 + Q_{11})\mathcal{A}^* - \bar{Q}_{11}]_+$. \square

A simple inductive generalization of Theorem 3.2' will establish the following algorithm for calculating the (unique) superoptimal approximation.

ALGORITHM 3.1.

Given any $G_0(s) \in \mathbb{R} \mathcal{H}_+^{\infty, p \times m}$, this algorithm finds $F_{so}(s) \in \mathcal{H}_-^{\infty, p \times m}(k)$, which is the superoptimal k th-order approximation of $G_0(s)$.

1. $r = \text{rank}(G_0) \leq \min(p, m)$
2. Find $F(s)$ for $G_0(s)$ (the generator of all optimal k -th-order approximations—use state-space formulas in (2.15)); set $F_0 = F$
3. $F_{so} = F_{11}$
4. $V = I_m$ and $W = I_p$
5. For $i = 0$ to $r - 1$
 1. Find $\xi_i(s)$ and $\psi_i(s)$ corresponding to $G_i(s)$, and construct $v_i(s)$, $w_i(s)$, $V_{\perp i}(s)$, and $W_{\perp i}(s)$ using state-space formulas (3.24) and (3.27)
 2. Define $G_{i+1}(s) \in \mathcal{H}_+^\infty$ and $Q_{i+1}(s) \in \mathcal{H}_-^\infty(k)$, through decompositions given in Lemma 3.3
 3. IF $\xi_i(s)$ and/or $\psi_i^*(s)$ have right-half-plane MacMillan zeros THEN
 1. Extract all-pass common factors $\mathcal{A}(s)$ and $\mathcal{B}(s)$ (see Theorem 3.2')
 2. Redefine

$$V_{\perp i}(s) := V_{\perp i}(s)\mathcal{B}(s), \quad W_{\perp i}^*(s) := \mathcal{A}(s)W_{\perp i}^*(s),$$

$$\tilde{Q}_{i+1}(s) := [\bar{Q}_{i+1}^{11}]_+ + [\mathcal{B}^*(G_{i+1} + Q_{i+1}^{11})\mathcal{A}^*]_-,$$

$$G_{i+1}(s) := [\mathcal{B}^*(G_{i+1} + Q_{i+1}^{11})\mathcal{A}^* - \tilde{Q}_{i+1}^{11}]_+,$$
 - ELSE $\tilde{Q}_{i+1}(s) := Q_{i+1}^{11}(s)$
 4. $l = \deg([F_i^{22}]_+)$
 5. Find F_{i+1} , the generator of all l th-order optimal approximations to G_{i+1} (using (2.15))
 6. $V = VV_{\perp i}$ and $W = WW_{\perp i}$
 7. $F_{so}(s) := F_{so} + V(F_{i+1}^{11} - \tilde{Q}_{i+1})W^*(s) \in \mathcal{H}_-^\infty(k)$

Note that if the above algorithm is terminated after $l < r$ steps, the first $l + 1$ singular values will be minimized and

$$(3.90) \quad F_{so}^{(l)}(s) = F_{11}(s) + \sum_{j=0}^l \left\{ \prod_{i=0}^j V_{\perp i}(-Q_{j+1} + F_{j+1}) \left(\prod_{i=0}^j W_{\perp i} \right)^* \right\}(s)$$

will have no more than k poles in the open left half plane.

Remark 3.3. In the usual case for which the realizations of f_{k+1} and g_{k+1}^* in (3.15) are free from left-half-plane zeros, a pole-zero cancellation analysis similar to the one carried out in [9] establishes the existence of extensions that are optimal with respect to the first two singular values and are such that $\deg(F_{so}^{(2)}) \leq 2n - 3$. If this assumption holds for all G_i 's generated by Algorithm 3.1, it can be shown that

$$\deg(F_{so}) \leq \sum_{i=1}^{\text{rank}(G_0)} (n - i).$$

The cancellation analysis is moderately intricate and is consequently omitted. \square

Example 3.1. In this example we illustrate a number of the features of Algorithm 3.1. Suppose $G(s) = C(sI - A)^{-1}B$ is given by

$$(3.91) \quad A = \begin{bmatrix} -2\mu(\mu^2 - 1)^{-2} & 2(\mu^2 - 1)^{-1} & a_{13} \\ 2\mu(\mu^2 - 1)^{-1} & -1 & -1 \\ a_{31} & 2 & -2 \end{bmatrix},$$

$$B = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & b_{12} \\ \sqrt{2} & 0 \\ -3\sqrt{2}/4 & \frac{1}{2}\sqrt{7/2} \end{bmatrix}, \quad C^T = \frac{1}{\sqrt{2}} \begin{bmatrix} \sqrt{2}\mu/(\mu^2 - 1) & -\sqrt{2}\mu/(\mu^2 - 1) \\ 1 & 1 \\ 1 & -1 \end{bmatrix},$$

in which $\mu > 1$ and

$$(3.92a) \quad a_{13} = \frac{19\mu^2 - 3 - \sqrt{7(4\mu^2 - (\mu^2 - 1)^2)}}{\sqrt{2}(\mu^2 - 1)(1 - 4\mu^2)},$$

$$(3.92b) \quad a_{31} = \frac{\sqrt{2}\mu(-1 - 3\mu^2 + \sqrt{7(4\mu^2 - (\mu^2 - 1)^2)})}{(\mu^2 - 1)(1 - 4\mu^2)},$$

$$(3.92c) \quad b_{12} = \frac{\sqrt{4\mu^2 - (\mu^2 - 1)^2}}{\mu^2 - 1}.$$

It may be verified that (3.91) is balanced with controllability and observability gram-mians

$$(3.93) \quad P = Q = \Sigma = \text{diag}(\mu/2, 0.5, 0.25).$$

By applying the triangularizing transformation

$$(3.94) \quad T = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ -2\mu(\mu^2 - 1)^{-1} & 0 & 1 \end{bmatrix}$$

to

$$(3.95) \quad \begin{bmatrix} sI - A_{11} & -A_{12} \\ C_1 & C_2 \end{bmatrix},$$

we conclude that the scaled Schmidt vector $\xi_3(s) = C_2 + C_1(sI - A_{11})^{-1}A_{12}$ corresponding to $\sigma_3 = 0.25$ has a single MacMillan zero in the open right half plane for every $\mu > 1$. In the remainder of this example we fix μ at $\mu = 1.2$ and seek the superoptimal Hankel-norm approximation to $G(s)$ over $\mathcal{H}_-^\infty(2)$.

A realization of $F(s)$ (defined in (2.15)) that generates all optimal approximations with respect to the first singular value may be calculated as

$$(3.96) \quad F(s) \triangleq \left[\begin{array}{cc|ccc} -11.196 & 0 & 3.8569 & 5.5031 & 0 \\ -5.0997 & -1.6667 & 2.6667 & 0 & -1.3333 \\ \hline -1.2868 & -0.4861 & 0.1326 & -0.1169 & -0.1768 \\ 1.2868 & -0.2210 & -0.1326 & 0.1169 & -0.1768 \\ \hline -0.8278 & -0.1654 & 0.1654 & 0.1875 & 0 \end{array} \right],$$

in which we note that a stable mode ($\lambda = -11.196$) is uncontrollable through the last column of the B -matrix (\hat{B}_2). The decomposition of Lemma 3.3 is now carried out to

give

$$(3.97) \quad Q(s) \triangleq \left[\begin{array}{cc|cc} -11.196 & 0 & 8.0841 & 0 \\ -5.0997 & -1.6667 & -1.9608 & -1.3333 \\ \hline 0 & -0.5767 & 0 & -0.2500 \\ -0.8278 & -0.1654 & 0.2500 & 0 \end{array} \right]$$

and

$$(3.98) \quad G_1(s) \triangleq \left[\begin{array}{cc|c} -0.9485 & -2.6797 & -2.6388 \\ 1.7808 & -11.662 & 4.7682 \\ \hline 0.7585 & 0.13606 & 0 \end{array} \right],$$

which may be written in transfer function form as

$$(3.99) \quad Q(s) = \left[\begin{array}{cc} \frac{1.3727(s+32.221)}{(s+11.196)(s+1.6667)} & -\frac{0.25(s-1.4142)}{s+1.6667} \\ \frac{0.25(s-1.4142)(s-11.196)}{(s+1.6667)(s+11.196)} & \frac{0.22048}{s+1.6667} \end{array} \right]$$

and

$$(3.100) \quad G_1(s) = -\frac{1.3532(s+24.434)}{(s+11.196)(s+1.4142)}.$$

Note that because of the presence of a minimum-phase system zero in the realization of $Q_{12}(s)$ in (3.97) (due to the uncontrollable mode $\lambda = -11.198$), $\mathcal{F}_l(Q, \sigma_3^{-1}\mathcal{B}\mathcal{H}^\infty)$ does not generate all the $\sigma_3 = 0.25$ -suboptimal approximations of $G_1(s)$ in $\mathcal{H}^\infty(2)$. We may now extract the inner factor

$$(3.101) \quad \mathcal{A}(s) = \frac{s-11.196}{s+11.196}$$

corresponding to this zero, so that

$$(3.102) \quad G_1(s) + \mathcal{F}_l(Q, \sigma_3^{-1}\Theta) = (\bar{G}_1 + \mathcal{F}_l(\bar{Q}, \sigma_3^{-1}\Theta))\mathcal{A}(s),$$

in which

$$(3.103) \quad \bar{G}_1 := -\frac{1.3532(s+24.434)}{(s-11.196)(s+1.4142)}$$

and

$$(3.104) \quad \bar{Q}(s) = \left[\begin{array}{cc} \frac{1.3727(s+32.221)}{(s-11.196)(s+1.6667)} & -\frac{0.25(s-1.4142)}{s+1.6667} \\ \frac{0.25(s-1.4142)}{s+1.6667} & \frac{0.22048}{s+1.6667} \end{array} \right].$$

Furthermore, it may be verified that

$$(3.105) \quad \mathcal{F}_l\left(\bar{Q} + \begin{bmatrix} [\bar{G}_1]_- & 0 \\ 0 & 0 \end{bmatrix}, \sigma_3^{-1}\mathcal{B}\mathcal{H}^\infty\right)$$

generates all σ_3 -suboptimal approximations of $[\bar{G}_1]_+$ in $\mathcal{H}^\infty(1)$, so that

$$(3.106) \quad s_2^\infty(G+F) = \inf_{F_1 \in \mathcal{H}^\infty(1)} \|[\bar{G}_1]_+ + F_1\|_\infty = 0,$$

which is in agreement with Remark 2.2. The superoptimal approximation is finally obtained as

$$(3.107) \quad F_{so} = F_{11} - V_{\perp}(G_1 + Q_{11})W_{\perp}^* \\ = \left[\begin{array}{ccc|cc} -11.244 & 0.5310 & 0 & 4.0836 & 5.6906 \\ -8.8849 & -1.3664 & 0 & 0.9722 & -1.2665 \\ 0 & 0 & 1.4142 & -0.1467 & -0.0541 \\ \hline -1.3554 & -0.6586 & -0.1297 & 0.1326 & -0.1169 \\ 1.1951 & -0.3677 & 0.3130 & -0.1326 & 0.1169 \end{array} \right].$$

4. Conclusions. The purpose of this paper is to develop an implementable state-space version of Young's algorithm for superoptimal Hankel-norm approximations [16]. The new Algorithm 3.1 requires only standard linear algebraic library routines and has the added advantage that it can be stopped after only $l < r$ steps. In this event, the procedure produces a representation formula for all the approximations in $\mathcal{H}_{-}^{\infty}(k)$ that minimize $\{s_1^{\infty}(G_0 + \mathcal{F}), s_2^{\infty}(G_0 + \mathcal{F}), \dots, s_l^{\infty}(G_0 + \mathcal{F})\}$ with respect to lexicographic ordering.

Appendix A.

LEMMA A.1. *Let \tilde{A} denote the A -matrix of a minimal realization of $V^*(s)$. Then there exists a matrix K such that $\lambda(A_f + B_{2f}K) \cap \lambda(\tilde{A}) = \emptyset$.*

Proof. Since \tilde{A} is stable, it suffices to show that every stable eigenvalue of A_f that is uncontrollable through B_{2f} does not belong to the spectrum of \tilde{A} . Suppose for contradiction that λ is such an eigenvalue. Then $\exists \beta \neq 0$ such that

$$(A.1) \quad \beta^*[\lambda I - A_f | B_{2f}] = 0.$$

It follows by using (2.15), (2.6), and (2.7) that

$$(A.2) \quad \Gamma^{-1}A_f^*\Gamma + \Sigma\Gamma^{-1}C_1^*C_{\perp}^*C_1 = \Gamma^{-1}(\sigma^2A_{11} + \Sigma A_{11}^*\Sigma - \sigma B_1U^*C_1)\Gamma \\ + \Sigma\Gamma^{-1}C_1^*(I - C_2C_2^*)C_1 \\ = \Gamma^{-1}(\sigma^2A_{11} + \sigma B_1B_2^*C_2^*C_1 - \Sigma^2A_{11} - \Sigma C_1^*C_2C_2^*C_1) \\ = -A_{11} + A_{12}C_2^*C_1.$$

Substituting (A.2) into (A.1) yields

$$(A.3) \quad \tilde{\beta}^*[\lambda I + A_{11}^* + C_1^*C_2A_{12}^* | C_1^*C_{\perp}^*] = 0,$$

where $\tilde{\beta} = \Gamma^{-1}\beta$. Next, we introduce the transformation T_1 , defined in (3.22), to (A.3). This gives

$$(A.4) \quad \begin{bmatrix} \hat{\beta}_1^* & \hat{\beta}_2^* \end{bmatrix} \begin{bmatrix} \lambda I + \tilde{A}_{11}^* - \tilde{C}_1^*C_2\tilde{A}_{13}^* & 0 & \tilde{C}_1^*C_{\perp}^* \\ \tilde{A}_{12}^* - \tilde{C}_2^*C_2\tilde{A}_{13}^* & \lambda I + \tilde{A}_{22}^* & \tilde{C}_2^*C_{\perp}^* \end{bmatrix} = 0,$$

which implies that

$$(A.5) \quad \hat{\beta}_1^*(\lambda I + \tilde{A}_{11}^* - \tilde{C}_1^*C_2\tilde{A}_{13}^*) + \hat{\beta}_2^*(\tilde{A}_{12}^* - \tilde{C}_2^*C_2\tilde{A}_{13}^*) = 0,$$

$$(A.6) \quad \hat{\beta}_2^*(\lambda I + \tilde{A}_{22}^*) = 0,$$

$$(A.7) \quad \hat{\beta}_1^*\tilde{C}_1^*C_{\perp}^* + \hat{\beta}_2^*\tilde{C}_2^*C_{\perp}^* = 0.$$

Now, since $\lambda \in \mathbb{C}_{-}$ and $\lambda(-\tilde{A}_{22}^*) \subseteq \lambda(-A_{11}^*) \subseteq \mathbb{C}_{+}$,

$$(A.8) \quad (A.6) \Rightarrow \hat{\beta}_2^* = 0 \Rightarrow \hat{\beta}_1^* \neq 0.$$

Thus

$$(A.9) \quad (A.5) \Rightarrow \hat{\beta}_1^*(\lambda I + \tilde{A}_{11}^* - \tilde{C}_1^* C_2 \tilde{A}_{13}^*) = 0,$$

$$(A.10) \quad (A.7) \Rightarrow \hat{\beta}_1^* \tilde{C}_1^* C_\perp^* = 0.$$

From the multiplication of $\hat{\beta}_1^*$, the left-hand side of (3.23), and $\hat{\beta}_1$ we obtain

$$(A.11) \quad -2 \operatorname{Re}(\lambda) \hat{\beta}_1^* \Omega_r \hat{\beta}_1 + \hat{\beta}_1^* \Omega_r \tilde{A}_{13} \tilde{A}_{13}^* \Omega_r \hat{\beta}_1 = 0 \Rightarrow \Omega_r \hat{\beta}_1 = 0,$$

since $\operatorname{Re}(\lambda) < 0$. It follows from (3.24) that

$$(A.12) \quad v^*(s) \triangleq \left[\frac{-\tilde{A}_{11}^* - (\Omega_r \tilde{A}_{13} - \tilde{C}_1^* C_2) \tilde{A}_{13}^*}{-\tilde{A}_{13}^*} \middle| \frac{\tilde{C}_1^* C_\perp^* C_\perp + \Omega_r \tilde{A}_{13} C_2}{C_2^*} \right],$$

and it is easy to show by using (A.11) that λ is an uncontrollable mode of this realization, which proves the result. \square

Appendix B.

LEMMA B.1. $[Q_{21} | Q_{22}]$ in (3.80) may be factored as

$$(B.1) \quad \left[\begin{array}{cc|cc} \hat{A}_{11} & \hat{A}_{13}^2 & \hat{B}_{11} & \hat{B}_{12} \\ 0 & \hat{A}_{33}^u & \hat{B}_{31}^2 & 0 \\ \hline \hat{C}_{21} & \hat{C}_{23}^2 & \sigma I & 0 \end{array} \right] * \left[\begin{array}{cc|cc} \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \sigma^{-1} \hat{C}_{23}^3 & I & 0 \\ 0 & 0 & I \end{array} \right],$$

in which $\mathcal{A}(s) \triangleq (\hat{A}_{33}^s, \hat{B}_{31}^3, \sigma^{-1} \hat{C}_{23}^3, I)$ is inner.

Proof. Consider the minimal realization

$$(B.2) \quad [Q_{21} | Q_{22}] \triangleq \left[\begin{array}{ccc|cc} \hat{A}_{11} & \hat{A}_{13}^2 & \hat{A}_{13}^3 & \hat{B}_{11} & \hat{B}_{12} \\ 0 & \hat{A}_{33}^u & \hat{A}_{33}^{23} & \hat{B}_{31}^2 & 0 \\ 0 & 0 & \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \hat{C}_{21} & \hat{C}_{23}^2 & \hat{C}_{23}^3 & \sigma I & 0 \end{array} \right]$$

with controllability grammian

$$(B.3) \quad P = \begin{bmatrix} P_{11} & P_{12} \\ P_{12}^* & P_{22} \end{bmatrix},$$

in which $\dim(P_{11}) = \dim(\hat{A}_{11}) + \dim(\hat{A}_{33}^u)$. We will assume the following without loss of generality:

(i) $P_{12} = 0$. This may be achieved by introducing the state-space transformation

$$(B.4) \quad T = \begin{bmatrix} I & -P_{12}P_{22}^{-1} \\ 0 & I \end{bmatrix}$$

in (B.2) while noting that \hat{A}_{33}^s asymptotically stable implies that $P_{22} > 0$. Note also that $\hat{A}_{13}^3, \hat{A}_{33}^{23}, \hat{C}_{23}^3, \hat{B}_{11}$, and \hat{B}_{31}^2 are redefined as the result of this transformation.

(ii) $P_{22} = I$, i.e., the realization $(\hat{A}_{33}^s, \hat{B}_{31}^3)$ is input balanced.

Next, consider the all-pass equations corresponding to

$$(B.5) \quad \sigma^{-1} [Q_{21} | Q_{22}] \triangleq \left[\begin{array}{ccc|cc} \hat{A}_{11} & \hat{A}_{13}^2 & \hat{A}_{13}^3 & \hat{B}_{11} & \hat{B}_{12} \\ 0 & \hat{A}_{33}^u & \hat{A}_{33}^{23} & \hat{B}_{31}^2 & 0 \\ 0 & 0 & \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \sigma^{-1} \hat{C}_{21} & \sigma^{-1} \hat{C}_{23}^2 & \sigma^{-1} \hat{C}_{23}^3 & I & 0 \end{array} \right] \\ \triangleq \left[\begin{array}{cc|cc} \tilde{A}_{11} & \tilde{A}_{12} & \tilde{B}_{11} & \tilde{B}_{12} \\ 0 & \hat{A}_{33}^s & \hat{B}_{31}^3 & 0 \\ \hline \sigma^{-1} \tilde{C}_1 & \sigma^{-1} \hat{C}_{23}^3 & I & 0 \end{array} \right].$$

These may be written out in full as

$$(B.6) \quad \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ 0 & \hat{A}_{33}^s \end{bmatrix} \begin{bmatrix} P_{11} & 0 \\ 0 & I \end{bmatrix} + \begin{bmatrix} P_{11} & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \tilde{A}_{11} & \tilde{A}_{12} \\ 0 & \hat{A}_{33}^s \end{bmatrix}^* \\ + \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ \hat{B}_{31}^3 & 0 \end{bmatrix} \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ \hat{B}_{31}^3 & 0 \end{bmatrix}^* = 0$$

and

$$(B.7) \quad [I \quad 0] \begin{bmatrix} \tilde{B}_{11} & \tilde{B}_{12} \\ \hat{B}_{31}^3 & 0 \end{bmatrix} + [\sigma^{-1} \tilde{C}_1 \quad \sigma^{-1} C_{23}^3] \begin{bmatrix} P_{11} & 0 \\ 0 & I \end{bmatrix} = 0,$$

from which we get

$$(B.8) \quad (\hat{B}_{31}^3)^* = -\sigma^{-1} \hat{C}_{23}^3$$

and

$$(B.9) \quad \tilde{A}_{12} = -\sigma^{-1} \tilde{B}_{11} \hat{C}_{23}^3.$$

(B.8) and (B.9) may now be used to establish the required decomposition, while (B.8) and the (2, 2) block of (B.6) show that $\mathcal{A}(s)$ is inner. \square

DYNAMICAL BOUNDARY CONTROL FOR ELASTIC PLATES OF GENERAL SHAPE*

LAWRENCE MARKUS† AND YUNCHENG YOU‡

Abstract. The control of transverse vibrations of elastic plates of general shape by feedback boundary control is formulated as an abstract evolution equation. Because the control acts locally on the boundary, which possesses a flanged rim with inertial properties of mass and bending moment, the analysis concerns dynamical controllability and stabilizability of a hybrid system. By the approach of energy decay inequalities and Hörmander's global uniqueness theorem, it is shown that the system is strongly stabilizable by a locally supported damping feedback of boundary velocity and boundary angular velocity, and hence the system is approximately controllable.

Key words. dynamical boundary control, hybrid system, elastic plate, abstract evolution equation, stabilization

AMS subject classifications. 35Q72, 47D06, 73C02, 93C20

1. Geometry of hybrid control systems: summary of results. Earlier investigations [10]–[12] established the ability to control and stabilize the transverse vibrations of an elastic beam, clamped at one end, by feedback damping with dynamical control forces and torques acting on the other end. The present study was motivated by the control requirements of a space satellite supporting an elastic beam (governed by the Euler-Bernoulli partial differential equation) attached to an antenna with mass and moment of inertia (governed by Newtonian ordinary differential equations) on which the control acts by means of rocket thrust and couples. In this sense the total system is a hybrid system consisting of a partial differential equation and two coupled ordinary differential equations through which the control dynamics are filtered.

This type of hybrid control system was generalized [17], [18] to two-dimensional, rectangular elastic plates with inertial properties along the controlled edge, which is rimmed with a flange or lip that has inertial properties. Here the distributed system is governed by the Petrovsky equation for the small displacement $u(t, x, y)$ of a homogeneous, thin elastic plate over the region Ω at time $t \geq 0$,

$$\frac{\partial^2 u}{\partial t^2} + \Delta^2 u = 0 \quad \text{in } R^+ \times \Omega,$$

with suitable boundary conditions at the three clamped sides and dynamical boundary control from the free side. As usual, Δ^2 is the biharmonic operator and the physical units are appropriately chosen. The control system is then reformulated as an abstract evolution equation in a suitable Hilbert space. This framework will also be used in the present investigation.

It is important to note that in all these previous investigations of elastic beams and rectangular plates with dynamical boundary control, the explicit distribution of eigenvalues plays an essential role. The methods in [11] show that the stabilization of beam vibration proceeds with a subexponential decay rate. It is possible, and this is an open issue, that this behavior is a feature common to all similar hybrid systems.

Of course, there is a highly developed theory of the exact controllability and stabilization of elastic systems, including plates governed by the usual (static) boundary control without any inertial properties arising from the boundary (see [3]–[9]). Since these other configurations have no dynamical equations ascribed to the controlled boundary, they do not fit the theory of hybrid control systems as it is developed in this paper. To the authors' knowledge, the well-known Hilbert uniqueness method [9] does not apply directly to our problem of the strong stabilization of hybrid control systems, because if the Hilbert uniqueness method could be adapted to this problem, then it would result in exact controllability and stabilization at a uniform exponential rate. However, by such a dynamical boundary-damping feedback one generally cannot expect an exponential decay rate, for some intrinsic reasons, as is indicated in [11] for the case of a one-dimensional beam.

Here we consider the small transverse deflection $u(t, x, y)$ of a thin, isotropic, homogeneous elastic plate over a region Ω at time $t \geq 0$. The region Ω is an open, bounded, and connected set in R^2 , with a boundary $\Gamma = \partial\Omega$ consisting of a finite set of simple closed curves. Assume that Γ is piecewise smooth and that the inward uniform cone condition is satisfied everywhere on Γ . For easy reference we shall designate Ω as a *region of finite genus*.

Assume that the boundary $\Gamma = \partial\Omega$ consists of two disjoint pieces: Γ_0 on which the plate is clamped and Γ_1 along which the plate is free on part Γ_f of Γ_1 and is controlled on $\Gamma_c = \Gamma_1 \setminus \Gamma_f$. Here, Γ_0 (the union of arcs on some boundary curves of Ω) is a closed subset of Γ with a nonempty relative interior in Γ , so Γ_1 is relatively open in Γ . Also, the controlled part Γ_c is relatively open in Γ_1 , and its linear measure is positive, i.e., $\text{meas}_1(\Gamma_c) > 0$. Moreover, the inertial properties of the rim are restricted to Γ_c only.

Following the classical elasticity theory [3]–[5], [14] of small vibrations $u(t, x, y)$ of thin, isotropic, homogeneous elastic plates over a plane region Ω of finite genus, we can formulate the aforementioned boundary control problem as follows:

$$\begin{aligned}
 & \frac{\partial^2 u}{\partial t^2} + \Delta^2 u = 0 && \text{in } R^+ \times \Omega, \\
 & u = \frac{\partial u}{\partial n} = 0, && \text{on } R^+ \times \Gamma_0 \text{ (clamped boundary } \Gamma_0), \\
 & \Delta u + (1 - \sigma)A_2 u = 0 && \text{on } R^+ \times \Gamma_f \text{ (no shearing force on } \Gamma_f), \\
 (1) \quad & \frac{\partial \Delta u}{\partial n} + (1 - \sigma)A_1 u = 0 && \text{on } R^+ \times \Gamma_f \text{ (no bending torque on } \Gamma_f), \\
 & \frac{\partial^2 u}{\partial t^2} = k_1 \left[\frac{\partial \Delta u}{\partial n} + (1 - \sigma)A_1 u \right] + f_1(t, x, y) && \text{on } R^+ \times \Gamma_c \text{ (control force),} \\
 & \frac{\partial^2 u_n}{\partial t^2} = -k_2 [\Delta u + (1 - \sigma)A_2 u] + f_2(t, x, y) && \text{on } R^+ \times \Gamma_c \text{ (control torque),} \\
 & u(0, x, y) = u_0(x, y) \quad \text{and} \quad u_t(0, x, y) = u_1(x, y) && \text{in } \Omega \text{ (initial data).}
 \end{aligned}$$

Here the inertial properties of the boundary are supported along the rim of Γ_c where the control shearing force (per unit boundary mass) $f_1(t, x, y)$ and the bending torque (without twisting) $f_2(t, x, y)$ act as dynamic controllers. Here $k_1^{-1} = \rho > 0$ is the linear boundary density and $k_2^{-1} = J > 0$ is the bending moment of inertia per unit length of the boundary, and these are constants with appropriate physical units.

The two operators A_1 and A_2 are defined by

$$(2) \quad A_1 u = \frac{\partial}{\partial s} [(n_1^2 - n_2^2)u_{xy} + n_1 n_2 (u_{yy} - u_{xx})], \quad A_2 u = 2n_1 n_2 u_{xy} - n_1^2 u_{yy} - n_2^2 u_{xx},$$

where $n = (n_1, n_2)$ is the outward unit normal vector to Γ and s is the arc length sensed by $(-n_2, n_1)$ along Γ . The physical constant $0 < \sigma < \frac{1}{2}$ is the Poisson ratio of elasticity.

Example. Let Ω be an annulus described in polar coordinates (r, θ) by

$$\Omega = \{(r, \theta) : 0 < \delta < r < 1, 0 \leq \theta < 2\pi\},$$

with Γ_0 being the inner circle ($r = \delta$) and $\Gamma_c = \Gamma_1$ being the outer circle ($r = 1$). Assume that the elastic plate over Ω is clamped on the inner circle Γ_0 and that the boundary dynamic controls act on Γ_c . We have $r = 1$, $s = \theta$, and $(n_1, n_2) = (\cos \theta, \sin \theta)$, so $u_n = \partial u / \partial r$ and the operators A_1 and A_2 take the form

$$A_1 u = \frac{\partial}{\partial \theta} \left[\cos(2\theta) u_{xy} + \frac{1}{2} \sin(2\theta) (u_{yy} - u_{xx}) \right],$$

$$A_2 u = \sin(2\theta) u_{xy} - \cos^2 \theta u_{yy} - \sin^2 \theta u_{xx}.$$

This example will be used later to illustrate our general results of Theorems 1 and 2.

Our main results in this paper assert that for the hybrid control system of an elastic plate of general shape (Ω is a plane region of finite genus), the corresponding evolution system is strongly stabilizable by boundary-damping feedback

$$f_1 = -\frac{\partial u}{\partial t}(t, x, y) \quad \text{and} \quad f_2 = -\frac{\partial^2 u}{\partial t \partial n}(t, x, y) \quad \text{on } R^+ \times \Gamma_c.$$

Consequently, this hybrid system is approximately controllable by open-loop controllers $f_1(t, x, y)$ and $f_2(t, x, y)$ supported on the arc Γ_c .

2. Abstract evolution equation. In this section we set a framework to deal with the hybrid control system described by (1). Denote by H the product Hilbert space

$$H = L^2(\Omega) \times L^2(\Gamma_c) \times L^2(\Gamma_c),$$

with the inner product defined by

$$\langle (u, u_1, u_2), (v, v_1, v_2) \rangle = \iint_{\Omega} uv \, dx \, dy + \frac{1}{k_1} \int_{\Gamma_c} u_1 v_1 \, ds + \frac{1}{k_2} \int_{\Gamma_c} u_2 v_2 \, ds.$$

Then H is a separable real Hilbert space. Here Ω is a plane region of finite genus with boundary $\Gamma = \Gamma_0 \cup \Gamma_f \cup \Gamma_c$ as specified above. Define operators A and B by

$$(3) \quad A(u, u_1, u_2) = \begin{bmatrix} \Delta^2 u & 0 & 0 \\ -k_1(\partial \Delta u / \partial n + (1 - \sigma)A_1 u)|_{\Gamma_c} & 0 & 0 \\ k_2(\Delta u + (1 - \sigma)A_2 u)|_{\Gamma_c} & 0 & 0 \end{bmatrix},$$

with the domain

$$D(A) = \left\{ (u(x, y), u_1(s), u_2(s)) \in H^4(\Omega) \times L^2(\Gamma_c) \times L^2(\Gamma_c) : u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \Gamma_0, \right. \\ \left. \Delta u + (1 - \sigma)A_2 u = 0, \quad \frac{\partial \Delta u}{\partial n} + (1 - \sigma)A_1 u = 0 \quad \text{on } \Gamma_f, \quad u = u_1, \quad \frac{\partial u}{\partial n} = u_2 \quad \text{on } \Gamma_c \right\},$$

and

$$(4) \quad B = \begin{pmatrix} 0 & 0 \\ I & 0 \\ 0 & I \end{pmatrix},$$

with I being the identity on $L^2(\Gamma_c)$. Thus we have $A: D(A) \rightarrow H$, and B is a bounded linear operator from $L^2(\Gamma_c) \times L^2(\Gamma_c)$ to H . Denote by

$$v(t) = \begin{bmatrix} u(t, x, y) | (x, y) \in \Omega \\ u(t, x, y) | (x, y) \in \Gamma_c \\ (\partial u / \partial n)(t, x, y) | (x, y) \in \Gamma_c \end{bmatrix}, \quad f(t) = \begin{bmatrix} f_1(t, x, y) | (x, y) \in \Gamma_c \\ f_2(t, x, y) | (x, y) \in \Gamma_c \end{bmatrix}.$$

Then the system (1) can be written as an evolution equation (compare [16]):

$$(5) \quad \frac{d^2 v}{dt^2} + Av(t) = Bf(t), \quad t \geq 0, \quad v(0) = v_0, \quad v_t(0) = v_1,$$

where

$$v_0 = \begin{bmatrix} u_0(x, y) \\ u_0 | \Gamma_c \\ (\partial u_0 / \partial n) | \Gamma_c \end{bmatrix} \quad \text{and} \quad v_1 = \begin{bmatrix} u_1 \\ u_1 | \Gamma_c \\ (\partial u_1 / \partial n) | \Gamma_c \end{bmatrix}.$$

Remark. Each classical solution of the initial-boundary-value problem (1) with smooth controllers f_1 and f_2 is clearly a solution of the evolution equation (5); conversely, each mild solution of (5) starting from smooth initial data yields a classical solution of (1). Hence for the approximate controllability and feedback stabilization of (1) it is sufficient to consider (5). Therefore, we shall interpret the control problems associated with classical solutions of (1) in terms of the corresponding control problems of the evolution equation (5) and, later on, of the first-order evolution equation (8).

LEMMA 1. *The operator $A: D(A) \rightarrow H$ is a densely defined, closable, symmetric, and coercively accretive operator. It admits a self-adjoint Friedrichs extension denoted by A_e , which has a compact resolvent.*

Proof (sketched). Through a straightforward calculation (see [17] for details) we can show that

$$\left\langle A \begin{bmatrix} u \\ u_1 \\ u_2 \end{bmatrix}, \begin{bmatrix} v \\ v_1 \\ v_2 \end{bmatrix} \right\rangle = \langle u, v \rangle = \left\langle \begin{bmatrix} u \\ u_1 \\ u_2 \end{bmatrix}, A \begin{bmatrix} v \\ v_1 \\ v_2 \end{bmatrix} \right\rangle,$$

where

$$\langle u, v \rangle = \iint_{\Omega} [\Delta u \Delta v + (1 - \sigma)(2u_{xy}v_{xy} - u_{xx}v_{yy} - u_{yy}v_{xx})] dx dy$$

for (u, u_1, u_2) and (v, v_1, v_2) in $D(A)$. It can be shown as in [17] that

$$\langle u, v \rangle = \langle A^{1/2}(u, u_1, u_2), A^{1/2}(v, v_1, v_2) \rangle.$$

Hence A is symmetric and coercively accretive. The symmetry and semibounded property imply that A admits a self-adjoint Friedrichs extension. Moreover, since

$$\|u_i\|_{L^2(\Gamma_c)} \leq \text{const} \|u\|_{H^2(\Omega)}, \quad i = 1, 2,$$

it can be shown by the Rellich theorem that both A and its extension A_e have a compact resolvent. \square

Denote $D(A^{1/2})$ with the graph norm by M , and define

$$X = M \times H,$$

which can be interpreted as the energy space. Now define two more operators:

$$(6) \quad G = \begin{bmatrix} 0 & I \\ -A_e & 0 \end{bmatrix} : D(G) \rightarrow X, \quad \text{where } D(G) = D(A) \times M,$$

$$(7) \quad K = \begin{bmatrix} 0 \\ B \end{bmatrix} : L^2(\Gamma_c) \times L^2(\Gamma_c) \rightarrow X.$$

The operator K is a bounded linear operator, and the operator G is the generator of a unitary group of linear operators $T(t)$ on X given by

$$T(t) = \begin{bmatrix} \cos(A^{1/2}t) & A^{-1/2} \sin(A^{1/2}t) \\ -A^{1/2} \sin(A^{1/2}t) & \cos(A^{1/2}t) \end{bmatrix}.$$

Let

$$w(t) = \begin{bmatrix} v(t) \\ (d/dt)v(t) \end{bmatrix} \quad \text{and} \quad w_0 = \begin{bmatrix} v_0 \\ v_1 \end{bmatrix},$$

where $(d/dt)v(t)$ stands for the strong derivative of $v(t)$ in H . Then the second-order evolution system (5) is reduced to the following first-order evolution system:

$$(8) \quad \begin{aligned} \frac{dw}{dt} &= Gw(t) + Kf(t), \quad t \geq 0, \\ w(0) &= w_0 \in X. \end{aligned}$$

The mild solution of the evolution equation (8) will be considered as the state function.

3. Energy decay with dissipative feedback. We introduce the feedback control

$$f = \begin{bmatrix} -(\partial u / \partial t)|_{\Gamma_c} \\ -(\partial u_n / \partial t)|_{\Gamma_c} \end{bmatrix}$$

as a dissipative perturbation of the generator G . The perturbed generator is denoted by

$$(9) \quad G_c = G - KK^*, \quad \text{with } D(G_c) = D(G).$$

Denote by $D(G^\infty)$ the dense subspace in X defined by

$$D(G^\infty) = \bigcap_{k=1}^{\infty} D(G^k),$$

where $D(G^k)$ is the domain of the operator G^k . Let the C_0 -contraction semigroup generated by G_c be $S(t)$, $t \geq 0$. As in [17, Lemmas 6 and 7], we can show that for each $w_0 \in D(G^\infty)$

- (i) $\|S(t)w_0\|$ and $\|G_c S(t)w_0\|$ are nonincreasing for $t \geq 0$;
- (ii) any trajectory $\{S(t)w_0; t \geq 0\}$ is located within a compact subset of X ;
- (iii) the ω -limit set associated with any initial data w_0 ,

$$\omega(w_0) = \bigcap_{\tau > 0} \left\{ \text{cl} \left[\bigcup_{t \geq \tau} S(t)w_0 \right] \right\},$$

is a nonempty compact subset of X ;

(iv) for each point $w_\infty \in \omega(w_0)$ the following limit holds:

$$\|w_\infty\| = \lim_{t \rightarrow \infty} \|S(t)w_0\| := E_\infty(w_0);$$

(v) for each point $w_\infty \in \omega(w_0)$ we have $w_\infty \in D(G^\infty)$ and

$$\|S(t)w_\infty\| = \|w_\infty\| = E_\infty(w_0) \quad \text{for } t \geq 0.$$

We shall show later in Lemma 5 that $E_\infty(w_0) = 0$.

LEMMA 2. *If $w_\infty \in \omega(w_0)$ and*

$$(10) \quad w_\infty(t) = S(t)w_\infty = \begin{bmatrix} v_\infty(t) \\ (d/dt)v_\infty(t) \end{bmatrix} = \begin{bmatrix} u_\infty(t, x, y) \\ u_\infty|_{\Gamma_c} \\ \partial u_\infty / \partial n|_{\Gamma_c} \\ \dot{u}_\infty(t, x, y) \\ \dot{u}_\infty|_{\Gamma_c} \\ \partial \dot{u}_\infty / \partial n|_{\Gamma_c} \end{bmatrix},$$

then $\varphi(t, x, y) := \dot{u}_\infty(t, x, y)$ is a classical solution of the following system:

$$(11) \quad \begin{aligned} \frac{\partial^2 \varphi}{\partial t^2} + \Delta^2 \varphi &= 0 && \text{in } R^+ \times \Omega, \\ \varphi = \frac{\partial \varphi}{\partial n} &= 0 && \text{on } R^+ \times \Gamma_0, \\ \Delta \varphi + (1 - \sigma)A_2 \varphi = \frac{\partial \Delta \varphi}{\partial n} + (1 - \sigma)A_1 \varphi &= 0 && \text{on } R^+ \times \Gamma_f, \\ \varphi = \frac{\partial \varphi}{\partial n} = \frac{\partial^2 \varphi}{\partial n^2} = \frac{\partial^3 \varphi}{\partial n^3} &= 0 && \text{on } R^+ \times \Gamma_c. \end{aligned}$$

Proof. By property (v) and the observation that $w_\infty(t) = S(t)w_\infty$ is a strong solution of the equation

$$(12) \quad \frac{dw}{dt} = (G - KK^*)w,$$

it follows that

$$\frac{d}{dt} \|w_\infty(t)\|^2 = -2\|K^*w_\infty(t)\|^2 = 0, \quad t \geq 0.$$

Hence

$$K^*w_\infty(t) = B^* \frac{d}{dt} v_\infty(t) = 0, \quad t \geq 0,$$

so that by (10)

$$(13) \quad \begin{aligned} \varphi(t, x, y)|_{\Gamma_c} &= 0, && t \geq 0, \\ \frac{\partial \varphi}{\partial n}(t, x, y)|_{\Gamma_c} &= 0, && t \geq 0. \end{aligned}$$

Classical regularity theory [13, § 6.6] shows that in this case $\varphi(t, x, y)$ is a sufficiently regular function of $(t, x, y) \in R^+ \times \Omega$ up to the boundary, that is, $\varphi \in C^\infty(\Omega)$ and has a C^∞ -extension in a neighborhood of each point on any smooth arc of Γ . Thus $\varphi(t, x, y)$ is a classical solution of the following system:

$$\begin{aligned}
 (14) \quad & \frac{\partial^2 \varphi}{\partial t^2} + \Delta^2 \varphi = 0 && \text{in } R^+ \times \Omega, \\
 & \varphi = \frac{\partial \varphi}{\partial n} = 0 && \text{on } R^+ \times \Gamma_0, \\
 & \Delta \varphi + (1 - \sigma) A_2 \varphi = \frac{\partial \Delta \varphi}{\partial n} + (1 - \sigma) A_1 \varphi = 0 && \text{on } R^+ \times \Gamma_f, \\
 & \varphi = \frac{\partial \varphi}{\partial n} = 0 && \text{on } R^+ \times \Gamma_c, \\
 & \Delta \varphi + (1 - \sigma) A_2 \varphi = \frac{\partial \Delta \varphi}{\partial n} + (1 - \sigma) A_1 \varphi = 0 && \text{on } R^+ \times \Gamma_c,
 \end{aligned}$$

according to (11) and (13). Since $\varphi = \partial \varphi / \partial n = 0$ along each arc of Γ_c for $t \geq 0$, we have

$$\frac{\partial \varphi}{\partial s} = \frac{\partial \varphi}{\partial n} = 0 \quad \text{on } R^+ \times \Gamma_c.$$

It is known [5] that on $R^+ \times \Gamma_c$

$$(15) \quad A_1 \varphi = \frac{\partial}{\partial s} \left[\frac{\partial^2 \varphi}{\partial n \partial s} - 2\kappa \frac{\partial \varphi}{\partial s} \right] = \frac{\partial^3 \varphi}{\partial s^2 \partial n} = 0,$$

and

$$(16) \quad A_2 \varphi = -\frac{\partial^2 \varphi}{\partial s^2} - \kappa \frac{\partial \varphi}{\partial n} = -\frac{\partial^2 \varphi}{\partial s^2} = 0$$

in terms of the curvature κ of Γ_c . Substituting (15) and (16) into the boundary conditions on $R^+ \times \Gamma_c$ in (14), we obtain

$$\varphi = \frac{\partial \varphi}{\partial n} = \Delta \varphi = \frac{\partial \Delta \varphi}{\partial n} = 0 \quad \text{on } R^+ \times \Gamma_c.$$

It follows that

$$(17) \quad \varphi = \frac{\partial \varphi}{\partial n} = \frac{\partial^2 \varphi}{\partial n^2} = \frac{\partial^3 \varphi}{\partial n^3} = 0 \quad \text{on } R^+ \times \Gamma_c.$$

Finally, (14) and (17) imply that $\varphi(t, x, y) = \dot{u}_\infty(t, x, y)$ is a classical solution of the system (11). \square

4. Global uniqueness. The boundary-value problem (11) for the two-dimensional Petrovsky equation is overdetermined. In order to assert that the only possible solution of (11) is the trivial solution $\varphi(t, x, y) = 0$ in $R^+ \times \Omega$, we shall invoke a global uniqueness theorem due to Hörmander.

LEMMA 3 [2]. *Let Q_1 and Q_2 be two open convex sets in R^n , such that $Q_2 \supset Q_1$. Let $P(D)$ be a differential operator with constant coefficients, such that every hyperplane that is characteristic with respect to $P(D)$ and intersects Q_2 also meets Q_1 . Then every*

distribution solution $u \in \mathcal{D}'(Q_2)$ satisfying $P(D)u = 0$ and vanishing in Q_1 must vanish in Q_2 .

Proof. See [2, Thm. 5.3.3].

LEMMA 4. The boundary-value problem (11) admits a unique solution $\varphi(t, x, y) = 0$ for $(t, x, y) \in R^+ \times \text{cl } \Omega$.

Proof. Let $P(D)$ be the Petrovsky operator: $P(D) = \partial^2 / \partial t^2 + \Delta^2$ in the 3-cylinder $Q = R^+ \times \Omega$. Since the associated characteristic vector is $\xi = (\xi_t, \xi_x, \xi_y) = (1, 0, 0)$, every characteristic 2-plane associated with $P(D)$ is parallel to the (x, y) plane.

Let $\varphi(t, x, y)$ be a solution of the boundary-value problem (11). Then $P(D)\varphi = 0$ and the last boundary condition in (11) implies that

$$(18) \quad \frac{\partial^k \varphi}{\partial n^k} = 0 \quad \text{on } \Sigma_c = R^+ \times \Gamma_c \quad \text{for all } k \geq 0.$$

Then the Holmgren local uniqueness theorem implies that $\varphi = 0$ identically in a neighborhood of Σ_c in Q . In fact, there is an open disk Ω_1 in Ω such that $\varphi = 0$ identically in $Q_1 = R^+ \times \Omega_1$.

Choose any point $p \in Q$ with its projection $\hat{p} \in \Omega$. Then there exists a finite chain $\{\Omega_j: j = 1, \dots, N = N(p)\}$ with the property that each Ω_j is an open disk in Ω centered at p_j with $R^2\text{-meas}(\Omega_j \cap \Omega_{j+1}) > 0$ for $j = 1, 2, \dots, N-1$ and with $p_N = \hat{p}$. Now use Lemma 3 to examine $\varphi(t, x, y)$ on the corresponding chain $Q_j = R^+ \times \Omega_j$ for $j = 1, 2, \dots, N$.

Consider the nonempty convex set $Q_1 \cap Q_2$ on which $\varphi = 0$ identically. Clearly, each characteristic 2-plane that meets Q_2 also meets $Q_1 \cap Q_2$, since these are each 3-cylinders in $Q = R^+ \times \Omega$. Thus we conclude by using Lemma 3, that $\varphi = 0$ identically in Q_2 . Continuing this argument along the chain $\{Q_j: j = 1, 2, \dots, N\}$, we finally conclude that $\varphi = 0$ identically in $Q_N = R^+ \times \Omega_N$, so $\varphi = 0$ at the point $p \in Q_N$. This completes the proof. \square

LEMMA 5. Let Ω be a plane region of finite genus as specified above. Then for each initial state $w_0 \in X$, it follows that the solution $w(t) = S(t)w_0$ of the evolution equation (8) satisfies

$$(19) \quad \lim_{t \rightarrow \infty} \|S(t)w_0\| = 0.$$

Proof. From Lemma 4 we have shown that

$$(20) \quad \varphi(t, x, y) = \frac{d}{dt} u_\infty(t, x, y) = 0 \quad \text{in } \text{cl } Q = \text{cl } (R^+ \times \Omega).$$

It follows that $u_\infty(t, x, y) = u_\infty(0, x, y)$ for all $t \geq 0$ and any $(x, y) \in \text{cl } \Omega$. Denote $u_\infty(0, x, y)$ by $\varphi_0(x, y)$. Then φ_0 satisfies the following boundary-value problem of the biharmonic equation:

$$(21) \quad \begin{aligned} \Delta^2 \varphi_0 &= 0 && \text{in } \Omega, \\ \varphi_0 = \frac{\partial \varphi_0}{\partial n} &= 0 && \text{on } \Gamma_0, \\ \frac{\partial \Delta \varphi_0}{\partial n} + (1 - \sigma)A_1 \varphi_0 &= 0 && \text{on } \Gamma_1, \\ \Delta \varphi_0 + (1 - \sigma)A_2 \varphi_0 &= 0 && \text{on } \Gamma_1. \end{aligned}$$

A straightforward calculation shows that

$$\begin{aligned} & \int \int_{\Omega} (\Delta^2 \varphi_0) \varphi_0 \, dx \, dy + \int_{\Gamma = \Gamma_0 \cup \Gamma_1} \left[(\Delta \varphi_0 + (1 - \sigma) A_2 \varphi_0) \frac{\partial \varphi_0}{\partial n} - \left(\frac{\partial \Delta \varphi_0}{\partial n} + (1 - \sigma) A_1 \varphi_0 \right) \varphi_0 \right] ds \\ &= \langle \varphi_0, \varphi_0 \rangle = \left\| A^{1/2} \begin{bmatrix} \varphi_0 \\ \varphi_0|_{\Gamma_c} \\ (\partial \varphi_0 / \partial n)|_{\Gamma_c} \end{bmatrix} \right\|^2 = 0. \end{aligned}$$

It follows that

$$\varphi_0(x, y) = 0 \quad \text{in } H^2(\Omega).$$

Therefore, we have the pointwise equality

$$u_{\infty}(t, x, y) = 0 \quad \text{in cl } Q,$$

so that

$$(22) \quad S(t)w_{\infty} = 0 \quad \text{for } t \geq 0.$$

Then by the properties of the ω -limit set $\omega(w_0)$, (22) implies that (19) holds. \square

5. Dynamic boundary stabilization. In this section we will achieve the main results in terms of stabilization and controllability for the evolution system (8) deduced from the original boundary control system (1) for an elastic plate of general shape.

THEOREM 1. *The evolution system (8), which models the elastic-plate system (1) over a region Ω of finite genus, is strongly stabilized by the following boundary-damping feedback:*

$$(23) \quad f_1(t, x, y) = -\frac{\partial u}{\partial t}(t, x, y) \quad \text{and} \quad f_2(t, x, y) = -\frac{\partial^2 u}{\partial t \partial n}(t, x, y),$$

for $t \geq 0$, $(x, y) \in \Gamma_c$.

Proof. From Lemma 5 it is known that the convergence (19) holds. This means that the linear feedback control

$$(24) \quad f(t) = -K^* w(t) = -B^* \frac{d}{dt} v(t) = - \begin{bmatrix} (\partial u / \partial t)|_{\Gamma_c} \\ (\partial^2 u / \partial t \partial n)|_{\Gamma_c} \end{bmatrix}, \quad t \geq 0,$$

strongly stabilizes the evolution system (8) because the solutions $S(t)w_0$ of the corresponding closed-loop system (12) strongly converge to the equilibrium at 0 for any initial data w_0 in the state space X . \square

THEOREM 2. *The evolution system (8), which models the elastic-plate system (1) over a region Ω of finite genus, is open-loop approximately controllable.*

Proof. By the controllability theory for linear systems in Hilbert spaces [1], [15], the strong stabilizability of the system (8) implies that it is approximately controllable in X by open-loop controllers f_1 and f_2 applied on Γ_c . Thus the conclusion of Theorem 2 is a consequence of Theorem 1. \square

Example. Let

$$\Omega = \{(r, \theta): \delta < r < 1, 0 \leq \theta < 2\pi\}, \quad 0 < \delta < 1 \text{ constant},$$

$$\Gamma_0 = \{(r, \theta): r = \delta\}, \quad \Gamma_1 = \{(r, \theta): r = 1\},$$

$$\Gamma_c = \{(r, \theta) \in \Gamma_1: \theta \in (\alpha, \beta) \text{ with } 0 < \beta - \alpha < 2\pi\},$$

$$\Gamma_f = \Gamma_1 \setminus \Gamma_c.$$

Consider a thin, isotropic, homogeneous, elastic annular plate over the region Ω . By the theory developed in this paper the corresponding plate system (1) is strongly stabilizable by the linear feedback (23) applied to the boundary arc Γ_c —no matter how small the controlled arc (α, β) is. As a consequence, this system is open-loop approximately controllable with the controllers supported on Γ_c .

BOUNDARY CONTROL OF SEMILINEAR ELLIPTIC EQUATIONS WITH POINTWISE STATE CONSTRAINTS*

EDUARDO CASAS[†]

Abstract. This paper is concerned with state constrained optimal control problems of semilinear elliptic equations, the control being on the boundary. Optimality conditions are derived and regularity of the optimal solution is investigated.

Key words. optimal control, boundary control, semilinear elliptic operators, optimality conditions, state constraints

AMS subject classifications. 49K20, 49J20

1. Introduction. This paper deals with state-constrained optimal control problems governed by a monotone semilinear and elliptic operator. A Neumann condition is considered, and the control should act on the boundary. Our aim is to derive the optimality conditions and to deduce some regularity results for the optimal control. This kind of optimal control problems arises in connection with some realistic problems; see Bermúdez and Martínez [2] and Luneville [12].

Optimal control problems with state constraints, governed by linear elliptic equations, have been studied by the author [6]–[9]. In these papers, the control was distributed in Ω or it was a coefficient of the operator. Abergel and Temam [1] studied some nonqualified problems of distributed control, deriving some nonstandard optimality conditions that become the usual ones when the problem is qualified. The semilinear case was considered by Bonnans and Casas [4], [5], the control being distributed in Ω , too. Optimality conditions for some boundary control problems with pointwise state constraints have been obtained by Mackenroth [13], [14] in the case of a linear operator with bounded controls; Luneville [12] in the case of Laplace operator and dimension 2 or 3 and the state subject to pointwise constraints only in a strict subset of Ω ; Bonnans and Casas [3] in the case of a particular semilinear equation. In the previous papers, except that of Luneville, the adjoint state equation is not investigated, and therefore regularity of the adjoint state was not deduced, which is essential to derive regularity results of optimal control.

In this paper, we show that, assuming the control to be in $L^t(\Gamma)$ for $t > n - 1$, $n > 1$ arbitrary, it is possible to derive the optimality conditions and to deduce some regularity results of the optimal control after having investigated regularity for the adjoint state.

The plan of this paper is as follows: in the next section, the control problem is formulated; in §3 the state equation is studied, in particular continuity of state is proved; in §4 we prove existence, uniqueness, and regularity of the solution of a Neumann problem governed by a linear elliptic equation with measures as data; finally, in §5 we apply this study to our control problem and derive the optimality conditions and regularity results.

2. Formulation of the control problem. Let Ω be an open bounded subset of \mathbb{R}^n ($n \geq 2$) with $C^{1,1}$ boundary Γ . Let us consider the following boundary value

problem:

$$(2.1) \quad \begin{aligned} Ay + \phi(y) &= f && \text{in } \Omega, \\ \partial_{\nu_A} y &= u && \text{on } \Gamma, \end{aligned}$$

with $f \in L^\rho(\Omega)$, $\rho > n/2$, $u \in L^t(\Gamma)$, $t > n - 1$, and

$$\begin{aligned} Ay &= - \sum_{i,j=1}^n \partial_{x_j} (a_{ij}(x) \partial_{x_i} y(x)) + a_0(x) y(x), \\ \partial_{\nu_A} y &= \sum_{i,j=1}^n a_{ij}(x) \partial_{x_i} y(x) \nu_j(x), \end{aligned}$$

where $\nu(x)$ denotes the unit outward normal to Γ at the point x ,

$$a_{ij} \in C^{0,1}(\overline{\Omega}) \quad \text{and} \quad a_0 \in L^\infty(\Omega),$$

$$(2.2) \quad \exists m > 0 \text{ such that } \sum_{i,j=1}^n a_{ij}(x) \xi_i \xi_j \geq m |\xi|^2 \quad \forall \xi \in R^n, x \in \Omega,$$

$$a_0(x) \geq 0 \quad \text{a.e. } x \in \Omega \text{ and } a_0 \not\equiv 0;$$

$$(2.3) \quad \begin{aligned} \phi : R &\longrightarrow R \text{ is of class } C^1, \\ \phi &\text{ is increasing monotone and } \phi(0) = 0. \end{aligned}$$

We consider the following control problem:

$$(P) \quad \begin{cases} \text{Minimize } J(u), \\ u \in K \text{ and } y_u \in C, \end{cases}$$

where K is a nonempty, convex, closed subset of $L^t(\Gamma)$; C is a closed and convex subset of $C(X)$ with nonempty interior, X being a compact subset of $\overline{\Omega}$; and the functional $J : L^t(\Gamma) \longrightarrow [0, +\infty]$ is defined by

$$J(u) = \frac{1}{2} \int_{\Omega} |y_u(x) - y_d(x)|^2 dx + \frac{N}{\sigma} \int_{\Gamma} |u(x)|^\sigma dm_{\Gamma}(x),$$

y_d being given in $L^2(\Omega)$, $\sigma \in (1, +\infty)$ and $N \geq 0$. Furthermore, we assume that one of the following hypotheses is satisfied:

(H1) K is bounded in $L^t(\Gamma)$, $t > n - 1$, and $\sigma \leq t$;

(H2) $N > 0$ and $\sigma \geq t > n - 1$.

As realistic examples, we can take

$$K = \{u \in L^\infty(\Gamma) : a \leq u(x) \leq b \text{ a.e. } [m_{\Gamma}] x \in \Gamma\}$$

and $\sigma = 2$, with $-\infty < a < b < +\infty$, which satisfies the first hypothesis, or

$$K = \{u \in L^t(\Gamma) : u(x) \geq 0 \text{ a.e. } [m_{\Gamma}] x \in \Gamma\}$$

and $\sigma = t$, which satisfies the second hypothesis. Above, m_{Γ} denotes the usual $(n - 1)$ -dimensional measure over Γ induced by the parametrization.

In the case where $n = 2$, we can take $\sigma = t = 2$, which is the most usual choice in control theory.

As examples of sets C , let us give

$$X = \overline{\Omega} \quad \text{and} \quad C = \{z \in C(\overline{\Omega}) : |z(x)| \leq \delta \quad \forall x \in \overline{\Omega}\},$$

$$X = \Gamma \quad \text{and} \quad C = \{z \in C(\Gamma) : |z(x)| \leq \delta \quad \forall x \in \Gamma\},$$

or

$$X \subset \Omega \quad \text{and} \quad C = \{z \in C(X) : |z(x)| \leq \delta \quad \forall x \in X\},$$

where $\delta > 0$ is a given constant.

Remark 1. In practice, the hypothesis $\phi(0) = 0$ is not a restriction because, if it is not verified, then it is enough to replace ϕ by $\phi - \phi(0)$ and f by $f - \phi(0)$, and so we have the required conditions.

3. Study of the state equation. In this section, we prove that the boundary problem (2.1) has a unique solution $y_u \in H^1(\Omega) \cap C(\overline{\Omega})$ for each $u \in L^t(\Gamma)$, $t > n - 1$, and that the relation between control and state is of class C^1 .

THEOREM 3.1. *For all $u \in L^t(\Gamma)$, with $t > n - 1$, and $f \in L^\rho(\Omega)$, $\rho > n/2$, there exists a unique solution y_u of the Neumann problem (2.1) belonging to $H^1(\Omega) \cap C(\overline{\Omega})$. Moreover, there exists a constant C_1 independent of f and u such that*

$$(3.1) \quad \|y_u\|_{H^1(\Omega)} + \|y_u\|_{C(\overline{\Omega})} \leq C_1 (\|f\|_{L^\rho(\Omega)} + \|u\|_{L^t(\Gamma)}).$$

Finally, if $\{u_k\} \subset L^t(\Gamma)$ converges weakly (or weak* in the case where $t = +\infty$) toward u in $L^t(\Gamma)$, then $\{y_{u_k}\}$ converges to y_u strongly in $H^1(\Omega) \cap C(\overline{\Omega})$.

Before proving this theorem, we must state the following lemma.

LEMMA 3.2. *Let us suppose that ϕ is a bounded function in R , $f \in L^\rho(\Omega)$ and $u \in W^{-1/r,r}(\Gamma)$, with $\rho > n/2$ and $r > n$. Then there exists a unique solution y_u in $H^1(\Omega) \cap L^\infty(\Omega)$ of the Neumann problem (2.1). Moreover, there exists a constant $C_2 > 0$ independent of u , f , and ϕ such that*

$$(3.2) \quad \|y_u\|_{H^1(\Omega)} + \|y_u\|_{L^\infty(\Omega)} \leq C_2 (\|f\|_{L^\rho(\Omega)} + \|u\|_{W^{-1/r,r}(\Gamma)}).$$

Proof. Utilizing the monotone operator theory (see Lions [11]), the existence and uniqueness of a solution $y_u \in H^1(\Omega)$ of (2.1) follows easily. On the other hand, arguing as in [17, Thm. 4.2], we obtain the boundedness of y_u and inequality (3.2). \square

Proof of Theorem 3.1. For every positive integer k , let us consider the functions $\phi_k : R \rightarrow R$ defined by

$$\phi_k(\theta) = \begin{cases} \phi(\theta) & \text{if } |\phi(\theta)| \leq k, \\ +k & \text{if } \phi(\theta) \geq +k, \\ -k & \text{if } \phi(\theta) \leq -k. \end{cases}$$

Then, due to Lemma 3.2, we know that the Neumann problem

$$\begin{aligned} Ay + \phi_k(y) &= f & \text{in } \Omega, \\ \partial_{\nu_A} y &= u & \text{on } \Gamma \end{aligned}$$

has a unique solution $y_k \in H^1(\Omega) \cap L^\infty(\Omega)$ and

$$(3.3) \quad \|y_k\|_{H^1(\Omega)} + \|y_k\|_{L^\infty(\Omega)} \leq C_2 (\|f\|_{L^\rho(\Omega)} + \|u\|_{W^{-1/r,r}(\Gamma)}),$$

where C_2 is independent of k . Therefore there exists a constant $c > 0$ such that $\|y_k\|_\infty \leq c$ for each k , which implies that there exists a positive integer $k_0 > 0$ such that $\phi_k(y_k) = \phi(y_k)$ for every $k \geq k_0$. That is, every y_k , with $k \geq k_0$, is a solution of the Neumann problem (2.1). On the other hand, the uniqueness of solution of this problem in $H^1(\Omega) \cap L^\infty(\Omega)$ is an immediate consequence of the properties of A and the monotonicity of ϕ .

Once we have proved existence, uniqueness, and the estimations in the norm $H^1(\Omega)$ and $L^\infty(\Omega)$ (consequence of inequality (3.3)), it remains to establish the continuity of y_u . For this, we utilize the density of $D(\Gamma)$ and $D(\Omega)$ in $L^t(\Gamma)$ and $L^\rho(\Omega)$, respectively. Let $\{u_k\} \subset D(\Gamma)$ and $\{f_k\} \subset D(\Omega)$ be two sequences converging to u and f in the topology of $L^t(\Gamma)$ and $L^\rho(\Omega)$, respectively, and let $y_k = y_{u_k}$ be the solution of the Neumann problem (2.1) corresponding to u_k and f_k . From the hypotheses on the regularity of A and Γ , it follows (see, for example, Grisvard [10]) that $\{y_k\} \subset W^{2,r}(\Omega) \subset C(\bar{\Omega})$. Now let us take $z_k = y_u - y_k$, $v_k = u - u_k$ and $g_k = f - f_k$, then z_k verifies that

$$\begin{aligned} Az_k + \alpha_k(x)z_k &= g_k & \text{in } \Omega, \\ \partial_{\nu_A} z_k &= v_k & \text{on } \Gamma, \end{aligned}$$

where

$$\alpha_k(x) = \begin{cases} \frac{\phi(y_u(x)) - \phi(y_k(x))}{y_u(x) - y_k(x)} & \text{if } y_u(x) \neq y_k(x), \\ 0 & \text{if } y_u(x) = y_k(x). \end{cases}$$

The monotonicity of ϕ implies the positivity of α_k . Applying Lemma 3.2, we obtain that

$$\|z_k\|_{L^\infty(\Omega)} \leq C_2 (\|g_k\|_{L^\rho(\Omega)} + \|v_k\|_{L^t(\Gamma)}) \rightarrow 0 \quad \text{if } k \rightarrow \infty,$$

which proves the uniform convergence of $\{y_k\}$ toward y_u and hence the continuity of y_u .

Finally, to prove the continuous dependence of y_u with respect to u , note that the weak convergence of $\{u_k\}$ to u in $L^t(\Gamma)$ implies the strong convergence in $W^{-1/r,r}(\Gamma)$. Therefore it is enough to again take $z_k = y_u - y_{u_k}$ and to argue as above to conclude the strong convergence of $\{y_{u_k}\}$ to y_u in $H^1(\Omega) \cap C(\bar{\Omega})$. \square

We finish this section proving that the relation between the control and the state is differentiable.

THEOREM 3.3. *The mapping $G : L^t(\Gamma) \rightarrow H^1(\Omega) \cap C(\bar{\Omega})$ defined by $G(u) = y_u$ is of class C^1 , and, for every $u, v \in L^t(\Gamma)$, the element $z = DG(u) \cdot v$ is the unique solution of the Neumann problem*

$$(3.4) \quad \begin{aligned} Az + \phi'(y_u)z &= 0 & \text{in } \Omega, \\ \partial_{\nu_A} z &= v & \text{on } \Gamma. \end{aligned}$$

Proof. First, we prove that G is Gâteaux differentiable. For it, let us take for every $h > 0$, y_h as the solution of the Neumann problem

$$\begin{aligned} Ay + \phi(y) &= f & \text{in } \Omega, \\ \partial_{\nu_A} y &= u + hv & \text{on } \Gamma. \end{aligned}$$

Then $z_h = (y_h - y_u)/h$ satisfies

$$\begin{aligned} Az_h + \alpha_h(x)z_h &= 0 & \text{in } \Omega, \\ \partial_{\nu_A} z_h &= v & \text{on } \Gamma, \end{aligned}$$

where $\alpha_h(x) = \phi'(y_u(x) + \theta_h(x)[y_h(x) - y_u(x)])$, with $\theta_h(x) \in (0, 1)$. Using Theorem 3.1, we obtain that $\{z_h\}$ is uniformly bounded in $H^1(\Omega) \cap C(\overline{\Omega})$. Therefore it is easy to pass to the limit in the previous problem and to deduce the convergence of $\{z_h\}$ to z in $H^1(\Omega) \cap C(\overline{\Omega})$, where z is the solution of problem (3.4). On the other hand, it is a consequence of Theorem 3.1 that the linear mapping $v \rightarrow z$ is continuous from $L^t(\Gamma)$ to $H^1(\Omega) \cap C(\overline{\Omega})$. Finally, due to the continuity of ϕ' , it follows easily that DG is continuous, which concludes the proof. \square

4. Study of a Neumann problem with measures as data. As we see in the next section, the adjoint state equation of the optimality system for our control problem has measures as data in Ω and on Γ . In this section, we study this type of boundary value problems, proving existence and uniqueness of a solution, deriving a regularity result, and stating a trace theorem and a Green's formula.

The model problem is the following:

$$(4.1) \quad \begin{aligned} Ap &= \mu_\Omega & \text{in } \Omega, \\ \partial_{\nu_A} p &= \mu_\Gamma & \text{on } \Gamma, \end{aligned}$$

where A is an elliptic operator as defined in §2, satisfying the conditions (2.2), and μ_Ω and μ_Γ are real regular Borel measures in Ω and Γ , respectively, Ω and Γ verifying also the conditions stated in §2.

We begin by establishing a trace theorem, but first it is necessary to introduce some function spaces. For every $s \in (1, n/(n-1))$, let us consider the space

$$V^s(\Omega) = \{\vec{p} \in L^s(\Omega)^n : \operatorname{div} \vec{p} \in M(\Omega)\},$$

where $M(\Omega)$ is the space formed by the real regular Borel measures in Ω . Endowed with the norm

$$\|\vec{p}\|_{V^s(\Omega)} = \|\vec{p}\|_{L^s(\Omega)^n} + \|\operatorname{div} \vec{p}\|_{M(\Omega)},$$

$V^s(\Omega)$ is a Banach space.

We will henceforth follow the notation

$$\langle \mu_\Omega, y \rangle_\Omega = \int_\Omega y(x) d\mu_\Omega(x) \quad \text{and} \quad \langle \mu_\Gamma, z \rangle_\Gamma = \int_\Gamma z(x) d\mu_\Gamma$$

for all functions $y \in C(\overline{\Omega})$ and $z \in C(\Gamma)$ and all real regular Borel measures $\mu_\Omega \in M(\Omega)$ and $\mu_\Gamma \in M(\Gamma)$.

We now have the following result.

THEOREM 4.1. *There exists a unique linear and continuous mapping*

$$\gamma_\nu : V^s(\Omega) \longrightarrow W^{-1/s, s}(\Gamma)$$

verifying

$$(4.2) \quad \gamma_\nu(\vec{p}) = \vec{p}|_\Gamma \cdot \vec{\nu} \quad \forall \vec{p} \in C^1(\overline{\Omega})^n,$$

$$(4.3) \quad \langle \gamma_\nu(\vec{p}), \gamma(z) \rangle = \int_\Omega \vec{p} \cdot \nabla z dx + \langle \operatorname{div} \vec{p}, z \rangle_\Omega \quad \forall z \in W^{1,r}(\Omega),$$

where r is the conjugate of s .

Proof. Let us take $g \in W^{1/s,r}(\Gamma) = \gamma(W^{1,r}(\Omega))$ and $z \in W^{1,r}(\Omega)$ such that $\gamma(z) = g$. Then we define

$$\langle \gamma_\nu(\vec{p}), g \rangle = \int_\Omega \vec{p} \cdot \nabla z dx + \langle \operatorname{div} \vec{p}, z \rangle_\Omega.$$

Let us prove that γ_ν is well defined. First, from the inequality $s < n/(n-1)$, it follows that $r > n$, and therefore $W^{1,r}(\Omega) \subset C(\overline{\Omega})$. On the other hand, if $z_1, z_2 \in W^{1,r}(\Omega)$ and $\gamma(z_1) = \gamma(z_2) = g$, then we must prove that

$$\int_\Omega \vec{p} \cdot \nabla z_1 dx + \langle \operatorname{div} \vec{p}, z_1 \rangle_\Omega = \int_\Omega \vec{p} \cdot \nabla z_2 dx + \langle \operatorname{div} \vec{p}, z_2 \rangle_\Omega.$$

To do this, let us take $z = z_1 - z_2 \in W_0^{1,r}(\Omega)$ and $\{z_k\} \subset D(\Omega)$ a sequence converging to z in $W_0^{1,r}(\Omega)$. Since $r > n$, we have that $\nabla z_k \rightarrow \nabla z$ in $L^r(\Omega)^n$ and $z_k \rightarrow z$ in $C(\overline{\Omega})$, from where we obtain that

$$\int_\Omega \vec{p} \cdot \nabla z dx + \langle \operatorname{div} \vec{p}, z \rangle_\Omega = \lim_{k \rightarrow \infty} \left\{ \int_\Omega \vec{p} \cdot \nabla z_k dx + \langle \operatorname{div} \vec{p}, z_k \rangle_{M(\Omega), C(\Omega)} \right\} = 0,$$

the last equality being a consequence of the definition of derivation in the distribution sense.

So we have that γ_ν is well defined, and, obviously, it is linear. Let us prove the continuity

$$|\langle \gamma_\nu(\vec{p}), g \rangle| \leq \|\vec{p}\|_{L^s(\Omega)^n} \|\nabla z\|_{L^r(\Omega)^n} + \|\operatorname{div} \vec{p}\|_{M(\Omega)} \|z\|_{C(\overline{\Omega})} \leq c \|\vec{p}\|_{V^s(\Omega)} \|z\|_{W^{1,r}(\Omega)}.$$

Taking now the infimum we obtain that

$$|\langle \gamma_\nu(\vec{p}), g \rangle| \leq c \|\vec{p}\|_{V^s(\Omega)} \inf_{\gamma(z)=g} \|z\|_{W^{1,r}(\Omega)} = c \|\vec{p}\|_{V^s(\Omega)} \|g\|_{W^{1/s,r}(\Gamma)},$$

which implies the continuity of γ_ν .

From the definition of γ_ν and using the Green's formula for regular functions, it is immediate to prove that (4.2) is satisfied. The uniqueness follows from (4.3) and the surjectivity of $\gamma : W^{1,r}(\Omega) \rightarrow W^{1/s,r}(\Gamma)$. \square

DEFINITION 4.2. Given $p \in W^{1,s}(\Omega)$, satisfying that $Ap \in M(\Omega)$, we define $\partial_{\nu_A} p = \gamma_\nu(\vec{w})$, where \vec{w} is given by

$$(4.4) \quad w_j(x) = \sum_{i=1}^n a_{ij}(x) \partial_{x_i} p(x), \quad 1 \leq j \leq n.$$

Let us note that $\vec{w} \in L^s(\Omega)^n$ and

$$\operatorname{div} \vec{w} = -Ap + a_0(x)p \in M(\Omega),$$

which implies that $\vec{w} \in V^s(\Omega)$. Hence $\gamma_\nu(\vec{w})$ is well defined as an element of the space $W^{-1/s,s}(\Gamma)$. From Theorem 4.1, we deduce that the previous definition agrees with

the usual definition when p is a regular function. We now study the existence and uniqueness of a solution of problem (4.1) in the space $W^{1,s}(\Omega)$.

THEOREM 4.3. *The Neumann problem (4.1) has a unique solution belonging to the space $W^{1,s}(\Omega)$ for every $s \in [1, n/(n-1))$. Furthermore, the following inequality is verified:*

$$(4.5) \quad \|p\|_{W^{1,s}(\Omega)} \leq C_3(\|\mu_\Omega\|_{M(\Omega)} + \|\mu_\Gamma\|_{M(\Gamma)}),$$

for some positive constant C_3 depending only on A and Ω .

Proof. Let $L : W^{2,r}(\Omega) \longrightarrow L^r(\Omega) \times W^{1/s,r}(\Gamma)$ be the operator defined by $L[z] = (A^*z, \partial_{\nu_{A^*}}z)$, where A^* is the adjoint operator of A . Due to the hypotheses on A and Γ , we have that L is an isomorphism; see Grisvard [10]. Then the adjoint operator $L^* : L^s(\Omega) \times W^{-1/s,s}(\Gamma) \longrightarrow (W^{2,r}(\Omega))'$ is also an isomorphism. Therefore, given $\mu = \mu_\Omega + \mu_\Gamma \in (W^{2,r}(\Omega))'$,

$$\langle \mu, z \rangle = \int_{\Omega} z(x) d\mu_\Omega(x) + \int_{\Gamma} z(x) d\mu_\Gamma(x),$$

there exists a unique element $(p, q) \in L^s(\Omega) \times W^{-1/s,s}(\Gamma)$ such that $L^*[(p, q)] = \mu$; that is,

$$(4.6) \quad \int_{\Omega} p A^* z dx + \langle q, \partial_{\nu_{A^*}} z \rangle = \int_{\Omega} z(x) d\mu_\Omega(x) + \int_{\Gamma} z(x) d\mu_\Gamma(x)$$

for all $z \in W^{2,r}(\Omega)$.

If we take $z \in D(\Omega)$ in the previous equation, we obtain that

$$(4.7) \quad Ap = \mu_\Omega \quad \text{in } \Omega.$$

Let us prove that $p \in W^{1,s}(\Omega)$. For every $\psi \in D(\Omega)$, let $z \in W^{2,r}(\Omega)$ be the solution of the Neumann problem

$$\begin{aligned} A^*z &= \partial_{x_j}\psi & \text{in } \Omega, \\ \partial_{\nu_{A^*}}z &= 0 & \text{on } \Gamma, \end{aligned}$$

with $1 \leq j \leq n$. Then, by using again [17, Thm. 4.2], we obtain that

$$\|z\|_{C(\bar{\Omega})} \leq c_1 \|\partial_{x_j}\psi\|_{W^{-1,r}(\Omega)} \leq c_1 \|\psi\|_{L^r(\Omega)}.$$

Using this inequality and (4.6), we obtain that

$$\begin{aligned} |\langle \partial_{x_j}p, \psi \rangle| &= \left| \int_{\Omega} p \partial_{x_j}\psi dx \right| = \left| \int_{\Omega} p A^*z dx \right| = \left| \int_{\Omega} z(x) d\mu_\Omega(x) + \int_{\Gamma} z(x) d\mu_\Gamma(x) \right| \\ &\leq (\|\mu_\Omega\|_{M(\Omega)} + \|\mu_\Gamma\|_{M(\Gamma)}) \|z\|_{C(\bar{\Omega})} \leq c_2 \|\psi\|_{L^r(\Omega)}, \end{aligned}$$

from where it follows, due to the density of $D(\Omega)$ in $L^r(\Omega)$, that $\partial_{x_j}p \in L^s(\Omega)$, $1 \leq j \leq n$. Hence we have that $p \in W^{1,s}(\Omega)$, and (4.5) follows from the previous inequality and the continuity of L^{-1} . Then, due to (4.7), $\partial_{\nu_{A^*}}p$ is well defined as an element of $W^{-1/s,s}(\Gamma)$; see Definition 4.2. Moreover, from (4.3), it follows that

$$(4.8) \quad \langle \partial_{\nu_{A^*}}p, \gamma(z) \rangle = a(p, z) - \int_{\Omega} z d\mu_\Omega \quad \forall z \in W^{1,r}(\Omega).$$

Now let us see that $\partial_{\nu_A} p = \mu_\Gamma$. First, we note that $\gamma(W^{1,r}(\Omega)) \subset C(\Gamma)$, and hence $M(\Gamma) \subset W^{-1/s,s}(\Gamma)$. Let $g \in W^{1+1/s,r}(\Gamma)$ arbitrary, and let us take $z \in W^{2,r}(\Omega)$ such that $\gamma(z) = g$ and $\partial_{\nu_{A^*}} z = 0$. This is possible because the mapping

$$\begin{array}{ccc} W^{2,r}(\Omega) & \longrightarrow & W^{1+1/s,r}(\Gamma) \times W^{1/s,r}(\Gamma), \\ z & \longrightarrow & (\gamma(z), \partial_{\nu_{A^*}} z) \end{array}$$

is surjective; see Lemma 4.4, proved below. From (4.8), integrating by parts and using (4.6), we obtain that

$$\begin{aligned} \langle \partial_{\nu_A} p, g \rangle &= \langle \partial_{\nu_A} p, \gamma(z) \rangle = a(p, z) - \int_{\Omega} z d\mu_{\Omega} \\ &= \int_{\Omega} p A^* z dx - \int_{\Omega} z d\mu_{\Omega} = \int_{\Gamma} z d\mu_{\Gamma} = \int_{\Gamma} g d\mu_{\Gamma}, \end{aligned}$$

which allows us to conclude that $\partial_{\nu_A} p$ and μ_Γ coincide over $W^{1+1/s,r}(\Gamma)$. Finally, from the density of $W^{1+1/s,r}(\Gamma)$ in $W^{1/s,r}(\Gamma)$, it follows the searched equality $\partial_{\nu_A} p = \mu_\Gamma$. Thus $p \in W^{1,s}(\Omega)$ is a solution of the Neumann problem (4.1). To finish this proof, it remains to state the unicity of solution.

Taking $g \in W^{1/s,r}(\Gamma)$ arbitrary and $z \in W^{2,r}(\Omega)$ such that $\gamma(z) = 0$ and $\partial_{\nu_{A^*}} z = g$, again using (4.8), (4.6), and integrating by parts, we obtain that

$$\begin{aligned} \int_{\Omega} z d\mu_{\Omega} &= a(p, z) = \int_{\Omega} p A^* z dx + \int_{\Gamma} \partial_{\nu_{A^*}} z \gamma(p) dm_{\Gamma}(x) \\ &= \int_{\Omega} z d\mu_{\Omega} - \langle q, \partial_{\nu_{A^*}} z \rangle + \int_{\Gamma} \partial_{\nu_{A^*}} z \gamma(p) dm_{\Gamma}(x); \end{aligned}$$

hence

$$\langle q, g \rangle = \int_{\Gamma} g \gamma(p) dm_{\Gamma}(x) \quad \forall g \in W^{1/s,r}(\Gamma),$$

which implies the equality $\gamma(p) = q$.

The uniqueness of solution of (4.1) in $W^{1,s}(\Omega)$ is obtained because every solution of (4.1) satisfies (4.6), which follows easily by using (4.3) and integrating by parts. \square

LEMMA 4.4. *The mapping*

$$\begin{array}{ccc} W^{2,r}(\Omega) & \longrightarrow & W^{1+1/s,r}(\Gamma) \times W^{1/s,r}(\Gamma), \\ z & \longrightarrow & (\gamma(z), \partial_{\nu_{A^*}} z) \end{array}$$

is surjective, where

$$\partial_{\nu_{A^*}} z = \sum_{i,j=1}^n a_{ji}(x) \partial_{x_j} z(x) \nu_i(x).$$

Proof. Let $(g, h) \in W^{1+1/s,r}(\Gamma) \times W^{1/s,r}(\Gamma)$. The vector $\nu_{A^*}(x)$ can be written in the form

$$\nu_{A^*}(x) = \alpha(x) \nu(x) + t(x),$$

where $t(x)$ is a tangent vector to Γ at the point x and

$$\alpha(x) = \nu_{A^*}(x) \cdot \nu(x) = \nu(x)^T (a_{ij}(x)) \nu(x) \geq m > 0.$$

Since Γ is of class $C^{1,1}$, $\nu(x)$ is a Lipschitz function on Γ . Therefore, remembering that the coefficients a_{ij} are Lipschitz, we deduce that α is a strictly positive Lipschitz function on Γ . Furthermore, $t(x)$ is also a Lipschitz function on Γ . Hence $(h - \partial_t g)/\alpha$ belongs to $W^{1/s,r}(\Gamma)$.

On the other hand, it is known that the mapping

$$\begin{array}{ccc} W^{2,r}(\Omega) & \longrightarrow & W^{1+1/s,r}(\Gamma) \times W^{1/s,r}(\Gamma), \\ z & \longrightarrow & (\gamma(z), \partial_\nu z) \end{array}$$

is surjective; see Grisvard [10] and Nečas [15]. Therefore there exists an element $z \in W^{2,r}(\Omega)$ such that $\gamma(z) = g$ and $\partial_\nu z = (h - \partial_t g)/\alpha$. Then we have that

$$\partial_{\nu_{A^*}} z(x) = \alpha(x) \partial_\nu z(x) + \partial_t z(x) = \alpha(x) \left[\frac{1}{\alpha(x)} (h(x) - \partial_t g(x)) \right] + \partial_t g(x) = h(x);$$

thus z is the searched element. \square

5. Study of the control problem. The first point to be considered in the study of the control problem (P) is the existence of a solution, which is proved in the next theorem.

THEOREM 5.1. *Under the hypotheses assumed in §2 and supposing the existence of a feasible control (i.e., a control $u \in K$ such that $y_u \in C$), then problem (P) has at least one solution. Moreover, if ϕ is linear, then the solution is unique.*

Proof. Let $\{u_k\}$ be a minimizing sequence in K . Because of hypothesis (H1) or (H2), this sequence is bounded in $L^t(\Gamma)$ (respectively, $L^\sigma(\Gamma)$). Then we can extract a subsequence, denoted in the same way, converging weakly to an element $\bar{u} \in K$ (since K is convex and closed). Now, using Theorem 3.1, we deduce that $y_{u_k} \rightarrow y_{\bar{u}}$ in $H^1(\Omega) \cap C(\bar{\Omega})$. Since $y_{u_k} \in C$ for every k and C is closed in $C(X)$, $X \subset \bar{\Omega}$, the uniform convergence implies that $y_{\bar{u}} \in C$; therefore \bar{u} is also a feasible control. Finally, it is immediate to verify that $\liminf J(u_k) \geq J(\bar{u})$, which proves that \bar{u} is a solution of (P).

If ϕ is linear, then problem (P) is strictly convex, and therefore the solution must be unique. \square

To derive the optimality conditions for problem (P), we must establish a preliminary result, which constitutes an abstract theorem of existence of Lagrange multiplier. Before stating this theorem, let us note that, in this paper, according to the most usual convention, the Gâteaux differential of a mapping is assumed linear and continuous.

THEOREM 5.2. *Let U and Z be two Banach spaces, and $K \subset U$ and $C \subset Z$ two convex subsets, C having a nonempty interior. Let $\bar{u} \in K$ be a solution of the optimization problem*

$$(Q) \begin{cases} \text{Min } J(u), \\ u \in K \text{ and } G(u) \in C, \end{cases}$$

where $J : U \rightarrow (-\infty, +\infty]$ and $G : U \rightarrow Z$ are two Gâteaux differentiable mappings at \bar{u} . Then there exist a real number $\bar{\lambda} \geq 0$ and an element $\bar{\mu} \in Z'$ such that

$$(5.1) \quad \bar{\lambda} + \|\bar{\mu}\|_{Z'} > 0,$$

$$(5.2) \quad \langle \bar{\mu}, z - G(\bar{u}) \rangle \leq 0 \quad \forall z \in C,$$

$$(5.3) \quad \langle \bar{\lambda} J'(\bar{u}) + [DG(\bar{u})]^* \bar{\mu}, u - \bar{u} \rangle \geq 0 \quad \forall u \in K.$$

Moreover, $\bar{\lambda}$ can be taken equal to 1 if the following condition of Slater type is satisfied:

$$(5.4) \quad \exists u_0 \in K \text{ such that } G(\bar{u}) + DG(\bar{u}) \cdot (u_0 - \bar{u}) \in \overset{\circ}{C}.$$

Proof. Let us consider the sets

$$A = \{(z, \lambda) \in Z \times R : \exists u \in K / z = G(\bar{u}) + DG(\bar{u}) \cdot (u - \bar{u}), \lambda = J'(\bar{u}) \cdot (u - \bar{u})\}$$

and $B = \overset{\circ}{C} \times (-\infty, 0)$. Using the linearity of $J'(\bar{u})$ and $DG(\bar{u})$, it is immediate to verify that A and B are convex sets. Moreover, they are disjoint. To see this, suppose that it is false; then there exists a point $u_0 \in K$ such that

$$\begin{aligned} z_0 &= G(\bar{u}) + DG(\bar{u}) \cdot (u_0 - \bar{u}) = G(\bar{u}) + \lim_{h \rightarrow 0} \frac{1}{h} [G(\bar{u} + h(u_0 - \bar{u})) - G(\bar{u})] \in \overset{\circ}{C}, \\ \lambda_0 &= J'(\bar{u}) \cdot (u_0 - \bar{u}) = \lim_{h \rightarrow 0} \frac{1}{h} (J(\bar{u} + h(u_0 - \bar{u})) - J(\bar{u})) < 0. \end{aligned}$$

Hence we can get a number $h_0 \in (0, 1)$ such that

$$\begin{aligned} z_h &= G(\bar{u}) + \frac{1}{h} (G(\bar{u} + h(u_0 - \bar{u})) - G(\bar{u})) \in \overset{\circ}{C} \quad \forall h \in (0, h_0), \\ \frac{1}{h} (J(\bar{u} + h(u_0 - \bar{u})) - J(\bar{u})) &< 0 \quad \forall h \in (0, h_0). \end{aligned}$$

Then we deduce that

$$G(\bar{u} + h(u_0 - \bar{u})) = h z_h + (1 - h) G(\bar{u}) \in \overset{\circ}{C} \quad \text{and} \quad J(\bar{u} + h(u_0 - \bar{u})) < J(\bar{u})$$

for every $h \in (0, h_0)$, which contradicts the fact that \bar{u} is a solution of (Q).

Now considering that B is an open set, from the geometric version of Hahn-Banach theorem, we deduce the existence of $\bar{\mu} \in Z'$ and $\bar{\lambda} \in R$, verifying that

$$(5.5) \quad \langle \bar{\mu}, z_1 \rangle + \bar{\lambda} \lambda_1 > \langle \bar{\mu}, z_2 \rangle + \bar{\lambda} \lambda_2 \quad \forall (z_1, \lambda_1) \in A, (z_2, \lambda_2) \in B.$$

Let us prove that $\bar{\lambda} \geq 0$. If $\bar{\lambda}$ were strictly negative, taking $\lambda_1 = 0$, $z_1 = G(\bar{u})$, $z_2 \in \overset{\circ}{C}$ fixed, and $\lambda_2 = -k$ in (5.5), with k positive integer, it follows that

$$\langle \bar{\mu}, G(\bar{u}) \rangle > \langle \bar{\mu}, z_2 \rangle - \bar{\lambda} k.$$

When k tends to infinity we arrive at a contradiction. Therefore $\bar{\lambda} \geq 0$. Furthermore, since inequality (5.5) is strict, $\bar{\lambda} = \bar{\mu} = 0$ is not an admissible possibility, which proves (5.1).

Now, from (5.5), since $\bar{B} = \bar{C} \times (-\infty, 0]$, we obtain that

$$(5.6) \quad \langle \bar{\mu}, z_1 \rangle + \bar{\lambda} \lambda_1 \geq \langle \bar{\mu}, z_2 \rangle + \bar{\lambda} \lambda_2 \quad \forall (z_1, \lambda_1) \in A, (z_2, \lambda_2) \in \bar{B}.$$

Thus it is enough to take $z_1 = G(\bar{u})$, $z_2 = z \in C$ and $\lambda_1 = \lambda_2 = 0$ to deduce (5.2). Inequality (5.3) is obtained by taking $z_1 = G(\bar{u}) + DG(\bar{u}) \cdot (u - \bar{u})$, $\lambda_1 = J'(\bar{u}) \cdot (u - \bar{u})$, with $u \in K$, $\lambda_2 = 0$ and $z_2 = G(\bar{u})$.

Finally, let us prove that $\bar{\lambda} \neq 0$ when the Slater condition is satisfied. Assume that (5.4) is verified and $\bar{\lambda} = 0$. As a first consequence, we have that

$$(5.7) \quad \langle \bar{\mu}, z - G(\bar{u}) \rangle < 0 \quad \forall z \in \overset{\circ}{C}.$$

To prove this inequality, it is enough to suppose that there exists $z_0 \in \overset{\circ}{C}$ such that $\langle \bar{\mu}, z_0 - G(\bar{u}) \rangle = 0$. Due to (5.2), we obtain that

$$\langle \bar{\mu}, z + z_0 - G(\bar{u}) \rangle \leq 0 \quad \forall z \in B_\epsilon(0),$$

with $\epsilon > 0$ small enough in a such way that $B_\epsilon(z_0) \subset \overset{\circ}{C}$. Hence $\langle \bar{\mu}, z \rangle \leq 0$ for every $z \in B_\epsilon(z_0)$, which implies that $\bar{\mu} = 0$, contradicting (5.1).

Now, taking $z = G(\bar{u}) + DG(\bar{u}) \cdot (u_0 - \bar{u}) \in \overset{\circ}{C}$ in (5.7), it follows that

$$\langle [DG(\bar{u})]^* \bar{\mu}, u_0 - \bar{u} \rangle = \langle \bar{\mu}, DG(\bar{u}) \cdot (u_0 - \bar{u}) \rangle < 0,$$

which contradicts (5.3); therefore $\bar{\lambda} > 0$. It is enough to divide (5.2) and (5.3) by $\bar{\lambda}$ and to again denote the quotient $\bar{\mu}/\bar{\lambda}$ by $\bar{\mu}$ to get the desired result. \square

Remark 2. If U is separable and J and G are of class C^1 in a neighborhood of \bar{u} , it is possible to prove, using the Clarke's generalized gradient calculus, that problem (Q) is normal almost always; this means that almost always we can take $\bar{\lambda} = 1$. More precisely, for all $\delta > 0$, let $C_\delta = (1 - \delta)z_0 + \delta C$ and

$$(Q_\delta) \begin{cases} \text{Min } J(u), \\ u \in K \text{ and } G(u) \in C_\delta. \end{cases}$$

If this problem has a solution for all number δ ranging an interval I , then (Q_δ) is normal for almost every $\delta \in I$; see Bonnans and Casas [3], [4].

Before applying the previous theorem to our control problem, let us introduce some notation. $M(X)$ denotes the space of real regular Borel measures in X ; that is, $M(X)$ is the dual space of $C(X)$ (note that X is a compact subset of $\bar{\Omega}$). The norm in $M(X)$ is given by

$$(5.8) \quad \|\mu\|_{M(X)} = |\mu|(X) = \sup \left\{ \int_X y(x) d\mu(x) : y \in C(X) \text{ and } \|y\|_\infty \leq 1 \right\},$$

where $|\mu|$ is the total variation measure; see Rudin [16]. Every element $\mu \in M(X)$ can be decomposed as a sum of two measures $\mu = \mu_\Omega + \mu_\Gamma$, μ_Ω and μ_Γ being regular real Borel measures in $\bar{\Omega}$, concentrated in $\Omega \cap X$ and $\Gamma \cap X$, respectively.

We now are ready to derive the optimality system for problem (P).

THEOREM 5.3. *Let \bar{u} be a solution of problem (P); then there exist a real number $\bar{\lambda} \geq 0$ and elements $\bar{y} \in H^1(\Omega) \cap C(\bar{\Omega})$, $\bar{p} \in W^{1,s}(\Omega)$ for all $s < n/(n-1)$ and $\bar{\mu} \in M(X)$ satisfying*

$$(5.9) \quad \bar{\lambda} + \|\bar{\mu}\|_{M(X)} > 0;$$

$$(5.10) \quad \begin{aligned} A\bar{y} + \phi(\bar{y}) &= f && \text{in } \Omega, \\ \partial_{\nu_A} \bar{y} &= \bar{u} && \text{on } \Gamma; \end{aligned}$$

$$(5.11) \quad \begin{aligned} A^* \bar{p} + \phi'(\bar{y}) \bar{p} &= \bar{\lambda}(\bar{y} - y_d) + \bar{\mu}_\Omega && \text{in } \Omega, \\ \partial_{\nu_A^*} \bar{p} &= \bar{\mu}_\Gamma && \text{on } \Gamma; \end{aligned}$$

$$(5.12) \quad \int_X (z - \bar{y}) d\bar{\mu} \leq 0 \quad \forall z \in C;$$

$$(5.13) \quad \int_{\Gamma} (\bar{p} + \bar{\lambda} N |\bar{u}|^{\sigma-2} \bar{u}) (u - \bar{u}) dm_{\Gamma}(x) \geq 0 \quad \forall u \in K,$$

where A^* is the adjoint operator of A . Moreover, if the following Slater condition is verified:

$$(5.14) \quad \exists (u_0, z_0) \in K \times (H^1(\Omega) \cap C(\bar{\Omega})) / (\bar{y} + z_0) \in \overset{\circ}{C},$$

where z_0 is the solution of the following Neumann problem:

$$\begin{aligned} Az_0 + \phi'(\bar{y})z_0 &= 0 & \text{in } \Omega, \\ \partial_{\nu_A} z_0 &= u_0 - \bar{u} & \text{on } \Gamma, \end{aligned}$$

then system (5.10)–(5.13) is satisfied with $\bar{\lambda} = 1$.

Proof. Theorem 5.3 is a consequence of Theorem 5.2. It is enough to take $U = L^t(\Gamma)$, $Z = C(X)$, J the functional to minimize, G the mapping that associates to each control the corresponding state, which is differentiable (Theorem 3.3), K the convex subset of $L^t(\Gamma)$, and C the convex subset of $Z = C(X)$ with nonempty interior. Theorem 5.2 states the existence of $\bar{\lambda}$ and $\bar{\mu}$ satisfying (5.9) and (5.12). Now let us take $\bar{y} = y_{\bar{u}}$ and $\bar{p} \in W^{1,s}(\Omega)$, the unique solution of (5.11); see Theorem 4.3. Then it remains to prove inequality (5.13), which is accomplished by using the corresponding inequality (5.3). For this, it is enough to establish the identity

$$(5.15) \quad \bar{\lambda} J'(\bar{u}) \cdot v + \langle [DG(\bar{u})]^* \bar{\mu}, v \rangle = \int_{\Gamma} (\bar{p} + \bar{\lambda} N |\bar{u}|^{\sigma-2} \bar{u}) v dm_{\Gamma}(x) \quad \forall v \in L^t(\Gamma).$$

Let $z \in H^1(\bar{\Omega}) \cap C(\bar{\Omega})$ be the solution of the Neumann problem (3.4) with $u = \bar{u}$, and let us take $\{v_k\} \subset D(\Gamma)$ converging to v in $L^t(\Gamma)$ and $z_k \in W^{2,r}(\Omega)$ satisfying

$$\begin{aligned} Az_k + \phi'(\bar{y})z_k &= 0 & \text{in } \Omega, \\ \partial_{\nu_A} z_k &= v_k & \text{on } \Gamma. \end{aligned}$$

Then it follows from Theorem 3.1 that $\{z_k\}$ converges to z uniformly in $\bar{\Omega}$ and strongly in $H^1(\Omega)$ toward z . Hence it follows from relation (4.6) applied to the operator $A^* + \phi'(\bar{y})$ (where $q = \gamma(\bar{p})$, as was proved there), taking $\mu_{\Omega} = \bar{\lambda}(\bar{y} - y_d) + \bar{\mu}_{\Omega}$ and $\mu_{\Gamma} = \bar{\mu}_{\Gamma}$, that

$$\begin{aligned} \bar{\lambda} \int_{\Omega} (\bar{y} - y_d) z dx + \int_{\bar{\Omega}} z d\bar{\mu} &= \lim_{k \rightarrow \infty} \left(\bar{\lambda} \int_{\Omega} (\bar{y} - y_d) z_k dx + \int_{\bar{\Omega}} z_k d\bar{\mu} \right) \\ &= \lim_{k \rightarrow \infty} \left(\bar{\lambda} \int_{\Omega} (\bar{y} - y_d) z_k dx + \int_{\Omega} z_k d\bar{\mu}_{\Omega} + \int_{\Gamma} z_k d\bar{\mu}_{\Gamma} \right) \\ &= \lim_{k \rightarrow \infty} \left(\int_{\Omega} \bar{p} (Az_k + \phi'(\bar{y})z_k) dx + \int_{\Gamma} \bar{p} \partial_{\nu_A} z_k dm_{\Gamma}(x) \right) \\ &= \lim_{k \rightarrow \infty} \int_{\Gamma} \bar{p} v_k dm_{\Gamma}(x) = \int_{\Gamma} \bar{p} v dm_{\Gamma}(x). \end{aligned}$$

Therefore (5.15) is deduced from the above relation and the equality

$$\begin{aligned} &\bar{\lambda} J'(\bar{u}) \cdot v + \langle [DG(\bar{u})]^* \bar{\mu}, v \rangle \\ &= \bar{\lambda} \int_{\Omega} (\bar{y} - y_d) z dx + \bar{\lambda} N \int_{\Gamma} |\bar{u}|^{\sigma-2} \bar{u} v dm_{\Gamma}(x) + \int_{\bar{\Omega}} z d\bar{\mu}. \end{aligned}$$

The qualification ($\bar{\lambda} = 1$) under the Slater condition (5.14) follows directly from Theorem 5.2. \square

Remark 3. If ϕ is a linear function, then the Slater condition (5.14) becomes

$$\exists u_0 \in K \quad \text{such that } y_{u_0} \in \overset{\circ}{C}.$$

Thus, assuming ϕ linear,

$$(5.16) \quad C = \{z \in C(X) : |z(x)| \leq \delta \quad \forall x \in X\},$$

and $\delta_0 > 0$ such that (P) has a feasible control for this value, then the Slater condition is satisfied for every $\delta > \delta_0$.

This condition allows us to deduce the optimality system (5.10)–(5.13) with $\bar{\lambda} = 1$. It is possible, however, to sometimes deduce that $\bar{\lambda} = 1$ without proving the Slater condition. For example, if C and δ_0 are defined as above, with ϕ not necessarily linear, then the optimality system is verified with $\bar{\lambda} = 1$ for almost all $\delta \in [\delta_0, +\infty)$; see Remark 2.

Remark 4. Let us suppose that C is given as above, and let be $\bar{\mu} = \bar{\mu}_\Omega + \bar{\mu}_\Gamma$; then $\bar{\mu}$ has a Jordan decomposition $\bar{\mu} = \bar{\mu}^+ - \bar{\mu}^-$ in such a way that $\bar{\mu}^+$ is concentrated in the Borel set X^+ and $\bar{\mu}^-$ is concentrated in X^- , where

$$X^+ = \{x \in X : \bar{y}(x) = +\delta\} \quad \text{and} \quad X^- = \{x \in X : \bar{y}(x) = -\delta\}.$$

In particular, if the equality $|\bar{y}(x)| = \delta$ is satisfied at a finite set of points $\{x_j\}_{j=1}^m$, then we have that

$$\bar{\mu} = \sum_{j=1}^m \lambda_j \delta_{x_j},$$

where $\lambda_j \in \mathbb{R}$ and δ_{x_j} is the Dirac measure concentrated at x_j . Furthermore, $\lambda_j \geq 0$ if $\bar{y}(x_j) = +\delta$ and $\lambda_j \leq 0$ if $\bar{y}(x_j) = -\delta$; see Casas [7].

Remark 5. From (5.13) we can deduce some qualitative properties of the optimal control \bar{u} . For example, if $N = 0$ or $\bar{\lambda} = 0$ and

$$K = \{u \in L^\infty(\Gamma) : a \leq u(x) \leq b \quad \text{a.e. } [m_\Gamma] \ x \in \Gamma\},$$

then \bar{u} has a behavior of bang-bang type. More precisely, $\bar{u}(x) = a$ if $\bar{p}(x) > 0$ and $\bar{u}(x) = b$ if $\bar{p}(x) < 0$. However, if $N\bar{\lambda} \neq 0$, then \bar{u} can possess additional regularity properties. Thus if there is not any constraint on the control, then from (5.13) it follows that

$$\bar{u}(x) = \frac{-1}{(N\bar{\lambda})^{1/(\sigma-1)}} |\bar{p}(x)|^{(2-\sigma)/(\sigma-1)} \bar{p}(x),$$

where σ is greater than or equal to $t > n - 1$.

Hence \bar{u} is continuous in the points where \bar{p} is continuous. If C is given by (5.16) and we suppose that $y_d \in L^r(\Omega)$, then \bar{p} is continuous in $\Gamma \setminus \text{support}(\bar{\mu})$, which follows from (5.11). Therefore \bar{u} is continuous in the points where the state constraint is not active.

If K is the set of positive controls, the situation is very similar, because, in this case,

$$\bar{u}(x) = \max \left\{ 0, \frac{-1}{(N\bar{\lambda})^{1/(\sigma-1)}} |\bar{p}(x)|^{(2-\sigma)/(\sigma-1)} \bar{p}(x) \right\}.$$

When $K = \{u \in L^\infty(\Gamma) : a \leq u(x) \leq b \text{ a.e. } [m_\Gamma] x \in \Gamma\}$, then σ can be taken equal to 2 and we have that

$$\bar{u}(x) = \text{Proj}_{[a,b]} \left(\frac{-1}{N\lambda} \bar{p}(x) \right).$$

Thus we can deduce again continuity of \bar{u} in the points where the state constraint is not active. Moreover, since the mapping $g : R \rightarrow R$ defined by

$$g(t) = \text{Proj}_{[a,b]} \left(\frac{-t}{N\lambda} \right)$$

is Lipschitz and $\gamma(\bar{p}) \in W^{1/r,s}(\Gamma)$, then $\bar{u} \in W^{1/r,s}(\Gamma)$, also.

SECOND-ORDER SUFFICIENT OPTIMALITY CONDITIONS FOR A CLASS OF NONLINEAR PARABOLIC BOUNDARY CONTROL PROBLEMS*

H. GOLDBERG[†] AND F. TRÖLTZSCH[†]

Abstract. In this paper sufficient second-order optimality conditions are established for parabolic boundary control problems with nonlinear boundary condition and constraints on the control and the state. The main idea is to extend the known theory for systems governed by ordinary differential equations to the case of partial differential equations. This is performed by means of a semigroup approach and a two-norm technique. The verification of the second-order conditions is discussed.

Key words. optimal control, nonlinear parabolic equation, second-order condition, sufficient optimality condition, semigroup

1. Introduction. This paper is a further contribution to the theory of optimality conditions for optimal control problems with distributed parameters. The control system under consideration is governed by a semilinear parabolic equation; hence the control problem belongs to the class of nonconvex optimization problems. In contrast to parabolic control problems with convex objective functional and linear equations, where the list of references on optimality conditions is very extensive, only a few investigations have been devoted to the case of nonlinear parabolic equations. We only mention Friedman [9], Sachs [22], Schmidt [23], and Tröltzsch [24], whose papers are closely related to our work. They are concerned mainly with first-order necessary optimality conditions in the form of “local” maximum principles. Another group of publications is devoted to generalizations of the Pontrjagin maximum principle, which avoids the linearization with respect to the control (being typical for “local” maximum principles). We refer to Fattorini [8], [6], and von Wolfersdorf [29].

First-order optimality conditions are very useful to derive structural properties of optimal controls such as bang-bang theorems and their generalizations (see, for instance, [24]). However, they are lacking in the sufficiency for nonconvex problems. Therefore, their application to the numerical analysis of optimal control problems is limited mainly to the convex case, where the strong convergence of sequences of optimal control of (FEM-) approximations of the control problems can be shown. A number of papers is concerned with such investigations, for instance by Lasiecka [15], [17], Knowles [13], Alt and Mackenroth [1], Malanowski [19], and others.

In nonconvex problems, sufficient second-order conditions at the optimal point are a substitute for convexity. The theory of sufficient second-order conditions for twice differentiable extremal problems in function spaces is known to be more rich and interesting than that for problems in finite-dimensional spaces. This is due to the so-called two-norm discrepancy, expressing the noncompatibility of the norms needed for second-order optimality conditions. This difficulty was resolved successfully by Ioffe [12] and Maurer [20]. Based on these general results a satisfactory theory of sufficient second-order conditions and its application to nonlinear optimal control problems governed by ordinary differential equations was worked out. Our paper seeks to

contribute to an analogous theory of second-order sufficient optimality conditions for control problems governed by semilinear parabolic initial-boundary value problems with constraints on the control and the state. We continue our investigations in [10], where a control problem for the one-dimensional heat equation without state constraints was considered. For a higher-dimensional version we refer to [11]. A first application of these results to the numerical approximations of the corresponding problem is contained in Tröltzsch [27].

The extension to higher-dimensional problems is based on a semigroup approach. We rely heavily upon recent results by Amann [3], [2], Fattorini [7], Lasiecka [16], and others. It should be emphasized that, in contrast to the treatment of control problems for ordinary differential equations, L_2 controls are not transformed to continuous state functions (even if the control appears only linearly). In view of this, a two-norm technique is indispensable for a satisfactory handling of the problems (at least, if continuity of the state is needed to define the objective functional or the state constraints).

In this paper we use the following notation.

Let X, Y be real Banach spaces. Then $\mathcal{L}(X, Y)$ is the space of linear continuous operators from X to Y , $\mathcal{L}(X) = \mathcal{L}(X, X)$. X^* denotes the dual space to X , $A^* \in \mathcal{L}(Y^*, X^*)$ the adjoint operator to $A \in \mathcal{L}(X, Y)$. By $(\cdot, \cdot)(D)$ the pairing between $L_p(D)$ and $L_q(D)$, $1/p + 1/q = 1$, $1 \leq p < \infty$, is denoted (if p, q are not specified, then this sign stands simply for integration on D). For $\Omega \in \mathbb{R}^n$ we shall write $\Omega_T = [0, T] \times \Omega$. Moreover, we will work in the following spaces:

$$\begin{aligned} X_p &= U_p &= L_p(0, T; L_p(\Gamma)), & 1 \leq p < \infty \\ X_\infty &= C([0, T], C(\Gamma)) \\ U_\infty &= L_\infty((0, T) \times \Gamma) \\ W_p^\sigma(\Omega) &- \text{Sobolev-Slobodeckij-space} \end{aligned}$$

2. Formulation of the control problem. We consider the optimal control problem to minimize

$$\int_{\Omega} \varphi(x, w(T, x)) dx + \int_0^T \int_{\Omega} \psi(t, x, w(t, x)) dx dt + \int_0^T \int_{\Gamma} \chi(t, x, w(t, x), u(t, x)) dS_x dt$$

subject to the equation of state

$$(2.1) \quad \begin{aligned} w_t(t, x) &= (\Delta_x - 1)w(t, x) && \text{on } (0, T] \times \Omega \\ w(0, x) &= w_0(x) && \text{on } \Omega \\ \frac{\partial w}{\partial n}(t, x) &= b(t, x, w(t, x), u(t, x)) && \text{on } (0, T] \times \Gamma, \end{aligned}$$

where u is looked upon as a *control* subject to

$$(2.2) \quad u_1(t, x) \leq u(t, x) \leq u_2(t, x) \quad \text{a.e. on } (0, T] \times \Gamma.$$

Furthermore, we are able to include state constraints:

$$(2.3) \quad \int_{\Omega} \Phi_i(x) w(t, x) dx \leq c_i(t) \quad \text{on } [0, T], \quad i = 1, \dots, k.$$

The state $w \in C([0, T], W_p^\sigma(\Omega))$ of the control system is defined below as mild solution for (2.1) and the control u is taken from $L_\infty((0, T) \times \Gamma)$. In the problem the following

quantities occur: $\Omega \in \mathbb{R}^n$, $n \geq 2$, is a bounded domain with C^∞ -boundary Γ , $T > 0$ is a fixed time. $\Phi_i \in W_p^\sigma(\Omega)$, $i = 1, \dots, k$, $w_0 \in W_p^\sigma(\Omega)$, $u_1, u_2 \in L_\infty((0, T) \times \Gamma)$ with $u_1(t, x) < u_2(t, x)$ on $[0, T] \times \Gamma$, and $c_i \in C[0, T]$, $i = 1, \dots, k$, are real-valued functions. Moreover, $\varphi : \Omega \times \mathbb{R} \rightarrow \mathbb{R}$, $\psi : [0, T] \times \Omega \times \mathbb{R} \rightarrow \mathbb{R}$, and $\chi, b : [0, T] \times \Gamma \times \mathbb{R}^2 \rightarrow \mathbb{R}$ are nonlinear functions. They are supposed for convenience to be twice continuously differentiable on their domains (although this could be weakened partially to natural measurability assumptions with respect to (t, x)). By $\partial/\partial n$ we denote the outward normal derivative at Γ , dS_x is the surface measure on Γ .

Remark 1. The choice of the differential operator $\Delta_x - I$ is only for technical reasons to make the corresponding elliptic Neumann problem uniquely solvable. By the simple transformation $\tilde{w}(t, x) = e^{-t}w(t, x)$ the case Δ_x can be transformed back to our problem (with redefined nonlinear functions). Moreover, the theory works analogously for more general uniformly elliptic differential operators with C^∞ -coefficients.

The function $b = b(t, x, w, u)$ defines a Nemytskij operator B by

$$B(w, u)(t, x) = b(t, x, w(t, x), u(t, x))$$

from $C([0, T] \times \Gamma) \times L_\infty((0, T) \times \Gamma)$ to $L_\infty((0, T) \times \Gamma)$. B is twice continuously Fréchet differentiable owing to the assumptions on b . However, we shall define B in slightly changed spaces.

It is obvious that $C([0, T] \times \Gamma) = C([0, T], C(\Gamma)) = X_\infty$. Moreover $L_p(0, T; L_p(\Gamma)) = L_p((0, T) \times \Gamma)$, $1 \leq p < \infty$ (each equivalence class of functions of a space can be represented by one, belonging to the other space), but only

$$L_\infty(0, T; L_\infty(\Gamma)) \subset L_\infty((0, T) \times \Gamma)$$

(cf. the simple example given by Fattorini [6]). Therefore, in what follows we regard B as an operator from $X_\infty \times U_\infty$ to X_p . Clearly B remains twice Fréchet differentiable in this more general setting. We indicate the trace operator by τ .

DEFINITION 1 (cf. [2] and [3]). Any $w \in W_p^\sigma(\Omega)$ satisfying

$$(2.4) \quad w(t) = S(t)w_0 + \int_0^t AS(t-s)NB(\tau w, u)(s) ds, \quad t \in [0, T],$$

is called a *mild solution* of (2.1). Here $A : L_p(\Omega) \supset D(A) \rightarrow L_p(\Omega)$ is defined by

$$D(A) = \left\{ w \in W_p^2(\Omega) : \frac{\partial w}{\partial n} = 0 \right\}, \quad Aw = -\Delta w + w,$$

S is the semigroup generated by $-A$ in $L_p(\Omega)$, and the Neumann operator $N : L_p(\Gamma) \rightarrow W_p^\sigma(\Omega)$ assigns to g the solution w of $\Delta w - w = 0$, $\partial w/\partial n = g$. The parameters p and σ are fixed subject to $p > n + 1$ and

$$(2.5) \quad \frac{n}{p} < \sigma < 1 + \frac{1}{p}.$$

We should note that (2.5) implies $W_p^\sigma(\Omega) \hookrightarrow C(\bar{\Omega})$ and $W_p^{\sigma-(1/p)}(\Gamma) \hookrightarrow C(\Gamma)$; hence $\tau w \in X_\infty$.

Completely analogous, operators $A_r, S_r(t)$, and N_r are introduced substituting $r \in (1, \infty)$ for p in Definition 1. Thus we have $A = A_p, S = S_p, N = N_p$.

The properties of the solution of (2.4) have been discussed extensively by Amann; we refer, for instance, to [2] and [3]. It was shown that a mild solution w is also a weak solution (cf. [2]). For the case of control problems see also Tröltzsch [28]: There is a sufficiently small $T > 0$ such that for all $u \in U_{ad}$ satisfying (2.2) a unique solution $w \in C([0, T], W_p^\sigma(\Omega))$ of (2.4) exists. The key to this result is that $A_r S_r(t) N_r$ is a continuous operator from $L_p(\Gamma)$ to $W_p^\sigma(\Omega)$ for $t > 0$ together with the estimate

$$(2.6) \quad \|A_r S_r(t) N_r\|_{L_r(\Gamma) \rightarrow W_p^\sigma(\Omega)} \leq ct^{-(1-(\sigma'-\sigma)y/2)},$$

for all $0 < \sigma < \sigma' < 1 + 1/r$ derived by Amann [3]. We assume throughout this paper that $T > 0$ meets this requirement. Often we can proceed on the assumption $T = \infty$, we mention only [23], which considered several practical important types of nonlinear boundary conditions.

The presence of the state-constraint (2.3) essentially complicates the treatment of our nonlinear optimal control problem. This difficulty can be resolved by embedding the problem into a general class of nonlinear programs in Banach spaces with equality and inequality constraints. Therefore, it is natural and necessary to invoke the corresponding extensive theory of optimality conditions. In view of this, we now convert the control problem into a mathematical programming problem.

We want to minimize

$$f(w, u) := f^1(w(T)) + f^2(w) + f^3(w, u),$$

where

$$\begin{aligned} f^1 &: C(\overline{\Omega}) \rightarrow \mathbb{R}, \\ f^1(w) &= \int_{\Omega} \varphi(x, w(x)) \, dx \\ f^2 &: C([0, T], C(\overline{\Omega})) \rightarrow \mathbb{R}, \\ f^2(w) &= \int_0^T \int_{\Omega} \psi(t, x, w(t, x)) \, dx \, dt \\ f^3 &: X_\infty \times L_\infty((0, T) \times \Gamma) \rightarrow \mathbb{R}, \\ f^3(w, u) &= \int_0^T \int_{\Gamma} \chi(t, x, w(t, x), u(t, x)) \, dS_x \, dt. \end{aligned}$$

The state constraints can be formalized by linear operators G_i ,

$$(G_i w)(t) = \int_{\Omega} \Phi_i(x) w(t, x) \, dx,$$

being continuous from $C([0, T], C(\overline{\Omega}))$ to $C[0, T]$. After introducing the operators

$$\begin{aligned} (Lz)(t) &= \int_0^t AS(t-s)Nz(s) \, ds, \\ (Kz)(t) &= (\tau Lz)(t), \\ \Lambda z &= (Lz)(T), \end{aligned}$$

the new state function $v(t) = \tau w(t)$, and $d(t) = S(t)w_0$, we can formulate our control problem as

$$(P) \quad \begin{aligned} & f^1(d(T) + \Lambda B(v, u)) + f^2(d + LB(v, u)) + f^3(v, u) = \min! \\ & v = \tau d + KB(v, u), \\ & G_i(d + LB(v, u)) \leq c_i, \quad i = 1, \dots, k, \\ & u \in C. \end{aligned}$$

3. First-order necessary optimality conditions. A pair $(v, u) \in X_\infty \times U_\infty$ satisfying all constraints of (P) is said to be *admissible*. In what follows let the admissible (v^o, u^o) be locally optimal for (P). Then u^o is said to be an *optimal control*. That means $F(v^o, u^o) \leq F(v, u)$ for all (v, u) being admissible and contained in a sufficiently small neighbourhood of (v^o, u^o) in the space $X_\infty \times U_\infty$. If u is sufficiently close to u^o , then so is v to v^o . Hence local optimality can also be formulated in terms of u only. For computing the Fréchet derivatives of the nonlinear functionals and operators under consideration we need the first- and second-order derivatives of φ , χ , ψ , b at the optimal pair. We indicate them by corresponding subscripts and omit the dependence on v^o , u^o , w^o . For instance,

$$\begin{aligned} \psi_w(t, x) &= \frac{\partial \psi}{\partial w}(t, x, w^o(t, x)), \\ \psi_{ww}(t, x) &= \frac{\partial^2 \psi}{\partial w^2}(t, x, w^o(t, x)). \end{aligned}$$

In this way, the first-order Fréchet derivatives admit the following form:

$$\begin{aligned} (f^1)'(w^o(T))w &= \int_{\Omega} \varphi_w(x)w(x) dx, \quad (f^2)'(w^o)w = \int_0^T \int_{\Omega} \psi_w(t, x)w(t, x) dx dt \\ (f^3)'(v^o)h &= \int_0^T \int_{\Gamma} \chi_w(t, x)v(t, x) dS_x dt + \int_0^T \int_{\Omega} \chi_u(t, x)z(t, x) dS_x dt, \\ (h = (v, z) \in X_\infty \times U_\infty), \end{aligned}$$

and

$$B'(v^o, u^o)h = B_v v + B_u z,$$

where

$$(B_v v)(t, x) = b_w(t, x)v(t, x), \quad (B_u z)(t, x) = b_u(t, x)z(t, x).$$

The functions φ_w , ψ_w , χ_w , χ_u , b_w , and b_u are bounded and measurable on their domains. Hence the linear functionals $(f^i)'$ and the linear operators B_v , B_u extend continuously to all corresponding L_p -spaces (p according to Definition 1). In the following we regard these extensions and use the same notation as before. In doing so, we have $(f^1)' \in L_p(\Omega)^*$, $(f^2)' \in X_p^*$, $(f^3)' \in X_p^* \times X_p^*$, $B_u, B_v \in \mathcal{L}(X_p)$. It should be emphasized that we first determine the derivative in $X_\infty \times U_\infty$. Only the derivatives, after having been computed, are extended to $X_p \times U_p$. The second-order Fréchet derivative of B at (v^o, u^o) is given by

$$(B''(v^o, u^o)[h, h])(t, x) = h(t, x)^T b''(t, x)h(t, x),$$

where $h(t, x)^T = (v(t, x), u(t, x))$ and

$$b''(t, x) = \begin{pmatrix} b_{ww}(t, x) & b_{wu}(t, x) \\ b_{uw}(t, x) & b_{uu}(t, x) \end{pmatrix}$$

(partial derivatives taken at $(t, x, v^o(t, x), u^o(t, x))$). To formulate the optimality conditions we introduce the *Lagrange function*

$$\begin{aligned} \mathcal{L}(v, u; y, \lambda) &= F(v, u) + \int_0^T \int_{\Gamma} (v - \tau d - KB(v, u))(t, x) y(t, x) dS_x dt \\ &+ \sum_{i=1}^k \int_0^T G_i(d + LB(v, u))(t) d\lambda_i(t). \end{aligned}$$

The operators K , L , and Λ have their range in spaces of continuous abstract functions. Embedding the range spaces into corresponding L_p -spaces we can regard them as operators from L_p to L_p . We do so in what follows; i.e., we define K , L , and Λ as operators between the following spaces: $K : X_p \rightarrow X_p$, $L : X_p \rightarrow L_p(0, T; L_p(\Omega))$, $\Lambda : X_p \rightarrow L_p(\Omega)$. Therefore, $K^* : X_q \rightarrow X_q$, $L^* : L_q(0, T; L_q(\Omega)) \rightarrow X_q$, $\Lambda^* : X_q \rightarrow L_q(\Omega)$ ($1/p + 1/q = 1$). The kernels of these operators are regarded in L_p -spaces, too: $AS(t)N : L_p(\Gamma) \rightarrow L_p(\Omega)$, $\tau AS(t)N : L_p(\Gamma) \rightarrow L_p(\Gamma)$, $t > 0$. Their adjoint operators can be determined by a simple integration by parts, cf. [24]: $(AS(t)N)^* = \tau S_q(t) : L_q(\Omega) \rightarrow L_q(\Gamma)$, $(\tau AS(t)N)^* = \tau A_q S_q(t) N_q : L_q(\Gamma) \rightarrow L_q(\Gamma)$. Thus

$$\begin{aligned} (K^*y)(t) &= \int_t^T \tau A_q S_q(s-t) N_q y(s) ds, \\ (L^*w)(t) &= \int_t^T \tau S_q(s-t) w(s) ds, \\ (\Lambda^*\varphi)(t) &= \tau S_q(T-t) \varphi. \end{aligned}$$

For the proof of a Lagrange multiplier rule we need a certain regularity condition.

DEFINITION 2. The pair $(v^o, u^o) \in X_\infty \times U_\infty$ is said to be *regular* for (P), if there exists a pair $(\bar{v}, \bar{u}) \in X_\infty \times C$ such that

$$(3.1) \quad \bar{v} - v^o = K(B_v(\bar{v} - v^o) + B_u(\bar{u} - u^o))$$

$$(3.2) \quad (G_i(w^o) + G_i L(B_v(\bar{v} - v^o) + B_u(\bar{u} - u^o)))(t) < c_i(t)$$

on $[0, T]$, $i = 1, \dots, k$, where $w^o := d + LB(v^o, u^o)$.

THEOREM 3.1. Suppose that (v^o, u^o) is a regular locally optimal solution of the optimal control problem (P). Then there are $y \in L_q(0, T; L_q(\Gamma))$ and monotone non-decreasing $\lambda_i \in NBV[0, T]^1$ such that

$$(3.3) \quad \mathcal{L}_v(v^o, u^o; y, \lambda) = 0$$

$$(3.4) \quad \mathcal{L}_u(v^o, u^o; y, \lambda)(u - u^o) \geq 0 \quad \forall u \in C$$

$$(3.5) \quad \int_0^T (G_i(w^o) - c_i)(t) d\lambda_i(t) = 0, \quad i = 1, \dots, k,$$

¹ Space of functions of bounded variation with the normalization condition $\lambda_i(T) = 0$.

where $\mathcal{L}_v, \mathcal{L}_u$ denote the partial Fréchet derivatives of L at (v^o, u^o) in the space $X_\infty \times U_\infty$, $\lambda = (\lambda_1, \dots, \lambda_k)$.

We sketch the proof only briefly. The underlying two-space technique is derived in a more elegant way in [24], [25]:

Proof. As a (nontrivial) conclusion of the regularity condition we know that (v^o, u^o) is the solution of the *linearized control problem*

$$\begin{aligned} F_v(v^o, u^o)v + F_u(v^o, u^o)u &= \min!, \\ v &= K(B_v v + B_u(u - u^o)), \\ G_i(w^o) + G_i L(B_v v + B_u(u - u^o)) &\leq c_i, \quad i = 1, \dots, k, \\ u &\in C. \end{aligned}$$

In the next step we extend the space $X_\infty \times U_\infty$ to $X_p \times U_p$; i.e., we look for all solutions of this problem in $X_p \times U_p$. As K and L map X_p into spaces of continuous functions, the linearized admissible set remains unchanged. Moreover, continuity and extension properties of $B_v, B_u, (f^i)'$, $i = 1, 2, 3$, imply that F_v and F_u can be continuously extended to X_p and U_p . In view of this, we can assume $F_v \in X_p^*, F_u \in U_p^*$. On the other hand, the linearized problem in $X_p \times U_p$ satisfies the regularity condition at (\bar{v}, \bar{u}) , too. Therefore, a Lagrange multiplier rule is valid: There exist $y \in X_q, \lambda_i \in NBV[0, T]$ such that

$$(3.6) \quad \begin{aligned} &(\Lambda B_v v, \varphi_w)(\Omega) + (LB_v v, \psi_w)(\Omega_T) + (\chi_w, v)(\Gamma_T) \\ &+ (v - KB_v v, y)(\Gamma_T) + \sum_{i=1}^k \int_0^T (G_i LB_v v)(t) d\lambda_i(t) = 0 \end{aligned}$$

for all $v \in X_p$,

$$(3.7) \quad \begin{aligned} &(\Lambda B_u(u - u^o), \varphi_w)(\Omega) + (LB_u(u - u^o), \psi_w)(\Omega_T) \\ &+ ((\chi_u - KB_u)(u - u^o), y)(\Gamma_T) + \sum_{i=1}^k \int_0^T (G_i LB_u(u - u^o))(t) d\lambda_i(t) \geq 0 \end{aligned}$$

for all $u \in C$, and the complementary slackness condition (3.5) holds. Writing down \mathcal{L}_v and \mathcal{L}_u we see that (3.6) and (3.7) are equivalent to (3.3) and (3.4). \square

The concrete expression of $(G_i L)^*$ is derived in the following lemma.

LEMMA 3.2. For $(G_i L)^* : NBV[0, T] \rightarrow L_q(0, T; L_q(\Gamma))$

$$(L^* G_i^* \Phi_i)(t) = \int_t^T \tau S_p(s - t) \Phi_i d\lambda_i(s)$$

holds. The function $S_p(s - t)\Phi_i$ belongs to $C(D, C(\bar{\Omega}))$, where $D = \{(t, s) | 0 \leq t \leq s \leq T\}$.

Proof. We have

$$(AS(s - t)N)^* \Phi_i = \tau S_q(s - t) \Phi_i = \tau S_p(s - t) \Phi_i,$$

as $\Phi_i \in W_p^\sigma(\Omega)$. This follows by means of Pazy [21, Chap. 4, Thm. 5.5]. Moreover, it is known that $S_p(t)$ restricts to a strongly continuous semigroup on $W_p^\sigma(\Omega)$, cf. [3]; hence

$S_p(s-t)\Phi_i$ is a continuous abstract function on D with values in $W_p^\sigma(\Omega) \hookrightarrow C(\overline{\Omega})$. This yields the second assertion of the lemma. Thus

$$\begin{aligned} \int_0^T (G_i Lz)(t) d\lambda_i(t) &= \int_0^T (\Phi_i, \int_0^t AS(t-s)Nz(s) ds)(\Omega) d\lambda_i(t) \\ &= \int_0^T \int_0^t (\tau S_p(t-s)\Phi_i, z(s))(\Gamma) ds d\lambda_i(t) \\ &= \int_0^T \int_t^T (\tau S_p(s-t)\Phi_i d\lambda_i(s), z(t))(\Gamma) dt \\ &= \int_0^T ((G_i L\Phi_i)^*(t), z(t))(\Gamma) dt, \end{aligned}$$

where the abstract Riemann–Stieltjes integral exists due to the continuity of $\tau S_p(s-t)\Phi_i$. \square

Using in (3.6) and (3.7) the (L_p-) adjoint of the linear operators we arrive at

$$\begin{aligned} \mathcal{L}_v(v^o, u^o; y, \lambda)v &= \left(v, y + B_v^* \left\{ -K^*y + \Lambda^*\varphi_w + \sum_{i=1}^k L^*G_i^*\lambda_i \right\} + \chi_w \right) (\Gamma_T) \\ (3.8) \quad &=: \int_0^T \int_{\Gamma} v(t, x) \mathcal{L}_v(t, x) dS_x dt, \end{aligned}$$

$$\begin{aligned} \mathcal{L}_u(v^o, u^o; y, \lambda)u &= \left(u, B_u^* \left\{ -K^*y + \Lambda^*\varphi_w + \sum_{i=1}^k L^*G_i^*\lambda_i \right\} + \chi_u \right) (\Gamma_T) \\ (3.9) \quad &=: \int_0^T \int_{\Gamma} u(t, x) \mathcal{L}_u(t, x) dS_x dt. \end{aligned}$$

From the optimality conditions,

$$y(t) = -b_w(t, \cdot) \left\{ -K^*y + \Lambda^*\varphi_w + L^*\psi_w + \sum_{i=1}^k L^*G_i^*\lambda_i \right\} (t) - \chi_w(t, \cdot);$$

hence, after inserting the expressions for the adjoint operators,

$$\begin{aligned} y(t, \cdot) &= -b_w(t, \cdot) \left\{ - \int_t^T \tau A_q S_q(s-t) N_q y(s) ds + \tau S_q(T-t) \varphi_w \right. \\ (3.10) \quad &\quad \left. + \int_t^T \tau S_q(s-t) \psi_w(s) ds + \sum_{i=1}^k \int_t^T \tau S_p(s-t) \Phi_i d\lambda_i(s) \right\} - \chi_w(t, \cdot). \end{aligned}$$

This may be defined as an adjoint equation. However, it is more convenient to intro-

duce

$$(3.11) \quad p(t, \cdot) = \left\{ - \int_t^T \tau A_q S_q(s-t) N_q y(s) ds + \tau S_q(T-t) \varphi_w \right. \\ \left. + \int_t^T \tau S_q(s-t) \psi_w(s) ds + \sum_{i=1}^k \int_t^T \tau S_p(s-t) \Phi_i d\lambda_i(s) \right\}$$

as a new adjoint state. This function can be interpreted as the mild solution of an adjoint parabolic initial boundary value problem (cf. [26]).

4. Second-order sufficient optimality conditions. In what follows let (v^o, u^o) be an admissible pair for (P). The set $M(v^o, u^o)$ consisting of all elements $(k, z) \in X_\infty \times U_\infty$ with

$$k = K(B_v k + B_u z), \quad G_i w^o + G_i L(B_v k + B_u z) \leq c_i, \quad i = 1, \dots, k,$$

$z = \lambda(u - u^o)$, $\lambda \geq 0$, $u \in C$, is said to be the *linearized set at (v^o, u^o)* . By $r_2^{\mathcal{L}}(h)$ we denote the second-order remainder term of \mathcal{L} at (v^o, u^o) in the direction $h = (v - v^o, u - u^o) \in X_\infty \times U_\infty$:

$$(4.1) \quad r_2^{\mathcal{L}}(h) = \mathcal{L}(v, u) - \mathcal{L}(v^o, u^o) - \langle \mathcal{L}_v, v - v^o \rangle - \langle \mathcal{L}_u, u - u^o \rangle - \frac{1}{2} \mathcal{L}''(v^o, u^o)[h, h].$$

Moreover, we will use the following norms throughout this section: For $1 \leq \alpha \leq \infty$ we denote by $\|\cdot\|_\alpha$ the norm of U_α . The product space $X_\alpha \times U_\alpha$ will be confined with the norm

$$\|(v, u)\|_\alpha := \max(\|v\|_\alpha, \|u\|_\alpha).$$

To overcome the known “two-norm discrepancy,” which is the main difficulty to derive sufficient second-order conditions, we follow Maurer [20] and make the following assumptions.

- (A1) For all admissible (v, u) there is a pair $(k, z) = (k(v, u), z(v, u))$ belonging to the linearized set $M(v^o, u^o)$ such that for $h = (v - v^o, u - u^o)$

$$\|(k, z) - h\|_2 \|h\|_2^{-1} \rightarrow 0,$$

as $\|h\|_\infty \rightarrow 0$.

- (A2) (i) $|r_2^{\mathcal{L}}(h)| \|h\|_2^{-2} \rightarrow 0$, as $\|h\|_\infty \rightarrow 0$;
(ii) There exists $c > 0$: $|\mathcal{L}''(v^o, u^o)[(v_1, u_1), (v_2, u_2)]| \leq c \|(v_1, u_1)\|_2 \|(v_2, u_2)\|_2$
for all $(v_i, u_i) \in X_\infty \times U_\infty$, $i = 1, 2$.

Then the following assertion holds.

THEOREM 4.1 (Second order sufficient optimality condition). *Suppose that (A1), (A2) are satisfied. Let (v^o, u^o) be admissible for (P) and fulfill the first-order necessary condition (3.3)–(3.5). Suppose further the existence of a $\delta > 0$ such that*

$$(4.2) \quad \mathcal{L}''(v^o, u^o)[(k, z), (k, z)] \geq \delta \|(k, z)\|_2^2$$

for all $(k, z) \in M(v^o, u^o)$. Then there exist positive α and ϱ such that

$$(4.3) \quad F(v, u) \geq F(v^o, u^o) + \alpha \|(v - v^o, u - u^o)\|_2^2$$

for all admissible (v, u) with $\|(v - v^o, u - u^o)\|_\infty \leq \varrho$.

Proof. We sketch the essential steps of the proof, differing in some details from that given by [20].

Suppose that (v, u) is an admissible pair. Assumption (A1) implies the existence of (k, z) belonging to $M(v^o, u^o)$ and

$$v - v^o = k(v, u) + w_1(v, u), \quad u - u^o = z(v, u) + w_2(v, u),$$

where

$$\|w_1(v, u)\|_2 \|v - v^o\|_2^{-1} \rightarrow 0, \quad \|w_2(v, u)\|_2 \|u - u^o\|_2^{-1} \rightarrow 0$$

as $\|(v - v^o, u - u^o)\|_\infty \rightarrow 0$. Now we begin to estimate the objective functional:

$$F(v, u) \geq \mathcal{L}(v, u)$$

follows from the fact that the state equation is fulfilled and the state constraints are satisfied. From the Taylor expansion of \mathcal{L} and (3.3)–(3.5)

$$\begin{aligned} F(v, u) &\geq F(v^o, u^o) + \frac{1}{2} \mathcal{L}''(v^o, u^o)[(v - v^o, u - u^o), (v - v^o, u - u^o)] \\ &\quad + r_2^{\mathcal{L}}(v - v^o, u - u^o). \end{aligned}$$

Using essentially (A2)(ii) it can be shown, that (4.2) remains true, if k and z underlie a sufficiently small perturbation: There exist positive δ_0 and γ such that

$$\mathcal{L}''(v^o, u^o)[(k + w_1, z + w_2), (k + w_1, z + w_2)] \geq \delta_0 \|(k + w_1, z + w_2)\|_2^2$$

holds for

$$\|w_1(v, u)\|_2 \leq \gamma \|k\|_2 \quad \text{and} \quad \|w_2(v, u)\|_2 \leq \gamma \|z\|_2.$$

These inequalities follow from (A1), if $\|(v - v^o, u - u^o)\|_\infty \leq \varrho_1$ with a certain positive ϱ_1 . We obtain

$$F(v, u) \geq F(v^o, u^o) + \frac{1}{2} \delta_0 \|(v - v^o, u - u^o)\|_2^2 + r_2^{\mathcal{L}}(v - v^o, u - u^o).$$

(A2)(i) yields the existence of a positive ϱ_2 , such that for all admissible (v, u) with $\|(v - v^o, u - u^o)\|_\infty \leq \varrho_2$

$$|r_2^{\mathcal{L}}(v - v^o, u - u^o)| \leq \frac{\delta_0}{4} \|(v - v^o, u - u^o)\|_2^2.$$

Choosing $\varrho = \min\{\varrho_1, \varrho_2\}$ and $\alpha = \delta_0/4$ we get (4.3).

Due to (4.3), $F(v, u) > F(v^o, u^o)$ for all admissible (v, u) in a sufficiently small $X_\infty \times U_\infty$ -neighbourhood of (v^o, u^o) . \square

Remark 2. In addition to the first- and second-order condition the proof of the theorem does not invoke any other assumptions than (A1), (A2), and the differentiability properties of B and \mathcal{L} . Therefore, Theorem 2 remains true for $U_\infty := L_p(0, T; L_p(\Gamma))$ and $\|(k, z)\|_\infty := \max\{\|k\|_\infty, \|z\|_p\}$, provided that B and \mathcal{L} are twice continuously differentiable in the space $X_\infty \times U_p$. This is true for the choice

$$(4.4) \quad b(t, x, w, u) = b_1(t, x, w) + b_2(t, x, w)u$$

and

$$(4.5) \quad \chi(t, x, w, u) = \chi_1(t, x, w) + \chi_2(t, x, w)u + (w, u)\chi_3(t, x)(w, u)^T,$$

where χ_3 is a 2×2 matrix with L_∞ entries.

In the remainder of our paper we shall verify the assumptions (A1), (A2). Assumption (A2) will follow from the differentiability properties of \mathcal{L} and the special behaviour of the linear operators K , L , Λ . Assumption (A1) is implied by the regularity of (v^o, u^o) .

The second-order derivative $\mathcal{L}''(v^o, u^o)[h_1, h_2]$, $h_i = (v_i, u_i) \in X_\infty \times U_\infty$, is

$$(4.6) \quad \begin{aligned} \mathcal{L}''(v^o, u^o)[h_1, h_2] = & \int_0^T \int_\Gamma h_1(t, x)^T \{ \chi''(t, x) + p(t, x)b''(t, x) \} h_2(t, x) dS_x dt \\ & + \int_0^T \int_\Omega \psi_{ww}(t, x)(LB'h_1)(t, x)(LB'h_2)(t, x) dx dt \\ & + \int_\Omega \varphi_{ww}(x)(\Lambda B'h_1)(x)(\Lambda B'h_2)(x) dx, \end{aligned}$$

where $\chi''(t, x)$ is defined analogously to $b''(t, x)$ in §3 and $p(t, x)$ is taken from (3.11),

$$\psi_{ww}(t, x) = \psi_{ww}(t, x, w^o(t, x)), \varphi_{ww} = \varphi_{ww}(x, w^o(T, x)) \text{ and } B' = B'(v^o, u^o).$$

The corresponding computations are too lengthy to be presented here. They are along the lines of the one-dimensional case discussed in [10] and use mainly the formula for the derivative of $q(z) = Q(e + TB(z))$ (with fixed element e , linear continuous operator T):

$$\begin{aligned} q''(z^o)[h_1, h_2] = & Q''(e + TB(z^o))[TB'(z^o)h_1, TB'(z^o)h_2] \\ & + \langle q'(z^o), TB''(z^o)[h_1, h_2] \rangle. \end{aligned}$$

Now we are going to verify (A1), (A2). The key to showing (A2) is that $y(t, x)$ and thus also $p(t, x)$ is bounded and measurable on $(0, T) \times \Gamma$.

LEMMA 4.2. *The function $y(t, x)$ is bounded and measurable on $(0, T) \times \Gamma$.*

Proof. Equation (3.10) admits the form

$$(4.7) \quad y(t, \cdot) = -b_w(t, \cdot) \left\{ h(t) - \int_t^T \tau A_q S_q(s-t) N_q y(s, \cdot) ds \right\} - \chi_w(t, \cdot)$$

with

$$h(t) = \tau S_q(T-t)\varphi_w + \int_t^T \tau S_q(s-t)\psi_w(s) ds + \sum_{i=1}^k \int_t^T \tau S_q(s-t)\Phi_i d\lambda_i(s).$$

We will prove below that $h \in L_\infty((0, T) \times \Gamma)$, thus $h \in X_p$, too. It follows from Pazy [21, Chap. 4, Thm. 5.5], that the part of A_q in $L_p(\Omega)$ is A_p and the restriction of $S_q(t)$ to $L_p(\Omega)$ coincides with $S_p(t)$. Therefore, $v \in X_p$ implies

$$(4.8) \quad A_q S_q(s-t) N_q v(s) = A_p S_p(s-t) N_p v(s).$$

The real-valued function $b_w = b_w(t, x)$ is bounded and measurable on $(0, T) \times \Gamma$. Now we regard the slightly changed equation

$$\hat{y}(t, \cdot) = -b_w(t, \cdot) \left\{ h(t) - \int_t^T \tau A_p S_p(s-t) N_p \hat{y}(s, \cdot) ds \right\} - \chi_w(t, \cdot).$$

It admits a unique solution $\hat{y} \in X_p$. Moreover \hat{y} is bounded and measurable on $(0, T) \times \Gamma$, as the integral operator maps X_p in X_∞ , $h, b_w, \chi_w \in L_\infty((0, T) \times \Gamma)$. From (4.8),

$$A_q S_q(s-t) N_q \hat{y}(s) = A_p S_p(s-t) N_p \hat{y}(s);$$

hence \hat{y} solves (4.7), too. By the uniqueness of the solution to (4.7) we conclude $y = \hat{y}$; hence $y \in L_\infty((0, T) \times \Gamma)$. It remains to show that $h \in L_\infty((0, T) \times \Gamma)$. The function $z(t) = S_q(T-t)\varphi_w$ solves the parabolic problem

$$-z_t(t, x) = \Delta z(t, x) - z(t, x), \quad z(T, x) = \varphi_w(x)$$

subject to homogeneous Neumann boundary conditions, where $\varphi_w(x) = \varphi_w(x, w^\circ(T, x))$. On the other hand, $w^\circ(T, x)$ is continuous on $\bar{\Omega}$, as $w^\circ \in W_p^\sigma(\Omega) \hookrightarrow C(\bar{\Omega})$. Invoking the maximum principle, $|z(t, x)| \leq \max_{x \in \bar{\Omega}} \varphi_w(x)$. Clearly, this implies $\tau z \in L_\infty((0, T) \times \Gamma)$. The real-valued function $\psi_w(t, x)$ is bounded and measurable on $(0, T) \times \Omega$, hence $\psi_w \in L_p(0, T; L_p(\Omega))$. From [2],

$$\|S_p(s-t)\|_{L_p(\Omega) \rightarrow W_p^\sigma(\Omega)} \leq c|s-t|^{-\sigma/2}$$

is known. In view of this,

$$z(t) = \int_t^T S_p(s-t) \psi_w(s) ds$$

belongs to $C([0, T], W_p^\sigma(\Omega)) \subseteq C([0, T], C(\bar{\Omega}))$, if $p > (1 - (\sigma/2))^{-1}$. The latter holds true for $p > 3$, as $\sigma < 1 + 1/p$. By $n \geq 2$ and $p > n + 1$ we have $p > 3$. The third part of h is bounded and measurable, too. By $\Phi_i \in W_p^\sigma(\Omega)$ we find as above that $S_q(s-t)\Phi_i = S_p(s-t)\Phi_i$; hence $v_i(t, s) = S_p(s-t)\Phi_i$ belongs to $C(D, W_p^\sigma(\Omega)) \subseteq C(D, C(\bar{\Omega}))$, where $D = \{(t, s) \in [0, T] \times [0, T] \setminus \{(t, s) | 0 \leq t \leq s\}\}$. Therefore the abstract Riemann–Stieltjes integrals

$$\int_t^T \tau S_q(s-t) \Phi_i d\lambda_i(s) \quad (i = 1, \dots, k)$$

exist and belong to the class of abstract functions of bounded variation on $[0, T]$ with values in $C(\Gamma)$. \square

LEMMA 4.3. *Assumption (A2) is satisfied under the assumptions imposed on Φ_1, \dots, Φ_n .*

Proof. We begin with (ii). All entries of $\chi''(t, x)$, $b''(t, x)$, and the functions φ_{ww} , ψ_{ww} , $p(t, x)$ are bounded and measurable. Therefore by (4.6),

$$\begin{aligned} |\mathcal{L}''(v^\circ, u^\circ)[h_1, h_2]| &\leq c_1 \|h_1\|_2 \|h_2\|_2 \\ &\quad + c_2 \|LB'h_1\|_{L_2(0, T; L_2(\Omega))} \|LB'h_2\|_{L_2(0, T; L_2(\Omega))} \\ &\quad + c_3 \|\Lambda B'h_1\|_{L_2(\Omega)} \|\Lambda B'h_2\|_{L_2(\Omega)}. \end{aligned} \tag{4.9}$$

Arguing as above we find

$$(Lz)(t) = \int_0^t A_2 S_2(t-s) N_2 z(s) ds,$$

$$\Lambda z = \int_0^T A_2 S_2(T-s) N_2 z(s) ds$$

for $z \in X_p$. The operators on the right-hand side are continuous from X_2 to $L_2(0, T; L_2(\Omega))$ and $L_2(\Omega)$, respectively (we use (2.6) for $r = 2$ and results about weakly singular integral operators in Krasnosel'skij [14]). B maps continuously $X_2 \times X_2$ into X_2 . Now (A2)(ii), follows directly from (4.9).

(i) By means of the second-order Taylor expansion of $\beta(t) = \mathcal{L}((v^o, u^o) + th, y)$ at $t = 0$,

$$2r_2^{\mathcal{L}}(h) = \int_0^T \int_{\Gamma} h(t, x)^T \{[\chi''_{\nu}(t, x) - \chi''(t, x)] + p(t, x)[b''_{\nu}(t, x) - b''(t, x)]\} h(t, x) dS_x dt$$

$$+ \int_0^T \int_{\Omega} [\psi_{ww}^{\nu} - \psi_{ww}](t, x) ((LB'h)(t, x))^2 dx dt$$

$$+ \int_{\Omega} [\varphi_{ww}^{\nu} - \varphi_{ww}](x) ((\Lambda B'h)(x))^2 dx,$$

where $\nu \in (0, 1)$ is independent of (t, x) , $h = (v, u)$,

$$\psi_{ww}^{\nu}(t, x) = \psi_{ww}(t, x, w^o(t, x) + \nu w(t, x))$$

($w = Lv$), and χ''_{ν} , b''_{ν} , φ_{ww}^{ν} are defined analogously at $(v^o + \nu v, u^o + \nu u)$ and $w^o(T) + \nu w(T)$, respectively. All terms in brackets tend to zero in L_{∞} as $\|h\|_{\infty} \rightarrow 0$ owing to the continuity of the corresponding Nemytskij operator in U_{∞} . The other parts can be estimated by $c\|h\|_2^2$. This yields (A2)(ii). \square

LEMMA 4.4. For all $z \in L_p(0, T; L_p(\Gamma))$,

$$\|(I - KB_v)^{-1} z\|_2 \leq c\|z\|_2.$$

Proof. It is well known that for $z \in X_p$ the Bochner integral equation

$$x(t) - \int_0^t \tau A S(t-s) N b_w(s) x(s) ds = z(t)$$

admits a unique solution $x \in X_p$. Arguing as in the proof of Lemma 4.2 we have

$$x(t) - \int_0^t \tau A_2 S_2(t-s) N_2 b_w(s) x(s) ds = z(t),$$

hence (with a generic c),

$$\begin{aligned}\|x(t)\|_{L_2(\Gamma)} &\leq c \int_0^t \|\tau A_2 S_2(t-s) N_2\|_{L_2(\Gamma) \rightarrow L_2(\Gamma)} \|x(s)\|_{L_2(\Gamma)} ds + \|z(t)\|_{L_2(\Gamma)} \\ &\leq \|z(t)\|_{L_2(\Gamma)} + c \int_0^t (t-s)^{-\frac{1}{4}+\varepsilon} \|x(s)\|_{L_2(\Gamma)} ds\end{aligned}$$

by (2.6), where $\varepsilon > 0$ can be taken arbitrarily small. This is a weakly singular integral inequality with positive kernel. Therefore, $\|x(t)\|$ can be estimated by $\|x(t)\| \leq \alpha(t)$, where

$$\alpha(t) = \|z(t)\|_{L_2(\Gamma)} + c \int_0^t (t-s)^{-\frac{1}{4}+\varepsilon} \alpha(s) ds.$$

(cf. Dixon and McKee [5]).

Now it follows from the theory of weakly singular integral equations for real functions that

$$\|\alpha\|_{L_2(0,T)} \leq c \left(\int_0^T \|z(t)\|_{L_2(\Gamma)}^2 dt \right)^{1/2} = c \|z\|_2;$$

hence $\|x\|_2 \leq c \|z\|_2$, too. \square

LEMMA 4.5. *Let (v^o, u^o) be regular and admissible. Then assumption (A1) is satisfied for problem (P).*

Proof. Let (v, u) be an admissible pair for problem (P). Then

$$(4.10) \quad v = KB(v, u) + \tau d,$$

$$(4.11) \quad G_i(LB(v, u) + d)(t) \leq c_i(t) \quad (i = 1, \dots, k).$$

From the Taylor expansion of B at (v^o, u^o) we obtain

$$(4.12) \quad v - v^o = K[B_v(v - v^o) + B_u(u - u^o)] + Kr_1^B(v - v^o, u - u^o)$$

and

$$(4.13) \quad G_i(w^o) + G_i L[B_v(v - v^o) + B_u(u - u^o)] + G_i Lr_1^B(v - v^o, u - u^o) \leq c_i$$

($i = 1, \dots, k$) (note that $w^o = LB(v^o, u^o) + d$).

Now consider the pair (v_1, u) solving the linearized state equation

$$(4.14) \quad v_1 - v^o = K[(B_v(v_1 - v^o) + B_u(u - u^o))].$$

Subtracting (4.14) from (4.12),

$$(4.15) \quad v - v_1 = KB_v(v - v_1) + Kr_1^B(v - v^o, u - u^o).$$

By Lemma 4.4,

$$(4.16) \quad \|v - v_1\|_2 \leq c \|Kr_1^B(v - v^o, u - u^o)\|_2 \leq c \|r_1^B(v - v^o, u - u^o)\|_2$$

(with generic c). It is known that for the Nemytskij operator B

$$(4.17) \quad \|r_1^B(v - v^o, u - u^o)\|_2 \|(v - v^o, u - u^o)\|_2^{-1} \rightarrow 0$$

as $\|(v - v^o, u - u^o)\|_\infty \rightarrow 0$. Therefore $k_1 = v_1 - v^o$, $z_1 = u - u^o$ could be a candidate for (A1), but (k_1, z_1) will possibly not fulfil the linearized constraints. (4.13) yields

$$(4.18) \quad G_i(w^o) + G_i L(B_v k_1 + B_u z_1) \leq c_i - G_i L(B_v(v - v_1) + r_1^B(v - v^o, u - u^o)),$$

$i = 1, \dots, k$. From the second assertion of Lemma 3.2 we conclude that $G_i L$ is continuous from X_2 to $C[0, T]$ (note that $(AS(t-s)N)^* \Phi_i = \tau S_q \Phi_i = \tau S_p \Phi_i$). Hence

$$\max_{[0, T]} |G_i L(B_v(v - v_1) + r_1^B)(t)| \leq \alpha_i(c + 1) \|r_1^B\|_2 \leq c^1 \|r_1^B\|_2$$

$i = 1, \dots, k$. As (v^o, u^o) is regular, there are (\bar{v}, \bar{u}) and a $\delta > 0$ such that

$$(4.19) \quad \bar{v} - v^o = K(B_v(\bar{v} - v^o) + B_u(\bar{u} - u^o)),$$

$$(4.20) \quad (G_i(w^o) + G_i L(B_v(\bar{v} - v^o) + B_u(\bar{u} - u^o)))(t) \leq c_i(t) - \delta$$

$i = 1, \dots, k$, $t \in [0, T]$. We put $\varepsilon = c^1 \|r_1^B\|_2$, $\lambda = \varepsilon/(\varepsilon + \delta)$,

$$u_2 = (1 - \lambda)u + \lambda \bar{u}, \quad v_2 = (1 - \lambda)v_1 + \lambda \bar{v}.$$

Then the pair $(v_2 - v^o, u_2 - u^o)$ belongs to $M(v^o, u^o)$. This follows simply from a convex combination of (4.14), (4.19) and (4.18), (4.20), respectively. We take $k = v_2 - v^o$, $z = u_2 - u^o$ and find

$$\begin{aligned} \|(k, z) - (v - v^o, u - u^o)\|_2 &\leq \|v_2 - v\|_2 + \|u_2 - u\|_2 \\ &\leq \|v - v_1\|_2 + \|v_2 - v_1\|_2 + \lambda \|\bar{u} - u\|_2 \\ &\leq c \|r_1^B\|_2 + \lambda (\|\bar{v} - v_1\|_2 + \|\bar{u} - u\|_2) \\ &\leq \|r_1^B\|_2 (c + \delta^{-1} c^1 (\|\bar{v} - v_1\|_2 + \|\bar{u} - u\|_2)), \end{aligned}$$

by (4.16) and the definition of λ . For $\|(v - v^o, u - u^o)\|_\infty \rightarrow 0$ we have $v_1 \rightarrow v^o$; hence the term in the last bracket remains bounded. The proof is completed by (4.17). \square

Summarizing, Theorem 4.1 and Lemmas 4.2–4.5 yield the main theorem.

THEOREM 4.6. *Let (v^o, u^o) be regular and admissible for the optimal control problem (P), $w^o = d + LB(v^o, u^o)$.*

If (v^o, u^o) satisfies the second-order condition (4.2), then (v^o, u^o) is locally optimal for (P), and (4.3) holds.

COROLLARY 1. *Under the assumptions of Theorem 3, there are $\rho > 0$, $\alpha > 0$, such that (4.3) holds for all admissible (v, u) such that $\|u - u^o\|_\infty \leq \rho$. Thus u^o is a locally optimal control.*

(The corollary follows from (4.3), since $\|v - v^o\|_\infty \rightarrow 0$ for $\|u - u^o\|_\infty \rightarrow 0$.)

COROLLARY 2. *If b and χ satisfy conditions (4.4) and (4.5), respectively, then Theorem 3 and Corollary 1 remain valid for $U_\infty := L_p(0, T; L_p(\Gamma))$ and $\|u - u^o\|_\infty := \|u - u^o\|_p$.*

This is a simple consequence of Remark 2.

Remark 3.

1. The method of this paper extends also to more general optimal control problems with additional control distributed in Ω . The equation of state would be of the type

$$\begin{aligned}w_t(t, x) &= (\Delta - 1)w(t, x) + b_1(t, x, w(t, x), u_1(t, x)) \\w(0, x) &= w_0(x) \\ \frac{\partial w}{\partial n}(t, x) &= b_2(t, x, w(t, x), u_2(t, x)).\end{aligned}$$

Introducing $v(t, x) = \tau w(t, x)$ this leads to a system of Bochner integral equations for the state $(v(t, x), w(t, x))$. However, the presentation of the theory is notationally much more complex.

2. State constraints of the form

$$\int_{\Omega} \langle \Phi_i(x), \nabla_x w(t, x) \rangle dx \leq c_i(t)$$

can be transformed to (2.3) integrating by parts, provided that

$$\Phi_j \in (W_p^{1+\sigma}(\Omega))^n \cap (\overset{\circ}{W}_p^1(\Omega))^n .$$

5. Verification of the second-order condition. To verify the strict positivity of quadratic forms is a difficult task in general. This refers also to (4.2). It is well known from the optimal control theory for systems of ordinary differential equations that matrix Riccati equations may be helpful to solve this problem, see, for instance, Bryson and Ho [4] or Malanowski [19]. A similar approach works for parabolic equations, where the control is distributed, i.e., acting only within the domain under consideration. In this way, parabolic equations of Riccati type are obtained for the kernels representing certain operator-valued functions. We refer to Lions [18, Chap. 3]. This method cannot be extended directly to boundary control problems.

On the other hand, even the solution of parabolic Riccati equations is a difficult question, which generally can only be answered numerically. Therefore, we propose the reduction of the problem to one for a system of ordinary differential equations by means of a finite element method.

We have

$$\mathcal{L}''((v^o, u^o))[(k, z), (k, z)] = Q(w, z),$$

where

$$\begin{aligned}Q(w, z) &= \int_0^T \int_{\Gamma} (w(t, x), z(t, x)) Q_1(t, x) (w(t, x), z(t, x))^T dS_x dt \\ &\quad + \int_0^T \int_{\Omega} Q_2(t, x) w(t, x)^2 dx dt \\ &\quad + \int_{\Omega} \Phi_{ww}(x) w(T, x)^2 dx, \\ &= Q_{11}(w, w) + Q_{12}(w, z) + Q_{22}(z, z),\end{aligned}$$

Q_1 is a certain 2×2 matrix with L_∞ entries, $Q_2 \in L_\infty$ (cf. (4.6)) and w solves

$$(5.1) \quad \begin{aligned} w_t(t, x) &= (\Delta - 1)w(t, x), \\ w(0, x) &= 0, \\ \frac{\partial w}{\partial n}(t, x) &= b_w(t, x)w(t, x) + b_u(t, x)z(t, x). \end{aligned}$$

Let $V_h \subset H^1(\Omega)$ be a finite element space depending on a discretization parameter $h > 0$, $V_h = \text{span}\{v_1, \dots, v_m\}$. We approximate (5.1) by the finite element scheme

$$(5.2) \quad \begin{aligned} \int_{\Omega} \left[\frac{d}{dt} w_h(t, x) v(x) + w_h(t, x) v(x) + \nabla w_h(t, x) \cdot \nabla v(x) \right] dx \\ = \int_{\Gamma} (b_w(t, x) w_h(t, x) + b_u(t, x) z(t, x)) v(x) dS_x, \\ w_h(0) = 0 \end{aligned}$$

for all $v \in V_h$, where $w_h(t, x) = \sum_{i=1}^m w_i(t) v_i(x)$. It can be shown that under natural assumptions on V_h

$$(5.3) \quad \begin{aligned} \max_{t \in [0, T]} \|w(t, \cdot) - w_h(t, \cdot)\|_{L_2(\Omega)}^2 + \int_0^T \|w(t, \cdot) - w_h(t, \cdot)\|_{H^1(\Omega)}^2 dt \\ \leq ch^\alpha \int_0^T \|z(t)\|_{L_2(\Gamma)}^2 dt \end{aligned}$$

where $\alpha > 0$. The proof is based on a technique, developed by Lasiecka [15] for boundary value problems with L_2 boundary data.

Equation (5.2) is equivalent to a system of ordinary differential equations for the vector valued function $w(t) = (w_1(t), \dots, w_m(t))$.

THEOREM 5.1. *Suppose that the error estimate (5.3) holds true. Then*

$$(5.4) \quad Q(w, z) \geq \delta \|z\|_2^2$$

if and only if

$$(5.5) \quad Q(w_h, z) \geq (\delta - \varepsilon) \|z\|_2^2$$

for all $\varepsilon > 0$ and all $h \leq h_0(\varepsilon)$.

Proof. Simple estimations yield

$$\begin{aligned} |Q_{11}(w_1, w_2)| &\leq c_1(\|w_1\|_C \|w_2\|_C + \|w_1\|_{H^1} \|w_2\|_{H^1}), \\ |Q_{12}(w, z)| &\leq c_2 \|w\|_{H^1} \|z\|_2, \end{aligned}$$

where $\|w\|_C = \|w\|_{C([0, T], L_2(\Omega))}$, $\|w\|_{H^1} = \|w\|_{L_2(0, T; H^1(\Omega))}$. Let (5.4) be satisfied. Then

$$(5.6) \quad \begin{aligned} Q(w_h, z) &= Q(w, z) + Q_{11}(w + w_h, w_h - w) + Q_{12}(w_h - w, z) \\ &\geq \delta \|z\|_2^2 - c_1(\|w + w_h\|_C \|w_h - w\|_C + \|w + w_h\|_{H^1} \|w_h - w\|_{H^1}) \\ &\quad - c_2 \|w_h - w\|_{H^1} \|z\|_2 \\ &\geq (\delta - ch^{\alpha/2}) \|z\|_2^2, \end{aligned}$$

as

$$\max\{\|w\|, \|w_h\|\} \leq c\|z\|_2$$

(see [28]) and (5.3) is true. Equation (5.5) is a consequence of (5.6).

Conversely, if (5.5) holds, then as in (5.6),

$$Q(w, z) \geq (\delta - \varepsilon)\|z\|_2^2 - ch^{\alpha/2}\|z\|_2^2$$

for all $h \leq h_0(\varepsilon)$. Equation (5.4) follows from $h \downarrow 0$, as ε was arbitrary. Theorem 5.1 permits us to investigate the positivity of the quadratic form Q for all solutions of a system of ordinary differential equations, where the known theory of Riccati equations applies. We will not discuss the details further.

Acknowledgment. The authors are very grateful to Prof. N. Weck for a valuable remark improving Lemma 4.2.

A LINEAR ALGEBRAIC FRAMEWORK FOR THE ANALYSIS OF DISCRETE-TIME NONLINEAR SYSTEMS*

J. W. GRIZZLE†

Abstract. A linear algebraic framework for the analysis of synthesis-type problems for discrete-time nonlinear systems is introduced. This is an extension of a similar tool for continuous-time systems that established important connections between many algorithms associated with right-invertibility, left-invertibility and dynamic decoupling, as well as between these algorithms and an approach based upon differential algebra. A similar payoff is seen to be possible in the discrete-time setting.

Key words. nonlinear systems, discrete-time, ranks, invertibility

AMS subject classifications. 93C10, 49E05

1. Introduction. This paper extends to the class of discrete-time nonlinear systems the linear algebraic framework of [4], which has proven useful in the analysis of several synthesis problems for the class of continuous-time nonlinear systems [1]–[3], [13], [16], [32]. Recall that [4], through the introduction of a chain of subspaces naturally associated with the output of a system, provided a high-level interpretation of the inversion and dynamic decoupling algorithms that are built around the recursive computation of certain ranks associated with left-invertibility, right-invertibility, and noninteracting control. In addition, it established relationships between these algorithms and the differential algebraic approach. This same linear algebraic setting has been used in [3] to formulate in an intrinsic way the regularity (constant rank) conditions common to several procedures for synthesizing nonlinear dynamic compensators.

The reader is reminded that the importance of algebraic techniques and reasoning for analyzing many aspects of discrete-time nonlinear systems has been firmly established in [8]–[12], [25], [28], [29], and the references therein. The techniques employed here are most closely related to those of [10] and [28].

When studying continuous-time nonlinear systems, the class of affine systems (so-called because the dynamics is affinely parametrized by the control variables) has received the bulk of the attention of the nonlinear community. This is true for several reasons, the most important of which is that the class of affine systems is general enough to encompass many models arising in practice. However, it is also specific enough to admit reasonably simple analyses from at least two perspectives: *geometrically*, we are working with a finite number of vector fields, a drift term, and m control vector fields, as opposed to some arbitrarily, smoothly parametrized family of vector fields; *algebraically*, the various derivatives of the outputs depend polynomially on the inputs and their derivatives (with coefficients depending on the state, and the highest order derivative of the input appearing affinely), as opposed to some more general nonlinear dependence on the input. However, if we accept as an axiom that

This work was completed while the author was a visiting professor (Poste Rouge, Centre National de la Recherche Scientifique) at the Laboratoire des Signaux et Systèmes, École Supérieure d'Électricité-Centre National de la Recherche Scientifique, Gif-sur-Yvette, France. This research was supported by the National Science Foundation contract NSF ECS-88-96136.

† Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, Michigan 48109-2122.

any interesting class of discrete-time systems should include time-sampled (digital) versions of the class of continuous-time affine systems, then we are obliged to consider systems of the form

$$\begin{aligned}x[k+1] &= f(x[k], u[k]), \\ y[k] &= h(x[k], u[k]),\end{aligned}$$

where f and h are sufficiently smooth functions, but otherwise arbitrary (consider sampling a continuous-time bilinear system). Consequently, it is not possible to assume that the dynamics is affine in the control variable (and hence, finitely parametrized); and even if it were, this would not entail that the iterates of the output depend polynomially on the inputs, with the highest-order delayed input appearing affinely. Consequently, the proof techniques of [4], based upon “global” interpretations of the inversion and dynamic extension algorithms, cannot be easily extended to discrete-time systems; a more intrinsic, “algorithm-free” analysis will be performed.

In §2 of this paper, the linear algebraic framework of [4] is developed for analytic discrete-time systems, thereby extending the notion of the rank of a system introduced in [10]. This includes the definition of a chain of subspaces constructed from the outputs of the system and their iterates and an analysis of the convergence properties of the chain of subspaces. It is noted that when the function f describing the dynamics is not a submersion, certain new phenomena can occur, requiring a slightly different analysis involving a combination of geometric and algebraic reasoning. Section 3 collects a few results that are useful for establishing relations between some existing work involving rank computations in an “algorithmic” form and the linear algebraic setting proposed here. Section 4 relates the abstract notion of rank, introduced in §2, to the injectivity and surjectivity properties of certain maps strongly connected with left- and right-invertibility. Finally, §5 points out the links between the approach used in this paper and that of [10]; §6 shows the affinity with the work of [28].

2. Rank and structure at infinity. The notion of the *rank* of a nonlinear system was introduced by Fliess in [8] and yielded fundamental results on right- and left-invertibility and noninteracting control of continuous-time systems. Extensions to a class of rational discrete-time systems have been given in [10], using difference algebra in place of differential algebra. Here, using elementary vector space techniques as in [4], the rank of a discrete-time system will be generalized to analytic systems admitting a global state space representation on \mathbb{R}^n . This may be a strong assumption.

2.1. Linear algebraic framework. Consider a discrete-time system

$$(2.1) \quad \Sigma: \quad \begin{aligned}x[k+1] &= f(x[k], u[k]), \\ y[k] &= h(x[k], u[k]),\end{aligned}$$

where $x[k] \in X = \mathbb{R}^n$, $u[k] \in U = \mathbb{R}^m$, $y[k] \in Y = \mathbb{R}^\mu$, f and h are analytic functions of their arguments, and $x[0] = x_0$. It is convenient to let $f^u(x) := f(x, u)$ so that we may write:

$$\begin{aligned}x[1] &= f^{u[0]}(x_0), \\ x[2] &= f^{u[1]}(x[1]) = f^{u[1]} \circ f^{u[0]}(x_0) \\ &\vdots \\ x[k] &= f^{u[k-1]} \circ \dots \circ f^{u[0]}(x_0),\end{aligned}$$

where \circ denotes composition. Then, since $y[k] = h^{u[k]}(x[k])$, where $h^u(x) := h(x, u)$,

$$(2.2) \quad \begin{aligned} y[k] &= y[k](x_0, u[0], \dots, u[k]) \\ &= h^{u[k]} \circ f^{u[k-1]} \circ \dots \circ f^{u[0]}(x_0). \end{aligned}$$

Because (2.1) is time-invariant,

$$(2.3) \quad \begin{aligned} y[k+1] &= y[k](x[1], u[1], \dots, u[k+1]) \\ &= y[k](f(x_0, u[0]), u[1], \dots, u[k+1]), \end{aligned}$$

which will be important later when establishing a certain finiteness property.

Let \mathcal{R}_k denote the ring of real analytic functions of the components of $(x, u[0], \dots, u[k])$, and let \mathcal{K}_k be the associated field of fractions, that is, the field of *meromorphic* functions in the variables $(x, u[0], \dots, u[k])$. A typical element of \mathcal{K}_k would have the form $\eta(v) = \pi(v)/\theta(v)$, where π and θ are elements of \mathcal{R}_k , θ is not the zero function, and $v = (v_1, \dots, v_j)$ denotes the various components of $(x, u[0], \dots, u[k])$. Recall that $\partial/\partial v_i$ acting on η is formally defined by the usual quotient rule of calculus,

$$(2.4) \quad \frac{\partial}{\partial v_i} \frac{\pi(v)}{\theta(v)} := \left(\theta(v) \frac{\partial}{\partial v_i} \pi(v) - \pi(v) \frac{\partial}{\partial v_i} \theta(v) \right) / \theta^2(v),$$

and the formal differential of η is

$$(2.5) \quad d\eta(v) := \sum_{i=1}^j \frac{\partial \eta(v)}{\partial v_i} dv_i.$$

Let \mathcal{E} denote the vector space over $\mathcal{K} := \mathcal{K}_n$ spanned by $\{dx_1, \dots, dx_n, du_1[0], \dots, du_m[0], du_1[n], \dots, du_m[n]\}$. Note that \mathcal{E} is a finite-dimensional vector space; indeed, its dimension is $n + (n+1)m$. For notational convenience, $\{dx_1, \dots, dx_n\}$ will simply be written as dx , $\{du_1[0], \dots, du_m[0]\}$ as $du[0]$, etc., so that $\mathcal{E} = \text{span}_{\mathcal{K}}\{dx, du[0], \dots, du[n]\}$.

Observe now, for all $0 \leq k \leq n$ and $1 \leq j \leq \mu$, that $dy_j[k] \in \mathcal{E}$, since

$$(2.6) \quad dy_j[k] = \sum_{i=1}^n \frac{\partial y_j[k]}{\partial x_i} dx_i + \sum_{\ell=0}^k \sum_{i=1}^m \frac{\partial y_j[k]}{\partial u_i[\ell]} du_i[\ell].$$

Define a chain of subspaces $\mathcal{E}_0 \subset \dots \subset \mathcal{E}_n$ of \mathcal{E} by [4] (see also [7])

$$(2.7) \quad \mathcal{E}_k := \text{span}_{\mathcal{K}}\{dx, dy[0], \dots, dy[k]\}$$

and the associated list of dimensions $\rho_0 \leq \rho_1 \leq \dots \leq \rho_n$ by

$$(2.8) \quad \rho_k = \dim_{\mathcal{K}} \mathcal{E}_k.$$

We emphasize that $dy[k]$ denotes $\{dy_1[k], \dots, dy_{\mu}[k]\}$ and that this abuse of notation will be used quite often to keep the notation compact.

It will turn out for *generically submersive* systems,¹ that is, for systems where

$$(2.9) \quad n = \text{rank}_{\mathcal{K}} \left[\frac{\partial f}{\partial x}(x, u[0]) : \frac{\partial f}{\partial u}(x, u[0]) \right],$$

¹ The mathematical importance of this assumption will be seen in the next subsection; in terms of control systems, it means that with a feedback, the drift dynamics could be made (generically) invertible, creating a kind of group action.

that

$$(2.10) \quad \rho^* := \rho_n - \rho_{n-1}$$

is a limiting value of the chain (2.7) in the sense that if we were to extend the chain in the obvious manner, then $\rho_{n+r} = \rho_n + r\rho^*$, for all integers $r \geq 0$. Many system models of the form (2.1) would satisfy (2.9), since it is equivalent to $f(\mathbb{R}^n, \mathbb{R}^m)$ having nonempty interior in \mathbb{R}^n , and this is a *necessary* condition for accessibility [17]. It is always satisfied for a time-sampled representation of a continuous-time system. Moreover, it has just been established in [11] that, in a certain sense, rational input-output systems admit *local* state space representations satisfying condition (2.9). To avoid passing to a local representation, the following construction is used here in the general case where (2.9) is not satisfied.

Let $\mathcal{K}^+ := \mathcal{K}_{2n}$, and define $\mathcal{E}^+ := \text{span}_{\mathcal{K}^+}\{dx, du[0], \dots, du[2n]\}$. Define a chain of subspaces $\mathcal{E}_0^+ \subset \dots \subset \mathcal{E}_n^+$ of \mathcal{E}^+ by

$$(2.11) \quad \mathcal{E}_k^+ := \text{span}_{\mathcal{K}^+}\{dx, du[0], \dots, du[n-1], dy[n], \dots, dy[n+k]\}$$

and the associated list of dimensions $\rho_0^+ \leq \dots \leq \rho_n^+$ by

$$(2.12) \quad \rho_k^+ := \dim \mathcal{E}_k^+.$$

Then, even without condition (2.9), it will turn out that

$$(2.13) \quad \rho^{+*} := \rho_n^+ - \rho_{n-1}^+$$

is a limiting value in the sense discussed earlier for ρ^* . Whenever the system (2.1) is generically submersive, it will be established that

$$(2.14) \quad \rho_k^+ = \rho_k + nm, \quad k \geq 0,$$

so that $\rho^{+*} = \rho^*$.

Anticipating these technical results, ρ^{+*} is defined to be the *rank* [10] of the system (2.1).

Remarks. (a) In [6], it is shown (for continuous-time systems) that the chain of subspaces (2.7) is closely related to classical objects in algebra, namely filtrations, and consequently, Hilbert polynomials; a similar result is true in discrete-time [7]. One of the main points of the analysis presented in this paper is the establishment of a priori bounds on the number of steps required to compute the limiting ranks of the filtrations whenever the system has a standard state-space representation; such bounds are not provided by the classical results of algebra, which, on the other hand, apply to more general situations.

(b) In analogy with [4], [22], the list of integers $\{\sigma_0, \dots, \sigma_n\}$ defined by

$$(2.15) \quad \sigma_i = \rho_i - \rho_{i-1}, \quad 0 \leq i \leq n$$

with the convention that $\rho_{-1} = n$, could be called the *transient structure at infinity*, while the list of integers $\{\sigma_0^+, \dots, \sigma_n^+\}$, defined by

$$(2.16) \quad \sigma_i^+ := \rho_i^+ - \rho_{i-1}^+, \quad 0 \leq i \leq n,$$

with the convention that $\rho_{-1}^+ = n + nm$ could be called the *persistent structure at infinity*. For generically submersive systems the two lists coincide, and we can speak simply of the *structure at infinity*; this is also the case for systems satisfying certain constant rank hypotheses in the neighborhood of an equilibrium point, as can be seen from the results of [18], [24], including (constant-coefficient) linear systems.

2.2. Convergence of the chain $\mathcal{E}_0 \subset \cdots \subset \mathcal{E}_n$. The goal of this subsection is to justify terminating the chain (2.7) at n , the dimension of the state space of (2.1), whenever the system is generically submersive. For a linear system, this would follow as an easy consequence of the Cayley–Hamilton theorem; in the case of nonlinear systems, more work is required.

Let $k \geq 0$ be any nonnegative finite integer, and recall that \mathcal{K}_k is the field of meromorphic functions of $(x, u[0], \dots, u[k])$. Before, when defining \mathcal{E}_k ($0 \leq k \leq n$), the span was taken with respect to $\mathcal{K} := \mathcal{K}_n$. It is easily seen that the dimension of \mathcal{E}_k does not change if instead the span is taken with respect to \mathcal{K}_k . For $k > n$, define \mathcal{E}_k in the obvious way, following (2.7), taking the span with respect to \mathcal{K}_k .

THEOREM 2.1. *Suppose that (2.1) is generically submersive. Then, for all integers $k \geq n$, $\dim \mathcal{E}_k - \dim \mathcal{E}_{k-1} = \dim \mathcal{E}_n - \dim \mathcal{E}_{n-1}$; that is, $\rho_k - \rho_{k-1} = \rho_n - \rho_{n-1}$.*

The proof of the theorem will be divided into several parts, each establishing a particular property of the chain (2.7) arising from the recursive manner in which the functions $y[k]$ are constructed from the system. Define $\delta : \mathcal{K}_{k-1} \rightarrow \mathcal{K}_k$ by

$$(2.17) \quad (\delta\eta)(x, u[0], \dots, u[k]) = \eta(f(x, u[0]), u[1], \dots, u[k]);$$

it is important that f be generically submersive, for otherwise, $\delta\eta$ may not be a meromorphic function (see (2.20) below). This induces an \mathbb{R} -linear mapping² $\Delta : \text{span}_{\mathcal{K}_{k-1}} \{d\eta | \eta \in \mathcal{K}_{k-1}\} \rightarrow \text{span}_{\mathcal{K}_k} \{d\lambda | \lambda \in \mathcal{K}_k\}$ by

$$(2.18) \quad \begin{aligned} \Delta(d\eta) &:= d(\delta\eta), \\ \Delta(\alpha_1 d\eta_1 + \alpha_2 d\eta_2) &:= \delta(\alpha_1) \Delta(d\eta_1) + \delta(\alpha_2) \Delta(d\eta_2) \end{aligned}$$

for $\eta, \eta_1, \eta_2, \alpha_1, \alpha_2 \in \mathcal{K}_{k-1}$. It should be noted that (2.18) is consistent with the chain rule for differentiation, and that, for instance,

$$(2.19) \quad \begin{aligned} dy_j[k+1] &= d(\delta(y_j[k])) \\ &= \Delta(dy_j[k]) \\ &= \sum_{i=1}^n \delta\left(\frac{\partial y_j[k]}{\partial x_i}\right) dx_i[1] + \sum_{\ell=0}^k \sum_{i=1}^m \delta\left(\frac{\partial y_j[k]}{\partial u_i[\ell]}\right) du_i[\ell+1]. \end{aligned}$$

The following two (equivalent) properties are easily established whenever the system (2.1) is generically submersive:

P1. For all $k \geq 1$, $\dim_{\mathcal{K}_{k-1}} \{dx[k]\} = n$.

P2. For all $k \geq 0$ and $\forall \eta \in \mathcal{R}_k$, if $\eta \neq 0$, then $\delta(\eta) \neq 0$.

As a consequence, if $\eta \in \mathcal{K}_k$, then $\delta(\eta)$ is well defined. To see the peculiarities a nonsubmersive system may exhibit, consider the example

$$(2.20) \quad \begin{aligned} x[k+1] &= 0, \\ y[k] &= x[k]u[k], \end{aligned}$$

where x, y , and u are in \mathbb{R} . The function $1/x$ is meromorphic, but $\delta(1/x)$ is not defined because $\delta(x) \equiv 0$.

The main ingredients of a proof of Theorem 2.1 are now presented. In the following, if S is a set, then $|S|$ denotes its cardinality.

² The fact that Δ is well defined follows easily from $\Delta(0) = 0$.

LEMMA 2.2. *Suppose that (2.1) is generically submersive and that for some $k \geq 0$, $I_0 \subset I_1 \subset \dots \subset I_k \subset \{1, \dots, \mu\}$ are index sets such that $\mathcal{E}_k = \text{span}_{\mathcal{K}_k} \{dx, dy_{i_0}[0], \dots, dy_{i_k}[k] | i_j \in I_j, 0 \leq j \leq k\}$, and $\dim \mathcal{E}_k = n + |I_0| + \dots + |I_{k-1}| + |I_k|$. Then, $\dim \text{span}_{\mathcal{K}_k} \{dx, dy_{i_0}[0], \dots, dy_{i_k}[k], dy_{i_k}[k+1] | i_j \in I_j, 0 \leq j \leq k\} = n + |I_0| + \dots + |I_{k-1}| + 2|I_k|$. In other words, once an output component becomes independent, it remains independent.*

Proof. For the proof, see Appendix A. \square

It immediately follows from the above that there exists a basis of a special form for the chain $\mathcal{E}_0 \subset \mathcal{E}_1 \subset \dots$.

LEMMA 2.3. *Suppose that (2.1) is generically submersive. Then, there exist index sets $I_0 \subset I_1 \subset \dots \subset \{1, \dots, \mu\}$ such that, for all $k \geq 1$, $\{dx, dy_{i_0}[0], \dots, dy_{i_k}[k] | i_j \in I_j, 0 \leq j \leq k\}$ is a basis for \mathcal{E}_k .*

Lemma 2.3 establishes that $\{\sigma_k\} = \{\rho_k - \rho_{k-1}\}$ is a nondecreasing sequence. Since $\sigma_k \leq \min\{m, \mu\}$, it follows that $\{\sigma_k\}$ converges in a finite number of steps. However, this does not allow us to terminate the calculations at the n th step unless the upper bound has already been attained. Considering once again (2.20), we calculate that $(\sigma_0) = 1$, but $(\sigma_1) = 0$; that is, the sequence $\{\sigma_k\}$ of “zeros at infinity of order less than or equal to k ” is not nondecreasing, as is always the case for linear systems and continuous-time nonlinear systems.

LEMMA 2.4. *Suppose that (2.1) is generically submersive, and let I_0, \dots, I_n be as in Lemma 2.3. Then, for each $1 \leq j \leq \mu$, there exists an integer N , $1 \leq N \leq n$, such that*

$$(2.21) \quad dy_j[N] \in \text{span}_{\mathcal{K}_N} \{dy_j[0], \dots, dy_j[N-1], dy_{i_0}[0], \dots, dy_{i_N}[N] | i_k \in I_k, 0 \leq k \leq N\}.$$

Proof. For the proof, see Appendix A. \square

The previous and the following lemmas combine to replace the Cayley–Hamilton theorem, which, in the case of a linear system, proves that the chain (2.7) converges in at most n steps.

LEMMA 2.5. *Suppose that (2.1) is generically submersive, and let I_0, \dots, I_n be as in Lemma 2.3. Suppose that $1 \leq j \leq \mu$, and let N be as in Lemma 2.4. Then, for all $k \geq N$,*

$$(2.22) \quad dy_j[k] \in \text{span}_{\mathcal{K}_k} \{dy_j[0], \dots, dy_j[N-1], dy_{i_0}[0], \dots, dy_{i_k}[k] | \\ \text{for } 1 \leq s \leq N, i_s \in I_s, \text{ and for } s > N, i_s \in I_N\}.$$

Proof. The proof is immediate from (2.18) and Lemma 2.4. \square

The proof of Theorem 2.1 is now given easily. Let $\{I_k\}$ be the collection of index sets determined by Lemma 2.2. By Lemma 2.5, $I_{n+r} = I_n$ for all $r \geq 1$. Hence, the components of the output either become independent by the n th iteration of the dynamics, or they remain dependent for all iterations. Consequently, for all $r \geq 1$, $\dim \mathcal{E}_{n+r} - \dim \mathcal{E}_{n+r-1} = \dim \mathcal{E}_n - \dim \mathcal{E}_{n-1} = \rho^*$.

2.3. Convergence of the chain $\mathcal{E}_0^+ \subset \mathcal{E}_1^+ \subset \dots$. This section addresses the convergence properties of the chain $\mathcal{E}_0^+ \subset \mathcal{E}_1^+ \subset \dots$ for systems that are not necessarily submersive. The idea behind the analysis is that the effect of the nilpotent part of the system on the output sequence is short lived and can be eliminated from the analysis by “ignoring” the first n time instances of the output; this is essentially what

is accomplished by including $\{du[0], \dots, du[n-1]\}$ in the definition of $\mathcal{E}_0^+ \subset \mathcal{E}_1^+ \subset \dots$. The analytical aspects of the proof are based on the following construction.

Let $M_0 := \mathbb{R}^n$ and define for $k \geq 1$

$$(2.23) \quad M_k := x[k] \left(\mathbb{R}^n \times (\mathbb{R}^m)^k \right).$$

Observe that $M_0 \supset M_1 \supset \dots$ since

$$(2.24) \quad M_{k+1} = f(M_k, \mathbb{R}^m).$$

Define $d_0 := n$ and for $k \geq 1$,

$$(2.25) \quad d_k := \text{rank}_{\mathcal{K}_{k-1}} x[k] := \dim \text{span}_{\mathcal{K}_{k-1}} \{dx[k]\}.$$

LEMMA 2.6. *The sequence of integers $\{d_k\}$ is nonincreasing, and if $d_k = d_{k-1}$ then $d_{k+1} = d_k$. Consequently, since d_j can decrease at most n -times, $d_j = d_n$ for all $j \geq n$.*

The proof is given in Appendix B. Very roughly speaking, Lemma 2.6 says that “ $f : M_k \times \mathbb{R}^m \rightarrow M_{k+1}$ behaves like a ‘submersion’ for $k \geq n$ since the ‘dimension’ of M_k is d_k .” Of course, M_k , in general, does not have the structure of a manifold, hence, the imprecision of such a statement. Nevertheless, if we pursue this line of thought for a moment and supposes that $M_0 \supset M_1 \supset \dots$ is a nested sequence of embedded analytic submanifolds, it is clear that, if $\dim M_k = \dim M_{k-1}$, then $\dim M_{k+1} = \dim M_k$, because the condition $\dim M_k = \dim M_{k-1}$ implies that $f : M_{k-1} \times \mathbb{R}^m \rightarrow M_k$ is a submersion. This combined with M_k being open in M_{k-1} gives the result. The proof in Appendix B makes this line of reasoning rigorous with a local analysis, which also establishes the following result: For $k \geq 2$, $j \geq 0$ define $\delta^k : \mathcal{R}_j \rightarrow \mathcal{R}_{j+k}$ by, if $\alpha \in \mathcal{R}_j$, and $0 \leq i \leq k-1$

$$(2.26) \quad \delta^{i+1}(\alpha) = \delta(\delta^i(\alpha)).$$

LEMMA 2.7. *Let $k \geq 0$, $\alpha \in \mathcal{R}_k$. If $\delta^n(\alpha) \neq 0$ (i.e., is not the identically zero function), then $\delta^{n+j}(\alpha) \neq 0$ for all $j \geq 1$.*

Let $\mathcal{R}_k^{\delta^n}$ be the set of real analytic functions

$$(2.27) \quad \mathcal{R}_k^{\delta^n} := \{\delta^n(\alpha) | \alpha \in \mathcal{R}_k\}.$$

$\mathcal{R}_k^{\delta^n} \subset \mathcal{R}_{n+k}$ as a subring, and thus, the associated set of fractions, denoted $\mathcal{K}_k^{\delta^n}$, is a field; indeed, it is a subfield of \mathcal{K}_{n+k} . Note that $\mathcal{K}_k^{\delta^{n+1}} \subset \mathcal{K}_{k+1}^{\delta^n}$.

By Lemma 2.7, for each $k \geq 0$, the two mappings

$$(2.28) \quad \delta : \mathcal{K}_k^{\delta^n} \rightarrow \mathcal{K}_k^{\delta^{n+1}} \subset \mathcal{K}_{k+1}^{\delta^n}$$

and

$$(2.29) \quad \Delta : \text{span}_{\mathcal{K}_k^{\delta^n}} \{d\lambda | \lambda \in \mathcal{K}_k^{\delta^n}\} \rightarrow \text{span}_{\mathcal{K}_{k+1}^{\delta^n}} \{d\eta | \eta \in \mathcal{K}_k^{\delta^{n+1}}\} \subset \text{span}_{\mathcal{K}_{k+1}^{\delta^n}} \{d\gamma | \gamma \in \mathcal{K}_{k+1}^{\delta^n}\}$$

can be defined as in (2.17) and (2.18), respectively.

The final step of the analysis is to reduce the study of the chain $\mathcal{E}_0^+ \subset \mathcal{E}_1^+ \subset \dots$ to that of a related chain to which the proof technique of §2.2, that is, Lemmas 2.2–2.5,

can be applied with only minor modifications. As in §2.2, it is necessary to slightly modify the definition of \mathcal{E}_k^+ without changing its dimension:

$$(2.30) \quad \mathcal{E}_k^+ := \text{span}_{\mathcal{K}_{n+k}} \{dx, du[0], \dots, du[n-1], dy[n], \dots, dy[n+k]\},$$

for all $k \geq 0$, and

$$(2.31) \quad \mathcal{E}_{-1}^+ := \text{span}_{\mathcal{K}_{n-1}} \{dx, du[0], \dots, du[n-1]\}.$$

Note that $\{dx[n]\} \subset \mathcal{E}_{-1}^+$. Let $L \subset \{1, \dots, n\}$ be such that $\{dx_i[n] | i \in L\}$ is a basis for $\text{span}_{\mathcal{K}_{n-1}} \{dx[n]\}$, and let \mathcal{W} be such that

$$(2.32) \quad \mathcal{E}_{-1}^+ = \text{span}\{dx_i[n] | i \in L\} \oplus \mathcal{W}.$$

Introduce

$$(2.33) \quad \begin{aligned} \tilde{\mathcal{S}}_k &:= \text{span}_{\mathcal{K}_{n+k}} \{dx_i[n], dy[n], \dots, dy[n+k] | i \in L\}, \\ \tilde{\mathcal{S}}_{-1} &:= \text{span}_{\mathcal{K}_{n-1}} \{dx_i[n] | i \in L\}. \end{aligned}$$

Since $y[n+j](x, u[0], \dots, u[n+j]) = y[j](x[n], u[n], \dots, u[n+j])$ for $j \geq 0$, it follows that

$$(2.34) \quad \mathcal{E}_k^+ = \tilde{\mathcal{S}}_k \oplus \mathcal{W}, \quad k \geq 1.$$

Hence, for $k \geq 0$,

$$(2.35) \quad \sigma_k^+ = \dim \tilde{\mathcal{S}}_k - \dim \tilde{\mathcal{S}}_{k-1}.$$

The reason for doing all of this is that the generators of $\tilde{\mathcal{S}}_k$, for $k \geq 1$, are elements of $\{d\lambda | \lambda \in \mathcal{K}_k^{\delta^n}\}$. Hence, letting

$$(2.36) \quad \begin{aligned} \mathcal{S}_k &:= \text{span}_{\mathcal{K}_k^{\delta^n}} \{dx_i[n], dy[n], \dots, dy[n+k] | i \in L\}, \\ \mathcal{S}_{-1} &:= \text{span}_{\mathcal{K}_{n-1}} \{dx_i[n] | i \in L\}, \end{aligned}$$

it follows that, for $k \geq 0$,

$$(2.37) \quad \sigma_k^+ = \dim \mathcal{S}_k - \dim \mathcal{S}_{k-1}.$$

Moreover, even though $\mathcal{S}_k \subset \mathcal{S}_{k+1}$ is *not* a subspace of \mathcal{S}_{k+1} ,

$$(2.38) \quad \dim \text{span}_{\mathcal{K}_{k+1}^{\delta^n}} \{\mathcal{S}_k\} = \dim \mathcal{S}_k,$$

and therefore, the proofs of the obvious modifications of Lemmas 2.2–2.5 for the chain $\mathcal{S}_0 \subset \mathcal{S}_1 \subset \dots$ go through with only minor changes, which will not be repeated here.

THEOREM 2.8. *For all integers $k \geq n$, $\dim \mathcal{E}_k^+ - \dim \mathcal{E}_{k-1}^+ = \dim \mathcal{E}_n^+ - \dim \mathcal{E}_{n-1}^+$; that is, $\rho_k^+ - \rho_{k-1}^+ = \rho_n^+ - \rho_{n-1}^+$. Moreover, whenever (2.1) is generically submersive, the ordered lists $\{\sigma_0, \sigma_1, \dots, \sigma_n\}$ and $\{\sigma_0^+, \dots, \sigma_n^+\}$ are equal.*

The last part of the theorem follows from the fact that when (2.1) is generically submersive, the index set L in (2.32) is equal to $\{1, \dots, n\}$. Then, since $y[n+j](x, u[0], \dots, u[n+j])$ can be expressed as $y[j](x[n], u[n], \dots, u[n+j])$, \mathcal{E}_k and \mathcal{S}_k are naturally isomorphic under $x \rightarrow x[n], u[0] \rightarrow u[n], \dots, u[k] \rightarrow u[n+k]$.

3. Further characterizations of the rank and structure at infinity. This section and the rest of the paper will concentrate on generically submersive systems. Similar results, as per the development of §2.3, can be stated for the general case.

3.1. Jacobian matrices. The goal here is to provide a computationally convenient means of evaluating the rank ρ^* . The same result is also useful for showing the invariance of ρ^* under the action of invertible (static or dynamic) state variable feedback.

Following [14], which, in turn, was based upon [23], consider the Jacobian matrices

$$(3.1) \quad J_k(x, u[0], \dots, u[k]) := \frac{\partial(y[0], \dots, y[k])}{\partial(u[0], \dots, u[k])},$$

for $0 \leq k \leq n$, and their associated ranks

$$(3.2) \quad R_k := \text{rank}_{\mathcal{K}} J_k.$$

Note that the matrices J_k can be evaluated symbolically; their ranks can be evaluated numerically since the rank over \mathcal{K} is the same as the generic rank considered in [23].

Applying arguments identical to those used in [4, §2.1] results in the following relation between the integers ρ_k and R_k .

PROPOSITION 3.1. *For each $0 \leq k \leq n$, $\rho_k = n + R_k$. Hence, if (2.1) is generically submersive, then $\rho^* = R_n - R_{n-1}$.*

A quite different way of obtaining a result similar to the first part of Proposition 3.1 is given in [6].

Consider now a discrete-time linear system

$$(3.3) \quad \begin{aligned} x[k+1] &= Ax[k] + Bu[k], \\ y[k] &= Cx[k] + Du[k]. \end{aligned}$$

Then the Jacobian matrix J_k is given by the usual Toeplitz matrix

$$(3.4) \quad J_k = \begin{bmatrix} D & 0 & 0 \\ CB & D & \\ CAB & CB & \vdots \\ \vdots & & 0 \\ CA^{k-1}B & CA^{k-2}B & \dots & D \end{bmatrix}.$$

The results of [21] and [26] in conjunction with Proposition 3.1 justify the terminology adopted in §2.2 concerning the rank and structure at infinity of a nonlinear system.

The following is the analogue of [10, III.B.2. Proposition].

COROLLARY 3.2. *In the case of a linear system, the rank ρ^* defined by (2.10) agrees with the classical rank of the transfer matrix. Moreover, the list of integers $\{\sigma_0, \dots, \sigma_n\}$ defined in (2.15) is precisely the structure at infinity as it is normally defined on the basis of the transfer matrix [21], [26].*

REMARK 3.3. For a linear system, it is easy to verify that the lists $\{\sigma_k^+\}$ and $\{\sigma_k\}$ coincide, whether or not the system is generically submersive.

3.2. A related chain of subspaces. Related to the chain $\mathcal{E}_0 \subset \mathcal{E}_1 \subset \dots$ is the chain $\mathcal{H}_0 \subset \mathcal{H}_1 \subset \dots$ defined solely in terms of the output [4]:

$$(3.5) \quad \mathcal{H}_k = \text{span}_{\mathcal{K}_k} \{dy[0], \dots, dy[k]\}.$$

It also can be used to determine the rank of the system, and this will be important for making contact with the fundamental work of [10].

THEOREM 3.4. *Suppose that (2.1) is generically submersive. For all integers $k \geq n$, $\rho^* = \dim \mathcal{H}_k - \dim \mathcal{H}_{k-1}$.*

Proof. By Lemma 2.5, for $k \geq n$ $\rho^* \geq \dim \mathcal{H}_k - \dim \mathcal{H}_{k-1}$. On the other hand, for $1 \leq j$, $\mathcal{H}_j = \mathcal{H}_{j-1} + \text{span}\{dy[j]\}$, $\mathcal{E}_j = \mathcal{E}_{j-1} + \text{span}\{dy[j]\}$ and $H_0 \subset \mathcal{E}_0$. Thus, $\dim \mathcal{H}_j - \dim \mathcal{H}_{j-1} \geq \dim \mathcal{E}_j - \dim \mathcal{E}_{j-1}$. \square

3.3. Remarks on the inversion algorithm. The importance of the inversion algorithm of Singh [27], which is an extension to nonlinear continuous-time systems of the well-known algorithm of Silverman [26], need not be underlined here. The algorithm has also been used in the study of discrete-time nonlinear systems [18] and [19], but always expressed in a form involving the implicit function theorem. Consequently, the results of the algorithm can be difficult to interpret unless one remains in a neighborhood of an equilibrium point. This problem can be removed by working at the level of the differentials of the outputs, which linearizes the computations and allows the analysis of [4] to be carried through to the discrete-time setting. Since the algorithm in the form we will use it has already appeared in several publications for continuous-time systems [3], [4], [16], the basic idea will only be sketched here by giving the first steps of the algorithm. Establishing the validity and convergence properties of the algorithm is quite easy using the analysis of §2.2.

It is assumed that (2.1) is generically submersive; an extension to general systems can be envisioned along the lines of §2.3.

Step 0. Calculate $dy[0]$ and write it as

$$(3.6) \quad dy[0] = a_0(x, u[0])dx + b_0(x, u[0])du[0] .$$

Define

$$(3.7) \quad s_0 := \text{rank}_{\mathcal{K}_0} b_0 .$$

Permute, if necessary, the components of y so that the first s_0 rows of b_0 are linearly independent. Decompose y so that

$$(3.8) \quad dy[0] = \begin{bmatrix} d\tilde{y}_0[0] \\ d\hat{y}_0[0] \end{bmatrix} = \begin{bmatrix} \tilde{a}_0 \\ \hat{a}_0 \end{bmatrix} dx + \begin{bmatrix} \tilde{b}_0 \\ \hat{b}_0 \end{bmatrix} du[0],$$

where \tilde{y}_0 has s_0 rows. Since the rows of \hat{b}_0 are \mathcal{K}_0 -dependent on the rows of \tilde{b}_0 , there exists a matrix $M_0(x, u[0])$ with entries in \mathcal{K}_0 such that

$$(3.9) \quad \hat{b}_0 = M\tilde{b}_0,$$

and thus,

$$(3.10) \quad \begin{aligned} d\hat{y}_0[0] &= \hat{a}_0 dx + M_0\{d\tilde{y}_0[0] - \tilde{a}_0 dx\} \\ &=: \bar{a}_0 dx + \bar{b}_0 d\tilde{y}_0[0]. \end{aligned}$$

End of Step 0.

Step 1. Compute

$$(3.11) \quad \begin{aligned} d\hat{y}_0[1] &= (\delta\bar{a}_0) dx[1] + (\delta\bar{b}_0) d\tilde{y}_0[1] \\ &=: a_1(x, u[0], u[1]) dx + b_1(x, u[0], u[1]) du[0] + c_1(x, u[0], u[1]) d\tilde{y}_0[1]. \end{aligned}$$

Define

$$(3.12) \quad s_1 := \text{rank}_{\mathcal{K}_1} \begin{bmatrix} \tilde{b}_0 \\ b_1 \end{bmatrix}$$

and repeat the basic operations of Step 1; see [3], [4], and [16], for example.

The validation of the steps in the algorithm is achieved by noting that it produces a basis for $\mathcal{E}_0 \subset \mathcal{E}_1 \subset \dots$, and thus, by Lemma 2.2, since $\{dx, d\tilde{y}_0[0]\}$ is a linearly independent set, so is $\{dx, d\tilde{y}_0[0], d\tilde{y}_0[1]\}$, etc. Its convergence in no more than n steps follows from Theorem 2.1.

A similar connection with the interesting work of [24] on dynamic feedback solutions to the noninteracting control problem could be pursued also along the lines already clearly established in [4].

4. Invertibility. A linear system is usually said to be right-invertible if the rank of its transfer matrix is equal to the number of output components, and left-invertible if its rank equals the number of input components. Systemically, right-invertibility means that by a proper choice of the initial condition *and* input sequence, any output sequence can be generated; that is, the map from initial conditions and inputs is onto $Y^\infty = Y \times Y \times \dots$, the space of all output sequences. Left-invertibility is equivalent to injectivity of the map from inputs to outputs, for a fixed initial condition.

In the case of nonlinear systems, though such global notions of invertibility are attractive, simple examples show the difficulty of trying to say anything intelligent about them; hence, we are led to localizing the concepts. Following [3], for $k \geq 0$, let $H_k : X \times U^{k+1} \rightarrow Y^{k+1}$ be the map that sends $(x, u[0], \dots, u[k])$ to $(y[0], \dots, y[k])$, and let $E_k : X \times U^{k+1} \rightarrow X \times Y^{k+1}$ by $(x, u[0], \dots, u[k]) \mapsto (x, y[0], \dots, y[k])$.

DEFINITION 4.1. The system (2.1) is *almost everywhere locally surjective*, if, for every $k \geq 0$, the image of H_k has nonempty interior. The system is *almost everywhere locally injective*, if, for every $k \geq 0$, there exists an open and dense subset \mathcal{O}_k of $X \times U^{k+1}$ with the property that, for each point $p = (x, u[0], \dots, u[k]) \in \mathcal{O}_k$ there exists an open neighborhood of p , $\tilde{\mathcal{O}}_k(p)$, and an analytic insertion³ $i_k : \tilde{\mathcal{O}}_k(p) \rightarrow X \times U^{k+1} \times U^n$ such that if $p_1, p_2 \in \tilde{\mathcal{O}}_k(p)$ and $E_{n+k}(i_k(p_1)) = E_{n+k}(i_k(p_2))$, then $p_1 = p_2$.

These properties can be characterized as follows.

THEOREM 4.2. Assume that the nonlinear system (2.1) is generically submersive. Then the system is almost everywhere locally surjective if and only if any one of the following equivalent conditions is satisfied:

- (a) for all $k \geq 0$, $\dim \text{span}\{dy[0], \dots, dy[k]\} = (k+1)\mu$;
- (b) $\dim \text{span}\{dy[0], \dots, dy[n]\} = (n+1)\mu$;
- (c) $\rho^* = \mu$; i.e., the rank of the system equals the number of output components.

The system is almost everywhere locally injective if, and only if, any one of the following equivalent conditions is satisfied:

- (d) for all $k \geq 0$, $\{du[0], \dots, du[k]\} \subset \text{span}\{dx, dy[0], \dots, dy[k+n]\}$
- (e) $du[0] \subset \text{span}\{dx, dy[0], \dots, dy[n]\}$;
- (f) $\rho^* = m$; i.e., the rank of the system equals the number of input components.

Proof. (a) \implies (b) is immediate. (b) \implies (c) is given by Theorem 3.4. (c) \implies (a) follows from the same kind of reasoning employed in proving Lemmas 2.4 and 2.5 and is not repeated here. It suffices to show that (a) is equivalent to almost everywhere

³ That is, if τ_k represents that natural projection of $X \times U^{k+1} \times U^n$ onto $X \times U^{k+1}$, then $\tau_k \circ i_k|_{\tilde{\mathcal{O}}_k(p)}$ is the identity.

local surjectivity. The image of H_k has nonempty interior if, and only if, there exists an open set of points where the rank of H_k over the reals equals $(k+1)\mu$. This is equivalent to H_k having rank $(k+1)\mu$ over \mathcal{K}_k , which is equivalent to (a). Turning to almost everywhere local injectivity, (d) \implies (e) is evident. (e) \iff (f) is Corollary A.2 in Appendix A. It is now shown that (e) \implies (d): Applying Δ to both sides of (e) yields

$$du[1] \subset \text{span}\{dx[1], dy[1], \dots, dy[n+1]\}.$$

Hence, adding $\text{span}\{dx, du[0], dy[0]\}$ to the right-hand side,

$$\begin{aligned} du[1] &\subset \{dx, du[0], dy[0], dy[1], \dots, dy[n+1]\} \\ &\subset \text{span}\{dx, dy[0], \dots, dy[n+1]\}, \end{aligned}$$

where (e) has been used in the last step. The remainder of a proof by induction is clear. To finish up, it suffices now to show that (d) is equivalent to almost everywhere local injectivity. Without loss of generality, it can be assumed that the neighborhood $\tilde{\mathcal{O}}_k$ is such that $E_{n+k} \circ i_k : \tilde{\mathcal{O}}_k \rightarrow X \times Y^{n+k+1}$ has constant rank. Then almost everywhere local injectivity means that this rank equals $n + (k+1) \cdot m$. This is equivalent to $\text{rank}_{\mathcal{K}_{n+k}} (\partial(y[0], \dots, y[n+k]) / \partial(u[0], \dots, u[k])) = (k+1)m$, which is equivalent to (d). \square

Remark. A quite different approach to invertibility is taken in [10]; the results of the next section show that, in the case of polynomial systems, the two approaches coincide.

5. Difference algebra and the transformal transcendence degree. The purpose of this section is to prove that the rank ρ^* defined in (2.10), when specialized to systems whose right-hand side depends polynomially on x and u (more precisely, on their components), corresponds to the transformal transcendence degree used in [10].

Consider a system

$$(5.1) \quad \begin{aligned} \Sigma_{P,Q} \quad x[k+1] &= P(x[k], u[k]) \\ y[k] &= Q(x[k], u[k]), \end{aligned}$$

where $P : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n$ and $Q : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^\mu$ are such that each of their components is a polynomial of x and u , with coefficients in \mathbb{R} . This system is clearly analytic, so the analysis of §2 applies. For the purpose of clarity in presenting the results, it will be assumed that (5.1) is generically submersive. An extension to rational systems could also be undertaken.

The following definition, adapted from [10], should actually be *derived* by constructing the difference field associated to $\Sigma_{P,Q}$ and then applying the definition used in [10].

DEFINITION 5.1. The transformal transcendence degree of $\Sigma_{P,Q}$, denoted $d^0(\Sigma_{P,Q})$ equals the maximal number of components of y , say $\{y_{i_1}, \dots, y_{i_\rho}\}$, such that for any $k \geq 0$ there does not exist any nontrivial polynomial π with coefficients in \mathbb{R} such that

$$\pi(y_{i_1}[0], \dots, y_{i_\rho}[0], \dots, y_{i_1}[k], \dots, y_{i_\rho}[k]) = 0.$$

In other words, for any $k \geq 0$, $y_{i_1}[0], \dots, y_{i_\rho}[0], \dots, y_{i_1}[k], \dots, y_{i_\rho}[k]$ viewed as polynomials of $x, u[0], \dots, u[k]$ are algebraically independent.

For those readers familiar with Kähler differentials, the equality $\rho^* = d^0(\Sigma_{P,Q})$ is immediate from Theorem 3.4. For the benefit of other readers, an independent, straightforward proof is given. Lemma 5.2, which follows, is well-known, though hard to find in the form presented (cf. [28]).

Let $v = (v_1, \dots, v_r)$ be an r -tuple of indeterminants, let $\mathbb{R}[v]$ denote the ring of polynomials of (v_1, \dots, v_r) with coefficients in \mathbb{R} and let $\mathbb{R}(v)$ be the corresponding field of rational functions. Define a vector space over $\mathbb{R}(v)$ by $V := \text{span}\{dv_1, \dots, dv_r\}$ and define the mapping $d : \mathbb{R}(v) \rightarrow V$ by

$$(5.2) \quad d\left(\frac{p(v)}{q(v)}\right) := \frac{1}{(q(v))^2} \sum_{j=1}^r \left(\frac{\partial p(v)}{\partial v_j} q(v) - p(v) \frac{\partial q(v)}{\partial v_j} \right) dv_j$$

in the usual way; see [30, Chap. 5, §10.5] for how to define a differential calculus of rational functions without taking limits.

LEMMA 5.2. *A collection of polynomials $\{P_1, \dots, P_k\} \subset \mathbb{R}[v]$ is algebraically independent if, and only if, the set $\{dP_1, \dots, dP_k\}$ is linearly independent in $(V, \mathbb{R}(v))$.*

Proof. Suppose that $\{P_1, \dots, P_k\}$ is algebraically independent; then $k \leq r$. Assume first that $k = r$. $\{P_1, \dots, P_r\}$ is then a basis for $\mathbb{R}[v]$, and consequently, for each $1 \leq i \leq r$, there is a nontrivial polynomial $Q_i(\lambda_1, \dots, \lambda_{r+1})$ such that $Q_i(v_i, P_1, \dots, P_r) = 0$.

PROPOSITION 5.3. *For each $1 \leq i \leq r$, the polynomial $\partial Q_i / \partial \lambda_1$ is nontrivial.*

Proof. Suppose it is trivial. Then $Q_i(v_i, P_1, \dots, P_r) = Q_i(0, P_1, \dots, P_r) =: \overline{Q}_i(P_1, \dots, P_r)$. Thus, \overline{Q}_i must be a trivial polynomial because $\{P_1, \dots, P_r\}$ is algebraically independent. It follows that Q_i is a trivial polynomial, which contradicts its definition. \square

Continuing with the proof of Lemma 5.2, since $0 = Q_i(v_i, P_1, \dots, P_r)$,

$$(5.3) \quad 0 = d(Q_i(v_i, P_1, \dots, P_r)) = \frac{\partial Q_i}{\partial \lambda_1}(v_i, P_1, \dots, P_r) dv_i + \sum_{j=1}^r \frac{\partial Q_i}{\partial \lambda_{j+1}}(v_i, P_1, \dots, P_r) dP_j;$$

see [30, Chap. 5] for the chain rule. By Proposition 5.3, $\partial Q_i / \partial \lambda_1$ is nontrivial, and thus,

$$(5.4) \quad dv_i = \sum_{j=1}^r k_{ij} dP_j,$$

where

$$k_{ij} := \left(\frac{\partial Q_i}{\partial \lambda_1}(v_i, P_1, \dots, P_r) \right)^{-1} \left(\frac{\partial Q_i}{\partial \lambda_{j+1}}(v_i, P_1, \dots, P_r) \right) \in \mathbb{R}(v).$$

Thus, $\text{span}\{dv_1, \dots, dv_r\} \subset \text{span}\{dP_1, \dots, dP_r\}$, proving the linear independence of $\{dP_1, \dots, dP_r\}$.

If $k < r$, then there exist P_{k+1}, \dots, P_r such that $\{P_1, \dots, P_r\}$ is a basis for $\mathbb{R}(v)$. From the above, $\{dP_1, \dots, dP_r\}$ is linearly independent, and therefore, so must be $\{dP_1, \dots, dP_k\}$.

To prove the other direction of the lemma, suppose that $\{P_1, \dots, P_k\}$ is algebraically dependent. Then there exists a nontrivial polynomial $Q(\lambda_1, \dots, \lambda_k)$ with coefficients in \mathbb{R} such that $Q(P_1, \dots, P_k) = 0$. Hence, $0 = \sum_{j=1}^k \partial Q / \partial \lambda_j (P_1, \dots, P_k) dP_j$,

proving that $\{dP_1, \dots, dP_k\}$ is a linearly dependent set in $(V, \mathcal{R}(v))$. This completes the proof of Lemma 5.2. \square

The constructions and results of §2 hold clearly for polynomial systems (5.1) with the field \mathcal{K} replaced⁴ by $\mathcal{R}[x, u[0], \dots, u[n]]$. This observation, combined with Lemma 5.2 and Theorem 3.4, yields the following result.

THEOREM 5.4. *For the polynomial system (5.1), $\rho^* = d^0(\Sigma_{P,Q})$.*

Remark. Lemma 5.2 can be equivalently stated as: The following two conditions are equivalent:

(a) There exists a nontrivial polynomial π such that $\pi(P_1, \dots, P_r) = 0$

(b) The set $\{dP_1, \dots, dP_r\}$ is linearly dependent in $(V, \mathcal{R}(v))$

The implication (a) \implies (b) remains true with π, P_1, \dots, P_r replaced by analytic functions. However, the converse is then true only *locally*, and even then only on subsets where certain constant dimensional conditions are met; indeed, this is the well-known Rank Theorem.

6. Relation to generic observation fields. The chain of subspaces $\mathcal{E}_0 \subset \dots \subset \mathcal{E}_k \subset \dots$ is measuring how the input components are appearing in the outputs, assuming that the initial state is known. In a similar manner, one could study how the initial state components appear in the outputs, assuming that the inputs are known. This is called *observability* [15], and in the context of the formalism of this paper, could be studied via the chain $\mathcal{O}_0 \subset \dots \subset \mathcal{O}_k \subset \dots$, where

$$(6.1) \quad \mathcal{O}_k := \text{span}_{\mathcal{K}_k} \{du[0], \dots, du[k], dy[0], \dots, dy[k]\}.$$

Then, as in [4] and this paper, a connection could be established between the ranks of certain Jacobian matrices, the dimensions of the subspaces \mathcal{O}_k and/or the transcendence degree of a certain (differential) field. This (plus a whole lot more, such as the construction of a realization theory for polynomial input-output maps) was done by Sontag [28] in 1979 for a very general class of discrete-time polynomial systems (cf. his generic observation fields, Q_f^K). An extension to analytic systems would follow along the lines of [31]. More recent work on the analysis of the observability of continuous-time systems by algebraic means can be found in [5] and the references therein.

Appendix A.

Proof of Lemma 2.2. For the sake of the study of invertibility in §3, it is useful to prove a little more than is required by the lemma. The following notation is used only in Appendix A; it will help to keep the formulas concise. If M is a subset of \mathcal{E} , then $[M]$ denotes its *span* (see [20, p. 16]). If $\{v_1, \dots, v_s\}$ is a set of *linearly independent* elements in \mathcal{E} , this will be denoted by $\{v_1, \dots, v_s\}^*$. For example, let $I_0 \subset \{1, \dots, \mu\}$ be such that $\{dx, dy_{i_0}[0] | i_0 \in I_0\}$ is a basis for \mathcal{E}_0 . Then, this can be succinctly stated as $[\{dx, dy_{i_0}[0] | i_0 \in I_0\}^*] = \mathcal{E}_0$.

Suppose that for some $0 \leq k$, index sets $I_0 \subset I_1 \subset \dots \subset I_k \subset \{1, \dots, \mu\}$ and $\{1, \dots, m\} \supset J_0 \supset J_1 \supset \dots \supset J_k$ have been selected so that for each $0 \leq t \leq k$,

$$(A.1) \quad \mathcal{E}_t = [\{dx, dy_{i_r}[r] | 0 \leq r \leq t, i_r \in I_r\}^*]$$

$$(A.2) \quad [dx, du[0], \dots, du[t]] = [\{dx, dy_{i_r}[r], du_{j_{t-r}}[r] | 0 \leq r \leq t, i_r \in I_r, j_r \in J_r\}^*].$$

⁴ So that the proof of Lemma 2.4, which used the Rank Theorem, can be carried over, one must note that (2.21) holds for (5.1) over \mathcal{K} if, and only if, it holds over $\mathcal{R}[x, u[0], \dots, u[n]]$.

and

$$(A.3) \quad du[0] \subset \mathcal{E}_t \oplus [\{du_j[0] | j \in J_t\}].$$

That this is possible for $k = 0$ is obvious. It will first be shown that $I_{k+1} \supset I_k$ can be chosen so that (A.1) holds for $0 \leq t \leq k + 1$.

CLAIM A.1. *The set*

$$\left\{ dx, dy_{i_r}[r], dy_{i_k}[k+1], du_{j_k}[0], du_{j_{k-r}}[r+1] | 0 \leq r \leq k, i_r \in I_r, j_r \in J_r \right\}$$

is linearly independent.

Proof. To see how the arguments go, consider first (A.2) for $t = 0$ and apply Δ to both sides to obtain

$$[dx[1], du[1]] = [\{dx[1], dy_{i_0}[1], du_{j_0}[1] | i_0 \in I_0, j_0 \in J_0\}].$$

Adding $[dx, du[0]]$ to both sides yields

$$[dx, du[0], du[1]] = [\{dx, du[0], dy_{i_0}[1], du_{j_0}[1] | i_0 \in I_0, j_0 \in J_0\}].$$

Applying (A.2) for $t = 0$ results in

$$[dx, du[0], du[1]] = [\{dx, dy_{i_0}[0], du_{j_0}[0], dy_{i_0}[1], du_{j_0}[1] | i_0 \in I_0, j_0 \in J_0\}].$$

The independence of the vectors on the left-hand side implies the independence of those on the right-hand side by counting the number of elements. In particular, the vectors $\{dx, dy_{i_0}[0], dy_{i_0}[1], | i_0 \in I_0, \}$ are linearly independent, and thus, one can choose $I_1 \supset I_0$ such that (A.1) holds for $0 \leq t \leq 1$.

In general, consider (A.2) for $t = k$ and apply Δ to both sides to obtain

$$(A.4) \quad \begin{aligned} & [dx[1], du[1], \dots, du[k+1]] \\ &= [\{dx[1], dy_{i_r}[r+1], du_{j_{k-r}}[r+1] | 0 \leq r \leq k, i_r \in I_r, j_r \in J_r\}]. \end{aligned}$$

Add $[dx, du[0]]$ to both sides to obtain

$$\begin{aligned} & [dx, du[0], \dots, du[k+1]] \\ &= [\{dx, du[0], dy_{i_r}[r+1], du_{j_{k-r}}[r+1] | 0 \leq r \leq k, i_r \in I_r, j_r \in J_r\}^*]. \end{aligned}$$

The independence of the vectors on the left-hand side implies the independence of those on the right-hand side by counting the number of elements. Applying (A.2) first for $t = 0$, and then successively for $t = 1, \dots, t = k$ results in

$$(A.5) \quad \begin{aligned} & [dx, du[0], \dots, du[k+1]] \\ &= [\{dx, dy_{i_0}[0], du_{j_0}[0], dy_{i_r}[r+1], du_{j_{k-r}}[r+1] | 0 \leq r \leq k, i_r \in I_r, j_r \in J_r\}^*] \\ &= [\{dx, dy_{i_0}[0], dy_{i_1}[1], du_{j_1}[0], dy_{i_s}[s+1], du_{j_{k-r}}[r+1] | 0 \\ &\quad \leq r \leq k, 1 \leq s \leq k, i_s \in I_s, j_r \in J_r\}^*] \\ &= [\{dx, dy_{i_0}[0], dy_{i_1}[1], dy_{i_2}[2], du_{j_2}[0], dy_{i_s}[s+1], du_{j_{k-r}}[r+1] | 0 \\ &\quad \leq r \leq k, 2 \leq s \leq k, i_r \in I_r, j_r \in J_r\}^*] \\ &= \text{for each } 0 \leq t \leq k \\ &= [\{dx, dy_{i_0}[0], \dots, dy_{i_t}[t], du_{j_t}[0], dy_{i_s}[s+1], du_{j_{k-r}}[r+1] | 0 \\ &= \quad \leq r \leq k, t \leq s \leq k, i_r \in I_r, j_r \in J_r\}^*]. \quad \square \end{aligned}$$

Hence, we can choose $I_{k+1} \supset I_k$ so that (A.1) holds for each $0 \leq t \leq k+1$. It is next shown that $J_{k+1} \subset J_k$ can be chosen such that (A.2) and (A.3) hold. From (A.3) for $t = k$, since $\mathcal{E}_k \subset \mathcal{E}_{k+1}$, we deduce

$$(A.6) \quad du[0] \subset \mathcal{E}_{k+1} + \{du_j[0] | j \in J_k\}.$$

By the definition of I_{k+1} ,

$$(A.7) \quad \mathcal{E}_{k+1} = \mathcal{E}_k \oplus [\{dy_{i_k}[k+1] | i_k \in I_{k+1}\}^*] \oplus [\{dy_\ell[k+1] | \ell \in I_{k+1} \setminus I_k\}^*].$$

For each $\ell \in I_{k+1} \setminus I_k$, $dy_\ell[k] \in \mathcal{E}_k$, and thus,

$$(A.8) \quad \begin{aligned} dy_\ell[k+1] &\in [\{dx[1], dy_{i_0}[1], \dots, dy_{i_k}[k+1] | i_r \in I_r, 0 \leq r \leq k\}] \\ &\subset (\mathcal{E}_k \oplus [\{dy_{i_k}[k+1] | i_k \in I_k\}^*]) + [du[0]] \\ &\subset (\mathcal{E}_k \oplus [\{dy_{i_k}[k+1] | i_k \in I_k\}^*]) + [du[0] | j \in J_k], \end{aligned}$$

where the last inclusion is from (A.3) for $t = k$. Thus, $(|I_{k+1}| - |I_k|)$ elements of $\{du_j[0] | j \in J_k\}$ are not independent of \mathcal{E}_{k+1} . One can therefore choose $J_{k+1} \subset J_k$ such that

$$(A.9) \quad du[0] \subset \mathcal{E}_{k+1} \oplus [\{du_j[0] | j \in J_{k+1}\}^*]$$

and

$$(A.10) \quad |J_{k+1}| = |J_k| - (|I_{k+1}| - |I_k|).$$

To finish up, from (A.5) and (A.9) it follows that

$$(A.11) \quad \begin{aligned} [dx, du[0], \dots, du[k+1]] &\subset [\{dx, dy_{i_0}[0], \dots, dy_{i_{k+1}}[k+1], du_{j_{k+1}}[0], \dots, \\ &\quad du_{j_0}[k+1] | i_t \in I_t, j_{k+1-t} \in J_t, 0 \leq t \leq k+1\}]. \end{aligned}$$

Since the reverse inclusion is obviously true, one has equality. By counting the number of vectors on the right-hand side of (A.11), we obtain (A.2) for $t = k+1$. \square

From (A.1) and (A.2), respectively, it follows that

$$(A.12) \quad \rho_k = n + \sum_{i=1}^k |I_i|$$

and

$$(A.13) \quad n + (k+1)m = n + \sum_{i=1}^k |I_i| + \sum_{i=1}^k |J_i|,$$

yielding

$$(A.14) \quad \rho_k - \rho_{k-1} = m - |J_k|.$$

This combined with (A.3) proves the following result.

COROLLARY A.2. *Suppose that (2.1) is generically submersive. Then*

$$\dim \mathcal{E}_k - \dim \mathcal{E}_{k-1} = m \text{ if and only if } \{du_1[0], \dots, du_m[0]\} \subset \mathcal{E}_k .$$

Proof of Lemma 2.4. We can view $y[k]$, $0 \leq k \leq N$ as being an analytic function on $X \times U^{N+1}$. Let \mathcal{O} be an open subset of $X \times U^{N+1}$.

By the definition of I_0, \dots, I_n , for any $0 \leq N \leq n$,

$$(A.15) \quad dy_j[N] \in \text{span}_{\mathcal{K}_N} \{dx, dy_{i_0}[0], \dots, dy_{i_N}[N] | i_k \in I_k, \ 0 \leq k \leq N\} .$$

Due to analyticity, (A.15) is equivalent to

$$(A.16) \quad dy_j[N]|_{\mathcal{O}} \in \text{span}_{\mathbf{R}} \{dx, dy_{i_0}[0], \dots, dy_{i_N}[N] | i_k \in I_k, \ 0 \leq k \leq N\}|_{\mathcal{O}} ,$$

where the left-hand side is viewed as a one-form on \mathcal{O} , the right-hand side is viewed as an analytic codistribution on \mathcal{O} , and the span is taken pointwise; without loss of generality, it can be assumed that the codistribution has constant dimension. After possibly shrinking \mathcal{O} , the Rank theorem implies that on \mathcal{O} , $y_j[N]$ can be expressed as an analytic function of $(x, y_{i_0}[0], \dots, y_{i_N}[N] | i_k \in I_k, \ 0 \leq k \leq N)$. Repeating the above reasoning, (2.21) is equivalent to

$$(A.17) \quad dy_j[N]|_{\mathcal{O}} \in \text{span}_{\mathcal{K}_N} \{dy_j[0], \dots, dy_j[N-1], dy_{i_0}[0], \dots, dy_{i_N}[N] | i_k \in I_k, \ 0 \leq k \leq N\}|_{\mathcal{O}} .$$

Hence, from (A.16), (2.21) holds if

$$(A.18) \quad \frac{\partial y_j[N]}{\partial x} dx \in \text{span}_{\mathcal{K}_N} \left\{ \frac{\partial y_j[0]}{\partial x} dx, \dots, \frac{\partial y_j[N-1]}{\partial x} dx \right\} .$$

Because the right-hand side of (A.18) can be at most n -dimensional, there must exist an N , $1 \leq N \leq n$, such that this is the case. \square

Appendix B.

Proofs of Lemmas 2.6 and 2.7. The inclusion $M_{k+1} \subset M_k$, implies $d_{k+1} \leq d_k \ \forall k \geq 0$. Since $x[k] : \mathbf{R}^n \times (\mathbf{R}^m)^k \rightarrow \mathbf{R}^n$ is an analytic function, there exists an open and dense subset $V_k \subset \mathbf{R}^n \times (\mathbf{R}^m)^k$ on which $x[k]$ has constant \mathbf{R} -rank equal to d_k ; that is, for each point $p \in V_k$,

$$(B.1) \quad \text{rank}_{\mathbf{R}} \left[\frac{\partial x[k]}{\partial (x, u[0], \dots, u[k-1])} \right] (p) = d_k .$$

Let $N_k := x[k](V_k)$. Then, N_k is an immersed submanifold of \mathbf{R}^n , but since the resulting topology may be different than the subset topology of \mathbf{R}^n , this property is of little interest. More importantly, the implicit function theorem implies that, for each point $q \in N_k$, there exists an open subset $\mathcal{O}_k \subset V_k$ such that $x[k](\mathcal{O}_k)$ is a d_k -dimensional, embedded, analytic submanifold of \mathbf{R}^n and q is in the interior of $x[k](\mathcal{O}_k)$. Since V_k is dense in $\mathbf{R}^n \times (\mathbf{R}^m)^k$, N_k is dense in M_k in the subset topology.

Let $\bar{f}_k : x[k](\mathcal{O}_k) \times \mathbf{R}^m \rightarrow \mathbf{R}^n$ denote f restricted to $x[k](\mathcal{O}_k) \times \mathbf{R}^m$ (the subscript k is to note that \bar{f}_k depends on \mathcal{O}_k). Whenever $\mathcal{O}_k \subset V_k$ is such that $x[k](\mathcal{O}_k)$ is a d_k -dimensional embedded submanifold of \mathbf{R}^n , then \bar{f}_k is an analytic function. Consequently, it will have constant \mathbf{R} -rank on an open and dense subset of its domain

of definition, which is called its *generic rank* and is denoted as $\text{gen rank } \bar{f}_k$. From (2.23) and (2.24) it follows that

$$(B.2) \quad d_{k+1} = \text{gen rank } \bar{f}_k : x[k](\mathcal{O}_k) \times \mathbb{R}^m \rightarrow \mathbb{R}^n$$

since, if $p \in \mathcal{O}_k$ and $q := x[k](p)$, then $T_q x[k](\mathcal{O}_k)$, the tangent space of $x[k](\mathcal{O}_k)$ at the point q , satisfies

$$(B.3) \quad T_q x[k](\mathcal{O}_k) = \text{Image} \left[\frac{\partial x[k]}{\partial (x, u[0], \dots, u[k-1])} \right] (p).$$

With the above preliminaries completed, the proof of Lemma 2.6 can be given. If $d_n = 0$, the result is obvious; suppose, therefore, that $d_n > 0$. Then, there exists $0 \leq k \leq n-1$ such that $d_k = d_{k-1}$. As before, choose \mathcal{O}_k to be an open subset of V_k such that $x[k](\mathcal{O}_k)$ is an embedded d_k -dimensional submanifold of \mathbb{R}^n . Since $M_k \subset M_{k-1}$, and N_k and N_{k-1} are dense in M_k and M_{k-1} , respectively, the condition $d_k = d_{k-1}$ implies that $x[k](\mathcal{O}_k)$ is an embedded $(d_{k-1} = d_k)$ -dimensional submanifold of \mathbb{R}^n and $x[k](\mathcal{O}_k) \cap x[k-1](\mathcal{O}_{k-1})$ has nonempty interior. Therefore,

$$(B.4) \quad \begin{aligned} d_{k+1} &= \text{gen rank } \bar{f}_k : x[k](\mathcal{O}_k) \times \mathbb{R}^m \rightarrow \mathbb{R}^n \\ &= \text{gen rank } \bar{f}_{k-1} : x[k-1](\mathcal{O}_{k-1}) \times \mathbb{R}^m \rightarrow \mathbb{R}^n \\ &= d_k, \end{aligned}$$

where the fact that \bar{f}_k and \bar{f}_{k-1} are the restrictions of a common map f and have a common nonempty open set in their domain of definition entails the second equality. This completes the proof of Lemma 2.6.

Turning to Lemma 2.7, let $d := d_n$, which is then equal to d_k for all $k > n$ by Lemma 2.6. If $d = 0$, then Lemma 2.7 is immediate, so in the following it is supposed that $d > 0$. Let $\alpha = \alpha(x, u[0], \dots, u[k])$ be an element of \mathcal{R}_k . For any $r > 0$, $\delta^r(\alpha) = \alpha(x[r], u[r], \dots, u[k+r])$. Let $\tilde{\mathcal{O}}_r \subset V_r$ be an open set such that $x[r](\tilde{\mathcal{O}}_r)$ is a d_r -dimensional submanifold of \mathbb{R}^n . Then $\delta^r(\alpha) \neq 0$ if, and only if, α restricted to $(x[r](\tilde{\mathcal{O}}_r) \times (\mathbb{R}^m)^{k+1}) \neq 0$. When $r > n$, there exists $\tilde{\mathcal{O}}_n \subset V_n$ such that $x[n](\tilde{\mathcal{O}}_n) \times (\mathbb{R}^m)^{k+1} \cap x[r](\tilde{\mathcal{O}}_r) \times (\mathbb{R}^m)^{k+1}$ has nonempty interior. Thus, α restricted to $(x[r](\tilde{\mathcal{O}}_r) \times (\mathbb{R}^m)^{k+1}) \neq 0$ if, and only if, α restricted to $(x[n](\tilde{\mathcal{O}}_n) \times (\mathbb{R}^m)^{k+1}) \neq 0$. \square

Acknowledgment. The author has benefited greatly from conversations with M. Fliess and C.H. Moog on the subject of this paper, as well as from the insightful comments provided by the reviewers. This work was completed while the author was a visiting researcher at the Laboratoire des Signaux et Systèmes, Gif-sur-Yvette, France (Poste Rouge, Directeur de Recherche Associé). Professors P. Bertrand, M. Fliess, and F. Lamnabhi-Lagarigue are sincerely thanked for contributing in diverse ways to a very enjoyable and worthwhile *séjour*.

STOCHASTIC APPROXIMATION WITH AVERAGING OF THE ITERATES: OPTIMAL ASYMPTOTIC RATE OF CONVERGENCE FOR GENERAL PROCESSES*

HAROLD J. KUSHNER^{†‡} AND JICHUAN YANG^{†§}

Abstract. Consider the stochastic approximation algorithm

$$X_{n+1} = X_n + a_n g(X_n, \xi_n).$$

In an important paper, Polyak and Juditsky [*SIAM J. Control Optim.*, 30 (1992), pp. 838–855] showed that (loosely speaking) if the coefficients a_n go to zero slower than $O(1/n)$, then the averaged sequence $\sum_{i=1}^n X_i/n$ converged to its limit, at an optimum rate, for any coefficient sequence. The conditions were rather special, and direct constructions were used. Here a rather simple proof is given that results of this type are generic to stochastic approximation, and essentially hold any time that the classical asymptotic normality of the normalized and centered iterates holds. Considerable intuitive insight is provided into the procedure. Simulations have well borne out the importance of the method.

Key words. stochastic approximation, stochastic approximation with averaged iterates, rate of convergence for stochastic algorithms

AMS subject classifications. 62L20, 60F05, 62E25

1. Introduction. Consider the stochastic approximation (SA)

$$(1.1) \quad X_{n+1} = X_n + a_n g(X_n, \xi_n),$$

where $0 < a_n \rightarrow 0$, $\sum_n a_n = \infty$ and $\{\xi_n\}$ is some “noise” sequence. Suppose that for some θ , $X_n \rightarrow \theta$ either with probability one or weakly. Then, under appropriate conditions $(X_n - \theta)/\sqrt{a_n}$ converges in distribution to a normal random variable with mean zero and some covariance matrix V_0 . The matrix V_0 is often considered to be a measure of the “rate of convergence,” taken together with the scale factors or gains $\{a_n\}$.

Suppose that $a_n \rightarrow 0$ “slower” than $1/n$. In particular, suppose that

$$(1.2) \quad a_n/a_{n+1} = 1 + o(a_n).$$

Define

$$(1.3) \quad \bar{X}_n = \frac{1}{n} \sum_1^n X_i.$$

Then, in a sequence of fundamental papers, Polyak [1] and Polyak and Juditsky [2] showed that $\sqrt{n}(\bar{X}_n - \theta)$ converged in distribution to a normal random variable with mean zero and covariance V , where V was the smallest possible in an appropriate sense. V did not depend on $\{a_n\}$, provided that (1.2) held. This relaxation of conditions on $\{a_n\}$ allows it to be “relatively large” and is quite important in applications.

Simulations have supported the theoretical conclusions and have shown the clear superiority of the use of averages of the type (1.3) over X_n directly. This superiority would not be true if a_n decreased as $O(1/n)$, and in this latter case, it was known for a long time that the asymptotic rates are the same for $\{\bar{X}_n\}$ and $\{X_n\}$. In the past, a great deal of attention was given to the problem of choosing optimal sequences $\{a_n\}$ via “adaptive” and generally unreliable means. The importance of this problem is now much reduced. The results in [1], [2] are similar in spirit to the approach of Ruppert [3] for a one-dimensional case.

The proofs in [1], [2] were by direct construction. They involved detailed expansions and estimates and made no use of prior results in SA. The function $g(\cdot)$ needed to be “smooth” and the conditions on the noise were restrictive, being essentially that $\{\xi_n\}$ were either i.i.d. or martingale differences, depending on the case. The conditions on the noise were weakened by Yin [4], [5] who allowed certain “mixing sequences,” but the proofs were still complicated and made no use of prior results in SA.

In this paper, it will be seen that a very simple use of prior results in SA allows us to get results of the above type under condition of considerable generality. In addition, the approach sheds more light on the reasons why averaged estimators such as (1.3) work well. In general, we use sums of the type (1.3), but where the lower index of summation goes to infinity as $n \rightarrow \infty$. We will work with several such averages.

In §2, we show that a very useful averaging result can be readily obtained via a weak convergence method under quite broad conditions. This result uses a “minimal window” of iterates, fewer than in (1.3), yet is quite useful in practice. Insight into the reasons why the averaging method works is obtained via an examination of a “two time scale SA” representation of (1.1), (1.3) in a simple case. The “window of averaging” is extended in §3.

2. The basic convergence theorem for the averaged iterates. Define the “interpolated time” $t_n = \sum_0^{n-1} a_i$, with $t_0 = 0$, and its “inverse” $m(t) = \max\{n : t_n \leq t\}$. For notational simplicity and without loss of generality, set $\theta = 0$. For each $n \geq 0$, define the interpolated processes $X^n(\cdot)$ and $U^n(\cdot)$ by

$$\left. \begin{aligned} X^n(t) &= X_{n+i} \\ U^n(t) &= X_{n+i}/\sqrt{a_{n+i}} \end{aligned} \right\} \text{ for } t \in [t_{n+i} - t_n, t_{n+i+1} - t_n], i \geq 0.$$

Let \Rightarrow denote weak convergence in the Skorohod topology on $D^r[0, \infty)$ [6], [7]. In Theorem 2.1, we will use the following assumption.

Assumption A2.1. There is a matrix G whose eigenvalues lie in the open left half plane and a positive definite symmetric matrix R_0 such that $X^n(\cdot) \Rightarrow$ zero process and $U^n(\cdot) \Rightarrow U(\cdot)$, where $U(\cdot)$ is the stationary solution to

$$(2.1) \quad dU = GUdt + R_0^{1/2}dw.$$

Comment on (A2.1). We prefer to state the condition in the form of (A2.1) since so many different sets of conditions imply (A2.1). Also, the main aim here is to show that a standard weak convergence result can be used to get an optimal rate of convergence under any of the sets of conditions which guarantee the usual limit result (A2.1). The references [8], [9], [11]–[13] contain various sets of conditions which guarantee (A2.1).

For $t > 0$, define $Z^n(\cdot)$ by

$$(2.2) \quad Z^n(t) = \frac{1}{\sqrt{t/a_n}} \sum_{i=n}^{n+t/a_n} X_i.$$

In sums of type \sum_{α}^{β} for real α, β , we always use the integer parts of α, β .

A basic convergence theorem.

THEOREM 2.1. *Assume (1.2) and (A2.1) and define $V = G^{-1}R_0(G')^{-1}$. For each t , $Z^n(t)$ converges in distribution to a random variable with mean zero and covariance $V_t = V + O(1/t)$.*

Proof. Define the processes

$$\tilde{Z}^n(t) = \frac{1}{\sqrt{t}} \int_0^t U^n(s) ds, \quad \tilde{Z}(t) = \frac{1}{\sqrt{t}} \int_0^t U(s) ds.$$

By the weak convergence in (A2.1), $\tilde{Z}^n(\cdot) \Rightarrow \tilde{Z}(\cdot)$. Define the covariance matrix $R(s) = EU(t)U'(t+s)$, where $U(\cdot)$ is the stationary solution to (2.1). Since $R(s) \rightarrow 0$ exponentially as $s \rightarrow \infty$,

$$\begin{aligned} \text{cov } \tilde{Z}(t) &= \frac{1}{t} \int_0^t \int_0^t R(s-\tau) ds d\tau \\ &= \int_{-\infty}^{\infty} R(s) ds + O(1/t), \end{aligned}$$

but $\int_{-\infty}^{\infty} R(s) ds = G^{-1}R_0(G^{-1})'$.

The basic result on the character of the averaged iterates is obtained by relating $Z^n(t)$ to $\tilde{Z}^n(t)$.

Write

$$(2.3) \quad \frac{a_n}{a_{n+i}} = 1 + \delta_{n,i}.$$

Then (1.2) implies that for any $t < \infty$,

$$(2.4) \quad \max\{i - n : 0 \leq t_i - t_n \leq t\} \cdot a_n/t \xrightarrow{n} 1.$$

Equation (2.4) will be heavily used. Note that (2.4) would not hold if $a_n = O(1/n)$.

Equation (2.4) follows from (1.2) as follows: Let $i > n$. Then $a_i/a_n = \prod_n^i (1 + o(a_j))$.

If $\sum_n^i a_j \leq t$, then the ratio goes to unity, uniformly in such i , as $n \rightarrow \infty$.

Using the "piecewise constant" definition of $U^n(\cdot)$, we have (modulo "end terms") for $i \geq n$

$$\begin{aligned} \sqrt{t}\tilde{Z}^n(t) &= \sum_{i:t_i-t_n \leq t} (X_i a_i^{-1/2}) a_i \\ &= \sum_{i:t_i-t_n \leq t} X_i (a_i^{1/2} - a_n^{1/2}) + a_n^{1/2} \sum_{i:t_i-t_n \leq t} X_i. \end{aligned}$$

(Alternatively, the sums can be written as $\sum_{m(t_n)}^{m(t_n+t)}$.) By the weak convergence of $U^n(\cdot)$ in (A2.1) and (2.4), the first sum on the right goes to zero in probability as

$n \rightarrow \infty$. By the same weak convergence and (2.4), the second sum on the right is asymptotically equivalent (in distribution) to

$$(2.5) \quad a_n^{1/2} \sum_{i=n}^{n+t/a_n} X_i.$$

This and the weak convergence $\tilde{Z}^n(t) \Rightarrow \tilde{Z}(t)$ yield the theorem. \square

Discussion of the theorem.

(a) On the optimality of the “rate of convergence.” Suppose that $U_n = X_n/\sqrt{a_n}$ converged in distribution to a normally distributed random variable \hat{U} with mean zero. It is common to consider the covariance of $\sqrt{a_n}\hat{U}$ as a “measure of the rate of convergence” or “asymptotic errors.” Then the best value of a_n is $O(1/n)$. Suppose that $a_n = A/n$, for A a positive definite matrix. Then, under appropriate conditions (see, e.g., [8], [9]), $U^n(\cdot) \Rightarrow \tilde{U}(\cdot)$, where $\tilde{U}(\cdot)$ is the stationary solution to

$$(2.6) \quad d\tilde{U} = \left(\frac{I}{2} + AG \right) \tilde{U} dt + AR_0^{1/2} dw,$$

where G and R_0 are as in (A2.1), and it is supposed that $(I/2 + AG)$ is a stable matrix. If we optimize the trace of the covariance matrix of (2.6) over A , we get the best value of A as

$$A = -G^{-1}.$$

With this value of A , the covariance of $\tilde{U}(0)$ is just the V used in Theorem 2.1. In this sense, the result in [1], [2] and of Theorem 2.1 is optimal. Let us note that the fact that $U^n(\cdot) \Rightarrow U(\cdot)$ satisfying (2.1), rather than (2.6), is of crucial importance. The integral of the correlation function of (2.6) depends on A . Again we emphasize that Theorem 2.1 requires that $a_n \rightarrow 0$ slower than $O(1/n)$. The result of Theorem 2.1 holds for some very complicated SAs, e.g., ones which arise due to distributed and asynchronous processing [13].

(b) The “window” of averaging. The value of t can be made as large as desired in (2.2), and can go to infinity slowly with n . More will be said about this in the next section. A two-sided average

$$\sqrt{\frac{a_n}{t_1 + t_2}} \sum_{n-t_1/a_n}^{n+t_2/a_n} X_i$$

can be used in lieu of (2.2) with the same results. For this case, the proof is nearly identical to the one given.

In (2.2), the “window” of the averaging is $O(1/a_n)$ as opposed to $O(n)$ in (1.3). Theorem 2.1 implies that the order $O(1/a_n)$ is the *smallest* which can be used. Suppose that $a_n = 1/n^\gamma$, $\gamma \in (0, 1)$. Then as $\gamma \rightarrow 0$, the minimal window of averaging decreases. Loosely speaking, for smaller rates of decrease of $\{a_n\}$, there is more “oscillation” of the iterates $\{X_n\}$ about the limit point, and less averaging is needed. This point will be supported by the following discussion of the singularly perturbed SA.

The theorem shows that the improvement, due to averaging, is a *natural property* of SA and is essentially a consequence of weak convergence of the normalized process $U^n(\cdot)$.

(c) Relationships between the use of (2.2) and a two time scale SA. For additional motivation and insight concerning the averaging method, let us rewrite the iteration for (X_n, U_n) as a two time scale or “singularly perturbed” SA. The following discussion is purely heuristic. Hence, for simplicity of presentation, we use a linear and one-dimensional model. For $A > 0$ and $\gamma \in (0, 1)$, define $\{X_n\}$ by

$$X_{n+1} = \left(1 - \frac{AG}{n^\gamma}\right)X_n + \frac{A\xi_n}{n^\gamma}.$$

Define $\bar{U}_n = \sum_1^n X_i/\sqrt{n}$. Then, putting the iterations for \bar{U}_n and X_n on the same time scale, we can write

$$(2.7a) \quad \frac{1}{n^{1-\gamma}}(X_{n+1} - X_n) = -\frac{AGX_n}{n} + \frac{A\xi_n}{n},$$

$$(2.7b) \quad \bar{U}_{n+1} - \bar{U}_n = -\frac{\bar{U}_n}{2n} \left(1 + O\left(\frac{1}{n}\right)\right) + \frac{X_{n+1}}{\sqrt{n+1}}.$$

\bar{U}_n is just \sqrt{n} times the averaged value $\sum_1^n X_i/n$, and a quantity whose asymptotic variance is of interest. Equation (2.7) can be viewed as a two time scale SA.

We can make a similar heuristic argument if \bar{U}_n is replaced by $\sqrt{t}Z^n(t)$. Define a new interpolation time $\tilde{t}_n = \sum_{i=1}^n 1/i$. Define the new continuous time interpolation $\tilde{X}^n(\cdot)$ by $\tilde{X}^n(t) = X_{n+i}$ on $[\tilde{t}_{n+i} - \tilde{t}_n, \tilde{t}_{n+i+1} - \tilde{t}_n)$, $i \geq 0$. In this new time scale, $\{X_n\}$ is “squeezed” or compressed more than it was in the $\{t_n\}$ scale and $\tilde{X}^n(\cdot)$ has a smaller correlation than $X^n(\cdot)$. This “smaller correlation” suggests that an averaging method will yield an improved result. Note that this two time scale effect doesn’t hold if $a_n = O(1/n)$.

A two time scale continuous parameter system that is loosely analogous to (2.7) is

$$(2.8) \quad \varepsilon dz^\varepsilon = A_{11}z^\varepsilon dt + dw_1$$

$$dx^\varepsilon = A_{22}x^\varepsilon dt + A_{12}z^\varepsilon dt + dw_2,$$

where ε is small. Under suitable stability conditions, [10, Chap. 10], $\int_0^t z^\varepsilon(s)ds$ converges weakly to a Wiener process. Hence, we might expect that, with (2.7), the function of t defined by

$$\frac{1}{\sqrt{n}} \sum_{i=0}^{nt} X_i$$

might also converge weakly to a Wiener process with covariance matrix V . Indeed, a similar result is proved in the next section.

Constant gain coefficients. Replace (1.1) by

$$(2.9) \quad X_{n+1}^\varepsilon = X_n^\varepsilon + \varepsilon g(X_n^\varepsilon, \xi_n), \quad \varepsilon > 0.$$

Define $X^\varepsilon(\cdot)$ and $U^\varepsilon(\cdot)$ by $X^\varepsilon(t) = X_n^\varepsilon, U^\varepsilon(t) = X_n^\varepsilon/\sqrt{\varepsilon}$ on $[n\varepsilon, n\varepsilon + \varepsilon)$. Suppose that there are $t_\varepsilon \xrightarrow{\varepsilon} \infty$ such that $U^\varepsilon(t_\varepsilon + \cdot) \Rightarrow U(\cdot)$, a stationary process which satisfies (2.1). Such results are proved in [11]. Fix $t > 0$ and let $t_i \geq 0$ such that $t = t_1 + t_2$. Define

$$Z^\varepsilon(t) = \sqrt{\frac{\varepsilon}{t}} \sum_{(t_\varepsilon - t_2)/\varepsilon}^{(t_\varepsilon + t_1)/\varepsilon} X_i.$$

Then, following the argument of Theorem 2.1 yields that for each t , $Z^\varepsilon(t)$ converges in distribution to a normally distributed random variable with mean zero and covariance $V + O(1/t)$.

A note on computation. In applications, averages of the type

$$\frac{1}{m_2(n) - m_1(n)} \sum_{m_1(n)}^{m_2(n)-1} X_i$$

are usually preferred to (1.3), where $m_i \rightarrow \infty$ and $m_2(n) - m_1(n) \rightarrow \infty$ as $n \rightarrow \infty$. Such averages cannot, in general, be computed recursively. However, memory requirements can be reduced by appropriate grouping of the iterates and selection of the times of updating.

3. Increasing the window of averaging in (2.2). In this section, we will see how fast we can let $t \rightarrow \infty$ and prove the above assertion concerning convergence to Wiener process.

For a sequence $n \geq q_n \rightarrow \infty$, define $M^n(t)$ by

$$(3.1) \quad M^n(t) = \frac{1}{\sqrt{q_n}} \sum_{i=n}^{n+q_n t} X_i.$$

We could use $\sum_{i=n-q'_n t}^{n+q''_n t}$ in (3.1) where $q''_n + q'_n = q_n$ and $q_n > \epsilon n$ for some $\epsilon > 0$, with the same end results. This is, in fact, a practical case since we would often wish to delete some initial fraction of the iterates from the averaging. To relate this last form to (1.3), let $t = 1$, $q_n = n$, $q'_n = (1 - \alpha)n$, $\alpha < 1$. Then we get

$$\frac{1}{n} \sum_{i=\alpha n}^{(1+\alpha)n} X_i.$$

Theorem 2.1 dealt with the case $q_n = O(1/a_n)$. In this section we need to assume that

$$(A3.1) \quad q_n a_n^{3/2} \rightarrow 0, \quad q_n a_n \rightarrow \infty, \quad q_n \leq k_0 n \quad \text{for some } k_0 < \infty.$$

Thus if $q_n = n$ and $a_n = 1/n^\gamma$, then $\gamma \in (2/3, 1)$ is needed. The result in [2], [3] required only $\gamma \in (1/2, 1)$, but our conditions on the noise and dynamics are more general. Under stronger conditions, the method of the following theorem can be carried through with $\gamma \in (1/2, 1)$. In the next section, it will be shown that $M^n(\cdot) \Rightarrow w(\cdot)$, a Wiener process with covariance matrix Vt , thus supporting the assertion at the end of the last section. In order to extend the "window of averaging" beyond t/a_n , we need $q_n a_n \rightarrow \infty$.

Discussion of the noise processes. Two types of noise processes are considered. For the first, the sequence $\{\xi_n\}$ is “exogenous.” Loosely speaking, the evolution of $\{X_n\}$ does not affect $\{\xi_n\}$. For the second, or “state dependent” noise, (X_n, ξ_n) is jointly Markov. There is a transition function $p(\xi, \cdot | x)$ such that $P\{\xi_{n+1} \in A | \xi_n = \xi, X_n = x\} = p(\xi, A | x)$. For each n and x , define the Markov process $\{\xi_j(x), j \geq n\}$ with initial condition $\xi_n(x) = \xi_n$ and transition function $p(\xi, \cdot | x)$. Such models were introduced in [11], [14], and also used in [9], [12].

The following additional conditions will be used. Let E_n denote the expectation conditioned on $\{X_i, i \leq n, \xi_i, i < n\}$.

Condition A3.2. There is a continuously differentiable “centering” function $\bar{g}(\cdot)$ such that with the definition $\psi_j(x) = g(x, \xi_j) - \bar{g}(x)$ (for the exogenous noise) and $\psi_j(x) = g(x, \xi_j(x)) - \bar{g}(x), j \geq n$ (for the state dependent noise) we have for each n and x ,

$$(3.2) \quad \sum_{j=n}^{\infty} a_j E_n \psi_j(x) = O(a_n)$$

where $O(a_n)$ is uniform in n, ω, x (where ω is the canonical point of the sample space), and $\psi_j(x)$ is bounded. In (3.2), for the state dependent noise case, the initial condition of $\{\xi_j(x), j \geq n\}$ is $\xi_n(x) = \xi_n$, following the usage in [12], [14].

Condition A3.3. $\bar{g}(x) = Gx + \delta g(x)$, where G has its eigenvalues in the open left half plane and $|\delta g(x)| = O(|x|^2)$.

Condition A3.4. $\sum_{j=n}^{\infty} a_j E_n [\psi_j(x) - \psi_j(y)] = O(a_n) |y - x|, |g(x, \xi)| \leq O(1) [|x| + 1]$.

Comments on the conditions (A3.2), (A3.4). Such conditions were initially introduced in [11], [15] and have been used in many of the other references; e.g., [4], [5], [9], [11], [12], [13]. They are essentially conditions on the “mixing rate” of the processes. A simple example of (3.2) is where the noise is “exogenous,” $\bar{g}(x) = Eg(x, \xi)$ is smooth, $\{\psi_j(x)\}$ is bounded and $\{\xi_n\}$ satisfies a mixing condition with a sufficiently fast mixing rate. Many specific examples are shown in [9], [12]. In [9], the sum in (A3.2) is the solution to the Poisson equation, and then (A3.4) is a condition on the smoothness of that solution. For the state dependent noise case, the transition kernel $p(\xi, \cdot | x)$ often assures that $\int g(x, \xi') p(\xi, d\xi' | x)$ is smooth enough so that (A3.4) holds [11].

We could replace $O(a_n)$ in (A3.2) by $O(a_n) \hat{g}(x)$ where $\hat{g}(x)$ has an appropriate growth rate, but we prefer to keep the development simple.

Stability of (1.1). A main problem in extending the window of averaging in Theorem 2.1 concerns the tightness of $\{X_n / \sqrt{a_n}\}$. Such results are basic to the proofs of (A2.1). In fact, given such tightness, straightforward averaging methods can often be used to get (A2.1). Theorem 3.1 requires the following bounds in Lemma 3.1, and to get that the following stability condition will be used. Recall that we use the assumption that the limit point is $\theta = 0$ for notational convenience and without loss of generality.

Condition A3.5. There is a nonnegative continuous function $V(\cdot)$ whose first and second mixed partial derivatives exist and are continuous. For some positive definite symmetric matrix A and some $\gamma > 0, K < \infty$,

$$V(x) = x' A x + o(|x|^2),$$

$$V'_x(x) \bar{g}(x) \leq -\gamma V(x), \quad |V_x(x)|^2 \leq K V(x),$$

$$|g(x, \xi)|^2 \leq K(V(x) + 1).$$

and $V_{xx}(x)$ is uniformly bounded.

Let \mathcal{F}_m denote the minimal σ -algebra which measures $\{X_i, i \leq m; \xi_i, i < m\}$.

LEMMA 3.1. Assume (A3.2)–(A3.5). Then $\{E|X_n|^4/a_n^2\}$ is bounded. Let $k < \infty$. For any \mathcal{F}_m -stopping time q with values in $[n, n + kn]$, we have $E|X_q|^2/a_n = O(1)$, uniformly in n and in q in the given class. The bounds also hold for the Y_i^n defined by (3.7).

Proof. The proof can be seen in the Appendix.

The following theorem gives us the largest window of averaging. It is largest in the sense that if $q_n = O(n)$, then the window is $O(n)$. The mutual independence of the increments of the Wiener process, which is the limit in the theorem, sheds additional light on the time scales which are used.

THEOREM 3.1. Under (1.2), (A2.1) and (A3.1)–(A3.5), $M^n(\cdot) \Rightarrow W(\cdot)$, a Wiener process with covariance Vt .

The proof will be divided into several parts. First we will show that it is sufficient to replace (1.1) by a simpler iteration. Then tightness of $\{M^n(\cdot)\}$ in the Skorohod topology is shown, and finally we prove that the limit of any weakly convergent subsequence is the asserted Wiener process.

Proof. It is notationally easier to do the proof if the rate at which $a_n \rightarrow 0$ is very slow. We will work with the additional assumption (see (1.2), (2.4))

$$(*) \quad \sup_{0 \leq i \leq kn} |\delta_{n,i}| \xrightarrow{n} 0$$

for each $k < \infty$. This will allow us to replace a_i by a_n when $0 \leq i - n \leq kn$. The modifications needed for the general case will be stated in Part 7.

Part 1. (In this part, (A3.1) can be replaced by $q_n a_n^2 \rightarrow 0$.) Define the quantity

$$\Pi(n, j) = \prod_{i=n}^j (I + a_i G), \quad j \geq n, \quad \Pi(n, n-1) = I.$$

Write (1.1) in the form

$$\begin{aligned} X_{n+1} &= X_n + a_n \bar{g}(X_n) + a_n \psi_n(X_n) \\ (3.3) \quad &= X_n + a_n G X_n + a_n \delta g(X_n) + a_n \psi_n(X_n). \end{aligned}$$

Then

$$\begin{aligned} (3.4) \quad X_{n+m+1} &= \Pi(n, n+m) X_n + \sum_{j=n}^{n+m} \Pi(j+1, n+m) a_j \delta g(X_j) \\ &\quad + \sum_{j=n}^{n+m} \Pi(j+1, n+m) a_j \psi_j(X_j) \\ &\equiv Q_{n,n+m}^1 + Q_{n,n+m}^2 + Y_{m+1}^n \end{aligned}$$

where the $Q_{n,j}^i$ and Y_m^n are defined in the obvious way.

It will be shown first that

$$(3.5) \quad \bar{Q}_n^i = \frac{1}{\sqrt{q_n}} \sum_{j=n}^{n+q_n t} E|Q_{n,j}^i| \xrightarrow{n} 0, \quad i = 1, 2.$$

This will allow us to drop the Q^1 and Q^2 terms in (3.4). The stability of G implies that there are $\lambda > 0$ and $c < \infty$ such that

$$(3.6) \quad \|\Pi(n, j)\| \leq ce^{-\lambda(t_j - t_n)}, \quad j \geq n.$$

Thus

$$E|Q_{n,j}^1| \leq ce^{-\lambda(t_j - t_n)} E|X_n|.$$

Using this bound and the estimate $E|X_n| = O(a_n^{1/2})$ from Lemma 3.1 yields

$$\bar{Q}_n^1 \leq O(1) \sum_{j=n}^{n+q_n t} e^{-\lambda(t_j - t_n)} O(\sqrt{a_n}) / \sqrt{q_n}.$$

By (A3.1), $1/\sqrt{a_n q_n} \rightarrow 0$. Using this and (2.3), (2.4) yields that

$$\bar{Q}_n^1 = O(1) \int_0^\infty e^{-\lambda s} ds / \sqrt{q_n a_n} \rightarrow 0.$$

Next we evaluate $Q_{n,n+m}^2$. For $m \in [n, kn]$, by Lemma 3.1 we have $E|\delta g(X_m)| = O(a_n)$. This and (3.6) yield

$$\begin{aligned} E|Q_{n,n+m}^2| &\leq O(1) \sum_{j=n}^{n+m} e^{-\lambda(t_{n+m} - t_{j+1})} a_j E|\delta g(X_j)| \\ &= O(1) a_n \int_0^\infty e^{-\lambda s} ds, \end{aligned}$$

which yields $E|Q_{n,n+m}^2| = O(a_n)$, $m \leq kn$. This implies that $\bar{Q}_n^2 \leq \sqrt{q_n t} O(a_n)$, which goes to zero as $n \rightarrow \infty$ by (A3.1).

Thus, to prove the theorem we can replace $\{X_m, m \geq n\}$ by the $\{Y_m^n, m \geq n\}$ process, which can be defined by

$$(3.7) \quad Y_{m+1}^n = (I + a_m G) Y_m^n + a_m \psi_m(X_m), m \geq n,$$

where we define $Y_n^n = 0$. Note that the stability of G in (A3.3) and the boundedness of $\{\psi_m(X_m)\}$ imply that $(Y_m^n, m \geq n)$ is bounded uniformly in n .

Part 2. Let $k > 0$ and let q be an \mathcal{F}_m -stopping time with values in $[n, n + kn]$. We next prove that

$$(3.8) \quad E|Y_q^n (E_q Y_j^n)'| = O(a_n^{3/2}) + O(a_n) E e^{-\lambda(t_j - t_q)},$$

for $kn \geq j \geq q$, where j and q are integers. A perturbed test function method will be used. For $n + kn \geq j \geq n$, define the ‘‘perturbations’’

$$(3.9) \quad \delta Y_j^n = \sum_{i=j}^\infty a_i E_j \psi_i(X_j) = O(a_j)$$

$$\tilde{Y}_j^n = Y_j^n + \delta Y_j^n$$

where the $O(a_j)$ value is due to (3.2). Note that the argument of the $\psi_i(\cdot)$ in (3.9) is X_j , the state at the lower index of summation.

Note the following:

$$(3.10a) \quad E_j Y_{j+1}^n - Y_j^n = a_j G Y_j^n + a_j E_j \psi_j(X_j),$$

$$(3.10b) \quad \begin{aligned} E_j \delta Y_{j+1}^n - \delta Y_j^n &= -a_j E_j \psi_j(X_j) \\ &+ \sum_{i=j+1}^{\infty} a_i E_j [\psi_i(X_{j+1}) - \psi_i(X_j)] \\ &= -a_j E_j \psi_j(X_j) + S_j, \end{aligned}$$

where S_j is defined in the obvious way. By (A3.4),

$$(3.11) \quad |S_j| = O(a_j^2)[|X_j| + 1].$$

Combining (3.10a), (3.10b) yields

$$(3.12) \quad E_j \tilde{Y}_{j+1}^n = (I + a_j G) \tilde{Y}_j^n + S_j - a_j G \delta Y_j^n.$$

Solving (3.12) yields

$$E_q \tilde{Y}_j^n = \Pi(q, j-1) \tilde{Y}_q^n + \sum_{i=q}^{j-1} \Pi(i, j-1) [E_q S_i - a_i E_q G \delta Y_i^n].$$

Hence, with the estimate $\delta Y_j^n = O(a_j)$ and (3.11), we can write

$$(3.13) \quad \begin{aligned} |E_q Y_j^n| &= O(1) e^{-\lambda(t_j - t_q)} |Y_q^n| \\ &+ O(1) \sum_{i=q}^{j-1} \Pi(i, j-1) a_i^2 (E_q |X_i| + 1) + O(a_n) \\ &= O(1) e^{-\lambda(t_j - t_q)} |Y_q^n| + O(a_n). \end{aligned}$$

By Lemma 3.1,

$$(3.14) \quad E|Y_q^n|^2 = O(a_n).$$

Now, combining (3.13) and (3.14) yields (3.8). Equation (3.13) will be used frequently in the sequel.

Part 3. Define

$$F^n(t) = \frac{1}{\sqrt{q_n}} \sum_{i=n}^{n+q_n t} Y_i^n.$$

By the results in Part 1, it is sufficient to prove the theorem for $F^n(\cdot)$ replacing $M^n(\cdot)$.

Tightness of $\{F^n(\cdot)\}$. Let $k < \infty$. Let $r(n)$ be a \mathcal{F}_m -stopping time, with values in $[n, n + kq_n]$. To prove tightness, it is sufficient ([7, Thm. 8.6] or, equivalently, [12, Thm. 3.3]) if $\sup_n E|F^n(t)| < \infty$ for each $t > 0$ and

$$(3.15) \quad \lim_{\delta \rightarrow 0} \limsup_n \sup_{r(n)} E|F^n(t_{r(n)} + \delta - t_n) - F^n(t_{r(n)} - t_n)|^2 = 0.$$

For notational simplicity, let the X_n and Y_j^n be real valued henceforth in the proof. The proof for the general case is the same. We can write

$$(3.16) \quad E|F^n(t_{r(n)} + \delta - t_n) - F^n(t_{r(n)} - t_n)|^2 = \frac{1}{q_n} E \sum_{i,j=r(n)}^{r(n)+q_n\delta} Y_i^n Y_j^n.$$

By (3.8) and the fact that $\sum_{j=m}^{\infty} e^{-\lambda(t_j - t_m)} a_j = O(1)$ uniformly in m , the above expression equals

$$\frac{1}{q_n} [\delta^2 q_n^2 O(a_n^{3/2}) + \delta q_n O(1)]$$

which goes to zero as needed due to (A3.1).

Part 4. We next show that the limit of any weakly convergent subsequence of $\{F^n(\cdot)\}$ is a martingale. Let $f(\cdot)$ be any bounded and continuous function of its arguments. For any integer p , fix $s \geq 0, \tau \geq 0$, and let $s_i \leq s, i = 1, \dots, p$. Then

$$\begin{aligned} Ef(F^n(s_i), i \leq p)[F^n(s + \tau) - F^n(s)] \\ = Ef(F^n(s_i), i \leq p)E_{n+q_ns}[F^n(s + \tau) - F^n(s)], \end{aligned}$$

where E_{n+q_ns} is the expectation given all data up to iterate $n + q_ns$ or, equivalently, given all data which is used to calculate $F^n(u), u \leq s$.

We have

$$\begin{aligned} E|E_{n+q_ns}F^n(s + \tau) - F^n(s)| \\ = E \frac{1}{\sqrt{q_n}} \left| E_{n+q_ns} \sum_{i=n+q_ns}^{n+q_ns+q_n\tau} Y_i^n \right|. \end{aligned}$$

By (3.13) and Lemma 3.1, this expression equals

$$\begin{aligned} (3.17) \quad & \frac{1}{\sqrt{q_n}} \left[q_n O(a_n) \tau + O(a_n^{1/2}) \sum_{i=n+q_ns}^{n+q_ns+q_n\tau} e^{-\lambda(t_i - t_n)} \right] \\ & \leq \sqrt{q_n} O(a_n) \tau + O(1) \sum_{i=n+q_ns}^{\infty} e^{-\lambda(t_i - t_n)} a_i / \sqrt{a_n q_n}, \end{aligned}$$

which goes to zero as $n \rightarrow \infty$ uniformly in any bounded τ -interval. Let $F(\cdot)$ denote the limit of a weakly convergent subsequence of $\{F^n(\cdot)\}$. By the fact that the right side of (3.16) is $O(\delta)$, $\{F^n(t)\}$ is uniformly integrable, for each $t < \infty$. This and the fact that expression (3.17) goes to zero as $n \rightarrow \infty$ yields

$$Ef(F(s_i), i \leq p)[F(s + \tau) - F(s)] = 0$$

for all s, τ, s_i, p and $f(\cdot)$ in the chosen classes. This implies that $F(\cdot)$ is a martingale. Since the discontinuities in $F^n(\cdot)$ are $O(q_n^{-1/2})$ and tend to zero as $n \rightarrow \infty$, $F(\cdot)$ is continuous. To prove that it is the asserted Wiener process, we need only identify its quadratic variation. This will be done in Part 6. In preparation for that, we need the following uniform integrability result.

Part 5. A uniform integrability result. For $s > 0, \tau > 0$, and given $T < \infty$ define the sets

$$I_\nu^n = [n + q_n s + \nu T/a_n, n + q_n s + (\nu + 1)T/a_n),$$

$\nu = 0, 1, \dots, \tau K_n - 1$, (assuming τK_n is an integer without loss of generality) where K_n is defined by

$$(3.18) \quad K_n(T/a_n) = q_n.$$

Then, starting at time s to “cover” $[s, s + \tau)$, we need $K_n \tau$ groups of (T/a_n) iterates each. Define

$$\delta F_\nu^n = \left(\frac{a_n}{T}\right)^{1/2} \sum_{i \in I_\nu^n} Y_i^n.$$

We will show that, for each T ,

$$(3.19) \quad \sup_{\nu \leq K_n \tau} E|\delta F_\nu^n|^4 < \infty.$$

For simplicity of notation, we work only with the real valued Y_i^n case. For $\nu \leq K_n \tau$, there is a $k < \infty$, such that the indices i for which Y_i^n is in δF_ν^n are all in the interval $[n, n + kn]$, so that (2.4) and the ratio $a_n/a_i \approx 1$ can be used. We have

$$E|\delta F_\nu^n|^4 = O(1) \left(\frac{a_n}{T}\right)^2 \sum_{i \leq j \leq k \leq \ell} EY_i^n Y_j^n Y_k^n Y_\ell^n,$$

where the indices vary over the set I_ν^n , subject to the indicated inequalities. By (3.13), this expression can be written as

$$\begin{aligned} & O(1) \left(\frac{a_n}{T}\right)^2 \sum_{i \leq j \leq k \leq \ell} EY_i^n Y_j^n Y_k^n E_k Y_\ell^n \\ & \leq O(1) \left(\frac{a_n}{T}\right)^2 \sum_{i \leq j \leq k \leq \ell} E|Y_i^n Y_j^n Y_k^n| \\ & \quad \times [e^{-\lambda(t_\ell - t_k)} |Y_k^n| + a_n]. \end{aligned}$$

Now, using Lemma 3.1 and the fact that $\sum_{j \geq n} e^{-\lambda(t_j - t_n)} a_j = O(1)$, uniformly in n yields that the sum is $O(1)$, uniformly in n and in the range of ν in question, which proves the assertion (3.19).

Part 6. The quadratic variation of the limit process. For notational simplicity, we continue to work with the case of real valued X_n, Y_i^n . We first present some consequences of the weak convergence in Theorem 2.1. Recall that

$$\sqrt{\frac{a_n}{T}} \sum_{i \in I_\nu^n} X_i \rightarrow N(0, V_T),$$

where the symbol $(\rightarrow N(0, V_T))$ means convergence in distribution to a normally distributed random variable with mean zero and variance V_T . Recall that $V_T = V + O(1/t)$.

Also, by the weak convergence in Theorem 2.1, the set

$$\left\{ \left(\frac{a_n}{T} \right)^{1/2} \sum_{i \in I_{k_j}^n} X_i, \quad j = 1, \dots, q \right\}$$

converges in distribution to a set of normal random variables $\{Z_1, \dots, Z_q\}$, with mean zero and covariance

$$\text{cov}[Z_i, Z_j] = O\left(e^{-\lambda T|k_i - k_j|}\right).$$

Furthermore, there is $\varepsilon(T) \rightarrow 0$ as $T \rightarrow \infty$ such that the following holds if $N_n \rightarrow \infty$ slowly enough:

$$(3.20) \quad \frac{1}{N_n} \sum_{\nu=1}^{N_n} (\delta F_\nu^n)^2 \xrightarrow{P} V(T),$$

where $V(T) \in [V - \varepsilon(T), V + \varepsilon(T)]$ and \xrightarrow{P} denotes convergence in probability. The result is a consequence of the weak convergence in Theorem 2.1, the equivalences and estimates in Part 1 of the proof, the uniform integrability of $\{(\delta F_\nu^n)^2, \nu \leq kK_n, n\}$ for any $k < \infty$, and a law of large numbers. By the uniform integrability, (3.20) also holds in the mean.

The bound on ν is chosen to assure that the time indices i of all the iterates Y_i^n fall in the range $[n, n + 2kn]$, so that (2.4) can be used.

Let n index a weakly convergent subsequence of $\{F^n(\cdot)\}$ with limit $F(\cdot)$. Let $f(\cdot)$ be a bounded continuous function, and let $\phi(\cdot)$ be continuous with compact support with the first two derivatives being continuous. For any integer p , let $s_i \leq s, i \leq p$, and let $\tau > 0$. To get the quadratic variation result, we need to show that for all such $f(\cdot), \phi(\cdot), s_i, \tau, s, p$,

$$\begin{aligned} & Ef(F^n(s_i), i \leq p)[\phi(F^n(s + \tau)) - \phi(F^n(s))] \\ (3.21) \quad & \rightarrow Ef(F(s_i), i \leq p)[\phi(F(s + \tau)) - \phi(F(s))] \\ & = Ef(F(s_i), i \leq p) \left[\frac{V}{2} \int_s^{s+\tau} \phi_{FF}(F(u)) du \right]. \end{aligned}$$

Note that

$$F^n\left(s + \frac{(\nu + 1)T}{a_n q_n}\right) - F^n\left(s + \frac{\nu T}{a_n q_n}\right) = \frac{1}{K_n^{1/2}} \delta F_\nu^n.$$

Now, expanding the left side of (3.21) yields

$$\begin{aligned} (3.22) \quad & Ef(F^n(s_i), i \leq p) \\ & \times \left[\frac{1}{K_n^{1/2}} \sum_{\nu=1}^{K_n \tau} \phi_F\left(F^n\left(s + \frac{\nu T}{a_n q_n}\right)\right) \delta F_\nu^n + \frac{1}{2K_n} \sum_{\nu=1}^{K_n \tau} \phi_{FF}\left(F^n\left(s + \frac{\nu T}{a_n q_n}\right)\right) (\delta F_\nu^n)^2 \right. \\ & \left. + \frac{1}{K_n^{3/2}} \sum_{\nu=1}^{K_n \tau} O(|\delta F_\nu^n|^3) \right]. \end{aligned}$$

By the results in Parts 1, 4, and 5, (3.22) is asymptotically equivalent to

$$(3.23) \quad Ef(F^n(s_i), i \leq p) \left[\frac{1}{2K_n} \sum_{\nu=1}^{K_n \tau} \phi_{FF} \left(F^n \left(s + \frac{\nu T}{a_n q_n} \right) \right) (\delta F_\nu^n)^2 \right].$$

By the tightness of $\{F^n(\cdot)\}$ and the uniform integrability of $\{|\delta F_\nu^n|^2\}$ shown by (3.19), we can “delay” the time argument of the $F^n(\cdot)$ in the ϕ_{FF} in (3.23) by an amount which goes to zero as $n \rightarrow \infty$, without changing the asymptotic value. This observation allows us to regroup the summands in (3.23) so that (3.20) can be used. In fact, (3.23) is asymptotically equivalent to (3.24), where we define v_n by $\tau K_n = N_n v_n$, with $N_n \rightarrow \infty$ as slowly as we wish but such that $K_n \rightarrow \infty$ and $v_n \rightarrow \infty$:

$$(3.24) \quad Ef(F^n(s_i), i \leq p) \times \left[\frac{1}{2v_n} \sum_{\nu=1}^{v_n} \left\{ \phi_{FF} \left(F^n \left(s + \frac{\nu N_n T}{a_n q_n} \right) \right) \frac{1}{N_n} \sum_{u=\nu N_n}^{\nu N_n + N_n - 1} (\delta F_u^n)^2 \right\} \right].$$

Finally, applying (3.20) to (3.24), taking limits as $n \rightarrow \infty$, and using the arbitrariness of T and $\varepsilon(T)$ yields the desired result, namely, the right side of (3.21).

Part 7. Dropping condition ().* When (*) is dropped, we need to regroup certain terms so that the same asymptotic expansions will hold. Define the increasing sequence ρ_v (depending on n) recursively by $\rho_0 = 0$, and for $v \geq 1$

$$\sum_{n+q_n s + \rho_{v-1}}^{n+q_n s + \rho_v} a_j \rightarrow T$$

as $n \rightarrow \infty$. Redefine the sets of indices I_v^n to be $I_v^n = [n+q_n s + \rho_{v-1}, n+q_n s + \rho_v)$. Thus the sums of the a_i in each set equal T asymptotically. Set $m(n, v) = n + q_n s + \rho_{v-1}$, the first index in the set I_v^n . In sums of the form $(a_n/T)^{1/2} \sum I_v^n$, replace the a_n by $a_{m(n,v)}$. Define $J_n = \min\{\alpha : \rho_\alpha \geq q_n \tau\}$. The J_n replace the K_n in the proof. Finally in the expansions from (3.22) to (3.24), replace the vT/a_n by ρ_v .

With these changes the proof goes through as done above. \square

Appendix.

Proof of Lemma 3.1. The proof will be given for the $\{X_n\}$ only. The proof for the $\{Y_i^n\}$ follows from this, and the details are omitted.

Part 1. Mean square bounds. A perturbed Liapunov function method will be used. Define the perturbation

$$V_1(x, n) = \sum_{j=n}^{\infty} a_j V'_x(x) E_n \psi_j(x) = O(a_n) |V_x(x)|,$$

where the right-hand inequality is due to (A3.2). We can write

$$(1) \quad \begin{aligned} E_n V(X_{n+1}) - V(X_n) &= a_n V'_x(X_n) \bar{g}(X_n) \\ &\quad + a_n V'_x(X_n) \psi_n(X_n) + a_n^2 O(1) |g(X_n, \xi_n)|^2 \end{aligned}$$

$$(2) \quad \begin{aligned} E_n V_1(X_{n+1}, n+1) - V_1(X_n, n) \\ = -a_n V'_x(X_n) \psi_n(X_n) + \sum_{j=n+1}^{\infty} E_n a_j [V'_x(X_{n+1}) \psi_j(X_{n+1}) - V'_x(X_n) \psi_j(X_n)]. \end{aligned}$$

The fact that the second term on the right side of (1) is the negative of the first term on the right side of (2) is the essential motivation behind the construction of $V_1(\cdot)$. Rewriting the last term on the right side of (2) as the sum of the left-hand sides in (3a), (3b) following and bounding them by use of (A3.2)–(A3.5) yields:

$$(3a) \quad \left| \sum_{n+1}^{\infty} E_n a_j V'_x(X_n) (\psi_j(X_{n+1}) - \psi_j(X_n)) \right| \\ \leq |V_x(X_n)| O(a_n^2) [V^{1/2}(X_n) + 1] \leq O(a_n^2) [V(X_n) + 1],$$

$$(3b) \quad \left| \sum_{n+1}^{\infty} a_j E_n [V'_x(X_{n+1}) - V'_x(X_n)] \psi_j(X_{n+1}) \right| \\ \leq O(a_n^2) |g(X_n, \xi_n)| \leq O(a_n^2) [V(X_n) + 1].$$

Define the perturbed Liapunov function $\tilde{V}_n = V(X_n) + V_1(X_n, n)$. Putting the estimates (2) and (3) together yields

$$E_n \tilde{V}_{n+1} - \tilde{V}_n \leq -a_n \gamma V(X_n) + O(a_n^2) \\ + O(a_n^2) [1 + V(X_n)]$$

and

$$(4) \quad E_n \tilde{V}_{n+1} - \tilde{V}_n \leq -\frac{a_n}{2} \gamma \tilde{V}_n + O(a_n^2).$$

Equation (4) implies that $\{E\tilde{V}_n/a_n, n < \infty\}$ is bounded from above. Then, using this and the estimate $V_1(x, n) = O(a_n)[V(x) + 1]$ yields the boundedness of $\{EV(X_n)/a_n, n < \infty\}$. This latter bound and the first equation of (A3.5) yield the boundedness of $\{E|X_n|^2/a_n, n < \infty\}$.

Equation (4) implies that there are β_n such that $E|\beta_n| < \infty$, $E_n \beta_n = 0$, and

$$(5) \quad \tilde{V}_{n+1} - \tilde{V}_n \leq \frac{-a_n}{2} \gamma \tilde{V}_n + O(a_n^2) + \beta_n,$$

from which we get

$$E_n \tilde{V}_q = O(a_n)$$

for any \mathcal{F}_m -stopping time q with values in $[n, n + kn]$. This, together with the above given bound on $V_1(x, n)$, yields the second assertion of the lemma.

Part 2. Fourth moments. We now prove $E|X_n|^4 = O(a_n^2)$. The procedure will be similar to that used in Part 1. Define the perturbation

$$(6) \quad V_2(x, n) = 2 \sum_{j=n}^{\infty} a_j E_n V(x) V'_x(x) \psi_j(x) = O(a_n) |V(x) V_x(x)|,$$

and the perturbed Liapunov function

$$(7) \quad \hat{V}(x, n) = V^2(x) + V_2(x, n).$$

We use \tilde{X}_n and \hat{X}_n to denote vectors in the interval $[X_n, X_{n+1}]$, and their values might change from case to case. Proceeding as for the second-order case, by a truncated Taylor series expansion we can write

$$(8) \quad E_n V^2(X_{n+1}) - V^2(X_n) = B_1 + B_2 + B_3 + B_4,$$

where

$$\begin{aligned} B_1 &= 2a_n V(X_n) V'_x(X_n) \bar{g}(X_n), \\ B_2 &= 2a_n E_n V(X_n) V'_x(X_n) \psi_n(X_n), \\ B_3 &= a_n^2 E_n g'(X_n, \xi_n) V_x(\tilde{X}_n) V'_x(\tilde{X}_n) g(X_n, \xi_n), \\ B_4 &= a_n^2 E_n V(\tilde{X}_n) g'(X_n, \xi_n) V_{xx}(\tilde{X}_n) g(X_n, \xi_n). \end{aligned}$$

Furthermore,

$$(9) \quad E_n V_2(X_{n+1}, n+1) - V_2(X_n, n) = B_5 + B_6,$$

where

$$\begin{aligned} B_5 &= -2a_n E_n V(X_n) V'_x(X_n) \psi_n(X_n), \\ B_6 &= 2 \sum_{j=n+1}^{\infty} a_j E_n \left[V(X_{n+1}) V'_x(X_{n+1}) \psi_j(X_{n+1}) - V(X_n) V'_x(X_n) \psi_j(X_n) \right]. \end{aligned}$$

The terms $B_i, i = 1, \dots, 6$, will now be bounded. Heavy use will be made of the inequalities in (A3.5) and the fact that $EV(X_n) = O(a_n)$ by Part 1 of the proof. We have

$$B_1 \leq -2a_n \gamma V^2(X_n).$$

B_2 is cancelled by B_5 . For appropriate \tilde{X}_n and \hat{X}_n ,

$$\begin{aligned} B_3 &= a_n^2 E_n g'(X_n, \xi_n) [V_x(X_n) + V_{xx}(\hat{X}_n)(\tilde{X}_n - X_n)] \\ &\quad \times [V_x(X_n) + V_{xx}(\hat{X}_n)(\tilde{X}_n - X_n)]' g(X_n, \xi_n) \\ &= C_1 + C_2 + C_3, \end{aligned}$$

where

$$\begin{aligned} EC_1 &= 2a_n^2 E g'(X_n, \xi_n) V_x(X_n) V'_x(X_n) g(X_n, \xi_n) \\ EC_2 &= O(a_n^2) E |g(X_n, \xi_n)|^2 |V_x(X_n)| |\tilde{X}_n - X_n| \\ EC_3 &= O(a_n^2) E |g(X_n, \xi_n)|^2 |\tilde{X}_n - X_n|^2. \end{aligned}$$

We have the following bounds:

$$\begin{aligned}
 EC_1 &\leq O(a_n^2)EV(X_n)(V(X_n) + 1) \\
 &\leq O(a_n^2)EV^2(X_n) + O(a_n^3) \\
 EC_2 &\leq O(a_n^2)E(V(X_n) + 1)|V_x(X_n)||\tilde{X}_n - X_n| \\
 &\leq O(a_n^2)E(V(X_n) + 1)|V_x(X_n)||X_{n+1} - X_n| \\
 &\leq O(a_n^3)E(V(X_n) + 1)^2 \leq O(a_n^3)EV^2(X_n) + O(a_n^3), \\
 EC_3 &\leq O(a_n^2)E(V(X_n) + 1)a_n^2(V(X_n) + 1) \\
 &\leq O(a_n^4)EV^2(X_n) + O(a_n^4).
 \end{aligned}$$

By a similar method, the other terms can be shown to satisfy

$$EB_i = O(a_n^2)EV^2(X_n) + O(a_n^3), \quad i = 4, 5, 6.$$

Finally, putting these estimates together yields

$$\begin{aligned}
 (10) \quad E\hat{V}(X_{n+1}, n+1) - E\hat{V}(X_n) &\leq -\gamma a_n EV^2(X_n) \\
 &\quad + O(a_n^2)EV^2(X_n) + O(a_n^3).
 \end{aligned}$$

Note that

$$\begin{aligned}
 (11) \quad |V_2(X_n, n)| &= O(a_n)V(X_n)(V(X_n) + 1) \\
 &\leq O(a_n)EV^2(X_n) + O(a_n^2).
 \end{aligned}$$

Using (10) and (11) yields, for large n ,

$$(12) \quad E\hat{V}(X_{n+1}, n+1) - E\hat{V}(X_n, n) \leq -\frac{\gamma}{2}a_n E\hat{V}(X_n, n) + O(a_n^3).$$

Then, following the procedure of Part 1, we get

$$\sup_n EV^2(X_n)/a_n^2 < \infty$$

and

$$E|X_n|^4/a_n^2 < \infty. \quad \square$$

IDENTIFIABLE SURFACES IN CONSTRAINED OPTIMIZATION*

STEPHEN J. WRIGHT†

Abstract. The concept of a “class- C^p identifiable surface” of a convex set in Euclidean space is introduced. The paper shows how the smoothness of these surfaces is related to the smoothness of the projection operator and presents finite identification results for certain algorithms for minimization of a function over this set. The work uses a partially geometric view of constrained optimization to generalize previous finite identification results.

Key words. constrained optimization, active set identification

AMS subject classifications. 90C25, 53A07, 26B10

1. Introduction. Here, we investigate the problem

$$(1) \quad \min_{x \in \Omega} F(x),$$

where F is continuously differentiable and $\Omega \subset \mathbb{R}^n$ is closed and convex. In particular, we are interested in finding subsets of Ω that can be identified by an optimization algorithm after a finite number of iterations. That is, if the solution x^* lies in one such subset, the iterates generated by the algorithm should eventually enter and remain within that subset. In the case in which Ω is defined by a set of algebraic inequalities, this property of the iterates corresponds to identifying the active constraints, and when Ω is a polyhedron, it means identifying the face, edge, or vertex, upon which the solution x^* lies.

The first-order conditions for x^* to be a solution of (1) are

$$-\nabla F(x^*) \in N(x^*),$$

where $N(x^*)$ is the normal cone to Ω at x^* . To prove the finite identification (capture) results, we assume a nondegeneracy condition due to Dunn [4]. This is stated simply as

$$(2) \quad -\nabla F(x^*) \in \text{ri}(N(x^*)),$$

where $\Lambda \subset \mathbb{R}^n$ and $\text{ri}(\Lambda)$ is the interior of Λ relative to $\text{aff}(\Lambda)$, the affine hull of Λ . A condition equivalent to (2) was assumed by Gafni and Bertsekas [7] for the case of polyhedral sets. The condition (2), which is a geometric generalization of the strict complementarity condition of nonlinear programming, has been used in the convergence analysis of Dunn [4] and Burke and Moré [1]. Both these papers specify similar classes of subsets of Ω that are finitely identifiable by gradient projection and Newton-like algorithms. We define these *open facets* as in [4].

DEFINITION 1.

(a) For any closed convex cone $K \subset \mathbb{R}^n$, we use K° to denote the polar of K , and define the lineality $\text{lin}(K)$ to be $(K^\circ)^\perp$;

(b) Let $T(x)$ be the tangent cone to Ω at x as defined in Clarke [2, Thm. 2.4.5]; the normal cone is $N(x) = T(x)^\circ$. A nonempty subset $S \subset \Omega$ is an *open facet* if the

† Mathematics and Computer Science Division, Argonne National Laboratory, Argonne, Illinois 60439.

set $V = x + \text{lin}(T(x))$ is independent of $x \in S$, and $S = \text{int}_V(\Omega \cap V)$, where $\text{int}_V(\cdot)$ denotes interior with respect to V .

It is easy to show that open facets are convex. When Ω is polyhedral, it can be partitioned into open facets, but when Ω has some curved boundaries, this is not the case. As an example, consider the set defined in [1, Eq. (2.2)]:

$$\Omega_1 = \left\{ (\xi_1, \xi_2) \mid \xi_2 \leq \sqrt{1 - \xi_1^2}, 0 \leq \xi_1 \leq 1 \right\}.$$

The open facets in this set are its interior, the point $(0, 1)$ and the edges $\{(0, \xi_2) \mid \xi_2 < 1\}$ and $\{(1, \xi_2) \mid \xi_2 < 0\}$. No subset of the curved face $\{(\xi_1, \xi_2) \mid \xi_1^2 + \xi_2^2 = 1, 0 < \xi_1 \leq 1\}$ satisfies Definition 1.

When Ω is defined by algebraic inequalities, that is,

$$(3) \quad \Omega = \{\xi \mid g_i(\xi) \leq 0, i = 1, \dots, m\},$$

it is often assumed that the g_i are C^2 and that the set

$$(4) \quad \{\nabla g_i(x) \mid i \in \mathcal{A}(x)\}, \quad \text{where} \quad \mathcal{A}(x) = \{i \mid 1 \leq i \leq m, g_i(x) = 0\}$$

is linearly independent. In this case, the nondegeneracy condition (2) (which reduces to the standard strict complementarity condition) ensures that surfaces defined by a particular active index set $\mathcal{A} \subset \{1, 2, \dots, m\}$ are finitely identifiable by a number of standard algorithms. Note that Ω_1 is not definable in the form (3),(4) for $g_i \in C^2$, since there is a curvature discontinuity in the boundary at $(1, 0)$. If we allow g_i to be only C^1 , then Ω_1 is definable as (3),(4), but then the curved surface is indistinguishable from the face $\{(1, \xi_2) \mid \xi_2 \leq 0\}$.

The next section defines the concept of a “class- C^p identifiable surface.” Loosely speaking, such a surface S is usually a connected “patch” on $\partial\Omega$, which is locally parametrizable by a collection of C^p functions, for some integer $p \geq 1$. (The interior of Ω is defined to be a class- C^∞ surface.) Moreover, these functions can be defined so that their gradients can enclose any given ray in the relative interior of $N(x)$, where x is a given point in S . We prove that open facets and subsets of (3) that are defined by particular choices of \mathcal{A} are identifiable surfaces. (For the set Ω_1 , the curved boundary, with its two endpoints excluded, is also an identifiable surface.) We show that class- C^p identifiable surfaces generate connected open regions in the exterior of Ω , within which the operation of projection onto Ω is $p - 1$ times continuously differentiable. In §3, we prove finite identification results for gradient projection and Newton-like algorithms.

In the remainder of the paper, $\|\cdot\|$ denotes the Euclidean norm, B denotes the open unit ball $\{\xi \in \mathbb{R}^n \mid \|\xi\| < 1\}$, and $\text{co}\{\cdot\}$ denotes the convex hull of a set of vectors. The projection operator and distance function are defined as follows, with reference to any closed subset A of \mathbb{R}^n :

$$P_A(y) = \min_{\bar{y} \in A} \frac{1}{2} \|\bar{y} - y\|, \quad d_A(y) = \arg \min_{\bar{y} \in A} \frac{1}{2} \|\bar{y} - y\|.$$

We use $P(\cdot)$ as shorthand for $P_\Omega(\cdot)$. Given a collection of functions $g_i : \mathbb{R}^n \rightarrow \mathbb{R}$, $i = 1, \dots, r$, we frequently use the notation

$$g(x) = [g_1(x), g_2(x), \dots, g_r(x)]^T, \quad \nabla g(x) = [\nabla g_1(x) \mid \dots \mid \nabla g_r(x)].$$

2. Identifiable surfaces and smoothness of the projection operator.

Throughout the remainder of this paper, we make this following assumption.

Assumption 1. Ω is closed and convex and has an interior in \mathbb{R}^n .

The last part of this assumption is made for convenience. If it does not hold, the results of this section can be recovered by restricting attention to $\text{aff}(\Omega)$.

DEFINITION 2. A connected set $S \subset \Omega$ is a *class- C^p identifiable surface*, p a positive integer, if either

- (a) S is an open subset of $\text{int}(\Omega)$, or
- (b) $S \subset \partial\Omega$, and for any $y \in \mathbb{R}^n \setminus \Omega$ such that $\bar{y} = P(y) \in S$ and $y - \bar{y} \in \text{ri}(N(\bar{y}))$, there exist functions g_i , $i = 1, \dots, r = r(y)$, and a constant $\epsilon = \epsilon(y) > 0$, such that
 - (i) $g_i \in C^p(\bar{y} + \epsilon B)$, $i = 1, \dots, r$;
 - (ii) $\{\nabla g_i(\bar{z}), i = 1, \dots, r\}$ is linearly independent for all $\bar{z} \in S(\bar{y}; \epsilon) \triangleq (\bar{y} + \epsilon B) \cap S$;
 - (iii) $\text{co}\{\nabla g_i(\bar{z}), i = 1, \dots, r\} \subset N(\bar{z})$ for all $\bar{z} \in S(\bar{y}; \epsilon)$;
 - (iv) $y - \bar{y} \in \text{ri}(\text{co}\{\nabla g_i(\bar{y}), i = 1, \dots, r\})$; and
 - (v) $S(\bar{y}; \epsilon) = \{\bar{z} \mid \|\bar{z} - \bar{y}\| < \epsilon, g_i(\bar{z}) = 0, i = 1, \dots, r\}$.

Obviously, if S is a class- C^p identifiable surface, then it is also a class- C^q identifiable surface, for any q with $1 \leq q < p$.

There are some significant differences between the functions g_i that are used in Definition 2 and the ones used in the algebraic parametrization (3). First, we are now only seeking a *local* parametrization. Second, and more importantly, we are trying to parametrize the surface S and a piece of the normal cone to Ω at points on S , rather than the set Ω itself. This latter property allows a wider range of sets to be decomposed into an intuitively reasonable collection of surfaces than was possible in the case of open facets or (3).

Before proceeding, to give a sense of how this definition differs from that of open facets and from (3), we review the example Ω_1 from §1, and give two more examples. The interior of Ω_1 , the point $(0, 1)$ and the edge $\{(0, \xi_2) \mid \xi_2 < 1\}$ are class- C^∞ identifiable surfaces. The remaining surface defined by

$$\left\{ (\xi_1, \xi_2) \mid \xi_2 = \sqrt{1 - \xi_1^2}, 0 \leq \xi_1 < 1 \right\} \cup \{(1, \xi_2) \mid \xi_2 < 0\} \cup \{(1, 0)\}$$

is class- C^1 identifiable. Each of the first two component subsets is class- C^∞ identifiable.

A second example is an inverted cone in \mathbb{R}^3 , whose apex is at the origin:

$$\Omega_2 = \left\{ (\xi_1, \xi_2, \xi_3) \mid \xi_3 \geq \sqrt{\xi_1^2 + \xi_2^2}, 0 \leq \xi_3 \leq 1 \right\}.$$

Ω_2 has just three open facets: the point $(0, 0, 0)$, the circular face $\{(\xi_1, \xi_2, 1) \mid \xi_1^2 + \xi_2^2 < 1\}$, and the interior. A finite algebraic parametrization (3),(4) is apparently not possible, even if we allow $g_i \in C^1$ (the difficulty is, of course, at the apex). However, the whole set *can* be partitioned into five maximal class- C^∞ identifiable surfaces. They are the three open facets just mentioned, the circle $\{(\xi_1, \xi_2, 1) \mid \xi_1^2 + \xi_2^2 = 1\}$, and the curved face $\{(\xi_1, \xi_2, \xi_3) \mid \xi_3 = \sqrt{\xi_1^2 + \xi_2^2}, 0 < \xi_3 < 1\}$. To show how the definition is satisfied in the case of $(0, 0, 0)$, take some $y \in \text{int}(N(0, 0, 0))$. Then $y = (y_1, y_2, y_3)$, with $y_3 < -\sqrt{y_1^2 + y_2^2}$. Clearly, we can choose $\gamma > 0$ such that

$y + \gamma B \subset \text{int}(N(0, 0, 0))$. Define three vectors as follows:

$$\begin{aligned} y^{(1)} &= (y_1 + \gamma, y_2, y_3) \\ y^{(2)} &= (y_1 - (1/2)\gamma, y_2 + (\sqrt{3}/2)\gamma, y_3) \\ y^{(3)} &= (y_1 - (1/2)\gamma, y_2 - (\sqrt{3}/2)\gamma, y_3). \end{aligned}$$

Elementary manipulation shows that these are linearly independent and that $y = (1/3)(y^{(1)} + y^{(2)} + y^{(3)})$. If we define $g_i(z) = z^T y^{(i)}$, the five conditions in Definition 2 are easily verified.

A third example is the set

$$\Omega_3 = \{(\xi_1, \xi_2, \xi_3) \mid \xi_3 \geq \xi_1^2 + |\xi_2| + \xi_2^{\sqrt{2}}\}.$$

This set is representable in the form (3),(4) by splitting the inequality into two (for the two possibilities $|\xi_2| = \pm \xi_2$), but the g_i are only C^1 . An algebraic parametrization that uses C^p functions, $p \geq 2$, is not possible. There are no open facets, except the interior. However, the set can be partitioned into four class- C^∞ identifiable surfaces. These are the interior, the face defined by

$$\{(\xi_1, \xi_2, \xi_3) \mid \xi_2 > 0, \xi_3 = \xi_1^2 + \xi_2 + \xi_2^{\sqrt{2}}\}$$

and its counterpart

$$\{(\xi_1, \xi_2, \xi_3) \mid \xi_2 < 0, \xi_3 = \xi_1^2 - \xi_2 + \xi_2^{\sqrt{2}}\},$$

and the ridge

$$\{(\xi_1, 0, \xi_3) \mid \xi_3 = \xi_1^2\}.$$

The ridge can be made to fit the definition by taking

$$\begin{aligned} g_1(\xi) &= \xi_1^2 + \xi_2 - \xi_3 \\ g_2(\xi) &= \xi_1^2 - \xi_2 - \xi_3, \end{aligned}$$

independently of the choice of $y \in \text{ri}(N(\xi))$.

The concept of a class- C^p identifiable surface is, in a certain sense, a generalization of the concept of a class- $C^{p,\alpha}$ boundary of a bounded domain $\Omega \subset \mathbb{R}^n$, as used extensively in the theory of partial differential equations (see, for example, the definition on page 94 of Gilbarg and Trudinger [9]). In fact, if Ω is convex, closed, and bounded, and its boundary $\partial\Omega$ is of class- $C^{p,0}$ according to the latter definition, then it can be partitioned into a class- C^∞ identifiable surface ($\text{int}(\Omega)$) and a class- C^p identifiable surface ($\partial\Omega$). Such sets have no “edges” or “corners”—the value of r corresponding to each $y \in \mathbb{R}^n \setminus \Omega$ is 1—and hence, they are not very interesting from the viewpoint of this paper.

We now derive some elementary properties of identifiable surfaces and the functions g_i that are used to describe them. We focus on the case $S \subset \partial\Omega$, since the corresponding results for $S \subset \text{int}(\Omega)$ are trivial.

LEMMA 2.1. *Let S be a class- C^p identifiable surface with $S \subset \partial\Omega$ and $p \geq 1$, and let $y \in \mathbb{R}^n \setminus \Omega$ be such that $\bar{y} = P(y) \in S$ and $y - \bar{y} \in \text{ri}(N(\bar{y}))$. Suppose that $r = r(y)$, $\epsilon = \epsilon(y)$, and g_i , $i = 1, \dots, r$ are chosen as in Definition 2. Then, for all $\bar{z} \in S(\bar{y}; \epsilon)$,*

- (i) $T_S(\bar{z}) \subset T(\bar{z})$, where $T_S(\cdot)$ is the tangent cone with respect to S , as defined in Clarke [2, Thm. 2.4.5];
- (ii) $T_S(\bar{z}) = \{s \mid s^T \nabla g_i(\bar{z}) = 0, i = 1, \dots, r\}$;
- (iii) $\text{lin}(T(\bar{z}))^\perp = \text{aff}(N(\bar{z})) = \text{span}\{\nabla g_i(\bar{z}), i = 1, \dots, r\} = T_S(\bar{z})^\perp$;
- (iv) $\text{ri}(\text{co}\{\nabla g_i(\bar{z}), i = 1, \dots, r\}) \subset \text{ri}(N(\bar{z}))$.
- (v) if $p \geq 2$, the projection of $\nabla^2 g_i(\bar{z})$, $i = 1, \dots, r$, onto $T_S(\bar{z})$ is positive semidefinite.

Proof.

(i) If $v \in T_S(\bar{z})$, it follows from the definition of tangent cone that for any sequence $\{t_j\}$ with $t_j \downarrow 0$ there is a sequence v_j such that $\bar{z} + t_j v_j \in S$ and $v_j \rightarrow v$. Since $S \subset \Omega$ and $\bar{z} + t_j v_j \in S$,

$$0 \leq d_\Omega(\bar{z} + t_j v) \leq d_S(\bar{z} + t_j v) = d_S(\bar{z} + t_j v_j + t_j(v - v_j)) \leq t_j \|v - v_j\|.$$

Hence,

$$0 \leq \lim_{j \rightarrow \infty} \frac{d_\Omega(\bar{z} + t_j v) - d_\Omega(\bar{z})}{t_j} \leq \lim_{j \rightarrow \infty} \|v - v_j\| = 0.$$

Since t_j is an arbitrary decreasing sequence,

$$d'_\Omega(\bar{z}; v) = \lim_{t \downarrow 0} \frac{d_\Omega(\bar{z} + tv) - d_\Omega(\bar{z})}{t} = 0,$$

and so, by a result of Clarke [2, p. 53], $v \in T(\bar{z})$.

(ii) This is a standard result, which follows from Definition 2(v).

(iii) We prove the second equality. By Definition 2(iii), $\text{span}\{\nabla g_i(\bar{z}), i = 1, \dots, r\} \subset \text{aff}(N(\bar{z}))$. Since both sets are subspaces, the containment can be strict only if there is some $v \in \text{aff}(N(\bar{z}))$ with $v \neq 0$ such that $v^T \nabla g_i(\bar{z}) = 0$, $i = 1, \dots, r$, that is, $v \in T_S(\bar{z})$. Clearly, also, $-v \in T_S(\bar{z})$. Part (i) of this Lemma implies that v and $-v$ are in $T(\bar{z})$, and hence, $v \in \text{lin}(T(\bar{z})) = N(\bar{z})^\perp$. Hence, $0 \neq v \in \text{aff}(N(\bar{z})) \cap N(\bar{z})^\perp$, giving a contradiction. The remaining equalities follow from Part (i) of the Theorem and

$$\text{lin}(T(\bar{z})) = N(\bar{z})^\perp = \text{aff}(N(\bar{z}))^\perp = T_S(\bar{z}).$$

(iv) From (iii), we have that the affine hulls of $\text{co}\{\nabla g_i(\bar{z}), i = 1, \dots, r\}$ and $N(\bar{z})$ are identical. The result follows from the definition of $\text{ri}(\cdot)$ and Definition 2(iii).

(v) Let $v \in T_S(\bar{z})$, and suppose for contradiction that $v^T \nabla^2 g_i(\bar{z}) v < 0$. There are sequences $v_j \rightarrow v$ and $\{t_j\}$ with $0 < t_j \in \mathbb{R}$, $t_j \rightarrow 0$ such that $\bar{z} + t_j v_j \in S \subset \Omega$, so $g_i(\bar{z} + t_j v_j) = 0$, $i = 1, \dots, r$. Since $\nabla g_i(\bar{z}) \in N(\bar{z})$, we have $\nabla g_i(\bar{z})^T t_j v_j \leq 0$, and so

$$0 = g_i(\bar{z} + t_j v_j) = g_i(\bar{z}) + \nabla g_i(\bar{z})^T (t_j v_j) + \frac{1}{2} t_j^2 v_j^T \nabla^2 g_i(\bar{z}) v_j,$$

where $\hat{v}_j \in [\bar{z}, \bar{z} + t_j v_j]$. Hence,

$$v_j^T \nabla^2 g_i(\hat{v}_j) v_j = -\frac{2}{t_j} v_j^T \nabla g_i(\bar{z}) \geq 0.$$

For j sufficiently large,

$$0 > \frac{1}{2} v^T \nabla^2 g_i(\bar{z}) v \geq v_j^T \nabla^2 g_i(\hat{v}_j) v_j \geq 0,$$

giving a contradiction. \square

The next result, which will be useful when we come to prove finite identification properties for constrained optimization algorithms, shows that the direct sum of an identifiable surface S and the relative interior of the normal cones along S , is a set that is open in \mathbb{R}^n . This property is analogous to that described for open facets in Theorem 2.8 of Burke and Moré [1].

LEMMA 2.2. *Suppose that S is as in Lemma 2.1 with $p \geq 2$. Define the set*

$$K = \{x + w \mid x \in S, w \in \text{ri}(N(x))\}.$$

For each $y \in K$, there is a $\delta \in (0, \epsilon(y))$ such that $y + \delta B \subset K$, that is, K is open in \mathbb{R}^n .

Proof. We start by finding $\delta > 0$ such that $u \in y + \delta B \Rightarrow P(u) \in S$. Let $\bar{y} = P(y)$, $r = r(y)$, $\epsilon = \epsilon(y)$ and g_i , $i = 1, \dots, r$ be chosen as in Definition 2. Let $\delta_1 \in (0, \epsilon)$ have the property that $(y + \delta_1 B) \cap \Omega = \emptyset$. By Definition 2(ii),(iv),(v), we know that there is $\lambda \in \mathbb{R}^r$ with $\lambda > 0$ such that

$$(5) \quad \begin{aligned} y - \bar{y} - \nabla g(\bar{y})\lambda &= 0, \\ g(\bar{y}) &= 0. \end{aligned}$$

From Definition 2(i) and Lemma 2.1(iii), we know that the matrix

$$\begin{bmatrix} I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(\bar{y}) & \nabla g(\bar{y}) \\ \nabla g(\bar{y})^T & 0 \end{bmatrix}$$

is nonsingular and continuous with respect to \bar{y} and λ . We can now view \bar{y} and λ as functions of y in (5), and apply the implicit function theorem to obtain the following result: There is $\delta \in (0, \delta_1]$ such that, if $\|u - y\| \leq \delta$, the solution (\bar{u}, λ^u) of the system

$$(6) \quad \begin{aligned} u - \bar{u} - \nabla g(\bar{u})\lambda^u &= 0, \\ g_i(\bar{u}) &= 0 \end{aligned}$$

satisfies

$$(7) \quad \lambda^u > 0, \quad \|\bar{u} - \bar{y}\| < \epsilon.$$

Now (6) and (7) imply that (\bar{u}, λ^u) solves the problem

$$\min_{\bar{u}} \frac{1}{2} \|u - \bar{u}\|^2, \quad g(\bar{u}) = 0, \quad \|\bar{u} - \bar{y}\| < \epsilon$$

and so, by Definition 2(v), \bar{u} is the projection of u onto $S(\bar{y}; \epsilon)$. From (6), (7), and Definition 2(iii), we have that

$$u - \bar{u} \in \text{co} \{ \nabla g_i(\bar{u}), i = 1, \dots, r \} \subset N(\bar{u}).$$

Now $\bar{u} \in \Omega$, $u - \bar{u} \in N(\bar{u})$ and uniqueness of the projection onto a convex set imply that $\bar{u} = P(u)$.

Finally, since $\lambda^u > 0$, we have

$$u - \bar{u} \in \text{ri}(\text{co} \{ \nabla g_i(\bar{u}), i = 1, \dots, r \}).$$

Hence, by Lemma 2.1(iv),

$$u - \bar{u} \in \text{ri}(N(\bar{u})),$$

and so $u \in K$, as required. \square

In the following two results, we show how open facets and active index sets relate to identifiable surfaces.

THEOREM 2.3. *Let S be an open facet in Ω . Then S is a class- C^∞ identifiable surface.*

Proof. The case $S = \text{int}(\Omega)$ is trivially true. Consider $S \subset \partial\Omega$. Burke and Moré [1] show that any open facet S is the relative interior of a quasipolyhedral face. Hence, $N(\bar{y})$ and $T(\bar{y})$ are the same for all $\bar{y} \in S$, and

$$(8) \quad \text{aff}(S) = \bar{y} + \text{lin}(T(\bar{y}))$$

for all $\bar{y} \in S$.

Suppose, as in Definition 2, that we are given some y such that $\bar{y} = P(y) \in S$ and $y - \bar{y} \in \text{ri}(N(\bar{y}))$. Then there is a constant $\gamma > 0$ such that $(y - \bar{y}) + \gamma v \in \text{ri}(N(\bar{y}))$ for all $v \in \text{aff}(N(\bar{y}))$ with $\|v\| = 1$. Supposing that $\text{aff}(N(\bar{y}))$ has dimension r , we can choose unit vectors v_1, \dots, v_{r-1} , such that $\{v_1, \dots, v_{r-1}, y - \bar{y}\}$ is linearly independent in $\text{aff}(N(\bar{y}))$, and hence a spanning set. Now set

$$v_r = -\frac{1}{r-1}(v_1 + \dots + v_{r-1})$$

and

$$\hat{v}_i = y - \bar{y} + \gamma v_i, \quad i = 1, \dots, r.$$

Clearly, $\hat{v}_i \in \text{aff}(N(\bar{y}))$ and $\|\hat{v}_i - (y - \bar{y})\| \leq \gamma\|v_i\| \leq \gamma$, so $\hat{v}_i \in \text{ri}(N(\bar{y}))$, $i = 1, \dots, r$. Moreover, we can show that $\{\hat{v}_1, \dots, \hat{v}_r\}$ is linearly independent by the following argument: Suppose there are real coefficients μ_1, \dots, μ_r such that $\sum \mu_i \hat{v}_i = 0$. Then

$$\begin{aligned} 0 &= \sum_{i=1}^r \mu_i \hat{v}_i = \left(\sum_{i=1}^r \mu_i \right) (y - \bar{y}) + \gamma \sum_{i=1}^r \mu_i v_i \\ &= \left(\sum_{i=1}^r \mu_i \right) (y - \bar{y}) + \gamma \sum_{i=1}^{r-1} [\mu_i - \mu_r / (r-1)] v_i. \end{aligned}$$

By the original choice of v_1, \dots, v_{r-1} , we must have

$$\sum_{i=1}^r \mu_i = 0, \quad \mu_i = \mu_r / (r-1), \quad i = 1, \dots, r-1,$$

and it follows that $\mu_1 = \dots = \mu_r = 0$, as desired. Now define $g_i(z) = (z - \bar{y})^T \hat{v}_i$, $i = 1, \dots, r$. Conditions (i) and (ii) of Definition 2 are readily verified. Condition (iii) follows since $N(\bar{z})$ is constant for $\bar{z} \in S$, and $\hat{v}_i \in \text{ri}(N(\bar{z}))$, $i = 1, \dots, r$. Condition (iv) is verified by noting that

$$y - \bar{y} = \sum_{i=1}^{r-1} \frac{\hat{v}_i}{2(r-1)} + \frac{\hat{v}_r}{2} \in \text{co}\{\hat{v}_i, i = 1, \dots, r\}.$$

To prove condition (v), we first take $V = \text{aff}(S)$ in Definition 1 and note that, if $\bar{y} \in S$, there is $\epsilon > 0$ such that $\bar{z} \in \text{aff}(S) \cap (\bar{y} + \epsilon B) \Rightarrow \bar{z} \in S$. That is,

$$S(\bar{y}; \epsilon) = \{\bar{z} \mid \|\bar{z} - \bar{y}\| \leq \epsilon, \bar{z} \in \text{aff}(S)\} = \text{aff}(S) \cap (\bar{y} + \epsilon B).$$

However, by (8),

$$\text{aff}(S) = \bar{y} + \text{lin}(T(\bar{y})) = \bar{y} + N(\bar{y})^\perp,$$

and so,

$$\bar{z} \in \text{aff}(S) \Leftrightarrow (\bar{z} - \bar{y})^T \hat{v}_i = 0, \quad i = 1, \dots, r.$$

Hence,

$$S(\bar{y}, \epsilon) = \{\bar{z} \mid \|\bar{z} - \bar{y}\| \leq \epsilon, \quad g_i(\bar{z}) = 0, \quad i = 1, \dots, r\},$$

as required. \square

THEOREM 2.4. *Suppose that Ω is defined by (3) and (4), where g_i , $i = 1, \dots, m$ are C^1 functions. Suppose that for some set $\mathcal{A} \subset \{1, \dots, m\}$, the surface S defined by*

$$S = \{z \mid g_i(z) = 0, \quad i \in \mathcal{A}, \quad g_i(z) > 0, \quad i \notin \mathcal{A}\}$$

is a connected subset of Ω . Then S is a class- C^1 identifiable surface. Moreover, if $g_i \in C^p$ for $i \in \mathcal{A}$ and $p \geq 2$, then S is a class- C^p identifiable surface.

Proof. This follows trivially, by identifying g_i , $i \in \mathcal{A}$ with g_i , $i = 1, \dots, r$, in Definition 2. \square

We now consider smoothness of the projection operator $P(\cdot)$. The motivation for this comes from the work of Holmes [10] and Fitzpatrick and Phelps [6], who consider closed convex sets with smooth boundaries. In these papers, smoothness of the boundary is defined in terms of smoothness of the gauge function

$$\rho_\Omega(x) = \inf\{t > 0 \mid x \in t(\Omega - x_0) + x_0\}, \quad \text{for some } x_0 \in \text{int}(\Omega),$$

and the boundary of Ω is said to be C^p if ρ_Ω is C^p in some neighborhood of $\partial\Omega$. By showing that this definition is equivalent to a local C^p parametrization of the boundary, Holmes [10] essentially shows that a C^p boundary (by the definition above) is the same as a class- $C^{p,0}$ boundary, as defined in [9]. Hence, as discussed earlier, $\partial\Omega$ is a class- C^p identifiable surface.

Holmes proves the following result.

THEOREM 2.5 ([10, Thm. 2]). *If Ω has a C^p boundary, for $p \geq 2$, then the projection operator $P(\cdot)$ is C^{p-1} in $\mathbb{R}^n \setminus \Omega$, and $P'(y)$ is invertible in $\text{lin}(T(P(y)))$.*

Fitzpatrick and Phelps [6, Thm. 3.10] prove the converse.

The case of $p = 2$ is the most interesting. It is a classical result [5, p. 216] that, since P is Lipschitz continuous, it is differentiable almost everywhere. Below, we extend Theorem 2.5 to sets with *piecewise* smooth boundaries, by showing that class- C^p identifiable surfaces generate open regions in $\mathbb{R}^n \setminus \Omega$ in which P is C^{p-1} .

THEOREM 2.6. *Let S and K be as defined in Lemma 2.2, with $p \geq 2$. Then $P(\cdot)$ is C^{p-1} on K . Also, $P'(y)$ is invertible in $\text{lin}(T(P(y)))$.*

Proof. For any $y \in K$, we can choose $\epsilon > 0$ and $\delta > 0$ as in Lemma 2.2 such that, when $u \in y + \epsilon B$, $P(u)$ is also the projection of u onto the set $\{\bar{z} \mid g_i(\bar{z}) = 0, \quad i = 1, \dots, r, \quad \|\bar{z} - \bar{y}\| \leq \epsilon\}$. Hence, we can differentiate the system (5) with respect to y to obtain

$$(9) \quad \begin{bmatrix} I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(\bar{y}) & \nabla g(\bar{y}) \\ \nabla g(\bar{y})^T & 0 \end{bmatrix} \begin{bmatrix} \frac{d\bar{y}}{dy} \\ \frac{d\lambda}{dy} \end{bmatrix} = \begin{bmatrix} I \\ 0 \end{bmatrix},$$

where $P'(y) = d\bar{y}/dy$. The first result follows immediately from (5) and the implicit function theorem (see, for example, Lang [11, p. 125]) by noting that the coefficient matrix in (9) is nonsingular.

For the second result, let $Z \in \mathbb{R}^{n \times (n-r)}$ be a matrix of full rank such that $\nabla g(\bar{y})^T Z = 0$. By Lemma 2.1(iii), the columns of Z span $\text{lin}(T(P(y)))$. The second equation in (9) implies that

$$P'(y) = \frac{d\bar{y}}{dy} = ZW^T$$

for some $W \in \mathbb{R}^{n \times (n-r)}$. Multiplying the first equation in (9) by Z^T , we find that

$$Z^T \left(I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(\bar{y}) \right) ZW^T = Z^T$$

and so

$$(10) \quad P'(y) = Z \left[Z^T \left(I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(\bar{y}) \right) Z \right]^{-1} Z^T.$$

It follows from (10) and Lemma 2.1(v) that $P'(y)$ has nonsingular projection onto $\text{lin}(T(P(y)))$. \square

We conjecture that the converse of this theorem is also true; that is, if there is an open connected region $K \subset \mathbb{R}^n \setminus \Omega$ such that $P(\cdot)$ is C^{p-1} on K , and $P'(y)$ is invertible in $\text{lin}(T(P(y)))$ for each $y \in K$, then $P(K)$ is a class- C^p identifiable surface. The continuity condition alone is not sufficient, as an example from Fitzpatrick and Phelps [6, p. 496] illustrates. Define

$$\Omega_4 = \{(\xi_1, \xi_2) \mid \xi_2 \geq |\xi_1| + \xi_1^{4/3}\}.$$

There is a corner in Ω_4 at $(0, 0)$, and the set has four maximal class- C^∞ identifiable surfaces: the corner, the interior, and the two edges. Tedious calculation shows that P is C^1 on $\mathbb{R}^n \setminus \Omega$, although $\partial\Omega$ is obviously not a class- C^2 surface. It can be shown that $P'(y) = 0$ along the lines $\{(\xi_1, \xi_2) \mid \xi_2 = -\xi_1, \xi_1 > 0\}$ and $\{(\xi_1, \xi_2) \mid \xi_2 = \xi_1, \xi_1 < 0\}$, and so the invertibility condition is not satisfied.

It is clear from (10) that the invertibility condition is related to the boundedness of the quantities $\lambda_i \nabla^2 g_i(\bar{y})$ on $\text{lin}(T(\bar{y}))$. Note that these quantities are invariant under scaling of the g_i s, that is, if g_i is replaced by αg_i , then λ_i becomes λ_i/α .

3. Finite identification in constrained optimization algorithms. We turn now to algorithms for solving the optimization problem (1).

In analyzing the gradient projection algorithm, we use the work of Dunn [4, §2], who provided a framework for proving capture results. Dunn states this algorithm as follows: Choosing constants γ_1 and γ_2 with $0 < \gamma_1 < \gamma_2 < 1$, and an initial iterate $x_0 \in \Omega$, set

$$(11) \quad x_{k+1} = P(x_k - \sigma_k \nabla F(x_k)),$$

where σ_k is chosen to satisfy

$$(12) \quad F(x_k) - F(P(x_k - \nabla F(x_k))) \geq \gamma_1 \Rightarrow \sigma_k = 1,$$

$$(13) \quad F(x_k) - F(P(x_k - \nabla F(x_k))) < \gamma_1 \Rightarrow \sigma_k \in (0, 1)$$

and

$$(14) \quad \gamma_1 \leq \frac{F(x_k) - F(P(x_k - \sigma_k \nabla F(x_k)))}{\nabla F(x_k)^T [x_k - P(x_k - \sigma_k \nabla F(x_k))]} \leq \gamma_2.$$

Gawande and Dunn [8] adapted Dunn's earlier work to prove capture and convergence results for *scaled* gradient projection algorithms and algebraic parametrizations (3) of the feasible set.

We start with a simple result that exploits openness of the set K of Lemma 2.2:

THEOREM 3.1. *Suppose that*

- (i) *Assumption 1 and (2) hold at some point x^* ;*
- (ii) *∇F is continuous at x^* ;*
- (iii) *$x^* \in S$, where S is a class- C^p identifiable surface of Ω with $p \geq 1$;*
- (iv) *there is $\bar{\sigma} > 0$ such that $\sigma_k \in [\bar{\sigma}, 1]$ for all k ; and*
- (v) *the sequence $\{x_k\}$ generated by (11)–(14) converges to x^* .*

Then $x_k \in S$ for all k sufficiently large.

Proof. Define the set K as in Lemma 2.2. Setting $y = x^* - \nabla F(x^*)$, we can apply Definition 2 to find $\delta > 0$ such that

$$x^* - \nabla F(x^*) + \delta B \subset K.$$

By construction of K , this implies that

$$x^* - \sigma \nabla F(x^*) + \sigma \delta B \subset K \quad \text{for all } \sigma \in [\bar{\sigma}, 1].$$

Now, choose \bar{k} such that, for all $k \geq \bar{k}$,

$$\|x_k - x^*\| + \|\nabla F(x_k) - \nabla F(x^*)\| \leq \bar{\sigma} \delta.$$

Then

$$\|[x_k - \sigma_k \nabla F(x_k)] - [x^* - \sigma_k \nabla F(x^*)]\| \leq \bar{\sigma} \delta,$$

and so

$$x_k - \sigma_k \nabla F(x_k) \in x^* - \sigma_k \nabla F(x^*) + \bar{\sigma} \delta B \subset x^* - \sigma_k \nabla F(x^*) + \sigma_k \delta B \subset K.$$

Hence, $x_{k+1} \in P(K) = S$, for $k \geq \bar{k}$. \square

Before proving the next result, we state second-order conditions and define some terms:

Assumption 2. Suppose that Ω satisfies Assumption 1 and that there is x^* that satisfies (2), such that $x^* \in S$, where S is a class- C^p identifiable surface of Ω with $p \geq 2$. Suppose that F is twice continuously differentiable in a neighborhood of x^* , and let g_i , $i = 1, \dots, r$ be as defined in Definition 2, for $y = x^* - \nabla F(x^*)$. Choose $\lambda^* \in \mathbb{R}^r$ such that $\lambda^* > 0$ and

$$(15) \quad -\nabla F(x^*) = \nabla g(x^*) \lambda^*,$$

and suppose that for all $h \in T_S(x^*)$,

$$h^T \left[\nabla^2 F(x^*) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^*) \right] h \geq \alpha \|h\|^2, \quad \text{for some } \alpha > 0.$$

DEFINITION 3.

(i) x^* is a proper local minimizer of F in Ω if there is $\rho_1 > 0$ such that

$$x \in \Omega, 0 < \|x - x^*\| \leq \rho_1 \Rightarrow F(x) > F(x^*).$$

(ii) x^* is a stable fixed point for (11)–(14) if $-\nabla F(x^*) \in N(x^*)$, and there are $d_1 > 0, d_2 > 0$ such that

$$\|x_0 - x^*\| \leq d_1 \Rightarrow \|x_k - x^*\| \leq d_2 \quad \text{for all } k \geq 0.$$

(iii) x^* is a stable local attractor for (11)–(14) if it is a stable fixed point, and $d_1 > 0$ can be chosen so that

$$\|x_0 - x^*\| \leq d_1 \Rightarrow \lim_{k \rightarrow \infty} x_k = x^*.$$

The following theorem contains capture and convergence results like those proved in Gawande and Dunn [8, §4]. Here, we prove these results for the gradient projection method on the identifiable surface containing x^* ; in [8], the focus was on scaled gradient projection methods and active index sets for Ω defined by (3).

THEOREM 3.2. *Suppose that Assumption 2 holds. Then*

(i) *there are positive scalars ρ_1 and α_1 such that*

$$x \in \Omega, \|x - x^*\| \leq \rho_1 \Rightarrow F(x) - F(x^*) \geq \alpha_1 \|x - x^*\|^2;$$

(ii) *there are positive scalars ρ_2 and α_2 such that*

$$x \in S, \|x - x^*\| \leq \rho_2 \Rightarrow \|x - P(x - \nabla F(x))\| \geq \alpha_2 \|x - x^*\|,$$

that is, the defect $E(x) = x - P(x - \nabla F(x))$, restricted to S , has an isolated zero at x^ ;*

(iii) *given any $\bar{\sigma} > 0$, there is $\rho_3 = \rho_3(\bar{\sigma}) > 0$ such that*

$$\|x - x^*\| \leq \rho_3, \sigma \in [\bar{\sigma}, 1] \Rightarrow P(x - \sigma \nabla F(x)) \in S;$$

(iv) *x^* is a stable local attractor for the gradient projection algorithm, and the sequences $\{x_k\}$ that approach x^* eventually enter and remain in S .*

Proof. Throughout the proof, let ϵ denote $\epsilon(x^* - \nabla F(x^*))$.

(i) We show first that if $w = \nabla g(x^*)\mu$ with $\nabla g_i(x^*)^T w \leq c_1$ for $c_1 \geq 0$ and $i = 1, \dots, r$, then there is some $\tau_1 > 0$ such that

$$(16) \quad \nabla F(x^*)^T w \geq \tau_1 \|w\| + O(c_1).$$

Using the definition of λ^* from Assumption 2, we have

$$\begin{aligned} \nabla F(x^*)^T w &= -\lambda^{*T} \nabla g(x^*)^T \nabla g(x^*) \mu \\ &\geq (\min_i \lambda_i^*) \|\nabla g(x^*)^T \nabla g(x^*) \mu\| + O(c_1). \end{aligned}$$

Since $\nabla g(x^*)$ has full rank, and $\|\mu\| \geq \|w\|/\|\nabla g(x^*)\|$, there is τ_2 such that

$$\|\nabla g(x^*)^T \nabla g(x^*) \mu\| \geq \tau_2 \|\mu\| \geq \frac{\tau_2}{\|\nabla g(x^*)\|} \|w\|.$$

By setting

$$\tau_1 = (\min_i \lambda_i^*) \frac{\tau_2}{\|\nabla g(x^*)\|},$$

we obtain (16).

Now, given x in the vicinity of x^* , we seek vectors $v \in \mathbb{R}^n$ and $\mu \in \mathbb{R}^r$ such that

$$\begin{aligned} v + \nabla g(x^*)\mu &= x - x^* \\ g(x^* + v) &= 0. \end{aligned} \quad (17)$$

We can again apply the implicit function theorem to (17) to find $\bar{\rho}_1 > 0$ such that a solution v, μ exists for $\|x - x^*\| \leq \bar{\rho}_1$. Moreover, $\bar{\rho}_1$ can be chosen small enough that $\|v\| \leq \epsilon$, and hence, $x^* + v \in S \subset \Omega$. It follows that, since $\nabla g_i(x^* + v) \in N(x^* + v)$ for $i = 1, \dots, r$, and since $x \in \Omega$,

$$\nabla g_i(x^* + v)^T [x - (x^* + v)] \leq 0, \quad i = 1, \dots, r.$$

Writing $w = \nabla g(x^*)\mu = x - (x^* + v)$, we have

$$\nabla g_i(x^*)^T w = \nabla g_i(x^* + v)^T w + O(\|v\|\|w\|) \leq O(\|v\|\|w\|), \quad i = 1, \dots, r.$$

Application of (16) shows that

$$(18) \quad \nabla F(x^*)^T w \geq \tau_1 \|w\| + O(\|v\|\|w\|).$$

Now consider the v component. Since $x^* + v \in S$, and since (15) holds,

$$\begin{aligned} F(x^* + v) - F(x^*) &= [F(x^* + v) + \lambda^{*T} g(x^* + v)] - [F(x^*) + \lambda^{*T} g(x^*)] \\ (19) \quad &= \frac{1}{2} v^T \left[\nabla^2 F(x^* + \beta_1 v) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^* + \beta_1 v) \right] v \end{aligned}$$

for some $\beta_1 \in (0, 1)$. Since $\nabla g_i(x^*)^T v = O(\|v\|^2)$, we can choose $\bar{\rho}_2 \in (0, \bar{\rho}_1]$ such that when $\|x - x^*\| \leq \bar{\rho}_2$, v is close enough to $T_S(x^*)$ and $\|v\|$ is small enough that

$$v^T \left[\nabla^2 F(x^* + \beta_1 v) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^* + \beta_1 v) \right] v \geq \frac{\alpha}{2} \|v\|^2,$$

for all $\beta_1 \in [0, 1]$. Hence, from (19),

$$(20) \quad F(x^* + v) - F(x^*) \geq \frac{\alpha}{4} \|v\|^2.$$

By using (18) and (20), we can now write that, for $x \in \Omega \cap (x^* + \bar{\rho}_2 B)$,

$$\begin{aligned} F(x) - F(x^*) &= F(x^* + v + w) - F(x^* + v) + F(x^* + v) - F(x^*) \\ &= \nabla F(x^*)^T w + O(\|v\|\|w\| + \|w\|^2) + F(x^* + v) - F(x^*) \\ &\geq \tau_1 \|w\| + \frac{\alpha}{4} \|v\|^2 + O(\|v\|\|w\| + \|w\|^2) \\ (21) \quad &\geq \tau_1 \|w\| + \frac{\alpha}{4} \|v\|^2 - c_2 (\|v\|\|w\| + \|w\|^2), \end{aligned}$$

where $c_2 > 0$ is some constant. Now, choose a constant $\delta_1 > 0$ such that

$$(22) \quad c_2 (\delta_1^2 + \delta_1) \leq \frac{\alpha}{8},$$

and define $\rho_1 \in (0, \bar{\rho}_2]$ such that both of the following conditions are satisfied:

$$(23) \quad x \in \Omega \cap (x^* + \rho_1 B) \Rightarrow \|w\| \leq \frac{\tau_1 \delta_1}{2c_2(1 + \delta_1)},$$

$$(24) \quad \rho_1 \leq \frac{4\tau_1 \delta_1 (1 + \delta_1)}{\alpha}.$$

In the case $\|w\| \geq \delta_1 \|v\|$, we have

$$(25) \quad \|x - x^*\| \leq \|w\| + \|v\| \leq \left(1 + \frac{1}{\delta_1}\right) \|w\|.$$

Also, from (21),

$$(26) \quad F(x) - F(x^*) \geq \tau_1 \|w\| - c_2 \left(1 + \frac{1}{\delta_1}\right) \|w\|^2.$$

Now, from (23), (25), and (26), we have that

$$F(x) - F(x^*) \geq \frac{\tau_1}{2} \|w\| \geq \frac{\tau_1 \delta_1}{2(1 + \delta_1)} \|x - x^*\| \geq \frac{\tau_1 \delta_1}{2(1 + \delta_1)\rho_1} \|x - x^*\|^2,$$

for $x \in \Omega \cap (x^* + \rho_1 B)$. Application of (24) yields that

$$(27) \quad F(x) - F(x^*) \geq \frac{\alpha}{8(1 + \delta_1)^2} \|x - x^*\|^2.$$

In the remaining case $\|w\| < \delta_1 \|v\|$, we find from (21) and (22) that

$$F(x) - F(x^*) \geq \frac{\alpha}{4} \|v\|^2 - c_2(\delta_1^2 + \delta_1) \|v\|^2 \geq \frac{\alpha}{8} \|v\|^2.$$

Also,

$$\|x - x^*\| \leq \|v\| + \|w\| < (1 + \delta_1) \|v\|,$$

and hence, (27) still applies. The result follows by setting

$$\alpha_1 = \frac{\alpha}{8(1 + \delta_1)^2}.$$

(ii) By setting $y = x^* - \nabla F(x^*)$ in Lemma 2.2, we can choose $\delta \in (0, \epsilon]$ such that $P(x^* - \nabla F(x^*) + \delta B) \subset S$. Now, there is a $\bar{\rho}_1 \in (0, \epsilon]$ such that

$$\|x - x^*\| \leq \bar{\rho}_1 \Rightarrow \|[x - \nabla F(x)] - [x^* - \nabla F(x^*)]\| \leq \delta,$$

and hence, $\hat{x} = P(x - \nabla F(x)) \in S$. By contractivity of $P(\cdot)$, $\|\hat{x} - x^*\| = \|P(x - \nabla F(x)) - P(x^* - \nabla F(x^*))\| \leq \delta \leq \epsilon$. It therefore follows from Definition 2 (v) that \hat{x} solves the projection subproblem

$$(28) \quad \min_{\hat{x}} \frac{1}{2} \|\hat{x} - (x - \nabla F(x))\|_2^2, \quad g(\hat{x}) = 0.$$

When $x = x^*$, then $\hat{x} = x^*$, and (15) holds. By the implicit function theorem, $\bar{\rho}_2 \in (0, \bar{\rho}_1]$ can be chosen small enough that there is λ such that, in fact,

$$(29) \quad \|x - x^*\| \leq \bar{\rho}_2 \Rightarrow [x - \nabla F(x)] - \hat{x} = \nabla g(\hat{x})\lambda,$$

with

$$\|\hat{x} - x^*\| = O(\|x - x^*\|), \quad \|\lambda - \lambda^*\| = O(\|x - x^*\|), \quad \lambda > 0.$$

Since $\|x - x^*\| \leq \bar{\rho}_1 \leq \epsilon$, we also have by Definition 2(v) that $g_i(x) = 0$, $i = 1, \dots, r$.

Let $Z \in \mathbb{R}^{n \times (n-r)}$ be an orthonormal matrix whose columns span the subspace $T_S(x^*)$. By using a Taylor series expansion of g about x^* , it is easy to show that there are vectors $\eta, \hat{\eta} \in \mathbb{R}^{n-r}$ and $\zeta, \hat{\zeta} \in \mathbb{R}^r$ such that

$$(30) \quad x - x^* = Z\eta + \nabla g(x^*)\zeta,$$

$$(31) \quad x - \hat{x} = Z\hat{\eta} + \nabla g(x^*)\hat{\zeta},$$

where $\|\zeta\| = O(\|x - x^*\|^2)$ and $\|\hat{\zeta}\| = O(\|x - x^*\|^2) + O(\|\hat{x} - x^*\|^2) = O(\|x - x^*\|^2)$. From the second-order conditions and boundedness of $\nabla^2 g_i$ in a neighborhood of x^* there exists a constant $c_2 > 0$ such that

$$(32) \quad \eta^T Z^T \left[\nabla^2 F(x^*) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^*) \right] Z\eta \geq \alpha \|\eta\|^2,$$

and

$$(33) \quad \left\| Z^T \left[I + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^*) \right] Z\eta \right\| \leq c_2 \|\eta\|,$$

for all $\eta \in \mathbb{R}^{n-r}$. It follows trivially from (32) that

$$(34) \quad \|Z^T \left[\nabla^2 F(x^*) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^*) \right] Z\eta\| \geq \alpha \|\eta\|.$$

Now, from (29),

$$\begin{aligned} x - \hat{x} &= \nabla F(x) + \nabla g(\hat{x})\lambda \\ \Rightarrow x - \hat{x} &= \nabla F(x) + \nabla g(x)\lambda^* + [\nabla g(\hat{x}) - \nabla g(x)]\lambda + \nabla g(x)[\lambda - \lambda^*] \\ \Rightarrow x - \hat{x} &= \left[\nabla^2 F(x^{(1)}) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^{(1)}) \right] (x - x^*) + \\ &\quad \sum_{i=1}^r \lambda_i \nabla^2 g_i(x^{(2)})(\hat{x} - x) + \nabla g(x^*)[\lambda - \lambda^*] + O(\|x - x^*\|^2), \end{aligned}$$

for $x^{(1)} \in [x, x^*]$ and $x^{(2)} \in [\hat{x}, x]$. Premultiplying this equation by Z^T , and using (30) and (31), we obtain

$$\begin{aligned} & Z^T \left[I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(x^{(2)}) \right] [Z\hat{\eta} + \nabla g(x^*)\hat{\zeta}] \\ &= Z^T \left[\nabla^2 F(x^{(1)}) + \sum_{i=1}^r \lambda_i^* \nabla^2 g_i(x^{(1)}) \right] [Z\eta + \nabla g(x^*)\zeta] + O(\|x - x^*\|^2). \end{aligned}$$

Now, from (33) and (34), we can choose $\bar{\rho}_3 \in (0, \bar{\rho}_2]$ small enough that, for $\|x - x^*\| \leq \bar{\rho}_3$,

$$\begin{aligned} 2c_2 \|\hat{\eta}\| &\geq \left\| Z^T \left[I + \sum_{i=1}^r \lambda_i \nabla^2 g_i(x^{(2)}) \right] Z \hat{\eta} \right\| \\ &\geq O(\|\hat{\zeta}\|) + O(\|\zeta\|) + O(\|x - x^*\|^2) + \frac{\alpha}{2} \|\eta\|. \end{aligned}$$

Since

$$\begin{aligned} \|\hat{\eta}\| &= \|x - \hat{x}\| + O(\|x - x^*\|^2), \\ \|\eta\| &= \|x - x^*\| + O(\|x - x^*\|^2), \end{aligned}$$

there is a constant $c_3 > 0$ such that

$$\begin{aligned} 2c_2 \|x - \hat{x}\| &\geq \frac{\alpha}{2} \|x - x^*\| - c_3 \|x - x^*\|^2 \\ \Rightarrow \|x - \hat{x}\| &\geq \frac{\alpha}{4c_2} \|x - x^*\| \left[1 - \frac{2c_3}{\alpha} \|x - x^*\| \right]. \end{aligned}$$

Now, choosing $\rho_2 = \min(\bar{\rho}_3, \alpha/(4c_3))$, the desired result follows, with $\alpha_2 = \alpha/(8c_2)$.

(iii) The proof of this part is identical to that of Theorem 3.1, and hence, is omitted.

(iv) This follows from Theorem 2.1 of Dunn [4], after we make the following observations. Part (i) of this theorem implies that x^* is a uniformly proper local minimizer of F in Ω . The fact that $F \in C^2$ in a neighborhood of x^* means that it is possible to choose a $\bar{\sigma} \in (0, 1)$ such that, for x_k in this neighborhood, any σ_k satisfying (12)–(14) lies in $[\bar{\sigma}, 1]$. \square

We turn now to Newton-like methods for (1). Here, an initial iterate $x_0 \in \Omega$ is chosen, and for each $k \geq 0$, the following subproblem is solved to find a search direction p_k :

$$(35) \quad \min_{p_k} \nabla F(x_k)^T p_k + \frac{1}{2} p_k^T B_k p_k, \quad x_k + p_k \in \Omega.$$

A steplength $\sigma_k \in [0, 1]$ is chosen, usually with the help of some “sufficient decrease” criterion, and the next iterate is obtained by setting

$$(36) \quad x_{k+1} = x_k + \sigma_k p_k.$$

A simple result, similar to Theorem 3.1, follows.

THEOREM 3.3. *Suppose that*

- (i) *Assumption 1 and (2) hold at some point x^* ;*
- (ii) *$\nabla F(x)$ is continuous at x^* ;*
- (iii) *$x^* \in S$, where S is some class- C^p identifiable surface of Ω with $p \geq 1$; and*
- (iv) *$x_k \rightarrow x^*$ and $p_k \rightarrow 0$ as $k \rightarrow \infty$, and $\{\|B_k\|\}$ is bounded.*

Then $x_k + p_k \in S$ for all k sufficiently large.

Proof. As in Lemma 2.2, we can find a set $K \subset \mathbb{R}^n \setminus \Omega$ with $P(K) \subset S$, and a scalar $\delta > 0$ such that

$$x^* - \nabla F(x^*) + \delta B \subset \text{int}(K).$$

First-order conditions for (35) are that

$$-\nabla F(x_k) - B_k p_k \in N(x_k + p_k) \Leftrightarrow x_k + p_k = P(x_k + p_k - \nabla F(x_k) - B_k p_k).$$

Now,

$$\begin{aligned} & \| (x_k + p_k - \nabla F(x_k) - B_k p_k) - (x^* - \nabla F(x^*)) \| \\ & \leq \| x_k - x^* \| + \| \nabla F(x_k) - \nabla F(x^*) \| + (1 + \| B_k \|) \| p_k \|. \end{aligned}$$

We can choose \bar{k} large enough that, for $k \geq \bar{k}$, the right-hand side of the above inequality does not exceed δ . Then $x_k + p_k \in S$, as required. \square

Finally, we prove a capture and convergence result for Newton's method, which makes use of the second-order conditions in Assumption 2.

THEOREM 3.4. *Suppose that Assumption 2 holds, and that, in addition, $\nabla^2 F(x)$ is Lipschitz continuous in a neighborhood of x^* . Let $B_k = \nabla^2 F(x_k)$ in (35). Then there are positive constants ρ_4 and α_4 such that, if $x_0 \in \Omega \cap (x^* + \rho_4 B)$ and $\sigma_k \equiv 1$ for all $k \geq 0$, then the algorithm (35), (36) generates a sequence $\{x_k\}$ such that*

$$\|x_{k+1} - x^*\| \leq \alpha_4 \|x_k - x^*\|^2 \quad \text{for all } k \geq 0.$$

In addition, $x_k \in S$ for all k sufficiently large.

Proof. The proof of the first part follows from results of Dunn [3, Thm. 3.1, Note 3.1] provided that we find positive constants $\bar{\alpha}_1$ and $\bar{\rho}_1$ such that

$$(37) \quad \nabla F(x^*)^T (x - x^*) + \frac{1}{2} (x - x^*)^T \nabla^2 F(x^*) (x - x^*) \geq \bar{\alpha}_1 \|x - x^*\|^2$$

for all $x \in \Omega \cup (x^* + \bar{\rho}_1 B)$.

Suppose we choose $\bar{\rho}_1$ small enough that F is twice Lipschitz continuously differentiable on the open ball $x^* + \bar{\rho}_1 B$, with Lipschitz constant L and, in addition, that

$$\bar{\rho}_1 \leq \min(\rho_1, \alpha_1/L),$$

where α_1 and ρ_1 are the constants from Theorem 3.2(i). For $\|x - x^*\| \leq \bar{\rho}_1$, we have

$$\begin{aligned} & \nabla F(x^*)^T (x - x^*) + \frac{1}{2} (x - x^*)^T \nabla^2 F(x^*) (x - x^*) \\ & \geq F(x) - F(x^*) - \frac{1}{2} L \|x - x^*\|^3 \\ & \geq [\alpha_1 - \frac{1}{2} L \|x - x^*\|] \|x - x^*\|^2 \\ & \geq \frac{1}{2} \alpha_1 \|x - x^*\|^2, \end{aligned}$$

and so (37) is satisfied if we set $\bar{\alpha}_1 = \frac{1}{2} \alpha_1$.

The final statement in the theorem follows from Theorem 3.3. \square

A DUAL APPROACH TO LINEAR INVERSE PROBLEMS WITH CONVEX CONSTRAINTS*

LEE C. POTTER[†] AND K. S. ARUN[‡]

Abstract. A simple constraint qualification is developed and used to derive an explicit solution to a constrained optimization problem in Hilbert space. A finite parameterization is obtained for the minimum norm element in the intersection of a linear variety of finite co-dimension and a closed convex constraint set. The result extends previous duality theorems for convex cone set constraints. A fixed point iteration is presented for computing the parameters and yields a least-squares solution when the variety and constraint set have empty intersection. Proofs rely on nearest-point projections onto convex sets and the properties of monotone, firmly nonexpansive, and averaged mappings.

Key words. constrained optimization, semi-infinite convex program, constraint qualification, successive approximations, nearest-point projection, monotone operator

AMS(MOS) subject classifications. 49A, 49B, 49D

1. Introduction. The recovery of a signal from linear measurements and prior information is a central problem in signal analysis and remote sensing applications ranging from tomographic imaging and radio astronomy to well logging and respiratory physiology. Simplicity and generality are sought in characterizing and computing signals that successfully reflect available prior knowledge. To this end, the signal is abstractly represented as an element of a Hilbert space, and each known property of the signal is incorporated by restricting the reconstructed signal to lie in a specified closed convex set. In addition, the requirement that the signal be consistent with a finite number of linear measurements defines a linear variety of finite co-dimension. The intersection of this variety and the convex constraint set is termed the *feasible set* of signals. In this paper, the recovery task is formulated as the infinite-dimensional programming problem of determining the feasible signal closest to a specified nominal signal.

The desired signal is shown to admit a dual parameterization by exploiting the properties of monotone operators and nearest-point mappings onto closed convex sets. The parameter vector is seen to be a fixed point of a nonlinear, monotone, firmly nonexpansive operator in a finite-dimensional space; these properties lead both to a novel constraint qualification assuring the existence of the parameters and to iterative computational schemes. Convergence to a least-squares fit of the linear measurements is obtained when the feasible set is empty. The duality result does not require the constraint sets to have interior and allows direct derivation of the optimal L_2 solution in [8]. In addition, more recent L_p optimization results [2], [9] that likewise eschew the traditional Slater-type constraint qualification are extended, in Hilbert space, from the special case of a convex cone to general convex set constraints.

2. Problem formulation. Let \mathcal{S} be a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$. By the Riesz representation theorem, any N continuous, linear measurement functionals on \mathcal{S} may be expressed by inner products with *measurement signals*

g_1, g_2, \dots, g_N in \mathcal{S} . Accordingly, define the mapping A from \mathcal{S} into Euclidean N -space \mathbb{R}^N by

$$Ax = [\langle x, g_1 \rangle, \dots, \langle x, g_N \rangle]^t,$$

where $[\cdot]^t$ denotes vector transpose. For a given $\beta \in \mathbb{R}^N$, the set of all x satisfying $Ax = \beta$ is a linear variety of co-dimension not exceeding N . The adjoint operator A^* maps a vector $\theta \in \mathbb{R}^N$ with k^{th} entry θ_k to the signal $A^*\theta = \sum_{k=1}^N \theta_k g_k$. Thus, $A^*\theta$ is very simply a linear combination of the N measurement signals, and the range of A^* is the finite-dimensional subspace $\mathcal{G} \subset \mathcal{S}$ spanned by the measurement signals: $\text{range}(A^*) = \mathcal{G} = \text{span}\{g_1, \dots, g_N\}$. Let Π be the orthogonal projection onto \mathcal{G} . The orthogonal complement of \mathcal{G} is the null space of A , denoted $\ker(A)$; the linear variety $\{x : Ax = \beta\}$ is a translate of $\ker(A)$ and is therefore a closed convex set.

Let $\mathcal{K}_1, \mathcal{K}_2, \dots, \mathcal{K}_M$ be closed convex sets with nonempty intersection \mathcal{K} . The set \mathcal{K} is referred to as the *constraint set*; \mathcal{K} may be infinite-dimensional and is not assumed to have interior. For a fixed measurement vector β the *feasible set* \mathcal{F} is defined to be the intersection of the variety $\{x : Ax = \beta\}$ with the constraint set \mathcal{K} . That is, \mathcal{F} is the closed and convex set $\{x \in \mathcal{K} : Ax = \beta\}$. Finally, let \mathcal{E} denote the *extendible set* in \mathbb{R}^N defined to consist of all measurement vectors β for which the associated \mathcal{F} is nonempty.

The recovery problem is to characterize and compute the signal in the feasible set \mathcal{F} closest to a specified nominal signal. Without loss of generality, the nominal signal, x_{nom} , is the origin: for $x_{nom} \neq 0$, the data vector is replaced by $\beta - Ax_{nom}$, and the constraint set is translated by $-x_{nom}$. This constrained inverse problem is concisely written

$$(P) \quad \min_{x \in \mathcal{K}} \|x\| \quad \text{subject to} \quad Ax = \beta.$$

The special case in which \mathcal{K} is a convex cone is considered in [2], [8], [9], and [25], and subspace or linear variety constraints are considered in [3], [14]. Problem (P) is the linear inverse problem $Ax = \beta$ with the additional convex set constraint $x \in \mathcal{K}$.

Were the distinction between the closed convex data constraint $Ax = \beta$ and the set constraint \mathcal{K} to be abandoned, the minimum norm element of the feasible set, \mathcal{F} , would be trivially characterized by the projection of the origin onto closed convex set \mathcal{F} . However, this conceptual approach is undesirable since the aim is to explicitly determine solutions. First, to combine the data constraint with the set \mathcal{K} forfeits the structural advantage afforded by the finite co-dimensionality of the linear variety. Second, the nearest-point projection operator onto \mathcal{F} may not be computable in a tractable manner; the set \mathcal{K} , on the other hand, typically arises from physically meaningful constraints that give rise to an easily implemented nearest-point projection operator onto \mathcal{K} . Third, the distinction between the data matching and set constraints allows for the computation of a least-squares solution when measurement noise renders the feasible set empty.

3. An optimality condition. In the absence of the constraints imposed by the convex set \mathcal{K} , the projection theorem, e.g., [13] simply and elegantly characterizes the minimum norm element of the variety $\{x : Ax = \beta\}$ as a linear combination $\sum_{k=1}^N \theta_k g_k$, where the parameters $\theta \in \mathbb{R}^N$ are determined by the normal equations. In a similar manner, the constraints embodied by \mathcal{K} are incorporated, and a particularly simple and geometrically appealing optimization result for (P) is obtained. The following theorem establishes a parsimonious parameterization of the solution \hat{x} .

First, two basic facts are reviewed for closed convex sets in a Hilbert space.

LEMMA 1. *Let \mathcal{K} denote any closed convex subset of a Hilbert space \mathcal{S} . Then there exists a unique $y \in \mathcal{K}$ such that $\inf_{z \in \mathcal{K}} \|x - z\| = \|x - y\|$.*

This correspondence is denoted by $y = P_{\mathcal{K}}(x)$, where $P_{\mathcal{K}} : \mathcal{S} \mapsto \mathcal{K}$ is said to be the *nearest-point projection operator*, or simply the *projection*, of \mathcal{S} onto the closed convex set \mathcal{K} . The operator $P_{\mathcal{K}}$ is linear if and only if \mathcal{K} is a subspace.

LEMMA 2. *Let \mathcal{K} be a closed convex subset of \mathcal{S} . Then the following are equivalent:*

- (a) $P_{\mathcal{K}}(x) = y$
- (b) $\|x - y\| \leq \|x - z\|$ for all $z \in \mathcal{K}$
- (c) $\langle x - y, z - y \rangle \leq 0$ for all $z \in \mathcal{K}$.

THEOREM 1. *If there exists $\theta \in \mathbb{R}^N$ such that $\beta = AP_{\mathcal{K}}A^*(\theta)$, then $\hat{x} = P_{\mathcal{K}}A^*(\theta)$ is the unique solution to (P).*

Proof [18], [20]. The feasible set $\mathcal{F} := \mathcal{K} \cap \{x : Ax = \beta\}$ is closed and convex, and the existence of a unique minimum norm element follows from Lemma 1, provided \mathcal{F} is nonempty. Let $y := A^*\theta$ where θ is the parameter vector of the hypothesis. It must be shown that

$$\inf_{x \in \mathcal{F}} \|x\| = \|P_{\mathcal{K}}(y)\|.$$

From Lemma 2, it suffices to show that $\langle P_{\mathcal{K}}(y), x - P_{\mathcal{K}}(y) \rangle \geq 0$ for all $x \in \mathcal{F}$. To this end, let x denote an arbitrary element of \mathcal{F} . Now write $P_{\mathcal{K}}(y)$ as $y - (y - P_{\mathcal{K}}(y))$ to yield

$$\langle P_{\mathcal{K}}(y), x - P_{\mathcal{K}}(y) \rangle = \langle y, x - P_{\mathcal{K}}(y) \rangle - \langle y - P_{\mathcal{K}}(y), x - P_{\mathcal{K}}(y) \rangle.$$

First, observe that $\langle y, x - P_{\mathcal{K}}(y) \rangle = 0$ since $y \in \mathcal{G} = \text{range}(A^*)$ and $Ax = \beta = AP_{\mathcal{K}}(y)$ implies $(x - P_{\mathcal{K}}(y)) \in \ker(A)$. Turning to the second term, observe from Lemma 2 that $\langle y - P_{\mathcal{K}}(y), x - P_{\mathcal{K}}(y) \rangle \leq 0$ for all $x \in \mathcal{K}$. In particular, \mathcal{F} is a subset of \mathcal{K} , so the inequality holds for all x in \mathcal{F} . Hence, $\langle P_{\mathcal{K}}(y), x - P_{\mathcal{K}}(y) \rangle \geq 0$ for all x in \mathcal{F} . \square

The result in Theorem 1 is a nonlinear generalization of the classical projection theorem, which follows as a simple corollary.

COROLLARY 1. *For $\mathcal{K} = \mathcal{S}$ and $\mathcal{F} \neq \emptyset$, the solution \hat{x} to (P) is given by $A^*\theta$, where θ satisfies the normal equations $AA^*\theta = \beta$.*

Figure 1 provides an illustration of Theorem 1 in the Euclidean plane and, although depicting the degenerate case of $\mathcal{S} = \mathbb{R}^2$, illuminates the similarities between Theorem 1 and the projection theorem. The minimum norm element x_{mn} of the variety $\{x : Ax = \beta\}$ is the orthogonal projection of the origin onto the variety. Thus, $x_{mn} = \sum_{k=1}^N \theta_k g_k$, where the coefficients θ_k are uniquely specified by the linear equations in Corollary 1. However, the minimum norm solution lies outside the constraint set \mathcal{K} , in general. Yet, the constrained minimum norm element \hat{x} is found in an analogous manner: \hat{x} is the nearest-point projection onto \mathcal{K} of an element $A^*\hat{\theta} = \sum_{k=1}^N \hat{\theta}_k g_k$ in \mathcal{G} , where the parameter vector $\hat{\theta}$ is determined by the equations in Theorem 1. Thus, in order to constrain the minimum norm solution to lie in the constraint set \mathcal{K} , the linear normal equations $AA^*\theta = \beta$ are replaced by the nonlinear equations $AP_{\mathcal{K}}A^*(\hat{\theta}) = \beta$, and the solution $x_{mn} = A^*\theta$ is replaced by $\hat{x} = P_{\mathcal{K}}A^*(\hat{\theta})$.

4. A constraint qualification. The hypothesis of Theorem 1 requires the existence of a solution $\hat{\theta}$ to a nonlinear system of equations, and the optimal signal \hat{x} is then parameterized by this solution via $\hat{x} = P_{\mathcal{K}}A^*(\hat{\theta})$. For a nonempty feasible set,

FIG. 1. The minimum norm feasible signal is the projection onto the constraint set of an element in the span of the measurement signals.

existence and uniqueness of a solution, \hat{x} , to (P) follow from Lemma 1. Therefore, the statement of the theorem immediately raises the questions: When does the representation of \hat{x} by $\hat{\theta}$ exist? Is the representation unique? How may it be computed? To address the issues of existence and uniqueness requires an investigation of the ranges of the nonlinear operator $AP_{\mathcal{K}}A^* : \mathbb{R}^N \mapsto \mathbb{R}^N$ and its set-valued inverse. That is, there exists a solution to $AP_{\mathcal{K}}A^*(\theta) = \beta$ if and only if β is in the range of $AP_{\mathcal{K}}A^*$, and the solution is unique if and only if $(AP_{\mathcal{K}}A^*)^{-1}(\beta)$ is single valued. Pertinent properties of these ranges are derived in this section by making use of their finite dimensionality and utilizing results from the theory of monotone operators. These properties are then used both to establish a novel constraint qualification (Cor. 2), which gives a condition on the data vector β to ensure the existence of a parameterization and to characterize uniqueness. The third issue, computation, is deferred to §5, where the solution of $AP_{\mathcal{K}}A^*(\theta) = \beta$ is viewed as a nonlinear fixed point problem.

A set \mathcal{M} in the Cartesian product $\mathbb{R}^N \times \mathbb{R}^N$ is said to be *monotone*, e.g., [27], if

$$\langle x^* - y^*, x - y \rangle \geq 0 \quad \forall (x, x^*), (y, y^*) \in \mathcal{M}.$$

A *maximal monotone* set is one not properly contained in another monotone set. A (possibly set valued) mapping $f : \mathbb{R}^N \mapsto 2^{\mathbb{R}^N}$ is called a *monotone operator* if its graph $\{(x, x^*) | x^* \in f(x)\}$ is a monotone set in $\mathbb{R}^N \times \mathbb{R}^N$; the operator is said to be *maximal monotone* if its graph is a maximal monotone set. The operator f^{-1} is defined as the mapping which has as its graph the set $\{(x^*, x) | (x, x^*) \in \text{graph of } f\}$. Since monotonicity is invariant under transposition of the domain and range of a map, f and f^{-1} are simultaneously monotone or maximal monotone. In the sequel, set-valued mappings will be viewed as multifunctions, and the notation $f : \mathbb{R}^N \mapsto \mathbb{R}^N$ will be employed.

The properties of maximal monotone operators in finite-dimensional spaces and convex sets in \mathbb{R}^N are combined to guarantee that for any data vector β in the relative interior of the extendible set \mathcal{E} there exists a parameter vector $\hat{\theta}$ providing the representation $\hat{x} = P_{\mathcal{K}}A^*(\hat{\theta})$. The requisite properties are established as two brief lemmas; the resulting theorem gives the desired constraint qualification as an immediate corollary.

LEMMA 3. *The operators $AP_{\mathcal{K}}A^* : \mathbb{R}^N \mapsto \mathbb{R}^N$ and $\Pi P_{\mathcal{K}}\Pi : \mathcal{S} \mapsto \mathcal{S}$ are maximal monotone operators.*

Proof. From the linearity of A and the definition of the adjoint A^* , it follows that

$$\begin{aligned}\langle AP_{\mathcal{K}}A^*(x) - AP_{\mathcal{K}}A^*(y), x - y \rangle &= \langle P_{\mathcal{K}}A^*(x) - P_{\mathcal{K}}A^*(y), A^*(x - y) \rangle \\ &= \langle P_{\mathcal{K}}(x^*) - P_{\mathcal{K}}(y^*), x^* - y^* \rangle,\end{aligned}$$

where $x^* = A^*x$ and $y^* = A^*y$. Immediately, this inner product is nonnegative since the projection $P_{\mathcal{K}}$ is monotone [7]. Next, since $AP_{\mathcal{K}}A^*$ is continuous and defined for all x in \mathfrak{R}^N , it is maximal monotone [15]. The proof for $\Pi P_{\mathcal{K}}\Pi$ is identical. \square

LEMMA 4 ([17]). *The closure of the range of a maximal monotone operator is a convex set.*

As defined above, the set of all data vectors β that can be generated by measuring some signal x from the constraint set \mathcal{K} is termed the *extendible set*. This set, $\mathcal{E} := \{\beta \in \mathfrak{R}^N : \beta = Ax, x \in \mathcal{K}\}$, is convex (immediately from the linearity of A) but not necessarily closed. Lemmas 3 and 4 are used to establish that the extendible set and the range of $AP_{\mathcal{K}}A^*$ are the same to within closure.

THEOREM 2. *The closure of the extendible set is equal to the closure of the set of all measurement vectors obtainable from parameterized signals of the form $x = P_{\mathcal{K}}A^*(\theta)$, $\theta \in \mathfrak{R}^N$; i.e., $\text{cl}(\mathcal{E}) := \text{cl}\{Ax : x \in \mathcal{K}\} = \text{cl}(\text{range}(AP_{\mathcal{K}}A^*))$.*

Proof. [19] It must be shown that

$$\inf_{\theta \in \mathfrak{R}^N} \|Aq - AP_{\mathcal{K}}A^*(\theta)\|^2 = 0 \quad \forall q \in \mathcal{K}.$$

To this end, observe that $\ker(A)$ is orthogonal to $\text{range}(A^*) = \mathcal{G}$ and recall Π is the orthogonal projection onto \mathcal{G} . Thus, it must be shown that

$$\inf_{p \in \mathcal{G}} \|\Pi(q - P_{\mathcal{K}}(p))\|^2 = 0 \quad \forall q \in \mathcal{K}.$$

If $\mathcal{G} = \text{range}(A^*) = 0$, then $\Pi = 0$ and the claim is proven; so attention is restricted to the case of \mathcal{G} nontrivial.

Proceeding by contradiction, assume there exists some $q \in \mathcal{K}$ for which the infimum is $\epsilon > 0$. The closure of $\text{range}(\Pi P_{\mathcal{K}}\Pi)$ is convex from Lemma 4. Let z denote the nearest point in $\text{cl}(\text{range}(\Pi P_{\mathcal{K}}\Pi))$ to Πq , with $\|\Pi q - z\|^2 = \epsilon$. Then, there exists a hyperplane \mathcal{H} in the finite dimensional subspace \mathcal{G} containing $h = \frac{1}{2}(\Pi q + z)$ and normal to $(\Pi q - z)$. The hyperplane \mathcal{H} separates Πq from $\text{range}(\Pi P_{\mathcal{K}}\Pi)$.

Next, a point p_t is constructed to provide a contradiction. Let $p_t = \Pi q + t(\Pi q - z)$, $t > 0$. For t sufficiently large, p_t is closer to q than to \mathcal{H} . In particular, let $Q = \|(I - \Pi)q\|^2$ and observe

$$\|p_t - q\|^2 = \|\Pi q + t(\Pi q - z) - (\Pi q + (I - \Pi)q)\|^2 = t^2\epsilon + Q$$

On the other hand, the projection of p_t onto \mathcal{H} is h for all $t > 0$. Thus,

$$\inf_{y \in \mathcal{H}} \|p_t - y\|^2 = \|\Pi q + t(\Pi q - z) - \frac{1}{2}(\Pi q + z)\|^2 = \left(t + \frac{1}{2}\right)^2 \epsilon.$$

Hence, for $(t + \frac{1}{4})\epsilon > Q$, $d(p_t, q) < d(p_t, \mathcal{H})$, where $d(\cdot, \cdot)$ is adopted as a distance notation. Now, let $\mathcal{J} = \mathcal{H} \oplus \mathcal{G}^\perp$ and let \mathcal{J}^+ denote the halfspace in \mathcal{S} containing $\text{range}(\Pi P_{\mathcal{K}}\Pi)$. Then,

$$d(p_t, \mathcal{K}) \leq d(p_t, q) < d(p_t, \mathcal{H}) = d(p_t, \mathcal{J}) \leq d(p_t, \mathcal{J}^+ \cap \mathcal{K})$$

implying $P_{\mathcal{K}}(p_t) \in \mathcal{J}^-$, whence $\Pi P_{\mathcal{K}}(p_t) \in \mathcal{J}^-$ and $\Pi P_{\mathcal{K}}(p_t) \notin \text{range}(\Pi P_{\mathcal{K}} \Pi)$. But $\Pi p_t = p_t$, providing a contradiction. Therefore, it must be the case that the infimum is indeed zero. \square

The *relative interior* of a convex set $\mathcal{C} \subset \mathbb{R}^N$, denoted $\text{ri}(\mathcal{C})$, is defined as the interior that results when \mathcal{C} is regarded as a subset of the intersection of all closed linear varieties containing \mathcal{C} . Given convex sets \mathcal{C}_1 and \mathcal{C}_2 in \mathbb{R}^N , $\text{cl}(\mathcal{C}_1) = \text{cl}(\mathcal{C}_2)$ if and only if $\text{ri}(\mathcal{C}_1) = \text{ri}(\mathcal{C}_2)$ [23]. The desired existence result now follows immediately from the theorem. This result can also be developed from convex duality theory [4].

COROLLARY 2 (CONSTRAINT QUALIFICATION). *If $\beta \in \text{ri}(\mathcal{E})$, then there exists θ such that $AP_{\mathcal{K}}A^*(\theta) = \beta$, i.e., $\beta \in \text{range}(AP_{\mathcal{K}}A^*)$.*

Proof. From Theorem 2, $\text{cl}(\mathcal{E}) = \text{cl}(\text{range}(AP_{\mathcal{K}}A^*))$. Hence, equivalence of the relative interiors follows: $\text{ri}(\mathcal{E}) = \text{ri}(\text{range}(AP_{\mathcal{K}}A^*))$. \square

In an infinite-dimensional Hilbert space there exist closed convex sets \mathcal{K} without interior for which support points are only dense in the boundary and form only a set of the first category, the complementary set being dense as well [10]. Yet, a simple consequence of Corollary 2 is that for $\beta \in \text{ri}(\mathcal{E})$, the solution \hat{x} to (P) is, in fact, a support point of \mathcal{K} and, moreover, some normal to \mathcal{K} at \hat{x} intersects the subspace \mathcal{G} .

Two commonly employed but more restrictive constraint qualifications found in the literature follow as corollaries to the result in Theorem 2.

COROLLARY 3 (SLATER CONSTRAINT). *If \mathcal{K} has interior and the feasible set $\mathcal{F} := \mathcal{K} \cap \{x : Ax = \beta\}$ contains points interior to \mathcal{K} , then there exists $\hat{\theta}$ such that $AP_{\mathcal{K}}A^*(\hat{\theta}) = \beta$.*

COROLLARY 4 ([2], [8]). *Let $\mathcal{S} = L_2$ and let \mathcal{K} be the closed convex cone of nonnegative functions in L_2 . If $\beta \in \text{int}(\mathcal{E})$, then there exists $\hat{\theta}$ such that $AP_{\mathcal{K}}A^*(\hat{\theta}) = \beta$.*

Theorem 2 answers the question of existence of the parameterization $\hat{x} = P_{\mathcal{K}}A^*(\theta)$. The second issue, uniqueness of a parameter vector, is equivalent to the single-valuedness of the operator $f = (AP_{\mathcal{K}}A^*)^{-1}$.

PROPOSITION 1. *If \mathcal{E} has nonempty interior, then a parameter vector θ satisfying $AP_{\mathcal{K}}A^*(\theta) = \beta$ is unique for almost every $\beta \in \mathcal{E}$.*

Proof. The mapping $(AP_{\mathcal{K}}A^*)^{-1}$ is a monotone operator by Lemma 3. From [27, Thm. 1], the set of points where a monotone operator on a finite-dimensional Hilbert space is not single valued has zero Lebesgue measure. \square

Furthermore, the set of points in \mathcal{E} for which the representation is unique is a subset of the relative interior of $\text{range}(AP_{\mathcal{K}}A^*)$ [22, Cor. 1.1]. For linearly dependent measurement signals $\{g_1, \dots, g_N\}$ the extendible set $\mathcal{E} \subset \mathbb{R}^N$ is contained in a subspace of dimension less than N and $\text{int}(\mathcal{E}) = \emptyset$.

5. Iterative computation. From Theorems 1 and 2, the solution \hat{x} to (P) is parameterized by $\hat{x} = P_{\mathcal{K}}A^*(\hat{\theta})$, where the vector $\hat{\theta}$ solves the nonlinear system $AP_{\mathcal{K}}A^*(\theta) = \beta$. Equivalently, the parameter vector $\hat{\theta}$ is a fixed point of the operator $T : \mathbb{R}^N \mapsto \mathbb{R}^N$ defined by $T(\theta) = \theta + \beta - AP_{\mathcal{K}}A^*(\theta)$. The operator T is not a contraction, nor does it have a compact domain; therefore, the well-known Banach and Brouwer fixed point results are not applicable. Nonetheless, the properties of firmly nonexpansive and averaged mappings are exploited to show that the sequence of Picard iterations

$$(1) \quad \theta^{(n+1)} = \theta^{(n)} + \lambda[\beta - AP_{\mathcal{K}}A^*(\theta^{(n)})], \quad \lambda \in (0, 2)$$

converges to a fixed point of T . Additionally, the sequence is shown to characterize a least-squares solution to (P) when there exists no fixed point.

Case 1. First, the sequence $\{\theta^{(n)}\}$ is considered for the case in which T has a fixed point. Convergence is established by relying on three simple lemmas in Euclidean N -space. A mapping $f : \mathbb{R}^N \mapsto \mathbb{R}^N$ is said to be *nonexpansive* if $\|f(x) - f(y)\| \leq \|x - y\|$ for all x, y in \mathbb{R}^N . Further, f is *firmly nonexpansive* if and only if $2f - I$ is nonexpansive [7].

LEMMA 5. *As defined above, let T be the operator given by $T(\theta) = \theta + \beta - AP_K A^*(\theta)$. If the measurement signals $\{g_1, \dots, g_N\}$ satisfy $\sum_{k=1}^N \|g_k\|^2 \leq 1$, then T is firmly nonexpansive.*

Proof. To show that T is firmly nonexpansive, $2T - I$ is shown to be nonexpansive. To this end, direct computation using the definitions of T and of the adjoint A^* yields

$$\|(2T - I)x - (2T - I)y\|^2 \leq \|x - y\|^2 \Leftrightarrow \langle P_K(x') - P_K(y'), x' - y' \rangle \geq \|A(P_K(x') - P_K(y'))\|^2,$$

where $x' := A^*x$ and $y' := A^*y$. From Lemma 2, $\langle P_K(x') - P_K(y'), x' - y' \rangle \geq \|P_K(x') - P_K(y')\|^2$. Furthermore, by hypothesis on the measurement signals and application of the Cauchy-Bunyakovskii-Schwarz inequality, A is nonexpansive:

$$\|Aw\|^2 = \sum_{k=1}^N (\langle g_k, w \rangle)^2 \leq \sum_{k=1}^N \|g_k\|^2 \|w\|^2 \leq \|w\|^2 \quad \forall w \in \mathcal{S}.$$

Hence,

$$\|P_K(x') - P_K(y')\|^2 \geq \|A(P_K(x') - P_K(y'))\|^2,$$

and T is firmly nonexpansive. \square

LEMMA 6 ([7]). *Let $f : \mathbb{R}^N \mapsto \mathbb{R}^N$ be a nonexpansive operator with a fixed point. Then, $\{f^n(x)\}$ converges to a fixed point of f if and only if f is asymptotically regular, i.e.,*

$$\lim_n f^n(x) - f^{n+1}(x) = 0 \text{ for all } x \in \mathbb{R}^N.$$

As an example of a nonexpansive operator \mathbb{R} to \mathbb{R} with a fixed point and not asymptotically regular, consider $f(x) = -x - 1$. Although a nonexpansive operator f may not be asymptotically regular, the *averaged mapping* $f_\lambda := \lambda f + (1 - \lambda)I$, where $0 < \lambda < 1$, shares the same fixed point set and has desirable asymptotic properties.

LEMMA 7 ([5]). *Let f be a nonexpansive operator in \mathbb{R}^N . Although the operator f itself may not be asymptotically regular, if f has a fixed point, then the averaged mapping f_λ is asymptotically regular.*

The result now follows directly.

THEOREM 3. *Assume T has a fixed point. For $\lambda \in (0, 2)$ let $f : \mathbb{R}^N \mapsto \mathbb{R}^N$ be defined by*

$$f(\theta) = \theta + \lambda[\beta - AP_K A^*(\theta)]$$

If the measurement signals $\{g_1, \dots, g_N\}$ satisfy $\sum_{k=1}^N \|g_k\|^2 \leq 1$, then the sequence of Picard iterates $\{f^n(\theta)\}$ converges to a fixed point of T for any $\theta \in \mathbb{R}^N$.

Proof. From Lemma 5, T is firmly nonexpansive, so $2T - I$ is nonexpansive and has the same fixed point set as T . Simply note that for $0 < \delta < 1$, f is the averaged mapping $f = \delta(2T - I) + (1 - \delta)I = 2\delta T + (1 - 2\delta)I$. By Lemma 7, f is asymptotically regular. Application of Lemma 6 then yields Picard iterates $\{f^n(\theta)\}$ converging to a

fixed point of $2T - I$. Thus, the limit $\hat{\theta}$ is a fixed point of T and, therefore, satisfies $AP_{\mathcal{K}}A^*(\hat{\theta}) = \beta$. \square

For all β in the relative interior of the extendible set \mathcal{E} , T has a fixed point by Corollary 2, and the Picard iteration $\{f^n(\theta)\}$ yields the solution to (P). The hypothesis that the measurement signals have square sum not exceeding one can always be satisfied by simple scaling.

Case 2. Next, the behavior of the sequence $\{f^n(\theta)\}$ is considered for the general case in which T may be fixed point free. First, T is trivially fixed point free when the measurement vector β is not extendible, i.e., when there exists no signal x in the constraint set \mathcal{K} for which $Ax = \beta$, and hence, no solution to (P). In application, such a nonextendible vector β may result from either measurement noise or from failure of the constraint set \mathcal{K} to reflect physical reality. In addition, T may have no fixed point for β in the relative boundary of \mathcal{E} .

The objective of determining a feasible signal $x \in \mathcal{S}$ satisfying both $x \in \mathcal{K}$ and $Ax = \beta$ is unobtainable when β fails to lie in the extendible set. A well-motivated and popular recourse is to find a signal in the constraint set \mathcal{K} that best matches the measurement vector β in the least-squares sense: $\inf_{x \in \mathcal{K}} \|Ax - \beta\|$. (This choice implicitly supposes greater confidence in the knowledge expressed by the constraint set \mathcal{K} than in the noisy measurement β .) If more than one signal achieves this infimum, then the unique infimizer of minimum norm is termed the *minimum norm least-squares* solution and solves

$$(P') \quad \min_{x \in \mathcal{K}} \|x\| \quad \text{subject to} \quad \|Ax - \beta\| = \inf_{y \in \mathcal{K}} \|Ay - \beta\|.$$

A weighted least-squares formulation is easily adopted with corresponding change in the definition of the adjoint, A^* . For a closed convex constraint set \mathcal{K} and a linear measurement operator A , the extendible set $\mathcal{E} = A(\mathcal{K}) \subset \mathbb{R}^N$, though not necessarily closed, is convex. Hence, for a measurement vector $\beta \notin \mathcal{E}$, there exists a unique closest vector in the closure of \mathcal{E} , namely, the projection of β onto $cl(\mathcal{E})$, $P_{\bar{\mathcal{E}}}(\beta)$.

PROPOSITION 2. *The infimum in (P') is achieved if and only if $P_{\bar{\mathcal{E}}}(\beta)$ is in \mathcal{E} .*

Proof. With $P_{\bar{\mathcal{E}}}$ as above, $\inf_{y \in \mathcal{K}} \|Ay - \beta\| = \|P_{\bar{\mathcal{E}}}(\beta) - \beta\|$. \square

Therefore, for $P_{\bar{\mathcal{E}}}(\beta) \in \mathcal{E}$, problem (P') is equivalent to (P) with measurement vector $P_{\bar{\mathcal{E}}}(\beta)$.

The asymptotic behavior of averaged mappings provides the solution to (P'), as readily demonstrated using the following asymptotic property of nonexpansive maps.

LEMMA 8 ([1]). *Let $h : \mathbb{R}^N \mapsto \mathbb{R}^N$ be nonexpansive and define the averaged mapping $h_{\lambda} = \lambda h + (1 - \lambda)I$, $\lambda \in (0, 1)$. Then for all θ in \mathbb{R}^N*

$$(a) \quad \lim_{n \rightarrow \infty} \frac{h_{\lambda}^n(\theta)}{n} = -\nu$$

$$(b) \quad \lim_{n \rightarrow \infty} [h_{\lambda}^n(\theta) - h_{\lambda}^{n+1}(\theta)] = \nu,$$

where ν is the unique point of least norm in $cl(\text{range}(I - h_{\lambda}))$. Additionally, h has no fixed point if and only if $\lim_{n \rightarrow \infty} \|h_{\lambda}^n(\theta)\| = \infty$ for all θ in \mathbb{R}^N .

In relation to the asymptotic regularity condition of Lemma 6, observe that $h^n(\theta)$ is a Cauchy sequence if and only if h has a fixed point and ν is the zero vector.

THEOREM 4. *Let $\beta \in \mathbb{R}^N$ be an observed measurement vector, and let $f : \mathbb{R}^N \mapsto \mathbb{R}^N$ be defined by $f(\theta) = \theta + \lambda[\beta - AP_{\mathcal{K}}A^*(\theta)]$ for $\lambda \in (0, 2)$. Also, assume $\sum_{k=1}^N \|g_k\|^2 \leq 1$. Let $\{\theta^{(n)}\}$ denote the sequence of Picard iterates $\theta^{(n)} = f^n(\theta^{(0)})$*

with initial iterate $\theta^{(0)}$. Then, for any $\theta^{(0)} \in \mathfrak{R}^N$, the sequence $\{AP_{\mathcal{K}}A^*(\theta^{(n)})\}$ converges to $P_{\mathcal{E}}(\beta)$, the projection of β onto the closure of the extendible set.

Proof. [19] By Theorem 2, $\text{cl}(\text{range}(AP_{\mathcal{K}}A^*)) = \text{cl}(\mathcal{E})$. Therefore, the closure of the range of $(I - f)$ is simply a scaled translate of the closure of the extendible set:

$$\text{cl}(\text{range}(I - f)) = \text{cl}\{\gamma : \gamma = \lambda(AP_{\mathcal{K}}A^*(\theta) - \beta), \theta \in \mathfrak{R}^N\} = \lambda\{\text{cl}(\mathcal{E}) - \beta\}.$$

Then, the minimum norm element of $\text{cl}(\text{range}(I - f))$ is $\lambda\nu$, where ν is the minimum norm element of $\text{cl}(\mathcal{E}) - \beta$. Hence, the projection of β onto $\text{cl}(\mathcal{E})$ is given by the sum $P_{\mathcal{E}}(\beta) = \beta + \nu$. By Lemma 8, given $\epsilon > 0$, there exists some integer M_{ϵ} such that for all n exceeding M_{ϵ}

$$\begin{aligned} \epsilon &> \|\lambda\nu - (\theta^{(n)} - \theta^{(n+1)})\| \\ &= \|\lambda\nu - \theta^{(n)} + \theta^{(n)} + \lambda[\beta - AP_{\mathcal{K}}A^*(\theta^{(n)})]\| \\ &= \lambda\|P_{\mathcal{E}}(\beta) - AP_{\mathcal{K}}A^*(\theta^{(n)})\|. \end{aligned}$$

Hence, $AP_{\mathcal{K}}A^*(\theta^{(n)}) \rightarrow P_{\mathcal{E}}(\beta)$ as $n \rightarrow \infty$. \square

COROLLARY 5. *If, in addition to the hypotheses of Theorem 4, $P_{\mathcal{E}}(\beta)$ is contained in the extendible set \mathcal{E} , then the sequence of approximate reconstructions $\{x^{(n)}\}$, $x^{(n)} := P_{\mathcal{K}}A^*(\theta^{(n)})$, is bounded, and there exists a subsequence $\{x^{(n_j)}\}$ that converges weakly to \hat{x} , the solution to (P') .*

Proof. From Proposition 2, there exists a solution, \hat{x} , to (P') . By Theorem 4, $\epsilon_n := \|\Pi(\hat{x} - x^{(n)})\| \rightarrow 0$. Then, employ Lemma 2, a direct sum decomposition with \mathcal{G} , and the Cauchy-Bunyakovskiĭ-Schwarz inequality to learn

$$\begin{aligned} 0 &\leq \|\hat{x} - A^*\theta^{(n)}\| - \|P_{\mathcal{K}}A^*\theta^{(n)} - A^*\theta^{(n)}\| \\ &\leq \|(I - \Pi)(\hat{x})\| - \|(I - \Pi)(P_{\mathcal{K}}A^*\theta^{(n)})\| + \\ &\quad \left| \|\Pi(\hat{x} - A^*\theta^{(n)})\| - \|\Pi(P_{\mathcal{K}}A^*\theta^{(n)} - A^*\theta^{(n)})\| \right| \\ &\leq \|(I - \Pi)(\hat{x})\| - \|(I - \Pi)(P_{\mathcal{K}}A^*\theta^{(n)})\| + \epsilon_n. \end{aligned}$$

Therefore, $x^{(n)} = P_{\mathcal{K}}A^*\theta^{(n)}$ is a bounded sequence in \mathcal{K} , and consequently there exists some subsequence $\{x^{(n_j)}\}$ that converges weakly. Let y be the weak limit. Now, $y \in \mathcal{K}$, $\Pi y = \Pi\hat{x}$, and $Ay = P_{\mathcal{E}}(\beta)$ by Theorem 4. Thus, $\|\hat{x}\| \leq \|y\|$ by definition of \hat{x} . Conversely, $\|(I - \Pi)(y)\| \leq \|(I - \Pi)(\hat{x})\|$ from above, whence $\|y\| = \|\hat{x}\|$. Since, from Lemma 1, \hat{x} is the unique element of minimum norm in \mathcal{K} for which $A\hat{x} = P_{\mathcal{E}}(\beta)$, it follows that $y = \hat{x}$. \square

A practical criterion for convergence in computer implementation of Theorem 4 is to test the sequence of differences in successive iterations for convergence to $\lambda\nu$ within a given tolerance. However, the vector ν is not known a priori and is zero if and only if β is an observation vector in the closure of the extendible set. Nonetheless, $\{\theta^{(n)} - \theta^{(n+1)}\}$ is indeed a Cauchy sequence in \mathfrak{R}^N by Lemma 8. Therefore, observing that

$$\theta^{(n)} - \theta^{(n+1)} = \theta^{(n)} - f(\theta^{(n)}) = \lambda[P_{\mathcal{K}}A^*(\theta^{(n)}) - \beta]$$

is simply the residual error scaled by λ , the iterations may be terminated when the change in the residual error from iterate n to $n + 1$ is less than some prescribed value. Moreover, this sequence of residual errors is monotonically nonincreasing in norm due to the nonexpansiveness of f . Although $\{\theta^{(n)}\}$ is divergent, it grows only linearly as $n\lambda\nu$. Therefore, the divergence presents no practical computational overflow problems, even for a large number of iterations, since $\|\nu\|^2$ is bounded by the noise power in the measurement β .

FIG. 2. An example in the plane.

6. Example. The results of §§3, 4, and 5 are illustrated by a simple example in the Euclidean plane. Although analytical nuances are lost from the infinite-dimensional case, the relationships among the relative interior of the extendible set, fixed points, and Picard iterations are clearly illuminated. (An example application to an infinite-dimensional problem is found in [21].) In the Hilbert space $\mathcal{S} = \mathbb{R}^2$ let the constraint set \mathcal{K} be the closed convex set depicted in Fig. 2. Let the measurement β be simply the first coordinate of a vector in \mathbb{R}^2 . Accordingly, the single measurement signal is $g_1 = [1 \ 0]^t$, yielding $A : \mathbb{R}^2 \mapsto \mathbb{R}$ given by $[1 \ 0]$ and $A^* = g_1$. The extendible set $\mathcal{E} := A(\mathcal{K})$ is the closed interval $[-1, 1]$. That \mathcal{E} is closed is implied by the boundedness of \mathcal{K} . For a given β , the feasible set \mathcal{F} is the intersection of \mathcal{K} with the line $x_1 = \beta$.

By Corollary 2, if the measurement is in the open interval $\text{ri}(\mathcal{E}) = (-1, 1)$, then there exists some scalar θ such that $\hat{x} = P_{\mathcal{K}} A^*(\theta)$ is the solution to (P). For the measurement $\beta = 1$ on the boundary of \mathcal{E} , no finite θ provides a parameterization; the measurement $\beta = -1$ is likewise on the boundary of \mathcal{E} , yet $\theta = -2$ provides the solution to (P). The dense uniqueness in Proposition 1 is illustrated by the infinitely many parameterizations, $\theta \in (\infty, -2]$, for $\beta = -1$. (A translation of \mathcal{K} by $[0 \ 1]^t$ provides an example of nonunique parameterization for β in the interior of \mathcal{E} .)

The iterative procedure of Theorems 3 and 4 is given by

$$f^{n+1}(\theta^{(0)}) = \theta^{(n+1)} = \theta^{(n)} + \lambda[\beta - AP_{\mathcal{K}} A^*(\theta^{(n)})], \quad \lambda \in (0, 2).$$

The action of $AP_{\mathcal{K}} A^* : \mathbb{R} \mapsto \mathbb{R}$ is depicted in Fig. 2 and is given by

$$AP_{\mathcal{K}} A^*(\theta) = \begin{cases} -1, & \theta \leq -2 \\ \frac{1}{2}\theta, & -2 < \theta < 0 \\ \theta(\theta^2 + 1)^{-\frac{1}{2}}, & \theta \geq 0. \end{cases}$$

The existence of a parameterization θ is equivalent to the existence of a fixed point for f . For $\beta \in [-1, 1)$, there exists a fixed point for f , and by Theorem 3, the sequence $\{\theta^{(n)}\}$ converges to a parameter yielding \hat{x} , the minimum norm element of the feasible set. For $\beta \geq 1$, f has no fixed point and $\{|\theta^{(n)}|\}$ diverges as $\lambda n \nu$, where $\nu = \beta - 1$ is the distance of β from the extendible set. Yet, by Theorem 4, the sequence $\{AP_{\mathcal{K}} A^*(\theta^{(n)})\}$ converges to $P_{\bar{\mathcal{E}}}$, and by Corollary 5, a subsequence of the

approximate reconstructions $\{P_{\mathcal{K}}A^*(\theta^{(n)})\}$ converges to the minimum norm, least-squares solution to (P') , $\hat{x} = [1 \ 1]^t$. Finally, the parameter vector is unique for every β in \mathcal{E} except $\beta = -1$, where the solution to (P) is not a regular point of \mathcal{K} .

7. Discussion. The method of successive projections is an alternative scheme for computing an element in the feasible set [26]. Treating the variety $Ax = \beta$ as an additional closed convex constraint set \mathcal{K}_{M+1} , the iteration

$$(2) \quad x^{(n+1)} = (P_{\mathcal{K}_{M+1}}P_{\mathcal{K}_M}P_{\mathcal{K}_{M-1}} \cdots P_{\mathcal{K}_1})x^{(n)}$$

converges weakly in \mathcal{S} to an element of the feasible set, provided one exists. The method is attractive in that any number of convex constraint sets may be incorporated without requiring synthesis of the projection onto the intersection $\mathcal{K} = \bigcap_{j=1}^M \mathcal{K}_j$. However, the technique does not allow the preferential selection of one feasible signal over others, as provided by the optimality criterion in (P') . In general, the limit point of Eq. (2) depends on both the initial estimate $x^{(0)}$ and the ordering of the composition of projection operators. Moreover, the iterations are performed in the (perhaps infinite-dimensional) signal space \mathcal{S} rather than in \mathfrak{R}^N and typically suffer from slow convergence rates and high computational cost per iteration [11], [24]. In addition, successive projections do not in general provide a least-squares solution when no feasible signal exists.

In contrast, the signal recovery algorithm established in Theorems 1–4 provides a finite-dimensional parameterization for a signal reconstruction. The iterative algorithm is performed in the parameter space to preferentially produce the unique least-squares solution consistent with the constraints and closest to a specified nominal signal. Moreover, Newton-Raphson iterations may typically be applied in \mathfrak{R}^N for quadratically convergent iterative computation; the requisite derivatives are guaranteed to exist almost everywhere since $AP_{\mathcal{K}}A^*$ is Lipschitz. A potential difficulty in implementing the iterative scheme in Eq. (1) is the need to construct $AP_{\mathcal{K}}A^*$, which may require numerical approximation of the projection onto \mathcal{K} , the intersection of constraint sets. Yet, in application, \mathcal{K} is physically motivated and, as such, typically gives rise to an intuitive and tractable projection operator. Furthermore, sensitivity of the solution \hat{x} to errors in the parameters $\hat{\theta}$ is low since $P_{\mathcal{K}}A^*$ is nonexpansive. Although the constraint set must be convex and the signal space is Hilbertian, the formulation admits a large and relevant class of sets for incorporating prior information.

Many well-known linear reconstruction results follow immediately from Theorem 1 for the special case of constraint sets \mathcal{K} that are subspaces, e.g., [3], [6], [12], [16]. Likewise, Theorems 1 and 2 extend, in Hilbert space, the optimization results in [2], [8], and [9] from closed convex cones to arbitrary closed convex constraint sets. For example, the minimum energy correlation extension presented in [8] and [25] may be directly obtained with $\mathcal{S} = L_2$ and \mathcal{K} the convex cone of nonnegative spectral estimates. Kuhn-Tucker, Lagrange multiplier, and Fenchel duality theorems, e.g., [13] are similar dual optimization results that have been applied to signal recovery problems and, in addition, admit cost functions more general than the weighted norm. However, the hypotheses of these classical results require nonempty interior and regularity conditions that are absent in Theorems 1–4. These seemingly technical restrictions are, in fact, of great importance to application in many practical reconstruction tasks since, for example, the set of nonnegative signals in L_2 is without interior.

8. Conclusion. Motivated by practical reconstruction, estimation, and interpolation problems, an explicit solution to a constrained minimization problem has been

derived. The finite parameterization led to a simple and computationally attractive iterative algorithm. The constraint qualification for the infinite-dimensional program with linear equality constraints and a convex set constraint extended previous results for a convex cone set constraint.

WHITE-NOISE REPRESENTATIONS IN STOCHASTIC REALIZATION THEORY*

VIVEK S. BORKAR†

Abstract. It is proved that any random sequence can be exhibited as the output of a stochastic dynamical system driven by white noise. Further refinements are obtained for Markov, stationary, and ergodic sequences. This settles some open problems in stochastic realization theory posed by Willems and Van Schuppen [*NATO ASI-AMS Seminar on Algebraic and Geometric Methods in Linear System Theory*, Harvard University, Cambridge, MA, 1979].

Key words. white-noise representation, stochastic realization theory, stochastic dynamical systems, ergodic decomposition of stationary processes, extremal measures

AMS subject classifications. 93E03, 60G05, 60G10

1. Introduction. The white-noise representation problem in stochastic realization theory is to show a given random sequence as the output of a white-noise-driven stochastic dynamical system. (This is made precise later.) The goal of this paper is to prove some conjectures of Willems and Van Schuppen [10] in this context. The paper is organized as follows: The remainder of this section recalls the problems of stochastic realization theory from [10]. Section 2 contains derivations of results concerning extremal probability measures on a product of Polish spaces with a given marginal. Section 2 somewhat overlaps [2], where similar results are used in a different context. In §3 the main result and some consequences thereof are proved. Section 4 explores the connection between the ergodic decomposition of stationary processes and their white-noise representation.

The results proved here were conjectured in [10]. See [9] and [10] for extensive surveys of stochastic realization theory and further references, and see [4] for the important special case of linear stochastic realization theory.

The principal problems of abstract stochastic realization theory are as follows.

(i) *Strong stochastic realization problem:* Given a random sequence $\{Y_n\}$ on a probability space (Ω, \mathcal{F}, P) , construct on this probability space another sequence of random variables $\{X_n\}$ such that $[(X_{n-1}, Y_{n-1}), (X_{n-2}, Y_{n-2}), \dots]$ and $[(X_n, Y_n), (X_{n+1}, Y_{n+1}), \dots]$ are conditionally independent, given X_n for each n . (In particular, $\{X_n\}$ is Markov.)

(ii) *Weak stochastic realization problem:* Given $\{Y_n\}$ as in problem (i), construct on some probability space $(\Omega', \mathcal{F}', P')$ random sequences $\{X'_n\}$ and $\{Y'_n\}$ such that $[(X'_{n-1}, Y'_{n-1}), (X'_{n-2}, Y'_{n-2}), \dots]$ and $[(X'_n, Y'_n), (X'_{n+1}, Y'_{n+1}), \dots]$ are conditionally independent given X'_n for each n and that $\{Y_n\}$ and $\{Y'_n\}$ agree in law. (Again, $\{X'_n\}$ is Markov.)

(iii) *Strong white-noise representation problem:* Given a strong realization as in (i), construct on the same probability space two independent and identically distributed sequences $\{W_n\}$, $\{W'_n\}$ independent of each other such that

$$(1.1) \quad X_{n+1} = f_n(W_n, X_n),$$

$$(1.2) \quad Y_n = g_n(W'_n, X_n)$$

for each n and measurable $\{f_n\}$ and $\{g_n\}$. $\{W_n\}$ and $\{W'_n\}$ are called white-noise sequences (signal and observation noise, respectively).

* Received by the editors May 20, 1991; accepted for publication (in revised form) February 6, 1992.

† Department of Electrical Engineering, Indian Institute of Science, Bangalore 560 012, India.

(iv) *Weak white-noise representation problem*: This is the same as problem (ii) for a given weak realization, except that $\{W_n\}$, $\{W'_n\}$ are now constructed on $(\Omega', \mathcal{F}', P')$ or an augmentation of it. (Here and later, an augmentation of a probability space (Ω, \mathcal{F}, P) will mean a new probability space $(\bar{\Omega}, \bar{\mathcal{F}}, \bar{P})$ such that for some measurable space (E, ξ) , $\bar{\Omega} = \Omega \times E$, $\bar{\mathcal{F}} = \mathcal{F} \times \xi$, and P is the image of \bar{P} under the projection $(\bar{\Omega}, \bar{\mathcal{F}}) \rightarrow (\Omega, \mathcal{F})$.)

(v) *Minimal realization problem*: A strong (respectively, weak) realization as in problem (i) (respectively, problem (ii)) is minimal if there is no other strong (respectively, weak) realization $\{\tilde{X}_n\}$ and $\{Y_n\}$ (respectively, $\{\tilde{X}_n\}$, and $\{Y'_n\}$) on the same probability space such that $\sigma(\tilde{X}_i, i \leq n) \subset \sigma(X_i, i \leq n)$ (respectively, $\sigma(X'_i, i \leq n)$) for each n with the inclusion being strict for at least one n . Characterize all minimal realizations.

We settle problem (iv) above completely and prove by example that problem (iii) does not always have a solution.

We have not yet specified the hypotheses on the spaces in which the above sequences take values. We assume these to be Polish spaces, i.e., separable and metrizable with a complete metric. An important result concerning Polish spaces is that, given two Polish spaces of the same cardinality (in particular, two uncountable Polish spaces), there is a measurable isomorphism between them ([5, Thm. 2.12]). We use this result often and refer to it simply as the *isomorphism theorem*. For any Polish space X , $P(X)$ will denote the Polish space of probability measures on X with Prohorov topology [1], [5].

2. Extremal measures with a given marginal. In this section, we recall from [2] some results on probability measures on a product of Polish spaces having a given marginal on one of them. Details are included to make the present account self-contained.

Let S_1, S_2 be Polish spaces endowed with their Borel σ -fields. Let μ be a probability measure on $S_1 \times S_2$ that disintegrates [8] as

$$(2.1) \quad \mu(dx, dy) = \nu(dx)v(x, dy),$$

where ν is the image of μ under the projection $S_1 \times S_2 \rightarrow S_1$ and $x \rightarrow v(x, \cdot) : S_1 \rightarrow P(S_2)$ is the regular conditional law defined ν -almost surely uniquely. Let Q be the set of all such μ when ν is a prescribed element of $P(S_1)$. Q is clearly closed convex in $P(S_1 \times S_2)$. Let Q_e be the set of all extreme points of Q , and let $Q_D \subset Q$ be the set of those μ for which $v(x, \cdot)$ is a Dirac measure for ν -almost surely x . The main result of this section is that $Q_e = Q_D$.

Let $f \in C_b(S_2)$, and let $q \in P(S_2)$. Let $b \in R$ be the unique least number such that

$$g(\{x | f(x) < b\}) \leq \frac{1}{2},$$

$$q(\{x | f(x) > b\}) \leq \frac{1}{2}.$$

Let $A_1 = \{x | f(x) < b\}$, $A_2 = \{x | f(x) > b\}$, and $A_3 = \{x | f(x) = b\}$. Let $\delta \in [0, 1]$ be such that

$$q(A_1) + \delta q(A_3) = q(A_2) + (1 - \delta)q(A_3) = \frac{1}{2},$$

where $\delta = 0$ when $q(A_3) = 0$. Define $\alpha_1(q), \alpha_2(q) \in P(S_2)$ by

$$\alpha_1(q) = 2(I_{A_1} + \delta I_{A_3})q,$$

$$\alpha_2(q) = 2(I_{A_2} + (1 - \delta)I_{A_3})q.$$

It is not difficult to verify that α_1, α_2 are measurable maps $P(S_2) \rightarrow P(S_2)$. In fact, by [3, Thm. 2.1] this is equivalent to verifying that, for all Borel $A \subset S_2$, the map $q \rightarrow \alpha_1(q)(A)$ is measurable for $i = 1, 2$. Consider, say, $i = 1$. Then

$$\alpha_1(q)(A) = 2q(A \cap A_1) + 2\delta q(A \cap A_3),$$

where A_1 , A_3 , and δ depend on q through their dependence on b . Write b as $b(q)$ to make its q dependence explicit. By the foregoing and [3, Thm. 2.1], it suffices to prove that the map $q \rightarrow b(q)$ is measurable. However, for $c \in R$,

$$\{q | b(q) > c\} = \{q | q(\{x | f(x) \geq c\}) > \frac{1}{2}\},$$

which is measurable by [3, Thm. 2.1], and we are done.

Note that

$$(2.2) \quad q = \frac{1}{2}(\alpha_1(q) + \alpha_2(q)).$$

LEMMA 2.1. *If $\mu \in Q \setminus Q_D$, there exist a Borel set $A \subset S_1$ and an $f \in C_b(S_2)$ such that $\nu(A) > 0$, and, for $x \in A$, $f(\cdot)$ is not a constant $\nu(x)$ -almost surely.*

Proof. Let $\{f_i\}$ be a countable subset of $C_b(S_2)$ that separates points of $P(S_2)$. (See Remark 2.1 below.) Suppose that for ν -almost surely x , f_i is $\nu(x)$ -almost surely a constant for all i . Then $\nu(x)$ is a Dirac measure for such x , contradicting the hypothesis $\mu \notin Q_D$. Thus there exists a Borel set $A' \subset S_1$ such that $\nu(A') > 0$ and for $x \in A'$, f_i is not a constant $\nu(x)$ -almost surely for some i . Let

$$A_i = \{x \in S_1 | f_i \text{ is not a constant } \nu(x)\text{-almost surely}\}, \quad i = 1, 2.$$

Then A_i is the complement of

$$(2.3) \quad \bigcap_m \left\{x \in S_1 \mid \int g_m f_i \, d\nu(x) = \int g_m \, d\nu(x) \int f_i \, d\nu(x)\right\}$$

for a countable collection $\{g_m\}$ in $C_b(S_2)$ with the property that $\int g_i \, dm_1 = \int g_i \, dm_2$ for all i implies that $m_1 = m_2$ for finite signed measures m_1 and m_2 on S_2 . Expression (2.3) and hence A_i are measurable. We may set $A' = \bigcup_i A_i$. Then $\nu(A') > 0$ implies that $\nu(A_{i_0}) > 0$ for some i_0 , and the claim follows with $f = f_{i_0}$, $A = A_{i_0}$. \square

Remark 2.1. The family $\{f_i\}$ can be chosen as follows. Let d be any complete metric on S_2 taking values in $[0, 1]$ and consistent with the topology of S_2 . Map S_2 homeomorphically onto a G_δ subset S'_2 of $[0, 1]^\infty$ as in [1, pp. 219–220]. Then S'_2 is compact, and therefore $C(\bar{S}'_2)$ is separable. Take a countable dense subset of $C(\bar{S}'_2)$, restrict it to S'_2 , and pull it back by means of the homeomorphism.

A similar remark applies to the choice of $\{g_m\}$.

LEMMA 2.2. $Q_e = Q_D$.

Proof. Let $\mu \in Q_e$. Suppose that $\mu \notin Q_D$. Pick A and f as in Lemma 2.1. Then $\alpha_1(\nu(x, \cdot))$ and $\alpha_2(\nu(x, \cdot))$ must differ from each other for $x \in A$. Define μ_1 and μ_2 by

$$\mu_i(dx, dy) = \nu(dx) \alpha_i(\nu(x, dy)), \quad i = 1, 2.$$

By (2.2), $\mu = (\mu_1 + \mu_2)/2$. Clearly, $\mu_1 \neq \mu_2$. Thus $\mu \notin Q_e$, a contradiction. Thus $Q_e \subset Q_D$. Conversely, supposed that $\mu \in Q_D$ is of the form $\mu = (\mu_1 + \mu_2)/2$ for some $\mu_1 \neq \mu_2$ in Q . Then, for

$$\mu_i(dx, dy) = \nu(dx) v_i(x, dy), \quad i = 1, 2,$$

$v_1(x, \cdot)$ and $v_2(x, \cdot)$ must differ for x in a set of strictly positive ν -measure. For such x , however, $\nu(x, \cdot) = (v_1(x, \cdot) + v_2(x, \cdot))/2$ cannot be Dirac, a contradiction. Thus $Q_D \subset Q_e$. \square

We deduce some important consequences of this based on a small extension of Choquet's theorem, which follows.

LEMMA 2.3. *Let X be a Polish space, and let $G \subset P(X)$ be a closed convex set, with $G_e \subset G$ the set of its extreme points. Then every element of G is the barycenter of a probability measure on G_e .*

Proof. If G is compact, the proof is immediate from the classical Choquet's theorem [6]. As described in Remark 2.1, X is homeomorphic to a G_δ subset Y of $[0, 1]^\infty$. We identify X and Y and denote by \bar{X} the closure of X in $[0, 1]^\infty$. (Note that the corresponding identification between $P(X)$ and $P(Y)$ preserves extreme points of convex sets.) \bar{X} and therefore $P(\bar{X})$ are compact. View $P(X)$ as a subset of $P(\bar{X})$ by identifying each element μ of $P(X)$ with its unique extension $\bar{\mu}$ in $P(\bar{X})$, i.e., $\bar{\mu}$ restricts to μ on X and $\bar{\mu}(\bar{X} \setminus X) = 0$. Let \bar{G} be the closure of G in $P(\bar{X})$, and let \bar{G}_e be the set of its extreme points. By Choquet's theorem, each $\mu \in G$ is the barycenter of some $\eta \in P(\bar{G}_e)$. Fix μ and η . If an element e of G_e is not in \bar{G}_e , it must be a convex combination of two distinct elements of \bar{G} at least one of which must charge $\bar{X} \setminus X$. (Otherwise, both are in G , contradicting $e \in G_e$.) However, then $e(\bar{X} \setminus X) > 0$, contradicting $e \in G$. Thus $G_e \subset \bar{G}_e$. If $\eta(\bar{G}_e \setminus G_e) > 0$, $\mu(\bar{X} \setminus X) > 0$ because each $\mu' \in \bar{G}_e \setminus G_e$ satisfies $\mu'(\bar{X} \setminus X) > 0$. This is impossible, however. Hence $\eta(G_e) = 1$, proving the claim. \square

COROLLARY 2.1. *Each $\mu \in Q$ is the barycenter of a probability measure η supported on Q_D .*

This is immediate in view of the foregoing. Suppose now that S_1 above is of the form $S' \times S''$, where S' and S'' are Polish spaces. Also, let μ of (2.1) be of the form

$$(2.4) \quad \mu(dx, dy, dz) = \varphi(dy)\psi_1(y, dx)\psi_2(y, dz)$$

for $\varphi \in P(S'')$ and $\psi_1 : S'' \rightarrow P(S')$, $\psi_2 : S'' \rightarrow P(S_2)$ measurable.

COROLLARY 2.2. *The measure μ of (2.4) is the barycenter of a probability measure η on Q_D satisfying the additional property that η is supported on the subset of Q_D consisting of probability measures of the type*

$$(2.5) \quad \varphi(dy)\psi_1(y, dx)q(y, dz),$$

where $q(y, \cdot) \in P(S_2)$ is a Dirac measure for φ -almost surely y .

Proof. Applying Corollary 2.1 to the measure

$$\varphi(dy)\psi_2(y, dz)$$

on $S'' \times S_2$, we see that it is the barycenter of a probability measure on the set of probability measures of the type

$$(2.6) \quad \varphi(dy)q(y, dz),$$

where $q(y, \cdot)$ is Dirac for φ -almost surely y . Given the obvious one-to-one correspondence between measures (2.5) and (2.6), the claim follows. \square

3. White-noise representation. Let X and Y be random variables on some probability space (Ω, \mathcal{F}, P) , taking values in Polish spaces S_1 and S_2 , respectively.

LEMMA 3.1. *There exists a probability space $(\Omega', \mathcal{F}', P')$ with random variables X', Y' , and Z' defined on it, taking values in S_1 , S_2 , and $P(S_1 \times S_2)$, respectively, such that (a) (X', Y') agree in law with (X, Y) , (b) (Y', Z') are independent, and (c) $X' = f(Z', Y')$ for a measurable $f : P(S_1 \times S_2) \times S_2 \rightarrow S_1$.*

Proof. Let the μ of (2.1) be the law of (Y, X) , and let η be as in Corollary 2.1. Then η is supported on probability measures on $S_2 \times S_1$ of the type

$$\nu(dx)\delta_{g(x)}(dy),$$

where δ_z is the Dirac measure at z . Let $\Omega' = P(S_1 \times S_2) \times S_2 \times S_1$ with \mathcal{F}' = the product σ -field and P' = the probability measure on (Ω', \mathcal{F}') defined by

$$P'(d\rho, dx, dy) = \eta(d\rho)\rho(dx, dy) = \eta(d\rho)\nu(dx)\delta_{f(\rho, x)}(dy)$$

for a measurable $f: P(S_1 \times S_2) \times S_2 \rightarrow S_1$. Let (Z', Y', X') be the canonically realized random variables on this probability space. (That is, if $\omega = (\omega_1, \omega_2, \omega_3)$ is a typical element of Ω' , then $Z'(\omega) = \omega_1$, $Y'(\omega) = \omega_2$, and $X'(\omega) = \omega_3$.) The claim follows. \square

COROLLARY 3.1. *In Lemma 3.1, $P(S_1 \times S_2)$ may be replaced by any prescribed uncountable Polish space S (say, $[0, 1]$) without any loss of generality.*

Proof. We may suppose that S_1 and S_2 are not singletons. (If, say, $S_1 = \{a\}$, replace it by $S_1 = \{a, b\}$, $b \neq a$, with $P(X = b) = 0$.) Then $P(S_1 \times S_2)$ is uncountable. By the isomorphism theorem there exists a measurable isomorphism $g: P(S_1 \times S_2) \rightarrow S$. Letting $\tilde{Z} = g(Z')$ and $\tilde{f}(\cdot, \cdot) = f(g^{-1}(\cdot), \cdot): S \times S_2 \rightarrow S_1$, we have $X' = \tilde{f}(\tilde{Z}, Y')$. \square

COROLLARY 3.2. *In Lemma 3.1 we may take $S = [0, 1]$ and \tilde{Z} to be uniformly distributed.*

Proof. Let $S = [0, 1]$, and let \tilde{f} and \tilde{Z} be as in Corollary 3.1. Let $F: [0, 1] \rightarrow [0, 1]$ be the distribution function of \tilde{Z} . Then F is nondecreasing and right-continuous. Defining $q: [0, 1] \rightarrow [0, 1]$ by

$$q(x) = \min F^{-1}(\min(F([0, 1]) \cap [x, 1])),$$

we check that the law of \tilde{Z} is the image of the uniform measure on $[0, 1]$ under q . For a random variable T uniformly distributed on $[0, 1]$, let $x \mapsto r(x, du): [0, 1] \rightarrow P([0, 1])$ denote a version of the regular conditional law of T , given $q(T)$. Augment the probability space $(\Omega', \mathcal{F}', P')$ in Lemma 3.1 as follows: Replace Ω' by $\Omega' \times [0, 1]$, replace \mathcal{F}' by its product with the Borel σ -field of $[0, 1]$, and replace P' by the probability measure $P'(dw)r(\tilde{Z}(w), dw')$. Define a new $[0, 1]$ -valued random variable Z on this probability space by $Z((w, w')) = w'$. Then Z is uniformly distributed on $[0, 1]$ and $\tilde{Z} = q(Z)$. Thus $X' = f'(Z, Y')$, where $f'(\cdot, \cdot) = \tilde{f}(q(\cdot), \cdot)$. \square

COROLLARY 3.3. *In Lemma 3.1 we may take $X' = X$ and $Y' = Y$, and we may take Z' (or \tilde{Z} or Z) to be a random variable constructed on an augmentation of the probability space (Ω, \mathcal{F}, P) .*

Proof. To be specific, we prove the statement for Z' . Augment (Ω, \mathcal{F}, P) as follows: Replace Ω by $\Omega \times P(S_1 \times S_2)$, replace \mathcal{F} by its product with the Borel σ -field of $P(S_1 \times S_2)$, and replace P by a new probability measure defined as follows. Let $v: S_1 \times S_2 \rightarrow P(P(S_1 \times S_2))$ be a version of the regular conditional law of Z' , given X' and Y' . Replace P by the probability measure

$$P(dw)v((X(w), Y(w)), dz).$$

Define a $P(S_1 \times S_2)$ -valued random variable \tilde{Z} on this new probability space by $\tilde{Z}((w, z)) = z$, where (w, z) is a typical sample point of $\Omega \times P(S_1 \times S_2)$. By construction, the laws of (X', Y', Z') and (X, Y, \tilde{Z}) agree. \square

The implications for stochastic realization theory follow. Let U be an uncountable Polish space.

THEOREM 3.1. *Let $\{X_n, n = 0, 1, 2, \dots\}$ be a random sequence taking values in a Polish space S and defined on a probability space (Ω, \mathcal{F}, P) . Then, on another probability space $(\Omega', \mathcal{F}', P')$, we can construct S -valued random variables $\{X'_n, n = 0, 1, 2, \dots\}$ and U -valued independent and identically distributed random variables $\{W_n\}$ such that $\{X_n\}$ and $\{X'_n\}$ agree in law, W_n is independent of $(X'_{n-1}, W_{n-1}, X'_{n-2}, W_{n-2}, \dots, X'_0, W_0)$ for each n and*

$$(3.1) \quad X'_n = f_n(W_n, X'_{n-1}, X'_{n-2}, \dots, X'_0)$$

for measurable $f_n: U \times S^n \rightarrow S$, $n = 1, 2, \dots$. Furthermore, if $\{X_n\}$ is Markov, (3.1) may be replaced by

$$(3.2) \quad X'_n = f_n(W_n, X'_{n-1})$$

for measurable $f_n: U \times S \rightarrow S$, $n = 1, 2, \dots$.

Proof. We first prove (3.1) for independent but not necessarily identically distributed $\{W_n\}$ with W_n independent of $(X'_{n-1}, X'_{n-2}, \dots)$ for each n . For $n = 1$ the claim follows from Lemma 3.1. Suppose that it is true for $n \leq m$. Let μ denote the law of $(X_0, \dots, X_m, W_1, \dots, W_m)$, written as

$$\begin{aligned} \mu(dx_0, \dots, dx_m, dw_1, \dots, dw_m) \\ = \nu(dx_0, \dots, dx_m)q((x_0, \dots, x_m), (dw_1, \dots, dw_m)), \end{aligned}$$

where ν is the law of (X_0, \dots, X_m) and $(x_0, \dots, x_m) \rightarrow q((x_0, \dots, x_m), (dw_1, \dots, dw_m))$ is a version of the regular conditional law of (W_1, \dots, W_m) , given (X_0, \dots, X_m) . Consider the probability measure

$$\begin{aligned} \bar{\mu}(dx_0, \dots, dx_{m+1}, dw_1, \dots, dw_m) \\ = \nu(dx_0, \dots, dx_m)q((x_0, \dots, x_m), (dw_1, \dots, dw_m))r((x_0, \dots, x_m), dx_{m+1}), \end{aligned}$$

where $(x_0, \dots, x_m) \rightarrow r((x_0, \dots, x_m), dx_{m+1})$ is the regular conditional law of X_{m+1} , given (X_0, \dots, X_m) . By Corollary 2.2 this is the barycenter of a measure η on $P(S^{m+2} \times U^m)$ concentrated on probability measures of the type

$$\nu(dx_0, \dots, dx_m)q((x_0, \dots, x_m), (dw_1, \dots, dw_m))\delta_{f(x_0, \dots, x_m)}(dx_{m+1}).$$

Consider $P(S^{m+2} \times U^m) \times S^{m+1} \times U^m \times S$ with the probability measure

$$\begin{aligned} \eta(d\rho)\rho(dx_0, \dots, dx_m, dw_1, \dots, dw_m, dx_{m+1}) \\ = \eta(d\rho)\mu(dx_0, \dots, dx_m, dw_1, \dots, dw_m)\delta_{\varphi(\rho, x_m, \dots, x_0)}(dx_{m+1}) \end{aligned}$$

for a measurable $\varphi: P(S^{m+2} \times U^m) \times S^{m+1} \rightarrow S$. If $(\bar{W}_{m+1}, X'_0, \dots, X'_m, W'_1, \dots, W'_m, X'_{m+1})$ denote the canonically realized random variables on this space, it follows by construction that

$$X'_{n+1} = \varphi(\bar{W}_{n+1}, X'_n, \dots, X'_n)$$

and that \bar{W}_{n+1} is independent of $X'_0, \dots, X'_n, W'_1, \dots, W'_n$. The desired claim now follows by induction. By adapting the argument of Corollary 3.1, we may replace $P(S^{n+2} \times U^n)$, $n = 0, 1, 2, \dots$, by $[0, 1]$ and then use the construction of Corollary 3.2 to replace $\{\bar{W}_n\}$ by independent and identically distributed random variables uniformly distributed on $[0, 1]$. In turn, the isomorphism theorem allows us to replace these by independent and identically distributed random variables taking values in any prescribed uncountable Polish space as in the proof of Corollary 3.1. Equation (3.2) is also proved by analogous arguments in view of Corollary 2.2. \square

THEOREM 3.2. Let $\{X_n, n = 0, \pm 1, \pm 2, \dots\}$ be a sequence of S -valued random variables on a probability space (Ω, \mathcal{F}, P) . Then we can construct on some probability space $(\Omega', \mathcal{F}', P')$ a sequence of S -valued random variables $\{X'_n, n = 0, \pm 1, \pm 2, \dots\}$ and U -valued independent and identically distributed random variables $\{W_n, n = 0, \pm 1, \pm 2, \dots\}$ such that $\{X_n\}$ and $\{X'_n\}$ agree in law, W_n is independent of $(X_{n-1}, W_{n-1}), (X_{n-2}, W_{n-2}), \dots$ for each n , and

$$X_n = f_n(W_n, X_{n-1}, X_{n-2}, \dots)$$

for measurable $f_n: U \times S^\infty \rightarrow S$, $n = 0, \pm 1, \pm 2, \dots$. Furthermore, if $\{X_n\}$ is a stationary process, $\{f_n\}$ may be taken to be independent of n .

Proof. Proceeding as in Theorem 3.1, we can construct a sequence of processes $(X_n^m, W_n^m, n = 0, \pm 1, \pm 2, \dots)$, $m = 1, 2, \dots$, such that $\{X_n^m\}$ and $\{X_n\}$ agree in law, $W_n^m, n = -m, -m + 1, -m + 2, \dots$ is an independent and identically distributed sequence uniformly distributed on $[0, 1]$ and satisfying the following: W_{-m+i}^m is independent of $(X_{-m+i-1}^m, W_{-m+i-1}^m), (X_{-m+i-2}^m, W_{-m+i-2}^m), \dots$, for each $i \geq 0$, $W_n^m =$ a prescribed element u of $[0, 1]$ for $n < -m$, and for each $n \geq -m$

$$X_n^m = f_n(W_n^m, X_{n-1}^m, X_{n-2}^m, \dots).$$

(We simply mimic the steps of Theorem 3.1 with $(X_0^m, X_{-1}^m, X_{-2}^m, \dots)$ in place of X_0^m . That f_n can be taken to be independent of m is a consequence of the fact that this choice depends purely on the joint law of $(X_n^m, X_{n-1}^m, X_{n-2}^m, \dots)$, which is the same as that of (X_n, X_{n-1}, \dots) and is thus independent of m .) As $m \rightarrow \infty$, this sequence of processes is seen to converge in law to a process $(X_n', W_n, n = 0, \pm 1, \pm 2, \dots)$, which satisfies the requirements of the first claim. The second claim then follows from the observation that the possible choices of f_n are dictated by the joint law of $X_n, X_{n-1}, X_{n-2}, \dots$, which is independent of n for a stationary process. Finally, the isomorphism theorem allows us, as usual, to replace $\{W_n\}$ above by independent and identically distributed random variables taking values in any prescribed uncountable Polish space U . \square

COROLLARY 3.4. Let $(X_n, n = 0, \pm 1, \pm 2, \dots)$ be a stationary Markov process on a probability space (Ω, \mathcal{F}, P) . Then there exist on some probability space $(\Omega', \mathcal{F}', P')$ processes $(X_n', W_n, n = 0, \pm 1, \pm 2, \dots)$ such that $\{X_n'\}$ and $\{X_n\}$ agree in law, $\{W_n\}$ are independent and identically distributed U -valued random variables with W_n independent of $(X_{n-1}', W_{n-1}'), (X_{n-2}', W_{n-2}', \dots)$ for each n , and $X_n = f(W_n, X_{n-1})$ for each n and some measurable $f: U \times S \rightarrow S$.

This is obvious from the foregoing. Recall the definitions of a weak realization (ii) and weak white-noise representation (iv).

THEOREM 3.3. Given a weak stochastic realization $(\{X_n'\}, \{Y_n'\})$ of a random sequence $\{Y_n\}$ of S -valued random variables, a weak white-noise representation as in (1.1)–(1.2) exists. At least one weak realization exists. Moreover, if $\{Y_n, n = 0, \pm 1, \pm 2, \dots\}$ is stationary, one exists in which $\{X_n\}$ is also stationary.

Proof. The first claim is proved by a straightforward adaptation of the proofs of Theorems 3.1 and 3.2. The second claim follows from the trivial observation that $X_n = [Y_n, Y_{n-1}, Y_{n-2}, \dots]$ (with $Y_{-m}, m \leq 1$, equal to a fixed element of S when the original $\{Y_n\}$ are defined for only $n = 0, 1, 2, \dots$) is an S^∞ -valued Markov process and $Y_n = g(X_n)$, where $g: S^\infty \rightarrow S$ is the projection onto the first factor space. The last claim also follows similarly. \square

Remark 3.1. As in Corollary 3.3, we may construct the processes $\{X_n'\}$ and $\{W_n'\}$ on an augmentation of the original probability space (Ω, \mathcal{F}, P) . This augmentation in general cannot be avoided, as the following example shows. (Thus the strong white-noise representation is not always feasible.) Let X and Y be random variables taking values in $\{a, b\}$ and $\{c, d\}$, respectively, with

$$P(Y = c) = P(Y = d) = \frac{1}{2},$$

$$P(X = a/Y = c) = \frac{1}{2} = P(X = b/Y = c),$$

$$P(X = a/Y = d) = \frac{1}{3} = 1 - P(X = b/Y = d).$$

The law of (X, Y) is then the barycenter of a probability measure supported on the four probability measures $\{\mu_1, \mu_2, \mu_3, \mu_4\}$ on $\{a, b\} \times \{c, d\}$ described as follows:

$$\mu_i(Y = c) = \mu_i(Y = d) = \frac{1}{2} \text{ for } 1 \leq i \leq 4 \text{ and}$$

$$\mu_1(X = a/Y = c) = 1 = \mu_1(X = b/Y = d),$$

$$\mu_2(X = b/Y = c) = 1 = \mu_2(X = b/Y = d),$$

$$\mu_3(X = a/Y = c) = 1 = \mu_3(X = a/Y = d),$$

$$\mu_4(X = b/Y = c) = 1 = \mu_4(X = a/Y = d).$$

In fact, $\eta(\{\mu_1\}) = \eta(\{\mu_2\}) = \frac{1}{3}$, and $\eta(\{\mu_3\}) = \eta(\{\mu_4\}) = \frac{1}{6}$.

As above, we can construct on a possibly augmented probability space a random variable W taking values in $\{\mu_1, \mu_2, \mu_3, \mu_4\}$ with law η such that $X = f(W, Y)$ for a suitably defined f . A simple calculation using the Bayes rule shows that $P(W = \mu_i/X = a, Y = c) > 0$ for $i = 1, 3$. Thus W cannot be expressed as a function of (X, Y) . Suppose that (X, Y) were canonically realized on their canonical space $\{a, b\} \times \{c, d\}$. Then any random variable defined on this space must be a function of (X, Y) , and therefore W cannot be realized on this space unless we allow for its augmentation.

4. Connections with the ergodic decomposition of stationary processes. This section proves another conjecture of Willems and Van Schuppen [10] concerning white-noise representations of stationary sequences (see [7] for some related work). Let $X_n, n = 0, \pm 1, \pm 2, \dots$ be a stationary sequence of S -valued random variables. As in Theorem 3.2, we have

$$X_n = f(W_n, X_{n-1}, X_{n-2}, \dots), \quad n = 0, \pm 1, \pm 2, \dots,$$

where $\{W_n\}$ are independent and identically distributed U -valued random variables such that W_n is independent of $(X_{n-1}, W_{n-1}), (X_{n-2}, W_{n-2}), \dots$. Thus

$$\begin{aligned} X_n &= f(W_n, f(W_{n-1}, X_{n-1}, X_{n-2}, \dots), f(W_{n-2}, X_{n-2}, X_{n-3}, \dots), \dots) \\ &= f(W_n, f(W_{n-1}, f(W_{n-2}, X_{n-2}, \dots)), f(W_{n-2}, f(W_{n-3}, X_{n-3}, \dots)), \dots). \end{aligned}$$

Iterating, we may hope to get

$$(4.1) \quad X_n = F(W_n, W_{n-1}, W_{n-2}, \dots), \quad n = 0, \pm 1, \pm 2, \dots,$$

for a measurable $F: U^\infty \rightarrow S$. As observed in [10], this may not always be possible. We prove below that such a representation holds if and only if $\{X_n\}$ is an ergodic sequence, as conjectured in [10]. For simplicity, we set $U = [0, 1]$ and assume $\{W_n\}$ to be uniformly distributed on $[0, 1]$. This causes no loss of generality, as already observed. We write $X = [\dots, X_{n-1}, X_n, X_{n+1}, \dots]$ and $W = [\dots, W_{n-1}, W_n, W_{n+1}, \dots]$. Also, let θ denote the shift operator on S^∞ or U^∞ , as the case may be, which maps $(\dots, x_{n-1}, x_n, \dots)$ into $(\dots, x_n, x_{n+1}, \dots)$.

In the setup of §2, let $S_1 = U^\infty$ and $S_2 = S^\infty$, and let Q be the set of $\mu \in P(S_1 \times S_2)$ satisfying the following: μ disintegrates as in (2.1) with both ν and $x \rightarrow v(x, \cdot)$ invariant under θ (that is, $\nu(A) = \nu(\theta^{-1}(A))$ and $v(x, B) = v(\theta x, \theta^{-1}(B))$ for all Borel $A \subset U^\infty$ and $B \subset S^\infty$ and for all $x \in U^\infty$). Argue as in §2 to show that the extreme points of Q are precisely those μ for which $x \rightarrow v(x, \cdot)$ is Dirac for ν -almost surely x (and, of course, θ -invariant). Thus each $\bar{\mu} \in Q$ is the barycenter of a probability measure on the set of such measures. Argue as for Lemma 3.1 and Corollary 3.3 to conclude that

$$(4.2) \quad X = g(Z, W)$$

for a random variable Z independent of W and uniformly distributed on $[0, 1]$, defined possibly on an augmentation of the original probability space, and a measurable $g : [0, 1] \times U^\infty \rightarrow S^\infty$, which, in view of the above discussion, satisfies

$$\theta g(\cdot, \cdot) = g(\cdot, \theta(\cdot)).$$

Hence (4.2) is equivalent to the infinitely many equations

$$(4.3) \quad X_n = f(Z, \theta^n(W)), \quad n = 0, \pm 1, \pm 2, \dots,$$

where $f = p \circ g$, where $p : S^\infty \rightarrow S$ is the projection $(\dots, x_{-1}, x_0, x_1, \dots) \rightarrow x_0$. For $z \in [0, 1]$, define

$$X^z = [\dots, X_{n-1}^z, X_n^z, X_{n+1}^z, \dots]$$

by

$$X_n^z = f(z, \theta^n(W)), \quad n = 0, \pm 1, \pm 2, \dots$$

Then $\{X_n^z, n = 0, \pm 1, \pm 2, \dots\}$ are stationary processes for $z \in [0, 1]$ with laws denoted by, say, $L_z \in P(S^\infty)$. By (4.3), $L =$ (the law of X) is the barycenter of a probability measure η on $L_z, z \in [0, 1]$. Suppose that L_z is not a constant element of $P(S^\infty)$ for almost every $z \in [0, 1]$. Then there exist $m \geq 1$ and $f \in C_b(S^m)$ such that

$$h(z) = \int f(x_1, \dots, x_m) dL_z(\dots, x_{-1}, x_0, x_1, \dots), \quad z \in [0, 1]$$

is not a constant Lebesgue almost everywhere. It is clear that

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^{n-1} f(X_{i+1}, X_{i+2}, \dots, X_{i+m}) = h(Z)$$

almost surely. The left-hand side is a random variable measurable with respect to the shift-invariant σ -field of X (consisting of all events of the type $\{X \in A\}$, A Borel in S^∞ , that satisfy $\{X \in A\} = \{\theta^n X \in A\}$ for all n). Since it is not a constant almost surely, this σ -field is not trivial, and therefore X cannot be ergodic. Hence, if X is ergodic, L_z must be a constant element of $P(S^\infty)$ for almost every z , and thus $X' = g(z, W)$ is a replica in law of X for almost every z in $[0, 1]$. On the other hand, if L_z is a constant element of $P(S^\infty)$ for almost every z in $[0, 1]$, then $X' = g(z, W)$ is a replica in law of X for almost every z in $[0, 1]$. The shift-invariant σ -field of X' (consisting of all events of the type $\{X' \in A\}$, A Borel on S^∞ , that satisfy $\{X' \in A\} = \{\theta^n X' \in A\}$ for all n) is contained in the shift-invariant σ -field of W . However, W is an ergodic process, and therefore its shift-invariant σ -field is trivial. Thus the shift-invariant σ -field of X' is trivial, and X' and therefore X are ergodic. We have proved that $X_n = f(\theta^n W)$ for all n and some measurable $f : U^\infty \rightarrow S$ if and only if X is ergodic. However, for each n , $(W_{n+1}, W_{n+2}, \dots)$ is independent of X_n, W_n, W_{n-1}, \dots . Thus the law of $[(W_{n+1}, W_{n+2}, \dots), (W_n, W_{n-1}, \dots), (X_n)]$ is of the form

$$\varphi_1(dW_{n+1}, dW_{n+2}, \dots) \varphi_2(dW_n, dW_{n-1}, \dots) q((W_n, W_{n-1}, \dots), dx_n)$$

for $\varphi_1, \varphi_2 \in P(U^\infty)$, $q : U^\infty \rightarrow P(S)$. If X_n is a function of $\theta^n W$, $q((W_n, W_{n-1}, \dots), dx_n)$ must be a Dirac measure at, say, $f'(W_n, W_{n-1}, \dots)$. However, then $X_n = f'(W_n, W_{n-1}, \dots)$. This completes the proof of our desired result.

THEOREM 4.1. $\{X_n\}$ has a representation (on a possibly augmented probability space) of the type (4.1) if and only if it is ergodic.

In conclusion, we remark on some important issues not touched on in this paper. The first, of course, is the minimal realization problem mentioned in the Introduction. It is not clear whether an explicit white-noise representation will contribute to its resolution. In the context of the white-noise representation in (1.1) and (1.2) (for a given weak realization), we can pose some interesting minimality questions. Consider the stationary Markov case for simplicity. The representation then is

$$X_n = f(W_n, X_{n-1}).$$

Both f and the distribution F of W_n are not unique, as already seen. Can we find the “best” pair (f, F) with respect to a suitable complexity measure? Obviously, “best” would mean “minimum complexity.” Possibly there would be a tradeoff between the (as yet undefined) complexities of f and F , which we can hope to quantify.

Another relevant issue not touched on here is whether we can give conditions on the law of $\{X_n\}$ that ensure a suitable level of regularity (continuity, Lipschitz property, and so forth) of the functions $\{f_n\}$ and $\{g_n\}$ featured in (1.1) and (1.2).

Note added in proof. After the editorial process for this paper was over, the author came across a paper by Brown [11] whose Lemma 1, p. 178 gives an easy proof of Theorem 3.1, above, for $[0, 1]$ -valued random variables. The general case may then be deduced by invoking the isomorphism theorem. The proof given in the present paper, however, is somewhat more direct in the case of general Polish spaces and may be of some value in pursuing the open issues listed in the concluding paragraphs of the present paper.

THE MINIMAL TIME FUNCTION IN INFINITE DIMENSIONS*

OVIDIU CÂRJĂ†

Abstract. The goal of this paper is to study regularity properties of the minimal time function $T(\cdot)$ associated with linear control systems in infinite dimensions. This paper proves that various regularity properties of $T(\cdot)$ hold on the whole reachable set provided they hold around the target. Some methods to obtain estimates on $T(\cdot)$ around the target are given and applications to both distributed and boundary control problems are presented.

Key words. infinite-dimensional control problem, minimal time function

AMS subject classifications. 49K40, 49N05

1. Introduction. Consider a control system represented by

$$(1.1) \quad \begin{aligned} y(t, x, u) &= S(t)x + H(t)u, \quad t > 0 \\ y(0, x, u) &= x, \end{aligned}$$

where y is the state, t the time, and u the control. Here, $S(t)$, $t \geq 0$, is a C_0 -semigroup on a Banach space X and $H(t)$, $t > 0$, is a family of bounded linear operators, $H(t) : L^p(0, t; U) \rightarrow X$, such that the following condition is satisfied:

$$(1.2) \quad \begin{aligned} H(t_1 + t_2)u &= S(t_2)H(t_1)u + H(t_2)J_{t_1}u, \\ \text{for all } t_1, t_2 > 0, \quad u &\in L^p(0, t_1 + t_2, U), \end{aligned}$$

where U is a Banach space, $1 \leq p \leq \infty$, and $\{J_s, s \in \mathbb{R}\}$ is a family of translation operators, $J_s : L^p_{\text{loc}}(\mathbb{R}^+; U) \rightarrow L^p_{\text{loc}}(\mathbb{R}^+; U)$,

$$(J_s u)(t) = u(t + s) \quad \text{for } s \geq 0 \quad \text{and}$$

$$(J_s u)(t) = \begin{cases} 0 & \text{if } 0 \leq t \leq |s| \\ u(t + s) & \text{if } t > |s|, \end{cases} \quad \text{for } s < 0.$$

Of course, $H(t_1)u$ in (1.2) means $H(t_1)P_{t_1}u$, where $P_{t_1}u$ is the projection of $L^p(0, t_1 + t_2, U)$ onto $L^p(0, t_1; U)$, i.e.,

$$(P_{t_1}u)(s) = \begin{cases} u(s) & \text{if } 0 \leq s \leq t_1 \\ 0 & \text{if } s \geq t_1 \end{cases}; \text{ similarly for } H(t_2)J_{t_1}u.$$

A nice representation theorem for a family $H(t)$ that satisfies (1.2) is given in [25], but we do not use this fact here.

There is a large class of control systems that can be represented as in (1.1). We give some examples at the end of this section.

Let us fix a target $x_1 \in X$ and an admissible set of controls $U_{\text{ad}} \in L^p_{\text{loc}}(\mathbb{R}^+; U)$. For $t \geq 0$, denote by $V(t)$ the set of states controllable to x_1 within time t by admissible controls; that is

$$V(t) = \{x \in X; y(t, x, u) = x_1 \text{ for some } u \in U_{\text{ad}}\}.$$

The set of states controllable to x_1 in free time by admissible controls is defined by

$$V = \bigcup_{t \geq 0} V(t).$$

Finally, define the minimal time function (the Bellman function) $T: X \rightarrow [0, \infty]$

$$(1.3) \quad \begin{aligned} T(x) &= \inf \{t; x \in V(t)\} \quad \text{for } x \in V \\ T(x) &= \infty \quad \text{for } x \notin V. \end{aligned}$$

The goal of this paper is to study some continuity properties of the minimal time function defined above. There is an extensive literature on the minimal time function associated with finite-dimensional control systems (see, e.g., [3] and the bibliography given there). The motivation for this interest comes from the fact that this function is used in the construction of feedback controls (see [13], [17, p. 146]) and that its properties provide a basis in the study of the dynamic programming equation (see [17], [3]). Moreover, the local growth of the minimal time function is closely related to the sensitivity of the optimal time with respect to perturbations in the initial state. However, in the infinite-dimensional case there are few papers that concern this subject (see [1], [5], [6]).

Very recently, Barbu [2] studied the minimal time function associated to some nonlinear infinite-dimensional control systems in connection with the theory of viscosity solution to the Bellman equation.

This paper is organized as follows. In § 2 we prove that various regularity properties of the minimal time function, such as local boundedness and uniform and Lipschitz continuity hold on the whole reachable set provided they hold around the target. In § 3, we relate the continuity of the minimal time function to the null controllability of (1.1) by unconstrained controls in arbitrarily short time and provide practical techniques to achieve estimates on $T(\cdot)$ around the target, in the case where $x_1 = 0$. Finally, in § 4, we apply the general theory to concrete examples.

This section concludes with some examples of control systems of type (1.1), which satisfy (1.2).

Example 1.1. Let $B \in L(U, X)$ and $H(t) = \int_0^t S(t-s)Bu(s) ds$, where $S(t)$ is a C_0 -semigroup on the Banach space X . It is easy to verify condition (1.2) for every $p \in [1, \infty]$. In this case, (1.1) gives the mild solution to the equation $y' = Ay + Bu$, $y(0) = x$.

Example 1.2. The heat equation with boundary control can also be considered as a control system of type (1.1) (see, e.g., [20]).

Example 1.3. Consider the wave equation defined on a smooth bounded domain $\Omega \subset \mathbb{R}^n$,

$$(1.4) \quad \begin{aligned} (a) \quad & y'' - \Delta y = 0 \quad \text{in } \Omega \times (0, t) \\ (b) \quad & y = u \quad \text{in } \partial\Omega \times (0, t) = \Sigma \\ (c) \quad & y(0) = y_0; \quad y'(0) = y_1 \quad \text{in } \Omega. \end{aligned}$$

Defining for $t \geq 0$, $S(t): L^2(\Omega) \times H^{-1}(\Omega) \rightarrow L^2(\Omega) \times H^{-1}(\Omega)$, $S(t)(y_0, y_1) = (y(t), y'(t))$, where $y(\cdot)$ is the solution to (1.4a), (1.4c) with $y = 0$ on Σ , $S(t)$ is a C_0 -semigroup on $L^2(\Omega) \times H^{-1}(\Omega)$ (see [24]). On the other hand, $H(t): L^2(\Sigma) \rightarrow L^2(\Omega) \times H^{-1}(\Omega)$, $H(t)u = (y(t), y'(t))$, where $y(\cdot)$ is the solution of (1.4a), (1.4b) with the initial condition $y(0) = 0$, $y'(0) = 0$, is bounded and, together with $S(t)$, verifies (1.2). Clearly, the solution of (1.4) may be written as (1.1) and condition (1.2) is verified with $p = 2$ and $U = L^2(\partial\Omega)$.

2. Qualitative properties of $T(\cdot)$. Throughout this section, we refer to a control system of type (1.1) with condition (1.2) and the associated minimal time function given by (1.3) corresponding to the admissible set of controls

$$(2.1) \quad U_{\text{ad}} = \bigcup_{t \geq 0} \{u \in L^p(0, t; U); \|u\|_p \leq \rho\},$$

where ρ is a given constant and $1 \leq p \leq \infty$. We begin with the following lemma.

LEMMA 2.1 (*Bellman optimality principle*). *For every $x \in V$ and $t \in [0, T(x)]$ we have*

$$T(x) = \inf \{t + T(y(t, x, u)); u \in U_{\text{ad}}\}.$$

Proof. First, we prove that

$$(2.2) \quad T(x) \leq t + T(y(t, x, u)) \quad \text{for every } u \in U_{\text{ad}}.$$

If $y(t, x, u) \notin V$, the inequality is clear. If $y(t, x, u) \in V(s)$ for some $s > 0$, then there exists $v \in U_{\text{ad}}$ such that $S(s)y(t, x, u) + H(s)v = x_1$. That is,

$$S(s)S(t)x + S(s)H(t)u + H(s)v = x_1.$$

By (1.2), the above relation may be written as

$$S(t + s)x + H(t + s)w = x_1,$$

where $w(\tau) = u(\tau)$, for $\tau \in [0, t]$ and $w(\tau) = v(\tau - t)$ for $\tau \in [t, t + s]$. Thus, $x \in V(t + s)$ and $T(x) \leq t + s$. This inequality holds for every s for which $y(t, x, u) \in V(s)$. Hence, (2.2) follows. To continue, let $\varepsilon > 0$. We have to prove that there exists $u \in U_{\text{ad}}$ such that $t + T(y(t, x, u)) \leq T(x) + \varepsilon$. Indeed, by the definition of $T(x)$, there exists $s > 0$ such that $s < T(x) + \varepsilon$ and $x \in V(s)$. Hence, there exists $v \in U_{\text{ad}}$ such that $S(s)x + H(s)v = x_1$. Since $t \leq T(x)$ we have that $t \leq s$. For $t = s$, all is clear. If $t < s$, by (1.2) we have

$$S(s - t)S(t)x + S(s - t)H(t)v + H(s - t)J_1v = x_1.$$

This shows that

$$S(t)x + H(t)v \in V(s - t),$$

hence, $T(y(t, x, v)) \leq s - t$. That is,

$$t + T(y(t, x, v)) \leq s < T(x) + \varepsilon.$$

The desired u is $P_t v$. The proof is complete.

Theorem 2.1, which follows, is the main result of this section. It relates the continuity of $T(\cdot)$ in x_1 to the same property on the whole set V . Moreover, a precise estimate is performed. The notation $\text{sign } \tau$ designates 1 for $\tau > 0$, -1 for $\tau < 0$, and 0 for $\tau = 0$.

THEOREM 2.1. *Assume $x_1 \in \text{int } V$. Then*

- (i) V is open.
- (ii) If, in addition, the minimal time function is bounded on a neighborhood of x_1 , then it is locally bounded on V .
- (iii) If, in addition, the minimal time function is continuous in x_1 , then it is locally uniformly continuous on V . More precisely, the following estimate holds:

$$(2.3) \quad |T(x) - T(y)| \leq T(h(x, y)) \quad \text{for } x, y \in V,$$

where $h(x, y) = x_1 + \text{sign}(T(x) - T(y))S(\min\{T(x), T(y)\})(x - y)$.

- (iv) If, in addition, the minimal time function is locally Lipschitz continuous in x_1 , that is, $T(x) \leq M\|x - x_1\|$, for some constant $M > 0$ and for every x in a neighborhood

of x_1 , then it is locally Lipschitz continuous on V , i.e., for every $x \in V$ there exist a neighborhood \mathcal{U} of x and a constant $M > 0$ such that

$$|T(y) - T(z)| \leq M\|y - z\| \quad \text{for every } y, z \in \mathcal{U}.$$

Proof. Suppose $x_1 \in \text{int } V$ and let us prove that V is open. To this end, let $z \in V$. More exactly, say $z \in V(t)$, and let us prove that $z \in \text{int } V$. Since V is a neighborhood of x_1 , taking into account that the operator $S(t)$ is bounded, we deduce the existence of a neighborhood \mathcal{U} of z such that $S(t)(x - z) + x_1 \in V$ for any $x \in \mathcal{U}$. Now, since $z \in V(t)$, there exists $v \in U_{\text{ad}}$ such that $y(t, z, v) = x_1$. Clearly, $S(t)(x - z) + x_1 = y(t, x, v)$. By Lemma 2.1, we obtain

$$(2.4) \quad T(x) \leq t + T(S(t)(x - z) + x_1), \quad x \in \mathcal{U},$$

which implies that $x \in V$. Hence, $\mathcal{U} \subset V$ and part (i) is proved. Part (ii) follows from (2.4). Let us now prove part (iii). Suppose that $T(\cdot)$ is continuous in x_1 and let $z \in V$. Consider \mathcal{U} and t as above. By (2.4), since $T(x_1) = 0$, we may infer that $\limsup_{x \rightarrow z} T(x) \leq t$. Since the above inequality is true for all $t > 0$ for which $z \in V(t)$, we obtain

$$\limsup_{x \rightarrow z} T(x) \leq T(z).$$

On the other hand, since V is open, there exists $\tau > T(z)$ such that $S(t)(x - z) + x_1 \in V$ for every $t \in (T(z), \tau)$. Consider $t \in (T(z), \tau)$ such that $z \in V(t)$. By (2.4) we obtain

$$T(x) - T(z) \leq \limsup_{t \downarrow T(z)} T(S(t)(x - z) + x_1) \leq T(S(T(z))(x - z) + x_1).$$

Interchanging the role of x and z , we get (2.3), as claimed. Combining (2.3) with the local boundedness of $T(\cdot)$ on V and with its continuity in x_1 we obtain that the minimal time function is locally uniformly continuous on V , and the proof of (iii) is completed. Finally, part (iv) follows easily from (iii).

We can now state a better result when $S(t)$ is a contraction semigroup.

COROLLARY 2.1. *Assume $x_1 \in \text{int } V$. Assume further that $S(t)$ is a contraction semigroup. Then, if the minimal time function is continuous in x_1 , then it is uniformly continuous on V . If, in addition, the minimal time function is locally Lipschitz continuous in x_1 , then it is Lipschitz continuous on V .*

Proof. The first part follows from Theorem 2.1. If $T(\cdot)$ is locally Lipschitz continuous in x_1 , then $L(x_1) < \infty$, where

$$L(x) = \limsup_{y \rightarrow x} \frac{|T(y) - T(x)|}{\|y - x\|}.$$

Let $x \in V$. From Theorem 2.1, $T(\cdot)$ is continuous on V , which is open. Hence, for y near x we have $y \in V$ and $h(x, y) \in V$. For such y , taking into account (2.3) we may infer that

$$\frac{|T(y) - T(x)|}{\|y - x\|} \leq \frac{T(h(x, y))}{\|y - x\|}.$$

Since $T(x_1) = 0$ and

$$\limsup_{y \rightarrow x} \frac{\|h(x, y) - x_1\|}{\|y - x\|} \leq 1$$

we deduce

$$L(x) \leq L(x_1) \quad \text{for every } x \in V.$$

We combine now this fact with the obvious inequality

$$|T(y) - T(x)| \leq \sup \{L(h); h \in [x, y]\} \|x - y\|,$$

for $x, y \in V$, to obtain that

$$|T(y) - T(x)| \leq L(x_1) \|y - x\|, \quad x, y \in V.$$

Here $[x, y]$ designates the entire segment from x to y . The proof is complete.

Remark 2.1. The proof of Theorem 2.1 uses primarily the Bellman optimality principle (Lemma 2.1). Because of this fact, similar results can be proved also for nonlinear control systems. Roughly speaking, we have the following principle: If a suitable continuity property of the solution with respect to the initial data holds true and the Bellman optimality principle is verified, then a continuity property of the minimal time function around the target implies a similar property on the whole reachable set (see [5]).

Remark 2.2. If the semigroup $S(t)$ is compact, then the continuity of $T(\cdot)$ in x_1 implies the weak continuity on V . See [1] and [2] for such results.

3. Estimates around the target. This section gives some general methods to obtain estimates for the minimal time function around the target. We consider here only the case $x_1 = 0$.

Let us recall first some results on constrained controllability for abstract linear control systems. In fact, these are results from operator theory.

LEMMA 3.1 (see [7]). *Let X, Y, Z be Banach spaces. Let $C : D(C) \subset X \rightarrow Y$ be linear with dense domain, and let $F \in L(X, Z)$. Then, the following conditions are equivalent:*

- (a) $F^*(Z^*) \subseteq C^*(Y^*)$;
- (b) *there exists $k_1 > 0$ such that $\|Fx\| \leq k_1 \|Cx\|, x \in D(C)$;*
- (c) *there exists $k_2 > 0$ such that*

$$\{F^*z^*; \|z^*\| \leq 1\} \subseteq \{C^*y^*; y^* \in D(C^*), \|y^*\| \leq k_2\}.$$

Moreover, in the equivalence (b) \Leftrightarrow (c) we can take $k_1 = k_2$.

LEMMA 3.2 (see [7]). *Let X, Y, Z be Banach spaces. Let $C : D(C) \subseteq X \rightarrow Y$ be linear, closed with dense domain, and let $F \in L(Z, Y)$. Let us state the conditions:*

- (i) $F(Z) \subset C(X)$;
- (ii) *there exists $k_1 > 0$ such that*

$$\{Fz; \|z\| \leq 1\} \subset \{Cx; x \in D(C), \|x\| \leq k_1\};$$

- (iii) *there exists $k_2 > 0$ such that*

$$\|F^*y^*\| \leq k_2 \|C^*y^*\|, \quad y^* \in D(C^*);$$

- (iv) *there exists $k_3 > 0$ such that*

$$\{Fz; \|z\| \leq 1\} \subseteq \text{cl} \{Cx; x \in D(C), \|x\| \leq k_3\}.$$

Then (i) \Leftrightarrow (ii), (iii) \Leftrightarrow (iv), with $k_2 = k_3$. If F is the identity operator, then (ii) \Leftrightarrow (iii) with $k_1 = k_2$.

Let us relate these abstract results to our problem (see also [7], [8], [10]). The control system (1.1) is null controllable at time t by L^p -controls, if $S(t)X \subseteq H(t)L^p(0, t; U)$. By virtue of Lemma 3.2, this is equivalent to the existence of $\alpha(t) > 0$ such that

$$(3.1) \quad \{S(t)x; \|x\| \leq \alpha(t)\} \subseteq \{H(t)u; u \in U_{\text{ad}}\},$$

which, in fact, means that $T(x) \leq t$ for $\|x\| \leq \alpha(t)$. We have thus proved the following result.

THEOREM 3.1. *Assume that U_{ad} is given by (2.1), $1 \leq p \leq \infty$. Then the control system (1.1) is null controllable at time t for every $t > 0$, by L^p -controls, if and only if the minimal time function is continuous in the origin of X .*

We also have the following corollary.

COROLLARY 3.1. *In the conditions of Theorem 3.1, assume further that the control system (1.1) is null controllable at every time $t > 0$, by L^p -controls. Then, V is open and the minimal time function is locally uniformly continuous on V . If, in addition, $1 < p \leq \infty$ and $S(t)$ is a contraction semigroup then $V = X$ and the minimal time function is uniformly continuous on X .*

Proof. The first part follows from Theorems 2.1 and 3.1. If $1 < p \leq \infty$ and $S(t)$ is a semigroup of contractions, then it follows by a result of Narukawa [19] that $V = X$. Finally, combining Theorem 3.1 and Corollary 2.1, we see that the minimal time function is uniformly continuous on X .

Remark 3.1. A more precise estimate for the function $\alpha(t)$ in (3.1) provides a corresponding estimate for the minimal time function around the origin (which here is considered as target). Along with Theorem 2.1, this provides a precise estimate for $T(\cdot)$ on the reachable set V . For example, suppose the function $\alpha : (0, \infty) \rightarrow (0, \infty)$ (or, at least, its restriction to $(0, \delta)$ for some $\delta > 0$) has an inverse. Then for x sufficiently near zero we take $t = \alpha^{-1}(\|x\|)$ and use (3.1). This implies $T(x) \leq \alpha^{-1}(\|x\|)$, for $\|x\|$ small. The problem lies in obtaining $\alpha(t)$ explicitly. One way might be by duality, using the equivalence (ii) \Leftrightarrow (iii) in Lemma 3.2, or (b) \Leftrightarrow (c) in Lemma 3.1. Note that Lemma 3.1 is useful in the case where the control process takes place in dual spaces, but this does not cover the situation when the control space is $L^1(0, t; U)$. More precisely, suppose that X and U are reflexive Banach spaces, $H(t) = C^*(t)$ and $1 < p \leq \infty$. Denoting $F(t) = S^*(t)$, if we provide an inequality of type

$$(3.2) \quad \omega(t) \|S^*(t)x^*\| \leq \|C(t)x^*\|, \quad x^* \in X^*,$$

then, using Lemma 3.1 we obtain (3.1) with $\alpha(t) = \rho\omega(t)$. See Example 4.2 for the illustration of this technique.

Another way to obtain the function $\alpha(t)$ in (3.1) is suggested by the work of Seidman [23]. Namely, let $C_t : X \rightarrow L^p(0, t; U)$ be the operator (initial data) \rightarrow (optimal null control for time t). Suppose that we have an estimate of type $\|C_t\| \leq \varphi(t)$ for t small. Then, we can take $\alpha(t) = \rho/\varphi(t)$ in (3.1). See Examples 4.3 and 4.4 for applications.

4. Examples. This section gives several applications of the abstract results and methods presented in §§ 2 and 3.

Example 4.1. Let us consider a control system described by the equation

$$(4.1) \quad y' = Ay + u,$$

where A generates a C_0 -semigroup, $S(t)$, $t \geq 0$, on a Banach space X . The mild solution

$$y(t, x, u) = S(t)x + \int_0^t S(t-s)u(s) ds, \quad t \geq 0,$$

is of type (1.1). We take

$$(4.2) \quad U_{\text{ad}} = \{u \in L^\infty(\mathbb{R}^+; X); \|u(t)\| \leq \rho \text{ a.e.}\}$$

and consider the target $x_1 \in X$.

THEOREM 4.1. *Let $x_1 \in D(A)$ be such that $\|Ax_1\| < \rho$. Let $M \geq 1$ and $\omega \geq 0$ be such that $\|S(t)\| \leq M \exp(\omega t)$. Then*

(a) *If $\omega > 0$, V is open and the minimal time function associated with (4.1), (4.2) is locally Lipschitz continuous on V .*

(b) *If $\omega = 0$, we have $V = X$, and the minimal time function associated with (4.1), (4.2) is Lipschitz continuous on X .*

Proof. Consider first $\omega > 0$. An easy calculation shows that if

$$\|x - x_1\| \leq \frac{\rho - \|Ax_1\|}{2\omega M},$$

then

$$\int_0^t \frac{1}{\|S(s)(x - x_1)\|} ds \geq \frac{1}{\rho - \|Ax_1\|}$$

for t sufficiently large.

Let $t > 0$ be such that we have equality and take the control

$$u(s) = -Ax_1 - \frac{\rho - \|Ax_1\|}{\|S(s)(x - x_1)\|} S(s)(x - x_1), \quad s \in [0, t].$$

Clearly, $u \in U_{ad}$ and $y(t, x, u) = x_1$. Hence, $x \in V(t)$ and therefore $T(x) \leq t$. We also have

$$(4.3) \quad \int_0^{T(x)} \frac{1}{\|S(s)(x - x_1)\|} dx \leq \frac{1}{\rho - \|Ax_1\|}.$$

This implies

$$T(x) \leq -\frac{1}{\omega} \log \frac{\rho - \|Ax_1\| - \omega M \|x - x_1\|}{\rho - \|Ax_1\|},$$

for all x that satisfies

$$\|x - x_1\| \leq \frac{\rho - \|Ax_1\|}{2\omega M}.$$

It is easy to prove now that the minimal time function is locally Lipschitz continuous in x_1 . By Theorem 2.1, it is locally Lipschitz continuous on V .

Note that if $S(s_0)(x - x_1) = 0$ for some s_0 , we can construct a continuous function $\varphi(\cdot)$ such that

$$\varphi(s) \leq 1/\|S(s)(x - x_1)\| \quad \text{for } s \geq 0$$

and such that $\int_0^\infty \varphi(s) ds = \infty$, and we work with $\varphi(\cdot)$ instead of $1/\|S(\cdot)(x - x_1)\|$.

In the case where $\omega = 0$, clearly, we have

$$\int_0^\infty \frac{ds}{\|S(s)(x - x_1)\|} = \infty \quad \text{for every } x \in X,$$

so that $V = X$ and

$$T(x) \leq \frac{M\|x - x_1\|}{\rho - \|Ax_1\|} \quad \text{for every } x \in X.$$

This shows that $T(\cdot)$ is Lipschitz continuous in x_1 , and hence, by Corollary 2.1, it is Lipschitz continuous on X .

Note that Corollary 2.1 was proved in the case where $\omega = 0$ and $M = 1$, but the proof also works in the case where $\omega = 0$ and every $M > 0$. This concludes the proof.

Remark 4.1. We have proved in [5], by another approach, a related result in the case where $x = 0$ and A (possibly) nonlinear.

Example 4.2. Consider the abstract wave equation

$$(4.4) \quad z'' = Az + u,$$

where A is a selfadjoint, positive definite linear operator defined on a dense domain $D(A)$ in a Hilbert space H . In addition, assume that A has a complete sequence of orthonormal eigenelements and a corresponding sequence $(\lambda_j)_{j \in \mathbb{N}}$ of real eigenvalues of finite multiplicity with $0 < \lambda_1 \leq \lambda_2 \leq \dots$ and $\lim_{j \rightarrow \infty} \lambda_j = \infty$. Let $V = D(A^{1/2})$, the domain of the square root of A , let $C(t) : H \rightarrow H(V \rightarrow V)$ and $S_1(t) : H \rightarrow V$ be the cosine and sine operators generated by A . See, e.g., [11], [14], and [15] for details.

For the initial conditions $z(0) = z_0$, $z'(0) = z_1$, $x = (z_0, z_1) \in V \times H$ and $u \in L^2_{\text{loc}}(R^+; H)$, the solution to system (4.4) is understood in the mild sense,

$$z(t, x, u) = C(t)z_0 + S_1(t)z_1 + \int_0^t S_1(t-s)u(s) ds,$$

and the derivation $z'(t, x, u)$ is given by

$$z'(t, x, u) = -AS_1(t)z_0 + C(t)z_1 + \int_0^t C(t-s)u(s) ds.$$

Let $y(t, x, u) = (z(t, x, u), z'(t, x, u)) \in V \times H$, $t \geq 0$. It is easy to see that $y(t, x, u)$ can be represented as in (1.1) in the space $V \times H$, where

$$S(t) = \begin{bmatrix} C(t) & S_1(t) \\ -AS_1(t) & C(t) \end{bmatrix}$$

and

$$H(t)u = \int_0^t S(t-s)Bu(s) ds,$$

with $B : H \rightarrow V \times H$ given by $Bu = \begin{pmatrix} 0 \\ u \end{pmatrix}$. (See Example 1.1.)

We study the minimal time function associated with (4.4) in two cases.

Case 1. The admissible set of controls is

$$(4.5) \quad U_{ad} = \{u \in L^\infty([0, \infty); H); \|u(t)\|_H \leq \rho \text{ a.e.}\}.$$

It is known that the control system (4.4) is null controllable at every time $t > 0$ by L^∞ -controls; that is, given some $t > 0$ and some initial state $x = (z_0, z_1) \in V \times H$, there exists a control function $u \in L^\infty([0, \infty); H)$ such that the corresponding mild solution $z(t, x, u)$ of (4.4) satisfies $z(t, x, u) = 0$ and $z'(t, x, u) = 0$ (see [4]). On the other hand, $S(t)$ is a contraction semigroup (in fact a group). Hence, by Corollary 3.1, the minimal time function associated with (4.4) and (4.5) is finite on $V \times H$ and uniformly continuous. We now give a more precise estimate.

THEOREM 4.2. *The minimal time function associated with (4.4) and (4.5) satisfies the estimate*

$$(4.6) \quad |T(x) - T(y)| \leq M_1 \|x - y\|^{1/3},$$

for every $x, y \in V \times H$ with $\|x - y\| \leq M_2$, where $M_1 = (30\sqrt{2}/\rho\lambda_1)^{1/3}$ and $M_2 = \sqrt{15/64}(\rho/\sqrt{\lambda_1})$. Here, for $x = (x_1, x_2) \in V \times H$, $\|x\| = (\|x_1\|^2 + \|x_2\|^2)^{1/2}$.

Proof. From the proof of Theorems 2.2 and 2.3 in [14] it follows that for every $x = (z_0, z_1) \in V \times H$ and $0 < t \leq \sqrt{15/8\lambda_1}$, there exists a control $u_t \in L^\infty(0, t; H)$ that transfers x to rest during $[0, t]$ and satisfies the estimate

$$\|u_t\| \leq \frac{30\sqrt{2}}{\lambda_1} t^{-3} \|x\|.$$

See [9] for more details. Note that a careful reading of [14] shows that this result is a consequence of an inequality of type (3.2). If $\|x\| \leq (t^3 \lambda_1 \rho)/(30\sqrt{2})$, then $u_t \in U_{\text{ad}}$, and thus, we obtain (3.1) with $\alpha(t) = (t^3 \lambda_1 \rho)/(30\sqrt{2})$ and $t \leq \sqrt{15/8\lambda_1}$. Taking $t = (30\sqrt{2}/\lambda_1 \rho)^{1/3} \|x\|^{1/3}$, we obtain

$$(4.7) \quad T(x) \leq M_1 \|x\|^{1/3} \quad \text{for } \|x\| \leq M_2.$$

See also Remark 3.1. We have just obtained an estimate for $T(\cdot)$ around zero. Since $S(t)$ is a group of contractions, (4.6) follows from (2.3) and (4.7).

Case 2. The admissible set of controls is

$$(4.8) \quad U_{\text{ad}} = \bigcup_{t>0} \{u \in L^2(0, t; H); \|u\|_2 \leq \rho\}.$$

THEOREM 4.3. *The minimal time function associated with (4.4) and (4.8) satisfies the estimate*

$$|T(x) - T(y)| \leq M_3 \|x - y\|^{2/3},$$

for every $x, y \in V \times H$ with $\|x - y\| \leq M_4$, where $M_3 = (30/\lambda_1)^{1/3} \rho^{-2/3}$ and $M_4 = \rho(15/8\lambda_1)^{1/3} (\lambda_1/30)^{3/4}$.

Proof. We apply again a result of [14] to deduce that for every $x = (z_1, z_2) \in V \times H$ and $0 < t \leq \sqrt{15/8\lambda_1}$ there exists a control $u_t \in L^2(0, t; H)$ that transfers x to zero within time t and satisfies the estimate

$$\|u_t\|_2 \leq 2 \left(\frac{15}{2\lambda_1} \right)^{1/2} t^{-3/2} \|x\|.$$

See also [9]. The proof is concluded in the same way as the proof of Theorem 4.2.

Example 4.3. Let Ω be a bounded domain in R^n whose boundary Γ is a C^∞ manifold. Let Δ denote the Laplacian operation on R^n and let the constants $a, b, a^2 + b^2 \neq 0, ab \geq 0$. We consider a control system described by the equation

$$(4.9) \quad \begin{aligned} y' - \Delta y &= 0 && \text{in } \Omega \times (0, \infty), \\ a \frac{\partial y}{\partial \nu} + by &= u && \text{in } \Gamma \times (0, \infty), \\ y(0) &= y_0 && \text{in } \Omega. \end{aligned}$$

Consider, first, the admissible set of controls

$$(4.10) \quad U_{\text{ad}} = \{u \in L^\infty(\Gamma \times (0, \infty)); |u(x, t)| \leq \rho \text{ a.e.}\}.$$

It is well known (see, e.g., [20]) that for $y_0 \in L^2(\Omega)$ and $u \in L^\infty(\Gamma \times (0, \infty))$, (4.9) has a unique weak solution $y(t, y_0, u)$ in $L^2(\Omega)$, which can be represented as in (1.1) such that (1.2) is verified. Clearly, in this case $p = \infty$, $U = L^\infty(\Gamma)$, and $X = L^2(\Omega)$. The semigroup $S(t)$ involved here is a C_0 -semigroup of contractions. On the other hand, in the case where $b \neq 0$, for every $t > 0$ the control system (4.9) is null controllable by $L^\infty(\Gamma \times (0, \infty))$ -controls (see [20]). Taking into account Corollary 3.1, we make the following deduction.

COROLLARY 4.1. *The minimal time function associated with (4.9) and (4.10), in the case where $b \neq 0$, is finite and uniformly continuous on $L^2(\Omega)$.*

We consider now the admissible set of controls

$$(4.11) \quad U_{\text{ad}} = \bigcup_{t>0} \{u \in L^2(0, t; L^2(\Gamma)), \|u\|_2 \leq \rho\}.$$

If $a \neq 0$, again the solution $y(t, y_0, u)$ is in $L^2(\Omega)$ for every $t > 0$ (see [21]), can be represented as in (1.1) with $H(t)$ continuous from $L^2(0, t; L^2(\Gamma))$ into $L^2(\Omega)$. Furthermore, we have the null controllability property for every $t > 0$ by L^2 -controls so we have (3.1). If $a = 0$, $H(t)u$ need not be in $L^2(\Omega)$ for every $u \in L^2(0, t; L^2(\Gamma))$. However, the operator $H(t) : D(H(t)) \rightarrow L^2(\Omega)$, where $D(H(t)) = \{u \in L^2(0, t; L^2(\Gamma)); H(t)u \in L^2(\Omega)\}$, is densely defined and closed (see [22, Lemma 2.15]); hence, we can apply Lemma 3.2 to deduce (3.1) from the null controllability property.

For $t > 0$, define the operator

$$C_t : L^2(\Omega) \rightarrow L^2(0, t; L^2(\Gamma)),$$

$$C_t y_0 = u_0,$$

where u_0 is the minimum norm control that transfers the initial state y_0 to zero within time t by controls in $L^2(0, t; L^2(\Gamma))$.

LEMMA 4.1 [23]. *There exists $\alpha > 0$, such that*

$$(4.12) \quad \|C_t\| \leq \exp(\alpha/t) \quad \text{for small } t.$$

We are now in position to prove the following theorem.

THEOREM 4.4. *The minimal time function associated with (4.9) and (4.11) satisfies the estimate*

$$(4.13) \quad |T(y_0) - T(z_0)| \leq \frac{k}{\log(\rho/\|y_0 - z_0\|)}$$

for some $k > 0$ and for every $y_0, z_0 \in L^2(\Omega)$ such that $\|y_0 - z_0\|$ is sufficiently small.

Proof. We first prove that

$$T(y_0) \leq \frac{\alpha}{\log(\rho/\|y_0\|)} \quad \text{for } \|y_0\| \text{ small,}$$

where α is given by Lemma 4.1.

Indeed, by (4.12), for small $t > 0$, every $y_0 \in L^2(\Omega)$ with $\|y_0\| < \rho$ can be transferred to zero by $u_0 \in L^2(0, t; L^2(\Gamma))$ with $\|u_0\| \leq \exp(\alpha/t)\|y_0\|$. Hence, if $\exp(\alpha/t)\|y_0\| \leq \rho$ then $y_0 \in V(t)$. Therefore, we have (3.1) with $\alpha(t) = \rho \exp(-\alpha/t)$. See also the final part of Remark 3.1. The inequality (4.14) now follows easily. To conclude the proof of our theorem we apply Theorem 2.1, more precisely, an inequality of type (2.4). Indeed,

$$\begin{aligned} |T(y_0) - T(z_0)| &\leq T(h(y_0, z_0)) \leq \frac{\alpha}{\log(\rho/\|h(y_0, z_0)\|)} \\ &\leq \frac{\alpha}{\log(\rho/\|y_0 - z_0\|)}. \end{aligned}$$

Here, $h(y_0, z_0) = \text{sign}(T(y_0) - T(z_0))S(\min\{T(y_0), T(z_0)\})(y_0 - z_0)$, and $\|h(y_0, z_0)\| \leq \|y_0 - z_0\|$ because $S(t)$ is a semigroup of contractions.

Remark 4.2. The estimate given in Theorem 4.4 seems to be optimal due to a result of Güichal [12], which states that the estimate (4.12) is optimal.

Example 4.4. Let us consider the boundary control problem of a vibrating plate

$$(4.15) \quad \begin{aligned} y'' + \Delta^2 y &= 0 && \text{on } \Omega \times (0, \infty), \\ \partial y / \partial \nu &= 0, \partial(\Delta y) / \partial \nu = u && \text{on } \Gamma \times (0, \infty), \\ y(0) &= y_0^1; y'(0) = y_0^2 && \text{on } \Omega, \end{aligned}$$

where $\Omega = (0, 1) \times (0, 1)$.

Resulting from [16], the control system (4.15) is null controllable for arbitrarily small time by L^2 -controls, with an estimate of type (4.12). Therefore, the minimal time function associated with the system (4.15) and the admissible set of controls (4.11) satisfies an estimate of type (4.13).

Example 4.5. Consider, finally, the wave equation with boundary control (Example 1.3). It is well known that the control system (1.4) is not null controllable for arbitrarily small time (see [18]). Therefore, by Theorem 3.1, the corresponding minimal time function is not continuous in zero.

Acknowledgment. I thank Professor Corneliu Ursescu for helpful discussions.

A STATE-SPACE ALGORITHM FOR THE SOLUTION OF THE 2-BLOCK SUPEROPTIMAL DISTANCE PROBLEM*

I. M. JAIMOUKHA† AND D. J. N. LIMEBEER†

Abstract. A state-space algorithm for computing the solution of the 2-block superoptimal distance problem (SODP) is presented. Given a rational and antistable matrix function $R(s) = [R_{11}(s) \ R_{12}(s)]$, find all stable approximations $Q(s)$ that lexicographically minimize the singular values of the error function $E(s) = [R_{11}(s) \ R_{12}(s) + Q(s)]$. Conditions are given for which the superoptimal approximation is unique. In addition, an a priori upper bound on the MacMillan degree of the approximation is given. The algorithm may be stopped after minimizing a given number of singular values. This premature termination of the algorithm carries with it an expected saving in the computational effort and a predictable reduction in the MacMillan degree of the approximation. The algorithm only requires standard linear algebraic computations and is, therefore, easily implemented.

Key words. superoptimal general distance problem, 2-block general distance problem, H_∞ -optimal control

AMS subject classification. 93C35

1. Notation and definitions.

$\mathbb{R}, \mathbb{R}_+, \mathbb{C}$	real, nonnegative and complex numbers
$\mathbb{C}_+(\bar{\mathbb{C}}_+), \mathbb{C}_-(\bar{\mathbb{C}}_-)$	open (respectively, closed) right half plane, open (respectively, closed) left half-plane
$\lambda(A), \lambda_{\max}(A)$	eigenvalue of square matrix A , largest eigenvalue of A
A^*	complex conjugate transpose of $A \in \mathbb{C}^{m \times l}$
$A \geq 0, A > 0$	A is positive semidefinite (respectively, positive definite)
$\mathcal{L}_\infty^{p \times m}$	space of $p \times m$ matrix functions with entries bounded on the $j\omega$ axis
$\ (\cdot)\ _\infty$	\mathcal{L}_∞ -norm of matrices in \mathcal{L}_∞
$\mathcal{H}_\infty^{+p \times m}, \mathcal{H}_\infty^{-p \times m}$	subspaces of $\mathcal{L}_\infty^{p \times m}$; matrices that are analytic in $\bar{\mathbb{C}}_+$ (respectively, $\bar{\mathbb{C}}_-$)
$[G(s)]^*, [G(s)]^{-*}$	$G(-\bar{s})^*$, the para-Hermitian conjugate of $G(s)$, $[G^*(s)]^{-1}$
$\deg [G(s)]$	MacMillan degree of the rational function $G(s)$
$[G(s)]_+, [G(s)]_-$	stable (respectively, antistable) projection of $G(s)$
Prefix \mathbb{R}	denotes real rational.

Associated with every rational transfer function matrix $G(s)$ is a *state-space realization* $G(s) = D + C(sI - A)^{-1}B$, where $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times l}$, $C \in \mathbb{R}^{m \times n}$ and $D \in \mathbb{R}^{m \times l}$, and where $n \geq \deg [G(s)]$. The alternative notation $G(s) = (A, B, C, D)$ or

$$G(s) \stackrel{s}{=} \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

is also used. Occasionally we write

$$\begin{bmatrix} R_{11}(s) & R_{12}(s) \\ R_{21}(s) & R_{22}(s) \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{array} \right],$$

* Received by the editors July 15, 1991; accepted for publication (in revised form) March 12, 1992. This research was supported in part by the Arab British Chamber Charitable Foundation Scholarship, and in part by the Overseas Research Studentship Award Scheme.

in which $R_{ij}(s) \stackrel{s}{=} (A, B_j, C_i, D_{ij})$ for $i, j = 1, 2$. If D is nonsingular, then

$$(1) \quad [G(s)]^{-1} \stackrel{s}{=} (A - BD^{-1}C, -BD^{-1}, D^{-1}C, D^{-1}).$$

If $[G(s)]^{-1} = [G(s)]^*$, then $G(s)$ is said to be an *all-pass* system and satisfies $[G(s)] \cdot [G(s)]^* = [G(s)]^* [G(s)] = I$. Occasionally, we say that $G(s)$ is all-pass for some $\gamma \in \mathbb{R}_+$. This is taken to mean that $\gamma^{-1}G(s)$ is all-pass. The rational function $G(s)$ is called *stable* if it has no poles in $\bar{\mathbb{C}}_+$. If $G(s)$ has no poles in $\bar{\mathbb{C}}_-$ it is called *antistable*. If $G(s) \in \mathcal{H}_\infty^+$ has $\|G\|_\infty \leq 1$, it is called a *stable contraction*. The set of all stable contractions is denoted \mathcal{BH}_∞^+ . We say that $G(s) \in \gamma^{-1}\mathcal{BH}_\infty^+$ if $\gamma G(s) \in \mathcal{BH}_\infty^+$. If a *basis change* T is introduced into a state-space realization of $G(s)$, this is taken to mean the similarity transformation

$$(2) \quad G(s) \stackrel{s}{=} (A, B, C, D) \xrightarrow{T} G(s) \stackrel{s}{=} (T^{-1}AT, T^{-1}B, CT, D).$$

In most cases, $G(s)$ will be abbreviated to G .

If $U \in \mathcal{L}_\infty^{l \times q}$ and

$$H = \begin{matrix} & m & l \\ p & \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} & \end{matrix} \in \mathcal{L}_\infty^{(p+q) \times (m+l)}$$

we define the *lower linear fractional map* (LLFM) $\mathcal{F}_l(H, U) := H_{11} + H_{12}U(I - H_{22}U)^{-1}H_{21}$ provided $[I - H_{22}(\infty)U(\infty)]$ is invertible. If $U \in \mathcal{L}_\infty^{m \times p}$ we define the *upper linear fractional map* (ULFM) $\mathcal{F}_u(H, U) := H_{22} + H_{21}U(I - H_{11}U)^{-1}H_{12}$ provided $[I - H_{11}(\infty)U(\infty)]$ is invertible. If \mathcal{U} is a set, then $\mathcal{F}_l(H, \mathcal{U})$ is taken to denote the set $\{\mathcal{F}_l(H, U) : U \in \mathcal{U}\}$. If $G_1, G_2, G_3 \in \mathcal{L}_\infty$ have appropriate dimensions, and \mathcal{U} is a set, then $G_1 + G_2\mathcal{U}G_3$ is taken to denote the set $\{G_1 + G_2UG_3 : U \in \mathcal{U}\}$.

A problem of presenting the superoptimal algorithm is the elaborate notation. To simplify the presentation, we adopt the following special notation and definitions. If $A \in \mathbb{C}^{p \times m}$, then $\sigma_i(A)$ denotes the i th largest singular value of A . If $G \in \mathcal{L}_\infty^{p \times m}$, then

$$s_i^\infty(G) := \sup_{\omega \in \mathbb{R}} \sigma_i[G(j\omega)]$$

denotes the supremum of the i th largest singular value of G over the imaginary axis (including ∞). Clearly, $s_1^\infty(G) = \|G\|_\infty$. If $R \in \mathbb{R}\mathcal{H}_\infty^{-p \times (l+m)}$ is partitioned as

$$(3) \quad R = \begin{matrix} & l & m \\ p & \begin{bmatrix} R_{11} & R_{12} \end{bmatrix} & \end{matrix} \in \mathbb{R}\mathcal{H}_\infty^{-p \times (l+m)},$$

we define the optimal level of R as

$$s_1(R) := \inf_{Q \in \mathcal{H}_\infty^{+p \times m}} s_1^\infty([R_{11} \quad R_{12} + Q]),$$

and the set of all optimal approximations of R as

$$\mathcal{S}_1(R) := \{Q \in \mathcal{H}_\infty^{+p \times m} : s_1^\infty([R_{11} \quad R_{12} + Q]) = s_1\}.$$

If p and m are both greater than 1, then we define the first and subsequent superoptimal levels of R as

$$s_i(R) := \inf_{Q \in \mathcal{S}_{i-1}(R)} s_i^\infty([R_{11} \quad R_{12} + Q]) \quad i = 1, 2, \dots,$$

and the set of all i th level superoptimal approximations of R as

$$\mathcal{S}_i(R) := \{Q \in \mathcal{S}_{i-1}(R) : s_i^\infty([R_{11} \quad R_{12} + Q]) = s_i(R)\} \quad i = 1, 2, \dots,$$

in which $s_0 = \infty$ and $S_0(R) = \mathcal{H}_{\infty}^{+p \times m}$. Clearly, the optimal level is equal to the first superoptimal level, and the set of all optimal approximations is equal to the set of all first-level superoptimal approximations. If $\gamma > s_1(R)$, then γ is said to be a suboptimal level of R . The set of all suboptimal approximations of R at level γ is defined as

$$\mathcal{S}(R, \gamma) := \{Q \in \mathcal{H}_{\infty}^{+p \times m} : s_1^{\infty}([R_{11} \quad R_{12} + Q]) \leq \gamma\}.$$

2. Introduction. It is well known [4], [14] that a large class of \mathcal{H}_{∞} -control problems may be reduced to the 2-block optimal distance problem via the Youla parametrization of all stabilizing controllers [18]. In the 2-block optimal distance problem, we are given $R \in \mathbb{R}\mathcal{H}_{\infty}^{-p \times (l+m)}$ partitioned as (3), and we seek to find the optimal level $s_1(R)$ and the set $S_1(R)$ of all optimal approximations of R . In control problems, R is a function of a plant model and various weighting functions [4], [14]. In general, the solution of the 2-block optimal distance problem is hardly ever unique [4], [14]. The question then arises as to whether any of these optimal solutions is best in some sense. One way of recovering uniqueness is to strengthen the optimality requirement. Specifically, we request that the second and subsequent singular values are minimized with respect to lexicographic ordering [19].

Problem 1. Suppose we are given a rational antistable matrix R partitioned as in (3). Then for $i = 1, 2, \dots$ we are required to find the superoptimal levels $s_1(R), \dots, s_i(R)$ and the set $S_i(R)$ of all i th level superoptimal approximations of R , where we set $s_0 = \infty$ and $S_0(R) = \mathcal{H}_{\infty}^{+p \times m}$.

When $R_{11} = 0$, Problem 1 reduces to the 1-block SODP first proposed by Young [19], who showed, using operator theoretic techniques, that the superoptimal approximation is unique [19]. State-space algorithms for calculating the solution are given in [9], [15], and [17], where it is shown that the superoptimal approximation has a surprisingly low MacMillan degree. Gu, Tsai, and Postlethwaite [8] give a solution to the 2-block SODP using a technique that is different from the one used in this paper. However, their algorithm is unnecessarily complicated and cannot be readily generalized to the solution of the 4-block SODP. In contrast, we give a new and simple algorithm for the solution of both the 1-block and 2-block SODPs, using essentially the same technique. More precisely, we prove that, under certain conditions, it is possible to construct a sequence of 2-block systems R_1, \dots, R_k of the same form as R such that $s_i(R) = s_1(R_i)$ and $S_i(R) = S_{i-1}[S_1(R_i)]$, where S_1, \dots, S_{k-1} is a sequence of operators to be defined later. Thus, the solution of the i th level SODP is reduced to the solution of i optimal problems. We also prove that there exist i th level superoptimal approximations of R of MacMillan degree $\leq (n-1) + (n-2) + \dots + (n-i)$, where $n = \deg(R)$. Furthermore, sufficient conditions are given for which the superoptimal approximation of R is unique. Finally, we demonstrate that the algorithm can be readily extended to the solution of the 4-block SODP.

The paper is laid out as follows. Section 3 gives a review of the 2-block optimal distance problem. Section 4 gives the solution of the second-level superoptimal problem and § 5 gives a cancellation analysis of this solution. Section 6 extends the solution to the full superoptimal problem and § 7 outlines the solution to the 4-block superoptimal problem. A few examples are given in § 8, and finally, the conclusions are given in § 9.

3. The 2-block optimal distance problem. This section outlines the solution of the 2-block optimal distance problem: for $R \in \mathbb{R}\mathcal{H}_{\infty}^{-p \times (l+m)}$ given by the state-space realization

$$(4) \quad R = \begin{bmatrix} R_{11} & R_{12} \end{bmatrix} \stackrel{l}{=} \begin{bmatrix} A & B_1 & B_2 \\ C_1 & 0 & 0 \end{bmatrix} \in \mathbb{R}\mathcal{H}_{\infty}^{-p \times (l+m)},$$

where

$$(5) \quad A \in \mathbb{R}^{n \times n}, \quad \operatorname{Re} [\lambda_i(A)] > 0 \quad \forall i,$$

find the optimal level $s_1(R)$ and the set $\mathbb{S}_1(R)$ of all optimal approximations of R . The solution to this problem has been developed in [2], [7], and [13]. We assume that the optimal level $s_1(R)$ can be calculated to any desired degree of accuracy using the γ -iteration [4], [7], and furthermore that

$$(6) \quad s_1(R) > \|R_{11}\|_\infty.$$

The following theorem gives the set $\mathbb{S}_1(R)$ in the form of a linear fractional map.

THEOREM 1 (see [2], [7], [13]). *Let $s_1 := s_1(R)$ and assume that (5) and (6) are satisfied. Then*

(i) *There exists an embedding of R of the form*

$$H := \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{array}{c} p \\ l \\ m-1 \end{array} \left[\begin{array}{cc|c} R_{11} & R_{12} + Q_{12} & Q_{13} \\ R_{21} & R_{22} + Q_{22} & Q_{23} \\ 0 & Q_{32} & Q_{33} \end{array} \right] \begin{array}{c} l \\ m \\ p-1 \end{array}$$

such that $HH^* = H^*H = s_1^2 I$; $R_{ij}, (R_{21})^{-1} \in \mathbb{RH}_\infty^-, i, j = 1, 2$; $Q_{ij} \in \mathbb{RH}_\infty^+, i = 1, 2, 3$; $j = 2, 3$ and

$$(7) \quad \|H_{22}\|_\infty < s_1.$$

Furthermore,

$$\mathbb{S}_1(R) = \mathcal{F}_1(Q_a, s_1^{-1} \mathcal{BH}_\infty^{(p-1) \times (m-1)})$$

and

$$[R_{11} \quad R_{12} + \mathbb{S}_1(R)] = \mathcal{F}_l(H, \mathcal{U}_1)$$

where

$$\mathcal{U}_1 := \{[0_{(p-1) \times l} \quad u] : u \in s_1^{-1} \mathcal{BH}_\infty^{(p-1) \times (m-1)}\}, \quad Q_a = \begin{bmatrix} Q_{12} & Q_{13} \\ Q_{32} & Q_{33} \end{bmatrix}.$$

(ii) *There exist real matrices*

$$\begin{aligned} A_H &= \begin{array}{c} n \\ n-1 \end{array} \begin{bmatrix} A & 0 \\ 0 & A_Q \end{bmatrix}, & B_H &= \begin{array}{c} l \\ n-1 \end{array} \begin{bmatrix} B_1 & B_2 & 0 \\ 0 & B_{Q_2} & B_{Q_3} \end{bmatrix}, \\ C_H &= \begin{array}{c} p \\ l \\ m-1 \end{array} \begin{bmatrix} C_1 & C_{Q_1} \\ C_2 & C_{Q_2} \\ 0 & C_{Q_3} \end{bmatrix}, & D_H &= \begin{array}{c} l \\ p \\ l \\ m-1 \end{array} \begin{bmatrix} 0 & D_{12} & D_{13} \\ s_1 I & 0 & 0 \\ 0 & D_{32} & 0 \end{bmatrix}, \\ P_H &= \begin{array}{c} n \\ n-1 \end{array} \begin{bmatrix} P_1 & P_3 \\ P_3^* & P_2 \end{bmatrix}, & Q_H &= \begin{array}{c} n \\ n-1 \end{array} \begin{bmatrix} Q_1 & Q_3 \\ Q_3^* & Q_2 \end{bmatrix} \end{aligned}$$

such that

$$(8) \quad A_Q \in \mathbb{R}^{(n-1) \times (n-1)}, \quad \operatorname{Re} [\lambda_i(A_Q)] < 0 \quad \forall i$$

$$P_H Q_H = Q_H P_H = s_1^2 I, \quad D_H D_H^* = D_H^* D_H = s_1^2 I, \quad A_H^* Q_H + Q_H A_H + C_H^* C_H = 0,$$

$$(9) \quad D_H^* C_H + B_H^* Q_H = 0, \quad D_H B_H^* + C_H P_H = 0, \quad A_H P_H + P_H A_H^* + B_H B_H^* = 0.$$

Furthermore, H and Q_a have state-space realizations given by

$$(10) \quad H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A_H & B_H \\ C_H & D_H \end{bmatrix}, \quad Q_a := \begin{bmatrix} Q_{12} & Q_{13} \\ Q_{32} & Q_{33} \end{bmatrix} \stackrel{s}{=} \begin{bmatrix} A_Q & B_{Q_2} & B_{Q_3} \\ C_{Q_1} & D_{12} & D_{13} \\ C_{Q_3} & D_{32} & 0 \end{bmatrix}.$$

Remark 1. In the interest of a clear presentation the optimal level s_1 is taken to have multiplicity one. Relaxing this assumption will lead to a messy indexing system without introducing any serious technical difficulties. See [7] for a full treatment of the general case for the optimal distance problem. The assumption in (4) that $R(\infty) = 0$ is used to simplify the notation and can be removed with minor modifications to the algorithm [7].

Remark 2. If $\min(p, m) = 1$, then the optimal, and hence, the superoptimal approximation of R is unique and given by Q_{12} . If $n = 1$, then Q_{12} is a constant equal to D_{12} . Using the results in [7] it can be shown that the error $[R_{11} \quad R_{12} + D_{12}]$ has rank one so that D_{12} is the superoptimal solution.

Remark 3. In this paper, we will not give an explicit construction of the optimal generator H . However, we make extensive use of its properties as summarized in Theorem 1. For a full construction of the optimal generator H , see [7, Thm. 4.4].

4. The second-level SODP. This section considers the solution of the second-level SODP.

Problem 2. Suppose we are given a rational antistable matrix R partitioned as in (4). Then we are required to find the second superoptimal level $s_2(R)$ and the set $\mathbb{S}_2(R)$ of all second-level superoptimal approximations of R .

In the following theorem we derive the solution of the second level SODP associated with R using H only. Since $HH^* = H^*H = s_1^2 I$, we can regard H as an all-pass embedding of H_{22} . The next theorem uses standard spectral factorization results to give a construction of another embedding \bar{H} of H_{22} , which also satisfies $\bar{H}\bar{H}^* = \bar{H}^*\bar{H} = s_1^2 I$.

THEOREM 2. Let H be the generator of all optimal error functions of R given by Theorem 1. Then (i) There exists an embedding of H_{22} of the form

$$(11) \quad \bar{H} = \begin{bmatrix} \bar{H}_{11} & \bar{H}_{12} \\ \bar{H}_{21} & \bar{H}_{22} \end{bmatrix} = \begin{matrix} l & m-1 & p-1 \\ p-1 & & \\ & l & \\ m-1 & & \end{matrix} \begin{bmatrix} \bar{R}_{11} & \hat{R}_{12} + \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{R}_{21} & \bar{R}_{22} + \bar{Q}_{22} & \bar{Q}_{23} \\ 0 & \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix}$$

such that

$$(12) \quad \bar{H}^* \bar{H} = \bar{H} \bar{H}^* = s_1^2 I,$$

$$(13) \quad \bar{R}_{21}^{-1}, \bar{R}_{21}, \bar{R}_{22}, \hat{R} := [\hat{R}_{11} \quad \hat{R}_{12}] \in \mathbb{R}\mathcal{H}_{\infty}^{-}, \quad \bar{Q}_{13}^{-1}, \bar{Q}_{32}^{-1}, \bar{Q}_{12}, \bar{Q}_{13}, \bar{Q}_{22}, \bar{Q}_{32} \in \mathbb{R}\mathcal{H}_{\infty}^{+}.$$

(ii) The set of all suboptimal approximations of \hat{R} is given by

$$(14) \quad \mathbb{S}(\hat{R}, s_1) = \mathcal{F}_l(\bar{Q}_a, s_1^{-1} \mathcal{B}\mathcal{H}_{\infty}^{+(p-1) \times (m-1)})$$

and the corresponding set of all suboptimal error functions of \hat{R} is given by

$$(15) \quad [\hat{R}_{11} \quad \hat{R}_{12} + \mathbb{S}(\hat{R}, s_1)] = \mathcal{F}_l(\bar{H}, \mathcal{U}_1),$$

where \mathcal{U}_1 is defined in Theorem 1 and

$$\bar{Q}_a := \begin{bmatrix} \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix}.$$

Proof. (i) Using (7), it is a simple exercise to give a construction of \bar{H} using standard spectral factorization theory [1] using either transfer function or state-space techniques. In this paper, we give a state-space construction of \bar{H} . It follows from Theorem 1 that H_{22} has the state-space realization

$$H_{22} \stackrel{s}{=} \left[\begin{array}{c|c} A_Q & B_{Q_3} \\ \hline C_{Q_2} & 0 \\ C_{Q_3} & 0 \end{array} \right].$$

Hence, it follows from (7) that there exist stabilizing solutions \bar{P}_2 and \bar{Q}_2 to the algebraic Riccati equations

$$(16) \quad \begin{aligned} A_Q \bar{P}_2 + \bar{P}_2 A_Q^* + B_{Q_3} B_{Q_3}^* + s_1^{-2} \bar{P}_2 C_{Q_3}^* C_{Q_3} \bar{P}_2 &= 0, \\ A_Q^* \bar{Q}_2 + \bar{Q}_2 A_Q + C_{Q_2}^* C_{Q_2} + C_{Q_3}^* C_{Q_3} + s_1^{-2} \bar{Q}_2 B_{Q_3} B_{Q_3}^* \bar{Q}_2 &= 0, \end{aligned}$$

respectively [2]. Since \bar{P}_2 and \bar{Q}_2 are stabilizing,

$$(17) \quad \operatorname{Re} [\lambda_i (A_Q + s_1^{-2} \bar{P}_2 C_{Q_3}^* C_{Q_3})] < 0 \quad \forall i, \quad \operatorname{Re} [\lambda_i (A_Q + s_1^{-2} B_{Q_3} B_{Q_3}^* \bar{Q}_2)] < 0 \quad \forall i.$$

Define

$$\bar{R} := \bar{Q}_2 \bar{P}_2 - s_1^2 I.$$

Then using the fact that \bar{P}_2 and \bar{Q}_2 are continuous and decreasing functions of s_1 [10], it is easy to show that (7) implies that $\lambda_{\max}(\bar{P}_2 \bar{Q}_2) < s_1^2$ [11], from which it follows that \bar{R} is invertible. Defining

$$(18) \quad \bar{H} = \begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} + \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{R}_{21} & \bar{R}_{22} + \bar{Q}_{22} & \bar{Q}_{23} \\ 0 & \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{cc|cc} \hat{A} & 0 & \hat{B}_1 & \hat{B}_2 & 0 \\ 0 & A_Q & 0 & \bar{B}_{Q_2} & B_{Q_3} \\ \hline \hat{C}_1 & \bar{C}_{Q_1} & 0 & 0 & s_1 I \\ \bar{C}_2 & C_{Q_2} & s_1 I & 0 & 0 \\ 0 & C_{Q_3} & 0 & s_1 I & 0 \end{array} \right] \stackrel{s}{=} \left[\begin{array}{c|c} A_{\bar{H}} & B_{\bar{H}} \\ \hline C_{\bar{H}} & D_{\bar{H}} \end{array} \right]$$

in which

$$(19) \quad \bar{Q}_a := \begin{bmatrix} \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|cc} A_Q & \bar{B}_{Q_2} & B_{Q_3} \\ \hline \bar{C}_{Q_1} & 0 & s_1 I \\ C_{Q_3} & s_1 I & 0 \end{array} \right],$$

and

$$(20) \quad \hat{R} = {}_{p-1} \begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|c} \hat{A} & \begin{matrix} \hat{B}_1 & \hat{B}_2 \end{matrix} \\ \hline \hat{C}_1 & \begin{matrix} 0 & 0 \end{matrix} \end{array} \right] \in \mathbb{R} \mathcal{H}_{\infty}^{-(p-1) \times (l+m-1)},$$

$$(21) \quad \begin{aligned} \hat{A} &:= -(A_Q + s_1^{-2} \bar{P}_2 C_{Q_3}^* C_{Q_3})^*, \\ \bar{C}_{Q_1} &:= -s_1^{-1} B_{Q_3}^* \bar{Q}_2, \quad \hat{B}_1 := s_1 \bar{R}^{-1} C_{Q_2}^*, \quad \hat{B}_2 := -s_1^{-1} C_{Q_3}^*, \\ \hat{C}_1 &:= s_1^{-1} B_{Q_3}^* \bar{R}, \quad \bar{C}_2 := -s_1^{-1} \hat{B}_1^* \bar{Q}_1, \quad \bar{B}_{Q_2} := -s_1^{-1} \bar{P}_2 C_{Q_3}^*. \end{aligned}$$

Then

$$(22) \quad \hat{A} \in \mathbb{R}^{(n-1) \times (n-1)}$$

since $A_Q \in \mathbb{R}^{(n-1) \times (n-1)}$. Furthermore, (17) implies that

$$(23) \quad \operatorname{Re} [\lambda_i(\hat{A})] > 0 \quad \forall i.$$

Equations (16) and definitions (21) are used to verify that the realization of \bar{H} given in (18) satisfies the all-pass equations

$$\begin{aligned} A_{\bar{H}}^* Q_{\bar{H}} + Q_{\bar{H}} A_{\bar{H}} + C_{\bar{H}}^* C_{\bar{H}} &= 0, \quad D_{\bar{H}}^* C_{\bar{H}} + B_{\bar{H}}^* Q_{\bar{H}} = 0, \quad D_{\bar{H}} D_{\bar{H}}^* = D_{\bar{H}}^* D_{\bar{H}} = s_1^2 I, \\ A_{\bar{H}} P_{\bar{H}} + P_{\bar{H}} A_{\bar{H}}^* + B_{\bar{H}} B_{\bar{H}}^* &= 0, \quad D_{\bar{H}} B_{\bar{H}}^* + C_{\bar{H}} P_{\bar{H}} = 0, \quad P_{\bar{H}} Q_{\bar{H}} = Q_{\bar{H}} P_{\bar{H}} = s_1^2 I \end{aligned}$$

with

$$P_{\bar{H}} = \begin{bmatrix} \hat{P}_1 & I \\ I & \bar{P}_2 \end{bmatrix} := \begin{bmatrix} \bar{Q}_2 \bar{R}^{-*} & I \\ I & \bar{P}_2 \end{bmatrix}, \quad Q_{\bar{H}} = \begin{bmatrix} \bar{Q}_1 & -\bar{R}^* \\ -\bar{R} & \bar{Q}_2 \end{bmatrix} := \begin{bmatrix} \bar{P}_2 \bar{R} & -\bar{R}^* \\ -\bar{R} & \bar{Q}_2 \end{bmatrix}.$$

Hence, \bar{H} is all-pass at s_1 from [5, Thm. 5.1] and this proves (12). The state-space realizations (18)–(20), definitions (21), and (16) yield the following identities

$$\begin{aligned} \bar{Q}_{13}^{-1} &\stackrel{s}{=} (A_Q - s_1^{-1} B_{Q_3} C_{Q_1}, -s_1^{-1} B_{Q_3}, s_1^{-1} C_{Q_1}, s_1^{-1} I) \\ &\stackrel{s}{=} (A_Q + s_1^{-2} B_{Q_3} B_{Q_3}^* \bar{Q}_2, -s_1^{-1} B_{Q_3}, s_1^{-1} \bar{C}_{Q_1}, s_1^{-1} I), \\ \bar{Q}_{32}^{-1} &\stackrel{s}{=} (A_Q - s_1^{-1} B_{Q_2} C_{Q_3}, -s_1^{-1} B_{Q_2}, s_1^{-1} C_{Q_3}, s_1^{-1} I) \\ &\stackrel{s}{=} (A_Q + s_1^{-2} \bar{P}_2 C_{Q_3}^* C_{Q_3}, -s_1^{-1} \bar{B}_{Q_2}, s_1^{-1} C_{Q_3}, s_1^{-1} I), \\ \bar{R}_{21}^{-1} &\stackrel{s}{=} (A - s_1^{-1} \hat{B}_1 \bar{C}_2, -s_1^{-1} \hat{B}_1, s_1^{-1} \bar{C}_2, s_1^{-1} I) \\ &\stackrel{s}{=} [-\bar{R}^{-1} (A_Q + s_1^{-2} B_{Q_3} B_{Q_3}^* \bar{Q}_2)^* \bar{R}, -s_1^{-1} \hat{B}_1, s_1^{-1} \bar{C}_2, s_1^{-1} I]. \end{aligned}$$

Hence, (17) and (23) prove (13).

(ii) The fact that $s_1(R)$ is a suboptimal level of \hat{R} follows from part (i) since $\bar{Q}_{12} \in \mathbb{R} \mathcal{H}_{\infty}^+$ and

$$\|\bar{H}_{11}\|_{\infty} = \|\begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} + \bar{Q}_{12} \end{bmatrix}\|_{\infty} \leq \|\bar{H}\|_{\infty} = s_1(R).$$

Finally, (14) and (15) follow from (i) and [7, Thm. 3.6]. \square

The next theorem, which is the main result, shows that the solution of the second-level SODP associated with R is equivalent to the solution of the optimal problem associated with \hat{R} .

THEOREM 3. *Let H and \bar{H} be as given in Theorems 1 and 2, respectively. Then*

$$(24) \quad s_2(R) = s_1(\hat{R})$$

and

$$(25) \quad \mathbb{S}_2(R) = S[\mathbb{S}_1(\hat{R})],$$

where

$$S(\cdot) = \mathcal{F}_l\{Q_a, \mathcal{F}_u[\bar{Q}_a^{-1}, (\cdot)]\},$$

and where Q_a and \bar{Q}_a are defined in Theorems 1 and 2, respectively.

Proof. Since $HH^* = H^*H = s_1^2 I$ and $\bar{H}\bar{H}^* = \bar{H}^*\bar{H} = s_1^2 I$, it follows that

$$(26) \quad H_{11}H_{21}^* = -H_{21}H_{22}^*, \quad \bar{H}_{11} = -\bar{H}_{12}H_{22}^*\bar{H}_{21}^*,$$

$$(27) \quad \bar{H}_{21}\bar{H}_{21}^* = s_1^2 I - H_{22}H_{22}^* = H_{21}H_{21}^*, \quad \bar{H}_{12}^*\bar{H}_{12} = s_1^2 I - H_{22}^*H_{22} = H_{12}^*H_{12}.$$

Define

$$(28) \quad V_\perp := H_{12}\bar{H}_{12}^{-1}, \quad W_\perp := H_{21}^*\bar{H}_{21}^*.$$

Then (27) implies that

$$V_\perp^*V_\perp = I_{p-1}, \quad W_\perp^*W_\perp = I_{l+m-1}.$$

Hence, there exist

$$V = [v \quad V_\perp] \in \mathbb{R}\mathcal{L}_\infty^{p \times p}, \quad W = [w \quad W_\perp] \in \mathbb{R}\mathcal{L}_\infty^{(l+m) \times (l+m)}$$

such that V and W are all-pass [5]. Using (26) and definition (28) we obtain

$$V_\perp^*H_{12} = \bar{H}_{12}^*H_{12}^*H_{12} = \bar{H}_{12}^*\bar{H}_{12}^*\bar{H}_{12} = \bar{H}_{12},$$

$$H_{21}W_\perp = H_{21}H_{21}^*\bar{H}_{21}^* = \bar{H}_{21}\bar{H}_{21}^*\bar{H}_{21}^* = \bar{H}_{21},$$

$$V_\perp^*H_{11}W_\perp = V_\perp^*H_{11}H_{21}^*\bar{H}_{21}^* = -V_\perp^*H_{12}H_{22}^*\bar{H}_{21}^* = -\bar{H}_{12}H_{22}^*\bar{H}_{21}^* = \bar{H}_{11}.$$

It follows that

$$(29) \quad \begin{bmatrix} V^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} \begin{bmatrix} W & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} v^*H_{11}w & v^*H_{11}W_\perp & v^*H_{12} \\ V_\perp^*H_{11}w & V_\perp^*H_{11}W_\perp & V_\perp^*H_{12} \\ H_{21}w & H_{21}W_\perp & H_{22} \end{bmatrix} \\ = \begin{bmatrix} v^*H_{11}w & v^*H_{11}W_\perp & v^*H_{12} \\ V_\perp^*H_{11}w & \bar{H}_{11} & \bar{H}_{12} \\ H_{21}w & \bar{H}_{21} & H_{22} \end{bmatrix}.$$

One can verify that

$$(30) \quad G_{22}, G = \begin{bmatrix} G_{11} & G_{12} \\ G_{21} & G_{22} \end{bmatrix} \text{ are all-pass at } \gamma \Rightarrow G_{12} = 0,$$

$$G_{21} = 0 \text{ and } G_{11} \text{ is all-pass at } \gamma.$$

Since V , W , $s_1^{-1}H$, and $s_1^{-1}\bar{H}$ are all-pass, we can use (30) and (29) to show that

$$(31) \quad \begin{bmatrix} V^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} \begin{bmatrix} W & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} v^*H_{11}w & v^*H_{11}W_\perp & v^*H_{12} \\ V_\perp^*H_{11}w & V_\perp^*H_{11}W_\perp & V_\perp^*H_{12} \\ H_{21}w & H_{21}W_\perp & H_{22} \end{bmatrix} \\ = \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \bar{H}_{11} & \bar{H}_{12} \\ 0 & \bar{H}_{21} & H_{22} \end{bmatrix},$$

where

$$(32) \quad a := s_1^{-1} v^* H_{11} w \in \mathbb{R} \mathcal{L}_\infty^{1 \times 1} \text{ is all-pass.}$$

Using the characterization of the set $[R_{11} \ R_{12} + \mathbb{S}_1(R)]$ given in Theorem 1, then with a slight abuse of notation, we have

$$(33) \quad \begin{bmatrix} v^* \\ V_\perp^* \end{bmatrix} [R_{11} \ R_{12} + \mathbb{S}_1(R)] \begin{bmatrix} w & W_\perp \end{bmatrix} \\ = \begin{bmatrix} v^* \\ V_\perp^* \end{bmatrix} \{ H_{11} + H_{12} \mathcal{U}_1 (I - H_{22} \mathcal{U}_1)^{-1} H_{21} \} \begin{bmatrix} w & W_\perp \end{bmatrix}.$$

Expanding the right-hand side of (33) and using (31) gives

$$(34) \quad V^* [R_{11} \ R_{12} + \mathbb{S}_1(R)] W = \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \mathcal{F}_1(\bar{H}, \mathcal{U}_1) \end{bmatrix} = \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \hat{R}_{11} & \hat{R}_{12} + \mathbb{S}(\hat{R}, s_1) \end{bmatrix},$$

where the second equality follows from part (ii) of Theorem 2. Suppose we write

$$(35) \quad V^* [R_{11} \ R_{12} + Q] W = \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \hat{R}_{11} & \hat{R}_{12} + \bar{Q} \end{bmatrix}.$$

Then (34) is equivalent to the following. For each $Q \in \mathbb{S}_1(R)$ there exists a $\bar{Q} \in \mathbb{S}(\hat{R}, s_1)$ such that (35) is satisfied. Conversely, for each $\bar{Q} \in \mathbb{S}(\hat{R}, s_1)$, there exists a $Q \in \mathbb{S}_1(R)$ such that (35) is satisfied. Furthermore, as Q ranges over the whole of $\mathbb{S}_1(R)$, \bar{Q} ranges over the whole of $\mathbb{S}(\hat{R}, s_1)$. Since V and W are all-pass, we have

$$s_2(R) := \inf_{Q \in \mathbb{S}_1(R)} s_2^\infty([R_{11} \ R_{12} + Q]) = \inf_{Q \in \mathbb{S}_1(R)} s_2^\infty(V^* [R_{11} \ R_{12} + Q] W).$$

Using (34) and the fact that a is all-pass and fixed,

$$(36) \quad s_2(R) = \inf_{\bar{Q} \in \mathbb{S}(\hat{R}, s_1)} s_1^\infty([\hat{R}_{11} \ \hat{R}_{12} + \bar{Q}]).$$

Since the set $\mathbb{S}(\hat{R}, s_1)$ consists of all suboptimal approximations of \hat{R} , then it includes all the optimal ones. Therefore, the set $\mathbb{S}(\hat{R}, s_1)$ in (36) can be replaced by the set $\mathcal{H}_\infty^{+(p-1) \times (m-1)}$, and (24) follows. Since V and W are all-pass we can write (34) as

$$(37) \quad [R_{11} \ R_{12} + \mathbb{S}_1(R)] = V \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \hat{R}_{11} & \hat{R}_{12} + \mathbb{S}(\hat{R}, s_1) \end{bmatrix} W^*.$$

Hence, it follows that the subset of $\mathbb{S}_1(R)$ whose elements minimize the second singular value of the left-hand side of (37) can be obtained by replacing the set $\mathbb{S}(\hat{R}, s_1)$ by $\mathbb{S}_1(\hat{R})$ in the right-hand side of (37), which proves that

$$(38) \quad [R_{11} \ R_{12} + \mathbb{S}_2(R)] = V \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \hat{R}_{11} & \hat{R}_{12} + \mathbb{S}_1(\hat{R}) \end{bmatrix} W^*.$$

To prove (25) we expand the right-hand side of (38) as

$$(39) \quad [R_{11} \ R_{12} + \mathbb{S}_2(R)] = [v \ V_\perp] \begin{bmatrix} s_1 a & 0 & 0 \\ 0 & \hat{R}_{11} & \hat{R}_{12} + \bar{Q}_{12} \end{bmatrix} \begin{bmatrix} w^* \\ W_\perp^* \end{bmatrix} \\ + [v \ V_\perp] \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & \mathbb{S}_1(\hat{R}) - \bar{Q}_{12} \end{bmatrix} \begin{bmatrix} w^* \\ W_\perp^* \end{bmatrix}.$$

Using (31), the first term in (39) is equal to $[R_{11} \ R_{12} + Q_{12}]$. Using definition (28) and the partitions of H and \bar{H} , it follows from (39) that

$$[R_{11} \ R_{12} + S_2(R)] = [R_{11} \ R_{12} + Q_{12}] \\ + Q_{13}\bar{Q}_{13}^{-1}[0 \ S_1(\hat{R}) - \bar{Q}_{12}]\begin{bmatrix} \bar{R}_{21}^{-1}R_{21} & * \\ 0 & \bar{Q}_{32}^{-1}Q_{32} \end{bmatrix},$$

where $*$ denotes an expression that is irrelevant for the present purpose. Thus,

$$S_2(R) = Q_{12} + Q_{13}\bar{Q}_{13}^{-1}[S_1(\hat{R}) - \bar{Q}_{12}]\bar{Q}_{32}^{-1}Q_{32} = \mathcal{F}_l[K, S_1(\hat{R})],$$

where

$$K = \begin{bmatrix} Q_{12} - Q_{13}\bar{Q}_{13}^{-1}\bar{Q}_{12}\bar{Q}_{32}^{-1}Q_{32} & Q_{13}\bar{Q}_{13}^{-1} \\ \bar{Q}_{32}^{-1}Q_{32} & 0 \end{bmatrix}.$$

A simple calculation will verify that $\mathcal{F}_l[K, (\cdot)] = \mathcal{F}_l\{Q_a, \mathcal{F}_u[\bar{Q}_a^{-1}, (\cdot)]\}$, which proves (25).

Remark 4. Compared with R , \hat{R} has a lower state dimension $\deg(\hat{R}) \leq \deg(R) - 1$ and

$$R = {}_p[R_{11} \ R_{12}] \in \mathbb{R}\mathcal{H}_{\infty}^{-} \Rightarrow \hat{R} = {}_{p-1}[\hat{R}_{11} \ \hat{R}_{12}] \in \mathbb{R}\mathcal{H}_{\infty}^{-}.$$

The solution of the second-level SODP associated with R is equivalent to the solution of an optimal problem of reduced dimensions and MacMillan degree.

To summarize the results of this section, the following procedure may be used to find the second-level solution of the 2-block SODP. We start with R partitioned as in (4).

(I) Find the optimal level $s_1 = s_1(R)$. If $s_1 = \|R_{11}\|_{\infty}$, stop. If $s_1 > \|R_{11}\|_{\infty}$, continue.

(II) Find H , the generator of all optimal error functions of R using Theorem 1.

(III) Find \bar{H} , the all-pass embedding of H_{22} using Theorem 2 and define $\hat{R} := (\bar{H}_{11})_-$.

The second superoptimal level of R is equal to the optimal level of \hat{R} and the set of all second-level superoptimal approximations of R is given in terms of the optimal approximations of \hat{R} as (25).

Remark 5. The calculation of the optimal levels $s_1(R)$ and $s_1(\hat{R})$ involves a binary search algorithm (the so-called γ -iteration), where each step involves the solution of two algebraic Riccati equations of order $n = \deg(R)$ and $n - 1 = \deg(\hat{R})$, respectively. The calculation of \hat{R} involves the solution of the algebraic Riccati equations (16), which are of order $n - 1$. Hence, the calculation of the second-level superoptimal solution is essentially equivalent to the calculation of the optimal solutions for R and \hat{R} .

Remark 6. If assumption (6) is not satisfied, then the set of all optimal error functions of R can, in general, be generated by an LLFM of the form

$$[R_{11} \ R_{12} + S_1(R)] = \mathcal{F}_l(H, \mathcal{U}), \quad \mathcal{U} := \{[0_{p \times l} \ u]: u \in s_1^{-1} \mathcal{BH}_{\infty}^{p \times m}\},$$

where H is all-pass at s_1 and satisfies [7],

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = {}_p \left[\begin{array}{cc|c} R_{11} & R_{12} + Q_{12} & Q_{13} \\ R_{21} & R_{22} + Q_{22} & Q_{23} \\ \hline 0 & Q_{32} & Q_{33} \end{array} \right] \quad \|H_{22}\|_{\infty} = s_1; H_{12}, H_{21} \text{ have full rank.}$$

It follows that (31) cannot be satisfied for any all-pass transformations V and W since H_{12} and H_{21} have full normal rank. This is because there do not exist vector transfer functions w and v such that the (1, 3) and (3, 1) blocks of (31) are satisfied. Consequently, it is not possible to carry out the diagonalization and the algorithm stops. If $\min(p, m) = 1$, then the optimal and superoptimal approximations are the same and the set of all optimal error functions has a continuum of solutions. This shows that if $s_1(R) = \|R_{11}\|_\infty$, then, in general, there does not exist a unique superoptimal approximation of R . See [11] for more details.

Remark 7. Previous solutions to the SODP are based on finding a maximal Schmidt pair, which are a pair of left and right singular vectors associated with the largest singular value $s_1(R)$ [3], [8], [9], [17]. This pair corresponds to the vectors v and w in (31). Here, in contrast, the solution of the SODP is obtained directly via the optimal generator H ; this is possible since all information about the optimal approximations is contained in this generator (Theorem 1). The advantage of this approach is that the same method can be used for the solution of the one-, two-, and four-block problems, since in each case, the optimal generators have the same form [7].

The solution of the second-level SODP associated with R is given in terms of the solution of the optimal problem associated with \hat{R} . Since \hat{R} has the same form as R , Theorem 1 can be used to give the solution of the optimal problem associated with \hat{R} , and Problem 2 is solved. In § 6, the solution of Problem 2 is used to give the solution of the full SODP (Problem 1).

5. MacMillan degree bounds. In this section, we carry out a cancellation analysis of the second-level superoptimal algorithm developed in the previous section. We will prove the existence of second-level superoptimal approximations of R of MacMillan degree $\leq (n-1) + (n-2)$, where $n = \text{MacMillan degree of } R$. The following lemma gives some properties about linear fractional maps in a state-space setting.

LEMMA 1. Let $P, \hat{P}, \tilde{U} \in \mathbb{R}\mathcal{L}_\infty$ have state-space realizations $\tilde{U} \stackrel{s}{=} (\hat{A}, \hat{B}, \hat{C}, \hat{D})$

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & D_{11} & D_{12} \\ C_2 & D_{21} & D_{22} \end{array} \right], \quad \hat{P} = \begin{bmatrix} \hat{P}_{11} & \hat{P}_{12} \\ \hat{P}_{21} & \hat{P}_{22} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|cc} \hat{A} & \hat{B}_1 & \hat{B}_2 \\ \hline \hat{C}_1 & \hat{D}_{11} & \hat{D}_{12} \\ \hat{C}_2 & \hat{D}_{21} & \hat{D}_{22} \end{array} \right],$$

respectively, and assume that the inverses

$\tilde{L} = (I - D_{22}\tilde{D})^{-1}$, $\tilde{K} = (I - \tilde{D}D_{22})^{-1}$, $\hat{K} = (I - \hat{D}_{11}D_{11})^{-1}$, $\hat{L} = (I - D_{11}\hat{D}_{11})^{-1}$ exist. Then

(i) $\deg(\mathcal{F}_l(P, \tilde{U})) \leq \deg(P) + \deg(\tilde{U})$ and $\deg(\mathcal{F}_u[\hat{P}, \tilde{U}]) \leq \deg(\hat{P}) + \deg(\tilde{U})$.

$$(ii) \mathcal{F}_l(P, \tilde{U}) \stackrel{s}{=} \left[\begin{array}{cc|c} A + B_2\tilde{D}\tilde{L}C_2 & B_2\tilde{K}\tilde{C} & B_1 + B_2\tilde{D}\tilde{L}D_{21} \\ \hline \tilde{B}\tilde{L}C_2 & \tilde{A} + \tilde{B}D_{22}\tilde{K}\tilde{C} & \tilde{B}\tilde{L}D_{21} \\ \hline C_1 + D_{12}\tilde{D}\tilde{L}C_2 & D_{12}\tilde{K}\tilde{C} & D_{11} + D_{12}\tilde{D}\tilde{L}D_{21} \end{array} \right].$$

(iii) $\mathcal{F}_u\{P, \mathcal{F}_l[\hat{P}, (\cdot)]\} = \mathcal{F}_l[J, (\cdot)]$ where

$$J \stackrel{s}{=} \left[\begin{array}{cc|cc} A + B_1\hat{D}_{11}\hat{L}C_1 & B_1\hat{K}\hat{C}_1 & B_2 + B_1\hat{D}_{11}\hat{L}D_{12} & B_1\hat{K}\hat{D}_{12} \\ \hline \hat{B}_1\hat{L}C_1 & \hat{A} + \hat{B}_1D_{11}\hat{K}\hat{C}_1 & \hat{B}_1\hat{L}D_{12} & \hat{B}_2 + \hat{B}_1D_{11}\hat{K}\hat{D}_{12} \\ \hline C_2 + D_{21}\hat{D}_{11}\hat{L}C_1 & D_{21}\hat{K}\hat{C}_1 & D_{22} + D_{21}\hat{D}_{11}\hat{L}D_{12} & D_{21}\hat{K}\hat{D}_{12} \\ \hline \hat{D}_{21}\hat{L}C_1 & \hat{C}_2 + \hat{D}_{21}D_{11}\hat{K}\hat{C}_1 & \hat{D}_{21}\hat{L}D_{12} & \hat{D}_{22} + \hat{D}_{21}D_{11}\hat{K}\hat{D}_{12} \end{array} \right].$$

Proof. The proof follows by routine computation. \square

To give an upper bound on the degree of the second-level superoptimal approximations of R , we need to characterize the set $\mathbb{S}_1(\hat{R})$ as required by Theorem 3. Assume that the optimal level $s_1(\hat{R})$ can be calculated to any desired degree of accuracy using the γ -iteration, and furthermore, that

$$s_2(R) = s_1(\hat{R}) > \|\hat{R}_{11}\|_\infty.$$

Since \hat{R} has the same form as R , Theorem 1 is used to give a characterization of the set $\mathbb{S}_1(\hat{R})$.

COROLLARY 1. *Theorem 1 is satisfied with all variables “hatted”; p , m , and n are replaced by $p - 1$, $m - 1$, and $n - 1$, respectively, and \mathcal{U}_1 and s_1 are replaced by \mathcal{U}_2 and s_2 , respectively.*

The next theorem proves a general cancellation phenomenon between the optimal and suboptimal approximations of a given 2-block system. This result is used to give an upper bound on the MacMillan degree of the second-level superoptimal approximations of R .

THEOREM 4. *Let \bar{Q}_a be the generator of all suboptimal approximations of \hat{R} at level s_1 . Then*

$$(40) \quad \hat{Q} \in \mathbb{S}_1(\hat{R}) \Rightarrow \deg[\mathcal{F}_u(\bar{Q}_a^{-1}, \hat{Q})] \leq \deg(\hat{Q}).$$

Hence,

$$(41) \quad \hat{Q} \in \mathbb{S}_1(\hat{R}) \Rightarrow \deg\{\mathcal{F}_l[Q_a, \mathcal{F}_u(\bar{Q}_a^{-1}, \hat{Q})]\} \leq \deg(\hat{Q}) + n - 1.$$

Finally, if \hat{Q}_{12} is the central optimal approximation of \hat{R} , then

$$(42) \quad \deg\{\mathcal{F}_l[Q_a, \mathcal{F}_u(\bar{Q}_a^{-1}, \hat{Q}_{12})]\} \leq (n - 1) + (n - 2).$$

Proof. Corollary 1 implies that

$$(43) \quad \deg(\hat{Q}_a) \leq n - 2.$$

Since $\hat{Q} \in \mathbb{S}_1(\hat{R})$, then \hat{Q} is generated by the LLFM

$$(44) \quad \hat{Q} = \mathcal{F}_l(\hat{Q}_a, \hat{U}) \text{ for some } \hat{U} \in \mathcal{U}_2.$$

Hence, $\deg(\hat{Q}) \leq \deg(\hat{U}) + n - 2$ from part (i) of Lemma 1. To simplify the proof, assume that, in fact,

$$(45) \quad \deg(\hat{Q}) = \deg(\hat{U}) + n - 2.$$

Using (19), (21), and (1) gives

$$\bar{Q}_a = \begin{bmatrix} \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{Q}_{32} & \bar{Q}_{33} \end{bmatrix} \stackrel{s}{=} \left[\begin{array}{c|cc} A_{Q_2} & \bar{B}_{Q_2} & B_{Q_3} \\ \hline \bar{C}_{Q_1} & 0 & s_1 I \\ C_{Q_3} & s_1 I & 0 \end{array} \right] \stackrel{s}{=} \left[\begin{array}{c|cc} -\hat{A}^* - \bar{B}_{Q_2} \hat{B}_2^* & \bar{B}_{Q_2} & B_{Q_3} \\ \hline -\hat{C}_1 \hat{P}_1 & 0 & s_1 I \\ -s_1 \hat{B}_2^* & s_1 I & 0 \end{array} \right]$$

and

$$\bar{Q}_a^{-1} \stackrel{s}{=} \left[\begin{array}{c|cc} -\hat{A}^* + s_1^{-1} B_{Q_3} \hat{C}_1 \hat{P}_1 & s_1^{-1} B_{Q_3} & s_1^{-1} \bar{B}_{Q_2} \\ \hline \hat{B}_2^* & 0 & s_1^{-1} I \\ s_1^{-1} \hat{C}_1 \hat{P}_1 & s_1^{-1} I & 0 \end{array} \right].$$

Part (iii) of Lemma 1, (44), Corollary 1, and (10) yield

$$(46) \quad \mathcal{F}_u(\bar{Q}_a^{-1}, \hat{Q}) = \mathcal{F}_u[\bar{Q}_a^{-1}, \mathcal{F}_l(\hat{Q}_a, \hat{U})] = \mathcal{F}_l(J, \hat{U}),$$

where

$$(47) \quad J \stackrel{s}{=} \left[\begin{array}{cc|cc} s_1^{-1}B_{Q_3}(\hat{C}_1\hat{P}_1 + \hat{D}_{12}\hat{B}_2^*) - \hat{A}^* & s_1^{-1}B_{Q_3}\hat{C}_{Q_1} & s_1^{-1}\bar{B}_{Q_2} + s_1^{-2}B_{Q_3}\hat{D}_{12} & s_1^{-1}B_{Q_3}\hat{D}_{13} \\ \hat{B}_{Q_2}\hat{B}_2^* & \hat{A}_Q & s_1^{-1}\hat{B}_{Q_2} & \hat{B}_{Q_3} \\ \hline s_1^{-1}(\hat{C}_1\hat{P}_1 + \hat{D}_{12}\hat{B}_2^*) & s_1^{-1}\hat{C}_{Q_1} & s_1^{-2}\hat{D}_{12} & s_1^{-1}\hat{D}_{13} \\ \hat{D}_{32}\hat{B}_2^* & \hat{C}_{Q_3} & s_1^{-1}\hat{D}_{32} & 0 \end{array} \right]$$

$$\stackrel{s}{=} \left[\begin{array}{cc|cc} A_{11} & A_{12} & B_{11} & B_{12} \\ A_{21} & A_{22} & B_{21} & B_{22} \\ \hline C_{11} & C_{12} & s_1^{-2}\hat{D}_{12} & s_1^{-1}\hat{D}_{13} \\ C_{21} & C_{22} & s_1^{-1}\hat{D}_{32} & 0 \end{array} \right].$$

Applying the change of basis $T = \begin{bmatrix} I & 0 \\ \hat{P}_3^* & I \end{bmatrix}$ to (47) and using (2),

$$(48) \quad J \stackrel{s}{=} \left[\begin{array}{cc|cc} \hat{A}_{11} & \hat{A}_{12} & \hat{B}_{11} & \hat{B}_{12} \\ \hat{A}_{21} & \hat{A}_{22} & \hat{B}_{21} & \hat{B}_{22} \\ \hline \hat{C}_{11} & \hat{C}_{12} & s_1^{-2}\hat{D}_{12} & s_1^{-1}\hat{D}_{13} \\ \hat{C}_{21} & \hat{C}_{22} & s_1^{-1}\hat{D}_{32} & 0 \end{array} \right]$$

in which

$$(49) \quad \begin{aligned} \hat{A}_{21} &= \hat{A}_Q\hat{P}_3^* + \hat{P}_3^*\hat{A}^* + \hat{B}_{Q_2}\hat{B}_2^* - s_1^{-1}\hat{P}_3^*B_{Q_3}(\hat{C}_1\hat{P}_1 + \hat{D}_{12}\hat{B}_2^* + \hat{C}_{Q_1}\hat{P}_3^*), \\ \hat{C}_{11} &= s_1^{-1}(\hat{C}_1\hat{P}_1 + \hat{D}_{12}\hat{B}_2^* + \hat{C}_{Q_1}\hat{P}_3^*), \quad \hat{C}_{21} = \hat{D}_{32}\hat{B}_2^* + \hat{C}_{Q_3}\hat{P}_3^* \\ \hat{A}_{22} &= \hat{A}_Q - s_1^{-1}\hat{P}_3^*B_{Q_3}\hat{C}_{Q_1}, \quad \hat{C}_{12} = s_1^{-1}\hat{C}_{Q_1}, \end{aligned}$$

$$(50) \quad \begin{aligned} \hat{B}_{21} &= s_1^{-1}[\hat{B}_{Q_2} - \hat{P}_3^*(\bar{B}_{Q_2} + s_1^{-1}B_{Q_3}\hat{D}_{12})], \quad \hat{C}_{22} = \hat{C}_{Q_3}, \\ \hat{B}_{22} &= \hat{B}_{Q_3} - s_1^{-1}\hat{P}_3^*B_{Q_3}\hat{D}_{13}. \end{aligned}$$

It follows from Corollary 1 that the all-pass equations (9) are satisfied for the state-space realization of the generator \hat{H} for some real matrices

$$P_{\hat{H}} = \begin{matrix} n-1 \\ n-2 \end{matrix} \begin{bmatrix} \hat{P}_1 & \hat{P}_3 \\ \hat{P}_3^* & \hat{P}_2 \end{bmatrix}, \quad Q_{\hat{H}} = \begin{matrix} n-1 \\ n-2 \end{matrix} \begin{bmatrix} \hat{Q}_1 & \hat{Q}_3 \\ \hat{Q}_3^* & \hat{Q}_2 \end{bmatrix}.$$

This implies that

$$(51) \quad \begin{aligned} &A_{\hat{H}}P_{\hat{H}} + P_{\hat{H}}A_{\hat{H}}^* + B_{\hat{H}}B_{\hat{H}}^* \\ &= \begin{bmatrix} \hat{A}\hat{P}_1 + \hat{P}_1\hat{A}^* + \hat{B}_1\hat{B}_1^* + \hat{B}_2\hat{B}_2^* & \hat{A}\hat{P}_3 + \hat{P}_3\hat{A}^* + \hat{B}_2\hat{B}_{Q_2} \\ \hat{A}_Q\hat{P}_3^* + \hat{P}_3^*\hat{A}^* + \hat{B}_{Q_2}\hat{B}_2^* & \hat{A}_Q\hat{P}_2 + \hat{P}_2\hat{A}^* + \hat{B}_{Q_2}\hat{B}_{Q_2}^* + \hat{B}_{Q_3}\hat{B}_{Q_3}^* \end{bmatrix} = 0 \end{aligned}$$

and

$$(52) \quad D_{\hat{H}} B_{\hat{H}}^* + C_{\hat{H}} P_{\hat{H}} \\ = \begin{bmatrix} \hat{C}_1 \hat{P}_1 + \hat{C}_{Q_1} \hat{P}_3^* + \hat{D}_{12} \hat{B}_2^* & \hat{C}_1 \hat{P}_3 + \hat{C}_{Q_1} \hat{P}_2 + \hat{D}_{12} \hat{B}_{Q_2}^* + \hat{D}_{13} \hat{B}_{Q_3}^* \\ -s_1^{-1} \hat{B}_1^* \hat{Q}_1 \hat{P}_1 + \hat{C}_{Q_2} \hat{P}_3^* + s_1 \hat{B}_1^* & -s_1^{-1} \hat{B}_1^* \hat{Q}_1 \hat{P}_3 + \hat{C}_{Q_2} \hat{P}_2 \\ \hat{C}_{Q_3} \hat{P}_3^* + \hat{D}_{32} \hat{B}_2^* & \hat{C}_{Q_3} \hat{P}_2 + \hat{D}_{32} \hat{B}_{Q_2}^* \end{bmatrix} = 0.$$

Hence, from (49), the (2, 1) block of (51), and the (1, 1) and (3, 1) blocks of (52), we have $\hat{A}_{21} = 0$, $\hat{C}_{11} = 0$, and $\hat{C}_{21} = 0$, so that (48) and (50) imply that

$$J \stackrel{\Delta}{=} \left[\begin{array}{c|cc} \hat{A}_Q - s_1^{-1} \hat{P}_3^* B_{Q_3} \hat{C}_{Q_1} & s_1^{-1} [\hat{B}_{Q_2} - \hat{P}_3^* (\bar{B}_{Q_2} + s_1^{-1} B_{Q_3} \hat{D}_{12})] & \hat{B}_{Q_3} - s_1^{-1} \hat{P}_3^* B_{Q_3} \hat{D}_{13} \\ \hline s_1^{-1} \hat{C}_{Q_1} & s_1^{-1} \hat{D}_{12} & s_1^{-1} \hat{D}_{13} \\ \hat{C}_{Q_3} & s_1^{-1} \hat{D}_{32} & 0 \end{array} \right].$$

Thus, $\deg(J) \leq n - 2$ since $\hat{A}_Q \in \mathbb{R}^{(n-2) \times (n-2)}$ and this, together with (46), implies that

$$\deg[\mathcal{F}_u(\bar{Q}_a^{-1}, \hat{Q})] \leq \deg(\hat{U}) + n - 2.$$

Hence, (45) proves (40), which, in turn, proves (41) from part (i) of Lemma 1. Finally, (42) follows from (41) since the central approximation $\hat{Q}_{12} \stackrel{\Delta}{=} (\hat{A}_Q, \hat{B}_{Q_2}, \hat{C}_{Q_1}, \hat{D}_{12})$ satisfies $\deg(\hat{Q}_{12}) \leq n - 2$. \square

6. The superoptimal algorithm. In this section, the full 2-block superoptimal algorithm is presented. Let $R_1 = R$, $\hat{R}_1 = \hat{R}$ and $S_1(\cdot) = S(\cdot)$, where $S(\cdot)$ is defined in Theorem 3. The results of §§ 3 and 4 indicate that the solution of the second level SODP associated with R_1 is given in terms of the solution of the ODP associated with \hat{R}_1 as $s_2(R) = s_1(\hat{R})$, $S_2(R) = S_1[S_1(\hat{R})]$, where \hat{R}_1 satisfies

$$\hat{R}_1 = \begin{bmatrix} l & m-1 \\ p-1 & \end{bmatrix} [\hat{R}_{1,11} \quad \hat{R}_{1,12}] \in \mathbb{R}\mathcal{H}_{\infty}^{-}, \quad \deg(\hat{R}_1) \leq n - 1.$$

If we set $R_2 = \hat{R}_1$, we can repeat this process to obtain a sequence of 2-block systems

$$R_i = \begin{bmatrix} l & p-i+1 \\ p-i+1 & \end{bmatrix} [R_{i,11} \quad R_{i,12}] \in \mathbb{R}\mathcal{H}_{\infty}^{-}, \quad i = 1, \dots, k$$

and a sequence of operators S_0, S_1, \dots, S_{k-1} , such that for $j = 1, \dots, k - 1$,

$$(53) \quad s_2(R_j) = s_1(R_{j+1}),$$

$$(54) \quad S_2(R_j) = S_{j-1}[S_1(R_{j+1})],$$

$$(55) \quad \deg(R_j) \leq n - j + 1$$

from Theorems 3 and 4. Hence, a simple induction argument will establish that for $i = 1, \dots, k$,

$$(56) \quad s_i(R_1) = s_1(R_i),$$

$$(57) \quad S_i(R_1) = S_0 \circ S_1 \circ \dots \circ S_{i-1}[S_1(R_i)],$$

where, for operators S_i and S_{i+1} , the operator $S_i \circ S_{i+1}(\cdot)$ is defined by $S_i[S_{i+1}(\cdot)]$. Equation (56) says that the i th superoptimal level for R_1 is equal to the optimal level for R_i , and (57) says that the set of all i th level superoptimal approximations of R_1 can be obtained from the set of all optimal approximations of R_i through the composite operator $S_0 \circ S_1 \circ \dots \circ S_{i-1}$. Thus, we obtain the following algorithm for the solution of the SODP.

ALGORITHM 1. Given $R \in \mathbb{R}\mathcal{H}_\infty^-$ partitioned as in (4):

- (0) Set $i = 1$, $R_1 = R$ and $S_0 = I$;
 (1) Find $s_i = s_1(R_i)$;
 (2) If $i = n$ then set $k = \min(p, m)$; $R_k = R_i$; $s_j = 0$ for $j = n + 1, \dots, k$ and stop;
 (3) If $s_i = \|R_{i,11}\|_\infty$ then set $k = i$ and stop;
 If
 (58) $s_i := s_1(R_i) > \|R_{i,11}\|_\infty$
 then continue;
 (4) If $i = \min(p, m)$ then set $k = \min(p, m)$ and stop;
 (5) Find \hat{R}_i and $S_{i-1}(\cdot)$;
 (6) If it is required to minimize more singular values, then set $R_{i+1} = \hat{R}_i$, $i = i + 1$ and go to step (1); else stop.

The superoptimal levels of R are given by $\{s_1, \dots, s_k\}$ and the set of all k th level superoptimal approximations of R is given by $\mathbb{S}_k(R) = S_0 \circ \dots \circ S_{k-1}[\mathbb{S}_1(R_k)]$.

Next, we generalize the cancellation analysis given in § 5. Theorems 3 and 4, when applied to R_{k-1} , imply that

$$Q \in \mathbb{S}_1(R_k) \Rightarrow S_{k-1}(Q) \in \mathbb{S}_2(R_{k-1}) \text{ and } \deg[S_{k-1}(Q)] \leq \deg(Q) + n - k + 1.$$

Since $\mathbb{S}_2(R_{k-1}) \subseteq \mathbb{S}_1(R_{k-1})$ (a second superoptimal approximation is also an optimal approximation), then by repeated application of Theorems 3 and 4 we obtain

$$(59) \quad Q \in \mathbb{S}_1(R_k) \Rightarrow \deg\{S_0 \circ \dots \circ S_{k-1}[\mathbb{S}_1(R_k)]\} \leq \deg(Q) + \sum_{i=1}^{k-1} n - i.$$

Since $\deg(R_k) \leq n - k + 1$ from (55), then it follows from Theorem 1 that the central optimal approximation $Q_{k,12}$ satisfies $\deg(Q_{k,12}) \leq n - k$. Hence, by taking $Q = Q_{k,12}$ in (59), it follows from (57) that there exist k th level superoptimal approximations of R whose MacMillan degree satisfies

$$(60) \quad \deg(Q_{so}) \leq \sum_{i=1}^k n - i.$$

The number of singular values that can be minimized is given by k , and the superoptimal approximation is unique only if the set $\mathbb{S}_1(R_k)$ has a unique element. If the algorithm stops at the end of step (3), then it follows from Remark 6 that the set $\mathbb{S}_1(R_k)$, in general, has a continuum of solutions, and the superoptimal approximation may not be unique. If the algorithm stops at the end of either steps (2) or (4), then the number of singular values that can be minimized is given by $k = \min(p, m)$, and it follows from Remark 2 that the set $\mathbb{S}_1(R_k)$ has a unique element. Hence, the superoptimal approximation is unique. It also follows from Remark 2 that if the algorithm stops at the end of step (2) then the last $[\min(p, m) - n]$ superoptimal levels are equal to zero.

Remark 8. The algorithm may be stopped prematurely at step (6). In this case, (56), (57), and (60) are still satisfied, which means that there is a saving in the complexity of the algorithm as well as a reduction in the MacMillan degree of the superoptimal approximations. This shows that the algorithm may be used to solve the related problem of minimizing a given number of singular values.

Condition (58) is sufficient for the existence and uniqueness of the superoptimal approximation. To see that this condition is not necessary for existence, consider the system $R = [R_{11} \ R_{12}] = [1/(s-1) \ 0]$. Then it is clear that for this example the

superoptimal approximations are the same as the optimal ones. It can be shown using the results in [7] that $s_1(R) = \|R_{11}\|_\infty = 1$ and that the set of all superoptimal approximations of R is given by $\mathcal{S}_1(R) = \{s/(s+1)u; u \in \mathcal{BH}_\infty^+\}$. Thus, the superoptimal approximation of R exists, although it is not unique. In this case, the superoptimal approach is not appropriate for restoring uniqueness to the optimal approximations, and other criteria must be used. To see that condition (58) is not necessary for uniqueness, consider the system $R = [R_{11} \ R_{12}] = [1/(s-1) \ 1/(s-1)]$. It can be shown using the results in [7] that $s_1(R) = \|R_{11}\|_\infty = 1$ and that the set of all superoptimal approximations of R has a unique element given by $Q_{12} = 1$. Although condition (58) is not satisfied for this example, we have a unique superoptimal approximation. A full discussion is given in [11].

7. The 4-block SODP. This section gives a brief outline of the solution of the 4-block SODP. Given $R \in \mathcal{SH}_\infty^-$ partitioned as

$$R = \begin{array}{c} l \quad m \\ \begin{array}{cc} R_{11} & R_{12} \\ R_{21} & R_{22} \end{array} \end{array},$$

we are required to find all stable Q that lexicographically minimize the singular values of the error function

$$E_Q = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix}.$$

The optimal level $s_1(R) := \inf_{Q \in \mathcal{H}_\infty^+} s_1^\infty(E_Q)$ is obtained using the γ -iteration [7]. If we assume that

$$s_1 := s_1(R) > \max \{ \| [R_{11} \ R_{12}] \|_\infty, \| [R_{11}^* \ R_{21}^*] \|_\infty \},$$

then [7] gives the set of all optimal error functions of R as the LLFM

$$\mathcal{E}_1(R) := \left\{ E_Q = \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} + Q \end{bmatrix} : Q \in \mathcal{H}_\infty^+, \|E_Q\|_\infty = s_1(R) \right\} = \mathcal{F}_l(H, \mathcal{U}_1),$$

where

$$\mathcal{U}_1 := \left\{ \begin{bmatrix} 0_{q \times l} & 0_{q \times (m-1)} \\ 0_{(p-1) \times l} & u \end{bmatrix} : u \in s_1^{-1} \mathcal{BH}_\infty^{(p-1) \times (m-1)} \right\},$$

and H satisfies $HH^* = H^*H = s_1^2 I$ and has the form

$$H = \begin{bmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{bmatrix} = \begin{array}{c} l \quad m \quad q \quad p-1 \\ \begin{array}{cc|cc} R_{11} & R_{12} & R_{13} & 0 \\ R_{21} & R_{22} + Q_{22} & R_{23} + Q_{23} & Q_{24} \\ \hline R_{31} & R_{32} + Q_{32} & R_{33} + Q_{33} & Q_{34} \\ 0 & Q_{42} & Q_{43} & Q_{44} \end{array} \end{array}.$$

In addition, $Q_{ij} \in \mathcal{RH}_\infty^+$, $i, j = 2, 3, 4$; R_{31}^{-1} , R_{13}^{-1} , $R_{ij} \in \mathcal{RH}_\infty^-$, $i, j = 1, 2, 3$ and $\|H_{22}\|_\infty < s_1$. By using arguments essentially similar to those used in the proof of Theorem 3 we obtain the following result, which gives the solution of the second-level 4-block SODP.

THEOREM 5 [11]. Let H be the generator of all optimal error functions of R . Then

(i) There exists an embedding of H_{22} that is all-pass at s_1 and satisfies

$$\bar{H} = \begin{bmatrix} \bar{H}_{11} & \bar{H}_{12} \\ \bar{H}_{21} & H_{22} \end{bmatrix} = \begin{matrix} & \begin{matrix} l & m-1 & q & p-2 \end{matrix} \\ \begin{matrix} q \\ p-1 \\ l \\ m-2 \end{matrix} & \left[\begin{array}{cc|cc} \hat{R}_{11} & \hat{R}_{12} & \bar{R}_{13} & 0 \\ \hat{R}_{21} & \hat{R}_{22} + \bar{Q}_{22} & \bar{R}_{23} + \bar{Q}_{23} & \bar{Q}_{24} \\ \hline \bar{R}_{31} & \bar{R}_{32} + \bar{Q}_{32} & R_{33} + Q_{33} & Q_{34} \\ 0 & \bar{Q}_{42} & Q_{43} & Q_{44} \end{array} \right] \end{matrix}$$

$\hat{R}_{12}, \hat{R}_{21}, \hat{R}_{22}, \bar{R}_{31}^{-1}, \bar{R}_{13}^{-1}, \bar{R}_{ij} \in \mathbb{RH}_{\infty}^{-}$; $i, j = 1, 2, 3$, $\bar{Q}_{24}^{-1}, \bar{Q}_{42}^{-1}, \bar{Q}_{ij} \in \mathbb{RH}_{\infty}^{+}$; $i, j = 2, 3, 4$, $\hat{R}_{11} \in \mathbb{RL}_{\infty}$.

Hence, the set of all suboptimal error functions of \hat{R} is generated by the LLFM

$$\mathcal{E}(\hat{R}, s_1) := \left\{ \hat{E}_Q = \begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} \\ \hat{R}_{21} & \hat{R}_{22} + Q \end{bmatrix} : Q \in \mathcal{H}_{\infty}^{+}, \|\hat{E}_Q\|_{\infty} \leq s_1 \right\} = \mathcal{F}_l(\bar{H}, \mathcal{U}_1).$$

(ii) The solution of the second-level SODP associated with R is given by (24) and (25), where

$$Q_a = \begin{bmatrix} Q_{22} & Q_{24} \\ Q_{42} & Q_{44} \end{bmatrix}, \quad \bar{Q}_a = \begin{bmatrix} \bar{Q}_{22} & \bar{Q}_{24} \\ \bar{Q}_{42} & \bar{Q}_{44} \end{bmatrix}.$$

Remark 9. A minor complication arises in the solution of the 4-block SODP since \hat{R}_{11} is not necessarily antistable. This can be resolved by noting that

1. There exists an all-pass matrix $X \in \mathbb{RH}_{\infty}^{-}$ such that $\hat{R}_{11} := \hat{R}_{11}X$, $\hat{R}_{21} := \hat{R}_{21}X \in \mathbb{RH}_{\infty}$.

2. The ODP associated with \hat{R} is equivalent to the ODP associated with

$$\tilde{R} := \begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} \\ \hat{R}_{21} & \hat{R}_{22} \end{bmatrix} = \begin{bmatrix} \hat{R}_{11} & \hat{R}_{12} \\ \hat{R}_{21} & \hat{R}_{22} \end{bmatrix} \begin{bmatrix} X & 0 \\ 0 & I \end{bmatrix} \in \mathbb{RH}_{\infty}^{-},$$

since X is all-pass [11].

8. Examples. This section gives a few examples to illustrate the superoptimal algorithm.

Example 1. We give a trivial example as a check, and to illustrate the various steps involved in the superoptimal algorithm. Let

$$R = [R_{11} \quad R_{12}] = \left[\begin{array}{c|c} \frac{4.8}{s-5} & \frac{8}{s-1/2} \\ \hline \frac{-6.4}{s-5} & \frac{6}{s-1/2} \end{array} \middle| \begin{array}{c} \frac{9.6}{s-5} \\ \frac{-12.8}{s-5} \end{array} \right] \in \mathbb{RH}_{\infty}^{-2 \times 3}.$$

Now

$$VR = \begin{bmatrix} .8 & .6 \\ .6 & -.8 \end{bmatrix} R = \left[\begin{array}{c|c} 0 & \frac{1}{s-1/2} \\ \hline \frac{8}{s-5} & \frac{16}{s-5} \end{array} \right],$$

where V is orthogonal. Thus, it follows that $s_i(R) = s_i(VR)$ for $i = 1, 2$. Hence,

$$s_1(R) = s_1(VR) = s_1\left(\left[\frac{8}{s-5} \middle| \frac{16}{s-5}\right]\right) = 2 \quad s_2(R) = s_1(VR) = s_1\left(\frac{1}{s-1/2}\right) = 1.$$

The superoptimal solution can be obtained using the following steps.

1. Using the results in [7], we have that $s_1(R) = 2$ and the generator H is given by

$$H = \left[\begin{array}{cc|c} R_{11} & R_{12} + Q_{12} & Q_{13} \\ R_{21} & R_{22} + Q_{22} & Q_{23} \\ 0 & Q_{32} & Q_{33} \end{array} \right] = \left[\begin{array}{cc|c} \frac{4.8}{s-5} & \frac{.8}{s-1/2} + \frac{4/15}{s+5/6} & \frac{9.6}{s-5} + 1.2 \\ -\frac{6.4}{s-5} & \frac{.6}{s-1/2} + \frac{.2}{s+5/6} & -\frac{12.8}{s-5} - 1.6 \\ 0 & 2\frac{s-3}{s-5} & 0 \end{array} \right] = \left[\begin{array}{cc|c} 2\frac{s-3}{s-5} & 0 & \frac{8}{s-5} \\ 0 & 2\frac{s+1/2}{s+5/6} & 0 \end{array} \right] \begin{array}{c} 1.6\frac{s+1/2}{s+5/6} \\ 1.2\frac{s+1/2}{s+5/6} \\ \frac{4/3}{s+5/6} \end{array}.$$

2. Using Theorem 2, it can be verified that the all-pass embedding of H_{22} (at s_1) is given by

$$\bar{H} = \left[\begin{array}{cc|c} \hat{R}_{11} & \hat{R}_{12} + \bar{Q}_{12} & \bar{Q}_{13} \\ \bar{R}_{21} & \bar{R}_{22} + \bar{Q}_{22} & \bar{Q}_{23} \\ 0 & \bar{Q}_{32} & \bar{Q}_{33} \end{array} \right] = \left[\begin{array}{cc|c} 0 & \frac{1}{s-1/2} + \frac{1/3}{s+5/6} & 2\frac{s+1/2}{s+5/6} \\ 2 & 0 & 0 \\ 0 & 2\frac{s+1/2}{s+5/6} & \frac{4/3}{s+5/6} \end{array} \right].$$

3. The second-level system \hat{R} is given by the antistable projection of \bar{H}_{11} so that

$$\hat{R} = [\bar{H}_{11}]_- = \left[\begin{array}{c} 1 \\ s - 1/2 \end{array} \right],$$

which defines an effectively one-block problem since $\hat{R}_{11} = 0$. Then it follows that

$$s_1(\hat{R}) = s_1\left(\frac{1}{s - 1/2}\right) = 1,$$

and it can be checked using Corollary 1 that the set $\mathbb{S}_1(\hat{R})$ has only one element given by $\hat{Q}_{12} = 1$.

4. Finally, we use Theorem 3 to obtain the second superoptimal level $s_2(R)$ as $s_2(R) = s_1(\hat{R}) = 1$ and the (unique) second-level superoptimal approximation of R as

$$S_2(R) = Q_{12} + Q_{13}\bar{Q}_{13}^{-1}[\hat{Q}_{12} - \bar{Q}_{12}]\bar{Q}_{32}^{-1}Q_{32} = \begin{bmatrix} .8 & 1.2 \\ .6 & -1.6 \end{bmatrix}.$$

Example 2. Let $R \in \mathbb{R}\mathcal{H}_\infty^{-2 \times 3}$ be given by

$$R = [R_{11} \quad R_{12}] = \left[\begin{array}{cc} \frac{2.5}{s-1.8} + \frac{0.5}{s-3.4} & \frac{12.5}{s-1.8} + \frac{0.5}{s-3.4} \\ \frac{0.5}{s-1.8} + \frac{3.5}{s-3.4} & \frac{2.5}{s-1.8} + \frac{3.5}{s-3.4} \end{array} \right] \begin{array}{c} \frac{2.5}{s-1.8} + \frac{3.5}{s-3.4} \\ \frac{0.5}{s-1.8} + \frac{24.5}{s-3.4} \end{array}.$$

Then by carrying out the steps given in this paper, the superoptimal levels are given by $s_1(R) = 5.0$, $s_2(R) = 2.40157$, and the (unique) superoptimal approximation of R is obtained as

$$Q_{so} = \frac{1}{(s + 2.46868)} \begin{bmatrix} 3.33701(s + 2.53702) & 1.24724(s + 2.66313) \\ 1.24724(s + 2.66313) & 4.06457(s + 2.53215) \end{bmatrix}.$$

A plot of the singular values of the superoptimal error system $[R_{11} \ R_{12} + Q_{so}]$ will verify that they are flat at the superoptimal levels. \square

9. Conclusion. Here we summarize the main contributions of this paper.

A new and simple algorithm is presented for the solution of the 2-block superoptimal distance problem. The algorithm reduces the superoptimal problem into a series of optimal problems, one for each extra singular value to be minimized. It is shown that the superoptimal solution is unique if each of these optimal problems has an optimal level satisfying (58).

An expression is obtained for the upper bound on the MacMillan degree of the superoptimal approximation. This gives a simple generalization of the bound already obtained for the 1-block problem [8], [15].

The superoptimal algorithm is shown to be truly recursive in that it can be stopped after minimizing a given number of singular values. In this case, there is a predictable saving in the computation and a corresponding reduction in the MacMillan degree of the approximation.

It is shown that the algorithm can be extended readily to the solution of the 4-block SODP.

Apart from providing a way of restoring uniqueness to the optimal approximations, superoptimal solutions can offer advantages over the optimal ones. Some work has already been done regarding the application of superoptimal approximations in control design problems. For example, in [17] superoptimality is justified for problems involving multiobjective disturbance rejection. In [9], the results in [12] are used to relate superoptimal approximations to robust stability \mathcal{H}_∞ design. The authors are currently considering the potential applications of the superoptimal approximations to model reduction problems.

PROPERTIES OF RELAXED TRAJECTORIES OF EVOLUTION EQUATIONS AND OPTIMAL CONTROL*

X. XIANG† AND N. U. AHMED‡

Abstract. This paper presents a density result for a general class of nonlinear infinite-dimensional systems that includes an unbounded linear part. A result on the existence of optimal controls for a corresponding uncertain system is also proved.

Key words. nonlinear, infinite-dimensional systems, relaxed trajectories, denseness, existence, optimal controls, uncertain systems

1. Introduction. Recently, in a very interesting paper, Papageorgiou [8] has studied the properties of relaxed trajectories of a general class of evolution equations in optimal control. He detected an error in an earlier paper of Ahmed [2] on the same topic and succeeded in giving a correct proof following the same procedure as Ahmed. In the process, however, Papageorgiou introduced several stronger assumptions on both the operators A and f (see [8, p. 271]), including compactness of the embedding $X \hookrightarrow H$. Hence the system considered by Papageorgiou does not cover the original model considered by Ahmed [2]. Later in his paper, Papageorgiou extends his results to a more general class $(**)$ (see [8, p. 279]), where he allows a fully nonlinear system rather than the semilinear one $(*)$ (see [8, p. 271]). Here, in the general case, A is assumed to have the same regularity properties (see [8, p. 279, $H(A_1)$]) as those used by Ahmed for the nonlinear part (see Ahmed [2]). In other words, the system considered by Ahmed has an additional term representing a linear unbounded operator that is missing from the fully nonlinear model of Papageorgiou. The nonlinear operator in both Papageorgiou and Ahmed is, in fact, bounded. This means that Papageorgiou's model is covered by the model considered in Ahmed's paper.

In this paper we present a density result for the more general system that includes the unbounded linear part. Furthermore, we also present a result on the existence of optimal controls for a class of uncertain systems.

2. Preliminaries. Let H be a separable Hilbert space and E a dense linear subspace of H carrying the structure of a reflexive Banach space with H^* and E^* denoting the corresponding (topological) duals. Identifying H with its dual, we have $E \hookrightarrow H \hookrightarrow E^*$ with the embeddings being continuous and dense. By $\langle \cdot, \cdot \rangle$ we will denote the duality brackets for the pair (E, E^*) and by (\cdot, \cdot) the inner product in H . The two are compatible in the sense that $\langle \cdot, \cdot \rangle_{E, H} = (\cdot, \cdot)_H$. The norms will be denoted by $\|\cdot\|_G$ for $G = (E, H, E^*)$. The Banach space G furnished with the weak topology will be denoted by G_w .

Let B be a Polish space and Γ a closed subset of B . Let U denote the set of all measurable functions u defined on $I = (0, T) \subset \mathbb{R}^+ = [0, \infty]$ with values $u(t) \in \Gamma$ almost everywhere. We call U the class of original controls. In this paper we assume Γ is compact. An example of a compact Polish space is the unit ball $\Gamma \equiv B_1(Y)$ of a Banach space Y

having a separable dual Y^* and furnished with the weak topology. For many other examples see [2].

Let $M(\Gamma)$ denote the space of all probability measures on the Borel σ -field of Γ and $C(\Gamma)$ the space of all real-valued bounded continuous functions on Γ . Suppose $M(\Gamma)$ is furnished with the w^* -topology. This topology is metrizable and $M(\Gamma)$, with this topology, becomes a compact Polish space. Let \mathcal{M} denote the family of all weakly measurable functions $\{\mu_t\}$ defined on I with values $\mu_t \in M(\Gamma)$ for all $t \in I$ (see [2]).

Let $B(I \times \Gamma)$ denote the (topological) Borel algebra of subsets of the set $I \times \Gamma$ and consider the measurable space $(I \times \Gamma, B(I \times \Gamma))$ and let $R(I, \Gamma)$ denote the space of all transition measures $\{\mu_t(d\sigma)dt\}$ on $B(I \times \Gamma)$ satisfying the following properties:

- (1) $\mu_t(\Gamma) = 1$ for a.e. $t \in I$;
- (2) $\int_{I \times \Gamma} \chi_{J \times \Gamma}(t, \sigma) \mu_t(d\sigma) dt = l(J)$, $J \in B(I)$;
- (3) $\int_{I \times \Gamma} g(t, \sigma) \mu_t(d\sigma) dt \geq 0$ for all $g \geq 0$,

where l denotes the Lebesgue measure and $\chi_{J \times \Gamma}$ the characteristic function of the set $J \times \Gamma$. The space $R(I, \Gamma)$ is furnished with the weakest topology, making the functionals $I_f(\mu) = \int_0^T \int_{\Gamma} f(t, \sigma) \mu_t(d\sigma) dt$ (for any Caratheodory integrand f , that is, functions measurable in t on I and continuous in σ on Γ) continuous (see [3]).

Since $\bar{I} = [0, T] \subseteq \mathbb{R}^+$ and Γ is a compact Polish space, the Caratheodory integrands on $I \times \Gamma$ may be identified with Lebesgue–Bochner space $L^1(I, C(\Gamma))$, abbreviated as $L^1(C(\Gamma))$. Now, by the Riesz representation theorem, $[C(\Gamma)]^* = M(\Gamma)$, the space of all bounded Borel measures on $B(\Gamma)$. $M(\Gamma)$ has the Radon–Nikodym property. Thus $(L^1(C(\Gamma)))^* = L^\infty(M(\Gamma)) \equiv L^\infty(I, M(\Gamma))$. So the weak topology on $R(I, \Gamma)$ coincides with relative topology $\sigma(L^\infty(M(\Gamma)), L^1(C(\Gamma)))$ (see [4] and [5]).

We consider the controlled system governed by the following nonlinear evolution equation:

$$(1) \quad dx/dt = A(t)x + f(t, x, u), \quad t \in I, \quad x(0) = x_0,$$

in the Banach space E , where $u \in U$, $\{A(t), t \in I\}$ is a family of densely defined linear operators with domain $D(A(t)) \subset E$ and range $R(A(t)) \subset E^*$ and, in general, $f: I \times E \times \Gamma \rightarrow E^*$.

Similarly, for a $\mu \in \mathcal{M}$, we consider the following evolution equation:

$$(2) \quad dx/dt = A(t)x + \int_{\Gamma} f(t, x, \sigma) \mu_t(d\sigma), \quad t \in I, \quad x(0) = x_0.$$

We call this the relaxed system.

For $1 < p, q < \infty$ with $1/p + 1/q = 1$, let L denote the operator determined by

$$D(L) = \{x \in L_p(I, E), x(t) \in D(A(t)) \cap D(A^*(t)),$$

$$\text{for a.e. } t \in I \text{ and } A(t)x(t), A^*(t)x(t), \dot{x}(t) \in C^0(I, E^*) \cap L_q(I, E^*)\}$$

with $(Lx)(t) = (d/dt - A(t))x, t \in I$ for $x \in D(L)$.

We assume throughout the paper that L is densely defined as a linear operator from $L_p(I, E)$ to $L_q(I, E^*)$ and that the strong and weak closures (sometimes called extensions) of L from $L_p(I, E)$ to $L_q(I, E^*)$ coincide (that is, $L_s = L_w$).

For a discussion on this assumption see the remark below.

For $x_0 \in D(A(t))$, $t \in I$, $u \in U$, an element $x_u \in L_p(I, E)$ is said to be a strong solution of the evolution equation (1) if $x_u(0) = x_0$ and $(L_s x_u)(t) = f(t, x_u(t), u(t))$ almost everywhere on I . We denote this family of solutions by $X = \{x_u | u \in U\}$ and call it the set of original trajectories. Similarly, for a generalized control $\mu \in \mathcal{M}$, an element $x_\mu \in L_p(I, E)$ is a strong solution of the evolution equation (2) if $x_\mu(0) = x_0$ and

$(L_s x_\mu)(t) = \int_\Gamma f(t, x_\mu(t), \sigma) \mu_t(d\sigma)$ almost everywhere on I . We denote this family of solutions by $X_r = \{x_\mu | \mu \in \mathcal{M}\}$ and call it the set of relaxed trajectories.

3. Existence and properties of solutions. We assume throughout the presentation, unless stated otherwise, that the operators A and f satisfy the following conditions.

CONDITION A1. $\{A(t), t \in I\}$ is a family of densely defined linear operators in H (not necessarily bounded) with domain $D(A(t)) \subset E$ and range $R(A(t)) \subset E^*$ for $t \in I$.

CONDITION A2. $\langle A(t)e, e \rangle_{E^*, E} \leq 0$ for all $e \in D(A(t)) \subset E$, $t \in I$ and the strong and weak extensions or equivalently closures of L from $L_p(I, E)$ to $L_q(I, E^*)$ coincide.

CONDITION F1. The function $t \rightarrow \langle f(t, e, \sigma), g \rangle_{E^*, E}$ is continuous on I for arbitrary $e, g \in E$ and $\sigma \in B$ and $f: I \times E \times B \rightarrow E^*$ is demicontinuous in the sense that whenever $t_n \rightarrow t$ in I , $\xi_n \rightarrow \xi$ in E and $v_n \rightarrow v$ in B

$$\langle f(t_n, \xi_n, v_n), e \rangle_{E^*, E} \rightarrow \langle f(t, \xi, v), e \rangle_{E^*, E}$$

for each $e \in E$.

CONDITION F2.

$$\langle f(t, x, \sigma) - f(t, y, \sigma), x - y \rangle_{E^*, E} \leq 0$$

for all $x, y \in E$ and $\sigma \in \Gamma$.

CONDITION F3. There exists an $h \in \Gamma_q(I, R^+)$ and $\alpha \geq 0$ such that

$$\|f(t, x, \sigma)\|_{E^*} \leq h(t) + \alpha \|x\|_E^{p/q}$$

for each $x \in E$ and for all $\sigma \in \Gamma$.

CONDITION F4. There exists an $h_1 \in L_1(I, R^+)$, $\beta > 0$, such that

$$\langle f(t, x, \sigma), x \rangle_{E^*, E} \leq h_1(t) - \beta \|x\|_E^p \text{ a.e.}$$

for each $x \in E$ and for all $\sigma \in \Gamma$.

CONDITION F5. If $e_n \rightarrow e$ in E_w , then, for each $x \in E$ and almost all $t \in I$,

$$\langle f(t, x, \sigma), e_n \rangle_{E^*, E} \rightarrow \langle f(t, x, \sigma), e \rangle_{E^*, E}$$

uniformly with respect $\sigma \in \Gamma$.

Remark on the identity $L_s = L_w$. This assumption was introduced by Browder in the study of a very general class of nonlinear evolution equations on Banach spaces (see Browder [10]–[12]). The proof of this result is by no means trivial. Several conditions under which this equivalence is valid are given in Browder [10, Thms. 6 and 7, pp. 73–77]. In an earlier paper (see Browder [11]), the evolution equation was considered in the Hilbert space setting, and in this case the coincidence of the weak and strong extensions was also proved (see [11, Thm. 5, p. 508]). For a discussion on the same topic see also Browder [12, Thm. 7, p. 39]. Browder's result was also extended by Kato [13], where $A(t)$ for each $t \in I$ was assumed to be the infinitesimal generator of a contraction semigroup along with the hypothesis that $(\lambda I - A(t))^{-1}$ is C^1 in $t \in I$ for $\lambda > 0$ in the strong operator topology. For a complete proof of this result see the proof of Theorem 4 of Kato [13, Thm. 4, pp. 61–65] where, among other things, the equivalence is proved.

LEMMA 3.1. Under Conditions A1, A2, and F1–F4,

- (1) for each (original) control $u \in U$ and initial state $x_0 \in E$, the evolution equation (1) has a unique strong solution $x_u \in L_p(I, E)$;
- (2) for each (relaxed) control $\mu \in \mathcal{M}$, and initial state $x_0 \in E$, the evolution equation (2) has a unique strong solution $x_\mu \in L_p(I, E)$.

Furthermore, in either case, $x_u, x_\mu \in C(I, E_w) \cap C(\bar{I}, H)$ and $x_u, x_\mu \in D(A)$ almost everywhere (see [2, Lemma 4.1]).

LEMMA 3.2. Suppose the operators A and f satisfy Conditions A1, A2, and F1–F4, respectively. Then the set of original trajectories X and the set of relaxed trajectories X_r are all conditionally sequentially compact subsets of $C(I, E_w)$. Furthermore, X_r is a sequentially compact subset of $C(I, E_w)$. (See Lemma 5.1 and Theorem 5.1 of [2].)

Now we give some properties of relaxed trajectories that are useful in the study of optimal controls.

THEOREM 3.1. Under Conditions A1, A2, and F1–F5 the family of original (relaxed) trajectories X (X_r) are bounded in $L_p(I, E)$ and $C(\bar{I}, H)$. Furthermore, whenever $\mu^n \xrightarrow{w} \mu^0$ in $R(I, \Gamma)$, the sequence x_{μ^n} has a subsequence converging to x_{μ^0} in the topology of $C(\bar{I}, H)$.

Proof. Let $x \in X$. It follows from (1) and Conditions A2 and F4, that

$$\begin{aligned} d/dt \|x(t)\|_H^2 &= 2(\langle A(t)x(t), x(t) \rangle + \langle f(t, x(t), u(t)), x(t) \rangle) \\ &\leq 2\langle f(t, x(t), u(t)), x(t) \rangle \leq 2(h_1(t) - \beta \|x(t)\|_E^p) \end{aligned}$$

for $0 \leq t \leq T$. Hence

$$\|x(t)\|_H^2 + 2\beta \int_0^t \|x(s)\|_E^p ds \leq \|x(0)\|_H^2 + 2 \int_0^t h_1(s) ds.$$

This inequality shows that X is a bounded subset of $L_\infty(\bar{I}, H) \cap L_p(I, E)$.

Furthermore, since $Ax \in L_q(I, E^*)$ for $x \in X$, we have $\{\dot{x}\} \in L_q(I, E^*)$ for $x \in X$. Hence $x \in C(\bar{I}, H)$ and X is a bounded subset of $C(\bar{I}, H)$. Similarly, X_r is a bounded subset of $L_p(I, E) \cap C(\bar{I}, H)$. For abbreviation, let $x_n = x_{\mu^n}$, $x_0 = x_{\mu^0}$. Using Conditions A2 and F2, we can verify that

$$\begin{aligned} &d/dt (\|x_0(t) - x_n(t)\|_H^2) \\ (*) \quad &\leq 2 \int_\Gamma \langle f(t, x_0, \sigma), x_0 - x_n \rangle \mu_t^0(d\sigma) - 2 \int_\Gamma \langle f(t, x_0, \sigma), x_0 - x_n \rangle \mu_t^n(d\sigma). \end{aligned}$$

By Lemma 3.2 we may assume that $x_n \rightarrow x^*$ in $C(I, E_w)$. Define

$$g_n(t, \sigma) = \langle f(t, x_0(t), \sigma), x_0(t) - x_n(t) \rangle$$

and

$$g(t, \sigma) = \langle f(t, x_0(t), \sigma), x_0(t) - x^*(t) \rangle.$$

By passing to a subsequence if necessary, it follows from Condition F5 that

$$g_n(t, \sigma) \rightarrow g(t, \sigma) \quad \text{in } C(\Gamma)$$

for almost all $t \in I$.

Consider the family of operators $\{T_n, n \in N \cup \{0\}\}$ from $\mathcal{L}(E^*, C(I))$ defined by

$$(T_n e^*)(t) = \langle x_n(t), e^* \rangle, \quad t \in I, \quad e^* \in E^*.$$

Since, by Lemma 2.2, X_r is a sequentially compact subset of $C(I, E_w)$, there exist constants k_{e^*} independent of n such that

$$\|T_n e^*\|_{C(I)} = \sup \{ |\langle x_n(t), e^* \rangle|, t \in I \} \leq k_{e^*}.$$

Then it follows from the uniform boundedness principle (see [1, Thm. 1.1.3]) that for all $n \in N \cup \{0\}$

$$\sup \|x_n(t)\|_E \leq K$$

for some constant K independent of n and t .

Hence, combining Lemma 2.2 and Condition F3, we have

$$\begin{aligned} |g_n(t, \sigma)| &= |\langle f(t, x_0(t), \sigma), x_0 - x_n \rangle| \\ &\leq 2K[h(t) + \alpha \|x_0(t)\|_E^{p/q}] = G(t). \end{aligned}$$

Obviously, $G \in L^1$. Hence, by virtue of the dominated convergence theorem, we obtain

$$(**) \quad g_n(t, \sigma) \rightarrow g(t, \sigma) \quad \text{in } L^1(C(\Gamma)).$$

Since $\mu^n \xrightarrow{w} \mu^0$ in $R(I, \Gamma)$, $\mu^n \xrightarrow{w^*} \mu^0$ in $L^\infty(M(\Gamma)) = [L^1(C(\Gamma))]^*$, for each $t \in I$,

$$(***) \quad \int_0^t \int_\Gamma g_n(s, \sigma) \mu_s^n(d\sigma) ds \rightarrow \int_0^t \int_\Gamma g(s, \sigma) \mu_s^0(d\sigma) ds.$$

Combining (*)–(***) , we have

$$x_n \rightarrow x_0 \quad \text{in } C(\bar{I}, H).$$

This completes the proof.

Notes.

1. If $\sigma \rightarrow f(t, x, \sigma)$ is continuous, then Condition F5 holds.
2. If $f: I \times E \times \Gamma \rightarrow H$ and the injection $E \hookrightarrow H$ is compact, then the same conclusion holds.

This last assumption was used in [8].

COROLLARY 3.1. *If the assumptions of Theorem 3.1 hold, then X_r is sequentially compact in $C(\bar{I}, H)$.*

Proof. From Theorem v-1 of Castaing and Valadier [6] we know that \mathcal{M} is w^* -compact in $L^\infty(M(\Gamma))$ and w -compact in $R(I, \Gamma)$. Using Theorem 3.1 we immediately reach the conclusion.

Finally, we give a denseness result for relaxed trajectories.

THEOREM 3.2. *Suppose Conditions A1, A2, and F1–F5 hold; then X is dense in X_r with respect to the usual topology of $C(\bar{I}, H)$.*

Proof. Let $x_0 \in X_r$, that is $x_0 = x_{\mu^0}$ for some $\mu^0 \in R(I, \Gamma) = L^\infty(M(\Gamma))$. By virtue of a result of Balder [7, Cor. 3], we can find $u_n \in U$ such that $\delta_{u_n} \xrightarrow{w^*} \mu^0$ in $R(I, \Gamma)$. Letting $y_n = x_{u_n}$, we have

$$\dot{x}_0(t) = A(t)x_0(t) + \int_\Gamma f(t, x_0(t), \sigma) \mu_t^0(d\sigma),$$

and

$$\begin{aligned} \dot{y}_n(t) &= A(t)y_n(t) + f(t, y_n(t), u_n) \\ &= A(t)y_n(t) + \int_\Gamma f(t, y_n(t), \sigma) \delta_{u_n}(d\sigma). \end{aligned}$$

Using the same procedure as in Theorem 3.1, and by passing to a subsequence if necessary, we can verify that

$$y_n \rightarrow x_0 \quad \text{in } C(I, H).$$

This means that X is dense in X_r , proving the assertion.

4. Existence of relaxed controls (uncertain system). In modeling physical systems, simplifying assumptions often are made to obtain a manageable differential or integral or a functional equation. Thus the behavior of the model may not precisely coincide with the experimental observations. Even if the exact form and order of the differential

equation is known, often the exact parameter values may be unknown due to the unavailability of basic scientific data. For example, in the case of a nonlinear heat equation, the conductivity of the material may be a function of temperature itself and its exact form may be unknown. Similarly, the modulus of rigidity of a beam made of trusses or nonhomogeneous materials is very difficult to determine experimentally. This may be further complicated by the presence of loose bolts and nuts or defective welding. In the Schrödinger equation, the precise functional form of the nuclear or Coulomb potential for many particle systems may be unknown. These facts lead to the concept of "uncertain" systems.

An uncertain version of the relaxed control system (2) may be given by

$$(3) \quad dx/dt = A(t)x + \int_{\Gamma} f(t, x, \sigma, z) \mu_t(d\sigma), \quad t \in I, \quad x(0) = x_0, \quad z \in \mathcal{Z}.$$

The set \mathcal{Z} may be another compact Polish space or, more generally, a Souslin space. Recall that a Hausdorff topological space \mathcal{Z} is a Souslin space if there exists a Polish space Y and a continuous surjection of Y to \mathcal{Z} . A Souslin space is always separable, an example being a separable Banach space endowed with the weak topology. The uncertainty of the system is reflected in the values the parameter z of f may take from the set \mathcal{Z} . A fact that distinguishes an uncertain system from that of a stochastic system is that even the probability measure on $B(\mathcal{Z})$ that could describe the uncertainty is not known. In fact, an uncertain system may be better described by a differential inclusion [9].

Consider the relaxed control system (3) and suppose that A satisfies Conditions A1 and A2 and $f(\cdot, \cdot, \cdot, z)$, $z \in \mathcal{Z}$, satisfies Conditions F1–F5 uniformly with respect to $z \in \mathcal{Z}$, with h, h_1, α, β possibly depending on the set \mathcal{Z} but not on its individual elements. Clearly, under these conditions the results of the preceding sections hold for each $z \in \mathcal{Z}$. Let x_{μ}^z denote the solution of the relaxed system (3) corresponding to $z \in \mathcal{Z}$ and $\mu \in \mathcal{M}$. Let $\mathcal{X}_{\mu} \equiv \{x_{\mu}^z, z \in \mathcal{Z}\}$ denote the family of solutions of the uncertain system (3) corresponding to a fixed relaxed control $\mu \in R(I, \Gamma)$. Let $l: I \times H \times \Gamma \rightarrow R$ be a Borel measurable map. Define the functional

$$J(x, \mu) = \int_I \int_{\Gamma} l(t, x, \sigma) \mu_t(d\sigma) dt$$

corresponding to $\mu \in \mathcal{M}$ and $x \in \mathcal{X}_{\mu}$. Since, a priori, it is not known which element z of \mathcal{Z} is in force, all that a system analyst can do is minimize the maximum risk. Thus the objective functional is taken as

$$J_0(\mu) \equiv \text{Sup} \{J(x, \mu), x \in \mathcal{X}_{\mu}\}.$$

We consider the question of existence of an optimal relaxed control $\mu^0 \in \mathcal{M}$ in the sense that

$$J_0(\mu^0) \leq J_0(\mu) \quad \text{for all } \mu \in \mathcal{M}.$$

We will make the following hypotheses concerning the integrand $l(\cdot, \cdot, \cdot)$.

CONDITION L. $l: I \times H \times \Gamma \rightarrow R$ maps bounded subsets of $I \times H \times \Gamma$ into bounded subsets of R and satisfies the following assumptions:

(1) $(t, x, \sigma) \rightarrow l(t, x, \sigma)$ is measurable with respect to the Borel field $B(I) \times B(H) \times B(\Gamma)$;

(2) $(x, \sigma) \rightarrow l(\cdot, x, \sigma)$ is lower semicontinuous;

(3) $\psi(t) \leq l(t, x, \sigma)$ almost everywhere with $\psi(\cdot) \in L^1$.

Since $f(\cdot, \cdot, \cdot, z)$, $z \in \mathcal{Z}$ satisfies Conditions F1–F5 uniformly with respect to the set \mathcal{Z} , for each $\mu \in \mathcal{M}$, the set \mathcal{X}_{μ} is a bounded subset of $C(I, H) \cap L_p(I, E)$. Hence it

follows from Theorem 3.1 and Condition L that the cost functional $J_0(\mu)$ is well defined and it is bounded for all $\mu \in \mathcal{M}$. Define

$$\inf \{J_0(\mu), \mu \in \mathcal{M}\} \equiv m.$$

THEOREM 4.1. *Suppose the operators A, f, l satisfy Conditions A1, A2, F1–F5, and L, respectively. Then there exists a $\mu^0 \in \mathcal{M}$ such that $J_0(\mu^0) = m$.*

Proof. Let $\{\mu^n\}$ be a minimizing sequence for the functional $J_0(\mu)$, that is,

$$\lim_{n \rightarrow \infty} J_0(\mu^n) = \inf \{J_0(\mu), \mu \in \mathcal{M}\} = m.$$

Recall that \mathcal{M} is w^* -compact in $L^\infty(M(\Gamma))$ and w -compact in $R(I, \Gamma)$. By passing to a subsequence if necessary, we may assume $\mu^n \xrightarrow{w} \mu^0$ in $R(I, \Gamma)$.

For any $\varepsilon > 0$, there exists $x_0 \in \mathcal{X}_{\mu^0}$ and hence $z_0 \in \mathcal{Z}$ such that $x_0 = x_{\mu^0}^{z_0}$ and

$$\begin{aligned} J_0(\mu^0) &= \sup \{J(x, \mu^0), x \in X_{\mu^0}\} \\ &\leq \int_0^T \int_{\Gamma} l(t, x_0, \sigma) \mu_t^0(d\sigma) dt + \varepsilon. \end{aligned}$$

Then, by Theorem 3.1, for the fixed $z_0 \in \mathcal{Z}$, we can find a sequence $\{x_n\}$ such that $x_n = x_{\mu^n}^{z_0}$ and $x_n \rightarrow x_0$ in $C(\bar{I}, H)$. Recalling that every lower semicontinuous measurable integrand (see Condition L(2)) is the limit of an increasing sequence of Caratheodory integrands, we have

$$\begin{aligned} m \leq J_0(\mu^0) &\leq \int_0^T \int_{\Gamma} l(t, x_0, \sigma) \mu_t^0(d\sigma) dt + \varepsilon \\ &\leq \liminf \int_0^T \int_{\Gamma} l(t, x_n(t), \sigma) \mu_t^n(d\sigma) dt + \varepsilon \\ &\leq \liminf J_0(\mu^n) + \varepsilon \leq m + \varepsilon. \end{aligned}$$

Since ε is arbitrary, $J_0(\mu^0) = m$. This proves the theorem.

Remark. Suppose that $U: I \rightarrow 2^\Gamma / \{\emptyset\}$ is graph measurable, and replace $U(\mathcal{M})$ by $S_U(S_\Sigma)$ where $S_U = \{u \in U, u \in U(t) \text{ almost everywhere}\}$, $S_\Sigma = \{\mu \in \mathcal{M}, \mu_t(U(t)) = 1 \text{ almost everywhere}\}$ (see [7]). Then all the results of this paper remain valid.

Some comments on applications. (1) Consider a semilinear heat equation on an open bounded connected domain $\Omega \subset R^3$, with a Dirichlet boundary condition

$$\begin{aligned} \partial x(t, \xi) / \partial t &= \Delta x + F(x, u), \\ x(t, \xi) &= 0, \xi \in \partial\Omega, \\ x(0, \xi) &= x_0(\xi). \end{aligned}$$

Define the operator A by

$$D(A) \equiv \{\phi \in L_2(\Omega): \Delta\phi \in L_2(\Omega), \phi|_{\partial\Omega} = 0\};$$

and

$$A\phi \equiv \Delta\phi \text{ for } \phi \in D(A).$$

Take $E \equiv H_0^1$ and $E^* \equiv H^{-1}$ and $H \equiv L_2(\Omega)$. The operator A as defined above is the generator of a C_0 -semigroup of contractions in H ; but, under the Dirichlet boundary condition, it is a bounded operator from E to E^* and $-A$ is monotone (in fact strictly monotone). For $x \in E$, $u \in U$, define $f(x, u) \equiv F(x(\cdot), u)$. Then, under the given

assumptions, the results presented in the paper easily apply to this example. In fact, here we can take the sum $A + f$ as the operator f in our main theoretical results. This gives a regular but strongly nonlinear problem. Our emphasis here is on the additional singularity introduced by the presence of an unbounded nonpositive linear operator $A(t)$ appearing in the evolution equations (1) and (2). The results presented in the paper thus applies to more general situations as stated in the next example.

(2) Consider $-A$ to be a maximal monotone operator with domain in E and range in E^* and $-f$ a monotone operator satisfying Conditions F1–F5. Then the results presented in the paper apply to the problem

$$dx/dt = Ax + f(x, u)$$

with I satisfying Condition L. Note that here the operator A can absorb certain non-homogenous but fixed boundary conditions not included in the space E and hence may not be a bounded operator from E to E^* . In view of the remarks on the identity $L_s = L_w$, as discussed in § 3, our results obviously hold for any generator A of a C_0 -semigroup of contractions in H .

Acknowledgments. The authors thank the anonymous reviewers for their valuable comments.

ON THE GLOBAL DYNAMICS OF ADAPTIVE SYSTEMS: A STUDY OF AN ELEMENTARY EXAMPLE*

MARTÍN D. ESPAÑA† AND LAURENT PRALY‡

Abstract. The inherent nonlinear character of adaptive systems poses serious theoretical problems for the analysis of their dynamics. On the other hand, the importance of their dynamic behavior is directly related to the practical interest in predicting such undesirable phenomena as nonlinear oscillations, abrupt transients, intermittence or a high sensitivity with respect to initial conditions. A geometrical/qualitative description of the phase portrait of a discrete-time adaptive system with unmodeled disturbances is given. For this, the motions in the phase space are referred to normally hyperbolic (structurally stable) locally invariant sets. The study is complemented with a local stability analysis of the equilibrium point and periodic solutions. The critical character of adaptive systems under rather usual working conditions is discussed. Special emphasis is put on the causes leading to intermittence. A geometric interpretation of the effects of some commonly used palliatives to this problem is given. The “dead-zone” approach is studied in more detail. The predicted dynamics are compared with simulation results.

Key words. adaptive systems, intermittency, dynamic systems, discrete time systems, periodic solutions, invariant sets

AMS subject classifications. 93B27, 93C10, 93C40

1. Introduction. It is an already well-known fact that adaptive systems may exhibit very complicated dynamics. For instance, Anderson (1985), first showed that, although bounded, abrupt and explosive transients may occur in the presence of disturbances. Such undesirable behavior is not exclusive to adaptive control schemes inasmuch as it can occur in any system with parametric feedback (i.e., whose parameters are functions of the signals generated by the system itself). Other examples are output error and serial-parallel identification schemes. The nonlinear character of these systems poses serious theoretical problems for its dynamic analysis. However, from a practical point of view, a successful implementation is based on a thorough knowledge of the circumstances under which nonlinear oscillations, abrupt transients, or even intermittency may occur. The study of the sensitivity of the solutions with respect to the initial conditions is also of obvious importance given that, as pointed out by Bergé, Pomeau, and Vidal (1984), this circumstance happens to be intimately related with the existence of strange attractors (and chaos). The influence of external inputs on the overall behavior also needs careful attention. The above considerations have been at the origin of increasing interest during the past years on the dynamic description of adaptive systems and, more specifically, in the explanation of the occurrence of intermittent bursts. In the presence of stochastic disturbances, Anderson (1985), suggests that “bursting” is a consequence of nonpersistently exciting reference signals. However, as shown in this paper, intermittency may subsist and (as already shown by Narendra and Anaswamy (1986)) even solutions with unbounded parametric components may take place if the reference, although persistently exciting, has not enough energy. Jaïdane-Saïdane and Macchi (1988) have proposed a heuristic explanation to the intermittent phenomenon and attributed to it a “self-stabilizing” property implying bounded signals of the closed-loop adaptive linear system. The general validity of the last conclusion has, however, been already criticized by Egardt

(1979), who has established that bounded perturbations and reference signals may produce unbounded outputs unless the parameters remain bounded. More recently, intermittent bursts have been studied extrapolating a local analysis (around critical points such as equilibria and 2-periodic solutions) performed using bifurcation techniques (Golden and Ydstie (1988); Rey, Bitmead, and Johnson (1991)). Analysis based on averaging approximations are performed in Sethares and Mareels (1991) and España (1991). The latter shows that intermittency with either a continuous change (in average) or almost fixed parameter values may take place, the latter case being associated with self-oscillating modes. The use of averaging can rigorously be justified by the existence of the attractive locally invariant set. A concept is developed in detail in this paper for a particular example (see also Praly (1990)). We think, however, that the key issue to understand, and thus to prevent, undesired dynamics, is to address the problem of the global description of the trajectories in the phase space. To our knowledge, this is the first time that a global geometrical description of the phase portrait has been given for an adaptive system. Only local results have been obtained before. They are almost all contained in Ljung and Soderstrom (1983), Anderson et al. (1986), Riedle and Kokotovic (1986), and Benveniste, Metvier, and Priouret (1987). Although this analysis is particular to our example, more general conclusions can be obtained, since we use mathematical tools as integral sets (Praly (1985), (1990); Riedle and Kokotovic (1986)) or the existence of periodic solutions (Ljung (1977); Bodson et al. (1986); Pomet, Coron, and Praly (1990)), which have been shown to be applicable in more general situations. The analysis is made in a deterministic context and special emphasis is put on the causes leading to intermittent bursting.

2. Problem formulation. A sufficiently general formulation of a linear discrete-time system in closed loop with an adaptive controller is given by the following equations (see, for instance, Pomet, Coron, and Praly (1990)):

$$y(t+1) = A(\theta)y(t) + B(\theta)w(t), \quad \theta(t+1) = \theta(t) + \mu C(y(t), \theta(t), w(t)),$$

where μ is usually used to control the adaptation speed; $w(t)$ represents all the external inputs, including the output reference signal $r(t)$ and any unmodeled disturbances. The first equation is the regressor model and the second is the parameters updating algorithm.

In what follows, a discrete-time first-order plant with an adaptive proportional output-feedback controller is considered. The objective is to regulate the plant's output to a constant value r . Any possible mismatch between the model, used for the control purposes, and the plant is represented by the unknown and unmeasurable equation error $d(t)$:

$$(1) \quad d(t) = y(t) - ay(t-1) - u(t-1).$$

We refer to "the ideal case" when $d(t) \equiv 0$. Normally, $d(t)$ is the result of unmeasured disturbances or unmodeled dynamics. In our analysis, $d(t)$ is supposed constant. This particular situation arises in practice when, due to a (possible temporary) misalignment in the actuator, a bias exists in the effective control action applied.

A proportional controller has as an effect to shift the pole of this plant, and if the parameter a is known, any possible stable value can be assigned for it. When a is unknown, the following adaptive controller with a normalized gradient type updating parameter equation (Goodwin and Sin (1984), also called stochastic approximation by Egardt (1979)),

$$(2) \quad u(t) = -\theta(t)y(t) + r$$

$$(3) \quad \theta(t) = \theta(t-1) + \mu \frac{y(t-1)(y(t) - r)}{(1 + y(t-1)^2)}$$

guarantees, for the ideal case and for any $a \in \mathbb{R}$, that $y(t) \rightarrow r$ when $t \rightarrow \infty$. Moreover, if $r \neq 0$, $\theta(t) \rightarrow a$ as $t \rightarrow \infty$. The choice of a normalized-type algorithm (plus, perhaps, a uniform bound for the parameters not considered here) is crucial in practice to assure bounded signals, particularly when (bounded) disturbances are present (Egardt (1979)).

The system (1) in closed loop with the controller (2), (3), results in

$$\begin{aligned} y(t+1) &= -\psi(t)y(t) + d + r \\ (\Sigma_1) \quad \psi(t+1) &= \psi(t) + \mu \frac{y(t)(d - \psi(t)y(t))}{1 + y(t)^2}, \end{aligned}$$

where $\psi = \theta - a$. When d is nonzero, the change of variables $x = y/d$; $\psi = \psi$; $\alpha = r/d$, transforms (Σ_1) into

$$\begin{aligned} x(t+1) &= -\psi(t)x(t) + 1 + \alpha \\ (\Sigma) \quad \psi(t+1) &= \psi(t) + d^2\mu \frac{x(t)(1 - \psi(t)x(t))}{1 + d^2x^2(t)}. \end{aligned}$$

This variable rescaling puts in relief the role played by the reference-to-disturbance relationship α , called by Narendra and Annaswamy (1986) "persistent excitation of the reference relative to the disturbance." Moreover, it allows us to better describe the system's behavior for r and d close to zero. As discussed later, this (slightly disturbed regulation regime) is a very critical working condition. In the rescaled system, d^2 controls the adaptation speed of the algorithm. For our purposes we can thus assume that $\mu = 1$. The developments that follow can be done for the original system (Σ_1) replacing, when appropriate, the statement " d^2 sufficiently small" for " μ sufficiently small." In the first case, the slow adaptation condition is a consequence of the low level of the signals involved.

We can easily verify that (Σ) has a fixed point in $(\psi, x) = (1/\alpha, \alpha)$ if and only if α is nonzero and that it is unique if and only if $\alpha \neq -1$. In terms of the original system, this equilibrium corresponds to the output equal to the reference signal. The control objective is thus perfectly achieved at the fixed point.

The simulations show that for small values of d^2 , the behavior of the solutions of (Σ) is characterized by the following stages.

(a) Explosive stage: growth of the modulus of the x -component in the "instability" set $\{|\psi| > 1\}$.

(b) ReInjection stage: decrease of the modulus of the ψ -component in the set $\{|x| \text{ "large", } |\psi| > 1\}$ until $|\psi| < 1$.

(c) Implosive stage: decrease of the modulus of the x -component in the "stability" set $\{|\psi| < 1\}$.

(d) Drift-ejection stage: slow growth of $|\psi|$ leading a solution from the "stability" set to the "instability" set.

(e) When (d) does not occur, the desired working condition is globally attractive.

Stages (a)–(c) are very short in time and, under certain conditions, stage (d) may be performed very slowly. In such a case, two successive occurrences of stages (a)–(c) are separated by a very long period of time. The result is an intermittent phenomenon, as studied by Pomeau and Manville (1980), characterized by a succession of "bursts" on the x -component separated by long quiescent periods. In practice, some palliatives (such as dead zone or leakage (Egardt (1979)), normalization (Praly (1983)), internal model principle (Elliott and Goodwin (1984)), filtering (Anderson et al. (1986)), etc.) are used to avoid intermittency and other nondesirable behaviors. However, if these remedies are not appropriately chosen, a qualitatively similar behavior may be observed for these more intricate cases (see Praly (1988)). The effect of some of these modifications

in our example is discussed in §§ 6 and 7. To give a geometrical explanation of stages (a)–(e), the existence of two locally invariant (under the action of (Σ)) sets is demonstrated using the graph transform technique (Shub (1987)). The first one is repellent, explaining stage (a). The second one is attractive and allows us to explain stages (c), (d), and (e). Finally, stage (b) results from (a), when, during bursts, the disturbance d becomes negligible with respect to the x -component of the solutions. These locally invariant graphs are easily computed when the ψ -component remains constant. For this, we consider the set of all bounded solutions of (Σ) when $d = 0$ given by

$$(4) \quad S_0 \equiv \{(\psi, h(\psi)) \in \mathbb{R}^2 / h(\psi) = (1 + \alpha)/(1 + \psi), \psi \neq -1\}.$$

S_0 , called the “frozen parameters invariant set,” is invariant under the map $\Sigma_{d=0}$ (i.e., $\Sigma_{d=0}(S_0) \subseteq S_0$) and has exactly the properties associated with (a) and (c). It seems reasonable to expect that, when $|d|$ is not zero but still small, locally invariant graphs, approximated by S_0 , still exist. The idea of using locally invariant sets or, more generally, locally integral sets, has been introduced by Riedle and Kokotovic (1986) and Praly (1985), (1990). However, their existence was only established for the “stability” set $\{|\psi| < 1\}$ and locally with respect to the x -components.

The paper is organized as follows. In § 3, the existence and properties of locally invariant sets are established. Critical elements and locally invariant sets are combined in § 4 to obtain theoretical results on the system global dynamics. These results are interpreted and compared with simulations in § 5. In § 6, the effects of introducing a “dead-zone” in the algorithm (3) is discussed. Finally, § 7 is dedicated to our concluding remarks. The critical elements—fixed points and periodic solutions—of (Σ) and the corresponding nearby local behavior needed to complement the global analysis are considered in the Appendix.

3. Locally invariant sets. In § 2, we observed that for $d = 0$, the set S_0 is invariant under $\Sigma_{d=0}$. Now from the definition of (Σ) , when $\psi(t)$ and $x(t)$ are such that $1 + \psi(t)$ and $1 + \psi(t) + d^2 x(t)(1 + x(t))$ are nonzero we have

$$\begin{aligned} \left(x(t+1) - \frac{1 + \alpha}{1 + \psi(t+1)} \right) &= -\psi(t) \left(x(t) - \frac{1 + \alpha}{1 + \psi(t)} \right) \\ &\quad + \frac{d^2(1 + \alpha)x(t)(x(t)\psi(t) - 1)}{(1 + \psi(t))(1 + \psi(t) + d^2 x(t)(1 + x(t)))}. \end{aligned}$$

The presence of d^2 in the second term on the right-hand side shows that S_0 is close to being a locally invariant set of (Σ) with d nonzero. Finally, for $d = 0$, this expression proves that (i) $S_0 \cap \{(\psi, x) | |\psi| > 1\}$ is exponentially repellent and (ii) $S_0 \cap \{(\psi, x) | |\psi| < 1\}$ is exponentially attractive. These remarks lead us to look for locally invariant sets close to S_0 , which are repellent in the set $\{|\psi| > 1\}$ and attractive in the set $\{|\psi| < 1\}$. These sets will be used as references for the global description of the solutions of (Σ) .

3.1. The repellent locally invariant set (RLIS). Given any nonzero d , let ε be the smallest positive root of

$$(5) \quad \Delta(\varepsilon) = \left(\varepsilon - \frac{|d|}{1 + \varepsilon} \right) - 2 \sqrt{\frac{|1 + \alpha||d|(1 + \varepsilon + |d|)}{\varepsilon}}.$$

For any function $M: \{|\psi| \geq 1 + \varepsilon\} \rightarrow \mathbb{R}$, we define its image by the operator T as

$$(6) \quad TM(\psi) = \frac{1 + \alpha - M(\phi_M(\psi))}{\psi},$$

where ϕ_M is defined in terms of the function

$$(7) \quad \hat{\phi}_M(\psi) = \psi + d^2 M(\psi) \frac{(1 - \psi M(\psi))}{1 + d^2 M^2(\psi)},$$

as follows:

$$(8) \quad \phi_M(\psi) = \begin{cases} \sup(1 + \varepsilon, \hat{\phi}_M(\psi)) & \text{if } \psi \geq 1 + \varepsilon, \\ \inf(-1 - \varepsilon, \hat{\phi}_M(\psi)) & \text{if } \psi < -1 - \varepsilon. \end{cases}$$

By definition, $\phi_M: \{|\psi| \geq 1 + \varepsilon\} \rightarrow \{|\psi| \geq 1 + \varepsilon\}$ is a continuous function and $\psi\phi_M(\psi)$ is positive. We are interested in the operator T because, if it has a fixed point H , then H satisfies the local invariance property:

$$(9) \quad H(\hat{\phi}_H(\psi)) = 1 + \alpha - \psi H(\psi) \quad \text{if } \psi \hat{\phi}_H(\psi) > 0, \quad |\psi| > 1 + \varepsilon, \quad |\hat{\phi}_H(\psi)| > 1 + \varepsilon.$$

The graph $\{(\psi, H(\psi)) / |\psi| \geq 1 + \varepsilon\}$ has two connected components in the plane (ψ, x) . They are such that, with its initial condition in one of these sets, any solution of (Σ) will stay in it unless its ψ -component leaves its corresponding definition interval $\{\psi > 1 + \varepsilon\}$ or $\{\psi < -(1 + \varepsilon)\}$. To exhibit the fixed point H , we consider the subset of $C^0(\{|\psi| \geq 1 + \varepsilon\}, \mathbb{R})$:

$$\mathcal{B} = \{M | \partial(M, 0) \leq m_0$$

$$\text{and } \text{sgn}(\psi_1) = \text{sgn}(\psi_2) \Rightarrow |M(\psi_1) - M(\psi_2)| \leq m_1 |\psi_1 - \psi_2|\}.$$

It is a complete metric space with the distance ∂ defined as

$$\partial(M_1, M_2) = \sup_{\{|\psi| \geq 1 + \varepsilon\}} |M_1(\psi) - M_2(\psi)|.$$

The constants m_0, m_1 are

$$(10) \quad m_0 = \frac{|1 + \alpha|}{\varepsilon}, \quad m_1 = \frac{2|1 + \alpha|}{\varepsilon(\varepsilon - |d|/1 + \varepsilon)}.$$

The next lemma and the uniform contraction theorem (see Hale (1980)) allow us to prove that T has a fixed point in \mathcal{B} .

LEMMA 1. For any nonzero d , let ε be given by (5), then (i) T maps \mathcal{B} into \mathcal{B} ; (ii) For $M_i, i = 1, 2$, in \mathcal{B} , we have $\partial(TM_1, TM_2) \leq \tau \partial(M_1, M_2)$, with

$$\tau = \frac{1}{1 + \varepsilon} + |d|m_1 \left(1 + \frac{|d|}{1 + \varepsilon}\right) < 1.$$

Proof. From (6) and definition (10), it can be easily shown that for all $M \in \mathcal{B}$, $\partial(TM, 0) \leq m_0$. The rest of the proof is obtained by showing that for all $M_1, M_2 \in \mathcal{B}$, if $\text{sgn}(\psi_1) = \text{sgn}(\psi_2)$ then $|TM_1(\psi_1) - TM_2(\psi_2)| \leq m_1 |\psi_1 - \psi_2| + \tau \partial(M_1, M_2)$. For this, use is made of (8) to write $|\hat{\phi}_M(\psi_1) - \hat{\phi}_M(\psi_2)| \geq |\phi_M(\psi_1) - \phi_M(\psi_2)|$. The details can be consulted in España and Praly (1988). \square

Another important property of H is the following. Let $(\psi_0, x_0) \in \{|\psi_0| > 1 + \varepsilon\} \times \mathbb{R}$. We denote by $(\psi_1, x_1) = \Sigma(\psi_0, x_0)$ its image by (Σ) . Suppose that $\text{sgn}(\psi_1) =$

$\operatorname{sgn}(\psi_0)$ and $|\psi| > 1 + \varepsilon$. With Lemma 1, the definition (7), (8), and the property (9) we have

$$\begin{aligned}
 |x_0 - H(\psi_0)| &\leq \left| \frac{H(\psi_1) - x_1}{\psi_0} \right| + \left| \frac{H(\phi_H(\psi_0)) - H(\psi_1)}{\psi_0} \right| \\
 &\leq \left| \frac{H(\psi_1) - x_1}{\psi_0} \right| + m_1 \left| \frac{\hat{\phi}_H(\psi_0) - \psi_1}{\psi_0} \right| \\
 (11) \quad &\leq \left| \frac{H(\psi_1) - x_1}{\psi_0} \right| + \frac{m_1 d^2}{|\psi_0|} \sup_x \left\{ \left| \frac{\partial}{\partial x} \left(\frac{x(1 - \psi_0 x)}{1 + d^2 x^2} \right) \right| \right\} |H(\psi_0) - x_0| \\
 &\leq \left| \frac{H(\psi_1) - x_1}{\psi_0} \right| + m_1 |d| \left(1 + \frac{|d|}{1 + \varepsilon} \right) |H(\psi_0) - x_0| \\
 &\leq \frac{1}{1 + (1 + \varepsilon)(1 - \tau)} |H(\psi_1) - x_1|.
 \end{aligned}$$

Hence, since τ is strictly smaller than 1, the distance from a solution to its projection, parallel to the x -axis, on the graph of H , must increase as long as its ψ -component stays in the same interval $\{\psi > 1 + \varepsilon\}$ or $\{\psi < -(1 + \varepsilon)\}$. Using the above derivations and the definitions (5), (10) it can be shown that

$$(12) \quad |H(\phi_H(\psi_0)) - H(\psi_1)| \leq \frac{m_1 |d| (1 + |d|/(1 + \varepsilon))}{1 - m_1 |d| (1 + |d|/(1 + \varepsilon))} |x_1 - H(\psi_1)|.$$

If we replace in (12) the value of m_1 given by (10) and use (5) again, we obtain

$$0 < m_1 |d| (1 + |d|/(1 + \varepsilon)) < \frac{1}{2} \Rightarrow |H(\phi_H(\psi_0)) - H(\psi_1)| < |x_1 - H(\psi_1)|.$$

Then from the following product, computed using the definition of (Σ) and the invariance property of H ,

$$(x_0 - H(\psi_0))(x_1 - H(\psi_1)) = -\frac{(H(\psi_1) - x_1)^2}{\psi_0} + \frac{(H(\phi_H(\psi_0)) - H(\psi_1))(x_1 - H(\psi_1))}{\psi_0}$$

we have $\operatorname{sgn}[(x_0 - H(\psi_0))(x_1 - H(\psi_1))] \neq \operatorname{sgn}(\psi_0)$. To summarize, we have established the following theorem.

THEOREM 1 (the RLIS). *For any nonzero d , let ε be given by (5). There exist a bounded Lipschitz continuous function H , defined on $\{|\psi| \geq 1 + \varepsilon\}$, with bound m_0 and a Lipschitz constant m_1 given by (10), such that*

(i) *If $|\psi| \geq 1 + \varepsilon$, $|\hat{\phi}_H(\psi)| \geq 1 + \varepsilon$, $\operatorname{sgn}(\hat{\phi}_H(\psi)) = \operatorname{sgn}(\psi)$, then*

$$(13) \quad H(\hat{\phi}_H(\psi)) = 1 + \alpha - \psi H(\psi).$$

(ii) *There exists ρ positive such that $(\psi, x) \in \{|\psi| \geq 1 + \varepsilon\} \times \mathbb{R}$, $(\phi, y) := \Sigma(\psi, x) \in \{|\psi| \geq 1 + \varepsilon\} \times \mathbb{R}$, and $\psi\phi > 0$ imply*

$$(14) \quad \operatorname{sgn}((x - H(\psi))(y - H(\phi))) \neq \operatorname{sgn}(\psi),$$

$$(15) \quad |y - H(\phi)| \geq (1 + \rho)|x - H(\psi)|.$$

(iii) *Approximation of $H : \sup_{\{|\psi| \geq 1 + \varepsilon\}} |H(\psi) - h(\psi)|/d^2$ is bounded when $d^2 \rightarrow 0$.*

Proof. Statements (i) and (ii) are already established. To prove (iii), we first note that h , defined in (4), belongs to \mathcal{B} . Then, using Lemma 1, we have $\partial(h, H) \leq \partial(h, Th) + \partial(Th, TH) \leq \partial(h, Th)/(1 - \tau)$. The result is finally obtained using the

definition of h and T to show that $|h(\psi) - Th(\psi)| = O(d^2)$. (The details can be consulted in España and Praly (1988).) \square

Remarks. 1. With (i) and (ii), this theorem establishes the existence of a globally, exponentially RLIS, given by the graph of a bounded continuous function $H : \{|\psi| > 1 + \varepsilon\} \rightarrow \mathbb{R}$ which, following (iii), can be approximated by the “frozen parameter invariant set,” for $|d|$ sufficiently small. It is important to emphasize at this point that the repulsiveness of this graph, expressed by (15), has a global character in the sense that it is valid for any starting point $x \in R$. This is a direct consequence of the use of a normalized updating parameter equation (see (3) and (11)).

2. According to the sign of its ψ -component, the x -component of any solution changes side or not with respect to the graph of H (see (14)).

3. Although T has a unique fixed point H in \mathcal{B} , H need not be the unique function in \mathcal{B} satisfying (13). This nonuniqueness comes from the arbitrariness of the function ϕ_M , which is not determined by (Σ) (see the discussion about the stopping function in Praly (1990)). In § 4 (see Theorem 3(b) and related remarks) the conditions under which the whole RLIS or a portion of it is unique are established.

3.2. The attractive locally invariant set (ALIS). Let

$$(16) \quad d^{*2} = \frac{1}{2|1 + \alpha|^2} \left(\sqrt{\frac{1 + 3|1 + \alpha|}{1 + 2|1 + \alpha|}} - 1 \right).$$

Taking $|d|$ in $(0, d^*)$, let η be the smallest positive root of

$$(17) \quad \Delta(\eta) = \left(\eta - \frac{d^2 n_0^2}{1 + d^2 n_0^2} \right) - 2 \sqrt{\frac{(1 + 2n_0)n_0 d^2}{1 + d^2 n_0^2}},$$

where n_0 is defined by

$$(18) \quad n_0 = \frac{|1 + \alpha|}{\eta}.$$

The constraint introduced on d assures that $\Delta(0)\Delta(1)$ is strictly negative. This implies that η is strictly smaller than 1. Now for any d , $0 < |d| < d^*$, we define an operator P acting on functions $N : \mathbb{R} \rightarrow \mathbb{R}$ by

$$(19) \quad PN(\phi) = \begin{cases} 1 + \alpha - \psi_N(\phi)N(\psi_N(\phi)) & \text{if } |\phi| \leq 1 - \eta, \\ PN(1 - \eta) \text{ (resp., } PN(\eta - 1)) & \text{if } \phi \geq 1 - \eta \text{ (resp., } \leq -(1 - \eta)), \end{cases}$$

where $\psi_N(\phi)$, mapping $\{|\psi| \leq 1 - \eta\}$ into $\{|\psi| \leq 1 - \eta\}$, is a function implicitly defined by the next two relations:

$$(20) \quad \phi = \frac{\hat{\psi}_N(\phi) + d^2 N(\hat{\psi}_N(\phi))}{1 + d^2 N^2(\hat{\psi}_N(\phi))},$$

$$(21) \quad \psi_N(\phi) = \begin{cases} \hat{\psi}_N(\phi) & \text{if } |\hat{\psi}_N(\phi)| \leq 1 - \eta, \\ (1 - \eta) \text{ (resp., } -(1 - \eta)) & \text{if } \hat{\psi}_N(\phi) > 1 - \eta \text{ (resp., } < -(1 - \eta)). \end{cases}$$

We are interested in the operator P because, if it has a fixed point G , then G satisfies the local invariance property:

$$(22) \quad G(\phi) = -\hat{\psi}_G(\phi)G(\hat{\psi}_G(\phi)) + 1 + \alpha, \text{ if } |\phi| \leq 1 - \eta \text{ and } |\hat{\psi}_G(\psi)| \leq 1 - \eta.$$

As for H in the “instability” set, the graph $\{(\psi, G(\psi))/|\psi| \leq 1 - \eta\}$ defines a set in the plane (ψ, x) . It is such that, with its initial condition in this set, any solution of (Σ) will stay in it unless its ψ -component leaves the set of “strict stability” $\{|\psi| \leq 1 - \eta\}$.

To exhibit the fixed point G , we consider the set of “saturated” functions:

$$(23) \quad \mathcal{C} = \left\{ N \in C^0(\mathbb{R}, \mathbb{R}) \left| \begin{array}{l} (1) \partial(N, 0) \leq n_0 \\ (2) \forall \psi_1, \psi_2 \in \mathbb{R}, |N(\psi_1) - N(\psi_2)| \leq n_1 |\psi_1 - \psi_2| \\ (3) N(\psi) = \begin{cases} N(1 - \eta) & \text{if } \psi \geq 1 - \eta \\ N(-(1 - \eta)) & \text{if } \psi \leq -(1 - \eta) \end{cases} \end{array} \right. \right\},$$

$$(24) \quad n_1 := \sqrt{(1 + d^2 n_0^2) n_0 / (1 + 2n_0) d^2},$$

which is a complete metric space with the distance

$$\partial(N_1, N_2) := \sup_{\mathbb{R}} \{|N_1(\psi) - N_2(\psi)|\}.$$

Before studying the operator P acting on \mathcal{C} , we must be sure that $\hat{\psi}_N(\phi)$, implicitly defined by (20), makes sense. For this we have the following lemma.

LEMMA 2. *For any d , $0 < |d| < d^*$ and η given by (17), there exists a function $D: \mathcal{C} \times \{|\phi| \leq 1 - \eta\} \rightarrow \mathbb{R}$ and positive numbers $b_\phi(n_0, n_1, d^2)$, $b_n(n_0, n_1, d^2)$ satisfying for (N_i, ϕ_i) in $\mathcal{C} \times \{|\phi| \leq 1 - \eta\}$ and $i = 1, 2$*

$$(25) \quad |D(N_1, \phi_1) - D(N_2, \phi_2)| \leq b_\phi |\phi_1 - \phi_2| + b_n \partial(N_1, N_2),$$

$$(26) \quad |D(N_i, \phi_i)| \leq n_0(1 + n_0),$$

$$(27) \quad D(N, \phi) = N(\phi - d^2 D)(1 - \phi N(\phi - d^2 D)).$$

Proof. The proof takes advantage of the “almost identity” character of the function defined by (20) and (21) when d^2 is sufficiently small. Moreover, it gives conditions on the sizes of d^2 and η (see (16), (17)). The details may be consulted in España and Praly (1988); a more general result is also established in Praly (1990). \square

With this function D , we can rewrite (20) as follows:

$$(28) \quad \hat{\psi}_N(\phi) = \phi - d^2 D(N, \phi).$$

The next lemma and the uniform contraction theorem (see Hale (1980)) allow us to prove that P has a fixed point in \mathcal{C} .

LEMMA 3. *For any d , $0 < |d| < d^*$ and η given by (17), we have (i) P maps \mathcal{C} into \mathcal{C} . (ii) For all N_i , $i = 1, 2$, in \mathcal{C} , we have $\partial(PN_1, PN_2) \leq \lambda \partial(N_1, N_2)$ with $\lambda < 1$.*

Proof. It can be easily checked using (18)–(21) that PN satisfies (1) and (3) of (23). By using the properties of N , D , and the fact that $|\phi| \leq 1 - \eta$, we obtain

$$(29) \quad \begin{aligned} |PN_1(\phi_1) - PN_2(\phi_2)| &\leq \lambda(\eta, d^2) \partial(N_1, N_2) + n_1^* |\phi_1 - \phi_2|, \\ n_1^* &:= ((1 - \eta)n_1 + n_0)(1 + d^2 b_\phi) \leq n_1. \end{aligned}$$

Now, thanks to the choice of η in (17) we can show that

$$(30) \quad \lambda(\eta, d^2) := (1 - \eta)(1 + d^2 b_n n_1) + n_0 b_n d^2 = \frac{1 - (1 + 2n_0)d^2 n_1}{1 + d^2 n_0^2} < 1.$$

The details can be found in España and Praly (1988). See also Lemma 1 of Praly (1990). \square

We next establish an important feature of the graph of G with respect to the solutions of (Σ) . Let (ψ_0, x_0) be an element of $\{|\psi| \leq (1 - \eta)\} \times \{|x| \leq \xi\}$ and (ψ_1, x_1) its image by (Σ) . Whenever $|\psi_1|$ is smaller than $1 - \eta$, from (28), (22), (19) we have

$$\begin{aligned} |x_1 - G(\psi_1)| &\leq |\psi_0| |G(\psi_0) - x_0| + |\psi_0| |G(\psi_G(\psi_1)) - G(\psi_0)| \\ &\quad + |G(\psi_G(\psi_1))| |\psi_G(\psi_1) - \psi_0| \\ &\leq |\psi_0| |G(\psi_0) - x_0| + (n_0 + |\psi_0| n_1) |\hat{\psi}_G(\psi_1) - \psi_0|. \end{aligned}$$

On the other hand, adding and subtracting $G(\psi_G)(1 - \psi_1 G(\psi_0))$ we obtain

$$\begin{aligned} |\hat{\psi}_G(\psi_1) - \psi_0| &= d^2 |x_0(1 - x_0 \psi_1) - G(\hat{\psi}_G(\psi_1))(1 - \psi_1 G(\hat{\psi}_G(\psi_1)))| \\ &\leq d^2(1 + \xi + n_0) |x_0 - G(\psi_0)| + d^2(1 + 2n_0)n_1 |\psi_0 - \hat{\psi}_G(\psi_1)| \\ &\leq \frac{d^2(1 + \xi + n_0)}{1 - d^2(1 + 2n_0)n_1} |x_0 - G(\psi_0)|. \end{aligned}$$

Hence, using (17) and (24), we have established

$$(31) \quad |x_1 - G(\psi_1)| \leq \sigma(\xi) |x_0 - G(\psi_0)|,$$

$$(32) \quad \sigma(\xi) = \frac{1 - (1 + 2n_0)d^2 n_1}{1 + d^2 n_0^2} + \frac{d^2 n_1}{1 + d^2 n_0^2} (\xi - n_0).$$

With (30), $\sigma(\xi) > 0$ is strictly smaller than 1 if

$$(33) \quad n_0 < \xi < n_0 + \frac{n_0^2 + n_1(1 + 2n_0)}{n_1}.$$

Thus, any solution staying in the set $\{|\psi| \leq (1 - \eta)\} \times \{|x| \leq \xi\}$, with ξ satisfying (33), exponentially approaches the graph of G . Moreover, with the above derivations, we have

$$|\psi_G(\psi_1)G(\psi_G(\psi_1)) - \psi_0 G(\psi_0)| \leq \frac{d^2(1 + \xi + n_0)n_1}{1 + d^2 n_0^2} |x_0 - G(\psi_0)|.$$

However, since the invariance property of G implies

$$\begin{aligned} \psi_0(x_1 - G(\psi_1))(x_0 - G(\psi_0)) &= -\psi_0^2(x_0 - G(\psi_0))^2 + \psi_0(x_0 - G(\psi_0)) \\ &\quad \cdot (\psi_G(\psi_1)G(\psi_G(\psi_1)) - \psi_0 G(\psi_0)), \end{aligned}$$

it follows that from $|x_0| \leq \xi$ and $d^2(1 + \xi + n_0)n_1/(1 + d^2 n_0^2) \leq |\psi_0| \leq 1 - \eta$ we obtain $\text{sgn}[(x_1 - G(\psi_1))(x_0 - G(\psi_0))] \neq \text{sgn}(\psi_0)$. To summarize, we have established the following theorem.

THEOREM 2 (the ALIS). *For any d , $0 < |d| < d^*$, and η given by (17), there exists a bounded Lipschitz continuous function G with bound n_0 and Lipschitz constant n_1 given, respectively, by (18) and (24), such that*

(i) *If $|\phi| \leq 1 - \eta$ and $|\hat{\psi}_G(\phi)| \leq 1 - \eta$, then*

$$(34) \quad G(\phi) = 1 + \alpha - \psi G(\psi) \quad \text{and} \quad \phi = \psi + d^2 \frac{G(\psi)(1 - \psi G(\psi))}{1 + d^2 G(\psi)^2}.$$

(ii) *Let ξ satisfy*

$$n_0 < \xi < n_0 + \frac{n_0^2 + n_1(1 + 2n_0)}{n_1},$$

then there exists $\sigma(\xi) < 1$ such that $(\psi, x) \in \{|\psi| < 1 - \eta\} \times \{|x| \leq \xi\}$ and $(\phi, y) := \Sigma(\psi, x) \in \{|\phi| \leq 1 - \eta\} \times \mathbb{R}$ imply

$$(35) \quad |y - G(\phi)| \leq \sigma(\xi)|x - G(\psi)|.$$

Moreover, if

$$\frac{d^2(1 + \xi + n_0)n_1}{1 + d^2n_0^2} \leq |\psi|,$$

then $\text{sgn}((y - G(\phi))(x - G(\psi))) \neq \text{sgn}(\psi)$.

(iii) Approximation of G : $\sup_{\{|\psi| < (1 - \eta)\}} |G(\psi) - h(\psi)|/d^2$ is bounded for $d^2 \rightarrow 0$.

Proof. Statement (i) is a direct consequence of Lemma 3. Statement (ii) follows from (31). To prove (iii), we first note that h , defined in (4), belongs to \mathcal{C} . Now, since G is the fixed point of P , Lemma 3(ii) gives $\partial(h, G) \leq \partial(h, Ph)/(1 - \lambda(\eta, d^2))$. The result is finally obtained using the definition of h and P to show that (see details in España and Praly (1988))

$$(36) \quad \partial(h, G) \leq d^2n_0(n_0 + n_1)(n_0 + 1)/(1 - \lambda(\eta, d^2)). \quad \square$$

Remarks. 1. This theorem establishes the existence of an (exponentially) ALIS given by the graph of a bounded continuous function $G: \{|\psi| < 1 - \eta\} \rightarrow \mathbb{R}$ which, following (iii), can be approximated by the “frozen-parameter invariant set,” when $|d|$ is sufficiently small.

2. If its ψ -component is larger than

$$\frac{d^2(1 + \xi + n_0)n_1}{1 + d^2n_0^2},$$

respectively, smaller than

$$-\frac{d^2(1 + \xi + n_0)n_1}{1 + d^2n_0^2},$$

the x -component of any solution changes side with respect to (respectively, remains on the same side of) the graph of G .

3. Even though G is the unique fixed point of P in \mathcal{C} , its graph need not be the only one satisfying (22). The nonuniqueness of the ALIS comes from the arbitrariness of the definition (21), which is not determined by (Σ) .

3.3. Additional characterization of the locally invariant sets. The existence Theorems 1 and 2 do not give enough information about the location of the locally invariant sets in the phase space. For this we have the following useful property.

Property 1. In their respective domains of definition, the functions H and G , determined by Theorems 1 and 2, belong to the family of functions F_α whose elements satisfy

(i) If $1/\alpha < -1$, then

$$\psi < 1/\alpha \Rightarrow M(\psi)(1 - \psi M(\psi)) \leq 0, \quad \text{and} \quad \psi > 1/\alpha \Rightarrow M(\psi)(1 - \psi M(\psi)) \geq 0.$$

(ii) If $1/\alpha > -1$, then

$$\psi < 1/\alpha \Rightarrow M(\psi)(1 - \psi M(\psi)) \geq 0, \quad \text{and} \quad \psi > 1/\alpha \Rightarrow M(\psi)(1 - \psi M(\psi)) \leq 0.$$

(iii) If $\alpha = -1 \Rightarrow M(\psi) \equiv 0$.

Proof. Statements (i) and (ii) are demonstrated by showing that, in the corresponding domain of definition, F_α is a closed subset of \mathcal{B} (respectively, \mathcal{C}) such that $TF_\alpha \subseteq$

F_α (respectively, $PF_\alpha \subseteq F_\alpha$) (see España and Praly (1988)). Note that F_α does not depend on d^2 . Statement (iii) results from a continuity argument.

4. Global behavior of the solutions: Technical results. Knowing the existence of critical elements and locally invariant sets, we are now in position for studying the behavior of the solutions. We decompose the plane (ψ, x) into nine subsets:

with ε given by (5), η by (17), and $\chi > 1/(1 - \eta)$. The global behavior of the solutions can be understood by looking at their evolution in each of these sets on the locally invariant graphs and outside them. We call $A \cup I$ the “strict instability” set, E the “strict stability” set, and $B \cup C \cup D \cup F \cup G \cup H$ the “critical stability” set.

4.1. Solutions in the locally invariant sets (RLIS and ALIS).

THEOREM 3(a) (the stationary solution). (i) For any nonzero d and ε given by (5), the (unique) equilibrium point of (Σ) belongs to the RLIS if and only if $|1/\alpha| \geq 1 + \varepsilon$.

(ii) For any d , $0 < |d| < d^*$, and with d^* , η given by (16), (17), the (unique) equilibrium point of (Σ) is in the ALIS if and only if $|1/\alpha| \leq 1 - \eta$.

(iii) When $\alpha = -1$, $H(\psi) \equiv 0$, $G(\psi) \equiv 0$ and any point in the RLIS or ALIS is an equilibrium point.

Proof. Given the global repulsiveness (respectively, attractiveness) of the RLIS (respectively, ALIS), the fixed point must be in the RLIS (respectively, ALIS) if it is in $\{|\psi| > 1 + \varepsilon\}$ (respectively, $\{|\psi| < 1 - \eta\}$). The rest follows from Theorem A in the Appendix and Property 1. \square

THEOREM 3(b) (the nonstationary solutions). If $\psi(t)$ is the ψ -component of any solution of (Σ) with initial condition in a locally invariant set, then

(i) if $1/\alpha > -1 \Rightarrow (\psi(t) - 1/\alpha)/(\psi(t+1) - 1/\alpha) > 1$.

(ii) if $1/\alpha < -1 \Rightarrow (\psi(t+1) - 1/\alpha)/(\psi(t) - 1/\alpha) > 1$.

Proof. Theorem 3(b) is a consequence of Property 1 and the definition of (Σ) . \square

Remarks. From Theorems 3(a) and 3(b), if $1/\alpha < 109-1$ (respectively, $1/\alpha > -1$), the ψ -component of the solutions on any locally invariant set moves monotonically away from (respectively, toward) the value $1/\alpha$.

1. If $|1/\alpha| > 1$ and $(\psi, x) \in \text{RLIS}$ with $\psi \in (-\infty, 1/\alpha) \cup (1 + \varepsilon, \infty)$, then it can be seen, with (8), that $\phi_H(\psi) = \hat{\phi}_H(\psi)$. Hence, the portion of the RLIS defined in $(-\infty, 1/\alpha) \cup (1 + \varepsilon, \infty)$ is unique since the “stopping mechanism” is not active here. Note that the whole RLIS is unique if $1/\alpha > 1 + \varepsilon$; moreover, in this case, the RLIS and the stable manifold of the fixed point coincide over $\{|\psi| > 1 + \varepsilon\}$ (see Iooss (1979)).

2. If $1/\alpha < -1$ the ψ -component of the trajectories in the RLIS with $\psi(0) \in (-\infty, 1/\alpha) \cup (1/\alpha, \infty)$ are asymptotically unbounded.

3. If the fixed point lies in the ALIS (i.e., $|1/\alpha| < 1 - \eta$), it is a global attractor inside the ALIS. If it lies in the RLIS, the solutions in the ALIS leave the set $\{|\psi| < 1 - \eta\}$ in a finite time through the boundary $\psi = 1 - \eta$. An estimation of the “traveling” speed of the ψ -component in the ALIS for this case will be of interest in our analysis and is given by the next theorem.

THEOREM 3(c). *If the fixed point is not in the ALIS, the solutions in it leave the “strict stability” set through the boundary $\psi = 1 - \eta$ in a finite time.*

Proof. From Property 1, $\psi G(\psi) < 1$ and $G(\psi) > 0$. Now, G being continuous on the compact set $\{|\psi| \leq 1 - \eta\}$, there exists η_1 , strictly positive, such that: $G(\psi) > \eta_1$ and $1 - \psi G(\psi) > \eta_1$. With the definition of (Σ) this implies that for all ψ ; $|\psi| < 1 - \eta$,

$$(37) \quad n_0(1 + n_0) > \frac{\phi - \psi}{d^2} = \frac{G(\psi)(1 - \psi G(\psi))}{1 + d^2 G(\psi)^2} > \frac{\eta_1^2}{1 + d^2 n_0^2}.$$

Therefore, in the ALIS, $\psi(t)$ moves with positive speed of the order of d^2 , thus leaving the set $\{|\psi| < 1 - \eta\}$ in a finite time through the boundary $\psi = 1 - \eta$. \square

4.2. Solutions in the “strict instability” set outside the RLIS.

THEOREM 4. *For any $d \neq 0$ and with ε given by (5), we have*

(i) *Global repulsiveness.* While the solution remains in $\{\psi \geq 1 + \varepsilon\}$ (respectively, $\{\psi \leq -(1 + \varepsilon)\}$), it exponentially diverges from the RLIS crossing it at each time t (respectively, remaining on the same side of the RLIS).

(ii) *Injection.* If for some time t_0 , a solution satisfies $|\psi(t_0)| \geq 1 + \varepsilon$, $x(t_0) \neq H(\psi(t_0))$, then there exists a finite time $t_1 > t_0$, such that $|\psi(t_1)| < 1 + \varepsilon$. Hence, there is no solution satisfying every $x \neq H(\psi)$ and $|\psi| \geq 1 + \varepsilon$.

Proof. Statement (i) is a direct consequence of (14), (15). To prove (ii), we first note that if $|x| > 1$ and $|\psi| > 1 + \varepsilon$ then

$$(38) \quad 0 < \frac{d^2 x^2 + |\psi x|}{(1 + d^2 x^2)|\psi x|} < 1 - \frac{\varepsilon d^2}{(1 + \varepsilon)(1 + d^2)} < 1.$$

Hence, by Theorem 1, if for all s in $[t_0, t]$, $\psi(s) \geq 1 + \varepsilon$ (respectively, $\leq -(1 + \varepsilon)$) then

$$(39) \quad |x(t) - H(\psi(t))| \geq (1 + \rho)^{t-t_0} |x(t_0) - H(\psi(t_0))|.$$

Now since $H(\psi)$ is bounded, there exists a first time t_1 (depending on $x(t_0)$, $\psi(t_0)$) such that either $|\psi(t_1)| \leq 1 + \varepsilon$ or $|x(t_1)| \geq 1$. In the latter case, from (38) and the definition of (Σ) , we have

$$(40) \quad |\psi(t)| \leq \left[1 - \frac{\varepsilon d^2}{(1 + \varepsilon)(1 + d^2)} \right] |\psi(t-1)| \quad \forall t > t_1,$$

which means that there exists $t_2 > t_1$ such that $|\psi(t_2)| < 1 + \varepsilon$. \square

4.3. Solutions in the “strict stability” set outside the ALIS.

THEOREM 5. *For any d , $0 < |d| \leq d^*$, with d^* , η given by (16), (17), we have*

(i) *Global attractiveness.* Any solution in $\{|\psi| \leq 1 - \eta\} \times \mathbb{R}$ exponentially approaches the ALIS. Moreover, a solution starting in $\{|\psi| \leq 1 - \eta\} \times \mathbb{R}$ remains in this set as long as it remains in the set $\{|x| \geq 1/(1 - \eta)\}$.

(ii) *Drift/Ejection.* If $|1/\alpha| > 1$ and for some time t_0 , a solution satisfies $|\psi(t_0)| \leq 1 - \eta$, then there exists a finite time t_1 such that $|\psi(t_1)| > 1 - \eta$. Hence, for $|1/\alpha| > 1$, there is no solution satisfying every $|\psi| \leq 1 - \eta$.

(iii) Moreover, while a solution remains in the set

$$\left\{ \frac{d^2(1 + \xi + n_0)n_1}{1 + d^2n_0^2} \leq \psi \leq 1 - \eta \right\} \times \{|x| \leq \xi\},$$

respectively, in the set

$$\left\{ -(1 - \eta) \leq \psi \leq -\frac{d^2(1 + \xi + n_0)n_1}{1 + d^2n_0^2} \right\} \times \{|x| \leq \xi\},$$

it crosses the ALIS at each time t (respectively, it remains on the same side).

Proof. (i) Since $|\psi| \leq 1 - \eta$ and $|x| \geq 1/(1 - \eta)$, then $|(\psi + d^2x)/(1 + d^2x^2)| \leq 1 - \eta$, a solution starting in $\{|\psi| \leq 1 + \eta\} \times \mathbb{R}$ remains in this set at least while it remains in the set $\{|x| \geq 1/(1 - \eta)\}$. To complete the proof of (i), with property (35), we only need to show that any solution remaining in $\{|\psi| \leq 1 - \eta\} \times \mathbb{R}$ enters the set $\{|x| < \xi\}$, (with ξ satisfying (33)) in a finite number of steps. In fact, let the constant $\xi' := (n_0 + \xi)/2$ be $n_0 < \xi' < \xi$ and $|x(t)| \geq \xi'$; then, from the equations of (Σ) and (18), we have

$$(41) \quad \left| \frac{x(t+1)}{x(t)} \right| \leq \left| \frac{1 + \alpha}{x(t)} \right| + (1 - \eta) < 1 - \eta + \frac{2n_0}{\xi + n_0} \eta < 1,$$

i.e., the absolute value of the x -component decreases exponentially as long as $|x| \geq \xi'$.

(ii) We have

$$(42) \quad \begin{aligned} \psi(t+1) = \psi(t) + & \frac{d^2G(\psi(t))(1 - \psi(t)G(\psi(t)))}{1 + d^2G(\psi(t))^2} \\ & + d^2[x(t) - G(\psi(t))] \frac{1 + \psi(t)(x(t) + G(\psi(t)))}{(1 + d^2G(\psi(t))^2)(1 + d^2x(t)^2)}. \end{aligned}$$

From (i), either the ψ -component of the solution leaves the interval $[-(1 - \eta), 1 - \eta]$ or, after a finite time, $x(t) - G(\psi(t))$ will be as small as we want. The result follows from a continuity argument and Theorem 3(c).

Statement (iii) is a direct consequence of Theorem 2(ii). \square

Remark. As in the discussion following Theorem 1, the global character of the attractiveness of this graph is a direct consequence of the use of a normalized algorithm. In general, nonnormalized algorithms, as treated by Praly (1990), may not lead to this kind of global result.

4.4. Solutions in the “critical stability” set.

THEOREM 6 (solutions in the sets B, D, F, H).

(i) As long as a solution remains in the set $\{(\psi, x)/1 - \eta < |\psi| < 1 + \varepsilon \text{ and } |x| > \chi\}$, the absolute value $|\psi|$ decays exponentially.

(ii) Any solution starting in the set $F \cup H$ (respectively, $B \cup D$) either enters the set G (respectively, C) or goes into the set E in a finite time.

Proof. Statement (i) follows exactly along the same lines as in (38)–(40).

(ii) From

$$\phi = \left(\frac{\psi x + d^2 x^2}{1 + d^2 x^2} \right) \frac{1}{x},$$

we easily obtain

$$\begin{aligned}(\psi, x) \in F &\Rightarrow \{\psi x > 1, x > 0\} \Rightarrow \phi > 1/x > 0, \\(\psi, x) \in H &\Rightarrow \{\psi x < -1, x < 0\} \Rightarrow \phi > 1/x \geq -(1 - \eta), \\(\psi, x) \in D &\Rightarrow \{\psi x > 1, x < 0\} \Rightarrow \phi < 1/x < 0, \\(\psi, x) \in B &\Rightarrow \{\psi x < -1, x > 0\} \Rightarrow \phi < 1/x < 1 - \eta,\end{aligned}$$

and the claim follows since from (i), $|\psi|$ decreases exponentially while $(\psi, x) \in B \cup D \cup F \cup H$. \square

THEOREM 7 (solutions in the set G). *For $|d|$ small enough, if $|1/\alpha|$ is larger than $1 + \varepsilon$, a 2-periodic orbit exists such that at least one of its points lies in the set*

$$G = \{(\psi, x)/1 - \eta < \psi < 1 + \varepsilon \text{ and } |x| < \chi\}.$$

Proof. According to Theorem A1 in the Appendix, for $|d|$ small enough, a 2-periodic orbit exists with its ψ component such that $1 - \psi = O(d^2)$. This implies that the 2-periodic orbit is contained in $F \cup G \cup H$ for a small enough d^2 . The result follows since from Theorem 6 the orbit cannot be entirely contained in $F \cup H$. \square

4.5. Boundedness of solutions.

THEOREM 8. *If $1/\alpha > -1$, all the solutions of (Σ) are bounded.*

Proof. With Theorem 4.1 of Egardt (1979) it is sufficient to prove that the sequence $\{|\psi(t)|\}$ is bounded for any solution of (Σ) . For this, we first show, from the second equation of (Σ) that when $|\psi| > |d|/2\sqrt{2}$, $|\psi(t+1)| > |\psi(t)|$ if and only if $\psi(t)x(t) \in (0, 1)$. The proof then follows by showing that, for $1/\alpha > -1$, there exists $\gamma > |d|/2\sqrt{2} > 0$ such that the points of the set $\Gamma \equiv \{(\psi, x)/|\psi| > \gamma; \psi x \in (0, 1)\}$ have no preimage in Γ (the trajectories starting in Γ leave it in one sampling time). This is combined with the relationship $|\psi(t+1)| < |\psi(t)| + |d|/2$ to show that if $\psi(0)$ satisfies

$$|\psi(0)| \leq \max \left\{ \frac{1 + 2 \max \{|\alpha|, |1 - \alpha|\}}{\max \{|\alpha|, |1 + \alpha|\}}, \frac{|d|}{2\sqrt{2}} \right\} + |d|,$$

then $\psi(t)$ satisfies the same inequality for all $t \geq 0$. If, on the other hand, $\psi(0)$ does not satisfy the above inequality, there exists a finite time T such that $\psi(T)$ does satisfy it (see details in España and Praly (1988)). \square

5. Global behavior of the solutions: Qualitative description and simulation results. Using the technical results of the previous sections (Theorems 1–8), we can explain the five stages of the solutions' behavior observed in simulation and mentioned in § 2. For this, use is made of the phase plane decomposition introduced at the beginning of § 4. Figures 1–5 are used to illustrate the system's dynamic behavior. The function h given by (4) has been plotted in the phase portrait part of each figure. As shown by Theorems 1(iii) and 2(iii), its graph, denoted by “ hg ,” approximates the RLIS and the ALIS, respectively, in their domain of definition.

5.1. The turbulent phase.

5.1.1. Explosive stage. According to Theorem 4(i), a solution in the sets A or I , either remains in the RLIS, which is the graph of a bounded function of ψ , or diverges exponentially from it (and, in practice, from its approximation (4)). This explains an exponential growth of the x -component, which becomes and remains large. Moreover, for a solution in the set I , at each time t , the x -component changes side with respect to

FIG. 1(a). Phase portrait, two stable focus of Σ^2 ($\alpha = 0.8$, $d^2 = 0.005$).

FIG. 1(b). Time response converging to a period-2 stable orbit ($\alpha = 0.8$, $d^2 = 0.005$).

FIG. 2(a). Phase portrait with a stable node ($\alpha = 1.5$, $d^2 = 0.005$).

FIG. 2(b). Time response of solution (a1) ($\alpha = 1.5$, $d^2 = 0.005$).

FIG. 3(a). Phase portrait with a stable focus ($\alpha = -1.008, d^2 = 0.005$).

FIG. 3(b). Time response of solution (b1) ($\alpha = -1.008, d^2 = 0.005$).

FIG. 4(a). Phase portrait with a saddle as equilibrium point ($\alpha = 0.1, d^2 = 0.005$).

FIG. 4(b). Time response of solution (a) ($\alpha = 0.1, d^2 = 0.005$).

FIG. 5(a). Phase portrait with an unstable node ($\alpha = -0.9$, $d^2 = 0.005$).FIG. 5(b). Time response of solution (b2) ($\alpha = 0.9$, $d^2 = 0.005$).

this graph. This explains the “bursts” with very high frequency content on x (see solutions (a) in Figs. 2, 4, and 5). Conversely, for a solution in the set A , the x -component remains on the same side of the graph. It corresponds to a burst without oscillations (see solutions (b) in Figs. 3–5). We conclude that the explosive stage (a) takes place in the set A or I for any value of the disturbance and the reference (and therefore also in the ideal case).

5.1.2. Reinjection stage. Following Theorem 4(ii), a solution in the set A or I with a large x -component or in the set $B \cup D$ or $F \cup H$ has its ψ -component exponentially decaying. This occurs for any value of the disturbance and the reference and explains the reinjection of the solutions into the set E (see solutions (a) and (b) in Figs. 2–5).

5.1.3. Implosive stage. Theorem 5(i) states that, at least for a sufficiently small disturbance, as soon as a solution enters the set E , it is exponentially attracted toward the ALIS, which is the graph of a bounded function of ψ approximated by the set hg . This explains the exponential decrease of the x -component and, were it present, the fast decay of its high frequency content (see solutions (a) in Figs. 2, 4, and 5). Consequently, at least for small values of the disturbance, this stage occurs for any value of the reference and takes place in the set E .

5.2. The laminar phase (or the drift/ejection stage). Following Theorem 5(ii), when $|1/\alpha| > 1$, all the solutions leave the set E in a finite time. However, if before leaving the set E , they become close to the ALIS (in Figs. 1–5 one can see how the solutions practically converge to the graph (hg) approximating the ALIS), they finally leave that set “drifting” over the ALIS while its ψ -component grows with a speed of the order of d^2 (see also Theorem 3(c)). The solutions, very likely, enter the set G .

After entering the set G , a solution may either remain in it (see Fig. 1), go to the set I , thus restarting the explosive stage and possibly initiating the intermittent phenom-

enon, or go to the set $F \cup H$. In the latter case, Theorem 6 shows that the solution may either be reinjected into the set E , restarting the implosive stage, or returned to the set G . Intermittency may also take place in this case.

5.3. Possible 2-periodic orbits or limit cycles as ω -limits. According to Theorems A1 (in the Appendix) and 7, for a reference-to-disturbance ratio strictly smaller than 1 and for a disturbance sufficiently small, a 2-periodic orbit exists with at least one point in G and the other in $F \cup G \cup H$. Each point of this orbit is an attractive focus of Σ^2 if reference and disturbance have the same signs and a repellent focus in the case of opposite signs. In the former case, intermittency may disappear asymptotically while the solutions converge toward a 2-periodic orbit (see Fig. 1 and solution (a) in Fig. 4). When the reference and the disturbance have different signs, it is hypothesized that the solutions either exhibit a permanent intermittency (see Fig. 5) or, due to the occurrence of a supercritical Hopf bifurcation of the 2-periodic orbit, have an ω -limit comprised of two limit cycles of Σ^2 each surrounding a fixed point of Σ^2 .

5.4. High sensitivity with respect to the initial conditions. From simulations and the approximations given in Theorems 1(iii) and 2(iii), it seems that the ALIS and the RLIS are smoothly connected through the set G (see Figs. 4 and 5). From Remark 1 following Theorem 3(b), if the fixed point lies in the RLIS, the portion of this set defined for $\psi > 1 + \varepsilon$ is unique. Its intersection with the boundary $\psi = 1 + \varepsilon$ being transverse, we expect that it is uniquely extended by an ALIS inside the strict stability region. Using this conjecture as a working hypothesis, the more a solution approaches the ALIS while it is in E , the more its evolution will be similar to the solutions in the RLIS when entering the set I . However, according to Theorem 3(b) and the remarks that follow, for a reference-to-disturbance ratio strictly smaller than 1 in absolute value and negative, the solutions in the RLIS starting in $\psi \in (1 + \varepsilon, \infty)$ are unbounded (the same as those starting in $(-\infty, 1/\alpha)$). On the other hand, the bigger its ψ -component is, the more the x -component of a solution in the set I , but not in the RLIS, is “pushed-away” (exponentially) from this invariant set. This reasoning shows the possibility of a very high sensitivity to initial conditions of solutions starting near the ALIS or, with Theorem 2, close to the graph of the function hg given in (4).

5.5. The desired behavior. Theorem A1 (see the Appendix) shows that, for a sufficiently small disturbance and a reference-to-disturbance ratio strictly larger than 1, the fixed point is exponentially stable and there is no other periodic solution. On the other hand, and under the same conditions, with Theorem 8, each solution remains in a compact set. This suggests that the fixed point is a global attractor. In this case, intermittency should not take place and the desired working conditions should be attained (see Figs. 2 and 3). Qualitatively speaking, this case most resembles the ideal case.

Summarizing, according to the reference-to-disturbance ratio α , three qualitatively different behaviors of the solutions of (Σ) can be predicted:

1. $|\alpha| > 1$ (high level excitation): bounded solutions, no intermittency, no periodic solution, a global attractive fixed point is conjectured, behavior similar to the ideal case.

2. $0 < \alpha < 1$ (low level excitation): bounded solutions, stable periodic solutions exist and are conjectured to be global attractors, the fixed point is a saddle, intermittency may occur but is conjectured to gradually disappear while converging asymptotically to a 2-periodic solution.

3. $-1 < \alpha \leq 0$ (low level excitation): unbounded solutions exist, unstable 2-periodic solutions exist, intermittency and/or possible nonlinear oscillations are present, the fixed point is an unstable node.

Since α is a relative quantity, drastic qualitative changes of the system's behavior may be expected when both r and d are close to zero, which is the natural working condition for an adaptive linear regulator.

6. A means to prevent intermittency: The dead zone. We study here the effects of an empirical modification to the second equation of (Σ) (and (Σ_1)). For some $\delta > 0$, we call the set $D_\delta = \{x / |x - \alpha| < \delta\}$ the δ -dead zone and substitute μ in (Σ) by:

$$\mu = \begin{cases} 0 & \text{iff } x \in D_\delta, \\ 1 & \text{iff } x \notin D_\delta. \end{cases}$$

It is expected that this modification will interrupt the drift stage of the solutions near the ALIS when $|1/\alpha| > 1$. To examine the validity of this, let us first introduce the following definition:

$$\nu(\eta, d^2) := \frac{d^2 n_0 (n_0 + n_1) (n_0 + 1)}{(1 - \lambda(\eta, d^2))},$$

where η and λ are given respectively by (17) and (30). We now make the following assertion.

Assertion. (i) If $|1/\alpha| > 1$ and d and δ are such that

$$\delta < \frac{1 - \alpha + \eta\alpha}{2 - \eta} - \nu(\eta, d^2),$$

there is no solution of (Σ) with δ -dead zone satisfying for all t : $|\psi(t)| < 1 - \eta$.

(ii) There is no solution leaving the set $\{|\psi| \leq 1\}$ if and only if $\delta \geq 1 + |\alpha|$.

Proof. (i) From the exponential attractiveness property of the ALIS and its approximation by the graph of h given by (4), (see Theorem 3 and (36)), we see that if $\alpha + \delta < h(1 - \eta) - \nu(\eta, d^2)$, any solution remaining in $\{|\psi| < 1 - \eta\}$ enters a set (the band around h of radius $\nu(\eta, d^2)$) whose intersection with the dead zone is empty for $|\psi| < 1 - \eta$. In this set, then, $\mu = 1$, the ψ -component is strictly increasing (Theorem 4(c) and (37)), and the solutions necessarily leave the domain $\{|\psi| < 1 - \eta\}$ in a finite time.

(ii) From the definition of (Σ) when $\mu = 1$ we have the following implications:

$$\begin{aligned} \{|\psi(t)| < 1 \text{ and } \psi(t+1) > 1\} &\Leftrightarrow \{1 > \psi(t) > 1 - d^2 x(1 - x)\}, \\ \{|\psi(t)| < 1 \text{ and } \psi(t+1) < -1\} &\Leftrightarrow \{-1 < \psi(t) < -1 - d^2 x(1 + x)\}. \end{aligned}$$

Thus, the solutions of (Σ) with dead zone will not leave the domain $\{|\psi| \leq 1\}$ if and only if the right hand side of both implications are realized inside the dead zone only. But this is clearly the case when $\delta > |\alpha| + 1$. \square

Remarks. The dead-zone modification may fail to work if an upper limit of the disturbance is not known. When it works, i.e., when δ is bigger than, say, some $\delta^* > (1 - \alpha + \eta\alpha)/(2 - \eta) + \nu(\eta, d^2)$, the original ALIS is transformed into a new one (possibly not given by the graph of a continuous function any more) containing a portion of the graph of h . Since h is a monotonically decreasing function in $|\psi| < 1 - \eta$, the part of the graph of h coinciding with the new ALIS is confined to the right of the interval $|\psi| < 1 - \eta$. However, the movement of the solutions over the ALIS is also in the sense of growing ψ 's. Consequently, in this case the modified scheme will very likely stop the solutions' drift near the ALIS before they enter into the "instability domain."

7. Concluding remarks. The ALIS and the RLIS play a key role in the qualitative and geometrical description of the phase portrait of our example. It can be shown that these two sets exist in more general systems since their definitions rest on some general properties of the adaptive systems (see, for instance, Praly (1990)). We can thus state that the intermittent behavior is the result of the absence of a global attractor in the ALIS combined with a property of the algorithm of maintaining all the signals bounded despite a model mismatch (L^∞ -robustness). In fact, since the ALIS is normally defined in a bounded open set of the parameter space (in general, the set of parameters mapped into the open unitary circle by the eigenvalues of the regressor model), the lack of a global attractor in it implies that some trajectories approaching the ALIS will eventually leave the strict stability set of parameters. This may be a very slow “quasi-stable” process. On the other hand, the L^∞ -robustness is responsible for the “reinjection mechanism” into the domain of attraction of the ALIS, provoking the abandon of the turbulent phase and the restart of the cycle. Since this reinjection is guaranteed by the (desirable) robustness, we can thus say that intermittency is essentially conditioned by the dynamics in the ALIS and thus, that any palliative to this phenomenon passes by an “adequate” modification of the dynamics in this set. However, the dynamics in the ALIS (and the ALIS itself) depend on the exogenous signals. Consequently, for any “good” modification of the ALIS dynamics it may be possible to find a “counter-example” given by a particular combination of model mismatch and reference signals. Moreover, the modifications introduced (to the algorithm and to the ALIS) may even exacerbate the situation. For instance, Rey, Bitmead, and Johnson (1989), reported that a previous (“unhelped”) nonintermittent system may become intermittent after the addition of leakage. This possibility seems less likely when a dead zone is used since its working principle consists in transforming part of the ALIS into the corresponding set of attractive bounded solutions of the “frozen system.” When the parameters are frozen, the drift phase is necessarily eliminated at least while the dead zone is active.

Clearly, more research must be done to find algorithms assuring a robust global attractor in the ALIS for (at least) a specified family of disturbances or model mismatches with a practical meaning. A possible general approach could be to stop the adaptation when some “ad-hoc” mechanism detects the drift phase. This decision can be taken, for instance, when the calculated increment in the parameters (possibly averaged) is smaller than a prespecified threshold. Note that here is not the error that counts, as in the dead zone, but its correlation with the regressor vector. This correlation should be viewed as an approximation of the gradient of the mean value of the error with respect to the parameters. When the reference signal is sufficiently persistently exciting or, more precisely, using a concept coined by Ioannou and Kokotovic (1983), persistently dominantly exciting, the ALIS has a natural global attractor in it; it corresponds to the desired working conditions. This attractor is hyperbolic (see Anderson et al. (1986)) and thus, structurally robust. However, for large disturbances (or model-mismatch), this attractor may cease to be globally attractive, disappear, or be pushed out of the ALIS in the RLIS region; this last circumstance motivates a bifurcation analysis. Any of these conditions can be at the origin of an intermittent behavior with persistent excitation, but in particular, when the attractor leaves the ALIS, the desired working conditions can never be attained even if by some means intermittency could ever be avoided. Clearly we can “solve the problem” by adding excitation in the dominant frequency range to the reference signals, but this does not imply that the original objective will be satisfied. On the other hand, when there is no persistent excitation (or there is but with a very low energy level or a bad frequency content), the functioning regime becomes very critical since the desired working conditions may not correspond to an hyperbolically stable set. In this case, a

very weak robustness of many properties is to be expected. Indeed, very different qualitative behaviors can be close to one another and the system may easily switch from the desired working condition to an intermittent behavior or a self-oscillating mode. With respect to the last mode of operation, we see, for the example considered, that a 2-periodic orbit (self-oscillating model) appears as a result of the bifurcation provoked by the expulsion of the desired working conditions out of the ALIS. This 2-periodic oscillation has also been encountered by other authors in a similar example (Sethares and Mareels (1991), Rey, Bitmead, and Johnson (1991)). Actually, this is a particularity of the example (one-dimensional parameter space) and of the excitation condition (constant reference and disturbance signals). In general, these self-oscillating modes, which determine the frequency content of the “bursts,” may have any period or not exist at all (see España, (1990), (1991)). When the ALIS has no attractor in it and there are no self-oscillations or there are but they are not attractive (see $1/\alpha < -1$ in our example), a nonperiodic permanent intermittent regime is likely to take place. This is favored by the fact that, while reentering in the “stability-domain,” the trajectories are attracted toward a region (near the ALIS) where the solutions are highly sensitive with respect to the initial conditions. As pointed out by Bergé, Pomeau, and Vidal (1984), this, together with the absence of a periodic or quasi periodic attractive solution, seems to be at the origin of strange attractors.

Summarizing, we may conjecture that the antidotes for intermittency, like leakage or internal model principle, whose active principle is not based in stopping the solutions in its drift phase near the ALIS (they just modify the dynamics in it), could provoke the undesired effect if combined with a particular excitation and/or model mismatch. The schemes based on freezing the parameters upon detecting the drift phase (the dead-zone approach included) may also need a priori information of the disturbances to succeed, but, even if they can possibly fail to do the job, they are less likely to provoke the undesired effect. They are based on a characteristic of the phenomenon that is independent of the excitation conditions. Nevertheless, none of them solve the problem of the attractive self-oscillations. Strongly dominantly exciting references signals produce robust desired working conditions. Otherwise, if no precautions are taken, the system may easily switch among very different qualitative behaviors.

Appendix. Local behavior near the equilibrium point and period-2 solutions. The analysis of the local behavior of (Σ) near its equilibrium $(\psi, x) = (1/\alpha, \alpha)$ is based in the Jacobian matrix of (Σ) at this point:

$$J = \begin{pmatrix} -1/\alpha & -\alpha \\ -d^2/(1 + d^2\alpha^2) & 1/(1 + d^2\alpha^2) \end{pmatrix}.$$

The product of its eigenvalues is $P = -1/\alpha$ and their sum is given by

$$(A) \quad S = P + 1 - \frac{d^2}{P^2 + d^2}.$$

In terms of S and P , exponential stability of the equilibrium point is given by

$$(B) \quad 1 - S + P > 0$$

$$(C) \quad 1 + S + P > 0,$$

$$(D) \quad 1 - P > 0,$$

and the eigenvalues are real if

$$(E) \quad S^2 - 4P \geq 0.$$

Thus, the equilibrium point is exponentially stable if and only if $1/\alpha \in (-1, p)$, where $p \in (\frac{1}{2}, 1)$ is the unique solution of $2(1-p)(p^2 + d^2) = d^2$. Consequently, unless $1/\alpha \in (-1, p)$, the “desired working conditions” do not correspond to a stable equilibrium point. The points of intersection of curves (A) and (E) correspond to the transition from real to complex eigenvalues and vice versa. They all occur for α negative, and we may have a stable ($\alpha < -1$) or an unstable ($\alpha > -1$) equilibrium point and a node or a focus depending on d^2 .

Independently of the value of d^2 , for α near -1 , the equilibrium point passes from being an attractive focus ($\alpha < -1$) to a repellent one ($\alpha > -1$) verifying the conditions for a postcritical Hopf bifurcation (see Iooss (1979)). For the particular value $\alpha = -1$ the whole ψ -axis is a set of fixed points implying a global bifurcation.

For α positive, we have either a stable node ($1/\alpha < p$) or a saddle ($1/\alpha > p$). When $1/\alpha$ crosses the value p , an eigenvalue passes through -1 , and a stable period-2 solution bifurcates from the stable fixed point while the latter becomes unstable (see Arnold (1983) or Iooss (1979)). The 2-periodic solutions can be determined evaluating the roots of the equation $\Sigma^2(\psi, x) - (\psi, x) = 0$, or, equivalently, for d nonzero, by computing the solution of

$$(A.1) \quad \begin{aligned} F_x(x, \psi, d) &:= -(\psi + d^2\phi)(-\psi x + 1 + \alpha) + (1 + \alpha - x) = 0 \\ F_\psi(x, \psi, d) &:= \phi + \frac{(-\psi x + 1 + \alpha)[1 - (\psi + d^2\phi)(-\psi x + 1 + \alpha)]}{1 + d^2(-\psi x + 1 + \alpha)^2} = 0, \end{aligned}$$

where $\phi = x(1 - \psi x)/(1 + d^2 x^2)$. For $d = 0$, the above system has three solutions:

$$(A.2) \quad (\psi_0 = \alpha^{-1}, x_0 = \alpha), \quad \left(\psi_{1,2} = 1, x_{1,2} = \frac{1 + \alpha \pm \sqrt{1 - \alpha^2}}{2} \right).$$

The first one is the equilibrium point; the two others exist if and only if the disturbance-to-reference ratio $1/\alpha$ is larger (in modulus) than 1. We make the following observation.

LEMMA (Existence of periodic solutions; Pomet, Coron, and Praly (1990)). *A necessary condition for $(\psi_{\text{per}}(t, d), x_{\text{per}}(t, d))$ to be a period- T solution of (Σ) that remains bounded as d goes to 0 is that the accumulation point of its initial condition be one of the three points in (A.2).*

To show that the existence of zeros $(\psi_{1,2}, x_{1,2})$ of (A.1) given by (A.2) is also sufficient for having period-2 solutions, use is made of the implicit function theorem with the following expression of the Jacobian matrix of (A.1) (nonsingular for $|\alpha| < 1$):

$$\partial F(x_{1,2}; \psi_{1,2}; 0) = \begin{bmatrix} 0 & \mp \sqrt{1 - \alpha^2} \\ \mp \sqrt{1 - \alpha^2} & * \end{bmatrix},$$

where the $(2, 2)$ -term is unimportant. Compared with our discussion on the stability of the fixed point of (Σ) we note that for $|d|$ small enough, the period-2 solutions emerge not only when an eigenvalue of J passes through -1 ($\alpha \approx +1$), from the stability side (for period-2 bifurcation condition), but also when a pair of conjugate eigenvalues of J crosses the unit circle at $\alpha = -1$. The latter corresponds to a global bifurcation. To summarize, we have the following theorem.

THEOREM A1 (Critical elements, España and Praly (1988)). (i) *The system (Σ) has a unique fixed point for all α different from 0 or -1 . It is the solution corresponding to the control objective. It is exponentially stable for $1/\alpha \in (-1, p)$ and exponentially unstable for $1/\alpha \notin [-1, p]$.* (ii) *For any $|\alpha| < 1$ we can find a strictly positive constant*

d_0 such that if $|d| \leq d_0$, there exists two locally unique period-2 solutions that can be approximated by

$$(A.3) \quad \psi_{1,2} = 1 - \frac{\alpha d^2}{2} \frac{1 + \alpha \mp \sqrt{1 - \alpha^2}}{2} + O(d^4), \quad x_{1,2} = \frac{1 + \alpha \pm \sqrt{1 - \alpha^2}}{2} + O(d^2).$$

These solutions are foci of Σ^2 , exponentially stable for $\alpha > 0$, exponentially unstable for $\alpha < 0$, and with a pseudoperiod approximated by $T = 2\pi/d(2(1 - \alpha^2)^{1/2})$.

Acknowledgments. The authors thank the reviewers for their thorough work. Their excellent comments and pertinent suggestions contributed immeasurably to improving the quality of this article.

OPTIMAL CONTROL FOR INTEGRODIFFERENTIAL EQUATIONS OF PARABOLIC TYPE*

GIUSEPPE DA PRATO[†] AND AKIRA ICHIKAWA[‡]

Abstract. Quadratic control problems for integrodifferential equations of parabolic type are considered. A state-space representation of the system is obtained by choosing an appropriate product space. By using the standard method based on Riccati equation, a unique optimal control over a finite horizon and under a stabilizability condition is obtained and the quadratic problem over an infinite horizon is solved. It is shown that the approach is also valid for some integrodifferential equations of different types. Two examples covered by the model are given.

Key words. optimal control, stabilizability, integrodifferential equations

AMS subject classifications. 93D15, 93C22, 93C25

1. Introduction. Let H and U be Hilbert spaces. Consider the control system

$$(1) \quad \begin{cases} y'(t) = Ay(t) + \int_0^t K(t-r)y(r) dr + Bu(t), \\ y(0) = y_0, \end{cases}$$

where A is the infinitesimal generator of an analytic semigroup e^{tA} in H . We denote by $D(A)$ the domain of A and by $|\cdot|_{D(A)}$ the graph norm of A . $K(\cdot)$ is an $L(D(A); H)$ -valued operator, and $B \in L(U; H)$. Under suitable conditions (see Hypothesis 1 below) there exists a resolvent operator (see [3], [13], [16]) associated with (1) and a unique classical solution to (1). For each $u \in L^2(0, T; U)$ we can define a mild solution to (1) in $C([0, T]; H)$. We then wish to minimize the functional

$$(2) \quad J(u) = \int_0^T \{ |My(t)|^2 + |u(t)|^2 \} dt + \langle Gy(T), y(T) \rangle$$

over all $u \in L^2(0, T; U)$. Here $M \in L(H; H_0)$, H_0 is a Hilbert space, and $G \in L^+(H)$ is the space of selfadjoint nonnegative operators on H . Under a stabilizability condition (see Hypothesis 4 below) we also wish to minimize the functional

$$(3) \quad J(u) = \int_0^\infty \{ |My(t)|^2 + |u(t)|^2 \} dt$$

over all $u \in L^2(0, \infty; U)$. To our knowledge there is no direct method to solve these problems. In this paper we give a state-space representation of (1) similar to those in [15] and [19]. As in [9]–[11] we then reduce our problems to linear quadratic problems of standard type [1].

We recall some fundamental results concerning the resolvent operator associated with (1). It is convenient to introduce equations

$$(4) \quad \begin{cases} y'(t) = Ay(t) + \int_0^t K(t-r)y(r) dr, \\ y(0) = y_0, \end{cases}$$

* Received by the editors October 22, 1990; accepted for publication (in revised form) January 17, 1992.

[†] Scuola Normale Superiore di Pisa, Piazza dei Cavalieri, 7, 56100, Pisa, Italy.

[‡] Department of Electrical Engineering, Shizuoka University, Hamamatsu 432, Japan.

$$(5) \quad \begin{cases} y'(t) = Ay(t) + \int_0^t K(t-r)y(r) dr + f(t), \\ y(0) = y_0, \end{cases}$$

In [6] and [16] the existence of a resolvent operator for (4) is shown under the following conditions.

Hypothesis 1.

- (i) $K(\cdot) \in L^1(0, \infty; L(D(A); H))$.
- (ii) For all $h \in D(A)$, the Laplace transform $\tilde{K}(\cdot)h$ can be extended to a sector $S = \{\lambda \in \mathbb{C} : \lambda \neq \omega, |\arg(\lambda - \omega)| < \varphi\}$, where $\omega \in \mathbb{R}, \varphi \in]\pi/2, \pi[$.
- (iii) There exist $\beta \in]0, 1]$ and $c > 0$ such that $|\lambda^\beta \tilde{K}(\cdot)h| \leq c|h|_{D(A)}$, $\lambda \in S$, $h \in D(A)$.

The following result is proved in [3] and [16].

THEOREM 1.1. *There exists an analytic resolvent operator $R(t) \in L(H; D(A))$, $t \geq 0$, such that*

- (i) $R(t)y_0$ is continuous for any $y_0 \in H$ and $R(0) = I$.
- (ii) For each $y_0 \in D(A)$ and $T > 0$,

$$R(t)y_0 \in C([0, T]; D(A)) \cap C^1([0, T]; H)$$

and it satisfies (4).

- (iii) For each $y_0 \in D(A)$ and $f \in C^\alpha([0, T]; H)$ (α -Hölder continuous), $y(t)$, given by

$$y(t) = R(t)y_0 + \int_0^t R(t-r)f(r) dr,$$

is a unique classical solution (see [3]), in

$$C([0, T]; H) \cap C([0, T]; D(A)) \cap C^1([0, T]; H).$$

- (iv) There exist $r_0 > 0$ and $\varphi_0 \in]\frac{\pi}{2}, \varphi]$ such that for any $\lambda \in S$ with $|\lambda| \geq r_0$, $|\arg \lambda| \leq \varphi_0$, the linear operator $\lambda - A - \tilde{K}(\lambda) : D(A) \rightarrow H$ is invertible and $(\lambda - A - \tilde{K}(\lambda))^{-1} \in L(H; D(A))$ coincides with the Laplace transform of $R(t)$.

For each $y_0 \in H$ and $u \in L^2(0, T; U)$

$$(6) \quad y(t) = R(t)y_0 + \int_0^t R(t-r)Bu(r) dr$$

is well defined and is in $C([0, T]; H)$. It is a mild solution of (1) in the sense

$$(7) \quad y(t) = e^{tA}y_0 + \int_0^t e^{(t-r)A} \int_0^r K(r-s)y(s) ds dr + \int_0^t e^{(t-r)A} Bu(r) dr.$$

Note that the cost function (2) makes sense for the mild solution.

For later use we establish additional properties of $R(t)$ that are not given in [3]. Let $D_A(\alpha, 2)$, $\alpha \in]0, 1[$ be the real interpolation space between $D(A)$ and H . Consider the problem

$$(8) \quad y'(t) = Ay(t) + f(t), \quad y(0) = y_0.$$

THEOREM 1.2. (i) Let $y_0 \in D_A(\frac{1}{2}, 2)$, and let $f \in L^2(0, T; H)$. Then the mild solution of (8) lies in

$$L^2(0, T; D(A)) \cap W^{1,2}(0, T; H) \subset C([0, T]; D_A(\frac{1}{2}, 2)).$$

There exists a unique solution y to (4) in $L^2(0, T; D(A)) \cap W^{1,2}(0, T; H)$. Hence $R(t)y_0, R \star f \in L^2(0, T; D(A)) \cap W^{1,2}(0, T; H)$.

(ii) Let $y_0 \in D(A)$, $f \in W^{1,2}(0, T; H)$, and $Ay_0 + f(0) \in D_A(\frac{1}{2}, 2)$. Then the mild solution of (8) lies in

$$W^{1,2}(0, T; D(A)) \cap W^{2,2}(0, T; H) \subset C^1([0, T]; D_A(\frac{1}{2}, 2)).$$

Moreover, there exists a unique solution y to (4) in $W^{1,2}(0, T; D(A)) \cap W^{2,2}(0, T; H)$. Hence $R(t)y_0, R \star f \in W^{1,2}(0, T; D(A)) \cap W^{2,2}(0, T; H)$.

Proof. The first assertion in (i) is well known [17]. To show the second assertion of (i) we consider the corresponding integral equation of the type (7). For a small T we apply a contraction-mapping theorem on $L^2(0, T; D(A))$. The general case then follows by splitting the interval into small subintervals. The first assertion in (ii) is proved as in [15]. The second part of (ii) follows by raising regularity and considering a contraction mapping on $W^{1,2}(0, T; D(A))$. See [15] for details. \square

To give a state-space representation [8], [9] of (1) we consider

$$(9) \quad \begin{cases} y'(t) = Ay(t) + \int_{-\infty}^t K(t-r)y(r) dr, \\ y(0) = y_0, \\ y(\theta) = y_1(\theta), \theta \in]-\infty, 0[, y_1 \in L^2(-\infty, 0; D(A)). \end{cases}$$

We now rewrite this as

$$(10) \quad \begin{cases} y'(t) = Ay(t) + \int_0^t K(t-r)y(r) dr + f(t), \\ y(0) = y_0, \end{cases}$$

where $f(t) = \int_{-\infty}^0 K(t-\theta)y_1(\theta) d\theta \in L^2(0, \infty; H)$.

Hypothesis 2. $K(\cdot) \in L^2(0, \infty; L(D(A); H))$.

If we assume Hypothesis 2 is true, then the operator \mathcal{K} defined by

$$(11) \quad \mathcal{K}y_1 = \int_{-\infty}^0 K(-\theta)y_1(\theta)d\theta, \quad y_1 \in L^2(-\infty, 0; D(A))$$

lies in $L(L^2(-\infty, 0; D(A)), H)$. Moreover, $f \in W^{1,2}(0, T; H)$ for any $y_1 \in W^{1,2}(-\infty, 0; D(A))$ since

$$f'(t) = K(t)y_1(0) + \int_{-\infty}^0 K(t-\theta)y_1'(\theta) d\theta \in L^2(0, T; H).$$

Note also $f(0) = \mathcal{K}y_1$. Using these observations and Theorem 1.2, we have the following corollary.

COROLLARY 1.3. (i) For each $y_0 \in D_A(\frac{1}{2}; 2)$ and $y_1 \in L^2(-\infty, 0; D(A))$ there exists a unique solution to (10) (and hence to (9)) in the space $L^2(0, T; D(A)) \cap W^{1,2}(0, T; H)$.

(ii) Assume Hypothesis 2, and let $y_1 \in W^{1,2}(-\infty, 0; D(A))$, $y_1(0) = y_0$, and $Ay_0 + \mathcal{K}y_1 \in D_A(\frac{1}{2}; 2)$. Then there exists a unique solution to (9) in

$$W^{1,2}(-\infty, 0; D(A)) \cap W^{2,2}(0, T; H) \subset C^1([0, T]; D_A(\frac{1}{2}; 2)).$$

Proof. Part (i) follows directly from Theorem 1.2(i). Under Hypothesis 2 $f \in W^{1,2}(0, T; H)$ and the assumptions in (ii) of Theorem 1.2 are satisfied. Hence (10) has a unique solution in $W^{1,2}(0, T; D(A)) \cap W^{2,2}(0, T; H)$. Since $y_1(0) = y_0 \in D(A)$, there exists a unique solution to (5) in $W^{1,2}(-\infty, T; D(A))$. \square

Now we write (9) in the form

$$\begin{aligned} y'(t) &= Ay(t) + \int_{-\infty}^t K(-\theta)y(t+\theta) d\theta, \\ y(0) &= y_0, \\ y(\theta) &= y_1(\theta), \quad \theta \in]-\infty, 0[. \end{aligned} \tag{12}$$

This is a delay equation with infinite delay. A more general delay equation, but with finite delay, was considered in [15], and a semigroup was constructed on the product space $D_A(\frac{1}{2}; 2) \times L^2(-r, 0; D(A))$. To obtain a similar result we assume Hypothesis 2 and rewrite (12) as

$$\begin{aligned} y'(t) &= Ay(t) + \mathcal{K}y_t, \\ y(0) &= y_0, \\ y(\theta) &= y_1(\theta), \quad \theta \in]-\infty, 0[. \end{aligned} \tag{13}$$

where $y_t(\cdot) = y(t + \cdot)$. The following result is a modification of [15, Thms. 4.1 and 4.2] for the case with infinite delay.

THEOREM 1.4. Assume Hypotheses 1 and 2 are true, and let y be the unique solution of (12) for $y_0 \in D_A(\frac{1}{2}; 2)$ and $y_1 \in L^2(-\infty, 0; D(A))$, which lies in $L^2(0, T; D(A)) \cap W^{1,2}(0, T; H)$ for any $T > 0$. Then the map

$$\underline{S}(t) : \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} \rightarrow \begin{pmatrix} y(t) \\ y_t(\cdot) \end{pmatrix} \tag{14}$$

on $\underline{Z} = D_A(\frac{1}{2}; 2) \times L^2(-\infty, 0; D(A))$ is a strongly continuous semigroup. Its infinitesimal generator is given by

$$\mathcal{A} \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} = \begin{pmatrix} Ay_0 + \mathcal{K}y_1 \\ \frac{dy_1}{d\theta} \end{pmatrix}, \tag{15}$$

$$D(\mathcal{A}) = \{(y_0, y_1) \in \underline{Z} : y_1 \in W^{1,2}(-\infty, 0; D(A)), \\ y_1(0) = y_0, Ay_0 + \mathcal{K}y_1 \in D_A(\frac{1}{2}; 2)\} \tag{16}$$

Proof. The only difference between (13) and the equation in [15] is the length of the memory involved. Hence one could repeat the proofs in [15]. However, we shall give a different proof for the characterization of the generator. Note first that the strong continuity and the semigroup property of $\underline{S}(t)$ follow from Corollary 1.3(i). We now show that \mathcal{A} , given by (15) and (16) is the infinitesimal generator of the semigroup $\underline{S}(t)$. Choose $[y_0, y_1]' \in D(\mathcal{A})$; then $\underline{S}(t)[y_0, y_1]' = [y(t), y_t(\cdot)]$, where $y(t)$ is the solution of (13) and hence of (9). Then by Corollary 1.3 (ii) we have

$$\lim_{t \rightarrow 0} \frac{y(t) - y_0}{t} = y'(0) = Ay_0 + \mathcal{K}y_1 \quad \text{in } D_A\left(\frac{1}{2}; 2\right),$$

$$\lim_{t \rightarrow 0} \frac{y_t(\cdot) - y_1(\cdot)}{t} = \frac{dy_1}{d\theta} \quad \text{in } L^2(-\infty, 0; D(A)).$$

This implies that the infinitesimal generator of the semigroup $\underline{S}(t)$ coincides with \mathcal{A} on $D(\mathcal{A})$ and is an extension of \mathcal{A} . To see that \mathcal{A} is in fact the generator we need to show only that the resolvent set of \mathcal{A} is nonempty. Now choose $\lambda > 0$ and consider

$$(\lambda - \mathcal{A})[y_0, y_1]' = [z_0, z_1]' \in \underline{Z}.$$

This is equivalent to

$$\lambda y_0 - Ay_0 - \mathcal{K}y_1 = z_0 \in D_A\left(\frac{1}{2}; 2\right),$$

$$\lambda y_1 - \frac{dy_1}{d\theta} = z_1 \in L^2(-\infty, 0; D(A)).$$

The second equation yields

$$y_1(\theta) = e^{\lambda\theta} y_1(0) + \int_{\theta}^0 e^{\lambda(\theta-\eta)} z_1(\eta) d\eta.$$

Setting $y_1(0) = y_0$ and substituting y_1 into the first equation, we obtain

$$(\lambda - \mathcal{A} - \mathcal{K}e^{\lambda\cdot})y_0 = z_0 + \mathcal{K} \int_{\theta}^0 e^{\lambda(\theta-\eta)} z_1(\eta) d\eta =: \bar{z}_0.$$

Noting that $\mathcal{K}e^{\lambda\cdot}y_0 = \tilde{K}(\lambda)y_0$, we have

$$(\lambda - \mathcal{A} - \tilde{K}(\lambda))y_0 = \bar{z}_0.$$

By virtue of Theorem 1.1(iv) this is solvable for any $\lambda > r_0$ and $y_0 = (\lambda - \mathcal{A} - \tilde{K}(\lambda))^{-1}\bar{z}_0 \in D(\mathcal{A})$. Then

$$y_1(\theta) = e^{\lambda\theta} (\lambda - \mathcal{A} - \tilde{K}(\lambda))^{-1}\bar{z}_0 + \int_{\theta}^0 e^{\lambda(\theta-\eta)} z_1(\eta) d\eta$$

lies in $W^{1,2}(-\infty, 0; D(A))$. We also have

$$Ay_0 + \mathcal{K}y_1 = \lambda y_0 - z_0 \in D_A\left(\frac{1}{2}; 2\right).$$

Hence $\lambda \in \rho(\mathcal{A})$ and \mathcal{A} is the infinitesimal generator of the semigroup $\underline{S}(t)$. \square

Remark 1.5. Let $A = A_0 + A_1$, where A_0 is selfadjoint and negative. If $A_1 \in L(D(-A)^{1/2}; H)$, then we can replace $D_A(\frac{1}{2}; 2)$ by $D(-A)^{1/2}$ and $D_A(-\frac{1}{2}; 2)$ by $D(-A^*)^{1/2}$ (see §2).

In [14] a special case of the delay equation in [15] was considered and a quadratic control problem on $D_A(\frac{1}{2}; 2) \times L^2(-r, 0; D(A))$ was solved.

If we take $B \in L(U; D_A(\frac{1}{2}; 2))$, $M \in L(D_A(\frac{1}{2}; 2), H_0)$, and $G \in L^+(D_A(\frac{1}{2}; 2))$, then by using the semigroup $\underline{S}(t)$ in Theorem 1.4 we can solve our control problem as in [14]; however, the state space \underline{Z} is not convenient in applications, and we wish to take the initial value y_0 in H rather than in $D_A(\frac{1}{2}; 2)$. Moreover, our cost functionals (2) or (3) are more natural, as we can see from examples (see Example 5.1). Thus we need a representation of our system (1) in a larger space.

2. The semigroup model. Let $D_A(-\alpha, 2)$, $\alpha \in]0, 1[$, be the extrapolation space of A (see [2]). To take y_0 in H rather than in $D_A(\frac{1}{2}; 2)$ we replace H (respectively, $D(A)$) by $D_A(-\frac{1}{2}; 2)$ (respectively, $D_A(\frac{1}{2}; 2)$) and assume, in addition to Hypothesis 1, the following hypothesis.

Hypothesis 3. $K(\cdot) \in L^2(0, \infty); L(D_A(-\frac{1}{2}; 2); D_A(\frac{1}{2}; 2))$.

Then the operator \mathcal{K} in (11) belongs to $L(L^2(-\infty, 0; D_A(\frac{1}{2}; 2)); D_A(-\frac{1}{2}; 2))$. By translation we obtain all results similar to those in §1. In particular, we state results corresponding to Corollary 1.3 and Theorem 1.4, respectively.

THEOREM 2.1. (i) *For each $y_0 \in H$ and $y_1 \in L^2(-\infty, 0; D_A(\frac{1}{2}; 2))$ there exists a unique solution to (10) in*

$$L^2(0, T; D_A(\frac{1}{2}; 2)) \cap W^{1,2}(0, T; D_A(-\frac{1}{2}; 2)) \subset C([0, T]; H).$$

(ii) *Assume Hypothesis 3, and let $y_1 \in W^{1,2}(-\infty, 0; D_A(\frac{1}{2}; 2))$, $y_1(0) = y_0$, and $Ay_0 + Ky_1 \in H$. Then there exists a unique solution to (9) in*

$$W^{1,2}(-\infty, T; D_A(\frac{1}{2}; 2)) \cap W^{2,2}(0, T; D_A(-\frac{1}{2}; 2)) \subset C^1([0, T]; H).$$

THEOREM 2.2. *Assume Hypothesis 1 and 3 with H (respectively $D(A)$) replaced by $D_A(-\frac{1}{2}; 2)$ (respectively $D_A(\frac{1}{2}; 2)$). Let $y_0 \in H$, let $y_1 \in L^2(-\infty, 0; D_A(\frac{1}{2}; 2))$, and let $y(t)$ be the solution of (9) (and hence of (13)) given in Theorem 2.1(i). Define the map on $Z = H \times L^2(-\infty, 0; D_A(\frac{1}{2}; 2))$*

$$(17) \quad S(t) : \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} \rightarrow \begin{pmatrix} y(t) \\ y_t(\cdot) \end{pmatrix}.$$

Then $S(t)$ is a strongly continuous semigroup on Z , and its infinitesimal generator is given by

$$(18) \quad \mathcal{A} \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} = \begin{pmatrix} Ay_0 + Ky_1 \\ \frac{dy_1}{d\theta} \end{pmatrix}$$

$$(19) \quad D(\mathcal{A}) = \{(y_0, y_1) \in Z : y_1 \in W^{1,2}(-\infty, 0; D_A(\frac{1}{2}; 2)), y_1(0) = y_0, Ay_0 + Ky_1 \in H\}.$$

Next we express $S(t)$ by using the resolvent operator. We write (9) as

$$(20) \quad y'(t) = Ay(t) + \int_0^t K(t-r)y(r) dr + K_1(t)y_1,$$

where

$$K_1(t)y_1 = \int_{-\infty}^0 K(t-\theta)y_1(\theta) d\theta \in L^2\left(0, \infty; D_A\left(-\frac{1}{2}; 2\right)\right) \cap C\left([0, T]; D_A\left(-\frac{1}{2}; 2\right)\right).$$

The solution of (20) can be written as

$$y(t) = R(t)y_0 + \int_0^t R(t-r)K_1(r)y_1 dr$$

Set

$$S(t) = \begin{pmatrix} S_{11}(t) & S_{12}(t) \\ S_{21}(t) & S_{22}(t) \end{pmatrix};$$

then $y(t) = S_{11}(t)y_0 + S_{12}(t)y_1$. Thus we have

$$S_{11}(t)y_0 = R(t)y_0,$$

$$S_{12}(t)y_1 = \int_0^t R(t-r)K_1(r)y_1 dr.$$

Similarly, we have

$$(S_{21}(t)y_0)(\cdot) = R(t+\cdot)y_0,$$

$$(S_{22}(t)y_1)(\cdot) = \int_0^{t+\cdot} R(t-r)K_1(r)y_1 dr.$$

Hypotheses 1 and 3 come from physical examples such as Example 5.1. If we assume, instead of Hypothesis 3, the following hypothesis, we have, in fact, Corollary 2.3.

Hypothesis 3'. $K(\cdot) \in L^2(0, \infty; L(D_A(\frac{1}{2}; 2); H)) \cap L^2(0, \infty; L(H; D_A(-\frac{1}{2}; 2)))$. then we can find a semigroup on $H \times L^2(-\infty, 0; H)$.

COROLLARY 2.3. *Assume Hypothesis 3'. Then for each $y_0 \in H$ and $y_1 \in L^2(-\infty, 0; H)$ there exists a unique solution $y(t)$ to (13) in*

$$L^2(0, T; D_A(\frac{1}{2}; 2)) \cap C([0, T]; H)$$

for any $T > 0$. The map

$$(21) \quad S(t) : \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} \rightarrow \begin{pmatrix} y(t) \\ y_t(\cdot) \end{pmatrix}$$

is a strongly continuous semigroup on $Z = H \times L^2(-\infty, 0; H)$. Its infinitesimal generator is given by

$$(22) \quad \mathcal{A} \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} = \begin{pmatrix} Ay_0 + Ky_1 \\ \frac{dy_1}{d\theta} \end{pmatrix},$$

$$(23) \quad D(\mathcal{A}) = \{(y_0, y_1) \in Z : y_1 \in W^{1,2}(-\infty, 0; H), y_1(0) = y_0, Ay_0 + Ky_1 \in H\}.$$

If $K(\cdot) \in L^2(0, \infty; H)$, then A need not be analytic.

Hypothesis 3''. $K(\cdot) \in L^2(0, \infty; L(H))$.

COROLLARY 2.4. *Let A be any infinitesimal generator of a strongly continuous semi-group on H . Assume Hypothesis 3''. Then for each $y_0 \in H$ and $y_1 \in L^2(-\infty, 0; H)$ there exists a unique solution $y(t)$ to (13) in $C([0, T]; H)$ for any $T > 0$. Define the map $S(t)$ as in (21). Then it is a strongly continuous semigroup on $Z = H \times L^2(-\infty, 0; H)$ with generator (22), (23).*

See [12] for more general cases of integrodifferential operators where A is not analytic.

3. Quadratic control on finite horizon. Now we consider (13) with control

$$(24) \quad \begin{cases} y'(t) = Ay(t) + Ky_t + Bu(t) \\ y(0) = y_0 \\ y(\theta) = y_1(\theta), \quad \theta \in]-\infty, 0], \end{cases}$$

where $y_1 \in L^2(-\infty, 0; D_A(\frac{1}{2}, 2))$. Then by setting $z(t) = [y(t), y_t(\cdot)]'$ we obtain

$$(25) \quad \begin{cases} z'(t) = Az(t) + \tilde{B}u(t), \\ z(0) = [y_0, y_1]', \end{cases}$$

where

$$\tilde{B} = \begin{pmatrix} B \\ 0 \end{pmatrix}.$$

For each $u \in L^2(0, T; U)$ we define the mild solution of (25) by

$$(26) \quad z(t) = S(t)[y_0, y_1]' + \int_0^t S(t-r)\tilde{B}u(r) dr.$$

The mild solution (6) of (1) corresponds to the first component of $z(t)$ of the special case $y_1 = 0$, i.e.,

$$(27) \quad z(t) = S(t)[y_0, 0] + \int_0^t S(t-r)\tilde{B}u(r) dr.$$

The cost functional (2) can be rewritten

$$(28) \quad J(u) = \int_0^T \left[|\tilde{M}z(t)|^2 + |u(t)|^2 \right] dt + \langle \tilde{G}z(T), z(T) \rangle,$$

where

$$\tilde{M} = \begin{pmatrix} M \\ 0 \end{pmatrix} \in L(Z; H_0) \quad \text{and} \quad \tilde{G} = \begin{pmatrix} G & 0 \\ 0 & 0 \end{pmatrix} \in L^+(Z).$$

The control problem (26), (28) is a standard quadratic problem [1] in the state-space form [8], [9]. As is well known, the optimal control is given by the feedback law

$$(29) \quad \underline{u} = -\tilde{B}^*Q(t)z(t),$$

where Q is the unique selfadjoint nonnegative solution of the Riccati equation

$$(30) \quad \begin{cases} Q' + \mathcal{A}^*Q + Q\mathcal{A} + \tilde{M}^*\tilde{M} - Q\tilde{B}\tilde{B}^*Q = 0, \\ Q(T) = \tilde{G}. \end{cases}$$

Setting

$$Q(t) = \begin{pmatrix} Q_{11}(t) & Q_{12}(t) \\ Q_{21}(t) & Q_{22}(t) \end{pmatrix},$$

we can write (29) in the form

$$(31) \quad \underline{u}(t) = -B^*[Q_{11}(t)y(t) + Q_{12}(t)y_t].$$

The minimal cost corresponding to \underline{u} is

$$(32) \quad J(\underline{u}) = \left\langle Q(0) \begin{pmatrix} y_0 \\ y_1 \end{pmatrix}, \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} \right\rangle.$$

Hence the minimal cost for the problem (1), (2) is given by

$$(33) \quad J(\underline{u}) = \langle Q_{11}(0)y_0, y_0 \rangle.$$

Summing up, we have the following theorem.

THEOREM 3.1. *Assume Hypothesis 1 and 3 are true. Then there exists a unique optimal control for the problem (1), (2). It is given by the feedback law (31), and the minimal cost is given by (33).*

For the control problem (1), (2), where $K(\cdot)$ satisfies either Hypothesis 3' or Hypothesis 3'', the feedback law (31) is still optimal and the optimal cost is given by (33).

4. Quadratic control on infinite horizon. Here we consider the control problem (1), (3). To avoid the trivial case we make the following assumption for (27).

Hypothesis 4. For each $y_0 \in H$ and $y_1 \in L^2(-\infty, 0; D_A(\frac{1}{2}, 2))$ there exists a control $u \in L^2(0, \infty; U)$ such that

$$(34) \quad J(u) = \int_0^\infty [|\tilde{M}z(t)|^2 + |u(t)|^2] dt < \infty.$$

Later we give sufficient conditions for Hypothesis 4. Let $Q_T(t)$ be the solution of the Riccati equation (30) with $Q_T(T) = 0$. Then the following is known.

PROPOSITION 4.1. *Assume Hypotheses 3 and 4 are true. Then there exists a strong limit Q_∞ of Q_T . Q_∞ is the minimal nonnegative solution of the algebraic Riccati equation*

$$(35) \quad \mathcal{A}^*Q + Q\mathcal{A} + \tilde{M}^*\tilde{M} - Q\tilde{B}\tilde{B}^*Q = 0.$$

If \mathcal{A} , \widetilde{M} is detectable, then Q_∞ is the unique nonnegative solution of (35). Moreover, $A - \widetilde{B}\widetilde{B}^*Q_\infty$ generates an exponentially stable semigroup on Z .

THEOREM 4.2. Assume Hypotheses 3 and 4 are true. Then there exists a unique optimal control for (26), (34). It is given by the feedback law

$$(36) \quad \underline{u} = -\widetilde{B}^*Q_\infty z(t),$$

and the minimal cost is

$$(37) \quad J(\underline{u}) = \left\langle Q_\infty \begin{pmatrix} y_0 \\ y_1 \end{pmatrix}, \begin{pmatrix} y_0 \\ y_1 \end{pmatrix} \right\rangle.$$

In particular, the optimal control for the problem (1), (2) is given by

$$(38) \quad \underline{u}(t) = -B^*[Q_{11}y(t) + Q_{12}y_t]$$

and

$$(39) \quad J(\underline{u}) = \langle Q_{11}y_0, y_0 \rangle,$$

where

$$Q_\infty = \begin{pmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{pmatrix}.$$

If $Q_{12}(y_1) = \int_{-\infty}^0 Q_{12}(-\theta)y_1(\theta) d\theta$ for some $Q_{12} \in L^2(0, \infty; L(D_A(\frac{1}{2}, 2); H))$, then the optimal closed-loop system corresponding to (38) is

$$(40) \quad y'(t) = (A - BB^*Q_{11})y(t) + \int_0^t [K(t-r) - BB^*Q_{12}(t-r)]y(r) dr$$

and of the same form as (1). If $(\mathcal{A}, \widetilde{M})$ is detectable, then the resolvent operator for (40) is exponentially stable.

A sufficient condition for Hypothesis 4 can be found in [7]. For the sake of completeness we quote some results from [7]. Let $\widehat{K}(\cdot)$ be a maximal analytic extension of the Laplace transform of K , and let Ω_0 be its domain of definition. We set

$$\begin{cases} \rho_0 = \{\lambda \in \Omega : \exists (\lambda - A - \widehat{K}(\lambda))^{-1}\}, \\ F(\lambda) = (\lambda - A - \widehat{K}(\lambda))^{-1} \quad \text{for } \lambda \in \rho_0, \end{cases}$$

and we denote by ρ_1 the set of all isolated removable singularity of $F(\cdot)$. Moreover, we set

$$\begin{cases} \rho = \rho_0 \cup \rho_1, \\ F(\lambda) = \lim_{z \rightarrow \lambda} F(z), \quad \lambda \in \rho \setminus \rho_0. \end{cases}$$

Define the *generalized spectrum* $\sigma = C \setminus \rho$. If λ_0 is a pole of $F(\cdot)$ of order m_0 , we set, for λ sufficiently close to λ_0 ,

$$F(\lambda) = \sum_{n=0}^{\infty} S_n(\lambda - \lambda_0)^n + \sum_{n=0}^{m_0-1} Q_n(\lambda - \lambda_0)^{-n-1},$$

where

$$\begin{cases} Q_n = \frac{1}{2\pi i} \int_{C(\lambda_0, \varepsilon)} F(\lambda)(\lambda - \lambda_0)^n d\lambda, \\ S_n = \frac{1}{2\pi i} \int_{C(\lambda_0, \varepsilon)} F(\lambda)(\lambda - \lambda_0)^{-n-1} d\lambda, \end{cases}$$

and $C(\lambda_0, \varepsilon)$ is the circle with center λ_0 having sufficiently small radius $\varepsilon > 0$.

Let $\omega > 0$ be such that $\sigma \cap \{\lambda \in C : \operatorname{Re} \lambda = -\omega\} = \emptyset$, and let $\sigma_+(\omega) = \sigma \cap \{\lambda \in C : \operatorname{Re} \lambda > -\omega\}$, $\sigma_-(\omega) = \sigma \cap \{\lambda \in C : \operatorname{Re} \lambda < -\omega\}$. We can make the following assumption.

Hypothesis 5. (i) $\sigma_+(\omega) = \{\lambda_1, \dots, \lambda_N\}$, where for each $j = 1, \dots, N$, λ_j is a pole of $F(\cdot)$ of order $m_j < \infty$.

(ii) The residues $R_{j,k}$, $k = 0, 1, \dots, m_j$, of $F(\cdot)$ at $\lambda = \lambda_j$ are finite-rank operators.

The condition below is called a *Hautus condition*.

Hypothesis 6. Range $Q_{j,k}^* \cap \operatorname{Ker} B^* = \{0\}$ for all $j = 1, 2, \dots, N$ and $k = 0, 1, \dots, m_j$.

Let X be a Banach space, and let $C_\omega([0, \infty[; X)$ be the space of bounded continuous functions $x(t)$ in X with property $\sup_{t>0} \|x(t)e^{\omega t}\|_X < +\infty$. Under Hypothesis 5 it is shown [7] that Hypothesis 6 holds if and only if the following is true:

For each $y_0 \in H$ there exists a control $u \in C_\omega([0, \infty[; U)$ (in fact, $u \in C_\omega^\alpha([0, \infty[; U)$) such that $y \in C_\omega([0, \infty[; H)$, where y is the solution of (1). Hence if Hypotheses 5 and 6 hold, then the control problem (1), (3) is well defined. Modifying slightly the proof of [7, Thm. 2.3], we can show that under Hypothesis 6 system (13) is stabilizable in the above sense. We have, in fact, the following result, the proof of which was suggested to us by A. Lunardi.

THEOREM 4.3. *If Hypothesis 6 holds, then the system (13) is stabilizable, i.e., for each $y_0 \in H$ there exists a control $u \in C_\omega([0, \infty[; U)$ such that $y \in C_\omega([0, \infty[; H)$ for some $\omega \in]0, \omega_0[$.*

Proof. Define

$$R_{\lambda_j}(t) = \frac{1}{2\pi i} \int_{C(\lambda_j, \varepsilon)} e^{\lambda t} F(\lambda) d\lambda = \sum_{k=0}^{m_j-1} \frac{e^{\lambda_j t} t^k}{k!} Q_{j,k}$$

and

$$R_+^{\omega_0}(t) = \sum_{j=1}^N R_{\lambda_j}(t).$$

Then as in [7, Prop. 1.1] we can show that problem (13) is stabilizable in the above sense if and only if for each $y_0 \in H$ and $y_1 \in L^2(-\infty, 0, D_A(\frac{1}{2}, 2))$ there exists $u \in C_\omega([0, \infty[; U)$ such that

$$(41) R_+^\omega(t) y_0 + \int_0^{+\infty} R_+^\omega(t-s) K_1(s) y_1 ds = - \int_0^{+\infty} R_+^\omega(t-s) B u(s) ds, \quad t \geq 0,$$

where $K_1(\cdot)$ is as given in §2. First, we assume $\operatorname{Re} \lambda_j > 0$, $j = 1, 2, \dots, N$, and show (41) with $\omega = \omega_0$. If there exists λ_j with $\operatorname{Re} \lambda_j = 0$, then we can set $\underline{v}(t) = e^{\varepsilon t} y(t)$ for sufficiently small $\varepsilon > 0$ and reduce the problem to the case for which $\omega = \omega_0 - \varepsilon$.

As in the proof of Theorem 2.3 in [7], we can show that (41) is equivalent to

$$\begin{aligned}
 (42) \quad & \sum_{j=1}^N \sum_{n=0}^{m_j-1} e^{\lambda_j t} \frac{t^n}{n!} Q_{j,n} y_0 + \sum_{j=1}^N \sum_{n=0}^{m_j-1} \sum_{k=n}^{m_j-1} e^{\lambda_j t} \frac{t^n}{n!} \int_0^{+\infty} e^{-\lambda_j s} (-s)^{k-n} Q_{j,k} K_1(s) y_1 ds \\
 &= - \sum_{j=1}^N \sum_{n=0}^{m_j-1} \sum_{k=n}^{m_j-1} e^{\lambda_j t} \frac{t^n}{n!} \int_0^{+\infty} e^{-\lambda_j s} (-s)^{k-n} Q_{j,k} B u(s) ds.
 \end{aligned}$$

Note that the second term is well defined since $K_1(\cdot)y_1$ is bounded and $\operatorname{Re} \lambda_j > 0$. Since the functions $t \rightarrow e^{\lambda_j t} t^n$ are linearly independent, (42) is equivalent to $\Gamma u = Q[y_0, K_1(\cdot)y_1]$, where

$$\Gamma : C_\omega([0, +\infty[; U) \rightarrow H^K, \quad K = \sum_{j=1}^N m_j,$$

$$\Gamma u = \left\{ \sum_{k=n}^{m_j-1} \int_0^{+\infty} e^{-\lambda_j s} (-s)^{k-n} Q_{j,k} B u(s) ds \right\}_{j=1, \dots, N; n=0, \dots, m_j-1},$$

and $Q : H \rightarrow H^K$,

$$\begin{aligned}
 & Q(y_0, K_1(\cdot)y_1) \\
 &= \left\{ Q_{j,n} y + \sum_{k=n}^{m_j-1} \int_0^{+\infty} e^{-\lambda_j s} (-s)^{k-n} Q_{j,k} K_1(s) y_1 ds \right\}_{j=1, \dots, N; n=0, \dots, m_j-1}.
 \end{aligned}$$

Since the range of Γ and Q are finite-dimensional, (42) holds if and only if

$$(43) \quad \operatorname{Ker} Q^* \supset \operatorname{Ker} \Gamma^*.$$

For each $(h_{jn}) = (h_{jn})_{j=1, \dots, N; n=0, \dots, m_j-1} \in H^K$ we have

$$\begin{aligned}
 \Gamma^*(h_{jn})u &= - \sum_{j=1}^N \sum_{k=0}^{m_j-1} \sum_{h=0}^{m_j-1-k} \int_0^{+\infty} \frac{(-s)^k}{k!} e^{-\lambda_j s} \langle u(s), B^* Q_{j,k+h}^* h_{j,k+h} \rangle ds \\
 &\quad + Q^*(h_{jn})(y_0, K_1(\cdot)y_1) \\
 &= \sum_{j=1}^N \sum_{h=0}^{m_j-1} \langle y_0, Q_{jh}^* h_{jh} \rangle \\
 &\quad + \sum_{j=1}^N \sum_{k=0}^{m_j-1} \sum_{h=0}^{m_j-1-k} \int_0^{+\infty} \frac{(-s)^k}{k!} e^{-\lambda_j s} \langle K_1(s) y_1, Q_{j,k+n}^* h_{j,k+n} \rangle ds
 \end{aligned}$$

so that

$$\begin{aligned}
 \operatorname{Ker} \Gamma^* &= \left\{ (h_{jn}) \in H^K : B^* \left(\sum_{h=k}^{m_j-1} Q_{jh}^* h_{jh} \right), j = 1, \dots, N, k = 0, 1, \dots, m_j - 1 \right\} \\
 &= \{ (h_{jn}) \in H^K : B^* Q_{jh}^* h_{jn}, j = 1, \dots, N, k = 0, 1, \dots, m_j - 1 \},
 \end{aligned}$$

$$\text{Ker } Q^* \supset \{(h_{jn}) \in H^K : \sum_{j=1}^N \sum_{h=0}^{m_j-1} Q_{jh}^* h_{jn} = 0\}.$$

Now we can show that (13) is stabilizable and is equivalent to (43). It is easy to see that if (13) is stabilizable, then (43) holds. Conversely, assume that (23) holds and let $h \in \text{Ker } B^* Q_{j_0 h_0}^*$ for some j_0, h_0 . Set $h_{jn} = \delta_{j,j_0} \delta_{n,n_0} h$; then $B^* Q_{jn}^* h_{jn} = 0$ for each $j = 1, \dots, N, h = 0, \dots, m_j - 1$. By (43) we have

$$\sum_{j=1}^N \sum_{h=0}^{m_j-1} Q_{jh}^* h_{jn} = Q_{j_0 n_0}^* h = 0.$$

Therefore, for each j_0, h_0 we have

$$\text{Ker } Q_{j_0 n_0}^* \supset B^* Q_{j_0 n_0}^*,$$

and (13) is stabilizable. \square

Now consider the detectability of $\mathcal{A}, \widetilde{M}$. It is useful to consider the following:

$$(44) \quad \begin{cases} \underline{\eta}'(t) = -A^* \underline{\eta}(t) - \int_t^T K^*(r-t) \underline{\eta}(r) dr, \\ \underline{\eta}(T) = \eta_1. \end{cases}$$

Suppose we have classical solutions for (4) and (44). Then by differentiating $\langle y(t), \underline{\eta}(t) \rangle$, integrating from $t = 0$ to T , and using the Fubini theorem we obtain

$$\langle y(T), \eta_1 \rangle = \langle y_0, \underline{\eta}(0) \rangle.$$

Hence (44) is the adjoint system of (4). Equations (44) can be also written

$$(45) \quad \begin{cases} \eta'(t) = A^* \eta(t) + \int_0^t K^*(t-r) \eta(r) dr, \\ \eta(0) = \eta_1. \end{cases}$$

Thus the detectability of $(\mathcal{A}, \widetilde{M})$ is translated into the stabilizability of the following system:

$$(46) \quad \eta'(t) = A^* \eta(t) + \int_0^t K^*(t-r) \eta(r) dr + \widetilde{M} v(t).$$

If A^* and K^* have properties similar to those of A and K we can obtain sufficient conditions for detectability. Finally, we note that we can also solve control problems for inhomogeneous systems as in [4], and [5].

Example 4.4. Let Ω be a bounded open domain in R^n with C^2 boundary $\partial\Omega$. Consider the heat equation in materials of the *fading-memory* type introduced by Nunziato [20]:

$$(47) \quad \begin{cases} b_0 \frac{\partial y}{\partial t}(t, x) + \frac{\partial}{\partial t} \int_0^t \beta(t-r) y(r, x) dr \\ \quad = c_0 \Delta y(t, x) - \int_0^t \gamma(t-r) \Delta y(r, x) dr + B_0 u(t, x), \quad t > 0, x \in \overline{\Omega}, \\ y(0, x) = y_0(x), \quad x \in \overline{\Omega}, \\ \Gamma y(t, x) = 0, \quad t > 0, \quad x \in \partial\Omega, \end{cases}$$

where $\Gamma y = y$ or $\Gamma y = \partial y / \partial n$. $y(t, x)$ represents the temperature at $x \in \bar{\Omega}$ at time t , b_0 , and c_0 are positive constants, and u is the heat supply. β and γ are completely monotone kernels with

$$\beta(t) = \int_0^\infty e^{-\omega t} \mu(d\omega), \quad \gamma(t) = \int_0^\infty e^{-\omega t} \nu(d\omega),$$

where μ and ν are positive Borel measures with compact support $\text{supp } \mu$ and $\text{supp } \nu$ contained in $]a, \infty[$, $a > 0$. Then the heat equation (47) can be written as (1) in $H = L^2(\Omega)$ with

$$Ah = \frac{1}{b_0}(c_0 \Delta h - \beta(0)h), \quad D(A) = \{h \in H : \Delta h \in H, \Gamma h = 0\},$$

$$K(t)h = \frac{1}{b_0}(-\beta'(t)h - \gamma(t)\Delta h),$$

$$B = \frac{1}{b_0}B_0.$$

Let $\tilde{\beta}(\cdot)$ and $\tilde{\gamma}(\cdot)$ be analytic extensions of the Laplace transforms of β and γ to $C \setminus \text{supp } \mu$ and $C \setminus \text{supp } \nu$, respectively. Then

$$\rho_0 = \left\{ \lambda \in C : c_0 - \tilde{\gamma}(\lambda) \neq 0, \frac{\lambda(b_0 + \tilde{\beta}(\lambda))}{c_0 - \tilde{\gamma}(\lambda)} \neq -\lambda_n \right\},$$

$$F(\lambda) = \frac{b_0}{\frac{\lambda(b_0 + \tilde{\beta}(\lambda))}{c_0 - \tilde{\gamma}(\lambda)}} R \left(\frac{\lambda(b_0 + \tilde{\beta}(\lambda))}{c_0 - \tilde{\gamma}(\lambda)}, \Delta \right),$$

where $\{-\lambda_n\}$ is the decreasing sequence of the eigenvalues of Δ . Hence

$$\{\lambda \in: \text{Re } \lambda \geq 0\} = \begin{cases} \emptyset & \text{if } \Gamma y = y \text{ on } \partial\Omega, \\ \{0\} & \text{if } \Gamma y = \frac{\partial y}{\partial n} \text{ on } \partial\Omega. \end{cases}$$

If $\Gamma y = y$, then (47) with $u = 0$ is stable. Hence our control problems (1), (2) and (1), (3) are well defined. If $\Gamma y = \frac{\partial y}{\partial n}$, then (47) with $u = 0$ is not stable, but satisfies Hypothesis 5. This implies that if $h(x) = h_0$ (constant different from 0) $\notin \text{Ker } B^*$, then (47) is stabilizable. If $Bu = b(x)u(t)$, $b(\cdot) \in H$, and u is a scalar, then $\int_\Omega b(x) dx \neq 0$ implies stabilizability. Hence the quadratic problems (1), (3) and, of course, (1), (2) are well defined. See [6] for more discussions on this example and other examples of system (1). See also [19] for heat equations with memory.

The following example was introduced to us by J. Zabczyk and is covered by our model.

Example 4.5. Consider the delay equation

$$(48) \quad \begin{cases} x''(t) = -k(0)x(t) - \int_{-\infty}^0 k'(-r)x(t+r) dr + u(t), \\ x(0) = x_0, \quad x'(0) = x_1, \end{cases}$$

which can be regarded as a model of the oscillation of a particle suspended by light linearly viscoelastic string, where the relaxation modulus $k : [0, \infty[\rightarrow \mathbb{R}$ is differentiable and such that

$$k(t) > 0, \quad k'(t) < 0, \quad k''(t) > 0, \quad \lim_{t \rightarrow \infty} k'(t) = 0.$$

Setting

$$y = \begin{pmatrix} x \\ x' \end{pmatrix},$$

we can write (48) as

$$y'(t) = \begin{pmatrix} 0 & 1 \\ -k(0) & 0 \end{pmatrix} y(t) - \int_0^t k(t-r) \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} y(r) dr + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u(t),$$

$$y(0) = y_0 = \begin{pmatrix} x_0 \\ x_1 \end{pmatrix}.$$

If $k \in L^2(0, \infty)$, then this is a special case covered by Theorem 4.2. If $k(t) = e^{-at}$, $a > 0$, the spectrum σ is given by

$$\sigma = \{\lambda : \lambda^3 + a\lambda^2 + k(0)\lambda + ak(0) - 1 = 0\}.$$

Set

$$A = \begin{pmatrix} 0 & 1 \\ -k(0) & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad M = [1, 0];$$

then (A, B) is controllable and (M, A) is observable. Hence the minimization problem

$$J(u) = \int_0^\infty [|x(t)|^2 + |u(t)|^2] dt$$

is well defined.

OPTIMAL CONTROL OF SWITCHING DIFFUSIONS WITH APPLICATION TO FLEXIBLE MANUFACTURING SYSTEMS*

MRINAL K. GHOSH[†], ARISTOTLE ARAPOSTATHIS[‡], AND STEVEN I. MARCUS[§]

Abstract. A controlled switching diffusion model is developed to study the hierarchical control of flexible manufacturing systems. The existence of a homogeneous Markov nonrandomized optimal policy is established by a convex analytic method. Using the existence of such a policy, the existence of a unique solution in a certain class to the associated Hamilton–Jacobi–Bellman equations is established and the optimal policy is characterized as a minimizing selector of an appropriate Hamiltonian.

Key words. flexible manufacturing system, Wiener process, switching diffusion, Poisson measure, Markov policy, dynamic programming equations

AMS subject classification. 93E20

1. Introduction. We study a controlled switching diffusion process that arises in numerous applications of systems with multiple modes or failure modes, including the hierarchical control of flexible manufacturing systems. A flexible manufacturing system (FMS) consists of a set of workstations capable of performing a number of different operations and interconnected by a transportation mechanism. An FMS produces a family of parts related by similar operational requirements or by belonging to the same final assembly [27]. The rapidly growing range of applicability of FMS includes metal cutting, assembly of printed circuit boards, integrated circuit fabrication, automobile assembly lines, etc. Due to their tremendous flexibility, FMSs are significantly more efficient in many ways than traditional manufacturing systems. However, the high capital cost of an FMS demands very efficient management of production and maintenance (repair/replacement) scheduling so that uncertain events can be taken care of such as random demand fluctuations, machine failures, inventory spoilage, sales returns, etc. The large size of the system and its associated complexities make it imperative to divide the control or management into a hierarchy consisting of a number of levels. Thus, the overall complex problem is reduced to a number of manageable subproblems at each level, and these levels are linked by means of a hierarchical integrative system. We refer to [1], [21], and [27] for a detailed description of these hierarchical schemes. We will confine our attention to the top two levels.

(i) generation of decision tables, which is accomplished by developing a suitable mathematical model describing the dynamical evolution of the system. This is done off-line.

(ii) The flow control level which plays the central role in the system. It determines, on line, the production and maintenance scheduling and continuously feeds the routing control level that calculates route splits, and that, in turn, governs the sequence controller which determines the scheduling times at which to dispatch parts. Since the top two levels directly govern the rest, it is of paramount importance to develop and study an appropriate mathematical model that will facilitate finding on-line, implementable, optimal feedback policies.

We first present a heuristic description of our model, which is a modified version of the model in [1], [21], and [27]. The FMS consists of L workstations, with each workstation having a number L_m of identical machines ($m = 1, 2, \dots, L$). A family of N types of different parts is produced. Let $u(t) = [u_1(t), \dots, u_N(t)]^T \in \mathbb{R}^N$ and $d(t) = [d_1(t), \dots, d_N(t)]^T \in \mathbb{R}^N$ denote the production rate (a control variable) and the downstream demand rate vectors of this family of parts, respectively. Also, $X(t) = [X_1(t), \dots, X_N(t)]^T \in \mathbb{R}^N$ denotes the downstream buffer stock. A negative value of $X_j(t)$, $j = 1, \dots, N$, indicates a backlogged demand for part j , while a positive value is the size of the inventory stored in the buffers. The evolution of $X(t)$ is governed by stochastic differential equations

$$(1.1) \quad \frac{dX(t)}{dt} = u(t) - d(t) + \text{diag}(\sigma_1, \dots, \sigma_N)\xi(t),$$

where $\sigma_i > 0$, $i = 1, \dots, N$ and $\xi(t) = [\xi_1(t), \dots, \xi_N(t)]^T$ is an N -dimensional white noise which can be interpreted as sales returns, inventory spoilage, sudden demand fluctuations, etc. (see [8]).

If $S_m(t)$ denotes the number of operational machines in station m at time t , then the state of the workstations may be represented by the L -tuple

$$S(t) = (S_1(t), \dots, S_L(t)).$$

The evolution of $S(t)$ is influenced by the inventory size and production scheduling, and can also be controlled by various decisions such as to produce, repair, or replace. The dynamics of $S(t)$ can be described as follows:

$$(1.2) \quad P\{S_m(t + \delta t) = \ell + 1 \mid S_m(t) = \ell\} \\ = \begin{cases} (L_m - \ell)v_m(t)\delta t + o(\delta t) & \text{for } 0 \leq \ell < L_m, \\ 0 & \text{otherwise,} \end{cases}$$

where $v_m(t)$, $m = 1, \dots, L$, are suitable control variables. In the uncontrolled case, $v_m(t) = \gamma_m$, which represents the infinitesimal repair rate at station m . These repair rates may depend implicitly on $X(t)$. This model also allows for a control variable reflecting the decision to repair or to replace on the basis of the inventory size. Also,

$$(1.3) \quad P\{S_m(t + \delta t) = \ell - 1 \mid S_m(t) = \ell\} \\ = \begin{cases} \ell p_m(X(t), u(t))\delta t + o(\delta t) & \text{for } 0 \leq \ell < L_m, \\ 0 & \text{otherwise,} \end{cases}$$

where p_m models the infinitesimal failure rate at the m th station. Equations (1.2) and (1.3) imply that

$$P\{S_m(t + \delta t) = \ell_1 \mid S_m(t) = \ell_2\} = 0 \quad \text{for } |\ell_1 - \ell_2| > 1.$$

With i and j denoting two states of the system, we define

$$\lambda_{ij}(\cdot)\delta t + o(\delta t) = P\{S(t + \delta t) = j \mid S(t) = i\}, \quad i \neq j$$

and

$$\lambda_{ii}(\cdot) = - \sum_{j \neq i} \lambda_{ij}(\cdot).$$

The machine state $S(t)$ can thus be modeled as a continuous time-controlled jump process taking values in a finite state space. In the uncontrolled case, $S(t)$ becomes a continuous time homogeneous Markov chain with infinitesimal generator given by the matrix $[\lambda_{ij}]$.

The choice of the production rate at each instant is constrained by the capacity of the currently operational machines. This translates into the requirement that at each time t the production rates must lie in some set $\Gamma(S(t))$ that depends on the machine state.

Let $y_{mn}^k(t)$ be the number of type n parts that undergo operation k at the m th station per unit interval of time and $\tau_{mn}^k(t)$ the length of time required for the completion of this operation. The product $y_{mn}^k(t)\tau_{mn}^k(t)$ is the portion of each unit time interval that one or more operational machines at station m must dedicate to perform operation k on type n parts, as dictated by the flow rate $y_{mn}^k(t)$. Since the amount of work completed at each station per unit time interval cannot exceed the time available at the operational machines, the following constraint applies:

$$(1.4) \quad \sum_n \sum_k y_{mn}^k(t)\tau_{mn}^k(t) \leq S_m(t) \quad \text{for all } m.$$

Also, assuming that no material is allowed to accumulate within the system, the throughput $u_n(t)$ of type n parts must satisfy

$$(1.5) \quad u_n(t) = \sum_m y_{mn}^k(t) \quad \text{for all } k \text{ and } n.$$

Therefore, for each state i , the set $\Gamma(i)$ is defined as the collection of all production rates $u = [u_1, \dots, u_N]^T$ for which, with the machine state $S(t) = i$, there exist feasible flow rates $y_{mn}^k(t)$ satisfying (1.4) and (1.5).

The flow control problem can now be stated. Given an initial buffer state $X(0) = x$ and machine state $S(0) = i$, we wish to specify a production plan and maintenance (repair/replacement) policy that minimizes the performance index

$$(1.6) \quad J(x, i, u, v) = E \left[\int_0^\infty e^{-\alpha t} c(X(t), S(t), u(t), v(t)) dt \mid X(0) = x, S(0) = i \right],$$

where $c(\cdot)$ is a cost function, $\alpha > 0$ is a discount factor, $u(\cdot)$ is the production rate, and $v(\cdot)$ is the maintenance rate. The objective is to find $u(\cdot)$, $v(\cdot)$ for which the minimum is achieved in (1.6). The ideal production and maintenance policy for a wide class of cost functions would minimize J by producing parts at exactly the demand rate, thereby keeping the buffer at zero. Such a policy is generally impossible because of the failures of the machines and various other uncertainties.

This FMS model motivates the study of a stochastic optimization problem in a more abstract setting that subsumes the flow control problem in the FMS as a special

case. This abstract problem is manifested in numerous other situations. In [17] it is encountered in a hybrid model proposed for the study of dynamic phenomena in large scale interconnected power networks. Sworder [39], [40] describes possible applications to macroeconomic models and dynamic renewal problems in general. In addition, it should be useful at other levels of the hierarchy described in [21].

We will briefly describe this problem formally; a rigorous description will be given in §2. Let $\mathcal{S} = \{1, 2, \dots, M\}$ and let U_i , $i = 1, \dots, M$, be prescribed compact metric spaces. For each $i, j \in \mathcal{S}$, let $b(\cdot, \cdot, i, \cdot) : \mathbb{R}_+ \times \mathbb{R}^N \times U_i \rightarrow \mathbb{R}^N$ and $\lambda_{ij} : \mathbb{R}_+ \times \mathbb{R}^N \times U_i \rightarrow \mathbb{R}$, satisfying $\lambda_{ij} \geq 0$, for $i \neq j$ and $\sum_j \lambda_{ij}(\cdot) = 0$. A stochastic process $(X(t), S(t))$ taking values in $\mathbb{R}^N \times \mathcal{S}$ is given by

$$(1.7) \quad X(t) = X(0) + \int_0^t b(\tau, X(\tau), S(\tau), u(\tau)) d\tau + \text{diag}(\sigma_1, \dots, \sigma_N)W(t),$$

$$(1.8) \quad P\{S(t + \delta t) = j \mid S(t) = i, X(s), S(s), s \leq t\} = \lambda_{ij}(t, X(t), u(t))\delta t + o(\delta t),$$

where $\sigma_i > 0$, $i = 1, \dots, N$, are constants and $W(\cdot) = [W_1(\cdot), \dots, W_N(\cdot)]^T$ is an N -dimensional standard Brownian motion. The control $u(\cdot)$ is a $U := \prod_{i=1}^N U_i$ -valued process such that when $S(t) = i$, $u(\cdot)$ takes values in U_i and $u(\cdot)$ is nonanticipative with respect to the driving Brownian motion $W(t)$. Let $c : \mathbb{R}_+ \times \mathbb{R}^N \times \mathcal{S} \times U \rightarrow \mathbb{R}_+$ be the cost function and $\alpha > 0$ a prescribed discount factor. Define a cost functional of the form

$$(1.9) \quad E \left[\int_0^\infty e^{-\alpha t} c(t, X(t), S(t), u(t)) dt \right].$$

The objective is to find an optimal control policy $u(\cdot)$ that minimizes (1.9) and takes the feedback form $u(t) = \bar{v}(t, X(t), S(t))$ for a suitably defined function \bar{v} . In the next section, we will assume appropriate conditions on b and λ which will guarantee that (1.7), (1.8) are well defined. We note here that for a performance index of the form (1.9), m, λ, c may be assumed to be independent of t without any loss of generality. Also, by replacing each U_k by $\prod_{k=1}^M U_k$ and $b(\cdot, i, \cdot)$ by its composition with the projection $\prod_{k=1}^M U_k \rightarrow U_i$, we may assume that each U_i is a replica of a fixed compact metric space.

We now briefly mention some earlier work leading to ours. The class of controlled piecewise deterministic models with jump Markov disturbances have been studied by Sworder [38], Rishel [35], Oldser and Suri [33], Davis [19], and Vermes [42] among many others. The piecewise deterministic FMS model has been studied by Kimenia and Gershwin [27], who have developed a heuristic numerical method based on the maximum principle established in [35]. Akella and Kumar [2] have studied a simplified model and obtained explicit solutions for one machine producing a single commodity. In all these papers the jump process is modeled as a continuous time (uncontrolled) Markov chain. Boukas and Haurie [14], [15] have modified the FMS model of Kimenia and Gershwin by introducing new state variables describing machine wear as well as a control parameter in the jump process; their model incorporates preventive maintenance. They have obtained a maximum principle, thereby extending Rishel's formalism in [35]. They have also considered piecewise deterministic models. To obtain an optimal policy of the feedback type in these models we must impose very strong conditions on terms like b, λ governing the system and stringent restrictions on the set of allowable policies. At the same time, it is assumed in these models that

between any two successive jumps of $S(t)$, the dynamics governing $X(t)$ are deterministic. Thus, certain unavoidable environmental uncertainties are not taken into account. These factors restrict the scope of applicability of these models. We have tried to circumvent these difficulties by adding an additive noise term in the state dynamics. This is specifically done to take into account the various sources of environmental randomness. Addition of this noise removes practically all restrictions imposed on the set of allowable control policies, thereby substantially enhancing the range of its applicability. The switching diffusion problem has also been studied by Bensoussan and Lions [7], using a martingale problem formulation. However, our motivation and approach are quite different. In [7], it is assumed that for some $\delta > 0$, $-\lambda_{ii} > \delta > 0$, for each i . We have, instead, used a strong formulation which is very important for practical applications. In our formulation we do not need the condition $-\lambda_{ii} > \delta > 0$. We also refer to [6], [8], [9], [16], [20], [32], [36], [37], and [43] for related work.

Our paper is structured as follows. A rigorous description of the mathematical model of the FMS is given in §2. The optimization problem is formulated and subsequently reduced to an equivalent convex optimization problem via the study of associated occupation measures. The compactness of laws is established in §3, the convexity and extremality of occupation measures are studied in §4, and the proof of existence of optimal policies is given in §5. Section 6 deals with the characterization of optimal policies via dynamic programming equations. In §7, we apply our theory to a simplified model and derive some interesting results. Finally, §8 contains some concluding remarks. Note that we have used a convex analytic approach for this problem, as opposed to the traditional analytic one. For the discounted cost criterion, the latter approach is more economical and is sketched in the Appendix. However, the convex analytic approach is interesting in its own right and would be more flexible and powerful for certain other purposes, e.g., the pathwise average cost problem or problems with several constraints where the analytic approach does not seem to be amenable. For (nonswitching) controlled diffusions, these problems have been treated in [11, Chap. VI] and [12] by a convex analytic approach. We hope our approach to switching diffusions would be useful in various other situations.

2. Mathematical model and preliminaries. Let U be a compact metric space and $\mathcal{S} = \{1, \dots, M\}$. Let $\bar{b} = [\bar{b}_1, \dots, \bar{b}_N]^T : \mathbb{R}^N \times \mathcal{S} \times U \rightarrow \mathbb{R}^N$. For each $i \in \mathcal{S}$, $\bar{b}(\cdot, i, \cdot)$ is assumed to be bounded, continuous, and Lipschitz in its first argument uniformly with respect to the third. For $i, j \in \mathcal{S}$, let $\bar{\lambda}_{ij} : \mathbb{R}^N \times U \rightarrow \mathbb{R}$ be bounded, continuous, and Lipschitz in its first argument uniformly with respect to the second. Also, assume that for $i, j \in \mathcal{S}$, $i \neq j$, $\bar{\lambda}_{ij} \geq 0$, and $\sum_{j=1}^M \bar{\lambda}_{ij} = 0$, for any $i \in \mathcal{S}$. Let $\sigma_i > 0$, $i = 1, 2, \dots, N$, be prescribed numbers. For a Polish space Y , $\mathfrak{B}(Y)$ will denote its Borel σ -field and $\mathcal{P}(Y)$ the space of probability measures on $\mathfrak{B}(Y)$ endowed with the Prohorov topology, i.e., the topology of weak convergence [10]. Let $\mathfrak{M}(Y)$ be the set of all nonnegative integer-valued, σ -finite measures on $\mathfrak{B}(Y)$. Let $\mathfrak{M}_\sigma(Y)$ be the smallest σ -field on $\mathfrak{M}(Y)$ with respect to which all maps from $\mathfrak{M}(Y)$ into $\mathbb{N} \cup \{\infty\}$ of the form $\mu \mapsto \mu(B)$, with $B \in \mathfrak{B}(Y)$, are measurable. $\mathfrak{M}(Y)$ will always be assumed to be endowed with this measurability structure. Let $\mathcal{V} = \mathcal{P}(U)$ and $b = [b_1, \dots, b_N]^T : \mathbb{R}^N \times \mathcal{S} \times \mathcal{V} \rightarrow \mathbb{R}^N$ be defined by

$$(2.1) \quad b_i(\cdot, \cdot, v) := \int_U \bar{b}_i(\cdot, \cdot, u) v(du), \quad v \in \mathcal{V}, \quad i = 1, \dots, N.$$

Similarly, for $i, j \in \mathcal{S}$, $\lambda_{ij} : \mathbb{R}^N \times \mathcal{V} \rightarrow \mathbb{R}$ is defined as

$$(2.2) \quad \lambda_{ij}(\cdot, v) := \int_U \bar{\lambda}_{ij}(\cdot, u) v(du), \quad v \in \mathcal{V}, \quad i, j \in \mathcal{S}.$$

For $i, j \in \mathcal{S}$, $x \in \mathbb{R}^N$, and $v \in \mathcal{V}$, we construct the intervals $\Delta_{ij}(x, v)$ of the real line in the following manner (see also [13], [17]):

$$\begin{aligned} \Delta_{12}(x, v) &= [0, \lambda_{12}(x, v)), \\ \Delta_{13}(x, v) &= [\lambda_{12}(x, v), \lambda_{12}(x, v) + \lambda_{13}(x, v)), \\ &\vdots \\ \Delta_{1M}(x, v) &= \left[\sum_{j=2}^{M-1} \lambda_{1j}(x, v), \sum_{j=2}^M \lambda_{1j}(x, v) \right), \\ \Delta_{21}(x, v) &= \left[\sum_{j=2}^M \lambda_{1j}(x, v), \sum_{j=2}^M \lambda_{1j}(x, v) + \lambda_{21}(x, v) \right), \\ &\vdots \\ \Delta_{2M}(x, v) &= \left[\sum_{j=2}^M \lambda_{1j}(x, v) + \sum_{\substack{j=1 \\ j \neq 2}}^{M-1} \lambda_{2j}(x, v), \sum_{j=2}^M \lambda_{1j}(x, v) + \sum_{\substack{j=1 \\ j \neq 2}}^M \lambda_{2j}(x, v) \right), \end{aligned}$$

and so on. For fixed x and v , these are disjoint intervals, and the length of $\Delta_{ij}(x, v)$ is $\lambda_{ij}(x, v)$. Now define a function $h : \mathbb{R}^N \times \mathcal{S} \times \mathcal{V} \times \mathbb{R} \rightarrow \mathbb{R}$ by

$$(2.3) \quad h(x, i, v, z) = \begin{cases} j - i & \text{if } z \in \Delta_{ij}(x, v), \\ 0 & \text{otherwise.} \end{cases}$$

Let $(X(t), S(t))$ be the $(\mathbb{R}^N \times \mathcal{S})$ -valued *controlled switching diffusion* process given by the stochastic differential equations

$$(2.4) \quad \begin{aligned} dX(t) &= b(X(t), S(t), v(t)) dt + \text{diag}(\sigma_1, \dots, \sigma_N) dW(t) \\ dS(t) &= \int_{\mathbb{R}} h(X(t), S(t-), v(t), z) \mathbf{p}(dt, dz), \end{aligned}$$

for $t \geq 0$, with $X(0) = X_0$ and $S(0) = S_0$, where

- (i) X_0 is a prescribed \mathbb{R}^N -valued random variable;
- (ii) S_0 is a prescribed \mathcal{S} -valued random variable;
- (iii) $W(\cdot) = [W_1(\cdot), \dots, W_N(\cdot)]^T$ is an N -dimensional standard Wiener process independent of X_0, S_0 ;
- (iv) $\mathbf{p}(dt, dz)$ is an $\mathfrak{M}(\mathbb{R}_+ \times \mathbb{R})$ -valued Poisson random measure with intensity $dt \times m(dz)$, where m is the Lebesgue measure on \mathbb{R} [25, p. 70];
- (v) $\mathbf{p}(\cdot, \cdot)$ and $W(\cdot)$ are independent;
- (vi) $v(\cdot)$ is a \mathcal{V} -valued process with measurable sample paths satisfying the following nonanticipative property: Let $\mathfrak{F}_t^v = \sigma\{v(s) : s \leq t\}$ and

$$\mathfrak{F}_{[t, \infty)}^{W, \mathbf{p}} = \sigma\{W(s) - W(t), \mathbf{p}(A, B) : A \in \mathfrak{B}([s, \infty)), B \in \mathfrak{B}(\mathbb{R}), s \geq t\}.$$

Then \mathfrak{F}_t^v and $\mathfrak{F}_{[t, \infty)}^{W, \mathbf{p}}$ are independent.

Such a process $v(\cdot)$ will be called an *admissible* (control) *policy*. If $v(\cdot)$ is a Dirac measure, i.e., $v(\cdot) = \delta_{u(\cdot)}$, where $u(\cdot)$ is a U -valued process, then it is called an admissible *nonrandomized* policy. An admissible policy $v(\cdot)$ is called *feedback* if $v(\cdot)$ is progressively measurable with respect to the natural filtration of $(X(\cdot), S(\cdot))$. A particular subclass of feedback policies is of special interest. A feedback policy $v(\cdot)$ is called a (nonhomogeneous) *Markov* policy if $v(\cdot) = \tilde{v}(\cdot, X(\cdot), S(\cdot))$ for a measurable map $\tilde{v} : \mathbb{R}_+ \times \mathbb{R}^N \times \mathcal{S} \rightarrow \mathcal{V}$. With an abuse of notation, the map \tilde{v} itself is called a Markov policy. If \tilde{v} has no explicit time dependence, it is called a *homogeneous* Markov policy. Thus, a homogeneous Markov nonrandomized policy can be identified with a measurable map $v : \mathbb{R}^N \times \mathcal{S} \rightarrow U$.

If $(W(\cdot), \mathbf{p}(\cdot, \cdot), X_0, S_0, v(\cdot))$, satisfying the above, are given on a prescribed probability space $(\Omega, \mathfrak{F}, P)$, then under our assumptions on b and λ , (2.4) will admit an almost surely unique strong solution [22, Chap. 3], [25, Chap. 3, §2c], and $X(\cdot) \in C(\mathbb{R}_+; \mathbb{R}^N)$, $S(\cdot) \in D(\mathbb{R}_+; \mathcal{S})$, where $D(\mathbb{R}_+; \mathcal{S})$ is the space of right continuous functions on \mathbb{R}_+ with left limits taking values in \mathcal{S} . However, if $v(\cdot)$ is a feedback policy, then there exists a measurable map

$$f : \mathbb{R}_+ \times C(\mathbb{R}_+; \mathbb{R}^N) \times D(\mathbb{R}_+; \mathcal{S}) \longrightarrow \mathcal{V}$$

such that for each $t \geq 0$, $v(t) = f(t, X(\cdot), S(\cdot))$ and is measurable with respect to the σ -field generated by $\{X(s), S(s) : s \leq t\}$. Thus, $v(\cdot)$ cannot be specified a priori in (2.4). Instead, we must replace $v(t)$ in (2.4) by $f(t, X(\cdot), S(\cdot))$ and (2.4) takes the form

$$\begin{aligned} dX(t) &= b(X(t), S(t), f(t, X(\cdot), S(\cdot))) dt + \text{diag}(\sigma_1, \dots, \sigma_N) dW(t), \\ (2.5) \quad dS(t) &= \int_{\mathbb{R}} h(X(t), S(t-), f(t, X(\cdot), S(\cdot)), z) \mathbf{p}(dt, dz), \end{aligned}$$

for $t \geq 0$, with $X(0) = X_0$ and $S(0) = S_0$. In general, (2.5) will not even admit a weak solution. However, if the feedback policy is a Markov policy, then the existence of a unique strong solution can be established. We now introduce some notation that will be used throughout. Define

$$L^1(\mathbb{R}^N \times \mathcal{S}) = \{f : \mathbb{R}^N \times \mathcal{S} \longrightarrow \mathbb{R} : \text{for each } i \in \mathcal{S}, f(\cdot, i) \in L^1(\mathbb{R}^N)\}.$$

$L^1(\mathbb{R}^N \times \mathcal{S})$ is endowed with the product topology of $(L^1(\mathbb{R}^N))^M$. Similarly, we define $C_0^\infty(\mathbb{R}^N \times \mathcal{S})$, $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$, etc. For $f \in W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$ and $u \in U$, we write

$$(2.6) \quad L^u f(x, i) = L_i^u f(x, i) + \sum_{j=1}^M \bar{\lambda}_{ij}(x, u) [f(x, j) - f(x, i)],$$

where

$$(2.7) \quad L_i^u f(x, i) = \frac{1}{2} \sum_{j=1}^N \sigma_j^2 \frac{\partial^2 f(x, i)}{\partial x_j^2} + \sum_{j=1}^N \bar{b}_j(x, i, u) \frac{\partial f(x, i)}{\partial x_j},$$

and more generally, for $v \in \mathcal{V}$,

$$(2.8) \quad L^v f(x, i) = \int_U L^u f(x, i) v(du).$$

THEOREM 2.1. *Under a Markov policy v , (2.4) admits an almost surely unique strong solution such that $(X(\cdot), S(\cdot))$ is a Feller process with differential generator L^v .*

Proof (Sketch). This proof is based on the technique involving the removal of drift [41], [10, Thm. 1.4, pp. 10–12]. Clearly, it suffices to prove the result in the interval $[0, T]$, for a fixed $T > 0$. For $T > 0$, let H be the function space defined by

$$(2.9) \quad H = \left\{ g \in W_{loc}^{1,2,p}([0, T] \times \mathbb{R}^N \times \mathcal{S}), 2 \leq p < \infty : \text{ for each } i \in \mathcal{S}, \right. \\ \left. \sup_{0 \leq t \leq T} |g(t, x, i)| \text{ grows slower than } \exp(k\|x\|^2) \text{ for all } k > 0 \right\}.$$

Fix an $i \in \mathcal{S}$. For $1 \leq j \leq N$, let $\varphi_i(t, x, j)$ be the unique solution in H (as in (2.9)) of

$$(2.10) \quad \frac{\partial \varphi_i(t, x, j)}{\partial t} + L_j^{v(t, x, j)} \varphi_i(t, x, j) = 0, \\ \varphi_i(T, x, j) = x_i,$$

where $x = (x_1, \dots, x_N)$. Let $\varphi = [\varphi_1, \dots, \varphi_N]^T$. It can be shown that for fixed j , $\varphi(t, \cdot, j)$ is a homeomorphism onto its range for each $t \in [0, T]$. Set $Y(t) = \varphi(t, X(t), S(t))$, $t \in [0, T]$. Using Ito's formula, it follows that $Y(t)$ satisfies

$$(2.11) \quad Y(t) = Y(0) + \int_0^t \left[(D\varphi_s \text{diag}(\sigma_1, \dots, \sigma_N)) \circ \varphi_s^{-1} \right] (Y(s)) dW(s) \\ + \int_0^t \int_{\mathbb{R}} \left[\varphi_s \left(\varphi_s^{-1}(Y(s-)) + \tilde{h}(\varphi_s^{-1}(Y(s-)), z) \right) - Y(s) \right] \mathfrak{p}(ds, dz),$$

where $D\varphi_s$, φ_s^{-1} denote, respectively, the Jacobian matrix and the inverse map of $\varphi(s, \cdot, S(s))$, “ \circ ” indicates composition of functions and

$$\tilde{h}(\cdot, \cdot, \cdot) = [0, 0, \dots, 0, h(\cdot, \cdot, \cdot)]^T \in \mathbb{R}^{N+1}.$$

Now by [41], (2.11) has an almost surely unique strong solution, which is a Markov process. The corresponding claim for $(X(t), S(t))$ follows via the homeomorphic property of φ . It remains to show the strong Feller property. Pick any bounded continuous function $f : \mathbb{R}^N \times \mathcal{S} \rightarrow \mathbb{R}$. The system of equations

$$(2.12) \quad \frac{\partial \psi(t, x, i)}{\partial t} + L^{v(t, x, i)} \psi(t, x, i) = 0, \\ \psi(T, x, i) = f(x, i),$$

can be shown to have a unique solution in H [18]. Therefore, by Ito's formula, it follows that

$$\psi(t, x, i) = E[f(X(T), S(T)) \mid X(t) = x, S(t) = i],$$

where the expectation is under the Markov policy v . By Sobolev's imbedding theorem [5, p. 53], $H \subset C([0, T] \times \mathbb{R}^N \times \mathcal{S})$ and hence $\psi(t, \cdot, i)$ is continuous for each $t \in [0, T]$. \square

Some comments are in order now.

Remark 2.1. (i) We have used Ito's formula for functions in $W_{loc}^{1,2,p}(\mathbb{R}_+ \times \mathbb{R}^N \times \mathcal{S})$. This generalization is due to Krylov [28, pp. 121–127] for “classical” diffusions. Its extension for the present system is routine.

(ii) The wellposedness of the Cauchy problem for the weakly coupled parabolic system (2.10) has been established in [18] under slightly stronger conditions on the first-order terms. However, in view of the results in [3] and [30, Chap. 7], its extension to the present case is straightforward.

Remark 2.2. We have seen in Theorem 2.1 that under a Markov policy the corresponding solution $(X(\cdot), S(\cdot))$ of (2.4) is a Markov process. We have the following converse result. Let $v(\cdot)$ be a feedback policy, such that the corresponding solution $(X(\cdot), S(\cdot))$ of (2.4) is a Markov process. Then $v(\cdot)$ may be taken to be a Markov policy. Since we do not need this result, we omit the proof.

2.1. The optimization problem. Let $\bar{c} : \mathbb{R}^N \times \mathcal{S} \times U \rightarrow \mathbb{R}_+$ be a bounded, continuous cost function, and let $c : \mathbb{R}^N \times \mathcal{S} \times \mathcal{V} \rightarrow \mathbb{R}_+$ be defined as

$$c(\cdot, \cdot, v) = \int_U \bar{c}(\cdot, \cdot, u) v(du).$$

Let $\alpha > 0$ be a prescribed discount factor. Let $v(\cdot)$ be an admissible policy and $(X(\cdot), S(\cdot))$ the corresponding process. Then the total α -discounted cost under $v(\cdot)$ is defined as

$$(2.13) \quad J_v(x, i) := E \left[\int_0^\infty e^{-\alpha t} c(X(t), S(t), v(t)) dt \mid X(0) = x, S(0) = i \right].$$

If the laws of X_0, S_0 are $\pi \in \mathcal{P}(\mathbb{R}^N)$, $\xi \in \mathcal{P}(\mathcal{S})$, respectively, then

$$(2.14) \quad J_v(\pi, \xi) = \sum_i \int_{\mathbb{R}^N} J_v(x, i) \pi(dx) \xi(i).$$

Let

$$(2.15) \quad V(x, i) := \inf_{v(\cdot)} \{ J_v(x, i) \},$$

$$(2.16) \quad V(\pi, \xi) := \inf_{v(\cdot)} \{ J_v(\pi, \xi) \}.$$

The function $V(x, i)$ is called the (α -discounted) value function. An admissible policy $v(\cdot)$ satisfying

$$J_v(\pi, \xi) = V(\pi, \xi)$$

is called an optimal policy for the initial law (π, ξ) . An admissible policy is called optimal if it is optimal for any initial law. Our aim is to find an admissible optimal policy which is homogeneous Markov and nonrandomized.

We now introduce the (discounted) occupation measures [12]. Let $v(\cdot)$ be an admissible policy and $(X(\cdot), S(\cdot))$ the corresponding process with initial law (π, ξ) . Define the occupation measure $\nu[\pi, \xi; v] \in \mathcal{P}(\mathbb{R}^N \times \mathcal{S} \times U)$ by

$$(2.17) \quad \int f d\nu[\pi, \xi; v] = \alpha E \left[\int_0^\infty e^{-\alpha t} \int_U f(X(t), S(t), u) v(t)(du) dt \right]$$

for $f \in C_b(\mathbb{R}^N \times \mathcal{S} \times U)$. Also, we define

$$(2.18) \quad M_1[\pi, \xi] = \{\nu[\pi, \xi; v] : v(\cdot) \text{ is admissible}\},$$

$$(2.19) \quad M_2[\pi, \xi] = \{\nu[\pi, \xi; v] : v(\cdot) \text{ is homogeneous Markov}\},$$

$$(2.20) \quad M_3[\pi, \xi] = \{\nu[\pi, \xi; v] : v(\cdot) \text{ is homogeneous nonrandomized Markov}\}.$$

In terms of these occupation measures

$$(2.21) \quad J_v(\pi, \xi) = \alpha^{-1} \int \bar{c} d\nu[\pi, \xi; v].$$

We will show in §4 that $M_1[\pi, \xi] = M_2[\pi, \xi]$ and that $M_2[\pi, \xi]$ is compact, convex, and $M_2^e[\pi, \xi] \subset M_3[\pi, \xi]$, where $M_2^e[\pi, \xi]$ is the set of extreme points of $M_2[\pi, \xi]$. Thus, for a fixed initial law, the optimization problem (2.13) will reduce to a convex optimization problem in view of (2.21).

3. Compactness of laws. We will establish the compactness of laws of the process $(X(\cdot), S(\cdot))$ under various policies using the approach in [11, Chap. 2]. Let $\pi_0 \in \mathcal{P}(\mathbb{R}^N)$, $\xi_0 \in \mathcal{P}(\mathcal{S})$. Let $\mathcal{L}_i[\pi_0, \xi_0] \subset \mathcal{P}(C(\mathbb{R}_+; \mathbb{R}^N) \times D(\mathbb{R}_+; \mathcal{S}))$, $i = 1, 2, 3$, denote the set of laws of $(X(\cdot), S(\cdot))$ under all admissible/Markov/homogeneous Markov policies with fixed initial law (π_0, ξ_0) .

THEOREM 3.1. *The set $\mathcal{L}_1[\pi_0, \xi_0]$ is compact in $\mathcal{P}(C(\mathbb{R}_+; \mathbb{R}^N) \times D(\mathbb{R}_+; \mathcal{S}))$.*

Proof. It clearly suffices to replace \mathbb{R}_+ by $[0, T]$ for arbitrary $T > 0$. Fix $T > 0$. Let $(X^n(\cdot), S^n(\cdot), W^n(\cdot), \mathbf{p}^n(\cdot, \cdot), v^n(\cdot), X_0^n, S_0^n)$, $n \geq 1$, satisfy (2.4) on probability spaces $(\Omega^n, \mathfrak{F}^n, P^n)$ respectively, the laws of X_0^n, S_0^n being π_0, ξ_0 respectively for all n . Let $\{f_i\}$ be a countable dense subset of the unit ball of $C(U)$. Define $\beta_j^n(t) = \int f_j dv^n(t)$, $t \in [0, T]$. Let B denote closed unit ball of $L^\infty[0, T]$ with the topology given by the weak topology of $L^2[0, T]$ relative to B . Let E be a countable product of replicas of B . Since B is compact and metrizable and hence Polish, the same follows for E . Let $\beta^n(\cdot) = [\beta_1^n(\cdot), \beta_2^n(\cdot), \dots]$, $n \geq 1$, viewed as E -valued random variables. Using the assumed conditions on b , it can be easily shown that for $t_1, t_2 \in [0, T]$,

$$E\left[\|X^n(t_2) - X^n(t_1)\|^4\right] \leq K|t_2 - t_1|^2$$

for some T -dependent $K > 0$. It follows that the laws of the sequence $\{X^n(\cdot)\}$ are tight in $\mathcal{P}(C(\mathbb{R}_+; \mathbb{R}^N))$. Since \mathcal{S} is finite and E is compact, it follows by Prohorov's theorem [24, Thm. 2.6, p. 7] that, for $A_1 \in \mathfrak{B}(\mathbb{R}_+)$, $A_2 \in \mathfrak{B}(\mathbb{R})$ fixed, the sequence $(X^n(\cdot), S^n(\cdot), \beta^n(\cdot), W^n(\cdot), \mathbf{p}^n(A_1 \times A_2))$ converges to a limit

$$(X(\cdot), S(\cdot), \beta(\cdot), W(\cdot), \mathbf{p}(A_1 \times A_2)).$$

Dropping to a subsequence if necessary and invoking Skorohod's theorem [24, p. 9], we may assume that all these random variables are defined on a common probability space and the convergence is almost surely on this probability space. By [11, Lemma II.1.2, p. 24] we can find a \mathcal{V} -valued process $v(\cdot)$ such that $\beta_i(t) = \int f_i dv(t)$, $i \geq 1$. Define $Z^n(\cdot) = [Z_1^n(\cdot), \dots, Z_N^n(\cdot)]^T$, $Y^n(\cdot)$, $n \geq 1$, by

$$Z_i^n(t) = X_i^n(t) - \int_0^t b_i(X^n(s), S^n(s), v^n(s)) ds, \quad t \geq 0,$$

$$Y^n(t) = S^n(t) - \sum_{j=1}^M \int_0^t \lambda_{S^n(s-), j}(X^n(s), v^n(s)) (j - S^n(s-)) ds, \quad t \geq 0,$$

and $Z(\cdot) = [Z_1(\cdot), \dots, Z_N(\cdot)]^T$, $Y(\cdot)$ by

$$Z_i(t) = X_i(t) - \int_0^t b_i(X(s), S(s), v(s)) ds, \quad t \geq 0,$$

$$Y(t) = S(t) - \sum_{j=1}^M \int_0^t \lambda_{S(s-), j}(X(s), v(s)) (j - S(s-)) ds, \quad t \geq 0.$$

Then, by [11, Lemma II.1.3, p. 26] and standard representation theorems for semimartingales [25, pp. 172–178] applied to $Z_i(t)$ and $Y(t)$, it follows that on an augmented probability space $(X(\cdot), S(\cdot))$ satisfies (2.4) for an admissible policy $v(\cdot)$ and driven by a Wiener process $\bar{W}(\cdot)$ and a Poisson random measure $\tilde{p}(\cdot, \cdot)$. \square

We now state the next theorem without proof as it would be almost identical to the proof in [11, Thm. II.2.1, p. 29], in view of the estimates in [30, p. 582].

THEOREM 3.2. *The sets $\mathcal{L}_2[\pi_0, \xi_0]$, $\mathcal{L}_3[\pi_0, \xi_0]$ are compact.*

Let $\{v_n\}$ be a sequence of homogeneous Markov policies and $(X^n(\cdot), S^n(\cdot))$ the corresponding solutions of (2.4) with $X^n(0) = x_0$, $S^n(0) = i_0$ for all $n \geq 0$. Let $p^n(t, x_0, i_0, y, j)$ be the fundamental solutions corresponding to the operators $(\frac{\partial}{\partial t} + L^{v_n})$. Let $(X^n(\cdot), S^n(\cdot)) \rightarrow (X^\infty(\cdot), S^\infty(\cdot))$, where the latter is governed by a homogeneous Markov policy v_∞ . Then, using the Hölder estimates on $p^n(t, x_0, i_0, y, j)$ [30, p. 582], we can show the following result as in [10, Thm. II.2.2, p. 33].

LEMMA 3.1. *For each $t > 0$, $p^n(t, x_0, i_0, \cdot, \cdot) \rightarrow p^\infty(t, x_0, i_0, \cdot, \cdot)$ in $L^1(\mathbb{R}^N \times \mathcal{S})$. In other words, the laws of $(X^n(t), S^n(t))$ converge to that of $(X^\infty(t), S^\infty(t))$ in total variation.*

Next, we introduce a topology to the space of all homogeneous Markov policies. Let $F = \{v : \mathbb{R}^N \times \mathcal{S} \rightarrow \mathcal{V} : v \text{ is measurable}\}$. We endow F with the topology described in [11, p. 30]. Then F is a compact metric space. Its topology is determined by the following convergence criterion [11, Lemma II.2.1, p. 32].

LEMMA 3.2. *Let $f \in L^2(\mathbb{R}^N \times \mathcal{S}) \cap L^1(\mathbb{R}^N \times \mathcal{S})$, $g \in C_b(\mathbb{R}^N \times \mathcal{S} \times U)$ and $v_n \rightarrow v$ in F . Then*

$$(3.1) \quad \int_{\mathbb{R}^N} f(x, i) \int_{\mathcal{S}} g(x, i, \cdot) dv_n(x, i) dx \xrightarrow{n \rightarrow \infty} \int_{\mathbb{R}^N} f(x, i) \int_{\mathcal{S}} g(x, i, \cdot) dv(x, i) dx$$

for each $i \in \mathcal{S}$. Conversely, if (3.1) holds for all such f, g , and $i \in \mathcal{S}$, then $v_n \rightarrow v$ in F .

Let $\mathcal{L}(v)$ denote the law of $(X(\cdot), S(\cdot))$ when $X(0) = x_0$, $S(0) = i_0$ and the homogeneous Markov policy v is used. Using Lemma 3.1, the following theorem can be proved exactly the same way as in [11, Thm. II.2.3, p. 34].

THEOREM 3.3. *The map $v \mapsto \mathcal{L}(v)$ from F into $\mathcal{P}(C(\mathbb{R}_+; \mathbb{R}^N) \times D(\mathbb{R}_+; \mathcal{S}))$ is continuous.*

4. Convexity and extremality of occupation measures. In this section we will study the properties of the occupation measures $\nu[\pi, \xi; v]$ introduced in (2.17), following the approach in [12].

LEMMA 4.1. *The sets $M_1[\pi, \xi]$, $M_2[\pi, \xi]$, $M_3[\pi, \xi]$ as defined in (2.18)–(2.20) are compact.*

Proof. This follows from Theorems 3.1 and 3.2. \square

LEMMA 4.2. *For each fixed initial law (π, ξ) , $M_1[\pi, \xi] = M_2[\pi, \xi]$.*

Proof. Let $\nu[\pi, \xi; v] \in M_1$. Disintegrate it as

$$(4.1) \quad \nu[\pi, \xi; v](dx \times \{i\} \times du) = \bar{\nu}[\pi, \xi; v](dx \times \{i\}) \bar{\nu}(x, i)(du),$$

where $\bar{\nu}[\pi, \xi; v]$ is the marginal of $\nu[\pi, \xi; v]$ on $\mathbb{R}^N \times \mathcal{S}$ and $\bar{v}(x, i)$ is a version of the regular conditional law defined $\bar{\nu}[\pi, \xi; v]$ almost surely. Pick any version from this equivalence class and keep it fixed henceforth. The map $\bar{v}(\cdot, \cdot)$ obviously defines a homogeneous Markov policy. Let $(X'(\cdot), S'(\cdot))$ be the solution of (2.4) with $v(\cdot)$ replaced by $v'(\cdot) = \bar{v}(X'(\cdot), S'(\cdot))$ and with initial law (π, ξ) . Let $f \in C_b(\mathbb{R}^N \times \mathcal{S} \times U)$ and let

$$(4.2) \quad \varphi(x, i) = E \left[\int_0^\infty e^{-\alpha t} \int_U f(X'(t), S'(t), u) v'(t)(du) dt \mid X'(0) = x, S'(0) = i \right].$$

Using the strong Markov property of $(X'(\cdot), S'(\cdot))$ (this follows from the Feller property) and the local solvability of weakly coupled systems of elliptic equations [31, Chap. 7, p. 388], it can be shown by employing standard arguments involving Ito's formula that $\varphi(x, i)$ is the unique solution in $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S}) \cap C_b(\mathbb{R}^N \times \mathcal{S})$, $2 \leq p < \infty$, to

$$(4.3) \quad L^{\bar{v}(x,i)} \varphi(x, i) - \alpha \varphi(x, i) + \int_U f(x, i, u) \bar{v}(x, i)(du) = 0.$$

Define a process $Y(\cdot)$ by

$$Y(t) = \int_0^t \int_U e^{-\alpha s} f(X(s), S(s), u) v(s)(du) ds + e^{-\alpha t} \varphi(X(t), S(t)).$$

Then

$$(4.4) \quad \begin{aligned} E[Y(t)] - E[Y(0)] &= E[Y(t)] - \sum_{j=1}^M \int_{\mathbb{R}^N} \varphi(x, j) \pi(dx) \xi(j) \\ &= E \left[\int_0^t e^{-\alpha s} \left[L^{v(s)} \varphi(X(s), S(s)) - \alpha \varphi(X(s), S(s)) \right. \right. \\ &\quad \left. \left. + \int_U f(X(s), S(s), u) v(s)(du) \right] ds \right]. \end{aligned}$$

Letting $t \rightarrow \infty$ and using the definition of $\bar{v}(\cdot, \cdot)$ and (4.3), it follows that the right-hand side in (4.4) tends to zero (cf. [11, Thm. 4.2, pp. 40–42]). Thus,

$$\begin{aligned} \lim_{t \rightarrow \infty} E[Y(t)] &= E[\varphi(X_0, S_0)] \\ &= E[\varphi(X'_0, S'_0)]. \end{aligned}$$

Since $f \in C_b(\mathbb{R}^N \times \mathcal{S} \times U)$ was arbitrary, it follows that $\nu[\pi, \xi; v] = \nu[\pi, \xi; \bar{v}]$. \square

Let $\nu[\pi, \xi; v] \in M_2[\pi, \xi]$. By a routine extension of the inequality [28, p. 66], it follows that $\bar{\nu}[\pi, \xi; v]$ (as in (4.1)) is absolutely continuous with respect to the product of the Lebesgue measure on \mathbb{R}^N and the counting measure on \mathcal{S} and therefore has a density $\varphi[\pi, \xi; v]$. Let $\bar{\nu}[\pi, \xi; v]$ be the marginal of $\bar{\nu}[\pi, \xi; v]$ on \mathcal{S} . With “supp” denoting the support of a measure, let

$$(4.5) \quad \text{supp}(\bar{\nu}[\pi, \xi; v]) = S_1[\pi, \xi; v] \subset \mathcal{S}.$$

It is not difficult to see that $\varphi[\pi, \xi; v](x, i) > 0$ almost everywhere $x \in \mathbb{R}^N$, $i \in S_1[\pi, \xi; v]$ and $\varphi[\pi, \xi; v](x, i) = 0$ for $i \in \mathcal{S} \setminus S_1[\pi, \xi; v]$. For $f \in W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$ define

$$(4.6) \quad L_\alpha^v f(x, i) = L^{v(x,i)} f(x, i) - \alpha f(x, i).$$

Then, $\varphi[\pi, \xi; v]$ is the unique solution in $L^1(\mathbb{R}^N \times \mathcal{S})$ to

$$(4.7) \quad \begin{aligned} \sum_{i=1}^M \int_{\mathbb{R}^N} L_{\alpha}^{v(x,i)} g(x, i) \varphi(x, i) dx &= - \sum_{i=1}^M \int_{\mathbb{R}^N} g(x, i) \pi(dx) \xi(i), \\ \sum_{i=1}^M \int_{\mathbb{R}^N} \varphi(x, i) dx &= 1, \quad \varphi(x, i) \geq 0, \end{aligned}$$

for every $g \in C_0^\infty(\mathbb{R}^N \times \mathcal{S})$. Using the above, we will show that $M_2[\pi, \xi]$ is convex.

LEMMA 4.3. *The set $M_2[\pi, \xi]$ is convex.*

Proof. Let v_1, v_2 be two homogeneous Markov policies and $0 \leq a \leq 1$. Define a homogeneous Markov policy by

$$(4.8) \quad v(x, i) = \frac{a\varphi[\pi, \xi; v_1](x, i)v_1(x, i) + (1-a)\varphi[\pi, \xi; v_2](x, i)v_2(x, i)}{a\varphi[\pi, \xi; v_1](x, i) + (1-a)\varphi[\pi, \xi; v_2](x, i)}$$

for $(x, i) \in \mathbb{R}^N \times \{S_1[\pi, \xi; v_1] \cup S_1[\pi, \xi; v_2]\}$ and arbitrary otherwise. Let $f \in C_0^\infty(\mathbb{R}^N \times \mathcal{S})$. It is easy to see that

$$L_{\alpha}^{v(x,i)} f(x, i) = \frac{a\varphi[\pi, \xi; v_1](x, i)L_{\alpha}^{v_1(x,i)} f(x, i) + (1-a)\varphi[\pi, \xi; v_2](x, i)L_{\alpha}^{v_2(x,i)} f(x, i)}{a\varphi[\pi, \xi; v_1](x, i) + (1-a)\varphi[\pi, \xi; v_2](x, i)}.$$

Let $\varphi(x, i) = a\varphi[\pi, \xi; v_1](x, i) + (1-a)\varphi[\pi, \xi; v_2](x, i)$. From (4.7) and (4.8) it follows that $\varphi = \varphi[\pi, \xi; v]$. Thus,

$$\begin{aligned} \nu[\pi, \xi; v](dx \times \{i\} \times du) &= \varphi[\pi, \xi; v](x, i) dx v(x, i)(du) \\ &= a\varphi[\pi, \xi; v_1](x, i) dx v_1(x, i)(du) + (1-a)\varphi[\pi, \xi; v_2](x, i) dx v_2(x, i)(du) \\ &= (a\nu[\pi, \xi; v_1] + (1-a)\nu[\pi, \xi; v_2])(dx \times \{i\} \times du). \quad \square \end{aligned}$$

Let

$$(4.9) \quad \mathcal{I}[\pi, \xi] = \{\bar{\nu}[\pi, \xi; v] \in \mathcal{P}(\mathbb{R}^N \times \mathcal{S}) : \nu[\pi, \xi; v] \in M_2[\pi, \xi]\},$$

where $\bar{\nu}[\pi, \xi; v]$ is as in (4.1).

The proof of the next lemma is analogous to that of [12, Lemma 3.2]. We present a brief sketch describing the essential ideas.

LEMMA 4.4. *The set $\mathcal{I}[\pi, \xi]$ is compact in $\mathcal{P}(\mathbb{R}^N \times \mathcal{S})$ in total variation.*

Proof. By a routine extension of the inequality [28, p. 66] to the present case, $\varphi[\pi, \xi; v]$ will be uniformly bounded in $L^p(\mathbb{R}^N)$. For the sake of convenience, assume that the initial condition is $(x_0, i_0) \in \mathbb{R}^N \times \mathcal{S}$. As in [11, Lemma 5.2, p. 44], we can show by considering appropriate estimates on the weakly coupled systems of elliptic equations [31, Chap. 7] that for any bounded open set A such that $\bar{A} \subset \mathbb{R}^N \setminus \{x_0\}$ and $i \in \mathcal{S} \setminus \{i_0\}$ there exists a $\beta > 0$ and a $K \in (0, \infty)$ such that

$$(4.10) \quad |\varphi[x_0, i_0; v](y, i) - \varphi[x_0, i_0; v](z, i)| \leq K\|y - z\|^\beta, \quad y, z \in A,$$

under any choice of a homogeneous Markov policy v . By Theorem 3.2, $\mathcal{I}[x_0, i_0]$ is compact in the Prohorov topology of $\mathcal{P}(\mathbb{R}^N \times \mathcal{S})$. Let $\{\bar{\nu}[x_0, i_0; v_n]\}$ be a sequence in

$\mathcal{I}[x_0, i_0]$ and $\bar{\nu}[x_0, i_0; v_\infty]$ be a weak limit point of $\{\bar{\nu}[x_0, i_0; v_n]\}$. We need to show that $\varphi[x_0, i_0; v_n] \rightarrow \varphi[x_0, i_0; v_\infty]$ in $L^1(\mathbb{R}^N \times \mathcal{S})$. The equicontinuity of $\{\varphi[x_0, i_0; v_n]\}$ follows from (4.10). Also (4.10) together with the uniform L^p -estimates implies pointwise boundedness. Thus, by the Arzela–Ascoli theorem, we may drop to a subsequence, if necessary, to conclude that for each $i \in \mathcal{S}$,

$$\varphi[x_0, i_0, v_n](\cdot, i) \rightarrow \psi(\cdot, i),$$

for some $\psi(\cdot, i)$, uniformly on compact subsets of \mathbb{R}^N . By the uniform L^p -estimates the convergence is also in $L^1(\mathbb{R}^N)$. Thus

$$(4.11) \quad \int_{\mathbb{R}^N} \varphi[x_0, i_0; v_n](y, i) f(y) dy \xrightarrow{n \rightarrow \infty} \int_{\mathbb{R}^N} \psi(y, i) f(y) dy,$$

for all $f \in C_b(\mathbb{R}^N)$. But (4.11) certainly holds with $\varphi[x_0, i_0; v_\infty](\cdot, i)$ replacing $\psi(\cdot, i)$. Therefore, $\varphi[x_0, i_0; v_\infty] \equiv \psi$. \square

We are now in a position to characterize the extreme points of $M_2[\pi, \xi]$. Let v be a homogeneous Markov policy such that, for each $x \in \mathbb{R}^N$ and $i \in \mathcal{S}$,

$$(4.12) \quad v(x, i) = av_1(x, i) + (1 - a)v_2(x, i),$$

where $a \in (0, 1)$ and v_1, v_2 are distinct homogeneous Markov policies, i.e., there exists at least one $i_0 \in \mathcal{S}$ such that $v_1(\cdot, i_0)$ and $v_2(\cdot, i_0)$ differ on a set of strictly positive measure. The proof of the next lemma closely follows that of [12, Lemma 3.3]; we therefore present only a brief sketch of the proof.

LEMMA 4.5. *Let v be as in (4.12). Then, $\nu[\pi, \xi; v]$ is not an extreme point of $M_2[\pi, \xi]$.*

Proof. We will show that if v satisfies (4.12), then there are homogeneous Markov policies \tilde{v}_1, \tilde{v}_2 , and $b \in (0, 1)$ such that

$$\nu[\pi, \xi; v] = b\nu[\pi, \xi; \tilde{v}_1] + (1 - b)\nu[\pi, \xi; \tilde{v}_2].$$

It suffices to find $b \in (0, 1)$ and \tilde{v}_1, \tilde{v}_2 satisfying

$$(4.13) \quad v(x, i) = \frac{b\varphi[\pi, \xi; \tilde{v}_1](x, i)\tilde{v}_1(x, i) + (1 - b)\varphi[\pi, \xi; \tilde{v}_2](x, i)\tilde{v}_2(x, i)}{b\varphi[\pi, \xi; \tilde{v}_1](x, i) + (1 - b)\varphi[\pi, \xi; \tilde{v}_2](x, i)}$$

for $(x, i) \in \mathbb{R}^N \times \{S_1[\pi, \xi; \tilde{v}_1] \cup S_1[\pi, \xi; \tilde{v}_2]\}$ (see (4.5)). For $R > 0$, let v'_1, v'_2 be homogeneous Markov policies defined by

$$(4.14) \quad v'_j(x, i) = \begin{cases} v_j(x, i), & \|x\| \leq R \\ v(x, i), & \|x\| > R \end{cases} \quad i \in \mathcal{S}, \quad j = 1, 2.$$

Let $\bar{v}(\cdot)$ be a given homogeneous Markov policy. Define a homogeneous Markov policy v''_2 via

$$(4.15) \quad \begin{aligned} v(x, i) &= av'_1(x, i) + (1 - a)v'_2(x, i) \\ &= \frac{b\varphi[\pi, \xi; v'_1](x, i)v'_1(x, i) + (1 - b)\varphi[\pi, \xi; \bar{v}](x, i)v''_2(x, i)}{b\varphi[\pi, \xi; v'_1](x, i) + (1 - b)\varphi[\pi, \xi; \bar{v}](x, i)} \end{aligned}$$

for $(x, i) \in \mathbb{R}^N \times \{S_1[\pi, \xi; v'_1] \cup S_1[\pi, \xi; \bar{v}]\}$ and arbitrary otherwise. The arguments used in the proof of [12, Lemma 3.3] mutatis mutandis will ensure a suitable choice of $b \in (0, 1)$ such that v''_2 is a genuine homogeneous Markov policy. Fix a $b \in (0, 1)$ as in (4.15). Given a homogeneous Markov policy $\bar{v}(\cdot)$, we obtain $v''_2(\cdot)$ via (4.15). Thus, we have a map $\bar{v}[\pi, \xi; \bar{v}] \mapsto \bar{v}[\pi, \xi; v''_2]$ from $\mathcal{I}[\pi, \xi]$ to $\mathcal{I}[\pi, \xi]$. Using Lemma 4.4, it can be shown as in the proof of [11, Lemma 3.3] that this map is continuous in the total variation. By Schauder's fixed point theorem [26, p. 220], this map has a fixed point. In other words, there exists a homogeneous Markov policy v''_2 such that

$$v(x, i) = \frac{b\varphi[\pi, \xi; v'_1](x, i)v'_1(x, i) + (1 - b)\varphi[\pi, \xi; v''_2]v''_2(x, i)}{b\varphi[\pi, \xi; v'_1](x, i) + (1 - b)\varphi[\pi, \xi; v''_2](x, i)}$$

for $(x, i) \in \mathbb{R}^N \times \{S_1[\pi, \xi; v'_1] \cup S_1[\pi, \xi; v''_2]\}$. Since $v'_1 \neq v$ on a set of strictly positive measure for sufficiently large R , $v''_2 \neq v'_1$ on this set. Thus

$$\nu[\pi, \xi; v] = b\nu[\pi, \xi; v'_1] + (1 - b)\nu[\pi, \xi; v''_2]$$

as desired. \square

The results in this section are now summarized as follows.

THEOREM 4.1. $M_1[\pi, \xi] = M_2[\pi, \xi]$, and $M_2[\pi, \xi]$ is compact and convex, and each of its extreme points corresponds to some $\nu[\pi, \xi; v]$, where v is a homogeneous Markov nonrandomized policy.

5. Existence of an optimal policy. Using the results of the previous section, we will establish the existence of an optimal policy.

THEOREM 5.1. *There exists a homogeneous Markov optimal policy.*

Proof. Let $(\pi, \xi) \in \mathcal{P}(\mathbb{R}^N) \times \mathcal{P}(\mathcal{S})$ such that $\text{supp}(\pi) = \mathbb{R}^N$ and $\text{supp}(\xi) = S$. Since \bar{c} is bounded and continuous, the map $M_2[\pi, \xi] \ni \nu \mapsto \int \bar{c} d\nu$ is continuous. Thus, there exists a homogeneous Markov policy v^* such that

$$J_{v^*}(\pi, \xi) = \min_v \{J_v(\pi, \xi) : v \text{ is homogeneous Markov}\}.$$

By Lemma 4.2, it follows that

$$J_{v^*}(\pi, \xi) = V(\pi, \xi).$$

Therefore, v^* is optimal for the initial law (π, ξ) . We will show that v^* is optimal for any initial law. It suffices to show that v^* is optimal for any initial condition $(x, i) \in \mathbb{R}^N \times \mathcal{S}$. Suppose there exist $(x_0, i_0) \in \mathbb{R}^N \times \mathcal{S}$ and a homogeneous Markov policy v such that

$$(5.1) \quad J_v(x_0, i_0) < J_{v^*}(x_0, i_0).$$

Using the fact that the solution of (2.4) under a Markov policy is a Feller process, it can be easily shown that the function $J_v(x, i)$ is continuous in x for each v . Thus, (5.1) holds in a neighborhood B of x_0 . Define a policy v' by

$$v'(t) = v^*(X(t), S(t))I\{X_0 \notin B\} + v(X(t), S(t))I\{X_0 \in B\},$$

where $(X(\cdot), S(\cdot))$ is governed by $v'(\cdot)$. Then, it is easily shown that

$$J_{v'}(\pi, \xi) < J_{v^*}(\pi, \xi),$$

which is a contradiction. Thus, v^* is optimal. \square

THEOREM 5.2. *There exists a homogeneous Markov nonrandomized optimal policy.*

Proof. Let v^* be as in Theorem 5.1. Let $M_2^e[\pi, \xi]$ be the set of extreme points of $M_2[\pi, \xi]$. Since $M_2[\pi, \xi]$ is compact, by Choquet's theorem [34], $\nu[\pi, \xi; v^*]$ is the barycenter of a probability measure m supported on $M_2^e[\pi, \xi]$. Therefore,

$$(5.2) \quad \int \bar{c} d\nu[\pi, \xi; v^*] = \int_{M_2^e[\pi, \xi]} \left(\int \bar{c} d\mu \right) m(d\mu).$$

Since v^* is optimal, it follows from (5.2) that there exists a $\nu[\pi, \xi; v] \in M_2^e[\pi, \xi]$ such that

$$\int \bar{c} d\nu[\pi, \xi; v^*] = \int \bar{c} d\nu[\pi, \xi; v].$$

Thus, v is also optimal. By Theorem 4.1 it is nonrandomized. \square

6. Dynamic programming equations. Using the existence results of the previous section, we will now derive the dynamic programming or Hamilton–Jacobi–Bellman (HJB) equations which in our case will be a weakly coupled system of quasi-linear elliptic equations, and then characterize the optimal policy as a minimizing selector of an appropriate “Hamiltonian.” The HJB equations for our problem are

$$(6.1) \quad \alpha\psi(x, i) = \inf_{u \in U} \{L^u\psi(x, i) + \bar{c}(x, i, u)\}.$$

THEOREM 6.1. *The value function $V(x, i)$ is the unique solution of (6.1) in the space $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S}) \cap C_b(\mathbb{R}^N \times \mathcal{S})$ for any $2 \leq p < \infty$.*

Proof. We have already seen in the proof of Theorem 5.1 that $V(x, i) \in C_b(\mathbb{R}^N \times \mathcal{S})$. Let v^* be a homogeneous Markov nonrandomized optimal policy and $(X(\cdot), S(\cdot))$ the corresponding solution of (2.4). Then, for $(x, i) \in \mathbb{R}^N \times \mathcal{S}$,

$$(6.2) \quad V(x, i) = E \left[\int_0^\infty e^{-\alpha t} \bar{c}(X(t), S(t), v^*(X(t), S(t))) dt \mid X(0) = x, S(0) = i \right].$$

By standard arguments (see the arguments following (4.2)), $V(x, i)$ is the unique solution in $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S}) \cap C_b(\mathbb{R}^N \times \mathcal{S})$, for any $2 \leq p < \infty$, of

$$(6.3) \quad \alpha V(x, i) = L^{v^*(x, i)} V(x, i) + \bar{c}(x, i, v^*(x, i)).$$

Suppose there exist $x_0 \in \mathbb{R}^N$, $i_0 \in \mathcal{S}$, $u \in U$, and $\delta > 0$ such that

$$\alpha V(x_0, i_0) > L^u V(x_0, i_0) + \bar{c}(x_0, i_0, u) + \delta.$$

Then, by the continuity of $V(\cdot, i_0)$, the above will hold in a neighborhood $N(x_0)$ of x_0 . Define a homogeneous Markov nonrandomized policy \tilde{v} as follows:

$$\tilde{v}(x, i) = \begin{cases} v^*(x, i) & \text{if } (x, i) \notin N(x_0) \times \mathcal{S}, \\ u & \text{if } (x, i) \in N(x_0) \times \mathcal{S}. \end{cases}$$

Then

$$\alpha V(x, i_0) > L^{\tilde{v}(x, i_0)} V(x, i_0) + \bar{c}(x, i_0, \tilde{v}(x, i_0)) + \delta I\{x \in N(x_0)\}.$$

It is easily seen that

$$V(x, i_0) \geq J_{\tilde{v}}(x, i_0) + \delta'$$

for some $\delta' > 0$, which is a contradiction. Hence, $V(x, i)$ satisfies (6.1). Let V' be another solution of (6.1) in the desired class. Then it can be shown using standard arguments (cf. [11, Thm. III.2.4, pp. 69–70]) that

$$|V(x, i) - V'(x, i)| \leq 2Ke^{-\alpha t},$$

where $K > 0$ is a constant. Letting $t \rightarrow \infty$, $V \equiv V'$. \square

COROLLARY 6.1. Assume that for each $i \in \mathcal{S}$, $\bar{c}(\cdot, i, \cdot)$ is Lipschitz in its first argument uniformly with respect to the third. Then $V(x, i)$ is the unique solution of (6.1) in $C^2(\mathbb{R}^N \times \mathcal{S}) \cap C_b(\mathbb{R}^N \times \mathcal{S})$.

Proof. It suffices to show that V is C^2 . Since $V(x, i) \in W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$ for any $2 \leq p < \infty$, by Sobolev's imbedding theorem, $V(x, i) \in C^{1,\gamma}(\mathbb{R}^N \times \mathcal{S})$, for $0 < \gamma < 1$, γ arbitrarily close to 1, and hence by our assumptions on \bar{b} , $\bar{\lambda}$, \bar{c} , it is easy to see that

$$\alpha V(x, i) - \inf_{u \in U} \left\{ \sum_{j=1}^N \bar{b}_j(x, i, u) \frac{\partial V(x, i)}{\partial x_j} + \sum_{j=1}^M \bar{\lambda}_{ij}(x, u) (V(x, j) - V(x, i)) + \bar{c}(x, i, u) \right\}$$

is in $C^{0,\gamma}$. By elliptic regularity [23, p. 287] applied to (6.1) (V replacing ψ), we conclude that $V \in C^{2,\gamma}$. \square

THEOREM 6.2. A homogeneous Markov nonrandomized policy v is optimal if and only if

$$\begin{aligned} (6.4) \quad & \sum_{j=1}^N \bar{b}_j(x, i, v(x, i)) \frac{\partial V(x, i)}{\partial x_j} \\ & + \sum_{k=1}^M \bar{\lambda}_{ik}(x, v(x, i)) (V(x, k) - V(x, i)) + \bar{c}(x, i, v(x, i)) \\ & = \inf_{u \in U} \left\{ \sum_{j=1}^N \bar{b}_j(x, i, u) \frac{\partial V(x, i)}{\partial x_j} + \sum_{k=1}^M \bar{\lambda}_{ik}(x, u) (V(x, k) - V(x, i)) \right. \\ & \quad \left. + \bar{c}(x, i, u) \right\}, \quad \text{a.e. } x \in \mathbb{R}^N, i \in \mathcal{S}. \end{aligned}$$

Proof. The “necessity” part is contained in the proof of Theorem 6.1. We establish the sufficiency. Let $v(\cdot, \cdot)$ satisfy (6.4). The existence of such a v is guaranteed by a standard measurable selection theorem [4, Lemma 1]. Let v' be any other homogeneous Markov nonrandomized policy. By standard arguments involving Ito's formula and the strong Markov property, we conclude that

$$J_v(x, i) \leq J_{v'}(x, i), \quad \text{a.e. } x \in \mathbb{R}^N, i \in \mathcal{S}.$$

Hence, by Lemma 4.2,

$$J_v(x, i) \leq J_{\bar{v}}(x, i)$$

for any admissible policy \bar{v} . Thus, v is optimal. \square

Remark 6.1. Thus far, we have assumed that the cost function \bar{c} is bounded. However, this condition can be relaxed, as we show in the Appendix.

7. An application to a simplified model. We consider a modified version of the model studied in [2]. Suppose there is one machine producing a single commodity. We assume that the demand rate is a constant $d > 0$. Let the machine state $S(t)$ take values in $\{0, 1\}$, $S(t) = 0$ or 1 , according to whether the machine is down or functional. Let $S(t)$ be a continuous time Markov chain with generator

$$\begin{bmatrix} -\lambda_0 & \lambda_0 \\ \lambda_1 & -\lambda_1 \end{bmatrix}.$$

The inventory $X(t)$ is governed by the Ito equation

$$(7.1) \quad dX(t) = (u(t) - d) dt + \sigma dW(t),$$

where $\sigma > 0$. The production rate $u(t)$ is constrained by

$$u(t) = \begin{cases} 0 & \text{if } S(t) = 0, \\ \in [0, R] & \text{if } S(t) = 1. \end{cases}$$

Let $c : \mathbb{R} \rightarrow \mathbb{R}_+$ be the cost function which is assumed to be convex and Lipschitz continuous. Let $\alpha > 0$ be the discount factor and let $V(x, i)$ denote the value function. In this case $V(x, i)$ is the minimal nonnegative C^2 solution of the HJB equation

$$(7.2) \quad \begin{aligned} & \left(\frac{\sigma^2}{2} V''(x, 0) - dV'(x, 0) \right. \\ & \left. \frac{\sigma^2}{2} V''(x, 1) - \min_{u \in [0, R]} \{ (u - d)V'(x, 1) \} \right) \\ & = \begin{bmatrix} \lambda_0 + \alpha & -\lambda_0 \\ \lambda_1 & \alpha - \lambda_1 \end{bmatrix} \begin{pmatrix} V(x, 0) \\ V(x, 1) \end{pmatrix} - \begin{pmatrix} 1 \\ 1 \end{pmatrix} c(x). \end{aligned}$$

Using the convexity of $c(\cdot)$, it can be shown as in [2] that $V(\cdot, i)$ is convex for each i . Hence, there exists an x^* such that

$$(7.3) \quad \begin{aligned} V'(x, 1) &\leq 0 \quad \text{for } x \leq x^*, \\ &\geq 0 \quad \text{for } x \geq x^*. \end{aligned}$$

From (7.2), it follows that the value of u which minimizes $(u - d)V'(x, 1)$ is

$$u = \begin{cases} R & \text{if } x \leq x^*, \\ 0 & \text{if } x \geq x^*. \end{cases}$$

At $x = x^*$, $V'(x^*, 1) = 0$ and therefore any $u \in [0, R]$ minimizes $(u - d)V'(x, 1)$. Thus, in view of Theorem 6.2, we can choose any $u \in [0, R]$ at $x = x^*$. To be specific, we choose $u = d$ at $x = x^*$. It follows that the following homogeneous Markov nonrandomized policy is optimal:

$$(7.4) \quad v(x, 0) = 0, \quad v(x, 1) = \begin{cases} R & \text{if } x < x^*, \\ d & \text{if } x = x^*, \\ 0 & \text{if } x > x^*. \end{cases}$$

We note at this point that the piecewise deterministic model, in general, would lead to a singular control problem when $V'(x, 1) = 0$ [2], [27]. In [2], Akella and Kumar have obtained the solution of the HJB equation (this would be (7.2) without the second-order term) in closed form and have computed an explicit expression for x^* . They have shown that a policy of the type (7.4) is optimal among all homogeneous Markov nonrandomized policies. In our case, the additive noise in (7.1) induces a smoothing effect to remove the singular situation; in addition, our results imply that the policy (7.4) is optimal among *all admissible policies*. The only limitation of our model is that it would, in general, be very difficult to solve (7.2) analytically. Therefore, we must rely on numerical methods to compute an optimal policy of the type (7.4).

We now discuss the manufacturing model studied in [27] as described in the introduction. The machine state $S(t)$ is again a prescribed continuous time Markov chain taking values in $S = \{1, \dots, M\}$. For each $i \in \mathcal{S}$, the production rate $u = (u_1, \dots, u_N)$ takes values in U_i , a convex polyhedron in \mathbb{R}^N . The demand rate is $d = [d_1, \dots, d_N]^T$. In this case, if the cost function $c : \mathbb{R}^N \rightarrow \mathbb{R}_+$ is Lipschitz continuous and convex, it can be shown that for each $i \in \mathcal{S}$, the value function $V(\cdot, i)$ is convex. But from this fact alone optimal policies of the type (7.4) cannot be obtained. However, since an optimal homogeneous Markov nonrandomized policy $v(x, i)$ is determined by minimizing

$$\sum_{j=1}^N (u_j - d_j) \frac{\partial V(x, i)}{\partial x_j}$$

over U_i , $v(x, i)$ takes values at extreme points of U_i . Thus, for each machine state i , an optimal policy divides the buffer state space into a set of regions in which the production rate is constant. If the gradient $\nabla V(x, i)$ is zero or orthogonal to a face of U_i , a unique minimizing value does not exist. But again, in view of Theorem 6.2, we may prescribe arbitrary production rates at those points where $\nabla V(x, i) = 0$, and if $\nabla V(x, i)$ is orthogonal to a face of U_i , we can choose any corner of that face. Hence, once again, we can circumvent the singular situation.

8. Concluding remarks. We have analyzed the optimal control of switching diffusions with a discounted criterion on the infinite horizon. The model allows a very general form of coupling between the continuous and the discrete components of the process. We have shown that there exists a homogeneous, nonrandomized Markov policy that is optimal in the class of all admissible policies. Also, the existence of a unique solution in a certain class to the associated HJB equations is established and the optimal policy is characterized as a minimizing selector of an appropriate Hamiltonian.

The primary motivation for this study is a class of control problems encountered in flexible manufacturing systems. By explicitly taking into account the noise present in the dynamics, we are able to remove singularities arising in the noiseless situation. In addition, we show that hedging type policies are optimal in a much wider class of nonanticipative policies than previously considered. We have confined our attention to the flow control level only. However, our results can be used to study control problems at other levels in hierarchical manufacturing systems [21], as well as control problems in other hybrid systems (see, e.g., [17], [38], [39]).

Here we have studied only the discounted criterion. Following [12], we can obtain similar results for the finite horizon and exit time criteria. However, the long-run average cost problem is more involved and is currently under study.

Appendix. Note that by the arguments of §5 we can establish the existence of a homogeneous Markov nonrandomized policy for each fixed initial law. The independence of the optimal policy of the initial law results from the dynamic programming characterization of the optimal policy via Theorem 6.2. Using probabilistic arguments, dynamic programming equations can be derived by suitably adapting the approach in [11, Chap. 3]. However, in a brief sketch we will present an alternative analytical approach, which parallels that used for classical diffusions in [29].

We assume that for each $i \in \mathcal{S}$, $\bar{c}(\cdot, i, \cdot)$ is Lipschitz in its first argument uniformly with respect to the third. We further assume that for each $x \in \mathbb{R}^N$ and $i \in \mathcal{S}$, the value function $V(x, i) < \infty$. (This assumption may be replaced by some ergodicity

hypotheses of the process under some homogeneous Markov policy.) Let $B_R = \{x \in \mathbb{R}^N : \|x\| < R\}$. Consider the Dirichlet problem on B_R

$$(A.1) \quad \begin{aligned} \inf_{u \in U} L^u \varphi(x, i) &= \alpha \varphi(x, i), \quad \text{in } B_R \times \mathcal{S}, \\ \varphi(x, i) \Big|_{\partial B_R} &= 0. \end{aligned}$$

The existence of a unique solution $\varphi_R(x, i)$ of (A.1) in $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$, $2 \leq p < \infty$, is guaranteed by [31, Thm. 5.1, p. 422]. Thus, to each $R > 0$ there corresponds a solution φ_R to (A.1) belonging to $W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$, for $2 \leq p < \infty$. Using elliptic regularity results as in Corollary 6.1, it follows that $\varphi_R(x, i) \in C^{2,\gamma}(B_R \times \mathcal{S})$, $0 < \gamma < 1$, γ arbitrarily close to 1. Let v_R be a homogeneous Markov nonrandomized policy that is a minimizing selector in (6.4). Standard arguments involving Ito's formula yield

$$(A.2) \quad \begin{aligned} \varphi_R(x, i) &= E \left[\int_0^{\tau_R} e^{-\alpha t} \bar{c}(X(t), S(t), v_R(X(t), S(t))) dt \mid X(0) = x, S(0) = i \right] \\ &= \inf_{u(\cdot)} E \left[\int_0^{\tau_R} e^{-\alpha t} \bar{c}(X(t), S(t), u(t)) dt \mid X(0) = x, S(0) = i \right], \end{aligned}$$

where τ_R is the hitting time of ∂B_R of the process $X(\cdot)$. Clearly, $\varphi_R(x, i) \leq V(x, i)$ and it can be easily seen from (A.2) that $\varphi_R(x, i)$ is increasing in R . Let $R' > R$. Then, by the interior estimates [31, pp. 398–402], $\{\varphi_{R'}\}_{R' > R}$ is bounded in B_R uniformly in R' and $\{\nabla \varphi_{R'}\}_{R' > R}$ is bounded in $W^{1,2}(B_R \times \mathcal{S})$ uniformly in R' . By Sobolev's imbedding theorem, $W^{1,2}(B_R \times \mathcal{S}) \hookrightarrow L^{2+\varepsilon}(B_R \times \mathcal{S})$, for some $\varepsilon > 0$. Then, by suitably modifying (4.10) of [31, p. 400], we obtain

$$\|\varphi_{R'}\|_{W^{2,2+\varepsilon}(B_R \times \mathcal{S})} \leq K_R,$$

where K_R is a constant that does not depend on R' . (The modification is needed because of the factor $\varepsilon > 0$, but it is routine.) Repeating the above procedure over and over again, we conclude that $\{\varphi_{R'}\}_{R' > R}$ is uniformly bounded in $W^{2,p}(B_R)$, for $2 \leq p < \infty$. Since $W^{2,p}(B_R) \hookrightarrow W^{1,p}(B_R)$ and the injection is compact, it follows that $\{\varphi_R\}$ converges strongly in $W^{1,p}(B_R)$. Thus, given any sequence $\{R_n\}$, $R_n \rightarrow \infty$, as $n \rightarrow \infty$ and for any fixed integer $N \geq 2$, we can choose a subsequence $\{R_{n_i}\}$ such that $\{\varphi_{R_{n_i}}\}$ converges strongly in $W^{1,p}(B_{N-1})$. Using a suitable diagonalization, we may assume that $\{\varphi_{R_{n_i}}\}$ converges strongly in $W^{1,p}(B_{N-1})$ for each integer $N \geq 2$. Let ψ be a limit point of $\{\varphi_{R_{n_i}}\}$. It can be shown as in [5, p. 148] (see also [31, p. 420]) that

$$\begin{aligned} \inf_{u \in U} \left\{ \sum_{k=1}^N \bar{b}_k(x, j, u) \frac{\partial \varphi_{R_{n_i}}(x, j)}{\partial x_k} + \sum_{\ell=1}^M \bar{\lambda}_{j\ell}(x, u) (\varphi_{R_{n_i}}(x, \ell) - \varphi_{R_{n_i}}(x, j)) + \bar{c}(x, j, u) \right\} \\ \longrightarrow \inf_{u \in U} \left\{ \sum_{k=1}^N \bar{b}_k(x, j, u) \frac{\partial \psi(x, j)}{\partial x_k} + \sum_{\ell=1}^M \bar{\lambda}_{j\ell}(x, u) (\psi(x, \ell) - \psi(x, j)) + \bar{c}(x, j, u) \right\} \end{aligned}$$

strongly in $L^p(B_{N-1})$. Therefore, $\psi \in W_{loc}^{1,p}(\mathbb{R}^N \times \mathcal{S})$ and ψ satisfies

$$\inf_{u \in U} L^u \psi(x, i) = \alpha \psi(x, i)$$

in $\mathcal{D}'(\mathbb{R}^N \times \mathcal{S})$, i.e., in the sense of distributions. By elliptic regularity, $\psi \in W_{loc}^{2,p}(\mathbb{R}^N \times \mathcal{S})$, $2 \leq p < \infty$. Therefore, as in Corollary 6.1, it follows that $\psi \in C^{2,\gamma}(\mathbb{R}^N \times \mathcal{S})$, $0 < \gamma < 1$, γ arbitrarily close to 1. Let v be a minimizing selector corresponding to ψ . Then, by standard arguments involving Ito's formula, it can be shown that

$$\begin{aligned}\psi(x, i) &= E \left[\int_0^\infty e^{-\alpha t} \bar{c}(X(t), S(t), v(X(t), S(t))) dt \mid X(0) = x, S(0) = i \right], \\ &= \inf_{u(\cdot)} E \left[\int_0^\infty e^{-\alpha t} \bar{c}(X(t), S(t), u(t)) dt \mid X(0) = x, S(0) = i \right].\end{aligned}$$

Thus, $\psi(x, i) = V(x, i)$. In this situation, (6.1) does not have a unique solution in general, but $V(x, i)$ can be identified as a minimal nonnegative solution of (6.1) in $C^2(\mathbb{R}^N \times \mathcal{S})$. The assertion of Theorem 6.2 is also valid in this case.

ON DIFFERENTIAL SYSTEMS WITH QUADRATIC IMPULSES AND THEIR APPLICATIONS TO LAGRANGIAN MECHANICS*

ALBERTO BRESSAN[†] AND FRANCO RAMPAZZO[‡]

Abstract. This paper is concerned with the basic dynamics and a class of variational problems for control systems of the form

$$(E) \quad \dot{x} = f(t, x, u) + g(t, x, u)\dot{u} + h(t, x, u)\dot{u}^2$$

These systems have impulsive character, due to the presence of the time derivative \dot{u} of the control. It is shown that trajectories can be well defined when the controls u are limits (in a suitable weak sense) of sequences (u_n) contained in the Sobolev space $W^{1,2}$. Roughly speaking, one can say that, in this case, the \dot{u}_n tend to the square root of a measure. Actually, this paper shows that the system (E) is essentially equivalent to an (affine) impulsive system of the form

$$\dot{x} = f(x) + g(x)v + h(x)\dot{w},$$

where $v \in L^2$ and \dot{w} is a nonnegative Radon measure not smaller than v^2 . This provides a characterization of the closure of the set of trajectories of (E), as the controls u range inside a fixed ball of $W^{1,2}$. The existence of (generalized) optimal controls for variational problems of Mayer type is also investigated. Since the main motivation for studying systems of form (E) comes from Rational Mechanics, this paper concludes by presenting an example of an impulsive Lagrangian system.

Key words. nonlinear impulsive system, L^1 convergence of solutions, existence of optimal generalized controls, Lagrangian mechanical system

AMS subject classifications. 34K35, 49A10, 70D10

1. Introduction and notation. To a mechanical Lagrangian system with $N+1$ degrees of freedom and locally parametrized by coordinates (q_i, u) , $i = 1, \dots, N$, one can superimpose new time-dependent constraints by assigning the motion $u(\cdot)$ of the coordinate u . This leads to *impulsive control systems* of the form

$$(E) \quad \dot{x} = f(t, x, u) + g(t, x, u)\dot{u} + h(t, x, u)\dot{u}^2, \quad x(0) = \bar{x} \in R^n \quad t \in [0, T],$$

where, as customary, the dot denotes differentiation with respect to time. The appellation *impulsive control systems* is here adopted because of the presence of the derivative of the control on the right-hand sides of the equations. We refer to §6 and to the references quoted there for a detailed description of the mechanical problems that motivate the study of equations having the form (E). In particular, (6.1) provides a concrete example where the derivative of the control appears quadratically. This equation concerns a swing where, unlike the situation considered in [9], the role of control is played by the angle formed by the swing and the vertical.

We remark that in the usual applications of control theory to classical mechanics the quantities identified with the controls have the character of forces or torques. This leads to ordinary control equations, which do not contain the derivative of the

control. On the contrary, here the control is one of the positional coordinates of the mechanical system Σ . For example, one could try to *guide* the entire motion of Σ just by assigning the motion of a part Π of Σ : in this case what one can practically measure is the time evolution of the positions of Π , while one does not know the forces necessary to generate such evolution, as it would be required by the classical approach of control theory to mechanics.

The important case $h \equiv 0$, which occurs in such mechanical applications under special assumptions on the geometry of the constraint manifold [14], [15], was considered in [2]–[5], [12], [16]–[18].

The aim of this paper is to provide a definition of solution of (E) valid for the general case, i.e., when the derivative \dot{u} appears quadratically, and for a suitably large class of inputs u . We study the existence, uniqueness, and continuous dependence (on the controls) for the corresponding Cauchy problem. This allows us to drop the aforementioned technical assumptions on the geometry of the constraint manifold and to cover a very large class of mechanical applications. In particular, all the problems where the forces depend on the velocities linearly and quadratically are within this class, without any assumption on the geometry of the constraints.

Observe first, that by possibly introducing the variables $x^0 = t$, $x^{n+1} = u$ and the new equations $\dot{x}^0 = 1$, $\dot{x}^{n+1} = \dot{u}$, it is not restrictive to assume that (E) takes the simpler form

$$(1.1) \quad \dot{x} = f(x) + g(x)\dot{u} + h(x)\dot{u}^2, \quad x(0) = \bar{x} \in R^n.$$

When u is absolutely continuous with square integrable derivative, the solutions of (1.1) are already well defined. In the special case, where $h \equiv 0$, it is known that the input-output map $\psi: u(\cdot) \rightarrow x(\cdot)$ can be extended continuously to a map from $L^1([0, T], R)$ into $L^1([0, T], R^n)$. However, as shown in [13], when $h \neq 0$, such continuous extension does not exist. On the other hand, as u ranges within bounded subsets of the Sobolev space $W^{1,2}([0, T], R)$, we show in §2 that the input-output map remains continuous also with respect to a new topology \mathcal{T} on the space of controls, somewhat weaker than the norm topology. This enables us to embed the map ψ in a larger domain consisting of couples (v, \dot{w}) , where $v \in L^2([0, T], R)$ and w is a nondecreasing function with the property

$$\int_a^b v^2(t) \, dt \leq w(b) - w(a) \quad \text{for all } 0 \leq a < b \leq T.$$

For any such couple we consider a problem of the form

$$(1.2) \quad \dot{x} = f(x) + g(x)v + h(x)\dot{w}, \quad x(0) = \bar{x}.$$

We prove that the solution of (1.2) depends continuously on the input pair (v, w) , where $v \in L^2_{\text{weak}}([0, T], R)$ and $w \in L^1([0, T], R)$. This also provides a characterization of the L^1 -closure of the set of trajectories of (1.1) whenever u ranges inside a fixed ball in $W^{1,2}([0, T], R)$.

Furthermore, we prove that the set reached at a time $t = \tau$, $\tau \in [0, T]$, by (generalized) solutions of (1.2) is compact. This guarantees the existence of (generalized) optimal controls for a class of variational problems having a dynamics of the form (E).

In §4, some examples display the difficulties that arise when no bound on the L^2 norm of \dot{u} is imposed. Still, if the vector field h satisfies a suitable coercivity

condition, then $|x(t)| \rightarrow \infty$ as $\int_0^t |\dot{u}(s)|^2 ds \rightarrow \infty$; hence, the boundedness of solutions $x(\cdot)$ automatically implies a bound on $\|\dot{u}\|_{L^2}$.

Finally, an application concerning an optimal control problem for a mechanical system is presented in §5.

The following is a list of the notation that will be used in the next sections.

The euclidean norm of a vector $y \in R^n$ is written $|y|$, while $B[u, \rho]$ denotes the closed ball centered at y with radius ρ . For $r = 1, 2, \dots$ [$r = 0$], we say that a map $f : R^\ell \mapsto R^m$ is of class C^r if f is r times continuously differentiable [if f is continuous]. When f is at least C^1 , by $Df(x)$ we denote the $m \times \ell$ Jacobian matrix of f at the point $x \in R^\ell$. $|Df(x)|$ indicates the operator norm of $Df(x)$.

Let h be a C^1 vector field on R^d . As customary, $(\exp th)(x)$ indicates the value at time t of the solution of the Cauchy problem

$$\dot{y} = h(y), \quad y(0) = x.$$

The differential of the map $x \mapsto (\exp th)(x)$ is denoted by $(\exp th)_*$. Observe that, for each $x \in R^d$, $(\exp th)_*$ is a linear map from the tangent space at x into the tangent space at the point $(\exp th)(x)$. In particular, if f is a vector field on R^d , one has

$$(1.3) \quad (\exp th)_* f(x) = \lim_{\varepsilon \rightarrow 0} \frac{(\exp th)(x + \varepsilon f(x)) - (\exp th)(x)}{\varepsilon} = v(t),$$

where $v(\cdot)$ is the solution of the linear Cauchy problem

$$(1.4) \quad \dot{v}(s) = Dh((\exp sh)(x)) \cdot v(s), \quad v(0) = f(x).$$

In the following, $W^{r,p}([a, b], R^d)$ is the Sobolev space of functions from $[a, b]$ into R^d whose distributional derivatives up to order r belong to L^p . If w is a map from $[a, b]$ into R^d , the total variation of w on the interval $[a, b]$ is written $V_{[a,b]}(w)$. We recall that

$$V_{[a,b]}(w) = \sup \left(\sum_{i=1}^n |f(t_i) - f(t_{i-1})| \right),$$

where the supremum is taken over all partitions $\{a = t_0 < t_1 < \dots < t_n = b\}$ of the interval $[a, b]$.

If E is a topological vector space, by E^* we denote its topological dual space. The convergence of a sequence $(v_n)_{n \geq 1}$ to a point v in E is written as $v_n \rightarrow v$, while “ \rightharpoonup ” indicates weak convergence.

2. Systems with linear impulses. As a preliminary, we provide a notion of generalized solution to the impulsive Cauchy problem

$$(2.1) \quad \begin{cases} \dot{x} = f(x) + g(x)v + h(x)\dot{w} \\ x(0) = \bar{x}, \end{cases}$$

corresponding to a control pair $(v, w)(\cdot)$, in the case where $v \in L^1([0, T], R)$ and w is a bounded, measurable function. Concerning the vector fields f, g, h we shall assume

(H) The maps f, g are C^1 . The vector field h is C^2 and *complete*, i.e., for every x the map $t \rightarrow (\exp th)(x)$ is defined for all $t \in R$.

Recalling the notation at (1.3), for a given $w : [0, T] \mapsto R$ consider the vector fields

$$f^w(t, y) \doteq (\exp(-w(t)h))_* f((\exp w(t)h)(y)),$$

$$g^w(t, y) \doteq (\exp(-w(t)h))_* g((\exp w(t)h)(y)).$$

DEFINITION 2.1. A map $x : [0, T] \rightarrow R^n$ is a *generalized solution* of (2.1) if

$$(2.2) \quad x(t) = (\exp w(t)h)(y(t)) \quad \forall t \in [0, T],$$

where $y(\cdot)$ is a Caratheodory solution of the Cauchy problem

$$(2.3) \quad \begin{cases} \dot{y}(t) = f^w(t, y(t)) + g^w(t, y(t)) \cdot v(t), \\ y(0) = (\exp(-w(0)h))(\bar{x}). \end{cases}$$

Remark 2.1. If w is smooth, the above definition is equivalent to the classical one. Theorem 2.2 will show that this is the unique extension to the case where $v \in L^1$ and w is bounded measurable.

Remark 2.2. If $w' : [0, T] \mapsto R$ is a measurable function such that $w'(0) = w(0)$ and $w'(t) = w(t)$ almost everywhere, then $f^{w'}(t, \cdot) = f^w(t, \cdot)$, $g^{w'}(t, \cdot) = g^w(t, \cdot)$ for almost every t . Hence, the corresponding solutions y' , y of (2.3) coincide. The value of the solution $x(\cdot)$ of (2.1) at a given time τ thus depends only on the L^1 equivalence class of v, w and on the values of w at $t = 0$ and at $t = \tau$.

In the following, when we are interested only in the value of a solution at a single time τ , we thus consider functions v, w defined up to L^1 equivalence on $[0, T]$, with w pointwise determined at $t = 0, \tau$.

THEOREM 2.1. *If the hypotheses (H) hold, then there exists $\tau > 0$ such that the Cauchy problem (2.1) has a unique generalized solution on $[0, \tau]$. If, in addition, the vector fields f, g, h satisfy the bounds*

$$(2.4) \quad |f(x)| \leq C(1 + |x|), \quad |g(x)| \leq C(1 + |x|), \quad |Dh(x)| \leq C$$

for some constant C and all $x \in R^n$, then the generalized solution of (2.1) exists on the whole interval $[0, T]$ and is uniquely defined.

Proof. By definition, it is clear that the generalized solution $x(\cdot)$ of (2.1) exists and is unique if and only if the same holds for the solution $y(\cdot)$ of (2.3). For any measurable bounded $w(\cdot)$, the functions f^w, g^w satisfy the hypotheses of Caratheodory's theorem. being measurable with respect to t and continuously differentiable with respect to y . Therefore, a unique local solution of (2.3) exists.

Concerning the global existence, if M_0, M_1 are constants for which

$$(2.5) \quad |h(0)| = M_0, \quad |w(t)| \leq M_1 \quad \forall t \in [0, T],$$

then the bounds (2.4), (2.5) imply

$$|h(y)| \leq M_0 + C|y|, \quad |(\exp(-w(t)h))_*| \leq e^{C|w(t)|},$$

$$|(\exp w(t)h)(y)| \leq e^{CM_1}|y| + \frac{M_0}{C}(e^{CM_1} - 1),$$

$$(2.6) \quad \begin{aligned} |f^w(t, y)| &= |(\exp(-w(t)h))_* f((\exp w(t)h)(y))| \\ &\leq e^{CM_1} \cdot C \left(1 + e^{CM_1}|y| + \frac{M_0}{C}(e^{CM_1} - 1) \right) \leq C_1(1 + |y|) \end{aligned}$$

for some constant C_1 . Similarly,

$$(2.7) \quad |g^w(t, y)| \leq C_2(1 + |y|).$$

Recalling that $v \in L^1$, the bounds (2.6) and (2.7) imply the global existence of the solution $y(\cdot)$ of (2.3), on the interval $[0, T]$.

The following approximation result justifies the notion of generalized solution introduced in Definition 2.1.

THEOREM 2.2. *Assume that the hypotheses (H) and (2.4) on the vector fields f, g, h hold, and let (v, w) be a control pair in $L^2([0, T], R) \times L^\infty([0, T], R)$, with w pointwise defined at a given $\tau \in [0, T]$ and at $t = 0$. Let $(v_n, w_n)_{n \in \mathbf{N}}$ be a sequence of control pairs in $L^2 \times W^{1,2}$, such that $\|v_n\|_{L^2} \leq L$, $V_{[0,T]}(w_n) \leq L$, for some constant L , and*

$$\begin{aligned} v_n &\rightharpoonup v \quad \text{in } L^2([0, T], R), \\ w_n &\rightarrow w \quad \text{in } L^1([0, T], R). \end{aligned}$$

Moreover, suppose that

$$w_n(0) \rightarrow w(0), \quad w_n(\tau) \rightarrow w(\tau).$$

Then the (Caratheodory) solutions x_n of (2.1) corresponding to the control pairs (v_n, w_n) satisfy

$$(2.8) \quad \begin{aligned} x_n &\rightarrow x \quad \text{in } L^1([0, T], R^n), \\ x_n(\tau) &\rightarrow x(\tau), \end{aligned}$$

where $x(\cdot)$ denotes the generalized solution of (2.1) corresponding to (v, w) , pointwise defined at $t = \tau$ and $t = 0$.

Proof. In order to prove (2.8) it will be shown that from every subsequence $(x_{n'})_{n' \geq 1}$ of $(x_n)_{n \geq 1}$ one can extract a further subsequence $(x_\nu)_{\nu \geq 1}$ converging to x in $L^1([0, T], R^n)$ and pointwise at τ .

For every $n' \geq 1$, let $y_{n'}$ be the solution of (2.6) corresponding to the control pair $(v_{n'}, w_{n'})$. By the hypotheses on f, g, h and on v_n, w_n , the variations $V_{[0,T]}(y_{n'})$ are uniformly bounded. Hence, by Helley's theorem, there exists a subsequence $(y_\nu)_{\nu \geq 1}$ converging to a map y_∞ pointwise on $[0, T]$. By possibly extracting a further subsequence, we can also assume $w_\nu(t) \rightarrow w(t)$ for almost every t . We claim that y_∞ coincides with the solution y corresponding to the control pair (v, w) . By the uniqueness of solutions of (2.3), this can be established by showing that

$$y_\infty(t) = y_\infty(0) + \int_0^t [f^w(s, y_\infty(s)) + g^w(s, y_\infty(s))v(s)] \, ds$$

for every $t \in [0, T]$. In fact, we have

$$(2.9) \quad \begin{aligned} &\left| y_\infty(t) - y_\infty(0) - \int_0^t [f^w(s, y_\infty(s)) + g^w(s, y_\infty(s))v(s)] \, ds \right| \\ &\leq |y_\infty(t) - y_\nu(t)| + |y_\infty(0) - y_\nu(0)| + \int_0^t |f^w(s, y_\infty(s)) - f^{w_\nu}(s, y_\nu(s))| \, ds \\ &\quad + \left| \int_0^t g^w(s, y_\infty(s))[v(s) - v_\nu(s)] \, ds \right| + \int_0^t |g^w(s, y_\infty(s)) - g^{w_\nu}(s, y_\nu(s))| \cdot |v_\nu(s)| \, ds. \end{aligned}$$

For every t , as $\nu \rightarrow \infty$, the first two terms on the right-hand side of (2.9) converge to zero. By construction we have $f^{w_\nu}(s, y_\nu(s)) \rightarrow f^w(s, y_\infty(s))$ for almost every s . Hence, by the Dominated Convergence theorem, the third term on the right-hand side of (2.9) also converges to zero. The fourth term converges to zero because $g^w(\cdot, y_\infty(\cdot))$ is a bounded function, and the v_ν converge to v weakly in L^2 . Finally, the Hölder inequality

$$\begin{aligned} \int_0^t |g^w(s, y_\infty(s)) - g^{w_\nu}(s, y_\nu(s))| \cdot |v_\nu(s)| \, ds \\ \leq \|g^w(\cdot, y_\infty(\cdot)) - g^{w_\nu}(\cdot, y_\nu(\cdot))\|_{L^2} \cdot \|v_\nu\|_{L^2} \end{aligned}$$

implies that also the fifth term on the right-hand side of (2.9) converges to zero. Indeed, $\|v_\nu\|_{L^2} \leq L$, and by dominated convergence, $g^{w_\nu}(\cdot, y_\nu(\cdot)) \rightarrow g^w(\cdot, y_\infty(\cdot))$ in L^2 .

From the equality $y_\infty(t) = y(t)$ for every $t \in [0, T]$, since $w_\nu(t) \rightarrow w(t)$ almost everywhere and at $t = \tau$, we obtain that

$$x_\nu(t) = (\exp w_\nu(t)h)(y_\nu(t)) \rightarrow (\exp w(t)h)(y(t)) = x(t)$$

almost everywhere and at $t = \tau$. This implies $x_\nu \rightarrow x$ in $L^1([0, T]; \mathbb{R}^n)$, because the x_ν are uniformly bounded. Since the subsequence $(x_{n'})_{n' \geq 1}$ was arbitrary, the theorem is proved.

3. Quadratic impulses. Consider again the Cauchy problem (1.1) and, for a fixed positive constant K , define the family of controls

$$U_K = \{u \in W^{1,2}([0, T], \mathbb{R}), \quad u(0) = 0, \quad \|\dot{u}\|_{L^2} \leq \sqrt{K}\}.$$

Observe that, if the vector fields f, g, h are continuously differentiable, then for every $u \in W^{1,2}$, a local Caratheodory solution to the Cauchy problem (1.1) exists. If, in addition, the assumptions (H) and (2.4) hold, then for every $u \in U_K$, the solution of (1.1) is defined on the entire interval $[0, T]$.

Denoting by X_K the set of solutions of (1.1) corresponding to the controls of U_K , we wish to characterize the L^1 -closure of X_K . For this purpose, consider the set \tilde{U}_K formed by the control pairs (v, w) such that:

- (i) The function v lies in L^2 , with $\|v\|_{L^2}^2 \leq K$.
- (ii) $w : [0, T] \rightarrow \mathbb{R}$ is nondecreasing, with $w(0) = 0$, $w(T) \leq K$.
- (iii) For every $[a, b] \subseteq [0, T]$ we have

$$(3.1) \quad \int_a^b v^2(t) \, dt \leq w(b) - w(a).$$

According to the results of the previous section, for every $(v, w) \in \tilde{U}_K$, there exists a generalized solution of (2.1). Let us denote by \tilde{X}_K the set of the generalized solutions of (2.1) corresponding to control pairs in \tilde{U}_K . The next two theorems show that \tilde{X}_K is a compact subset of $L^1([0, T], \mathbb{R}^n)$ and coincides with the closure of X_K . In the following, we assume that the vector fields f, g, h satisfy the assumptions (H) and (2.4).

THEOREM 3.1. *Let $(u_n)_{n \geq 1}$ be a sequence in U_K , and let $x(u_n)$ be the corresponding solutions of (1.1). Then, there exists a subsequence $(u_{\nu})_{\nu \geq 1}$ such that the $x(u_\nu)$ converge to some $x \in \tilde{X}_K$ in $L^1([0, T], \mathbb{R}^n)$ and pointwise everywhere on $[0, T]$.*

THEOREM 3.2. *If $x \in \tilde{X}_K$, then there exists a sequence $(u_n)_{n \geq 1}$ in U_K such that the corresponding solutions $x(u_n)$ of (1.1) converge to x in $L^1([0, T], \mathbb{R}^n)$ and pointwise everywhere on $[0, T]$.*

Proof of Theorem 3.1. By hypothesis, the maps $v_n = \dot{u}_n$ belong to the closed ball $B[0, \sqrt{K}]$ in L^2 . Since this ball is weakly compact, there exists a subsequence $(v_{n'})_{n' \geq 1}$ such that $v_{n'} \rightharpoonup v$ for some $v \in B[0, \sqrt{K}]$.

Next, consider the sequence of nondecreasing functions $w_{n'} : [0, T] \mapsto [0, K]$, defined as

$$w_{n'}(t) = \int_0^t v_{n'}^2(s) \, ds.$$

By Helley's theorem, one can extract a further subsequence, say w_ν , such that

$$w_\nu(t) \rightarrow w(t) \quad \forall t \in [0, T]$$

for some nondecreasing function $w : [0, T] \mapsto [0, K]$, with $w(0) = 0$. We claim that the control pair (v, w) lies in \tilde{U}_K . The properties (i) and (ii) are already clear. Moreover, for every $[a, b] \subseteq [0, T]$

$$(3.2) \quad w(b) - w(a) = \lim_{\nu \rightarrow \infty} \int_a^b v_\nu^2(t) \, dt \geq \int_a^b v^2(s) \, ds,$$

because the functional $v \mapsto \|v\|_{L^2}^2$ is convex, hence weakly lower semicontinuous (see [11], Prop. III.12). This proves (iii).

Now let $x \in \tilde{X}_K$ be the solution of (2.1) corresponding to the control pair $(v, w) \in \tilde{U}_K$. Observe that the solutions $x(u_\nu)$ of (1.1) satisfy

$$\begin{cases} \dot{x}_\nu = f(x_\nu) + g(x_\nu)v_\nu + h(x_\nu)\dot{w}_\nu, \\ x_\nu(0) = \bar{x}. \end{cases}$$

By Theorem 2.2, from the weak convergence $v_\nu \rightharpoonup v$, the pointwise convergence $w_\nu(t) \rightarrow w(t)$ for all $t \in [0, T]$ and the uniform boundedness of the sequence w_ν , it follows that $x_\nu(\cdot) \rightarrow x(\cdot)$ pointwise everywhere on $[0, T]$ and in $L^1([0, T]; \mathbb{R}^n)$. \square

Proof of Theorem 3.2. Define the functions

$$p(t) = \int_0^t v^2(s) \, ds, \quad \psi(t) = w(t) - p(t).$$

Observe that p, ψ are nondecreasing, with $p(0) = \psi(0) = 0$, $\psi(T) \leq w(T) \leq K$. Since ψ has bounded variation, it can have at most countably many points of discontinuity, say $\{\tau_i; i \geq 1\}$. Moreover, let $\{\xi_i; i \geq 1\}$ be any sequence of points dense on $[0, T]$. For every $n \geq 1$, consider the set

$$S_n = \{0, T\} \cup \{\tau_1, \dots, \tau_n\} \cup \{\xi_1, \dots, \xi_n\}.$$

Arrange S_n in increasing order, say

$$S_n = \{0 = t_{n,0} < t_{n,1} < \dots < t_{n,\nu_n} = T\},$$

where, of course, $\nu_n \leq 2n + 1$. For each $i \in \{1, \dots, \nu_n\}$, set

$$t_{n,i}^- = t_{n,i} - \frac{t_{n,i} - t_{n,i-1}}{n}, \quad \omega_{n,i} = \sqrt{n \cdot \frac{\psi(t_{n,i}) - \psi(t_{n,i-1})}{t_{n,i} - t_{n,i-1}}}$$

and define the functions

$$\begin{aligned} v_n(t) &= \begin{cases} 0 & \text{if } t \in [t_{n,i}^-, t_{n,i}] \text{ for some } i, \\ v(t) & \text{otherwise,} \end{cases} \\ \psi_n(t) &= \begin{cases} \omega_{n,i} & \text{if } t \in [t_{n,i}^-, t_{n,i}] \text{ for some } i, \\ 0 & \text{otherwise,} \end{cases} \\ u_n(t) &= \int_0^t [v_n(s) + \psi_n(s)] \, ds, \\ w_n(t) &= \int_0^t \dot{u}_n^2(s) \, ds. \end{aligned}$$

Observe that the above definitions imply

$$\begin{aligned} v_n(t)\psi_n(t) &= 0, \quad \dot{u}_n^2(t) = v_n^2(t) + \psi_n^2(t) \quad \forall t \in [0, T]. \\ \int_{t_{n,i-1}}^{t_{n,i}} \psi_n^2(t) \, dt &= \psi(t_{n,i}) - \psi(t_{n,i-1}) \quad \forall i \in \{1, \dots, \nu_n\}. \end{aligned}$$

By construction, the solution $x(u_n)$ then solves

$$\dot{x} = f(x) + g(x)(v_n + \psi_n) + h(x)\dot{w}_n.$$

In order to apply Theorem 2.2 and conclude that $x(u_n) \rightarrow x$ pointwise everywhere on $[0, T]$, we need to show that

$$(3.3) \quad v_n + \psi_n \rightharpoonup v \quad \text{in } L^2,$$

$$(3.4) \quad w_n(t) \rightarrow w(t) \quad \forall t \in [0, T].$$

Observing that $0 \leq v_n^2 \leq v^2 \in L^1$ and that

$$\text{meas} \left(\bigcup_{i=1}^{\nu_n} [t_{n,i}^-, t_{n,i}] \right) = \frac{T}{n},$$

by the dominated convergence theorem we conclude that $v_n \rightarrow v$ in the L^2 norm.

To show that $\psi_n \rightarrow 0$, fix any $\phi \in L^2([0, T]; \mathbb{R})$. For any $\varepsilon > 0$, choose $\phi' \in C([0, T]; \mathbb{R})$ such that $\|\phi' - \phi\|_{L^2} \leq \varepsilon$. Then

$$\begin{aligned} \limsup_{n \rightarrow \infty} \int_0^T \psi_n \phi \, dt &\leq \limsup_{n \rightarrow \infty} \int_0^T \psi_n \phi' \, dt + \limsup_{n \rightarrow \infty} \int_0^T \psi_n (\phi' - \phi) \, dt \\ &\leq \limsup_{n \rightarrow \infty} \|\psi_n\|_{L^1} \cdot \|\phi'\|_{L^\infty} + \limsup_{n \rightarrow \infty} \|\psi_n\|_{L^2} \cdot \|\phi' - \phi\|_{L^2} \leq 0 + \sqrt{K}\varepsilon. \end{aligned}$$

Since ε was arbitrary, this proves (3.3).

To prove (3.4), consider first a point t where w is discontinuous. Then $t = \tau_\nu$ for some ν . Hence, for every $n \geq \nu$ we have

$$\int_0^t \psi_n^2(s) \, ds = \psi(t),$$

while

$$\lim_{n \rightarrow \infty} \int_0^t v_n^2(s) \, ds = \int_0^t v^2(s) \, ds.$$

Hence, (3.4) holds. The same argument can of course be applied when $t = 0$ or $t = T$.

Next, consider the case where w is continuous at t . For any $\varepsilon > 0$, choose $\xi_\mu < t < \xi_\nu$ such that

$$w(t) - \varepsilon \leq w(\xi_\mu) \leq w(\xi_\nu) \leq w(t) + \varepsilon.$$

If $n \geq \max\{\mu, \nu\}$, then

$$\int_0^{\xi_\mu} \psi_n^2(s) \, ds = \int_0^{\xi_\mu} \psi(s) \, ds, \quad \int_0^{\xi_\nu} \psi_n^2(s) \, ds = \int_0^{\xi_\nu} \psi(t) \, dt.$$

Hence,

$$\begin{aligned} w(t) - \varepsilon \leq w(\xi_\mu) &= \lim_{n \rightarrow \infty} w_n(\xi_\mu) \leq \liminf_{n \rightarrow \infty} w_n(t) \\ &\leq \limsup_{n \rightarrow \infty} w_n(t) \leq \lim_{n \rightarrow \infty} w_n(\xi_\nu) = w(\xi_\nu) \leq w(t) + \varepsilon. \end{aligned}$$

Since ε was arbitrary, (3.4) is proved in this case as well.

An application of Theorem 2.2 now implies $x(u_n)(t) \rightarrow x(t)$ for every $t \in [0, T]$, and hence, $x(u_n) \rightarrow x$ in L^1 , by dominated convergence. \square

The above results motivate the following definition.

DEFINITION 3.1. For every $K > 0$, \tilde{U}_K is called the set of U_K -generalized controls for (1.1), and \tilde{X}_K is called the set of U_K -generalized trajectories of (1.1).

By Theorems 3.1–3.2, a bounded trajectory x is a U_K -generalized solution of (1.1) if and only if x is the pointwise limit of (Caratheodory) solutions of (1.1) corresponding to controls in U_K .

In connection with the system (1.1), for any $t \in [0, T]$ and $K > 0$, we also define the reachable set $R_K(t)$ at time t , with generalized controls in \tilde{U}_K :

$$R_K(t) \doteq \{x(t); \, x \text{ is a solution of (2.1), with } (v, w) \in \tilde{U}_K\}.$$

From the previous analysis it follows

COROLLARY 3.1. Let the vector fields f, g, h satisfy the assumptions (H) and (2.4). Then, for every $\tau \in [0, T]$ and $K > 0$, the reachable set $\mathcal{R}_K(\tau)$ is compact.

Indeed, let $(\hat{x}_n)_{n \geq 1}$ be a sequence of points in $R_K(t)$. By definition, there exists $(w_n, v_n) \in \tilde{U}_K$ such that $\hat{x}_n = x(v_n, w_n)(t)$. Choose a subsequence $(v_\nu, w_\nu)_{\nu \geq 1}$ such that, for some $(v, w) \in \tilde{U}_K$, one has

$$v_\nu \rightarrow v \quad \text{and} \quad w_\nu(t) \rightarrow w(t) \quad \forall t \in [0, T].$$

This is possible because the ball $B[0, \sqrt{K}]$ in L^2 is weakly compact and because of Helly's theorem. The inequality

$$\int_a^b v^2(s) \, ds \leq w(b) - w(a)$$

is then established as in (2.4). By Theorem 2.2 we now have $x(v_\nu, w_\nu)(t) \rightarrow x(v, w)(t)$ for every t . Hence, in particular, the sequence \hat{x}_ν converges to $x(v, w)(t) \in R_K(t)$, proving that $R_K(T)$ is compact.

Remark 3.1. The above results remain true if, in place of the hypothesis (2.4), one assumes that all trajectories of (1.1) with $u \in U_K$ remain inside a fixed compact set S . Indeed, one can then replace the vector fields f, g, h with

$$\tilde{f} = f \cdot \varphi, \quad \tilde{g} = g \cdot \varphi, \quad \tilde{h} = h \cdot \varphi,$$

where φ is a C^∞ scalar function with compact support such that

$$\varphi(x) \equiv 1 \quad \text{if } x \in S.$$

Then we can apply all previous results to the system

$$\dot{x} = \tilde{f}(x) + \tilde{g}(x)\dot{u} + \tilde{h}(x)\dot{u}^2.$$

Remark 3.2. In particular, Corollary 3.1 guarantees the existence of an optimal control for a variational problem of the form

$$(3.5) \quad \min \{ \Phi(x(\tau)); \quad x \in \tilde{U}_K \},$$

where $\Phi : R^n \mapsto R$ is lower semicontinuous. Indeed, on the compact set $R_K(\tau)$, the function Φ does attain its global minimum.

4. Controls with bounded variation. By Corollary 3.1, the set $\mathcal{R}(T)$ reached at $t = T$ by the U_K -generalized solutions of (1.1) defined at $t = T$ is compact. This is no longer true if instead of a bound on the L^2 norm of \dot{u} only a bound on the total variation $V_{[0,T]}(u)$, i.e., on the L^1 norm of \dot{u} , is imposed: for example, consider the control system

$$\begin{cases} \dot{x} = \dot{u}^2 \\ x(0) = 0 \end{cases}$$

on the time interval $[0, 1]$ and the sequence $(u_n)_{n \geq 1}$ of controls defined by

$$(4.1) \quad u_n(t) = \begin{cases} nt & \text{if } t \in [0, 1/n], \\ 1 & \text{if } t \in (1/n, 1]. \end{cases}$$

For every n , one trivially has $V_{[0,T]}(u_n) = \|\dot{u}_n\|_{L^1} = 1$. On the other hand, $x_n(1) = n$ diverges to $+\infty$.

It may also happen that the trajectories of (1.1) and the variations of the controls are uniformly bounded, while the L^2 norms of the derivatives of the controls diverge to $+\infty$.

For example, consider the control system

$$(4.2) \quad \begin{cases} \dot{x} = h(x)\dot{u}^2 \\ x(0) = \bar{x} \in R^2, \end{cases}$$

where $0 < |\bar{x}| < 1$ and h is the vector field on R^2 defined by

$$h(x) = \begin{pmatrix} -x_2 + x_1(1 - x_1^2 - x_2^2) \\ +x_1 + x_2(1 - x_1^2 - x_2^2) \end{pmatrix}.$$

For a positive constant C , consider the set of admissible controls

$$(4.3) \quad U_C^1 = \{u \mid u \in W^{1,2}([0, T], R), \quad u(0) = 0 \quad V_{[0, T]}(u) = \|\dot{u}\|_1 \leq C\}.$$

It is easy to check that for every control $u \in U_C^1$ the corresponding solution of (4.2) remains inside the closed ball $B[0; 1]$. As a matter of fact, the circle of equation $x_1^2 + x_2^2 = 1$ is the ω -limit of all trajectories of h starting outside the origin. On the other hand, the controls u_n defined at (4.1) belong to U_C^1 with $C = 1$, while their L^2 norms $\|\dot{u}_n\|_2 = n$ diverge to $+\infty$.

In the case where all positive orbits of h diverge to infinity, however, any bound on the solutions of (1.1) implies that the L^2 norms of the derivatives \dot{u} are uniformly bounded as well. Precisely, we have:

THEOREM 4.1. *Assume that for every $x \in B[0; R]$ one has*

$$(4.4) \quad \lim_{t \rightarrow +\infty} |(\exp th)(x)| = \infty.$$

Fix $C > 0$ and define U as the set of all controls $u \in U_C^1$ whose corresponding trajectory of (1.1) satisfies $|x(u)(t)| \leq R$ for all t .

Then, there exists a constant K such that

$$\|\dot{u}\|_2 \leq \sqrt{K} \quad \forall u \in U.$$

COROLLARY 4.1. *Let X be the set of solutions of (1.1) corresponding to the controls belonging to U , defined as in Theorem 4.1, and let \bar{X} denote its closure in $L^1([0, T], R^n)$. If h satisfies (4.4), then*

$$\bar{X} \subset \tilde{X}_K,$$

for a suitable constant K . In particular, X is precompact in $L^1([0, T], R^n)$.

Proof of Theorem 4.1. By (4.4) and by the compactness of $B[0; R]$, there exists a $\tau > 0$ and an $\alpha \geq 1$ such that

$$(4.5) \quad R + 1 \leq |(\exp \tau h)(x)| \leq R + \alpha,$$

for every $x \in B[0; R]$.

Set

$$M_f = \max_{|x| \leq R + \alpha} |f(x)| \quad M_g = \max_{|x| \leq R + \alpha} |g(x)|$$

and let λ be the Lipschitz constant of h on $B[0; R + \alpha]$. Moreover, call N the smallest integer such that

$$(4.6) \quad e^{\lambda\tau}(TM_f + CM_g) < N.$$

We claim that

$$(4.7) \quad \|\dot{u}\|_{L^2}^2 < N\tau,$$

for every $u \in U$. Assume, on the contrary, that (4.7) does not hold for some control $u^* \in U$. Then, there exist $N + 1$ instants $0 = t_0 < t_1 < t_N \leq T$ such that

$$(4.8) \quad \int_{t_{i-1}}^{t_i} \dot{u}^{*2}(s) \, ds = \tau,$$

for every $i = 1, \dots, N$.

Denoting by $y_i : [t_{i-1}, t_i] \mapsto R^n$ the solution of the Cauchy problem

$$\begin{cases} \dot{y} = h(y)(\dot{u}^*)^2 \\ y_i(t_{i-1}) = x(u^*, t_{i-1}), \end{cases}$$

Gronwall's lemma yields

$$(4.9) \quad |x(u^*, t_i) - y_i(t_i)| \leq e^{\lambda\tau} \int_{t_{i-1}}^{t_i} |p(t)| dt,$$

for every $i = 1, \dots, N$, where

$$p(t) = f(x(u^*, t)) + g(x(u^*, t))\dot{u}^*(t).$$

Since $x(u^*, t) < R$ for every t , from (4.5), (4.7), and (4.9) we obtain

$$\int_{t_{i-1}}^{t_i} |p(t)| dt \geq e^{-\lambda\tau} |x(u^*, t_i) - y_i(t_i)| \geq e^{-\lambda\tau},$$

for every $i = 1, \dots, N$. Hence, we have

$$TM_f + CM_g \geq \int_0^T |p(t)| dt = \sum_{i=1}^N \int_{t_{i-1}}^{t_i} |p(t)| dt \geq Ne^{-\lambda\tau}.$$

This contradicts the inequality (4.6), proving the theorem with $K = N\tau$. \square

5. An application to Lagrangian mechanics. The study of equations of the form (1.1) is primarily motivated by applications (see [6]–[10], [14], [15]) to Lagrangian systems in classical mechanics. In fact, given a Lagrangian system Σ , locally parametrized by coordinates (q_i, u_α) , one can superimpose new time-dependent (holonomic) constraints by assigning the motion $u_\alpha(\cdot)$ of the last M coordinates u_α —the latter to be thought as controls. The right-hand sides of the resulting equations for the coordinates q_i and their conjugate momenta p_i contain the derivative \dot{u}_α of the controls. Typically, this functional dependence on the \dot{u}_α is quadratic, because of the Riemannian structure yielded by the kinetic energy on the state-space. In certain cases, however, it is possible to choose coordinates (q_i, u_α) (M -fit coordinates), which guarantee that the u_α appear only linearly in the equations for the q_i and the p_i (see, e.g., [8], [14], [15]). Because of the lack of an analytical theory for the quadratic case, all previous applications were confined to systems for which this special choice of the coordinates is possible ([6]–[10]).

In this section, we present an example concerning a simple Lagrangian system Σ , where the right-hand side of the dynamical equations depends on the square of the derivative of the control, regardless of the choice of the local coordinates (q_i, u_α) . In particular, we shall use some results of the previous sections to study an optimal control problem for the system Σ .

Let us consider a mechanical system Σ formed by a mass concentrated at a point P , sliding without friction along a rectilinear guide, which rotates on a vertical plane

FIG. 1. *Pendulum with variable length.*

around a fixed point O . Let q denote the distance $|P-O|$ and let u measure (clockwise) the angle formed by the ascending vertical and the segment $P-O$ (see Fig. 1).

If the active forces acting on the particle P reduce to the gravitational force, then, up to a rescaling of the physical quantities, the motion of P is governed by the following differential equations:

$$(5.1) \quad \begin{cases} \dot{q} = p \\ \dot{p} = -\cos u + q\dot{u}^2. \end{cases}$$

Let the initial conditions for q, p and u be given by

$$(5.2) \quad \begin{cases} q(0) = q_0 \\ p(0) = p_0 \\ u(0) = 0. \end{cases}$$

In connection with the control system (5.1)–(5.2), consider the optimization problem

$$(5.3) \quad \inf \left\{ \int_0^T [p^2(t) + (q(t) - \bar{q})^2] ds, \quad u \in \mathcal{U}_K \right\},$$

where

$$\mathcal{U}_K = \{u | u \in W^{1,2}([0, T], R), \quad \|\dot{u}\|_{L^2}^2 \leq K\}.$$

In (5.2) and (5.3), we assume $q_0, \bar{q} > 0$, $p_0 \in R$. Observe that the inequality $\|\dot{u}\|_2^2 \leq K$ can be thought as an a priori bound on the time average of the *kinetic energy of the guide*.

In order to apply the results of the previous sections to our problem, let us introduce the variables x_1, x_2, x_3, x_4 by setting

$$x_1 = q, \quad x_2 = p, \quad x_3 = u, \quad x_4 = \int_0^t [(x_2(s))^2 + (x_1(s) - \bar{q})^2] ds.$$

Then the system (5.1)–(5.2) is replaced by

$$(5.4) \quad \begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -\cos x_3 + x_1 \dot{u}^2 \\ \dot{x}_3 = \dot{u} \\ \dot{x}_4 = (x_2)^2 + (x_1 - \bar{q})^2 \\ (x_1, x_2, x_3, x_4)(0) = (q_0, p_0, 0, 0), \end{cases}$$

and our variational problem can be written as

$$(\mathcal{P}) \quad \min\{x_4(T), \quad u \in \mathcal{U}_K\},$$

with $U_K \subset W^{1,2}$ as in §3. On the basis of the results of the previous sections we can associate to (5.4) the impulsive system

$$(5.5) \quad \begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -\cos x_3 + x_1 \dot{w} \\ \dot{x}_3 = v \\ \dot{x}_4 = (x_2)^2 + (x_1 - \bar{q})^2 \\ (x_1, x_2, x_3, x_4)(0) = (\bar{q}, \bar{p}, 0, 0), \end{cases}$$

where $(v, w) \in \tilde{U}_K$, also defined in §3.

By the compactness of the set reachable by solutions of (5.5) (see Cor. 3.1), for any $K > 0$ we obtain the existence of an optimal control pair for the extended problem

$$(\mathcal{P}') \quad \min \{x_4(T), \quad (v, w) \in \tilde{U}_K\},$$

where now $x_4(\cdot)$ denotes the fourth component of the solution of (5.5). In order to explicitly compute the optimal solution, when K is sufficiently large, we first write the Euler necessary conditions for the variational problem

$$(5.6) \quad \min \int_0^T [(q(t) - \bar{q})^2 + \dot{q}^2(t)] dt, \quad q(0) = q_0.$$

Solving the two-point boundary value problem

$$\ddot{q}(t) = q(t) - \bar{q}, \quad q(0) = q_0, \quad \dot{q}(T) = 0,$$

one finds the unique optimal solution of (5.6)

$$(5.7) \quad q(t) = \bar{q} + \left(\frac{q_0 - \bar{q}}{\cosh(T)} \right) \cosh(t - T).$$

Therefore, if K is sufficiently large and

$$(5.8) \quad \dot{q}(0+) = \left(\frac{q_0 - \bar{q}}{\cosh(T)} \right) \sinh(-T) \geq p_0,$$

then the trajectory

$$(5.9) \quad (x_1, x_2, x_3, x_4)(t) = \left(q(t), \dot{q}(t), 0, \int_0^t [(q(s) - \bar{q})^2 + \dot{q}^2(s)] ds \right)$$

is an optimal one for the generalized system (5.5).

This trajectory corresponds to the control pair (v, w) , with $v(t) \equiv 0$, $w(0) = 0$ and

$$(5.10) \quad w(t) = \frac{\dot{q}(0+) - p_0}{q_0} + \int_0^t \frac{1 + \ddot{q}(s)}{q(s)} ds \quad \forall t > 0.$$

FIG. 2. The optimal trajectories $q(t)$ and $p(t) [= \dot{q}(t)]$.

More precisely, (5.9) yields an optimal trajectory in the class \tilde{X}_K provided that (5.8) holds together with the bounds

$$(5.11) \quad \dot{\omega}(t) \geq 0 \quad \forall t > 0$$

and

$$w(T) = \frac{\dot{q}(0+) - p_0}{p_0} + \int_0^T \frac{1 + \ddot{q}(s)}{q(s)} ds \leq K.$$

For instance, (5.11) is automatically satisfied when $q_0 > \bar{q}$ (see Fig. 2).

We remark that, if (5.8) fails, then (5.9) is no longer an admissible trajectory of (5.5). This happens because the centrifugal force $x_1 \dot{w} = x_1 \dot{u}^2$ can only assume nonnegative values. Hence, a jump in w can take \dot{q} from p_0 to the optimal initial value $\dot{q}(0+)$ only when (5.8) holds.

Observe that, whenever the inequality in (5.8) is strict, no optimal control can exist for the original problem (\mathcal{P}) . Indeed, for every control $u \in W^{1,2}$, the corresponding solution $q = q(u)$ of (5.1) has an absolutely continuous derivative, satisfying

$$\lim_{t \rightarrow 0+} \dot{q}(t) = p_0,$$

hence, it cannot coincide with the unique optimal solution of (5.6).

On the other hand, if $\dot{q}(0+) = p_0$, then several optimal controls exist for the original problem (\mathcal{P}) . To construct such controls, define the function $\dot{q}(\cdot)$ as in (5.7) and let u be a solution to the multivalued differential equation

$$\dot{u}(t) = \pm \sqrt{\frac{\dot{q}(t) + \cos u}{q(t)}}, \quad u(0) = 0,$$

defined on $[0, T]$. The corresponding trajectory of (5.4) then satisfies

$$(x_1, x_2, x_3, x_4)(t) = \left(q(t), \dot{q}(t), u(t), \int_0^t [(q(s) - \bar{q})^2 + \dot{q}^2(s)] ds \right),$$

and therefore, is optimal.

IDENTIFICATION OF THE COEFFICIENT IN ELLIPTIC EQUATIONS*

ROBERT ACAR[†]

Abstract. This paper seeks to identify the space-distributed diffusion coefficient a in the steady-state diffusion equation $-\operatorname{div}(a \operatorname{grad} u) = f$ in a bounded region of the real plane; u , f , and the flux at the boundary are observed. This problem is solved by a least square method, choosing for the cost function the “equation error” defined in a natural way by the Riesz representation theorem. The method is stable if a smoothing term is added to the cost function (Tikhonov regularisation); this paper shows that selection strategies of the smoothing coefficient exist that insure convergence under the only condition that a be sufficiently smooth. The case is also considered where a is piecewise smooth and it is shown how to extend the previous formulation. In both cases computational results are presented.

1. Introduction. The steady-state diffusion equation in a transmissive two-dimensional medium, using a familiar notation, is

$$(1) \quad -\nabla(a(x) \nabla u(x)) = f(x).$$

This holds in a domain Ω of the plane; $a(x)$ is the permeability coefficient, $u(x)$ the fluid potential, and f the sink distribution. We seek to solve the problem: *Given observations of f and ∇u , and some additional information involving a , determine the permeability $a(x)$.* This problem, as well as the one arising from the time-dependent diffusion equation, has been studied extensively:

$$(2) \quad c(x) \frac{\partial u}{\partial t} - \nabla(a \nabla u) = f(t, x).$$

Indeed, (2) models groundwater flow, with a being the space-distributed permeability and u the piezometric head. The domain is then three-dimensional, but in most situations the permeability varies very slowly, or not at all, with depth, so that (assuming that sinks are placed vertically) the flow may be viewed as two dimensional.

Since the medium is transmissive everywhere, there holds $a(x) \geq c_0 > 0$ (even though we may not know c_0 a priori). As an equation in u , (1) is then seen to be elliptic. The *forward problem* is regular in the sense that small variations of a in L^∞ induce small variations of u in H^1 . However, since we are interested in the *inverse problem* (that of recovering a from ∇u), we need to know that large variations in a induce large variations in ∇u (so that small variations in ∇u could only be caused by small variations in a , boding well for the sensitivity of the measurements ∇u). Unfortunately, this is not the case; we can find examples of sequences (a_n) that remain

*Received by the editors January 16, 1989; accepted for publication (in revised form) April 3, 1992.

uniformly distant from a certain a_0 in the L^∞ norm, and yet such that the gradient ∇u_n of the corresponding solution tends to ∇u_0 in L^2 . This says that the inverse problem is ill posed with respect to the above topologies. Of importance in such examples is the oscillatory behaviour of a_n in one of the variables, similar to the example in one dimension given by Murat (see [L]). These examples show that it is hopeless to try solving (1) unless we assume that the oscillations in a remain bounded; in other words, a successful numerical scheme producing iterates that have a limit in L^∞ must enforce some “compactification” which, in effect, penalises any oscillatory behaviour.

There have been two main thrusts in attacking the inverse problem. The first thrust reformulates the problem as an optimisation problem and relies on some iterative procedure to solve it. The second thrust uses the observation that (1) or (2) is a hyperbolic first-order partial differential equation (PDE) in a and uses direct methods to solve it. Although the first methods may have some smoothing embedded in them, direct methods are more vulnerable to the illposedness and must include some auxiliary smoothing device.

In [R1], Richter uses a direct method to solve the steady-state identification problem (using data on a on the inflow boundary). Making some assumptions on u (such as $\inf_\Omega \max(|\nabla u|, \Delta u) > 0$), he derives a continuous dependence result on the hyperbolic problem, and formulates favorable “test conditions” of u (i.e., for which no Cauchy data is needed on a). In [R2], Richter applies the previous ideas to the discretised case, using a finite-difference scheme explicit upwind along the characteristics (that happen to be the curves of steepest ascent of u); the previous estimates on $|a|_\infty$ are carried over to the discrete setup. Falk ([F]) minimises an observation error criterion $J(u, a)$ given an observation z on u ; the admissible u ’s obey a Neumann condition, and are normalised so that $\int_\Omega (u - z) = 0$. u is computed from a by writing (1) in weak form (see §2). Then under assumptions of smoothness of u , and of the boundary piece where $\partial u / \partial n > 0$, and an assumption on the field ∇u (its direction is contained in a proper cone), Falk is able to estimate the L^2 -norm of the error in a in terms of the L^2 -norm of the error in u (and of the size of the grid). Kravaris and Seinfeld ([KS]) seek to minimise a similar cost function, and they add a smoothing term that includes the H^2 -norm of a (Tikhonov regularisation) to insure convergence and stability; they show how this may be applied to coefficient identification in a class of second-order linear parabolic systems. Hoffman and Sprekels ([HS]) solve the problem by embedding it in a family of time-dependent parabolic equations and regarding it as the steady-state limit. In [A], Alessandrini examines the identification problem with boundary data on a , and establishes convergence of an elliptic regularisation (singular perturbation) algorithm under regularity hypotheses in a with a stability result with respect to the u data. Chicone and Gerlach ([CG]) define pointwise uniqueness of $a(x)$, and characterise the region of uniqueness in terms of “nonwandering” sets of the dynamical system associated with the gradient field of u . Closest to the spirit of the present work, Kohn and Lowe ([KL]) investigate methods that handle different aspects of the equation error, some including a regularising term. By choosing weights related to the mesh size, they obtain convergence rates under the assumption that $\|u^m - u_*\|$ is $O(h^\alpha)$ where $\alpha > 1$, u_* is the true pressure u^m is the measured pressure, and h the mesh size.

Without making any claim to completeness, let us also mention [Kr], [JJ], [J], [EdM], [FP], [CDL], [Kl], [LY], [P], [CS], [BK2], [S], [Ne], [SYD], [Nu], [CY] and [YT]. For other references as well as a comprehensive discussion of the background of this problem, see [BK1].

An inherent difficulty with direct methods is the choice of the piece of the bound-

ary where we specify a . Since information is carried along the streamlines, we must specify a on a piece of the boundary where each streamline is intersected exactly once. This choice depends, in turn, on the geometry of the streamlines, which is sensitive to reading errors in ∇u . The advantage of methods which rely on error minimisation is that they easily lend themselves to overdeterminacy of the data, such as observing a all around the boundary of the domain.

We describe how to carry out the identification of a in (1) by a least square method. We cope with the illposedness of a by adding a smoothing term and assuming that a is sufficiently smooth. In §2, we derive the convergence and stability results for the equation error method. In §3, we discuss the numerical solution and present results. In §4, we show how the method can be extended to the case where a is discontinuous along fracture lines in the domain, and give computational results as well.

2. The equation error method.

2.1. Existence. If we are to solve the inverse problem (viewed as a first-order PDE in a) exactly, assuming that we have no data on a in the interior of Ω , we need to know a on the boundary. We assume in this section that a is continuous.

∇u determines the geometry of characteristics in Ω , which in turn determines whether a portion of the boundary is suitable for specifying a . Since we do not quite know which portion of Γ is a good portion to chose (not exactly knowing ∇u), we assume that we observe the flux $a(\partial u)/(\partial n)$ throughout the boundary Γ , say, $a(\partial u)/(\partial n) = g$.

Denoting $H^1(\Omega)$ by V , we may then rewrite (1) in variational form

$$(3) \quad \forall \phi \in V, \quad \int_{\Omega} a \nabla u \nabla \phi = \langle f, \phi \rangle_{V', V} + \int_{\Gamma} g \phi.$$

We see that if we take this as the effective interpretation of (1), we only need a to be in L^∞ ; so the assumption that a is continuous is sufficient.

This problem has no solution unless g is “consistent” (i.e., the whole of it consistent with any part construed as Cauchy data). This may again be asking for too much, since there are errors in observing g . We avoid this by trying to make the “equation error”

$$- \int_{\Omega} a \nabla u \nabla \phi + \langle f, \phi \rangle_{V', V} + \int_{\Gamma} g \phi$$

small, in the following sense: Note that

$$\phi \mapsto - \int_{\Omega} a \nabla u \nabla \phi + \langle f, \phi \rangle_{V', V} + \int_{\Gamma} g \phi$$

is a linear functional, continuous over V (using Cauchy–Schwarz for the first term, and continuity of the 0-trace from $H^1(\Omega)$ into $L^2(\Gamma)$ for the third term), so by the Riesz representation theorem, then

$$(4) \quad \exists v \in V: \quad \langle v, \phi \rangle_V \equiv - \int_{\Omega} a \nabla u \nabla \phi + \langle f, \phi \rangle_{V', V} + \int_{\Gamma} g \phi.$$

Then putting $J_e(a) = |v(\nabla u, a)|_V^2$, the problem at hand is to minimise $J_e(a)$.

Noting that $v(\nabla u, a)$ is an affine function of a , we see that $J_e(a)$ is convex. Furthermore, if $v(a)$ is injective, then $J_e(a)$ is strictly convex, and a minimising it

would be unique, as long as the domain of a is convex. When a is continuous, a sufficient condition that v be injective is that ∇u be zero at most on a set of measure zero: indeed, if v_1 and v_2 correspond to a_1 and a_2 , then $\langle v_2 - v_1, \phi \rangle = -\int (a_2 - a_1) \nabla u \nabla \phi$ for all ϕ in V , and if $a_2 - a_1 \neq 0$ in C^0 , then $a_2 - a_1 \neq 0$ on an open set, and the same holds for $(a_2 - a_1) \nabla u$, so choosing $\phi = u$ shows that $v_2 - v_1 \neq 0$.

But the problem of minimising J_e for a , say, in L^2 or C^0 , is not stable: *L^2 -small perturbations in ∇u may produce large perturbations in a .*

2.2. Stability. To make the minimisation problem stable, we need to introduce some compactification in a . One way to do this is to impose a priori bounds on a , as many have done in the case of the observation error method. Another useful device, which is the one we use, is *Tikhonov regularisation* (introduced by Tikhonov in conjunction with the solution of Fredholm integral equations of the first kind; see [Ti1] and [Ti2]). It consists of adding a smoothing term (the norm of a in a sufficiently high Sobolev space) to the cost function.

Hence we set to minimise the smoothed cost function

$$\begin{aligned} J_\lambda(\nabla u, a) &= |v(\nabla u, a)|_V^2 + \lambda |a|_{\mathcal{R}}^2, \\ &=: J_e(\nabla u, a) + \lambda J_s(a). \end{aligned}$$

Among the Sobolev spaces $W^{n,2}$ (i.e., with derivatives up to order n in L^2) embedded in $C^0(\Omega)$, $W^{2,2}$ (also denoted H^2) is the one of lowest order. Therefore, take the set of admissible a 's to be \mathcal{R} , where

$$\mathcal{R} = \{ a \in H^2(\Omega) : a \frac{\partial u}{\partial n} = g \text{ on } \Gamma \}.$$

This choice insures the existence of a global minimum of $J_\lambda(\nabla u, \cdot)$. Indeed, if $m = \inf \{ J_\lambda(\nabla u, a) : a \in \mathcal{R} \}$, there exists (a_n) in $\mathcal{R} : \lim \downarrow J_\lambda(\nabla u, a_n) = m$. Since $J_\lambda(\nabla u, a_n)$ decreases, the sequence (a_n) remains bounded in \mathcal{R}

$$\begin{aligned} \forall n, \quad |a_n|_{\mathcal{R}}^2 &\leq \frac{1}{\lambda} J_\lambda(\nabla u, a_n), \\ &\leq \frac{1}{\lambda} J_\lambda(\nabla u, a_1). \end{aligned}$$

Then there is a subsequence $(a_{n,k})$ weakly converging to some $\bar{a} \in \mathcal{R}$, and convergence also holds in the C^0 norm. It follows then that \bar{a} yields the global minimum of $J_\lambda(\nabla u, \cdot)$ from the following two facts: (i) $a \mapsto |a|_{\mathcal{R}}^2$ is weakly lower semicontinuous, and (ii) $a \mapsto |v(\nabla u, a)|_V^2$ is continuous. Indeed, a perturbation δa of a corresponds to the perturbation δv solving

$$\forall \phi \in V, \quad \langle \delta v, \phi \rangle_V = - \int \delta a \nabla u \nabla \phi,$$

so that

$$\begin{aligned} |\langle \delta v, \phi \rangle_V| &\leq |\delta a|_\infty |\nabla u|_{L^2} |\nabla \phi|_{L^2}, \\ &\leq |\delta a|_\infty |\nabla u|_{L^2} |\phi|_V \end{aligned}$$

implying that

$$|\delta v|_V \leq |\nabla u|_{L^2} |\delta a|_\infty,$$

and then,

$$\delta J_e = 2 \langle v, \delta v \rangle_V + |\delta v|_V^2,$$

implying that

$$|\delta J_e| \leq 2|v(\nabla u, a)|_V \cdot |\delta v|_V + |\delta v|_V^2,$$

so $|\delta J_e|$ is, in turn, bounded in terms of $|\delta a|_\infty$.

Also, \bar{a} is unique by strict convexity of $J_\lambda(\nabla u, \cdot)$ (J_e is convex, and the \mathcal{R} -norm is strictly convex). We denote the global minimum of $J_\lambda(\nabla u, \cdot)$ by a_λ .

Note that we did not require a in \mathcal{R} to be bounded away from zero; this is justified by the next theorem, where, for ε small enough, a_λ will be bounded away from zero if a_* is also bounded away.

THEOREM 1 (Stability). *Assume that (u_*, a_*) is a solution pair of (3) (so that $v(\nabla u_*, a_*) = 0$), and that $v(\nabla u_*, \cdot)$ is injective (say, $\nabla u_* = 0$ at most on a set of measure 0). Then*

$$\begin{aligned} \forall \varepsilon > 0, \quad \exists \delta_0 > 0 : \quad \forall \delta \leq \delta_0, \quad \forall \lambda \in [l(\delta), r(\delta)], \\ |\nabla u - \nabla u_*|_{L^2} \leq \delta \quad \Rightarrow \quad |a_\lambda - a_*|_\infty \leq \varepsilon, \end{aligned}$$

where l, r are functions satisfying

- (i) $\exists C > 0 : \quad \delta^2 \leq Cl(\delta),$
- (ii) $r(\delta) > l(\delta),$ and $\lim r(\delta) = 0$ as $\delta \rightarrow 0$.

(Recall from a previous observation that a_* is then unique.) The theorem states that a_λ converges to a_* as λ and the error on ∇u_* go to zero, but they cannot be arbitrarily made small; (i) states that λ should not converge to zero faster than the square of δ , otherwise we lose our grip on a_λ . The proof uses the following observations.

Remark 1. For all admissible a , $|v(\nabla u, a) - v(\nabla w, a)|_V \leq |a|_\infty |\nabla u - \nabla w|_{L^2}$. Indeed, for all $\phi \in V$,

$$\langle v, \phi \rangle_V = - \int a (\nabla u - \nabla w) \nabla \phi.$$

Remark 2. If $|\nabla u - \nabla u_*|_{L^2} \leq \delta \leq \delta_0$ and $\lambda \in [l(\delta), r(\delta)]$ (where $l(\delta), r(\delta)$ are as above), then a_λ stays uniformly bounded in \mathcal{R} :

$$\begin{aligned} \lambda |a_\lambda|_{\mathcal{R}}^2 &\leq J_\lambda(\nabla u, a_\lambda) \\ &\leq J_\lambda(\nabla u, a_*) \\ &= |v(\nabla u, a_*)|_V^2 + \lambda |a_*|_{\mathcal{R}}^2 \\ &\leq |a_*|_\infty^2 \delta^2 + \lambda |a_*|_{\mathcal{R}}^2 \\ &\leq |a_*|_\infty^2 C \lambda + \lambda |a_*|_{\mathcal{R}}^2; \end{aligned}$$

(this is where we needed (i))

$$\Rightarrow |a_\lambda|_{\mathcal{R}}^2 \leq C |a_*|_\infty^2 + |a_*|_{\mathcal{R}}^2.$$

Proof of Theorem 1. Let us assume that the claim is not true. Then

$$\begin{aligned} \exists \varepsilon > 0 : \quad \forall n, \quad \exists \delta_n \leq 1/n, \quad \exists \lambda_n \in [l(\delta_n), r(\delta_n)], \quad \exists u_n : \\ |\nabla u_n - \nabla u_*| \leq \delta_n \quad \&\quad |a_{\lambda_n} - a_*|_\infty > \varepsilon. \end{aligned}$$

By Remark 2, $a_{\lambda_n} \rightharpoonup \tilde{a}$ (weakly in \mathcal{R}) along a subset \mathbb{M} of \mathbb{N} , implying that $a_{\lambda_n} \rightarrow \tilde{a}$ in C^0 . For any λ_n , denoting a_{λ_n} by a_n for short,

$$|v(\nabla u_*, a_n)|_V \leq |v(\nabla u_n, a_n)|_V + |v(\nabla u_*, a_n) - v(\nabla u_n, a_n)|_V.$$

By Remark 1, the second term is smaller than $|a_n|_\infty \delta_n$, and $|a_n|_\infty$ remains bounded by Remark 2. For the first term,

$$\begin{aligned} |v(\nabla u_n, a_n)|_V^2 &\leq J_{\lambda_n}(\nabla u_n, a_n) \\ &\leq J_{\lambda_n}(\nabla u_n, a_*) \\ &\leq |a_*|_\infty^2 \delta_n^2 + \lambda_n |a_*|_{\mathcal{R}}^2, \end{aligned}$$

so that $\lim |v(\nabla u_*, a_n)|_V = 0$ as $n \rightarrow \infty$, $n \in \mathbb{M}$, contradicting $\lim |v(\nabla u_*, a_n)|_V = |v(\nabla u_*, \tilde{a})|_V \neq 0$, since $\tilde{a} \neq a_*$.

2.3. Parameter selection strategies. For Theorem 1 to be fully relevant, it should allow us to prescribe rules for choosing the smoothing coefficient λ , given a bound on the error $|\nabla u - \nabla u_*|_{L^2}$ and possibly information on a_* . Two such rules are discussed in [KS] in the case of the observation-error method. We briefly indicate how these rules also be applied to the equation-error method.

One way (see, also, [Mi]) is as follows: If K is a known upper bound on $|a_*|_\infty$, E on $|a_*|_{\mathcal{R}}$, and δ on $|\nabla u - \nabla u_*|_{L^2}$, then choose $l(\delta)$ and $r(\delta)$ proportional to $K^2\delta^2/E^2$.

Indeed, if, say,

$$l(\delta) = \gamma K^2 \delta^2 / E^2, \quad r(\delta) = \Gamma K^2 \delta^2 / E^2,$$

then (i) and (ii) of Theorem 1 hold, and

$$\begin{aligned} J_\lambda(\nabla u, a_\lambda) &\leq J_\lambda(\nabla u, a_*) \\ &\leq |a_*|_\infty^2 \delta^2 + \lambda |a_*|_{\mathcal{R}}^2 \\ &\leq K^2 \delta^2 + \Gamma K^2 \delta^2, \end{aligned}$$

so that

$$|v(\nabla u, a_\lambda)|_V \leq \sqrt{1 + \Gamma} K \delta$$

and

$$|a_\lambda|_{\mathcal{R}} \leq \sqrt{\frac{1 + \Gamma}{\gamma}} E.$$

To choose γ and Γ , keeping in mind that the a priori bounds on $|v(\nabla u, a_*)|_V$ and $|a_\lambda|_{\mathcal{R}}$ are $K\delta$ and E , we may ask that the larger of the factors $\sqrt{1 + \Gamma}$ and $\sqrt{\frac{1 + \Gamma}{\gamma}}$ be as small as possible; i.e., solve

$$\text{minimise } \left\{ \max \left(\sqrt{1 + \Gamma}, \sqrt{\frac{1 + \Gamma}{\gamma}} \right) : 0 < \gamma < \Gamma \right\}.$$

The solution is easily seen to be $\gamma = \Gamma = 1$, which is Miller's choice [Mi].

Another method of choosing λ , suggested by Tikhonov and Arsenin [TA], is this: if $\sqrt{\delta}$ is a bound on $|\nabla u - \nabla u_*|_{L^2}$, choose λ such that the corresponding a_λ satisfies

$$|v(\nabla u, a_\lambda)|_V^2 = \delta.$$

It will follow that $\lim |a_\lambda - a_*|_\infty = 0$ as $\delta \rightarrow 0$; first, we must show the existence of such a λ .

Some notation is given as follows:

$$\begin{aligned} J_\lambda(\nabla u, a) &:= |v(\nabla u, a)|_V^2 + \lambda |a|_{\mathcal{R}}^2 = J_e(\nabla u, a) + \lambda J_s(a); \\ a_{\min} &:= \text{the min-norm element of } \mathcal{R}; \\ \delta_{\max} &:= J_e(\nabla u, a_{\min}); \\ \delta_{\min} &:= \inf \{ J_e(a) : a \in \mathcal{R} \}. \end{aligned}$$

(a) Given ∇u and the corresponding δ_{\min} and δ_{\max} , then if $\delta_{\min} < \delta < \delta_{\max}$, there exists λ such that the minimiser a_λ of $J_\lambda(\nabla u, a)$ over \mathcal{R} satisfies $J_e(a_\lambda) = \delta$. We sketch the following proof.

(i) The map $\lambda \mapsto a_\lambda$ is continuous for $\lambda > 0$: if $\lambda \leq \mu$, it is easily seen that $J_S(a_\lambda) \geq J(a_\mu)$ and that $J_e(a_\lambda) \leq J_e(a_\mu)$. We may then write

$$\begin{aligned} J_e(a_\lambda) + \lambda J_S(a_\lambda) &\leq J_e(a_\mu) + \lambda J_S(a_\mu) \\ &\leq J_e(a_\mu) + \mu J_S(a_\mu) \\ &\leq J_e(a_\lambda) + \mu J_S(a_\lambda). \end{aligned}$$

Assume for now that λ is fixed and μ approaches λ from above; then $J_\lambda(a_\mu) - J_\lambda(a_\lambda) \leq J_\mu(a_\lambda) - J_\lambda(a_\lambda)$. Since J_λ has bounded lower level sets, we see that a_μ is bounded in \mathcal{R} , and weakly converges to a_λ . The case where μ is fixed and λ approaches μ from below is similar.

(ii) For some value of λ , $J_\lambda(a_\lambda) < \delta$: choose indeed λ such that $J_\lambda(a_0) < \delta$, where $J_e(a_0) = \delta_{\min}$.

(iii) $\lim_{\lambda \rightarrow \infty} J_\lambda(a_\lambda) = \delta_{\max}$: since $|a_\lambda|_{\mathcal{R}}^2 \leq (J_S + \frac{1}{\lambda} J_e)(a_\lambda) \leq (J_S + \frac{1}{\lambda} J_e)(a_{\min})$, $|a_\lambda|_{\mathcal{R}}^2$ will be bounded for $\lambda \geq 1$. So $J_e(a_\lambda)$ stays bounded since J_e is weakly continuous, and any weakly convergent subsequence (as $\lambda \rightarrow \infty$) must have a_{\min} as limit: if $a_\lambda \rightharpoonup \bar{a}$, then $J_S(a_{\min}) \geq \liminf J_S(a_\lambda) \geq J_S(\bar{a})$ since $(J_S + \frac{1}{\lambda} J_e)(a_{\min}) \geq (J_S + \frac{1}{\lambda} J_e)(a_\lambda)$.

We conclude by the intermediate value theorem.

(b) For λ such as in (a), a_λ yields the minimum of J_S over $\{J_e \leq \delta\}$. Indeed, if $J_e(a) \leq \delta$ and $J_S(a) \leq J_S(a_\lambda)$, then $(J_e + \lambda J_S)(a) \leq \delta + \lambda J_S(a_\lambda) = (J_e + \lambda J_S)(a_\lambda)$, implying that $a = a_\lambda$.

The following convergence theorem then justifies using the Tikhonov parameter selection rule.

THEOREM 2. Assume that $\exists! a_* \in \mathcal{R} : v(\nabla u_*, a_*) = 0$. Then

$$\begin{aligned} \forall \varepsilon > 0, \quad \exists \delta_0 > 0 : \forall \delta \leq \delta_0, \\ |\nabla u - \nabla u_*|_{L^2} < \alpha \sqrt{\delta} \implies |a_{\lambda(\delta)} - a_*|_\infty \leq \varepsilon, \end{aligned}$$

where $\alpha = 1/|a_*|_\infty$, and $\lambda(\delta)$ is a smoothing parameter given by (a) above; i.e., such that $J_e(a_{\lambda(\delta)}) = \delta$.

By the discussion above, $\lambda(\delta)$ exists, for if $|\nabla u - \nabla u_*|_{L^2} < \alpha \sqrt{\delta}$, then $\min \{J_e(\nabla u, a) : a \in \mathcal{R}\} < \delta$, because

$$\begin{aligned} J_e(\nabla u, a_*) &= |v(\nabla u, a_*)|_V^2 \\ &\leq |a_*|_\infty^2 |\nabla u - \nabla u_*|_{L^2}^2 \\ &< \delta \end{aligned}$$

(i.e., in our notation, $\delta > \delta_{\min}$). Recall also that a_* , if it exists, is unique.

Proof. Let $\tilde{A} := \{a \in \mathcal{R} : |a|_{\mathcal{R}} \leq |a_*|_{\mathcal{R}}\}$. We assume that the claim is not true, then

$$\begin{aligned} \exists \varepsilon > 0 : \quad \forall n, \quad \exists \delta_n \leq 1/n, \\ \exists u_n : \quad |\nabla u - \nabla u_*|_{L^2} \leq \alpha \sqrt{\delta_n}, \\ \exists \lambda_n, \end{aligned}$$

such that

$$\begin{aligned} |v(\nabla u_n, a_{\lambda_n})|_V^2 &= \delta_n, \\ |a_{\lambda_n} - a_*|_\infty &> \varepsilon. \end{aligned}$$

a_{λ_n} minimises J_S over $\{a \in \mathcal{R} : |v(\nabla u_n, a)|_V^2 \leq \delta_n\}$. However,

$$\begin{aligned} |v(\nabla u_n, a_*)|_V^2 &\leq |a_*|_\infty^2 |\nabla u_n - \nabla u_*|_{L^2}^2 \\ &\leq \delta_n, \end{aligned}$$

so a_* belongs to the set above; hence $J_S(a_{\lambda_n}) \leq J_S(a_*)$ implying that the a_{λ_n} all stay in \tilde{A} . So along some subsequence, $a_{\lambda_n} \rightarrow \hat{a}$ in C^0 . Then

$$|v(\nabla u_*, a_{\lambda_n})|_V \leq |v(\nabla u_n, a_{\lambda_n})|_V + |v(\nabla u_*, a_{\lambda_n}) - v(\nabla u_n, a_{\lambda_n})|_V,$$

so the left-hand side tends to zero as $n \rightarrow \infty$. But it also tends to $|v(\nabla u_*, \hat{a})|_V$, which cannot be zero since $\hat{a} \neq a_*$ ($|\hat{a} - a_*|_\infty \geq \varepsilon$). Finally, if a_1 minimises J_{λ_1} and a_2 minimises J_{λ_2} , then $\lambda_1 < \lambda_2 \Rightarrow J_e(a_{\lambda_1}) \leq J_e(a_{\lambda_2})$.

Consequence. To find $\lambda(\delta)$, use an interval-halving algorithm.

Remark 3. The question of selection strategies is of obvious theoretical interest; however, in practice, the cost of computations precludes finding the smoothing parameter that exactly satisfies the criterion. For one thing, we should not expect to have a real bound, but rather a rough estimate on the error δ . Other fairly general selection strategies and their extensions are discussed in great detail by Morozov [Mo].

3. Numerical implementation.

3.1. Procedure. We describe numerical experiments with the equation-error method. We choose a , u , and f satisfying (1); assuming u , f , and the flux data on the boundary given, compute a by the equation-error method and compare it to the real a .

We use a finite-element discretisation with an uniform rectangular grid on the square $\Omega = (-1, 1) \times (-1, 1)$. We use the same grid for the finite-element approximations of v and a . They are tensor products of C^0 (respectively, C^1) univariate splines; the latter are the first and second Hermite cubics. Their tensor products assume, respectively, one (for C^0) or four (for C^1) shapes.

Call V_h and A_h the finite-dimensional discretisations of the admissible spaces for v and a . The “degrees of freedom” are: for v^h , the value of the function; for a^h , the value of the function and of its first derivatives and mixed second derivatives at the nodes.

The discrete version of (4) is

$$(5) \quad \forall \phi^h \in V_h, \quad \langle v^h, \phi^h \rangle_V = - \int a^h \nabla u \nabla \phi^h + \langle f, \phi^h \rangle_{V', V} + \int_\Gamma g \phi^h,$$

and the discrete minimisation is over the quantity $J_\lambda^h(a^h) := J_e^h(\nabla u, a^h) + \lambda |a^h|_{\mathcal{R}}^2$ where $J_e^h(\nabla u, a^h) = |v^h(\nabla u, a^h)|_{H^1}^2$. Since this is a quadratic in a^h , we use the conjugate gradient method. The initial point is taken to be a starting guess.

3.2. Convergence. To discuss convergence of the “discrete” solution (solution of the discretised problem) to that of the continuous problem, we introduce more notation: recall that $v \in V (= H^1(\Omega))$, $a \in \mathcal{R}$. By discretising, we are replacing V and \mathcal{R} by finite-dimensional subspaces V_h and \mathcal{R}_k provided with the induced norms. For a in \mathcal{R} , $v^h(\nabla u, a)$ solves

$$\langle v^h, \phi \rangle_V = - \int a \nabla u \nabla \phi + \langle f, \phi \rangle_{V', V} + \int_\Gamma g \phi, \quad \phi \in V_h,$$

and a_λ^k solves

$$\min |v^h(\nabla u, a)|_V^2 + \lambda |a|_{\mathcal{R}}^2, \quad a \in \mathcal{R}_k.$$

A consequence is that $|v^h(\nabla u, a)|_V \leq |v(\nabla u, a)|_V$.

Theorem 1 now acquires more elaborate wording.

THEOREM 1'. *Under the hypotheses of Theorem 1, and assuming that $\bigcup_h V_h$ and $\bigcup_k \mathcal{R}_k$ are dense in V and \mathcal{R} , respectively,*

$$\begin{aligned} \forall \varepsilon > 0, \quad \exists \delta_0 > 0 : \quad \forall \delta \leq \delta_0, \quad \forall \lambda \in [l(\delta), r(\delta)], \\ \exists h_0, k_0 : \quad \forall h \leq h_0, \quad \forall k \leq k_0, \\ |\nabla u - \nabla u_*|_{L^2} \leq \delta \quad \Rightarrow \quad |a_\lambda^k - a_*|_\infty \leq \varepsilon. \end{aligned}$$

The proof relies on Remark 1 following Theorem 1, and on Remark 2 where a_λ^k replaces a_λ .

Fact. If $|\nabla u - \nabla u_*|_{L^2} \leq \delta \leq \delta_0$ and $\lambda \in [l(\delta), r(\delta)]$, then a_λ^k stays bounded in \mathcal{R} as long as $k(\lambda)$ is such that $|a_*^k - a_*|_{\mathcal{R}}^2 \leq \lambda$, where a_*^k is the projection of a_* on \mathcal{R}_k . Indeed,

$$\begin{aligned} \lambda |a_\lambda^k|_{\mathcal{R}}^2 &= J_\lambda^h(\nabla u, a_\lambda^k) \\ &\leq J_\lambda^h(\nabla u, a_*^k) \\ (6) \quad &= |v^h(\nabla u, a_*^k)|_V^2 + \lambda |a_*^k|_{\mathcal{R}}^2 \\ &\leq |v(\nabla u, a_*^k)|_V^2 + \lambda |a_*^k|_{\mathcal{R}}^2 \end{aligned}$$

(the last inequality follows from the consequence stated before Theorem 1').

To show that a_λ^k remains bounded, it is enough to bound the right-hand side of (6) by λ . Now $|a_*^k|_{\mathcal{R}} \leq |a_*|_{\mathcal{R}}$, and

$$\begin{aligned} |v(\nabla u, a_*^k)|_V &\leq |v(\nabla u, a_*^k) - v(\nabla u_*, a_*^k)|_V + |v(\nabla u_*, a_*^k) - v(\nabla u_*, a_*)|_V \\ &\leq |a_*|_\infty |\nabla u - \nabla u_*|_{L^2} + |\nabla u_*|_{L^2} |a_*^k - a_*|_{\mathcal{R}}. \end{aligned}$$

So, $|v(\nabla u, a_*^k)|_V^2$ is indeed bounded in terms of λ .

Proof of theorem. Assume otherwise that

$$\begin{aligned} \exists \varepsilon > 0 : \quad \forall n, \quad \exists \delta_n \leq 1/n, \quad \exists \lambda_n \in [l(\delta_n), r(\delta_n)], \\ \forall h_0 > 0, \quad \forall k_0 > 0, \quad \exists h_n \leq h_0, \quad \exists k_n \leq k_0 : \\ |\nabla u_n - \nabla u_*|_{L^2} \leq \delta \quad \& \quad |a_{\delta_n}^{k_n} - a_*|_{\mathcal{R}} > \varepsilon. \end{aligned}$$

Denote, for short, $a_{\lambda_n}^{k_n}$ by a_n . Taking k_0 small enough so that a_n remains bounded, we may again consider a subsequence $a_n \rightarrow \tilde{a}$ (and $a_n \rightarrow \tilde{a}$ in C^0). However,

$$v(\nabla u_n, a_n) = v^{h_n}(\nabla u_n, a_n) + v(\nabla u_n, a_n) - v^{h_n}(\nabla u_n, a_n).$$

Now

$$\begin{aligned} |v^{h_n}(\nabla u_n, a_n)|^2 &\leq J_{\lambda_n}^{h_n}(\nabla u_n, a_n) \\ &\leq |v(\nabla u_n, a_n^{k_n})|_V^2 + \lambda_n |a_n^{k_n}|_{\mathcal{R}}^2 \end{aligned}$$

(see (6)). The last quantity tends to zero as $n \rightarrow \infty$ by continuity of v and $\lim \lambda_n = 0$.

 &\quad + v(\nabla u_*, a_n) - v(\nabla u_*, \tilde{a}) \\
 &\quad + v(\nabla u_*, \tilde{a}) - v^{h_n}(\nabla u_*, \tilde{a}) \\
 &\quad + v^{h_n}(\nabla u_*, \tilde{a}) - v^{h_n}(\nabla u_*, a_n) \\
 &\quad + v^{h_n}(\nabla u_*, a_n) - v^{h_n}(\nabla u_n, a_n),
 \end{aligned}$$

and all these differences tend to zero; the third one by an appropriate choice of $h_0(\lambda_n)$. As before, this contradicts $\lim v(\nabla u_n, a_n) = v(\nabla u_*, \tilde{a}) \neq 0$.

3.3. Results. This method was tested on a few examples. For each example, we tried different values of the parameter λ and we show the corresponding equation error J_e , and the smoothing term broken down in J_1 and J_2 , contributions from the first- and second-order derivatives. We also keep track of the number of conjugate gradient iterations and the relative error ϵ (in the C^0 -norm) of the computed to the real a .

3.3.1. Example 1. In this example, let

$$\begin{aligned}
 u &= -(x + y)^2, \\
 f &\equiv 4,
 \end{aligned}$$

$$g = \begin{cases} 2(y - 1) & \text{on the left side of } \Omega, \\ 2(x - 1) & \text{at the bottom,} \\ -2(y + 1) & \text{on the right,} \\ -2(x + 1) & \text{on top,} \end{cases}$$

(so the solution is $a \equiv 1$).

We tried to see how the method behaves as the starting guess and λ vary. Figure 1 shows the result for an exact starting guess and no smoothing. Figure 2 shows that absence of smoothing may seriously affect the result if the starting guess is bad. Table 1 shows the result of runs for the same perturbed starting guess and different values of λ . Figure 3 shows the result for $\lambda = 10^{-3}$.

FIG. 2. *Perturbed starting guess. $n = 8$, $\lambda = 0.0000\text{E} + 00$.*FIG. 3. *Perturbed starting guess. $n = 8$, $\lambda = 0.1000\text{E} - 02$.*

In this example, by choice of a , $J_S(a)$ should be zero at the solution, and very small nearby. The results for $\lambda = 10^{-2}$ and 10^{-3} illustrate the numerical difficulty of giving the smoothing term too much weight:

(i) Convergence of the conjugate gradient method is very slow (202 iterations for $\lambda = 10^{-2}$);

(ii) the J_2 portion of J_S actually takes negative values.

Both are symptoms of the same phenomenon: $J_2(a)$ is a quadratic form that is not positive definite ($J_2(a) = 0$ if q is constant). Its discrete version is represented by a matrix with some eigenvalues very near 0; we performed a singular-value decomposition of it (actually, of its restriction to an element patch; but the whole matrix is obtained by patching up such matrices) and we found no negative eigenvalues, but the smallest eigenvalues are small indeed ($\simeq 10^{-15}$). When a is constant (so that all the degrees of freedom corresponding to function values are nearly constant and those corresponding to derivatives nearly zero), loss of significance occurs when evaluating J_2 , caused by canceling. This behaviour disappears when λ is made small enough, for then the solution q departs from the null variety of J_2 , less importance being given to J_2 . At any rate, a negative value for J_2 shows that the solution is nearly flat, and hence is a very good approximation since, in such cases, there is no need to refine the mesh. The only trouble comes from the ill conditioning of J_2 ; this is where it is important to reduce λ .

3.3.2. Example 2. In this example, let

$$u = -(x + y),$$

$$f = -2(x + y),$$

$$g = \begin{cases} 2 - y^2 & \text{on the left side of } \Omega, \\ 2 - x^2 & \text{at the bottom,} \\ y^2 - 2 & \text{on the right,} \\ x^2 - 2 & \text{on top,} \end{cases}$$

FIG. 4. $a = 1 + (1+x)(1-x) + (1+y)(1-y)$.

The shape of the true a , $1 + (1+x)(1-x) + (1+y)(1-y)$, is shown in Fig. 4. Here again, we examined the effect of the starting guess by taking an exact one (Fig. 5), a “low” one ($a \equiv 1$ inside Ω ; see Fig. 6), and a perturbation of the latter ($p \equiv 1$ inside Ω with a spike down at a single node; see Fig. 7). This confirms what we observed with the first example that, without smoothing, variations in the starting guess tend to produce jagged and readily oscillatory solutions. With the same perturbed starting guess, we varied λ ; the results are summarised in Table 2. Figure 8 shows the solution for $\lambda = 10^{-3}$.

TABLE 2
Example 2.

λ	No. iter.	J_e	J_1	J_2	J_λ	ϵ
0	21	$5.09 \cdot 10^{-6}$	28.8	$8.50 \cdot 10^4$	$5.09 \cdot 10^{-6}$.39
10^{-2}	103	$1.66 \cdot 10^{-1}$	4.17	53.5	$7.43 \cdot 10^{-1}$.18
10^{-3}	67	$3.92 \cdot 10^{-2}$	8.12	81.6	$1.33 \cdot 10^{-1}$.067
10^{-4}	24	$2.40 \cdot 10^{-2}$	9.92	$1.28 \cdot 10^2$	$3.77 \cdot 10^{-2}$.068
10^{-5}	24	$1.15 \cdot 10^{-2}$	10.5	$6.85 \cdot 10^2$	$1.84 \cdot 10^{-2}$.070

3.2.3. Example 3. Here, we make the choice of a true a that oscillates; of course, we keep the oscillation period large with respect to the mesh, otherwise we cannot expect much.

$$\begin{aligned}
 u &= (x + y), \\
 f &= (1 - y^2) \pi \cos \pi(1 + x) - 2y \sin \pi(1 + x), \\
 g &= \begin{cases} -1 & \text{on the left side of } \Omega, \\ -1 & \text{at the bottom,} \\ 1 & \text{on the right,} \\ 1 & \text{on top.} \end{cases}
 \end{aligned}$$

Therefore, $a = 1 - (1+y)(1-y) \sin \pi(1+x)$ as shown in Fig. 9. Figure 10 shows the result of taking $a \equiv 1$ as a starting guess. A perturbed starting guess is obtained by adding a spike to the previous one; here again, the solution is sluggish in departing

FIG. 5. *Exact starting guess.* $n = 8$, $\lambda = 0.0000\text{E} + 00$.

FIG. 6. *Low starting guess.* $n = 8$, $\lambda = 0.0000\text{E} + 00$.

FIG. 7. *Perturbed starting guess.* $n = 8$, $\lambda = 0.0000\text{E} + 00$.

from the starting guess without smoothing (Fig. 11). For the perturbed starting guess, test runs are summarised in Table 3. Figure 12 shows the results for $\lambda = 10^{-6}$.

4. Identification of discontinuous transmissivity. We now turn to the situation where a is known to have jump discontinuities across the domain. This will be the case if the material making up the domain is not homogeneous at the macroscopic

FIG. 8. *Perturbed starting guess.* $n = 8$, $\lambda = 0.1000\text{E} - 02$.TABLE 3
Example 3.

λ	No. iter.	J_e	J_1	J_2	J_λ	ϵ
0	13	$7.52 \cdot 10^{-6}$	10.4	$1.73 \cdot 10^4$	$7.52 \cdot 10^{-6}$.34
10^{-2}	96	$2.74 \cdot 10^{-1}$.00435	1.69	$2.91 \cdot 10^{-1}$.49
10^{-3}	49	$1.30 \cdot 10^{-1}$	1.53	64.5	$1.96 \cdot 10^{-1}$.36
10^{-4}	23	$2.60 \cdot 10^{-2}$	7.67	$3.53 \cdot 10^2$	$6.21 \cdot 10^{-2}$.19
10^{-5}	14	$8.93 \cdot 10^{-3}$	10.9	$9.28 \cdot 10^2$	$1.83 \cdot 10^{-2}$.17
10^{-6}	20	$6.75 \cdot 10^{-4}$	12.2	$3.32 \cdot 10^3$	$4.01 \cdot 10^{-3}$.16

FIG. 9. $a = 1 - (1 + y)(1 - y) \sin(\pi(1 + x))$.

scale; in our model, this translates into fracture curves.

To simplify the analysis, we assume that there is a single such fracture curve across Ω , and that it is smooth. It divides Ω into two subdomains, Ω_1 and Ω_2 . Our assumptions on the data are the same as before: we know f , ∇u , and the flux $a(\partial u)/(\partial n)$ at the boundary of Ω . We also assume conservation of flux across the fracture curve;

FIG. 10. *Flat starting guess. $n = 8$, $\lambda = 0.0000\text{E} + 00$.*FIG. 11. *Perturbed starting guess. $n = 8$, $\lambda = 0.0000\text{E} + 00$.*FIG. 12. *Perturbed starting guess. $n = 8$, $\lambda = 0.1000\text{E} - 05$.*

this is the *Rankine–Hugoniot condition*: if a_1 and u_1 are the transmissivity and potential in Ω_1 , and a_2 and u_2 the corresponding quantities in Ω_2 , then along the fracture curve

$$(7) \quad a_1 \frac{\partial u_1}{\partial n} + a_2 \frac{\partial u_2}{\partial n} = 0,$$

where $\partial u_i / \partial n$ is the derivative of u in the outer normal direction to Ω_i .

Assuming that we have no data on the flux along the fracture curve, we suggest extending the equation-error method to this case. The class of admissible a 's consists now of pairs (a_1, a_2) such that:

- (i) Ω_1, Ω_2 form a partition of Ω , separated by a smooth curve C ;
- (ii) $a_1 \in H^2(\Omega_1)$ and $a_2 \in H^2(\Omega_2)$;
- (iii) a_1 and a_2 (along with $\nabla u_1, \nabla u_2$) satisfy condition (7) along C .

In this setup, (3) is still a valid formulation; we may again define the equation error $v(\nabla u, a)$ by (4), and, in the same spirit as before, we want to minimise a suitable modification of $J_e(\nabla u, a)$. The procedure is then as follows: For each admissible smooth curve C satisfying condition (i), consider the set of a 's satisfying (ii) and (iii). The problem of minimising (C still fixed)

$$J_\lambda(a) := J_e(\nabla u, a) + \lambda(|a_1|_{H^2(\Omega_1)}^2 + |a_2|_{H^2(\Omega_2)}^2)$$

over all admissible a 's is stable; we call its solution a_C . Then minimise $J_\lambda(a_C)$ over all admissible curves C .

4.1. Numerical implementation. In this setup, we assume that C joins the midpoints of the top and bottom of Ω . While this is a simplistic assumption (in practice, we do not know where the lines of discontinuity are), it may be justified by the fact that discontinuities in the boundary flux may be "seen." We approximate it by a broken line; the mesh is generated by horizontal scaling on each side of C . Since the mesh is no longer regular, the basic "pseudo-tensor" splines obtained by patching up contiguous shapes have discontinuous derivatives across horizontal lines, so that now A_k is an external approximation of $H^2(\Omega_i)$ (see [Te]). If a_C minimises $J_C(a)$ given C , the optimum function is

$$C \longmapsto \Phi(C) := J_C(a_C).$$

The problem now is to minimise $\Phi(C)$, where C is constrained to stay in the domain; the inner loop computes $\Phi(C)$, the outer loop moves C . There are library numerical routines that perform such constrained minimisation problems (for example, in the NAG library), assuming that Φ is nearly differentiable in its vector argument (but not requiring the user to specify the gradient) and using quasi-Newton steps. A typical solution would require, however quite a few evaluations of Φ and it would not have been advisable to do this on the VAX/780 which we used because each single evaluation of Φ , using a tiling of Ω with 16 mesh nodes, would take a few hours if the conjugate gradient method was carried to term (even with a tolerance on a^h of, say, 10^{-3}).

Since convergence of the conjugate gradient search was found to be fast at first, then considerably slow, we truncated the number of iterations to less than 10, and had to trust the results thus obtained. As for the outer loop, we generated a few profiles C^h in the neighbourhood of the true one, and recorded the value $\Phi(C^h)$ yielded by the conjugate gradient search for each C^h . The purpose of this simulation of the constrained problem corresponding to the outer loop is to check whether the true profile indeed gives the lowest value for Φ . A few experiments tended to justify this rudimentary procedure, in that for different samples C^h , we truncated the conjugate gradient procedure at different stages (10 versus 20 iterations), and we observed that at each stage the ordering of the values $\Phi(C^h)$ was roughly the same; also, that the shape of the solution (at least those values corresponding to values of a itself, not its derivatives) settled rather fast.

4.2. Results. We tested the method on two examples; one where C is a straight line, and the other where C is an arc of parabola. In each case, we generated six curves representing perturbations of C and three randomly generated curves, so that we had ten curves including C itself. With different values of λ we recorded, for each curve (or profile), the quantities J_e , J_2 , and J_λ , as well as the relative error ϵ . The mesh number in both examples is $n = 4$.

4.2.1. Example 4. In this example, C is the line $x = 0$, dividing Ω in Ω_1 , and Ω_2 on the left and right.

$$\begin{aligned} u_1 &= 2x + y, \\ u_2 &= x + y, \\ f &= 0, \\ g_1 &= \begin{cases} 1 & \text{on top,} \\ -2 & \text{on the left,} \\ -1 & \text{on the bottom,} \end{cases} \\ g_2 &= \begin{cases} 2 & \text{on top,} \\ 2 & \text{on the right,} \\ -2 & \text{on the bottom.} \end{cases} \end{aligned}$$

Profiles are represented by their intercepts x_1, x_2, x_3 on the horizontal lines of the grid. We denote them by $\pm i$ ($1 \leq i \leq 3$) and a, b, c ; the first are perturbations of C , and the last three are generated from a normal distribution centered about C :

$$\begin{aligned} a_{-1} &\leftrightarrow (-.1, 0, 0), \\ a_1 &\leftrightarrow (.1, 0, 0), \\ a_{-2} &\leftrightarrow (0, -.1, 0), \\ a_2 &\leftrightarrow (0, .1, 0), \\ a_{-3} &\leftrightarrow (0, 0, -.1), \\ a_3 &\leftrightarrow (0, 0, .1), \\ a_0 &\leftrightarrow (0, 0, 0), \\ a_a &\leftrightarrow (.11, .26, .32), \\ a_b &\leftrightarrow (-.01, .3, -.09), \\ a_c &\leftrightarrow (-.15, .05, .04). \end{aligned}$$

Tables 4 and 5 show the results for $\lambda = 10^{-5}$ and 10^{-4} . In both cases, the method picks the profile C itself; Table 6 shows the results for the true profile and various values of λ . As could be expected for this example, high values of λ give better results.

Figure 13 shows the computed solution for $\lambda = 10^{-3}$, and Fig. 14 shows the computed solution in the absence of smoothing ($\lambda = 0$).

4.2.2. Example 5. In this example, C is the curve of equation $4x - y^2 + 1 = 0$

TABLE 4

as shown in Fig. 15.

$$u_1 = 4x - y^2 + 1 + x,$$

$$u_2 = 2x - y^2/2 + 1/2 + x,$$

$$f_1 = 6 + 3y^2,$$

$$f_2 = 5 + 3y^2,$$

$$g_1 = \begin{cases} -7 & \text{on top,} \\ -5(3 + y^2/2) & \text{on the left,} \\ -7 & \text{on the bottom,} \end{cases}$$

$$g_2 = \begin{cases} -6 & \text{on top,} \\ 3(5 + y^2) & \text{on the right,} \\ -6 & \text{at the bottom.} \end{cases}$$

FIG. 13. $x_1 = 0.0000$, $x_2 = 0.000$, $x_3 = 0.0000$.

FIG. 14. $x_1 = 0.0000$, $x_2 = 0.0000$, $x_3 = 0.0000$.

FIG. 15. *Fracture line.*

The solution is then $a_1 = 3 + y^2/2$, $a_2 = 5 + y^2$ as shown in Fig. 16.

FIG. 16. $a = 3 + y^2/2$ at left, $5 + y^2$ at right.

The profiles now are

$$\begin{aligned}
 a_{-1} &\leftrightarrow (-.2875, -.25, -.1875), \\
 a_1 &\leftrightarrow (-.0875, -.25, -.1875), \\
 a_{-2} &\leftrightarrow (-.1875, -.35, -.1875), \\
 a_2 &\leftrightarrow (-.1875, -.15, -.1875), \\
 a_{-3} &\leftrightarrow (-.1875, -.25, -.2875), \\
 a_3 &\leftrightarrow (-.1875, -.25, -.0875), \\
 a_0 &\leftrightarrow (-.1875, -.25, -.1875), \\
 a_a &\leftrightarrow (-.08, -.25, -.34), \\
 a_b &\leftrightarrow (.07, .05, -.14), \\
 a_c &\leftrightarrow (.13, -.33, -.15).
 \end{aligned}$$

Tables 7 and 8 show the results for $\lambda = 10^{-5}$ and 10^{-6} , respectively. For the first value of λ , we had to pass up the outlier profile a_{-3} which was run early on, for unlike the other profiles tested, we allowed the conjugate gradient procedure for this one to run for more than 20 iterations. So the method picks profile a_{-2} , which is indeed a better approximation of C than a_0 , which is an inner envelope lying on one side of C .

For comparison, Table 9 is for $\lambda = 0$.

Figures 17 and 18 show the solution for $\lambda = 10^{-6}$ and profiles -3 and 3 , respectively. Figure 19 shows the solution for the same profile in the absence of smoothing.

Note. A similar approach to the one developed here has been implemented by Patricia Lamm in the case of the observation error criterion; see [La]. In her paper, a is assumed to be piecewise constant, and compactification in a is enforced by bound constraints instead of smoothing.

5. Conclusion. The transmissivity identification problem is ill posed, and no solution method is entirely satisfactory. The method under consideration, compared with the observation error method, presents the advantage of easier analysis stemming from convexity of the objective function. Some results, such as the validity of the Tikhonov–Arsenin parameter selection strategy, carry through with some of their hypotheses (usually impossible to check in the case of the observation-error method)

ral criterion than the observation error: it reflects less the direct readings of u , and depends more on the coupling between a and u . Both methods require the use of some smoothing for stability. The main disadvantage of this method is the increased complexity in computation; computing J_2 , the second-order portion of the H^2 -norm, is the main culprit for the CPU time used (40 seconds per function evaluation on the VAX/780). The same term accounts also for defective convergence of the conjugate gradient method, as we noted when we unduly increased λ . On the other hand, while the theoretical convergence results rely on H^2 -smoothing, we did observe the remarkable fact that overspecifying the boundary data (as in §4) seems enough to enforce smoothing on the computed a (without the help of H^2 -smoothing).

Acknowledgments. The author is grateful to David Russell for proposing the topic for this work and for his unfaltering encouragement, patience and support; to Seymour Parter and Grace Wahba for their guidance and many useful discussions; and, to Fritz Colonius who told him about Tikhonov regularisation. He also thanks an anonymous referee for pointing out references [A], [CG], [HS], and [KL].

LINEAR SYSTEMS WITH SIGN-OBSERVATIONS*

RENÉE KOPLON[†] AND EDUARDO D. SONTAG[‡]

Abstract. This paper deals with systems that are obtained from linear time-invariant continuous- or discrete-time devices followed by a function that just provides the sign of each output. Such systems appear naturally in the study of quantized observations as well as in signal processing and neural network theory. Results are given on observability, minimal realizations, and other system-theoretic concepts. Certain major differences exist with the linear case, and other results generalize in a surprisingly straightforward manner.

Key words. observability, minimal realization, neural networks, quantization effects

1. Introduction. A central issue in current control theory and signal processing concerns the interface between, on the one hand, the continuous, physical, world and, on the other hand, discrete devices such as digital computers, capable of symbolic processing. Classical control techniques, especially for linear systems, have proved spectacularly successful in automatically regulating relatively simple systems. However, for large-scale problems, controllers resulting from the application of the well-developed theory are used as building blocks of more complex systems. The integration of these systems is often accomplished by means of ad hoc techniques that combine pattern recognition devices, various types of switching controllers, and humans—or, more recently, expert systems—in supervisory capabilities.

Recently, there has been renewed interest in the formulation of mathematical models in which this interface between the continuous and the symbolic is naturally accomplished and system-theoretic questions can be formulated and resolved for the resulting models. Successful approaches will eventually allow the interplay of modern control theory with automata theory and other techniques from computer science. This interest has motivated much research into areas such as discrete-event systems, supervisory control, and, more generally, “intelligent control systems.”

One possible first step in a systematic attack of this problem is the study of partial (discrete) measurements on the state of a continuous dynamical system. When no controls are present, this is closely related to classical work on symbolic dynamics, and in fact has been pursued in the control theory literature, where Ramadge studied in [9] the dynamical behavior of observation sequences corresponding to such systems.

If inputs are available, one of the first questions that we may address in this context is that of the nature of the information that can be deduced by a symbolic “supervisor” from data transmitted by such a “lower level” continuous device, using appropriate controls to obtain more information about the system. Here the work of Delchamps, especially in [3]–[5], is especially relevant. His work dealt with what we may call “single-experiment observability” of *constrained-output systems*, systems for which the dynamics are linear but the outputs reflect various limitations of measuring

devices. These are systems, in discrete or continuous time, whose equations can be expressed as

$$(1) \quad \begin{aligned} x(t+1) \text{ [or } \dot{x}(t)] &= Ax(t) + Bu(t), \\ y(t) &= \sigma(Cx), \end{aligned}$$

for some $n \times n$ real matrix A , $n \times m$ matrix B , and $p \times n$ matrix C , and where σ is a memory-free map: $\mathbb{R}^p \rightarrow \mathbb{R}^p$ —in the case of Delchamp's work, a quantizer. (The simplest example of a constrained-output system occurs if σ is the identity. Then we are dealing with the class of all finite-dimensional linear systems. See [12] for precise definitions of "system" and related terms.) Models of the form (1) with quantizer σ arise also in a variety of other areas besides control. For instance, in signal processing, when modeling linear channels transmitting digital data from a quantized source, the channel equalization problem becomes one of systems inversion for such systems; see [2] and also the related paper [8].

In contrast to Delchamp's work, in this paper we look at the more standard notion of multiple-experiment observability, which is different for nonlinear systems from the single-experiment concept (for purely linear systems, both concepts do coincide, of course). We will be especially interested in the case in which σ simply takes the sign of each coordinate, that is, *sign-linear systems*, those for which

$$\sigma(x) = \text{sign}(x)$$

(applied to each coordinate independently), where

$$\text{sign}(x) = \begin{cases} 1 & \text{if } x > 0, \\ 0 & \text{if } x = 0, \\ -1 & \text{if } x < 0. \end{cases}$$

Sign-linear systems correspond to the 1-bit quantization case of Delchamps' model and are also motivated by pattern recognition applications (see below), but many technical results will be given in the paper in somewhat more generality.

Among the most popular techniques in pattern classification are those based on the use of *perceptrons* or linear discriminants (see, e.g., [6], [13]). Mathematically, these are simply functions of the type

$$\mathbb{R}^n \mapsto \mathbb{R}^p, \quad v \mapsto y = \text{sign}(Cv),$$

typically with large n and small p ; again, the sign is understood as being taken in each coordinate separately. Perceptrons are used to classify input patterns $v = (v_1, \dots, v_n)$ into classes, and they form the basis of many statistical techniques. In many practical situations arising in speech processing or learning finite automata and languages (see, e.g., [7]), the vector v really represents a finite window

$$(2) \quad u(t-1), \dots, u(t-s)$$

of a sequence of m -dimensional inputs $u(1), u(2), \dots$, where the components of (2) have been listed as v (and $sm = n$). In that case, the perceptron can be understood as a sign-linear system of dimension n , with a shift-register used to store the previous inputs (2). Borrowing from the signal processing terminology, perceptrons are "finite impulse response" sign-linear systems. As such, they are not suited to modeling time dependencies and recurrences in the data. More general sign-linear systems are called

for, and this motivated the introduction of such systems in [1], using the name “infinite impulse response” again by analogy to the classical linear case. In that paper, the authors studied practical problems of systems identification but did not address the more system-theoretic types of questions with which this paper deals.

As a final reason for studying sign-linear systems, we point out that such systems provide a natural class of nonsmooth nonlinear systems, a class that combines logical and switching devices together with more classical continuous variables. When the nonlinearities appear in the feedback loops, the problems become far more difficult; in that context, see, for instance, [11] for results about the computational power of systems of the type $x(t+1) = \sigma(Ax(t) + Bu(t))$.

1.1. Summary of paper. As mentioned earlier, the focus of this paper is the class of *sign-linear systems*, that is, those of the type (1) with $\sigma(x) = \text{sign}(x)$ (the sign is understood as being taken in each coordinate, so that the output value space could be taken simply as $\{-1, 0, 1\}^p$; careful definitions are given later). Also of interest are the associated *sign-linear input/output (i/o) maps* of the form

$$y(t) = \text{sign}(\mathcal{A}_1 u(t) + \cdots + \mathcal{A}_t u(1))$$

or the analogous continuous-time maps (convolution followed by sign).

For a system such as (1), we call any triple (A, B, C) such that the equations of the system can be expressed in terms of that triple, a *triple associated to the system* Σ . Note that in some cases there may be many triples associated to a single system:

Example 1.1. Let Σ be a sign-linear system with state-space \mathbb{R}^2 defined by the equations

$$\begin{aligned} x(t+1) &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} x(t) + \begin{pmatrix} 1 \\ 0 \end{pmatrix} u(t), \\ y(t) &= \text{sign}(x_1 + 2x_2). \end{aligned}$$

Then the following triples are both associated to Σ :

$$\begin{aligned} A &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad C = (1 \ 2), \\ A &= \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad C = (2 \ 4). \end{aligned}$$

The results that we describe parallel those known for standard linear systems, but with a few, perhaps unexpected, differences. We may summarize the main conclusions on sign-linear systems as follows:

(a) Although stronger than just observability of the pair (A, C) , observability of sign-linear systems can be characterized in an elegant manner. The characterization is different in the continuous- and discrete-time cases, in contrast to what happens for linear systems. Moreover, in another characteristic that is typical of *nonlinear* systems, the degree of controllability of the system does affect observability.

(b) Minimal-dimensional realizations of sign-linear i/o maps by sign-linear systems are unique up to a change of variables in the state space and a positive rescaling of outputs. This is basically as in the linear case, except for the obvious need to rescale. Moreover, finite-dimensional realizability can be characterized in the usual manner using Hankel matrices.

(c) If a realization of a given sign-linear i/o map is controllable and observable, in the usual sense of control theory, then it is minimal. Conversely, a minimal realization is necessarily final-state observable (that is, there is a control allowing for determination of the state at the end of the interval of application) but, in the discrete-time case, minimal realizations may not be observable. (In continuous-time, final-state and plain —initial-state— observability coincide.)

(d) Because of the possible lack of observability of minimal realizations, for some discrete-time sign-linear i/o maps it is the case that the abstract “canonical” realization, known to exist from automata-theoretic arguments, is not given by a sign-linear system. We discuss the canonical systems that result when minimal realizations are not observable, obtaining a description in terms of cascades of finite automata and linear systems.

The paper ends in § 6, where we show how some of the continuous-time observability results can be seen as consequences of the corresponding discrete-time results by sampling at appropriate frequencies.

Some of the results to be given can be stated in more generality, in terms of constrained-output systems as in (1), where σ is a fixed nonlinearity satisfying some (or all) of the following axioms:

1. $\text{sign}(\sigma(x)) = \text{sign}(x)$.
2. Finite precision sensor: $\sigma(x) = \text{constant}$ for $x \in (0, \varepsilon]$ and $x \in [-\varepsilon, 0)$, for some $\varepsilon > 0$.
3. Sensor saturation: $\sigma(x) = \text{constant}$ for $x > K > 0$ and $x < -K < 0$, for some $K > 0$.
4. $\sigma(x)$ is not constant on $(0, \infty)$ or $(-\infty, 0)$.

(Again, for a vector $z \in \mathbb{R}^p$, the notation $\sigma(z)$ denotes the vector $(\sigma(z_1), \dots, \sigma(z_p)) \in \mathbb{R}^p$.) The main systems of interest in this paper, sign-linear ones, are those for which $\sigma(x) = \text{sign}(x)$, which satisfies axioms 1,2,3. Some other examples of constrained-output systems are as follows:

- Output-saturated systems (satisfying 1,3,4) are those with $\sigma(x) = s(x)$, where

$$s(x) = \begin{cases} 1 & \text{if } x > 1, \\ x & \text{if } |x| \leq 1, \\ -1 & \text{if } x < -1. \end{cases}$$

The output space for output-saturated systems is $[-1, 1]^p$.

- Quantized systems (satisfying 1,2,4) are defined by $\sigma(x) = \lfloor x \rfloor$, with output space \mathbb{Z}^p .
- Saturated-quantized systems (satisfying 1–4) are systems for which

$$\sigma(x) = \begin{cases} K \text{sign}(x) & \text{if } |x| > K, \\ \lfloor x \rfloor & \text{if } |x| < K \end{cases}$$

for some fixed $K > 0$. Saturated-quantized systems have output space $\{n \in \mathbb{Z} : |n| \leq K\}^p$.

More details about such functions, and results specific for some of these classes, are described in [10].

2. Observability. Our notion of observability is the usual concept of multiple-experiment observability. Let us recall the main ideas. For formal definitions, please refer to [12, §5.1].

DEFINITION 2.1. A system Σ is *observable* if for any two initial states, there is some control that produces different outputs for each of the two initial states. This is not in general equivalent to single-experiment observability in which there exists one control function (or sequence of controls) that distinguishes any pair of states. The control we use to distinguish two states may depend on the two given states. This concept of observability really tells us only that we may *distinguish* between any two initial states, not that we may *determine* the initial state using one special control. For linear systems, multiple- and single-experiment observability are equivalent. If a linear system is observable, then the zero control will distinguish any pair of states.

DEFINITION 2.2. A system Σ is *final-state observable* if for any two initial states, there is some control and some time T so that either the output before time T is different for each of the two states, or the states at time T are the same. For continuous-time systems, final-state observability is equivalent to observability ([12, Prop. 5.1.9]).

We now state a few general necessary conditions for observability of constrained-output systems. Later, we will provide necessary and sufficient conditions for the class of sign-linear systems. The following result is obvious.

LEMMA 2.3. *If Σ is an observable constrained-output system, then (A, C) is an observable pair.*

Conversely, if σ is one-to-one, then observability of the pair (A, C) implies observability of Σ , but in general the implication does not hold. The following lemma gives an additional necessary condition when σ is not one-to-one.

LEMMA 2.4. *If Σ is an observable discrete-time constrained-output system with a single output channel ($p = 1$), and σ is not one-to-one, then $\det A \neq 0$.*

Proof. Suppose $\det A = 0$. Then there exists a nonzero $x \in \ker A$. The output sequence for the initial state x is $\{\sigma(Cx), \dots\}$ where the part not shown is independent of x . Since Σ is observable, (A, C) is an observable pair, so $Cx \neq 0$. Let $\sigma(\mu) = \sigma(\nu)$, $\mu \neq \nu$. Then, we may choose $\alpha_1 \neq \alpha_2$ so that $\alpha_1 Cx = \mu$ and $\alpha_2 Cx = \nu$. Then $\alpha_1 x \neq \alpha_2 x$ are indistinguishable, contradicting observability. \square

For $p > 1$, this lemma is not necessarily true. Consider the following counterexample. We will use the notation $x^+(t)$ to mean $x(t+1)$, and we drop the argument t from now on.

Example 2.5. Let Σ be the system with equations $x^+ = 0$, $y_1 = \sigma(x)$, $y_2 = \sigma(2x)$; and

$$\sigma(x) = \begin{cases} x & x \notin [1, 2] \\ 1 & x \in [1, 2] \end{cases}.$$

The nonlinearity σ is not one-to-one, but the map $x \mapsto (\sigma(x), \sigma(2x))$ is one-to-one, so the system is observable. However, A is not invertible.

If the measurement limiter σ is some form of saturation or σ has finite precision near 0, observability does imply that A is invertible, even in the multiple output case, since the following lemma will apply.

LEMMA 2.6. *If Σ is an observable discrete-time constrained-output system and σ either models sensor saturation*

$$\sigma(x) = \text{constant for } x > K > 0 \text{ and } x < -K < 0$$

for some $K > 0$, or has finite precision

$$\sigma(x) = \text{constant for } x \in (0, \varepsilon] \text{ and } x \in [-\varepsilon, 0)$$

for some $\varepsilon > 0$, then $\det A \neq 0$.

Proof. If $\det A = 0$, then there exists a nonzero $x \in \ker A$. In the saturated case, choose λ so that for all i satisfying $C_i x \neq 0$, then $|\lambda C_i x| > K$. Then λx and $2\lambda x$ are indistinguishable. In the finite precision case, choose λ so that $|\lambda C_i x| \leq \varepsilon$ for all $i = 1, \dots, p$. Then λx and $\frac{1}{2}\lambda x$ are indistinguishable. \square

Before stating the next lemma we introduce the following definition.

DEFINITION 2.7. Let Σ be a constrained-output system and let (A, B, C) be any triple associated to Σ . Then the sequence of $p \times m$ matrices

$$\mathcal{A} = \{\mathcal{A}_1, \mathcal{A}_2, \mathcal{A}_3, \dots\},$$

where

$$\mathcal{A}_i = CA^{i-1}B, \quad i = 1, 2, 3, \dots$$

is called a *Markov parameter sequence* associated to Σ . Since in general C is not uniquely defined from the system equations, there may be more than one Markov sequence associated to a given system; this issue is discussed later.

LEMMA 2.8. Assume that Σ is a single-output observable discrete-time constrained-output system defined by the triple (A, B, C) , and σ has finite precision

$$\sigma(x) = \text{constant for } x \in (0, \varepsilon] \text{ and } x \in [-\varepsilon, 0).$$

If A has an eigenvalue λ satisfying $|\lambda| \leq 1$, then $\mathcal{A} \not\equiv 0$, for any Markov sequence associated to Σ .

Proof. Let \mathcal{A} be any Markov sequence associated to Σ . Let v be a nonzero eigenvector for A corresponding to λ and let $\gamma = \|v\|$ (where $\|\cdot\|$ denotes Euclidean norm). Then $A^k v = \lambda^k v$ for all k , so $\|A^k v\| \leq \gamma$ for all k . Write $v = v_1 + iv_2$, where v_1, v_2 are real vectors. Then $\|A^k v_1\| \leq \|A^k v\| \leq \gamma$ for all k . Note that $\|C\| \neq 0$ since (A, C) is an observable pair. Then

$$x := \frac{v_1 \varepsilon}{\gamma \|C\|}$$

satisfies

$$|CA^k x| \leq \|C\| \|A^k x\| \leq \frac{\|C\| \gamma \varepsilon}{\gamma \|C\|} = \varepsilon$$

for all k . If $\mathcal{A} \equiv 0$, then $x, \frac{1}{2}x$ are indistinguishable, contradicting observability. \square

3. Sign-linear systems. Now we concentrate on the observability of sign-linear systems. Sign-linear input/output maps and their realizations will be discussed in §§ 4 and 5.

DEFINITION 3.1. A *sign-linear system* Σ is a system with state, input, and output-value spaces \mathbb{R}^n , \mathbb{R}^m , and $\{-1, 0, 1\}^p$, respectively, for which there exist matrices $A \in \mathbb{R}^{n \times n}$, $B \in \mathbb{R}^{n \times m}$, $C \in \mathbb{R}^{p \times n}$, so that the equations of Σ take the form

$$\begin{aligned} x^+ (\text{or } \dot{x}) &= Ax + Bu, \\ y &= \text{sign}(Cx) \end{aligned}$$

in discrete- (or continuous-) time. If (A, B, C) is a triple like this, we denote $\Sigma = (A, B, C)_s$. Whether we are dealing with discrete- or continuous-time will be clear

from the context. The integer n is the *dimension* of the system. It is convenient to include the degenerate case $n = 0$, corresponding to the system with zero-dimensional state space.

Note that $(A, B, C)_s = (\hat{A}, \hat{B}, \hat{C})_s$ if and only if $A = \hat{A}$, $B = \hat{B}$, and $C = \Lambda \hat{C}$, where Λ is a *scaling matrix* in the following sense.

DEFINITION 3.2. A $p \times p$ *scaling matrix* is a matrix of the type

$$\Lambda = \text{diag}(\lambda_1, \dots, \lambda_p) = \begin{pmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_p \end{pmatrix},$$

where $\lambda_i > 0$, $i = 1, \dots, p$. Any triple for which $\Sigma = (A, B, C)_s$ will be said to be *associated* to Σ . Observe that the properties of (A, B) being a controllable pair, (A, C) being an observable pair, and (A, B, C) being canonical (controllable and observable), in the usual linear systems sense, are independent of which of the associated triples is considered.

The following trivial observation will be used often.

Remark 3.3. If \mathcal{H} is a real pre-Hilbert space (that is, a space with a nondegenerate inner product), and if $c \in \mathcal{H}$, c nonzero, $a, b \in \mathbb{R}$, $a \neq b$, then there is a $u \in \mathcal{H}$ so that

$$\text{sign}(a + \langle c, u \rangle) \neq \text{sign}(b + \langle c, u \rangle).$$

Indeed, without loss of generality, we may assume that $a > b$. Let

$$\alpha := -\frac{a+b}{2\|c\|^2}.$$

Then $u := \alpha c$ satisfies $a + \langle c, u \rangle > 0$ and $b + \langle c, u \rangle < 0$.

Since controllability of a system does not depend on outputs, a sign-linear system is controllable if and only if (A, B) is a controllable pair in the usual sense ([12]). Observability requires a bit more than in the linear case, as illustrated by the system

$$x(t+1) = u(t), \quad y(t) = \text{sign}(x(t)).$$

Observability of the pair (A, C) is not sufficient to guarantee observability of the corresponding sign-linear system.

We will say that a triple (A, B, C) has *property \mathcal{P}* if not only is (A, C) observable, but we can choose a subset of outputs which allow observability of the pair (A, C) and for each of which the corresponding row of the Markov sequence \mathcal{A} is nonzero. In the case $p = 1$, this just means that (A, C) is an observable pair and $\mathcal{A} \neq 0$, or equivalently, that (A, C) is an observable pair and $B \neq 0$. For $p > 1$, \mathcal{A} has p rows and we only require that enough of those rows are nonzero. More precisely, let

$$I(\mathcal{A}) = \{i_1, \dots, i_k\}$$

be the indices of the nonzero rows of \mathcal{A} ; then property \mathcal{P} is the condition that

$$(3) \quad \bigcap_{\substack{j \in I(\mathcal{A}) \\ q=0, \dots, n-1}} \ker(C_j A^q) = \{0\},$$

where C_j denotes the j th row of C . Note that if C and \hat{C} differ only by multiplication by a scaling matrix, property \mathcal{P} holds for (A, B, C) if and only if it holds for (A, B, \hat{C}) .

Thus there is no ambiguity in the following statements. For discrete- and continuous-time the following theorems state necessary and sufficient conditions for observability.

THEOREM 3.4. *Let $\Sigma = (A, B, C)_s$ be a sign-linear discrete-time system of dimension $n > 0$. Then, Σ is observable if and only if the following conditions hold:*

1. $\det A \neq 0$,
2. (A, B, C) has property \mathcal{P} .

Proof. Necessity. Suppose Σ is observable. We know $\det A \neq 0$ from Lemma 2.6. Now assume that property \mathcal{P} would not hold, and pick $x \neq 0$ in the intersection in (3). The output sequence for any given control sequence $\{u_1, u_2, \dots\}$ is $\{y(0), y(1), \dots\}$ where

$$y(k) = \text{sign} \left(CA^k x + \sum_{l=1}^k \mathcal{A}_l u_{k-l+1} \right).$$

For the chosen x in that intersection, each row of each term in the output sequence has the form

$$y(k)_j = \begin{cases} \text{sign}(C_j A^k x + 0) & \text{if } j \notin I(\mathcal{A}), \\ \text{sign}(0 + *) & \text{if } j \in I(\mathcal{A}), \end{cases}$$

where $*$ denotes a (possibly nonzero) function of the inputs and the Markov parameters. Then, x and λx for any $\lambda > 0$, $\lambda \neq 1$, cannot be distinguished, so observability is contradicted.

Sufficiency. Now suppose $\det A \neq 0$ and (A, B, C) has property \mathcal{P} . We must show that Σ is observable. Pick an integer $l > 0$ so that the i th row of

$$(\mathcal{A}_1 \mathcal{A}_2 \cdots \mathcal{A}_l)$$

is nonzero for every $i \in I(\mathcal{A})$. Note that since A is invertible,

$$(4) \quad \bigcap_{\substack{j \in I(\mathcal{A}) \\ q=0, \dots, n-1}} \ker(C_j A^{q+l}) = \{0\},$$

which follows from (3).

Now look at the following n terms in the output sequence for initial state x :

$$\begin{aligned} & \text{sign}(CA^l x + \mathcal{A}_l u_1 + \cdots + \mathcal{A}_1 u_l), \\ & \text{sign}(CA^{l+1} x + \mathcal{A}_{l+1} u_1 + \cdots + \mathcal{A}_1 u_{l+1}), \dots, \\ & \text{sign}(CA^{l+n-1} x + \mathcal{A}_{l+n-1} u_1 + \cdots + \mathcal{A}_1 u_{l+n-1}). \end{aligned}$$

Given $x \neq z$ we must show that x, z are distinguishable. If we can choose a sequence $u_1, u_2, \dots, u_{l+n-1}$ so that some row of some term above is different for the initial states x and z , then x, z are distinguishable. As $x - z \neq 0$, we may pick some $j \in I(\mathcal{A})$ and some $q = 0, \dots, n-1$ so that

$$C_j A^{q+l} x \neq C_j A^{q+l} z.$$

Since $j \in I(\mathcal{A})$, the j th row of $(\mathcal{A}_1 \cdots \mathcal{A}_l)$ is nonzero by our choice of l . Denote $k := q + l$ so that the j th row of $(\mathcal{A}_1 \cdots \mathcal{A}_k)$ is also nonzero. Let \mathcal{A}_i^j be the j th row of

\mathcal{A}_i . Then we may apply Remark 3.3 (with $\mathcal{H} = \mathbb{R}^k$ and the standard inner product) and obtain u_1, u_2, \dots, u_k so that

$$\begin{aligned} & \text{sign}(C_j A^k x + \mathcal{A}_k^j u_1 + \dots + \mathcal{A}_1^j u_k) \\ & \neq \text{sign}(C_j A^k z + \mathcal{A}_k^j u_1 + \dots + \mathcal{A}_1^j u_k). \end{aligned}$$

Thus, x and z are distinguishable. This completes the proof. \square

We will say that a triple (A, B, C) is *discrete-time sign-linear observable* if the triple satisfies the observability conditions in Theorem 3.4.

For continuous-time sign-linear systems, the conditions for observability are slightly weaker, as invertibility of the matrix A is not needed.

THEOREM 3.5. *Let $\Sigma = (A, B, C)_s$ be a sign-linear continuous-time system of dimension $n > 0$. Then Σ is observable if and only if (A, B, C) has property \mathcal{P} .*

Proof. The proof is exactly the same as in the discrete-time case. Indeed, if (3) is not satisfied and $x \neq 0$ is in the intersection of the kernels, consider the output

$$y(t) = \text{sign} \left(C e^{At} x + \int_0^t \sum_{k=1}^{\infty} \frac{\mathcal{A}_k(t-s)^{k-1}}{(k-1)!} u(s) ds \right).$$

Each row has the form

$$y(t)_j = \begin{cases} \text{sign}(C_j e^{At} x + 0) & \text{if } j \notin I(\mathcal{A}), \\ \text{sign}(0 + *) & \text{if } j \in I(\mathcal{A}), \end{cases}$$

where $*$ denotes a (possibly nonzero) function of the inputs and the Markov parameters. Then x and λx for any $\lambda > 0$, $\lambda \neq 1$, are indistinguishable, contradicting observability.

Now suppose (A, B, C) satisfies property \mathcal{P} . We must show that Σ is observable. Look at the output function for initial state x :

$$y(t) = \text{sign} \left(C e^{At} x + \int_0^t K(t-s) u(s) ds \right),$$

where

$$K(t-s) := \sum_{k=1}^{\infty} \frac{\mathcal{A}_k(t-s)^{k-1}}{(k-1)!}.$$

Given $x \neq z$ we must show that x, z are distinguishable. If we can choose a t and a control function $u(\cdot)$ of length t so that some row of $y(t)$ is different for the initial states x and z , then x, z are distinguishable. As $x - z \neq 0$, we may pick some $j \in I(\mathcal{A})$ and some $t \geq 0$ so that

$$C_j e^{At} x \neq C_j e^{At} z,$$

by property \mathcal{P} . Since $C_j e^{At} x$ is an analytic function of t , this is true in a neighborhood of $t = 0$ so we may, in fact, fix a $t > 0$ so that the inequality holds.

Next note that since $j \in I(\mathcal{A})$, $\mathcal{A}^j \neq 0$ so also $K_j(\cdot) \neq 0$. Now apply Remark 3.3 with $a = C_j e^{At} x$, $b = C_j e^{At} z$, $\mathcal{H} = \mathcal{L}^\infty[0, t]$ with the \mathcal{L}^2 inner product

$$\langle v(\cdot), u(\cdot) \rangle := \int_0^t v(s) u(s) ds,$$

and $c = K_j(t-s) \in \mathcal{H}$. Thus we may choose a measurable essentially bounded $u(\cdot)$ so that

$$\text{sign} \left(Ce^{At}x + \int_0^t K(t-s)u(s)ds \right) \neq \text{sign} \left(Ce^{At}z + \int_0^t K(t-s)u(s)ds \right).$$

This $u(\cdot)$ distinguishes x, z and the proof is complete. \square

4. Sign-linear realizations. We now focus on questions of realizability for the class of sign-linear systems. As we mentioned earlier, a sign-linear system does not have a *unique* associated Markov sequence. However, for sign-linear systems, we have the following obvious fact.

Remark 4.1. A Markov parameter sequence associated to $\Sigma = (A, B, C)_s$ is any sequence of $p \times m$ matrices $\mathcal{A} = \{\mathcal{A}_1, \mathcal{A}_2, \mathcal{A}_3, \dots\}$ so that

$$(5) \quad \mathcal{A}_i = \Lambda C A^{i-1} B, \quad i = 1, 2, 3, \dots$$

for some scaling matrix Λ .

For the degenerate system, its (only) associated sequence is $\mathcal{A} \equiv 0$. If \mathcal{A} is associated to Σ , we also say that Σ *realizes* \mathcal{A} . If (A, B, C) is a triple of matrices and $\mathcal{A} = \{\mathcal{A}_1, \mathcal{A}_2, \dots\}$ is a Markov sequence so that $\mathcal{A}_i = C A^{i-1} B$ holds, we will say that (A, B, C) is a *linear representation* of \mathcal{A} . The standard terminology is “realization” (as a linear system), but this can lead to confusion here, since we are interested in sign-linear realizations. Note that the above definitions imply that for any given triple (A, B, C) , and any sequence of $p \times m$ matrices \mathcal{A} , the sign-linear system $\Sigma = (A, B, C)_s$ realizes \mathcal{A} if and only if $(A, B, \Lambda C)$ is a linear representation of \mathcal{A} for some scaling matrix Λ . In other words, there must exist a triple associated to Σ that represents \mathcal{A} .

The matrix

$$H_{s,t} = \begin{pmatrix} \mathcal{A}_1 & \cdots & \mathcal{A}_t \\ \vdots & \ddots & \vdots \\ \mathcal{A}_s & \cdots & \mathcal{A}_{s+t-1} \end{pmatrix}$$

is called the $s \times t$ *Hankel matrix* for the Markov sequence \mathcal{A} . The (*Hankel*) *rank* of a sequence \mathcal{A} is defined to be

$$\sup_{s,t} \text{rank } H_{s,t}.$$

An i/o map (for a precise definition, see [12, Rem. 2.2.2], is a function of controls u defined on some time interval $[\sigma, \tau]$, which gives the entire output function for the time interval $[\sigma, \tau]$.

DEFINITION 4.2. A $(p \times m)$ *discrete-time sign-linear i/o map* α is a discrete-time i/o map for which there exists some sequence of $(p \times m)$ matrices $\mathcal{A}_1, \mathcal{A}_2, \dots$, so that

$$(6) \quad \alpha(u)(j) = \text{sign}(\mathcal{A}_j u_1 + \cdots + \mathcal{A}_1 u_j)$$

for each input sequence $\{u_1, u_2, u_3, \dots\}$. A *continuous-time sign-linear i/o map* is a continuous-time i/o map α for which there exists an analytic kernel $K(t)$ with expansion

$$(7) \quad K(t) = \sum_{i=1}^{\infty} \mathcal{A}_i \frac{t^{i-1}}{(i-1)!}$$

so that

$$(8) \quad \alpha(u)(t) = \text{sign} \left(\int_0^t K(t-s)u(s)ds \right)$$

for every measurable essentially bounded control function $u(\cdot)$. In either case, any sequence of matrices $\mathcal{A}_1, \mathcal{A}_2, \dots$ as above is called a *Markov sequence* of the map α . We will study realizations of these i/o maps by sign-linear systems. It will be helpful to have a simple example in mind as we go through the definitions and results.

Example 4.3. Let $\mathcal{A} = \{1, -1, 1, -1, \dots\}$. Then α is a 1×1 discrete-time i/o map, where

$$\alpha(u)(j) = \text{sign} \left((-1)^{j-1}u_1 + \dots + u_{j-2} - u_{j-1} + u_j \right).$$

For the control $u = \{1, 0, 0, \dots\}$, $\alpha(u)(j) = (-1)^{j-1}$ for all j . For the control $u = \{1, 2, 3, 0, 0, 0, \dots\}$, the values of the i/o function are

$$\begin{aligned} \alpha(u)(1) &= \text{sign}(1) = 1, \\ \alpha(u)(2) &= \text{sign}(-1 + 2) = 1, \\ \alpha(u)(3) &= \text{sign}(1 - 2 + 3) = 1, \\ \alpha(u)(4) &= \text{sign}(-1 + 2 - 3) = -1, \\ \alpha(u)(j) &= (-1)^{j-1} \text{ for } j > 4. \end{aligned}$$

DEFINITION 4.4. Two triples (A, B, C) and $(\hat{A}, \hat{B}, \hat{C})$ are *sign-similar* if there is a $T \in Gl(n)$ and a scaling matrix Λ such that

$$\begin{aligned} T^{-1}AT &= \hat{A}, \\ T^{-1}B &= \hat{B}, \\ CT &= \Lambda\hat{C}. \end{aligned}$$

If $\Sigma = (A, B, C)_s$ and $\hat{\Sigma} = (\hat{A}, \hat{B}, \hat{C})_s$ are sign-linear systems, they are called *sign-similar* if the corresponding triples are. Note that sign-similarity is an equivalence relation, and that the ambiguity in defining a triple associated to Σ causes no difficulties in the above definition.

DEFINITION 4.5. Two Markov sequences

$$\mathcal{A} = \{\mathcal{A}_1, \mathcal{A}_2, \dots\}, \quad \text{and} \quad \hat{\mathcal{A}} = \{\hat{\mathcal{A}}_1, \hat{\mathcal{A}}_2, \dots\}$$

are *sign-equivalent* if there exists a scaling matrix Λ so that

$$\mathcal{A}_j = \Lambda\hat{\mathcal{A}}_j, \quad j = 1, 2, 3, \dots$$

Note that if $K(\cdot)$ and $\hat{K}(\cdot)$ are as in (7) for the sequences \mathcal{A} and $\hat{\mathcal{A}}$, sign-equivalence of \mathcal{A} and $\hat{\mathcal{A}}$ is the same as asking that $K(t) = \Lambda\hat{K}(t)$ for all t , where Λ is a scaling matrix. The Markov sequence \mathcal{A} in Example 4.3 is sign-equivalent to $\hat{\mathcal{A}} = \{a, -a, a, -a, \dots\}$ for any $a > 0$.

4.1. Basic facts about realizations. The next lemma says that the Markov sequence \mathcal{A} is uniquely determined by a sign-linear i/o map α up to multiplication by a scaling matrix. That is, a sign-linear i/o map is defined by many Markov sequences, but these sequences are related by scaling.

Observe that the impulse response of a sign-linear i/o map (e.g., for discrete-time systems, the response to the input $u = \{1, 0, 0, 0, \dots\}$) is not enough to uniquely characterize the i/o map. For a discrete-time sign-linear i/o map α , the impulse response is just the sequence of signs of the Markov parameters: $\{\text{sign}(\mathcal{A}_1), \text{sign}(\mathcal{A}_2), \dots\}$. Such a sign sequence represents infinitely many different families of sign-equivalent Markov sequences, as illustrated by the following example.

Example 4.6. Let α_1 be the discrete-time sign-linear i/o map defined by $\mathcal{A} = \{1, 3, 1, 3, \dots\}$ and $\hat{\alpha}$ the map defined by $\hat{\mathcal{A}} = \{3, 1, 3, 1, \dots\}$. Then the impulse response for both i/o maps is $\{+1, +1, +1, \dots\}$; however the two maps are not the same as shown by considering the output corresponding to the input $u = \{1, -1, 1, -1, \dots\}$:

$$\begin{aligned}\alpha(u)(1) &= +1; & \hat{\alpha}(u)(1) &= +1, \\ \alpha(u)(2) &= +1; & \hat{\alpha}(u)(2) &= -1, \\ \alpha(u)(3) &= -1; & \hat{\alpha}(u)(3) &= +1, \\ \alpha(u)(4) &= +1; & \hat{\alpha}(u)(4) &= -1.\end{aligned}$$

LEMMA 4.7. \mathcal{A} and $\hat{\mathcal{A}}$ define the same i/o map if and only if they are sign-equivalent.

Proof. If \mathcal{A} and $\hat{\mathcal{A}}$ are sign-equivalent, then $\mathcal{A}_i = \Lambda \hat{\mathcal{A}}_i$ for all i , where Λ is a scaling matrix. It is then clear from (6)–(8) that the corresponding i/o maps coincide. To prove the converse, we can assume, without loss of generality, looking at each component of the output and each row of \mathcal{A} , that $p = 1$. We first prove the following easy observation.

Remark 4.8. If \mathcal{V} is a real pre-Hilbert space and if $v, w \in \mathcal{V}$ are nonzero and such that

$$\text{sign} \langle v, u \rangle = \text{sign} \langle w, u \rangle$$

for all $u \in \mathcal{V}$, then there exists $\lambda > 0$ so that $v = \lambda w$.

Proof. Suppose first that v and w are linearly independent, and consider the plane they span. Let $u \neq 0$ be in this plane and perpendicular to $v + w$. As $\langle v + w, u \rangle = 0$, necessarily $\langle v, u \rangle \neq 0$ and $\langle w, u \rangle \neq 0$, since if either of these is zero, then the other one is too, and that would contradict linear independence. Then

$$\langle v, u \rangle + \langle w, u \rangle = \langle v + w, u \rangle = 0.$$

So $\langle v, u \rangle = -\langle w, u \rangle \neq 0$, contradicting the assumption. Thus, either $v = \lambda w$ with $\lambda > 0$, or $v = -\mu w$ with $\mu > 0$. If $v = -\mu w$, then

$$\langle v, u \rangle = \langle -\mu w, u \rangle = -\mu \langle w, u \rangle \neq 0$$

and so $\text{sign} \langle v, u \rangle \neq \text{sign} \langle w, u \rangle$, again a contradiction. The only remaining possibility is that there exists a $\lambda > 0$ so that $v = \lambda w$. \square

Now we can continue the proof of Lemma 4.7. For discrete-time, we must show that if

$$\text{sign} \left(\sum_{i=1}^l \mathcal{A}_i u_{l-i+1} \right) = \text{sign} \left(\sum_{i=1}^l \hat{\mathcal{A}}_i u_{l-i+1} \right)$$

for all $l \geq 1$ and for all u_1, u_2, \dots, u_l , then $\mathcal{A} = \lambda \hat{\mathcal{A}}$ for some $\lambda > 0$. First choose an l so that $(\mathcal{A}_1, \dots, \mathcal{A}_l) \neq 0$. Note that $\mathbb{R}^{lm} = (\mathbb{R}^m)^l$ forms a pre-Hilbert space with the standard inner product

$$\left\langle \begin{pmatrix} v_1 \\ \vdots \\ v_l \end{pmatrix}, \begin{pmatrix} u_1 \\ \vdots \\ u_l \end{pmatrix} \right\rangle := \sum_{i=1}^l v'_i u_i.$$

Applying Remark 4.8 with $v = (\mathcal{A}_1, \dots, \mathcal{A}_l)'$, $w = (\hat{\mathcal{A}}_1, \dots, \hat{\mathcal{A}}_l)'$ and $u = (u'_1, \dots, u'_l)'$, we see that there exists a $\lambda > 0$ so that

$$(\mathcal{A}_1, \dots, \mathcal{A}_l) = \lambda(\hat{\mathcal{A}}_1, \dots, \hat{\mathcal{A}}_l).$$

Now pick any $q > l$. Applying the same argument to $(\mathbb{R}^m)^q$, we obtain a $\lambda_q > 0$ so that

$$(\mathcal{A}_1, \dots, \mathcal{A}_q) = \lambda_q(\hat{\mathcal{A}}_1, \dots, \hat{\mathcal{A}}_q).$$

Since $(\mathcal{A}_1, \dots, \mathcal{A}_l)$ is a subvector of $(\mathcal{A}_1, \dots, \mathcal{A}_q)$, and similarly $(\hat{\mathcal{A}}_1, \dots, \hat{\mathcal{A}}_l)$ a subvector of $(\hat{\mathcal{A}}_1, \dots, \hat{\mathcal{A}}_q)$, this implies that $\lambda = \lambda_q$. Thus $\mathcal{A}_q = \lambda \hat{\mathcal{A}}_q$ for all $q \geq 1$.

For continuous-time, we need to show that if

$$\text{sign} \left(\int_0^t K(t-s)u(s)ds \right) = \text{sign} \left(\int_0^t \hat{K}(t-s)u(s)ds \right)$$

for all $t \in [0, \infty)$ and for all $u(\cdot)$, measurable and essentially bounded on $[0, t]$, then $K(t) = \lambda \hat{K}(t)$ for some $\lambda > 0$ and for all $t \geq 0$. Note that $\mathcal{L}^\infty[0, t]$ forms a pre-Hilbert space with the \mathcal{L}^2 inner product

$$\langle v(\cdot), u(\cdot) \rangle := \int_0^t v(s)u(s)ds.$$

Applying Remark 4.8 with $v(s) = K(t-s)$ and $w(s) = \hat{K}(t-s)$, we see that there exists a $\lambda_t > 0$ so that $K(\cdot)|_{[0,t]} = \lambda_t \hat{K}(\cdot)|_{[0,t]}$. Using an argument similar to the one used in the discrete-time case, we can conclude that there exists a $\lambda > 0$ so that $K(t) = \lambda \hat{K}(t)$ for all $t \geq 0$. \square

COROLLARY 4.9. *Let α be a sign-linear i/o map, with Markov sequence \mathcal{A} , and let $\Sigma = (A, B, C)_s$ be any sign-linear realization of α , with Markov sequence $\hat{\mathcal{A}}$. Then \mathcal{A} and $\hat{\mathcal{A}}$ are sign-equivalent.*

Proof. Just note that \mathcal{A} and $\hat{\mathcal{A}}$ define the same i/o map, namely α . Thus, the previous lemma applies. \square

4.2. Minimality.

DEFINITION 4.10. A sign-linear system of dimension n is *minimal* if any other sign-linear system realizing the same i/o map has dimension $n_1 \geq n$. Recall that a triple (A, B, C) is *canonical* if and only if it is a minimal-dimensional linear representation of its Markov sequence ([12, Thm. 20]). The next lemma states that minimality of a sign-linear system is equivalent to minimality of the associated linear system.

LEMMA 4.11. *The sign-linear system $(A, B, C)_s$ is a minimal realization of α if and only if the triple (A, B, C) is canonical.*

Proof. Suppose the sign-linear system $\Sigma = (A, B, C)_s$ is a minimal realization of the i/o map α and \mathcal{A} is a Markov sequence associated to α . If (A, B, C) is not canonical, then there exists another triple $(\hat{A}, \hat{B}, \hat{C})$ of smaller dimension that is a linear representation of the same Markov sequence $\hat{\mathcal{A}}$ as (A, B, C) . Then $\Sigma = (A, B, C)_s$ also realizes $\hat{\mathcal{A}}$ so $\hat{\mathcal{A}}$ is sign-equivalent to \mathcal{A} by Corollary 4.9. But then since $(\hat{A}, \hat{B}, \hat{C})_s$ realizes $\hat{\mathcal{A}}$, it also realizes \mathcal{A} (a Markov sequence associated to a sign-linear system is only determined up to sign-equivalence). Thus, $(\hat{A}, \hat{B}, \hat{C})_s$ is a sign-linear system realizing α and of smaller dimension than $(A, B, C)_s$, contradicting minimality.

Conversely, suppose the triple (A, B, C) is canonical of dimension n , which implies, in particular, that it is minimal. If $(A, B, C)_s$ is not also minimal, then there exists a sign-linear system $\hat{\Sigma} = (\hat{A}, \hat{B}, \hat{C})_s$ of dimension $n_1 < n$ that realizes the same i/o map α as $(A, B, C)_s$. Let \mathcal{A} be the Markov sequence represented by (A, B, C) and $\hat{\mathcal{A}}$ the sequence represented by $(\hat{A}, \hat{B}, \hat{C})$. Then $(A, B, C)_s$ realizes \mathcal{A} and $(\hat{A}, \hat{B}, \hat{C})_s$ realizes $\hat{\mathcal{A}}$. Since the two sign-linear systems realize the same i/o map α , \mathcal{A} and $\hat{\mathcal{A}}$ are sign-equivalent (Corollary 4.9). Thus, there exists a scaling matrix Λ so that $\mathcal{A}_j = \Lambda \hat{\mathcal{A}}_j$ for all $j \geq 1$. So

$$CA^{i-1}B = \Lambda \hat{C} \hat{A}^{i-1} \hat{B}, \quad i = 1, 2, 3, \dots$$

But then $(\hat{A}, \hat{B}, \Lambda \hat{C})$ is a linear representation of \mathcal{A} of dimension $n_1 < n$, contradicting the minimality of (A, B, C) . \square

Remark 4.12. If \mathcal{A} and $\hat{\mathcal{A}}$ are two Markov sequences associated to the same i/o map α , then $\text{rank } \mathcal{A} = \text{rank } \hat{\mathcal{A}}$. Thus, we can define the *Hankel rank* of α as the rank of any of the associated Markov sequences. Indeed, by Lemma 4.7, we know that \mathcal{A} and $\hat{\mathcal{A}}$ are sign-equivalent. Thus there is a scaling matrix Λ with $\mathcal{A}_j = \Lambda \hat{\mathcal{A}}_j$, $j = 1, 2, 3, \dots$. We then have, for any $s, t \geq 1$,

$$H_{s,t} = \Lambda_s \hat{H}_{s,t},$$

where $\hat{H}_{s,t}$ is the $s \times t$ Hankel matrix for $\hat{\mathcal{A}}$ and $\Lambda_s = \text{diag}(\Lambda, \dots, \Lambda)$. Since this is true for every s, t ,

$$\begin{aligned} \text{rank}(\mathcal{A}) &= \sup_{s,t} \{\text{rank}(H_{s,t})\} \\ &= \sup_{s,t} \{\text{rank}(\hat{H}_{s,t})\} = \text{rank}(\hat{\mathcal{A}}), \end{aligned}$$

as claimed.

THEOREM 4.13. *Let α be a sign-linear i/o map. Then α is realizable by a sign-linear system if and only if α has finite Hankel rank.*

Proof. If α has finite rank then any Markov sequence for α , \mathcal{A} , has finite rank. It then follows that there exists a linear representation for \mathcal{A} , (A, B, C) . Then the corresponding sign-linear system $(A, B, C)_s$ realizes α .

Conversely, given a sign-linear i/o map α that is realizable by a sign-linear system $(A, B, C)_s$, we would like to show that α has finite rank. One Markov sequence for $(A, B, C)_s$ is the impulse response of the linear system (A, B, C) . This impulse response \mathcal{A} is a Markov sequence for α . From linear realization theory, we know that \mathcal{A} has finite rank. Thus, by the remark above, α has finite rank. \square

LEMMA 4.14. *If (A, B, C) is a canonical representation of a Markov sequence \mathcal{A} , then (A, B, C) satisfies property \mathcal{P} .*

Proof. Suppose (A, B, C) does not satisfy property \mathcal{P} . Then by observability there is some $i \notin I(\mathcal{A})$ (i.e., so that the i th row \mathcal{A}^i of \mathcal{A} is zero) so that

$$\bigcap_{\substack{j \in I(\mathcal{A}) \\ l=0, \dots, n-1}} \ker(C_j A^l) \neq \{0\},$$

but

$$(9) \quad \bigcap_{\substack{j \in I(\mathcal{A}) \cup \{i\} \\ l=0, \dots, n-1}} \ker(C_j A^l) \subsetneq \bigcap_{\substack{j \in I(\mathcal{A}) \\ l=0, \dots, n-1}} \ker(C_j A^l).$$

Since $\mathcal{A}^i \equiv 0$ then $C_i(A^j B) = 0$ for all j , so in particular,

$$C_i \begin{pmatrix} B & AB & A^2 B & \dots & A^{n-1} B \end{pmatrix} = 0.$$

The pair (A, B) is controllable so

$$\begin{pmatrix} B & AB & A^2 B & \dots & A^{n-1} B \end{pmatrix}$$

has full row rank. Thus $C_i = 0$, contradicting (9). So property \mathcal{P} indeed holds. \square

LEMMA 4.15. *If (A, B, C) is a triple satisfying property \mathcal{P} , then the sign-linear system $\Sigma = (A, B, C)_s$ is final-state observable.*

Proof. First suppose $\Sigma = (A, B, C)_s$ is a discrete-time sign-linear system. Perform a change of variables in the state space. Let

$$z = T^{-1}x = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix},$$

where $T \in Gl(n)$ is chosen so that

$$T^{-1}AT = \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix},$$

with A_1 of size $n_1 \times n_1$ nilpotent and A_2 of size $n_2 \times n_2$ nonsingular. (This can be done, for instance, by first putting A in real canonical form and then reordering the blocks so that the blocks corresponding to 0 eigenvalues come first.) Then

$$y = \text{sign}(CTz)$$

can be written as

$$y = \text{sign} \left[\begin{pmatrix} C_1 & C_2 \end{pmatrix} z \right],$$

and we can also write

$$T^{-1}B = \begin{pmatrix} B_1 \\ B_2 \end{pmatrix}.$$

Since (A, C) is an observable pair, the n columns of

$$\begin{pmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{pmatrix} = \begin{pmatrix} C_1 & C_2 \\ C_1 A_1 & C_2 A_2 \\ \vdots & \vdots \\ C_1 A_1^{n-1} & C_2 A_2^{n-1} \end{pmatrix} T^{-1}$$

are linearly independent. As T^{-1} is an invertible matrix, both (A_1, C_1) and (A_2, C_2) must be observable pairs. Property \mathcal{P} implies that the subset of outputs indexed by $I(\mathcal{A})$ allows observability of the pair (A, C) . Then the outputs indexed by $I(\mathcal{A})$ also allow observability of the pair (A_2, C_2) . We know that $\mathcal{A}^i \neq 0$ for $i \in I(\mathcal{A})$. Since A_1 is nilpotent, after $n + 1$ steps the output sequence looks like

$$\begin{aligned} & \text{sign}(C_2 A_2^{n+1} z_2 + \mathcal{A}_1 u_{n+1} + \cdots + \mathcal{A}_{n+1} u_1), \\ & \text{sign}(C_2 A_2^{n+2} z_2 + \mathcal{A}_1 u_{n+2} + \cdots + \mathcal{A}_{n+2} u_1), \dots \end{aligned}$$

Now we have (A_2, C_2) is an observable pair, $\det A_2 \neq 0$, and

$$\bigcap_{\substack{j \in I(\mathcal{A}) \\ q=0, \dots, n_2-1}} \ker((C_2)_j A_2^q) = \{0\},$$

where $\mathcal{A}^i \neq 0$ for $i \in I(\mathcal{A})$. Now using Remark 3.3, we may always choose appropriate controls to distinguish any distinct z_2 and \tilde{z}_2 . Also, z_1 goes to zero (in less than n time steps). So the system is final-state observable.

For a continuous-time sign-linear system, $\Sigma = (A, B, C)_s$, property \mathcal{P} alone implies that the system is observable, by Lemma 3.5. Hence, Σ is also final-state observable. (Observability and final-state observability are equivalent in continuous-time.) \square

THEOREM 4.16.

1. *If a sign-linear realization is controllable and observable then it is minimal.*
2. *If it is minimal then it is controllable and final-state observable.*
3. *Any two minimal sign-linear realizations are sign-similar.*

Proof. 1. If the sign-linear system $(A, B, C)_s$ is controllable and observable then in particular the triple (A, B, C) is canonical so the sign-linear system is minimal by Lemma 4.11.

2. If the system $\Sigma = (A, B, C)_s$ is minimal, then the triple (A, B, C) is canonical. If $\mathcal{A} \equiv 0$, then the minimal realization has dimension 0 and is trivially final-state observable. So now assume that we are dealing with dimension $n > 0$. We know that the triple (A, B, C) is canonical, so it satisfies property \mathcal{P} (Lemma 4.14). Next, applying Lemma 4.15, we conclude that $\Sigma = (A, B, C)_s$ is final-state observable.

3. Given two minimal realizations $(A, B, C)_s$ and $(\hat{A}, \hat{B}, \hat{C})_s$, of a sign-linear map α , with Markov sequence \mathcal{A} , we must show that they are sign-similar. The corresponding triples (A, B, C) and $(\hat{A}, \hat{B}, \hat{C})$ represent Markov sequences \mathcal{A}^1 and \mathcal{A}^2 , respectively, which are both sign-equivalent to \mathcal{A} (Corollary 4.9). That is, we have scaling matrices Λ_1, Λ_2 satisfying

$$\mathcal{A} = \Lambda_1 \mathcal{A}^1, \quad \mathcal{A} = \Lambda_2 \mathcal{A}^2.$$

Since the sign-linear realizations are minimal, the linear representations are canonical (Lemma 4.11). Since Λ_1 and Λ_2 have full rank, this implies that $(A, \Lambda_1 C)$ and $(\hat{A}, \Lambda_2 \hat{C})$ are also observable pairs. Thus, $(A, B, \Lambda_1 C)$ and $(\hat{A}, \hat{B}, \Lambda_2 \hat{C})$ are both canonical linear representations of the same Markov sequence \mathcal{A} . By [12], Thm. 20, they must be similar, i.e., there exists some $T \in Gl(n)$ so that $T^{-1}AT = \hat{A}$, $T^{-1}B = \hat{B}$, and $\Lambda_1 CT = \Lambda_2 \hat{C}$. Thus $(A, B, C)_s$ and $(\hat{A}, \hat{B}, \hat{C})_s$ are sign-similar, with T as above and scaling matrix $\Lambda = \Lambda_1^{-1} \Lambda_2$. \square

The rank of $\mathcal{A} = \{1, -1, 1, -1, \dots\}$ from Example 4.3, is 1, which is clearly finite. The triple $A = -1$, $B = 1$, $C = 1$ is a realization of the i/o map α , which is

controllable and observable; hence it is minimal. An example of a nonminimal sign-linear realization of the same α is

$$A = \begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix}; B = \begin{pmatrix} 1 \\ 1 \end{pmatrix}; C = \begin{pmatrix} 1 & 0 \end{pmatrix}.$$

In this case (A, B) is a controllable pair, but (A, C) is not an observable pair.

4.3. Counterexamples. Note that the converses of parts 1 and 2 of Theorem 4.16 are not true for discrete-time systems. If a sign-linear system is minimal, it is not necessarily observable. For example, the system with $x^+ = u$ and $y = \text{sign}(x)$ is minimal, but $A = 0$ so it is not observable. Also, a system may be final-state observable, and yet not be minimal. For example,

$$\begin{aligned} x^+ &= \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} x + \begin{pmatrix} 1 \\ 1 \end{pmatrix} u, \\ y &= \text{sign} \left[\begin{pmatrix} 0 & 1 \end{pmatrix} x \right] \end{aligned}$$

is final-state observable. After k steps (for any $k \geq 1$) any state (x_1, x_2) ends up at (u_k, x_2) and x_2 can be identified. However, (A, C) is not an observable pair. If this system would be minimal, then the corresponding triple would be canonical by Lemma 4.11. But then (A, C) would have to be an observable pair. The minimal system for this i/o map is one of dimension 1, namely, $x^+ = x + u$, $y = \text{sign}(x)$.

5. Canonical realizations of sign-linear i/o maps. We noted that for sign-linear systems (unlike for linear systems) it is not true that a system is minimal if and only if it is canonical. The problem is that a minimal *discrete-time* sign-linear system may have $\det A = 0$, in which case it is not observable (Theorem 3.4). We may then ask—what is the canonical realization of a minimal sign-linear system which is guaranteed to exist by abstract realization theory ([12, §5.8])? The answer, for $p = 1$, is that for any α realizable by a sign-linear system, there exists a canonical (reachable and observable) system $\tilde{\Sigma}$ that realizes α , where $\tilde{\Sigma}$ is in the form of a cascade of a sign-linear system and shift registers. (In the general case, $p > 1$, the result has to be modified: we can only conclude that there is a system of this cascade form in which the minimal system may be embedded.)

We know there exists some canonical realization. We need only to show that there is a canonical realization of the form described above. Next we sketch the construction for the single-output case ($p = 1$). First find a minimal sign-linear realization Σ of α . Then we know (A, B, C) is a canonical triple and satisfies property \mathcal{P} (Lemmas 4.11 and 4.14). Perform a change of variables in the state space so that A has the form

$$\begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix}$$

with A_1 an $n_1 \times n_1$ invertible matrix and A_2 an $n_2 \times n_2$ nilpotent matrix. (Note that if Σ is already observable, then A is invertible and there is no A_2 . This Σ is already in the canonical form we are looking for.) Now the system equations have the form

$$\begin{aligned} x_1^+ &= A_1 x_1 + B_1 u, \\ x_2^+ &= A_2 x_2 + B_2 u, \\ y &= \text{sign}(C_1 x_1 + C_2 x_2). \end{aligned}$$

From now on, assume Σ has the form described above. Let κ be the relative degree of the system and $l := \min\{\kappa, n_2\}$. Let $\tilde{\Sigma}$ be the discrete-time system with state space $\mathbb{R}^{n-l} \times \{-1, 0, 1\}^l$, and system equations

$$(10) \quad \begin{aligned} \xi^+ &= F\xi + Gu, \\ \zeta_1^+ &= \text{sign}(\xi_{n-l} + \mathcal{A}_l u), \\ \zeta_2^+ &= \zeta_1, \\ &\vdots \\ \zeta_l^+ &= \zeta_{l-1}, \\ \eta &= \zeta_l, \end{aligned}$$

where $(F, G) = (A_1, B_1)$ when $l = n_2$, and when $l < n_2$,

$$F = \begin{pmatrix} A_1 & 0 & 0 \\ C_1 A_1^{n_2} & 0 & 0 \\ 0 & I & 0 \end{pmatrix}, \quad G = \begin{pmatrix} B_1 \\ \mathcal{A}_{n_2} \\ \mathcal{A}_{n_2-1} \\ \vdots \\ \mathcal{A}_{l+1} \end{pmatrix},$$

and I is the identity matrix of size $n_2 - l - 1$. (When $l = n_2 - 1$, there is no “ I ” part.) This can be seen as a cascade of a sign-linear system and shift registers.

LEMMA 5.1. *The system $\tilde{\Sigma}$ is the observable reduction of Σ .*

Proof. First we show that two states x and z are indistinguishable for Σ if and only if

$$(11) \quad x_1 = z_1$$

$$(12) \quad \begin{cases} CA^{n_2-1}x &= CA^{n_2-1}z \\ &\vdots \\ CA^{l+1}x &= CA^{l+1}z \\ CA^l x &= CA^l z \end{cases}$$

$$(13) \quad \begin{cases} \text{sign}(CA^{l-1}x) &= \text{sign}(CA^{l-1}z) \\ &\vdots \\ \text{sign}(Cx) &= \text{sign}(Cz). \end{cases}$$

In the case $l = n_2$, we have only (11) and (13). Suppose all equalities hold. Since $l <$ relative degree, the first l output terms for Σ are independent of the control. Then the last l equalities imply that the first l output terms coincide for x and z , for any input. Equations (12) imply that actually the first n_2 output terms coincide for x and z .

The remaining outputs only involve the first n_1 components of the state because of the nilpotency of A_2 . So if $x_1 = z_1$, then we see that all the remaining output terms are equal for initial states x and z . Thus, x and z are indistinguishable.

On the other hand, if x, z are indistinguishable, then using any control sequence, the outputs for the two initial states are always equal. In particular, the first l output terms are independent of the control so we obtain the last l equalities directly. For equalities (12) (in the case $l < n_2$) look at the next $n_2 - l$ output terms. If

$$CA^k x \neq CA^k z, \text{ for some } l \leq k \leq n_2 - 1,$$

then property \mathcal{P} and Remark 3.3 would imply that there is some control that would cause the k th output to be different for x, z , contradicting indistinguishability. Thus, those equalities hold too. Finally, for (11), we may focus on the output terms $y(k)$ for $k \geq n_2$. Indistinguishability implies that in particular, for the 0 control, all output terms are equal. Then $CA^k x_1 = CA^k z_1$ for all $k \geq n_2$. But (A_1, C_1) is an observable pair and $\det A_1 \neq 0$ so this implies $x_1 = z_1$.

Now consider the mapping $\phi : \mathbb{R}^n \rightarrow \mathbb{R}^{n-l} \times \{-1, 0, 1\}^l$ given by $\phi(x) = (\xi, \zeta)$, where

$$\xi = \begin{pmatrix} x_1 \\ CA^{n_2-1}x \\ \vdots \\ CA^l x \end{pmatrix} \in \mathbb{R}^{n-l},$$

$$\zeta = \begin{pmatrix} \text{sign}(CA^{l-1}x) \\ \vdots \\ \text{sign}(CAx) \\ \text{sign}(Cx) \end{pmatrix} \in \{-1, 0, 1\}^l$$

and $\xi = x_1$ if $l = n_2$. We just proved that x and z are indistinguishable if and only if $\phi(x) = \phi(z)$. To show that the map is onto, we must show that for any $(\xi, \zeta) \in \mathbb{R}^{n-l} \times \{-1, 0, 1\}^l$, there is some $x \in \mathbb{R}^n$ so that $\phi(x) = (\xi, \zeta)$. Since (A, C) is an observable pair, (A_2, C_2) is also an observable pair. Thus, we may let x_1 be the first n_1 components of ξ and x_2 the solution to

$$\begin{pmatrix} C_2 A_2^{n_2-1} \\ \vdots \\ C_2 A_2 \\ C_2 \end{pmatrix} x_2 = \begin{pmatrix} \xi_{n_1+1} - C_1 A_1^{n_2-1} x_1 \\ \vdots \\ \xi_{n-l} - C_1 A_1^l x_1 \\ \zeta_1 - C_1 A_1^{l-1} x_1 \\ \vdots \\ \zeta_l - C_1 x_1 \end{pmatrix}.$$

Then clearly, $\phi(x) = (\xi, \zeta)$. Furthermore, it is easy to verify that ϕ commutes with the dynamics of Σ so it is a system morphism in the sense of [12], §5.8. \square

LEMMA 5.2. *The system $\tilde{\Sigma}$ is reachable and observable and realizes the same i/o behavior as Σ .*

Proof. Since $\tilde{\Sigma}$ is the observable reduction of Σ , and Σ is reachable, [12, Lemma 5.8.3] implies that $\tilde{\Sigma}$ is both reachable and observable with the same input/output behavior as Σ . \square

Example 5.3. Let Σ be the system with state space \mathbb{R}^2 and

$$\begin{aligned} x_1^+ &= u, \\ x_2^+ &= x_2 + u, \\ y &= \text{sign}(x_1 + x_2). \end{aligned}$$

Then Σ is minimal. But this sign-linear system is not observable, since $\det A = 0$. Perform a change of variables in the state space so that the A matrix is in the form discussed above. In the new coordinates, (z_1, z_2) , the equations take the form

$$z_1^+ = z_1 - u,$$

$$\begin{aligned} z_2^+ &= u, \\ y &= \text{sign}(-z_1 + z_2). \end{aligned}$$

The Markov sequence is $\mathcal{A} = \{2, 1, 1, 1, \dots\}$, $n_2 = 1$, relative degree = 1, so $l = 1$. The state space for $\tilde{\Sigma}$ is $\mathbb{R} \times \{-1, 0, 1\}$ and the equations for $\tilde{\Sigma}$ are

$$\begin{aligned} \xi^+ &= \xi - u, \\ \zeta^+ &= \text{sign}(\xi + 2u), \\ \eta &= \zeta. \end{aligned}$$

This system is reachable and observable.

6. Sampling. In this section we make some remarks about the time-sampling of sign-linear systems. This is the process of replacing a given continuous-time sign-linear system by the discrete-time one that results when only piecewise constant inputs (with a fixed sampling time) are used. The results in this section can be used to obtain the continuous-time results of Theorem 3.5 as a consequence of those of Theorem 3.4, and they clarify the differences between the two types of results, in particular, the fact that invertibility of the A matrix is not needed in the continuous-time case.

Remark 6.1. Suppose that (A, B, C) has property \mathcal{P} . Then the continuous-time sign-linear system $(A, B, C)_s$ is observable.

Proof. We will prove this by studying the associated sampled system. Using the notations and terminology in [12, §2.10], for each $\delta > 0$, the δ -sampled system corresponding to Σ is

$$\Sigma_\delta : \begin{cases} x^+ &= Fx + Gu, \\ y &= \text{sign}(Cx), \end{cases}$$

where $F = e^{\delta A}$, $G = A^{(\delta)}B$, and $A^{(\delta)} = \int_0^\delta e^{(\delta-s)A}ds$. We want to show that there is a $\delta > 0$ so that if (A, B, C) has property \mathcal{P} then the δ -sampled system satisfies condition 2 of Theorem 3.4. If this is true then the sampled system would be observable (clearly $\det e^{\delta A} \neq 0$). Hence, Σ is observable using only piecewise constant controls that are constant on intervals of length δ , and the result is proved.

Apply Kalman's sampling theorem (see [12, Prop. 5.2.11]), to the pair (A, \hat{C}) obtained by dropping the rows of C not in $I(\mathcal{A})$. For any δ satisfying

$$(14) \quad \delta(\lambda - \mu) \neq 2\pi ik, \quad k = \pm 1, \pm 2, \pm 3, \dots,$$

for every two eigenvalues λ, μ of A , we have that

$$\bigcap_{\substack{j \in I(\mathcal{A}) \\ q=0, \dots, n-1}} \ker(C_j(e^{\delta A})^q) = \{0\}.$$

What is left is to show that

$$I(\mathcal{A}) = I(\mathcal{A}_\delta),$$

where \mathcal{A}_δ is the Markov sequence of $(e^{\delta A}, A^{(\delta)}B, C)$. Note that $I(\mathcal{A}_\delta) \subseteq I(\mathcal{A})$ is always true for any δ , so the other inclusion is the interesting one. We will prove that if the k th row \mathcal{A}^k of \mathcal{A} is nonzero then the k th row \mathcal{A}_δ^k of \mathcal{A}_δ is nonzero for all δ satisfying (14). This will be done by showing the stronger result that \mathcal{A}^k and \mathcal{A}_δ^k have the same Hankel rank.

Fix a $k \in I(\mathcal{A})$. By restricting our attention to the linear system described by (A, B, C_k) , whose Markov sequence is \mathcal{A}^k and sampled-Markov sequence is \mathcal{A}_δ^k , we may, and will, assume without loss of generality that \mathcal{A} is a sequence with $p = 1$ and C has only one row. Thus we need to show that if \mathcal{A} is a Markov sequence with $p = 1$ represented by the triple (A, B, C) and if δ satisfies (14) then \mathcal{A}_δ , the Markov sequence of $(e^{\delta A}, A^{(\delta)}B, C)$, has the same Hankel rank as \mathcal{A} .

So let $\delta, \mathcal{A}, \mathcal{A}_\delta$ and (A, B, C) be as described. Next define a sequence $\mathcal{A}^{(\delta)}$ as follows. If

$$K(t) = \sum_{i=1}^{\infty} \mathcal{A}_i \frac{t^{i-1}}{(i-1)!},$$

then the output function for $\Sigma = (A, B, C)$ is $y(t) = \int_0^t K(t-s)u(s)ds$. If we restrict to sampled controls of length δ , then

$$y(l\delta) = \sum_{j=0}^{l-1} \left[\int_{j\delta}^{(j+1)\delta} K(l\delta - s)ds \right] u_{j+1}.$$

Letting

$$\mathcal{A}_j^{(\delta)} = \int_{j\delta}^{(j+1)\delta} K(l\delta - s)ds, \quad j = 0, 1, 2, \dots$$

we get

$$y(l\delta) = \sum_{j=0}^{l-1} \mathcal{A}_j^{(\delta)} u_{j+1}.$$

Look at any linear representation of the Markov sequence \mathcal{A} . Take the δ -sampled system for that representation. The Markov sequence for the δ -sampled system is $\mathcal{A}^{(\delta)}$. In particular, applied to the given triple (A, B, C) , this means that

$$\mathcal{A}^{(\delta)} = \mathcal{A}_\delta.$$

Take now a canonical representation (A^c, B^c, C^c) of \mathcal{A} of dimension n^c . Its eigenvalues, i.e., the eigenvalues of the matrix A^c , are among the eigenvalues of the (possibly non-canonical) original triple (A, B, C) . Thus, δ also satisfies $\delta(\lambda - \mu) \neq 2\pi ik$, $k = \pm 1, \pm 2, \pm 3, \dots$, for any two eigenvalues λ and μ of A^c . Then controllability and observability of (A^c, B^c, C^c) are preserved by sampling at this δ ; and thus the sampled triple $(e^{\delta A^c}, (A^c)^{(\delta)}B^c, C^c)$ is itself canonical and is a linear representation of $\mathcal{A}_\delta = \mathcal{A}^{(\delta)}$. The rank of a Markov sequence is equal to the dimension of a canonical linear representation of that sequence ([12, Cor. 5.5.7]). Therefore,

$$\text{rank } \mathcal{A}^{(\delta)} = n^c = \text{rank } \mathcal{A},$$

as desired. \square

REPRESENTATIONS OF SYMMETRIC LINEAR DYNAMICAL SYSTEMS*

FABIO FAGNANI[†] AND JAN WILLEMS[‡]

Abstract. The purpose of this paper is to study static symmetries in linear time-invariant differential dynamical systems. The main result is a representation theorem which brings the symmetry strongly into evidence. This result is then applied to a number of examples involving permutations and rotations. We close by proving a general result on the representation of compact groups on the ring of unimodular polynomial matrices.

Key words. linear systems, symmetry, representations, canonical forms, group representations, permutations, rotations

AMS subject classifications. 93A, 93B

1. Introduction. *Symmetry* is a very appealing concept in many scientific endeavors. It plays a major role particularly in physics and in chemistry (for example, in crystallography). It has also been extensively studied in the classical theory of dynamical systems. A salient result in this area is Noether's theorem showing the equivalence of symmetries and conservation laws in Hamiltonian dynamics.

Also, many control problems will exhibit symmetry. For example, it is of interest to ascertain if a platform suspended on four pivots with a 90° rotation symmetry can be adequately stabilized by a control mechanism that also has this symmetry. Many mechanical systems will have a rotation symmetry, and an analogous question occurs in this case. A classical control problem that can be viewed as a symmetry question is whether an optimal controller for a time-invariant system will itself be time-invariant.

Although some interesting work has been done on symmetry questions in control, it is not a standard problem area. Notable contributions are the papers by Hazewinkel and Martin [5], [6] and Martin [8] motivated by certain questions related to the stabilization of linear systems by means of symmetric feedback control laws. Other places in control where symmetry problems have been studied are [1], [4], [11]–[13]. These authors are mainly concerned with nonlinear systems.

The purpose of the present paper is a fundamental study of symmetry in the context of linear systems described by differential equations. We will mainly consider representation questions. In a later paper, we plan to apply these results to control problems. The mathematical formulation follows the setting proposed in [14]. In a sense, the paper is a sequel to [2], where an elegant representation result has been obtained for *time-reversible* systems (cf. Theorem 2). In the present paper, we will study *static* symmetries and apply the representation results obtained especially to systems that are invariant under permutations or under rotations.

In an essential way, the paper uses the theory of group representations, a rather abstract area of mathematics whose original motivation lies very much in various aspects of symmetry. For an introduction to the theory of group representations, refer to [9].

We close this introduction with a few words about notation and nomenclature.

Throughout, \mathbb{K} will denote \mathbb{R} or \mathbb{C} . Some of our results will be rather different for \mathbb{R} and for \mathbb{C} . \mathbb{K}^n denotes the n -dimensional (column) vectors over \mathbb{K} , and $\mathbb{K}^{n_1 \times n_2}$ denotes the matrices over \mathbb{K} with n_1 rows and n_2 columns. We will always consider vectors as columns and occasionally write the n -column vector x in term of its components as $\text{col}(x_1, x_2, \dots, x_n)$. A composite matrix will be written as $M = [M_1; M_2]$, and so forth; $\text{diag}(m_1, m_2, \dots, m_n)$ denotes then $n \times n$ diagonal matrix with (i, i) th element m_i . A similar notation will be used for block diagonal matrices. The determinant of a matrix is denoted as \det .

Let $f : A \rightarrow B$. For $A' \subset A$, the restriction of f to A' will be denoted as $f|_{A'}$. The map that identifies an element of $A' \subset A$ with the same element in A will be called the canonical injection. \ker means kernel, and im means image. The set of infinitely differentiable maps from A to B will be denoted as $C^\infty(A; B)$.

The set of polynomial matrices over \mathbb{K} with n_1 rows and n_2 columns in the indeterminate s will be denoted by $\mathbb{K}^{n_1 \times n_2}[s]$; $\mathbb{K}^{\bullet \times n}[s]$ denotes the set of polynomial matrices with n columns and any (of course, finite) number of rows. An element $R \in \mathbb{K}^{n_1 \times n_2}[s]$ is said to be of full row rank if it contains a $n_1 \times n_1$ submatrix with determinant nonzero. We will denote the set of full row rank elements of $\mathbb{K}^{\bullet \times n}[s]$ by $\mathbb{K}_{fr}^{\bullet \times n}[s]$; of $\mathbb{K}_{fr}^{n_1 \times n_2}[zs]$ denotes the elements of $\mathbb{K}_{fr}^{\bullet \times n_2}[s]$ with n_1 rows.

Let \mathcal{R} be a ring with an identity. An element $U \in \mathcal{R}$ is said to be *unimodular* if there exists $U^{-1} \in \mathcal{R}$ such that $UU^{-1} = U^{-1}U$ is equal to the identity. The unimodular elements of \mathcal{R} clearly form a multiplicative group, called the group of units of \mathcal{R} . The set of $n \times n$ matrices over \mathcal{R} also forms a ring. Its group of units will be denoted by $GL(n, \mathcal{R})$. The following two examples will be very important to us throughout the paper.

1. $GL(n, \mathbb{K})$, the set of nonsingular elements of $\mathbb{K}^{n \times n}$;
2. $GL(n, \mathbb{K}[s])$, the set of unimodular $(n \times n)$ polynomial matrices. Thus $U \in \mathbb{K}^{n \times n}[s]$ belongs to $GL(n, \mathbb{K}[s])$ if and only if its determinant is nonzero and belongs to \mathbb{K} , i.e., if it is a nonzero constant.

The set of isomorphisms on the vector space V is denoted by $GL(V)$. Thus, by considering the matrix representation of elements of $GL(\mathbb{K}^n)$ with respect to the standard basis, $GL(\mathbb{K}^n) \cong GL(n, \mathbb{K})$. As such, we will not make a distinction between these two sets and use $GL(\mathbb{K}^n)$ even where it may be more natural to write $GL(n, \mathbb{K})$.

Let M be a set. A *parametrization* (P, π) of M consists of a set P and a surjective map $\pi : P \rightarrow M$. The set P is called the parameter space. Typically, M is an abstract set, while P consists of concrete objects (as matrices or polynomial matrices—in which case, we refer to a matrix parametrization or a polynomial matrix parametrization of M). Note that π is surjective but not necessarily bijective. If π is a bijection, we will call the parametrization trim. In any case, the map $\pi : P \rightarrow M$ leads to the equivalence relation E on P defined by $(p_1 E p_2) :\Leftrightarrow (\pi(p_1) = \pi(p_2))$. This equivalence relation leads to canonical forms and to invariants. A subset $P_c \subseteq P$ will be called a *canonical form* for the parametrization (P, π) if $\pi(P_c) = M$, i.e., if $(P_c, \pi|_{P_c})$ is also parametrization of M . It is a trim canonical form if $\pi|_{P_c} : P_c \rightarrow M$ is a bijection.

2. Differential dynamical systems. Following the terminology explained in [15], we will define a *dynamical system* Σ to consist of a triple, $\Sigma = (\mathbb{T}, \mathbb{W}, \mathcal{B})$, with \mathbb{T} a subset of \mathbb{R} , called the *time axis*; \mathbb{W} a set called the *signal space*; and \mathcal{B} a subset of $\mathbb{W}^{\mathbb{T}}$ ($:=$ all maps from \mathbb{T} to \mathbb{W}), called the *behavior*. Thus the behavior consists of a given family of trajectories $w : \mathbb{T} \rightarrow \mathbb{W}$.

We will consider continuous-time dynamical systems with time axis $\mathbb{T} = \mathbb{R}$ and

with signal space $\mathbb{W} = \mathbb{K}^q$, with $\mathbb{K} = \mathbb{R}$ (the real case) or $\mathbb{K} = \mathbb{C}$ (the complex case). We will treat both cases in parallel. As we will see, there are distinct advantages, stemming from the theory of group representations, not to limit attention to the real case, although, admittedly, it is the real case that is of interest in applications. However, in §7.4 we see that rotation symmetries actually lead to complex systems!

The dynamical system $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B})$ is said to be *linear* if \mathcal{B} is a linear subspace of $(\mathbb{K}^q)^{\mathbb{R}}$ (the set of all maps from \mathbb{R} to \mathbb{K}^q) and *time-invariant* if $\sigma^t \mathcal{B} = \mathcal{B}$ for all $t \in \mathbb{R}$; σ^t denotes the backward t -shift (specifically, for $f : \mathbb{R} \rightarrow \mathbb{K}^q$ and $t \in \mathbb{R}$, $\sigma^t f : \mathbb{R} \rightarrow \mathbb{K}^q$ is defined by $(\sigma^t f)(t') := f(t + t')$).

In the present paper, we study behaviors \mathcal{B} that are the solution set of a system of constant coefficient linear differential equations

$$(1) \quad R \left(\frac{d}{dt} \right) w = 0$$

defined in terms of a polynomial matrix $R \in \mathbb{K}^{\bullet \times q}[s]$. The solution set of (1) is formally defined as follows:

$$\mathcal{B} = \left\{ w \in C^\infty(\mathbb{R}; \mathbb{K}^q) \mid \left(R \left(\frac{d}{dt} \right) w \right) (t) = 0 \text{ for all } t \in \mathbb{R} \right\}.$$

The assumption that w is infinitely differentiable is used mainly for convenience. The results may be generalized without difficulty to the case that \mathcal{B} also allows locally integrable functions, or distributions. However, for the purposes of the present paper, the smoothness assumption simplifies the analysis somewhat. In other applications, the C^∞ assumption may be very awkward.

The class of dynamical systems studied in this paper consists of those whose behavior is the kernel of a constant coefficient linear differential operator (with, for $R \in \mathbb{K}^{p \times q}[s]$, $R(d/dt)$ viewed as a map from $C^\infty(\mathbb{R}; \mathbb{K}^q)$ to $C^\infty(\mathbb{R}; \mathbb{K}^p)$). We will denote this class of dynamical systems as \mathcal{L}^q and refer to its elements as *differential dynamical systems*.

The above shows that $(\mathbb{K}^{\bullet \times q}[s], \pi)$ is a parametrization of \mathcal{L}^q with for $R \in \mathbb{K}^{\bullet \times q}[s]$, $\pi(R) := (\mathbb{R}, \mathbb{K}^q, \ker R(d/dt))$. This induces the equivalence relation \sim on $\mathbb{K}^{\bullet \times q}[s]$ defined by $(R_1 \sim R_2) \Leftrightarrow (\pi(R_1) = \pi(R_2))$. Note, in fact, that π is not injective. Indeed, if $R \in \mathbb{K}^{p \times q}[s]$ and $U \in GL(p, \mathbb{K}[s])$ (thus U is unimodular), then clearly $UR \sim R$.

We will call the system of differential equations (1) or, equivalently, R , a *behavioral equation representation* of $\pi(R)$; (1) or, equivalently, R is called a *minimal* (behavioral equation) representation of $\pi(R)$ if $(R_1 \in \mathbb{K}^{p_1 \times q}[s], R \in \mathbb{K}^{p \times q}[s], \text{ and } R_1 \sim R)$ implies $(p_1 \geq p)$. Let $\Sigma \in \mathcal{L}^q$ and let R be a minimal behavioral equation of Σ . Obviously, the number of rows of $R \in \mathbb{K}^{\bullet \times q}[s]$ will depend only on Σ but not on the particular minimal representation R of Σ . We will denote the number of rows of R by $p(\Sigma)$. Actually, $p(\Sigma)$ is equal to the number of output variables in any input/output representation of Σ (see [10]).

The following characterization of minimal representations will play an important role throughout the paper.

PROPOSITION 1. (1) *is minimal if and only if $R \in \mathbb{K}_{f_r}^{\bullet \times q}[s]$ (that is, $R \in \mathbb{K}^{\bullet \times q}[s]$ is of full row rank). Moreover, if (1) is minimal and if $R_1 \in \mathbb{K}^{\bullet \times q}[s]$, then $(R_1 \sim R \text{ and } R_1 \text{ is also minimal}) \Leftrightarrow (R_1 \text{ and } R \text{ both belong to } \mathbb{K}^{p(\Sigma) \times q}[s], \text{ and there exists a } U \in GL(p(\Sigma), \mathbb{K}[s]) \text{ such that } R_1 = UR)$. Finally, this U is unique.*

Proof. For the proof, see [10]. \square

This proposition implies that all minimal representations may be obtained from one by acting (as premultiplication) with the unimodular group. The freedom that this implies on the representations of a given dynamical system in terms of (minimal) behavioral equations will allow us to choose R 's in (1) that have an appealing form, reflecting symmetries.

3. Symmetric systems. The purpose of this paper is to study symmetries of dynamical systems in \mathcal{L}^q . A symmetry is induced by a transformation group, the basic idea being that we have a group of transformations mapping a dynamical system $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B}) \in \mathcal{L}^q$ into another such dynamical system. If this transformation does not change Σ , then we will call Σ symmetric. We will now formalize this.

3.1. Transformation groups. Let S be a set and G be a group. Let T be a map from G into the group of bijections on S . We will denote the T -image of $g \in G$ by T_g . Then T is said to be a *transformation group* on S if T is a group homomorphism, that is, if $T_{g_1 g_2} = T_{g_1} T_{g_2}$. (The multiplication $g_1 g_2$ refers to the multiplication in the group G , while $T_{g_1} T_{g_2}$ refers to composition of maps on S .) For $s \in S$, the set $O_s := \{s' \in S \mid \exists g \in G \text{ such that } s' = T_g s\}$ is called the *orbit* through s . It is easily seen that, for $s_1, s_2 \in S$, either $O_{s_1} = O_{s_2}$, or $O_{s_1} \cap O_{s_2} = \emptyset$, the first situation occurring if and only if $s_2 \in O_{s_1}$. The collection of orbits $\{O_s \mid s \in S\}$ hence defines a partition of S and thus an equivalence relation on S .

3.2. Symmetries. Let T be a transformation group on \mathcal{L}^q . We will call the dynamical system $\Sigma \in \mathcal{L}^q$, *T-symmetric* if $T_g \Sigma = \Sigma$ for all $g \in G$. Thus, for a symmetric element Σ , the orbit O_Σ is equal to the singleton $\{\Sigma\}$.

Let us now consider a few examples of symmetries on \mathcal{L}^q .

Example 1 (time-invariance). Let $G = \mathbb{R}$ and define, for $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B}) \in \mathcal{L}^q$, $T_g \Sigma$ as $T_g \Sigma = (\mathbb{R}, \mathbb{K}^q, \sigma^g \mathcal{B})$ (with σ^g the backward g -shift). It is easy to see that $T_g \Sigma = \Sigma$ for all $g \in \mathbb{R}$, and hence all elements of \mathcal{L}^q are symmetric in this sense. It is this symmetry that we call *time-invariance*. It formalizes the fact that the laws governing a dynamical system do not depend explicitly on time.

Example 2 (time-reversibility). Many examples of symmetries involve the group consisting of only two elements, $G = \{1, g\}$, $1 \neq g = g^{-1}$. Then $T_g = (T_g)^{-1}$; i.e. T_g is an *involution*. Define, for $\Sigma \in \mathcal{L}^q$, $T_g \Sigma$ as $T_g \Sigma := (\mathbb{R}, \mathbb{R}^q, \text{rev } \mathcal{B})$ with for $w : \mathbb{R} \rightarrow \mathbb{R}^q$, $\text{rev } w : \mathbb{R} \rightarrow \mathbb{R}^q$, the *time-reverse* of defined by $(\text{rev } w)(t) := w(-t)$. This Σ will be symmetric with respect to this transformation group if and only if $\mathcal{B} = \text{rev } \mathcal{B}$. This symmetry is called *time-reversibility*. It expresses the fact that the system looks identical when viewed backward in time. We have studied this symmetry in detail in [2] and will return to it later in this paper.

3.3. Static symmetries. Let T be a transformation group acting on \mathbb{K}^q ; T induces a symmetry on \mathcal{L}^q by defining for $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B}) \in \mathcal{L}^q$, $T_g \Sigma$ as $T_g \Sigma := (\mathbb{R}, \mathbb{K}^q, T_g \mathcal{B})$ with $T_g \mathcal{B} := \{w : \mathbb{R} \rightarrow \mathbb{R}^q \mid \exists w' : \mathbb{R} \rightarrow \mathbb{K}^q \text{ such that } w(t) = T_g w'(t) \text{ for all } t \in \mathbb{R}\}$. Note that, by a minor abuse of notation, we use the same symbol T_g as acting on \mathcal{L}^q , on \mathcal{B} , and on \mathbb{K}^q . Thus Σ is symmetric in this sense if $w \in \mathcal{B}$ implies $T_g w \in \mathcal{B}$ for all $g \in G$. Since T_g transforms the trajectories w in \mathcal{B} by applying the memoryless map T_g (that is, since it transforms trajectories w in a nondynamic way), we will call such a symmetry a *static symmetry*. In fact, we will be particularly interested in the case where T_g is linear for all $g \in G$. Such transformation groups are the subject of the theory of group representations. It is customary to denote T by ρ in that case.

3.4. Group representations. Let V be a vector space over the field \mathbb{K} . A group homomorphism $\rho : G \rightarrow GL(V)$ is said to be a (linear) *representation* of the group G on V . If V is finite-dimensional, then the representation is called *finite-dimensional*, and the dimension of V as a vector space is called the *order* of the representation. In particular, if V is n -dimensional and if we represent elements of $GL(V)$ as matrices with respect to a fixed basis on V , then a representation of G will correspond to each element of the group G , a nonsingular $(n \times n)$ matrix over \mathbb{K} such that group multiplication goes over in multiplication of matrices. In particular, the identity matrix will correspond to the unit element in G .

Example 3 (permutations). As a specific example of a static symmetry, let S_q denote the group of permutations of q elements. This group is called the *symmetric group*; it is a finite group consisting of $q!$ elements. Now consider the map $\rho : S_q \rightarrow GL(\mathbb{K}^q)$, which associates with the permutation $g : \{1, 2, \dots, q\} \rightarrow \{1, 2, \dots, q\}$ the linear bijection on \mathbb{K}^q that takes the vector $\text{col}(x_1, x_2, \dots, x_q)$ into the vector $\text{col}(x_{g(1)}, x_{g(2)}, \dots, x_{g(q)})$. Clearly, ρ defines a representation of S_q on \mathbb{K}^q . Thus ρ in this case maps onto the group of $q \times q$ permutation matrices. A dynamical system $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B})$ will be symmetric in the sense of the static symmetry induced by this representation of S_q , provided that $w = \text{col}(w_1, w_2, \dots, w_q) \in \mathcal{B}$ if and only if $w' = \text{col}(w'_1, w'_2, \dots, w'_q) \in \mathcal{B}$ with $(w'_1, w'_2, \dots, w'_q)$ any permutation of (w_1, w_2, \dots, w_q) . We can think of this symmetry as occurring when Σ models the dynamics of the positions of q identical particles on the line: feasible motions will remain feasible motions after we interchange the positions of the particles. More meaningful symmetries as representations of S_q (involving particles in the plane or in 3-space), or of subgroups of S_q , will be considered later.

Let $\rho : G \rightarrow GL(V)$ be a representation of G on V , with V a finite-dimensional vector space over \mathbb{K} . Throughout this paper, we will assume that G is either finite or compact. In the compact case, G is assumed to be a compact Hausdorff topological space with the group multiplication and the inverse continuous maps. A representation $\rho : G \rightarrow GL(V)$ is then always assumed to be continuous.

A subspace $V_1 \subseteq V$ is said to be *invariant* if $\rho_g V_1 \subseteq V_1$ for all $g \in G$. The representation ρ is said to be *irreducible* if its only invariant subspaces are V and $\{0\}$. When V_1 is invariant, then ρ^{V_1} , defined by $\rho^{V_1} : G \rightarrow GL(V_1)$ with $\rho^{V_1}_g := \rho_g|_{V_1}$, yields another finite-dimensional representation of G : ρ^{V_1} is called a subrepresentation. It is a standard result from the theory of group representations that, if G is compact, then a finite-dimensional subrepresentation can be written as the direct sum of irreducible representations.

Let $\rho^1 : G \rightarrow GL(V_1)$ and $\rho^2 : G \rightarrow GL(V_2)$ be two finite-dimensional representations of the same group G . Then they are said to be *isomorphic* if V_1 and V_2 have the same dimension and if there exists an isomorphism $S : V_1 \rightarrow V_2$ such that $\rho^2_g = S \rho^1_g S^{-1}$ for all $g \in G$. Isomorphism of ρ_1 and ρ_2 will be denoted by $\rho_1 \cong \rho_2$. If ρ_1 is not isomorphic to ρ_2 , then ρ_1 and ρ_2 are said to be *distinct*.

Thus the above implies that a representation ρ admits a decomposition of the following type:

$$\rho \cong m_1 \rho_1 \oplus m_2 \rho_2 \oplus \cdots \oplus m_k \rho_k,$$

where $\rho_1 \cdots \rho_k$ are distinct irreducible representation and where

$$m_j \rho_j := \underbrace{\rho_j \oplus \rho_j \oplus \cdots \oplus \rho_j}_{m_j \text{--times}}.$$

Example 3 (continued). Recall that S_q denotes the group of permutations of q elements. It is a finite group containing $q!$ elements. The irreducible representations of S_q have been studied in much detail in the literature. However, we will need only two of them. Consider the following representations of S_q :

1. The *identity representation*, $\rho_1 : S_q \rightarrow GL(\mathbb{K})$ with $\rho_{1,g} = 1$ for all $g \in S_q$. This representation is of order 1 and hence irreducible;

2. The representation ρ_2 defined as follows. Let V be the subspace of \mathbb{K}^q consisting of those vectors $\text{col}(x_1, x_2, \dots, x_q)$ such that $\sum_{i=1}^q x_i = 0$. Let S_q act on V by $\rho_{2,g} \text{col}(x_1, x_2, \dots, x_q) := \text{col}(x_{g(1)}, x_{g(2)}, \dots, x_{g(q)})$. It is easy to prove that ρ_2 defines an irreducible representation of S_q . Since $\dim V = q - 1$, its order is $q - 1$.

Let $\rho : S_q \rightarrow GL(\mathbb{K}^q)$ be the representation of S_q introduced in Example 3: $\rho_g \text{col}(x_1, x_2, \dots, x_q) := \text{col}(x_{g(1)}, x_{g(2)}, \dots, x_{g(q)})$. Write $\mathbb{K}^q = V_1 \oplus V_2$ with $V_1 = \{\text{col}(x_1, x_2, \dots, x_q) \in \mathbb{K}^q \mid x_1 = x_2 = \dots = x_q\}$ and $V_2 = \{\text{col}(x_1, x_2, \dots, x_q) \in \mathbb{K}^q \mid x_1 + x_2 + \dots + x_q = 0\}$. Clearly, V_1 and V_2 are ρ -invariant subspaces, $\rho^{V_1} \cong \rho_1$ and $\rho^{V_2} \cong \rho_2$. Hence, in this case, the decomposition of ρ in terms of the irreducible representations of S_q becomes $\rho \cong \rho_1 \oplus \rho_2$. (We hence have $m_1 = m_2 = 1$, while all the other m_i 's are zero. Furthermore, $n_1 = 1$ and $n_2 = q - 1$.)

4. Representation questions for symmetric systems. Assume that $\rho : G \rightarrow GL(\mathbb{K}^q)$ is a representation of the group G on \mathbb{K}^q and assume that $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B}) \in \mathcal{L}^q$ is symmetric in the sense of the static symmetry induced by this representation. The problem studied in this paper is the following: *Can this symmetry be put into evidence by an appropriate behavioral equation representation of Σ as (1), in which the polynomial matrix R is such that this static symmetry becomes evident?* Otherwise stated, we want to come up with a *parametrization*, with a *canonical form* for the behavioral equations of systems with a static symmetry.

To give an example of the type of results that we seek, we repeat the main result of [2]. This result involves time-reversibility, which, it should be noted, is not a static symmetry.

THEOREM 2. $\Sigma \in \mathcal{L}^q$ is time-reversible if and only if it allows a minimal behavioral equation representation (1) with $R(s) = JR(-s)$ with J a matrix of the type

$$J = \begin{bmatrix} I_1 & 0 \\ 0 & -I_2 \end{bmatrix},$$

where I_1 and I_2 are identity matrices.

Observe that $R(s) = JR(-s)$ is equivalent to stating that (1) consists of a number of scalar differential equations, some of which contain only even-order derivatives, while the others contain only odd-order derivatives. If the equations in (1) are indeed of this form, then time-reversibility is obvious. Note, in particular, that time-reversible systems cannot always be represented by differential equations containing only even-order derivatives. (Actually, any representation as obtained in Theorem 2 will have the dimension of I_1 and I_2 as invariants.)

While this paper is only concerned with static symmetries, it is worthwhile noting that it is possible to view also reciprocity, a much-studied property of electrical networks [17], as a (dynamic) symmetry.

5. The main result. Assume in this section that $\rho : G \rightarrow GL(\mathbb{K}^q)$ is a given representation of a compact group G on \mathbb{K}^q . Then ρ defines a static symmetry on \mathcal{L}^q as described in §3.4; $\Sigma = (\mathbb{R}, \mathbb{K}^q, \mathcal{B}) \in \mathcal{L}^q$ is thus ρ -symmetric if and only if $\rho_g \mathcal{B} = \mathcal{B}$ for all $g \in G$.

Let (1) be a minimal representation for such a ρ -symmetric $\Sigma \in \mathcal{L}^q$. It then follows immediately from Proposition 1 that, for each $g \in G$, there will exist a unimodular polynomial matrix $U_g(s)$ such that $R(s)\rho_g = U_g(s)R(s)$. Our main result tells us that R can be chosen such that $U_g(s)$ is a constant nonsingular matrix, thus independent of s !

THEOREM 3. *Let $\rho : G \rightarrow GL(\mathbb{K}^q)$ be a representation of the compact group G on \mathbb{K}^q . $\Sigma \in \mathcal{L}^q$ is ρ -symmetric if and only if there exists a minimal representation $R(d/dt)w = 0$ of Σ and a representation $\rho' : G \rightarrow GL(\mathbb{K}^{p(\Sigma)})$ of the group G on $\mathbb{K}^{p(\Sigma)}$ such that*

$$R(s)\rho_g = \rho'_g R(s)$$

for all $g \in G$. Moreover, ρ' will be isomorphic to a subrepresentation of ρ .

Proof. To prove the “if” part, assume that $R(s)\rho_g = \rho'_g R(s)$. Then, since ρ'_g is an invertible matrix (hence a unimodular polynomial matrix), $\ker R(d/dt) = \ker R(d/dt)\rho_g$. Hence $\rho_g \mathcal{B} = \mathcal{B}$ for all $g \in G$; ρ -symmetry follows. As a general feature of the type of representation results that we seek, note that also here (as in Theorem 2) the “if” is immediate: if $R(s)\rho_g = \rho'_g R(s)$ for all $g \in G$, then ρ -symmetry of (1) is basically immediate. The converse however is more difficult.

The “only if” part is based on Theorems 4 and 5 and will be proved later.

To see that ρ' is isomorphic to a subrepresentation of ρ , pick an element $\lambda \in \mathbb{R}$ such that $R(\lambda)$ has full row rank $p(\Sigma)$. Since R is minimal and hence of full row rank as a polynomial matrix, such a $\lambda \in \mathbb{K}$ exists. Now observe that $R(\lambda)\rho_g = \rho'_g R(\lambda)$ for all $g \in G$. Let $N := \ker R(\lambda)$. Obviously, N is ρ -invariant. Hence there exists a linear subspace M of \mathbb{K}^q such that M is ρ -invariant and $\mathbb{K}^q = N \oplus M$. Therefore $R(\lambda) \mid_M \rho_g \mid_M = \rho'_g R(\lambda) \mid_M$. Since $R(\lambda) \mid_M$ is a bijection, this shows that ρ' is isomorphic to the subrepresentation ρ^M of ρ . \square

6. Canonical forms for symmetric systems. We will now show that establishing Theorem 3 is equivalent to establishing the existence of a very nice explicit canonical forms for symmetric systems. At this point, it becomes necessary to treat the complex case ($\mathbb{K} = \mathbb{C}$) and the real case ($\mathbb{K} = \mathbb{R}$) separately.

6.1. Complex systems. The representations $\rho : G \rightarrow GL(\mathbb{C}^q)$ and $\rho' : G \rightarrow GL(\mathbb{C}^{p(\Sigma)})$ obtained in §5 can be decomposed in terms of irreducible ones as

$$\begin{aligned} \rho &\cong m_1 \rho_1 \oplus m_2 \rho_2 \oplus \cdots \oplus m_k \rho_k, \\ \rho' &\cong m'_1 \rho_1 \oplus m'_2 \rho_2 \oplus \cdots \oplus m'_k \rho_k. \end{aligned}$$

Since ρ' is isomorphic to a subrepresentation of ρ , it follows that the integers $m'_i \in \mathbb{Z}_+$ satisfy

$$0 \leq m'_i \leq m_i, \quad i = 1, 2, \dots, k$$

The above decomposition of ρ implies that there exists a nonsingular matrix $V \in \mathbb{C}^{q \times q}$ such that

$$V \rho_g V^{-1} = \text{diag} (m_1 \rho_{1,g}, \dots, m_k \rho_{k,g}) =: \tilde{\rho}_g,$$

where

$$m_i \rho_{i,g} := \text{diag} (\underbrace{\rho_{i,g}, \dots, \rho_{i,g}}_{m_i \text{--times}}).$$

Proceeding in a similar manner for ρ' , we obtain a nonsingular matrix $V' \in \mathbb{C}^{p(\Sigma) \times p(\Sigma)}$ such that

$$V' \rho'_g (V')^{-1} = \text{diag} (m'_1 \rho_{1,g}, m'_2 \rho_{2,g}, \dots, m'_k \rho_{k,g}) =: \tilde{\rho}'_g.$$

Note that applying the nonsingular transformation V corresponds to changing the signal variables in $\Sigma = (\mathbb{R}, \mathbb{C}^q, \mathcal{B})$ from $w : \mathbb{R} \rightarrow \mathbb{C}^q$ to $\tilde{w} : \mathbb{R} \rightarrow \mathbb{C}^q$ with $\tilde{w}(t) := Vw(t)$; in other words, it corresponds to choosing a convenient basis in the signal space \mathbb{C}^q . We will call such a basis a ρ -adapted basis, and the corresponding coordinates ρ -adapted coordinates (these are sometimes called *normal coordinates*). On the other hand, premultiplying R in (1) by nonsingular matrix V' corresponds to choosing a convenient basis in the equation space $\mathbb{C}^{p(\Sigma)}$. By Proposition 1, this does not change the behavior, and hence we can always assume that we are using such a basis on the equation space.

Now, assume that ρ and ρ' satisfy the conditions of Theorem 3. It follows thus that in a ρ -adapted basis the system $\Sigma = (\mathbb{R}, \mathbb{C}^q, \mathcal{B}) \in \mathcal{L}^q$ will admit a minimal representation

$$(2) \quad \tilde{R} \left(\frac{d}{dt} \right) \tilde{w} = 0,$$

where $\tilde{R} \in \mathbb{C}^{p(\Sigma) \times q}[s]$ satisfies

$$(3) \quad \tilde{R}(s) \tilde{\rho}_g = \tilde{\rho}'_g \tilde{R}(s).$$

Now partition \tilde{R} conformably as $\tilde{\rho}$ and $\tilde{\rho}'$, yielding

$$(4) \quad \tilde{R}(s) = \begin{bmatrix} \tilde{R}_{11}(s) & \tilde{R}_{12}(s) & \cdots & \tilde{R}_{1k}(s) \\ \tilde{R}_{21}(s) & \tilde{R}_{22}(s) & \cdots & \tilde{R}_{2k}(s) \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{R}_{k1}(s) & \tilde{R}_{k2}(s) & \cdots & \tilde{R}_{kk}(s) \end{bmatrix}.$$

Then (3) implies that $\tilde{R}_{ij}(s) m_j \rho_j = m'_i \rho_i \tilde{R}_{ij}(s)$. By the Schur lemma [9], these equalities imply the following strong conclusions about \tilde{R} :

$$(5) \quad \tilde{R}_{ij} = 0 \quad \text{for } i \neq j$$

and

$$\tilde{R}_{ii}(s) = \begin{bmatrix} \lambda_{11}(s) I_{n_i} & \lambda_{12}(s) I_{n_i} & \cdots & \lambda_{1m_i}(s) I_{n_i} \\ \lambda_{21}(s) I_{n_i} & \lambda_{22}(s) I_{n_i} & \cdots & \lambda_{2m_i}(s) I_{n_i} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_{m'_i 1}(s) I_{n_i} & \lambda_{m'_i 2}(s) I_{n_i} & \cdots & \lambda_{m'_i m_i}(s) I_{n_i} \end{bmatrix},$$

where n_i is the order of the representation ρ_i . In the Kronecker product notation, \tilde{R}_{ii} may be written as

$$(6) \quad \tilde{R}_{ii}(s) = \Lambda_i(s) \otimes I_{n_i},$$

where

$$\Lambda_i(s) = \begin{bmatrix} \lambda_{11}(s) & \lambda_{12}(s) & \cdots & \lambda_{1m_i}(s) \\ \lambda_{21}(s) & \lambda_{22}(s) & \cdots & \lambda_{2m_i}(s) \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_{m'_i 1}(s) & \lambda_{m'_i 2}(s) & \cdots & \lambda_{m'_i m_i}(s) \end{bmatrix}.$$

This proves that, for $\mathbb{K} = \mathbb{C}$, Theorem 3 is equivalent to the following theorem.

THEOREM 4. *Let G be a compact group and let $\rho : G \rightarrow GL(\mathbb{C}^q)$ be a representation of G on \mathbb{C}^q . Assume that $\rho \cong m_1\rho_1 \oplus m_2\rho_2 \oplus \cdots \oplus m_k\rho_k$, with $\rho_i : G \rightarrow GL(\mathbb{C}^{n_i})$, $i = 1, 2, \dots, k$, distinct irreducible representations. Assume that the basis in \mathbb{C}^q is ρ -adapted (to emphasise this, we write the signal variables as \tilde{w} , $\tilde{w} = \text{col}(\tilde{w}_1, \tilde{w}_2, \dots, \tilde{w}_k)$ with $\tilde{w}_i : \mathbb{R} \rightarrow (\mathbb{C}^{n_i})^{m_i}$). Then $\Sigma = (\mathbb{R}, \mathbb{C}^q, \mathcal{B}) \in \mathcal{L}^q$ is ρ -symmetric if and only if there exist $m'_i \in \mathbb{Z}_+$, $0 \leq m'_i \leq m_i$, and polynomial matrices $\Lambda_i \in \mathbb{C}_{fr}^{m'_i \times m_i}[s]$ such that Σ admits a minimal representation*

$$(7) \quad \left(\Lambda_i \left(\frac{d}{dt} \right) \otimes I_{n_i} \right) \tilde{w}_i = 0, \quad i = 1, 2, \dots, k.$$

Note that, from the above theorem, we may conclude that the ρ -adapted variables $\tilde{w}_1, \tilde{w}_2, \dots, \tilde{w}_k$ are completely noninteracting!

6.2. Real systems. In the case ($\mathbb{K} = \mathbb{R}$) of systems with signal space \mathbb{R}^q , Theorem 4 remains, of course, valid but may yield a representation (7) with complex coefficients. However, in this case, we want to obtain differential equations in a canonical form analogous to (7) but with real coefficients. The theory becomes more involved, since the irreducible representations ρ_i introduced in §6.1 are irreducible over \mathbb{C} and need not be real. In particular, Schur's lemma in the form in which it was used in §6.1 would yield complex representations. Nevertheless, quite explicit results may also be obtained now.

As it is shown in [9], a irreducible representation $\rho : G \rightarrow GL(\mathbb{C}^n)$ can be of *real* type, of *complex* type, or of *quaternionic* type; ρ is of real type if it is the complexification of a real representation. Now, if ρ is an irreducible representation of complex or of quaternionic type, then so will be its complex conjugate, ρ^* (thus the matrices ρ_g and ρ_g^* are complex conjugates for all $g \in G$). By combining $\rho \oplus \rho^*$, these complex representations lead to real ones. All together, this leads to the following decomposition of a real representation.

A real representation $\rho : G \rightarrow GL(\mathbb{R}^q)$ of a compact group G admits a decomposition

$$(8a) \quad \rho \cong \rho_{\mathbb{R}} \oplus \rho_{\mathbb{C}} \oplus \rho_{\mathbb{H}}$$

with $\rho_{\mathbb{R}}$, $\rho_{\mathbb{C}}$, and $\rho_{\mathbb{H}}$ referring to the further decomposition into irreducible representations of real, complex, or quaternionic type. These representations can indeed be further decomposed as follows:

$$(8b) \quad \rho_{\mathbb{R}} = m_{\mathbb{R},1}\rho_{\mathbb{R},1} \oplus m_{\mathbb{R},2}\rho_{\mathbb{R},2} \oplus \cdots \oplus m_{\mathbb{R},k}\rho_{\mathbb{R},k},$$

$$(8c) \quad \rho_{\mathbb{C}} = m_{\mathbb{C},1}\rho_{\mathbb{C},1} \oplus m_{\mathbb{C},2}\rho_{\mathbb{C},2} \oplus \cdots \oplus m_{\mathbb{C},k}\rho_{\mathbb{C},k},$$

$$(8d) \quad \rho_{\mathbb{H}} = m_{\mathbb{H},1}\rho_{\mathbb{H},1} \oplus m_{\mathbb{H},2}\rho_{\mathbb{H},2} \oplus \cdots \oplus m_{\mathbb{H},k}\rho_{\mathbb{H},k}$$

with $\rho_{\mathbb{R},i} : G \rightarrow GL(\mathbb{R}^{n_{\mathbb{R},i}})$ such that its complexification is irreducible over \mathbb{C} ; $\rho_{\mathbb{C},i} : G \rightarrow GL(\mathbb{R}^{2n_{\mathbb{C},i}})$ such that the complexification of $\rho_{\mathbb{C},i}$ is isomorphic (over \mathbb{C}) to $\tilde{\rho}_{\mathbb{C},i} \oplus \tilde{\rho}_{\mathbb{C},i}^*$ with $\tilde{\rho}_{\mathbb{C},i} : G \rightarrow GL(\mathbb{C}^{n_{\mathbb{C},i}})$ irreducible over \mathbb{C} ; similarly, $\rho_{\mathbb{H},i} : G \rightarrow GL(\mathbb{R}^{4n_{\mathbb{H},i}})$, $\rho_{\mathbb{H},i} \cong \tilde{\rho}_{\mathbb{H},i} \oplus \tilde{\rho}_{\mathbb{H},i}^*$ with $\tilde{\rho}_{\mathbb{H},i} : G \rightarrow GL(\mathbb{C}^{2n_{\mathbb{H},i}})$ also irreducible over \mathbb{C} .

The representations $\rho_{\mathbb{R},1}, \dots, \rho_{\mathbb{R},k_{\mathbb{R}}}; \tilde{\rho}_{\mathbb{C},1}, \dots, \tilde{\rho}_{\mathbb{C},k_{\mathbb{C}}}; \tilde{\rho}_{\mathbb{C},1}^*, \dots, \tilde{\rho}_{\mathbb{C},k_{\mathbb{C}}}^*; \tilde{\rho}_{\mathbb{H},1}, \dots, \tilde{\rho}_{\mathbb{H},k_{\mathbb{H}}}$ are the distinct irreducible representations of real, complex, and quaternionic type, respectively, involved in the decomposition of ρ ,

$$n_{\mathbb{R},1}, \dots, n_{\mathbb{R},k_{\mathbb{R}}}; n_{\mathbb{C},1}, \dots, n_{\mathbb{C},k_{\mathbb{C}}}; n_{\mathbb{H},1}, \dots, n_{\mathbb{H},k_{\mathbb{H}}},$$

their respective orders, and

$$m_{\mathbb{R},1}, \dots, m_{\mathbb{R},k_{\mathbb{R}}}; m_{\mathbb{C},1}, \dots, m_{\mathbb{C},k_{\mathbb{C}}}; m_{\mathbb{H},1}, \dots, m_{\mathbb{H},k_{\mathbb{H}}},$$

their respective multiplicities.

A real subrepresentation ρ' of ρ will allow a similar representation as (8), but with the analogous multiplicities $m'_{\mathbb{R},i}$, $m'_{\mathbb{C},i}$ and $m'_{\mathbb{H},i}$ satisfying $0 \leq m'_{\mathbb{R},i} \leq m_{\mathbb{R},i}$, $0 \leq m'_{\mathbb{C},i} \leq m_{\mathbb{C},i}$ and $0 \leq m'_{\mathbb{H},i} \leq m_{\mathbb{H},i}$.

Now, assume that ρ and ρ' satisfy the conditions of Theorem 3. Proceeding as in the complex case, we obtain (in the analogous partition of \tilde{R}) that, in a basis compatible with (8), $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathcal{B}) \in \mathcal{L}^q$ will admit a (real) minimal representation as (2) with (5) still satisfied. Hence the off-diagonal blocks of \tilde{R} will still be zero: the components of \tilde{w} will again be noninteracting.

However, Schur's lemma allows us to conclude the simple form (6) for the diagonal blocks of \tilde{R} only for the diagonal blocks corresponding to the real representations, the $\rho_{\mathbb{R},i}$'s. The diagonal blocks of \tilde{R} corresponding to the $\rho_{\mathbb{C},i}$'s and the $\rho_{\mathbb{H},i}$'s will be more complicated, and it is here that the difference between the real, complex, and quaternionic type plays a role. To obtain a convenient form for the corresponding diagonal blocks of \tilde{R} , we should choose the basis in the $\mathbb{R}^{2n_{\mathbb{C},i}}$'s such that $\rho_{\mathbb{C},i}$ takes the form

$$(9a) \quad \rho_{\mathbb{C},i} \cong \begin{bmatrix} A_{\mathbb{C},i} & -B_{\mathbb{C},i} \\ B_{\mathbb{C},i} & A_{\mathbb{C},i} \end{bmatrix},$$

and in the $\mathbb{R}^{4n_{\mathbb{H},i}}$'s such that $\rho_{\mathbb{H},i}$ takes the form

$$(9b) \quad \rho_{\mathbb{H},i} \cong \begin{bmatrix} A_{\mathbb{H},i} & -B_{\mathbb{H},i} & -C_{\mathbb{H},i} & -D_{\mathbb{H},i} \\ B_{\mathbb{H},i} & A_{\mathbb{H},i} & D_{\mathbb{H},i} & -C_{\mathbb{H},i} \\ C_{\mathbb{H},i} & -D_{\mathbb{H},i} & A_{\mathbb{H},i} & B_{\mathbb{H},i} \\ D_{\mathbb{H},i} & C_{\mathbb{H},i} & -B_{\mathbb{H},i} & A_{\mathbb{H},i} \end{bmatrix}.$$

It can be shown that there exists a (real) choice of the basis in \mathbb{R}^q that is compatible with the decomposition (8a) and in which the $\rho_{\mathbb{C},i}$'s and the $\rho_{\mathbb{H},i}$'s have the above form. We will call such a basis choice *real ρ -adapted*.

Schur's lemma then allows to conclude that in a real ρ -adapted basis in \mathbb{R}^q and in a real ρ' -adapted basis in $\mathbb{R}^{p(\Sigma)}$ we will obtain a representation (2) with

$$(10a) \quad \tilde{R}_{ij}(s) = 0 \quad \text{for } i \neq j$$

and

$$(10b) \quad \tilde{R}_{ii}(s) = \tilde{A}_i(s) \otimes I_{n_{\mathbb{R},i}}$$

for the diagonal blocks corresponding to the $\rho_{\mathbb{R},i}$'s

$$(10c) \quad \tilde{R}_{ii}(s) = \begin{bmatrix} \tilde{A}_i(s) & -\tilde{B}_i(s) \\ \tilde{B}_i(s) & \tilde{A}_i(s) \end{bmatrix} \otimes I_{n_{\mathbb{C},i}}$$

for the diagonal blocks corresponding to the $\rho_{C,i}$'s, and

$$(10d) \quad \tilde{R}_{ii}(s) = \begin{bmatrix} \tilde{A}_i(s) & -\tilde{B}_i(s) & -\tilde{C}_i(s) & -\tilde{D}_i(s) \\ \tilde{B}_i(s) & \tilde{A}_i(s) & -\tilde{D}_i(s) & \tilde{C}_i(s) \\ \tilde{C}_i(s) & \tilde{D}_i(s) & \tilde{A}_i(s) & -\tilde{B}_i(s) \\ \tilde{D}_i(s) & -\tilde{C}_i(s) & \tilde{B}_i(s) & \tilde{A}_i(s) \end{bmatrix} \otimes I_{n_{H,i}}$$

for the diagonal blocks corresponding to the $\rho_{H,i}$'s.

The notation may be further streamlined by using complex numbers in (9a) and (10c) and quaternions in (9b) and (10d). Coding a typical vector $\text{col}(\tilde{w}_{C,i}^1, \tilde{w}_{C,i}^2) \in \mathbb{R}^{2n_{C,i}}$ in (9a) as the complex vector $\tilde{w}_{C,i}^1 + i\tilde{w}_{C,i}^2 \in \mathbb{C}^{n_{C,i}}$, ensures that multiplication by (10c) corresponds to multiplication by the complex polynomial matrix $(\tilde{A}_i(s) + i\tilde{B}_i(s)) \otimes I_{n_{C,i}}$. Coding a typical vector $\tilde{w}_{H,i} = \text{col}(\tilde{w}_{H,i}^1, \tilde{w}_{H,i}^2, \tilde{w}_{H,i}^3, \tilde{w}_{H,i}^4)$ in (9b) as the quaternionic vector $\tilde{w}_{H,i}^1 + i\tilde{w}_{H,i}^2 + j\tilde{w}_{H,i}^3 + k\tilde{w}_{H,i}^4$ ensures that multiplication by (10d) corresponds to multiplication by the quaternionic polynomial matrix $(\tilde{A}_i(s) + i\tilde{B}_i(s) + j\tilde{C}_i(s) + k\tilde{D}_i(s)) \otimes I_{n_{H,i}}$. For the multiplication rules for quaternions, see Example 8 and §10.

In the following theorem, we assume that the real ρ -adapted basis has been streamlined in this way. These considerations prove that, for $\mathbb{K} = \mathbb{R}$, Theorem 3 is equivalent to the following theorem.

THEOREM 5. *Let G be a compact group and let $\rho : G \rightarrow GL(\mathbb{R}^q)$ be a representation of G on \mathbb{R}^q . Assume that ρ is decomposed as (8) and that the basis in \mathbb{R}^q is real ρ -adapted. To emphasize this, we write the signal variables as \tilde{w} ,*

$$\begin{aligned} \tilde{w} &= \text{col}(\tilde{w}_{\mathbb{R}}, \tilde{w}_{\mathbb{C}}, \tilde{w}_{\mathbb{H}}), \\ \tilde{w}_{\mathbb{R}} &= \text{col}(\tilde{w}_{\mathbb{R},1}, \tilde{w}_{\mathbb{R},2}, \dots, \tilde{w}_{\mathbb{R},k_{\mathbb{R}}}) \quad \text{with} \quad \tilde{w}_{\mathbb{R},i} : \mathbb{R} \rightarrow (\mathbb{R}^{n_{\mathbb{R},i}})^{m_{\mathbb{R},i}}, \\ \tilde{w}_{\mathbb{C}} &= \text{col}(\tilde{w}_{\mathbb{C},1}, \tilde{w}_{\mathbb{C},2}, \dots, \tilde{w}_{\mathbb{C},k_{\mathbb{C}}}) \quad \text{with} \quad \tilde{w}_{\mathbb{C},i} : \mathbb{R} \rightarrow (\mathbb{C}^{n_{\mathbb{C},i}})^{m_{\mathbb{C},i}}, \\ \tilde{w}_{\mathbb{H}} &= \text{col}(\tilde{w}_{\mathbb{H},1}, \tilde{w}_{\mathbb{H},2}, \dots, \tilde{w}_{\mathbb{H},k_{\mathbb{H}}}) \quad \text{with} \quad \tilde{w}_{\mathbb{H},i} : \mathbb{R} \rightarrow (\mathbb{H}^{n_{\mathbb{H},i}})^{m_{\mathbb{H},i}}, \end{aligned}$$

as explained in the preamble.

Then $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathcal{B}) \in \mathcal{L}^q$ is ρ -symmetric if and only if there exist $m'_{\mathbb{R},i} \in \mathbb{Z}_+$, $0 \leq m'_{\mathbb{R},i} \leq m_{\mathbb{R},i}$; $m'_{\mathbb{C},i} \in \mathbb{Z}_+$, $0 \leq m'_{\mathbb{C},i} \leq m_{\mathbb{C},i}$; $m'_{\mathbb{H},i} \in \mathbb{Z}_+$, $0 \leq m'_{\mathbb{H},i} \leq m_{\mathbb{H},i}$, and polynomial matrices $A_i \in \mathbb{R}_{fr}^{m'_{\mathbb{R},i} \times m_{\mathbb{R},i}}[s]$, $C_i \in \mathbb{C}_{fr}^{m'_{\mathbb{C},i} \times m_{\mathbb{C},i}}[s]$, $H_i \in \mathbb{H}_{fr}^{m'_{\mathbb{H},i} \times m_{\mathbb{H},i}}[s]$ such that Σ admits a minimal representation

$$(11) \quad \begin{aligned} \left(A_i \left(\frac{d}{dt} \right) \otimes I_{n_{\mathbb{R},i}} \right) \tilde{w}_{\mathbb{R},i} &= 0, & i = 1, 2, \dots, k_{\mathbb{R}}, \\ \left(C_i \left(\frac{d}{dt} \right) \otimes I_{n_{\mathbb{C},i}} \right) \tilde{w}_{\mathbb{C},i} &= 0, & i = 1, 2, \dots, k_{\mathbb{C}}, \\ \left(H_i \left(\frac{d}{dt} \right) \otimes I_{n_{\mathbb{H},i}} \right) \tilde{w}_{\mathbb{H},i} &= 0, & i = 1, 2, \dots, k_{\mathbb{H}}. \end{aligned}$$

7. Applications.

7.1. Permutation symmetries.

Example 4 (simple permutations). Our first class of examples all involve the symmetric group S_q defined in Example 3, and we use the notation introduced there.

Let us now apply Theorem 5 to a system $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathcal{B}) \in \mathcal{L}^q$ with $\rho : S_q \rightarrow GL(\mathbb{R}^q)$ where $\rho_g \text{col}(w_1, w_2, \dots, w_q) := \text{col}(w_{g(1)}, w_{g(2)}, \dots, w_{g(q)})$. We obtain a suitable ρ -adapted basis by taking as new coordinates $\tilde{x}_1 := x_{av}$, $\tilde{x}_2 := \Delta x_2, \dots, \tilde{x}_q := \Delta x_q$, with $x_{av} := (1/q)(x_1 + x_2 + \dots + x_q)$ and $\Delta x_i = x_i - x_{av}$ ($i = 1, 2, \dots, q$). Clearly, $V_1 = \{\text{col}(\tilde{x}_1, \tilde{x}_2, \dots, \tilde{x}_q) \in \mathbb{R}^q \mid \tilde{x}_2 = \dots = \tilde{x}_q = 0\}$ and $V_2 = \{\text{col}(\tilde{x}_1, \tilde{x}_2, \dots, \tilde{x}_q) \in \mathbb{R}^q \mid \tilde{x}_1 = 0\}$. Observe that both the representations ρ_1 and ρ_2 introduced in Example 3 are of real type. Hence the decomposition $\rho \cong \rho_1 \oplus \rho_2$ applies to the real case. It follows that, in terms of the notation of Theorem 5, $m_{\mathbb{R},1} = m_{\mathbb{R},2} = 1$ and that all the other multiplicities are zero. Furthermore, $n_{\mathbb{R},1} = 1$ and $n_{\mathbb{R},2} = q - 1$. Thus we must consider the following choices of $m'_{\mathbb{R},i}$'s:

$$\begin{aligned} m'_{\mathbb{R},1} &= m'_{\mathbb{R},2} = 0, \\ m'_{\mathbb{R},1} &= 1; \quad m'_{\mathbb{R},2} = 0, \\ m'_{\mathbb{R},1} &= 0; \quad m'_{\mathbb{R},2} = 1, \\ m'_{\mathbb{R},1} &= m'_{\mathbb{R},2} = 1. \end{aligned}$$

The first case corresponds to the trivial situation $\mathcal{B} = C^\infty(\mathbb{R}, \mathbb{R}^q)$. In the second case, ρ -symmetry corresponds to a minimal representation of the form

$$r_{av} \left(\frac{d}{dt} \right) w_{av} = 0$$

with $w_{av} := (1/q)(w_1 + w_2 + \dots + w_q)$. This representation is determined by the nonzero polynomial $r_{av} \in \mathbb{R}[s]$. The third case yields

$$r_\Delta \left(\frac{d}{dt} \right) \Delta w_i = 0, \quad i = 2, \dots, q$$

with $\Delta w_i := w_i - w_{av}$. This representation is completely determined by the nonzero polynomial $r_\Delta \in \mathbb{R}[s]$. Note that these equations imply the redundant equation $r_\Delta (d/dt) \Delta w_1 = 0$, and hence, by letting the above equation range over $i = 1, 2, \dots, q$, we obtain an equivalent but not minimal representation. In the fourth case, we will obtain one equation on w_{av} and one on each of the Δw_i 's, and these equations are all identical.

It is clear that, by allowing nonminimal representations, all four cases can be captured in one. It follows that $\Sigma \in \mathcal{L}^q$ will be ρ -symmetric in the case of these simple permutations if and only if there exist (not necessarily nonzero) polynomials $r_{av} \in \mathbb{R}[s]$, $r_\Delta \in \mathbb{R}[s]$ such that Σ is described by

$$\begin{aligned} r_{av} \left(\frac{d}{dt} \right) w_{av} &= 0, \\ r_\Delta \left(\frac{d}{dt} \right) \Delta w_i &= 0, \quad i = 1, 2, \dots, q \end{aligned}$$

with $w_{av} := (1/q)(w_1 + w_2 + \dots + w_q)$ and $\Delta w_i := w_i - w_{av}$. Hence a symmetric system is governed by two equations. One equation governs the dynamics of the average (consider it an equation governing the *center of mass* in the case of motion of identical particles on the line). The second equation is identical for each of the components and governs the dynamics of the distance from the average and is identical for each of the components (consider this equation as governing the motion of the *displacement* of the particle from the center of mass). Note that either one or both of these equations
