**PROPOSITION 4.2.** *Whenever  $\mathfrak{M}_c$  is nonempty, each of the maps  $\pi_1$  and  $\pi_2$  is a local diffeomorphism.*

**5. Injectivity of  $\pi_2$  and the generalized moment problem for polynomial measures.** Since the map

$$L_+ : \mathfrak{P}_+ \rightarrow \mathfrak{C}_+, \quad p \mapsto \int_b^a \begin{pmatrix} \alpha_0 \\ \alpha_1 \\ \vdots \\ \alpha_n \end{pmatrix} \frac{P}{Q} dt, \quad k = 0, 1, \dots, n,$$

is linear in  $p$  for a fixed  $q \in \mathfrak{P}_+$ , the inverse image  $\pi_2^{-1}(q)$  in  $\mathfrak{M}_c$  is convex for each fixed  $q \in \mathfrak{P}_+$ . If  $\pi_2^{-1}(q)$  is nonempty, then Proposition 4.2 implies that it consists of a single point.

**LEMMA 5.1.** *The map  $\pi_2$  is an injection.*

The question of whether  $\pi_2^{-1}$  is nonempty is more interesting. To this end, we shall now keep  $q$  fixed and vary  $p$ . It follows from the above that the corresponding

map  $L_+ : \mathfrak{P}_+ \rightarrow \mathfrak{C}_+$  from a positive polynomial  $p$  to a positive sequence  $c$  is a convex injection. To say that  $L_+(p) = c$  is to say that  $(p, q) \in \mathfrak{M}_c$ , so we are interested in the image of  $L_+$ . This is also of independent interest. For example, if  $\mathfrak{P}$  contains the constant functions, choosing  $q = 1$  leads to a special case of Problem 1.6.

PROBLEM 5.2. Given a sequence of complex numbers  $c_0, c_1, \dots, c_n$  and a subspace  $\mathfrak{P}$ , the generalized moment problem for polynomial measures is to parameterize all positive polynomial measures  $P(t)dt$  such that

$$(5.1) \quad \int_a^b \alpha_k(t) P(t) dt = c_k, \quad k = 0, 1, \dots, n.$$

More generally, to say that  $L_+$  is surjective for a fixed  $q \in \mathfrak{P}_+$  is equivalent to asserting that  $L_+ : \partial\mathfrak{P}_+ \rightarrow \partial\mathfrak{C}_+$ . This is trivially true for  $\dim(\mathfrak{P}) = 1$ . In order to analyze the image of  $L_+$ , we shall assume an auxiliary hypothesis, introduced in [8] in a similar context.

HYPOTHESIS 5.3. The zero set of any  $p \in \mathfrak{P}$  has Lebesgue measure zero.

Remark 5.4. Every  $\mathfrak{P}$  spanned by a Chebyshev system (or T-system) satisfies Hypothesis 5.3. In particular, this applies to the power moment problem. The spaces  $\mathfrak{P}$  corresponding to the trigonometric moment problem and the Nevanlinna–Pick interpolation problem satisfy Hypothesis 5.3. More generally, finite-dimensional spaces of analytic functions always satisfy Hypothesis 5.3.

PROPOSITION 5.5. *If Hypothesis 5.3 holds, then the convex injection  $L_+$  fails to be surjective in dimensions greater than one.*

Proof. Following [21] consider the curve

$$U(t) = \begin{pmatrix} u_0(t) \\ u_1(t) \\ \vdots \\ u_n(t) \end{pmatrix}, \quad a \leq t \leq b,$$

and the subset  $U = \{U(t) : t \in [a, b]\} \subset \mathbb{C}^{n+1}$ . Let  $K(U)$  denote its closed convex conic hull. Clearly, the dual cone satisfies  $K(U)^\top = \overline{\mathfrak{P}}_+$ , from which we have the following theorem.

THEOREM 5.6 (see [21]).  $K(U) = \overline{\mathfrak{C}}_+$ .

Therefore to say that  $L_+(\overline{\mathfrak{P}}_+) = \overline{\mathfrak{C}}_+$  is to say that  $U \subset L_+(\overline{\mathfrak{P}}_+)$ . In particular, for each  $t_0 \in [a, b]$  there exists  $p_{t_0} \in \overline{\mathfrak{P}}_+$  such that

$$(5.2) \quad \int_a^b r(t) \frac{P_{t_0}(t)}{Q(t)} dt = r(t_0)$$

for  $r \in \mathfrak{P}$ . Clearly,  $P_{t_0}(t_0) = \int_a^b \frac{P_{t_0}^2(t)}{Q(t)} dt \geq 0$  with equality only if  $P_{t_0} = 0$ . On the other hand,  $P_{t_0} = 0$  is impossible since there exists  $r \in \mathfrak{P}_+$  with  $R(t) > 0$ , which would contradict (5.2).

Now suppose  $r \in \overline{\mathfrak{P}}_+$ . We claim that either  $R$  never vanishes or  $r = 0$ . Indeed, if  $R(t_0) = 0$  for some  $t_0 \in [a, b]$ , then

$$(5.3) \quad \int_a^b R(t) \frac{P_{t_0}(t)}{Q(t)} dt = R(t_0) = 0,$$

and therefore  $R(t)P_{t_0}(t) = 0$  for all  $t \in [a, b]$ . Since  $P_{t_0}(t_0) \neq 0$ , there exists  $\epsilon > 0$  such that  $R(t) = 0$  for  $t \in [t_0 - \epsilon, t_0 + \epsilon]$ , contrary to Hypothesis 5.3.

Since any positive  $R$  satisfies  $R \in \mathfrak{P}_+$ , this implies that  $\partial\mathfrak{P}_+ = \{0\}$  and hence  $n = 0$  and  $\dim(\mathfrak{P}) = 1$ .  $\square$

In particular, this shows that the generalized moment problem for polynomial measures is unsolvable for a set of positive sequences having positive measure, whenever  $\mathfrak{P}$  has dimension at least two.

**6. Hadamard's theorem and bijectivity of  $\pi_1$ .** As in the previous section, we shall begin with an analysis of the “fiber”  $\pi_1^{-1}(p)$  of the map  $\pi_1$  over a fixed  $p$  in  $\mathfrak{P}_+$ , and, as before, for an arbitrary  $c \in \mathfrak{C}_+$ , this leads to a related constrained moment problem, defined as follows.

Consider the function

$$(6.1) \quad F^p : \mathfrak{P}_+ \rightarrow \mathfrak{C}_+,$$

defined componentwise via

$$F_k^p(q) = \int_a^b \alpha_k(t) \frac{P(t)}{Q(t)} dt,$$

and a given positive sequence  $c = (c_0, \dots, c_n)$ .

**PROPOSITION 6.1.** *If  $\mathfrak{P}$  consists of Lipschitz continuous functions, the map (6.1) is a surjective local diffeomorphism.*

*Proof.* We want to show that the image of the map (6.1) is both open and closed in  $\mathfrak{C}_+$ . We begin with a lemma ensuring that  $F^p(\mathfrak{P}_+)$  is open.

**LEMMA 6.2.** *For each  $q \in \mathfrak{P}_+$ ,  $\det \text{Jac}(F^p)|_q \neq 0$ .*

*Proof.* This follows immediately from the fact that  $\text{Jac}(F^p)|_q = M_q$ , where  $M_q$  is the invertible matrix defined in (4.3).  $\square$

In particular, by the inverse function theorem,  $F^p$  is a local diffeomorphism and by the implicit function theorem,  $F^p(\mathfrak{P}_+) \subset \mathfrak{C}_+$  is open. Since  $\mathfrak{C}_+$  is connected, the proposition will follow provided that  $F^p(\mathfrak{P}_+)$  is also closed in  $\mathfrak{C}_+$ .

**LEMMA 6.3.** *If  $\mathfrak{P}$  consists of Lipschitz continuous functions, the map (6.1) is proper.*

*Proof.* We show that, for any compact set  $K$  in  $\mathfrak{C}_+$ ,  $(F^p)^{-1}(K)$  is bounded. To see this, suppose  $(c_j)$  is a sequence in  $\mathfrak{C}_+$  converging to  $c \in \mathfrak{C}_+$  such that  $F^p(q_j) = c_j$  for some  $q_j \in \mathfrak{P}_+$ . We claim that the sequence  $M_j := \|q_j\|$  is bounded in any norm on the vector space  $\mathfrak{P}_+$ . Setting  $r_j := q_j/M_j$ , we first observe

$$F_k^p(q_j) = M_j \int_a^b \alpha_k \frac{P}{R_j} dt.$$

In particular,

$$(6.2) \quad \lim_{j \rightarrow \infty} M_j \int_a^b \frac{P^2}{R_j} dt = \lim_{j \rightarrow \infty} \langle c_j, p \rangle = \langle c, p \rangle > 0.$$

Since the sequence  $(P^2/R_j)$  is bounded away from zero, it follows that the sequence  $(M_j)$  is bounded. Therefore, the preimage of a convergent sequence in  $K$  has a cluster point in the closure of  $\mathfrak{P}_+$ . If  $q$  lies on the boundary of  $\mathfrak{P}_+$ , then  $Q$  is a nonnegative function in  $\mathfrak{P}$  having a zero  $t_0 \in [a, b]$ . Since  $Q$  is Lipschitz continuous at  $t_0$ , by

definition, there exist an  $\varepsilon > 0$  and an  $M > 0$  such that  $Q(t) \leq M|t - t_0|$  whenever  $|t - t_0| < \varepsilon$  and  $t \in [a, b]$ . In particular, if  $t_0 \in (a, b)$ ,

$$\int_a^b \frac{P^2}{Q} dt \geq \frac{1}{M} \int_{t_0-\varepsilon}^{t_0+\varepsilon} \frac{P^2}{|t - t_0|} dt = +\infty,$$

contrary to the assumption. If  $t_0 = a$  or  $t_0 = b$ , a similar estimate holds. Hence,  $q \in \mathfrak{P}_+$ , establishing that  $F^p$  is proper.  $\square$

Since the image of a proper map is closed, this concludes the proof of the proposition.  $\square$

COROLLARY 6.4. *If  $\mathfrak{P}$  consists of Lipschitz continuous functions, then  $\mathfrak{M}_c \neq \emptyset$  for each  $c \in \mathfrak{C}_+$ .*

We have shown that (6.1) is a proper, local diffeomorphism onto the convex set  $\mathfrak{C}_+$ . Since any open convex subset of  $\mathbb{R}^n$  is itself diffeomorphic to  $\mathbb{R}^n$  (see, e.g., [5, p. 771]), (6.1) is a diffeomorphism by Hadamard’s theorem. We record this important fact as follows.

THEOREM 6.5. *If  $\mathfrak{P}$  consists of Lipschitz continuous functions, the mapping*

$$F^p : \mathfrak{P}_+ \rightarrow \mathfrak{C}_+$$

*is a diffeomorphism.*

Remark 6.6. An alternative proof of this result was derived in [8] using convex optimization methods.

COROLLARY 6.7. *If  $\mathfrak{P}$  consists of Lipschitz continuous functions, for each  $c \in \mathfrak{C}_+$  the restriction*

$$\pi_1 : \mathfrak{M}_c \rightarrow \mathfrak{P}_+$$

*of the first projection is bijective. That is, for every positive sequence  $c$  and every choice of  $p$  in  $\mathfrak{P}_+$ , there is a unique  $q$  such that  $(p, q)$  lies in  $\mathfrak{M}_c$ .*

The conclusion of Corollary 6.7 defines, for each fixed  $c \in \mathfrak{C}_+$ , a map

$$g^c : \mathfrak{P}_+ \rightarrow \mathfrak{P}_+,$$

where  $g^c(p)$  is the unique  $q$  such that  $(p, q) \in \mathfrak{M}_c$ . This map was also studied in [8]. In more explicit terms,  $q$  is the unique function in  $\mathfrak{P}_+$  such that  $Q$  is the denominator in the rational measure with numerator  $P$  solving the moment equations

$$\int_a^b \alpha_k(t) \frac{P(t)}{Q(t)} dt = c_k, \quad k = 0, 1, \dots, n,$$

for  $c$ . Moreover, in the language of Theorem 2.2, we see that

$$g^c = \pi_2 \circ \pi_1^{-1}.$$

We summarize these observations in the following result.

COROLLARY 6.8 (see [8]). *The mapping*

$$g^c : \mathfrak{P}_+ \rightarrow \mathfrak{P}_+$$

*is a diffeomorphism onto its image.*

## EFFICIENT ON-LINE COMPUTATION OF CONSTRAINED OPTIMAL CONTROL\*

MATO BAOTIĆ<sup>†</sup>, FRANCESCO BORRELLI<sup>‡</sup>, ALBERTO BEMPORAD<sup>§</sup>, AND  
MANFRED MORARI<sup>¶</sup>

**Abstract.** We consider constrained finite-time optimal control problems for discrete-time linear time-invariant systems with constraints on inputs and outputs based on linear and quadratic performance indices. The solution to such problems is a time-varying piecewise affine (PWA) state-feedback law and can be computed by means of multiparametric programming. By exploiting the properties of the value function and the piecewise affine optimal control law of the constrained finite-time optimal control (CFTOC), we propose two new algorithms that avoid storing the polyhedral regions. The new algorithms significantly reduce the on-line storage demands and computational complexity during evaluation of the PWA feedback control law resulting from the CFTOC.

**Key words.** constrained finite time optimal control, multiparametric programming, piecewise affine function evaluation

**DOI.** 10.1137/060659314

**1. Introduction.** Recently, in [4, 3], the authors have shown how to compute the solution to the constrained finite-time optimal control (CFTOC) problem as a piecewise affine (PWA) state-feedback law. Such a law is computed off-line by using a multiparametric programming solver [4, 7, 13], which divides the state space into polyhedral regions, and for each region determines the linear gain and offset which produces the optimal control action.

This method reveals its effectiveness when a receding horizon control (RHC) strategy is used [14, 15]. RHC requires solving at each sampling time an open-loop CFTOC problem. The optimal command signal is applied to the process only during the sampling interval that follows. At the next time step a new optimal control problem based on new measurements of the state is solved over a shifted horizon. Having a precomputed solution as an explicit PWA function of the state vector reduces the on-line computation of the RHC control law to a function evaluation, thus avoiding the on-line solution of a quadratic or linear program.

The only drawback of such a PWA feedback control law is that the number of polyhedral regions could grow dramatically with the number of constraints in the optimal control problem. In this paper we focus on efficient on-line methods for the evaluation of such a PWA control law. The simplest algorithm would require (i) the storage of the list of polyhedral regions and of the corresponding affine control laws

---

and (ii) a sequential search through the list of polyhedra for the  $i$ th polyhedron that contains the current state in order to implement the  $i$ th control law. By exploiting the properties of the value function and the optimal control law, for CFTOC problems based on linear programming (LP) and quadratic programming (QP), we propose two new algorithms that avoid storing the polyhedral regions. The new algorithms significantly reduce the on-line storage demands and computational complexity during evaluation of the explicit solution of the CFTOC problem.

The same problem has been recently approached in a different manner in [23]. The algorithm proposed there—with the controller gains of the PWA control law organized on a balanced search tree—is less efficient in terms of memory requirements, but has a logarithmic average computation complexity. At the expense of the optimality of the solution a similar computational complexity can be achieved with an approximate point location algorithm described in [12].

Several papers also propose the use of fast solvers for the on-line solution of constrained predictive control problems (cf. [16, 10]); these algorithms pursue the same goal as this paper, namely, to reduce the on-line computational burden in RHC, but from a different perspective. They use fast LP or QP solvers (in place of a general-purpose solver) tailored to the special dynamic structure of the underlying optimal control problem [16]. Note that a proper comparison of the proposed algorithms with “fast” on-line LP and QP solvers requires the simultaneous analysis of several issues such as speed of computation, storage demand, and real time code verifiability. This is an involved study and as such is outside the scope of this paper.

The paper is organized as follows. For discrete-time linear time-invariant systems the basics of CFTOC problems and of RHC are summarized in section 2. In section 3, for LP-based and QP-based optimal control we present two new algorithms to evaluate on-line explicit optimal control laws and compare their complexity in terms of time and storage against the simplest algorithm mentioned above. Finally, in section 4 an example is given that confirms the efficiency of the new methods.

**2. CFTOC, RHC, and their state-feedback PWA solution.** Throughout this paper (lower and upper case) italic letters denote scalars, vectors, and matrices (e.g.,  $A, a, \dots$ ), while upper case calligraphic letters denote sets (e.g.,  $\mathcal{A}, \mathcal{B}, \dots$ ). For a matrix (vector)  $A$ ,  $A'$  denotes its transpose, while  $A_{(i)}$  denotes the  $i$ th row (element),  $\mathbb{R}$  is the set of real numbers, and  $\mathbb{N}$  is the set of positive integer numbers.

**2.1. CFTOC problem formulation.** Consider the discrete-time linear time-invariant system

$$(1) \quad x(t+1) = Ax(t) + Bu(t)$$

subject to the constraints

$$(2) \quad E^x x(t) + E^u u(t) \leq E$$

at all time instants  $t \geq 0$ .

In (1)–(2),  $n_x \in \mathbb{N}$ ,  $n_u \in \mathbb{N}$ , and  $n_E \in \mathbb{N}$  are the number of states, inputs, and constraints; respectively,  $x(t) \in \mathbb{R}^{n_x}$  is the state vector,  $u(t) \in \mathbb{R}^{n_u}$  is the input vector,  $A \in \mathbb{R}^{n_x \times n_x}$ ,  $B \in \mathbb{R}^{n_x \times n_u}$ ,  $E^x \in \mathbb{R}^{n_E \times n_x}$ ,  $E^u \in \mathbb{R}^{n_E \times n_u}$ ,  $E \in \mathbb{R}^{n_E}$ , the pair  $(A, B)$  is stabilizable, and the vector inequality (2) is considered elementwise.

Let  $x_0 = x(0)$  be the initial state and consider the constrained finite-time optimal

control problem

$$(3) \quad \begin{aligned} J^*(x_0) &:= \min_U J(x_0, U) \\ \text{s.t.} \quad &\begin{cases} x_{k+1} = Ax_k + Bu_k, \\ E^x x_k + E^u u_k \leq E, \quad k = 0, \dots, N-1, \end{cases} \end{aligned}$$

where  $N \in \mathbb{N}$  is the horizon length,  $U := [u'_0, \dots, u'_{N-1}]' \in \mathbb{R}^{n_u N}$  is the optimization vector,  $x_i$  denotes the state at time  $i$  if the initial state is  $x_0$  and the control sequence  $\{u_0, \dots, u_{i-1}\}$  is applied to the system (1),  $J^* : \mathbb{R}^{n_x} \rightarrow \mathbb{R}$  is the value function, and the cost function  $J : \mathbb{R}^{n_x} \times \mathbb{R}^{n_u N} \rightarrow \mathbb{R}$  is given either as a piecewise linear function (i.e., sum of  $l_1$  or  $l_\infty$  norms)

$$(4a) \quad J(x_0, U) = \|Q^{x_N} x_N\|_\ell + \sum_{k=0}^{N-1} \|Q^x x_k\|_\ell + \|Q^u u_k\|_\ell, \quad \ell \in \{1, \infty\},$$

or as a quadratic function

$$(4b) \quad J(x_0, U) = x'_N Q^{x_N} x_N + \sum_{k=0}^{N-1} x'_k Q^x x_k + u'_k Q^u u_k.$$

In the following, we will assume that  $Q^x$ ,  $Q^u$ ,  $Q^{x_N}$  are full column rank matrices when the cost function (4a) is used, and that  $Q^x = (Q^x)' \succeq 0$ ,  $Q^u = (Q^u)' \succ 0$ ,  $Q^{x_N} \succeq 0$ , when the cost function (4b) is used, where  $Q \succ 0$  denotes positive definiteness (resp.,  $Q \succeq 0$  positive semidefiniteness).

The optimization problem (3) can be translated into a linear program (LP) when the piecewise linear cost function (4a) is used [3] or into a quadratic program (QP) when the quadratic cost function (4b) is used [4]. We denote by  $U^* = [(u_0^*)', \dots, (u_{N-1}^*)']'$  one of the possible optimizers of problem (3)–(4). An optimizer  $U^*$  can be computed by solving an LP or a QP once  $x_0$  is fixed or can be computed explicitly for all  $x_0$  within a given range of values as explained in subsections 2.3 and 2.4.

**2.2. RHC strategy.** Consider the problem of regulating the discrete-time linear time-invariant system (1) to the origin while fulfilling the constraints (2). The solution  $U^*$  to CFTOC problem (3)–(4) is an open-loop optimal control trajectory over a finite horizon. A receding horizon control strategy employs it to obtain a feedback control law in the following way: Assume that a full measurement of the state  $x(t)$  is available at the current time  $t \geq 0$ . Then, the CFTOC problem (3)–(4) is solved at each time  $t$  for  $x_0 = x(t)$ , and

$$(5) \quad u(t) = u_0^*$$

is applied as an input to system (1). For a detailed discussion on RHC strategy, see, e.g., [21, 9, 18, 4, 3, 14].

**2.3. Solution of CFTOC, linear cost case.** Consider the problem (3) with the piecewise linear cost function (4a) and  $\ell = \infty$ . Using a standard transformation [3], we introduce the vector  $v := [u'_0, \dots, u'_{N-1}, \varepsilon_1^x, \dots, \varepsilon_N^x, \varepsilon_0^u, \dots, \varepsilon_{N-1}^u]' \in \mathbb{R}^{n_v}$ ,  $n_v :=$

$(n_u + 2)N$ ,  $\varepsilon_k^x \geq \|Q^x x_k\|_\infty$ ,  $\varepsilon_N^x \geq \|Q^{x_N} x_N\|_\infty$ ,  $\varepsilon_k^u \geq \|Q^u u_k\|_\infty$ , and substitute  $x_k = A^k x_0 + \sum_{j=0}^{k-1} A^j B u_{k-1-j}$  in (3)–(4), which can be rewritten as the linear program<sup>1</sup>

$$(6) \quad \begin{aligned} J^*(x) &:= \min_v \quad c^T v \\ \text{s.t.} \quad &L^v v \leq L + L^x x, \end{aligned}$$

where  $x = x_0$ , and matrices  $c \in \mathbb{R}^{n_v}$ ,  $L^v \in \mathbb{R}^{n_L \times n_v}$ ,  $L^x \in \mathbb{R}^{n_L \times n_x}$ ,  $L \in \mathbb{R}^{n_L}$  are easily obtained from  $Q^x$ ,  $Q^u$ ,  $Q^{x_N}$  and (3)–(4), as explained in [3]. For a given  $x$  we denote with  $\mathcal{V}^*(x)$  the set of optimizers for the problem (6). Note that, in general,  $\mathcal{V}^*(x)$  is a set valued function, i.e.,  $\mathcal{V}^* : \mathbb{R}^{n_x} \rightarrow 2^{\mathbb{R}^{n_v}}$ .

Because the problem depends on  $x$  the implementation of RHC can be performed in two different ways: solve the LP (6) on-line at each time step for a given  $x$  or solve (6) *off-line* for all  $x$  within a given range of values, i.e., by considering (6) as a *multiparametric linear program* (mp-LP) [11].

Solving an mp-LP means computing the value function  $J^*(x) : \mathbb{R}^{n_x} \rightarrow \mathbb{R}$  and one (out of possibly many) optimizer function  $v^*(x) : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^{n_v}$  for all possible vectors  $x$  in a given set  $\mathcal{X}$ . The solution to mp-LP problems can be approached simply by exploiting the properties of the primal and dual optimality conditions as proposed in [7, 11].

In [11] the following results about the properties of the solution are proved.

**THEOREM 1.** *Consider the mp-LP (6). Then the set of feasible parameters  $\mathcal{X}_f$  is convex. The value function  $J^* : \mathcal{X}_f \rightarrow \mathbb{R}$  is convex and piecewise affine. There always exists a continuous and PWA selection of an optimizer function  $v^* : \mathcal{X}_f \rightarrow \mathbb{R}^{n_v}$ . In particular, if the optimizer  $\mathcal{V}^*(x)$  is unique for all  $x \in \mathcal{X}_f$ , then  $v^*(x) = \mathcal{V}^*(x)$ .*

Once the multiparametric problem (6) has been solved off-line for a polyhedral set  $\mathcal{X} \subseteq \mathbb{R}^{n_x}$  of states, the explicit solution  $v^*(x)$  of CFTOC problem (6) is available as a PWA function of  $x$ , and the receding horizon controller (3)–(5) is also available explicitly, as the optimal input  $u(t)$  consists simply of  $n_u$  components of  $v^*(x(t))$ ,

$$(7) \quad u(t) = [I_{n_u} \ 0 \ \cdots \ 0] v^*(x(t)).$$

**COROLLARY 1.** *The RHC (7), defined by the optimization problem (3), (4a), and (5), is a continuous and piecewise affine function,  $u : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^{n_u}$ , and has the form*

$$(8) \quad u(x) = F_i x + G_i \quad \forall x \in \mathcal{P}_i, \quad i = 1, \dots, N_{\mathcal{P}},$$

where  $F_i \in \mathbb{R}^{n_u \times n_x}$ ,  $G_i \in \mathbb{R}^{n_u}$ ,  $\{\mathcal{P}_i\}_{i=1}^{N_{\mathcal{P}}}$  is a polyhedral partition of  $\mathcal{X}_f$  (i.e.,  $\cup_i \mathcal{P}_i = \mathcal{X}_f$ , and  $\mathcal{P}_i$  and  $\mathcal{P}_j$  have disjoint interiors  $\forall i \neq j$ ), with  $\mathcal{P}_i = \{x \in \mathbb{R}^{n_x} \mid P_i^x x \leq P_i\}$ ,  $P_i^x \in \mathbb{R}^{p_i \times n_x}$ ,  $P_i \in \mathbb{R}^{p_i}$ , and  $p_i$  is the number of halfspaces defining polyhedron  $\mathcal{P}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ .

In the rest of this paper we will assume, without loss of generality, that  $\mathcal{P}_i$  in (8) and  $i = 1, \dots, N_{\mathcal{P}}$ , are full dimensional sets in  $\mathbb{R}^{n_x}$  corresponding to the so-called critical regions of the optimization problem (6) (see [7] for more details). We will denote with  $N_{\mathcal{H}}$  the total number of halfspaces defining the polyhedral partition of  $\mathcal{X}_f$ ,

$$(9) \quad N_{\mathcal{H}} := \sum_{i=1}^{N_{\mathcal{P}}} p_i.$$

<sup>1</sup>The same holds for  $\ell = 1$  with a different optimization vector [3].

*Remark 2.1.* Typically the total number of halfspaces defining polyhedral partition of feasible set  $\mathcal{X}_f$  is much bigger than the number of polyhedral regions in it, i.e.,  $N_{\mathcal{H}} \gg N_{\mathcal{P}}$ . The reasoning is the following. Assume, as is the case in practical applications, that all  $\mathcal{P}_i$  are bounded. Since the smallest number of halfspaces defining a bounded polyhedron in  $\mathbb{R}^{n_x}$  is  $n_x + 1$  (achieved by a simplex), we have  $N_{\mathcal{H}} \geq (n_x + 1)N_{\mathcal{P}}$ .

**2.4. Solution of CFTOC, quadratic cost case.** Consider the problem (3) with the quadratic cost function (4b). By substituting  $x_k = A^k x_0 + \sum_{j=0}^{k-1} A^j B u_{k-1-j}$  in (3)–(4), this can be rewritten as the quadratic program

$$(10) \quad \begin{aligned} J^*(x) = \frac{1}{2} x' Y x + \min_U \quad & \frac{1}{2} U' H U + x' F U \\ \text{s.t.} \quad & M^U U \leq M + M^x x, \end{aligned}$$

where  $x = x_0$ , the column vector  $U := [u'_0, \dots, u'_{N-1}]' \in \mathbb{R}^{n_U}$ ,  $n_U := n_u N$ , is the optimization vector,  $H = H' \succ 0$ , and  $H, F, Y, M^U, M^x, M$  are easily obtained from  $Q^x, Q^u, Q^{x_N}$  and (3)–(4) (see [4] for details).

As in the linear cost case, because the problem depends on  $x$ , the implementation of RHC can be performed by either solving the QP (10) on-line or, as shown in [4, 22], by solving problem (10) *off-line* for all  $x$  within a given range of values, i.e., by considering (10) as a *multiparametric quadratic program* (mp-QP).

Once the multiparametric problem (10) is solved off-line, i.e., the solution  $U^*(x)$  of the CFTOC problem (10) is found, the state-feedback PWA RHC law is simply

$$(11) \quad u(t) = [I_{n_u} \ 0 \ \cdots \ 0] U^*(x(t)).$$

In [4] the authors give a self-contained proof of the following properties of the solution.

**THEOREM 2.** *Consider the multiparametric quadratic program (10), and let  $H \succ 0$ . Then the set of feasible parameters  $\mathcal{X}_f$  is convex, the optimizer  $U^* : \mathcal{X}_f \rightarrow \mathbb{R}^s$  is continuous and piecewise affine, and the value function  $J^* : \mathcal{X}_f \rightarrow \mathbb{R}$  is continuous, convex, and piecewise quadratic.*

The proof of the properties listed in Theorem 2 can be found in [5, “Maximum Theorem” on page 116]. It also follows from [1, Theorem 3.2.1(I) and Theorem 3.3.3].

**COROLLARY 2.** *The RHC control law (11), defined by the optimization problem (3), (4b), and (5), is continuous and piecewise affine and has the form (8).*

The optimization problem (10), where  $\mathcal{X}_f$  is a lower dimensional set, can be dealt with in the same way as in the linear cost case (see [7] for details). Hence, in the following we will assume, without loss of generality, that  $\mathcal{P}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ , are full dimensional sets in  $\mathbb{R}^{n_x}$  corresponding to the so-called critical regions of the optimization problem (10); cf. [4].

Corollaries 1 and 2 state that by using a multiparametric solver the computation of RHC action becomes a simple PWA function evaluation. In the next section we propose a method to efficiently evaluate such a PWA function without storing the polyhedral regions  $\mathcal{P}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ .

**3. Efficient on-line algorithms.** The on-line implementation of the control law (8) is executed simply according to the following algorithm.

## ALGORITHM 1.

1. Measure the current state  $x(t)$
2. Search for the  $i$ th polyhedron that contains  $x(t)$ ,  $(P_i^x x(t) \leq P_i)$
3. Implement the  $i$ th control law  $(u(t) = F_i x(t) + G_i)$

In Algorithm 1, step 2 is critical and is the only step whose efficiency can be improved. A simple implementation of step 2 would consist of searching for the polyhedral region that contains the state  $x(t)$  as in the following algorithm.

## ALGORITHM 2.

1.  $i = 0$ , notfound=TRUE
2. WHILE  $i \leq N_{\mathcal{P}}$  AND notfound
  - 2.1.  $j = 0$ , feasible=TRUE
  - 2.2. WHILE  $j \leq p_i$  AND feasible
    - 2.2.1. IF  $(P_i^x)_{(j)} x(t) > (P_i)_{(j)}$  THEN feasible=FALSE
  - 2.3. END
  - 2.4. IF feasible THEN notfound=FALSE
3. END

Recalling the expression (9) for  $N_{\mathcal{H}}$  (the total number of halfspaces defining the polyhedral partition of the feasible set  $\mathcal{X}_f$ ), it is easy to see that Algorithm 2 requires  $(n_x + 1)N_{\mathcal{H}}$  real numbers to store all polyhedra  $\mathcal{P}_i$ , and in the worst case (when the state is contained in the last region of the list) Algorithm 2 will give a solution after  $n_x N_{\mathcal{H}}$  multiplications,  $(n_x - 1)N_{\mathcal{H}}$  sums, and  $N_{\mathcal{H}}$  comparisons.

*Remark 3.1.* In the algorithms presented in the following sections we implicitly assume that  $x(t)$  belongs to the feasible set  $\mathcal{X}_f$ . If this (reasonable) assumption does not hold, then we should include a set of *boundaries* of feasible parameter space  $\mathcal{X}_f$ , and we should (before using any of proposed algorithms) first check if the point  $x(t)$  is inside the boundaries of  $\mathcal{X}_f$ . Note that such a step is not needed for Algorithm 2 since there we automatically detect if the point  $x(t)$  is outside of the feasible set  $\mathcal{X}_f$ .

By using the properties of the value function, we will show how Algorithm 2 can be replaced by more efficient algorithms that have less computational complexity and *avoid storing the polyhedral regions*  $\mathcal{P}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ , therefore reducing the storage demand significantly.

In the following we will distinguish between optimal control based on LP and optimal control based on QP.

**3.1. Efficient implementation, linear cost case.** From Theorem 1, the value function  $J^*(x)$  corresponding to the solution of the CFTOC problem (3) with the piecewise linear cost (4a) is convex and PWA:

$$(12) \quad J^*(x) = T'_i x + V_i \quad \forall x \in \mathcal{P}_i, \quad i = 1, \dots, N_{\mathcal{P}},$$

where  $T_i \in \mathbb{R}^{n_x}$ ,  $V_i \in \mathbb{R}$ .

By exploiting the convexity of the value function the storage of the polyhedral regions  $\mathcal{P}_i$  can be avoided. From the equivalence of the representations of PWA convex functions (cf. [17], [8, page 80]) the function  $J^*(x)$  in (12) can be represented alternatively as

$$(13) \quad J^*(x) = \max \{T'_i x + V_i\}_{i=1}^{N_{\mathcal{P}}} \quad \text{for } x \in \mathcal{X}_f = \cup_{i=1}^{N_{\mathcal{P}}} \mathcal{P}_i.$$

FIG. 1. Example for Algorithm 3 in one dimension: For a given point  $x \in \mathcal{P}_3$  ( $x = 5$ ), we have  $f_3(x) = \max(f_1(x), f_2(x), f_3(x), f_4(x))$ .

TABLE 1  
Complexity comparison of Algorithms 2 and 3.

	Algorithm 2	Algorithm 3
Storage demand (real numbers)	$(n_x + 1)N_{\mathcal{H}}$	$(n_x + 1)N_{\mathcal{P}}$
Number of flops (worst case)	$2n_x N_{\mathcal{H}}$	$2n_x N_{\mathcal{P}}$

From (12) and (13), the polyhedral region  $\mathcal{P}_j$  containing  $x$  can be identified simply by searching for the maximum number in the list  $\{T'_i x + V_i\}_{i=1}^{N_{\mathcal{P}}}$ ,

(14) 
$$x \in \mathcal{P}_j \Leftrightarrow T'_j x + V_j = \max \{T'_i x + V_i\}_{i=1}^{N_{\mathcal{P}}}.$$

Therefore, instead of searching for the polyhedron  $j$  that contains the point  $x$  via Algorithm 2, we can just store the value function and identify region  $j$  by searching for the maximum in the list of numbers composed of the single affine function  $T'_i x + V_i$  evaluated at  $x$ .

ALGORITHM 3.

- 1. Compute the list  $\mathcal{T} = \{t_i := T'_i x + V_i\}_{i=1}^{N_{\mathcal{P}}}$
- 2. Find  $i$  such that  $t_i = \max_{t_j \in \mathcal{T}} t_j$

For illustration, see the example in Figure 1, where we have  $N_{\mathcal{P}} = 4$ ,  $f_1(x) = -0.5x + 3$ ,  $f_2(x) = 2$ ,  $f_3(x) = 0.5x$ , and  $f_4(x) = 2x - 9$ .

Algorithm 3 requires the storage of  $(n_x + 1)N_{\mathcal{P}}$  real numbers and will give a solution after  $n_x N_{\mathcal{P}}$  multiplications,  $(n_x - 1)N_{\mathcal{P}}$  sums, and  $N_{\mathcal{P}} - 1$  comparisons. In Table 1 we compare the complexity of Algorithm 3 against Algorithm 2 in terms of storage demand and number of flops.

*Remark 3.2.* Algorithm 3 will outperform Algorithm 2 since typically the total number of halfspaces defining polyhedral partition of feasible set  $\mathcal{X}_f$  is much larger than the number of polyhedral regions, i.e.,  $N_{\mathcal{H}} \gg N_{\mathcal{P}}$  (see Remark 2.1).

*Remark 3.3.* Note that Algorithm 3 cannot be applied if the solution to (6) contains dual degenerate regions, i.e., two regions  $\mathcal{P}_i$  and  $\mathcal{P}_j$  that have the same cost expressions but different control expressions (i.e.,  $[T'_i \ V_i] = [T'_j \ V_j]$ ,  $[F'_i \ G_i] \neq [F'_j \ G_j]$ ). If dual degeneracy occurs one can use Algorithm 4 combined with the procedure

described in section 3.2.2. An alternative approach consists of modifying Algorithm 3 in order to be able to discern between dual degenerate regions (e.g., by means of Algorithm 2).

**3.2. Efficient implementation, quadratic cost case.** Consider the explicit solution of CFTOC problem (3) with the quadratic cost (4b). Theorem 2 states that the value function  $J^*(x)$  is convex and piecewise quadratic and the simple Algorithm 3 described in the previous subsection cannot be used here. Instead, a modified approach is described below.

We will first establish the following general result: given a general polyhedral partition of the state space, we can locate where the state lies (i.e., in which polyhedron) by using a search procedure based on the information provided by an “appropriate” PWA continuous function defined over the same polyhedral partition. We will refer to such an “appropriate” PWA function as a *PWA descriptor function*. In the following, first we outline the properties of the PWA descriptor function and then we describe the search procedure itself. In later subsections we will finally show how the gradient of the value function (under certain regularity conditions) and the optimizer (always) can be used for the construction of PWA descriptor functions.

**DEFINITION 1.** *Two polyhedra  $\mathcal{P}_i, \mathcal{P}_j$  of  $\mathbb{R}^{n_x}$  are called neighboring polyhedra if their interiors are disjoint and  $\mathcal{P}_i \cap \mathcal{P}_j$  is  $(n_x - 1)$ -dimensional (i.e., is a common facet).*

Let  $\{\mathcal{P}_i\}_{i=1}^{N_P}$  be the polyhedral partition obtained by solving the mp-QP (10). For each polyhedra  $\mathcal{P}_i$  we denote with  $\mathcal{C}_i$  the list of all its neighbors,

$$(15) \quad \mathcal{C}_i := \{j \mid \mathcal{P}_j \text{ is a neighbor of } \mathcal{P}_i, j = 1, \dots, N_P, j \neq i\}, \quad i = 1, \dots, N_P.$$

In the following, we will assume that every facet is shared by only two neighboring polyhedral regions. This so-called *facet-to-facet* property is almost always satisfied by the solution of the mp-QP (10); cf. [19]. In such a case the list  $\mathcal{C}_i$  has at most  $p_i$  elements ( $p_i$  is the number of halfspaces defining polyhedron  $\mathcal{P}_i$ ) since some of the boundaries of  $\mathcal{P}_i$  may be outer boundaries of the polyhedral partition  $\{\mathcal{P}_i\}_{i=1}^{N_P}$  and they would not introduce element in the list  $\mathcal{C}_i$ . We give the following definition of a PWA descriptor function.

**DEFINITION 2 (PWA descriptor function).** *A scalar continuous real-valued PWA function  $f : \mathcal{X}_f \rightarrow \mathbb{R}$*

$$(16) \quad f(x) = f_i(x) := A'_i x + B_i \quad \text{if } x \in \mathcal{P}_i,$$

*with  $A_i \in \mathbb{R}^{n_x}$ ,  $B_i \in \mathbb{R}$ , is called a descriptor function if*

$$(17) \quad A_i \neq A_j \quad \forall j \in \mathcal{C}_i, \quad i = 1, \dots, N_P,$$

*where  $\cup_i \mathcal{P}_i = \mathcal{X}_f \subset \mathbb{R}^{n_x}$ , and  $\mathcal{C}_i$  is the list of neighbors of  $\mathcal{P}_i$ .*

In the following, we will show that the PWA descriptor function defined above has all of the properties we need to be able to locate in which polyhedron the state  $x$  lies, because the sign of  $f_i(x) - f_j(x)$  changes only when the point  $x$  crosses the separating hyperplane between  $\mathcal{P}_i$  and  $\mathcal{P}_j$ . Thus for all  $x$  in  $\mathcal{P}_i$ , the difference  $f_i(x) - f_j(x)$  has the same sign.

**DEFINITION 3 (ordering function).** *Let  $f(x)$  be a PWA descriptor function on the polyhedral partition  $\{\mathcal{P}_i\}_{i=1}^{N_P}$ . We define ordering function  $O_i(x)$  as*

$$(18) \quad O_i(x) := [O_{i,j}(x)]_{j \in \mathcal{C}_i},$$

where

$$(19) \quad O_{i,j}(x) := \begin{cases} +1 & \text{if } f_i(x) \geq f_j(x), \\ -1 & \text{if } f_i(x) < f_j(x), \end{cases}$$

with  $i \in \{1, \dots, N_{\mathcal{P}}\}$ ,  $j \in \mathcal{C}_i$ . Note that, for simplicity, we will assume that the order in which the elements of  $\mathcal{C}_i$  are used when creating  $O_i(x)$  in (18) is uniquely defined. Namely, we use sorted (e.g., in an increasing order) list  $\mathcal{C}_i$ .

**THEOREM 3.** Let  $f(x)$  be a PWA descriptor function on the polyhedral partition  $\{\mathcal{P}_i\}_{i=1}^{N_{\mathcal{P}}}$ . Let  $\xi_i \in \mathbb{R}^{n_x}$  be any point in the interior of  $\mathcal{P}_i$ , and define

$$(20) \quad S_{i,j} := O_{i,j}(\xi_i),$$

$$(21) \quad S_i := O_i(\xi_i),$$

with  $i = 1, \dots, N_{\mathcal{P}}$ ,  $j \in \mathcal{C}_i$ . Then the following holds:

$$(22) \quad x \in \text{int}(\mathcal{P}_i) \Leftrightarrow O_{i,j}(x) = S_{i,j} \quad \forall j \in \mathcal{C}_i \Leftrightarrow O_i(x) = S_i.$$

*Proof.* Let  $\mathcal{F} = \mathcal{P}_i \cap \mathcal{P}_j$  be the common facet of two neighboring polyhedra  $\mathcal{P}_i$  and  $\mathcal{P}_j$ . Define the linear function

$$(23) \quad g_{i,j}(x) = f_i(x) - f_j(x).$$

From the continuity of descriptor function  $f(x)$ , it follows that  $g_{i,j}(x) = 0 \quad \forall x \in \mathcal{F}$ . As  $\mathcal{P}_i$  and  $\mathcal{P}_j$  are disjoint convex polyhedra and  $A_i \neq A_j$ , it follows that  $g_{i,j}(x) = 0$  is a separating hyperplane between  $\mathcal{P}_i$  and  $\mathcal{P}_j$ . We have the following.

(i) “ $\Rightarrow$ ” part. Since  $g_{i,j}(x) = 0$  is a separating hyperplane between  $\mathcal{P}_i$  and  $\mathcal{P}_j$  it follows that  $g_{i,j}(x)$  does not change sign for all  $x \in \text{int}(\mathcal{P}_i)$ . Hence, we have  $O_{i,j}(x) = S_{i,j}$ .

(ii) “ $\Leftarrow$ ” part by contradiction. Assume that  $O_{i,j}(\bar{x}) = S_{i,j}$  while  $\bar{x} \notin \mathcal{P}_i$ . It is easy to see that  $\forall \bar{x} \notin \mathcal{P}_i$ ,  $\exists j \in \mathcal{C}_i$  such that  $(P_i^x)_{(j)}\bar{x} > (P_i)_{(j)}$ . This, however, implies that  $g_{i,j}(\bar{x})$  has a different sign compared to  $g_{i,j}(\xi)$ ,  $\xi \in \text{int}(\mathcal{P}_i)$ . Hence we have  $O_{i,j}(\bar{x}) \neq S_{i,j}$ , a contradiction.  $\square$

Theorem 3 states that the ordering function  $O_i(x)$  and the vector  $S_i$  uniquely characterize  $\mathcal{P}_i$ . Therefore, to check on-line if the polyhedral region  $\mathcal{P}_i$  contains the state  $x$  it is sufficient to compute the binary vector  $O_i(x)$  and compare it with  $S_i$ . Vectors  $S_i$  are calculated off-line for  $i = 1, \dots, N_{\mathcal{P}}$ , by comparing the values of  $f_i(x)$  and  $f_j(x) \quad \forall j \in \mathcal{C}_i$ , in a point  $\xi$  belonging to  $\text{int}(\mathcal{P}_i)$ , for instance, the Chebyshev center of  $\mathcal{P}_i$ .

In Figure 2 a one dimensional example illustrates the procedure with  $N_{\mathcal{P}} = 4$  regions and for  $f_1(x) = x$ ,  $f_2(x) = 2$ ,  $f_3(x) = x - 3$ ,  $f_4(x) = -\frac{1}{3}x + \frac{19}{3}$ . The list of neighboring regions  $\mathcal{C}_i$  and the vector  $S_i$  can be constructed by simply looking at the figure:  $\mathcal{C}_1 = \{2\}$ ,  $\mathcal{C}_2 = \{1, 3\}$ ,  $\mathcal{C}_3 = \{2, 4\}$ ,  $\mathcal{C}_4 = \{3\}$ ,  $S_1 = -1$ ,  $S_2 = [-1 \ 1]$ ,  $S_3 = [1 \ -1]$ ,  $S_4 = -1$ . The point  $x = 4$  is in region 2 and we have  $O_2(x) = [-1 \ 1] = S_2$ , while  $O_3(x) = [-1 \ -1] \neq S_3$ ,  $O_1(x) = 1 \neq S_1$ ,  $O_4(x) = 1 \neq S_4$ . The failure of a match  $O_i(x) = S_i$  provides information on good search direction(s). The solution can be found by searching in the direction where a constraint is violated, i.e., we should check the neighboring region  $\mathcal{P}_j$  for which  $O_{i,j}(x) \neq S_{i,j}$ .

FIG. 2. Example for Algorithm 4 in one dimension: For a given point  $x \in \mathcal{P}_2$  ( $x = 4$ ) we have  $O_2(x) = [-1 \ 1] = S_2$ , while  $O_1(x) = 1 \neq S_1 = -1$ ,  $O_3(x) = [-1 \ -1] \neq S_3 = [1 \ -1]$ ,  $O_4(x) = 1 \neq S_4 = -1$ .

The overall procedure is composed of two parts:

1. (*off-line*). Construction of the scalar continuous real-valued PWA function  $f(\cdot)$  in (16) satisfying (17), and computation of the list of neighbors  $\mathcal{C}_i$  and the vector  $S_i$ ,
2. (*on-line*). Search for the  $i$ th polyhedron that contains  $x(t)$  by the execution of the following algorithm.

ALGORITHM 4.

1.  $\mathcal{I} = \{1, \dots, N_{\mathcal{P}}\}$
2.  $i \leftarrow \mathcal{I}$
3.  $\mathcal{I} = \mathcal{I} \setminus \{i\}$ ,  $\mathcal{C} = \mathcal{C}_i$
4. WHILE  $\mathcal{C} \neq \emptyset$ 
  - 4.1.  $j \leftarrow \mathcal{C}$ ,  $\mathcal{C} = \mathcal{C} \setminus \{j\}$
  - 4.2. Compute  $O_{i,j}(x)$
  - 4.3. IF  $O_{i,j}(x) \neq S_{i,j}$ 
    - 4.3.1. IF  $j \notin \mathcal{I}$  THEN GOTO step 2. ELSE  $i = j$  and GOTO step 3.
  - 4.4. END
5. END

Algorithm 4 does not require the storage of the polyhedra  $\mathcal{P}_i$ , but only the storage of one affine function  $f_i(x)$  per polyhedron, i.e.,  $N_{\mathcal{P}}(n_x + 1)$  real numbers and the list of neighbors  $\mathcal{C}_i$  which demands (at most)  $N_{\mathcal{H}}$  integers. Algorithm 4 in the worst case terminates after  $N_{\mathcal{P}}n_x$  multiplications,  $N_{\mathcal{P}}(n_x - 1)$  sums, and  $N_{\mathcal{H}}$  comparisons.

In Table 2 we compare the complexity of Algorithm 4 against the standard Algorithm 2 in terms of storage demand and the number of flops.

*Remark 3.4.* Note that the computation of  $O_i(x)$  in Algorithm 4 requires the evaluation of  $p_i$  linear functions, but the overall computation never exceeds  $N_{\mathcal{P}}$  linear function evaluations. Consequently, Algorithm 4 will outperform Algorithm 2, since typically  $N_{\mathcal{H}} \gg N_{\mathcal{P}}$ .

Now that we have shown how to locate the polyhedron in which the state lies by using a PWA descriptor function, we need a procedure for the construction of such a function.

TABLE 2  
Complexity comparison of Algorithms 2 and 4.

	Algorithm 2	Algorithm 4
Storage demand (real numbers)	$(n_x + 1)N_{\mathcal{H}}$	$(n_x + 1)N_{\mathcal{P}}$
Number of flops (worst case)	$2n_x N_{\mathcal{H}}$	$(2n_x - 1)N_{\mathcal{P}} + N_{\mathcal{H}}$

The image of the descriptor function is the set of real numbers  $\mathbb{R}$ . In the following, we will show how a descriptor function can be generated from a vector valued function  $m : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^s$ . This general result will be used in the next subsections.

DEFINITION 4 (vector valued PWA descriptor function). *A continuous vector valued PWA function  $m : \mathcal{X}_f \rightarrow \mathbb{R}^s$ ,*

$$(24) \quad m(x) = \bar{A}_i x + \bar{B}_i \quad \text{if } x \in \mathcal{P}_i,$$

*is called a vector valued PWA descriptor function if*

$$(25) \quad \bar{A}_i \neq \bar{A}_j \quad \forall j \in \mathcal{C}_i, \quad i = 1, \dots, N_{\mathcal{P}},$$

where  $\cup_i \mathcal{P}_i = \mathcal{X}_f \subset \mathbb{R}^{n_x}$ ,  $\bar{A}_i \in \mathbb{R}^{s \times n_x}$ ,  $\bar{B}_i \in \mathbb{R}^s$ ,  $s \in \mathbb{N}$ ,  $s \geq 2$ , and  $\mathcal{C}_i$  is the list of neighbors of  $\mathcal{P}_i$ .

THEOREM 4. *Let  $m : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^s$  be a vector valued PWA descriptor function defined over a polyhedral partition  $\{\mathcal{P}_i\}_{i=1}^{N_{\mathcal{P}}}$ . Then  $\exists w \in \mathbb{R}^s$  such that  $f(x) := w'm(x)$  is a PWA descriptor function defined over the same polyhedral partition.*

*Proof.* Let  $\mathcal{N}_{i,j}$  be the null-space of  $(\bar{A}_i - \bar{A}_j)'$ . Since, by definition,  $\bar{A}_i - \bar{A}_j \neq \mathbf{0}$ , it follows that  $\mathcal{N}_{i,j}$  is not full dimensional, i.e.,  $\mathcal{N}_{i,j} \subseteq \mathbb{R}^{s-1}$ . Consequently, it is always possible to find a vector  $w \in \mathbb{R}^s$  such that  $w'(\bar{A}_i - \bar{A}_j) \neq \mathbf{0}$  holds for all  $i = 1, \dots, N_{\mathcal{P}}$  and  $\forall j \in \mathcal{C}_i$ . Clearly,  $f(x) = w'm(x)$  is then a valid PWA descriptor function.  $\square$

As shown in the proof of Theorem 4, once we have vector valued PWA descriptor function, practically any randomly chosen vector  $w \in \mathbb{R}^s$  is likely to be satisfactory for the construction of a PWA descriptor function. From a numerical point of view, however, we would like to obtain  $w$ , which is as far away as possible from the null-spaces  $\mathcal{N}_{i,j}$ . We show one algorithm for finding such a vector  $w$ .

For a given vector valued PWA descriptor function we form a set of vectors  $a_k \in \mathbb{R}^s$ ,  $\|a_k\| = 1$ ,  $k = 1, \dots, N_a$ , by taking and normalizing one (and only one) nonzero column from each matrix  $(\bar{A}_i - \bar{A}_j) \forall j \in \mathcal{C}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ . Here  $N_a := \sum_i |\mathcal{C}_i|/2 \leq N_{\mathcal{H}}$  and  $|\mathcal{C}_i|$  denotes cardinality of set  $\mathcal{C}_i$ . The vector  $w \in \mathbb{R}^s$  satisfying the set of equations  $w'a_k \neq 0$ ,  $k = 1, \dots, N_a$ , can then be constructed by using the following algorithm.<sup>2</sup>

ALGORITHM 5.

1.  $w \leftarrow [1, \dots, 1]'$ ,  $R \leftarrow 1$
2. WHILE  $k \leq N_a$ 
  - 2.1.  $d \leftarrow w'a_k$
  - 2.2. IF  $0 \leq d \leq R$  THEN  $w \leftarrow w + \frac{1}{2}(R - d)a_k$ ,  $R \leftarrow \frac{1}{2}(R + d)$
  - 2.3. IF  $-R \leq d < 0$  THEN  $w \leftarrow w - \frac{1}{2}(R + d)a_k$ ,  $R \leftarrow \frac{1}{2}(R - d)$
3. END

Essentially, Algorithm 5 constructs a sequence of balls  $\mathcal{B} = \{x \mid x = w + r, \|r\|_2 \leq R\}$ . As depicted in Figure 3, we start with the initial ball of radius  $R = 1$ ,

<sup>2</sup>Index  $k$  goes to  $N_a := \sum_i |\mathcal{C}_i|/2$  since the term  $(\bar{A}_j - \bar{A}_i)$  is the same as  $(\bar{A}_i - \bar{A}_j)$ , and thus there is no need to consider it twice.

DEFINITION 5 (nondegenerate QP). *We say that the QP (10) is nondegenerate if, for each  $x \in \mathcal{X}_f$ , the rows of  $M_{(\mathcal{A}^*(x))}^U$  are linearly independent.*

LEMMA 1. *Suppose that the QP problem (10) is nondegenerate. Consider the value function  $J^*(x)$  in (26), and let  $\mathcal{P}_i, \mathcal{P}_j$  be two neighboring polyhedra corresponding to the set of active constraints  $\mathcal{A}_i$  and  $\mathcal{A}_j$ , respectively. Then*

$$(28) \quad Q_i - Q_j \preceq 0 \quad \text{or} \quad Q_i - Q_j \succeq 0 \quad \text{and} \quad Q_i \neq Q_j$$

and

$$(29) \quad Q_i - Q_j \preceq 0 \quad \text{iff} \quad \mathcal{A}_i \subset \mathcal{A}_j.$$

*Proof.* Let  $\mathcal{P}_i$  and  $\mathcal{P}_j$  be two neighboring polyhedra, and let  $\mathcal{A}_i$  and  $\mathcal{A}_j$  be the corresponding sets of active constraints at the optimum of QP (10). Let  $\mathcal{A}_i \subset \mathcal{A}_j$ . We want to prove that the difference between the quadratic terms of  $q_i(x)$  and  $q_j(x)$  is negative semidefinite, i.e.,  $Q_i - Q_j \preceq 0$  and  $Q_i \neq Q_j$ .

Without loss of generality, we can assume that  $\mathcal{A}_i = \emptyset$ . If this is not the case, then a simple substitution of variables based on the set of active constraints  $M_{(\mathcal{A}_i)}^U U = M_{(\mathcal{A}_i)} + M_{(\mathcal{A}_i)}^x x$  transforms problem (10) into a QP in a lower dimensional space.

With the substitution  $z = U + H^{-1}F'x$ , problem (10) can be translated into the following:

$$(30) \quad \begin{aligned} J_z^*(x) &= \min_z \frac{1}{2} z' H z \\ \text{s.t. } Gz &\leq W + Sx, \end{aligned}$$

where  $G := M^U$ ,  $W := M$ ,  $S := M^x + M^U H^{-1}F'$ , and  $J_z^*(x) = J^*(x) - \frac{1}{2}x'(Y - FH^{-1}F')x$ . For the unconstrained case we have  $z^* = 0$  and  $J_z^*(x) = 0$ . Consequently,

$$(31) \quad q_i(x) = \frac{1}{2}x'(Y - FH^{-1}F')x.$$

For the constrained case, as shown in [4], from the set of active constraints  $G_{(\mathcal{A}_j)}z = W_{(\mathcal{A}_j)} + S_{(\mathcal{A}_j)}x$  and the Karush–Kuhn–Tucker (KKT) conditions we obtain

$$(32) \quad z = H^{-1}G'_{(\mathcal{A}_j)}\Gamma^{-1}(W_{(\mathcal{A}_j)} + S_{(\mathcal{A}_j)}x),$$

$$(33) \quad \lambda_{(\mathcal{A}_j)} = -\Gamma^{-1}(W_{(\mathcal{A}_j)} + S_{(\mathcal{A}_j)}x),$$

where  $\Gamma = G_{(\mathcal{A}_j)}H^{-1}G'_{(\mathcal{A}_j)}$ ,  $\Gamma = \Gamma' \succ 0$  as the rows of  $G_{(\mathcal{A}_j)}$  are linearly independent, and  $\lambda_{(\mathcal{A}_j)}$  are the Lagrange multipliers of the active constraints  $\lambda_{(\mathcal{A}_j)} \geq 0$ . The corresponding value function is

$$(34) \quad \begin{aligned} q_j(x) &= \frac{1}{2}x'(Y - FH^{-1}F' + S'_{(\mathcal{A}_j)}\Gamma^{-1}S_{(\mathcal{A}_j)})x \\ &\quad + W'_{(\mathcal{A}_j)}\Gamma^{-1}S_{(\mathcal{A}_j)}x + \frac{1}{2}W'_{(\mathcal{A}_j)}\Gamma^{-1}W_{(\mathcal{A}_j)}. \end{aligned}$$

The difference of the quadratic terms of  $q_i(x)$  and  $q_j(x)$  gives

$$(35) \quad Q_i - Q_j = -\frac{1}{2}S'_{(\mathcal{A}_j)}\Gamma^{-1}S_{(\mathcal{A}_j)} \preceq 0.$$

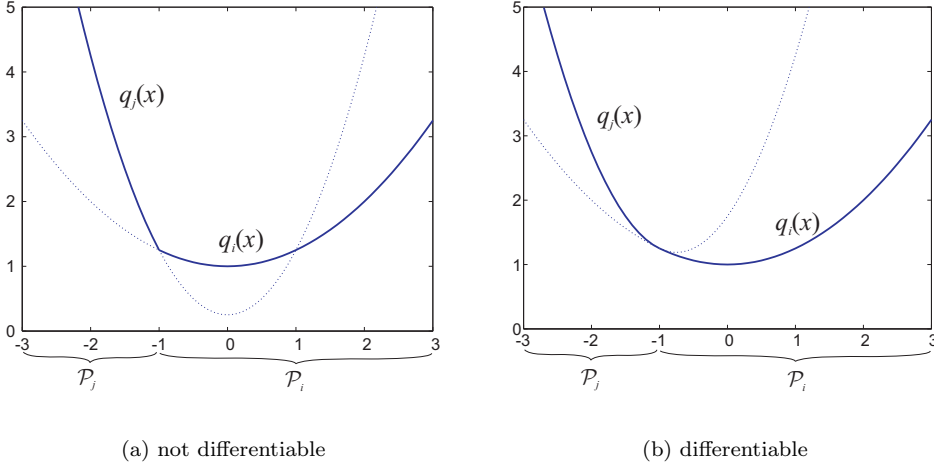

FIG. 4. Two piecewise quadratic convex functions.

What is left to prove is that  $Q_i \neq Q_j$ . We will prove it by showing that  $Q_i = Q_j$  if and only if  $\mathcal{P}_i = \mathcal{P}_j$ . For this purpose we recall [4] that the polyhedron  $\mathcal{P}_j$ , where the set of active constraints  $\mathcal{A}_j$  is constant, is defined as

$$(36) \quad \mathcal{P}_j = \left\{ x \mid GH^{-1}G'_{(\mathcal{A}_j)}\Gamma^{-1}(W_{(\mathcal{A}_j)} + S_{(\mathcal{A}_j)}x) \leq W + Sx, -\Gamma^{-1}(W_{(\mathcal{A}_j)} + S_{(\mathcal{A}_j)}x) \geq 0 \right\}.$$

From (35) we conclude that  $Q_i = Q_j$  if and only if  $S_{(\mathcal{A}_j)} = 0$ . The continuity of  $J_z^*(x)$  implies that  $q_i(x) - q_j(x) = 0$  on the common facet of  $\mathcal{P}_i$  and  $\mathcal{P}_j$ . Therefore, by comparing (31) and (34) we see that  $S_{(\mathcal{A}_j)} = 0$  implies  $W_{(\mathcal{A}_j)} = 0$ . Finally, for  $S_{(\mathcal{A}_j)} = 0$  and  $W_{(\mathcal{A}_j)} = 0$ , from (36) it follows that  $\mathcal{P}_j = \mathcal{P}_i := \{x \mid 0 \leq W + Sx\}$ .  $\square$

The following property of CPWQ functions was proved in [20].

**THEOREM 6.** Consider the value function  $J^*(x)$  in (26) satisfying (28) and its quadratic expression  $q_i(x)$  and  $q_j(x)$  on two neighboring polyhedra  $\mathcal{P}_i, \mathcal{P}_j$ . Then

$$(37) \quad q_i(x) = q_j(x) + (a'x - b)(\gamma a'x - \bar{b}),$$

where  $\gamma \in \mathbb{R}/\{0\}$ ,  $a \in \mathbb{R}^{n_x}$ ,  $b \in \mathbb{R}$ ,  $\bar{b} \in \mathbb{R}$ .

Equation (37) states that the functions  $q_i(x)$  and  $q_j(x)$  in two neighboring regions  $\mathcal{P}_i, \mathcal{P}_j$  of a CPWQ function satisfying (28) either intersect on two parallel hyperplanes,  $a'x - b$  and  $\gamma a'x - \bar{b}$  if  $\bar{b} \neq \gamma b$  (see Figure 4(a)), or are tangent in one hyperplane,  $a'x - b$  if  $\bar{b} = \gamma b$  (see Figure 4(b)). We will prove next that if the QP problem (10) is nondegenerate, then  $J^*(x)$  is a  $C^{(1)}$  function by showing that the case depicted in Figure 4(a) is not consistent with Lemma 1. In fact, Figure 4(a) depicts case  $Q^i - Q^j \preceq 0$ , that implies  $\mathcal{A}_i \subset \mathcal{A}_j$  by Lemma 1. However,  $q_j(0) < q_i(0)$  and from the definition of  $q_i$  and  $q_j$  this contradicts the fact that  $\mathcal{A}_i \subset \mathcal{A}_j$ .

**THEOREM 7.** If the QP problem (10) is nondegenerate, then the value function  $J^*(x)$  in (26) is  $C^{(1)}$ .

*Proof.* To show that  $J^*$  is  $C^{(1)}$  we need to prove that the cost functions  $q_i(x)$  and  $q_j(x)$  of any two neighboring regions  $\mathcal{P}_i$  and  $\mathcal{P}_j$  have the same gradient on the

common boundary. It is straightforward to see from (37) that this is indeed the case for  $\bar{b} = \gamma b$ . We will prove by contradiction that  $\bar{b} = \gamma b$ . Suppose there exist two neighboring polyhedra  $\mathcal{P}_i$  and  $\mathcal{P}_j$  such that  $\bar{b} \neq \gamma b$ . Without loss of generality, assume that (i)  $Q_i - Q_j \preceq 0$  and (ii)  $\mathcal{P}_i$  is in the halfspace  $a'x \leq b$  defined by the common boundary. Let  $\mathcal{F}_{ij}$  be the common facet between  $\mathcal{P}_i$  and  $\mathcal{P}_j$  and  $\text{relint}(\mathcal{F}_{ij})$  its relative interior.

From both (i) and (37), either  $\gamma < 0$  or  $\gamma = 0$  if  $Q_i - Q_j = 0$ . Take  $x_0 \in \text{relint}(\mathcal{F}_{ij})$ . For sufficiently small  $\varepsilon \geq 0$ , the point  $x := x_0 - a\varepsilon$  belongs to  $\mathcal{P}_i$ .

Let  $J^*(\varepsilon) := J^*(x_0 - a\varepsilon)$ ,  $q_i(\varepsilon) := q_i(x_0 - a\varepsilon)$ , and consider that

$$(38) \quad q_j(\varepsilon) = q_j(\varepsilon) + (a'a\varepsilon)(\gamma a'a\varepsilon + (\bar{b} - \gamma b)).$$

From convexity of  $J^*(\varepsilon)$ ,  $J^{*-}(\varepsilon) \leq J^{*+}(\varepsilon)$ , where  $J^{*-}(\varepsilon)$  and  $J^{*+}(\varepsilon)$  are the left and right derivatives of  $J^*(\varepsilon)$  with respect to  $\varepsilon$ . This implies  $q'_j(\varepsilon) \leq q'_i(\varepsilon)$ , where  $q'_j(\varepsilon)$  and  $q'_i(\varepsilon)$  are the derivatives of  $q_j(\varepsilon)$  and  $q_i(\varepsilon)$ , respectively. Condition  $q'_j(\varepsilon) \leq q'_i(\varepsilon)$  is true if and only if  $-(\bar{b} - \gamma b) \leq 2\gamma(a'a)\varepsilon$ , which implies  $-(\bar{b} - \gamma b) < 0$  since  $\gamma < 0$  and  $\varepsilon > 0$ .

From (38)  $q_j(\varepsilon) < q_i(\varepsilon) \forall \varepsilon \in (0, \frac{-(\bar{b}-\gamma b)}{\gamma a'a})$ .

Thus there exists  $x \in \mathcal{P}_i$  with  $q_j(x) < q_i(x)$ . This is a contradiction since from Theorem 5,  $\mathcal{A}_i \subset \mathcal{A}_j$ .  $\square$

Note that, in case of degeneracy, the value function  $J^*(x)$  in (26) may not be  $C^{(1)}$ ; counterexamples are given in [6].

In Theorem 7 we have proven that the value function is  $C^{(1)}$  for the nondegenerate QP (10). Now we want to show that the gradient of  $J^*(x)$  is a vector valued PWA descriptor function.

**THEOREM 8.** *Consider the value function  $J^*(x)$  in (26), and assume that the CFTOC problem (3) leads to a nondegenerate QP (10). Then the gradient  $m(x) := \nabla J^*(x)$  is a vector valued PWA descriptor function.*

*Proof.* From Theorem 7 we see that  $m(x)$  is a continuous vector valued PWA function, while from (26) we get

$$(39) \quad m(x) := \nabla J^*(x) = 2Q_i x + T_i \quad \text{if } x \in \mathcal{P}_i, \quad i = 1, \dots, N_P.$$

Since from Lemma 1 we know that  $Q_i \neq Q_j$  for all neighboring polyhedra, it follows that  $m(x)$  satisfies all conditions for a vector valued PWA descriptor function.  $\square$

Combining results of Theorems 8 and 4, it follows that by using Algorithm 5 we can construct a PWA descriptor function from the gradient of the value function  $J^*(x)$ .

*Remark 3.5.* Note that some CFTOC problems may lead to a degenerate QP (10). Identifying the classes of control problems which are guaranteed to be nondegenerate is currently an unsolved problem and the topic of ongoing research. An example of a control problem where the nondegeneracy fails is when, for some initial point, the optimal control is saturated on the whole time horizon (this gives as many active constraints as the dimension of  $U^*$ ) and the state hits the state constraint at least once (so there are more active constraints than the dimension of  $U^*$ ). However, degeneracy does not necessarily imply the loss of continuous differentiability of the value function, which thus might have no effect on our procedure. Next, we provide a simple example of a nondegenerate CFTOC which, by adding a terminal constraint, becomes degenerate and whose cost is not continuously differentiable.

FIG. 5. Solution to the CFTOC problem (42).

**Example.** Consider the system

$$(40) \quad x_{k+1} = -1.5x_k + u_k,$$

where  $x_k \in \mathbb{R}$  and  $u_k \in \mathbb{R}$  are state and input at time  $k$ , respectively, subject to the following constraints  $\forall k \geq 0$ :

$$(41) \quad -1 \leq x_k \leq 1, \quad -0.5 \leq u_k \leq -0.1.$$

Consider the CFTOC problem (3) for system (40)–(41) with quadratic cost (4a), weighting matrices  $Q^x = 0.1$ ,  $Q^u = 10$ ,  $Q^{x_N} = 0$ , and horizon  $N = 3$ , i.e.,

$$(42) \quad \begin{aligned} J^*(x(0)) = \min_{u_0, u_1, u_2} \quad & \sum_{k=0}^2 0.1x_k^2 + 10u_k^2 \\ \text{s.t.} \quad & x_{k+1} = -1.5x_k + u_k, \quad k = 0, \dots, 2, \\ & -1 \leq x_k \leq 1, \quad k = 0, \dots, 2, \\ & -0.5 \leq u_k \leq -0.1, \quad k = 0, \dots, 2, \\ & x_0 = x(0). \end{aligned}$$

Then the corresponding QP (10) is nondegenerate and  $J^*(x(0))$  is continuously differentiable everywhere in its domain (see Figure 5). However, if the additional constraint  $x_3 = 0$  is added to the CFTOC problem (42), then the corresponding QP (10) becomes degenerate and  $J^*(x(0))$  is not continuously differentiable at  $x(0) = -0.0518$  (see Figure 6).

**3.2.2. Generating a PWA descriptor function from the optimizer.** A clear drawback of the procedure described in the previous subsection is the requirement that the QP (10) be nondegenerate. Luckily, there is another way to construct a vector valued PWA descriptor function  $m(x)$  that always works and does not require any additional checking. This second procedure emerges naturally if we look at the properties of the optimizer  $U^*(x)$  corresponding to the state feedback solution of the CFTOC problem (3). From Theorem 2, the optimizer  $U^*(x)$  is continuous in  $x$  and

FIG. 6. Solution to the CFTOC problem (42) with additional constraint  $x_3 = 0$ .

PWA:

$$(43) \quad U^*(x) = l_i(x) := \bar{F}_i x + \bar{G}_i \quad \text{if } x \in \mathcal{P}_i, \quad i = 1, \dots, N_{\mathcal{P}},$$

where  $\bar{F}_i \in \mathbb{R}^{s \times n_x}$ ,  $\bar{G}_i \in \mathbb{R}^s$ , and  $\mathcal{P}_i$ ,  $i = 1, \dots, N_{\mathcal{P}}$ , are the full dimensional critical regions of the optimization problem (10); cf. [4].

All we need to show now is the following lemma.

LEMMA 2. Consider the CFTOC problem (3) and corresponding QP (10). Let  $\mathcal{P}_i$ ,  $\mathcal{P}_j$  be two (full dimensional) neighboring polyhedra of the state feedback solution (43). Then  $\bar{F}_i \neq \bar{F}_j$ .

*Proof.* We prove Lemma 2 by contradiction. Suppose that the optimizer is the same for both polyhedra, i.e.,  $[\bar{F}_i \ \bar{G}_i] = [\bar{F}_j \ \bar{G}_j]$ . Let  $\mathcal{A}_i$  and  $\mathcal{A}_j$  be the sets of active constraints for  $\mathcal{P}_i$  and  $\mathcal{P}_j$ . From (27) we see that for an active constraint in  $\mathcal{P}_i$ ,  $v \in \mathcal{A}_i$ , the following holds:

$$(44) \quad M_{(v)}^U(\bar{F}_i x + \bar{G}_i) = M_{(v)} + M_{(v)}^x x \quad \forall x \in \mathcal{P}_i, \forall v \in \mathcal{A}_i,$$

because (44) must hold  $\forall x \in \mathcal{P}_i$ , where  $\mathcal{P}_i$  is a full dimensional polyhedron in  $\mathbb{R}^{n_x}$ . Since  $M_{(v)}^U \bar{F}_i - M_{(v)}^x \in \mathbb{R}^{n_x}$  the above statement is satisfied if and only if

$$(45) \quad M_{(v)}^U \bar{F}_i - M_{(v)}^x = \mathbf{0}', \quad M_{(v)}^U \bar{G}_i - M_{(v)} = 0 \quad \forall v \in \mathcal{A}_i.$$

By assumption  $[\bar{F}_i \ \bar{G}_i] = [\bar{F}_j \ \bar{G}_j]$ , hence the expression (45) implies that

$$(46) \quad M_{(v)}^U(\bar{F}_j x + \bar{G}_j) = M_{(v)} + M_{(v)}^x x \quad \forall x, \forall v \in \mathcal{A}_i.$$

Clearly, (46) holds  $\forall x \in \mathcal{P}_j$ , and we conclude that all active constraints of  $\mathcal{P}_i$  are also active in  $\mathcal{P}_j$ . The same reasoning holds for  $\mathcal{P}_j$  and  $\forall v \in \mathcal{A}_j$ , thus implying that  $\mathcal{A}_i = \mathcal{A}_j$ . However, the same sets of active constraints and the same optimal control law in QP (10) can generate only one region, thus implying that  $\mathcal{P}_i = \mathcal{P}_j$ , which contradicts the assumption of Lemma 2. Therefore we have  $[\bar{F}_i \ \bar{G}_i] \neq [\bar{F}_j \ \bar{G}_j]$ . Finally, observing that for the two neighboring polyhedra, due to the continuity of  $U^*(x)$ ,  $\bar{F}_i = \bar{F}_j$  implies  $\bar{G}_i = \bar{G}_j$ , for which we prove that  $\bar{F}_i \neq \bar{F}_j$ .  $\square$

From Lemma 2 and Theorem 4 it follows that an appropriate PWA descriptor function  $f(x)$  can be calculated from the optimizer  $U^*(x)$  by using Algorithm 5.

*Remark 3.6.* Note that even if we are implementing RHC strategy, the construction of the PWA descriptor function is based on the full optimization vector  $U^*(x)$  and the corresponding matrices  $\bar{F}_i$  and  $\bar{G}_i$ .

*Remark 3.7.* In some cases the use of the optimal control profile  $U^*(x)$  for the construction of a descriptor function  $f(x)$  can be extremely simple. If there is a row  $r$ ,  $r \leq n_u$  ( $n_u$  is the dimension of  $u$ ), for which  $(\bar{F}_i)_{(r)} \neq (\bar{F}_j)_{(r)} \forall i = 1, \dots, N_P, \forall j \in \mathcal{C}_i$ , it is enough to set  $A_i' = (\bar{F}_i)_{(r)}$  and  $B^i = (\bar{G}_i)_{(r)}$ , where  $(\bar{F}_i)_{(r)}$  and  $(\bar{G}_i)_{(r)}$  denote the  $r$ th row of the matrices  $\bar{F}_i$  and  $\bar{G}_i$ , respectively. In this way we *avoid* the storage of the descriptor function, since it is equal to one component of the control law, which is stored anyway.

*Remark 3.8.* A natural question is whether this approach can be readily extended to the control of PWA systems. In general, the answer is no. However, we point out that whenever a PWA descriptor function can be found one can use Algorithm 4. For instance, the optimal control of a PWA system with piecewise linear cost results in a PWA control over polyhedral partition of the feasible state space (cf. [2]). If this control law satisfies conditions of the vector valued PWA descriptor function (see Definition 4), then we can use Algorithm 4. Note that the value function (12) in the linear cost case is also a descriptor function.

All described algorithms can be easily implemented and combined with available tools for deriving optimal controllers for linear systems (e.g., multiparametric toolbox [13] under MATLAB).

**4. Example.** As an example, we compare the performance of Algorithms 2, 3, and 4 on a CFTOC problem for the discrete-time system

$$(47) \quad \begin{cases} x(t+1) = \begin{bmatrix} 4 & -1.5 & 0.5 & -0.25 \\ 4 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0.5 \\ 0 \\ 0 \\ 0 \end{bmatrix} u(t), \\ y(t) = [0.08333 \quad 0.2292 \quad 0.1146 \quad 0.02083] x(t) \end{cases}$$

resulting from the linear system  $y = \frac{1}{s^4}u$ , sampled at  $T_s = 1$ , and subject to the input and output constraints

$$(48) \quad -1 \leq u(t) \leq 1, \quad -10 \leq y(t) \leq 10.$$

**4.1. CFTOC, linear cost case.** To regulate (47)–(48), we design a receding horizon controller based on the optimization problem (3) with the piecewise linear cost function (4a),  $\ell = \infty$ ,  $N = 2$ ,  $Q = \text{diag}\{5, 10, 10, 10\}$ ,  $R = 0.8$ ,  $P = 0$ . The PWA solution of the mp-LP problem was computed in 240 s on a Pentium III 900 MHz machine running MATLAB 6.0. The corresponding polyhedral partition of the state-space consists of  $N_P = 136$  regions with  $N_H = 1138$  halfspaces. In Table 3 we report the comparison between the complexity of Algorithms 2 and 3 for this example.

The average on-line RHC computation for a set of 1000 random points in the state space is 2259 flops (Algorithm 2) and 1088 flops (Algorithm 3).

**4.2. CFTOC, quadratic cost case.** To regulate (47)–(48), we design a receding horizon controller based on the optimization problem (3) with the quadratic cost

TABLE 3

function (4b),  $N = 7$ ,  $Q = I$ ,  $R = 0.01$ ,  $P = 0$ . The PWA solution of the mp-QP problem was computed in 560 s on a Pentium III 900 MHz machine running MATLAB 6.0. The corresponding polyhedral partition of the state space consists of  $N_{\mathcal{P}} = 213$  regions with  $N_{\mathcal{H}} = 1948$  halfspaces. For this example the choice of  $w = [1 \ 1 \ 1 \ 1 \ 1 \ 1 \ 1]'$  is satisfactory to obtain a descriptor function from the optimizer. In Table 4 we report the comparison between the complexity of Algorithms 2 and 4 for this example.

The average on-line RHC computation for a set of 1000 random points in the state space is 2114 flops (Algorithm 2) and 175 flops (Algorithm 4).

**5. Conclusion.** By exploiting properties of the value function and the optimal solution to the CFTOC problem, we presented two algorithms that significantly improved the efficiency of the on-line calculation of the control action (LP-based and QP-based) in terms of storage demand and computational complexity. The following improvements are then achieved:

1. There is no need to store the polyhedral partition of the state space.
2. In the worst case, the optimal control law is computed after the evaluation of one linear function per polyhedron.

**Acknowledgments.** The authors would like to thank the anonymous reviewers whose careful scrutiny and many useful suggestions considerably improved the quality of this manuscript.

## PARTIALLY OBSERVED INVENTORY SYSTEMS: THE CASE OF RAIN CHECKS\*

ALAIN BENSOUSSAN<sup>†</sup>, METIN ÇAKANYILDIRIM<sup>‡</sup>, J. ADOLFO MINJÁREZ-SOSA<sup>§</sup>,  
SURESH P. SETHI<sup>¶</sup>, AND RUIXIA SHI<sup>‡</sup>

**Abstract.** In many inventory control contexts, inventory levels are only partially (i.e., not fully) observed. This may be due to nonobservation of demand, spoilage, misplacement, or theft of inventory. We study a discrete-time periodic-review inventory system where the unmet demand is backordered. When the inventory level is nonnegative, the inventory manager does not know the exact inventory level. Otherwise, inventory shortages occur, and the inventory manager issues rain checks to customers. The shortages are fully observed via the rain checks. The inventory manager determines the order quantity based on the partial information on the inventory level. The objective is to minimize the expected total discounted cost over an infinite horizon. The dynamic programming formulation of this problem has an infinite dimensional state space. We use the methodology of the unnormalized probability to establish the existence of an optimal feedback policy when the periodic cost has linear growth. Moreover, uniqueness and continuity of the solution to dynamic programming equations are proved when the discount factor is sufficiently small.

**1. Introduction.** Most inventory models assume that the inventory levels at any given time are fully observed. Under this assumption, some of the most celebrated results, such as the optimality of the base stock policy [1], have been obtained. However, in reality, the inventory levels are often only partially observed. In such cases, most of the well-known inventory policies are not even admissible, let alone optimal.

There are a number of reasons for partial observability of inventory levels. We list only some, as they have been discussed in detail in Bensoussan, Çakanyildirim, and Sethi [4] (referred to as BCS hereafter) and references therein. Demand may be incorrectly observed or observed with some delay. Inventory may be misplaced or stolen. Some products such as groceries and drugs deteriorate over time and are no longer fit for sale after a period of time. In addition, the saleable quantities received may be different from those ordered because of uncertain yields.

Even though partial observations in inventory systems are very common, there has not been much research activity in this area. The main reason may be the mathematical difficulty. While a finite dimensional space suffices to accommodate the system state in the full observation case, an infinite dimensional state space is required in the partial observation setting. More specifically, the inventory level at

a given time is no longer a system state in  $\mathbb{R}^n$ ; it must now be represented by its conditional probability given the partial observations available at that time. Thus, the analysis takes place in the space of probability distributions.

When there is no physical inventory, i.e., the inventory is zero or negative, then none of the following would happen: transaction errors, misplaced inventories, spoilage, or theft. Most companies pay utmost attention to an item when its inventory reaches zero. In these companies, employees walk around the shelves to see if the item is stocked out. This process is implemented at the office supply store Staples and is called “zero-balance walk” in [9] and [12]. BCS study this situation, in which the positive inventory is represented by a conditional distribution, no backordering is allowed, and an empty shelf is noticed when the inventory reaches zero. BCS were the first to introduce a methodology to handle the difficulty of dealing with partially observed discrete-time inventory systems.

This paper extends BCS to the case when backordering is allowed, i.e., when sales are not lost. It is very common in reality that a store issues rain checks to a customer when there is a stockout. A rain check is an assurance to a customer that a sold out item can be purchased later at the same price. Usually, the inventory manager (IM) monitors the issuing of the rain checks. Thus, in the inventory systems with rain checks, the negative inventory level is fully observed by the IM. It is the purpose of this paper to formulate and analyze the partially observed inventory system with rain checks. However, compared to the work of BCS, where the inventory level is observed when it is zero, the full observation of negative inventory in the present paper makes the analysis much more difficult. Indeed, in the model of BCS, the optimality equation is represented by a pair formed by a constant and a function of the conditional distribution of the inventory level. The constant corresponds to the case of zero inventory (observable term), while the function represents the optimality equation with positive inventory (nonobservable term). However, in the present model, instead of a constant, the observable term via rain checks is represented by a function of the backordered amount. Therefore, the present study must consider suitable functional spaces to define appropriate dynamic programming operators, which necessitates a more complicated mathematical analysis.

It is worth emphasizing that even though the study of the rain check model is more involved than that of the zero-balance walk model, we are able to develop an alternative approach that allows us to improve the results in BCS. They show the existence of a solution to the dynamic programming equations for the problem by obtaining a decreasing sequence of solutions from a value iteration scheme that converge to the value function. Furthermore, the existence of an optimal ordering policy in BCS is obtained under the condition of bounded ordering quantities or with a sufficiently small discount factor. We, on the other hand, do not require these conditions to get the existence of an optimal feedback ordering policy. This is accomplished by first proving the convergence of an increasing sequence of solutions, obtained from a value iteration algorithm, to the value function, and then using a selection theorem to establish the existence of an optimal feedback policy. Furthermore, for a sufficiently small discount factor, and using a decreasing approximation scheme as in BCS, we show in addition that the value function is continuous and is the unique solution of the optimality equation. Moreover, the value iteration procedure developed in this paper is a valid approximation scheme for any discount factor, whereas the BCS scheme is restricted to a sufficiently small discount factor.

The mathematical treatment for our problem is similar to those applying to the standard partially observed stochastic control problems. These consist of introducing

a filtering process for the partially observed variable, and then the partially observed problem is transformed into an equivalent fully observed problem where the filter becomes the new system state. In our case, the filtering process is defined by the conditional density of the inventory level given the observed history. The filters are obtained recursively in Theorem 1. Besides the difficulties associated with the infinite dimensional state space of the new problem, the equation defining the filtering process is highly nonlinear, which leads to a nontrivial problem. However, by introducing what is known as the unnormalized probability, we transform this equation to a linear one. Therefore, our approach finally consists of using an unnormalized filtering process, which allows us to easily prove our main results.

The rest of this paper is organized as follows. In the next section we describe our model and obtain the evolution equation for the inventory distribution, which is linearized by introducing the unnormalized probability. In section 3, we formulate the problem and provide the dynamic programming equations for both normalized and unnormalized probabilities. We present our results in section 4 and prove them in section 5.

**2. Model development.** We study an infinite-horizon, single-item, discrete-time periodic-review inventory system in which the inventory level is partially observed due to unobservable demand. We assume that the unmet demand is backordered. Because of the rain checks, the IM knows exactly the backordered quantity. But when the inventory is nonnegative, he or she knows only the probability distribution of the inventory level. Thus, the IM only partially observes the inventory level.

We divide the timeline into intervals of equal length. Each interval is called a period. In practice, a period can be one week, one month, etc. The sequence of events in any given period  $t$  is as follows: at the beginning of the period (before the demand occurs), the IM observes if the inventory level is negative or nonnegative. If the inventory level is nonnegative, he or she has the probability distribution of the inventory level based on prior observations. Otherwise, the IM knows exactly the backordered quantity. Then, the IM determines how much to order, and the order is delivered immediately. Next the demand occurs, and the IM's order can be used to meet the demand of period  $t$ . But the demand is not observed by the IM unless the inventory level falls below zero. In each period, the IM incurs inventory related costs.

We let  $I_t$  denote the inventory level at the beginning of period  $t$ ,  $q_t$  denote the order quantity determined by the IM at that time taking values in  $\mathbb{R}^+ := [0, \infty)$ , and  $D_t$  denote the random demand occurring in period  $t$ . We assume that  $D_t$ ,  $t = 1, 2, 3, \dots$ , are nonnegative, independently and identically distributed random variables, and let the generic demand be denoted by  $D \geq 0$  with the density and distribution functions  $f$  and  $F$ , respectively. We assume that  $E(D) < \infty$ . Unsatisfied demand is fully backordered, so that the evolution of inventory is given by

$$(1) \quad I_{t+1} = I_t + q_t - D_t \quad \text{for } t \geq 1.$$

$I_t$  can be either negative or nonnegative. If  $I_t$  is negative, the demand in period  $t - 1$  is not fully met, and the negative part of  $I_t$  represents the backordered amount. Let  $z_t$  denote the backordered amount in period  $t$ ; then  $z_t = (I_t)^-$ . If  $I_t$  is nonnegative, obviously it is the ending inventory carried over from period  $t - 1$ . But the IM cannot tell exactly how much it is. What he or she can do, however, is to evolve the conditional distribution of the inventory level.

In our model, for period  $t \geq 1$ , the IM can only observe

$$(2) \quad z_t = (I_t)^- \quad \text{for } t \geq 1,$$

where  $(x)^- = \max\{0, -x\}$ . If  $z_t > 0$ , it is the backordered quantity. If  $z_t = 0$ , the inventory level at the beginning of period  $t$  is nonnegative, and a distribution of the inventory level can be derived based on prior observations. The IM determines the order quantity  $q_t$  for each period  $t$ . The order quantity  $q_t$  is adapted to the sigma field  $\mathcal{Z}_t := \sigma(\{z_j : 1 \leq j \leq t\})$ . Thus,  $\mathcal{Z}_t$  is the history available to the IM in period  $t$ . By an ordering policy (or simply a policy), we mean a sequence  $\tilde{q} = \{q_t\}$  of  $\mathbb{R}^+$ -valued random variables such that  $q_t$  is  $\mathcal{Z}_t$ -measurable for each  $t \geq 1$ . Let  $\Gamma$  be the set of such policies.

When the demand is met entirely in period  $t - 1$ , inventory holding costs are incurred on the remaining inventory carried from period  $t - 1$  to period  $t$ .<sup>1</sup> Otherwise, there are backorder costs. Then, given the cost function  $c(I_t, q_t)$  depending only on the inventory level  $I_t$  and the order size  $q_t$  in period  $t$ ,  $t = 1, 2, 3, \dots$ , and given the policy  $\tilde{q} \in \Gamma$ , the total expected discounted cost can be written as

$$J(\zeta, \pi, \tilde{q}) := \mathbb{E} \sum_{t=1}^{\infty} \alpha^{t-1} c(I_t, q_t),$$

where  $0 < \alpha < 1$  is the discount factor. The pair  $(\zeta, \pi(\cdot))$  is the inventory state at the beginning of period 1. When  $\zeta > 0$ ,  $\zeta$  is the backordered quantity at the beginning of period 1. If  $\zeta = 0$ , the inventory level  $I_1$  is nonnegative and  $\pi \in \Pi$  is the probability density of  $I_1$ , where  $\Pi$  is the set of density functions such that  $\int x\pi(x)dx < \infty$ . Observe that  $f \in \Pi$ .

We want to find a policy  $\tilde{q} \in \Gamma$  that minimizes  $J(\zeta, \pi, \tilde{q})$ . When  $\zeta > 0$ ,  $\pi$  is of no consequence and  $J(\zeta, \pi, \tilde{q})$  does not depend on  $\pi$ , which will be noted explicitly below.

**2.1. Evolution of state probabilities.** At the beginning of the first period, a prior probability density  $\pi \in \Pi$  of nonnegative inventory is given. From the second period on, the IM needs to derive the probability distribution function for nonnegative inventory to use in his or her decision process. In what follows, we show how these distribution functions evolve over time.

It is convenient to introduce the indicator random variables

$$(3) \quad \mathbb{I}_{z_t=0} = \mathbb{I}_{I_t^- = 0} = \mathbb{I}_{I_t \geq 0} \quad \text{for } t \geq 1.$$

When there is no backorder, i.e.,  $z_t = I_t^- = 0$  or  $I_t \geq 0$ ,  $\mathbb{I}_{z_t=0} = 1$ . Otherwise,  $\mathbb{I}_{z_t=0} = 0$ . The indicator random variable  $\mathbb{I}_{z_t=0}$  is a discrete-time Markov chain with the state space  $\{0, 1\}$ : 1 means there is no backorder, and 0 means there is.

Let  $\pi_t(\cdot)$  be the conditional density of  $I_t$  given  $\mathcal{Z}_{t-1}$  and  $I_t \geq 0$ . That is,

$$P(I_t \leq x | \mathcal{Z}_{t-1}, I_t \geq 0) = \int_0^x \pi_t(y) dy.$$

<sup>1</sup>See Remark 2.3 in [8] for inventory holding cost accounting based on ending or beginning inventory levels.

For any bounded real test function  $\varphi(\cdot)$ , the conditional Bayes theorem gives

$$(4) \quad \int_0^\infty \varphi(x) \pi_t(x) dx = E[\varphi(I_t) | \mathcal{Z}_{t-1}, I_t \geq 0] = \frac{E[\varphi(I_t) \mathbb{I}_{I_t \geq 0} | \mathcal{Z}_{t-1}]}{E[\mathbb{I}_{I_t \geq 0} | \mathcal{Z}_{t-1}]} \\ = \frac{E[\varphi(I_t) \mathbb{I}_{I_t \geq 0} | \mathcal{Z}_{t-1}]}{P(I_t \geq 0 | \mathcal{Z}_{t-1})}.$$

In order to obtain a recursive expression for  $\pi_t$  in terms of  $\pi_{t-1}$ , we express  $E(\varphi(I_t) | \mathcal{Z}_t)$  in terms of the conditional density  $\pi_t$  in the following lemma.

LEMMA 1.

$$(5) \quad E(\varphi(I_t) | \mathcal{Z}_t) = \mathbb{I}_{z_t > 0} \varphi(-z_t) + \mathbb{I}_{z_t = 0} \int_0^\infty \varphi(\eta) \pi_t(\eta) d\eta.$$

From this lemma we can derive the density function  $\pi_t$  as stated in the following theorem.

THEOREM 1. *For  $t \geq 2$ , the conditional density  $\pi_t$  can be expressed recursively as follows:*

$$(6) \quad \pi_t(x) = \mathbb{I}_{z_{t-1} > 0} \left\{ \frac{f(-z_{t-1} + q_{t-1} - x) \mathbb{I}_{-z_{t-1} + q_{t-1} - x \geq 0}}{F(q_{t-1} - z_{t-1})} \right\} \\ + \mathbb{I}_{z_{t-1} = 0} \left\{ \frac{\int_{(x-q_{t-1})^+}^\infty f(y + q_{t-1} - x) \pi_{t-1}(y) dy}{\int_0^\infty F(y + q_{t-1}) \pi_{t-1}(y) dy} \right\}.$$

For  $t = 1$ ,  $\pi_1(x) = \pi(x)$ .

Thus,  $\pi_t$  evolves according to a highly nonlinear equation which corresponds to the Kushner equation [11] in our inventory context.

We can use the following method to linearize (6). We define the sequence of functions  $\{p_t\}$  by the recursive linear equation

$$(7) \quad p_t(x) = \mathbb{I}_{z_{t-1} > 0} f(-z_{t-1} + q_{t-1} - x) \mathbb{I}_{-z_{t-1} + q_{t-1} - x \geq 0} \\ + \mathbb{I}_{z_{t-1} = 0} \int_{(x-q_{t-1})^+}^\infty f(y + q_{t-1} - x) p_{t-1}(y) dy, \\ p_1(x) = \pi(x),$$

which corresponds to the Zakai equation obtained in the context of systems with diffusions in [2] and [13]. Also,

$$\lambda_t = \int_0^\infty p_t(x) dx.$$

Then, we have  $\lambda_1 = 1$  and, for  $t \geq 2$  from (7),

$$(8) \quad \lambda_t = \mathbb{I}_{z_{t-1} > 0} F(-z_{t-1} + q_{t-1}) + \mathbb{I}_{z_{t-1} = 0} \int_0^\infty F(q_{t-1} + y) p_{t-1}(y) dy.$$

Moreover,

$$(9) \quad p_t(x) = \lambda_t \pi_t(x).$$

Clearly, (9) holds for  $t = 1$ . Assuming (9) to hold for any  $t$ , we proceed to  $t + 1$  by multiplying (6) side-by-side by (8) to obtain

$$\begin{aligned} \lambda_{t+1}\pi_{t+1}(x) &= \mathbb{I}_{z_t > 0} f(-z_t + q_t - x) \mathbb{I}_{-z_t + q_t - x \geq 0} \\ &+ \mathbb{I}_{z_t = 0} \frac{\int_{(x-q_t)^+}^{\infty} f(y + q_t - x) \pi_t(y) dy \int_0^{\infty} F(q_t + y) p_t(y) dy}{\int_0^{\infty} F(y + q_t) \pi_t(y) dy}. \end{aligned}$$

By multiplying the numerator and the denominator of the second term on the right-hand side by  $\lambda_t$ , we establish (9) for  $t + 1$ .

On account of the weighting factor  $\lambda_t$  in (9),  $p_t(x)$  can be viewed as an unnormalized probability; see [10] or [13]. We can easily get the normalized probability  $\pi_t(x)$  by

$$\pi_t(x) = \frac{p_t(x)}{\int_0^{\infty} p_t(x) dx}.$$

To write (6) and (7) in the operator form, we define the spaces

$$\mathcal{H} := \left\{ p \in L^1(\mathbb{R}^+) : \int_0^{\infty} x |p(x)| dx < \infty \right\} \quad \text{and} \quad \mathcal{H}^+ := \{ p \in \mathcal{H} | p(x) \geq 0, x \in \mathbb{R}^+ \},$$

where  $L^1(\mathbb{R}^+)$  is the space of integrable functions whose domain is the set of nonnegative real numbers. Note that  $\Pi \subseteq \mathcal{H}^+$ . Observe that  $\mathcal{H}^+$  is not a subspace of  $\mathcal{H}$ , for it does not include  $-p$  for some  $p$ . In the remainder, we identify  $\mathcal{H}^+$  as the set of all unnormalized probabilities with the norm

$$\|p\| := \int_0^{\infty} |p(x)| dx + \int_0^{\infty} x |p(x)| dx.$$

Since  $\Pi \subseteq \mathcal{H}^+$ , the norm applies to the normalized probability  $\pi$  to say that the inventory level must have a finite mean. For a sequence  $\{p_n\}$  in  $\mathcal{H}^+$  and  $p \in \mathcal{H}^+$ , “ $p_n \rightarrow p$ ” means  $\|p_n - p\| \rightarrow 0$  as  $n \rightarrow \infty$ , which is equivalent to

$$(10) \quad \int_0^{\infty} |p_n(x) - p(x)| dx \rightarrow 0 \quad \text{and} \quad \int_0^{\infty} x |p_n(x) - p(x)| dx \rightarrow 0.$$

Let  $\mathbb{L}$  be the space of functions  $\phi$  with linear growth, i.e.,

$$\mathbb{L} := \left\{ \phi : \sup_{x \geq 0} \frac{|\phi(x)|}{1+x} < \infty \right\}$$

with the norm

$$\|\phi\|_{\mathbb{L}} := \sup_{x \geq 0} \frac{|\phi(x)|}{1+x}.$$

Furthermore, we define the product

$$\langle p, \phi \rangle := \int_0^{\infty} p(x) \phi(x) dx \quad \text{for } p \in \mathcal{H}, \phi \in \mathbb{L}.$$

Similarly, we define the space  $\mathbb{L}^+ := \{\phi \in \mathbb{L} : \phi(x) \geq 0, x \in \mathbb{R}^+\}$ . We assume that, for every fixed  $q_t$ , the one-period cost  $c(I_t, q_t)$  is in  $\mathbb{L}^+$ .

For any order quantity  $q$  and the inventory level  $y$  before the receipt of the order, we let  $w = y + q$  be the inventory level after the receipt. We also let  $\mathcal{L}(\mathcal{H}, \mathcal{H})$  denote the space of bounded linear maps from  $\mathcal{H}$  to  $\mathcal{H}$ . Then, for  $y \geq 0$ , we can define the linear operator  $\varrho(q) \in \mathcal{L}(\mathcal{H}, \mathcal{H})$  as

$$\varrho(q)p(x) := \int_{(x-q)^+}^{\infty} f(y+q-x)p(y)dy.$$

For  $y < 0$ , we define

$$\varrho_0(w)(x) := \begin{cases} f(w-x)\mathbb{I}_{x \leq w} & \text{if } w \geq 0, \\ 0 & \text{if } w < 0. \end{cases}$$

After defining the operators above, we can define the corresponding nonlinear operator  $\theta(q, \cdot)$  and the function  $\theta_0(w)$ , respectively, as

$$\begin{aligned} \theta(q, p) &:= \frac{\varrho(q)p}{\int_0^{\infty} F(y+q)p(y)dy}, \\ \theta_0(w) &:= \frac{\varrho_0(w)}{F(w)}. \end{aligned}$$

From the definition of  $\theta(q, p)$ , we can see that the operator  $\theta$  is homogenous of degree 0 in  $p$  and is well defined if  $\langle \varrho(q)p, 1 \rangle > 0$ ; i.e.,

$$(11) \quad \langle \varrho(q)p, 1 \rangle = \int_0^{\infty} p(y)F(y+q)dy \neq 0.$$

With these operators, we can write (6) and (7) in the operator form

$$(12) \quad \pi_t = \mathbb{I}_{z_{t-1} > 0} \theta_0(q_{t-1} - z_{t-1}) + \mathbb{I}_{z_{t-1} = 0} \theta(q_{t-1}, \pi_{t-1}),$$

$$(13) \quad p_t = \mathbb{I}_{z_{t-1} > 0} \varrho_0(q_{t-1} - z_{t-1}) + \mathbb{I}_{z_{t-1} = 0} \varrho(q_{t-1})p_{t-1},$$

with the initial conditions  $\pi_1 = p_1 = \pi$ . Once again, we emphasize that (13) is a linear equation, while (12) is not.

For the linear operator  $\varrho(q)$ , the norm is defined as

$$\|\varrho(q)\|_{\mathcal{L}} := \sup_{p \in \mathcal{H}} \frac{\|\varrho(q)p\|}{\|p\|},$$

where we adopt the convention that  $0/0 = 0$ , here and throughout. For this norm, we have the following lemma.

LEMMA 2.  $\|\varrho(q)p\| \leq \|p\| + q \int_0^{\infty} |p(y)| dy$  and  $\|\varrho(q)\|_{\mathcal{L}} \leq 1 + q$ .

From this lemma we can see that, when  $q = 0$ , the operator  $\varrho(q)p$  is a contraction mapping. Additional properties of operators  $\varrho$  and  $\theta$  are given in BCS.

**3. Dynamic programming formulation.** We assume that  $c(I, q)$  is a continuous function of linear growth in  $I$  for every fixed  $q$ ; i.e.,  $c(\cdot, q) \in \mathbb{L}^+$ . A cost function with linear growth satisfies the following inequality:

$$(14) \quad \text{Linear growth assumption: } c(y, q) \leq c_0 + c_1 q + h y^+ + s y^-, \quad y \in \mathfrak{R},$$

where  $c_1$ ,  $h$ , and  $s$  are positive constants. The constant  $c_0$  can be interpreted as the maximum expected backorder cost that can be incurred in a period if the beginning inventory level is zero. Indeed, we set  $c_0 = c(0, 0)$ .  $c_0$  will be bounded by the cost of backordering  $E(D)$  units. If the unit order cost is  $c$ , obviously the ordering cost  $cq$  constitutes a lower bound on  $c(I, q)$ . Under the linear growth assumption, we have the following lemma.

LEMMA 3. *If  $q_n \rightarrow q$  in the Euclidean norm and  $p_n \rightarrow p$  in the norm  $\|\cdot\|$  as  $n \rightarrow \infty$ , then*

$$\int_0^\infty c(y, q_n) p_n(y) dy \rightarrow \int_0^\infty c(y, q) p(y) dy.$$

From this lemma, we can see that the function

$$(15) \quad (q, p) \rightarrow \int_0^\infty c(y, q) p(y) dy$$

is continuous.

An example of a single-period cost with linear growth is  $c(I, q) = cq + hI^+ + sE[(D - I - q)^+]$ , which is common in the inventory literature [7]. The cost parameters  $c$ ,  $h$ , and  $s$  can be interpreted as the unit ordering cost, the unit holding cost for each unit of inventory carried to this period from the previous period, and the penalty cost for each backordered unit. Since  $c(I, q) = cq + hI^+ + sE[(D - I - q)^+] \leq cq + hI^+ + sE[(D - I)^+] \leq cq + hI^+ + sE(D) + sI^- = c_0 + cq + hI^+ + sI^-$ , it holds that  $c(I, q)$  is of linear growth in  $I$  for a fixed  $q$ .

The total cost function can be written as

$$(16) \quad \begin{aligned} J(\zeta, \pi, \tilde{q}) &= \sum_{t=1}^{\infty} \alpha^{t-1} E[E[c(I_t, q_t) | \mathcal{Z}_t]] \\ &= \sum_{t=1}^{\infty} \alpha^{t-1} E\{\mathbb{I}_{z_t > 0} c(-z_t, q_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, q_t), \pi_t \rangle\}, \end{aligned}$$

where  $\pi_t$  is the solution of (6) and  $z_1 = \zeta \in \mathbb{R}^+$  is the initial condition. When  $\zeta = 0$ , the inventory level at the beginning of the first period is nonnegative and the given density function is  $\pi_1 = \pi$ . When  $\zeta > 0$ , it is the observed backordered quantity at the beginning of period one.

The value function is defined as

$$(17) \quad V(\zeta, \pi) := \inf_{\tilde{q} \in \Gamma} J(\zeta, \pi, \tilde{q}).$$

By looking one period ahead from period one, the value function can be written as

$$(18) \quad V(\zeta, \pi) = \inf_q \left\{ \mathbb{I}_{\zeta > 0} c(-\zeta, q) + \mathbb{I}_{\zeta = 0} \int_0^\infty c(y, q) \pi(y) dy + \alpha E[V(z_2, \pi_2) | \zeta, \pi] \right\},$$

which is the inventory-related cost in period one plus the cost-to-go.

By (1) and (2), we can express

$$z_2 = (I_1 + q - D_1)^- = \mathbb{I}_{\zeta > 0} (-\zeta + q - D_1)^- + \mathbb{I}_{\zeta = 0} (I_1 + q - D_1)^-.$$

Then, the cost-to-go can be written as

$$(19) \quad \begin{aligned} \mathbb{E}[V(z_2, \pi_2)|\zeta, \pi] &= \mathbb{I}_{\zeta>0} \mathbb{E}[V((- \zeta + q - D)^-, \theta_0(q - \zeta))] \\ &\quad + \mathbb{I}_{\zeta=0} \mathbb{E}[V((I_1 + q - D)^-, \theta(q, \pi))]. \end{aligned}$$

By conditioning on the event  $[q - \zeta < D]$ , we can express the first term on the right-hand side of (19) as

$$(20) \quad \begin{aligned} \mathbb{E}[V((- \zeta + q - D)^-, \theta_0(q - \zeta))] &= V(0, \theta_0(q - \zeta))F(q - \zeta) \\ &\quad + \int_{q-\zeta}^{\infty} V(\eta + \zeta - q, \theta_0(q - \zeta))f(\eta)d\eta. \end{aligned}$$

For a fixed  $I_1$ , we obtain

$$(21) \quad \begin{aligned} \mathbb{E}[V((I_1 + q - D)^-, \theta(q, \pi))|I_1] &= V(0, \theta(q, \pi))F(I_1 + q) \\ &\quad + \int_{q+I_1}^{\infty} V(\eta - I_1 - q, \theta(q, \pi))f(\eta)d\eta. \end{aligned}$$

Using (21), we can express the second term on the right-hand side of (19) explicitly as

$$\begin{aligned} &\mathbb{I}_{\zeta=0} \mathbb{E}[V((I_1 + q - D)^-, \theta(q, \pi))] \\ &= \mathbb{I}_{\zeta=0} V(0, \theta(q, \pi)) \int_0^{\infty} F(y + q)\pi(y)dy \\ &\quad + \mathbb{I}_{\zeta=0} \int_0^{\infty} \pi(y) \left[ \int_{q+y}^{\infty} V(\eta - y - q, \theta(q, \pi))f(\eta)d\eta \right] dy \\ &= \mathbb{I}_{\zeta=0} V(0, \theta(q, \pi)) \int_0^{\infty} F(y + q)\pi(y)dy \\ &\quad + \mathbb{I}_{\zeta=0} \int_0^{\infty} \pi(y) \int_0^{\infty} V(\eta, \theta(q, \pi))f(q + y + \eta)d\eta dy. \end{aligned}$$

From (20) and the above equation, we obtain

$$\begin{aligned} &\mathbb{E}[V(z_2, \pi_2)|\zeta, \pi] \\ &= \mathbb{I}_{\zeta>0} \left\{ V(0, \theta_0(q - \zeta))F(q - \zeta) + \int_0^{\infty} V(\eta, \theta_0(q - \zeta))f(\eta + q - \zeta)d\eta \right\} \\ &\quad + \mathbb{I}_{\zeta=0} V(0, \theta(q, \pi)) \int_0^{\infty} F(y + q)\pi(y)dy \\ &\quad + \mathbb{I}_{\zeta=0} \int_0^{\infty} \pi(y) \int_0^{\infty} V(\eta, \theta(q, \pi))f(q + y + \eta)d\eta dy. \end{aligned}$$

From the above expression, we can see that, when  $\zeta > 0$ , we have

$$\begin{aligned} V(\zeta, \pi) &= \inf_q \left\{ c(-\zeta, q) + \alpha V(0, \theta_0(q - \zeta))F(q - \zeta) \right. \\ &\quad \left. + \alpha \int_0^{\infty} V(\eta, \theta_0(q - \zeta))f(\eta + q - \zeta)d\eta \right\}. \end{aligned}$$

Since  $V(\zeta, \pi)$  is independent of  $\pi$  when  $\zeta > 0$ , we can let  $v(\zeta) := V(\zeta, \pi)$ .

On the other hand, when  $\zeta = 0$ ,

$$\begin{aligned} V(0, \pi) = \inf_q \bigg\{ & \int_0^\infty c(y, q) \pi(y) dy \\ & + \alpha V(0, \theta(q, \pi)) \int_0^\infty F(y + q) \pi(y) dy \\ & + \alpha \int_0^\infty \pi(y) \int_0^\infty V(\eta, \theta(q, \pi)) f(q + y + \eta) d\eta dy \bigg\}. \end{aligned}$$

If we denote  $W(\pi) := V(0, \pi)$ , then together with  $v(\zeta)$  we have the system

$$\begin{aligned} v(\zeta) = \inf_q \bigg\{ & c(-\zeta, q) + \alpha W(\theta_0(q - \zeta)) F(q - \zeta) \\ & + \alpha \int_0^\infty v(\eta) f(\eta + q - \zeta) d\eta \bigg\} \quad \text{for } \zeta > 0, \end{aligned} \quad (22)$$

$$\begin{aligned} W(\pi) = \inf_q \bigg\{ & \int_0^\infty c(y, q) \pi(y) dy \\ & + \alpha W(\theta(q, \pi)) \int_0^\infty F(y + q) \pi(y) dy \\ & + \alpha \int_0^\infty \pi(y) \int_0^\infty v(\eta) f(q + y + \eta) d\eta dy \bigg\}. \end{aligned} \quad (23)$$

Observe that

$$V(\zeta, \pi) = \mathbb{I}_{\zeta > 0} v(\zeta) + \mathbb{I}_{\zeta = 0} W(\pi), \quad (\zeta, \pi) \in \mathbb{R}^+ \times \Pi. \quad (24)$$

Since  $\pi$  evolves according to the nonlinear operator  $\theta$ , a direct study of the system (22)–(23) is not easy. If we can use  $p \in \mathcal{H}^+$  as the system state instead of  $\pi$ , then the analysis becomes much easier, because  $p$  evolves with the linear operator  $\varrho$ . To make ideas concrete, we define a new value function  $Y(\cdot)$  as follows:

$$Y(p) := W\left(\frac{p}{\lambda}\right) \lambda, \quad \lambda := \int_0^\infty p(x) dx. \quad (25)$$

Then, from (23) we have

$$\begin{aligned}
 Y(p) &= \lambda \inf_q \left\{ \int_0^\infty c(y, q)(p(y)/\lambda) dy \right. \\
 &\quad + \alpha W(\theta(q, p/\lambda)) \int_0^\infty F(y + q)(p(y)/\lambda) dy \\
 &\quad \left. + \alpha \int_0^\infty p(y)/\lambda \int_0^\infty v(\eta) f(q + y + \eta) d\eta dy \right\} \\
 &= \inf_q \left\{ \int_0^\infty c(y, q)p(y) dy + \alpha \left[ W(\theta(q, p)) \int_0^\infty F(y + q)p(y) dy \right. \right. \\
 &\quad \left. \left. + \int_0^\infty p(y) \int_0^\infty v(\eta) f(q + y + \eta) d\eta dy \right] \right\}.
 \end{aligned}$$

The above equation follows from the fact that the operator  $\theta$  is homogenous of degree 0. Next, we simplify the term  $W(\theta(q, \pi))$  and  $W(\theta_0(q - \zeta))$  on the right-hand side of the above equation and of (22), respectively. From the definition of  $\theta$  and (11), we get

$$\begin{aligned}
 Y(\varrho(q)p) &= \left\{ \int_0^\infty \varrho(q)p(x) dx \right\} \left\{ W \left( \frac{\varrho(q)p}{\langle \varrho(q)p, 1 \rangle} \right) \right\} \\
 &\stackrel{(11)}{=} \left\{ \int_0^\infty F(y + q)p(y) dy \right\} \{ W(\theta(q, p)) \}.
 \end{aligned}$$

By the definition of  $\theta_0$ , we get

$$Y(\varrho_0(q - \zeta)) = W \left( \frac{\varrho_0(q - \zeta)}{F(q - \zeta)} \right) F(q - \zeta) = W(\theta_0(q - \zeta)) F(q - \zeta).$$

Using these results in the expression of  $Y(p)$ , we obtain the following new system of equations:

$$(26) \quad v(\zeta) = \inf_q \left\{ c(-\zeta, q) + \alpha \int_0^\infty v(\eta) f(\eta + q - \zeta) d\eta + \alpha Y(\varrho_0(q - \zeta)) \right\}, \quad \zeta \in \mathfrak{R}^+,$$

$$\begin{aligned}
 Y(p) &= \inf_q \left\{ \int_0^\infty c(y, q)p(y) dy + \alpha Y(\varrho(q)p) \right. \\
 (27) \quad &\quad \left. + \alpha \int_0^\infty p(y) \int_0^\infty v(\eta) f(y + q + \eta) d\eta dy \right\}, \quad p \in \mathcal{H}^+.
 \end{aligned}$$

As in (24), observe that the corresponding unnormalized value function  $Z : \mathfrak{R}^+ \times \mathcal{H}^+ \rightarrow \mathfrak{R}$  takes the form

$$(28) \quad Z(\zeta, p) = \mathbb{I}_{\zeta > 0} v(\zeta) + \mathbb{I}_{\zeta = 0} Y(p), \quad (\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+.$$

Moreover,

$$(29) \quad Y(\mu p) = \mu Y(p) \quad \text{for every } \mu > 0.$$

Thus,  $Y(0) = 0$ .

Compared with the value functions in BCS, the left-hand side of (26) is an unknown number  $v$ , but in the present paper it is a function  $v(\cdot)$ . This makes the analysis of the system more difficult. In what follows, we will show the details of the methodology we use to prove the existence of an optimal control. Important costs and spaces are summarized in Table 1. Sequences of cost functions and some of the spaces will be formally defined soon. In this paper, we interpret decreasing and increasing sequences in a nonstrict way.

TABLE 1

Decreasing value iteration sequence	$\{V^n\}$	$\tilde{\mathcal{G}}$	$\{Z^n\}$	$\mathcal{G}$

**4. Main results.** When the cost functions are bounded, we can apply commonplace arguments of the standard theory (see, e.g., [6]) to obtain a contraction property for an appropriate operator. Then by using Banach's fixed point theorem, we prove directly the existence and uniqueness of the solution to the optimality equation as well as the value iteration algorithm. However, consideration of the unbounded one-period costs as in (14) brings some challenges. For instance, the nice contraction property does not work for the discounted cost criterion, and so we need to consider ceiling functions for the optimal cost. These functions, in turn, will define the appropriate functional space where the solution to the system (22)–(23) is unique and is the value function. Moreover, besides the result of existence of the optimal ordering policy, ceiling functions allow us to prove that the value iteration algorithm converges to the value function.

Before proving our main results, we give some preliminaries.

**4.1. Preliminaries.** We define the functional space

$$\mathcal{B} := \left\{ \phi(p) : \mathcal{H} \rightarrow \mathbb{R} : \sup_{p \in \mathcal{H}} \frac{|\phi(p)|}{\|p\|} < \infty \right\}$$

with the norm

$$\|\phi\|_{\mathcal{B}} := \sup_{p \in \mathcal{H}} \frac{|\phi(p)|}{\|p\|}.$$

From the definition, we can see that  $\mathcal{B}$  is a Banach space. For any  $\phi \in \mathcal{B}$ , we must have  $\phi(0) = 0$ .

We define the space

$$\mathcal{B}^+ := \left\{ \phi : \mathcal{H}^+ \rightarrow \mathfrak{R}^+ : \sup_{p \in \mathcal{H}^+} \frac{\phi(p)}{\|p\|} < \infty \right\} \subseteq \mathcal{B}$$

and denote by  $\mathcal{B}^\Pi$  the subset of  $\mathcal{B}^+$  restricted to  $\Pi$ . That is,

$$\mathcal{B}^\Pi := \left\{ \phi : \Pi \rightarrow \mathfrak{R}^+ : \sup_{\pi \in \Pi} \frac{\phi(\pi)}{\|\pi\|} < \infty \right\}.$$

Similar to  $\mathbb{L}^+$ ,  $\mathcal{B}^+$  is also used to accommodate the dynamic programming cost.

We consider  $v^0 \in \mathbb{L}^+$  and  $Y^0 \in \mathcal{B}^+$  defined as

$$(30) \quad v^0(\zeta) := \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s\zeta}{1-\alpha}, \quad \zeta \in \mathfrak{R}^+.$$

$$(31) \quad Y^0(p) := \frac{a_0}{1-\alpha} \|p\|, \quad p \in \mathcal{H}^+,$$

where

$$a_0 = \max \left\{ h, \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + sE(D)}{1-\alpha} \right\}.$$

For any  $\phi_1 \in \mathbb{L}^+$  and  $\phi_2 \in \mathcal{B}^+$  such that  $\phi_1(\cdot) \leq v^0(\cdot)$  and  $\phi_2(\cdot) \leq Y^0(\cdot)$ , we define the set

$$\mathcal{G} = \left\{ \phi : \mathfrak{R}^+ \times \mathcal{H}^+ \rightarrow \mathfrak{R} \mid \phi(\zeta, p) = \mathbb{I}_{\zeta > 0} \phi_1(\zeta) + \mathbb{I}_{\zeta = 0} \phi_2(p) \right.$$

$$\left. \text{and } \phi(\zeta, p) \leq \mathbb{I}_{\zeta > 0} v^0(\zeta) + \mathbb{I}_{\zeta = 0} Y^0(p) \right\}.$$

Thus the domain of the members of the set  $\mathcal{G}$  is  $\mathcal{H}^+ \times \mathfrak{R}^+$ , where  $\mathcal{H}^+$  is the space of unnormalized probabilities. If  $\phi_1(\zeta)$  and  $\phi_2(p)$  are solutions of the system (26)–(27), then they correspond to  $v(\zeta)$  and  $Y(p)$ , respectively. As a result,  $\phi(\zeta, p)$  corresponds to  $Z(\zeta, p)$ . The counterpart of the normalized probabilities  $\Pi \times \mathfrak{R}^+$  is denoted by  $\tilde{\mathcal{G}}$  and defined for functions  $\tilde{\phi}_1 \in \mathbb{L}^+$  and  $\tilde{\phi}_2 \in \mathcal{B}^\Pi$  such that  $\tilde{\phi}_1(\cdot) \leq v^0(\cdot)$  and  $\tilde{\phi}_2(\cdot) \leq Y^0(\cdot)$ :

$$\tilde{\mathcal{G}} = \left\{ \tilde{\phi} : \mathfrak{R}^+ \times \Pi \rightarrow \mathfrak{R} \mid \tilde{\phi}(\zeta, \pi) = \mathbb{I}_{\zeta > 0} \tilde{\phi}_1(\zeta) + \mathbb{I}_{\zeta = 0} \tilde{\phi}_2(\pi) \right.$$

$$\left. \text{and } \tilde{\phi}(\zeta, \pi) \leq \mathbb{I}_{\zeta > 0} v^0(\zeta) + \mathbb{I}_{\zeta = 0} Y^0(\pi) \right\}.$$

If  $\tilde{\phi}_1$  and  $\tilde{\phi}_2$  are solutions of the system (22)–(23), then  $\tilde{\phi}_1$  corresponds to  $v(\zeta)$  and  $\tilde{\phi}_2$  corresponds to  $W(\pi)$ . As a result  $\tilde{\phi}(\zeta, \pi) = V(\zeta, \pi)$ . In the next subsection, we will show that the value functions  $Z$  and  $V$  are in the sets  $\mathcal{G}$  and  $\tilde{\mathcal{G}}$ , respectively.

For  $\phi \in \mathcal{G}$ , we define the operators

$$T_q^{(1)}(\phi_1, \phi_2) = c(-\zeta, q) + \alpha \int_0^\infty \phi_1(\eta) f(\eta + q - \zeta) d\eta + \alpha \phi_2(\varrho_0(q - \zeta)),$$

$$\begin{aligned} T_q^{(2)}(\phi_1, \phi_2) &= \int_0^\infty c(y, q) p(y) dy \\ &\quad + \alpha \int_0^\infty p(y) \int_0^\infty \phi_1(\eta) f(y + q + \eta) d\eta dy + \alpha \phi_2(\varrho(q)p). \end{aligned}$$

We can see that if  $\phi_1$  and  $\phi_2$  are solutions of (26)–(27), then  $T_q^{(1)}(\phi_1, \phi_2)$  and  $T_q^{(2)}(\phi_1, \phi_2)$  represent the cost when the ordering quantity is  $q$  and when there are backorders and no backorders, respectively. By combining these two cases, we define the operator  $T_q$  as follows:

$$T_q\phi(\zeta, p) := \mathbb{I}_{\zeta>0}T_q^{(1)}(\phi_1, \phi_2) + \mathbb{I}_{\zeta=0}T_q^{(2)}(\phi_1, \phi_2).$$

Let

$$(32) \quad \begin{aligned} T^{(1)}(\phi_1, \phi_2) &:= \inf_{q \geq 0} T_q^{(1)}(\phi_1, \phi_2), \\ T^{(2)}(\phi_1, \phi_2) &:= \inf_{q \geq 0} T_q^{(2)}(\phi_1, \phi_2), \\ T\phi(\zeta, p) &:= \inf_{q \geq 0} T_q\phi(\zeta, p). \end{aligned}$$

The operators  $T^1$ ,  $T^2$ , and  $T$  represent the corresponding optimal costs. After defining the above operators, we have the following lemma.

LEMMA 4. *When  $\zeta \geq 0$ , for any  $\tilde{q} \in \Gamma$ ,  $J(\zeta, \pi, \tilde{q}) \leq v^0(\zeta)$ . Moreover, the operator  $T$  maps  $\mathcal{G}$  into itself, and, for  $\phi_1 \leq v^0$  and  $\phi_2 \leq Y^0$ ,  $T^{(1)}(\phi_1, \phi_2) \leq v^0(\zeta)$  and  $T^{(2)}(\phi_1, \phi_2) \leq Y^0(p)$ .*

From this lemma, we can see that  $v^0$  and  $Y^0$  are ceiling functions for the optimal cost. The solution  $(v, Y)$  of the system (26)–(27) satisfies  $v \leq v^0$  and  $Y \leq Y^0$ .

**4.2. Existence of a solution of the Bellman equation and an optimal feedback policy.** We define a value iteration procedure as follows. Let  $\{v_n\}$  and  $\{Y_n\}$  be sequences of functions defined by  $v_1 = Y_1 = 0$ , and, for  $n \geq 1$ ,

$$(33) \quad v_{n+1} = T^{(1)}(v_n, Y_n), \quad Y_{n+1} = T^{(2)}(v_n, Y_n).$$

From the definitions of operators  $T^{(1)}$  and  $T^{(2)}$ ,  $\{v_n\}$  and  $\{Y_n\}$  are increasing sequences. This can be established by induction. Clearly,  $v_1 \leq v_2$  and  $Y_1 \leq Y_2$ . Let us assume that  $v_n \leq v_{n+1}$  and  $Y_n \leq Y_{n+1}$ . Then,

$$\begin{aligned} v_{n+1}(\zeta) &= T^{(1)}(v_n, Y_n) \\ &= \inf_{q \geq 0} \left\{ c(-\zeta, q) + \alpha \int_0^\infty v_n(\eta) f(\eta + q - \zeta) d\eta + \alpha Y_n(\varrho_0(q - \zeta)) \right\} \\ &\leq \inf_{q \geq 0} \left\{ c(-\zeta, q) + \alpha \int_0^\infty v_{n+1}(\eta) f(\eta + q - \zeta) d\eta + \alpha Y_{n+1}(\varrho_0(q - \zeta)) \right\} \\ &= T^{(1)}(v_{n+1}, Y_{n+1}) = v_{n+2}(\zeta), \end{aligned}$$

and similarly we prove that  $Y_{n+1}(p) \leq Y_{n+2}(p)$ .

Let

$$(34) \quad Z_n(\zeta, p) := \mathbb{I}_{\zeta>0}v_n(\zeta) + \mathbb{I}_{\zeta=0}Y_n(p), \quad (\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+.$$

Observe that

$$(35) \quad Z_{n+1}(\zeta, p) = \mathbb{I}_{\zeta>0}T^{(1)}(v_n(\zeta), Y_n(p)) + \mathbb{I}_{\zeta=0}T^{(2)}(v_n(\zeta), Y_n(p)) = TZ_n(\zeta, p).$$

Then we have the following theorem.

THEOREM 2. (a) *There exist lower semicontinuous (l.s.c.) functions  $\bar{Y} \leq Y^0$  and  $\bar{v} \leq v^0$  such that  $Z_n \nearrow \bar{Z}$  and  $\bar{Z} = T\bar{Z}$ , where*

$$\bar{Z}(\zeta, p) := \mathbb{I}_{\zeta > 0} \bar{v}(\zeta) + \mathbb{I}_{\zeta = 0} \bar{Y}(p), \quad (\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+.$$

(b) *For each  $(\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+$ , there exists a measurable function  $g_{\bar{Z}} : \mathbb{R}^+ \times \mathcal{H}^+ \rightarrow \mathbb{R}^+$  such that  $T\bar{Z}(\zeta, p) = T_{g_{\bar{Z}}(\zeta, p)} \bar{Z}(\zeta, p)$ .*

From this theorem we can see that  $\bar{v} \in \mathcal{H}^+$  and  $\bar{Y} \in \mathcal{B}^+$ . So far we have analyzed the unnormalized system (26)–(27). We show that there exists a solution of this system. Next, we will show that there is a solution of system (22)–(23). This result immediately follows from Theorem 2. Let  $\{(W_n, v_n)\}$  be the normalized value iteration functions corresponding to  $\{(Y_n, v_n)\}$ . That is,  $W_n$  is a function on  $\Pi$  satisfying (see (25))

$$(36) \quad Y_n(p) = W_n \left( \frac{p}{\int p(x) dx} \right) \int_0^\infty p(x) dx.$$

Let  $V_n(\zeta, \pi) := \mathbb{I}_{\zeta > 0} v_n(\zeta) + \mathbb{I}_{\zeta = 0} W_n(\pi)$ ,  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ . Then, as  $v_1 = W_1 = 0$ , we have  $V_1 = 0$ . Moreover,

$$V_{n+1}(\zeta, \pi) = \tilde{T}V_n(\zeta, \pi) := \inf_{q \geq 0} \tilde{T}_q V_n(\zeta, \pi), \quad (\zeta, \pi) \in \mathbb{R}^+ \times \Pi,$$

where, for a function  $\tilde{\phi} \in \tilde{\mathcal{G}}$ ,

$$\tilde{T}_q \tilde{\phi}(\zeta, \pi) := \mathbb{I}_{\zeta > 0} \tilde{T}_q^{(1)}(\tilde{\phi}_1(\zeta), \tilde{\phi}_2(\pi)) + \mathbb{I}_{\zeta = 0} \tilde{T}_q^{(2)}(\tilde{\phi}_1(\zeta), \tilde{\phi}_2(\pi))$$

and

$$\begin{aligned} \tilde{T}_q^{(1)}(\tilde{\phi}_1, \tilde{\phi}_2) &= c(-\zeta, q) + \alpha \tilde{\phi}_2(\theta_0(q - \zeta)) F(q - \zeta) + \alpha \int_0^\infty \tilde{\phi}_1(\eta) f(\eta + q - \zeta) d\eta, \\ \tilde{T}_q^{(2)}(\tilde{\phi}_1, \tilde{\phi}_2) &= \int_0^\infty c(y, q) \pi(y) dy + \alpha \left[ \tilde{\phi}_2(\theta(q, \pi)) \int_0^\infty F(y + q) \pi(y) dy \right. \\ &\quad \left. + \int_0^\infty \pi(y) \int_0^\infty \tilde{\phi}_1(\eta) f(q + y + \eta) d\eta dy \right]. \end{aligned}$$

The above two equations correspond to (22) and (23), which yield the value functions for the normalized probabilities.

We know that  $Y_n(\pi) = W_n(\pi)$  for all  $\pi \in \Pi$  from (36). From (29), Theorem 2(a) yields the existence of an l.s.c. function  $\bar{W}(\pi) \leq Y^0(\pi)$  such that  $W_n \nearrow \bar{W}$ . After defining  $\bar{V}(\zeta, \pi) := \mathbb{I}_{\zeta > 0} \bar{v}(\zeta) + \mathbb{I}_{\zeta = 0} \bar{W}(\pi)$ ,  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ , we have

$$(37) \quad V_n \nearrow \bar{V} \quad \text{as } n \rightarrow \infty,$$

and  $\bar{V}(\zeta, \pi) = \tilde{T}\bar{V}(\zeta, \pi)$  for  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ . Hence, similarly to (18), for each  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ ,

$$(38) \quad \bar{V}(\zeta, \pi) = \inf_q \left\{ \mathbb{I}_{\zeta > 0} c(-\zeta, q) + \mathbb{I}_{\zeta = 0} \int_0^\infty c(y, q) \pi(y) dy + \alpha E[\bar{V}(z_2, \pi_2) | \zeta, \pi] \right\}.$$

Furthermore, from Theorem 2(b), there exists a map  $\bar{g} : \mathbb{R}^+ \times \Pi \rightarrow \mathbb{R}^+$  such that

$$(39) \quad \bar{V}(\zeta, \pi) = \tilde{T}\bar{V}(\zeta, \pi) = \tilde{T}_{\bar{g}(\zeta, \pi)} \bar{V}(\zeta, \pi), \quad (\zeta, \pi) \in \mathbb{R}^+ \times \Pi.$$

So we can see that there is a solution of the system (22)–(23). In the next theorem, we establish that this solution is actually the value function.

**THEOREM 3.** (a) *For each  $(\zeta, \pi) \in \mathfrak{R}^+ \times \Pi$ , we have  $\bar{V}(\zeta, \pi) = V(\zeta, \pi)$ , where  $V$  is the optimal value function defined in (17). Hence,  $\bar{Z}(\zeta, p) = Z(\zeta, p)$  for each  $(\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ .*

(b) *The functions  $\bar{V}$  and  $\bar{Z}$  are the minimal solutions in  $\tilde{\mathcal{G}}$  and  $\mathcal{G}$  of the optimality equations (24) and (28), respectively.*

(c) *There exists an optimal feedback policy  $\tilde{q}^* \in \Gamma$  for the partially observed inventory problem. That is,*

$$V(\zeta, \pi) := \inf_{\tilde{q} \in \Gamma} J(\zeta, \pi, \tilde{q}) = J(\zeta, \pi, \tilde{q}^*) \quad \forall (\zeta, \pi) \in \mathfrak{R}^+ \times \Pi.$$

In this subsection, we have shown that, starting from  $v^0$  and  $Y^0$ , sequences  $\{v_n\}$  and  $\{Y_n\}$  are increasing and converge to  $\bar{v}$  and  $\bar{Y}$ , respectively, and that the pair  $(\bar{v}, \bar{Y})$  is a solution of the system (26)–(27). Since  $Y_n(\pi) = W_n(\pi)$ , sequences  $v_n$  and  $W_n$  converge to  $\bar{v}$  and  $\bar{W}$ , respectively. As a result the pair  $(\bar{v}, \bar{W})$  is a solution of (22)–(23). Theorem 3 states that  $\bar{V}(\zeta, \pi)$  is the value function defined in (17). In the next subsection, we will show that the solution of the system (26)–(27) is unique. As a result, the solution of the system (22)–(23) is also unique.

#### 4.3. Uniqueness and continuity of the solution of the Bellman equation.

We consider the unnormalized value iteration procedure (33)–(35), but starting with the functions  $v^0$  and  $Y^0$ . That is, for  $(\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ ,

$$(40) \quad \begin{aligned} v^1(\zeta) &= v^0(\zeta), & Y^1(p) &= Y^0(p), \\ v^{n+1}(\zeta) &= T^{(1)}(v^n(\zeta), Y^n(p)), & Y^{n+1}(p) &= T^{(2)}(v^n(\zeta), Y^n(p)). \end{aligned}$$

Using induction arguments, it is easy to see that  $\{v^n\}$  and  $\{Y^n\}$  are nonnegative decreasing sequences. From the previous subsection we have  $v^2 \leq v^1$  and  $Y^2 \leq Y^1$ . To establish the decreasing property for  $n \geq 1$ , we assume that it holds for  $n = k$ , that is,  $v^k \leq v^{k-1}$  and  $Y^k \leq Y^{k-1}$ , and then establish it for  $n = k+1$ . It follows that

$$\begin{aligned} v^{k+1}(\zeta) &= T^{(1)}(v^k, Y^k) \\ &= \inf_{q \geq 0} \left\{ c(-\zeta, q) + \alpha \int_0^\infty v^k(\eta) f(\eta + q - \zeta) d\eta + \alpha Y^k(\varrho_0(q - \zeta)) \right\} \\ &\leq \inf_{q \geq 0} \left\{ c(-\zeta, q) + \alpha \int_0^\infty v^{k-1}(\eta) f(\eta + q - \zeta) d\eta + \alpha Y^{k-1}(\varrho_0(q - \zeta)) \right\} \\ &= T^{(1)}(v^{k-1}, Y^{k-1}) = v^k(\zeta), \end{aligned}$$

and similarly we prove that  $Y^{k+1}(p) \leq Y^k(p)$ .

Since  $\{v^n\}$  and  $\{Y^n\}$  are nonnegative decreasing sequences and both have lower bounds 0, there exist functions  $\underline{v} \leq v^0$  and  $\underline{Y} \leq Y^0$  such that

$$(41) \quad v^n \searrow \underline{v} \quad \text{and} \quad Y^n \searrow \underline{Y} \quad \text{as} \quad n \rightarrow \infty.$$

In other words, if we denote

$$\begin{aligned} Z^n(\zeta, p) &= \mathbb{I}_{\zeta > 0} v^n(\zeta) + \mathbb{I}_{\zeta = 0} Y^n(p), \\ \underline{Z}(\zeta, p) &= \mathbb{I}_{\zeta > 0} \underline{v}(\zeta) + \mathbb{I}_{\zeta = 0} \underline{Y}(p), \quad (\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+, \end{aligned}$$

we have

$$(42) \quad Z^{n+1} = TZ^n \text{ and } \underline{Z} \in \mathcal{G}, \quad Z^n \searrow \underline{Z}, \quad \text{as } n \rightarrow \infty.$$

Since  $Z^n$  is a decreasing sequence, we have  $Z^n \geq \underline{Z}$  for a finite  $n$ . Applying  $T$  infinitely many times on both sides, we obtain

$$(43) \quad \underline{Z} \geq T\underline{Z}.$$

Moreover, by applying the monotone convergence theorem together with (40) and (41), we can prove that for all  $q \in \mathbb{R}^+$ ,  $\underline{v}(\zeta) \leq T_q^{(1)}(\underline{v}(\zeta), \underline{Y}(p))$  and  $\underline{Y}(p) \leq T_q^{(2)}(\underline{v}(\zeta), \underline{Y}(p))$ , which implies  $\underline{Z}(\zeta, p) \leq T\underline{Z}(\zeta, p)$ . This inequality combined with (43) yields

$$(44) \quad \underline{Z}(\zeta, p) = T\underline{Z}(\zeta, p).$$

Now, because  $Z \in \mathcal{G}$  (see (28) and Theorem 3(b)), we have  $v(\zeta) \leq v^0(\zeta)$  and  $Y(p) \leq Y^0(p)$ . Then, as  $Z(\zeta, p)$  is a fixed point of the operator  $T$ , we obtain  $Z(\zeta, p) \leq Z^n(\zeta, p)$  for all  $n$ , which implies from (42) that

$$(45) \quad Z(\zeta, p) \leq \underline{Z}(\zeta, p) \quad \forall (\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+.$$

On the other hand, let  $W^n : \Pi \rightarrow \mathbb{R}$  be the corresponding normalized value iteration function defined in the same way as (36), and define  $V^n(\zeta, \pi) = \mathbb{I}_{\zeta > 0} v^n(\zeta) + \mathbb{I}_{\zeta = 0} W^n(\pi)$ . Observe that  $V^{n+1} = \tilde{T}V^n$ . Then, there exists a function  $\underline{V} \in \tilde{\mathcal{G}}$  such that  $V^n \searrow \underline{V}$ . Furthermore, from (44) and (45), we can prove that, for each  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ ,

$$(46) \quad \underline{V}(\zeta, \pi) = \tilde{T}\underline{V}(\zeta, \pi)$$

and

$$(47) \quad V(\zeta, \pi) \leq \underline{V}(\zeta, \pi).$$

**THEOREM 4.** Suppose  $\alpha(1 + \frac{a_0}{c(1-\alpha)}) < 1$ . Then we have the following.

(a) For each  $(\zeta, \pi) \in \mathbb{R}^+ \times \Pi$ ,  $V(\zeta, \pi) = \underline{V}(\zeta, \pi)$ . Moreover,  $\underline{V}$  is the maximal solution in  $\tilde{\mathcal{G}}$  of the optimality equation (24). Hence,  $Z(\zeta, p) = \underline{Z}(\zeta, p)$  for each  $(\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+$ , and  $\underline{Z}$  is the maximal solution of (28) in  $\mathcal{G}$ . Moreover, the solutions of (24) and (28) are unique.

(b) The value functions  $V$  and  $Z$  are continuous on  $\mathbb{R}^+ \times \Pi$  and  $\mathbb{R}^+ \times \mathcal{H}^+$ , respectively.

**4.4. Conclusions.** We have studied an infinite-horizon single-stage periodic-review inventory control system with backorders. In this system, the inventory level is partially observed when it is nonnegative. Partial inventory observations eventually lead to a dynamic program in the space of probability distributions. This dynamic program is highly nonlinear. We apply the methodology of unnormalized probability to linearize the dynamic programming equations. This linearization facilitates the analysis.

As we discussed in the introduction, partial observations in inventory systems are very common. But there is not much research done on this topic. This motivated us to analyze this problem with rain checks. In Theorems 2 and 3, we prove the convergence of a value iteration algorithm to the optimal value function, as well as

the existence of an optimal feedback ordering policy. In addition, the value function is the minimal solution of the optimality equation. Furthermore, from Theorem 4, for a sufficiently small discount factor, the solution of the optimality equation is unique and continuous, and it is the value function.

We conclude the paper by describing an extension of the model and discussing some computational aspects related to the rain check model.

Sometimes, when the customer comes to the store during a stock out, he or she does not ask for a rain check, leaves the store, and comes back later. Some stores do not have a practice of offering rain checks. In the absence of rain checks, the IM cannot fully observe the backordered quantity. This setting gives rise to an interesting model where even less information is available to IM than in the current model. That is, in this new context, the IM cannot fully observe the negative inventory, and the available information to make his or her decisions in each period would be the sign of the inventory. The authors currently are studying this extension [3].

Although the unnormalized probability simplifies the analysis, it does not lead to a dynamic program in finite dimensional spaces. Finiteness of these spaces, which accommodate the conditional distribution  $p$  of the inventory level, can be imposed to develop approximations. The challenge here is to find an appropriate finite family of functions to represent  $p$ . This is a computational issue worth exploring. We provide some numerical techniques in [5] to solve the dynamic programming equation.

## 5. Proofs.

### 5.1. Preliminary results.

LEMMA 5. *The function*

$$(48) \quad (q, p) \rightarrow \int p(y) \int \phi_1(\eta) f(q + y + \eta) d\eta dy$$

is continuous for every bounded function  $\phi_1 : \mathbb{R}^+ \rightarrow \mathbb{R}$ .

*Proof.* Let  $\phi_1$  be a bounded function and  $\{(q_n, p_n)\}$  be a sequence in  $\mathbb{R}^+ \times \mathcal{H}^+$  converging to  $(q, p) \in \mathbb{R}^+ \times \mathcal{H}^+$ . Then, by adding and subtracting the term  $\int \int \phi_1(\eta) f(q_n + y + \eta) p(y) d\eta dy$ , we have

$$\begin{aligned} & \left| \int \int \phi_1(\eta) f(q_n + y + \eta) p_n(y) d\eta dy - \int \int \phi_1(\eta) f(q + y + \eta) p(y) d\eta dy \right| \\ & \leq \int \int \phi_1(\eta) f(q_n + y + \eta) |p_n(y) - p(y)| d\eta dy \\ & \quad + \int \int \phi_1(\eta) p(y) |f(q_n + y + \eta) - f(q + y + \eta)| d\eta dy, \end{aligned}$$

which, by the dominated convergence theorem, converges to zero as  $n \rightarrow \infty$ . This proves the continuity of the function defined in (48).  $\square$

The next lemma is a key result to prove that the operators  $T_q$  and  $T$  map continuous functions into continuous functions (see Remark 1(b) and Lemma 7). Thus, in each iteration of the monotone approximations introduced in section 4, we get continuous functions when we use both increasing and decreasing processes.

LEMMA 6. *For each nonnegative measurable function  $\phi_1$  on  $\mathbb{R}^+$ , the function*

$$(49) \quad (q, p) \rightarrow \int p(y) \int \phi_1(\eta) f(q + y + \eta) d\eta dy$$

is continuous.

*Proof.* Let  $\{(q_n, p_n)\}$  be a sequence in  $\mathbb{R}^+ \times \mathcal{H}^+$  converging to  $(q, p) \in \mathbb{R}^+ \times \mathcal{H}^+$ , and let  $\phi_1$  be a measurable function on  $\mathbb{R}^+$ . Then, there exists a sequence  $\{\phi_1^k\}$  of bounded functions on  $\mathbb{R}^+$  such that  $\phi_1^k \nearrow \phi_1$ , as  $k \rightarrow \infty$ . Therefore from Lemma 5, for each  $k \in \mathbb{N}$ ,

$$\liminf_{n \rightarrow \infty} \int \int \phi_1^k(\eta) f(q_n + y + \eta) p_n(y) d\eta dy = \int \int \phi_1^k(\eta) f(q + y + \eta) p(y) d\eta dy.$$

Thus,

$$\begin{aligned} \liminf_{n \rightarrow \infty} \int \int \phi_1(\eta) f(q_n + y + \eta) p_n(y) d\eta dy \\ \geq \liminf_{n \rightarrow \infty} \int \int \phi_1^k(\eta) f(q_n + y + \eta) p_n(y) d\eta dy \\ = \int \int \phi_1^k(\eta) f(q + y + \eta) p(y) d\eta dy. \end{aligned}$$

Letting  $k \rightarrow \infty$  and using Fatou's lemma, we obtain

$$\liminf_{n \rightarrow \infty} \int \int \phi_1(\eta) f(q_n + y + \eta) p_n(y) d\eta dy \geq \int \int \phi_1(\eta) f(q + y + \eta) p(y) d\eta dy.$$

That is, the function (49) is l.s.c. Now, applying the same arguments to the function  $-\phi_1$ , we have that  $-\int \int \phi_1(\eta) f(q + y + \eta) p(y) d\eta dy$  is l.s.c. in  $(q, p)$ . Hence, the function (49) is upper semicontinuous (u.s.c.), which yields the desired result.  $\square$

*Remark 1.* (a) Applying arguments similar to those in the proofs of Lemmas 5 and 6, we can show the continuity of the functions

$$(x, q, p) \rightarrow \int f(y + q - x) p(y) dy, \quad (x, q, p) \in \mathbb{R}^+ \times \mathbb{R}^+ \times \mathcal{H}^+,$$

and

$$(x, q) \rightarrow \int \phi_1(\eta) f(q - x + \eta) d\eta, \quad (x, q) \in \mathbb{R}^+ \times \mathbb{R}^+,$$

for each measurable function  $\phi_1$  on  $\mathbb{R}^+$ .

(b) Let  $\phi \in \mathcal{G}$  be a continuous function on  $\mathbb{R}^+ \times \mathcal{H}^+$ . That is,  $\phi$  is a function of the form  $\phi(\zeta, p) = \mathbb{I}_{\zeta > 0} \phi_1(\zeta) + \mathbb{I}_{\zeta = 0} \phi_2(p)$ , where  $\phi_1$  and  $\phi_2$  are continuous functions on  $\mathbb{R}^+$  and  $\mathcal{H}^+$ , respectively. Then, in view of (15), Lemmas 5 and 6, and Remark 1(a), we have that  $T_q \phi(\zeta, p)$  is continuous in  $(\zeta, q, p) \in \mathbb{R}^+ \times \mathbb{R}^+ \times \mathcal{H}^+$ .

*Remark 2.* (a) Observe that by defining the operator  $T$  for each  $\phi \in \mathcal{G}$ , we can obtain bounds for the range of  $q$  for which  $T_q^{(1)}(\phi_1, \phi_2) \leq v^0(\zeta)$  and  $T_q^{(2)}(\phi_1, \phi_2) \leq Y^0(p)$ ,  $(\zeta, p) \in \mathbb{R}^+ \times \mathcal{H}^+$ . Hence, if we denote by  $q_-$  and  $q_+$  the ordering quantity under the negative and nonnegative initial inventory levels, respectively, then from Lemma 4 we have

$$cq_- \leq T_q^{(1)}(\phi_1(\zeta), \phi_2(p)) \leq v^0(\zeta) = \frac{\alpha s E(D)}{(1 - \alpha)^2} + \frac{c_0 + s\zeta}{1 - \alpha}.$$

Hence,

$$(50) \quad q_- \leq \frac{\alpha s E(D)}{(1 - \alpha)^2 c} + \frac{c_0 + s\zeta}{(1 - \alpha)c}.$$

Similarly, we have

$$cq_+ \int_0^\infty p(y)dy \leq T_q^{(2)}(\phi_1(\zeta), \phi_2(p)) \leq Y^0(p) = \frac{a_0}{1-\alpha} \|p\|,$$

which implies

$$(51) \quad q_+ \leq \frac{a_0}{c(1-\alpha) \int_0^\infty p(x)dx} \|p\|.$$

Then from (50) and (51), for each  $(\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ ,  $q$  must belong to  $\mathcal{Q}^*(\zeta, p) := \mathcal{Q}_1^*(\zeta) \cup \mathcal{Q}_2^*(p)$ , where

$$\mathcal{Q}_1^*(\zeta) := \left\{ q \in \mathfrak{R}^+ : q \leq \frac{\alpha s E(D)}{(1-\alpha)^2 c} + \frac{c_0 + s\zeta}{(1-\alpha)c} \right\}$$

and

$$\mathcal{Q}_2^*(p) := \left\{ q \in \mathfrak{R}^+ : q \leq \frac{a_0}{c(1-\alpha) \int_0^\infty p(x)dx} \|p\| \right\}.$$

Thus, for a fixed  $(\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ ,  $q$  remains bounded.

(b) Taking into account the latter, since for each  $\phi \in \mathcal{G}$  the map  $(\zeta, p, q) \rightarrow T_q \phi(\zeta, p)$  is continuous, there exists a measurable function  $g_\phi: \mathfrak{R}^+ \times \mathcal{H}^+ \rightarrow \mathfrak{R}^+$  that attains the minimum in (32). That is,

$$(52) \quad T\phi(\zeta, p) = T_{g_\phi} \phi(\zeta, p) \quad \forall (\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+.$$

LEMMA 7. For each continuous function  $\phi \in \mathcal{G}$ ,  $T\phi(\zeta, p)$  is continuous in  $(\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ .

*Proof.* Let  $\{(\zeta_k, p_k)\}$  be a sequence in  $\mathfrak{R}^+ \times \mathcal{H}^+$  such that  $(\zeta_k, p_k) \rightarrow (\zeta, p) \in \mathfrak{R}^+ \times \mathcal{H}^+$ ,  $p \neq 0$ , and  $q_k = g_\phi(\zeta_k, p_k) \in \mathcal{Q}^*(\zeta_k, p_k)$  satisfies (see Remark 2(b))

$$(53) \quad T\phi(\zeta_k, p_k) = T_{q_k} \phi(\zeta_k, p_k).$$

Clearly  $q_k$  remains in a compact set. Then, we can extract a subsequence  $\{(\zeta_{k_l}, p_{k_l}, q_{k_l})\}$  of  $\{(\zeta_k, p_k, q_k)\}$  such that  $(\zeta_{k_l}, p_{k_l}, q_{k_l}) \rightarrow (\zeta, p, q')$  for some  $q' \in \mathcal{Q}^*(\zeta, p)$ . Now from the continuity of  $T_q \phi(\zeta, p)$  (see Remark 1(b)), we have

$$\lim_{l \rightarrow \infty} T_{q_{k_l}} \phi(\zeta_{k_l}, p_{k_l}) = T_{q'} \phi(\zeta, p).$$

Hence, from (53) and (32),

$$(54) \quad \liminf_{k \rightarrow \infty} T\phi(\zeta_k, p_k) = T_{q'} \phi(\zeta, p) \geq T\phi(\zeta, p).$$

On the other hand, we have

$$T\phi(\zeta_k, p_k) \leq T_q \phi(\zeta_k, p_k) \quad \forall q \in \mathfrak{R}^+.$$

Then, again from the continuity of  $T_q \phi(\zeta, p)$ ,

$$\limsup_{k \rightarrow \infty} T\phi(\zeta_k, p_k) \leq T_q \phi(\zeta, p) \quad \forall q \in \mathfrak{R}^+,$$

which yields

$$(55) \quad \limsup_{k \rightarrow \infty} T\phi(\zeta_k, p_k) \leq T\phi(\zeta, p).$$

Therefore, by combining (54) and (55), we obtain

$$\lim_{k \rightarrow \infty} T\phi(\zeta_k, p_k) = T\phi(\zeta, p). \quad \square$$

*Remark 3.* (a) If  $\phi \in \mathcal{G}$  is only l.s.c., we can follow arguments similar to those in the proof of Lemma 7 (see also Remark 1(b)) to show that the functions  $T_q\phi(\zeta, p)$  and  $T\phi(\zeta, p)$  are l.s.c. in  $(\zeta, p, q)$  and  $(\zeta, p)$ , respectively. In addition, the selection theorem ensures the existence of a measurable function  $g_\phi: \mathfrak{R}^+ \times \mathcal{H}^+ \rightarrow \mathfrak{R}^+$  satisfying (52).

(b) It is worth noting that if  $\phi_1: \mathfrak{R}^+ \rightarrow \mathfrak{R}^+$  and  $\phi_2: \mathcal{H}^+ \rightarrow \mathfrak{R}^+$  are continuous, then  $T^{(1)}(\phi_1(\zeta), \phi_2(p))$  and  $T^{(2)}(\phi_1(\zeta), \phi_2(p))$  are continuous (see (64) and (65) for definitions of  $T^{(1)}$  and  $T^{(2)}$ ).

**5.2. Proof of Lemma 1.** We can express the left-hand side of (5) as

$$(56) \quad \mathbb{E}(\varphi(I_t)|\mathcal{Z}_t) = \mathbb{E}[\varphi(I_t)(\mathbb{I}_{z_t>0} + \mathbb{I}_{z_t=0})|\mathcal{Z}_t] = \varphi(-z_t)\mathbb{I}_{z_t>0} + \mathbb{E}[\varphi(I_t)\mathbb{I}_{z_t=0}|\mathcal{Z}_t].$$

From the last term of (56), we have

$$\begin{aligned} \mathbb{E}(\varphi(I_t)\mathbb{I}_{z_t=0}|\mathcal{Z}_t) &= \mathbb{I}_{z_t=0}\mathbb{E}(\varphi(I_t)|\mathcal{Z}_t) \\ &= \mathbb{I}_{z_t=0}\psi(z_1, \dots, z_{t-1}, z_t) \\ (57) \quad &= \mathbb{I}_{z_t=0}\psi(z_1, \dots, z_{t-1}, 0), \end{aligned}$$

where the first equality follows from the fact that  $\mathbb{I}_{z_t=0}$  is  $\mathcal{Z}_t$  measurable. The second equality introduces a measurable function  $\psi$  to express  $\mathbb{E}(\varphi(I_t)|\mathcal{Z}_t)$  as  $\psi(z_1, \dots, z_{t-1}, z_t)$ . If we set  $z_t = 0$  into the second equality, we can obtain the last equality.

Taking conditional expectation of (57) with respect to  $\mathcal{Z}_{t-1}$  and observing that  $\mathcal{Z}_{t-1} \subseteq \mathcal{Z}_t$  and  $\psi(z_1, \dots, z_{t-1}, 0)$  is  $\mathcal{Z}_{t-1}$ -measurable, we obtain

$$\begin{aligned} \mathbb{E}[\varphi(I_t)\mathbb{I}_{z_t=0}|\mathcal{Z}_{t-1}] &= \psi(z_1, \dots, z_{t-1}, 0)\mathbb{E}[\mathbb{I}_{I_t \geq 0}|\mathcal{Z}_{t-1}] \\ &= \psi(z_1, \dots, z_{t-1}, 0)\mathbb{P}(I_t \geq 0|\mathcal{Z}_{t-1}) \end{aligned}$$

or

$$(58) \quad \psi(z_1, \dots, z_{t-1}, 0) = \frac{\mathbb{E}(\varphi(I_t)\mathbb{I}_{I_t \geq 0}|\mathcal{Z}_{t-1})}{\mathbb{P}(I_t \geq 0|\mathcal{Z}_{t-1})}.$$

We insert (58) into (57) and then the result into (56) to get

$$\mathbb{E}(\varphi(I_t)|\mathcal{Z}_t) = \mathbb{I}_{z_t>0}\varphi(-z_t) + \mathbb{I}_{z_t=0} \frac{\mathbb{E}(\varphi(I_t)\mathbb{I}_{z_t=0}|\mathcal{Z}_{t-1})}{\mathbb{P}(I_t \geq 0|\mathcal{Z}_{t-1})}.$$

By using (3) and (4), we have

$$\mathbb{E}(\varphi(I_t)|\mathcal{Z}_t) = \mathbb{I}_{z_t>0}\varphi(-z_t) + \mathbb{I}_{z_t=0} \int_0^\infty \varphi(\eta)\pi_t(\eta)d\eta. \quad \square$$

**5.3. Proof of Theorem 1.** We start to prove this theorem from the right-hand side of (4). Take the numerator and obtain

$$\begin{aligned}
 & \mathbb{E}(\varphi(I_t) \mathbb{I}_{z_t=0} | \mathcal{Z}_{t-1}) \\
 &= \mathbb{E}(\varphi(I_{t-1} + q_{t-1} - D_{t-1}) \mathbb{I}_{I_{t-1}+q_{t-1}-D_{t-1} \geq 0} | \mathcal{Z}_{t-1}) \\
 &= \mathbb{E} \left( \mathbb{E}(\varphi(I_{t-1} + q_{t-1} - D_{t-1}) \mathbb{I}_{I_{t-1}+q_{t-1}-D_{t-1} \geq 0} | \mathcal{Z}_{t-1}, I_{t-1}) | \mathcal{Z}_{t-1} \right) \\
 &\quad \text{because } \mathcal{Z}_{t-1} = \sigma(\{z_1, \dots, z_{t-1}\}) \subseteq \sigma(\{z_1, \dots, z_{t-1}, I_{t-1}\}) \\
 &= \mathbb{E} \left( \int_0^\infty \varphi(I_{t-1} + q_{t-1} - y) \mathbb{I}_{I_{t-1}+q_{t-1}-y \geq 0} f(y) dy | \mathcal{Z}_{t-1} \right) \\
 &\quad \text{set } x := I_{t-1} + q_{t-1} - y \\
 &= \mathbb{E} \left( \int_0^\infty \varphi(x) f(I_{t-1} + q_{t-1} - x) \mathbb{I}_{I_{t-1}+q_{t-1}-x \geq 0} dx | \mathcal{Z}_{t-1} \right) \\
 (59) \quad &= \int_0^\infty \varphi(x) \mathbb{E} (f(I_{t-1} + q_{t-1} - x) \mathbb{I}_{I_{t-1}+q_{t-1}-x \geq 0} | \mathcal{Z}_{t-1}) dx.
 \end{aligned}$$

Letting the time index in the first equality of (5) be  $t-1$  instead of  $t$  and replacing  $\varphi(I_{t-1})$  with  $f(I_{t-1} + q_{t-1} - x) \mathbb{I}_{I_{t-1}+q_{t-1}-x \geq 0}$ , we obtain

$$\begin{aligned}
 & \mathbb{E}(f(I_{t-1} + q_{t-1} - x) \mathbb{I}_{I_{t-1}+q_{t-1}-x \geq 0} | \mathcal{Z}_{t-1}) \\
 &= \mathbb{I}_{z_{t-1} > 0} f(-z_{t-1} + q_{t-1} - x) \mathbb{I}_{-z_{t-1}+q_{t-1}-x \geq 0} \\
 (60) \quad &+ \mathbb{I}_{z_{t-1}=0} \int_{(x-q_{t-1})^+}^\infty f(\eta + q_{t-1} - x) \pi_{t-1}(\eta) d\eta.
 \end{aligned}$$

By inserting (60) into (59), we get

$$\begin{aligned}
 \mathbb{E}(\varphi(I_t) \mathbb{I}_{z_t=0} | \mathcal{Z}_{t-1}) &= \mathbb{I}_{z_{t-1} > 0} \int_0^\infty \varphi(x) f(-z_{t-1} + q_{t-1} - x) \mathbb{I}_{-z_{t-1}+q_{t-1}-x \geq 0} dx \\
 &+ \mathbb{I}_{z_{t-1}=0} \int_0^\infty \varphi(x) \left( \int_{(x-q_{t-1})^+}^\infty f(\eta + q_{t-1} - x) \pi_{t-1}(\eta) d\eta \right) dx.
 \end{aligned}$$

Similarly, we can express explicitly the denominator of the right-hand side of (4) as

$$\begin{aligned}
 \mathbb{P}(I_t \geq 0 | \mathcal{Z}_{t-1}) &= \mathbb{E}(\mathbb{I}_{I_{t-1}+q_{t-1}-D_{t-1} \geq 0} | \mathcal{Z}_{t-1}) \\
 &= \mathbb{E}\{\mathbb{E}(\mathbb{I}_{I_{t-1}+q_{t-1}-D_{t-1} \geq 0} | \mathcal{Z}_{t-1}, I_{t-1}) | \mathcal{Z}_{t-1}\} \\
 &= \mathbb{E}\{F(I_{t-1} + q_{t-1}) | \mathcal{Z}_{t-1}\} \\
 &= \mathbb{I}_{z_{t-1} > 0} F(-z_{t-1} + q_{t-1}) + \mathbb{I}_{z_{t-1}=0} \int_0^\infty F(y + q_{t-1}) \pi_{t-1}(y) dy.
 \end{aligned}$$

Because we have already obtained explicit expressions of the numerator and denominator of the right-hand side of (4), we can express the fraction, say the right-hand side of (4), as follows:

$$\begin{aligned} \frac{\mathbb{E}(\varphi(I_t)\mathbb{I}_{Z_t=0}|\mathcal{Z}_{t-1})}{\mathbb{P}(I_t \geq 0|\mathcal{Z}_{t-1})} &= \mathbb{I}_{z_{t-1}>0} \frac{\int_0^\infty \varphi(x)f(-z_{t-1}+q_{t-1}-x)\mathbb{I}_{-z_{t-1}+q_{t-1}-x \geq 0}dx}{F(-z_{t-1}+q_{t-1})} \\ &\quad + \mathbb{I}_{z_{t-1}=0} \frac{\int_0^\infty \varphi(x) \left( \int_{(x-q_{t-1})^+}^\infty f(\eta+q_{t-1}-x)\pi_{t-1}(\eta)d\eta \right) dx}{\int_0^\infty F(y+q_{t-1})\pi_{t-1}(y)dy}. \end{aligned}$$

Then, we have

$$\begin{aligned} \int_0^\infty \varphi(\eta)\pi_t(\eta)d\eta &= \mathbb{I}_{z_{t-1}>0} \frac{\int_0^\infty \varphi(x)f(-z_{t-1}+q_{t-1}-x)\mathbb{I}_{-z_{t-1}+q_{t-1}-x \geq 0}dx}{F(-z_{t-1}+q_{t-1})} \\ &\quad + \mathbb{I}_{z_{t-1}=0} \frac{\int_0^\infty \varphi(x) \left( \int_{(x-q_{t-1})^+}^\infty f(\eta+q_{t-1}-x)\pi_{t-1}(\eta)d\eta \right) dx}{\int_0^\infty F(y+q_{t-1})\pi_{t-1}(y)dy}. \end{aligned}$$

Since the above equation is satisfied for all test functions  $\varphi(x)$ , we have

$$\begin{aligned} \pi_t(x) &= \mathbb{I}_{z_{t-1}>0} \left\{ \frac{f(-z_{t-1}+q_{t-1}-x)\mathbb{I}_{-z_{t-1}+q_{t-1}-x \geq 0}}{F(q_{t-1}-z_{t-1})} \right\} \\ &\quad + \mathbb{I}_{z_{t-1}=0} \left\{ \frac{\int_{(x-q_{t-1})^+}^\infty f(y+q_{t-1}-x)\pi_{t-1}(y)dy}{\int_0^\infty F(y+q_{t-1})\pi_{t-1}(y)dy} \right\}. \end{aligned}$$

This equality is exactly (6), which completes the proof.  $\square$

**5.4. Proof of Lemma 2.** By changing the order of integration, we obtain

$$\begin{aligned} \int_0^\infty |\varrho(q)p(x)|dx &\leq \int_0^\infty \int_{(x-q)^+}^\infty f(y+q-x)|p(y)|dydx \\ &= \int_0^\infty \int_0^{y+q} f(y+q-x)|p(y)|dx dy \\ &= \int_0^\infty |p(y)| \int_0^{y+q} f(y+q-x)dx dy \\ (61) \qquad &\leq \int_0^\infty |p(y)|F(y+q)dy. \end{aligned}$$

Using similar operations, we see that

$$\begin{aligned} \int_0^\infty x|\varrho(q)p(x)|dx &\leq \int_0^\infty \int_{(x-q)^+}^\infty xf(y+q-x)|p(y)|dydx \\ &= \int_0^\infty \int_0^{y+q} xf(y+q-x)|p(y)|dx dy \\ &= \int_0^\infty |p(y)| \int_0^{y+q} (y+q-z)f(z)dz dy \\ (62) \qquad &\leq \int_0^\infty (y+q)|p(y)|F(y+q)dy. \end{aligned}$$

Using inequalities (61) and (62), we get

$$\begin{aligned}
 \|\varrho(q)p\| &= \int_0^\infty |\varrho(q)p(x)|dx + \int_0^\infty x|\varrho(q)p(x)|dx \\
 &\stackrel{(61,62)}{\leq} \int_0^\infty |p(y)|F(y+q)dy + \int_0^\infty |p(y)|(y+q)F(y+q)dy \\
 (63) \quad &\leq \|p\| + q \int_0^\infty |p(y)|dy.
 \end{aligned}$$

From (63) we can easily obtain  $\|\varrho(q)\|_{\mathcal{L}} \leq 1 + q$ .  $\square$

**5.5. Proof of Lemma 3.** Since  $c(y, q) \geq 0$ ,  $p_n \in \mathcal{H}^+$ , and  $p \in \mathcal{H}^+$ , we have

$$\begin{aligned}
 &\lim_{n \rightarrow \infty} \left| \int_0^\infty c(y, q_n)p_n(y)dy - \int_0^\infty c(y, q)p(y)dy \right| \\
 &= \lim_{n \rightarrow \infty} \left| \int_0^\infty c(y, q_n)p_n(y)dy - \int_0^\infty c(y, q)p_n(y)dy \right. \\
 &\quad \left. + \int_0^\infty c(y, q)p_n(y)dy - \int_0^\infty c(y, q)p(y)dy \right| \\
 &\leq \lim_{n \rightarrow \infty} \left| \int_0^\infty c(y, q_n)p_n(y)dy - \int_0^\infty c(y, q)p_n(y)dy \right| \\
 &\quad + \lim_{n \rightarrow \infty} \left| \int_0^\infty c(y, q)p_n(y)dy - \int_0^\infty c(y, q)p(y)dy \right| \\
 &= \lim_{n \rightarrow \infty} \left| \int_0^\infty [c(y, q_n) - c(y, q)]p_n(y)dy \right| + \lim_{n \rightarrow \infty} \int_0^\infty c(y, q)|p_n(y) - p(y)|dy \\
 &\leq \lim_{n \rightarrow \infty} \int_0^\infty |c(y, q_n) - c(y, q)|p_n(y)dy \\
 &\quad + \lim_{n \rightarrow \infty} \int_0^\infty [c_0 + c_1q + hy]|p_n(y) - p(y)|dy = 0,
 \end{aligned}$$

where both limits approach zero, respectively, on account of continuity of  $c(y, q)$  in  $q$  and (10).  $\square$

**5.6. Proof of Lemma 4.** The function  $v^0$  is an upper bound for the discounted cost of backordering. Indeed, let  $\tilde{q}_0 = \{0, 0, \dots\} \in \Gamma$  and  $\tilde{q} \in \Gamma$  be an arbitrary policy.

Then,

$$\begin{aligned}
 J(\zeta, \pi, \tilde{q}) &\leq J(\zeta, \pi, \tilde{q}_0) = \sum_{t=1}^{\infty} \alpha^{t-1} \mathbb{E}\{\mathbb{I}_{z_t > 0} c(-z_t, q_t)\} \leq \sum_{t=1}^{\infty} \alpha^{t-1} \mathbb{E}\{\mathbb{I}_{z_t > 0} (c_0 + sz_t)\} \\
 &\leq (c_0 + s\zeta) + \alpha \left( c_0 + s(\zeta + E(D)) \right) + \alpha^2 \left( c_0 + s(\zeta + 2E(D)) \right) \\
 &\quad + \alpha^3 \left( c_0 + s(\zeta + 3E(D)) \right) + \cdots \\
 &= c_0 + s\zeta + sE(D) + (c_0 + s\zeta)(\alpha + \alpha^2 + \alpha^3 + \cdots) \\
 &\quad + sE(D)(2\alpha + 3\alpha^2 + 4\alpha^3 + 5\alpha^4 + \cdots) \\
 &= \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s\zeta}{1-\alpha} = v^0(\zeta), \quad \zeta \in \mathbb{R}^+,
 \end{aligned}$$

where we use the upper bound of the cost in (14) to obtain the second inequality.

For  $\phi_1 \leq v^0$  and  $\phi_2 \leq Y^0$ , since  $Y^0(0) = 0$ ,

$$\begin{aligned}
 T^{(1)}(\phi_1, \phi_2) &= \inf_q T_q^{(1)}(\phi_1, \phi_2) \leq c(-\zeta, 0) + \alpha \int_0^\infty v^0(\eta) f(\eta - \zeta) d\eta + \alpha Y^0(0) \\
 &= c(-\zeta, 0) + \alpha \int_0^\infty v^0(\eta) f(\eta - \zeta) d\eta \\
 &= c_0 + s\zeta + \alpha \int_0^\infty \left[ \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s\eta}{1-\alpha} \right] f(\eta - \zeta) d\eta.
 \end{aligned}$$

We know that  $\int_0^\infty \eta f(\eta - \zeta) d\eta \leq E(D) + \zeta$ , for  $\zeta \in \mathbb{R}^+$ . Then,

$$\begin{aligned}
 T^{(1)}(\phi_1, \phi_2) &\leq c_0 + s\zeta + \frac{\alpha^2 s E(D)}{(1-\alpha)^2} + \frac{\alpha c_0}{1-\alpha} + \alpha(E(D) + \zeta) \frac{s}{1-\alpha} \\
 (64) \qquad &= \frac{\alpha^2 s E(D)}{(1-\alpha)^2} + \frac{c_0 + s\zeta}{1-\alpha} \leq v^0(\zeta).
 \end{aligned}$$

Thus,  $T^{(1)}(\phi_1, \phi_2) \in \mathbb{L}^+$ .

For  $\phi_1 \leq v^0$  and  $\phi_2 \leq Y^0$ ,

$$\begin{aligned}
 T^{(2)}(\phi_1, \phi_2) &= \inf_q T_q^{(2)}(\phi_1, \phi_2) \leq T_0^{(2)}(\phi_1, \phi_2) \leq T_0^{(2)}(v^0, Y^0) \\
 &= \int_0^\infty c(y, 0)p(y)dy + \alpha \int_0^\infty p(y) \int_0^\infty v^0(\eta)f(y+\eta)d\eta dy + \alpha Y^0(\varrho(0)p) \\
 &\leq \int_0^\infty (c_0 + hy)p(y)dy \\
 &\quad + \alpha \int_0^\infty p(y) \int_0^\infty \left[ \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s\eta}{1-\alpha} \right] f(y+\eta)d\eta dy \\
 &\quad + \alpha \frac{a_0}{1-\alpha} \|\varrho(0)p\| \\
 &\leq \left\{ c_0 + \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{\alpha c_0 + s E(D)}{1-\alpha} \right\} \int_0^\infty p(y)dy \\
 &\quad + h \int_0^\infty yp(y)dy + \alpha \frac{a_0}{1-\alpha} \|p\| \\
 (65) \quad &\leq a_0 \|p\| + \alpha \frac{a_0}{1-\alpha} \|p\| = \frac{a_0}{1-\alpha} \|p\| = Y^0(p).
 \end{aligned}$$

Obviously,  $T^{(2)}(\phi_1, \phi_2) \in \mathcal{B}^+$ . Therefore, the operator  $T$  maps  $\mathcal{G}$  into itself. For  $\phi_1 \leq v^0$  and  $\phi_2 \leq Y^0$ ,  $T^{(1)}(\phi_1, \phi_2) \leq v^0(\zeta)$ ,  $T^{(2)}(\phi_1, \phi_2) \leq Y^0(p)$ .  $\square$

**5.7. Proof of Theorem 2.** From Remark 3(a), part (b) of the theorem is a consequence of part (a).

To prove part (a), observe that, since  $Y_1 = v_1 = 0$ , we have  $v_1 \leq v^0$  and  $Y_1 \leq Y^0$ . Since  $\{v_n\}$  and  $\{Y_n\}$  are increasing sequences of continuous functions such that  $v_n \leq v^0$  and  $Y_n \leq Y^0$  for all  $n \geq 1$ , there are l.s.c. functions  $\bar{v} \leq v^0$  and  $\bar{Y} \leq Y^0$  such that

$$v_n \nearrow \bar{v} \quad \text{and} \quad Y_n \nearrow \bar{Y} \quad \text{as } n \rightarrow \infty.$$

Hence, we have that, for each  $(\zeta, p) \in \mathcal{R}^+ \times \mathcal{H}^+$ ,

$$(66) \quad Z_n(\zeta, p) \nearrow \bar{Z}(\zeta, p)$$

and  $\bar{Z} \in \mathcal{G}$ . Now, using the fact that the operators  $T^{(1)}$  and  $T^{(2)}$  are monotone, we have  $Z_n = TZ_{n-1} \leq T\bar{Z}$ . Thus, from (66),

$$(67) \quad \bar{Z}(\zeta, p) \leq T\bar{Z}(\zeta, p), \quad (\zeta, p) \in \mathcal{R}^+ \times \mathcal{H}^+.$$

To obtain the reverse inequality, let  $\bar{q}_n = \bar{g}_{Z_n}(\zeta, p)$  be such that  $Z_{n+1}(\zeta, p) = TZ_n(\zeta, p) = T_{\bar{q}_n}Z_n(\zeta, p)$ . Thus, observe that for any  $N$ ,

$$Z_{n+1}(\zeta, p) \geq T_{\bar{q}_n}Z_N(\zeta, p) \quad \forall n \geq N.$$

Then from (66),

$$(68) \quad \bar{Z}(\zeta, p) \geq T_{\bar{q}_n}Z_N(\zeta, p).$$

In addition, we can extract a subsequence  $\{\bar{q}_{n_k}\}$  of  $\{\bar{q}_n\}$  such that  $\bar{q}_{n_k} \rightarrow \bar{q} \in \mathcal{Q}^*(\zeta, p)$  as  $k \rightarrow \infty$ . Then, by the continuity of the function  $q \rightarrow T_qZ_N(\zeta, p)$ , we have that  $T_{\bar{q}_{n_k}}Z_N(\zeta, p) \rightarrow T_{\bar{q}}Z_N(\zeta, p)$  as  $k \rightarrow \infty$ . Therefore, from (68), we have  $\bar{Z}(\zeta, p) \geq T_{\bar{q}}Z_N(\zeta, p)$ . Letting  $N \rightarrow \infty$ , we obtain  $\bar{Z}(\zeta, p) \geq T_{\bar{q}}\bar{Z}(\zeta, p) \geq T\bar{Z}(\zeta, p)$ , which, combined with (67), yields  $\bar{Z}(\zeta, p) = T\bar{Z}(\zeta, p)$  for each  $(\zeta, p) \in \mathcal{R}^+ \times \mathcal{H}^+$ .  $\square$

**5.8. Proof of Theorem 3.** (a) Because  $V_1 = 0$ , we have  $V_1 \leq V$ . Then, by applying induction arguments, we can prove that  $V_n(\zeta, \pi) \leq V(\zeta, \pi)$  for all  $n$  and  $(\zeta, \pi) \in \mathfrak{R}^+ \times \Pi$ . Therefore (see (37)), since  $V_n \nearrow \bar{V}$  as  $n \rightarrow \infty$ ,

$$(69) \quad \bar{V}(\zeta, \pi) \leq V(\zeta, \pi) \quad \forall (\zeta, \pi) \in \mathfrak{R}^+ \times \Pi.$$

To prove the reverse inequality, let  $\hat{q}_t = \hat{g}(z_t, \pi_t)$  be the map satisfying (see (38) and (39))

$$(70) \quad \bar{V}(z_t, \pi_t) = \mathbb{E} [\mathbb{I}_{z_t > 0} c(-z_t, \hat{q}_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, \hat{q}_t), \pi_t \rangle | \mathcal{Z}_t] + \alpha \mathbb{E} [\bar{V}(z_{t+1}, \pi_{t+1}) | \mathcal{Z}_t].$$

Hence,

$$\begin{aligned} & \mathbb{E} [\alpha^{t-1} \bar{V}(z_t, \pi_t)] - \mathbb{E} [\alpha^t \bar{V}(z_{t+1}, \pi_{t+1})] \\ &= \alpha^{t-1} \mathbb{E} [\mathbb{I}_{z_t > 0} c(-z_t, \hat{q}_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, \hat{q}_t), \pi_t \rangle]. \end{aligned}$$

Summing up for  $t = 1, 2, \dots, M$  yields

$$\begin{aligned} \bar{V}(\zeta, \pi) &= \sum_{t=1}^M \alpha^{t-1} \mathbb{E} [\mathbb{I}_{z_t > 0} c(-z_t, \hat{q}_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, \hat{q}_t), \pi_t \rangle] + \alpha^M \mathbb{E} [\bar{V}(z_{M+1}, \pi_{M+1})] \\ (71) \quad &\geq \sum_{t=1}^M \alpha^{t-1} \mathbb{E} [\mathbb{I}_{z_t > 0} c(-z_t, \hat{q}_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, \hat{q}_t), \pi_t \rangle]. \end{aligned}$$

Letting  $M \rightarrow \infty$  and denoting  $\hat{q} = \{\hat{g}, \hat{g}, \dots\}$ , from (16) and (17), we get

$$(72) \quad \bar{V}(\zeta, \pi) \geq J(\zeta, \pi, \hat{q}) \geq V(\zeta, \pi) \quad \forall (\zeta, \pi) \in \mathfrak{R}^+ \times \Pi,$$

which, from (69), proves part (a).

(b) Let  $\tilde{\phi} \in \tilde{\mathcal{G}}$  be an arbitrary function such that  $\tilde{\phi}(\zeta, \pi) = \tilde{T}\tilde{\phi}(\zeta, \pi)$ . That is,  $\tilde{\phi}$  is of the form  $\tilde{\phi}(\zeta, \pi) = \mathbb{I}_{\zeta > 0} \tilde{\phi}_1(\zeta) + \mathbb{I}_{\zeta = 0} \tilde{\phi}_2(\pi)$ , and  $\tilde{\phi}_1$  and  $\tilde{\phi}_2$  satisfy the system (22)–(23). Then, applying the arguments in the proof of part (a) with  $\tilde{\phi}$  instead of  $\bar{V}$  (see (72)), we conclude that  $\tilde{\phi} \geq V$ . Since  $V = \bar{V}$ , it follows that  $\bar{V} \leq \tilde{\phi}$ . Hence,  $\bar{V}$  is minimal in  $\tilde{\mathcal{G}}$ . In addition, the corresponding unnormalized value function  $\bar{Z}$  is minimal in  $\mathcal{G}$ .

(c) Let  $\tilde{q}^* = \{g^*, g^*, \dots\} \in \Gamma$  be the policy determined by the map  $g^* : \mathfrak{R}^+ \times \Pi \rightarrow \mathcal{Q}$ . By denoting  $q_t^* = g^*(z_t, \pi_t)$  (see (38) and (39)), we write

$$V(z_t, \pi_t) = \mathbb{E} [\mathbb{I}_{z_t > 0} c(-z_t, q_t^*) + \mathbb{I}_{z_t = 0} \langle c(I_t, q_t^*), \pi_t \rangle | \mathcal{Z}_t] + \alpha \mathbb{E} [V(z_{t+1}, \pi_{t+1}) | \mathcal{Z}_t].$$

Then the first inequality in (72) implies

$$V(\zeta, \pi) \geq J(\zeta, \pi, \tilde{q}^*) \quad \forall (\zeta, \pi) \in \mathfrak{R}^+ \times \Pi.$$

Therefore, from (17),  $\tilde{q}^*$  is optimal.  $\square$

**5.9. Proof of Theorem 4.** (a) Let  $\tilde{q} \in \Gamma$  be an arbitrary policy and  $\{q_1, q_2, \dots\}$  be the decisions corresponding to application of  $\tilde{q}$ . Then, from (46), we can proceed as in (70) and (71) to obtain

(73)

$$\underline{V}(\zeta, \pi) = \sum_{t=1}^M \alpha^{t-1} E [\mathbb{I}_{z_t > 0} c(-z_t, \hat{q}_t) + \mathbb{I}_{z_t = 0} \langle c(I_t, \hat{q}_t), \pi_t \rangle] + \alpha^M E [\underline{V}(z_{M+1}, \pi_{M+1})].$$

Now, as  $\underline{V} \in \tilde{\mathcal{G}}$ , it follows that

$$(74) \quad \underline{V}(z_{M+1}, \pi_{M+1}) \leq \mathbb{I}_{z_{M+1} > 0} v^0(z_{M+1}) + \mathbb{I}_{z_{M+1} = 0} Y^0(\pi_{M+1}).$$

On the other hand, observe that from (2)  $z_t > 0$  if and only if  $I_t < 0$ , for each  $t \geq 1$ . Then, if  $z_{M+1} > 0$ , we have  $z_{M+1} = -I_{M+1} \leq D_M - I_M$ . Hence, if  $z_t > 0$  for all  $t$ , iterating this inequality we have

$$-E[I_{M+1}] \leq (M-1)E(D) - \zeta,$$

where  $I_1 = \zeta$ . Therefore, from (30),

$$\begin{aligned} & \alpha^N E [\mathbb{I}_{z_{M+1} > 0} v^0(z_{M+1})] \\ &= \alpha^M E \left[ \mathbb{I}_{z_{M+1} > 0} \left[ \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s z_{M+1}}{1-\alpha} \right] \right] \\ (75) \quad & \leq \alpha^M E \left[ \frac{\alpha s E(D)}{(1-\alpha)^2} + \frac{c_0 + s(M-1)E(D) - s\zeta}{1-\alpha} \right] \rightarrow 0 \quad \text{as } M \rightarrow \infty. \end{aligned}$$

On the other hand, from (31),

$$\begin{aligned} Y^0(\pi_{M+1}) &= \frac{a_0}{1-\alpha} \|\pi_{M+1}\| = \frac{a_0}{1-\alpha} \left( 1 + \int_0^\infty x \pi_{M+1}(x) dx \right) \\ &= \frac{a_0}{1-\alpha} (1 + E[I_{M+1} | \mathcal{Z}_M]). \end{aligned}$$

Then,

$$(76) \quad E[Y^0(\pi_{M+1})] = \frac{a_0}{1-\alpha} + \frac{a_0}{1-\alpha} E[I_{M+1}].$$

If  $z_{M+1} = 0$ , we have, from (51),

$$\begin{aligned} I_{M+1} &= I_M + q_M - D_M \leq I_M + q_M \leq I_M + \frac{a_0}{c(1-\alpha)} \|\pi_M\| \\ &= I_M + \frac{a_0}{c(1-\alpha)} + \frac{a_0}{c(1-\alpha)} E[I_M | \mathcal{Z}_{M-1}]. \end{aligned}$$

Hence,

$$E[I_{M+1}] \leq \left( 1 + \frac{a_0}{c(1-\alpha)} \right) E[I_M] + \frac{a_0}{c(1-\alpha)}.$$

Therefore, if  $z_t = 0$  for all  $t$ , iteration of this inequality yields

$$E[I_{M+1}] \leq \left(1 + \frac{a_0}{c(1-\alpha)}\right)^M (E(I_1) + 1) - 1.$$

Thus, from (76), as  $M \rightarrow \infty$ ,

$$(77) \quad \alpha^M E[\mathbb{I}_{z_{M+1}=0} Y^0(\pi_{M+1})] \leq \alpha^M \left[ \frac{a_0}{1-\alpha} (1 + E(I_1)) \left(1 + \frac{a_0}{c(1-\alpha)}\right)^M \right] \rightarrow 0.$$

Combining (74), (75), and (77), we have

$$\alpha^M [\underline{V}(z_{M+1}, \pi_{M+1})] \rightarrow 0 \text{ as } M \rightarrow \infty.$$

Letting  $M \rightarrow \infty$  in (73), we get  $\underline{V}(\zeta, \pi) \leq J(\zeta, \pi, \tilde{q})$ , and, as  $\tilde{q} \in \Gamma$  was arbitrary, we have

$$(78) \quad \underline{V}(\zeta, \pi) \leq V(\zeta, \pi).$$

This combined with (47) yields  $V(\zeta, \pi) = \underline{V}(\zeta, \pi)$ .

Finally, let  $\tilde{\phi} \in \tilde{\mathcal{G}}$  be an arbitrary function such that  $\tilde{\phi}(\zeta, \pi) = \tilde{T}\tilde{\phi}(\zeta, \pi)$ . Then, by using  $\tilde{\phi}$  instead of  $\underline{V}$ , we obtain  $V \geq \tilde{\phi}$  (see (78)). Since  $\underline{V} = V$ ,  $\underline{V} \geq \tilde{\phi}$ . Then,  $\underline{V}$  is maximal in  $\tilde{\mathcal{G}}$ . Similarly,  $\underline{Z}$  is maximal in  $\mathcal{G}$ . Furthermore, in view of the results in Theorem 3, we can conclude that the solutions of (24) and (28) are unique.

(b) According to part (a), we see that the value iteration functions  $Z^n$  converge decreasingly to the value function  $Z$ ; that is,

$$(79) \quad Z^n \searrow Z \text{ as } n \rightarrow \infty.$$

On the other hand, since  $v^1(\zeta) = v^0(\zeta)$  and  $Y^1(p) = Y^0(p)$  are continuous functions, we have from Lemma 7 that  $Z^n$  is continuous on  $\mathfrak{R}^+ \times \mathcal{H}^+$  for all  $n \geq 1$ . Therefore, from (79), we can ensure that the value function  $Z$  is u.s.c. Hence, from the lower semicontinuity of  $Z$  given in Theorems 2 and 3, we conclude that  $Z$  is continuous on  $\mathfrak{R}^+ \times \mathcal{H}^+$ . This result also yields the continuity of  $V$  on  $\mathfrak{R}^+ \times \Pi$ . This completes the proof.  $\square$

# STABILITY OF SOLUTIONS FOR SOME CLASSES OF NONLINEAR DAMPED WAVE EQUATIONS\*

GENNI FRAGNELLI<sup>†</sup> AND DIMITRI MUGNAI<sup>‡</sup>

**Abstract.** We consider two classes of semilinear wave equations with nonnegative damping which may be of type “on–off” or integrally positive. In both cases we give a sufficient condition for the asymptotic stability of the solutions. In the case of integrally positive damping we show that such a condition is also necessary.

**Key words.** damped nonlinear wave equations, integrally positive damping, on–off damping

**AMS subject classifications.** 35L70, 93D20, 35B35

**DOI.** 10.1137/070689735

**1. Introduction.** We are concerned with some classes of nonlinear abstract damped wave equations, whose prototype is the usual wave equation in a bounded domain  $\Omega \subset \mathbb{R}^N$ ,  $N \geq 1$ ,

$$(W) \quad u_{tt} = \Delta u - h(t)u_t + f(u),$$

and its associated Cauchy problem,

$$(1.1) \quad \begin{cases} u_{tt} = \Delta u - h(t)u_t + f(u) & \text{in } (0, +\infty) \times \Omega, \\ u(t, x) = 0 & \text{in } (0, +\infty) \times \partial\Omega, \\ u(0, x) = u_0(x), \quad u_t(0, x) = u_1(x) & x \in \Omega, \end{cases}$$

though we can handle equations in a more general Banach setting of the form

$$(E) \quad u'' + B(t)u' + Au = f(u),$$

with  $B$  and  $A$  suitably given (see section 2 for the precise setting).

This problem has been already investigated by many authors in the case of ordinary differential equations or systems of ordinary differential equations (i.e., when  $u$  depends only on  $t$ ) when  $f$  is linear (for example, see [5], [8]) and also when  $f$  is nonlinear (see [16], [18], [19]).

In the case of hyperbolic partial differential equations like (1.1), the problem has been studied when  $f$  is linear (see [4], [12]), when  $f$  is nonlinear but with linear growth (see [22]), and when  $f$  is nonlinear with superlinear growth (see [14] in the case of constant damping; see [17] for more general cases).

Concerning the damping  $h$ , the following different assumptions are alternatively made: on–off [7], increasing [1], bounded (in many senses) [4], [20], integrally positive

[22], etc. In particular, on–off dampers are suitable for describing a wide variety of communication network models (circuits which can be switched on or off), as well as systems where a control depending on time is necessary.

Very interesting results in the special case of  $f \equiv 0$  and damping of type on–off can be found in [7], and also when the term  $a(t)u_t$  in (1.1) is replaced by  $a(t)g(u_t)$ , where  $g$  is a nonlinear function with linear growth (see also [13]). For the case  $f \equiv 0$  we also mention a logarithmic decay estimate proved in [3] when the term  $a(t)u_t$  in (1.1) is replaced by  $(1+t)^\theta a(x)g(u_t)$ , with  $a$  bounded and strictly positive on a subdomain of  $\Omega$  and  $g$  possibly having superlinear growth at infinity.

In [22] Zhang shows that, if  $f$  has linear growth and  $h$  is integrally positive (see Definition 3.1 below), then any solution  $u(u_0, u_1)$  of (2.1) converges to 0 in the norm  $\|\nabla u\|_{L^2} + \|u_t\|_{L^2}$  if and only if

$$(1.2) \quad \int_0^\infty e^{-H(t)} \int_0^t e^{H(s)} ds dt = +\infty,$$

where  $H(t) = \int_0^t h(s)ds$ . Actually, the proof contains some gaps, in particular, in proving that the  $L^2$ -norm of  $u'$  converges to 0 as  $t \rightarrow \infty$ . However, we recover that result in section 3.

In this paper we show that when  $h$  is integrally positive, condition (1.2) is sufficient to prove global stability for problem (1.1), and also when  $f$  is superlinear and satisfies a sign condition. More precisely, in Theorem 3.1 we prove that condition (1.2) is sufficient under the assumption

$$uf(u) \leq 0 \quad \text{for every } u \in \mathbb{R},$$

which was already assumed, for example, in [17] and [20]. Note that such a condition is trivially verified when  $f(u) = -|u|^{p-1}u$ ,  $p \geq 1$ , which is our prototype, and which was studied, for example, in [14], where a global existence result is proved for  $h = \text{constant}$ . Under a natural nonsupercritical growth condition on  $f$ , we also show that (1.2) is also a necessary condition for global stability to hold (see Theorem 3.2). We remark that the requirement  $uf(u) \leq 0$  is a bit stronger than  $sf(s) < \lambda_1 s^2$ ,  $s \neq 0$ , which is essentially assumed in [22], and also in [9] where the damping is concentrated in a subset of  $\omega$  and Neumann-type conditions are assumed on the boundary (as in [2])—as usual, here  $\lambda_1$  denotes the first eigenvalue of  $-\Delta$  on  $H_0^1(\Omega)$ .

For damping of type on–off, in [7] the following case is considered: Let  $(a_n, b_n)_n$  be a sequence of open disjoint intervals of  $(0, \infty)$  such that  $a_n \rightarrow \infty$  and suppose there exists  $M_n \geq m_n > 0$  such that

$$(1.3) \quad m_n \leq h(t) \leq M_n \quad \forall t \in (a_n, b_n).$$

If  $f \equiv 0$ , then any solution  $u(u_0, u_1)$  of (2.1) converges to 0 in the norm  $\|\nabla u\|_{L^2} + \|u_t\|_{L^2}$  if

$$(1.4) \quad \sum_{n=1}^\infty m_n(b_n - a_n) \min \left( (b_n - a_n)^2, \frac{1}{1 + m_n M_n} \right) = \infty.$$

In this result the fact that  $f \equiv 0$  is essential in the proof of stability. In the nonlinear case under consideration, with the assumption

$$sf(s) - \int_0^s f(\sigma) d\sigma \leq 0 \quad \forall s \in \mathbb{R},$$

we show that (1.4), which was essentially already introduced in [16] for systems of ordinary differential equations, is again sufficient for the stability (see Theorem 4.2). As for the case  $f \equiv 0$  in [7], we still don't know if (1.4) is also necessary for stability to hold.

However, in the case of integrally positive damping, we give a complete characterization of stability for signed nonsupercritical nonlinearities.

**2. The abstract setting.** We will use an abstract setting which is a bit less general than the one in [7], but more natural for our purposes. Let us consider a second order evolution problem of the form

$$(2.1) \quad \begin{cases} u'' + B(t)u' + Au = f(u), & t > 0, \\ u(0) = u_0 \in V, \ u'(0) = u_1 \in H. \end{cases}$$

Here  $H$  denotes a real Hilbert space with scalar product  $\langle \cdot, \cdot \rangle_H$  and norm  $\| \cdot \|_H$ ,  $A : D(A) \subset H \rightarrow H$  is a linear self-adjoint coercive operator on  $H$  with dense domain, and  $V = D(A^{1/2})$  with norm  $\|v\|_V = \|A^{1/2}v\|_H$  is such that

$$(2.2) \quad \begin{aligned} &V \hookrightarrow H \equiv H' \hookleftarrow V' \quad \text{with dense embeddings, and} \\ &\exists \lambda_1 > 0 : \|v\|_H^2 \leq \frac{1}{\lambda_1} \|v\|_V^2 = \frac{1}{\lambda_1} \|A^{1/2}v\|_H^2 \quad \text{for any } v \in V. \end{aligned}$$

Concerning the time-dependent operator  $B$ , in section 3 we assume it is actually a nonnegative function which can be 0 in a set of measure 0 (see Definition 3.1 below), while for the results of section 4 we let it be a more particular “positive” nonlinear operator (see below for the precise assumptions), for which we assume that  $B \in L^\infty(0, \infty; \text{Lip}(H, H'))$ .

Finally, on the nonlinearity  $f$  we assume alternatively

$$(2.3) \quad sf(s) \leq 0 \quad \forall s \in \mathbb{R},$$

which implies

$$F(s) := \int_0^s f(\sigma) d\sigma \leq 0 \quad \forall s \in \mathbb{R}$$

or

$$(2.4) \quad sf(s) - F(s) \leq 0 \quad \forall s \in \mathbb{R}.$$

*Remark 2.1.* In both cases,  $f(u) = -|u|^{p-1}u$ ,  $p \geq 1$ , is the prototype function.

We also remark that the sign assumptions on  $f$  look quite reasonable and hard to relax. Indeed, it is well known that solutions of  $u_{tt} + a(x, t)u_t - \Delta u = |u|^{p-1}u$  in  $\Omega$ ,  $a(x, t) \geq 0$  and  $p > 1$  might blow up in finite time (see, for example, [10] or [11]).

By *solution* of (2.1), we mean a function  $u$  such that for any  $T > 0$  there holds  $u \in L^2(0, T; V) \cap H^1(0, T; H) \cap H^2(0, T; V')$  with  $\langle Bu', u' \rangle_H \in L^2(0, T)$  and

$$Au \in L^2(0, T; V'), \quad Bu' \in L^2(0, T; V'), \quad f(u) \in L^2(0, T; H),$$

with  $u(0) = u_0$ ,  $u'(0) = u_1$ , and such that

$$u'' + Bu' + Au = f(u) \quad \text{in } L^2(0, T; V').$$

*Remark 2.2.* In the case of problem (1.1) the condition  $f(u) \in L^2(0, T; H)$  is automatically satisfied when  $H = L^2(\Omega)$ ,  $V = H_0^1(\Omega)$ , and  $f(u) = -|u|^{p-1}u$ ,  $p \geq 1$  if  $N = 1, 2$  or  $1 \leq p \leq N/(N-2)$  if  $N \geq 3$ .

For any solution  $u$  of problem (2.1) we denote by  $E_u$ , or simply by  $E$ , if there is no need to specify  $u$ , the energy associated to such a solution,

$$(2.5) \quad E(t) = \frac{1}{2} \|u'(t)\|_H^2 + \frac{1}{2} \|u(t)\|_V^2 - \mathcal{F}(u(t)),$$

where  $\mathcal{F}(u)$  is the real-valued functional such that

$$\mathcal{F}(0) = 0 \text{ and } \mathcal{F}'(u)(\phi) = \langle f(u), \phi \rangle_{V', V}.$$

Of course in the case of problem (1.1) we have  $H = L^2(\Omega)$ ,  $V = H_0^1(\Omega)$ , and

$$\mathcal{F}(u) = \int_{\Omega} F(u) dx.$$

The following result, proved in [7] when  $f \equiv 0$ , still holds true in the nonlinear case thanks to the assumption  $f(u) \in L^2(0, T; H)$ . The proof is an adaptation to the one given therein and is thus omitted.

LEMMA 2.1. *For any solution  $u$  of (2.1) we have that*

- $u \in C([0, T]; V) \cap C^1([0, T]; H)$ ;
- *the associated energy  $E_u$  is locally absolutely continuous on  $[0, \infty)$  and*

$$(2.6) \quad E'_u(t) = -\langle B(t)u'(t), u'(t) \rangle_H \quad \text{a.e. in } [0, \infty).$$

In our setting we will also need the following obvious corollary.

LEMMA 2.2. *If in addition  $\langle B(t)w, w \rangle_H \geq 0$  for a.e.  $t \geq 0$  and for every  $w \in H$ , then for any solution  $u$  of (2.1) we have that  $E_u$  is nonincreasing.*

*Remark 2.3.* In the case of problem (1.1) equality (2.6) reads

$$E'(t) = - \int_{\Omega} h(t) u_t^2 dx,$$

which is nonpositive if  $h \geq 0$  a.e. in  $[0, \infty)$ .

**3. The integrally positive case.** Let us start with the following definitions.

DEFINITION 3.1. *A function  $h : [0, +\infty) \rightarrow [0, +\infty)$  is said to be integrally positive if for every  $a > 0$  there exists  $\delta > 0$  such that*

$$\int_t^{t+a} h(s) ds \geq \delta \quad \forall t > 0.$$

*Remark 3.1.* We underline the fact that according to this definition, the function  $h$  may vanish somewhere, but not on any interval.

DEFINITION 3.2. *Solutions of (E) are said to be uniformly bounded in  $D(A) \times D(A^{1/2})$  if for any  $B_1 > 0$  there exists  $B_2 > 0$  such that*

$$\text{if } (u_0, u_1) \in D(A) \times D(A^{1/2}), \quad \|Au_0\|_H + \|A^{1/2}u_1\|_H \leq B_1, \text{ and } t_0 \in [0, \infty),$$

*and if  $u(t, t_0, u_0, u_1)$  denotes the solution of (E) such that  $u(t_0) = u_0$  and  $u'(t_0) = u_1$ , then  $\forall t \geq t_0$ ,*

- $f(u(t, t_0, u_0, u_1)) \in H$  and

$$\bullet \|Au(t, t_0, u_0, u_1)\|_H + \|A^{1/2}u'(t, t_0, u_0, u_1)\|_H + \|f(u(t, t_0, u_0, u_1))\|_H \leq B_2.$$

Let us remark that such a definition is a natural modification of the one introduced in [22], due to the presence of the requirement on  $\|f(u)\|_H$ . Moreover, we also underline the fact that  $B_2$  is independent of the initial time  $t_0$ .

For the following result we concentrate on (1.1), where  $A = -\Delta$ ,  $D(A) = H^2(\Omega) \cap H_0^1(\Omega)$ ,  $D(A^{1/2}) = H_0^1(\Omega)$ , and  $H = L^2(\Omega)$ , and we recall that  $\|\Delta u\|_2$  is a norm on  $H^2(\Omega) \cap H_0^1(\Omega)$  which is equivalent to the usual one (for example, see [15]), where we have set  $\|\cdot\|_2 = \|\cdot\|_{L^2(\Omega)}$ .

Having in mind the prototype  $f(s) = -|s|^{p-1}s$ ,  $p \geq 1$ , we also make the following natural assumption:

If  $u$  solves (2.1),  $\forall T > 0 \exists C = C(u, T) > 0$  and  $q = q(u, T) > 0$  such that

$$(3.1) \quad \left| \int_{\Omega} F(u(t)) dx \right| \leq C \|A^{1/2}u(t)\|_2^q \quad \forall t \geq T.$$

Of course, in the model case  $f(s) = -|s|^{p-1}s$ ,  $p \geq 1$ , and  $p \leq N/(N-2)$  if  $N \geq 3$  described in Remark 2.2, we have also  $p+1 \leq (2N-2)/(N-2)$  if  $N \geq 3$ ; thus the Sobolev inequality can be applied, and we can always take  $q = p+1$  and  $C$  depending only on the measure of  $\Omega$  and the Sobolev constant.

Now we can state our first fundamental result.

**THEOREM 3.1.** *Assume (1.2), (2.3), and (3.1). If  $h$  is integrally positive and solutions of (W) are uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ , then every solution  $u$  of (1.1) satisfies*

$$(3.2) \quad \|A^{1/2}u(t)\|_2 + \|u'(t)\|_2 \rightarrow 0 \quad \text{as } t \rightarrow +\infty.$$

*Proof.* Take  $(u_0, u_1) \in D(A) \times D(A^{1/2})$  and denote by  $u$  the associated solution of (1.1). By Remark 2.3 there exists  $E_{\infty} \geq 0$  such that

$$(3.3) \quad \begin{aligned} & \lim_{t \rightarrow +\infty} E(t) \\ &= \lim_{t \rightarrow +\infty} \left( \frac{1}{2} \|u'(t)\|_2^2 + \frac{1}{2} \|A^{1/2}u(t)\|_2^2 - \int_{\Omega} F(u) dx \right) = E_{\infty}. \end{aligned}$$

We want to show that  $E_{\infty} = 0$ , so let us assume by contradiction that  $E_{\infty} > 0$ .

By (2.3)  $F(s) = \int_0^s f(\tau) d\tau \leq 0$  for any  $s \in \mathbb{R}$ , so that by (3.3) there exists  $L \in [0, 2E_{\infty}]$  such that

$$(3.4) \quad \limsup_{t \rightarrow +\infty} \|u'(t)\|_2^2 = L.$$

Assume by contradiction that  $L > 0$ . We must distinguish several cases.

*Case 1.*  $\|u'(t)\|_2^2 \equiv L \forall t > 0$ . Then, by (2.6) and Remark 2.3 we get

$$(3.5) \quad \begin{aligned} 0 < E_{\infty} &= E(0) + \int_0^{\infty} E'(\tau) d\tau = E(0) - \int_0^{\infty} h(\tau) \|u'(\tau)\|_2^2 d\tau \\ &= E(0) - L \int_0^{\infty} h(\tau) d\tau. \end{aligned}$$

Since  $h$  is integrally positive, there exists  $\delta > 0$  such that

$$(3.6) \quad \int_n^{n+1} h(\tau) d\tau \geq \delta \quad \forall n \in \mathbb{N}.$$

Therefore, (3.5) and (3.6) imply

$$0 < E(0) - L \sum_{n=1}^{\infty} \delta = -\infty,$$

and a contradiction arises.

*Case 2.*  $\|u'(t)\|_2^2 \neq L$ . Set  $\liminf_{t \rightarrow +\infty} \|u'(t)\|_2^2 = \ell \in [0, L]$ , and assume first that  $\ell < L$ . Then, since  $u \in C^1([0, T]; H)$  by Lemma 2.1, there exist two sequences  $(s_n)_n$  and  $(t_n)_n$  such that

1.  $0 < s_n < t_n < s_{n+1} \quad \forall n \in \mathbb{N}$ ;
2.  $s_n \rightarrow +\infty$  as  $n \rightarrow \infty$ ;
3.  $\frac{L+\ell}{2} = \|u'(s_n)\|_2^2 < \|u'(t_n)\|_2^2 = \frac{3L+\ell}{4} \quad \forall n \in \mathbb{N}$ ;
4.  $\frac{L+\ell}{2} \leq \|u'(t)\|_2^2 \leq \frac{3L+\ell}{4} \quad \forall t \in (s_n, t_n)$ .

Since solutions of (1.1) are uniformly bounded, there exists  $M > 0$ , depending on  $\|Au_0\|_2$  and  $\|A^{1/2}u_1\|_2$ , such that

$$\begin{aligned} \frac{d}{dt} \|u'(t)\|_2^2 &= 2\langle u'(t), u''(t) \rangle \\ &= -2\langle u'(t), Au(t) \rangle - 2h(t)\|u'(t)\|_2^2 + 2\langle u'(t), f(u) \rangle \\ &\leq 2\|u'(t)\|_2 \|Au(t)\|_2 + 2\|u'(t)\|_2 \|f(u)\|_2 \leq M. \end{aligned}$$

Therefore

$$\frac{L-\ell}{4} = \frac{3L+\ell}{4} - \frac{L+\ell}{2} = \int_{s_n}^{t_n} \frac{d}{dt} \|u'(t)\|_2^2 dt \leq M(t_n - s_n),$$

so that

$$(3.7) \quad t_n - s_n \geq \frac{L-\ell}{4M} \quad \forall n \in \mathbb{N}.$$

In this way, by (2.6) and (3.7) we get

$$\begin{aligned} (3.8) \quad 0 < E_{\infty} &= E(0) + \int_0^{\infty} E'(\tau) d\tau \leq E(0) - \int_{\cup_n (s_n, t_n)} h(\tau) \|u'(\tau)\|_2^2 d\tau \\ &\leq E(0) - \frac{L+\ell}{2} \int_{\cup_n (s_n, s_n + \frac{L-\ell}{4M})} h(\tau) d\tau. \end{aligned}$$

Since  $h$  is integrally positive, there exists  $\delta > 0$  such that

$$\int_{(s_n, s_n + \frac{L-\ell}{4M})} h(\tau) d\tau \geq \delta \quad \forall n \in \mathbb{N},$$

so that (3.8) again gives  $0 < -\infty$ .

*Case 3.*  $u'(t)$  has limit. Now assume that there exists  $\lim_{t \rightarrow +\infty} \|u'(t)\|_2^2 = L$ . Then there exists  $M > 0$  such that

$$(3.9) \quad \|u'(t)\|_2^2 \geq \frac{L}{2} \quad \forall t \geq M.$$

In this way, by (2.6), Remark 2.3, and (3.9) we get

$$\begin{aligned}
 0 < E_\infty &= E(0) + \int_0^\infty E'(\tau) d\tau \leq C_M - \int_M^\infty h(\tau) \|u'(\tau)\|_2^2 d\tau \\
 (3.10) \qquad &\leq C_M - \frac{L}{2} \int_M^\infty h(\tau) d\tau,
 \end{aligned}$$

where  $C_M$  is a constant depending on  $E(0)$  and  $M$ . Since  $h$  is integrally positive, as in (3.6), there exists  $\delta > 0$  such that

$$\int_n^{n+1} h(\tau) d\tau \geq \delta \quad \forall n \in \mathbb{N},$$

so that (3.10) gives  $0 < -\infty$ , again a contradiction.

Thus we can conclude that  $L = 0$ , i.e.,

$$(3.11) \qquad \lim_{t \rightarrow +\infty} \|u'(t)\|_2 = 0.$$

As a consequence, (3.3) implies

$$\lim_{t \rightarrow \infty} \left( \frac{1}{2} \|A^{1/2} u(t)\|_2^2 - \int_\Omega F(u(t)) dx \right) = E_\infty > 0.$$

Then there exists  $T > 0$  such that for any  $t \geq T$ , one has

$$\frac{1}{2} \|A^{1/2} u(t)\|_2^2 - \int_\Omega F(u(t)) dx \geq \frac{E_\infty}{2}.$$

By (3.1), there exists  $\gamma = \gamma(u) > 0$  such that

$$(3.12) \qquad \|A^{1/2} u(t)\|_2 \geq \gamma \quad \forall t > T.$$

Now set

$$(3.13) \qquad v(t) = \langle u(t), u'(t) \rangle = \frac{1}{2} \frac{d}{dt} \|u(t)\|_2^2,$$

so that

$$\begin{aligned}
 v'(t) &= \|u'(t)\|^2 + \langle u(t), -h(t)u'(t) - Au + f(u) \rangle_{L^2} \\
 &= \|u'(t)\|^2 - h(t)v(t) - \|A^{1/2}u\|_2^2 + \langle u, f(u) \rangle_{L^2} \\
 &\leq \|u'(t)\|^2 - h(t)v(t) - \|A^{1/2}u\|_2^2
 \end{aligned}$$

by (2.3). Finally, (3.11) and (3.12) imply that there exist  $T_0 > T$  and  $\delta > 0$  such that

$$v'(t) \leq -\delta - h(t)v(t) \quad \forall t \geq T_0,$$

that is,

$$\frac{d}{dt} \left( v(t) e^{H(t)} \right) \leq -\delta e^{H(t)} \quad \forall t \geq T_0,$$

where  $H(t) = \int_0^t h(\tau) d\tau$ . Integrating between  $T_0$  and  $t$  gives

$$v(t) \leq v(T_0)e^{-H(t)+H(T_0)} - \delta e^{-H(t)} \int_{T_0}^t e^{H(\tau)} d\tau.$$

Integrating again between  $T_0$  and  $t$ , by (3.13) we get

$$\begin{aligned} \frac{1}{2}\|u(t)\|_2^2 &\leq \frac{1}{2}\|u(T_0)\|_2^2 \\ &+ v(T_0)e^{H(T_0)} \int_{T_0}^t e^{-H(s)} ds - \delta \int_{T_0}^t e^{-H(s)} \int_{T_0}^s e^{H(\tau)} d\tau ds. \end{aligned}$$

Letting  $t \rightarrow \infty$ , by (1.2) the right-hand side of the previous inequality goes to  $-\infty$ , and a contradiction arises. In fact, by (3.6) we get  $H(t) = \int_0^t h(\tau) d\tau > \delta[t] \geq \delta(t-1)$ , where  $[t]$  denotes the integer part of  $t$  (i.e., the greatest integer not bigger than  $t$ ), and then

$$\int_{T_0}^t e^{-H(\tau)} d\tau \leq \int_{T_0}^t e^{-\delta(\tau-1)} d\tau \leq \frac{e^{-\delta(T_0-1)}}{\delta}.$$

Thus  $E_\infty = 0$ , and since  $F(u) \leq 0$  for any  $u$ , (3.3) implies that  $\|u'(t)\|_2^2 + \|A^{1/2}u(t)\|_2^2 \rightarrow 0$  as  $t \rightarrow \infty$  and (3.2) clearly follows.  $\square$

*Remark 3.1.* 1. In proving the previous result, actually what is really needed is that

$$\text{if } (u_0, u_1) \in D(A) \times H \text{ and } \|Au_0\|_H + \|u_1\|_H \leq B_1,$$

then  $\forall t \geq t_0$   $f(u(t, t_0, u_0, u_1)) \in H$  and

$$\|Au(t, t_0, u_0, u_1)\|_H + \|u'(t, t_0, u_0, u_1)\|_H + \|f(u(t, t_0, u_0, u_1))\|_H \leq B_2.$$

However, we preferred to maintain the definition proposed in [22], since it is natural to deal with solutions whose time derivative is still in  $H_0^1(\Omega)$ , as it happens when it is possible to apply a regularity result.

2. Moreover, the proof above extends immediately to the abstract case, and this is the reason why we maintained the abstract formulation, writing, for example,  $\|A^{1/2}u\|_2$  in place of  $\|Du\|_2$ .

*Remark 3.2.* In proving the analogue of Theorem 3.1 in [22] for a sublinear  $f$ , Zhang didn't take into account the different possibilities about the limit  $L$  defined in (3.4). However, adapting our proof to any function  $f$  with sublinear growth and such that  $sf(s) < \lambda_1 s^2$ ,  $s \neq 0$ , like in [22], we can recover the stability result quoted therein.

As in [22], we prove that condition (1.2) is also necessary for asymptotic stability to hold, even without the assumption that  $h$  is integrally positive and without the sign assumption on  $f$ , though we need  $f$  to be nonsupercritical, in the usual sense. Moreover, we can even require a weaker a priori bound condition.

**DEFINITION 3.1.** *Solutions of (E) are said weakly uniformly bounded in  $D(A^{1/2}) \times H$  if for any  $B_1 > 0$  there exists  $B_2 > 0$  such that*

$$\text{if } (u_0, u_1) \in D(A^{1/2}) \times H, \|A^{1/2}u_0\|_H + \|u_1\|_H \leq B_1, \text{ and } t_0 \in [0, \infty),$$

then  $\forall t \geq t_0$ ,

- $f(u(t, t_0, u_0, u_1)) \in H$  and
- $\|A^{1/2}u(t, t_0, u_0, u_1)\|_H + \|u'(t, t_0, u_0, u_1)\|_H + \|f(u(t, t_0, u_0, u_1))\|_H \leq B_2$ , where  $u(t, t_0, u_0, u_1)$  denotes the solution of (E) such that  $u(t_0) = u_0$  and  $u'(t_0) = u_1$ .

**THEOREM 3.2.** Suppose that (2.3) holds and that solutions of (W) are weakly uniformly bounded in  $D(A^{1/2}) \times L^2(\Omega)$ . In addition, assume that

$$(3.14) \quad \exists a, b \geq 0, p \in \begin{cases} [1, \infty) & \text{if } N = 1, 2, \\ [1, \frac{N}{N-2}] & \text{if } N \geq 3, \end{cases} \text{ such that } |f(s)| \leq a + b|s|^p \quad \forall s \in \mathbb{R}.$$

If every solution of (1.1) satisfies (3.2), then (1.2) holds.

*Proof.* Since all solutions of (W) are weakly uniformly bounded in  $D(A^{1/2}) \times L^2(\Omega)$ , for any  $D > 0$  there exists  $M > 0$  such that, for any  $u_0, u_1 \in D(A^{1/2}) \times L^2(\Omega)$  with  $\|A^{1/2}u_0\|_2^2 + \|u_1\|_2^2 \leq D$ , for any  $t_0 \geq 0$  there holds in particular

$$(3.15) \quad \|A^{1/2}u(t, t_0, u_0, u_1)\|_2 \leq M \quad \forall t > 0.$$

Moreover, by the Hölder and Sobolev inequalities, there exist  $S_1, S_{p+1} > 0$  such that for any  $u \in H_0^1(\Omega)$  there holds

$$(3.16) \quad \int_{\Omega} |u| dx \leq S_1 \|A^{1/2}u\|_2 \quad \text{and} \quad \int_{\Omega} |u|^{p+1} dx \leq S_{p+1} \|A^{1/2}u\|_2^{p+1}.$$

In fact, note that if  $N \geq 3$ , then  $p+1 \leq (2N-2)/(N-2)$  and Sobolev's theorem can be applied.

Assume by contradiction that

$$\int_0^\infty e^{-H(t)} \int_0^t e^{H(s)} ds dt < \infty.$$

Then, for any  $\gamma > 0$  there exists  $t_0$  such that

$$(3.17) \quad \int_{t_0}^\infty e^{-H(t)} \int_{t_0}^t e^{H(s)} ds dt < \frac{D}{8\gamma}.$$

Now take  $\phi \in H_0^1(\Omega)$  such that  $\|A^{1/2}\phi\|_2^2 = D/2$ ,  $\|\phi\|_2^2 = D/2$ , and consider the solution  $u$  of (W) such that  $u(t_0) = \phi$  and  $u_t(t_0) = 0$ , so that  $(\phi, 0)$  guarantees  $\|A^{1/2}u(t_0)\|_2^2 + \|u_t(t_0)\|_2^2 \leq D$ . Finally, for  $t \geq t_0$ , set  $w(t) = \langle u(t), u'(t) \rangle_{L^2} = \frac{1}{2}(\|u(t)\|_2^2)'$ . Differentiating, we get

$$\begin{aligned} w'(t) &= \|u'(t)\|_2^2 + \langle u(t), u''(t) \rangle_{L^2} \\ &= \|u'(t)\|_2^2 + \langle u(t), -Au \rangle - h(t)w(t) + \langle u(t), f(u) \rangle_{L^2} \\ (3.18) \quad &= \|u'(t)\|_2^2 - \|A^{1/2}u(t)\|_2^2 - h(t)w(t) + \langle u(t), f(u) \rangle_{L^2} \\ &\geq -\|A^{1/2}u(t)\|_2^2 - h(t)w(t) - \int_{\Omega} (a|u(t)| + b|u(t)|^{p+1}) dt. \end{aligned}$$

By (3.16) we get

$$(3.19) \quad w'(t) \geq -\|A^{1/2}u(t)\|_2^2 - h(t)w(t) - aS_1 \|A^{1/2}u\|_2 - bS_{p+1} \|A^{1/2}u\|_2^{p+1}.$$

By the Young inequality we can find  $\eta > 0$  such that (3.19) gives

$$w'(t) \geq -\eta(1 + \|A^{1/2}u(t)\|_2^{p+1}) - h(t)w(t) - bS_{p+1}\|A^{1/2}u\|_2^{p+1},$$

and by (3.15),

$$w'(t) \geq -(\eta + \eta M^{p+1} + bS_{p+1}M^{p+1}) - h(t)w(t).$$

Setting  $\gamma = \eta + \eta M^{p+1} + bS_{p+1}M^{p+1} > 0$  (which is independent of  $t_0$ ), we have  $w'(t) + h(t)w(t) \geq -\gamma$ , i.e.,

$$(3.20) \quad (e^{H(t)}w(t))' \geq -\gamma.$$

Integrating (3.20) twice between  $t_0$  and  $t$  gives

$$\frac{1}{2}\|u(t)\|_2^2 \geq \frac{1}{2}\|u(t_0)\|_2^2 - \gamma \int_{t_0}^t e^{-H(s)} \int_{t_0}^s e^{H(\tau)} d\tau ds.$$

Finally, by (3.17), we get

$$\frac{1}{2}\|u(t)\|_2^2 \geq \frac{D}{8}.$$

By Poincaré's inequality we obtain

$$\|A^{1/2}u(t)\|_2^2 \geq \frac{\lambda_1 D}{4},$$

so that (3.2) cannot hold.  $\square$

*Remark 3.3.* 1. Of course a uniform bound implies a weak uniform bound by Poincaré's inequality. However, we preferred to present Theorem 3.2 under the more general assumption of a weak uniform bound on the set of solutions.

2. Again, in the proof of Theorem 3.2 we maintained the abstract form  $A$  for  $-\Delta$ , since an analogous version for the abstract problem (2.1) can be provided at once, where  $\lambda_1$  is now given by (2.2).

Summing up, in view of Theorems 3.2 and 3.1, and recalling that (3.14) implies (3.1) when  $a = 0$ , we can conclude with the following result.

**THEOREM 3.3.** *Let  $\Omega$  be a bounded domain of  $\mathbb{R}^N$ ,  $N \geq 1$ . Assume (2.3), (3.1), and (3.14); moreover, suppose that  $h$  is integrally positive and that solutions of (W) are uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ . Then every solution of (1.1) verifies*

$$\|Du(t)\|_2 + \|u'(t)\|_2 \rightarrow 0 \quad \text{as } t \rightarrow +\infty$$

if and only if (1.2) holds.

**4. The on-off case.** As in section 2, we set  $V = D(A^{1/2}) \subset H$ , and by (2.2) there exists  $\lambda_1 > 0$  such that

$$\|v\|_H^2 \leq \frac{1}{\lambda_1} \|v\|_V^2 = \frac{1}{\lambda_1} \|A^{1/2}v\|_H^2 \quad \text{for any } v \in V.$$

We remark that in the standard case of problem (1.1) we have  $H = L^2(\Omega)$ ,  $V = H_0^1(\Omega)$  and  $\lambda_1$  is the first eigenvalue of  $-\Delta$  on  $H_0^1(\Omega)$ , the inequality above being the usual Poincaré's inequality.

The inequality expressed in (2.4) can be replaced in the abstract case by the condition that

$$(4.1) \quad \langle f(u), u \rangle_{V',V} - \mathcal{F}(u) \leq 0 \quad \forall u \in V,$$

though it would suffice to hold only for those  $u$ 's which solve (2.1). Of course this condition, in effect, reduces to (2.4) in the model case of problem (1.1).

THEOREM 4.1. *Fix  $T > 0$  and assume there exist  $M, m > 0$  such that*

$$(4.2) \quad m\|v\|_H^2 \leq \langle B(t)v, v \rangle_H \quad \forall t \in [0, T], \forall v \in H,$$

$$(4.3) \quad \|B(t)v\|_H^2 \leq M\langle B(t)v, v \rangle_H \quad \forall t \in [0, T], \forall v \in H.$$

Moreover, suppose that (2.2) and (4.1) hold. Then for every  $(u_0, u_1) \in V \times H$  the solution  $u$  of problem (2.1) satisfies

$$(4.4) \quad E_u(T) \leq \frac{1}{1 + \frac{T^3}{30} \frac{1}{\frac{4}{\lambda_1 m} + \frac{3T^2}{32m} + \frac{MT^2}{16\lambda_1}}} E_u(0).$$

*Proof.* As in [6] and [7], for any  $t \in [0, T]$  we set  $\theta(t) = t^2(T - t)^2$ , so that  $\theta'(t) = 2t(T - t)(T - 2t)$  and

$$(4.5) \quad |\theta'(t)| \leq 2T\theta^{1/2}(t) \quad \forall t \in [0, T],$$

$$(4.6) \quad \max_{t \in [0, T]} \theta(t) = \frac{T^4}{16},$$

and

$$(4.7) \quad \int_0^T \theta(t) dt = \frac{T^5}{30}.$$

Therefore (2.6) gives

$$(4.8) \quad E(0) - E(T) = \int_0^T \langle Bu', u' \rangle_H dt \geq 0.$$

Multiplying (2.1) by  $\theta u$  gives

$$\int_0^T \theta \left\{ \langle u'' + Bu', u \rangle_{V',V} + \|A^{1/2}u\|_H^2 - \langle f(u), u \rangle_{V',V} \right\} dt = 0.$$

Therefore, integrating by parts,

$$\int_0^T \theta \|A^{1/2}u\|_H^2 dt = \int_0^T \left\{ \langle (\theta u)', u' \rangle_H - \theta \langle Bu', u \rangle_H + \theta \langle f(u), u \rangle_{V',V} \right\} dt,$$

that is,

$$\int_0^T \theta \|A^{1/2}u\|_H^2 dt = \int_0^T \left\{ \theta \|u'\|_H^2 + \theta' \langle u, u' \rangle_H - \theta \langle Bu', u \rangle_H + \theta \langle f(u), u \rangle_{V',V} \right\} dt.$$

Thus for any  $\varepsilon, \eta > 0$  we get

$$\begin{aligned} \int_0^T \theta \|A^{1/2}u\|_H^2 dt &\leq \int_0^T \left\{ \varepsilon \theta \|u\|_H^2 + \frac{1}{4\varepsilon} \theta \|Bu'\|_H^2 \right. \\ &\quad \left. + \eta \theta'^2 \|u\|_H^2 + \frac{1}{4\eta} \|u'\|_H^2 + \theta \|u'\|_H^2 + \theta \langle f(u), u \rangle_{V',V} \right\} dt. \end{aligned}$$

By (4.5), (4.6), (4.3), and (2.2) we get

$$\begin{aligned} (4.9) \quad \int_0^T \theta \|A^{1/2}u\|_H^2 dt &\leq \int_0^T \left\{ \frac{\varepsilon}{\lambda_1} \theta \|A^{1/2}u\|_H^2 + \frac{MT^4}{64\varepsilon} \langle Bu', u' \rangle_H \right. \\ &\quad \left. + \frac{4\eta T^2}{\lambda_1} \theta \|A^{1/2}u\|_H^2 + \frac{1}{4\eta} \|u'\|_H^2 + \frac{T^4}{16} \|u'\|_H^2 + \theta \langle f(u), u \rangle_{V',V} \right\} dt. \end{aligned}$$

Let us choose  $\varepsilon$  and  $\eta$  so that

$$\frac{4\eta T^2}{\lambda_1} = \frac{\varepsilon}{\lambda_1} = \frac{1}{4}.$$

Then (4.9) reads

$$\begin{aligned} \int_0^T \theta \|A^{1/2}u\|_H^2 dt &\leq \int_0^T \left\{ \frac{1}{4} \theta \|A^{1/2}u\|_H^2 + \frac{MT^4}{16\lambda_1} \langle Bu', u' \rangle_H + \theta \langle f(u), u \rangle_{V',V} \right. \\ &\quad \left. + \frac{1}{4} \theta \|A^{1/2}u\|_H^2 + \frac{4T^2}{\lambda_1} \|u'\|_H^2 + \frac{T^4}{16} \|u'\|_H^2 \right\} dt, \end{aligned}$$

so that

$$\begin{aligned} &\frac{1}{2} \int_0^T \theta \|A^{1/2}u\|_H^2 dt \\ &\leq \int_0^T \left\{ C_T \|u'\|_H^2 + \frac{MT^4}{16\lambda_1} \langle Bu', u' \rangle_H + \theta \langle f(u), u \rangle_{V',V} \right\} dt, \end{aligned}$$

where  $C_T = \frac{4T^2}{\lambda_1} + \frac{T^4}{16}$ . By (4.8) this means

$$\begin{aligned} (4.10) \quad &\frac{1}{2} \int_0^T \theta \|A^{1/2}u\|_H^2 dt \\ &\leq \int_0^T \left\{ C_T \|u'\|_H^2 + \theta \langle f(u), u \rangle_{V',V} \right\} dt + \frac{MT^4}{16\lambda_1} (E(0) - E(T)). \end{aligned}$$

By (2.5),

$$\frac{1}{2} \int_0^T \theta \|A^{1/2}u\|_H^2 dt = \int_0^T \theta E(t) dt - \frac{1}{2} \int_0^T \theta \|u'\|_H^2 dt + \int_0^T \theta \mathcal{F}(u) dt,$$

and by Lemma 2.2,

$$\begin{aligned} (4.11) \quad &\frac{1}{2} \int_0^T \theta \|A^{1/2}u\|_H^2 dt \\ &\geq E(T) \int_0^T \theta(t) dt - \frac{1}{2} \int_0^T \theta \|u'\|_H^2 dt + \int_0^T \theta \mathcal{F}(u) dt. \end{aligned}$$

Therefore (4.7), (4.10), (4.6), and (4.11) give

$$\begin{aligned} \frac{T^5}{30} E(T) &\leq \int_0^T \theta[\langle f(u), u \rangle_{V', V} - \mathcal{F}(u)] dt \\ &+ \left( C_T + \frac{T^4}{32} \right) \int_0^T \|u'\|_H^2 dt + \frac{MT^4}{16\lambda_1} (E(0) - E(T)), \end{aligned}$$

which implies, together with (4.1),

$$\left( \frac{T^5}{30} + \frac{MT^4}{16\lambda_1} \right) E(T) \leq \left( C_T + \frac{T^4}{32} \right) \int_0^T \|u'\|_H^2 dt + \frac{MT^4}{16\lambda_1} E(0).$$

By (4.2) we get

$$\left( \frac{T^5}{30} + \frac{MT^4}{16\lambda_1} \right) E(T) \leq \frac{1}{m} \left( C_T + \frac{T^4}{32} \right) \int_0^T \langle Bu', u' \rangle_H dt + \frac{MT^4}{16\lambda_1} E(0).$$

By (2.6) this implies

$$\left( \frac{T^5}{30} + \frac{MT^4}{16\lambda_1} \right) E(T) \leq \frac{1}{m} \left( C_T + \frac{T^4}{32} \right) (E(0) - E(T)) + \frac{MT^4}{16\lambda_1} E(0),$$

and so

$$\left( \frac{T^5}{30} + \frac{C_T}{m} + \frac{T^4}{32m} + \frac{MT^4}{16\lambda_1} \right) E(T) \leq \left( \frac{C_T}{m} + \frac{T^4}{32m} + \frac{MT^4}{16\lambda_1} \right) E(0)$$

and (4.4) follows.  $\square$

*Remark 4.1.* Theorem 4.1 can be generalized to any interval  $[a, b]$ , obtaining

$$E_u(b) \leq \frac{1}{1 + \frac{T^3}{30} \frac{1}{\frac{4}{\lambda_1 m} + \frac{3T^2}{32m} + \frac{MT^2}{16\lambda_1}}} E_u(a)$$

with  $T = b - a$ . Indeed, in  $[a, b]$  take  $\theta(t) = (t - a)^2(b - t)^2$ ; then  $\theta'(t) = 2\sqrt{\theta}(b - 2t + a)$ , so that (4.5), (4.6), (4.7) are replaced by  $|\theta'(t)| \leq 2(b - a)\theta^{1/2}(t)$ ,  $\max_{[a, b]} \theta = \frac{(b-a)^4}{16}$ , and

$$\int_a^b \theta(t) dt = \int_0^T x^2(T - x)^2 dx = \frac{(b - a)^5}{30},$$

respectively, which are the same formal estimates, since  $b - a = T$ . Analogously, (4.8) is replaced by

$$E(a) - E(b) = \int_a^b \langle Bu', u' \rangle_H dt \geq 0.$$

Now multiply (2.1) by  $\theta u$  and integrate in  $[a, b]$ ; performing the same estimates as in the proof of Theorem 4.1, we get the desired result.

Theorem 4.1 is the essential tool for the following stability result, which can be proved by extending the method of Smith (see [21]) as already done in [7].

**THEOREM 4.2.** *Let  $(a_n, b_n)_n$  be a sequence of disjoint open intervals in  $(0, +\infty)$  with  $a_n \rightarrow +\infty$  and assume that (1.3), (1.4), (2.2), and (4.1) hold. Then for every  $(u_0, u_1) \in D(A^{1/2}) \times H$  the solution  $u$  of problem (2.1) is such that  $E_u(t) \rightarrow 0$  as  $t \rightarrow +\infty$ .*

*Proof.* The proof is now similar to the proof of [7, Theorem 3.2], since the main tool in this proof is an inequality of the type of (4.4) proved in Theorem 4.1. We sketch it for completeness.

Apply Theorem 4.1 in the form of Remark 4.1 in the interval  $(a_n, b_n)$  instead of the interval  $(0, T)$ , obtaining

$$(4.12) \quad E_u(b_n) \leq \frac{1}{1 + \frac{T_n^3}{30} \frac{1}{\frac{4}{\lambda_1 m_n} + \frac{3T_n^2}{32m_n} + \frac{M_n T_n^2}{16\lambda_1}}} E_u(a_n),$$

where we have set  $T_n = b_n - a_n$ .

Defining

$$k_n := \frac{m_n T_n^3}{128 + 3\lambda_1 T_n^2 + 2m_n M_n T_n^2} \quad \text{and} \quad c = \frac{16\lambda_1}{15},$$

(4.12) can be rewritten as

$$E_u(b_n) \leq \frac{1}{1 + ck_n} E_u(a_n).$$

Since  $E$  is nonincreasing, by iteration we get that for any  $n \in \mathbb{N}$ ,

$$E(a_{n+1}) \leq E(b_n) \leq \frac{1}{1 + ck_n} E_u(a_n) \leq E(a_0) \prod_{j=0}^n \frac{1}{1 + ck_j} \leq E(0) \prod_{j=0}^n \frac{1}{1 + ck_j}.$$

Since  $E$  is nonincreasing, Theorem 4.2 will be proved if we show that  $E(a_{n+1}) \rightarrow 0$  as  $n \rightarrow \infty$ ; therefore, let us show that

$$\prod_{j=0}^{\infty} \frac{1}{1 + ck_j} = 0, \quad \text{or equivalently,} \quad \sum_{j=0}^{\infty} \log \frac{1}{1 + ck_j} = -\infty.$$

This condition obviously holds if  $k_j \not\rightarrow 0$  as  $j \rightarrow \infty$ , while if  $k_j \rightarrow 0$ , it means that

$$\sum_{j=1}^{\infty} k_j = +\infty.$$

This last condition is equivalent to (1.4); indeed, if  $T_j^2(3\lambda_1 + 2m_j M_j) := T_j^2 c_j \geq 128$ , then  $k_j \geq \frac{1}{2c_j}$ , while if  $T_j^2 c_j \leq 128$ , then  $k_j \geq \frac{T_j^2}{2 \times 128}$ , concluding that

$$k_j \geq \frac{1}{2} m_j (b_j - a_j) \min \left( \frac{(b_j - a_j)^2}{128}, \frac{1}{\lambda_1 + 2m_j M_j} \right).$$

On the other hand,

$$k_j \leq m_j (b_j - a_j) \min \left( \frac{(b_j - a_j)^2}{128}, \frac{1}{\lambda_1 + 2m_j M_j} \right),$$

and the claim follows.  $\square$

### 5. Some concrete applications.

**5.1. The integrally positive case.** Consider again problem (1.1), where  $\Omega$  is a bounded domain of  $\mathbb{R}^N$ ,  $N \geq 1$ . First, let us briefly show that the set of solutions of (W) is weakly uniformly bounded in  $H_0^1(\Omega) \times L^2(\Omega)$  under the subcritical growth assumption on  $f$  of Theorem 3.2, even without any sign condition on  $f$ . Indeed, by Lemma 2.2, if  $u$  solves (E) with  $u(t_0) = u_0$  and  $u'(t_0) = u_1$  for some  $t_0 \geq 0$ , we get for  $t \geq t_0$ ,

$$E(t) \leq E(t_0) = \frac{1}{2}\|u_1\|_2^2 + \frac{1}{2}\|u_0\|_{H_0^1(\Omega)}^2 - \int_{\Omega} F(u_0) \, dx.$$

But

$$\int_{\Omega} |F(u_0)| \, dx \leq a \int_{\Omega} |u_0| \, dx + \frac{b}{p+1} \int_{\Omega} |u_0|^{p+1} \, dx,$$

and by (3.16) there exists  $S > 0$ ,

$$\int_{\Omega} |F(u_0)| \, dx \leq S \left( \|u_0\|_{H_0^1(\Omega)} + \|u_0\|_{H_0^1(\Omega)}^{p+1} \right).$$

Therefore, if  $\|u_0\|_{H_0^1(\Omega)} + \|u_1\|_2 \leq B_1$ , then

$$E(t_0) \leq \frac{B_1^2}{2} + S(B_1 + B_1^p) := B_2.$$

Hence for every  $t \geq t_0$ ,

$$\begin{aligned} \|u(t, t_0, u_0, u_1)\|_{H_0^1(\Omega)}^2 + \|u'(t, t_0, u_0, u_1)\|_2^2 \\ = 2E(t) + 2 \int_{\Omega} F(u) \, dx \leq 2E(t_0) = 2B_2; \end{aligned}$$

that is, Definition 3.1 is verified, as claimed, whatever  $t_0$  is.

Finally, we recall that the request that the set of solutions of (1.1) is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$  is not so strange. Several examples are considered in [22], and we refer to those cases therein for a sublinear  $f$ , simply recalling the following.

*Example 5.1* (see [22, Example 3.1]). Assume that  $f(s) = \alpha s$  for some constant  $\alpha < \lambda_1$ , where  $\lambda_1$  is the first eigenvalue of  $-\Delta$  on  $H_0^1(\Omega)$ . Then the set of solutions of (1.1) is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ .

Finally, we show that the set of solutions of (1.1) is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$  also in more general cases. This result appears in [22] for  $f$  having linear growth, under the additional assumptions that  $h$  is bounded above and below by strictly positive constants (though there is a mistake in the final step on page 198). We take the latter assumption, but we let  $f$  have superlinear growth. However, let us note that the growth condition we give on  $f$  immediately implies condition (3.1), which is therefore useless from now on.

**LEMMA 5.1.** *Suppose that  $N = 1$ , and that  $f$  is an absolutely continuous function satisfying (2.3) such that*

$$\exists b_1 > 0, p \in [1, \infty) : \quad |f'(s)| \leq b_1 |s|^{p-1} \quad \forall s \in \mathbb{R}.$$

Assume that there exist two positive constants  $\alpha < \beta$  such that  $\alpha \leq h(t) \leq \beta$  for any  $t \geq 0$ . Finally, assume that  $\forall P > 0$  there exists  $Q > 0$  such that  $\|Du\|_2 \leq P$  implies  $\|Df(u)\|_2 \leq Q\|Du\|_2$ . Then the set of solutions of (W) is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ .

*Proof.* First, let us note that the condition on  $f'$  implies that  $|f(s)| \leq b_2|s|^p$  for any  $s$ . Now take  $B_1 > 0$  and  $(u_0, u_1) \in H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$  such that  $\|\Delta u_0\|_2 + \|Du_1\|_2 \leq B_1$ ; take  $t_0 \geq 0$ , and observe that the growth condition on  $f$  and the Sobolev inequality immediately ensure that  $f(u) \in L^2(\Omega)$  for any  $t \geq t_0$ .

By Lemma 2.2 and Remark 2.3 we get, setting  $u(t) = u(t, t_0, u_0, u_1)$ ,

$$\begin{aligned} \|u'(t)\|_2^2 + \|Du(t)\|_2^2 &\leq 2E(t_0) + 2 \int_{\Omega} F(u(t)) dx \\ &\leq 2E(t_0) = \|u_1\|_2^2 + \|Du_0\|_2^2 - 2 \int_{\Omega} F(u_0) dx. \end{aligned}$$

By the Poincaré and Sobolev inequalities and the growth condition on  $f$ , we get

$$\|u_1\|_2^2 + \|Du_0\|_2^2 - 2 \int_{\Omega} F(u_0) dx \leq C \left( \|Du_1\|_2^2 + \|\Delta u_0\|_2^2 + \|u\|_1 + \|u\|_{p+1}^{p+1} \right).$$

Applying again the Poincaré and Sobolev inequalities, since  $\|\Delta u_0\|_2 + \|Du_1\|_2 \leq B_1$ , we get the existence of a constant  $B > 0$  such that

$$(5.1) \quad \|u'(t)\|_2^2 + \|Du(t)\|_2^2 \leq B \quad \forall t \geq t_0.$$

Now set

$$V(t) = \int_{\Omega} u(t)u'(t) dx.$$

Proceeding as in [22], we can find

$$V'(t) = \int_{\Omega} (u'(t)^2 + u''(t)u(t)) dx,$$

and using the equation in (1.1),

$$V'(t) = \int_{\Omega} u'(t)^2 dx - \int_{\Omega} |Du(t)|^2 dx - h(t) \int_{\Omega} u'(t)u(t) dx + \int_{\Omega} f(u(t))u(t) dx.$$

By (2.3) and the Hölder, Young, and Poincaré inequalities,

$$V'(t) \leq \left(1 + \frac{\beta^2}{2\varepsilon}\right) \int_{\Omega} u'(t)^2 dx + \left(\frac{\varepsilon}{2\lambda_1} - 1\right) \int_{\Omega} |Du(t)|^2 dx$$

for any  $\varepsilon > 0$ . Therefore

$$V(t) \leq V(t_0) + \left(1 + \frac{\beta^2}{2\varepsilon}\right) \int_{t_0}^t \|u'(\tau)\|_2^2 d\tau + \left(\frac{\varepsilon}{2\lambda_1} - 1\right) \int_{t_0}^t \|Du(\tau)\|_2^2 d\tau.$$

Choosing  $\varepsilon < 2\lambda_1$  we get the existence of a positive constant  $C$  such that

$$\int_{t_0}^t \|Du(\tau)\|_2^2 d\tau \leq C \left( V(t_0) + \int_{t_0}^t \|u'(\tau)\|_2^2 d\tau \right) - V(t) \quad \forall t \geq t_0.$$

But

$$|V(t)| \leq \|u'(t)\|_2 \|u(t)\|_2 \leq \frac{1}{\sqrt{\lambda_1}} \|u'(t)\|_2 \|Du(t)\|_2 \leq \frac{B}{\sqrt{\lambda_1}} \quad \forall t \geq t_0$$

by (5.1), so that

$$(5.2) \quad \int_{t_0}^t \|Du(\tau)\|_2^2 d\tau \leq C_1 \left( 1 + \int_{t_0}^t \|u'(\tau)\|_2^2 d\tau \right) \quad \forall t \geq t_0$$

for some positive constant  $C_1$ .

Using again Lemma 2.2 and Remark 2.3, we have

$$E(t) = E(t_0) - \int_{t_0}^t h(\tau) \|u'(\tau)\|_2^2 d\tau,$$

so that

$$\int_{t_0}^t \|u'(\tau)\|_2^2 d\tau \leq \frac{E(t_0)}{\alpha} \leq C_2 \quad \forall t \geq t_0$$

for some positive constant  $C_2$ . In this way (5.2) implies the existence of  $C_3 > 0$  such that

$$(5.3) \quad \int_{t_0}^t \|Du(\tau)\|_2^2 d\tau \leq C_3 \quad \forall t \geq t_0.$$

Finally, introduce

$$W(t) = \frac{1}{2} \int_{\Omega} |Du'(t)|^2 dx + \frac{1}{2} \int_{\Omega} |\Delta u(t)|^2 dx.$$

As in [22], we find

$$W(t) = W(t_0) - \int_{t_0}^t h(\tau) \|Du'(\tau)\|_2^2 d\tau + \int_{t_0}^t \int_{\Omega} Du'(\tau) \cdot Df(u(\tau)) dx d\tau,$$

so that by Cauchy's inequality,

$$W(t) \leq W(t_0) - \int_{t_0}^t h(\tau) \|Du'(\tau)\|_2^2 d\tau + \int_{t_0}^t \|Du'(\tau)\|_2 \|Df(u(\tau))\|_2 d\tau.$$

By Young's inequality, for any  $\varepsilon > 0$ ,

$$\begin{aligned} W(t) \leq & W(t_0) - \int_{t_0}^t h(\tau) \|Du'(\tau)\|_2^2 d\tau \\ & + \varepsilon \int_{t_0}^t \|Du'(\tau)\|_2^2 d\tau + \frac{1}{2\varepsilon} \int_{t_0}^t \|Df(u(\tau))\|_2^2 d\tau. \end{aligned}$$

By assumption on  $h$ , we finally get

$$W(t) \leq W(t_0) + (\varepsilon - \alpha) \int_{t_0}^t h(\tau) \|Du'(\tau)\|_2^2 d\tau + \frac{1}{2\varepsilon} \int_{t_0}^t \|Df(u(\tau))\|_2^2 d\tau.$$

Choosing  $\varepsilon < \alpha$  and recalling that  $\|\Delta u_0\|_2 + \|Du_1\|_2 \leq B_1$ , we get

$$(5.4) \quad W(t) \leq C + C \int_{t_0}^t \|Df(u(\tau))\|_2 d\tau \quad \forall t \geq t_0$$

for some positive constant  $C$ .

By assumption, taking  $P := \sqrt{B}$  in (5.1), from (5.4) we get

$$(5.5) \quad W(t) \leq C + CQ \int_{t_0}^t \|Du(\tau)\|_2^p d\tau \quad \forall t \geq t_0.$$

By (5.3) we find  $D > 0$  such that  $W(t) \leq D$  for any  $t$ ; i.e., the set of solutions is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ , as claimed.  $\square$

As a final application, Lemma 5.1 gives the following.

**PROPOSITION 5.1.** *Suppose that  $N = 1$ , and that  $f$  is an absolutely continuous function satisfying (2.3) such that*

$$\exists b_1 > 0, p \in [1, \infty) : \quad |f'(s)| \leq b_1 |s|^{p-1} \quad \forall s \in \mathbb{R}.$$

*Finally, assume that there exist two positive constants  $\alpha < \beta$  such that  $\alpha \leq h(t) \leq \beta$  for any  $t \geq 0$ . Then the set of solutions of (W) is uniformly bounded in  $H^2(\Omega) \cap H_0^1(\Omega) \times H_0^1(\Omega)$ .*

*Proof.* The only thing to prove is that for any  $P > 0$  there exists  $Q > 0$  such that  $\|Du\|_2 \leq P$  implies  $\|Df(u)\|_2 \leq Q$ . But this is just an application of Sobolev's and Poincaré's inequalities. Indeed, if  $\|Du\|_2 \leq P$ , then

$$\begin{aligned} \|Df(u)\|_2 &= \|f'(u)Du\|_2 \leq b_1 \| |u|^{p-1} Du \|_2 \\ &\leq C \|Du\|_2^p \leq CP^{p-1} \|Du\|_2 = Q \|Du\|_2, \end{aligned}$$

as soon as  $Q = CP^{p-1}$ . Now apply Lemma 5.1.  $\square$

Summing up, Theorems 3.1 and 3.2 and Proposition 5.1 imply the following final result.

**PROPOSITION 5.2.** *Assume  $N = 1$  and suppose that  $f$  is an absolutely continuous function satisfying (2.3) and such that*

$$\exists b_1 > 0, p \in [1, \infty) : \quad |f'(s)| \leq b_1 |s|^{p-1} \quad \forall s \in \mathbb{R}.$$

*Moreover, assume that there exist two positive constants  $\alpha < \beta$  such that  $\alpha \leq h(t) \leq \beta$  for any  $t \geq 0$ . Then every solution of (1.1) satisfies*

$$\|u\|_{H_0^1(\Omega)} + \|u'\|_{L^2(\Omega)} \rightarrow 0 \quad \text{as } t \rightarrow +\infty$$

*if and only if (1.2) holds.*

We end up with the following.

**Remark 5.1.** If  $h(t) \geq \alpha > 0 \forall t \geq 0$ , as in the previous cases, it is easily seen that  $h$  is integrally positive, and if  $h(t) \equiv \alpha > 0$ , then also (1.2) holds. A more interesting example is given by the periodic function  $h(t) = |\sin t|$ , which also satisfies (1.2); indeed, denoting again the integer part of a real number  $x$  by  $[x]$ , we have

$$2\frac{t}{\pi} - 2 \leq 2\left[\frac{t}{\pi}\right] \leq H(t) = \int_0^{\left[\frac{t}{\pi}\right]\pi} |\sin s| ds + \int_{\left[\frac{t}{\pi}\right]\pi}^t |\sin s| ds \leq 2\left[\frac{t}{\pi}\right] + 2 \leq 2\frac{t}{\pi} + 2,$$

so that  $\int_0^t e^{H(s)} ds \geq \frac{\pi}{2}(e^{2t/\pi-2} - e^{-2})$  and

$$\int_0^\tau e^{-H(t)} \int_0^t e^{H(s)} ds dt \geq \frac{\pi}{2} \int_0^\tau (e^{-4} - e^{-2t/\pi-4}) dt \rightarrow \infty$$

as  $\tau \rightarrow \infty$ , so that (1.2) holds.

**5.2. The on-off case.** A particular case of the abstract problem considered in section 4 is the following nonlinear wave system in a bounded domain  $\Omega$  of  $\mathbb{R}^N$ ,  $N \geq 1$ :

$$(\widetilde{W}) \quad \begin{cases} u_{tt} = \Delta u - h(t)g(u_t) + f(u) & \text{in } (0, +\infty) \times \Omega, \\ u(t, x) = 0 & \text{in } (0, +\infty) \times \partial\Omega, \\ u(0, x) = u_0(x), \quad u_t(0, x) = u_1(x), & x \in \Omega, \end{cases}$$

where the following assumptions are made:

$$(A) \quad \begin{cases} g : \mathbb{R} \longrightarrow \mathbb{R} \text{ is a } C^1 \text{ function with } g(0) = 0, \\ \exists B \geq A > 0 \text{ such that } 0 < A \leq g'(v) \leq B \quad \forall v \in \mathbb{R}, \\ f \text{ satisfies (2.4),} \end{cases}$$

while  $u_0 \in H_0^1(\Omega)$  and  $u_1 \in L^2(\Omega)$ .

In this case Theorem 4.1 can be easily generalized as follows.

**THEOREM 5.1.** *Fix  $T > 0$  and assume there exist  $M, m > 0$  such that*

$$(5.6) \quad 0 < m \leq h(t) \leq M \quad \forall t \in [0, T].$$

*Suppose (A) holds. Then for every  $(u_0, u_1) \in H_0^1(\Omega) \times L^2(\Omega)$  the solution  $u$  of problem  $(\widetilde{W})$  satisfies*

$$E(T) \leq \frac{1}{1 + \frac{T^3}{30} \frac{1}{\frac{4}{\lambda_1} + \frac{3T^2}{32m} + \frac{MT^2}{16\lambda_1}}} E(0).$$

In the same way as Theorem 4.2 is implied by Theorem 4.1, Theorem 5.1 immediately gives the following fundamental application.

**THEOREM 5.2.** *Let  $(a_n, b_n)_n$  be a sequence of disjoint open intervals in  $(0, +\infty)$  with  $a_n \rightarrow +\infty$  and assume that (1.3), (1.4), and (A) hold. Then for every  $(u_0, u_1) \in H_0^1(\Omega) \times L^2(\Omega)$  the solution  $u$  of problem  $(\widetilde{W})$  is such that  $E_u(t) \rightarrow 0$  as  $t \rightarrow +\infty$ .*

Of course the abstract setting we gave in section 2 lets us deal with higher order problems. Indeed, consider the problem

$$(H) \quad \begin{cases} u_{tt} = \Delta^{2m} u - h(t)g(u_t) + f(u) & \text{in } (0, +\infty) \times \Omega, \\ Cu(t, x) = 0 \in \mathbb{R}^{2m} & \text{in } (0, +\infty) \times \partial\Omega, \\ u(0, x) = u_0(x) \in D(\Delta^m), \quad u_t(0, x) = u_1(x), & x \in \Omega, \end{cases}$$

where  $m \in \mathbb{N}$ ,  $g$  is as before, and  $C$  is a boundary operator. For example, if  $m = 1$  and  $Cu = (u, \partial u / \partial \nu)$ ,  $\nu$  being the unit outward normal to  $\partial\Omega$ , we have  $D(\Delta^m) = H_0^2(\Omega)$ , while, in the case  $Cu = (u, \Delta u)$  we have  $D(\Delta^m) = H_0^1(\Omega) \cap H^2(\Omega)$ . Other generalizations are easy to do. For this case we have the following.

**THEOREM 5.3.** *Let  $(a_n, b_n)_n$  be a sequence of disjoint open intervals in  $(0, +\infty)$  with  $a_n \rightarrow +\infty$  and assume that (1.3), (1.4), and (2.4) hold. Then for every  $(u_0, u_1) \in D(\Delta^m) \times L^2(\Omega)$  the solution  $u$  of problem (H) is such that  $E_u(t) \rightarrow 0$  as  $t \rightarrow +\infty$ .*

**Acknowledgments.** The authors wish to thank Prof. Hatvani for some interesting discussions on this subject and for bringing [22] to their attention.

## STOCHASTIC DYNAMIC OPTIMIZATION WITH DISCOUNTED STOCHASTIC DOMINANCE CONSTRAINTS\*

DARINKA DENTCHEVA<sup>†</sup> AND ANDRZEJ RUSZCZYŃSKI<sup>‡</sup>

**Abstract.** We introduce a stochastic dynamic optimization problem, where risk aversion is expressed by a stochastic ordering constraint. The constraint requires that a random reward sequence depending on our decisions dominates a given benchmark random sequence. The dominance is defined by discounting both processes with a family of discount sequences, and by applying a univariate order. We describe the generator of this order. We develop necessary and sufficient conditions of optimality for convex stochastic control problems with the new ordering constraint, and we derive an equivalent control problem featuring implied utility functions. Furthermore, we prove the existence of an optimal random discount sequence such that the solution of the risk averse problem is also a solution of an expected value problem with this discount. Finally, we derive a version of the maximum principle for the problem with discounted dominance constraints.

**1. Introduction.** In our earlier publications [5, 6], we have introduced and analyzed the following optimization model with stochastic dominance constraints:

$$\begin{aligned} (1.1) \quad & \max \mathbb{E}[H(z)] \\ (1.2) \quad & \text{s.t. } G(z) \succeq_{(2)} Y, \\ (1.3) \quad & z \in Z_0. \end{aligned}$$

In this problem  $Z_0$  is a convex closed subset of a Banach space  $\mathcal{Z}$ , and  $G$  and  $H$  are continuous operators from  $\mathcal{Z}$  to the space of integrable random variables  $\mathcal{L}_1(\Omega, \mathcal{F}, P)$ . The random variable  $Y$  plays the role of a benchmark outcome. For example, one may set  $Y = G(\bar{z})$ , where  $\bar{z} \in Z_0$  is some reasonable value of the decision vector, which is currently employed in the system.

The relation  $\succeq_{(2)}$  used in (1.2) is the *stochastic dominance* relation of the second order. It is defined as follows: A random variable  $X$  *dominates* another random variable  $Y$  in the second order if

$$(1.4) \quad \mathbb{E}[u(X)] \geq \mathbb{E}[u(Y)]$$

for every concave nondecreasing function  $u(\cdot)$ , for which these expected values are finite. The relation  $\succeq_{(2)}$  is also called an *increasing concave order* (see [24, 33] and

the references therein). This relation is used in economics for comparing random outcomes.

Model (1.1)–(1.3) is a convenient way to express risk-aversion in a stochastic optimization problem. It has recently been applied to electricity market models in [2] and to financial optimization in [7]. Also, the idea of a stochastic ordering constraint has been recently borrowed by [10].

Our objective in this paper is to extend our model (1.1)–(1.3) to a dynamic setting, with  $G(z)$  representing a random sequence, rather than a scalar random variable. We are interested in modeling risk aversion in a stochastic control problem for a discrete-time linear dynamic system governed by the equations

$$s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T.$$

Here  $s_t$  denotes the state vector at time  $t$  and  $v_t$  denotes the control vector. The vectors  $e_t$  and the matrices  $A_t$  and  $B_t$  are random. The initial state  $s_1$  is given.

Assume that on the probability space  $(\Omega, \mathcal{F}, P)$  we have a filtration  $\mathcal{F}_1 \subset \mathcal{F}_2 \subset \dots \subset \mathcal{F}_{T+1}$ , with  $\mathcal{F}_1 = \{\emptyset, \Omega\}$  and  $\mathcal{F}_{T+1} = \mathcal{F}$ . The  $\sigma$ -field  $\mathcal{F}_t$  is generated by the information available at time  $t$ , when control  $v_t$  is chosen. We assume that  $e_t \in \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_{t+1}, P)$ ,  $v_t \in \mathcal{L}_p^{n_v}(\Omega, \mathcal{F}_t, P)$ ,  $s_t \in \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_t, P)$ , with some  $p \in [1, \infty)$ . The matrices  $A_t$  and  $B_t$  are elements of spaces of matrices of appropriate dimensions, which are measurable with respect to  $\mathcal{F}_t$  and essentially bounded. The standard symbol  $\mathcal{L}_p^m(\Omega, \mathcal{F}, P)$  denotes the space of all  $\mathcal{F}$ -integrable mappings  $X : \Omega \rightarrow \mathbb{R}^m$ , for which  $\mathbb{E}\|X\|^p < \infty$ . If the values are taken in  $\mathbb{R}$ , then the superscript  $m$  is omitted.

Specific conditions impose additional constraints on our actions:  $v_t \in V_t$ ,  $P$ -a.s., where each  $V_t$  is a convex closed set in  $\mathbb{R}^{n_v}$ .

Assume that the random outcomes  $X_t$ , representing the performance measures of the system at  $t = 1, \dots, T+1$ , are scalar and given by

$$(1.5) \quad \begin{aligned} X_t(\omega) &= g_t(s_t(\omega), v_t(\omega)), \quad \text{for } t = 1, \dots, T, \\ X_{T+1}(\omega) &= g_{T+1}(s_{T+1}(\omega)), \quad \omega \in \Omega. \end{aligned}$$

The functions  $g_t : \mathbb{R}^{n_s} \times \mathbb{R}^{n_v} \rightarrow \mathbb{R}$  are concave and satisfy the growth condition

$$|g_t(s, v)| \leq C_1 + C_2(\|s\|^p + \|v\|^p),$$

with some constants  $C_1$  and  $C_2$ . If  $p = 1$ , then this condition (for concave functions) amounts to global Lipschitz continuity.

We adopt the convention that larger values of  $X_t$  are preferred; for example,  $X_t$  may represent profits at time  $t$ .

Relations (1.5) define mappings  $G_t : \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_t, P) \times \mathcal{L}_p^{n_v}(\Omega, \mathcal{F}_t, P) \rightarrow \mathcal{L}_1(\Omega, \mathcal{F}_t, P)$ ,  $t = 1, \dots, T$ , and  $G_{T+1} : \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_{T+1}, P) \rightarrow \mathcal{L}_1(\Omega, \mathcal{F}_{T+1}, P)$ , in the following way:

$$\begin{aligned} [G_t(s_t, v_t)](\omega) &= g_t(s_t(\omega), v_t(\omega)), \quad t = 1, \dots, T, \\ [G_{T+1}(s_{T+1})](\omega) &= g_{T+1}(s_{T+1}(\omega)), \quad \omega \in \Omega. \end{aligned}$$

We write  $G(s, v) = (G_1(s_1, v_1), \dots, G_T(s_T, v_T), G_{T+1}(s_{T+1}))$ . Here  $s = (s_1, \dots, s_{T+1})$  and  $v = (v_1, \dots, v_T)$  represent the variables of our problem.

In the simplest formulation of the problem the objective functional is just the expected value; the problem reads

$$(1.6) \quad \begin{aligned} & \max \sum_{t=1}^T \mathbb{E} G_t(s_t, v_t) + \mathbb{E} G_{T+1}(s_{T+1}) \\ & \text{s.t. } s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T, \\ & \quad v_t \in V_t \text{ a.s., } \quad t = 1, \dots, T. \end{aligned}$$

Owing to the growth condition on  $g_t(\cdot, \cdot)$ , the objective functional is finite and continuous everywhere.

Our goal is to model risk aversion in this problem by using stochastic orders. To this end we compare the multivariate distribution of the rewards  $(X_1, X_2, \dots, X_{T+1})$  with the distribution of some benchmark outcomes  $(Y_1, Y_2, \dots, Y_{T+1})$ . We shall add to the problem formulation an appropriate stochastic ordering constraint

$$(1.7) \quad (X_1, X_2, \dots, X_{T+1}) \succeq (Y_1, Y_2, \dots, Y_{T+1}).$$

In section 2 we specify the multivariate stochastic ordering constraint (1.7) as a discounted stochastic dominance and construct a generator of this order. In section 3 we introduce and analyze a control problem with the discounted stochastic dominance constraint and develop necessary and sufficient conditions of optimality by deriving an equivalent formulation featuring implied utility functions. These results refine and generalize to the dynamic case the optimality conditions obtained in [5, 6, 8]. In section 4, we derive the existence of random discount factors in the necessary conditions of optimality. Finally, in section 5 we prove a version of the maximum principle for our model.

Let us introduce some notation used throughout this paper. The space of continuous functions on a compact set  $D \subset \mathbb{R}^n$  is denoted  $\mathcal{C}(D)$ . The space of regular countably additive measures on a compact set  $D \subset \mathbb{R}^n$  having finite variation is denoted  $\mathcal{M}(D)$ ; its subset of nonnegative measures is denoted by  $\mathcal{M}_+(D)$ . For a Banach space  $\mathcal{Z}$  we denote its topological dual by  $\mathcal{Z}^*$ . We denote the space of the random outcomes by  $\mathcal{X} = \mathcal{L}_1(\Omega, \mathcal{F}_1, P) \times \dots \times \mathcal{L}_1(\Omega, \mathcal{F}_{T+1}, P)$ . Its dual is  $\mathcal{X}^* = \mathcal{L}_\infty(\Omega, \mathcal{F}_1, P) \times \dots \times \mathcal{L}_\infty(\Omega, \mathcal{F}_{T+1}, P)$ .

**2. Stochastic dominance for random reward sequences.** The notion of stochastic ordering for scalar random variables (or *stochastic dominance of first order*) has been introduced in statistics in [20, 17] and further applied and developed in economics [26, 11, 12]. It is defined as follows. For a random variable  $X$  we consider its distribution function,  $F(X; \eta) = P[X \leq \eta]$ ,  $\eta \in \mathbb{R}$ . We say that a random variable  $X$  *dominates in the first order* a random variable  $Y$  if

$$(2.1) \quad F(X; \eta) \leq F(Y; \eta) \quad \text{for all } \eta \in \mathbb{R}.$$

We denote this relation by  $X \succeq_{(1)} Y$ . We refer the reader to [21, 24, 33, 35] for a detailed treatment of stochastic ordering.

Consider a scalar random variable  $X \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$  and define the function

$$(2.2) \quad F_2(X; \eta) = \int_{-\infty}^{\eta} F(X; \alpha) d\alpha \quad \text{for } \eta \in \mathbb{R}.$$

As an integral of a nondecreasing function, it is a convex function of  $\eta$ .

DEFINITION 2.1. A random variable  $X \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$  dominates in the second order another random variable  $Y \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$  if

$$(2.3) \quad F_2(X; \eta) \leq F_2(Y; \eta) \quad \text{for all } \eta \in \mathbb{R}.$$

We denote relation (2.3) by  $X \succeq_{(2)} Y$ . In a similar way, we can define higher order dominance relations (see [24]).

The stochastic dominance relation  $\succeq_{(2)}$  introduces a preorder among integrable random variables (see, e.g., [21] and the references therein). Partial orders appear in abstract optimization problems when the values of the objective operator are elements of a topological vector space (see, e.g., [19]). It is usually assumed that the partial order is generated by a convex cone. The stochastic dominance relations in  $\mathcal{L}_1(\Omega, \mathcal{F}, P)$  are not generated by cones in this space therefore we cannot follow the theory in the spirit of [19].

Changing the order of integration in (2.2), we get (see, e.g., [25])

$$(2.4) \quad F_2(X; \eta) = \mathbb{E}[(\eta - X)_+].$$

Therefore, an equivalent representation of the second order stochastic dominance relation is

$$(2.5) \quad \mathbb{E}[(\eta - X)_+] \leq \mathbb{E}[(\eta - Y)_+] \quad \text{for all } \eta \in \mathbb{R}.$$

Let us consider the set  $\mathcal{U}$  of concave nondecreasing functions  $u : \mathbb{R} \rightarrow \mathbb{R}$  satisfying the following conditions:

$$(2.6) \quad \begin{aligned} \lim_{t \rightarrow -\infty} u(t)/t &< \infty, \\ \lim_{t \rightarrow \infty} u(t) &= 0. \end{aligned}$$

With every  $u \in \mathcal{U}$  we can associate a measure  $\nu$  on  $\mathbb{R}$  as follows:  $\nu([\tau, \infty)) = u'_-(\tau)$ , where  $u'_-$  is the left derivative of  $u$ . We can represent  $u(t)$  as follows:

$$(2.7) \quad \begin{aligned} u(t) &= - \int_t^\infty u'_-(\tau) d\tau = - \int_t^\infty \nu([\tau, \infty)) d\tau \\ &= - \int_t^\infty \int_\tau^\infty \nu(d\eta) d\tau = - \int_t^\infty \int_t^\eta d\tau \nu(d\eta) \\ &= - \int_t^\infty (\eta - t) \nu(d\eta) = - \int_{-\infty}^\infty \max(0, \eta - t) \nu(d\eta). \end{aligned}$$

By (2.6), for every random variable  $X \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$  and for every  $u \in \mathcal{U}$  the quantity

$$\mathbb{E}[u(X)] = \int u(X(\omega)) P(d\omega)$$

is well defined and finite. The following fact is well known in the theory of stochastic dominance.

PROPOSITION 2.2. For each  $X, Y \in \mathcal{L}_1(\Omega, \mathcal{F}, P)$  the relation  $X \succeq_{(2)} Y$  is equivalent to

$$(2.8) \quad \mathbb{E}[u(X)] \geq \mathbb{E}[u(Y)] \quad \text{for all } u \in \mathcal{U}.$$

Consider random vectors  $(X_1, \dots, X_{T+1})$  and  $(Y_1, \dots, Y_{T+1})$  in  $\mathcal{L}_1^{T+1}(\Omega, \mathcal{F}, P)$ . The simplest way to define a stochastic ordering relation  $X \succeq_{(2)}^{\text{sep}} Y$  between these vectors, is to require the stochastic dominance relation for each coordinate

$$(2.9) \quad X_t \succeq_{(2)} Y_t, \quad t = 1, \dots, T+1.$$

The analysis in our earlier paper [6] includes this case. This approach, however, ignores the temporal structure and the dependency between the coordinates of the vector  $(X_1, \dots, X_{T+1})$ .

Therefore, we are taking a different approach, by considering discounted sums of the rewards,  $\sum_{t=1}^{T+1} \varrho_t X_t$ , and the corresponding discounted sums of the benchmark  $\sum_{t=1}^{T+1} \varrho_t Y_t$ . The sequence of discount factors  $\{\varrho_t\}$  is assumed to belong to a compact set  $D$ , where

$$D \subseteq \{\varrho \in \mathbb{R}^{T+1} : 1 \geq \varrho_1 \geq \varrho_2 \geq \dots \geq \varrho_{T+1} \geq 0\}.$$

DEFINITION 2.3. A random sequence  $(X_1, \dots, X_{T+1}) \in \mathcal{X}$  dominates a random sequence  $(Y_1, \dots, Y_{T+1}) \in \mathcal{X}$  in the discounted second order, if for all  $\varrho \in D$  the relation

$$(2.10) \quad \sum_{t=1}^{T+1} \varrho_t X_t \succeq_{(2)} \sum_{t=1}^{T+1} \varrho_t Y_t$$

is satisfied.

We denote this relation by  $X \succeq_{(2)}^D Y$ .

The example below shows that the discounted order  $\succeq_{(2)}^D$  neither implies nor is implied by the coordinate order (2.9).

Example 1. Consider the special case with finite set  $D$ , consisting of  $T+1$  elements  $\varrho^k$ ,  $k = 1, \dots, T+1$ , with

$$(2.11) \quad \varrho_t^k = \begin{cases} 1 & \text{if } t \leq k, \\ 0 & \text{if } t > k. \end{cases}$$

Then the relation  $X \succeq_{(2)}^D Y$  is equivalent to the following system of dominance relations:

$$(2.12) \quad \sum_{t=1}^k X_t \succeq_{(2)} \sum_{t=1}^k Y_t, \quad k = 1, \dots, T+1.$$

Consider now three random sequences:  $X$ ,  $Y$ , and  $Z$ , and let  $\varepsilon > 0$ . The sequence  $Y$  has i.i.d. components  $Y_t$ ,  $t = 1, \dots, T$  with expected value  $\mu$  and variance  $\sigma^2$ , the sequence  $X$  has components  $X_t = Y_1 + \varepsilon$ ,  $t = 1, \dots, T$ , where  $\varepsilon > 0$ , and the sequence  $Z$  has components  $Z_1 = Y_1 + \varepsilon$ ,  $Z_2 = Y_2 - \varepsilon$ ,  $Z_t = Y_t$ ,  $t = 3, \dots, T$ .

It is obvious that  $X_t \succeq_{(2)} Y_t$ ,  $t = 1, \dots, T$ . However,  $X \not\succeq_{(2)}^D Y$ , if  $F_2(Y_1; \mu - \varepsilon) > 0$ , and  $T$  is large enough. Indeed, for every  $k$  we have to verify relation (2.12). As

the second order stochastic dominance relation is preserved under multiplication by positive constants, we need to compare

$$Y_1 + \varepsilon \quad \text{and} \quad \frac{1}{k} \sum_{t=1}^k Y_t.$$

At  $\eta = \mu$  we have

$$F_2 \left( \frac{1}{k} \sum_{t=1}^k X_t; \mu \right) = \mathbb{E} \left[ (\mu - Y_1 - \varepsilon)_+ \right] = F_2(Y_1; \mu - \varepsilon) > 0.$$

On the other hand, by the central limit theorem

$$\lim_{k \rightarrow \infty} F_2 \left( \frac{1}{k} \sum_{t=1}^k Y_t; \mu \right) = \mathbb{E} \left[ \left( \mu - \frac{1}{k} \sum_{t=1}^k Y_t \right)_+ \right] = 0.$$

Therefore, for  $T$  and  $k$  large enough, we shall have

$$\sum_{t=1}^k X_t \not\prec_{(2)} \sum_{t=1}^k Y_t.$$

Consider now the sequences  $Z$  and  $Y$ . Clearly,  $Z_2 \not\prec_{(2)} Y_2$ . However, directly from (2.12) we see that  $Z \succeq_{(2)}^D Y$ .

Suppose, for simplicity, that all  $Y_t$  are normal, and let the sequence  $W$  have components  $W_1 = \mu + \alpha(Y_1 - \mu)$ ,  $W_2 = \mu + \beta(Y_2 - \mu)$ ,  $W_t = Y_t$ ,  $t = 3, \dots, T$ , where  $\alpha \in (0, 1)$ ,  $\beta \in (1, \sqrt{2 - \alpha^2})$ . Again, it is easy to see that  $W_2 \not\prec_{(2)} Y_2$ , since  $W_2$  and  $Y_2$  have equal expected values, but  $W_2$  has a larger variance than  $Y_2$ . Still, we can verify (2.12) under the specified assumptions, and establish that  $W \succeq_{(2)}^D Y$ .

In fact, the relations  $Z \succeq_{(2)}^D Y$  and  $W \succeq_{(2)}^D Y$  hold true for every set  $D$  such that  $q_1$  is bounded from below. This concludes the example.

A very special case occurs when  $D = \{(1, 1, \dots, 1)\}$ . In this case we are interested in the total terminal wealth and require that it dominates (in the second order) some benchmark wealth distribution. The information about the whole process  $Y$  is irrelevant in this case, only the distribution of the sum  $Y_1 + \dots + Y_{T+1}$  matters.

The question of orderings of linear or positive combinations of random vectors was investigated in several earlier publications [23, 22, 32]. One approach to defining a multivariate stochastic order is to specify its generator. This approach is adopted in [23], where further conditions are specified under which linear combinations of the vector components are related via a univariate order. In [23], the concept of a directional convex order for random vectors is introduced, by specifying that the generator contains all directionally convex functions. The directional convex order of two vectors implies a convex order of nonnegative linear combinations of the components of the vectors. In a similar way one can also derive a directional concave *nondecreasing* order, which will imply stochastic dominance of nonnegative linear combinations. Our approach is different: we define the order by requiring stochastic dominance of nonnegative combinations and then we derive its generator.

Example 1 shows that the coordinate order  $X_i \succeq_{(2)} Y_i$ ,  $i = 1, \dots, n$ , does not carry over to the multivariate order  $X \succeq_{(2)}^D Y$ . The directional convex order is implied by the coordinate order if both vectors have a common copula of a certain type

(see [23]). A similar implication holds true for our order  $\succeq_{(2)}^D$  if we know that all random reward vectors occurring in our optimization problem have a common copula (of this type) with the benchmark. In this case, we would be able to replace the multivariate dominance constraint by univariate constraints for the marginals. This would allow solving the problem by the techniques of [5, 6]. Unfortunately, imposing a constraint on a copula in an optimization problem appears to be difficult. Without that, constraints on the marginals are insufficient.

Inverse versions of multivariate orders (based on generalizations of the Lorenz curve) were analyzed in [1, 15, 16].

For brevity we write

$$\langle \varrho, X \rangle = \sum_{t=1}^{T+1} \varrho_t X_t.$$

By virtue of Proposition 2.2 we obtain the following relation:

$$(2.13) \quad \mathbb{E}[u(\langle \varrho, X \rangle)] \geq \mathbb{E}[u(\langle \varrho, Y \rangle)] \quad \text{for all } u \in \mathcal{U} \text{ and all } \varrho \in D.$$

Using (2.7), we conclude that for every nonnegative measure  $\nu$  on  $\mathbb{R}$  and for every  $\varrho \in D$

$$\int_{\Omega} \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, X(\omega) \rangle) \nu(d\eta) P(d\omega) \leq \int_{\Omega} \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, Y(\omega) \rangle) \nu(d\eta) P(d\omega).$$

For every  $\lambda \in \mathcal{M}_+(\mathbb{R} \times D)$  we define a concave nondecreasing function  $\varphi_{\lambda} : \mathbb{R}^{T+1} \rightarrow \mathbb{R}$  as follows:

$$\varphi_{\lambda}(x) = - \int_{\mathbb{R} \times D} \max(0, \eta - \langle \varrho, x \rangle) \lambda(d\eta, d\varrho).$$

We now show that the class of functions

$$\Phi = \{\varphi_{\lambda} : \lambda \in \mathcal{M}_+(\mathbb{R} \times D)\}$$

is a generator of the order  $\succeq_{(2)}^D$ .

PROPOSITION 2.4. *For each  $X, Y \in \mathcal{X}$  the relation  $X \succeq_{(2)}^D Y$  is equivalent to*

$$(2.14) \quad \mathbb{E}[\varphi(X)] \geq \mathbb{E}[\varphi(Y)] \quad \text{for all } \varphi \in \Phi.$$

*Proof.* Assume  $X \succeq_{(2)}^D Y$ . Take any  $\lambda \in \mathcal{M}_+(\mathbb{R} \times D)$ . We shall show inequality (2.14) for  $\varphi_{\lambda}$ . Let  $\lambda_{\varrho}$  be the conditional measure of  $\lambda$  on  $\mathbb{R}$ , for  $\varrho \in D$  (see, e.g., [9, Theorem 10.2.2]). Denote by  $\mu$  the marginal measure of  $\lambda$  on  $D$ . The integral over  $\mathbb{R} \times D$  can be written as an iterated integral (see, e.g., [9, Theorem 10.21])

$$\varphi_{\lambda}(x) = - \int_D \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, x \rangle) \lambda_{\varrho}(d\eta) \mu(d\varrho).$$

From the definition of  $\succeq_{(2)}^D$  and (2.13) it follows that

$$\int_{\Omega} \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, X(\omega) \rangle) \lambda_{\varrho}(d\eta) P(d\omega) \leq \int_{\Omega} \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, Y(\omega) \rangle) \lambda_{\varrho}(d\eta) P(d\omega).$$

Integrating with the measure  $\mu$  and changing the order of integration, we obtain

$$\begin{aligned}\mathbb{E}[\varphi_\lambda(X)] &= - \int_{\Omega} \int_D \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, X(\omega) \rangle) \lambda_{\varrho}(d\eta) \mu(d\varrho) P(d\omega) \\ &\geq - \int_{\Omega} \int_D \int_{\mathbb{R}} \max(0, \eta - \langle \varrho, Y(\omega) \rangle) \lambda_{\varrho}(d\eta) \mu(d\varrho) P(d\omega) = \mathbb{E}[\varphi_\lambda(Y)],\end{aligned}$$

as required. To prove the converse, we observe that we can choose measures  $\lambda$  such that their marginal measures  $\mu$  on  $D$  are atomic. The last displayed inequality becomes equivalent to the inequality in (2.13). The latter is equivalent to the definition of the order  $\succeq_{(2)}^D$ .  $\square$

It is clear from our analysis that an order can be defined using any compact set  $D \subset \mathbb{R}_+^{T+1}$ , and the generator of this order will have the form specified in Proposition 2.4. However, discounting of future rewards is a standard approach in stochastic control and in the practice of finance, and this is the reason for requiring the monotonicity of the sequences  $\varrho$  included in  $D$ .

Another way to characterize the relation  $\succeq_{(2)}^D$  is to use the integrated distribution functions. From (2.3) we obtain the equivalent characterization:

$$(2.15) \quad F_2(\langle \varrho, X \rangle; \eta) \leq F_2(\langle \varrho, Y \rangle; \eta) \quad \text{for all } \varrho \in D \text{ and all } \eta \in \mathbb{R}.$$

**3. Optimality conditions. The implied utility functions.** We introduce the following stochastic dynamic optimization problem with discounted dominance constraints:

$$\begin{aligned}(3.1) \quad & \max \sum_{t=1}^T \mathbb{E}G_t(s_t, v_t) + \mathbb{E}G_{T+1}(s_{T+1}) \\ & \text{s.t. } s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T, \\ & (G_1(s_1, v_1), \dots, G_T(s_T, v_T), G_{T+1}(s_{T+1})) \succeq_{(2)}^D (Y_1, \dots, Y_T, Y_{T+1}) \\ & v_t \in V_t \text{ a.s., } \quad t = 1, \dots, T.\end{aligned}$$

Define the space of controls  $(v_1, \dots, v_T)$  by  $\mathcal{V} = \mathcal{L}_p^{n_v}(\Omega, \mathcal{F}_1, P) \times \dots \times \mathcal{L}_p^{n_v}(\Omega, \mathcal{F}_T, P)$ . The space of state trajectories  $(s_2, \dots, s_{T+1})$  is denoted by  $\mathcal{S} = \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_2, P) \times \dots \times \mathcal{L}_p^{n_s}(\Omega, \mathcal{F}_{T+1}, P)$ .

The relation  $X \succeq_{(2)}^D Y$  can be equivalently formulated as (2.15). For technical reasons, which will become apparent later, we restrict the range of  $\eta \in \mathbb{R}$ , for which we impose (2.15), to an interval  $[a, b]$ . This slightly changes the generator of the relation, which will be discussed in due course. We relax problem (3.1) to the following:

$$\begin{aligned}(3.2) \quad & \max \sum_{t=1}^T \mathbb{E}G_t(s_t, v_t) + \mathbb{E}G_{T+1}(s_{T+1}) \\ (3.3) \quad & \text{s.t. } s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T, \\ (3.4) \quad & F_2(\langle \varrho, G(s, v) \rangle; \eta) \leq F_2(\langle \varrho, Y \rangle; \eta) \text{ for all } \varrho \in D \text{ and all } \eta \in [a, b], \\ (3.5) \quad & v_t \in V_t \text{ a.s., } \quad t = 1, \dots, T.\end{aligned}$$

If all  $G_t(s_t, v_t)$  have uniformly bounded distributions, (3.4) is equivalent to  $X \succeq_{(2)}^D Y$  for appropriately chosen  $a$  and  $b$ . However, if the distributions are not uniformly bounded, (3.4) is a relaxation of the relation  $X \succeq_{(2)}^D Y$ . This means that every feasible solution of problem (3.1) is also feasible for (3.2)–(3.5), but not necessarily the other way around. Even with this relaxation the problem remains very difficult. In the very special case when  $a = b$ , problem (3.2)–(3.5) is still much more difficult than an expected value problem. Observe that if  $D = \{(1, \dots, 1)\}$ , constraint (3.4) is a conditional value at risk constraint for the cumulative wealth.

We define the set  $\mathcal{U}([a, b])$  of functions  $u(\cdot)$  satisfying the following conditions:

$u(\cdot)$  is concave and nondecreasing;

$u(t) = 0$  for all  $t \geq b$ ;

$u(t) = u(a) + \gamma(t - a)$  for all  $t \leq a$ , where  $\gamma > 0$ .

It is evident that  $\mathcal{U}([a, b])$  is a convex cone. Moreover, the subgradients of each function  $u \in \mathcal{U}([a, b])$  are bounded for all  $t \in \mathbb{R}$ .

Define the class of functions

$$\Phi([a, b], D) = \{\varphi_\lambda : \lambda \in \mathcal{M}_+([a, b] \times D)\},$$

where

$$\varphi_\lambda(x) = - \int_{[a, b] \times D} \max(0, \eta - \langle \varrho, x \rangle) \lambda(d\eta, d\varrho).$$

By exactly the same argument as Proposition 2.4 we obtain the following observation.

**PROPOSITION 3.1.** *The set  $\Phi([a, b], D)$  is a generator of the order (3.4).*

We introduce the functional  $L : \mathcal{S} \times \mathcal{V} \times \Phi([a, b], D) \rightarrow \mathbb{R}$ , which plays the role of a partial Lagrangian associated with problem (3.2)–(3.5):

$$\begin{aligned} L(s, v, \varphi) = \mathbb{E} & \left[ \sum_{t=1}^T G_t(s_t, v_t) + G_{T+1}(s_{T+1}) \right. \\ & \left. + \left( \varphi(G_1(s_1, v_1), \dots, G_T(s_T, v_T), G_{T+1}(s_{T+1})) - \varphi(Y_1, \dots, Y_T, Y_{T+1}) \right) \right]. \end{aligned}$$

For a fixed  $\varphi(\cdot)$ , we use  $L$  as an objective functional in an auxiliary control problem:

$$(3.6) \quad \max \mathbb{E} \left[ \sum_{t=1}^T G_t(s_t, v_t) + G_{T+1}(s_{T+1}) \right. \\ \left. + \left( \varphi(G_1(s_1, v_1), \dots, G_T(s_T, v_T), G_{T+1}(s_{T+1})) - \varphi(Y_1, \dots, Y_T, Y_{T+1}) \right) \right]$$

$$(3.7) \quad \text{s.t. } s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T,$$

$$(3.8) \quad v_t \in V_t \text{ a.s., } \quad t = 1, \dots, T.$$

Let  $Z_0$  denote the convex set of  $(s, v)$  satisfying conditions (3.7)–(3.8). The following property plays the role of a constraint qualification condition.

DEFINITION 3.2. *Problem (3.2)–(3.5) satisfies the uniform dominance condition if there exists a pair  $(\tilde{s}, \tilde{v}) \in Z_0$  such that*

$$\inf_{(\eta, \varrho) \in [a, b] \times D} \left\{ F_2(\langle \varrho, Y \rangle; \eta) - F_2(\langle \varrho, G(\tilde{s}, \tilde{v}) \rangle; \eta) \right\} > 0.$$

This condition is the reason for considering constraints (3.3) in the finite interval  $[a, b]$ . A constraint qualification of Slater type cannot be satisfied for  $\eta \in \mathbb{R}$  since for any random variable  $X$  the function  $F_2(X; \eta)$  converges to zero, whenever  $\eta \rightarrow -\infty$ .

*Example 2.* Consider any compact set  $D$  such that  $\varrho_1$  is uniformly bounded from below by a positive number for  $\varrho \in D$ . Consider the sequence  $Y$ , where all  $Y_t$  are independent and have normal distribution with mean  $\mu$  and variance  $\sigma^2 > 0$ . Let the sequence  $W = G(\tilde{s}, \tilde{v})$  have components  $W_1 = \mu + \alpha(Y_1 - \mu)$ ,  $W_2 = \mu + \beta(Y_2 - \mu)$ ,  $W_t = Y_t$ ,  $t = 3, \dots, T$ , where  $\alpha \in (0, 1)$ ,  $\beta \in (1, \sqrt{2 - \alpha^2})$ . We considered this pair in Example 1 and know that  $W \succeq_{(2)}^D Y$ . For every bounded interval  $[a, b]$  the random variable  $W$  satisfies the uniform dominance condition, because for all  $\varrho \in D$

$$\mathbb{E}\langle \varrho, W \rangle = \mathbb{E}\langle \varrho, Y \rangle \quad \text{and} \quad \text{Var}\langle \varrho, W \rangle < \text{Var}\langle \varrho, Y \rangle$$

and all random variables involved are normal. Observe that strict dominance would not hold if the interval  $[a, b]$  was replaced by an infinite interval. This concludes the example.

THEOREM 3.3. *Assume that the uniform dominance condition is satisfied. If  $(\hat{s}, \hat{v})$  is an optimal solution of (3.2)–(3.5), then there exist  $\hat{\varphi} \in \Phi([a, b], D)$  such that  $(\hat{s}, \hat{v})$  is an optimal solution of problem (3.6)–(3.8) with  $\varphi = \hat{\varphi}$ , and*

$$(3.9) \quad \mathbb{E}[\hat{\varphi}(G(\hat{s}, \hat{v}))] = \mathbb{E}[\hat{\varphi}(Y)].$$

*Conversely, if for some function  $\hat{\varphi} \in \Phi([a, b], D)$  an optimal solution  $(\hat{s}, \hat{v})$  of (3.6)–(3.8) satisfies (3.4) and (3.9), then  $(\hat{s}, \hat{v})$  is an optimal solution of (3.2)–(3.5).*

*Proof.* Let us rewrite (3.2)–(3.5) in the general form

$$\max \sum_{t=1}^T \mathbb{E}G_t(s_t, v_t) + \mathbb{E}G_{T+1}(s_{T+1})$$

$$\text{s.t. } \Gamma(s, v) \in K,$$

$$(s, v) \in Z_0,$$

where  $\Gamma : \mathcal{S} \times \mathcal{V} \rightarrow \mathcal{C}([a, b] \times D)$  is a continuous operator defined as

$$[\Gamma(s, v)](\eta, \varrho) = F_2(\langle \varrho, Y \rangle; \eta) - F_2(\langle \varrho, G(s, v) \rangle; \eta), \quad \eta \in [a, b], \quad \varrho \in D.$$

The set  $K$  is the cone of nonnegative functions in  $\mathcal{C}([a, b] \times D)$ . Observe that for every  $\varrho \in D$  the function  $(s, v) \rightarrow \eta - \langle \varrho, G(s, v) \rangle$  is convex for almost all  $\omega \in \Omega$ , and the function  $x \rightarrow (x)_+$  is convex and nondecreasing. Therefore, the composition

$$F_2(\langle \varrho, G(s, v) \rangle; \eta) = \mathbb{E}[(\eta - \langle \varrho, G(s, v) \rangle)_+]$$

is a convex function of  $(s, v)$ . It follows that the operator  $\Gamma$  is concave with respect to the cone  $K$ , that is, for any  $(s^1, v^1), (s^2, v^2)$  in  $Z_0$  and all  $\alpha \in [0, 1]$ ,

$$\Gamma(\alpha s^1 + (1 - \alpha)s^2, \alpha v^1 + (1 - \alpha)v^2) - [\alpha \Gamma(s^1, v^1) + (1 - \alpha)\Gamma(s^2, v^2)] \in K.$$

By the Riesz representation theorem, the dual space to  $\mathcal{C}([a, b] \times D)$  is the space  $\mathcal{M}([a, b] \times D)$ . We introduce the Lagrangian  $\Lambda : \mathcal{S} \times \mathcal{V} \times \mathcal{M}_+([a, b] \times D) \rightarrow \mathbb{R}$ ,

$$(3.10) \quad \Lambda(s, v, \lambda) = \sum_{t=1}^T \mathbb{E} G_t(s_t, v_t) + \mathbb{E} G_{T+1}(s_{T+1}) + \int_{[a, b] \times D} [\Gamma(s, v)](\eta, \varrho) \lambda(d\eta, d\varrho).$$

Let us observe that the uniform dominance condition implies that the following generalized Slater condition is satisfied. There exists a point  $(\tilde{s}, \tilde{v}) \in Z_0$  such that

$$\Gamma(\tilde{s}, \tilde{v}) \in \text{int } K.$$

Moreover,  $(\tilde{s}, \tilde{v}) \in Z_0$ . By [3, Proposition 2.106], this is equivalent to the regularity condition

$$0 \in \text{int}[\Gamma(Z_0) - K].$$

Therefore we can use the necessary conditions of optimality in Banach spaces (see, e.g., [3, Theorem 4]). We conclude that there exists a measure  $\hat{\lambda} \in \mathcal{M}_+([a, b] \times D)$  such that

$$(3.11) \quad \Lambda(\hat{s}, \hat{v}, \hat{\lambda}) = \max_{(s, v) \in Z_0} \Lambda(s, v, \hat{\lambda})$$

and

$$(3.12) \quad \int_{[a, b] \times D} [F_2(\langle \varrho, Y \rangle; \eta) - F_2(\langle \varrho, G(\hat{s}, \hat{v}) \rangle; \eta)] \hat{\lambda}(d\eta, d\varrho) = 0.$$

We shall transform these conditions to the postulated form. Using the representation of  $F_2$  as expected shortfall and changing the order of integration, we obtain

$$\begin{aligned} \int_{[a, b] \times D} F_2(\langle \varrho, Y \rangle; \eta) \hat{\lambda}(d\eta, d\varrho) &= \int_{[a, b] \times D} \int_{\Omega} \max(0, \eta - \langle \varrho, Y(\omega) \rangle) P(d\omega) \hat{\lambda}(d\eta, d\varrho) \\ &= \int_{\Omega} \int_{[a, b] \times D} \max(0, \eta - \langle \varrho, Y(\omega) \rangle) \hat{\lambda}(d\eta, d\varrho) P(d\omega) = -\mathbb{E} \hat{\varphi}(Y). \end{aligned}$$

We have set

$$(3.13) \quad \hat{\varphi}(x) = \varphi_{\hat{\lambda}}(x) = - \int_{[a, b] \times D} \max(0, \eta - \langle \varrho, x \rangle) \hat{\lambda}(d\eta, d\varrho).$$

Clearly,  $\hat{\varphi} \in \Phi([a, b] \times D)$ . Thus, condition (3.11) implies the optimality in problem (3.6)–(3.8), and condition (3.12) implies (3.9).

Let us now prove the converse. If  $\hat{\varphi} \in \Phi([a, b] \times D)$ , then there exist a measure  $\hat{\lambda} \in \mathcal{M}_+([a, b] \times D)$  such that

$$\hat{\varphi}(x) = - \int_{[a, b] \times D} \max(0, \eta - \langle \varrho, x \rangle) \hat{\lambda}(d\eta, d\varrho)$$

and therefore

$$\mathbb{E} \hat{\varphi}(Y) = - \int_{[a, b] \times D} F_2(\langle \varrho, Y \rangle; \eta) \hat{\lambda}(d\eta, d\varrho).$$

Thus, the maximizer  $(\hat{s}, \hat{v})$  of problem (3.6)–(3.8) is also the maximizer of  $\Lambda(s, v, \hat{\lambda})$ . It follows from sufficient conditions of optimality (see, e.g., [3, Proposition 3.3]) that if  $(\hat{s}, \hat{v})$  satisfies (3.3) and (3.9), then it is optimal for (3.2)–(3.5).  $\square$

The main result of this section is an equivalent formulation with an implied utility function  $\hat{\varphi}(\cdot)$  in (3.6). In general, it cannot be decomposed into terms corresponding to successive time periods.

We return to the special case of a finite set  $D$  defined by (2.11). The integral with respect to  $\hat{\lambda}$  can be written as an iterated integral with respect to its marginal measure  $\mu$  in  $D$  and the conditional measures  $\lambda_{\varrho}$  on  $[a, b]$ . Denoting  $\mu_t = \mu(\{\varrho^t\})$ , we obtain

$$\hat{\varphi}(x) = - \sum_{t=1}^{T+1} \mu_t \int_a^b \max(0, \eta - (x_1 + \cdots + x_t)) \lambda_{\varrho^t}(d\eta) = \sum_{t=1}^{T+1} u_t(x_1 + \cdots + x_t),$$

where  $u_t(s) = \mu_t \int_a^b \max(0, \eta - s) \lambda_{\varrho^t}(d\eta)$  is an element of  $\mathcal{U}([a, b])$ . It follows that the resulting optimal control problem has the form

$$\begin{aligned} \max \quad & \sum_{t=1}^T \mathbb{E}(G_t(s_t, v_t) + u_t(G_1(s_1, v_1) + \cdots + G_t(s_t, v_t))) \\ & + \mathbb{E}G_{T+1}(s_{T+1}) + \mathbb{E}u_{T+1}(G_1(s_1, v_1) + \cdots + G_T(s_T, v_T) + G_{T+1}(s_{T+1})) \\ \text{s.t.} \quad & s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T, \\ & v_t \in V_t \text{ a.s.,} \quad t = 1, \dots, T. \end{aligned}$$

We observe that the objective functional (1.6) is modified by adding to each term an expected utility of the cumulative reward up to time  $t$ . If we add a state variable  $W_t$  representing the cumulative reward up to time  $t$ , then the utility becomes decomposable.

**4. The implied random discount.** We can now apply techniques of convex optimization to analyze the auxiliary control problem (3.6)–(3.8). For related expected value models (without the implied utility function  $\varphi(\cdot)$ ), see [14, 30, 31].

Our goal in this section is to demonstrate the existence of random discount factors in (1.6) such that the optimal solution of (3.1) is also optimal for the discounted expected value problem.

After skipping the term depending on  $Y$ , problem (3.6)–(3.8) can be compactly written as follows:

$$(4.1) \quad \max_{(s,v) \in Z_0} \mathbb{E} \left[ \sum_{t=1}^T G_t(s_t, v_t) + G_{T+1}(s_{T+1}) + \varphi(G_1(s_1, v_1), \dots, G_T(s_T, v_T), G_{T+1}(s_{T+1})) \right].$$

**THEOREM 4.1.** *Assume that the uniform dominance condition is satisfied. If  $(\hat{s}, \hat{v})$  is an optimal solution of (3.2)–(3.5), then there exist  $\xi_t \in \mathcal{L}_{\infty}(\Omega, \mathcal{F}_t, P)$ ,  $t = 1, \dots, T+1$ , with*

$$(4.2) \quad \xi_1 \geq \xi_2 \geq \cdots \geq \xi_T \geq \xi_{T+1} \geq 0, \quad \text{a.s.,}$$

such that  $(\hat{s}, \hat{v})$  is an optimal solution of the control problem

$$\begin{aligned}
 (4.3) \quad & \max \sum_{t=1}^T \mathbb{E}(1 + \xi_t)G_t(s_t, v_t) + \mathbb{E}(1 + \xi_{T+1})G_{T+1}(s_{T+1}) \\
 & \text{s.t. } s_{t+1} = A_t s_t + B_t v_t + e_t, \quad t = 1, \dots, T, \\
 & v_t \in V_t \text{ a.s., } \quad t = 1, \dots, T.
 \end{aligned}$$

*Proof.* By virtue of Theorem 3.3, the optimal solution of problem (3.2)–(3.5) is also a solution of problem (4.1) where  $Z_0$  is the set of  $(s, v)$  satisfying conditions (3.7)–(3.8). As the function  $\varphi(\cdot)$  is nondecreasing, problem (4.1) is equivalent to

$$\begin{aligned}
 (4.4) \quad & \max \mathbb{E} \left[ \sum_{t=1}^{T+1} X_t + \varphi(X_1, \dots, X_T, X_{T+1}) \right] \\
 & \text{s.t. } G_t(s_t, v_t) \geq X_t, \quad t = 1, \dots, T, \\
 & G_{T+1}(s_{T+1}) \geq X_{T+1}, \\
 & (s, v) \in Z_0, \\
 & X_t \in \mathcal{L}_1(\Omega, \mathcal{F}_t, P), \quad t = 1, \dots, T+1.
 \end{aligned}$$

Indeed, if  $(\hat{s}, \hat{v})$  is an optimal solution of (4.1), then the triple  $(\hat{s}, \hat{v}, \hat{X})$ , with  $\hat{X}_t = G_t(\hat{s}_t, \hat{v}_t)$ ,  $t = 1, \dots, T$  and with  $\hat{X}_{T+1} = G_{T+1}(\hat{s}_{T+1})$ , is an optimal solution of (4.4). Conversely, if a triple  $(\bar{s}, \bar{v}, \bar{X})$  is an optimal solution of (4.4), then also the triple  $(\bar{s}, \bar{v}, \hat{X})$ , with  $\hat{X}_t = G_t(\bar{s}_t, \bar{v}_t)$ ,  $t = 1, \dots, T$ , and with  $\hat{X}_{T+1} = G_{T+1}(\bar{s}_{T+1})$ , is an optimal solution of this problem. Then it is evident that the pair  $(\bar{s}, \bar{v})$  solves (4.1).

Let us define the set  $C$  of the triples  $(s, v, X) \in \mathcal{S} \times \mathcal{V} \times \mathcal{X}$  satisfying the constraints of problem (4.4). The set  $C$  is convex. The objective functional of this problem is concave and continuous. Therefore, we can apply optimality conditions to the problem

$$\begin{aligned}
 (4.5) \quad & \max \mathbb{E} \left[ \sum_{t=1}^{T+1} X_t + \varphi(X_1, \dots, X_T, X_{T+1}) \right] \\
 & \text{s.t. } (s, v, X) \in C.
 \end{aligned}$$

To this end, we need to subdifferentiate the objective functional. By the definition of the class  $\Phi([a, b] \times D)$ , the nonlinear part of the objective functional can be rewritten as follows:

$$I(X) = \mathbb{E}\varphi(X_1, \dots, X_T, X_{T+1}) = - \int_{\Omega} \int_{[a, b] \times D} \max(0, \eta - \langle \varrho, X(\omega) \rangle) \lambda(d\eta, d\varrho) P(d\omega)$$

for some measure  $\lambda \in \mathcal{M}_+([a, b] \times D)$ . This shows that  $I(\cdot)$  is concave and continuous on  $\mathcal{X}$ . The subdifferential of  $I(\cdot)$  can be calculated by the theory of convex integral functionals [27, 28, 29, 4]. According to [4, Theorem VII–7],

$$\begin{aligned}
 \partial I(X) &= \partial \int_{\Omega} \varphi(X_1(\omega), \dots, X_T(\omega), X_{T+1}(\omega)) P(d\omega) \\
 &= \left\{ \xi \in \mathcal{X}^* : \xi(\omega) \in \partial \varphi(X_1(\omega), \dots, X_T(\omega), X_{T+1}(\omega)), \text{ a.s.} \right\}.
 \end{aligned}$$

It remains to calculate  $\partial\varphi(\cdot)$ . The subdifferential of the integrand  $x \rightarrow \max(0, \eta - \langle \varrho, x \rangle)$  is given by the following multifunction:  $M : \mathbb{R}^{T+1} \times [a, b] \times D \rightrightarrows \mathbb{R}^{T+1}$ ,

$$M(x, \eta, \varrho) = \begin{cases} \{-\varrho\} & \text{if } \langle \varrho, x \rangle < \eta, \\ \text{conv}\{-\varrho, 0\} & \text{if } \langle \varrho, x \rangle = \eta, \\ \{0\} & \text{if } \langle \varrho, x \rangle > \eta. \end{cases}$$

By Strassen's theorem (see [34] and [18, Theorem 1.1]),

$$\partial\varphi(x) = -\partial \int_{[a,b] \times D} \max(0, \eta - \langle \varrho, x \rangle) \lambda(d\eta, d\varrho) = - \int_{[a,b] \times D} M(x, \eta, \varrho) \lambda(d\eta, d\varrho).$$

The last integral is understood as the collection of integrals of all measurable selections of  $M$ .

Now we can formulate the optimality conditions for problem (4.5). If  $(\hat{s}, \hat{v}, \hat{X})$  is an optimal solution of this problem, then we can assume that  $\hat{X}_t = G_t(\hat{s}_t, \hat{v}_t)$ ,  $t = 1, \dots, T$  and  $\hat{X}_{T+1} = G_{T+1}(\hat{s}_{T+1})$ , as already argued. The necessary and sufficient condition of optimality reads: there exists a subgradient

$$(4.6) \quad (\xi_1, \dots, \xi_{T+1}) \in \partial\hat{\varphi}(\hat{X}_1, \dots, \hat{X}_T, \hat{X}_{T+1})$$

such that the triple  $(\hat{s}, \hat{v}, \hat{X})$  is also a solution of the problem

$$\begin{aligned} \max \mathbb{E} \sum_{t=1}^{T+1} (1 + \xi_t) X_t \\ \text{s.t. } (s, v, X) \in C. \end{aligned}$$

Observe that the coordinates of every element of  $-M(x, \eta, \varrho)$  are nonincreasing, because the coordinates of  $\varrho$  are nonincreasing. Therefore the coordinates of every element of  $\partial\varphi(x)$  are nonincreasing. Thus, for almost every  $\omega \in \Omega$ , the coordinates of  $\xi(\omega)$  are nonincreasing and nonnegative.  $\square$

It follows from Theorem 4.1 that a random discount sequence  $(1 + \xi_t)$ ,  $t = 1, \dots, T$ , applied to the rewards in the expected value formulation yields the optimal solution of the dominance-constrained problem. The monotonicity of the random discount factors is inherited from the monotonicity of the sequences  $\varrho \in D$ . However, none of the deterministic discount sequences  $\varrho \in D$  (or their convex combinations) can be substituted for  $\xi$  or for its realizations, as can be seen from formulae (3.13) and (4.6).

**5. The maximum principle.** In this section we consider the discounted control problem (4.3) with the aim of deriving a counterpart of the maximum principle.

As the functionals  $\mathbb{E}G_t(\cdot, \cdot)$  are continuous, they are subdifferentiable. By virtue of Strassen's theorem (see [34] and [18, Theorem 1.1]), every subgradient  $(\sigma_t^s, \sigma_t^v) \in \partial\mathbb{E}G_t(s_t, v_t)$  has the form  $(\sigma_t^s(\omega), \sigma_t^v(\omega)) \in \partial g_t(\hat{s}_t(\omega), \hat{v}_t(\omega))$ . We apply necessary and sufficient conditions of optimality as formulated in [13, Theorem 5]. At the optimal solution  $(\hat{s}, \hat{v})$  there exist the following:

- dual variables  $\hat{y}_t \in \mathcal{L}_q^{n_s}(\Omega, \mathcal{F}_{t+1}, P)$ ,  $t = 1, \dots, T$ , with  $1/p + 1/q = 1$ , and
- subgradients  $(\sigma_t^s, \sigma_t^v) \in \mathcal{L}_q^{n_s}(\Omega, \mathcal{F}_t, P) \times \mathcal{L}_q^{n_v}(\Omega, \mathcal{F}_t, P)$ ,  $t = 1, \dots, T$ , and  $\sigma_{T+1}^s \in \mathcal{L}_q^{n_s}(\Omega, \mathcal{F}_{T+1}, P)$  such that for all  $t$  and  $P$ -almost all  $\omega \in \Omega$

$$\begin{aligned} (5.1) \quad & (\sigma_t^s(\omega), \sigma_t^v(\omega)) \in \partial g_t(\hat{s}_t(\omega), \hat{v}_t(\omega)), \\ & \sigma_{T+1}^s(\omega) \in \partial g_{T+1}(\hat{s}_{T+1}(\omega)), \end{aligned}$$

and the pair  $(\hat{s}, \hat{v})$  is also a solution of the problem

$$\begin{aligned} \max \mathbb{E} \sum_{t=1}^{T+1} (1 + \xi_t) \langle \sigma_t^s, s_t \rangle + \mathbb{E} \sum_{t=1}^T (1 + \xi_t) \langle \sigma_t^v, v_t \rangle + \mathbb{E} \sum_{t=1}^T \langle \hat{y}_t, A_t s_t + B_t v_t - s_{t+1} \rangle \\ \text{s.t. } v_t \in V_t \text{ a.s., } t = 1, \dots, T. \end{aligned}$$

Observe that  $\mathbb{E} \langle \hat{y}_t, A_t s_t + B_t v_t - s_{t+1} \rangle = \mathbb{E} \langle \mathbb{E}[\hat{y}_t | \mathcal{F}_t], A_t s_t + B_t v_t \rangle - \mathbb{E} \langle \hat{y}_t, s_{t+1} \rangle$ . For the last optimization problem to have a solution, it is necessary that the dual variables  $\hat{y}$  satisfy the adjoint equations

$$\begin{aligned} (5.2) \quad y_T &= (1 + \xi_{T+1}) \sigma_{T+1}^s, \\ y_{t-1} &= A'_t \mathbb{E}[y_t | \mathcal{F}_t] + (1 + \xi_t) \sigma_t^s, \quad t = T, \dots, 2. \end{aligned}$$

Here  $A'_t$  is the transpose of  $A_t$ . Assuming that they hold true for  $\hat{y}$ , we obtain the problem

$$\begin{aligned} \max \sum_{t=1}^T \mathbb{E} \langle (1 + \xi_t) \sigma_t^v + B'_t \hat{y}_t, v_t \rangle \\ \text{s.t. } v_t \in V_t \text{ a.s., } t = 1, \dots, T. \end{aligned}$$

It follows that for  $t = 1, \dots, T$  and for  $P$ -almost all  $\omega \in \Omega$ , the optimal control  $\hat{v}_t(\omega)$  is a solution of the deterministic problem

$$(5.3) \quad \max_{v_t(\omega) \in V_t} \langle (1 + \xi_t(\omega)) \sigma_t^v(\omega) + B'_t(\omega) \mathbb{E}[y_t | \mathcal{F}_t](\omega), v_t(\omega) \rangle.$$

We summarize these considerations in the following statement.

**THEOREM 5.1.** *Assume that the uniform dominance condition is satisfied. If  $(\hat{s}, \hat{v})$  is an optimal solution of (3.2)–(3.5), then there exist discount factors  $\xi_t \in \mathcal{L}_\infty(\Omega, \mathcal{F}_t, P)$ ,  $t = 1, \dots, T + 1$ , subgradients  $(\sigma_t^s, \sigma_t^v) \in \mathcal{L}_q^{n_s}(\Omega, \mathcal{F}_t, P) \times \mathcal{L}_q^{n_v}(\Omega, \mathcal{F}_t, P)$  satisfying (5.1), and dual variables  $\hat{y}_t \in \mathcal{L}_q^{n_s}(\Omega, \mathcal{F}_{t+1}, P)$ ,  $t = 1, \dots, T$ , such that the adjoint equations (5.2) are satisfied and for all  $t = 1, \dots, T$  and for almost all  $\omega \in \Omega$  the control  $\hat{v}_t(\omega)$  is a solution of (5.3).*

Observing that in (5.3) the vector  $\sigma_t^v(\omega)$  is a subgradient of  $g(\hat{s}_t(\omega), \cdot)$  at  $\hat{v}_t(\omega)$ , we can reformulate the maximum principle by using the Pontryagin function

$$P(s_t(\omega), v_t(\omega), y_t(\omega), \xi_t(\omega)) = (1 + \xi_t(\omega))g(s_t(\omega), v_t(\omega)) + \langle \mathbb{E}[y_t | \mathcal{F}_t](\omega), B_t(\omega)v_t(\omega) \rangle.$$

It follows that for all  $t = 1, \dots, T$  and for almost all  $\omega \in \Omega$ , the control  $\hat{v}_t(\omega)$  is a solution of the problem

$$(5.4) \quad \max_{v_t(\omega) \in V_t} P(\hat{s}_t(\omega), v_t(\omega), y_t(\omega), \xi_t(\omega)).$$

It is important to stress that this theorem provides necessary conditions only. Even if the operators  $G$  are linear, the risk-averse control problem (3.1) is nonlinear, because the ordering constraint results in nonlinear utility functions  $\varphi(\cdot)$  in the necessary and sufficient conditions of Theorem 3.3 of this paper.

## NUMERICAL VERIFICATION OF OPTIMALITY CONDITIONS\*

ARND RÖSCH<sup>†</sup> AND DANIEL WACHSMUTH<sup>‡</sup>

**Abstract.** A class of optimal control problems for a semilinear elliptic partial differential equation with control constraints is considered. It is well known that sufficient second-order conditions ensure the stability of optimal solutions, and the convergence of numerical methods. Otherwise, such conditions are very difficult to verify (analytically or numerically). We will propose a new approach as follows: Starting with a numerical solution for a fixed mesh we will show the existence of a local minimizer of the continuous problem. Moreover, we will prove that this minimizer satisfies the sufficient second-order conditions.

**Key words.** optimal control, sufficient optimality condition, semilinear elliptic equation, numerical verification, error estimates

**AMS subject classifications.** Primary, 49K20; Secondary, 49M25, 65N15

**DOI.** 10.1137/060663714

**1. Introduction.** In this paper, we consider the optimal control problem (P) of minimizing  $J(y, u)$  given by

$$(1.1) \quad J(y, u) := \frac{1}{2} \|y - y_d\|_{L^2(\Omega)}^2 + \frac{\nu}{2} \|u\|_{L^2(\Omega)}^2$$

subject to the semilinear boundary value problem

$$(1.2) \quad \begin{aligned} (Ay)(x) + f(y(x)) &= u(x) && \text{in } \Omega \\ y &= 0 && \text{on } \Gamma \end{aligned}$$

and to the control constraints

$$(1.3) \quad a \leq u(x) \leq b \text{ a.e. in } \Omega.$$

In this setting,  $A$  is a uniformly bounded elliptic differential operator and  $\Omega$  is a bounded domain of  $\mathbb{R}^N$ ,  $N = 2, 3$ , with boundary  $\Gamma$ . Moreover,  $\nu$  is a fixed positive number. Precise assumptions on and definitions of the quantities introduced above are formulated at the end of this section.

Sufficient second-order optimality conditions are well-established mathematical tools. The development of such conditions for control constrained problems governed by partial differential equations started with the papers of Goldberg and Tröltzsch [7, 8]. Two new trends narrowed the gap between necessary and sufficient optimality conditions a few years later. Dontchev et al. [6] introduced strongly active sets in the theory of sufficient second-order conditions. The idea is that no coercivity is needed on subspaces where the first-order conditions are sufficient. The equivalence of the coercivity condition with a positivity condition for the second derivative of the Lagrangian for a class of semilinear elliptic problems was proved by Bonnans [4].

Lipschitz stability results for optimal control problems governed by partial differential equations (PDEs) can be proved using second-order optimality conditions; see for instance the papers of Malanowski and Tröltzsch [11, 12] and Tröltzsch [16]. Moreover, it is possible to show locally quadratic convergence of the SQP-method; see Arada, Raymond, and Tröltzsch [3]. These conditions are necessary to derive error estimates for discretized optimal control problems; see Arada, Casas, and Tröltzsch [2] and Casas, Mateos, and Tröltzsch [5].

For all of these results, it is essential to assume that the *unknown* solution satisfies a sufficient optimality condition. To the best of our knowledge, there are only four references available in which it is shown that such a condition is fulfilled: the articles of Arada, Raymond, and Tröltzsch [3] and Casas, Mateos, and Tröltzsch [5]; the book chapter of Mittelman and Tröltzsch [13]; and the monograph of Tröltzsch [17]. However, [17] essentially used the fact that the solution of the considered problems is *known*. If that is not the case and the optimization problem is not convex, then there is no known way up to now to check whether the sufficient optimality condition is satisfied or not. Consequently, the validity of results based thereon is not clear. Even if the numerical method behaves well for a finite sequence of meshes, it is not clear whether the numerical solution is close to a stationary point of the original problem or not.

The numerical verification of a second-order optimality condition is the main concern of this paper. Our starting point is the following very realistic situation: A numerical solution of a discretized optimal control problem is given with information on the mesh size and the discretization error. Under certain conditions, we will show that a local minimum of the continuous problem exists in a neighborhood of the numerical solution.

The paper is organized as follows. Section 2 is devoted to optimality conditions of the continuous problem. In section 3 we sketch our strategy. The state equation, discretization, and objective functional are estimated in the following sections 4–6. The main theorem on verification of optimality conditions is stated and proved in section 7. We will discuss all assumptions and the results through a numerical example in section 8.

**Assumptions.** First, we want to specify the assumptions on the various ingredients of the considered optimal control problem.

(A1)  $\Omega \subset \mathbb{R}^N$ ,  $N \in \{2, 3\}$ , is a bounded domain that is either convex and polygonal or of the class  $C^{1,1}$ . The parameter  $\nu$  is assumed to be positive. The control bounds  $a, b$  are real numbers satisfying  $a < b$ .

We denote by the  $H^1$ -norm  $\|\cdot\|_{H^1(\Omega)}$  as follows:  $\|y\|_{H^1(\Omega)}^2 = \|y\|_{L^2(\Omega)}^2 + \|\nabla y\|_{L^2(\Omega)}^2$ . We will denote the imbedding constants from  $H_0^1(\Omega)$  to  $L^p(\Omega)$  by  $I_p$ , i.e.,

$$\|y\|_{L^p(\Omega)} \leq I_p \|y\|_{H^1(\Omega)} \quad \forall y \in H_0^1(\Omega).$$

$A$  is a uniformly elliptic differential operator defined by

$$(Ay)(x) = - \sum_{i,j=1}^N \frac{\partial}{\partial x_i} \left( a_{ij}(x) \frac{\partial}{\partial x_j} y(x) \right) + c_0(x)y(x)$$

with functions  $a_{ij}$  that belong to  $C^{0,1}(\bar{\Omega})$ , satisfying the condition  $a_{ij}(x) = a_{ji}(x)$  and

$$\delta_0 \|y\|_{H^1(\Omega)}^2 \leq \langle Ay, y \rangle_{H^{-1}, H^1}, \quad \langle Ay_1, y_2 \rangle_{H^{-1}, H^1} \leq \delta_1 \|y_1\|_{H^1(\Omega)} \|y_2\|_{H^1(\Omega)} \quad \forall y \in H_0^1(\Omega).$$

Let us denote by  $a(\cdot, \cdot)$  as follows the bilinear form induced by  $A$ :

$$a(u, v) = \langle Au, v \rangle_{H^{-1}, H^1}.$$

**(A2)** The function  $f = f(y) : \Omega \rightarrow \mathbb{R}$  is of class  $C^2$  with  $f(0) = 0$ . It satisfies the following conditions on boundedness and Lipschitz-continuity: For all  $\tilde{M} > 0$  there are constants  $c_f, c_{f'}, c_{f''} > 0$  such that

$$\begin{aligned} |f(y_1) - f(y_2)| &\leq c_f |y_1 - y_2|, \\ |f'(y_1) - f'(y_2)| &\leq c_{f'} |y_1 - y_2|, \\ |f''(y_1) - f''(y_2)| &\leq c_{f''} |y_1 - y_2| \end{aligned}$$

hold for all  $|y_i| \leq \tilde{M}$ ,  $i = 1, 2$ . Moreover, we require  $f'(y) \geq 0$  in  $\mathbb{R}$ .

**2. Optimality conditions for the continuous problem.** A function  $y$  is called a weak solution of the semilinear elliptic equation (see section 4) if it satisfies

$$(2.1) \quad a(y, v) + (f(y), v) = (u, v) \quad \forall v \in V = H^1(\Omega) \cap C(\bar{\Omega}).$$

Solvability as well as regularity results for the weak formulation of the state equation are stated in section 4.

The set of admissible controls  $U_{ad} \subset U := L^2(\Omega)$  is defined by

$$U_{ad} = \{u \in L^2(\Omega) : a \leq u(x) \leq b \text{ a.e. in } \Omega\}.$$

We define the Lagrange functional by

$$(2.2) \quad L(y, u, p) = J(y, u) - a(y, p) - (f(y), p) + (u, p).$$

Then the necessary first-order optimality conditions are given by

$$(2.3) \quad L_y(\bar{y}, \bar{u}, \bar{p})(v) = 0 \quad \text{for } v \in V,$$

$$(2.4) \quad L_u(\bar{y}, \bar{u}, \bar{p})(u - \bar{u}) \geq 0 \quad \text{for } u \in U_{ad}.$$

Every admissible point  $(u, y)$  is called stationary if there exists an adjoint  $p$  such that the optimality system (2.3)–(2.4) is satisfied. Equation (2.3) is equivalent to the adjoint equation defined by

$$(2.5) \quad a(v, p) + (f'(\bar{y})p, v) = (y - y_d, v) \quad \forall v \in V = H^1(\Omega) \cap C(\bar{\Omega}).$$

Existence and regularity results for the adjoint equation can be found in section 4.

A sufficient second-order condition, henceforth called (SSC), is given by

$$(2.6) \quad L''_{(y,u)}(\bar{y}, \bar{u}, \bar{p})(y, u) \geq \delta \|u\|_{L^2(\Omega)}^2$$

for all  $(y, u) \in V \times U$  satisfying the linearized equation

$$(2.7) \quad a(y, v) + (f'(\bar{y})y, v) = (u, v) \quad \forall v \in V.$$

Here, the second derivative of the Lagrangian is given by

$$(2.8) \quad L''_{(y,u)}(\bar{y}, \bar{u}, \bar{p})(y, u) = \|y\|_{L^2(\Omega)}^2 + \nu \|u\|_{L^2(\Omega)}^2 + (f''(\bar{y})y^2, \bar{p}).$$

Note that checking (SSC) requires the knowledge of  $(\bar{y}, \bar{u}, \bar{p})$ , which typically cannot be assumed. Hence, it is impossible to show that (SSC) holds in advance.

**3. The discretized problem.** Typically, control and state are discretized (for instance, by finite elements) to obtain numerical approximations  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$  of solutions of the continuous problem. Here, the following questions arise:

- Is the numerical solution close to a stationary point of the continuous (i.e., undiscretized) problem?
- Is the numerical solution close to a local minimizer of the continuous problem?

In this article, we will derive conditions for the solution of the discretized problem  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$  that ensure the existence of a local minimizer of (P) in a specified neighborhood of the numerical solution  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$ . Under additional assumptions, we can even show that this unknown minimizer fulfills (SSC).

We will formulate general assumptions for the discretization of the optimal control problem. The assumption fits into finite element discretizations of the elliptic state equation (2.1), which is replaced by

$$(3.1) \quad a(y_h, v_h) + (f(y_h), v_h) = (u, v_h) \quad \forall v_h \in V_h,$$

where  $V_h \subset V$  is a finite dimensional space. The set of admissible controls is given by

$$(3.2) \quad U_{ad}^h := \{u_h \in U_h : a \leq u_h(x) \leq b\},$$

where  $U_h$  is the space of functions that are piecewise constant over the elements of a triangulation of  $\Omega$ . We refer to section 5 for the precise formulation of the assumptions on the discretization.

The corresponding discretized adjoint equation is given by

$$(3.3) \quad a(v_h, p_h) + (f'(\bar{y}_h)p_h, v_h) = (y - y_d, v_h) \quad \forall v_h \in V_h.$$

The discretized optimal control problem is given by the following: Minimize  $J(y_h, u_h)$  subject to the discretized equation (3.1) and to the control constraint  $u \in U_{ad}^h$ .

In what follows, we assume that  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$  solves that discretized problem without numerical errors. However, it would be sufficient for all results that the numerical error is smaller than the discretization error. There are different types of numerical errors in a practical computation, e.g., rounding errors, iterative solvers (Newton), quadrature rules for the evaluation of the right-hand sides, and so on. In our computations we chose the numerical methods in such a way that these types of numerical errors are essentially smaller than the discretization error.

Now, let us sketch our strategy. We *assume* a condition similar to (2.6), namely, that

$$(3.4) \quad L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u) \geq \delta \|u\|_{L^2(\Omega)}^2$$

holds for all  $(y, u) \in V \times U$  fulfilling the linearized equation

$$(3.5) \quad a(y, v) + (f'(\bar{y}_h)y, v) = (u, v) \quad \forall v \in V.$$

So we assume the coercivity for the discretized solution instead of the continuous one. Note that this condition is required for all  $u \in U$  (and not only in  $U^h$ ). The inequality (3.4) means

$$(3.6) \quad \|y\|_{L^2(\Omega)}^2 + \nu \|u\|_{L^2(\Omega)}^2 + (f''(\bar{y}_h)y^2, \bar{p}_h) \geq \delta \|u\|_{L^2(\Omega)}^2.$$

Since  $\bar{y}_h, \bar{p}_h$  are known, there is a chance to verify this condition; i.e., it would suffice, for instance, that

$$(3.7) \quad f''(\bar{y}_h(x))\bar{p}_h(x) > -1$$

hold on  $\Omega$ . Moreover, if  $(\bar{y}, \bar{u}, \bar{p})$  satisfies (SSC), then such an assumption will be true for sufficiently fine discretizations.

The main difference between the conditions (3.4)–(3.5) and (SSC) is that the point  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$ , where the second-derivative of  $L$  is evaluated in (3.4), is known. Hence, there is the possibility to check that condition. Indeed, inequality (3.7), which is easy to verify, is sufficient for the fulfillment of (3.4). As discussed above, it is much more difficult to prove (SSC) for the unknown solution  $\bar{u}$ . However, one cannot guarantee that (SSC) or (3.4) is fulfilled if, for instance, good convergence of numerical algorithms is observed, since both are indeed sufficient conditions.

One could of course try to check the inequality (2.6) above for all admissible controls  $u \in U_{ad}$  with associated state  $y$  and adjoint  $p$ . Then this inequality must hold for all  $(u, y, p)$  instead of  $(\bar{u}, \bar{y}, \bar{p})$ . However, this is the global convexity of the original problem. It is clear that in the convex case all theoretical results are valid.

Let us continue with the sketch of our strategy. The pair  $(\bar{u}_h, \bar{y}_h)$  is not admissible for the continuous problem. Therefore, we introduce the auxiliary state  $y^h$  as the solution of the elliptic equation with right-hand side  $\bar{u}_h$ ,

$$(3.8) \quad a(y^h, v) + (f(y^h), v) = (\bar{u}_h, v) \quad \forall v \in V.$$

Under the assumption that  $\delta$  in (3.4) is large enough, we will show the existence of a radius  $r > 0$  such that

$$J(y, u) - J(y^h, \bar{u}_h) > 0 \quad \text{if } \|u - \bar{u}_h\|_{L^2(\Omega)} = r.$$

This result will be the key for our argumentation; i.e., since  $(y^h, \bar{u}_h)$  is an admissible pair for the continuous problem, we obtain the existence of a local minimizer  $\hat{u}$  of (P) in the neighborhood  $\{u \in U_{ad} : \|u - \bar{u}_h\|_{L^2(\Omega)} < r\}$  of  $\bar{u}_h$ ; see section 6. Under additional assumptions, this local minimizer is unique and fulfills the sufficient condition (SSC). That is, we get the fulfillment of (SSC) as an a posteriori result and not as an a priori assumption.

In order to get a computable bound for the radius  $r$ , all estimations have to be carried out carefully, and all constants have to be known. A representative collection of those constants includes

- embedding constants  $H_0^1(\Omega) \hookrightarrow L^p(\Omega)$ ,
- interpolation constants for the finite elements,
- global bounds on the state, and
- norm of the solution operators of the PDEs.

In the following sections, we will estimate several ingredients of the optimal control problem and its discretization. The solution operator of the semilinear elliptic equation is studied in section 4. The finite element discretization and associated error estimates for the state equations can be found in section 5. The difference between the objective functionals  $J(y, u) - J(y^h, \bar{u}_h)$  is investigated and estimated in section 6. The existence of a local minimizer  $\hat{u}$  of (P) in the neighborhood of  $\bar{u}_h$  is proved in section 7. Also the proof that  $\hat{u}$  satisfies (SSC) is contained in that section.

#### 4. State equation. Now, let us study briefly the state equation.

**THEOREM 4.1.** *The semilinear state equation admits a unique solution  $y \in V \cap H^2(\Omega)$  for all  $u \in L^2$  and satisfies the estimates*

$$(4.1) \quad \|y\|_{H^2(\Omega)} \leq c_S \|u\|_{L^2(\Omega)},$$

$$(4.2) \quad \|y\|_{L^\infty(\Omega)} \leq c_{SL^\infty} \|u\|_{L^2(\Omega)}.$$

Since  $U_{ad}$  is bounded, we have in addition

$$(4.3) \quad \|y\|_{L^\infty(\Omega)} < M$$

for all solutions  $y$  associated with admissible controls  $u$ .

For the proof we refer to Grisvard [9].

Thanks to Theorem 4.1, we can interpret all assumptions of **(A2)**, which were defined on bounded sets, as global estimates as follows

**(A2)'** The function  $f = f(y) : \Omega \rightarrow \mathbb{R}$  is of class  $C^2$  with  $f(0) = 0$ . It satisfies the following conditions on boundedness and Lipschitz-continuity: There are constants  $c_f, c_{f'}, c_{f''} > 0$  such that

$$\begin{aligned} |f(y_1) - f(y_2)| &\leq c_f |y_1 - y_2|, \\ |f'(y_1) - f'(y_2)| &\leq c_{f'} |y_1 - y_2|, \\ |f''(y_1) - f''(y_2)| &\leq c_{f''} |y_1 - y_2| \end{aligned}$$

hold for all  $y_1, y_2 \in \mathbb{R}$ .

This assumption implies the boundedness of the derivatives of  $f$ :  $|f'(y)| \leq c_f$  and  $|f''(y)| \leq c_{f'}$  for all  $y \in \mathbb{R}$ .

The Lipschitz-continuity of the control-to-state mapping is an immediate consequence of the monotonicity of  $f$ .

LEMMA 4.2. *Let  $y_1$  and  $y_2$  be the solutions of (2.1) for controls  $u_1$  and  $u_2$ , respectively. Then the estimate*

$$(4.4) \quad \|y_1 - y_2\|_{L^2(\Omega)} \leq \|y_1 - y_2\|_{H^1(\Omega)} \leq c_L \|u_1 - u_2\|_{L^2(\Omega)}$$

is valid with  $c_L = \frac{I_2}{\delta_0}$ .

A similar estimate is available for solutions of the linearized system

$$(4.5) \quad a(y, v) + (f'(\bar{y})y, v) = (u, v) \quad \forall v \in V = H^1(\Omega) \cap C(\bar{\Omega}).$$

Here,  $\bar{y}$  is a given function of  $V$ .

COROLLARY 4.3. *The linearized state equation (4.5) admits a unique solution  $y$  for each  $u \in U$ , and it holds that*

$$\|y_1 - y_2\|_{L^2(\Omega)} \leq \|y_1 - y_2\|_{H^1(\Omega)} \leq c_L \|u_1 - u_2\|_{L^2(\Omega)}$$

with the same constant  $c_L$  as in (4.4) above.

We conclude this section with the state of an existence result for the adjoint equation (2.5).

LEMMA 4.4. *The adjoint equation (2.5) admits a unique solution. Moreover, the estimate*

$$(4.6) \quad \|p\|_{H^2(\Omega)} \leq c_p \|y - y_d\|_{L^2(\Omega)}$$

is valid.

For the proof we refer to Grisvard [9].

**5. Finite element discretization.** The state  $V$  is approximated by a finite dimensional subspace  $V_h \subset V$ . Here, we impose the following requirement.

**(A3)** The mesh parameter  $h$  is assumed to be smaller than 1. We assume the existence of an operator  $i_h : V \rightarrow V_h$  with the following properties:

$$(5.1) \quad \|y - i_h y\|_{L^2(\Omega)} \leq c_1 h^2 \|y\|_{H^2(\Omega)},$$

$$(5.2) \quad \|y - i_h y\|_{H^1(\Omega)} \leq c_2 h \|y\|_{H^2(\Omega)}.$$

This assumption is a standard property of conforming finite element discretizations.

The control is discretized piecewise constant on a mesh  $\mathcal{T}_h$  containing open sets  $T$  (finite elements),

$$U_h := \{q_h \in L^2(\Omega) : q_h|_T = \text{const for all } T \in \mathcal{T}_h\}.$$

We require the following for the mesh  $\mathcal{T}_h$ .

(A4) The diameter of the largest element of  $\mathcal{T}_h$  is bounded by  $h$ . Moreover,

$$\bigcup_{T \in \mathcal{T}_h} \bar{T} = \bar{\Omega}, \quad T_i \cap T_j = \emptyset \quad \forall T_i, T_j \in \mathcal{T}_h, i \neq j.$$

Now, we give an error estimate for the semilinear equation.

LEMMA 5.1. *Let  $y$  and  $y_h$  be the unique solutions of the semilinear equations (2.1) and (3.1), respectively. Then, the following error estimates are valid:*

$$(5.3) \quad \|y - y_h\|_{L^2(\Omega)} \leq c_{L^2} h^2 \|y\|_{H^2(\Omega)},$$

$$(5.4) \quad \|y - y_h\|_{H^1(\Omega)} \leq c_{H^1} h \|y\|_{H^2(\Omega)}$$

with  $c_{L^2} = (\delta_1 c_2 + c_f c_1) c_{H^1} c_M$  and  $c_{H^1} = (\delta_1 c_2 + c_f c_1) / \delta_0$ .

*Proof.* Using the ellipticity assumption (A1), the monotonicity of  $f$  in (A2)', and Galerkin orthogonality, the  $H^1$ -estimate follows by standard arguments. For the  $L^2$ -estimate, we introduce an auxiliary state  $g$  as the solution of

$$a(g, v) + (f_y^{y_h} g, v) = (e, v) \quad \forall v \in V$$

with  $e = \frac{y - y_h}{\|y - y_h\|_{L^2(\Omega)}}$ . The expression  $f_y^{y_h} g$  is defined by

$$f_y^{y_h} g = \int_0^1 f'(y_h + s(y - y_h)) g \, ds.$$

Note that  $\|e\|_{L^2(\Omega)} = 1$ . Since  $f'$  is globally bounded, we have

$$\|g\|_{H^2(\Omega)} \leq c_M$$

with some constant  $c_M > 0$ . Using these definitions, we find

$$\begin{aligned} \|y - y_h\|_{L^2(\Omega)} &= (e, y - y_h) \\ &= a(g, y - y_h) + (f_y^{y_h} g, y - y_h) \\ &= a(g, y - y_h) + (g, f_y^{y_h}(y - y_h)) \\ &= a(g, y - y_h) + (g, f(y) - f(y_h)). \end{aligned}$$

Testing the difference of the weak formulation (2.1) and the discrete equation (3.1) by  $v_h = i_h g$ , we obtain

$$\begin{aligned} \|y - y_h\|_{L^2(\Omega)} &= a(g - i_h g, y - y_h) + (g - i_h g, f(y) - f(y_h)) \\ &\leq \delta_1 \|g - i_h g\|_{H^1(\Omega)} \|y - y_h\|_{H^1(\Omega)} + c_f \|g - i_h g\|_{L^2(\Omega)} \|y - y_h\|_{L^2(\Omega)} \\ &\leq \delta_1 c_2 c_{H^1} h^2 \|g\|_{H^2(\Omega)} \|y\|_{H^2(\Omega)} + c_f c_1 h^2 \|g\|_{H^2(\Omega)} \|y - y_h\|_{L^2(\Omega)} \\ &\leq (\delta_1 c_2 c_{H^1} c_M h^2 + c_f c_1 c_{H^1} c_M h^3) \|y\|_{H^2(\Omega)}. \end{aligned}$$

Now, for  $h < 1$  we have  $c_{L^2} = (\delta_1 c_2 + c_f c_1) c_{H^1} c_M$ .  $\square$

Applying these results, we can give error estimates for the auxiliary function  $y^h$  introduced in (3.8).

COROLLARY 5.2. *It holds for the difference  $y^h - \bar{y}_h$  that*

$$(5.5) \quad \|y^h - \bar{y}_h\|_{L^2(\Omega)} \leq c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)},$$

$$(5.6) \quad \|y^h - \bar{y}_h\|_{H^1(\Omega)} \leq c_{H^1} c_S h \|\bar{u}_h\|_{L^2(\Omega)}.$$

*Proof.* The claim follows directly from Lemma 5.1 and Theorem 4.1.  $\square$

**6. Estimation of the objective functional; existence of a local minimizer.** Throughout the following sections, we assume the fulfillment of **(A1)**, **(A3)**, and **(A4)**, which are assumptions concerning the state equation and the discretization.

Let us fix a mesh according to assumptions **(A3)** and **(A4)**. Let  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$  be the solution of the discretized problem for this particular mesh. Hence, the discretized state equation (3.1), the discretized adjoint equation (3.3), and the variational inequality

$$(\nu \bar{u}_h + \bar{p}_h, u_h - \bar{u}_h) \geq 0 \quad \forall u_h \in U_{ad}^h$$

are satisfied. Furthermore, we impose the following conditions on the discrete solution  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$ .

**(A5)** We assume that the coercivity condition (3.4)–(3.5) holds at  $(\bar{y}_h, \bar{u}_h, \bar{p}_h)$  with some  $\delta > 0$ . We require the regularities  $\bar{y}_h \in L^\infty(\Omega)$  and  $\bar{p}_h \in W^{1,\infty}(\Omega)$ .

The latter assumption allows us to use the modified assumption **(A2)'** on the bounded set  $\{y \in L^\infty(\Omega) : \|y\|_\infty \leq \max(M, \|\bar{y}_h\|_\infty)\}$ . Here,  $M$  is the global bound provided by Theorem 4.1.

We are only interested in discretized solutions for a fixed mesh. Hence, the regularity assumptions  $\bar{y}_h \in L^\infty(\Omega)$  and  $\bar{p}_h \in W^{1,\infty}(\Omega)$  are in fact assumptions on the finite element space. We do not require that the norms  $\|\bar{y}_h\|_{L^\infty(\Omega)}$  and  $\|\bar{p}_h\|_{W^{1,\infty}(\Omega)}$  be bounded independently of  $h$ .

Now, we will investigate the behavior of the objective functional in the neighborhood of  $\bar{u}_h$ . The following lemma expresses  $J(y, u) - J(y^h, \bar{u}_h)$  as the sum of several addends, which will be estimated in what follows.

LEMMA 6.1. *Let  $u$  be an admissible control and  $y$  the associated state (solution of (2.1)). Then we can represent the difference of the objective values as*

$$(6.1) \quad J(y, u) - J(y^h, \bar{u}_h) = L(\bar{y}_h, \bar{u}_h, \bar{p}_h) - L(y^h, \bar{u}_h, \bar{p}_h)$$

$$(6.2) \quad + L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h)$$

$$(6.3) \quad + L_u(\bar{y}_h, \bar{u}_h, \bar{p}_h)(u - \bar{u}_h)$$

$$(6.4) \quad + \frac{1}{2} L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h, u - \bar{u}_h)^2$$

$$(6.5) \quad + r_2,$$

where  $r_2$  denotes a second-order remainder term.

Now, we will estimate the terms (6.1)–(6.5).

LEMMA 6.2. *The discretization error in the Lagrange function can be estimated by*

$$(6.6) \quad |L(y^h, \bar{u}_h, \bar{p}_h) - L(\bar{y}_h, \bar{u}_h, \bar{p}_h)| < c_j h^2 \|\bar{u}_h\|_{L^2(\Omega)}$$

with  $c_j = c_{L^2} c_S (\|\bar{y}_h - y_d\|_{L^2(\Omega)} + \frac{1}{2} c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)})$ .

*Proof.* Here, we find for the objective

$$\begin{aligned} |J(y^h, \bar{u}_h) - J(\bar{y}_h, \bar{u}_h)| &= \left| \frac{1}{2} \|y^h - y_d\|_{L^2(\Omega)}^2 - \frac{1}{2} \|\bar{y}_h - y_d\|_{L^2(\Omega)}^2 \right| \\ &= \left| \frac{1}{2} \|y^h - \bar{y}_h\|_{L^2(\Omega)}^2 + (\bar{y}_h - y_d, y^h - \bar{y}_h) \right| \\ &\leq c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)} \left( \|\bar{y}_h - y_d\|_{L^2(\Omega)} + \frac{1}{2} c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)} \right). \end{aligned}$$

It remains to estimate the term associated with the semilinear equation in the difference  $L(y^h, \bar{u}_h, \bar{p}_h) - L(\bar{y}_h, \bar{u}_h, \bar{p}_h)$ . The semilinear equation is satisfied for the pair  $(y^h, \bar{u}_h)$ . Consequently, this term vanishes. The pair  $(\bar{y}_h, \bar{u}_h)$  fulfills only the equation in  $V_h$ . However, the test function  $\bar{p}_h$  belongs to  $V_h$ . Hence, this term vanishes, too. Consequently, the assertion is true with  $c_j = c_{L^2} c_S (\|\bar{y}_h - y_d\|_{L^2(\Omega)} + \frac{1}{2} c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)})$ .  $\square$

LEMMA 6.3. *The error in the adjoint equation can be estimated by*

$$(6.7) \quad |L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h)| \leq c_y h^2 \|\bar{y}_h - y_d\|_{L^2(\Omega)} \|y\|_{H^2(\Omega)} \quad \forall y \in V$$

with  $c_y = c_p(c_{H^1} \delta_1 + c_{L^2} c_f)$ .

*Proof.* We start with

$$L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h) = (\bar{y}_h - y_d, y - \bar{y}_h) - a(\bar{p}_h, y - \bar{y}_h) - (f'(\bar{y}_h) \bar{p}_h, y - \bar{y}_h).$$

Moreover, we define a function  $p^h$  as a solution of

$$(6.8) \quad a(p^h, v) + (f'(\bar{y}_h) p^h, v) = (\bar{y}_h - y_d, v) \quad \forall v \in V.$$

We obtain for  $v = y - \bar{y}_h$ ,

$$(\bar{y}_h - y_d, y - \bar{y}_h) = a(p^h, y - \bar{y}_h) + (f'(\bar{y}_h) p^h, y - \bar{y}_h).$$

Therefore, we can continue using Galerkin orthogonality as follows:

$$\begin{aligned} L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h) &= a(p^h - \bar{p}_h, y - \bar{y}_h) + (f'(\bar{y}_h)(p^h - \bar{p}_h), y - \bar{y}_h) \\ &= a(p^h - \bar{p}_h, y - i_h y) + (f'(\bar{y}_h)(p^h - \bar{p}_h), y - i_h y) \\ &\quad + a(p^h - \bar{p}_h, i_h y - \bar{y}_h) + (f'(\bar{y}_h)(p^h - \bar{p}_h), i_h y - \bar{y}_h) \\ &= a(p^h - \bar{p}_h, y - i_h y) + (f'(\bar{y}_h)(p^h - \bar{p}_h), y - i_h y). \end{aligned}$$

Consequently, we obtain

$$\begin{aligned} |L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h)| &\leq \delta_1 \|p^h - \bar{p}_h\|_{H^1(\Omega)} \|y - i_h y\|_{H^1(\Omega)} \\ &\quad + c_f \|p^h - \bar{p}_h\|_{L^2(\Omega)} \|y - i_h y\|_{L^2(\Omega)}. \end{aligned}$$

The proving technique of Lemma 5.1 delivers

$$(6.9) \quad \|p^h - \bar{p}_h\|_{H^1(\Omega)} \leq c_{H^1} h \|p^h\|_{H^2(\Omega)} \quad \text{and} \quad \|p^h - \bar{p}_h\|_{L^2(\Omega)} \leq c_{L^2} h^2 \|p^h\|_{H^2(\Omega)}.$$

Moreover, we can apply the inequalities (5.1) and (5.2) for the interpolation error of  $y$ . Finally, we get

$$|L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h)| \leq (c_{H^1} \delta_1 + c_{L^2} c_f h^2) h^2 \|p^h\|_{H^2(\Omega)} \|y\|_{H^2(\Omega)}.$$

Of course, the norm  $\|p^h\|_{H^2(\Omega)}$  can be estimated by means of Lemma 4.4,

$$(6.10) \quad \|p^h\|_{H^2(\Omega)} \leq c_p \|\bar{y}_h - y_d\|_{L^2(\Omega)},$$

and (6.7) is obtained with  $c_y = c_p(c_{H^1}\delta_1 + c_{L^2}c_f)$  if  $h \leq 1$ .  $\square$

LEMMA 6.4. *The error in the optimality condition can be estimated by*

$$(6.11) \quad L_u(\bar{y}_h, \bar{u}_h, \bar{p}_h)(u - \bar{u}_h) \geq -c_u h \|u - \bar{u}_h\|_{L^2(\Omega)} \|\bar{p}_h\|_{W^{1,\infty}(\Omega)} \quad \forall u \in U_{ad}$$

with  $c_u = |T_h^i|^{1/2}$ , where  $T_h^i$  is the set of elements, where  $\bar{p}_h + \nu \bar{u}_h$  changes the sign.

*Proof.* The optimality condition for  $\bar{u}_h$  is given by

$$(6.12) \quad (\bar{p}_h + \nu \bar{u}_h, u_h - \bar{u}_h) \geq 0 \quad \forall u_h \in U_{ad}^h.$$

This implies  $u_h = a$  on all elements  $T_h$  where  $\bar{p}_h + \nu \bar{u}_h$  is a.e. positive. Analogously  $u_h = b$  holds on all elements  $T_h$  where  $\bar{p}_h + \nu \bar{u}_h$  is a.e. negative. For the set  $T_h^a$  of all such elements we find for arbitrary  $u \in U_{ad}$

$$(6.13) \quad (\bar{p}_h + \nu \bar{u}_h, u - \bar{u}_h)_{L^2(T_h^a)} \geq 0 \quad \forall u \in U_{ad}.$$

It remains to estimate the error on the set  $T_h^i$  of elements where the expression  $\bar{p}_h + \nu \bar{u}_h$  changes the sign. Since  $\bar{u}_h$  is constant on each element, we find

$$|\bar{p}_h + \nu \bar{u}_h| \leq h \|\bar{p}_h\|_{W^{1,\infty}(\Omega)} \quad \text{on } T_h^i.$$

From this, we conclude

$$(6.14) \quad (\bar{p}_h + \nu \bar{u}_h, u - \bar{u}_h)_{L^2(T_h^i)} \geq -|T_h^i|^{1/2} h \|u - \bar{u}_h\|_{L^2(T_h^i)} \|\bar{p}_h\|_{W^{1,\infty}(\Omega)} \quad \forall u \in U_{ad}.$$

Combining (6.13) and (6.14), (6.11) is obtained with  $c_u = |T_h^i|^{1/2}$ .  $\square$

LEMMA 6.5. *Let  $u \in U_{ad}$  be given together with the associated solution  $y$  of the semilinear state equation (2.1). Then it holds with  $r = \|u - \bar{u}_h\|_{L^2(\Omega)}$  that*

$$(6.15) \quad L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h, u - \bar{u}_h)^2 \geq \delta r^2 - d_1 h r^2 - d_2 h^2 r - d_3 r^3 - d_4 h^4$$

with constants  $d_i$  specified below; see (6.21).

*Proof.* At first, let us define  $d$  as the solution of the linearized equation

$$a(d, v) + (f'(\bar{y}_h)d, v) = (u - \bar{u}_h, v) \quad \forall v \in V.$$

Observe that  $d$  can be used as a test function in the coercivity condition (3.4), whereas  $y - \bar{y}_h$  would not be suitable there. Furthermore, we have by Corollary 4.3 the estimate

$$(6.16) \quad \|d\|_{L^2(\Omega)} \leq c_L \|u - \bar{u}_h\|_{L^2(\Omega)}.$$

Now, we rewrite the left-hand side in (6.15) as

$$(6.17) \quad \begin{aligned} L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h, u - \bar{u}_h)^2 \\ = L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(d, u - \bar{u}_h)^2 + L_{yy}(\bar{y}_h, \bar{u}_h, \bar{p}_h)[y - \bar{y}_h - d, y - \bar{y}_h + d]. \end{aligned}$$

The first addend gives the coercivity  $\geq \delta r^2$  using the sufficient condition (3.4). The second one can be estimated using (2.8) by

$$(6.18) \quad \begin{aligned} |L_{yy}(\bar{y}_h, \bar{u}_h, \bar{p}_h)[y - \bar{y}_h - d, y - \bar{y}_h + d]| \\ \leq (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|y - \bar{y}_h - d\|_{L^2(\Omega)} \|y - \bar{y}_h + d\|_{L^2(\Omega)}. \end{aligned}$$

Using (4.4), (5.5), and (6.16), we find

$$\begin{aligned}
 \|y - \bar{y}_h + d\|_{L^2(\Omega)} &\leq \|y - y^h\|_{L^2(\Omega)} + \|y^h - \bar{y}_h\|_{L^2(\Omega)} + \|d\|_{L^2(\Omega)} \\
 (6.19) \quad &\leq c_L \|u - \bar{u}_h\|_{L^2(\Omega)} + c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)} + c_L \|u - \bar{u}_h\|_{L^2(\Omega)} \\
 &= 2c_L r + c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)} h^2.
 \end{aligned}$$

We could treat  $y - \bar{y}_h - d$  in the same way. However, we need a sharper result. To this end, we use the splitting  $y - \bar{y}_h - d = (y - y^h - d) + (y^h - \bar{y}_h)$ .

The first function  $y - y^h - d =: y_1$  is the weak solution of

$$a(y_1, v) + (f'(\bar{y}_h)y_1, v) = -(f(y) - f(y^h) - f'(\bar{y}_h)(y - y^h), v) \quad \forall v \in V.$$

We transform the right-hand side into

$$\begin{aligned}
 f(y) - f(y^h) - f'(\bar{y}_h)(y - y^h) &= (f'(y^h) - f'(\bar{y}_h))(y - y^h) \\
 &\quad + \int_0^1 [f'(y^h + s(y - y^h)) - f'(y^h)](y - y^h) ds.
 \end{aligned}$$

Its  $L^2$ -norm is estimated by

$$\begin{aligned}
 \|f(y) - f(y^h) - f'(\bar{y}_h)(y - y^h)\|_{L^2(\Omega)} \\
 \leq c_{f'} \left( \|y^h - \bar{y}_h\|_{L^4(\Omega)} \|y - y^h\|_{L^4(\Omega)} + \frac{1}{2} \|y - y^h\|_{L^4(\Omega)}^2 \right).
 \end{aligned}$$

Hence, we can estimate

$$\begin{aligned}
 \|y_1\|_{L^2(\Omega)} &= \|y - d - y^h\|_{L^2(\Omega)} \leq c_L \|f(y) - f(y^h) - f'(\bar{y}_h)(y - y^h)\|_{L^2(\Omega)} \\
 &\leq c_L c_{f'} \left( \|y^h - \bar{y}_h\|_{L^4(\Omega)} \|y - y^h\|_{L^4(\Omega)} + \frac{1}{2} \|y - y^h\|_{L^4(\Omega)}^2 \right).
 \end{aligned}$$

Analogously to (5.5) we get an  $L^4$ -error estimate for  $y - y^h$  by Lemma 5.1,

$$\|y^h - \bar{y}_h\|_{L^4(\Omega)} \leq I_4 c_{H^1} h c_S \|\bar{u}_h\|_{L^2(\Omega)}.$$

Applying Corollary 4.3, we find

$$\|y - y^h\|_{L^4(\Omega)} \leq I_4 \|y - y^h\|_{H^1(\Omega)} \leq I_4 c_L r.$$

Altogether, we derived the estimate

$$\|y - d - y^h\|_{L^2(\Omega)} \leq c_L^2 c_{f'} I_4^2 \left( c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} h r + \frac{1}{2} c_L r^2 \right),$$

which yields

$$\begin{aligned}
 (6.20) \quad \|y - \bar{y}_h - d\|_{L^2(\Omega)} &\leq \|y - y^h - d\|_{L^2(\Omega)} + \|y^h - \bar{y}_h\|_{L^2(\Omega)} \\
 &\leq c_L^2 c_{f'} I_4^2 \left( c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} h r + \frac{1}{2} c_L r^2 \right) + c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)}.
 \end{aligned}$$

Now we can proceed with the estimation of  $L_{yy}$  already started in (6.18) using the inequalities (6.19) and (6.20),

$$\begin{aligned}
 & |L_{yy}(\bar{y}_h, \bar{u}_h, \bar{p}_h)[y - \bar{y}_h - d, y - \bar{y}_h + d]| \\
 & \leq (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|y - \bar{y}_h + d\|_{L^2(\Omega)} \|y - \bar{y}_h - d\|_{L^2(\Omega)} \\
 & \leq (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) (2c_L r + c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)} h^2) \\
 & \quad \cdot \left( c_L^2 c_{f'} I_4^2 \left( c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} h r + \frac{1}{2} c_L r^2 \right) + c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)} \right) \\
 & \leq d_1 h r^2 + d_2 h^2 r + d_3 r^3 + d_4 h^4
 \end{aligned}$$

with constants defined by

$$\begin{aligned}
 (6.21) \quad & d_0 = (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}), \\
 & d_1 = d_0 \cdot c_L^2 c_{f'} I_4^2 \cdot \left( c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} \cdot 2c_L + \frac{1}{2} c_L c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)} \right), \\
 & d_2 = d_0 \cdot (c_L^2 c_{f'} I_4^2 \cdot c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} \cdot c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)} + 2c_L \cdot c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)}), \\
 & d_3 = d_0 \cdot c_L^2 c_{f'} I_4^2 \cdot c_L^2, \\
 & d_4 = d_0 \cdot (c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)})^2.
 \end{aligned}$$

Here, we used again  $h < 1$ . Finally, we obtain for the second derivative

$$L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h, u - \bar{u}_h)^2 \geq \delta r^2 - d_1 h r^2 - d_2 h^2 r - d_3 r^3 - d_4 h^4,$$

and the claim is proved.  $\square$

LEMMA 6.6. *Assume that (2.6) holds. Then, the estimate*

$$(6.22) \quad J(y, u) - J(y^h, \bar{u}_h) \geq \delta r^2 - a_1 h^2 - a_2 h r - a_3 h^2 r - a_4 r^3 - a_5 h r^2$$

is valid for all  $(y, u)$  satisfying (2.1) and  $\|u - \bar{u}_h\|_{L^2(\Omega)} = r$ . The constants  $a_i$  are computed in the course of the proof; see (6.26).

*Proof.* Since  $(y, u)$  and  $(y^h, \bar{u}_h)$  fulfill (2.1), we find

$$\begin{aligned}
 J(y, u) - J(y^h, \bar{u}_h) &= L(y, u, \bar{p}_h) - L(y^h, \bar{u}_h, \bar{p}_h) \\
 &= L(y, u, \bar{p}_h) - L(\bar{y}_h, \bar{u}_h, \bar{p}_h) \\
 (6.23) \quad &+ L(\bar{y}_h, \bar{u}_h, \bar{p}_h) - L(y^h, \bar{u}_h, \bar{p}_h).
 \end{aligned}$$

The second difference was already estimated in Lemma 6.2. We will now focus on the first difference,

$$\begin{aligned}
 L(y, u, \bar{p}_h) - L(\bar{y}_h, \bar{u}_h, \bar{p}_h) &= L_y(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h) + L_u(\bar{y}_h, \bar{u}_h, \bar{p}_h)(u - \bar{u}_h) \\
 (6.24) \quad &+ \frac{1}{2} L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y - \bar{y}_h, u - \bar{u}_h)^2 + r_2.
 \end{aligned}$$

Note that the quadratic part of the objective is approximated exactly. Only the nonlinear function  $f$  causes the remainder part  $r_2$ . We estimated all addends in Lemmas 6.3, 6.4, and 6.5. It remains to investigate the remainder term. Here, we find

$$\begin{aligned}
 (6.25) \quad |r_2| &= \left| \int_{\Omega} \int_0^1 \int_0^s (f''(\bar{y}_h + t(y - \bar{y}_h)) - f''(\bar{y}_h)) (y - \bar{y}_h)^2 dt ds \bar{p}_h dx \right| \\
 &\leq \frac{1}{6} c_{f''} \|y - \bar{y}_h\|_{L^3(\Omega)}^3 \|\bar{p}_h\|_{L^\infty(\Omega)}.
 \end{aligned}$$

We estimate the right-hand side of (6.25) using Lemma 4.2 and Corollary 5.2 as

$$\begin{aligned} \|y - \bar{y}_h\|_{L^3(\Omega)} &\leq \|y - y^h\|_{L^3(\Omega)} + \|y^h - \bar{y}_h\|_{L^3(\Omega)} \\ &\leq c_L I_3 \|u - \bar{u}_h\|_{L^2(\Omega)} + c_{H^1} c_S I_3 h \|\bar{u}_h\|_{L^2(\Omega)}. \end{aligned}$$

Using  $\|u - \bar{u}_h\|_{L^2(\Omega)} = r$  and  $(a + b)^3 \leq 4(a^3 + b^3)$  for positive  $a, b$ , we obtain

$$|r_2| \leq \frac{2}{3} c_{f''} \|\bar{p}_h\|_{L^\infty(\Omega)} (c_L^3 I_3^3 r^3 + (c_{H^1} c_S I_3 \|\bar{u}_h\|_{L^2(\Omega)})^3 h^3) =: c_{r1} r^3 + c_{r2} h^3.$$

By means of Lemmas 6.2, 6.3, 6.4, and 6.5 and (6.25) we get

$$\begin{aligned} J(y, u) - J(y^h, \bar{u}_h) &\geq -c_j \|\bar{u}_h\|_{L^2(\Omega)} h^2 - c_y \|\bar{y}_h - y_d\|_{L^2(\Omega)} \|y\|_{H^2(\Omega)} h^2 \\ &\quad - c_u \|\bar{p}_h\|_{W^{1,\infty}(\Omega)} h r + \delta r^2 - d_1 h r^2 - d_2 h^2 r - d_3 r^3 - d_4 h^4 - c_{r1} r^3 - c_{r2} h^3. \end{aligned}$$

Here, it remains to estimate  $\|y\|_{H^2(\Omega)}$ :

$$\|y\|_{H^2(\Omega)} \leq c_S \|u\|_{L^2(\Omega)} \leq c_S (\|\bar{u}_h\|_{L^2(\Omega)} + r).$$

Consequently, we obtain

$$\begin{aligned} J(y, u) - J(y^h, \bar{u}_h) &\geq \delta r^2 - (c_y \|\bar{y}_h - y_d\|_{L^2(\Omega)} c_S \|\bar{u}_h\|_{L^2(\Omega)} + c_{r2} + d_4 h^2) h^2 \\ &\quad - (c_u \|\bar{p}_h\|_{W^{1,\infty}(\Omega)}) h r - (c_y \|\bar{y}_h - y_d\|_{L^2(\Omega)} c_S + d_2) h^2 r - (d_3 + c_{r1}) r^3 - d_1 h r^2. \end{aligned}$$

Setting

$$\begin{aligned} a_1 &:= c_j \|\bar{u}_h\|_{L^2(\Omega)} + c_y \|\bar{y}_h - y_d\|_{L^2(\Omega)} c_S \|\bar{u}_h\|_{L^2(\Omega)} + c_{r2} + d_4, \\ a_2 &:= c_u \|\bar{p}_h\|_{W^{1,\infty}(\Omega)}, \\ (6.26) \quad a_3 &:= c_y \|\bar{y}_h - y_d\|_{L^2(\Omega)} c_S + d_2, \\ a_4 &:= d_3 + c_{r1}, \\ a_5 &:= d_1, \end{aligned}$$

the assertion is obtained.  $\square$

Now, let us fix a mesh-size  $h$  with associated solution  $\bar{u}_h$ . Suppose that the polynomial given by (6.22) is positive for some  $r > 0$ . Then we have that the value  $J(y, u)$  is greater than the  $J(y^h, \bar{u}_h)$  for all  $u$  having  $L^2$ -distance  $r$  to  $\bar{u}_h$ . Hence, there exists a local minimum of the optimal control problem (1.1)–(1.3) inside the neighborhood  $\{u : \|u - \bar{u}_h\|_{L^2(\Omega)} < r\}$  of  $\bar{u}_h$ .

**COROLLARY 6.7.** *Assume that there exists a positive value  $r$  such that*

$$-a_4 r^3 + (\delta - a_5 h) r^2 - (a_2 h + a_3 h^2) r - a_1 h^2 > 0.$$

*Then*

$$(6.27) \quad J(y, u) - J(y^h, \bar{u}_h) > 0$$

*holds for all  $(y, u)$  satisfying (2.1) and  $\|u - \bar{u}_h\|_{L^2(\Omega)} = r$ .*

A sufficient condition that the assumption of the previous Corollary 6.7 is fulfilled is given as the last result in this section.

COROLLARY 6.8. *Let us assume that  $\sigma := \delta - a_5 h > 0$  holds. Let us suppose further that there exists  $r_+ > 0$  that fulfills*

$$(6.28) \quad r_+ > \max \left\{ \frac{3(a_2 h + a_3 h^2)}{\sigma}, \sqrt{\frac{3a_1 h^2}{\sigma}} \right\},$$

and if  $a_4 > 0$  additionally, then

$$(6.29) \quad r_+ < \frac{\sigma}{3a_4}.$$

Then the prerequisite of Corollary 6.7 is satisfied.

*Proof.* The first condition, (6.28), gives

$$\frac{2}{3}(\delta - a_5 h)r_+^2 = \frac{2}{3}\sigma r_+^2 > (a_2 h + a_3 h^2)r_+ + a_1 h^2 \geq 0.$$

If  $a_4$  is not zero, then the second one implies  $\frac{1}{3}\sigma r_+^2 > a_4 r_+^3 > 0$ . Now, the polynomial  $-a_4 r^3 + (\delta - a_5 h)r^2 - (a_2 h + a_3 h^2)r - a_1 h^2$  admits a positive value for  $r_+$ . Thus, it satisfies the assumptions of the previous Corollary 6.7.  $\square$

**Remark 6.9.** The assumptions of Corollary 6.7 directly link the discretization parameter  $h$  to the coercivity factor  $\delta$ . The discretization has to be fine enough; i.e.,  $h$  has to be small enough, such that  $\delta - a_5 h > 0$  can be fulfilled. Hence, if the sufficient condition (2.6) holds for the solution of the original, continuous problem, then for sufficiently small  $h$  the assumptions of Corollary 6.7 will be satisfied.

**7. Verification of optimality conditions.** In the following,  $r$  denotes a fixed radius fulfilling the assumptions of Corollary 6.7. We are now going to prove that in an  $r$ -neighborhood of  $\bar{u}_h$  there exists a solution of the optimality system connected with the continuous problem (1.1)–(1.3).

**THEOREM 7.1.** *There exist at least one control  $\hat{u}$  with associated state  $\hat{y}$  and adjoint state  $\hat{p}$  in an  $r$ -neighborhood of  $\bar{u}_h$  fulfilling the first-order necessary optimality conditions (2.3).*

*Proof.* We investigate the optimal control problem for

$$U_{ad}^r := U_{ad} \cap \{u \in U : \|u - \bar{u}_h\|_{L^2(\Omega)} \leq r\}.$$

This set is weakly compact. Hence, there exists at least one solution  $\hat{u}$  of the modified problem. Since  $\bar{u}_h$  is feasible and

$$J(y, u) - J(y^h, \bar{u}_h) > 0$$

is satisfied for all controls  $u$  with  $\|u - \bar{u}_h\|_{L^2(\Omega)} = r$ , we have  $\|\hat{u} - \bar{u}_h\|_{L^2(\Omega)} < r$ . Consequently, the local minimizer  $\hat{u}$  of the modified problem is also a local minimizer for the original problem. In particular,  $\hat{u}$  has to fulfill the first-order necessary optimality conditions.  $\square$

As a consequence, we can give an error estimate for the associated state  $\hat{y}$  and adjoint state  $\hat{p}$  in terms of  $r$  and  $h$ .

**LEMMA 7.2.** *Let  $(\hat{y}, \hat{u}, \hat{p})$  fulfill the first-order necessary optimality conditions. Then one can estimate the distance to the discrete solution by*

$$(7.1) \quad \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \leq c_{y1} r + c_{y2} h^2$$

and

$$(7.2) \quad \|\hat{p} - \bar{p}_h\|_{L^2(\Omega)} \leq c_{p1} r + c_{p2} h^2,$$

with constants  $c_{yi}$  and  $c_{pi}$  independent of  $h$ ,  $r$ , and  $(\hat{y}, \hat{u}, \hat{p})$ :

$$\begin{aligned} c_{y1} &= c_L, \quad c_{y2} = c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)}, \quad c_{p1} = c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) c_{y1}, \\ c_{p2} &= c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) c_{y2} + c_p c_{L^2} \|\bar{y}_h - y_d\|_{L^2(\Omega)}. \end{aligned}$$

*Proof.* The difference  $\hat{y} - \bar{y}_h$  can be treated using the auxiliary function  $y^h$  defined in (3.8),

$$\begin{aligned} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} &\leq \|\hat{y} - y^h\|_{L^2(\Omega)} + \|y^h - \bar{y}_h\|_{L^2(\Omega)} \\ &\leq c_L r + c_{L^2} c_S h^2 \|\bar{u}_h\|_{L^2(\Omega)}. \end{aligned}$$

Here, we applied the estimate (5.5). The claim (7.1) follows with  $c_{y1} = c_L$  and  $c_{y2} = c_{L^2} c_S \|\bar{u}_h\|_{L^2(\Omega)}$ .

For the estimation of the adjoint states, recall the definition of  $p^h$  in (6.8) and the corresponding estimate (6.9),

$$\|p^h - \bar{p}_h\|_{L^2(\Omega)} \leq c_{L^2} h^2 \|p^h\|_{H^2(\Omega)} \leq c_p c_{L^2} h^2 \|\bar{y}_h - y_d\|_{L^2(\Omega)}.$$

Now, we introduce the splitting

$$\|\hat{p} - \bar{p}_h\|_{L^2(\Omega)} \leq \|\hat{p} - p^h\|_{L^2(\Omega)} + \|p^h - \bar{p}_h\|_{L^2(\Omega)},$$

and it remains to investigate  $d := \hat{p} - p^h$ . It is a solution of

$$a(d, v) + (f'(\hat{y})d, v) = (\hat{y} - \bar{y}_h, v) - ((f'(\hat{y}) - f'(\bar{y}_h))\bar{p}_h, v) \quad \forall v \in V.$$

Hence, we obtain

$$\begin{aligned} \|\hat{p} - p^h\|_{L^2(\Omega)} &\leq c_L (\|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} + \|(f'(\hat{y}) - f'(\bar{y}_h))\bar{p}_h\|_{L^2(\Omega)}) \\ &\leq c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)}. \end{aligned}$$

The estimate (7.2) is satisfied with  $c_{p1} = c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) c_{y1}$  and  $c_{p2} = c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) c_{y2} + c_p c_{L^2} \|\bar{y}_h - y_d\|_{L^2(\Omega)}$ .  $\square$

With the same technique, we get an  $H^1$ -error estimate for the state and adjoint state.

**COROLLARY 7.3.** *Under the assumptions of the previous lemma, we have*

$$\|\hat{y} - \bar{y}_h\|_{H^1(\Omega)} \leq c_L r + c_{H^1} c_S \|\bar{u}_h\|_{L^2(\Omega)} h$$

and

$$\|\hat{p} - \bar{p}_h\|_{H^1(\Omega)} \leq c_L (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|\hat{y} - \bar{y}_h\|_{H^1(\Omega)} + c_p c_{H^1} \|\bar{y}_h - y_d\|_{L^2(\Omega)} h.$$

Next, we will introduce additional assumptions on  $r$  that guarantee that the control  $\hat{u}$  fulfills a second-order sufficient optimality condition.

**THEOREM 7.4.** *Under the assumption*

$$r < \frac{\delta - c_h h^2}{c_r}$$

every control  $\hat{u}$  in an  $r$ -neighborhood of  $\bar{u}_h$  fulfills, together with its associated state  $\hat{y}$  and adjoint  $\hat{p}$ , the coercivity

$$(7.3) \quad L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 \geq \delta' \|u\|_{L^2(\Omega)}^2$$

for all  $y$  given as a solution of

$$(7.4) \quad a(y, v) + (f'(\hat{y})y, v) = (u, v) \quad \forall v \in V.$$

Moreover, there exists only one local minimum in this neighborhood.

The constants  $c_r$  and  $c_h$  will be determined in the course of the proof.

*Proof.* Let  $\hat{u}$  be a stationary point with associated state  $\hat{y}$  and adjoint state  $\hat{p}$ . Further, let  $u \in U$  be an arbitrary control with associated solutions  $y$  and  $y^h$  of the linearized equations (7.4) and (3.5), respectively. Then the pair  $(y, u)$  is suitable in (7.3), whereas  $(y^h, u)$  can be utilized as test functions in (3.4).

At first, we have to estimate the difference  $d := y - y^h$  as well as the sum  $y + y^h$  in terms of  $u$  and  $h$ . The difference fulfills the equation

$$0 = a(d, v) + (f'(\hat{y})y, v) - (f'(\bar{y}_h)y^h, v) = a(d, v) + (f'(\hat{y})d, v) + ((f'(\hat{y}) - f'(\bar{y}_h))y^h, v)$$

for all  $v \in V$ . Testing with  $d$  itself, we obtain

$$\|d\|_{H^1(\Omega)} \leq \frac{I_4}{\delta_0} \|(f'(\hat{y}) - f'(\bar{y}_h))y^h\|_{L^{4/3}(\Omega)}.$$

Hence, we can estimate  $d$  as a solution of a linearized equation with right-hand side  $-(f'(\hat{y}) - f'(\bar{y}_h))y^h$ , which is estimated by

$$\begin{aligned} \|(f'(\hat{y}) - f'(\bar{y}_h))y^h\|_{L^{4/3}(\Omega)} &\leq c_{f'} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|y^h\|_{L^4(\Omega)} \\ &\leq c_{f'} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} c_L I_4 \|u\|_{L^2(\Omega)}. \end{aligned}$$

Collecting all these inequalities, we find for  $d = y - y^h$

$$\begin{aligned} \|y - y^h\|_{L^2(\Omega)} &\leq c_L I_4 \|(f'(\hat{y}) - f'(\bar{y}_h))y^h\|_{L^2(\Omega)} \\ &\leq c_L \delta_0^{-1} I_4^2 c_{f'} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|u\|_{L^2(\Omega)}. \end{aligned}$$

The sum  $y + y^h$  is estimated by

$$\|y + y^h\|_{L^2(\Omega)} \leq 2c_L \|u\|_{L^2(\Omega)}.$$

Now, we can investigate the second derivative of the Lagrangian. We start with the decomposition

$$\begin{aligned} L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 &= L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 - L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u)^2 \\ &\quad + L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u)^2 - L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y^h, u)^2 \\ &\quad + L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y^h, u)^2. \end{aligned}$$

The last addend gives us the desired coercivity by (3.4). So we have to estimate the

two differences in this equation. The first one yields

$$\begin{aligned}
 & \left| L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u)^2 - L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y^h, u)^2 \right| \\
 &= \left| (y - y^h, y + y^h) + \int_{\Omega} f''(\bar{y}_h) \bar{p}_h (y - y^h)(y + y^h) \right| \\
 &\leq (1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|y - y^h\|_{L^2(\Omega)} \|y + y^h\|_{L^2(\Omega)} \\
 &\leq \underbrace{(1 + c_{f'} \|\bar{p}_h\|_{L^\infty(\Omega)}) 2c_L^2 \delta_0^{-1} I_4^2 c_{f'}}_{C_1} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|u\|_{L^2(\Omega)}^2 \\
 &\leq C_1 \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|u\|_{L^2(\Omega)}^2.
 \end{aligned}$$

Let us proceed with the second difference,

$$\begin{aligned}
 & \left| L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 - L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u)^2 \right| \\
 &= \left| \int_{\Omega} (f''(\hat{y})\hat{p} - f''(\bar{y}_h)\bar{p}_h) y^2 dx \right| \leq \|f''(\hat{y})\hat{p} - f''(\bar{y}_h)\bar{p}_h\|_{L^2(\Omega)} \|y\|_{L^4(\Omega)}^2 \\
 &\leq c_L^2 I_4^2 \|f''(\hat{y})\hat{p} - f''(\bar{y}_h)\bar{p}_h\|_{L^2(\Omega)} \|u\|_{L^2(\Omega)}^2.
 \end{aligned}$$

Using Lipschitz estimates, we obtain for the right-hand side,

$$\begin{aligned}
 \|f''(\hat{y})\hat{p} - f''(\bar{y}_h)\bar{p}_h\|_{L^2(\Omega)} &\leq \|f''(\hat{y})\hat{p} - f''(\hat{y})\bar{p}_h\|_{L^2(\Omega)} + \|f''(\hat{y})\bar{p}_h - f''(\bar{y}_h)\bar{p}_h\|_{L^2(\Omega)} \\
 &\leq c_{f'} \|\hat{p} - \bar{p}_h\|_{L^2(\Omega)} + c_{f''} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|\bar{p}_h\|_{L^\infty(\Omega)}.
 \end{aligned}$$

Hence, we arrive at

$$\begin{aligned}
 & \left| L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 - L''_{(y,u)}(\bar{y}_h, \bar{u}_h, \bar{p}_h)(y, u)^2 \right| \\
 &\leq c_L^2 I_4^2 (c_{f'} \|\hat{p} - \bar{p}_h\|_{L^2(\Omega)} + c_{f''} \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|u\|_{L^2(\Omega)}^2.
 \end{aligned}$$

So, we find

$$\begin{aligned}
 L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 &\geq \left\{ \delta - (c_L^2 I_4^2 c_{f'}) \|\hat{p} - \bar{p}_h\|_{L^2(\Omega)} \right. \\
 &\quad \left. - (C_1 + c_L^2 I_4^2 c_{f''} \|\bar{p}_h\|_{L^\infty(\Omega)}) \|\hat{y} - \bar{y}_h\|_{L^2(\Omega)} \right\} \|u\|_{L^2(\Omega)}^2.
 \end{aligned}$$

Here, we can apply the estimates of  $\|\hat{p} - \bar{p}_h\|_{L^2(\Omega)}$  and  $\|\hat{y} - \bar{y}_h\|_{L^2(\Omega)}$  of Lemma 7.2. We get consequently,

$$L''_{(y,u)}(\hat{y}, \hat{u}, \hat{p})(y, u)^2 \geq \{\delta - c_r r - c_h h^2\} \|u\|_{L^2(\Omega)}^2$$

with

$$c_r = C_1 c_{y_1} + c_L^2 I_4^2 (c_{f'} c_{p1} + c_{f''} \|\bar{p}_h\|_{L^\infty(\Omega)} c_{y1})$$

and

$$c_h = C_1 c_{y_2} + c_L^2 I_4^2 (c_{f'} c_{p2} + c_{f''} \|\bar{p}_h\|_{L^\infty(\Omega)} c_{y2}),$$

and the claim is proved.  $\square$

Finally, the sufficient condition provided by the previous theorem gives local optimality of  $\hat{u}$ . Moreover, the method of proof yields an estimate of the neighborhood of  $\hat{u}$ , where  $\hat{u}$  is locally optimal.

**THEOREM 7.5.** *Let the assumptions of Theorem 7.4 be satisfied. Then it holds with some  $\hat{\delta} > 0$  that*

$$J(y, u) - J(\hat{y}, \hat{u}) \geq \hat{\delta} \|u - \hat{u}\|_{L^2(\Omega)}^2$$

for all admissible  $u \in U_{ad}$  with  $\|u - \hat{u}\|_{L^2(\Omega)} < r'$  for some sufficiently small  $r'$ .

*Proof.* By assumption,  $(\hat{y}, \hat{u}, \hat{p})$  fulfills the necessary optimality conditions together with the coercivity relation (7.3). Let  $(y, u)$  be another admissible pair. We have

$$J(\hat{y}, \hat{u}) = L(\hat{y}, \hat{u}, \hat{p}) \quad \text{and} \quad J(y, u) = L(y, u, \hat{p}),$$

since  $(\hat{y}, \hat{u})$  and  $(y, u)$  are admissible. Taylor expansion of the Lagrange function yields

$$\begin{aligned} J(y, u) - J(\hat{y}, \hat{u}) &= L(y, u, \hat{p}) - L(\hat{y}, \hat{u}, \hat{p}) \\ (7.5) \quad &= L_y(\hat{y}, \hat{u}, \hat{p})(y - \hat{y}) + L_u(\hat{y}, \hat{u}, \hat{p})(u - \hat{u}) \\ &\quad + \frac{1}{2} L''(\hat{y}, \hat{u}, \hat{p})[(y - \hat{y}, u - \hat{u})]^2 + r_2. \end{aligned}$$

Since the necessary conditions (2.3) are satisfied at  $\hat{y}, \hat{u}$  with adjoint state  $\hat{p}$ , the first term vanishes. The second addend is nonnegative due to the variational inequality. The remainder term  $r_2$  satisfies (cf. (6.25))

$$(7.6) \quad |r_2| \leq \frac{1}{6} c_{f''} \|y - \hat{y}\|_{L^4(\Omega)}^3 \|\hat{p}\|_{L^4(\Omega)} \leq \frac{1}{6} c_{f''} c_L^3 I_4^4 \|u - \hat{u}\|_{L^2(\Omega)}^3 \|\hat{p}\|_{H^1(\Omega)}.$$

The pair  $(y - \hat{y}, u - \hat{u})$  is not suitable as a test function in (7.3), since  $y - \hat{y}$  is not the solution of a linearized equation. Let us introduce an auxiliary state  $d$  as the weak solution of

$$a(d, v) + (f'(\hat{y})d, v) = (u - \hat{u}, v) \quad \forall v \in V.$$

When we use  $d$  instead of  $y - \hat{y}$ , we make the small error  $r_1 := (y - \hat{y}) - d$ , which is itself the weak solution of

$$a(r_1, v) + (f_y^{\hat{y}} r_1, v) = ((f_y^{\hat{y}} - f'(\hat{y}))d, v) \quad \forall v \in V$$

with  $f_y^{\hat{y}} = \int_0^1 f'(\hat{y} + s(y - \hat{y})) ds$ . Since  $f'$  and  $f_y^{\hat{y}}$  are nonnegative, we get the estimate

$$\begin{aligned} (7.7) \quad \|r_1\|_{H^1(\Omega)} &\leq c_L \|(f_y^{\hat{y}} - f'(\hat{y}))d\|_{L^2(\Omega)} \leq \frac{1}{2} c_L c_{f'} \|y - \hat{y}\|_{L^4(\Omega)} \|d\|_{L^4(\Omega)} \\ &\leq \frac{1}{2} c_L^3 c_{f'} I_4^2 \|u - \hat{u}\|_{L^2(\Omega)}. \end{aligned}$$

Substituting  $y - \hat{y}$  by  $d + r_1$ , we obtain

$$\begin{aligned} \frac{1}{2} L_{yy}(\hat{y}, \hat{u}, \hat{p})[y - \hat{y}]^2 &= \frac{1}{2} L_{yy}(\hat{y}, \hat{u}, \hat{p})[d]^2 + L_{yy}(\hat{y}, \hat{u}, \hat{p})[d, r_1] + \frac{1}{2} L_{yy}(\hat{y}, \hat{u}, \hat{p})[r_1]^2 \\ &= \frac{1}{2} L_{yy}(\hat{y}, \hat{u}, \hat{p})[d]^2 + \frac{1}{2} \tilde{r}_2. \end{aligned}$$

The remainder term is given by

$$\tilde{r}_2 = (r_1, 2d + r_1) + \int_{\Omega} f''(\hat{y}) \hat{p} r_1 (2d + r_1) dx$$

and can be estimated by

$$(7.8) \quad \begin{aligned} |\tilde{r}_2| &\leq (1 + c_{f'} I_4^3 \|\hat{p}\|_{H^1(\Omega)}) \|r_1\|_{H^1(\Omega)} (\|d\|_{H^1(\Omega)} + \|r_1\|_{H^1(\Omega)}) \\ &\leq \underbrace{\frac{1}{2} (1 + c_{f'} I_4^3 \|\hat{p}\|_{H^1(\Omega)}) (2c_L \|u - \hat{u}\|_{L^2(\Omega)} + \|r_1\|_{H^1(\Omega)}) c_L^3 c_{f'} I_4^2}_{r_0} \|u - \hat{u}\|_{L^2(\Omega)}^2 \end{aligned}$$

with  $r_0 \rightarrow 0$  as  $\|u - \hat{u}\|_{L^2(\Omega)} \rightarrow 0$ .

So far, we achieved the following estimate for the difference of the objective values:

$$J(y, u) - J(\hat{y}, \hat{u}) \geq \frac{1}{2} L''(\hat{y}, \hat{u}, \hat{p}) [d, u]^2 - |r_2| - r_0 \|u - \hat{u}\|_{L^2(\Omega)}^2.$$

In the next step, we apply the coercivity (7.3) given by Theorem 7.4. Furthermore, we utilize the estimates of  $r_0$ ,  $r_1$ , and  $r_2$  in (7.6), (7.7), and (7.8), respectively. To shorten the estimates, let us assume  $\|u - \hat{u}\|_{L^2(\Omega)} \leq R$ . We obtain

$$(7.9) \quad \begin{aligned} J(y, u) - J(\hat{y}, \hat{u}) &\geq \left\{ \frac{\delta'}{2} - \frac{1}{2} c_L^3 c_{f'} I_4^2 (1 + c_{f'} I_4^3 \|\hat{p}\|_{H^1(\Omega)}) \left( 2c_L R + \frac{1}{2} c_L^3 c_{f'} I_4^2 R^2 \right) \right. \\ &\quad \left. - \frac{1}{6} c_{f''} I_4^4 R^3 \|\hat{p}\|_{H^1(\Omega)} \right\} \|u - \hat{u}\|_{L^2(\Omega)}^2. \end{aligned}$$

It remains to estimate  $\|\hat{p}\|_{H^1(\Omega)}$ . Using the splitting

$$\|\hat{p}\|_{H^1(\Omega)} \leq \|\hat{p} - \bar{p}_h\|_{H^1(\Omega)} + \|\bar{p}_h\|_{H^1(\Omega)},$$

Corollary 7.3 provides us with a computable estimate of that norm.

For  $R < R_0$  small enough, the factor in braces in (7.9) is greater than zero. This implies quadratic growth of the objective functional in the neighborhood  $\{u \in U_{ad} : \|u - \hat{u}\|_{L^2(\Omega)} \leq R_0\}$ .  $\square$

**8. Example.** In this section, we will apply our results to consider the optimal control problem of minimizing  $J(y, u)$  given by

$$(8.1) \quad J(y, u) := \frac{1}{2} \|y - y_d\|_{L^2(\Omega)}^2 + \frac{\nu}{2} \|u\|_{L^2(\Omega)}^2$$

subject to the semilinear boundary value problem

$$(8.2) \quad \begin{aligned} -(\Delta y)(x) + y^3(x) &= u(x) && \text{in } \Omega \\ y &= 0 && \text{on } \Gamma \end{aligned}$$

and to the control constraints

$$(8.3) \quad -0.1 \leq u(x) \leq 0.5 \text{ a.e. in } \Omega.$$

The domain  $\Omega$  is the unit square  $\Omega = (0, 1)^2$ , its boundary denoted by  $\Gamma$ . The parameter  $\nu$  was chosen as  $\nu = 0.1$ . The desired state  $y_d$  is given by

$$(8.4) \quad y_d = 8 \sin \pi x_1 \sin \pi x_2 - 4.$$

We find that the set of admissible controls is bounded in  $L^2(\Omega)$  by

$$\|u\|_{L^2(\Omega)} \leq 0.5 =: M_U \quad \forall u \in U_{ad}.$$

FIG. 8.1. *Discrete solution: control  $\bar{u}_h$  and state  $\bar{y}_h$ .*

**8.1. The solution.** At first, let us show the computed solutions for a fixed discretization. The state and adjoint state were discretized using piecewise linear and continuous functions on a regular triangulation of the domain. The control was discretized according to **(A3)** by piecewise constant functions. See also section 8.3.4 below for the discretization details. The grid consists of 20,000 triangles with 10,201 nodes. The discretization parameter was  $h = \sqrt{2}/100 = 0.01414\dots$ . Here and in what follows “ $\dots$ ” means truncation of floating point numbers after four leading digits. For the approximate evaluation of integrals we used a six-point quadrature of fourth order; see [15, Table 4.1]. A plot of the computed control  $\bar{u}_h$  and state  $\bar{y}_h$  can be found in Figure 8.1.

Now let us report the norms of the solution, which are needed for the following computations:

$$\begin{aligned} \|y_h\|_{L^\infty(\Omega)} &= 0.02752\dots, \quad \|y_h\|_{H^1(\Omega)} = 0.05638\dots, \quad \|y_h - y_d\|_{L^2(\Omega)} = 2.457\dots, \\ \|u_h\|_{L^2(\Omega)} &= 0.2856\dots, \\ \|p_h\|_{L^\infty(\Omega)} &= 0.1092\dots, \quad \|p_h\|_{H^1(\Omega)} = 0.2434\dots, \quad \|p_h\|_{W^{1,\infty}(\Omega)} = 0.3541\dots \end{aligned}$$

The set of elements  $T_h^i$ , where the control constraint is inactive (see Lemma 6.4), has measure  $|T_h^i| = 0.7220\dots$ .

**8.2. Check of the condition.** Now, let us report whether the condition (3.4) on the discrete solution is satisfied. For the computed solution it holds that

$$f''(\bar{y}_h(x))\bar{p}_h(x) \geq -0.01803\dots$$

Hence, the condition (3.7) and

$$\|y\|_{L^2(\Omega)}^2 + \nu\|u\|_{L^2(\Omega)}^2 + (f''(\bar{y}_h)y^2, \bar{p}_h) \geq \delta\|u\|_{L^2(\Omega)}^2$$

are satisfied with  $\delta = \nu = 0.1$ .

**8.3. Computation of the constants.** In the following short sections, we will explain how all those constants involved in the proofs are computed.

**8.3.1. Imbedding constants.** At first, we will compute the imbedding constants  $I_p$  of the imbeddings  $H_0^1(\Omega) \hookrightarrow L^p(\Omega)$ . We obtain, with the use of the eigenfunction of  $-\Delta$ , the constant of the imbedding in  $L^2(\Omega)$  as

$$I_2 = \frac{1}{\pi + 1} = 0.2415\dots$$

For the imbedding constants  $I_4$  and  $I_6$  we have the following. Because of the inequalities  $\|y\|_{L^4(\Omega)}^4 \leq \frac{1}{2}\|y\|_{L^2(\Omega)}^2\|\nabla y\|_{L^2(\Omega)}^2$  and  $\|y\|_{L^6(\Omega)}^6 \leq \frac{9}{8}\|y\|_{L^4(\Omega)}^4\|\nabla y\|_{L^2(\Omega)}^2$  (see [14]), the imbedding constants  $I_4$  and  $I_6$  can be computed as

$$I_4 = \left(\frac{1}{2}I_2^2\right)^{1/4} = 2^{-1/4}I_2^{1/2} = 0.4132\dots, \quad I_6 = \left(\frac{9}{8}I_4^4\right)^{1/6} = 0.5658\dots$$

Now, it remains to compute  $I_3$  for the imbedding in  $L^3(\Omega)$ . Using the interpolation inequality  $\|y\|_{L^3(\Omega)} \leq \|y\|_{L^2(\Omega)}^{1/3}\|y\|_{L^4(\Omega)}^{2/3}$ , we find

$$I_3 = I_2^{1/3}I_4^{2/3} = 0.3454\dots$$

The interpolation between  $L^2(\Omega)$  and  $L^6(\Omega)$  would give a larger imbedding constant of  $\tilde{I}_3 = I_2^{1/2}I_6^{1/2} = 0.3696\dots$  in our case.

**8.3.2. Solution mapping  $u \mapsto y$ .** At first, we investigate the bilinear form  $a$ . We have  $|a(y_1, y_2)| \leq \|y_1\|_{H^1(\Omega)}\|y_2\|_{H^1(\Omega)}$ , which gives  $\delta_1 = 1$ . Furthermore it holds that

$$a(y, y) = \|\nabla y\|_{L^2(\Omega)}^2 = \|y\|_{H^1(\Omega)}^2 - \|y\|_{L^2(\Omega)}^2 \geq (1 - I_2^2)\|y\|_{H^1(\Omega)}^2,$$

and we obtain  $\delta_0 = 1 - I_2^2 = 0.9417\dots$

The Lipschitz constant of the solution mapping now is given by Lemma 4.2 as

$$c_L = \frac{I_2}{\delta_0} = 0.2564\dots$$

In the following, we will apply the identity  $|y|_{H^2(\Omega)} = \|\Delta y\|_{L^2(\Omega)}$ , which can easily be proved by Fourier expansion. Now, let us estimate the constant  $c_S$  of Theorem 4.1. Since  $f(0) = 0$  holds, we find for the nonlinear equation,

$$\|y\|_{H^1(\Omega)} \leq c_L\|u\|_{L^2(\Omega)}.$$

Hence, we can derive

$$\begin{aligned} \|\Delta y\|_{L^2(\Omega)} &\leq \|f(y)\|_{L^2(\Omega)} + \|u\|_{L^2(\Omega)} \\ &\leq \|y\|_{L^6(\Omega)}^3 + \|u\|_{L^2(\Omega)} \leq (I_6^3 c_L^3 \|u\|_{L^2(\Omega)}^2 + 1)\|u\|_{L^2(\Omega)} \\ &\leq (I_6^3 c_L^3 M_U^2 + 1)\|u\|_{L^2(\Omega)}, \end{aligned}$$

which gives finally

$$\|y\|_{H^2(\Omega)} \leq \sqrt{c_L^2 + (I_6^3 c_L^3 M_U^2 + 1)^2}\|u\|_{L^2(\Omega)}$$

and the value of the constant  $c_S = \sqrt{c_L^2 + (I_6^3 c_L^3 M_U^2 + 1)^2} = 1.033\dots$

**8.3.3. Global estimates of the nonlinearity.** Furthermore, we need an  $L^\infty$ -bound of the solutions to the state equation. Here, we use Stampacchia's result; see [10, 17].

**COROLLARY 8.1.** *Let  $y$  be the solution of the nonlinear state equation (2.1) for a given right-hand side  $u \in L^2(\Omega)$ . Then it holds that  $y \in L^\infty(\Omega)$  with*

$$\|y\|_{L^\infty(\Omega)} \leq 4 \frac{I_6^2}{\sqrt{\delta_0}} |\Omega|^{1/6} \|u\|_{L^2(\Omega)}.$$

*Proof.* Let  $k$  be a real number. Define

$$v(x) = \begin{cases} y(x) - k & \text{if } y(x) \geq k, \\ 0 & \text{if } |y(x)| < k, \\ y(x) + k & \text{if } y(x) \leq -k, \end{cases} \quad \Omega(k) = \{x : |y(x)| \geq k\}.$$

Now, we test (2.1) by  $v$ ,

$$a(y, v) + (f(y), v) = (u, v).$$

Because of  $f(0) = 0$  and the monotonicity of  $f$ , it holds that  $(f(y), v) \geq 0$ . The right-hand side we estimate by

$$\begin{aligned} |(u, v)| &\leq \|u\|_{L^2(\Omega)} \|v\|_{L^2(\Omega)} \leq \|u\|_{L^2(\Omega)} \|v\|_{L^6(\Omega)} |\Omega(k)|^{1/3} \\ (8.5) \quad &\leq \|u\|_{L^2(\Omega)} |\Omega(k)|^{1/3} I_6 \|v\|_{H^1(\Omega)} \leq \frac{\delta_0}{2} \|v\|_{H^1(\Omega)}^2 + \frac{|\Omega(k)|^{2/3} I_6^2}{2\delta_0} \|u\|_{L^2(\Omega)}^2. \end{aligned}$$

Further, it holds that

$$|a(y, v)| \geq a(v, v) \geq \delta_0 \|v\|_{H^1(\Omega)}^2.$$

Now, we proceed with

$$(8.6) \quad \|v\|_{H^1(\Omega)}^2 \geq \frac{1}{I_6^2} \|v\|_{L^6(\Omega)}^2 = \frac{1}{I_6^2} \left( \int_{\Omega(k)} (|y| - k)^6 dx \right)^{1/3}.$$

Since  $\Omega(h) \subset \Omega(k)$  for  $h > k$ , we find

$$\begin{aligned} \left( \int_{\Omega(k)} (|y| - k)^6 dx \right)^{1/3} &\geq \left( \int_{\Omega(h)} (|y| - k)^6 dx \right)^{1/3} \geq \left( \int_{\Omega(h)} (h - k)^6 dx \right)^{1/3} \\ &= (h - k)^2 |\Omega(h)|^{1/3}. \end{aligned}$$

Altogether, we obtain

$$\frac{\delta_0}{I_6^2} (h - k)^2 |\Omega(h)|^{1/3} \leq \frac{I_6^2}{\delta_0} |\Omega(k)|^{2/3} \|u\|_{L^2(\Omega)}^2,$$

or, equivalently,

$$|\Omega(h)| \leq \left( \frac{I_6^4 \|u\|_{L^2(\Omega)}^2}{\delta_0^2} \right)^3 \frac{1}{(h - k)^6} |\Omega(k)|^2.$$

Then by a result of Stampacchia it holds that  $|\Omega(d)| = 0$  for

$$d = 4 \frac{I_6^2 \|u\|_{L^2(\Omega)}}{\delta_0} |\Omega|^{1/6}.$$

This implies

$$\|y\|_{L^\infty(\Omega)} \leq d = 4 \frac{I_6^2}{\delta_0} |\Omega|^{1/6} \|u\|_{L^2(\Omega)},$$

and the claim is proved. Due to the assumptions on  $f$  this estimate is valid for every suitable choice of the semilinearity.  $\square$

In our case, the constant  $c_{SL^\infty} = 4 \frac{I_6^2}{\delta_0} |\Omega|^{1/6}$  (see Theorem 4.1) has the value  $c_{SL^\infty} = 1.3596 \dots$ . Choices of  $L^p$ -spaces other than  $L^6$  in the estimates (8.5) and (8.6) yield other values of  $c_{SL^\infty}$ . Using the imbedding constants computed in this section,  $p = 6$  gave the smallest constant over all possible combinations from  $\{3, 4, 6\}$ .

Now, we can compute the global bound of the  $L^\infty$ -norms of all possible states by

$$M = c_{SL^\infty} M_U = 0.6798 \dots$$

Then the Lipschitz estimates of  $f$  holds with the following constants:

$$\begin{aligned} c_f &= 3M^2 = 1.386 \dots, \\ c_{f'} &= 6M = 4.079 \dots, \\ c_{f''} &= 6. \end{aligned}$$

Now, let us check whether the condition (3.6) holds uniformly for all admissible controls  $u$  with associated states  $y$  and adjoints  $p$ . To do so, we have to compute bounds of the  $L^\infty$ -norm of  $f''(y)p$ . Straightforward estimation gives

$$\begin{aligned} \|f''(y)p\|_{L^\infty(\Omega)} &\leq c_{f'} \|p\|_{L^\infty(\Omega)} \leq c_{f'} c_{SL^\infty} \|y - y_d\|_{L^2(\Omega)} \\ &\leq c_{f'} c_{SL^\infty} (I_2 c_L M_U + \|y_d\|_{L^2(\Omega)}) \leq 13.82 \dots \end{aligned}$$

Since this bound is larger than one, we cannot prove a priori that condition (3.7) holds for all admissible controls.

**8.3.4. Finite elements constants.** The discrete space  $V_h$  is chosen to be the set of continuous functions that are linear on the triangles of the triangulation  $T$ , e.g.,

$$V_h = \{v \in C(\bar{\Omega}) : v|_{T_h} \in P_1(T_h) \quad \forall T_h \in T, v|_\Gamma = 0\}.$$

The unit square was triangulated uniformly by orthogonal and congruent triangles.

It is known that the interpolation operator fulfills the requirements (5.1) and (5.2) of **(A3)**. However, we could not find any estimate of the associated constant  $c_1$  in the literature. So we decided to define the operator  $i_h$  as follows.

For  $y \in H_2(\Omega) \cap H_0^1(\Omega)$ , we set  $y_h := i_h y$  to be the solution of

$$a(y_h, v) = (-\Delta y, v) \quad \forall v \in V_h.$$

Then, the following upper bounds for the values of  $c_1$  and  $c_2$  can be found in [1, Theorem 5]:

$$c_1 = 0.2381 \dots, \quad c_2 = 0.4888 \dots$$

Before we can derive the constants of Lemma 5.1, we have to compute the constant  $c_M$  that appears in the proof of that lemma. The norm of the auxiliary function  $g$  defined there can be estimated by  $\|g\|_{H^1(\Omega)} \leq c_L$ . The  $L^2$ -norm of its Laplacian is

$$\|\Delta g\|_{L^2(\Omega)} \leq \|e\|_{L^2(\Omega)} + \|f_y^{y_h} g\|_{L^2(\Omega)} \leq 1 + \|g\|_{L^2(\Omega)} c_f \leq 1 + c_f c_L.$$

Hence, we obtain  $c_M = \sqrt{c_L^2 + (1 + c_f c_L)^2} = 1.504 \dots$

Now, we can compute the desired constants as

$$\begin{aligned} c_{L^2} &= (\delta_1 c_2 + c_f c_1) c_{H^1} c_M = 0.9806 \dots, \\ c_{H^1} &= (\delta_1 c_2 + c_f c_1) / \delta_0 = 0.8688 \dots \end{aligned}$$

**8.3.5. Auxiliary constants.** Now, let us investigate the auxiliary adjoint state  $p^h$  defined in (6.8). Here we want to compute the constant  $c_p$  as used in (6.10). By Corollary 4.3, we find

$$\|p^h\|_{H^1(\Omega)} \leq c_L \|\bar{y}_h - y_d\|_{L^2(\Omega)},$$

and with

$$\begin{aligned} \|\Delta p^h\|_{L^2(\Omega)} &= \|f'(\bar{y}_h)p^h\|_{L^2(\Omega)} + \|\bar{y}_h - y_d\|_{L^2(\Omega)} \\ &\leq 3I_2 \|\bar{y}_h\|_{L^\infty(\Omega)}^2 \|p^h\|_{H^1(\Omega)} + \|\bar{y}_h - y_d\|_{L^2(\Omega)} \\ &\leq (3I_2 c_L \|\bar{y}_h\|_{L^\infty(\Omega)}^2 + 1) \|\bar{y}_h - y_d\|_{L^2(\Omega)} \end{aligned}$$

we find  $c_p = \sqrt{c_L^2 + (3I_2 c_L \|\bar{y}_h\|_{L^\infty(\Omega)}^2 + 1)^2} = 1.032\dots$

**8.4. Verification results.** Finally, we report the estimates of the objective functional. The coefficients in the polynomial (6.22) were computed to

$$a_1 = 2.503\dots, a_2 = 0.3009\dots, a_3 = 5.843\dots, a_4 = 0.00337\dots, a_5 = 0.00786\dots,$$

which leads to the estimate

$$J(y, u) - J(y^h, \bar{u}_h) \geq -0.00337r^3 + 0.09989r^2 - 0.00542r - 0.00050.$$

This polynomial admits positive values for  $r \in [0.1033, 29.60]$ . That implies the existence of a local minimizer  $\hat{u}$  of  $J$  within the set

$$B_h = \{u \in U_{ad} : \|u - \bar{u}_h\|_{L^2(\Omega)} < 0.1033\}.$$

Furthermore, it follows that the global minimizer of  $J$  belongs to that neighborhood, since the upper bound 29.60 of the positivity interval is much larger than the diameter of the set of admissible controls.

Regarding the check of the sufficient condition—coercivity of the second-derivative of the Lagrangian—we achieved the following. For every  $r < 5.978$ , Theorem 7.4 gives coercivity of  $L''_{(y,u)}$  with a positive  $\delta'$ . Finally, Theorem 7.5 yields quadratic growth of the cost functional in an  $L^2$ -neighborhood of  $\hat{u}$  with radius  $r = 0.8543$ . Hence, it follows that the local minimizer  $\hat{u}$  of  $J$ , whose existence is proved above, is unique in the specified neighborhood  $B_h$ . Moreover, we know already that the global minimizer belongs to that neighborhood. Consequently, the function  $\hat{u}$  is the *unique globally optimal control* of our original problem (P). That is, the optimal control problem (8.1)–(8.4) is uniquely solvable.

Let us emphasize, that we proved a posteriori that the sufficient optimality condition holds at the still unknown control  $\hat{u}$ . Also we computed an approximation  $\bar{u}_h$  of that control with a computable error bound  $\|\hat{u} - \bar{u}_h\|_{L^2(\Omega)} < 0.1033$ .

**8.5. Dependence on  $h$ .** We computed the solution of the discrete problem for a sequence of discretizations. Then we performed the calculation of the different radii as above.

In Table 8.1,  $r_+$  denotes the smallest positive number such that the polynomial in the estimate in the estimation of the cost functional admits a positive value. That is,  $r_+$  is an upper bound for the approximation error in the controls. Our computable error bound decreases linearly with  $h$ , which is the expected convergence order for piecewise constant trial functions for the control [2].

## FAST SWITCHING ANALYSIS OF LINEAR SWITCHED SYSTEMS USING EXPONENTIAL SPLITTING\*

M. PORFIRI<sup>†</sup>, D. G. ROBERSON<sup>‡</sup>, AND D. J. STILWELL<sup>‡</sup>

**Abstract.** Stability of periodic switched linear systems with fast switching patterns is studied by combining the method of averaging with exponential splitting. This approach yields less conservative bounds on stabilizing fast switching rates than can be obtained with prior approaches. Such bounds can be useful for analysis and design of switching control laws. The method is also generalized to arbitrary (including nonperiodic nonswitched) time-varying systems. In particular, the effects of time-varying state perturbations on the stability of linear periodic switched systems are analyzed.

**DOI.** 10.1137/060665750

**1. Introduction.** A switched system is a dynamical system which consists of a family of time-invariant subsystems and a policy that oversees the switching among them. For example,

$$\dot{x} = A_{\rho(t)}x,$$

where  $\rho(t)$  is a piecewise constant switching signal that selects from a family of matrix-valued coefficients  $\Theta = \{A_1, A_2, \dots, A_M\}$ , represents such a system. This class of dynamical systems finds extensive application in various areas of engineering practice such as power electronics, network communication, hybrid control, traffic flow, biosystem modeling, etc. (see, e.g., [16] and references therein). Switched systems have been studied for several decades in the systems and control literature (see, e.g., [8]).

Switching among the possible system configurations may be orchestrated according to different protocols, as discussed in [16] and [19]. Switching events may occur as a function of the system state, or at given instants in time independent of the system state. In the latter case, when one or more of the subsystems (the elements of  $\Theta$ ) are stable, dwell time approaches, where the switching signal selects stable subsystems for relatively long time intervals, are effective in ensuring system stability. However, when no subsystems are stable, or when system constraints prevent long intervals between switching instants, alternate strategies must be considered. Periodic switching is another well-studied strategy (see, e.g., [20]) that can be useful when such restrictions exist.

Periodic switching is a state-independent switching scheme that utilizes a periodic rule for selecting subsystems. That is, there is a  $T > 0$  such that  $\rho(t) = \rho(t + T)$  for

all  $t \geq 0$ . The stability of the resulting periodic linear system may be analyzed using a number of different techniques. The spectral properties and contractibility of the state transition matrix over a switching period may be used to characterize system stability. Such an approach involves computation and multiplication of matrix exponentials, which may present computational challenges (see, e.g., [10]), especially as the system dimension and the number of subsystems grow. Standard Floquet arguments may also be used to study the periodic system, as in [6]. The main drawback of this approach is its inherent dependence on matrix logarithms, which limits qualitative system analysis and control design. In [4] sufficient conditions for uniform asymptotic stability are stated in terms of convex combinations of the matrix measures of the elements of  $\Theta$ . In [13] the conditions of [4] are generalized by including matrix condition numbers in the sufficient conditions. In [17] it is shown that the stability of a switched system may be assessed by studying an auxiliary time-invariant system whose state coefficient matrix is a certain time average of the original system. In particular, it is shown that the stability of the average system is inherited by the switched system whenever the switching signal is sufficiently fast, or equivalently when the switching period  $T$  is sufficiently small (fast switching). In [20] the average system is used to design a stabilizing feedback law for periodic switched systems. More specifically, it is shown that if the average system is stabilizable and detectable, then for any feedback matrix that stabilizes the average system there exists a minimum switching rate that guarantees stability of the periodic system.

Computing the slowest allowable switching rate (or the maximum switching period) is an important factor to consider when analyzing stability and designing feedback control laws. In [17] the estimate of the maximum switching period is based on a perturbation analysis of the system spectral properties. The estimate may also be established by specializing to switched linear systems the method of averaging proposed in [7] for general linear time-varying systems (see, e.g., [11]). The approach of [7] relies on a decomposition of the system transition matrix into a part due to the time average of the system dynamics and a perturbation that is on the order of  $T^2$ , where  $T$  is the switching period. For the time-varying system  $\dot{x} = \mathbf{A}(t)x$ , the state transition matrix satisfies

$$\Phi(s + \tau, s) = e^{\bar{\mathbf{A}}_\tau(s)\tau} + \mathbf{E}_\tau(s),$$

where

$$\bar{\mathbf{A}}_\tau(s) = \frac{1}{\tau} \int_s^{s+\tau} \mathbf{A}(\sigma) d\sigma$$

and

$$\|\mathbf{E}_\tau(s)\| \leq \alpha^2 \tau^2 e^{\alpha\tau}$$

if  $\|\mathbf{A}(t)\| \leq \alpha$  for all  $t$ . This decomposition is well known and appears in several textbooks (see, e.g., [1] and [12, Exercise 4.25]). Henceforth, this approach to estimating the maximum switching period is referred to as the standard approach, and the estimate itself as the standard estimate. The estimate of [17] is difficult to compute numerically, as it involves quantifying the sensitivity of matrices to perturbations. The standard estimate is easily applicable and requires the knowledge of elementary quantities. Nevertheless, it generally leads to conservative results that may be even a few orders of magnitude less than the exact value computed using Floquet theory.

The present work is focused on characterizing the slowest stabilizing switching rate through a computationally tractable expression. Loosely speaking, improved bounds are due to directly expressing the effects of the commutation relationship of the elements of  $\Theta$ . The general idea stems from combining the standard approach with well-developed results from numerical algebra (see, e.g., [14, 10]). By exploiting the concept of matrix exponential splitting, which is widely used in numerical analysis of partial differential equations (see, e.g., [9]), a novel switching rate estimate is obtained. The estimate bounds the slowest switching rate that guarantees uniform asymptotic stability of switched systems characterized by asymptotically stable averages. The new estimate is compared to the standard estimate and its improvement is shown. These results are also extended to a more general linear class of dynamical systems, and new results on the method of averaging are established. In particular, the effects of time-varying state perturbations on the stability of linear periodic switched systems are analyzed.

The paper is organized as follows. Section 2 contains the general system description and a discussion of fundamental matrix measure and exponential splitting concepts. Section 3 addresses our principle contribution, an improved estimate for the maximum switching period for stability under fast switching. Section 4 addresses the stability analysis of more general dynamical systems and presents stability conditions for perturbed switched systems. Section 5 contains concluding remarks.

**2. System description.** We consider the homogeneous linear time-varying system

$$(2.1) \quad \dot{\mathbf{x}} = \mathbf{A}(t)\mathbf{x},$$

where  $t \in \mathbb{R}^+$  indicates the time variable,  $\mathbf{x} \in \mathbb{R}^n$  is the system state, and  $\mathbf{A}(\cdot) : \mathbb{R}^+ \rightarrow \mathbb{R}^{n \times n}$  is a bounded and right continuous matrix function. By a right continuous function in  $\mathbb{R}^+$  we mean a function whose value at each point  $t$  in  $\mathbb{R}^+$  equals its right-hand limit at  $t$ . We further assume that the number of discontinuities of  $\mathbf{A}$  is finite over any finite interval  $[s, s + \tau]$ , where  $s, \tau \in \mathbb{R}^+$ . Thus we do not consider systems which exhibit Zeno behavior or chattering, as described in [8] and [16].

The homogeneous systems that we consider include switched systems for which  $\mathbf{A}(t) = \mathbf{A}_{\rho(t)}$  with  $\rho(t)$  being a switching signal that selects from among a family of constant matrix functions. In section 3 this class of switched systems is considered, with the additional conditions that  $\rho(t)$  is periodic and selects from among a finite set of matrix functions  $\Theta = \{A_1, A_2, \dots, A_M\}$ . The switched systems considered in section 4 are not subject to the additional conditions, so that  $\rho(t)$  may be nonperiodic and  $\Theta$  may be countably infinite. In section 4 we also consider more general linear time-varying systems, where  $\mathbf{A}(t)$  may be nonconstant between points of discontinuity. For existence and uniqueness of these types of problems one may refer to [3] and [18].

**2.1. Matrix measure.** Let  $\|\cdot\|$  denote a norm in  $\mathbb{R}^n$  and the corresponding induced norm in  $\mathbb{R}^{n \times n}$ . The one-sided directional derivative of  $\|\cdot\|$  at the identity matrix  $\mathbf{I} \in \mathbb{R}^{n \times n}$  in the direction  $\mathbf{A} \in \mathbb{R}^{n \times n}$  is called the matrix measure of  $\mathbf{A}$  and is denoted by  $\mu(\mathbf{A})$ . That is,

$$(2.2) \quad \mu(\mathbf{A}) = \lim_{h \rightarrow 0^+} \frac{\|\mathbf{I} + h\mathbf{A}\| - 1}{h}.$$

Basic properties of the matrix measure for  $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{n \times n}$  and  $c \in \mathbb{R}$  are

$$\begin{aligned}
 (2.3a) \quad & \mu(\mathbf{I}) = 1, \quad \mu(-\mathbf{I}) = -1, \quad \mu(\mathbf{0}) = 0, \\
 (2.3b) \quad & \mu(c\mathbf{A}) = |c|\mu(\operatorname{sgn}(c)\mathbf{A}), \quad \mu(\mathbf{A} + c\mathbf{I}) = \mu(\mathbf{A}) + c, \\
 (2.3c) \quad & \mu(\mathbf{A} + \mathbf{B}) \leq \mu(\mathbf{A}) + \mu(\mathbf{B}), \\
 (2.3d) \quad & \|e^{\mathbf{A}}\| \leq e^{\mu(\mathbf{A})}, \\
 (2.3e) \quad & \max_{i=1, \dots, n} [\operatorname{Re}(\lambda_i(\mathbf{A}))] \leq \mu(\mathbf{A}) \leq \|\mathbf{A}\|,
 \end{aligned}$$

where  $\lambda_i(\mathbf{A})$  indicates the  $i$ th eigenvalue of  $\mathbf{A}$ . These properties hold for the matrix measure defined in any induced matrix norm. Derivation of the relationships (2.3) may be found in [15]. An additional property of the matrix measure (see, e.g., [7]) places upper and lower bounds on the transition matrix norm of the system (2.1) according to the relationship

$$(2.4) \quad e^{-\int_{\tau}^t \mu(-\mathbf{A}(\vartheta))d\vartheta} \leq \|\Phi(t, \tau)\| \leq e^{\int_{\tau}^t \mu(\mathbf{A}(\vartheta))d\vartheta}$$

for all  $t, \tau \in \mathbb{R}^+$  and  $t \geq \tau$ .

The computation of the matrix measure is generally very involved, but there are special cases where reduced effort is needed (see, e.g., [15, 2]). In what follows, we primarily make use of the vector  $\mathbf{P}$ -norm and the corresponding matrix induced norm and matrix measure, defined as

$$\begin{aligned}
 (2.5) \quad & \|\mathbf{x}\|_P = \sqrt{\mathbf{x}^T \mathbf{P} \mathbf{x}}, \quad \|\mathbf{A}\|_P = \max_{i=1, \dots, n} \sigma_i(\mathbf{P}^{1/2} \mathbf{A} \mathbf{P}^{-1/2}), \\
 & \mu_P(\mathbf{A}) = \frac{1}{2} \max_{i=1, \dots, n} \lambda_i(\mathbf{P}^{1/2} \mathbf{A} \mathbf{P}^{-1/2} + \mathbf{P}^{-1/2} \mathbf{A}^T \mathbf{P}^{1/2}),
 \end{aligned}$$

where  $\mathbf{x} \in \mathbb{R}^n$ ,  $\mathbf{A} \in \mathbb{R}^{n \times n}$ ,  $\sigma_i(\mathbf{A})$  indicates the  $i$ th singular value of  $\mathbf{A}$ , and  $\mathbf{P}$  is any symmetric positive definite matrix in  $\mathbb{R}^{n \times n}$ . In particular, when  $\mathbf{P} = \mathbf{I}$  the matrix measure corresponding to the Euclidean norm is obtained.

**2.2. Exponential splitting.** Exponential splitting methods are numerical tools for computing matrix exponentials (see, e.g., [9]). They involve decomposing a matrix into the sum of matrices, whose exponentials can be easily computed, and approximating the original matrix exponential in terms of the exponentials of the simpler matrices. That is, traditional splitting methods approximate the matrix exponential  $e^{(\mathbf{A}+\mathbf{B})h}$  by the product  $e^{\mathbf{A}h}e^{\mathbf{B}h}$ , where  $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{n \times n}$  and  $h \in \mathbb{R}^+$ , and where  $e^{\mathbf{A}h}$  and  $e^{\mathbf{B}h}$  are relatively easy to compute.

We apply splitting methods in the opposite direction. That is, we approximate the product of exponentials  $e^{\mathbf{A}h}e^{\mathbf{B}h}$  by the single exponential  $e^{(\mathbf{A}+\mathbf{B})h}$ . The motivation for this approach is the recognition that the product represents the state transition matrix for a switched system, and the single exponential represents the transition matrix for a corresponding average system. We consider the problem of estimating the global error in the first order exponential splitting by defining

$$\mathbf{E}(h) = e^{\mathbf{A}h}e^{\mathbf{B}h} - e^{(\mathbf{A}+\mathbf{B})h}.$$

PROPOSITION 2.1. *Given  $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{n \times n}$  and  $h \in \mathbb{R}^+$ ,*

$$\|\mathbf{E}(h)\| \leq \frac{1}{2} h^2 \|[\mathbf{A}, \mathbf{B}]\| e^{h(\mu(\mathbf{A}) + \mu(\mathbf{B}))},$$

where

$$[\mathbf{A}, \mathbf{B}] = \mathbf{AB} - \mathbf{BA}$$

is the commutator of  $\mathbf{A}$  and  $\mathbf{B}$ .

*Proof.* Part of the following arguments are borrowed from [14]. The main difference in those results lies in the estimate itself, where we make use of additional properties of the matrix measure. By differentiating  $\mathbf{E}(h)$ , we obtain

$$\frac{d}{dh} \mathbf{E}(h) = (\mathbf{A} + \mathbf{B})\mathbf{E}(h) + [e^{\mathbf{A}h}, \mathbf{B}] e^{\mathbf{B}h}.$$

The above ordinary differential equation (ODE) with homogeneous initial conditions may be solved to obtain

$$(2.6) \quad \mathbf{E}(h) = \int_0^h e^{(h-\vartheta)(\mathbf{A}+\mathbf{B})} \mathbf{S}(\vartheta) e^{\vartheta \mathbf{B}} d\vartheta,$$

where

$$\mathbf{S}(\vartheta) = [e^{\mathbf{A}\vartheta}, \mathbf{B}].$$

It is clear that  $\mathbf{S}(0) = 0$ . By differentiating  $\mathbf{S}(\vartheta)$ , we obtain

$$\frac{d}{d\vartheta} \mathbf{S}(\vartheta) = \mathbf{AS}(\vartheta) + [\mathbf{A}, \mathbf{B}] e^{\mathbf{A}\vartheta}.$$

The above ODE may be solved, yielding

$$(2.7) \quad \mathbf{S}(\vartheta) = \int_0^\vartheta e^{(\vartheta-p)\mathbf{A}} [\mathbf{A}, \mathbf{B}] e^{p\mathbf{A}} dp.$$

Substituting (2.7) into (2.6), we obtain

$$\mathbf{E}(h) = \int_0^h e^{(h-\vartheta)(\mathbf{A}+\mathbf{B})} \left( \int_0^\vartheta e^{(\vartheta-p)\mathbf{A}} [\mathbf{A}, \mathbf{B}] e^{p\mathbf{A}} dp \right) e^{\vartheta \mathbf{B}} d\vartheta.$$

Applying standard matrix norm inequalities, then using property (2.3d) followed by (2.3b), we obtain

$$\begin{aligned} \|\mathbf{E}(h)\| &\leq \int_0^h \left\| e^{(h-\vartheta)(\mathbf{A}+\mathbf{B})} \right\| \int_0^\vartheta \left\| e^{(\vartheta-p)\mathbf{A}} \right\| \left\| [\mathbf{A}, \mathbf{B}] \right\| \left\| e^{p\mathbf{A}} \right\| dp \left\| e^{\vartheta \mathbf{B}} \right\| d\vartheta \\ &\leq \left\| [\mathbf{A}, \mathbf{B}] \right\| \int_0^h e^{\mu((h-\vartheta)\mathbf{A}) + \mu((h-\vartheta)\mathbf{B})} e^{\mu(\vartheta \mathbf{B})} \int_0^\vartheta e^{\mu((\vartheta-p)\mathbf{A})} e^{\mu(p\mathbf{A})} dp d\vartheta \\ &= \left\| [\mathbf{A}, \mathbf{B}] \right\| \int_0^h e^{(h-\vartheta)\mu(\mathbf{A})} e^{(h-\vartheta)\mu(\mathbf{B})} e^{\vartheta \mu(\mathbf{B})} \int_0^\vartheta e^{(\vartheta-p)\mu(\mathbf{A})} e^{p\mu(\mathbf{A})} dp d\vartheta \\ &= \left\| [\mathbf{A}, \mathbf{B}] \right\| \int_0^h e^{h\mu(\mathbf{A})} e^{h\mu(\mathbf{B})} \int_0^\vartheta dp d\vartheta \\ &= \frac{1}{2} h^2 \left\| [\mathbf{A}, \mathbf{B}] \right\| e^{h(\mu(\mathbf{A}) + \mu(\mathbf{B}))}. \quad \square \end{aligned}$$

The problem of estimating the global error in the first order exponential splitting has also been studied in [5], using a Lie algebraic framework. The resulting error bound in Proposition 2 of [5] involves the determination of the limit of a series of nested commutators, arising from the Baker–Campbell–Hausdorff formula, which can be potentially difficult to compute.

**3. Stability analysis of periodic switching systems.** The present section is devoted to the analysis of homogeneous time-varying systems of the form (2.1), where  $\mathbf{A}$  is a  $T$ -periodic piecewise constant bounded matrix function. At any point in time,  $\mathbf{A}(t)$  takes values from the set  $\Theta = \{\mathbf{A}_1, \mathbf{A}_2, \dots, \mathbf{A}_M\}$  according to the policy

$$(3.1) \quad \mathbf{A}(t) = \mathbf{A}_m \text{ for } t \in \left[ kT + T \sum_{i=0}^{m-1} \delta_i, kT + T \sum_{i=0}^m \delta_i \right),$$

where  $\delta_i$  is the duty cycle of the subsystem corresponding to the matrix  $\mathbf{A}_i$  with the convention  $\delta_0 = 0$ , so that  $0 \leq \delta_i < 1$  and  $\sum_{i=1}^M \delta_i = 1$ , and where  $k \in \mathbb{N}$ . Our goal is to determine an estimate for the maximum switching period  $T$  for which (2.1) is uniformly asymptotically stable.

For the periodic switched linear system (3.1), the transition matrix  $\Phi$  over any period  $[kT, (k+1)T)$  is called a monodromy. Due to periodicity, the monodromy over the interval for any  $k$  equals the monodromy over the interval for  $k = 0$ , so that

$$(3.2) \quad \begin{aligned} \Phi((k+1)T, kT) &= \Phi(T, 0) = \Phi\left(T, T \sum_{i=1}^{M-1} \delta_i\right) \cdots \Phi(T(\delta_1 + \delta_2), T\delta_1) \Phi(T\delta_1, 0) \\ &= e^{T\mathbf{A}_M \delta_M} \cdots e^{T\mathbf{A}_2 \delta_2} e^{T\mathbf{A}_1 \delta_1}. \end{aligned}$$

In what follows we show a sufficient condition for uniform asymptotic stability based on the transition matrix contractibility.

PROPOSITION 3.1. *If for some norm*

$$(3.3) \quad \sum_{i=1}^M \delta_i \mu(\mathbf{A}_i) < 0,$$

*then the system is uniformly asymptotically stable for every positive  $T$ . Otherwise, if the average system matrix*

$$(3.4) \quad \bar{\mathbf{A}}_T = \sum_{i=1}^M \delta_i \mathbf{A}_i$$

*is Hurwitz, then there exists a  $T^* > 0$  such that when  $T < T^*$  the system is uniformly asymptotically stable.  $T^*$  satisfies*

$$(3.5) \quad e^{T^* \mu_P(\bar{\mathbf{A}}_T)} + \frac{1}{2} (T^*)^2 \Gamma_P(\mathbf{A}) \exp\left(T^* \sum_{i=1}^M \delta_i \mu_P(\mathbf{A}_i)\right) = 1,$$

*where*

$$(3.6) \quad \Gamma_P(\mathbf{A}) = \sum_{i=1}^{M-1} \sum_{j=i+1}^M \delta_i \delta_j \|\mathbf{A}_i, \mathbf{A}_j\|_P.$$

*The norm is constructed as in (2.5), with  $\mathbf{P}$  being the unique symmetric positive definite solution of*

$$(3.7) \quad \bar{\mathbf{A}}_T^T \mathbf{P} + \mathbf{P} \bar{\mathbf{A}}_T + \mathbf{R} = 0,$$

*where  $\mathbf{R} = \mathbf{R}^T > 0$  is arbitrary.*

The proof of Proposition 3.1 is given at the end of the section, after a preliminary proposition on the application of exponential splitting to the monodromy matrix. We note that although Proposition 3.1 provides sufficient stability conditions, the condition of Hurwitz  $\bar{\mathbf{A}}_T$  is actually necessary for stability for small  $T$ . Indeed, if  $\bar{\mathbf{A}}_T$  is not Hurwitz, there exists a  $T^* > 0$  such that the system is unstable for all  $T < T^*$ , as Theorem 2.1 in [7] indicates. Constructing the norm as in (3.7) guarantees that the measure of  $\bar{\mathbf{A}}_T$  is negative, given (2.5) and the fact that  $\bar{\mathbf{A}}_T$  is Hurwitz. If an arbitrary norm is chosen, the corresponding measure of  $\bar{\mathbf{A}}_T$  may be positive, even if  $\bar{\mathbf{A}}_T$  is Hurwitz. The commutators appearing in (3.6) reflect the similarity of the eigenvectors of the subsystem state coefficient matrices, a set of relationships not considered in the standard approach. If all of the matrices  $\mathbf{A}_1, \dots, \mathbf{A}_M$  commute and  $\bar{\mathbf{A}}_T$  is Hurwitz, the switching system is uniformly asymptotically stable. Indeed, the commutator in (3.5) vanishes for every  $i, j$ , and the monodromy matrix is a contraction for any  $T$ . If all of the matrices  $\mathbf{A}_1, \dots, \mathbf{A}_M$  are symmetric and negative definite, then  $\bar{\mathbf{A}}_T$  is Hurwitz and the switched system is uniformly asymptotically stable. Indeed, the matrix measure induced by the Euclidean norm satisfies (3.3).

**PROPOSITION 3.2.** *For the switched periodic linear system defined by (3.1), the difference  $\mathbf{E}_T$  between the monodromy matrix over the period  $[0, T)$  and the transition matrix of the average system over the same period, defined by*

$$(3.8) \quad \Phi(T, 0) = \mathbf{E}_T + e^{T\bar{\mathbf{A}}_T},$$

*satisfies the norm bound*

$$(3.9) \quad \|\mathbf{E}_T\| \leq \frac{1}{2} T^2 \Gamma(\mathbf{A}) \exp \left( T \sum_{i=1}^M \delta_i \mu(\mathbf{A}_i) \right),$$

*where*

$$(3.10) \quad \Gamma(\mathbf{A}) = \sum_{i=1}^{M-1} \sum_{j=i+1}^M \delta_i \delta_j \|[\mathbf{A}_i, \mathbf{A}_j]\|.$$

*Proof.* We rewrite the global error in (3.8) as

$$\begin{aligned} \mathbf{E}_T = & \sum_{i=0}^{M-2} e^{T\mathbf{A}_{M+1}\delta_{M+1}} e^{T\mathbf{A}_M\delta_M} \dots e^{T\mathbf{A}_{M+1-i}\delta_{M+1-i}} \\ & \times \left( e^{T\delta_{M-i}\mathbf{A}_{M-i}} e^{T\sum_{j=i+1}^{M-1} \delta_{M-j}\mathbf{A}_{M-j}} - e^{T\sum_{j=i}^{M-1} \delta_{M-j}\mathbf{A}_{M-j}} \right), \end{aligned}$$

where  $\mathbf{A}_{M+1} = \mathbf{I}$  and  $\delta_{M+1} = 0$ . Applying Proposition 2.1 for each bracketed term, the Schwarz inequality, the triangle inequality, and the measure properties (2.3b),

(2.3c), and (2.3d), we obtain

$$\begin{aligned}
 \|\mathbf{E}_T\| &\leq \sum_{i=0}^{M-2} \|e^{T\mathbf{A}_{M+1}\delta_{M+1}}\| \dots \|e^{T\mathbf{A}_{M+1-i}\delta_{M+1-i}}\| \\
 &\quad \times \left\| e^{T\mathbf{A}_{M-i}} e^{T\sum_{j=i+1}^{M-1} \delta_{M-j}\mathbf{A}_{M-j}} - e^{T\sum_{j=i}^{M-1} \delta_{M-j}\mathbf{A}_{M-j}} \right\| \\
 &\leq \frac{1}{2} T^2 \sum_{i=0}^{M-2} \left\| \left[ \delta_{M-i}\mathbf{A}_{M-i}, \sum_{j=i+1}^{M-1} \delta_{M-j}\mathbf{A}_{M-j} \right] \right\| \\
 &\quad \times e^{T(\sum_{j=0}^i \delta_{M-j}\mu(\mathbf{A}_{M-j}) + \mu(\sum_{j=i+1}^{M-1} \delta_{M-j}\mathbf{A}_{M-j}))} \\
 &\leq \frac{1}{2} T^2 \sum_{i=0}^{M-2} \sum_{j=i+1}^{M-1} \delta_{M-i}\delta_{M-j} \|\mathbf{A}_{M-i}, \mathbf{A}_{M-j}\| e^{T\sum_{l=0}^{M-1} \delta_{M-l}\mu(\mathbf{A}_{M-l})}. \quad \square
 \end{aligned}$$

*Proof of Proposition 3.1.* To demonstrate uniform asymptotic stability, we show that the monodromy matrix  $\Phi(T, 0)$  is a contraction. This approach relies on the boundedness of the transition matrix over any interval whose duration is less than one switching period, due to the fact that the set  $\Theta$  of state coefficient matrices contains a finite number of elements. If the monodromy is a contraction,  $\|\Phi(t, 0)\|$  can be made arbitrarily small by choosing  $t$  sufficiently large, establishing uniform asymptotic stability (see, e.g., [12, Exercise 6.15]).

To establish the first sufficient condition, we use (3.2) to obtain an expression for the monodromy matrix norm in the norm for which (3.3) holds. Applying the Schwarz inequality and matrix measure properties (2.3b) and (2.3d) yields

$$\|\Phi(T, 0)\| \leq e^{T\delta_M\mu(\mathbf{A}_M)} \dots e^{T\delta_2\mu(\mathbf{A}_2)} e^{T\delta_1\mu(\mathbf{A}_1)} = e^{T\sum_{i=1}^M \delta_i\mu(\mathbf{A}_i)} < 1.$$

This condition appeared in [4] for the Euclidean norm.

To establish the second sufficient condition, we use (3.8) to obtain a matrix measure norm expression. Using the triangle inequality together with (2.3d) yields

$$\|\Phi(T, 0)\| \leq \|\mathbf{E}_T\| + e^{T\mu(\bar{\mathbf{A}}_T)}.$$

Thus, considering Proposition 3.2, we look for switching periods satisfying

$$(3.11) \quad \frac{1}{2} T^2 \Gamma(\mathbf{A}) \exp\left(T \sum_{i=1}^M \delta_i \mu(\mathbf{A}_i)\right) + e^{T\mu(\bar{\mathbf{A}}_T)} < 1.$$

We specialize to the norm defined in (2.5), where  $\mathbf{P}$  is the solution of (3.7). Because the matrix  $\mathbf{P}$ -norm is induced from the vector  $\mathbf{P}$ -norm, properties (2.3) hold for the matrix measure derived from this norm. The measure of the average matrix is

$$\begin{aligned}
 \mu_P(\bar{\mathbf{A}}_T) &= \frac{1}{2} \max_{i=1, \dots, n} \lambda_i \left( \mathbf{P}^{1/2} \bar{\mathbf{A}}_T \mathbf{P}^{-1/2} + \mathbf{P}^{-1/2} \bar{\mathbf{A}}_T^T \mathbf{P}^{1/2} \right) \\
 &= \frac{1}{2} \max_{i=1, \dots, n} \lambda_i \left( \mathbf{P}^{-1/2} (\bar{\mathbf{A}}_T^T \mathbf{P} + \mathbf{P} \bar{\mathbf{A}}_T) \mathbf{P}^{-1/2} \right) \\
 &= \frac{1}{2} \max_{i=1, \dots, n} \lambda_i \left( -\mathbf{P}^{-1/2} \mathbf{R} \mathbf{P}^{-1/2} \right).
 \end{aligned}$$

Because both  $\mathbf{P}$  and  $\mathbf{R}$  are positive definite, it follows that  $\mu_P(\bar{\mathbf{A}}_T) < 0$ . For the chosen norm, then, the second term of the LHS of (3.11) is a decreasing function of

$T$  which attains the value 1 at  $T = 0$ . On the other hand, the first term is a function that increases with  $T$ , since (3.3) does not hold by hypothesis. However, the first term vanishes at  $T = 0$ , and, moreover, its derivative with respect to  $T$  is 0 at  $T = 0$ . Observing that the LHS of (3.11) is continuous in  $T$ , it can be characterized as a function that equals 1 at  $T = 0$ , decreases for small  $T$ , and increases with larger  $T$ . Hence there is a time  $T^*$  such that (3.5) holds. Because the LHS of (3.11) provides an upper bound on  $\|\Phi(T, 0)\|$ , it follows that when  $T < T^*$ , the monodromy matrix is a contraction with respect to  $\|\cdot\|_P$ .  $\square$

In [13], condition (3.3) for the Euclidean norm is generalized by applying a modified version of property (2.3d), where a similarity transformation is exploited and the norm of the matrix exponential is bounded by using the condition number of the transformation and the measure of the transformed matrix. In [13], it is shown that this condition may yield equivalent, less conservative, or more conservative results than (3.3), depending on the problem at hand and on the used similarity transformation.

Since they are defined in terms of a matrix norm, the matrix measure and commutator norm quantities appearing in (3.5) and (3.10) do not grow with matrix dimension. Therefore, the estimate of the slowest stabilizing switching period provided by (3.5) does not degrade with system dimension. It should be noted that because (3.10) accounts for all possible commutation relationships between subsystem matrices, it tends to make the estimate of (3.5) more conservative as the number of subsystems grows. Nevertheless, it is always less conservative than the standard estimate represented by the RHS of (3.12). The following proposition formalizes this result.

**PROPOSITION 3.3.** *For the switched system in (3.1), it is the case that*

$$(3.12) \quad \frac{1}{2} T^2 \Gamma(\mathbf{A}) \exp \left( T \sum_{i=1}^M \delta_i \mu(\mathbf{A}_i) \right) \leq T^2 \alpha^2 e^{T\alpha},$$

where  $\Gamma(\mathbf{A})$  is defined in (3.10) and

$$\alpha = \operatorname{esssup}_{t \in [0, T]} \|\mathbf{A}(t)\| = \max_{i=1, \dots, M} \|\mathbf{A}_i\|.$$

*Proof.* By noticing that for any  $i, j \in \{1, \dots, M\}$ ,

$$\|[\mathbf{A}_i, \mathbf{A}_j]\| \leq 2\|\mathbf{A}_i \mathbf{A}_j\| \leq 2\alpha^2,$$

and that

$$\sum_{i=1}^{M-1} \sum_{j=i+1}^M \delta_i \delta_j \leq 1,$$

a trivial application of the matrix measure properties (2.3c) and (2.3e) leads to the claim (3.12).  $\square$

The standard estimate shows severe limitations since it discards the properties of the commutators, and, moreover, never yields decreasing global estimates. Loosely speaking, the standard estimate ignores the relations between the eigenvectors of the state matrices that are accounted for by the commutator. This means that even when (3.3) is satisfied, or when the matrices all commute and have a Hurwitz average, it still provides an upper bound for the maximum switching period.

As a numerical example, consider the two-dimensional periodic switched system from [19], whose state matrices are

$$\mathbf{A}_1 = \begin{bmatrix} -4 & -5 \\ 7 & 7 \end{bmatrix}, \quad \mathbf{A}_2 = \begin{bmatrix} 3 & 5 \\ -7 & -13 \end{bmatrix},$$

with the normalized time durations  $\delta_1 = 0.6, \delta_2 = 0.4$ . It is easy to check that (i)  $\mathbf{A}_1$  and  $\mathbf{A}_2$  are not Hurwitz; (ii)  $\bar{\mathbf{A}}_T$  is Hurwitz; and (iii) condition (3.3) for Euclidean norms is not satisfied. We estimate the maximum time that guarantees the stability of the switched system with three different methods: (i) solving (3.5) as elucidated by Proposition 3.1, with the matrix measure defined by the norm computed with  $\mathbf{R} = \mathbf{I}$ ; (ii) solving (3.5) upon using the error bound (3.12) as done in [11]; and (iii) determining directly the maximum switching period that guarantees the contraction property of the monodromy matrix with respect to the norm suggested in Proposition 3.1. These estimates are compared with the exact solution obtained by requiring that the characteristic multipliers (see, e.g., [12]) be less than one. In Table 1, we report the results of the computations. We emphasize that both the standard and the present approaches approximate the estimate obtained from the contraction condition. Nevertheless, the present approach provides a better estimation, as predicted by the theoretical analysis and illustrated by the numerical example.

TABLE 1

*Different estimates of the maximum switching period for uniform asymptotic stability and exact solution.*

	Switching period
Present work	$1.2 \times 10^{-1}$
Standard estimate	$4.3 \times 10^{-3}$
Contraction condition	$3.2 \times 10^{-1}$
Exact solution	$9.6 \times 10^{-1}$

Although the expression (3.5) appears complicated, it actually provides a convenient computational approach to estimating the critical switching period  $T^*$ . Indeed,  $\Gamma(\mathbf{A})$  defined in (3.10) is independent of  $T^*$ , as are the matrix measures of the individual subsystems and the average system. In contrast, the exact solution from Floquet theory requires expensive matrix logarithm computations that must be repeated for each candidate  $T^*$ . Any algorithm using Floquet theory should consider small time steps beginning at zero to account for the oscillatory behavior of Floquet exponents.

**4. Stability analysis of general linear time-varying systems.** In the present section we focus on the generalization of the method of averaging to arbitrary time-varying linear systems. The state matrix in (2.1) may be continuous, in which case the theory developed in this section provides a useful bound on the error incurred by estimating the transition matrix of the time-varying system over some time interval by the transition matrix of the average system over the same time interval. The state matrix may have points of discontinuity, however. In contrast to the switching systems studied in section 3, the state matrix  $\mathbf{A}(t)$  may vary between the discontinuities, and the system is not constrained to be periodic.

We begin by specifying a technique for estimating the transition matrix of (2.1) over an interval. The method involves dividing the interval into a large number of subintervals and approximating the state matrix over each subinterval by its value at the beginning of the subinterval. The transition matrix of the time-varying system (2.1) is then approximated by the transition matrix of the resulting switched system.

PROPOSITION 4.1. *Suppose that  $\mathbf{A}(t)$  in (2.1) is right continuous, with a finite number  $D$  of discontinuities on the interval  $[s, s + \tau]$  for any  $s, \tau \in \mathbb{R}^+$ . Consider a set of  $N + 1$  time instants  $\{t_i\}$  in  $[s, s + \tau]$ , where  $s = t_0 < t_1 < \cdots < t_N = s + \tau$ , consisting of the union of the points of discontinuity of  $\mathbf{A}(t)$  and the points  $s + k\frac{\tau}{M}$ , where  $k = 0, \dots, M$ , so that  $M \leq N \leq M + D$ . Define  $\mathbf{A}_i^\# = \mathbf{A}(t_{i-1})$  for all  $i = 1, \dots, N$ . Let  $\mathbf{A}^\#(t)$  be the corresponding switched system state matrix, whose pointwise in time value is selected from the set  $\Theta^\# = \{\mathbf{A}_1^\#, \dots, \mathbf{A}_N^\#\}$ . Let  $\Phi(t, s)$  be the transition matrix associated with  $\mathbf{A}(t)$ , and let  $\Phi^\#(t, s)$  be the transition matrix associated with  $\mathbf{A}^\#(t)$ . Then  $\Phi^\#(t, s) \rightarrow \Phi(t, s)$  uniformly on  $[s, s + \tau]$  as  $M \rightarrow \infty$ , that is, as  $N \rightarrow \infty$ .*

*Proof.* Let  $\mathbf{R}(t, s) = \Phi^\#(t, s) - \Phi(t, s)$ , and differentiate to obtain

$$(4.1) \quad \begin{aligned} \dot{\mathbf{R}}(t, s) &= \mathbf{A}^\#(t)\Phi^\#(t, s) - \mathbf{A}(t)\Phi(t, s) \\ &= \mathbf{A}(t)\mathbf{R}(t, s) + (\mathbf{A}^\#(t) - \mathbf{A}(t))\Phi^\#(t, s). \end{aligned}$$

Since  $\mathbf{R}(t, s) = 0$  at  $t = s$ , the solution to the differential equation (4.1) is

$$\mathbf{R}(t, s) = \int_s^t \Phi(t, \xi)(\mathbf{A}^\#(\xi) - \mathbf{A}(\xi))\Phi^\#(\xi, s)d\xi.$$

The error may be bounded as

$$\|\mathbf{R}(t, s)\| \leq \int_s^t \|\Phi(t, \xi)\| \|\mathbf{A}^\#(\xi) - \mathbf{A}(\xi)\| \|\Phi^\#(\xi, s)\| d\xi \leq \alpha\beta\gamma\tau,$$

where

$$\alpha = \operatorname{esssup}_{s, t \in [s, s + \tau]} \|\Phi(t, s)\|, \quad \beta = \operatorname{esssup}_{t \in [s, s + \tau]} \|\mathbf{A}^\#(t) - \mathbf{A}(t)\|, \quad \gamma = \operatorname{esssup}_{s, t \in [s, s + \tau]} \|\Phi^\#(t, s)\|.$$

Let

$$\zeta = \operatorname{esssup}_{t \in [s, s + \tau]} e^{\|\mathbf{A}(t)\|\tau}.$$

Because  $\mathbf{A}(t)$  has a finite number of discontinuities,  $\|\mathbf{A}(t)\|$  is bounded on the compact interval  $[s, s + \tau]$ . Using (2.3d), (2.3e), and (2.4), it follows that both  $\alpha$  and  $\gamma$  are bounded by  $\zeta$ , a quantity that is not influenced by switching behavior. As  $N \rightarrow \infty$ , the maximum time interval between switching instants vanishes, and right continuity of  $\mathbf{A}(t)$  ensures that  $\beta \rightarrow 0$ . It follows that  $\|\mathbf{R}(t, s)\| \rightarrow 0$ , so that the error between the transitions matrices  $\Phi^\#(t, s)$  and  $\Phi(t, s)$ , at every point  $t \in [s, s + \tau]$ , is bounded by a common vanishing quantity. Therefore  $\Phi^\#(t, s) \rightarrow \Phi(t, s)$  uniformly on  $[s, s + \tau]$  as  $N \rightarrow \infty$ .  $\square$

This result is now used to bound the difference between the time-varying system transition matrix and the corresponding average system transition matrix over a time interval.

PROPOSITION 4.2. *Suppose that  $\mathbf{A}(t)$  in (2.1) is right continuous and bounded, with a finite number of discontinuities on the interval  $[s, s + \tau]$  for any  $s, \tau \in \mathbb{R}^+$ . The transition matrix  $\Phi(s + \tau, s)$  of (2.1) over the interval  $[s + \tau, s]$  is given by*

$$(4.2) \quad \Phi(s + \tau, s) = \bar{\Phi}_\tau(s + \tau, s) + \mathbf{E}_\tau(s),$$

where  $\bar{\Phi}_\tau(s + \tau, s)$  is the transition matrix of the time-invariant average system represented by the sample average of  $\mathbf{A}(t)$  on the interval  $[s, s + \tau]$ . That is, the transition

matrix of

$$(4.3) \quad \bar{\mathbf{A}}_\tau(s) = \frac{1}{\tau} \int_s^{s+\tau} \mathbf{A}(\vartheta) d\vartheta$$

and  $\mathbf{E}_\tau(s)$  satisfies

$$(4.4) \quad \|\mathbf{E}_\tau(s)\| \leq \frac{1}{2} \int_s^{s+\tau} \int_\vartheta^{s+\tau} \|[\mathbf{A}(\vartheta), \mathbf{A}(\xi)]\| d\xi d\vartheta \exp\left(\int_s^{s+\tau} \mu(\mathbf{A}(\xi)) d\xi\right).$$

*Proof.* Define the  $N+1$  time instants  $\{t_i\}$  in  $[s, s+\tau]$ , the switching system state matrix  $\mathbf{A}^\#(t)$ , and the transition matrix  $\bar{\Phi}^\#(t, s)$  as in Proposition 4.1. Define the average  $\bar{\mathbf{A}}_\tau^\#(s)$  of the  $\mathbf{A}_i^\#$  matrices over the interval  $[s, s+\tau]$  as

$$\bar{\mathbf{A}}_\tau^\#(s) = \sum_{i=1}^N \delta_i \mathbf{A}_i^\#, \quad \delta_i = \frac{t_i - t_{i-1}}{\tau}.$$

Define  $\bar{\Phi}_\tau^\#(s+\tau, s)$  as the transition matrix over the interval  $[s, s+\tau]$  of the time-invariant system whose state matrix is  $\bar{\mathbf{A}}_\tau^\#(s)$ , and define the error  $\mathbf{E}_\tau^\#(s) = \Phi^\#(s+\tau, s) - \bar{\Phi}_\tau^\#(s+\tau, s)$ . From (3.9),  $\mathbf{E}_\tau^\#(s)$  is bounded by

$$(4.5) \quad \|\mathbf{E}_\tau^\#(s)\| \leq \frac{1}{2} \tau^2 \Gamma(\mathbf{A}^\#) \exp\left(\tau \sum_{i=1}^N \delta_i \mu(\mathbf{A}_i^\#)\right),$$

where  $\Gamma$  is defined as in (3.10). According to Proposition 4.1,  $\Phi^\#(s+\tau, s) \rightarrow \Phi(s+\tau, s)$  as  $N \rightarrow \infty$ . Similarly,  $\bar{\Phi}_\tau^\#(s+\tau, s) \rightarrow \bar{\Phi}_\tau(s+\tau, s)$  as  $N \rightarrow \infty$ . It follows that  $\mathbf{E}_\tau^\#(s) \rightarrow \mathbf{E}_\tau(s)$  as  $N \rightarrow \infty$ . The summations on the RHS of (4.5), including the double summation appearing in  $\Gamma(\mathbf{A}^\#)$ , are performed over the set of time instants  $\{t_i\}$  on the interval  $[s, s+\tau]$ , with the size of the steps between time instants determined by the  $\delta_i$ . Because of the way the  $N+1$  time instants are defined, the maximum step size approaches zero as  $N \rightarrow \infty$ . Thus the summations are consistent with the definition of Riemann sums (see, e.g., [3]), and they converge to integrals as  $N \rightarrow \infty$ . It follows that the RHS of (4.5) converges to the RHS of (4.4), and therefore that condition (4.4) holds.  $\square$

When the matrix  $\mathbf{A}$  is constant, the remainder in (4.2) vanishes. In this case, the present estimate yields the exact result since the commutator is zero. This is in sharp contrast with the standard estimate, which disregards the influence of the commutator, resulting in a generally looser bound depending only on the supremum of the time-varying matrix norm.

As a sample application of Proposition 4.2 (in the following proposition) we consider perturbed periodic switched systems.

**PROPOSITION 4.3.** *Consider the system (2.1) with*

$$(4.6) \quad \mathbf{A}(t) = \mathbf{F}(t) + \varepsilon \mathbf{B}(t),$$

where  $\mathbf{F}$  is a  $T$ -periodic switching matrix of the form (3.1),  $\mathbf{B}$  is a bounded right continuous matrix function which has at most a finite number of discontinuities within any switching period, and  $\varepsilon$  scales the perturbation magnitude. Assume that  $\mathbf{B}$  has zero average over any switching period. If for some norm

$$\sum_{i=1}^M \delta_i \mu(\mathbf{F}_i) + \varepsilon \operatorname{esssup}_{t \in \mathbb{R}^+} \mu(\mathbf{B}(t)) < 0,$$

then the system (4.6) is uniformly asymptotically stable for every positive  $T$ . Otherwise, if the average matrix

$$\bar{\mathbf{A}}_T = \sum_{i=1}^M \delta_i \mathbf{F}_i$$

of (4.6) is Hurwitz, then there exists a  $T^* > 0$  such that when  $T < T^*$  the system is uniformly asymptotically stable.  $T^*$  satisfies

$$e^{T^* \mu_P(\bar{\mathbf{A}}_T)} + \frac{1}{2} (T^*)^2 (\Gamma_P(\mathbf{F}) + 2\beta_1\varepsilon + \beta_2\varepsilon^2) \exp\left(T^* \left(\sum_{l=1}^M \delta_l \mu_P(\mathbf{F}_l) + \varepsilon\beta_3\right)\right) = 1,$$

where  $\Gamma_P$  is defined as in (3.6), the norm is constructed according to (3.7), and

$$\begin{aligned} \beta_1 &= \operatorname{esssup}_{t \in \mathbb{R}^+, i=1, \dots, M} \|[\mathbf{F}_i, \mathbf{B}(t)]\|_P, & \beta_2 &= \operatorname{esssup}_{t, \xi \in \mathbb{R}^+} \|[\mathbf{B}(t), \mathbf{B}(\xi)]\|_P, \\ \beta_3 &= \operatorname{esssup}_{t \in \mathbb{R}^+} \mu_P(\mathbf{B}(t)). \end{aligned}$$

*Proof.* We look for switching periods where the transition matrix of the system (4.6) from  $kT$  to  $(k+1)T$  is a contraction for every  $k \in \mathbb{Z}^+$ . To establish the first sufficient condition, we use matrix measure properties (2.4), (2.3c), and (2.3b) to obtain a bound on the transition matrix between consecutive switching events

$$\begin{aligned} \left\| \Phi\left(kT + \sum_{j=0}^i \delta_j T, kT + \sum_{j=0}^{i-1} \delta_j T\right) \right\| &\leq \exp\left(\delta_i T \operatorname{esssup}_{t \in \mathbb{R}^+} \mu(\mathbf{A}(t))\right) \\ &\leq \exp\left(\delta_i T \mu(\mathbf{F}_i) + \delta_i T \varepsilon \operatorname{esssup}_{t \in \mathbb{R}^+} \mu(\mathbf{B}(t))\right), \end{aligned}$$

where  $\delta_0 = 0$  by convention. Using the Schwarz inequality then yields

$$\|\Phi((k+1)T, kT)\| \leq \exp\left(T \sum_{i=1}^M \delta_i \mu(\mathbf{F}_i) + T \varepsilon \operatorname{esssup}_{t \in \mathbb{R}^+} \mu(\mathbf{B}(t))\right) < 1.$$

To establish the second sufficient condition, note that because  $\mathbf{B}$  has zero average over any switching period, Proposition 4.2 can be applied to the transition matrix of (4.6) to yield

$$(4.7) \quad \Phi((k+1)T, kT) = \exp(\bar{\mathbf{A}}_T T) + \mathbf{E}_T(kT),$$

where  $\|\mathbf{E}_T(kT)\|$  is bounded according to (4.4). We specialize to the norm constructed in (2.5), where  $\mathbf{P}$  is the unique symmetric positive definite solution of (3.7), and where  $\mathbf{R} = \mathbf{R}^T > 0$  is arbitrary. We look for switching periods satisfying

$$(4.8) \quad \frac{1}{2} \int_{kT}^{(k+1)T} \int_{\vartheta}^{(k+1)T} \|[\mathbf{A}(\vartheta), \mathbf{A}(\xi)]\|_P d\xi d\vartheta \exp\left(\int_{kT}^{(k+1)T} \mu_P(\mathbf{A}(\xi)) d\xi\right) + e^{T \mu_P(\bar{\mathbf{A}}_T)} < 1.$$

By applying the triangle inequality and accounting for the boundedness of  $\mathbf{B}$ , the double integral in (4.8) may be further bounded by

$$\int_{kT}^{(k+1)T} \int_{\vartheta}^{(k+1)T} \|[\mathbf{A}(\vartheta), \mathbf{A}(\xi)]\|_P d\xi d\vartheta \leq \Gamma_P(\mathbf{F}) + \beta_1\varepsilon + \beta_2\varepsilon^2.$$

By applying property (2.3c) to the exponent in (4.4), by applying the norm triangle inequality to (4.7), and by using property (2.3d), the claim follows.  $\square$

In the general case, when the state matrix is not of the form (4.6), the averaging method applies to systems of type (2.1) with state matrix  $\varpi\mathbf{A}(t)$ , where  $\varpi > 0$ . The averaging method addresses the effects of  $\varpi$  on the system stability. The small parameter  $\varpi$  has the effect of rescaling the system (2.1) to the fast time  $t/\varpi$ . Indeed, by a change of variable, the system may be rewritten as

$$\dot{\mathbf{x}}(t) = \mathbf{A}\left(\frac{t}{\varpi}\right)\mathbf{x}(t).$$

**PROPOSITION 4.4.** *Under the hypotheses of Proposition 4.2 and assuming that  $\mathbf{A}$  is bounded, if there is a period  $T$  such that*

$$(4.9) \quad \mu(\bar{\mathbf{A}}_T(kT)) < -\beta$$

*for all  $k \in \mathbb{N}$  and for some positive  $\beta$ , then there exists an  $\eta > 0$  such that the system (2.1) with state matrix  $\varpi\mathbf{A}(t)$ , where  $\varpi > 0$ , is uniformly asymptotically stable for  $\varpi T < \eta$ .*

*Proof.* From Proposition 4.2 the transition matrix of the system (2.1) with state matrix  $\varpi\mathbf{A}(t)$  from  $kT$  to  $(k+1)T$  is

$$(4.10) \quad \Phi((k+1)T, kT) = \exp(\varpi\bar{\mathbf{A}}_T(kT)T) + \mathbf{E}_T(kT),$$

where  $\|\mathbf{E}_T(kT)\|$  is bounded according to (4.4). That is,

$$\begin{aligned} \|\mathbf{E}_T(kT)\| &\leq \frac{1}{2} \varpi^2 \int_{kT}^{(k+1)T} \int_{\vartheta}^{(k+1)T} \|[\mathbf{A}(\vartheta), \mathbf{A}(\xi)]\| d\sigma d\vartheta \\ &\quad \times \exp\left(\varpi \int_{kT}^{(k+1)T} \mu(\mathbf{A}(\xi)) d\sigma\right). \end{aligned}$$

Since  $\mathbf{A}$  is bounded, the RHS of the previous inequality may be further bounded by

$$g(\varpi T) = \frac{1}{2} \varpi^2 T^2 \varepsilon \exp(\varpi T \alpha),$$

where

$$(4.11) \quad \alpha = \operatorname{esssup}_{t \in \mathbb{R}^+} \mu(\mathbf{A}(t)), \quad \varepsilon = \operatorname{esssup}_{t, \xi \in \mathbb{R}^+} \|[\mathbf{A}(t), \mathbf{A}(\xi)]\|.$$

The function  $g(\varpi T)$  is zero at  $\varpi = 0$ , as is its first derivative with respect to  $\varpi$ . By computing the norm of both sides of (4.10), by applying the norm triangle inequality and property (2.3d), and by accounting for (4.9), we obtain

$$\|\Phi((k+1)T, kT)\| \leq \exp(-\varpi T \beta) + g(\varpi T).$$

The condition (4.9) is analogous to (3.3) in Proposition 3.1 and ensures that the matrix measure is uniformly negative for the more general system considered here. Thus by

selecting  $\varpi$  sufficiently small,  $\Phi$  defines a contraction between any two consecutive instants  $kT, (k+1)T$ , and the system is asymptotically stable.  $\square$

**5. Conclusions.** A novel framework for analyzing periodic linear switched systems has been presented. By combining results on exponential splitting methods with the method of averaging, we have provided an improved understanding of the switching mechanism. We have elucidated the importance of commuting relations among the different subsystems constituting the switched system on stability properties. A new estimate of the maximum switching period that guarantees that the switched system is uniformly asymptotically stable when the average system matrix is Hurwitz has been established. It has been shown that this estimate is less conservative than the standard estimate. Moreover, our estimate is consistent with sufficient stability conditions in the literature, such as in [4]. The estimate effectiveness has been validated through a sample problem from [19] and compared to other estimates and to the exact solution from Floquet theory. The effect of time-varying perturbations on the system stability has been discussed and a modified estimate of the switching rate accounting for additive perturbations has been developed. Moreover, the method has been generalized to arbitrary time-varying linear systems, and a sufficient condition for uniform asymptotic stability is stated in terms of some properties of sampled averages.

**Acknowledgments.** The authors thank the anonymous reviewers for their helpful comments, and particularly for a correction in the proof of Proposition 3.1.

## A CONSTRUCTIVE APPROACH TO A CLASS OF ERGODIC HJB EQUATIONS WITH UNBOUNDED AND NONSMOOTH COST\*

PATRICK CATTIAUX<sup>†</sup>, PAOLO DAI PRA<sup>‡</sup>, AND SYLVIE ROELLY<sup>§</sup>

**Abstract.** We consider a class of ergodic Hamilton–Jacobi–Bellman (HJB) equations related to long-time asymptotics of nonsmooth multiplicative functional of diffusion processes. Under suitable ergodicity assumptions on the underlying diffusion, we show existence of these asymptotics and that they solve the related HJB equation in the viscosity sense.

**Key words.** long-time asymptotics, cluster expansion, viscosity solution, HJB equation

**AMS subject classifications.** 47D07, 49L25, 60H10, 60J35, 60J60, 93E20

**DOI.** 10.1137/070698634

**1. Introduction.** Let  $(x_t)_{t \geq 0}$  be a continuous-time, homogeneous Markov process with infinitesimal generator  $L$ . To fix ideas, assume  $x_t$  is  $\mathbb{R}^d$ -valued. Given a function  $c : \mathbb{R}^d \rightarrow \mathbb{R}$  and  $\gamma > 0$ , we are interested in obtaining long-time asymptotics of the functional

$$S(T, x) := \log E_x \left[ \exp \left( \gamma \int_0^T c(x_t) dt \right) \right],$$

where  $E_x$  is the expectation conditioned to  $x_0 = x$ . Let  $\varphi(T, x) = e^{S(T, x)}$ . At least at the formal level,  $\varphi$  is a solution of the equation

$$\partial_t \varphi(t, x) = L\varphi(t, x) + \gamma c(x)\varphi(t, x).$$

If a Perron–Frobenius-type theorem holds for the operator  $L + \gamma c$ , then for  $T$  large  $\varphi(T, x)$  gets close to  $e^{\lambda T} v(x)$ , where  $\lambda$  is the largest eigenvalue of  $L + \gamma c$ , and  $v$  is the corresponding strictly positive eigenfunction. In other words, setting  $V(x) := \log v(x)$ , we obtain

$$S(T, x) = \lambda T + V(x) + o(T),$$

i.e.,

$$(1.1) \quad \lambda = \lim_{T \rightarrow +\infty} \frac{1}{T} \log E_x \left[ \exp \left( \gamma \int_0^T c(x_t) dt \right) \right]$$

and

$$(1.2) \quad V(x) = \lim_{T \rightarrow +\infty} \left\{ \log E_x \left[ \exp \left( \gamma \int_0^T c(x_t) dt \right) \right] - \lambda T \right\}.$$

---

Note also that the pair  $(\lambda, V)$  is a solution of the nonlinear equation

$$(1.3) \quad \lambda = e^{-V} L(e^V) + \gamma c.$$

The actual proof of the existence of the limits (1.1) and (1.2) is, in general, not simple, and various assumptions are required. If the empirical measures

$$\mathcal{L}_t := \frac{1}{t} \int_0^t \delta_{x_s} ds$$

of the Markov process obey a large deviation principle with rate function  $i(\mu)$  (which is known under fairly general conditions), and  $c(\cdot)$  is measurable and bounded (but suitable growth conditions on  $c(\cdot)$  may suffice), then the limit (1.1) exists, and

$$(1.4) \quad \lambda = \sup_{\mu} \left[ \int c d\mu - i(\mu) \right],$$

where in (1.3)  $\mu$  varies over probability measures on  $\mathbb{R}^d$ . The existence of the limit (1.2), i.e., the second-order asymptotics of  $S(T, x)$ , is a harder problem to solve. For processes taking values in a compact space, where things are simpler, we refer to [7, section 4]. In this paper we consider  $\mathbb{R}^d$ -valued diffusions of the form

$$(1.5) \quad dx_t = b(x_t)dt + dB_t,$$

where  $(B_t)_{t \geq 0}$  is a standard Brownian motion and  $b$  is a regular drift function. Thus the associated infinitesimal generator is  $L = \frac{1}{2}\Delta + b(x) \cdot \nabla$ . The first results in this context date back to [6] and [14], where conditions are given for the existence of the solution of (1.3), which takes the form of the Hamilton–Jacobi–Bellman (HJB) equation

$$(1.6) \quad \begin{aligned} \lambda &= \frac{1}{2}\Delta V(x) + \max_{u \in \mathbb{R}^d} \left[ (b(x) + u) \cdot \nabla V(x) + \gamma c(x) - \frac{1}{2}|u|^2 \right] \\ &= \frac{1}{2}\Delta V(x) + b(x) \cdot \nabla V(x) + \frac{1}{2}|\nabla V(x)|^2 + \gamma c(x). \end{aligned}$$

In [6] it is also shown that, under sufficient ergodicity of  $(x_t)_{t \geq 0}$  and if  $c(\cdot)$  is bounded and sufficiently smooth, then (1.3) has a solution, which need not be the unique one, for which (1.1) and (1.2) hold. More recent results, which require boundedness from above of  $c(\cdot)$  but not smoothness, can be found in [5, Appendix B] or [20, Proposition 6.4].

The case of  $c(\cdot)$  unbounded has been recently dealt with in [11] and [10].

In [11] the authors deal with a discrete-time process; it is plausible that many of their proofs can be adapted to continuous time. Their approach is based on a rather sophisticated spectral theory (see also [12]). The translation of their results into our context would allow to prove the existence of the limits (1.1) and (1.2) for any measurable  $c(\cdot)$  whose growth at infinity is *strictly less* than quadratic. The assumptions are related to contractivity of the transition operator. In term of continuous-time diffusions, this corresponds to existence of *spectral gap* for the infinitesimal generator of the diffusion, in the space  $L^2(m)$ , where  $m$  is the invariant measure (see assumption A5 below).

In [10] the authors allow quadratic growth for  $c(\cdot)$ , but require differentiability. Using PDE methods they show, under reasonable conditions on  $b(\cdot)$ , that (1.3) indeed has multiple solutions, even after identifying solutions that differ by a constant. It is shown in [10] that there exists  $\lambda \in \mathbb{R}$  such that the equation

$$\mu = \frac{1}{2}\Delta V + b \cdot \nabla V + \frac{1}{2}|\nabla V|^2 + \gamma c$$

has a (smooth) solution if and only if  $\mu \geq \lambda$ . Moreover, for  $\mu = \lambda$ , this solution is unique up to additive constant. Kaise and Sheu also indicate that this  $\lambda$  should be as in (1.1). They do not address the possibility of interpreting *one* solution  $V$  as in (1.2).

The main objective of this paper is to propose a totally different approach to the above problems. On one hand we tackle (1.1) and (1.2), for the diffusion (1.5), directly, without relying on properties of (1.3). This makes it easy to avoid any regularity condition on  $c(\cdot)$ . On the other hand, unlike in [11], we allow  $c(\cdot)$  to have quadratic growth. We remark that quadratic growth of  $c(\cdot)$  makes a Gaussian concentration property (see assumption A3 below) a natural assumption. This property is by no means implied by existence of spectral gap for the generator (which corresponds to our assumption A5). Our assumptions A1–A6 are discussed in detail in section 3.

The method we propose is based on *cluster expansion*, a well-known method in statistical mechanics and combinatorics. Besides the technical advantage of allowing quadratic growth without requiring regularity, our approach has, we believe, other positive aspects as follows:

1. It is considerably simpler than both PDE and spectral methods. Moreover, in principle it allows us to obtain explicit estimates on the limits (1.1) and (1.2) in terms of various parameters related to the drift  $b(\cdot)$ .
2. It is a very robust method which can be adapted to various modifications of the problem considered here. For example, in (1.1) and (1.2) the integral

$$\int_0^T c(x_t) dt$$

could be replaced by

$$\int_{[0,T]} c(x_t) d\mu(t),$$

where  $\mu$  could be of the following forms:

- i.  $\mu$  is a  $\sigma$ -finite periodic measure, for instance,  $\mu(dt) = \sum_{k \geq 0} \delta_{k\Delta}(dt)$  for some  $\Delta > 0$ . In this last case the cost acts only at discrete time.
- ii.  $\mu$  is a random measure, independent of  $(B_t)_{t \geq 0}$ , translation invariant, and sufficiently ergodic in law. For instance, we could take  $\mu(dt) = \sum_n \delta_{\tau_n}(dt)$ , where  $(\tau_n)_{n \geq 0}$  are the points of a Poisson process.

Moreover, jump processes, rather than diffusions, should also be treatable.

We also remark that, although in this paper we consider diffusions whose diffusion coefficient is the identity matrix, the uniformly elliptic case could be dealt with after minor modifications. It is worth noticing that the whole content of section 2 is based on assumptions A1–A6 below, which do not refer to any specific form of the Markov process. The fact that the process is a diffusion plays a role in sections 3 and 4.

In the case when  $c(\cdot)$  has quadratic growth,  $S(t, x)$  could possibly explode in finite time, unless  $\gamma$  is sufficiently small. At the present stage, our results hold for  $\gamma$  in some

interval  $[0, \bar{\gamma}]$ , which is certainly *not optimal*. Note, however, that one could get an explicit expression for  $\bar{\gamma}$  (carefully following the proofs) as a function of the constants  $c_b$  and  $K_b$  appearing in conditions (DC) and (CC) of section 3.

The paper is organized as follows. In section 2 we prove existence of the limits (1.1) and (1.2) under some general conditions (A1–A6 below) on the diffusion process. In section 3 we give explicit sufficient conditions on the drift  $b$  for A1–A6 to hold. In section 4 we show that  $V$  and  $\lambda$  given by (1.2) and (1.1), respectively, are linked to (1.6); more precisely, we show that  $V$  is a viscosity solution of (1.6).

**2. Existence of the limits  $(\lambda, V)$ .** We begin by stating our assumptions on the  $\mathbb{R}^d$ -valued diffusion

$$(2.1) \quad dx_t = b(x_t)dt + dB_t.$$

**A1.** Equation (2.1) has, for every deterministic initial condition, a unique strong solution.

**A2.** There is a  $C > 0$  such that

$$|c(x)| \leq C(|x|^2 + 1), \quad x \in \mathbb{R}^d.$$

**A3.** The process  $(x_t)_t$  which is a solution of (2.1) has a unique invariant probability measure  $m(dx)$  such that, for some  $\beta > 0$ ,

$$\int e^{\beta|x|^2} m(dx) < +\infty.$$

**A4.** The transition probability of the process  $(x_t)_t$  admits a density  $p_t(x, y)$  with respect to the measure  $m$ . Furthermore, there exist  $K > 0$ ,  $p > 2$ , and  $t_0 > 0$  such that

$$\sup_{t \geq t_0} \|p_t(\cdot, \cdot)\|_{\mathbb{L}^p(m \otimes m)} \leq K.$$

**A5.** Let  $P_t$  be the semigroup associated with the process  $(x_t)_t$ . It extends as a continuous semigroup on  $\mathbb{L}^2(m)$  and satisfies

$$\forall f \in \mathbb{L}^2(m), \quad \lim_{t \rightarrow +\infty} \|P_t f - \int f dm\|_{\mathbb{L}^2(m)} = 0.$$

**A6.** For all  $a > 0$  and all  $x$ , there exists  $\beta_{a,x} > 0$  such that

$$E_x \left[ e^{\beta_{a,x} \int_0^a |x_s|^2 ds} \right] < +\infty.$$

We shall say that A6 is uniformly satisfied if for all  $a > 0$  there exist  $\beta_a > 0$  and a locally bounded function  $h_a$  such that for all  $x$ ,

$$E_x \left[ e^{\beta_a \int_0^a |x_s|^2 ds} \right] \leq h_a(x).$$

Section 3 will be devoted to giving sufficient conditions for these hypotheses to hold.

*Remark 1.* Assumption A4 implies that the semigroup  $P_t$  is continuous from  $\mathbb{L}^2(m)$  into  $\mathbb{L}^p(m)$ ,  $p > 2$ , for  $t \geq t_0$ . Hence, according to the Gross hypercontractivity theorem (see, e.g., [1]),  $m$  satisfies a defective logarithmic Sobolev inequality. If  $m$  is absolutely continuous with respect to the Lebesgue measure,  $m(dx) = e^{-V} dx$ , and

$V$  is locally bounded, a result by Röckner and Wang says that  $m$  satisfies a so-called weak Poincaré inequality; hence, thanks to a result by Aida,  $m$  will satisfy a tight log-Sobolev inequality (for all these results see the book of Wang [19]). In particular  $m$  will satisfy both a spectral gap inequality, so that Assumption A5 is satisfied, and a Gaussian concentration inequality implying A3.

**THEOREM 1.** *Under A1–A6 there is  $\bar{\gamma} > 0$  such that for every  $\gamma < \bar{\gamma}$  the limits (1.1) and (1.2) exist.*

*Furthermore, if A6 is uniformly satisfied, the convergence in (1.2) is uniform on compact sets.*

*Proof of Theorem 1.* We begin by showing that the limits (1.1) and (1.2) exist along suitable sequences.

**PROPOSITION 1.** *Under A1–A6, for every time-step  $a > 0$  large enough, there exists  $\gamma(a)$  such that for all  $\gamma < \gamma(a)$  and all  $x \in \mathbb{R}^d$ , the limits*

$$(2.2) \quad \lambda_a = \lim_{n \rightarrow +\infty} \frac{1}{an} \log E_x \left[ \exp \left( \gamma \int_0^{an} c(x_t) dt \right) \right]$$

and

$$(2.3) \quad V_a(x) = \lim_{n \rightarrow +\infty} \left\{ \log E_x \left[ \exp \left( \gamma \int_0^{an} c(x_t) dt \right) \right] - \lambda_a an \right\}$$

exist.

*Proof of Proposition 1.* The proof is done via a cluster expansion technique. The convergence of the expansion requires us to choose  $\gamma$  small enough and the time-step  $a$  large enough.

Define

$$(2.4) \quad \psi_\gamma(t, x, y) := \log E_{xy} \left[ \exp \left( \gamma \int_0^t c(x_s) ds \right) \right],$$

where  $E_{xy}$  denotes the expectation under the law of the bridge of  $(x_s)_{0 \leq s \leq t}$  between  $x$  and  $y$ , and consider a time-step  $a > 0$ . Then

$$(2.5) \quad e^{S(an, x)} = E_x \left[ \exp \left( \sum_{k=0}^{n-1} \psi_\gamma(a, x_{ka}, x_{(k+1)a}) \right) \right] = \mathbb{E} \left[ \exp \left( \sum_{k=0}^{n-1} \phi_\gamma(a, \xi_k, \xi_{k+1}) \right) \right],$$

where  $\mathbb{E}$  is the expectation with respect to a probability  $\mathbb{P}$ , and  $\xi_0 = x$ ,  $\xi_1, \dots, \xi_n$  are random variables that, under  $\mathbb{P}$ , are independent and identically distributed (i.i.d.) with law  $m(dx)$ , and

$$\phi_\gamma(a, x, y) = \psi_\gamma(a, x, y) + \log p_a(x, y).$$

A cluster in this context is a subset of  $\mathbb{Z}^+ := \{0, 1, 2, \dots\}$  of the form  $\{k, k+1, \dots, k+l\}$ . We say that two clusters are separated if there is an integer which is strictly larger than all elements of one cluster and strictly smaller than all elements of the other. We denote by  $\mathcal{C}$  the set of all clusters, while  $\mathcal{C}_n$  denotes the set of clusters

contained in  $\{0, 1, \dots, n-1\}$ . The usual cluster expansion procedure yields

$$\begin{aligned} \exp \left( \sum_{k=0}^{n-1} \phi_\gamma(a, \xi_k, \xi_{k+1}) \right) &= \prod_{k=0}^{n-1} \left[ \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right) + 1 \right] \\ &= \sum_{\tau \subseteq \{0, 1, \dots, n-1\}} \prod_{k \in \tau} \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right) = \sum_{p \geq 0} \frac{1}{p!} \sum_{\substack{\tau_1, \dots, \tau_p \in \mathcal{C}_n \\ \text{separated}}} \prod_{i=1}^p \prod_{k \in \tau_i} \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right) \\ &= \sum_{p \geq 0} \frac{1}{p!} \sum_{\substack{\tau_1, \dots, \tau_p \in \mathcal{C}_n \\ \text{separated}}} q_{\tau_1} q_{\tau_2} \cdots q_{\tau_p}, \end{aligned}$$

where

$$q_{\tau_i} := \prod_{k \in \tau_i} \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right),$$

and we have used the fact that any subset of  $\{0, \dots, n-1\}$  is a union of  $p$  separated clusters for some  $p \geq 0$ , and these clusters can be rearranged in  $p!$  ways. The key fact is that if  $\tau_i$  and  $\tau_j$  are separated clusters, then  $q_{\tau_i}$  and  $q_{\tau_j}$  are independent. Thus, by (2.5),

$$e^{S(an, x)} = \sum_{p \geq 0} \frac{1}{p!} \sum_{\substack{\tau_1, \dots, \tau_p \in \mathcal{C}_n \\ \text{separated}}} \mathbb{E}(q_{\tau_1}) \mathbb{E}(q_{\tau_2}) \cdots \mathbb{E}(q_{\tau_p}).$$

The logarithm of the above expression can be rewritten as

$$S(an, x) = \sum_{\tau \in \mathcal{C}_n, \tau \neq \emptyset} \sum_{p \geq 0} \sum_{\substack{\tau_1, \dots, \tau_p \in \mathcal{C}_n \\ \tau_1 \cup \dots \cup \tau_p = \tau}} a_p(\tau_1, \tau_2, \dots, \tau_p) \mathbb{E}(q_{\tau_1}) \mathbb{E}(q_{\tau_2}) \cdots \mathbb{E}(q_{\tau_p}) =: \sum_{\tau \in \mathcal{C}_n, \tau \neq \emptyset} \Gamma_\tau,$$

where the coefficients  $a_p(\tau_1, \dots, \tau_p)$  come from the Taylor expansion of the logarithm (see [13, page 492]). Now note that  $\Gamma_\tau$  depends on  $x$  if and only if  $0 \in \tau$ , i.e.,  $\tau = \{0, 1, \dots, m\}$  for some  $m$ . In what follows, we write  $\Gamma_m$  in place of  $\Gamma_{\{0, 1, \dots, m\}}$ . Thus

$$(2.6) \quad \sum_{\tau \in \mathcal{C}_n, \tau \neq \emptyset} \Gamma_\tau = \sum_{m=0}^{n-1} \Gamma_m + \sum_{i=1}^{n-1} \sum_{\substack{\tau \in \mathcal{C}_n, \tau \not\ni 0 \\ i \in \tau}} \frac{1}{|\tau|} \Gamma_\tau = \sum_{m=0}^{n-1} \Gamma_m + (n-1) \sum_{\substack{\tau \in \mathcal{C}_n, \tau \not\ni 0 \\ 1 \in \tau}} \frac{1}{|\tau|} \Gamma_\tau,$$

where we used the fact that, for  $0 \notin \tau$ ,  $\Gamma_\tau$  is invariant by translation and permutation of  $\tau$ . Thus, at a formal level, the limits (2.2) and (2.3) should be given by

$$(2.7) \quad \lambda_a = \frac{1}{a} \sum_{\substack{\tau \in \mathcal{C}, \tau \not\ni 0 \\ 1 \in \tau}} \frac{1}{|\tau|} \Gamma_\tau,$$

$$(2.8) \quad V_a(x) = \sum_{m=0}^{+\infty} \Gamma_m - a \lambda_a.$$

As usual (see, e.g., [4]), the convergence of the above sums will follow from the following strong cluster estimates:

$$(2.9) \quad \exists \rho < 1 \quad \forall \tau \in \mathcal{C} \text{ with } 0 \notin \tau, \quad |\mathbb{E}(q_\tau)| \leq \rho^{|\tau|}$$

and

$$(2.10) \quad \forall \tau \in \mathcal{C} \text{ with } \tau \ni 0, \quad |\mathbb{E}(q_\tau)| \leq C(x)\rho^{|\tau|},$$

where  $C(\cdot)$  is a locally bounded function of  $x$ .

Thus, we have only to prove the estimates (2.9) and (2.10) for  $\gamma$  sufficiently small. We begin by proving (2.9). By the generalized H  lder inequality in [15, Lemma 5.2], we have

$$(2.11) \quad |\mathbb{E}(q_\tau)| = \left| \mathbb{E} \left[ \prod_{k \in \tau} \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right) \right] \right| \leq \prod_{k \in \tau} \mathbb{E}^{1/2} \left[ \left( e^{\phi_\gamma(a, \xi_k, \xi_{k+1})} - 1 \right)^2 \right] = \rho^{|\tau|},$$

where

$$\rho := \mathbb{E}^{1/2} \left[ \left( e^{\phi_\gamma(a, \xi_1, \xi_2)} - 1 \right)^2 \right].$$

We now show that  $\rho$  can be made strictly less than 1 by choosing  $a$  sufficiently large and  $\gamma$  small enough:

$$\begin{aligned} \rho^2 &= \mathbb{E} \left( \left( e^{\psi_\gamma(a, \xi_1, \xi_2)} p_a(\xi_1, \xi_2) - 1 \right)^2 \right) \\ &= \int_{\mathbb{R}^{2d}} \left[ E_{xy} \left( e^{\gamma \int_0^a c(x_s) ds} \right) p_a(x, y) - 1 \right]^2 m(dx) m(dy) \\ &= \int_{\mathbb{R}^{2d}} \left[ E_{xy} \left( e^{\gamma \int_0^a c(x_s) ds} - 1 \right) p_a(x, y) + (p_a(x, y) - 1) \right]^2 m(dx) m(dy) \\ &\leq 2 \int_{\mathbb{R}^{2d}} E_{xy}^2 \left( e^{\gamma \int_0^a c(x_s) ds} - 1 \right) p_a^2(x, y) m(dx) m(dy) \\ &\quad + 2 \int_{\mathbb{R}^{2d}} (p_a(x, y) - 1)^2 m(dx) m(dy) \\ &=: 2I_1(a, \gamma) + 2I_2(a). \end{aligned}$$

We first analyze  $I_1(a, \gamma)$ . For any  $\varepsilon \in ]0, 1[$ , by the H  lder inequality,

$$\begin{aligned} I_1(a, \gamma) &= \left[ \int_{\mathbb{R}^{2d}} E_{xy}^{2/\varepsilon} \left( e^{\gamma \int_0^a c(x_s) ds} - 1 \right) p_a(x, y) m(dx) m(dy) \right]^\varepsilon \\ &\quad \cdot \left[ \int_{\mathbb{R}^{2d}} p_a^{\frac{2-\varepsilon}{1-\varepsilon}}(x, y) m(dx) m(dy) \right]^{1-\varepsilon} \\ &\leq E_m^\varepsilon \left( |e^{\gamma \int_0^a c(x_s) ds} - 1|^{2/\varepsilon} \right) \| p_a \|_{\mathbb{L}^{\frac{2-\varepsilon}{1-\varepsilon}}(m \otimes m)}^{2-\varepsilon}, \end{aligned}$$

where  $E_m$  denotes the expectation under the law of  $(x_t)_t$  with initial measure  $m$ . Thanks to assumption A4, for  $a$  large enough and  $\varepsilon$  small enough (such that  $\frac{2-\varepsilon}{1-\varepsilon} \leq p$ ),

$\| p_a \|_{\mathbb{L}^{\frac{2-\varepsilon}{1-\varepsilon}}(m \otimes m)}^{2-\varepsilon} < +\infty$ . To control  $J(a, \gamma) := E_m(|e^{\gamma \int_0^a c(x_s) ds} - 1|^{2/\varepsilon})$ , we represent  $e^{\gamma \int_0^a c(x_s) ds} - 1$  as  $\gamma \int_0^a c(x_s) ds \int_0^1 e^{u\gamma \int_0^a c(x_s) ds} du$  and obtain

$$\begin{aligned} J(a, \gamma) &= \gamma^{2/\varepsilon} E_m \left( \left| \int_0^a c(x_s) ds \right|^{2/\varepsilon} \left( \int_0^1 e^{u\gamma \int_0^a c(x_s) ds} du \right)^{2/\varepsilon} \right) \\ &\leq \gamma^{2/\varepsilon} E_m^{1/2} \left( \left| \int_0^a c(x_s) ds \right|^{4/\varepsilon} \right) E_m^{1/2} \left( e^{\frac{4\gamma}{\varepsilon} \int_0^a c(x_s) ds} \right). \end{aligned}$$

By Jensen's inequality,

$$\begin{aligned} J(a, \gamma) &\leq \gamma^{2/\varepsilon} a^{2/\varepsilon - 1/2} E_m^{1/2} \left( \int_0^a |c(x_s)|^{4/\varepsilon} ds \right) \left[ \frac{1}{a} \int_0^a E_m \left( e^{\frac{4\gamma}{\varepsilon} ac(x_s)} \right) ds \right]^{1/2} \\ &\leq (\gamma a)^{2/\varepsilon} \left[ \int |c(x)|^{4/\varepsilon} m(dx) \right]^{1/2} \left[ \int e^{\frac{4\gamma a}{\varepsilon} c(x)} m(dx) \right]^{1/2}. \end{aligned}$$

The first integral term on the right-hand side in the above inequality is finite due to assumptions A2 and A3. For the same reason, if  $\gamma a < \frac{\varepsilon}{4C}\beta$ , the last integral term of the right-hand side is finite. Then, for  $\gamma a$  small enough,  $J(a, \gamma)$  and  $I_1(a, \gamma)$  are as small as we want.

We now prove that  $I_2(a)$  goes to 0 as  $a \rightarrow +\infty$ .

LEMMA 1. *If A4 and A5 are satisfied,  $\lim_{a \rightarrow +\infty} \int_{\mathbb{R}^{2d}} (p_a(x, y) - 1)^2 m(dx) m(dy) = 0$ .*

*Proof.* By assumption A5, the semigroup  $P_t$  is a contraction on  $\mathbb{L}^2(m)$ , and

$$\lim_{t \rightarrow +\infty} \int \left| P_t f(x) - \left( \int f dm \right) \right|^2 m(dx) = 0.$$

Notice also that, for  $a > b > 0$  and  $m$  almost all  $y$ ,

$$p_a(x, y) = P_{a-b} p_b(\cdot, y)(x)$$

in  $\mathbb{L}^2(m)$  for all rational times  $a$  and  $b$  and, by invariance of  $m$ ,  $\int p_b(x, y) m(dx) = 1$ . Consider now an increasing sequence  $(a_n)_{n \geq 0}$  such that  $a_n \rightarrow +\infty$ . We have to show that, for any such sequence,

$$(2.12) \quad \lim_n \int_{\mathbb{R}^{2d}} (p_{a_n}(x, y) - 1)^2 m(dx) m(dy) = 0.$$

It is not restrictive to assume  $a_1 > t_0$ , where  $t_0$  is the constant in assumption A4. For ( $m$  almost all) fixed  $y$ ,

$$\int (p_{a_n}(x, y) - 1)^2 m(dx) = \int (P_{a_n - a_1} p_{a_1}(\cdot, y)(x) - 1)^2 m(dx) \rightarrow 0$$

by assumption A5. But thanks to assumption A4, the sequence

$$y \mapsto \int (p_{a_n}(x, y) - 1)^2 m(dx)$$

is uniformly integrable, which implies (2.12) by the Vitali convergence theorem.  $\square$

We can now conclude that for  $\gamma a$  small enough and for  $a$  large enough, the cluster estimate  $\rho$  is smaller than 1, which completes the proof of (2.9).

For the proof of (2.10), we proceed in the same way, just observing that the first factor in the right-hand side of (2.11) is now dependent on  $x$ . The additional term to control is  $E_x \left[ e^{q\gamma \int_0^a c(x_s) ds} \right]$  for some large  $q > 1$ . This can be done using A2 and A6. Thus, we completed the proof of Proposition 1.

To complete the proof of Theorem 1, we shall show why the limits (2.2) and (2.3) do not depend on the time-step  $a$ , yielding the limits (1.1) and (1.2). So we choose once and for all some convenient  $a$  and consider the corresponding set of convenient  $\gamma$ 's, yielding for each  $\gamma$  a  $\lambda$  obtained thanks to Proposition 1. For large  $T$  we choose  $n$  such that  $a(n-1) \leq T < an$ .

Notice that

$$S^-(an, x) \leq S(T, x) \leq S^+(an, x),$$

where

$$e^{S^-(an, x)} := E_x \left[ e^{\gamma \int_0^{a(n-1)} c(x_s) ds} e^{-\gamma \int_{a(n-1)}^{an} c^-(x_s) ds} \right]$$

and

$$e^{S^+(an, x)} := E_x \left[ e^{\gamma \int_0^{a(n-1)} c(x_s) ds} e^{\gamma \int_{a(n-1)}^{an} c^+(x_s) ds} \right].$$

Both  $S^-(an, x)$  and  $S^+(an, x)$  can be calculated using the same cluster expansion, except that now we have to replace  $\psi_\gamma(a, x_{a(n-1)}, x_{an})$  with a function  $\psi^-$  (resp.,  $\psi^+$ ) obtained by replacing  $c$  with  $-c^-$  (resp.,  $c^+$ ). We thus obtain a similar decomposition  $S^-(an, x) = \sum_{T \in \mathcal{C}_n, T \neq \emptyset} \Gamma_T^-$  with  $\Gamma_T^- = \Gamma_T$  if  $n-1 \notin T$  and with  $\Gamma_T^-$  obviously modified if  $n-1 \in T$ . In particular, in the decomposition (2.6) we see that, in the first sum, the only modified term is  $\Gamma_{n-1}$ . But since  $-c^-$  also satisfies A2, estimates similar to those in (2.9) and (2.10) hold true for both  $S^-$  and  $S^+$ , whose difference goes to 0 as  $n$  goes to infinity. This yields the desired result.

### 3. Some properties of diffusion processes and their invariant measures.

In this section we provide explicit conditions on the drift  $b(\cdot)$  for assumptions A1 and A3–A6 to hold for the diffusion process in (2.1). Our main result, Theorem 2 below, will be stated in terms of the following two drift conditions:

$$(3.1) \quad \text{Condition (DC)} \quad \exists c_b > 0 \text{ and } \exists R \geq 0 \text{ s.t. for } |x| \geq R, \quad b(x) \cdot x \leq -c_b |x|^2.$$

The second condition is usually called a ‘‘curvature condition.’’ Assume  $b \in C^1$ , and for  $\xi \in \mathbb{R}^d$  recall the notation

$$(3.2) \quad \langle \nabla_\xi b(x), \xi \rangle = \sum_{i,j} \xi_i \partial_i b_j(x) \xi_j.$$

The curvature condition is then as follows:

$$(3.3) \quad \text{Condition (CC)} \quad \exists K_b \in \mathbb{R} \text{ s.t. } \forall x \text{ and all } \xi, \quad \langle \nabla_\xi b(x), \xi \rangle \leq K_b |\xi|^2.$$

In what follows,  $L$  denotes the generator  $b(x) \cdot \nabla + \frac{1}{2} \Delta$ , and  $P_t$  denotes the associated semigroup.

**THEOREM 2.** *Let  $b \in C^1$ . If (DC) holds, then Assumptions A1 and A3 are satisfied, and assumption A6 is uniformly satisfied.*

*If (DC) and (CC) are both satisfied with constants  $c_b, K_b$  such that  $c_b > 2K_b$ , then assumptions A4 and A5 are satisfied.*

**Remark 2.** The condition  $c_b > 2K_b$  is a mild condition. Indeed, if we replace (DC) by a stronger (but more symmetric) condition, namely,

$$(b(x) - b(y)) \cdot (x - y) \leq -c_b |x - y|^2$$

(if  $b = -\nabla V$ , this is a convexity assumption), then we may choose  $K_b < 0$ .

It is also worth noticing that if we reinforce (DC), assuming the condition

$$\lim_{|x| \rightarrow \infty} b(x) \cdot \frac{x}{|x|^2} = -\infty,$$

then we may always choose  $c_b > 2K_b$  (if  $K_b$  is finite, of course). In this situation it can be shown (see [19, Corollary 5.7.7]) that the semigroup  $P_t$  is superbounded.

*Proof of Theorem 2.* We divide the proof into several steps.

*Step 1. A1 holds under (DC).* Since  $b \in C^1$ , it is locally Lipschitz; thus existence and strong uniqueness are ensured up to the explosion time, starting from any  $x$ . Define now  $\psi(x) = 1 + |x|^2$ . By condition (DC) it is easy to check that  $L\psi \leq C\psi$  for some  $C > 0$ . By applying Ito's rule to  $\psi(x_t)$  up to the exit time of the level sets of  $\psi$  (in the same spirit as in [16, Théorème 2.2.19]), it follows that the explosion time is a.s. infinite.

*Step 2. A3 holds under (DC).* Existence and uniqueness of the invariant measure  $m$  under (DC) follow, for instance, from [17, Theorem 7.4.21]. We prove here that, if (DC) holds, then for all  $\beta < c_b$ ,  $\int e^{\beta|y|^2} m(dy) < +\infty$ . Since (DC) holds, there exists  $D > 0$  such that  $b(x) \cdot x \leq -c_b|x|^2 + D$  for all  $x$ ; we set  $c = c_b$  in the proof of this step.

Let  $g_n$  be a smooth nondecreasing concave function defined on  $\mathbb{R}^+$  such that  $g_n(u) = u$  if  $u \leq n-1$  and  $g_n(u) = n$  if  $u \geq n$  (such a function exists). Let  $f_n(x) = \exp(\beta g_n(|x|^2))$  for  $\beta < c$ .

Then  $\nabla f_n(x) = 2\beta f_n(x)g'_n(|x|^2)x$  and

$$\Delta f_n(x) = 2\beta f_n(x) (2g''_n(|x|^2)|x|^2 + 2\beta(g'_n)^2(|x|^2)|x|^2 + dg'_n(|x|^2))$$

so that

$$\begin{aligned} Lf_n(x) &= \beta f_n(x) ((2g''_n(|x|^2)|x|^2 + dg'_n(|x|^2)) + 2g'_n(|x|^2)(\beta g'_n(|x|^2)|x|^2 + b(x) \cdot x)) \\ &\leq \beta f_n(x)(d + 2D - 2(c - \beta)|x|^2) \\ &\leq \beta(d + 2D)e^{\beta \frac{d+2D}{c-\beta}} - \beta(d + 2D) f_n(x) \end{aligned}$$

since

$$d + 2D - 2(c - \beta)|x|^2 \leq -(c - \beta)|x|^2 \leq -(d + 2D)$$

for  $|x|^2 \geq \frac{d+2D}{c-\beta}$ .

In short, there exist  $c_1$  and  $c_2$  positive constants such that for all  $n$ ,  $Lf_n \leq c_1 - c_2 f_n$ .

Define  $h_n(s) = E_x[e^{\beta g_n(|x_s|^2)}]$ . Ito's formula yields

$$h_n(t) \leq h_n(0) + c_1 t - c_2 \int_0^t h_n(s) ds,$$

and hence by applying Gronwall's lemma, we obtain

$$(3.4) \quad E_x \left[ e^{\beta g_n(|x_t|^2)} \right] \leq \frac{c_1}{c_2} + e^{-c_2 t} e^{\beta g_n(|x|^2)}.$$

Integrating (3.4) with respect to the invariant measure  $m$  yields

$$(1 - e^{-c_2 t}) \int e^{\beta g_n(|y|^2)} m(dy) \leq \frac{c_1}{c_2}.$$

We may thus choose  $t$  large enough for  $e^{-c_2 t} \leq 1/2$  and then use the monotone convergence theorem with  $n \rightarrow +\infty$  in order to obtain  $\int e^{\beta|y|^2} m(dy) < +\infty$  for  $\beta < c_b$ .

*Step 3.* A6 is uniformly satisfied under (DC). Using Ito's formula up to the exit time  $T_M$  of the ball of center 0 and radius  $M$ , we have

$$E_x \left[ e^{\theta |x_{t \wedge T_M}|^2} \right] = e^{\theta |x|^2} + E_x \left[ \int_0^{t \wedge T_M} (2\theta b(x_s) \cdot x_s + d\theta + 2\theta^2 |x_s|^2) e^{\theta |x_s|^2} ds \right].$$

In particular, if condition (DC) holds with  $c_b > \theta$ , the integrand in the right-hand side is nonpositive for large values of  $|x_s|$ , and hence we can let  $M$  go to infinity in order to show that there exists some constant  $\kappa$  (depending on (DC) and  $\theta$ ) such that

$$E_x \left[ e^{\theta |x_t|^2} \right] < e^{\theta |x|^2} + \kappa t.$$

Accordingly, using the Jensen inequality, we obtain

$$\begin{aligned} E_x \left[ e^{\int_0^a \beta |x_s|^2 ds} \right] &= E_x \left[ e^{\frac{1}{a} \int_0^a a \beta |x_s|^2 ds} \right] \\ &\leq \frac{1}{a} E_x \left[ \int_0^a e^{a \beta |x_s|^2} ds \right] < +\infty \end{aligned}$$

as soon as  $a\beta < c_b$ . The proof is completed.

*Step 4.* A4 holds if (DC) and (CC) are both satisfied and if  $c_b > 2K_b$ . Since  $b \in C^1$ , Malliavin calculus shows that the law of  $x_t$  is absolutely continuous w.r.t. the Lebesgue measure for all initial conditions  $x$  and all  $t > 0$ . Hence  $m$  is also absolutely continuous w.r.t. the Lebesgue measure, and it can be shown that  $dm/dy$  is a.e. positive. Thus, the existence of  $p_t(x, y)$  follows. The proof of the integrability condition stated in A4 relies on a beautiful Harnack inequality derived by Wang (see [19, Theorem 2.5.2]),

$$(3.5) \quad (P_t f(x))^\alpha \leq P_t f^\alpha(y) \exp \left( \frac{\alpha}{2(\alpha-1)} K_b (1 - e^{-2K_b t})^{-1} |x - y|^2 \right),$$

holding for  $t > 0$ ,  $\alpha > 1$ , all  $(x, y)$ , and all nonnegative continuous and bounded  $f$ , with the convention  $K_b(1 - e^{-2K_b t})^{-1} = 1/2t$  if  $K_b \leq 0$  (see also [1, Lemma 7.5.4] if  $\alpha = 2$ ).

Using (3.5), we show that for all  $p > 2$ ,  $p_t(\cdot, \cdot) \in \mathbb{L}^p(m \otimes m)$  for all  $t$  such that

$$c_b > \frac{K_b p(p-1)}{1 - e^{-2K_b t}}.$$

In particular, if  $K_b \leq 0$ , then for all  $p > 2$  there exists  $t_p$  such that  $p_t(\cdot, \cdot) \in \mathbb{L}^p(m \otimes m)$  for  $t \geq t_p$ , while for  $K_b > 0$  such a  $t_p$  exists provided  $c_b > K_b p(p-1)$ . We shall first derive an upper bound for the density.

Let  $\alpha > 1$ ,  $D_t := \{x \in \mathbb{R}^d, |x| \leq \gamma(t)\}$  for some increasing function  $\gamma$  going to  $\infty$ , and let  $f$  be nonnegative and bounded. Integrating the Harnack inequality for  $P_t$  with respect to  $m(dy)$  on  $D_t$  and denoting

$$\kappa(t) = \frac{\alpha}{2(\alpha-1)} K_b (1 - e^{-2K_b t})^{-1},$$

we get

$$\begin{aligned} ((P_t f)(x))^\alpha &\leq \int_{D_t} (P_t f^\alpha)(y) e^{\kappa(t)|x-y|^2} m(dy)/m(D_t) \\ &\leq \int f^\alpha(y) (P_t^*(\mathbf{1}_{D_t}(\cdot) e^{\kappa(t)|x-\cdot|^2}))(y) m(dy)/m(D_t) \\ &\leq e^{2\kappa(t)(|x|^2 + \gamma^2(t))} \int f^\alpha(y) m(dy)/m(D_t) \end{aligned}$$

since

$$\| \mathbb{1}_{D_t}(\cdot) e^{\kappa(t)|x-\cdot|^2} \|_\infty \leq e^{2\kappa(t)(|x|^2 + \gamma^2(t))}.$$

If

$$\theta(t, x) = \left( e^{2\kappa(t)\gamma^2(t)} / m(D_t) \right) e^{2\kappa(t)|x|^2},$$

we thus have

$$(3.6) \quad ((P_t f)(x))^\alpha \leq \theta(t) \int f^\alpha(y) m(dy).$$

Applying the previous inequality with a continuous approximation of  $f_N(z) = p_t^\beta(x, z) \mathbb{1}_{\{p_t(x, z) \leq N\}}$  and then taking limits, we have

$$\left( \int p_t^{1+\beta}(x, z) \mathbb{1}_{\{p_t(x, z) \leq N\}} m(dz) \right)^\alpha \leq \theta(t, x) \int p_t^{\alpha\beta}(x, y) \mathbb{1}_{\{p_t(x, y) \leq N\}} m(dy);$$

i.e., by letting  $N$  go to  $\infty$  and choosing  $1 + \beta = \alpha\beta$  and hence  $\beta = 1/(\alpha - 1)$  we obtain

$$(3.7) \quad \int p_t^{\frac{\alpha}{\alpha-1}}(x, y) m(dy) \leq \theta^{1/(\alpha-1)}(t, x).$$

By Step 2, the right-hand side in (3.7) is in  $\mathbb{L}^1(m)$  provided

$$(3.8) \quad c_b > \frac{2\kappa(t)}{\alpha - 1} = \frac{\alpha K_b}{(\alpha - 1)^2(1 - e^{-2K_b t})}.$$

In particular if  $p > 2$ , define  $1 < \alpha = p/(p - 1) < 2$ . Hence  $p_t(\cdot, \cdot) \in \mathbb{L}^p(m \otimes m)$  provided

$$c_b > \frac{K_b p(p - 1)}{1 - e^{-2K_b t}}.$$

*Step 5.* A5 holds if (DC) and (CC) are both satisfied, and  $c_b > K_b$ . (Note that the condition needed here is weaker than  $c_b > 2K_b$ .) It is well known that the  $L^2(m)$ -contractivity stated in assumption A5 is implied by *hypercontractivity* of  $P_t$ , which means that for all  $1 < p < q < +\infty$  there exists  $t_{p,q}$  such that for  $t \geq t_{p,q}$ ,  $P_t$  is a bounded operator from  $\mathbb{L}^p(m)$  into  $\mathbb{L}^q(m)$  with norm equal to 1. The fact that  $c_b > K_b$  implies hypercontractivity of  $P_t$  is shown in [19, Theorem 5.7.3, Corollary 5.7.2, and Theorem 5.7.1].

**4. The limiting function as viscosity solution.** We consider the function

$$(4.1) \quad \varphi(t, x) := E_x \left[ \exp \left( \gamma \int_0^t c(x_s) ds \right) \right].$$

We have shown that (under some assumptions we shall assume to be in force below), for  $\gamma$  sufficiently small, the limits

$$(4.2) \quad \lambda := \lim_t \frac{1}{t} \log \varphi(t, x)$$

and

$$(4.3) \quad V(x) := \lim_t [\log \varphi(t, x) - \lambda t]$$

exist uniformly over compact sets. We want to show that  $V$  is a *viscosity solution* of the HJB equation (1.6) or, equivalently, that  $v(x) := e^{V(x)}$  is a viscosity solution of the linear equation

$$(4.4) \quad - \left[ \frac{1}{2} \Delta v + b \cdot \nabla v + \gamma c v \right] + \lambda v = 0.$$

We first prove that  $\varphi(T - t, x)$  is a continuous viscosity solution of a suitable evolution equation. Then by using (4.3) we show that (4.4) holds.

This problem has been dealt with in [9] in a much more general setting. However, the assumptions given in [9] are not satisfied here, due to the unboundedness of  $c$ . Thus, some modifications of their proof are needed.

**PROPOSITION 2.** *Assume that conditions A1–A5 are satisfied and that condition (DC) is satisfied, so that condition A6 is uniformly satisfied (in particular, the strong Feller property holds). Moreover, let  $\bar{\gamma}$  be as in Theorem 1, and assume  $\gamma < \bar{\gamma}$  (hence the limits (4.2) and (4.3) exist). Then  $v(\cdot)$  is continuous and is a viscosity solution of (4.4).*

*Proof. Step 1. Continuity of  $\varphi(t, x)$ .* We first establish continuity in  $x$ .

First note that, according to the proofs in section 2, for  $\gamma < \bar{\gamma}$ , one can find some  $\delta \in ]1, \frac{\bar{\gamma}}{\gamma}[$  and some function  $h_\gamma(t, x)$ , which is bounded on compact sets such that

$$(4.5) \quad E_x \left[ \exp \left( \gamma \delta \int_0^t |c(x_s)| ds \right) \right] \leq h_\gamma(t, x)$$

for all  $t > 0$  and  $x \in \mathbb{R}^d$ .

Note that, for  $0 < \epsilon < t$ ,

$$(4.6) \quad \begin{aligned} & |\varphi(t, x) - \varphi(t, y)| \\ &= \left| E_x \left[ \varphi(t - \epsilon, x_\epsilon) \exp \left( \gamma \int_0^\epsilon c(x_s) ds \right) \right] \right. \\ &\quad \left. - E_y \left[ \varphi(t - \epsilon, x_\epsilon) \exp \left( \gamma \int_0^\epsilon c(x_s) ds \right) \right] \right| \\ &\leq E_x \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right| \varphi(t - \epsilon, x_\epsilon) \right] + E_y \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right| \varphi(t - \epsilon, x_\epsilon) \right] \\ &\quad + |E_x[\varphi(t - \epsilon, x_\epsilon)] - E_y[\varphi(t - \epsilon, x_\epsilon)]|. \end{aligned}$$

We begin by estimating the first term in the right-hand side of (4.6). By the Hölder inequality,

$$(4.7) \quad \begin{aligned} & E_x \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right| \varphi(t - \epsilon, x_\epsilon) \right] \\ &\leq \left\{ E_x \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right|^p \right] \right\}^{1/p} \left\{ E_x \left[ \exp \left( \gamma \delta \int_0^t |c(x_s)| ds \right) \right] \right\}^{1/\delta}, \end{aligned}$$

where  $p = \frac{\delta}{\delta-1}$ . Our goal is to show that the left-hand side of (4.7) goes to 0 as  $\epsilon \rightarrow 0$ , uniformly in  $x$  varying in a compact set. By (4.5), the second factor in the right-hand side of (4.7) is locally bounded. Thus, it is enough to show that

$$E_x \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right|^p \right]$$

goes to zero uniformly in compact sets. By the inequality  $|e^x - 1| \leq |x|e^{|x|}$ , the Cauchy-Schwarz inequality, and Jensen's inequality,

$$\begin{aligned} E_x \left[ \left| e^{\gamma \int_0^\epsilon c(x_s) ds} - 1 \right|^p \right]^2 &\leq \gamma^{2p} E_x \left[ \left( \int_0^\epsilon c(x_s) ds \right)^p e^{\gamma p \int_0^\epsilon |c(x_s)| ds} \right]^2 \\ &\leq \gamma^{2p} E_x \left[ \left( \int_0^\epsilon c(x_s) ds \right)^{2p} \right] E_x \left[ e^{2\gamma p \int_0^\epsilon |c(x_s)| ds} \right] \\ &\leq \epsilon^{2p-1} \gamma^{2p} \int_0^\epsilon E_x [|c(x_s)|^{2p}] ds E_x \left[ e^{2\gamma p \int_0^\epsilon |c(x_s)| ds} \right] \\ (4.8) \quad &\leq \epsilon^{2p-2} \gamma^{2p} \int_0^\epsilon E_x [|c(x_s)|^{2p}] ds \int_0^\epsilon E_x \left[ e^{2\gamma p \epsilon |c(x_s)|} \right] ds. \end{aligned}$$

Since  $p > 1$ , it is enough to show that the two integrals in (4.8) are locally bounded. This follows easily from the assumption that  $c(\cdot)$  has quadratic growth (see A2, where the constant  $C$  is defined), and from the proof of the first part of Theorem 2, as soon as  $2\gamma p C \epsilon < c_b$ , that holds true for  $\epsilon$  small enough. Indeed we get some exponential integrability which is strong enough to control both terms.

It remains to deal with the last term in (4.6). It is enough to show that, for given  $\epsilon > 0$ , the map

$$(4.9) \quad x \mapsto E_x[\varphi(t - \epsilon, x_\epsilon)]$$

is continuous in  $x$ . For this purpose, we realize all diffusion starting from any  $x \in \mathbb{R}^d$  in the same probability space. We denote by  $X_t(x)$  the diffusion starting from  $x$ , and denote by  $E$  the expectation in this probability space. Thus

$$E_x[\varphi(t - \epsilon, x_\epsilon)] = E[\varphi(t - \epsilon, X_\epsilon(x))].$$

By (4.5),

$$E[\varphi^\delta(t - \epsilon, X_\epsilon(x))]$$

is locally bounded in  $x$ . This implies that, for any ball  $B$ , the family of random variables

$$(\varphi(t - \epsilon, X_\epsilon(x)))_{x \in B}$$

is uniformly integrable. Thus, letting  $\varphi_M(x) := \varphi(t - \epsilon, x) \mathbf{1}_{[0, M]}(|\varphi(t - \epsilon, x)|)$  ( $\mathbf{1}_A$  is the indicator function of the set  $A$ ), we have that

- for every  $M > 0$ ,  $E[\varphi_M(X_\epsilon(x))]$  is continuous in  $x$  by the strong Feller property; and
- $E[\varphi(t - \epsilon, X_\epsilon(x))] - E[\varphi_M(X_\epsilon(x))]$  goes to zero as  $M \rightarrow +\infty$  uniformly in  $x \in B$  for any ball  $B$ .

From these two statements, continuity of (4.9) follows.

To get joint continuity in  $(t, x)$  just observe that, by the integrability condition (4.5), we can differentiate in  $t$   $\varphi(t, x)$  and show that this derivative is locally bounded. Thus  $\varphi(t, x)$  is locally Lipschitz in  $t$ , locally uniformly in  $x$ . This, together with continuity in  $x$ , implies joint continuity.

*Step 2. Viscosity solution of the parabolic equation.* In what follows we introduce the upper-semicontinuous (resp., lower-semicontinuous) extension  $c^*$  (resp.,  $c_*$ ) of  $c(\cdot)$ :

$$c^*(x) := \limsup_{y \rightarrow x} c(y), \quad c_*(x) := \liminf_{y \rightarrow x} c(y).$$

Moreover, let  $v_T(t, x) := \varphi(T - t, x)$ . We now show that  $v_T$  is a viscosity solution (in  $[0, T]$ ) of the parabolic equation

$$(4.10) \quad - \left( \partial_t v_T + b \cdot \nabla v_T + \frac{1}{2} \Delta v_T + \gamma c v_T \right) = 0.$$

Since  $v_T$  is continuous, this amounts to showing that the following two properties hold true:

- i. (supersolution property). Let  $(t, x) \in [0, T) \times \mathbb{R}^d$  and let  $\psi : [0, T) \times \mathbb{R}^d \rightarrow \mathbb{R}$  be a smooth function such that  $\psi(t, x) = v_T(t, x)$  and  $v_T - \psi$  has a local maximum at  $(t, x)$  (there may be no such function). Then

$$- \left( \partial_t \psi(t, x) + b(x) \cdot \nabla \psi(t, x) + \frac{1}{2} \Delta \psi(t, x) + \gamma c^*(x) v_T(t, x) \right) \leq 0.$$

- ii. (subsolution property). Let  $(t, x) \in [0, T) \times \mathbb{R}^d$  and let  $\psi : [0, T) \times \mathbb{R}^d \rightarrow \mathbb{R}$  be a smooth function such that  $\psi(t, x) = v_T(t, x)$  and  $v_T - \psi$  has a local minimum at  $(t, x)$ . Then

$$- \left( \partial_t \psi(t, x) + b(x) \cdot \nabla \psi(t, x) + \frac{1}{2} \Delta \psi(t, x) + \gamma c_*(x) v_T(t, x) \right) \geq 0.$$

$v_T - \psi$  has a *strict* local extreme in  $(t, x)$ . Indeed, if  $v_T - \psi$  has a local extreme at  $(t, x)$  and  $\tilde{\psi}(s, y) := \psi(s, y) \pm [(s - t)^2 + |x - y|^4]$  (where the sign depends on whether we are dealing with a maximum or a minimum), then  $v_T - \tilde{\psi}$  has a *strict* local extreme in  $(t, x)$ , and  $\psi$  and  $\tilde{\psi}$  have the same first space and time derivatives and second space derivatives at  $(t, x)$ . We now observe the following identities:

$$\begin{aligned} \varphi(t, x) &= 1 - \int_0^t \frac{d}{ds} E_x \left[ \exp \left( \int_s^t \gamma c(x_\tau) d\tau \right) \right] ds \\ &= 1 + \gamma \int_0^t E_x \left[ c(x_s) \exp \left( \gamma \int_s^t c(x_\tau) d\tau \right) \right] ds \\ &= 1 + \gamma \int_0^t E_x [c(x_s) \varphi(t - s, x_s)] ds, \end{aligned}$$

where all steps are justified by (4.5). It follows that, for  $\epsilon > 0$ ,

$$\varphi(t, x) - E_x[\varphi(t - \epsilon, x_\epsilon)] = \gamma E_x \left[ \int_0^\epsilon c(x_s) \varphi(t - s, x_s) ds \right].$$

By a change  $t \mapsto T - t$  of the time variable, we get

$$(4.11) \quad v_T(t, x) - E_x[v_T(t + \epsilon, x_\epsilon)] = \gamma E_x \left[ \int_0^\epsilon c(x_s) v_T(t + s, x_s) ds \right].$$

Now we use (4.11) to prove that  $v_T$  has the subsolution property. The supersolution property is proved in the same way. Note that both properties are local, so it is not restrictive to assume the test functions  $\psi$  to have compact support.

So let  $\psi$  be a smooth function with compact support such that  $\psi(t, x) = v_T(t, x)$  and  $v_T - \psi$  has a local minimum at  $(t, x)$ . We first claim that

$$(4.12) \quad \limsup_{\epsilon \rightarrow 0} \frac{v_T(t, x) - E_x[v_T(t + \epsilon, x_\epsilon)]}{\epsilon} \leq \limsup_{\epsilon \rightarrow 0} \frac{\psi(t, x) - E_x[\psi(t + \epsilon, x_\epsilon)]}{\epsilon}.$$

This is done by a simple localization. Let  $\rho > 0$  be such that  $v_T(s, y) \geq \psi(s, y)$  for  $(s, y) \in [t - \rho, t + \rho] \times B(x, \rho)$ . Then, for  $|\epsilon| < \rho$ ,

$$\begin{aligned} & \frac{v_T(t, x) - E_x[v_T(t + \epsilon, x_\epsilon)]}{\epsilon} \\ &= E_x \left[ \frac{v_T(t, x) - v_T(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| \leq \rho} \right] + E_x \left[ \frac{v_T(t, x) - v_T(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| > \rho} \right] \\ &\leq E_x \left[ \frac{\psi(t, x) - \psi(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| \leq \rho} \right] + E_x \left[ \frac{v_T(t, x) - v_T(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| > \rho} \right] \\ &= E_x \left[ \frac{\psi(t, x) - \psi(t + \epsilon, x_\epsilon)}{\epsilon} \right] \\ &\quad - E_x \left[ \frac{\psi(t, x) - \psi(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| > \rho} \right] + E_x \left[ \frac{v_T(t, x) - v_T(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| > \rho} \right]. \end{aligned}$$

Thus, in order to obtain (4.12), it is enough to show that the last two terms go to zero as  $\epsilon \rightarrow 0$ . We deal only with the last (the others being easier),

$$\begin{aligned} \left| E_x \left[ \frac{v_T(t, x) - v_T(t + \epsilon, x_\epsilon)}{\epsilon} \mathbb{1}_{|x_\epsilon - x| > \rho} \right] \right| &\leq \frac{2}{\epsilon} E_x \left[ e^{\gamma \int_0^T |c(x_s)| ds} \mathbb{1}_{|x_\epsilon - x| > \rho} \right] \\ &\leq \frac{2}{\epsilon} E_x \left[ e^{\gamma \delta \int_0^T |c(x_s)| ds} \right] E_x(\mathbb{1}_{|x_\epsilon - x| > \rho})^{1 - \frac{1}{\delta}}, \end{aligned}$$

which goes to zero as  $\epsilon \rightarrow 0$  since, by small time estimates (see, e.g., [18]),  $E_x(\mathbb{1}_{|x_\epsilon - x| > \rho}) = o(\epsilon)$ . This establishes (4.12). On the other hand, by Ito's rule,

$$(4.13) \quad \lim_{\epsilon \rightarrow 0} \frac{\psi(t, x) - E_x[\psi(t + \epsilon, x_\epsilon)]}{\epsilon} = - \left( \partial_t \psi(t, x) + b(t, x) \cdot \nabla \psi(t, x) + \frac{1}{2} \Delta \psi(t, x) \right).$$

Putting together (4.11), (4.12), and (4.13), the subsolution property follows from

$$(4.14) \quad \liminf_{\epsilon \rightarrow 0} \frac{1}{\epsilon} E_x \left[ \int_0^\epsilon c(x_s) v_T(t + s, x_s) ds \right] \geq c_*(x) v_T(t, x),$$

where the above convergence is again controlled by small time estimates and the fact that  $v_T$  is continuous.

*Step 3. Conclusion.* Letting  $\tilde{v}_T(t, x) := v_T(t, x)e^{-\lambda(T-t)}$ , it is easily checked that  $\tilde{v}_T$  is a viscosity solution of

$$(4.15) \quad - \left( \partial_t \tilde{v}_T + b \cdot \nabla \tilde{v}_T + \frac{1}{2} \Delta \tilde{v}_T + \gamma c v_T \right) + \lambda \tilde{v} = 0.$$

Moreover,  $\tilde{v}_T(t, x) \rightarrow v(x)$  as  $T \rightarrow +\infty$  uniformly on compact sets. In particular,  $v$  is continuous. We now sketch a standard argument to show that  $v$  is a viscosity solution of (4.4).

Let  $x \in \mathbb{R}^d$ , and let  $\psi : \mathbb{R}^d \rightarrow \mathbb{R}$  be a smooth function such that  $v(x) = \psi(x)$  and  $v - \psi$  has a local minimum at  $x$ . Fix  $t > 0$ , and define  $\tilde{\psi}(s, y) := \psi(y) - |y - x|^4 - (s - t)^2$ . Note that  $v - \tilde{\psi}$  has a *strict* local minimum at  $(t, x)$ , and

$$(4.16) \quad \partial_t \tilde{\psi}(t, x) + b(t, x) \cdot \nabla \tilde{\psi}(t, x) + \frac{1}{2} \Delta \tilde{\psi}(t, x) = b(x) \cdot \nabla \psi(x) + \frac{1}{2} \Delta \psi(x).$$

A simple exercise in uniform convergence shows that there is a sequence  $(t_n, x_n) \rightarrow (t, x)$  as  $n \rightarrow +\infty$  such that  $\tilde{v}_n - \tilde{\psi}$  has a local minimum at  $(t_n, x_n)$ . Therefore, since  $\tilde{v}$  is a viscosity solution of (4.15),

$$(4.17) \quad - \left( \partial_t \tilde{\psi}(t_n, x_n) + b(x_n) \cdot \nabla \tilde{\psi}(t_n, x_n) + \frac{1}{2} \Delta \tilde{\psi}(t_n, x_n) + \gamma c_*(x_n) \tilde{v}_n(x_n) \right) + \lambda \tilde{v}_n(x_n) \geq 0.$$

Letting  $n \rightarrow +\infty$  and using (4.16) and lower-semicontinuity of  $c_*$ , we obtain the subsolution property for (4.4). The supersolution property is obtained in the same way.  $\square$

## DYNAMIC PROGRAMMING PRINCIPLE FOR ONE KIND OF STOCHASTIC RECURSIVE OPTIMAL CONTROL PROBLEM AND HAMILTON–JACOBI–BELLMAN EQUATION\*

ZHEN WU<sup>†</sup> AND ZHIYONG YU<sup>‡</sup>

**Abstract.** In this paper, we study one kind of stochastic recursive optimal control problem with the obstacle constraint for the cost functional described by the solution of a reflected backward stochastic differential equation. We give the dynamic programming principle for this kind of optimal control problem and show that the value function is the unique viscosity solution of the obstacle problem for the corresponding Hamilton–Jacobi–Bellman equation.

**1. Introduction.** The nonlinear backward stochastic differential equation (BSDE) was been introduced by Pardoux and Peng [12]. Independently, Duffie and Epstein [6] introduced BSDE from economic background. In [6] they presented a stochastic differential recursive utility which is an extension of the standard additive utility with the instantaneous utility depending not only on the instantaneous consumption rate but also on the future utility. Actually, it corresponds to the solution of a particular BSDE whose generator does not depend on the variable  $z$ . From a mathematical point of view the results in [12] are more general. Then El Karoui, Peng, and Quenez [11] gave some important properties of BSDEs such as comparison theorem and applications in mathematical finance and optimal control theory. And also in the same paper, the authors gave the formulation of recursive utilities and their properties from the BSDE point of view. The recursive optimal control problem is presented as a kind of optimal control problem whose cost functional is described by the solution of BSDE. In 1992, Peng [13] got the Bellman’s dynamic programming principle for this kind of problem and proved that the value function is a viscosity solution of one kind of quasi-linear second order partial differential equation (PDE) which is the well known Hamilton–Jacobi–Bellman equation. Later in 1997, he virtually generalized these results to a much more general situation, under Markovian and even non-Markovian framework (see [14, Chapter 2]). In the Chinese version, Peng used the backward semigroup property of BSDE to prove Bellman’s dynamic programming principle for the recursive optimal problem introduced by a BSDE under Markovian and non-Markovian framework. He also proved that the value function is a viscosity solution of a generalized Hamilton–Jacobi–Bellman equation.

In 1997, El Karoui et al. [9] studied the reflected BSDE with one continuous barrier. The solution of the reflected BSDE is forced to stay above a given continuous stochastic process called the barrier. For this purpose they introduced an increasing process to push the solution upwards in a kind of minimal way. Using two different methods, optimal stopping problem with fixed point principle and penalization method, they got the existence and uniqueness of the solution for this kind of reflected BSDE. The solution of reflected BSDE provides a probabilistic representation for the unique viscosity solution of an obstacle problem for a nonlinear parabolic partial differential equation within the Markovian framework. This kind of reflected BSDE also has applications in the financial market. We know from El Karoui et al. [11] that the pricing of the European contingent claim can be formulated in terms of BSDEs. Since pricing an American option can be formulated as an optimal stopping problem, El Karoui, Pardoux, and Quenez [10], showed that the price of an American option corresponds to the solution of a reflected BSDE, even in an imperfect market.

Cvitanic and Karatzas [5] extended the result to reflected BSDE with upper and lower barriers. Hamadène and Lepeltier [7] used reflected BSDE to solve a mixed optimal stochastic control problem. In this kind of problem, the controller has two actions, one is control and the other is stopping his control strategy in order to maximize his payoff. And then Hamadène, Lepeltier, and Wu [8] generalized the results for infinite horizon reflected BSDEs with one or two barriers and also applied those results to the mixed control and mixed game problem.

In our paper, we study one kind of recursive optimal control problem with the obstacle constraint for the cost functional; i.e., the cost functional of the control system is described by the solution of a reflected BSDE with one lower barrier. This kind of recursive optimal control problem has some practical meaning. For example, in the financial market, an investor requires his recursive utility function to be bigger than a certain function of his wealth. For this purpose, an increasing process is introduced to push the cost functional upward; we require this push to be minimum. From the results in [9] and [7], we know that, in many cases, this problem can be regarded as a mixed optimal stochastic control problem. We also will show that the pricing problem of the American option when loan interest is higher than deposit interest can be reformulated to this kind of recursive optimal control problem.

One of our interesting problems is that if the dynamic programming principle still holds for this recursive optimal control problem. Using some properties of the reflected BSDE and analysis techniques we give a positive answer for this question. Then we show that, if the problem is formulated within a Markovian framework, the value function is the unique viscosity solution of the obstacle problem for a nonlinear parabolic PDE which is called the Hamilton–Jacobi–Bellman (HJB) equation.

Our paper generalizes the dynamic programming principle of the recursive control problem in [13] and [14] to the obstacle constraint case and has the following advantages and improvements. First, in Peng [13] and [14], the recursive cost function does not have the obstacle constraint. In our paper, the optimization problem has obstacle constraints for the cost function which is described by the solution of reflected BSDEs. Such a problem has more financial applications and can formulate the pricing problem of the American option in a complete or incomplete market. Many ideas and methods of proof in our paper for dynamic programming principle come from [13] and [14]. However, we generalize the results to obstacle constraint case whose coefficients just satisfy Lipschitz condition, so our results are more general. Second, the method of proof in our paper is mainly based on elementary mathematics analysis technique and the properties of reflected BSDEs. We improved two properties of

reflected BSDEs in [9] (see Propositions 2.1 and 2.2) which play important roles for the continuation of the value function about  $t$  (see Proposition 3.12, also our proof is more clear). Finally, the proof of existence for the viscosity solution of the obstacle problem for the corresponding HJB equations in our paper is completely different from the one in Peng [13] and [14]. Our result is the generalization of the one in Karoui et al. [9] for the obstacle problem of nonlinear parabolic PDEs. We need to consider changing the order between  $\lim$  and  $\sup$  as according to Peng, [13] and [14], there lacks the uniqueness proof for the viscosity solution. In our paper, we apply the method introduced by Barles, Buckdahn, and Pardoux [1] to give the uniqueness proof for the viscosity solution of corresponding HJB equations.

The paper is organized as follows. In section 2, we present some preliminary results about reflected BSDE which play an important role to study the dynamic programming principle of the optimal control problem. In section 3, we formulate the recursive optimal control problem with the obstacle constraint for the cost functional and prove that the dynamic programming principle holds. In section 4, we prove that the value function of the control problem is the unique viscosity solution of the obstacle problem for the corresponding HJB equation.

**2. Preliminary results of the reflected BSDE.** In this section, we give some preliminary results of the reflected BSDE which are useful for the dynamic programming principle for the recursive optimal control problem with the obstacle constraint for the cost functional.

Let  $\{W_t, 0 \leq t \leq T\}$  be a  $d$ -dimensional standard Brownian motion defined on a probability space  $(\Omega, \mathcal{F}, P)$ . Let  $\{\mathcal{F}_t, 0 \leq t \leq T\}$  be the natural filtration of  $\{W_t\}$ , where  $\mathcal{F}_0$  contains all  $P$ -null sets of  $\mathcal{F}$ , and, let  $\mathcal{P}$  be the  $\sigma$ -algebra of predictable subsets of  $\Omega \times [0, T]$ .

Let us introduce some notations

$$L^2 = \left\{ \xi \text{ is an } \mathcal{F}_T\text{-measurable random variable s.t. } \mathbb{E}(|\xi|^2) < +\infty \right\},$$

$$H^2 = \left\{ \{\varphi_t, 0 \leq t \leq T\} \text{ is an adapted process s.t. } \mathbb{E} \int_0^T |\varphi_t|^2 dt < +\infty \right\},$$

$$S^2 = \left\{ \{\varphi_t, 0 \leq t \leq T\} \text{ is an adapted process s.t. } \mathbb{E} \left( \sup_{0 \leq t \leq T} |\varphi_t|^2 \right) < +\infty \right\},$$

and the following reflected BSDE with one barrier:

$$(2.1) \quad Y_t = \xi + \int_t^T g(s, Y_s, Z_s) ds + K_T - K_t - \int_t^T Z_s dW_s, \quad 0 \leq t \leq T.$$

Here  $\xi \in L^2$ ,  $g$  is a map from  $\Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d$  into  $\mathbb{R}$  satisfying

- (i) for all  $(y, z) \in \mathbb{R} \times \mathbb{R}^d$ ,  $g(\cdot, y, z) \in H^2$ ,
- (ii) for some  $L > 0$  and all  $y, y' \in \mathbb{R}$ ,  $z, z' \in \mathbb{R}^d$ , a.s.

$$|g(t, y, z) - g(t, y', z')| \leq L(|y - y'| + |z - z'|),$$

$\{S_t, 0 \leq t \leq T\}$  called an “obstacle” is a continuous adapted real-valued process satisfying

- (iii)  $\mathbb{E}(\sup_{0 \leq t \leq T} |S_t|^2) < +\infty$ .

Then from Theorem 5.2 in [9], there exists a unique solution  $\{(Y_t, Z_t, K_t), 0 \leq t \leq T\}$  taking values in  $\mathbb{R}$ ,  $\mathbb{R}^d$  and  $\mathbb{R}_+$ , respectively, and satisfying

(iv)  $Y \in S^2$ ,  $Z \in H^2$ , and  $K_T \in L^2$ ;

(v)  $Y_t \geq S_t$ ,  $0 \leq t \leq T$ ;

(vi)  $\{K_t\}$  is adapted, continuous and increasing,  $K_0 = 0$ , and  $\int_0^T (Y_t - S_t) dK_t = 0$ .

Now we give two more accurate estimates of the solutions than that of Propositions 3.5 and 3.6 in [9]. They are necessary for proof of the dynamic programming principle of our optimal control problem and play an important role for the continuation properties of value function  $u(t, x)$  about  $t$  and  $x$ . The analogous generalization results for the nonreflected case can be seen in [2]. Since some proof technique is derived from [2], we omit it.

PROPOSITION 2.1. *Let  $\{(Y_t, Z_t, K_t), 0 \leq t \leq T\}$  be the solution of the above reflected BSDE  $(\xi, g, S)$ , then there exists a constant  $C$  such that*

$$\begin{aligned} & \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} Y_s^2 + \int_t^T |Z_s|^2 + |K_T - K_t|^2 \right\} \\ & \leq C \mathbb{E}^{\mathcal{F}_t} \left\{ \xi^2 + \left( \int_t^T g(s, 0, 0) ds \right)^2 + \sup_{t \leq s \leq T} S_s^2 \right\}. \end{aligned}$$

PROPOSITION 2.2. *Let  $(\xi, g, S)$  and  $(\xi', g', S')$  be two triplets satisfying the above assumptions. Suppose  $(Y, Z, K)$  is the solution of the reflected BSDE  $(\xi, g, S)$  and  $(Y', Z', K')$  is the solution of the reflected BSDE  $(\xi', g', S')$ . Define*

$$\Delta \xi = \xi - \xi', \quad \Delta g = g - g', \quad \Delta S = S - S';$$

$$\Delta Y = Y - Y', \quad \Delta Z = Z - Z', \quad \Delta K = K - K'.$$

Then there exists a constant  $C$  such that

$$\begin{aligned} & \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |\Delta Y_s|^2 + \int_t^T |\Delta Z_s|^2 ds + |\Delta K_T - \Delta K_t|^2 \right\} \\ & \leq C \mathbb{E}^{\mathcal{F}_t} \left\{ |\Delta \xi|^2 + \left( \int_t^T |\Delta g(s, Y_s, Z_s)| ds \right)^2 \right\} + C \left( \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |\Delta S_s|^2 \right\} \right)^{1/2} \Psi_{t,T}^{1/2}, \end{aligned}$$

where

$$\begin{aligned} \Psi_{t,T} = \mathbb{E}^{\mathcal{F}_t} \left\{ & |\xi|^2 + \left( \int_t^T |g(s, 0, 0)| ds \right)^2 + \sup_{t \leq s \leq T} |S_s|^2 \right. \\ & \left. + |\xi'|^2 + \left( \int_t^T |g'(s, 0, 0)| ds \right)^2 + \sup_{t \leq s \leq T} |S'_s|^2 \right\}. \end{aligned}$$

**3. Formulation of the problem and the dynamic programming principle.** In this section, we first formulate one kind of stochastic recursive optimal control problem with the obstacle constraint for the cost functional, and then we prove that the dynamic programming principle still holds for this kind of optimization problem.

We introduce the admissible control set  $\mathcal{U}$  defined by

$$\mathcal{U} := \{v(\cdot) \in H^2 \mid v(\cdot) \text{ take value in } U \subset \mathbb{R}^k\}.$$

An element of  $\mathcal{U}$  is called an admissible control. Here  $U$  is a compact subset of  $\mathbb{R}^k$ ; however, this restriction is often satisfied in practical applications.

For a given admissible control, we consider the following control system:

$$(3.1) \quad \begin{cases} dX_s^{t,\zeta;v} &= b(s, X_s^{t,\zeta;v}, v_s)ds + \sigma(s, X_s^{t,\zeta;v}, v_s)dW_s, & s \in [t, T], \\ X_t^{t,\zeta;v} &= \zeta, \end{cases}$$

where  $t \geq 0$  is regarded as the initial time, and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$  as the initial state. The mappings

$$b : [0, T] \times \mathbb{R}^n \times U \rightarrow \mathbb{R}^n, \quad \sigma : [0, T] \times \mathbb{R}^n \times U \rightarrow \mathbb{R}^{n \times d}$$

satisfy the following conditions:

(H3.1)  $b$  and  $\sigma$  are continuous in  $t$ ,

(H3.2) for some  $L > 0$ , and all  $x, x' \in \mathbb{R}^n$ ,  $v, v' \in U$ , a.s.

$$|b(t, x, v) - b(t, x', v')| + |\sigma(t, x, v) - \sigma(t, x', v')| \leq L(|x - x'| + |v - v'|).$$

Obviously, under the above assumptions, for any  $v(\cdot) \in \mathcal{U}$ , the control system (3.1) has a unique strong solution  $\{X_s^{t,\zeta;v}, 0 \leq t \leq s \leq T\}$ , and we also have the following estimates:

PROPOSITION 3.1. For all  $t \in [0, T]$ ,  $\zeta, \zeta' \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ ,  $v(\cdot), v'(\cdot) \in \mathcal{U}$ ,

$$(3.2) \quad \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |X_s^{t,\zeta;v}|^2 \right\} \leq C(1 + |\zeta|^2),$$

$$(3.3) \quad \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |X_s^{t,\zeta;v} - X_s^{t,\zeta';v'}|^2 \right\} \leq C|\zeta - \zeta'|^2 + C\mathbb{E}^{\mathcal{F}_t} \left\{ \int_t^T |v_s - v'_s|^2 ds \right\},$$

where the constant  $C$  depends on  $L, T$ , and the compact set  $U$ .

PROPOSITION 3.2. For all  $t \in [0, T]$ ,  $x \in \mathbb{R}^n$ ,  $v(\cdot) \in \mathcal{U}$ ,  $\delta \in [0, T - t]$ ,

$$(3.4) \quad \mathbb{E} \left\{ \sup_{t \leq s \leq t+\delta} |X_s^{t,x;v} - x|^2 \right\} \leq C\delta,$$

where the constant  $C$  depends on  $x, L$ , and the compact set  $U$ .

Now for any given admissible control  $v(\cdot) \in \mathcal{U}$ , we consider the following reflected BSDE:

$$(3.5) \quad \begin{aligned} Y_s^{t,\zeta;v} &= \Phi(X_T^{t,\zeta;v}) + \int_s^T g(r, X_r^{t,\zeta;v}, Y_r^{t,\zeta;v}, Z_r^{t,\zeta;v}, v_r)dr \\ &\quad + K_T^{t,\zeta;v} - K_s^{t,\zeta;v} - \int_s^T Z_r^{t,\zeta;v} dW_r, \quad t \leq s \leq T, \end{aligned}$$

where

$$\Phi = \Phi(x) : \mathbb{R}^n \rightarrow \mathbb{R}, \quad h = h(t, x) : [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R},$$

$$g = g(t, x, y, z, v) : [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U \rightarrow \mathbb{R}$$

satisfy the following conditions:

(H3.3)  $g$  and  $h$  are continuous in  $t$ ;

(H3.4) for some  $L > 0$ , and all  $x, x' \in \mathbb{R}^n$ ,  $y, y' \in \mathbb{R}$ ,  $z, z' \in \mathbb{R}^d$ ,  $v, v' \in U$ , a.s.

$$\begin{aligned} & |g(t, x, y, z, v) - g(t, x', y', z', v')| + |\Phi(x) - \Phi(x')| + |h(t, x) - h(t, x')| \\ & \leq L(|x - x'| + |y - y'| + |z - z'| + |v - v'|). \end{aligned}$$

Then from Theorem 5.2 in [9], there exists a triple  $(Y^{t,\zeta;v}, Z^{t,\zeta;v}, K^{t,\zeta;v})$ , which is the unique solution of the reflected BSDE (3.5), satisfying

- (i)  $Y^{t,\zeta;v} \in S^2$ ,  $Z^{t,\zeta;v} \in H^2$  and  $K_T^{t,\zeta;v} \in L^2$ ;
- (ii)  $Y_s^{t,\zeta;v} \geq h(s, X_s^{t,\zeta;v})$ ,  $t \leq s \leq T$ ;
- (iii)  $\{K_s^{t,\zeta;v}\}$  is increasing and continuous,  $K_t^{t,\zeta;v} = 0$ , and

$$\int_t^T (Y_s^{t,\zeta;v} - h(s, X_s^{t,\zeta;v})) dK_s^{t,\zeta;v} = 0.$$

Moreover, we get the following estimates for the solution of (3.5) from Propositions 2.1 and 2.2.

PROPOSITION 3.3.

$$(3.6) \quad \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |Y_s^{t,\zeta;v}|^2 + \int_t^T |Z_s^{t,\zeta;v}|^2 ds + |K_T^{t,\zeta;v}|^2 \right\} \leq C(1 + |\zeta|^2).$$

PROPOSITION 3.4.

$$\begin{aligned} & \mathbb{E}^{\mathcal{F}_t} \left\{ \sup_{t \leq s \leq T} |Y_s^{t,\zeta;v} - Y_s^{t,\zeta';v'}|^2 + \int_t^T |Z_s^{t,\zeta;v} - Z_s^{t,\zeta';v'}|^2 ds \right. \\ & \quad \left. + |K_T^{t,\zeta;v} - K_T^{t,\zeta';v'}|^2 \right\} \\ (3.7) \quad & \leq C|\zeta - \zeta'|^2 + C\mathbb{E}^{\mathcal{F}_t} \left\{ \int_t^T |v_s - v'_s|^2 ds \right\} \\ & \quad + C(1 + |\zeta| + |\zeta'|) \left( |\zeta - \zeta'|^2 + \mathbb{E}^{\mathcal{F}_t} \left\{ \int_t^T |v_s - v'_s|^2 ds \right\} \right)^{1/2}. \end{aligned}$$

Given a control process  $v(\cdot) \in \mathcal{U}$ , we introduce the associated cost functional

$$(3.8) \quad J(t, x; v(\cdot)) := Y_s^{t,x;v} \Big|_{s=t}, \quad (t, x) \in [0, T] \times \mathbb{R}^n,$$

and we define the value function of the stochastic optimal control problem

$$(3.9) \quad u(t, x) := \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} J(t, x; v(\cdot)), \quad (t, x) \in [0, T] \times \mathbb{R}^n.$$

*Remark 3.5.* This is one kind of stochastic recursive optimal control problem with the obstacle constraint for the cost functional  $Y_s^{t,x;v} \geq h(s, X_s^{t,x;v})$ ,  $t \leq s \leq T$ . In the financial market, if  $X_s^{t,x;v}$  represents the wealth of the investor and  $Y_s^{t,x;v}$  represents the recursive utility cost functional, then the constraint means that the investor requires his cost functional value to be bigger than a given function of his wealth at any time. For this, an additional increasing process is introduced to push  $Y_s^{t,x;v}$  upwards in a kind of minimal way. In addition, for an investment policy the investor may choose the terminal time (as a stopping time) up to which he maximizes his wealth. We precise this point as follows.

For any  $(t, x) \in [0, T] \times \mathbb{R}^n$  and a given admissible control  $v(\cdot) \in \mathcal{U}$ , let  $(Y^{t,x;v}, Z^{t,x;v}, K^{t,x;v})$  be the solution of the reflected BSDE (3.5). From Proposition 2.3 in [9], we know that, for each  $s \in [t, T]$ ,

$$Y_s^{t,x;v} = \operatorname{esssup}_{\tau \in \mathcal{T}_s} \mathbb{E}^{\mathcal{F}_s} \left\{ \int_s^\tau g(r, X_r^{t,x;v}, Y_r^{t,x;v}, Z_r^{t,x;v}, v_r) dr \right. \\ \left. + h(\tau, X_\tau^{t,x;v}) \mathbf{1}_{\{\tau < T\}} + \Phi(X_T^{t,x;v}) \mathbf{1}_{\{\tau = T\}} \right\},$$

where  $\mathcal{T}$  is the set of all stopping times dominated by  $T$ , and  $\mathcal{T}_s = \{\tau \in \mathcal{T}; s \leq \tau \leq T\}$ . Furthermore, the stopping time

$$(3.10) \quad D_s^{t,x;v} = \inf\{s \leq r \leq T; Y_r^{t,x;v} = h(r, X_r^{t,x;v})\}$$

is optimal.

Here  $g$  is a function of  $(s, X, Y, Z, v)$  satisfying assumptions (H3.3) and (H3.4); we will give some special examples to illustrate some applications for this recursive optimization problem.

*Example 1.* If  $g$  is independent on  $(y, z)$ , then our problem is a mixture of an optimal stopping time problem and a “classical” optimal stochastic control problem. The value function is

$$u(t, x) := \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} Y_t^{t,x;v} = \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} \operatorname{esssup}_{\tau \in \mathcal{T}_t} \mathbb{E}^{\mathcal{F}_t} \left\{ \int_t^\tau g(r, X_r^{t,x;v}, v_r) dr \right. \\ \left. + h(\tau, X_\tau^{t,x;v}) \mathbf{1}_{\{\tau < T\}} + \Phi(X_T^{t,x;v}) \mathbf{1}_{\{\tau = T\}} \right\}.$$

Furthermore, the stopping time  $D_t^{t,x;v}$  defined by (3.10) is optimal. The details about this mixed optimal control problem can be found in [7] and [8].

*Example 2.* Let  $(\beta_t, \gamma_t)$  be a bounded  $(\mathbb{R}, \mathbb{R}^d)$ -valued predictable continuous vector process, and  $\varphi(t, x, v)$  be a  $\mathbb{R}$ -valued continuous function which is Lipschitz continuous in  $(x, v)$  and, for each  $(x, v)$ ,  $\varphi(\cdot, x, v)$  belongs to  $H^2$ . Let

$$g(t, x, y, z, v) = \varphi(t, x, v) + \beta_t y + \langle \gamma, z \rangle.$$

Let  $\{\Gamma_{t,s}, t \leq s \leq T\}$  be the adjoint process satisfying the linear SDE:

$$d\Gamma_{t,s} = \Gamma_{t,s}[\beta_s ds + \langle \gamma_s, dW_s \rangle], \quad \Gamma_{t,t} = 1.$$

Then the value function is

$$u(t, x) := \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} Y_t^{t, x; v} = \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} \operatorname{esssup}_{\tau \in \mathcal{T}_t} \mathbb{E}^{\mathcal{F}_t} \left\{ \int_t^\tau \Gamma_{t, r} \varphi(r, X_r^{t, x; v}, v_r) dr \right. \\ \left. + \Gamma_{t, \tau} h(\tau, X_\tau^{t, x; v}) \mathbf{1}_{\{\tau < T\}} + \Gamma_{t, T} \Phi(X_T^{t, x; v}) \mathbf{1}_{\{\tau = T\}} \right\}.$$

Furthermore, the stopping time  $D_t^{t, x; v}$  defined by (3.10) is optimal. This is also a mixed optimal control problem.

*Example 3.* This involves hedging the American option when loan interest is higher than deposit interest.

In [10], El Karoui, Pardoux, and Quenez proved that the price of an American option corresponds to the solution of a reflected BSDE. Now we will show that under some requirements in a financial market, such as when loan interest is higher than deposit interest, the price of an American option corresponds to the value function of a recursive optimal control problem with the obstacle constraints described by the solution of reflected BSDE.

We take the same notations as those in section 3 of [11] and in section 5 of [10], all variables are 1-dimensional for simplification. We suppose that the investor is allowed to borrow money at time  $t$  at an interest rate  $R_t > r_t$ , where  $r_t$  the bond rate. Then, from the results in [11] and [10], the wealth of the investor satisfies

$$-dX_t = b(t, X_t, Z_t)dt - Z_t dW_t, \quad 0 \leq t \leq T,$$

$$b(t, X_t, Z_t) := - \left[ r_t X_t + \theta_t Z_t - (R_t - r_t) \left( X_t - \frac{Z_t}{\sigma_t} \right)^- \right],$$

where  $Z_t := \sigma_t \pi_t$ ,  $\theta_t := \sigma_t^{-1}(b_t - r_t)$ . Also,  $b_t$  represents the instantaneous expected return rate in stock;  $\sigma_t$  implies that the instantaneous volatility of the stock is invertible;  $b_t$ ,  $r_t$ ,  $R_t$ , and  $\sigma_t$  are all deterministic bounded functions; and  $\sigma_t^{-1}$  is also bounded.

We consider the problem of pricing an American contingent claim at each time  $t$ , which consists of the selection of a stopping time  $\tau \in \mathcal{T}_t$  and a payoff  $S_\tau$  on exercise if  $\tau < T$  and  $\xi$  if  $\tau = T$ . Here  $\{S_t, 0 \leq t \leq T\}$  satisfies assumptions (H3.3)–(H3.4). Set

$$\tilde{S}_s = \xi \mathbf{1}_{\{\tau = T\}} + S_s \mathbf{1}_{\{\tau < T\}}, \quad 0 \leq s \leq T,$$

then the price of American contingent claim  $(\tilde{S}_s, 0 \leq s \leq T)$  at time  $t$  is given by

$$X_t = \operatorname{esssup}_{\tau \in \mathcal{T}_t} X_t(\tau, \tilde{S}_\tau),$$

where  $X_t(\tau, \tilde{S}_\tau)$ , noted by  $X_t^\tau$ , satisfies BSDE:

$$\begin{cases} -dX_s^\tau = b(s, X_s^\tau, Z_s^\tau)ds - Z_s^\tau dW_s, & 0 \leq s \leq \tau, \\ X_\tau^\tau = \tilde{S}_\tau. \end{cases}$$

For each  $(\omega, t)$ ,  $b(t, x, z)$  is a convex function of  $(x, z)$ . It follows from Proposition 3.6 and (3.22) in [10] (pp. 40–41) that we have

$$X_t^\tau = \operatorname{esssup}_{r_t \leq \beta_t \leq R_t} X_t^{\beta, \tau},$$

where  $X_t^{\beta, \tau}$  satisfies

$$\begin{cases} -dX_s^{\beta, \tau} = b^\beta(s, X_s^{\beta, \tau}, Z_s^{\beta, \tau})ds - Z_s^{\beta, \tau}dW_s, & 0 \leq s \leq \tau, \\ X_\tau^{\beta, \tau} = \tilde{S}_\tau, \end{cases}$$

$$b^\beta(t, X_t, Z_t) := -\beta_t X_t - \left[ \theta_t + \frac{r_t - \beta_t}{\sigma_t} \right] Z_t,$$

and  $\beta_t$  is a bounded  $\mathbb{R}$ -valued adapted process which can be regarded as an interest rate process in finance. So,

$$\begin{aligned} X_t &:= \operatorname{esssup}_{\tau \in \mathcal{T}_t} X_t(\tau, \tilde{S}_\tau) \\ &= \operatorname{esssup}_{\tau \in \mathcal{T}_t} \operatorname{esssup}_{r_t \leq \beta_t \leq R_t} X_t^{\beta, \tau} = \operatorname{esssup}_{r_t \leq \beta_t \leq R_t} \operatorname{esssup}_{\tau \in \mathcal{T}_t} X_t^{\beta, \tau} \\ &= \operatorname{esssup}_{r_t \leq \beta_t \leq R_t} X_t^\beta, \end{aligned}$$

where  $X_t^\beta := \operatorname{esssup}_{\tau \in \mathcal{T}_t} X_t^{\beta, \tau}$ . Then from Proposition 5.1 in [10], there exist  $Z_s^\beta \in H^2$  and  $K_s^\beta$ , which is an increasing adapted continuous process with  $K_0 = 0$ , such that  $(X_s^\beta, Z_s^\beta, K_s^\beta)$  satisfies the following reflected BSDE:

$$\begin{cases} -dX_s^\beta = b^\beta(s, X_s^\beta, Z_s^\beta)ds + dK_s^\beta - Z_s^\beta dW_s, \\ X_T^\beta = \xi, \quad 0 \leq s \leq T, \end{cases}$$

with  $X_t^\beta \geq S_t$ ,  $0 \leq t \leq T$ , and  $\int_0^T (X_t^\beta - S_t) dK_t^\beta = 0$ . Here process  $K_t^\beta$  may be interpreted as a cumulative consumption process. Furthermore, the stopping time

$$D_t^\beta = \inf\{t \leq s \leq T; X_s^\beta = S_s\}$$

is optimal. Then we formulate the pricing problem of an American option to the stochastic recursive optimal control problem with the obstacle constraint which is studied in our paper.

The above example provides the practical background for our optimal control problem (3.9). Now we continue to prove that the celebrated dynamic programming principle still holds for this optimization problem. Some proof ideas come from the proof of the dynamic programming principle for recursive problem given by Peng in the Chinese version [14]. However, we generalize his conclusion to the obstacle constraint case and improve proof method which becomes more readable.

For each  $t > 0$ , we denote by  $\{\mathcal{F}_s^t, t \leq s \leq T\}$  the natural filtration of the Brownian motion  $\{W_s - W_t, t \leq s \leq T\}$ , augmented by the P-null sets of  $\mathcal{F}$ . Also, we introduce the following subspaces of  $\mathcal{U}$ :

$$\begin{aligned} \mathcal{U}^t &:= \left\{ v(\cdot) \in \mathcal{U} \mid v(s) \text{ is } \{\mathcal{F}_s^t\} \text{ progressively measurable } \forall t \leq s \leq T \right\}, \\ \bar{\mathcal{U}}^t &:= \left\{ v_s = \sum_{j=1}^N v_s^j 1_{A_j} \mid v_s^j \in \mathcal{U}^t, \{A_j\}_{j=1}^N \text{ is a partition of } (\Omega, \mathcal{F}_t) \right\}. \end{aligned}$$

Now we will prove the following proposition.

PROPOSITION 3.6. *Under the assumptions (H3.1)–(H3.4), the value function  $u(t, x)$  defined in (3.9) is a deterministic function.*

*Proof.* First, we will prove

$$(3.11) \quad \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} J(t, x; v(\cdot)) = \operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)).$$

Obviously, from the fact that  $\bar{\mathcal{U}}^t$  is a subset of  $\mathcal{U}$ , we get

$$\operatorname{esssup}_{v(\cdot) \in \mathcal{U}} J(t, x; v(\cdot)) \geq \operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)).$$

We need to consider the inverse inequality. For any  $v(\cdot), \tilde{v}(\cdot) \in \mathcal{U}$ , from Proposition 3.4 we know

$$\mathbb{E} \left\{ \left| Y_t^{t,x;v} - Y_t^{t,x;\tilde{v}} \right|^2 \right\} \leq C \mathbb{E} \int_t^T |v_s - \tilde{v}_s|^2 ds + C(1 + |x|) \left( \mathbb{E} \int_t^T |v_s - \tilde{v}_s|^2 ds \right)^{1/2}.$$

Note that  $\bar{\mathcal{U}}^t$  is dense in  $\mathcal{U}$ , then, for each  $v(\cdot) \in \mathcal{U}$ , there exists a sequence  $\{v_n(\cdot)\}_{n=1}^\infty \in \bar{\mathcal{U}}^t$  such that

$$\lim_{n \rightarrow \infty} \mathbb{E} \left\{ \left| Y_t^{t,x;v_n} - Y_t^{t,x;v} \right|^2 \right\} = 0.$$

So there exists a subsequence, we denote without loss of generality  $\{v_n(\cdot)\}_{n=1}^\infty$ , such that

$$\lim_{n \rightarrow \infty} Y_t^{t,x;v_n} = Y_t^{t,x;v} \quad a.s..$$

From the definition in (3.8),

$$\lim_{n \rightarrow \infty} J(t, x; v_n(\cdot)) = J(t, x; v(\cdot)) \quad a.s..$$

By the arbitrariness of  $v(\cdot)$  and the definition of essential supremum, we get

$$\operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)) \geq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} J(t, x; v(\cdot)).$$

Then we obtain (3.11).

Second, we want to prove

$$(3.12) \quad \operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)) = \operatorname{esssup}_{v(\cdot) \in \mathcal{U}^t} J(t, x; v(\cdot)).$$

Obviously,

$$\operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)) \geq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}^t} J(t, x; v(\cdot)).$$

In order to get the inverse inequality, we need Lemma 3.7. The main idea of the lemma is to consider the partition of probability space, which is first introduced by Theorem 4.7 in [14]. The proof of Lemma 3.7 is essentially the same as that in [14], hence we omit it.

LEMMA 3.7.

$$\begin{aligned} X^{t,x;\sum_{j=1}^N v^j 1_{A_j}} &= \sum_{j=1}^N 1_{A_j} X^{t,x;v^j}, & Y^{t,x;\sum_{j=1}^N v^j 1_{A_j}} &= \sum_{j=1}^N 1_{A_j} Y^{t,x;v^j}, \\ Z^{t,x;\sum_{j=1}^N v^j 1_{A_j}} &= \sum_{j=1}^N 1_{A_j} Z^{t,x;v^j}, & K^{t,x;\sum_{j=1}^N v^j 1_{A_j}} &= \sum_{j=1}^N 1_{A_j} K^{t,x;v^j}. \end{aligned}$$

For all  $v(\cdot) \in \bar{\mathcal{U}}^t$ , we have

$$J(t, x; v(\cdot)) = J\left(t, x; \sum_{j=1}^N v^j(\cdot) 1_{A_j}\right) = \sum_{j=1}^N 1_{A_j} J(t, x; v^j(\cdot)).$$

Note that  $v^j(\cdot)$  ( $j = 1, 2, \dots, N$ ) are  $\{\mathcal{F}_s^t\}$  progressively measurable, then  $J(t, x; v^j(\cdot))$  ( $j = 1, 2, \dots, N$ ) are deterministic. Without loss of generality, we assume that

$$J(t, x; v^1(\cdot)) \geq J(t, x; v^j(\cdot)) \quad \forall j = 2, 3, \dots, N.$$

So

$$J(t, x; v(\cdot)) \leq J(t, x; v^1(\cdot)) \leq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}^t} J(t, x; v(\cdot)).$$

Since  $v(\cdot)$  is arbitrary, we get

$$\operatorname{esssup}_{v(\cdot) \in \bar{\mathcal{U}}^t} J(t, x; v(\cdot)) \leq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}^t} J(t, x; v(\cdot)),$$

then obtain (3.12).

However, when  $v(\cdot) \in \mathcal{U}^t$ , the cost functional  $J(t, x; v(\cdot))$  is deterministic; hence

$$u(t, x) = \sup_{v(\cdot) \in \mathcal{U}^t} J(t, x; v(\cdot))$$

is deterministic and the proof is completed.  $\square$

Next we will discuss the continuity of value function  $u(t, x)$  with respect to  $x$ . We have the following estimates:

LEMMA 3.8. *For each  $t \in [0, T]$ ,  $x$  and  $x' \in \mathbb{R}^n$ , we have*

- (i)  $|u(t, x) - u(t, x')|^2 \leq C|x - x'|^2 + C(1 + |x| + |x'|)|x - x'|$ ,
- (ii)  $|u(t, x)| \leq C(1 + |x|)$ .

*Proof.* In order to prove this lemma, Propositions 2.1 and 2.2 as well as Propositions 3.3 and 3.4, play important roles.

From Propositions 3.3 and 3.4, for each admissible control  $v(\cdot) \in \mathcal{U}$ , we have

$$(3.13) \quad |J(t, x; v(\cdot))| \leq C(1 + |x|),$$

$$(3.14) \quad |J(t, x; v(\cdot)) - J(t, x'; v(\cdot))|^2 \leq C|x - x'|^2 + C(1 + |x| + |x'|)|x - x'|.$$

On the other hand, for each  $\varepsilon > 0$ , there exist  $v(\cdot)$  and  $v'(\cdot) \in \mathcal{U}$  such that

$$J(t, x; v'(\cdot)) \leq u(t, x) \leq J(t, x; v(\cdot)) + \varepsilon, \quad J(t, x'; v(\cdot)) \leq u(t, x') \leq J(t, x'; v'(\cdot)) + \varepsilon.$$

Then from the estimate (3.13) of  $J$ , we get

$$-C(1 + |x|) \leq J(t, x; v'(\cdot)) \leq u(t, x) \leq J(t, x; v(\cdot)) + \varepsilon \leq C(1 + |x|) + \varepsilon.$$

From the arbitrariness of  $\varepsilon$ , we obtain (ii). Similarly,

$$J(t, x; v'(\cdot)) - J(t, x'; v'(\cdot)) - \varepsilon \leq u(t, x) - u(t, x') \leq J(t, x; v(\cdot)) - J(t, x'; v(\cdot)) + \varepsilon,$$

$$\begin{aligned} & |u(t, x) - u(t, x')| \\ & \leq \max \left\{ |J(t, x; v(\cdot)) - J(t, x'; v(\cdot))|, |J(t, x; v'(\cdot)) - J(t, x'; v'(\cdot))| \right\} + \varepsilon, \\ & |u(t, x) - u(t, x')|^2 \\ & \leq 2 \max \left\{ |J(t, x; v(\cdot)) - J(t, x'; v(\cdot))|^2, |J(t, x; v'(\cdot)) - J(t, x'; v'(\cdot))|^2 \right\} + 2\varepsilon^2 \\ & \leq 2C|x - x'|^2 + 2C(1 + |x| + |x'|)|x - x'| + 2\varepsilon^2. \end{aligned}$$

Then we can obtain (i).  $\square$

We also have

LEMMA 3.9. *For all  $t \in [0, T]$ , for all  $v(\cdot) \in \mathcal{U}$ , and for all  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we have*

$$J(t, \zeta; v(\cdot)) = Y_t^{t, \zeta; v}.$$

*Proof.* We first study a simple case.  $\zeta$  is in the following form:  $\zeta = \sum_{i=1}^N 1_{A_i} x_i$ , where  $\{A_i\}_{i=1}^N$  is a finite partition of  $(\Omega, \mathcal{F}_t)$ , and  $x_i \in \mathbb{R}^n$ , for  $1 \leq i \leq N$ . The similar argument in Lemma 3.7 leads to

$$Y_s^{t, \zeta; v} = Y_s^{t, \sum_{i=1}^N 1_{A_i} x_i; v} = \sum_{i=1}^N 1_{A_i} Y_s^{t, x_i; v}, \quad s \in [t, T].$$

From the definition of cost functional (3.8), we deduce that

$$Y_t^{t, \zeta; v} = \sum_{i=1}^N 1_{A_i} Y_t^{t, x_i; v} = \sum_{i=1}^N 1_{A_i} J(t, x_i; v(\cdot)) = J\left(t, \sum_{i=1}^N 1_{A_i} x_i; v(\cdot)\right) = J(t, \zeta; v(\cdot)).$$

Therefore, for simple functions, we get the desired result.

Given a general  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we can choose a sequence of simple functions  $\{\zeta_i\}$  which converges to  $\zeta$  in  $L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ . Consequently, from Proposition 3.4 and

estimate (3.14), we have

$$\begin{aligned}
& \mathbb{E} \left\{ \left| Y_t^{t, \zeta; v} - Y_t^{t, \zeta_i; v} \right|^2 \right\} \\
& \leq \mathbb{E} \left\{ C |\zeta - \zeta_i|^2 + C(1 + |\zeta| + |\zeta_i|) |\zeta - \zeta_i| \right\} \\
& \leq C \mathbb{E} \left\{ |\zeta - \zeta_i|^2 \right\} + C \left( \mathbb{E} \left\{ (1 + |\zeta| + |\zeta_i|)^2 \right\} \right)^{1/2} \left( \mathbb{E} \left\{ |\zeta - \zeta_i|^2 \right\} \right)^{1/2} \\
& \rightarrow 0 \quad \text{as } i \rightarrow \infty, \\
& \mathbb{E} \left\{ |J(t, \zeta; v(\cdot)) - J(t, \zeta_i; v(\cdot))|^2 \right\} \\
& \leq \mathbb{E} \left\{ C |\zeta - \zeta_i|^2 + C(1 + |\zeta| + |\zeta_i|) |\zeta - \zeta_i| \right\} \\
& \leq C \mathbb{E} \left\{ |\zeta - \zeta_i|^2 \right\} + C \left( \mathbb{E} \left\{ (1 + |\zeta| + |\zeta_i|)^2 \right\} \right)^{1/2} \left( \mathbb{E} \left\{ |\zeta - \zeta_i|^2 \right\} \right)^{1/2} \\
& \rightarrow 0 \quad \text{as } i \rightarrow \infty.
\end{aligned}$$

With the help of  $Y_t^{t, \zeta_i; v} = J(t, \zeta_i; v(\cdot))$ , the proof is completed.  $\square$

For the value function of our recursive optimal control problem, we have the following lemma.

LEMMA 3.10. *Fixed  $t \in [0, T)$  and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , for each  $v(\cdot) \in \mathcal{U}$ , we have*

$$(3.15) \quad u(t, \zeta) \geq Y_t^{t, \zeta; v}.$$

*On the other hand, for each  $\varepsilon > 0$ , there exists an admissible control  $v(\cdot) \in \mathcal{U}$  such that*

$$(3.16) \quad u(t, \zeta) \leq Y_t^{t, \zeta; v} + \varepsilon, \quad a.s..$$

*Proof.* We first prove (3.15). When  $\zeta$  is a simple function:  $\zeta = \sum_{i=1}^N 1_{A_i} x_i$ , for all  $v(\cdot) \in \mathcal{U}$ , we have

$$Y_t^{t, \zeta; v} = Y_t^{t, \sum_{i=1}^N 1_{A_i} x_i; v} = \sum_{i=1}^N 1_{A_i} Y_t^{t, x_i; v} \leq \sum_{i=1}^N 1_{A_i} u(t, x_i) = u(t, \zeta).$$

If  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we can choose a sequence of simple functions  $\{\zeta_i\}$  which converges to  $\zeta$  in  $L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ . Consequently, similar to Lemma 3.9, we have

$$\mathbb{E} \left\{ \left| Y_t^{t, \zeta; v} - Y_t^{t, \zeta_i; v} \right|^2 \right\} \rightarrow 0; \quad \mathbb{E} \left\{ |u(t, \zeta) - u(t, \zeta_i)|^2 \right\} \rightarrow 0.$$

Then there exists a subsequence, without loss of generality we use same notation, such that

$$\lim_{i \rightarrow \infty} Y_t^{t, \zeta_i; v} = Y_t^{t, \zeta; v}, \quad a.s., \quad \lim_{i \rightarrow \infty} u(t, \zeta_i) = u(t, \zeta), \quad a.s..$$

Here  $Y_t^{t, \zeta_i; v} \leq u(t, \zeta_i)$ ,  $i = 1, 2, \dots$ , so  $Y_t^{t, \zeta; v} \leq u(t, \zeta)$ .

We now turn to (3.16). We first consider the case that  $\zeta$  is a bounded random variable:  $\zeta \in L^\infty(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ . We suppose that  $|\zeta| \leq M$ , and construct a simple

random variable  $\eta \in L^\infty(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ ,  $\eta = \sum_{i=1}^N 1_{A_i} x_i$  such that

- (i)  $|\eta| \leq |\zeta|$ ,
- (ii)  $|\eta - \zeta| \leq \min \left\{ \frac{\varepsilon}{6\sqrt{C}}, \frac{\varepsilon^2}{36C(1+2M)} \right\}$ .

For any  $v(\cdot) \in \mathcal{U}$ , we have

$$\left| Y_t^{t, \zeta; v} - Y_t^{t, \eta; v} \right| \leq \frac{\varepsilon}{3}, \quad |u(t, \zeta) - u(t, \eta)| \leq \frac{\varepsilon}{3}.$$

Then, for each  $x_i$ , we can choose an  $\{\mathcal{F}_s^t\}$ -adapted admissible control  $v^i(\cdot)$  such that

$$u(t, x_i) \leq Y_t^{t, x_i; v^i} + \frac{\varepsilon}{3}.$$

We denote  $v(\cdot) := \sum_{i=1}^N 1_{A_i} v^i(\cdot)$ , then

$$\begin{aligned} Y_t^{t, \zeta; v} &\geq - \left| Y_t^{t, \zeta; v} - Y_t^{t, \eta; v} \right| + Y_t^{t, \eta; v} \geq -\frac{\varepsilon}{3} + \sum_{i=1}^N 1_{A_i} Y_t^{t, x_i; v^i} \\ &\geq -\frac{\varepsilon}{3} + \sum_{i=1}^N 1_{A_i} \left( u(t, x_i) - \frac{\varepsilon}{3} \right) = -\frac{2}{3}\varepsilon + u(t, \eta) \\ &\geq -\varepsilon + u(t, \zeta). \end{aligned}$$

Therefore, for  $\zeta \in L^\infty(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we have the desired result (3.16).

Given a general  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we note that  $\zeta$  has the following form:

$$\zeta = \sum_{i=1}^{\infty} 1_{A_i} \zeta_i,$$

where  $\{A_i\}_{i=1}^{\infty}$  is a partition of  $(\Omega, \mathcal{F}_t)$ ,  $x_i \in \mathbb{R}^n$  ( $i = 1, 2, \dots$ ),  $|\zeta_i| \leq i$ , and  $\zeta_i \in L^\infty(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ . So, for every  $\zeta_i$ , there exists  $v^i(\cdot) \in \mathcal{U}$ , such that

$$u(t, \zeta_i) \leq Y_t^{t, \zeta_i; v^i} + \varepsilon.$$

We denote  $v(\cdot) = \sum_{i=1}^{\infty} 1_{A_i} v^i(\cdot)$  and get

$$\begin{aligned} u(t, \zeta) &= u\left(t, \sum_{i=1}^{\infty} 1_{A_i} \zeta_i\right) = \sum_{i=1}^{\infty} 1_{A_i} u(t, \zeta_i) \leq \sum_{i=1}^{\infty} 1_{A_i} (Y_t^{t, \zeta_i; v^i} + \varepsilon) \\ &= \sum_{i=1}^{\infty} 1_{A_i} Y_t^{t, \zeta_i; v^i} + \varepsilon = Y_t^{t, \zeta; v} + \varepsilon. \end{aligned}$$

The proof is now completed.  $\square$

Now we start to discuss the (generalized) dynamic programming principle for our recursive optimal control problem (3.9).

First, we introduce a family of (backward) semigroups which is original from Peng's idea in [14].

Given the initial condition  $(t, x)$ , an admissible control  $v(\cdot) \in \mathcal{U}$ , a positive number  $\delta \leq T - t$ , and a real-valued random variable  $\eta \in L^2(\Omega, \mathcal{F}_{t+\delta}, P; \mathbb{R})$ , we denote

$$G_{t, t+\delta}^{t, x; v}[\eta] := Y_t,$$

where  $(Y_s, Z_s, K_s)_{t \leq s \leq t+\delta}$  is the solution of the following reflected BSDE with time horizon  $t + \delta$ :

$$\begin{aligned} Y_s &= \eta + \int_s^{t+\delta} g(r, X_r^{t,x;v}, Y_r, Z_r, v_r) dr + K_{t+\delta} - K_s \\ &\quad - \int_s^{t+\delta} Z_r dW_r, \quad t \leq s \leq t + \delta, \end{aligned}$$

satisfying

- (i)  $Y \in S^2$ ,  $Z \in H^2$  and  $K_{t+\delta} \in L^2$ ,
- (ii)  $Y_s \geq h(s, X_s^{t,x;v})$ ,  $t \leq s \leq t + \delta$ ,
- (iii)  $\{K_s\}$  is increasing and continuous,  $K_t = 0$ ,  $\int_t^{t+\delta} (Y_s - h(s, X_s^{t,x;v})) dK_s = 0$ .

Obviously,

$$G_{t,T}^{t,x;v}[\Phi(X_T^{t,x;v})] = G_{t,t+\delta}^{t,x;v}[Y_{t+\delta}^{t,x;v}].$$

Then our (generalized) dynamic programming principle holds.

**THEOREM 3.11.** *Under the assumptions (H3.1)–(H3.4), the value function  $u(t, x)$  obeys the following dynamic programming principle: For each  $0 < \delta \leq T - t$ ,*

$$(3.17) \quad u(t, x) = \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t,t+\delta}^{t,x;v}[u(t + \delta, X_{t+\delta}^{t,x;v})].$$

*Proof.* We have

$$\begin{aligned} u(t, x) &= \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t,T}^{t,x;v}[\Phi(X_T^{t,x;v})] = \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t,t+\delta}^{t,x;v}[Y_{t+\delta}^{t,x;v}] \\ &= \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t,t+\delta}^{t,x;v} \left[ Y_{t+\delta}^{t+\delta, X_{t+\delta}^{t,x;v};v} \right]. \end{aligned}$$

From Lemma 3.10 and the comparison theorem of reflected BSDE (Theorem 4.1 in [9]),

$$u(t, x) \leq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t,t+\delta}^{t,x;v}[u(t + \delta, X_{t+\delta}^{t,x;v})].$$

On the other hand, from Lemma 3.10, for every  $\varepsilon > 0$ , we can find an admissible control  $\bar{v}(\cdot) \in \mathcal{U}$  such that

$$u(t + \delta, X_{t+\delta}^{t,x;v}) \leq Y_{t+\delta}^{t+\delta, X_{t+\delta}^{t,x;v};\bar{v}} + \varepsilon.$$

For each  $v(\cdot) \in \mathcal{U}$ , we denote  $\tilde{v}(s) = 1_{\{s \leq t+\delta\}} v(s) + 1_{\{s > t+\delta\}} \bar{v}(s)$ . From the above inequality and the comparison theorem, we get

$$Y_{t+\delta}^{t+\delta, X_{t+\delta}^{t,x;\tilde{v}};\tilde{v}} \geq u(t + \delta, X_{t+\delta}^{t,x;\tilde{v}}) - \varepsilon, \quad u(t, x) \geq \operatorname{esssup}_{\tilde{v}(\cdot) \in \mathcal{U}_{\bar{v}}} G_{t,t+\delta}^{t,x;\tilde{v}}[u(t + \delta, X_{t+\delta}^{t,x;\tilde{v}}) - \varepsilon],$$

and here

$$\mathcal{U}_{\bar{v}} := \{\tilde{v}(\cdot) \in \mathcal{U}; \tilde{v}(s) = 1_{\{s \leq t+\delta\}} v(s) + 1_{\{s > t+\delta\}} \bar{v}(s) \text{ for some } v(\cdot) \in \mathcal{U}\}.$$

By Proposition 2.2, there exists a positive constant  $C_0$  such that

$$u(t, x) \geq \operatorname{esssup}_{\tilde{v}(\cdot) \in \mathcal{U}_{\tilde{v}}} G_{t, t+\delta}^{t, x; \tilde{v}}[u(t + \delta, X_{t+\delta}^{t, x; \tilde{v}})] - C_0 \varepsilon.$$

Therefore, letting  $\varepsilon \downarrow 0$ , we obtain

$$u(t, x) \geq \operatorname{esssup}_{\tilde{v}(\cdot) \in \mathcal{U}_{\tilde{v}}} G_{t, t+\delta}^{t, x; \tilde{v}}[u(t + \delta, X_{t+\delta}^{t, x; \tilde{v}})].$$

Because  $\tilde{v}(\cdot)$  acts only on  $[t, t + \delta]$  for  $G_{t, t+\delta}^{t, x; \tilde{v}}$ , from the definition of  $\tilde{v}(\cdot)$  and the arbitrariness of  $v(\cdot) \in \mathcal{U}$ , we know that the above inequality can be written as

$$u(t, x) \geq \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} G_{t, t+\delta}^{t, x; v}[u(t + \delta, X_{t+\delta}^{t, x; v})],$$

which is our desired conclusion.  $\square$

At the end of this section, we devote ourselves to the continuity of  $u(t, x)$  with respect to  $t$ .

**PROPOSITION 3.12.** *Under the Assumption (H3.1)–(H3.4), the value function  $u(t, x)$  defined by (3.9) is continuous in  $t$ .*

*Proof.* We define  $Y_s^{t, x; v}$  for all  $s \in [0, T]$  by choosing  $Y_s^{t, x; v} \equiv Y_t^{t, x; v}$  for  $0 \leq s \leq t$ . And we define the “obstacle”

$$S_s^{t, x; v} = \begin{cases} h(s, X_s^{t, x; v}), & t \leq s \leq T, \\ h(t, x), & 0 \leq s \leq t. \end{cases}$$

For fixed  $x \in \mathbb{R}^n$  for all  $0 \leq t_1 \leq t_2 \leq T$ , we analyze the difference between  $u(t_1, x)$  and  $u(t_2, x)$ . For all  $\varepsilon > 0$ , there exist  $v_1(\cdot) \in \mathcal{U}$ ,  $v_2(\cdot) \in \mathcal{U}$ , such that

$$Y_{t_1}^{t_1, x; v_2} \leq u(t_1, x) \leq Y_{t_1}^{t_1, x; v_1} + \varepsilon, \quad Y_{t_2}^{t_2, x; v_1} \leq u(t_2, x) \leq Y_{t_2}^{t_2, x; v_2} + \varepsilon.$$

Then

$$Y_{t_1}^{t_1, x; v_2} - Y_{t_2}^{t_2, x; v_2} - \varepsilon \leq u(t_1, x) - u(t_2, x) \leq Y_{t_1}^{t_1, x; v_1} - Y_{t_2}^{t_2, x; v_1} + \varepsilon,$$

$$|u(t_1, x) - u(t_2, x)| \leq \max \{ |Y_{t_1}^{t_1, x; v_1} - Y_{t_2}^{t_2, x; v_1}|, |Y_{t_1}^{t_1, x; v_2} - Y_{t_2}^{t_2, x; v_2}| \} + \varepsilon.$$

Here we only estimate  $|Y_{t_1}^{t_1, x; v_1} - Y_{t_2}^{t_2, x; v_1}|$  since it is same as estimating  $|Y_{t_1}^{t_1, x; v_2} - Y_{t_2}^{t_2, x; v_2}|$ . From Proposition 2.2, we have

$$\begin{aligned} & |Y_{t_1}^{t_1, x; v_1} - Y_{t_2}^{t_2, x; v_1}|^2 = |Y_0^{t_1, x; v_1} - Y_0^{t_2, x; v_1}|^2 \\ & \leq \mathbb{E} \left\{ \sup_{0 \leq s \leq T} |Y_s^{t_1, x; v_1} - Y_s^{t_2, x; v_1}|^2 \right\} \\ & \leq C \mathbb{E} \{ |\Phi(X_T^{t_1, x; v_1}) - \Phi(X_T^{t_2, x; v_1})|^2 \} \\ (3.18) \quad & + C \mathbb{E} \left\{ \left( \int_0^T |1_{[t_1, T]} g(s, X_s^{t_1, x; v_1}, Y_s^{t_1, x; v_1}, Z_s^{t_1, x; v_1}, v_1(s)) \right. \right. \\ & \quad \left. \left. - 1_{[t_2, T]} g(s, X_s^{t_2, x; v_1}, Y_s^{t_1, x; v_1}, Z_s^{t_1, x; v_1}, v_1(s)) \right| ds \right)^2 \right\} \\ & + C \Psi_{0, T}^{1/2} \left( \mathbb{E} \left\{ \sup_{0 \leq s \leq T} |S_s^{t_1, x; v_1} - S_s^{t_2, x; v_1}|^2 \right\} \right)^{1/2}, \end{aligned}$$

where

$$\begin{aligned} \Psi_{0,T} = \mathbb{E} & \left\{ |\Phi(X_T^{t_1,x;v_1})|^2 + \left( \int_{t_1}^T |g(s, X_s^{t_1,x;v_1}, 0, 0, v_1(s))| ds \right)^2 \right. \\ & + \sup_{t_1 \leq s \leq T} |h(s, X_s^{t_1,x;v_1})|^2 + |\Phi(X_T^{t_2,x;v_1})|^2 \\ & \left. + \left( \int_{t_2}^T |g(s, X_s^{t_2,x;v_1}, 0, 0, v_1(s))| ds \right)^2 + \sup_{t_2 \leq s \leq T} |h(s, X_s^{t_2,x;v_1})|^2 \right\}. \end{aligned}$$

Now we consider the items for the right-hand side of inequality (3.18).

For the first item: From the Lipschitz condition and Propositions 3.1 and 3.2, we get

$$I \leq C \mathbb{E} \{ |X_T^{t_1,x;v_1} - X_T^{t_2,x;v_1}|^2 \} \leq C \mathbb{E} \{ |X_{t_1}^{t_2,x;v_1} - x|^2 \} \leq C(t_2 - t_1).$$

For the second item: By the Lipschitz condition,  $(a+b)^2 \leq a^2/2 + b^2/2$ , and Propositions 3.1, 3.2, and 3.3, we get

$$II \leq C(t_2 - t_1).$$

For the third item: By the same arguments we get

$$\Psi_{0,T} \leq C.$$

Next, we know that

$$\begin{aligned} |S_s^{t_1,x;v_1} - S_s^{t_2,x;v_1}|^2 &= |h(s, X_s^{t_1,x;v_1}) - h(s, X_s^{t_2,x;v_1})|^2 \\ &\leq C |X_s^{t_1,x;v_1} - X_s^{t_2,x;v_1}|^2, & s \in [t_2, T], \\ |S_s^{t_1,x;v_1} - S_s^{t_2,x;v_1}|^2 &= |h(s, X_s^{t_1,x;v_1}) - h(t_2, x)|^2 \\ &\leq C |X_s^{t_1,x;v_1} - x|^2 + 2|h(s, x) - h(t_2, x)|^2, & s \in [t_1, t_2], \\ |S_s^{t_1,x;v_1} - S_s^{t_2,x;v_1}|^2 &= |h(t_1, x) - h(t_2, x)|^2, & s \in [0, t_1]. \end{aligned}$$

So we have

$$\begin{aligned} & \mathbb{E} \left\{ \sup_{0 \leq s \leq T} |S_s^{t_1,x;v_1} - S_s^{t_2,x;v_1}|^2 \right\} \\ & \leq \mathbb{E} \left\{ \left( \sup_{0 \leq s \leq t_1} + \sup_{t_1 \leq s \leq t_2} + \sup_{t_2 \leq s \leq T} \right) |S_s^{t_1,x;v_1} - S_s^{t_2,x;v_1}|^2 \right\} \\ & \leq C(t_2 - t_1) + |h(t_1, x) - h(t_2, x)|^2 + 2 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)|^2 \\ & \leq C(t_2 - t_1) + 3 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)|^2. \end{aligned}$$

From the previous analysis, we get

$$\begin{aligned} |Y_{t_1}^{t_1,x;v_1} - Y_{t_2}^{t_2,x;v_1}|^2 &\leq C(t_2 - t_1) + 3 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)|^2, \\ |Y_{t_1}^{t_1,x;v_1} - Y_{t_2}^{t_2,x;v_1}| &\leq C(t_2 - t_1)^{1/2} + 3 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)|. \end{aligned}$$

With the same arguments applying to  $|Y_{t_1}^{t_1,x;v_2} - Y_{t_2}^{t_2,x;v_2}|^2$ , we have

$$|u(t_1, x) - u(t_2, x)| \leq C(t_2 - t_1)^{1/2} + 3 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)| + \varepsilon.$$

Because of the arbitrariness of  $\varepsilon$ , we get

$$|u(t_1, x) - u(t_2, x)| \leq C(t_2 - t_1)^{1/2} + 3 \sup_{t_1 \leq s \leq t_2} |h(s, x) - h(t_2, x)|.$$

From the continuity of  $h(t, x)$  with respect to  $t$ , we obtain the continuity of  $u(t, x)$  with respect to  $t$ . The proof is now completed.  $\square$

*Remark 3.13.* Lemma 3.8(i) and Proposition 3.12 imply the joint continuity of  $u$  in  $(t, x)$ , which is required in the next section.

#### 4. Viscosity solution of an obstacle problem for the HJB equation.

In this section, we consider the relation between the value function of the above recursive optimal control problem and the following obstacle problem for nonlinear second-order parabolic PDE, which is called the Hamilton–Jacobi–Bellman equation:

$$(4.1) \quad \begin{cases} \min \left( u(t, x) - h(t, x), \right. \\ \quad \left. -\frac{\partial u}{\partial t}(t, x) - \sup_{v \in U} \{ \mathcal{L}(t, x, v)u(t, x) \right. \\ \quad \left. + g(t, x, u(t, x), \nabla u(t, x)\sigma(t, x, v), v) \} \right) = 0, \\ u(T, x) = \Phi(x), \end{cases}$$

where  $\mathcal{L}$  is a family of second order linear partial differential operators,

$$\mathcal{L}(t, x, v)\varphi = \frac{1}{2} \text{Tr}((\sigma\sigma^T)(t, x, v)D^2\varphi) + \langle b(t, x, v), D\varphi \rangle.$$

Here the function  $b, \sigma, g, \Phi, h$  satisfies (H3.1) and (H3.4), respectively.

We want to prove that the value function  $u(t, x)$  introduced by (3.9) is the unique viscosity solution of the obstacle problem for HJB equation obstacle problem (4.1). We first recall the definition of a viscosity solution for (4.1) from [4] and [1]. Below,  $S^n$  will denote the set of  $n \times n$  symmetric matrices and  $\Theta_{s,t} := [s, t] \times \mathbb{R}^n$ .

**DEFINITION 4.1.** Let  $u(t, x) \in C(\Theta_{0,T})$  and  $(t, x) \in [0, T] \times \mathbb{R}^n$ . We denote by  $\mathcal{P}_{\Theta_{0,T}}^{2,+}u(t, x)$ , the parabolic superjet of  $u$  at  $(t, x)$ , the set of triples  $(p, q, X) \in \mathbb{R} \times \mathbb{R}^n \times S^n$  which satisfies

$$u(s, y) \leq u(t, x) + p(s - t) + \langle q, y - x \rangle + \frac{1}{2} \langle X(y - x), y - x \rangle + o(|s - t| + |y - x|^2).$$

Similarly, we denote by  $\mathcal{P}_{\Theta_{0,T}}^{2,-}u(t, x)$ , the parabolic subjet of  $u$  at  $(t, x)$ , the set of triples  $(p, q, X) \in \mathbb{R} \times \mathbb{R}^n \times S^n$  which satisfies

$$u(s, y) \geq u(t, x) + p(s - t) + \langle q, y - x \rangle + \frac{1}{2} \langle X(y - x), y - x \rangle + o(|s - t| + |y - x|^2).$$

*Example 4.* Suppose that  $\varphi \in C^{1,2}(\Theta_{0,T})$ . If  $u - \varphi$  attains local maximum at  $(t, x)$ , then

$$\left( \frac{\partial \varphi}{\partial t}(t, x), \nabla \varphi(t, x), D^2 \varphi(t, x) \right) \in \mathcal{P}_{\Theta_{0,T}}^{2,+} u(t, x).$$

If  $u - \varphi$  reaches a local minimum at  $(t, x)$ , then

$$\left( \frac{\partial \varphi}{\partial t}(t, x), \nabla \varphi(t, x), D^2 \varphi(t, x) \right) \in \mathcal{P}_{\Theta_{0,T}}^{2,-} u(t, x).$$

DEFINITION 4.2.

- (a) We call  $u(t, x) \in C([0, T] \times \mathbb{R}^n)$  a viscosity subsolution of (4.1) if  $u(T, x) \leq \Phi(x)$ ,  $x \in \mathbb{R}^n$ , and at any point  $(t, x) \in \Theta_{0,T}$ , for any  $(p, q, X) \in \mathcal{P}_{\Theta_{0,T}}^{2,+} u(t, x)$ , we have

$$\min \left( u(t, x) - h(t, x), \right. \\ \left. -p - \sup_{v \in U} \left\{ \frac{1}{2} Tr(aX) + \langle b, q \rangle + g(t, x, u(t, x), q\sigma(t, x, v), v) \right\} \right) \leq 0.$$

In other words, at any point  $(t, x)$  where  $u(t, x) > h(t, x)$ , we have

$$-p - \sup_{v \in U} \left\{ \frac{1}{2} Tr(aX) + \langle b, q \rangle + g(t, x, u(t, x), q\sigma(t, x, v), v) \right\} \leq 0.$$

- (b) We call  $u(t, x) \in C([0, T] \times \mathbb{R}^n)$  a viscosity supersolution of (4.1) if  $u(T, x) \geq \Phi(x)$ ,  $x \in \mathbb{R}^n$ , and at any point  $(t, x) \in \Theta_{0,T}$ , for any  $(p, q, X) \in \mathcal{P}_{\Theta_{0,T}}^{2,-} u(t, x)$ , we have

$$\min \left( u(t, x) - h(t, x), \right. \\ \left. -p - \sup_{v \in U} \left\{ \frac{1}{2} Tr(aX) + \langle b, q \rangle + g(t, x, u(t, x), q\sigma(t, x, v), v) \right\} \right) \geq 0.$$

In other words, at each point, we have both  $u(t, x) \geq h(t, x)$  and

$$-p - \sup_{v \in U} \left\{ \frac{1}{2} Tr(aX) + \langle b, q \rangle + g(t, x, u(t, x), q\sigma(t, x, v), v) \right\} \geq 0.$$

- (c)  $u(t, x) \in C([0, T] \times \mathbb{R}^n)$  is said to be a viscosity solution of (4.1) if it is both a viscosity sub- and supersolution.

We are going to use the approximation of the reflected BSDE by penalization, which was studied in section 6 of [9]. For each  $(t, x) \in [0, T] \times \mathbb{R}^n$ ,  $n \in \mathbb{N}$ , let  $\{( {}^n Y_s^{t,x;v}, {}^n Z_s^{t,x;v} ), t \leq s \leq T \}$  be the solution of the BSDEs

$$\begin{aligned} {}^n Y_s^{t,x;v} &= \Phi(X_T^{t,x;v}) + \int_s^T g(r, X_r^{t,x;v}, {}^n Y_r^{t,x;v}, {}^n Z_r^{t,x;v}, v_r) dr \\ &\quad + n \int_s^T ( {}^n Y_r^{t,x;v} - h(r, X_r^{t,x;v}) )^- dr - \int_s^T {}^n Z_r^{t,x;v} dW_r, \quad t \leq s \leq T. \end{aligned}$$

We define

$$(4.2) \quad J_n(t, x; v(\cdot)) := {}^n Y_t^{t, x; v}, \quad v(\cdot) \in \mathcal{U}, \quad 0 \leq t \leq T, \quad x \in \mathbb{R}^n;$$

$$(4.3) \quad u_n(t, x) := \operatorname{esssup}_{v(\cdot) \in \mathcal{U}} J_n(t, x; v(\cdot)), \quad 0 \leq t \leq T, \quad x \in \mathbb{R}^n.$$

It is known from [13] and [14] that  $u_n(t, x)$  defined in (4.3) is the viscosity solution of the PDE

$$\begin{cases} -\frac{\partial u_n}{\partial t}(t, x) - \sup_{v \in U} \{ \mathcal{L}(t, x, v) u_n(t, x) + g_n(t, x, u_n(t, x), \nabla u_n(t, x) \sigma(t, x, v), v) \} = 0, \\ u_n(T, x) = \Phi(x), \end{cases}$$

where

$$g_n(t, x, r, p\sigma(t, x, v), v) = g(t, x, r, p\sigma(t, x, v), v) + n(r - h(t, x))^-.$$

Then

LEMMA 4.3.  $u_n(t, x) \uparrow u(t, x)$ ,  $0 \leq t \leq T$ ,  $x \in \mathbb{R}^n$ .

*Proof.* From the result of section 6 in [9], for each  $0 \leq t \leq T$ ,  $x \in \mathbb{R}^n$ ,

$$J_n(t, x; v(\cdot)) \uparrow J(t, x; v(\cdot)) \quad \text{as } n \rightarrow \infty.$$

From the monotonic property of  $J_n$  and the definition of  $u_n$  in (4.3), we get the monotonic property of  $u_n$ . Next, we will prove that  $u_n$  converges in  $n$ .

For each  $0 \leq t \leq T$ ,  $x \in \mathbb{R}^n$  for all  $\varepsilon > 0$ , there exists  $v(\cdot) \in \mathcal{U}$  such that

$$u(t, x) < Y_t^{t, x; v} + \varepsilon,$$

then

$$0 \leq u(t, x) - u_n(t, x) \leq Y_t^{t, x; v} - {}^n Y_t^{t, x; v} + \varepsilon.$$

Because  ${}^n Y_t^{t, x; v} \uparrow Y_t^{t, x; v}$ , a.s., we take limit on both sides,

$$0 \leq \limsup_{n \rightarrow \infty} (u(t, x) - u_n(t, x)) \leq \varepsilon.$$

From the arbitrariness of  $\varepsilon$ , we get the desired result.  $\square$

Remark 4.4. Since  $u_n$  and  $u$  are continuous, it follows from Dini's theorem that the convergence in the lemma is uniform on compact sets.

THEOREM 4.5.  $u$  defined by (3.9) is a viscosity solution of HJB equation (4.1).

*Proof.* We first prove that  $u$  is a subsolution of (4.1). Let  $(t, x)$  be a point where  $u(t, x) > h(t, x)$ , and let  $(p, q, X) \in \mathcal{P}_{\Theta_{0,T}}^{2,+} u(t, x)$ . From Lemma 6.1 in [4], there exists sequences

$$n_j \rightarrow +\infty, \quad (t_j, x_j) \rightarrow (t, x), \quad (p_j, q_j, X_j) \in \mathcal{P}_{\Theta_{0,T}}^{2,+} u_{n_j}(t_j, x_j),$$

such that

$$(p_j, q_j, X_j) \rightarrow (p, q, X).$$

But for any  $j$ ,

$$\begin{aligned} -p_j - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right. \\ \left. + n_j(u_{n_j}(t_j, x_j) - h(t_j, x_j))^- \right\} \leq 0. \end{aligned}$$

From the assumption that  $u(t, x) > h(t, x)$  and the uniform convergence of  $u_n$ , it follows that for  $j$  large enough  $u_{n_j}(t_j, x_j) > h(t_j, x_j)$ , hence

$$-p_j - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right\} \leq 0.$$

Let us admit for a moment the following lemma.

LEMMA 4.6.

$$\begin{aligned} \lim_{j \rightarrow \infty} \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right\} \\ = \sup_{v \in U} \lim_{j \rightarrow \infty} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right\}. \end{aligned}$$

Letting  $j \rightarrow \infty$  in the above inequality yields

$$-p - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX) + \langle b, q \rangle + g(t, x, u(t, x), q \sigma(t, x, v), v) \right\} \leq 0,$$

then we get that  $u$  is a subsolution of (4.1).

We will obtain the result by proving that  $u$  is a supersolution of (4.1). Let  $(t, x)$  be an arbitrary point in  $\Theta_{0,T}$ , and  $(p, q, X) \in \mathcal{P}_{\Theta_{0,T}}^{2,-} u(t, x)$ . We already know that  $u(t, x) \geq h(t, x)$ . By the same arguments as above, there exist sequences

$$n_j \rightarrow +\infty, \quad (t_j, x_j) \rightarrow (t, x), \quad (p_j, q_j, X_j) \in \mathcal{P}_{\Theta_{0,T}}^{2,-} u_{n_j}(t_j, x_j),$$

such that

$$(p_j, q_j, X_j) \rightarrow (p, q, X).$$

While for any  $j$ , we have

$$\begin{aligned} -p_j - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right. \\ \left. + n_j(u_{n_j}(t_j, x_j) - h(t_j, x_j))^- \right\} \geq 0. \end{aligned}$$

Because  $n_j(u_{n_j}(t_j, x_j) - h(t_j, x_j))^- \geq 0$ , we get

$$-p_j - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v) \right\} \geq 0.$$

As  $j \rightarrow \infty$ , we conclude that

$$-p - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}(aX) + \langle b, q \rangle + g(t, x, u(t, x), q \sigma(t, x, v), v) \right\} \geq 0. \quad \square$$

To complete the proof, we need the proof of Lemma 4.6.

*Proof of Lemma 4.6.* For convenience, we denote

$$f_j(v) = \frac{1}{2}Tr(a, X_j) + \langle b, q_j \rangle + g(t_j, x_j, u_{n_j}(t_j, x_j), q_j \sigma(t_j, x_j, v), v).$$

First, for all  $v \in U$ ,

$$f_j(v) \leq \sup_{v \in U} f_j(v), \quad \lim_{j \rightarrow \infty} f_j(v) \leq \liminf_{j \rightarrow \infty} \sup_{v \in U} f_j(v),$$

so

$$(4.4) \quad \sup_{v \in U} \lim_{j \rightarrow \infty} f_j(v) \leq \liminf_{j \rightarrow \infty} \sup_{v \in U} f_j(v).$$

Second, we consider a subsequence  $\{j_k\}_{k=1}^{\infty}$  such that

$$\lim_{j_k \rightarrow \infty} \sup_{v \in U} f_{j_k}(v) = \limsup_{j \rightarrow \infty} \sup_{v \in U} f_j(v).$$

For all  $\varepsilon > 0$ , for all  $j_k$ ,  $\exists v_{j_k} \in U$  such that

$$\sup_{v \in U} f_{j_k}(v) \leq f_{j_k}(v_{j_k}) + \varepsilon.$$

Because  $U$  is compact, there also exists a convergent subsequence denoted by  $\{v_{j_k}\}_{k=1}^{\infty}$ , the limit is denoted by  $v_0$ . We consider the difference between  $f_{j_k}(v_{j_k})$  and  $f_{j_k}(v_0)$ : From the Lipschitz condition we get

$$|f_{j_k}(v_{j_k}) - f_{j_k}(v_0)| \leq C|v_{j_k} - v_0|^2 + C|v_{j_k} - v_0|,$$

where  $C$  only depends on the Lipschitz constant. It follows that for  $j_k$  large enough

$$|f_{j_k}(v_{j_k}) - f_{j_k}(v_0)| \leq \varepsilon.$$

Then

$$\sup_{v \in U} f_{j_k}(v) \leq f_{j_k}(v_0) + 2\varepsilon,$$

$$\limsup_{j \rightarrow \infty} \sup_{v \in U} f_j(v) = \lim_{j_k \rightarrow \infty} \sup_{v \in U} f_{j_k}(v) \leq \lim_{j_k \rightarrow \infty} f_{j_k}(v_0) + 2\varepsilon = \lim_{j \rightarrow \infty} f_j(v_0) + 2\varepsilon,$$

$$\limsup_{j \rightarrow \infty} \sup_{v \in U} f_j(v) \leq \sup_{v \in U} \lim_{j \rightarrow \infty} f_j(v_0) + 2\varepsilon.$$

Since  $\varepsilon$  is arbitrary,

$$(4.5) \quad \limsup_{j \rightarrow \infty} \sup_{v \in U} f_j(v) \leq \sup_{v \in U} \lim_{j \rightarrow \infty} f_j(v_0).$$

Combine (4.4) and (4.5), the result follows.  $\square$

To establish a uniqueness result for viscosity solution of (4.1), we use some techniques and methods from [1]. These techniques and methods can also be found in [3] for the uniqueness for viscosity solutions of Hamilton–Jacobi–Bellman–Isaacs equations related to stochastic differential games.

LEMMA 4.7. *Let  $u_1 \in C([0, T] \times \mathbb{R}^n)$  be a viscosity subsolution and  $u_2 \in C([0, T] \times \mathbb{R}^n)$  be a viscosity supersolution of (4.1). Then the function  $w := u_1 - u_2$  is a viscosity subsolution of the system*

$$(4.6) \quad \begin{cases} \min \left( w(t, x) \right. \\ \left. - \frac{\partial w}{\partial t}(t, x) - \sup_{v \in U} \{ \mathcal{L}(t, x, v)w(t, x) + L|w| + L|\nabla w \sigma(t, x, v)| \} \right) = 0, \\ w(T, x) = 0. \end{cases}$$

The proof is similar to Lemma 3.7 in [1], hence we omit it.

Now we are going to construct one suitable smooth supersolution for (4.6).

LEMMA 4.8. *For any  $A > 0$ , there exists  $C_1 > 0$  such that the function*

$$\chi(t, x) = \exp \{ (C_1(T - t) + A)\psi(x) \},$$

where

$$\psi(x) = \left[ \log \left( (|x|^2 + 1)^{\frac{1}{2}} \right) + 1 \right]^2$$

satisfies

$$\min \left( \chi(t, x), -\frac{\partial \chi}{\partial t}(t, x) - \sup_{v \in U} \{ \mathcal{L}(t, x, v)\chi(t, x) + L\chi(t, x) + L|\nabla \chi \sigma(t, x, v)| \} \right) > 0$$

in  $[t_1, T] \times \mathbb{R}^n$ , where  $t_1 = T - (A/C_1)$ .

*Proof.* Obviously, the function  $\chi$  defined in Lemma 4.8 satisfies  $\chi(t, x) > 0$ , for each  $(t, x) \in [0, T] \times \mathbb{R}^n$ . We consider estimates on the first and second order derivatives of  $\psi$ :

$$|D\psi(x)| \leq \frac{2[\psi(x)]^{\frac{1}{2}}}{(|x|^2 + 1)^{\frac{1}{2}}} \quad \text{and} \quad |D^2\psi(x)| \leq \frac{C \left( 1 + [\psi(x)]^{\frac{1}{2}} \right)}{|x|^2 + 1} \quad \text{in } \mathbb{R}^n.$$

These estimates imply that, if  $t \in [t_1, T]$ ,

$$|D\chi(t, x)| \leq C\chi(t, x) \frac{[\psi(x)]^{\frac{1}{2}}}{(|x|^2 + 1)^{\frac{1}{2}}}, \quad |D^2\chi(t, x)| \leq C\chi(t, x) \frac{\psi(x)}{|x|^2 + 1},$$

where the constant  $C$  only depend on  $A$ . Then we get

$$(4.7) \quad \begin{aligned} & \frac{\partial \chi}{\partial t}(t, x) + \sup_{v \in U} \{ \mathcal{L}(t, x, v)\chi(t, x) + L\chi(t, x) + L|\nabla \chi \sigma(t, x, v)| \} \\ &= \frac{\partial \chi}{\partial t}(t, x) + \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}((\sigma \sigma^T) D^2 \chi) + \langle b, D\chi \rangle + L\chi(t, x) + L|\nabla \chi \sigma(t, x, v)| \right\} \\ &\leq -C_1\chi(t, x)\psi(x) + \sup_{v \in U} \left\{ \frac{1}{2} \frac{|\sigma(t, x, v)|^2}{|x|^2 + 1} C\chi(t, x)\psi(x) \right. \\ &\quad \left. + \frac{|b(t, x, v)|}{(|x|^2 + 1)^{\frac{1}{2}}} C\chi(t, x)[\psi(x)]^{\frac{1}{2}} + L\chi(t, x) + L \frac{|\sigma(t, x, v)|}{(|x|^2 + 1)^{\frac{1}{2}}} C\chi(t, x)[\psi(x)]^{\frac{1}{2}} \right\}. \end{aligned}$$

Because  $b$  and  $\sigma$  are linear growth in  $x$ ,  $[\psi(x)]^{\frac{1}{2}} \leq \psi(x)$ , and  $1 \leq \psi(x)$ , the inequality (4.7) satisfies

$$\begin{aligned} (4.7) &< -C_1\chi(t, x)\psi(x) + \frac{1}{2}C\chi(t, x)\psi(x) + C\chi(t, x)\psi(x) \\ &\quad + L\chi(t, x)\psi(x) + LC\chi(t, x)\psi(x) \\ &= -(C_1 - \frac{1}{2}C - C - L - LC)\chi(t, x)\psi(x). \end{aligned}$$

It is clear that when  $C_1$  is large enough the right-hand side of the above inequality is negative and the proof is completed.  $\square$

With these preparations we can prove the uniqueness result for the viscosity solution of (4.1).

**THEOREM 4.9.** *Assume that  $b$ ,  $\sigma$ ,  $g$ ,  $\Phi$ , and  $h$  satisfy (H3.1) and (H3.4), respectively. Then there exists at most one viscosity solution of HJB equation (4.1) in the class of continuous functions which grow at most polynomially at infinity.*

*Proof.* Let  $u_1, u_2 \in C([0, T] \times \mathbb{R}^n)$  be two viscosity solutions of HJB equation (4.1). We define  $w := u_1 - u_2$ , then we have

$$\lim_{|x| \rightarrow \infty} w(t, x) e^{-A[\log((|x|^2+1)^{\frac{1}{2}})]^2} = 0$$

uniformly for  $t \in [0, T]$ , for some  $A > 0$ . This implies, in particular, that  $w(t, x) - \alpha\chi(t, x)$  is bounded from above in  $[t_1, T] \times \mathbb{R}^n$  for any  $\alpha > 0$  and that

$$M := \max_{[t_1, T] \times \mathbb{R}^n} (w - \alpha\chi)(t, x) e^{-L(T-t)}$$

is achieved at some point  $(t_0, x_0) \in [t_1, T] \times \mathbb{R}^n$  (depend on  $\alpha$ ). Here  $t_1$  is defined as in Lemma 4.8. Then we have two cases.

The first case:  $w(t_0, x_0) \leq 0$ .

Therefore we have

$$u_1(t, x) - u_2(t, x) \leq \alpha\chi(t, x), \quad (t, x) \in [t_1, T] \times \mathbb{R}^n.$$

Letting  $\alpha$  tend to zero, we obtain

$$(4.8) \quad u_1(t, x) \leq u_2(t, x), \quad (t, x) \in [t_1, T] \times \mathbb{R}^n.$$

The second case:  $w(t_0, x_0) > 0$ .

By the maximum point property, we deduce that

$$w(t, x) - \alpha\chi(t, x) \leq (w(t_0, x_0) - \alpha\chi(t_0, x_0))e^{-L(t-t_0)}, \quad (t, x) \in [t_1, T] \times \mathbb{R}^n,$$

and this inequality implies that the function  $w - \varphi$  has a global maximum point at  $(t_0, x_0)$  where

$$\varphi(t, x) = \alpha\chi(t, x) + (w(t_0, x_0) - \alpha\chi(t_0, x_0))e^{-L(t-t_0)}.$$

Since  $w$  is a viscosity subsolution of (4.6) from Lemma 4.7 and  $\varphi(t_0, x_0) = w(t_0, x_0) > 0$ , if  $t_0 \in [t_1, T]$ , we notice that

$$((\partial/\partial t)\varphi(t_0, x_0), \nabla\varphi(t_0, x_0), D^2\varphi(t_0, x_0)) \in \mathcal{P}_{\Theta_{t_1, T}}^{2,+} u(t_0, x_0),$$

then

$$\begin{aligned} & -\frac{\partial \varphi}{\partial t}(t_0, x_0) - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}((\sigma \sigma^T)(t_0, x_0, v) D^2 \varphi(t_0, x_0)) + \langle b(t_0, x_0, v), D\varphi(t_0, x_0) \rangle \right. \\ & \left. + L\varphi(t_0, x_0) + L|\nabla \varphi(t_0, x_0) \sigma(t_0, x_0, v)| \right\} \leq 0. \end{aligned}$$

By the definition of  $\varphi$ , we rewrite the above inequality as

$$\begin{aligned} & \alpha \left[ -\frac{\partial \chi}{\partial t}(t_0, x_0) - \sup_{v \in U} \left\{ \frac{1}{2} \text{Tr}((\sigma \sigma^T)(t_0, x_0, v) D^2 \chi(t_0, x_0)) + \langle b(t_0, x_0, v), D\chi(t_0, x_0) \rangle \right. \right. \\ & \left. \left. + L\chi(t_0, x_0) + L|\nabla \chi(t_0, x_0) \sigma(t_0, x_0, v)| \right\} \right] \leq 0. \end{aligned}$$

This is a contradiction with Lemma 4.8. Therefore  $t_0 = T$ , which is a contradiction with the fact that  $w(t, x)$  is a viscosity subsolution of (4.6) (see Lemma 4.7). Then the second case does not happen.

If we change  $w(t, x) = u_1 - u_2$  for  $w'(t, x) = u_2 - u_1$ , then the same arguments lead to

$$(4.9) \quad u_2(t, x) \leq u_1(t, x), \quad (t, x) \in [t_1, T] \times \mathbb{R}^n.$$

Combining (4.8) with (4.9), we have

$$u_1(t, x) = u_2(t, x), \quad (t, x) \in [t_1, T] \times \mathbb{R}^n.$$

Applying successively the same argument on the intervals  $[t_2, t_1]$  where  $t_2 = (t_1 - A/C_1)^+$  and then, if  $t_2 > 0$  on  $[t_3, t_2]$  where  $t_3 = (t_2 - A/C_1)^+$ , etc. We finally obtain that

$$u_1(t, x) = u_2(t, x), \quad (t, x) \in [0, T] \times \mathbb{R}^n.$$

The proof is completed.  $\square$

**Acknowledgments.** The authors express their gratitude to Prof. Shige Peng for his elicitation and inspiring idea in recursive stochastic dynamic programming principle. The authors also thank Dr. Juan Li and Dr. Mingyu Xu for their constructive suggestions. In particular, the authors would like to thank the associate editor and two anonymous referees for their careful reading and helpful comments and suggestions which greatly improved this paper.

## ROBUST STABILITY OF POLYTOPIC SYSTEMS VIA AFFINE PARAMETER-DEPENDENT LYAPUNOV FUNCTIONS\*

GUANG-HONG YANG<sup>†</sup> AND JIUXIANG DONG<sup>‡</sup>

**Abstract.** This paper studies robust stability of linear systems with polytopic uncertainty. New necessary and sufficient conditions for the existence of an affine parameter-dependent Lyapunov function assuring the Hurwitz or the Schur stability of a polytopic system are presented. These conditions are composed of a family of linear matrix inequality conditions of increasing precision. At each step, a set of linear matrix inequalities provides sufficient conditions for the existence of the affine parameter-dependent Lyapunov function, and necessity is asymptotically attained. Compared with the existing results in the literature, it is shown that the new stability conditions provide less conservative tests at each step. Numerical examples are given to illustrate the effectiveness of the new results.

**Key words.** linear systems, polytopic uncertainty, Hurwitz stability, Schur stability, linear matrix inequalities (LMIs), parameter-dependent Lyapunov functions

**DOI.** 10.1137/060668948

**1. Introduction.** Robust stability analysis of systems with uncertainties is one of the most fundamental problems in system and control theory [1]. In particular, the Lyapunov approach is popular in investigating the Hurwitz and Schur stabilities of linear systems with polytopic uncertainty. In past years, the Hurwitz and the Schur stabilities of linear systems with polytopic uncertainty has received a great deal of attention, and some significant results have been obtained; see [2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15] and the references therein. For obtaining less conservative evaluations of stability domains, higher degree parameter-dependent Lyapunov functions have been exploited. Sufficient conditions based on homogeneous polynomially parameter-dependent Lyapunov functions  $v(x) = x^T P(\alpha)x$  with  $P(\alpha)$  of arbitrary degree on  $\alpha$  are given in [16], and a family of linear matrix inequality (LMI) conditions of increasing precision for the Hurwitz stability is presented in [17]. The paper [18] provides a systematic procedure for generating sufficient LMI conditions for assuring robust stability based on homogeneous polynomially parameter-dependent Lyapunov matrix functions of arbitrary degree on the uncertain parameters. Moreover, in [19],

a piecewise Lyapunov function, instead of a single Lyapunov function, method is also exploited to reduce conservatism. In particular, based on Pólya's theorem [21], necessary and sufficient conditions for the existence of an affine parameter-dependent Lyapunov function assuring the Hurwitz or the Schur stability of a polytopic system are given in [20], and a systematic procedure for constructing a family of LMI conditions of increasing precision is developed, where the necessity is asymptotically attained.

This paper will continue to study the Hurwitz and Schur stabilities of polytopic systems. New necessary and sufficient conditions for the existence of an affine parameter-dependent Lyapunov function assuring the Hurwitz or Schur stability of a polytopic system are derived, which are composed of a family of linear matrix inequality conditions of increasing precision. At each step, a set of LMIs provides sufficient conditions for the existence of the affine parameter-dependent Lyapunov function, and necessity is asymptotically attained. Compared with the results in [20], the new stability conditions provide less conservative tests at each step and allow faster convergence to the necessary conditions for the existence of an affine parameter-dependent Lyapunov function in terms of steps. However, it should be pointed out that the faster convergence is not in terms of time, since the numerical complexity of the new proposed conditions is much greater than that in [20].

The paper is organized as follows. In the next section, system description and some preliminaries are given. In section 3, new necessary and sufficient conditions for the existence of an affine parameter-dependent Lyapunov function assuring the Hurwitz or Schur stability of a polytopic system are presented. Section 4 presents two examples to illustrate the effectiveness of the proposed methods. Finally, section 5 concludes the paper.

*Notation.* For a square matrix  $E$ ,  $\text{He}(E)$  is defined as  $\text{He}(E) = E + E^T$ .  $\mathbb{R}$  represents the set of real numbers,  $\mathbb{N}$  denotes the natural numbers set  $\{0, 1, 2, \dots\}$ , and  $p!$  denotes factorial, i.e.,  $p! = p(p-1)(p-2) \cdots (2)(1)$  for  $p \in \mathbb{N}$  with  $0! = 1$ .

**2. System description and preliminaries.** Consider a linear system described by

$$\dot{x}(t) = A(\alpha)x(t)$$

for the continuous-time case, and by

$$x(k+1) = A(\alpha)x(k)$$

for the discrete-time case, where  $A(\alpha)$  belongs to a polytope of real square matrices defined by

$$(1) \quad \mathcal{A} = \left\{ A(\alpha) : A(\alpha) = \sum_{i=1}^N \alpha_i A_i; \alpha \in \Delta_N \right\},$$

$$\Delta_N = \left\{ \alpha \in \mathbb{R}^N : \sum_{i=1}^N \alpha_i = 1; \alpha_i \geq 0 \right\},$$

where  $N$  is the number of vertices and  $\Delta_N$  stands for unit simplex.

In this paper, the Hurwitz and Schur stabilities problem of  $\mathcal{A}$  will be studied by considering an affine parameter-dependent Lyapunov matrix given by

$$(2) \quad P(\alpha) = \sum_{i=1}^N \alpha_i P_i, \quad \alpha \in \Delta_N,$$

with  $P_i = P_i^T > 0$ ,  $i = 1, \dots, N$ . Through the use of the Lyapunov function  $V(x) = x^T P(\alpha)x$ , the Hurwitz stability of  $\mathcal{A}$  can be assured if and only if the following condition holds:

$$(3) \quad \Gamma(\alpha) = A^T(\alpha)P(\alpha) + P(\alpha)A(\alpha) < 0;$$

the Schur stability of  $\mathcal{A}$  can be assured if and only if the following condition holds:

$$A^T(\alpha)P(\alpha)A(\alpha) - P(\alpha) < 0.$$

By  $\sum_{i=1}^N \alpha_i = 1$ , (3) can be rewritten as

$$(4) \quad \Gamma(\alpha) = \left( \sum_{i=1}^N \alpha_i \right)^d (A^T(\alpha)P(\alpha) + P(\alpha)A(\alpha)) < 0,$$

where  $d \in \mathbb{N}$ . By writing (4) (with  $\alpha_i$  as a variable) as a sum of terms in an extended form and using the known Pólya's theorem [21], two computationally verifiable necessary and sufficient conditions, which guarantee that (3) holds, are given in [20, Lemmas 1 and 2].

The purpose of this paper is to derive new necessary and sufficient conditions, provide less conservative tests at each step, and allow faster convergence to exact robust stability bounds for the existence results of an affine parameter-dependent Lyapunov function.

The following definitions are needed, which are consistent with those in [20]. Define  $\mathcal{K}(d)$  as the set of  $N$ -tuples obtained as all possible combinations of  $k_1, k_2, \dots, k_N$ ,  $k_i \in \mathbb{N}$ ,  $i = 1, \dots, N$ , such that  $k_1 + k_2 + \dots + k_N = d$ .  $\mathcal{K}_\ell(d)$  is the  $\ell$ th  $N$ -tuple of  $\mathcal{K}(d)$  which is lexically ordered  $\ell = 1, \dots, J(d)$ . For a fixed  $N$ , the number of elements in  $\mathcal{K}(d)$  is given by  $J(d) = (N + d - 1)! / (d!(N - 1)!)$ , and the associated standard multinomial coefficients are  $\mathcal{C}^\ell(d) = d! / (k_1!k_2! \cdots k_N!)$ ,  $k_1k_2 \cdots k_N = \mathcal{K}_\ell(d)$ ,  $\ell = 1, \dots, J(d)$ . As an example consider the case when  $N = 3$  and  $d = 2$ , which yields  $J(2) = 6$ ,  $\mathcal{K}(2) = \{002, 011, 020, 101, 110, 200\}$ , and the coefficients  $\mathcal{C}^\ell(d) = \{1, 2, 1, 2, 2, 1\}$ .

Consider the modified multinomial coefficients

$$\begin{aligned} \mathcal{C}_i^\ell(d, a) &= \begin{cases} \frac{d!}{k_1! \cdots (k_i - a)! \cdots k_N!} & \text{if } k_i - a \in \mathbb{N}, \\ 0 & \text{otherwise,} \end{cases} \\ \mathcal{C}_{ij}^\ell(d, a, b) &= \begin{cases} \frac{d!}{k_1! \cdots (k_i - a)! \cdots (k_j - b)! \cdots k_N!} & \text{if } \begin{cases} k_i - a \in \mathbb{N}, \\ k_j - b \in \mathbb{N}, \end{cases} \\ 0 & \text{otherwise,} \end{cases} \\ \mathcal{C}_{ij\ell}^\ell(d, a, b, c) &= \begin{cases} \frac{d!}{k_1! \cdots (k_i - a)! \cdots (k_j - b)! \cdots (k_\ell - c)! \cdots k_N!} & \text{if } \begin{cases} k_i - a \in \mathbb{N}, \\ k_j - b \in \mathbb{N}, \\ k_\ell - c \in \mathbb{N}, \end{cases} \\ 0 & \text{otherwise,} \end{cases} \end{aligned}$$

all of which depend on  $k_1k_2 \cdots k_N = \mathcal{K}_\ell(d)$ ,  $\ell = 1, \dots, J(d)$ .

LEMMA 1 (see [20]). (i) *An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the Hurwitz stability of  $\mathcal{A}$  if and only if there exist symmetric positive definite matrices  $P_i$ ,  $i = 1, \dots, N$ , and a sufficiently large  $d$ , such that the*

following LMIs hold:

$$(5) \quad T_\ell = \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) T_{H_i} + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) T_{H_{ij}} < 0, \\ k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2),$$

where

$$T_{H_i} = A_i^T P_i + P_i A_i, \\ T_{H_{ij}} = A_i^T P_j + P_j A_i + A_j^T P_i + P_i A_j.$$

(ii) An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the Schur stability of  $\mathcal{A}$  if and only if there exist symmetric positive definite matrices  $P_i$ ,  $i = 1, \dots, N$ , and a sufficiently large  $d$ , such that the following LMIs hold:

$$D_\ell = \sum_{i=1}^N \mathcal{C}_i^\ell(d, 3) T_{S_i} + \sum_{i=1}^N \sum_{j \neq i; j=1}^N \mathcal{C}_{ij}^\ell(d, 2, 1) T_{S_{ij}} + \sum_{i=1}^{N-2} \sum_{j=i+1}^{N-1} \sum_{k=j+1}^N \mathcal{C}_{ijk}^\ell(d, 1, 1, 1) T_{S_{ijk}} < 0, \\ k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+3) \quad \text{for } \ell = 1, \dots, J(d+3),$$

where

$$T_{S_i} = A_i^T P_i A_i - P_i, \\ T_{S_{ij}} = A_i^T P_i A_j + A_j^T P_i A_i + A_i^T P_j A_i - 2P_i - P_j, \\ T_{S_{ijk}} = A_j^T P_i A_k + A_k^T P_i A_j + A_i^T P_j A_k + A_k^T P_j A_i + A_i^T P_k A_j + A_j^T P_k A_i \\ - 2(P_i + P_j + P_k).$$

LEMMA 2 (see [20]). An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the stability of  $\mathcal{A}$  if and only if there exist symmetric positive definite matrices  $P_i$ ,  $i = 1, \dots, N$ , matrices  $X_i \in \mathbb{R}^{2n \times 2n}$ ,  $i = 1, \dots, N$ , and a sufficiently large  $d$  such that the following LMIs hold:

$$(6) \quad \Lambda_\ell = \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) T_{F_i} + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) T_{F_{ij}} < 0, \\ k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2),$$

where

$$(7) \quad T_{F_i} = Q_i + X_i B_i + B_i^T X_i^T, \\ T_{F_{ij}} = Q_i + Q_j + X_j B_i + B_i^T X_j^T + X_i B_j + B_j^T X_i^T, \\ B_i = \begin{bmatrix} A_i & -I \end{bmatrix},$$

and  $Q_i$ ,  $i = 1, \dots, N$ , are, respectively, given, for the Hurwitz and Schur cases, by

$$(8) \quad Q_{H_i} = \begin{bmatrix} 0 & P_i \\ P_i & 0 \end{bmatrix}, \quad Q_{S_i} = \begin{bmatrix} -P_i & 0 \\ 0 & P_i \end{bmatrix}.$$

It should be pointed out that the condition of Lemma 2 is less conservative than that of Lemma 1 for each  $d$ .

In particular, the following equality from [20] will be used in the next section:

$$\begin{aligned}
 (9) \quad & (\alpha_1 + \cdots + \alpha_N)^d (A^T(\alpha)P(\alpha) + P(\alpha)A(\alpha)) \\
 &= (\alpha_1 + \cdots + \alpha_N)^d \left( \sum_{i=1}^N \alpha_i^2 T_{H_i} + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \alpha_i \alpha_j T_{H_{ij}} \right) \\
 &= \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell,
 \end{aligned}$$

where  $P(\alpha)$  is the same as in (2);  $T_{H_i}$ ,  $T_{H_{ij}}$ , and  $T_\ell$  are the same as in (5).

Moreover, the following two technical lemmas will be needed in the later development.

LEMMA 3. (i)

$$\begin{aligned}
 (10) \quad & \sum_{\ell=1}^{J(d+2)} \sum_{1 \leq i \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-2} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \\
 &= \sum_{\ell=1}^{J(d)} (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_N^{k_N}) \sum_{1 \leq i \leq N} (\alpha_i^2) J_{ii}^{k_1 \cdots k_i \cdots k_N},
 \end{aligned}$$

where

$$(11) \quad J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} = 0 \quad \text{for } k_i - 2 < 0.$$

(ii)

$$\begin{aligned}
 & \sum_{\ell=1}^{J(d+2)} \operatorname{He} \left( \sum_{1 \leq i < j \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-1} \cdots \alpha_j^{k_j-1} \cdots \alpha_N^{k_N}) (\alpha_i \alpha_j) J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) \\
 &= \sum_{\ell=1}^{J(d)} (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_j^{k_j} \cdots \alpha_N^{k_N}) \sum_{1 \leq i < j \leq N} (\alpha_i \alpha_j) \operatorname{He}(J_{ij}^{k_1 \cdots k_i \cdots k_j \cdots k_N}),
 \end{aligned}$$

where

$$J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} = 0 \quad \text{for } k_i - 1 < 0 \quad \text{or } k_j - 1 < 0.$$

*Proof.* (i) Consider an arbitrary term of the left-hand side of equality (10) given by

$$(12) \quad (\alpha_1^{k_1} \cdots \alpha_i^{k_i-2} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N},$$

where  $k_1 + \cdots + k_N = d + 2$ .

If  $k_i - 2 < 0$ , then from (11), the term (12) is zero.

If  $k_i - 2 \geq 0$ , then  $k_1 \cdots (k_i - 2) \cdots k_N \in \mathcal{H}(d)$ , which implies that (12) also is one term of the right-hand side of equality (10).

On the other hand, consider an arbitrary term of the right-hand side of equality (10) given by

$$(13) \quad (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots k_i \cdots k_N},$$

where  $k_1 + \dots + k_N = d$ . Since  $k_1 \dots k_i \dots k_N \in \mathcal{K}(d)$ ,  $k_1 \dots (k_i + 2) \dots k_N \in \mathcal{K}(d + 2)$ . Equation (13) can be rewritten as

$$(\alpha_1^{k_1} \dots \alpha_i^{k_i+2-2} \dots \alpha_N^{k_N})(\alpha_i^2)J_{ii}^{k_1 \dots (k_i+2-2) \dots k_N},$$

which implies that (13) also is one term of the left-hand side of equality (10).

Moreover, all terms are different from each other in the left-hand (right-hand) side of equality (10), so both sides of equality (10) are the same. Thus, it follows that equality (10) holds.

(ii) The proof is similar to that for (i), and thus is omitted here.  $\square$

LEMMA 4. *If*

$$(14) \quad \begin{aligned} J^{k_1 k_2 \dots k_N} &= \begin{bmatrix} J_{ij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} > 0, \\ k_1 k_2 \dots k_N &= \mathcal{K}_\ell(d) \quad \text{for } \ell = 1, \dots, J(d), \end{aligned}$$

then for arbitrary  $\epsilon > 0$ , the following inequalities hold:

$$(15) \quad \begin{aligned} J_b^{k_1 k_2 \dots k_N} &= \begin{bmatrix} J_{bij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} > 0, \\ k_1 k_2 \dots k_N &= \mathcal{K}_\ell(d) \quad \text{for } \ell = 1, \dots, J(d), \end{aligned}$$

where

$$\begin{aligned} J_{bii}^{k_1 k_2 \dots k_N} &= \begin{bmatrix} J_{ii}^{k_1 k_2 \dots k_N} + \epsilon I & 0 \\ 0 & \epsilon I \end{bmatrix}, \quad 1 \leq i \leq N, \\ J_{bij}^{k_1 k_2 \dots k_N} &= \begin{bmatrix} J_{ij}^{k_1 k_2 \dots k_N} & 0 \\ 0 & 0 \end{bmatrix}, \quad 1 \leq i < j \leq N. \end{aligned}$$

*Proof.* From condition (14), we have

$$(16) \quad \begin{aligned} J_a^{k_1 k_2 \dots k_N} &= \begin{bmatrix} J_{aij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} \geq 0, \\ k_1 k_2 \dots k_N &= \mathcal{K}_\ell(d) \quad \text{for } \ell = 1, \dots, J(d), \end{aligned}$$

where

$$J_{aij}^{k_1 k_2 \dots k_N} = \begin{bmatrix} J_{ij}^{k_1 k_2 \dots k_N} & 0 \\ 0 & 0 \end{bmatrix}, \quad 1 \leq i \leq j \leq N;$$

then from (16), for arbitrary  $\epsilon > 0$ , it follows that

$$(17) \quad \begin{aligned} J_a^{k_1 k_2 \dots k_N} + \text{diag}[\epsilon I \dots \epsilon I] &= \begin{bmatrix} J_{aij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} + \text{diag}[\epsilon I \dots \epsilon I] > 0, \\ k_1 k_2 \dots k_N &= \mathcal{K}_\ell(d) \quad \text{for } \ell = 1, \dots, J(d). \end{aligned}$$

Choose

$$\begin{aligned} J_{bii}^{k_1 k_2 \dots k_N} &= J_{a ii}^{k_1 k_2 \dots k_N} + \epsilon I, \quad 1 \leq i \leq N, \\ J_{bij}^{k_1 k_2 \dots k_N} &= J_{a ij}^{k_1 k_2 \dots k_N}, \quad 1 \leq i < j \leq N. \end{aligned}$$

By (17), it follows that (15) holds. Thus, the proof is complete.  $\square$

**3. Main results.** In the following, new necessary and sufficient conditions are given for  $\mathcal{A}$  to be Hurwitz or Schur stable via an affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2).

**THEOREM 5.** (i) *An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the Hurwitz stability of  $\mathcal{A}$  if and only if there exist a sufficiently large  $d$ , symmetric positive matrices  $P_i$ ,  $i = 1, \dots, N$ ,  $J_{ii}^{k_1 k_2 \dots k_N}$  and matrices  $J_{ij}^{k_1 k_2 \dots k_N} = (J_{ji}^{k_1 k_2 \dots k_N})^T$ ,  $k_1 k_2 \dots k_N = \mathcal{K}_\ell(d)$  for  $\ell = 1, \dots, J(d)$  such that the following LMIs hold:*

$$(18) \quad T_\ell + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) < 0,$$

$$k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2),$$

$$(19) \quad J^{k_1 k_2 \dots k_N} = \begin{bmatrix} J_{ij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} > 0,$$

$$k_1 k_2 \dots k_N = \mathcal{K}_\ell(d) \quad \text{for } \ell = 1, \dots, J(d),$$

where

$$J_{ii}^{k_1 \dots (k_i-2) \dots k_N} = 0 \quad \text{for } k_i - 2 < 0,$$

$$J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} = 0 \quad \text{for } k_i - 1 < 0 \quad \text{or } k_j - 1 < 0,$$

and  $T_\ell$ ,  $\ell = 1, \dots, J(d+2)$  are the same as in (5).

(ii) *An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the Schur stability of  $\mathcal{A}$  if and only if there exist a sufficiently large  $d$ , symmetric positive matrices  $P_i$ ,  $i = 1, \dots, N$ ,  $J_{ii}^{k_1 k_2 \dots k_N}$  and matrices  $J_{ij}^{k_1 k_2 \dots k_N} = (J_{ji}^{k_1 k_2 \dots k_N})^T$ ,  $k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+1)$  for  $\ell = 1, \dots, J(d+1)$  such that the following LMIs hold:*

$$D_\ell + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) < 0,$$

$$k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+3) \quad \text{for } \ell = 1, \dots, J(d+3),$$

$$J^{k_1 k_2 \dots k_N} = \begin{bmatrix} J_{ij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} > 0,$$

$$k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+1) \quad \text{for } \ell = 1, \dots, J(d+1),$$

where

$$J_{ii}^{k_1 \dots (k_i-2) \dots k_N} = 0 \quad \text{for } k_i - 2 < 0,$$

$$J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} = 0 \quad \text{for } k_i - 1 < 0 \quad \text{or } k_j - 1 < 0,$$

and  $D_\ell$ ,  $\ell = 1, \dots, J(d+3)$  are the same as in (5).

*Proof.* (i) *Sufficiency.* By pre- and postmultiplying (19) by

$$\begin{bmatrix} \alpha_1 I & \alpha_2 I & \dots & \alpha_N I \end{bmatrix}$$

and its transpose, we then have

$$(20) \quad \sum_{1 \leq i \leq N} \alpha_i^2 J_{ii}^{k_1 k_2 \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} \alpha_i \alpha_j J_{ij}^{k_1 k_2 \dots k_N} \right) > 0,$$

$$k_1 k_2 \dots k_N = \mathcal{K}_\ell(d), \quad \ell = 1, \dots, J(d).$$

Multiplying (18) by  $\alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} = \mathcal{K}_\ell(d+2)$ , it follows that

$$\begin{aligned}
 (21) \quad & \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} \left( T_\ell + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \right. \\
 & \quad \left. + \operatorname{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) \right) \\
 & = \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} \sum_{1 \leq i \leq N} J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \\
 & \quad + \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} \operatorname{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) \\
 & = \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \sum_{1 \leq i \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-2} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \\
 & \quad + \operatorname{He} \left( \sum_{1 \leq i < j \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-1} \cdots \alpha_j^{k_j-1} \cdots \alpha_N^{k_N}) (\alpha_i \alpha_j) J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) < 0, \\
 & \quad k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2), \quad \ell = 1, \dots, J(d+2).
 \end{aligned}$$

By summing (21) from  $\ell = 1$  to  $J(d+2)$ , we then can obtain

$$\begin{aligned}
 (22) \quad & \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \sum_{\ell=1}^{J(d+2)} \sum_{1 \leq i \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-2} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \\
 & + \sum_{\ell=1}^{J(d+2)} \operatorname{He} \left( \sum_{1 \leq i < j \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-1} \cdots \alpha_j^{k_j-1} \cdots \alpha_N^{k_N}) (\alpha_i \alpha_j) J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) < 0.
 \end{aligned}$$

Applying Lemma 3 to (22), it follows that

$$\begin{aligned}
 & \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \sum_{\ell=1}^{J(d+2)} \sum_{1 \leq i \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-2} \cdots \alpha_N^{k_N}) (\alpha_i^2) J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} \\
 & + \sum_{\ell=1}^{J(d+2)} \operatorname{He} \left( \sum_{1 \leq i < j \leq N} (\alpha_1^{k_1} \cdots \alpha_i^{k_i-1} \cdots \alpha_j^{k_j-1} \cdots \alpha_N^{k_N}) (\alpha_i \alpha_j) J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) \\
 & = \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \sum_{\ell=1}^{J(d)} (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_N^{k_N}) \sum_{1 \leq i \leq N} (\alpha_i^2) J_{ii}^{k_1 \cdots k_i \cdots k_N} \\
 & + \sum_{\ell=1}^{J(d)} (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_j^{k_j} \cdots \alpha_N^{k_N}) \sum_{1 \leq i < j \leq N} (\alpha_i \alpha_j) \operatorname{He} (J_{ij}^{k_1 \cdots k_i \cdots k_j \cdots k_N})
 \end{aligned}$$

$$\begin{aligned}
&= \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell + \sum_{\ell=1}^{J(d)} (\alpha_1^{k_1} \cdots \alpha_i^{k_i} \cdots \alpha_N^{k_N}) \\
&\quad \times \left( \sum_{1 \leq i \leq N} (\alpha_i^2) J_{ii}^{k_1 \cdots k_i \cdots k_N} + \sum_{1 \leq i < j \leq N} (\alpha_i \alpha_j) \text{He} (J_{ij}^{k_1 \cdots k_i \cdots k_j \cdots k_N}) \right) < 0.
\end{aligned}$$

Combining the above inequality with (20), we have

$$(23) \quad \sum_{\ell=1}^{J(d+2)} \alpha_1^{k_1} \alpha_2^{k_2} \cdots \alpha_N^{k_N} T_\ell < 0.$$

From (9) and (23), it follows that

$$\begin{aligned}
&(\alpha_1 + \cdots + \alpha_N)^d (A(\alpha)^T P(\alpha) + P(\alpha) A(\alpha)) \\
&= A(\alpha)^T P(\alpha) + P(\alpha) A(\alpha) < 0,
\end{aligned}$$

which implies that  $\mathcal{A}$  is stable. Thus, the proof of the sufficiency is complete.

*Necessity.* If  $\mathcal{A}$  is stable via an affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2), then by Lemma 1, there exist symmetric positive definite matrices  $P_i$ ,  $i = 1, \dots, N$ , and a sufficiently large  $d$  such that (5) holds for  $\ell = 1, \dots, J(d+2)$ . Therefore, there exists a scalar  $\epsilon > 0$  such that

$$\begin{aligned}
(24) \quad &\sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) T_{H_i} + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) T_{H_{ij}} + \epsilon I \\
&= T_\ell + \epsilon I < 0, \\
&k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2), \quad \ell = 1, \dots, J(d+2).
\end{aligned}$$

Choose

$$\begin{aligned}
(25) \quad &J_{ii}^{k_1 k_2 \cdots k_N} = \frac{1}{N} \epsilon I, \quad 1 \leq i \leq N, \quad k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d), \quad \ell = 1, \dots, J(d), \\
&J_{ij}^{k_1 k_2 \cdots k_N} = 0, \quad 1 \leq i < j \leq N, \quad k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d), \quad \ell = 1, \dots, J(d).
\end{aligned}$$

Then

$$\begin{aligned}
(26) \quad &T_\ell + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) \\
&\leq T_\ell + N \frac{1}{N} \epsilon I, \quad k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2), \quad \ell = 1, \dots, J(d+2).
\end{aligned}$$

From (24) and (26), we then have

$$\begin{aligned}
&T_\ell + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} \right) < 0, \\
&k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2), \quad \ell = 1, \dots, J(d+2);
\end{aligned}$$

i.e., (18) holds. Moreover, by (25), it follows that (19) holds. Thus, the conditions (18) and (19) are satisfied.

(ii) The proof is similar to that for (i), and thus is omitted here.  $\square$

*Remark 1.* Theorem 5 presents a necessary and sufficient condition for an affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) to assure the stability of  $\mathcal{A}$  in terms of solutions of a set of LMIs. For each fixed  $d$ , the condition given by Theorem 5 is sufficient to assure the stability of  $\mathcal{A}$ , which is less conservative than that given by Lemma 1 (see [20]). In fact, if the condition given by Lemma 1 holds for a given  $d$ , then the condition given by Theorem 5 holds for a sufficiently small  $\epsilon > 0$  and  $J^{k_1 k_2 \dots k_N} = \epsilon I$ . Thus, compared with Lemma 1 (see [20]), the new stability condition provide a less conservative test for each  $d$ , which allows faster convergence to the necessary conditions for the existence of an affine parameter-dependent Lyapunov function in terms of  $d$ . However, it should be pointed out that the faster convergence is not on the time, since the numerical complexity of the condition given by Theorem 5 is much greater than that of Lemma 1 (see [20]); see Table 1.

The following theorem presents the relationship between the conditions of Theorem 5 for  $d = p$  and  $d = p + 1$ .

**THEOREM 6.** *If the condition of Theorem 5 holds for  $d = p$ , then the condition of Theorem 5 also holds for  $d = p + 1$ .*

*Proof.* If  $d = p$ , the condition of Theorem 5 holds; i.e., there exist symmetric positive matrices  $P_i$ ,  $i = 1, \dots, N$ ,  $J_{ii}^{k_1 k_2 \dots k_N}$  and matrices  $J_{ij}^{k_1 k_2 \dots k_N} = (J_{ji}^{k_1 k_2 \dots k_N})^T$ ,  $k_1 k_2 \dots k_N \in \mathcal{K}_\ell(p)$  for  $\ell = 1, \dots, J(p)$  satisfying (18) and (19).

By  $\sum_{i=1}^N \alpha_i = 1$ , we have

$$\begin{aligned} & (\alpha_1 + \dots + \alpha_N)^{p+1} (A^T(\alpha)P(\alpha) + P(\alpha)A(\alpha)) \\ &= (\alpha_1 + \dots + \alpha_N)^p (A^T(\alpha)P(\alpha) + P(\alpha)A(\alpha)). \end{aligned}$$

Combining the above equality with (9), it follows that

$$\sum_{\ell=1}^{J(p+3)} \alpha_1^{k_1} \alpha_2^{k_2} \dots \alpha_N^{k_N} T_{k_1 \dots k_N} = (\alpha_1 + \dots + \alpha_N) \sum_{\ell=1}^{J(p+2)} \alpha_1^{k_1} \alpha_2^{k_2} \dots \alpha_N^{k_N} T_{k_1 \dots k_N}$$

which further implies that, for  $k_1 k_2 \dots k_N \in \mathcal{K}(p+3)$ ,

$$T_{k_1 \dots k_N} = \sum_{r=1, k_r \geq 1}^N T_{k_1 \dots (k_r-1) \dots k_N}.$$

For  $k_1 k_2 \dots k_N \in \mathcal{K}(p+1)$ , choose

$$\begin{aligned} J_{ii}^{k_1 \dots k_N} &= \sum_{r=1, k_r \geq 1}^N J_{ii}^{k_1 \dots (k_r-1) \dots k_N}, \\ J_{ij}^{k_1 \dots k_N} &= \sum_{r=1, k_r \geq 1}^N J_{ij}^{k_1 \dots (k_r-1) \dots k_N}. \end{aligned}$$

Then, for  $k_1 k_2 \dots k_N \in \mathcal{K}(p+3)$ ,

$$\begin{aligned} (27) \quad & T_{k_1 \dots k_N} + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) \\ &= \sum_{r=1, k_r \geq 1}^N \left( T_{k_1 \dots (k_r-1) \dots k_N} + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots (k_r-1) \dots k_N} \right. \\ & \quad \left. + \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots (k_r-1) \dots k_N} \right). \end{aligned}$$

From (18) with  $d = p$ , it follows that (27) is less than zero, which implies that for  $d = p + 1$ , (18) holds. Moreover, for  $k_1 k_2 \cdots k_N \in \mathcal{K}(p + 1)$ ,

$$\begin{aligned}
 (28) \quad & J^{k_1 k_2 \cdots k_N} \\
 &= \left[ J_{ij}^{k_1 k_2 \cdots k_N} \right]_{N \times N} \\
 &= \left[ \sum_{i=1, k_r \geq 1}^N J_{ij}^{k_1 \cdots (k_r-1) \cdots k_N} \right]_{N \times N} \\
 &= \sum_{i=1, k_r \geq 1}^N \left[ J_{ij}^{k_1 \cdots (k_r-1) \cdots k_N} \right]_{N \times N}.
 \end{aligned}$$

From (19) with  $d = p$ , it follows that (28) is greater than zero, which further implies that for  $d = p + 1$ , (19) holds. Thus, the condition of Theorem 5 for  $d = p + 1$  holds.  $\square$

*Remark 2.* Theorem 6 shows that the family of LMI conditions given by Theorem 5 is of increasing precision.

For a better understanding and comparison of the LMI conditions of Lemma 1 and Theorem 5, the concise LMIs are presented in the following for a polytope  $\mathcal{A}$  with  $N = 2$  vertices. For this case,

$$T_{H_1} = A_1^T P_1 + P_1 A_1; \quad T_{H_2} = A_2^T P_2 + P_2 A_2; \quad T_{H_{12}} = A_1^T P_2 + P_2 A_1 + A_2^T P_1 + P_1 A_2.$$

Then, for  $d = 0$ , we have  $J(2) = 3$ ,  $\mathcal{K}(0) = \{00\}$ ,  $\mathcal{K}(2) = \{02, 11, 20\}$ . The LMIs of Lemma 1 are

$$\begin{aligned}
 T_{H_1} &< 0, \\
 T_{H_2} &< 0, \\
 T_{H_{12}} &< 0.
 \end{aligned}$$

The LMIs of Theorem 5 are

$$\begin{aligned}
 T_{H_1} + J_{11}^{00} &< 0, \\
 T_{H_2} + J_{22}^{00} &< 0, \\
 T_{H_{12}} + \mathbf{He}(J_{12}^{00}) &< 0, \\
 \begin{bmatrix} J_{11}^{00} & J_{12}^{00} \\ (J_{12}^{00})^T & J_{22}^{00} \end{bmatrix} &> 0.
 \end{aligned}$$

For  $d = 1$ ,  $J(3) = 4$ ,  $\mathcal{K}(1) = \{01, 10\}$ ,  $\mathcal{K}(3) = \{03, 12, 21, 30\}$ . The LMIs of Lemma 1 are

$$\begin{aligned}
 T_{H_1} &< 0, \\
 T_{H_2} &< 0, \\
 T_{H_1} + T_{H_{12}} &< 0, \\
 T_{H_2} + T_{H_{12}} &< 0.
 \end{aligned}$$

The LMIs of Theorem 5 are

$$\begin{aligned}
 T_{H_1} + J_{11}^{10} &< 0, \\
 T_{H_2} + J_{22}^{01} &< 0, \\
 T_{H_1} + T_{H_{12}} + J_{11}^{01} + \mathbf{He}(J_{12}^{10}) &< 0,
 \end{aligned}$$

$$\begin{aligned} T_{H_2} + T_{H_{12}} + J_{22}^{10} + \text{He}(J_{12}^{01}) &< 0, \\ \begin{bmatrix} J_{11}^{10} & J_{12}^{10} \\ (J_{12}^{10})^T & J_{22}^{10} \end{bmatrix} &> 0, \\ \begin{bmatrix} J_{11}^{01} & J_{12}^{01} \\ (J_{12}^{01})^T & J_{22}^{01} \end{bmatrix} &> 0. \end{aligned}$$

For  $d = 2$ , we have  $J(4) = 5$ ,  $\mathcal{K}(2) = \{02, 11, 20\}$ ,  $\mathcal{K}(4) = \{04, 13, 22, 31, 40\}$ . The LMIs of Lemma 1 are

$$\begin{aligned} T_{H_1} &< 0, \\ T_{H_2} &< 0, \\ 2T_{H_1} + T_{H_{12}} &< 0, \\ T_{H_1} + T_{H_2} + 2T_{H_{12}} &< 0, \\ 2T_{H_2} + T_{H_{12}} &< 0. \end{aligned}$$

The LMIs of Theorem 5 are

$$\begin{aligned} T_{H_1} + J_{11}^{20} &< 0, \\ T_{H_2} + J_{22}^{02} &< 0, \\ 2T_{H_1} + T_{H_{12}} + J_{11}^{11} + \text{He}(J_{12}^{20}) &< 0, \\ T_{H_1} + T_{H_2} + 2T_{H_{12}} + J_{11}^{02} + J_{22}^{20} + \text{He}(J_{12}^{11}) &< 0, \\ 2T_{H_2} + T_{H_{12}} + J_{22}^{11} + \text{He}(J_{12}^{02}) &< 0, \\ \begin{bmatrix} J_{11}^{20} & J_{12}^{20} \\ (J_{12}^{20})^T & J_{22}^{20} \end{bmatrix} &> 0, \\ \begin{bmatrix} J_{11}^{11} & J_{12}^{11} \\ (J_{12}^{11})^T & J_{22}^{11} \end{bmatrix} &> 0, \\ \begin{bmatrix} J_{11}^{02} & J_{12}^{02} \\ (J_{12}^{02})^T & J_{22}^{02} \end{bmatrix} &> 0. \end{aligned}$$

**THEOREM 7.** *An affine parameter-dependent Lyapunov matrix  $P(\alpha)$  given by (2) assures the stability of  $\mathcal{A}$  if and only if there exist a sufficiently large  $d$ , symmetric positive definite matrices  $P_i$ ,  $i = 1, \dots, N$ ,  $J_{ii}^{k_1 k_2 \dots k_N}$  and matrices  $X_i \in \mathbb{R}^{2n \times 2n}$ ,  $i = 1, \dots, N$ ,  $J_{ij}^{k_1 k_2 \dots k_N} = (J_{ji}^{k_1 k_2 \dots k_N})^T$ ,  $k_1 k_2 \dots k_N = \mathcal{K}_\ell(d)$ ,  $\ell = 1, \dots, J(d)$ , such that the following LMIs hold:*

$$\begin{aligned} (29) \quad \Lambda_\ell + \sum_{1 \leq i \leq N} J_{bii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{bij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) &< 0, \\ k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+2), \quad \ell = 1, \dots, J(d+2), \\ J_b^{k_1 k_2 \dots k_N} = \begin{bmatrix} J_{bij}^{k_1 k_2 \dots k_N} \end{bmatrix}_{N \times N} &> 0, \\ (30) \quad k_1 k_2 \dots k_N = \mathcal{K}_\ell(d), \quad \ell = 1, \dots, J(d), \end{aligned}$$

where

$$\begin{aligned} J_{bii}^{k_1 \dots (k_i-2) \dots k_N} &= 0 \quad \text{for} \quad k_i - 2 < 0, \\ J_{bij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} &= 0 \quad \text{for} \quad k_i - 1 < 0 \quad \text{or} \quad k_j - 1 < 0, \end{aligned}$$

and  $\Lambda_\ell$ ,  $\ell = 1, \dots, J(d+2)$ , are the same as in Lemma 2.

*Proof.* The proof is similar to that for Theorem 5, and omitted here.  $\square$

*Remark 3.* For each fixed  $d$ , the condition given by Theorem 7 is sufficient to assure the stability of  $\mathcal{A}$ , which is less conservative than that given by Lemma 2 (see [20]), and allows faster convergence to the necessary conditions for the existence of an affine parameter-dependent Lyapunov function in terms of  $d$ . Moreover, similarly to Theorem 6, it can be shown that the family of LMI conditions given by Theorem 7 is of increasing precision.

For the relationship between Theorems 5 and 7, we have the following theorem.

**THEOREM 8.** *For a fixed  $d$ , if condition (i) (resp., (ii)) of Theorem 5 holds, then the condition of Theorem 7 for assuring the Hurwitz (resp., Schur) stability of  $\mathcal{A}$  holds.*

*Proof.* First, consider the Hurwitz stability of  $\mathcal{A}$ .

For a fixed  $d$ , if condition (i) of Theorem 5 holds, then there exist symmetric positive matrices  $P_i$ ,  $i = 1, \dots, N$ ,  $J_{ii}^{k_1 k_2 \dots k_N}$  and matrices  $J_{ij}^{k_1 k_2 \dots k_N} = (J_{ji}^{k_1 k_2 \dots k_N})^T$ ,  $k_1 k_2 \dots k_N = \mathcal{K}_\ell(d)$  for  $\ell = 1, \dots, J(d)$  such that (18) and (19) hold. Equation (18) can be rewritten as follows:

$$\begin{aligned} & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(A_i^T P_i) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(A_i^T P_j + A_j^T P_i) \\ & + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) < 0, \\ & k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2). \end{aligned}$$

Then there exists a symmetric positive matrix  $G$  such that

$$\begin{aligned} (31) \quad & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(A_i^T P_i) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(A_i^T P_j + A_j^T P_i) \\ & + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) \\ & + \eta^{-1} \left( \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) A_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (A_i + A_j) \right)^T G \\ & \times \left( \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) A_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (A_i + A_j) \right) < 0, \\ & k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2), \end{aligned}$$

where

$$\eta = 2 \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) + 4 \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1).$$

Applying the Schur complement to (31), we then have

$$\begin{aligned} (32) \quad & \begin{bmatrix} R_{11}^{k_1 k_2 \dots k_N} & * \\ R_{21}^{k_1 k_2 \dots k_N} & R_{22}^{k_1 k_2 \dots k_N} \end{bmatrix} < 0, \quad k_1 k_2 \dots k_N = \mathcal{K}_\ell(d+2) \\ & \text{for } \ell = 1, \dots, J(d+2), \end{aligned}$$

where

$$\begin{aligned}
 R_{11}^{k_1 k_2 \dots k_N} &= \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(A_i^T P_i) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(A_i^T P_j + A_j^T P_i) \\
 &\quad + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right), \\
 R_{21}^{k_1 k_2 \dots k_N} &= G \left( \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) A_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (A_i + A_j) \right), \\
 R_{22}^{k_1 k_2 \dots k_N} &= -\eta G = - \left( 2 \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) + 4 \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \right) G.
 \end{aligned}$$

Let

$$(33) \quad X_{i1} = P_i, \quad X_{i2} = G;$$

then  $R_{11}^{k_1 k_2 \dots k_N}$ ,  $R_{21}^{k_1 k_2 \dots k_N}$ , and  $R_{22}^{k_1 k_2 \dots k_N}$  can be rewritten as follows:

$$\begin{aligned}
 R_{11}^{k_1 k_2 \dots k_N} &= \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(A_i^T X_{i1}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(A_i^T X_{j1} + A_j^T X_{i1}) \\
 &\quad + \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right), \\
 R_{21}^{k_1 k_2 \dots k_N} &= \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) X_{i2} A_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (X_{j2} A_i + X_{i2} A_j), \\
 R_{22}^{k_1 k_2 \dots k_N} &= \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(-X_{i2}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(-X_{i2} - X_{j2}).
 \end{aligned}$$

By (32), it follows that

$$\begin{aligned}
 (34) \quad &\left[ \begin{array}{c} \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(A_i^T X_{i1}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(A_i^T X_{j1} + A_j^T X_{i1}) \\ \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) X_{i2} A_i + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (X_{j2} A_i + X_{i2} A_j) \\ \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \text{He}(-X_{i2}) + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \text{He}(-X_{i2} - X_{j2}) \\ + \left[ \begin{array}{c} \sum_{1 \leq i \leq N} J_{ii}^{k_1 \dots (k_i-2) \dots k_N} + \text{He} \left( \sum_{1 \leq i < j \leq N} J_{ij}^{k_1 \dots (k_i-1) \dots (k_j-1) \dots k_N} \right) \\ 0 \end{array} \right] \end{array} \right] \begin{array}{c} * \\ 0 \\ 0 \end{array} \\
 &= \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \left[ \begin{array}{cc} \text{He}(A_i^T X_{i1}) & * \\ X_{i2} A_i & -\text{He}(X_{i2}) \end{array} \right]
 \end{aligned}$$

$$\begin{aligned}
& + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \begin{bmatrix} \text{He}(A_i^T X_{j1} + A_j^T X_{i1}) & * \\ X_{j2} A_i + X_{i2} A_j & -\text{He}(X_{i2} + X_{j2}) \end{bmatrix} \\
& + \sum_{1 \leq i \leq N} \begin{bmatrix} J_{ii}^{k_1 \cdots (k_i-2) \cdots k_N} & 0 \\ 0 & 0 \end{bmatrix} \\
& + \sum_{1 \leq i < j \leq N} \text{He} \left( \begin{bmatrix} J_{ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} & 0 \\ 0 & 0 \end{bmatrix} \right) \\
& = \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \begin{bmatrix} \text{He}(A_i^T X_{i1}) & * \\ X_{i2} A_i & -\text{He}(X_{i2}) \end{bmatrix} \\
& + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \begin{bmatrix} \text{He}(A_i^T X_{j1} + A_j^T X_{i1}) & * \\ X_{j2} A_i + X_{i2} A_j & -\text{He}(X_{i2} + X_{j2}) \end{bmatrix} \\
& + \sum_{1 \leq i \leq N} J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \sum_{1 \leq i < j \leq N} \text{He}(J_{a ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}) < 0, \\
& k_1 k_2 \cdots k_N = \mathcal{C}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2),
\end{aligned}$$

where

$$J_{a ij}^{k_1 k_2 \cdots k_N} = \begin{bmatrix} J_{ij}^{k_1 k_2 \cdots k_N} & 0 \\ 0 & 0 \end{bmatrix}, \quad 1 \leq i \leq j \leq N.$$

From (33) and (34), we then can obtain

$$\begin{aligned}
(35) \quad & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) \begin{bmatrix} \text{He}(A_i^T X_{i1}) & * \\ X_{i2} A_i + P_i - X_{i1}^T & -\text{He}(X_{i2}) \end{bmatrix} \\
& + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) \\
& \quad \times \begin{bmatrix} \text{He}(A_i^T X_{j1} + A_j^T X_{i1}) & * \\ X_{j2} A_i + X_{i2} A_j + P_i + P_j - X_{i1}^T - X_{j1}^T & -\text{He}(X_{i2} + X_{j2}) \end{bmatrix} \\
& + \sum_{1 \leq i \leq N} J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \sum_{1 \leq i < j \leq N} \text{He}(J_{a ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}) < 0, \\
& k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2).
\end{aligned}$$

Let

$$X_i = \begin{bmatrix} X_{i1} \\ X_{i2} \end{bmatrix}.$$

By (35), we have

$$\begin{aligned}
(36) \quad & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2) (Q_i + X_i B_i + B_i^T X_i^T) \\
& + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1) (Q_i + Q_j + X_j B_i + B_i^T X_j^T + X_i B_j + B_j^T X_i^T)
\end{aligned}$$

$$\begin{aligned}
 & + \sum_{1 \leq i \leq N} J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \sum_{1 \leq i < j \leq N} \operatorname{He}(J_{a ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}) < 0, \\
 & k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2),
 \end{aligned}$$

where  $B_i$  are the same as in (7), and  $Q_i$  are the same as in (8).

From (36), there exists a sufficiently small  $\epsilon > 0$  such that

$$\begin{aligned}
 (37) \quad & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2)(Q_i + X_i B_i + B_i^T X_i^T) \\
 & + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1)(Q_i + Q_j + X_j B_i + B_i^T X_j^T + X_i B_j + B_j^T X_i^T) \\
 & + \sum_{1 \leq i \leq N} J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \sum_{1 \leq i < j \leq N} \operatorname{He}(J_{a ij}^{k_1 \cdots (k_i-2) \cdots k_N}) + N\epsilon I \\
 = & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2)(Q_i + X_i B_i + B_i^T X_i^T) \\
 & + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1)(Q_i + Q_j + X_j B_i + B_i^T X_j^T + X_i B_j + B_j^T X_i^T) \\
 & + \sum_{1 \leq i \leq N} (J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \epsilon I) + \sum_{1 \leq i < j \leq N} \operatorname{He}(J_{a ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}) < 0, \\
 & k_1 k_2 \cdots k_N = \mathcal{K}_\ell(d+2) \quad \text{for } \ell = 1, \dots, J(d+2).
 \end{aligned}$$

For  $k_1 k_2 \cdots k_N \in \mathcal{K}(d+2)$ , let

$$\begin{aligned}
 (38) \quad & J_{b ii}^{k_1 \cdots (k_i-2) \cdots k_N} = \begin{cases} J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \epsilon I & \text{if } k_i - 2 \geq 0, \\ 0 & \text{otherwise,} \end{cases} \quad 1 \leq i \leq N, \\
 & J_{b ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N} = J_{a ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}, \quad 1 \leq i < j \leq N.
 \end{aligned}$$

Then

$$\sum_{1 \leq i \leq N} J_{b ii}^{k_1 \cdots (k_i-2) \cdots k_N} \leq \sum_{1 \leq i \leq N} (J_{a ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \epsilon I).$$

By (37), it follows that

$$\begin{aligned}
 (39) \quad & \sum_{i=1}^N \mathcal{C}_i^\ell(d, 2)(Q_i + X_i B_i + B_i^T X_i^T) \\
 & + \sum_{i=1}^{N-1} \sum_{j=i+1}^N \mathcal{C}_{ij}^\ell(d, 1, 1)(Q_i + Q_j + X_j B_i + B_i^T X_j^T + X_i B_j + B_j^T X_i^T) \\
 & + \sum_{1 \leq i \leq N} J_{b ii}^{k_1 \cdots (k_i-2) \cdots k_N} + \sum_{1 \leq i < j \leq N} \operatorname{He}(J_{b ij}^{k_1 \cdots (k_i-1) \cdots (k_j-1) \cdots k_N}) < 0;
 \end{aligned}$$

i.e., (29) holds. Moreover, from Lemma 4, (19), and (38), it follows that (30) holds. Thus, the condition of Theorem 7 is satisfied for assuring the Hurwitz stability of  $\mathcal{A}$ . For the case of Schur stability, the proof is similar, and thus is omitted here.  $\square$

TABLE 1  
Numbers of LMIs and decision variables.

Methods	Number of LMIs	Number of decision variables
Lemma 1 (i) [20]	$J(d+2)$	$nN(n+1)/2$
Lemma 1 (ii) [20]	$J(d+3)$	$nN(n+1)/2$
Theorem 5 (i)	$J(d+2)+J(d)$	$nN(n+1)/2+nN(nN+1)J(d)/2$
Theorem 5 (ii)	$J(d+3)+J(d+1)$	$nN(n+1)/2+nN(nN+1)J(d+1)/2$
Lemma 2 [20]	$J(d+2)$	$nN(n+1)/2+4n^2N$
Theorem 7	$J(d+2)+J(d)$	$nN(n+1)/2+4n^2N+nN(2nN+1)J(d)$

*Remark 4.* Theorem 8 shows that for a fixed  $d$ , the condition given by Theorem 7 is less conservative than that given by Theorem 5, which allows faster convergence to the necessary conditions for the existence of an affine parameter-dependent Lyapunov function in terms of  $d$ . But, more computational time for the stability test given by Theorem 7 is required for each  $d$ , since more decision variables are involved in the condition given by Theorem 7.

*Remark 5.* Regarding computational complexity, the number of decision variables and the number of LMIs are used as measures of computational burden. Table 1 summarizes the numbers of decision variables and LMIs for each method with a fixed  $d$ . From the table, it is easy to see that Theorems 5 and 7 require more decision variables and LMIs than Lemmas 1 and 2, respectively, which implies that the methods given by Theorems 5 and 7 are of more computational burden for a given  $d$ .

**4. Example.** In this section, two numerical examples are given to illustrate the effectiveness of the robust stability criteria given by Theorems 5 and 7.

*Example 1.* Consider an uncertain matrix  $\mathcal{A}$  described by (1) with  $N = 2$ ,

$$A_1 = \begin{bmatrix} -0.0996 & 0.9846 & -0.4496 \\ -0.9045 & -0.0387 & 0.9657 + \delta \\ 0.6933 & -0.7612 & -0.4179 \end{bmatrix}, \quad A_2 = \begin{bmatrix} -0.6327 & -0.3142 & 0.8716 \\ 0.6263 & -0.6932 & 0.9598 \\ -0.0090 & -0.9367 & 0.3422 \end{bmatrix}.$$

It is concerned with the robust Hurwitz stability for  $|\delta| \leq \gamma$ . Applying Lemmas 1 and 2 and Theorems 5 and 7 to this example, the stability bounds and cpu times are obtained as shown in Tables 2–6.

TABLE 2

Total cpu time (sec)	12.3551	0.5779	0.6166	7.8750

From the above computational results, it can be seen that Theorems 5 and 7 cannot provide more conservative results than Lemmas 1 and 2 for the same  $d$ . However, Theorems 5 and 7 require more computational time for each  $d$  than Lemmas 1 and 2, respectively. Table 6 shows that Lemma 2 performs best for the example since it has the lowest consumed cpu time for obtaining the stability bound of 0.00843.

*Example 2.* Consider an uncertain matrix  $\mathcal{A}$  described by (1) with  $N = 3$ ,

$$A_1 = \begin{bmatrix} -0.646 & -0.875 & -0.997 \\ -0.732 & -0.993 & -0.126 \\ 0.707 & 0.289 & -0.3 + \delta \end{bmatrix}, \quad A_2 = \begin{bmatrix} -0.419 & 0.896 & -0.854 \\ -0.198 & -0.417 & 0.592 \\ 0.574 & 0.113 & -0.970 \end{bmatrix},$$

$$A_3 = \begin{bmatrix} -0.789 & -0.533 & 0.353 \\ -0.469 & -0.390 & 0.676 \\ -0.970 & -0.914 & 0.053 \end{bmatrix}.$$

It also is concerned with the robust Hurwitz stability for  $|\delta| \leq \gamma$ . Applying Lemmas 1 and 2 and Theorems 5 and 7 to this example, the stability bounds and cpu times are obtained, as shown in Tables 7–11.

From the computational results, it can be seen that Theorems 5 and 7 can provide less conservative results than Lemmas 1 and 2 for the same  $d$ , respectively. For this example, Theorem 7 performs best for the example, since the total cpu times consumed by using Lemmas 1 and 2 and Theorem 5 for obtaining the smaller stability bounds have exceeded the total consumed cpu time of 656.3907 seconds by using Theorem 7 for obtaining the stability bound of 0.27025.

These two examples show that, in general, Lemma 1 (resp., Lemma 2) will usually perform better than Theorem 5 (resp., Theorem 7) for obtaining a stability bound if it can be achieved by using Lemma 1 (resp., Lemma 2) for a smaller  $d$ . But, if the stability bound is achieved by using Lemma 1 (resp., Lemma 2) for a much larger  $d$  than that used by Theorem 5 (resp., Theorem 7), then Theorem 5 (resp., Theorem 7) will be preferred, because the programming for a larger  $d$  also is costly in terms of time.

**5. Conclusion.** In this paper, new necessary and sufficient conditions for the existence of an affine parameter-dependent Lyapunov function assuring the Hurwitz or Schur stability of a polytopic system are given, which are composed of a family of LMI conditions of increasing precision. At each step, a set of LMIs provides sufficient conditions for the existence of the affine parameter-dependent Lyapunov function, and necessity is asymptotically attained. Compared with the results in [20], the new stability conditions provide less conservative tests at each step and allow faster convergence to the necessary conditions for the existence of an affine parameter-dependent Lyapunov function in terms of steps. But, it should be emphasized that the faster convergence is not in terms of time, since the numerical complexity of the new proposed conditions is much greater than that in [20]. The numerical examples have shown the effectiveness of the new proposed stability criteria.

## MESH INDEPENDENCE OF KLEINMAN–NEWTON ITERATIONS FOR RICCATI EQUATIONS IN HILBERT SPACE\*

J. A. BURNS<sup>†</sup>, E. W. SACHS<sup>‡</sup>, AND L. ZIETSMAN<sup>†</sup>

**Abstract.** In this paper we consider the convergence of the infinite dimensional version of the Kleinman–Newton algorithm for solving the algebraic Riccati operator equation associated with the linear quadratic regulator problem in a Hilbert space. We establish mesh independence for this algorithm and apply the result to systems governed by delay equations. Numerical examples are presented to illustrate the results.

**Key words.** Riccati, Kleinman–Newton, mesh independence

**AMS subject classifications.** 49, 65, 93

**DOI.** 10.1137/060653962

**1. Introduction.** The problem of constructing numerical schemes for optimization-based design and control of infinite dimensional systems leads to technical and practical issues that are not present if one is interested only in simulation. For example, if one uses finite elements or the method of lines to simulate a system of partial differential equations (PDEs), then the resulting finite dimensional approximate system is often very large and can have millions of state variables. The corresponding approximating Riccati equations are immense, and special numerical techniques are required to solve such equations. Many of these large-scale Riccati solvers are based on iterative algorithms (see [9], [10], and [30]) and take advantage of the mathematical structure of the approximating system (symmetry, sparseness, etc.).

There are two basic issues that need to be addressed in developing practical numerical approximations for control. First, it is essential that the approximation scheme leads to finite dimensional approximating Riccati equations that converge (under mesh refinement) to the solution of the infinite dimensional Riccati equation. This is a well-studied problem (see [7], [14], [26], [33], and [43]). It is now well known that to obtain norm convergence for the Riccati equation, the approximation scheme must satisfy some form of convergence, dual convergence, and uniform preservation of stabilizability and detectability under mesh refinement (see [7] and [33]). These concepts will be made more precise in section 7.1. The important point here is that many “standard” convergent approximation schemes do not satisfy all the conditions necessary for norm convergence of the Riccati operators (see [16]). If this issue is ignored when one develops an approximation scheme for control design and optimization, then the resulting numerical algorithm can fail to produce accurate and useful results (see the numerical examples in section 9). In this paper we show that these properties are also key ingredients in establishing mesh independence of Newton-type algorithms.

The second important issue is concerned with the development of an effective algorithm for the numerical solution of the (large-scale) finite dimensional Riccati equations that arise once the problem has been discretized. During the past five years considerable attention has been devoted to the problem of developing accurate and fast numerical methods for control of large-scale systems. In 2004, the first issue of the *IEEE Control Systems Magazine* (Volume 24, Issue 1) was devoted to this topic. Much of the motivation for this emphasis comes from the fact that such systems often arise as discretizations of control problems with PDEs as the governing system. The observation that these large-scale finite dimensional Riccati equations come from discretizations of PDE control systems makes it possible to exploit special algorithms such as multigrid techniques (see [42] and [45]) and parallel iterative solvers (see [30]). Considerable progress has been made at this level by Benner and Saak (see [9] and [10]). Also, Grasedyck, Hackbusch, and Khoromskij (see [30] and the references therein) have developed impressive computational algorithms for Riccati and Lyapunov equations that arise in these cases. Many of these large-scale Riccati solvers are based on iterative algorithms.

It is impossible to address all the potential problems in constructing approximation schemes for optimal control of infinite dimensional systems in a single paper, so we limit our discussion to the well-studied linear quadratic optimal control problem and show how specific approximation assumptions are needed to address convergence and efficiency of an algorithm. In particular, we focus on convergence and mesh independence of the Kleinman–Newton algorithm for solving the operator Riccati equation defined by the linear quadratic regulator (LQR) problem. This problem is simple enough to allow for a rather complete analysis of convergence and mesh independence and yet complex enough to illustrate how both convergence and mesh independence might fail for perfectly good “standard” (convergent) numerical approximations.

**2. A short review of the mesh independence principle.** There are two basic aspects of the mesh independence principle (MIP) for Newton-type methods (see [1] and [2]). Roughly speaking, the MIP may be broken down into convergence under mesh refinement of the Newton iteration counts on a given mesh.

Let  $\mathcal{F} : D(\mathcal{F}) \subseteq E \longrightarrow E$  be a nonlinear operator on an infinite dimensional Hilbert space  $E$ , and consider the equation

$$(2.1) \quad \mathcal{F}(x) = 0.$$

Let  $E^N \subseteq E$  be a sequence of finite dimensional approximating spaces, and consider the sequence of discretized equations

$$(2.2) \quad \mathcal{F}^N(x^N) = 0,$$

where  $\mathcal{F}^N : D(\mathcal{F}^N) \subseteq E^N \longrightarrow E^N$ . In this paper we are interested in the problem of solving the Riccati operator equation associated with LQR feedback control of systems governed by delay and PDEs. In this setting, (2.1) is an infinite dimensional Riccati equation defined by a PDE control system, and (2.2) is an approximating Riccati equation obtained by some type of finite element or finite difference scheme applied to the PDE system. Here  $N$  is related to the size of the mesh used to define the discretized equations on a grid. Assume that (2.1) and (2.2) have unique solutions  $x_\infty \in D(\mathcal{F})$  and  $x_\infty^N \in D(\mathcal{F}^N)$ , respectively. We say that the *approximation scheme converges* if

$$(2.3) \quad \lim_{N \rightarrow +\infty} \|x_\infty^N - P^N x_\infty\|_{E^N} = 0,$$

where  $P^N : E \rightarrow E^N$  is the orthogonal projection of  $E$  onto  $E^N$ .

Now assume that one applies a Newton-type algorithm to the infinite dimensional problem (2.1) and that the same algorithm is also applied to the corresponding finite dimensional approximate problem (2.2). For the moment assume both schemes produce quadratically convergent iterations  $x_k$  and  $x_k^N$ ,  $k = 1, 2, \dots$ . For a given  $\varepsilon > 0$ ,  $x_0 \in D(\mathcal{F})$  and  $x_0^N \in D(\mathcal{F}^N)$  define the numbers  $M(\varepsilon, x_0)$  and  $M^N(\varepsilon, x_0^N)$  by

$$M(\varepsilon, x_0) \triangleq \inf\{k : \|x_k - x_\infty\| < \varepsilon\} \quad \text{and} \quad M^N(\varepsilon, x_0^N) \triangleq \inf\{k : \|x_k^N - x_\infty^N\|_{E^N} < \varepsilon\},$$

respectively. Here,  $x_0$  and  $x_0^N$  are the starting values for the iterations. The (strong) MIP (see Theorem 2.1 in [2]) takes the form

$$(2.4) \quad M(\varepsilon, x_0) = M^N(\varepsilon, P^N x_0) + \tau(N),$$

where  $\tau(N) \rightarrow 0$  as  $N \rightarrow +\infty$ . Also, assume there are constants  $c$  and  $c^N$  such that

$$(2.5) \quad \|x_{k+1} - x_\infty\| \leq c \|x_k - x_\infty\|^2$$

and

$$(2.6) \quad \|x_{k+1}^N - x_\infty^N\|_{E^N} \leq c^N \|x_k^N - x_\infty^N\|_{E^N}^2,$$

respectively. Let  $\hat{c}$  and  $\hat{c}^N$  be the minimal values of  $c$  and  $c^N$  that satisfy (2.5) and (2.6), where  $x_0^N = P^N x_0$ . As noted in [2], since  $P^N : E \rightarrow E^N$  is the orthogonal projection of  $E$  onto  $E^N$ , in some cases one can show that another form of the strong MIP is given by

$$(2.7) \quad \hat{c}^N = \hat{c} + \gamma(N),$$

where  $\gamma(N) \rightarrow 0$  as  $N \rightarrow +\infty$ . The basic idea behind these strong versions of mesh independence is that the number of iterations required to achieve a given error tolerance is independent of the mesh size and asymptotically converges to the number of infinite dimensional iterations (theoretically) required to attain the same tolerance. A weaker form of the MIP would require only that, if one has the estimates (2.5) and (2.6), then

$$(2.8) \quad c^N = c + \delta(N),$$

where  $\delta(N) \rightarrow 0$  as  $N \rightarrow +\infty$ . Although the constants  $c$  and  $c^N$  are not the minimal values, it follows that the number of iterations required to solve the discretized equations  $\mathcal{F}^N(x^N) = 0$  is essentially independent of the mesh size.

**3. Mesh independence for the infinite dimensional Riccati equation.** In this paper we focus on the case where the nonlinear function  $\mathcal{F} = \mathcal{F}(\Pi)$  is defined by an infinite dimensional Riccati operator equation of the form

$$(3.1) \quad \mathcal{F}(\Pi) = A^* \Pi + \Pi A - \Pi B B^* \Pi + C^* C = 0,$$

where  $A$  generates a strongly continuous semigroup on a Hilbert space  $H$ . Here  $\mathcal{F} : D(\mathcal{F}) \subseteq E \rightarrow E$ , where  $E$  is the space of bounded linear operators on  $H$ .

*Remark 3.1.* It is important to note that in most applications the operator  $A$  is unbounded, and even if the  $B$  and  $C$  operators are bounded, the nonlinear operator

$\mathcal{F}$  will not be continuous on its domain. Therefore,  $\mathcal{F}$  will not have a Lipschitz continuous Fréchet derivative, and the analysis used in [1] and [2] is not directly applicable. In particular, convergence proofs for the infinite dimensional Newton algorithm that depend on the existence of the Fréchet derivative cannot be used in this setting. As noted by Damm and Hinrichsen in [23], the existence of the Fréchet derivative can be relaxed if one works in ordered Banach spaces. Indeed, they provide a general convergence result under the blanket assumptions that  $E$  is ordered by a closed, solid, regular convex cone and that  $\mathcal{F}$  is continuous on its domain (see page 50 in [23]). Moreover, even when using the ordered space approach, we see that Fréchet differentiability was needed to obtain quadratic convergence of the Newton method (see page 56 in [23]). However, for the delay systems below (and other PDE control systems) these assumptions do not hold.

In the finite dimensional case, the “natural” space of operators is the set  $E = \mathcal{H}^n$  of  $n \times n$  Hermitian matrices with (Frobenius) trace norm. As noted in [23], if one uses the cone  $\mathcal{C} = \mathcal{H}_+^n = \{\Pi \in \mathcal{H}^n : \Pi \geq 0\}$ , then  $\mathcal{C}$  satisfies the blanket assumptions above. In an infinite dimensional setting, verifying these assumptions is nontrivial or impossible, depending on the choice of  $E$ . One might be tempted to use the infinite dimensional analogue and set  $E = \mathcal{H}$  to be the set of all trace class operators on the Hilbert space  $H$ . If the solution  $\Pi$  to (3.1) is not of trace class (see Example 1), then this is not a reasonable choice for  $E$ . Even if the solution is of trace class, one might still need to work in a larger space to develop practical approximation schemes for numerical solutions. In this setting, if  $E = \mathcal{L}(H, H)$  is the space of bounded linear operators on  $H$  and one sets  $\mathcal{C} = \mathcal{H}_+ = \{\Pi \in \mathcal{H} : \Pi \geq 0\}$  to be the cone of nonnegative definite trace operators, then  $\mathcal{C}$  is not solid. Hence, a direct application of the results in [23] is not possible.

In the case when the nonlinear equation (3.1) is a Riccati equation defining an LQR controller, it is possible to extend the finite dimensional proof of Mehrmann in [40] to a rather general class of infinite dimensional problems. We take this approach and present a complete convergence proof for the infinite dimensional Kleinman–Newton algorithm in the space  $E = \mathcal{L}(H, H)$ . Although this proof is similar in spirit to the results in [40], there are some technical details that require attention. Moreover, this approach provides explicit bounds and estimates that we later use to establish mesh independence. This is another reason we do not use the approach in [23] based on ordered spaces. The following example illustrates that even if  $A$ ,  $B$ , and  $C$  are bounded, the solution to the operator Riccati equation (3.1) does not have to be of trace class. Later we shall use this example to illustrate the importance of the compactness assumptions.

*Example 1.* Let  $H = \mathbb{R} \times L^2$ , and define the operators  $A$ ,  $B$ , and  $C$  on  $H$  by

$$A = \begin{bmatrix} -1 & 0 \\ 0 & -I \end{bmatrix}, \quad B = \begin{bmatrix} 1 & 0 \end{bmatrix}^T, \quad \text{and} \quad C = \begin{bmatrix} \sqrt{3} & 0 \\ 0 & \sqrt{2}I \end{bmatrix},$$

respectively. Here  $I$  is the identity on  $L^2$ . By direct computation it follows that

$$\Pi = \begin{bmatrix} 1 & 0 \\ 0 & I \end{bmatrix}$$

is the solution to the Riccati equation (3.1). Since the identity operator is not compact,  $\Pi$  is not of trace class. On the other hand, for this simple example,  $\mathcal{F}$  is continuously Fréchet differentiable, and convergence of the infinite dimensional Kleinman–Newton algorithm follows directly from [1] and [2].

It is well known that under very mild conditions on the LQR problem, and assuming that the discretization scheme preserves the basic control system properties, both (2.1) and (2.2) have unique solutions in the set of nonnegative self-adjoint bounded linear operators. The issues to be resolved are as follows:

- (i) What conditions must be placed on the discretization scheme to guarantee that the solutions to the approximating equations (2.2) converge *in norm* to the solution of the infinite dimensional problem (2.1)? In some sense this is a classic numerical analysis problem. However, for the Riccati equation (3.1), the conditions for norm convergence are nontrivial and the best results are stated in terms of control system properties.
- (ii) Does the infinite dimensional Kleinman–Newton algorithm converge quadratically when applied to the infinite dimensional operator Riccati equation? As noted above, there are several approaches to this question. For applications to delay and PDE systems, our approach offers explicit bounds which are helpful in establishing mesh independence, and this approach does not require continuity of  $\mathcal{F}$ .
- (iii) Finally, what conditions must be placed on the discretization scheme to guarantee that the Kleinman–Newton algorithm satisfies MIP estimates of the form (2.4), (2.7), or (2.8)?

In this paper we focus on these issues. First, we give a brief review of what is known about convergence of discretization schemes for the infinite dimensional LQR control problem.

**4. A summary of approximation results for LQR control.** Most of the numerical schemes for approximating systems governed by PDEs developed during the past 50 years focused on methods that provided convergent and efficient simulations. However, the LQR problem is an optimal control problem on an infinite time interval, and it is possible to clearly identify two additional requirements that need to be placed on an approximation scheme to ensure convergence of the control design. Moreover, we shall show that these requirements also play a role in determining mesh independence of the Kleinman–Newton algorithm. In particular, dual convergence and preservation of exponential stability (POES) play central roles in both convergence and mesh independence. The POES condition was first introduced by Banks and Kunisch in [7] as a technical assumption needed to establish strong convergence of the Riccati operators for parabolic PDE control problems. This condition is equivalent to the uniform stabilizability defined in Assumption 7.3 below. In some cases one can relax the POES assumption and still obtain strong (and even norm) convergence of the Riccati operators. For example, the spline scheme developed for delay systems by Kappel and Salamon in [36] produced convergent Riccati operators even though POES was not satisfied (see [35] and [37]). Kappel and Salamon replaced the POES assumption with a uniform output and input-output stability condition and proved strong convergence of the Riccati operators. Ito [33], [34] used the version given in Assumption 7.3 to establish norm convergence. We will say more about this when we discuss the numerical results below.

In 1969 Sasai and Shimemura [47] was among the first researchers to recognize the importance of dual convergence for infinite dimensional LQR problems (also see [46] and [48]). Gibson (see [27], [28], [29]) established a general framework for developing approximation schemes for LQR problems and applied his results to control systems governed by delay and hyperbolic PDEs. If one is interested only in weak convergence of the functional gains, then dual convergence may not be essential (see [24] and

[25]). However, as observed in [8] and [13], weak convergence may not be sufficient for practical design, and, as shown in [16], not all standard schemes yield dual convergent algorithms. In particular, the finite element scheme developed in [5] is not dual convergent and does not produce strongly convergent functional gains.

At this point, there is no general method that can address the issue of dual convergence. However, for delay systems, two approaches have emerged. The first method is based on constructing numerical schemes that are dual convergent. The excellent survey by Kappel [35] focuses on this approach. A second approach is based on constructing separate numerical schemes for the forward problem and the dual problem. This is the approach carried out for delay equations by Germani, Manes, and Pepe in the paper [26]. It is important to note that extending any of these methods to other types of PDE-based systems is not a trivial exercise.

The key point here is that in order to develop numerical schemes for control of infinite dimensional systems, one must first ensure that certain control system properties are preserved under the approximation. Once this issue is resolved, it is important to consider the problem of numerically solving the finite dimensional problem. In particular, it is possible to construct several numerical schemes that preserve the required control system properties (stabilizability, detectability, etc.), but the resulting finite dimensional control problems may differ dramatically in conditioning and computational complexity.

In this paper we focus on an iterative method for solving the Riccati equations associated with LQR problems. We show that the infinite dimensional Kleinman–Newton iterations converge to the Riccati operator for the infinite dimensional problem, and we investigate mesh independence. Although the basic ideas used in the proof are similar to those found in papers on the finite dimensional problem, there are certain estimates that provide insight into general connections between preservation of control system properties, convergence, and mesh independence. These results provide a framework that can be employed to analyze specific finite dimensional approximations. We close with an application of these results to delay systems and a discussion of the averaging schemes found in [3] and [16] and the spline/finite element schemes given in [4], [5], and [8].

As noted above, the MIP does not make sense unless one has *norm convergence* of the discretized Riccati operators. It is known (see [16]) that the spline/finite element scheme for delay systems given in [5] does not produce norm convergent Riccati operators. This problem can also be seen in the much simpler Example 2 given in section 7.1 below.

**5. Problem setting and basics.** We consider the following LQR problem in an abstract Hilbert space setting. Let  $U$ ,  $H$ , and  $Y$  be Hilbert spaces over the reals. If  $Z$  and  $W$  are any two Hilbert spaces, then we denote by  $\mathcal{L}(Z, W)$  the linear space of linear bounded operators from  $Z$  into  $W$ . In the special case where  $W = Z$ , we set  $\mathcal{L}(Z) = \mathcal{L}(Z, Z)$ . The system equation is given in state space form by

$$(5.1) \quad \dot{z}(t) = Az(t) + Bu(t), \quad t \geq 0, \quad z(0) = z_0 \in H,$$

where  $A$  generates a strongly continuous semigroup on  $H$  and  $B \in \mathcal{L}(U, H)$ .

The assumption that  $B \in \mathcal{L}(U, H)$  implies we are considering only bounded input operators. Let  $C \in \mathcal{L}(H, Y)$ , and define the quadratic cost function  $J(u)$  by

$$(5.2) \quad J(u) = \int_0^\infty (\|Cz(s)\|^2 + \|u(s)\|^2) ds,$$

where  $z(s)$  is the solution to (5.1) for a given control  $u \in L^2(0, \infty; U)$ . The LQR control problem is to minimize the quadratic cost  $J(u)$  over all controls  $u \in L^2(0, \infty; U)$ .

It is well known (see [11], [12]) that under certain assumptions, the optimal control is given by state feedback  $u_{opt} = -Kz(t)$ , where

$$(5.3) \quad K = B^*X,$$

and  $X \in \mathcal{L}(H)$  is a solution of an abstract algebraic Riccati operator equation of the form

$$(5.4) \quad A^*X + XA - XBB^*X + C^*C = 0.$$

In order to formulate an abstract Newton method for solving this nonlinear operator equation in  $\mathcal{L}(H)$ , we first have to specify the appropriate mappings. Let  $\Sigma(H) = \{\Pi \in \mathcal{L}(H) : \Pi \text{ self-adjoint}\}$  be the space of self-adjoint bounded linear operators on  $H$ , and let  $\Sigma^+(H) = \{\Pi \in \Sigma(H) : (\Pi x, x) \geq 0 \text{ for all } x \in H\}$  denote the subspace of nonnegative operators in  $\Sigma(H)$ .

Since  $A$  is an unbounded operator in (5.4), we define a map  $\mathcal{A}$  which can be formally written as  $\mathcal{A}(\Pi) = A^*\Pi + \Pi A$  and can be defined rigorously as in [12, page 151]. In particular, for a given  $\Pi \in \Sigma(H)$ , set

$$\phi_\Pi(x, y) = (\Pi x, Ay) + (Ax, \Pi y), \quad x, y \in D(A),$$

and define

$$D(\mathcal{A}) = \{\Pi \in \Sigma(H) : \phi_\Pi \text{ can be extended to a continuous sesquilinear operator on } H \times H\}.$$

This unique extension of  $\phi_\Pi$  as a continuous sesquilinear form on  $H \times H$  will also be denoted by  $\phi_\Pi$ . For each  $\Pi \in D(\mathcal{A})$ , one can define a linear operator, denoted by  $\mathcal{A}(\Pi) \in \Sigma(H)$ , by the identity

$$(5.5) \quad (\mathcal{A}(\Pi)x, y) = \phi_\Pi(x, y) = (\Pi x, Ay) + (Ax, \Pi y), \quad x, y \in D(A), \quad \Pi \in D(\mathcal{A}).$$

Therefore, we have defined a linear operator  $\mathcal{A} : D(\mathcal{A}) \subset \Sigma(H) \rightarrow \Sigma(H)$ , and in [12, page 152], it is shown that for  $\Pi \in D(\mathcal{A})$  and  $x \in D(A)$  one has  $\Pi x \in D(A^*)$  and

$$(5.6) \quad \mathcal{A}(\Pi)x = A^*\Pi x + \Pi Ax.$$

The previous notation allows us to precisely define a solution of the abstract Riccati operator equation.

**DEFINITION 5.1.** *The bounded linear operator  $X$  is called a strict solution of the Riccati equation (5.4) if  $X \in D(\mathcal{A})$  and*

$$(5.7) \quad \mathcal{A}(X) - XBB^*X + C^*C = 0.$$

*The bounded linear operator  $X$  is called a weak solution of the Riccati equation (5.4) if  $X \in D(\mathcal{A})$  and*

$$(5.8) \quad (Xx, Ay) + (Ax, Xy) - (B^*Xx, B^*Xy) + (Cx, Cy) = 0, \quad x, y \in D(A).$$

It is shown on page 262 in [12] that for  $X \in \Sigma^+(H)$  a strict solution is equivalent to a weak solution of (5.4). Although we might use the notation of the operator equation, in this paper we deal with weak solutions. The existence and uniqueness of

solutions to the Riccati operator equation are not necessarily guaranteed. We follow the definitions and notation in [12].

DEFINITION 5.2. (i) *The system  $(A, B)$  is called stabilizable if there exists a bounded linear operator  $K : H \rightarrow U$  such that  $(A - BK)$  generates an exponentially stable  $C_0$ -semigroup on  $H$ .*

(ii) *The pair  $(A, C)$  is called detectable if there exists a bounded linear operator  $F : Y \rightarrow X$  such that  $(A + FC)$  generates an exponentially stable  $C_0$ -semigroup on  $H$ .*

Since  $B$  and  $C$  are bounded, the following theorem follows from [11, Part III, Prop. 2.3, Prop. 3.2, and Cor. 4.2].

THEOREM 5.3. *If  $(A, B)$  is stabilizable, then there exists a minimal solution  $X_{\min} \in \Sigma^+(H)$  of the Riccati equation (5.8). If, in addition,  $(A, C)$  is detectable, then  $A - BB^*X_{\min}$  generates an exponentially stable semigroup and  $X_{\min}$  is the unique solution of the Riccati equation (5.8) in  $\Sigma^+(H)$ .*

In the Newton iteration, we will see that the Newton steps are defined by the solutions of a generalized Lyapunov equation. Therefore, we recall a few facts about Lyapunov equations in Hilbert spaces. The following result is found on pages 19–28 in [11].

THEOREM 5.4. *Let  $S(\cdot)$  denote a strongly continuous semigroup on a Hilbert space  $H$  with an infinitesimal generator  $A$ . Then the following statements are equivalent.*

(i) *The semigroup  $S(\cdot)$  is exponentially stable; i.e., there exist  $\omega > 0$  and  $M \geq 1$  such that*

$$(5.9) \quad \|S(t)x\| \leq Me^{-\omega t}\|x\| \quad \text{for all } x \in H, \quad t \geq 0.$$

(ii) *There exists a positive  $P \in \Sigma^+(H)$  such that*

$$(5.10) \quad (Px, Ay) + (Ax, Py) + (x, y) = 0, \quad x, y \in D(A).$$

When applying Newton's method, we obtain Lyapunov equations that are more general where the identity term  $(x, y)$  is replaced by a more general term  $(x, Qy)$  with possible nonnegativity or positivity properties. However, from the representation formula for solutions of Lyapunov equations, one can establish the following result (see [22, page 252]).

THEOREM 5.5. *Let  $S(\cdot)$  denote a strongly continuous semigroup on a Hilbert space  $H$  with an infinitesimal generator  $A$ . If  $S(\cdot)$  is exponentially stable and  $Q \in \Sigma(H)$ , then there exists a unique solution  $X \in \Sigma(H)$  of*

$$(5.11) \quad (Xx, Ay) + (Ax, Xy) + (x, Qy) = 0, \quad x, y \in D(A).$$

Moreover,  $X$  has the representation

$$(5.12) \quad X = \int_0^\infty S^*(t)QS(t)dt,$$

and if  $Q \in \Sigma^+(H)$ , then  $X \in \Sigma^+(H)$ .

**6. The Kleinman–Newton method in Hilbert space.** In this section we define the Kleinman–Newton algorithm and establish convergence. Throughout this section we make the following assumption.

ASSUMPTION 6.1. *Let  $A$  be the infinitesimal generator of a semigroup on  $H$ ,  $B \in \mathcal{L}(U, H)$ , and  $C \in \mathcal{L}(H, Y)$ . We assume that*

- (i) the system  $(A, B)$  is stabilizable and the pair  $(A, C)$  is detectable, and
- (ii) an operator  $X_0 \in \Sigma^+(H)$  is given such that  $A - BB^*X_0$  generates an exponentially stable semigroup on  $H$ .

We solve the abstract algebraic equation (5.7) by Newton's method. We seek a bounded linear operator  $X \in D(\mathcal{A})$ , which provides a solution to the Riccati equation  $\mathcal{F}(X) = 0$  where the nonlinear mapping  $\mathcal{F} : D(\mathcal{A}) \subset \Sigma(H) \rightarrow \Sigma(H)$  is defined by

$$(6.1) \quad \mathcal{F}(X) = \mathcal{A}(X) - XBB^*X + C^*C.$$

In particular, we look for weak solutions to the equation  $\mathcal{F}(X) = 0$  as defined by (5.8).

Formally applying Newton's method to  $\mathcal{F}(X) = 0$  leads to the iteration

$$(6.2) \quad \begin{aligned} &\mathcal{A}(X_{k+1} - X_k) - X_kBB^*(X_{k+1} - X_k) - (X_{k+1} - X_k)BB^*X_k \\ &+ \mathcal{A}(X_k) - X_kBB^*X_k + C^*C = 0, \end{aligned}$$

or equivalently,

$$(6.3) \quad \mathcal{A}(X_{k+1}) - X_kBB^*X_{k+1} - X_{k+1}BB^*X_k + X_kBB^*X_k + C^*C = 0.$$

After rearranging some terms, it follows that the weak formulation of this scheme has the form

$$(6.4) \quad \begin{aligned} &(X_{k+1}x, (A - BB^*X_k)y) + ((A - BB^*X_k)x, X_{k+1}y) \\ &= -(B^*X_kx, B^*X_ky) - (Cx, Cy), \quad x, y \in D(A). \end{aligned}$$

In what follows we will establish the following convergence theorems for Newton's method. We split up the statements into three parts according to the tools being used in the proof. We follow the structure of the proof for the finite dimensional case given in [40] (see pages 91–94).

**THEOREM 6.2.** *If Assumption 6.1 holds, then*

- (i) the Newton iteration (6.4) is well defined and has a unique solution  $X_k \in \Sigma^+(H)$ ,  $k = 1, 2, \dots$ , and
- (ii) the closed-loop operators  $A - BB^*X_k$ ,  $k = 1, 2, \dots$ , generate exponentially stable semigroups  $S_k(t)$ .

*Proof.* Let us assume, by induction, that  $X_k \in \Sigma^+(H)$  is such that  $A - BB^*X_k$  generates an exponentially stable semigroup  $S_k(t)$ . In particular, there exist  $M_k \geq 1$  and  $\omega_k > 0$  such that

$$(6.5) \quad \|S_k(t)\| \leq M_k e^{-\omega_k t}.$$

Theorem 5.5 applied to equation (6.4) yields the existence of the next iterate,  $X_{k+1} \in \Sigma^+(H)$ . By adding and subtracting terms involving  $X_{k+1}$  and reordering, (6.4) can now be rewritten as

$$(6.6) \quad \begin{aligned} &(X_{k+1}x, (A - BB^*X_{k+1})y) + ((A - BB^*X_{k+1})x, X_{k+1}y) \\ &= -(B^*X_{k+1}x, B^*X_{k+1}y) - (Cx, Cy) \\ &\quad - (B^*(X_{k+1} - X_k)x, B^*(X_{k+1} - X_k)y), \quad x, y \in D(A). \end{aligned}$$

From (6.6) the operator  $X_{k+1}$  can be viewed as a solution  $X_{k+1} \in \Sigma^+(H)$  of a Lyapunov equation of the form (5.11) with the infinitesimal generator  $A - BB^*X_{k+1}$  of a semigroup denoted by  $S_{k+1}(t)$ . Since  $X_{k+1}$  exists, we define

$$V(t, z) := (X_{k+1}S_{k+1}(t)z, S_{k+1}(t)z), \quad z \in D(A - BB^*X_{k+1}).$$

It follows from (6.6) that  $\frac{dV}{dt}(t, z) = -\Phi(t)$ , where

$$\Phi(t) = \|B^*X_{k+1}S_{k+1}(t)z\|^2 + \|CS_{k+1}(t)z\|^2 + \|B^*(X_{k+1} - X_k)S_{k+1}(t)z\|^2.$$

Since  $X_{k+1} \in \Sigma^+(H)$ , an integration of the previous equation yields

$$\int_0^t \Phi(s) ds = V(0, z) - V(t, z) \leq V(0, z)$$

for all  $t > 0$  and  $z \in D(A - BB^*X_{k+1})$ . The domain  $D(A - BB^*X_{k+1})$  is dense in  $H$ , which implies that for all  $z \in H$  there is a constant  $c_z$  such that

$$(6.7) \quad \int_0^\infty \|B^*(X_{k+1} - X_k)S_{k+1}(t)z\|^2 dt \leq \int_0^\infty \Phi(t) dt \leq c_z.$$

Set  $A_k = A - BB^*X_k$  so that  $A_{k+1} = A - BB^*X_{k+1} = A_k + BB^*(X_k - X_{k+1})$ . Observe that  $z_{k+1}(t) = S_{k+1}(t)z$  is the solution of

$$\dot{z}_{k+1}(t) = A_{k+1}z_{k+1}(t) = A_k z_{k+1}(t) + BB^*(X_k - X_{k+1})z_{k+1}(t), \quad z_{k+1}(0) = z,$$

and is given by

$$z_{k+1}(t) = S_k(t)z + \int_0^t S_k(t-s)BB^*(X_k - X_{k+1})z_{k+1}(s)ds.$$

Using the assumption that  $S_k(t)$  is exponentially stable so that (6.5) holds, we have

$$\begin{aligned} \|z_{k+1}(t)\| &\leq \|S_k(t)z\| + \int_0^t \|S_k(t-s)\| \|BB^*(X_k - X_{k+1})z_{k+1}(s)\| ds \\ &\leq M_k e^{-\omega_k t} \|z\| + M_k \|B\| \int_0^t e^{-\omega_k(t-s)} \|B^*(X_k - X_{k+1})\| \|z_{k+1}(s)\| ds. \end{aligned}$$

Gronwall's inequality, together with (6.7), yields

$$\int_0^\infty \|S_{k+1}(t)z\|^2 dt = \int_0^\infty \|z_{k+1}(t)\|^2 dt \leq c_z, \quad z \in D(A - BB^*X_{k+1}).$$

By density this holds for all  $z \in H$ , and by Theorem 5.1.2 in [22] we obtain that  $S_{k+1}$  is an exponentially stable semigroup. This concludes the induction step and the proof.  $\square$

**THEOREM 6.3.** *If Assumption 6.1 holds, then*

- (i) *the sequence  $X_k$  converges in  $\Sigma^+(H)$  and  $\lim_{k \rightarrow \infty} X_k = X_\infty \in \Sigma^+(H)$ . Moreover,  $X_\infty$  is a weak solution to  $\mathcal{F}(X_\infty) = 0$ ;*
- (ii) *the closed-loop operator  $A - BB^*X_\infty$  generates an exponentially stable semigroup  $S_\infty(t)$  satisfying*

$$(6.8) \quad \|S_\infty(t)\| \leq M e^{-\omega t}$$

*for constants  $M \geq 1$  and  $\omega > 0$ ;*

- (iii) *the Newton iterates satisfy  $0 \leq X_\infty \leq \cdots \leq X_{k+1} \leq X_k \leq \cdots \leq X_1$ .*

*Proof.* If we increase the index in (6.4) by one, we obtain

$$\begin{aligned} (X_{k+2}x, (A - BB^*X_{k+1}y)) + ((A - BB^*X_{k+1})x, X_{k+2}y) \\ = -(B^*X_{k+1}x, B^*X_{k+1}y) - (Cx, Cy), \quad x, y \in D(A). \end{aligned}$$

Subtracting this from (6.6) yields

$$(6.9) \quad \begin{aligned} & ((X_{k+1} - X_{k+2})x, (A - BB^*X_{k+1}y)) + ((A - BB^*X_{k+1})x, (X_{k+1} - X_{k+2})y) \\ & = -(B^*(X_{k+1} - X_k)x, (B^*(X_{k+1} - X_k)y)), \quad x, y \in D(A). \end{aligned}$$

We can infer from Theorem 5.5 that  $X_{k+1} - X_{k+2} \geq 0$ ,  $k = 0, 1, 2, \dots$

Therefore  $X_k \in \Sigma^+(H)$  is a sequence of operators which is decreasing and bounded from below by 0. By [39, page 282], there exists an  $X_\infty \in \Sigma^+(H)$  with

$$\lim_{k \rightarrow +\infty} X_k x = X_\infty x \quad \text{for all } x \in H.$$

Passing to the limit in (6.4), we deduce that  $X_\infty$  satisfies the Riccati equation (5.8) in its weak form, and hence  $\mathcal{F}(X_\infty) = 0$ . Theorem 5.3 implies that the solution  $X_\infty$  is unique, and by Assumption 6.1,  $A - BB^*X_\infty$  generates an exponentially stable semigroup.  $\square$

THEOREM 6.4. *If Assumption 6.1 holds, then for all  $k = 0, 1, 2, \dots$ ,*

$$\|X_{k+1} - X_\infty\| \leq c\|X_k - X_\infty\|^2,$$

where

$$c = \int_0^\infty \|S_\infty^*(t)\| \|BB^*\| \|S_\infty(t)\| dt \leq \frac{M^2}{2\omega} \|BB^*\|$$

and the constants  $M \geq 1$  and  $\omega > 0$  are given by (6.8).

*Proof.* By (6.3), the limit operator  $X_\infty$  satisfies the equation

$$(6.10) \quad \mathcal{A}(X_\infty) - X_\infty BB^*X_\infty + C^*C = 0.$$

To shorten notation in the rest of the proof, all the equations are to be understood in the weak sense. Equation (6.10) can be rewritten as

$$(6.11) \quad \begin{aligned} & (A - BB^*X_{k+1})^*X_\infty + X_\infty(A - BB^*X_{k+1}) \\ & = -X_\infty BB^*X_\infty - C^*C + (X_\infty - X_{k+1})BB^*X_\infty + X_\infty BB^*(X_\infty - X_{k+1}). \end{aligned}$$

If we subtract (6.6) from (6.11), we obtain

$$(6.12) \quad \begin{aligned} & (A - BB^*X_{k+1})^*(X_\infty - X_{k+1}) + (X_\infty - X_{k+1})(A - BB^*X_{k+1}) \\ & = X_\infty BB^*X_\infty - X_{k+1} BB^*X_\infty - X_\infty BB^*X_{k+1} + X_{k+1} BB^*X_{k+1} \\ & \quad + (X_{k+1} - X_k)BB^*(X_{k+1} - X_k) \\ & = (X_\infty - X_{k+1})BB^*(X_\infty - X_{k+1}) + (X_{k+1} - X_k)BB^*(X_{k+1} - X_k). \end{aligned}$$

This implies that

$$(6.13) \quad \begin{aligned} & (A - BB^*X_\infty)^*(X_\infty - X_{k+1}) + (X_\infty - X_{k+1})(A - BB^*X_\infty) \\ & = -(X_\infty - X_{k+1})BB^*(X_\infty - X_{k+1}) + (X_{k+1} - X_k)BB^*(X_{k+1} - X_k). \end{aligned}$$

Note that  $\Delta = X_\infty - X_{k+1}$  is the solution to the Lyapunov equation

$$(A_\infty)^* \Delta + \Delta(A_\infty) = -\hat{Q},$$

where

$$\hat{Q} = (X_\infty - X_{k+1})BB^*(X_\infty - X_{k+1}) - (X_{k+1} - X_k)BB^*(X_{k+1} - X_k)$$

and  $A_\infty = A - BB^*X_\infty$  generates the exponentially stable semigroup  $S_\infty(t)$ . It follows from (5.12) in Theorem 5.5 above that the representation formula in Corollary 4.2 of [28] can be used to derive the following:

(6.14)

$$\begin{aligned} 0 \leq X_{k+1} - X_\infty &= \int_0^\infty S_\infty^*(t) \{ -(X_\infty - X_{k+1})BB^*(X_\infty - X_{k+1}) \\ &\quad + (X_{k+1} - X_k)BB^*(X_{k+1} - X_k) \} S_\infty(t) dt \\ &\leq \int_0^\infty S_\infty^*(t) ((X_{k+1} - X_k)BB^*(X_{k+1} - X_k)) S_\infty(t) dt. \end{aligned}$$

Taking norms and using the fact that, for self-adjoint operators,  $\|S\| = \sup_{\|x\| \leq 1} (x, Sx)$ , we obtain

(6.15)

$$\|X_{k+1} - X_\infty\| \leq \|X_{k+1} - X_k\|^2 \int_0^\infty \|S_\infty^*(t)\| \|BB^*\| \|S_\infty(t)\| dt = c \|X_{k+1} - X_k\|^2,$$

where

(6.16)

$$c = \int_0^\infty \|S_\infty^*(t)\| \|BB^*\| \|S_\infty(t)\| dt = \|BB^*\| \int_0^\infty \|S_\infty^*(t)\| \|S_\infty(t)\| dt \leq \frac{M^2}{2\omega} \|BB^*\|$$

follows from (6.8). Since all the operators are self-adjoint, we have

$$0 \leq X_k - X_{k+1} \leq X_k - X_\infty \quad \Rightarrow \quad \|X_k - X_{k+1}\| \leq \|X_k - X_\infty\|,$$

which implies the quadratic rate of convergence

$$\|X_{k+1} - X_\infty\| \leq c \|X_k - X_\infty\|^2. \quad \square$$

**7. Approximation and mesh independence results.** In this section we focus on the problem of developing numerical schemes that yield convergent and mesh-independent approximations of the infinite dimensional Riccati equation

$$\mathcal{F}(X) = \mathcal{A}(X) - XBB^*X + C^*C = 0,$$

where  $BB^*, CC^* \in \mathcal{L}(H)$  and  $\mathcal{A} : D(\mathcal{A}) \subset \Sigma(H) \rightarrow \Sigma(H)$  is defined as in section 5 by  $\mathcal{A}(\Pi)x = A^*\Pi x + \Pi Ax$ . Although it is possible to work in a very abstract setting, we use the approximation setup found in Ito's paper [33]. The resulting framework is general enough to handle a large class of problems and helps us keep the technical discussion to a minimum.

We consider a sequence of approximating problems defined by  $(H^N, A^N, B^N, C^N)$ , where  $H^N \subset H$  is a sequence of finite dimensional subspaces of  $H$ , and  $A^N \in$

$\mathcal{L}(H^N, H^N)$ ,  $B^N \in \mathcal{L}(U, H^N)$ , and  $C^N \in \mathcal{L}(H^N, Y)$  are bounded linear operators. Let  $P^N : H \rightarrow H^N$  denote the orthogonal projection of  $H$  onto  $H^N$  satisfying  $\|P^N\| \leq 1$ , and as  $N \rightarrow \infty$  we have  $\|P^N x - x\| \rightarrow 0$  for all  $x \in H$ . Note that if  $T^N$  is any bounded linear operator on  $H^N$ , i.e.,  $T^N \in \mathcal{L}(H^N, H^N)$ , then  $T^N P^N$  belongs to  $\mathcal{L}(H, H^N)$  and the operator norms satisfy

$$\|T^N\|_{\mathcal{L}(H^N, H^N)} = \|T^N P^N\|_{\mathcal{L}(H, H^N)}.$$

Therefore, we can use the notation  $\|T^N\| = \|T^N P^N\|$  without referring to the specific spaces.

Define the finite dimensional approximations for  $\mathcal{A}$ ,

$$\mathcal{A}^N : \Sigma(H^N) \rightarrow \Sigma(H^N), \quad N = 1, 2, \dots,$$

by

$$\mathcal{A}^N(\Pi^N) = [A^N]^* \Pi^N + \Pi^N A^N.$$

The resulting approximating Riccati equation becomes

$$(7.1) \quad \mathcal{F}^N(X^N) = \mathcal{A}^N(X^N) - X^N B^N (B^N)^* X^N + (C^N)^* C^N = 0.$$

In this section we distinguish between two types of sequences. Let  $X_k \in \mathcal{L}(H)$  denote the iterates of the Newton method for the infinite dimensional Riccati equation  $\mathcal{F}(X) = 0$ . Likewise,  $X_k^N \in \mathcal{L}(H^N)$  denotes the iterates of the Newton method for the discretized Riccati equation  $\mathcal{F}^N(X^N) = 0$ .

We first review the conditions on the approximating scheme  $(H^N, A^N, B^N, C^N)$  which are sufficient to guarantee that the approximating Riccati equation (7.1) admits a unique nonnegative solution  $X_\infty^N$ , and  $X_\infty^N P^N$  converges to the unique nonnegative solution  $X_\infty$  of the operator Riccati equation (6.1). These results can be found in Ito's paper [33]. We then focus on the issue of mesh independence for the Kleinman-Newton algorithm and present convergence rates.

**7.1. Convergence of approximating Riccati operators.** In order to discuss convergence of the finite dimensional approximating Riccati operators, we need to assume that the numerical scheme preserves the basic stabilizability and detectability conditions needed to guarantee that the LQR problem is well-posed. It is important to note that even standard numerical schemes may not preserve these important control system properties. However, for the delay systems considered below it is known that all of the schemes discussed in Kappel's survey [35] satisfy these conditions (see [15], [18], [19], and [28]). Moreover, as we see below, although these conditions are sufficient for the finite dimensional Newton iterates to converge, they do not guarantee that the limit of the Newton iterates  $X_\infty^N$  converges to  $X_\infty$  as  $N \rightarrow +\infty$ . We shall need additional properties on the approximating sequence  $(H^N, A^N, B^N, C^N)$ . We break these assumptions into three distinct hypotheses concerning the convergence of the operators, convergence of the adjoint operators, and preservation of uniform stabilizability/detectability under the approximation.

**ASSUMPTION 7.1 (convergence).** Assume that there is an  $N_s$  such that for all  $N > N_s$  the following conditions hold:

(C-i) For each  $x \in H$ ,  $S^N(t)P^N x \rightarrow S(t)x$  and the convergence is uniform in  $t$  on bounded subintervals of  $[0, +\infty)$ .

(C-ii) For each  $u \in U$ ,  $B^N u \rightarrow Bu$ , and for each  $x \in H$ ,  $C^N P^N x \rightarrow Cx$ .

ASSUMPTION 7.2 (dual convergence). Assume that there is an  $N_s$  such that for all  $N > N_s$  the following conditions hold:

(C\*-i) For each  $x \in H$ ,  $[S^N(t)]^* P^N x \longrightarrow S^*(t)x$  and the convergence is uniform in  $t$  on bounded subintervals of  $[0, +\infty)$ .

(C\*-ii) For each  $x \in H$ ,  $[B^N]^* P^N x \longrightarrow B^* x$ , and for each  $y \in Y$ ,  $[C^N]^* y \longrightarrow C^* y$ .

ASSUMPTION 7.3 (uniformly stabilizable and detectable). Assume that there is an  $N_s$  such that for all  $N > N_s$  the following conditions hold:

(US) The family of pairs  $(A^N, B^N)$  is uniformly stabilizable; i.e., there exist a sequence of operators  $K^N \in \mathcal{L}(H^N, U)$  and positive constants  $M_1 \geq 1$ ,  $\omega_1 > 0$  such that  $\sup \|K^N\| < +\infty$  and the semigroups  $e^{(A^N - B^N K^N)t}$  generated by closed-loop operators  $A^N - B^N K^N$  satisfy

$$\|e^{(A^N - B^N K^N)t} P^N\| \leq M_1 e^{-\omega_1 t}, \quad t \geq 0.$$

(UD) The family of pairs  $(A^N, C^N)$  is uniformly detectable; i.e., there exist a sequence of operators  $G^N \in \mathcal{L}(Y, H^N)$  and positive constants  $M_2 \geq 1$ ,  $\omega_2 > 0$  such that  $\sup \|G^N\| < +\infty$  and the semigroups  $e^{(A^N - G^N C^N)t}$  generated by closed-loop operators  $A^N - G^N C^N$  satisfy

$$\|e^{(A^N - G^N C^N)t} P^N\| \leq M_2 e^{-\omega_2 t}, \quad t \geq 0.$$

The following results may be found in [33, Theorems 2.1 and 2.2].

THEOREM 7.4. If Assumptions 7.1, 7.2, and 7.3 hold, then for all  $N > N_s$  the Riccati equation (7.1) admits a unique nonnegative solution  $X_\infty^N$ ,  $\sup \|X_\infty^N\| < +\infty$ , and there exist positive constants  $M_3 \geq 1$ ,  $\omega_3 > 0$  (independent of  $N$ ) such that the closed-loop semigroups  $S_\infty^N(t)$  generated by operators  $(A^N - B^N [B^N]^* X_\infty^N)$  satisfy

$$(7.2) \quad \|S_\infty^N(t)\| = \|S_\infty^N(t) P^N\| \leq M_3 e^{-\omega_3 t}, \quad t \geq 0.$$

THEOREM 7.5. If  $(A, B)$  is stabilizable,  $(A, C)$  is detectable, and Assumptions 7.1, 7.2, and 7.3 hold, then the unique nonnegative solutions  $X_\infty^N$  to the Riccati equation (7.1) converge strongly to  $X_\infty$ . Moreover, the closed-loop semigroups  $S_\infty^N(t)$  converge strongly to the closed-loop semigroup  $S_\infty(t)$  and

$$(7.3) \quad \|S_\infty(t)\| \leq M_3 e^{-\omega_3 t}, \quad t \geq 0.$$

Note that the previous results yield only strong convergence of the solutions of the Riccati equations. However, if  $B$  is bounded with finite dimensional range, then strong convergence of  $X_\infty^N$  to  $X_\infty$  implies norm convergence of the feedback gain operators. In particular, if  $\text{rank}(B) < +\infty$ , then

$$(7.4) \quad \lim_{N \rightarrow +\infty} \|K^N - K\| = 0,$$

where  $K^N = [B^N]^* X_\infty^N$  (see Theorems 6.2 and 6.8 in [28]). Moreover, under certain compactness assumptions on  $B$  and  $C$ , one can establish norm convergence of the Riccati operators. There are a number of results along this line (see [24], [28], [33], [34], [43], and [44]) and some make use of the smoothing property of the semigroup (e.g., analytic, differentiable). The following theorem is not the most general result, but it is directly applicable to delay and parabolic PDE control systems. Also, this result can be used to obtain rates of convergence for the approximating Riccati operators. The proof follows directly from Ito's paper [33, pp. 158–160].

**THEOREM 7.6.** *Suppose Assumptions 7.1, 7.2, and 7.3 hold,  $B$  and  $C$  are compact, and  $X_\infty x \in D(A^*)$  for all  $x \in H$ . If  $B^N = P^N B$  and  $C^N = C P^N$ , then  $(A, B)$  is stabilizable,  $(A, C)$  is detectable, and there exists a constant  $\hat{\beta} > 0$  such that*

$$(7.5) \quad \|X_\infty^N - P^N X_\infty P^N\| \leq \Delta^N,$$

where  $\Delta^N$  is given by

$$(7.6) \quad \Delta^N \triangleq \hat{\beta} \{ \|(A^* - [A^N]^* P^N) X_\infty\| + \|B\| \|(B^* - [B^N]^* P^N) X_\infty\| \}.$$

If, in addition,  $\lim_{N \rightarrow +\infty} \|(A^* - [A^N]^* P^N) X_\infty\| = 0$ , then

$$\lim_{N \rightarrow +\infty} \|X_\infty^N - P^N X_\infty P^N\| = 0.$$

*Remark.* The assumptions of convergence, dual convergence, and uniform preservation of stability and detectability in Ito's result are sufficient, but it is not yet clear if they are necessary for operator norm convergence (see [13], [16], and [26]). However, most approximations that yield operator norm convergence satisfy these or even stronger assumptions (see [14]). We note that, especially for nonnormal problems, it may not be easy to check these conditions for a specific approximation scheme. For example, it is not known which numerical algorithms used in computational fluid dynamics are dual convergent when applied to nonnormal control systems typical in this area (see [15] and [20]).

At first glance the compactness assumptions on the  $B$  and  $C$  operators seem rather strong. This assumption certainly excludes some idealized boundary control problems. On the other hand, if one includes actuator or sensor dynamics at the boundary (a reasonable assumption in many boundary control problems), then the resulting  $B$  and  $C$  operators are often compact in practical problems. Moreover, the simple example below provides some insight into the importance of this assumption and perhaps a way out of this technical difficulty.

*Example 2.* Consider Example 1 above and let  $H^N = \mathbb{R} \times \mathbb{R}^N$ , and define  $P^N : H \rightarrow H^N$  to be the natural projection onto  $H^N$ . If  $A^N = P^N A$ ,  $B^N = P^N B$ , and  $C^N = C P^N$ , then all the conditions in the previous theorem are satisfied except that  $C$  is not compact. The solution to the finite dimensional Riccati equation

$$\mathcal{F}^N(X) \triangleq [A^N]^* X^N + X^N [A^N] - X^N [B^N] [B^N]^* X^N + Q^N = 0$$

is  $X^N = \begin{bmatrix} 1 & 0 \\ 0 & I^N \end{bmatrix}$ , where  $I^N$  is the identity on  $\mathbb{R}^N$ . Clearly,  $X^N$  does not converge to  $X$  in the uniform operator norm since  $I$  is not compact. It is interesting to note that the feedback gain operators

$$(7.7) \quad K^N = [B^N]^* X^N = \begin{bmatrix} 1 & 0 \end{bmatrix} = K$$

converge uniformly. This situation occurs in many problems and can be exploited to address mesh independence issues. We shall discuss this issue in a future paper. We turn now to the issue of mesh independence.

**7.2. Mesh independence of the Kleinman-Newton algorithm.** We turn now to the application of the Kleinman-Newton algorithm to the finite dimensional Riccati equation

$$(7.8) \quad \mathcal{F}^N(X^N) = \mathcal{A}^N(X^N) - X^N B^N (B^N)^* X^N + (C^N)^* C^N = 0.$$

We solve the abstract algebraic equation (7.8) by Newton's method. In particular, we seek a bounded linear operator  $X^N \in D(\mathcal{A}^N)$ , which provides a solution to the Riccati equation  $\mathcal{F}^N(X^N) = 0$ , where the nonlinear mapping  $\mathcal{F}^N : D(\mathcal{A}^N) \subset \Sigma(H^N) \rightarrow \Sigma(H^N)$  is as defined by (7.1) above. Just as for the infinite dimensional case, applying Newton's method to  $\mathcal{F}^N(X^N) = 0$  leads to the iteration

$$(7.9) \quad \begin{aligned} \mathcal{A}^N(X_{k+1}^N - X_k^N) - X_k^N B^N [B^N]^* (X_{k+1}^N - X_k^N) - (X_{k+1}^N - X_k^N) B^N [B^N]^* X_k^N \\ + \mathcal{A}^N(X_k^N) - X_k^N B^N [B^N]^* X_k^N + [C^N]^* C^N = 0, \end{aligned}$$

or equivalently,

$$(7.10) \quad \mathcal{A}^N(X_{k+1}^N) - X_k^N B^N [B^N]^* X_{k+1}^N - X_{k+1}^N B^N [B^N]^* X_k^N + X_k^N B^N [B^N]^* X_k^N + [C^N]^* C^N = 0.$$

We assume that the approximation scheme preserves the basic Assumption 6.1 for all  $N$  sufficiently large. This ensures that the Newton iterations in the finite dimensional spaces converge monotonically as in Theorem 6.3. In particular, we shall use the following hypothesis.

**ASSUMPTION 7.7.** *Let  $S^N(t)$  be the semigroup generated by  $A^N$  on  $H^N$ ,  $B^N \in \mathcal{L}(U, H^N)$ , and  $C^N \in \mathcal{L}(H^N, Y)$ . Assume that there is an  $N_s$  such that for all  $N > N_s$  the following conditions hold:*

- (N-i) *The system  $(A^N, B^N)$  is stabilizable and the pair  $(A^N, C^N)$  is detectable.*
- (N-ii) *An operator  $X_0^N \in \Sigma^+(H^N)$  is given such that  $A^N - B^N(B^N)^* X_0^N$  generates an exponentially stable semigroup on  $H^N$ .*

The following results are the finite dimensional versions of Theorems 6.3 and 6.4 above. The proofs are almost identical.

**THEOREM 7.8.** *If Assumption 7.7 holds, then for all  $N > N_s$ ,*

- (i) *the sequence  $X_k^N$  converges in  $\Sigma^+(H^N)$  and  $\lim_{k \rightarrow +\infty} X_k^N = X_\infty^N \in \Sigma^+(H^N)$ . Moreover,  $X_\infty^N$  is a solution to  $\mathcal{F}^N(X_\infty^N) = 0$ ;*
- (ii) *the closed-loop operator  $A^N - B^N[B^N]^* X_\infty^N$  generates an exponentially stable semigroup  $S_\infty^N(t)$  satisfying*

$$(7.11) \quad \|S_\infty^N(t)\| \leq M_N e^{-\omega_N t}$$

*for constants  $M_N \geq 1$  and  $\omega_N > 0$ ;*

- (iii) *the Newton iterates satisfy  $0 \leq X_\infty^N \leq \dots \leq X_{k+1}^N \leq X_k^N \leq \dots \leq X_1^N$ .*

**THEOREM 7.9.** *If Assumption 7.7 holds, then for all  $N > N_s$  and  $k = 0, 1, 2, \dots$ ,*

$$\|X_{k+1}^N - X_\infty^N\| \leq c^N \|X_k^N - X_\infty^N\|^2,$$

where

$$(7.12) \quad \begin{aligned} c^N &= \int_0^\infty \| [S_\infty^N(t)]^* \| \| B^N [B^N]^* \| \| S_\infty^N(t) \| \, dt \\ &= \| B^N [B^N]^* \| \int_0^\infty \| [S_\infty^N(t)]^* \| \| S_\infty^N(t) \| \, dt \leq (M_N^2 / 2\omega_N) \| B^N [B^N]^* \| \end{aligned}$$

and the constants  $M_N \geq 1$  and  $\omega_N > 0$  are as given by (7.11) above.

The constant  $c^N$  in Theorem 7.9 is not necessarily the minimal value  $\hat{c}^N$ . However, it is possible that there exists an  $\alpha$ , independent of  $N$ , such that the finite dimensional iterates  $X_k^N$  satisfy

$$(7.13) \quad \|X_{k+1}^N - X_\infty^N\| \leq \alpha \|X_k^N - X_\infty^N\|^2.$$

Clearly, the bound

$$c^N \leq (M_N^2/2\omega_N)\|B^N[B^N]^*\|$$

is not tight. As we shall see below, there are convergent approximation schemes satisfying Assumption 7.1 and a fixed  $\alpha$  satisfying (7.13) with

$$c^N \leq \alpha < \lim_{N \rightarrow +\infty} (M_N^2/2\omega_N)\|B^N[B^N]^*\| = +\infty.$$

Therefore, the rate of convergence dictated by the constant  $\alpha$  in (7.13) provides some level of mesh independence for the finite dimensional problems. However, it is important to note that the previous estimates do not imply that the approximating Riccati operators  $X_\infty^N$  converge in norm to  $X_\infty$ . Hence, even the existence of a constant  $\alpha$  for which (7.13) holds does not provide true mesh independence.

Although the previous theorem is well known, the explicit value of the constant  $c^N$  in (7.12) provides some insight into those approximation properties that might be important in establishing an MIP. There are several factors that influence this constant, but clearly the choice of the approximation scheme  $(H^N, A^N, B^N, C^N)$  plays a fundamental role in determining  $c^N$  and its value as the mesh is refined. We shall illustrate this dependency with the numerical examples below. However, using Ito's theorem, Theorem 7.4 above, we have the following mesh independence result.

**THEOREM 7.10.** *If Assumptions 7.1, 7.2, and 7.3 hold and  $B$  is compact, then there exist  $\alpha^N$  and  $\alpha$  such that*

$$(7.14) \quad \|X_{k+1}^N - X_\infty^N\| \leq \alpha^N \|X_k^N - X_\infty^N\|^2,$$

$$(7.15) \quad \|X_{k+1} - X_\infty\| \leq \alpha \|X_k - X_\infty\|^2,$$

and  $\alpha^N = \alpha + \delta(N)$ , where  $\delta(N) \rightarrow 0$  as  $N \rightarrow +\infty$ .

*Proof.* First note that Assumption 7.3 implies that Assumption 7.7 holds so that the Kleinman-Newton iterates  $X_k^N$  exist and Theorem 7.9 is valid. From Assumption 7.1 we have convergence  $B^N u \rightarrow Bu$  for  $u \in U$ , and Assumption 7.2 yields the dual convergence  $[B^N]^* P^N x \rightarrow B^* x$  for  $x \in H$ . Since  $B$  is compact, it follows from Theorem 3.2 in [21] that  $\|B^N - B\| \rightarrow 0$ , and  $\|[B^N]^* P^N - B^*\| \rightarrow 0$  so that  $\|B^N[B^N]^* P^N - BB^*\| \rightarrow 0$ . Let

$$(7.16) \quad \beta(N) = \|B^N[B^N]^* P^N\| - \|BB^*\|.$$

Theorem 7.4 yields the existence of positive constants  $M_3 \geq 1$ ,  $\omega_3 > 0$  (independent of  $N$ ) such that the closed-loop semigroups  $S_\infty^N(t)$  generated by the operators  $(A^N - B^N[B^N]^* X_\infty^N)$  satisfy

$$\|S_\infty^N(t)^*\| = \|S_\infty^N(t)\| \leq M_3 e^{-\omega_3 t}, \quad t \geq 0,$$

and

$$\|S_\infty^*(t)\| = \|S_\infty(t)\| \leq M_3 e^{-\omega_3 t}, \quad t \geq 0.$$

Hence, the estimate for  $c^N$  in (7.12) is bounded by

$$c^N = \int_0^\infty \|S_\infty^N(t)^*\| \|B^N[B^N]^*\| \|S_\infty^N(t)\| dt \leq \frac{M_3^2}{2\omega_3} \|B^N[B^N]^* P^N\|.$$

Let

$$\alpha^N = \frac{M_3^2}{2\omega_3} \|B^N [B^N]^* P^N\| \geq c^N \text{ and } \alpha = \frac{M_3^2}{2\omega_3} \|BB^*\| \geq c,$$

where  $c$  is given by (6.16). It follows that  $\alpha^N$  and  $\alpha$  satisfy (7.14) and (7.15), respectively. Moreover,

$$\alpha^N = \frac{M_3^2}{2\omega_3} \|B^N [B^N]^* P^N\| = \frac{M_3^2}{2\omega_3} \{\|BB^*\| + \beta(N)\} = \alpha + \frac{M_3^2}{2\omega_3} \beta(N) = \alpha + \delta(N),$$

where

$$\delta(N) = \frac{M_3^2}{2\omega_3} \beta(N) \longrightarrow 0 \text{ as } N \longrightarrow +\infty,$$

and this completes the proof.  $\square$

All that one can imply from Theorem 7.10 is that the finite dimensional iterates  $X_k^N$  satisfy

$$\|X_{k+1}^N - X_\infty^N\| \leq (\alpha + \delta(N)) \|X_k^N - X_\infty^N\|^2.$$

If, in addition, one has norm convergence  $\lim_{N \rightarrow +\infty} \|P^N X_\infty P^N - X_\infty^N\| = 0$ , then the inequality

$$\begin{aligned} \|X_{k+1}^N - P^N X_\infty P^N\| &= \|X_{k+1}^N - X_\infty^N + X_\infty^N - P^N X_\infty P^N\| \\ &\leq \|X_{k+1}^N - X_\infty^N\| + \|X_\infty^N - P^N X_\infty P^N\| \\ &\leq (\alpha + \delta(N)) \|X_k^N - X_\infty^N\|^2 + \|X_\infty^N - P^N X_\infty P^N\| \end{aligned}$$

provides a useful overall convergence rate of

$$(7.17) \quad \|X_{k+1}^N - P^N X_\infty P^N\| \leq (\alpha + \delta(N)) \|X_k^N - X_\infty^N\|^2 + \|X_\infty^N - P^N X_\infty P^N\|$$

in terms of the Newton iterates and the finite dimensional approximations. Applying Theorems 7.5 and 7.6 above yields the following mesh independence result.

**THEOREM 7.11.** *Suppose Assumptions 7.1, 7.2, and 7.3 hold,  $B$  and  $C$  are compact, and  $X_\infty x \in D(A^*)$  for all  $x \in H$ . If  $B^N = P^N B$  and  $C^N = C P^N$ , then there exist  $\delta(N) \longrightarrow 0$  as  $N \longrightarrow +\infty$  and  $\hat{\beta}$  such that*

$$(7.18) \quad \|X_{k+1}^N - P^N X_\infty P^N\| \leq (\alpha + \delta(N)) \|X_k^N - X_\infty^N\|^2 + \Delta^N,$$

where  $\alpha$  is as given by (7.15) in Theorem 7.10 and  $\Delta^N = \hat{\beta} \{ \|(A^* - [A^N]^* P^N) X_\infty\| + \|B\| \|(B^* - [B^N]^* P^N) X_\infty\| \}$ . If, in addition, for some  $p > 0$  we have

$$\Delta^N = O(1/N^p),$$

then the MIP holds with a rate of  $O(1/N^p)$ .

Observe that the rate determined by

$$\Delta^N = \hat{\beta} \{ \|(A^* - [A^N]^* P^N) X_\infty\| + \|B\| \|(B^* - [B^N]^* P^N) X_\infty\| \}$$

depends on the order of the approximating scheme  $(H^N, A^N, B^N, C^N)$ . In particular, the rate of convergence for the adjoint approximations  $[A^N]^*$  plays a key role. For

the delay systems discussed below, it follows that  $B^* = [B^N]^*$  for all  $N > 1$  so that the rate is essentially determined by how well one can approximate  $A^*$ , i.e., if one can obtain an estimate of the form

$$\|(A^* - [A^N]^* P^N)X_\infty\| = O(1/N^p).$$

We shall apply this estimate to the delay systems considered in the next section. In general, the convergence results depend on the regularity of the semigroups and the type of approximations. Obtaining these rates depends on each individual problem. Ito considered both delay systems and parabolic PDE control systems. He established convergence rates for the standard finite element scheme applied to the parabolic PDE problem. He also gave convergence rates for the two schemes we will discuss below involving delay systems (see [33] and [34]). In both cases he made heavy use of the regularity of the semigroups generated by  $A$ .

**8. Control of delay systems.** In this section we consider the LQR problem for delay differential equations. In particular, the system is defined by

$$(8.1) \quad \dot{x}(t) = A_0 x(t) + A_1 x(t-r) + B_0 u(t), \quad t > 0,$$

with initial data

$$(8.2) \quad x(0) = \eta, \quad x(s) = \varphi(s), \quad -r < s < 0,$$

where  $\eta \in \mathbb{R}^n$  and  $\varphi(\cdot) \in L^2(-r, 0; \mathbb{R}^n)$ . Here,  $A_0$  and  $A_1$  are  $n \times n$  constant real matrices and  $B_0$  is an  $n \times m$  matrix.

Let  $C_0 = [C_0]^T \geq 0$  be a symmetric real-valued matrix and define the cost function

$$(8.3) \quad J(u) = \int_0^{+\infty} \{(C_0 x(s))^T C_0 x(s) + \|u(s)\|^2\} ds.$$

The corresponding LQR problem is to minimize the quadratic cost (8.3) over all controls  $u \in L^2(0, +\infty; \mathbb{R}^m)$ .

In order to present this problem in an infinite dimensional setting we use the Hilbert space  $H = \mathbb{R}^n \times L^2(-r, 0; \mathbb{R}^n)$ . Define the operator  $A$  with domain

$$D(A) = \{(\eta, \phi(\cdot)) \in H : \phi(\cdot) \in H^1(-r, 0; \mathbb{R}^n) \quad \text{and} \quad \phi(0) = \eta\}$$

by

$$A \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix} = \begin{bmatrix} A_0 \eta + A_1 \varphi(-r) \\ \phi'(\cdot) \end{bmatrix}.$$

Also, let  $B : \mathbb{R}^m \rightarrow H$  be defined by

$$Bu = \begin{bmatrix} B_0 u \\ 0 \end{bmatrix},$$

and let  $C : H \rightarrow \mathbb{R}^m$  be given by

$$Cz = C \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix} = C_0 \eta.$$

It is well known (see [3]) that  $A$  generates a  $C_0$ -semigroup  $S(t) : H \rightarrow H$ ,  $t \geq 0$ , such that

$$(8.4) \quad S(t)(\eta, \phi(\cdot)) = (x(t), x_t(\cdot)) \in H$$

for all  $(\eta, \phi(\cdot)) \in H$ , where  $x(t)$  is the solution to (8.1)–(8.2) and  $x_t(s) = x(t+s)$  for all  $-r < s < 0$ . Moreover, the delay system is equivalent to the infinite dimensional system in  $H$  defined by

$$(8.5) \quad \dot{z}(t) = Az(t) + Bu(t), \quad t > 0,$$

with initial data

$$(8.6) \quad z(0) = \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix},$$

and the LQR cost function has the form

$$J(u) = \int_0^{+\infty} \{\|Cz(s)\|^2 + \|u(s)\|^2\} ds.$$

Finally, the Hilbert adjoint  $A^*$  is defined on the domain

$$D(A^*) = \{(\xi, \psi(\cdot)) \in H : \psi(\cdot) \in H^1(-r, 0; \mathbb{R}^n), \quad \psi(-r) = A_1^T \xi\}$$

by

$$A^* \begin{bmatrix} \xi \\ \psi(\cdot) \end{bmatrix} = \begin{bmatrix} A_0^T \xi + \psi(0) \\ -\psi'(\cdot) \end{bmatrix}.$$

Observe that the linear operator  $A$  is not normal; this can cause problems when approximating the LQR control problem (see [8], [13], [16], [15], and [35]).

**8.1. Approximations of the delay system.** We consider two different numerical schemes for approximating the LQR control problem for the delay system. Since the  $B$  and  $C$  operators act only on the finite dimensional part of the state, the main issue is how to approximate  $A$ . We focus on a finite volume method known as the “AVE” scheme in [4] and a conforming finite element scheme first described by Banks and Kappel in [5], and hence we do not give the details here. The key difference between these two schemes is how they approximate the initial condition  $\phi$  in (8.1). The “AVE” scheme uses an averaging technique and characteristic functions, while the Banks–Kappel scheme uses a continuous finite element technique. Although both schemes are convergent, only the “AVE” scheme is dual convergent, and hence produces convergent approximations of the operator

$$\mathcal{A}(\Pi) = A^* \Pi + A \Pi, \quad \Pi \in D(\mathcal{A}).$$

The papers by Rosen (see [43], [44], and [45]) provide considerable insight in this problem.

**The AVE/finite volume scheme.** For each  $N > 1$ , create a partition on  $[-r, 0]$  by defining  $\tau_j^N = -jr/N$ , where  $j = 0, \dots, N$ . On  $[-r, 0]$ , define  $\chi_j^N(\cdot)$  to be the characteristic function on  $[\tau_j^N, \tau_{j-1}^N)$  for  $j = 2, \dots, N$ , and define  $\chi_1^N(\cdot)$  to be the

characteristic function on  $[\tau_1^N, \tau_0^N]$ . Define the finite dimensional subspace  $H_{AVE}^N$  of  $H$  by

$$(8.7) \quad H_{AVE}^N \equiv \left\{ (\eta, \phi^N(\cdot)) \in H : \phi^N(s) = \sum_{j=1}^N v_j^N \chi_j^N(s), v_j^N \in \mathbb{R}^n \right\}.$$

The projection  $P^N$  of  $H$  into  $H_{AVE}^N$  is defined by

$$P^N(\eta, \phi(\cdot)) = \left( \phi_0^N, \sum_{j=1}^N \phi_j^N \chi_j^N(\cdot) \right),$$

where

$$\phi_0^N \equiv \eta \quad \text{and for } j = 1, \dots, N, \quad \phi_j^N \equiv \frac{N}{r} \int_{\tau_j^N}^{\tau_{j-1}^N} \phi(s) ds.$$

To approximate the operator  $A$ , we first define  $L^N : H_{AVE}^N \rightarrow \mathbb{R}^n$  and  $D^N : H_{AVE}^N \rightarrow L^2(-r, 0; \mathbb{R}^n)$  by

$$L^N \left( \eta, \sum_{j=1}^N v_j^N \chi_j^N(\cdot) \right) = A_0 \eta + A_1 v_N^N$$

and

$$D^N \left( \eta, \sum_{j=1}^N v_j^N \chi_j^N(\cdot) \right) = \frac{N}{r} \sum_{j=1}^N \{v_{j-1}^N - v_j^N\} \chi_j^N(\cdot),$$

respectively, where  $v_0^N = \eta$ . The AVE approximation  $A_{AVE}^N : H_{AVE}^N \rightarrow H_{AVE}^N \subseteq H$  is given by

$$(8.8) \quad A_{AVE}^N(\eta, \psi) \equiv (L^N(\eta, \psi), D^N(\eta, \psi)).$$

In order to complete the approximation scheme, we define

$$(8.9) \quad B_{AVE}^N = P^N B \quad \text{and} \quad C_{AVE}^N = C P^N,$$

and this yields the AVE approximation scheme  $(H_{AVE}^N, A_{AVE}^N, B_{AVE}^N, C_{AVE}^N)$ .

Observe that

$$B_{AVE}^N u = P^N \begin{bmatrix} B_0 u \\ 0 \end{bmatrix} = \begin{bmatrix} B_0 u \\ 0 \end{bmatrix} = Bu$$

and

$$C_{AVE}^N \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix} = C P^N \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix} = C \begin{bmatrix} \eta \\ \phi^N(\cdot) \end{bmatrix} = C_0 \eta = C \begin{bmatrix} \eta \\ \phi(\cdot) \end{bmatrix}.$$

Hence, the operators  $B$  and  $C$  are compact and satisfy the conditions in Theorem 7.6. Norm convergence of the input and output operators is trivial for this approximation.

Since  $\|B^N[B^N]^*P^N\| = \|BB^*\|$  for all  $N \geq 1$ , it follows that  $\beta(N)$  defined in (7.16) satisfies

$$\beta(N) = \|B^N[B^N]^*P^N\| - \|BB^*\| = 0,$$

and hence  $\delta(N) = \frac{M_3^2}{2\omega_3}\beta(N) = 0$  for all  $N \geq 1$ . Moreover, the AVE scheme satisfies all the assumptions in Theorem 7.6 above, and the following convergence and mesh independence result holds (see pages 164–166 in [33]).

**THEOREM 8.1.** *The AVE approximation scheme  $(H_{AVE}^N, A_{AVE}^N, B_{AVE}^N, C_{AVE}^N)$  satisfies all the assumptions in Theorem 7.6. There exist constants  $\hat{M}$  and  $\alpha$  independent of  $N$  such that*

$$\|X_\infty^N - P^N X_\infty P^N\| \leq \frac{\hat{M}}{\sqrt{N}},$$

and the finite dimensional Kleinman–Newton iterates satisfy

$$\|X_{k+1}^N - P^N X_\infty P^N\| \leq \alpha \|X_k^N - X_\infty^N\|^2 + \frac{\hat{M}}{\sqrt{N}}.$$

Note that the overall convergence rate for the AVE scheme is  $O(1/\sqrt{N})$ . In order to improve this rate, several “high order” spline-based schemes were proposed. The first of these schemes was developed by Banks and Kappel in [5]. Because this spline scheme failed to produce strongly convergent Riccati operators, several modifications were developed to overcome this issue. A nice summary of these schemes and their properties can be found in Kappel’s survey paper [35]. We briefly describe the scheme below.

**The Banks–Kappel (BK) spline scheme.** We now describe the “BK” finite element spline-based scheme first proposed by Banks and Kappel in [5]. For each  $N > 1$ , create a partition on  $[-r, 0]$  by defining  $\tau_j^N = -jr/N$ , where  $j = 0, \dots, N$ . For ease of notation we set  $\tau_{N+1}^N = -r$  and  $\tau_{-1}^N = 0$ . On  $[-r, 0]$ , define the standard linear B-splines by

$$B_j^N(s) = \begin{cases} \frac{N}{r}(s - \tau_{j+1}^N), & s \in [\tau_{j+1}^N, \tau_j^N], \\ \frac{N}{r}(\tau_{j-1}^N - s), & s \in [\tau_j^N, \tau_{j-1}^N], \\ 0 & \text{otherwise.} \end{cases}$$

Define the finite dimensional subspace  $H_{BK}^N$  of  $H$  by

$$(8.10) \quad H_{BK}^N \equiv \left\{ (\phi^N(0), \phi^N(\cdot)) \in H : \phi^N(s) = \sum_{j=0}^N v_j^N B_j^N(s), v_j^N \in \mathbb{R}^n \right\}.$$

Let  $P^N$  denote the orthogonal projection of  $H$  into  $H_{BK}^N$  and note that since  $H_{BK}^N \subseteq D(A) \subseteq H$ , the range of  $P^N$  is contained in the domain of  $A$ . Therefore, we define the spline approximation  $A_{BK}^N : H_{BK}^N \rightarrow H_{BK}^N \subseteq H$  by

$$(8.11) \quad A_{BK}^N = P^N A = P^N A P^N.$$

In order to complete the approximation scheme, we define

$$(8.12) \quad B_{BK}^N = P^N B \quad \text{and} \quad C_{BK} = C P^N,$$

and this yields the BK spline approximation scheme  $(H_{BK}^N, A_{BK}^N, B_{BK}^N, C_{BK}^N)$ .

**Note.** The BK spline scheme satisfies Assumption 7.1 and hence yields a convergent numerical scheme in the sense that, for a given initial condition and input function, the approximations of the forward problem converge on finite time intervals. However, unlike the AVE scheme above, the BK spline scheme fails to satisfy the dual convergence assumption, Assumption 7.2 (see [16]), and the uniformly stabilizable and detectable assumption, Assumption 7.3 (see [17] and [18]). The BK spline scheme does satisfy the basic assumption, Assumption 7.7, so that the finite dimensional Kleinman–Newton algorithm converges quadratically with constant  $c^N$  possibly depending on  $N$ . However, the approximating Riccati operators do not converge strongly so, in particular, norm convergence fails.

In the next section we present numerical results based on these two schemes. The numerical results will confirm (as Theorem 8.1 implies) that the AVE scheme is mesh independent and the approximating Riccati operators converge. However, the numerical results below also show that the BK spline scheme is not mesh independent, although there is a bound on  $c^N$ .

**9. Numerical results.** In this section we illustrate the importance of Assumptions 7.1, 7.2, and 7.3 in obtaining strong convergence (norm convergence) of feedback gain operators as well as strong mesh independence of the Kleinman–Newton iterations.

For this discussion we use the two schemes discussed in section 8.1. The AVE scheme satisfies all the assumptions of Theorems 7.6 and 7.10. Therefore, both forms of strong mesh independence, (2.4) and (2.7), are satisfied and the approximate Riccati operators converge in norm to  $X_\infty$ . This is not the case for the BK scheme since it fails to satisfy Assumptions 7.2 and 7.3. In the numerical approximations below,  $X_\infty$  is taken as the (converged) fine grid solution of the Riccati equation using the AVE scheme.

In this section we use the following notation: Let  $\hat{c}_{AVE}^N$  and  $\hat{c}_{BK}^N$ , respectively, denote the values  $\hat{c}^N$  if the AVE and BK schemes are used for the approximations. Also, let  $\hat{M}_{AVE}^N(\varepsilon, x_0^N)$  and  $\hat{M}_{BK}^N(\varepsilon, x_0^N)$  denote the values  $\hat{M}^N(\varepsilon, x_0^N)$  for the AVE and BK schemes.

Mesh independence implies that a finite dimensional process behaves asymptotically the same as the underlying infinite dimensional process. Thus, in order to compare the behavior of the approximation schemes, it is necessary that the starting operators in the approximation spaces are the projections of the starting operator in the infinite dimensional space onto the respective approximation spaces. To accomplish this,  $X_{0,AVE}^N$  and  $X_{0,BK}^N$  are expressed in terms of multiples of the identity operator in the respective approximation spaces. For the other obvious choice, the zero operator, the convergence was too fast to make observations about quadratic convergence or mesh independence. Since the mass matrices,  $\text{MASS}_{AVE}$  and  $\text{MASS}_{BK}$ , are the projections of  $I_{\mathbb{R} \times L_2(0,1)}$  onto the approximation spaces  $H_{AVE}^N$  and  $H_{BK}^N$ , respectively, the starting matrices will be multiples of the appropriate mass matrices.

All computations in this section have been performed on a PowerPC G5, 2.7GHz, using MATLAB version 7.0.0. All Lyapunov equations are solved by implementing the MATLAB Lyapunov solver which uses the SLICOT routines SB03MD and SG03AD.

**Numerical Example 1.** The results presented here are typical for all the runs on a one-dimensional delay equation,

$$\dot{x}(t) = x(t) + x(t-1) + u(t),$$

with cost function

$$J(u(\cdot)) = \int_0^{+\infty} \{10^4[x(t)]^2 + [u(t)]^2\} dt.$$

The starting operator,  $X_0$ , equals 100 times the identity in  $H = \mathbb{R} \times L_2(0, 1)$ ; thus  $X_0 = 100I_{\mathbb{R} \times L_2(0,1)}$ . The finite dimensional approximations for  $X_0$  using the AVE and BK schemes result in  $X_{0,AVE}^N = 100\text{MASS}_{AVE}$  and  $X_{0,BK}^N = 100\text{MASS}_{BK}$ , respectively. The tolerance is set to be  $\|X_k^N - X_\infty^N\| < 10^{-8} = \varepsilon$ .

Since the AVE scheme satisfies the criteria for both forms of strong mesh independence, (2.4) and (2.7), we expect mesh-independent behavior of the quantities in Table 9.1. Indeed, we notice that  $\hat{c}_{AVE}^N \rightarrow 10^{-2}$  and  $\hat{M}_{AVE}^N \rightarrow 3$ , confirming the theoretical results.

For the BK scheme this observation cannot be made from the numerical results. This is in line with the fact that the BK scheme fails to satisfy Assumptions 7.2 and 7.3. Note that mesh independence would imply that  $\hat{c}_{BK}^N \rightarrow \hat{c} \approx 10^{-2}$  and  $\hat{M}_{BK}^N \rightarrow M(10^{-8}, 100I) \approx 3$  based on the results from the AVE scheme. The results for the BK scheme show that  $\hat{c}_{BK}^{1024} \approx 1.6 \times 10^2 \gg \hat{c}$  and  $\hat{M}_{BK}^N \geq 5 > M(10^{-8}, 100I)$ .

A further comparison of the two approximation schemes includes the actual CPU-time per Newton iteration that was used by the MATLAB process. This was computed using the MATLAB function `cputime` as well as `tic` and `toc`. The resulting times were identical. Both schemes use roughly the same amount of CPU-time per iteration. For example, for  $N = 256$ , the size of the problem is 257. The AVE scheme uses on average 10.9s of CPU-time per iteration, and the BK scheme uses 10.6s. Consequently, the number of iterations that the two schemes use is a direct measure of the total computational time. In general, the BK scheme needs more iterations than the AVE scheme to obtain a specific accuracy, and in some cases significantly more.

**Numerical Example 2.** We present typical results for the two-dimensional delay equation,

$$\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ -1.6 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ -1 & -1 \end{bmatrix} x(t-1) + \begin{bmatrix} 1 \\ 0 \end{bmatrix} u(t),$$

with cost function

$$J(u(\cdot)) = \int_0^{+\infty} \left\{ \left( \begin{bmatrix} 10 & 0 \\ 0 & 0 \end{bmatrix} x(t) \right)^2 + [u(t)]^2 \right\} dt.$$

The starting operator,  $X_0$ , equals twice the identity in  $H = \mathbb{R}^2 \times L_2(0, 1; \mathbb{R}^2)$ ; thus  $X_0 = 2I_{\mathbb{R}^2 \times L_2(0,1;\mathbb{R}^2)}$ . For the AVE and BK schemes, the starting matrices are  $X_{0,AVE}^N = 2\text{MASS}_{AVE}$  and  $X_{0,BK}^N = 2\text{MASS}_{BK}$ , respectively. As before,  $\varepsilon$  is taken to be  $10^{-8}$ ,  $\|X_k^N - X_\infty^N\| < 10^{-8}$ .

The results presented in Table 9.2 are similar to the results observed in Example 1. The AVE scheme yields strong mesh independence, and the Riccati operators converge strongly, while this is not true for the BK scheme. In particular, the optimal feedback law defined by (5.3) has the form

$$Kz(t) = k_0z(t) + \int_{-1}^0 k_1(s)z(t+s)ds + \int_{-1}^0 k_2(s)z(t+s)ds,$$

where  $k_i(s)$ ,  $i = 1, 2$ , are called the functional gains. Figures 9.1 and 9.2 illustrate that the AVE scheme (the solid line) yields strong convergence of the gains, while the BK scheme (the dashed line) does not.

TABLE 9.1

$N$	$\hat{c}_{AVE}^N$	$\hat{M}_{AVE}^N$	$\hat{c}_{BK}^N$	$\hat{M}_{BK}^N$
8	$1.01497 \times 10^{-2}$	3	$3.98797 \times 10^6$	14
16	$6.12638 \times 10^{-3}$	3	$3.31429 \times 10^6$	12
32	$6.18756 \times 10^{-3}$	3	$1.81757 \times 10^6$	10
64	$6.57817 \times 10^{-3}$	3	$5.04459 \times 10^5$	8
128	$7.11713 \times 10^{-3}$	3	$3.04030 \times 10^4$	7
256	$7.78503 \times 10^{-3}$	3	$7.82120 \times 10^4$	7
512	$8.55008 \times 10^{-3}$	3	$6.02653 \times 10^3$	6
1024	$9.32057 \times 10^{-3}$	3	$1.59829 \times 10^2$	5

TABLE 9.2

$N$	$\hat{c}_{AVE}^N$	$\hat{M}_{AVE}^N$	$\hat{c}_{BK}^N$	$\hat{M}_{BK}^N$
8	$4.77751 \times 10^{-2}$	8	$1.28997 \times 10^6$	16
16	$4.94581 \times 10^{-2}$	8	$8.69896 \times 10^5$	14
32	$4.98913 \times 10^{-2}$	8	$4.56992 \times 10^4$	12
64	$5.04197 \times 10^{-2}$	9	$3.59473 \times 10^3$	11
128	$5.07046 \times 10^{-2}$	9	$9.31569 \times 10^3$	11
256	$5.08547 \times 10^{-2}$	9	$4.18416 \times 10^1$	10
512	$5.09322 \times 10^{-2}$	9	$2.38082 \times 10^1$	10

As in Numerical Example 1, the two schemes use roughly the same CPU-time per Newton iteration. For  $N = 256$ , the problem size is 514, and the average CPU-time per iteration is 102s for the AVE scheme and 105s for the BK scheme.

We note that Figures 9.1 and 9.2 verify the theoretical results in this paper as well as those established in the earlier paper by Burns, Ito, and Propst [16]. In particular, in [16] it was proved that the BK scheme does not produce approximating Riccati operators that converge in norm. Hence the oscillations seen in these figures, which are indicative of weak convergence, are the best one can expect. However, the AVE scheme is norm convergent and this is also illustrated in Figures 9.1 and 9.2.

We close this section with an example that illustrates the need for infinite dimensional feedback. As noted earlier, the convergence theory in Damm and Hinrichsen [23] is easily applied to a wide variety of finite dimensional (matrix) Riccati equations. However, applying this method to infinite dimensional Riccati equations is not straightforward. A special feedback problem for a delay system was used to illustrate their results. They considered the problem of stabilizing a delay system with finite dimensional feedback only, which leads to a finite dimensional Riccati type (matrix) equation. In particular, the control system considered in [23] is given by the delay differential equation

$$\dot{x}(t) = A_0x(t) + A_1x(t-r) + Bu(t).$$

The problem (see problem 5 on page 58 in [23]) is to find a finite dimensional feedback law of the form

$$u(t) = -Kx(t)$$

so that the closed-loop system

$$\dot{x}(t) = [A_0 - BK]x(t) + A_1x(t-r)$$

FIG. 9.1. *Numerical Example 2: Functional gain  $k_1$ .*FIG. 9.2. *Numerical Example 2: Functional gain  $k_2$ .*

is stable for all delays  $r > 0$ . This leads to a matrix Riccati equation for the matrix  $K$ .

If one considers the retarded delay equation,

$$(9.1) \quad \dot{x}(t) = \alpha x(t) + \beta x(t-r) + \gamma \int_{-r}^0 x(t+s)ds,$$

then one will know (see Corollary 2.8 in [32]) that (9.1) is stable independent of delay if and only if

$$\alpha < 0, \quad \gamma < 0, \quad 0 < -\gamma \leq \frac{\alpha^2 - \beta^2}{2}.$$

If  $\gamma > 0$ , then (9.1) is not stable for all  $r > 0$ . If one starts with the control system

$$(9.2) \quad \dot{x}(t) = x(t) + 2x(t-r) + \int_{-r}^0 x(t+s)ds + u(t)$$

and uses only current state feedback

$$u(t) = -kx(t),$$

then the closed-loop system has the form

$$(9.3) \quad \dot{x}(t) = [1 - k]x(t) + 2x(t - r) + \int_{-r}^0 x(t + s)ds,$$

and this system is never stable independent of delay since  $\gamma = +1$ . On the other hand, the complete state (infinite dimensional) feedback law,

$$u(t) = -k_0x(t) + (k_1 - 1) \int_{-r}^0 x(t + s)ds,$$

leads to the closed loop system

$$(9.4) \quad \dot{x}(t) = [1 - k_0]x(t) + 2x(t - r) + k_1 \int_{-r}^0 x(t + s)ds,$$

which is stable independent of delay if and only if

$$1 < k_0, \quad k_1 < 0, \quad 0 < -k_1 \leq \frac{[1 - k_0]^2 - 4}{2}.$$

If we set  $k_0 = 4$  and  $k_1 = 5/4 < 5/2$ , then (9.4) is stable independent of delay. In particular, the control system (9.2) is stable independent of delay, and the MIP holds if we apply the AVE scheme to this problem. Numerical results on mesh independence and convergence for this problem are almost identical to the previous two numerical examples and will not be presented here.

**10. Conclusions.** The theoretical results above provide precise conditions on approximation schemes needed to guarantee an MIP. The numerical results are interesting for two reasons. First, they provide numerical support for the mesh independence of the AVE scheme. Also, since the BK scheme does not generate norm convergent Riccati solutions, it is certainly not a mesh-independent scheme. However, the numerical results alone might be used to *incorrectly* justify some type of mesh independence.

There are many PDE control problems in which the linearization is not normal. For example, in channel flow control, when one linearizes about a nonzero equilibrium, the resulting  $A$  operator is highly nonnormal. Thus dual convergence is extremely important. Moreover, we have tested the theoretical results above on self-adjoint parabolic PDE control systems such as the ones considered by Banks and Kunisch [7]. Since dual convergence is not an issue and in [7] POES is established for this class of problems, our results imply mesh independence for standard finite element schemes. We have also applied the theory to some non-self-adjoint PDE problems. These PDE results, along with numerical examples, will appear in a forthcoming paper.

We have established a mesh independence result for the infinite dimensional version of the Kleinman-Newton algorithm for solving the algebraic Riccati operator equation associated with the LQR problem in a Hilbert space. We applied the results to systems governed by delay equations and presented numerical examples to illustrate the ideas. The results provide insight into the type of approximation schemes that lead to mesh independence. In particular, we showed that it is sufficient that the approximation be convergent, dual convergent, and uniformly stabilizable and detectable. As noted by Kappel in [35], it is possible to obtain (at least strong) convergence of the approximating Riccati operators without POES. This leaves open the

question of whether or not it is possible to achieve mesh independence without preserving stabilizability and detectability *uniformly* under approximation. However, it is important to note again that mesh independence alone does not imply convergence. We are currently looking into this issue and other issues concerning the numerical conditioning of the finite dimensional approximating Riccati equations.

**Acknowledgments.** The authors wish to thank the referees for their feedback and many helpful suggestions.

## PROBABILISTIC ROBUSTNESS ANALYSIS—RISKS, COMPLEXITY, AND ALGORITHMS\*

XINJIA CHEN<sup>†</sup>, KEMIN ZHOU<sup>†</sup>, AND JORGE ARAVENA<sup>†</sup>

**Abstract.** It is becoming increasingly apparent that probabilistic approaches can overcome conservatism and computational complexity of the classical worst-case deterministic framework and may lead to designs that are actually safer. In this paper we argue that a comprehensive probabilistic robustness analysis requires a detailed evaluation of the robustness function, and we show that such an evaluation can be performed with essentially any desired accuracy and confidence using algorithms with complexity that is linear in the dimension of the uncertainty space. Moreover, we show that the average memory requirements of such algorithms are absolutely bounded and well within the capabilities of today's computers. In addition to efficiency, our approach permits control over statistical sampling error and the error due to discretization of the uncertainty radius. For a specific level of tolerance of the discretization error, our techniques provide an efficiency improvement upon conventional methods which is inversely proportional to the accuracy level; i.e., our algorithms get better as the demands for accuracy increase.

**Key words.** robustness analysis, risk analysis, randomized algorithms, uncertain system, computational complexity

**1. Introduction.** In recent years, a number of researchers have proposed probabilistic control methods for overcoming the computational complexity and conservatism of the deterministic worst-case robust control framework (see, e.g., [1, 2, 3, 4, 5, 6, 7, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22] and the references therein).

The philosophy of probabilistic control theory is to sacrifice cases of extreme uncertainty. Such a paradigm has led to the concept of *confidence degradation function* (originated by Barmish, Lagoa, and Tempo [2]), which has been demonstrated to be extremely powerful for the robustness analysis of uncertain systems. Such a function,  $\mathcal{P}(\cdot)$ , is defined as  $\mathcal{P}(r) = \inf_{0 < \rho \leq r} \mathbb{P}(\rho)$  with

$$\mathbb{P}(\rho) = \text{vol}\{X \in \mathcal{B}_\rho \mid \text{the robustness requirement is guaranteed for } X\} / \text{vol}\{\mathcal{B}_\rho\},$$

where the volume function  $\text{vol}\{\cdot\}$  is the Lebesgue measure, and  $\mathcal{B}_\rho$  denotes the uncertainty bounding set with radius  $\rho$ . Interestingly, it was discovered in [2] that such a function is not necessarily monotone decreasing in the uncertainty radius. In view of this fact, and for the purpose of avoiding confusion with the concept of *confidence band* used in the evaluation of the accuracy of the estimate of  $\mathbb{P}(r)$ , the confidence degradation function is referred to as the *robustness function* in this paper. Accordingly, a graph representation of the robustness function is called the *robustness curve*. It can be seen that the robustness function is a natural extension of the concept of robustness margin. From the robustness curve, one can determine the *probabilistic robustness margin* [2] and estimate the deterministic robustness margin.

In addition to overcoming the NP hard complexity and conservatism of deterministic robustness analysis methods, the robustness function can address very complex problems which are intractable by deterministic worst-case methods. Moreover, the probability that the robustness requirement is guaranteed can be inferred from the robustness function, while the deterministic margin loses the connection with such a probability. Based on the assumption that the density function of uncertainty is radially symmetric and nonincreasing with respect to the norm of uncertainty, it has been shown in [2] that the probability that the robustness requirement is guaranteed is no less than  $\mathcal{P}(r) = \inf_{\rho \in (0, r]} \mathbb{P}(\rho)$  when the uncertainty is included in a bounding set with radius  $r$ . The underlying assumption is supported by modeling and manufacturing considerations that the uncertainty is unstructured so that all directions are equally likely and that small perturbations from the nominal model are more likely than large perturbations. Since  $\mathbb{P}(\cdot)$  is not monotonically decreasing [2], the lower bound of the probability depends on  $\mathbb{P}(\rho)$  for all  $\rho \in (0, r]$ . It is not clear whether it is feasible to estimate  $\mathcal{P}(r)$ , since the estimation of  $\mathbb{P}(\rho)$  for every  $\rho$  relies on intensive Monte Carlo simulation and  $\mathbb{P}(\rho)$  needs to be estimated for numerous values of  $\rho$ . For such a probabilistic method to overcome the NP hard of worst-case methods, it is necessary to show that the complexity for estimating  $\mathcal{P}(r)$  for a given  $r$  is polynomial in terms of computer running *time* and memory *space*. In this paper, we demonstrate that the complexity in terms of space and time is surprisingly low and is *linear in the uncertainty dimension and the logarithm of the relative width of the range of uncertainty radius*.

In the next section we argue that both the deterministic robustness margin and its risk-adjusted version—the probabilistic robustness margin—have inherent limitations. We note that, as compared to robustness margins, the robustness function with respect to an uncertainty radius varying over a wide range can provide more insight into the system performance. In order to construct the robustness function for a wide range of uncertainty radii, the conventional method independently estimates  $\mathbb{P}(r_i)$  for each grid point of uncertainty. If there are  $m$  grid points and  $N$  is the sample size for each radius, then the total number of simulations is  $Nm$ . In section 3, we use the sample reuse principle and demonstrate that the robustness curve for an arbitrarily wide range of uncertainty radii can be accurately constructed with surprisingly low complexity. Clearly, the number of grid points,  $m$ , must tend to infinity as the tolerance tends to zero. However, we show that with our algorithms, the *equivalent number of grid points* (ENGP),  $m_{eq}$ , is strictly bounded from above in the sense that in order to guarantee the same level of accuracy for the estimation of the robustness function, the required average computational effort is the same as that of a conventional grid with  $m_{eq}$  points. Moreover, we show that the average memory requirement is also absolutely bounded and is well within the reach of modern computers.

The remainder of the paper is organized as follows. Section 2 provides an example illustrating the pitfalls of the deterministic robustness margin and the probabilistic robustness margin. Section 4 discusses the control of estimation error of the robustness function and the required complexity. Section 5 investigates the difficulties of the conventional data structure. Section 6 describes our new algorithms, analyzes the complexity of data processing and memory space, and introduces the concept of confidence band. The proposed randomized algorithms are applied to control problems in section 7. Section 8 is the conclusion. The proofs of all the theorems are included in the appendices.

Throughout this paper, all probabilistic statements are associated with the same probability space,  $(\Omega, \mathcal{F}, \text{Pr})$ , where the uncertainty is defined as a multivariate

random variable. The notations  $\Omega$ ,  $\mathcal{F}$ , and  $\Pr$  denote, respectively, the sample space,  $\sigma$ -algebra, and probability measure.

**2. The risk of robustness margins.** In this section we make the case for the need to have a robustness function in order to properly estimate how well a control system tolerates uncertainties. Conventional robust control approaches the issue with a “worst-case” philosophy. In this regard, it has been demonstrated (see Chen, Aravena and Zhou [5]) that it is not uncommon for a probabilistic controller to be significantly less risky than a deterministic worst-case control. The reasons are the “uncertainty in modeling uncertainties” and the fact that the worst-case design cannot, in some instances, be “all encompassing.” Therefore, the worst-case approach has an associated risk that usually is overlooked, while the probabilistic approach acknowledges the risk and manages it.

From manufacturing and modeling considerations, it is reasonable to assume that the density of the distribution of uncertainty decreases with an increasing uncertainty norm. Such an assumption leads to the worst-case property of uniform distribution in robustness analysis [2]. However, the decay rate of density is generally unknown to the designer. Therefore, for a given uncertainty radius  $r$ , one does not have adequate knowledge about the probability that the uncertainty is included in set  $\mathcal{B}_r$ . It is important to note that the system robustness depends critically on the distribution of the uncertainty norm.

Attempts to improve the analysis have led to the definitions of a *deterministic robustness margin* and a *probabilistic robustness margin*. Both are numbers that purportedly allow the user to estimate the tolerance to uncertainties. We contend that both can be misleading—and essentially for the same reason. To demonstrate this viewpoint, we consider a feedback system, shown in Figure 1.

FIG. 1. Standard feedback configuration.

The transfer function of the plant is  $G(s) = \frac{q}{s-p}$ , where  $p$  and  $q$  are uncertain parameters. The uncertainty bounding set with radius  $r > 0$  is

$$\mathcal{B}_r = \{(x, y) : |x - q_0| \leq r, \quad |y - p_0| \leq r\}, \quad p_0 < 0, \quad q_0 > 0.$$

Consider two controllers  $C_A = \frac{K_A}{s+\sigma}$ ,  $\sigma > 0$ , and  $C_B = K_B$  such that

$$1 < K_B < \frac{K_A}{\sigma}, \quad \frac{K_A q_0 - \sigma p_0}{K_A + \sigma} < \sigma - p_0.$$

Suppose that the robustness requirement is stability. It can be shown that the robustness function for controller  $A$  is

$$\mathcal{P}^A(r) = \begin{cases} 1 & \text{for } 0 < r < \rho_A, \\ \frac{1}{2} - \frac{K_A \left( r + \frac{\sigma}{K_A} - q_0 \right)^2}{8\sigma r^2} - \frac{p_0 - \beta}{2r} & \text{for } \rho_A \leq r \leq \rho_A^*, \\ \frac{1}{2} - \frac{(r + \beta - p_0) \left( r + \frac{\sigma(\beta + p_0 - r)}{2K_A} - q_0 \right)}{4r^2} - \frac{(p_0 - \beta)}{2r} & \text{for } r > \rho_A^*, \end{cases}$$

where

$$\rho_A = \frac{K_A q_0 - \sigma p_0}{K_A + \sigma}$$

is the deterministic robustness margin,  $\beta = \min(\sigma, p_0 + r)$ , and  $\rho_A^* = \frac{K_A q_0 - \sigma p_0}{K_A - \sigma}$ . It can be shown that the robustness function for controller  $B$  is given by

$$\mathcal{P}^B(r) = \begin{cases} 1 & \text{for } 0 < r < \rho_B, \\ 1 - \frac{K_B \left(r + \frac{p_0+r}{K_B} - q_0\right)^2}{8r^2} & \text{for } \rho_B \leq r \leq \rho_B^*, \\ \frac{1}{2} - \frac{\frac{p_0}{K_B} - q_0}{2r} & \text{for } r > \rho_B^*, \end{cases}$$

where

$$\rho_B = \frac{K_B q_0 - p_0}{K_B + 1}$$

is the deterministic robustness margin and  $\rho_B^* = \frac{K_B q_0 - p_0}{K_B - 1}$ .

We consider an example with  $p_0 = -10$ ,  $q_0 = 50$ ,  $\sigma = 40$ ,  $K_A = 100\sigma$ , and  $K_B = 10$ . The corresponding robustness functions are displayed in Figure 2. We obtained deterministic margins  $\rho_A = 49.6040$  and  $\rho_B = 46.3636$ . Since  $\rho_A > \rho_B$ , a comparison based on the deterministic margin simply suggests that controller  $A$  is more robust than controller  $B$ . Quite to the contrary, a judgment based on the robustness curves indicates that controller  $B$  may be more robust. The risk of the probabilistic robustness margin can also be illustrated by this example.

FIG. 2. Comparison of controller alternatives.

Robust analysis should be able to help a designer reliably determine which controller design is more robust. However, it appears that the concepts of robustness margin fail to meet such fundamental needs of control engineering. On the other

hand, the robustness curve serves the purpose of giving the designer complete information on how well a control system tolerates uncertainties.

From the previous discussion, it can be seen that there are two crucial factors to be considered in order to make a reliable judgment about the system robustness:

- (i) How fast the robustness curve rolls off.
- (ii) The dependency of coverage probability of uncertainty bounding set  $\mathcal{B}_r$  on the radius  $r$ . Here the coverage probability refers to the probability that the uncertainty is included in the bounding set.

The second factor can be difficult since a designer generally lacks knowledge of the coverage probability corresponding to a bounding set of fixed radius. To overcome such a difficulty, the only choice is to construct the robustness curve for a wide range of uncertainty radius. The construction of the robustness curve may be seen as a computationally challenging task since the probability of guaranteeing a robustness requirement needs to be estimated for many values of uncertainty radius. However, as we demonstrate in the next section, by using the sample reuse principle one can construct the robustness curve for virtually the entire scope of uncertainty range  $(0, \infty)$  with absolutely bounded average computational complexity, regardless of the size of the grid. For example, we shall show that for an uncertainty range as large as  $(10^{-10}, 10^{10})$ , on average, one needs less than 50 times memory and computational resources than those needed to evaluate the uncertainty range  $(1, e)$  with the same resolution.

**3. Equivalent number of grid points.** Throughout this paper, we assume that the uncertainty sets are homogeneous star-shaped (see, e.g., [2]). That is, the uncertainty bounding set with radius  $r$  is  $\mathcal{B}_r = \{rX \mid X \in \mathcal{B}_1\}$ , where  $\mathcal{B}_1$  denotes the uncertainty bounding set such that  $cX \in \mathcal{B}_1$  for any  $X \in \mathcal{B}_1$  and any  $c \in [0, 1]$ . Clearly, most of the commonly used uncertainty bounding sets such as the  $l_p$  balls and spectral norm balls are homogeneous star-shaped.

We shall consider the problem of constructing the robustness curve for the arbitrary robustness requirement under the assumption of uncertainty sets. Conventionally, the robustness curve for a range of uncertainty radii  $[\frac{a}{\lambda}, a]$  with  $a > 0$ ,  $\lambda > 1$  is constructed by choosing a set of grid points  $\frac{a}{\lambda} = r_1 < r_2 < \dots < r_m = a$  and, for every grid point, performing  $N$  independent and identically distributed (i.i.d.) Monte Carlo simulations. Hence, the total number of simulations is a deterministic constant  $mN$ . To reduce computational complexity, we shall make use of the following intuitive concept:

*Let  $X$  be an observation of a random variable with uniform distribution over  $\mathcal{B}_\rho \supseteq \mathcal{B}_r$  such that  $X \in \mathcal{B}_r$ . Then  $X$  can also be viewed as an observation of a random variable with uniform distribution over  $\mathcal{B}_r$ .*

In order to apply this concept, it is necessary to perform the simulation in a backward direction so that appropriate evaluations of the robust requirement for larger uncertainty sets can be saved for later use in simulations on smaller uncertainty sets [6]. The sample reuse principle allows a single simulation to be used for multiple radii. Thus, the actual total number of simulations is significantly reduced if the dimension of the uncertainty is not too high. In order to quantify this reduction, we introduce the *equivalent number of grid points* (ENGP),  $m_{\text{eq}}$ , defined as

$$m_{\text{eq}} = \frac{\text{expected total number of simulations}}{N}.$$

In our approach, the number of simulations required at uncertainty radius  $r_i$ , denoted by  $\mathbf{n}_i$  for  $i = 1, \dots, m$ , is a random number. The total number of simulations

can be represented by the random variable  $\mathbf{n} = \sum_{i=1}^m \mathbf{n}_i$ . The expected value of the total number of simulations is  $\mathbb{E}[\mathbf{n}] = \sum_{i=1}^m \mathbb{E}[\mathbf{n}_i]$ , where  $\mathbb{E}[X]$  denotes the expectation of random variable  $X$ . Hence, we can formally define

$$m_{\text{eq}} = \frac{\mathbb{E}[\mathbf{n}]}{N}.$$

Due to sample reuse, we can achieve a substantial reduction of simulations, i.e.,  $\mathbb{E}[\mathbf{n}] \ll mN$ . To quantify the reduction of the computational effort, we have introduced the notion of *sample reuse factor* [6], which is defined as

$$(3.1) \quad \mathcal{F}_{\text{reuse}} = \frac{mN}{\mathbb{E}[\mathbf{n}]} = \frac{m}{m_{\text{eq}}}.$$

In our approach,  $N$  i.i.d. simulation results are collected for each grid point. Hence, the accuracy of estimation is the same as that of the conventional method. However, the average number of simulations in our approach is  $\mathbb{E}[\mathbf{n}]$ , which is equivalent to the complexity of  $m_{\text{eq}}$  grid points in the conventional scheme. As a direct consequence of Theorem 1 of [6], we have that, for any discretization scheme,  $m_{\text{eq}}$  is independent of the sample size  $N$ . Moreover, we have the following general result.

**THEOREM 3.1.** *Let  $d$  be the dimension of uncertainty parameter space. Then, for an arbitrary gridding scheme, the equivalent number of grid points based on the principle of sample reuse is strictly bounded from above by  $1 + d \ln \lambda$ , i.e.,*

$$m_{\text{eq}} < 1 + d \ln \lambda.$$

See Appendix A for a proof. As mentioned at the end of the introduction, all probabilistic statements in this paper refer to the same probability space  $(\Omega, \mathcal{F}, \text{Pr})$  used to define the uncertainty variable. To make this possible, one can define  $m \times N$  mutually independent random variables  $X_{ij}$ ,  $i = 1, \dots, m$ ;  $j = 1, \dots, N$ , on the same probability space  $(\Omega, \mathcal{F}, \text{Pr})$  such that for each  $i$ ,  $X_{ij}$ ,  $j = 1, \dots, N$ , are i.i.d. random variables uniformly distributed over the bounding set with radius  $r_i$ . Each simulation corresponds to obtaining an observation for  $X_{ij}$  and evaluating the performance of the system for that observation. Without sample reuse, one needs to obtain  $m \times N$  observations corresponding to these  $m \times N$  random variables. The idea of sample reuse is to reuse observations and the corresponding evaluation results of system performance. Clearly, the number of simulations  $\mathbf{n}_i$ , associated with uncertainty radius  $r_i$ , is a random variable which can be defined as a function of random variables  $X_{ij}$ ,  $i = 1, \dots, m$ ;  $j = 1, \dots, N$ . Needless to say, the definition of such a function is complex. It can be shown that other variables can be implicitly defined on the same probability space  $(\Omega, \mathcal{F}, \text{Pr})$ .

By an “arbitrary” discretization scheme, we mean two things: (i) the number of grid points can be arbitrarily large, and (ii) the grid points can be distributed arbitrarily over the specified range of uncertainty radius.

A fundamental question of robust control is whether randomized algorithms have polynomial complexity. In light of the fact that the cost of each simulation depends on problem cases, the computational complexity is usually measured in terms of the number of simulations. This theorem reveals the following important facts:

- (a) The complexity is linear in the dimension of the uncertainty space.
- (b) The complexity depends linearly on the logarithm of the “relative” width,  $\lambda$ , of the interval of uncertainty radii. This proves that our algorithms are capable of estimating the robustness function for a wide range of uncertainty.

- (c) Our algorithms can arbitrarily reduce the grid error while keeping the complexity strictly below a constant bound.

In order to illustrate these points, Figure 3 displays the variation of  $m_{\text{eq}}$  for various dimensions of the uncertainty space and for values of  $\lambda$  up to  $\lambda = 10^{20}$  corresponding to the uncertainty range  $(10^{-10}, 10^{10})$  (which may be deemed a good approximation to  $(0, \infty)$ ). As can be seen from Figure 3, even for dimensions as high as  $d = 1024$  the equivalent number of grid points,  $m_{\text{eq}}$ , is very reasonable.

It should be noted that the sample reuse technique does not work well for high dimension  $d$ . The reason is that, for very large  $d$ , the samples tend to concentrate on the “surface” of the bounding set, and thus the efficiency of sample reuse is diminished.

FIG. 3. Absolute bounds for  $m_{\text{eq}}$  (ENGP) ( $d = 2^i$ ,  $i = 1, \dots, 10$ ).

**4. Error control.** In addition to efficiency, another important issue in any numerical approach is error control. This point has been emphasized in many control engineering problems. For instance, when computing the  $H_\infty$  norm of a system, a lower bound and an upper bound are obtained, and it is required that the gap between them be less than a prescribed tolerance. A similar situation arises in the computation of the structured singular value ( $\mu$ ).

For the specific case of the estimation of the robustness function, there are two sources of error: (i) the statistical sampling error due to the finiteness of the sample size,  $N$  (sample size error), and (ii) the discretization error due to the finite number of points in any partition. Control of the sample size error has been well studied and emphasized. Existing techniques include the Chernoff bounds [9], binomial confidence interval [7, 10], etc. However, we claim that control of the discretization error is not sufficiently emphasized. In fact, one can argue that *controlling the sample size error can be meaningless if the discretization error is not controlled*. This will be the case, for example, for those situations where a risk at the level of a small  $\varepsilon$  (e.g.,  $\varepsilon = 0.001$ ) may be significant or unacceptable. *How can any estimation be useful if the discretization error is not ensured to be less than the tolerance  $\varepsilon$ ?*

In this section, we first introduce an interpolation result necessary for analyzing error control methods. Afterward, we discuss two different schemes which ensure a discretization error less than a given  $\epsilon \in (0, 1)$ . The first is a uniform partition whereby the uncertainty radius interval  $[\frac{a}{\lambda}, a]$  is partitioned by  $m$  points,

$$(4.1) \quad r_i = a - \frac{(m-i)(\lambda-1)}{(m-1)\lambda}a, \quad i = 1, \dots, m.$$

In the second scheme we consider a geometric-type partition of the form

$$(4.2) \quad r_i = a \left( \frac{1}{\lambda} \right)^{\frac{m-i}{m-1}}, \quad i = 1, \dots, m.$$

For any partition of the uncertainty radius interval, we have the following linear interpolation results.

**THEOREM 4.1.** *Given an arbitrary partition of the uncertainty radius interval  $[\frac{a}{\lambda}, a]$  with  $\frac{a}{\lambda} = r_1 < r_2 < \dots < r_m = a$ , define*

$$\mathbb{P}^*(r) = \frac{(r - r_i) \mathbb{P}(r_{i+1}) + (r_{i+1} - r) \mathbb{P}(r_i)}{r_{i+1} - r_i},$$

$$g(r) = (r_{i+1} - r) \left( \frac{r}{r_i} \right)^{-d} + (r - r_i) \left( \frac{r_{i+1}}{r} \right)^{-d}.$$

Then, for all  $r \in [r_i, r_{i+1}]$ ,

$$|\mathbb{P}(r) - \mathbb{P}^*(r)| \leq 1 - \frac{g(r_*)}{r_{i+1} - r_i} \leq \frac{d}{2r_i}(r_{i+1} - r_i),$$

where  $r_* \in (r_i, r_{i+1})$  is the unique solution of equation

$$\left( \frac{r_{i+1}}{r} \right)^{-d} \left[ 1 + \left( 1 - \frac{r_i}{r} \right) d \right] - \left( \frac{r}{r_i} \right)^{-d} \left[ 1 + \left( \frac{r_{i+1}}{r} - 1 \right) d \right] = 0$$

with respect to  $r$ , which can be solved by a bisection search.

See Appendix B for a proof. As mentioned before, these interpolation results will be used in the construction of a tight confidence band for the robustness function.

*Remark 1.* To guarantee a prescribed tolerance  $\epsilon \in (0, 1)$ , the number of grid points must be larger than a certain number. It has been shown by Barmish, Lagoa, and Tempo [2] that if

$$(4.3) \quad m \geq 1 + \frac{2(\lambda-1)d}{\epsilon},$$

then  $|\mathbb{P}(r) - \mathbb{P}(r_i)| < \epsilon$  for all  $r \in [r_i, r_{i+1}]$  for  $i = 1, \dots, m-1$ . This bound shows that, for fixed error  $\epsilon$ , the complexity is polynomial. From another perspective, it also shows that the number of grid points and the computational complexity tend to infinity as the tolerance tends to zero. For example, the robustness analysis problem for complex uncertainty of size  $30 \times 30$  over an interval of uncertainty with  $\lambda = 10$  requires  $m \geq 3,240,000,001$  in order to guarantee  $\epsilon \leq 10^{-5}$ . The bound, however, does not account for the sample reuse principle. Using our approach, the equivalent number of grid points for this case is bounded from above by  $1 + 1800 \times \ln(10)$ .

The following result is our extension of the result by Barmish, Lagoa, and Tempo cited above, and quantifies the advantage of using linear interpolation.

THEOREM 4.2. *Let*

$$(4.4) \quad m = 2 + \left\lfloor \frac{(\lambda - 1)d}{2\epsilon} \right\rfloor,$$

where  $\lfloor \cdot \rfloor$  denotes the floor function. Then, for a uniform gridding scheme,

$$|\mathbb{P}(r) - \mathbb{P}^*(r)| < \epsilon \quad \forall r \in [r_i, r_{i+1}]$$

for  $i = 1, \dots, m - 1$ . Moreover, the equivalent number of grid points is

$$m_{\text{eq}}(\epsilon) = m - \sum_{i=1}^{m-1} \left( 1 - \frac{1}{\frac{m-1}{\lambda-1} + i} \right)^d.$$

See Appendix C for a proof.

*Remark 2.* We point out that when using linear interpolation, the number of grid points given by (4.4) is approximately  $\frac{1}{4}$  of the bound given by (4.3).

We now analyze a discretization scheme whereby the partition of the uncertainty interval under study is defined by a geometric series.

THEOREM 4.3. *For a geometric discretization scheme with*

$$(4.5) \quad m = 2 + \left\lfloor \frac{\ln \lambda}{\ln \left( 1 + \frac{2\epsilon}{d} \right)} \right\rfloor$$

and

$$r_i = a \left( \frac{1}{\lambda} \right)^{\frac{m-i}{m-1}}$$

for  $i = 1, \dots, m$ , the following statements hold true:

(I)

$$|\mathbb{P}(r) - \mathbb{P}^*(r)| < \epsilon \quad \forall r \in [r_i, r_{i+1}], \quad i = 1, \dots, m - 1.$$

(II)

$$m_{\text{eq}}(\epsilon) = 1 + \left( 1 + \left\lfloor \frac{\ln \lambda}{\ln \left( 1 + \frac{2\epsilon}{d} \right)} \right\rfloor \right) \left[ 1 - \left( \frac{1}{\lambda} \right)^{1 + \frac{d}{\left\lfloor \frac{\ln \lambda}{\ln \left( 1 + \frac{2\epsilon}{d} \right)} \right\rfloor}} \right].$$

(III)

$$\mathcal{F}_{\text{reuse}} > \frac{1}{2\epsilon} \left( 1 - \frac{1}{1 + d \ln \lambda} \right).$$

See Appendix D for a proof.

*Remark 3.* Since  $1 + d \ln \lambda \gg 1$  in many situations, the sample reuse factor for the geometric discretization scheme may be written in a more elegant form. That is,

$$\mathcal{F}_{\text{reuse}} \approx \frac{1}{2\epsilon},$$

which is inversely proportional to the tolerance of the discretization error. For example, to ensure that the discretization error is less than  $10^{-4}$ , which is a rather weak requirement for many applications, our algorithm reduces the computational effort by a factor of 5,000 when compared to a conventional approach.

The two discretization schemes considered here, and others, have bounded complexity, but the distributions of the total number of simulations are different. Hence it is reasonable to ask if there is a “best discretization.” Our results indicate that the geometric scheme is generally more efficient, as shown by the comparison of grid points in Figure 4 and the comparison of ENGP in Figure 5.

FIG. 4. Comparison of the number of grid points ( $\lambda = 10^3$ ,  $d = 500$ ).

**5. The difficulties of conventional data structure.** Our previous sample reuse algorithm [6] uses the same data structure as that of the conventional algorithm. That is, the data structure for implementing the algorithms is basically a matrix of fixed size. In such a data structure, for each grid point  $r_i$ , there is a record  $(k_i, n_i)$ , where  $k_i$  represents the number of cases guaranteeing (or violating) the robustness requirement among  $n_i$  simulations. In the course of our experiment, the number  $n_i$  increases from 0 to sample size  $N$ . In the following two subsections, we demonstrate that the conventional data structure is not suitable for controlling the error due to finite gridding.

**5.1. The issue of data processing.** Clearly, the total number of records is exactly the number of grid points  $m$ . For the conventional method, to accomplish  $N$  simulations for each grid point, the total number of times that we update the data record is  $Nm$ . As illustrated in section 4, to control the error due to finite gridding requires an extremely large number,  $m$ , of grid points even for the moderate requirement of  $\epsilon$ . Therefore,  $Nm$  is usually a *very large number*. It can be shown that *if the sample reuse algorithm employs the same data structure as that of the conventional method, then, for any gridding scheme with  $m$  grid points, the total number of times that we update the data record is also  $Nm$ .* This is true because, for every time a

FIG. 5. Comparison of  $m_{\text{eq}}$  ( $\lambda = 10^3$ ,  $d = 5$ ,  $1 + d \ln \lambda = 35.5388$ ).

record  $(k_i, n_i)$  is updated, the number  $n_i$  can be increased only by 1, and the number  $n_i$  must be  $N$  when the experiment is completed. To see that data processing with the conventional data structure is a severe challenge, one can consider the example discussed in Remark 1 of section 4. With  $m \geq 3,240,000,001$  and normal sample size  $10^4 < N < 10^6$ , it can be seen that  $Nm$  will be in the range of  $3 \times 10^{13}$  to  $3 \times 10^{15}$ . This is an enormous burden for today's computing technology. For a modern computer with 1.9 GHz CPU and 256 M bytes RAM, it takes about 20 seconds to execute  $10^7$  times the command  $n_i \leftarrow n_i + 1$  written in the MATLAB language. It can be reasonably inferred that updating the data record  $3 \times 10^{13}$  times will take about  $20 \times 10^{-7} \times 3 \times 10^{13}$  seconds (i.e., about 700 days).

**5.2. The issue of memory space.** For the conventional data structure, the total number of records is  $m$ . To execute the sample reuse algorithm or the conventional one with such a data structure, each record must occupy some physical addresses. Such addresses are necessary for storing and visualizing the outcome of simulations. Of course, to obtain the outcome simulations may require a much higher amount of computer internal memory to execute the algorithm. Since  $m$  is usually a very large number, the consumption of memory used to store and visualize the output of simulation can be enormous. To see this, consider again the example discussed in Remark 1 of section 4. Since a floating point number occupies 2 bytes, storing a tuple of the form  $(k_i, n_i)$  needs 4 bytes. For  $m \geq 3,240,000,001$ , the data record will consume  $4 \times 3,240,000,001 \approx 13 \times 10^9$  bytes (i.e., about 13 giga bytes) of RAM. Such a requirement, just for visualizing the outcome of the simulations, is a challenging task even for modern computers.

**6. New techniques of sample reuse.** In the previous section, we have shown that any algorithm using the conventional data structure suffers from the problems of the complexity of data processing and memory space. This is because the sample size  $N$  is usually very large and the number,  $m$ , of points in the partition of uncertainty

radius approaches infinity as the tolerance,  $\epsilon$ , approaches zero (see Theorem 4.2). In this section, we shall demonstrate that, by introducing a dynamic data structure and a new sample reuse algorithm, the average requirement of memory and the computational effort devoted to data processing are absolutely bounded, independent of the tolerance, and well within the power of modern computers.

**6.1. Data structure.** In order to address the memory issue and minimize the effort devoted to data processing, an appropriate data structure is critical. The key idea is to make use of the observation that, *for a set of consecutive grid points with identical records of simulation results, it suffices to store the information of the smallest and the largest grid points.* To illustrate our techniques, we enumerate, in chronological order of generation, the samples generated from various uncertainty bounding sets as  $X_1, X_2, \dots$ . When samples  $X_1, X_2, \dots, X_j$  have been generated, *the state of the experiment is completely represented by functions  $\mathbf{s}(i, j)$  and  $\mathbf{v}(i, j)$* , where

$$\mathbf{s}(i, j) = \sum_{k=1}^{l(i, j)} Y_i^k, \quad \mathbf{v}(i, j) = \sum_{k=1}^{l(i, j)} Z_i^k$$

with

$$(6.1) \quad Y_i^k = \begin{cases} 1 & \text{if } X_k \in \mathcal{B}_{r_i}, \\ 0 & \text{otherwise,} \end{cases}$$

$$(6.2) \quad l(i, j) = \max \left\{ \ell : 1 \leq \ell \leq j, \sum_{k=1}^{\ell} Y_i^k \leq N \right\},$$

and

$$(6.3) \quad Z_i^k = \begin{cases} 1 & \text{if } X_k \in \mathcal{B}_{r_i} \text{ and the robustness requirement is violated for } X_k, \\ 0 & \text{otherwise} \end{cases}$$

for  $i = 1, \dots, m$  and  $k = 1, \dots, j$ . The definitions of  $Y_i^k$ ,  $Z_i^k$  given in (6.1) and (6.3) are based on the principle of sample reuse in that a sample of uncertainty originally generated from larger bounding sets can be reused for smaller bounding sets.

The reason we introduce variable  $l(i, j)$  by (6.2) is that, for grid point  $r_i$ , once  $N$  equivalent simulations are available, the subsequent simulations can be ignored. By the principle of sample reuse,  $\mathbf{s}(i, j)$  and  $\mathbf{v}(i, j)$  are, respectively, the numbers of samples and violations (of the robustness requirement) for an uncertainty bounding set with radius  $r_i$ , collected from various bounding sets when samples  $X_1, X_2, \dots, X_j$  have been generated. When the experiment is completed, we have  $\mathbf{n}$  samples  $X_1, X_2, \dots, X_{\mathbf{n}}$  and

$$\mathbf{s}(i, \mathbf{n}) = N, \quad \mathbb{P}(r_i) = 1 - \frac{\mathbf{v}(i, \mathbf{n})}{N}, \quad i = 1, \dots, m.$$

For each value of  $j$  in the course of the simulation experiment, it suffices to record  $\mathbf{s}(i, j)$  and  $\mathbf{v}(i, j)$  for  $i = 1, \dots, m$  in order to save the outcome of simulation. Since the number of grid points,  $m$ , can be huge, this direct method of storing simulation results requires too much memory and data processing effort. To address this problem, we need to make use of the observation that  $\mathbf{s}(i, j)$  is piecewise constant with respect to

$i$  in the sense that  $\mathbf{s}(i, j)$  is like a discrete stair function of  $i$ . Thus, to record  $\mathbf{s}(i, j)$  for  $i = 1, \dots, m$ , we need only record the values of  $i$  at which  $\mathbf{s}(i, j)$  changes and the different values of  $\mathbf{s}(i, j)$ . This method also applies to  $\mathbf{v}(i, j)$ . To implement such a method, we shall introduce two matrices  $S^j$  and  $V^j$  as follows.

Since  $\mathbf{s}(i, j)$  is piecewise constant with respect to  $i$ , there exists a matrix  $S^j$  such that, for  $i = 1, \dots, m$ ,

$$(6.4) \quad \mathbf{s}(i, j) = \begin{cases} [S^j]_{\ell, 2} & \text{for } [S^j]_{\ell, 1} \leq i < [S^j]_{\ell+1, 1} \quad \text{with } 1 \leq \ell \leq \kappa - 1, \\ [S^j]_{\kappa, 2} & \text{for } [S^j]_{\kappa, 1} \leq i \leq m, \end{cases}$$

where  $\kappa$  is the number of rows of  $S^j$  and  $[A]_{i,j}$  denotes the element of matrix  $A$  in the  $i$ th row and the  $j$ th column. According to (6.4), for any positive integer  $i$  no greater than  $m$ , we can determine  $\mathbf{s}(i, j)$  from matrix  $S^j$  based on two cases. In the case that  $[S^j]_{\kappa, 1} \leq i \leq m$ , we can set  $\mathbf{s}(i, j) = [S^j]_{\kappa, 2}$ . In the case that there exists an integer  $\ell$  such that  $1 \leq \ell \leq \kappa - 1$  and that  $[S^j]_{\ell, 1} \leq i < [S^j]_{\ell+1, 1}$ , we can set  $\mathbf{s}(i, j) = [S^j]_{\ell, 2}$ . Roughly speaking, the first column of matrix  $S^j$  records the indexes of grid points for which the accumulated numbers of samples are jumping to different values. The second column of matrix  $S^j$  records the corresponding accumulated numbers of samples.

Similarly,  $\mathbf{v}(i, j)$  is piecewise constant with respect to  $i$ , and there exists a matrix  $V^j$  such that, for  $i = 1, \dots, m$ ,

$$(6.5) \quad \mathbf{v}(i, j) = \begin{cases} [V^j]_{\ell, 2} & \text{for } [V^j]_{\ell, 1} \leq i < [V^j]_{\ell+1, 1} \quad \text{with } 1 \leq \ell \leq \tau - 1, \\ [V^j]_{\tau, 2} & \text{for } [V^j]_{\tau, 1} \leq i \leq m, \end{cases}$$

where  $\tau$  is the number of rows of  $V^j$ . According to (6.5), for any positive integer  $i$  no greater than  $m$ , we can determine  $\mathbf{v}(i, j)$  from matrix  $V^j$  based on two cases. In the case that  $[V^j]_{\tau, 1} \leq i \leq m$ , we can set  $\mathbf{v}(i, j) = [V^j]_{\tau, 2}$ . In the case that there exists an integer  $\ell$  such that  $1 \leq \ell \leq \tau - 1$  and that  $[V^j]_{\ell, 1} \leq i < [V^j]_{\ell+1, 1}$ , we can set  $\mathbf{v}(i, j) = [V^j]_{\ell, 2}$ . Loosely speaking, the first column of matrix  $V^j$  records the indexes of grid points for which the accumulated numbers of violations are jumping to different values. The second column of matrix  $V^j$  records the corresponding accumulated numbers of violations.

In this paper, matrices  $S^j$  and  $V^j$  are, respectively, referred to as the *matrix of sample sizes* and the *matrix of violations*. At any stage in which samples  $X_1, \dots, X_j$  have been generated, the status of the experiment is completely characterized by matrices  $S^j, V^j$ . Both matrices are of two columns but of varying number of rows in the course of our experiment. Obviously, the numbers of rows of these matrices can be substantially less than the number of grid points  $m$ .

To save memory and data processing effort, we shall take advantage of the piecewise constant property of the accumulated numbers of samples and violations by constructing matrices  $S^j$  and  $V^j$  when we have generated uncertainty samples  $X_1, \dots, X_j$ . As can be seen in what follows, such matrices can be constructed recursively. Once we have  $S^j$  and  $V^j$ , we can generate sample  $X_{j+1}$  and update  $S^j, V^j$  as  $S^{j+1}, V^{j+1}$  in accordance with (6.4) and (6.5).

**6.2. Sample reuse algorithm.** In this section, we shall present our sample reuse algorithms as follows.

**Initialization** We initialize the matrices of sample sizes and violations by the following steps:

◇ Generate sample  $X_1$  uniformly from uncertainty set with radius  $r_m$ .

◇ Compute  $j$  such that  $X_1 \in \mathcal{B}_{r_i}$  for  $j \leq i \leq m$  and  $X_1 \notin \mathcal{B}_{r_i}$  for  $1 \leq i \leq j-1$ .

◇ Let  $S^1 = \begin{bmatrix} 1 & 1 \end{bmatrix}$  if  $j = 1$  and  $S^1 = \begin{bmatrix} 1 & 0 \\ j & 1 \end{bmatrix}$  if  $j > 1$ .

◇ Let  $V^1 = \begin{bmatrix} 1 & 0 \end{bmatrix}$  if the robustness requirement is satisfied for  $X_1$ , and let  $V^1 = S^1$  if the robustness requirement is violated for  $X_1$ .

**Sample generation** If  $[S^j]_{\kappa,1} < N$  then generate sample  $X_{j+1}$  uniformly from uncertainty set with radius  $r_m$ , otherwise generate sample  $X_{j+1}$  uniformly from uncertainty set with radius  $[S^j]_{\kappa-1,1}$ .

**Updating matrices** Update  $S^j$  as  $S^{j+1}$  by the method described in section 6.2.1. If the robustness requirement is satisfied for  $X_{j+1}$  then let  $V^{j+1} = V^j$ , otherwise update  $V^j$  as  $V^{j+1}$  by the method described in section 6.2.2.

**Stopping criterion** The sampling process is terminated if  $S^j$  has only one row and  $[S^j]_{1,2} = N$ .

In the above, we describe the basic steps of our sample reuse algorithm. The main purpose of the initialization is to build the starting matrices  $S^1$  and  $V^1$  based on the first sample generated from the largest bounding set. The first sample must be drawn from the bounding set of the largest radius  $r_m$ . The second step of initiation is to determine the index  $j$  of the smallest bounding set which includes the sample  $X_1$ . The third step of initiation is to determine the starting matrix of sample sizes. If  $j = 1$ , then the sample  $X_1$  can be used by all bounding sets, and thus  $\mathbf{s}(i, 1) = 1$  for  $i = 1, \dots, m$ . It follows that we should let  $S^1 = \begin{bmatrix} 1 & 1 \end{bmatrix}$  in accordance with (6.4). If  $j > 1$ , then  $\mathbf{s}(i, 1) = 1$  for  $i = j, \dots, m$  and  $\mathbf{s}(i, 1) = 0$  for  $i = 1, \dots, j-1$ . Consequently, we should let  $S^1 = \begin{bmatrix} 1 & 0 \\ j & 1 \end{bmatrix}$  according to (6.4). The fourth step of initiation is to determine the starting matrix of violations. If the robustness requirement is satisfied for  $X_1$ , then  $\mathbf{v}(i, 1) = 0$  for  $i = 1, \dots, m$ , and thus we should let  $V^1 = \begin{bmatrix} 1 & 0 \end{bmatrix}$  be consistent with (6.5). On the other hand, if the robustness requirement is violated for  $X_1$ , then the matrix of violations is the same as the matrix of sample sizes.

In the step of sample generation, a new sample is generated from the currently largest bounding set for which the number of collected samples has not reached  $N$ . The new sample is used to update the data record based on (6.4) and (6.5) in the step of updating matrices. Finally, all bounding sets will have enough collected samples, and thus the simulation should be stopped when  $S^j$  has one row and  $[S^j]_{1,2} = N$ .

**6.2.1. Sample sizes tracking.** In this section, we describe how to update the matrix of sample sizes. The key idea is to ensure condition (6.4). Let  $\kappa$  be the number of rows of  $S^j$ . We proceed as follows.

**Step (1)** Compute an index  $j^*$  such that  $X_{j+1} \in \mathcal{B}_{r_i}$  for  $j^* \leq i \leq m$  and  $X_{j+1} \notin \mathcal{B}_{r_i}$  for  $1 \leq i \leq j^* - 1$  (note that explicit formulas for computing  $j^*$  are available when using uniform or geometric grid scheme).

The purpose of this step is to find the index of the smallest bounding set which includes the new sample  $X_{j+1}$ . The bounding sets with index no less than  $j^*$  can use the new sample.

**Step (2)** Modify  $S^j$  as a temporary matrix  $\widehat{S}^{j+1}$  based on the following three cases.

Case (1).  $[S^j]_{\ell^*,1} < j^* < [S^j]_{\ell^*+1,1}$  for some  $\ell^* \in \{1, \dots, \kappa-1\}$ ;

Case (2).  $j^* = [S^j]_{\ell^*,1}$  for some  $\ell^* \in \{1, \dots, \kappa\}$ ;

Case (3).  $j^* > [S^j]_{\kappa,1}$ .

Case (1) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_p$  and  $r_q$  such that  $p = [S^j]_{\ell^*,1}$ ,  $q = [S^j]_{\ell^*+1,1}$  and wherein bounding set  $\mathcal{B}_{r_i}$  has the same number of collected samples for all  $i$  satisfying  $p \leq i < q$ . Therefore, a new row

needs to be inserted into the matrix of sample sizes. Moreover, the number of collected samples needs to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq j^*$ . Specifically, this can be accomplished as follows:

In Case (1), define  $\widehat{S}^{j+1}$  as a  $(\kappa + 1) \times 2$  matrix such that

$$\begin{aligned} [\widehat{S}^{j+1}]_{\ell,1} &= [S^j]_{\ell,1}, & [\widehat{S}^{j+1}]_{\ell,2} &= [S^j]_{\ell,2}, & \ell &= 1, \dots, \ell^*, \\ [\widehat{S}^{j+1}]_{\ell^*+1,1} &= j^*, & [\widehat{S}^{j+1}]_{\ell^*+1,2} &= 1 + [S^j]_{\ell^*,2}, \\ [\widehat{S}^{j+1}]_{\ell+1,1} &= [S^j]_{\ell,1}, & [\widehat{S}^{j+1}]_{\ell+1,2} &= 1 + [S^j]_{\ell,2}, & \ell &= \ell^* + 1, \dots, \kappa. \end{aligned}$$

Case (2) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_{p-1}$  and  $r_p$  such that  $p = [S^j]_{\ell^*,1}$ . The new sample can be used by bounding set  $\mathcal{B}_{r_i}$  with  $i \geq p$ . No new row needs to be inserted into the matrix of sample sizes. However, by the principle of sample reuse, the number of collected samples needs to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq p$ . Specifically, this can be accomplished as follows:

In Case (2), define  $\widehat{S}^{j+1}$  as a  $\kappa \times 2$  matrix such that

$$\begin{aligned} [\widehat{S}^{j+1}]_{\ell,1} &= [S^j]_{\ell,1}, & [\widehat{S}^{j+1}]_{\ell,2} &= [S^j]_{\ell,2}, & \ell &= 1, \dots, \ell^* - 1, \\ [\widehat{S}^{j+1}]_{\ell,1} &= [S^j]_{\ell,1}, & [\widehat{S}^{j+1}]_{\ell,2} &= 1 + [S^j]_{\ell,2}, & \ell &= \ell^*, \dots, \kappa. \end{aligned}$$

Case (3) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_p$  and  $r_m$  such that  $p = [S^j]_{\kappa,1}$ . The new sample can be used by bounding set  $\mathcal{B}_{r_i}$  with  $p \leq i \leq m$ . A new row needs to be added to the matrix of sample sizes. Moreover, by the principle of sample reuse, the number of collected sample sizes needs to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq p$ . Specifically, this can be accomplished as follows:

In Case (3), define  $\widehat{S}^{j+1}$  as a  $(\kappa + 1) \times 2$  matrix such that

$$\begin{aligned} [\widehat{S}^{j+1}]_{\ell,1} &= [S^j]_{\ell,1}, & [\widehat{S}^{j+1}]_{\ell,2} &= [S^j]_{\ell,2}, & \ell &= 1, \dots, \kappa, \\ [\widehat{S}^{j+1}]_{\kappa+1,1} &= j^*, & [\widehat{S}^{j+1}]_{\kappa+1,2} &= 1 + [S^j]_{\kappa,2}. \end{aligned}$$

**Step (3)** Let  $\widehat{\kappa}$  denote the number of rows of  $\widehat{S}^{j+1}$ . If  $[\widehat{S}^{j+1}]_{\widehat{\kappa},2} < N$ , then let  $S^{j+1} = \widehat{S}^{j+1}$ ; otherwise find index  $\ell_*$  by a bisection search such that  $[\widehat{S}^j]_{\ell_*,1,2} < N \leq [\widehat{S}^j]_{\ell_*,2}$  and define  $S^{j+1}$  as an  $\ell_* \times 2$  matrix such that

$$\begin{aligned} [S^{j+1}]_{\ell,1} &= [\widehat{S}^{j+1}]_{\ell,1}, & [S^{j+1}]_{\ell,2} &= [\widehat{S}^{j+1}]_{\ell,2}, & \ell &= 1, \dots, \ell_* - 1, \\ [S^{j+1}]_{\ell_*,1} &= [\widehat{S}^{j+1}]_{\ell_*,1}, & [S^{j+1}]_{\ell_*,2} &= [\widehat{S}^{j+1}]_{\ell_*,2}. \end{aligned}$$

The purpose of this step is to make sure that no more than  $N$  samples are used for each bounding set. In this step, the records for those bounding sets having enough collected samples have been merged.

**6.2.2. Violations tracking.** In this section, we describe how to update the matrix of violations in the case that the robustness requirement is violated for  $X_{j+1}$ . The key idea is to ensure condition (6.5). Let  $\kappa$  be the number of rows of  $S^j$ . Let  $\tau$  be the number of rows of  $V^j$ . Let  $j^*$  be the index obtained in the process of updating  $S^j$  such that  $X_{j+1} \in \mathcal{B}_{r_i}$  for  $j^* \leq i \leq m$  and  $X_{j+1} \notin \mathcal{B}_{r_i}$  for  $1 \leq i \leq j^* - 1$ . We proceed as follows.

**Step (i)** Identify the *maximal* number  $\iota$  such that the experiment for uncertainty radius  $r_p$  with  $p = [V^j]_{\iota,1}$  has not been completed by the following method.

◇ If  $[S^j]_{\kappa,2} < N$ , then let  $\iota = \kappa$ ; otherwise find  $\iota$  by a bisection search such that  $[V^j]_{\iota,1} < [S^j]_{\kappa,1}$ ,  $[V^j]_{\iota+1,1} \geq [S^j]_{\kappa,1}$ .

Here “the experiment for a bounding set is completed” means that the number of collected samples reaches  $N$ . Obviously, if  $[S^j]_{\kappa,2} < N$ , the experiment has not completed for all bounding sets. If  $[S^j]_{\kappa,2} = N$ , then the experiment is completed for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq [S^j]_{\kappa,1}$ . The maximal number  $\iota$  satisfies  $[V^j]_{\iota,1} < [S^j]_{\kappa,1}$ ,  $[V^j]_{\iota+1,1} \geq [S^j]_{\kappa,1}$ .

**Step (ii)** Modify  $V^j$  as a temporary matrix  $\widehat{V}^j$  based on the following two cases.

Case (a).  $[S^j]_{\kappa,2} < N$  or  $[S^j]_{\kappa,2} = N$ ,  $[V^j]_{\iota+1,1} = [S^j]_{\kappa,1}$ .

Case (b).  $[S^j]_{\kappa,2} = N$  and the index  $\iota$  guarantees  $[V^j]_{\iota+1,1} > [S^j]_{\kappa,1}$ .

In Case (a), we define  $\widehat{V}^j = V^j$ . In Case (b), we define  $\widehat{V}^j$  as a  $(\tau + 1) \times 2$  matrix such that

$$\begin{aligned} [\widehat{V}^j]_{\ell,1} &= [V^j]_{\ell,1}, & [\widehat{V}^j]_{\ell,2} &= [V^j]_{\ell,2}, & \ell &= 1, \dots, \iota, \\ [\widehat{V}^j]_{\iota+1,1} &= [S^j]_{\kappa,1}, & [\widehat{V}^j]_{\iota+1,2} &= [V^j]_{\iota,2}, \\ [\widehat{V}^j]_{\ell+1,1} &= [V^j]_{\ell,1}, & [\widehat{V}^j]_{\ell+1,2} &= [V^j]_{\ell,2}, & \ell &= \iota + 1, \dots, \tau. \end{aligned}$$

This step prepares us for updating the matrix of violations in Step (iii). It is ensured that, in both Cases (a) and (b), the rows of matrix  $\widehat{V}^j$  of index greater than  $\iota$  correspond to the completed experiments. Hence, as will be seen in Step (iii), such rows of matrix  $\widehat{V}^j$  need not to be updated.

**Step (iii)** Obtain  $V^{j+1}$  by modifying  $\widehat{V}^j$  based on the following three cases.

Case (i).  $[\widehat{V}^j]_{\ell^*,1} < j^* < [\widehat{V}^j]_{\ell^*+1,1}$  for some  $\ell^* \in \{1, \dots, \iota - 1\}$ .

Case (ii).  $j^* = [\widehat{V}^j]_{\ell^*,1}$  for some  $\ell^* \in \{1, \dots, \iota\}$ .

Case (iii).  $j^* > [\widehat{V}^j]_{\iota,1}$ .

Case (i) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_p$  and  $r_q$  such that  $p = [\widehat{V}^j]_{\ell^*,1}$ ,  $q = [\widehat{V}^j]_{\ell^*+1,1}$  and wherein bounding set  $\mathcal{B}_{r_i}$  has the same number of collected violations for all  $i$  satisfying  $p \leq i < q$ . Therefore, a new row needs to be inserted into the matrix of violations. Moreover, the number of collected violations needs to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq j^*$ . Recall that the rows of  $\widehat{V}^j$  of index greater than  $\iota$  correspond to the complete experiments; those rows should be passed without change to  $V^{j+1}$ . Specifically, this can be accomplished as follows:

Let  $\widehat{\tau}$  be the number of rows of  $\widehat{V}^j$ . In Case (i), define  $V^{j+1}$  as a  $(\widehat{\tau} + 1) \times 2$  matrix such that

$$\begin{aligned} [V^{j+1}]_{\ell,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= 1, \dots, \ell^*, \\ [V^{j+1}]_{\ell^*+1,1} &= j^*, & [V^{j+1}]_{\ell^*+1,2} &= 1 + [\widehat{V}^j]_{\ell^*,2}, \\ [V^{j+1}]_{\ell+1,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell+1,2} &= 1 + [\widehat{V}^j]_{\ell,2}, & \ell &= \ell^* + 1, \dots, \iota, \\ [V^{j+1}]_{\ell+1,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell+1,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= \iota + 1, \dots, \widehat{\tau}. \end{aligned}$$

Case (ii) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_{p-1}$  and  $r_p$  such that  $p = [\widehat{V}^j]_{\ell^*,1}$ . The new sample can be used by bounding set  $\mathcal{B}_{r_i}$  with  $i \geq p$ . No new row needs to be inserted into the matrix of violations. However, by the principle of sample reuse, the number of collected violations needs

to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq p$ . The rows of  $\widehat{V}^j$  of index greater than  $\iota$  should be directly passed to  $V^{j+1}$ . Specifically, this can be accomplished as follows:

In Case (ii), define  $V^{j+1}$  as a  $\widehat{\tau} \times 2$  matrix such that

$$\begin{aligned} [V^{j+1}]_{\ell,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= 1, \dots, \ell^* - 1, \\ [V^{j+1}]_{\ell,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell,2} &= 1 + [\widehat{V}^j]_{\ell,2}, & \ell &= \ell^*, \dots, \iota, \\ [V^{j+1}]_{\ell,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= \iota + 1, \dots, \widehat{\tau}. \end{aligned}$$

Case (iii) corresponds to the situation wherein the new sample  $X_{j+1}$  falls between two nested bounding sets with radius  $r_p$  and  $r_m$  such that  $p = [\widehat{V}^j]_{\iota,1}$ . The new sample can be used by bounding set  $\mathcal{B}_{r_i}$  with  $j^* \leq i \leq m$  if the experiment has not been completed. A new row needs to be added to the matrix of violations. Moreover, by the principle of sample reuse, the number of collected violations needs to be increased for bounding set  $\mathcal{B}_{r_i}$  with  $i \geq j^*$  if the experiment has not been completed. Specifically, this can be accomplished as follows:

In Case (iii), define  $V^{j+1}$  as a  $(\widehat{\tau} + 1) \times 2$  matrix such that

$$\begin{aligned} [V^{j+1}]_{\ell,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= 1, \dots, \iota, \\ [V^{j+1}]_{\iota+1,1} &= j^*, & [V^{j+1}]_{\iota+1,2} &= 1 + [\widehat{V}^j]_{\iota,2}, \\ [V^{j+1}]_{\ell+1,1} &= [\widehat{V}^j]_{\ell,1}, & [V^{j+1}]_{\ell+1,2} &= [\widehat{V}^j]_{\ell,2}, & \ell &= \iota + 1, \dots, \widehat{\tau}. \end{aligned}$$

**6.3. Complexity of data processing and memory.** It can be seen that the memory requirement and the computation due to data processing are determined by the sizes of matrices  $S^j$  and  $V^j$ . To quantify the complexity, we have the following results.

THEOREM 6.1.

For any  $j$ , the following statements hold true:

- (I) The number of rows of matrix  $S^j$  is no more than  $N$ .
- (II) The expected number of rows of matrix  $V^j$  is no greater than

$$(6.6) \quad 1 + N \left[ P_e(a) + 2d \int_{\frac{a}{\hbar}}^a \frac{P_e(x)}{x} dx \right] \leq 1 + N P_e(a) (1 + 2d \ln \hbar)$$

where  $P_e(x) = 1 - \min_{y \in [\frac{a}{\lambda}, x]} \mathbb{P}(y)$  for all  $x \in [\frac{a}{\lambda}, a]$  and

$$\hbar = \max \left( \min \left( \lambda, \frac{a}{\rho_0} \right), 1 \right)$$

with  $\rho_0 = \sup\{r \mid \mathbb{P}(r) = 1\}$ .

See Appendix E for a proof. We now revisit the robustness analysis problem discussed in Remark 1 of section 4 from the perspective of memory complexity. Assume that each data record  $(k_i, n_i)$  (i.e., each row of  $V^j$ ) occupies 4 bytes of computer internal memory (RAM). As illustrated in section 5.2, when using the conventional data structure, it takes 13G (gigabytes) of RAM to save the data and visualize the results. On the other hand, in our new algorithm, if the smallest proportion is

$p_* = \min_{r \in [\frac{a}{\lambda}, a]} \mathbb{P}(r) > 0.999$  and  $\hbar < \frac{3}{2}$ , the RAM requirement will be equivalent to

$$\begin{aligned} & 4 \times [1 + (1 - p_*) (1 + 2d \ln \hbar) N] \\ &= 4 \times \left[ 1 + (1 - 0.999) \times \left( 1 + 2 \times 1800 \times \ln \frac{3}{2} \right) \times 10^6 \right] \\ &< 6.2 \times 10^6 \text{ bytes} \approx 6.2 \text{ M bytes.} \end{aligned}$$

It can be seen that such a memory requirement is extremely low as compared to that of the conventional method. Theorem 6.1 also reveals that the complexity of data processing is very low.

**6.4. Confidence band.** To be useful, any numerical techniques should provide a method for error assessment. Monte Carlo simulation is no exception. The following results allow us to construct a confidence band for the robustness curve. Such a post-experimental statistical inference can remedy the conservatism of an a priori choice of sample size  $N$  based on the Chernoff bound. In order to overcome the computational complexity of the Clopper–Pearson confidence interval [10], we have developed new methods to facilitate the construction of the confidence band.

**THEOREM 6.2.** *Let  $\delta \in (0, 1)$ . Let  $\mathcal{L}(k) = \frac{k}{N} + \frac{3}{4} \frac{1 - \frac{2k}{N} - \sqrt{1 + 4\theta k(1 - \frac{k}{N})}}{1 + \theta N}$  and  $\mathcal{U}(k) = \frac{k}{N} + \frac{3}{4} \frac{1 - \frac{2k}{N} + \sqrt{1 + 4\theta k(1 - \frac{k}{N})}}{1 + \theta N}$  with  $\theta = \frac{9}{8 \ln \frac{2}{\delta}}$ . Let  $\zeta = \frac{r - r_i}{r_{i+1} - r_i}$ . Let*

$$K_i = N - \mathbf{v}(i, \mathbf{n}), \quad i = 1, \dots, m.$$

*Let  $\varsigma = 1 - \frac{g(r_*)}{r_{i+1} - r_i}$ . Define  $\bar{\mathbb{P}}(r) = \zeta \mathcal{U}(K_i) + (1 - \zeta) \mathcal{U}(K_{i+1}) + \varsigma$  and  $\underline{\mathbb{P}}(r) = \zeta \mathcal{L}(K_i) + (1 - \zeta) \mathcal{L}(K_{i+1}) - \varsigma$ . Then*

$$\Pr\{\underline{\mathbb{P}}(r) < \mathbb{P}(r) < \bar{\mathbb{P}}(r) \ \forall r \in [r_i, r_{i+1}]\} > 1 - \delta.$$

See Appendix F for a proof. The family of intervals  $[\underline{\mathbb{P}}(r), \bar{\mathbb{P}}(r)]$ ,  $r \in [a/\lambda, a]$ , is referred to as the *confidence band*. It is important to note that the confidence band can be efficiently constructed by making use of the piecewise constant property of  $\mathbf{v}(i, \mathbf{n})$ . It can be shown that the computational complexity of constructing the confidence band is also absolutely bounded.

**7. Examples.** In this section, we shall illustrate by examples the application of our techniques in control of uncertain systems. For a robustness analysis problem, one can define an indicator function  $\mathbb{I}(\cdot)$  such that

$$\mathbb{I}(\Delta) = \begin{cases} 1 & \text{if the robustness requirement is satisfied for } \Delta, \\ 0 & \text{otherwise} \end{cases}$$

for any uncertainty instance  $\Delta$ . Let  $\Delta_1, \dots, \Delta_N$  be  $N$  i.i.d. samples uniformly distributed over an uncertainty bounding set  $\mathcal{B}_r$ . Then,  $\mathbb{I}(\Delta_i)$ ,  $i = 1, \dots, N$ , are i.i.d. Bernoulli random variables with a success probability  $\mathbb{P}(r)$ . A minimum variance unbiased estimator of  $\mathbb{P}(r)$  is taken as

$$\hat{\mathbb{P}}(r) = \frac{\sum_{i=1}^N \mathbb{I}(\Delta_i)}{N}.$$

The Chernoff bound [9] asserts that, for any  $\varepsilon$ ,  $\delta \in (0, 1)$ ,

$$\Pr\left\{\left|\hat{\mathbb{P}}(r) - \mathbb{P}(r)\right| < \varepsilon\right\} > 1 - \delta$$

provided that

$$(7.1) \quad N > \frac{\ln \frac{2}{\delta}}{2\epsilon^2}.$$

Since the explicit bound (7.1) is independent of the quantity  $\mathbb{P}(r)$  that we want to estimate, we can use it as the guideline for the choice of sample size  $N$ .

Now we first consider the robust stability problem studied in [12] by a deterministic approach. The system considered in [12] is represented by Figure 6. The compensator is  $C(s) = \frac{s+2}{s+10}$  and the plant is  $P(s) = \frac{800(1+0.1\delta_1)}{s(s+4+0.2\delta_2)(s+6+0.3\delta_3)}$  with parametric uncertainty  $\Delta = [\delta_1, \delta_2, \delta_3]$ . For  $\epsilon = \delta = 0.01$ , we determined the sample size  $N$  from the Chernoff bound (7.1) as  $N = 26492$ . In order to make the discretization error  $\epsilon$  be less than  $10^{-4}$  with a geometrical gridding over uncertainty radius interval [3, 8], we obtained the number of grid point as  $m = 14714$  by formula (4.5). In this problem case, the evaluation of system performance for sample  $\Delta_i$  is actually the evaluation of the indicator function

$$\mathbb{I}(\Delta_i) = \begin{cases} 1 & \text{if the closed-loop system is stable for } \Delta_i, \\ 0 & \text{otherwise.} \end{cases}$$

FIG. 6. *Uncertain system.*

The deterministic robustness margin is found to be 3.44 by a branch and bound technique (see page 163 of [12]). As shown in Figure 7, we have applied our new sample reuse algorithms to obtain an estimation of the function  $\mathbb{P}(r)$  and corresponding confidence band with confidence coefficient 99% (based on Theorem 6) for assessing the accuracy of the estimation. Owing to the power of the new method of sample reuse, the ENGP is less than 4 and the memory requirement is negligible. In addition to the low computational complexity, the robustness curve obtained by the new algorithms provides more insight into the system robustness than the deterministic robustness margin.

Next, we consider a robust performance problem involving time-domain specifications for the same system shown by Figure 6. The robustness requirement is that the rise time and settling time should be no more than 0.25 and 3.5 seconds, respectively, and the overshoot should be no more than 70% under the condition that the closed-loop system is stable. For this robust performance problem, the corresponding indicator function becomes

$$\mathbb{I}(\Delta_i) = \begin{cases} 1 & \text{if the closed-loop system is stable} \\ & \text{and the time specification is satisfied for } \Delta_i, \\ 0 & \text{otherwise.} \end{cases}$$

The estimation of  $\mathbb{P}(r)$  together with its corresponding confidence band are shown in Figure 8, where the sample size  $N$  is taken as 26,492 and the number of grid

FIG. 7. Robustness analysis with stability requirement.

FIG. 8. Robustness analysis with time specifications.

points is taken by (4.5) as 16,481 to ensure the discretization error less than  $10^{-4}$  for a geometric gridding over uncertainty radius interval  $[0.1, 0.3]$ . It is well known that this type of problem is, in general, intractable by the deterministic approach. However, the new sample reuse algorithms can provide an efficient and insightful solution.

**8. Conclusion.** It is possible to make a case for the statement that the probabilistic robustness analysis is essentially the study of the robustness function,

especially its probabilistic implications, efficient evaluation, and computational complexity. We have addressed these issues in this paper. In particular, we have developed randomized algorithms which offer more insights for system robustness. We rigorously show that, in both aspects of computer running time and memory requirement, the complexity of such randomized algorithms is not only linear in the dimension of uncertainty space, but also surprisingly low. While the complexity of the conventional method grows linearly with the number of grid points, and the error due to interpolation is not well controlled, our techniques completely resolve such issues. In short, our method guarantees accuracy and efficiency.

**Appendix A. Proof of Theorem 3.1.** We first establish a basic inequality that will be used to prove the theorem.

LEMMA A.1. *For any  $x > 1$ ,*

$$\frac{1}{x} + \ln x > 1.$$

*Proof.* Let

$$f(x) = \frac{1}{x} + \ln x.$$

Then  $f(1) = 1$  and

$$\frac{d f(x)}{d x} = \frac{x-1}{x^2} > 0 \quad \forall x > 1.$$

It follows that  $f(x) > 1$  for all  $x > 1$ .  $\square$

Now we are in the position to prove Theorem 3.1. Observing that

$$\left(\frac{r_m}{r_1}\right)^d = \prod_{i=1}^{m-1} \left(\frac{r_{i+1}}{r_i}\right)^d,$$

we have

$$\ln \left(\frac{r_m}{r_1}\right)^d = \sum_{i=1}^{m-1} \ln \left(\frac{r_{i+1}}{r_i}\right)^d.$$

Therefore,

$$\sum_{i=1}^{m-1} \left(\frac{r_i}{r_{i+1}}\right)^d + \ln \left(\frac{r_m}{r_1}\right)^d = \sum_{i=1}^{m-1} \left[ \frac{1}{\left(\frac{r_{i+1}}{r_i}\right)^d} + \ln \left(\frac{r_{i+1}}{r_i}\right)^d \right].$$

Since  $\left(\frac{r_{i+1}}{r_i}\right)^d > 1$ ,  $i = 1, \dots, m-1$ , it follows from Lemma A.1 that

$$\frac{1}{\left(\frac{r_{i+1}}{r_i}\right)^d} + \ln \left(\frac{r_{i+1}}{r_i}\right)^d > 1, \quad i = 1, \dots, m-1.$$

Hence,

$$\sum_{i=1}^{m-1} \left(\frac{r_i}{r_{i+1}}\right)^d + \ln \left(\frac{r_m}{r_1}\right)^d > m-1,$$

or equivalently,

$$m - \sum_{i=1}^{m-1} \left( \frac{r_i}{r_{i+1}} \right)^d < 1 + \ln \left( \frac{r_m}{r_1} \right)^d = 1 + d \ln \lambda.$$

Finally, by Theorem 1 of [6] and the definition of  $m_{\text{eq}}$ , we have

$$m_{\text{eq}} = m - \sum_{i=1}^{m-1} \left( \frac{r_i}{r_{i+1}} \right)^d < 1 + d \ln \lambda.$$

**Appendix B. Proof of Theorem 4.1.** To prove the theorem, we need some preliminary results. It is derived in [2] that  $\left| \frac{d\mathbb{P}(r)}{dr} \right| < \frac{2d}{r}$  when  $\mathbb{P}(\cdot)$  is differentiable. The following lemma indicates that the bound on the rate of variation of  $\mathbb{P}(\cdot)$  can be much tighter.

LEMMA B.1. *For the arbitrary robustness requirement,*

$$|\mathbb{P}(r + \Delta r) - \mathbb{P}(r)| \leq 1 - \left( 1 + \frac{\Delta r}{r} \right)^{-d} < \frac{d}{r} \Delta r$$

for any  $r > 0$  and any  $\Delta r > 0$ .

*Proof.* Let  $\mathcal{Q}_r \subseteq \mathcal{B}_r$  be the set such that the robustness requirement is satisfied. Let

$$I_1 = \frac{\text{vol}(\mathcal{Q}_{r+\Delta r})}{\text{vol}(\mathcal{B}_{r+\Delta r})} - \frac{\text{vol}(\mathcal{Q}_r)}{\text{vol}(\mathcal{B}_{r+\Delta r})}, \quad I_2 = \frac{\text{vol}(\mathcal{Q}_r)}{\text{vol}(\mathcal{B}_{r+\Delta r})} - \frac{\text{vol}(\mathcal{Q}_r)}{\text{vol}(\mathcal{B}_r)}.$$

Let “ $\setminus$ ” denote the operation of set minus. Observing that  $\mathcal{Q}_{r+\Delta r} \setminus \mathcal{Q}_r \subseteq \mathcal{B}_{r+\Delta r} \setminus \mathcal{B}_r$ , we have  $\text{vol}(\mathcal{Q}_{r+\Delta r}) - \text{vol}(\mathcal{Q}_r) \leq \text{vol}(\mathcal{B}_{r+\Delta r}) - \text{vol}(\mathcal{B}_r)$ . Using this fact and the identity  $\text{vol}(\mathcal{B}_r) = r^d \text{vol}(\mathcal{B}_1)$ , we have

$$0 \leq I_1 \leq \frac{\text{vol}(\mathcal{B}_{r+\Delta r}) - \text{vol}(\mathcal{B}_r)}{\text{vol}(\mathcal{B}_{r+\Delta r})} = 1 - \left( 1 + \frac{\Delta r}{r} \right)^{-d}$$

and

$$- \left[ 1 - \left( 1 + \frac{\Delta r}{r} \right)^{-d} \right] \leq - \frac{\text{vol}(\mathcal{Q}_r)}{\text{vol}(\mathcal{B}_r)} \frac{\text{vol}(\mathcal{B}_{r+\Delta r}) - \text{vol}(\mathcal{B}_r)}{\text{vol}(\mathcal{B}_{r+\Delta r})} = I_2.$$

Therefore,  $|\mathbb{P}(r + \Delta r) - \mathbb{P}(r)| = |I_1 + I_2| \leq 1 - \left( 1 + \frac{\Delta r}{r} \right)^{-d} < \frac{d}{r} \Delta r$ , where the last inequality follows from inequality  $1 - \left( 1 + \frac{x}{r} \right)^{-d} < \frac{dx}{r}$  for all  $x > 0$ . To prove this inequality, we can define function  $h(x) = 1 - \left( 1 + \frac{x}{r} \right)^{-d} - \frac{dx}{r}$ ,  $x > 0$ , and check that  $h(0) = 0$  and  $\frac{\partial h(x)}{\partial x} = \frac{d}{r} \left[ \left( 1 + \frac{x}{r} \right)^{-(d+1)} - 1 \right] < 0$  for all  $x > 0$ .  $\square$

We are now in the position to prove the theorem. It can be shown that

$$\begin{aligned} |\mathbb{P}(r) - \mathbb{P}^*(r)| &= \left| \frac{(r_{i+1} - r)[\mathbb{P}(r) - \mathbb{P}(r_i)] + (r - r_i)[\mathbb{P}(r) - \mathbb{P}(r_{i+1})]}{r_{i+1} - r_i} \right| \\ (B.1) \quad &\leq \frac{(r_{i+1} - r)|\mathbb{P}(r) - \mathbb{P}(r_i)| + (r - r_i)|\mathbb{P}(r) - \mathbb{P}(r_{i+1})|}{r_{i+1} - r_i}. \end{aligned}$$

By Lemma B.1 and inequality (B.1), we have

$$\begin{aligned} |\mathbb{P}(r) - \mathbb{P}^*(r)| &\leq \frac{(r_{i+1} - r) \left[ 1 - \left( \frac{r}{r_i} \right)^{-d} \right] + (r - r_i) \left[ 1 - \left( \frac{r_{i+1}}{r} \right)^{-d} \right]}{r_{i+1} - r_i} \\ &= 1 - \frac{g(r)}{r_{i+1} - r_i}. \end{aligned}$$

Note that

$$\frac{\partial g(r)}{\partial r} = \Phi(r) - \Psi(r),$$

where

$$\Phi(r) = \left( \frac{r_{i+1}}{r} \right)^{-d} \left[ 1 + \left( 1 - \frac{r_i}{r} \right) d \right], \quad \Psi(r) = \left( \frac{r}{r_i} \right)^{-d} \left[ 1 + \left( \frac{r_{i+1}}{r} - 1 \right) d \right].$$

It can be verified that

$$\Phi(r_i) = \left( \frac{r_{i+1}}{r_i} \right)^{-d} < 1, \quad \Psi(r_i) = 1 + \left( \frac{r_{i+1}}{r_i} - 1 \right) d > 1, \quad \frac{\partial g(r)}{\partial r} \Big|_{r=r_i} < 0,$$

$$\Phi(r_{i+1}) = 1 + \left( 1 - \frac{r_i}{r_{i+1}} \right) d > 1, \quad \Psi(r_{i+1}) = \left( \frac{r_{i+1}}{r_i} \right)^{-d} < 1, \quad \frac{\partial g(r)}{\partial r} \Big|_{r=r_{i+1}} > 0.$$

It can be checked that  $\Phi(r)$  is a monotone increasing function of  $r$  and that  $\Psi(r)$  is a monotone decreasing function of  $r$ . Hence,  $\frac{\partial g(r)}{\partial r}$  is a monotone increasing function of  $r$ . Moreover, there exists a unique number  $r_\star \in (r_i, r_{i+1})$  such that  $\frac{\partial g(r)}{\partial r} \Big|_{r=r_\star} = 0$ , i.e.,  $\Phi(r_\star) = \Psi(r_\star)$ . Furthermore,  $g(r)$  is a convex function of  $r$ . Consequently,

$$\min_{r \in [r_i, r_{i+1}]} g(r) = g(r_\star),$$

and we have shown

$$|\mathbb{P}(r) - \mathbb{P}^*(r)| \leq 1 - \frac{g(r_\star)}{r_{i+1} - r_i} \quad \forall r \in [r_i, r_{i+1}].$$

Since  $\frac{\partial g(r)}{\partial r}$  is a monotone increasing function of  $r$ , we can compute  $r_\star$  by a bisection search over interval  $(r_i, r_{i+1})$ .

By Lemma B.1 and inequality (B.1), we have

$$\begin{aligned} |\mathbb{P}(r) - \mathbb{P}^*(r)| &\leq \frac{(r_{i+1} - r)(r - r_i) \frac{d}{r_i} + (r - r_i)(r_{i+1} - r) \frac{d}{r}}{r_{i+1} - r_i} \\ &\leq \frac{(r_{i+1} - r)(r - r_i) \frac{d}{r_i} + (r - r_i)(r_{i+1} - r) \frac{d}{r_i}}{r_{i+1} - r_i} \\ &\leq \frac{2d}{r_i(r_{i+1} - r_i)} \max_{r \in [r_i, r_{i+1}]} (r_{i+1} - r)(r - r_i) \\ &= \frac{2d}{r_i(r_{i+1} - r_i)} \frac{(r_{i+1} - r_i)^2}{4} \\ &= \frac{d(r_{i+1} - r_i)}{2r_i}. \end{aligned}$$

**Appendix C. Proof of Theorem 4.2.** By Theorem 4.1,  $|\mathbb{P}(r) - \mathbb{P}^*(r)| \leq \frac{d(r_{i+1}-r_i)}{2r_i}$  for all  $r \in [r_i, r_{i+1}]$ . Thus, it suffices to show  $\frac{d(r_{i+1}-r_i)}{2r_i} < \epsilon$ , i.e.,

$$(C.1) \quad \frac{r_{i+1}}{r_i} < 1 + \frac{2\epsilon}{d}.$$

By definition (4.1), for  $i = 1, \dots, m-1$ ,

$$\begin{aligned} \frac{r_{i+1}}{r_i} &= \frac{a - \frac{(m-i-1)(\lambda-1)}{(m-1)\lambda}a}{a - \frac{(m-i)(\lambda-1)}{(m-1)\lambda}a} \\ &= 1 + \frac{\lambda-1}{m-1 + (\lambda-1)(i-1)} \\ &\leq 1 + \frac{\lambda-1}{m-1}. \end{aligned}$$

By virtue of (C.1), to guarantee that the gridding error is less than  $\epsilon$ , it suffices to ensure  $1 + \frac{\lambda-1}{m-1} < 1 + \frac{2\epsilon}{d}$ , i.e.,  $m > 1 + \frac{d(\lambda-1)}{2\epsilon}$ . Hence, it suffices to have

$$m \geq 2 + \left\lfloor \frac{(\lambda-1)d}{2\epsilon} \right\rfloor.$$

It can be verified that

$$\frac{r_i}{r_{i+1}} = 1 - \frac{1}{\frac{m-1}{\lambda-1} + i}, \quad i = 1, \dots, m-1.$$

By Theorem 1 of [6], the sample reuse factor is given by

$$\begin{aligned} \mathcal{F}_{\text{reuse}} &= \frac{m}{m - \sum_{i=1}^{m-1} \left( \frac{r_i}{r_{i+1}} \right)^d} \\ &= \frac{m}{m - \sum_{i=1}^{m-1} \left( 1 - \frac{1}{\frac{m-1}{\lambda-1} + i} \right)^d}. \end{aligned}$$

Therefore,

$$m_{\text{eq}}(\epsilon) = \frac{m}{\mathcal{F}_{\text{reuse}}} = m - \sum_{i=1}^{m-1} \left( 1 - \frac{1}{\frac{m-1}{\lambda-1} + i} \right)^d.$$

**Appendix D. Proof of Theorem 4.3.** By virtue of (4.2), we have  $\frac{r_{i+1}}{r_i} = \lambda^{\frac{1}{m-1}}$ . Hence, by (C.1), it suffices to show  $\lambda^{\frac{1}{m-1}} < 1 + \frac{2\epsilon}{d}$ , which can be reduced to  $m > 1 + \frac{\ln \lambda}{\ln(1 + \frac{2\epsilon}{d})}$ . This inequality is equivalent to  $m \geq 2 + \left\lfloor \frac{\ln \lambda}{\ln(1 + \frac{2\epsilon}{d})} \right\rfloor$ . By equation (3.1) and Theorem 1 of [6], we have  $\mathbb{E}[\mathbf{n}] = \left[ m - (m-1) \left( \frac{1}{\lambda} \right)^{\frac{d}{m-1}} \right] N$  and hence obtain  $m_{\text{eq}}(\epsilon)$ . Note that

$$\mathcal{F}_{\text{reuse}} = \frac{m}{m_{\text{eq}}(\epsilon)} > \frac{m}{1 + d \ln \lambda} = \frac{2 + \left\lfloor \frac{\ln \lambda}{\ln(1 + \frac{2\epsilon}{d})} \right\rfloor}{1 + d \ln \lambda} > \frac{\frac{\ln \lambda}{\ln(1 + \frac{2\epsilon}{d})}}{1 + d \ln \lambda}.$$

Making use of the inequality  $\ln(1+x) < x$  for all  $x > 0$ , we have  $\ln\left(1 + \frac{2\epsilon}{d}\right) < \frac{2\epsilon}{d}$ . Therefore,

$$\begin{aligned}\mathcal{F}_{\text{reuse}} &> \frac{\frac{\ln \lambda}{\frac{2\epsilon}{d}}}{1 + d \ln \lambda} \\ &= \frac{1}{2\epsilon} \left(1 - \frac{1}{1 + d \ln \lambda}\right).\end{aligned}$$

### Appendix E. Proof of Theorem 6.1.

**Proof of statement (I).** Obviously,  $[S^j]_{1,2} \geq 1$ ,  $[S^j]_{\kappa,2} \leq N$ . From the rules of sampling, we can perform induction with respect to  $j$  and have  $[S^j]_{\ell+1,2} - [S^j]_{\ell,2} \geq 1$ ,  $\ell = 1, \dots, \kappa - 1$ . Observing that

$$\begin{aligned}[S^j]_{\kappa,2} &= [S^j]_{1,2} + \sum_{\ell=1}^{\kappa-1} ([S^j]_{\ell+1,2} - [S^j]_{\ell,2}) \\ &\geq 1 + \sum_{\ell=1}^{\kappa-1} ([S^j]_{\ell+1,2} - [S^j]_{\ell,2}) \\ &\geq 1 + \kappa - 1 \\ &= \kappa,\end{aligned}$$

we have  $\kappa \leq [S^j]_{\kappa,2} \leq N$ .

**Proof of statement (II).** We need some preliminary results.

LEMMA E.1. *Let  $1 \leq i \leq m - 1$ . Then*

$$\left| \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - \frac{d(r_{i+1} - r_i)}{r_{i+1}} \right| \leq \frac{d(d-1)}{2} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2.$$

*Proof.* Note that

$$\begin{aligned}\left| \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - \frac{d(r_{i+1} - r_i)}{r_{i+1}} \right| &= \left| \left( \frac{r_i}{r_{i+1}} \right)^d - \left( 1 - \frac{d(r_{i+1} - r_i)}{r_{i+1}} \right) \right| \\ &= \left| (1-t)^d - (1-dt) \right|,\end{aligned}$$

where  $t = \frac{r_{i+1} - r_i}{r_{i+1}}$ . It can be checked that  $\left| (1-t)^d - (1-dt) \right| = \frac{d(d-1)}{2} t^2$  for  $d = 1, 2$ . For  $d \geq 3$ , by Taylor's expansion formula, there exists  $\xi \in (0, t)$  such that

$$(1-t)^d = 1 - dt + \frac{d(d-1)}{2} (1-\xi)^{d-2} t^2.$$

Observing that  $0 < t < 1$  since  $0 < r_i < r_{i+1}$ , we hence have  $0 < (1-\xi)^{d-2} < 1$  and  $\left| (1-t)^d - (1-dt) \right| < \frac{d(d-1)}{2} t^2$  for  $d \geq 3$ . Therefore, for any  $d \geq 1$ ,

$$\begin{aligned}\left| \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - \frac{d(r_{i+1} - r_i)}{r_{i+1}} \right| \\ \leq \frac{d(d-1)}{2} t^2 = \frac{d(d-1)}{2} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2. \quad \square\end{aligned}$$

LEMMA E.2. Define the maximum gap between grid points as

$$\varpi = \max_{1 \leq i \leq m-1} (r_{i+1} - r_i).$$

Then,

$$\sum_{i=1}^{m-1} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2 < \frac{\lambda(\lambda-1)\varpi}{a}.$$

*Proof.* Note that

$$\sum_{i=1}^{m-1} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2 \leq \varpi \sum_{i=1}^{m-1} \frac{r_{i+1} - r_i}{r_{i+1}^2} < \varpi \sum_{i=1}^{m-1} \frac{r_{i+1} - r_i}{\left(\frac{a}{\lambda}\right)^2}.$$

By successive cancellation,

$$\sum_{i=1}^{m-1} (r_{i+1} - r_i) = r_m - r_1 = a - \frac{a}{\lambda}.$$

Hence,

$$\sum_{i=1}^{m-1} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2 < \varpi \sum_{i=1}^{m-1} \frac{r_{i+1} - r_i}{\left(\frac{a}{\lambda}\right)^2} = \varpi \frac{a - \frac{a}{\lambda}}{\left(\frac{a}{\lambda}\right)^2} = \frac{\lambda(\lambda-1)\varpi}{a}. \quad \square$$

LEMMA E.3. The expected number of rows of the matrix of violations  $V^{\mathbf{n}}$  is no greater than  $1 + NP_e(a) + 2N \sum_{j=1}^{m-1} P_e(r_j) \left[ 1 - \left(\frac{r_j}{r_{j+1}}\right)^d \right]$ .

*Proof.* Let  $X_1^j, \dots, X_{\mathbf{n}_j}^j$  be the samples generated from the uncertainty set with radius  $r_j$ . For  $i = 1, \dots, m$ , define the random variable  $Y_i^j$  such that  $Y_i^j = X_i^j$  if the robustness requirement is violated for  $X_i^j$  and  $Y_i^j = 0$  otherwise. By the principle of sample reuse, the value of  $\mathbf{n}_j$  depends only on the samples generated from uncertainty sets with radius  $r_k$ ,  $j+1 \leq k \leq m$ . Consequently, event  $\{\mathbf{n}_j = \nu\}$  is independent of event  $\{Y_i^j = 1\}$  and  $\Pr\{Y_i^j = 1, \mathbf{n}_j = \nu\} = \Pr\{Y_i^j = 1\} \Pr\{\mathbf{n}_j = \nu\}$ . By the definitions of  $Y_i^j$  and  $P_e(\cdot)$ , we have  $\Pr\{Y_i^j = 1\} = 1 - \mathbb{P}(r_j) \leq P_e(r_j)$ . Therefore,

$$\begin{aligned} \mathbb{E} \left[ \sum_{i=1}^{\mathbf{n}_j} Y_i^j \right] &= \sum_{\nu=1}^N \sum_{i=1}^{\nu} \Pr\{Y_i^j = 1, \mathbf{n}_j = \nu\} \\ &= \sum_{\nu=1}^N \sum_{i=1}^{\nu} \Pr\{Y_i^j = 1\} \Pr\{\mathbf{n}_j = \nu\} \\ &\leq \sum_{\nu=1}^N \nu P_e(r_j) \Pr\{\mathbf{n}_j = \nu\} \\ &= P_e(r_j) \mathbb{E}[\mathbf{n}_j] \end{aligned}$$

for  $j = 1, \dots, m$ . We now consider  $V^{\mathbf{n}}$  with  $\mathbf{n} = \sum_{i=1}^m \mathbf{n}_i$ . By the mechanism of the sample reuse algorithms, for  $j = 1, \dots, m-1$ , every new sample from the uncertainty set with radius  $r_j$  at most creates  $2Y_i^j$ ,  $i = 1, \dots, \mathbf{n}_j$ , new rows for the matrix of violations (see section 6.2.2). Note that  $X_1$  creates at most  $1 + Y_1^m$  rows

for  $V^1$ . Every new sample from the uncertainty set with radius  $r_m$  creates at most  $Y_i^m$ ,  $i = 2, \dots, \mathbf{n}_m$ , new rows for the matrix of violations. Hence,

$$\begin{aligned} & \mathbb{E} [\text{the number of rows of matrix } V^{\mathbf{n}}] \\ & \leq 1 + \mathbb{E} \left[ \sum_{i=1}^{\mathbf{n}_m} Y_i^m \right] + 2 \mathbb{E} \left[ \sum_{j=1}^{m-1} \sum_{i=1}^{\mathbf{n}_j} Y_i^j \right] \\ & \leq 1 + P_e(r_m) \mathbb{E}[\mathbf{n}_m] + 2 \sum_{j=1}^{m-1} P_e(r_j) \mathbb{E}[\mathbf{n}_j]. \end{aligned}$$

By Lemma 6 of [6], we have

$$(E.1) \quad \mathbb{E}[\mathbf{n}_j] = \left[ 1 - \left( \frac{r_j}{r_{j+1}} \right)^d \right] N, \quad j = 1, \dots, m-1.$$

By (E.1) and using the fact that  $\mathbb{E}[\mathbf{n}_m] = N$ ,  $P_e(r_m) = P_e(a)$ , we have

$$\begin{aligned} & \mathbb{E} [\text{the number of rows of matrix } V^{\mathbf{n}}] \\ & \leq 1 + NP_e(a) + 2N \sum_{j=1}^{m-1} P_e(r_j) \left[ 1 - \left( \frac{r_j}{r_{j+1}} \right)^d \right]. \quad \square \end{aligned}$$

LEMMA E.4. *For any grid scheme,*

$$\begin{aligned} & \left| \sum_{i=1}^{m-1} P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & < \frac{d(d-1)\lambda(\lambda-1)\varpi}{2a} + \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_{i+1})(r_{i+1} - r_i) - \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_i)(r_{i+1} - r_i). \end{aligned}$$

*Proof.* Note that

$$\begin{aligned} & \left| \sum_{i=1}^{m-1} P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & \leq \sum_{i=1}^{m-1} \left| P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \frac{P_e(r_i)(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & \quad + \sum_{i=1}^{m-1} \left| d \frac{P_e(r_i)(r_{i+1} - r_i)}{r_{i+1}} - d \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & < \sum_{i=1}^{m-1} \left| \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - \frac{d(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & \quad + \frac{\lambda d}{a} \sum_{i=1}^{m-1} [P_e(r_{i+1})(r_{i+1} - r_i) - P_e(r_i)(r_{i+1} - r_i)], \end{aligned}$$

where the last inequality follows from the facts that  $0 \leq P_e(r_i) \leq P_e(r_{i+1}) \leq 1$  and

$r_{i+1} > \frac{a}{\lambda}$ . Making use of Lemmas E.1 and E.2, we have

$$\begin{aligned}
 & \left| \sum_{i=1}^{m-1} P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} \right| \\
 & \leq \frac{d(d-1)}{2} \sum_{i=1}^{m-1} \left( \frac{r_{i+1} - r_i}{r_{i+1}} \right)^2 \\
 & \quad + \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_{i+1})(r_{i+1} - r_i) - \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_i)(r_{i+1} - r_i) \\
 & \leq \frac{d(d-1)\lambda(\lambda-1)\varpi}{2a} + \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_{i+1})(r_{i+1} - r_i) \\
 & \quad - \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_i)(r_{i+1} - r_i). \quad \square
 \end{aligned}$$

LEMMA E.5. For a set of grid points  $\mathcal{G} = \{r_\ell \mid 1 \leq \ell \leq m\}$  with  $\frac{a}{\lambda} = r_1 < r_2 < \dots < r_m = a$ , define function  $\aleph(\cdot)$  such that

$$\aleph(\mathcal{G}) = \sum_{\ell=1}^{m-1} P_e(r_\ell) \left[ 1 - \left( \frac{r_\ell}{r_{\ell+1}} \right)^d \right].$$

Then, for any two sets of grid points  $\mathcal{G}_1$  and  $\mathcal{G}_2$  such that  $\mathcal{G}_1 \subset \mathcal{G}_2$ ,

$$\aleph(\mathcal{G}_1) \leq \aleph(\mathcal{G}_2).$$

*Proof.* Consider two sequences of grid points  $\mathcal{G}_1 = \{r_\ell \mid 1 \leq \ell \leq m\}$  and  $\mathcal{G}_2 = \{\hat{r}_\ell \mid 1 \leq \ell \leq m+1\}$  such that

$$\frac{a}{\lambda} = r_1 < r_2 < \dots < r_m = a, \quad \frac{a}{\lambda} = \hat{r}_1 < \hat{r}_2 < \dots < \hat{r}_{m+1} = a,$$

and such that  $\mathcal{G}_2$  is obtained from  $\mathcal{G}_1$  by adding a grid point  $\hat{r}_{i+1}$  to interval  $(r_i, r_{i+1})$  where  $1 \leq i \leq m-1$ , i.e.,  $\hat{r}_j = r_j$ ,  $j = 1, \dots, i$  and  $\hat{r}_{j+1} = r_j$ ,  $j = i+1, \dots, m$ . By the definition of function  $\aleph(\cdot)$ , we have

$$\begin{aligned}
 & \aleph(\mathcal{G}_2) - \aleph(\mathcal{G}_1) \\
 & = \sum_{\tau=1}^m P_e(\hat{r}_\tau) \left[ 1 - \left( \frac{\hat{r}_\tau}{\hat{r}_{\tau+1}} \right)^d \right] - \sum_{\tau=1}^{m-1} P_e(r_\tau) \left[ 1 - \left( \frac{r_\tau}{r_{\tau+1}} \right)^d \right] \\
 & = P_e(r_i) \left[ 1 - \left( \frac{r_i}{\hat{r}_{i+1}} \right)^d \right] + P_e(\hat{r}_{i+1}) \left[ 1 - \left( \frac{\hat{r}_{i+1}}{r_{i+1}} \right)^d \right] - P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right].
 \end{aligned}$$

By virtue of the fact that  $P_e(\hat{r}_{i+1}) \geq P_e(r_i)$ , we have

$$\begin{aligned}
 & \aleph(\mathcal{G}_2) - \aleph(\mathcal{G}_1) \\
 & \geq P_e(r_i) \left[ 1 - \left( \frac{r_i}{\hat{r}_{i+1}} \right)^d \right] + P_e(r_i) \left[ 1 - \left( \frac{\hat{r}_{i+1}}{r_{i+1}} \right)^d \right] - P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] \\
 & = P_e(r_i) \left[ 1 - \left( \frac{r_i}{\hat{r}_{i+1}} \right)^d - \left( \frac{\hat{r}_{i+1}}{r_{i+1}} \right)^d + \left( \frac{r_i}{r_{i+1}} \right)^d \right].
 \end{aligned}$$

Recalling that  $r_i < \widehat{r}_{i+1} < r_{i+1}$ , we have

$$\begin{aligned} & 1 - \left( \frac{r_i}{\widehat{r}_{i+1}} \right)^d - \left( \frac{\widehat{r}_{i+1}}{r_{i+1}} \right)^d + \left( \frac{r_i}{r_{i+1}} \right)^d \\ &= \frac{\widehat{r}_{i+1}^d - r_i^d}{\widehat{r}_{i+1}^d} - \frac{\widehat{r}_{i+1}^d - r_i^d}{r_{i+1}^d} \\ &= \frac{(\widehat{r}_{i+1}^d - r_i^d)(r_{i+1}^d - \widehat{r}_{i+1}^d)}{\widehat{r}_{i+1}^d r_{i+1}^d} \\ &> 0. \end{aligned}$$

It follows that  $\aleph(\mathcal{G}_2) - \aleph(\mathcal{G}_1) \geq 0$ .  $\square$

We are now in the position to prove statement (II) of the theorem. For any set of grid points, we can reduce the maximal gap between grid points by adding grid points. Every new grid point is placed at the middle of one of the previous intervals which possesses the *largest* width in order to ensure that, as more grid points are added, the maximal gap of grid points tends to zero. In this process, we create a series of nested sets of grid points  $\mathcal{G}_k$ ,  $k = 1, 2, \dots, \infty$ , such that  $\mathcal{G}_1 \subset \mathcal{G}_2 \subset \mathcal{G}_3 \subset \dots$ . Note that

$$\begin{aligned} & \left| \sum_{i=1}^{m-1} P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx \right| \\ & \leq \left| \sum_{i=1}^{m-1} P_e(r_i) \left[ 1 - \left( \frac{r_i}{r_{i+1}} \right)^d \right] - d \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} \right| \\ & \quad + \left| d \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} - d \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx \right| \\ (E.2) \quad & \leq \frac{d(d-1)\lambda(\lambda-1)\varpi}{2a} + \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_{i+1})(r_{i+1} - r_i) \\ & \quad - \frac{\lambda d}{a} \sum_{i=1}^{m-1} P_e(r_i)(r_{i+1} - r_i) \\ & \quad + d \left| \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} - \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx \right|, \end{aligned}$$

where inequality (E.2) follows from Lemma E.4. By Lemma B.1,  $\mathbb{P}(\cdot)$  is a continuous function with respect to  $r$ . Consequently,  $\frac{P_e(x)}{x}$  is Riemann integrable over interval  $[\frac{a}{\lambda}, a]$  and

$$\lim_{\varpi \rightarrow 0} \sum_{i=1}^{m-1} \frac{P_e(r_{i+1})(r_{i+1} - r_i)}{r_{i+1}} = \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx.$$

Moreover, since  $P_e(x)$  is Riemann integrable, we have

$$\lim_{\varpi \rightarrow 0} \sum_{i=1}^{m-1} P_e(r_{i+1})(r_{i+1} - r_i) = \lim_{\varpi \rightarrow 0} \sum_{i=1}^{m-1} P_e(r_i)(r_{i+1} - r_i) = \int_{\frac{a}{\lambda}}^a P_e(x) dx.$$

Hence, the right-hand side of inequality (E.2) can be made arbitrarily small by successively cutting the gap between grid points in half with new grid points. This proves

that

$$\lim_{k \rightarrow \infty} \aleph(\mathcal{G}_k) = d \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx.$$

On the other hand, by Lemma E.5, we have  $\aleph(\mathcal{G}_1) \leq \aleph(\mathcal{G}_2) \leq \aleph(\mathcal{G}_3) \leq \dots$ . Combining the convergency and the monotone property of sequence  $\{\aleph(\mathcal{G}_k)\}_{k=1}^\infty$ , we can conclude that  $\aleph(\mathcal{G}) \leq d \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx$  for any set of grid points  $\mathcal{G}$ . By Lemma E.3, the expected number of rows of the matrix of violations  $V^n$  is no greater than

$$\begin{aligned} 1 + NP_e(a) + 2N\aleph(\mathcal{G}) &\leq 1 + NP_e(a) + 2Nd \int_{\frac{a}{\lambda}}^a \frac{P_e(x)}{x} dx \\ &= 1 + NP_e(a) + 2Nd \int_{\frac{a}{h}}^a \frac{P_e(x)}{x} dx \end{aligned}$$

for any  $\mathcal{G}$ . Such a bound applies to any  $V^j$  because the number of rows of  $V^j$  is nondecreasing with respect to  $j$ . Finally, the inequality of (6.6) can be proved by making use of the observation that  $P_e(x) \leq P_e(a)$  for all  $x \in [\frac{a}{h}, a]$ .

**Appendix F. Proof of Theorem 6.2.** We need the following lemma, which has recently been obtained in [8].

LEMMA F.1. *Let  $X_i$ ,  $i = 1, \dots, N$ , be i.i.d. Bernoulli random variables such that  $\Pr\{X_i = 1\} = 1 - \Pr\{X_i = 0\} = \mathbb{P}_X > 0$ . Let  $K = \frac{\sum_{i=1}^N X_i}{N}$ . Then*

$$\Pr\{\mathcal{L}(K) < \mathbb{P}_X < \mathcal{U}(K)\} > 1 - \delta.$$

Applying Lemma F.1, we have  $\Pr\{\mathcal{L}(K_{i+1}) < \mathbb{P}(r_{i+1}) < \mathcal{U}(K_{i+1})\} > 1 - \frac{\delta}{2}$  and  $\Pr\{\mathcal{L}(K_i) < \mathbb{P}(r_i) < \mathcal{U}(K_i)\} > 1 - \frac{\delta}{2}$ . Hence, by Bonferroni's inequality [11],

$$\Pr\{\mathcal{L}(K_{i+1}) < \mathbb{P}(r_{i+1}) < \mathcal{U}(K_{i+1}), \mathcal{L}(K_i) < \mathbb{P}(r_i) < \mathcal{U}(K_i)\} > 1 - \delta.$$

By the definitions of  $\mathbb{P}^*(r)$ ,  $\bar{\mathbb{P}}(r)$ , and  $\underline{\mathbb{P}}(r)$ , we have that event  $\{\mathcal{L}(K_{i+1}) < \mathbb{P}(r_{i+1}) < \mathcal{U}(K_{i+1}), \mathcal{L}(K_i) < \mathbb{P}(r_i) < \mathcal{U}(K_i)\}$  implies event  $\{\underline{\mathbb{P}}(r) + \varsigma < \mathbb{P}^*(r) < \bar{\mathbb{P}}(r) - \varsigma$  for all  $r \in [r_i, r_{i+1}]\}$ . Hence,  $\Pr\{\underline{\mathbb{P}}(r) + \varsigma < \mathbb{P}^*(r) < \bar{\mathbb{P}}(r) - \varsigma$  for all  $r \in [r_i, r_{i+1}]\} > 1 - \delta$ . By Theorem 4.1 and the gridding scheme,  $\Pr\{|\mathbb{P}^*(r) - \mathbb{P}(r)| < \varsigma$  for all  $r \in [r_i, r_{i+1}]\} = 1$ . Applying Bonferroni's inequality, we have

$$(F.1) \quad \Pr\{\underline{\mathbb{P}}(r) + \varsigma < \mathbb{P}^*(r) < \bar{\mathbb{P}}(r) - \varsigma, |\mathbb{P}^*(r) - \mathbb{P}(r)| < \varsigma \forall r \in [r_i, r_{i+1}]\} > 1 - \delta.$$

Finally, the theorem is proved by observing that the left-hand side of inequality (F.1) is no greater than  $\Pr\{\underline{\mathbb{P}}(r) < \mathbb{P}(r) < \bar{\mathbb{P}}(r)$  for all  $r \in [r_i, r_{i+1}]\}$ .

## ROBUSTNESS OF $\lambda$ -TRACKING IN THE GAP METRIC\*

ACHIM ILCHMANN<sup>†</sup> AND MARKUS MUELLER<sup>†</sup>

**Abstract.** For  $m$ -input,  $m$ -output, finite-dimensional, linear systems satisfying the classical assumptions of adaptive control (i.e., (i) minimum phase, (ii) relative degree one, and (iii) “positive” high-frequency gain), it is well known that the adaptive  $\lambda$ -tracker “ $u = -k e$ ,  $k = \max\{0, |e| - \lambda\}|e|$ ” achieves  $\lambda$ -tracking of the tracking error  $e$  if applied to such a system: all states of the closed-loop system are bounded, and  $|e|$  is ultimately bounded by  $\lambda$ , where  $\lambda > 0$  is prespecified and may be arbitrarily small. Invoking the conceptual framework of the nonlinear gap metric, we show that the  $\lambda$ -tracker is robust. In the present setup this means in particular that the  $\lambda$ -tracker copes with bounded input and output disturbances, and, more importantly, it may even be applied to a system not satisfying any of the classical conditions (i)–(iii) as long as the initial conditions and the disturbances are “small” and the system is “close” (in terms of “small” gap) to a system satisfying (i)–(iii).

**Key words.** adaptive control,  $\lambda$ -tracking, gap metric, robust stability

$W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell)$  the Sobolev space of absolutely continuous functions  $y : \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell$  with  $y, \dot{y} \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell)$  and norm

$$\|y\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell)} = \|y\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell)} + \|\dot{y}\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^\ell)}$$

$W_{\text{loc}}^{1,\infty}(I \rightarrow \mathbb{R}^\ell)$  the space of absolutely continuous functions  $y : I \rightarrow \mathbb{R}^\ell$ , with  $y, \dot{y} \in L_{\text{loc}}^\infty(I \rightarrow \mathbb{R}^\ell)$ , where  $I \subset \mathbb{R}_{\geq 0}$  is an interval

$$\text{dist}(e, [-\lambda, \lambda]) = \max\{0, |e| - \lambda\} \text{ for } e \in \mathbb{R}^m \text{ and } \lambda > 0$$

$$d_\lambda(e) = \max\{0, |e| - \lambda\} \text{ for } e \in \mathbb{R}^m \text{ and } \lambda > 0$$

**1. Introduction.** In this paper we show robustness of  $\lambda$ -stabilization and  $\lambda$ -tracking (i.e., stabilization and tracking with a final accuracy of prespecified  $\lambda > 0$ ) for linear  $n$ -dimensional,  $m$ -input,  $m$ -output systems of the form

$$(1.1) \quad \begin{cases} \dot{x}(t) = Ax(t) + Bu_1(t), & x(0) = x^0, \\ y_1(t) = Cx(t), \end{cases}$$

where  $A \in \mathbb{R}^{n \times n}$ ,  $B, C^T \in \mathbb{R}^{n \times m}$ ,  $x^0 \in \mathbb{R}^n$ , subject to additive input/output disturbances  $u_0, y_0$ , respectively,

$$(1.2) \quad u_0 = u_1 + u_2, \quad y_0 = y_1 + y_2,$$

as depicted in Figure 1, where the *plant*  $P$  maps the interior input signal  $u_1$  to the interior output signal  $y_1$  and the *controller*  $C$  maps the interior output signal  $y_2$  to the interior input signal  $u_2$ . In our setup,  $P$  will always be a linear initial value problem of the form (1.1) and the controller  $C$  will be a dynamical system, specified in due course. In case of zero disturbances  $u_0 \equiv y_0 \equiv 0$ , it is well known that (1.1) can be stabilized by proportional high-gain ( $k \gg 0$ ) output feedback

$$(1.3) \quad u_2(t) = -k y_2(t),$$

provided (1.1) is *minimum phase*, i.e.,

$$\forall s \in \overline{\mathbb{C}}_+ : \det \begin{bmatrix} sI - A & B \\ C & 0 \end{bmatrix} \neq 0,$$

and its transfer function  $C(sI - A)^{-1}B$  has *strict relative degree* one with “positive” high-frequency gain, i.e.,  $CB + (CB)^T > 0$ . This system class is denoted, for  $n, m \in \mathbb{N}$  with  $n \geq m$ , as

$$\widetilde{\mathcal{M}}_{n,m} := \left\{ (A, B, C) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m} \times \mathbb{R}^{m \times n} \left| \begin{array}{l} CB + (CB)^T > 0 \\ \forall s \in \overline{\mathbb{C}}_+ : \det \begin{bmatrix} sI_n - A & B \\ C & 0 \end{bmatrix} \neq 0 \end{array} \right. \right\}.$$

Note that the state space dimension  $n \in \mathbb{N}$  need not be known but only the input/output dimension  $m \in \mathbb{N}$ , and, most importantly, only structural assumptions are required, but the system entries are completely unknown. A sufficiently high-gain  $k$  in (1.3) can be found adaptively. More precisely, any system  $(A, B, C) \in \widetilde{\mathcal{M}}_n$  can be stabilized adaptively, in the presence of  $L^2$  input/output disturbances, by the controller (ubiquitous in the adaptive control literature)

$$(1.4) \quad \begin{cases} \dot{k}(t) = |y_2(t)|^2, & k(0) = k^0 \in \mathbb{R}, \\ u_2(t) = -k(t) y_2(t) \end{cases}$$

FIG. 1. The closed-loop system  $[P, C]$ .

in the sense that all states of the closed-loop system (1.1), (1.2), (1.4) are bounded and  $\lim_{t \rightarrow \infty} y_1(t) = 0$ . This approach has been introduced by the seminal work of [14, 15, 17]; see also the survey [6].

The surprising property of the controller (1.4) is not only its simplicity but also its robustness: it is also applicable in the presence of additive  $L^2$  input/output disturbances, and it may stabilize systems (1.1) not belonging to  $\widetilde{\mathcal{M}}_{n,m}$  but sufficiently “close”—in terms of the *gap metric* defined in section 3—to some  $(A, B, C)$  in normal form and belonging to  $\widetilde{\mathcal{M}}_{n,m}$ . This has been proved in [4].

However, the controller (1.4) has the shortcomings that, if tracking is the control objective, it needs to be combined with an internal model (thus becoming more involved) and, more importantly, fails for stabilizing nonlinear systems or in the presence of additive arbitrarily small input or output  $L^\infty$ -disturbances. To overcome these shortcomings, the so-called  $\lambda$ -tracker

$$(1.5) \quad \begin{cases} \dot{k}(t) = \text{dist}(y_2(t), [-\lambda, \lambda]) \cdot |y_2(t)|, & k(0) = k^0, \\ u_2(t) = -k(t)y_2(t) \end{cases}$$

for  $\lambda > 0$  and  $k^0 \in \mathbb{R}$  has been introduced by [9]. The application of the  $\lambda$ -tracker (1.5) to any system (1.1) belonging to  $\widetilde{\mathcal{M}}_{n,m}$ , via (1.2), satisfies, in the presence of arbitrary input/output disturbances  $u_0, y_0$  which are bounded with essentially bounded derivative, arbitrary initial conditions  $x^0 \in \mathbb{R}^n$ ,  $k^0 \in \mathbb{R}$  and any arbitrarily small design parameter  $\lambda > 0$ , the control objectives of  $\lambda$ -tracking:

- all signals and their derivatives of the closed-loop system (1.1), (1.2), (1.5) are bounded;
- $\limsup_{t \rightarrow \infty} \text{dist}(y_2(t), [-\lambda, \lambda]) = 0$ .

This result has been generalized to nonlinear and infinite-dimensional systems [10] and applied, to name but a few, to regulate biogas tower reactors [8], chemical reactors [12], and insulin delivery for diabetic patients [2] by preserving the simplicity of the control strategy. Note also that it is a tracking result without invoking an internal model: set  $y_0(\cdot) \equiv y_{\text{ref}}(\cdot)$  as a prespecified reference signal.

The purpose of the present paper is to show robustness properties of the  $\lambda$ -tracker in terms of the gap metric. For example, we consider

$$(1.6) \quad \begin{cases} \dot{x} = \tilde{A}x + \tilde{b}u_1, & x(0) = \tilde{x}^0, \\ y_1 = \tilde{c}x, \end{cases}$$

with  $\tilde{x}^0 \in \mathbb{R}^3$  and where, for  $\alpha, N, M > 0$ ,

$$\tilde{A} := \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \alpha NM & -NM + \alpha N + \alpha M & \alpha - N - M \end{bmatrix}, \quad \tilde{b} := \begin{bmatrix} 0 \\ 0 \\ N \end{bmatrix}, \quad \tilde{c} := [M, -1, 0].$$

This system does not belong to the class  $\widetilde{\mathcal{M}}_{3,1}$ ; its transfer function  $\frac{N(M-s)}{(s-\alpha)(s+N)(s+M)}$  does not satisfy any of the classical structural assumptions in adaptive control:

$$(1.7) \quad \left\{ \begin{array}{l} \bullet \text{ it is not minimum phase;} \\ \bullet \text{ it has relative degree two;} \\ \bullet \text{ and its high-frequency gain } -N < 0 \text{ has the "wrong" sign.} \end{array} \right.$$

However, defining, for  $n, m \in \mathbb{N}$  with  $n \geq m$ , the system class

$$\mathcal{P}_{n,m}$$

$$:= \{ (A, B, C) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m} \times \mathbb{R}^{m \times n} \mid (A, B, C) \text{ is stabilizable and detectable} \},$$

(1.6) belongs to  $\mathcal{P}_{3,1}$ , and we will show in subsection 3.5 and Example 4.6 that (1.6) is close (in terms of the gap metric) to a system belonging to  $\widetilde{\mathcal{M}}_{1,1}$  for  $N, M$  sufficiently large and  $\tilde{x}^0$  sufficiently small, and thus (1.5) applied to (1.6) achieves  $\lambda$ -tracking.

Instead of systems  $(A, B, C) \in \widetilde{\mathcal{M}}_{n,m}$  we restrict our attention to systems in Byrnes–Isidori normal form; see, for example, [13, section 4]. That is, for each  $(A, B, C) \in \widetilde{\mathcal{M}}_{n,m}$  the matrix

$$T = [B(CB)^{-1}, V], \text{ where } V \in \mathbb{R}^{n \times (n-m)} \text{ with } \text{rk } V = n - m \text{ and } \text{im } V = \ker C,$$

converts (1.1) via the coordinate transformation  $\begin{pmatrix} y_1 \\ z \end{pmatrix} = T^{-1}x$  into

$$(1.8) \quad \left\{ \begin{array}{lll} \dot{y}_1 & = & A_1 y_1 + A_2 z + CB u_1, & y_1(0) & = & y_1^0 \in \mathbb{R}, \\ \dot{z} & = & A_3 y_1 + A_4 z, & z(0) & = & z^0 \in \mathbb{R}^{n-m}, \end{array} \right. \quad \begin{pmatrix} y_1^0 \\ z^0 \end{pmatrix} = T^{-1}x^0,$$

where

$$\begin{bmatrix} A_1 & A_2 \\ A_3 & A_4 \end{bmatrix} := T^{-1}AT, \quad \begin{bmatrix} B_1 \\ 0_{(n-m) \times m} \end{bmatrix} := \begin{bmatrix} CB \\ 0 \end{bmatrix} = T^{-1}B, \quad [I_m \quad 0_{m \times (n-m)}] = CT.$$

By the minimum-phase property,  $A_4$  has spectrum in the open left half complex plane  $\mathbb{C}_-$ . Therefore, we introduce, for  $n, m \in \mathbb{N}$  with  $n \geq m$ , the system class

$$\mathcal{M}_{n,m}$$

$$:= \left\{ (A, B, C) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times m} \times \mathbb{R}^{m \times n} \left| \begin{array}{l} A = \begin{bmatrix} A_1 & A_2 \\ A_3 & A_4 \end{bmatrix}, \quad B = \begin{bmatrix} B_1 \\ 0 \end{bmatrix}, \\ C = [I_m \quad 0], \quad B_1, A_1 \in \mathbb{R}^{m \times m}, \\ \text{spec}(A_4) \subset \mathbb{C}_-, \quad B_1 + B_1^T > 0. \end{array} \right. \right\}.$$

We will study properties of the closed-loop system generated by the application of the  $\lambda$ -tracker (1.5) to systems (1.1) of class  $\mathcal{M}_{n,m}$  or of class  $\mathcal{P}_{n,m}$  in the presence of disturbances  $(u_0, y_0) \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  satisfying the interconnection equations (1.2). The closed-loop system (1.8), (1.5), (1.2) is depicted in Figure 2.

The paper is organized as follows. In section 2 we show that  $\lambda$ -tracking is possible for all linear systems (1.1) belonging to class  $\mathcal{M}_{n,m}$  in the presence of  $W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow$

FIG. 2. The adaptive closed-loop system.

$\mathbb{R}^m$ ) input/output disturbances; see Figure 2. In section 3, we collect the basics of the framework of gap metric and graph topology from [5, 3, 4] necessary for our setup. Section 4 contains our main result, i.e., robustness of  $\lambda$ -tracking. We show that if the initial conditions, the input/output disturbances, and the gap between a nominal system belonging to class  $\mathcal{P}_{q,m}$  and a system belonging to class  $\mathcal{M}_{n,m}$  (for  $m, q, n \in \mathbb{N}$  with  $q, n \geq m$ ) are sufficiently small, then the controller (1.5) achieves  $\lambda$ -tracking for the nominal system.

**2.  $\lambda$ -tracking.** In this section we show that the control strategy given by (1.5) applied to any linear system of class  $\mathcal{M}_{n,m}$  achieves  $\lambda$ -tracking in the presence of  $W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  input/output disturbances; see Figure 2. Set, for  $n, m \in \mathbb{N}$  with  $n \geq m$ ,

$$\mathcal{D}_{n,m} := \mathcal{M}_{n,m} \times (\mathbb{R}^m \times \mathbb{R}^{n-m} \times \mathbb{R}) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m).$$

**PROPOSITION 2.1.** *Let  $m, n \in \mathbb{N}$  with  $n \geq m$  and  $\lambda > 0$ . Then there exists a continuous map  $\nu: \mathcal{D}_{n,m} \rightarrow \mathbb{R}_{\geq 0}$  such that, for all  $d = ([\begin{smallmatrix} A_1 & A_2 \\ A_3 & A_4 \end{smallmatrix}], B, C, (y_1^0, z^0, k^0), u_0, y_0) \in \mathcal{D}_{n,m}$ , the associated closed-loop initial value problem (1.8), (1.2), (1.5) satisfies*

$$(2.1) \quad \|(u_2, y_2, z, k)\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^{m+n+1})} \leq \nu(d)$$

and

$$(2.2) \quad \limsup_{t \rightarrow \infty} |y_2(t)| \leq \lambda.$$

The result that  $\lambda$ -tracking works for the class of systems  $\mathcal{M}_n$  goes back to [9], and input disturbances are also considered in [7]. However, to prove the robustness of the  $\lambda$ -tracker in section 4, the existence of a continuous function  $\nu(\cdot)$  satisfying (2.1) is crucial. Therefore, we had to find a new proof showing (2.1) which easily shows (2.2).

*Proof of Proposition 2.1.* Let  $d = ([\begin{smallmatrix} A_1 & A_2 \\ A_3 & A_4 \end{smallmatrix}], B, C, (y_1^0, z^0, k^0), u_0, y_0) \in \mathcal{D}_{n,m}$  and set, for notational convenience,

$$\begin{aligned} h(\cdot) &:= \dot{y}_0(\cdot) - A_1 y_0(\cdot) - C B u_0(\cdot), \\ e(\cdot) &:= y_2(\cdot). \end{aligned}$$

The closed-loop initial value problem (1.8), (1.2), (1.5) is then given by

$$(2.3) \quad \begin{cases} \dot{e} = A_1 e - A_2 z - k C B e + h, & e(0) = e^0 := y_0(0) - y_1^0, \\ \dot{z} = -A_3 e + A_4 z + A_3 y_0, & z(0) = z^0, \\ \dot{k} = d_\lambda(e) |e|, & k(0) = k^0, \end{cases}$$

where  $d_\lambda$  is defined in the Nomenclature. We divide the proof into 10 steps.

*Step 1.* Since the right-hand side of (2.3) is continuous and locally Lipschitz, it follows from the theory of ordinary differential equations that (2.3) has a solution

$$(e, z, k): [0, \omega) \rightarrow \mathbb{R}^{n-m} \times \mathbb{R}^m \times \mathbb{R}_{\geq 0}$$

on a maximal interval of existence  $[0, \omega)$  for some  $\omega \in (0, \infty]$ . This solution is unique.

*Step 2.* We define some constants that are used in the following steps of the proof.

Since  $\text{spec}(A_4) \subset \mathbb{C}_-$  we have

$$(2.4) \quad \exists M_1, \mu > 0 \quad \forall t \geq 0 : |\exp(A_4 t)| \leq M_1 \exp(-\mu t).$$

Set

$$\sigma_1 := \min \text{spec} (CB + (CB)^T) / 2,$$

$$M_2 := M_1 + M_1 |A_3| (\|y_0\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} + \lambda + \mu) / \mu,$$

$$M_3 := M_2 (1 + |z^0|) / \lambda + M_2 (1 + 1/\mu),$$

$$M_4 := |A_1| + |A_2| + \|h\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} / \lambda,$$

$$M_5 := |k^0| + 2(M_4 + M_3 M_4 + 1) / \sigma_1,$$

$$M_6 := M_5 + |k^0| + |e^0|^2 / 2,$$

$$M_7 := (d_\lambda(e^0)^2 + 2(M_6 + |k^0|) [\sigma_1 (M_6 + |k^0|) / 2 + M_4 + M_3 M_4])^{\frac{1}{2}} + \lambda,$$

$$M_8 := M_2 (1 + |z^0| + M_7 / \mu).$$

*Step 3.* We estimate the  $z$ -dynamics in the form

$$(2.5) \quad \forall t \in [0, \omega) : \int_0^t d_\lambda(e(\tau)) |z(\tau)| d\tau \leq M_3 [k(t) - k^0].$$

Applying variation of constants to the second equation in (2.3) and invoking (2.4) gives, for all  $t \in [0, \omega)$ ,

$$\begin{aligned} |z(t)| &\leq M_1 e^{-\mu t} |z^0| + \int_0^t M_1 e^{-\mu(t-\tau)} |A_3| (|e(\tau)| + |y_0(\tau)|) d\tau \\ &\leq M_1 e^{-\mu t} |z^0| + M_1 |A_3| \int_0^t e^{-\mu(t-\tau)} (d_\lambda(e(\tau)) + \|y_0\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} + \lambda) d\tau \\ &\leq M_1 e^{-\mu t} |z^0| + M_1 |A_3| \int_0^t e^{-\mu(t-\tau)} \|y_0\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} d\tau \\ &\quad + M_1 |A_3| \int_0^t e^{-\mu(t-\tau)} \lambda d\tau + M_1 |A_3| \int_0^t e^{-\mu(t-\tau)} d_\lambda(e(\tau)) d\tau \\ &\leq M_1 |z^0| + \frac{M_1 |A_3|}{\mu} (\|y_0\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} + \lambda) + M_1 |A_3| \int_0^t e^{-\mu(t-\tau)} d_\lambda(e(\tau)) d\tau \\ (2.6) \quad &\leq M_2 \left[ 1 + |z^0| + \int_0^t e^{-\mu(t-\tau)} d_\lambda(e(\tau)) d\tau \right]. \end{aligned}$$

Let

$$\forall t \in [0, \infty) \quad \forall \varphi \in L^2_{\text{loc}}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}) : (L * \varphi)(t) := \int_0^t e^{-\mu(t-\tau)} \varphi(\tau) \, d\tau.$$

Invoking the well-known inequality (see, for example, [16, p. 298])

$$\forall t \geq 0 : \|L * \varphi\|_{L^2([0,t] \rightarrow \mathbb{R})} \leq \|e^{-\mu \cdot}\|_{L^1(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})} \|\varphi\|_{L^2([0,t] \rightarrow \mathbb{R})} = \frac{1}{\mu} \|\varphi\|_{L^2([0,t] \rightarrow \mathbb{R})}$$

and the fact that

$$\forall e \in \mathbb{R} : d_\lambda(e)^2 \leq d_\lambda(e) |e|$$

yields, by (2.3), (2.6), and the Cauchy–Schwarz inequality, for all  $t \in [0, \omega)$ ,

$$\begin{aligned} & \int_0^t d_\lambda(e(\tau)) |z(\tau)| \, d\tau \\ & \leq M_2 \int_0^t d_\lambda(e(\tau)) [1 + |z^0| + (L * d_\lambda(e))(\tau)] \, d\tau \\ & \leq M_2 [1 + |z^0|] \frac{1}{\lambda} \int_0^t d_\lambda(e(\tau)) |e(\tau)| \, d\tau \\ & \quad + M_2 \left[ \|d_\lambda(e)\|_{L^2([0,t] \rightarrow \mathbb{R})}^2 + \|L * d_\lambda(e)\|_{L^2([0,t] \rightarrow \mathbb{R})}^2 \right] \\ & \leq M_2 [1 + |z^0|] \frac{1}{\lambda} \int_0^t d_\lambda(e(\tau)) |e(\tau)| \, d\tau + M_2 \left( 1 + \frac{1}{\mu} \right) \int_0^t d_\lambda(e(\tau))^2 \, d\tau. \end{aligned}$$

This proves (2.5).

*Step 4.* We estimate the  $e$ -dynamics in the form

$$(2.7) \quad \forall t \in [0, \omega) :$$

$$\frac{1}{2} d_\lambda(e(t))^2 \leq \frac{1}{2} d_\lambda(e^0)^2 - (k(t) - k^0) \left[ \frac{\sigma_1}{2} (k(t) + k^0) - M_4 - M_3 M_4 \right].$$

By (2.3) and Step 2 we have, omitting the argument  $t$ ,

$$\begin{aligned} \frac{d}{dt} \left( \frac{1}{2} d_\lambda(e(t))^2 \right) &= d_\lambda(e) |e|^{-1} e^T \dot{e} \\ &= d_\lambda(e) |e|^{-1} e^T [A_1 e - A_2 z - k C B e + h] \\ &\leq d_\lambda(e) |e| |A_1| + d_\lambda(e) |z| |A_2| + d_\lambda(e) \|h\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} \\ &\quad - k d_\lambda(e) |e|^{-1} e^T \left( \frac{1}{2} (C B + (C B)^T) e \right) \\ &\leq -(k \sigma_1 - |A_1|) d_\lambda(e) |e| + |A_2| d_\lambda(e) |z| + d_\lambda(e) \|h\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} \\ &\leq -(k \sigma_1 - |A_1|) d_\lambda(e) |e| + |A_2| d_\lambda(e) |z| + d_\lambda(e) \frac{|e|}{\lambda} \|h\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)} \\ &\leq -(k \sigma_1 - M_4) d_\lambda(e) |e| + M_4 d_\lambda(e) |z|, \end{aligned}$$

and hence, by integration and invoking (2.5), we arrive at

$$\forall t \in [0, \omega) : \frac{1}{2}d_\lambda(e(t))^2 \leq \frac{1}{2}d_\lambda(e^0)^2 - \int_0^t (k(\tau)\sigma_1 - M_4)\dot{k}(\tau) d\tau + M_3M_4[k(t) - k^0],$$

which yields (2.7).

*Step 5.* We show boundedness of  $k$  in the form

$$(2.8) \quad \forall t \in [0, \omega) : k(t) \leq M_6.$$

Suppose there exists  $T \in [0, \omega)$  such that  $k(T) = M_5$ ; otherwise (2.8) is obvious. Then, by monotonicity of  $k$ , it follows from (2.7) that, for all  $t \in [T, \omega)$ ,

$$\begin{aligned} 0 &\leq \frac{1}{2}d_\lambda(e(t))^2 \leq \frac{1}{2}d_\lambda(e^0)^2 - \frac{\sigma_1}{2}(k(t) - k^0) \left[ k(t) + k^0 - \frac{2}{\sigma_1}(M_4 + M_3M_4) \right] \\ &\leq \frac{1}{2}d_\lambda(e^0)^2 - \frac{\sigma_1}{2}(k(t) - k^0) \left[ M_5 + k^0 - \frac{2}{\sigma_1}(M_4 + M_3M_4) \right] \\ &= \frac{1}{2}d_\lambda(e^0)^2 - \frac{\sigma_1}{2}(k(t) - k^0) \left[ |k^0| + k^0 + \frac{2}{\sigma_1} \right] \\ &\leq \frac{1}{2}d_\lambda(e^0)^2 - (k(t) - k^0), \end{aligned}$$

and thus

$$\forall t \in [T, \omega) : k(t) - k^0 \leq \frac{1}{2}d_\lambda(e^0)^2 \leq \frac{1}{2}|e^0|^2$$

and

$$\forall t \in [0, T) : k(t) - k^0 \leq M_5 - k^0,$$

whence (2.8).

*Step 6.* We show boundedness of  $e$  in the form

$$(2.9) \quad \forall t \in [0, \omega) : |e(t)| \leq M_7.$$

An application of (2.8) to (2.7) gives, for all  $t \in [0, \omega)$ ,

$$\begin{aligned} |e(t)| &\leq d_\lambda(e(t)) + \lambda \\ &\leq \left( d_\lambda(e^0)^2 - 2(k(t) - k^0) \left[ \frac{\sigma_1}{2}(k(t) + k^0) - M_4 - M_3M_4 \right] \right)^{\frac{1}{2}} + \lambda \\ &\leq \left( d_\lambda(e^0)^2 + 2(M_6 + |k^0|) \left[ \frac{\sigma_1}{2}(M_6 + |k^0|) + M_4 + M_3M_4 \right] \right)^{\frac{1}{2}} + \lambda. \end{aligned}$$

Note that the argument of the root in the second line is nonnegative; see Step 5. Now (2.9) follows from Step 2.

*Step 7.* Boundedness of  $z$  in the form

$$(2.10) \quad \forall t \in [0, \omega) : |z(t)| \leq M_2 \left[ 1 + |z^0| + \int_0^t e^{-\mu(t-\tau)} M_7 d\tau \right] \leq M_8$$

follows from applying (2.9) to (2.6).

*Step 8.* We show  $\omega = \infty$ .

Since  $\omega$  was chosen maximal, (2.8)–(2.10) yield  $\omega = \infty$ .

*Step 9.* We show (2.1).

It follows from Steps 5–8 that  $(u_2, y_2, z, k)$  is uniformly bounded in terms of  $d = ([\begin{smallmatrix} A_1 & A_2 \\ A_3 & A_4 \end{smallmatrix}], B, C, (y_1^0, z^0, k^0), u_0, y_0)$ . Moreover, applying Steps 5–8 again and invoking (2.3) yields uniform boundedness of  $(\dot{u}_2, \dot{y}_2, \dot{z}, \dot{k})$  in terms of  $d$ . Now the existence of a continuous function  $\nu: \mathcal{D}_{n,m} \rightarrow \mathbb{R}_{\geq 0}$  such that (2.1) holds is straightforward by invoking the constants from Step 2.

*Step 10.* We show (2.2).

Since  $k \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$  by (2.1) it follows from  $\|d_\lambda(y_2) |y_2|\|_{L^1([0,t] \rightarrow \mathbb{R})} = k(t) - k^0$  that  $d_\lambda(y_2) |y_2| \in L^1(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ .

Since  $y_2 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  there exists  $M > 0$  such that  $\text{ess sup}_{t \geq 0} |(\dot{y}_2)_i(t)| < M$  for all  $i \in \{1, \dots, m\}$ , which gives

$$\forall s \geq 0 \, \forall i \in \{1, \dots, m\} \, \forall t \in [0, s] \, \exists \tau_i \in (t, s) : (\dot{y}_2)_i(\tau_i) = \frac{(y_2)_i(s) - (y_2)_i(t)}{s - t} < M,$$

and so

$$\forall i \in \{1, \dots, m\} \, \forall t \in [0, s] : |(y_2)_i(s) - (y_2)_i(t)| < M(s - t).$$

For  $\delta = \frac{\varepsilon}{M}$  we arrive at

$$\forall i \in \{1, \dots, m\} \, \forall \varepsilon > 0 \, \exists \delta > 0 \, \forall t, s \in \mathbb{R}_{\geq 0} \text{ with } |t - s| < \delta : |(y_2)_i(t) - (y_2)_i(s)| < \varepsilon;$$

i.e.,  $y_2$  is uniformly continuous. Boundedness and uniform continuity of  $y_2$  and the continuity of  $e \mapsto d_\lambda(e) |e|$  give uniform continuity of  $t \mapsto d_\lambda(y_2(t)) |y_2(t)|$ . So Barb alat’s lemma (see [1]) gives

$$\lim_{t \rightarrow \infty} d_\lambda(y_2(t)) |y_2(t)| = 0,$$

which yields (2.2) and completes the proof.  $\square$

**3. The concept of gap metric.** The material in this section is based on [5, section II], [4, section 2], and [3, section 2] and contains the fundamental results necessary for proving robustness in section 4.

**3.1. Terminology.** Let  $\mathcal{X}$  be a nonempty set and, for  $0 < \omega \leq \infty$ , let  $\mathcal{S}_\omega$  denote the set of locally integrable maps  $[0, \omega) \rightarrow \mathcal{X}$ . For simplicity, we write  $\mathcal{S} := \mathcal{S}_\infty$ . For  $0 < \tau < \omega \leq \infty$ ,  $T_\tau : \mathcal{S}_\omega \rightarrow \mathcal{S}$  denotes the operator given by

$$T_\tau v := \begin{cases} v(t), & t \in [0, \tau), \\ 0, & t \in [\tau, \infty). \end{cases}$$

With  $\mathcal{V} \subset \mathcal{S}$  we associate spaces as follows:

$$\mathcal{V}_e = \{v \in \mathcal{S} \mid \forall \tau > 0 : T_\tau v \in \mathcal{V}\}, \quad \text{the extended space;}$$

$$\mathcal{V}_\omega = \{v \in \mathcal{S}_\omega \mid \forall \tau \in (0, \omega) : T_\tau v \in \mathcal{V}\}, \quad 0 < \omega \leq \infty;$$

$$\mathcal{V}_a = \bigcup_{\omega \in (0, \infty]} \mathcal{V}_\omega, \quad \text{the ambient space.}$$

The ambient space  $\mathcal{V}_a$  is a subset of the union of all  $\mathcal{S}_\omega$ ,  $\omega \in (0, \infty]$ . Thus, for  $v \in \mathcal{V}_a$  the domain of  $v$ , i.e., the set of values in  $[0, \infty)$  where  $v$  is defined, denoted by  $\text{dom}(v)$ , is not obvious. If  $v, w \in \mathcal{V}_a$  with  $v|_I = w|_I$  on  $I = \text{dom}(v) \cap \text{dom}(w)$ , then we write  $v = w$ . For  $(u, y) \in \mathcal{V}_a \times \mathcal{V}_a$ , the domains of  $u$  and  $y$  may be different; we adopt the convention

$$\text{dom}(u, y) := \text{dom}(u) \cap \text{dom}(y).$$

We say  $\mathcal{V} \subset \mathcal{S}$  is a *signal space* if and only if it is a vector space and has the property that  $\sup_{\tau \geq 0} \|T_\tau v\|_{\mathcal{V}} < \infty$  implies  $v \in \mathcal{V}$ . In our applications,  $\mathcal{V}$  will frequently be the normed signal space  $W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , in which case  $\mathcal{V}_e = W_{\text{loc}}^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ ,  $\mathcal{V}_\omega = W_{\text{loc}}^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$  for  $\omega \in (0, \infty]$ , and  $\mathcal{V}_a = \cup_{0 < \omega \leq \infty} W_{\text{loc}}^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$ . It is important to note that  $\mathcal{V}_\omega \supsetneq W^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$ .

For a normed signal space  $\mathcal{U}$  and the Euclidean space  $\mathbb{R}^l$ ,  $l \in \mathbb{N}$ , we will also consider subsets of  $\mathcal{V} = \mathbb{R}^l \times \mathcal{U}$ , which, on identifying each  $\theta \in \mathbb{R}^l$  with the constant signal  $t \mapsto \theta$ , can be thought of as a normed signal space with the norm given by  $\|(\theta, x)\|_{\mathcal{V}} = \sqrt{|\theta|^2 + \|x\|_{\mathcal{U}}^2}$ .

**3.2. Well posedness.** A mapping  $Q: \mathcal{X}_1 \rightarrow \mathcal{X}_2$  between signal spaces is said to be *causal* if and only if, for all  $\tau > 0$ ,  $x, y \in \mathcal{X}_1$ ,  $T_\tau x = T_\tau y$  implies  $T_\tau Qx = T_\tau Qy$ . Let  $\mathcal{U}$  and  $\mathcal{Y}$  be normed signal spaces and let  $P: \mathcal{U}_a \rightarrow \mathcal{Y}_a$  and  $C: \mathcal{Y}_a \rightarrow \mathcal{U}_a$  be causal mappings representing a plant and controller, respectively. Our central concern is the system of equations

$$(3.1) \quad [P, C] : \quad y_1 = Pu_1, \quad u_2 = Cy_2, \quad u_0 = u_1 + u_2, \quad y_0 = y_1 + y_2$$

corresponding to the closed-loop feedback configuration as depicted in Figure 1; see section 1. By a solution of (3.1) we mean the following. For  $w_0 = (u_0, y_0) \in \mathcal{W} := \mathcal{U} \times \mathcal{Y}$ , a pair  $(w_1, w_2) = ((u_1, y_1), (u_2, y_2)) \in \mathcal{W}_a \times \mathcal{W}_a$ ,  $\mathcal{W}_a := \mathcal{U}_a \times \mathcal{Y}_a$ , is a *solution* of (3.1) if and only if (3.1) holds on  $\text{dom}(w_1, w_2)$ . The (possibly empty) set of all solutions is denoted by

$$\mathcal{X}_{w_0} := \{(w_1, w_2) \in \mathcal{W}_a \times \mathcal{W}_a \mid (w_1, w_2) \text{ solves (3.1)}\}.$$

The closed-loop system  $[P, C]$ , given by (3.1), is said to have

- the *existence property* if and only if  $\mathcal{X}_{w_0} \neq \emptyset$ ,
- the *uniqueness property* if and only if

$$\begin{aligned} \forall w_0 \in \mathcal{W} : \quad & \left[ (\hat{w}_1, \hat{w}_2), (\tilde{w}_1, \tilde{w}_2) \in \mathcal{X}_{w_0} \right. \\ & \left. \implies (\hat{w}_1, \hat{w}_2) = (\tilde{w}_1, \tilde{w}_2) \quad \text{on} \quad \text{dom}(\hat{w}_1, \hat{w}_2) \cap \text{dom}(\tilde{w}_1, \tilde{w}_2) \right]. \end{aligned}$$

Assume that  $[P, C]$  has the existence and uniqueness properties. For each  $w_0 \in \mathcal{W}$ , define  $\omega_{w_0}$ ,  $0 < \omega_{w_0} \leq \infty$ , by the property

$$[0, \omega_{w_0}) := \bigcup_{(\hat{w}_1, \hat{w}_2) \in \mathcal{X}_{w_0}} \text{dom}(\hat{w}_1, \hat{w}_2)$$

and define  $(w_1, w_2) \in \mathcal{W}_a \times \mathcal{W}_a$ , with  $\text{dom}(w_1, w_2) = [0, \omega_{w_0})$ , by the property  $(w_1, w_2)|_{[0, t)} \in \mathcal{X}_{w_0}$  for all  $t \in [0, \omega_{w_0})$ . This construction induces the operator

$$H_{P,C} : \mathcal{W} \rightarrow \mathcal{W}_a \times \mathcal{W}_a, \quad w_0 \mapsto (w_1, w_2).$$

The closed-loop system  $[P, C]$ , given by (3.1), is said to be

- *locally well posed* if and only if it has the existence and uniqueness properties and the operator  $H_{P,C}: \mathcal{W} \rightarrow \mathcal{W}_a \times \mathcal{W}_e$ ,  $w_0 \mapsto (w_1, w_2)$ , is causal,
- *globally well posed* if and only if it is locally well posed and  $H_{P,C}(\mathcal{W}) \subset \mathcal{W}_e \times \mathcal{W}_e$ ,
- $\mathcal{W}$ -*stable* if and only if it is locally well posed and  $H_{P,C}(\mathcal{W}) \subset \mathcal{W} \times \mathcal{W}$ ,
- *regularly well posed* if and only if it is locally well posed and

$$(3.2) \quad \forall w_0 \in \mathcal{W} : [\omega_{w_0} < \infty \implies T_{\omega_{w_0}} H_{P,C}(w_0) \notin \mathcal{W} \times \mathcal{W}].$$

If  $[P, C]$  is globally well posed, then for each  $w_0 \in \mathcal{W}$  the solution  $H_{P,C}(w_0)$  exists on the half-line  $\mathbb{R}_{\geq 0}$ . Regular well posedness means that if the closed-loop system has a finite escape time  $\omega_{w_0} > 0$  for some disturbance  $w_0 \in \mathcal{W}$ , then at least one of the components  $u_1$ ,  $u_2$  or  $y_1$ ,  $y_2$  is not a restriction to  $[0, \omega_{w_0})$  of a function in  $\mathcal{U}$  or  $\mathcal{Y}$ , respectively. If  $[P, C]$  is regularly well posed and satisfies

$$\forall w_0 \in \mathcal{W} : [\omega_{w_0} < \infty \implies T_{\omega_{w_0}} H_{P,C}(w_0) \in \mathcal{W} \times \mathcal{W}],$$

there does not exist a solution of  $[P, C]$  with a finite escape time, and therefore  $[P, C]$  is globally well posed. However, global well posedness does not guarantee that each solution belongs to  $\mathcal{W} \times \mathcal{W}$ ; the latter is ensured by  $\mathcal{W}$ -stability of  $[P, C]$ . Note also that neither regular nor global well posedness implies the other.

**3.3. Graphs and gain-function stability.** In our investigation of robustness of stability properties of a closed-loop system, the concept of graphs and gain-function stability will play a central role. Corresponding to a plant operator  $P$  (respectively, the controller operator  $C$ ) is a subset of  $\mathcal{W}$ , called the *graph* of the plant  $\mathcal{G}_P$  (respectively, the controller  $\mathcal{G}_C$ ), defined as

$$\mathcal{G}_P = \left\{ \begin{pmatrix} u \\ Pu \end{pmatrix} \middle| u \in \mathcal{U}, Pu \in \mathcal{Y} \right\} \subset \mathcal{W}, \quad \mathcal{G}_C = \left\{ \begin{pmatrix} Cy \\ y \end{pmatrix} \middle| Cy \in \mathcal{U}, y \in \mathcal{Y} \right\} \subset \mathcal{W}.$$

Note that we identify  $\mathcal{G}_P \ni \begin{pmatrix} u \\ Pu \end{pmatrix} = (u, Pu) \in \mathcal{W}$ , and analogously for  $\mathcal{G}_C$ .

A causal operator  $F: \mathcal{X} \rightarrow \mathcal{V}_a$ , where  $\mathcal{X}, \mathcal{V}$  are subsets of normed signal spaces, is said to be *gain-function stable* if and only if  $F(\mathcal{X}) \subset \mathcal{V}$  and the following nonlinear so-called *gain function* is well defined:

$$(3.3) \quad g[F]: (r_0, \infty) \rightarrow \mathbb{R}_{\geq 0},$$

$$r \mapsto g[F](r) = \sup \left\{ \|T_\tau Fx\|_{\mathcal{V}} \mid x \in \mathcal{X}, \|T_\tau x\|_{\mathcal{X}} \in (r_0, r], \tau > 0 \right\},$$

where  $r_0 := \inf_{x \in \mathcal{X}} \|x\|_{\mathcal{X}} < \infty$ . Observe that  $\|T_\tau Fx\|_{\mathcal{V}} \leq g[F](\|T_\tau x\|_{\mathcal{X}})$ . A closed-loop system  $[P, C]$  is said to be *gain-function stable* if and only if it is globally well posed and  $H_{P,C}: \mathcal{W} \rightarrow \mathcal{W}_e \times \mathcal{W}_e$  is gain-function stable.

Note the following facts:

- global well posedness of  $[P, C]$  implies that  $\text{im } H_{P,C} \subset \mathcal{W}_e \times \mathcal{W}_e$ ;
- gain-function stability of  $[P, C]$  implies  $\mathcal{W}$ -stability of  $[P, C]$ ;
- if  $[P, C]$  is  $\mathcal{W}$ -stable, then  $H_{P,C}: \mathcal{W} \rightarrow \mathcal{G}_P \times \mathcal{G}_C$  is a bijective operator with inverse  $H_{P,C}^{-1}: (w_1, w_2) \mapsto w_1 + w_2$ .

To see (iii), note that  $H_{P,C}(\mathcal{W}) \subset \mathcal{W} \times \mathcal{W}$  implies that  $H_{P,C}(\mathcal{W}) \subset \mathcal{G}_P \times \mathcal{G}_C$ , and since for any  $w_1 \in \mathcal{G}_P \subset \mathcal{W}$ ,  $w_2 \in \mathcal{G}_C \subset \mathcal{W}$  we have  $w_1 + w_2 \in \mathcal{W}$ , it follows that  $H_{P,C}(\mathcal{W}) \supset \mathcal{G}_P \times \mathcal{G}_C$ . Therefore, we can think of a gain-function stable  $H_{P,C}$  as a surjective operator  $H_{P,C}: \mathcal{W} \rightarrow \mathcal{G}_P \times \mathcal{G}_C$ . The inverse of  $H_{P,C}: \mathcal{W} \rightarrow \mathcal{G}_P \times \mathcal{G}_C$  is obviously  $H_{P,C}^{-1}: (w_1, w_2) \mapsto w_1 + w_2$ .

Finally, with a closed-loop system  $[P, C]$ , we associate the following two parallel projection operators:  $\Pi_{P//C}: \mathcal{W} \rightarrow \mathcal{W}_a$ ,  $w_0 \mapsto w_1$ , and  $\Pi_{C//P}: \mathcal{W} \rightarrow \mathcal{W}_a$ ,  $w_0 \mapsto w_2$ . Clearly,  $H_{P,C} = (\Pi_{P//C}, \Pi_{C//P})$  and  $\Pi_{P//C} + \Pi_{C//P} = I$ . Therefore, gain-function stability of one of the operators  $\Pi_{P//C}$  and  $\Pi_{C//P}$  implies the gain-function stability of the other, and so gain-function stability of either operator implies gain-function stability of the closed-loop system  $[P, C]$ .

**3.4. The nonlinear gap.** The essence of the paper is a study of robust stability in a specific adaptive control context. Robust stability is the property that the stability properties of a globally well-posed closed-loop system  $[P, C]$  persists under “sufficiently small” perturbations of the plant. In other words, robust stability is the property that  $[P_1, C]$  inherits the stability properties of  $[P, C]$  when the plant  $P$  is replaced by any plant  $P_1$  sufficiently “close” to  $P$ . In the context of this paper, plants  $P$  and  $P_1$  are deemed to be close if and only if their respective graphs are *close* in the gap sense of [5]. The nonlinear gap is defined as follows:

Let, for signal spaces  $\mathcal{U}$  and  $\mathcal{Y}$ ,

$$\Gamma := \{P: \mathcal{U}_a \rightarrow \mathcal{Y}_a \mid P \text{ is causal}\}$$

and, for  $P_1, P_2 \in \Gamma$ , define the (possibly empty) set

$$\mathcal{O}_{P_1, P_2} := \{\Phi: \mathcal{G}_{P_1} \rightarrow \mathcal{G}_{P_2} \mid \Phi \text{ is causal, surjective, and } \Phi(0) = 0\}.$$

The *directed nonlinear gap* is given by

$$\vec{\delta}: \Gamma \times \Gamma \rightarrow [0, \infty],$$

$$(P_1, P_2) \mapsto \vec{\delta}(P_1, P_2) := \inf_{\Phi \in \mathcal{O}_{P_1, P_2}} \sup_{x \in \mathcal{G}_{P_1} \setminus \{0\}, \tau > 0} \left( \frac{\|T_\tau(\Phi - I)(x)\|_{\mathcal{U} \times \mathcal{Y}}}{\|T_\tau x\|_{\mathcal{U} \times \mathcal{Y}}} \right),$$

with the convention that  $\vec{\delta}(P_1, P_2) := \infty$  if  $\mathcal{O}_{P_1, P_2} = \emptyset$ , and the *nonlinear gap*  $\delta$  is

$$\delta: \Gamma \times \Gamma \rightarrow [0, \infty], \quad (P_1, P_2) \mapsto \delta(P_1, P_2) := \max\{\vec{\delta}(P_1, P_2), \vec{\delta}(P_2, P_1)\}.$$

**3.5. Example.** In this subsection we illustrate the previous graph and gap concepts by two operators  $P_\alpha, P_{N,M,\alpha}$  induced by state space systems

$$(3.4) \quad \begin{cases} P_\alpha & : & \dot{x} = \alpha x + u_1, & x(0) = x^0, \\ & & y_1 = x, \end{cases}$$

$$(3.5) \quad \begin{cases} P_{N,M,\alpha} & : & \dot{x} = \tilde{A}x + \tilde{b}u_1, & x(0) = \tilde{x}^0, \\ & & y_1 = \tilde{c}x \end{cases}$$

for  $\alpha > 0$ ,  $x^0 \in \mathbb{R}$ , and  $(\tilde{A}, \tilde{b}, \tilde{c})$  as in (1.6), with  $\tilde{x}^0 \in \mathbb{R}^3$ . Throughout this example assume that  $x^0 = 0$ ,  $\tilde{x}^0 = 0$ . The second purpose of this example is to show that  $P_\alpha$  is close to  $P_{N,M,\alpha}$  in the sense that

$$(3.6) \quad \limsup_{M \rightarrow \infty} \vec{\delta}(P_\alpha, P_{2M,M,\alpha}) = 0.$$

First, recall that  $(\widetilde{A}, \widetilde{b}, \widetilde{c}) \in \mathcal{P}_{3,1} \setminus \widetilde{\mathcal{M}}_{3,1}$  and  $(\alpha, 1, 1) \in \mathcal{M}_{1,1}$ .

Second, recall that the graphs of  $P_\alpha$  and  $P_{N,M,\alpha}$  are given, respectively, by

$$\mathcal{G}_{P_\alpha} = \left\{ \begin{pmatrix} u_1 \\ y_1 \end{pmatrix} \middle| u_1, y_1 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}), \, y_1 \text{ solves (3.4)} \right\},$$
$$\mathcal{G}_{P_{N,M,\alpha}} = \left\{ \begin{pmatrix} u_1 \\ y_1 \end{pmatrix} \middle| u_1, y_1 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}), \, y_1 \text{ solves (3.5)} \right\}.$$

To determine an upper bound for the *gap* between  $P_\alpha$  and  $P_{N,M,\alpha}$ , consider the bijective mapping  $\Phi$  from graph  $\mathcal{G}_{P_\alpha}$  to graph  $\mathcal{G}_{P_{N,M,\alpha}}$  given by

$$\Phi : \mathcal{G}_{P_\alpha} \rightarrow \mathcal{G}_{P_{N,M,\alpha}}, \quad \begin{pmatrix} u \\ \int_0^\cdot e^{\alpha(\cdot-s)} u(s) \, ds \end{pmatrix} \mapsto \begin{pmatrix} u \\ \widetilde{c} \int_0^\cdot e^{\widetilde{A}(\cdot-s)} \widetilde{b} u(s) \, ds \end{pmatrix}.$$

By the definition of the nonlinear gap (see section 3.4), we obtain

$$\vec{\delta}(P_\alpha, P_{N,M,\alpha}) \leq \sup_{w \in \mathcal{G}_{P_\alpha} \setminus \{0\}} \frac{\|(\Phi - I)(w)\|_{\mathcal{W}}}{\|w\|_{\mathcal{W}}},$$

where  $\mathcal{W} := W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$  and, for  $w = (u, y) \in \mathcal{W}$ , the norm is defined by

$$\|(u, y)\|_{\mathcal{W}} := \|u\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})} + \|y\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})}.$$

To estimate

$$|(\Phi - I)(w)(t)| \quad \text{for } w := \begin{pmatrix} u \\ \int_0^\cdot e^{\alpha(\cdot-s)} u(s) \, ds \end{pmatrix} \in \mathcal{G}_{P_\alpha}$$

we calculate that the output  $y_1$  of (3.5) is given, for all  $t \geq 0$ , by

$$\begin{aligned} y_1(t) &= \widetilde{c} \int_0^t e^{\widetilde{A}(t-s)} \widetilde{b} u_1(s) \, ds = \int_0^t \frac{N(M - \alpha)}{(\alpha + N)(\alpha + M)} e^{\alpha(t-s)} u_1(s) \, ds \\ &\quad + \int_0^t \frac{N(N + M)}{(N - M)(\alpha + N)} e^{-N(t-s)} u_1(s) \, ds \\ &\quad + \int_0^t \frac{-2NM}{(N - M)(\alpha + M)} e^{-M(t-s)} u_1(s) \, ds, \end{aligned}$$

and thus, for all  $t \geq 0$ ,

$$\begin{aligned}
 |(\Phi - I)(w)(t)| &\leq \left| \left( \frac{N(M-\alpha)}{(\alpha+N)(\alpha+M)} - 1 \right) \int_0^t e^{\alpha(t-s)} u(s) \, ds \right| \\
 &\quad + \left| \frac{N(N+M)}{(N-M)(\alpha+N)} \int_0^t e^{-N(t-s)} u(s) \, ds \right| \\
 &\quad + \left| \frac{-2NM}{(N-M)(\alpha+M)} \int_0^t e^{-M(t-s)} u(s) \, ds \right| \\
 &\leq \left| \frac{N(M-\alpha)}{(\alpha+N)(\alpha+M)} - 1 \right| \left| \int_0^t e^{\alpha(t-s)} u(s) \, ds \right| \\
 &\quad + \left( \left| \frac{N(N+M)}{(N-M)(\alpha+N)} \int_0^t e^{-N(t-s)} \, ds \right| \right. \\
 &\quad \left. + \left| \frac{-2NM}{(N-M)(\alpha+M)} \int_0^t e^{-M(t-s)} \, ds \right| \right) \|u\|_{L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})} \\
 &\leq \left| \frac{N(M-\alpha)}{(\alpha+N)(\alpha+M)} - 1 \right| \left\| \int_0^\cdot e^{\alpha(\cdot-s)} u(s) \, ds \right\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})} \\
 &\quad + \left( \left| \frac{N+M}{(N-M)(\alpha+N)} \right| + \left| \frac{2N}{(N-M)(\alpha+M)} \right| \right) \|u\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})}.
 \end{aligned}$$

Hence

$$\vec{\delta}(P_\alpha, P_{N,M,\alpha}) \leq \left| \frac{N(M-\alpha)}{(\alpha+N)(\alpha+M)} - 1 \right| + \left| \frac{N+M}{(N-M)(\alpha+N)} \right| + \left| \frac{2N}{(N-M)(\alpha+M)} \right|,$$

which yields (3.6).

#### 4. Robustness of the $\lambda$ -tracker.

**4.1. Well posedness of the closed-loop system.** For  $m, n \in \mathbb{N}$  with  $n \geq m$ , consider  $\mathcal{P}_{n,m}$  as a subspace of the Euclidean space  $\mathbb{R}^{n^2+2mn}$  by identifying a plant  $\theta = (A, B, C)$  with a vector  $\theta$  consisting of the elements of the plant matrices, ordered lexicographically. With normed signal spaces  $\mathcal{U}$  and  $\mathcal{Y}$  and  $(\theta, x^0) \in \mathcal{P}_{n,m} \times \mathbb{R}^n$ , where  $x^0 \in \mathbb{R}^n$  is the initial value of a linear system (1.1), we associate the causal plant operator

$$(4.1) \quad \tilde{P}(\theta, x^0) : \mathcal{U}_a \rightarrow \mathcal{Y}_a, \quad u_1 \mapsto \tilde{P}(\theta, x^0)(u_1) := y_1,$$

where, for  $u_1 \in \mathcal{U}_a$  with  $\text{dom}(u_1) = [0, \omega)$ , we have  $y_1 = cx$ ,  $x$  being the unique solution of (1.1) on  $[0, \omega)$ . Note that  $\tilde{P}$  is a map from  $\cup_{n \geq m} (\mathcal{P}_{n,m} \times \mathbb{R}^n)$  to the space of maps  $\mathcal{U}_a \rightarrow \mathcal{Y}_a$ . Consider, for  $\lambda > 0$ , the adaptive strategy (1.5) and associate the causal control operator, parameterized by  $\lambda$  and the initial value  $k^0 \in \mathbb{R}$ , i.e.,

$$(4.2) \quad \tilde{C}(\lambda, k^0) : \mathcal{Y}_a \rightarrow \mathcal{U}_a, \quad y_2 \mapsto \tilde{C}(\lambda, k^0)(y_2) := u_2.$$

Note that  $\tilde{C}$  is a map from  $\mathbb{R}_{>0} \times \mathbb{R}$  to the space of causal maps  $\mathcal{Y}_a \rightarrow \mathcal{U}_a$ .

In this subsection we show that, for  $\mathcal{U} = \mathcal{Y} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , the closed-loop system  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  of any plant of the form (1.1) (with associated operator  $\tilde{P}(\theta, x^0)$ ) and adaptive controller (1.5) (with associated operator  $\tilde{C}(\lambda, k^0)$ ), where  $(\theta, x^0) \in \mathcal{P}_{n,m} \times \mathbb{R}^n$  and  $(\lambda, k^0) \in \mathbb{R}_{>0} \times \mathbb{R}$ , is regularly well posed. Furthermore, we show that, for  $\theta \in \mathcal{M}_{n,m}$ , the closed-loop system  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  is globally well posed and  $(\mathcal{U} \times \mathcal{Y})$ -stable.

**PROPOSITION 4.1.** *Let  $m, n \in \mathbb{N}$  with  $n \geq m$ ,  $\lambda > 0$ ,  $(\theta, x^0, k^0) \in \mathcal{M}_{n,m} \times \mathbb{R}^n \times \mathbb{R}$ , and  $u_0, y_0 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ . Then, for plant operator  $\tilde{P}(\theta, x^0)$  and control operator  $\tilde{C}(\lambda, k^0)$ , given by (4.1) and (4.2), respectively, the closed-loop initial value problem  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$ , given by (1.8), (1.2), (1.5), is globally well posed and  $(W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m))$ -stable.*

*Proof.* The proposition is a direct consequence of Proposition 2.1.  $\square$

Note that, for  $(A, B, C) \in \mathcal{P}_{n,m}$ ,  $x^0 \in \mathbb{R}^n$ ,  $\lambda > 0$ , and  $k^0 \in \mathbb{R}$ , the closed-loop initial value problem (1.1), (1.2), (1.5) may be written as

$$(4.3) \quad \begin{cases} \dot{x}(t) &= Ax(t) + B[u_0(t) - u_2(t)], & x(0) = x^0 \in \mathbb{R}^n, \\ \dot{k}(t) &= d_\lambda(y_2(t)) |y_2(t)|, & k(0) = k^0 \in \mathbb{R}, \\ y_2(t) &= y_0(t) - Cx(t), \\ u_2(t) &= -k(t)y_2(t), \end{cases}$$

where  $d_\lambda$  is defined in the Nomenclature.

**PROPOSITION 4.2.** *Let  $m, n \in \mathbb{N}$  with  $n \geq m$ ,  $\lambda > 0$ ,  $(\theta, x^0, k^0) \in \mathcal{P}_{n,m} \times \mathbb{R}^n \times \mathbb{R}$ , and  $u_0, y_0 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ . Then, for plant operator  $\tilde{P}(\theta, x^0)$  and control operator  $\tilde{C}(\lambda, k^0)$ , given by (4.1) and (4.2), respectively, the closed-loop initial value problem  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$ , given by (4.3), has the following properties:*

- (i) *there exists a unique maximal solution  $(x, k) : [0, \omega) \rightarrow \mathbb{R}^n \times \mathbb{R}$  for some  $\omega \in (0, \infty]$ ;*
- (ii) *if  $k \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R})$ , then  $\omega = \infty$ ;*
- (iii) *if  $y_2 \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$ , then  $\omega = \infty$ ;*
- (iv)  *$[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  is regularly well posed.*

*Proof.* (i) Since the right-hand side of (4.3) is continuous and locally Lipschitz, the statement follows from the theory of ordinary differential equations.

(ii) Suppose  $k \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R})$  and, for contradiction,  $\omega < \infty$ . Since  $d_\lambda(y_2)^2 \leq d_\lambda(y_2) |y_2| = \dot{k} \in L^\infty([0, \omega) \rightarrow \mathbb{R}_{\geq 0})$ , we have  $d_\lambda(y_2) \in L^\infty([0, \omega) \rightarrow \mathbb{R}_{\geq 0})$  and  $d_\lambda(y_2) + \lambda \in L^\infty([0, \omega) \rightarrow \mathbb{R}_{\geq 0})$ . Thus  $y_2 \in L^\infty([0, \omega) \rightarrow \mathbb{R}^m)$ .

Since  $k \in L^\infty([0, \omega) \rightarrow \mathbb{R})$ , variation of constants applied to (4.3) yields the existence of constants  $c_0, c_1 > 0$  such that

$$(4.4) \quad \forall t \in [0, \omega) : |x(t)| \leq c_0 \left( e^{c_1 \omega} + \int_0^\omega e^{c_1(\omega-s)} (|u_0(s)| + |y_2(s)|) ds \right).$$

Since  $y_2 \in L^\infty([0, \omega) \rightarrow \mathbb{R}^m)$  and  $u_0 \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , it follows from the convolution in (4.4) that the right-hand side of (4.4) is bounded on  $[0, \omega)$ , which contradicts the maximality of the solution  $x$ . Hence  $\omega = \infty$ .

(iii) Suppose  $y_2 \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$  and, for contradiction,  $\omega < \infty$ . Then  $\dot{k} = d_\lambda(y_2) |y_2| \in L^\infty([0, \omega) \rightarrow \mathbb{R})$ , and, combined with

$$\forall t \in [0, \omega) :$$

$$k(t) - k^0 = \int_0^t d_\lambda(y_2(s)) |y_2(s)| \, ds \leq \int_0^t \|y_2\|_{L^\infty([0, \omega) \rightarrow \mathbb{R}^m)}^2 \, ds = \omega \|y_2\|_{L^\infty([0, \omega) \rightarrow \mathbb{R}^m)}^2,$$

we arrive at  $k \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R})$ . Now (ii) yields that  $\omega = \infty$ . This is a contradiction, and so  $\omega = \infty$ .

(iv) Let  $\mathcal{W} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ . By (i), the closed-loop  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  is locally well posed. To prove that  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  is regularly well posed, it suffices to show that (3.2) holds. For arbitrary  $w_0 = (u_0, y_0) \in \mathcal{W}$  consider  $(w_1, w_2) = H_{\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)}(w_0)$ , where  $\text{dom}(w_1, w_2) = [0, \omega)$  is maximal. Suppose, contrary to the right-hand side of (3.2), that  $T_\omega(w_1, w_2) \in \mathcal{W} \times \mathcal{W}$ . Then  $y_2 \in W^{1,\infty}([0, \omega) \rightarrow \mathbb{R}^m)$ , which, in view of (iii), yields  $\omega = \infty$ , i.e., the contrary of the left-hand side of (3.2). Hence the closed-loop system is regularly well posed.  $\square$

**4.2. Robustness.** In Propositions 4.1 and 4.2 we have established that, for  $(\theta, x^0, k^0) \in \mathcal{M}_{n,m} \times \mathbb{R}^n \times \mathbb{R}$  and  $m, n \in \mathbb{N}$  with  $n \geq m$ ,  $\lambda > 0$ ,  $u_0, y_0 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , the closed-loop system  $[\tilde{P}(\theta, x^0), \tilde{C}(\lambda, k^0)]$  is globally well posed and has certain stability properties. Furthermore, in Proposition 2.1  $\lambda$ -tracking is shown for linear systems belonging to class  $\mathcal{M}_{n,m}$ .

The purpose of this subsection is to determine conditions under which these properties are maintained when the plant  $\tilde{P}(\theta, x^0)$  is perturbed to a plant  $\tilde{P}(\tilde{\theta}, \tilde{x}^0)$ , where  $(\tilde{\theta}, \tilde{x}^0) \in \mathcal{P}_{q,m} \times \mathbb{R}^q$  for some  $q \in \mathbb{N}$ , in particular when  $\tilde{\theta} \notin \mathcal{M}_{q,m}$ . The main result, Theorem 4.5, shows that stability properties and  $\lambda$ -tracking persist if (a) the plants  $\tilde{P}(\tilde{\theta}, 0)$  and  $\tilde{P}(\theta, 0)$  are sufficiently close (in the gap sense) and (b) the initial data  $\tilde{x}^0$  and disturbance  $w_0 = (u_0, y_0)$  are sufficiently small.

To establish gap margin results, we will need to construct the augmented plant and controller operators as in [4]. Note that  $0 \notin \mathcal{M}_{n,m}$ . Define  $\tilde{\mathcal{U}} := \mathbb{R}^{n^2+2n} \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  and let  $\tilde{\mathcal{W}} := \tilde{\mathcal{U}} \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , which can be considered as signal spaces by identifying  $\theta \in \mathbb{R}^{n^2+2mn}$  with the constant function  $t \mapsto \theta$  and endowing  $\tilde{\mathcal{U}}$  with the norm  $\|(\theta, u)\|_{\tilde{\mathcal{U}}} := \sqrt{|\theta|^2 + \|u\|_{W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)}^2}$ . For given  $\tilde{P}(\theta, 0)$  as in (4.1), we define the (augmented) plant operator as

$$(4.5) \quad P : \tilde{\mathcal{U}}_a \rightarrow W_a^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m), \quad (\theta, u_1) = \tilde{u}_1 \mapsto y_1 = P(\tilde{u}_1) := \tilde{P}(\theta, 0)(u_1).$$

Fix  $\lambda > 0$  and  $k^0 \in \mathbb{R}$  and define, for  $\tilde{C}(\lambda, k^0)$  as in (4.2), the (augmented) controller operator as

$$(4.6) \quad C : W_a^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \rightarrow \tilde{\mathcal{U}}_a, \quad y_2 \mapsto \tilde{u}_2 = C(y_2) := \left(0, \tilde{C}(\lambda, k^0)(y_2)\right) = (0, u_2).$$

For each nonempty  $\Omega \subset \mathcal{M}_{n,m}$ , define

$$(4.7) \quad \mathcal{W}^\Omega := (\Omega \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \quad \text{and} \quad H_{P,C}^\Omega := H_{P,C}|_{\mathcal{W}^\Omega}.$$

It follows from Proposition 4.1 that  $H_{P,C}^\Omega : \mathcal{W}^\Omega \rightarrow \widetilde{\mathcal{W}} \times \widetilde{\mathcal{W}}$  is a causal operator for any  $\Omega \subset \mathcal{M}_{n,m}$ . In Proposition 4.3 we show gain-function stability of  $H_{P,C}^\Omega$ . This is a supposition of Theorem 5.2 in [3], the latter being used to show Proposition 4.4 and thus the main result, Theorem 4.5.

**PROPOSITION 4.3.** *Let  $m, n \in \mathbb{N}$  with  $n \geq m$ ,  $k^0 \in \mathbb{R}$ , and  $\lambda > 0$  and assume  $\Omega \subset \mathcal{M}_{n,m}$  is closed. Then, for the closed-loop system  $[P, C]$  given by (3.1), (4.5), and (4.6), the operator  $H_{P,C}^\Omega$  given by (4.7) is gain-function stable.*

*Proof.* Note that  $((\theta, u_1), y_1) = ((\theta, u_0), y_0) - ((0, u_2), y_2)$ . For  $\nu : \mathcal{D}_{n,m} \rightarrow \mathbb{R}_{\geq 0}$  as in Proposition 2.1 and  $\mathcal{W}^\Omega$  given by (4.7), we have

$$\forall ((\theta, u_0), y_0) \in \mathcal{W}^\Omega :$$

$$\begin{aligned} \|H_{P,C}^\Omega((\theta, u_0), y_0)\|_{\widetilde{\mathcal{W}} \times \widetilde{\mathcal{W}}} &= \|((\theta, u_1), y_1), ((0, u_2), y_2))\|_{\widetilde{\mathcal{W}} \times \widetilde{\mathcal{W}}} \\ &\leq \|((\theta, u_0), y_0)\|_{\widetilde{\mathcal{W}}} + 2\|((0, u_2), y_2)\|_{\widetilde{\mathcal{W}}} \\ &\leq \|(u_0, y_0)\|_{\mathcal{W}} + |\theta| + 2\nu(\theta, (0, k^0), u_0, y_0), \end{aligned}$$

and so, for  $r_0 := \inf_{w \in \mathcal{W}^\Omega} \|w\|_{\widetilde{\mathcal{W}}}$  and  $r \in (r_0, \infty)$ , closedness of  $\Omega$  yields

$$\begin{aligned} &g[H_{P,C}^\Omega](r) \\ &:= \sup \left\{ \|(u_0, y_0)\|_{\mathcal{W}} + |\theta| + 2\nu(\theta, (0, k^0), u_0, y_0) \mid \begin{array}{l} (\theta, u_0, y_0) \in \mathcal{W}^\Omega, \\ \|(\theta, u_0, y_0)\|_{\widetilde{\mathcal{W}}} \leq r \end{array} \right\} < \infty. \end{aligned}$$

Thus, a gain function for  $H_{P,C}^\Omega$  exists, and the proof is complete.  $\square$

The following proposition establishes  $(W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m))$ -stability of the closed-loop system  $[\tilde{P}(\tilde{\theta}, \tilde{x}^0), \tilde{C}(\lambda, k^0)]$  for a system  $\tilde{\theta}$  belonging to the system class  $\mathcal{P}_{q,m}$  if, for a system  $\theta$  belonging to  $\mathcal{M}_{n,m}$ , the gap between  $\tilde{P}(\tilde{\theta}, 0)$  and  $\tilde{P}(\theta, 0)$ , the initial value  $\tilde{x}^0 \in \mathbb{R}^q$  and the input/output disturbances  $w_0 = (u_0, y_0)$  are sufficiently small. The proof is based on results from [3].

**PROPOSITION 4.4.** *Let  $m, n, q \in \mathbb{N}$  with  $n, q \geq m$ ,  $\mathcal{U} = \mathcal{Y} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ ,  $\mathcal{W} = \mathcal{U} \times \mathcal{Y}$ , and  $\theta \in \mathcal{M}_{n,m}$ . For  $(\tilde{\theta}, \tilde{x}^0, k^0) \in \mathcal{P}_{q,m} \times \mathbb{R}^q \times \mathbb{R}$  and  $\lambda > 0$ , consider  $\tilde{P}(\tilde{\theta}, \tilde{x}^0) : \mathcal{U}_a \rightarrow \mathcal{Y}_a$  and  $\tilde{C}(\lambda, k^0) : \mathcal{Y}_a \rightarrow \mathcal{U}_a$  defined by (4.1) and (4.2), respectively. Then there exist a continuous function  $\eta : (0, \infty) \rightarrow (0, \infty)$  and a function  $\psi : \mathcal{P}_{q,m} \rightarrow (0, \infty)$  such that the following holds:*

$$(4.8) \quad \forall (\tilde{\theta}, \tilde{x}^0, w_0, r) \in \mathcal{P}_{q,m} \times \mathbb{R}^q \times \mathcal{W} \times (0, \infty) :$$

$$\left. \begin{array}{l} \psi(\tilde{\theta})|\tilde{x}^0| + \|w_0\|_{\mathcal{W}} \leq r, \\ \tilde{\delta}(\tilde{P}(\tilde{\theta}, 0), \tilde{P}(\tilde{\theta}, 0)) \leq \eta(r) \end{array} \right\} \implies H_{\tilde{P}(\tilde{\theta}, \tilde{x}^0), \tilde{C}(\lambda, k^0)}(w_0) \in \mathcal{W} \times \mathcal{W}.$$

*Proof.* We need to show how the gain-function stability of the augmented closed loop  $[P, C]$ , given by (4.5) and (4.6), yields the robustness property (4.8) for the unaugmented closed-loop system  $[\tilde{P}(\tilde{\theta}, \tilde{x}^0), \tilde{C}(\lambda, k^0)]$ .

By Proposition 4.2 the closed-loop system  $[\tilde{P}(\tilde{\theta}, \tilde{x}^0), \tilde{C}(\lambda, k^0)]$  is regularly well posed for all  $\tilde{\theta} \in \mathcal{P}_{q,m}$ . Consider the augmented operators defined by (4.5) and (4.6),

i.e.,

$$\begin{aligned} P: \mathcal{P}_{n,m} \times \mathcal{U}_a &\rightarrow \mathcal{Y}_a, & (\tilde{\theta}, u_1) &\mapsto P(\tilde{\theta}, u_1) = \tilde{P}(\tilde{\theta}, 0)(u_1), \\ C: \mathcal{Y}_a &\rightarrow \mathcal{P}_{n,m} \times \mathcal{U}_a, & y_2 &\mapsto C(y_2) = (0, \tilde{C}(\lambda, k^0)(y_2)). \end{aligned}$$

For  $\theta \in \mathcal{M}_{n,m}$  set  $\Omega = \{\theta\}$ . By Proposition 4.3,  $H_{\tilde{P},C}^\Omega = H_{P,C}|_{\mathcal{W}^\Omega}$ , given by (4.7), is gain-function stable. By, for example, the proof of Theorem 4.D in [18],  $T_\tau \Pi_{\tilde{P}(\theta,0)/\tilde{C}(\lambda,k^0)}$  is continuous for all  $\tau > 0$ , and so  $T_\tau \Pi_{P/C}|_{\mathcal{W}^\Omega}$  is continuous for all  $\tau > 0$ .

Then [3, Theorem 5.2] gives the existence of a continuous function  $\mu: (0, \infty) \times \Omega \rightarrow (0, \infty)$  such that

$$\forall (\theta, \tilde{\theta}, w_0, r) \in \Omega \times \mathcal{P}_{q,m} \times \mathcal{W} \times (0, \infty) :$$

$$\left[ \|w_0\|_{\mathcal{W}} \leq r \wedge \delta \left( \tilde{P}(\theta, 0), \tilde{P}(\tilde{\theta}, 0) \right) \leq \mu(r, \theta) \right] \implies H_{\tilde{P}(\tilde{\theta},0), \tilde{C}(\lambda,k^0)}(w_0) \in \mathcal{W} \times \mathcal{W}.$$

Note that the proof of [3, Theorem 5.2] holds also for the signal space  $W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , although it is proved in [3] for  $\mathcal{U} = \mathcal{Y} = L^p(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ ,  $1 \leq p \leq \infty$ .

To prove (4.8) we will use [3, Theorem 5.3]. The statement of [3, Theorem 5.3] has been proved for  $\mathcal{U} = \mathcal{Y} = L^p(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ ,  $1 \leq p \leq \infty$ . The statement holds also for  $\mathcal{U} = \mathcal{Y} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ . To see this, invoke the fact that for any Hurwitz matrix  $M \in \mathbb{R}^{n \times n}$  it is  $(t \mapsto \exp(Mt))$ ,  $(t \mapsto \frac{d}{dt} \exp(Mt)) \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^{n \times n})$ . Now the statement of [3, Theorem 5.3] for  $\mathcal{U} = \mathcal{Y} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  yields the existence of a continuous function  $\mu: (0, \infty) \times \Omega \rightarrow (0, \infty)$  and a function  $\psi: \mathcal{P}_{q,m} \rightarrow (0, \infty)$  such that

$$(4.9) \quad \forall (\tilde{\theta}, \theta, \tilde{x}^0, w_0, r) \in \mathcal{P}_{q,m} \times \mathcal{M}_{n,m} \times \mathbb{R}^q \times \mathcal{W} \times (0, \infty) :$$

$$\left. \begin{aligned} &\psi(\tilde{\theta})|\tilde{x}^0| + \|w_0\|_{\mathcal{W}} \leq r, \\ &\delta \left( \tilde{P}(\theta, 0), \tilde{P}(\tilde{\theta}, 0) \right) \leq \mu(r, \theta) \end{aligned} \right\} \implies H_{\tilde{P}(\tilde{\theta},\tilde{x}^0), \tilde{C}(\lambda,k^0)}(w_0) \in \mathcal{W} \times \mathcal{W}.$$

Finally, statement (4.8) follows on setting  $\eta(\cdot) = \mu(\cdot, \theta)$ .  $\square$

Note that [3, Theorem 5.3] requires stabilizability of system  $\tilde{\theta} \in \mathcal{P}_{q,m}$ .

Finally, we are in the position to state and prove the main result of the present paper. Loosely speaking, we show that the  $\lambda$ -tracker also works for systems  $(\tilde{A}, \tilde{B}, \tilde{C}) \in \mathcal{P}_{q,m}$  which are not necessarily minimum phase, may have higher relative degree, and may have negative high-frequency gain. However,  $(\tilde{A}, \tilde{B}, \tilde{C})$  has to be sufficiently close—in the terms of the gap metric—to a system  $(A, B, C) \in \tilde{\mathcal{M}}_{n,m}$ , and the initial value  $\tilde{x}^0 \in \mathbb{R}^q$  for  $(\tilde{A}, \tilde{B}, \tilde{C})$  and the input/output disturbances  $(u_0, y_0)$  have to be sufficiently small.

**THEOREM 4.5.** *Let  $m, n, q \in \mathbb{N}$  with  $n, q \geq m$ ,  $\mathcal{U} = \mathcal{Y} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ ,  $\mathcal{W} = \mathcal{U} \times \mathcal{Y}$ ,  $k^0 \in \mathbb{R}$ ,  $\lambda > 0$ , and  $\theta \in \mathcal{M}_{n,m}$ . For  $(\tilde{\theta}, \tilde{x}^0) \in \mathcal{P}_{q,m} \times \mathbb{R}^q$  consider the associated operators  $\tilde{P}(\tilde{\theta}, \tilde{x}^0): \mathcal{U}_a \rightarrow \mathcal{Y}_a$  and  $\tilde{C}(\lambda, k^0): \mathcal{Y}_a \rightarrow \mathcal{U}_a$  defined by (4.1) and (4.2), respectively, and the closed-loop initial value problem (1.1), (1.2), (1.5). Then there exist a continuous function  $\eta: (0, \infty) \rightarrow (0, \infty)$  and a function  $\psi: \mathcal{P}_{q,m} \rightarrow (0, \infty)$*

such that the following holds:

$$(4.10) \quad \forall \left( \tilde{\theta}, \tilde{x}^0, w_0, r \right) \in \mathcal{P}_{q,m} \times \mathbb{R}^q \times \mathcal{W} \times (0, \infty) :$$

$$\left. \begin{array}{l} \psi(\tilde{\theta})|\tilde{x}^0| + \|w_0\|_{\mathcal{W}} \leq r, \\ \vec{\delta} \left( \tilde{P}(\tilde{\theta}, 0), \tilde{P}(\tilde{\theta}, 0) \right) \leq \eta(r) \end{array} \right\} \implies \begin{cases} \limsup_{t \rightarrow \infty} |y_2(t)| \leq \lambda, \\ k \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}), \\ x \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q), \end{cases}$$

where  $(x, k)$  and  $y_2$  satisfy (4.3).

*Proof. Step 1.* We show that

$$(4.11) \quad ((u_1, y_1), (u_2, y_2)) = H_{\tilde{P}(\tilde{\theta}, \tilde{x}^0), \tilde{C}(\lambda, k^0)}(w_0) \in \mathcal{W} \times \mathcal{W}.$$

Choose functions  $\eta: (0, \infty) \rightarrow (0, \infty)$  and  $\psi: \mathcal{P}_{q,m} \rightarrow (0, \infty)$  from Proposition 4.4. Let

$$\left( \tilde{\theta}, \tilde{x}^0, w_0, r \right) \in \mathcal{P}_{q,m} \times \mathbb{R}^q \times \mathcal{W} \times (0, \infty) :$$

$$\psi(\tilde{\theta})|\tilde{x}^0| + \|w_0\|_{\mathcal{W}} \leq r \wedge \vec{\delta} \left( \tilde{P}(\tilde{\theta}, 0), \tilde{P}(\tilde{\theta}, 0) \right) \leq \eta(r).$$

Then Proposition 4.4 gives (4.11).

*Step 2.* By Proposition 4.2 it follows that (4.3) has a unique solution

$$(x, k): [0, \omega) \rightarrow \mathbb{R}^q \times \mathbb{R}$$

on a maximal interval of existence  $[0, \omega)$  for some  $\omega \in (0, \infty]$ . Proposition 4.2(iii) yields  $\omega = \infty$ .

*Step 3.* We show that  $\dot{k} \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ . Suppose, for contradiction, that  $\dot{k} \notin L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ ; i.e., there exists a sequence  $(t_i) \in (\mathbb{R}_{\geq 0})^\mathbb{N}$  with  $t_i > t_{i+1}$  and  $\lim_{i \rightarrow \infty} \dot{k}(t_i) = \infty$ . Then

$$\lim_{i \rightarrow \infty} d_\lambda(y_2(t_i)) |y_2(t_i)| = \infty$$

and thus

$$\lim_{i \rightarrow \infty} |y_2(t_i)| = \infty,$$

a contradiction to Step 1.

*Step 4.* We show that  $k \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ . Suppose, for contradiction, that  $k \notin L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ ; i.e.,  $\lim_{t \rightarrow \infty} k(t) = \infty$ . Since  $u_2 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ , the fourth equation in (4.3) yields  $\lim_{t \rightarrow \infty} y_2(t) = 0$ , and thus

$$\exists T > 0 \quad \forall t \geq T : \dot{k}(t) = d_\lambda(y_2(t)) |y_2(t)| = 0,$$

which contradicts the assumption on  $k$ .

*Step 5.* By Steps 3 and 4 we obtain  $k \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ .

*Step 6.* By Proposition 4.4 we have in particular  $y_2, \dot{y}_2 \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$ . Similar to Step 10 of the proof of Proposition 2.1, we may establish that  $y_2$  is uniformly continuous.

*Step 7.* By Step 6 and continuity of  $e \mapsto d_\lambda(e)|e|$  we obtain that  $t \mapsto d_\lambda(y_2(t)) |y_2(t)|$  is uniformly continuous. Hence, in view of  $\dot{k} = d_\lambda(y_2) |y_2| \in L^1(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$

$\mathbb{R}$ ), which is equivalent to  $k \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ , and Barbălat's lemma (see [1]),  $\lim_{t \rightarrow \infty} d_\lambda(y_2(t))|y_2(t)| = 0$  holds. This gives  $\limsup_{t \rightarrow \infty} |y_2(t)| \leq \lambda$ .

*Step 8.* It remains to show that  $x \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q)$ . Let  $(\tilde{A}, \tilde{B}, \tilde{C}) \in \mathcal{P}_{q,m}$  associated with (1.1). Detectability of  $(\tilde{A}, \tilde{B}, \tilde{C})$  yields the existence of  $F \in \mathbb{R}^{q \times m}$  such that  $\text{spec}(\tilde{A} + F\tilde{C}) \subset \mathbb{C}_-$ . Setting  $g := -[F + k\tilde{B}](y_0 - y_2) + \tilde{B}u_0 + \tilde{B}ky_0$  gives

$$(4.12) \quad \dot{x} = [\tilde{A} - k\tilde{B}\tilde{C}]x + \tilde{B}u_0 + \tilde{B}ky_0 = [\tilde{A} + F\tilde{C}]x + g.$$

By Proposition 4.4 and Step 5 we have  $y_2 \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  and  $k \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ , and since  $w_0 = (u_0, y_0) \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^m)$  it follows that  $g \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q)$ . Hence, by (4.12) we obtain  $x \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q)$ . The first equation in (4.3) then gives  $\dot{x} \in L^\infty(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q)$ , which shows that  $x \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^q)$ , and the proof is complete.  $\square$

*Example 4.6.* Finally, we revisit example (1.6).

In subsection 3.5 we have already shown that for zero initial conditions the gap between the system  $(\tilde{A}, \tilde{b}, \tilde{c}) \in \mathcal{P}_{3,1} \setminus \mathcal{M}_{3,1}$  and  $(\alpha, 1, 1) \in \mathcal{M}_{1,1}$  tends to zero as  $N = 2M$  and  $M$  tends to infinity; see (3.6). Now, in view of Theorem 4.5, there exist a continuous function  $\eta: (0, \infty) \rightarrow (0, \infty)$  and a function  $\psi: \mathcal{P}_{3,1} \rightarrow (0, \infty)$  such that

$$\forall (\tilde{x}^0, w_0, r) \in \mathbb{R}^3 \times \mathcal{W} \times (0, \infty) :$$

$$\left. \begin{aligned} &\psi((\tilde{A}, \tilde{b}, \tilde{c}))|\tilde{x}^0| + \|w_0\|_{\mathcal{W}} \leq r, \\ &\delta\left(\tilde{P}_1((\alpha, 1, 1), 0), \tilde{P}_2((\tilde{A}, \tilde{b}, \tilde{c}), 0)\right) \leq \eta(r) \end{aligned} \right\} \implies \begin{cases} k \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}), \\ \limsup_{t \rightarrow \infty} |y_0(t) - y_1(t)| \leq \lambda, \\ x \in W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}^3), \end{cases}$$

where  $\mathcal{W} = W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R}) \times W^{1,\infty}(\mathbb{R}_{\geq 0} \rightarrow \mathbb{R})$ .

This means in particular that  $\lambda$ -tracking is achieved by the adaptive control strategy (1.5) applied to system (1.6) despite the fact that it has unstable zero dynamics, has relative degree two, and has negative high-frequency gain. The only restrictions are that the zero is “far” in the right half complex plane, the initial condition  $\tilde{x}^0$  is “small,” and the  $W^{1,\infty}$  input/output disturbances  $u_0$  and  $y_0$  are “small,” too.

**5. Conclusions.** We have shown the robustness of the  $\lambda$ -tracker (1.5) for a class of linear systems close in the gap metric to minimum phase systems with strict relative degree one; moreover, the  $\lambda$ -tracker copes with certain bounded input/output disturbances. Although this result may be worth knowing, the shortcoming of the control strategy (1.5) is that the gain  $k(\cdot)$  is a monotone nondecreasing function which converges to a potentially “too high” gain, thus amplifying noise. Recently, a simple time-varying proportional output feedback law called “funnel control” has been introduced to achieve “practical” tracking with prespecified transient behavior [11]; this control law is applicable even to nonlinear minimum phase systems, and the gain is no longer monotone but may decrease again. The conceptual results of the present paper may indicate how to use the gap metric framework to show the robustness of the funnel controller.

## A SECTOR CONDITION FOR LIMIT CYCLE ROBUSTNESS\*

ULF T. JÖNSSON†

**Abstract.** Robustness of periodic oscillations in autonomous feedback systems is considered for systems with separable nonlinearities. Local quadratic separation of the nonlinear dynamics from the linear part of the dynamics is used to characterize a set of systems that exhibit periodic oscillation in a bounded frequency and amplitude range. The quadratic constraint is generated as a time-periodic sector condition that characterizes the nonlinearity around a nominal periodic solution. The main analysis condition is formulated as an operator inequality involving the nominal dynamics and the sector constraint. This is an infinite dimensional robustness test that must be truncated to be verified numerically. We discuss two possible ways of performing the analysis.

**Key words.** limit cycles, uncertain system, robustness

**AMS subject classifications.** 93D09, 37C27, 49N20

**DOI.** 10.1137/070701108

**1. Introduction.** We consider the existence and robustness of periodic solutions of the feedback system

$$(1.1) \quad \begin{aligned} y &= \Phi(w), \\ w &= Hy, \end{aligned}$$

where  $H$  is a bounded, linear time-invariant operator and  $\Phi$  is a nonlinear operator. The case of our interest is when  $H$  is only approximately known. We will assume that there exists a nominal model and that the size of the uncertainty in this model is characterized by one parameter. This is not restrictive and allows us to consider the uncertainty class in the structured singular value framework [15, 3, 17].

The question to be addressed is if a periodic solution to the nominal system implies the existence of a periodic solution to every system in the uncertainty class. Bounds on the possible location of such periodic solutions will also be obtained. The result thus provides a quantitative measure on whether a simplified model of an oscillator predicts the real limit cycle solution with acceptable accuracy. This is a fundamental problem in modeling and analysis of systems with limit cycle solutions, which has application in areas such as systems biology [19] and oscillatory control of mechanical systems [6].

The results are obtained using local quadratic constraints to separate the nonlinear from the linear part of the dynamics. The quadratic constraints are chosen to be time periodic in order to explore as much as possible the structure of the nonlinear part of the dynamics. The verification of the resulting quadratic inequality on the linear dynamics is performed using relaxation techniques from the robust control field. The techniques used and the problem under investigation are related to classical 1970's works on harmonic balance and describing functions; see, e.g., [13, 11, 12, 2, 16]. The

focus of the present paper is on the robustness of a given limit cycle to perturbations in the dynamics, while the focus of the 1970's research was on predicting the existence of a limit cycle in a given system. However, it turns out that both of these questions can be addressed simultaneously in all the above works. Various sector criteria are also used to derive the results in [13, 11, 2], but two major differences compared to our approach are that the sector bounds are either time invariant or based on the describing function in [13, 11, 2] and that the separation between the nonlinear and linear parts of the dynamics is more explicit in our paper. Moreover, the verification of the sector bounds in this paper is based on techniques that were not fully developed in the 1970's. Quadratic constraints for predicting oscillations have also previously been used in [21, 14]. More recent works using control theoretic methods to address fundamental robustness issues for limit cycle systems can be found in [5, 18, 9]. The technique employed in this paper and the obtained results are significantly different from these works. Our main contribution is to show how time-varying sector bounds can be used in the analysis of limit cycles.

The paper is organized as follows. In section 2 the system model and properties of the limit cycle are discussed. Uncertainty is introduced to the system model in section 3, where our basic robustness result is also derived. This result provides the foundation for all subsequent results of the paper. We prove that our proposed method always works, provided that the predefined uncertainty descriptions are sufficiently small, and we show that the verification of the robustness conditions involves the computation of a robustness margin for the nominal system. In section 4 we show that the main conditions after truncation can be verified using linear matrix inequalities. Finally, we apply the ideas of the paper to an example involving a Van der Pol oscillator connected to a mass and spring system.

**Notation.** We let  $\mathbf{L}_2(1)$  denote the space of square integrable 1-periodic functions and  $C(1)$  the set of continuous 1-periodic functions equipped with the norm  $\|v\|_{C(1)} = \max_{t \in [0,1]} |v(t)|$ , where  $|\cdot|$  denotes the Euclidean norm. The functions in  $\mathbf{L}_2(1)$  and  $C(1)$  are assumed to take values in  $\mathbf{R}^m$ , but we suppress this information from the notation.

We make extensive use of the topological inclusion  $C(1) \hookrightarrow \mathbf{L}_2(1)$ , which follows since  $\|v\|_{\mathbf{L}_2(1)} \leq \|v\|_{C(1)}$ . We will almost always denote inner products, norms, and induced norms on  $\mathbf{L}_2(1)$  without the suffix, e.g.,  $\|\cdot\| := \|\cdot\|_{\mathbf{L}_2(1)}$  and  $\|\cdot\| := \|\cdot\|_{\mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1)}$ . At several places we consider the space  $C(1) \times \mathbf{R}$  with the norm  $\|(y, T)\|_{C(1) \times \mathbf{R}} = (\|y\|_{C(1)}^2 + |T|^2)^{1/2}$  and similarly for  $\mathbf{L}_2(1) \times \mathbf{R}$ . We define

$$l_2(\mathbf{C}) = \left\{ \{\hat{y}[k]\}_{k=-\infty}^{\infty} : \hat{y}[k] \in \mathbf{C}^m; \hat{y}[-k] = \overline{\hat{y}[k]}; \sum_{k=-\infty}^{\infty} |\hat{y}[k]|^2 < \infty \right\}$$

and let  $\mathcal{F} : \mathbf{L}_2(1) \rightarrow l_2$  denote the Fourier transform defined by  $\hat{y}[k] = (\mathcal{F}y)[k] = \int_0^1 y(t) e^{-j2\pi kt} dt$ . We use that the Fourier transform is an isometric isomorphism between these two spaces, and we frequently use the Parseval relation that relates the inner product of the two spaces:

$$\langle y_1, y_2 \rangle = \int_0^1 y_1(t)^T y_2(t) dt = \sum_{k=-\infty}^{\infty} \hat{y}_1[k]^* \hat{y}_2[k].$$

Given a periodic matrix function  $\beta \in C(1)$  we define the corresponding frequency

domain representation using the (bi-infinite) block Toeplitz matrix

$$(1.2) \quad \text{Toep}[\beta] = \begin{bmatrix} \ddots & & & & \\ & \hat{\beta}[0] & \hat{\beta}[1] & \hat{\beta}[2] & \\ \dots & \hat{\beta}[-1] & \hat{\beta}[0] & \hat{\beta}[1] & \dots \\ & \hat{\beta}[-2] & \hat{\beta}[-1] & \hat{\beta}[0] & \\ & & & \ddots & \ddots \end{bmatrix},$$

which defines the frequency domain representation of multiplication, i.e.,  $\mathcal{F}\beta v = \text{Toep}[\beta]\hat{v}$  for any  $v \in \mathbf{L}_2(1)$ .

Let  $\Psi : \mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1)$  be a bounded self-adjoint linear operator and  $\hat{\Psi}$  its corresponding frequency domain representation ( $\hat{\cdot}$  notation always refers to a frequency domain representation). Using  $\Psi$ , a continuous quadratic form  $\sigma_\Psi : \mathbf{L}_2(1) \rightarrow \mathbf{R}$  can be defined as

$$\sigma_\Psi(v) = \langle v, \Psi v \rangle_{\mathbf{L}_2(1)} = \left\langle \hat{v}, \hat{\Psi} \hat{v} \right\rangle_{l_2},$$

where the explicit dependence of  $\sigma$  on  $\Psi$  normally will be suppressed from the notation. One possibility is to use multiplication operators defined by  $(\Psi v)(t) = \psi(t)v(t)$ , where  $\psi \in C(1)$  and then  $\hat{\Psi} = \text{Toep}[\psi]$ . We define

$$\lambda_{\max}(\Psi) = \sup_{v \in \mathbf{L}_2(1)} \frac{\langle v, \Psi v \rangle_{\mathbf{L}_2(1)}}{\|v\|_{\mathbf{L}_2(1)}^2} \quad \text{and} \quad \lambda_{\min}(\Psi) = \inf_{v \in \mathbf{L}_2(1)} \frac{\langle v, \Psi v \rangle_{\mathbf{L}_2(1)}}{\|v\|_{\mathbf{L}_2(1)}^2}.$$

The operator  $\Psi$  is called positive definite if  $\lambda_{\min}(\Psi) > 0$ . The notation  $\lambda_{\min}$  and  $\lambda_{\max}$  is used to indicate that the above quantities are the maximum and minimum spectral values. If  $\Psi$  is positive definite, we often use that  $\langle v, \Psi v \rangle = \|\Psi^{1/2}v\|^2$ , where  $\Psi^{1/2}$  is the unique positive definite square root of  $\Psi$  [22].

We let  $P_N$  denote the orthogonal projection onto the  $2N + 1$  dimensional space spanned by the Fourier bases  $\{e^{j\omega k}\}_{-N}^N$  and  $Q_N = I - P_N$ .

If  $X \subset \mathbf{X}$  is a proper subspace, then the inclusion map  $I_X : X \rightarrow \mathbf{X}$  is defined by  $I_X x = x$  for all  $x \in X$ .

Finally,  $\text{cl } D$  denotes the closure of the set  $D$ , and  $\partial D$  denotes its boundary.

**2. Limit cycle model.** In this section we define some preliminaries that are adopted from [8]. Here a *limit cycle* will denote a periodic solution of (1.1). One of the main difficulties in limit cycle analysis is that both the trajectory and the period time may change as the dynamics are perturbed. In order to simplify the use of standard techniques from robust control we normalize the period time to one. By doing this the actual period time becomes a parameter in the linear dynamics. To understand how this works, let the nonlinear operator  $\Phi : \mathbf{L}_\infty(-\infty, \infty) \rightarrow \mathbf{L}_\infty(-\infty, \infty)$  in (1.1) be defined by the time-domain relation

$$(2.1) \quad (\Phi(w))(t) = \varphi(w(t)),$$

where  $\varphi : \mathbf{R}^m \rightarrow \mathbf{R}^m$  will be assumed to be  $C^1$ . We further assume that the linear part of the dynamics is defined by a strictly proper transfer function  $H(s)$  with corresponding convolution kernel  $h$ . If under these conditions there exists a  $T_0$  periodic solution  $y$  to (1.1), then the following equivalent closed loop equation holds:

$$y(t) = \varphi \left( \int_{-\infty}^{\infty} h(t - \tau)y(\tau)d\tau \right),$$

where  $y(t + T_0) = y(t)$  for all  $t$ . We may now normalize the period time and define  $y_0(t) = y(tT_0)$ , which is a 1-periodic function. Then the system equation can be rewritten as

$$y_0(t) = \varphi \left( \int_{-\infty}^{\infty} T_0 h(T_0(t - \tau)) y_0(\tau) d\tau \right),$$

which in operator notation is  $y_0 = \varphi(H[T_0]y_0)$ , where  $H[T_0](s) = H(s/T_0)$ . The conclusion is that we can always normalize the period time of  $y$  to be 1 by making the true period time a parameter in the system dynamics. Hence, searching for a limit cycle corresponds to searching for a pair  $z = (y, T)$  of a 1-periodic function and a period time. The above transformation simplifies the search for a limit cycle and has previously been used in various equivalent forms; see, e.g., [13].

The discussion above motivates us to consider the system

$$(2.2) \quad y = \Phi(H[T]y),$$

where  $H[T](s) = H(s/T)$  and  $\Phi : \mathbf{L}_{\infty}(-\infty, \infty) \rightarrow \mathbf{L}_{\infty}(-\infty, \infty)$  is a memoryless nonlinear operator defined by the time-domain relation in (2.1). We assume that the convolution operators corresponding to the transfer functions  $H(s)$ ,  $sH(s)$ , and  $sH'(s)$  are bounded, e.g. (here  $\mathcal{L}$  denotes the two-sided Laplace transform)

$$\mathcal{L}^{-1}\{sH(s)\} = \dot{h}_c(t) + \sum_{k=0}^{\infty} \dot{h}_k \delta(t - T_k),$$

where  $\dot{h}_c(\cdot) \in \mathbf{L}_1(-\infty, \infty)$  and  $\sum_{k=0}^{\infty} |\dot{h}_k| < \infty$ , and  $T_0 < T_1 < T_2 \dots$ . We have the following time-domain representation when  $H$  acts on functions in  $\mathbf{L}_2(1)$  (and  $C(1)$ ):

$$(2.3) \quad \begin{aligned} y(t) &= \int_{-\infty}^{\infty} h(t - \tau) v(\tau) d\tau \\ &= \int_0^1 \tilde{h}(t, \tau) v(\tau) d\tau, \end{aligned}$$

where  $\tilde{h} : [0, 1] \times [0, 1] \rightarrow \mathbf{R}^{m \times m}$  is defined by

$$\tilde{h}(t, \tau) = \sum_{k=-\infty}^{\infty} h(t + k - \tau)$$

and it satisfies the periodicity property  $\tilde{h}(1, \tau) = \tilde{h}(0, \tau)$ , for  $\tau \in [0, 1]$ , which ensures that  $y(t)$  is 1-periodic for any  $v \in \mathbf{L}_2(1)$ . The assumptions imply that any periodic solution of the system equation will be absolutely continuous. We will embed this solution into the larger space  $\mathbf{L}_2(1)$  while the output of the linear part of the dynamics is embedded into  $C(1)$ . The use of these two different topologies will in the next section allow us to locally characterize the nonlinear part of the dynamics using quadratic forms. This leads to a resulting robustness criterion that can be formulated as a frequency domain inequality on the linear dynamics. Finally, we note that the linear part of the dynamics is not restricted to be causal, although this is usually the case in applications.

We will next define the return difference operator for the system in (2.2). Its derivative is a measure of the local robustness of the limit cycle which will be used

in our results. Let  $z = (y, T) \in \mathbf{L}_2(1) \times \mathbf{R}$  and define the return difference  $F : \mathbf{L}_2(1) \times \mathbf{R} \rightarrow \mathbf{L}_2(1)$  by

$$(2.4) \quad F(z) = y - \Phi(H[T]y).$$

We note that any solution to  $F(z) = 0$  with  $T > 0$  corresponds to a limit cycle. By using (2.3) it follows that the operator  $F$  has the following equivalent time-domain representations:

$$\begin{aligned} (F(z))(t) &= y(t) - \varphi \left( \int_{-\infty}^{\infty} Th(T(t-\tau))y(\tau)d\tau \right) \\ &= y(t) - \varphi \left( \int_0^1 T\tilde{h}(Tt, T\tau)y(\tau)d\tau \right). \end{aligned}$$

It is now easy to see that the limit cycle at best is unique modulo time translations. Indeed, let  $z_0 = (y_0, T_0)$  be a nontrivial 1-periodic solution of (2.2) and let  $S_d : C(1) \times \mathbf{R} \rightarrow C(1) \times \mathbf{R}$  be the time translation operator defined by  $S_d(y(t), T) = (y(t-d), T)$ . Then using the first representation of  $F$  above

$$\begin{aligned} (F(S_d z_0))(t) &= y_0(t-d) - \varphi \left( \int_{-\infty}^{\infty} T_0 h(T_0(t-\tau))y_0(\tau-d)d\tau \right) \\ &= y_0(t-d) - \varphi \left( \int_{-\infty}^{\infty} T_0 h(T_0(t-d-\tau))y_0(\tau)d\tau \right) \\ (2.5) \quad &= (F(z_0))(t-d) = 0, \end{aligned}$$

which holds for any  $d \in \mathbf{R}$ . This shows that the time translated 1-periodic solution is still a valid periodic solution of (2.2). The limit cycle is thus not unique but belongs to the manifold  $\mathcal{Z}_0 = \{S_d z_0 : d \in [0, 1]\}$ , which, since  $(\mathcal{F}y(t-d))[k] = e^{j2\pi kd}\hat{y}[k]$ , equivalently can be represented in the frequency domain as

$$(2.6) \quad \mathcal{Z}_0 = \{(\hat{y}, \omega_0) : \hat{y}[k] = e^{j2\pi kd}\hat{y}_0[k]; d \in [0, 1]\},$$

where  $\omega_0 = 2\pi/T_0$ .

In order to proceed we need an expression for the derivative of the return difference.

**PROPOSITION 2.1.** *The operator  $F : \mathbf{L}_2(1) \times \mathbf{R} \rightarrow \mathbf{L}_2(1)$  defined in (2.4) has the Fréchet derivative  $F'(z_0) \in \mathcal{L}(\mathbf{L}_2(1) \times \mathbf{R}, \mathbf{L}_2(1))$  with block structure*

$$(2.7) \quad F'(z_0) = \begin{bmatrix} F'_y(z_0) & F'_T(z_0) \end{bmatrix} = \begin{bmatrix} I - L(z_0) & K(z_0) \end{bmatrix},$$

where  $L(z_0) : \mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1)$ ,  $K(z_0) : \mathbf{R} \rightarrow \mathbf{L}_2(1)$  are defined as

$$(2.8) \quad \begin{aligned} L(z_0) &= \Phi'(H[T_0]y_0) \circ H[T_0], \\ K(z_0) &= -\Phi'(H[T_0]y_0) \circ D_T H[T_0]y_0 \end{aligned}$$

and where  $(\Phi'(w_0))(t) = \varphi'(w_0(t))$  and

$$(D_T H[T_0])(s) = -\frac{s}{T_0^2} H' \left( \frac{s}{T_0} \right).$$

*Proof.* We first show that  $\Phi' : C(1) \rightarrow \mathcal{L}(C(1), \mathbf{L}_2(1))$  can be defined by  $(\Phi'(w)h)(t) = \varphi'(w(t))h(t)$ . Indeed, since  $\varphi$  is  $C^1$  we have

$$\begin{aligned} \lim_{\|h\|_{C(1)} \rightarrow 0} \frac{\|\Phi(w+h) - \Phi(w) - \Phi'(w)h\|_{\mathbf{L}_2(1)}}{\|h\|_{C(1)}} \\ \leq \lim_{\|h\|_{C(1)} \rightarrow 0} \frac{\|\Phi(w+h) - \Phi(w) - \Phi'(w)h\|_{C(1)}}{\|h\|_{C(1)}} = 0, \end{aligned}$$

which proves differentiability. Due to the assumptions on  $H$  one can show that

$$\|H\|_{\mathbf{L}_2(1) \rightarrow C(1)}^2 \leq \sup_{t \in [0,1]} \int_0^1 |\tilde{h}(t, \tau)|^2 d\tau < \infty$$

and  $D_T H[T_0]y_0 \in C(1)$ . It follows by the composite mapping theorem that  $F = I - \Phi \circ H$  has a well-defined Fréchet derivative on the form given in the theorem statement.  $\square$

Differentiation of (2.5) with respect to  $d$  at  $d = 0$  gives

$$\begin{aligned} \dot{y}_0(t) &= \varphi'((H[T_0]y_0)(t)) \int_{-\infty}^{\infty} T_0 h(T_0(t - \tau)) \dot{y}_0(\tau) d\tau \\ &= (L(z_0)\dot{y}_0)(t). \end{aligned}$$

This shows that  $(\dot{y}_0, 0) \in \text{Ker } F'(z_0)$ , where  $F'(z_0)$  is the Fréchet derivative.

A right inverse of  $F'(z_0)$  is a bounded linear operator  $F'^{\dagger} \in \mathcal{L}(\mathbf{L}_2(1), \mathbf{L}_2(1) \times \mathbf{R})$  satisfying  $F'(z_0)F'^{\dagger} = I$ . The next result shows that  $\text{Ker } F'(z_0) = \text{span}\{(\dot{y}_0, 0)\}$  is a necessary and sufficient condition for the existence of a right inverse.

**PROPOSITION 2.2.** *There exists a bounded right inverse  $F'(z_0)^{\dagger}$  if and only if  $\text{Ker } F'(z_0) = \text{span}\{(\dot{y}_0, 0)\}$ . Moreover, the periodic solution  $z_0 \in \mathbf{L}_2(1) \times \mathbf{R}$  of (2.2) is isolated if  $F'(z_0)$  has a bounded right inverse.*

*Proof.* Since  $L(z_0)$  and  $K(z_0)$  are compact it follows that  $F'(z_0)$  is a Fredholm operator with index  $\text{Ind}(F'(z_0)) = 1$ . It thus follows that  $F'(z_0)$  is surjective if and only if  $\dim \text{Ker } F'(z_0) = 1$ , which by the Banach isomorphism theorem implies that there exists a bounded linear operator  $F'(z_0)^{\dagger} \in \mathcal{L}(\mathbf{L}_2(1), \mathbf{L}_2(1) \times \mathbf{R})$  such that  $F'(z_0)F'(z_0)^{\dagger} = I$ .

The last statement is related to the submersion theorem; see Theorem 3.5.4 in [1].  $\square$

A limit cycle solution of (2) belongs to the manifold  $\mathcal{Z}_0$  in (2.6), and it is thus only unique modulo time translation. By fixing the phase a priori we get a unique solution which simplifies the analysis. For this reason we introduce the space

$$(2.9) \quad \mathbf{Y} = \{y \in \mathbf{L}_2(1) : \langle y, v \rangle = 0\},$$

where the choice of  $v$  is either of the following:

- (a) A common choice is to let  $\langle y, v \rangle = \text{re} \{e_1^T \hat{y}[1]\} = 0$ ,<sup>1</sup> where  $e_1 = [1 \ 0 \ \dots \ 0]^T$  is the first unit vector.
- (b) The choice  $v = \dot{y}_0$  implies that  $\mathbf{Y}$  is the set of periodic functions in “phase” with the nominal solution  $y_0$ .

<sup>1</sup>Here we assume that  $e_1^T \hat{y}_0[1] \neq 0$  so that the constraint defines useful phase information. This assumption remains throughout the paper.

We let  $\mathbf{Z} = \mathbf{Y} \times \mathbf{R}$  and restrict  $F$  in (2.4) to  $\mathbf{Z}$ . By considering the system on  $\mathbf{Z}$  implies that we fix the phase and ideally consider one particular point on the limit cycle manifold. For the choice of  $v$  in (a) above, this is evident since it implies that only the phase  $d = 0$  is valid in (2.6). In (b) a similar conclusion holds (at least) locally. To see this we notice that  $f(d) = \langle S_d y_0, \dot{y}_0 \rangle$  satisfies  $f(0) = 0$  and  $f'(0) = \|\dot{y}_0\|^2 \neq 0$ . For both cases (a) and (b) we may use the following simplified version of Proposition 2.2 for the Fréchet derivative of the restricted return difference

**COROLLARY 2.3.** *Let  $F : \mathbf{Z} \rightarrow \mathbf{L}_2(1)$  be defined as in (2.4). The derivative  $F'(z_0)$  is defined as in (2.7) with  $L(z_0) : \mathbf{Y} \rightarrow \mathbf{L}_2(1)$ ,  $K(z_0) : \mathbf{R} \rightarrow \mathbf{L}_2(1)$  defined as in (2.8). It follows that  $F'(z_0)$  has a bounded inverse if and only if  $\text{Ker } F'(z_0) = 0$ .*

*Proof.* The proof follows easily from Proposition 2.2. Indeed, the restriction of  $F$  in (2.4) to the subspace  $\mathbf{Z}$  can be formulated as  $F|_{\mathbf{Z}} = F \circ (I_{\mathbf{Y}}, I_{\mathbf{R}})$ , where  $I_{\mathbf{Y}}$  is the inclusion of  $\mathbf{Y}$  into  $\mathbf{L}_2(1)$  defined by  $I_{\mathbf{Y}}y = y$  for all  $y \in \mathbf{Y}$ , and  $I_{\mathbf{R}}$  is the identity on  $\mathbf{R}$ . Therefore we need only show that  $\text{Ker } F'(z_0) = \text{span}\{(\dot{y}_0, 0)\} \Leftrightarrow \text{Ker } F'|_{\mathbf{Z}}(z_0) = \{(0, 0)\}$ . This is obvious if  $v = \dot{y}_0$  in (2.9) because then  $\text{span}\{(\dot{y}_0, 0)\} \cap \mathbf{Y} \times \mathbf{R} = \{0\}$ . For the second case of our concern, we have  $\mathbf{Y} = \{y \in \mathbf{L}_2(1) : e_1^T \text{Re } \hat{y}[1] = 0\}$ . Since  $\hat{y}_0[1] = j\omega_0 \hat{y}_0[1] \in \mathbf{R}$  and is nonzero by assumption we again have  $\text{span}\{(\dot{y}_0, 0)\} \cap \mathbf{Y} \times \mathbf{R} = \{0\}$ . Hence, the proof of Corollary 2.3 follows from Proposition 2.2.  $\square$

**3. Robustness of limit cycle.** In this section we derive an existence and robustness result for limit cycles. The conditions are formulated as integral quadratic constraints on the linear and nonlinear parts of the system. We consider the set of systems

$$(3.1) \quad y = \Phi(H[T, \theta])y), \quad \theta \in [0, 1],$$

where the following hold:

- (A1)  $\Phi : C(1) \rightarrow \mathbf{L}_2(1)$  is a nonlinear operator, which in time domain is defined by  $(\Phi(w))(t) = \varphi(w(t))$ , where  $\varphi : \mathbf{R}^m \rightarrow \mathbf{R}^m$  is a  $C^1$  function.
- (A2)  $H[T, \theta](s) = H(s/T, \theta)$  is for each  $\theta \in [0, 1]$  a strictly proper transfer function as defined in section 2. We assume that the dependence on the parameter  $\theta$  is Lipschitz continuous, i.e., for  $\theta_1, \theta_2 \in [0, 1]$

$$\|H[T, \theta_1] - H[T, \theta_2]\|_{\mathbf{L}_2(1) \rightarrow C(1)} \leq c|\theta_1 - \theta_2|,$$

where  $c$  is a positive constant. This bound is assumed to be uniform over all period times in the set  $\mathcal{T}$  defined in (3.4) below.

The system (3.1) is called *nominal* when  $\theta = 0$ , and we assume that the nominal system has a solution. Our goal is to prove that there remains a limit cycle solution in a neighborhood of the nominal solution for all values of the perturbation parameter  $\theta \in [0, 1]$ .

We will exploit that the linear part of the system maps to continuous signals, where the sup-norm topology can be used to define neighborhoods of the nominal solution. It is then reasonably easy to describe how the nonlinear operator maps this neighborhood to the output. We will do this using “local” integral quadratic constraints.

We know from above that the limit cycle is only unique modulo time translation. We will therefore fix the phase in order to get unique solutions and easier analysis. This is done by restricting the analysis to the space  $\mathbf{Y}$  defined in (2.9). We next summarize some further assumptions and definitions.

- (A3) We assume that the nominal system has a solution  $z_0 = (y_0, T_0) \in \mathbf{Z}$ , i.e.,  $y_0 = \Phi(H[T_0, 0]y_0)$ , where  $\mathbf{Z} = \mathbf{Y} \times \mathbf{R}$  with norm  $\|z\| = (\|y\|^2 + T^2)^{1/2}$  and where  $\mathbf{Y}$  is defined in (2.9).
- (D1) Let  $\mathcal{Z} \subset \mathbf{Z}$  be a bounded, convex, and open set defined as

$$(3.2) \quad \mathcal{Z} = \{z = (y, T) \in \mathbf{Z} : \|\Psi_Z^{1/2}(z - z_0)\| < 1\},$$

where  $\Psi_Z$  is a positive definite operator on  $\mathbf{L}_2(1) \times \mathbf{R}$  with block structure

$$(3.3) \quad \Psi_Z = \begin{bmatrix} \Psi_Y & 0 \\ 0 & \psi_T \end{bmatrix}.$$

The constraint in (3.2) can equivalently be written as  $\sigma_Z(z - z_0) < 0$ , where  $\sigma_Z : \mathbf{L}_2(1) \times \mathbf{R} \rightarrow \mathbf{R}^+$  is a continuous quadratic form defined as

$$\sigma_Z(z) = \langle z, \Psi_Z z \rangle - 1, \quad \text{where} \quad \langle z, \Psi_Z z \rangle = \langle y, \Psi_Y y \rangle + \psi_T T^2.$$

The above definition implies that the period time belongs to

$$(3.4) \quad \mathcal{T} = (T_{\min}, T_{\max}),$$

where  $T_{\min} = T_0 - \psi_T^{-1/2}$  and  $T_{\max} = T_0 + \psi_T^{-1/2}$ . We assume  $T_{\min} > 0$ , which ensures that  $H[T, \theta]$  is continuous for all  $T \in \mathcal{T}$ .

- (D2) Let  $\mathcal{W} \subset C(1)$  be a bounded, closed, and convex set that contains  $w_0 = H[T_0]y_0$  in its interior. The restriction of the nonlinear operator to  $\mathcal{W}$ ,  $\Phi|_{\mathcal{W}}(\cdot) : \mathcal{W} \rightarrow \mathbf{L}_2(1)$  will be Lipschitz continuous due to (A1), and we denote the Lipschitz constant  $L_\Phi$ .

We use that the operator in the right-hand side of (3.1) is continuous and compact under (A1)–(A3), (D1)–(D2).

**LEMMA 3.1.** *The operator  $\Psi : \mathbf{Z} \times [0, 1] \rightarrow \mathbf{L}_2(1)$  defined by  $\Psi(z, \theta) = \Phi(H[T, \theta]y)$  is compact on  $\text{cl } \mathcal{Z}$  for each  $\theta \in [0, 1]$ . Moreover,  $F : \text{cl } \mathcal{Z} \times [0, 1] \rightarrow \mathbf{L}_2(1)$  defined as  $F(z, \theta) = z - \Psi(z, \theta)$  is a homotopy of compact transformations on  $\text{cl } \mathcal{Z}$ . This means that for given  $\epsilon > 0$  there exists  $\delta > 0$  such that*

$$\|\Psi(z, \theta_1) - \Psi(z, \theta_2)\| \leq \epsilon \quad \forall z \in \text{cl } \mathcal{Z}, \quad |\theta_1 - \theta_2| \leq \delta.$$

*Proof.*  $\Psi = \Phi \circ H$  is compact since it is a composition of a compact operator  $H$  with a continuous operator with bounded range  $\Phi$  (by (D2)). The continuity with respect to  $\theta$  follows from (D2). Indeed, due to the Lipschitz continuity of  $\Phi$  there exists  $L_\Phi$  such that

$$\begin{aligned} \|\Phi(H[T, \theta_2]y) - \Phi(H[T, \theta_1]y)\| &\leq L_\Phi \|H[T, \theta_2] - H[T, \theta_1]\|_{C(1)} \|y\| \\ &\leq c L_\Phi \sup_{y \in \text{cl } \mathcal{Y}} \|y\| |\theta_2 - \theta_1|, \end{aligned}$$

where  $\mathcal{Y} = \{y \in \mathbf{Y} : \|\Psi_Y^{1/2}(y - y_0)\| < 1\}$  and  $c$  was defined in (A2).  $\square$

We use topological degree theory to derive a robustness result for the system in (3.1). The degree provides a modulo two count of the number of solutions to an operator equation in a given set. Let  $F = I - \Psi$ , where  $\Psi : Z \rightarrow Z$  is a compact operator on a Banach space  $Z$  with a countable basis. In our application  $F$  will depend on a parameter as in Lemma 3.1, and we will derive conditions under which

the existence of a solution to  $F(z_0, 0) = 0$  implies the existence of a solution to  $F(z, 1) = 0$ . The proof relies on an invariance property of the topological degree, which in our case will be verified using time-periodic sector conditions.

To define the degree  $d(F, D, 0)$  of  $F$  at 0 with respect to a bounded open set  $D$  we let  $P_n$  denote a projection on the finite dimensional space spanned by the first  $n$  basis elements,  $F_n = P_n \circ F \circ P_n$ , and  $D_n = P_n D$ . If  $F$  is  $C^1$ , then we define the degree as

$$d(F, D, 0) = \lim_{n \rightarrow \infty} d(F_n, D_n, 0),$$

$$\text{where } d(F_n, D_n, 0) = \sum_{z \in F_n^{-1}(0) \cap D_n} \text{sign}(\det(F'_n(z))).$$

Here it is assumed that  $0 \notin F_n(\partial D_n)$  and  $\det(F'_n(z)) \neq 0$  for all  $z \in F_n^{-1}(0) \cap D_n$ . Otherwise let  $F_\epsilon = I - \Psi_\epsilon$ , where  $\Psi_\epsilon$  is a compact  $C^1$  approximation such that  $\|F - F_\epsilon\| \leq \epsilon$  and define

$$d(F, D, 0) = \lim_{\epsilon \rightarrow 0} d(F_\epsilon, D, 0).$$

We refer the reader to [4, 10, 13] for treatments of degree theory and its application to periodic systems analysis. The next result is derived using degree theory and provides the foundation for the subsequent results of the paper.

**THEOREM 3.2.** *Consider the set of systems (3.1) under the assumptions (A1)–(A3) and (D1)–(D2). Let  $F : \text{cl } \mathcal{Z} \times [0, 1] \rightarrow \mathbf{L}_2(1)$  be defined as*

$$(3.5) \quad F(z, \theta) = y - \Phi(H[T, \theta]y).$$

*Suppose that*

- (i)  $F'_z(z_0, 0) : \mathbf{Z} \rightarrow \mathbf{L}_2(1)$  has a bounded inverse;
- (ii)  $H[T, \theta]y \subset \mathcal{W}$  for all  $(y, T) \in \text{cl } \mathcal{Z}$  and  $\theta \in [0, 1]$ ;

*and suppose that there exists a continuous quadratic form  $\sigma : \mathbf{L}_2(1) \times \mathbf{L}_2(1) \rightarrow \mathbf{R}$  such that*

- (iii)  $\sigma(w - w_0, \Phi(w) - \Phi(w_0)) \geq 0$  for all  $w \in \mathcal{W}$ ;
- (iv) *there exists  $\epsilon > 0$  such that*
  - (a)  $\sigma(H[T, \theta]y - H[T_0, 0]y_0, y - y_0) \leq -\epsilon$  for all  $(y, T) \in \partial \mathcal{Z}$ ,  $\theta \in [0, 1]$ ;
  - (b)  $\sigma(H[T, 0]y - H[T_0, 0]y_0, y - y_0) \leq -\epsilon \|z - z_0\|^2$  for all  $z = (y, T) \in \mathcal{Z}$ .

*Then for all  $\theta \in [0, 1]$  there exists  $(y_\theta, T_\theta) \in \mathcal{Z}$  such that  $y_\theta = \Phi(H[T_\theta, \theta]y_\theta)$ .*

**Remark 1.** It is generally not evident that (iv)(a) would imply (iv)(b). We will develop computational tests that provide sufficient conditions that simultaneously verify both (iv)(a) and (iv)(b).

**Proof.** By assumption (A3),  $F(z_0, 0) = 0$ . We will use topological degree theory to show that for all  $\theta \in [0, 1]$  there exists  $z_\theta \in \mathcal{Z}$  such that  $F(z_\theta, \theta) = 0$ . In order to make the problem considered here fit the basic case in [10] we introduce  $\tilde{F} : \text{cl } \mathcal{Z} \times [0, 1] \rightarrow \mathbf{Z}$  defined as

$$\tilde{F}(z, \theta) = (P_Y F(z, \theta), \langle F(z, \theta), v \rangle),$$

where  $P_Y : \mathbf{L}_2(1) \rightarrow \mathbf{Y}$  is the projection onto  $\mathbf{Y}$ . To prove the result we will show that

- (a)  $\deg(\tilde{F}(\cdot, 0), \mathcal{Z}, 0) \neq 0$ ;
- (b) (ii)–(iv) implies that  $0 \notin \tilde{F}(\partial \mathcal{Z}, \theta)$  for all  $\theta \in [0, 1]$ .

These two properties together with Lemma 3.1 imply by the invariance of the degree under homotopy that  $\deg(\tilde{F}(\cdot, \theta), \mathcal{Z}, \theta) = \text{const} \neq 0$  for  $\theta \in [0, 1]$ . This in turn implies the existence of  $(y_\theta, T_\theta) \in \mathcal{Z}$  such that  $\tilde{F}(z, \theta) = 0$  for all  $\theta \in [0, 1]$ . See [10] for a proof of these facts.

We can use the representation  $\tilde{F} = \Pi \circ F$ , where  $\Pi : \mathbf{L}_2(1) \rightarrow \mathbf{Z}$  defined by  $\Pi y = (P_Y y, \langle y, v \rangle)$  is an invertible linear operator. Therefore

$$\deg(\tilde{F}(\cdot, \theta), \mathcal{Z}, 0) \neq 0 \quad \Leftrightarrow \quad \deg(F(\cdot, \theta), \mathcal{Z}, 0) \neq 0,$$

and it is thus sufficient to prove properties (a) and (b) for  $F$  in order to conclude that there exists  $(y_\theta, T_\theta) \in \mathcal{Z}$  such that  $F(z, \theta) = 0$ , i.e.,  $y = \Phi(H[T, \theta])y$ , for all  $\theta \in [0, 1]$ .

We will first use (ii)–(iv) to show that  $\|F(z, \theta)\| > 0$  for all  $z \in \partial\mathcal{Z}$  and  $\theta \in [0, 1]$ . This proves that  $0 \notin F(\partial\mathcal{Z}, \theta)$  for all  $\theta \in [0, 1]$ . We consider solutions to the equation system

$$(3.6) \quad \begin{aligned} y &= \Phi(w), \\ w &= H[T, \theta]y. \end{aligned}$$

If  $z = (y, T) \in \partial\mathcal{Z}$ , then by (ii),  $w = H[T, \theta]y \in \mathcal{W}$ . We can therefore use (iii)–(iv) to derive quantitative relations for solutions  $(y, T, w)$  of (3.6) in  $\partial\mathcal{Z} \times \mathcal{W}$ .

We have by (ii) and (iv)(a)  $(F(z, \theta) = y - \Phi(w))$  and  $(F(z_0, 0) = y_0 - \Phi(w_0))$

$$\begin{aligned} -\epsilon &\geq \sigma(H[T, \theta]y - H[T_0, 0]y_0, y - y_0) \\ &= \sigma(w - w_0, y - y_0 - (\Phi(w) - \Phi(w_0)) + (\Phi(w) - \Phi(w_0))) \\ &\geq \sigma(w - w_0, \Phi(w) - \Phi(w_0)) - \bar{c}_1 \|F(z, \theta) - F(z_0, 0)\|^2 \\ &\quad - \bar{c}_2 (\|w - w_0\| + \|\Phi(w) - \Phi(w_0)\|) \cdot \|F(z, \theta) - F(z_0, 0)\| \\ &\geq -\bar{c}_1 \|F(z, \theta) - F(z_0, 0)\|^2 - \bar{c}_3 \|w - w_0\|_{C(1)} \cdot \|F(z, \theta) - F(z_0, 0)\|, \end{aligned}$$

where  $\bar{c}_1, \bar{c}_2$  are nonnegative constants determined by the quadratic form and

$$\bar{c}_3 = \bar{c}_2 + \bar{c}_2 L_\Phi.$$

We used that  $\|\Phi(w) - \Phi(w_0)\|_{\mathbf{L}_2(1)} \leq L_\Phi \|w - w_0\|_{\mathbf{L}_2(1)} \leq L_\Phi \|w - w_0\|_{C(1)}$  to obtain the last inequality. This gives the inequality

$$\|F(z, \theta) - F(z_0, 0)\| \geq -\frac{\bar{c}_3 \|w - w_0\|_{C(1)}}{2\bar{c}_1} + \sqrt{\frac{\epsilon}{\bar{c}_1} + \frac{(\bar{c}_3 \|w - w_0\|_{C(1)})^2}{4\bar{c}_1^2}}.$$

This in turn shows that  $\|F(z, \theta) - F(z_0, 0)\| = \|F(z, \theta)\| > 0$  for  $z \in \partial\mathcal{Z}$ ,  $\theta \in [0, 1]$ . If  $\bar{c}_1 = 0$ , then we have

$$\|F(z, \theta) - F(z_0, 0)\| \geq \frac{\epsilon}{\bar{c}_3 \|w - w_0\|_{C(1)}},$$

and the same conclusion holds.

An analogous derivation using (iv)(b) shows that

$$\|F(z, 0) - F(z_0, 0)\| \geq \delta(\|z - z_0\|) \quad \forall z \in \text{cl } \mathcal{Z},$$

where  $\delta(\cdot)$  is a positive definite function. For example, if  $\bar{c}_1 \neq 0$ , then we can take

$$\delta(\|z - z_0\|) = \begin{cases} \left( \sqrt{\frac{\epsilon}{\bar{c}_1} + \frac{\bar{c}_2^2 \|w - w_0\|_{C(1)}^2}{4\bar{c}_1^2}} - \frac{\bar{c}_2}{2\bar{c}_1} \frac{\|w - w_0\|_{C(1)}}{\|z - z_0\|} \right) \|z - z_0\|, & z \neq z_0, \\ 0, & z = z_0. \end{cases}$$

Using that  $F(z_0, 0) = 0$  implies that  $\|F(z, 0)\| > 0$  when  $z \neq z_0$  in  $\text{cl } \mathcal{Z}$  and hence that  $z_0$  is a unique periodic solution of the nominal system in  $\mathcal{Z}$ . Therefore, since  $F'_z(z_0, 0)$  has a bounded inverse,

$$\deg(F(\cdot, 0), \mathcal{Z}, 0) = \lim_{N \rightarrow \infty} \text{sign}(\det(F'_N(z_0, 0))) \neq 0,$$

where  $F_N(\cdot, 0) = P_N F(P_N \cdot, 0)$  denotes the truncation of  $F$  to the finite dimensional space  $P_N \mathbf{L}_2(1)$ .

We have shown that conditions (a) and (b) above hold, and this implies that the conclusion of the theorem is valid.  $\square$

In the next sections we discuss the choice of quadratic forms and the verification of conditions (ii), (iii), and (iv) of Theorem 3.2.

**3.1. Quadratic forms.** The constraint (iii) in Theorem 3.2 typically originates from a pointwise sector condition on the form

$$(3.7) \quad (\beta(t)(w(t) - w_0(t)) - ((\Phi(w))(t) - (\Phi(w_0))(t)))^T \\ \times ((\Phi(w))(t) - (\Phi(w_0))(t) - \alpha(t)(w(t) - w_0(t))) \geq 0 \quad \forall t \in [0, 1],$$

where  $\beta, \alpha \in C(1)$  (note that  $\beta, \alpha$  may be matrix valued functions). This corresponds to a quadratic inequality on the form  $\sigma(w - w_0, \Phi(w) - \Phi(w_0)) \geq 0$ , where

$$(3.8) \quad \sigma(w - w_0, \Phi(w) - \Phi(w_0)) = \left\| \frac{\beta - \alpha}{2}(w - w_0) \right\|^2 - \left\| \Phi(w) - \Phi(w_0) - \frac{\beta + \alpha}{2}(w - w_0) \right\|^2,$$

which may be equivalently formulated as

$$(3.9) \quad \sigma(w, y) = \left\langle \begin{bmatrix} w \\ y \end{bmatrix}, \Psi \begin{bmatrix} w \\ y \end{bmatrix} \right\rangle,$$

where  $\Psi : \mathbf{L}_2(1) \times \mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1) \times \mathbf{L}_2(1)$  has the block representation

$$(3.10) \quad \Psi = \begin{bmatrix} \Psi_{11} & \Psi_{12} \\ \Psi_{12}^* & -I \end{bmatrix}$$

with  $\Psi_{11} = -\frac{1}{2}(\beta^T \alpha + \alpha^T \beta)$  and  $\Psi_{12} = \frac{1}{2}(\beta + \alpha)$ . We primarily use the formulation in (3.9)–(3.10) in the remaining sections of the paper.

**3.2. A proof of the method.** Next we show that it always will be possible to verify robustness using Theorem 3.2, provided that  $\mathcal{Z}$  is small, and  $H[T, \theta]$  and  $H[T_0, 0]$  are close enough. For simplicity, we consider only the case with one scalar nonlinearity.

**PROPOSITION 3.3.** *Let  $\mathcal{W} \subset C(1)$  and suppose  $(\Phi(w))(t) = \varphi(w(t))$  satisfies the sector condition (3.7) for all  $w \in \mathcal{W}$  when*

$$\beta(t) = \varphi'(w_0(t)) + \epsilon^{1/2} \quad \text{and} \quad \alpha(t) = \varphi'(w_0(t)) - \epsilon^{1/2}.$$

*Let  $F'(z_0, 0) : \mathbf{Z} \rightarrow \mathbf{L}_2(1)$  be defined as*

$$F'(z_0, 0) = \begin{bmatrix} I - \Phi'(w_0)H[T_0, 0] & -\Phi'(w_0)D_T H[T_0, 0]y_0 \end{bmatrix}.$$

If  $F'(z_0, 0)$  has a bounded inverse and if  $\|H[T, \theta] - H[T, 0]\|$  is small enough, then condition (iv) in Theorem 3.2 can be verified by making  $\epsilon$  and  $\mathcal{Z}$  sufficiently small.

*Remark 2.* The remaining conditions of Theorem 3.2 will be satisfied under weak assumptions. For example, if in (A1) it is assumed that  $\varphi \in C^2$ , then it is possible to take  $\epsilon^{1/2} = O(\|z - z_0\|^2)$ , where  $O(\cdot)$  is the ordo notation. From (3.12) below, it follows that (iv) is satisfied if  $\mathcal{Z}$  is sufficiently small (provided that  $\|H[T, \theta] - H[T, 0]\|$  is small enough). In addition, it can also easily be verified that then (ii) and (iii) can be satisfied if  $\mathcal{W}$  and  $\mathcal{Z}$  are chosen appropriately small.

*Proof.* Using (3.7) with  $\alpha$  and  $\beta$  as in the statement of the proposition it follows that (iv)(a) gives the condition<sup>2</sup>

$$(3.11) \quad \|y - y_0 - \Phi'(w_0)H[T, \theta](y - y_0) - \Phi'(w_0)(H[T, \theta] - H[T_0, 0])y_0\|^2 \geq \epsilon(1 + \|\Delta_1(z, \theta)\|^2)$$

for all  $(y, T) \in \partial\mathcal{Z}$ , where  $\Delta_1(z, \theta) := H[T, \theta]y - H[T_0, 0]y_0$ . The expression within the left-hand side norm can be rewritten as  $F'(z_0, 0)(z - z_0) + \Delta_2$ , where

$$\begin{aligned} \Delta_2(z, \theta) &= -\Phi'(w_0)(H[T, \theta] - H[T_0, 0])(y - y_0) \\ &\quad - \Phi'(w_0)(H[T, \theta] - H[T_0, 0] - D_T H[T_0, 0](T - T_0))y_0. \end{aligned}$$

By using that  $F'(z_0, 0)$  has a bounded inverse we can bound the norm on the left-hand side of (3.11) as

$$\begin{aligned} \|F'(z_0)(z - z_0) + \Delta_2\| &\geq \|F'(z_0)(z - z_0)\| - \|\Delta_2\| \\ &\geq \|F'(z_0)^{-1}\|^{-1}\|z - z_0\| - \|\Delta_2\|. \end{aligned}$$

Hence, condition (iv)(a) in Theorem 3.2 is implied by the condition

$$(3.12) \quad \|F'(z_0)^{-1}\|^{-1} \geq \sup_{z \in \partial\mathcal{Z}} \frac{1}{\|z - z_0\|} \left( \epsilon^{1/2} \sqrt{1 + \|\Delta_1(z, \theta)\|^2} + \|\Delta_2(z, \theta)\| \right).$$

If the perturbation of  $H$  is sufficiently small, then there exist  $c_1(\mathcal{Z}), c_2(\mathcal{Z}) > 0$  such that (since  $\|\Delta_2(z, 0)\| = O(\|z - z_0\|^2)$  and  $\|\Delta_1(z, 0)\| = O(\|z - z_0\|)$ , where  $O(\cdot)$  is the ordo notation)

$$\begin{aligned} \|\Delta_2(z, \theta)\| &\leq c_1(\mathcal{Z})\|z - z_0\|^2, \\ \|\Delta_1(z, \theta)\| &\leq c_2(\mathcal{Z})\|z - z_0\| \end{aligned}$$

for all  $z \in \partial\mathcal{Z}$ . It follows that the right-hand side of (3.12) can be made sufficiently small for the inequality to be satisfied by making  $\epsilon$  and  $\mathcal{Z}$  small enough.

For condition (iv)(b) we let  $\theta = 0$ . The same arguments as above gives the condition

$$\|F'(z_0)^{-1}\|^{-1} \geq \sup_{z \in \mathcal{Z}, z \neq z_0} \frac{1}{\|z - z_0\|} \left( \epsilon^{1/2} \sqrt{\|z - z_0\|^2 + \|\Delta_1(z, 0)\|^2} + \|\Delta_2(z, 0)\| \right),$$

which by the above arguments holds if  $\epsilon$  and  $\mathcal{Z}$  are sufficiently small.  $\square$

<sup>2</sup>We use that the quadratic form is real valued, and hence  $\langle w, y \rangle = \langle y, w \rangle$ .

**3.3. Verification of the quadratic constraints in (iv).** Here we discuss how condition (iv) in Theorem 3.2 can be formulated as a condition on a stability margin that can be computed from an operator inequality that involves the nominal dynamics, the sector description of the nonlinearity, and the set description in (D1). Let us start to derive a description of  $H[T, \theta]y - H[T_0, 0]y_0$  that is more tractable for our analysis. It can be rewritten as

$$(3.13) \quad H[T, \theta]y - H[T_0, 0]y_0 = \tilde{H}(z - z_0) + \tilde{w}(z, \theta),$$

where  $\tilde{w}(z, \theta) = \tilde{\Delta}[T, \theta](z - z_0) + w_{\Delta}[T, \theta]$  and

$$(3.14) \quad \tilde{H} = \begin{bmatrix} H[T_0, 0] & D_T H[T_0, 0]y_0 \end{bmatrix},$$

$$(3.15) \quad \tilde{\Delta}[T, \theta] = \begin{bmatrix} \Delta[T, \theta] & \delta[T] \end{bmatrix},$$

$$(3.16) \quad w_{\Delta}[T, \theta] = (H[T, \theta] - H[T, 0])y_0$$

and where

$$(3.17) \quad \begin{aligned} \Delta[T, \theta] &= H[T, \theta] - H[T_0, 0], \\ \delta[T] &= \begin{cases} \frac{1}{T - T_0} (H[T, 0] - H[T_0, 0] - D_T H[T_0, 0](T - T_0))y_0, & T \neq T_0, \\ 0, & T = T_0. \end{cases} \end{aligned}$$

We assume that we have the following constraint for the nonlinearity:

$$(3.18) \quad \sigma(w - w_0, \Phi(w) - \Phi(w_0)) \geq 0 \quad \forall w \in \mathcal{W},$$

where the quadratic form is defined by the self-adjoint operator  $\Psi : \mathbf{L}_2(1) \times \mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1) \times \mathbf{L}_2(1)$ . Then we have the following result.

**THEOREM 3.4.** *Suppose there exists  $\tau > 0$  such that*

$$(3.19) \quad I_{\mathbf{Z}}^*(\Pi^* \Psi \Pi + \tau \Psi_Z) I_{\mathbf{Z}} \leq 0,$$

where  $\Psi_Z$  is defined in (3.3),

$$\Pi = \begin{bmatrix} H[T_0, 0] & D_T H[T_0, 0]y_0 \\ I & 0 \end{bmatrix},$$

and  $I_{\mathbf{Z}} : \mathbf{Z} \rightarrow \mathbf{L}_2(1) \times \mathbf{R}$  is the inclusion of  $\mathbf{Z}$  into  $\mathbf{L}_2(1) \times \mathbf{R}$ . Then condition (iv) in Theorem 3.2 holds if

$$(3.20) \quad \tau \geq \epsilon + 2 \sup_{\theta \in [0, 1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]),$$

where  $\mathcal{T}$  is defined in (3.4),

$$\Upsilon_1[T, \theta] = \Omega_1[T, \theta] + \Omega_1[T, \theta]^*,$$

and

$$\Omega_1[T, \theta] = \begin{bmatrix} \tilde{\Delta}[T, \theta] \Psi_Z^{-1/2} & w_\Delta[T, \theta] \\ \begin{bmatrix} 0 & 0 \end{bmatrix} & 0 \end{bmatrix}^* \Psi \begin{bmatrix} (\tilde{H} + \frac{1}{2} \tilde{\Delta}[T, \theta]) \Psi_Z^{-1/2} & \frac{1}{2} w_\Delta[T, \theta] \\ \begin{bmatrix} \Psi_Y^{-1/2} & 0 \end{bmatrix} & 0 \end{bmatrix}.$$

*Remark 3.* We have  $I_Z = \begin{bmatrix} I_Y & 0 \\ 0 & 1 \end{bmatrix}$ , where  $I_Y$  is the inclusion of  $\mathbf{Y}$  in  $\mathbf{L}_2(1)$ . The inequality in (3.19) cannot be verified unless the phase is fixed using the inclusion map. There would otherwise be a zero eigenvalue in the first term of (3.19) that forces  $\tau$  to be zero.

*Remark 4.* The parameter  $\tau$  in (3.19) is a measure on how much uncertainty (size of  $\mathcal{Z}$  and perturbation of  $H$ ) can be tolerated by the nominal limit cycle solution. It can be interpreted as a stability margin, which should be as large as possible for a given set description in (D1).

*Remark 5.* The operator inequality (3.19) can be truncated and verified as a linear matrix inequality in the frequency domain. We discuss this in more detail in the next section, where we also show how relaxation techniques from robust control can be used to integrate (3.19) and (3.20) into a parameterized operator inequality of form similar to (3.19).

*Proof.* Let us first consider (iv)(a). We have  $(\bar{z} = \begin{bmatrix} z \\ 1 \end{bmatrix}) \in \mathbf{Z} \times \mathbf{R}$  and likewise for  $\bar{z}_0$

$$\begin{aligned} \sigma(H[T, \theta]y - H[T_0, 0]y_0, y - y_0) &= \left\langle \begin{bmatrix} \tilde{H} + \tilde{\Delta}[T, \theta] & w_\Delta \\ \begin{bmatrix} I & 0 \end{bmatrix} & 0 \end{bmatrix} (\bar{z} - \bar{z}_0), \Psi \begin{bmatrix} \tilde{H} + \tilde{\Delta}[T, \theta] & w_\Delta \\ \begin{bmatrix} I & 0 \end{bmatrix} & 0 \end{bmatrix} (\bar{z} - \bar{z}_0) \right\rangle \\ &= \langle z - z_0, \Pi^* \Psi \Pi (z - z_0) \rangle + \langle \bar{z} - \bar{z}_0, \tilde{\Upsilon}_1[T, \theta] (\bar{z} - \bar{z}_0) \rangle \\ &= \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \sigma_{\tilde{\Upsilon}_1}(\bar{z} - \bar{z}_0), \end{aligned}$$

where  $\tilde{\Upsilon}_1 = \tilde{\Psi}_Z^{1/2} \Upsilon_1 \tilde{\Psi}_Z^{1/2}$  and where  $\tilde{\Psi}_Z = \text{diag}(\Psi_Z, 1)$ .

By using this representation of the quadratic form, we get the following implications:

$$\begin{aligned} \sup_{z \in \partial \mathcal{Z}} \sigma(H[T, \theta]y - H[T_0, 0]y_0, y - y_0) &= \sup_{z \in \partial \mathcal{Z}} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \sigma_{\tilde{\Upsilon}_1}(\bar{z} - \bar{z}_0) \\ &\leq \sup_{z \in \partial \mathcal{Z}} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + 2 \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]), \end{aligned}$$

where we used that the second term is bounded by

$$\begin{aligned} \sup_{z \in \partial \mathcal{Z}} \sigma_{\tilde{\Upsilon}_1}(\bar{z} - \bar{z}_0) &= \sup_{z \in \partial \mathcal{Z}} \langle \bar{z} - \bar{z}_0, \tilde{\Upsilon}_1(\bar{z} - \bar{z}_0) \rangle \\ &= \sup_{\|\tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0)\|^2=1} \langle \tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0), \Upsilon_1 \tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0) \rangle \\ &\leq \sup_{\|\tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0)\|^2=2} \langle \tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0), \Upsilon_1 \tilde{\Psi}_Z^{1/2}(\bar{z} - \bar{z}_0) \rangle \\ &\leq 2 \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]). \end{aligned}$$

By Lagrange relaxation (S-procedure relaxation) we can further simplify:<sup>3</sup>

$$\begin{aligned}
 & \sup_{z \in \partial \mathcal{Z}} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + 2 \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) \\
 &= \inf_{\tau \in \mathbf{R}} \sup_{z \in \mathbf{Z}} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \tau \sigma_Z(z - z_0) + 2 \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) \\
 &= \inf_{\tau \in \mathbf{R}} \sup_{z \in \mathbf{Z}} \langle z - z_0, (\Pi^* \Psi \Pi + \tau \Psi_Z)(z - z_0) \rangle + 2 \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) - \tau \\
 &\leq 2 \sup_{\theta \in [0, 1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) - \tau \leq -\epsilon,
 \end{aligned}$$

where in the second last inequality we used (3.19) and the last inequality follows from (3.20). This implies (iv)(a).

We next consider condition (iv)(b). For this we need to introduce  $\Upsilon_2[T] = \Omega_2[T] + \Omega_2[T]^*$ , where

$$\Omega_2[T] = \begin{bmatrix} \tilde{\Delta}[T, 0] \Psi_Z^{-1/2} \\ 0 \end{bmatrix}^* \Psi \begin{bmatrix} \tilde{H} + \frac{1}{2} \tilde{\Delta}[T, 0] \Psi_Z^{-1/2} \\ [\Psi_Y^{-1/2} \quad 0] \end{bmatrix}.$$

We have

$$\begin{aligned}
 & \sigma(H[T, 0]y - H[T_0, 0]y_0, y - y_0) \\
 &= \left\langle \begin{bmatrix} \tilde{H} + \tilde{\Delta}[T, 0] \\ I \quad 0 \end{bmatrix} (z - z_0), \Psi \begin{bmatrix} \tilde{H} + \tilde{\Delta}[T, 0] \\ I \quad 0 \end{bmatrix} (z - z_0) \right\rangle \\
 &= \langle z - z_0, (\Pi^* \Psi \Pi + \tilde{\Upsilon}_2[T])(z - z_0) \rangle \\
 &= \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \sigma_{\tilde{\Upsilon}_2}(z - z_0),
 \end{aligned}$$

where  $\tilde{\Upsilon}_2 = \Psi_Z^{1/2} \Upsilon_2 \Psi_Z^{1/2}$ .

Now let  $\mathcal{Z}(\eta) = \{z \in \mathbf{Z} : \sigma_Z(z - z_0, \eta) = 0\}$ , where  $\sigma_Z(z, \eta) = \langle z, \Psi_Z z \rangle - \eta$  and  $\eta \in [0, 1]$ . By using this representation of the quadratic form, we get the following inequality:

$$\begin{aligned}
 \sup_{z \in \mathcal{Z}(\eta)} \sigma(H[T, 0]y - H[T_0, 0]y_0, y - y_0) &= \sup_{z \in \mathcal{Z}(\eta)} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \sigma_{\tilde{\Upsilon}_2}(z - z_0) \\
 &\leq \sup_{z \in \mathcal{Z}(\eta)} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_2[T])\eta,
 \end{aligned}$$

where we used that the last term can be bounded by

$$\begin{aligned}
 \sup_{z \in \mathcal{Z}(\eta)} \sigma_{\tilde{\Upsilon}_2}(z - z_0) &= \sup_{\|\Psi_Z^{1/2}(z - z_0)\|^2 = \eta} \langle \Psi_Z^{1/2}(z - z_0), \Upsilon_2 \Psi_Z^{1/2}(z - z_0) \rangle \\
 &= \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_2[T])\eta.
 \end{aligned}$$

<sup>3</sup>The first implication is an equivalence since this is a relaxation of one quadratic form defined over a real space [20].

Next we use the S-procedure lossless condition in [20], which gives

$$\begin{aligned}
 & \sup_{z \in \mathcal{Z}(\eta)} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \lambda_{\max}(\Upsilon_2[T])\eta \\
 &= \inf_{\tau \in \mathbf{R}} \sup_{z \in \mathbf{Z}} \sigma_{\Pi^* \Psi \Pi}(z - z_0) + \tau \sigma_Z(z - z_0, \eta) + \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_2[T])\eta \\
 &= \inf_{\tau \in \mathbf{R}} \sup_{z \in \mathbf{Z}} \langle z - z_0, (\Pi^* \Psi \Pi + \tau \Psi_Z)(z - z_0) \rangle + \sup_{T \in \mathcal{T}} (\lambda_{\max}(\Upsilon_2[T]) - \tau)\eta \\
 &\leq \left( \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_2[T]) - \tau \right) \eta \leq -\epsilon \eta \leq -\epsilon \lambda_{\min}(\Psi_Z) \|z - z_0\|^2,
 \end{aligned}$$

where we used (3.19) in the second inequality. In the third inequality we use (3.20) and that  $\sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_2[T]) = \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, 0]) \leq 2 \sup_{\theta \in [0, 1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta])$  (because  $\sup_{\theta} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) \geq 0$ ). Finally, the last inequality follows since

$$\eta = \langle z - z_0, \Psi_Z(z - z_0) \rangle \geq \lambda_{\min}(\Psi_Z) \|z - z_0\|^2 \quad \forall z \in \mathcal{Z}(\eta).$$

This implies (iv)(b).  $\square$

**3.4. The set inclusion.** Estimates of  $\mathcal{W}$  can be obtained in several ways. It is generally useful to have bounds in terms of the  $C(1)$ -topology, and this is achieved using the next result.

**PROPOSITION 3.5.** *Suppose that  $\mathcal{Z}$  is characterized as in (D1). We have*

$$H[T, \theta]y \in \mathcal{W} = \{w \in C(1) : |w(t) - w_0(t)| \leq \nu(t)\}$$

for all  $(y, T) \in \text{cl } \mathcal{Z}$  and  $\theta \in [0, 1]$ , where

$$\nu(t) = \|\mathbf{1}(e^{j2\pi t}) \hat{H} \hat{\Psi}_Z^{-1/2}\| + \sup_{\theta \in [0, 1], T \in \mathcal{T}} \{\|\tilde{\Delta}[T, \theta] \Psi_Z^{-1/2}\|_{\mathbf{L}_2(1) \times \mathbf{R} \rightarrow C(1)} + \|w_{\Delta}[T, \theta]\|_{C(1)}\}$$

and where  $\hat{H}$  is the frequency domain representation of the operator defined in (3.14),  $\tilde{\Delta}$  and  $w_{\Delta}$  are defined in (3.15)–(3.16),  $\mathcal{T}$  is defined in (3.4), and

$$(3.21) \quad \mathbf{1}(e^{j2\pi t}) = \begin{bmatrix} \dots & e^{j4\pi t} I & e^{j2\pi t} I & I & e^{-j2\pi t} I & e^{-j4\pi t} I & \dots \end{bmatrix}.$$

If  $\hat{\Psi}_Z$  is diagonal, then we can use

$$(3.22) \quad \|\tilde{\Delta}[T, \theta] \Psi_Z^{-1/2}\|_{\mathbf{L}_2(1) \times \mathbf{R} \rightarrow C(1)} \leq \sqrt{\sum_{k=-\infty}^{\infty} |\Delta(j2\pi k/T, \theta) \hat{\Psi}_Y^{-1/2}(k, k)|^2 + \|\delta[T] \psi_T^{-1/2}\|_{C(1)}^2}.$$

*Proof.* We use that  $w(t) = \mathbf{1}(e^{j2\pi t})\hat{w}$ , and therefore we have

$$\begin{aligned}
 |w(t) - w_0(t)| &= |\mathbf{1}(e^{j2\pi t})(\hat{H}[T, \theta]\hat{y} - \hat{H}[T_0, 0]\hat{y}_0)| \\
 &= \left| \mathbf{1}(e^{j2\pi t}) \hat{H}(\hat{z} - \hat{z}_0) + \mathbf{1}(e^{j2\pi t}) \hat{\Delta}[T, \theta](\hat{z} - \hat{z}_0) + \mathbf{1}(e^{j2\pi t}) \hat{w}_{\Delta} \right| \\
 &\leq \|\mathbf{1}(e^{j2\pi t}) \hat{H} \hat{\Psi}_Z^{-1/2}\| \cdot \|\hat{\Psi}_Z^{1/2}(\hat{z} - \hat{z}_0)\| \\
 &\quad + \|\tilde{\Delta}[T, \theta] \Psi_Z^{-1/2}\|_{\mathbf{L}_2(1) \times \mathbf{R} \rightarrow C(1)} \|\Psi_Z^{1/2}(z - z_0)\| + |\mathbf{1}(e^{j2\pi t}) \hat{w}_{\Delta}| \\
 &\leq \|\mathbf{1}(e^{j2\pi t}) \hat{H} \hat{\Psi}_Z^{-1/2}\| + \|\tilde{\Delta}[T, \theta] \Psi_Z^{-1/2}\|_{\mathbf{L}_2(1) \times \mathbf{R} \rightarrow C(1)} + \|w_{\Delta}\|_{C(1)},
 \end{aligned}$$

where we used that  $\|\Psi_Z^{1/2}(z - z_0)\| \leq 1$  by the definition of  $\mathcal{Z}$  in (3.2).  $\square$

**4. Algorithm for robustness analysis.** Here we will assemble the results of the previous sections into an algorithm that allows us to verify the robustness of limit cycles. From Theorems 3.2 and 3.4 we get the following algorithm:

- (R1) Verify that  $F'_z(z_0, 0)$  has a bounded inverse.
- (R2) Verify that  $H[T, \theta]y \in \mathcal{W}$  for all  $(y, T) \in \text{cl } \mathcal{Z}$ ,  $\theta \in [0, 1]$ .
- (R3) Determine the sector bound (iii) in Theorem 3.2 with  $\sigma$  on the form (3.9)–(3.10).
- (R4a) Solve  $\max_{\tau > 0}$  such that  $I_Z^*(\Pi^* \Psi \Pi + \tau \Psi_Z)I_Z \leq 0$ .
- (R4b) Verify that  $\tau > 2 \sup_{\theta \in [0, 1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta])$ .

Given (RA1)–(RA4) we can conclude that for each  $\theta \in [0, 1]$  there exists a solution  $(y_\theta, T_\theta) \in \mathcal{Z}$  of  $y = \Phi(H[T, \theta]y)$ .

We will next discuss how the steps of the algorithm can be verified numerically. For the first step we may use Proposition 4 in [8]. For the second step we use Proposition 3.5. An application will be illustrated in our example in the next section. The third step is simply to determine  $\alpha, \beta \in C(1)$  such that the time-varying sector bound in (3.7) holds. The last two steps are more involved and will be discussed in detail in the next two subsections. Using (R4a)–(R4b) may lead to unnecessary conservatism, and as an alternative we will also show that (R3)–(R4) can be replaced by the following:

- (R4') Use quadratic relaxation of the uncertainties to verify condition (iv) in Theorem 3.2.

**4.1. Verifying the operator inequality in (R4a).** The operator inequality in step (R4) is infinite dimensional and must be truncated in order to be verified. This is possible due to the compactness of  $H$  and since the sector condition in (3.8) can be defined by functions  $\alpha$  and  $\beta$  of limited frequency content. The inequality has a frequency domain representation, and for the computation we truncate the high frequency contribution to obtain a finite dimensional inequality. The Schur complement formula together with estimates of the high frequency contributions can be used to derive conditions under which the finite dimensional formula gives a lower bound on  $\tau$  in step (R4a).

We next define a high versus low frequency decomposition of each operator according to the following definitions and notation, where  $I_N$  and  $I_{\bar{N}}$  are the identity operators on  $P_N \mathbf{L}_2(1)$  and  $Q_N \mathbf{L}_2(1)$ , respectively, and where we assume the phase is fixed according to

$$(4.1) \quad \mathbf{Y} = \{y \in \mathbf{L}_2(1) : \text{re } e_1^T \hat{y}[1] = 0\},$$

where  $e_1$  is the first unit vector.

- (F1) For the inclusion map  $I_Z : Q_N \mathbf{L}_2(1) \oplus \mathbf{Y}_N \times \mathbf{R} \rightarrow Q_N \mathbf{L}_2(1) \oplus P_N \mathbf{L}_2(1) \times \mathbf{R}$  we use the block structure

$$(4.2) \quad I_Z = \begin{bmatrix} I_{\bar{N}} & 0 \\ 0 & I_{Z_N} \end{bmatrix}, \quad \text{where} \quad I_{Z_N} = \begin{bmatrix} I_{Y_N} & 0 \\ 0 & 1 \end{bmatrix},$$

where  $I_{Y_N}$  is the inclusion map from  $\mathbf{Y}_N = P_N \mathbf{Y}$  into  $P_N \mathbf{L}_2(1)$ .

- (F2) The operator  $\Psi_Y$  defined in (D1) has the low versus high frequency block decomposition  $\Psi_Y : Q_N \mathbf{L}_2(1) \oplus P_N \mathbf{L}_2(1) \rightarrow Q_N \mathbf{L}_2(1) \oplus P_N \mathbf{L}_2(1)$ ,

$$(4.3) \quad \Psi_Y = \begin{bmatrix} \psi_{Y_{\bar{N}}} I_{\bar{N}} & 0 \\ 0 & \Psi_{Y_N} \end{bmatrix},$$

and we let

$$(4.4) \quad \Psi_{Z_N} = \begin{bmatrix} \Psi_{Y_N} & 0 \\ 0 & \psi_T \end{bmatrix}.$$

(F3) We use the following block decompositions:

$$\begin{aligned} H[T_0, 0] &= \begin{bmatrix} H_{\bar{N}}[T_0, 0] & 0 \\ 0 & H_N[T_0, 0] \end{bmatrix}, \\ D_T H[T_0, 0] &= \begin{bmatrix} D_T H_{\bar{N}}[T_0, 0] & 0 \\ 0 & D_T H_N[T_0, 0] \end{bmatrix}, \\ \Pi_N &= \begin{bmatrix} H_N[T_0, 0] & D_T H_N[T_0, 0] y_{0,N} \\ I_N & 0 \end{bmatrix}, \end{aligned}$$

where  $H_N = I_{P_N \mathbf{L}_2(1)}^* H I_{P_N \mathbf{L}_2(1)}$  and  $H_{\bar{N}} = I_{Q_N \mathbf{L}_2(1)}^* H I_{Q_N \mathbf{L}_2(1)}$ , and similarly for  $D_T H_{\bar{N}}[T_0, 0]$  and  $D_T H_N[T_0, 0]$ . Finally,  $y_{0,N} = P_N y_0$ .

(F4) We let the blocks of  $\Psi$  in (3.10) have the high versus low frequency decompositions

$$\Psi_{11} = \begin{bmatrix} \Psi_{11, \bar{N}\bar{N}} & \Psi_{11, \bar{N}N} \\ \Psi_{11, N\bar{N}} & \Psi_{11, NN} \end{bmatrix}, \quad \Psi_{12} = \begin{bmatrix} \Psi_{12, \bar{N}\bar{N}} & \Psi_{12, \bar{N}N} \\ \Psi_{12, N\bar{N}} & \Psi_{12, NN} \end{bmatrix},$$

where

$$\begin{aligned} \Psi_{11, NN} &= I_{P_N \mathbf{L}_2(1)}^* \Psi_{11} I_{P_N \mathbf{L}_2(1)}, \\ \Psi_{11, N\bar{N}} &= I_{P_N \mathbf{L}_2(1)}^* \Psi_{11} I_{Q_N \mathbf{L}_2(1)}, \\ \Psi_{11, \bar{N}N} &= I_{Q_N \mathbf{L}_2(1)}^* \Psi_{11} I_{P_N \mathbf{L}_2(1)}, \\ \Psi_{11, \bar{N}\bar{N}} &= I_{Q_N \mathbf{L}_2(1)}^* \Psi_{11} I_{Q_N \mathbf{L}_2(1)}, \end{aligned}$$

and analogously for the blocks in defining the decomposition of  $\Psi_{12}$ . Finally, let  $\Psi_N = I_{P_N \mathbf{L}_2(1)}^* \Psi I_{P_N \mathbf{L}_2(1)}$ .

It is straightforward to see that

$$(4.5) \quad I_{\mathbf{Z}}^* (\Pi^* \Psi \Pi + \tau \Psi_Z) I_{\mathbf{Z}} = \begin{bmatrix} \Delta_{11} + (\tau \psi_{Y_{\bar{N}}} - 1) I_{\bar{N}} & \Delta_{12} \\ \Delta_{12}^* & I_{\mathbf{Z}_N}^* (\Pi_N^* \Psi_N \Pi_N + \tau \Psi_{Z_N}) I_{\mathbf{Z}_N} + \Delta_{22} \end{bmatrix},$$

where

$$\begin{aligned} \Delta_{11} &= H_{\bar{N}}^* \Psi_{11, \bar{N}\bar{N}} H_{\bar{N}} + H_{\bar{N}}^* \Psi_{12, \bar{N}\bar{N}} + \Psi_{12, \bar{N}\bar{N}}^* H_{\bar{N}}, \\ \Delta_{12} &= \left[ (H_{\bar{N}}^* \Psi_{11, \bar{N}N} + \Psi_{12, \bar{N}N}^*) H_N I_{\mathbf{Y}_N} + H_{\bar{N}}^* \Psi_{12, \bar{N}N} I_{\mathbf{Y}_N} \quad (H_{\bar{N}}^* \Psi_{11, \bar{N}} + \Psi_{12, \bar{N}}^*) D_T H y_0 \right], \\ \Delta_{22} &= \begin{bmatrix} 0 & (H_N^* \Psi_{11, N\bar{N}} + \Psi_{12, N\bar{N}}^*) D_T H_{\bar{N}} y_{0, \bar{N}} \\ (\cdot)^* & y_0^* D_T H[T_0, 0]^* \Psi_{11} D_T H[T_0, 0] y_0 - y_{0,N}^* D_T H_N[T_0, 0]^* \Psi_{11, NN} D_T H_N[T_0, 0] y_{0,N} \end{bmatrix} \end{aligned}$$

and where in  $\Delta_{12}$  we used the notation

$$\Psi_{11, \bar{N}} = \begin{bmatrix} \Psi_{11, \bar{N}\bar{N}} & \Psi_{11, \bar{N}N} \end{bmatrix}, \quad \Psi_{12, \bar{N}}^* = \begin{bmatrix} \Psi_{12, \bar{N}\bar{N}}^* & \Psi_{12, \bar{N}N}^* \end{bmatrix}.$$

Using the above definitions we can state the following result.

PROPOSITION 4.1. *Suppose there exist  $\epsilon > 0$  and  $\rho \in (0, 1 - \|\Delta_{11}\|)$  such that*

- (i)  $\tau = (1 - \rho - \|\Delta_{11}\|)/\psi_{Y_N}$ ;
- (ii)  $\epsilon > \|\Delta_{22}\| + \|\Delta_{12}\|^2/\rho$ ;
- (iii)  $I_{\mathbf{Z}_N}^*(\Pi_N^* \Psi_N \Pi_N + \tau \Psi_{\mathbf{Z}_N}) I_{\mathbf{Z}_N} \leq -\epsilon$ .

Then  $I_{\mathbf{Z}}^*(\Pi^* \Psi \Pi + \tau \Psi_{\mathbf{Z}}) I_{\mathbf{Z}} \leq 0$ .

*Proof.* The upper left block of (4.5) satisfies

$$\Delta_{11} + (\tau \psi_{Y_N} - 1) I_N \leq -\rho I_N$$

by (i). We can therefore apply the Schur complements formula and conclude that  $I_{\mathbf{Z}}^*(\Pi^* \Psi \Pi + \tau \Psi_{\mathbf{Z}}) I_{\mathbf{Z}} < 0$  since

$$\begin{aligned} I_{\mathbf{Z}_N}^*(\Pi_N^* \Psi_N \Pi_N + \tau \Psi_{\mathbf{Z}_N}) I_{\mathbf{Z}_N} + \Delta_{22} - \Delta_{12}^* (\Delta_{11} + (\tau \psi_{Y_N} - 1) I_N)^{-1} \Delta_{12} \\ \leq -\epsilon + \|\Delta_{22}\| + \|\Delta_{12}\|^2/\rho < 0. \quad \square \end{aligned}$$

The inequality in (iii) can be verified in the frequency domain as the finite dimensional linear matrix inequality

$$(4.6) \quad \hat{I}_{\mathbf{Z}_N}^* (\hat{\Pi}_N^* \hat{\Psi}_N \hat{\Pi}_N + \tau \hat{\Psi}_{\mathbf{Z}_N}) \hat{I}_{\mathbf{Z}_N} \leq -\epsilon \hat{I}_N,$$

where  $\hat{I}_N$  is a unit matrix of dimension  $2N + 1$ ,

$$\hat{\Pi}_N = \begin{bmatrix} \hat{H}_N[T_0, 0] & D_T \hat{H}_N[T_0, 0] \hat{y}_{0,N} \\ \hat{I}_N & 0 \end{bmatrix},$$

where  $\hat{y}_{0,N}$  is the Fourier transform of  $y_0$  truncated at its lowest  $N$  frequencies,

$$(4.7) \quad \hat{H}_N[T, 0] = \text{diag}(H(j2k\pi N/T, 0) : k = N, \dots, -N),$$

and analogously for  $D_T \hat{H}_N[T_0, 0]$ . Further,  $\hat{\Psi}_{\mathbf{Z}_N}$  is the frequency domain representation of  $\Psi_{\mathbf{Z}_N}$  in (4.4),  $\hat{I}_{\mathbf{Z}_N}$  is the frequency domain representation of the inclusion map  $I_{\mathbf{Z}_N}$  defined in (4.2), and, finally,  $\hat{\Psi}_N$  is the  $2N + 1 \times 2N + 1$  block Toeplitz representation of  $\Psi_N$ . It has the form

$$\hat{\Psi}_N = \begin{bmatrix} -P_N \left( \frac{1}{2} (\mathcal{B}^* \mathcal{A} + \mathcal{A}^* \mathcal{B}) \right) P_N & \frac{1}{2} P_N (\mathcal{A} + \mathcal{B}) P_N \\ \frac{1}{2} P_N (\mathcal{A} + \mathcal{B})^* P_N & -I_N \end{bmatrix},$$

where  $\mathcal{B} = \text{Toep}[\beta]$ ,  $\mathcal{A} = \text{Toep}[\alpha]$  are (bi-infinite) block Toeplitz matrices defined as in (1.2).

The maximal value of the parameter  $\tau$  for which (4.6) is satisfied can be computed as

$$\tau = -\lambda_{\min}((\hat{I}_{\mathbf{Z}_N}^* \hat{\Psi}_{\mathbf{Z}_N} \hat{I}_{\mathbf{Z}_N})^{-1/2} (\hat{I}_{\mathbf{Z}_N}^* \hat{\Pi}_N^* \hat{\Psi}_N \hat{\Pi}_N \hat{I}_{\mathbf{Z}_N} + \epsilon \hat{I}_N) (\hat{I}_{\mathbf{Z}_N}^* \hat{\Psi}_{\mathbf{Z}_N} \hat{I}_{\mathbf{Z}_N})^{-1/2}).$$

Note that all norms  $\|\Delta_{k,l}\|$ ,  $k, l = 1, 2$ , in Proposition 4.1 can be made arbitrarily small by choosing  $N$  large enough compared to the frequency content in  $\Psi$  and the roll-off decay of  $H$ . Hence, if (iii) is satisfied, then the remaining inequalities in Proposition 4.1 will be satisfied if  $N$  is large enough.

**4.2. Verifying the perturbation bound.** A straightforward calculation shows that

$$\Upsilon_1[T, \theta] = \begin{bmatrix} \Upsilon_{11}[T, \theta] & \Upsilon_{12}[T, \theta] & \Upsilon_{13}[T, \theta] \\ \Upsilon_{12}^*[T, \theta] & \Upsilon_{22}[T, \theta] & \Upsilon_{23}[T, \theta] \\ \Upsilon_{13}^*[T, \theta] & \Upsilon_{23}^*[T, \theta] & \Upsilon_{33}[T, \theta] \end{bmatrix},$$

where (here we suppress the dependence on  $T$  and  $\theta$ )

$$\begin{aligned} \Upsilon_{11} &= \Psi_Y^{-1/2}(\Delta^* \Psi_{11} \Delta + \text{Sym}(\Delta^* \Psi_{11} H) + \text{Sym}(\Delta^* \Psi_{12})) \Psi_Y^{-1/2}, \\ \Upsilon_{12} &= \Psi_Y^{-1/2}(\Delta^* \Psi_{11}(D_T H + \delta) + (H^* \Psi_{11} + \Psi_{12}^*) \delta) \psi_T^{-1/2}, \\ \Upsilon_{13} &= \Psi_Y^{-1/2}((\Delta^* + H^*) \Psi_{11} + \Psi_{12}^*) w_\Delta, \\ \Upsilon_{22} &= \text{Sym} \left( \psi_T^{-1/2} \delta^* \Psi_{11} \left( D_T H + \frac{1}{2} \delta \right) \psi_T^{-1/2} \right), \\ \Upsilon_{23} &= \psi_T^{-1/2}(\delta + D_T H)^* \Psi_{11} w_\Delta, \\ \Upsilon_{33} &= w_\Delta^* \Psi_{11} w_\Delta, \end{aligned}$$

where  $\text{Sym}(H) = H + H^*$  and  $\Delta, \delta$  are defined in (3.17). We will use the following result.

PROPOSITION 4.2.

$$\sup_{\theta \in [0,1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_1[T, \theta]) \leq \lambda_{\max} \left( \begin{bmatrix} \gamma_{11} & \gamma_{12} & \gamma_{13} \\ \gamma_{12} & \gamma_{22} & \gamma_{23} \\ \gamma_{13} & \gamma_{23} & \gamma_{33} \end{bmatrix} \right),$$

where

$$\begin{aligned} \gamma_{kk} &= \sup_{\theta \in [0,1]} \sup_{T \in \mathcal{T}} \lambda_{\max}(\Upsilon_{kl}[T, \theta]), \quad k = 1, 2, 3, \\ \gamma_{kl} &= \sup_{\theta \in [0,1]} \sup_{T \in \mathcal{T}} \|\Upsilon_{kl}[T, \theta]\|, \quad k \neq l. \end{aligned}$$

*Proof.* Note that  $\Upsilon_1 : \mathbf{L}_2(1) \times \mathbf{R}^2 \rightarrow \mathbf{L}_2(1) \times \mathbf{R}^2$ . An arbitrary unit length vector  $v \in \mathbf{L}_2(1) \times \mathbf{R}^2$  can be decomposed as  $v = \sum_{k=1}^3 \alpha_k \bar{v}_k$ , where  $\bar{v}_1 = (v_1, 0, 0)$  with  $v_1 \in \mathbf{L}_2(1)$  and  $\|v_1\| = 1$ , and  $\bar{v}_2 = (0, v_2, 0)$ ,  $\bar{v}_3 = (0, 0, v_3)$  with  $v_2, v_3 \in [-1, 1]$ , and the real valued scalars  $\alpha_k$  satisfy  $\sum_{k=1}^3 \alpha_k^2 = 1$ . It follows that

$$\begin{aligned} \lambda_{\max}(\Upsilon_1) &= \sup_{\|v\|_{\mathbf{L}_2(1) \times \mathbf{R}^2} = 1} \langle v, \Upsilon_1 v \rangle \\ &= \sup_{|\alpha|=1} \sup_{\|v_1\|=1} \sup_{v_2, v_3 \in [-1, 1]} \sum_{k=1}^3 \sum_{l=1}^3 \alpha_k \alpha_l \langle v_k, \Upsilon_{kl} v_l \rangle \\ &\leq \sup_{|\alpha|=1} \alpha_k \alpha_l \gamma_{kl} \\ &= \lambda_{\max}(\Gamma), \end{aligned}$$

where  $\Gamma = [\gamma_{kl}]_{k,l=1}^3$ . This concludes the proof.  $\square$

The coefficients needed in Proposition 4.2 can easily be estimated. To avoid unnecessary conservatism, it is important to explore that  $\Psi_{11}$  is usually not positive definite, and simple minded norm estimates should therefore be avoided.

**4.3. Relaxation of uncertainties using quadratic forms.** Here we will discuss how condition (iv) in Theorem 3.2 can be verified using relaxation techniques from robust control. This provides an alternative means of verifying steps (R4a)–(R4b) in the algorithm for robustness analysis, which often is less conservative but computationally more demanding.

We assume that the nonlinearity satisfies the quadratic form (3.18), where  $\Psi$  is defined as in (F4). By using the representation in (3.14)–(3.16), we obtain the following equivalent representation of (3.13) as a linear fractional transformation [23]:

$$(4.8) \quad \begin{bmatrix} \delta w \\ v \end{bmatrix} = \underbrace{\begin{bmatrix} \tilde{H} & II_{\Delta} & I_W \\ I & 0 & 0 \end{bmatrix}}_G \begin{bmatrix} \delta z \\ u \\ \check{w}_{\Delta} \end{bmatrix},$$

$$(4.9) \quad u = \underbrace{\begin{bmatrix} I_{\Delta}^{-1} \Delta[T, \theta] & 0 \\ 0 & I_{\delta}^{-1} \delta[T] \end{bmatrix}}_{\check{\Delta}} v,$$

$$(4.10) \quad II_{\Delta} = \begin{bmatrix} I_{\Delta} & I_{\delta} \end{bmatrix},$$

where  $\check{w}_{\Delta} = I_W^{-1} w_{\Delta}$ ,  $\delta z = z - z_0$ , and  $\delta w = H[T, \theta]y - H[T_0, 0]y_0$ . The operators  $I_{\Delta}$ ,  $I_{\delta}$ , and  $I_W$  are introduced in order to create roll off so that the same computational ideas as in Proposition 4.1 can be used. In order to apply Proposition 4.1 for truncation of the operator inequality in (ii)(a) in Proposition 4.3 below we may assume that the operators act through multiplication in the frequency domain according to  $\hat{u}[k] = \hat{I}_{\Delta}[k]\hat{v}[k]$ , where

$$(4.11) \quad \hat{I}_{\Delta}[k] = \begin{cases} I, & |k| \leq N, \\ \nu, & |k| > N, \end{cases}$$

and where  $N$  is a large integer and  $\nu$  is a small number.  $I_{\delta}$  and  $I_W$  may be defined analogously. For the discussion up to the next proposition including its proof one may assume that these operators are equal to the identity.

We will use quadratic constraints to characterize the uncertainties in the system according to the following definitions:

1. The uncertain operator  $\check{\Delta}[T, \theta]$  defined in (4.9) is assumed to satisfy the quadratic inequality

$$(4.12) \quad \sigma_{\Delta}(v, \check{\Delta}[T, \theta]v, \lambda) \geq 0 \quad \forall \lambda \in \Lambda, \theta \in [0, 1], T \in \mathcal{T},$$

where  $\Lambda$  is a convex cone of parameters. The parameterization can be used to characterize the structure of  $\check{\Delta}$  as in  $\mu$ -analysis [15, 3, 17]. We assume that the quadratic form has the representation

$$(4.13) \quad \sigma_{\Delta}(v, u, \lambda) = \left\langle \begin{bmatrix} v \\ u \end{bmatrix}, \Psi_{\Delta}(\lambda) \begin{bmatrix} v \\ u \end{bmatrix} \right\rangle, \quad \Psi_{\Delta} = \begin{bmatrix} \Psi_{\Delta, (11)} & \Psi_{\Delta, (12)} \\ \Psi_{\Delta, (12)}^* & \Psi_{\Delta, (22)} \end{bmatrix},$$

where  $\Psi_{\Delta}$  is assumed to be linear in  $\lambda$ .

2. The uncertain signal  $\check{w}_{\Delta} = I_W^{-1} w_{\Delta}$  satisfies the quadratic inequality

$$(4.14) \quad \sigma_{W_{\Delta}}(\check{w}_{\Delta}) = 1 - \langle \check{w}_{\Delta}, \Psi_{W_{\Delta}} \check{w}_{\Delta} \rangle \geq 0,$$

where the positive definite and self-adjoint operator  $\Psi_{W_\Delta}$  can be constructed as a diagonal operator with components that estimate the size of the frequency components of  $w_\Delta$ .

By using the standard S-procedure relaxation technique we obtain the following condition that can replace (iv) in Theorem 3.2.

PROPOSITION 4.3. *Condition (iv) in Theorem 3.2 is satisfied if there exist  $\tau_1, \tau_2 \geq 0$  and  $\lambda \in \Lambda$  such that*

- (a)  $I_Z^*(\check{\Pi}^* \Psi \check{\Pi} + \check{\Psi}_Z(\tau_1, \tau_2, \lambda))I_Z \leq 0$ ,
- (b)  $\tau_1 > \tau_2$ ,

where

$$\begin{aligned} \check{\Pi} &= \begin{bmatrix} \check{H} \\ I & 0 \end{bmatrix} := \begin{bmatrix} H[T_0, 0] & [D_T H[T_0, 0]y_0 & II_\Delta & I_W] \\ I & \begin{bmatrix} 0 & 0 & 0 \end{bmatrix} \end{bmatrix}, \\ \check{\Psi}_Z(\tau_1, \tau_2, \lambda) &= \begin{bmatrix} \Psi_{\Delta,11}(\lambda) + \tau_1 \Psi_Z & \Psi_{\Delta,12}(\lambda) & 0 \\ \Psi_{\Delta,12}^*(\lambda) & \Psi_{\Delta,22}(\lambda) & 0 \\ 0 & 0 & -\tau_2 \Psi_{W_\Delta} \end{bmatrix}, \\ I_Z &= \begin{bmatrix} I_Z & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}, \end{aligned}$$

where  $\Psi$  is defined in (F4),  $\Psi_\Delta$  is defined in (4.13), and  $II_\Delta$  is defined in (4.10).

*Remark 6.* The same computational ideas as presented in Proposition 4.1 can be applied to verify (a). The parameters  $N$  and  $\nu$  in (4.11) must be chosen sufficiently large and small, respectively, so that the norms  $\|\Delta_{k,l}\|$  are small enough.

*Proof.* To verify (iv)(a) in Theorem 3.2 we consider the optimization problem  $(\delta z = (\delta y, \delta T) = (y - y_0, T - T_0))$ :

$$\begin{aligned} &\sup_{\delta z, u, \check{w}_\Delta} \sigma(\delta w, \delta y) \\ &\text{subject to } \begin{bmatrix} \delta w \\ v \end{bmatrix} = G \begin{bmatrix} \delta z \\ u \\ \check{w}_\Delta \end{bmatrix} \quad \text{such that} \quad \begin{cases} \sigma_\Delta(v, u, \lambda) \geq 0 & \forall \lambda \in \Lambda, \\ \sigma_Z(\delta z) = 0, \\ \sigma_{W_\Delta}(\check{w}_\Delta) \geq 0 \end{cases} \\ (4.15) \quad &\leq \inf_{\tau_1 \in \mathbf{R}, \tau_2 \geq 0, \lambda \in \Lambda} \sup_{\delta z, u, w_\Delta} \sigma(\tilde{H}\delta z + II_\Delta u + I_W w_\Delta, \delta y) + \sigma_\Delta(\delta z, u, \lambda) \\ &\quad + \tau_1 \sigma_Z(\delta z) + \tau_2 \sigma_{W_\Delta}(\check{w}_\Delta) \\ &= \inf_{\tau_1 \in \mathbf{R}, \tau_2 \geq 0, \lambda \in \Lambda} \sup_{\delta z, u, w_\Delta} \xi^* I_Z^* (\check{\Pi}^* \Psi \check{\Pi} + \check{\Psi}_Z(\tau_1, \tau_2, \lambda)) I_Z \xi - \tau_1 + \tau_2 \\ &\leq -\tau_1 + \tau_2 < 0, \end{aligned}$$

where  $\xi = [\delta z^* \quad u^* \quad \check{w}_\Delta^*]^*$  and  $G$  was defined in (4.8). The first inequality follows by S-procedure relaxation, the operator representation obtained after the equality follows by the definition of  $\check{\Pi}$  and  $\check{\Psi}_Z$ , and, finally, the last two inequalities follow by conditions (a)–(b) in the statement of the proposition.

Next we show that condition (iv)(b) in Theorem 3.2 follows from (a)–(b). We

need to introduce the operators

$$G_2 = \begin{bmatrix} \tilde{H} & II_\Delta \\ I & 0 \end{bmatrix},$$

$$\check{\Pi}_2 = \begin{bmatrix} H[T_0, 0] & [D_T H[T_0, 0]y_0 & II_\Delta] \\ I & \begin{bmatrix} 0 & 0 \end{bmatrix} \end{bmatrix},$$

$$\check{\Psi}_{\check{Z}_2}(\tau, \lambda) = \begin{bmatrix} \Psi_{\Delta, 11}(\lambda) + \tau \Psi_Z & \Psi_{\Delta, 12}(\lambda) \\ \Psi_{\Delta, 12}^*(\lambda) & \Psi_{\Delta, 22}(\lambda) \end{bmatrix}, \quad I_{\check{Z}_2} = \begin{bmatrix} I_Z & 0 \\ 0 & I \end{bmatrix}$$

and let  $\mathcal{Z}(\eta) = \{z \in \mathbf{Z} : \sigma_Z(z - z_0, \eta) = 0\}$ , where  $\sigma_Z(z, \eta) = \langle z, \Psi_Z z \rangle - \eta$  and  $\eta \in [0, 1]$ . Again we consider S-procedure relaxation ( $\eta \in [0, 1]$ ):

$$\begin{aligned} & \sup_{z \in \mathcal{Z}(\eta)} \sigma(H[T, 0]y - H[T_0, 0]y_0, y - y_0) \\ & \leq \sup_z \sigma(\delta w, \delta y, \lambda) \\ & \quad \text{subject to } \begin{bmatrix} \delta w \\ v \end{bmatrix} = G_2 \begin{bmatrix} \delta z \\ u \end{bmatrix} \quad \text{such that} \quad \begin{cases} \sigma_\Delta(v, u, \lambda) \geq 0 & \forall \lambda \in \Lambda \\ \sigma_Z(\delta z, \eta) = 0 \end{cases} \\ & \leq \inf_{\tau, \lambda \in \Lambda} \sup_{\delta z, u} \sigma(\tilde{H}\delta z + II_\Delta u, \delta y, \lambda) + \sigma_\Delta(\delta z, u, \lambda) + \tau \sigma_Z(\delta z, \eta) \\ & = \inf_{\tau, \lambda \in \Lambda} \sup_{\delta z, u} \xi^* I_{\check{Z}_2}^* (\check{\Pi}_2^* \Psi_1 \check{\Pi}_2 + \check{\Psi}_{\check{Z}_2}(\tau, \lambda)) I_{\check{Z}_2} \xi - \tau \eta \\ & \leq -\tau \eta, \end{aligned}$$

where  $\xi = [\delta z^* \quad u^*]^*$ . Here the last inequality follows because condition (a) implies that  $I_{\check{Z}_2}^* (\check{\Pi}_2^* \Psi_1 \check{\Pi}_2 + \check{\Psi}_{\check{Z}_2}(\tau, \lambda)) I_{\check{Z}_2} \leq 0$ . In order to continue the proof we notice that the definition of  $\mathcal{Z}(\eta)$  implies that

$$\|\Psi_Z^{1/2}(z - z_0)\|^2 = \eta,$$

which by the above inequality implies that

$$\sigma(H[T, 0]y - H[T_0, 0]y_0, y - y_0) \leq -\tau \eta \leq -L \|z - z_0\|^2,$$

where  $L = \tau \lambda_{\min}(\Psi_Z) > 0$  since  $\tau > 0$  and  $\Psi_Z > 0$ . This proves condition (iv)(b).  $\square$

**5. Example.** Let us consider the Van der Pol oscillator

$$\ddot{w}(t) + m(w(t)^2 - 1)\dot{w}(t) + w(t) = \theta \Delta(\dot{w}).$$

To represent this system on the form (3.1) we introduce the new coordinates

$$\begin{aligned} x_1 &= -\dot{w} - m(w^3/3 - w), \\ x_2 &= w. \end{aligned}$$

The transformed system can be shown to have the form (3.1) with  $\varphi(w) = -mw^3/3 + (2 + m)w$  and

$$H(s, \theta) = (I - \theta H_0(s) \Delta(s))^{-1} H_0(s),$$

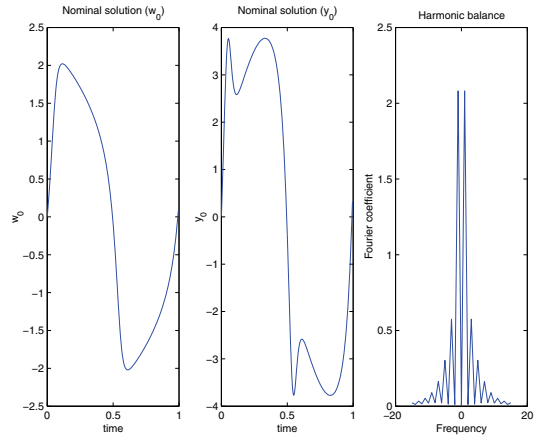

FIG. 5.1. The nominal limit cycle solution. The left-hand figure shows  $w_0(t)$ , and the middle figure shows  $y_0(t) = \varphi(w_0(t))$ . The right-hand figure shows the spectrum of the nominal solution  $|\hat{y}_0[k]|$ .

FIG. 5.2. The functions  $\alpha(t)$  and  $\beta(t)$  that define the low frequency sector condition.

where  $H_0(s) = \frac{s}{s^2+2s+1}$  and where  $\Delta$  is a stable transfer function with  $|\Delta(j\omega)| \leq \mu$  for all  $\omega \in \mathbf{R}$ . The nominal Van der Pol oscillator has a periodic solution with  $T_0 = 7.7$  and the corresponding 1-periodic trajectories in Figure 5.1.

We will use Theorem 3.2 to derive a bound on  $\mu$  for which the perturbed Van der Pol oscillator has a periodic solution in a neighborhood of  $(y_0, T_0)$  defined as in (D1) with  $\Psi_Y$  the diagonal operator,

$$\hat{\Psi}_Y[k, k] = \begin{cases} \psi_{Y_N} k, & |k| \leq 7, \\ \psi_{Y_{\bar{N}}}, & |k| > N, \end{cases}$$

where  $\psi_{Y_N} = 45$ , and  $\psi_{Y_{\bar{N}}} = 45$ . We let  $\psi_T = 45$ , which implies that  $\mathcal{T} = (7.55, 7.85)$ .

We first consider the case when  $\mu = 0.0082$  and verify (i)–(iv) in Theorem 3.2.

- (R1) It can be verified numerically that condition (i) in Theorem 3.2 is satisfied.
- (R2) We use Proposition 3.5. Some detailed information on the computation can be found in the appendix. We obtained the bound  $\|w - w_0\|_{C(1)} \leq 0.17$ .
- (R3) For  $\mathcal{W} = \{w \in C(1) : \|w - w_0\|_{C(1)} \leq 0.17\}$  we use a quadratic constraint on the form (3.9)–(3.10) with  $\alpha$  and  $\beta$  as in Figure 5.2.
- (R4) We use Proposition 4.3. We let the uncertainties be characterized by the

quadratic forms

$$\sigma_{\Delta}(v, u, \lambda) = \hat{v}^* \begin{bmatrix} \Lambda_1 I & 0 \\ 0 & \lambda_2 \end{bmatrix} \hat{v} - \hat{u}^* \begin{bmatrix} \hat{\Psi}_{\Delta}(\lambda_1) & 0 \\ 0 & \lambda_2 \gamma_{\delta} I \end{bmatrix} \hat{u},$$

where  $\lambda_2 \geq 0$  and  $\Lambda_1 = \text{diag}(\dots \lambda_{12}, \lambda_{1,1}, \lambda_{1,0}, \lambda_{1,-1}, \lambda_{1,-2}, \dots)$ , where  $\lambda_{1,k} = \lambda_{1,-k} \geq 0$  for all  $k$ . We use  $\hat{\Psi}_{\Delta} = \text{diag}(\lambda_{1k} \gamma_{\Delta}[k])_{k=-\infty}^{\infty}$ , with

$$\begin{aligned} \gamma_{\Delta}[k]^{-1/2} &= \sup_{T \in \mathcal{T}} \sup_{\theta \in [0,1]} |H(j2\pi k/T, \theta) - H_0(j2\pi k/T_0)| \\ &\leq \sup_{T \in \mathcal{T}} \frac{|H_0(j2\pi k/T) - H_0(j2\pi k/T_0)| + \mu |H_0(j2\pi k/T) H_0(j2\pi k/T_0)|}{1 - \mu |H_0(j2\pi k/T)|}, \end{aligned}$$

and we let

$$\begin{aligned} (5.1) \quad \gamma_{\delta}^{-1} &= \sup_{T \in \mathcal{T}} \|\delta[T]\|^2 \\ &= \sup_{T \in \mathcal{T}} \sum_{k=-\infty}^{\infty} \frac{|(H_0(j2\pi k/T) - H_0(j2\pi k/T_0)) - D_T H_0(j2\pi k/T_0)(T - T_0)) \hat{y}_0[k]|^2}{(T - T_0)^2}. \end{aligned}$$

For  $w_{\Delta}$  we use the quadratic constraint in (4.14) with  $\hat{\Psi}_{W_{\Delta}} = \gamma_w I_{2N+1}$ , where

$$\gamma_w^{-1} = \sup_{T \in \mathcal{T}} \sum_{k=-\infty}^{\infty} \frac{\mu^2 |H_0(j2\pi k/T)^2 \hat{y}_0[k]|^2}{(1 - \mu |H(j2\pi k/T)|)^2}.$$

The condition of Proposition 4.3 can be verified numerically as follows: With  $\tau_1 = 2.01 \cdot 10^{-4}$ ,  $\tau_2 = 2.00 \cdot 10^{-4}$ ,  $\lambda_{1,k} = 4.16 \cdot 10^{-4}$  for all  $k$ , and  $\lambda_2 = 0.0034$  we have

- (a)  $I_{\check{Z}}^*(\check{\Pi}^* \Psi \check{\Pi} + \check{\Psi}_{\check{Z}}(\tau_1, \tau_2, \lambda)) I_{\check{Z}} \leq 0$ , where we used the quadratic forms introduced above;
- (b)  $\tau_1 > \tau_2$ .

Further results can be found in Table 5.1, where the column for  $\|w - w_0\|_{C(1)}$  is the estimate the maximal perturbation of the trajectory obtained in (R2) and  $|T - T_0| = 1/\sqrt{\psi_T}$  is the maximum perturbation of the period time in the set  $\mathcal{Z}$ . The theoretical estimates compare fairly well with simulation results where we used

$$(5.2) \quad \Delta(s) = \mu_{sim} \omega_0^2 / (s^2 + 2\zeta \omega_0 s + \omega_0^2)$$

with  $\zeta = 0.2$  and  $\omega_0 = 0.83$ , which corresponds to  $\|\Delta\|_{\infty} \approx 0.01$  when  $\mu_{sim} = 0.004$ . Further simulations in Table 5.2 show that the period time is very sensitive to perturbations.

The case with  $\Delta$  as in (5.2) is a model of a mass and spring system excited by a Van der Pol oscillator; see Figure 5.3. The oscillator adapts its frequency to the resonance frequency of the mechanical system, and that is the reason why our analysis indicates large sensitivity to model uncertainty. The analysis agrees very well with the simulation for small perturbations. The upper bounds obtained from the simulations are only about 20% larger than the computed bounds.

TABLE 5.1

The table shows the performance of the algorithm for three different sizes of the perturbation. The last column indicates how large the perturbation is in relation to the  $\mathbf{H}_\infty$ -norm of the nominal dynamics.

$\Psi_{Y_N}$	$\psi_{Y_N}$	$\psi_T$	$\mu$	$\ w - w_0\ _{C(1)}$	$ T - T_0 $	$\frac{\mu}{\ H_0\ _{\mathbf{H}_\infty}}$
45	700	45	0.0082	0.17	0.15	1.6%
45	700	20	0.0095	0.19	0.22	1.9%
35	600	15	0.0099	0.20	0.26	2.0%

TABLE 5.2

The table shows the perturbation of the trajectory and the period time obtained by simulating the Van der Pol oscillator with the perturbation in (5.2). The last column indicates that the bounds on  $\mu$  obtained in Table 5.1 predict the perturbation of the period time well.

$\mu_{sim}$	$\ \Delta\ _\infty$	$\ w - w_0\ _{C(1)}$	$ T - T_0 $	$\frac{\mu}{\ \Delta\ _\infty}$
0.040	0.0102	0.010	0.15	0.80
0.046	0.0117	0.012	0.22	0.81
0.049	0.0125	0.012	0.28	0.79

FIG. 5.3. Van der Pol oscillator interconnected with a mass and spring system.

**6. Discussion.** The numerical example indicates that the method has the potential to accurately predict the effect of perturbation. However, as the perturbation becomes larger the uncertainty in model, period time, and trajectory accumulate, and it becomes difficult to make the estimates accurate. The reason is partly due to the set inclusion test (ii) in Theorem 3.2, which is not developed to its full potential. Another reason is that the coefficients defining the quadratic constraints could be improved using structured singular value calculations.

In our results we have used a neighborhood  $\mathcal{Z}$  defining the limit cycle but also a neighborhood  $\mathcal{W}$  defining the trajectory at the input of the nonlinearity. We let  $\mathcal{Z}$  be defined by  $\mathbf{L}_2$ -topology, while  $\mathcal{W}$  is defined in the uniform topology in order to allow the incremental sector condition for the nonlinearity to be defined in time domain. It should also be mentioned that the set inclusion condition (the linear part of the dynamics maps the set  $\mathcal{Z}$  into  $\mathcal{W}$ ) could be integrated with the sector condition. We believe there are both advantages and disadvantages in doing so.

In a previous work [7] we presented ideas related to the present paper. However, there we used a different assumption on the neighborhood  $\mathcal{Z}$  of the nominal solution, which appears to be harder to use than the one defined in the present paper. In fact, the boundary of the neighborhood was interpreted wrongly in Theorem 1 of [7], which led to mistakes in the computations.

**7. Concluding remarks.** We have derived a new robustness result for limit cycles of systems with separable nonlinearities. In our main results we use a time-varying sector condition to characterize the nonlinearity around an a priori given

neighborhood of the nominal solution. By using relaxation results from robust control we obtain linear matrix inequalities defined by the sector condition, which, if satisfied, proves the existence of a limit cycle within the predefined neighborhood of the nominal solution.

**Appendix.** For the first term in the expression for  $\nu$  we exploit that  $H[T_0, 0] : \mathbf{L}_2(1) \rightarrow \mathbf{L}_2(1)$  are compact operators. This implies that we can truncate the expression at some sufficiently high frequency and obtain the bound

$$\nu_1(t) = \sigma_{\max} \left( \mathbf{1}_N(e^{j2\pi t}) \begin{bmatrix} \hat{H}_N[T_0, 0] & D_T \hat{H}_N[T_0, 0] \end{bmatrix} \hat{\Psi}_{Z_N}^{-1/2} \right),$$

where  $\hat{H}_N$  is defined as in (4.7), analogously for  $D_T \hat{H}_N[T_0, 0]$ , and

$$\mathbf{1}_N(e^{j2\pi t}) = \begin{bmatrix} e^{j2\pi Nt} I & \dots & e^{j2\pi Nt} I & I & e^{-j2\pi Nt} I & \dots & e^{-j2\pi Nt} I \end{bmatrix}.$$

Let us next consider the third term  $\nu_3 = \sup_{\theta \in [0,1]} \sup_{T \in \mathcal{T}} \|w_\Delta[T, \theta]\|_{C(1)}$ . We use that

$$w_\Delta[T, \theta] = (H[T, \theta] - H[T_0, 0])y_0 = \theta H_0[T] \Delta[T] (I - \theta H_0[T] \Delta[T])^{-1} H_0[T] y_0,$$

which suggests the norm bound

$$\|w_\Delta[T, \theta]\|_{C(1)} \leq \|H_0[T]\|_{\mathbf{L}_2(1) \rightarrow C(1)} \|\Delta[T] (I - \theta H_0[T] \Delta[T])^{-1} H_0[T] y_0\|_{\mathbf{L}_2(1)},$$

where

$$\begin{aligned} \|H_0[T]\|_{\mathbf{L}_2(1) \rightarrow C(1)} &= \sqrt{\sum_{k=-\infty}^{\infty} |H_0(j2\pi k/T)|^2}, \\ \|\Delta[T] (I - \theta H_0[T] \Delta[T])^{-1} H_0[T] y_0\|_{\mathbf{L}_2(1)} &\leq \mu \|H_0[T] y_0\|_{\mathbf{L}_2(1)} / (1 - \mu \|H_0[T]\|), \end{aligned}$$

where  $\|H_0[T]\| = \sup_k |H_0[T]|$ . We can once again exploit compactness of  $H_0$  and truncate the expressions at some sufficiently high frequency.

For the second term we may use that  $\hat{\Psi}_Z$  is chosen diagonal and therefore use the simplified expression given in (3.22) in Proposition 3.5. We use the bound

$$\begin{aligned} &|\Delta(j2\pi k/T, \theta) \hat{\Psi}_Y(k, k)^{-1/2}| \\ &\leq \frac{|H_0(j2\pi k/T) - H_0(j2\pi k/T_0)| + \mu |H_0(j2\pi k/T) H_0(j2\pi k/T_0)|}{(1 - \mu |H_0(j2\pi k/T)|) |\hat{\Psi}_Y(k, k)|^{1/2}} \end{aligned}$$

for the first term, and for the second term we use the bound

$$\|\delta[T] \psi_T^{-1/2}\|_{C(1)} \leq \|H_0[T_0]\|_{\mathbf{L}_2(1) \rightarrow C(1)} \|\check{\delta}[T]\|_{\mathbf{L}_2(1)},$$

where

$$\check{\delta}[T] = H_0[T_0]^{-1} \delta[T] \psi_T^{-1/2},$$

which can be estimated in a similar way as  $\|\delta[T]\|_{\mathbf{L}_2(1)}$  in (5.2).

## OPTIMAL CONTROL FOR NONCONVEX RATE-INDEPENDENT EVOLUTION PROCESSES\*

FILIP RINDLER†

**Abstract.** Energetic solutions to rate-independent systems allow for an effective modeling of many physical systems displaying hysteretic effects, e.g., phase transformations in shape-memory alloys, elastoplasticity, and ferroelectricity. For some engineering applications, optimal control of such systems is desirable. We establish existence results for these continuous-time optimal control problems by a combination of the direct method with  $\Gamma$ -convergence arguments. Applicability to the common situation of a controlled external loading is demonstrated and a concrete partial differential inclusion as well as an academic model of the foreign exchange market including trading costs are investigated.

**Key words.** optimal control, optimization, rate-independent system, differential inclusion, variational inequality, energetic solution

**DOI.** 10.1137/080718711

**1. Introduction.** Many nonlinear physical systems possess the property of rate-independence, which means that their solution behavior does not depend on the speed of the forcing, but solely on its *path*. Examples from the material sciences include such diverse phenomena as phase transformation in shape-memory alloys [12, 20], elastoplasticity [1, 8, 14], and ferroelectricity (electrostriction) [9, 21]; see also the unifying approach of the theory of generalized standard materials in [16]. Sometimes, these systems are also referred to as “quasistatic,” because evolution takes place on a much longer time-scale than the system relaxation time. In engineering applications [24, 27], the need arises to (optimally) control such systems, for example in systems involving so-called “smart actuators.” Further, optimization with respect to material parameters could be desirable. Contrary to the situation for parabolic problems, cf., e.g., [22, 28], only very few investigations seem to have been carried out in the rate-independent or hysteretic case; cf. [9, 11].

The aim of this work is to show existence for optimal control problems involving rate-independent systems, especially in the situation where an external loading (e.g., a force or an electromagnetic field) is controlled. To illustrate the results, we also consider two concrete applications: We look at the optimal control problem for an evolutionary partial differential inclusion and we consider a simplistic model of controlling currency trading conditions on the foreign exchange market, taking into account transaction costs and (feedback) effects on the real values of the currencies caused by (large) transactions.

We base the optimal control results on the concept of energetic solutions; cf. [6, 13, 17, 18, 19] and the survey [15]. In the finite-dimensional (spatially discretized) setting, optimal control problems for such systems have recently been investigated as “mathematical programs with evolutionary equilibrium constraints” (MPEECs) in [9, 11] (with applications to delamination and micromagnetics). To the best of the

author's knowledge, however, no results for the infinite-dimensional case are available at present.

When dealing with the problems previously described, one has to overcome the difficulty that, in general, solutions are not guaranteed to be unique and no continuous dependence of the solution on the data can be assumed (this holds only if the problems are uniformly convex); cf. [2]. In general, this disallows the use of the standard implicit programming approach, where the occurrence of the solution corresponding to a control is expressed through a continuous solution operator and thus is eliminated from the minimization problem; cf. [23] for a recent monograph. In certain cases, though, uniqueness and stability of solutions are guaranteed and the implicit programming approach is feasible; cf. [9, 11]. We choose a different path here and work with joint minimizing sequences of controls and corresponding solutions and exploit upper semicontinuity properties of the (set-valued) solution operators.

This paper is organized as follows: After describing the general setup in section 2, we show solvability of the optimal control problem in a fairly general setting in section 3. Then, in section 4, we demonstrate the application of the existence result to the common situation in which the control parameter is an external loading (e.g., an external force) and conclude with the aforementioned concrete applications in section 5. The appendix presents some terminology on the Sobolev–Bochner spaces  $W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$  and, for the convenience of the reader, a direct proof of a well-known compactness result.

**2. Setup.** To explain the setup in a special case, assume for the moment that we are given two Banach spaces  $\mathcal{Z}, \mathcal{U}$ , where  $\mathcal{Z}$  is the *state space* of the system, and  $\mathcal{U}$  is the *admissible control space*. Rate-independent systems can be modeled as *evolutionary doubly-nonlinear (sub)differential inclusions* [3, 25], here including a *control parameter*  $u \in \mathcal{U}$ ,

$$(DI) \quad 0 \in \partial_y \mathcal{R}(y(t), \dot{y}(t); u) + D_y \mathcal{E}(t, y(t); u) \quad (\text{in } \mathcal{Z}^*)$$

for almost every  $t \in [0, T]$ . By writing out the definition of the subdifferential, this is equivalent to the *evolutionary quasivariational inequality*

$$(VI) \quad \langle D_y \mathcal{E}(t, y(t); u), z - \dot{y}(t) \rangle + \mathcal{R}(y(t), z; u) - \mathcal{R}(y(t), \dot{y}(t); u) \geq 0$$

for all  $z \in \mathcal{Z}$  and almost all  $t \in [0, T]$ . In both cases,  $\mathcal{E}: [0, T] \times \mathcal{Z} \times \mathcal{U} \rightarrow \mathbb{R}_\infty = \mathbb{R} \cup \{+\infty\}$  is a possibly nonconvex, Gâteaux-differentiable *energy-storage functional*. The *dissipation potential*  $\mathcal{R}: \mathcal{Z} \times \mathcal{Z} \times \mathcal{U} \rightarrow \mathbb{R}_\infty$  is such that for all  $u \in \mathcal{U}$ ,  $\mathcal{R}(z, \cdot; u): \mathcal{Z} \rightarrow \mathbb{R}_\infty$  is convex and 1-homogeneous, i.e.,  $\mathcal{R}(z, \lambda \dot{z}; u) = \lambda \mathcal{R}(z, \dot{z}; u)$  for all  $(z, \dot{z}, u) \in \mathcal{Z} \times \mathcal{Z} \times \mathcal{U}$ . This implies 0-homogeneity of  $\partial \mathcal{R}(\dot{z}, \cdot; u)$ , i.e., the mathematical manifestation of rate-independence. Additionally, we impose an *initial condition*  $y(0) = y_0 \in \mathcal{Z}$  (in fact, not all initial values are admissible, but this will be made precise later). The optimal control problem then consists of minimizing a given *cost functional*  $\mathcal{J}(y, u)$  over all admissible controls  $u$  and corresponding solutions  $y$ .

We deliberately omitted specifying the space in which we look for solutions to (DI) or (VI), but it should be noted that these two formulations are only sensible if  $y$  is at least weakly differentiable in time. Rate-independent systems, however, do not always yield solutions that are so regular and we must switch to a different notion of solution. This is accomplished by the framework of energetic solutions [6, 13, 17, 18, 19]. Consider the basic setup as presented in the survey [15] and assume the *state space*  $\mathcal{Z}$  of the system to be a Hausdorff topological space. We

further need a Hausdorff *control space*  $\mathcal{U}$ , which contains all admissible controls (in fact, optimization with respect to material parameters is also possible, but we stick to the term “control” for clarity). In the following, all topological notions (in particular *convergence* and *compactness*) are to be understood in a sequential sense. Also note that we do *not* identify functions on the interval  $[0, T]$  (into some space) that are equal almost everywhere, because modification on a null set may change whether a given function is a solution (to the energetic formulation introduced below).

In the terminology of [15], we will always be working in the case of a “reduced” energy functional, which means that  $\mathcal{Z}$  might be part of a larger state space  $\mathcal{Q} = \mathcal{F} \times \mathcal{Z}$ , where  $\mathcal{F}$  and  $\mathcal{Z}$  contain the conservative and dissipative parts of a state, respectively, and the energy functional  $\mathcal{E}$  is given through  $\mathcal{E}(t, z) = \min\{\mathcal{E}_0(t, \varphi, z) : \varphi \in \mathcal{F}\}$  for  $t \in [0, T]$ ,  $z \in \mathcal{Z}$ , with some energy functional  $\mathcal{E}_0: [0, T] \times \mathcal{F} \times \mathcal{Z} \rightarrow \mathbb{R}_\infty$ . If the minimizer of  $\mathcal{E}_0(t, \varphi, z)$  is unique for fixed  $t, z$ , then one can reconstruct the conservative part from the dissipative part. Usually, for the subsequent assumptions to hold, one must also require continuous dependence of this unique minimizer on  $t$  and  $z$  (which holds in many interesting applications); see [15, section 3.4] for details. Sometimes (as in the concrete partial differential inclusion in section 5.1), the distinction between the conservative and dissipative parts of the state space is not existent and we can directly work with the setup as presented below.

The system properties are modeled by an energy-storage functional  $\mathcal{E}: [0, T] \times \mathcal{Z} \times \mathcal{U} \rightarrow \mathbb{R}_\infty := \mathbb{R} \cup \{+\infty\}$  (now not necessarily Gâteaux-differentiable anymore) and a *dissipation distance*  $\mathcal{D}: \mathcal{Z} \times \mathcal{Z} \times \mathcal{U} \rightarrow [0, \infty]$ . While  $\mathcal{E}(t, z; u)$  is the potential energy of the state  $z \in \mathcal{Z}$  at time  $t \in [0, T]$  and with control  $u \in \mathcal{U}$ , the dissipation distance  $\mathcal{D}(z_1, z_2; u)$  measures the dissipated energy when the state is changed from  $z_1 \in \mathcal{Z}$  to  $z_2 \in \mathcal{Z}$  (in the situation of (DI), (VI):  $\mathcal{D}(z_1, z_2; u) := \inf\{\int_0^1 \mathcal{R}(v(\tau), \dot{v}(\tau); u) \, d\tau : v \in W^{1,1}(0, 1; \mathcal{Z}), v(0) = z_1, v(1) = z_2\}$  or simply  $\mathcal{D}(z_1, z_2; u) = \mathcal{R}(z_2 - z_1; u)$  if  $D_y \mathcal{R} \equiv 0$ ; cf. sections 3.6 and 4.1 of [15]). Therefore, we require  $\mathcal{D}(\cdot, \cdot; u)$  to be a *quasimetric*, i.e., we assume the triangle inequality and the positivity  $\mathcal{D}(z_1, z_2; u) = 0$  if and only if  $z_1 = z_2$  (see (A3)). With our physical interpretation in mind,  $\mathcal{D}(\cdot, \cdot; u)$  does not need to be symmetric (consider, for example, crack formation in brittle materials [4, 5] or delamination [10]). Our control on the system is expressed through the dependence of  $\mathcal{E}$  and  $\mathcal{D}$  on the control parameter  $u \in \mathcal{U}$ . We tacitly assume  $\mathcal{E}(t, \cdot; u)$  to be proper, i.e., not identically  $+\infty$  for all  $t \in [0, T]$  and  $u \in \mathcal{U}$ .

For a process  $y: [0, T] \rightarrow \mathcal{Z}$ , the *total dissipation*  $\text{Diss}_{\mathcal{D}}(y; [r, s]; u)$  of  $y$  in the subinterval  $[r, s] \subseteq [0, T]$  is the total (pointwise)  $\mathcal{D}$ -variation of  $y$ , i.e.,

$$\text{Diss}_{\mathcal{D}}(y; [r, s]; u) := \sup \left\{ \sum_{j=1}^N \mathcal{D}(y(\tau_{j-1}), y(\tau_j); u) : r = \tau_0 < \dots < \tau_N = s \right\}.$$

The space  $\text{BV}_{\mathcal{D}}([0, T]; \mathcal{Z}; \mathcal{U})$  of *functions with bounded dissipation* consists of all processes  $y: [0, T] \rightarrow \mathcal{Z}$  such that  $\text{Diss}_{\mathcal{D}}(y; [0, T]; u) < \infty$  for all  $u \in \mathcal{U}$ . Since the spaces  $\mathcal{Z}$  and  $\mathcal{U}$  will always be clear from the context, we abbreviate  $\text{BV}_{\mathcal{D}}([0, T]; \mathcal{Z}; \mathcal{U})$  to  $\text{BV}_{\mathcal{D}}([0, T])$ . We say that a sequence  $(y_k)_k \subseteq \text{BV}_{\mathcal{D}}([0, T])$  converges in  $\text{BV}_{\mathcal{D}}([0, T])$  to  $y \in \text{BV}_{\mathcal{D}}([0, T])$  if  $\sup_{k \in \mathbb{N}} \text{Diss}_{\mathcal{D}}(y_k; [0, T]; u) < \infty$  for all  $u \in \mathcal{U}$  and  $y_k(t) \rightarrow y(t)$  for all  $t \in [0, T]$  (pointwise convergence). The generalized Helly selection principle [13, Theorem 3.2] is the fundamental compactness result in  $\text{BV}_{\mathcal{D}}([0, T])$  and says that from each sequence with uniformly bounded dissipation we can select a subsequence converging in  $\text{BV}_{\mathcal{D}}([0, T])$ , i.e., pointwise.

The *set of stable states* at time  $t \in [0, T]$  is defined to be

$$\mathcal{S}(t; u) := \left\{ z \in \mathcal{Z} : \mathcal{E}(t, z; u) < \infty \text{ and } \mathcal{E}(t, z; u) \leq \mathcal{E}(t, \hat{z}; u) + \mathcal{D}(z, \hat{z}; u) \right. \\ \left. \text{for all } \hat{z} \in \mathcal{Z} \right\}.$$

The “stability” expresses itself through the fact that the system must leave these states only when the exterior conditions change (i.e., if  $\mathcal{E}$  and hence the stable states change in the course of time).

Given a control  $u \in \mathcal{U}$  and an initial value  $y_0 \in \mathcal{S}(0; u)$ , let

$$\text{Sol}: \mathcal{Z} \times \mathcal{U} \rightrightarrows \text{BV}_{\mathcal{D}}([0, T]), \quad (y_0, u) \mapsto \text{Sol}(y_0, u) \subseteq \text{BV}_{\mathcal{D}}([0, T])$$

denote the set-valued solution operator that associates with  $(y_0, u)$  all *energetic solutions* to the (initial-value) evolution problem associated with  $\mathcal{E}(\cdot, \cdot; u)$  and  $\mathcal{D}(\cdot, \cdot; u)$ , i.e., all processes  $y \in \text{BV}_{\mathcal{D}}([0, T])$  that satisfy the *stability condition*

$$(S) \quad y(t) \in \mathcal{S}(t; u)$$

and the *energy balance*

$$(E) \quad \mathcal{E}(t, y(t); u) + \text{Diss}(y; [0, t]; u) = \mathcal{E}(0, y(0); u) + \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau$$

for all  $t \in [0, T]$  (this includes the requirement that  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T)$ ), as well as the *initial condition*  $y(0) = y_0$ .

If the assumptions stated after the subdifferential inclusion (DI) and variational inequality (VI) are satisfied,  $\mathcal{E}(t, \cdot; u)$  is *convex*, and  $y \in W^{1,1}(0, T; \mathcal{Z})$ , then the energetic formulation is equivalent to (DI) and (VI); cf. [15, 19]. In comparison, however, the integrated formulation of energetic solutions has the advantage that the solution  $y$  need not be differentiable, and neither a linear structure on  $\mathcal{Z}$  nor Gâteaux-differentiability of the functional  $\mathcal{E}$  needs to be assumed. Further, the dissipation distance  $\mathcal{D}$  need not be given through a dissipation potential  $\mathcal{R}$  and hence more general types of dissipation can be treated.

The optimal control problem for a rate-independent system consists of minimizing a given *cost functional*  $\mathcal{J}: \text{BV}_{\mathcal{D}}([0, T]) \times \mathcal{U} \rightarrow \mathbb{R}_{\infty}$ , depending on the control and the corresponding solution. Thus, our objective is the following continuous-time *optimal control problem*:

$$(OC) \quad \begin{cases} \text{For given initial value } y_0 \in \mathcal{Z}, \text{ find an } \textit{optimal control } u \in \mathcal{U} \\ \text{and a corresponding } \textit{optimal solution } y \in \text{Sol}(y_0, u), \text{ satisfying} \\ y \in \text{Argmin}\{ \mathcal{J}(\hat{y}, \hat{u}) : \hat{y} \in \text{Sol}(y_0, \hat{u}), \hat{u} \in \mathcal{U} \}. \end{cases}$$

As for noncontrolled systems, the initial value needs to fulfill a certain compatibility property; we will come back to that later; see (CC).

Later, we will also incorporate side conditions on the solution  $y$  and the control  $u$  in the form  $y(t) \in R_{\text{sol}} \subseteq \mathcal{Z}$  for all  $t \in [0, T]$  and  $u \in R_{\text{ctrl}} \subseteq \mathcal{U}$  with  $R_{\text{sol}}, R_{\text{ctrl}}$  closed; cf. Remark 3.7.

**3. Existence of optimal controls and processes.** In this section, we establish solvability of the optimal control problem (OC) stated in the previous section. After some auxiliary lemmas we prove a generalization of the standard existence theorem

in the theory of rate-independent systems; cf. [13, 15, 17]. In particular, an improved version of the lower energy estimate, Proposition 3.2, allows us to dispense with the uniform continuity assumption on the power  $\partial_t \mathcal{E}$ . As eventually we are interested in optimal control, this is an important generalization. Also, we employ different convergence conditions (in particular (C4)) than in the cited works in order to make the theory applicable to the scenarios we have in mind.

**3.1. Assumptions.** Most of the following assumptions are by now standard in the theory of energetic solutions to rate-independent systems:

*Uniform control of power:*

- (A1) There exist  $c_0^E \geq 0$ ,  $c_1^E > 0$  such that for all  $u \in \mathcal{U}$  and  $z \in \mathcal{Z}$  with  $\mathcal{E}(s, z; u) < \infty$  for some  $s \in [0, T]$ , it holds that
- (i)  $\mathcal{E}(\cdot, z; u) \in W^{1,\infty}(0, T)$  and
  - (ii)  $|\partial_t \mathcal{E}(t, z; u)| \leq c_1^E(\mathcal{E}(t, z; u) + c_0^E)$  for all  $t \in [0, T]$ .

*Uniform coercivity:*

- (A2) For all  $t \in [0, T]$ ,  $u \in \mathcal{U}$ , and  $E \in \mathbb{R}$ , it holds that
- $$\bigcup_{u \in \mathcal{U}} \{z \in \mathcal{Z} : \mathcal{E}(t, z; u) \leq E\} \text{ is relatively compact.}$$

*Quasimetric:*

- (A3) For all  $u \in \mathcal{U}$  and all  $z_1, z_2, z_3 \in \mathcal{Z}$ , it holds that
- (i)  $\mathcal{D}(z_1, z_2; u) = 0$  if and only if  $z_1 = z_2$  (*positivity*) and
  - (ii)  $\mathcal{D}(z_1, z_3; u) \leq \mathcal{D}(z_1, z_2; u) + \mathcal{D}(z_2, z_3; u)$  (*triangle inequality*).

Note that (ii) from (A1) implicitly contains the lower bound  $\mathcal{E}(\cdot, z; u) \geq -c_0^E$ . By the Gronwall inequality, we also get

$$(3.1) \quad \mathcal{E}(t, z; u) + c_0^E \leq (\mathcal{E}(s, z; u) + c_0^E) e^{c_1^E |t-s|}$$

for all  $z \in \mathcal{Z}$ ,  $u \in \mathcal{U}$ , and  $t, s \in [0, T]$ ; cf. [15, section 3.1].

We further need certain continuity properties of  $\mathcal{E}$  and  $\mathcal{D}$ :

*Lower semicontinuity of energy-storage functional:*

- (C1) For all  $t \in [0, T]$ ,  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $z^k \rightarrow z$  in  $\mathcal{Z}$  with  $\sup_{k \in \mathbb{N}} \mathcal{E}(t, z^k; u^k) < \infty$ , it holds that
- $$\mathcal{E}(t, z; u) \leq \liminf_{k \rightarrow \infty} \mathcal{E}(t, z^k; u^k).$$

*Lower semicontinuity of dissipation distance:*

- (C2) For all  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $z^k \rightarrow z$ ,  $\tilde{z}^k \rightarrow \tilde{z}$  in  $\mathcal{Z}$  with  $\sup_{k \in \mathbb{N}, t \in [0, T]} (\mathcal{E}(t, z^k; u^k) + \mathcal{E}(t, \tilde{z}^k; u^k)) < \infty$ , it holds that
- $$\mathcal{D}(z, \tilde{z}; u) \leq \liminf_{k \rightarrow \infty} \mathcal{D}(z^k, \tilde{z}^k; u^k).$$

*Upper semicontinuity of stability sets:*

- (C3) For all  $t_k \rightarrow t$  in  $[0, T]$ ,  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $z^k \rightarrow z$  in  $\mathcal{Z}$  satisfying  $z^k \in \mathcal{S}(t_k; u^k)$  and  $\sup_{k \in \mathbb{N}} \mathcal{E}(t_k, z^k; u^k) < \infty$ , it holds that  $z \in \mathcal{S}(t, u)$ .

*Convergence of power in mean:*

For all  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $y^k \rightarrow y$  in  $\text{BV}_{\mathcal{D}}([0, T])$  with

$$(C4) \quad \sup_{k \in \mathbb{N}, t \in [0, T]} \mathcal{E}(t, y^k(t); u^k) < \infty \text{ and } \tau \mapsto \partial_t \mathcal{E}(\tau, y^k(\tau); u^k) \in L^1(0, T),$$

it holds that  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T)$  and

$$\int_0^s \partial_t \mathcal{E}(\tau, y^k(\tau); u^k) \, d\tau \longrightarrow \int_0^s \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau$$

for all  $s \in [0, T]$ .

*Convergence of suitable power interpolants:*

For all  $u \in \mathcal{U}$ ,  $y \in \text{BV}_{\mathcal{D}}([0, T])$  and  $s \in [0, T]$  such that

$$(C5) \quad \tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T), \text{ there exists a sequence of partitions}$$

$$(\Pi_k = (r = \tau_0^k, \dots, \tau_{N(k)}^k = s))_k \text{ of } [0, s] \text{ with } \|\Pi_k\| \rightarrow 0 \text{ and}$$

$$\sum_{j=1}^{N(k)} \int_{\tau_{j-1}^k}^{\tau_j^k} \partial_t \mathcal{E}(\xi, y(\tau_j^k); u) \, d\xi \longrightarrow \int_0^s \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau.$$

Note that by (3.1) in (C2) it suffices to require  $\sup_{k \in \mathbb{N}} (\mathcal{E}(t, z^k; u^k) + \mathcal{E}(t, \tilde{z}^k; u^k)) < \infty$  for *some*  $t \in [0, T]$ . Further, it is easy to see that conditions (A2), (A3), and (C2) together imply the following positivity property of the dissipation distance:

$$(3.2) \quad \begin{aligned} &\text{For all } u \in \mathcal{U}, (z^k)_k \subseteq \mathcal{Z} \text{ with } \sup_{k \in \mathbb{N}, t \in [0, T]} \mathcal{E}(t, z^k; u) < \infty \text{ and} \\ &\min \{ \mathcal{D}(z^k, z; u), \mathcal{D}(z, z^k; u) \} \rightarrow 0 \text{ for some } z \in \mathcal{Z}, \text{ it holds that} \\ &z^k \rightarrow z \text{ in } \mathcal{Z}. \end{aligned}$$

The conditional upper semicontinuity (C3) of the stability sets can be established, for example, by strengthening the assumptions (C1) and (C2) on  $\mathcal{E}$  and  $\mathcal{D}$  (cf. [17] for a fine hierarchy of increasingly stronger conditions):

*$\Gamma$ -continuity of energy-storage functional:*

For all  $t \in [0, T]$ ,  $u^k \rightarrow u$  in  $\mathcal{U}$ , it holds that

$$(C1') \quad \begin{aligned} (i) \quad &\text{For all } z^k \rightarrow z \text{ in } \mathcal{Z} \text{ with } \sup_{k \in \mathbb{N}} \mathcal{E}(t, z^k; u^k) < \infty, \text{ the} \\ &\text{lim inf-inequality } \mathcal{E}(t, z; u) \leq \liminf_{k \rightarrow \infty} \mathcal{E}(t, z^k; u^k) \text{ holds.} \\ (ii) \quad &\text{For all } z \in \mathcal{Z} \text{ with } \mathcal{E}(t, z; u) < \infty, \text{ there exists a recovery} \\ &\text{sequence } z^k \rightarrow z \text{ in } \mathcal{Z}, \text{ i.e., } \mathcal{E}(t, z; u) = \lim_{k \rightarrow \infty} \mathcal{E}(t, z^k; u^k). \end{aligned}$$

*Continuity of dissipation distance:*

For all  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $z^k \rightarrow z, \tilde{z}^k \rightarrow \tilde{z}$  in  $\mathcal{Z}$  with

$$(C2') \quad \sup_{k \in \mathbb{N}, t \in [0, T]} (\mathcal{E}(t, z^k; u^k) + \mathcal{E}(t, \tilde{z}^k; u^k)) < \infty, \text{ it holds that}$$

$$\mathcal{D}(z^k, \tilde{z}^k; u^k) \rightarrow \mathcal{D}(z, \tilde{z}; u).$$

Notice that (C1') means that  $\mathcal{E}(t, \cdot; u) = \Gamma\text{-}\lim_k \mathcal{E}(t, \cdot; u^k)$  on sets of bounded energy. Obviously, the last two requirements are stronger than (C1) and (C2), respectively. As mentioned above, (C1') and (C2') together also imply (C3) as observed in Proposition 2.2 of [17]. For the convenience of the reader and because in the cited work even more general statements are made, we here show an adapted version.

LEMMA 3.1. *Conditions (C1') and (C2') imply (C3).*

*Proof.* First, note that by (A1) and (3.1), for all  $\tilde{z} \in \mathcal{Z}$  and  $u \in \mathcal{U}$  such that  $\mathcal{E}(s, \tilde{z}; u) < E$  for some  $s \in [0, T]$ , there exists a Lipschitz constant  $L = L(E) > 0$  such that

$$(3.3) \quad |\mathcal{E}(t, \tilde{z}; u) - \mathcal{E}(s, \tilde{z}; u)| \leq L |t - s|$$

for all  $s, t \in [0, T]$  (in fact,  $L(E) = c_1^E(E^* + c_0^E)e^{c_1^E T}$ ).

For a concise notation, define

$$\mathcal{H}(t, z, \hat{z}; u) := \mathcal{E}(t, \hat{z}; u) + \mathcal{D}(z, \hat{z}; u) - \mathcal{E}(t, z; u)$$

for  $u \in \mathcal{U}$ ,  $z, \hat{z} \in \mathcal{Z}$ . Note that  $z \in \mathcal{S}(t; u)$  if and only if  $\mathcal{H}(t, z, \hat{z}; u) \geq 0$  for all  $\hat{z} \in \mathcal{Z}$  with  $\mathcal{E}(t, \hat{z}; u) < \infty$ .

Now, let  $u^k \rightarrow u$  in  $\mathcal{U}$ ,  $(t_k, z^k) \rightarrow (t, z)$  in  $[0, T] \times \mathcal{Z}$  and  $z^k \in \mathcal{S}(t_k; u^k)$  with  $E^* := \sup_{k \in \mathbb{N}} \mathcal{E}(t_k, z^k; u^k) < \infty$ . To show  $\mathcal{H}(t, z, \hat{z}; u) \geq 0$  for all  $\hat{z} \in \mathcal{Z}$  with  $\mathcal{E}(t, \hat{z}; u) < \infty$ , let  $\hat{z}^k \rightarrow \hat{z}$  in  $\mathcal{Z}$  be a recovery sequence for  $\hat{z}$  with respect to the  $\Gamma$ -converging sequence  $(\mathcal{E}(t, \cdot; u^k))_k$ , which exists by (C1'). In particular, also employing the Lipschitz-continuity (3.3), we have

$$\limsup_{k \rightarrow \infty} \mathcal{E}(t_k, \hat{z}^k; u^k) \leq \limsup_{k \rightarrow \infty} \mathcal{E}(t, \hat{z}^k; u^k) + \lim_{k \rightarrow \infty} L_1 |t - t_k| \leq \mathcal{E}(t, \hat{z}; u),$$

where  $L_1$  is the Lipschitz constant associated to the energy bound on the recovery sequence. From the lim inf-inequality of  $\mathcal{E}(\cdot, z^k; u^k)$ , we further get

$$\limsup_{k \rightarrow \infty} -\mathcal{E}(t_k, z^k; u^k) \leq -\liminf_{k \rightarrow \infty} \mathcal{E}(t, z^k; u^k) + \lim_{k \rightarrow \infty} L_2 |t - t_k| \leq -\mathcal{E}(t, z; u)$$

with  $L_2$  corresponding to the energy bound  $E^*$ .

Combining the previous two estimates and using the continuous convergence  $\mathcal{D}(z^k, \hat{z}^k; u^k) \rightarrow \mathcal{D}(z, \hat{z}; u)$  of the dissipation distance (C2'), we arrive at

$$\mathcal{H}(t, z, \hat{z}; u) \geq \limsup_{k \rightarrow \infty} \mathcal{H}(t_k, z^k, \hat{z}^k; u^k) \geq 0,$$

where the last inequality holds, because  $z^k \in \mathcal{S}(t_k; u^k)$ .  $\square$

Finally, we require the control space  $\mathcal{U}$  and the cost functional  $\mathcal{J}$  to satisfy the following standard requirements:

(J1) *Compactness of  $\mathcal{U}$ :*  
 $\mathcal{U}$  is compact.

*Lower semicontinuity of  $\mathcal{J}$ :*  
 For all  $u^k \rightarrow u$  in  $\mathcal{U}$  and  $y^k \rightarrow y$  in  $\text{BV}_{\mathcal{D}}([0, T])$  with  $y^k \in \text{Sol}(y_0, u^k)$ ,  
 (J2)  $y \in \text{Sol}(y_0, u)$  and  $\sup_{k \in \mathbb{N}, t \in [0, T]} \mathcal{E}(t, z^k; u^k) < \infty$ , it holds that  

$$\mathcal{J}(y; u) \leq \liminf_{k \rightarrow \infty} \mathcal{J}(y^k; u^k).$$

Condition (J1) might seem restrictive, but can be omitted if additional coerciveness conditions with respect to  $u$  are imposed on  $\mathcal{J}$ . As many cost functionals, however, do not even depend on  $u$ , here we give priority to the situation with compact  $\mathcal{U}$ .

**3.2. Existence of solutions for a fixed control.** To construct solutions, we will rely on a *discrete-time incremental problem*. For this, fix for each  $k \in \mathbb{N}$  a partition

$$\Pi_k = (0 = t_0^k, t_1^k, \dots, t_{N(k)}^k = T),$$

of the interval  $[0, T]$ , where the *fineness*  $\|\Pi_k\| := \max\{(t_j^k - t_{j-1}^k) : j = 1, \dots, N(k)\}$  goes to zero as  $k \rightarrow \infty$ . For a control  $u \in \mathcal{U}$  and a stable initial value  $y_0 \in \mathcal{S}(0; u)$ , we then want to find solutions  $y^k = (y_0^k, \dots, y_N^k) = (y^k(t_0), \dots, y^k(t_N)) \in \mathcal{Z}^{\Pi_k}$  to

$$(IP_k) \quad \begin{cases} \text{Given } y_0^k = y_0 \in \mathcal{S}(0; u), \text{ inductively find } y_j^k \in \mathcal{Z} \text{ such that} \\ y_j^k \in \operatorname{Argmin}\{\mathcal{E}(t_j^k, \hat{z}; u) + \mathcal{D}(y_{j-1}^k, \hat{z}; u) : \hat{z} \in \mathcal{Z}\} \text{ for } j = 1, \dots, N. \end{cases}$$

The next proposition is a generalized version of Proposition 5.7 in [15] (see also [6, 20]). In this version, we do not need uniform continuity of the power  $\partial_t \mathcal{E}(\cdot, z; u)$  for fixed  $z \in \mathcal{Z}$  (and  $u \in \mathcal{U}$ ) anymore. This generalization is necessary in order to allow for nonsmooth controls (which can cause the time-evolution of the functionals to be nonsmooth).

**PROPOSITION 3.2.** *Assume (A1) and (C5). Let  $u \in \mathcal{U}$ , and let  $y \in \operatorname{BV}_{\mathcal{D}}([0, T])$  be a stable process, i.e.,  $y(t) \in \mathcal{S}(t; u)$  for all  $t \in [0, T]$ . Further, let  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T)$ . Then, for all  $t \in [0, T]$  the process  $y$  satisfies the lower energy estimate*

$$\mathcal{E}(t, y(t); u) + \operatorname{Diss}_{\mathcal{D}}(y; [0, t]; u) \geq \mathcal{E}(0, y(0); u) + \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau.$$

*Proof.* Let  $0 = \tau_0 < \tau_1 < \dots < \tau_N = t$  be any partition of  $[0, t]$ . The stability of  $y(\tau_{j-1})$  tested with  $y(\tau_j)$  gives

$$\begin{aligned} \mathcal{E}(\tau_{j-1}, y(\tau_{j-1}); u) &\leq \mathcal{E}(\tau_{j-1}, y(\tau_j); u) + \mathcal{D}(y(\tau_{j-1}), y(\tau_j); u) \\ &= \mathcal{E}(\tau_j, y(\tau_j); u) - \int_{\tau_{j-1}}^{\tau_j} \partial_t \mathcal{E}(\xi, y(\tau_j); u) \, d\xi \\ &\quad + \mathcal{D}(y(\tau_{j-1}), y(\tau_j); u). \end{aligned}$$

Summing this over  $j = 1, \dots, N$  leads to

$$\begin{aligned} \mathcal{E}(t, y(t); u) + \operatorname{Diss}(y; [0, t]; u) &\geq \mathcal{E}(t, y(t); u) + \sum_{j=1}^N \mathcal{D}(y(\tau_{j-1}), y(\tau_j); u) \\ &\geq \mathcal{E}(0, y(0); u) + \sum_{j=1}^N \int_{\tau_{j-1}}^{\tau_j} \partial_t \mathcal{E}(\xi, y(\tau_j); u) \, d\xi. \end{aligned}$$

By (C5), the last sum converges to  $\int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau$  for a suitable sequence of partitions.  $\square$

We now have all of the necessary ingredients to prove the existence of a solution to (S) and (E) for some arbitrary, but fixed, control. In other words, we show that  $\operatorname{Sol}(y_0; u)$  is nonempty for all  $u \in \mathcal{U}$  and  $y_0 \in \mathcal{S}(0; u)$ .

**THEOREM 3.3.** *Assume (A1)–(A3), (C1)–(C5), and let  $u \in \mathcal{U}$ . Then, for all initial values  $y_0 \in \mathcal{S}(0; u)$ , there exists a solution process  $y \in \operatorname{BV}_{\mathcal{D}}([0, T])$ , i.e.,  $y \in \operatorname{Sol}(y_0; u)$ , for which it holds that*

- (i)  *$y$  is the pointwise limit of a subsequence (not renumbered) of the piecewise-constant, right-continuous interpolants  $\bar{y}^k$  of solutions  $y^k$  to  $(IP_k)$ ,*

- (ii)  $\mathcal{E}(t, \bar{y}^k(t); u) \rightarrow \mathcal{E}(t, y(t); u)$  for all  $t \in [0, T]$ ,
- (iii)  $\text{Diss}_{\mathcal{D}}(\bar{y}^k; [0, t]; u) \rightarrow \text{Diss}_{\mathcal{D}}(y; [0, t]; u)$  for all  $t \in [0, T]$ .

*Proof. Step 1: Incremental problems.* For each  $k \in \mathbb{N}$ , by assumptions (C1) and (C2) (which imply lower semicontinuity of  $\mathcal{E}(t_j^k, \cdot; u) + \mathcal{D}(y_{j-1}^k, \cdot; u)$ ) the direct method of the Calculus of Variations, applied inductively for  $j = 1, \dots, N(k)$ , shows existence of a discrete-time solution  $y^k = (y_0^k, y_1^k, \dots, y_{N(k)}^k)$  of  $(\text{IP}_k)$ .

*Step 2: A priori estimates.* For brevity of notation, set  $e_j^k := \mathcal{E}(t_j^k, y_j^k; u)$  and  $\delta_j^k := \mathcal{D}(y_{j-1}^k, y_j^k; u)$ . Since  $y_j^k$  is a minimizer of  $\mathcal{E}(t_j^k, \cdot; u) + \mathcal{D}(y_{j-1}^k, \cdot; u)$ , we have for all  $\hat{z} \in \mathcal{Z}$  and  $j = 1, \dots, N(k)$  that

$$e_j^k \leq \mathcal{E}(t_j^k, \hat{z}; u) + \mathcal{D}(y_{j-1}^k, \hat{z}; u) - \delta_j^k \leq \mathcal{E}(t_j^k, \hat{z}; u) + \mathcal{D}(y_j^k, \hat{z}; u),$$

i.e.,  $y_j^k \in \mathcal{S}(t_j^k; u)$ . For  $j = 0$  we assumed  $y_0^k = y_0 \in \mathcal{S}(0; u)$ .

Similarly, testing the minimality of  $y_j^k$  with  $y_{j-1}^k$  and using the growth estimate (A1) and its consequence (3.1) gives

$$(3.4) \quad e_j^k + \delta_j^k \leq \mathcal{E}(t_j^k, y_{j-1}^k; u) = e_{j-1}^k + \int_{t_{j-1}^k}^{t_j^k} \partial_t \mathcal{E}(\tau, y_{j-1}^k; u) \, d\tau$$

$$(3.5) \quad \begin{aligned} &\leq e_{j-1}^k + \int_{t_{j-1}^k}^{t_j^k} c_1^E (e_{j-1}^k + c_0^E) e^{c_1^E (\tau - t_{j-1}^k)} \, d\tau \\ &= e_{j-1}^k + (e_{j-1}^k + c_0^E) (e^{c_1^E (t_j^k - t_{j-1}^k)} - 1). \end{aligned}$$

The last estimate implies  $e_j^k + \delta_j^k + c_0^E \leq (e_{j-1}^k + c_0^E) e^{c_1^E (t_j^k - t_{j-1}^k)}$  and, by repeated application,

$$(3.6) \quad e_j^k + \delta_j^k + c_0^E \leq (e_0^k + c_0^E) e^{c_1^E t_j^k}.$$

Combining this with a similar estimate as in (3.5), for the right-continuous, piecewise-constant interpolant  $\bar{y}^k$  of  $y^k$ , we deduce the uniform energy bound (recall  $\delta_j^k, c_0^E \geq 0$ )

$$(3.7) \quad \bar{e}^k(t) := \mathcal{E}(t, \bar{y}^k(t); u) \leq (\mathcal{E}(0, y_0; u) + c_0^E) e^{c_1^E t} =: E^* e^{c_1^E t}$$

for all  $k \in \mathbb{N}$ ,  $t \in [0, T]$ . By (A1), we get

$$(3.8) \quad \bar{P}^k(t) := \partial_t \mathcal{E}(t, \bar{y}^k(t); u) \leq c_1^E (E^* e^{c_1^E t} + c_0^E)$$

for all  $k \in \mathbb{N}$ ,  $t \in [0, T]$ .

Rearranging (3.5), summing up, and using (3.6) gives

$$\begin{aligned} \sum_{j=1}^{N(k)} \delta_j^k &\leq e_0^k - e_{N(k)}^k + \sum_{j=1}^{N(k)} (e_{j-1}^k + c_0^E) (e^{c_1^E (t_j^k - t_{j-1}^k)} - 1) \\ &\leq (e_0^k + c_0^E) - (e_{N(k)}^k + c_0^E) + (e_0^k + c_0^E) \sum_{j=1}^{N(k)} (e^{c_1^E t_j^k} - e^{c_1^E t_{j-1}^k}) \\ &\leq E^* e^{c_1^E T} \end{aligned}$$

since  $e_{N(k)}^k \geq -c_0^E$ , which is contained implicitly in point (ii) of (A1). It follows that the dissipation of  $\bar{y}^k$  stays uniformly bounded, i.e.,

$$(3.9) \quad \text{Diss}(\bar{y}^k; [0, T]; u) = \sum_{j=1}^{N(k)} \delta_j^k \leq E^* e^{c_1^E T}.$$

*Step 3: Selection of subsequences.* The  $k$ -independent bounds (3.7), (3.9) together with the assumptions (A2), (A3), (C2), and (3.2), allow us to invoke the generalized Helly selection principle, Theorem 3.2 in [13], in order to get subsequences (not renumbered) and limit functions  $y \in \text{BV}_{\mathcal{D}}([0, T])$  and  $\delta^\infty: [0, T] \rightarrow \mathbb{R}$  such that for all  $t, r, s \in [0, T]$  with  $r < s$ , it holds that

$$(3.10) \quad \begin{aligned} \bar{y}^k(t) &\rightarrow y(t), & \text{Diss}(\bar{y}^k; [0, t]; u) &\rightarrow \delta^\infty(t), & \text{and} \\ \text{Diss}(y; [r, s]; u) &\leq \delta^\infty(s) - \delta^\infty(r), & \delta^\infty(0) &= 0. \end{aligned}$$

The convergence of the power in mean (C4) (with  $u^k := u$ , and notice that  $\bar{P}^k$  is measurable by (A1) and in  $L^1(0, T)$  by (3.8)) now implies  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T)$  and

$$(3.11) \quad \int_0^t \bar{P}^k(\tau) \, d\tau \longrightarrow \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau$$

for all  $t \in [0, T]$ .

*Step 4: Stability of the limit process.* Fix  $t \in [0, T]$ , and let  $m(t, k) \in \{1, \dots, N(k)\}$  be the largest integer such that  $t_{m(t, k)}^k \leq t$ . If  $t > 0$ , then also  $m(t, k) > 0$  for  $k$  large enough and because  $\bar{y}^k(t) = \bar{y}^k(t_{m(t, k)}^k) \in \mathcal{S}(t_{m(t, k)}^k; u)$  (this was shown in Step 2), (3.10), and assumption (C3) (with  $u^k := u$ ) imply that  $y(t) \in \mathcal{S}(t; u)$ . For the initial value, we already know  $y(0) = y_0 \in \mathcal{S}(0; u)$  by hypothesis. Hence, the limit process satisfies (S).

*Step 5: Energy estimates in the limit.* By the lower semicontinuity assumption (C1) on the energy functional we get

$$(3.12) \quad \mathcal{E}(t, y(t); u) \leq \liminf_{k \rightarrow \infty} \bar{e}^k(t) =: e_\infty(t) \leq e^\infty(t) := \limsup_{k \rightarrow \infty} \bar{e}^k(t).$$

Let  $m(t, k)$  be defined as above. We sum (3.4) for  $j = 1, \dots, m(t, k)$  and get, also employing the uniform bound (3.8) on  $\bar{P}^k = \partial_t \mathcal{E}(\cdot, \bar{y}^k(\cdot); u)$ ,

$$\begin{aligned} \bar{e}^k(t) + \text{Diss}(\bar{y}^k; [0, t]; u) &\leq \bar{e}_{m(t, k)}^k + \sum_{j=1}^{m(t, k)} \delta_j^k + c \|\Pi_k\| \\ &\leq \bar{e}^k(0) + \int_0^t \bar{P}^k(\tau) \, d\tau + c \|\Pi_k\| \end{aligned}$$

for all  $t \in [0, T]$ . Passing to the limit in this inequality and using (3.10), (3.12), and the convergence of the power in mean (3.11) as well as  $\bar{e}^k(0) = \mathcal{E}(0, y_0; u)$  and  $\delta^\infty(0) = 0$ , we get

$$(3.13) \quad \begin{aligned} \mathcal{E}(t, y(t); u) + \text{Diss}(y; [0, t]; u) &\leq e_\infty(t) + \delta^\infty(t) \leq e^\infty(t) + \delta^\infty(t) \\ &\leq \mathcal{E}(0, y_0; u) + \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau \end{aligned}$$

for all  $t \in [0, T]$ , i.e., the upper half of (E).

The lower energy estimate follows directly from Proposition 3.2 (cf. Step 3). Hence, (3.13) is an equality and we have shown (E) as well as the convergence  $\bar{e}^k(t) \rightarrow e_\infty(t) = e^\infty(t)$ . Then,  $\mathcal{E}(t, y(t); u) \leq e_\infty(t)$  and  $\text{Diss}_{\mathcal{D}}(y; [0, t]; u) \leq \delta^\infty(t)$  (by (C1) and (3.10), respectively) imply (ii) and (iii) from the statement of the theorem.  $\square$

**3.3. Existence of optimal controls.** After having established the existence of a solution, we can now move to the principal aim of this work, i.e., the existence proof for optimal controls and corresponding solutions. We combine the direct method and an upper semicontinuity property of the solution operator  $u^k \mapsto \text{DSol}(y_0; u^k)$  with respect to the convergence  $u^k \rightarrow u$  in  $\mathcal{U}$  (a variant of the “ $\Gamma$ -stability” first discovered in Theorem 3.1 of [17]).

**THEOREM 3.4.** *Assume (A1)–(A3), (C1)–(C5), and (J1)–(J2). Further, let the initial value  $y_0 \in \mathcal{Z}$  satisfy the compatibility condition*

$$(CC) \quad \begin{aligned} (i) \quad & y_0 \in \bigcap_{u \in \mathcal{U}} \mathcal{S}(0; u) \\ (ii) \quad & \mathcal{E}(0, y_0; u^k) \rightarrow \mathcal{E}(0, y_0; u) \quad \text{for all } u^k \rightarrow u \text{ in } \mathcal{U}. \end{aligned}$$

*Then (OC) has at least one solution.*

**REMARK 3.5.** *Obviously, if  $\mathcal{E}$  satisfies the continuity property that  $\mathcal{E}(t, z; u^k) \rightarrow \mathcal{E}(t, z; u)$  for all  $u^k \rightarrow u$  in  $\mathcal{U}$  and all  $t \in [0, T]$ ,  $z \in \mathcal{Z}$  fixed, then the compatibility condition (CC) reduces to point (i) alone.*

*Proof.* Let  $(y^k, y^k) \in \mathcal{U} \times \text{BV}_{\mathcal{D}}([0, T])$  with  $y^k \in \text{Sol}(y_0; u^k)$  be a minimizing sequence for  $\mathcal{J}$ , i.e.,

$$\mathcal{J}(y^k; u^k) \rightarrow \inf \{ \mathcal{J}(\hat{y}, \hat{u}) : \hat{y} \in \text{Sol}(y_0, \hat{u}), \hat{u} \in \mathcal{U} \}.$$

By (J1), we can select a converging subsequence (not relabelled)  $u^k \rightarrow u$  in  $\mathcal{U}$ . We show that there exists  $y \in \text{BV}_{\mathcal{D}}([0, T])$  with  $y \in \text{Sol}(y_0; u)$  such that  $y^k(t) \rightarrow y(t)$  in  $\mathcal{Z}$  for all  $t \in [0, T]$ . By an inspection of the proof of Theorem 3.3, we see that in (3.7) and (3.9), the value of  $E^*$  can be chosen independently of  $k$  by point (ii) of (CC). Thus, as in the previous theorem, invoking the generalized Helly selection principle (this time the  $\Gamma$ -convergence version in Theorem A.1 of [17]) we conclude that there exists  $y: [0, T] \rightarrow \mathcal{Z}$  such that  $y^k(t) \rightarrow y(t)$  for all  $t \in [0, T]$ . Assumption (C4) gives

$$(3.14) \quad \int_0^t \partial_t \mathcal{E}(\tau, y^k(\tau); u^k) \, d\tau \longrightarrow \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau$$

for all  $t \in [0, T]$ .

By the uniform boundedness of  $\mathcal{E}(0, y_0; u^k)$  (cf. point (ii) of (CC)) and (A1), from Gronwall’s inequality it follows that  $\mathcal{E}(t, y^k(t); u^k)$  is uniformly bounded [15, section 3.1]. Thus, the stability (S) of  $y$  follows immediately from the upper semicontinuity of the stability sets (C3) (note that we have pointwise convergence of the processes  $y^k$  to  $y$  and each  $y^k$  is stable).

The upper part of the energy balance can be derived using the energy balances  $(E_k)$  for  $y^k$  together with assumptions (C1), (C2), and (ii) of the compatibility

condition (CC) as follows:

$$\begin{aligned} & \mathcal{E}(t, y(t); u) + \text{Diss}_{\mathcal{D}}([0, t]; y(t); u) \\ & \leq \liminf_{k \rightarrow \infty} (\mathcal{E}(t, y^k(t); u^k) + \text{Diss}_{\mathcal{D}}([0, t]; y^k(t); u^k)) \\ & = \liminf_{k \rightarrow \infty} \left( \mathcal{E}(0, y_0; u^k) + \int_0^t \partial_t \mathcal{E}(\tau, y^k(\tau); u^k) \, d\tau \right) \\ & = \mathcal{E}(0, y_0; u) + \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau, \end{aligned}$$

where we have also employed (3.14) and the fact that by (C2)

$$\text{Diss}_{\mathcal{D}}(y; [0, t]; u) \leq \liminf_{k \rightarrow \infty} \text{Diss}_{\mathcal{D}}(y^k; [0, t]; u^k).$$

The lower half of the energy balance follows again from Proposition 3.2.

Hence, we have found  $(u, y) = \lim_{k \rightarrow \infty} (u^k, y^k)$  with  $y \in \text{Sol}(y; u)$ , which, by the choice of  $(u^k, y^k)$  and the lower semicontinuity (J2), must be a minimizer for  $\mathcal{J}$ .  $\square$

**REMARK 3.6.** *If the initial value  $y_0$  does not satisfy (CC) (which might be difficult to check), then the solution  $y$  need not be stable at time  $t = 0$ . In this case, however, a solution immediately jumps to a stable state as soon as  $t > 0$  (see Step 2 in the proof of Theorem 3.3, where stability is shown for all points of the discrete solution away from the initial value). This “self-stabilization” is a very useful feature in the framework of energetic solutions. Of course, (CC) is not necessary for initial stability of an optimal control-solution pair  $(u, y)$ . If further knowledge on the possible optimal controls is available, it suffices to require initial stability for such controls.*

**REMARK 3.7.** *Certain side-conditions can be incorporated into the optimal control problem as well: Constraints on the control may be enforced by setting*

$$\tilde{\mathcal{J}}(y; u) := \begin{cases} \mathcal{J}(y; u) & \text{if } u \in R_{\text{ctrl}}, \\ +\infty & \text{otherwise,} \end{cases}$$

where  $R_{\text{ctrl}} \subseteq \mathcal{U}$  is closed. Closed and time-independent constraints on the solution may be directly incorporated into the functional  $\mathcal{E}$  in a similar manner. In both cases, all assumptions from section 3.1 are easily verified. Note that time-independent constraints cannot be treated since if  $\mathcal{E}(s, z; u) < \infty$  for one  $s \in [0, T]$ , then already  $\mathcal{E}(s, z; u) < \infty$  for all  $s \in [0, T]$  by (3.1).

**4. Optimal control of external loadings.** In many applications,  $\mathcal{Z}$  is a Banach space equipped with its weak topology, and controls act on the process in the form of an external loading (e.g., a force). Technically, this means that  $\mathcal{U}$  is a space of functions with values in (a subset of) the dual space  $\mathcal{Z}^*$  and the energy-storage functional depends on  $u$  only through the duality pairing  $\langle u(t), y(t) \rangle$  (we will specify later in which space the duality product is taken). In this section, we apply and adapt the previously developed results to this special situation and also give conditions on the space  $\mathcal{U}$  and on the functional  $\mathcal{J}$  such that (J1) and (J2) are fulfilled.

**4.1. Control space.** To gain the necessary compactness for the general theory, on several instants we need not only the space  $\mathcal{Z}$  itself, but also a larger *pivot space*  $\mathcal{P}$  such that the compact embeddings

$$(4.1) \quad \mathcal{Z} \xhookrightarrow{c} \mathcal{P} \quad \text{and} \quad \mathcal{P}^* \xhookrightarrow{c} \mathcal{Z}^*$$

hold. Of course, by Schauder's theorem, only the first compact embedding needs to be verified. Note that if, additionally,  $\mathcal{P}$  is a Hilbert space, then we can identify  $\mathcal{P}$  and  $\mathcal{P}^*$  and get the Gelfand triple  $\mathcal{Z} \hookrightarrow \mathcal{P} \cong \mathcal{P}^* \hookrightarrow \mathcal{Z}^*$ . Here, however, we do not need the additional Hilbert space structure. Further, we require  $\mathcal{Z}$  and  $\mathcal{P}$  to be reflexive and separable.

EXAMPLE 4.1. *The most prominent example for spaces  $\mathcal{Z}, \mathcal{P}$  as in (4.1) is given through the Gelfand triple  $H_0^1(\Omega) \hookrightarrow L^2(\Omega) \hookrightarrow H^{-1}(\Omega)$ , i.e.,  $\mathcal{P} = \mathcal{P}^* = L^2(\Omega)$ ,  $\mathcal{Z} = H_0^1(\Omega)$  (equipped with the norm  $\|z\|_{H_0^1(\Omega)} := \|\nabla z\|_{L^2(\Omega)}$ ), where  $\Omega \subseteq \mathbb{R}^d$  is a bounded Lipschitz domain.*

The control space  $\mathcal{U}$  is rooted on the framework of Sobolev–Bochner spaces. Some results from this theory are collected in the appendix. The space  $\mathcal{U}$  will always be a subset of the space  $W^{1,\infty}(0, T; \mathcal{P}^*)$  equipped with its weak\* topology. Further, we require (also cf. the remark after (J2))

*Boundedness of  $\mathcal{U}$ :*

(U) There exists a constant  $M_{\mathcal{U}} \geq 0$  such that for all  $u \in \mathcal{U}$

$$\|u\|_{W^{1,\infty}(0,T;\mathcal{P}^*)} \leq M_{\mathcal{U}}.$$

In many applications (see the choice of the energy functional in the next section), the last condition means that the power  $\tau \mapsto \partial_t \mathcal{E}(\tau, z; u) = \langle \dot{u}(\tau), z \rangle_{\mathcal{P}^* \times \mathcal{P}}$  ( $z \in \mathcal{Z}$ ,  $u \in \mathcal{U}$ ) stays  $L^\infty$ -bounded on bounded subsets of the state space  $\mathcal{Z}$ .

EXAMPLE 4.2. *The simplest choice for  $\mathcal{U}$  is*

$$\mathcal{U} := B_{W^{1,\infty}(0,T;\mathcal{P}^*)}(M_{\mathcal{U}}),$$

*the ball in  $W^{1,\infty}(0, T; \mathcal{P}^*)$  with radius  $M_{\mathcal{U}} > 0$ . This bounded set is weakly\* sequentially compact; also cf. the appendix.*

**4.2. Energy-storage functional and dissipation distance.** We assume the energy-storage functional to have the form of a sum of potential energy and external loading, i.e.,

$$(4.2) \quad \mathcal{E}(t, z; u) = \mathcal{W}(z) + \langle u(t), z \rangle_{\mathcal{P}^* \times \mathcal{P}}$$

with  $\mathcal{W}: \mathcal{Z} \rightarrow \mathbb{R}_\infty$ . We only treat time-independent  $\mathcal{W}$ , but cf. Remark 4.5.

To fulfill all of the requirements on  $\mathcal{E}$  in our special case, we require

*Superlinear growth of  $\mathcal{W}$ :*

(W1) There exist  $\mu > 0$ ,  $\kappa \geq 0$ ,  $s > 1$  such that  $\mathcal{W}(z) \geq \mu \|z\|_{\mathcal{Z}}^s - \kappa$  for all  $z \in \mathcal{Z}$ .

*Lower semicontinuity of  $\mathcal{W}$ :*

(W2)  $\mathcal{W}$  is in weakly sequentially lower semicontinuous in  $\mathcal{Z}$ .

LEMMA 4.3. *Let  $\mathcal{U} \subseteq W^{1,\infty}(0, T; \mathcal{P}^*)$  fulfill (U), let  $\mathcal{E}$  be defined through (4.2), and assume (W1) and (W2). Then, (A1), (A2), (C1'), (C4), and (C5) hold.*

*Proof.* Point (i) of assumption (A1) is clear. Let  $\gamma$  be the operator norm of the continuous embedding  $\mathcal{Z} \hookrightarrow \mathcal{P}$ , i.e.,  $\|z\|_{\mathcal{P}} \leq \gamma \|z\|_{\mathcal{Z}}$  for all  $z \in \mathcal{Z}$ . Choose  $K$  be so large that  $\mu\gamma^{-1}K^{s-1} - M_{\mathcal{U}} > 0$ . Using (W1), (4.2), we get for all  $t \in [0, T]$ ,  $z \in \mathcal{Z}$  with  $\|z\|_{\mathcal{Z}} \geq K$  and  $u \in \mathcal{U}$

$$\mathcal{E}(t, z; u) \geq \mathcal{W}(z) - M_{\mathcal{U}} \|z\|_{\mathcal{P}} \geq \mu \|z\|_{\mathcal{Z}}^s - \kappa - M_{\mathcal{U}} \|z\|_{\mathcal{P}} \geq (\mu\gamma^{-1}K^{s-1} - M_{\mathcal{U}}) \|z\|_{\mathcal{P}} - \kappa.$$

Then also

$$|\partial_t \mathcal{E}(t, z; u)| = |\langle \dot{u}(t), z \rangle_{\mathcal{P}^* \times \mathcal{P}}| \leq M_{\mathcal{U}} \|z\|_{\mathcal{P}} \leq \frac{M_{\mathcal{U}}}{\mu \gamma^{-1} K^{s-1} - M_{\mathcal{U}}} (\mathcal{E}(t, z; u) + \kappa).$$

For  $\|z\|_{\mathcal{Z}} \leq K$  we have

$$|\partial_t \mathcal{E}(t, z; u)| \leq \gamma K M_{\mathcal{U}} \quad \text{and} \quad \mathcal{E}(t, z; u) \geq -\kappa - \gamma K M_{\mathcal{U}}.$$

Hence, the uniform control of the power, point (ii) of (A1), follows with  $c_1^E := M_{\mathcal{U}}/(\mu \gamma^{-1} K^{s-1} - M_{\mathcal{U}}) > 0$  and  $c_0^E := \kappa + \gamma K M_{\mathcal{U}} + \gamma K(\mu \gamma^{-1} K^{s-1} - M_{\mathcal{U}}) > 0$ .

By (W1), for  $\|z\|_{\mathcal{Z}} \geq K$  we also have

$$\mathcal{E}(t, z; u) \geq \mathcal{W}(z) - M_{\mathcal{U}} \|z\|_{\mathcal{P}} \geq \mu \|z\|_{\mathcal{Z}}^s - \kappa - \gamma M_{\mathcal{U}} \|z\|_{\mathcal{Z}} \geq (\mu K^{s-1} - \gamma M_{\mathcal{U}}) \|z\|_{\mathcal{Z}} - \kappa.$$

Thus, for all  $E \in \mathbb{R}$ , the set  $\bigcup_{u \in \mathcal{U}} \{z \in \mathcal{Z} : \mathcal{E}(t, z; u) \leq E\}$  is contained in the weakly sequentially compact  $\mathcal{Z}$ -ball with radius  $\max\{K, (E + \kappa)/(\mu K^{s-1} - \gamma M_{\mathcal{U}})\} < \infty$  and (A2) follows.

To show (C4), let  $u^k \xrightarrow{*} u$  in  $\mathcal{U}$  and  $y^k(t) \rightharpoonup y(t)$  in  $\mathcal{Z}$  for all  $t \in [0, T]$ , and assume  $\mathcal{E}(t, y^k(t), u^k) \leq E^*$  for all  $t \in [0, T]$ ,  $k \in \mathbb{N}$ , and some fixed  $E^* \in \mathbb{R}$ . Because  $y$  is the pointwise weak limit of Bochner-measurable functions  $y^k$ , it is itself weakly measurable (for each fixed  $z^* \in \mathcal{Z}^*$ , the real functions  $\tau \mapsto \langle z^*, y^k(\tau) \rangle$  are measurable and converge pointwise to the measurable function  $\tau \mapsto \langle z^*, y(\tau) \rangle$ ). Hence, by the Pettis theorem (see, e.g., [29, p. 131]),  $y$  is Bochner-measurable. Then, the measurability of  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u)$  follows from the fact that  $\partial_t \mathcal{E}(\cdot, \cdot; u)$  is a Carathéodory mapping.

As shown above, all sublevels of  $\mathcal{E}(t, \cdot; u)$  are uniformly (in  $t, u$ ) norm-bounded in  $\mathcal{P}$ , and hence the processes  $y^k$  and  $y$  are also uniformly (in  $t, k$ ) bounded in  $\mathcal{P}$ . Because  $\mathcal{Z} \xhookrightarrow{c} \mathcal{P}$ , the pointwise weak convergence in  $\mathcal{Z}$  of  $y^k(t)$  to  $y(t)$  implies  $y^k(t) \rightarrow y(t)$  (strongly) in  $\mathcal{P}$  for all  $t \in [0, T]$ . By Lebesgue's dominated convergence theorem, pointwise-a.e. (strong) convergence in  $\mathcal{P}$  implies (strong) convergence of  $y^k \rightarrow y$  in  $L^1(0, T; \mathcal{P})$  and  $\tau \mapsto \partial_t \mathcal{E}(\tau, y(\tau); u) \in L^1(0, T)$ . Because  $L^1(0, T; \mathcal{P})^* \cong L^\infty(0, T; \mathcal{P}^*)$  (see the appendix), we have for all  $t \in [0, T]$

$$\begin{aligned} \int_0^t \partial_t \mathcal{E}(\tau, y^k(\tau); u^k) \, d\tau &= \int_0^t \langle \dot{u}^k(\tau), y^k(\tau) \rangle_{\mathcal{P}^* \times \mathcal{P}} \, d\tau \\ &= \langle \dot{u}^k, y^k \rangle_{L^\infty(0, t; \mathcal{P}^*) \times L^1(0, t; \mathcal{P})} \\ &\longrightarrow \langle \dot{u}, y \rangle_{L^\infty(0, t; \mathcal{P}^*) \times L^1(0, t; \mathcal{P})} = \int_0^t \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau, \end{aligned}$$

because of the (weak  $\times$  strong)-continuity of the duality pairing. This shows (C4).

From Proposition A.2 and the (weak  $\times$  strong)-continuity of the duality pairing, for *every* fixed  $t \in [0, T]$ , the continuity of  $(u, z) \mapsto \langle u(t), z \rangle_{\mathcal{P}^* \times \mathcal{P}}$  with respect to sequences converging in  $(W^{1, \infty}(0, T; \mathcal{P}^*), \text{weak}^*) \times (\mathcal{Z}, \text{weak})$  follows. Hence,  $\mathcal{E}$  is the sum of the lower semicontinuous function  $\mathcal{W}$  and the continuous perturbation  $\langle u(t), z \rangle_{\mathcal{P}^* \times \mathcal{P}}$ ; therefore (C1') holds (take constant recovery sequences  $z^k := z$ ).

The convergence of suitable interpolants of the power (C5) can be seen by observing

$$\begin{aligned} &\left| \sum_{j=1}^N \int_{\tau_{j-1}}^{\tau_j} \partial_t \mathcal{E}(\xi, y(\tau_j); u) \, d\xi - \int_0^s \partial_t \mathcal{E}(\tau, y(\tau); u) \, d\tau \right| \\ &\leq M_{\mathcal{U}} \sum_{j=1}^N \int_{\tau_{j-1}}^{\tau_j} \|y(\tau_j) - y(\tau)\|_{\mathcal{P}} \, d\tau \end{aligned}$$

for any partition  $\Pi = (0 = \tau_0, \dots, \tau_N = s)$  and selecting a suitable sequence of partitions such that the last integrand vanishes by Lemma 4.12 from [4].  $\square$

REMARK 4.4. *Of course, the same proof also works in the case  $s = 1$  (linear growth) if we additionally require  $\mu\gamma^{-1} - M_{\mathcal{U}} > 0$ .*

REMARK 4.5. *Also time-dependent  $\mathcal{W} = \mathcal{W}(t, z)$  can be treated if (W1) is satisfied uniformly in  $t$  and if  $\mathcal{W}$  fulfills assumptions (A1), (C4), and (C5).*

For the dissipation distance  $\mathcal{D}: \mathcal{Z} \times \mathcal{Z} \times \mathcal{U} \rightarrow [0, \infty]$ , we require (A3) to hold. For reasons of simplicity, we also assume the property (C2'). Of course, more general situations are imaginable, in which only the weaker property (C2) is satisfied, but requiring (C2'), we immediately have (C3) as observed in Lemma 3.1.

REMARK 4.6. *If  $\mathcal{Z} \xhookrightarrow{c} \mathcal{P} \hookrightarrow \mathcal{V}$ , we can always choose the  $\mathcal{V}$ -norm (not depending on  $u \in \mathcal{U}$ ) as dissipation distance, i.e.,*

$$\mathcal{D}(z_1, z_2; u) := \|z_2 - z_1\|_{\mathcal{V}} \quad \text{for } z_1, z_2 \in \mathcal{Z}.$$

*Then, assumption (A3) holds by the properties of the norm. The validity of (C2') follows, because  $\|\cdot\|_{\mathcal{V}}$  is weaker than the weak topology in  $\mathcal{Z}$  since  $\mathcal{Z} \xhookrightarrow{c} \mathcal{V}$ .*

EXAMPLE 4.7. *Like in Example 4.1, consider the spaces  $\mathcal{Z} = H_0^1(\Omega)$ ,  $\mathcal{P} = L^2(\Omega)$ , and let  $\mathcal{D}(z_1, z_2; u) := \|z_2 - z_1\|_{L^1(\Omega)}$ . By the previous remark, this dissipation distance is admissible.*

**4.3. Initial value.** Concerning the compatibility condition (CC) on the initial value, Remark 3.5 applies by Proposition A.2 and we only have to show point (i) in (CC), i.e.,

$$y_0 \in \bigcap_{u \in \mathcal{U}} \mathcal{S}(0; u).$$

If  $\mathcal{D}(\cdot, \cdot; u) = \mathcal{D}(\cdot, \cdot)$  does not depend on the control  $u$ , then in our situation of a stored-energy functional  $\mathcal{E}(t, z; u) = \mathcal{W}(z) + \langle u(t), z \rangle_{\mathcal{P}^* \times \mathcal{P}}$ , this condition translates into

$$\mathcal{W}(y_0) + \langle u(0), y_0 \rangle_{\mathcal{P}^* \times \mathcal{P}} \leq \mathcal{W}(\hat{z}) + \langle u(0), \hat{z} \rangle_{\mathcal{P}^* \times \mathcal{P}} + \mathcal{D}(y_0, \hat{z})$$

for all  $\hat{z} \in \mathcal{Z}$ ,  $u \in \mathcal{U}$ . Adding the zero  $\mathcal{D}(y_0, y_0)$  on the left-hand side and rearranging, we see that this is equivalent to the variational inequality

$$\mathcal{W}(y_0) + \mathcal{D}(y_0, y_0) - \langle u(0), \hat{z} - y_0 \rangle_{\mathcal{P}^* \times \mathcal{P}} \leq \mathcal{W}(\hat{z}) + \mathcal{D}(y_0, \hat{z})$$

and (if  $z \mapsto \mathcal{W}(z) + \mathcal{D}(y_0, z)$  is convex, or if we extend the definition of subdifferential to nonconvex functions) to the differential inclusion

$$-u(0) \in \partial(\mathcal{W}(\cdot) + \mathcal{D}(y_0, \cdot))[y_0] \quad (\text{in } \mathcal{P}^*) \quad \text{for all } u \in \mathcal{U}.$$

If we have an additional condition on the initial value of  $u$ , e.g.,  $u(0) = 0$ , then this last condition can be statically checked before the optimization is started. In case of zero initial values  $u(0) = 0$  for the controls, the above condition translates to  $y_0 \in \mathcal{S}_{\mathcal{W}}(0)$ , where  $\mathcal{S}_{\mathcal{W}}(0)$  denotes the stability set at time  $t = 0$  for the functional  $\mathcal{W}$ .

**4.4. Cost functional.** Which functionals are now lower semicontinuous in our concrete setting?

EXAMPLE 4.8. One simple example of a cost functional  $\mathcal{J}$  satisfying (J2) is given through

$$\mathcal{J}(y; u) := \|y(T) - v\|_{\mathcal{Z}} \quad (\text{or } \|y(T) - v\|_{\mathcal{P}}),$$

where  $v \in \mathcal{Z}$  is some fixed element. This functional represents a prescribed terminal datum and seeks to find a solution minimizing the distance, measured in the  $\mathcal{Z}(\mathcal{P})$ -norm, to this fixed element. Condition (J2) holds by the weak lower semicontinuity of norms.

The following proposition is more general.

PROPOSITION 4.9. Let  $g: [0, T] \times \mathcal{P} \times \mathcal{U} \rightarrow \mathbb{R}_{\infty}$  be such that

- (i)  $g(\cdot, z; u): [0, T] \rightarrow \mathbb{R}_{\infty}$  is Lebesgue-measurable for fixed  $z \in \mathcal{P}$  and  $u \in \mathcal{U}$ .
- (ii)  $|g(t, z_1; u) - g(t, z_2; u)| \leq \omega_1(\|z_1 - z_2\|_{\mathcal{P}})$  for all  $z_1, z_2 \in \mathcal{Z}$ ,  $t \in [0, T]$ , and  $u \in \mathcal{U}$ , where  $\omega_1: [0, \infty) \rightarrow [0, \infty)$  is a modulus of continuity, i.e., increasing and  $\omega_1(0) = 0$  ( $\omega_1$  not depending on  $u$ ).
- (iii)  $g(t, z; \cdot): \mathcal{U} \rightarrow \mathbb{R}_{\infty}$  for fixed  $t \in [0, T]$  and  $z \in \mathcal{Z}$ , is continuous with respect to sequences converging weakly\* in  $\mathcal{U}$ .
- (iv)  $|g(t, z; u)| \leq h(t)(1 + \omega_2(\max\{\|z\|_{\mathcal{P}}, \|u\|_{\mathcal{U}}\}))$  for all  $t \in [0, T]$ , where the function  $\omega_2: [0, \infty) \rightarrow [0, \infty)$  is bounded on bounded sets and  $h \in L^1(0, T)$ .

Then the functional

$$\mathcal{J}(y; u) := \int_0^T g(t, y(t); u) \, dt$$

fulfills (J2).

*Proof.* We commence with a pointwise lower semicontinuity property of the integrand. For this, let  $z^k \rightarrow z$  strongly in  $\mathcal{P}$  and  $u^k \xrightarrow{*} u$  in  $\mathcal{U}$ . Then, for all  $t \in [0, T]$ , by (ii)

$$\begin{aligned} g(t, z; u) &= g(t, z; u) - g(t, z; u^k) + g(t, z; u^k) - g(t, z^k; u^k) + g(t, z^k; u^k) \\ &\leq (g(t, z; u) - g(t, z; u^k)) + \omega_1(\|z - z^k\|_{\mathcal{P}}) + g(t, z^k; u^k). \end{aligned}$$

By (iii),  $g(t, z; u) \leq \liminf_{k \rightarrow \infty} g(t, z^k; u^k)$ , and  $g(t, \cdot; \cdot): \mathcal{P} \times \mathcal{U} \rightarrow \mathbb{R}_{\infty}$  is (strong  $\times$  weak\*)-sequentially lower semicontinuous.

Now the integrand is the composition of the Carathéodory function  $g$  with a Bochner-measurable function  $y$  and hence it is measurable itself (this can be shown in a standard way using approximations of  $y$  by simple functions and exploiting assumptions (i), (ii)).

We now show the lower semicontinuity property (J2). For this, let  $u^k \xrightarrow{*} u$  in  $\mathcal{U}$ ,  $y^k \rightarrow y$  in  $BV_{\mathcal{D}}([0, T])$ , in particular  $y^k(t) \rightarrow y(t)$  strongly in  $\mathcal{P}$  for all  $t \in [0, T]$ , and  $E^* := \sup_{k \in \mathbb{N}, t \in [0, T]} \mathcal{E}(t, y^k(t); u^k) < \infty$ . By (A2), established in Lemma 4.3, the set  $\bigcup_{u \in \mathcal{U}} \{z \in \mathcal{Z} : \mathcal{E}(t, z; u) \leq E^*\}$  is relatively weakly compact. Thus,  $\|y^k(t)\|_{\mathcal{P}}$  stays uniformly (in  $t$  and  $k$ ) bounded. As  $u^k \xrightarrow{*} u$ , this also holds for  $\|u^k\|_{\mathcal{U}}$ , and (iv) yields an integrable majorant to  $|g(t, y^k(t); u^k)|$ . Thus, using Fatou's lemma, we infer from the pointwise lower semicontinuity of the integrand  $g$ ,

$$\mathcal{J}(y; u) \leq \liminf_{k \rightarrow \infty} \mathcal{J}(y^k; u^k),$$

i.e., (J2).  $\square$

Note that the modulus of continuity  $\omega_1$  from (ii) may depend on a bound on  $\|z_1\|_{\mathcal{P}}, \|z_2\|_{\mathcal{P}}$  as well, because the uniform energy bound required in (J2) implies as before that for any sequence of  $y^k$  occurring in (J2) we can find a uniform (in  $t, k$ ) bound on  $\|y^k(t)\|_{\mathcal{P}}$ .

An important example for such a cost functional  $\mathcal{J}$  is the following.

EXAMPLE 4.10. For  $g(t, z; u) := \|z - w(t)\|_{\mathcal{P}}^2$  with  $w \in L^\infty(0, T; \mathcal{P})$ , the last proposition and the small remark preceding this example show that

$$\mathcal{J}(y; u) := \int_0^T \|y(t) - w(t)\|_{\mathcal{P}}^2 dt = \|y - w\|_{L^2(0, T; \mathcal{P})}^2$$

is an admissible cost functional. We can now optimize the control as to make the system process follow this prescribed movement  $w$  as closely as possible in the  $L^2$ -sense.

**5. Applications.** This section presents two concrete applications of the abstract theory developed so far.

**5.1. Optimal control of a partial differential inclusion.** One possible application of the theory presented so far is the task to (optimally) control solutions of the initial-boundary value problem for the partial differential inclusion [3, 13]

$$(5.1) \quad \begin{cases} 0 \in \kappa \operatorname{Sign}(\dot{y}) - \operatorname{div}[a \nabla y] + D_y F(\cdot, y) - u & \text{in } [0, T] \times \Omega, \\ y = 0 & \text{on } [0, T] \times \partial\Omega, \quad \text{and} \quad y(0, \cdot) = y_0 & \text{in } \Omega. \end{cases}$$

Here,  $\Omega$  is a bounded Lipschitz domain in  $\mathbb{R}^d$ ,  $a \in L^\infty(\Omega)$  is a function bounded from below by  $2\mu > 0$ , and  $\kappa \in L^\infty(\Omega)$  is a function bounded from above and below by positive constants. The function  $F: \Omega \times \mathbb{R} \rightarrow [0, \infty]$  is assumed bounded, continuous, and differentiable in the second argument. As usual,  $\dot{y}$  and  $\nabla y$  denote the temporal derivative and the spatial gradient, respectively. We want to control  $u: [0, T] \times \Omega \rightarrow \mathbb{R}$  under the constraints

$$(5.2) \quad u(0, \cdot) = 0, \quad \varphi_*(t, x) \leq u(t, x) \leq \varphi^*(t, x), \quad \psi_*(t, x) \leq \partial_t u(t, x) \leq \psi^*(t, x)$$

for all  $t \in [0, T]$  and a.e.  $x \in \Omega$ , where  $\varphi_*, \varphi^*, \psi_*, \psi^* \in L^\infty(0, T; L^2(\Omega))$  (note that we do not identify functions which are equal a.e. in time), and the pointwise condition

$$(5.3) \quad \gamma_*(x) \leq y(t, x) \leq \gamma^*(x) \quad \text{for all } t \in [0, T] \text{ and a.e. } x \in \Omega,$$

where  $\gamma_*, \gamma^*: \Omega \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$ . Note that if  $\gamma_* \equiv -\infty$ ,  $\gamma^* \equiv +\infty$ , then we have not imposed any pointwise condition on  $y$  at all.

Concerning the spaces, we choose  $\mathcal{Z} := H_0^1(\Omega)$ ,  $\mathcal{P} := L^2(\Omega)$  (see Example 4.1) and

$$\mathcal{U} := \{u \in W^{1,\infty}(0, T; L^2(\Omega)) : u \text{ satisfies condition (5.2)}\}.$$

For any  $p \in (1, \infty)$ , consider  $\mathcal{U}$  as a subset of  $W^{1,p}(0, T; L^2(\Omega))$ , and observe that in this space,  $\mathcal{U}$  is weakly closed (since it is strongly closed and convex). Hence, because weak\* convergence in the space  $W^{1,\infty}(0, T; L^2(\Omega))$  implies weak convergence in the space  $W^{1,p}(0, T; L^2(\Omega))$ , the control space  $\mathcal{U}$  is weakly\* closed in  $W^{1,\infty}(0, T; L^2(\Omega))$  (the boundedness allows us to work with sequences). The pointwise restriction (5.3) is weakly closed in  $H_0^1(\Omega)$ , because it only affects the functions itself (and not their gradients) and for these we can assume pointwise a.e. convergence.

The energetic formulation of the partial differential inclusion (5.1) is based on the following functionals:

$$\begin{aligned}\mathcal{E}(t, z; u) &:= \mathcal{W}(z) - \int_{\Omega} u(t, x) z(x) \, dx, \\ \mathcal{W}(z) &:= \int_{\Omega} \frac{a(x)}{2} |\nabla z(x)|^2 + F(x, z(x)) \, dx, \\ \mathcal{D}(z_1, z_2) &:= \int_{\Omega} \kappa(x) |z_2(x) - z_1(x)| \, dx.\end{aligned}$$

For the initial value, we require

$$y_0 \in \mathcal{S}_{\mathcal{W}}(0) = \operatorname{Argmin}\{ \mathcal{W}(\hat{z}) + \mathcal{D}(y_0, \hat{z}) : \hat{z} \in H_0^1(\Omega) \}.$$

While this might still be difficult to verify (note that  $y_0$  also occurs under the integral), by section 4.3, this is exactly the compatibility condition (CC) in our concrete setting. The system, however, self-corrects an inadmissible initial value if necessary, cf. Remark 3.6.

As the cost functional, we choose

$$(5.4) \quad \mathcal{J}(y) := \int_0^T \int_{\Omega} |y(t, x) - w(t, x)|^2 \, dx \, dt,$$

i.e., we want to make the solution follow the function  $w \in L^\infty(0, T; L^2(\Omega))$  (cf. Example 4.10).

By the positivity of  $a(\cdot)$ , it is clear that (W1) holds with  $s = 2$ ,  $\mu > 0$  (the lower bound for  $a(\cdot)$  was  $2\mu$ ), and  $\kappa = 0$ . Condition (W2) follows from the fact that sublevels of  $\mathcal{W}$  must be closed by the weak lower semicontinuity of norms and the term with  $F$  is weakly continuous by Lebesgue's dominated convergence theorem. Hence, Lemma 4.3 implies (A1), (A2), (C1'), (C4), and (C5). From the assumptions on  $\kappa(\cdot)$ ,  $\mathcal{D}(\cdot, 0)$  is an equivalent norm to the norm of  $L^1(\Omega)$  and Remark 4.6 (see also Example 4.7) yields the validity of assumptions (A3) and (C2'). Lemma 3.1 gives (C3).

Finally, our choice for  $\mathcal{J}$  is admissible by Example 4.10. Thus, Theorem 3.4 (also cf. Remark 3.7) shows solvability of the optimal control problem, meaning that there exists an optimal control  $u \in W^{1,\infty}(0, T; L^2(\Omega))$  and a corresponding solution process  $y \in \operatorname{BV}_{\mathcal{D}}([0, T]; L^1(\Omega)) \cap L^\infty(0, T; H_0^1(\Omega))$  fulfilling (5.1)–(5.3), and minimizing the cost functional  $\mathcal{J}$  as defined in (5.4) over all such constrained choices for the control and solution.

**5.2. Stackelberg games and the foreign exchange market.** The optimal control problem (OC) can be viewed as an asymmetric (evolutionary) Stackelberg game, which we can employ to look at a simplistic proof-of-concept model of currency trading.

Set  $\mathcal{Z} := \{ z \in \mathbb{R}^n : z \geq 0 \text{ and } |z|_1 = 1 \}$ , where  $|\cdot|_1$  denotes the 1-norm. We think of  $z \in \mathcal{Z}$  as representing the fractions of a trader's total amount of money, which are invested in one of  $n$  different currencies

Define the *real-value functional*

$$\tilde{\mathcal{E}}(t, z; u) := (r(t) - f(z) + u(t)) \cdot z \quad \text{and} \quad \mathcal{D}(z, \tilde{z}) := \frac{\gamma}{2} |\tilde{z} - z|_1 \quad \text{for } z, \tilde{z} \in \mathbb{R}^n$$

with a (in reality estimated or predicted) *rating function*  $r \in W^{1,\infty}(0, T; \mathbb{R}^n)$  for the currencies ( $r(t)_j > 1$ , the  $j$ th component of  $r(t)$ , means that the currency is undervalued and  $r(t)_j < 1$  means that it is overvalued) and a Lipschitz-continuous *feedback function*  $f \in C(\mathbb{R}^n; \mathbb{R}^n)$  simulating the effect of large buys on the currency's real value (with respect to purchasing power, "the law of one price"). As a simple choice, one can take  $f(z) = cz$  with  $c > 0$  (not too large). Then, buying more currency will make the real value of the currency decrease linearly (adjustment of exchange rates). We assume that  $f$  satisfies the coercivity inequality  $f(z) \cdot z \geq \mu |z|_1^s - \kappa$  for some fixed  $\mu > 0$ ,  $\kappa \geq 0$ ,  $s > 1$ . The control  $u \in \mathcal{U} := \{u \in W^{1,\infty}(0, T; \mathbb{R}^n) : \|u\|_{W^{1,\infty}(0, T; \mathbb{R}^n)} \leq M_{\mathcal{U}}\}$ ,  $M_{\mathcal{U}} > 0$ , represents the external command we have over the market (for example, a central bank can raise or lower interests). Finally, with  $\gamma > 0$  expressing the fractional trading costs (assumed uniform for all currencies),  $\mathcal{D}$  models the total costs when currencies are exchanged.

At each point in time, the  $j$ th component of the vector  $r(t) - f(y(t)) + u(t)$  represents the total value factor of the  $j$ th currency. The currency traders will now want to maximize the value of their money, but taking into account the trading costs. If  $z_0 \in \mathcal{Z}$  is the current state and we are at time  $t \in (0, T]$ , then the traders will always seek to maximize  $\hat{\mathcal{E}}(t, \hat{z}; u) - \mathcal{D}(z_0, \hat{z})$  over all  $\hat{z} \in \mathcal{Z}$ . Setting  $\mathcal{E}(t, z; u) := -\hat{\mathcal{E}}(t, z; u)$  and switching from a maximization to a minimization problem, we arrive at the discrete-time incremental problem (IP). Hence, the energetic formulation (S) and (E) with the functionals  $\mathcal{E}$  and  $\mathcal{D}$  is the continuous-time system that models the described behavior.

We want to exercise our control over the market to reach some objective, for example keeping the real currency values as close to 1 as possible (in the Euclidean sense). The latter goal can be modeled by taking

$$\mathcal{J}(y, u) := \int_0^T |r(t) - f(y(t)) + u(t) - (1, \dots, 1)^T|_2^2 \, dt.$$

It should be noted that if several solutions  $y$  exist for a fixed control  $u$ , then here we "choose" the best one as to minimize our functional. This optimistic view might not be realistic in certain applications. However, if unique solvability of the rate-independent system is guaranteed or if we have another mechanism of forcing the "right" solution, then this problem does not occur. Other cases might lead to saddle point problems and are not considered here.

Just as before, the tools of section 4 are applicable (with  $\mathcal{Z} = \mathcal{P} = \mathbb{R}^n$  and the  $|\cdot|_1$ -norm) and Theorem 3.4 shows solvability of the optimal control problem.

**Appendix. Sobolev–Bochner spaces.** This appendix presents some facts about Sobolev–Bochner spaces. In particular, for the convenience of the reader we prove a rather well-known compactness result in a somewhat more direct fashion than in [26]. For a general reference on these spaces, see, e.g., [25, Chapter 7] and [7, 26].

For a separable, reflexive Banach space  $\mathcal{X}$ , denote by  $L^p(0, T; \mathcal{X})$ ,  $p \in [1, \infty]$ , the space of  $p$ -Bochner-integrable functions with values in  $\mathcal{X}$ . It is well known that for  $p \in [1, \infty)$ , the space  $L^p(0, T; \mathcal{X})$  is separable and  $L^p(0, T; \mathcal{X})^* \cong L^{p'}(0, T; \mathcal{X}^*)$ , where  $1/p + 1/p' = 1$ ; cf. [7, section IV.1].

For a separable, reflexive Banach space  $\mathcal{X}$ , and a separable Banach space  $\mathcal{Y}$  with  $\mathcal{X} \hookrightarrow \mathcal{Y}$ , the *Sobolev–Bochner space*  $W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$ ,  $p \in [1, \infty]$  is defined as

$$W^{1,p}(0, T; \mathcal{X}; \mathcal{Y}) := \{u \in L^p(0, T; \mathcal{X}) : \dot{u} \in L^p(0, T; \mathcal{Y})\},$$

where  $\dot{u}$  is the generalized (or distributional) time-derivative, i.e.,

$$\int_0^T u(t) \dot{\varphi}(t) \, dt = - \int_0^T \dot{u}(t) \varphi(t) \, dt \quad (\text{in } \mathcal{Y}) \quad \text{for all } \varphi \in C_c^\infty(0, T).$$

The space  $W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$  is a Banach space with the norm

$$\|u\|_{W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})} := \begin{cases} \|u\|_{L^p(0, T; \mathcal{X})} + \|\dot{u}\|_{L^p(0, T; \mathcal{Y})} & \text{if } p \in [1, \infty), \\ \max \{ \|u\|_{L^\infty(0, T; \mathcal{X})}, \|\dot{u}\|_{L^\infty(0, T; \mathcal{Y})} \} & \text{if } p = \infty. \end{cases}$$

If  $\mathcal{X} = \mathcal{Y}$ , we write  $W^{1,p}(0, T; \mathcal{X})$  for  $W^{1,p}(0, T; \mathcal{X}; \mathcal{X})$ . If there is another Banach space  $\mathcal{Y}$  with  $\mathcal{X} \hookrightarrow \mathcal{Y}$ , it is obvious that  $W^{1,p}(0, T; \mathcal{X}) \hookrightarrow W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$ .

For  $p \in (1, \infty)$  and  $\mathcal{X}, \mathcal{Y}$  reflexive, by identifying  $W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$  with a closed subspace of the product  $L^p(0, T; \mathcal{X}) \times L^p(0, T; \mathcal{Y})$  of reflexive Banach spaces [7, Bemerkung IV.1.11], one easily sees that  $W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$  is reflexive. Weak convergence  $u_n \rightharpoonup u$  of a sequence  $(u_n)_n \subseteq W^{1,p}(0, T; \mathcal{X}; \mathcal{Y})$ ,  $p \in (1, \infty)$ , means that  $u_n \rightharpoonup u$  in  $L^p(0, T; \mathcal{X})$  and  $\dot{u}_n \rightharpoonup \dot{u}$  in  $L^p(0, T; \mathcal{Y})$ . For  $p = \infty$ ,  $u_n \overset{*}{\rightharpoonup} u$  in  $W^{1,\infty}(0, T; \mathcal{X}; \mathcal{Y})$  means  $u_n \overset{*}{\rightharpoonup} u$  in  $L^\infty(0, T; \mathcal{X})$  and  $\dot{u}_n \overset{*}{\rightharpoonup} \dot{u}$  in  $L^\infty(0, T; \mathcal{Y})$ .

For  $p' \in (1, \infty]$ , norm-bounded sets in  $W^{1,p'}(0, T; \mathcal{X}^*)$  are weakly (weakly\* if  $p' = \infty$ ) relatively compact. More precisely, let  $(u_n)_n \subseteq W^{1,p'}(0, T; \mathcal{X}^*)$  be bounded. Then, since  $L^p(0, T; \mathcal{X})$  is the separable predual to  $L^{p'}(0, T; \mathcal{X}^*)$ , where  $1/p + 1/p' = 1$ , there exists a subsequence (not relabelled) such that  $u_n \rightharpoonup u$  ( $u_n \overset{*}{\rightharpoonup} u$ ) and  $\dot{u} \rightharpoonup v$  ( $\dot{u} \overset{*}{\rightharpoonup} v$ ) in  $L^{p'}(0, T; \mathcal{X}^*)$  and an integration by parts shows  $v = \dot{u}$ .

The following lemma shows how we can deduce uniform (strong) convergence from  $L^p$ -convergence if the involved functions are uniformly equicontinuous.

**LEMMA A.1.** *Let  $\mathcal{X}$  be a Banach space, and let  $(u_n)_n \subseteq C([0, T]; \mathcal{X})$ ,  $n \in \mathbb{N} \cup \{\infty\}$ , be a sequence of uniformly equicontinuous functions, i.e., for all  $\varepsilon > 0$  we can find  $\delta > 0$  such that*

$$\|u_n(s) - u_n(r)\|_{\mathcal{X}} < \varepsilon \quad \text{for all } n \in \mathbb{N}_\infty \text{ and } r, s \in [0, T] \text{ with } |s - r| < \delta.$$

*Then, for all  $p \in [1, \infty]$ ,  $u_n \rightarrow u_\infty$  in  $L^p(0, T; \mathcal{X})$  implies  $u_n \rightarrow u_\infty$  in  $C([0, T]; \mathcal{X})$ .*

*Proof.* The case  $p = \infty$  is trivial; therefore let  $p \in [1, \infty)$ . By contradiction, assume that there exists a (sub)sequence  $(t_n)_n \subseteq [0, T]$  such that  $\|u_\infty(t_n) - u_n(t_n)\|_{\mathcal{X}} \geq 3\varepsilon > 0$  for all  $n \in \mathbb{N}$ . As  $[0, T]$  is compact, we can assume without loss of generality that  $t_n \rightarrow t \in [0, T]$ . By equicontinuity, choose  $\delta \in (0, T)$  such that

$$\|u_n(s) - u_n(r)\|_{\mathcal{X}} \leq \varepsilon$$

for all  $n \in \mathbb{N}_\infty$  and all  $r, s \in [0, T]$  with  $|s - r| < \delta$ . For  $n$  so large that  $|t - t_n| < \delta/2$  and all  $s \in [0, T]$  with  $|s - t| < \delta/2$ , in particular  $|s - t_n| < \delta$ , it holds that

$$\begin{aligned} \|u_n(s) - u_\infty(s)\|_{\mathcal{X}} &\geq \left\| (u_n(s) - u_n(t_n)) - (u_\infty(s) - u_\infty(t_n)) \right\|_{\mathcal{X}} \\ &\quad - \|u_\infty(t_n) - u_n(t_n)\|_{\mathcal{X}} \geq \varepsilon. \end{aligned}$$

Hence,

$$\begin{aligned} \|u_n - u_\infty\|_{L^p(0, T; \mathcal{X})}^p &= \int_0^T \|u_n(\tau) - u_\infty(\tau)\|_{\mathcal{X}}^p \, d\tau \\ &\geq \int_{\max\{t-\delta/2, 0\}}^{\min\{t+\delta/2, T\}} \|u_n(\tau) - u_\infty(\tau)\|_{\mathcal{X}}^p \, d\tau \geq \frac{\delta \varepsilon^p}{2}, \end{aligned}$$

contradicting  $\|u_n - u_\infty\|_{L^p(0,T;\mathcal{X})} \rightarrow 0$ .  $\square$

Applying this lemma, we can show the compact embedding  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \xhookrightarrow{c} C([0,T];\mathcal{X})$  if  $\mathcal{X} \xhookrightarrow{c} \mathcal{Y}$ .

PROPOSITION A.2. *If  $\mathcal{X} \xhookrightarrow{c} \mathcal{Y}$ , then it holds that  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \xhookrightarrow{c} C([0,T];\mathcal{Y})$  for all  $p \in (1, \infty]$ .*

*Proof.* It is a well-known fact that  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \hookrightarrow C([0,T];\mathcal{Y})$ ; see, e.g., [25, Lemma 7.1]. The continuous representative of  $v \in W^{1,p}(0,T;\mathcal{X};\mathcal{Y})$  is given through

$$\tilde{v}(t) = \tilde{v}(0) + \int_0^t v'(\tau) \, d\tau \quad (\in \mathcal{Y})$$

(note that  $v' \in L^1(0,T;\mathcal{Y})$  by the Hölder inequality, and that  $\tilde{v}(0)$  has a sense with respect to the continuous representative). We therefore have

$$(A.1) \quad \|\tilde{v}(t) - \tilde{v}(s)\|_{\mathcal{Y}} \leq \int_s^t \|v'(\tau)\|_{\mathcal{Y}} \, d\tau \leq (t-s)^{(p-1)/p} \|v'\|_{L^p(0,T;\mathcal{Y})},$$

by the Hölder inequality.

Since the space  $C([0,T];\mathcal{Y})$  is metric, it suffices to work with sequences to show the compact embedding. Therefore let  $(v_n)_n$  be a bounded sequence in  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y})$ . The Aubin–Lions lemma [25, Lemma 7.7] applied to the inclusions  $\mathcal{X} \xhookrightarrow{c} \mathcal{Y} \hookrightarrow \mathcal{Y}$  shows  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \xhookrightarrow{c} L^p(0,T;\mathcal{Y})$ ; hence, we can select a subsequence (not relabelled) such that  $v_n \rightarrow v$  (strongly) in  $L^1(0,T;\mathcal{X})$ . The last estimate (A.1) shows that the sequence  $(v_n)_n$  and its limit  $v$  are uniformly equicontinuous. Now, Lemma A.1 implies  $v_n \rightarrow v$  (strongly) in  $C([0,T];\mathcal{Y})$ . Hence, the compact embedding  $W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \xhookrightarrow{c} C([0,T];\mathcal{Y})$  holds.  $\square$

In the situation of the preceding proposition, it is clear that  $W^{1,p}(0,T;\mathcal{X}) \hookrightarrow W^{1,p}(0,T;\mathcal{X};\mathcal{Y}) \xhookrightarrow{c} C([0,T];\mathcal{Y})$ , and hence the result also holds for  $W^{1,p}(0,T;\mathcal{X})$ .

## THE MODIFIED OPTIMAL $\mathcal{H}_\infty$ CONTROL PROBLEM FOR DESCRIPTOR SYSTEMS\*

PHILIP LOSSE<sup>†</sup>, VOLKER MEHRMANN<sup>‡</sup>, LISA KATRIN POPPE<sup>‡</sup>, AND TIMO REIS<sup>‡</sup>

**Abstract.** The  $\mathcal{H}_\infty$  control problem is studied for linear constant coefficient descriptor systems. Necessary and sufficient optimality conditions are derived for systems of arbitrary index. These conditions are formulated in terms of deflating subspaces of even matrix pencils containing only the parameters of the original system. It is shown that this approach leads to a more numerically robust and efficient method in computing the optimal value  $\gamma$  in contrast to other methods such as the widely used Riccati- and linear matrix inequality (LMI)-based approaches. The results are illustrated by a numerical example.

**Key words.** descriptor system,  $\mathcal{H}_\infty$  control, algebraic Riccati equation, even matrix pencil,  $\gamma$ -iteration, deflating subspace

**DOI.** 10.1137/070710093

**1. Introduction.** Solving the optimal infinite-horizon output (or measurement) feedback  $\mathcal{H}_\infty$  control problem is one of the central tasks in robust control; see, e.g., [16, 19, 28, 39, 40]. For standard state space systems, where the dynamics of the system is modeled by a linear constant coefficient ordinary differential equation (ODE), the analysis of this problem is well studied [10] and numerical methods have been developed and integrated in control software packages such as [5, 20, 1, 29]. These methods work well for a wide range of problems in computing close to optimal (sub-optimal) controllers, but the exact computation of the optimal value  $\gamma$  in  $\mathcal{H}_\infty$  control is considered a challenge [8]. In order to avoid some of the numerical difficulties that arise when approaching the optimum, in [3, 4] several improvements in the previously known methods were presented. These are based on the solution of structured eigenvalue problems with structured methods.

In this paper we study the more general case that the dynamics is constrained, i.e., described by a *differential-algebraic equation (DAE)* or *descriptor system*. Descriptor systems arise in the control of constrained mechanical systems (see, e.g., [12, 30, 35, 36, 37]), in electrical circuit simulation (see, e.g., [18, 17]), and in particular in heterogeneous systems, where different models are coupled [27].

Robust control for descriptor systems has been studied in [31, 32, 33] using linear matrix inequalities (LMIs) and in [38] via generalized Riccati equations and  $J$ -spectral factorization. In contrast to these approaches, we extend the analysis and the robust numerical methods that were derived via deflating subspaces in [3, 4]. We discuss

descriptor systems of the form

$$(1.1) \quad \mathbf{P} : \begin{aligned} E\dot{x}(t) &= Ax(t) + B_1w(t) + B_2u(t), & x(t_0) &= x^0, \\ z(t) &= C_1x(t) + D_{11}w(t) + D_{12}u(t), \\ y(t) &= C_2x(t) + D_{21}w(t) + D_{22}u(t), \end{aligned}$$

where  $E, A \in \mathbb{R}^{n,n}$ ,  $B_i \in \mathbb{R}^{n,m_i}$ ,  $C_i \in \mathbb{R}^{p_i,n}$ , and  $D_{ij} \in \mathbb{R}^{p_i,m_j}$  for  $i, j = 1, 2$ . (Here, by  $\mathbb{R}^{k,l}$  we denote the set of real  $k \times l$  matrices.)

In this system,  $x(t) \in \mathbb{R}^n$  is the state vector,  $u(t) \in \mathbb{R}^{m_2}$  is the control input vector, and  $w(t) \in \mathbb{R}^{m_1}$  is an exogenous input that may include noise, linearization errors, and unmodeled dynamics. The vector  $y(t) \in \mathbb{R}^{p_2}$  contains measured outputs, while  $z(t) \in \mathbb{R}^{p_1}$  is a regulated output or an estimation error. Our approach can also be extended to rectangular systems, and systems in behavior formulation, using a remodeling, as was suggested in [23, 22] (see also [24]), but here we study only the formulation in (1.1).

The optimal  $\mathcal{H}_\infty$  control problem is typically formulated in a frequency domain. For this we need the following notation. The space  $\mathcal{H}_\infty^{p,m}$  consists of all  $\mathbb{C}^{p,m}$ -valued functions that are analytic and bounded in the complex half-plane

$$\mathbb{C}^+ = \{s \in \mathbb{C} : \operatorname{Re}(s) > 0\}.$$

For  $F \in \mathcal{H}_\infty^{p,m}$  the  $\mathcal{H}_\infty$ -norm is given by

$$\|F\|_\infty = \sup_{s \in \mathbb{C}^+} \sigma_{\max}(F(s)),$$

where  $\sigma_{\max}(F(s))$  denotes the maximal singular value of the matrix  $F(s)$ .

In robust control,  $\|F\|_\infty$  is used as a measure of the worst-case influence of the disturbances  $w$  on the output  $z$ , where in this case  $F$  is the transfer function mapping noise or disturbance inputs to error signals [40].

Solving the optimal  $\mathcal{H}_\infty$  control problem is the task of designing a dynamic controller, as presented in Figure 1.1, that minimizes (or at least approximately minimizes) this measure.

FIG. 1.1. Interconnection with controller.

Put more rigorously, the optimal  $\mathcal{H}_\infty$  control problem is the following.

DEFINITION 1.1 (the optimal  $\mathcal{H}_\infty$  control problem). *For the descriptor system (1.1), determine a controller (dynamic compensator)*

$$(1.2) \quad \mathbf{K} : \begin{aligned} \hat{E}\dot{\hat{x}}(t) &= \hat{A}\hat{x}(t) + \hat{B}y(t), \\ u(t) &= \hat{C}\hat{x}(t) + \hat{D}y(t) \end{aligned}$$

with  $\hat{E}, \hat{A} \in \mathbb{R}^{N,N}$ ,  $\hat{B} \in \mathbb{R}^{N,p_2}$ ,  $\hat{C} \in \mathbb{R}^{m_2,N}$ ,  $\hat{D} \in \mathbb{R}^{m_2,p_2}$ , and transfer function  $K(s) = \hat{C}(s\hat{E} - \hat{A})^{-1}\hat{B} + \hat{D}$  such that the closed-loop system resulting from the combination of (1.1) and (1.2), that is,

$$\begin{aligned} E\dot{x}(t) &= (A + B_2\hat{D}Z_1C_2)x(t) + (B_2Z_2\hat{C})\hat{x}(t) + (B_1 + B_2\hat{D}Z_1D_{21})w(t), \\ (1.3) \quad \hat{E}\dot{\hat{x}}(t) &= \hat{B}Z_1C_2x(t) + (\hat{A} + \hat{B}Z_1D_{22}\hat{C})\hat{x}(t) + \hat{B}Z_1D_{21}w(t), \\ z(t) &= (C_1 + D_{12}Z_2\hat{D}C_2)x(t) + D_{12}Z_2\hat{C}\hat{x}(t) + (D_{11} + D_{12}\hat{D}Z_1D_{21})w(t) \end{aligned}$$

with  $Z_1 = (I_{p_2} - D_{22}\hat{D})^{-1}$  and  $Z_2 = (I_{m_2} - \hat{D}D_{22})^{-1}$ , has the following properties:

- (1) System (1.3) is internally stable; that is, the solution  $\begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix}$  of the system with  $w \equiv 0$  is asymptotically stable, i.e.,  $\lim_{t \rightarrow \infty} \begin{bmatrix} x(t) \\ \hat{x}(t) \end{bmatrix} = 0$ .
- (2) The closed-loop transfer function  $T_{zw}(s)$  from  $w$  to  $z$  satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  and is minimized in the  $\mathcal{H}_\infty$ -norm.

In principle, there is no restriction on the dimension  $N$  of the auxiliary state  $\hat{x}$  in (1.2), although smaller dimensions  $N$  are preferred for practical implementation and computation.

As in the case of the optimal  $\mathcal{H}_\infty$  control problems for ordinary state space systems, it is also necessary to study two closely related optimization problems, the modified optimal  $\mathcal{H}_\infty$  control problem and the suboptimal  $\mathcal{H}_\infty$  control problem.

**DEFINITION 1.2** (the modified optimal  $\mathcal{H}_\infty$  control problem). *For the descriptor system (1.1) let  $\Gamma$  be the set of positive real numbers  $\gamma$  for which there exists an internally stabilizing dynamic controller of the form (1.2) so that the transfer function  $T_{zw}(s)$  of the closed-loop system (1.3) satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  with  $\|T_{zw}\|_\infty < \gamma$ . Determine  $\gamma_{mo} = \inf \Gamma$ . If no internally stabilizing dynamic controller exists, we set  $\Gamma = \emptyset$  and  $\gamma_{mo} = \infty$ .*

Note that it is possible that there is no internally stabilizing dynamic controller with the property  $\|T_{zw}\|_\infty = \gamma_{mo}$ . In this case one solves the suboptimal  $\mathcal{H}_\infty$  control problem.

**DEFINITION 1.3** (the suboptimal  $\mathcal{H}_\infty$  control problem). *For the descriptor system (1.1) and  $\gamma \in \Gamma$  with  $\gamma > \gamma_{mo}$ , determine an internally stabilizing dynamic controller of the form (1.2) such that the closed-loop transfer function satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  with  $\|T_{zw}\|_\infty < \gamma$ . We call such a controller a  $\gamma$ -suboptimal controller or simply a suboptimal controller.*

The outline of the paper is as follows. In the forthcoming section we present the notation and some definitions that are used throughout the paper. Section 3 contains the main result of the paper and states conditions for the existence of an appropriate controller in terms of deflating subspaces of matrix pencils. The proof is given in three parts. First, we briefly discuss the standard state space case. The results are then generalized to descriptor systems of index 1 and, thereafter, to systems with arbitrary index. In section 4 we illustrate the presented theory by means of a numerical example.

**2. Preliminaries.** In this section we introduce some notation and definitions. For symmetric matrices  $A$  and  $B$ , by  $A \geq B$  and  $A > B$  we denote that  $A - B$  is positive semidefinite and positive definite, respectively. The spectral radius of a matrix  $A \in \mathbb{R}^{n,n}$  is denoted by  $\rho(A)$ . The set of complex numbers with positive real part is denoted by  $\mathbb{C}^+$  and the set of positive real numbers by  $\mathbb{R}^+$ .

Let  $\lambda E - A$  be a matrix pencil with  $E, A \in \mathbb{R}^{n,n}$ . Then  $\lambda E - A$  is called *regular* if  $\det(\lambda E - A) \neq 0$  for some  $\lambda \in \mathbb{C}$ .

A pencil  $P(\lambda) = \lambda E - A$  is called *even* if  $P(-\lambda)^T = P(\lambda)$ , i.e., if  $E = -E^T$  and  $A = A^T$ .

For regular pencils, *generalized eigenvalues* are the pairs  $(\alpha, \beta) \in \mathbb{C}^2 \setminus \{(0, 0)\}$  for which  $\det(\alpha E - \beta A) = 0$ . If  $\beta \neq 0$ , then the pair represents the finite eigenvalue  $\lambda = \alpha/\beta$ . If  $\beta = 0$ , then  $(\alpha, \beta)$  represent the eigenvalue infinity. In the following we use the notation with  $\lambda$ .

The solution and many properties of the *free descriptor system* (with  $u, w = 0$ ) can be characterized in terms of the *Weierstrass canonical form* (WCF).

**THEOREM 2.1** (see [13]). *For a regular matrix pencil  $\lambda E - A$ , there exist matrices  $W_f, V_f \in \mathbb{R}^{n_f, n_f}$ ,  $W_\infty, V_\infty \in \mathbb{R}^{n_\infty, n_\infty}$  with the property that  $W = \begin{bmatrix} W_f & W_\infty \end{bmatrix}$ ,  $V = \begin{bmatrix} V_f & V_\infty \end{bmatrix}$  are square and invertible, with*

$$(2.1a) \quad W^T E V = \begin{bmatrix} W_f^T \\ W_\infty^T \end{bmatrix} E \begin{bmatrix} V_f & V_\infty \end{bmatrix} = \begin{bmatrix} I_{n_f} & 0 \\ 0 & N \end{bmatrix},$$

$$(2.1b) \quad W^T A V = \begin{bmatrix} W_f^T \\ W_\infty^T \end{bmatrix} A \begin{bmatrix} V_f & V_\infty \end{bmatrix} = \begin{bmatrix} A_f & 0 \\ 0 & I_{n_\infty} \end{bmatrix},$$

$A_f \in \mathbb{R}^{n_f, n_f}$  is in real Jordan canonical form, and  $N \in \mathbb{R}^{n_\infty, n_\infty}$  is a nilpotent matrix, also in Jordan canonical form. We call  $n_f, n_\infty$  the number of finite or infinite eigenvalues, respectively.

The index of nilpotency of the nilpotent matrix  $N$  in (2.1a) is called the *index* of the system, and if  $E$  is nonsingular, then the pencil is said to have *index zero*.

**DEFINITION 2.2.** *A subspace  $\mathcal{L} \subset \mathbb{R}^n$  is called a deflating subspace for the pencil  $\lambda E - A$  if for a matrix  $X_{\mathcal{L}} \in \mathbb{R}^{n, k}$  with full column rank and  $\text{im } X_{\mathcal{L}} = \mathcal{L}$  there exist matrices  $Y_{\mathcal{L}} \in \mathbb{R}^{n, k}$ ,  $R_{\mathcal{L}} \in \mathbb{R}^{k, k}$ , and  $U_{\mathcal{L}} \in \mathbb{R}^{k, k}$  such that*

$$(2.2) \quad EX_{\mathcal{L}} = Y_{\mathcal{L}}R_{\mathcal{L}}, \quad AX_{\mathcal{L}} = Y_{\mathcal{L}}U_{\mathcal{L}}.$$

*A deflating subspace  $\mathcal{L}$  of  $\lambda E - A$  is called stable (semistable) if all finite eigenvalues of  $\lambda R_{\mathcal{L}} - U_{\mathcal{L}}$  are in the open (closed) left half-plane.*

*Let  $\mathcal{J} = \begin{bmatrix} 0 & I_n \\ -I_n & 0 \end{bmatrix}$ , where  $I_n$  is the  $n \times n$  identity matrix. A subspace  $\mathcal{L} \subset \mathbb{R}^{2n}$  is called isotropic if  $x^T \mathcal{J} y = 0$  for all  $x, y \in \mathcal{L}$ . An isotropic subspace with  $\dim \mathcal{L} = n$  is called Lagrangian.*

In the notation of (2.1a)–(2.1b) with

$$(2.3) \quad B_{i,f} = W_f^T B_i, \quad B_{i,\infty} = W_\infty^T B_i, \quad C_{i,f} = C_i V_f, \quad C_{i,\infty} = C_i V_\infty, \quad i = 1, 2,$$

classical solutions of (1.2) take the form  $x(t) = V_f x_f(t) + V_\infty x_\infty(t)$ , where  $x_f$  and  $x_\infty$  satisfy

$$(2.4a) \quad \dot{x}_f(t) = A_f x_f(t) + B_{1,f} w(t) + B_{2,f} u(t),$$

$$(2.4b) \quad N \dot{x}_\infty(t) = x_\infty(t) + B_{1,\infty} w(t) + B_{2,\infty} u(t).$$

If the pencil  $\lambda E - A$  has index  $\nu$ , then this system has the explicit solution

$$(2.5a) \quad x_f(t) = e^{A_f(t-t_0)} x_f(t_0) + \int_{t_0}^t e^{A_f(t-\tau)} (B_{1,f} w(\tau) + B_{2,f} u(\tau)) d\tau,$$

$$(2.5b) \quad x_\infty(t) = - \sum_{i=0}^{\nu-1} \frac{d^i}{dt^i} N^i (B_{1,\infty} w(t) + B_{2,\infty} u(t)).$$

In contrast to standard state space systems, this shows that the initial condition  $x_\infty(t_0)$  is restricted by (2.5b). Moreover, if  $\nu > 1$ , then the solution will depend on derivatives of the input  $u$  and the disturbance  $w$ .

Note further that for the closed-loop system (1.3) to be *internally stable*, the controller has to be designed so that both  $x_f$  and  $x_\infty$  are asymptotically stable. While for the finite part this can be guaranteed if the spectrum of the matrix  $A_f$  lies in the open left half-plane, for the infinite part this has to be explicitly achieved by the construction of the controller.

As in the case of standard state space systems, certain conditions will be needed to guarantee the existence of optimal  $\mathcal{H}_\infty$  controls. First, these are stabilizability and detectability conditions, which for descriptor systems are the following; see [6, 9].

DEFINITION 2.3. Let  $E, A \in \mathbb{R}^{n,n}$ ,  $B \in \mathbb{R}^{n,m}$ , and  $C \in \mathbb{R}^{p,n}$ . Further, let  $T_\infty, S_\infty$  be matrices with  $\text{im } T_\infty = \ker E^T$  and  $\text{im } S_\infty = \ker E$ .

- (i) The triple  $(E, A, B)$  is called *finite dynamics stabilizable* if  $\text{rank}[\lambda E - A, B] = n$  for all  $\lambda \in \mathbb{C}^+$ ;
- (ii)  $(E, A, B)$  is *impulse controllable* if  $\text{rank}[E, AS_\infty, B] = n$ ;
- (iii)  $(E, A, B)$  is *strongly stabilizable* if it is both *finite dynamics stabilizable* and *impulse controllable*;
- (iv) the triple  $(E, A, C)$  is *finite dynamics detectable* if  $\text{rank}[\lambda E^T - A^T, C^T] = n$  for all  $\lambda \in \mathbb{C}^+$ ;
- (v)  $(E, A, C)$  is *impulse observable* if  $\text{rank}[E^T, A^T T_\infty, C^T] = n$ ;
- (vi)  $(\lambda E - A, C)$  is *strongly detectable* if it is both *finite dynamics detectable* and *impulse observable*.

After introducing our notation and giving some preliminary results, in the next section we derive the theoretical basis for the optimal  $\mathcal{H}_\infty$  control problem for descriptor systems.

**3. The modified optimal  $\mathcal{H}_\infty$  control problem.** In this section we approach the problem of determining  $\gamma_{mo}$  for a given system (1.1). As in the case of standard state space systems (see [16, 19, 28, 40]), we need several assumptions on the system matrices. In the following we set  $r = \text{rank } E$ .

*Assumptions.*

- (A1) The triple  $(E, A, B_2)$  is strongly stabilizable and the triple  $(E, A, C_2)$  is strongly detectable; see Definition 2.3.
- (A2)  $\text{rank} \begin{bmatrix} A - i\omega E & B_2 \\ C_1 & D_{12} \end{bmatrix} = n + m_2$  for all  $\omega \in \mathbb{R}$ .
- (A3)  $\text{rank} \begin{bmatrix} A - i\omega E & B_1 \\ C_2 & D_{21} \end{bmatrix} = n + p_2$  for all  $\omega \in \mathbb{R}$ .
- (A4) For matrices  $T_\infty, S_\infty \in \mathbb{R}^{n,n-r}$  with  $\text{im } S_\infty = \ker E$  and  $\text{im } T_\infty = \ker E^T$ , the following hold:

$$\begin{aligned} \text{rank} \begin{bmatrix} T_\infty^T AS_\infty & T_\infty^T B_2 \\ C_1 S_\infty & D_{12} \end{bmatrix} &= n + m_2 - r, \\ \text{rank} \begin{bmatrix} T_\infty^T AS_\infty & T_\infty^T B_1 \\ C_2 S_\infty & D_{21} \end{bmatrix} &= n + p_1 - r. \end{aligned}$$

It is well known for standard state space systems that assumption (A1) is essential for the existence of a controller that internally stabilizes the system. We will see that a similar result holds for the descriptor case. Assumptions (A2) and (A3) correspond to the typical claim that the system does not have transmission zeros on the imaginary axis. This is assumed in many works about  $\mathcal{H}_\infty$  control of standard state space

systems, since eigenvalues on the imaginary axis of the Hamiltonian matrices that are used in the computation of an optimal controller usually lead to problems in the computation of a semistable subspace; see [26, 34].

Further typical assumptions in the  $\mathcal{H}_\infty$  control of standard state space systems are that  $D_{12}, D_{21}^T$  have full column rank; see [19, 28, 40]. The conditions in (A4) reduce to these rank conditions if  $E$  is invertible.

For the construction of optimal or suboptimal controllers, we will make use of the following two even matrix pencils, which generalize the pencils constructed in [3, 4]. Let

$$(3.1) \quad \lambda N_H + M_H(\gamma) = \left[ \begin{array}{cc|ccc} 0 & -\lambda E^T - A^T & 0 & 0 & -C_1^T \\ \lambda E - A & 0 & -B_1 & -B_2 & 0 \\ \hline 0 & -B_1^T & -\gamma^2 I_{m_1} & 0 & -D_{11}^T \\ 0 & -B_2^T & 0 & 0 & -D_{12}^T \\ -C_1 & 0 & -D_{11} & -D_{12} & -I_{p_1} \end{array} \right]$$

and

$$(3.2) \quad \lambda N_J + M_J(\gamma) = \left[ \begin{array}{cc|ccc} 0 & -\lambda E - A & 0 & 0 & -B_1 \\ \lambda E^T - A^T & 0 & -C_1^T & -C_2^T & 0 \\ \hline 0 & -C_1 & -\gamma^2 I_{p_1} & 0 & -D_{11} \\ 0 & -C_2 & 0 & 0 & -D_{21} \\ -B_1^T & 0 & -D_{11}^T & -D_{21}^T & -I_{m_1} \end{array} \right].$$

Our approach is based on considering deflating subspaces of the matrix pencils (3.1) and (3.2), where the subspaces are spanned by the columns of the matrices  $X_H$  and  $X_J$  that are partitioned conformably with the pencils, i.e.,

$$(3.3) \quad X_H(\gamma) = \begin{bmatrix} X_{H,1}(\gamma) \\ X_{H,2}(\gamma) \\ X_{H,3}(\gamma) \\ X_{H,4}(\gamma) \\ X_{H,5}(\gamma) \end{bmatrix}, \quad X_J(\gamma) = \begin{bmatrix} X_{J,1}(\gamma) \\ X_{J,2}(\gamma) \\ X_{J,3}(\gamma) \\ X_{J,4}(\gamma) \\ X_{J,5}(\gamma) \end{bmatrix},$$

with

$$\begin{aligned} X_{H,1}(\gamma), X_{H,2}(\gamma), X_{J,1}(\gamma), X_{J,2}(\gamma) &\in \mathbb{R}^{n,r}, & X_{H,4}(\gamma) &\in \mathbb{R}^{m_2,r}, \\ X_{J,4}(\gamma) &\in \mathbb{R}^{p_2,r}, & X_{H,3}(\gamma), X_{J,5}(\gamma) &\in \mathbb{R}^{m_1,r}, & X_{H,5}(\gamma), X_{J,3}(\gamma) &\in \mathbb{R}^{p_1,r}. \end{aligned}$$

We extend the results in [3, 4] to general descriptor systems and use deflating subspaces of the even pencils (3.1) and (3.2) to characterize the elements of the set  $\Gamma$  in Definition 1.1. For this we introduce the following conditions which will be necessary for the existence of a controller with the desired properties associated with a parameter  $\gamma \in \Gamma$ .

- (C1) The index of both pencils (3.1) and (3.2) is at most one.
- (C2) There exists a matrix  $X_H(\gamma)$  as in (3.3) such that
  - (C2.a) the space  $\text{im } X_H(\gamma)$  is a semistable deflating subspace of  $\lambda N_H + M_H(\gamma)$  and  $\text{im} \begin{bmatrix} E X_{H,1} \\ X_{H,2} \end{bmatrix}$  is an  $r$ -dimensional isotropic subspace of  $\mathbb{R}^{2n}$ ;
  - (C2.b)  $\text{rank } E X_{H,1}(\gamma) = r$ .

(C3) There exists a matrix  $X_J(\gamma)$  as in (3.3) such that

(C3.a) the space  $\text{im } X_J(\gamma)$  is a semistable deflating subspace of  $\lambda N_J + M_J(\gamma)$  and  $\text{im} \begin{bmatrix} E^T X_{J,1} \\ X_{J,2} \end{bmatrix}$  is an  $r$ -dimensional isotropic subspace of  $\mathbb{R}^{2n}$ ;

(C3.b)  $\text{rank } E^T X_{J,1}(\gamma) = r$ .

Based on these conditions on the pencils, we introduce the following sets.

DEFINITION 3.1. Consider system (1.1) and the associated even pencils  $\lambda N_H + M_H(\gamma)$  in (3.1) and  $\lambda N_J + M_J(\gamma)$  in (3.2). Define the sets

$$\Gamma_H = \{\gamma \in \mathbb{R}^+ \mid \text{the index of } \lambda N_H + M_H(\gamma) \text{ is greater than one}\},$$

$$\Gamma_J = \{\gamma \in \mathbb{R}^+ \mid \text{the index of } \lambda N_J + M_J(\gamma) \text{ is greater than one}\},$$

and set  $\hat{\gamma}_H = \sup \Gamma_H$ ,  $\hat{\gamma}_J = \sup \Gamma_J$ , and  $\hat{\gamma} = \max\{\hat{\gamma}_H, \hat{\gamma}_J\}$ .

Note that, in general, the sets  $\Gamma_H$  and  $\Gamma_J$  may be all of  $\mathbb{R}^+$ , but as we will show later it follows from assumptions (A1)–(A4) that  $\hat{\gamma}_H$  and  $\hat{\gamma}_J$ , and therefore also  $\hat{\gamma}$  are finite. If  $\gamma > \hat{\gamma}$  then, since both  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  have index at most one, it follows that these pencils have  $2r$  finite eigenvalues, where  $r = \text{rank } E$ . Due to the fact that the pencils are even, and thus the eigenvalues occur in pairs  $\lambda, -\lambda$  (see [25]), it follows that there exist at least  $r$  eigenvalues in the closed left half-complex plane and at most  $r$  eigenvalues in the open left half-plane.

The next group of sets is related to conditions (C2.a) and (C2.b).

DEFINITION 3.2. Consider (1.1) and the associated even pencils  $\lambda N_H + M_H(\gamma)$  in (3.1) and  $\lambda N_J + M_J(\gamma)$  in (3.2). Define the sets

$$\Gamma_H^L = \{\gamma \geq \hat{\gamma} \mid \text{the pencil } \lambda N_H + M_H(\gamma) \text{ satisfies (C2.a)}\},$$

$$\Gamma_J^L = \{\gamma \geq \hat{\gamma} \mid \text{the pencil } \lambda N_J + M_J(\gamma) \text{ satisfies (C3.a)}\}, \quad \Gamma^L = \Gamma_J^L \cap \Gamma_H^L,$$

$$\Gamma_H^R = \{\gamma \geq \hat{\gamma} \mid \text{the pencil } \lambda N_H + M_H(\gamma) \text{ satisfies (C2)}\},$$

$$\Gamma_J^R = \{\gamma \geq \hat{\gamma} \mid \text{the pencil } \lambda N_J + M_J(\gamma) \text{ satisfies (C3)}\}, \quad \Gamma^R = \Gamma_J^R \cap \Gamma_H^R,$$

and set

$$\begin{aligned} \hat{\gamma}_H^L &= \inf \Gamma_H^L, & \hat{\gamma}_J^L &= \inf \Gamma_J^L, & \hat{\gamma}^L &= \inf \Gamma^L, \\ \hat{\gamma}_H^R &= \inf \Gamma_H^R, & \hat{\gamma}_J^R &= \inf \Gamma_J^R, & \hat{\gamma}^R &= \inf \Gamma^R. \end{aligned}$$

For the numerical method to compute the optimal or suboptimal  $\mathcal{H}_\infty$ , it will turn out to be essential to figure out these extremal values. Finally, we discuss the situation of finite purely imaginary eigenvalues.

DEFINITION 3.3. Consider (1.1) and the associated even pencils  $\lambda N_H + M_H(\gamma)$  in (3.1) and  $\lambda N_J + M_J(\gamma)$  in (3.2). Define the sets

$$\Gamma_H^I = \left\{ \gamma \geq \hat{\gamma} \mid \begin{array}{l} \text{the pencil } \lambda N_H + M_H(\gamma) \text{ has at least one} \\ \text{finite eigenvalue on the imaginary axis} \end{array} \right\},$$

$$\Gamma_J^I = \left\{ \gamma \geq \hat{\gamma} \mid \begin{array}{l} \text{the pencil } \lambda N_J + M_J(\gamma) \text{ has at least one} \\ \text{finite eigenvalue on the imaginary axis} \end{array} \right\}, \quad \Gamma^I = \Gamma_J^I \cap \Gamma_H^I,$$

and set

$$\hat{\gamma}_H^I = \inf \Gamma_H^I, \quad \hat{\gamma}_J^I = \inf \Gamma_J^I, \quad \hat{\gamma}^I = \inf \Gamma^I.$$

In the case where  $\Gamma_H^I$ ,  $\Gamma_J^I$ , or  $\Gamma^I$  is empty, we set  $\hat{\gamma}_H^I = \infty$ ,  $\hat{\gamma}_J^I = \infty$ , or  $\hat{\gamma}^I = \infty$ , respectively.

As in the classical  $\mathcal{H}_\infty$  control problem for state space systems (see [4]), we also need some further rank conditions, which are characterized in the following theorem that is proved in full generality in subsection 3.3.

**THEOREM 3.4.** *Consider a system of the form (1.1) satisfying assumptions (A1)–(A4). Let  $X_H(\gamma)$  and  $X_J(\gamma)$  be deflating subspace matrices of the form (3.3) that satisfy conditions (C2) and (C3), respectively. Then there exist parameters  $\hat{\gamma}_H^k \geq \hat{\gamma}_H^L$ ,  $\hat{\gamma}_J^k \geq \hat{\gamma}_J^L$ , and  $\hat{k}_H, \hat{k}_J \in \mathbb{N}$  with the property that for all  $\gamma_{H,1}, \gamma_{H,2} > \hat{\gamma}_H^k$ ,  $\gamma_{J,1}, \gamma_{J,2} > \hat{\gamma}_J^k$ , the rank conditions hold:*

$$(3.4) \quad \begin{aligned} \text{rank } E^T X_{H,2}(\gamma_{H,1}) &= \text{rank } E^T X_{H,2}(\gamma_{H,2}) = \hat{k}_H, \\ \text{rank } EX_{J,2}(\gamma_{J,1}) &= \text{rank } EX_{J,2}(\gamma_{J,2}) = \hat{k}_J. \end{aligned}$$

This rank property will be the basis for the formulation of a further condition on the pencils in (3.1) and (3.2) and on the blocks of the deflating subspace matrices  $X_H(\gamma) \in \mathbb{R}^{2n+m_1+m_2+p_1, r}$ ,  $X_J(\gamma) \in \mathbb{R}^{2n+p_1+p_2+m_1, r}$  satisfying (C2) (resp., (C3)).

(C4) The matrix

$$(3.5) \quad \mathcal{Y}(\gamma) = \begin{bmatrix} -\gamma X_{H,2}^T(\gamma) E X_{H,1}(\gamma) & X_{H,2}^T(\gamma) E X_{J,2}(\gamma) \\ X_{J,2}^T(\gamma) E^T X_{H,2}(\gamma) & -\gamma X_{J,2}^T(\gamma) E^T X_{J,1}(\gamma) \end{bmatrix}$$

is symmetric and positive semidefinite and satisfies  $\text{rank } \mathcal{Y}(\gamma) = \hat{k}_H + \hat{k}_J$ . Since  $X_H(\gamma)$  and  $X_J(\gamma)$  are unique up to a multiplication from the right with invertible matrices,  $\mathcal{Y}(\gamma)$  is unique up to a block-diagonal congruence transformation. Therefore, the value  $\text{rank } \mathcal{Y}(\gamma)$  is well defined.

Note that if we consider  $\mathcal{Y}(\gamma)$  in the standard case  $E = I_n$ , then it slightly differs from the matrix  $\mathcal{Y}(\gamma)$  used in [4]. This is due to the fact that the pencils (3.1) and (3.2) are expressed in a slightly different form in the generalization to descriptor systems.

Condition (C4) then leads to another set that has to be considered.

**DEFINITION 3.5.** *Consider a system of the form (1.1) that satisfies assumptions (A1)–(A4). Then we define*

$$\Gamma^\rho = \left\{ \gamma \geq \hat{\gamma} \mid \begin{array}{l} \text{the matrix } \mathcal{Y}(\gamma) \text{ is positive semidefinite} \\ \text{with } \text{rank } \mathcal{Y}(\gamma) = \hat{k}_H + \hat{k}_J \end{array} \right\}$$

and we set  $\hat{\gamma}^\rho := \inf \Gamma^\rho$ .

In this section we have introduced several assumptions and conditions as well as sets of  $\gamma$ -parameters that will be used in the next section to derive conditions for the optimal and suboptimal  $\gamma$ -parameters.

We proceed in three steps, first recalling the standard state space case in subsection 3.1, then considering the index one case in subsection 3.2, and finally considering the general case in subsection 3.3.

**3.1. The standard state space case.** In the first step, we briefly review the results from [10, 4] for the standard state space, that is,  $E = I_n$ . The relation between the values introduced in Definitions 3.1–3.3 is given by the following proposition.

**PROPOSITION 3.6** (see [4]). *Consider a system of the form (1.1) with  $E = I_n$ . Then the following inequality holds:*

$$(3.6) \quad 0 \leq \hat{\gamma} \leq \hat{\gamma}^L \leq \hat{\gamma}^R.$$

If  $\hat{\gamma}^I < \infty$ , then  $\hat{\gamma}^I = \hat{\gamma}^L > \hat{\gamma}$ . If  $\hat{\gamma}^\rho$  exists, then  $\hat{\gamma}^\rho \geq \hat{\gamma}^R$ .

Furthermore, it was shown in [4] that Theorem 3.4 holds if  $E = I_n$ . Therefore, (C4) represents a well-defined condition, and we can present the main result for the modified optimal  $\mathcal{H}_\infty$  control problem of standard systems.

**PROPOSITION 3.7** (see [4]). *Consider system (1.1) with  $E = I_n$  and the even pencils  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  as in (3.1) and (3.2), respectively. Suppose that assumptions (A1)–(A4) hold.*

*Then there exists an internally stabilizing controller such that the transfer function from  $w$  to  $z$  satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  with  $\|T_{zw}\|_\infty < \gamma$  if and only if  $\gamma$  is such that conditions (C1)–(C4) hold.*

*Furthermore, the set of  $\gamma$  satisfying conditions (C1)–(C4) is nonempty.*

**3.2. The index one case.** To extend Proposition 3.7 to the case where the index of  $\lambda E - A$  is  $\nu = 1$ , we will make use of the WCF from Theorem 2.1. Transforming system (1.1) and using the notation introduced in (2.3), the explicit solution (2.5b) reduces to  $x_\infty(t) = -B_{1,\infty}w(t) - B_{2,\infty}u(t)$ . Inserting this into the transformed out equations, we obtain the standard state space system (often called the slow or finite dynamics subsystem)

$$(3.7) \quad \begin{aligned} \dot{x}_f(t) &= A_f x_f(t) + B_{1,f}w(t) + B_{2,f}u(t), \\ z(t) &= C_{1,f}x_f(t) + (D_{11} - C_{1,\infty}B_{1,\infty})w(t) + (D_{12} - C_{1,\infty}B_{2,\infty})u(t), \\ y(t) &= C_{2,f}x_f(t) + (D_{21} - C_{2,\infty}B_{1,\infty})w(t) + (D_{22} - C_{2,\infty}B_{2,\infty})u(t). \end{aligned}$$

**LEMMA 3.8.** *Consider system (1.1) and suppose that the index of  $\lambda E - A$  is at most one. Then for  $i \in \{1, 2, 3, 4\}$ , system (1.1) satisfies (Ai) if and only if the slow subsystem (3.7) satisfies (Ai).*

*Proof.* Any system of index at most one is both impulse controllable and observable (see [9, 26]) and, furthermore, finite dynamics stabilizability (detectability) is equivalent to stabilizability (detectability) of the slow subsystem obtained from the WCF. Then from Theorem 2.1 (see also [9, 26]), the equivalence of the corresponding conditions (A1) is immediate.

The equivalence for the corresponding conditions (A2) is obtained by using the transformation matrices to WCF, since

$$\begin{aligned} & \begin{bmatrix} W_f^T & 0 \\ -C_{1,\infty}W_\infty^T & I_{p_1} \\ W_\infty^T & 0 \end{bmatrix} \begin{bmatrix} A - i\omega E & B_2 \\ C_1 & D_{12} \end{bmatrix} \begin{bmatrix} V_f & -V_\infty B_{2,\infty} & V_\infty \\ 0 & I_{m_2} & 0 \end{bmatrix} \\ &= \begin{bmatrix} A_f - i\omega I_{n_f} & B_{2,f} & 0 \\ C_{1,f} & D_{12} - C_{2,\infty}B_{2,\infty} & 0 \\ 0 & 0 & I_{n_\infty} \end{bmatrix}. \end{aligned}$$

The proof for the equivalence of the corresponding conditions (A3) is analogous.

We now consider condition (A4). By definition, the columns of the matrices  $T_\infty, S_\infty$  span the left and right nullspace of  $E$ . Thus there exist invertible matrices  $M_l, M_r \in \mathbb{R}^{n_\infty, n_\infty}$  such that  $W_\infty = T_\infty M_l$ ,  $V_\infty = S_\infty M_r$ . The assertion then

follows from

$$\begin{aligned} & \begin{bmatrix} M_l^T & 0 \\ -C_{1,\infty}M_l^T & I_{p_1} \end{bmatrix} \begin{bmatrix} T_\infty^T A S_\infty & T_\infty^T B_2 \\ C_1 S_\infty & D_{12} \end{bmatrix} \begin{bmatrix} M_r & -M_r B_{2,\infty} \\ 0 & I_{m_2} \end{bmatrix} \\ &= \begin{bmatrix} I_{n_\infty} & 0 \\ 0 & D_{12} - C_{1,\infty} B_{2,\infty} \end{bmatrix}, \\ & \begin{bmatrix} M_l^T & 0 \\ -C_{2,\infty}M_l^T & I_{p_2} \end{bmatrix} \begin{bmatrix} T_\infty^T A S_\infty & T_\infty^T B_1 \\ C_2 S_\infty & D_{21} \end{bmatrix} \begin{bmatrix} M_r & -M_r B_{1,\infty} \\ 0 & I_{m_1} \end{bmatrix} \\ &= \begin{bmatrix} I_{n_\infty} & 0 \\ 0 & D_{21} - C_{2,\infty} B_{1,\infty} \end{bmatrix}. \quad \square \end{aligned}$$

After proving the equivalence of the conditions (Ai), we now show that the  $\Gamma$  sets and  $\gamma$  parameters introduced in Definitions 3.1–3.3 and 3.5 are those of the slow subsystem. We denote by  $\lambda N_{H,st} + M_{H,st}(\gamma)$  and  $\lambda N_{J,st} + M_{J,st}(\gamma)$  the even pencils (3.1) and (3.2) constructed from the data of system (3.7).

LEMMA 3.9. *Consider the system (1.1) and assume that the index of  $\lambda E - A$  is at most one. Let  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  be the even pencils constructed from the data of (1.1), and let  $\lambda N_{H,st} + M_{H,st}(\gamma)$ ,  $\lambda N_{J,st} + M_{J,st}(\gamma)$  be the corresponding pencils constructed from the data of (3.7).*

*Let  $\Gamma_H, \Gamma_J, \Gamma_H^L, \Gamma_J^L, \Gamma_H^R, \Gamma_J^R, \Gamma_H^I, \Gamma_J^I$  be the sets introduced in Definitions 3.1–3.3 and 3.5, and let  $\mathcal{Y}(\gamma)$  be the matrix introduced in (3.5).*

*Analogously, let  $\Gamma_{H,st}, \Gamma_{J,st}, \Gamma_{H,st}^L, \Gamma_{J,st}^L, \Gamma_{H,st}^R, \Gamma_{J,st}^R, \Gamma_{H,st}^I, \Gamma_{J,st}^I$ , and  $\mathcal{Y}_{st}(\gamma)$  be correspondingly defined for the slow subsystem (3.7). Then,*

$$\begin{aligned} \Gamma_{J,st} &= \Gamma_H, & \Gamma_{H,st}^L &= \Gamma_H^L, & \Gamma_{H,st}^R &= \Gamma_H^R, & \Gamma_{H,st}^I &= \Gamma_H^I, \\ \Gamma_{J,st} &= \Gamma_J, & \Gamma_{J,st}^L &= \Gamma_J^L, & \Gamma_{J,st}^R &= \Gamma_J^R, & \Gamma_{J,st}^I &= \Gamma_J^I, & \text{rank } \mathcal{Y}(\gamma) &= \text{rank } \mathcal{Y}_{st}(\gamma). \end{aligned}$$

*Proof.* First, we consider the pencil  $\lambda N_H + M_H(\gamma)$  and introduce the transformation matrix

$$(3.8) \quad P_H = \begin{bmatrix} V_f^T & 0 & 0 & 0 & 0 \\ 0 & W_f^T & 0 & 0 & 0 \\ B_{1,\infty}^T V_\infty^T & 0 & I_{m_1} & 0 & 0 \\ B_{2,\infty}^T V_\infty^T & 0 & 0 & I_{m_2} & 0 \\ 0 & -C_{1,\infty} W_\infty^T & 0 & 0 & I_{p_2} \\ V_\infty^T & 0 & 0 & 0 & 0 \\ 0 & W_\infty^T & 0 & 0 & 0 \end{bmatrix}^T.$$

We obtain that

$$(3.9) \quad \lambda P_H^T N_H P_H + P_H^T M_H(\gamma) P_H = \begin{bmatrix} \lambda N_{H,st} + M_{H,st}(\gamma) & 0 & 0 \\ 0 & I_{n_\infty} & 0 \\ 0 & 0 & I_{n_\infty} \end{bmatrix}.$$

This directly implies  $\Gamma_{H,st} = \Gamma_H$  and  $\Gamma_{H,st}^I = \Gamma_H^I$ . Analogously, we can show that  $\Gamma_{J,st} = \Gamma_J$  and  $\Gamma_{J,st}^I = \Gamma_J^I$ . Furthermore, it can be concluded from (3.9) that the columns of a matrix

$$X_{H,st} = [X_{H,st,1}^T \quad X_{H,st,2}^T \quad X_{H,st,3}^T \quad X_{H,st,4}^T \quad X_{H,st,5}^T]^T$$

partitioned conformably to the block structure of  $\lambda N_{H,st} + M_{H,st}(\gamma)$  span a semistable deflating subspace if and only if the columns of

$$(3.10) \quad \begin{bmatrix} X_{H,1} \\ X_{H,2} \\ X_{H,3} \\ X_{H,4} \\ X_{H,5} \end{bmatrix} = \begin{bmatrix} V_f X_{H,st,1} + V_\infty B_{1,\infty} X_{H,st,3} + V_\infty B_{2,\infty} X_{H,st,4} \\ W_f X_{H,st,2} - W_\infty C_{1,\infty}^T X_{H,st,5} \\ X_{H,st,3} \\ X_{H,st,4} \\ X_{H,st,5} \end{bmatrix}$$

span the semistable deflating subspace of  $\lambda N_H + M_H(\gamma)$ .

An analogous relation can be derived for the relation between spanning matrices of deflating subspaces of  $\lambda N_J + M_J(\gamma)$  and  $\lambda N_{J,st} + M_{J,st}(\gamma)$ . Using the fact that  $EV_\infty = 0$ ,  $W_\infty^T E = 0$  and  $W_f^T EV_f = I_{n_f}$ , it follows that

$$(3.11a) \quad \text{rank } EX_{H,1}(\gamma) = \text{rank } X_{H,st,1}(\gamma),$$

$$(3.11b) \quad \text{rank } E^T X_{J,1}(\gamma) = \text{rank } X_{J,st,1}(\gamma),$$

$$(3.11c) \quad \text{rank } E^T X_{H,2}(\gamma) = \text{rank } X_{H,st,2}(\gamma),$$

$$(3.11d) \quad \text{rank } EX_{J,2}(\gamma) = \text{rank } X_{J,st,2}(\gamma),$$

$$(3.11e) \quad X_{H,2}(\gamma)^T EX_{H,1}(\gamma) = X_{H,st,2}(\gamma)^T X_{H,st,1}(\gamma),$$

$$(3.11f) \quad X_{H,2}(\gamma)^T EX_{J,2}(\gamma) = X_{H,st,2}(\gamma)^T X_{J,st,2}(\gamma),$$

$$(3.11g) \quad X_{J,2}(\gamma)^T E^T X_{J,1}(\gamma) = X_{J,st,2}(\gamma)^T X_{J,st,1}(\gamma).$$

Equations (3.11e) and (3.11g) and the relations between the stable deflating subspaces of  $\lambda N_H + M_H(\gamma)$ ,  $\lambda N_{H,st} + M_{H,st}(\gamma)$  and  $\lambda N_J + M_J(\gamma)$ ,  $\lambda N_{J,st} + M_{J,st}(\gamma)$ , respectively, imply that  $\Gamma_{H,st}^L = \Gamma_H^L$  and  $\Gamma_{J,st}^L = \Gamma_J^L$ . Additionally, from (3.11a) and (3.11b), we obtain  $\Gamma_{H,st}^R = \Gamma_H^R$  and  $\Gamma_{J,st}^R = \Gamma_J^R$ .

By using (3.11e)–(3.11g) we then obtain that the matrices  $\mathcal{Y}(\gamma)$  and  $\mathcal{Y}_{st}(\gamma)$  coincide; in particular, we have  $\text{rank } \mathcal{Y}(\gamma) = \text{rank } \mathcal{Y}_{st}(\gamma)$ .  $\square$

An immediate consequence is that Proposition 3.6 holds for systems of index at most one. Furthermore, from (3.11c) and (3.11b) and the corresponding fact for standard systems, we can conclude that Theorem 3.4 holds for systems of index at most one.

With these preparations we can formulate the following extension of Proposition 3.7 for systems of index at most one.

**PROPOSITION 3.10.** *Consider system (1.1) such that the index of the pencil  $\lambda E - A$  is at most one, and the even pencils  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  as in (3.1) and (3.2), respectively. Suppose that assumptions (A1)–(A4) hold.*

*Then there exists an internally stabilizing controller such that the transfer function from  $w$  to  $z$  satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  with  $\|T_{zw}\|_\infty < \gamma$  if and only if  $\gamma$  is such that conditions (C1)–(C4) hold.*

*Furthermore, the set of  $\gamma$  satisfying conditions (C1)–(C4) is nonempty.*

*Proof.* The closed-loop transfer function  $T_{zw}(s)$  of the system (3.7) with a controller of the form (1.2) is equal to the closed-loop transfer function of the system (1.1) with the same controller.

Since (1.1) is strongly stabilizable (strongly detectable), if and only if system (3.7) is stabilizable (detectable), a controller that internally stabilizes (3.7) also stabilizes the finite dynamics of (1.1).

Therefore, the existence of a controller with desired properties for (1.1) is equivalent to the existence of such a controller for (3.7). Since by Lemma 3.8 the validity

of assumptions (A1)–(A4) for (3.7) is equivalent to those of (1.1) and, furthermore, also by Lemma 3.9 the corresponding conditions (C1)–(C4) of these two systems are equivalent, the assertion follows.  $\square$

We have seen so far that the standard state space case and the index one case follow after some simple transformation. In the next subsection we now study the general case.

**3.3. The general case.** In this section we formulate the results for the modified optimal  $\mathcal{H}_\infty$  control problem for descriptor systems of arbitrary index. A key tool in the proof will be an a priori static output feedback  $u(t) = Ky(t) + \bar{u}(t)$  resulting in a system

$$(3.12) \quad \begin{aligned} E\dot{x}(t) &= (A + B_2KC_2)x(t) + (B_1 + B_2KD_{21})w(t) + B_2\bar{u}(t), & x(t_0) &= x^0, \\ z(t) &= (C_1 + D_{12}KC_2)x(t) + (D_{11} + D_{12}KD_{21})w(t) + D_{12}\bar{u}(t), \\ y(t) &= C_2x(t) + D_{21}w(t). \end{aligned}$$

The feedback matrix  $K$  will be constructed in a way so that system (3.12) has index one. Then we are able to apply the results of the previous section. If (1.2) is a controller for (3.12), then a controller for system (1.1) is given by

$$(3.13) \quad \begin{aligned} \hat{E}\dot{\hat{x}}(t) &= \hat{A}\hat{x}(t) + \hat{B}y(t), \\ u(t) &= \hat{C}\hat{x}(t) + (\hat{D} - K)y(t). \end{aligned}$$

To proceed, we need the following results about the existence of a static output feedback  $K$  that leads to a system of index at most one.

LEMMA 3.11 (see [7, 9]). *Consider matrices  $C \in \mathbb{R}^{p,n}$  and  $B \in \mathbb{R}^{n,m}$  and a regular matrix pencil  $\lambda E - A$ . Then there exists  $K \in \mathbb{R}^{p,m}$  such that the pencil  $\lambda E - (A + BKC)$  is regular and has index at most one if and only if the triple  $(E, A, B)$  is impulse controllable and the triple  $(E, A, C)$  is impulse observable; see Definition 2.3.*

To make use of this result, we show that a static output feedback does not change assumptions (A1)–(A4).

LEMMA 3.12. *Consider system (1.1) and let  $K \in \mathbb{R}^{m_2,p_2}$  such that the pencil  $\lambda E - (A + B_2KC_2)$  is regular. Then for every  $i \in \{1, 2, 3, 4\}$ , system (1.1) satisfies (Ai) if and only if the system (3.12) satisfies (Ai).*

*Proof.* The invariance of strong stabilizability and strong detectability under output feedback is trivial. The proof for the equivalence of the corresponding assumptions (A2) follows from the identity

$$\begin{bmatrix} A - i\omega E & B_2 \\ C_1 & D_{12} \end{bmatrix} \begin{bmatrix} I_n & 0 \\ KC_2 & I_{m_2} \end{bmatrix} = \begin{bmatrix} A + B_2KC_2 - i\omega E & B_2 \\ C_1 + D_{12}KC_2 & D_{12} \end{bmatrix},$$

while the equivalence statement for (A3) can be shown analogously. The fact that (3.12) satisfies (A4) if and only if (1.1) satisfies (A4) is a consequence of

$$\begin{aligned} \begin{bmatrix} T_\infty^T AS_\infty & T_\infty^T B_2 \\ C_1 S_\infty & D_{12} \end{bmatrix} \begin{bmatrix} I_{n-r} & 0 \\ KC_2 S_\infty & I_{m_2} \end{bmatrix} &= \begin{bmatrix} T_\infty^T (A + B_2KC_2) S_\infty & T_\infty^T B_2 \\ (C_1 + D_{12}KC_2) S_\infty & D_{12} \end{bmatrix}, \\ \begin{bmatrix} I_{n-r} & T_\infty^T B_2 K \\ 0 & I_{p_2} \end{bmatrix} \begin{bmatrix} T_\infty^T AS_\infty & T_\infty^T B_1 \\ C_2 S_\infty & D_{21} \end{bmatrix} &= \begin{bmatrix} T_\infty^T (A + B_2KC_2) S_\infty & T_\infty^T (B_1 + B_2KD_{21}) \\ C_2 S_\infty & D_{21} \end{bmatrix}. \quad \square \end{aligned}$$

In the following lemma we show that the sets introduced in Definitions 3.1–3.3 and 3.5 are invariant under output feedback as well.

LEMMA 3.13. Consider the system (1.1) and let  $K \in \mathbb{R}^{m_2, p_2}$  be such that the pencil  $\lambda E - (A + BKC)$  is regular. Let  $\Gamma_H, \Gamma_J, \Gamma_H^L, \Gamma_J^L, \Gamma_H^R, \Gamma_J^R, \Gamma_H^I, \Gamma_J^I$  be the sets introduced in Definitions 3.1–3.3 and 3.5, and let  $\mathcal{Y}(\gamma)$  be the matrix introduced in (3.5). Furthermore, let  $\Gamma_{H,K}, \Gamma_{J,K}, \Gamma_{H,K}^L, \Gamma_{J,K}^L, \Gamma_{H,K}^R, \Gamma_{J,K}^R, \Gamma_{H,K}^I, \Gamma_{J,K}^I$ , and  $\mathcal{Y}_K(\gamma)$  be the corresponding quantities for the system (3.12). Then,

$$\begin{aligned} \Gamma_{J,K} &= \Gamma_H, & \Gamma_{H,K}^L &= \Gamma_H^L, & \Gamma_{H,K}^R &= \Gamma_H^R, & \Gamma_{H,K}^I &= \Gamma_H^I, \\ \Gamma_{J,K} &= \Gamma_J, & \Gamma_{J,K}^L &= \Gamma_J^L, & \Gamma_{J,K}^R &= \Gamma_J^R, & \Gamma_{J,K}^I &= \Gamma_J^I, & \text{rank } \mathcal{Y}(\gamma) &= \text{rank } \mathcal{Y}_K(\gamma). \end{aligned}$$

*Proof.* Let  $\lambda N_{H,K} + M_{H,K}(\gamma)$  be the even pencil associated with the system (3.12). Then, with the transformation matrices

$$T_{H,K} = \begin{bmatrix} I_n & 0 & 0 & 0 & 0 \\ 0 & I_n & 0 & 0 & 0 \\ 0 & 0 & I_{m_1} & 0 & 0 \\ KC_2 & 0 & KD_{21} & I_{m_2} & 0 \\ 0 & 0 & 0 & 0 & I_{p_1} \end{bmatrix}, \quad T_{J,K} = \begin{bmatrix} I_n & 0 & 0 & 0 & 0 \\ 0 & I_n & 0 & 0 & 0 \\ 0 & 0 & I_{p_1} & 0 & 0 \\ K^T B_2^T & 0 & K^T D_{12}^T & I_{p_2} & 0 \\ 0 & 0 & 0 & 0 & I_{m_1} \end{bmatrix},$$

we have the identities

$$\begin{aligned} \lambda T_{H,K}^T N_H T_{H,K} + T_{H,K}^T M_H(\gamma) T_{H,K} &= \lambda N_{H,K} + M_{H,K}(\gamma), \\ \lambda T_{J,K}^T N_J T_{J,K} + T_{J,K}^T M_J(\gamma) T_{J,K} &= \lambda N_{J,K} + M_{J,K}(\gamma). \end{aligned}$$

Thus, we have that the pencils  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_{H,K} + M_{H,K}(\gamma)$  have the same index and eigenvalues. Similarly, this holds for  $\lambda N_J + M_J(\gamma)$  and  $\lambda N_{J,K} + M_{J,K}(\gamma)$ . Therefore we have  $\Gamma_{H,K} = \Gamma_H, \Gamma_{J,K} = \Gamma_J, \Gamma_{H,K}^L = \Gamma_H^L, \Gamma_{J,K}^L = \Gamma_J^L$ . The relations  $\Gamma_{H,K}^R, \Gamma_{J,K}^R, \Gamma_{H,K}^I, \Gamma_{J,K}^I$  follow from the facts that

$$\begin{aligned} \text{im} \begin{bmatrix} X_{H,1}^T & X_{H,2}^T & X_{H,3}^T & X_{H,4}^T & X_{H,5}^T \end{bmatrix}^T, \\ \text{im} \begin{bmatrix} X_{J,1}^T & X_{J,2}^T & X_{J,3}^T & X_{J,4}^T & X_{J,5}^T \end{bmatrix}^T \end{aligned}$$

are semistable deflating subspaces of  $\lambda N_{H,K} + M_{H,K}(\gamma)$  and  $\lambda N_{J,K} + M_{J,K}(\gamma)$ , respectively, if and only if

$$(3.14) \quad \begin{aligned} \text{im} \begin{bmatrix} X_{H,1}^T & X_{H,2}^T & X_{H,3}^T & (X_{H,4} + KC_2 X_{H,1} + KD_{21} X_{H,3})^T & X_{H,5}^T \end{bmatrix}^T, \\ \text{im} \begin{bmatrix} X_{J,1}^T & X_{J,2}^T & X_{J,3}^T & (X_{J,4} + K^T B_2^T X_{J,1} + K^T D_{12}^T X_{J,3})^T & X_{J,5}^T \end{bmatrix}^T \end{aligned}$$

are semistable deflating subspace of  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$ . From (3.14), we further obtain that  $\mathcal{Y}(\gamma) = \mathcal{Y}_K(\gamma)$ , and thus their ranks coincide.  $\square$

With these auxiliary results, we are now in a position to prove Theorem 3.4.

*Proof of Theorem 3.4.* First we apply an a priori feedback  $K \in \mathbb{R}^{m_2, p_2}$  to (1.1) such that the resulting system (3.12) has index at most one. Then we know from (3.14) that the corresponding matrices  $X_{H,1}, X_{H,2}, X_{J,1}, X_{J,2}$  of (1.1) and (3.12) are equal. Since Theorem 3.4 holds for systems of index one, the assertion follows.  $\square$

Lemma 3.13 also implies that the assertion of Proposition 3.6 still holds for the general case; i.e., for (1.1), the inequality  $0 \leq \hat{\gamma} \leq \hat{\gamma}^L \leq \hat{\gamma}^R$  is valid. In the case where  $\hat{\gamma}^I < \infty$ , we have  $\hat{\gamma}^I = \hat{\gamma}^L > \hat{\gamma}$ , and if  $\hat{\gamma}^\rho$  exists, then  $\hat{\gamma}^\rho \geq \hat{\gamma}^R$ .

With the described framework, we can now formulate the main result for the modified  $\mathcal{H}_\infty$  control problem for descriptor systems.

**THEOREM 3.14.** *Consider system (1.1) and the even pencils  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  as in (3.1) and (3.2), respectively. Suppose that assumptions (A1)–(A4) hold.*

*Then there exists an internally stabilizing controller such that the transfer function from  $w$  to  $z$  satisfies  $T_{zw} \in \mathcal{H}_\infty^{p_1, m_1}$  with  $\|T_{zw}\|_\infty < \gamma$  if and only if  $\gamma$  is such that the conditions (C1)–(C4) hold.*

*Furthermore, the set of  $\gamma$  satisfying conditions (C1)–(C4) is nonempty.*

*Proof.* Due to Lemma 3.11, there exists a matrix  $K \in \mathbb{R}^{m_2, p_2}$  such that system (3.12) has index at most one. Lemma 3.12 implies that (3.12) satisfies (A1)–(A4) as well. Furthermore, by Lemma 3.13, the validity of conditions (C1)–(C4) for system (1.1) is equivalent to the respective conditions for system (3.12).

Proposition 3.10 then implies that conditions (C1)–(C4) for (3.12) are fulfilled if and only if there exists a desired controller for (3.12).

Since an application of the controller (1.2) to (3.12) yields the same closed-loop system as that given by (3.13) with controller (1.1), the desired result follows immediately.  $\square$

**THEOREM 3.15.** *Consider system (1.1) and suppose that assumptions (A1)–(A4) hold. Then the set  $\Gamma^\rho$  is nonempty, and optimal  $\gamma$  for the modified optimal  $\mathcal{H}_\infty$  control problem is given by*

$$(3.15) \quad \gamma_{mo} = \hat{\gamma}^\rho.$$

*Proof.* Let  $\Gamma$  be the set of  $\gamma > 0$  for which an internally stabilizing controller exists such that the transfer function from  $w$  to  $z$  satisfies  $\|T_{zw}\|_\infty < \gamma$ .

We know from Theorem 3.14 that  $\Gamma$  is nonempty, and for some  $\gamma > 0$ , we have  $\gamma \in \Gamma$  if and only if conditions (C1)–(C4) are fulfilled. By the definition of  $\Gamma_H$ ,  $\Gamma_J$ ,  $\Gamma^R$ , and  $\Gamma^\rho$ , the existence of a controller with desired properties is therefore equivalent to

$$(3.16) \quad \gamma \in \Gamma_H \cap \Gamma_J, \quad \gamma \in \Gamma^R, \quad \gamma \in \Gamma^\rho.$$

Especially, we have that  $\Gamma^\rho$  is nonempty. By the definition of  $\hat{\gamma}$ ,  $\hat{\gamma}^R$ , and  $\hat{\gamma}^\rho$ , condition (3.16) is the same as

$$(3.17) \quad \gamma > \hat{\gamma}, \quad \gamma > \hat{\gamma}^R, \quad \gamma \in \hat{\gamma}^\rho.$$

Hence,  $\gamma \in \Gamma$  is equivalent to

$$(3.18) \quad \gamma > \max\{\hat{\gamma}, \hat{\gamma}^R, \hat{\gamma}^\rho\}.$$

However, since by Lemma 3.13 we have that Proposition 3.6 still holds for arbitrary descriptor systems, the equation  $\hat{\gamma}^\rho = \max\{\hat{\gamma}, \hat{\gamma}^R, \hat{\gamma}^\rho\}$  holds. Thus we have that  $\hat{\gamma}_{mo} = \inf \Gamma = \hat{\gamma}^\rho$ .  $\square$

**4. Numerical example.** To illustrate the functionality of our approach, consider the following example from [38] which is also discussed in [31]. The descriptor system is given by (1.1) with  $D_{21} = 1$ ,  $D_{11} = D_{22} = 0$ , and

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad A = \begin{bmatrix} -1 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix},$$

$$C_1 = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix}, \quad C_2 = [1 \ 0 \ 1], \quad D_{12} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

This system is of index two, and the associated pencils  $\lambda N_H + M_H(\gamma)$  and  $\lambda N_J + M_J(\gamma)$  have index one for  $\gamma \neq 0$ . The goal is to find the minimum value  $\gamma$  that satisfies conditions (C1)–(C4). Using our experimental code for the computation of stable deflating subspaces of structured matrix pencils as in [2] and a bisection to determine the optimal value for  $\gamma$ , we computed  $\gamma_{opt}$  given by  $\gamma^p = 0.7678$ , which is smaller than the suboptimal value obtained in [38, 31].

**5. Conclusion.** In this paper we have developed conditions for optimal and suboptimal  $\mathcal{H}_\infty$  control for descriptor systems of arbitrary index. We have expressed criteria for the existence of an internally stabilizing controller in terms of even pencils containing only parameters of the original system. With these criteria the  $\gamma$ -iteration can be performed in a numerically stable way, especially if a structure-preserving method is used for the computation of the deflating subspaces. The computation of a controller for a given  $\gamma$  can be performed by first following the steps in the proofs and then using controller formulas for standard systems [14, 15, 11]. However, this approach does not lead to controller formulas stated in terms of the original system variables. In [21] such formulas are given for systems with nonsingular system matrix  $E$ ; the general case is currently under investigation.

## THE EXISTENCE OF STRONGLY MDS CONVOLUTIONAL CODES\*

RYAN HUTCHINSON†

**Abstract.** It is known that maximum distance separable and maximum distance profile convolutional codes exist over large enough finite fields of any characteristic for all parameters  $(n, k, \delta)$ . It has been conjectured that the same is true for convolutional codes that are strongly maximum distance separable. Using methods from linear systems theory, we resolve this conjecture by showing that, over a large enough finite field of any characteristic, codes which are simultaneously maximum distance profile and strongly maximum distance separable exist for all parameters  $(n, k, \delta)$ .

**Key words.** MDS codes, convolutional codes, column distances, linear systems, minimal partial realization problem

**AMS subject classification.** 94B10

**DOI.** 10.1137/050638977

**1. Introduction.** In recent literature on convolutional codes, several new classes of codes with optimal distance properties have been introduced. These classes of codes are known as maximum distance separable (MDS) codes, maximum distance profile (MDP) codes, and strongly MDS (sMDS) codes. MDS codes are characterized by the property that they have the maximum possible free distance for a given choice of code parameters. sMDS codes are a subclass of MDS codes having the property that this maximum possible free distance is attained at the earliest possible encoding step. MDP codes are characterized by the property that their column distances grow at the maximum possible rate for a given choice of code parameters.

In [18], it is shown that MDS convolutional codes exist for all parameters  $(n, k, \delta)$  over sufficiently large finite fields; in [11], a similar result is obtained for codes having the MDP property. In [8], sMDS convolutional codes are introduced and studied, and they are shown to exist for parameters  $(n, k, \delta)$  satisfying  $(n - k) \mid \delta$ . In addition, it is conjectured that convolutional codes possessing the MDP and sMDS properties together exist for all  $(n, k, \delta)$ . In this work, we show that this conjecture is correct. The approach used is systems-theoretic in nature; to obtain the proof, we make use of the well-known interpretation of a convolutional code as an input-state-output linear system as well as results from partial realization theory.

The structure of this paper is as follows. In section 2, we review relevant ideas from the theory of convolutional codes. We recall as well a connection between convolutional codes and input-state-output linear systems that we will use to obtain our results. In section 3, we use a linear systems representation of convolutional codes to give a characterization of the sMDS property. In section 4, we use this characterization to show the existence, for all parameters  $(n, k, \delta)$ , of codes possessing both the MDP and sMDS properties.

**2. Convolutional codes and linear systems.** In this section, we recall some facts about convolutional codes and their connection with linear systems. Throughout

this paper,  $0$  will be understood to be the zero matrix or vector of the appropriate size. Let  $k$  and  $n$  be positive integers with  $k < n$ ,  $p$  a prime number,  $\mathbb{K}$  the algebraic closure of the prime field  $\mathbb{F}_p$ , and  $\mathbb{F}$  a finite subfield of  $\mathbb{K}$ .

DEFINITION 2.1. A convolutional code  $\mathcal{C}$  of rate  $k/n$  is a rank- $k$  direct summand of  $\mathbb{F}[s]^n$ .

$\mathcal{C}$  is a free  $\mathbb{F}[s]$ -module and may thus be viewed as the column space of a full-rank matrix  $G(s) \in \mathbb{F}[s]^{n \times k}$ , called a *generator matrix* for  $\mathcal{C}$ . Two full-rank  $n \times k$  matrices  $G_1(s)$  and  $G_2(s)$  generate the same code if and only if there exists a unimodular matrix  $U(s) \in \mathbb{F}[s]^{k \times k}$  such that  $G_1(s) = G_2(s)U(s)$ .

When convenient, we will (at times with a slight abuse of notation) make use of the fact that  $\mathbb{F}[s]^n$  and  $\mathbb{F}^n[s]$  are isomorphic  $\mathbb{F}[s]$ -modules and think of codewords as elements of  $\mathbb{F}^n[s]$ . For example, the columns of a generator matrix  $G(s)$  may be thought of as polynomials with coefficients in  $\mathbb{F}^n$ ; we refer to the degrees of these polynomials as the *column degrees* of  $G(s)$  and denote the degree of the  $j$ th column by  $\delta_j$ . The *high-order coefficient matrix* of  $G(s)$ ,  $G_\infty$ , is the matrix whose  $j$ th column is the column coefficient of  $s^{\delta_j}$  in the  $j$ th column of  $G(s)$ . In general,  $G_\infty$  need not have full rank. It is always possible, though, to find a unimodular matrix  $U(s) \in \mathbb{F}[s]^{k \times k}$  such that  $G(s)U(s)$  has a full-rank high-order coefficient matrix (see [7]). If  $G_\infty$  has full rank, then  $G(s)$  is called a *minimal generator matrix*.

An important invariant of a convolutional code is its degree, defined as follows.

DEFINITION 2.2. The degree  $\delta$  of a convolutional code  $\mathcal{C}$  is the maximal degree of a (polynomial) determinant of a  $k \times k$  submatrix of a generator matrix of  $\mathcal{C}$ .

This definition makes sense, as multiplication by a unimodular matrix preserves the degrees of such determinants. We note that, if  $G(s)$  is a minimal generator matrix of  $\mathcal{C}$  with column degrees  $\delta_1, \dots, \delta_k$ , then  $\delta = \sum_{j=1}^k \delta_j$ . A code of rate  $k/n$  and degree  $\delta$  will be referred to as an  $(n, k, \delta)$ -code.

We turn next to notions of distance. We first recall the definition of Hamming weight.

DEFINITION 2.3. Let  $v \in \mathbb{F}^n$  and  $v(s) := \sum_{t=0}^d v_t s^t \in \mathbb{F}^n[s]$ . The Hamming weight of  $v$ ,  $\text{wt}(v)$ , is the number of nonzero components of  $v$ . The Hamming weight of  $v(s)$  is  $\text{wt}(v(s)) := \sum_{t=0}^d \text{wt}(v_t)$ .

For the purpose of error control coding, it is important that the minimum weight among the codewords of a code be as large as possible. This leads to the concept of free distance.

DEFINITION 2.4. The free distance of a convolutional code  $\mathcal{C}$  is

$$d_{\text{free}}(\mathcal{C}) := \min\{\text{wt}(v(s)) \mid v(s) \in \mathcal{C} \setminus \{0\}\}.$$

Column distances also play an important part in what follows. They measure the minimum possible distance between truncated codewords.

DEFINITION 2.5. Let  $\mathcal{C}$  be a convolutional code. For  $j \in \mathbb{N}_0$ , the  $j$ th column distance of  $\mathcal{C}$  is

$$d_j^{\mathcal{C}} := \min \left\{ \sum_{t=0}^j \text{wt}(v_t) \mid v(s) \in \mathcal{C} \text{ and } v_0 \neq 0_n \right\},$$

where  $v_j = 0_n$  if  $j > \deg v(s)$ .

The following result gives upper bounds for the column distances and the free distance of a convolutional code.

PROPOSITION 2.6. *Let  $\mathcal{C}$  be an  $(n, k, \delta)$ -code.*

1. *For every  $j \in \mathbb{N}_0$ ,*

$$d_j^c(\mathcal{C}) \leq (n - k)(j + 1) + 1.$$

*If  $d_j^c(\mathcal{C}) = (n - k)(j + 1) + 1$  for some  $j$ , then  $d_i^c(\mathcal{C}) = (n - k)(i + 1) + 1$  if  $i \in \{0, \dots, j\}$ .*

- 2.

$$d_{free}(\mathcal{C}) \leq (n - k) \left( \left\lfloor \frac{\delta}{k} \right\rfloor + 1 \right) + \delta + 1.$$

Statement 1 is proved in [8], and statement 2 is proved in [18]. The bound in 2 is called the *generalized Singleton bound*.

Set  $L := \lfloor \frac{\delta}{k} \rfloor + \lfloor \frac{\delta}{n-k} \rfloor$  and  $M := \lfloor \frac{\delta}{k} \rfloor + \lceil \frac{\delta}{n-k} \rceil$ . We are now ready to define the code properties of interest in this work.

DEFINITION 2.7. *Let  $\mathcal{C}$  be an  $(n, k, \delta)$ -code. Then,*

1.  *$\mathcal{C}$  is called a maximum distance profile (MDP) code if*

$$d_L^c(\mathcal{C}) = (n - k)(L + 1) + 1.$$

2.  *$\mathcal{C}$  is called a maximum distance separable (MDS) code if*

$$d_{free}(\mathcal{C}) = (n - k) \left( \left\lfloor \frac{\delta}{k} \right\rfloor + 1 \right) + \delta + 1.$$

3.  *$\mathcal{C}$  is called a strongly MDS (sMDS) code if*

$$d_M^c(\mathcal{C}) = (n - k) \left( \left\lfloor \frac{\delta}{k} \right\rfloor + 1 \right) + \delta + 1.$$

Using the fact that no column distance of  $\mathcal{C}$  can exceed the generalized Singleton bound, one can show that  $L$  is the largest possible value of  $j$  for which  $d_j^c(\mathcal{C})$  can attain the upper bound in statement 1 of Proposition 2.6. If  $\mathcal{C}$  is an MDP code, then, by Proposition 2.6,  $d_i^c(\mathcal{C})$  attains this upper bound when  $i \in \{0, \dots, L\}$ . Thus, statement 1 says that the column distances of an MDP code are maximal until it is no longer possible. Similarly, one can show that, if  $j < M$ , then  $d_j^c(\mathcal{C}) < (n - k)(\lfloor \frac{\delta}{k} \rfloor + 1) + \delta + 1$ . Thus, statement 3 says that, for an sMDS code, the sequence  $\{d_j^c(\mathcal{C})\}_{j \geq 0}$  attains the generalized Singleton bound at the smallest possible value of  $j$ .

In the second part of this section, we introduce a connection between convolutional codes and linear systems that we will use to obtain our results. Background information for this discussion and applications of ideas from systems theory to the construction of convolutional codes may be found, for example, in [2, 3, 17, 19, 20].

Let  $A \in \mathbb{K}^{\delta \times \delta}$ ,  $B \in \mathbb{K}^{\delta \times k}$ ,  $C \in \mathbb{K}^{(n-k) \times \delta}$ , and  $D \in \mathbb{K}^{(n-k) \times k}$ . Note that, since the number of entries in the matrices  $(A, B, C, D)$  is finite, these matrices are actually defined over a finite subfield  $\mathbb{F}$  of  $\mathbb{K}$ . The matrices  $(A, B, C, D)$  describe a time-invariant linear system through the equations

$$\begin{aligned} (2.1) \quad & x_{t+1} = Ax_t + Bu_t, \\ & y_t = Cx_t + Du_t, \\ & x_0 = 0, \end{aligned}$$

where  $x_t \in \mathbb{F}^\delta$ ,  $u_t \in \mathbb{F}^k$ , and  $y_t \in \mathbb{F}^{n-k}$  are called the *state vector*, *input vector*, and *output vector* at time  $t$ , respectively. The matrix quadruple  $(A, B, C, D)$  is called a *realization* for the system. We recall the following well-known definition.

DEFINITION 2.8.  $(A, B)$  is called a reachable pair if

$$\text{rank} \left( \begin{bmatrix} B & AB & \cdots & A^{\delta-2}B & A^{\delta-1}B \end{bmatrix} \right) = \delta.$$

$(A, C)$  is called an observable pair if

$$\text{rank} \left( \begin{bmatrix} C^T & (CA)^T & \cdots & (CA^{\delta-2})^T & (CA^{\delta-1})^T \end{bmatrix}^T \right) = \delta.$$

If  $(A, B)$  is a reachable pair and  $(A, C)$  is an observable pair, then  $(A, B, C, D)$  is called a *minimal realization*. In this case,  $\delta$  is called the *McMillan degree* of the system. We denote by  $S_{k,n}^\delta$  the set of minimal realizations of systems over  $\mathbb{K}$  having input vectors of size  $k$ , output vectors of size  $n - k$ , and McMillan degree  $\delta$ .

Let  $\{x_t\}_{t \geq 0}$  be a sequence of vectors in  $\mathbb{F}^\delta$  and  $\{(y_t)\}_{t \geq 0}$ , where  $y_t \in \mathbb{F}^{n-k}$  and  $u_t \in \mathbb{F}^k$ , a sequence of vectors in  $\mathbb{F}^n$  having the following properties:

1. Equations (2.1) are satisfied for all  $t \in \mathbb{N}_0$ .
2. There exists a  $d \in \mathbb{N}_0$  such that  $x_{d+1} = 0$  and  $u_t = 0$  for  $t \geq d + 1$ .

These properties guarantee that the sequence  $\{(y_t)\}_{t \geq 0}$  has finite weight. We refer to the truncated sequence  $\{(y_t)\}_{t=0}^d$  as a *finite-weight sequence* for  $(A, B, C, D)$ . The following remarks connect finite-weight sequences and codewords.

Let  $(A, B, C, D) \in S_{k,n}^\delta$ . The corresponding transfer function is  $T(s) := C(sI - A)^{-1}B + D$ . Let  $Q^{-1}(s)P(s)$  be a left coprime factorization of  $T(s)$ , and set  $H(s) := [-Q(s) \ P(s)]$ . Set

$$y(s) := y_0s^d + y_1s^{d-1} + \cdots + y_d \in \mathbb{F}^{n-k}[s]$$

and

$$u(s) := u_0s^d + u_1s^{d-1} + \cdots + u_d \in \mathbb{F}^k[s],$$

and use their coefficients to form the vector sequence  $\{(y_t)\}_{t=0}^d$ . We then have the following equivalent conditions; see [3, 19, 20] for more details.

1. The set  $\{(y_t)\}_{t=0}^d$  of vectors is a finite-weight sequence for  $(A, B, C, D)$ .
- 2.

$$\left[ \begin{array}{c|cccccc} 0 & \cdots & 0 & A^d B & A^{d-1} B & \cdots & AB & B \\ \hline & & & D & 0 & \cdots & \cdots & 0 \\ & & & CB & D & \ddots & & \vdots \\ & & & CAB & CB & \ddots & \ddots & \vdots \\ & & & \vdots & \vdots & \ddots & \ddots & 0 \\ & & & CA^{d-1} B & CA^{d-2} B & \cdots & CB & D \end{array} \right] \begin{bmatrix} y_0 \\ y_1 \\ \vdots \\ y_d \\ \hline u_0 \\ u_1 \\ \vdots \\ u_d \end{bmatrix} = 0.$$

3. There exists a “state vector polynomial”

$$x(s) = x_0s^d + x_1s^{d-1} + \cdots + x_d \in \mathbb{F}^\delta[s]$$

such that

$$\begin{bmatrix} sI - A & 0 & -B \\ -C & I_{n-k} & -D \end{bmatrix} \begin{bmatrix} x(s) \\ y(s) \\ u(s) \end{bmatrix} = 0.$$

4.

$$H(s) \begin{bmatrix} y(s) \\ u(s) \end{bmatrix} = [-Q(s)P(s)] \begin{bmatrix} y(s) \\ u(s) \end{bmatrix} = 0.$$

5.

$$y(s) = T(s)u(s).$$

Further, the right  $\mathbb{F}[s]$ -kernel of  $H(s)$  is an  $(n, k, \delta)$ -code  $\mathcal{C}$ .

The code  $\mathcal{C}$  is not quite suitable for our purposes. This is due to the fact that the finite-weight sequence

$$\begin{pmatrix} y_0 \\ u_0 \end{pmatrix}, \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}, \dots, \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}, \begin{pmatrix} y_d \\ u_d \end{pmatrix}$$

corresponds with the codeword

$$\begin{pmatrix} y_d \\ u_d \end{pmatrix} + \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}s + \dots + \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}s^{d-1} + \begin{pmatrix} y_0 \\ u_0 \end{pmatrix}s^d \in \mathcal{C}.$$

Working in the systems setting, we will show that there is a realization  $(A, B, C, D) \in S_{k,n}^\delta$  for which any finite-weight sequence

$$\begin{pmatrix} y_0 \\ u_0 \end{pmatrix}, \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}, \dots, \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}, \begin{pmatrix} y_d \\ u_d \end{pmatrix}$$

(with  $u_0 \neq 0$ ) formed using (2.1) has the properties that

$$\sum_{t=0}^L \text{wt} \left( \begin{pmatrix} y_t \\ u_t \end{pmatrix} \right) = (L+1)(n-k) + 1$$

and

$$\sum_{t=0}^M \text{wt} \left( \begin{pmatrix} y_t \\ u_t \end{pmatrix} \right) \geq (n-k) \left( \left\lfloor \frac{\delta}{k} \right\rfloor + 1 \right) + \delta + 1.$$

Due to the order reversal noted above, it will not necessarily be true that  $d_L^c(\mathcal{C}) = (L+1)(n-k) + 1$ . The next result shows how to overcome this problem.

**PROPOSITION 2.9.** *Let  $\mathcal{C}$  be an  $(n, k, \delta)$ -code with minimal generator matrix  $G(s)$ . Let  $\overline{G(s)}$  be the matrix obtained by replacing each entry  $p_{ij}(s)$  of  $G(s)$  by  $\overline{p_{ij}(s)} := s^{\delta_j} p_{ij}(s^{-1})$ , where  $\delta_j$  is the  $j$ th column degree of  $G(s)$ . Then,  $\overline{G(s)}$  is a minimal generator matrix of an  $(n, k, \delta)$ -code  $\overline{\mathcal{C}}$ , and*

$$\begin{pmatrix} y_0 \\ u_0 \end{pmatrix} + \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}s + \dots + \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}s^{d-1} + \begin{pmatrix} y_d \\ u_d \end{pmatrix}s^d \in \overline{\mathcal{C}}$$

*if and only if*

$$\begin{pmatrix} y_d \\ u_d \end{pmatrix} + \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}s + \dots + \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}s^{d-1} + \begin{pmatrix} y_0 \\ u_0 \end{pmatrix}s^d \in \mathcal{C}.$$

*Proof.* First,  $\overline{G(s)}$  has rank  $k$ , since a  $k \times k$  minor of  $\overline{G(s)}$  is zero if and only if the corresponding minor of  $G(s)$  is.

Next, let  $G_0$  denote the  $n \times k$  matrix whose  $ij$ th entry is  $p_{ij}(0)$  and  $\overline{G}_0$  the  $n \times k$  matrix whose  $ij$ th entry is  $\overline{p_{ij}(0)}$ . Because  $\mathcal{C}$  is a summand of  $\mathbb{F}[s]^n$ ,  $G_0$  has full rank, so that each column of  $G_0$  has at least one nonzero entry. This means that  $G_0 = \overline{G}_\infty$ ,  $\overline{G}_\infty$  has full rank, corresponding columns of  $G(s)$  and  $\overline{G(s)}$  have the same column degrees, and  $\overline{\overline{G(s)}} = G(s)$ . From the definition of  $\overline{G(s)}$ , we have that  $G_\infty = \overline{G}_0$ ; since  $G(s)$  is minimal, it follows that  $\overline{G}_0$  also has full rank.

Suppose  $p(s) \in \mathbb{F}[s]$  has degree  $d$  and is a common divisor of the  $k \times k$  minors of  $\overline{G(s)}$ . Then,  $p(0) \neq 0$ , since  $\overline{G}_0$  has full rank, so that  $s^d p(s^{-1})$  has degree  $d$ . Since  $\overline{\overline{G(s)}} = G(s)$ ,  $s^d p(s^{-1})$  is a common divisor of the  $k \times k$  minors of  $G(s)$ . As  $\mathcal{C}$  is a summand of  $\mathbb{F}[s]^n$ , it follows that  $d = 0$ , so that the only common divisors of the  $k \times k$  minors of  $\overline{G(s)}$  are the nonzero elements of  $\mathbb{F}$ . Thus, the column space of  $\overline{G(s)}$  is a summand of  $\mathbb{F}[s]^n$ , which means that it is a rate  $k/n$  convolutional code  $\overline{\mathcal{C}}$ . It follows from the remarks in the preceding paragraph that  $\overline{G(s)}$  is a minimal generator matrix of  $\overline{\mathcal{C}}$  and that  $\overline{\mathcal{C}}$  has degree  $\delta$ .

Consider the vector polynomials

$$v(s) := v_d + v_{d-1}s + \cdots + v_1s^{d-1} + v_0s^d$$

and

$$\overline{v(s)} := v_0 + v_1s + \cdots + v_{d-1}s^{d-1} + v_ds^d$$

in  $\mathbb{F}^n[s]$ , and note that  $\overline{\overline{v(s)}} = s^d v(s^{-1})$ . Thinking of  $v(s)$  and  $\overline{v(s)}$  as column vectors in  $\mathbb{F}[s]^n$ , we observe that a  $(k+1) \times (k+1)$  minor of  $\begin{bmatrix} G(s) & | & v(s) \end{bmatrix}$  is zero if and only if the corresponding minor of  $\begin{bmatrix} \overline{G(s)} & | & \overline{v(s)} \end{bmatrix}$  is. Since  $\mathcal{C}$  and  $\overline{\mathcal{C}}$  are summands of  $\mathbb{F}[s]^n$ , this means that  $v(s) \in \mathcal{C}$  if and only if  $\overline{v(s)} \in \overline{\mathcal{C}}$ .  $\square$

This result, together with the remarks preceding it, shows that

$$\begin{pmatrix} y_0 \\ u_0 \end{pmatrix}, \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}, \dots, \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}, \begin{pmatrix} y_d \\ u_d \end{pmatrix}$$

is a finite-weight sequence for  $(A, B, C, D)$  if and only if

$$\begin{pmatrix} y_0 \\ u_0 \end{pmatrix} + \begin{pmatrix} y_1 \\ u_1 \end{pmatrix}s + \cdots + \begin{pmatrix} y_{d-1} \\ u_{d-1} \end{pmatrix}s^{d-1} + \begin{pmatrix} y_d \\ u_d \end{pmatrix}s^d \in \overline{\mathcal{C}}.$$

$\overline{\mathcal{C}}$ , then, will have the property that  $d_M^c(\overline{\mathcal{C}}) = (n-k)(\lfloor \frac{\delta}{k} \rfloor + 1) + \delta + 1$ . For the rest of the paper, we will refer to the code  $\overline{\mathcal{C}}$  as the code represented by the matrices  $(A, B, C, D)$ .

**3. Trivial rank deficiency and the sMDS property.** In this section, we give conditions on the entries of the matrices in a realization  $(A, B, C, D) \in S_{k,n}^\delta$  guaranteeing that the convolutional code these matrices represent has both the MDP and sMDS properties. For  $(A, B, C, D) \in S_{k,n}^\delta$  and  $j \in \mathbb{N}_0$ , we form the matrices

$$(3.1) \quad \mathcal{T}_j := \begin{bmatrix} D & 0 & \cdots & \cdots & 0 \\ CB & D & \ddots & & \vdots \\ CAB & CB & \ddots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ CA^{j-1}B & CA^{j-2}B & \cdots & CB & D \end{bmatrix}.$$

NOTATION 3.1. Let  $l_1, l_2 \in \mathbb{N}$  satisfy  $1 \leq l_1 \leq (j+1)(n-k)$  and  $1 \leq l_2 \leq (j+1)k$ . Let  $1 \leq i_1 < \dots < i_{l_1} \leq (j+1)(n-k)$  and  $1 \leq j_1 < \dots < j_{l_2} \leq (j+1)k$  be two sequences of integers. We denote by  $(\mathcal{T}_j)_{j_1, \dots, j_{l_2}}^{i_1, \dots, i_{l_1}}$  the  $l_1 \times l_2$  submatrix obtained from  $\mathcal{T}_j$  by intersecting rows  $i_1, \dots, i_{l_1}$  and columns  $j_1, \dots, j_{l_2}$ .

Notice that, if  $(\mathcal{T}_j)_{j_1}^{i_1} \neq 0$ , then  $j_1 \leq \lceil \frac{i_1}{n-k} \rceil k$ .

In what follows, the notion of trivial rank deficiency plays an important role. To define trivial rank deficiency, we think of replacing the entries of the block matrices in  $\mathcal{T}_j$  with the indeterminates of the polynomial ring  $R := \mathbb{K}[x_1, x_2, \dots, x_{(j+1)(n-k)k}]$ . Specifically, we replace the entry  $(s, t)$  of the matrix  $D$  with the indeterminate  $x_{(s-1)k+t}$  and the entry  $(s, t)$  of the matrix  $CA^iB$  with the indeterminate  $x_{(i+1)(n-k)k+(s-1)k+t}$ . The zero entries above the block diagonal remain zero.

DEFINITION 3.2. Let  $c$  be an integer with  $0 \leq c \leq n-k-1$ , and let  $l$  be an integer satisfying  $1 \leq l \leq \min\{(j+1)(n-k)-c, (j+1)k\}$ . A square submatrix of  $\mathcal{T}_j$  is said to be trivially rank deficient if the determinant of this submatrix is zero when it is viewed as a matrix over  $R$  in the manner described above. A submatrix  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  of  $\mathcal{T}_j$  is called trivially rank deficient if all  $\binom{l+c}{l}$   $l \times l$  submatrices of  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  are trivially rank deficient.

To say that  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  is trivially rank deficient is to say that  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  has less than full rank regardless of how elements of  $\mathbb{K}$  are substituted for the indeterminates of  $R$ . The next lemma shows how to determine if a given submatrix is trivially rank deficient.

LEMMA 3.3. Let  $l$  be an integer with  $1 \leq l \leq \min\{(j+1)(n-k)-c, (j+1)k\}$ , and let  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  be an  $(l+c) \times l$  submatrix of  $\mathcal{T}_j$ . Then, the following are equivalent:

1.  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$  is trivially rank deficient.
2.  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_{1+c}, i_{2+c}, \dots, i_{l+c}}$  is trivially rank deficient.
3. The inequality

$$j_t > \left\lceil \frac{i_{t+c}}{n-k} \right\rceil k$$

holds for some  $t \in \{1, \dots, l\}$ .

*Proof.* For notational convenience, we set  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}} := (\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_{1+c}, i_{2+c}, \dots, i_{l+c}}$  and  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}} := (\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+c}}$ .

$1 \implies 2$ : Suppose  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient. Then, by definition, all  $\binom{l+c}{l}$   $l \times l$  submatrices of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  are trivially rank deficient. In particular,  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient.

$2 \implies 3$ : Suppose that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient. We first use induction on  $l$  to prove that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is lower block triangular and has a 0 on its diagonal. If  $l = 1$  and  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient, then the claim is trivially true. Suppose  $l$  satisfies  $2 \leq l \leq \min\{(j+1)(n-k)-c, (j+1)k\}$ , that the induction hypothesis is satisfied for  $1, 2, \dots, l-1$ , and that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient. If  $(\mathcal{T}_j)_{j_1}^{i_{l+c}} = 0$ , then every entry in  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is 0, and thus all diagonal entries are 0. If  $(\mathcal{T}_j)_{j_1}^{i_{l+c}} \neq 0$ , then let  $x_\ell$  be the indeterminate corresponding with  $(\mathcal{T}_j)_{j_1}^{i_{l+c}}$  when  $\mathcal{T}_j$  is viewed over  $R$  in the manner described before Definition 3.2. Notice that, when  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is viewed in this way, the indeterminate  $x_\ell$  appears exactly once. Since  $x_\ell$  is transcendental over  $\mathbb{K}(x_1, \dots, x_{\ell-1})$ , doing a cofactor expansion along the first column of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  (still

viewing  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  over  $R$ ) shows that the  $(l-1) \times (l-1)$  submatrix  $(\mathcal{T}_j)_{j_2, j_3, \dots, j_l}^{i_1+c, i_2+c, \dots, i_{l-1}+c}$  is trivially rank deficient. By the induction hypothesis,  $(\mathcal{T}_j)_{j_2, j_3, \dots, j_l}^{i_1+c, i_2+c, \dots, i_{l-1}+c}$  is lower block triangular and has a 0 on its diagonal. It follows that there is an integer  $h$  satisfying  $1 \leq h \leq l-1$  such that  $(\mathcal{T}_j)_{j_{h+1}}^{i_{h+c}} = 0$ . This, in turn, means that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is lower block triangular. Because we assumed that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient, it follows that at least one of  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_h}^{i_1+c, i_2+c, \dots, i_h+c}$  and  $(\mathcal{T}_j)_{j_{h+1}, j_{h+2}, \dots, j_l}^{i_{h+1}+c, i_{h+2}+c, \dots, i_l+c}$  is trivially rank deficient. By the induction hypothesis, at least one of these submatrices is lower block triangular and has a 0 on its diagonal. As the diagonals of these submatrices lie on the diagonal of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$ , the claim follows.

Next, we note that the diagonal entries of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  are the entries  $(\mathcal{T}_j)_{j_1}^{i_1+c}, (\mathcal{T}_j)_{j_2}^{i_2+c}, \dots, (\mathcal{T}_j)_{j_l}^{i_l+c}$ . From the structure of  $\mathcal{T}_j$ , it is clear that, when  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is viewed over  $R$ , a diagonal entry  $(\mathcal{T}_j)_{j_t}^{i_t+c}$  is 0 if and only if

$$j_t > \left\lceil \frac{i_t+c}{n-k} \right\rceil k.$$

It follows that

$$j_t > \left\lceil \frac{i_t+c}{n-k} \right\rceil k$$

for some  $t \in \{1, \dots, l\}$ .

$3 \implies 1$ : If

$$j_t > \left\lceil \frac{i_t+c}{n-k} \right\rceil k$$

for some  $t \in \{1, \dots, l\}$ , then  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  has a 0 on its diagonal and is lower block triangular.  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is therefore trivially rank deficient. Let  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{w_1, w_2, \dots, w_l}$  be a submatrix of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$ . Since  $w_t \leq i_t+c$ ,

$$j_t > \left\lceil \frac{w_t}{n-k} \right\rceil k$$

holds as well. As before, it follows that  $(\mathcal{T}_j)_{j_1, j_2, \dots, j_l}^{w_1, w_2, \dots, w_l}$  is trivially rank deficient. Consequently, all  $\binom{l+c}{l}$   $l \times l$  submatrices of  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  are trivially rank deficient, so that  $(\mathcal{T}_j)_{\bar{j}}^{\bar{i}}$  is trivially rank deficient.  $\square$

We next characterize the MDP and sMDS properties in terms of trivial rank deficiency. We denote by  $r$  the difference of the generalized Singleton bound and the upper bound for the  $L$ th column distance:

$$\begin{aligned} r &:= (n-k) \left( \left\lfloor \frac{\delta}{k} \right\rfloor + 1 \right) + \delta + 1 - \left( \left\lfloor \frac{\delta}{k} \right\rfloor + \left\lfloor \frac{\delta}{n-k} \right\rfloor + 1 \right) (n-k) - 1 \\ &= \delta - \left\lfloor \frac{\delta}{n-k} \right\rfloor (n-k). \end{aligned}$$

Note that  $r$  is the remainder of  $\delta$  on division by  $n-k$ . If  $r = 0$ , then  $L = M$ , and a code is MDP if and only if it is sMDS. This case was considered in [8] and [11], so we will assume that  $r \in \{1, \dots, n-k-1\}$ . In this situation,  $M = L + 1$ .

**THEOREM 3.4.** *Let  $(A, B, C, D) \in S_{k,n}^\delta$  and  $\mathcal{C}$  be the  $(n, k, \delta)$ -code represented by  $(A, B, C, D)$ . Then,  $\mathcal{C}$  is an MDP code if and only if every square submatrix of  $\mathcal{T}_L$*

that is not trivially rank deficient has full rank.  $\mathcal{C}$  is an sMDS code if and only if, for every integer  $l$  satisfying  $1 \leq l \leq \min\{(M+1)(n-k) - (n-k-r), (M+1)k\}$ , every submatrix  $(\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+n-k-r}}$  that is not trivially rank deficient has full rank.

*Proof.* The first statement is [11, Corollary 2.5]. Next we consider the second statement.

$\Leftarrow$ : Suppose that

$$v := \begin{bmatrix} y_0^T & y_1^T & \cdots & y_M^T & | & u_0^T & u_1^T & \cdots & u_M^T \end{bmatrix}^T$$

is formed from the first  $M+1$  vectors of a finite-weight sequence for  $(A, B, C, D)$  with  $u_0 \neq 0$ , so that the matrix equation

$$\begin{bmatrix} -I_{(M+1)(n-k)} & \begin{bmatrix} D & 0 & \cdots & \cdots & 0 \\ CB & D & \ddots & & \vdots \\ CAB & CB & \ddots & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ CA^{M-1}B & CA^{M-2}B & \cdots & CB & D \end{bmatrix} \end{bmatrix} v = 0$$

is satisfied, and denote the weight of

$$u := \begin{bmatrix} u_0^T & u_1^T & \cdots & u_M^T \end{bmatrix}^T$$

by  $w$ . For  $t \in \{1, \dots, w\}$ , let  $j_t$  denote the position of the  $t$ th nonzero entry in  $u$ , and let  $\bar{u}$  denote the vector obtained from  $u$  by deleting all of the zero entries. Suppose that  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}} := (\mathcal{T}_M)_{j_1, j_2, \dots, j_w}^{i_1, i_2, \dots, i_{w+n-k-r}}$  is a submatrix of  $\mathcal{T}_M$  such that

$$(3.2) \quad (\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}} \bar{u} = 0.$$

Since  $u_0 \neq 0$ , we have that

$$j_1 \leq k \leq \left\lceil \frac{i_1}{n-k} \right\rceil k \leq \left\lceil \frac{i_{1+n-k-r}}{n-k} \right\rceil k.$$

By Lemma 3.3,  $(\mathcal{T}_M)_{j_1}^{i_1, i_2, \dots, i_{1+n-k-r}}$  is not trivially rank deficient, so that it has full rank. This means that at least one of its entries is nonzero, and, since (3.2) holds, it follows that

$$j_2 \leq \left\lceil \frac{i_{1+n-k-r}}{n-k} \right\rceil k \leq \left\lceil \frac{i_{2+n-k-r}}{n-k} \right\rceil k.$$

By Lemma 3.3,  $(\mathcal{T}_M)_{j_1, j_2}^{i_1, i_2, \dots, i_{2+n-k-r}}$  is not trivially rank deficient, so that it has full rank. Consequently, at least one  $2 \times 2$  minor of  $(\mathcal{T}_M)_{j_1, j_2}^{i_1, i_2, \dots, i_{2+n-k-r}}$  is nonzero. Again, since (3.2) holds, it follows that

$$j_3 \leq \left\lceil \frac{i_{2+n-k-r}}{n-k} \right\rceil k \leq \left\lceil \frac{i_{3+n-k-r}}{n-k} \right\rceil k.$$

Continuing, we see that, for  $t \in \{1, \dots, w\}$ ,

$$j_t \leq \left\lceil \frac{i_{t+n-k-r}}{n-k} \right\rceil k.$$

A final application of Lemma 3.3 gives that  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}}$  is not trivially rank deficient. By hypothesis, it must have full rank, which contradicts the hypothesis that  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}} \bar{u} = 0$ . Consequently, at most  $w+n-k-r-1$  rows of  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}}$  are in the left kernel of  $\bar{u}$ . It follows that  $v$  has weight at least  $w + ((M+1)(n-k) - (w+n-k-r-1)) = M(n-k) + 1 + r = (L+1)(n-k) + 1 + r$ , which means that  $d_M^c(\mathcal{C}) \geq (L+1)(n-k) + 1 + r$ . Recalling Proposition 2.6 and the definition of  $r$ , we conclude that  $d_M^c(\mathcal{C}) = (L+1)(n-k) + 1 + r$ , so that  $\mathcal{C}$  is sMDS.

$\Rightarrow$ : We prove the contrapositive. Suppose that the matrix (3.1) has a  $(w+n-k-r) \times w$  submatrix  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}} := (\mathcal{T}_M)_{j_1, j_2, \dots, j_w}^{i_1, i_2, \dots, i_{w+n-k-r}}$  that is not trivially rank deficient and that has less than full rank. There then exists a vector  $(\mathcal{T}_M)_{\tilde{j}}^{\tilde{i}} \bar{u} \neq 0$  of weight  $w' \leq w$  such that  $\bar{u} = 0$ . Let

$$u := \begin{bmatrix} u_0^T & u_1^T & \cdots & u_M^T \end{bmatrix}^T \in \mathbb{F}^{Mk}$$

be the vector in which the  $j_t$ th entry is the  $t$ th entry of  $\bar{u}$  and all other entries are zero; because of the block Toeplitz structure of  $\mathcal{T}_M$ , we may assume that  $u_0 \neq 0$ . Using (2.1), we form the vector

$$v := \begin{bmatrix} y_0^T & y_1^T & \cdots & y_M^T & | & u_0^T & u_1^T & \cdots & u_M^T \end{bmatrix}^T.$$

Because  $[-I_{(M+1)(n-k)} \mid \mathcal{T}_M]v = 0$ , the weight of  $v$  is at most  $w' + (M+1)(n-k) - (w+n-k-r) \leq (M+1)(n-k) - (n-k-r) = (L+1)(n-k) + r < (L+1)(n-k) + r + 1$ . We may choose additional information vectors  $u_{M+1}, \dots, u_d$  so that  $x_d = 0$  (see, for example, [2]); in other words, it is possible to extend  $v$  to a finite-weight sequence for  $(A, B, C, D)$  with weight less than the generalized Singleton bound. Thus,  $d_M^c(\mathcal{C}) < (L+1)(n-k) + r + 1$ , so that  $\mathcal{C}$  is not an sMDS code.  $\square$

Theorem 3.4 gives polynomial conditions on the entries of a realization  $(A, B, C, D) \in S_{k,n}^\delta$  that may be used to determine whether or not the convolutional code these matrices represent has the MDP and sMDS properties. In the next section, we use this information to show that we can find a realization  $(A, B, C, D) \in S_{k,n}^\delta$  representing an  $(n, k, \delta)$ -code that has the MDP and sMDS properties.

**4. Proof of the existence of sMDS convolutional codes.** Recall that we defined the block matrices making up  $\mathcal{T}_M$  in terms of matrices  $(A, B, C, D)$ . In this section, we will work in the opposite direction. Let  $\{F_0, F_1, \dots, F_j\}$  be a sequence of matrices in  $\mathbb{K}^{(n-k) \times k}$ . Slightly abusing notation, we set

$$(4.1) \quad \mathcal{T}_j := \begin{bmatrix} F_0 & 0 & \cdots & 0 \\ F_1 & F_0 & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ F_j & F_{j-1} & \cdots & F_0 \end{bmatrix}.$$

The plan is to show the existence of a sequence  $\{F_0, F_1, \dots, F_M\}$  of matrices in  $\mathbb{K}^{(n-k) \times k}$  such that

1.  $\mathcal{T}_M$  has the property that, for all integers  $l$  with  $1 \leq l \leq \min\{(M+1)(n-k) - (n-k-r), (M+1)k\}$ , every submatrix  $(\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+n-k-r}}$  that is not trivially rank deficient has full rank;
2. there is a minimal partial realization  $(A, B, C, D) \in S_{k,n}^\delta$  of this matrix sequence (this means that  $D = F_0$  and  $CA^{i-1}B = F_i$  for  $1 \leq i \leq M$ ).

The matrices  $(A, B, C, D)$  will represent the desired code. We begin with the following lemma.

LEMMA 4.1. *There exists a sequence  $\{F_0, F_1, \dots, F_L\}$  of matrices in  $\mathbb{K}^{(n-k) \times k}$  such that every square submatrix of  $\mathcal{T}_L$  that is not trivially rank deficient has full rank.*

*Proof.* Note that we may think of such a matrix sequence  $\{F_0, F_1, \dots, F_L\}$  as a point in  $\mathbb{K}^{(L+1)(n-k)k}$ . To begin, think of the matrix (4.1) with  $j = L$  as being defined over the polynomial ring  $\mathbb{K}[x_1, x_2, \dots, x_{(L+1)(n-k)k}]$ , the entries corresponding with the indeterminates of this ring in a manner analogous to that in the previous section. When viewed in this way, the determinant of a square submatrix of  $\mathcal{T}_L$  that is not trivially rank deficient is a nonzero polynomial in  $\mathbb{K}[x_1, x_2, \dots, x_{(L+1)(n-k)k}]$ , and there is a finite number of such polynomials. The solution sets of these polynomials make up a proper algebraic subset of  $\mathbb{K}^{(L+1)(n-k)k}$ , the complement of which is a nonempty Zariski open set. Choose  $\{F_0, \dots, F_L\}$  to be a point in this open set.  $\square$

To determine the degree of a minimal partial realization of a matrix sequence  $\{F_0, F_1, \dots, F_M\}$ , we consider the matrices

$$\mathcal{F}_{x,y} := \begin{bmatrix} F_1 & F_2 & \cdots & F_y \\ F_2 & F_3 & \cdots & F_{y+1} \\ \vdots & \vdots & & \vdots \\ F_x & F_{x+1} & \cdots & F_{x+y-1} \end{bmatrix}.$$

In [22, Lemma 3], it is shown that the degree of a minimal partial realization of  $\{F_0, F_1, \dots, F_M\}$  is given by the expression

$$(4.2) \quad \sum_{x=1}^M \text{rank } \mathcal{F}_{x, M+1-x} - \sum_{x=1}^{M-1} \text{rank } \mathcal{F}_{x, M-x}.$$

The next results show that, starting with a matrix sequence  $\{F_0, F_1, \dots, F_L\}$  as described in Lemma 4.1, we can find a matrix  $F_M$  so that the expression (4.2) evaluates to  $\delta$ .

LEMMA 4.2. *Let  $\{F_0, \dots, F_M\}$  be a sequence of matrices in  $\mathbb{K}^{(n-k) \times k}$  such that every square submatrix of  $\mathcal{T}_L$  that is not trivially rank deficient has full rank. Then,*

1. *for  $x \in \{1, \dots, M-1\}$ ,  $\text{rank } \mathcal{F}_{x, M-x} = \min\{x(n-k), (M-x)k\}$ .*
2. *If  $\text{rank } \mathcal{F}_{x, M+1-x} < \min\{x(n-k), (M+1-x)k\}$ , then  $x = \lceil M \frac{k}{n} \rceil$ . If  $x \in \{1, \dots, M\} \setminus \{\lceil M \frac{k}{n} \rceil\}$ , then  $\text{rank } \mathcal{F}_{x, M+1-x} = \min\{x(n-k), (M+1-x)k\}$ .*
3. *Set  $\bar{x} := \lceil M \frac{k}{n} \rceil$ . The expression (4.2) reduces to  $\text{rank } \mathcal{F}_{\bar{x}, M+1-\bar{x}}$ .*

*Proof.* To verify the first claim, observe that  $\mathcal{F}_{x, M-x}$  differs by a column permutation from a submatrix of  $\mathcal{T}_L$  that has full rank.

For the second claim, suppose first that  $x(n-k) \leq (M+1-x)k$ . The hypothesis is then that  $\text{rank } \mathcal{F}_{x, M+1-x} < x(n-k)$ . If  $x < M$ , it follows from 1 that  $\text{rank } \mathcal{F}_{x, M-x} = \min\{x(n-k), (M-x)k\}$ , which means that  $x(n-k) > (M-x)k$ . Together, this gives

$$(M-x)k < x(n-k) \leq (M+1-x)k$$

(note that the first inequality also holds if  $x = M$ ). This can be rewritten as

$$M \frac{k}{n} < x \leq (M+1) \frac{k}{n}.$$

If we suppose instead that  $(M+1-x)k \leq x(n-k)$ , similar reasoning leads to

$$(M+1)\frac{k}{n} \leq x < M\frac{k}{n} + 1.$$

In all, we have

$$M\frac{k}{n} < x < M\frac{k}{n} + 1.$$

Since  $x$  is an integer,  $x = \lceil M\frac{k}{n} \rceil$ . The second statement follows immediately.

The third claim follows directly from the first two, since  $x < \bar{x} \implies x(n-k) < (M-x)k$  and  $x > \bar{x} \implies x(n-k) > (M+1-x)k$ .  $\square$

**THEOREM 4.3.** *Let  $\{F_0, \dots, F_L\}$  be a sequence of matrices in  $\mathbb{K}^{(n-k) \times k}$  such that every square submatrix of  $\mathcal{T}_L$  that is not trivially rank deficient has full rank. Then, one can find a matrix  $F_M \in \mathbb{K}^{(n-k) \times k}$  such that*

1. *the matrix*

$$\mathcal{F}_{\bar{x}, M+1-\bar{x}} = \begin{bmatrix} F_1 & F_2 & \cdots & F_{M+1-\bar{x}} \\ F_2 & F_3 & \cdots & F_{M+2-\bar{x}} \\ \vdots & \vdots & \ddots & \vdots \\ F_{\bar{x}} & F_{\bar{x}+1} & \cdots & F_M \end{bmatrix}$$

*has rank  $\delta$ ;*

2. *the matrix  $\mathcal{T}_M$  has the property that, for every integer  $l$  with  $1 \leq l \leq \min\{(M+1)(n-k)-(n-k-r), (M+1)k\}$ , every submatrix  $(\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+n-k-r}}$  that is not trivially rank deficient has full rank.*

*Proof.* We may write

$$\delta = \left\lfloor \frac{\delta}{n-k} \right\rfloor (n-k) + r = \left\lfloor \frac{\delta}{k} \right\rfloor k + r',$$

where  $1 \leq r < n-k$  and  $0 \leq r' < k$ . Since

$$M = L+1 = \left\lfloor \frac{\delta}{n-k} \right\rfloor + \left\lfloor \frac{\delta}{k} \right\rfloor + 1,$$

we see that

$$\begin{aligned} \frac{Mk}{n} &= \left\lfloor \frac{\delta}{n-k} \right\rfloor \frac{k}{n} + \left\lfloor \frac{\delta}{k} \right\rfloor \frac{k}{n} + \frac{k}{n} = \left\lfloor \frac{\delta}{n-k} \right\rfloor - \left\lfloor \frac{\delta}{n-k} \right\rfloor \frac{n-k}{n} + \left\lfloor \frac{\delta}{k} \right\rfloor \frac{k}{n} + \frac{k}{n} \\ &= \left\lfloor \frac{\delta}{n-k} \right\rfloor - \frac{\delta-r}{n} + \frac{\delta-r'}{n} + \frac{k}{n} = \left\lfloor \frac{\delta}{n-k} \right\rfloor + \frac{k-r'+r}{n}. \end{aligned}$$

Since  $1 < k-r'+r < n$ , we have  $\lfloor \frac{\delta}{n-k} \rfloor = \bar{x}-1$ , so that  $\delta = (\bar{x}-1)(n-k) + r$  and

$$\frac{Mk}{n} = \bar{x}-1 + \frac{k-r'+r}{n}.$$

Multiplying both sides by  $n$  and subtracting  $\bar{x}k$  from both sides, we get

$$(M-\bar{x})k = (\bar{x}-1)(n-k) + r - r' = \delta - r',$$

from which it follows that  $(M-\bar{x})k \leq \delta$ . Since  $r' < k$ , it also follows that  $\delta < (M+1-\bar{x})k$ .

We next want to see that we may find a matrix  $F_M$  as described in the statement of the theorem. We first consider the top  $r$  rows of  $F_M$ . Using the same reasoning as in the proof of Lemma 4.1, we may find elements of  $\mathbb{K}$  to form these top  $r$  rows so that all square submatrices of the top  $M(n-k) + r$  rows of  $\mathcal{T}_M$  that are not trivially rank deficient have full rank. In particular, all square submatrices of the top  $\delta$  rows of  $\mathcal{F}_{\bar{x}, M+1-\bar{x}}$  have full rank. Denote the  $r \times k$  matrix consisting of these  $r$  rows by  $F'_M$ . Since  $\delta < (M+1-\bar{x})k$ ,  $\text{rank } \mathcal{F}_{\bar{x}, M+1-\bar{x}} \geq \delta$  will hold regardless of how the entries of the bottom  $n-k-r$  rows of  $F_M$  are chosen. To find entries for these rows so that  $\text{rank } \mathcal{F}_{\bar{x}, M+1-\bar{x}} = \delta$ , consider the top  $\delta$  rows of  $\mathcal{F}_{\bar{x}, M-\bar{x}}$ . Since  $\delta \geq (M-\bar{x})k$ , we may choose  $M-\bar{x}$  of these  $\delta$  rows to form an  $(M-\bar{x})k \times (M-\bar{x})k$  submatrix that necessarily has full rank. This means that the last  $n-k-r$  rows of  $\mathcal{F}_{\bar{x}, M-\bar{x}}$  may each be expressed as a linear combination of the rows of our chosen submatrix. Consequently, we may take the last  $n-k-r$  rows of  $F_M$  to be the corresponding linear combinations of the rows of

$$\begin{bmatrix} F_{M+1-\bar{x}} \\ F_{M+2-\bar{x}} \\ \vdots \\ F'_M \end{bmatrix}$$

extending the rows of our chosen submatrix. With this, we have found an  $F_M$  so that  $\text{rank } \mathcal{F}_{\bar{x}, M+1-\bar{x}} = \delta$ .

Suppose finally that  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}} := (\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_{l+n-k-r}}$  is a submatrix of  $\mathcal{T}_M$  that is not trivially rank deficient and does not have full rank. Then, in particular,  $(\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_l}$  does not have full rank. Since  $(\mathcal{T}_M)_{j_1, j_2, \dots, j_l}^{i_1, i_2, \dots, i_l}$  is contained in the top  $M(n-k) + r$  rows of  $\mathcal{T}_M$ , it must be trivially rank deficient. By Lemma 3.3, there exists a smallest integer  $t \in \{1, \dots, l\}$  such that

$$j_t > \left\lceil \frac{i_t}{n-k} \right\rceil k.$$

Since  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}}$  is not trivially rank deficient, it also follows from Lemma 3.3 that

$$j_\tau \leq \left\lceil \frac{i_\tau + n - k - r}{n - k} \right\rceil k \quad \forall \tau \in \{1, \dots, l\},$$

so that  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}} := (\mathcal{T}_M)_{j_t, j_{t+1}, \dots, j_l}^{i_t + n - k - r, i_{t+1} + n - k - r, \dots, i_{l+n-k-r}}$  is not trivially rank deficient. Since  $j_t > k$ ,  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}}$  must be a submatrix of  $\mathcal{T}_L$ , which means that  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}}$  has full rank. Recalling how  $t$  was chosen, we see that  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}}$  has full rank. This is a contradiction. We conclude that if a submatrix  $(\mathcal{T}_M)_{\bar{j}}^{\bar{i}}$  is not trivially rank deficient, then it has full rank.  $\square$

**COROLLARY 4.4.** *Let  $\{F_0, \dots, F_M\}$  be as in Theorem 4.3. Then, the expression (4.2) evaluates to  $\delta$ .*

We are now ready to finish our existence proof.

**THEOREM 4.5.** *An MDP and sMDS  $(n, k, \delta)$ -code exists over a sufficiently large finite field of characteristic  $p$ .*

*Proof.* By Lemma 4.1 and Theorem 4.3, we can find a sequence  $\{F_0, \dots, F_M\}$  of matrices in  $\mathbb{K}^{(n-k) \times k}$  such that

1. every square submatrix of  $\mathcal{T}_L$  that is not trivially rank deficient has full rank;

2. every  $(l + n - k - r) \times l$  submatrix of  $\mathcal{T}_M$  that is not trivially rank deficient has full rank;
3. the minimum possible degree of a partial realization of  $\{F_0, \dots, F_M\}$  is  $\delta$ .

Since there are a finite number of entries in the matrices  $\{F_0, \dots, F_M\}$ , the entries all belong to some finite subfield  $\mathbb{F}$  of  $\mathbb{K}$ . From [22, Theorem 1], there is a minimal realization  $(A, B, C, D) \in S_{k,n}^\delta$  of the sequence  $\{F_0, \dots, F_M\}$  with entries in  $\mathbb{F}$ . By Theorem 3.4, the  $(n, k, \delta)$ -code represented by  $(A, B, C, D)$  is both MDP and sMDS.  $\square$

With this, we have shown that the conjecture in [8] that codes having both the MDP and sMDS properties exist for all parameters  $(n, k, \delta)$  is correct. It is still an open problem as to how one may construct matrices of the form (3.1) leading to codes with these properties, and this must be left for future research.

**Acknowledgments.** The author wishes to thank Joachim Rosenthal, Heide Gluesing-Luerssen, and José Ignacio Iglesias Curto for helpful comments during the preparation of this paper. He also wishes to thank the anonymous referees for their careful readings and detailed comments.

## MINIMAL TIME SEQUENTIAL BATCH REACTORS WITH BOUNDED AND IMPULSE CONTROLS FOR ONE OR MORE SPECIES\*

P. GAJARDO<sup>†</sup>, H. RAMÍREZ C.<sup>‡</sup>, AND A. RAPAPORT<sup>§</sup>

**Abstract.** We consider the optimal control problem of feeding in minimal time a tank where several species compete for a single resource, with the objective being to reach a given level of the resource. We allow controls to be bounded measurable functions of time plus possible impulses. For the one-species case, we show that the immediate one-impulse strategy (filling the whole reactor with one single impulse at the initial time) is optimal when the growth function is monotonic. For nonmonotonic growth functions with one maximum, we show that a particular singular arc strategy (precisely defined in section 3) is optimal. These results extend and improve former ones obtained for the class of measurable controls only. For the two-species case with monotonic growth functions, we give conditions under which the immediate one-impulse strategy is optimal. We also give optimality conditions for the singular arc strategy (at a level that depends on the initial condition) to be optimal. The possibility for the immediate one-impulse strategy to be nonoptimal while both growth functions are monotonic is a surprising result and is illustrated with the help of numerical simulations.

**1. Introduction.** Sequential batch reactors (SBR) are often used in biotechnological industries, notably in waste-water treatment. Typically, a tank is filled with activated sludge or biological microorganisms capable of degrading some undesirable substrate. The method then consists of a sequence of cycles composed of three phases:

- Phase 1: Filling the reactor with water to be treated,
- Phase 2: Waiting for the concentration of the undesirable substrate to decrease until a given (low) concentration,
- Phase 3: Emptying the *clean* water from the reactor, leaving the sludge inside.

The time necessary to achieve such cycles can be substantially long and can have an economic impact on the overall process. Manipulating the input flow during the filling phase clearly has an influence on the total duration of the cycle (more precisely, the duration of Phases 1 and 2, the duration of Phase 3 being fixed). But the nonlinear kinetics of the biological reactions do not always make easy the determination of the input flow strategy that minimizes the total time obvious.

Very similar problems (optimizing the production of biomass at a fixed terminal time) have already been tackled with the help of optimal control theory [1, 11, 10],

which has led to computational methods [30, 12]. For models with one biological species, a solution of the minimal time problem has been proposed by Moreno in [20] for monotonic as well as nonmonotonic kinetics. It has been proved that, for monotonic growth functions, such as the Monod law (see [29]), the optimal solution consists of a *most rapid approach* strategy, namely, filling the tank up to its maximum capacity as fast as possible and then waiting. For nonmonotonic growths with one maximum, such as the Haldane law (see [29]), a *singular arc* strategy which consists of maintaining the resource level that maximizes the growth function for most of the time, have been proved to be optimal. The optimality proofs are based on a technique due to Miele [13] using Green's theorem. More precisely, proofs rely on a reformulation of the problem in a planar one.

In the present work, we consider minimal time problems where more than one species can compete for the same substrate. For these cases, the problem cannot be reformulated into a planar one, and the technique mentioned above does not apply. Nevertheless, we are interested in characterizing biological systems for which the *most rapid approach* strategy is again optimal. We are also interested in identifying conditions for which a *singular arc* strategy could be optimal.

We shall allow adding unbounded or impulsive controls to the usual measurable bounded controls. The practical motivation for such a consideration comes from the fact that a bounded measurable control can be incorporated into a device that tunes the speed of a pump over a certain range, while an unbounded control can be assimilated to an instantaneous dilution of a positive volume, as in [9]. A similar optimal control problem for fed-batch processes has been studied in [32] but for a fixed terminal time and a final cost. A characterization of minimal time functions with impulse controls and state constraints has been proposed in [7, 26]. In [7], some restrictive conditions are considered on the jumps that do not apply to the present problem. In [26], the minimal time function is characterized but as a function of a bound on the total variation allowed on the unbounded control. For related results concerning the regularity of the value function for minimal time problems, see [24] and the references therein.

For our problem with a scalar control, we use a smooth time parameterization in the spirit of [33] and [34], which differs from more general approaches that use discontinuous time transformation (see, for instance, [3, 8, 14, 15, 16, 18, 19] or [35]). The possibility of immediately reaching the target with a single jump has also led us to extend the definition of the singular arc strategy to the framework of impulse controls.

Even though the main contribution of this paper is the analysis of the two species case, it is worth noting that the former results of Moreno [20] for the one-species case without impulse controls did not consider the parametric configuration  $s^* < s_{out}$  (the notation will be defined in section 3). This case leads to more complicated optimal trajectories, as we shall show. Furthermore, we provide an explicit expression for the value function for any parametric configuration.

The paper is organized as follows. In the next section, we state the minimal time problem with impulse control and give an equivalent formulation with measurable controls. In section 3, we define the *one-impulse* and *singular arc* strategies. Section 4 characterizes the cost of the *one-impulse* strategy, which plays an important role in the following sections. Section 5 gives the Hamilton–Jacobi formulation of the problem and states optimality results for the strategies presented in section 3. The use of the minimum principle is presented in section 6. Finally, applications to the one- and two-species cases are given in sections 7 and 8, respectively.

**2. Formulation of the problem.** The dynamics of an SBR with several species can be described by the following set of ordinary differential equations (see [29]):

$$(2.1) \quad \begin{cases} \dot{x}_i = \mu_i(s)x_i - \frac{F}{v}x_i, & x_i(t_0) = y_i \quad (i = 1 \cdots n), \\ \dot{s} = -\sum_{j=1}^n \mu_j(s)x_j + \frac{F}{v}(s_{in} - s), & s(t_0) = z, \\ \dot{v} = F, & v(t_0) = w, \end{cases}$$

where  $x_i$ ,  $s$ , and  $v$  stand, respectively, for the concentration of the  $i$ th species, the concentration of the substrate, and the current volume of water present in the tank. The parameter  $s_{in} > 0$  is a constant which represents the substrate concentration in the input flow. The growth functions  $\mu_i(\cdot)$  are nonnegative smooth functions such that  $\mu_i(0) = 0$ , and the input flow  $F$  is a nonnegative control variable.

Given a (desirable) substrate concentration  $s_{out} \in ]0, s_{in}[$  and a volume (of the reactor)  $v_{max} > 0$ , consider the domain  $\mathcal{D} = (\mathbb{R}_+^n \setminus \{0\}) \times ]0, s_{in}] \times ]0, v_{max}[$  and the target  $\mathcal{T} = \mathbb{R}_+^n \times ]0, s_{out}] \times \{v_{max}\}$ . From any initial condition  $\xi = (y, z, w)$  in  $\mathcal{D}$  at time  $t_0$ , the objective is to reach  $\mathcal{T}$  in minimal time. Let us write  $V(\cdot)$  the value function of the problem

$$(2.2) \quad V(\xi) = \inf_{F(\cdot)} \{t - t_0 \mid s^{t_0, \xi, F}(t) \leq s_{out}, v^{t_0, \xi, F}(t) = v_{max}\},$$

where  $s^{t_0, \xi, F}(\cdot)$ ,  $v^{t_0, \xi, F}(\cdot)$  denote solutions of (2.1), with initial condition  $\xi \in \mathcal{D}$  at time  $t_0$  and control  $F(\cdot)$ .

We allow here  $F(\cdot)$  to be a nonnegative measurable function plus possible positive impulses. The question of the proper treatment of optimal control problems with unbounded or *impulse* controls has already been studied in the literature (see [5, 6, 8, 14, 15, 17, 18, 19, 21, 22, 23, 26, 27, 35]). Instead of an ordinary control  $F(\cdot)$ , we consider a measure  $dF(\cdot)$  that we decompose into a sum of a measure absolutely continuous with respect to the Lebesgue measure  $u(t)dt$  and a singular or *impulsive* part  $d\sigma$  (see [33, 34]):

$$(2.3) \quad dF(t) = u(t)dt + d\sigma.$$

Here,  $u(\cdot)$  is a measurable nonnegative control that we impose to be bounded from above by  $u_{max}$ , because it corresponds to the use of a *pump* device. At time  $t$ , the nonnegative *impulse*  $d\sigma$  corresponds to an (instantaneous) addition of volume from  $v^-(t)$  to  $v^+(t)$ . When  $d\sigma$  is nonnull, it implies that the concentrations  $x_i$  and  $s$  jump as follows:

$$\begin{cases} x_i^+(t) = x_i^-(t) \frac{v^-(t)}{v^+(t)}, \\ s^+(t) = s^-(t) \frac{v^-(t)}{v^+(t)} + s_{in} \left(1 - \frac{v^-(t)}{v^+(t)}\right). \end{cases}$$

Notice that such a jump is equivalent to integrate the dynamics

$$(2.4) \quad \frac{dx_i}{d\tau} = -\frac{u}{v}x_i, \quad \frac{ds}{d\tau} = \frac{u}{v}(s_{in} - s), \quad \frac{dv}{d\tau} = u,$$

from  $\tau^-$  to  $\tau^+$ , with any regular nonnegative control  $u(\cdot)$  bounded from above by  $u_{max}$ , provided that the integral constraint is fulfilled:

$$(2.5) \quad \int_{\tau^-}^{\tau^+} u(\tau)d\tau = v^+(t) - v^-(t).$$

FIG. 2.1. Time parameterization.

Consider then a time parameterization  $\tau \geq t_0$  such that  $dt = r(\tau)d\tau$  (see Figure 2.1), where

$$r(\tau) = \begin{cases} 1 & \text{when } dF \text{ is absolutely continuous (a.c.) at } t(\tau), \\ 0 & \text{otherwise.} \end{cases}$$

Then, dynamics (2.1) with  $dF$  regular, and dynamics (2.4) with nonnull  $d\sigma$  can be gathered into the system

$$(2.6) \quad \begin{cases} \frac{dx_i}{d\tau} = r\mu_i(s)x_i - \frac{u}{v}x_i & (i = 1 \cdots n), \\ \frac{ds}{d\tau} = -r \sum_{j=1}^n \mu_j(s)x_j + \frac{u}{v}(s_{in} - s), \\ \frac{dv}{d\tau} = u, \end{cases}$$

where the controls  $u(\cdot)$  and  $r(\cdot)$  are sought among measurable functions w.r.t.  $\tau$ , taking values in  $[0, u_{\max}]$  and  $\{0, 1\}$ , respectively. Notice that, in this formulation,  $u(\cdot)$  plays both the role of an ordinary control when  $r = 1$  and the control of the amplitude of the jump (2.5) when  $r = 0$ , with the same single constraint  $u \in [0, u_{\max}]$ .

*Remark 1.* We could have considered two distinct controls, as in [18], for instance, if we write the system (2.1) as

$$\dot{X}(t) = f(X(t)) + F(t)g(X(t)),$$

where  $X = (x_i, s, v)$ ,  $i = 1, \dots, n$  and functions  $f$  and  $g$  are suitably chosen to be compatible with the dynamics (2.1), we could consider

$$\dot{X}(t) = f(X(t)) + (u_1(t) + u_2(t))g(X(t)),$$

with  $u_1$  a measurable nonnegative bounded (by  $u_{\max}$ ) control and  $u_2$  is an unbounded nonnegative control.

In this framework, the time reparametrization  $dt = r d\tau$ , with  $r \in [0, 1]$ , leads to the dynamics

$$(2.7) \quad \frac{dX}{d\tau} = r(\tau)[f(X(\tau)) + u_1(\tau)g(X(\tau))] + (1 - r(\tau))w_2(\tau)g(X(\tau)),$$

with  $u_1$  and  $w_2$  nonnegative bounded controls. One can also require  $w_2$  to be bounded by the same bounds  $u_{\max}$  as  $u_1$ , where  $u_1(\tau)r(\tau)d\tau = u_1(t)dt$  and  $(1 - r(\tau))w_2(\tau)d\tau = du_2(t)$ . The dynamics (2.7) is equivalent to

$$\frac{dX}{d\tau} = r(\tau)f(X(\tau)) + u(\tau)g(X(\tau)),$$

where  $u = ru_1 + (1 - r)w_2$  belongs to  $[0, u_{\max}]$ .

*Remark 2.* Since one can always take  $r = 0$  and  $u = 0$  on an arbitrarily large  $\tau$ -interval without modifying the total time  $\int_{t_0}^{\tau} r(\theta)d\theta$ , the minimal time problem has no unique solution. Hence, without loss of generality, we will be only interested in controls that never take null values simultaneously, that is, satisfying  $r(\tau) \neq 0$  or  $u(\tau) \neq 0$  for all time  $\tau$ .

Let us define the set of admissible controls by

$$(2.8) \quad \mathcal{C} = \{(u, r) : [0, +\infty) \mapsto [0, u_{\max}] \times \{0, 1\} \setminus \{(0, 0)\} \text{ Lebesgue measurable}\},$$

and let us write now  $V(\cdot)$  the value function of the reformulated problem (2.6)

$$(2.9) \quad V(\xi) = \inf_{(u, r)(\cdot) \in \mathcal{C}} \left\{ \int_{t_0}^{\tau} r(\theta)d\theta \mid s^{t_0, \xi, u, r}(\tau) \leq s_{out}, v^{t_0, \xi, u, r}(\tau) = v_{\max} \right\},$$

where  $s^{t_0, \xi, u, r}(\cdot)$ ,  $v^{t_0, \xi, u, r}(\cdot)$  denote solutions of (2.6), with initial condition  $\xi \in \mathcal{D}$  at time  $t_0$  and controls  $u(\cdot)$  and  $r(\cdot)$ .

*Remark 3.* Any trajectory of the dynamics (2.6) with initial condition  $\xi = (y, z, w) \in \mathcal{D}$  lies in the region defined by

$$(2.10) \quad \rho(\xi) = v \left( \sum_{j=1}^n x_j + s - s_{in} \right) = w \left( \sum_{j=1}^n y_j + z - s_{in} \right).$$

By using the above fact, one can write the variable  $s$  in terms of the other variables as follows:

$$(2.11) \quad s = \frac{\rho(\xi)}{v} - \sum_{j=1}^n x_j + s_{in}.$$

This is a key step in the approach used in Moreno [20] that reformulates the problem with one species in a planar one. However, since it does not simplify our results, we shall work with all of the variables. In the proof of Proposition 7.4 only, equality (2.11) will be used.

**3. The one-impulse and singular arc strategies.** From an initial state  $\xi = (y, z, w) \in \mathcal{D}$  at time  $t_0$ , we define the *immediate one impulse* strategy (that we shall denote *IOI strategy* in the following), which consists in making the following:

1. An impulse of volume  $v_{\max} - w$  at  $t_0$ . This can be achieved by  $r(\tau) = 0$ ,  $u(\tau) = u_{\max}$ , for  $\tau \in [t_0, t_0 + (v_{\max} - w)/u_{\max}]$ .
2. A null control (no feeding) until the concentration  $s(\tau)$  reaches  $s_{out}$ .

For convenience, we shall denote by  $\tilde{y}(\xi)$  and  $\tilde{z}(\xi)$  the concentrations obtained with an impulse of volume  $v_{\max} - w$  from a state  $\xi = (y, z, w) \in \mathcal{D}$ :

$$(3.1) \quad \tilde{y}(\xi) = y \frac{w}{v_{\max}}, \quad \tilde{z}(\xi) = z \frac{w}{v_{\max}} + s_{in} \left( 1 - \frac{w}{v_{\max}} \right).$$

Notice that, for the particular case  $\tilde{z}(\xi) \leq s_{out}$ , the first step only is used.

A second strategy considered in this paper is defined as follows. Consider a time  $t_0$ , a state  $\xi = (y, z, w) \in \mathcal{D}$ , a level substrate  $\bar{s}$  in  $]0, s_{in}[$ , and define the quantity

$$(3.2) \quad s^\dagger(\bar{s}, w) = s_{in} - (s_{in} - \max(\bar{s}, s_{out})) \frac{v_{\max}}{w}.$$

The *singular arc* strategy on the level  $\bar{s}$ , denoted by  $SA(\bar{s})$ , consists of the following steps.

1. *First step*:

- a. If  $z > s^\dagger(\bar{s}, w)$  and  $z < \bar{s}$ , make an impulse of volume  $w(\bar{s} - z)/(s_{in} - \bar{s})$  at  $t_0$ . This can be achieved by  $r(\tau) = 0$  and  $u(\tau) = u_{\max}$ , for  $\tau \in [t_0, \bar{t}]$ , where  $\bar{t} = t_0 + w(\bar{s} - z)/u_{\max}(s_{in} - \bar{s})$  (then  $s$  and  $v$  jump to  $\bar{s}$  and  $\bar{v} = w(s_{in} - z)/(s_{in} - \bar{s}) \leq v_{\max}$ , respectively).
- b. If  $z \geq \bar{s}$  and  $z > s^\dagger(\bar{s}, w)$ , apply a null control (no feeding) until the concentration  $s(\cdot)$  reaches the value  $\max(\bar{s}, s^\dagger(\bar{s}, w))$ , i.e.,  $r(\tau) = 1$ ,  $u(\tau) = 0$  for  $\tau \in [t_0, \bar{t}]$ , where  $\bar{t}$  is such that  $s^{t_0, y, z}(\bar{t}) = \max(\bar{s}, s^\dagger(\bar{s}, w))$  and  $s^{t_0, y, z}(\cdot)$  is the solution of the free dynamics

$$(3.3) \quad \begin{cases} \frac{dx_i}{d\tau} = \mu_i(s)x_i, & x_i(t_0) = y_i \quad (i = 1 \cdots n), \\ \frac{ds}{d\tau} = -\sum_{j=1}^n \mu_j(s)x_j, & s(t_0) = z. \end{cases}$$

- c. If  $z \leq s^\dagger(\bar{s}, w)$ , make an impulse of volume  $v_{\max} - w$  and go to the third step.

2. *Second step*:

- a. If the current state  $s$  is equal to  $\bar{s}$ , make a *singular arc*<sup>1</sup> by taking  $r(\tau) = 1$  and a suitable control  $u(\cdot)$  ensuring  $s(\tau) = \bar{s}$  for any  $\tau \in (\bar{t}, \tilde{T}]$ , where  $\tilde{T}$  is such that  $v(\tilde{T}^+) = v^\dagger(\bar{s})$  and the volume  $v^\dagger(\bar{s})$  is defined as follows:

$$(3.4) \quad v^\dagger(\bar{s}) = v_{\max} \min \left( 1, \frac{s_{in} - s_{out}}{s_{in} - \bar{s}} \right).$$

If  $v^\dagger(\bar{s}) < v_{\max}$  (or, equivalently,  $\bar{s} < s_{out}$ ), then make an impulse of volume  $v_{\max} - v^\dagger(\bar{s})$ , and the process is finished. Otherwise, go to the third step.

- b. If the current state  $s$  is equal to  $s^\dagger(\bar{s}, w)$ , make an impulse of volume  $v_{\max} - w$ , and the process is finished.

3. *Third step*: Apply  $r = 1$  and a null control  $u$  until the concentration  $s(\cdot)$  reaches  $s_{out}$ .

<sup>1</sup>See [4, Part III Chapter 2] for a formal definition.

 FIG. 3.1. The  $SA(\bar{s})$  synthesis when  $\bar{s} > s_{out}$ .

Notice that  $z \leq s^\dagger(\bar{s}, w)$  implies that before reaching the substrate level  $\bar{s}$  with an impulse of volume, one reaches the volume  $v_{\max}$ . When  $z > s^\dagger(\bar{s}, w)$  and  $s^\dagger(\bar{s}, w) > \bar{s}$ , the variable  $s$  reaches the value  $s^\dagger(\bar{s}, w)$  before  $\bar{s}$ , and then an impulse drives directly to the target.

Observe also that, in order to apply the singular arc strategy on  $\bar{s}$ , imposing  $ds/d\tau = 0$ , the following constraint on the control  $u$  must be satisfied:

$$\frac{v}{(s_{in} - \bar{s})} \sum_{j=1}^n \mu_j(\bar{s}) x_j = u \leq u_{\max}.$$

Since the maximum level of substrate on which one can apply a singular arc, starting from  $\xi \in \mathcal{D}$ , is given by  $\tilde{z}(\xi)$  defined in (3.1), a sufficient condition, on the initial condition  $\xi$ , in order to guarantee the above inequality is to have

$$(3.5) \quad M \left( \frac{\rho(\xi)}{s_{in} - \tilde{z}(\xi)} + v_{\max} \right) \leq u_{\max},$$

where  $\rho(\xi)$  is defined by (2.10) and

$$M = \max_{\substack{s \in [0, s_{in}] \\ j=1, \dots, n}} \mu_j(s).$$

Indeed, from the definition of  $\rho(\xi)$ , one has

$$\begin{aligned} \frac{v}{(s_{in} - \bar{s})} \sum_{j=1}^n \mu_j(\bar{s}) x_j &\leq M \frac{v}{(s_{in} - \bar{s})} \sum_{j=1}^n x_j = M \left( \frac{\rho(\xi)}{s_{in} - \bar{s}} + v \right) \\ &\leq M \left( \frac{\rho(\xi)}{s_{in} - \tilde{z}(\xi)} + v_{\max} \right). \end{aligned}$$

The synthesis of the  $SA(\bar{s})$  strategy is depicted on Figures 3.1 and 3.2, depending on the position of  $\bar{s}$  relatively to  $s_{out}$ .

FIG. 3.2. The  $SA(\bar{s})$  synthesis when  $\bar{s} < s_{out}$ .

*Remark 4.* An impulse of volume  $\delta w$  at time  $\tau$  can be achieved by any control law  $u(\cdot)$  such that there exists  $\delta\tau > 0$  satisfying

$$\int_{\tau}^{\tau+\delta\tau} u(\theta)d\theta = \delta w,$$

with  $r(\theta) = 0$  for  $\theta \in [\tau, \tau + \delta\tau]$ . For the sake of simplicity, we shall systematically take  $u(\theta) = u_{\max}$  for  $\theta \in [\tau, \tau + \delta w/u_{\max}]$ .

**4. The cost of the one-impulse strategies.** We consider a family of functions  $\varphi_c(\cdot)$  defined on  $(\mathbb{R}_+^n \setminus \{0\}) \times \mathbb{R}_+$  and parameterized by  $c > 0$ :

$$(4.1) \quad \varphi_c(y, z) = \inf \left\{ t - t_0 \mid s^{t_0, y, z}(t) \leq c \right\},$$

where  $s^{t_0, y, z}(\cdot)$  is the solution of the free dynamics (3.3). A standard analysis of minimal time problems shows that  $\varphi_c(\cdot)$  are Lipschitz-continuous functions and solutions, in the viscosity sense, of the partial differential equation (see, for instance, [2])

$$(4.2) \quad \sum_{j=1}^n (\partial_{y_j} \varphi_c(y, z) - \partial_z \varphi_c(y, z)) \mu_j(z) y_j + 1 = 0$$

on the domain  $(\mathbb{R}_+^n \setminus \{0\}) \times (c, +\infty)$ , with boundary conditions

$$(4.3) \quad \varphi_c(\cdot, z) = 0 \quad \forall z \in (0, c].$$

The time cost of the IOI strategy can then be simply written in terms of the above functions as follows:

$$(4.4) \quad T_{IOI}(\xi) = \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)),$$

where  $\tilde{y}(\xi)$  and  $\tilde{z}(\xi)$  are given by (3.1).

*Remark 5.* Observe that the suboptimal IOI strategy has a finite time cost  $T_{IOI}(\xi)$  for a any initial condition  $\xi$  in the domain  $\mathcal{D}$ . Consequently, the optimal value  $V(\xi)$  is finite for any  $\xi$  in  $\mathcal{D}$ .

**5. The Hamilton–Jacobi characterization.** Let us define the *Hamiltonian* as the mapping  $H : \mathbb{R}_+^n \times [0, s_{in}] \times [0, v_{\max}] \times [0, u_{\max}] \times [0, 1] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$  given by

$$(5.1) \quad H(x, s, v, u, r, p, k, q) = r + qu + k \left( \frac{u}{v} (s_{in} - s) - r \sum_{j=1}^n x_j \mu_j(s) \right) + \sum_{j=1}^n p_j x_j \left( r \mu_j(s) - \frac{u}{v} \right).$$

The Hamilton–Jacobi–Bellman equation associated to minimal time problem with dynamics (2.6) is

$$(5.2) \quad \min_{u \in [0, u_{\max}]} \min_{r \in \{0, 1\}} H(y, z, w, u, r, \partial_y V(\xi), \partial_z V(\xi), \partial_w V(\xi)) = 0,$$

or equivalently

$$(5.3) \quad \min \left( 0, \sum_{j=1}^n (\partial_{y_j} V(\xi) - \partial_z V(\xi)) \mu_j(z) y_j + 1 \right) + \frac{u_{\max}}{w} \min \left( 0, - \sum_{j=1}^n \partial_{y_j} V(\xi) y_j + \partial_z V(\xi) (s_{in} - z) + \partial_w V(\xi) w \right) = 0,$$

for any  $\xi \in \mathcal{D}$ , with the boundary condition

$$(5.4) \quad V(\xi) = 0 \quad \forall \xi \in \mathcal{T}.$$

*Remark 6.* Notice that the control variable  $r(\cdot)$  does not take values in a convex set. This does not a priori guarantee the existence of an admissible optimal trajectory in  $\mathcal{C}$  defined in (2.8). In the following, we prove the existence of optimal trajectories by exhibiting particular strategies for which  $r(\cdot)$  takes values 0 or 1.

It is straightforward to check that (5.3) is equivalent to a system of two partial differential inequalities:

$$(5.5) \quad \Delta_r V(\xi) = \sum_{j=1}^n (\partial_{y_j} V(\xi) - \partial_z V(\xi)) \mu_j(z) y_j + 1 \geq 0,$$

$$(5.6) \quad \Delta_u V(\xi) = - \sum_{j=1}^n \partial_{y_j} V(\xi) y_j + \partial_z V(\xi) (s_{in} - z) + \partial_w V(\xi) w \geq 0,$$

independently of the upper bound  $u_{\max}$ .

*Remark 7.* Note that the situation when  $\Delta_r V$  and  $\Delta_u V$  are both strictly positive corresponds to controls  $u = 0$  and  $r = 0$ . Since we consider only controls in  $\mathcal{C}$  (defined in (2.8)), we obtain that inequalities (5.5)–(5.6) are equivalent to

$$\min\{\Delta_r V(\xi), \Delta_u V(\xi)\} = 0.$$

As it is well known from the theory of first order Hamilton–Jacobi partial differential equation (p.d.e.) [2], the differentiability of the value function is not guaranteed. Furthermore, in the present case, the uniqueness of the solution of system (5.4)–(5.5)–(5.6) among smooth functions is not guaranteed either (one can easily check that  $V \equiv 0$  is always a solution). Nevertheless, one has the following result, providing sufficient conditions for the existence of an optimal trajectory in  $\mathcal{C}$  and the smoothness of the value function.

PROPOSITION 5.1. *If there exist*

- (a) *a nonnegative continuous function  $V(\cdot)$  that fulfills the boundary condition (5.4) and such that at any  $\xi \in \mathcal{D}$ , with  $V(\xi) > 0$ ,  $V(\cdot)$  is  $C^1$  and fulfills the partial differential inequalities (5.5) and (5.6);*
- (b) *two maps  $\xi \mapsto u^*(\xi) \geq 0$ ,  $\xi \mapsto r^*(\xi) \in \{0, 1\}$ , with*

$$H(\xi, u^*(\xi), r^*(\xi), \nabla V(\xi)) = 0, \quad \forall \xi \in \mathcal{D} \text{ such that (s.t.) } V(\xi) > 0,$$

$$r^*(\xi) = 0, \quad \forall \xi \in \mathcal{D} \text{ s.t. } V(\xi) = 0,$$

*and such that the closed-loop dynamics*

$$(5.7) \quad \begin{cases} \frac{dx_i}{d\tau} = r^*(X(\tau))\mu_i(s)x_i - \frac{u^*(X(\tau))}{v}x_i & (i = 1 \cdots n), \\ \frac{ds}{d\tau} = -r^*(X(\tau)) \sum_{j=1}^n \mu_j(s)x_j + \frac{u^*(X(\tau))}{v}(s_{in} - s), \\ \frac{dv}{d\tau} = u^*(X(\tau)), \end{cases}$$

*admits an absolutely continuous solution  $X(\cdot) = (x(\cdot), s(\cdot), v(\cdot))$  that reaches the target in finite time, for any initial condition  $X(t_0) = \xi \in \mathcal{D}$ , then  $V(\xi)$  is the value function (2.9) at any  $\xi \in \mathcal{D}$  such that the solution of (5.7) fulfills  $u^*(X(\tau)) \leq u_{\max}$  for any  $\tau \geq t_0$  such that  $X(\theta) \notin \mathcal{T}$  whatever is  $\theta \in [t_0, \tau)$ .*

*Proof.* Fix an initial condition  $\xi \in \mathcal{D}$  at time  $t_0$ , and consider admissible controls  $(r(\cdot), u(\cdot)) \in \mathcal{C}$  such that the trajectory  $X(\cdot) = (x(\cdot), s(\cdot), v(\cdot))$  solution of system (2.6) reaches the target in finite time, say, at time  $\tau_c$ . Define then the function

$$\mathcal{V}(\tau) = V(X(\tau)),$$

and consider the set  $\mathcal{N} = \{\tau \in [t_0, \tau_c] \mid \mathcal{V}(\tau) > 0\}$ . Clearly,  $\mathcal{V}(\cdot)$  is absolutely continuous on  $\mathcal{N}$  and one has

$$\begin{aligned} \mathcal{V}(\tau_c) - \mathcal{V}(t_0) &= \int_{\mathcal{N}} \mathcal{V}'(\tau) d\tau \\ &= \int_{\mathcal{N}} H(x(\tau), s(\tau), v(\tau), u(\tau), r(\tau), \partial_y V(X(\tau)), \partial_z V(X(\tau)), \partial_w V(X(\tau)) - r(\tau) d\tau. \end{aligned}$$

From (5.2), one deduces the inequality

$$\mathcal{V}(\tau_c) - \mathcal{V}(t_0) \geq - \int_{\mathcal{N}} r(\tau) d\tau,$$

and with the boundary condition (5.4),

$$V(\xi) = \mathcal{V}(t_0) \leq \int_{\mathcal{N}} r(\tau) d\tau \leq \int_{t_0}^{\tau_c} r(\tau) d\tau.$$

This last inequality being valid for any admissible controls  $(u(\cdot), r(\cdot))$ , one deduces that

$$\inf_{u(\cdot), r(\cdot)} \left\{ \int_{t_0}^{\tau} r(\theta) d\theta \mid s^{t_0, \xi, u, r}(\tau) \leq s_{out}, v^{t_0, \xi, u, r}(\tau) = v_{\max} \right\} \geq V(\xi).$$

Consider now the trajectory  $X^*(\cdot)$  solution of (5.7) that reaches the target at time  $\tau_c^*$ . The function  $\mathcal{V}^*(\cdot) = V(X^*(\cdot))$  and the set  $\mathcal{N}^* = \{\tau \in [t_0, \tau_c^*] \mid \mathcal{V}^*(\tau) > 0\}$  verify that

$$\mathcal{V}^*(\tau_c^*) = \mathcal{V}^*(t_0) - \int_{\mathcal{N}^*} r^*(\tau) d\tau = \mathcal{V}^*(t_0) - \int_{t_0}^{\tau_c^*} r^*(\tau) d\tau.$$

We finally obtain

$$\begin{aligned} V(\xi) &= \mathcal{V}^*(t_0) = \int_{t_0}^{\tau_c^*} r^*(\tau) d\tau \\ &\geq \inf_{u(\cdot), r(\cdot)} \left\{ \int_{t_0}^{\tau} r(\theta) d\theta \mid s^{t_0, \xi, u, r}(\tau) \leq s_{out}, v^{t_0, \xi, u, r}(\tau) = v_{max} \right\}, \end{aligned}$$

which proves that  $V(\cdot)$  is the value function.  $\square$

*Remark 8.* For a function  $V(\cdot)$  that fulfills condition (a) of Proposition 5.1 independently of  $u_{max}$ , the existence of a pair of admissible feedbacks  $u^*(\cdot), r^*(\cdot)$  that leads to the target is related to the value of  $u_{max}$ .

On the other hand, the above result establish that there exists at most one function  $V$  (the value function of our problem) satisfying the conditions of Proposition 5.1. Nevertheless, one cannot conclude the uniqueness of the optimal trajectory.

*Remark 9.* One can easily check that the function  $V \equiv 0$  is a  $C^1$  solution of the Hamilton–Jacobi–Bellman equation (5.3) that fulfills the boundary condition (5.4). But (5.2) imposes to have  $r \equiv 0$ . Clearly, such controls do not allow one to reach the target, and the conditions of Proposition 5.1 are not fulfilled.

For technicalities, we shall assume in the following that functions  $\varphi_c(\cdot)$  defined in (4.1) possess some regularity.

*Assumption A0.* For any  $c > 0$ , the function  $\varphi_c(\cdot)$  is  $C^1$  on  $(\mathbb{R}_+^n \setminus \{0\}) \times (c, +\infty)$ .

**LEMMA 5.2.** *Under Assumption A0, at any  $\xi \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$ , one has*

$$(5.8) \quad \Delta_r T_{IOI}(\xi) = \sum_{j=1}^n (\partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi))) \tilde{y}_j (\mu_j(z) - \mu_j(\tilde{z}(\xi))).$$

*Proof.* At  $\xi = (y, z, w) \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$ , Assumption A0 guarantees that  $T_{IOI}(\cdot)$  is  $C^1$ . Let us write its partial derivatives as follows:

$$\begin{cases} \partial_{y_j} T_{IOI}(\xi) = \frac{w}{v_{max}} \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) & (j = 1 \cdots n), \\ \partial_z T_{IOI}(\xi) = \frac{w}{v_{max}} \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)), \\ \partial_w T_{IOI}(\xi) = \sum_j \frac{y_j}{v_{max}} \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \frac{s_{in} - z}{v_{max}} \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)). \end{cases}$$

Then, one has

$$(5.9) \quad \Delta_r T_{IOI}(\xi) = \sum_j \left( \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \right) \mu_j(z) \tilde{y}_j(\xi) + 1.$$

Equation (4.2) with  $c = s_{out}$  at  $(\tilde{y}(\xi), \tilde{z}(\xi))$  provides the equality

$$(5.10) \quad \sum_j \left( \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \right) \mu_j(\tilde{z}(\xi)) \tilde{y}_j(\xi) = -1.$$

Combining (5.9) and (5.10) gives, finally,

$$\begin{aligned} \Delta_r T_{IOI}(\xi) &= \sum_j \left( \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \right. \\ &\quad \left. - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \right) \tilde{y}_j(\xi) (\mu_j(z) - \mu_j(\tilde{z}(\xi))). \quad \square \end{aligned}$$

We then obtain the following result concerning the optimality of the IOI strategy for any initial condition.

PROPOSITION 5.3. *Under Assumption A0, the IOI strategy is optimal for any  $\xi \in \mathcal{D}$  if and only if*

$$(5.11) \quad \Delta_r T_{IOI}(\xi) \geq 0 \quad \forall \xi \in \mathcal{D} \text{ s.t. } T_{IOI}(\xi) > 0.$$

*Proof.* We proceed to show that the function  $T_{IOI}(\cdot)$  fulfills conditions of Proposition 5.1.

If  $\xi \in \mathcal{T}$ , one has  $T_{IOI}(\xi) = 0$ , thus boundary condition (5.4) is fulfilled. At  $\xi \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$ ,  $T_{IOI}(\cdot)$  is  $C^1$  under assumption A0.

Notice that condition (5.11) is exactly the first partial differential inequality (5.5). The verification of the second partial differential inequality (5.6) is easy:

$$\begin{aligned} \Delta_u T_{IOI}(\xi) &= - \sum_j \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \tilde{y}_j + \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{w}{v_{\max}} (s_{in} - z) \\ &\quad + \sum_j \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \tilde{y}_j - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{w}{v_{\max}} (s_{in} - z) = 0. \end{aligned}$$

So, condition (a) of Proposition 5.1 is fulfilled.

Finally, the IOI strategy, as defined in section 3, straightforwardly fulfills condition (b) of Proposition 5.1.  $\square$

Let us now consider the function

$$\psi(\xi, c) = \varphi_c(y, z) + T_{IOI}(x_c, c, w), \quad \xi \in \mathcal{D}, \quad c \in (0, z),$$

where  $x_c = x^{t_0, y, z}(t_c)$  such that  $s^{t_0, y, z}(t_c) = c$ , with  $(x^{t_0, y, z}(\cdot), s^{t_0, y, z}(\cdot))$  solution of the free dynamics (3.3). Concerning the optimality of the IOI strategy, the study of the function  $\psi(\cdot)$  allows us to show that condition (5.11) is also necessary for a given initial condition  $\xi \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$ . For this purpose, the next technical lemma will be useful.

LEMMA 5.4. *Under Assumption A0, one has*

$$\partial_c \psi(\xi, z) = - \frac{\Delta_r T_{IOI}(\xi)}{n}, \quad \xi \in \mathcal{D} \text{ s.t. } T_{IOI}(\xi) > 0.$$

$$\sum_{j=1} \mu_j(z) y_j$$

*Proof.* From (3.3), one has

$$\frac{\partial x_i(t_c)}{\partial c} = -\frac{\mu_i(c)x_i(t_c)}{\sum_{j=1}^n \mu_j(c)x_j(t_c)}, \quad \partial_c \varphi_c(y, z) = -\frac{1}{\sum_{j=1}^n \mu_j(c)x_j(t_c)}.$$

Then, one can write

$$\begin{aligned} \partial_c \psi(\xi, z) &= [\partial_c \varphi_c(y, z)]_{c=z} \\ &+ \left[ \sum_{j=1}^n \partial_{y_j} T_{IOI}(x(t_c), c, w) \frac{\partial x_j(t_c)}{\partial c} + \partial_z T_{IOI}(x(t_c), c, w) \right]_{c=z} \\ &= -\frac{1}{\sum_{j=1}^n \mu_j(z)y_j} - \frac{\frac{w}{v_{\max}} \sum_{j=1}^n \partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \mu_j(z)y_j}{\sum_{j=1}^n \mu_j(z)y_j} \\ &+ \frac{w}{v_{\max}} \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \\ &+ \frac{1 + \sum_{j=1}^n (\partial_{y_j} \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi))) \mu_j(z) \tilde{y}_j(\xi)}{\sum_{j=1}^n \mu_j(z)y_j}. \end{aligned}$$

Using the property (4.2) for  $c = s_{out}$  at  $(\tilde{y}(\xi), \tilde{z}(\xi))$ , and the expression (5.8) given by Lemma 5.2, finally gives

$$\partial_c \psi(\xi, c) = -\frac{\Delta_r T_{IOI}(\xi)}{\sum_{j=1}^n \mu_j(z)y_j}. \quad \square$$

Proposition 5.3 states that if (5.11) is not satisfied, then there exists an initial condition  $\xi \in \mathcal{D}$  for which the IOI strategy is not optimal. The following proposition characterizes some initial conditions for when this occurs.

**PROPOSITION 5.5.** *At states  $\xi \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$  and  $\Delta_r T_{IOI}(\xi) < 0$ , the IOI strategy cannot be optimal.*

*Proof.* When  $T_{IOI}(\xi) > 0$  and  $\Delta_r T_{IOI}(\xi) < 0$  at  $\xi \in \mathcal{D}$ , Lemma 5.4 gives the existence of  $c^* < z$  such that  $\psi(\xi, c^*) < \psi(\xi, z) = T_{IOI}(\xi)$ . Consequently, there is a strategy (consisting in applying a null control until the time  $t_{c^*}$  such that  $s(t_{c^*}) = c^*$  and then the IOI strategy) which has a better cost than the IOI strategy.  $\square$

**6. Derivation from the minimum principle.** In this section we apply the Pontryagin's minimum principle (PMP) (see [4, 25]) to the minimal time problem with dynamics (2.6).

The PMP states that when  $(x, s, v, u, r)(\cdot)$  is a solution of the minimal time problem associated to the system (2.6), then there exists an  $n$ -dimensional *multiplier*  $p(\cdot)$

and scalar multipliers  $q(\cdot)$  and  $k(\cdot)$  such that

$$(6.1) \quad \begin{cases} \frac{dp_i}{d\tau} = p_i u/v - r(p_i - k)\mu_i(s), & p_i(T) = 0, \\ \frac{dk}{d\tau} = -r \sum_{j=1}^n (p_j - k)x_j \mu'_j(s) + ku/v, & k(T) = 1, \\ \frac{dq}{d\tau} = \frac{u}{v^2} \left( k(s_{in} - s) - \sum_{j=1}^n p_j x_j \right), \end{cases}$$

where  $T$  is the optimal terminal time. In addition, the Hamiltonian (defined in (5.1))

$$(u, r) \longrightarrow H(x(\tau), s(\tau), v(\tau), u, r, p(\tau), k(\tau), q(\tau))$$

is minimized in  $u(\tau)$  and  $r(\tau)$ , at any  $\tau \in [t_0, T]$ .

Define the auxiliary variables  $\tilde{p}_i = p_i - k$ , who play an important role in what follows.

First, we observe that the dynamics of  $\tilde{p} = (\tilde{p}_1, \dots, \tilde{p}_n)$  can be written as follows:

$$(6.2) \quad \frac{d\tilde{p}}{d\tau} = A(\tau)\tilde{p}, \quad \tilde{p}_i(T) = -1,$$

where  $A(\tau)$  is an  $n \times n$  time dependent matrix. Consequently, one has  $\tilde{p}(\tau) \neq 0$  for any  $\tau \in [t_0, T]$ .

On another hand, one has

$$(6.3) \quad \operatorname{argmin}_{u,r} H(x, s, v, u, r, p, k, q) = \operatorname{argmin}_{u,r} u\phi_u(x, s, v, p, k, q) + r\phi_r(x, s, p, k),$$

where

$$(6.4) \quad \begin{cases} \phi_u(x, s, v, p, k, q) = q + \frac{k}{v}(s_{in} - s) - \frac{1}{v} \sum_{j=1}^n p_j x_j, \\ \phi_r(x, s, p, k) = 1 + \sum_{j=1}^n (p_j - k)\mu_j(s)x_j = 1 + \sum_{j=1}^n \tilde{p}_j \mu_j(s)x_j. \end{cases}$$

If we derive with respect to the fictitious time  $\tau$ , we obtain

$$(6.5) \quad \begin{cases} \frac{d\phi_u}{d\tau} = -r \frac{(s_{in} - s)}{v} \langle \tilde{p}, m \rangle, \\ \frac{d\phi_r}{d\tau} = u \frac{(s_{in} - s)}{v} \langle \tilde{p}, m \rangle, \end{cases}$$

where  $m = m(\tau)$  is given by

$$(6.6) \quad m(\tau) = \begin{pmatrix} \mu'_1(s(\tau))x_1(\tau) \\ \vdots \\ \mu'_n(s(\tau))x_n(\tau) \end{pmatrix}$$

and  $\langle \cdot, \cdot \rangle$  is the Euclidean inner product in  $\mathbb{R}^n$ . Finally, it is straightforward to check that (see (6.2))

$$(6.7) \quad \frac{d}{d\tau} \langle \tilde{p}, m \rangle = \left\langle \tilde{p}, A^\top m + \frac{dm}{d\tau} \right\rangle.$$

The next result links the optimal value function  $V(\cdot)$  to Pontryagin's multipliers  $(p, q, k)(\cdot)$ .

**PROPOSITION 6.1.** *Let  $V(\cdot)$  be the optimal value function defined in (2.2). Consider an initial vector  $\xi = (y, z, w) \in \mathcal{D}$  and denote by  $(p, q, k)(\cdot)$  the corresponding Pontryagin's multipliers. If the value function  $V$  is  $C^1$  at  $\xi$ , it holds that*

$$(6.8) \quad \Delta_r V(\xi) = \phi_r(x, s, p, k) \quad \text{and} \quad \Delta_u V(\xi) = v\phi_u(x, s, p, k, q),$$

where  $\Delta_r V(\xi)$  and  $\Delta_u V(\xi)$  are defined by (5.5) and (5.6), respectively.

*Proof.* See Theorem 12.5.1 in [31].  $\square$

We end this section by introducing our second assumption and a lemma whose proof is direct.

**Assumption A1.** The functions  $\mu_i(\cdot)$  are nondecreasing.

**LEMMA 6.2.** *Under Assumption A1, the following assertions hold:*

- i. *The matrix  $A(\tau)$  has nonnegative off-diagonal terms, i.e., the dynamical system (6.2) is cooperative (see [28]);*
- ii. *The vector  $m(\cdot)$ , defined in (6.6), lies in  $\mathbb{R}_+^n$ .*

**7. The one-species case.** For this case, it is straightforward to check that, for any  $c > 0$ , the partial differential equation (4.2) with boundary condition (4.3) admits the (unique) nonnegative continuous solution that is  $C^1$  on  $(\mathbb{R}_+ \setminus \{0\}) \times (c, +\infty)$ , given by the expression

$$(7.1) \quad \varphi_c(y, z) = \begin{cases} \int_c^z \frac{d\zeta}{\mu(\zeta)(y + z - \zeta)} & \text{for } z > c, \\ 0 & \text{for } z \leq c. \end{cases}$$

Hence, Assumption A0 is fulfilled. We give a technical lemma that will be useful in the following.

**LEMMA 7.1.** *Let  $z > c > 0$ . If  $\mu(\cdot)$  is nonincreasing on  $[c, z]$ , then the following inequalities are satisfied:*

$$(7.2) \quad \partial_z \varphi_c(y, z) \geq \frac{1}{\mu(z)(y + z - c)},$$

$$(7.3) \quad \partial_z \varphi_c(y, z) \leq \frac{1}{\mu(c)(y + z - c)} + \frac{1}{\mu(z)y} - \frac{1}{\mu(c)y}.$$

*Proof.* Notice first that the partial derivative of function  $\varphi_c$  given in (7.1) verifies

$$\partial_z \varphi_c(y, z) = \frac{1}{\mu(z)y} - \int_c^z \frac{d\zeta}{\mu(\zeta)(y + z - \zeta)^2}.$$

Since  $\mu(\cdot)$  is nonincreasing, one can write

$$\partial_z \varphi_c(y, z) \geq \frac{1}{\mu(z)y} - \int_c^z \frac{d\zeta}{\mu(z)(y + z - \zeta)^2} = \frac{1}{\mu(z)(y + z - c)},$$

and

$$\begin{aligned} \partial_z \varphi_c(y, z) &\leq \frac{1}{\mu(z)y} - \int_c^z \frac{d\zeta}{\mu(c)(y + z - \zeta)^2} \\ &= \frac{1}{\mu(z)y} + \frac{1}{\mu(c)(y + z - c)} - \frac{1}{\mu(c)y}. \quad \square \end{aligned}$$

### 7.1. Increasing growth functions.

PROPOSITION 7.2. *Under Assumption A1, the IOI strategy is optimal for any initial condition  $\xi$  in  $\mathcal{D}$ , and the value function is*

$$(7.4) \quad V(\xi) = \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)),$$

where  $\varphi_{s_{out}}(\cdot)$  is given by (7.1) and  $(\tilde{y}(\xi), \tilde{z}(\xi))$  by (3.1).

*Proof.* For  $(\tilde{y}(\xi), \tilde{z}(\xi))$  such that  $\tilde{z}(\xi) > s_{out}$ , the map  $\xi \mapsto \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi))$  is  $C^1$  at  $\xi$ , and from (4.2), one has

$$(\partial_y \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)))\mu(\tilde{z}(\xi))\tilde{y}(\xi) = -1.$$

Then, condition (5.11) of Proposition 5.3 simply becomes  $\mu(\tilde{z}(\xi)) - \mu(z) \geq 0$ , which is fulfilled when  $\mu(\cdot)$  is nondecreasing and  $\tilde{z} \geq z$ .  $\square$

*Remark 10.* This proposition extends to impulse controls a result obtained by Moreno [20] for measurable control (with a different technique based on Green's theorem). It states that, for a monotonic growth functions  $\mu$ , the *one bang* control

$$F = \begin{cases} F_{\max} & \text{if } v < v_{\max}, \\ 0 & \text{if } v = v_{\max}, \end{cases}$$

is optimal.

It is clear that there is no uniqueness of optimal control laws (see Remarks 2 and 4). Eventually, we could have another control  $(u(\cdot), r(\cdot))$  that implies a strategy different to the IOI one, with the same value function defined in (7.4). The following proposition shows that the IOI strategy is, in fact, the unique admissible optimal one. This result is obtained using PMP.

PROPOSITION 7.3. *Under Assumption A1, one has that, for any initial condition  $\xi$  in  $\mathcal{D}$ , the IOI strategy is the unique optimal control law.*

*Proof.* From the PMP, there exist multipliers  $p$  and  $k$  solutions of system (6.1), which, in this case ( $n = 1$ ), satisfies  $\langle \tilde{p}, m \rangle = \tilde{p}\mu'(s)x < 0$  for  $m$  defined by (6.6) and  $\tilde{p} = p - k$ . Then, from (6.5), one has that  $\frac{d\phi_r}{d\tau} \leq 0$  and  $\frac{d\phi_u}{d\tau} \geq 0$  along all of the optimal trajectories. Also, relations (6.8), (5.5), and (5.6) imply that  $\phi_u \geq 0$  and  $\phi_r \geq 0$ .

Since the admissible controls  $(u, r)$  are in  $\mathcal{C}$  defined by (2.8) (see Remark 2) and the states of the system (2.6) must reach the target  $\mathcal{T}$ , the only possibilities for  $\phi_u$  and  $\phi_r$  are as follows:

- i.  $\phi_u = 0$  at the beginning and then  $\phi_u > 0$ ;
- ii.  $\phi_r > 0$  at the beginning and then  $\phi_r = 0$ .

Indeed, the admissible control set  $\mathcal{C}$  allows us to consider only configurations such that  $\phi_u \cdot \phi_r = 0$ , and  $u \neq 0$  or  $r \neq 0$ . This, together with (6.5), discards the choices  $\phi_u > 0$  or  $\phi_r = 0$ , at the beginning.

On the other hand, (6.5) implies also that  $u \neq 0$  until the time when  $\phi_u$  switches from  $\phi_u = 0$  to  $\phi_u > 0$ . This time coincides with the time when  $v = v_{\max}$  and, consequently, also with the time when  $\phi_r$  switches from  $\phi_r > 0$  to  $\phi_r = 0$  (because  $u$  becomes null at such time). Therefore, one has the following:

- i.  $u = u_{\max}$  until  $v$  reaches  $v_{\max}$  and then  $u = 0$ ;
- ii.  $r = 0$  until  $v = v_{\max}$  and then  $u = 0$  and  $r = 1$  until the concentration  $s$  reaches  $s_{out}$ .

This proves the optimality of the IOI strategy, and, by construction, we have uniqueness.  $\square$

**7.2. Nonmonotonic growth functions with one maximum.** In this section we consider a continuously differentiable growth function  $\mu(\cdot)$ , which is nonmonotonic and attains a unique isolated maximum point  $s^* \in (0, s_{in})$ . More precisely, this growth function satisfies  $\mu'(s) > 0$  for all  $s \in [0, s^*)$ ,  $\mu'(s) < 0$  for all  $s > s^*$ , and  $\mu'(s^*) = 0$ .

One instance of such functions is typically the Haldane law, given by the expression

$$\mu(s) = \frac{\bar{\mu}s}{K + s + s^2/R},$$

where  $K$  is the affinity constant and  $R$  is the inhibition constant. This kind of growth function occurs in bioprocesses where the substrate is a toxic substance and, for big concentrations, inhibits the activity of the microorganisms [29].

The following proposition solves our minimal time problem for this type of growth function. This solution has been previously obtained in [20] for the class of measurable and bounded controls, and under the assumption  $s^* > s_{out}$ . Furthermore, we give the expression of the value function  $V(\cdot)$ . For convenience, we define the number

$$s^\diamond = \max(s^*, s_{out}).$$

**PROPOSITION 7.4.** *For any initial condition  $\xi = (y, z, w) \in \mathcal{D}$  that satisfies (3.5), the  $SA(s^*)$  strategy (defined in section 3) is optimal. Furthermore, the value function at  $\xi$  is given by the expression*

$$(7.5) \quad V(\xi) = \begin{cases} \varphi_{s^*}(y, z) + \gamma(\xi) + \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond), & \text{for } z > s^* \geq s^\dagger(s^*, w), \\ \gamma\left(y \frac{s_{in} - s^*}{s_{in} - z}, s^*, w \frac{s_{in} - z}{s_{in} - s^*}\right) + \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond), & \text{for } z \leq s^* \text{ and } z > s^\dagger(s^*, w), \\ \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)), & \text{for } z \leq s^\dagger(s^*, w), \\ \varphi_{s^\dagger(s^*, w)}(y, z) & \text{for } z > s^\dagger(s^*, w) > s^*, \end{cases}$$

where  $\varphi(\cdot)$  is given by (7.1),  $\tilde{y}(\cdot)$  and  $\tilde{z}(\cdot)$  by (3.1),  $s^\dagger(\cdot)$  by (3.2), and

$$(7.6) \quad \gamma(\xi) = \frac{1}{\mu(s^*)} \log \left( \frac{w(y + z - s_{in}) + v_{\max}(s_{in} - s^\diamond)}{w(y + z - s^*)} \right).$$

*Proof.* First, observe that if the initial condition  $\xi$  is in the target, i.e.,  $z \leq s_{out}$  and  $w = v_{\max}$ , then  $s^\dagger(s^*, w) = s^\diamond \geq s_{out} \geq z$  and  $\tilde{z}(\xi) = z$  and, therefore it corresponds to the third case in the definition of  $V$  obtaining  $\varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) = 0$ , and hence the boundary condition (5.4) is satisfied. We prove now that  $V(\cdot)$  is  $C^1$  and fulfills the Hamilton–Jacobi inequalities (5.5) and (5.6), concluding the result from Proposition 5.1 because one can easily check that  $V(\xi)$  is the cost associated to the  $SA(s^*)$  strategy from initial condition  $\xi$ .

For  $z > s^*$  and  $s^* \geq s^\dagger(s^*, w)$ ,  $V(\cdot)$  is  $C^1$  and its partial derivatives are

$$\begin{aligned}
 (7.7) \quad \partial_y V(\xi) &= \partial_y \varphi_{s^*}(y, z) + \frac{1}{\mu(s^*)} \left( \frac{w}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} - \frac{1}{y+z-s^*} \right) \\
 &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{w}{v_{\max}}, \\
 \partial_z V(\xi) &= \partial_z \varphi_{s^*}(y, z) + \frac{1}{\mu(s^*)} \left( \frac{w}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} - \frac{1}{y+z-s^*} \right) \\
 &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{w}{v_{\max}}, \\
 \partial_w V(\xi) &= \frac{1}{\mu(s^*)} \left( \frac{y+z-s_{in}}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} - \frac{1}{w} \right) \\
 &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{y+z-s_{in}}{v_{\max}}.
 \end{aligned}$$

Then, one has straightforwardly

$$\begin{aligned}
 \Delta_r V(\xi) &= (\partial_y \varphi_{s^*}(y, z) - \partial_z \varphi_{s^*}(y, z)) \mu(z)y + 1, \\
 \Delta_u V(\xi) &= -\partial_y \varphi_{s^*}(y, z)y + \partial_z \varphi_{s^*}(y, z)(s_{in} - z) + \frac{1}{\mu(s^*)} \left( \frac{y+z-s_{in}}{y+z-s^*} - 1 \right).
 \end{aligned}$$

Using the property (4.2) fulfilled by the function  $\varphi_{s^*}$ , one obtains

$$\begin{aligned}
 \Delta_r V(\xi) &= 0, \\
 \Delta_u V(\xi) &= (s_{in} - s^*) \left( \partial_z \varphi_{s^*}(y, z) - \frac{1}{\mu(s^*)(y+z-s^*)} \right) \\
 &\quad + (y+z-s^*) \left( \frac{1}{\mu(z)(y+z-s^*)} - \partial_z \varphi_{s^*}(y, z) \right).
 \end{aligned}$$

Consequently, inequality (5.5) is fulfilled. For the second inequality (5.6), we distinguish two cases:

i.  $y+z-s_{in} \leq 0$ . Since  $\mu(z) \leq \mu(s^*)$ , one can write the inequality

$$\Delta_u V(\xi) \geq (y+z-s_{in}) \left( \frac{1}{\mu(s^*)(y+z-s^*)} - \partial_z \varphi_{s^*}(y, z) \right),$$

and with inequality (7.2) given by Lemma 7.1 with  $c = s^*$ , one deduces that

$$\Delta_u V(\xi) \geq \frac{y+z-s_{in}}{y+z-s^*} \left( \frac{1}{\mu(s^*)} - \frac{1}{\mu(z)} \right) \geq 0.$$

ii.  $y+z-s_{in} > 0$ . With inequality (7.3) given by Lemma 7.1 with  $c = s^*$ , one can write

$$\begin{aligned}
 \Delta_u V(\xi) &= (s_{in} - y - z) \partial_z \varphi_{s^*}(y, z) + \frac{1}{\mu(z)} - \frac{s_{in} - s^*}{\mu(s^*)(y+z-s^*)} \\
 &\geq (s_{in} - y - z) \left( \frac{1}{\mu(z)y} + \frac{1}{\mu(s^*)(y+z-s^*)} - \frac{1}{\mu(s^*)y} \right) + \frac{1}{\mu(z)} \\
 &\quad - \frac{1}{\mu(s^*)} - \frac{s_{in} - y - z}{\mu(s^*)(y+z-s^*)} \\
 &= \frac{s_{in} - z}{y} \left( \frac{1}{\mu(z)} - \frac{1}{\mu(s^*)} \right) \geq 0.
 \end{aligned}$$

For  $z < s^*$  and  $z > s^\dagger(s^*, w)$ ,  $V(\cdot)$  is  $C^1$  and its partial derivatives are

$$(7.8) \quad \begin{aligned} \partial_y V(\xi) &= \frac{1}{\mu(s^*)} \left( \frac{w}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} - \frac{1}{y} \right) \\ &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{w}{v_{\max}}, \\ \partial_z V(\xi) &= \frac{1}{\mu(s^*)} \frac{w}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} \\ &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{w}{v_{\max}}, \\ \partial_w V(\xi) &= \frac{1}{\mu(s^*)} \left( \frac{y+z-s_{in}}{w(y+z-s_{in}) + (s_{in} - s^\diamond)v_{\max}} - \frac{1}{w} \right) \\ &\quad + \partial_y \varphi_{s_{out}}(\tilde{y}(\xi) + \tilde{z}(\xi) - s^\diamond, s^\diamond) \frac{y+z-s_{in}}{v_{\max}}. \end{aligned}$$

One has clearly, from (7.1),

$$\partial_y \varphi_{s^*}(y, s^*) = 0 \quad \text{and} \quad \partial_z \varphi_{s^*}(y, s^*) = \frac{1}{\mu(s^*)y},$$

which implies, from expressions (7.7) and (7.8),

$$\lim_{z \rightarrow s^*+} \nabla V(\xi) = \lim_{z \rightarrow s^*-} \nabla V(\xi).$$

Consequently,  $V(\cdot)$  is  $C^1$  at points  $\xi$  such that  $z = s^*$ . From the expressions (7.8), one can straightforward check the following equalities:

$$\Delta_r V(\xi) = 1 - \frac{\mu(s^*)}{\mu(z)} \geq 0 \quad \text{and} \quad \Delta_u V(\xi) = 0.$$

Consider now points  $\xi$  such that  $z < s^\dagger(s^*, w)$  and  $V(\xi) > 0$ . At such points,  $V(\cdot)$  is  $C^1$  and its partial derivatives are

$$\begin{cases} \partial_y V(\xi) = \partial_y \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{w}{v_{\max}}, \\ \partial_z V(\xi) = \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{w}{v_{\max}}, \\ \partial_w V(\xi) = \partial_y \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{y}{v_{\max}} - \partial_z \varphi_{s_{out}}(\tilde{y}(\xi), \tilde{z}(\xi)) \frac{s_{in} - z}{v_{\max}}. \end{cases}$$

Notice that when  $z = s^\dagger(s^*, w)$ , with  $s^\dagger(s^*, w) > s^*$ , one has  $V(\xi) = 0$ . One can easily check that  $V(\cdot)$  is also  $C^1$  at points  $\xi$  such that  $z = s^\dagger(s^*, w)$  and  $V(\xi) > 0$ , because, at such points, one has  $\tilde{z}(\xi) = s^\diamond = s^*$ , and furthermore, function  $\varphi_{s_{out}}(\cdot)$  fulfills the property (from (4.2))

$$\partial_z \varphi_{s_{out}}(\tilde{y}(\xi), s^*) = \partial_y \varphi_{s_{out}}(\tilde{y}(\xi), s^*) + \frac{1}{\mu(s^*)\tilde{y}(\xi)}.$$

Notice that one has also  $V(\xi) = T_{IOI}(\xi)$ . Since  $\Delta_u T_{IOI}(\xi) = 0$  (see the proof of Proposition 5.3), the function  $V(\cdot)$  is a solution of the Hamilton–Jacobi equation

(5.3) at  $\xi$  when the single condition  $\Delta_r T_{IOI}(\xi) \geq 0$  is fulfilled. Here, this condition simply becomes  $\mu(\tilde{z}(\xi)) - \mu(z) = \mu(s^*) - \mu(z) \geq 0$ , which is fulfilled because  $s^*$  is the maximum of the function  $\mu$ .

Finally, we consider situations for which  $z > s^\dagger(s^*, w) > s^*$ . This case occurs only when  $s^* < s_{out}$ . At such points  $\xi = (y, z, w)$ , the function  $V(\cdot)$  is  $C^1$  and its partial derivatives are

$$\begin{cases} \partial_y V(\xi) = \partial_y \varphi_{s^\dagger(s^*, w)}(y, z), \\ \partial_z V(\xi) = \partial_z \varphi_{s^\dagger(s^*, w)}(y, z), \\ \partial_w V(\xi) = -\frac{(s_{in} - s_{out})v_{\max}}{\mu(s^\dagger(s^*, w))(y + z - s^\dagger(s^*, w))w^2}. \end{cases}$$

One can easily check that the first inequality  $\Delta_r V(\xi) \geq 0$  is fulfilled. For the second one, let us write

$$\begin{aligned} (7.9) \quad \Delta_u V(\xi) &= -\partial_y \varphi_{s^\dagger(s^*, w)}(y, z)y + \partial_z \varphi_{s^\dagger(s^*, w)}(y, z)(s_{in} - z) \\ &\quad - \frac{(s_{in} - s_{out})v_{\max}}{\mu(s^\dagger(s^*, w))(y + z - s^\dagger(s^*, w))w^2} \\ &= \frac{1}{\mu(z)} + \partial_z \varphi_{s^\dagger(s^*, w)}(y, z)(s_{in} - z - y) \\ &\quad - \frac{(s_{in} - s_{out})v_{\max}}{\mu(s^\dagger(s^*, w))(y + z - s^\dagger(s^*, w))w^2} \end{aligned}$$

from the expression (4.2). We distinguish now two cases.

- i.  $s_{in} - z - y \geq 0$ . Expressions (7.9) and (7.2) given by Lemma 7.1 with  $c = s^\dagger(s^*, w)$  give together

$$\Delta_u V(\xi) \geq \frac{s_{in} - s^\dagger(s^*, w)}{y + z - s^\dagger(s^*, w)} \left( \frac{1}{\mu(z)} - \frac{1}{\mu(s^\dagger(s^*, w))} \right) \geq 0.$$

- ii.  $s_{in} - z - y < 0$ . Gathering expressions (7.9) and (7.3) given by Lemma 7.1 with  $c = s^\dagger(s^*, w)$  leads to the following inequality:

$$\Delta_u V(\xi) \geq \frac{s_{in} - z}{y} \left( \frac{1}{\mu(z)} - \frac{1}{\mu(s^\dagger(s^*, w))} \right) \geq 0. \quad \square$$

*Remark 11.* For initial conditions  $\xi = (y, z, w)$ , with  $z \geq s^* > s^\dagger(s^*, w)$ , the value of  $\gamma(\xi)$ , defined by (7.6), represents the time spent on the singular arc  $s = s^*$  from volume  $w$  up to volume  $v^\dagger(\bar{s})$  defined in (3.4). Indeed, at time  $t_1 = \varphi_{s^*}(y, z)$ , one has  $s(t_1) = s^*$ ,  $v(t_1) = w$ , and  $x(t_1) = y + z - s^*$  (see the invariant  $\rho(\xi)$  defined in (2.10)). Then, the suitable control in order to keep  $s = s^*$  is obtained from the equation  $\frac{ds}{d\tau} = 0$ , that is,

$$u = u_s(v) = \frac{\mu(s^*)}{s_{in} - s^*} \rho(\xi) + v\mu(s^*).$$

This implies that the  $v(\cdot)$  is the solution of the ordinary differential equation

$$\frac{dv}{d\tau} = u_s(v) = \frac{\mu(s^*)}{s_{in} - s^*} w(y + z - s_{in}) + \mu(s^*)v$$

up to time  $t_2$  such that  $v(t_2) = v^\dagger$ , that can be solved analytically, leading to  $t_2 - t_1 = \gamma(\xi)$ .

*Remark 12.* Proposition 7.4 extends to impulse controls the result obtained by Moreno [20] for measurable controls, based on a Green's theorem argumentation.

Moreover, notice that when  $s^* < s_{out}$ , the  $SA(s^*)$  strategy imposes a final impulse before reaching the target. Such situations were not considered in [20].

*Remark 13.* Proposition 7.4 establishes that the time associated to the singular arc strategy is the optimal value function, but we could have that there exists another optimal control different to this strategy. Nevertheless, one can prove uniqueness (analogously as in Proposition 7.3) using the PMP. We will not develop this approach here because it is very similar to the one used in Proposition 7.3 and in the proof of Theorem 8.2 below.

**8. The two-species case.** We first consider functions  $\mu_i(\cdot)$  that are  $C^2$  and such that  $\mu'_1/\mu'_2$  is a strictly monotonic function. Without loss of generality, we assume that  $\mu'_1/\mu'_2$  is strictly decreasing, which is equivalent to the following condition.

*Assumption A2.*  $\mu'_1(s)\mu''_2(s) > \mu''_1(s)\mu'_2(s)$  for any  $s \in (0, s_{in}]$ .

*Remark 14.* Assumption A2 is fulfilled for nonproportional Monod growth functions. That is, for growth functions

$$\mu_i(s) = \frac{\mu_{\max,i}s}{K_i + s},$$

Assumption A2 holds when  $K_1 < K_2$ .

**LEMMA 8.1.** *Under Assumption A2, a singular arc<sup>2</sup>  $I$  is characterized by  $\frac{ds}{d\tau} = 0$  on  $I$ .*

*Proof.* Consider  $p$  and  $k$  solutions of PMP-system (6.1) and  $m$  defined in (6.6). Define the auxiliary variable  $\tilde{p} = p - k$ . Recall that the property  $\tilde{p}(\tau) \neq 0$ , for any time  $\tau$ , follows from (6.2).

If  $I$  is a singular arc, it follows that the first derivatives of  $\phi_u$  and  $\phi_r$  are null on  $I$ . Since controls  $u$  and  $r$  are not simultaneously null, it is equivalent to write  $\langle \tilde{p}, m \rangle = 0$  on  $I$  (via (6.5)). Differentiating this last equation w.r.t.  $\tau$  and using expression (6.7), it holds that

$$(8.1) \quad \langle \tilde{p}, m \rangle = 0 \quad \text{and} \quad \left\langle \tilde{p}, A^\top m + \frac{dm}{d\tau} \right\rangle = 0 \quad \text{on } I.$$

Since  $\tilde{p}$  is always nonnull and has dimension 2, equalities (8.1) are satisfied if  $m$  and  $A^\top m + \frac{dm}{d\tau}$  are linearly dependent on  $I$ . We easily verify that, under A2, this is equivalent to  $\frac{ds}{d\tau} = 0$  on  $I$ . Indeed, a simple computation leads to

$$\left\| m \times \left( A^\top m + \frac{dm}{d\tau} \right) \right\| = \left| \frac{ds}{d\tau} \right| x_1 x_2 (\mu'_1(s)\mu''_2(s) - \mu''_1(s)\mu'_2(s)).$$

Vectors  $A^\top m + \frac{dm}{d\tau}$  are linearly dependent exactly when their cross product (in  $\mathbb{R}^3$ ) is null, which holds if and only if  $\frac{ds}{d\tau} = 0$ . We have thus proved that if  $I$  is a singular arc, then  $\frac{ds}{d\tau} = 0$  on  $I$ .

<sup>2</sup>See [4, Part III Chapter 2] for an exact definition. In our case, a singular arc consists of an open interval of time  $I$ , where  $\phi_u = \phi_r = 0$ , and then no information on controls  $u$  and  $r$  can be obtained directly from (6.3).

Reciprocally, suppose that  $\frac{ds}{d\tau} = 0$  on  $I$ . The above arguments imply that  $m$  and  $A^\top m + \frac{dm}{d\tau}$  are linearly dependent on  $I$ , obtaining from (6.7) that  $\frac{d\langle \tilde{p}, m \rangle}{d\tau} = \lambda(\tau) \langle \tilde{p}, m \rangle$  on  $I$ , for a real-valued continuous map  $\lambda : I \rightarrow \mathbb{R}$ .

This is equivalent to saying that  $\langle \tilde{p}, m \rangle = Ce^{\int_0^\tau \lambda(t) dt}$  on  $I$  for a real constant  $C$  and a real-valued continuous map  $\lambda : I \rightarrow \mathbb{R}$ . Moreover, by replacing  $\frac{ds}{d\tau} = 0$  in (2.6), it necessarily requires strictly positive controls  $u$  and  $r$ .

Suppose first that  $C = 0$ . Then (6.5) implies that  $\phi_u$  and  $\phi_r$  are both constant on  $I$ . Since  $u$  and  $r$  are strictly positive, this holds only if  $\phi_u = \phi_r = 0$  on  $I$ , i.e.,  $I$  is a singular arc.

Now, suppose that  $C \neq 0$ . One obtains from (6.5) that  $\phi_u$  and  $\phi_r$  are both strictly monotonic on  $I$ . This, together with inequalities (5.5)–(5.6), implies that  $\phi_u$  and  $\phi_r$  are both strictly positive on  $I$ . But, since  $u$  and  $r$  are also strictly positive, it contradicts (6.3). We thus conclude that  $C = 0$ , and hence  $I$  is a singular arc.  $\square$

Consider now the next assumption on growth functions  $\mu_i(\cdot)$ .

*Assumption A3.* For any  $s_1, s_2 \in [s_{out}, s_{in}]$ , one has

$$(8.2) \quad s_2 \geq s_1 \Rightarrow \mu_2(s_2)\mu_1(s_1) \geq \mu_1(s_2)\mu_2(s_1).$$

*Remark 15.* Assumption A3 is fulfilled for growth functions constant or linear on  $[s_{out}, s_{in}]$ . For Monod functions

$$\mu_i(s) = \frac{\mu_{\max, i} s}{K_i + s},$$

condition (8.2) is exactly fulfilled when  $K_1 \leq K_2$ .

**THEOREM 8.2.** *Assume that Assumptions A0–A1–A2–A3 are fulfilled. Then, for any initial condition in  $\mathcal{D}$  that satisfies (3.5), the optimal solution of the minimal time problem associated to dynamics (2.6) consists in either the IOI strategy or the SA( $s^*$ ) strategy for some  $s^* \in ]s_{out}, s_{in}[$ .*

To prove this theorem, we need the three following technical lemmas.

**LEMMA 8.3.** *Under Assumptions A1 and A3, one has*

$$(8.3) \quad \tilde{p}_1 \geq 0 \text{ and } \phi_r = 0 \Rightarrow \langle \tilde{p}, m \rangle \leq 0.$$

*Proof of Lemma 8.3.* Observe that Assumption A3 implies that  $\mu'_1\mu_2 - \mu_1\mu'_2 \leq 0$ . If  $\phi_r = 0$ , then

$$\tilde{p}_2 = \frac{-(1 + \tilde{p}_1\mu_1x_1)}{\mu_2x_2},$$

and then

$$\langle \tilde{p}, m \rangle = \frac{\tilde{p}_1}{\mu_2}(\mu'_1\mu_2 - \mu_1\mu'_2)x_1 - \frac{\mu'_2}{\mu_2},$$

which proves the desired result.  $\square$

**LEMMA 8.4.** *Under Assumptions A1 and A2, for  $\tilde{p}(\tau) \in E(\tau) = \{\tilde{p} = (\tilde{p}_1, \tilde{p}_2) \mid \langle \tilde{p}, m(\tau) \rangle = 0\}$ , one has*

$$(8.4) \quad \operatorname{sgn} \left( \frac{d}{d\tau} \langle \tilde{p}, m \rangle \right) = -\operatorname{sgn} \left( \frac{ds}{d\tau} \tilde{p}_1 \right).$$

*Proof of Lemma 8.4.* Let  $\tilde{p}(\tau) = (\tilde{p}_1, \tilde{p}_2)$  be in  $E(\tau)$ , that is,  $\tilde{p}_2 = -\tilde{p}_1\mu'_1(s)x_1/\mu'_2(s)x_2$ . It is straightforward to check that the property

$$\frac{d}{d\tau}\langle\tilde{p}, m\rangle = \left\langle A^\top m + \frac{dm}{d\tau}, \tilde{p} \right\rangle = \frac{ds}{d\tau}\tilde{p}_1 \left[ \mu''_1 - \frac{\mu'_1\mu''_2}{\mu'_2} \right] x_1$$

is fulfilled, from which (8.4) is deduced (recalling A2).  $\square$

LEMMA 8.5. *If, for some interval of time  $[\tau_-, \tau_+]$ , one has  $\phi_r = \phi_u = 0$ , then*

- (a) *if  $\tilde{p}_1 > 0$ ,  $\phi_r$  and  $\phi_u$  remain equal to zero for all  $\tau \geq \tau_+$ ;*
- (b) *if  $\tilde{p}_1 < 0$ , either  $\langle\tilde{p}, m\rangle \geq 0$  for all  $\tau \geq \tau_+$  or  $\langle\tilde{p}, m\rangle \leq 0$  for all  $\tau \geq \tau_+$ .*

*Proof of Lemma 8.5.* Notice that if we have  $\phi_r = \phi_u = 0$  in some interval of time, necessarily, by (6.5),  $\langle\tilde{p}, m\rangle = 0$  on this interval. Since  $(\tilde{p}_1, \tilde{p}_2) \neq (0, 0)$  for all  $\tau$  and the vector  $m$  lies in  $]0, +\infty[ \times ]0, +\infty[$  (under Assumption 1), we deduce that  $\tilde{p}_1 \neq 0$ , and therefore it does not change its sign in this interval.

Suppose now that  $\bar{\tau} = \sup\{\tau \mid \langle\tilde{p}, m\rangle = 0\} < +\infty$ . If

$$(8.5) \quad \exists \bar{\delta} > 0 \quad \text{such that} \quad \forall \delta \in ]0, \bar{\delta}], \quad \text{one has} \quad \langle\tilde{p}(\bar{\tau} + \delta), m(\bar{\tau} + \delta)\rangle > 0,$$

since  $\phi_r$  and  $\phi_u$  have to be nonnegative, necessarily, according to (6.5), the control  $r$  must be zero,  $u = u_{\max}$ , and therefore  $\frac{ds}{d\tau} > 0$  until  $\langle\tilde{p}, m\rangle$  changes its sign.

- (a) If  $\tilde{p}_1 > 0$  on  $[\tau_-, \tau_+]$ , let us prove that  $\langle\tilde{p}, m\rangle$  does not become positive. If it occurs, we have (8.5), and, in such a case,  $\frac{ds}{d\tau} > 0$ . Nevertheless, by (8.4), we obtain  $\frac{d}{d\tau}\langle\tilde{p}, m\rangle \leq 0$  at  $\bar{\tau}$ , which contradicts (8.5).

With similar arguments, one can prove that  $\langle\tilde{p}, m\rangle$  does not become negative, and hence  $\bar{\tau} = +\infty$ .

- (b) For the case  $\tilde{p}_1 < 0$ , if we have (8.5), then  $\frac{ds}{d\tau} > 0$  until  $\langle\tilde{p}, m\rangle$  changes its sign. This change will never happen, because, from (8.4), one has  $\frac{d}{d\tau}\langle\tilde{p}, m\rangle \geq 0$  on the set  $E(\tau) = \{\tilde{p} = (\tilde{p}_1, \tilde{p}_2) \mid \langle\tilde{p}, m(\tau)\rangle = 0\}$ , and therefore,  $\langle\tilde{p}, m\rangle$  remains nonnegative.

Analogous arguments allow us to prove that if there exists  $\bar{\delta} > 0$  such that for all  $\delta \in ]0, \bar{\delta}]$  one has  $\langle\tilde{p}(\bar{\tau} + \delta), m(\bar{\tau} + \delta)\rangle < 0$ , then  $\langle\tilde{p}, m\rangle$  remains nonpositive.  $\square$

As a corollary of Lemma 8.5, one has that if the optimal strategy includes a singular arc ( $\phi_r = \phi_u = 0$  during an interval), then it must occur with  $\tilde{p}_1 < 0$ . Indeed, if  $\tilde{p}_1 > 0$  and  $\phi_r = \phi_u = 0$  during an interval, the last equalities will remain for every larger time. This situation is not allowed because  $\tilde{p}$  must be equal to  $(-1, -1)$  at the final time.

On the other hand, if the optimal strategy includes a singular arc (with  $\tilde{p}_1 < 0$ ), after this process, necessarily,  $\langle\tilde{p}, m\rangle$  must be negative. In fact, if  $\langle\tilde{p}, m\rangle$  is positive, it does not change its sign, and then  $\tilde{p}$  will never be equal to  $(-1, -1)$ .

Thus, if a singular arc occurs, the volume at the end of this process must be equal to  $v_{\max}$  because, as  $\langle\tilde{p}, m\rangle$  will remain nonpositive and  $\phi_r$  and  $\phi_u$  have to be nonnegative, the control  $u$  is equal to zero and  $r = 1$  for the rest of time, and then the process of filling the tank has necessarily finished.

As a last consequence of Lemma 8.5, we obtain that in the case of a singular arc, which is equivalent to keep the level of substrate  $s$  constant (see Lemma 8.1), this level has to be greater than  $s_{out}$ . Indeed, if it is not the case, we have that all of the processes finish at the end of the singular arc because  $v = v_{\max}$  and  $s_{out}$  is greater than the current substrate level, and hence the target has been reached. This cannot occur, because, at the end, the vector  $\tilde{p}$  must be equal to  $(-1, -1)$ .

*Proof of Theorem 8.2.* As in the proof of Proposition 7.3, the positivity of  $\phi_u$  and  $\phi_r$  plays a crucial role (cf. (6.8), (5.5), and (5.6)).

Moreover, the considered admissible control set  $\mathcal{C}$  (see Remark 2) tell us that only optimal controls such that  $u \neq 0$  or  $r \neq 0$  are considered. And, therefore,  $\phi_u$  and  $\phi_r$  cannot be both strictly positive.

Recall that, under Assumption A1, the matrix  $A$  of system (6.2) is cooperative and the vector  $m$ , defined by (6.6), is always in  $]0, +\infty[ \times ]0, +\infty[$ . Then, since  $\tilde{p} = (p_1 - k, p_2 - k)$  is equal to  $(-1, -1)$  at the final time  $T$ , we deduce that  $\tilde{p} \notin \mathbb{R}_+^2$  at any time  $\tau$ , and moreover, once  $\tilde{p}$  reaches the negative octant  $\mathbb{R}_-^2$ , it remains there until time  $T$ . Thus, thanks to Lemma 8.4, the study of the sign of  $\tilde{p}_1$  will be a key issue in the proof. Indeed, the arguments above imply that either  $\tilde{p}_1$  remains always negative, or it is positive at initial time and then it becomes negative until the final time  $T$ .

Hence, our proof splits into the following two cases.

*Case 1:*  $\tilde{p}_1(t_0) > 0$ . Let us first discard the following case:

(a)  $v < v_{\max}$ ,  $\tilde{p}_1 > 0$ ,  $\langle \tilde{p}, m \rangle < 0$ , and  $\phi_r = 0$ .

In this situation, one has necessarily  $u = 0$  and  $r = 1$  in order to keep  $\phi_r$  nonnegative. Thus,  $s$  decreases,  $\phi_u$  increases, and there exists a time  $\tau$  such that  $\langle \tilde{p}, m \rangle = 0$  at  $\tau$  and  $\langle \tilde{p}, m \rangle > 0$  for larger time (because  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle > 0$ , cf. (8.4)). Since  $\phi_r = 0$ , we obtain a contradiction with Lemma 8.3.

Thus, if  $v < v_{\max}$ ,  $\tilde{p}_1 > 0$ , and  $\langle \tilde{p}, m \rangle < 0$ , then  $\phi_r > 0$  and  $\phi_u = 0$ . In such a case, one has  $r = 0$  and  $u = u_{\max}$ , which implies that  $s$  increases and  $\phi_r$  decreases until a time such that  $\phi_r = 0$  (in order to reach the target). Since a singular arc is not possible with  $\tilde{p}_1 > 0$  (see Lemma 8.5), we discard the case  $\langle \tilde{p}, m \rangle = \frac{d}{d\tau} \langle \tilde{p}, m \rangle = 0$ . On the other hand, as the case (a) above is not possible and  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle \leq 0$  (on the set  $E(\tau)$ ), the equality  $v = v_{\max}$  has to be fulfilled when  $\phi_r = 0$ . For larger times, since  $\phi_r$  must be nonnegative, one has  $u = 0$ ,  $r = 1$ , and then the obtained trajectory is exactly synthesized by the IOI strategy.

If  $v < v_{\max}$ ,  $\tilde{p}_1 > 0$ , and  $\langle \tilde{p}, m \rangle > 0$ , from Lemma 8.3, the unique possibility is to have  $\phi_r > 0$ , and consequently  $\phi_u = 0$ . In such a case, one has  $r = 0$  and  $u = u_{\max}$ . Hence,  $s$  and  $\phi_r$  increase. Then, there exists necessarily a time such that  $\langle \tilde{p}, m \rangle = 0$ , in order to reach the target. Note that, for larger time,  $\langle \tilde{p}, m \rangle < 0$  holds due to  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle < 0$ . In this situation,  $\phi_r$  decreases until  $\phi_r = 0$ , and from Lemma 8.3, it has to coincide with the time at which  $v = v_{\max}$ . After, since  $\phi_r$  must be nonnegative, one has  $u = 0$  and  $r = 1$ . The obtained trajectory is again synthesized by the IOI strategy.

Hence, we have proved that when  $\tilde{p}_1(t_0)$  is positive, the IOI strategy is optimal.

*Case 2:*  $\tilde{p}_1(t_0) < 0$ . Recall, from the above discussion, that  $\tilde{p}_1$  remains always negative. We now proceed to discard the following cases:

(b)  $v < v_{\max}$ ,  $\tilde{p}_1 < 0$ ,  $\phi_u > 0$ , and  $\langle \tilde{p}, m \rangle < 0$ .

This case implies that  $u = 0$  and  $r = 1$ . Thus,  $s$  decreases, and, by (6.5),  $\phi_u$  increases. This together with (8.4) imply that the sign of  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle$  is negative (on the set  $E(\tau)$  defined in Lemma 8.4). Consequently,  $\langle \tilde{p}, m \rangle$  remains always negative, and  $\phi_u$  always increases. Then the target cannot be reached because the tank is never fulfilled.

(c)  $v < v_{\max}$ ,  $\tilde{p}_1 < 0$ ,  $\phi_u = 0$ , and  $\langle \tilde{p}, m \rangle > 0$ .

In this case, one necessarily obtains  $r = 0$  and  $u = u_{\max}$  (in order to keep  $\phi_u$  nonnegative). Hence,  $s$  and  $\phi_r$  increase (see (6.5)). This together with (8.4) imply that the sign of  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle$  is positive (on  $E(\tau)$ ). Consequently,  $\langle \tilde{p}, m \rangle$  remains always positive, which is a contradiction with  $\tilde{p} = (-1, -1)$  at the final time.

Hence, if  $v < v_{\max}$ ,  $\tilde{p}_1 < 0$ , and  $\langle \tilde{p}, m \rangle > 0$  necessarily  $\phi_u > 0$  and  $\phi_r = 0$ , then one has  $u = 0$  and  $r = 1$  implying that  $s$  and  $\phi_u$  decrease until  $\langle \tilde{p}, m \rangle = 0$ . Equation (8.4) allows us to say that the sign of  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle$  is nonpositive, and hence  $\langle \tilde{p}, m \rangle \leq 0$  for larger times. If at time such that  $\langle \tilde{p}, m \rangle = 0$ , we have  $\phi_u > 0$  immediately after one has  $\langle \tilde{p}, m \rangle < 0$ . Then  $u = 0$  (in order to keep  $\phi_r$  nonnegative), and consequently  $\phi_u$  remains always positive, and the tank will not be fulfilled, which discard this case. Thus, necessarily  $\varphi_u$  becomes zero when  $\langle \tilde{p}, m \rangle = 0$ . If  $\langle \tilde{p}, m \rangle$  remains equal to zero for an interval of time, this corresponds to a singular arc. If not, that is,  $\langle \tilde{p}, m \rangle < 0$  immediately after, this situation implies that  $u = 0$  and  $r = 1$  onwards, which is impossible because the tank will never be filled.

Finally, we study the remaining case  $v < v_{\max}$ ,  $\tilde{p}_1 < 0$ ,  $\phi_u = 0$ , and  $\langle \tilde{p}, m \rangle < 0$ . One has necessarily  $r = 0$  and  $u = u_{\max}$ , in order to keep  $\phi_u$  nonnegative. Therefore,  $s$  increases and  $\phi_r$  decreases (see (6.5)) until a time  $\tau^*$  when one of the following three cases occur:

- case  $\phi_r > 0$  and  $\langle \tilde{p}, m \rangle = 0$ . This implies that  $u = u_{\max}$  and  $r = 0$ , and consequently  $s$  increases. This together with (8.4) implies that the sign of  $\frac{d}{d\tau} \langle \tilde{p}, m \rangle$  is positive. Consequently,  $\phi_r$  will always remain positive, which cannot allow one to reach the target. This case is thus discarded.
- case  $\phi_r = 0$  and  $\langle \tilde{p}, m \rangle < 0$ . This implies that  $u = 0$  and  $r = 1$ , and therefore (by (6.5))  $\phi_u$  becomes positive. Since (b) of Case 2 above has been discarded, it necessarily follows that  $v$  reaches  $v_{\max}$  at the same time  $\tau^*$ . The optimal trajectory is synthesized by the IOI strategy.
- case  $\phi_r = 0$  and  $\langle \tilde{p}, m \rangle = 0$ . Due to equality  $\phi_u = 0$  holding at the same time  $\tau^*$ , this configuration corresponds to a singular arc.

Thus, we have proved that if  $(u, r)(\cdot) \in \mathcal{C}$  is optimal, then it corresponds to an IOI strategy or to the singular arc strategy for a level  $s^* \geq s_{out}$ . We finish concluding that a singular arc cannot be applied on a substrate level greater than  $s_{in}$  because the domain  $\mathcal{D} = (\mathbb{R}_+^n \setminus \{0\}) \times ]0, s_{in}] \times ]0, v_{\max}[$  is invariant.  $\square$

*Remark 16.* The value of  $s^*$  depends on the initial condition and cannot be, in general, explicitly determined as in the case with one nonmonotonic species (see Proposition 7.4).

We give now an example that shows that an  $SA(\cdot)$  strategy can be better than an IOI strategy.

*Example 1.* We consider functions  $\mu_1(\cdot)$ ,  $\mu_2(\cdot)$  that fulfill Assumptions A1, A2, and A3, but not A4:

$$\mu_1(s) = s^2, \quad \mu_2(s) = 5\sqrt{s}$$

for the values  $s_{out} = 0.1$  and  $s_{in} = 5$  (see Figure 8.1).

We compare the strategies IOI and  $SA(s^*)$ , where  $s^*$  minimizes the cost of the  $SA(\bar{s})$  strategy for  $\bar{s} \in (s_{out}, s_{in})$ . For  $v_{\max} = 10$  and initial conditions with  $y_1 = 1$ ,  $z = 3$ , and  $w = 1$ , we have computed numerically  $s^*$  for different values of  $y_2$ . Results are reported in Table 8.1.

This example shows that, in the presence of a small population of a species more efficient for small substrate concentrations, the singular arc strategy may be better than the IOI one.

We focus now on sufficient conditions for which the IOI strategy is always optimal. We first consider functions  $\mu_i(\cdot)$  such that their graphs do not cross away from 0 (without loss of generality, one can assume that  $\mu_2$  is above  $\mu_1$ ).

*Assumption A4.*  $\mu_2(s) \geq \mu_1(s) \quad \forall s \in (0, s_{in}]$ .

Then, the functions  $\varphi_c(\cdot)$  possess the following properties.

FIG. 8.1. Graphs of the two growth functions.

LEMMA 8.6. Under Assumptions A0, A1, and A4, for any  $c \in (0, s_{in})$ ,  $(y, z) \in (\mathbb{R}^2_+ \setminus \{0\}) \times (c, s_{in}]$ , one has

- i.  $\partial_z \varphi_c(y, z) \geq \partial_{y_2} \varphi_c(y, z)$ ,
- ii.  $\partial_{y_1} \varphi_c(y, z) \geq \partial_{y_2} \varphi_c(y, z)$ ,
- iii.  $\partial_{y_2} \varphi_c(y, z) \leq 0$ .

*Proof.* Notice that the dynamics (3.3) possesses the property that  $M = x_1 + x_2 + s$  is constant. Then, fix a value  $M$ , and consider the reduced system

(8.6) 
$$\begin{cases} \frac{dx_1}{d\tau} = f_1(x_1, s) = \mu_1(s)x_1, \\ \frac{ds}{d\tau} = f_2(x_1, s, M) = -\mu_1(s)x_1 - \mu_2(s)(M - s - x_1). \end{cases}$$

The Jacobian matrix  $\mathcal{J}_M$  of this two-dimensional vector field has the structure

$$\mathcal{J}_M(x_1, s) = \begin{pmatrix} \star & \mu_1'(s)x_1 \\ \mu_2(s) - \mu_1(s) & \star \end{pmatrix},$$

which has nonnegative off-diagonal terms for any fixed  $M$ . So, the dynamical system (8.6) is cooperative (see [28]).

- i. Consider two sets of initial conditions for system (3.3):

$$(y_1^-, y_2^-, z^-) = (y_1, y_2 + \delta, z) \quad \text{and} \quad (y_1^+, y_2^+, z^+) = (y_1, y_2, z + \delta),$$

where  $\delta$  is a positive (small) number. We check that these two initial conditions have the same invariant  $x_1 + x_2 + s = M + \delta$ , and, from the cooperative property of system (8.6) with  $M + \delta$ , one has  $s^+(t) \geq s^-(t)$  for any  $t \geq 0$ . Thus  $\varphi_c(y_1, y_2, z + \delta) \geq \varphi_c(y_1, y_2 + \delta, z)$ , or equivalently

$$\frac{\varphi_c(y_1, y_2, z + \delta) - \varphi_c(y_1, y_2, z)}{\delta} \geq \frac{\varphi_c(y_1, y_2 + \delta, z) - \varphi_c(y_1, y_2, z)}{\delta},$$

and letting  $\delta$  take arbitrary small values, we obtain

$$\partial_z \varphi_c(y, z) \geq \partial_{y_2} \varphi_c(y, z).$$

ii. Similarly, we consider the sets of initial conditions

$$(y_1^-, y_2^-, z^-) = (y_1, y_2 + \delta, z) \quad \text{and} \quad (y_1^+, y_2^+, z^+) = (y_1 + \delta, y_2, z)$$

and obtain, when  $\delta$  tends toward zero,

$$\partial_{y_1} \varphi_c(y, z) \geq \partial_{y_2} \varphi_c(y, z).$$

iii. We consider the sets of initial conditions

$$(y_1^-, y_2^-, z^-) = (y_1, y_2 + \delta, z) \quad \text{and} \quad (y_1^+, y_2^+, z^+) = (y_1, y_2, z),$$

with nonnegative  $\delta$ . The first initial condition leads to the invariant  $x_1 + x_2 + s = M + \delta$ , while the second one has  $x_1 + x_2 + s = M$  as an invariant. Dynamics (8.6) is such that  $f_2(x_1, s, M + \delta) \leq f_2(x_1, s, M)$ , and, by the cooperative property, we conclude that  $\varphi_c(y_1, y_2 + \delta, z) \leq \varphi_c(y_1, y_2, z)$  or equivalently

$$\partial_{y_2} \varphi_c(y, z) \leq 0. \quad \square$$

*Remark 17.* From expression (3.1), one can notice that inequality

$$(8.7) \quad \tilde{z} \geq z$$

is always fulfilled. Thus, under assumptions A0, A1, and A4, if the function  $\varphi_{s_{out}}(\cdot)$  is such that

$$(8.8) \quad \partial_z \varphi_{s_{out}}(y, z) \geq \partial_{y_1} \varphi_{s_{out}}(y, z), \quad \forall (y, z) \in (\mathbb{R}_+^2 \setminus \{0\}) \times (s_{out}, s_{in}],$$

then, along with point i. of Lemma 8.6, inequality (8.7), and Lemma 5.2, we deduce immediately that condition (5.11) of Proposition 5.3 is fulfilled. Unfortunately, condition (8.8) is rarely met, even for simple growth rates. In Figure 8.2, we plot iso-values of the function

$$\psi_c(y) = \varphi_c(y, M - y_1 - y_2)$$

(computed numerically) for  $\mu_1(s) = s$ ,  $\mu_2(s) = 5s$ ,  $M = 10$ , and  $c = 1$ . We see that  $\partial_{y_2} \psi_c(\cdot)$  is everywhere nonpositive, but the sign of  $\partial_{y_1} \psi_c(\cdot)$  can change. Notice that the partial derivatives of  $\psi_c(\cdot)$  are linked to the partial derivatives of  $\varphi_c(\cdot)$  as follows:

$$\partial_{y_j} \psi_c(y) = \partial_{y_j} \varphi_c(y, z) - \partial_z \varphi_c(y, z), \quad (j = 1, 2),$$

with  $z = M - y_1 - y_2$ , and we conclude that condition (8.8) is not fulfilled.

FIG. 8.2. Iso-values of the function  $\psi_c(\cdot)$ .

The following proposition imposes conditions on growth functions  $\mu_i(\cdot)$  that guarantee the optimality of the IOI strategy.

**PROPOSITION 8.7.** *Under Assumptions A0, A3, and A4, the IOI strategy is optimal for any initial condition in  $\mathcal{D}$ .*

*Proof.* Consider  $\xi \in \mathcal{D}$  such that  $T_{IOI}(\xi) > 0$ . Let us write  $\Delta_r T_{IOI}(\xi)$  given in (5.8) as follows:

$$\Delta_r T_{IOI}(\xi) = \sum_{j=1}^2 \left( \partial_{y_j} \varphi_{s_{out}}(\tilde{y}, \tilde{z}) - \partial_z \varphi_{s_{out}}(\tilde{y}, \tilde{z}) \right) \mu_j(\tilde{z}) \tilde{y}_j \frac{\mu_j(z) - \mu_j(\tilde{z})}{\mu_j(\tilde{z})}.$$

Recall that  $\tilde{z} \geq z$  (8.7) and  $\mu_i(\cdot)$  are nondecreasing (Assumption A1). Then, by Assumption A3, one has

$$\frac{\mu_2(z) - \mu_2(\tilde{z})}{\mu_2(\tilde{z})} \leq \frac{\mu_1(z) - \mu_1(\tilde{z})}{\mu_1(\tilde{z})} \leq 0.$$

Lemma 8.6 gives the inequality

$$\partial_{y_2} \varphi_{s_{out}}(\tilde{y}, \tilde{z}) - \partial_z \varphi_{s_{out}}(\tilde{y}, \tilde{z}) \leq 0,$$

and consequently, from equation (4.2), we obtain

$$\begin{aligned} \Delta_r T_{IOI}(\xi) &\geq \sum_{j=1}^2 \left( \partial_{y_j} \varphi_{s_{out}}(\tilde{y}, \tilde{z}) - \partial_z \varphi_{s_{out}}(\tilde{y}, \tilde{z}) \right) \mu_j(\tilde{z}) \tilde{y}_j \frac{\mu_1(z) - \mu_1(\tilde{z})}{\mu_1(\tilde{z})} \\ &= - \frac{\mu_1(z) - \mu_1(\tilde{z})}{\mu_1(\tilde{z})} \geq 0 \end{aligned}$$

and conclude by Proposition 5.3.  $\square$

**9. Conclusion.** In this work, we have analyzed the minimal time problem for fed-batch reactors with several species, for which impulse controls are allowed. We

have shown that even when all of the growth functions are monotonic, the most rapid approach strategy is not necessarily optimal. In certain situations, it is better to follow a singular arc instead of applying an impulse, a departure from the optimal strategy in the one-species case. We believe that this result holds important implications for biotechnological applications.

# UNIFORM BOUNDARY CONTROLLABILITY OF A SEMIDISCRETE 1-D WAVE EQUATION WITH VANISHING VISCOSITY\*

SORIN MICU†

**Abstract.** This article deals with the approximation of the boundary control of the linear one-dimensional wave equation. It is known that the high frequency spurious oscillations that the classical methods of finite difference and finite element introduce lead to nonuniform controllability properties (see [J. A. Infante and E. Zuazua, *M2AN Math. Model. Numer. Anal.*, 33 (1999), pp. 407–438]. A space-discrete scheme with an added numerical vanishing viscous term is introduced and analyzed. The extra numerical damping filters out the high numerical frequencies and ensures the convergence of the sequence of discrete controls to a control of the continuous conservative wave equation when the mesh size tends to zero.

**Key words.** control, wave equation, semidiscrete approximation, numerical viscosity

**AMS subject classifications.** 93B40, 65M06, 93B05

**DOI.** 10.1137/070696933

**1. Introduction.** The following boundary exact controllability property for the one-dimensional (1-D) linear wave equation is known to hold: given  $T \geq 2$  and  $(u^0, u^1) \in L^2(0, 1) \times H^{-1}(0, 1)$  there exists a control function  $v \in L^2(0, T)$  such that the solution of the wave equation

$$(1.1) \quad \begin{cases} u'' - u_{xx} = 0 & \text{for } x \in (0, 1), \ t > 0, \\ u(t, 0) = 0, \quad u(t, 1) = v(t) & \text{for } t > 0, \\ u(0, x) = u^0(x), \quad u'(0, x) = u^1(x) & \text{for } x \in (0, 1) \end{cases}$$

satisfies

$$(1.2) \quad u(T, \cdot) = u'(T, \cdot) = 0.$$

By  $'$  we denote the time derivative.

For the study of this controllability problem the moments theory has been successfully used (see, for instance, [1, 25]). Also, the Hilbert uniqueness method (HUM) (see [16]) has provided a different and general way to study this and similar multidimensional problems.

In past years there was an increasing interest in the numerical approximations of the controls. For instance, HUM was used in [8, 10, 11] to deduce numerical algorithms with finite differences in the context of the two dimensional (2-D) wave equation. In these references a bad behavior of the approximate controls was observed. Let us briefly explain this phenomenon.

Generally speaking, the control's approximation strategy consists in discretizing the continuous problem (1.1), finding a control for each discrete problem, and finally making the mesh size  $h$  tend to zero. What one normally expects is to get a control of (1.1). However, as mentioned before, this is not necessarily true. Indeed, negative

numerical results may be obtained as a consequence of the spurious high frequency oscillations that do not exist at the continuous level but that are generated by any semidiscrete dynamics. Precisely the controls of the highest modes may have large norms which are not uniformly bounded in  $h$ . Moreover, a dispersion phenomenon appears, and the velocity of propagation of these high frequency numerical waves may converge to zero when the mesh size  $h$  tends to zero. Hence, neither is the control time uniformly bounded. All of these phenomena occur in the semidiscrete models obtained by finite differences or by the classical finite element method (see [13, 30] for a detailed analysis of the 1-D case and [29] for the 2-D case, in the context of the dual observability problem). In any of these models, the controllability property is *not uniform* as the discretization parameter  $h$  goes to zero. As a consequence there are initial data of the wave equation (even regular ones) for which the corresponding sequence of discrete controls will diverge in the  $L^2$ -norm.

Note that the spurious oscillations correspond to the high frequencies of the discrete model, and therefore they weakly converge to zero. Consequently, their existence is compatible with the convergence of the numerical scheme. However, when we are dealing with the exact controllability problem, the role of the high frequencies becomes much more important.

Since the main problem is the existence of the spurious high frequencies generated by the discretization process, the idea of eliminating or reducing them in one way or another arises naturally. All of the numerical experiments using a Tychonoff regularization technique [10, 11], a bigrid algorithm [8, 11] or a mixed finite element approximation [9] are based on this idea. How to do that in an optimal and general way and how to show mathematically the uniform controllability results are less clear. Nevertheless, in past years many theoretical results were obtained. In [18] the high frequency modes of the discrete initial data are filtered out in an appropriate manner to ensure the existence of a uniformly bounded sequence of discrete controls. In [2] a mixed finite element method is analyzed and an explicit sequence of discrete controls which tends to the HUM control of the limit wave equation (1.1) is constructed. The analysis of a bigrid method is presented in [21], where uniform results are also proved.

This paper considers a different method to achieve the uniform controllability. The idea is to introduce in the discrete equation a numerical viscous term which vanishes when the mesh size  $h$  tends to zero. The dissipation has the role to damp out the bad spurious high frequencies responsible for the large norm controls, eventually ensuring the uniform controllability of the system. The method has the advantage of being simple, general, and quite natural. Note that the amount of dissipation introduced in the discrete system is very important. If the dissipation is uniformly bounded in  $h$  (i.e., all of the eigenvalues belong to a vertical strip), it cannot compensate for the effect of the controls' growth, and the uniform result does not hold. On the other hand, the damping term should vanish in the limit and therefore cannot be enforced too much. We have treated a particular case in which we were able to prove the uniform controllability result. However, to give the optimal amount of dissipation capable of ensuring the best convergence rate and at the same time the uniformity needs further investigation (see Remark 1).

The proof of the uniform controllability result is based on the moments theory. More precisely, we construct a biorthogonal sequence in  $L^2(-\frac{T}{2}, \frac{T}{2})$  to the family of complex exponentials  $\Lambda = (e^{-\bar{\lambda}_n(h)t})_n$ , where  $\lambda_n(h)$  are the eigenvalues of the corresponding discrete operator. This is done via the Fourier transform of some entire functions of exponential type. A careful analysis of the behavior of these entire functions on the real axis gives estimates for the norm of the biorthogonal sequence.

These will allow us to show the uniform boundedness on  $h$  of the corresponding sequence of discrete controls for a large class of initial data.

Estimates for biorthogonal sequences to families of exponential functions may be found, for instance, in [6, 7] for the case of the heat equation, [5] for the case of a multidimensional wave equation, or [12] for the case of a dissipative beam equation. However, our family of exponentials has several different characteristics which make the study more difficult, such as the dependence on the discretization step  $h$  and the complexity of the exponents, which are contained neither in a sector of the real axis nor on a vertical strip of the imaginary axis as in the previous works. The Fourier transform of the biorthogonal elements has two qualitatively different behaviors on the real axis, depending on if the value of  $|x|$  is smaller than  $\frac{1}{h}$  or not. This gives interesting and new type estimates reflecting the behavior of the real parts of our exponents, which are of order  $h$  for the low frequencies but become of order  $\frac{1}{h}$  for the highest ones.

In [28] the controllability of a hyperbolic-parabolic coupled system is studied. The corresponding spectrum is a union of two families  $\{\lambda_l^l\}_{l \geq 1} \cup \{\lambda_k^h\}_{k \geq 1}$ . The first one is purely real and behaves like  $-l^2\pi^2$ , and the second one is complex and looks like  $-\frac{1}{\sqrt{2k\pi}} + k\pi i$ . Taken separately, each family has good controllability properties, and the main problem is to join them. Although there are similarities with our case (the spectrum is contained neither in a sector of the real axis nor on a vertical strip of the imaginary axis), we cannot use the technique from [28] since the high part of our spectrum is far away from any known controllable family of eigenfunctions.

The numerical viscosity technique was used in many different contexts (see, for instance, [4, 17] in the case of hyperbolic conservation laws or [22, 23, 26, 27] in the case of the semidiscrete dissipative plate or wave equation). In [22, 26, 27] an additional vanishing viscosity term is introduced in the interior of the domain to make the initially dissipative system uniformly stable. Consequently, the uniform controllability property holds if a vanishing control is added in the interior of the domain. However, our aim is more ambitious and consists of showing that no additional control is needed to ensure the convergence of this scheme. From the numerical point of view this is an advantage since the extra storage and computation for an additional control are avoided.

In [3] a singular limit problem from a parabolic to a hyperbolic equation is studied from the controllability point of view. Although the context and the approach are different, there exists at least one similarity to our case: the parabolic character vanishes in the limit when a controlled hyperbolic system is obtained.

It is known that a structural damping of the form  $-\varepsilon u_{txx}$  makes the continuous wave equation not even spectrally controllable (see [24]). This is due to the accumulation of the spectrum on  $-\varepsilon$ . In our semidiscrete case the viscosity parameter  $\varepsilon$  and the mesh size  $h$  are related and tend to zero simultaneously. The resulting system is consistent with the conservative wave equation, and therefore, unlike in [24], the uniform controllability property does hold.

The article is organized in the following way. The discrete control problem is presented in section 2, and an analysis of the energy decay rate is given in section 3. The control problem is transformed into an equivalent problem of moments in section 4. The main result is contained in section 5, where a biorthogonal sequence is constructed and evaluated. The technical but fundamental proof of the estimate on the real axis of the entire functions whose Fourier transforms give the biorthogonal sequence is given in the appendix at the end of the paper. In section 6 the existence of a bounded sequence of discrete controls is proved, and it is shown that any weak

limit is a control of the continuous wave equation. Section 7 presents some numerical experiments to support the theoretical results obtained in the paper.

**2. The discrete problem.** In this paper we study a finite-difference space discretization of (1.1). In order to do this, let us consider  $N \in \mathbb{N}^*$ , a step  $h = \frac{1}{N+1}$ , and an equidistant mesh of the interval  $(0, 1)$ ,  $0 = x_0 < x_1 < \dots < x_N < x_{N+1} = 1$ , with  $x_j = jh$ ,  $0 \leq j \leq N+1$ . The central finite-difference approximation of the space derivatives leads to the following semidiscretization of (1.1):

$$(2.1) \quad \begin{cases} u_j''(t) - \frac{u_{j+1}(t) + u_{j-1}(t) - 2u_j(t)}{h^2} = 0 & \text{for } 1 \leq j \leq N, \ t > 0, \\ u_0(t) = 0, \ u_{N+1}(t) = v_h(t) & \text{for } t > 0, \\ u_j(0) = u_j^0(x), \ u_j' = u_j^1(x) & \text{for } 1 \leq j \leq N. \end{cases}$$

System (2.1) consists of  $N$  linear differential equations with  $N$  unknowns  $u_1, u_2, \dots, u_N$ . Roughly speaking,  $u_j(t)$  approximates  $u(t, x_j)$ , the solution of (1.1), provided that  $(u_j^0, u_j^1)_{0 \leq j \leq N+1}$  is an approximation for the initial datum in (1.1). In fact, we shall choose

$$(2.2) \quad u_j^0 = u^0(jh), \quad u_j^1 = u^1(jh), \quad 0 \leq j \leq N+1.$$

Our aim is to study the following controllability property for (2.1): *given  $T > 2$  and  $(u_j^0, u_j^1)_{1 \leq j \leq N} \in \mathbb{C}^{2N}$ , there exists a control function  $v_h \in H^1(0, T)$  such that the corresponding solution  $(u_j, u_j')_{1 \leq j \leq N}$  of (2.1) satisfies*

$$(2.3) \quad u_j(T) = u_j'(T) = 0, \quad 1 \leq j \leq N.$$

If this holds for any  $(u_j^0, u_j^1)_{1 \leq j \leq N} \in \mathbb{C}^{2N}$ , we say that (2.1) is *exactly controllable in time  $T$* .

It is not difficult to see that the controllability problem we have just addressed has a positive answer and a sequence of discrete controls  $(v_h)_{h>0}$  may be easily found. Considerably more difficult is to show that the sequence  $(v_h)_{h>0}$  converges in some sense to a control  $v$  of the continuous wave equation (1.1), corresponding to the initial datum  $(u^0, u^1)$ , which verifies (2.2). In fact, due to the spurious high frequencies introduced by the discretization, the numerical scheme (2.1) gives an unbounded sequence of controls  $(v_h)_{h>0}$  even when very regular initial data  $(u^0, u^1)$  are considered (see [13, 18]).

In order to deal with the spurious high frequencies, we add a dissipative term, vanishing when the mesh size tends to zero. More precisely, we consider instead of (2.1) the following scheme:

$$(2.4) \quad \begin{cases} u_j''(t) - \frac{u_{j+1}(t) + u_{j-1}(t) - 2u_j(t)}{h^2} - \varepsilon \frac{u_{j+1}'(t) + u_{j-1}'(t) - 2u_j'(t)}{h^2} = 0, & t > 0, \\ u_0(t) = 0, \ u_{N+1}(t) = v_h(t), & t > 0, \\ u_j(0) = u_j^0(x), \ u_j' = u_j^1(x), & 1 \leq j \leq N, \end{cases}$$

and we address the same controllability problem as before.

The parameter  $\varepsilon$ , which multiplies the viscous term  $\frac{u_{j+1}'(t) + u_{j-1}'(t) - 2u_j'(t)}{h^2}$ , depends on the step size  $h$  and tends to zero as  $h \rightarrow 0$ :

$$(2.5) \quad \lim_{h \rightarrow 0} \varepsilon(h) = 0.$$

Hence, in (2.4), the term  $\varepsilon \frac{u'_{j+1}(t) + u'_{j-1}(t) - 2u'_j(t)}{h^2}$  represents a vanishing numerical viscosity that will eventually ensure the boundedness of the sequence  $(v_h)_{h>0}$ .

*Remark 1.* A similar damping term, with  $\varepsilon = h^2$ , is used in [27] in order to ensure an exponentially uniform decay rate of the discrete energy, when a dissipative term is already present on the boundary. In this case, the extra damping constitutes a bounded perturbation sufficient to restore the uniform decay rate. The spectrum of the corresponding operator is shifted to the left, but it remains in a vertical strip. However, this is not sufficient to ensure the uniform boundary controllability property. Therefore, we shall reinforce the damping by considering  $\varepsilon = h$ . This selection verifies (2.5) and, at the same time, ensures the amount of dissipation needed for the uniform control of the high frequencies. Let us finally mention that we do not know the optimal choice for  $\varepsilon(h)$ , ensuring both the uniformity in  $h$  and the best convergence rate. For instance, any  $\varepsilon(h) = h^\alpha$ , with  $\alpha \in (1, 2)$ , could still produce uniform controllability results with a better convergence rate. The numerical experiments confirm this, but the theoretical study is more difficult and needs further investigation. In [23] such dissipative terms were used to achieve uniform stability of the approximating models.

Let us first write (2.4) in a vectorial form, which is easier to deal with. We define the following matrix from  $\mathcal{M}_{N \times N}(\mathbb{R})$ :

$$A_h = \frac{1}{h^2} \begin{pmatrix} 2 & -1 & 0 & 0 & \dots & 0 & 0 \\ -1 & 2 & -1 & 0 & \dots & 0 & 0 \\ 0 & -1 & 2 & -1 & \dots & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & 0 & \dots & 2 & -1 \\ 0 & 0 & 0 & 0 & \dots & -1 & 2 \end{pmatrix}.$$

If we denote the unknown of (2.4) by  $U_h(t) = (u_1(t), u_2(t), \dots, u_N(t))^T$ , system (2.4) may be written in the following equivalent vectorial form:

$$(2.6) \quad \begin{cases} U_h''(t) + A_h U_h(t) + \varepsilon A_h U_h'(t) = F_h(t), & \text{for } t > 0, \\ U_h(0) = U_h^0, \quad U_h'(0) = U_h^1, \end{cases}$$

$U_h^0 = (u_j^0)_{1 \leq j \leq N}$  and  $U_h^1 = (u_j^1)_{1 \leq j \leq N}$  being the initial data of (2.4). The vector  $F_h$  is given by

$$F_h(t) = \begin{pmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ \frac{1}{h^2} (v_h(t) + \varepsilon v_h'(t)) \end{pmatrix}.$$

In (2.6) we have taken into account that  $u_{N+1}(t) = v_h(t)$  and  $u_0(t) = 0$  for all  $t > 0$ .

Before studying the decay properties of the solutions of (2.6), let us define in  $\mathbb{C}^N$  the canonical inner product

$$(2.7) \quad (f, g) = h \sum_{k=1}^N f_k \overline{g_k},$$

where  $f = (f_k)_{1 \leq k \leq N}$  and  $g = (g_k)_{1 \leq k \leq N}$  belong to  $\mathbb{C}^N$ .

Also, we consider in  $\mathbb{C}^{2N}$  the inner product defined by

$$(2.8) \quad (f, g)_1 = h \left[ \sum_{k=1}^{N-1} \frac{f_{k+1} - f_k}{h} \frac{\bar{g}_{k+1} - \bar{g}_k}{h} + \frac{1}{h^2} (f_1 \bar{g}_1 + f_N \bar{g}_N) \right] + h \sum_{k=N+1}^{2N} f_k \bar{g}_k,$$

where  $f = (f_k)_{1 \leq k \leq 2N}$  and  $g = (g_k)_{1 \leq k \leq 2N}$  are two vectors from  $\mathbb{C}^{2N}$ . The corresponding norm will be denoted by  $\|\cdot\|_1$ .

*Remark 2.* The following equivalent form of the inner product (2.8) justifies its definition and its usefulness for our problem:

$$(2.9) \quad (f, g)_1 = (A_h f^1, g^1) + (f^2, g^2),$$

where  $f^1 = (f_k)_{1 \leq k \leq N}$ ,  $f^2 = (f_k)_{N+1 \leq k \leq 2N}$ ,  $g^1 = (g_k)_{1 \leq k \leq N}$ ,  $g^2 = (g_k)_{N+1 \leq k \leq 2N}$  and  $f = (f_1, f_2)$ ,  $g = (g_1, g_2)$ .

The following discrete duality product will be needed in the study of the control problem:

$$(2.10) \quad \langle (f^1, f^2), (g^1, g^2) \rangle_D = - (f^1, g^2) + (f^2 + \varepsilon A_h f^1, g^1),$$

where  $f = (f^1, f^2)$  and  $g = (g^1, g^2)$  are two vectors from  $\mathbb{C}^{2N}$  as in Remark 2.

**3. Energy estimates.** In this section we briefly study system (2.4) in the uncontrolled case, i.e., when  $v_h = 0$ , and show its dissipative character. Here (2.4) is a homogeneous linear system of  $N$  differential equations of order two and has a unique solution  $U \in \mathcal{C}^\omega([0, \infty), \mathbb{R}^N)$  (the set of analytic functions defined in  $[0, \infty)$  and with values in  $\mathbb{R}^N$ ). The energy of (2.4) is defined by

$$(3.1) \quad E_h(t) = \frac{h}{2} \sum_{j=0}^N \left[ |u'_j(t)|^2 + \left| \frac{u_{j+1}(t) - u_j(t)}{h} \right|^2 \right]$$

and represents a discretization of the continuous energy corresponding to (1.1)

$$(3.2) \quad E(t) = \frac{1}{2} \int_0^1 [|u'(t)|^2 + |u_x(t)|^2] dx.$$

*Remark 3.* The energy may be expressed in terms of the inner product (2.7):

$$(3.3) \quad E_h(t) = \frac{1}{2} [(U'_h(t), U'_h(t)) + (U_h(t), A_h U_h(t))].$$

It is easy to show that system (2.4) is dissipative. More precisely, we have the following proposition.

**PROPOSITION 3.1.** *If  $v_h = 0$  in (2.4) and  $E_h(t)$  is the energy function (3.1), then*

$$(3.4) \quad \frac{dE_h}{dt}(t) = -\varepsilon (A_h U'_h(t), U'_h(t)) = -\varepsilon h \sum_{j=0}^N \left| \frac{u'_{j+1}(t) - u'_j(t)}{h} \right|^2.$$

*Proof.* Equality (3.4) follows easily, multiplying (2.6) by  $U'_h$ . Indeed,

$$\begin{aligned} 0 &= (U''_h + A_h U_h + \varepsilon A_h U'_h, U'_h) \\ &= \frac{1}{2} [(U'_h, U'_h) + (A_h U_h, U_h)]' + \varepsilon (A_h U'_h, U'_h) \\ &= \frac{dE_h}{dt}(t) + \varepsilon (A_h U'_h, U'_h), \end{aligned}$$

and the proof finishes.  $\square$

Proposition 3.1 indicates that the energy of (2.4) decreases with  $t$ . In the next theorem we shall give an estimate for the decay rate of the energy. Let us first consider the Fourier decomposition of the solutions of (2.4) by using the eigenvectors of the self-adjoint operator  $A_h$ . It is well known (see, for instance, [15]) that the eigenvalues of  $A_h$  are  $(\nu_j^2)_{1 \leq j \leq N}$ , where

$$(3.5) \quad \nu_j = \frac{2}{h} \sin\left(\frac{j\pi h}{2}\right), \quad 1 \leq j \leq N,$$

and the corresponding eigenvectors are given by

$$(3.6) \quad \varphi^j = \sqrt{2}(\sin(j\pi hk))_{1 \leq k \leq N} \in \mathbb{R}^N, \quad 1 \leq j \leq N.$$

The following property holds.

LEMMA 3.2. *The set of vectors  $(\varphi^j)_{1 \leq j \leq N}$  forms an orthonormal basis in  $\mathbb{C}^N$  with respect to the inner product defined by (2.7).*

*Proof.* We have

$$(\varphi^l, \varphi^j) = 2h \sum_{k=1}^N \sin(j\pi hk) \sin(l\pi hk) = h \sum_{k=0}^N (\cos((l-j)\pi hk) - \cos((l+j)\pi hk)).$$

But, for  $q \in \mathbb{Z}$ ,

$$\sum_{k=0}^N \cos(q\pi hk) = \begin{cases} N+1 & \text{if } q = 0, \\ \frac{1-(-1)^q}{2} & \text{if } q \in \mathbb{Z}^*. \end{cases}$$

It follows that  $(\varphi^l, \varphi^j) = \delta_{lj}$ , and the proof finishes.  $\square$

Let us expand the initial datum  $(U_h^0, U_h^1)$  of (2.6) as follows:

$$(3.7) \quad U_h^0 = \sum_{j=1}^N a_{jh}^0 \varphi^j \quad \text{and} \quad U_h^1 = \sum_{j=1}^N a_{jh}^1 \varphi^j.$$

The corresponding solution  $U_h(t)$  is given by

$$(3.8) \quad U_h(t) = \sum_{j=1}^N a_{jh}(t) \varphi^j,$$

where the coefficients  $a_{jh}(t)$  can be computed explicitly. Indeed, we have the following lemma.

LEMMA 3.3. *If the initial datum  $(U_h^0, U_h^1)$  of system (2.6) are given by (3.7), then the corresponding solution of (2.6), with  $v_h = 0$ , is given by (3.8), where*

$$(3.9) \quad a_{jh}(t) = \frac{a_{jh}^1 - \lambda_j^- a_{jh}^0}{\lambda_j^+ - \lambda_j^-} e^{\lambda_j^+ t} - \frac{a_{jh}^1 - \lambda_j^+ a_{jh}^0}{\lambda_j^+ - \lambda_j^-} e^{\lambda_j^- t}$$

and

$$(3.10) \quad \lambda_j^\pm = \frac{1}{2} \left( -\varepsilon \nu_j^2 \pm \sqrt{\varepsilon^2 \nu_j^4 - 4\nu_j^2} \right), \quad j = 1, 2, \dots, N.$$

*Proof.* The proof is elementary, and we omit it.  $\square$

*Remark 4.* The values  $(\lambda_j^\pm)_{1 \leq j \leq N}$  from (3.10) are the eigenvalues of the operator

$$\mathcal{A} = \begin{pmatrix} 0 & -I \\ A_h & \varepsilon A_h \end{pmatrix}$$

corresponding to (2.6). Note that they are complex numbers with a negative real part. We shall write

$$\lambda_j = \frac{1}{2} \left( -\varepsilon \nu_j^2 + \operatorname{sgn}(j) \sqrt{\varepsilon^2 \nu_j^4 - 4 \nu_j^2} \right), \quad 1 \leq |j| \leq N.$$

Let us remark that, in the case  $\varepsilon = h$ ,  $\lambda_j$  has the simpler form

$$(3.11) \quad \lambda_j = i \frac{2}{h} \sin \left( \frac{j\pi h}{2} \right) \left( \cos \left( \frac{j\pi h}{2} \right) + i \sin \left( \frac{j\pi h}{2} \right) \right).$$

We pass now to evaluate the decay rate of the energy corresponding to (2.6).

From now on we shall suppose that  $\varepsilon = h$ . This is the case we shall analyze from the controllability point of view later on in the paper.

**THEOREM 3.4.** *Let  $\varepsilon = h$  and  $v_h = 0$  in (2.4). There exist two positive constants  $C$  and  $\omega$ , not depending on  $h$ , such that*

$$(3.12) \quad E_h(t) \leq \frac{C}{h^2} e^{-\omega h t} E_h(0) \quad \forall t > 0.$$

*Proof.* From (3.3) and Lemmas 3.2 and 3.3 we have that

$$E_h(t) = \frac{1}{2} [(U'(t), U'(t)) + (A_h U(t), U(t))] = \frac{1}{2} \left[ \sum_{j=1}^N (|a'_{jh}(t)|^2 + \nu_j^2 |a_{jh}(t)|^2) \right].$$

From (3.9) we obtain that, for  $1 \leq j \leq N$ ,

$$\begin{aligned} |a'_{jh}(t)|^2 + \nu_j^2 |a_{jh}(t)|^2 &\leq 8e^{-\varepsilon \nu_j^2 t} \frac{|\lambda_j^+|^2 + \nu_j^2}{|\lambda_j^+ - \lambda_j^-|^2} [|a_{jh}^1|^2 + |\lambda_j^+|^2 |a_{jh}^0|^2] \\ &= 16e^{-\varepsilon \nu_j^2 t} \frac{\nu_j^2}{|\lambda_j^+ - \lambda_j^-|^2} [|a_{jh}^1|^2 + \nu_j^2 |a_{jh}^0|^2]. \end{aligned}$$

Hence,

$$(3.13) \quad E_h(t) \leq 8 \sum_{j=1}^N \left[ e^{-\varepsilon \nu_j^2 t} \frac{\nu_j^2}{|\lambda_j^+ - \lambda_j^-|^2} (|a_{jh}^1|^2 + \nu_j^2 |a_{jh}^0|^2) \right].$$

It follows that

$$E_h(t) \leq 8 \max_{1 \leq j \leq N} \left\{ \frac{\nu_j^2}{|\lambda_j^+ - \lambda_j^-|^2} \right\} e^{-\omega h t} \sum_{j=1}^N [|a_{jh}^1|^2 + \nu_j^2 |a_{jh}^0|^2] \leq \frac{1}{4h^2} e^{-\omega h t} E_h(0),$$

with

$$0 < \omega \leq 4 \leq \frac{4}{h^2} \sin^2 \frac{\pi h}{2} = \frac{1}{h} \min_{1 \leq j \leq N} \{\varepsilon \nu_j^2\}.$$

The proof is finished.  $\square$

*Remark 5.* Note that the decay rate of the energy is not uniform when  $h$  tends to zero. Nevertheless, from (3.13), it follows that

$$(3.14) \quad E_h(t) \leq \sum_{j=1}^N e^{-h\nu_j^2 t} \frac{2}{\cos\left(\frac{j\pi h}{2}\right)} (|a_{jh}^1|^2 + \nu_j^2 |a_{jh}^0|^2).$$

Since  $h\nu_j^2$  increases with  $j$ , it follows that the high frequencies are sensibly more dissipated than the lower ones. This is precisely the mechanism we shall take advantage of in the control problem.

**4. The problem of moments.** We return now to the controllability problem for (2.6). Let us recall that (2.6) is exactly controllable in time  $T$  if, for any  $(U_h^0, U_h^1) \in \mathbb{C}^{2N}$ , there exists a control function  $v_h \in H^1(0, T)$  such that the corresponding solution  $(U_h, U_h')$  of (2.6) satisfies  $U_h(T) = U_h'(T) = 0$ .

First, we deduce a variational characterization of the controllability property. Let  $(\phi_h, \phi_h')$  be the solution of the following backward homogeneous system:

$$(4.1) \quad \begin{cases} \phi_h''(t) + A_h \phi_h(t) - \varepsilon A_h \phi_h'(t) = 0 & \text{for } t \in (0, T), \\ \phi_h(T) = \phi_h^0, \quad \phi_h'(T) = \phi_h^1, \end{cases}$$

where  $(\phi^0, \phi^1) \in \mathbb{C}^{2N}$  are given.

Multiplying (4.1) by the solution  $U_h$  of (2.6) and integrating in time, we obtain

$$\begin{aligned} 0 &= \int_0^T (U_h, \phi_h'' + A_h \phi_h - \varepsilon A_h \phi_h') dt \\ &= [-(U_h' + \varepsilon A_h U_h, \phi_h) + (U_h, \phi_h')]_0^T + \int_0^T (U_h'' + A_h U_h + \varepsilon A_h U_h', \phi_h) dt \\ &= [-(U_h' + \varepsilon A_h U_h, \phi_h) + (U_h, \phi_h')]_0^T + \int_0^T (F_h, \phi_h) dt. \end{aligned}$$

Hence,

$$(4.2) \quad \langle (U_h(t), U_h'(t)), (\phi_h(t), \phi_h'(t)) \rangle_D \Big|_0^T = \int_0^T \frac{1}{h} (v_h(t) + \varepsilon v_h'(t)) \overline{\phi_N(t)} dt.$$

For any  $f_h \in L^2(0, T)$ , let  $v_h \in H^1(0, T)$  be a solution of

$$(4.3) \quad \varepsilon v_h' + v_h = f_h, \quad t \in (0, T).$$

From (4.2) we obtain the following variational characterization of the controllability property.

**LEMMA 4.1.** *Given  $T > 0$ , system (2.4) is exactly controllable in time  $T$  if and only if, for any  $(U_h^0, U_h^1) \in \mathbb{C}^{2N}$ , there exists  $f_h \in L^2(0, T)$  such that, for any  $(\phi_h^0, \phi_h^1) \in \mathbb{C}^{2N}$ ,*

$$(4.4) \quad \int_0^T f_h(t) \frac{\overline{\phi_N(t)}}{h} dt = - \langle (U_h^0, U_h^1), (\phi_h(0), \phi_h'(0)) \rangle_D,$$

$(\phi_h, \phi_h')$  being the corresponding solution of (4.1). A control  $v_h$  for (2.4) is any solution of (4.3).

In order to write (4.4) as an equivalent problem of moments, we use the Fourier expansion of the solutions of (4.1) as we have done for (2.6). Let us decompose the initial datum  $(\phi^0, \phi^1)$  of (4.1) as

$$(4.5) \quad \phi_h^0 = \sum_{j=1}^N b_{jh}^0 \varphi^j \text{ and } \phi_h^1 = \sum_{j=1}^N b_{jh}^1 \varphi^j.$$

The corresponding solution  $\phi_h$  of (4.1) has the form

$$(4.6) \quad \phi_h(t) = \sum_{j=1}^N b_{jh}(t) \varphi^j,$$

where the coefficients  $b_{jh}(t)$  are given by

$$(4.7) \quad b_{jh}(t) = \frac{b_{jh}^1 - \mu_j^- b_{jh}^0}{\mu_j^+ - \mu_j^-} e^{\mu_j^+(t-T)} + \frac{-b_{jh}^1 + \mu_j^+ b_{jh}^0}{\mu_j^+ - \mu_j^-} e^{\mu_j^-(t-T)},$$

and  $\mu_j^\pm = \frac{1}{2} \left( \varepsilon \nu_j^2 \pm \sqrt{\varepsilon^2 \nu_j^4 - 4\nu_j^2} \right)$  are the roots of the characteristic equation

$$(4.8) \quad \mu^2 - \varepsilon \nu_j^2 \mu + \nu_j^2 = 0, \quad 1 \leq j \leq N.$$

In the sequel we shall write

$$\mu_n = \frac{1}{2} \left( \varepsilon \nu_n^2 + \operatorname{sgn}(n) \sqrt{\varepsilon^2 \nu_n^4 - 4\nu_n^2} \right) = \begin{cases} \mu_n^+ & \text{if } n > 0, \\ \mu_n^- & \text{if } n < 0, \end{cases}$$

and these are the eigenvalues of the adjoint problem (4.1). We have the following new characterization of the controllability property in terms of a problem of moments.

**THEOREM 4.2.** *Let  $T > 0$ . System (2.6) is exactly controllable in time  $T$  if and only if, for any  $(U_h^0, U_h^1) \in \mathbb{C}^{2N}$  of form (3.7), there exists  $f_h \in L^2(0, T)$  such that*

$$(4.9) \quad \int_0^T f_h(t) e^{\mu_n t} dt = \frac{(-1)^n h}{\sqrt{2} \sin(|n|\pi h)} \left( \frac{\nu_n^2}{\mu_n} a_{|n|h}^0 + a_{|n|h}^1 \right), \quad 1 \leq |n| \leq N.$$

*Proof.* The proof is a direct consequence of Lemma 4.1. Indeed, it is sufficient to verify (4.4) for  $(\phi_h^0, \phi_h^1) = (\varphi^{|n|}, \mu_n \varphi^{|n|})$ ,  $1 \leq |n| \leq N$ . By taking into account (4.6)–(4.7), we deduce that in this case  $\phi = e^{(t-T)\mu_n} \varphi^{|n|}$  and

$$\phi_N(t) = (-1)^{n+1} \sqrt{2} \sin(|n|\pi h) e^{(t-T)\mu_n}.$$

On the other hand,

$$\begin{aligned} \langle (U_h^0, U_h^1), (\phi_h(0), \phi_h'(0)) \rangle_D &= \left\langle (U_h^0, U_h^1), e^{-\mu_n T} \left( \varphi^{|n|}, \mu_n \varphi^{|n|} \right) \right\rangle_D \\ &= e^{-\bar{\mu}_n T} \left( -\bar{\mu}_n \sum_{1 \leq m \leq N} a_{mh}^0 \left( \varphi^m, \varphi^{|n|} \right) \right. \\ &\quad \left. + \sum_{1 \leq m \leq N} (a_{mh}^1 + \varepsilon \nu_m^2 a_{mh}^0) \left( \varphi^m, \varphi^{|n|} \right) \right) \\ &= e^{-\bar{\mu}_n T} \left( a_{|n|h}^0 (-\bar{\mu}_n + \varepsilon \nu_n^2) + a_{|n|h}^1 \right) \\ &= e^{-\bar{\mu}_n T} \left( \frac{\nu_n^2}{\bar{\mu}_n} a_{|n|h}^0 + a_{|n|h}^1 \right). \end{aligned}$$

From Lemma 4.1 it follows immediately that (4.9) holds.  $\square$

*Remark 6.* According to Theorem 4.2 a control  $v_h$  for (2.6) is obtained by solving the following problem of moments: find  $g_h \in L^2(-\frac{T}{2}, \frac{T}{2})$  such that

$$(4.10) \quad \int_{-\frac{T}{2}}^{\frac{T}{2}} g_h(t) e^{\mu_n t} dt = \beta_{nh} e^{-\mu_n \frac{T}{2}}, \quad 1 \leq |n| \leq N,$$

where  $g_h(s - \frac{T}{2}) = f_h(s)$  and  $\beta_{nh} = \frac{(-1)^{n+1}h}{\sqrt{2} \sin(|n|\pi h)} (\frac{\nu_n^2}{\mu_n} a_{|n|h}^0 + a_{|n|h}^1)$ .

**5. Biorthogonal sequences.** Let us consider the sequence  $(\mu_n)_{\substack{|n| \leq N \\ n \neq 0}}$  of the eigenvalues of the matrix operator

$$\mathcal{A}^* = \begin{pmatrix} 0 & -I \\ A_h & -\varepsilon A_h \end{pmatrix}$$

corresponding to the adjoint problem (4.1). Recall that we have considered  $\varepsilon = h$  and consequently

$$(5.1) \quad \mu_n = i \frac{2}{h} \sin\left(\frac{n\pi h}{2}\right) \left( \cos\left(\frac{n\pi h}{2}\right) - i \sin\left(\frac{n\pi h}{2}\right) \right).$$

To solve the problem of moments (4.10), we construct an explicit biorthogonal sequence  $(\Theta_m)_{\substack{|m| \leq N \\ m \neq 0}}$  to the family of complex exponentials  $(e^{\mu_n t})_{\substack{|n| \leq N \\ n \neq 0}}$  in  $L^2(-\frac{T}{2}, \frac{T}{2})$  and we estimate the norm of the elements of this biorthogonal sequence.

We recall that  $(\Theta_m)_{\substack{|m| \leq N \\ m \neq 0}}$  is a biorthogonal sequence to  $(e^{\mu_n t})_{\substack{|n| \leq N \\ n \neq 0}}$  in  $L^2(-\frac{T}{2}, \frac{T}{2})$  if (see [1] and [31])

$$(5.2) \quad \int_{-\frac{T}{2}}^{\frac{T}{2}} \Theta_m(t) e^{\mu_n t} dt = \delta_{mn} \quad \forall m, n = \pm 1, \pm 2, \dots, \pm N.$$

*Remark 7.* If  $(\Theta_m)_{1 \leq |m| \leq N}$  is a biorthogonal sequence in  $L^2(-\frac{T}{2}, \frac{T}{2})$  to the family  $(e^{\mu_n t})_{1 \leq |n| \leq N}$ , then

$$(5.3) \quad g_h(t) = \sum_{\substack{|n| \leq N \\ n \neq 0}} \beta_{nh} e^{-\mu_n \frac{T}{2}} \Theta_n$$

is a solution of the problem of moments (4.10). Note that in (5.3) we have a finite sum, but the number of terms tends to infinity as  $h$  goes to zero. We also have

$$(5.4) \quad \|g_h\|_{L^2} \leq \sum_{\substack{|n| \leq N \\ n \neq 0}} |\beta_{nh}| e^{-\Re(\mu_n) \frac{T}{2}} \|\Theta_n\|_{L^2},$$

and an estimate for the norm of  $g_h$  is obtained from the estimate of the norm of the biorthogonal sequence. From (5.4) we see that the  $L^2$ -norm of  $g_h$  may be uniformly bounded in  $h$  even if  $\|\Theta_n\|_{L^2}$  is large, provided that the negative exponentials  $e^{-\Re(\mu_n) \frac{T}{2}}$  (due to the dissipation term we have introduced) are small enough. Our aim is to show that, for  $T$  sufficiently large,  $\|\Theta_n\|_{L^2} e^{-\Re(\mu_n) \frac{T}{2}}$  is sufficiently small to ensure the uniform boundedness of the sum.

Since  $(e^{\mu_n t})_{\substack{|n| \leq N \\ n \neq 0}}$  is a finite family of exponential functions, it follows immediately that it has infinitely many biorthogonal families in  $L^2(-\frac{T}{2}, \frac{T}{2})$ . However, we are interested not only in the existence but also on the dependence of these biorthogonal families on  $N$ . Our aim is to construct an explicit biorthogonal and to evaluate the norm of its elements. We shall do that in several steps:

1. We construct an entire function of exponential type, the product  $\Upsilon_m$ , with the property that  $\Upsilon_m(-i\mu_n) = \delta_{mn}$  (Lemma 5.1).
2. We evaluate  $\Upsilon_m$  on the real axis (Lemma 5.2).
3. We construct an entire function, the multiplier  $G$ , of exponential type such that  $\Upsilon_m G$  is bounded on the real axis (Lemma 5.3).
4. The Fourier transform of the entire function  $\Upsilon_m(z)G(z)(\frac{\sin(z+i\mu_m)}{z+i\mu_m})^2$  gives the element  $\Theta_m$  of a biorthogonal sequence. Moreover, from the Plancherel theorem, an estimate for the norm of  $\Theta_m$  is obtained too (Theorem 5.4).

This method was used in several controllability problems for the heat [6] or the wave equations [5]. However, here we deal with two parameters  $h$  and  $m$  and complex exponents  $\mu_n$ . The most difficult part consists in the estimate at step 2. This estimate will have different forms, according to the relation existing between  $x$  and  $h$ .

**5.1. The product.** Let us first define, for each  $m$  such that  $1 \leq |m| \leq N$ , the following product function:

$$(5.5) \quad \Upsilon_m(z) = \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \left( \frac{1 + \frac{z}{i\mu_n}}{1 - \frac{\mu_m}{\mu_n}} \right) \prod_{1 \leq |n| \leq N} \exp\left(-\frac{z + i\mu_m}{i\mu_n}\right).$$

LEMMA 5.1. *The function  $\Upsilon_m$  has the following properties:*

- (i)  $\Upsilon_m(-i\mu_n) = \delta_{nm}$ ,  $1 \leq |n| \leq N$ ;
- (ii) *There exists a constant  $B_1$  independent of  $h$  and  $m$  such that  $\Upsilon_m$  is an entire function of exponential type at most  $B_1$ ; i.e., there exists a constant  $0 < A_m < 1$  such that*

$$(5.6) \quad |\Upsilon_m(z)| \leq A_m \exp(B_1|z|) \quad \forall z \in \mathbb{C}.$$

*Proof.* The first property is evident. Let us pass directly to show (5.6). Since  $\mu_{-n} = \overline{\mu_n}$ , we have that, for any  $z \in \mathbb{C}$ ,

$$\prod_{1 \leq |n| \leq N} \exp\left(\frac{z}{\mu_n}\right) = \exp\left(z \sum_{1 \leq |n| \leq N} \frac{1}{\mu_n}\right) = \exp\left(z \sum_{1 \leq n \leq N} \frac{2\Re(\mu_n)}{|\mu_n|^2}\right) = \exp(Nh z)$$

and therefore

$$(5.7) \quad \left| \exp\left(-\frac{z}{i\mu_m}\right) \prod_{1 \leq |n| \leq N} \exp\left(-\frac{\mu_m}{\mu_n}\right) \right| \leq \exp(-Nh \Re(\mu_m)) \exp\left(\frac{|z|}{2}\right).$$

On the other hand, for any  $z \neq -i\mu_n$ ,

$$\begin{aligned} & \left| \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \left(1 + \frac{z}{i\mu_n}\right) \exp\left(-\frac{z}{i\mu_n}\right) \right| = \exp\left(\sum_{\substack{1 \leq |n| \leq N \\ n \neq m}} \ln \left| \left(1 + \frac{z}{i\mu_n}\right) \exp\left(-\frac{z}{i\mu_n}\right) \right| \right) \\ &= \exp\left(\sum_{\substack{1 \leq |n| \leq [|z|] \\ n \neq m}} \ln \left| 1 + \frac{z}{i\mu_n} \right| - \sum_{\substack{1 \leq |n| \leq [|z|] \\ n \neq m}} \Re\left(\frac{z}{i\mu_n}\right) + \sum_{\substack{[|z|]+1 \leq |n| \leq N \\ n \neq m}} \ln \left| \left(1 + \frac{z}{i\mu_n}\right) \exp\left(-\frac{z}{i\mu_n}\right) \right| \right). \end{aligned}$$

Since  $|\mu_n| = \frac{2}{h} \sin(\frac{|n|\pi h}{2}) \geq 2|n|$  and  $|\frac{z}{\mu_n}| < \frac{1}{2}$  if  $[|z|] + 1 \leq |n|$ , we deduce that

$$\begin{aligned} \sum_{\substack{1 \leq |n| \leq [|z|] \\ n \neq m}} \ln \left| 1 + \frac{z}{i\mu_n} \right| &\leq 2 \sum_{1 \leq n \leq [|z|]} \ln \left( 1 + \frac{|z|}{2n} \right) \leq 2 \int_0^{|z|} \ln \left( 1 + \frac{|z|}{2s} \right) ds \\ &= |z| (3 \ln 3 - 2 \ln 2) < 2|z|, \\ \sum_{\substack{[|z|]+1 \leq |n| \leq N \\ n \neq m}} \ln \left| \left( 1 + \frac{z}{i\mu_n} \right) \exp \left( -\frac{z}{i\mu_n} \right) \right| &\leq \sum_{\substack{[|z|]+1 \leq |n| \leq N \\ n \neq m}} \left| \frac{z}{i\mu_n} \right|^2 \leq \sum_{[|z|]+1 \leq |n| \leq N} \frac{|z|^2}{4n^2} \\ &\leq \frac{|z|}{2}, \exp \left( -\sum_{\substack{1 \leq |n| \leq [|z|] \\ n \neq m}} \Re \left( \frac{z}{i\mu_n} \right) \right) \\ &\leq \left| \exp \left( iz \sum_{1 \leq |n| \leq [|z|]} \frac{2\Re(\mu_n)}{|\mu_n|^2} \right) \right| \exp \left( \frac{|z|}{|\mu_m|} \right) \\ &\leq \exp \left( Nh|z| + \frac{|z|}{2} \right). \end{aligned}$$

It follows that

$$(5.8) \quad \left| \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \left( 1 + \frac{z}{i\mu_n} \right) \exp \left( -\frac{z}{i\mu_n} \right) \right| \leq \exp(4|z|).$$

Finally, we evaluate

$$\begin{aligned} \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \left| \frac{\mu_n}{\mu_n - \mu_m} \right|^2 &= \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \frac{\sin^2 \left( \frac{n\pi h}{2} \right)}{\sin^2 \left( \frac{(n-m)\pi h}{2} \right)} \\ &= \frac{\prod_{k=N-|m|+1}^N \sin^2 \left( \frac{k\pi h}{2} \right)}{\prod_{k=N+1}^{N+|m|} \sin^2 \left( \frac{k\pi h}{2} \right)} = \frac{\prod_{k=1}^{|m|} \cos^2 \left( \frac{k\pi h}{2} \right)}{\prod_{k=0}^{|m|-1} \cos^2 \left( \frac{k\pi h}{2} \right)} = \cos^2 \left( \frac{m\pi h}{2} \right). \end{aligned}$$

Hence,

$$(5.9) \quad \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \left| \frac{\mu_n}{\mu_n - \mu_m} \right| = \cos \left( \frac{m\pi h}{2} \right).$$

From (5.7), (5.8), and (5.9) we obtain that

$$|\Upsilon_m(z)| \leq \cos \left( \frac{m\pi h}{2} \right) \exp(-Nh \Re(\mu_m)) \exp \left( \frac{9}{2}|z| \right),$$

and (5.6) follows if  $B_1 > \frac{9}{2}$  and  $A_m = \cos \left( \frac{m\pi h}{2} \right) \exp(-Nh \Re(\mu_m))$ .  $\square$

**5.2. Estimate of the product on the real axis.** A key point in the construction and evaluation of the biorthogonal sequence is the following result concerning the behavior of  $\Upsilon_m$  on the real axis.

LEMMA 5.2. *The following estimate holds for the function  $\Upsilon_m$  on the real axis:*

$$(5.10) \quad |\Upsilon_m(x)| \leq \begin{cases} C_1 \cos\left(\frac{m\pi h}{2}\right) \left| \frac{x - i\mu_m}{i\mu_m} \right| \exp\left(\omega_1 \sqrt{\frac{|x|}{h}}\right), & |x| \geq \frac{1}{h}, \\ C_1 \cos\left(\frac{m\pi h}{2}\right) \left| \frac{x - i\mu_m}{i\mu_m} \right| \exp(\omega_1 h |x|^2), & |x| \leq \frac{1}{h}, \end{cases}$$

where  $\omega_1$  and  $C_1$  are two positive constants independent of  $h$ .

*Proof.* The proof is technical, and it will be given in the appendix.  $\square$

*Remark 8.* An estimate of the product function on the real axis is always important in these type of problems. For instance, in [6], where the heat equation is considered and consequently only real exponents are used, the product has a behavior like  $\exp(\omega\sqrt{x})$ . On the other hand, if purely imaginary exponents are considered, as in the wave equation, it is easy to see that the corresponding product is bounded. Estimate (5.10) combines these two behaviors. Our product is like the wave equation if  $hx$  is small and like the heat equation if  $hx$  is sufficiently large.

**5.3. The multiplier.** The aim of this section is to construct an entire function with a sufficient decay on the real axis to compensate for the growth of the product  $\Upsilon_m$  evaluated in Lemma 5.2. We adapt an idea of Ingham [14], used several times in the study of completeness problems for exponential functions.

LEMMA 5.3. *Let  $\varepsilon > 0$  and  $\varphi : \mathbb{R} \rightarrow \mathbb{R}$  be the function defined by*

$$(5.11) \quad \varphi(x) = \begin{cases} \varepsilon x^2, & |x| \leq \frac{1}{\varepsilon}, \\ \sqrt{\frac{|x|}{\varepsilon}}, & |x| > \frac{1}{\varepsilon}. \end{cases}$$

*There exists an entire function  $G_\varepsilon$  of exponential type such that*

$$(5.12) \quad |G_\varepsilon(x)| \leq C_2 \exp(-\varphi(x)) \quad \forall x \in \mathbb{R},$$

$$(5.13) \quad |G_\varepsilon(-i\mu_m)| \geq \exp(-\omega_2 \Re(\mu_m)), \quad 1 \leq |m| \leq N,$$

where  $C_2$  and  $\omega_2$  are two positive constants, independent of  $N$  and  $\varepsilon$ .

*Proof.* Let  $(\rho_n)_{n \geq 1}$  be the nonincreasing sequence defined by

$$(5.14) \quad \rho_n = \begin{cases} e\varepsilon, & n \leq \frac{1}{\varepsilon}, \\ e\sqrt{\frac{1}{\varepsilon n^3}}, & n > \frac{1}{\varepsilon}. \end{cases}$$

Note that  $\rho_n = e \frac{\varphi(n)}{n^2}$  and

$$\begin{aligned} \sum_{n \geq 1} \rho_n &= e \sum_{n=1}^{\left[\frac{1}{\varepsilon}\right]} \varepsilon + e \sum_{n=\left[\frac{1}{\varepsilon}\right]+1}^{\infty} \sqrt{\frac{1}{\varepsilon n^3}} \\ &\leq e + \int_{\left[\frac{1}{\varepsilon}\right]}^{\infty} \sqrt{\frac{1}{\varepsilon s^3}} ds = e + \frac{2e}{\sqrt{\varepsilon}} \frac{1}{\sqrt{\left[\frac{1}{\varepsilon}\right]}} \\ &\leq e + \frac{2e}{\sqrt{1-\varepsilon}} := l < \infty. \end{aligned}$$

Now, we define the function

$$H(z) = \prod_{n \geq 1} \frac{\sin(\rho_n z)}{\rho_n z}.$$

Since

$$\left| \frac{\sin(\rho_n z)}{\rho_n z} \right| = \left| \sum_{k \geq 0} (-1)^k \frac{(\rho_n z)^{2k}}{(2k+1)!} \right| \leq \sum_{k \geq 0} \frac{|\rho_n z|^{2k}}{(2k)!} \leq \exp(\rho_n |z|),$$

we have that

$$|H(z)| = \prod_{n \geq 1} \left| \frac{\sin(\rho_n z)}{\rho_n z} \right| \leq \exp \left( |z| \sum_{n \geq 1} \rho_n \right)$$

and  $H$  is an entire function of exponential type less than  $l$ .

We pass to evaluate  $H(x)$  by considering the following two cases:

- $|x| > \frac{1}{\varepsilon}$ . We consider  $\nu = \lceil \sqrt{\frac{|x|}{\varepsilon}} \rceil \geq [\frac{1}{\varepsilon}]$ , and we have that

$$\begin{aligned} |H(x)| &\leq \prod_{n=1}^{\nu} \frac{|\sin(\rho_n x)|}{|\rho_n x|} \leq \prod_{n=1}^{\nu} \frac{1}{\rho_n |x|} \leq \left( \frac{1}{\rho_{\nu} |x|} \right)^{\nu} \\ &= \left( \frac{\sqrt{\varepsilon \nu^3}}{e |x|} \right)^{\nu} \leq e^{-\nu} \leq e \exp \left( -\sqrt{\frac{|x|}{\varepsilon}} \right). \end{aligned}$$

- $|x| \leq \frac{1}{\varepsilon}$ . We consider  $\nu = [\frac{1}{\varepsilon}]$ , and we have that

$$|H(x)| \leq \prod_{n=1}^{\nu} \frac{|\sin(\rho_n x)|}{|\rho_n x|} = \left( \frac{|\sin(e \varepsilon x)|}{|e \varepsilon x|} \right)^{\nu}.$$

Since  $e \varepsilon |x| \leq e$  and  $\sin(t) \leq t - \frac{\sin(e)}{6e} t^3$  for all  $t \in [0, e]$ , it follows that

$$\begin{aligned} H(x) &\leq \left( 1 - \frac{\sin(e)}{6e} (e \varepsilon |x|)^2 \right)^{\nu} = \exp \left( \nu \ln \left( 1 - \frac{\sin(e)}{6e} (e \varepsilon |x|)^2 \right) \right) \\ &\leq \exp \left( -\nu \frac{\sin(e)}{6e} (e \varepsilon |x|)^2 \right) \leq \exp \left( \frac{e \sin(e)}{6} \right) \exp \left( -\frac{1}{\varepsilon} \frac{\sin(e)}{6e} (e \varepsilon |x|)^2 \right) \\ &\leq e \exp \left( -\frac{e \sin(e)}{6} \varepsilon |x|^2 \right) \leq e \exp \left( -\frac{1}{6} \varepsilon |x|^2 \right). \end{aligned}$$

It follows that the function  $G_{\varepsilon}(z) = (H(z))^6$  verifies (5.12), with  $C_2 = e^6$ .

We prove that (5.13) holds too. We have that

$$|H(-i \mu_m)| = \prod_{n=1}^{\infty} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| = \prod_{\rho_n |\mu_m| \leq 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| \prod_{\rho_n |\mu_m| > 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right|.$$

If  $\rho_n |\mu_m| \leq 1$ ,

$$|\sin(i \rho_n \mu_m)| \geq \sin(\rho_n |\mu_m|) \geq \rho_n |\mu_m| - \frac{(\rho_n |\mu_m|)^3}{6}$$

and consequently

$$\begin{aligned} \prod_{\rho_n |\mu_m| \leq 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| &= \exp \left( \sum_{\rho_n |\mu_m| \leq 1} \ln \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| \right) \\ &\geq \exp \left( \sum_{\rho_n |\mu_m| \leq 1} \ln \left( 1 - \frac{(\rho_n |\mu_m|)^2}{6} \right) \right) \\ &\geq \exp \left( -\frac{|\mu_m|^2}{6} \sum_{n \geq 1} \rho_n^2 \right). \end{aligned}$$

Since

$$\sum_{n \geq 1} \rho_n^2 = \sum_{n \leq [\frac{1}{\varepsilon}]} e^2 \varepsilon^2 + \sum_{n > [\frac{1}{\varepsilon}]} e^2 \frac{1}{\varepsilon n^3} \leq e^2 \varepsilon + \frac{e^2}{\varepsilon} \int_{[\frac{1}{\varepsilon}]}^{\infty} \frac{ds}{s^3} \leq 4e^2 \varepsilon,$$

it follows that

$$(5.15) \quad \prod_{\rho_n |\mu_m| \leq 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| \geq \exp \left( -\frac{2e^2}{3} \Re(\mu_m) \right).$$

If  $\rho_n |\mu_m| > 1$ , we have that  $|\mu_m| > \frac{1}{\rho_n} \geq \frac{1}{e\varepsilon}$  and

$$\Re(\rho_n \mu_m) = \rho_n \Re(\mu_m) = \rho_n \varepsilon |\mu_m|^2 \geq \varepsilon |\mu_m| \geq \frac{1}{e}.$$

It follows that

$$\begin{aligned} \prod_{\rho_n |\mu_m| > 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| &= \prod_{\rho_n |\mu_m| > 1} \left| \frac{e^{\rho_n \mu_m} - e^{-\rho_n \mu_m}}{2\rho_n \mu_m} \right| \\ &\geq \prod_{\rho_n |\mu_m| > 1} \frac{e^{\rho_n \Re(\mu_m)} - e^{-\rho_n \Re(\mu_m)}}{2\rho_n |\mu_m|} \geq \prod_{\rho_n |\mu_m| > 1} \frac{2\rho_n \Re(\mu_m)}{2\rho_n |\mu_m|} \\ &= \prod_{\rho_n |\mu_m| > 1} \varepsilon |\mu_m| \geq \prod_{\rho_n |\mu_m| > 1} \frac{1}{e} \\ &= \exp \left( -\left| \left\{ n \geq 1 : \rho_n \geq \frac{1}{|\mu_m|} \right\} \right| \right). \end{aligned}$$

Since  $|\mu_m| > \frac{1}{e\varepsilon}$  we have that

$$\left| \left\{ n \geq 1 : \rho_n \geq \frac{1}{|\mu_m|} \right\} \right| = \left\lceil \sqrt[3]{\frac{e^2}{\varepsilon} |\mu_m|^2} \right\rceil \leq e^2 \varepsilon |\mu_m|^2 = e^2 \Re(\mu_m)$$

and therefore

$$(5.16) \quad \prod_{\rho_n |\mu_m| > 1} \left| \frac{\sin(i \rho_n \mu_m)}{i \rho_n \mu_m} \right| \geq \exp(-e^2 \Re(\mu_m)).$$

From (5.15) and (5.16) it follows that inequality (5.13) holds with  $\omega_2 = 10e^2$ , and the proof ends.  $\square$

**5.4. Biorthogonal function estimates.** We are now ready to prove the desired result on the biorthogonal sequence.

**THEOREM 5.4.** *For any  $T > 0$  sufficiently large but independent of  $h$ , there exists a sequence  $(\Theta_m)_{\substack{|m| \leq N \\ m \neq 0}}$ , biorthogonal in  $L^2(-\frac{T}{2}, \frac{T}{2})$  to the family  $(e^{\mu_n t})_{\substack{|n| \leq N \\ n \neq 0}}$ , such that*

$$(5.17) \quad \|\Theta_m\|_{L^2(-\frac{T}{2}, \frac{T}{2})} \leq M \cos\left(\frac{m\pi h}{2}\right) \exp(\omega \Re(\mu_m)), \quad 1 \leq |m| \leq N,$$

where  $M$  and  $\omega$  are positive constants, independent of  $m$  and  $N$ .

*Remark 9.* Theorem 5.4 provides a biorthogonal set for any  $T > 0$ . However, for estimate (5.17) we need a time  $T$  sufficiently large (but independent of the discretized problem). The value  $T = 2(B_1 + 74\pi^4 e + 2)$ , for any  $B_1 > \frac{9}{2}$ , is obtained in the proof. We may improve it by finer estimates, but we are still far from  $T = 2$ , which is probably the optimal value.

*Proof.* We define

$$(5.18) \quad \Xi_m(z) = \Upsilon_m(z) \left[ \frac{G_h(z)}{G_h(-i\mu_m)} \right]^{\omega_1} \left( \frac{\sin(z + i\mu_m)}{z + i\mu_m} \right)^2,$$

where  $\Upsilon_m$  is given by (5.5) and  $G_h$  is the function constructed in Lemma 5.3, with  $\varepsilon = h$ . We have that

- $\Xi_m(-i\mu_n) = \delta_{nm}$ ,  $1 \leq |n|, |m| \leq N$ ;
- $\Xi_m$  is an entire function of exponential type  $B = B_1 + 6l\omega_1 + 2$ , independent of  $N$ ;
- by using the properties of  $G_h$  from Lemma 5.3 and the estimates of  $\Upsilon_m$  from Lemma 5.2, we obtain that

$$\begin{aligned} \int_{-\infty}^{\infty} |\Xi_m(x)|^2 dx &\leq \frac{C_1^2 C_2^{2\omega_1} \cos^2\left(\frac{m\pi h}{2}\right)}{|G(-i\mu_m)|^{2\omega_1}} \int_{-\infty}^{\infty} \left| \frac{x - i\mu_m}{i\mu_m} \right|^2 \left| \frac{\sin(x + i\mu_m)}{x + i\mu_m} \right|^4 dx \\ &\leq \frac{2C_1^2 C_2^{2\omega_1} \cos^2\left(\frac{m\pi h}{2}\right)}{|G(-i\mu_m)|^{2\omega_1}} \left( \frac{e^{2\Re(\mu_m)}}{|\mu_m|^2} \int_{-\infty}^{\infty} \left| \frac{\sin(t + i\Re(\mu_m))}{t + i\Re(\mu_m)} \right|^2 dt \right. \\ &\quad \left. + 4 \int_{-\infty}^{\infty} \left| \frac{\sin(t + i\Re(\mu_m))}{t + i\Re(\mu_m)} \right|^4 dt \right) \\ &\leq \frac{8C_1^2 C_2^{2\omega_1} \cos^2\left(\frac{m\pi h}{2}\right)}{|G(-i\mu_m)|^{2\omega_1}} e^{2(1+\pi)\Re(\mu_m)} \int_{-\infty}^{\infty} \left| \frac{\sin(t)}{t} \right|^2 dt \\ &\leq 8\pi C_1^2 C_2^{2\omega_1} \cos^2\left(\frac{m\pi h}{2}\right) e^{(2+2\pi+2\omega_1\omega_2)\Re(\mu_m)}. \end{aligned}$$

We introduce now the Fourier transform of  $\Xi_m$

$$(5.19) \quad \Theta_m(z) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \Xi_m(x) e^{-xz} dx,$$

and we note that  $\{\Theta_m\}_{\substack{|m| \leq N \\ m \neq 0}}$  is the biorthogonal sequence we are looking for.

Indeed, from the properties of  $\Xi_m$ , by using the Paley–Wiener theorem, it follows that  $\Theta_m(t)$  has compact support in  $[-B, B]$ , it belongs to  $L^2(-B, B)$ , and

$$\int_{-B}^B \Theta_m(t) e^{\mu_n t} dt = \Xi_m(-i\mu_n) = \delta_{nm}, \quad 1 \leq |n| \leq N.$$

It follows that  $(\Theta_m)_{\substack{|m| \leq N \\ m \neq 0}}$  is a biorthogonal sequence to  $\{e^{\mu_n t}\}_{\substack{|n| \leq N \\ n \neq 0}}$  in  $L^2(-B, B)$ . Moreover, from Plancherel's theorem we have

$$\sqrt{2\pi} \|\Theta_m\|_{L^2(-B, B)} = \|\Xi_m\|_{L^2(-\infty, \infty)} \leq C_1 C_2^{\omega_1} \sqrt{8\pi} \cos\left(\frac{m\pi h}{2}\right) e^{(1+\pi+\omega_1\omega_2)\Re(\mu_m)},$$

and the proof is finished.  $\square$

**6. Convergence results.** The aim of this section is to show that a control for the continuous system (1.1) may be obtained as a limit of controls of the corresponding semidiscrete problems (2.6). The control time  $T$  will be considered sufficiently large (but independent of the discretized problem) such that estimate (5.17) from Theorem 5.4 holds.

Let  $(u^0, u^1) \in L^2(0, 1) \times H^{-1}(0, 1)$  be the initial datum of (1.1). We consider that  $(u^0, u^1)$  has a Fourier decomposition

$$(6.1) \quad (u^0, u^1) = \sum_{n \geq 1} (a_n^0, a_n^1) \sqrt{2} \sin(n\pi x).$$

Since  $\sqrt{2} \sin(n\pi x)$  is orthonormal in  $L^2(0, 1)$ , it follows that  $(u^0, u^1) \in L^2(0, 1) \times H^{-1}(0, 1)$  if and only if

$$(6.2) \quad \sum_{n \geq 1} \left( |a_n^0|^2 + \frac{1}{|n|^2 \pi^2} |a_n^1|^2 \right) < \infty.$$

Now, let  $(U_h^0, U_h^1)_{h>0}$  be a sequence of discretizations of  $(u^0, u^1)$  given by (3.7). Assume that  $(a_{nh}^0, a_{nh}^1)_{n \in \mathbb{Z}^*}$ , the Fourier coefficients of the discrete initial data, verify

$$(6.3) \quad (a_{nh}^0)_n \rightharpoonup (a_n^0)_n, \quad \left( \frac{a_{nh}^1}{\lambda_n} \right)_n \rightharpoonup \left( \frac{a_n^1}{n\pi i} \right)_n \text{ when } h \rightarrow 0 \text{ in } \ell^1.$$

*Remark 10.* The usual discretization by points

$$(6.4) \quad (U_h^0, U_h^1) = \left( (u^0(jh))_{1 \leq j \leq N}, (u^1(jh))_{1 \leq j \leq N} \right)$$

leads to a convergence property of the Fourier coefficients sequence that depends on the regularity of  $(u^0, u^1)$ . Indeed, it is not difficult to prove the following:

(i) If  $u^0$  and  $u^1$  are piecewise continuous functions in  $[0, 1]$ , then

$$(6.5) \quad (a_{nh}^0)_n \rightarrow (a_n^0)_n, \quad \left( \frac{a_{nh}^1}{\lambda_n} \right)_n \rightarrow \left( \frac{a_n^1}{n\pi i} \right)_n \text{ when } h \rightarrow 0 \text{ in } \ell^1.$$

(ii) If  $u^0$  and  $u^1$  are one-time derivable with a continuous derivative in  $[0, 1]$ , then

$$(6.6) \quad (a_{nh}^0)_n \rightarrow (a_n^0)_n, \quad \left( \frac{a_{nh}^1}{\lambda_n} \right)_n \rightarrow \left( \frac{a_n^1}{n\pi i} \right)_n \text{ when } h \rightarrow 0 \text{ in } \ell^1.$$

We prove now the existence of a bounded sequence of controls for the semidiscrete problem.

**THEOREM 6.1.** *Let us suppose that the initial data of (1.1) are such that*

$$(6.7) \quad \sum_{n \geq 1} \left( |a_n^0| + \frac{1}{n\pi} |a_n^1| \right) < \infty.$$

There exists a control  $v_h$  of the semidiscrete problem (2.4), with  $\varepsilon = h$ , such that the sequence  $(v_h)_{h>0}$  is bounded in  $L^2(0, T)$ .

*Proof.* Let  $(\Theta_m)_{\substack{|m| \leq N \\ m \neq 0}}$  be the biorthogonal sequence in  $L^2(-\frac{T}{2}, \frac{T}{2})$  to  $\{e^{i\lambda_n t}\}_{\substack{|n| \leq N \\ n \neq 0}}$  constructed in Theorem 5.4. From Remarks 6 and 7, we obtain that

$$(6.8) \quad f_h(t) = \sum_{1 \leq |n| \leq N} \frac{(-1)^{n+1}h}{\sqrt{2} \sin(|n|\pi h)} \left( \frac{\nu_n^2}{\mu_n} a_{|n|h}^0 + a_{|n|h}^1 \right) e^{-\mu_n \frac{T}{2}} \Theta_n \left( t - \frac{T}{2} \right)$$

is a solution of (4.10). Moreover,

$$(6.9) \quad \|f_h\|_{L^2(0,T)} \leq \sum_{1 \leq |n| \leq N} \frac{h \exp\left(-\Re(\mu_n) \frac{T}{2}\right)}{\sqrt{2} |\sin(n\pi h)|} \left( |\nu_n| |a_{|n|h}^0| + |a_{|n|h}^1| \right) \|\Theta_n\|_{L^2(-\frac{T}{2}, \frac{T}{2})}.$$

From the estimates for the norm of  $\Theta_n$  given by Theorem 5.4, it follows that for any  $T > 2\omega$ ,

$$\|f_h\|_{L^2(0,T)} \leq M \sum_{1 \leq |n| \leq N} \left( a_{|n|h}^0 + \frac{1}{|\nu_n|} a_{|n|h}^1 \right).$$

It follows that any sequence of controls  $(v_h)_{h>0}$  given by (4.3) is uniformly bounded in  $L^2(0, T)$ , and the proof ends.  $\square$

*Remark 11.* Theorem 6.1 shows that the initial data which verify (6.7) can be uniformly controlled with the scheme (2.4). The method we have used does not allow us to prove the optimal result for the initial data in  $L^2 \times H^{-1}$  which verifies (6.2). This is a general limitation of the biorthogonal technique already mentioned in [6].

Since the sequence of controls  $(v_h)_h$  given by Theorem 6.1 is bounded in  $L^2(0, T)$ , there exists a subsequence, denoted in the same way, and  $v \in L^2(0, T)$  such that  $v_h \rightharpoonup v$  in  $L^2(0, T)$  when  $h \rightarrow 0$ . In the next theorem we show that  $v$  is a control for the corresponding continuous problem.

**THEOREM 6.2.** *If  $v \in L^2(0, T)$  is a weak limit of the bounded sequence  $(v_h)_h$  given by Theorem 6.1, then  $v$  is a control for the continuous problem (1.1).*

*Proof.* Like in the case of the semidiscrete problem, it is easy to prove that  $v \in L^2(0, T)$  is a control for (1.1) if and only if the equality

$$(6.10) \quad \int_0^T v(t) \overline{\varphi}_x(t, 1) dt = \langle u^1, \overline{\varphi}(0) \rangle_{H^{-1}, H_0^1} - \int_0^1 u^0 \overline{\varphi}'(0)$$

holds for any  $(\varphi^0, \varphi^1) \in H_0^1(0, 1) \times L^2(0, 1)$  and for  $\varphi$  the solution of the adjoint equation

$$(6.11) \quad \begin{cases} \varphi'' - \varphi_{xx} = 0 & \text{for } x \in (0, 1), \ t > 0, \\ \varphi(t, 0) = \varphi(t, 1) = 0 & \text{for } t > 0, \\ \varphi(T, x) = \varphi^0(x), \ \varphi'(T, x) = \varphi^1(x) & \text{for } x \in (0, 1). \end{cases}$$

Now, the Fourier decomposition allows us to show that  $v$  is a control for (1.1) if and only if

$$(6.12) \quad \int_0^T v(t) e^{-in\pi t} dt = \frac{(-1)^n}{\sqrt{2}} \left( -a_{|n|}^0 i + \frac{a_{|n|}^1}{n\pi} \right) \quad \forall n \neq 0.$$

Note that this is the moment problem for the continuous system (1.1), similar to (4.9) from Theorem 4.2. Let  $v$  be a weak limit in  $L^2(0, T)$  of the sequence  $(v_h)_h$ . It follows that  $v$  is a weak limit of the sequence  $(f_h)_h$  too.

Note that, for each  $n \in \mathbb{Z}^*$ ,

$$e^{\mu_n t} \rightarrow e^{-in\pi t} \text{ in } L^2(0, T)$$

and

$$\frac{h}{\sin(|n|\pi h)} \left( \frac{\nu_n^2}{\mu_n} a_{|n|h}^0 + a_{|n|h}^1 \right) \rightarrow a_n^0 i + \frac{a_n^1}{n\pi}$$

when  $h$  tends to zero.

By passing to the limit in (4.9), it follows that  $v$  satisfies (6.12). Hence, the limit  $v$  is a control for the problem (1.1), and the proof finishes.  $\square$

*Remark 12.* The weak convergence of the controlled discrete solutions to the controlled continuous solution of (1.1) may be proved too. Moreover, if the discrete initial data converge stronger to the continuous ones, the sequence of discrete HUM controls converges strongly to the continuous HUM control. Both proofs are rather technical and very similar to Theorems 3.2 and 3.3 from [2], and we omit them.

**7. Numerical results.** In this section we present a numerical experiment based on the scheme with an added viscosity term. More precisely, we approximate the HUM control for (1.1) (the control of minimal  $L^2$ -norm) denoted by  $\hat{v}$  by using (2.4) as the discretization of (1.1).

The algorithm we have used to compute the approximate controls is inspired by the one proposed by Glowinski, Li, and Lions [10] (see also [8, 11]), and it is based on a conjugate gradient implementation of the HUM method. To this end, we use the approximations  $(U_h^0, U_h^1)$  of the initial data by taking the values of  $u^0$  and  $u^1$  at the nodes. Then, we minimize the following functional

$$(7.1) \quad J(\phi_h^0, \phi_h^1) = \frac{1}{2} \int_0^T \left( \frac{\phi_N(t) - \varepsilon \phi'_N(t)}{h} \right)^2 dt + \langle (U_h^0, U_h^1), (\phi_h(0), \phi'_h(0)) \rangle_D$$

over all  $(\phi^0, \phi^1) \in \mathbb{C}^{2N}$ ,  $\phi_N$  being the last component of  $\phi$ , the solution of the adjoint system (4.1).

The minimizer  $(\hat{\phi}_h^0, \hat{\phi}_h^1)$  of  $J$  provides the control  $\hat{v}_h$  of the discrete system (2.4) with minimal  $L^2$ -norm. Since in Theorem 6.1 we have proved the existence of a bounded sequence of discrete controls, it follows that  $(\hat{v}_h)_{h>0}$  is bounded too. Its (unique) weak limit is the HUM control of (1.1) denoted by  $\hat{v}$ .

In the algorithm several wave equations have to be solved. To do that, we also need a time discretization. Except for these numerical experiments, our article does not deal with the fully discrete problem, and the convergence remains to be done. However, the uniform results we have obtained for the semidiscrete case suggest that this is a good scheme to be discretized in time. The full discrete problem is analyzed, for instance, in [19, 20].

Let  $\Delta t$  be the time step and  $l = \frac{\Delta t}{h}$  be the Courant number. We recall that the classical central difference scheme for the constant coefficients 1-D wave equation, with Courant number  $l$  equal to one, provides the exact solution at the nodes. Therefore, in this very particular situation, the 1-D version of the conjugate gradient algorithm described in [8, 11] gives a very accurate approximation of the control for any  $h > 0$ . We use this special situation to compute “exact” controls that allow us to compare the results obtained with our method. However, this scheme fails to converge if  $l \neq 1$ . Note that, in view of the possible generalizations to other types of equations

FIG. 1. *Initial data  $(u^0, u^1)$  to be controlled.*FIG. 2. *The controlled position and velocity with  $h = \frac{1}{50}$ .*

or multidimensional domains, it is of utmost importance to find robust algorithms which are not sensitive on the various discretization parameters. As the numerical results illustrate, the convergence of our method does not depend on the election of the Courant number  $l = \Delta t/h$ , which is related to the theoretical uniform result we have obtained.

**Numerical example.** In this example we consider a singular situation with discontinuous initial data  $(u^0, u^1)$ . We take

$$u^0(x) = \begin{cases} 20x & \text{if } x \in (0, 1/2), \\ 0 & \text{if } x \in (1/2, 1), \end{cases} \quad u^1(x) = 0.$$

In Figure 1 we present a picture of these data. Note that  $u^0 \in L^2(0, 1) \setminus H^1(0, 1)$ .

Since we are not looking for the optimal control time, we take  $T = 4$ . This is an arbitrary choice. The value of  $T$  for which we have proved the convergence is much larger, and it is given in Remark 9. It may be improved by finer estimates, but, in this case, our option was for simplicity.

The algorithm based on the finite difference scheme (2.1) gives, when  $l := \Delta t/h < 1$ , unsatisfactory approximations of the HUM control corresponding to  $(u^0, u^1)$ . In the following experiments we have taken  $l = 7/8$  and we have used (2.4). Figure 2 shows the controlled solution (position and velocity) when  $h = 1/50$ . Figure 3 illustrates the convergence of the discrete controls (dashed line) as  $h$  is decreased. The results are compared with those obtained by the finite difference scheme, with  $\Delta t = h$  (solid line). We may conclude that, even in this singular situation, the viscosity method (2.4) provides satisfactory approximations of the HUM control.

The first line of results in Table 7.1 shows that the error in the  $L^2$ -norm decreases with  $h$  but at a slow rate when  $\varepsilon = h$ . It seems that this may be improved by choosing

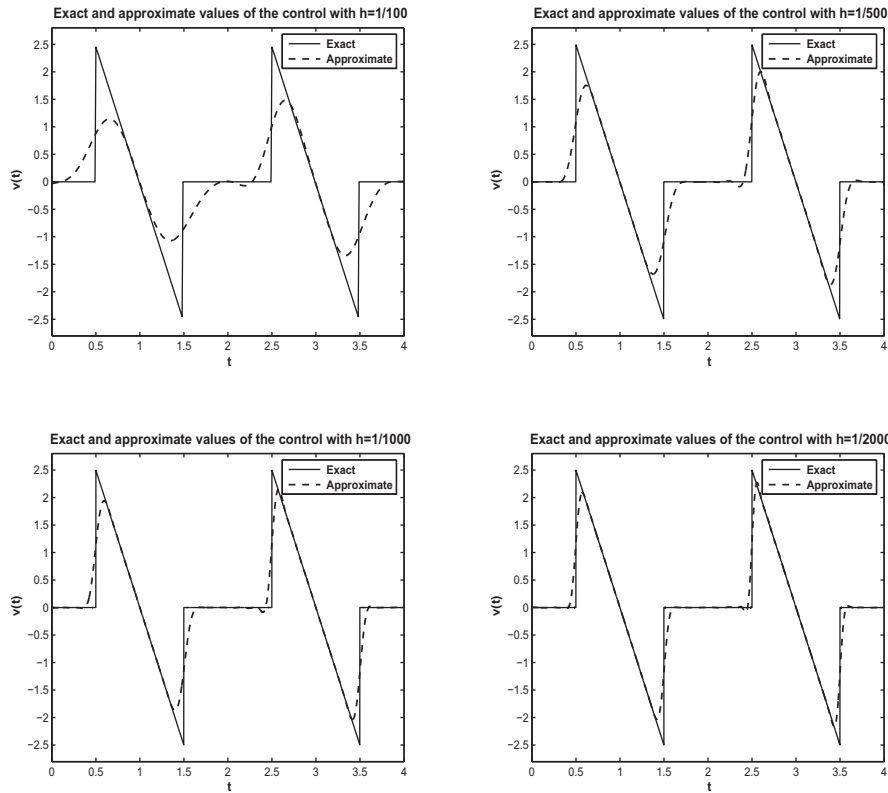

FIG. 3. Approximations of the control with  $h = \frac{1}{100}, \frac{1}{500}, \frac{1}{1000}$ , and  $\frac{1}{2000}$ .

TABLE 7.1  
Numerical results for  $\|v_h\|_{L^2}$  obtained with  $\Delta t = 7/8h$  and different values of the parameters  $\varepsilon$  and  $h$ . The exact result is  $\|v\|_{L^2} = 2.0106$ .

h	1/100	1/500	1/1000
$\ v_h\ _{L^2}$ with $\varepsilon = h$	1.4656	1.8013	1.8750
$\ v_h\ _{L^2}$ with $\varepsilon = h^{1.5}$	1.8495	1.9877	2.0101
$\ v_h\ _{L^2}$ with $\varepsilon = h^{1.7}$	1.9117	2.0100	2.0242
$\ v_h\ _{L^2}$ with $\varepsilon = h^{1.9}$	1.9540	2.0225	2.0316

$\varepsilon = h^\alpha$ , with  $\alpha \in (1, 2)$  in (2.4). Numerical simulations with different values of the parameter  $\varepsilon$  are presented in Figure 4 and Table 7.1. We note better convergence rates with larger values of  $\alpha$ , with an optimum close to 1.7. However, the theoretical analysis of this problem should be based on the error estimates for the control, which, to our knowledge, have not been yet obtained, regardless of the convergent discrete scheme.

8. Appendix. Proof of Lemma 5.2. We have that

$$\Upsilon_m(x) = \left(1 + \frac{x}{i\mu_{-m}}\right) \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \frac{\mu_n}{\mu_m - \mu_n} \prod_{\substack{1 \leq |n| \leq N \\ n \neq |m|}} \left(1 + \frac{x}{i\mu_n}\right) \prod_{1 \leq |n| \leq N} \exp\left(-\frac{x + i\mu_m}{i\mu_n}\right).$$

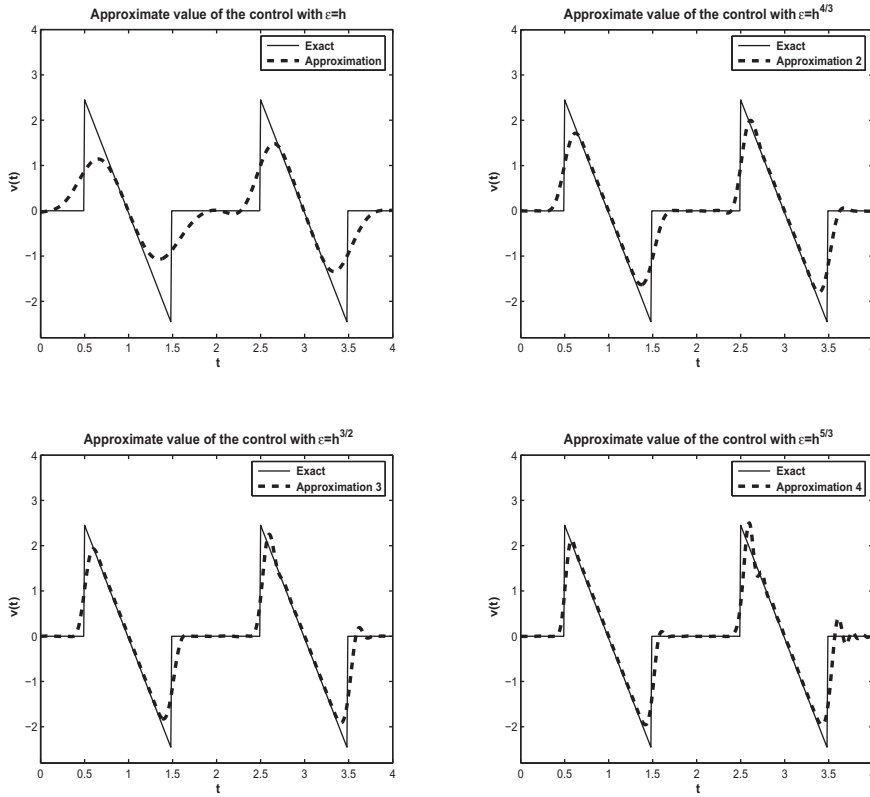

FIG. 4. Approximations of the control with different values of the parameter  $\varepsilon$  when  $h = \frac{1}{100}$ .

The first product in  $\Upsilon_m$  is evaluated in (5.9), and we have that

$$\left| \prod_{\substack{1 \leq |n| \leq N \\ n \neq m}} \frac{\mu_n}{\mu_m - \mu_n} \right| = \cos \left( \frac{m\pi h}{2} \right) \leq 1.$$

For the third product in  $\Upsilon_m$  we have that

$$\begin{aligned} \left| \prod_{1 \leq |n| \leq N} \exp \left( -\frac{x + i\mu_m}{i\mu_n} \right) \right| &= \prod_{1 \leq |n| \leq N} \left| \exp \left( \frac{ix}{\mu_n} \right) \right| \prod_{1 \leq |n| \leq N} \left| \exp \left( -\frac{\mu_m}{\mu_n} \right) \right| \\ &= \exp(-Nh \Re(\mu_m)) < 1. \end{aligned}$$

We pass to evaluate the second product in  $\Upsilon_m$ . We denote

$$P(x) = \prod_{\substack{1 \leq |n| \leq N \\ n \neq |m|}} \left| 1 + \frac{x}{i\mu_n} \right|^2 = \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{\left( x^2 - \frac{4}{h^2} \sin^2 \left( \frac{n\pi h}{2} \right) \right)^2 + \frac{16x^2}{h^2} \sin^4 \left( \frac{n\pi h}{2} \right)}{\frac{16}{h^4} \sin^4 \left( \frac{n\pi h}{2} \right)},$$

and we consider the cases  $|x| \leq \pi$ ,  $|x| > \frac{1}{2h}$ , and  $\pi < |x| \leq \frac{1}{2h}$ .

Case 1 ( $|x| \leq \pi$ ). In this case we have that

$$\begin{aligned} P(x) &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{\left(\pi^2 + \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2 + \frac{16\pi^2}{h^2} \sin^4\left(\frac{n\pi h}{2}\right)}{\frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right)} \\ &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \left( \left(1 + \frac{\pi^2}{\frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)}\right)^2 + \pi^2 h^2 \right) \leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \left( \left(1 + \frac{\pi^2}{4n^2}\right)^2 + \pi^2 h^2 \right) \\ &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \left(1 + \pi h + \frac{\pi^2}{4n^2}\right)^2 \leq \exp \left( 2 \sum_{\substack{1 \leq n \leq N \\ n \neq |m|}} \left(\pi h + \frac{\pi^2}{4n^2}\right) \right). \end{aligned}$$

Hence,

$$(8.1) \quad P(x) \leq \exp(2\pi + \pi^2) \quad \forall |x| \leq \pi.$$

Case 2 ( $|x| > \frac{1}{2h}$ ). We have that

$$\begin{aligned} P(x) &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{x^4 + \frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right) + \frac{16x^2}{h^2} \sin^4\left(\frac{n\pi h}{2}\right)}{\frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right)} \leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{x^4 + \frac{16}{h^4} + \frac{16x^2}{h^2}}{\frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right)} \\ &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{x^4 (1 + 256 + 64)}{\frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right)} \leq \prod_{\substack{1 \leq n \leq N \\ n \neq |m|}} \frac{256x^4}{n^4} = \exp \left( 4 \sum_{\substack{1 \leq n \leq N \\ n \neq |m|}} \ln \left( \frac{4|x|}{n} \right) \right) \\ &\leq \exp \left( 4 \int_0^N \ln \left( \frac{4|x|}{s} \right) ds \right) = \exp \left( 4N \ln \left( \frac{4|x|}{N} \right) + 4N \right) \leq \exp \left( 8N \sqrt{\frac{4|x|}{N}} \right), \end{aligned}$$

where we have used that  $\frac{4|x|}{N} > 2$  and  $\ln(t) + 1 \leq 2\sqrt{t}$  for any  $t > 1$ . It follows that

$$(8.2) \quad P(x) \leq \exp \left( 16 \sqrt{\frac{|x|}{h}} \right), \quad \forall |x| > \frac{1}{2h}.$$

Case 3 ( $\pi \leq |x| \leq \frac{1}{2h}$ ). The analysis of this case is much more difficult. First of all let us note that, in view of the particular form of  $P(x)$ , it is sufficient to consider  $x > 0$ . Moreover, there exists a unique  $x_h \in (1, N)$  such that

$$(8.3) \quad x = \frac{2}{h} \sin \left( \frac{x_h \pi h}{2} \right),$$

and let  $p^* \in [1, N] \cap \mathbb{N}$  be the nearest integer to  $x_h$ . We have that

$$(8.4) \quad 2x_h \leq x \leq \pi x_h,$$

$$(8.5) \quad p^* - \frac{1}{2} \leq x_h \leq p^* + \frac{1}{2},$$

$$(8.6) \quad \frac{1}{2}x_h \leq p^* \leq x_h + \frac{1}{2} \leq \frac{x+1}{2} \leq \frac{1}{4h} + \frac{1}{2}.$$

We write  $P(x) = P_1(x)P_2(x)P_3(x)$ , where

$$P_1(x) = \frac{\left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{p^*\pi h}{2}\right)\right)^2 + \frac{16x^2}{h^2} \sin^4\left(\frac{p^*\pi h}{2}\right)}{\frac{16}{h^4} \sin^4\left(\frac{p^*\pi h}{2}\right)},$$

$$P_2(x) = \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \frac{\left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2 + \frac{16x^2}{h^2} \sin^4\left(\frac{n\pi h}{2}\right)}{\left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2},$$

$$P_3(x) = \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \frac{\left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2}{\frac{16}{h^4} \sin^4\left(\frac{n\pi h}{2}\right)}.$$

We shall evaluate  $P_1$ ,  $P_2$ , and  $P_3$  successively. First of all note that

$$\left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2 = \frac{16}{h^4} \sin^2\left(\frac{(x_h - n)\pi h}{2}\right) \sin^2\left(\frac{(x_h + n)\pi h}{2}\right),$$

and since  $(x_h + n)h \leq \frac{3}{2}$  and  $\sin^2\left(\frac{(x_h + n)\pi h}{2}\right) \geq \frac{2(x_h + n)^2 h^2}{9}$  we obtain that

$$(8.7) \quad \frac{32(x_h + n)^2(x_h - n)^2}{9} \leq \left(x^2 - \frac{4}{h^2} \sin^2\left(\frac{n\pi h}{2}\right)\right)^2 \leq \pi^4(x_h + n)^2(x_h - n)^2.$$

We have that

$$P_1(x) \leq \frac{\pi^4|x_h - p^*|^2|x_h + p^*|^2}{16(p^*)^4} + x^2 h^2 \leq \frac{9\pi^4}{16(p^*)^2}|x_h - p^*|^2 + x^2 h^2$$

from where we deduce that

$$(8.8) \quad P_1(x) \leq \frac{9\pi^6}{16x^2} + x^2 h^2.$$

Now, we evaluate  $P_2$ :

$$\begin{aligned} P_2(x) &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \left(1 + \frac{\frac{16x^2}{h^2} \sin^4\left(\frac{n\pi h}{2}\right)}{\frac{32}{9}(x_h + n)^2(x_h - n)^2}\right) \leq \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \left(1 + \frac{9\pi^4 x^2 h^2 n^4}{32(x_h + n)^2(x_h - n)^2}\right) \\ &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \left(1 + \frac{9\pi^4 x^2 h^2 n^2}{32(x_h - n)^2}\right) = \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \left(1 + \frac{r n^2}{(x_h - n)^2}\right), \end{aligned}$$

where  $r = \frac{9\pi^4 x^2 h^2}{32}$ . We have that

$$\begin{aligned}
 \prod_{\substack{1 \leq n \leq N \\ n \neq p^*, |m|}} \left( 1 + \frac{r n^2}{(x_h - n)^2} \right) &\leq \prod_{\substack{1 \leq n \leq N \\ n \neq p^*}} \left( 1 + \frac{r n^2}{(x_h - n)^2} \right) \\
 &= \prod_{\substack{1 \leq n \leq N \\ n \notin \{p^*, p^* - 1, p^* + 1\}}} \left( 1 + \frac{r n^2}{(x_h - n)^2} \right) \left( 1 + \frac{r (p^* - 1)^2}{(x_h - p^* + 1)^2} \right) \\
 &\quad \left( 1 + \frac{r (p^* + 1)^2}{(x_h - p^* - 1)^2} \right) \\
 &\leq (1 + 4r(p^* + 1)^2)^2 \prod_{\substack{1 \leq n \leq N \\ n \notin \{p^*, p^* - 1, p^* + 1\}}} \left( 1 + \frac{r n^2}{(x_h - n)^2} \right) \\
 &\leq \exp(3\pi^2 h x^2) \exp \left( \int_0^{N+1} \ln \left( 1 + \frac{r s^2}{(x_h - s)^2} \right) ds \right).
 \end{aligned}$$

Now,

$$\begin{aligned}
 \int_0^{N+1} \ln \left( 1 + \frac{r s^2}{(x_h - s)^2} \right) ds &= \left( \int_0^{x_h} + \int_{x_h}^{N+1} \right) \ln \left( 1 + \frac{r s^2}{(x_h - s)^2} \right) ds \\
 &= (N + 1 - x_h) \ln \left( 1 + \frac{r (N + 1)^2}{(N + 1 - x_h)^2} \right) \\
 &\quad + \left( \int_0^{x_h} + \int_{x_h}^{N+1} \right) \frac{2rsx_h ds}{rs^2 + (x_h - s)^2}.
 \end{aligned}$$

Moreover,

$$\begin{aligned}
 (N + 1 - x_h) \ln \left( 1 + \frac{r (N + 1)^2}{(N + 1 - x_h)^2} \right) &\leq \frac{r (N + 1)^2}{N + 1 - x_h} \leq \frac{4r}{3} (N + 1) \\
 &= \frac{3\pi^4}{8} h x^2, \int_{\frac{x_h}{1+hx_h}}^{\frac{x_h}{1-hx_h}} \frac{2rsx_h ds}{rs^2 + (s - x_h)^2} \\
 &\leq \int_{\frac{x_h}{1+hx_h}}^{\frac{x_h}{1-hx_h}} \frac{2rsx_h ds}{rs^2} = 2x_h \ln \left( \frac{1 + hx_h}{1 - hx_h} \right) \\
 &\leq 4h(x_h)^2, \left( \int_0^{\frac{x_h}{1+hx_h}} + \int_{\frac{x_h}{1-hx_h}}^{N+1} \right) \frac{2rsx_h ds}{rs^2 + (s - x_h)^2} \\
 &\leq \int_0^{\frac{x_h}{1+hx_h}} \frac{2r(x_h)^2 ds}{(s - x_h)^2} \\
 &\quad + \int_{\frac{x_h}{1-hx_h}}^{N+1} \left( \frac{2rx_h ds}{(s - x_h)} + \frac{2r(x_h)^2 ds}{(s - x_h)^2} \right) \\
 &= \frac{2r}{h} + 4rx_h \ln \left( \frac{1 - hx_h}{hx_h} \right) \\
 &\quad + 2r \frac{(1 - hx_h)^2 - h^2(x_h)^2}{h(1 - hx_h)} \\
 &\leq \frac{2r}{h} + 4\frac{r}{h} + 2\frac{r}{h} \leq \frac{9\pi^4}{4} h x^2.
 \end{aligned}$$

It follows that

$$(8.9) \quad P_2(x) \leq \exp\left(\frac{3\pi^4}{8}hx^2 + \frac{4}{3}hx^2 + \frac{9\pi^4}{4}hx^2\right) \leq \exp(3\pi^4hx^2).$$

Finally, we evaluate  $P_3$ . First, note that if  $m \neq p^*$ ,

$$\left(\frac{\frac{4}{h^2}\sin^2\left(\frac{m\pi h}{2}\right)}{x^2 - \frac{4}{h^2}\sin^2\left(\frac{m\pi h}{2}\right)}\right)^2 \leq \frac{9m^4\pi^4}{32(x_h + m)^2(x_h - m)^2} \leq \frac{9\pi^4 m^2}{32(x_h - m)^2} \leq \frac{9\pi^4 x^2}{8}.$$

Therefore,

$$P_3(x) \leq \frac{9\pi^4 x^2}{8} \prod_{\substack{1 \leq n \leq N \\ n \neq p^*}} \frac{\sin^2\left(\frac{(x_h - n)\pi h}{2}\right) \sin^2\left(\frac{(x_h + n)\pi h}{2}\right)}{\sin^4\left(\frac{n\pi h}{2}\right)}.$$

We have that  $x_h = p^* + \alpha$ , with  $\alpha \in [-\frac{1}{2}, \frac{1}{2}]$ , and we evaluate

$$\begin{aligned} E(x) &= \prod_{\substack{1 \leq n \leq N \\ n \neq p^*}} \frac{\sin^2\left(\frac{(p^* + \alpha - n)\pi h}{2}\right) \sin^2\left(\frac{(p^* + \alpha + n)\pi h}{2}\right)}{\sin^4\left(\frac{n\pi h}{2}\right)} \\ &= \frac{\prod_{\substack{1 \leq k \leq 2p^* - 1 \\ k \neq p^*}} \sin^2\left(\frac{(k + \alpha)\pi h}{2}\right) \prod_{k=1}^{N-p^*} \sin^2\left(\frac{(k - \alpha)\pi h}{2}\right) \prod_{k=2p^*+1}^{N+p^*} \sin^2\left(\frac{(k + \alpha)\pi h}{2}\right)}{\prod_{\substack{1 \leq k \leq N \\ k \neq p^*}} \sin^4\left(\frac{k\pi h}{2}\right)} \\ &= \frac{\sin^4\left(\frac{p^*\pi h}{2}\right)}{\sin^2\left(\frac{(2p^* + \alpha)\pi h}{2}\right) \sin^2\left(\frac{(p^* + \alpha)\pi h}{2}\right)} \\ &\quad \times \prod_{k=1}^N \frac{\sin^2\left(\frac{(k + \alpha)\pi h}{2}\right) \sin^2\left(\frac{(k - \alpha)\pi h}{2}\right)}{\sin^4\left(\frac{k\pi h}{2}\right)} \prod_{k=N-p^*+1}^N \frac{\sin^2\left(\frac{(k + p^* + \alpha)\pi h}{2}\right)}{\sin^2\left(\frac{(k - \alpha)\pi h}{2}\right)}. \end{aligned}$$

By taking into account that  $\sin(a)\sin(b) \leq \sin^2\left(\frac{a+b}{2}\right)$  and  $2p^* + 1 < \frac{1}{2h}$ , we deduce that

$$E(x) \leq \frac{\sin^2\left(\frac{p^*\pi h}{2}\right)}{\sin^2\left(\frac{(p^* + \alpha)\pi h}{2}\right)} \prod_{k=N-p^*+1}^N \frac{\sin^2\left(\frac{(k + p^* + \alpha)\pi h}{2}\right)}{\sin^2\left(\frac{(k - \alpha)\pi h}{2}\right)}.$$

Since  $0 \leq \frac{p^* + \alpha}{2}\pi h \leq \pi$  and the function  $h(x) = \frac{\sin x}{x}$  is decreasing on  $[0, \pi]$ , it follows that

$$\frac{\sin\left(\frac{(k + p^* + \alpha)\pi h}{2}\right)}{\sin\left(\frac{(k - \alpha)\pi h}{2}\right)} \leq \frac{k + p^* + \alpha}{k - \alpha}$$

and thus

$$\begin{aligned}
 E(x) &\leq 2 \prod_{k=N-p^*+1}^N \left( \frac{k+p^*+\alpha}{k-\alpha} \right)^2 = 2 \exp \left( 2 \sum_{k=N-p^*+1}^N \ln \left( 1 + \frac{p^*+2\alpha}{k-\alpha} \right) \right) \\
 &\leq 2 \exp \left( 2 \int_{N-p^*}^N \ln \left( 1 + \frac{p^*+2\alpha}{s-\alpha} \right) ds \right) \leq 2 \exp \left( 2(p^*+2\alpha) \int_{N-p^*}^N \frac{ds}{s-\alpha} \right) \\
 &= 2 \exp \left( 2(p^*+2\alpha) \ln \left( \frac{N-\alpha}{N-p^*-\alpha} \right) \right) \leq 2 \exp \left( 2(p^*+2\alpha) \frac{p^*}{N-p^*-\alpha} \right) \\
 &\leq 2 \exp \left( 4(p^*)^2 \frac{1}{N - \frac{N+1}{4} - 1} \right) \leq 2 \exp \left( 16(p^*)^2 \frac{1}{3N-5} \right).
 \end{aligned}$$

Hence,

$$(8.10) \quad P_3(x) \leq \frac{9\pi^4 x^2}{4} \exp(16hx^2).$$

Finally from (8.8), (8.9), and (8.10) we obtain that

$$P(x) \leq \frac{9\pi^4 x^2}{4} \left( \frac{9\pi^6}{16x^2} + x^2 h^2 \right) \exp(3\pi^4 hx^2 + 16hx^2) \leq \frac{81\pi^{10}}{32} \exp(4\pi^4 hx^2).$$

The proof is complete, with  $C_1 = \frac{81\pi^{10}}{32}$  and  $\omega_1 = 4\pi^4$ .  $\square$

## ON THE LINEAR-EXPONENTIAL FILTERING PROBLEM FOR GENERAL GAUSSIAN PROCESSES\*

M. L. KLEPTSZYNA<sup>†</sup>, A. LE BRETON<sup>‡</sup>, AND M. VIOT<sup>‡</sup>

**Abstract.** The explicit solution of the filtering problem with exponential criteria for a general Gaussian signal is obtained through an approach which is based on a conditional Cameron–Martin-type formula. This key formula is derived for conditional expectations of exponentials of some quadratic functionals of a general continuous Gaussian process. The formula involves conditional expectations and conditional covariances in some auxiliary optimal risk-neutral filtering problem which is used in the proof. Closed form equations of the Itô–Volterra- and Riccati–Volterra-types for these ingredients are provided. Particular cases for which the results can be further elaborated are investigated.

**Key words.** Gaussian process, optimal filtering, filtering error, Riccati–Volterra equation, risk-sensitive filtering, exponential criteria

**AMS subject classifications.** Primary, 60G15; Secondary, 60G44, 62M20

**DOI.** 10.1137/070705908

**1. Introduction.** The linear exponential Gaussian (LEG) filtering problem, i.e., with an exponential of integral performance index (see definition (2) below), and the so-called risk-sensitive (RS) filtering problem (see [3] and the statement (64) below) have been given a great deal of interest over the last decades. Numerous results have been already reported in specific models, specially around Markov models, but, as far as we know, without exhibiting the relationship between these two problems. See, e.g., Whittle [24], [25], [26], Speyer, Fan, and Banavar [23], Elliott et al. [2], [6], [7], Dey and Moore [4], [5], and Bensoussan and van Schuppen [1] for contributions on this subject and related LEG and RS control problems. Therein the notion of the “information state” has been introduced without any clear probabilistic meaning for auxiliary processes which are involved, even in the Gauss–Markov case. Moreover, the method proposed in [2] does not work in a non-Markovian situation. On the other hand, the general solution for the optimal risk-neutral linear filtering problem and a Cameron–Martin-type formula for a general Gaussian process has been obtained in [10], [11], and [17]. It seems natural to use the approach proposed in [10] and [11] to derive the solution of the LEG and RS filtering problems for a general Gaussian process, to refine their link and also to give a probabilistic interpretation for the ingredients of the information state. For details, see sections 5 and 6, where in particular we prove that the LEG and RS filtering problems have the same solution and we propose an example to show that, in a bit more general setting, two similar problems may have different solutions.

In the present paper we deal with a signal process  $X = (X_t, t \geq 0)$ , which is an arbitrary  $n$ -dimensional continuous Gaussian process, and an observation process

$Y = (Y_t, t \geq 0)$  in  $\mathbb{R}^d$  governed by the linear equation

$$(1) \quad Y_t = \int_0^t A(s)X_s ds + \tilde{B}_t, \quad t \geq 0.$$

Here the deterministic function  $A = (A(s), s \geq 0)$  is continuous with values in the set of  $d \times n$  matrices, and  $\tilde{B} = (\tilde{B}_t, t \geq 0)$  denotes a  $d$ -dimensional standard Brownian motion independent of  $X$ . Clearly the pair  $(X, Y)$  is Gaussian but, in the general setting, neither Markovian nor a semimartingale.

Suppose that only  $Y$  is observed and one wishes to minimize with respect to  $h \in \mathcal{H}$  and  $g \in \mathcal{G}$  the following quantity:

$$(2) \quad L_T(h, g, \mu) = \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_T - g)' M (X_T - g) + \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \right],$$

where  $h = (h(s), 0 \leq s \leq T) \in \mathcal{H}$  means that  $h$  is a  $(\mathcal{Y}_s)$ -adapted process and  $g \in \mathcal{G}$  means that  $g$  is a  $\mathcal{Y}_T$ -measurable variable. Here nonnegative definite symmetric deterministic matrices  $M$  and  $Q_s, 0 \leq s \leq T$ , are given, and  $(\mathcal{Y}_s)$  is the natural filtration of  $Y$ , i.e.,  $\mathcal{Y}_s = \sigma(\{Y_u, 0 \leq u \leq s\}), 0 \leq s \leq T$ . Note that, according to the sign of the real parameter  $\mu$ , there are two different cases for this LEG filtering problem (the terminology is taken from the LEG optimal control problem):

- $\mu < 0$ , called the *risk-preferring* filtering problem,
- $\mu > 0$ , called the *risk-averse* filtering problem.

It is well-known (see, e.g., [23] for the discrete time Markov case setting) that the solution to this problem is not the conditional expectation of  $X_t$  given the  $\sigma$ -field  $\mathcal{Y}_t$ . Our first aim is to show that the solution can be completely explicit: the characteristics of the optimal solution are obtained as the solution of a closed form system of Volterra-type equations which actually reduce to the equations known for the RS setting when the signal process  $X$  is Gauss–Markov (see, e.g., [20]). Our second aim is to give the probabilistic interpretation of this optimal solution in terms of an auxiliary optimal *risk-neutral* filtering problem. Actually, we extend the filtering approach initiated in [11] for one-dimensional (1D) processes to obtain a conditional Cameron–Martin-type formula for the *conditional Laplace transform* of a quadratic functional of the involved process. Namely, we give an explicit representation for the random variable

$$(3) \quad \mathcal{L}_T = \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} (X_T - g)' M (X_T - g) + \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \middle/ \mathcal{Y}_T \right].$$

The paper is organized as follows. In section 2 we derive the solution of the LEG filtering problem in the case  $M = 0$ ; explicit Itô–Volterra-type equations, involving the covariance function of the filtered process, are obtained. In particular, in section 2.1, an appropriate auxiliary risk-neutral filtering problem is matched to that of deriving the key Cameron–Martin-type formula for the *conditional Laplace transform* of a quadratic functional of the involved process. The solution of this auxiliary filtering

problem is discussed in section 2.2. In section 3 we investigate some specific cases where the results can be further elaborated. In particular, more general observation models where the observation noise is not a Brownian motion or it is not independent of the signal are considered. Section 4 is devoted to the case  $M$  nonnegative definite. Of course, the results of section 2 are particular cases of those of section 4, but we prefer to keep both sections because a really simple independent proof can be given when  $M = 0$ . In section 5 we discuss the relation between LEG and RS filtering problems. Finally, section 6 is devoted to the interpretation for the ingredients of the information state.

**2. Solution of the LEG filtering problem: The case  $M = 0$ .** It what follows all random variables and processes are defined on a given stochastic basis  $(\Omega, \mathcal{F}, (\mathcal{F}_t), \mathbb{P})$  satisfying the usual conditions, and processes are  $(\mathcal{F}_t)$ -adapted. We consider a  $\mathbb{R}^n$ -valued continuous Gaussian process  $X = (X_t, t \geq 0)$  with mean function  $m = (m_t, t \geq 0)$  and covariance function  $\Gamma = (\Gamma(t, s), t \geq 0, s \geq 0)$ , i.e.,

$$\mathbb{E}X_t = m_t, \quad \mathbb{E}(X_t - m_t)(X_s - m_s)' = \Gamma(t, s), \quad t \geq 0, s \geq 0.$$

Let us introduce the following condition  $(C_\mu)$ .

$(C_\mu)$  the Riccati–Volterra equation

$$(4) \quad \bar{\gamma}(t, s) = \Gamma(t, s) - \int_0^s \bar{\gamma}(t, r)[A_r' A_r - \mu Q_r] \bar{\gamma}'(s, r) dr$$

has a unique and bounded solution on  $\{(t, s) : 0 \leq s \leq t \leq T\}$  such that for  $0 \leq t \leq T$  the matrix  $\bar{\gamma}(t, t)$  is nonnegative definite.

Notice that for all  $\mu$  *negative* the condition  $(C_\mu)$  is satisfied (cf. Theorem 2 below), and if  $\mu$  is *positive*, the condition  $(C_\mu)$  is satisfied for  $\mu$  sufficiently small, for example, those such that for any  $t \leq T$ ,  $A_t' A_t - \mu Q_t$  is nonnegative definite.

The first result of the present paper is the following theorem.

**THEOREM 1.** *Suppose that the condition  $(C_\mu)$  is satisfied. Let  $\bar{h} = (\bar{h}(t), 0 \leq t \leq T)$  be the unique solution of the Itô–Volterra equation*

$$(5) \quad \bar{h}(t) = m_t + \int_0^t \bar{\gamma}(t, s) A_s' [dY_s - A_s \bar{h}(s) ds],$$

where  $\bar{\gamma}$  is the unique solution of (4).

Then  $\bar{h} = (\bar{h}(t), 0 \leq t \leq T)$  is the solution of the LEG filtering problem, i.e.,

$$(6) \quad \bar{h} = \arg \min_{h \in \mathcal{H}} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \right].$$

Moreover, the corresponding optimal risk is given by

$$\mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - \bar{h}(s))' Q_s (X_s - \bar{h}(s)) ds \right\} \right] = \mu \exp \left\{ \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \right\}.$$

Theorem 1 is a direct consequence of the results of section 2.1. Its proof will be given at the end of section 2.1.

*Remark 1.*

- (i) When  $\mu$  is *negative*, functions  $\bar{h}$  and  $\bar{\gamma}$  can be interpreted in terms of an appropriate *risk-neutral* filtering problem (see the proofs of Proposition 1 and Theorem 1), but when  $\mu$  is *positive*, there is no such connection anymore.

- (ii) Let us note that in the Markovian case, (4) and (5) reduce to those given in Elliott, Aggoun, and Moore [7] for the solution of the risk-sensitive filtering problem. See also sections 3 and 5 for more details.
- (iii) It is worth emphasizing that, taking  $\mu = \mathbf{0}$  in (4), one gets through (5) the solution  $\bar{h}$  of the *risk-neutral* filtering problem of the signal  $X$ , given the observation  $Y$ , i.e.,  $\bar{h}(t) = \mathbb{E}(X_t/\mathcal{Y}_t)$  (see, e.g., [10]).

**2.1. Conditional version of a Cameron–Martin formula: The case  $M = \mathbf{0}$ .** In [10] and [11] it was proved that for any  $\mathbb{R}^n$ -valued continuous Gaussian process  $X = (X_t, t \geq 0)$ , with mean function  $m = (m_t, t \geq 0)$  and covariance function  $\Gamma = (\Gamma(t, s), t \geq 0, s \geq 0)$ , the following equality holds for any  $T > 0$  and  $\mu$  negative :

$$(7) \quad \mathbb{E} \exp \left\{ \frac{\mu}{2} \int_0^T X'_s Q_s X_s ds \right\} = \exp \left\{ \frac{\mu}{2} \int_0^T [z'(s) Q_s z(s) + \text{tr}(\gamma(s, s) Q_s)] ds \right\},$$

where  $\gamma = (\gamma(t, s), 0 \leq s \leq t \leq T)$  is the unique solution of the Riccati–Volterra equation

$$(8) \quad \gamma(t, s) = \Gamma(t, s) + \int_0^s \gamma(t, u) \mu Q_u \gamma'(s, u) du, \quad 0 \leq s \leq t \leq T,$$

such that  $\gamma(t, t)$  is nonnegative definite and  $z = (z_s, 0 \leq s \leq T)$  is the unique solution of the integral equation

$$(9) \quad z_s = m_s + \int_0^s \gamma(s, u) \mu Q_u z_u du.$$

Moreover, in [10] and [11] the link between the computation of the Laplace transform (7) and the resolution of an appropriate *risk-neutral* filtering problem was exhibited, and hence the probabilistic interpretation of functions  $z$  and  $\gamma$  was established. More precisely, new processes  $\bar{Y} = (\bar{Y}_t, t \geq 0)$  and  $\bar{\xi} = (\bar{\xi}_t, t \geq 0)$  were defined by

$$(10) \quad d\bar{Y}_t = (-\mu Q_t)^{\frac{1}{2}} X_t dt + d\bar{B}_t, \quad t \geq 0,$$

and

$$(11) \quad d\bar{\xi}_t = X'_t (-\mu Q_t)^{\frac{1}{2}} d\bar{Y}_t, \quad t \geq 0,$$

where  $\bar{B} = (\bar{B}_t; t \in [0, T])$  is a Brownian motion, independent of  $X$ . It was established that

- $\gamma(t, t)$  is nothing but the covariance of the filtering error of  $X$ , given  $\bar{Y}$ , i.e.,

$$(12) \quad \gamma(t, t) = \gamma_{XX}(t) = \mathbb{E}[X_t - \bar{\pi}_t(X)][X_t - \bar{\pi}_t(X)]',$$

and

- $z_t = \bar{\pi}_t(X) - \gamma_{X\bar{\xi}}(t)$ , with

$$(13) \quad \gamma_{X\bar{\xi}}(t) = \mathbb{E}[(X_t - \bar{\pi}_t(X))(\bar{\xi}_t - \bar{\pi}_t(\bar{\xi})) / \bar{\mathcal{Y}}_t],$$

where for any process  $\eta = (\eta_t; t \in [0, T])$  such that  $\mathbb{E}|\eta_t| < +\infty$ , the notation  $\bar{\pi}_t(\eta)$  is used for the conditional expectation of  $\eta_t$ , given the *auxiliary*  $\sigma$ -field  $\bar{\mathcal{Y}}_t = \sigma(\{\bar{Y}_s, 0 \leq s \leq t\})$ ,

$$\bar{\pi}_t(\eta) = \mathbb{E}(\eta_t / \bar{\mathcal{Y}}_t).$$

*Remark 2.* Let us mention that, since the pair  $(X, \xi)$  is only conditionally Gaussian given  $\bar{\mathcal{Y}}_t$ , the conditional covariance  $\gamma_{X\xi}(t)$  is random as well as  $\bar{\pi}_t(X)$ . But the difference  $z_t = \bar{\pi}_t(X) - \gamma_{X\xi}(t)$ , which is the solution of (9), is actually deterministic.

*Remark 3.* If  $\mu$  is *positive*, but sufficiently small in order that (8) has a unique and bounded solution on  $\{(t, s) : 0 \leq s \leq t \leq T\}$ , due to analytical properties of involved functions with respect to  $\mu$ , equality (7) is still valid. But it is worth emphasizing that there is no connection anymore between functions  $z$  and  $\bar{\gamma}$  and a risk-neutral filtering problem.

In this section we are interested in a conditional version of (7). We assume that the observation process  $Y$  satisfies (1). We fix some arbitrary  $(\mathcal{Y}_t)$ -adapted  $\mathbb{R}^n$ -valued continuous process  $h = (h(t), t \geq 0)$  and some continuous deterministic function  $Q_t$  with values in the set of nonnegative definite symmetric  $n \times n$  matrices. We denote  $G_t$  by

$$(14) \quad G_t = \exp \left\{ \frac{\mu}{2} \int_0^t (X_s - h(s))' Q_s (X_s - h(s)) ds \right\}$$

or, in the differential form,  $dG_t = \frac{\mu}{2} G_t (X_t - h(t))' Q_t (X_t - h(t)) dt$ . We denote by  $\mathbb{J}_T$  the conditional expectation of  $G_T$ , given the  $\sigma$ -field  $\mathcal{Y}_T$ :

$$(15) \quad \mathbb{J}_T = \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \middle/ \mathcal{Y}_T \right] = \pi_T(G),$$

where for any process  $\eta = (\eta_t, t \in [0, T])$  such that  $\mathbb{E}|\eta_t| < +\infty$ , the notation  $\pi_t(\eta)$  is used for the conditional expectation of  $\eta_t$ , given the  $\sigma$ -field  $\mathcal{Y}_t = \sigma(\{Y_s, 0 \leq s \leq t\})$ ,

$$\pi_t(\eta) = \mathbb{E}(\eta_t / \mathcal{Y}_t).$$

Then we can state the following proposition.

**PROPOSITION 1.** *Suppose that the condition  $(C_\mu)$  is satisfied. Let  $z^h = (z_s^h, 0 \leq s \leq T)$  be the unique solution of the Itô–Volterra equation*

$$(16) \quad z_t^h = m_t + \int_0^t \bar{\gamma}(t, s) \mu Q_s [z_s^h - h(s)] ds + \int_0^t \bar{\gamma}(t, s) A'_s [dY_s - A_s z_s^h ds],$$

where  $\bar{\gamma}$  is the unique solution of (4).

Then the following equality holds:

$$(17) \quad \mathbb{J}_T = \exp \left\{ \frac{\mu}{2} \int_0^T (z_s^h - h(s))' Q_s (z_s^h - h(s)) ds + \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \right. \\ \left. + \int_0^T (z_s^h - \pi_s(X))' A'_s d\nu_s - \frac{1}{2} \int_0^T \|A_s (z_s^h - \pi_s(X))\|^2 ds \right\},$$

where  $(\nu_t, t \geq 0)$  is the innovation process associated to  $Y$ , i.e.,

$$(18) \quad d\nu_t = dY_t - A_t \pi_t(X) dt, \quad \nu_0 = 0.$$

*Remark 4.* For  $\mu$  *negative* the probabilistic interpretation of functions  $z_t^h$  and  $\bar{\gamma}$  will be clarified below in terms of the solution of an auxiliary *risk-neutral* filtering problem.

*Remark 5.* Let us note that if  $A_t \equiv 0$  and  $h_t \equiv 0$ , then the conditional expectation is nothing else but the ordinary expectation, and the result of Proposition 1 reduces to that of [10] and [11] (see (7)–(9) above).

*Proof of Proposition 1.* Actually, for our goals it is sufficient to work with  $\mu < 0$  since the result will be valid for sufficiently small  $\mu > 0$ , because of the analytical properties of the involved functions. To simplify the notations we work with  $\mu = -1$ ; then for the general situation it is sufficient to replace  $Q$  by  $-\mu Q$ .

In this proof we follow directly the idea of [11] for the ordinary Cameron–Martin formula for general Gaussian processes. Let us introduce the auxiliary pair of processes  $\bar{Y}_t = (Y_t^1, Y_t^2)$  such that

$$(19) \quad \begin{cases} dY_t^1 = dY_t, & Y_0^1 = 0, \\ dY_t^2 = Q_t^{\frac{1}{2}}(X_t - h(t))dt + d\bar{B}_t, & Y_0^2 = 0, \end{cases}$$

where  $\bar{B}_t$  is a standard Brownian motion, independent of  $(X, \tilde{B})$ . We emphasize that the first component  $Y^1$  is exactly our observation process.

Below, for any process  $\eta = (\eta_t; t \in [0, T])$  such that  $\mathbb{E}|\eta_t| < +\infty$ , again the notation  $\bar{\pi}_t(\eta)$  is used for the conditional expectation of  $\eta_t$ , given the *new auxiliary*  $\sigma$ -field  $\bar{\mathcal{Y}}_t = \sigma(\{\bar{Y}_s, 0 \leq s \leq t\})$ ,

$$\bar{\pi}_t(\eta) = \mathbb{E}(\eta_t / \bar{\mathcal{Y}}_t) .$$

Let also  $\xi_t$  be defined by

$$(20) \quad d\xi_t = (X_t - h(t))' Q_t^{\frac{1}{2}} dY_t^2, \quad \xi_0 = 0.$$

We see that the conditional distribution of  $(X_t, \xi_t)$  with respect to  $\bar{\mathcal{Y}}_t$  is Gaussian with the conditional expectation  $(\bar{\pi}_t(X), \bar{\pi}_t(\xi))$  and the conditional covariance  $\begin{pmatrix} \bar{\gamma}_{XX}(t) & \bar{\gamma}_{X\xi}(t) \\ \bar{\gamma}_{X\xi}(t)' & \bar{\gamma}_{\xi\xi}(t) \end{pmatrix}$ , where

$$(21) \quad \begin{aligned} \bar{\gamma}_{XX}(t) &= \mathbb{E}[(X_t - \bar{\pi}_t(X))(X_t - \bar{\pi}_t(X))' / \bar{\mathcal{Y}}_t] , \\ \bar{\gamma}_{X\xi}(t) &= \mathbb{E}[(X_t - \bar{\pi}_t(X))(\xi_t - \bar{\pi}_t(\xi)) / \bar{\mathcal{Y}}_t] , \end{aligned}$$

and

$$(22) \quad \bar{\gamma}_{\xi\xi}(t) = \mathbb{E}[(\xi_t - \bar{\pi}_t(\xi))(\xi_t - \bar{\pi}_t(\xi)) / \bar{\mathcal{Y}}_t] .$$

Of course, since the pair  $(X, \bar{Y})$  is Gaussian, the conditional covariance  $\bar{\gamma}_{XX}(t)$  is deterministic and is nothing but the covariance of the filtering error, i.e.,

$$(23) \quad \bar{\gamma}_{XX}(t) = \mathbb{E}[(X_t - \bar{\pi}_t(X))(X_t - \bar{\pi}_t(X))'] .$$

Now, we turn to the proof of equality (17) with  $\mu = -1$ . The general filtering theorem in [18] gives the following representation (where  $G$  is defined by (14)):

$$(24) \quad d\pi_t(G) = -\frac{1}{2}\pi_t[G(X - h)'Q(X - h)]dt + [\pi_t'(GX) - \pi_t(G)\pi_t'(X)]A_t'd\nu_t,$$

with the innovation process  $\nu_t$ . We emphasize that here  $\pi$  means again the conditional expectation with respect to a  $\sigma$ -algebra generated by the observation process

$Y$ . Representation (24) can be rewritten in the following equivalent integral form:

$$(25) \quad \pi_t(G) = \exp \left\{ -\frac{1}{2} \int_0^t \alpha_2(s) ds + \int_0^t [\alpha_1(s) - \pi_s(X)]' A'_s d\nu_s \right. \\ \left. - \frac{1}{2} \int_0^t \|A_s(\alpha_1(s) - \pi_s(X))\|^2 ds \right\},$$

with

$$\alpha_1(t) = \frac{\pi_t(XG)}{\pi_t(G)}$$

and

$$\alpha_2(t) = \frac{\pi_t(G(X-h)'Q(X-h))}{\pi_t(G)}.$$

Now, for a fixed  $t \geq 0$ , we define the random variable  $\zeta_t$  by

$$\zeta_t = \int_0^t (X_s - h(s))' Q_s^{\frac{1}{2}} d\bar{B}_s + \frac{1}{2} \int_0^t (X_s - h(s))' Q_s (X_s - h(s)) ds.$$

Since the pair  $(X, Y)$  is independent of  $\bar{B}$  it is easy to check that  $\mathbb{E}e^{-\zeta_t} = 1$ , and so we can define the new probability  $\tilde{\mathbb{P}}_t$  such that

$$(26) \quad \rho_t = \frac{d\tilde{\mathbb{P}}_t}{d\mathbb{P}} = e^{-\zeta_t}.$$

The Girsanov theorem tells us that under  $\tilde{\mathbb{P}}_t$  the distribution of the system  $((X_s, \bar{Y}_s), 0 \leq s \leq t)$  (where  $\bar{Y}$  is given by (19)) is the same as that of  $((X_s, Y_s^1, \bar{B}_s), 0 \leq s \leq t)$  under  $\mathbb{P}$ . Therefore, denoting by  $\tilde{\mathbb{E}}_t$  a conditional expectation computed with respect to  $\tilde{\mathbb{P}}_t$ , we obtain

$$\alpha_1(t) = \frac{\tilde{\mathbb{E}}_t(X_t G_t / \mathcal{Y}_t)}{\tilde{\mathbb{E}}_t(G_t / \mathcal{Y}_t)}$$

and

$$\alpha_2(t) = \frac{\tilde{\mathbb{E}}_t(G_t(X_t - h(t))' Q_t(X_t - h(t)) / \mathcal{Y}_t)}{\tilde{\mathbb{E}}_t(G_t / \mathcal{Y}_t)}.$$

Since in particular under  $\tilde{\mathbb{P}}_t$ ,  $X$  and  $Y^1$  are independent of  $\bar{B}$ , the above conditional expectations can be replaced by conditional expectations given  $\bar{\mathcal{Y}}_t$  under  $\tilde{\mathbb{P}}_t$  so that

$$\alpha_1(t) = \frac{\tilde{\mathbb{E}}_t(X_t G_t / \bar{\mathcal{Y}}_t)}{\tilde{\mathbb{E}}_t(G_t / \bar{\mathcal{Y}}_t)}$$

and

$$\alpha_2(t) = \frac{\tilde{\mathbb{E}}_t(G_t(X_t - h(t))' Q_t(X_t - h(t)) / \bar{\mathcal{Y}}_t)}{\tilde{\mathbb{E}}_t(G_t / \bar{\mathcal{Y}}_t)}.$$

But from the well-known Bayes formula of the filtering theory, these equalities can be rewritten as

$$\alpha_1(t) = \frac{\mathbb{E}(X_t G_t \rho_t / \bar{\mathcal{Y}}_t)}{\mathbb{E}(\rho_t / \bar{\mathcal{Y}}_t)} \frac{\mathbb{E}(\rho_t / \bar{\mathcal{Y}}_t)}{\mathbb{E}(G_t \rho_t / \bar{\mathcal{Y}}_t)}$$

and

$$\alpha_2(t) = \frac{\mathbb{E}(G_t \rho_t (X_t - h(t))' Q_t (X_t - h(t)) / \bar{\mathcal{Y}}_t)}{\mathbb{E}(\rho_t / \bar{\mathcal{Y}}_t)} \frac{\mathbb{E}(\rho_t / \bar{\mathcal{Y}}_t)}{\mathbb{E}(G_t \rho_t / \bar{\mathcal{Y}}_t)}.$$

Hence, since from definitions (19) and (20) we have  $e^{-\xi_t} = G_t \rho_t$ , it follows that

$$\alpha_1(t) = \frac{\mathbb{E}(X_t e^{-\xi_t} / \bar{\mathcal{Y}}_t)}{\mathbb{E}(e^{-\xi_t} / \bar{\mathcal{Y}}_t)}$$

and

$$\alpha_2(t) = \frac{\mathbb{E}(e^{-\xi_t} (X_t - h(t))' Q_t (X_t - h(t)) / \bar{\mathcal{Y}}_t)}{\mathbb{E}(e^{-\xi_t} / \bar{\mathcal{Y}}_t)}.$$

Now, we observe that (under  $\mathbb{P}$ ) the conditional distribution of  $X$ , given the  $\sigma$ -field  $\mathcal{Y}_t$ , is Gaussian, and moreover from (20) for any  $t \geq 0$ , given  $\bar{\mathcal{Y}}_t$ , the variable  $\xi_t$  is a linear functional of  $X$ . Consequently, the conditional distribution of  $(X_t, \xi_t)$ , given the  $\bar{\mathcal{Y}}_t$ , is also Gaussian. The classical properties of Gaussian vectors give the following equalities:

$$\alpha_1(t) = \frac{\mathbb{E}(X_t e^{-\xi_t} / \bar{\mathcal{Y}}_t)}{\mathbb{E}(e^{-\xi_t} / \bar{\mathcal{Y}}_t)} = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$$

and

$$\begin{aligned} \alpha_2(t) &= \frac{\mathbb{E}((X_t - h(t))' Q_t (X_t - h(t)) e^{-\xi_t} / \bar{\mathcal{Y}}_t)}{\mathbb{E}(e^{-\xi_t} / \bar{\mathcal{Y}}_t)} \\ &= [\bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t) - h(t)]' Q_t [\bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t) - h(t)] + \text{tr}(\bar{\gamma}_{XX}(t) Q_t). \end{aligned}$$

Inserting this into (25) gives immediately (17), with  $z_t^h = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$  and  $\bar{\gamma}(t, t) = \bar{\gamma}_{XX}(t)$ . To complete the proof of Proposition 1, the equations for  $z^h$  and  $\bar{\gamma}$  will be derived in section 2.2.  $\square$

*Remark 6.*

- (i) Actually, the probabilistic meaning of  $z_t^h$  and  $\bar{\gamma}(t, s)$  in terms of a risk-neutral filtering problem is valid only when  $\mu$  is negative. It is worth mentioning that  $\bar{\pi}_t(X)$  and  $\bar{\gamma}_{X\xi}(t)$  are only  $\bar{\mathcal{Y}}_t$ -measurable variables but that the difference  $z_t^h = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$  is actually a  $\mathcal{Y}_t$ -measurable variable.
- (ii) Of course, the proof above is still valid if we suppose only that the conditional distribution of the signal  $X$ , given the observation  $Y$ , is Gaussian. Hence, in this case, (17) holds but with modified equations for the ingredients  $z_t^h$  and  $\bar{\gamma}(t, s)$ .

*Proof of Theorem 1.* The statement of Theorem 1 is the direct consequence of Proposition 1. Indeed, we claim that the following chain of inequalities holds for any

$h \in \mathcal{H}$ :

$$\begin{aligned}
 & \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \right] \\
 &= \mathbb{E} \left[ \mu \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \middle| \mathcal{Y}_T \right] \right] \\
 &\stackrel{(a)}{\geq} \exp \left\{ \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \right\} \\
 &\quad \times \mu \mathbb{E} \left[ \exp \left\{ \int_0^T (z_s^h - \pi_s(X))' A'_s d\nu_s - \frac{1}{2} \int_0^T \|A_s (z_s^h - \pi_s(X))\|^2 ds \right\} \right] \\
 &\stackrel{(b)}{\geq} \mu \exp \left\{ \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \right\}.
 \end{aligned}$$

Of course, under condition  $(C_\mu)$ , since the term in the last line is finite, it is sufficient to consider the case

$$(27) \quad \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \right] < \infty,$$

which gives the first equality. Inequality (a) follows directly from Proposition 1. For inequality (b) we consider separately the cases  $\mu < 0$  and  $\mu > 0$ .

For  $\mu < 0$ , inequality (b) is due to the submartingale property:

$$\mathbb{E} \left[ \exp \left\{ \int_0^T (z_s^h - \pi_s(X))' A'_s d\nu_s - \frac{1}{2} \int_0^T \|A_s (z_s^h - \pi_s(X))\|^2 ds \right\} \right] \leq 1.$$

For  $\mu > 0$ , (16) and conditions  $(C_\mu)$  and (27) give that the property  $\sup_{0 \leq s \leq T} \mathbb{E} [\exp \{\varepsilon \|z_s^h - \pi_s(X)\|^2\}] < \infty$  holds for some  $\varepsilon > 0$ , and hence, due to Theorem 6.1 in [18],

$$\mathbb{E} \left[ \exp \left\{ \int_0^T (z_s^h - \pi_s(X))' A'_s d\nu_s - \frac{1}{2} \int_0^T \|A_s (z_s^h - \pi_s(X))\|^2 ds \right\} \right] = 1.$$

Now, to obtain the lower bound we must take  $\bar{h} = z^{\bar{h}}$ , where  $z^h$  is the solution of (16), which means that  $\bar{h}$  is the unique solution of (5). Finally, for  $\bar{h}$  the lower bound is attained because the system  $(X, Y, \bar{h})$  is Gaussian, and hence inequalities (a) and (b) are actually equalities (see Example 3a in section 6.2 of [18]).  $\square$

**2.2. Auxiliary filtering problem.** Here we deal with the filtering problem of the signal  $(X, \xi)$ ,  $\xi$  defined in (20) from the observation of  $\bar{Y}$  defined in (19) (see [9, Chapter 10] and [10] for a similar setting).

The following statement provides equations for the conditional mean and the variance of the filtering error. Let us observe that, contrary to the Markov case, to update these quantities one needs to have access to the entire past observation record.

**THEOREM 2.** *The conditional mean  $\bar{\pi}_t(X)$  and the variance of the filtering error  $\bar{\gamma}_{XX}(t)$  are given by the equations*

$$(28) \quad \bar{\pi}_t(X) = m_t + \int_0^t \bar{\gamma}(t, s) \left[ A'_s d\bar{\nu}_s^1 + Q_s^{\frac{1}{2}} d\bar{\nu}_s^2 \right], \quad t \geq 0,$$

$$(29) \quad \bar{\gamma}_{xx}(t) = \bar{\gamma}(t, t), \quad t \geq 0,$$

where  $\bar{\gamma}$  is the unique solution of (4), with  $\mu = -1$ , such that  $\bar{\gamma}(t, t)$ ,  $t \geq 0$ , is a nonnegative definite symmetric matrix and  $\bar{\nu}_t = (\bar{\nu}_t^1, \bar{\nu}_t^2)$  is the innovation process for the pair  $(Y^1, Y^2)$ :

$$(30) \quad d\bar{\nu}_t^1 = dY_t^1 - A_t \bar{\pi}_t(X) dt, \quad d\bar{\nu}_t^2 = dY_t^2 - Q_t^{\frac{1}{2}} [\bar{\pi}_t(X) - h(t)] dt.$$

*Proof.* The difficulty is that in general  $X$  is not a semimartingale. To go over it in order to be able to apply the well-known filtering theory for semimartingales (see, e.g., [18, 19]), for a fixed  $t \geq 0$ , we introduce the process  $X^t = (X_s^t, 0 \leq s \leq t)$  as follows:

$$X_s^t = \mathbb{E}[X_t / \sigma(\{X_r, 0 \leq r \leq s\})], \quad 0 \leq s \leq t.$$

Clearly, by its definition, the process  $X^t$  is a continuous martingale (with mean  $m_t$ ) and  $X_t^t = X_t$ . Moreover, the pair  $(X, X^t)$  is Gaussian and independent of  $(B, \tilde{B})$ , and so the distribution of  $(X, X^t, Y)$  is still Gaussian. In particular, the conditional covariance  $\bar{\gamma}(t, s) = \mathbb{E}[(X_s^t - \bar{\pi}_s(X^t))(X_s - \bar{\pi}_s(X))' / \bar{\mathcal{Y}}_s]$  is deterministic. Hence, setting

$$\delta_X(s) = X_s - \bar{\pi}_s(X), \quad \delta_X^t(s) = X_s^t - \bar{\pi}_s(X^t), \quad 0 \leq s \leq t,$$

we can write

$$(31) \quad \bar{\gamma}(t, s) = \mathbb{E} \delta_X^t(s) \delta_X(s)', \quad 0 \leq s \leq t.$$

Of course, due to  $X_t^t = X_t$ , which also implies  $\delta_X^t(t) = \delta_X(t)$ , for  $s = t$  equality (31) reduces to (29).

Applying the fundamental filtering theorem to the pair  $(X^t, \bar{Y})$  of semimartingales, we obtain immediately that

$$(32) \quad \bar{\pi}_s(X^t) = m_t + \int_0^s \bar{\gamma}(t, r) \left[ A_r' d\bar{\nu}_r^1 + Q_r^{\frac{1}{2}} d\bar{\nu}_r^2 \right], \quad 0 \leq s \leq t.$$

Hence, again because  $X_t^t = X_t$  and due to definition (30) of  $\bar{\nu}$ , for  $s = t$  (32) reduces to (28).

Therefore, to complete the proof of the first part of the theorem, we need only to show that the function  $\bar{\gamma}$  which has just been defined in (31) is nothing but the unique solution of (4) such that  $\bar{\gamma}(t, t)$ ,  $t \geq 0$ , is a nonnegative symmetric matrix. From (32), using (1) and (30), we can write

$$(33) \quad \begin{aligned} \delta_X^t(s) = (X_s^t - m_t) &- \int_0^s \bar{\gamma}(t, r) A_r' [dB_r + A_r \delta_X(r) dr] \\ &- \int_0^s \bar{\gamma}(t, r) Q_r^{1/2} [d\bar{B}_r + Q_r^{1/2} \delta_X(r) dr]. \end{aligned}$$

Then, fixing  $0 \leq s \leq t$ , we may apply the Itô formula to obtain the semimartingale

decomposition of the process  $(\delta_X^t(u)\delta_X^s(u)', 0 \leq u \leq s)$ :

$$\begin{aligned}
 \delta_X^t(u)\delta_X^s(u)' &= \int_0^u \delta_X^t(r) \{dX_r^s - \bar{\gamma}(s, r)A_r'[dB_r + A_r\delta_X(r)dr]\}' \\
 &\quad + \int_0^u \delta_X^t(r) \left\{dX_r^s - \bar{\gamma}(s, r)Q_r^{\frac{1}{2}} \left[d\bar{B}_r + Q_r^{\frac{1}{2}}\delta_X(r)dr\right]\right\}' \\
 (34) \quad &\quad + \int_0^u \{dX_r^t - \bar{\gamma}(t, r)A_r'[dB_r + A_r\delta_X(r)dr]\}(\delta_X^s(r))' \\
 &\quad + \int_0^u \left\{dX_r^t - \bar{\gamma}(t, r)Q_r^{\frac{1}{2}} \left[d\bar{B}_r + Q_r^{\frac{1}{2}}\delta_X(r)dr\right]\right\}(\delta_X^s(r))' \\
 &\quad + \langle X^t - m_t, X^s - m_s \rangle_u + \int_0^u \bar{\gamma}(t, r)[Q_r + A_r'A_r]\bar{\gamma}(s, r)'dr.
 \end{aligned}$$

Let us point out here that, due to the Gaussian property of the pair  $(X^t, X^s)$  of martingales, the bracket  $\langle X^t - m_t, X^s - m_s \rangle_u$  is given by

$$\langle X^t - m_t, X^s - m_s \rangle_u = \mathbb{E}(X_u^t - m_t)(X_u^s - m_s)'$$

(see, e.g., Theorem 4.9.5 in [19]), and in particular for  $u = s$  one gets

$$\langle X^t - m_t, X^s - m_s \rangle_s = \Gamma(t, s).$$

Then let us put  $u = s$  in (34) and compute the expectations of both sides, taking into account the martingale property of  $X^t, X^s$ , and  $(B, \bar{B})$  and definition (31). It is easy to check that this shows that  $\bar{\gamma}$  defined in (31), which of course is such that  $\bar{\gamma}(t, t)$ ,  $t \geq 0$ , satisfies (4), with  $\mu = -1$ . The uniqueness of such a solution of (4) is proved below in Lemma 2, which completes the proof of the theorem.  $\square$

Now, we identify the function  $\bar{\pi}_s(X) - \bar{\gamma}_{X\xi}(s)$  appearing in the proof of Proposition 1.

LEMMA 1. *Let  $\bar{\pi}_t(X)$  and  $\bar{\gamma}_{X\xi}(s)$  be the conditional mean and the conditional covariance given by (28) and (21), respectively. Then the quantity*

$$(35) \quad z_s^h = \bar{\pi}_s(X) - \bar{\gamma}_{X\xi}(s), \quad s \geq 0,$$

*satisfies (16), with  $\mu = -1$ .*

*Proof.* Using the complementary notation

$$\delta_\xi(s) = \xi_s - \bar{\pi}_s(\xi), \quad 0 \leq s \leq t,$$

we define

$$\tilde{\gamma}(t, s) = \mathbb{E}(\delta_X^t(s)\delta_\xi(s)/\bar{\mathcal{Y}}_s), \quad 0 \leq s \leq t.$$

Of course, because  $X_t^t = X_t$ , the quantity that we want to identify is nothing but  $\bar{\gamma}_{X\xi}(t) = \tilde{\gamma}(t, t)$ . From (1) and (20) the process  $\xi$  is a semimartingale with the decomposition

$$(36) \quad \xi_t = \int_0^t (X_s - h(s))'Q_s(X_s - h(s))ds + \int_0^t (X_s - h(s))'Q_s^{\frac{1}{2}}d\bar{B}_s.$$

Hence, the fundamental filtering theorem gives

$$\begin{aligned}
 \bar{\pi}_t(\xi) &= \int_0^t \bar{\pi}_s((X_s - h(s))'Q_s(X_s - h(s)))ds \\
 (37) \quad &\quad + \int_0^t [\bar{\pi}_s((X_s - h(s)))' + \bar{\gamma}'_{X\xi}(s)]Q_s^{\frac{1}{2}}d\bar{B}_s^2 + \int_0^t \bar{\gamma}_{X\xi}(s)A_s'd\bar{B}_s^1.
 \end{aligned}$$

From the two previous equations, using (30), it follows that for  $0 \leq s \leq t$

$$\begin{aligned}
 \delta_\xi(t) = & \int_0^t ((X_s - h(s))' Q_s ((X_s - h(s)) - \bar{\pi}_s((X - h)' Q(X - h))) ds \\
 (38) \quad & - \int_0^t (\delta_X'(s) Q_s \bar{\pi}_s(X - h) + \bar{\gamma}'_{X\xi}(s) [Q_s + A'_s A_s] \delta_X(s)) ds \\
 & + \int_0^t (\delta_X(s) - \bar{\gamma}_{X\xi}(s))' Q_s^{\frac{1}{2}} d\bar{B}_s - \int_0^t \bar{\gamma}'_{X\xi}(s) A'_s dB_s.
 \end{aligned}$$

Using (33) and (38), applying the Itô formula, it is easy to determine the semimartingale decomposition of the process  $(\delta_X^t(s) \delta_\xi(s), 0 \leq s \leq t)$ . Then, again applying the fundamental filtering theorem and using the conditional Gaussian properties of  $(X_s, X_s^t, \xi_s)$ , given the  $\sigma$ -field  $\bar{\mathcal{Y}}_s$ , the following equation is readily obtained:

$$\begin{aligned}
 (39) \quad \bar{\gamma}(t, s) = & \int_0^s \bar{\gamma}(t, r) Q_r^{\frac{1}{2}} d\bar{\nu}_r^2 - \int_0^s \bar{\gamma}(t, r) [Q_r + A'_r A_r] \bar{\gamma}_{X\xi}(r) dr \\
 & + \int_0^s [\bar{\gamma}(t, r) Q_r \bar{\pi}_r(X_r - h(r))] dr.
 \end{aligned}$$

Putting  $s = t$  we can write the difference (28) and (39) which leads to

$$\begin{aligned}
 \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t) = & m_t - \int_0^t \bar{\gamma}(t, r) [Q_r + A'_r A_r] [\bar{\pi}_r(X) - \bar{\gamma}_{X\xi}(r)] dr \\
 & + \int_0^t \bar{\gamma}(t, r) Q_r h(r) dr + \int_0^t \bar{\gamma}(t, r) A'_r dY_r.
 \end{aligned}$$

This means exactly that  $z_r = \bar{\pi}_r(X) - \bar{\gamma}_{X\xi}(r)$  satisfies (16). The uniqueness of the solution of this equation is proved in Lemma 2, which achieves the proof of the present lemma.  $\square$

Actually, as a direct consequence of (38) we have the following corollary, which will be useful in section 4.

**COROLLARY 1.** *The auxiliary conditional expectation  $\bar{\pi}_t(\xi)$  and the auxiliary filtering error  $\bar{\gamma}_{\xi\xi}(t)$  satisfy the following equations:*

$$\begin{aligned}
 (40) \quad \bar{\pi}_t(\xi) = & \int_0^t \text{tr}(\bar{\gamma}_{XX}(s) Q(s)) ds + \int_0^t (\bar{\pi}_s(X) - h(s))' Q_s (\bar{\pi}_s(X) - h(s)) ds \\
 & + \int_0^t [(\bar{\pi}_s(X) - h(s))' + \bar{\gamma}'_{X\xi}(s)] Q_s^{\frac{1}{2}} d\bar{\nu}_s^2 + \int_0^t \bar{\gamma}'_{X\xi}(s) A'_s d\bar{\nu}_s^1,
 \end{aligned}$$

$$\begin{aligned}
 (41) \quad \bar{\gamma}_{\xi\xi}(t) = & \int_0^t \text{tr}(\bar{\gamma}_{XX}(s) Q(s)) ds + 2 \int_0^t \bar{\gamma}_{X\xi}(s) Q_s^{\frac{1}{2}} d\bar{\nu}_s^2 \\
 & - \int_0^t \bar{\gamma}'_{X\xi}(s) [Q(s) + A'(s) A(s)] \bar{\gamma}_{X\xi}(s) ds \\
 & + 2 \int_0^t (\bar{\pi}_s(X) - h(s))' Q(s) \bar{\gamma}_{X\xi}(s) ds.
 \end{aligned}$$

Finally, to complete the proof of Theorem 2, we derive uniqueness concerning (4) and (16).

**LEMMA 2.** *For arbitrary negative and sufficiently small positive  $\mu$ , (4) and (16) have unique continuous solutions  $\bar{\gamma}$  and  $z^h$  such that  $\bar{\gamma}(t, t)$ ,  $0 \leq t \leq T$ , is a nonnegative definite symmetric matrix.*

*Proof.* The proof for the 1-D case, when  $\bar{\gamma}(t, t) \geq 0$ ,  $t \geq 0$  and  $\mu < 0$ , has been done in [11], and the general case  $n \geq 1$  can be treated by the same way, using the simple fact that for a symmetric nonnegative definite matrix  $\gamma$  we have  $\lambda' \gamma \lambda \geq 0$  for any  $\lambda \in \mathbb{R}^n$ . Also, the proof proposed in [11] is valid for sufficiently small positive  $\mu$ , for example, those such that for any  $t \leq T$ ,  $A_t' A_t - \mu Q_t$  is nonnegative.  $\square$

**3. Particular cases and applications.** Here we deal with some specific cases where the results can be further elaborated. Strictly speaking, only the models which are investigated in subsections 3.1 and 3.3 are particular cases since they involve an observation noise  $\tilde{B}$ , which is both a Brownian motion and independent of the signal  $X$ . For these two examples, we can apply directly Theorem 1, and moreover the special structure of the covariances allows us to simplify the answer. Another method is also proposed. Actually, a direct consequence of Proposition 1 is that only equations for the variance of the filtering error  $\bar{\gamma}_{XX}(t)$  and for the difference  $z_t^h = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$  must be written. Here the conditional terms correspond to the auxiliary filtering problem of  $(X, \xi)$ , given the observations  $\tilde{Y}$  defined by (19). Equations for these ingredients will be first obtained for  $\mu = -1$  by means of a direct application of the general filtering theorem (see section 8.1 in [18]) or an approach to filtering proposed in [17] for Itô–Volterra-type models. Then, for any  $\mu$  such that the condition  $(C_\mu)$  is satisfied, it is sufficient to replace  $Q$  by  $-\mu Q$  in the equations. But it is worth emphasizing again that the replacement  $Q$  by  $-\mu Q$  means that the equations obtained from the auxiliary filtering problem cease to have a filtering interpretation. Finally, to get the solution of the LEG filtering problem defined by (6), we just have to take  $\bar{h}(t) = z_t^h$  for  $t \in [0, T]$ .

In the models under study in the other subsections, either  $X$  is not independent of  $\tilde{B}$  (cf. subsection 3.2) or  $\tilde{B}$  is not a Brownian motion (cf. subsections 3.4 and 3.5), and hence Theorem 1 is not directly applicable. Each of these cases is handled by means of an appropriate transformation of the considered original model into a standard scheme, where the Brownian and independence properties are satisfied, to which Theorem 1 can be applied. To this end, either a simple extension of the state space is used or the approach proposed in [14], [15], and [13] for a fractional Brownian noise is applied. Actually, more general settings should be tractable through a similar approach (see also Mandal and Mandrekar [21] for complementary relevant material), but this is kept for possible further investigation.

In what follows of this section we will use the notation  $(B, \tilde{B}) = ((B_t, \tilde{B}_t), t \geq 0)$  for a  $(n + d)$ -dimensional standard Brownian motion.

**3.1. Ornstein–Uhlenbeck-type signal observed through a linear channel with an independent Brownian noise.** At first we deal with the standard Gauss–Markov case where the  $\mathbb{R}^n$ -valued process  $X$  is governed by the stochastic differential equation

$$(42) \quad dX_t = a(t)X_t dt + \sigma_1(t)dB_t, \quad t \geq 0, \quad X_0 = 0,$$

where  $a = (a(t), t \geq 0)$  and  $\sigma_1 = (\sigma_1(t), t \geq 0)$  are  $n \times n$  matrix-valued continuous functions and  $B = (B_t, t \geq 0)$  is a standard Brownian motion in  $\mathbb{R}^n$ . Here, due to (42), denoting by  $\Pi_s$  the solution of the differential equation  $\dot{\Pi}_s = a(s)\Pi_s$ ,  $s \geq 0$ , with the initial condition  $\Pi_0 = I_n$  ( $n \times n$  identity matrix), we have

$$\Gamma(t, s) = \Pi_t \Pi_s^{-1} \Gamma(s, s), \quad 0 \leq s \leq t,$$

where  $\Gamma(s, s)$  solves the Lyapunov differential equation

$$\frac{d}{ds}\Gamma(s, s) = a(s)\Gamma(s, s) + \Gamma(s, s)a'(s) + \sigma_1(s)\sigma_1'(s), \quad s \geq 0, \quad \Gamma(0, 0) = 0.$$

Denote by  $\bar{\gamma}_{xx}$  the unique nonnegative definite solution of the Riccati differential equation

$$(43) \quad \begin{aligned} \dot{\bar{\gamma}}_{xx}(s) &= \sigma_1(s)\sigma_1'(s) + a(s)\bar{\gamma}_{xx}(s) + \bar{\gamma}_{xx}(s)a'(s) \\ &\quad - \bar{\gamma}_{xx}(s)[- \mu Q_s + A'(s)A(s)]\bar{\gamma}_{xx}(s), \quad 0 \leq s \leq T, \end{aligned}$$

with initial condition  $\bar{\gamma}_{xx}(0) = 0$ . From the classical filtering theory it is well-known that (for  $\mu < 0$ )  $\bar{\gamma}_{xx}(s)$  is nothing but the covariance of the filtering error of the signal  $X$  given by the auxiliary observation  $\bar{Y}$ , defined by (19). Then, it is readily seen that the function  $\bar{\gamma}(t, s)$ , where  $\bar{\gamma}(t, s) = \Pi_t \Pi_s^{-1} \bar{\gamma}_{xx}(s)$ , is the solution of (4) and that moreover (5) for the solution  $\bar{h}$  of the LEG filtering problem (6) can be reduced to the following one:

$$(44) \quad d\bar{h}_t = a(t)\bar{h}_t dt + \bar{\gamma}_{xx}(t)A'(t) [dY_t - A(t)\bar{h}_t dt].$$

Actually, (44) can also be obtained directly from the general filtering theory (for  $\mu = -1$  and replacing  $Q$  by  $-\mu Q$ ). For arbitrary  $h$  the general filtering theorem gives the following equation for  $z^h$ :

$$(45) \quad dz_t^h = a(t)z_t^h dt + \bar{\gamma}_{xx}(t)\mu Q_t [z_t^h - h_t] dt + \bar{\gamma}_{xx}(t)A'(t) [dY_t - A(t)z_t^h dt],$$

where  $\bar{\gamma}_{xx}$  is the solution of (43). Hence, again the solution  $\bar{h} = z^{\bar{h}}$  of the LEG filtering problem (6) is given by (44).

Let us emphasize that these equations are nothing but those given in Elliott, Aggoun, and Moore [7] for the solution of the RS filtering problem. Below, in section 5, it will be explained why the LEG and RS filtering problems have the same solution.

**3.2. Correlated signal-observation noises.** Actually, it is a slight generalization of the previous setting. We suppose that the  $\mathbb{R}^n$ -valued signal process  $X$  is governed by the stochastic differential equation

$$dX_t = a_t X_t dt + \sigma_1(t)dB_t + \sigma_2(t)d\tilde{B}_t, \quad X_0 = 0,$$

and the observation process  $Y$  is governed by (1). Applying the general filtering theorem (for arbitrary  $h$ ) we obtain

$$(46) \quad \begin{cases} dz_t^h = a_t z_t^h dt + \bar{\gamma}_{xx}(t)\mu Q_t [z_t^h - h(t)]dt \\ \quad \quad \quad + [\sigma_2(t) + \bar{\gamma}_{xx}(t)A'(t)][dY_t - A(t)z_t^h dt], \\ \dot{\bar{\gamma}}_{xx}(t) = [a(t) - \sigma_2(t)A_t]\bar{\gamma}_{xx}(t) + \bar{\gamma}_{xx}(t)[a(t) - \sigma_2(t)A(t)]' \\ \quad \quad \quad - \bar{\gamma}_{xx}(t)[- \mu Q_t + A'(t)A(t)]\bar{\gamma}_{xx}(t) + \sigma_1(t)\sigma_1'(t). \end{cases}$$

The solution  $\bar{h}$  of the LEG filtering problem (6) is given by

$$(47) \quad d\bar{h}_t = a(t)\bar{h}_t dt + [\sigma_2(t) + \bar{\gamma}_{xx}(t)A'(t)] [dY_t - A(t)\bar{h}_t dt].$$

**3.3. Itô–Volterra-type signal observed through a linear channel with Brownian noise.** Here we deal with the case where the  $\mathbb{R}^n$ -valued process  $X$  is governed by the stochastic integral equation

$$(48) \quad X_t = \int_0^t a(t, s) X_s ds + \int_0^t K(t, s) dB_s, \quad t \geq 0,$$

where  $a$  is a continuous function and the kernel  $K$  is such that the stochastic integral is well-defined and continuous with respect to  $t$ . Following the approach proposed in [17] we can introduce the auxiliary process  $X_t^\tau$ :

$$(49) \quad X_t^\tau = \int_0^t a(\tau, s) X_s ds + \int_0^t K(\tau, s) dB_s, \quad 0 \leq t \leq \tau,$$

which is a Gaussian semimartingale (for fixed  $\tau$ ). We see that since  $X_t^\tau = X_t$  the covariance function of the signal  $X$  can be represented in the form

$$\Gamma(t, s) = \int_s^t a(t, r) \Gamma(r, s) dr + G(t, s), \quad 0 \leq s \leq t,$$

where  $G(\tau, s) = \mathbb{E} X_s^\tau X_s'$  is the unique solution of the equation

$$G(t, s) = \int_0^s [a(t, r) G(s, r) + G(t, r) a'(s, r)] + \int_0^s K(t, r) K'(s, r) dr.$$

Let us denote by  $\gamma(t, s)$  the unique solution of the integral equation

$$(50) \quad \begin{aligned} \gamma(t, s) = & \int_0^s [a(t, r) \gamma(s, r) + \gamma(t, r) a'(s, r)] dr \\ & - \int_0^s \gamma(t, r) [-\mu Q_r + A_r' A_r] \gamma(s, r) dr + \int_0^s K(t, r) K'(s, r) dr. \end{aligned}$$

It follows from [17] that (for  $\mu < 0$ )  $\gamma(\tau, s)$  is nothing but the covariance of the filtering error of the signal  $X^\tau$  given the auxiliary observations  $\bar{Y}$  defined by (19):  $\gamma(\tau, s) = \mathbb{E}(X_s^\tau - \bar{\pi}_s(X^\tau))(X_s - \bar{\pi}_s(X))'$ . It can be shown that  $\bar{\gamma}(t, s)$ , where

$$(51) \quad \bar{\gamma}(t, s) = \int_s^t a(t, r) \bar{\gamma}(r, s) dr + \gamma(t, s), \quad 0 \leq s \leq t,$$

is the solution of (4). Now, using (51), we can reduce (5) for the solution  $\bar{h}$  of the LEG filtering problem (6) to the following one:

$$(52) \quad \bar{h}_t = \int_0^t a(t, s) \bar{h}_s ds + \int_0^t \gamma(t, s) A'(s) [dY_s - A(s) \bar{h}_s ds].$$

Actually, using an approach proposed in [17], (52) can also be obtained directly from the general filtering theory (for  $\mu = -1$  and replacing  $Q$  by  $-\mu Q$ ) which gives for arbitrary  $h$  the following equation for  $z^h$ :

$$(53) \quad \begin{aligned} z_t^h = & \int_0^t a(t, s) z_s^h ds + \int_0^t \gamma(t, s) \mu Q_s [z_s^h - h_s] ds \\ & + \int_0^t \gamma(t, s) A'(s) [dY_s - A(s) z_s^h ds], \end{aligned}$$

where  $\gamma$  is the solution of (50). Hence, again the solution  $\bar{h} = z^{\bar{h}}$  of the LEG filtering problem (6) is given by (52).

**3.4. Ornstein–Uhlenbeck-type signal observed through linear channel with Ornstein–Uhlenbeck-type noises.** Here we deal with the system

$$\begin{cases} dX_t = a(t)X_t dt + dG_t, \\ dY_t = A(t)X_t dt + d\tilde{G}_t, \end{cases}$$

where  $\tilde{G}_t$  and  $G_t$  are two independent Ornstein–Uhlenbeck processes, which means that

$$\begin{cases} dG_t = \beta_t G_t dt + dB_t, \\ d\tilde{G}_t = \tilde{\beta}_t \tilde{G}_t dt + d\tilde{B}_t. \end{cases}$$

To write the solution of the LEG filtering problem (6) for this model, it is sufficient to introduce the extension of the state space and to apply the result formulated in section 3.2. Indeed, our observation model can be written in the form

$$\begin{cases} d\tilde{X}_t = \tilde{a}_t \tilde{X}_t dt + \tilde{\sigma}_1(t) dB_t + \tilde{\sigma}_2(t) d\tilde{B}_t, \\ dY_t = \tilde{A}_t \tilde{X}_t dt + d\tilde{B}_t, \end{cases}$$

with  $\tilde{X}'_t = (X_t \quad \tilde{G}_t \quad G_t)$ ,  $\tilde{\sigma}'_1 = (1 \quad 0 \quad 1)$ ,  $\tilde{\sigma}'_2 = (0 \quad 1 \quad 0)$ ,

$$\tilde{a}_t = \begin{pmatrix} a(t) & 0 & \beta_t \\ 0 & \tilde{\beta}_t & 0 \\ 0 & 0 & \beta_t \end{pmatrix}, \text{ and } \tilde{A}_t = \begin{pmatrix} A(t) & \tilde{\beta}_t & 0 \end{pmatrix}.$$

Also, we can rewrite the quantity (2) as

$$(54) \quad L_T(h, \mu) = \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \int_0^T \left( \tilde{X}_s - \tilde{h}(s) \right)' \tilde{Q}_s \left( \tilde{X}_s - \tilde{h}(s) \right) ds \right\} \right],$$

with  $\tilde{h}'_t = (h_t \quad h_t^2 \quad h_t^3)$  and

$$\tilde{Q}_t = \begin{pmatrix} Q_t & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Thus the solution of the LEG filtering problem  $\bar{h}$  is the first component of the solution of a LEG filtering problem which can be obtained from the result of section 3.2 (see (46)–(47) with appropriate changes).

**3.5. Fractional Ornstein–Uhlenbeck-type signal observed through linear channel with fractional Brownian noise.** In this section we deal with the observation model

$$\begin{cases} dX_t = aX_t dt + dB_t^H, \quad X_0 = 0, \\ dY_t = AX_t dt + d\tilde{B}_t^H, \quad Y_0 = 0, \end{cases}$$

with constant coefficients  $a$  and  $A$ . The case of varying coefficients can be treated by the same way, using the approach proposed in [13] and [15].

Here  $B_t^H$  and  $\tilde{B}_t^H$  are two independent *normalized fractional Brownian motions* on  $[0, T]$  with the same Hurst parameter  $H \in [1/2, 1)$ . By the definition,  $V^H =$

$(V_t^H, t \in [0, T])$  is a *normalized fractional Brownian motion* on  $[0, T]$  with Hurst parameter  $H$  means that  $V^H$  is a Gaussian process with continuous paths such that  $V_0^H = 0$ ,  $\mathbb{E}V_t^H = 0$ , and

$$(55) \quad \mathbb{E}V_s^H V_t^H = \frac{1}{2} \left[ s^{2H} + t^{2H} - |s - t|^{2H} \right], \quad 0 \leq s, t \leq T.$$

Of course, the fractional Brownian motion reduces to the standard Brownian motion when  $H = 1/2$ , and for  $H \neq 1/2$ , the fractional Brownian motion is outside the world of semimartingales. Nevertheless, it is proved in [12]–[13] that the initial observation model  $(X, Y)$  can be analyzed as a part of the Gaussian signal-observation model  $((X, \zeta)', Z^0)$ , where the filtration generated by  $Z^0$  coincides with  $(\mathcal{Y}_t)$ :

$$(56) \quad \begin{cases} X_t = \int_0^t a X_s ds + \int_0^t K_H(t, s) dM_s^H, \\ \zeta_t = \int_0^t \frac{a}{2} A_H(s) \zeta_s ds + \int_0^t b_H(s) dM_s^H, \\ Z_t^0 = \int_0^t \frac{A}{2} \sqrt{\lambda_H} s^{H-\frac{1}{2}} b'_{1-H}(s) \zeta_s ds + \tilde{B}_t, \end{cases}$$

where the  $2 \times 2$  matrix  $A_H(s)$  and the 2-D vector  $b_H(s)$  are given by

$$A_H(s) = \begin{pmatrix} 1 & s^{1-2H} \\ s^{2H-1} & 1 \end{pmatrix}, \quad b_H(s) = (1 \quad s^{1-2H}).$$

Here for  $H \in (1/2, 1)$

$$(57) \quad K_H(t, s) = H(2H - 1) \int_s^t r^{H-\frac{1}{2}} (r - s)^{H-\frac{3}{2}} dr, \quad 0 \leq s \leq t,$$

and for  $H = 1/2$  the convention  $K_{1/2} \equiv 1$  is used. The process  $M^H$  is a Gaussian martingale, called in [22] the *fundamental martingale*, whose variance function  $\langle M^H \rangle$  is  $\langle M^H \rangle_t = \lambda_H^{-1} t^{2-2H}$ , with

$$\lambda_H = \frac{2H\Gamma(3-2H)\Gamma(H+1/2)}{\Gamma(3/2-H)}.$$

Now, we are in a particular situation of section 3.3. Indeed, it is sufficient to introduce the new matrices

$$\begin{aligned} \tilde{a}(t, s) &= \begin{pmatrix} a & 0 \\ 0 & \frac{a}{2} A_H(s) \end{pmatrix}, \\ \tilde{A}_t &= \begin{pmatrix} 0 & \frac{A}{2} \sqrt{\lambda_H} t^{H-\frac{1}{2}} b'_{1-H}(t) \end{pmatrix}, \\ \tilde{K}'(t, s) &= (\sqrt{\lambda_H} s^{\frac{1}{2}-H} K_H(t, s) \quad \sqrt{\lambda_H} s^{\frac{1}{2}-H} b'_H(s)). \end{aligned}$$

As it was done in section 3.4 we can rewrite the quantity (2) as (54) with  $\tilde{X}' = (X \quad \zeta')$ ,  $\tilde{h}'_t = (h_t \quad (h_t^2)')$ , and

$$\tilde{Q}_t = \begin{pmatrix} Q_t & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Thus the solution of the LEG filtering problem  $\bar{h}$  is the first component of the solution of a LEG filtering problem which can be obtained from the result of section 3.3 (see (50)–(52) with appropriate changes).

Let us note that the case  $H < \frac{1}{2}$  can be treated in the same way, using Corollary 5.2 from [8].

**4. Solution of the LEG filtering problem: The case  $M$  nonnegative definite.** In this section we work with a more general setting of the LEG filtering problem than in section 2. Let us formulate the condition  $(C_\mu^*)$ .

$(C_\mu^*)$  the Riccati–Volterra equation (4) has a unique and bounded solution on  $\{(t, s) : 0 \leq s \leq t \leq T\}$  such that for  $0 \leq t \leq T$  the matrix  $\bar{\gamma}(t, t)$  is nonnegative definite and moreover

$$\det(Id - \mu M \bar{\gamma}(T, T)) > 0.$$

Of course, if  $M = 0$ , then condition  $(C_\mu^*)$  reduces to condition  $(C_\mu)$ , and again for all  $\mu$  negative  $(C_\mu^*)$  is satisfied, and if  $\mu$  is positive,  $(C_\mu^*)$  is satisfied for  $\mu$  sufficiently small.

We state the following extension of Theorem 1.

**THEOREM 3.** *Suppose that the condition  $(C_\mu^*)$  is satisfied. Let  $\bar{h} = (\bar{h}(t), 0 \leq t \leq T)$  be the unique solution of the Itô–Volterra equation (5). Then the pair  $(\bar{h}, \bar{g})$ , where  $\bar{g} = \bar{h}(T)$ , is the solution of the LEG filtering problem, i.e.,*

$$(58) \quad \begin{aligned} (\bar{h}, \bar{g}) = \arg \min_{(h, g) \in \mathcal{H} \times \mathcal{G}} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_T - g)' M (X_T - g) \right. \right. \\ \left. \left. + \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \right]. \end{aligned}$$

Moreover, the corresponding optimal risk is given by

$$\begin{aligned} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_T - \bar{g})' M (X_T - \bar{g}) + \frac{\mu}{2} \int_0^T (X_s - \bar{h}(s))' Q_s (X_s - \bar{h}(s)) ds \right\} \right] \\ = \mu [\det(Id - \mu M \bar{\gamma}(T, T))]^{-\frac{1}{2}} \exp \left\{ \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \right\}. \end{aligned}$$

Theorem 3 is a direct consequence of the results of section 4.1. Its proof will be given in section 4.1.

**4.1. Conditional version of Cameron–Martin formula: The case  $M$  nonnegative definite.** In this section we give the generalization of representation (17) including the final conditions. Indeed, in this section we are interested in the explicit representation

$$(59) \quad \mathcal{J}_T = \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} (X_T - g)' M (X_T - g) \right. \right. \\ \left. \left. + \frac{\mu}{2} \int_0^T (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \middle/ \mathcal{Y}_T \right],$$

with any  $(\mathcal{Y}_s)$ -adapted process  $h(s)$ ,  $\mathcal{Y}_T$ -measurable variable  $g$ , and symmetric deterministic nonnegative definite matrices  $M$  and  $Q$ . Here the observation process  $Y$  is defined by (1).

PROPOSITION 2. Suppose that the condition  $(C_\mu^*)$  is satisfied. Let  $z^h = (z_s^h, 0 \leq s \leq T)$  be the unique solution of the Itô-Volterra equation (16). Then the following equality holds:

$$\begin{aligned} \mathcal{J}_T = & [\det(Id - \mu M \bar{\gamma}(T, T))]^{-\frac{1}{2}} \exp \left\{ \frac{1}{2} (z_T^h - g)' [Id - \mu M \bar{\gamma}(T, T)]^{-1} \mu M (z_T^h - g) \right. \\ & + \frac{\mu}{2} \int_0^T (z_s^h - h(s))' Q_s (z_s^h - h(s)) ds + \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s, s) Q_s) ds \Big\} \\ & \times \exp \left\{ \int_0^T (z_s^h - \pi_s(X))' A'_s d\nu_s - \frac{1}{2} \int_0^T \|A(s) (z_s^h - \pi_s(X))\|^2 ds \right\}. \end{aligned}$$

*Proof.* The proof is based on the idea developed in the proof of Proposition 1. Again, we work with  $\mu = -1$ , and then we can replace  $Q$  and  $M$  by  $-\mu Q$  and  $-\mu M$ , respectively. For the proof we shall note only that the classical Bayes formula gives that

$$(60) \quad \mathcal{J}_T = \frac{\mathbb{E} [\exp(-\frac{1}{2}(X_T - g)' M (X_T - g) - \xi_T) / \bar{\mathcal{Y}}_T]}{\mathbb{E} [\rho_T / \bar{\mathcal{Y}}_T]} = \frac{\varphi_1(T)}{\bar{\pi}_T(\rho)},$$

where  $\rho_t$  and  $\xi_t$  are defined by (26) and (20), respectively. But the conditional Gaussian properties of the pair  $(X, \xi)$ , given  $\bar{\mathcal{Y}}_T$ , gives the following:

$$\begin{aligned} \ln \varphi_1(T) = & -\frac{1}{2} \ln[\det(Id + M \bar{\gamma}_{XX}(T))] \\ (61) \quad & -\frac{1}{2} (z_T^h - g)' [(Id + M \bar{\gamma}_{XX}(T))]^{-1} M (z_T^h - g) \\ & - \bar{\pi}_T(\xi) + \frac{1}{2} \bar{\gamma}_{\xi\xi}(T) \end{aligned}$$

(see, for example, [18, Lemma 11.6]).

Since

$$d\rho_t = -\rho_t (X_t - h(t))' Q_t^{\frac{1}{2}} d\bar{B}_t,$$

thanks to the general filtering theorem we can write

$$(62) \quad d\bar{\pi}_t(\rho) = \bar{\pi}_t(\rho) \left\{ -\bar{\pi}'_t(X - h) Q_t^{\frac{1}{2}} d\bar{\nu}_t^2 + \left[ \frac{\bar{\pi}'_t(\rho X)}{\bar{\pi}_t(\rho)} - \bar{\pi}'_t(X) \right] A'_t d\bar{\nu}_t^1 \right\}.$$

The same arguments that we have used for the proof of Proposition 1 give the equality

$$\frac{\bar{\pi}_t(\rho X)}{\bar{\pi}_t(\rho)} = \pi_t(X).$$

Hence,

$$d\bar{\pi}_t(\rho) = \bar{\pi}_t(\rho) \left\{ -\bar{\pi}'_t(X - h) Q_t^{\frac{1}{2}} d\bar{\nu}_t^2 + [\pi'_t(X) - \bar{\pi}'_t(X)] A'_t d\bar{\nu}_t^1 \right\}$$

or equivalently

$$\begin{aligned} (63) \quad \bar{\pi}_T(\rho) = & \exp \left\{ -\int_0^T \bar{\pi}'_s(X - h) Q_s^{\frac{1}{2}} d\bar{\nu}_s^2 + \int_0^T [\pi'_s(X) - \bar{\pi}'_s(X)] A'_s d\bar{\nu}_s^1 \right. \\ & \left. - \frac{1}{2} \int_0^T \|A_s [\pi_s(X) - \bar{\pi}_s(X)]\|^2 ds - \frac{1}{2} \int_0^T \|Q_s^{\frac{1}{2}} [\bar{\pi}_s(X - h)]\|^2 ds \right\}. \end{aligned}$$

Now, it follows from (61) that to prove the statement of the proposition it is sufficient to write the expression for

$$\Psi_T = \frac{\exp(-\bar{\pi}_T(\xi) + \frac{1}{2}\bar{\gamma}_{\xi\xi}(T))}{\bar{\pi}_T(\rho)}.$$

The equalities (40), (41), and (63) imply

$$\begin{aligned} \ln(\Psi_t) = & -\frac{1}{2} \int_0^T \operatorname{tr}(\bar{\gamma}(s, s)Q_s)ds - \frac{1}{2} \int_0^T \bar{\pi}_s((X-h))'Q_s\bar{\pi}_s((X-h))ds \\ & + \int_0^T (\bar{\pi}_s(X) - h(s))'Q_s\bar{\gamma}_{X\xi}(s)ds - \frac{1}{2} \int_0^t \bar{\gamma}'_{X\xi}(s)Q_s\bar{\gamma}_{X\xi}(s)ds \\ & + \int_0^T [\pi_s(X) - \bar{\pi}_s(X) - \bar{\gamma}_{X\xi}(s)]'A'(s)d\bar{\nu}_s^1 \\ & - \frac{1}{2} \int_0^T \bar{\gamma}'_{X\xi}(s)A'(s)A(s)\bar{\gamma}_{X\xi}(s)ds + \frac{1}{2} \int_0^T \|A_s[\pi_s(X) - \bar{\pi}_s(X)]\|^2 ds. \end{aligned}$$

Replacing  $d\bar{\nu}_t^1$  by  $d\bar{\nu}_t^1 = d\nu_t + A(t)[\pi_t(X) - \bar{\pi}_t(X)]dt$ , we obtain that

$$\begin{aligned} \ln(\Psi_t) = & -\frac{1}{2} \int_0^T \operatorname{tr}(\bar{\gamma}(s, s)Q_s)ds - \frac{1}{2} \int_0^T (\bar{\pi}_s(X-h) - \bar{\gamma}_{X\xi}(s))'Q_s(\bar{\pi}_s(X-h) - \bar{\gamma}_{X\xi}(s))ds \\ & + \int_0^T [\pi_s(X) - \bar{\pi}_s(X) - \bar{\gamma}_{X\xi}(s)]'A'(s)d\nu_s - \frac{1}{2} \int_0^T \|A(s)(\pi_s(X) - \bar{\pi}_s(X) - \bar{\gamma}_{X\xi}(s))\|^2 ds, \end{aligned}$$

and it gives the statement of the proposition.  $\square$

*Proof of Theorem 3.* We follow the same lines as in the proof of Theorem 1, starting here from Proposition 2. Again, we claim that the following chain of inequalities holds for any  $(g, h) \in \mathcal{G} \times \mathcal{H}$ :

$$\begin{aligned} & \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_T - g)'M(X_T - g) + \frac{\mu}{2} \int_0^T (X_s - h(s))'Q_s(X_s - h(s))ds \right\} \right] \\ & \stackrel{(a)}{\geq} [\det(Id - \mu M\bar{\gamma}(T, T))]^{-\frac{1}{2}} \exp \left\{ \frac{\mu}{2} \int_0^T \operatorname{tr}(\bar{\gamma}(s, s)Q_s)ds \right\} \\ & \times \mathbb{E} \mu \left[ \exp \left\{ \int_0^T (z_s^h - \pi_s(X))'A'_s d\nu_s - \frac{1}{2} \int_0^T \|A(s)(z_s^h - \pi_s(X))\|^2 ds \right\} \right] \\ & \stackrel{(b)}{\geq} \mu [\det(Id - \mu M\bar{\gamma}(T, T))]^{-\frac{1}{2}} \exp \left\{ \frac{\mu}{2} \int_0^T \operatorname{tr}(\bar{\gamma}(s, s)Q_s)ds \right\}. \end{aligned}$$

Inequality (a) follows directly from Proposition 2, and inequality (b) is valid due to the same arguments as those we used in the proof of Theorem 1. Here to attain the lower bound we must take  $\bar{h} = z^{\bar{h}}$  and  $\bar{g} = z^{\bar{h}}_T$ , where  $z^h$  is the solution of (16), which means that  $\bar{h}$  is the unique solution of (5). Again, for  $(\bar{g}, \bar{h})$  the lower bound is attained because the system  $(X, Y, \bar{h})$  is Gaussian, and hence inequalities (a) and (b) are actually equalities.

**5. LEG and RS filtering problems.** Let  $\bar{h} = (\bar{h}(s), 0 \leq s \leq T)$  be the solution of the LEG filtering problem (6) on  $[0, T]$  given by (5). For any fixed  $t \leq T$ , let us

denote  $\hat{g}_t$  by

$$\hat{g}_t = \arg \min_{g \in \mathcal{Y}_t} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_t - g)' Q_t (X_t - g) + \frac{\mu}{2} \int_0^t (X_s - \bar{h}(s))' Q_s (X_s - \bar{h}(s)) ds \right\} / \mathcal{Y}_t \right],$$

where  $g \in \mathcal{Y}_t$  means that  $g$  is a  $\mathcal{Y}_t$ -measurable variable. It follows directly from Proposition 2 that, provided that  $\det(Id - \mu Q_t \bar{\gamma}(t, t)) > 0$ , the equality  $\hat{g}_t = z_t^{\bar{h}}$  holds. Since it was noted in the proof of Theorem 3 that  $\bar{h}(t) = z_t^{\bar{h}}$ , hence we have also  $\hat{g}_t = \bar{h}(t)$ . It means that for  $t \in [0, T]$  the solution  $\bar{h}$  of the LEG filtering problem satisfies the following recursive equation:

$$(64) \quad \bar{h}(t) = \arg \min_{g \in \mathcal{Y}_t} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} (X_t - g)' Q_t (X_t - g) + \frac{\mu}{2} \int_0^t (X_s - \bar{h}(s))' Q_s (X_s - \bar{h}(s)) ds \right\} / \mathcal{Y}_t \right].$$

Indeed, in the literature, the recursion (64) is the basic *definition* of the so-called RS filtering problem which was introduced in [6]. Therefore, we have also proved the following statement where  $(C_\mu^{**})$  denotes the condition.

$(C_\mu^{**})$  the Riccati–Volterra equation (4) has a unique and bounded solution on  $\{(t, s) : 0 \leq s \leq t \leq T\}$  such that for  $0 \leq t \leq T$  the matrix  $\bar{\gamma}(t, t)$  is nonnegative definite and moreover

$$\det(Id - \mu Q_t \bar{\gamma}(t, t)) > 0.$$

**THEOREM 4.** *Assume that the condition  $(C_\mu^{**})$  is satisfied. Let  $\bar{h} = (\bar{h}(t), 0 \leq t \leq T)$  be the unique solution of the Itô–Volterra equation (5), i.e.,  $\bar{h}$  is the solution of the LEG filtering problem (6). Then  $\bar{h}$  is the solution of the RS filtering problem (64).*

Actually, we did not find in the literature any trace of the discussion about the relation between the LEG filtering problem (6) and the RS filtering problem (64), even in a Gauss–Markov case. As a complement to our observation that these two problems have the same solution, we propose an example to show that in a bit more general setting, two similar problems may have different solutions.

For given positive symmetric deterministic matrices  $\Lambda_s, 0 \leq s \leq T$ , let us set  $\Phi_t(h) = (X_t' h(t)') \Lambda_t \begin{pmatrix} X_t \\ h(t) \end{pmatrix}$ . We can define  $\bar{h} \in \mathcal{H}$  as a solution of a *LEG-type filtering problem*:

$$(65) \quad \bar{h} = \arg \min_{h \in \mathcal{H}} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \int_0^T \Phi_s(h) ds \right\} \right],$$

where  $h = (h(s), 0 \leq s \leq T) \in \mathcal{H}$  means that  $h$  is a  $(\mathcal{Y}_s)$ -adapted process.

We can also define  $\hat{h}$  as the solution of the following recursive equation (*RS-type filtering problem*):

$$(66) \quad \hat{h}(t) = \arg \min_{g \in \mathcal{Y}_t} \mathbb{E} \left[ \mu \exp \left\{ \frac{\mu}{2} \Phi_t(g) + \frac{\mu}{2} \int_0^t \Phi_s(\hat{h}) ds \right\} / \mathcal{Y}_t \right],$$

where  $g \in \mathcal{Y}_t$  means that  $g$  is a  $\mathcal{Y}_t$ -measurable variable.

The question which we discuss now is the following: Does the equality  $\bar{h} = \hat{h}$  hold?

As we have just proved, the answer is positive for singular matrices  $\Lambda$ , namely, when  $\Lambda_{11} = \Lambda_{22} = -\Lambda_{12} = Q$ . But in the general situation the answer may be negative. Without technical details, which can be found in [16], we propose the following example:  $\Lambda = \begin{pmatrix} 2 & -1 \\ -1 & 1 \end{pmatrix}$ ,  $A = 1$ ,  $\mu = -1$ , and  $X_t = B_t$ . Even in this Markov case,  $\hat{h} \neq \bar{h}$ . More explicitly, one gets

$$\bar{h}(t) = \int_0^t \bar{H}(T, t, s) dY_s,$$

where

$$\begin{aligned} \bar{H}(T, t, s) &= \frac{\sinh(\sqrt{3}s) \cosh(T-t)}{\sqrt{\alpha_t \alpha_s}}, \\ \alpha_t &= \frac{\sqrt{3}+1}{2} \cosh(T + (\sqrt{3}-1)t) + \frac{\sqrt{3}-1}{2} \cosh(T - (\sqrt{3}+1)t). \end{aligned}$$

Clearly,  $\bar{H}$  depends on  $T$ , and by the definition of recursion (66),  $\hat{h}(t)$  does not depend on  $T$ . More precisely, one obtains

$$\hat{h}(t) = \int_0^t \hat{H}(t, s) dY_s,$$

where

$$\hat{H}(t, s) = \frac{\sinh(\sqrt{3}s) \sqrt[3]{\cosh(\sqrt{3}t)}}{\sqrt{3}(\cosh(\sqrt{3}s))^{\frac{2}{3}}},$$

and so  $\hat{h}$  and  $\bar{h}$  are different.

**6. Information state, interpretation.** In this section we discuss the probabilistic interpretation of the ingredients of the “information state” which was introduced in the context of RS filtering and LEG control problems. By the definition, the information state contains all of the information needed to describe the solution of the concerned optimization problem. In particular, it takes into account the cost function but not only estimates of the signal, and it should give the total information about the model states available in the measurement.

*Risk-sensitive filtering.* In the context of the RS filtering problem the definition of the information state can be found, for example, in [7]. It is the density  $\lambda_t$ , with respect to the Lebesgue measure, of the nonnormalized random measure  $\omega_t$ :

$$(67) \quad \omega_t(dx) = \mathbb{E} \left[ \mathbb{I}(X_t \in dx) \exp \left\{ \frac{\mu}{2} \int_0^t (X_s - h(s))' Q_s (X_s - h(s)) ds \right\} \middle/ \mathcal{Y}_t \right],$$

where  $h \in \mathcal{H}$  and the observation  $Y$  is defined by (1).

In a classical Gauss–Markov setting, an explicit representation of  $\lambda_t$  can be obtained as the solution of some stochastic partial differential equation (see, e.g., [3]).

We claim that for a general Gaussian signal  $X$  the density  $\lambda_t$  satisfies the following equality:

$$(68) \quad \begin{aligned} \lambda_t(x) = & [(2\pi)^n \det(\bar{\gamma}(t, t))]^{-\frac{1}{2}} \exp \left\{ -\frac{1}{2} (x - z_t^h)' \bar{\gamma}^{-1}(t, t) (x - z_t^h) \right. \\ & + \frac{\mu}{2} \int_0^t (z_s^h - h(s))' Q_s (z_s^h - h(s)) ds + \frac{\mu}{2} \int_0^t \text{tr}(\bar{\gamma}(s, s) Q_s) ds \Big\} \\ & \times \exp \left\{ \int_0^t (z_s^h - \pi_s(X))' A'(s) d\nu_s - \frac{1}{2} \int_0^t \|A(s) (z_s^h - \pi_s(X))\|^2 ds \right\}, \end{aligned}$$

where  $\bar{\gamma}$  and  $z^h$  are the solutions of (4) and (16), respectively.

Indeed, to prove (68) we can replace the equality (60) by the following:

$$\omega_t(dx) = \frac{\mathbb{E} [\mathbb{I}(X_t \in dx) \exp(-\xi_t) / \bar{\mathcal{Y}}_t]}{\mathbb{E} [\rho_t / \bar{\mathcal{Y}}_t]},$$

where  $\rho_t$  and  $\xi_t$  are defined by (26) and (20), respectively. Again, conditionally Gaussian properties of the pair  $(X, \xi)$  imply that

$$(69) \quad \begin{aligned} & \mathbb{E} [\mathbb{I}(X_t \in dx) \exp \{-\xi_t\} / \bar{\mathcal{Y}}_t] = [(2\pi)^n \det(\bar{\gamma}(t, t))]^{-\frac{1}{2}} \\ & \times \exp \left\{ -\frac{1}{2} (x - z_t^h)' \bar{\gamma}^{-1}(t, t) (x - z_t^h) - \bar{\pi}_t(\xi) + \frac{1}{2} \bar{\gamma}_{\xi\xi}(t) \right\} dx. \end{aligned}$$

Now, it is sufficient to replace (61) in the proof of Proposition 2 by (69).

It is worth emphasizing that (for negative  $\mu$ ) now we know the probabilistic interpretation of the involved pair  $(z^h, \bar{\gamma})$ . Actually, we have proved that  $z^h$  is the difference  $\bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$  and  $\bar{\gamma}$  is nothing but the covariance of the filtering error of  $X$  in view of auxiliary observations  $\bar{Y}$ .

Of course, after a simple integration of  $\lambda_t$ , (68) gives Propositions 1 and 2 and therefore the solution of the LEG and RS filtering problems.

*Linear exponential Gaussian control.* In the context of the LEG control problem for a partially observed process, the information state is also defined (see, e.g., [7]) as the density  $\lambda_t$ , with respect to the Lebesgue measure, of the nonnormalized random measure  $\omega_t$ :

$$(70) \quad \omega_t(dx) = \mathbb{E} \left[ \mathbb{I}(X_t \in dx) \exp \left\{ \frac{\mu}{2} \int_0^t X_s' Q_s X_s ds \right\} / \mathcal{Y}_t \right],$$

where  $X$  is the controlled state governed by the equation

$$(71) \quad dX_t = a(t)X_t dt + b(t)u_t dt + \sigma_1(t)dB_t, \quad t \geq 0, \quad X_0 = 0,$$

driven by a standard Brownian motion  $B = (B_t, t \geq 0)$  in  $\mathbb{R}^n$  and  $u \in \mathcal{H}$  corresponding to the available observation  $Y$  defined by (1).

By the same way that we have just explained, for the conditionally Gaussian pair  $(X, Y)$ , one can check that the density  $\lambda_t$  satisfies the following equality:

$$(72) \quad \begin{aligned} \lambda_t(x) = & [(2\pi)^n \det(\bar{\gamma}(t, t))]^{-\frac{1}{2}} \exp \left\{ -\frac{1}{2} (x - z_t)' \bar{\gamma}^{-1}(t, t) (x - z_t) \right. \\ & + \frac{\mu}{2} \int_0^t z_s' Q_s z_s ds + \frac{\mu}{2} \int_0^t \text{tr}(\bar{\gamma}(s, s) Q_s) ds \Big\} \\ & \times \exp \left\{ \int_0^t (z_s - \pi_s(X))' A'(s) d\nu_s - \frac{1}{2} \int_0^t \|A(s)(z_s - \pi_s(X))\|^2 ds \right\}, \end{aligned}$$

where  $\bar{\gamma}$  is the solution of (43) and  $z$  is the solution of the equation

$$(73) \quad dz_t = a(t)z_t dt + b(t)u_t dt + \bar{\gamma}(t)\mu Q_t z_t dt + \bar{\gamma}(t)A'(t)[dY_t - A(t)z_t dt].$$

Actually, it is the equation for the difference  $z = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$ , where the conditional expectations are taken with respect to the auxiliary observation process  $\bar{Y}$  defined by (19), with  $h = 0$ .

Equality (72) gives the possibility to rewrite the cost function in terms of the completely observable process  $z$ , namely,

$$\begin{aligned} & \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T X_s' Q_s X_s ds \right\} \right] \\ &= \mathbb{E} \left\{ \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T X_s' Q_s X_s ds \right\} \middle/ \mathcal{Y}_T \right] \right\} \\ &= \mathbb{E} \left[ \exp \left\{ \frac{\mu}{2} \int_0^T z_s' Q_s z_s ds + \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s) Q_s) ds + \int_0^T (z_s - \pi_s(X))' A'(s) d\nu_s \right. \right. \\ &\quad \left. \left. - \frac{1}{2} \int_0^T \|A(s)(z_s - \pi_s(X))\|^2 ds \right\} \right] \\ &= \exp \left\{ \frac{\mu}{2} \int_0^T \text{tr}(\bar{\gamma}(s) Q_s) ds \right\} \tilde{\mathbb{E}} \exp \left\{ \frac{\mu}{2} \int_0^T z_s' Q_s z_s ds \right\}, \end{aligned}$$

where  $\tilde{\mathbb{E}}$  stands for an expectation with respect to the new measure  $\tilde{\mathbb{P}}$  such that

$$\frac{d\tilde{\mathbb{P}}}{d\mathbb{P}} = \exp \left\{ \int_0^T (z_s - \pi_s(X))' A'(s) d\nu_s - \frac{1}{2} \int_0^T \|A(s)(z_s - \pi_s(X))\|^2 ds \right\}.$$

With respect to this new measure the solution of (73) can be represented as

$$(74) \quad dz_t = a(t)z_t dt + b(t)u_t dt + \bar{\gamma}(t)\mu Q_s z_t dt + \bar{\gamma}(t)A'(t)d\tilde{\nu}_t,$$

with the new Brownian motion  $\tilde{\nu}$ :

$$(75) \quad d\tilde{\nu}_t = d\nu_t - A(t)(z_t - \pi_t(X)) dt.$$

Thus, the new process  $z$  plays the role of the completely observed controlled state (see [1]).

Now, we emphasize that the probabilistic interpretation of the information state  $z$  used in [1] is nothing but  $z = \bar{\pi}_t(X) - \bar{\gamma}_{X\xi}(t)$ , where the conditional expectations are taken with respect to the auxiliary observation process  $\bar{Y}$  defined by (19), with  $h = 0$ . Also,  $\bar{\gamma}$  is the conditional covariance of  $X$ .

## POLICY ITERATION AND THE MAX-PLUS FINITE ELEMENT METHOD\*

D. MCCAFFREY†

**Abstract.** We set out a policy iteration algorithm for the solution of a nonconvex nonlinear-affine finite horizon differential game. This involves the use of a max-plus finite element method (FEM) to solve a convex optimal control problem in the value determination step of the algorithm, where this convex problem is the result of fixing the policy of the second, or outer, player. A quadratic program is then solved in the policy improvement step to improve the feedback policy employed by the outer player. We show that the algorithm converges in a finite number of steps and that the approximation error at convergence is of order  $\sqrt{\Delta t} + \Delta x(\Delta t)^{-1}$ .

**Key words.** max-plus algebra, policy iteration, nonconvex differential game, finite element method, Hamilton–Jacobi–Isaacs equation,  $H_\infty$  control

**DOI.** 10.1137/070705465

**1. Introduction.** We consider the finite horizon differential game

$$(1) \quad v(x, T) = \inf_{a(\cdot)} \sup_{b(\cdot)} \int_0^T \left\{ \frac{1}{2}x(s)^2 + \frac{1}{2}a(s)^2 - \frac{\gamma^2}{2}b(s)^2 \right\} ds + \phi(x(T))$$

over trajectories  $(x(\cdot), a(\cdot), b(\cdot))$  satisfying

$$(2) \quad \dot{x}(s) = f(x(s)) + g(x(s))a(s) + h(x(s))b(s), \quad x(0) = x,$$

where

$$x(s) \in X \subseteq \mathbb{R}^n, \quad a(s) \in U \subseteq \mathbb{R}^m, \quad b(s) \in W \subseteq \mathbb{R}^r.$$

This problem arises, for example, as the differential game formulation of a well-known class of nonlinear affine  $H_\infty$  control problems. The reader can consult [11] for an exposition of the differential game approach to general nonlinear  $H_\infty$  control, and [12, 13, 8] for background on the specific nonlinear affine subclass of  $H_\infty$  control problems considered here. It is sufficient to note that the first (or inner) player, with input  $b(\cdot)$ , is referred to as the disturbance, and the second (or outer) player, who responds with policy  $a(\cdot)$ , is referred to as the control. In a strict formulation of the problem, the second player actually responds with strategies, i.e., nonanticipating functionals from the space of disturbance inputs to the space of control inputs, but for our purposes here, where we apply very coarse discretization to the space of control inputs, the above notation will be sufficient, provided the reader bears in mind the simplifications we are making. Also note that the value  $\gamma$  appearing in the cost function in (1) is given as an external parameter.

†Department of Automatic Control and Systems Engineering, University of Sheffield, Mappin Street, Sheffield, S1 3JD, UK (david@mccaffrey275.fsnet.co.uk).

The problem is usually considered over an infinite horizon, where the objective of the second player is to maintain the  $L_2$  system output  $\int \frac{1}{2}x(s)^2 + \frac{1}{2}a(s)^2 ds$  less than or equal to  $\gamma^2$  times the  $L_2$  system input  $\int \frac{1}{2}b(s)^2 ds$ , i.e., to achieve an attenuation level  $\leq \gamma^2$ . Under suitable regularity assumptions, usually expressed in terms of the local controllability and observability at the origin of the system (2), it is known that the infinite horizon problem is solvable, in the sense that the value function is finite, on some nonlocal neighborhood of the origin for  $\gamma$  above some minimum level. So in particular it is known (see, for instance, [11]) that the value function  $v(x, t)$  for the finite horizon problem is a (possibly nonsmooth) solution to the Hamilton–Jacobi–Isaacs equation

$$(3) \quad H(x, \partial v / \partial x) = \partial v / \partial t$$

with initial condition  $v(x, 0) = \phi(x)$  for  $(x, t) \in X \times (0, T]$ , where the Hamiltonian is defined as

$$H(x, p) = \min_a \max_b \left\{ p(f(x) + g(x)a + h(x)b) + \frac{1}{2}x^2 + \frac{1}{2}a^2 - \frac{\gamma^2}{2}b^2 \right\}.$$

Note that this Hamiltonian is nonconvex in  $p$ .

Suppose we choose some feedback function  $\hat{a}(x)$  and, on any solution trajectory  $(x(\cdot), a(\cdot), b(\cdot))$ , define the control input  $a(s) = \hat{a}(x(s))$  for all  $s$ . We can then define  $f_{\hat{a}}(x, b) = f(x) + g(x)\hat{a}(x) + h(x)b$  and  $l_{\hat{a}}(x, b) = \frac{1}{2}x^2 + \frac{1}{2}\hat{a}(x)^2 - \frac{\gamma^2}{2}b^2$ , and consider the finite horizon optimal control problem

$$(4) \quad v_{\hat{a}}(x, T) = \sup_{b(\cdot)} \int_0^T l_{\hat{a}}(x(s), b(s)) ds + \phi(x(T))$$

over trajectories  $(x(\cdot), b(\cdot))$  satisfying

$$\dot{x}(s) = f_{\hat{a}}(x(s), b(s)), \quad x(0) = x.$$

In this case, the value function  $v_{\hat{a}}(x, t)$  satisfies the Hamilton–Jacobi equation

$$(5) \quad H_{\hat{a}}(x, \partial v_{\hat{a}} / \partial x) = \partial v_{\hat{a}} / \partial t$$

with initial condition  $v_{\hat{a}}(x, 0) = \phi(x)$  for  $(x, t) \in X \times (0, T]$ , where the Hamiltonian is defined as  $H_{\hat{a}}(x, p) = \max_b \{ p f_{\hat{a}}(x, b) + l_{\hat{a}}(x, b) \}$ . Note that this Hamiltonian is convex in  $p$  for all  $x$ .

A max-plus analogue of the finite element method (FEM) is set out in [1] for the numerical computation of the value function  $v_{\hat{a}}$  solving convex optimal control problem (4). This involves a max-plus variational formulation in which successive time steps of the semigroup action are approximated by projection onto two idempotent semimodules, the first spanned by a set of test functions and the second by a set of finite element basis functions. The errors associated with these projections are estimated in [1] to be of order  $\sqrt{\Delta t} + \Delta x(\Delta t)^{-1}$ , where  $\Delta t$  is the time discretization step and  $\Delta x$  the space discretization step.

In this paper, we set out a policy iteration algorithm for the solution of the nonconvex differential game (1). This involves the use of the max-plus FEM to solve (5) for a given fixed control feedback  $a(x)$  in the value determination step of the algorithm, and then the use of a quadratic program to improve the control feedback in the policy improvement step. This quadratic program is given explicitly and very naturally

in terms of the coefficients of the max-plus basis functions appearing in the value determination step. We show that the algorithm converges in a finite number of steps and that the approximation error arising from projection of the converged solution is also of order  $\sqrt{\Delta t} + \Delta x(\Delta t)^{-1}$ . We leave open the question of how to formulate the policy iteration algorithm for the steady state solution to the corresponding infinite horizon differential game, although we make some comments in this direction at the end of the paper.

**2. Policy iteration.** In order to provide context and notation for what follows, we briefly set out here, in abstract terms, a policy iteration algorithm for games. This goes back to [6]. Here we have adapted it to a finite horizon context. In section 4, we will develop a concrete implementation of this algorithm adapted to the max-plus FEM.

Let  $S^t$  denote the evolution semigroup of the PDE (3). This associates to any function  $\phi$  the function  $v^t = v(\cdot, t)$ , where  $v$  is the value function of the differential game (1). Similarly, let  $S_{\hat{a}}^t$  denote the evolution semigroup of the PDE (5) for some fixed feedback function  $\hat{a}(\cdot)$ . This associates to any function  $\phi$  the function  $v_{\hat{a}}^t = v_{\hat{a}}(\cdot, t)$ , where  $v_{\hat{a}}$  is the value function of the optimal control problem (4). Maslov [7] observed that the semigroup  $S_{\hat{a}}^t$  is max-plus linear.

Now let  $p$  denote the cycle index within the policy iteration algorithm, and let  $q \in \{0, \dots, N-1\}$  denote the time step index, so that the full time horizon  $T$  is divided into  $N$  equal steps of length  $\tau$ , i.e.,  $T = N\tau$ , with the  $q$ th step running from  $q\tau$  to  $(q+1)\tau$ .

Suppose, on the  $p$ th cycle of policy iteration, we are given some fixed time dependent control policy  $\hat{a}_p = (\hat{a}_p^0(x), \dots, \hat{a}_p^{N-1}(x))$ . Note that, for each  $x \in X$ , this policy is constant on time step  $q\tau$  to  $(q+1)\tau$  for each  $q$ . Then, for a given  $q$ , we can consider the evolution semigroup  $S_{\hat{a}_p^q}^\tau$  of the PDE (5) with  $\hat{a} = \hat{a}_p^q$ . By application of the time iteration

$$v_p^{(q+1)\tau}(\cdot) = S_{\hat{a}_p^q}^\tau(v_p^{q\tau}(\cdot))$$

for  $q \in \{0, \dots, N-1\}$ , and defining  $v_p^0(\cdot) = \phi(\cdot)$ , we can then compute a time-discretization  $\{v_p^\tau(\cdot), \dots, v_p^{N\tau}(\cdot)\}$  of the value function  $v_{\hat{a}_p}^t$  of the optimal control problem (4) with time-dependent control policy  $\hat{a}_p$ . This is the value determination step of the algorithm, and it is max-plus linear.

The policy improvement step then involves computing the value function, which is obtained after “one step” of the differential game (1) if we start from function  $v_{\hat{a}_p}^t$ . This is achieved by computing

$$(6) \quad u_{p+1}^{(q+1)\tau}(\cdot) = S^\tau(v_p^{q\tau}(\cdot))$$

for  $q \in \{0, \dots, N-1\}$ . The policy improvement is then obtained by choosing a new policy  $\hat{a}_{p+1} = (\hat{a}_{p+1}^0(x), \dots, \hat{a}_{p+1}^{N-1}(x))$  which minimizes the right-hand side of (6) for each  $q \in \{0, \dots, N-1\}$ . This computation (6) is max-plus nonlinear. We will see below that it can be expressed as a quadratic program in the coefficients of a max-plus basis expansion of  $v_p^{q\tau}$ .

The algorithm is initiated by making some sensible choice of initial fixed time-dependent control policy  $\hat{a}_0 = (\hat{a}_0^0(x), \dots, \hat{a}_0^{N-1}(x))$ . On each new cycle  $p+1$  for  $p \geq 0$ , we start with  $v_{p+1}^0(\cdot) = v_p^0(\cdot) = \phi(\cdot)$ . Assume, with a view to induction on  $q$ , that  $v_{p+1}^{q\tau}(\cdot) \leq v_p^{q\tau}(\cdot)$  for  $q \geq 0$ . Then by the order preserving character of  $S_{\hat{a}}^t$ , we have

$$v_{p+1}^{(q+1)\tau} = S_{\hat{a}_{p+1}^q}^\tau(v_{p+1}^{q\tau}) \leq S_{\hat{a}_{p+1}^q}^\tau(v_p^{q\tau}).$$

Then since  $\hat{a}_{p+1}^q$  is the argmin in (6), we have

$$(7) \quad S_{\hat{a}_{p+1}^q}^\tau(v_p^{q\tau}) = S^\tau(v_p^{q\tau}) \leq S_{\hat{a}_p^q}^\tau(v_p^{q\tau}) = v_p^{(q+1)\tau}.$$

It then follows by induction on  $q$  that  $v_{p+1}^{q\tau}(\cdot) \leq v_p^{q\tau}(\cdot)$  for all  $q \in \{0, \dots, N\}$ ; i.e., the policy improvement step (6) does indeed lead to a lower value function of the optimal control problem (4) on the next iteration of value determination.

In general, it is necessary to impose conditions to guarantee that this process converges to a time discretization  $\{v^\tau(\cdot), \dots, v^{N\tau}(\cdot)\}$  of the value function  $v^t$  of the differential game (1). Typical conditions are that the sequence  $\{v_p^{q\tau}(\cdot)\}$  is uniformly bounded below and strictly monotone in  $p$ , which in turn usually follows by suitably restricting the class of control policies over which the minimization in (6) is performed.

In our case, given the particular structure of the differential game (1) and the specific discretizations which we apply within the context of the max-plus FEM, we show that the sequence of policy improvements actually terminates after  $N$  steps; i.e., the first iteration of policy improvement produces the optimal policy for the outer player on the first time step, the second iteration of policy improvement produces the optimal outer player policy on the second time step, and so on. This means that in practice the algorithm can be implemented without needing to cycle through policy iterations. Rather, it can be implemented like a value iteration with one pass through each of the  $N$  steps of the time discretization in turn, so that starting with initial data  $v_0^0(\cdot) = \phi(\cdot)$  and an initial choice of control policy  $\hat{a}_0^0(\cdot)$  at time zero, the value determination and policy improvement steps are applied to the one step game to compute the value function  $v_1^1(\cdot)$  and optimal outer player policy  $\hat{a}_1^1(\cdot)$  after one time step. These are then used as starting values for value determination and policy improvement applied again to the one step game to compute the value function  $v_2^2(\cdot)$  and optimal outer player policy  $\hat{a}_2^2(\cdot)$  after two time steps, and so on. However, in order to prove that this process is well defined, we consider below the full iteration of policy over the whole time horizon and show that the diagonal path stabilizes within this scheme. Also, the policy iteration framework allows for a potential generalization of the algorithm to deal with the infinite horizon problem, which we outline in the final section of the paper.

**3. The max-plus FEM.** We now briefly review the max-plus FEM set out in [1] for the numerical computation of the value function  $v_{\hat{a}}$  solving the optimal control problem (4). The various results on idempotent semirings, semimodules, linear maps, residuation, and projectors can be found in, for instance, [2, 3, 4].

Let  $\mathbb{R}_{\max}$  denote the idempotent semiring obtained from  $\mathbb{R}$ , with its usual order  $\leq$ , by defining idempotent addition as  $a \oplus b := \max(a, b)$  and multiplication as  $ab := a + b$ . Then let  $\bar{\mathbb{R}}_{\max} := \mathbb{R}_{\max} \cup \{+\infty\}$ , with the convention that  $-\infty$  is absorbing for the multiplication. This has the property of being complete as an idempotent semiring, which means that any subset has a least upper bound and the left and right multiplications  $x \mapsto ax$  and  $x \mapsto xa$  are residuated. This in turn means that the sets  $\{x \in \bar{\mathbb{R}}_{\max} : ax \leq b\}$  and  $\{x \in \bar{\mathbb{R}}_{\max} : xa \leq b\}$  both have maximal elements.

For a set  $X$ , we consider the set  $\bar{\mathbb{R}}_{\max}^X$  of  $\bar{\mathbb{R}}_{\max}$  valued functions on  $X$ . This is a semimodule over  $\bar{\mathbb{R}}_{\max}$  with respect to componentwise addition  $(u, v) \mapsto u \oplus v$ , defined by  $(u \oplus v)(x) = u(x) \oplus v(x)$ , and componentwise scalar multiplication  $(\lambda, u) \mapsto u\lambda$ , defined by  $(u\lambda)(x) = u(x)\lambda$ , where  $u, v \in \bar{\mathbb{R}}_{\max}^X$ ,  $\lambda \in \bar{\mathbb{R}}_{\max}$ , and  $x \in X$ . Note that the natural order on  $\bar{\mathbb{R}}_{\max}^X$  arising from the idempotent addition, i.e., the order defined by  $u \leq v \iff u \oplus v = v$ , corresponds to the componentwise partial order  $u \leq v \iff$

$u(x) \leq v(x)$  for all  $x \in X$ . Then  $\bar{\mathbb{R}}_{\max}^X$  has the property of being complete as a semi-module, which means again that any subset has a least upper bound (with respect to the natural order) and the right and left multiplications  $R_\lambda : \bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^X : u \mapsto u\lambda$  and  $L_u : \bar{\mathbb{R}}_{\max} \rightarrow \bar{\mathbb{R}}_{\max}^X : \lambda \mapsto u\lambda$  are residuated. This in turn means that the sets  $\{u \in \bar{\mathbb{R}}_{\max}^X : u\lambda \leq v\}$  and  $\{\lambda \in \bar{\mathbb{R}}_{\max} : u\lambda \leq v\}$  both have maximal elements.

Now consider a map  $f : S \rightarrow T$  between partially ordered sets  $S$  and  $T$ . Suppose that  $f$  is monotone, i.e.,  $s \leq s' \Rightarrow f(s) \leq f(s')$ . Then  $f$  is said to be residuated if and only if for all  $t \in T$ , the set  $\{s \in S : f(s) \leq t\}$  has a maximal element. The residual map  $f^\# : T \rightarrow S$  is then defined as

$$f^\#(t) = \max\{s \in S : f(s) \leq t\}.$$

It follows that the left multiplication map  $L_u : \bar{\mathbb{R}}_{\max} \rightarrow \bar{\mathbb{R}}_{\max}^X$  is residuated. The action of the residual map  $L_u^\#$  on a given  $v \in \bar{\mathbb{R}}_{\max}^X$  is then defined as

$$L_u^\#(v) = \max\{\lambda \in \bar{\mathbb{R}}_{\max} : u\lambda \leq v\}.$$

Now let  $X$  and  $Y$  be sets and consider an operator  $A : \bar{\mathbb{R}}_{\max}^Y \rightarrow \bar{\mathbb{R}}_{\max}^X$  from  $\bar{\mathbb{R}}_{\max}$  valued functions on  $Y$  to  $\bar{\mathbb{R}}_{\max}$  valued functions on  $X$ . Such an operator is called linear if, for all  $u_1, u_2 \in \bar{\mathbb{R}}_{\max}^Y$ , and  $\lambda_1, \lambda_2 \in \bar{\mathbb{R}}_{\max}$ ,  $A(u_1\lambda_1 \oplus u_2\lambda_2) = A(u_1)\lambda_1 \oplus A(u_2)\lambda_2$ . Given some  $\bar{\mathbb{R}}_{\max}$  valued function  $a \in \bar{\mathbb{R}}_{\max}^{X \times Y}$  on  $X \times Y$ , we are then interested in the linear operator  $A : \bar{\mathbb{R}}_{\max}^Y \rightarrow \bar{\mathbb{R}}_{\max}^X$  with kernel  $a$  which maps any function  $u \in \bar{\mathbb{R}}_{\max}^Y$  to the function  $Au \in \bar{\mathbb{R}}_{\max}^X$  defined, in terms of the normal arithmetic operations on  $\mathbb{R}$ , by

$$(8) \quad Au(x) = \sup_{y \in Y} \{a(x, y) + u(y)\}.$$

Then, as shown in [3], this kernel operator  $A$  is residuated; i.e., for any  $v \in \bar{\mathbb{R}}_{\max}^X$ , the set  $\{u \in \bar{\mathbb{R}}_{\max}^Y : Au \leq v\}$  has a maximal element. The residual map  $A^\# : \bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^Y$  then takes any  $v \in \bar{\mathbb{R}}_{\max}^X$  to this maximal element in  $\bar{\mathbb{R}}_{\max}^Y$  defined, again in terms of the normal arithmetic operations on  $\mathbb{R}$ , as the function

$$(9) \quad (A^\#v)(y) = \inf_{x \in X} \{-a(x, y) + v(x)\}.$$

The next notion to be introduced, for a kernel operator  $B : \bar{\mathbb{R}}_{\max}^Y \rightarrow \bar{\mathbb{R}}_{\max}^X$ , is that of projection on the image  $\text{im}B$  of  $B$ . The projector is denoted  $P_{\text{im}B}$  and is a map  $\bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^X$  defined for all  $v \in \bar{\mathbb{R}}_{\max}^X$  by

$$P_{\text{im}B}(v) = \max\{w \in \text{im}B : w \leq v\}.$$

As shown in [4], this projector on the subsemimodule  $\text{im}B$  can be expressed as a composition

$$P_{\text{im}B} = B \circ B^\#$$

of  $B$  and its residual  $B^\#$ . If  $b(x, y)$  denotes the kernel of  $B$ , then this formula can be expressed, in the normal arithmetic of  $\mathbb{R}$ , as

$$(10) \quad B \circ B^\#(v)(x) = \sup_{y \in Y} \left( b(x, y) + \inf_{\xi \in X} (-b(\xi, y) + v(\xi)) \right).$$

Given a kernel operator  $C : \bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^Z$  with kernel  $c(z, x)$ , we can consider the transposed operator  $C^* : \bar{\mathbb{R}}_{\max}^Z \rightarrow \bar{\mathbb{R}}_{\max}^X$  with kernel  $c^*(x, z) = c(z, x)$ . We can then define a dual projector on the  $\bar{\mathbb{R}}_{\min}$ -subsemimodule  $-\text{im}C^*$  in terms of

$$P^{-\text{im}C^*}(v) = \min\{w \in -\text{im}C^* : w \geq v\}$$

for all  $v \in \bar{\mathbb{R}}_{\max}^X$ . Then, as above, this projector can be expressed as a composition

$$P^{-\text{im}C^*} = C^\# \circ C,$$

which, in the normal arithmetic of  $\mathbb{R}$ , has the form

$$(11) \quad C^\# \circ C(v)(x) = \inf_{z \in Z} \left( -c(z, x) + \sup_{\xi \in X} (c(z, \xi) + v(\xi)) \right).$$

In greater generality than given here, it is proved in Theorem 1 of [1] that, with  $\Pi_B^C := P_{\text{im}B} \circ P^{-\text{im}C^*}$ , then for all  $v \in \bar{\mathbb{R}}_{\max}^X$ ,

$$(12) \quad \Pi_B^C(v) = \max\{w \in \text{im}B : Cw \leq Cv\}.$$

Now we can define the max-plus FEM for approximating the value function  $v_a^t = v_a(\cdot, t)$  for the optimal control problem (4). Let  $Y = \{1, \dots, I\}$ ,  $X = \mathbb{R}^n$ , and  $Z = \{1, \dots, J\}$ . Consider a family  $\{w_1, \dots, w_I\}$  of finite element functions  $w_i : X \rightarrow \bar{\mathbb{R}}_{\max}$ , and a family  $\{z_1, \dots, z_J\}$  of test functions  $z_j : X \rightarrow \bar{\mathbb{R}}_{\max}$ . The vectors  $\lambda = (\lambda_i)_{i=1, \dots, I} \in \bar{\mathbb{R}}_{\max}^I$  and  $\mu = (\mu_j)_{j=1, \dots, J} \in \bar{\mathbb{R}}_{\max}^J$  can be considered as  $\bar{\mathbb{R}}_{\max}$  valued functions on  $Y$  and  $Z$ , respectively. So, as above in (8), we can define max-plus kernel operators  $W : \bar{\mathbb{R}}_{\max}^Y \rightarrow \bar{\mathbb{R}}_{\max}^X$  and  $Z^* : \bar{\mathbb{R}}_{\max}^Z \rightarrow \bar{\mathbb{R}}_{\max}^X$  with kernels  $W = \text{col}(w_i)_{1 \leq i \leq I}$  and  $Z^* = \text{col}(z_j)_{1 \leq j \leq J}$ . The action of  $W$ , which plays the role of operator  $B$  above, is

$$W\lambda(x) = \sup_{i \in Y} \{w_i(x) + \lambda_i\},$$

while  $Z^*$  gives rise to the transposed operator  $Z : \bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^Z$  which plays the role of operator  $C$  above, and acts as

$$(Zv)_j = \sup_{x \in X} \{z_j(x) + v(x)\} = \langle z_j | v \rangle,$$

where  $\langle \cdot | \cdot \rangle$  denotes the max-plus scalar product. Then from (10) and (11), we can give the specific form of the corresponding two projectors,

$$(13) \quad P_{\text{im}W}(v)(x) = \sup_{i \in Y} \left( w_i(x) + \inf_{\xi \in X} (-w_i(\xi) + v(\xi)) \right),$$

$$(14) \quad P^{-\text{im}Z^*}(v)(x) = \inf_{j \in Z} \left( -z_j(x) + \sup_{\xi \in X} (z_j(\xi) + v(\xi)) \right).$$

To start the algorithm, we approximate the initial data  $v_a^0 = \phi$  with the maximal element  $\leq v_a^0$  in the space  $\text{im}W$  spanned by the finite element functions. The approximation of  $v_a^0$  is denoted with a subscript  $h$  and takes the form

$$v_{ah}^0(x) = (W\lambda^0)(x) = \sup_{i \in Y} (w_i(x) + \lambda_i^0),$$

where the coefficients  $\lambda_i^0$  are determined from the residuation of  $W$  given in formula (9) as

$$(15) \quad \lambda_i^0 = \inf_{x \in X} (-w_i(x) + \phi(x)).$$

As an induction assumption, suppose that at time step  $q\tau$  we have a vector of coefficients  $\lambda_i^{q\tau}$  giving an approximation

$$v_{\hat{a}h}^{q\tau}(x) = \sup_{i \in Y} (w_i(x) + \lambda_i^{q\tau})$$

of  $v_{\hat{a}}^{q\tau}$  by the maximal element  $\leq v_{\hat{a}}^{q\tau}$  in the space  $\text{im}W$ . Then the approximation  $v_{\hat{a}h}^{(q+1)\tau}$  of  $v_{\hat{a}}^{(q+1)\tau}$  at the next time step can be calculated as

$$v_{\hat{a}h}^{(q+1)\tau}(\cdot) = P_{\text{im}W} \circ P^{-\text{im}Z^*} \circ S_{\hat{a}}^\tau \circ v_{\hat{a}h}^{q\tau}(\cdot)$$

The coefficients of this approximation are given, from (13) and (14), by

$$\lambda_i^{(q+1)\tau} = \inf_{\xi \in X} \left( -w_i(\xi) + \inf_{j \in Z} \left( -z_j(\xi) + \sup_{\eta \in X} (z_j(\eta) + S_{\hat{a}}^\tau \circ v_{\hat{a}h}^{q\tau}(\eta)) \right) \right).$$

It follows from (12) that  $v_{\hat{a}h}^{(q+1)\tau}$  is the maximal element in the space  $\text{im}W$  spanned by the finite element functions which satisfies  $Zv_{\hat{a}h}^{(q+1)\tau} \leq ZS_{\hat{a}}^\tau v_{\hat{a}h}^{q\tau}$ , i.e., the maximal element satisfying  $\langle z_j | v_{\hat{a}h}^{(q+1)\tau} \rangle \leq \langle z_j | S_{\hat{a}}^\tau v_{\hat{a}h}^{q\tau} \rangle$  for each test function  $z_j$ . So  $v_{\hat{a}h}^{(q+1)\tau}$  is the maximal solution to a max-plus variational formulation of the semigroup equation.

If (see section 3.3 of [1]) we further approximate the semigroup action  $S_{\hat{a}}^\tau v_{\hat{a}h}^{q\tau}$  by

$$(16) \quad \left( \tilde{S}_{\hat{a}}^\tau v_{\hat{a}h}^{q\tau} \right)(x) = \sup_{i \in Y} (w_i(x) + \lambda_i^{q\tau} + \tau H_{\hat{a}}(x, \partial w_i / \partial x)),$$

then  $\lambda_i^{(q+1)\tau}$  can be written explicitly as

$$(17) \quad \lambda_i^{(q+1)\tau} = \inf_{\xi \in X} \left( -w_i(\xi) + \inf_{j \in Z} \left( -z_j(\xi) + \sup_{\eta \in X} \left( z_j(\eta) + \sup_{k \in Y} (w_k(\eta) + \lambda_k^{q\tau} + \tau H_{\hat{a}}(\eta, \partial w_k / \partial x|_{\eta})) \right) \right) \right).$$

It is shown in [1] that the error  $\|v_{\hat{a}h}^T - v_{\hat{a}}^T\|_\infty$  on this approximation of the value function at time  $T$  is less than the sum of the approximation errors

$$\|P_{\text{im}W}(v_{\hat{a}}^{q\tau}) - v_{\hat{a}}^{q\tau}\|_\infty \quad \text{and} \quad \|P^{-\text{im}Z^*}(v_{\hat{a}}^{q\tau}) - v_{\hat{a}}^{q\tau}\|_\infty$$

for  $q = 0, \dots, N$ , arising from the projections on  $\text{im}W$  and  $-\text{im}Z^*$ , plus a term  $\sup_{i \in Y} \|\tilde{S}_{\hat{a}}^\tau w_i - S_{\hat{a}}^\tau w_i\|_\infty$  arising from the approximation of the semigroup action on the finite elements  $w_i$ .

In particular, if we choose two sets  $(\hat{x}_i)_{i \in Y}$  and  $(\hat{x}_j)_{j \in Z}$  of discretization points, and take the finite element functions to be  $w_i(x) = -\frac{c}{2} \|x - \hat{x}_i\|_2^2$  for some fixed constant  $c$ , and test functions to be  $z_j(x) = -\alpha \|x - \hat{x}_j\|_1$  for some fixed constant  $\alpha$ , then by Theorem 22 of [1] the error  $\|v_{\hat{a}h}^T - v_{\hat{a}}^T\|_\infty = O(\tau + \Delta x(\tau)^{-1})$ , where  $\Delta x$  is the maximal radius of the cells of the two Voronoi tessellations centered on the points  $(\hat{x}_i)_{i \in Y}$  and  $(\hat{x}_j)_{j \in Z}$ , respectively. See [10] for details on Voronoi tessellations. Below we will consider two cases for the test functions  $z_j$ , the first being the notationally simpler, limiting case where  $\alpha \rightarrow \infty$ , and the second being the more general case of  $\alpha < \infty$ .

#### 4. Policy iteration with max-plus FEM in the value determination step.

Recall from section 2 that  $p$  denotes the cycle index within the policy iteration algorithm, and  $q \in \{0, \dots, N-1\}$  denotes the time step index. Recall also that we restrict consideration of time-dependent feedback control policies  $a(x, t)$  to those in the form of sequences of  $N$  constant-in-time policy components  $(a^0(x), \dots, a^{N-1}(x))$ . In this section, we further restrict our choice of the individual policy components to functions  $a^q(\cdot)$  chosen from the set  $A = \{a(\cdot) : X \rightarrow U\}$  of functions which are locally constant with respect to  $x$  on cells of the Voronoi tessellation  $V_Z$  centered on the origins  $(\hat{x}_j)_{j \in Z}$  of the test functions  $z_j$ .

So suppose, as an induction hypothesis, that on iteration  $p$ , we have a set of constant vectors  $\{a_p^{qj}\}$  for  $q \in \{0, \dots, N-1\}$  and  $j \in Z$ , where each  $a_p^{qj} \in U \subseteq \mathbb{R}^m$ . These give rise to a fixed policy  $a_p$  which, for a given  $q$ , takes the form  $a_p^q(x) = a_p^{q\mu(x)}$ , where  $\mu(x) \in Z$  is the index of the cell of the Voronoi tessellation  $V_Z$  containing  $x$ . Note that the process can be initiated for  $p = 0$  by choosing some set of fixed vectors  $a^j$  (say, for all  $j$ , set them equal to the zero vector) such that  $a_0^q(x) = a^j$  for all  $q \in \{0, \dots, N-1\}$  and for all  $x \in \text{cell } j$  of  $V_Z$ , where cell  $j$  is the one centered on the origin  $\hat{x}_j$  of test function  $z_j$ .

**4.1. Value determination step.** The max-plus FEM outlined above can be applied to approximate the value function  $v_{a_p}^t$  solving the optimal control problem (4) with fixed strategy  $a_p$ . The coefficients of the expansion of this approximation, with respect to the finite elements  $w_i$ , are obtained as follows. For  $q = 0$  and  $i \in Y$ , the coefficients  $\lambda_{pi}^0 = \lambda_i^0$  are defined in (15) above. Then, using (17), for  $q \in \{0, \dots, N-1\}$  and  $i \in Y$  we get

$$\lambda_{pi}^{(q+1)\tau} = \inf_{\xi \in X} \left( -w_i(\xi) + \inf_{j \in Z} \left( -z_j(\xi) + \sup_{\eta \in X} \left( z_j(\eta) + \sup_{k \in Y} \left( w_k(\eta) + \lambda_{pk}^{q\tau} + \tau H_{a_p^q}(\eta, \partial w_k / \partial x|_{\eta}) \right) \right) \right) \right).$$

Note that in the Hamiltonian  $H_{a_p^q}$  we apply the policy  $a_p^q(\eta) = a_p^{q\mu(\eta)}$ , where  $\mu(\eta) \in Z$  is the index of the cell of the Voronoi tessellation  $V_Z$  containing  $\eta$ . The above can be rearranged to give

$$\begin{aligned} \lambda_{pi}^{(q+1)\tau} &= \inf_{j \in Z} \left( \inf_{\xi \in X} (-w_i(\xi) - z_j(\xi)) + \sup_{\eta \in X} \left( z_j(\eta) + \sup_{k \in Y} \left( w_k(\eta) + \lambda_{pk}^{q\tau} + \tau H_{a_p^q}(\eta, \partial w_k / \partial x|_{\eta}) \right) \right) \right) \\ &= \inf_{j \in Z} \left( -\langle w_i | z_j \rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \sup_{\eta \in X} (z_j(\eta) + w_k(\eta) + \tau H_{a_p^q}(\eta, \partial w_k / \partial x|_{\eta})) \right) \right). \end{aligned}$$

For a given policy  $a$ , let

$$(18) \quad T_{jka} = \sup_{\eta \in X} (z_j(\eta) + w_k(\eta) + \tau H_a(\eta, \partial w_k / \partial x|_{\eta})).$$

In the normal max-plus FEM, the  $T_{jka}$  terms can be calculated offline. This would be difficult in the application of max-plus FEM to policy iteration, since we don't know

the policies  $a$  in advance. The relevant  $a$  for each  $p$  iteration is known at the start of that iteration and so, in principle, the next set of  $T_{jka}$  terms for a given  $a$  could be calculated at the start of that iteration. However, this would be slow. An alternative is to approximate the  $T_{jka}$  online by

$$(19) \quad \tilde{T}_{jka} = \langle z_j | w_k \rangle + \tau H_a \left( \eta_{jk}^{opt}, \partial w_k / \partial x |_{\eta_{jk}^{opt}} \right),$$

where  $\eta_{jk}^{opt} = \arg \sup \langle z_j | w_k \rangle = \arg \sup (z_j(\eta) + w_k(\eta))$ . Note that this approximation  $\tilde{T}$  is presented in [1], where it is shown in Theorem 22 that the resulting error estimate on the max-plus FEM deteriorates to  $\|v_{ah}^T - v_a^T\|_\infty = O(\sqrt{\tau} + \Delta x(\tau)^{-1})$ . So, finally, the coefficients of the expansion of the approximation to the value function  $v_{a_p}^t$  for fixed strategy  $a_p$  are given by

$$(20) \quad \lambda_{pi}^{(q+1)\tau} = \inf_{j \in Z} \left( -\langle w_i | z_j \rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{jka_p^q} \right) \right).$$

**4.2. Policy improvement step.** For each  $i$  and  $q$ , there exists  $\bar{j}(iq) \in Z$ , which achieves the inf in (20), so that

$$(21) \quad \lambda_{pi}^{(q+1)\tau} = -\langle w_i | z_{\bar{j}} \rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}ka_p^q} \right).$$

For each  $k$ , the Hamiltonian within  $\tilde{T}_{\bar{j}ka_p^q}$  is evaluated at  $\eta_{jk}^{opt}$ , and so the strategy  $a_p^q$  applied in the Hamiltonian term takes the value  $a_p^{q\mu(\bar{j}k)}$ , where  $\mu(\bar{j}k) \in Z$  is the index of the cell of the Voronoi tessellation  $V_Z$  containing  $\eta_{jk}^{opt}$ .

Now suppose, as our first simpler case, that the constant term  $\alpha \rightarrow \infty$  in the test functions  $z_j(x) = -\alpha \|x - \hat{x}_j\|_1$ . The test functions are therefore defined as

$$(22) \quad z_j = \begin{cases} 0 & \text{at } x = \hat{x}_j, \\ -\infty & \text{otherwise} \end{cases}$$

for each  $j \in Z$ .

Then we have  $\eta_{jk}^{opt} = \hat{x}_{\bar{j}}$  for all  $k \in Y$ , and the index  $\mu(\bar{j}k) \in Z$  of the cell of the Voronoi tessellation  $V_Z$  containing  $\hat{x}_{\bar{j}}$  can be denoted simply  $\mu(\bar{j})$ . We note that  $\mu(\bar{j})$  can of course be represented simply as  $\bar{j}$ . However, it is useful for developing the later discussion of general test functions if we denote the cell index in the current discussion by  $\mu(\bar{j})$ .

It follows that  $a_p^q(\hat{x}_{\bar{j}}) = a_p^{q\mu(\bar{j})}$  is the policy value applied in the Hamiltonian term in  $\tilde{T}_{\bar{j}ka_p^q}$  for all  $k$ . So every term  $\tilde{T}_{\bar{j}ka_p^q}$  uses the same policy value  $a_p^{q\mu(\bar{j})}$  for all  $k \in Y$  within the  $\sup_{k \in Y}$  operation in (21).

Now let  $\bar{k}(iq) = \arg \sup_{k \in Y}$  in (21), so that

$$\lambda_{pi}^{(q+1)\tau} = -\langle w_i | z_{\bar{j}} \rangle + \lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^q}.$$

Then we can improve the policy  $a_p^q$  in cell  $\mu(\bar{j})$  of  $V_Z$  by taking

$$(23) \quad \min_{a \in U} \tilde{T}_{\bar{j}\bar{k}a}$$

subject to

$$(24) \quad \lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a} \geq \lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^q}$$

for all  $k \in Y$ , i.e., subject to

$$\lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a} \geq \sup_{k \neq \bar{k} \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}ka} \right).$$

This optimization is feasible since the current policy value  $a_p^{q\mu(\bar{j})}$  satisfies

$$\lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^{q\mu(\bar{j})}} \geq \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}ka_p^{q\mu(\bar{j})}}$$

for all  $k \in Y$ . Furthermore, the function  $\tilde{T}_{\bar{j}\bar{k}a}$  is convex in  $a$ . In fact, the Hamiltonian within  $\tilde{T}_{\bar{j}\bar{k}a}$  is evaluated at fixed  $x = \hat{x}_{\bar{j}}$  and  $p = \partial w_{\bar{k}} / \partial x|_{\hat{x}_{\bar{j}}}$  and so is a positive definite quadratic form in  $a$ . Similarly, expanding the constraint (24) for each  $k$ , as is done below in section 4.3, shows that this is just a set of linear constraints in  $a$ . So the optimization (23) is a positive definite quadratic program and has a unique global minimum.

**THEOREM 4.1.** *For each  $q \in \{0, \dots, N-1\}$  and  $i \in Y$ , there is a  $\bar{j}(iq)$  and a  $\bar{k}(iq)$  defined as above. For this  $\bar{j}$  and  $\bar{k}$ , let  $\bar{a} = \arg \min_{a \in U} \tilde{T}_{\bar{j}\bar{k}a}$  subject to the constraint (24). For all  $x \in \text{cell}$  with index  $\mu(\bar{j})$  of the Voronoi tessellation  $V_Z$ , take new policy*

$$a_{p+1}^q(x) = a_{p+1}^{q\mu(\bar{j})} := \bar{a}.$$

*Note that for each  $q$ , there may be some remaining cells of  $V_Z$  whose indices  $\neq \mu(\bar{j}(iq))$  for any  $i \in Y$ . In these cells we leave the policy at time step  $q$  unchanged; i.e., if  $\mu^*$  is the index of such a cell, then for all  $x \in \text{cell}$  with index  $\mu^*$ ,*

$$a_{p+1}^q(x) = a_p^{q\mu^*}.$$

*Then the resulting new policy  $a_{p+1} = \{a_{p+1}^{qj}\}$  is an improvement on the old one  $a_p = \{a_p^{qj}\}$  in the sense that the corresponding functions  $v_{a_{(p+1)h}}^{q\tau}$  and  $v_{a_ph}^{q\tau}$ , i.e., the approximations to the value functions which solve the optimal control problem (4) with fixed policies  $a_{p+1}$  and  $a_p$ , respectively, satisfy*

$$(25) \quad v_{a_{(p+1)h}}^{q\tau} \leq v_{a_ph}^{q\tau}$$

*for all  $q \in \{0, \dots, N\}$ . Furthermore, this sequence of policy improvements terminates after at most  $N$  steps, so that the sequence  $\{v_{a_{Nh}}^{\tau}(\cdot), \dots, v_{a_{Nh}}^{N\tau}(\cdot)\}$  constitutes a time-discretized finite element approximation to the value function  $v^t$  of the differential game (1).*

*Proof.* First we deal with uniqueness. If, for a given  $q$ , there are two  $i$  giving rise to the same  $\bar{j}(iq)$ , then these both result in the same policy improvement  $a_{p+1}^q(x) = \bar{a}$  in cell  $\mu(\bar{j})$  since the term  $\tilde{T}_{\bar{j}\bar{k}a_p^q}$  in (21) does not depend on  $i$ . Similarly, if there are  $i_1$  and  $i_2$  giving rise to  $\bar{j}_1 = (i_1q) \neq \bar{j}(i_2q) = \bar{j}_2$ , then the corresponding cells  $\mu(\bar{j}_1)$  and  $\mu(\bar{j}_2)$  of  $V_Z$  are different, and so the optimizations (23) and (24), applied separately to  $\bar{j}_1$  and  $\bar{j}_2$ , give rise to policy improvements in different cells of  $V_Z$ .

Next, we show that the above quadratic program does lead to a policy improvement. Suppose, with a view to induction on  $q$ , that  $\lambda_{(p+1)i}^{q\tau} \leq \lambda_{pi}^{q\tau}$  for all  $i$ . Then

$$\begin{aligned}
 \lambda_{pi}^{(q+1)\tau} &= -\langle w_i | z_{\bar{j}} \rangle + \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^q} \\
 &= -\langle w_i | z_{\bar{j}} \rangle + \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^{q\mu(\bar{j})}} \\
 &\geq -\langle w_i | z_{\bar{j}} \rangle + \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}\bar{a}} \\
 &= -\langle w_i | z_{\bar{j}} \rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}\bar{a}} \right) \\
 &\geq -\langle w_i | z_{\bar{j}} \rangle + \sup_{k \in Y} \left( \lambda_{(p+1)k}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}\bar{a}} \right) \\
 &= -\langle w_i | z_{\bar{j}} \rangle + \sup_{k \in Y} \left( \lambda_{(p+1)k}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_{p+1}^q} \right)
 \end{aligned}$$

since every term  $\tilde{T}_{\bar{j}\bar{k}a_{p+1}^q}$  uses the same policy value in the same cell  $\mu(\bar{j})$ . So

$$(26) \quad \lambda_{pi}^{(q+1)\tau} \geq \inf_{\bar{j}} \left( -\langle w_i | z_{\bar{j}} \rangle + \sup_{k \in Y} \left( \lambda_{(p+1)k}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_{p+1}^q} \right) \right) = \lambda_{(p+1)i}^{(q+1)\tau}.$$

Since this holds for all  $i$ , it then follows that for any  $x \in X$ ,

$$\sup_i \left( \lambda_{(p+1)i}^{(q+1)\tau} + w_i(x) \right) \leq \sup_i \left( \lambda_{pi}^{(q+1)\tau} + w_i(x) \right),$$

i.e.,  $v_{a_{(p+1)h}}^{(q+1)\tau}(x) \leq v_{a_ph}^{(q+1)\tau}(x)$ . The proof follows by induction, after noting that from (15) the coefficients at the initial time step  $q = 0$  satisfy  $\lambda_{(p+1)i}^0 = \lambda_{pi}^0 = \lambda_i^0$ .

Lastly, we deal with termination in  $N$  steps. Again this is done by induction on  $q$ . To start with, note that the coefficients  $\lambda_i^0$  at the zeroth time step are independent of all choices of control policy and so constitute a terminal point for the policy iteration algorithm at step  $q = 0$  of the time discretization, i.e.,  $\lambda_{(p+1)i}^0 = \lambda_{pi}^0 = \lambda_i^0$  for all  $p \geq 0$ .

Suppose as an induction hypothesis that the coefficients  $\lambda_{pi}^{q\tau}$  for the  $q$ th time discretization step stabilize after  $p = q$  iterations of the above policy improvement process, i.e.,  $\lambda_{(p+1)i}^{q\tau} = \lambda_{pi}^{q\tau}$  for all  $p \geq q$ . Then consider what happens to  $\lambda_{(p+1)i}^{(q+1)\tau}$  for a given  $i \in Y$  during the  $(p+1)$ th policy improvement iteration. First, we identify the active  $\bar{j}(iq) \in Z$  and  $\bar{k}(iq) \in Y$ , which achieve the inf and sup in (20) and (21), respectively. Then we perform the minimization (23) subject to constraints (24) with these values of  $\bar{j}$  and  $\bar{k}$ . Now, as noted above, this is a positive definite quadratic program in  $a$  and so has a unique global minimum  $\bar{a}$ , which represents the policy to be applied at time step  $q$  in cell  $\mu(\bar{j})$  on iteration  $(p+1)$ . Furthermore, the  $\lambda_{pk}^{q\tau}$  terms appearing in (24) are all assumed by induction to be constant for all  $p \geq q$ , and all the other terms appearing in (23) and (24) are fixed by our choice of  $\bar{j}$  and  $\bar{k}$ . So the improved policy  $\bar{a}$ , computed on iteration  $(p+1)$  and to be applied at time step  $q$  in cell  $\mu(\bar{j})$ , is unique and will not change if recomputed for the same time step  $q$  and index  $\bar{j}$  at any later iteration  $(p+r) > (p+1)$  of the policy improvement cycle.

Now examination of (26) shows that, for each  $i$ , two things can happen on the  $(p+1)$ th policy improvement iteration during the improvement from  $\lambda_{pi}^{(q+1)\tau}$  to  $\lambda_{(p+1)i}^{(q+1)\tau}$ . First, the active  $\bar{j}(iq)$  which achieves the inf can remain the same. In this case, the above described unique improvement  $\bar{a}$  to the policy applied at time step

$q$  in cell  $\mu(\bar{j})$  continues to be the policy value applied in the Hamiltonian term appearing within  $\tilde{T}_{\bar{j}\bar{k}a_{p+1}^q}$  in the evaluation of  $\lambda_{(p+1)i}^{(q+1)\tau}$ . This then remains unchanged by subsequent policy improvement iterations.

Alternatively, the active  $\bar{j}(iq)$  which achieves the inf can change in (26) between iteration  $p$  and  $(p+1)$ . Let  $\bar{j}_p$  and  $\bar{j}_{p+1}$  denote the active  $\bar{j}$  on iterations  $p$  and  $(p+1)$ , respectively. Then on iteration  $p$  we have

$$\lambda_{pi}^{(q+1)\tau} = -\left\langle w_i | z_{\bar{j}_p} \right\rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}_p k a_p^q} \right),$$

while on iteration  $(p+1)$  we have

$$\begin{aligned} \lambda_{(p+1)i}^{(q+1)\tau} &= -\left\langle w_i | z_{\bar{j}_{p+1}} \right\rangle + \sup_{k \in Y} \left( \lambda_{(p+1)k}^{q\tau} + \tilde{T}_{\bar{j}_{p+1} k a_{p+1}^q} \right) \\ &= -\left\langle w_i | z_{\bar{j}_{p+1}} \right\rangle + \sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}_{p+1} k a_{p+1}^q} \right) \end{aligned}$$

by our induction hypothesis. So for the active  $\bar{j}$  to change, the term

$$\sup_{k \in Y} \left( \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}_{p+1} k a_{p+1}^q} \right)$$

must have decreased during the  $(p+1)$ th policy improvement iteration. In other words,  $\bar{j}_{p+1} = \bar{j}(i^*q)$  must be the value of  $j$  which achieves the inf in (20) on iteration  $p$  for some other  $i^* \neq i$ . The optimization in (23) and (24) must therefore also be evaluated for this  $\bar{j}(i^*q)$ , on the same iteration  $(p+1)$  of policy improvement, to produce a unique improvement (denote it as  $\bar{a}^*$ ) applied at time step  $q$  in cell  $\mu(\bar{j}(i^*q))$ . The improvement  $\bar{a}^*$  in this particular cell is then applied in the Hamiltonian term appearing within  $\tilde{T}_{\bar{j}_{p+1}\bar{k}a_{p+1}^q}$  in the evaluation of  $\lambda_{(p+1)i}^{(q+1)\tau}$ . By the same argument as above, this policy value  $\bar{a}^*$ , applied at time step  $q$  in cell  $\mu(\bar{j}(i^*q))$ , then remains unchanged by subsequent policy improvement iterations.

It follows that in both cases  $\lambda_{(p+2)i}^{(q+1)\tau} = \lambda_{(p+1)i}^{(q+1)\tau}$  for  $p \geq q$ , i.e., for  $p+1 \geq q+1$ , and the induction step is proved. Since there is a total of  $N$  steps in the time discretization, the policy improvement algorithm converges after  $N$  steps.  $\square$

It follows from the above proof that, as mentioned at the end of section 2, the algorithm in practice can be implemented without needing to cycle through policy iterations, but rather can be implemented like a value iteration, with the above defined value determination and policy improvement steps applied to each step of the time discretization in turn.

**4.3. Quadratic program optimization.** The Hamiltonian appearing in (5) has the form

$$\begin{aligned} H_a(x, p) &= \max_b \{ p f_a(x, b) + l_a(x, b) \} \\ &= p(f + ga) + \frac{1}{2}x^2 + \frac{1}{2}a^2 + \frac{1}{2\gamma^2}phh^T p, \end{aligned}$$

and for  $z_j$  given by (22),  $\tilde{T}_{\bar{j}\bar{k}a}$  has the specific form

$$\tilde{T}_{\bar{j}\bar{k}a} = w_{\bar{k}}(\hat{x}_{\bar{j}}) + \tau H_a(\hat{x}_{\bar{j}}, \partial w_{\bar{k}} / \partial x |_{\hat{x}_{\bar{j}}}).$$

The policy improvement optimization set out in (23) and (24) can then be formulated as

$$\min_{a \in U} \tau H_a(\hat{x}_{\bar{j}}, \partial w_{\bar{k}} / \partial x |_{\hat{x}_{\bar{j}}})$$

subject to

$$\tau H_a(\hat{x}_{\bar{j}}, \partial w_{\bar{k}} / \partial x|_{\hat{x}_{\bar{j}}}) \geq \lambda_{pk}^{q\tau} - \lambda_{p\bar{k}}^{q\tau} + w_k(\hat{x}_{\bar{j}}) - w_{\bar{k}}(\hat{x}_{\bar{j}}) + \tau H_a(\hat{x}_{\bar{j}}, \partial w_k / \partial x|_{\hat{x}_{\bar{j}}})$$

for all  $k \in Y$ . This can be simplified into the quadratic program

$$\min_{a \in U} \left( \frac{\partial w_{\bar{k}}}{\partial x} ga + \frac{1}{2} a^2 \right)$$

subject to

$$\begin{aligned} \left( \frac{\partial w_{\bar{k}}}{\partial x} - \frac{\partial w_k}{\partial x} \right) ga &\geq \frac{1}{\tau} (w_k - w_{\bar{k}}) + \frac{1}{\tau} (\lambda_{pk}^{q\tau} - \lambda_{p\bar{k}}^{q\tau}) \\ &+ \frac{1}{2\gamma^2} \left( \frac{\partial w_k}{\partial x} - \frac{\partial w_{\bar{k}}}{\partial x} \right)^T h h^T \left( \frac{\partial w_k}{\partial x} + \frac{\partial w_{\bar{k}}}{\partial x} \right) \\ &+ \left( \frac{\partial w_k}{\partial x} - \frac{\partial w_{\bar{k}}}{\partial x} \right) f \end{aligned}$$

for all  $k \in Y$ , and evaluated at  $\hat{x}_{\bar{j}}$ . It can thus be seen that the constraints (24) are just a set of linear constraints on  $a$ .

It is interesting to examine the two cases under which the unique minimum of (23) and (24) is obtained. The first case is an unconstrained minimum and occurs at

$$a = -g^T(\hat{x}_{\bar{j}}) \frac{\partial w_{\bar{k}}}{\partial x} \Big|_{\hat{x}_{\bar{j}}} = c g^T(\hat{x}_{\bar{j}}) (\hat{x}_{\bar{j}} - \hat{x}_{\bar{k}}).$$

Now the max-plus FEM, with test functions given by (22), only evaluates the control feedback at the points  $\hat{x}_{\bar{j}}$ . So for  $x \in \text{cell } \mu(\bar{j})$  of  $V_Z$ , we can consider this unconstrained minimum to be an approximation to the feedback

$$(27) \quad \hat{a}(x) = -g^T(x) \frac{\partial w_{\bar{k}}}{\partial x} \Big|_x = c g^T(x) (x - \hat{x}_{\bar{k}}).$$

Furthermore, as in the proof of the above theorem, if this unconstrained minimum represents the feedback to be applied in cell  $\mu(\bar{j})$  at time step  $q$  and is obtained on iteration  $(p+1)$  of the policy improvement cycle, then we can assume that the value function  $v_{a_{ph}}^{q\tau}$  at time step  $q$  has already converged on iteration  $p$  to the finite element approximation to the value function for the differential game (1). In other words, on iteration  $(p+1)$ , the initial condition for the  $(q+1)$ th time step is the final approximation, obtained on iteration  $p$ , to the optimal value of the differential game at time step  $q$ . If we examine (16) and (17), we can see that this final approximation term, evaluated at  $\eta_{\bar{j}\bar{k}}^{opt} = \hat{x}_{\bar{j}}$ , is given by

$$(28) \quad v_{a_{ph}}^{q\tau}(\hat{x}_{\bar{j}}) = w_{\bar{k}}(\hat{x}_{\bar{j}}) + \lambda_{p\bar{k}}^{q\tau},$$

where  $\lambda_{p\bar{k}}^{q\tau}$  is the final value of the  $\bar{k}$ th coefficient of the value function at time step  $q$ . Now, by the Pontryagin maximum principle, along an extremal of the Hamilton–Jacobi–Isaacs equation (3),  $a(\cdot)$  should satisfy (27). Within the cell  $\mu(\bar{j})$ , the initial condition for the Cauchy problem (3) is given (approximately) by the smooth function (28), and so for sufficiently small time step  $\tau$ , this extremal will be unique, and therefore optimal. Hence, the unconstrained minimum represents an approximation

to the classical optimal feedback solution to the problem (1) in the case where there is a unique extremal over time step  $\tau$ , as identified, for instance, in [12, 13].

The second case is a constrained minimum and occurs when

$$(29) \quad \lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a} = \lambda_{pk}^{q\tau} + \tilde{T}_{\bar{j}ka}$$

for some  $k \in Y$  with  $k \neq \bar{k}$ . To understand what is happening here, we note that the term  $\tilde{T}_{\bar{j}ka}$  defined in (19) is an approximation to the term  $T_{\bar{j}ka}$  defined in (18), which in turn, if we go back to (16) and (17), can be seen to be the  $\bar{j}$ th coefficient of the projection on the space of test functions of the approximation of the semigroup

$$\tilde{S}_a^\tau w_k$$

at time step  $q+1$ , acting on the basis function  $w_k$  at time step  $q$ . If we combine this with (28), then we can see that the left-hand side of (29) is the approximate evaluation at  $\eta_{\bar{j}\bar{k}}^{opt} = \hat{x}_{\bar{j}}$  of the semigroup  $\tilde{S}_a^\tau$  acting on the initial condition  $w_{\bar{k}} + \lambda_{p\bar{k}}^{q\tau}$ , while the right-hand side is evaluation at  $\eta_{\bar{j}k}^{opt} = \hat{x}_{\bar{j}}$  of the same semigroup acting on the initial condition  $w_k + \lambda_{pk}^{q\tau}$ . So the left-hand side of (29) corresponds to the action of the semigroup on the particular component of the basis expansion of  $v_{a_p h}^{q\tau}$  which turns out to be active in cell  $\mu(\bar{j})$  at time step  $q+1$ , namely, the component corresponding to the  $\bar{k}$  which achieves the sup in (21). As the policy  $a$  applied during the  $(q+1)$ th step is reduced in the  $(p+1)$ th cycle of policy iteration, the constraint in (29) becomes active for some  $k \neq \bar{k}$  when we can no longer uniquely identify the source of the active component in cell  $\mu(\bar{j})$  at time step  $q+1$ , i.e., when there are two extremals through  $\hat{x}_{\bar{j}}$ , one corresponding to the semigroup action in time  $\tau$  starting from initial data  $w_{\bar{k}} + \lambda_{p\bar{k}}^{q\tau}$  and the other corresponding to the same semigroup action over the same time period but starting from initial data  $w_k + \lambda_{pk}^{q\tau}$ .

**4.4. General case  $z_j$  test functions.** Recall from above that we have

$$\tilde{T}_{jka} = \langle z_j | w_k \rangle + \tau H_a \left( \eta_{jk}^{opt}, \partial w_k / \partial x |_{\eta_{jk}^{opt}} \right)$$

and

$$\eta_{jk}^{opt} = \arg \sup \langle z_j | w_k \rangle,$$

and assume now that for each  $j \in Z$ ,  $z_j(x) = -\alpha \|x - \hat{x}_j\|_1$  for some constant  $\alpha < \infty$ .

In order to obtain the above theorem in this more general case, we need only one condition, namely, that for a given  $j$ , the set of points  $\eta_{jk}^{opt} : k \in Y$  must lie in the same cell of the Voronoi tessellation  $V_Z$  as the origin  $\hat{x}_j$  of the test function  $z_j$ . We denoted the index of this cell above as  $\mu(\bar{j})$ . This can clearly be arranged by a suitable choice of the two grids of origins  $\hat{x}_k$  and  $\hat{x}_j$  of the basis and test functions, respectively, since this choice is made in advance of the execution of the algorithm. We give here a simple sufficient condition which guarantees slightly more than this, namely, that for a given  $j$ ,  $\eta_{jk}^{opt} = \hat{x}_j$  for all  $k \in Y$ .

**LEMMA 4.2.** *Suppose that the fixed constant  $\alpha$  which appears in each test function  $z_j$  satisfies  $\frac{c}{2} \text{diam} X \leq \alpha$ , where  $c$  is the fixed constant which appears in each basis function  $w_k$  and  $X$  is the region of state space within which the problem is defined. Then for a given  $k \in Y$  and  $j \in Z$ , the function  $w_k(x) + z_j(x) = -\frac{c}{2} \|x - \hat{x}_k\|_2^2 - \alpha \|x - \hat{x}_j\|_1$  has a global maximum at  $\hat{x}_j$ .*

*Proof.*

$$\begin{aligned}
 -\frac{c}{2} \|\hat{x}_j - \hat{x}_k\|_2^2 - \alpha \|\hat{x}_j - \hat{x}_j\|_1 &= -\frac{c}{2} \|\hat{x}_j - \hat{x}_k\|_2^2 \\
 &\geq -\frac{c}{2} \|x - \hat{x}_k\|_2^2 - \frac{c}{2} \|x - \hat{x}_j\|_2^2 \\
 &\geq -\frac{c}{2} \|x - \hat{x}_k\|_2^2 - \frac{c}{2} \text{diam} X \|x - \hat{x}_j\|_1 \\
 &\geq -\frac{c}{2} \|x - \hat{x}_k\|_2^2 - \alpha \|x - \hat{x}_j\|_1. \quad \square
 \end{aligned}$$

Now we can repeat the argument of section 4.2. For each  $i$  and  $q$ , there exists  $\bar{j}(iq) \in Z$  which achieves the inf in (20). Then for each  $k$ , the Hamiltonian within the  $\tilde{T}_{\bar{j}ka_p^q}$  term is evaluated at  $\eta_{\bar{j}k}^{opt}$ , and by our assumption above, the grids of origins have been chosen so as to ensure that  $\eta_{\bar{j}k}^{opt} \in \text{cell } \mu(\bar{j})$  of  $V_Z$  for each  $k \in Y$ . It follows that the strategy  $a_p^q$  applied in the Hamiltonian term within  $\tilde{T}_{\bar{j}ka_p^q}$  takes the value  $a_p^{q\mu(\bar{j})}$ . Then let  $\bar{k}(iq) = \arg \sup_{k \in Y}$  in (21), so that

$$\lambda_{pi}^{(q+1)\tau} = -\langle w_i | z_{\bar{j}} \rangle + \lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a_p^q}.$$

Then we can improve the policy  $a_p^q$  in cell  $\bar{\mu}(\bar{j})$  of  $V_Z$  by taking

$$\min_{a \in U} \tilde{T}_{\bar{j}\bar{k}a}$$

subject to

$$\lambda_{p\bar{k}}^{q\tau} + \tilde{T}_{\bar{j}\bar{k}a} \geq \lambda_{pk}^{q\tau} + \tilde{T}_{jka}$$

for all  $k \in Y$ . As above, this optimization is a positive definite quadratic program and so has a unique minimum. So Theorem 4.1 still holds for this more general set of test functions; i.e., the above minimization gives a strict policy improvement on each iteration and terminates after at most  $N$  steps.

**5. Error estimation.** Recall that we are denoting by  $v^t$  the value function of the differential game (1). The projected policy iteration algorithm outlined in the previous section converges in a finite number of steps to a time-discretized finite element approximation to  $v^t$ , which we denote by  $v_h^t$ . Suppose that the final optimal policy for the projected policy iteration algorithm is  $a_1$ , and that the true optimal policy, in the same class of policies, for the exact problem is  $a_2$ . Then we can consider  $v_h^t$  to be the value function of the optimal control problem obtained by fixing  $a_1$  as the policy of the outer player in the projected version of the game, i.e.,  $v_h^t = v_{a_1h}^t$ . Similarly, we can consider  $v^t$  to be the value function of the optimal control problem obtained by fixing  $a_2$  as the policy of the outer player in the exact version of the game, i.e.,  $v^t = v_{a_2}^t$ . The semigroup  $S_{a_2}$  associated with this exact optimal control problem is then max-plus linear. Then we need to estimate

$$\|S_{a_1h} - S_{a_2}\|_\infty \leq \|S_{a_1h} - S_{a_2h}\|_\infty + \|S_{a_2h} - S_{a_2}\|_\infty,$$

where  $S_{a,h} = P_{\text{im}W} \circ P^{-\text{im}Z^*} \circ S_a$  is the projection of the semigroup action  $S_a$  with policy  $a$ . The second term on the right-hand side is the FEM error already estimated in Theorem 22 of [1], namely,  $O(\sqrt{\tau} + \Delta x(\tau)^{-1})$ , where the constant in the big- $O$  term

is expressed in terms of  $\text{diam}X$ , with the constants  $c$  and  $\alpha$  appearing in the basis and test functions, and Lipschitz constants and bounds for the two functions  $f_{a_2}$  and  $l_{a_2}$  appearing in (4). So to estimate the total error, it suffices to prove the following.

PROPOSITION 5.1.  $\|S_{a_1h} - S_{a_2h}\|_\infty = 0$ .

*Proof.* If  $a_1$  is also the final optimal policy for the exact algorithm, then  $a_1 = a_2$  and we are done.

Suppose  $a_1$  is not the optimal policy for the exact problem. Then since  $a_2$  has to be an improvement on  $a_1$ , we have  $S_{a_2} \leq S_{a_1}$  with respect to the natural order on  $\bar{\mathbb{R}}_{\max}^X$ . It follows from the lemma below that  $S_{a_2h} \leq S_{a_1h}$ . But since  $a_1$  is the final optimal policy for the projected algorithm, we must also have  $S_{a_1h} \leq S_{a_2h}$ . Hence  $S_{a_1h} = S_{a_2h}$ , and the result is proved.  $\square$

LEMMA 5.2. *For arbitrary residuated (kernel) operators  $B : \bar{\mathbb{R}}_{\max}^Y \rightarrow \bar{\mathbb{R}}_{\max}^X$  and  $C : \bar{\mathbb{R}}_{\max}^X \rightarrow \bar{\mathbb{R}}_{\max}^Z$  between complete semimodules of  $\bar{\mathbb{R}}_{\max}$  valued functions on sets  $Y$ ,  $X$ , and  $Z$ , let  $v_h = \Pi_B^C(v) = P_{\text{im}B} \circ P^{-\text{im}C^*} \circ v$ . If functions  $v_1 \geq v_2$  in the natural order on  $\bar{\mathbb{R}}_{\max}^X$ , then  $v_{1,h} \geq v_{2,h}$ .*

*Proof.* Recall from above that

$$\begin{aligned} P_{\text{im}B}(v) &= \max\{w \in \text{im}B : w \leq v\}, \\ P^{-\text{im}C^*}(v) &= \min\{w \in -\text{im}C^* : w \geq v\}. \end{aligned}$$

So, for  $v_1 \geq v_2$ , it follows that

$$(30) \quad P^{-\text{im}C^*}(v_1) \geq P^{-\text{im}C^*}(v_2).$$

Now

$$\begin{aligned} P_{\text{im}B} \circ P^{-\text{im}C^*}(v_1) &= \max\{w \in \text{im}B : w \leq P^{-\text{im}C^*}(v_1)\}, \\ P_{\text{im}B} \circ P^{-\text{im}C^*}(v_2) &= \max\{w \in \text{im}B : w \leq P^{-\text{im}C^*}(v_2)\}. \end{aligned}$$

By (30), any  $w$  in the second set must be  $\leq P^{-\text{im}C^*}(v_1)$ . Hence, any such  $w$  must be  $\leq \max\{w \leq P^{-\text{im}C^*}(v_1)\} = P_{\text{im}B} \circ P^{-\text{im}C^*}(v_1)$ , and so  $\max\{\text{any such } w\}$  must be  $\leq P_{\text{im}B} \circ P^{-\text{im}C^*}(v_1)$ , i.e.,  $P_{\text{im}B} \circ P^{-\text{im}C^*}(v_2) \leq P_{\text{im}B} \circ P^{-\text{im}C^*}(v_1)$  as required.  $\square$

**6. Conclusion.** In this paper, we have set out a policy iteration algorithm for the solution of a nonconvex nonlinear-affine finite horizon differential game. This involves the use of a max-plus finite element method (FEM) to solve a convex optimal control problem in the value determination step of the algorithm, where this convex problem is the result of fixing the policy of the second, or outer, player. A quadratic program is then solved in the policy improvement step in order to improve the control feedback. We have shown that the algorithm converges in a finite number of steps and that the approximation error at convergence is of order  $\sqrt{\tau} + \Delta x(\tau)^{-1}$ .

We make some brief remarks here on the question of how to formulate the policy iteration algorithm for the steady state solution to the corresponding infinite horizon differential game. The results of [9] give conditions under which the infinite horizon convex nonlinear-affine optimal control problem, arising from fixing the policy of the outer player, has a unique steady state solution. Furthermore, this reference gives an algorithm, which converges in a finite number of steps, for the computation of a max-plus approximation to this steady state solution. As remarked in section 4 of [1], this approximation can be considered as the limit of the above max-plus FEM in the case where the operator  $Z$  is the identity, i.e., where the space of test functions is the set of all functions. So if the infinite horizon differential game can be formulated in such a way that the conditions of [9] are satisfied by the corresponding optimal

control problem for all relevant choices of fixed outer player policy, then we have a guaranteed unique fixed point for each such problem, i.e., a unique solution to the max-plus linear problem

$$v_p = S_{\hat{a}_p}^\tau(v_p)$$

obtained by setting the outer player policy to  $\hat{a}_p$ . Furthermore we have an approximation to  $v_p$  in the form of a max-plus expansion relative to the basis of finite element functions  $\{w_i\}$ . As in section 2 above, we then compute the one step iteration

$$u_{p+1} = S^\tau(v_p)$$

of the nonconvex game and select a new (stationary) policy  $\hat{a}_{p+1}$ , which minimizes the right-hand side of the iteration. If we approximate  $v_p$  by its max-plus basis expansion, and use the max-plus FEM to compute the evolution of the coefficients  $\lambda_i$  of the max-plus basis expansion under the action of the semigroup with a given outer player policy, then we can use the policy improvement method of section 4.2 to determine the minimizing policy via a quadratic program. We can then compute the fixed point of the new convex optimal control problem

$$v_{p+1} = S_{\hat{a}_{p+1}}^\tau(v_{p+1})$$

obtained by setting the outer player policy to  $\hat{a}_{p+1}$ , again using the algorithm of [9]. Since

$$v_p = S_{\hat{a}_p}^\tau(v_p) \geq S^\tau(v_p) = u_{p+1} = S_{\hat{a}_{p+1}}^\tau(v_p)$$

it follows from Lemma 24 of [5] that  $v_p$  is  $\geq$  the fixed point of  $S_{\hat{a}_{p+1}}^\tau$ , i.e.,  $v_p \geq v_{p+1}$ . This descending sequence is bounded below by the fixed point of the nonconvex game, the existence of which on a nonlocal neighborhood of the origin is given by the results of [8] for the particular nonlinear affine form of game considered here, or more generally, by the results of [11].

Finally, by an argument similar to that described in the second to last paragraph of section 2, we could then hope to prove that the policy iteration on the infinite horizon differential game converges, subject to the following two pieces of work being successfully completed. The first, as mentioned above, is to formulate conditions on the infinite horizon differential game to ensure that the results of [9] can be applied to deduce unique fixed points for the sequence of infinite horizon convex optimal control problems. The second is to work out the details of combining the max-plus approximation of [9], for solving the eigenvector equation  $v_p = S_{\hat{a}_p}^\tau(v_p)$ , with the max-plus FEM approximation to the one step iteration  $u_{p+1} = S^\tau(v_p)$  of the nonconvex game and the policy improvement quadratic program for determining a new minimizing policy. This is left to a future paper.

**Acknowledgment.** I would like to thank Stephane Gaubert for useful conversations during the development of this paper.

## DISSIPATIVITY OF UNCONTROLLABLE SYSTEMS, STORAGE FUNCTIONS, AND LYAPUNOV FUNCTIONS\*

DEBASATTAM PAL<sup>†</sup> AND MADHU N. BELUR<sup>†</sup>

**Abstract.** Dissipative systems have played an important role in the analysis and synthesis of dynamical systems. The commonly used definition of dissipativity often requires an assumption on the controllability of the system. In this paper we use a definition of dissipativity that is slightly different (and less often used in the literature) to study a linear, time-invariant, possibly uncontrollable dynamical system. We provide a necessary and sufficient condition for an uncontrollable system to be strictly dissipative with respect to a supply rate under the assumption that the uncontrollable poles are not “mixed”; i.e., no pair of uncontrollable poles is symmetric about the imaginary axis. This condition is known to be related to the solvability of a Lyapunov equation; we link Lyapunov functions for autonomous systems to storage functions of an uncontrollable system. The set of storage functions for a controllable system has been shown to be a convex bounded polytope in the literature. We show that for an uncontrollable system the set of storage functions is unbounded, and that the unboundedness arises precisely due to the set of Lyapunov functions for an autonomous linear system being unbounded. Further, we show that stabilizability of a system results in this unbounded set becoming bounded from below. Positivity of storage functions is known to be very important for stability considerations because the maximum stored energy that can be drawn out is bounded when the storage function is positive. In this paper we establish the link between stabilizability of an uncontrollable system and existence of positive definite storage functions. In most of the results in this paper, we assume that no pair of the uncontrollable poles of the system is symmetric about the imaginary axis; we explore the extent of necessity of this assumption and also prove some results for the case of single output systems regarding this necessity.

**1. Introduction.** Dissipativity of dynamical systems helps in the analysis and design of control systems. Dissipativity theory allows problems like LQR, circle criterion, Popov criterion, passivity synthesis,  $\mathcal{H}_\infty$  control, and Riccati inequalities to be analyzed under a common framework. An important assumption in some of these developments is that of controllability of the dynamical system. In this paper we study dissipativity of general linear time-invariant systems, possibly uncontrollable.

Uncontrollable systems arise naturally in the process of modeling dynamical systems. The inability to shape one or more system variables in an arbitrary desired fashion is frequently encountered in systems. For example, loss of controllability could happen to otherwise controllable systems when certain system parameters satisfy relevant equations arising in controllability check methods: see a simple electrical circuit below in section 5.1. Uncontrollability could also arise generically due to *structural* inabilities to influence one or more system variables. (See [14, 12] and references therein about structural controllability studies.)

In the context of synthesis of a dynamical system, one sometimes has to settle for an uncontrollable realization of a given transfer function: the case of nonminimality of

the transformerless synthesis of a positive real transfer function is well known. This issue concerns the synthesis of a positive real transfer matrix using only resistors, capacitors, and inductors. The currently known methods (the Bott–Duffin method [3] and its variants) bring us naturally to systems that are dissipative, but are not controllable. See [6] for a recent overview about this classical problem.

Dissipativity of a system is about the absence of any source of energy within the system, and hence all interactions with the environment have to satisfy the condition that the “net energy” is directed inwards. This is made precise below in Definition 3.1. Such a property is intrinsic to the system and therefore should be independent of the question of controllability. For example, a passive electrical network made out of passive circuit elements must continue to be dissipative even if it loses controllability. In this paper we consider a general linear time-invariant system and work on a theory of dissipativity free from any controllability assumption. Our work is based on the signature characteristic of a dissipative system to store energy, i.e., existence of a storage function. An important issue that immediately arises is whether to include unobservable variables to describe this storage of energy (see [33, 5]). Our main result sorts out this issue: for the case of strict dissipativity, we show that a storage function depending only on the manifest variables suffices, and no unobservable variables are necessary (see Remark 5.1).

The present theory of dissipative systems is well-developed primarily for controllable systems because it is possible there to define dissipativity without taking recourse to the existence of a storage function. This is done using an integral inequality involving only the compactly supported trajectories allowed by the system. This definition turns out to be inadequate for a general, possibly uncontrollable, linear behavior. In order to overcome this inadequacy, there has been prior work of taking existence of storage functions satisfying a dissipation inequality as a definition of dissipativity; see [28, 5], for example. In this paper we further develop using this definition, prove results regarding existence, and relate it to the situation of controllability. The principal finding is that a certain condition on the uncontrollable poles, which we call as the *unmixing* condition, plays a key role. If no pair of the uncontrollable poles of the system is symmetric with respect to the imaginary axis, then the noncontrollability poses no hindrance to strict dissipativity, i.e., the strict dissipativities of the behavior and its controllable part are equivalent (Theorem 3.4). This result is utilized to show useful identities about positive storage functions and unboundedness of the set of storage functions for the case of uncontrollability.

The paper is structured as follows. The rest of this section has a few words about the notation we follow. Section 2 contains some preliminaries we require regarding behavioral theory. The next section (section 3) has some definitions that we need in order to state the main result of this paper and for the proofs. In this section we also present the main result: a necessary and sufficient condition for a general linear time-invariant system to be strictly dissipative with respect to a supply rate that depends on the manifest variables, under the assumption that the set of uncontrollable poles satisfies the unmixing condition. Interestingly, this unmixing condition on the uncontrollable poles is reminiscent of the solvability condition of Lyapunov equations: this is elaborated in sections 3 and 8. This paper utilizes the wealth of existing literature on Hamiltonian matrices and Riccati equations; section 4 has results about relations among Riccati equations, the Hamiltonian matrix, and dissipativity. A proof of the main result follows in section 5, together with some auxiliary results. In section 6 we present a necessary and sufficient condition for existence of positive storage functions: here we relate stabilizability to positive storage functions. In section 7 we present

some insight on the nature, namely, unboundedness and convexity, of the set of all storage functions of an uncontrollable dissipative behavior. (The set of storage functions is known to be *bounded* in the case of controllability.) Section 8 explores into the extent of necessity of the unmixing property that we have assumed throughout this paper. In this section we show an interesting result about rank one symmetric matrices and the solvability of the Lyapunov equation. When one or more pairs of the uncontrollable poles have symmetry about the imaginary axis, it turns out that the solvabilities of a certain Riccati equation and the corresponding Riccati *inequality* differ significantly from the situation in the controllable case. We conclude the paper in section 9 following which is an appendix containing some proofs and peripheral results needed for the proofs.

The notation we follow is standard.  $\mathbb{R}$  and  $\mathbb{C}$  stand for the fields of real and complex numbers. The ring of polynomials in  $\xi$  with real coefficients is denoted by  $\mathbb{R}[\xi]$ .  $\mathbb{R}^{p \times w}[\xi]$  stands for the set of  $p \times w$  matrices with entries from  $\mathbb{R}[\xi]$ . In the context of quadratic differential forms, we require polynomials in two indeterminates:  $\zeta$  and  $\eta$ . The set of such polynomials with real coefficients is denoted by  $\mathbb{R}[\zeta, \eta]$ , and the set of  $w \times w$  matrices with entries from  $\mathbb{R}[\zeta, \eta]$  by  $\mathbb{R}^{w \times w}[\zeta, \eta]$ .  $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^w)$  denotes the space of all infinitely often differentiable functions from  $\mathbb{R}$  to  $\mathbb{R}^w$ , and  $\mathcal{D}(\mathbb{R}, \mathbb{R}^w)$  denotes its subspace of all compactly supported trajectories. We use  $\bullet$  when it is unnecessary to specify a dimension. For example,  $R \in \mathbb{R}^{\bullet \times w}$  means  $R$  is a real matrix with  $w$  columns. When dealing with many variables, in order to keep track of the dimensions, we use the same letter as a generic variable  $w$ , but in typewriter font  $\mathfrak{w}$ , to denote the number of components; for example,  $w \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathfrak{w}})$ . In the context of stability, we require certain regions of the complex plane  $\mathbb{C}$ . The open left and right half complex planes are denoted by  $\mathbb{C}^-$  and  $\mathbb{C}^+$ , respectively. To improve readability within text, we use  $\text{col}(\cdot, \cdot)$  to stack its arguments into a column, i.e.,  $\text{col}(w_1, w_2) = [w_1^T \ w_2^T]^T$ .

**2. Behaviors, QDFs, and state representations.** A linear differential behavior  $\mathfrak{B}$  is defined to be the subspace of  $\mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathfrak{w}})$  consisting of the solutions to a set of ordinary linear differential equations with constant coefficients; i.e.,

$$\mathfrak{B} := \left\{ w \in \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathfrak{w}}) \mid R \left( \frac{d}{dt} \right) w = 0 \right\},$$

where  $R(\xi)$  is a polynomial matrix having  $\mathfrak{w}$  number of columns:  $R \in \mathbb{R}^{\bullet \times \mathfrak{w}}[\xi]$ . We shall denote the set of linear differential behaviors with  $\mathfrak{w}$  number of variables by  $\mathfrak{L}^{\mathfrak{w}}$ . The linear differential behavior  $\mathfrak{B} \in \mathfrak{L}^{\mathfrak{w}}$  can also be written as  $\mathfrak{B} = \ker R(\frac{d}{dt})$ . That is why this representation is called a *kernel representation* of  $\mathfrak{B}$ . We call  $w$  the *manifest variable*; these are the variables of interest. In this paper,  $w$  is the variable through which the system exchanges energy with the environment. It turns out that we can assume, without loss of generality, that  $R(\xi)$  is of full row rank (see [17]); in this paper, a kernel representation matrix  $R(\xi)$  is assumed to be of full row rank. For a behavior  $\mathfrak{B} = \ker R(\frac{d}{dt})$ , the row rank of  $R(\xi)$  gives the output cardinality (number of outputs in the system). Though the variables  $w$  can often be partitioned into inputs and outputs in more than one way, the output cardinality remains the same:  $\text{rank } R$ . Further, the cardinality does not depend on the  $R$  used to define it, but depends only on  $\mathfrak{B}$ . In this sense, the output cardinality is an integer invariant of  $\mathfrak{B}$  and we denote it by  $\mathfrak{p}(\mathfrak{B})$ . The number of inputs to the system, the input cardinality, is another integer invariant of  $\mathfrak{B}$ . This integer is denoted by  $\mathfrak{m}(\mathfrak{B})$  and is calculated using  $\mathfrak{m}(\mathfrak{B}) = \mathfrak{w} - \mathfrak{p}(\mathfrak{B})$ , where  $\mathfrak{w}$  is the number of components in the manifest variable  $w$ .

A concept of central importance for this paper is that of controllability. A behavior  $\mathfrak{B} \in \mathfrak{L}^w$  is said to be *controllable* if for every  $w', w'' \in \mathfrak{B}$ , there exists a  $w \in \mathfrak{B}$  and a  $\tau > 0$  such that

$$\begin{aligned} w(t) &= w'(t) & \text{for all } t \leq 0, \\ &= w''(t) & \text{for all } t \geq \tau. \end{aligned}$$

We denote the set of all controllable behaviors with  $w$  variables as  $\mathfrak{L}_{\text{cont}}^w$ . A behavior  $\mathfrak{B} = \ker R(\frac{d}{dt})$  is controllable if and only if  $R(\lambda)$  does not lose rank for any  $\lambda \in \mathbb{C}$ . An important characterization of controllable behaviors is that they also admit *image representations*. It was shown in [31] that  $\mathfrak{B}$  is controllable if and only if it can be represented as

$$\mathfrak{B} := \left\{ w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^w) \mid \exists \ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m) \text{ such that } w = M \left( \frac{d}{dt} \right) \ell \right\},$$

for some polynomial matrix  $M \in \mathbb{R}^{w \times m}[\xi]$ . This representation of  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  is called an image representation. It turns out that for an image representation, without loss of generality, one can assume  $M(\xi)$  to have the property that  $M(\lambda)$  has full column rank for every  $\lambda \in \mathbb{C}$ . We call such an  $M$  satisfying this property a *right-prime* polynomial matrix.  $M$  being right-prime means that we are able to deduce the  $\ell$  trajectory corresponding to a  $w$  trajectory satisfying the equation  $w = M(\frac{d}{dt})\ell$ . Hence, such an  $M$  is also said to induce an *observable* image representation.

In the context of uncontrollable systems, we use the key notion of *uncontrollable poles* and *uncontrollable characteristic polynomial*. Suppose  $\mathfrak{B} = \ker R(\frac{d}{dt})$  and suppose  $\mathfrak{B}$  is *not* controllable. Then there exist one or more complex numbers  $\lambda$  such that  $R(\lambda)$  loses rank. These complex numbers, together with multiplicities,<sup>1</sup> are defined as uncontrollable poles in the definition below. Uncontrollable poles are the roots of a monic polynomial called the uncontrollable characteristic polynomial. See [32] for details.

**DEFINITION 2.1.** Let  $R \in \mathbb{R}^{p \times w}[\xi]$  have full row rank and suppose  $R(\frac{d}{dt})w = 0$  is a kernel representation for  $\mathfrak{B}$ . Consider a factorization of  $R$  into  $R(\xi) = F(\xi)R_{\text{cont}}(\xi)$  such that  $R_{\text{cont}} \in \mathbb{R}^{p \times w}[\xi]$ ,  $R_{\text{cont}}(\lambda)$  has full row rank for every complex number  $\lambda$ , and  $\det F$  is a monic polynomial. The uncontrollable characteristic polynomial of  $\mathfrak{B}$ , denoted by  $\chi_{\text{un}}(\mathfrak{B})$ , is defined as  $\det F$ . The set of uncontrollable poles is defined as roots of  $\chi_{\text{un}}$ , and is denoted by  $\Lambda_{\text{un}}(\mathfrak{B})$ .

If the behavior  $\mathfrak{B}$  is clear from the context, we write just  $\chi_{\text{un}}$  and  $\Lambda_{\text{un}}$ . Notice that if  $\mathfrak{B}$  is controllable, then  $\chi_{\text{un}} = 1$ . When a behavior is not controllable, we often require the *controllable part* of  $\mathfrak{B}$ . This is the largest controllable behavior contained in  $\mathfrak{B}$ ; the controllable part of  $\mathfrak{B}$  is denoted by  $\mathfrak{B}_{\text{cont}}$ . Consider the above definition in which  $R$  has been factorized as described to obtain  $R_{\text{cont}}$ . A kernel representation for  $\mathfrak{B}_{\text{cont}}$  is induced by  $R_{\text{cont}}$ . For a detailed exposition on behaviors, controllability, and uncontrollable characteristic polynomial, we refer the reader to [17, 32].

This paper deals with dissipativity and in this context we deal with quadratic forms in the system variables and a finite number of their derivatives. It turns out to be very natural to associate two variable polynomial matrices to such quadratic forms. Consider a two variable polynomial matrix  $\Phi(\zeta, \eta) := \sum_{i,k} \Phi_{ik} \zeta^i \eta^k \in \mathbb{R}^{w \times w}[\zeta, \eta]$ , where  $\Phi_{ik} \in \mathbb{R}^{w \times w}$ . A Quadratic Differential Form (QDF)  $Q_\Phi$  induced by  $\Phi(\zeta, \eta)$  is a

<sup>1</sup>See Remark 4.2 below.

map  $Q_\Phi : \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^w) \rightarrow \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R})$  defined by

$$Q_\Phi(w) := \sum_{i,k} \left( \frac{d^i w}{dt^i} \right)^T \Phi_{ik} \left( \frac{d^k w}{dt^k} \right).$$

When dealing with quadratic forms in  $w$  and its derivatives, we can assume without loss of generality that  $\Phi(\zeta, \eta) = \Phi^T(\eta, \zeta)$ . We call such  $\Phi(\zeta, \eta)$  a symmetric two-variable polynomial matrix, and we denote the set of all such symmetric two-variable polynomial matrices by  $\mathbb{R}_s^{w \times w}[\zeta, \eta]$ . A quadratic form induced by a real symmetric constant matrix  $S \in \mathbb{R}_s^{w \times w}$  is a special QDF and we shall often need this in this paper. For a given  $\Phi \in \mathbb{R}_s^{w \times w}[\zeta, \eta]$ , we often require the one variable polynomial matrix  $\Phi(-\xi, \xi)$ : we shall denote this by  $\partial\Phi(\xi)$ . Due to the symmetry of  $\Phi(\zeta, \eta)$  the one variable polynomial matrix  $\partial\Phi(\xi)$  is *para-Hermitian*, i.e.,  $\partial\Phi(-\xi) = \partial\Phi^T(\xi)$ . Notice that this property makes  $\partial\Phi(j\omega)$  Hermitian for all  $\omega \in \mathbb{R}$ . Throughout this paper, ample use is made of the well-developed theory of QDFs; only the essential results of which are reviewed here. See [28] for a thorough and complete treatment on QDFs.

The notion of state is central to this paper due to the claim that, for uncontrollable systems, also the storage of energy is possible due to memory elements in the system. The state variable  $x$  is an auxiliary variable that relates to the memory of the system. Consider a behavior  $\mathfrak{B} \in \mathfrak{L}^w$  with manifest variables  $w$ . A variable  $x$  of the system is called a state variable if it satisfies the system equations together with  $w$ , and has the concatenation property. More precisely, if  $(w', x')$  and  $(w'', x'')$  are two smooth trajectories allowed by the system, and  $x'(0) = x''(0)$ , then the new trajectory  $(w, x)$  formed by concatenating  $(w', x')$  and  $(w'', x'')$  at  $t = 0$ , i.e.,

$$\begin{aligned} (w, x)(t) &= (w', x')(t) && \text{for all } t \leq 0 \\ &= (w'', x'')(t) && \text{for all } t > 0, \end{aligned}$$

also satisfies the system equations in a distributional sense. A formal treatment on this is contained in [19], where it was proved that a variable  $x$  is a state variable for  $\mathfrak{B}$  if and only if the behavior satisfies

$$\mathfrak{B} = \left\{ w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^w) \mid \exists x \in \mathfrak{C}^\infty \text{ such that } E \frac{d}{dt} x + Fx + Gw = 0 \right\}$$

for suitable real constant matrices  $E, F$  and  $G$ . The above first order representation is called a state representation. Such a representation is said to be minimal if it has the least number of state variables among all state representations describing the behavior. The dimension of the state space for a minimal state representation is defined to be the *McMillan degree* of the behavior, and is denoted by  $\mathbf{n}(\mathfrak{B})$ . It was shown in [19] that a set of state variables can be obtained through the manifest variables by a *state map*,  $X \in \mathbb{R}^{\bullet \times w}[\xi]$ , which gives the state variables by  $x = X(\frac{d}{dt})w$ . Among all state maps, if  $X$  has the minimum number of rows, then it is called a minimal state map; in this case, the number of rows equals  $\mathbf{n}(\mathfrak{B})$ . If  $\mathfrak{B} \in \mathfrak{L}^w$  has an *input/output* partition  $w = \text{col}(w_1, w_2)$  where  $w_1$  is input and  $w_2$  is output such that the transfer function from  $w_1$  to  $w_2$  is *proper*, then  $\mathfrak{B}$  admits a minimal state representation that is more special and well known: an *input/state/output* (i/s/o) representation

$$\frac{d}{dt}x = Ax + Bw_1, \quad w_2 = Cx + Dw_1,$$

with  $(C, A)$  observable. Controllability of the behavior  $\mathfrak{B}$  and that of the pair  $(A, B)$  are related as shown in the following well-known result. We write  $\Lambda_{\text{un}}^{(A, B)}$  for the set of

uncontrollable eigenvalues of the  $(A, B)$  pair (counted with multiplicities). Proposition 2.2 shows when a behavior allows a state map that gives rise to an i/s/o representation with observability properties (see [31, 19]). We state this as a proposition for easy reference later in this paper.

**PROPOSITION 2.2.** *Let behavior  $\mathfrak{B} \in \mathfrak{L}^w$  be given by  $\mathfrak{B} = \ker R(\frac{d}{dt})$ , where  $R(\xi)$  has full row rank. Let  $(w_1, w_2)$  be an input/output partition of  $w$  such that the resulting transfer function matrix is proper. Suppose  $n$  is the McMillan degree of  $\mathfrak{B}$  and  $X \in \mathbb{R}^{n \times w}[\xi]$  gives a minimal state map. Then there exist  $A \in \mathbb{R}^{n \times n}$ ,  $B \in \mathbb{R}^{n \times m}$ ,  $C \in \mathbb{R}^{p \times n}$ , and  $D \in \mathbb{R}^{p \times m}$ , such that  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$  with  $(C, A)$  observable, and  $x = X(\frac{d}{dt})w$ . Moreover,  $\mathfrak{B}$  is controllable if and only if the above i/s/o representation is state-controllable. If  $\mathfrak{B}$  is uncontrollable, then  $\Lambda_{\text{un}}(\mathfrak{B})$ , the set of uncontrollable poles of  $\mathfrak{B}$ , is equal to  $\Lambda_{\text{un}}^{(A, B)}$  the set of uncontrollable eigenvalues of  $A$  (counted with multiplicities).*

**3. Dissipative systems: Definition and main result.** Dissipative systems are those that have no source of energy within, and hence any energy stored within the system has to have been supplied from its environment. This intuitive physical concept was made concrete in [30, 28] using the *dissipation inequality*: the rate of increase of stored energy is at most the power supplied to the system. In this paper, the power supplied and the stored energy are both QDFs in the manifest variables  $w$  of the system. (See Remark 5.1 below regarding storage function's dependence on just the manifest variables.) In this paper we use the following definition of dissipativity; its relation to other definitions is discussed below.

**DEFINITION 3.1.** *A linear differential behavior  $\mathfrak{B} \in \mathfrak{L}^w$  is said to be dissipative with respect to supply rate  $S \in \mathbb{R}_s^{w \times w}$  if there exists a quadratic differential form  $Q_\Psi(w)$  such that*

$$(3.1) \quad \frac{d}{dt}Q_\Psi(w) \leq Q_S(w) \text{ for all } w \in \mathfrak{B}.$$

*The quadratic differential form  $Q_\Psi$  is called a storage function for  $\mathfrak{B}$  with respect to the supply rate  $S$ .*

The inequality (3.1) above is called the dissipation inequality. In some control problems like in LQR and the suboptimal  $\mathcal{H}_\infty$  control, a stricter notion of dissipativity plays a key role. In this paper we shall deal primarily with strict dissipativity, although many of our results are valid for just dissipativity also (see Remark 5.7 below). We define strict dissipativity as follows.

**DEFINITION 3.2.** *A linear differential behavior  $\mathfrak{B} \in \mathfrak{L}^w$  is said to be strictly dissipative with respect to  $S \in \mathbb{R}_s^{w \times w}$  if there exists an  $\epsilon > 0$  and a storage function  $Q_\Psi(w)$  such that*

$$\frac{d}{dt}Q_\Psi(w) \leq Q_S(w) - \epsilon|w|^2 \quad \text{for all } w \in \mathfrak{B}.$$

Because the above definitions require the existence of a hitherto unknown storage function, it has been common to use an equivalent statement for the definition of (strict) dissipativity when dealing with *controllable* systems. The following result from [28] shows the equivalence.

**PROPOSITION 3.3.** *Let  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  and  $S \in \mathbb{R}_s^{w \times w}$  be nonsingular. Then the following statements are equivalent.*

1. *There exists a storage function  $Q_\Psi(w)$  such that  $\frac{d}{dt}Q_\Psi(w) \leq Q_S(w) - \epsilon|w|^2$  for all  $w \in \mathfrak{B}$ .*

2. For all  $w \in \mathfrak{B} \cap \mathfrak{D}$  the integral inequality  $\int_{\mathbb{R}} Q_S(w) dt \geq \epsilon \int_{\mathbb{R}} |w|^2 dt$  is satisfied.

The above proposition shows that the existence of a storage function satisfying the dissipation inequality is equivalent to saying that the total energy transferred into the system is strictly positive whenever we start the system from rest and bring the system back to rest. Statement 2 was used as the definition of strict dissipativity in [28]. With  $\epsilon = 0$ , we get the definition of nonstrict dissipativity given in [28, 29]. It is important to note here that the second statement above holds over only compactly supported trajectories in  $\mathfrak{B}$ , while the first holds for all  $w \in \mathfrak{B}$ . Controllability of  $\mathfrak{B}$  is crucial for the compactly supported trajectories in  $\mathfrak{B}$  to be representative enough of the whole behavior for the above equivalence to hold (see [16]). Definitions using an integral over a finite interval (which means energy supplied for a finite period of time) ends up having initial and final storage function values in the defining inequality. Use of compactly supported trajectories makes the integrals over the whole of  $\mathbb{R}$  well-defined and also makes the defining integral inequality free from the initial and final storage function values. However, for an uncontrollable behavior, Statement 2 of Proposition 3.3 puts no restrictions on the trajectories in the behavior which are outside the controllable part (see [16]), and hence this cannot be used as a definition of dissipativity.

We define signature of a real symmetric nonsingular matrix  $S$ , denoted by  $\sigma(S)$  as the pair of integers  $\sigma(S) = (\sigma_-(S), \sigma_+(S))$ , where  $\sigma_-(S)$  and  $\sigma_+(S)$  are the number of negative and positive eigenvalues of  $S$ , respectively. In this paper we shall deal only with the case when the positive signature  $\sigma_+(S)$  equals the input cardinality  $\mathfrak{m}(\mathfrak{B})$  of the behavior  $\mathfrak{B}$ . Dissipativity with respect to this matrix is required for the  $\mathcal{H}_\infty$  norm of a corresponding transfer matrix to be at most one. Further, as shown in [29, Proposition 2, Part I],  $\sigma_+(S) = \mathfrak{m}(\mathfrak{B})$  means that the behavior has as high an input cardinality as  $S$ -dissipativity allows; we call this condition the *maximum input cardinality condition*.

We are now ready to state one of the main results of this paper. The following theorem tells that if a certain unmixing condition is satisfied for the uncontrollable poles, then the controllable part of a behavior being strictly dissipative is equivalent to the existence of a storage function for the whole behavior's strict dissipativity. Recall from Definition 2.1 that the uncontrollable characteristic polynomial  $\chi_{\text{un}}$  of  $\mathfrak{B}$  is the monic polynomial whose roots (with suitable multiplicities) are those complex numbers where  $R(\xi)$  loses rank. Theorem 3.4 below states that if the uncontrollable poles are such that no pair of the uncontrollable poles is symmetric with respect to the imaginary axis, then noncontrollability of  $\mathfrak{B}$  poses no hindrance to strict dissipativity of  $\mathfrak{B}$ ; i.e., strict dissipativities of  $\mathfrak{B}$  and  $\mathfrak{B}_{\text{cont}}$  are equivalent.

**THEOREM 3.4.** *Consider a linear differential behavior  $\mathfrak{B} \in \mathfrak{L}^w$  and a nonsingular  $S \in \mathbb{R}_s^{w \times w}$  with the input cardinality of  $\mathfrak{B}$  equal to the positive signature of  $S$ :  $\mathfrak{m}(\mathfrak{B}) = \sigma_+(S)$ . Assume that the uncontrollable characteristic polynomial of  $\mathfrak{B}$ ,  $\chi_{\text{un}}$ , is such that  $\chi_{\text{un}}(\xi)$  and  $\chi_{\text{un}}(-\xi)$  are coprime. Then,  $\mathfrak{B}$  is strictly  $S$ -dissipative if and only if its controllable part  $\mathfrak{B}_{\text{cont}}$  is strictly  $S$ -dissipative.*

We call the condition of coprimeness of  $\chi_{\text{un}}(\xi)$  and  $\chi_{\text{un}}(-\xi)$  the *unmixing condition*. In the context of autonomous systems, it is well known (see [34], for example) that the unmixing condition is a necessary and sufficient condition for the existence of a unique solution to the Lyapunov equation. In section 8 we explore the extent of necessity of this condition. For some autonomous behaviors (and hence some uncontrollable behaviors), we show that the unmixing condition is not necessary (section 8).

Throughout this paper, we shall assume  $S$  has the following form:

$$(3.2) \quad \Sigma := \begin{bmatrix} I_m & 0 \\ 0 & -I_p \end{bmatrix}.$$

Lemma 3.5 below shows that, for dissipativity considerations, taking  $\Sigma$  as in (3.2) is without any loss of generality. Dissipativity with respect to a different constant matrix  $S$  can be easily treated by modifying the behavior suitably, as shown in the following lemma.

**LEMMA 3.5.** *Consider  $\mathfrak{B} \in \mathfrak{L}^w$  and a real symmetric nonsingular matrix  $S \in \mathbb{R}^{w \times w}$ . Let  $S = T^T \Sigma T$ , with  $T \in \mathbb{R}^{w \times w}$  nonsingular, be a symmetric factorization of  $S$ . Define  $\tilde{\mathfrak{B}} := T\mathfrak{B}$ . Then  $\mathfrak{B}$  is  $S$ -dissipative if and only if  $\tilde{\mathfrak{B}}$  is  $\Sigma$ -dissipative.*

Before we continue with other preliminaries, results, and proofs, we list the assumptions we make in the rest of this paper that are without loss of any generality. While we do write these standing assumptions explicitly in some results, they are sometimes skipped for brevity. For a kernel representation, the polynomial matrix  $R(\xi)$  is assumed to be full row rank, and the matrix  $M(\xi)$  in an image representation is assumed to be right-prime. Further, when we start with an i/s/o representation of a behavior, we assume this to be minimal. In the context of dissipativity,  $\Sigma$  is used for the supply rate. We assume  $\Sigma$  to be symmetric and nonsingular.

**4. Dissipativity, Riccati equation, and Hamiltonian matrix.** In this section we first briefly review existing literature about how the dissipation inequality gives us a well-studied Linear Matrix Inequality (LMI). We bring out the connection between a certain para-Hermitian polynomial matrix related to the behavior and an associated Hamiltonian matrix. See [8, 13, 25] for related results.

For the case that the input cardinality of the behavior is equal to the positive signature of  $\Sigma$ , a necessary condition for dissipativity of  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  is that a partition of  $w = (w_1, w_2)$  corresponding to the matrix  $\Sigma$  (see (3.2)) results in an input/output partition for  $\mathfrak{B}$  such that  $w_1$  is input and  $w_2$  is output (see [28, Remark 5.11]). Note that the above partition means  $Q_\Sigma(w) = |w_1|^2 - |w_2|^2$ . Further, due to the dissipativity, the transfer function from  $w_1$  to  $w_2$  turns out to be *proper*. This implies that  $\mathfrak{B}$  allows an i/s/o representation as

$$(4.1) \quad \frac{d}{dt}x = Ax + Bw_1, \quad w_2 = Cx + Dw_1,$$

with  $(C, A)$  observable (see Proposition 2.2). The link among dissipativity of a controllable behavior, storage functions, and LMIs is the subject of [30, 21, 4]; we state this result below for easy reference.

**PROPOSITION 4.1.**  *$\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  is  $\Sigma$ -dissipative if and only if there exists a solution  $K = K^T \in \mathbb{R}^{n \times n}$  for the following LMI*

$$(4.2) \quad \begin{bmatrix} (C^T C + A^T K + K A) & (K B + C^T D) \\ (B^T K + D^T C) & -(I_m - D^T D) \end{bmatrix} \leq 0,$$

where  $\frac{d}{dt}x = Ax + Bw_1$  and  $w_2 = Cx + Dw_1$  is a state-controllable and state-observable i/s/o representation of  $\mathfrak{B}$  with the input/output partition induced by the block matrix  $\Sigma$ .

In the above proposition, the memoryless state function  $x^T K x$  acts as a storage function for the controllable behavior  $\mathfrak{B}$ . See Corollary 5.6 below for our result regarding uncontrollable behaviors. The above LMI is the well-known *bounded-real*

LMI. Assume  $(I_m - D^T D) > 0$  (some implications of this assumption will be clarified in the next section). The Schur complement of  $(I_m - D^T D)$  in inequality (4.2) gives the Algebraic Riccati Inequality (ARI)<sup>2</sup>

$$(4.3) \quad \begin{aligned} & \left( A + B(I_m - D^T D)^{-1} D^T C \right)^T K + K \left( A + B(I_m - D^T D)^{-1} D^T C \right) \\ & + C^T (I_p - DD^T)^{-1} C + KB(I_m - D^T D)^{-1} B^T K \leq 0. \end{aligned}$$

Note that  $K$  satisfies the ARI if and only if  $K$  satisfies the above LMI.

The corresponding equation is the Algebraic Riccati Equation (ARE), and we use properties of this equation for various results in this paper. Interestingly, the solution to the ARE can be found from certain  $n$ -dimensional invariant subspaces of a  $2n \times 2n$  matrix known as the *Hamiltonian* matrix. This paper uses properties of the Hamiltonian matrix to relate to dissipativity. The procedure of constructing a solution to the ARE from an  $n$ -dimensional eigenspace of the Hamiltonian matrix comes in several texts, for example, [7, 10]. For easy reference we present this result as Proposition 4.4 below. We first define *Lambda-sets* of the roots of an even polynomial  $p(\xi)$  having no roots on the imaginary axis, for it will be of importance in the sequel.

*Remark 4.2.* As a convention in this paper, a set of roots of a polynomial (or that of eigenvalues of a real constant matrix) has every element appearing as many number of times as its multiplicity (algebraic multiplicity in case of eigenvalues), and therefore equality of such sets means equality with the multiplicities counted. This helps avoid writing certain polynomials are equal after ensuring monicity.

The definition of a Lambda-set plays an important role in the partition of a set of complex numbers which are symmetric with respect to the imaginary axis. This notion is similar to that of an  $S$ -set [20].  $\bar{\Lambda}$  below denotes the set of complex conjugates of the elements in  $\Lambda$ .

**DEFINITION 4.3.** Let  $p(\xi)$  be a nonzero even polynomial in  $\xi$  with no roots on the imaginary axis. A set of complex numbers  $\Lambda \subset \text{roots}(p(\xi))$  is said to be a Lambda-set of roots  $(p(\xi))$  if it satisfies the following properties:

1.  $\Lambda = \bar{\Lambda}$ ,
2.  $\Lambda \cap (-\Lambda) = \emptyset$ , and
3.  $\Lambda \cup (-\Lambda) = \text{roots}(p(\xi))$  (counted with multiplicity).

The disjointness condition (condition 2) requires that  $p$  has no roots on the imaginary axis. We called this the unmixing condition in the remark following Theorem 3.4. Proposition 4.4 below is well known; it relates ARE solutions to the *Hamiltonian* matrix  $H$ , defined below.

**PROPOSITION 4.4.** Consider the ARE:  $A^T K + KA + C^T C + KBB^T K = 0$  in the unknown real symmetric matrix  $K = K^T \in \mathbb{R}^{n \times n}$ . Corresponding to this ARE, construct the Hamiltonian matrix,  $H := \begin{bmatrix} A & BB^T \\ -C^T C & -A^T \end{bmatrix}$ . Assume  $H$  does not have eigenvalues on the imaginary axis and let  $\Lambda$  be a Lambda-set of  $\text{spec}(H)$ . Suppose the  $n$ -dimensional  $H$ -invariant subspace corresponding to  $\Lambda$  is given by

$$(4.4) \quad \mathcal{X}_\Lambda(H) := \text{im} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix},$$

where  $X_1, X_2 \in \mathbb{R}^{n \times n}$ . A real symmetric solution  $K$  to the ARE satisfying  $\text{spec}(A + BB^T K) = \Lambda$  exists if and only if  $X_1$  is nonsingular.

<sup>2</sup>We used the fact that positive definiteness of  $I_m - D^T D$  and  $I_p - DD^T$  are equivalent.

If  $X_1$  as defined above is nonsingular, then  $K := X_2 X_1^{-1}$  is a solution to the ARE. Thus the solvability of the ARE through suitable  $n$ -dimensional invariant subspaces of the Hamiltonian matrix gives a condition for the existence of a storage function (state function) that satisfies the dissipation inequality. Note that the above result is independent of any controllability assumption. For controllable behaviors that have an i/s/o representation given by (4.1) such that  $(A, B)$  is controllable and  $(C, A)$  is observable, it turns out that the eigenvalues of the Hamiltonian matrix are exactly equal to the roots of the determinant of the corresponding para-Hermitian matrix  $\partial\Phi(\xi)$  coming from the image representation matrix of the behavior and  $\Sigma$ . We state this result as a lemma below. The result is quite expected, and we prove it (in Appendix A) for the sake of completeness, and since we shall extend it to the case of uncontrollability in Theorem 5.4.

**LEMMA 4.5.** *Let  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  have an i/s/o representation,  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$  with  $(A, B)$  controllable and  $(C, A)$  observable and  $\Sigma := \begin{bmatrix} I_m & 0 \\ 0 & -I_p \end{bmatrix}$ . Assume  $(I_m - D^T D) > 0$ . Define the real  $2n \times 2n$  Hamiltonian matrix*

$$H := \begin{bmatrix} A + B(I_m - D^T D)^{-1} D^T C & B(I_m - D^T D)^{-1} B^T \\ -C^T(I_p - DD^T)^{-1} C & -(A + B(I_m - D^T D)^{-1} D^T C)^T \end{bmatrix}.$$

*Suppose  $w = M(\frac{d}{dt})\ell$ ;  $\ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m)$  is an observable image representation of  $\mathfrak{B}$  and consider  $\partial\Phi(\xi) := M^T(-\xi)\Sigma M(\xi)$ . Then, the Hamiltonian matrix eigenvalues are same as the zeros of  $\partial\Phi(\xi)$ , counted with multiplicities, i.e.,  $\text{spec}(H) = \text{roots}(\det \partial\Phi(\xi))$ .*

*Proof.* See Appendix A.  $\square$

The para-Hermitian matrix  $\partial\Phi(\xi)$  comes from the image representation of the behavior and  $\Sigma$ , whereas the Hamiltonian matrix is formed from the i/s/o representation with the i/o partition induced by  $\Sigma$ . Lemma 4.5 above nicely brings out a relation between these two matrices and helps in establishing a system theoretic meaning to the Hamiltonian matrix (see [15]). We shall make use of this lemma in proving our main result: Theorem 3.4.

For the special case that  $(A, B)$  is controllable, the result in Proposition 4.4 can be further extended. It has been shown in [7, 10] that if  $(A, B)$  is controllable and if  $H$  has no eigenvalues on the imaginary axis, then  $H$  gives a solution to the ARE. We state this result as a proposition below. We shall make use of this result within some proofs in the sequel to infer about the existence of a solution to an ARE coming from a strict dissipation inequality

**PROPOSITION 4.6.** *Consider the Hamiltonian matrix given by  $H := \begin{bmatrix} A & BB^T \\ -C^T C & -A^T \end{bmatrix}$ . If  $(A, B)$  is controllable and  $H$  has no roots on the imaginary axis, then there exists a real symmetric solution to the ARE:  $A^T K + KA + C^T C + KBB^T K = 0$ .*

**5. Dissipativity of uncontrollable behaviors.** In this section we prove Theorem 3.4 using the results presented in the last section and some more presented here. We first consider an example of a simple electrical circuit as shown in Figure 5.1. Under the condition  $R_1 C \neq L/R_2$ , the port variables (manifest variables)  $(v, i)$  satisfy the following differential equation:

$$\left[ \left( LC \frac{d^2}{dt^2} + (R_1 + R_2)C \frac{d}{dt} + 1 \right) - \left( R_1 LC \frac{d^2}{dt^2} + (R_1 R_2 C + L) \frac{d}{dt} + R_2 \right) \right] \begin{bmatrix} v \\ i \end{bmatrix} = 0.$$

FIG. 5.1. An LCR circuit.

For the case that  $R_1 C = L/R_2$ , and  $R_1 = R_2$ , the system becomes uncontrollable. The corresponding kernel representation is

$$\left[ \left( R_2 C \frac{d}{dt} + 1 \right) - \left( L \frac{d}{dt} + R_2 \right) \right] \begin{bmatrix} v \\ i \end{bmatrix} = 0.$$

If the voltage across the capacitor  $v_C$  and current through the inductor  $i_L$  are considered as internal system variables, then we can write the following dissipation inequality:

$$\frac{d}{dt} (C v_C^2 + L i_L^2) \leqslant \begin{bmatrix} v & i \end{bmatrix} \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} v \\ i \end{bmatrix}.$$

However, it turns out that the latent variables  $(v_C, i_L)$  are not observable from  $(v, i)$ , and so the storage function in the left-hand side of above inequality cannot be written in terms of a QDF in just the manifest variables (see Remark 5.1 below). We ask the question: is it possible to find a storage function in terms of the manifest variables, or do we have to have, for some cases, storage functions in terms of “hidden” variables only (variables that are unobservable from the manifest variables are also said to be hidden)? Our main result Theorem 3.4 addresses this issue under the unmixing assumption, and gives a necessary and sufficient condition for the existence of a storage function in terms of manifest variables. Thus Theorem 3.4 rules out the necessity of hidden variables to construct storage functions.

For the case of the above example, as derived in [33],  $q(v - R_1 i)^2$  with any  $q > 0$  is a storage function, i.e.,

$$\frac{d}{dt} q(v - R_1 i)^2 \leqslant v i,$$

which is a dissipation inequality in just the manifest variables. The fact that this storage function has no apparent interpretation as physical energy is discussed in Remark 5.1 below. Further,  $q > 0$  makes the set of storage functions unbounded for this case: in section 7 we shall prove the unboundedness for general uncontrollable behaviors.

*Remark 5.1.* The question of whether to allow unobservable variables into the storage function has been an issue in [33, 5]. We call a storage function *observable* if it can be expressed as a function of the manifest variables  $w$  and its derivatives. In this paper a storage function is observable by definition. In certain physical systems, like the electrical circuit above, one is able to construct a storage function from the configuration of the individual elements within the system. However, as noted in above references, the situation that the internal system variables may not be observable from

the manifest variables (for example, in the above circuit,  $(v, i)$ , through which energy is exchanged with the environment) raises the issue of whether to allow a storage function to depend on unobservable system variables also. An important contribution of this paper is that we have resolved this issue at least for the case of strict dissipativity. Under the unmixing and the maximum input cardinality conditions, we have obtained an observable storage function for strictly dissipative behaviors. However, it may turn out for some cases, like in the circuit above, that the observable storage function we obtain has no physical energy interpretation. In general for a network consisting of an interconnection of passive elements, which are either lossless elements with memory and strictly dissipative elements without memory (see [30, p. 336]), the sum of energies stored in the individual passive elements gives a natural storage function. The fact that this property is not presently captured in the definition is perhaps causing the lack of physical energy interpretation of the observable storage function.

The following example shows that we have improved one of the main results (Theorem 2) in [5] regarding observable storage functions. Consider the uncontrollable behavior,  $\mathfrak{B} \in \mathfrak{L}^2$ , given by the kernel representation  $R(\frac{d}{dt})w = 0$ , where  $R(\xi) = [2(\xi^2 + 3\xi + 2) - (2\xi^2 + 3\xi + 1)]$ . The QDF induced by  $X^T(\zeta)KX(\eta)$  with

$$X(\xi) := \begin{bmatrix} (2\xi + 6) & -(2\xi + 3) \\ 1 & -1 \end{bmatrix} \quad \text{and} \quad K := \frac{1}{4} \begin{bmatrix} 0.118 & -0.014 \\ -0.014 & 0.472 \end{bmatrix}$$

serves as an observable storage function with respect to the supply rate  $S = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$ .

Before the proof of Theorem 3.4 we state and prove the following theorem, which is an important result in its own right and will also be of importance for proving Theorem 3.4. We show that for a controllable behavior, though the definition of strict dissipativity is existential in  $\epsilon$ , it is equivalent to a pair of conditions that are verifiable without  $\epsilon$ . The second condition ensures that  $\partial\Phi(\xi)$  has no zeros on the imaginary axis while the first condition, loosely speaking, rules out the existence of zeros of  $\partial\Phi(\xi)$  at infinity.

**THEOREM 5.2.** *Consider  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^v$  that has an observable image representation  $\mathfrak{B} = \text{im } M(\frac{d}{dt})$ . Define  $\partial\Phi(\xi) = M^T(-\xi)\Sigma M(\xi)$ . Let  $\mathbf{n}$  be the McMillan degree of  $\mathfrak{B}$ . Then  $\mathfrak{B}$  is strictly dissipative with respect to  $\Sigma$  if and only if the following are satisfied:*

1.  $\deg(\det \partial\Phi(\xi)) = 2\mathbf{n}$ ,
2.  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$ .

In order to prove the above theorem, we use the following lemma, whose proof is in the appendix. Notice that in both, the theorem above and the lemma below, condition 2 does *not* imply condition 1. Strictness of the dissipativity (i.e., existence of an  $\epsilon > 0$ ) plays a role in this implication.

**LEMMA 5.3.** *Let a controllable behavior  $\mathfrak{B} = \text{im } M(\frac{d}{dt})$  have i/s/o representation  $\frac{d}{dt}x = Ax + Bw_1$  and  $w_2 = Cx + Dw_1$ . Suppose  $\mathbf{n}$  is the McMillan degree of  $\mathfrak{B}$ . Define  $\partial\Phi(\xi) = M^T(-\xi)\Sigma M(\xi)$ . Then  $(I_{\mathbf{m}} - D^TD) > 0$  if the following conditions are satisfied:*

1.  $\deg(\det \partial\Phi(\xi)) = 2\mathbf{n}$ ,
2.  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$ .

*Proof.* See Appendix A.  $\square$

*Proof of Theorem 5.2. (If)* Assuming both conditions 1 and 2 are true, we shall show that the behavior is strictly  $\Sigma$ -dissipative. It follows from [28, Proposition 5.2] that the second condition,  $\partial\Phi(j\omega) > 0$  for all real  $\omega$ , implies that  $\mathfrak{B}$  is guaranteed to be dissipative with respect to  $\Sigma$ . Therefore, it follows from Proposition 4.1 that  $\mathfrak{B}$

allows an i/s/o representation (4.1) and there exists  $K = K^T \in \mathbb{R}^{n \times n}$  such that the following LMI is satisfied:

$$\begin{bmatrix} (C^T C + A^T K + K A) & (K B + C^T D) \\ (B^T K + D^T C) & -(I_m - D^T D) \end{bmatrix} \leq 0.$$

Using Lemma 5.3, it follows that conditions 1 and 2 of Theorem 5.2 imply  $(I_m - D^T D) > 0$ . Therefore, the LMI has rank-minimizing solutions coming from the following ARE:

$$\begin{aligned} & \left( A + B (I_m - D^T D)^{-1} D^T C \right)^T K + K \left( A + B (I_m - D^T D)^{-1} D^T C \right) \\ & + C^T (I_p - D D^T)^{-1} C + K B (I_m - D^T D)^{-1} B^T K = 0. \end{aligned}$$

So from Proposition 4.4 there exists a Hamiltonian matrix  $H$  given below corresponding to the above ARE such that its solutions come from the  $n$ -dimensional (generalized) eigenspaces of

$$H := \begin{bmatrix} A + B (I_m - D^T D)^{-1} D^T C & B (I_m - D^T D)^{-1} B^T \\ -C^T (I_p - D D^T)^{-1} C & - \left( A + B (I_m - D^T D)^{-1} D^T C \right)^T \end{bmatrix}.$$

It follows from Lemma 4.5 that  $\text{spec}(H) = \text{roots}(\det \partial \Phi(\xi))$ . Since  $\partial \Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$  roots  $(\det \partial \Phi(\xi)) \cap j\mathbb{R} = \emptyset$ . Therefore, due to Lemma 4.5,  $H$  does not have any purely imaginary eigenvalues. So from the continuity of eigenvalues (see [11]) there exists  $\epsilon \in \mathbb{R}$  small enough such that the following matrix

$$H_\epsilon = H - \epsilon \begin{bmatrix} 0 & 0 \\ C^T C & 0 \end{bmatrix}$$

also has no eigenvalues on the imaginary axis. Note that from Proposition A.1 in the appendix,  $(A, B)$  controllable implies so is  $[(A + B(I_m - D^T D)^{-1} D^T C), B(I_m - D^T D)^{-1/2}]$ .

Hence it follows from Proposition 4.6 that  $H_\epsilon$  gives a solution  $K$  to the corresponding ARE

$$\begin{aligned} & \left( A + B (I_m - D^T D)^{-1} D^T C \right)^T K + K \left( A + B (I_m - D^T D)^{-1} D^T C \right) \\ & + C^T (I_p - D D^T)^{-1} C + \epsilon C^T C + K B (I_m - D^T D)^{-1} B^T K = 0, \end{aligned}$$

which implies, from Proposition 4.1, that  $\mathfrak{B}$  is dissipative with respect to  $\begin{bmatrix} I_m & 0 \\ 0 & -(1 + \epsilon)I_p \end{bmatrix}$  for some  $\epsilon > 0$ .

Utilizing the Lemma A.2 in the appendix, we conclude that  $\mathfrak{B}$  being dissipative with respect to  $\begin{bmatrix} I_m & 0 \\ 0 & -(1 + \epsilon)I_p \end{bmatrix}$  implies  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative, and this completes the “if” part of Theorem 5.2.

**(Only if)** First we show that  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative implies condition 2 holds. Then we shall further show that assuming condition 2 holds,  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative implies that condition 1 holds. Assume that  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative. Definition 3.2 implies there exists  $\epsilon > 0$  such that  $\mathfrak{B}$  is dissipative with respect to  $\Sigma - \epsilon I_m$ . It then follows from Proposition 3.3 and [28, Proposition 5.2] that

$$(5.1) \quad \partial \Phi(j\omega) \geq \epsilon M^T(-j\omega) M(j\omega).$$

Note that  $M^T(-j\omega)M(j\omega) \geq 0$  for all real  $\omega$ . Since  $M(\xi)$  is right-prime, it follows from Lemma A.5 that  $M^T(-j\omega)M(j\omega) > 0$  for all  $\omega \in \mathbb{R}$ . This implies, from inequality (5.1) that  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$ . This shows that if  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative, then condition 2 holds.

Now we show that  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative together with  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$  implies that  $\deg(\det \partial\Phi(\xi)) = 2n$ . Consider a spectral factorization of  $\partial\Phi(\xi) = N^T(-\xi)N(\xi)$  (existence of  $N \in \mathbb{R}^{n \times n}[\xi]$  is guaranteed due to the inequality  $\partial\Phi(j\omega) > 0$ ; see [18]). Again, since  $M(\xi)$  is right-prime,  $M^T(-j\omega)M(j\omega) > 0$  for all  $\omega \in \mathbb{R}$  (Lemma A.5). So  $M^T(-\xi)M(\xi)$  also allows a spectral factorization

$$M^T(-\xi)M(\xi) = D^T(-\xi)D(\xi); \quad D \in \mathbb{R}^{n \times n}(\xi).$$

By Lemma A.5 in the appendix,  $M(\xi)$  being a right-prime polynomial matrix implies that  $\deg(\det(M^T(-\xi)M(\xi))) = 2n$ . Therefore  $\deg(\det D(\xi)) = n$ . Since  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative, inequality (5.1) holds, which we can now rewrite in terms of the spectral factors of  $\partial\Phi(\xi)$  and  $M^T(-\xi)M(\xi)$  as

$$\begin{aligned} N^T(-j\omega)N(j\omega) &\geq \epsilon D^T(-j\omega)D(j\omega) \quad \forall \omega \in \mathbb{R} \\ (5.2) \quad &\Rightarrow [N(-j\omega)D^{-1}(-j\omega)]^T [N(j\omega)D^{-1}(j\omega)] \geq \epsilon I_m \quad \forall \omega \in \mathbb{R}. \end{aligned}$$

The above inequality (5.2) implies that there exists a real  $\epsilon > 0$  such that the minimum singular value of the rational function matrix  $N(j\omega)D^{-1}(j\omega)$  is at least  $\epsilon$  for all real  $\omega$ . This further implies that  $\det(N(\xi)D^{-1}(\xi))$  is a biproper rational function, which means  $\deg(\det N(\xi)) = n$  and hence  $\deg(\det \partial\Phi(\xi)) = 2n$ .  $\square$

The following result will be important in order to prove the main result: Theorem 3.4. It is an extension of Lemma 4.5, where we saw that for a controllable behavior  $\mathfrak{B}$  the set of eigenvalues of the Hamiltonian matrix is equal to the set of roots of the determinant of the para-Hermitian matrix  $\partial\Phi(\xi)$ . For the case of uncontrollability we show that every uncontrollable pole  $\lambda$  of  $\mathfrak{B}$ , together with  $-\lambda$ , is an eigenvalue of  $H$ , in addition to those coming from the controllable part of  $\mathfrak{B}$  like in Lemma 4.5.

**THEOREM 5.4.** *Let  $\mathfrak{B} \in \mathfrak{L}^w$  and let  $\chi_{\text{un}}$  be its uncontrollable characteristic polynomial. Assume  $\mathfrak{B}$  has an observable i/s/o representation  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$ , and suppose  $I_m - D^T D$  is invertible. Let  $\mathfrak{B}_{\text{cont}} = \text{im } M(\frac{d}{dt})$ . Define  $\partial\Phi(\xi) = M^T(-\xi)\Sigma M(\xi)$ . Construct the Hamiltonian matrix*

$$H := \begin{bmatrix} A + B(I_m - D^T D)^{-1} D^T C & B(I_m - D^T D)^{-1} B^T \\ -C^T(I_p - DD^T)^{-1} C & -\left(A + B(I_m - D^T D)^{-1} D^T C\right)^T \end{bmatrix},$$

*Then, the Hamiltonian matrix eigenvalues, the zeros of  $\partial\Phi(\xi)$ , and the uncontrollable poles of  $\mathfrak{B}$  are related by:  $\text{spec}(H) = \text{roots}[\det \partial\Phi(\xi) \chi_{\text{un}}(\xi) \chi_{\text{un}}(-\xi)]$ , counted with multiplicities.*

*Proof.* See Appendix A.  $\square$

The next result is one of the main results of this paper and it is pivotal for proving Theorem 3.4. It brings out an important property about certain  $n$ -dimensional invariant subspaces of the Hamiltonian matrix. We already know from Proposition 4.4 that statement 2 in the theorem below is equivalent to existence of a solution to the ARE. In this sense, Theorem 5.5 below is an important extension to Proposition 4.6. The theorem shows that a given Lambda set results in a solution to the ARE if and only if this Lambda set contains the uncontrollable poles of the system. The proof

comes following a line of argument similar to the one used in proving [10, Theorem 7.2].

**THEOREM 5.5.** *Consider the Hamiltonian matrix,  $H = \begin{bmatrix} A & BB^T \\ -C^T C & -A^T \end{bmatrix}$ . Define  $\Lambda_{\text{un}}^{(A,B)}$  to be the set of uncontrollable eigenvalues of  $(A, B)$  pair and let  $\Lambda$  be a Lambda-set of  $\text{spec}(H)$ . Then the following are equivalent.*

1.  $\Lambda \supseteq \Lambda_{\text{un}}^{(A,B)}$ .
2. The  $n$ -dimensional invariant subspace of  $H$  corresponding to  $\Lambda$  is complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$ .

*Proof. (1  $\Rightarrow$  2)* Denote by  $\mathcal{X}_\Lambda(H)$  the invariant subspace of  $H$  corresponding to a Lambda-set  $\Lambda$  of  $\text{spec}(H)$ . Since  $\Lambda$  is a Lambda-set of  $\text{spec}(H)$   $\Lambda \cap (-\Lambda) = \emptyset$  and  $\Lambda \cup (-\Lambda) = \text{spec}(H)$ , and therefore  $\dim(\mathcal{X}_\Lambda(H)) = n$ . Let  $\mathcal{X}_\Lambda(H)$  be given by

$$(5.3) \quad \mathcal{X}_\Lambda(H) = \text{im} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix},$$

where  $X_1, X_2 \in \mathbb{R}^{n \times n}$ . Since  $\mathcal{X}_\Lambda(H)$  is an invariant subspace corresponding to  $\Lambda$ , we have the following equality

$$(5.4) \quad H \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} H_\Lambda,$$

where  $H_\Lambda \in \mathbb{R}^{n \times n}$  is such that  $\text{spec}(H_\Lambda) = \Lambda$ .

In order to prove that  $\mathcal{X}_\Lambda(H)$  is complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$ , we have to show that  $\ker X_1 = \{0\}$ . Assume to the contrary that  $\ker X_1$  is nontrivial; we shall show that this will lead to a contradiction to  $\Lambda \supseteq \Lambda_{\text{un}}^{(A,B)}$ .

We may assume without loss of generality that  $\mathcal{X}_\Lambda(H)$  is a generalized (right) eigenspace of  $H$  with respect to  $\Lambda$ . Using Lemma A.4 from the appendix we get,  $\text{im} \begin{bmatrix} X_2 \\ -X_1 \end{bmatrix}$  is a generalized left-eigenspace of  $H$  corresponding to  $-\Lambda$ . Since  $\Lambda$  is a Lambda-set,  $\Lambda \cap (-\Lambda) = \emptyset$ , so the two generalized eigenspaces are orthogonal to each other, i.e.,

$$\begin{bmatrix} X_2^T & -X_1^T \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = 0.$$

Because  $\mathcal{X}_\Lambda(H)$  is  $H$ -invariant, the last equation leads to

$$(5.5) \quad \begin{aligned} & \begin{bmatrix} X_2^T & -X_1^T \end{bmatrix} \begin{bmatrix} A & BB^T \\ -C^T C & -A^T \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = 0 \\ \Rightarrow & X_2^T A X_1 + X_1^T A^T X_2 + X_1^T C^T C X_1 + X_2^T B B^T X_2 = 0. \end{aligned}$$

Let  $x \in \ker X_1$ . Pre- and postmultiplying (5.5) by  $x^T$  and  $x$ , respectively, we get  $x^T X_2^T B B^T X_2 x = 0$ , which implies that  $B^T X_2 x = 0$ . Consider (5.4), which gives  $A X_1 + B B^T X_2 = X_1 H_\Lambda$ . After postmultiplying by  $x$  we get

$$\begin{aligned} A X_1 x + B B^T X_2 x &= X_1 H_\Lambda x \\ \Rightarrow X_1 H_\Lambda x &= 0 \quad \Rightarrow H_\Lambda x \in \ker X_1. \end{aligned}$$

This implies  $\ker X_1$  is  $H_\Lambda$ -invariant. Therefore, there exists  $v \neq 0$  an eigenvector of  $H_\Lambda$  such that  $X_1 v = 0$ . Let the eigenvalue corresponding to  $v$  be  $\lambda$ . Since  $\text{spec}(H_\Lambda) = \Lambda$ ,  $\lambda \in \Lambda$ . Now, from (5.4) we can write

$$(5.6) \quad -C^T C X_1 - A^T X_2 = X_2 H_\Lambda.$$

Postmultiplying (5.6) by  $v$  we get

$$\begin{aligned} -C^T C X_1 v - A^T X_2 v &= X_2 H_\Lambda v \\ \Rightarrow -A^T X_2 v &= \lambda X_2 v. \end{aligned}$$

But this means  $X_2 v$  is a left eigenvector of  $A$  with eigenvalue  $-\lambda$ . Moreover  $-\lambda \notin \Lambda$  (because  $\Lambda \cap (-\Lambda) = \emptyset$ ) and  $B^T X_2 v = 0$ . This together means that  $-\lambda$  is an uncontrollable eigenvalue of  $A$ , which is a contradiction to  $\Lambda \supseteq \Lambda_{\text{un}}^{(A,B)}$ . Thus  $\ker X_1$  cannot be nontrivial, and therefore  $\mathcal{X}_\Lambda$  is complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$ .

**(2  $\Rightarrow$  1)** We assume that  $\mathcal{X}_\Lambda(H)$ , the generalized eigenspace of  $H$  corresponding to  $\Lambda$  (a Lambda-set of  $\text{spec}(H)$ ), is complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$ , and we show that  $\Lambda \supseteq \Lambda_{\text{un}}^{(A,B)}$ . Suppose  $\Lambda \not\supseteq \Lambda_{\text{un}}^{(A,B)}$ . Then there exists  $\lambda \in \Lambda_{\text{un}}^{(A,B)}$  but  $\lambda \notin \Lambda$ . Since  $\Lambda$  is a Lambda-set of  $\text{spec}(H)$ ,  $\Lambda \cup (-\Lambda) = \text{spec}(H)$ . Also  $\Lambda_{\text{un}}^{(A,B)} \subset \text{spec}(H)$  (see Theorem 5.4). These two facts together imply that  $-\lambda \in \Lambda$ . Now  $\lambda \in \Lambda_{\text{un}}^{(A,B)}$  implies that there exists a nonzero vector  $v \in \mathbb{C}^n$  such that  $v^T A = \lambda v^T$  and  $v^T B = 0$ . Therefore the  $2n$  vector constructed as  $w = \text{col}(0_n, v)$  satisfies  $Hw = -\lambda w$ ; i.e.,  $w$  is an eigenvector of  $H$  with eigenvalue  $-\lambda$ . Since  $-\lambda \in \Lambda$ , the last  $w$  being an eigenvector of  $H$  with eigenvalue  $-\lambda$  means  $\mathcal{X}_\Lambda$  is *not* complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$  because  $w$  has the upper  $n$  entries zero. Thus  $\Lambda \not\supseteq \Lambda_{\text{un}}^{(A,B)}$  leads to a contradiction to statement 2. This proves “2  $\Rightarrow$  1.”  $\square$

With the above results we are now in a position to prove our main result, Theorem 3.4. The “if” part requires construction of a storage function for the uncontrollable behavior  $\mathfrak{B}$  to show strict dissipativity. We use the Hamiltonian matrix properties proved above, combined with some perturbation arguments, to show the Riccati equality and inequality have solutions, and then construct a storage function for proving the strict dissipativity. The unmixing property plays a key role in this construction.

*Proof of Theorem 3.4. (Only if)* We assume that  $\mathfrak{B} \in \mathfrak{L}^w$  is strictly  $\Sigma$ -dissipative, and we show that this implies  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative. Since  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative, according to Definition 3.2 there exists  $\Psi(\zeta, \eta) \in \mathbb{R}_s^{w \times w}[\zeta, \eta]$  and a real number  $\epsilon > 0$  such that

$$\frac{d}{dt} Q_\Psi(w) \leq Q_\Sigma(w) - \epsilon |w|^2 \quad \text{for all } w \in \mathfrak{B}.$$

Integrating both sides of the above inequality, considering only those trajectories in  $\mathfrak{B} \cap \mathfrak{D}$  we get

$$\int_{-\infty}^{\infty} Q_\Sigma(w) dt \geq \epsilon \int_{-\infty}^{\infty} |w|^2 dt \quad \text{for all } w \in \mathfrak{B} \cap \mathfrak{D}.$$

Since  $\mathfrak{B} \cap \mathfrak{D} = \mathfrak{B}_{\text{cont}} \cap \mathfrak{D}$  (see [16]), the above inequality implies that  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative.

**(If)** We assume that the controllable part  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative and that the unmixing condition on the uncontrollable poles holds. We show that  $\mathfrak{B}$  too is strictly  $\Sigma$ -dissipative. A necessary condition for  $\mathfrak{B}_{\text{cont}}$  to be strictly  $\Sigma$ -dissipative is that the transfer function for  $\mathfrak{B}_{\text{cont}}$  with the i/o partition induced by  $\Sigma$  is proper. Therefore, from Proposition 2.2 above,  $\mathfrak{B}$  has a state map  $X(\xi)$  and an i/s/o representation with  $x = X(\frac{d}{dt})w$  such that  $\frac{d}{dt}x = \tilde{A}x + \tilde{B}w_1$ ,  $w_2 = \tilde{C}x + \tilde{D}w_1$  with  $(\tilde{C}, \tilde{A})$  pair observable and  $(\tilde{A}, \tilde{B})$  pair uncontrollable with  $\Lambda_{\text{un}}^{(\tilde{A}, \tilde{B})} = \Lambda_{\text{un}}(\mathfrak{B})$ , counting mul-

tiplicities. Let  $\mathfrak{B}_{\text{cont}}$  have an image representation

$$\mathfrak{B}_{\text{cont}} = \text{im} \begin{bmatrix} W_1 \left( \frac{d}{dt} \right) \\ W_2 \left( \frac{d}{dt} \right) \end{bmatrix}; \quad W_1 \in \mathbb{R}^{m \times m}[\xi], W_2 \in \mathbb{R}^{p \times m}[\xi].$$

Since  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative, from Theorem 5.2,

$$\begin{aligned} \deg \left( \det \left[ W_1^T(-\xi)W_1(\xi) - W_2^T(-\xi)W_2(\xi) \right] \right) &= 2 \times n(\mathfrak{B}_{\text{cont}}) \text{ and} \\ W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega) &> 0 \quad \forall \omega \in \mathbb{R}. \end{aligned}$$

Again, from Lemma 5.3, these two facts together imply that  $I_m - \tilde{D}^T \tilde{D} > 0$ . This implies that there exists a Hamiltonian matrix given by

$$H = \begin{bmatrix} \tilde{A} + \tilde{B} \left( I_m - \tilde{D}^T \tilde{D} \right)^{-1} \tilde{D}^T \tilde{C} & \tilde{B} \left( I_m - \tilde{D}^T \tilde{D} \right)^{-1} \tilde{B}^T \\ -\tilde{C}^T \left( I_p - \tilde{D} \tilde{D}^T \right)^{-1} \tilde{C} & - \left( \tilde{A} + \tilde{B} \left( I_m - \tilde{D}^T \tilde{D} \right)^{-1} \tilde{D}^T \tilde{C} \right)^T \end{bmatrix}.$$

Define  $A := \tilde{A} + \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-1} \tilde{D}^T \tilde{C}$ ,  $B := \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-\frac{1}{2}}$ , and  $C := (I_p - \tilde{D} \tilde{D}^T)^{-\frac{1}{2}} \tilde{C}$ . Using Theorem 5.4 we get  $\text{spec}(H) = \text{roots} [\det \partial \Phi(\xi) \chi_{\text{un}}(\xi) \chi_{\text{un}}(-\xi)]$ , where  $\partial \Phi(\xi) := W_1^T(-\xi)W_1(\xi) - W_2^T(-\xi)W_2(\xi)$ . Since  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative, Theorem 5.2 implies that  $\text{roots}(\det \partial \Phi(\xi)) \cap j\mathbb{R} = \emptyset$ . By assumption  $\chi_{\text{un}}(\xi)$  and  $\chi_{\text{un}}(-\xi)$  are coprime, i.e.,  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \emptyset$ . Thus  $H$  has no eigenvalues on the imaginary axis and so  $\text{spec}(H)$  allows a Lambda-set  $\Lambda$ . Moreover, we can construct  $\Lambda$  in such a way that  $\Lambda_{\text{un}} \subseteq \Lambda$ . From Proposition 2.2 it follows that the set of uncontrollable eigenvalues of  $(A, B)$  pair is exactly equal to  $\Lambda_{\text{un}}$ . Hence from Theorem 5.5 a generalized eigenspace of  $H$  corresponding to  $\Lambda$ ,  $\mathcal{X}_\Lambda := \text{im} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$ , with  $X_1, X_2 \in \mathbb{R}^{n \times n}$ , is complementary to  $\text{im} \begin{bmatrix} 0_n \\ I_n \end{bmatrix}$ , which implies  $X_1$  is nonsingular allowing us to define  $K = X_2 X_1^{-1} \in \mathbb{R}^{n \times n}$ . Again since  $\Lambda \cap (-\Lambda) = \emptyset$ , applying Lemma A.4 we get

$$\begin{bmatrix} X_2^T & -X_1^T \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix} = 0, \text{ which implies that } (X_2 X_1^{-1})^T = X_2 X_1^{-1}.$$

Thus  $K = K^T$  is a symmetric solution to the ARE:  $A^T K + K A + C^T C + K B B^T K = 0$ .

In order to complete the proof we have to show that there exists a storage function for the strict dissipation inequality of Definition 3.2. For this we make use of Lemma A.2 of Appendix A to infer that the strict dissipation inequality is equivalent to the following LMI

$$(5.7) \quad \begin{bmatrix} - \left( \tilde{C}^T \tilde{C} + \tilde{A}^T K + K \tilde{A} \right) & - \left( K \tilde{B} + \tilde{C}^T \tilde{D} \right) \\ - \left( \tilde{B}^T K + \tilde{D}^T \tilde{C} \right) & s I_m - \tilde{D}^T \tilde{D} \end{bmatrix} - \epsilon \begin{bmatrix} \tilde{C}^T \tilde{C} & 0 \\ 0 & 0 \end{bmatrix} \geq 0,$$

for some  $\epsilon > 0$ . The corresponding Hamiltonian matrix turns out to be

$$\begin{aligned} H_\epsilon &:= \begin{bmatrix} \tilde{A} + \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-1} \tilde{D}^T \tilde{C} & \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-1} \tilde{B}^T \\ -\tilde{C}^T (I_p - \tilde{D} \tilde{D}^T)^{-1} \tilde{C} & -(\tilde{A} + \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-1} \tilde{D}^T \tilde{C})^T \end{bmatrix} - \epsilon \begin{bmatrix} 0 & 0 \\ \tilde{C}^T \tilde{C} & 0 \end{bmatrix} \\ &= H - \epsilon \begin{bmatrix} 0 & 0 \\ \tilde{C}^T \tilde{C} & 0 \end{bmatrix}. \end{aligned}$$

Observe that the kind of perturbation that takes  $H$  to  $H_\epsilon$  is such that  $\text{spec}(H_\epsilon) \supset \Lambda_{\text{un}}$ . Further, since the perturbation is analytic, according to [11], there exists an  $\epsilon_1 > 0$  small enough such that the following property of  $H$  holds for  $H_{\epsilon_1}$  also:

$$\text{spec}(H_{\epsilon_1}) \cap j\mathbb{R} = \phi.$$

Therefore,  $\text{spec}(H_{\epsilon_1})$  also allows a Lambda-set  $\Lambda_{\epsilon_1}$  such that  $\Lambda_{\epsilon_1} \supseteq \Lambda_{\text{un}}$ . It follows from Theorem 5.5 that there exists  $K_{\epsilon_1} = K_{\epsilon_1}^T \in \mathbb{R}^{n \times n}$ , which is a rank-minimizing solution to the LMI (5.7) with  $\epsilon = \epsilon_1$ .

The observable i/s/o representation is obtained from the manifest variables through a state map as  $x = X(\frac{d}{dt})w$ . Thus,  $X(\xi)$  and  $K_{\epsilon_1}$  give  $\Psi(\zeta, \eta) := X^T(\zeta)K_{\epsilon_1}X(\eta)$  that satisfies

$$\frac{d}{dt}Q_\Psi(w) = \frac{d}{dt} \left[ \left( X \left( \frac{d}{dt} \right) w \right)^T K_{\epsilon_1} X \left( \frac{d}{dt} \right) w \right] \leq Q_\Sigma(w) - \epsilon_1 |w|^2 \quad \forall w \in \mathfrak{B},$$

which from Definition 3.2 means that  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative.  $\square$

It is evident from the above proof that the storage function we construct to show strict dissipativity is, in fact, a memoryless quadratic function of the state of the system. More concretely, under the assumption that the uncontrollable poles are unmixed, such a storage function, which is a memoryless state function, exists if the behavior is strictly dissipative. We state this important consequence as a corollary below.

**COROLLARY 5.6.** *Suppose  $\mathfrak{B} \in \mathfrak{L}^w$  has uncontrollable poles satisfying  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \phi$ , and let  $X \in \mathbb{R}^{n \times w}[\xi]$  give a minimal state map for  $\mathfrak{B}$ . Consider a nonsingular  $\Sigma \in \mathbb{R}_s^{w \times w}$  with  $\mathfrak{m}(\mathfrak{B}) = \sigma_+(\Sigma)$ . Then, the following are equivalent.*

1.  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative.
2. There exists a  $K \in \mathbb{R}^{n \times n}$  and  $\epsilon > 0$  such that  $\frac{d}{dt}[(X(\frac{d}{dt})w)^T K X(\frac{d}{dt})w] \leq w^T(\Sigma - \epsilon I)w$  for all  $w \in \mathfrak{B}$ .

The above important and intuitive result that storage of energy requires memory elements, namely states, was proved formally for the controllable case in [27]. Note that for the special case that the behavior is controllable we have provided a new and alternative proof of the main result of [27], by showing that for a strictly dissipative behavior there exists a storage function which is a state function.

**Remark 5.7.** In this paper we have worked with strict dissipativity as defined in Definition 3.2. One of the main reasons to invoke strictness is that it guarantees nonsingularity of  $I_m - D^T D$  and hence the existence of the Hamiltonian matrix and the Riccati equation. It also rules out the possibility of the Hamiltonian matrix having purely imaginary eigenvalues, and thus enables us to use Lambda-set arguments. It remains to explore which of the above results are true for the case of nonstrict dissipativity.

**Remark 5.8.** The question of solvability of the positive-real LMI without imposing system theoretic assumptions like controllability or observability has been dealt with in [9]. However, a very restrictive assumption made there is that the whole set of eigenvalues of the system matrix  $A$  satisfies the unmixing property, i.e.,  $\text{spec}(A) \cap \text{spec}(-A) = \phi$ . According to our main result (Theorem 3.4) this assumption is not necessary. It is sufficient that only the uncontrollable poles satisfy the unmixing property. We shall see later in section 8 the extent of necessity of this unmixing property. The following example shows how the positive-real LMI is solvable when some elements of  $\text{spec}(A)$  have symmetry with respect to the imaginary axis and the system is uncontrollable.

*Example 5.9.* Consider an i/s/o system with the following  $A, B, C, D$  matrices:

$$A = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} -1 \\ -1 \end{bmatrix}, \quad C = \begin{bmatrix} 0 & 1 \end{bmatrix}, \quad D = 1.$$

Observe that  $\text{spec}(A) = \{1, -1\}$ , which is symmetric with respect to the imaginary axis. Here  $\Lambda_{\text{un}} = \{-1\}$ , and the other eigenvalue ( $= 1$ ) is controllable. An equivalent kernel representation of the manifest behavior is given by

$$\left[ \left( \frac{d^2}{dt^2} - \frac{d}{dt} - 2 \right) \quad - \left( \frac{d^2}{dt^2} - 1 \right) \right] \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = 0.$$

We ask the question: is this i/s/o system  $S := \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$  dissipative or equivalently, is there a real symmetric solution  $K = K^T \in \mathbb{R}^{2 \times 2}$  for the following LMI

$$\begin{bmatrix} -A^T K - K A & C^T - K B \\ C - B^T K & D + D^T \end{bmatrix} \geq 0?$$

Obviously,  $\Lambda_{\text{un}} = \{-1\}$  satisfies the unmixing property, and one can check that the controllable part  $\mathfrak{B}_{\text{cont}} = \ker \begin{bmatrix} \frac{d}{dt} - 2 & \frac{d}{dt} + 1 \end{bmatrix}$  is strictly  $S$ -dissipative, which from Theorem 3.4 implies that  $\mathfrak{B}$  is strictly  $S$ -dissipative. This can be verified by checking that the following real symmetric matrix induces a storage function that satisfies the dissipation inequality

$$K = \begin{bmatrix} -0.957 & -1.457 \\ -1.457 & -1.957 \end{bmatrix},$$

and therefore solves the LMI.

**6. Positive storage functions and stabilizability.** In this section we establish an important link between stabilizability of systems and positive definiteness of storage functions of strictly dissipative systems. The importance of this link lies in the fact that the energy stored in physical systems is a nonnegative quantity and dissipative physical systems satisfy an additional property that, if the system was initially discharged, then the net energy supplied into the system *upto any time instant* is nonnegative; this is called *half-line dissipativity*. We review these concepts (from [28]) below and prove similar results for uncontrollable systems in this section.

For this paper, we need half-line dissipativity for only the negative half of the real line:  $\mathbb{R}_-$ . A controllable behavior  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  is said to be  $\Sigma$ -dissipative on  $\mathbb{R}_-$  if  $\int_{-\infty}^0 Q_{\Sigma}(w)dt \geq 0$  for all  $w \in \mathfrak{B} \cap \mathfrak{D}$ . (Due to time invariance of  $\mathfrak{B}$ , it is enough to integrate up to 0.) Half-line dissipativity is related to (semi-)definiteness of the storage function. A storage function  $Q_{\Psi}$  is called nonnegative if  $Q_{\Psi}(w)(t) \geq 0$  for all  $t \in \mathbb{R}$  and  $w \in \mathfrak{B}$ . For controllable behaviors, it was shown in [28] that existence of a nonnegative storage function is equivalent to dissipativity of  $\mathfrak{B}$  on  $\mathbb{R}_-$ . The importance of nonnegative storage functions is due to such functions being bounded from below (namely, by zero), because of which we expect that when the supply of energy is stopped, then the trajectories cannot become unbounded. This link to stability was made precise and proved in [29, Proposition 1, Part I].

We saw in Corollary 5.6 that, for a dissipative behavior  $\mathfrak{B}$  with a minimal state map  $X \in \mathbb{R}^{n \times w}[\xi]$ , a storage function  $Q_{\Psi}$  is associated to a symmetric matrix  $K \in \mathbb{R}^{n \times n}$  such that  $Q_{\Psi}(w) = (X(\frac{d}{dt})w)^T K X(\frac{d}{dt})w$ . Hence  $Q_{\Psi}$  is nonnegative if and only

if  $K \geq 0$  (see [28]). In the context of strict dissipativity, we define a *positive definite* storage function. A storage function  $Q_\Psi$  is called positive definite if  $K > 0$ .

The following result is one of the main results of this paper. It relates existence of positive definite storage functions to stability of the autonomous part of the uncontrollable dissipative behavior. A behavior with a stable autonomous part is nothing but a *stabilizable* behavior. A behavior  $\mathfrak{B} \in \mathfrak{L}^w$  is called stabilizable if for every  $w \in \mathfrak{B}$ , there exists a  $w' \in \mathfrak{B}$  such that  $w(t) = w'(t)$  for  $t \leq 0$  and  $w'(t) \rightarrow 0$  as  $t \rightarrow \infty$ . A behavior is stabilizable if and only if  $\Lambda_{\text{un}} \subset \mathbb{C}^-$  (see [32]).

**THEOREM 6.1.** *Let a linear differential behavior  $\mathfrak{B} \in \mathfrak{L}^w$  be strictly  $\Sigma$ -dissipative with  $\mathfrak{m}(\mathfrak{B}) = \sigma_+(\Sigma)$ . Then there exists a positive definite storage function if and only if the following are satisfied:*

1. *there exists  $\epsilon > 0$  such that  $\int_{\mathbb{R}_-} Q_\Sigma(w) dt \geq \int_{\mathbb{R}_-} \epsilon |w|^2 dt$  for all  $w \in \mathfrak{B} \cap \mathfrak{D}$  and*
2.  *$\Lambda_{\text{un}} \subset \mathbb{C}^-$ .*

The first condition is clearly a necessary condition for existence of a positive definite storage function; namely, the controllable part has to be strictly dissipative on  $\mathbb{R}_-$ . The second condition is also necessary because of the notion that the storage function behaves like a Lyapunov function for an autonomous system, and as is well known, a positive Lyapunov function exists if and only if the autonomous system is asymptotically stable. The fact that these two conditions are together *sufficient* for the existence of a positive definite storage function for the whole behavior is one of the main contributions of this paper. Also notice that  $\Lambda_{\text{un}} \subset \mathbb{C}^-$  is a very special case of the unmixing condition. Thus the uncontrollability of the stabilizable behavior poses no hindrance to existence of a storage function for strict dissipativity as long as the controllable/autonomous parts allow storage/Lyapunov functions individually. As noted above, this is the principal finding of this paper.

*Proof. (If)* In this part of the proof we show that the existence of  $\epsilon > 0$  such that  $\int_{\mathbb{R}_-} Q_\Sigma(w) dt \geq \int_{\mathbb{R}_-} \epsilon |w|^2 dt$  for all  $w \in \mathfrak{B} \cap \mathfrak{D}$  and  $\Lambda_{\text{un}} \subset \mathbb{C}^-$  together imply that  $\mathfrak{B}$  has a positive definite storage function. First, let the controllable part be given by an observable image representation

$$\begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} W_1(\frac{d}{dt}) \\ W_2(\frac{d}{dt}) \end{bmatrix} \ell; \quad \ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m),$$

where  $W_1 \in \mathbb{R}^{m \times m}[\xi]$  and  $W_2 \in \mathbb{R}^{p \times m}[\xi]$ . Since  $\mathfrak{B} \cap \mathfrak{D} = \mathfrak{B}_{\text{cont}} \cap \mathfrak{D}$ ,  $\int_{\mathbb{R}_-} Q_\Sigma(w) dt \geq 0$  for all  $w \in \mathfrak{B} \cap \mathfrak{D}$  implies that the QDF induced by the two-variable polynomial matrix  $\Phi(\zeta, \eta) := [W_1^T(\zeta) \ W_2^T(\zeta)] \Sigma [W_1^T(\eta) \ W_2^T(\eta)]^T$  is strictly *half-line* positive, that is  $\int_{\mathbb{R}_-} Q_\Phi(\ell) dt > 0$  for all nonzero  $\ell \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^m)$ . This, according to Theorem 6.4 of [28], implies that  $W_1(\xi)$  is Hurwitz. Since  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative the transfer function from  $w_1$  to  $w_2$  is proper, and so from Proposition A.3,  $\mathfrak{B}$  has a state observable i/s/o representation in Kalman decomposed form as

$$A = \begin{bmatrix} A_c & A_{cp} \\ 0 & A_u \end{bmatrix}, B = \begin{bmatrix} B_c \\ 0 \end{bmatrix}, C = [C_c \ C_u],$$

where  $\frac{d}{dt}x_c = A_c x_c + B_c w_1, w_2 = C_c x + D w_1$  gives a state controllable and state observable i/s/o representation of the controllable part  $\mathfrak{B}_{\text{cont}}$ . This implies that roots  $(\det W_1(\xi)) = \text{spec}(A_c)$ , and, therefore,  $W_1(\xi)$  being Hurwitz implies that so is  $A_c$ . Once again, from Proposition A.3, the set of uncontrollable poles  $\Lambda_{\text{un}} = \text{spec}(A_u)$ . So  $\Lambda_{\text{un}} \subset \mathbb{C}^-$  implies  $A_u$  is also Hurwitz. Hence  $A$  is Hurwitz. Because  $\mathfrak{B}$  is strictly

$\Sigma$ -dissipative, the following ARI has a solution

$$(6.1) \quad A^T K + K A + C^T C + (D^T C + B^T K)^T (I_m - D^T D)^{-1} (D^T C + B^T K) \leq 0.$$

Since  $(D^T C + B^T K)^T (I_m - D^T D)^{-1} (D^T C + B^T K) \geq 0$ ,  $(C, A)$  being observable implies that  $[C^T C + (D^T C + B^T K)^T (I_m - D^T D)^{-1} (D^T C + B^T K), A]$  too is observable (see [34]). Hence the above inequality (6.1), when treated as a Lyapunov equation  $A^T K + K A + Q \leq 0$ , where  $Q := [C^T C + (D^T C + B^T K)^T (I_m - D^T D)^{-1} (D^T C + B^T K)]$ , has  $(Q, A)$  observable and  $A$  Hurwitz, which means that all the solutions  $K$  are positive definite (see [34]). Thus a positive definite solution to (6.1) induces a positive definite storage function and this completes the proof of the “if” part.

**(Only if)** First we shall show that  $\mathfrak{B}$  being strictly dissipative with respect to  $\Sigma$  with a positive definite storage function implies that there exists  $\epsilon > 0$  such that  $\int_{\mathbb{R}_-} Q_\Sigma(w) dt \geq \int_{\mathbb{R}_-} \epsilon |w|^2 dt$  for all  $w \in \mathfrak{B} \cap \mathfrak{D}$ . Let  $Q_\Psi$  be a positive definite storage function that satisfies the strict dissipation inequality

$$(6.2) \quad \frac{d}{dt}(Q_\Psi(w)) \leq Q_\Sigma(w) - \epsilon |w|^2, \text{ for all } w \in \mathfrak{B}.$$

Considering only those trajectories in  $\mathfrak{B} \cap \mathfrak{D}$  and integrating over  $\mathbb{R}_-$  we get

$$\int_{\mathbb{R}_-} Q_\Sigma(w) dt - \int_{\mathbb{R}_-} \epsilon |w|^2 dt \geq Q_\Psi(w)(0) \Rightarrow \int_{\mathbb{R}_-} Q_\Sigma(w) dt \geq \int_{\mathbb{R}_-} \epsilon |w|^2 dt,$$

where the last implication uses  $Q_\Psi(w) \geq 0$ .

Next we show that  $\mathfrak{B}$  being strictly dissipative with a positive storage function implies that  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ . Observe that  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative implies that the partition  $w = (w_1, w_2)$  induced by  $\Sigma$  results in  $\mathfrak{B}_{\text{cont}}$  having a *proper* transfer function from  $w_1$  to  $w_2$ . Hence it follows from Proposition 2.2 that  $\mathfrak{B}$  allows an i/s/o representation  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$ , where  $(A, B)$  is state uncontrollable and  $(C, A)$  is state observable. In order to show that  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ , we shall show, in fact, that  $A$  is Hurwitz. We show this implication by contradiction, i.e., if  $\lambda \notin \mathbb{C}^-$  is an eigenvalue of  $A$ , then there does not exist *any* nonnegative definite storage functions. Let  $\lambda \in \text{spec}(A)$  and  $x_0 \neq 0$ , the corresponding eigenvector of  $A$ . The following  $w$  is an element of  $\mathfrak{B}$

$$(6.3) \quad \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} 0 \\ Cx_0 e^{\lambda t} \end{bmatrix}.$$

The behavior  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative implies that there exists a storage function  $Q_\Psi(w)$  that satisfies the following strict dissipation inequality:

$$(6.4) \quad \frac{d}{dt}(Q_\Psi(w)) \leq |w_1|^2 - |w_2|^2 - \epsilon |w|^2 \text{ for all } w \in \mathfrak{B}.$$

Putting  $w$  as in (6.3) we get, by direct differentiation of the left hand-side,

$$(6.5) \quad 2\Re(\lambda)Q_\Psi(w) \leq -x_0^T C^T C x_0 e^{2\Re(\lambda)t} - \epsilon |w|^2.$$

Consider the case when  $\lambda \in \mathbb{C}^+$ . The right-hand side of the above inequality is negative definite, which implies that  $Q_\Psi(w) \not\geq 0$  for this  $w \in \mathfrak{B}$ . This proves the contradiction for the case  $\Re(\lambda) > 0$ . Next we consider the case when  $\lambda \in j\mathbb{R}$ . In that case  $\Re(\lambda) = 0$ , which makes inequality (6.5) impossible. Thus we have shown that

$\lambda \notin \mathbb{C}^-$  eliminates nonnegativity of *any* storage function. Hence in order to have a positive definite storage function it is necessary that  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ . This completes the proof that existence of a nonnegative storage function implies  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ .  $\square$

Within the above proof, we have, in fact, shown that *every* storage function for the behavior is positive definite. This has been shown for the controllable case in [28, Theorem 6.4]. Intuitively, storage functions being positive is closer to their interpretation as energy-like functions. Also, the meaning of dissipativity that there is no source of energy in the system appeals to both positive definite storage functions and the stabilizability of the system. In the following section we explore other properties of the set of storage functions, like (un)boundedness of this set.

**7. Set of all storage functions for an uncontrollable system.** Another important topic of interest is the set of all storage functions of a dissipative behavior. For LQR/LQG theory and  $\mathcal{H}_\infty$  control, certain extremum storage functions give stabilizing controllers. In this section we show that the set of storage functions is unbounded for uncontrollable dissipative systems and that for stabilizable systems, this set is bounded from below.

We have seen before how the solutions to an ARI give storage functions as state functions. Thus to further explore the set of all storage functions we shall look into the set of solutions of a related ARI. It has been shown (in [27, 28], for example) that with respect to a given state space representation i.e., with respect to a given state map  $x = X(\frac{d}{dt})w$ , there is a one to one correspondence between storage functions and solutions to the ARI. Moreover, it is known that the set of storage functions for a controllable dissipative behavior is a bounded convex polytope with its vertices given by the storage functions coming from so-called spectral factorizations of  $\partial\Phi(\xi)$ . These storage functions correspond to the algebraic Riccati *equality* solutions. However, this set of solutions to the ARI turns out to lose the boundedness property when the behavior loses controllability. This constitutes the theorem below, one of the main results of this paper.

**THEOREM 7.1.** *Let  $\mathfrak{B} \in \mathfrak{L}^w$  be uncontrollable, and suppose the set of its uncontrollable poles  $\Lambda_{\text{un}}$  satisfies the unmixing property, i.e.,  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \emptyset$ . Further, let  $\mathfrak{B}$  be strictly  $\Sigma$ -dissipative. Then the set of all storage functions is an unbounded convex set.*

*Proof.* By Proposition 2.2,  $\mathfrak{B}$  allows an i/s/o representation as  $\frac{d}{dt}x = \tilde{A}x + \tilde{B}w_1$ ,  $w_2 = \tilde{C}x + \tilde{D}w_1$ . Since  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative,  $(I_m - \tilde{D}^T\tilde{D}) > 0$  and all the storage functions come from real symmetric solutions of the following ARI

$$A^TK + KA + C^TC + KBB^TK \leq 0,$$

where  $A := \tilde{A} + \tilde{B}(I_m - \tilde{D}^T\tilde{D})^{-1}\tilde{D}^T\tilde{C}$ ,  $B := \tilde{B}(I_m - \tilde{D}^T\tilde{D})^{-\frac{1}{2}}$ , and  $C := (I_p - \tilde{D}\tilde{D}^T)^{-\frac{1}{2}}\tilde{C}$ . That the set of solutions to this ARI is convex is well known (see [4], for example). In order to show the unboundedness of the solution set, we once again make use of the Kalman decomposition result (Proposition A.3): there exists a similarity transformation that results in  $A, B, C$  matrices in the following forms:  $A = \begin{bmatrix} A_c & A_{cp} \\ 0 & A_u \end{bmatrix}$ ,  $B = \begin{bmatrix} B_c \\ 0 \end{bmatrix}$ , and  $C = [C_c \quad C_u]$ . In order to show that the set of ARI solutions is unbounded, we shall show that there exists a nonzero  $P \in \mathbb{R}_s^{n \times n}$  such that if  $K \in \mathbb{R}_s^{n \times n}$  is a solution to the ARI, then for all  $\lambda > 0$ , the new real symmetric matrix defined by  $\tilde{K} := K + \lambda P$  is also a solution of the ARI. Define  $P$

$$P := \begin{bmatrix} 0 & 0 \\ 0 & P_1 \end{bmatrix},$$

where  $P_1 \in \mathbb{R}_s^{n_u \times n_u}$  satisfies the following Lyapunov inequality

$$(7.1) \quad A_u^T P_1 + P_1 A_u \leq 0.$$

Since the set of uncontrollable poles satisfy the unmixing property, that is,  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \emptyset$ , the Lyapunov inequality is guaranteed to have a nonzero solution. Consider the following expression in  $\tilde{K}$ :

$$\begin{aligned} & A^T \tilde{K} + \tilde{K} A + C^T C + \tilde{K} B B^T \tilde{K} \\ &= A^T K + K A + C^T C + K B B^T K + \lambda (A^T P + P A) + \lambda^2 P B B^T P \\ & \quad + \lambda (K B B^T P + P B B^T K). \end{aligned}$$

Using the Kalman decomposed form of  $A, B$ , and  $C$  above and the structure of  $P$ , the above expression simplifies to

$$(A^T K + K A + C^T C + K B B^T K) + \lambda \begin{bmatrix} 0 & 0 \\ 0 & A_u^T P_1 + P_1 A_u \end{bmatrix}.$$

From the fact that  $K$  is a solution to the ARI, and that  $P_1$  satisfies the Lyapunov inequality (7.1) the above expression is negative semidefinite for all  $\lambda > 0$ . Thus  $A^T \tilde{K} + \tilde{K} A + C^T C + \tilde{K} B B^T \tilde{K} \leq 0$ , and  $\tilde{K}$  is also a solution of the ARI for all  $\lambda > 0$ . This proves that the set of solutions to the ARI is unbounded.  $\square$

Notice that within the above proof we used that, if a solution  $K$  to the Riccati inequality exists, then a solution  $P_1$  to the Lyapunov inequality (7.1) can be added to  $K$  giving solutions  $\tilde{K}$  of the ARI. Though we have demonstrated the existence of solutions to the ARI primarily under the unmixing condition on the uncontrollable poles, this method shows that whenever the Riccati inequality admits solutions, uncontrollability forces the set of storage functions to be unbounded.

The following simple example shows a pictorial representation of the set of all storage functions for a controllable behavior.

*Example 7.2.* Consider behavior  $\mathfrak{B}$  having an i/s/o representation with  $A = \begin{bmatrix} 0 & -2 \\ 1 & -3 \end{bmatrix}$ ,  $B = \begin{bmatrix} 10 \\ 1 \end{bmatrix}$ ,  $C = [0 \quad 1]$  and supply rate  $S = \begin{bmatrix} 100 & 0 \\ 0 & -1 \end{bmatrix}$ . Let all the symmetric solutions to the corresponding ARI be of the form  $K = \begin{bmatrix} k_1 & k_2 \\ k_2 & k_3 \end{bmatrix}$ . The figure below shows the set of all ARI solutions. Clearly, the set is a bounded convex polytope.

*Remark 7.3.* Figure 7.1 corresponds to a controllable behavior, and hence the set is bounded. As the behavior becomes uncontrollable, all Lambda-sets no longer admit Riccati equation solutions (see Theorem 5.5). However, the set of storage functions is now unbounded along certain directions specified by the Lyapunov equation corresponding to the autonomous part of the behavior (as shown in Theorem 7.1). For some specific examples, the transition to uncontrollability causes the Riccati equation solutions corresponding to inadmissible Lambda-sets to move to infinity along the direction of the Lyapunov equation solution. Further, loosely speaking, when restricted to the controllable part, the storage functions corresponding to the Riccati equation solutions are unaffected by translation along this direction. It remains to formulate these observations concretely and prove them.

A very interesting fact about this unbounded set of all storage functions comes up for the case when the behavior is uncontrollable but stabilizable; i.e., the set of uncontrollable poles  $\Lambda_{\text{un}}$  is contained in the open left half of the complex plane (see the previous section for the definition and related results about stabilizability). We

FIG. 7.1. The set of all storage functions.

show below that for stabilizability, the set of storage functions, though an unbounded set, is bounded from below. In other words, there exists a storage function  $Q_{\Psi_-}$  such that every storage function  $Q_{\Psi}$  satisfies  $Q_{\Psi}(w) - Q_{\Psi_-}(w) \geq 0$  for all  $w \in \mathfrak{B}$ . We state this result as a theorem below.

**THEOREM 7.4.** *Let  $\mathfrak{B} \in \mathfrak{L}^w$  be an uncontrollable, strictly  $\Sigma$ -dissipative behavior. Also assume that the set of uncontrollable poles  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ . Then the set of all storage functions is bounded from below; i.e., there exists a storage function  $Q_{\Psi_-}(w)$  for  $\mathfrak{B}$  such that for each storage function  $Q_{\Psi}(w)$  for  $\mathfrak{B}$ ,  $Q_{\Psi_-}(w) \leq Q_{\Psi}(w)$  for all  $w \in \mathfrak{B}$ .*

Note the analogy of this result with that for controllable behaviors, where the set of storage functions is bounded and has a maximum and a minimum element (see [28, Theorem 5.7]). While we have shown unboundedness for the case of uncontrollability, stabilizability ensures the existence of the minimum element in this unbounded set.

*Proof.* To prove the above result, we use Corollary 5.6 and look into the solutions to the corresponding ARI. Let the behavior  $\mathfrak{B}$  have an i/s/o representation:  $\frac{d}{dt}x = \tilde{A}x + \tilde{B}w_1$ ,  $w_2 = \tilde{C}x + \tilde{D}w_1$ . Then the set of all storage functions comes from the solution set of the following ARI

$$A^T K + K A + C^T C + K B B^T K \leq 0,$$

where  $A := \tilde{A} + \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-1} \tilde{D}^T \tilde{C}$ ,  $B := \tilde{B}(I_m - \tilde{D}^T \tilde{D})^{-\frac{1}{2}}$ , and  $C := (I_p - \tilde{D} \tilde{D}^T)^{-\frac{1}{2}} \tilde{C}$ . Construct the corresponding Hamiltonian matrix

$$H := \begin{bmatrix} A & B B^T \\ -C^T C & -A^T \end{bmatrix}.$$

By assumption,  $\mathfrak{B}$  is strictly  $\Sigma$ -dissipative, which implies  $\text{spec}(H) \cap j\mathbb{R} = \emptyset$ . Also from Theorem 5.4,  $\text{spec}(H) \supset \Lambda_{\text{un}}$  and by assumption  $\Lambda_{\text{un}} \subset \mathbb{C}^-$ . These facts together imply that there exists a Lambda-set (say  $\Lambda$ ) of  $\text{spec}(H)$  such that  $\Lambda \supset \Lambda_{\text{un}}$  and  $\Lambda \subset \mathbb{C}^-$ . By Theorem 5.5, since  $\Lambda \supseteq \Lambda_{\text{un}}$ , there exists a real symmetric solution,  $K_-$  to the ARE such that  $\text{spec}(A + B B^T K_-) = \Lambda$ . We shall show that this particular solution to the ARE serves as a “minimum” storage function. To show this consider any real symmetric solution  $K$  to the ARI

$$(7.2) \quad A^T K + K A + C^T C + K B B^T K \leq 0.$$

Also rewrite the ARE in  $K_-$  as follows

$$(7.3) \quad (A + BB^T K_-)^T K_- + K_- (A + BB^T K_-) + C^T C - K_- BB^T K_- = 0.$$

Subtracting (7.3) from (7.2), and further adding and subtracting the terms  $K_- BB^T K_-$  and  $K BB^T K_-$  we get

$$(7.4) \quad (A + BB^T K_-)^T (K - K_-) + (K - K_-) (A + BB^T K_-) + (K - K_-) BB^T (K - K_-) \leq 0.$$

Observe that the above inequality closely resembles the Lyapunov inequality. In order to conclude that  $(K - K_-) \geq 0$ , it is enough to notice that  $\text{spec}(A + BB^T K_-) = \Lambda \subset \mathbb{C}^-$ , and the constant-like term  $(K - K_-) BB^T (K - K_-)$  is nonnegative. This proves our claim that the set of all storage functions is bounded from below.  $\square$

We saw in the previous section that, for a strictly dissipative and stabilizable behavior  $\mathfrak{B}$ , dissipativity on  $\mathbb{R}_-$  of  $\mathfrak{B}_{\text{cont}}$  assures the existence of positive definite storage functions. Combining this result with the one above, we infer that the lower bound of the set of storage functions is, in fact, positive (see discussions following Theorem 6.1). This formalizes the intuition that such a system is devoid of any energy sources within it, and hence the maximum extractable energy<sup>3</sup> from *any* given state is bounded.

Using a very similar argument as in the above proof, one can show that if the behavior is antistabilizable, meaning all the uncontrollable poles are unstable, i.e.,  $\Lambda_{\text{un}} \subset \mathbb{C}^+$ , then the set of storage functions is bounded *from above*.

**8. Necessity of the unmixing of uncontrollable poles.** As seen in Theorem 3.4, the unmixing property of the uncontrollable poles makes strict dissipativity of the controllable part equivalent to that of the whole behavior. In this section we shall see to what extent the unmixing property is necessary. As mentioned in the introduction, the unmixing property serves as a sufficient condition for solvability of a Lyapunov equation and the corresponding Lyapunov operator becomes singular when this condition is not satisfied. We show in this section that the Lyapunov operator is onto if and only if there exists an observable rank one symmetric matrix in its image. This interesting result is utilized for exploring the extent of the unmixing condition for strict dissipativity. Theorem 8.3 below shows that for a system with single output, unmixing is necessary for existence of nonzero lossless trajectories satisfying a dissipation *equality* (see Remark 8.4 below).

When the Lyapunov operator is singular, then nonsymmetric solutions can exist even when the constant term is symmetric. This general solvability condition can be obtained from a certain eigenspace of a Hamiltonian matrix. The fact that a Lyapunov equation is a special case of an ARE with the quadratic term being zero motivates the following result. We state this as a lemma below since it will be needed later in this section. Related results on Lyapunov equation solvability can be found in [24].

**LEMMA 8.1.**  $K \in \mathbb{R}^{n \times n}$  is a solution (not necessarily symmetric) to the following Lyapunov equation  $A^T K + K A + C^T C = 0$  if and only if  $\text{im} \begin{bmatrix} I_n \\ K \end{bmatrix}$  is an invariant space of the Hamiltonian matrix defined as

$$H = \begin{bmatrix} A & 0 \\ -C^T C & -A^T \end{bmatrix}.$$

<sup>3</sup>This has been called *available storage* in [28].

*Proof. (If)* We first assume that  $\mathcal{X}_A := \text{im} \begin{bmatrix} I_n \\ K \end{bmatrix}$  is an  $n$ -dimensional invariant subspace of  $H$ . We shall show that this implies  $K$  satisfies the Lyapunov equation  $A^T K + K A + C^T C = 0$ . Clearly  $\begin{bmatrix} K & -I_n \end{bmatrix} \begin{bmatrix} I_n \\ K \end{bmatrix} = 0$ . Since  $\mathcal{X}_A$  is  $H$ -invariant the last equation can be written as  $\begin{bmatrix} K & -I_n \end{bmatrix} \begin{bmatrix} A & 0 \\ -C^T C & -A^T \end{bmatrix} \begin{bmatrix} I_n \\ K \end{bmatrix} = 0$ . Hence  $A^T K + K A + C^T C = 0$ .

**(Only if)** In this part we shall show that  $K$  being a solution to the Lyapunov equation  $A^T K + K A + C^T C = 0$  implies that  $\text{im} \begin{bmatrix} I_n \\ K \end{bmatrix}$  is an  $n$ -dimensional invariant subspace of  $H$ . Assuming  $K$  satisfies the Lyapunov equation, we can write the following equality:

$$\begin{bmatrix} A & 0 \\ -C^T C & -A^T \end{bmatrix} \begin{bmatrix} I_n \\ K \end{bmatrix} = \begin{bmatrix} I_n \\ K \end{bmatrix} A.$$

This implies that  $\text{im} \begin{bmatrix} I_n \\ K \end{bmatrix}$  is an eigenspace of  $H$  corresponding to  $\text{spec}(A)$ .  $\square$

It follows from the lemma above that there is only one set of eigenvalues of the Hamiltonian matrix, which gives a solution to the Lyapunov equation: namely, the eigenvalues of  $A$ . Unlike the ARE, for the Lyapunov equation there is no choice for the set of eigenvalues of the Hamiltonian matrix. Another important fact that follows is that the set of eigenvalues, i.e.,  $\text{spec}(A)$  is no longer a Lambda-set when there is mixing, i.e.,  $\text{spec}(A) \cap \text{spec}(-A) \neq \emptyset$ . Owing to this particular fact, the eigenspace of the Hamiltonian matrix which gives a solution is no longer guaranteed to be perpendicular to the left-eigenspace corresponding to the rest of the eigenvalues of  $H$ . However, from Lemma A.4 if  $\text{im} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$  is a (generalized) right-eigenspace of dimension  $n$  corresponding  $\text{spec}(A)$ , then  $\text{im} \begin{bmatrix} X_2 \\ -X_1 \end{bmatrix}$  is an  $n$ -dimensional (generalized) left-eigenspace corresponding to  $\text{spec}(-A)$ . Since the right and left eigenspaces are no longer guaranteed to be perpendicular, we do not necessarily have  $X_2 X_1^{-1} = X_1^{-T} X_2^T$ . This implies that when the unmixing condition is not satisfied there can be nonsymmetric and nonunique solutions to the Lyapunov equation. However, the existence of a nonsymmetric solution guarantees existence of a symmetric solution. If  $K$  is a solution to the Lyapunov equation, then so are  $K^T$  and  $(K + K^T)/2$ . With this simple observation we now give a necessary and sufficient condition for the existence of solution to a Lyapunov equation for the special case that the constant term is of rank one. Interestingly for this case when the constant term is rank 1 the unmixing condition becomes necessary!

**THEOREM 8.2.** *Consider the Lyapunov equation  $A^T K + K A + C^T C = 0$  with  $(C, A)$  pair observable. Assume  $\text{rank}(C^T C) = 1$ . Then there exists a solution  $K$  to the Lyapunov equation if and only if  $\text{spec}(A) \cap \text{spec}(-A) = \emptyset$ .*

*Proof. (If)* This implication is well known (see [26], for example). In fact, uniqueness and symmetry are guaranteed.

**(Only if)** Suppose  $A$  has a mixed spectrum, that is,  $\text{spec}(A) \cap \text{spec}(-A) \neq \emptyset$ . We shall show that this implies that the Lyapunov equation  $A^T K + K A + C^T C = 0$  has no solution  $K$ . In Theorem 8.1 it has been shown that the eigenspace of the Hamiltonian matrix corresponding to only  $\text{spec}(A)$  can give a solution to the Lyapunov equation. Hence to prove that there does not exist any solution  $K$ , it is sufficient to show that any eigenvector of the Hamiltonian matrix

$$H := \begin{bmatrix} A & 0 \\ -C^T C & -A^T \end{bmatrix},$$

corresponding to an eigenvalue  $\lambda \in \text{spec}(A) \cap \text{spec}(-A)$  shall have all upper  $n$  elements zero. For that, let  $v := \text{col}(v_1, v_2) \in \mathbb{C}^{2n}$ ,  $v \neq 0$  be an eigenvector of  $H$  corresponding to  $\lambda \in \text{spec}(A) \cap \text{spec}(-A^T)$ . It then follows that

$$\begin{bmatrix} A & 0 \\ -C^T C & -A^T \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \lambda \begin{bmatrix} v_1 \\ v_2 \end{bmatrix},$$

which means  $Av_1 = \lambda v_1$  and  $[\lambda I_n - (-A^T)]v_2 = -C^T C v_1$ . Suppose  $v_1 \neq 0$ , then the above implies  $v_1$  is an eigenvector of  $A$ . Since  $(C, A)$  is observable  $Cv_1 \neq 0$ . Further,  $\text{rank}(C^T C) = 1$ ,  $Cv_1 \neq 0$  together imply  $[\lambda I_n - (-A^T)]v_2 = -C^T C v_1$  implies<sup>4</sup>

$$(8.1) \quad \text{im } C^T \subseteq \text{im } [\lambda I_n - (-A^T)].$$

This gives  $\ker C \supseteq \ker [\lambda I_n - (-A)]$ . Since  $\lambda \in \text{spec}(A) \cap \text{spec}(-A)$ ,  $-\lambda \in \text{spec}(A)$ . But the inclusion  $\ker C \supseteq \ker [\lambda I_n - (-A)]$  implies  $\begin{bmatrix} -\lambda I_n & -A \\ C & \end{bmatrix}$  loses rank, which means  $-\lambda$  is unobservable. This contradicts the observability of  $(C, A)$ . Hence  $v_1 = 0$ , and therefore, the eigenspace of  $H$  corresponding to  $\text{spec}(A)$  cannot have the form  $\text{im } \begin{bmatrix} I_n \\ K \end{bmatrix}$ . Thus, using Lemma 8.2, the Lyapunov equation is not solvable.  $\square$

It is well known that the unmixing condition is equivalent to existence and uniqueness of solution to the Lyapunov equation. In other words, the unmixing condition is equivalent to the image of the Lyapunov operator containing *all* symmetric matrices. The above theorem shows that unmixing is necessary and sufficient for the image to contain a symmetric matrix of rank one (satisfying observability conditions). However, the corresponding Lyapunov inequality can have solutions when the equation is not solvable; see Remark 8.4 below.

We have seen in the previous sections how dissipativity is related to the solvability of certain ARE/ARI. For an uncontrollable system the corresponding ARE behaves like a Lyapunov equation on certain subspaces of the state space. Following this observation we shall now utilize Theorem 8.2 to show how the unmixing becomes necessary for the solvability of the ARE. We shall make use of the fact that  $C^T C$  being rank one means that the system has only one output.

**THEOREM 8.3.** *Consider  $\mathfrak{B} \in \mathfrak{L}^w$  having a single output, i.e.,  $p(\mathfrak{B}) = 1$ . Suppose  $R \in \mathbb{R}^{1 \times w}[\xi]$ , with  $R \neq 0$ , gives a kernel representation for  $\mathfrak{B}$ . Define  $\Lambda_{\text{un}} = \{\lambda \in \mathbb{C} \mid R(\lambda) = 0\}$  and let  $(A, B, C, D)$  give a minimal i/s/o representation for  $\mathfrak{B}$ , with  $(C, A)$  observable. Then, the following are equivalent.*

1.  $I_m - D^T D > 0$  and there exists  $K$  satisfying

$$(8.2) \quad A^T K + K A + C^T C + (K B + C^T D)(I_m - D^T D)^{-1}(B^T K + D^T C) = 0,$$

with  $\text{spec}(A + B(I_m - D^T D)^{-1}(B^T K + D^T C)) \cap j\mathbb{R} = \emptyset$ .

2.  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \emptyset$  and  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative.

*Proof.* **(2  $\Rightarrow$  1)** From Lemma 5.3 strict dissipativity of  $\mathfrak{B}_{\text{cont}}$  implies  $I_m - D^T D > 0$ , so the following Hamiltonian matrix exists

$$(8.3) \quad H := \begin{bmatrix} A + B(I_m - D^T D)^{-1} D^T C & B(I_m - D^T D)^{-1} B^T \\ -C^T (I_p - D D^T)^{-1} C & -\left(A + B(I_m - D^T D)^{-1} D^T C\right)^T \end{bmatrix}.$$

<sup>4</sup>Existence of a solution  $v_2$  for just one  $v_1 \neq 0$  implies the inclusion (8.1) because of the rank condition.

Let the observable image representation of  $\mathfrak{B}_{\text{cont}}$  induce the para-Hermitian matrix  $\partial\Phi(\xi)$ . Then by Theorem 5.4 we get  $\text{spec}(H) = \text{roots} [\det \partial\Phi(\xi) \chi_{\text{un}}(\xi) \chi_{\text{un}}(-\xi)]$ . Once again strict  $\Sigma$ -dissipativity of  $\mathfrak{B}_{\text{cont}}$  implies  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$  (see Theorem 5.2) meaning  $\text{roots} (\det \partial\Phi(\xi))$  has no roots on the imaginary axis. This together with the assumption  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) = \emptyset$  implies that  $\text{spec}(H) \cap j\mathbb{R} = \emptyset$  and so it allows a Lambda-set  $\Lambda \supseteq \Lambda_{\text{un}}$ . It then follows from Theorem 5.5 that there exists  $K \in \mathbb{R}^{n \times n}$  such that  $\text{im} \begin{bmatrix} I_n \\ K \end{bmatrix}$  is the  $n$ -dimensional invariant subspace of  $H$  corresponding to  $\Lambda$ . This shows that  $K$  solves the ARE. Also this solution  $K$  has the property  $\text{spec}(A + B(I_m - D^T D)^{-1}(B^T K + D^T C)) = \Lambda$  (see Proposition 4.4) which means  $\text{spec}(A + B(I_m - D^T D)^{-1}(B^T K + D^T C)) \cap j\mathbb{R} = \emptyset$  because  $\Lambda \subset \text{spec}(H)$  and  $\text{spec}(H) \cap j\mathbb{R} = \emptyset$ .

**(1  $\Rightarrow$  2)** We shall first show that statement 1 implies that  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative.  $I_m - D^T D$  is assumed to be positive definite, and therefore the Hamiltonian matrix of equation (8.3) exists. Again, Theorem 5.4 implies  $\text{spec}(H) = \text{roots} [\det \partial\Phi(\xi) \chi_{\text{un}}(\xi) \chi_{\text{un}}(-\xi)]$ . Counting multiplicities both sides we get  $\deg (\det \partial\Phi(\xi)) = 2n(\mathfrak{B}_{\text{cont}})$ . We claim that  $H$  has no eigenvalues on the imaginary axis, because otherwise any solution to the ARE, if it exists, would result in  $\text{spec}(A + B(I_m - D^T D)^{-1}(B^T K + D^T C)) \cap j\mathbb{R} \neq \emptyset$  which contradicts statement 1. Thus  $\partial\Phi(\xi)$  also has no zeros on the imaginary axis, which implies  $\partial\Phi(j\omega) > 0$  for all  $\omega \in \mathbb{R}$ . This positive definiteness together with  $\deg (\det \partial\Phi(\xi)) = 2n_c$  implies that  $\mathfrak{B}_{\text{cont}}$  is strictly  $\Sigma$ -dissipative (see Theorem 5.2).

In order to complete the proof it remains to show that the ARE (8.2) having a solution implies that  $\Lambda_{\text{un}}$  is unmixed. Since  $(C, A)$  is observable  $K$  is nonsingular (see [7, Lemma 3]). We have assumed that  $\mathfrak{B}$  is uncontrollable; therefore,  $(A, B)$  pair is also uncontrollable and the set of uncontrollable poles  $\Lambda_{\text{un}}$  is exactly equal to the set of uncontrollable eigenvalues of  $A$  (this follows from Proposition 2.2). So if  $\Lambda_{\text{un}}$  has cardinality  $n_u$  (counting multiplicities), then there exists a full column rank matrix  $T_u \in \mathbb{R}^{n \times n_u}$  obtained from the generalized eigenvectors of  $A^T$  such that  $A^T T_u = T_u A_u$  and  $T_u^T B = 0$ , where  $A_u \in \mathbb{R}^{n_u \times n_u}$  is in Jordan form with  $\text{spec}(A_u) = \Lambda_{\text{un}}$ . Also, since  $K$  is nonsingular, there exists  $T \in \mathbb{R}^{n \times n_u}$  full column rank, such that  $KT = T_u$ . Then pre- and postmultiplying the ARE (8.2) by  $T^T$  and  $T$ , respectively, and making use of the fact that  $A^T T_u = T_u A_u$  and  $T_u^T B = 0$  we get

$$T^T K T A_u + A_u^T T^T K T + T^T C^T (I_p - D D^T)^{-1} C T = 0.$$

Define  $K_u := T^T K T \in \mathbb{R}^{n_u \times n_u}$  and  $C_u := (I_p - D D^T)^{-\frac{1}{2}} C T$ . The above Lyapunov equation can be rewritten as  $A_u^T K_u + K_u A_u + C_u^T C_u = 0$ .

Now we show that the new positive semidefinite matrix  $C_u^T C_u$  is also rank one. In order to prove this we shall use a contradiction argument. Since  $T$  is full column rank,  $\text{rank } C_u^T C_u \leq 1$ . Assume  $\text{rank } C_u^T C_u = 0$ . This implies  $C T = 0$  because  $\mathfrak{B}$  being strictly  $\Sigma$ -dissipative implies  $(I_p - D D^T)^{-1} > 0$  (see footnote 2 in section 4). Postmultiplying the ARE (8.2) by  $T$  and utilizing the fact that  $B^T K T = 0$  we get  $A^T K T + K A T + C^T (I_p - D D^T)^{-1} C T = 0$ . Since  $C T = 0$  and  $A^T T_u = T_u A_u$  the last equation gives

$$(8.4) \quad K T A_u + K A T = 0.$$

Equation (8.4) along with the fact that  $K$  is nonsingular implies that  $\text{im } T$  is  $A$ -invariant. This means  $\text{im } T$  is a nontrivial  $A$ -invariant subspace contained in  $\ker C$ , which is not possible due to observability of  $(C, A)$ . Hence  $C T \neq 0$  and so

$\text{rank}(C_u^T C_u) = 1$ . Therefore, from Theorem 8.2 it follows that  $\text{spec}(A_u) = \Lambda_{\text{un}}$  satisfies the unmixing property.  $\square$

*Remark 8.4.* Statement 1 above would have been equivalent to strict dissipativity of  $\mathfrak{B}$  if  $\mathfrak{B}$  were controllable, but this is not the case in general. More precisely, under controllability assumptions on  $(A, B)$ , the ARE not having a solution implies that the ARI also does not have a solution (see [22, 23]). However, this turns out to be untrue for an uncontrollable behavior. For example, consider the special case of an autonomous system with  $A = \text{diag}([1 \ -1])$  and  $C = [1 \ 1]$ . For this case the Lyapunov equation is not solvable, though the corresponding inequality admits a solution. More generally the ARE having a solution means that there exist nonzero lossless trajectories in the behavior (see [1]). For a controllable dissipative behavior, there are always nonzero lossless trajectories. The last theorem makes it clear that for an uncontrollable system with a single output, unmixing of uncontrollable poles is necessary for the existence of nontrivial lossless trajectories. We do not digress more into the notion of losslessness because it is not central to the subject of this paper. A thorough understanding of the necessity of the unmixing condition requires further investigation.

That the unmixing is not necessary in general for more than one output is quite expected. The following example gives one such simple instance.

*Example 8.5.* Consider the autonomous system with i/s/o representation  $\frac{d}{dt}x = Ax$ ,  $y = Cx$ , where

$$A = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}.$$

Observe that  $A$  has “mixed” eigenvalues, i.e.,  $\Lambda_{\text{un}} \cap (-\Lambda_{\text{un}}) \neq \emptyset$ .  $\Sigma$ -dissipativity of such an autonomous system together with  $\sigma_+(\Sigma) = \mathfrak{m}(\mathfrak{B})$  is equivalent to existence of a real symmetric solution to the following Lyapunov inequality:  $A^T K + K A + C^T C \leq 0$ . Notice that  $K = \begin{bmatrix} 2+b & a \\ a & -2-c \end{bmatrix}$  with  $a, b, c \in \mathbb{R}$  and  $b, c \geq 0$  gives a solution to the above Lyapunov inequality. This example shows that the unmixing condition of uncontrollable poles is not necessary for the system to be dissipative.

**9. Concluding remarks.** In this paper we studied dissipativity for a general, possibly uncontrollable, LTI system. Our starting point was a more appropriate, though less often used, definition of dissipativity in terms of a differential inequality called the dissipation inequality. With this definition we brought out an equivalence between the dissipativities of a behavior and its controllable part, under the important unmixing condition (Theorem 3.4). For the case of strict dissipativity, Theorem 3.4 also settles the issue of whether to allow unobservable variables in the defining dissipation inequality: the theorem rules out the requirement of unobservable variables. The important intuitive idea that storage of energy should take place through the state variables comes as a natural consequence of Theorem 3.4. We stated this result as a corollary.

Next we looked into the set of all storage functions for a strictly  $\Sigma$ -dissipative system. It is well known that this set is a bounded convex polyhedron for a controllable system. We showed that for an uncontrollable system the set loses its boundedness property. Further, this set becomes bounded from below if the system is stabilizable. If in addition the controllable part is strictly  $\Sigma$ -dissipative on  $\mathbb{R}_-$ , then we showed that this lower bound on the set is positive. We used this result to formalize the physical notion of stored energy being finite in a dissipative system that has no source of energy within: it is *not* possible to extract an indefinite amount of energy from a stabilizable

system whose controllable part is strictly dissipative on  $\mathbb{R}_-$ . In this paper, though we utilized results about Hamiltonian matrices and Riccati equations, our main results pertain to the system directly, without an *a priori* input/output partition of the system variables. This is an important feature and advantage of the behavioral approach.

The unmixing condition plays a crucial role in most of the main results of this paper. In order to address the necessity of the unmixing condition we made use of the important observation that for an uncontrollable behavior a storage function acts like a Lyapunov function over certain trajectories, and we showed that unmixing is not necessary in general for existence of a Lyapunov function and therefore for dissipativity. However, an interesting situation arises when the system has only one output. In Theorem 8.2 we showed that under suitable observability conditions a singular Lyapunov operator cannot have a rank one symmetric matrix in its image. This helped us to bring out the fact that the unmixing is necessary for an uncontrollable behavior to have nonzero lossless trajectories in it. The extent of unmixing condition for a more general situation remains to be investigated.

In this paper we have dealt only with the maximum input cardinality case, i.e., the case when the number of inputs is equal to the positive signature of the supply rate function  $\Sigma$ . A study of the general case can also be utilized for dissipativity synthesis problems for uncontrollable systems.

#### Appendix A. Auxiliary results and proofs.

The following standard result from state space theory [34] is needed in the proof of Lemma 4.5; we state it for easy reference.

**PROPOSITION A.1.** *Consider the following state space representation of a dynamical system.  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$ . Let  $F_c \in \mathbb{R}^{m \times n}$ ,  $F_o \in \mathbb{R}^{n \times p}$  and  $G_c \in \mathbb{R}^{m \times m}$ ,  $G_o \in \mathbb{R}^{p \times p}$  with  $G_c, G_o$  nonsingular. Then,*

- $(A + BF_c, BG_c)$  is controllable if and only if  $(A, B)$  is controllable,
- $(G_o C, A + F_o C)$  is observable if and only if  $(C, A)$  is observable.

*Proof of Lemma 4.5.* As seen earlier, the supply function matrix  $\Sigma$  induces an input/output partition  $w = (w_1, w_2)$  where  $w_1$  is input and  $w_2$  is output. To prove this theorem we shall consider two cases, first the case when  $\mathfrak{B}$  has a *strictly* proper transfer function from  $w_1$  to  $w_2$  and secondly the case when  $\mathfrak{B}$  has a proper transfer function (not necessarily strictly proper) with the same input/output partition. For the second case we shall show that there exists a simple transformation that changes it to the first case and thus the proof is complete.

**Case 1 ( $\mathfrak{B}$  has strictly proper transfer function from  $w_1$  to  $w_2$ ) :**  $\mathfrak{B}$  allows an i/s/o representation with  $D = 0$  as follows

$$(A.1) \quad \frac{d}{dt}x = Ax + Bw_1, \quad w_2 = Cx.$$

$\Sigma$  is given as  $\begin{bmatrix} I_n & 0 \\ 0 & -I_p \end{bmatrix}$ , so the corresponding Hamiltonian matrix is  $H = \begin{bmatrix} A & BB^T \\ -C^T C & -A^T \end{bmatrix}$ . Consider the observable image representation of  $\mathfrak{B}$ :  $w = M(\frac{d}{dt})\ell$ , and partition  $M$  corresponding to  $w = (w_1, w_2)$  to get

$$(A.2) \quad \begin{bmatrix} w_1 \\ w_2 \end{bmatrix} = \begin{bmatrix} W_1(\frac{d}{dt}) \\ W_2(\frac{d}{dt}) \end{bmatrix} \ell.$$

Without loss of generality we can assume that  $\det(W_1(\xi))$  is a monic polynomial. Now, the transfer function for  $\mathfrak{B}$  is given by  $G(\xi) := W_2(\xi)W_1^{-1}(\xi) = C(\xi I_n - A)^{-1}B$ .

The characteristic polynomial of  $H$  is given by  $\chi(H) = \det(\xi I_{2n} - H)$ . Using Schur complement this can be written as

$$\begin{aligned}\chi(H) &= \det(\xi I_n - A) \det[(\xi I_n + A^T) + C^T C(\xi I_n - A)^{-1} B B^T] \\ &= \det(\xi I_n - A) \det(\xi I_n + A^T) \det\left[I_n + (\xi I_n + A^T)^{-1} C^T C(\xi I_n - A)^{-1} B B^T\right].\end{aligned}$$

Now using the identity,  $\det(I + PQ) = \det(I + QP)$  we get

$$\begin{aligned}\chi(H) &= \det(\xi I_n - A) \det(\xi I_n + A^T) \det\left[I_m + B^T (\xi I_n + A^T)^{-1} C^T C(\xi I_n - A)^{-1} B\right] \\ &= \det(\xi I_n - A) \det(\xi I_n + A^T) \det[I_m - G^T(-\xi)G(\xi)] \\ &= \det(\xi I_n - A) \det(\xi I_n + A^T) \det\left[W_1^{-T}(-\xi)(W_1^T(-\xi)W_1(\xi) \right. \\ &\quad \left. - W_2^T(-\xi)W_2(\xi))W_1^{-1}(\xi)\right] \\ &= \left(\frac{\det(\xi I_n - A) \det(\xi I_n + A^T)}{\det W_1^T(-\xi) \det W_1(\xi)}\right) \det[W_1^T(-\xi)W_1(\xi) - W_2^T(-\xi)W_2(\xi)].\end{aligned}$$

Since  $(A, B)$  is controllable and  $(C, A)$  is observable, and due to observability of the image representation (A.2),  $\det W_1(\xi) = \det(\xi I_n - A)$ ; therefore, the above equation simplifies to

$$\begin{aligned}\chi(H) &= -\det[W_1^T(-\xi)W_1(\xi) - W_2^T(-\xi)W_2(\xi)] \\ &= -\det \partial \Phi(\xi)\end{aligned}$$

This proves  $\text{spec}(H) = \text{roots}(\det \partial \Phi(\xi))$  and hence the lemma for the strictly proper transfer matrix case.

**Case 2 ( $\mathfrak{B}$  has proper transfer function from  $w_1$  to  $w_2$ ):**  $\mathfrak{B}$  allows the following i/s/o representation,  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$  with  $(A, B)$  controllable and  $(C, A)$  observable. Since  $(I_m - D^T D) > 0$ , the corresponding Hamiltonian matrix is given by

$$H := \begin{bmatrix} A + B(I_m - D^T D)^{-1} D^T C & B(I_m - D^T D)^{-1} B^T \\ -C^T(I_p - DD^T)^{-1} C & -(A + B(I_m - D^T D)^{-1} D^T C)^T \end{bmatrix}.$$

Because  $D$  is nonzero, the arguments in case 1 do not hold. As mentioned earlier, we show that there exists a transformation on the manifest variables that changes this situation to that in case 1. Consider the quadratic form  $Q_\Sigma(w)$

$$\begin{aligned}Q_\Sigma(w) &= |w_1|^2 - |w_2|^2 = w_1^T w_1 - x^T C^T C x - x^T C^T D w_1 - w_1^T D^T C x - w_1^T D^T D w_1 \\ &= \begin{bmatrix} w_1 \\ x \end{bmatrix}^T \Sigma_1 \begin{bmatrix} w_1 \\ x \end{bmatrix},\end{aligned}$$

where  $\Sigma_1$  is defined as  $\Sigma_1 := \begin{bmatrix} I_n - D^T D & -D^T C \\ -C^T D & -C^T C \end{bmatrix}$ . Notice that  $\Sigma_1$  can be factorized as

$$(A.3) \quad \begin{bmatrix} (I_m - D^T D)^{\frac{1}{2}} & -(I_m - D^T D)^{-\frac{1}{2}} D^T C \\ 0 & I_n \end{bmatrix}^T \tilde{\Sigma} \begin{bmatrix} (I_m - D^T D)^{\frac{1}{2}} & -(I_m - D^T D)^{-\frac{1}{2}} D^T C \\ 0 & I_n \end{bmatrix},$$

where  $\tilde{\Sigma} := \begin{bmatrix} I_m & 0 \\ 0 & -C^T(I_p - DD^T)^{-1}C \end{bmatrix}$ . Define  $T := \begin{bmatrix} (I_m - D^TD)^{\frac{1}{2}} & -(I_m - D^TD)^{-\frac{1}{2}}D^TC \\ 0 & I_n \end{bmatrix}$ . Further define  $\begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix} := T \begin{bmatrix} w_1 \\ x \end{bmatrix}$ . Then from (A.3) we have

$$(A.4) \quad Q_{\Sigma}(w) = \begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix}^T \tilde{\Sigma} \begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix}.$$

Now, since  $(w_1, x)$  satisfies the state equation,  $(\tilde{w}_1, \tilde{x})$  must satisfy the following:

$$\begin{aligned} & [-B \quad \frac{d}{dt}I_n - A] T^{-1} \begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix} = 0 \\ \Rightarrow & [-B \quad \frac{d}{dt}I_n - A] \begin{bmatrix} (I_m - D^TD)^{-\frac{1}{2}} & (I_m - D^TD)^{-1}D^TC \\ 0 & I_n \end{bmatrix} \begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix} = 0 \\ \Rightarrow & [-B(I_m - D^TD)^{-\frac{1}{2}} \quad \frac{d}{dt}I_n - A - B(I_m - D^TD)^{-1}D^TC] \begin{bmatrix} \tilde{w}_1 \\ \tilde{x} \end{bmatrix} = 0. \end{aligned}$$

Therefore,  $(\tilde{w}_1, \tilde{x})$  satisfies the state equation,  $\frac{d}{dt}\tilde{x} = \tilde{A}\tilde{x} + \tilde{B}\tilde{w}_1$ , where  $\tilde{A} := A + B(I_m - D^TD)^{-1}D^TC$ ,  $\tilde{B} := B(I_m - D^TD)^{-\frac{1}{2}}$ . By denoting  $\tilde{C} := (I_p - DD^T)^{-\frac{1}{2}}C$ , we can define a new behavior  $\tilde{\mathfrak{B}}$  that has an i/s/o representation given by  $\frac{d}{dt}\tilde{x} = \tilde{A}\tilde{x} + \tilde{B}\tilde{w}_1$ ,  $\tilde{w}_2 = \tilde{C}\tilde{x}$ . Now, from (A.4) we have  $\tilde{w} := \text{col}(\tilde{w}_1, \tilde{w}_2)$  satisfies

$$(A.5) \quad Q_{\Sigma}(\tilde{w}) = Q_{\Sigma}(w).$$

In order to infer about the controllability of the new behavior  $\tilde{\mathfrak{B}}$ , we make use of Proposition A.1 above; since  $(A, B)$  is controllable, so is  $(\tilde{A}, \tilde{B})$ , and similarly, since  $(C, A)$  is observable, so is  $(\tilde{C}, \tilde{A})$ . Therefore,  $\tilde{\mathfrak{B}}$  allows an observable image representation

$$\tilde{\mathfrak{B}} = \text{im} \begin{bmatrix} \tilde{W}_1(\frac{d}{dt}) \\ \tilde{W}_2(\frac{d}{dt}) \end{bmatrix}.$$

From (A.5) we have

$$\partial\tilde{\Phi}(\xi) := \tilde{W}_1^T(-\xi)\tilde{W}_1(\xi) - \tilde{W}_2^T(-\xi)\tilde{W}_2(\xi) = \partial\Phi(\xi).$$

Also,  $\tilde{\mathfrak{B}}$  gives the Hamiltonian matrix,  $\tilde{H} = \begin{bmatrix} \tilde{A} & \tilde{B}\tilde{B}^T \\ -\tilde{C}^T\tilde{C} & -\tilde{A}^T \end{bmatrix} = H$ . Thus for every  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^w$  with an input/output partition such that the transfer function is proper, there exists  $\tilde{\mathfrak{B}} \in \mathfrak{L}_{\text{cont}}^w$  with a corresponding i/o partition that gives a strictly proper transfer function, such that  $\partial\Phi(\xi)$  matrices coming from  $\mathfrak{B}$  and  $\tilde{\mathfrak{B}}$  are the same and so are the corresponding Hamiltonian matrices. Therefore, from case 1 it follows that

$$\text{spec}(\tilde{H}) = \text{roots}(\det \partial\tilde{\Phi}(\xi)) \Rightarrow \text{spec}(H) = \text{roots}(\det \partial\Phi(\xi)).$$

This completes the proof of Lemma 4.5.  $\square$

*Proof of Lemma 5.3.* Let the image representation matrix have a partition as

$$M(\xi) = \begin{bmatrix} W_1(\xi) \\ W_2(\xi) \end{bmatrix}; \quad W_1 \in \mathbb{R}^{m \times m}[\xi], W_2 \in \mathbb{R}^{p \times m}[\xi].$$

Since the image representation is observable,  $W_1(\xi)$  and  $W_2(\xi)$  are relatively right-prime. So the transfer function from  $w_1$  to  $w_2$  is given by  $G(\xi) = W_2(\xi)W_1^{-1}(\xi)$ . Also, since this i/o partition allows an i/s/o representation with state dimension  $\mathbf{n}$ ,  $G(\xi)$  is proper and  $\deg(\det W_1(\xi)) = \mathbf{n}$ . From the i/s/o representation we have the transfer function as  $G(\xi) = C(\xi I_{\mathbf{n}} - A)^{-1}B + D$ . Now the second condition can be written as

$$\begin{aligned} \partial\Phi(j\omega) &> 0 \quad \forall \omega \in \mathbb{R} \\ \Rightarrow W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega) &> 0 \quad \forall \omega \in \mathbb{R}. \end{aligned}$$

Since  $\deg(\det \partial\Phi(\xi)) = 2\mathbf{n}$  and  $\deg(\det W_1(\xi)) = \mathbf{n}$ , we infer the biproperness of the rational function  $\det[W_1^{-T}(-j\omega)[W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega)]W_1^{-1}(j\omega)]$ . Using the biproperness, we can see that

$$\lim_{\omega \rightarrow \infty} (\det[W_1^{-T}(-j\omega)[W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega)]W_1^{-1}(j\omega)]) \neq 0.$$

This fact together with  $W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega) > 0$  for all  $\omega \in \mathbb{R}$  implies that

$$\lim_{\omega \rightarrow \infty} W_1^{-T}(-j\omega)[W_1^T(-j\omega)W_1(j\omega) - W_2^T(-j\omega)W_2(j\omega)]W_1^{-1}(j\omega) > 0.$$

The expression within the above limit is nothing but  $I_{\mathbf{m}} - G^T(-j\omega)G(j\omega)$ , the limit of which is  $I_{\mathbf{m}} - D^TD$ . This proves  $(I_{\mathbf{m}} - D^TD) > 0$ , and completes the proof of Lemma 5.3.  $\square$

The following lemma related to the strict dissipation inequality was used in the proof of Theorem 5.2 above. The proof is straightforward and so omitted (see [2]).

LEMMA A.2. *Let  $\mathfrak{B} \in \mathfrak{L}_{\text{cont}}^{\mathbf{w}}$ . Then  $\mathfrak{B}$  is strict  $\Sigma$ -dissipative if and only if  $\mathfrak{B}$  is dissipative with respect to  $\Sigma_1 := \begin{bmatrix} I_{\mathbf{m}} & 0 \\ 0 & -(1 + \epsilon_1)I_{\mathbf{p}} \end{bmatrix}$  for some  $\epsilon_1 > 0$ .*

The following proposition is regarding the standard Kalman decomposition (see [34]); we require it in the proof of Theorem 5.4, which follows after this proposition.

PROPOSITION A.3. *Let  $\mathfrak{B}$  be uncontrollable with an i/s/o representation  $\frac{d}{dt}x = Ax + Bw_1$ ,  $w_2 = Cx + Dw_1$ , where  $w = (w_1, w_2)$ . Then there exists a nonsingular matrix  $T \in \mathbb{R}^{\mathbf{n} \times \mathbf{n}}$  such that  $T^{-1}AT = \begin{bmatrix} A_c & A_{cp} \\ 0 & A_u \end{bmatrix}$ ,  $TB = \begin{bmatrix} B_c \\ 0 \end{bmatrix}$ , and  $CT^{-1} = [C_c \quad C_u]$ . Further,*

$$(A.6) \quad \frac{d}{dt}x_c = A_c x_c + B_c w_1, \quad w_2 = C_c x_c + D w_1$$

*gives an i/s/o representation for  $\mathfrak{B}_{\text{cont}}$ .*

*Proof of Theorem 5.4.* The last proposition enables us to consider the following i/s/o representation without loss of generality:

$$\begin{aligned} \frac{d}{dt} \begin{bmatrix} x_c \\ x_u \end{bmatrix} &= \begin{bmatrix} \tilde{A}_c & \tilde{A}_{cp} \\ 0 & \tilde{A}_u \end{bmatrix} \begin{bmatrix} x_c \\ x_u \end{bmatrix} + \begin{bmatrix} \tilde{B}_c \\ 0 \end{bmatrix} w_1 \\ w_2 &= \begin{bmatrix} \tilde{C}_c & \tilde{C}_u \end{bmatrix} \begin{bmatrix} x_c \\ x_u \end{bmatrix} + \tilde{D} w_1. \end{aligned}$$

Then the corresponding Hamiltonian matrix gets the following form

$$H = \begin{bmatrix} A_c & A_{cp} & B_c B_c^T & 0 \\ 0 & A_u & 0 & 0 \\ -C_c^T C_c & -C_c^T C_u & -A_c^T & 0 \\ -C_u^T C_c & -C_u^T C_u & -A_{cp}^T & -A_u^T \end{bmatrix},$$

where

$$\begin{aligned} A_c &= \tilde{A}_c + \tilde{B}_c \left( I_m - \tilde{D}^T \tilde{D}^T \right)^{-1} \tilde{D}^T \tilde{C}_c, & B_c &= \tilde{B}_c \left( I_m - \tilde{D}^T \tilde{D} \right)^{-\frac{1}{2}}, \\ A_{cp} &= \tilde{A}_{cp} + \tilde{B}_c \left( I_m - \tilde{D}^T \tilde{D}^T \right)^{-1} \tilde{D}^T \tilde{C}_u, & C_c &= \left( I_p - \tilde{D} \tilde{D}^T \right)^{-\frac{1}{2}} \tilde{C}_c, \\ A_u &= \tilde{A}_u, & C_u &= \left( I_p - \tilde{D} \tilde{D}^T \right)^{-\frac{1}{2}} \tilde{C}_u. \end{aligned}$$

Once again from Proposition A.3,  $\frac{d}{dt}x_c = \tilde{A}_c x_c + \tilde{B}_c w_1$ ,  $w_2 = \tilde{C}_c x_c + \tilde{D} w_1$  is an i/s/o representation of  $\mathfrak{B}_{\text{cont}}$ . So the corresponding Hamiltonian matrix for  $\mathfrak{B}_{\text{cont}}$  is given by  $H_c := \begin{bmatrix} \tilde{A}_c & \tilde{B}_c \tilde{C}_c^T \\ -\tilde{C}_c^T \tilde{C}_c & -\tilde{A}_c^T \end{bmatrix}$ . Now from Proposition 2.2 we can assume the i/s/o representation for  $\mathfrak{B}$  to be state observable, which implies that the controllable part is state observable; i.e., the  $(\tilde{C}_c, \tilde{A}_c)$  pair is observable. Again, since  $(\tilde{C}_c, \tilde{A}_c)$  is observable and  $\mathfrak{B}_{\text{cont}}$  is controllable, the i/s/o representation of  $\mathfrak{B}_{\text{cont}}$  is also state controllable; that is, the  $(\tilde{A}_c, \tilde{B}_c)$  pair is controllable. Therefore from Lemma 4.5, we get  $\text{spec}(H_c) = \text{roots}(\det \partial \Phi(\xi))$ . Again, from the Kalman-decomposed i/s/o representation of  $\mathfrak{B}$ , we get

$$\Lambda_{\text{un}} = \text{spec}(\tilde{A}_u) = \text{spec}(A_u).$$

Thus to prove Theorem 5.4, all we need to show is  $\det(\xi I_{2n} - H) = \det(\xi I - H_c) \det(\xi I - A_u) \det(\xi I + A_u)$ .

To show the above equality we shall find the determinant of the polynomial matrix  $(\xi I_{2n} - H)$  applying some elementary transformations on it as shown below. Let  $\mathbf{n}_c$  be the number of controllable eigenvalues and  $\mathbf{n}_u$  be that of uncontrollable eigenvalues.

$$\begin{aligned} \det(\xi I_{2n} - H) &= \det \left( \begin{bmatrix} I_{\mathbf{n}_c} & 0 & 0 & 0 \\ 0 & 0 & I_{\mathbf{n}_c} & 0 \\ 0 & I_{\mathbf{n}_u} & 0 & 0 \\ 0 & 0 & 0 & I_{\mathbf{n}_u} \end{bmatrix} (\xi I_{2n} - H) \begin{bmatrix} I_{\mathbf{n}_c} & 0 & 0 & 0 \\ 0 & 0 & I_{\mathbf{n}_u} & 0 \\ 0 & I_{\mathbf{n}_c} & 0 & 0 \\ 0 & 0 & 0 & I_{\mathbf{n}_u} \end{bmatrix} \right) \\ &= \det \begin{bmatrix} \xi I_{\mathbf{n}_c} - A_c & -B_c B_c^T & -A_{cp} & 0 \\ C_c^T C_c & \xi I_{\mathbf{n}_c} + A_c^T & C_c^T C_u & 0 \\ 0 & 0 & \xi I_{\mathbf{n}_u} - A_u & 0 \\ C_u^T C_c & A_{cp}^T & C_u^T C_u & \xi I_{\mathbf{n}_u} + A_u^T \end{bmatrix}. \end{aligned}$$

Now, exploiting the block structure of the above matrix, we can find out its determinant as

$$\begin{aligned} &\det \begin{bmatrix} \xi I_{\mathbf{n}_c} - A_c & -B_c B_c^T & -A_{cp} & 0 \\ C_c^T C_c & \xi I_{\mathbf{n}_c} + A_c^T & C_c^T C_u & 0 \\ 0 & 0 & \xi I_{\mathbf{n}_u} - A_u & 0 \\ C_u^T C_c & A_{cp}^T & C_u^T C_u & \xi I_{\mathbf{n}_u} + A_u^T \end{bmatrix} \\ &= \det(\xi I_{\mathbf{n}_u} + A_u^T) \det(\xi I_{\mathbf{n}_u} - A_u) \det \begin{bmatrix} \xi I_{\mathbf{n}_c} - A_c & -B_c B_c^T \\ C_c^T C_c & \xi I_{\mathbf{n}_c} + A_c^T \end{bmatrix} \\ &= \det(\xi I_{\mathbf{n}_u} + A_u^T) \det(\xi I_{\mathbf{n}_u} - A_u) \det(\xi I_{\mathbf{n}_c} - H_c) \\ (A.7) \quad &\Rightarrow \text{spec}(H) = \text{roots}[\chi_{\text{un}}(-\xi) \chi_{\text{un}}(\xi) \partial \Phi(\xi)], \end{aligned}$$

where the last equality follows from Lemma 4.5.  $\square$

The following well-known result about left and right eigenspaces of the Hamiltonian matrix was used in the proof of Theorem 5.5. This lemma can be proved by straightforward verification.

LEMMA A.4. *Let  $\Lambda$  be a set of eigenvalues of the Hamiltonian matrix  $H$ . If  $\text{im} \begin{bmatrix} X_1 \\ X_2 \end{bmatrix}$  is the generalized right eigenspace of  $H$  corresponding to  $\Lambda$  with  $X_1, X_2 \in \mathbb{R}^{n \times \bullet}$ , then  $\text{im} \begin{bmatrix} X_2 \\ -X_1 \end{bmatrix}$  is the generalized left eigenspace of  $H$  corresponding to  $-\Lambda$ .*

The following lemma is used in the proof of 5.2. The result says that right-primeness is equivalent to the absence of any zeros in the complex plane for the corresponding Hermitian matrix. Statement 3 below makes a similar statement, but at the point  $\infty$ .

LEMMA A.5. *Consider  $M \in \mathbb{R}^{w \times n}[\xi]$  with  $M$  having full column rank. Suppose the behavior having the image representation  $w = M(\frac{d}{dt})\ell$  has McMillan degree  $n$ . Then, the following are equivalent.*

1.  $M(\xi)$  is right-prime,
2.  $M^T(\bar{\lambda})M(\lambda) > 0$  for all  $\lambda \in \mathbb{C}$ , and
3.  $\deg [\det (M^T(-\xi)M(\xi))] = 2n$ .

*Proof.* We shall prove the following chain of implications:  $1 \Rightarrow 2$ ,  $2 \Rightarrow 1$ ,  $1 \Rightarrow 3$  and  $3 \Rightarrow 1$ .

(1  $\Rightarrow$  2) We assume right-primeness of  $M$  and show that  $M^T(\bar{\lambda})M(\lambda)$  is positive definite for all  $\lambda \in \mathbb{C}$ . That  $M^T(\bar{\lambda})M(\lambda) \geq 0$  for all  $\lambda \in \mathbb{C}$  is obvious. Due to the right-primeness,  $M(\lambda)$  has full column rank for all  $\lambda \in \mathbb{C}$ , and this implies the required positive definiteness for all  $\lambda$ .

(2  $\Rightarrow$  1)  $M^T(\bar{\lambda})M(\lambda) > 0$  for all  $\lambda \in \mathbb{C}$  means that  $M(\lambda)$  is injective for all  $\lambda$  proving its full column rank property for all  $\lambda$ , and hence right-primeness.

(1  $\Rightarrow$  3)  $M(\xi)$  can be partitioned (after a permutation of rows, if needed) into  $\text{col}(W_1(\xi), W_2(\xi))$  such that  $W_2W_1^{-1}$  is a proper rational matrix, and  $W_1(\xi)$  has determinant of degree  $n$ . Suppose  $G(\xi) := W_2(\xi)W_1(\xi)^{-1}$ . (See [19] for McMillan degree's relation to an *observable* image representation, and observability of the image representation is equivalent to right-primeness of the matrix  $M$ .) Consider  $\det (M^T(-\xi)M(\xi))$  which equals  $\det (W_1^T(-\xi)W_1(\xi) + W_2^T(-\xi)W_2(\xi))$

$$\begin{aligned} &= \det (W_1(-\xi))\det (W_1(\xi))\det \left( I + (W_2(-\xi)W_1(-\xi)^{-1})^T (W_2(\xi)W_1(\xi)^{-1}) \right) \\ &= \det (W_1(-\xi))\det (W_1(\xi))\det (I + G^T(-\xi)G(\xi)). \end{aligned}$$

In order to determine the degree of  $\det (M^T(-\xi)M(\xi))$ , we let  $\xi \rightarrow \infty$  to get rid of the strictly proper part within the last term above:  $\lim_{\xi \rightarrow \infty} \det (I + G(-\xi)^T G(\xi)) = a$  (say). Notice that  $0 < a < \infty$ ;  $a < \infty$  because of the properness of  $W_2W_1^{-1} = G$ , while due to the positive definiteness of  $(I + \lim_{\xi \rightarrow \infty} G^T(-\xi)G(\xi))$  we obtain that its determinant  $a > 0$ . Thus the degree of  $\det (M(-\xi)^T M(\xi))$  is twice the degree of  $\det W_1$ , and is thus  $2n$ .

(3  $\Rightarrow$  1) In order to prove this, we assume  $M(\xi)$  is not right-prime and arrive at the required contradiction. Non-right-primeness of  $M$  means that  $M$  can be factored into  $M = \bar{M}F$  such that  $\bar{M}$  is right-prime, and  $F$  has a nonzero and non-constant polynomial as its determinant. This implies that  $w = \bar{M}(\frac{d}{dt})\ell$  is an observable kernel representation for  $\mathfrak{B}$  and hence  $\bar{M}$  can be partitioned (after possibly a permutation of rows) into  $\bar{M} = \text{col}(W_1, W_2)$  such that degree of  $\det W_1 = n$ . Notice that  $\det (M^T(-\xi)M(\xi)) = \det F(-\xi) \det F(\xi) \det (\bar{M}(-\xi)^T \bar{M}(\xi))$ . We now use the proof of (1  $\Rightarrow$  3) above and that  $\bar{M}$  is right-prime to conclude that the degree of  $\det (\bar{M}(-\xi)^T \bar{M}(\xi))$  is  $2n$ . Hence degree of  $\det M^T(-\xi)M(\xi)$  equals

$2n + 2(\deg(\det F))$ . Since  $F$  has determinant a nonzero, nonconstant polynomial, we obtain  $\det M^T(-\xi)M(\xi) > 2n$ , thus obtaining the required contradiction. This proves  $(3 \Rightarrow 1)$  and also the lemma.  $\square$

**Acknowledgments.** During the course of this work, we had several useful discussions with Dr. Harish K. Pillai; we thank him for his insightful input. We also thank Prof. Jan C. Willems for his constructive suggestions.

## A BEHAVIORAL APPROACH TO PLAY IN MECHANICAL NETWORKS\*

FRANK SCHEIBE<sup>†</sup> AND MALCOLM C. SMITH<sup>†</sup>

**Abstract.** This paper shows that the treatment of play or backlash as an input-output operator in mechanical networks leads to solutions which are unsatisfactory from a physical point of view. This contrasts with a simple behavioral definition of ideal play. With this definition, play cannot be treated in isolation as an input-output relation. As a result, methods of nonlinear feedback systems are not readily applicable to establish well-posedness of solutions of mechanical networks incorporating this play element. By means of simple network examples, this paper explores the issues involved in establishing well-posedness of mechanical networks incorporating springs, dampers, masses, and inerters together with the behavioral model of ideal play. Connections with the approach of Nordin, Galic, and Gutman are analyzed and a model implementation given.

**1. Introduction.** This paper is concerned with the mathematical modeling of mechanical networks made up of standard linear elements and a single nonlinear element, play. There are two main themes in the paper. The first is the question of how well the mathematical models match the behavior of actual physical devices. The second is a purely mathematical question of the well-posedness of interconnections of the linear dynamical elements with play. Our approach will exhibit a close connection between these themes.

A number of different models for play have been proposed in the literature. Figure 1 shows two different definitions, the dead-zone model and the hysteresis model. These have been justified by the expected behavior of a clearance in series with a spring and damper, respectively; see [3, p. 122] and [7, p. 68]. The hysteresis model is commonly used as a basis for a formal mathematical approach to play [11, 1]. Both definitions aim to describe an apparently well-defined phenomena and give rise to two different mathematical descriptions. This raises the question of which model, or indeed if either, is more satisfactory? The hysteresis model will be considered in detail in section 2 in its formal mathematical definition as the “play operator.” We will argue that this definition leads to behavior in mechanical networks which appears unrealistic from a physical point of view. A similar point can be made with respect to the dead-zone model (cf. [13]).

In section 3 we propose a formal definition of play, in which only the sign of the force at the extremes of relative displacement is specified, and the force is zero between the extremes. This model can be thought of as a behavioral model of play in the sense of Willems [20], since it does not admit an input-output definition in isolation. This appears to be the simplest possible definition which avoids the objection raised in section 2. We note that this definition does not seek to model the contact mechanics which might be relevant at engagement and disengagement.

FIG. 2. The play operator. (a) Physical representation. (b) Input-output modeling symbol. (c) Terminal modeling symbol.

Section 3 goes on to examine the question of well-posedness of mechanical networks incorporating this play element. So far it has not been possible to develop a general framework for well-posedness with this play element, such as the linear complementarity framework for a class of hybrid systems developed in [18, 12, 9, 2]. Instead, we will examine a number of typical cases from first principles. We will encounter situations in which not only unique solutions are obtained, but also networks which admit multiple solutions. In the latter case we are able to illuminate this nonuniqueness by energy considerations at transitions. A further perspective is provided by the incorporation of compliance and buffer networks and the study of their limiting behavior. These networks are strongly suggestive of models proposed for impact mechanics.

Section 4 considers a semi-ideal model for play which consists of a parallel spring-damper buffer in series with our behavioral model of ideal play. We point out that the definition coincides almost always with a model of Nordin, Galic, and Gutman [13]. The latter model is expressed as a dynamical system in input-output form. A numerical implementation of this semi-ideal play is described.

The paper is structured as follows. Section 2 is a critique of the play operator. Section 3 describes the behavioral definition of play and analyzes the well-posedness of a simple network. Sections 3.3–3.6 examine the well-posedness of a network with play in series with an inerter. Section 4 analyzes a semi-ideal play model and its relation to a model of Nordin, Galic, and Gutman and presents a numerical implementation. Concluding remarks are given in section 5.

**2. The play operator: A critique.** A standard treatment of play between mechanical elements makes use of the play operator (hysteron). The formal definition of the operator is illustrated in Figure 2(a). The position of the piston ( $v$ ) is considered to be the input, and the position of the cylinder ( $w$ ) is considered to be the output (follower). The behavior of the play operator is then characterized by the graph of Figure 1(b). Within the play region  $|v - w| < \epsilon$  the follower  $Q$  remains stationary. Otherwise, it follows  $P$  with an offset of  $\pm\epsilon$ . The input-output behavior of this model

FIG. 3. Input-output representation of play in feedback arrangement.

FIG. 4. Terminal modeling symbol with input and follower reversed.

can be defined formally for piecewise monotonic (continuous) inputs (see [1, pp. 24–25] and [11, pp. 6–8]). The model can then be extended to inputs which are continuous functions by a limiting argument (see [1, p. 42] and [11, pp. 14–15]). This defines the “play operator.” Two alternative modeling symbols are used to represent the play operator, depending on the need for an input-output or a terminal representation (see Figure 2(b),(c)).

When the play element is connected to a network with dynamical elements, the well-posedness of the dynamical equations can be analyzed as shown in Figure 3.

**PROPOSITION 2.1.** *Let  $S$  be an linear time-invariant dynamical system with transfer function  $G(s)$ . If  $G(s)$  is proper and  $|G(\infty)| < 1$ , then the dynamical system of Figure 3 is well-posed.*

*Proof.* This relies on the notion of instantaneous gain in a feedback loop and makes use of the contraction mapping theorem in Banach spaces. General results of this type can be found in [19, sec. 4.3.3] and [4, p. 48].  $\square$

The behavior of the play operator as shown in Figure 1(b) can also be expressed as a condition on three hybrid states as follows:

G1 (engagement–extension):  $w = v + \epsilon$ ,  $\dot{v} = \dot{w} \leq 0$ .

G2 (engagement–compression):  $w = v - \epsilon$ ,  $\dot{v} = \dot{w} \geq 0$ .

G3 (disengagement):  $|v - w| < \epsilon$ ,  $\dot{w} = 0$ .

If the terminals in Figure 2(a) are reversed so that  $Q$  is the input and  $P$  is the follower as represented in Figure 4, then the three hybrid states become the following:

H1 (engagement–extension):  $v = w - \epsilon$ ,  $\dot{v} = \dot{w} \geq 0$ .

H2 (engagement–compression):  $v = w + \epsilon$ ,  $\dot{v} = \dot{w} \leq 0$ .

H3 (disengagement):  $|v - w| < \epsilon$ ,  $\dot{v} = 0$ .

**2.1. A network example.** This section analyzes the behavior of the mechanical network illustrated in Figure 5. The dynamical equations are

$$(2.1a) \quad m_2 \ddot{y} = k(z - y) + c(\dot{z} - \dot{y}),$$

$$(2.1b) \quad m_1 \ddot{z} = -k(z - y) - c(\dot{z} - \dot{y}).$$

Eliminating  $z$ , we can then calculate the transfer function

$$\frac{\hat{y}(s)}{\hat{u}(s)} = -\frac{m_1 cs}{m_1 m_2 s^2 + m_2 cs + k(m_1 + m_2)},$$

which is strictly proper. Hence, from Proposition 2.1 the network in Figure 5 is well-posed. Next, the dynamical equations in each of the states H1–H3 are evaluated explicitly, assuming the constants to be  $m_1 = m_2 = 1$  kg,  $c = 2$  Nsm<sup>−1</sup>, and  $k = 5/2$  Nm<sup>−1</sup>.

FIG. 5. Damped harmonic oscillator network.

H1 (engagement–extension). This corresponds to  $u = y - \epsilon$  and  $\dot{u} = \dot{y} \geq 0$ . The dynamical equations can be written in the form  $\dot{x}(t) = A_{H1}x(t)$  with  $x = [y, \dot{y}, z, \dot{z}]^T$ . Choosing the initial conditions

$$(2.2) \quad x(0) = [A, B - 2A, -A, -B + 2A]^T + [C, D, C, D]^T,$$

we can calculate  $x(t) = e^{A_{H1}t}x(0)$  to find

$$(2.3a) \quad y(t) - z(t) = 2e^{-2t}(A \cos(t) + B \sin(t)),$$

$$(2.3b) \quad y(t) + z(t) = 2(C + Dt).$$

H2 (engagement–compression). This corresponds to  $u = y + \epsilon$  and  $\dot{u} = \dot{y} \leq 0$ . The equations for  $x(t)$ ,  $y(t)$ , and  $z(t)$  are identical to those in case H1.

H3 (disengagement). This corresponds to  $|y - u| < \epsilon$  and  $\dot{u} = 0$ . The dynamical equations can be written in the form  $\dot{x}(t) = A_{H3}x(t)$  with  $x = [y, \dot{y}, z, \dot{z}]^T$ . In the following, only the solution in the special case  $x(0) = [A, 0, -A, 0]$  is needed. By explicit computation we can find  $x(t) = e^{A_{H3}t}x(0)$ , which gives

$$(2.4) \quad y(t) = -z(t) = 1/2e^{-t}A(2 \cos(2t) + \sin(2t)).$$

**2.1.1. The force through the play element.** Here, a particular solution for the network of section 2.1 is calculated, which involves a transition from state H1 to state H3. Consider an initial condition of the form (2.2) in which  $A = C = D = 0$  and  $B > 0$ . From (2.3a) and (2.3b) we find that  $y(t) = e^{-2t}B \sin(t)$ . It follows that a transition from state H1 to state H3 must occur at the first time  $t_1 = \arctan(1/2)$  for which  $\dot{y}(t_1) = 0$ , since otherwise  $\dot{y}$  becomes negative in violation of the conditions for state H1. The corresponding displacement at disengagement is  $y(t_1) = B \exp(-2 \arctan(1/2))/\sqrt{5}$ . For simplicity we choose  $B$  so that  $y(t_1) = 1$ , and from (2.4) we find that for  $t > t_1$ ,  $y(t - t_1) = e^{-(t-t_1)}(2 \cos(2(t - t_1)) + \sin(2(t - t_1)))/2$ . It is straightforward to see that this solution is consistent with a transition to state H3, namely,  $|y(t) - u(t)| < \epsilon$  for  $t - t_1$  sufficiently small, since  $u(t) = 1 - \epsilon$  for  $t > t_1$  in state H3. The solution can be continued forward in time until the next transition occurs to state H2 when  $y(t_2) = 1 - 2\epsilon$ . For  $t > t_1$  and in state H3, the force exerted by the damper is equal to

$$(2.5) \quad cz(t - t_1) = 5e^{-(t-t_1)} \sin(2(t - t_1))/2.$$

This is also equal to the force through the play element.

Equation (2.5) highlights our first observation about the play operator in mechanical networks that appears unsatisfactory; that is, during the disengagement state H3 the force transmitted by the play element is not necessarily zero.

FIG. 6. Figure 5 with reversed terminals of  $\mathcal{H}$ .

**2.1.2. Dependence on inertial frame.** Next, the particular solution of section 2.1.1 is considered, but with a steady “drift” term added. Setting  $A = C = 0$  we find that  $y(t) = e^{-2t}B \sin(t) + Dt$ . This, and the corresponding solution for  $z(t)$ , differs only from that in section 2.1.1 by the addition of a constant velocity  $D$ . As before, a transition from state H1 to H3 occurs when  $\dot{y}(t) = 0$ . But it is easy to see that  $\dot{y}(t) > 0$  for all  $t \geq 0$  if  $D$  is sufficiently large. In such a case there will be no transition to state H3. Even if a transition occurs, the transition time will be dependent on  $D$ . Evidently, the behavior of the system fails to be invariant to a simple translation of the inertial frame. This is the second property of the play operator that appears unsatisfactory from a physical point of view. It is also curious that the output of the play operator remains stationary during disengagement.

For this solution we now consider the force through the play element, which is the same as the force through the damper, which equals

$$c(\dot{z} - \dot{y}) = -4e^{-2t}B(\cos(t) - 2\sin(t)).$$

Clearly the sign of this force oscillates. This again appears unsatisfactory from a physical point of view, since we would expect the force acting on the play element to be positive in the extension state.

**2.1.3. Reversal of terminals of the play operator.** The network in Figure 5 is considered next, but with the terminals of the play operator reversed (see Figure 6), and with the same parameters as in section 2.1. The dynamical equations are again given by (2.1), and on eliminating  $z$  we find that

$$\frac{\hat{u}(s)}{\hat{y}(s)} = -\frac{m_1 m_2 s^2 + m_2 cs + k(m_1 + m_2)}{m_1 cs}.$$

Since this transfer function is nonproper, it is not possible to use Proposition 2.1 and give a general statement on well-posedness. However, we show below that solutions can be computed in specific cases. The dynamical equations in each of the states G1–G3 are as follows:

G1 (engagement–extension). This corresponds to  $y = u + \epsilon$ ,  $\dot{u} = \dot{y} \leq 0$ . The equations of  $u(t)$ ,  $y(t)$ , and  $z(t)$  are identical to those in case H1 in section 2.1.

G2 (engagement–compression). This corresponds to  $y = u - \epsilon$ ,  $\dot{u} = \dot{y} \geq 0$ . The equations for  $u(t)$ ,  $y(t)$ , and  $z(t)$  are identical to those in case H2 in section 2.1.

G3 (disengagement). This corresponds to  $|y - u| < \epsilon$ ,  $\dot{y} = 0$ . In this state  $y(t) \equiv y^*$  (say) and the dynamical equations become

$$(2.6a) \quad 0 = k(z - y^*) + c(\dot{z} - \dot{u}),$$

$$(2.6b) \quad m_1 \ddot{z} = -k(z - y^*) - c(\dot{z} - \dot{u}).$$

Adding both equations gives  $0 = m_1 \ddot{z}$ , which implies  $z(t) = E_1 + E_2 t$ . From (2.6a) we can find an expression of  $\dot{u}(t)$ , which leads to

$$(2.7) \quad u(t) = E_3 + (E_2 + (k/c)(E_1 - y^*))t + kt^2 E_2 / (2c),$$

where  $E_1$ ,  $E_2$ , and  $E_3$  are constants.

Now consider an initial condition of the form (2.2) in which  $A = C = D = 0$  and  $B > 0$  for the network of section 2.1.3, and a transition from G2 to G3. Again from (2.3a) and (2.3b) we find that a transition to G3 occurs when  $t_1 = \arctan(1/2)$ . Once again  $B$  is chosen so that  $y(t_1) = 1$  (which is the same value as obtained in section 2.1.1). In order that a solution for the dynamical equations in (2.1) exists through  $t_1$ , it is necessary that  $y(t)$ ,  $z(t)$ ,  $\dot{y}(t)$ , and  $\dot{z}(t)$  are continuous at  $t = t_1$ . Therefore, a solution to the equations in the G3 state is sought with the following initial conditions:  $y(t_1) = -z(t_1) = 1$ ,  $\dot{y}(t_1) = \dot{z}(t_1) = 0$ . It follows that  $y(t) \equiv 1$ , while the G3 state persists. Since  $\ddot{y}(t) + \ddot{z}(t) = 0$  we must also have  $z(t) \equiv -1$ , while the G3 state persists. From (2.7) we find that  $u(t) = 1 + \epsilon - 5t/2$ . Since  $y - u = -\epsilon + 5t/2$ , the solution is consistent with a transition to G3 at  $t = t_1$ .

It is interesting to make a comparison between this solution and the one in section 2.1.1 without the terminals reversed. Dynamically, the two solutions are identical for  $0 < t < t_1$ , except for the fact that the play element is in compression rather than extension. During disengagement the two solutions differ. With the choice of terminals used in this section, the solution during disengagement appears curious in that the play operator results in both masses being stationary, while the input terminal of the play operator moves with constant velocity.

**2.2. Summary of critique.** For a simple mechanical network incorporating the play operator in series with a damper, we have identified several properties of the network behavior which appear unsatisfactory from a physical point of view. These are summarized as follows:

1. During disengagement the force through the play element is not necessarily zero.
2. The solutions of the network equations depend on the choice of inertial frame, namely, the addition of a constant velocity to all states may change switching times or eliminate them altogether.
3. During engagement the force through the play element is not restricted in sign.
4. The behavior of the network is not invariant to a switch of terminals of the play operator.

A similar critique can be given for the dead-zone model of play. (See [13], where some similar points are made for the dead-zone model.)

**3. The ideal play.** This section proposes a definition of ideal play which does not suffer from the criticism identified in section 2. Since the ideal play does not admit an input-output graph, mathematical properties like well-posedness and the exclusion of limit points of switching are arrived at by analyzing individual transition scenarios.

**3.1. A behavioral definition of the ideal play.** Consider a physical representation of play as shown in Figure 7(a) where  $z_1, z_2$  are the terminal positions and  $F$  is the equal and opposite force applied at the terminals. The ideal play is defined to be completely characterized by the following three states:

- I1 (engagement–extension):  $z_2 - z_1 = \epsilon$ ,  $F \leq 0$ .
- I2 (engagement–compression):  $z_2 - z_1 = -\epsilon$ ,  $F \geq 0$ .
- I3 (disengagement):  $|z_2 - z_1| < \epsilon$ ,  $F = 0$ .

Note that the definition is invariant to terminal reversal (i.e., the transformation  $z_1 \rightarrow -z_2$ ,  $z_2 \rightarrow -z_1$ ,  $F \rightarrow F$ ). Also, objections 1 and 3 in section 2.2 no longer apply. Finally, we note that this definition allows the mechanical network to maintain invariance to the choice of inertial frame, since the three states depend only on the

FIG. 7. (a) *Physical representation of ideal play.* (b) *Terminal modeling symbol for ideal play.*

FIG. 8. *Damped harmonic oscillator network with ideal play.*

difference between  $z_1$  and  $z_2$ . We will use the network symbol shown in Figure 7(b) to represent the ideal play.

It is important to remark that the ideal play cannot be represented as a function or input-output operator since  $F$  does not determine  $z_2 - z_1$  uniquely—nor does  $z_2 - z_1$  determine  $F$  uniquely. Fundamentally, the ideal play will need to be connected to other elements in order that the complete network has a unique solution for given initial conditions.

The issue of well-posedness for networks incorporating the ideal play will be explored in the rest of this section. A number of typical cases will be examined from first principles. So far it has not been possible to derive general conditions for well-posedness by, for example, exploiting general approaches to hybrid or switched systems, e.g., the linear complementarity approach of [18, 12, 9, 2]. The use of such methods to consider well-posedness with ideal play is a topic for future research.

**3.2. A network incorporating ideal play.** Consider the network in Figure 8, which is the same as the networks considered in Figures 5 and 6 but with the new ideal model of play. The dynamical equations are

$$(3.1a) \quad m_2 \ddot{y} = k(z - y) + F,$$

$$(3.1b) \quad m_1 \ddot{z} = -k(z - y) - F,$$

$$(3.1c) \quad F = c(\dot{z} - \dot{u}).$$

We will now write down the form of the solutions in each state.

I1 (engagement–extension). This corresponds to  $y - u = \epsilon$  and  $F \leq 0$ . The dynamical equations for  $x = [y, \dot{y}, z, \dot{z}]$  are identical to those in state H1 in section 2.1.

I2 (engagement–compression). This corresponds to  $y - u = -\epsilon$  and  $F \geq 0$ . The dynamical equations are identical to those in state H2 in section 2.1.

I3 (disengagement). This corresponds to  $|y - u| < \epsilon$  and  $F = 0$ . It can be seen directly from (3.1) that

$$(3.2a) \quad y(t) - z(t) = A \cos(\omega_3 t) + B \sin(\omega_3 t),$$

$$(3.2b) \quad m_2 y(t) + m_1 z(t) = C + Dt,$$

where  $\omega_3 = \sqrt{\frac{k(m_1 + m_2)}{m_1 m_2}}$ .

We immediately see that the solution of the network of Figure 8 differs from the networks of both Figure 5 and Figure 6 as is seen from the purely oscillatory form of the dynamical equations in the disengagement region.

**3.2.1. A special well-posedness argument.** We now establish a well-posedness property of the network in Figure 8. The approach taken is to examine in detail all possible transition scenarios and to show that there is a well-defined transition in all cases. The proposition describes only the transitions between I1 and I3—the transitions between I2 and I3 are analogous. The terminology “just before  $t_0$ ” means formally “for  $t < t_0$  and  $|t_0 - t|$  sufficiently small,” and a similar meaning holds for “just after  $t_0$ ”.

**PROPOSITION 3.1.** *Consider the network of Figure 8 in which the displacements  $y(t)$ ,  $z(t)$ ,  $u(t)$  are assumed to be continuous.*

(a) *For any solutions of the network,  $\dot{y}(t)$  and  $\dot{z}(t)$  are always continuous, including transitions between states; however,  $\dot{u}(t)$  need not be continuous at transitions.*

(b) *Suppose the system is in state I1 just before  $t_0$  and that  $F(t) \uparrow 0$  as  $t \uparrow t_0$ . Then there is a unique continuation of the system into either state I1 or I3 after  $t_0$ .*

(c) *Suppose the system is in I3 just before  $t_0$  and  $y - u \uparrow \epsilon$ . If  $\dot{y}(t_0) - \dot{u}(t_0^-) > 0$ , then there is a unique continuation of the system into state I1 after  $t_0$ . If  $\dot{y}(t_0) - \dot{u}(t_0^-) = 0$ , then there is a unique continuation of the system into either I1 or I3 after  $t_0$ .*

(d) *Given any initial condition at time  $t = 0$ , the solutions of the network exist,  $y(t) - z(t)$  is uniformly bounded on  $[0, \infty)$ , and there are no limit points of switching between the states I1, I2, I3.*

*Proof.* (a) Suppose that there is a discontinuity in either  $\dot{y}$  or  $\dot{z}$ . By direct observation of the differential equations (3.1a)–(3.1b) this implies a  $\delta$ -function in  $\ddot{y}$  or  $\ddot{z}$ , which means that  $F$  must provide an impulsive force. From (3.1c) this can happen only if the displacement  $u(t)$  is discontinuous, which is excluded. Therefore,  $\dot{y}(t)$ ,  $\dot{z}(t)$  are always continuous, including transitions between states, whereas  $\dot{u}(t)$  need not be continuous at transitions.

(b) Suppose the network is in state I1 just before time  $t_0$  and that  $\dot{z}(t) - \dot{u}(t) \uparrow 0$  as  $t \uparrow t_0$ . Since  $y(t) - u(t) = \epsilon$  just before  $t_0$ , we have the following conditions:  $y(t_0) - u(t_0) = \epsilon$ ,  $\dot{y}(t_0) = \dot{u}(t_0^-) = \dot{z}(t_0)$ . If the system remains in state I1, then  $\dot{u}(t_0^+) = \dot{y}(t_0)$ , whereas if there is a transition to I3, then  $\dot{u}(t_0^+) = \dot{z}(t_0)$ . Thus, in either case  $\dot{u}(t_0^-) = \dot{u}(t_0^+)$ . Let us therefore consider an “initial” condition  $x(t_0) = [Y, D, Z, D]^T$ . If the network were to continue in the state I1, then we could calculate that

$$(3.3) \quad \dot{z} - \dot{u} = \dot{z} - \dot{y} = -4(Z - Y) \frac{\omega_3}{\omega_1} \exp\left(-\frac{c(m_1 + m_2)}{2m_1 m_2}(t - t_0)\right) \sin(\omega_1(t - t_0)),$$

where  $\omega_1 = \sqrt{\frac{(m_1 + m_2)(4km_1 m_2 - c^2(m_1 + m_2))}{4m_1^2 m_2^2}}$ , which is consistent with  $F \leq 0$  if and only if  $Z - Y \geq 0$ . If the network were to continue in state I3, we could calculate that  $\dot{y} - \dot{u} = \dot{y} - \dot{z} = \omega_3(Z - Y) \sin(\omega_3(t - t_0))$ , which is consistent with  $y - u < \epsilon$  after  $t_0$  if and only if  $Z - Y < 0$ . Thus, there is always an unambiguous continuation into I1 or I3.

(c) Suppose the network is in state I3 just before time  $t_0$  and that  $y(t) - u(t) \uparrow \epsilon$  as  $t \uparrow t_0$ . It follows that  $\dot{y}(t_0) - \dot{u}(t_0^-) \geq 0$  since  $y - u$  tends to  $\epsilon$  from below. Let us suppose that  $\dot{y}(t_0) - \dot{u}(t_0^-) > 0$ . The network cannot remain in state I3 after time  $t_0$  since the condition  $|y(t) - u(t)| < \epsilon$  would be violated. (Note that if the network remains in I3,  $\dot{z}(t_0^-) - \dot{u}(t_0^-) = \dot{z}(t_0^+) - \dot{u}(t_0^+) = 0$ , so that  $\dot{u}(t_0^+) = \dot{u}(t_0^-)$ .) For a transition to I1 we need the condition  $\dot{u}(t_0^+) = \dot{y}(t_0)$ , whereas  $\dot{u}(t_0^-) = \dot{z}(t_0)$ , which suggests a discontinuity in  $\dot{u}$  at  $t = t_0$ . For a valid transition to I1 it is necessary that  $F \leq 0$  after  $t_0$ ,

FIG. 9. (Ideal) inerter modeling symbol.

which must hold since  $\dot{z}(t_0) - \dot{u}(t_0^+) = \dot{u}(t_0^-) - \dot{y}(t_0) < 0$ . The only remaining case is when  $\dot{y}(t_0) - \dot{u}(t_0^-) = 0$ . Since  $\dot{u}(t_0^-) = \dot{z}(t_0)$  we expect  $\dot{u}(t)$  to be continuous at  $t = t_0$  irrespective of any transition to I1 or I3. This case therefore reduces to the precise situation analyzed in (b).

(d) Within I1 or I2,

$$(3.4) \quad (\ddot{y} - \ddot{z}) + (c/m)(\dot{y} - \dot{z}) + (k/m)(y - z) = 0,$$

where  $m = m_1 m_2 / (m_1 + m_2)$ , and within I3,

$$(3.5) \quad (\ddot{y} - \ddot{z}) + (k/m)(y - z) = 0.$$

We can check that  $V = (y - z)^2 + (m/k)(\dot{y} - \dot{z})^2$  is a common Lyapunov function for (3.4) and (3.5). Hence,

$$(3.6) \quad |y(t) - z(t)| \leq \sqrt{(y(0) - z(0))^2 + (m/k)(\dot{y}(0) - \dot{z}(0))^2}$$

for all  $t \geq 0$ , independent of switching between states.

Suppose now that a switching occurs at  $t_0$  as in (b). We will show that the “dwell time” in state I3 is bounded from below. If there is a unique continuation of the system into state I1, then there is nothing to prove. So let us assume that there is a unique continuation in I3. As in (b) we can find that  $Y - Z > 0$  and  $y - u = \epsilon + (Y - Z)(\cos(\omega_3(t - t_0)) - 1)$ . There are two possibilities. If  $Y - Z \leq \epsilon$ , then the system returns to I1 after one oscillation cycle with  $t_1 - t_0 = 2\pi/\omega_3$ . If  $Y - Z > \epsilon$ , there is a transition to I2 with

$$(3.7) \quad t_1 - t_0 = \arccos\left(1 - \frac{2\epsilon}{Y - Z}\right) / \omega_3.$$

Since  $Y - Z$  is bounded above by the right-hand side of (3.6), the dwell time given by (3.7) is bounded from below.

Consequently, it is concluded that there can be no limit point of switching times since the sequence of states occupied by the system must alternate between I3 and either I1 or I2. This in turn means that we can find solutions for  $y(t)$ ,  $z(t)$ ,  $u(t)$  for all  $t \geq 0$ .  $\square$

**3.3. The inerter.** In [16] an ideal modeling element termed the *inerter* was introduced with the following definition. The (ideal) inerter is defined to be a two-terminal mechanical element with the property that the equal and opposite force applied at the terminals is equal to the relative acceleration between them, i.e.,  $F = b(\ddot{z}_1 - \ddot{z}_2)$  in the notation of Figure 9, where  $b$  is the constant of proportionality in kilograms. For the purpose of modeling mechanical networks we will assume that the ideal inerter has zero mass (which is similar to the assumption that ideal springs and dampers have zero mass). Mechanical realizations of inerters have been described in [17, 15].

FIG. 10. *Harmonic oscillator network with an inerter and ideal play.*

**3.4. A network incorporating an inerter with play.** Consider the network in Figure 10, which differs from Figure 8 only in that an inerter replaces the damper. The dynamical equations are

$$(3.8a) \quad m_2 \ddot{y} = k(z - y) + F,$$

$$(3.8b) \quad m_1 \ddot{z} = -k(z - y) - F,$$

$$(3.8c) \quad F = b(\ddot{z} - \ddot{u}).$$

We will now write down the form of the solutions in each state.

J1 (engagement–extension). This corresponds to  $y - u = \epsilon$  and  $F \leq 0$ . The dynamical equations have solutions given by

$$\begin{aligned} y(t) - z(t) &= A_1 \cos(\omega_1 t) + B_1 \sin(\omega_1 t), \\ m_2 y(t) + m_1 z(t) &= C_1 + D_1 t. \end{aligned}$$

where  $\omega_1 = \sqrt{\frac{k(m_1 + m_2)}{m_1 m_2 + b(m_1 + m_2)}}$ .

J2 (engagement–compression). This corresponds to  $y - u = -\epsilon$  and  $F \geq 0$ . The dynamical equations are identical to state J1.

J3 (disengagement). This corresponds to  $|y - u| < \epsilon$  and  $F = 0$ . The dynamical equations have solutions given by

$$\begin{aligned} (3.9) \quad y(t) - z(t) &= A_3 \cos(\omega_3 t) + B_3 \sin(\omega_3 t), \\ m_2 y(t) + m_1 z(t) &= C_3 + D_3 t. \end{aligned}$$

where  $\omega_3 = \sqrt{\frac{k(m_1 + m_2)}{m_1 m_2}}$ .

**3.4.1. Well-posedness and the need for impulsive forces.** We will now study the well-posedness of the network in Figure 10. We will show that there is a qualitative difference in the behavior compared to the network of Figure 8. In the first place, the dynamical equations (3.8) do not imply directly that  $\dot{y}(t)$  and  $\dot{z}(t)$  are continuous (as was the case in Proposition 3.1(a)). This leaves open the possibility of impulsive forces being generated at transitions between states. Physical intuition might suggest the absence of impulsive forces for transitions from engagement to disengagement (Remark 1). With such an assumption we will show that there are uniquely defined transitions in such cases (Proposition 3.2(a)). For transitions from disengagement to engagement it is not obvious that impulsive forces can be dispensed with. In Proposition 3.2(b) we will show that impulsive forces are needed for there to be a well-defined transition. We will also see that the dynamical equations do not define the strength of the impulse uniquely. Thus, multiple solutions of the dynamical equations exist and well-posedness is lost. Once again, the proposition is stated only for transitions between J1 and J3.

PROPOSITION 3.2. *Consider the network of Figure 10 in which the displacements  $y(t)$ ,  $z(t)$ , and  $u(t)$  are assumed to be continuous.*

(a) *Suppose the system is in state J1 just before  $t_0$  and  $F = b(\ddot{z} - \ddot{u}) \uparrow 0$  (strictly) as  $t \uparrow t_0$ . Then the system undergoes a well-defined transition to J3 at  $t_0$  under the assumption that no impulsive forces are generated.*

(b) *Suppose the system is in state J3 just before  $t_0$  and  $y(t) - u(t) \uparrow \epsilon$  as  $t \uparrow t_0$ . Then  $\dot{y}(t_0^-) - \dot{u}(t_0^-) =: \alpha \geq 0$ . A well-defined transition to J1 occurs under the following two conditions:*

(i) *An impulsive force  $P\delta(t - t_0)$  occurs with  $P = P_0 := -(m_1 m_2 b)/(m_1 m_2 + b(m_1 + m_2))\alpha$  in the inerter;*

(ii)  *$\ddot{y}(t_0^-) - \ddot{u}(t_0^-) > 0$ .*

*A well-defined transition to J3 occurs under the following condition:*

(iii) *An impulsive force  $P\delta(t - t_0)$  in the inerter occurs with  $P < P_0$ .*

*In all cases of well-defined transitions  $P$  is negative, which is consistent with the engagement condition being extensive. There is no solution of the system equations assuming an impulsive force with  $P > P_0$ .*

*Proof.* (a) Suppose the network is in state J1 just before time  $t_0$  and that  $\ddot{z}(t) - \ddot{u}(t) \uparrow 0$  as  $t \uparrow t_0$ . Since  $y(t) - u(t) = \epsilon$  just before  $t_0$ , we have the following conditions:  $y(t_0) - u(t_0) = \epsilon$ ,  $\dot{y}(t_0^-) - \dot{u}(t_0^-) = 0$ ,  $\ddot{z}(t_0^-) = \ddot{u}(t_0^-) = \ddot{y}(t_0^-)$ . Within J1 we can check from (3.8a) and (3.8b) that

$$(3.10) \quad z - y = -\frac{m_1 m_2 + b(m_1 + m_2)}{k(m_1 + m_2)} (\ddot{z} - \ddot{y}).$$

This implies  $z(t_0) = y(t_0)$  (but there is no obvious relationship between  $\dot{z}(t_0^-)$  and  $\dot{y}(t_0^-)$ ). This means  $y(t) - z(t) = B_1 \sin(\omega_1(t - t_0))$  just before  $t = t_0$ , and we deduce from (3.10) that  $B_1 \geq 0$  in order to respect the sign constraint on  $F$  in J1.

By assumption, no impulsive forces are generated at  $t_0$ , so  $\dot{z}(t_0^+) = \dot{z}(t_0^-)$ ,  $\dot{y}(t_0^+) = \dot{y}(t_0^-)$ , and  $\dot{u}(t_0^+) = \dot{u}(t_0^-)$ . We conclude that  $\dot{y}(t_0) - \dot{z}(t_0) = B_1 \geq 0$ . Furthermore, there cannot be a continuation of the network after  $t_0$  in state J1 unless  $B_1 = 0$ .

Let us consider whether a continuation in state J3 is always possible. From (3.9) we find that  $y(t) - z(t) = (B_1/\omega_3) \sin(\omega_3(t - t_0))$ . Further, we have  $u(t) = z(t) - \epsilon + B_1(t - t_0)$  after  $t_0$  since  $\ddot{u} = \ddot{z}$  in J3,  $u(t_0) - z(t_0) = -\epsilon$ , and  $\dot{u}(t_0) - \dot{z}(t_0) = \dot{y}(t_0) - \dot{z}(t_0) = B_1$ . Therefore,

$$\begin{aligned} y(t) - u(t) &= y(t) - z(t) + \epsilon - B_1(t - t_0) \\ &= \epsilon + B_1 (\omega_3^{-1} \sin(\omega_3(t - t_0)) - (t - t_0)), \end{aligned}$$

which we can readily check to be decreasing after  $t_0$ , which is consistent with a transition to J3.

(b) We now consider a possible transition from J3 to J1. Suppose the network is in state J3 and  $y(t) - u(t) \uparrow \epsilon$  as  $t \uparrow t_0$  and  $\ddot{z} = \ddot{u}$  just before time  $t_0$ . Again we must have  $\dot{y}(t_0^-) - \dot{u}(t_0^-) \geq 0$  since  $y(t) - u(t) \uparrow \epsilon$ . Let us consider the case  $\dot{y}(t_0^-) - \dot{u}(t_0^-) =: \alpha > 0$ . If there is a transition from J3 to J1, it must be true that  $\dot{y}(t_0^+) - \dot{u}(t_0^+) = 0$ . Thus, there must be discontinuities in velocities. This in turn implies that there must be an impulsive force in the inerter. Let us consider an impulse of the form  $P\delta(t - t_0)$  in  $F$ . (On physical grounds we would expect  $P \leq 0$  since J1 is extensive.) From (3.8c) we observe that

$$(3.11a) \quad (\dot{z}(t_0^+) - \dot{u}(t_0^+)) - (\dot{z}(t_0^-) - \dot{u}(t_0^-)) = P/b,$$

while (3.8a) and (3.8b) imply

$$(3.11b) \quad \dot{y}(t_0^+) - \dot{y}(t_0^-) = P/m_2,$$

$$(3.11c) \quad \dot{z}(t_0^+) - \dot{z}(t_0^-) = -P/m_1.$$

We therefore find that

$$0 = \dot{y}(t_0^+) - \dot{u}(t_0^+) = P/m_1 + P/m_2 + P/b + \alpha,$$

which means that  $P = P_0$  and indeed we have  $P < 0$ . For a valid transition to J1 we must have  $F \leq 0$  for  $t > t_0$ . If the state remains in J1, we must have  $\ddot{z}(t) - \ddot{y}(t) = A_1 \cos(\omega_1(t - t_0)) + B_1 \sin(\omega_1(t - t_0))$  and  $\ddot{u}(t) = \ddot{y}(t)$ . Therefore,  $F \leq 0$  after  $t_0$  requires  $A_1 < 0$ . Note that  $A_1 = y(t_0) - z(t_0) = -\omega_3^{-2}(\ddot{y}(t_0^-) - \ddot{u}(t_0^-))$ . This establishes the required conditions (i) and (ii) for a well-defined transition to J1.

Let us now consider the possibility that an impulsive force at  $t_0$  allows a continuation for the system in state J3 after  $t_0$ . We can check that if  $P < P_0$ , then  $\dot{y}(t_0^+) - \dot{u}(t_0^+) < 0$ , and that we have a valid solution for the state J3 after  $t_0$ . If  $P > P_0$ , there is no valid solution.  $\square$

*Remark 1.* In Proposition 3.2(a) the analysis was restricted to the case where no impulse occurs at disengagement. In the next paragraph we will show that if an impulse does occur at disengagement, the system experiences an overall increase in energy. Thus, it seems reasonable to exclude such behavior on the grounds that the system is passive.

Assume (3.11) applies. Without loss of generality we can restrict our attention to trajectories for which  $m_2 y + m_1 z \equiv 0$  (cf. (3.8)), so we may take

$$(3.12) \quad [y, \dot{y}, z, \dot{z}](t_0^-) = [A, B, -(m_2/m_1)A, -(m_2/m_1)B].$$

Suppose the system transfers from J1 to J3 at  $t_0$ , as in Proposition 3.2(a). Then  $\dot{y}(t_0^+) = -(m_1/m_2)\dot{z}(t_0^+) = P/m_2 + B$  and  $\dot{u}(t_0^+) = B - P(m_1^{-1} + b^{-1})$  from (3.11). Let  $E = (m_1 \dot{z}^2 + m_2 \dot{y}^2 + b(\dot{z} - \dot{u})^2)/2$  denote the kinetic energy of the system. Then we can verify that

$$\begin{aligned} E(t_0^-) &= \frac{1}{2} m_2 B^2 \left( 1 + b \left( \frac{1}{m_2} + \frac{1}{m_1} \right) \right) \left( 1 + \frac{m_2}{m_1} \right), \\ E(t_0^+) &= E(t_0^-) + \frac{1}{2} P^2 \left( \frac{1}{m_1} + \frac{1}{m_2} + \frac{1}{b} \right). \end{aligned}$$

We observe that for any  $P \neq 0$ ,  $E(t_0^+) > E(t_0^-)$ .

*Remark 2.* It is interesting to calculate the change in kinetic energy of the system when an impulse occurs at engagement as in Proposition 3.2(b). In the next paragraph we will show that energy is dissipated, providing  $2P_0 < P \leq P_0$  (recall that  $P_0 < 0$ ). We will see that the maximum energy is dissipated when  $P = P_0$  and energy is conserved when  $P = 2P_0$ . If  $P < 2P_0$ , then the impulse leads to an increase in kinetic energy.

To see this, consider (3.11) with (3.12) and  $\dot{y}(t_0^-) - \dot{u}(t_0^-) := \alpha \geq 0$ . Then we can verify that

$$\begin{aligned} \dot{z}(t_0^+) &= -(m_2/m_1)\dot{y}(t_0^+) = -P/m_1 - (m_2/m_1)B, \\ \dot{z}(t_0^-) - \dot{u}(t_0^-) &= \alpha - B(m_2/m_1 + 1), \\ \dot{z}(t_0^+) - \dot{u}(t_0^+) &= \alpha - B(m_2/m_1 + 1) + P/b. \end{aligned}$$

FIG. 11. Change in kinetic energy due to an impulse of strength  $P$  at  $t = t_0$ . From Proposition 3.2, solutions of the system equations exist only if  $P \leq P_0$ . Energy is dissipated when  $2P_0 < P \leq P_0$  and energy increases when  $P < 2P_0$ .

FIG. 12. Network with an inerter, a compliance spring, and ideal play.

As in Remark 1 we can compute the kinetic energy at  $t_0^-$  and  $t_0^+$  to find that

$$E(t_0^-) = \frac{1}{2} (m_2 B)^2 (m_1^{-1} + m_2^{-1}) + \frac{1}{2} b \left( \alpha - m_2 B (m_1^{-1} + m_2^{-1}) \right)^2,$$

$$E(t_0^+) = \frac{1}{2} (P + m_2 B)^2 (m_1^{-1} + m_2^{-1}) + \frac{1}{2} b \left( \alpha - m_2 B (m_1^{-1} + m_2^{-1}) + \frac{P}{b} \right)^2.$$

The required conclusions follow from these expressions. In particular we can show that  $E(t_0^+)$  has a minimum at  $P = P_0$ . This is illustrated in Figure 11.

**3.5. Compliance in series with an inerter and play.** Consider the network in Figure 12 which differs from Figure 10 by the insertion of a spring in series with the inerter and play. The dynamical equations are

$$(3.13a) \quad m_2 \ddot{y} = k(z - y) + F$$

$$(3.13b) \quad m_1 \ddot{z} = -k(z - y) - F,$$

$$(3.13c) \quad F = b(\ddot{z} - \ddot{r}),$$

$$(3.13d) \quad F = k_1(r - u).$$

We now write down the form of the solutions in each state.

K1 (engagement–extension). This corresponds to  $u = y - \epsilon$ ,  $F \leq 0$ . We can solve for  $\ddot{r}$  and reduce the dynamical equations to

$$(3.14a) \quad \ddot{y} = m_2^{-1} (k(z - y) + k_1(r - u)),$$

$$(3.14b) \quad \ddot{z} = -m_1^{-1} (k(z - y) + k_1(r - u)),$$

$$(3.14c) \quad \ddot{r} = -m_1^{-1} (k(z - y) + k_1(r - u) (1 + m_1/b)).$$

These can be written in state-space form as follows:  $\dot{x}(t) = A_{K1}x(t) + B_{K1}\epsilon$  with  $x = [y, \dot{y}, z, \dot{z}, r, \dot{r}]^T$ . In section 3.5.2 we will solve the equations symbolically by means of the expression

$$(3.15) \quad \mathcal{L}^{-1}\{X(s)\} = \mathcal{L}^{-1}\{\Psi(s)\}x(0) + \mathcal{L}^{-1}\{s^{-1}\Psi(s)\}B_{K1}\epsilon,$$

where the resolvent of  $A_{K1}$ ,  $\Psi(s) = (sI - A_{K1})^{-1}$ , is obtained using Maple.

K2 (engagement–compression). This corresponds to  $u = y + \epsilon$ ,  $F \geq 0$ . The dynamical equations are identical to state K1 but with a sign change in  $\epsilon$ .

K3 (disengagement). This corresponds to  $|y - u| < \epsilon$  and  $F = 0$ . The dynamical equations for  $y$  and  $z$  are identical to case J3 and we have  $\ddot{z}(t) = \ddot{r}(t)$  and  $r(t) = u(t)$ .

**3.5.1. A special well-posedness argument.** This section shows that there is a qualitative difference between the behaviors of the networks of Figures 10 and 12. In the first place, the inclusion of the series spring prevents impulsive forces from being generated. Second, the modeling equations specify a unique transition from disengagement to engagement.

**PROPOSITION 3.3.** *Consider the network of Figure 12 in which the displacements  $y(t)$ ,  $z(t)$ ,  $u(t)$ ,  $r(t)$  are assumed to be continuous.*

(a) *For any solutions of the network,  $\dot{y}(t)$ ,  $\dot{z}(t)$ ,  $\dot{r}(t)$ ,  $\ddot{y}(t)$ ,  $\ddot{z}(t)$ , and  $\ddot{r}(t)$  are continuous including transitions between states. However,  $\dot{u}(t)$  is not necessarily continuous at transitions.*

(b) *Suppose the system is in state K1 just before  $t_0$  and  $F \uparrow 0$  (strictly), i.e.,  $\dot{r}(t_0^-) - \dot{u}(t_0^-) > 0$ . Then there is a well-defined transition to state K3.*

(c) *Suppose the system is in state K3 just before  $t_0$  and  $y - u \uparrow \epsilon$  (strictly), i.e.,  $\dot{y}(t_0^-) - \dot{u}(t_0^-) > 0$ . Then there is a well-defined transition to state K1.*

*Proof.* (a) Substitution of (3.13d) into (3.13a) and (3.13b) shows that  $\ddot{y}$ ,  $\ddot{z}$  are continuous, and equating (3.13c) and (3.13d) shows that  $\ddot{r}$  is continuous. Hence,  $\dot{y}$ ,  $\dot{z}$ , and  $\dot{r}$  are continuous, but it is not necessarily true that  $\dot{u}$  is continuous.

(b) Since

$$(3.16) \quad \dot{r}(t_0^-) - \dot{u}(t_0^-) = \dot{r}(t_0^-) - \dot{y}(t_0^-) > 0,$$

a continuation in state K1 is not possible, as this would violate the condition that  $F \leq 0$ . A well-defined transition to K3 occurs if

$$(3.17) \quad \dot{y}(t_0^+) - \dot{u}(t_0^+) < 0.$$

By definition of state K3 we must have  $\dot{r}(t_0^+) = \dot{u}(t_0^+)$ . From (a),  $\dot{y}(t_0^+) = \dot{y}(t_0^-)$  and  $\dot{r}(t_0^+) = \dot{r}(t_0^-)$ . Therefore,  $\dot{y}(t_0^+) - \dot{u}(t_0^+) = \dot{y}(t_0^-) - \dot{r}(t_0^-)$ . Hence, (3.17) follows from (3.16). Incidentally, we have also shown that  $\dot{u}$  is discontinuous at  $t_0$  since  $\dot{u}(t_0^+) - \dot{u}(t_0^-) = \dot{r}(t_0^-) - \dot{y}(t_0^-)$ . This follows since  $y = u + \epsilon$  just before  $t_0$  so that  $\dot{u}(t_0^-) = \dot{y}(t_0^-)$ .

(c) Since

$$(3.18) \quad \dot{y}(t_0^-) - \dot{u}(t_0^-) > 0,$$

a continuation in state K3 is not possible, as this would violate the condition  $|y - u| < \epsilon$ . For a well-defined transition to K1 we need  $F \leq 0$  after  $t_0$ . For this to happen it would be sufficient to have

$$(3.19) \quad \dot{r}(t_0^+) - \dot{u}(t_0^+) < 0.$$

By definition of state K3 we must have  $\dot{r}(t_0^+) = \dot{u}(t_0^+)$ . Therefore, from (a)  $\dot{y}(t_0^-) - \dot{u}(t_0^-) = \dot{y}(t_0^+) - \dot{r}(t_0^+)$ . Hence, (3.19) follows from (3.18). As in (b) we have shown that  $\dot{u}$  is discontinuous at  $t_0$ .  $\square$

*Remark 3.* In the following we extend Proposition 3.3(b) to the case  $\dot{r}(t_0^-) - \dot{u}(t_0^-) = 0$  when the system is in state K1 and  $F \uparrow 0$ . For a transition to K3 we require  $y - u < \epsilon$  for  $t > t_0$ . We now derive a condition for this to hold. For a transition to K3,  $\dot{r}(t_0^+) - \dot{u}(t_0^+) = 0$ . Since  $\dot{r}$  is continuous (see Proposition 3.3(a)),  $\dot{u}$

is continuous at  $t_0$ . This gives  $\dot{y}(t_0^-) - \dot{u}(t_0^-) = \dot{y}(t_0^+) - \dot{u}(t_0^+) = 0$ . Hence it is necessary to consider  $\ddot{y}(t_0^+) - \ddot{u}(t_0^+)$ . From Proposition 3.3(a) and  $F \equiv 0$  for  $t > t_0$  it follows that  $\ddot{r}(t_0^-) = \ddot{r}(t_0^+) = \ddot{u}(t_0^+)$ . Also, without loss of generality, we can restrict our attention to trajectories for which  $m_2 y + m_1 z \equiv 0$  so that  $y(t_0^-) = A$ ,  $z(t_0^-) = -(m_2/m_1)A$ , and  $r(t_0^-) = A - \epsilon$ . We can calculate

$$(3.20) \quad \ddot{y}(t_0^+) - \ddot{u}(t_0^+) = \ddot{y}(t_0^-) - \ddot{r}(t_0^-) = -m_2 k (m_1^{-1} + m_2^{-1})^2 A,$$

where the right-hand side follows from (3.14a) and (3.14c). Thus, from (3.20) there is a transition to K3 if  $A > 0$ . (Note that the sign of  $A$  is the opposite to the sign of the force in the spring  $k$  since  $z(t_0^-) - y(t_0^-) = -(1 + m_2/m_1)A$ .)

Now let us consider the possibility that there is no transition to K3, but the system remains in K1 (again with  $F \uparrow 0$  and  $\dot{r}(t_0^-) - \dot{u}(t_0^-) = 0$ ). For this to occur it is necessary that  $F < 0$  after  $t_0$ , i.e.,  $\ddot{r} - \ddot{u} < 0$  after  $t_0$ . Note that  $\ddot{u}$  is continuous at  $t_0$  since  $\ddot{y}$  is continuous and  $\ddot{y} = \ddot{u}$  in K1. Therefore,

$$(3.21) \quad \ddot{r}(t_0^+) - \ddot{u}(t_0^+) = \ddot{r}(t_0^-) - \ddot{u}(t_0^-) = -(\ddot{y}(t_0^-) - \ddot{r}(t_0^-)).$$

Comparing (3.21) with (3.20) we see that the system remains in state K1 if  $A < 0$ .

To conclude, even in the pathological case that  $F \uparrow 0$  from state K1 and  $\dot{r}(t_0^-) - \dot{u}(t_0^-) = 0$ , we have a well-defined transition to K3 or K1, depending on the sign of the force in the spring  $k$ . The case where  $A = 0$  requires consideration of  $\ddot{y}(t_0^+) - \ddot{u}(t_0^+)$  and  $\ddot{r}(t_0^+) - \ddot{u}(t_0^+)$  to determine whether there is a transition to K3 or whether the system remains in K1. The details are cheerfully left to the reader.<sup>1</sup>

Similarly, we can extend Proposition 3.3(c) to include the case  $\dot{y}(t_0^-) - \dot{u}(t_0^-) = 0$  when the system is in state K3 and  $y - u \uparrow \epsilon$ . We will now show that the conditions are identical to the ones laid out above. For a transition back to K3,  $\ddot{r}(t_0^-) = \ddot{u}(t_0^-)$  and  $\ddot{r}(t_0^+) = \ddot{u}(t_0^+)$  and the case is identical to the one analyzed in (3.20), namely, the situation occurs if  $A > 0$ . For a transition to K1,  $F \leq 0$  for  $t > t_0$  and we require again  $r - u < 0$  for  $t > t_0$ . Since  $\dot{y}(t_0^+) = \dot{u}(t_0^+)$ ,  $\dot{u}$  is continuous at  $t_0$ , and we also have  $\dot{y}(t_0) = \dot{r}(t_0)$ . Therefore, for a transition to K1, we need  $\ddot{r}(t_0^+) - \ddot{u}(t_0^+) < 0$ . We can check that

$$(3.22) \quad \begin{aligned} \ddot{r}(t_0^+) - \ddot{u}(t_0^+) &= \ddot{r}(t_0^+) - \ddot{y}(t_0^+) = \ddot{r}(t_0^-) - \ddot{y}(t_0^-) = -(\ddot{y}(t_0^-) - \ddot{z}(t_0^-)) \\ &= -k (m_1^{-1} + m_2^{-1}) (z(t_0^-) - y(t_0^-)) = m_2 k (m_1^{-1} + m_2^{-1})^2 A, \end{aligned}$$

where the right-hand side follows from (3.13a) and (3.13b) with  $F \equiv 0$  in state K3. Equation (3.22) is the same condition as in (3.21) and (3.20). Thus, there is a well-defined transition to K1 if  $A < 0$ .

**3.5.2. Convergence to a solution of section 3.4.1.** The networks in Figures 10 and 12 are similar and differ only by the spring  $k_1$ . In this section we investigate the convergence behavior of the latter network when  $k_1 \rightarrow \infty$ . We will focus on the transition from disengagement to engagement, where impulsive forces were needed for the network in Figure 10. We will show that the “dwell time” in the engagement state tends to zero as  $k_1 \rightarrow \infty$ . Furthermore, the force through the play element in the engagement state approaches an impulse in the limit as  $k_1 \rightarrow \infty$ . Finally, the strength of the impulse is uniquely determined and implies conservation of energy through the

<sup>1</sup>We are pleased to cite Professor Harry Dym as the originator of this useful sentence [5, p. 454].

impulsive impact. For simplicity we carry out the analysis with numerical values for the parameters  $m_1$ ,  $m_2$ ,  $b$ , and  $k$ .

First, consider the solution in case K1. The determinant of  $sI - A_{K1}$  is given by

$$\left( s^4 + \frac{m_1 m_2 k_1 + b(k + k_1)(m_1 + m_2)}{m_1 m_2 b} s^2 + \frac{k k_1 (m_1 + m_2)}{m_1 m_2 b} \right) s^2.$$

With  $m_1 = m_2 = 1$  kg,  $b = 1/2$  kg, and  $k = 1$  Nm<sup>-1</sup>, two roots are at the origin, and the roots of the quadratic in  $s^2$  are

$$-\left( 2k_1 + 1 \pm \sqrt{4k_1^2 + 1} \right) = -k_1 \left( 2 + \frac{1}{k_1} \pm 2 \left( 1 + \frac{1}{8k_1^2} + O(k_1^{-4}) \right) \right).$$

Thus, the natural frequencies are given by  $s = \pm j\omega_1, \pm j\omega_2$ , where

$$\begin{aligned} \omega_1 &= 1 + O(k_1^{-1}), \\ \omega_2 &= \sqrt{4k_1 + 1} + O(k_1^{-3/2}). \end{aligned}$$

From (3.13a) and (3.13b) we see that  $m_2 \ddot{y} + m_1 \ddot{z} = 0$ . Without loss of generality we can restrict our attention to trajectories for which  $m_2 y(t) + m_1 z(t) \equiv 0$ . We therefore consider a transition from K3 to K1, with the initial condition for the dynamic equations in state K1 equal to

$$(3.23) \quad x_0 = [A, B, -(m_2/m_1)A, -(m_2/m_1)B, A - \epsilon, B - K]^T.$$

We then solve (3.15) to find that there is a single dominant term in the force through the inerter given by  $-bK\omega_2 \sin(\omega_2 t)/2$ . We observe that this dominant term is negative for  $0 < t < t_1 := \pi/\omega_2$ . This suggests that the system will remain in state K1 until time  $t_1$  (approximately) at which there is a transition to K3. Qualitatively, this behavior is approaching one where there is an impulsive force at engagement with an immediate transition back to state K3. This is similar to behavior that was identified in section 3.4.1. Further note that

$$(3.24) \quad -\int_0^{\pi/\omega_2} bK\omega_2 \sin(\omega_2 t)/2 = -K/2,$$

which would be the expected strength of the impulse.

It is also interesting to find that the dominant term in  $\dot{y}(t) - \dot{r}(t)$  is equal to  $K \cos(\omega_2 t)$  for large  $k_1$ . This shows that  $\dot{y}(t_1) - \dot{r}(t_1) = -K$ . Note that  $\dot{u}(t_1^+) = \dot{r}(t_1)$  since there is a transition back to K3 at  $t_1$ . Therefore, we obtain

$$(3.25) \quad \dot{y}(t_0^+) - \dot{u}(t_0^+) = -K$$

in the limit as  $k_1 \rightarrow \infty$ . Using the method of section 3.4.1, (3.25) together with the assumption that  $\dot{y}(t_0^-) - \dot{u}(t_0^-) = K$  requires

$$(3.26) \quad P = -2K \frac{m_1 m_2 b}{m_1 b + m_2 b + m_1 m_2},$$

which gives the same value as (3.24). It is also interesting to note that this limiting solution is one in which energy is conserved through the impulsive impact, as discussed in Remark 2.

FIG. 13. Network with an inerter, a parallel spring-damper buffer, and ideal play.

**3.6. Buffer in series with an inerter and play.** Consider the network in Figure 13, which differs from Figure 10 by the insertion of a buffer consisting of a parallel spring-damper in series with the inerter and play. The dynamical equations are

$$(3.27a) \quad m_2 \ddot{y} = k(z - y) + F$$

$$(3.27b) \quad m_1 \ddot{z} = -k(z - y) - F,$$

$$(3.27c) \quad F = b(\ddot{z} - \ddot{r}),$$

$$(3.27d) \quad F = k_1(r - u) + c_1(\dot{r} - \dot{u}).$$

We now write down the form of the solutions in each state.

L1 (engagement–extension). This corresponds to  $u = y - \epsilon$ ,  $F \leq 0$ . We can solve for  $\ddot{r}$  and reduce the dynamical equations to

$$(3.28a) \quad \ddot{y} = m_2^{-1}(k(z - y) + k_1(r - u) + c_1(\dot{r} - \dot{u})),$$

$$(3.28b) \quad \ddot{z} = -m_1^{-1}(k(z - y) + k_1(r - u) + c_1(\dot{r} - \dot{u})),$$

$$(3.28c) \quad \ddot{r} = -m_1^{-1}(k(z - y) + (k_1(r - u) + c_1(\dot{r} - \dot{u}))(1 + m_1/b)).$$

These can be written in state-space form with  $x = [y, \dot{y}, z, \dot{z}, r, \dot{r}]^T$ . In section 3.6.2 we will solve these equations symbolically.

L2 (engagement–compression). This corresponds to  $u = y + \epsilon$ ,  $F \geq 0$ . The dynamical equations are identical to state L1 but with a sign change in  $\epsilon$ .

L3 (disengagement). This corresponds to  $|y - u| < \epsilon$  and  $F = 0$ . The dynamical equations for  $y$  and  $z$  are identical to case J3, and we have  $\ddot{z}(t) = \ddot{r}(t)$ .

**3.6.1. A special well-posedness argument.** This section shows that there is a qualitative difference between the behaviors of the networks of Figures 10 and 13. In the first place, the inclusion of the parallel spring-damper prevents impulsive forces from being generated. Second, the modeling equations specify unique transitions between system states.

**PROPOSITION 3.4.** *Consider the network of Figure 13 in which the displacements  $y(t)$ ,  $z(t)$ ,  $u(t)$ ,  $r(t)$  are assumed to be continuous.*

(a) *For any solutions of the network,  $\dot{y}(t)$ ,  $\dot{z}(t)$ , and  $\dot{r}(t)$  are continuous, including transitions between states, and no impulsive forces may occur. Furthermore,  $\dot{u}(t)$  is continuous for a transition from engagement to disengagement as also are  $\ddot{y}$ ,  $\ddot{z}$ , and  $\ddot{r}$ . On the other hand,  $\dot{u}$  may be discontinuous for a transition from state L3 to engagement.*

(b) *Suppose the system is in state L1 just before  $t_0$  and  $F \uparrow 0$  (strictly), i.e.,  $\dot{F}(t_0^-) > 0$ . Then there is a well-defined transition to state L3.*

(c) *Suppose the system is in state L3 just before  $t_0$  and  $y - u \uparrow \epsilon$  (strictly), i.e.,  $\dot{y}(t_0^-) - \dot{u}(t_0^-) > 0$ . Then there is a well-defined transition to state L1.*

*Proof.* (a) Substitution of (3.27d) into (3.27a) and (3.27b) shows that  $\dot{y}$ ,  $\dot{z}$  are continuous; otherwise impulsive behavior occurs, which would violate the continuity of  $r$  and  $u$ . Equating (3.27c) and (3.27d) shows that  $\dot{r}$  is continuous.

For a transition from state L1 to L3, we expect the force through the buffer to be continuous, i.e.,  $F(t_0^-) = F(t_0^+)$ . Since  $r$ ,  $u$ ,  $\dot{r}$  are continuous,  $\dot{u}$  has to be continuous through the transition from (3.27d). Consequently, (3.27a), (3.27b), and (3.27c) show that also  $\ddot{y}$ ,  $\ddot{z}$ ,  $\ddot{r}$  are continuous.

For a transition from state L3 to L1,  $F(t_0^-) = 0$  and  $F(t_0^+) \leq 0$ . Since  $r$ ,  $u$ , and  $\dot{r}$  are continuous,  $\dot{u}$  will be discontinuous if  $F(t_0^+) < 0$  from (3.27d).

(b) A continuation in state L1 would require that  $F(t) \leq 0$  for  $t > t_0$ , which is not possible since  $F(t_0) = 0$  and  $\dot{F}(t_0^-) > 0$  (solutions not leaving L1 will have  $\dot{F}$  continuous).

A well-defined transition to L3 requires that  $y(t) - u(t) < \epsilon$  for  $t$  just after  $t_0$ . We will now verify that this holds. Let us assume that a transition to L3 occurs. We first observe that  $F(t) = 0$  for  $t$  just after  $t_0$  and  $F(t_0^-) = 0$  so that  $F(t)$  is continuous at  $t_0$ . (There cannot be an impulse in  $F(t)$  at  $t_0$  since this would violate continuity of displacements using (3.27d).) Since  $r$ ,  $u$ , and  $\dot{r}$  are continuous at  $t_0$ , then  $\dot{u}$  is continuous at  $t_0$  from (3.27d). Therefore,  $\dot{y}(t_0^+) - \dot{u}(t_0^+) = \dot{y}(t_0^-) - \dot{u}(t_0^-) = 0$ . Hence, we need to consider  $\ddot{y}(t_0^+) - \ddot{u}(t_0^+)$ . By assumption,  $F \equiv 0$  after  $t_0$ , which means that

$$\dot{F}(t_0^+) = k_1 (\dot{r}(t_0^+) - \dot{u}(t_0^+)) + c_1 (\ddot{r}(t_0^+) - \ddot{u}(t_0^+)) = 0.$$

Now observe that

$$\begin{aligned} \ddot{y}(t_0^+) - \ddot{u}(t_0^+) &= \ddot{y}(t_0^-) - (k_1/c_1 (\dot{r}(t_0^-) - \dot{u}(t_0^-)) + \ddot{r}(t_0^-)) \\ &= - (k_1 (\dot{r}(t_0^-) - \dot{u}(t_0^-)) + c_1 (\ddot{r}(t_0^-) - \ddot{u}(t_0^-))) / c_1 \\ (3.29) \quad &= -\dot{F}(t_0^-) / c_1 < 0, \end{aligned}$$

using the facts that  $\dot{r}$ ,  $\dot{u}$ ,  $\ddot{r}$  are continuous and that  $\ddot{y}(t_0^-) - \ddot{u}(t_0^-) = 0$ . Equation (3.29) shows that  $y(t) - u(t) < \epsilon$  after  $t_0$ .

(c) A continuation in L3 would require  $y - u < \epsilon$ , which is not possible since  $\dot{y}(t_0^-) - \dot{u}(t_0^-) > 0$  (solutions not leaving L3 will have  $\dot{y} - \dot{u}$  continuous). A well-defined transition to L1 requires that  $F \leq 0$  after  $t_0$ . We will now verify that this holds. In L1,  $y(t) \equiv u(t) + \epsilon$  so that  $\dot{y}(t_0^+) = \dot{u}(t_0^+)$ . Hence

$$\begin{aligned} F(t_0^+) &= k_1 (r(t_0^+) - u(t_0^+)) + c_1 (\dot{r}(t_0^+) - \dot{u}(t_0^+)) \\ &= k_1 (r(t_0^-) - u(t_0^-)) + c_1 (\dot{r}(t_0^-) - \dot{u}(t_0^-)) + c_1 (\dot{u}(t_0^-) - \dot{u}(t_0^+)) \\ &= c_1 (\dot{u}(t_0^-) - \dot{y}(t_0^-)) < 0. \quad \square \end{aligned}$$

**3.6.2. Convergence to solutions of section 3.4.1.** The networks in Figures 10 and 13 are similar and differ only by the spring  $k_1$  and damper  $c_1$ . In this section we investigate the convergence behavior of the network of Figure 13 when  $c_1 = a\sqrt{k_1}$  and  $k_1 \rightarrow \infty$ . This choice of  $c_1$  renders imaginary all (four) nonzero roots of the characteristic equation corresponding to state L1 in the interval  $a \in [0, 1)$ . We will focus on the transition from disengagement to engagement where impulsive forces were needed for the network in Figure 10. We will show that the “dwell time” in the engagement state tends to zero as  $k_1 \rightarrow \infty$ . Furthermore, the force through the play element in the engagement state approaches an impulse in the limit as  $k_1 \rightarrow \infty$ . Finally, the strength of the impulse is uniquely determined and covers a range of impulse

strengths  $P$  as a function of  $a$  as determined in Remark 2. For simplicity we carry out the analysis with numerical values for the parameters  $m_1$ ,  $m_2$ ,  $b$ , and  $k$ .

Consider first the solution in case L1. The determinant of  $sI - A_{L1}$  is given by

$$s^2 \left( s^4 + c_1 \frac{m_1 m_2 + b(m_1 + m_2)}{m_1 m_2 b} s^3 + \frac{m_1 m_2 k_1 + b(m_1 + m_2)(k + k_1)}{m_1 m_2 b} s^2 + k \frac{m_1 + m_2}{m_1 m_2 b} (c_1 s + k_1) \right).$$

Two roots are at the origin, and with  $m_1 = m_2 = 1$  kg,  $b = 1/2$  kg, and  $k = 1$  Nm<sup>-1</sup> the roots of the quartic are

$$\begin{aligned} s_{1,2} &= \pm j + O\left(k_1^{-1/2}\right), \\ s_{3,4} &= -2a\sqrt{k_1} \pm j2\sqrt{k_1}\sqrt{1-a^2} + O\left(k_1^{-1/2}\right). \end{aligned}$$

From (3.27a) and (3.27b) we see that  $m_2 \ddot{y} + m_1 \ddot{z} = 0$ . Without loss of generality we can restrict our attention to trajectories for which  $m_2 y + m_1 z \equiv 0$ . We therefore consider a transition from L3 to L1 with the initial condition for the dynamic equations in state L1 as in (3.23). We then solve the state-space equations for L1 to find the dominant term in the force through the inerter given by

$$b(\ddot{z} - \ddot{r})_{\text{Dom}} = -b \left( \frac{1-2a^2}{\sqrt{1-a^2}} \sin(\omega_2 t) + 2a \cos(\omega_2 t) \right) \sqrt{k_1} K \exp\left(-2a\sqrt{k_1} t\right),$$

where  $\omega_2 = 2\sqrt{k_1}\sqrt{1-a^2}$  (subscript Dom means dominant term). In order that  $F \leq 0$  in state L1, it is necessary that  $K > 0$ . We calculate that this dominant term is negative for  $0 < t < t_1$ . Time  $t_1$  marks the first zero crossing of  $(1-2a^2)/\sqrt{1-a^2} \sin(\omega_2 t_1) + 2a \cos(\omega_2 t_1) = 0$ . This suggests that the system remains in state L1 until time  $t_1$  (approximately) at which there is a transition to L3. Qualitatively, this behavior is approaching one where there is an impulsive force at engagement with an immediate transition back to state L3. This is similar to behavior that was identified in section 3.4.1. We can further calculate the expected strength of the impulse as follows:

$$\begin{aligned} (3.30) \quad P(a) &:= \int_0^{t_1} b(\ddot{z} - \ddot{r})_{\text{Dom}} dt \\ &= -\frac{bK}{2} e^{-2a\sqrt{k_1} t} \left[ 2a \left( \sqrt{1-a^2} \sin(\omega_2 t) - a \cos(\omega_2 t) \right) \right. \\ &\quad \left. - \frac{1-2a^2}{\sqrt{1-a^2}} \left( \sqrt{1-a^2} \cos(\omega_2 t) + a \sin(\omega_2 t) \right) \right] \Big|_0^{t_1}. \end{aligned}$$

The function is strictly monotonic with  $P(0) = -K/2$  and  $\lim_{a \rightarrow 1} P(a) = -(1 + e^{-2})K/4$ .

In summary, we have determined a range of unique solutions for network Figure 13, depending on the amount of damping  $c_1$ , which approximate an impulse in the limit as  $k_1 \rightarrow \infty$ . The buffer network provides impulse strengths in the range  $2P_0 < P < (1 + e^{-2})P_0$  for the chosen numerical values. This captures some, but not all, dissipative solutions illustrated in Figure 11. In particular, the coalescing case where  $P = P_0$  is not captured.

FIG. 14. *Semi-ideal play model.*FIG. 15. *Surface compliance models. (a) Standard linear solid model. (b) Maxwell fluid.*

**4. Semi-ideal play.** We define a semi-ideal play model as having an ideal play element in series with a parallel spring-damper network (Figure 14). The parallel spring-damper buffer was used in section 3.6 for the study of well-posedness, and it is also related to the Kelvin–Voigt model of solids [6, p. 7] to account for the elasticity and friction of bodies in contact. We mention that other buffer networks have also been proposed, e.g., the standard linear and the Maxwell models [8, p. 24], [10, p. 184] shown in Figure 15.

Consider the displacement across the semi-ideal play element to be  $z_d = z_1 - z_3$ , the displacement of the parallel spring-damper buffer network to be  $z_n = z_1 - z_2$ , and the displacement of the ideal play element to be  $z_p = z_2 - z_3$ , with corresponding velocities. Then we can write the following equation for the force:

$$(4.1) \quad F(t) = k_1 (z_d(t) - z_p(t)) + c_1 (\dot{z}_d(t) - \dot{z}_p(t)).$$

Three disjoint cases follow from the description of the ideal play element introduced in section 3.1:

$$(4.2a) \quad (\text{engagement-extension}): F \leq 0, \quad z_p(t) = -\epsilon,$$

$$(4.2b) \quad (\text{disengagement}): |z_p(t)| < \epsilon, \quad F = 0,$$

$$(4.2c) \quad (\text{engagement-compression}): F \geq 0, \quad z_p(t) = \epsilon.$$

**4.1. Connections to an approach of Nordin, Galic, and Gutman.** In [13, sec. 2.1], [14, sec. 2.2] a rotational backlash model is proposed consisting of a compliant shaft in series with a clearance gap. In translational form this can be represented by a network of the type shown in Figure 14, namely, a parallel spring-damper in series with some play element. The corresponding mathematical model given in [13] is as follows:

$$(4.3) \quad \dot{z}_p = \begin{cases} (a) & \max(0, \dot{z}_d + (k_1/c_1)(z_d - z_p)) & \text{if } z_p = -\epsilon, \\ (b) & \dot{z}_d + (k_1/c_1)(z_d - z_p) & \text{if } |z_p| < \epsilon, \\ (c) & \min(0, \dot{z}_d + (k_1/c_1)(z_d - z_p)) & \text{if } z_p = \epsilon \end{cases}$$

with output

$$(4.4) \quad F = \begin{cases} 0 & \text{if } |z_p| < \epsilon, \\ k_1 (z_d - z_p) + c_1 \dot{z}_d & \text{if } |z_p| = \epsilon. \end{cases}$$

FIG. 16. Semi-ideal play model implementation using Simulink.

At first sight it is not clear what definition of play is being used; however, we will now show that it is practically identical with our behavioral definition.

**PROPOSITION 4.1.** *Let  $(t_1, t_2)$  be an open interval in which (4.1) and (4.2a) hold; then (4.3a) and (4.4) hold over the same interval. The converse statement also holds. The corresponding equivalences for (b) and (c) also hold.*

*Proof.* (4.1), (4.2a)  $\Rightarrow$  (4.3a), (4.4). Since  $z_p(t) = -\epsilon$  on  $(t_1, t_2)$ ,  $\dot{z}_p(t) = 0$  on  $(t_1, t_2)$ . Hence, from (4.1),  $F = k_1(z_d(t) - z_p(t)) + c_1\dot{z}_d(t)$ , which gives (4.4), and we can also write  $\dot{z}_p(t) = \max(0, \dot{z}_d(t) + (k_1/c_1)(z_d(t) - z_p(t)))$  since  $F \leq 0$ , which shows (4.3a).

(4.3a), (4.4)  $\Rightarrow$  (4.1), (4.2a). Since  $z_p(t) = -\epsilon$  on  $(t_1, t_2)$ ,  $\dot{z}_p(t) = 0$  on  $(t_1, t_2)$ . Hence, from (4.3a),  $\dot{z}_d(t) + (k_1/c_1)(z_d(t) - z_p(t)) \leq 0$  on  $(t_1, t_2)$ , and hence (4.1) and (4.2a) hold on  $(t_1, t_2)$ .

(4.1), (4.2b)  $\Leftrightarrow$  (4.3b), (4.4). These are trivially identical.

(4.1), (4.2c)  $\Leftrightarrow$  (4.3c), (4.4). This is similar to (4.1), (4.2a)  $\Leftrightarrow$  (4.3a), (4.4).  $\square$

**Remark 4.** For network interconnections where switching between engagement and disengagement happens at isolated times, the solutions of (4.1)–(4.2) and (4.3)–(4.4) coincide almost everywhere. For solutions in which displacements are continuous, displacements must agree at all times, with the possibility that velocities disagree at isolated times.

**Remark 5.** The definition of semi-ideal play as an input-output model suggests the possibility of using results from feedback systems to establish well-posedness of networks with play, as in Proposition 2.1. We point out that this may be more difficult than with the play operator since the model may give discontinuous outputs for continuous inputs.

**4.2. A network implementation of semi-ideal play.** This section presents a numerical implementation of the play model (4.3)–(4.4) which appears to work well in both ordinary and pathological cases. To determine the state of operation it is necessary to observe the relative displacement across the ideal play element  $z_p(t)$ , which can be calculated by integration of the relative velocity  $\dot{z}_p = \dot{z}_d - \dot{z}_n$ . Integration followed by saturation introduces integrator wind-up. To avoid such complications, we consider a saturating integrator,

$$z_p(t) = \int_0^t \zeta \dot{z}_p(t) dt \quad \text{with} \quad \zeta = \begin{cases} 0 & \text{if } |z_p(t)| = \epsilon, \\ 1 & \text{if } |z_p(t)| < \epsilon, \end{cases}$$

which is readily available in MATLAB Simulink. The complete model is shown in Figure 16 with input  $\dot{z}_d$ , output  $F$ , and  $u = (k_1/c_1)z_d + \dot{z}_d$ .

The saturating integrator produces a saturation signal, which outputs one of the three states  $(-1, 0, 1)$  corresponding to  $(z_p(t) = -\epsilon, -\epsilon < z_p(t) < \epsilon, z_p(t) = \epsilon)$ . This signal would suffice to switch the force output correctly in a continuous time system.

However, the sample time in a digital implementation delays the signal  $z_p(t)$ , the output of the integrator, by a time step to the corresponding force signal  $F$ . Thus,  $F$  can change sign during a transition. This single step instant violates the model description in (4.3)–(4.4). It is recommended to reduce the integrator sample time to much below the time frame of any principle dynamics to reduce this effect.

Figure 17 shows numerical simulations obtained with the implementation of Figure

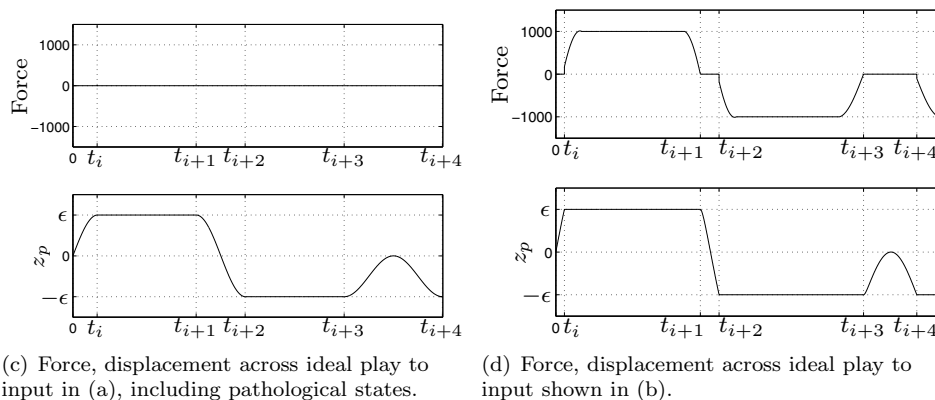

FIG. 17. Input and output signals to network in Figure 16. Figures (a) and (c), and (b) and (d), are signal pairs under the same conditions. The parameters used are  $\epsilon = 0.1$ ,  $k = 10 \text{ kNm}^{-1}$ ,  $c = 1 \text{ kNsm}^{-1}$ .

16. Figures 17(a), (c) consider a very special situation in which  $\dot{z}_d$  is chosen so that engagement and disengagement “only just” occur with the force remaining at zero throughout. Figures 17(b), (d), (e) show ordinary situations of engagement and disengagement in which the force is continuous at disengagement, but not at engagement.

**5. Conclusions.** This paper has shown that the treatment of play as an input-output operator in mechanical networks leads to unsatisfactory solutions from a physical point of view (see section 2.2 for a summary). In contrast, a behavioral definition of play does not suffer from these objections and appears more reasonable from a physical point of view. Well-posedness has been analyzed for several simple networks by considering in detail the transitions between engagement and disengagement states. Networks incorporating inerters were also considered, and it was shown that impulsive forces may sometimes be generated. In such cases multiple solutions may exist with different amounts of instantaneous energy loss. It was shown that the incorporation of a buffer network (either a spring or a parallel spring-damper) recovers well-posedness, and in the limit as the stiffness of the buffer tends to infinity, a range of impulse strengths is obtained. It was seen that the use of such buffer networks is related to the modeling of impact in contact mechanics. Finally, connections with the work of Nordin, Galic, and Gutman were studied. It was pointed out that their input-output model was essentially identical with the ideal play (behavioral definition) in series with a parallel spring-damper. A MATLAB Simulink implementation of the model was presented.

## OPTIMAL CONSUMPTION IN A GROWTH MODEL WITH THE COBB–DOUGLAS PRODUCTION FUNCTION\*

HIROAKI MORIMOTO<sup>†</sup> AND XUN YU ZHOU<sup>‡</sup>

**Abstract.** An optimal consumption problem is studied in a growth model for the Cobb–Douglas production function in a finite horizon. The problem is transferred into a stochastic Ramsey problem so as to reduce the dimension of the state space. The corresponding state equation is a stochastic differential equation with inherently non-Lipschitz coefficients, whose unique solvability is established. The unique existence of the classical solution of the Hamilton–Jacobi–Bellman equation associated with the original problem is proved, and a synthesis of the optimal consumption policy is presented in the feedback form.

**Key words.** economic growth, Cobb–Douglas production function, Ramsey problem, Hamilton–Jacobi–Bellman equation, viscosity solutions

**1. Introduction.** We deal with the economic growth model originated by Merton [7] for the Cobb–Douglas production function in the finite horizon. We define the following quantities:

$T$  = finite horizon;  
 $y_t$  = labor supply at time  $t \in [0, T]$ ;  
 $z_t$  = capital stock at time  $t \in [0, T]$ ;  
 $\nu$  = the constant rate of depreciation,  $\nu \geq 0$ ;  
 $c_t z_t$  = consumption rate at time  $t \in [0, T]$ ,  $0 \leq c(t) \leq 1$ ;  
 $c_t z_t / y_t$  = the totality of consumption rate per person;  
 $F(z, y)$  = the Cobb–Douglas production function  $z^\alpha y^{1-\alpha}$ ,  $0 < \alpha < 1$ , producing the commodity for the capital stock  $z > 0$  and the labor force  $y > 0$ ;  
 $n, \sigma$  = nonzero constant coefficients;  
 $U(c)$  = the utility function for the consumption rate  $c \geq 0$ .

We assume that the labor supply  $y_t$  and the capital stock  $z_t$  are governed by the stochastic differential equation (SDE)

$$(1.1) \quad dy_t = ny_t dt + \sigma y_t dB_t, \quad y_0 = y > 0,$$

$$(1.2) \quad \dot{z}_t = F(z_t, y_t) - \nu z_t - c_t z_t, \quad 0 < t \leq T, \quad z_0 = z > 0,$$

on a complete probability space  $(\Omega, \mathcal{F}, P)$  carrying a standard Brownian motion  $\{B_t\}$ . Let  $c = \{c_t\}$  be a consumption policy per capita such that

$$(1.3) \quad c_t \text{ is progressively measurable with respect to the filtration } \mathcal{F}_t = \sigma(B_s, s \leq t), \\ 0 \leq c_t \leq 1, \quad 0 \leq t \leq T,$$

and we denote by  $\mathcal{A}$  the class of all consumption policies  $\{c_t\}$  per capita.

The purpose of this paper is to present a synthesis of optimal consumption policy  $c^*$  so as to maximize the expected utilities

$$(1.4) \quad J(c) = E \left[ \int_0^T U(c_t z_t / y_t) dt \right]$$

per person with finite horizon  $T$  over the class  $\mathcal{A}$ . The Hamilton–Jacobi–Bellman (HJB) equation associated with this problem is given by

$$(1.5) \quad V_t + \frac{1}{2} \sigma^2 y^2 V_{yy} + n y V_y + \{F(z, y) - \nu z\} V_z + \max_{0 \leq c \leq 1} \{U(c z / y) - c z V_z\} = 0, \quad 0 \leq t < T, \\ V(T, z, y) = 0, \quad z > 0, \quad y > 0,$$

where the subscripts denote the partial derivatives, and the utility function  $U(c)$  is assumed to have the following properties:

$$(1.6) \quad U \in C[0, \infty) \cap C^2(0, \infty), \quad U''(c) < 0 \text{ for } c > 0, \\ U'(\infty) = U(0+) = 0, \quad U'(0+) = U(\infty) = \infty.$$

The last two conditions constitute what is known as the Inada condition. Its economic interpretation is that, while the utility is very small (respectively, very large) for a very small (respectively, very large) consumption rate, the marginal utility diminishes as the consumption rate becomes extremely large.

Under (1.6), by the uniform continuity of  $U$  near 0, we have that

$$(1.7) \quad \forall \varepsilon > 0, \exists C_\varepsilon > 0 : |U(c) - U(\bar{c})| \leq C_\varepsilon |c - \bar{c}| + \varepsilon \quad \text{for } c, \bar{c} > 0.$$

The technical difficulty in solving the problem lies in the fact that the HJB equation (1.5) is a parabolic PDE with two spatial variables  $y$  and  $z$ . The main approach to be employed is to reduce the dimension by turning the problem into a so-called Ramsey problem [7]. Through an analysis of the Ramsey problem, together with the viscosity solution technique, we are able to show that (1.5) admits a smooth solution  $V$ , and the optimal consumption policy  $c^*$  can be represented in a feedback form. A major technical hurdle to overcome is to prove the existence and uniqueness of solutions to the state equation of the Ramsey problem, whose drift coefficient is inherently non-Lipschitz. Moreover, we need to estimate the Hölder order of the solution in time. It should be noted that the stochastic Ramsey problem is analytically studied in [5], but in the *infinite* time horizon. The resulting HJB equation is an elliptic PDE, which is very different from the parabolic PDE dealt with in the present paper. We also refer to [6] for the growth model with the constant-returns-to-scale production function replacing  $F(z, y)$  of (1.2).

This paper is organized as follows. In sections 2 and 3, we reduce (1.5) to the two-dimensional HJB equation associated with the stochastic Ramsey problem, and we show the existence of viscosity solutions of the HJB equation. Sections 4 and 5, respectively, are devoted to the  $C^2$ -regularity and the concavity of the viscosity solution. In section 6, we give a synthesis of the optimal consumption policy.

**2. The stochastic Ramsey problem.** We consider the HJB equation (1.5) and seek the solution  $V(t, z, y)$  of (1.5) of the form

$$(2.1) \quad V(t, z, y) = v(t, x), \quad x = z/y.$$

Clearly,

$$(2.2) \quad yV_y = -xv_x, \quad yV_z = v_x, \quad y^2V_{yy} = x^2v_{xx} + 2xv_x.$$

Then, by (1.5),  $v(t, x)$  solves the HJB equation

$$(2.3) \quad \begin{aligned} v_t(t, x) + \frac{1}{2}\sigma^2 x^2 v_{xx}(t, x) + (x^\alpha - \mu x)v_x(t, x) + \tilde{U}(x, v_x(t, x)) &= 0, \quad 0 \leq t < T, \\ v(T, x) &= 0, \quad x > 0, \end{aligned}$$

where  $\mu = n + \nu - \sigma^2$  and

$$(2.4) \quad \tilde{U}(x, p) = \max_{0 \leq c \leq 1} \{U(cx) - cpx\}, \quad p \in \mathbf{R}.$$

We observe that (2.3) is the HJB equation associated with the stochastic Ramsey problem so as to maximize

$$(2.5) \quad \bar{J}(c) = E \left[ \int_0^T U(c_t R_t) dt \right]$$

over the class  $\mathcal{A}$ , subject to

$$(2.6) \quad \begin{aligned} dR_t &= (R_t^\alpha - \mu R_t - c_t R_t)dt - \sigma R_t dB_t, \quad 0 < t \leq T, \\ R_0 &= x > 0. \end{aligned}$$

The above SDE does not satisfy the Lipschitz condition, as normally required for existence and uniqueness. Moreover, we need to estimate the dependence, if any, of the solution on the time and the initial state. We solve these problems by an ad hoc technique.

**PROPOSITION 2.1.** *For each  $c \in \mathcal{A}$ , there exists a unique positive solution  $\{R_t\} = \{R_t^x\}$  of (2.6), which satisfies*

$$(2.7) \quad E \left[ \sup_{0 \leq t \leq T} R_t^2 \right] \leq C(1 + x^2),$$

$$(2.8) \quad E[|R_r - R_s|] \leq C(1 + x)|r - s|^{1/2}, \quad 0 \leq s \leq r \leq T,$$

$$(2.9) \quad E[|R_s^x - R_s^y|] \leq C|x - y|^{1-\alpha}(1 + x^\alpha + y^\alpha), \quad x, y > 0, \quad 0 \leq s \leq T,$$

where the constant  $C > 0$  depends only on  $\alpha, T, \mu, \sigma$ .

*Proof.* By Itô's formula,

$$\begin{aligned} dR_t^{1-\alpha} &= (1 - \alpha)R_t^{-\alpha}\{(R_t^\alpha - \mu R_t - c_t R_t)dt - \sigma R_t dB_t\} \\ &\quad + \frac{1}{2}\sigma^2(1 - \alpha)(-\alpha)R_t^{-\alpha-1}R_t^2 dt. \end{aligned}$$

Hence, setting  $x_t = R_t^{1-\alpha}$ , we have

$$\begin{aligned}
 (2.10) \quad dx_t &= (1-\alpha) \left\{ 1 - \left( \mu + c_t + \frac{1}{2} \sigma^2 \alpha \right) x_t \right\} dt - (1-\alpha) \sigma x_t dB_t \\
 &= (1-\alpha) \left\{ 1 - \left( c_t + \frac{1}{2} \sigma^2 \alpha \right) x_t \right\} dt - x_t (1-\alpha) (\mu dt + \sigma dB_t), \quad x_0 = x^{1-\alpha}.
 \end{aligned}$$

By linearity, (2.11) admits a unique solution  $\{x_t\}$ . Also, we apply the comparison theorem to (2.11) and

$$d\bar{x}_t = (1-\alpha) \left\{ - \left( \mu + c_t + \frac{1}{2} \sigma^2 \alpha \right) \bar{x}_t \right\} dt - (1-\alpha) \sigma \bar{x}_t dB_t, \quad \bar{x}_0 = x_0.$$

Then

$$\begin{aligned}
 (2.11) \quad x_t &\geq \bar{x}_t \\
 &= x_0 \exp \left\{ (1-\alpha) \left( -\mu t - \int_0^t c_s ds - \frac{1}{2} \sigma^2 \alpha t \right) \right. \\
 &\quad \left. - (1-\alpha) \sigma B_t - \frac{1}{2} (1-\alpha)^2 \sigma^2 t \right\} > 0.
 \end{aligned}$$

Thus, we obtain a positive solution  $\{R_t\}$  of (2.6). Let  $\{\hat{x}_t\}$  be the solution of

$$d\hat{x}_t = -\hat{x}_t (1-\alpha) (\mu dt + \sigma dB_t), \quad \hat{x}_0 = x_0.$$

Setting  $H_t = x_t / \hat{x}_t$  and  $\bar{\alpha} = \sigma^2 (1-\alpha) \alpha / 2$ , we have

$$\begin{aligned}
 dH_t &= (1-\alpha) \left\{ \frac{1}{\hat{x}_t} - \left( c_t + \frac{1}{2} \sigma^2 \alpha \right) H_t \right\} dt \\
 &\leq \left( \frac{1-\alpha}{\hat{x}_t} - \bar{\alpha} H_t \right) dt, \quad H_0 = 1.
 \end{aligned}$$

Therefore

$$(2.12) \quad x_t \leq \hat{x}_t e^{-\bar{\alpha} t} \left\{ 1 + (1-\alpha) \int_0^t \frac{e^{\bar{\alpha} s}}{\hat{x}_s} ds \right\},$$

which yields (2.7).

Now, let  $\beta = 1/(1-\alpha) > 1$  and  $M_t = \exp\{-(1-\alpha)\sigma B_t - (1/2)(1-\alpha)^2\sigma^2 t\}$ . By (2.12) and Doob's maximal inequality, we have

$$\begin{aligned}
 (2.13) \quad E \left[ \sup_{0 \leq t \leq T} x_t^\beta \right] &\leq C \left( 1 + x_0^\beta E \left[ \sup_{0 \leq t \leq T} M_t^\beta \right] \right) \\
 &\leq C \left( 1 + x_0^\beta \left( \frac{\beta}{\beta-1} \right)^\beta E[M_T^\beta] \right) \\
 &\leq C'(1+x),
 \end{aligned}$$

where the constant  $C' > 0$  depends only on  $\alpha, T, \mu, \sigma$ . Hence, by (2.11), (2.13), and the moment inequality for martingales, we get

$$\begin{aligned} E[|x_r - x_s|^\beta] &\leq 2^\beta \left( E \left[ \left| \int_s^r (1 - \alpha) \left\{ 1 - \left( \mu + c_t + \frac{1}{2} \sigma^2 \alpha \right) x_t \right\} dt \right|^\beta \right] \right. \\ &\quad \left. + E \left[ \left| \int_s^r (1 - \alpha) \sigma x_t dB_t \right|^\beta \right] \right) \\ &\leq C \left( E \left[ \left( \int_s^r (1 + x_t^2) dt \right)^{\beta/2} \right] |r - s|^{\beta/2} + E \left[ \left( \int_s^r x_t^2 dt \right)^{\beta/2} \right] \right) \\ &\leq C'(1 + x) |r - s|^{\beta/2}, \quad 0 \leq s \leq r \leq T. \end{aligned}$$

Since

$$|x^\beta - y^\beta| = \left| \int_y^x \beta t^{\beta-1} dt \right| \leq \beta |x - y| (|x|^{\beta-1} + |y|^{\beta-1}), \quad x, y \geq 0,$$

we observe by Hölder's inequality that

$$\begin{aligned} E[|R_r - R_s|] &= E[|x_r^\beta - x_s^\beta|] \\ &\leq \beta (E[|x_r - x_s|^\beta])^{1/\beta} (E[(|x_r|^{\beta-1} + |x_s|^{\beta-1})^{\beta/(\beta-1)}])^{1-1/\beta} \\ &\leq \beta (C'(1 + x) |r - s|^{\beta/2})^{1/\beta} \left( E \left[ 2^{\beta/(\beta-1)} \sup_{0 \leq t \leq T} |x_t|^\beta \right] \right)^{1-1/\beta} \\ &\leq C(1 + x) |r - s|^{1/2}, \end{aligned}$$

which implies (2.8).

Next, we set  $r_t = (R_t^y)^{1-\alpha}$ . Then, by (2.11),

$$d(x_t - r_t) = (1 - \alpha) \left( -\mu - c_t - \frac{1}{2} \sigma^2 \alpha \right) (x_t - r_t) dt - (1 - \alpha) \sigma (x_t - r_t) dB_t,$$

or equivalently,

$$\begin{aligned} x_s - r_s &= (x_0 - r_0) \exp \left\{ (1 - \alpha) \left( -\mu t - \int_0^s c_t dt - \frac{1}{2} \sigma^2 \alpha s \right) \right. \\ &\quad \left. - (1 - \alpha) \sigma B_s - \frac{1}{2} (1 - \alpha)^2 \sigma^2 s \right\}. \end{aligned}$$

Hence

$$E[|x_s - r_s|^\beta] \leq C |x_0 - r_0|^\beta.$$

By Hölder's inequality, we deduce

$$\begin{aligned} E[|R_s^x - R_s^y|] &= E[|x_s^\beta - r_s^\beta|] \\ &\leq \beta (E[|x_s - r_s|^\beta])^{1/\beta} (E[(|x_s|^{\beta-1} + |r_s|^{\beta-1})^{\beta/(\beta-1)}])^{1-1/\beta} \\ &\leq C |x_0 - r_0| (1 + x^\alpha + y^\alpha), \end{aligned}$$

which implies (2.9).

**3. Viscosity solutions.** We study the viscosity solution  $v$  of the HJB equation (2.3), i.e.,

$$(3.1) \quad v_t + \frac{1}{2}\sigma^2 x^2 v_{xx} + (x^\alpha - \mu x)v_x + \tilde{U}(x, v_x) = 0 \quad \text{in } Q := [0, T] \times (0, \infty),$$

$$(3.2) \quad v(T, x) = 0, \quad x > 0.$$

DEFINITION 3.1. *Let  $v \in C([0, T] \times (0, \infty))$  satisfy (3.2). Then  $v$  is called a viscosity solution of (3.1) if the following assertions are satisfied:*

$$a + \frac{1}{2}\sigma^2 x^2 X + (x^\alpha - \mu x)\lambda + \tilde{U}(x, \lambda) \geq 0 \quad \forall (a, \lambda, X) \in \mathcal{P}^{2,+}v(s, x), \quad \forall (s, x) \in Q,$$

$$a + \frac{1}{2}\sigma^2 x^2 X + (x^\alpha - \mu x)\lambda + \tilde{U}(x, \lambda) \leq 0 \quad \forall (a, \lambda, X) \in \mathcal{P}^{2,-}v(s, x), \quad \forall (s, x) \in Q,$$

where  $\mathcal{P}^{2,+}$  and  $\mathcal{P}^{2,-}$  are the second parabolic superdifferentials and subdifferentials [1] defined by

$$\begin{aligned} \mathcal{P}^{2,+}v(s, x) &= \left\{ (a, \lambda, X) \in \mathbf{R}^3 : \right. \\ &\quad \left. \limsup_{(t,y) \in Q \rightarrow (s,x)} \frac{v(t, y) - v(s, x) - a(t-s) - \lambda(y-x) - \frac{1}{2}X(y-x)^2}{|t-s| + |y-x|^2} \leq 0 \right\}, \\ \mathcal{P}^{2,-}v(s, x) &= \left\{ (a, \lambda, X) \in \mathbf{R}^3 : \right. \\ &\quad \left. \liminf_{(t,y) \in Q \rightarrow (s,x)} \frac{v(t, y) - v(s, x) - a(t-s) - \lambda(y-x) - \frac{1}{2}X(y-x)^2}{|t-s| + |y-x|^2} \geq 0 \right\}. \end{aligned}$$

Define

$$(3.3) \quad v(s, x) = \sup_{c \in \mathcal{A}} E \left[ \int_s^T U(c_t X_t) dt \right],$$

where  $\{X_t\}$  is the solution of (2.6) for  $t \in (s, T]$  with  $X_s = x$ , that is,

$$(3.4) \quad dX_t = (X_t^\alpha - \mu X_t - c_t X_t)dt - \sigma X_t dB_t, \quad s < t \leq T, \quad X_s = x > 0,$$

and the supremum is taken over all systems  $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; \{B_t\}, \{c_t\})$ . We choose  $b_1 > 0$  such that  $x^\alpha - \mu x \leq b_1$ . Taking sufficiently large  $b_0 > b_1$ , we observe that  $\zeta(t, x) := e^{T-t}(x + b_0)$  fulfills

$$\begin{aligned} \zeta_t + \frac{1}{2}\sigma^2 x^2 \zeta_{xx} + (x^\alpha - \mu x)\zeta_x + \tilde{U}(x, \zeta_x) &\leq e^{T-t}\{-b_0 + (x^\alpha - \mu x)\} + \tilde{U}(x, e^{T-t}) \\ (3.5) \quad &\leq e^{T-t}(-b_0 + b_1) + U \circ (U')^{-1}(e^{T-t}) \\ &\leq -b_0 + b_1 + U \circ (U')^{-1}(1) < 0, \quad (t, x) \in [0, T] \times (0, \infty). \end{aligned}$$

LEMMA 3.2. *We assume (1.6). Then the following assertions are valid:*

$$(3.6) \quad 0 \leq v(s, x) \leq \zeta(s, x).$$

For any  $\varepsilon > 0$ , there exists  $C_\varepsilon > 0$  such that

$$(3.7) \quad \begin{aligned} |v(s, x) - v(r, y)| &\leq C_\varepsilon \{|s - r|^{1/2}(1 + x + y) + |x - y|\} + \varepsilon(1 + x + y), \\ x, y > 0, \quad 0 \leq r \leq s \leq T. \end{aligned}$$

*Proof.* By Itô's formula and (3.5), we have

$$(3.8) \quad \begin{aligned} 0 &\leq \zeta(T, X_T) \\ &= \zeta(s, x) + \int_s^T \left\{ \zeta_t(t, X_t) + [(X_t)^\alpha - \mu X_t - c_t X_t] \zeta_x(t, X_t) \right. \\ &\quad \left. + \frac{1}{2} \sigma^2 X_t^2 \zeta_{xx}(t, X_t) \right\} dt - \int_s^T \sigma X_t \zeta_x(t, X_t) dB_t \\ &\leq \zeta(s, x) - \int_s^T U(c_t X_t) dt - \int_s^T \sigma X_t e^{T-t} dB_t \quad a.s. \end{aligned}$$

By (2.7), we note that  $\{\int_s^t \sigma X_r e^{-r} dB_r\}$  is a martingale. Therefore, we deduce (3.6). Now, by (3.3), we have

$$(3.9) \quad \begin{aligned} |v(s, x) - v(r, y)| &\leq \sup_{c \in \mathcal{A}} E \left[ \left| \int_s^T U(c_t X_t) dt - \int_r^T U(c_t Y_t) dt \right| \right] \\ &\leq \sup_{c \in \mathcal{A}} E \left[ \int_s^T |U(c_t X_t) - U(c_t Y_t)| dt \right] + \sup_{c \in \mathcal{A}} E \left[ \int_r^s U(c_t Y_t) dt \right] \\ &\equiv J_1 + J_2, \end{aligned}$$

where  $\{Y_t\}$  denotes the solution of (3.4) with  $Y_r = y$ . By (2.9) and Young's inequality, choosing a suitable constant  $\delta > 0$  for any  $\varepsilon' > 0$ , we note that

$$\begin{aligned} E[|X_t - Y_t|] &\leq C \left\{ \frac{1 - \alpha}{\delta} (|x - y|^{1-\alpha})^{1/(1-\alpha)} + \alpha \delta (1 + x^\alpha + y^\alpha)^{1/\alpha} \right\} \\ &= C_{\varepsilon'} |x - y| + \varepsilon' (1 + x + y). \end{aligned}$$

Also, by (2.7),

$$E[X_t] \leq C(1 + x).$$

Hence, by (1.7),

$$\begin{aligned} J_1 &\leq \sup_{c \in \mathcal{A}} E \left[ \int_0^T \{C_\varepsilon |X_t - Y_t| + \varepsilon\} dt \right] \\ &\leq C_\varepsilon T \{C_{\varepsilon'} |x - y| + \varepsilon' (1 + x + y)\} + \varepsilon T. \end{aligned}$$

By the same calculation as (3.8), taking into account (2.7) and (2.8), we get

$$\begin{aligned} J_2 &\leq E[\zeta(r, Y_r) - \zeta(s, Y_s)] \\ &\leq E[|\zeta(r, Y_r) - \zeta(r, Y_s)|] + E[|\zeta(r, Y_s) - \zeta(s, Y_s)|] \\ &\leq e^T \{E[|Y_s - Y_r|] + E[|s - r| |Y_s + b_0|]\} \\ &\leq C |s - r|^{1/2} (1 + y). \end{aligned}$$

Therefore, we deduce (3.7).

**THEOREM 3.3.** *We assume (1.6). Then the value function  $v$  of (3.3) is a viscosity solution of (3.1).*

*Proof.* By Lemma 3.2, we see that  $v \in C([0, T] \times (0, \infty))$ , and by (3.3),  $v(T, x) = 0$ . According to [2], the viscosity property of  $v$  follows from the dynamic programming principle for  $v$ ; that is,

$$(3.10) \quad v(s, x) = \sup_{c \in \mathcal{A}} E \left[ \int_s^\tau U(c_t X_t) dt + v(\tau, X_\tau) \right] \quad \forall (s, x) \in [0, T] \times (0, \infty)$$

for any  $\tau \in [s, T]$ , where the supremum is taken over all systems  $(\Omega, \mathcal{F}, P, \{\mathcal{F}_t\}; \{B_t\}, \{c_t\})$ .

Let  $\bar{v}$  be the right-hand side of (3.10) and set  $J_{(s,x)}(c) = E[\int_s^T U(c_t X_t) dt]$ . For each  $c = \{c_t\} \in \mathcal{A}$ , let  $\tilde{X}_t = X_{t+\tau}$  and  $\tilde{B}_t = B_{t+\tau} - B_\tau$ . Then we have

$$d\tilde{X}_t = (\tilde{X}_t^\alpha - \mu \tilde{X}_t - \tilde{c}_t \tilde{X}_t) dt - \sigma \tilde{X}_t d\tilde{B}_t, \quad t \in (0, T - \tau], \quad \tilde{X}_0 = X_\tau,$$

where  $\tilde{c} = \{\tilde{c}_t\}$  is the shifted process of  $c$  by  $\tau$ , i.e.,  $\tilde{c}_t = c_{t+\tau}$ . By (3.4), we see that

$$E \left[ \int_\tau^T U(c_t X_t) dt | \mathcal{F}_\tau \right] = E \left[ \int_0^{T-\tau} U(\tilde{c}_t \tilde{X}_t) dt | \mathcal{F}_\tau \right] = J_{(\tau, X_\tau)}(c) \quad \text{a.s.}$$

with respect to the conditional probability measure  $P(\cdot | \mathcal{F}_\tau)$ . Hence

$$\begin{aligned} J_{(s,x)}(c) &= E \left[ \int_s^\tau U(c_t X_t) dt + \int_\tau^T U(c_t X_t) dt \right] \\ &\leq E \left[ \int_s^\tau U(c_t X_t) dt + v(\tau, X_\tau) \right]. \end{aligned}$$

Taking the supremum, we deduce  $v \leq \bar{v}$ .

Conversely, let  $\{S_j : j = 1, \dots, n+1\}$  be a sequence of disjoint subsets of  $(0, \infty)$  such that

$$\text{diam}(S_j) < \delta, \quad \bigcup_{j=1}^n S_j = (0, R), \quad \text{and} \quad S_{n+1} = [R, \infty)$$

for  $\delta, R > 0$  chosen later. For any  $\varepsilon > 0$ , we take  $x_j \in S_j$  and  $c^{(j)} \in \mathcal{A}$  such that

$$(3.11) \quad v(\tau, x_j) - \varepsilon \leq J_{(\tau, x_j)}(c^{(j)}), \quad j = 1, \dots, n+1.$$

By the same argument as (3.7), we note that

$$|J_{(\tau, x)}(c) - J_{(\tau, y)}(c)| + |v(\tau, x) - v(\tau, y)| \leq C_\varepsilon |x - y| + \frac{\varepsilon}{4}(1 + x + y), \quad x, y > 0, \quad c \in \mathcal{A},$$

for some constant  $C_\varepsilon > 0$ . We choose  $0 < \delta < 1$  such that  $C_\varepsilon \delta < \varepsilon/2$ . Then, we have

$$|J_{(\tau, x)}(c^{(j)}) - J_{(\tau, y)}(c^{(j)})| + |v(\tau, x) - v(\tau, y)| \leq \varepsilon(1 + x), \quad x, y \in S_j,$$

from which

$$J_{(\tau, X_\tau)}(c^{(j)}) \geq J_{(\tau, x_j)}(c^{(j)}) - \varepsilon(1 + X_\tau) \quad \text{if} \quad X_\tau \in S_j, \quad j = 1, \dots, n.$$

Hence

$$\begin{aligned}
 J_{(\tau, X_\tau)}(c^{(j)}) &= J_{(\tau, X_\tau)}(c^{(j)}) - J_{(\tau, x_j)}(c^{(j)}) + J_{(\tau, x_j)}(c^{(j)}) \\
 (3.12) \quad &\geq -\varepsilon(1 + X_\tau) + v(\tau, x_j) - \varepsilon \\
 &\geq -2\varepsilon(1 + X_\tau) + v(\tau, X_\tau) - \varepsilon \quad \text{if } X_\tau \in S_j, \quad j = 1, \dots, n.
 \end{aligned}$$

By definition, we find  $c \in \mathcal{A}$  such that

$$\bar{v}(s, x) - \varepsilon \leq E \left[ \int_s^\tau U(c_t X_t) dt + v(\tau, X_\tau) \right].$$

As in the proof of Theorem IV-1.1 of [3], we can take  $c, c^{(j)}$  on the same probability space. Define

$$c_t^\tau = c_t 1_{\{t < \tau\}} + c_t^{(j)} 1_{\{\tau \leq t \leq T\}} \quad \text{if } X_\tau \in S_j, \quad j = 1, \dots, n+1.$$

It is easy to see that  $\{c_t^\tau\}$  belongs to  $\mathcal{A}$ . Let  $\{X_t^\tau\}$  be the solution of

$$dX_t^\tau = [(X_t^\tau)^\alpha - \mu X_t^\tau - c_t^\tau X_t^\tau] dt - \sigma X_t^\tau dB_t, \quad s < t \leq T, \quad X_s^\tau = x > 0.$$

Clearly,  $X_t^\tau = X_t$  a.s. if  $s \leq t < \tau$ . Further, for each  $j = 1, \dots, n+1$ , we have on  $\{X_\tau \in S_j\}$ ,

$$X_r^\tau = X_\tau + \int_\tau^r [(X_t^\tau)^\alpha - \mu X_t^\tau - c_t^\tau X_t^\tau] dt - \int_\tau^r \sigma X_t^\tau dB_t, \quad \tau < r \leq T \quad \text{a.s.}$$

Hence  $X_t^\tau = X_t^{(j)}$  for all  $t \in [\tau, T]$  a.s. on  $\{X_\tau \in S_j\}$ , where  $\{X_t^{(j)}\}$  denotes the solution of

$$dX_t^{(j)} = [(X_t^{(j)})^\alpha - \mu X_t^{(j)} - c_t^{(j)} X_t^{(j)}] dt - \sigma X_t^{(j)} dB_t, \quad \tau < t \leq T, \quad X_\tau^{(j)} = X_\tau.$$

Thus, we get

$$\begin{aligned}
 J_{(\tau, X_\tau)}(c^\tau) &= E \left[ \int_\tau^T U(c_t^\tau X_t^\tau) dt | \mathcal{F}_\tau \right] \\
 (3.13) \quad &= E \left[ \int_\tau^T U(c_t^{(j)} X_t^{(j)}) dt | \mathcal{F}_\tau \right] \\
 &= J_{(\tau, X_\tau)}(c^{(j)}) \quad \text{a.s. on } \{X_\tau \in S_j\}.
 \end{aligned}$$

Next, taking into account (3.6) and (2.7), we choose  $R > 0$  such that

$$\begin{aligned}
 \sup_{c \in \mathcal{A}} E[v(\tau, X_\tau) 1_{\{X_\tau \geq R\}}] &\leq \sup_{c \in \mathcal{A}} e^T E[(X_\tau + b_0) 1_{\{X_\tau \geq R\}}] \\
 (3.14) \quad &\leq \sup_{c \in \mathcal{A}} \frac{e^T}{R} E[X_\tau^2 + b_0 X_\tau] \\
 &\leq \frac{e^T}{R} \{(1 + b_0)C(1 + x^2) + b_0\} < \varepsilon.
 \end{aligned}$$

By (3.11)–(3.14) and (2.7), we have

$$\begin{aligned}
 E \left[ \int_{\tau}^T U(c_t^{\tau} X_t^{\tau}) dt \right] &= E \left[ E \left[ \int_{\tau}^T U(c_t^{\tau} X_t^{\tau}) dt | \mathcal{F}_{\tau} \right] \right] \\
 &= E[J_{(\tau, X_{\tau})}(c^{\tau})] \\
 &= E \left[ \sum_{j=1}^{n+1} J_{(\tau, X_{\tau})}(c^{(j)}) 1_{\{X_{\tau} \in S_j\}} \right] \\
 &\geq E \left[ \sum_{j=1}^n \{v(\tau, X_{\tau}) - 3\varepsilon(1 + X_{\tau})\} 1_{\{X_{\tau} \in S_j\}} \right] \\
 &\geq E[\{v(\tau, X_{\tau}) - v(\tau, X_{\tau}) 1_{\{X_{\tau} \geq R\}}\}] - 3\varepsilon E[1 + X_{\tau}] \\
 &\geq E[v(\tau, X_{\tau})] - \varepsilon - 3\varepsilon\{2 + C(1 + x^2)\}.
 \end{aligned}$$

Thus

$$\begin{aligned}
 v(s, x) &\geq E \left[ \int_s^{\tau} U(c_t^{\tau} X_t^{\tau}) dt + \int_{\tau}^T U(c_t^{\tau} X_t^{\tau}) dt \right] \\
 &\geq E \left[ \int_s^{\tau} U(c_t X_t) dt + v(\tau, X_{\tau}) \right] - 4\varepsilon\{2 + C(1 + x^2)\} \\
 &\geq \bar{v}(s, x) - \varepsilon - 4\varepsilon\{2 + C(1 + x^2)\}.
 \end{aligned}$$

Therefore, letting  $\varepsilon \rightarrow 0$ , we obtain  $\bar{v} \leq v$ . The proof is complete.

**4. Classical solutions.** In this section, we study the classical solutions of the HJB equation (3.1) with the terminal condition (3.2). First, for any interval  $[\xi_1, \xi_2]$  with  $\xi_1 > 0$ , we consider the parabolic equation

$$(4.1) \quad u_t + \frac{1}{2}\sigma^2 x^2 u_{xx} + (x^{\alpha} - \mu x)u_x + \tilde{U}(x, u_x) = 0, \quad 0 \leq t < T, \quad \xi_1 < x < \xi_2,$$

with the (parabolic) boundary condition

$$(4.2) \quad u(T, x) = v(T, x) = 0, \quad x \in [\xi_1, \xi_2],$$

$$(4.3) \quad u(t, \xi_1) = v(t, \xi_1), \quad u(t, \xi_2) = v(t, \xi_2), \quad t \in [0, T).$$

**THEOREM 4.1.** *Let  $u_i \in C([0, T] \times [\xi_1, \xi_2])$ ,  $i = 1, 2$ , be two viscosity solutions of (4.1)–(4.3). Then, under (1.6), we have  $u_1 = u_2$ .*

*Proof.* It is sufficient to show that  $u_1 \leq u_2$ . Suppose there exists  $(t_0, x_0) \in [0, T) \times (\xi_1, \xi_2)$  such that  $u_1(t_0, x_0) - u_2(t_0, x_0) > 0$ . Then we find  $\eta > 0$  such that

$$\varrho := \sup_{(t, x) \in (0, T) \times (\xi_1, \xi_2)} \left\{ u_1(t, x) - u_2(t, x) - 2\eta \frac{1}{t} \right\} > 0.$$

By boundedness, we have

$$(4.4) \quad u_1(t, x) - u_2(t, x) - 2\eta \frac{1}{t} \rightarrow -\infty \quad \text{uniformly in } x \text{ as } t \downarrow 0.$$

Thus, by (4.2) and (4.3), there exists  $(\bar{t}, \bar{x}) \in (0, T) \times (\xi_1, \xi_2)$  such that

$$\varrho = u_1(\bar{t}, \bar{x}) - u_2(\bar{t}, \bar{x}) - 2\eta \frac{1}{\bar{t}}.$$

Define

$$\Psi_k(t, x, y) = u_1(t, x) - u_2(t, y) - \frac{k}{2}|x - y|^2 - 2\eta \frac{1}{t}$$

for  $k > 0$ . By (4.2) and (4.4), there exists  $(t_k, x_k, y_k) \in (0, T) \times [\xi_1, \xi_2]^2$  such that

$$(4.5) \quad \Psi_k(t_k, x_k, y_k) = \sup \Psi_k(t, x, y) \geq \Psi_k(\bar{t}, \bar{x}, \bar{x}) = \varrho,$$

from which

$$\frac{k}{2}|x_k - y_k|^2 < u_1(t_k, x_k) - u_2(t_k, y_k) - 2\eta \frac{1}{t_k}.$$

Thus

$$(4.6) \quad |x_k - y_k| \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

By the definition of  $(t_k, x_k, y_k)$ , we have

$$\Psi_k(t_k, x_k, y_k) \geq \Psi_k(t_k, x_k, x_k).$$

Hence, by uniform continuity,

$$(4.7) \quad \frac{k}{2}|x_k - y_k|^2 \leq u_2(t_k, x_k) - u_2(t_k, y_k) \rightarrow 0 \quad \text{as } k \rightarrow \infty.$$

By (4.6), (4.5), and (4.3), and by extracting a subsequence, we have

$$t_k \rightarrow \tilde{t} \in (0, T), \quad (x_k, y_k) \rightarrow (\tilde{x}, \tilde{x}) \in (\xi_1, \xi_2)^2 \quad \text{as } k \rightarrow \infty.$$

Now, we may consider that  $(t_k, x_k, y_k) \in (0, T) \times (\xi_1, \xi_2)^2$ . Applying Ishii's lemma [1, Thm. 8.3] to

$$\Psi_k(t, x, y) = w_1(t, x) - w_2(t, y) - \frac{k}{2}|x - y|^2,$$

we obtain  $a, b \in \mathbf{R}$  and  $X, Y \in \mathbf{R}$  such that

$$(4.8) \quad \begin{aligned} (a, k(x_k - y_k), X) &\in \bar{\mathcal{P}}^{2,+} w_1(t_k, x_k), \\ (b, k(x_k - y_k), Y) &\in \bar{\mathcal{P}}^{2,-} w_2(t_k, y_k), \\ a - b = 0, \quad \begin{pmatrix} X & 0 \\ 0 & -Y \end{pmatrix} &\leq 3k \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}, \end{aligned}$$

where  $w_1(t, x) = u_1(t, x) - \eta/t$  and  $w_2(t, y) = u_2(t, y) + \eta/t$ . From the definition of  $\mathcal{P}^{2,+} u_1(t_k, x_k)$ ,  $\mathcal{P}^{2,-} u_2(t_k, y_k)$ , it follows that

$$\mathcal{P}^{2,+}u_1(t, x) = \left\{ (\hat{a}, \lambda, \hat{X}) + \eta \left( \frac{-1}{t^2}, 0, 0 \right) : (\hat{a}, \lambda, \hat{X}) \in \mathcal{P}^{2,+}w_1(t, x) \right\},$$

$$\mathcal{P}^{2,-}u_2(t, x) = \left\{ (\hat{a}, \lambda, \hat{X}) - \eta \left( \frac{-1}{t^2}, 0, 0 \right) : (\hat{a}, \lambda, \hat{X}) \in \mathcal{P}^{2,-}w_2(t, x) \right\}.$$

Hence

$$(\bar{a}, \lambda_1, \bar{X}) := (a, k(x_k - y_k), X) + \eta \left( \frac{-1}{t_k^2}, 0, 0 \right) \in \bar{\mathcal{P}}^{2,+}u_1(t_k, x_k),$$

$$(\bar{b}, \lambda_2, \bar{Y}) := (b, k(x_k - y_k), Y) - \eta \left( \frac{-1}{t_k^2}, 0, 0 \right) \in \bar{\mathcal{P}}^{2,-}u_2(t_k, y_k).$$

By Definition 3.1,

$$\begin{aligned} \bar{a} + \frac{1}{2}\sigma^2 x_k^2 \bar{X} + (x_k^\alpha - \mu x_k)\lambda_1 + \tilde{U}(x_k, \lambda_1) &\geq 0, \\ \bar{b} + \frac{1}{2}\sigma^2 y_k^2 \bar{Y} + (y_k^\alpha - \mu y_k)\lambda_2 + \tilde{U}(y_k, \lambda_2) &\leq 0. \end{aligned}$$

Putting these inequalities together, we get

$$\begin{aligned} 2\eta \frac{1}{t_k^2} &\leq \frac{1}{2}\sigma^2 (x_k^2 \bar{X} - y_k^2 \bar{Y}) + \{(x_k^\alpha - \mu x_k)\lambda_1 - (y_k^\alpha - \mu y_k)\lambda_2\} \\ &\quad + |\tilde{U}(x_k, \lambda_1) - \tilde{U}(y_k, \lambda_2)| \\ &\equiv I_1 + I_2 + I_3. \end{aligned}$$

By (4.8) and (4.7), it is clear that

$$I_1 = \frac{\sigma^2}{2}(x_k^2 X - y_k^2 Y) \leq \frac{\sigma^2}{2}3k|x_k - y_k|^2 \quad \rightarrow \quad 0 \quad \text{as } k \rightarrow \infty.$$

Since  $x^\alpha$  is Lipschitz on  $[\xi_1, \xi_2]$ , we see by (4.7) that

$$I_2 = k\{(x_k^\alpha - y_k^\alpha) - \mu(x_k - y_k)\}(x_k - y_k) \quad \rightarrow \quad 0 \quad \text{as } k \rightarrow \infty.$$

By (1.7), (4.6), and (4.7), we have

$$\begin{aligned} I_3 &\leq \max_{0 \leq c \leq 1} |U(cx_k) - U(cy_k)| + |x_k \lambda_1 - y_k \lambda_2| \\ &\leq C_\varepsilon |x_k - y_k| + \varepsilon + k|x_k - y_k|^2 \\ &\rightarrow 0 \quad \text{as } k \rightarrow \infty \quad \text{and } \varepsilon \rightarrow 0. \end{aligned}$$

Consequently, we deduce

$$2\eta \frac{1}{T^2} \leq 2\eta \frac{1}{t^2} \leq 0,$$

which is a contradiction.

**THEOREM 4.2.** *We assume (1.6). Then there exists a solution  $v \in C^{1,2}([0, T] \times (0, \infty)) \cap C([0, T] \times (0, \infty))$  of (3.1), (3.2).*

*Proof.* By (1.6), we have

$$U(0) \leq U'(c)(-c) + U(c) \quad \forall c > 0.$$

Then for any  $\xi_1 > 0$ ,

$$C_0 := \sup_{0 < c \leq \xi_1} cU'(c) \leq U(\xi_1) < \infty.$$

Hence, for  $x_1, x_2 \in [\xi_1, \xi_2]$  where  $\xi_2 > \xi_1$ ,

$$|U(cx_1) - U(cx_2)| \leq cU'(c\xi_1)|x_1 - x_2| \leq \frac{C_0}{\xi_1}|x_1 - x_2|, \quad 0 \leq c \leq 1.$$

Thus, for  $p_1, p_2 \in \mathbf{R}$ ,

$$\begin{aligned} |\tilde{U}(x_1, p_1) - \tilde{U}(x_2, p_2)| &\leq \max_{0 \leq c \leq 1} |U(cx_1) - U(cx_2)| + |x_1 p_1 - x_2 p_2| \\ &\leq \left( \frac{C_0}{\xi_1} + |p_1| \right) |x_1 - x_2| + \xi_2 |p_1 - p_2|. \end{aligned}$$

According to [4], by uniform ellipticity, there exists a unique solution  $u \in C([0, T] \times [\xi_1, \xi_2]) \cap C^{1,2}([0, T] \times (\xi_1, \xi_2))$  of (4.1)–(4.3). Clearly,  $v$  is a viscosity solution of (4.1)–(4.3). By Theorem 4.1, we have  $u = v$  and  $v$  is smooth. Since  $\xi_1, \xi_2$  are arbitrary, we obtain the assertion.

**COROLLARY 4.3.** *We make the assumption of Theorem 4.2. Then there exists a solution  $V \in C^{1,2}([0, T] \times (0, \infty)^2)$  of (1.5).*

*Proof.* The proof follows from Theorem 4.2 and (2.1).

**5. Concavity.** In this section, we study the concavity of the solution  $v$  to (3.1), (3.2).

**THEOREM 5.1.** *We assume (1.6). Then  $v(s, x)$  is concave in  $x \in (0, \infty)$  for each  $s \in [0, T]$ . In addition, we have*

$$(5.1) \quad v_x(s, x) > 0 \quad \text{for } x > 0.$$

*Proof.* Let  $x_i > 0, i = 1, 2$ , and  $0 \leq \theta \leq 1$ . For any  $\varepsilon > 0$ , there exists  $c^{(i)} \in \mathcal{A}$  such that

$$v(s, x_i) - \varepsilon < E \left[ \int_s^T U(c_t^{(i)} X_t^{(i)}) dt \right],$$

where  $\{X_t^{(i)}\}$  denotes the solution of (3.4) corresponding to  $c^{(i)}$  with  $X_s^{(i)} = x_i$  on the same probability space. We set

$$\bar{c}_t = \frac{\theta c_t^{(1)} X_t^{(1)} + (1 - \theta) c_t^{(2)} X_t^{(2)}}{\theta X_t^{(1)} + (1 - \theta) X_t^{(2)}},$$

which belongs to  $\mathcal{A}$ . Define  $\{\bar{X}_t\}$  and  $\{\tilde{X}_t\}$  by

$$\begin{aligned} d\bar{X}_t &= [(\bar{X}_t)^\alpha - \mu \bar{X}_t - \bar{c}_t \bar{X}_t] dt - \sigma \bar{X}_t dB_t, \quad s < t \leq T, \quad \bar{X}_s = \theta x_1 + (1 - \theta) x_2, \\ \tilde{X}_t &= \theta X_t^{(1)} + (1 - \theta) X_t^{(2)}. \end{aligned}$$

By concavity

$$\tilde{X}_r \leq \theta x_1 + (1 - \theta)x_2 + \int_s^r [(\tilde{X}_t)^\alpha - \mu \tilde{X}_t - \bar{c}_t \tilde{X}_t] dt - \int_s^r \sigma \tilde{X}_t dB_t \quad \text{a.s.}$$

By the comparison theorem, we have

$$\tilde{X}_t \leq \bar{X}_t, \quad t \in (s, T] \quad \text{a.s.}$$

Thus,

$$\begin{aligned} v(s, \theta x_1 + (1 - \theta)x_2) &\geq E \left[ \int_s^T U(\bar{c}_t \bar{X}_t) dt \right] \geq E \left[ \int_s^T U(\bar{c}_t \tilde{X}_t) dt \right] \\ &= E \left[ \int_s^T U(\theta c_t^{(1)} X_t^{(1)} + (1 - \theta) c_t^{(2)} X_t^{(2)}) dt \right] \\ &\geq \theta E \left[ \int_s^T U(c_t^{(1)} X_t^{(1)}) dt \right] + (1 - \theta) E \left[ \int_s^T U(c_t^{(2)} X_t^{(2)}) dt \right] \\ &> \theta v(s, x_1) + (1 - \theta)v(s, x_2) - \varepsilon. \end{aligned}$$

Therefore, letting  $\varepsilon \rightarrow 0$ , we obtain the concavity of  $v$ .

To prove (5.1), by Theorem 4.2, we note that  $v$  is smooth. By nonnegativity and concavity, we see that

$$v_x(s, x) \geq 0, \quad x > 0,$$

for every  $s \in [0, T)$ . Suppose that  $v_x(s, x_0) = 0$  for some  $x_0 > 0$ . Then,  $v_x(s, x) = 0$  for all  $x \geq x_0$ . Hence  $v(s, x)$  can be written as  $v(s, x) = h(s)$  for  $x \geq x_0$ . By (3.1), we have

$$U(x) = -v_t(s, x) = -h'(s), \quad x \geq x_0.$$

This is contrary to (1.6). Therefore we obtain (5.1).

**6. Optimal policies.** We give a synthesis of the optimal policy  $c^* = \{c_t^*\}$  for the optimization problem (1.4) subject to (1.1)–(1.3). We consider the SDE

$$(6.1) \quad dX_t^* = [(X_t^*)^\alpha - \mu X_t^* - \gamma(t, X_t^*) X_t^*] dt - \sigma X_t^* dB_t, \quad 0 < t \leq T, \quad X_0^* = x > 0,$$

where  $\gamma(t, x) = I(x, v_x(t, x))$  and  $I(x, p)$  denotes the maximizer of (2.4) for  $x, p > 0$ , i.e.,

$$(6.2) \quad I(x, p) = \begin{cases} (U')^{-1}(p)/x & \text{if } U'(x) \leq p, \\ 1 & \text{otherwise.} \end{cases}$$

LEMMA 6.1. *Under (1.6), there exists a unique positive solution  $\{X_t^*\}$  of (6.1).*

*Proof.* By (5.1), we notice that  $\gamma(t, x)$  is well defined. Let  $\{N_t\}$  be the solution of (2.6) corresponding to  $c_t = 0$ . Define the probability measure  $\hat{P}$  on  $(\Omega, \mathcal{F}_T, P)$  by

$$d\hat{P}/dP = \exp \left\{ \int_0^T \gamma(s, N_s)/\sigma dB_s - \frac{1}{2} \int_0^T (\gamma(s, N_s)/\sigma)^2 ds \right\}.$$

By the very definition (6.2) we have  $0 \leq \gamma(t, x) \leq 1$ ; so Girsanov's theorem yields that

$$\hat{B}_t := B_t - \int_0^t \gamma(s, N_s)/\sigma \, ds \quad \text{is a Brownian motion on } (\Omega, \mathcal{F}_T, \hat{P}).$$

Hence,

$$dN_t = [(N_t)^\alpha - \mu N_t - \gamma(t, N_t)N_t]dt - \sigma N_t d\hat{B}_t \quad \text{under } \hat{P}.$$

Thus, (6.1) admits a positive weak solution.

Now, by (6.2), we have

$$\gamma(t, x)x = \min\{(U')^{-1} \circ v_x(t, x), x\}.$$

Also, by (1.6) and concavity,

$$\frac{\partial}{\partial x}(U')^{-1} \circ v_x(t, x) = \frac{v_{xx}(t, x)}{U'' \circ (U')^{-1} \circ v_x(t, x)} \geq 0.$$

Thus,  $\gamma(t, x)x$  is nondecreasing on  $(0, \infty)$  for each  $t$ . We rewrite (6.1) in the form of (2.11). Then, we see that the pathwise uniqueness holds for (6.1). Therefore, by the Yamada–Watanabe theorem [3], we deduce that (6.1) admits a unique strong solution  $\{X_t^*\}$ .

**THEOREM 6.2.** *We assume (1.6). Then the optimal consumption policy  $\{c_t^*\}$  is given by the feedback form*

$$(6.3) \quad c_t^* = c^*(t, z_t^*, y_t),$$

where  $c^*(t, z, y) = I(z/y, yV_z(t, z, y))$  and  $\{z_t^*\}$  is the unique solution of

$$(6.4) \quad \dot{z}_t^* = F(z_t^*, y_t) - \nu z_t^* - c_t^* z_t^*, \quad 0 < t \leq T, \quad z_0^* = z > 0.$$

*Proof.* We set  $X_t^* = z_t^*/y_t$ . By Itô's formula and (2.2), we see that  $X_t^*$  solves (6.1). Therefore, by Lemma 6.1, there exists a unique positive solution  $\{z_t^*\}$  of (6.4).

By Theorems 4.2 and 5.1, we note that

$$0 < v_x(t, x)x \leq v(t, x) - v(t, 0+) \leq v(t, x), \quad x > 0.$$

Hence, by (3.6) and (2.7),

$$\begin{aligned} E \left[ \int_0^T \{v_x(s, X_s^*)X_s^*\}^2 ds \right] &\leq E \left[ \int_0^T \{v(s, X_s^*)\}^2 ds \right] \\ &\leq E \left[ \int_0^T \zeta(s, X_s^*)^2 ds \right] < \infty. \end{aligned}$$

By (2.2), this yields that  $\{\int_0^t \sigma y_s V_y(s, z_s^*, y_s) dB_s\}$  is a martingale. By (1.5) and (6.2),  $c^*$  satisfies

$$V_t + \frac{1}{2}\sigma^2 y^2 V_{yy} + nyV_y + \{F(z, y) - \nu z\}V_z + \{U(c^*z/y) - c^*zV_z\} = 0.$$

Applying Itô's formula to (1.1) and (6.4), we get

$$E[V(T, z_T^*, y_T)] = V(0, z, y) - E \left[ \int_0^T U(c_t^* z_t^*/y_t) dt \right],$$

which implies

$$E \left[ \int_0^T U(c_t^* z_t^*/y_t) dt \right] = V(0, z, y).$$

By the same calculation as above, we obtain

$$E \left[ \int_0^T U(c_t z_t/y_t) dt \right] \leq V(0, z, y)$$

for any  $c \in \mathcal{A}$ . The proof is complete.

*Remark 6.3.* From the proof of Theorem 6.2, it follows that

$$\sup_{c \in \mathcal{A}} E \left[ \int_s^T U(c_t z_t/y_t) dt \right] = V(s, z, y).$$

Thus, under (1.6), we see that the smooth solution  $V$  of the HJB equation (1.5) is unique. Furthermore, let  $u$  be the solution of (4.1) on the entire domain  $[0, T] \times (0, \infty)$  with  $u(T, x) = 0$ ,  $x > 0$ . Setting  $x = z/y$  and  $V(t, z, y) = u(t, z/y)$  for  $z, y > 0$ , by (2.2), we have that  $V$  satisfies (1.5). Therefore, we obtain the uniqueness of  $u$ .

**Acknowledgments.** The authors wish to thank the two anonymous referees for their comments which led to an improved version of this paper.

## ANALYTICAL PARAMETERIZATION OF ROTORS AND PROOF OF A GOLDBERG CONJECTURE BY OPTIMAL CONTROL THEORY\*

TÉRENCE BAYEN†

**Abstract.** Curves which can be rotated freely in an  $n$ -gon (that is, a regular polygon with  $n$  sides) so that they always remain in contact with every side of the  $n$ -gon are called rotors. Using optimal control theory, we prove that the rotor with minimal area consists of a finite union of arcs of circles. Moreover, the radii of these arcs are exactly the distances of the diagonals of the  $n$ -gon from the parallel sides. Finally, using the extension of Noether's theorem to optimal control (as performed in [D. F. M. Torres, *WSEAS Trans. Math.*, 3 (2004), pp. 620–624]), we show that a minimizer is necessarily a regular rotor, which proves a conjecture formulated in 1957 by Goldberg (see [M. Goldberg, *Amer. Math. Monthly*, 64 (1957), pp. 71–78]).

**1. Introduction.** In this paper, we investigate properties of *rotors*, that is, convex curves that can be freely rotated inside a regular polygon  $P_n$  with  $n$  sides,  $n \geq 3$ , while remaining in contact with every side of  $P_n$ . When  $n = 4$ ,  $P_4$  is a square of side  $\alpha$ , and a rotor of  $P_4$  is called a curve of constant width  $\alpha$  or an orbiform. When  $n = 3$ ,  $P_3$  is an equilateral triangle, and a rotor of  $P_3$  is called a  $\Delta$ -curve. There are infinitely many such curves besides the circle (see section 2).

Orbiforms have been studied geometrically since the 19th century (see [5], [22], [24], [27], [34]). In particular, Reuleaux's name is attached to those orbiforms obtained by intersecting a finite number of discs of equal radii  $\alpha$ . The Reuleaux triangle is the most famous of these orbiforms: it consists of the intersection of three circles of radius one and whose centers are on the vertices of an equilateral triangle of side one. Orbiforms have many interesting properties and applications in mechanics (see [5], [6], [7], [23], [24], [25], [34]). For example, Reuleaux triangles are used in boring square holes, and they are also part of the Wankel engine used by Japan's Mazda cars. Nowadays, the study of rotors is potentially interesting in mechanics for the design of engines or propellers, for example, in the Navy.

An interesting shape optimization problem consists in determining the convex body maximizing or minimizing the area in the class of rotors. It is easy to show that the disc always has maximal area in this class. This is a consequence of the isoperimetric inequality, as all rotors have the same perimeter (see Barbier's theorem in section 2.3). The question of finding a rotor of least area is more difficult. First, notice that the problem of minimizing the area is well posed, as rotors are convex bodies (see section 2.2). This question has been solved for  $n = 4$  (that is, in the case of orbiforms) by Blaschke using the mixed-volume (see [5]) and Lebesgue (see [22]). They show that the Reuleaux triangle has the least area in the class of constant width bodies of  $\mathbb{R}^2$ . Fujiwara has given the first analytic proof of this result (see [11], [12]).

†Laboratoire des Signaux et Systèmes, Ecole Supérieure d'Electricité, 91192 Gif-sur-Yvette, France (terence.bayen@lss.supelec.fr).

More recently, Harrell gave a modern proof using minimization under constraints (see [18]). The study of these problems in  $\mathbb{R}^2$  is useful for extensions in  $\mathbb{R}^3$  and in the domain of spectral analysis. For example, the problem of finding a constant width body of minimal volume in  $\mathbb{R}^3$  has recently been investigated (see [4], [20]). The optimization of eigenvalues with respect to the domain  $\Omega$  is also an intense field of research (see [19] for an overview of many spectral problems involving convexity). These questions require a careful study of dimension 2.

The  $\Delta$ -curves have many similar geometrical properties to the orbiforms (see [7], [34]). Fujiwara gave an analytic proof in [11] that, among all  $\Delta$ -curves inscribed in an equilateral triangle of side one, the one of minimal area is the  $\Delta$ -biangle or lens. It consists of two circular arcs of radius  $\frac{\sqrt{3}}{2}$  and of length  $\frac{\pi}{3}$ . This result was also established by Blaschke and later by Weissbach (see [33]).

Whereas the cases  $n = 3$  and  $n = 4$  have been investigated, the question of finding the rotor of least area for  $n \geq 5$  is open. Standard geometrical proofs cannot be applied in this case (see [13]). In [15] and [16], Goldberg constructs a family of “trammel” rotors in a regular polygon,  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*}$ , that have  $2(ln \pm 1)$  symmetries, and he conjectured in [15] that the minimizer is a rotor called  $O_n^{n-1}$  obtained for  $l = 1$ . The boundary of a rotor  $O_n^{ln\pm 1}$  consists of a finite union of arcs of circles of different radii  $r_i$  and of equal sectors (see section 2.6). The values  $r_i$  are exactly the distances of the diagonals of the  $n$ -gon from the parallel sides. In this class,  $O_n^{n-1}$  has the minimum number of arcs. An analytic description of these regular rotors is given in [10] by Focke. In 1975, Klötzler made an analytic study of the minimization problem using optimal control theory (see [2], [3], [21]). He showed in [21] that a minimizer consists of a union of arcs of circles of radii  $r_i$ , but he failed to prove that a minimizer is in the class  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*}$ . His idea consists in reformulating the initial minimization problem into an optimal control problem by choosing the radius of curvature as the control variable. Unfortunately, he seems to prove that the regular rotors  $O_n^{ln\pm 1}$  are local minimizers of the area in the subclass  $\mathcal{R}_n^{ln\pm 1}$  of rotors having the same number of arcs and the same radii of curvature. This result contradicts the one of Firey (see [9]) in the case  $n = 4$ : the author shows that regular Reuleaux polygons with  $N$  sides,  $N \geq 5$ , maximize the area in the class of Reuleaux polygons with the same number of sides. Moreover, in [2], the author performs only convex perturbations of a regular rotor  $O_n^{ln\pm 1}$ . This kind of perturbation increases the area by the concavity of the functional (the Brunn–Minkowski theorem; see [8]). The main difficulty is to consider nonconvex perturbations of those rotors which are not obtained by a strictly convex combination of two rotors.

The aim of the paper is to prove the following theorem conjectured by Goldberg in 1957 (see [15]).

**THEOREM 1.1.** *Among all rotors of a regular polygon  $P_n$  ( $n \geq 3$ ), the one of minimal area is the regular rotor  $O_n^{n-1}$ .*

In section 2, we give an analytic parameterization of a rotor using the support function of a convex body (see [6] or [28] for an overview of the properties of the support function). In section 3, we formulate the minimization problem into an optimal control problem which is similar to the one obtained by Klötzler (see [21]). Indeed, the convexity constraints enable us to choose the radius of curvature of the boundary of a rotor as the control variable. Thanks to this new parameterization, the initial shape optimization is well posed. By the Pontryagin maximum principle (PMP), we show that the extremal trajectories are “bang-bang,” and we determine the corresponding number of switching points. We thus restrict the class of extremal trajectories step by step. Whereas the computation of the extremal trajectories performed by Klötzler is

incomplete (he does not show that the switching points of an extremal trajectory are equidistant), we prove, in section 4, Theorem 1.1 by using an extension of Noether's theorem to optimal control theory provided in [29]. We compute conserved quantities along an extremal trajectory, and thus we can characterize the switching points of an extremal (see section 4). This shows that the rotors corresponding to the extremal trajectories belong to the class  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*}$ . We then conclude the proof of Goldberg's conjecture by Proposition 2.11. Note that by this proposition, there is no need to examine the optimality of extremal trajectories.

## 2. Construction of a rotor.

**2.1. Support function of a convex body.** A body or a domain in  $\mathbb{R}^N$ ,  $N \geq 2$ , is a nonempty compact connected subset of  $\mathbb{R}^N$ . Let  $K$  be a convex body. The support function of  $K$  is defined as the map  $h_K : \mathbb{R}^N \setminus \{0\} \rightarrow \mathbb{R}$  with

$$h_K(\nu) := \max_{x \in K} x \cdot \nu, \quad \nu \in \mathbb{R}^N \setminus \{0\}.$$

The support function is clearly homogeneous of degree 1. A convex body is uniquely determined by its support function (see [6, p. 29] or [20]). Let  $K$  be a convex body of nonempty interior and assume that the origin is inside  $K$ . Recall that, for a convex body, a hyperplane  $H$  is a hyperplane of support for  $K$  if there exists  $x \in K \cap H$  such that  $K$  is included in one of the half-spaces defined by  $H$ . If  $\nu$  belongs to  $\mathcal{S}^{N-1}$ ,  $h_K(\nu)$  can be interpreted as the distance from the origin to the support hyperplane of  $K$  with normal vector  $\nu$  (see Figure 1). The support function is nonnegative if and only if the origin is inside  $K$ . The next proposition characterizes the degree of regularity of the support function (see [6, p. 28] or [28]).

**PROPOSITION 2.1.** *Let  $K$  be a convex body of  $\mathbb{R}^N$  and  $h_K$  its support function. Then  $h_K$  is of class  $C^1$  if and only if  $K$  is strictly convex.*

From now on, we consider convex bodies in dimension 2. The support function of a convex body  $K$  of  $\mathbb{R}^2$  will be denoted by  $p_K(\theta) := h_K(e^{i\theta})$ ,  $\theta \in \mathbb{R}$ , or  $p(\theta)$  to simplify. The function  $p_K$  is  $2\pi$ -periodic. If  $K$  is a convex body, we denote by  $\partial K$  its boundary. Given  $(z_1, z_2) \in \mathbb{C}^2$ , their scalar product in  $\mathbb{R}^2$  will be written indifferently  $\Re(\overline{z_1} z_2)$  or  $z_1 \cdot z_2$ .

FIG. 1. The support function of a convex body  $K$  is the distance  $p(\theta)$  between the tangent to  $K$  orthogonal to  $(\cos(\theta), \sin(\theta))$  and the origin.

**PROPOSITION 2.2.** *Let  $K$  be a strictly convex body and  $p$  its support function. We assume that the boundary of  $K$ ,  $\partial K$ , is Lipschitz. Then  $\partial K$  can be described by the equations*

$$(2.1) \quad \begin{cases} x(\theta) = p(\theta) \cos(\theta) - \dot{p}(\theta) \sin(\theta), \\ y(\theta) = p(\theta) \sin(\theta) + \dot{p}(\theta) \cos(\theta), \end{cases}$$

where  $\theta \in \mathbb{R}$ .

*Proof.* Let  $\theta$  be in  $[0, 2\pi]$  and  $u_\theta$  be the vector of coordinates  $(\cos(\theta), \sin(\theta))$ . The support function  $p(\theta)$  is defined by

$$p(\theta) := \max_{x \in K} x \cdot u_\theta,$$

and  $p$  is of class  $C^1$  by strict convexity. As  $K$  is compact, the maximum is reached at some point of coordinates  $(x(\theta), y(\theta))$ , and we have

$$(2.2) \quad x(\theta) \cos(\theta) + y(\theta) \sin(\theta) = p(\theta).$$

As the boundary of  $K$  is Lipschitz, the functions  $(x, y)$  are differentiable a.e. (Rademacher's theorem). Moreover, the vector  $u_\theta$  is orthogonal to the support line given by  $X \cos(\theta) + Y \sin(\theta) = 0$ ; hence, we must have

$$(\dot{x}(\theta), \dot{y}(\theta)) \cdot \vec{u}_\theta = 0.$$

By derivation of (2.2), we get

$$-x(\theta) \sin(\theta) + y(\theta) \cos(\theta) = \dot{p}(\theta),$$

which gives (2.1).  $\square$

Equation (2.1) can be rewritten as  $z(\theta) := x(\theta) + iy(\theta) = (p(\theta) + i\dot{p}(\theta))e^{i\theta}$ .

In the following, the space  $C^{1,1}$  denotes the set of maps  $p : \mathbb{R} \rightarrow \mathbb{R}$ , of class  $C^1$ , and such that  $\dot{p}$  is locally Lipschitz.

**PROPOSITION 2.3.** *Let  $K$  be a convex body and  $p$  its support function. We assume that  $p$  is of class  $C^{1,1}$ . Then the radius of curvature  $p + \ddot{p}$  of the boundary  $\partial K$  exists a.e., and, for a.e.  $\theta \in \mathbb{R}$ ,*

$$(2.3) \quad p(\theta) + \ddot{p}(\theta) \geq 0.$$

*Proof.* As  $p$  is of class  $C^{1,1}$ , the functions  $(x(\theta), y(\theta))$  are differentiable a.e., and by standard formulas, the radius of curvature  $f$  of  $\partial K$  is given by  $f = p + \ddot{p}$ . As the body  $K$  is convex,  $f$  must be nonnegative, and consequently we have  $f(\theta) = p(\theta) + \ddot{p}(\theta) \geq 0$  for a.e.  $\theta \in \mathbb{R}$ .  $\square$

If  $K$  is a convex body of support function  $p$  and if  $p$  is of class  $C^{1,1}$ , the tangent vector to  $\partial K$  is given by

$$\dot{z}(\theta) = i(p(\theta) + \ddot{p}(\theta))e^{i\theta}.$$

When  $p + \ddot{p} = 0$  on a set  $A$  of positive measure, then we have  $\dot{z} = 0$ . Geometrically speaking, this means that the boundary  $\partial K$  has a corner: for  $\theta \in A$ , the point  $z(\theta)$  is stationary. For a given function  $f \in L^\infty(\mathbb{R}, \mathbb{R})$  and  $2\pi$ -periodic, we denote by

$$c_1(f) = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) e^{i\theta} d\theta$$

the first Fourier coefficient of  $f$ .

PROPOSITION 2.4. *Let  $f \in L^\infty(\mathbb{R}, \mathbb{R})$  be a  $2\pi$ -periodic function. Then any function  $p$  that satisfies  $f = p + \ddot{p}$  is of class  $C^{1,1}$ , and  $p$  is  $2\pi$ -periodic if and only if  $c_1(f) = 0$ .*

*Proof.* Let  $f \in L^\infty(\mathbb{R}, \mathbb{R})$  be a  $2\pi$ -periodic function. A function  $p$  satisfies  $f = p + \ddot{p}$  if and only if there exists  $(a, b) \in \mathbb{R}^2$  such that, for all  $\theta \in \mathbb{R}$ ,

$$(2.4) \quad p(\theta) = \int_0^\theta f(t) \sin(\theta - t) dt + a \cos(\theta) + b \sin(\theta).$$

By (2.4), any function  $p$  that satisfies  $p + \ddot{p} = f$  is of class  $C^{1,1}$ . Moreover, any such function  $p$  is of class  $C^{1,1}$  and is  $2\pi$ -periodic if and only if its restriction on  $[0, 2\pi]$  satisfies  $p(0) = p(2\pi)$ ,  $\dot{p}(0) = \dot{p}(2\pi)$ . But we have

$$\int_0^{2\pi} (p(\theta) + \ddot{p}(\theta)) e^{i\theta} d\theta = \dot{p}(2\pi) - \dot{p}(0) - i(p(2\pi) - p(0)).$$

Hence, any function  $p$  satisfying (2.4) is  $2\pi$ -periodic if and only if  $p(2\pi) = p(0)$  and  $\dot{p}(2\pi) = \dot{p}(0)$ , that is, if and only if  $c_1(f) = 0$ .  $\square$

If we deal with  $f = p + \ddot{p}$  instead of  $p$ , we get an additional condition  $c_1(f) = 0$  which says that the boundary  $\partial K$  given by (2.1) is closed. The next theorem is a consequence of the two previous propositions.

THEOREM 2.1. (i) *Let  $K$  be a strictly convex body of  $\mathbb{R}^2$  and  $p$  its support function. If  $p$  is of class  $C^{1,1}$ , then  $p + \ddot{p} \geq 0$ .*

(ii) *Conversely, let  $f \in L^\infty(\mathbb{R}, \mathbb{R})$  be a  $2\pi$ -periodic function such that  $f \geq 0$  and  $c_1(f) = 0$ . If  $p$  is a function satisfying  $f = p + \ddot{p}$ , then  $p$  is of class  $C^{1,1}$ , is  $2\pi$ -periodic (in the sense of  $C^{1,1}$  maps), and is the support function of a strictly convex body.*

Let  $K$  be a strictly convex body. We denote by  $p$  its support function of class  $C^1$  and by  $\mathcal{A}(p)$  its area. By Stokes's formula and by (2.1), we have

$$(2.5) \quad \mathcal{A}(p) = \frac{1}{2} \int_0^{2\pi} (p^2(\theta) - \dot{p}^2(\theta)) d\theta.$$

By integrating by parts, the area becomes

$$(2.6) \quad \mathcal{A}(p) = \frac{1}{2} \int_0^{2\pi} p(\theta) (p(\theta) + \ddot{p}(\theta)) d\theta,$$

which has a sense because  $p + \ddot{p}$  is a positive Radon measure, and (2.6) can be interpreted as the product of a positive Radon measure and a continuous function. In the next section, we show that the support function of a rotor is of class  $C^{1,1}$ , and (2.6) is clearly defined in that case.

**2.2. Construction of a rotor by its support function.** In this section, we recall classical definitions and properties of rotors (see [6], [17], [34]). Let  $K$  be a convex domain and  $P$  be a convex polygon.  $P$  will be called a *tangential polygon* of  $K$  and  $K$  an *osculating domain* in  $P$  if  $K \subset P$  and every side of  $P$  has a nonempty intersection with  $K$  (see [17]). We say that a polygon  $P$  is *equiangular* if all of its interior angles at the vertices are equal. We say that a convex polygon  $P$  is an  $n$ -gon if it is a regular polygon with  $n$  sides,  $n \geq 3$ .

DEFINITION 2.1. *A convex domain  $K$  will be called a rotor in a polygon  $Q$  if, for every rotation  $\rho$ , there exists a translation vector  $p_\rho$  such that  $\rho K + p_\rho$  is an osculating domain in  $K$ .*

In the following, we assume that  $Q$  is a regular polygon with  $n \geq 3$  sides; that is, we consider only rotors of a regular polygon. Hence,  $K$  is a rotor in a regular  $n$ -gon  $Q$  if and only if all tangential equiangular  $n$ -gons are regular and have equal perimeters. A rotor of an  $n$ -gon  $P_n$  has the property to rotate inside  $P_n$  while remaining in contact with all sides of  $P_n$ . The disc is the most simple example of a rotor. A rotor is a strictly convex domain (see [17], [34]). Consequently, the support function of a rotor is of class  $C^1$ .

Let  $r$  be the radius of the inscribed circle of the  $n$ -gon  $P_n$  and let  $\delta := \frac{2\pi}{n}$ . We give in the following theorem an analytic description of a rotor which will be used in the rest of the paper.

THEOREM 2.2. (i) *Let  $K$  be a rotor and  $p$  its support function. Then  $p$  satisfies*

$$(2.7) \quad p(\theta) - 2\cos(\delta)p(\theta + \delta) + p(\theta + 2\delta) = 4r\sin^2\left(\frac{\delta}{2}\right) \quad \forall \theta \in [0, 2\pi].$$

Moreover,  $p$  is of class  $C^{1,1}$  and satisfies (2.3).

(ii) *Conversely, let  $p$  be a  $2\pi$ -periodic function of class  $C^{1,1}$ . Assume that  $p$  satisfies (2.3) and (2.7). Then  $p$  is the support function of a rotor  $K$ .*

The characterization of a rotor by (2.7) is well known (see [7], [10], [21]), but we show in particular that the support function of a rotor is actually of class  $C^{1,1}$ . Before doing the proof of the theorem, we set some notation:

$$(2.8) \quad S_n(p) := p(\theta) - 2\cos(\delta)p(\theta + \delta) + p(\theta + 2\delta)$$

and

$$(2.9) \quad C_n := 4r\sin^2\left(\frac{\delta}{2}\right).$$

*Proof of (i).* We refer the reader to Chapter 8 of [34] for the following geometric property. By definition of a rotor, the tangents to  $\partial K$  at each contact point are the sides of the  $n$ -gon. Hence, the perpendiculars to these paths at their contact points meet in a point which is the instantaneous center of rotation of the body. A simple computation yields (2.7). We now prove that  $p$  is of class  $C^{1,1}$ . First, we have

$$(2.10) \quad \sum_{0 \leq k \leq n-1} p(\theta + k\delta) = nr \quad \forall \theta \in \mathbb{R}.$$

Indeed, by writing (2.7) at points  $\theta, \theta + \delta, \dots, \theta + (n-1)\delta$  and adding all of these equalities, we get (2.10). As  $K$  is strictly convex, its support function  $p$  is of class  $C^1$ . We now show that  $p$  satisfies the inequality

$$(2.11) \quad (\dot{p}(\theta') - \dot{p}(\theta))\sin(\theta - \theta') \leq (p(\theta) + p(\theta'))(1 - \cos(\theta - \theta')) \quad \forall (\theta, \theta') \in [0, 2\pi].$$

By definition of the support function, we have, for all  $(\theta, \theta') \in [0, 2\pi]$ ,

$$(x(\theta'), y(\theta')) \cdot (\cos(\theta), \sin(\theta)) \leq p(\theta).$$

Taking into account (2.1), we get

$$\dot{p}(\theta')\sin(\theta - \theta') \leq p(\theta) - p(\theta')\cos(\theta' - \theta).$$

If we permute  $\theta$  and  $\theta'$ , we obtain

$$\dot{p}(\theta)\sin(\theta' - \theta) \leq p(\theta') - p(\theta)\cos(\theta' - \theta).$$

Adding the last two inequalities yields (2.11). We now write (2.11) at the points  $\theta + k\delta$  and  $\theta' + k\delta$ ,  $0 \leq k \leq n-1$ . We get, for all  $(\theta, \theta') \in [0, 2\pi]$  and  $0 \leq k \leq n-1$ ,

(2.12)

$$(\dot{p}(\theta' + k\delta) - \dot{p}(\theta + k\delta)) \sin(\theta - \theta') \leq (p(\theta + k\delta) + p(\theta' + k\delta))(1 - \cos(\theta - \theta')).$$

By (2.10), we obtain, for all  $(\theta, \theta') \in [0, 2\pi]$ ,

$$(2.13) \quad \sum_{1 \leq k \leq n-1} p(\theta + k\delta) = nr - p(\theta)$$

and

$$(2.14) \quad \sum_{1 \leq k \leq n-1} \dot{p}(\theta + k\delta) = -\dot{p}(\theta).$$

Combining (2.12), (2.13), and (2.14), we obtain

$$(-\dot{p}(\theta') + \dot{p}(\theta)) \sin(\theta - \theta') \leq (2nr - p(\theta) - p(\theta'))(1 - \cos(\theta - \theta')).$$

Therefore, by (2.11) and the previous inequality, we get, for all  $(\theta, \theta') \in [0, 2\pi]$ ,

$$|(\dot{p}(\theta') - \dot{p}(\theta)) \sin(\theta - \theta')| \leq 2nr \sin^2 \left( \frac{\theta - \theta'}{2} \right).$$

Consequently,  $\dot{p}$  satisfies the inequality

$$|\dot{p}(\theta') - \dot{p}(\theta)| \leq 2nr \left| \tan \left( \frac{\theta - \theta'}{2} \right) \right|$$

for all  $(\theta, \theta') \in [0, 2\pi]$  such that  $|\theta - \theta'| \notin \{0, \pi, 2\pi\}$ . This inequality proves that  $\dot{p}$  is Lipschitz, and thus  $p$  is of class  $C^{1,1}$ . As  $K$  is convex and  $p$  is of class  $C^{1,1}$ , it satisfies (2.3). This concludes the proof of (i).

*Proof of (ii).* Let us assume that conditions (2.3) and (2.7) are satisfied. As  $p$  is of class  $C^{1,1}$ , is  $2\pi$ -periodic, and satisfies (2.3), it is the support function of a strictly convex body  $K$ . A straightforward computation using (2.7) shows that an osculating polygon to  $K$  is equiangular; consequently,  $K$  is a rotor.  $\square$

An example of a function  $p$  satisfying (2.7) is given by

$$(2.15) \quad p(\theta) = 1 + \frac{1}{1 - (ln - 1)^2} \cos((ln - 1)\theta),$$

where  $l \in \mathbb{N}^*$  (see Figure 2). A simple computation shows that we have  $S_n(p) = C_n$  with  $r = 1$ . Moreover, we easily have  $p(\theta) + \ddot{p}(\theta) = 1 + \cos((ln - 1)\theta) \geq 0$  for all  $\theta \in \mathbb{R}$ . Hence,  $p$  is the support function of a rotor  $K$  in an  $n$ -gon. The boundary of  $K$  is of class  $C^\infty$  because  $p$  is of class  $C^\infty$ .

In the following, we denote by  $E$  the set of the functions  $p \in C^{1,1}(\mathbb{R})$  that are  $2\pi$ -periodic and that satisfy (2.3) and (2.7). The problem of finding a rotor of minimal area is now equivalent to the optimization problem

$$(2.16) \quad \min_{p \in E} \mathcal{A}(p).$$

The existence of a minimizer for problem (2.16) easily follows from standard compactness arguments (see [32], [34]).

FIG. 2. Example of rotors whose support function is given by (2.15) for  $n = 3$ ,  $l = 2$  and  $n = 5$ ,  $l = 1, 2$ .

**2.3. Basic properties of rotors.** This section is devoted to well-known results about rotors which can be found in the case  $n = 3$  or  $n = 4$  in [5], [7], and [34]. Let us first recall Barbier’s theorem, which is a simple consequence of (2.7).

**THEOREM 2.3.** *Let  $r$  be the radius of the inscribed circle in  $P_n$ . Then the perimeter of every rotor  $\mathcal{R}$  of  $P_n$  is equal to  $2\pi r$ .*

*Proof.* Let  $\mathcal{R}$  be a rotor and  $p$  be its support function. The perimeter  $L$  of  $\mathcal{R}$  is given by the integral of the radius of curvature:

$$L = \int_0^{2\pi} (p(\theta) + \ddot{p}(\theta))d\theta,$$

which is well defined, as  $p$  is of class  $C^{1,1}$ . As  $\dot{p}$  is  $2\pi$ -periodic, the perimeter becomes  $L = \int_0^{2\pi} p(\theta)d\theta$ . Now integrating (2.7) on the interval  $[0, 2\pi]$  and using the  $2\pi$ -periodicity of  $p$ , we get  $L = 2\pi r$ .  $\square$

**PROPOSITION 2.5.** *Among all rotors of a regular polygon  $P_n$ , the one of maximal area is the disc of radius  $r$ .*

*Proof.* By the isoperimetric inequality, the body of maximal area among all closed curves having the same perimeter is the disc, and the disc is a rotor of  $P_n$ .  $\square$

When  $n = 4$ , a rotor is called a constant width body.

**DEFINITION 2.2.** *The width of a convex curve in a given direction is the distance between a pair of supporting lines of the curve perpendicular to this direction. If the width is constant in every direction, the curve is a curve of constant width.*

Equivalently, a constant width body has the property to rotate inside a square while remaining tangent to the four sides of the square. The relation (2.7) can be simplified in the case  $n = 4$ , which corresponds to the constant width bodies. The support function of  $K$  in this case satisfies

$$(2.17) \quad p(\theta) + p(\theta + \pi) = 2r \quad \forall \theta \in \mathbb{R},$$

which is exactly saying that any pair of parallel support lines to  $K$  is separated by the distance  $2r$  (see [14]).

**2.4. Formulation of the constraints on the interval  $[0, 2\delta]$ .** In this section, we derive consequences of (2.7) which will be useful in formulating the optimal control problem associated with the minimization problem. Let us define the reals  $s_k$  and  $t_k$  for  $k = 0, \dots, n - 1$  by

$$(2.18) \quad s_k := \frac{\sin(k\delta)}{\sin(\delta)}, \quad t_k := 2 \frac{\sin(\frac{k\delta}{2}) \sin(\frac{(k-1)\delta}{2})}{\cos(\frac{\delta}{2})} r.$$

LEMMA 2.1. *Let  $p$  be a  $2\pi$ -periodic map in  $C^{1,1}(\mathbb{R})$  satisfying (2.7). Then we have*

$$(2.19) \quad p(\theta + k\delta) = s_k p(\theta + \delta) - s_{k-1} p(\theta) + t_k \quad \forall \theta \in [0, 2\pi].$$

*Proof.* Let  $\theta \in [0, 2\pi]$  and  $v_k := p(\theta + k\delta)$ . We have by (2.7)

$$(2.20) \quad v_k - 2\cos(\delta)v_{k+1} + v_{k+2} = 4r\sin^2\left(\frac{\delta}{2}\right).$$

We solve this linear recurrent sequence and get

$$v_k = a\omega^k + \overline{a}\overline{\omega}^k + r,$$

where  $\omega := e^{i\delta}$  and  $v_0 = p(\theta)$ ,  $v_1 = p(\theta + \delta)$ . This gives (2.19).  $\square$

COROLLARY 2.1. *If  $n$  is even, a rotor  $K$  in an  $n$ -gon is a constant width body.*

*Proof.* Let  $K$  be a rotor and  $p$  be its support function which satisfies (2.7). We assume that  $n = 2m$ ,  $m \in \mathbb{N}^*$ . Using (2.19) with  $k = m$ , we get  $s_m = 0$ ,  $s_{m-1} = 1$ , and  $t_m = 2r$ . Consequently,  $p$  satisfies

$$p(\theta + m\delta) = -p(\theta) + 2r,$$

which is exactly saying that  $K$  is of constant width as  $m\delta = \pi$ .  $\square$

We now reformulate the area of a rotor on the interval  $[0, 2\delta]$ . Let  $r$  be the radius of the inscribed circle to the  $n$ -gon and  $P \in C^{1,1}(\mathbb{R}, \mathbb{R})$ ,  $F \in L^\infty(\mathbb{R}, \mathbb{R})$  be the maps defined by

$$(2.21) \quad \begin{cases} P(\theta) := p(\theta) - r, \\ F(\theta) := p(\theta) + \ddot{p}(\theta) - r = P(\theta) + \ddot{P}(\theta). \end{cases}$$

LEMMA 2.2. *Let  $p$  be the support function of a rotor and  $f$  its radius of curvature. The area of a rotor is given by*

$$\mathcal{A}(p) = \frac{n}{4\sin^2(\frac{\delta}{2})} \tilde{\mathcal{A}}(P) + \pi r^2,$$

where

$$(2.22) \quad \begin{aligned} \tilde{\mathcal{A}}(P) = \int_0^\delta & \left( P(\theta)F(\theta) + P(\theta + \delta)F(\theta + \delta) \right. \\ & \left. - \cos(\delta)(F(\theta)P(\theta + \delta) + F(\theta + \delta)P(\theta)) \right) d\theta. \end{aligned}$$

*Proof.* We have by (2.6)

$$\begin{aligned} \mathcal{A}(f) &= \frac{1}{2} \int_0^{2\pi} p(\theta)f(\theta)d\theta = \frac{1}{2} \sum_{0 \leq k \leq n-1} \int_{k\delta}^{(k+1)\delta} p(\theta)f(\theta)d\theta \\ &= \frac{1}{2} \sum_{0 \leq k \leq n-1} \int_0^\delta p(\theta + k\delta)f(\theta + k\delta)d\theta. \end{aligned}$$

Replacing  $p(\theta + k\delta)$  and  $f(\theta + k\delta)$  using (2.19), we get the result by the equalities

$$\sum_{0 \leq k \leq n-1} s_k^2 = \sum_{0 \leq k \leq n-1} s_{k-1}^2 = \frac{2}{2 \sin^2(\delta)}$$

and

$$\sum_{0 \leq k \leq n-1} s_k t_k = -\frac{n}{4 \cos^2(\frac{\delta}{2})}, \quad \sum_{0 \leq k \leq n-1} s_k s_{k-1} = \frac{n \cos(\delta)}{2 \sin^2(\delta)}. \quad \square$$

Note that in the special case of sets of constant width ( $n = 4$ ), one finds the usual functional (see [14]):

$$(2.23) \qquad \mathcal{A}(p) = \pi r^2 - \int_0^\pi p(\theta)(1 - f(\theta))d\theta,$$

which can be easily obtained by (2.6) and (2.17).

**2.5. Simplification of the functional.** Before going into details for solving the minimization problem (2.16), we diagonalize the functional (2.22) (see [21] for the same parameterization). In particular, we establish the equivalence between the parameterization of a rotor by its support function and the new parameterization. The following parameterization will be useful in defining an optimal control problem equivalent to (2.16). We set

$$\gamma := \cos(\delta), \quad \sigma := \sin(\delta), \quad \omega^{\frac{1}{2}} := e^{\frac{i\delta}{2}}, \quad \omega^{-\frac{1}{2}} := e^{-\frac{i\delta}{2}};$$

that is, we denote by  $\omega^{\frac{1}{2}}$  and  $\omega^{-\frac{1}{2}}$  a square root of  $\omega$  and  $\overline{\omega}$ .

Recall that given a rotor  $K$  of support function  $p$ , the functions  $P$  and  $F$  are defined by (2.21), and by (2.8) and (2.9) we have  $S_n(f) = C_n$  if and only if  $S_n(F) = 0$ . We now define the functions  $W \in C^{1,1}(\mathbb{R}, \mathbb{C})$  and  $Z \in L^\infty(\mathbb{R}, \mathbb{C})$  by

$$(2.24) \qquad \begin{cases} W(\theta) := P(\theta) - \overline{\omega}P(\theta + \delta), \\ Z(\theta) := F(\theta) - \overline{\omega}F(\theta + \delta), \end{cases}$$

where  $\theta \in \mathbb{R}$ , so that

$$(2.25) \qquad W + \check{W} = Z.$$

The functions  $W$  and  $Z$  can be interpreted as the *complex support function* and the *complex radius of curvature* associated with a rotor. We denote by  $X_1, X_3, U, V$  the real and imaginary parts of  $W$  and  $Z$ :

$$\begin{cases} W = X_1 + iX_3, \\ Z = U + iV, \end{cases}$$

so that we have

$$(2.26) \qquad \begin{cases} X_1(\theta) = P(\theta) - \gamma P(\theta + \delta), \\ X_3(\theta) = \sigma P(\theta + \delta), \\ U(\theta) = F(\theta) - \gamma F(\theta + \delta), \\ V(\theta) = \sigma F(\theta + \delta). \end{cases}$$

We have, equivalently,

$$(2.27) \quad \begin{cases} P(\theta) = X_1(\theta) + \frac{\gamma}{\sigma} X_3(\theta), \\ P(\theta + \delta) = \frac{1}{\sigma} X_3(\theta), \\ F(\theta) = U(\theta) + \frac{\gamma}{\sigma} V(\theta), \\ F(\theta + \delta) = \frac{1}{\sigma} V(\theta + \delta). \end{cases}$$

PROPOSITION 2.6. *The functions  $W$  and  $Z$  satisfy the relations*

$$(2.28) \quad \begin{cases} W(\theta + \delta) = \overline{\omega} W(\theta) \quad \forall \theta \in \mathbb{R}, \\ Z(\theta + \delta) = \overline{\omega} Z(\theta) \quad \text{a.e. } \theta \in \mathbb{R}. \end{cases}$$

*Proof.* Let  $p$  be the support function of a rotor. We have by (2.7)  $S_n(p) = C_n$ , where  $C_n$  is given by (2.9). Thus,  $S_n(P) = 0$ , that is,

$$(2.29) \quad \forall \theta \in \mathbb{R}, \quad P(\theta) - 2\gamma P(\theta + \delta) + P(\theta + 2\delta) = 0.$$

Eliminating  $P(\theta + 2\delta)$  in the equation above, we get

$$\forall \theta \in \mathbb{R}, \quad W(\theta + \delta) = P(\theta + \delta) - \overline{\omega}(2\gamma P(\theta + \delta) - P(\theta)),$$

which gives  $W(\theta + \delta) = \overline{\omega} W(\theta)$  for all  $\theta \in \mathbb{R}$ . By derivation of the previous equation, we get  $Z(\theta + \delta) = \overline{\omega} Z(\theta)$  for all  $\theta \in \mathbb{R}$ .  $\square$

In the following,  $\mathcal{P}_n$  denotes the regular polygon whose center is the origin and whose vertices are the points of coordinates  $(r^* \omega^k e^{i\alpha})_{0 \leq k \leq n-1}$ , where  $r^* := 2r \sin(\frac{\delta}{2})$  and  $\alpha := -\frac{\pi}{2} - \frac{\delta}{2}$ .

PROPOSITION 2.7. *Let  $K$  be a rotor,  $p$  its support function, and  $f = p + \ddot{p}$  its radius of curvature. We denote by  $Z$  its complex radius of curvature. Then we have  $f \geq 0$  if and only if  $Z(\theta) \in \mathcal{P}_n$  for a.e.  $\theta \in [0, \delta]$ .*

*Proof.* Let us consider for  $0 \leq k \leq n-1$  the map defined by

$$u_k(x, y) = s_k y - s_{k-1} x + t_k.$$

By Lemma 2.1, we have, for  $\theta \in [0, \delta]$  and for  $0 \leq k \leq n-1$ ,

$$f(\theta + k\delta) = u_k(f(\theta), f(\theta + \delta)).$$

Therefore, we have, for  $\theta \in [0, \delta]$ ,

$$\begin{aligned} f \geq 0 &\iff u_k(f(\theta), f(\theta + \delta)) \geq 0, \quad k = 0, \dots, n-1 \\ &\iff s_k(f(\theta + \delta) - r) - s_{k-1}(f(\theta) - r) + t_k + r(s_k - s_{k-1}) \geq 0 \\ &\iff \sin(k\delta)F(\theta + \delta) - \sin((k-1)\delta)F(\theta) \geq -\sigma r \\ &\iff \Im(\sin(k\delta)Z(\theta) - \sin((k-1)\delta)Z(\theta - \delta)) \geq -\sigma^2 r \\ &\iff \Im(\sin(k\delta)Z(\theta) - \sin((k-1)\delta)\omega Z(\theta)) \geq -\sigma^2 r \\ &\iff \Im(\omega^{k-1}Z(\theta)) \geq -\sigma r. \end{aligned}$$

Let  $z = x + iy$  be a complex number,  $D_k$  the hyperplane of equation  $\Im(\omega^{k-1}z) = -\sigma r$ , and  $H_k$  the half-plane defined for  $z \in \mathbb{C}$  by  $\Im(\omega^{k-1}z) \geq -\sigma r$ . We easily have that  $z \in D_{k+1}$  if and only if  $\omega z \in D_k$ . Hence, for  $\theta \in [0, \delta]$ ,  $Z(\theta)$  satisfies  $\Im(\omega^{k-1}Z(\theta)) \geq -\sigma r$ ,  $0 \leq k \leq n-1$ , if and only if  $Z(\theta)$  belongs to the intersection of the half-spaces  $H_k$ . This intersection is nonempty, as 0 belongs to  $H_k$  for all  $0 \leq k \leq n-1$  and is convex as all  $H_k$  are convex; hence it is a nonempty convex polygon. Moreover, a simple computation yields that the vertices of  $\mathcal{P}_n$  are given by the intersection  $D_k \cap D_{k+1}$  and are of coordinates  $-2ir \sin(\frac{\delta}{2})e^{i(k-\frac{1}{2})\delta}$  for  $0 \leq k \leq n-1$ .  $\square$

It is convenient to work with  $\mathcal{P}_n$  because we will see in the next section that the optimal control takes its values at the vertices of  $\mathcal{P}_n$  (the extremal points of  $\mathcal{P}_n$ ).

PROPOSITION 2.8. *Let  $p$  be the support function of a rotor  $K$ . Then the area of  $K$  is given by*

$$(2.30) \quad \mathcal{A}(p) = \pi r^2 + \frac{n}{4\sigma^2} \int_0^\delta U X_1 + V X_3 = \pi r^2 + \frac{n}{4\sigma^2} \int_0^\delta \Re(Z\overline{W}).$$

*Proof.* The area of the rotor  $K$  described by  $p \in E$  is given by (2.22). Replacing  $P(\theta)$ ,  $P(\theta + \delta)$ ,  $F(\theta)$ , and  $F(\theta + \delta)$  by  $W(\theta)$ ,  $W(\theta + \delta)$ ,  $Z(\theta)$ , and  $Z(\theta + \delta)$ , we get (2.30) by using (2.28).  $\square$

Notice the similarity between (2.6) and (2.30).

DEFINITION 2.3. *Let  $\Gamma$  be the set of the complex functions  $W$  in  $C^{1,1}([0, \delta])$  that satisfy*

$$(2.31) \quad \begin{cases} W(\delta) = \overline{\omega}W(0), \\ \dot{W}(\delta) = \overline{\omega}\dot{W}(0) \end{cases}$$

*and such that the function  $Z = W + \ddot{W}$  takes its values in the polygon  $\mathcal{P}_n$ .*

DEFINITION 2.4. *We denote by  $\mathcal{Z}$  the set of the complex valued functions  $Z \in L^\infty(\mathbb{R}, \mathbb{C})$  satisfying*

$$Z(\theta + \delta) = \overline{\omega}Z(\theta) \quad \forall \theta \in \mathbb{R}$$

*and*

$$Z(\theta) \in \mathcal{P}_n \quad \forall \theta \in \mathbb{R}.$$

We can now prove the equivalence between the parameterization of a rotor  $K$  by its support function  $p$  and its complex support function  $W$ .

THEOREM 2.4. (i) *Let  $W = X_1 + iX_3$  be a function in  $\Gamma$ . Let us define the function  $\tilde{p}$  on  $[0, 2\delta]$  by  $\tilde{p} = P + r$ , where  $P$  is given by (2.27). Then, if we extend  $\tilde{p}$  on the interval  $[0, 2\pi]$  by (2.19) and if we denote by  $p$  this extension, then  $p$  is the support function of a rotor.*

(ii) *Conversely, if  $p$  is the support function of a rotor  $K$  and  $P := p - r$ , then the function  $W|_{[0, \delta]}$  defined by (2.24) belongs to  $\Gamma$ .*

*Proof of (i).* First, let us take  $W = X_1 + iX_3 \in \Gamma$ . We have by (2.31)

$$(2.32) \quad \begin{cases} \frac{1}{\sigma}X_3(0) = X_1(\delta) + \frac{\gamma}{\sigma}X_3(\delta), \\ \sigma X_1(0) - \gamma X_3(0) = -X_3(\delta) \end{cases}$$

and

$$(2.33) \quad \begin{cases} \frac{1}{\sigma}\dot{X}_3(0) = \dot{X}_1(\delta) + \frac{\gamma}{\sigma}\dot{X}_3(\delta), \\ \sigma\dot{X}_1(0) - \gamma\dot{X}_3(0) = -\dot{X}_3(\delta). \end{cases}$$

We now define a function  $P$  on the interval  $[0, 2\delta]$  by

$$P(\theta) = X_1(\theta) + \frac{\gamma}{\sigma} X_3(\theta), \quad P(\theta + \delta) = \frac{1}{\sigma} X_3(\theta)$$

for  $\theta \in [0, \delta]$ . By (2.32), we have

$$P(\delta^-) = P(\delta^+),$$

and by (2.33) we have

$$\dot{P}(\delta^-) = \dot{P}(\delta^+).$$

Consequently, the function  $P$  is of class  $C^1$  on  $[0, 2\delta]$ . By (2.32) we also get

$$S_n(P)(0) = 0,$$

and by (2.33) we get

$$S_n(\dot{P})(0) = 0.$$

Hence, the functions  $P$  and  $\dot{P}$  satisfy  $S_n(P) = 0$  and  $S_n(\dot{P}) = 0$  for  $\theta = 0$ . If we extend  $p = P + r$  to the interval  $[0, 2\pi]$  by (2.19) and to  $\mathbb{R}$  by  $2\pi$ -periodicity, it satisfies, by construction,  $S_n(p) = C_n$ . We also have  $p(0) = p(2\pi)$  and  $\dot{p}(0) = \dot{p}(2\pi)$  by (2.19) so that the function  $p$  is of class  $C^1$ . Finally, we have  $p + \ddot{p} \geq 0$  because  $Z \in \mathcal{P}_n$ . We conclude that  $p$  is the support function of a rotor.

*Proof of (ii).* Let us now consider the support function  $p$  of a rotor. We define a function  $W$  by (2.24). First, the condition (2.3) satisfied by  $p$  implies that  $Z = W + \ddot{W}$  takes its value in  $\mathcal{P}_n$ . Let us show that  $W$  satisfies (2.31). By (2.26), we have

$$\frac{1}{\sigma} X_3(0) = X_1(\delta) + \frac{\gamma}{\sigma} X_3(\delta),$$

and by using  $S_n(P)(0) = 0$ , we get

$$\sigma X_1(0) - \gamma X_3(0) = -X_3(\delta).$$

These two real conditions imply  $W(\delta) = \overline{\omega}W(0)$ . By using (2.27) and the equality  $S_n(\dot{P})(0) = 0$ , we get  $\dot{W}(\delta) = \overline{\omega}\dot{W}(0)$ . Hence,  $W$  belongs to  $\Gamma$ .  $\square$

*Remark 2.1.* Let us make two remarks. First, any function  $W \in \Gamma$  such that  $Z = W + \ddot{W}$  satisfies, by (2.31), the condition

$$(2.34) \quad \int_0^\delta Z(\theta) e^{i\theta} d\theta = 0.$$

Second, (2.30) remains unchanged if we replace  $W$  by  $W e^{i\alpha}$  and  $Z$  by  $Z e^{i\alpha}$ , where  $\alpha \in \mathbb{R}$ .

From now on, we will mainly deal with the set  $\Gamma$  instead of the set  $E$ , as there is a one-to-one correspondence between these two sets. For  $W \in \Gamma$  such that  $W = X_1 + iX_3$  and  $Z = W + \ddot{W} = U + iV$ , we denote by  $J(W)$  the functional

$$(2.35) \quad J(W) = \int_0^\delta U X_1 + V X_3 = \int_0^\delta \Re(Z \overline{W})$$

and by  $\mathcal{A}(W)$  the area of a rotor. An integration by parts shows that we have

$$J(W) = \int_0^\delta Z \overline{W} = \int_0^\delta |W|^2 - |\dot{W}|^2,$$

and as  $J(W) \in \mathbb{R}$ , we have

$$\int_0^\delta \Im(Z \overline{W}) = 0.$$

The area of a rotor becomes

$$\mathcal{A}(W) = \pi r^2 + \frac{n}{4\sigma^2} J(W).$$

The initial problem, finding the rotor of least area (problem (2.16)), is now equivalent to

$$(2.36) \quad \min_{W \in \Gamma} J(W).$$

In sections 3 and 4, we will solve problem (2.36) using the optimal control theory.

**2.6. Fourier series of regular rotors.** Before going further into the analysis of (2.36), we describe by Fourier series the two families of regular rotors  $O_n^{ln \pm 1}$  introduced in section 1. An analogous description is given by Focke (see [10]), but here we use the new parameterization  $(W, Z)$ , which simplifies the computations.

We consider the subset  $J \subset \mathbb{Z}$  defined for  $n \geq 3$  by

$$J = (n\mathbb{Z} + 1) \cup (n\mathbb{Z} - 1) \setminus \{\pm 1\}$$

and let  $p$  be the support function of a rotor. Then  $p$  is given by

$$(2.37) \quad p(\theta) = r + c_1 e^{i\theta} + c_{-1} e^{-i\theta} + \sum_{j \in J} c_j e^{ij\theta},$$

where  $c_j$  are the Fourier coefficients of  $p$ . In the case of constant width bodies, the support function becomes

$$p(\theta) = r + c_1 e^{i\theta} + c_{-1} e^{-i\theta} + \sum_{l \in \mathbb{Z}^*} \left( c_{4l-1} e^{i(4l-1)\theta} + c_{4l+1} e^{i(4l+1)\theta} \right).$$

By the Parseval equality, the area of a rotor  $K$  becomes

$$(2.38) \quad \mathcal{A}(p) = \pi \left( r^2 - \sum_{j \in J} \frac{|c_j|^2}{j^2 - 1} \right).$$

Let  $m \in \mathbb{N}^*$ ,  $\varepsilon = \pm 1$ ,  $L = mn - \varepsilon$ ,  $\tau = \frac{\delta}{L}$ , and  $s = L - 1$ . We can easily check that the complex function defined by

$$(2.39) \quad Z(\theta) = \sum_{0 \leq j \leq s} \omega^{\varepsilon j} \mathbb{1}_{[j\tau, (j+1)\tau[}$$

is an element of  $\mathcal{Z}$ . We will define the regular rotors by (2.39).

DEFINITION 2.5. We call regular rotor any element  $W$  of  $\Gamma$  such that  $W + \ddot{W}$  is of the form (2.39). The first series consists of the rotors obtained for  $\varepsilon = 1$ , and the second series is obtained for  $\varepsilon = -1$ .

The integer  $L = s + 1$  denotes the number of intervals of the subdivision  $[0, \delta]$ . We now consider the set

$$J_\varepsilon = \left\{ k \in \mathbb{Z}, \quad k \equiv \varepsilon[n] \right\}.$$

PROPOSITION 2.9. The Fourier series of a regular rotor is given by

$$(2.40) \quad Z(\theta) = \frac{n}{\pi} e^{-\frac{i\varepsilon\delta}{2}} \sin\left(\frac{\varepsilon\delta}{2}\right) \sum_{k \in J_\varepsilon} \frac{e^{ikL\theta}}{k}.$$

*Proof.* The function  $\theta \mapsto e^{i\theta} Z(\theta)$  is  $\delta$ -periodic, as we have  $Z(\theta + \delta) = \overline{\omega} Z(\theta)$ . Thus, one has, for a.e.  $\theta \in \mathbb{R}$ ,

$$Z(\theta) e^{i\theta} = \sum_{k \in \mathbb{Z}} c_k e^{ikn\theta},$$

where the Fourier coefficients are given by

$$c_k = \frac{n}{2\pi} \int_0^\delta e^{-i(kn-1)\theta} Z(\theta) d\theta.$$

Using (2.39), we get, for  $k \in \mathbb{Z}$ ,

$$c_k = \frac{i}{kn-1} (e^{-i(kn-1)\tau} - 1) \sum_{0 \leq j \leq s} \omega^{\varepsilon j} e^{-i(kn-1)j\tau}.$$

The previous sum can be easily computed, and we get  $c_0 = 0$  and

$$c_k \neq 0 \iff \omega^\varepsilon e^{-i(kn-1)\tau} = 1,$$

because  $\tau = \frac{\delta}{L}$ . For  $\varepsilon = 1$ , one has

$$\omega^\varepsilon e^{-i(kn-1)\tau} = 1 \iff \exists j \in \mathbb{Z}, \quad kn-1 = (jn+1)L.$$

For  $\varepsilon = +1$ , we finally obtain

$$c_k = \frac{n}{\pi(jn+1)} e^{-i\frac{\delta}{2}} \sin\left(\frac{\delta}{2}\right).$$

For  $\varepsilon = -1$ , a similar computation yields

$$c_k = -\frac{n}{\pi(jn-1)} e^{i\frac{\delta}{2}} \sin\left(\frac{\delta}{2}\right).$$

This gives (2.40).  $\square$

The Fourier series of  $Z$  can also be written as

$$Z(\theta) = \frac{n}{\pi} e^{-i\varepsilon\frac{\delta}{2}} \sin\left(\frac{\varepsilon\delta}{2}\right) \sum_{j \in \mathbb{Z}} \frac{e^{i((mnj-\varepsilon j+\varepsilon m)n-1)\theta}}{jn+\varepsilon}.$$

The first series of rotors obtained for  $\varepsilon = +1$  will be called  $O_n^{mn-1}$ , and the second series obtained for  $\varepsilon = -1$  will be called  $O_n^{mn+1}$  (see [10], [21]). For  $n = 4$ , the two families  $O_4^{4m-1}$  and  $O_4^{4m+1}$  describe the odd Reuleaux polygons (see [9]). A Reuleaux polygon consists of the intersection of  $N$  circles of radii 1 ( $N$  is odd) and whose centers are the vertices of an  $N$ -gon of side 1. An analogous geometrical description of  $O_n^{ln\pm 1}$  can be found in [16].

PROPOSITION 2.10. *Let  $K$  be a rotor and  $Z$  its complex radius of curvature. If  $Z$  is given by (2.39), then the area of  $K$  becomes*

$$(2.41) \quad \mathcal{A}(K) = \pi r^2 - \frac{r^2 n^2}{2\pi} \tan^2 \left( \frac{\delta}{2} \right) \sum_{j \in \mathbb{Z}} \frac{1}{(jn+1)^2 ((mn-\varepsilon)^2 (jn+1)^2 - 1)}.$$

*Proof.* By (2.30), we have

$$\mathcal{A}(K) = \pi r^2 + \frac{n}{4\sigma^2} \int_0^\delta \overline{Z}(\theta) W(\theta) d\theta,$$

where  $W$  is in  $\Gamma$  and satisfies  $W + \ddot{W} = Z$ . By (2.40), the function  $W$  is given by

$$W(\theta) = -\frac{n}{\pi} e^{-i\varepsilon \frac{\delta}{2}} \sum_{k \in J_\varepsilon} \frac{e^{ikL\theta}}{k(k^2 L^2 - 1)}.$$

Applying the Parseval equality yields (2.41).  $\square$

The following proposition has been proved in [10]. It will be useful for proving Goldberg's conjecture (see section 4). We give a short proof using the expression of the area of a rotor given by (2.41).

PROPOSITION 2.11. *In the class of the regular rotors  $O_n^{mn\pm 1}$ , the one of minimal area is  $O_n^{n-1}$  obtained for  $m = 1$  and  $\varepsilon = +1$ . Its Fourier series is given by*

$$(2.42) \quad Z(\theta) = \frac{n}{\pi} e^{-i\frac{\delta}{2}} \sin \left( \frac{\delta}{2} \right) \sum_{j \in \mathbb{Z}} \frac{e^{i(((n-1)j+1)n-1)\theta}}{jn+1}.$$

*Proof.* The area of a rotor  $K$  described by  $Z \in \mathcal{Z}$  is an increasing function of  $m \in \mathbb{N}^*$  by (2.41). Thus the minimum in the class of regular rotors is obtained for  $m = 1$ . The minimum between  $O_n^{n-1}$  and  $O_n^{n+1}$  is clearly  $O_n^{n-1}$ .  $\square$

It is easy to see that  $O_n^{n-1}$  is invariant with respect to the action of the dihedral group of order  $2(n-1)$ ,  $D_{n-1}$ . For example, the Reuleaux triangle is invariant with respect to the group  $D_3$  and the  $\Delta$ -biangle is invariant with respect to the group  $D_2$ . Anyway, it seems difficult to prove that a minimizer of problem (2.36) has these symmetries.

### 3. The minimization problem as an optimal control problem.

**3.1. First consequences of the PMP.** In the case of the sets of constant width ( $n = 4$ ), one can deal with one control on the interval  $[0, \pi]$  because the functional to minimize is given by (2.23) (see [14]). The optimal control problem in the general case ( $n \geq 3$ ) requires a sharper analysis here because we have to deal with a control  $(U, V) \in \mathbb{R}^2$  on  $[0, \delta]$  as  $\gamma \neq 0$ .

Let us consider the polygon  $\mathcal{P}'_n$  which corresponds to the initial polygon  $\mathcal{P}_n$  by a homotheticity of ratio  $\lambda = \frac{1}{2 \sin(\frac{\delta}{2})}$  and a rotation of angle  $\alpha = \frac{\pi}{2} + \frac{\delta}{2}$ . Hence, the vertices of the polygon  $\mathcal{P}'_n$  are the points of coordinates  $(\omega^j)_{0 \leq j \leq n-1}$ . We consider

the differential system (harmonic oscillator) on the interval  $[0, \delta]$  described by the equations

$$(3.1) \quad \begin{cases} \dot{X}_1 = X_2, \\ \dot{X}_2 = -X_1 + U, \\ \dot{X}_3 = X_4, \\ \dot{X}_4 = -X_3 + V, \end{cases}$$

where the control  $(U, V)$  takes its values within the polygon  $\mathcal{P}'_n$ . As the vector  $(X_1, X_3)$  satisfies the boundary conditions given by (2.31), the PMP will lead to transversality conditions. Notice that the initial and final states are not fixed, but they are linked by (2.31).

By the linearity of (3.1), the problem (2.36) is clearly equivalent to minimizing (2.30), where  $(X_1, X_2, X_3, X_4)$  satisfies (2.31) and (3.1) and the control  $(U, V)$  takes its values within the polygon  $\mathcal{P}'_n$ . We have thus reformulated the initial shape optimization problem into an optimal control problem:

$$(3.2) \quad \min \left\{ \int_0^\delta U X_1 + V X_3, (U, V) \in \mathcal{P}'_n, (X_1, X_2, X_3, X_4) \text{ satisfies (2.31) and (3.1)} \right\}.$$

DEFINITION 3.1. We denote by  $X = (X_1, X_2, X_3, X_4) \in \mathbb{R}^4$  the state variable and  $q = (q_1, q_2, q_3, q_4) \in \mathbb{R}^4$  the dual variable. The Hamiltonian of the system  $H := H(X, q, U, V, p_0)$  is given by

$$(3.3) \quad H = q_1 X_2 + q_2 (-X_1 + U) + q_3 X_4 + q_4 (-X_3 + V) + p_0 (U X_1 + V X_3),$$

where  $p_0 \in \mathbb{R}$ .

We first prove the existence of an optimal control of (3.2).

THEOREM 3.1. There exists an optimal control for problem (3.2).

*Proof.* There exists an admissible trajectory of (3.2) corresponding to  $Z = 0$ ; hence, the set of admissible trajectories is nonempty. The existence of an optimal control will follow from an application of Filippov's theorem (see [1] or [31, p. 98]). First, we check that the trajectories are uniformly bounded. Indeed, the set of admissible controls is compact, and by linearity of (3.1), we obtain a uniform bound by Gronwall's lemma. Second, given  $(X_1, X_2, X_3, X_4) \in \mathbb{R}^4$ , the set defined by

$$\left\{ (X_1 U + X_3 V, X_2, -X_1 + U, X_4, -X_3 + V), (U, V) \in \mathcal{P}'_n \right\}$$

is clearly convex. By Filippov's theorem (see [31]), we get the result.  $\square$

By the PMP, there exists a map  $X : [0, \delta] \rightarrow \mathbb{R}^4$  absolutely continuous, a map  $q : [0, \delta] \rightarrow \mathbb{R}^4$  absolutely continuous, a constant  $p_0 \leq 0$ , and an optimal control  $Z(\theta) = (U(\theta), V(\theta))$  satisfying the equations

$$(3.4a) \quad \dot{X} = \frac{\partial H}{\partial q},$$

$$(3.4b) \quad \dot{q} = -\frac{\partial H}{\partial X},$$

and

$$(3.5) \quad \max_{(\tilde{U}, \tilde{V}) \in \mathcal{P}'_n} H(X(\theta), q(\theta), \tilde{U}, \tilde{V}, p_0) = H(X(\theta), q(\theta), U(\theta), V(\theta), p_0).$$

Moreover, the pair  $(p_0, q)$  is nontrivial, and  $q$  satisfies transversality conditions that we will make explicit in the paragraph below.

DEFINITION 3.2. *We will call an extremal trajectory a quadruplet  $(X, q, p_0, Z)$  satisfying (3.4a), (3.4b), (3.5) and such that the pair  $(X, q)$  is absolutely continuous on  $[0, \delta]$ ,  $p_0 \leq 0$ , and  $(p_0, q)$  is nonzero. The control  $Z = (U, V)$  corresponding to an extremal trajectory will be called an extremal control.*

As the system is autonomous, the Hamiltonian of the system is conserved along the extremal trajectories of the system. By (3.4b), the variable  $q$  satisfies the dual system:

$$(3.6) \quad \begin{cases} \dot{q}_1 = q_2 - p_0 U, \\ \dot{q}_2 = -q_1, \\ \dot{q}_3 = q_4 - p_0 V, \\ \dot{q}_4 = -q_3. \end{cases}$$

The system (3.1) can also be written as

$$(3.7) \quad \ddot{W} + W = Z,$$

where

$$W = X_1 + iX_3, \quad Z = U + iV,$$

and from now on, for convenience, we will mainly deal with complex variables. We write the dual variable  $q = (q_1, q_2, q_3, q_4)$  in the following way:

$$(3.8) \quad \Pi = q_2 + iq_4,$$

so that we have

$$(3.9) \quad \dot{\Pi} = -q_1 - iq_3.$$

We get from (3.6)

$$(3.10) \quad \ddot{\Pi} + \Pi = p_0 Z.$$

It follows that  $W$  and  $\Pi$  are of class  $C^{1,1}$  on the interval  $[0, \delta]$ , as the control  $Z$  is bounded. Let us now compute the transversality conditions by using the variables  $(W, \Pi)$ . The vector of  $\mathbb{C}^4$ ,

$$(W(0), \dot{W}(0), W(\delta), \dot{W}(\delta)),$$

takes its values in the subspace  $M$  of  $\mathbb{C}^4$  defined by

$$M := \{(A, B, \bar{\omega}A, \bar{\omega}B), (A, B) \in \mathbb{C}^2\}.$$

The orthogonal of  $M$  in  $\mathbb{C}^4$  (with respect to the canonical scalar product in  $\mathbb{C}^4$ ) is simply

$$M^\perp = \{(A', B', -\bar{\omega}A', -\bar{\omega}B'), (A', B') \in \mathbb{C}^2\}.$$

By the PMP, the vector  $(-q(0), q(\delta)) = (-\Pi(0), -\dot{\Pi}(0), \Pi(\delta), \dot{\Pi}(\delta))$  is in  $M^\perp$  (see [26], [31] for transversality conditions in the periodic case). Hence, we have  $\Pi(\delta) = \overline{\omega}\Pi(0)$  and  $\dot{\Pi}(\delta) = \overline{\omega}\dot{\Pi}(0)$ ; consequently,  $\Pi$  satisfies (2.31), that is, the same boundary conditions as  $W$ . Note that the Hamiltonian can be expressed as follows:

$$(3.11) \quad H = -\Re(W\overline{\Pi}) - \Re(\dot{W}\overline{\dot{\Pi}}) + \Re((p_0W + \Pi)\overline{Z}).$$

By (3.8) and (3.9), the scalar product in  $\mathbb{C}^2$  between  $W$  and  $\Pi$  is given by

$$(3.12) \quad \langle W, \Pi \rangle := \sum_{1 \leq i \leq 4} q_i X_i = -\Re(W\overline{\Pi}) + \Re(\dot{W}\overline{\dot{\Pi}}).$$

We now simplify the system (3.4a)–(3.4b) by expressing the dual variable  $\Pi$  as a function of the state variable  $W$ . This corresponds to a reduction of the number of degrees of freedom of the system (3.4a)–(3.4b).

LEMMA 3.1. *Let  $W$  be an extremal trajectory of the system and  $\Pi = q_2 + iq_4$  its dual variable. Then there exists  $A \in \mathbb{C}$  such that the function  $\Pi - p_0W$  is of the form*

$$\Pi(\theta) - p_0W(\theta) = Ae^{-i\theta}, \quad \theta \in [0, \delta].$$

*Proof.* We have by (3.7) and (3.10)

$$\ddot{\Pi} + \Pi = p_0(U + iV) = p_0Z = p_0(\ddot{W} + W),$$

and, consequently, the function  $y = \Pi - p_0W$  satisfies  $\ddot{y} + y = 0$ . There exist two constants  $(A, B) \in \mathbb{C}^2$  such that, for all  $\theta \in [0, \delta]$ , we have

$$(3.13) \quad \Pi(\theta) - p_0W(\theta) = Ae^{-i\theta} + Be^{i\theta}.$$

Let us prove that  $B = 0$ . For  $\theta = 0$  and  $\theta = \delta$ , we get

$$\Pi(0) - p_0W(0) = A + B, \quad \Pi(\delta) - p_0W(\delta) = A\overline{\omega} + B\omega.$$

But, as  $(W, \Pi)$  belong to  $\Gamma$ , we have by the transversality conditions

$$\Pi(\delta) - p_0W(\delta) = \overline{\omega}\Pi(0) - p_0\overline{\omega}W(0) = A\overline{\omega} + B\overline{\omega}.$$

Thus, we conclude that  $B = 0$ .  $\square$

We now show that an extremal trajectory is not abnormal.

LEMMA 3.2. *Let  $(X, q, p_0, Z)$  be an extremal trajectory. Then the constant  $p_0$  is strictly negative.*

*Proof.* Let us assume that  $p_0 = 0$ . As the point  $(0, 0)$  belongs to  $\mathcal{P}'_n$ , we get by the PMP the following: for almost  $\theta \in [0, \delta]$ ,

$$q_2(\theta)U(\theta) + q_4(\theta)V(\theta) \geq 0.$$

Consequently,

$$\int_0^\delta (q_2(\theta)U(\theta) + q_4(\theta)V(\theta))d\theta \geq 0.$$

But, we have

$$\int_0^\delta (q_2(\theta)U(\theta) + q_4(\theta)V(\theta))dt = \int_0^\delta \operatorname{Re}(\overline{\Pi}(\theta)Z(\theta))d\theta,$$

and by the previous lemma and (2.34), we have

$$\int_0^\delta \bar{\Pi} Z = \int_0^\delta \bar{A} e^{i\theta} Z(\theta) d\theta = 0.$$

Hence, the function  $\Re(\Pi Z)$  must be zero on the interval  $[0, \delta]$ . If  $\Pi$  is not zero, then the extremal control associated with this trajectory is orthogonal to  $\Pi$ . This contradicts (3.5) by choosing a control  $\tilde{Z} \in \mathcal{P}'_n$  such that  $\Re(\Pi \tilde{Z}) > 0$ . Hence,  $\Pi$  must be 0 everywhere. This is not possible because by the PMP, the pair  $(\Pi, p_0)$  is not zero.  $\square$

In the following, we take  $p_0 = -1$  for any extremal trajectory of the system. Let  $(W, \Pi, Z)$  be an extremal trajectory defined by  $\frac{\partial H}{\partial U} = \frac{\partial H}{\partial V} = 0$ ; that is, we have  $\Pi = W$ . As  $p_0 = -1$ , we get by Lemma 3.1

$$W(\theta) = \frac{A}{2} e^{-i\theta}, \quad \theta \in [0, \delta].$$

Such an extremal trajectory represents the disc which maximizes the area, and this case can be excluded.

LEMMA 3.3. *Let  $W$  be an extremal trajectory of the system and  $\Pi$  its dual variable. Then there exists an extremal trajectory of the system,  $W_1$ , with dual variable  $\Pi_1$ , such that*

$$\Pi_1 = -W_1$$

*and such that the functional of both extremals is identical.*

*Proof.* For  $\lambda \in \mathbb{C}$ , we consider the functions  $(W_1, \Pi_1)$  defined on  $[0, \delta]$  by

$$\begin{cases} W_1(\theta) = W(\theta) + \lambda e^{-i\theta}, \\ \Pi_1(\theta) = \Pi(\theta) + \lambda e^{-i\theta}. \end{cases}$$

We have

$$\ddot{W}_1 + W_1 = Z, \quad \ddot{\Pi}_1 + \Pi_1 = -Z.$$

We can easily check that  $W_1$  and  $\Pi_1$  satisfy (2.31). By (2.34), the functional remains unchanged:

$$\int_0^\delta \Re(Z \bar{W}_1) = \int_0^\delta \Re(Z \bar{W}).$$

Hence,  $(W_1, \Pi_1)$  is also an optimal trajectory. Recall that the Hamiltonian along this trajectory is defined by

$$H_1 = -\Re(W_1 \bar{\Pi}_1) - \Re(W'_1 \bar{\Pi}'_1) + \Re((\Pi_1 - W_1) \bar{Z}).$$

Using Lemma 3.1, we have  $\Pi = -W + A e^{-i\theta}$ , and by a computation, we get

$$H_1 = H + 2\Re(A \bar{\lambda}) + 2|\lambda|^2,$$

where  $H$  is given by (3.11). This shows that the PMP (3.5) gives the same extremal control for  $(W, \Pi)$  and for  $(W_1, \Pi_1)$ , as both Hamiltonian are equal up to a constant. Finally, we have

$$\Pi_1 + W_1 = (A + 2\lambda) e^{-i\theta},$$

and by taking  $\lambda$  such that  $A = -2\lambda$ , we get the lemma.  $\square$

From now on, we consider extremal solutions  $(W, Z)$  of the system such that the dual variable  $\Pi$  satisfies  $\Pi = -W$  (by Lemma 3.3). To simplify, we will say that  $W$  is an extremal trajectory of the system if  $\Pi = -W$  and if it satisfies the PMP. The Hamiltonian of the system is constant along such an extremal and can be written using (3.11):

$$(3.14) \quad H = |W|^2 + |\dot{W}|^2 - 2\Re(W \cdot \bar{Z}) = |W - Z|^2 + |\dot{W}|^2 - |Z|^2.$$

*Remark 3.1.* By (3.14), and by using (3.5), we get  $H \geq 0$  along an extremal trajectory.

**3.2. Computation of the extremal control.** We now examine in more detail the consequences of the PMP to describe the extremal trajectories. Let us recall the definition of a switching point.

**DEFINITION 3.3.** Let  $Z = (U, V)$  be an extremal control of problem (3.2). A point  $\tau \in ]0, \delta[$  is called a switching point if, for every  $\varepsilon > 0$  such that  $[\tau - \varepsilon, \tau + \varepsilon] \subset ]0, \delta[$ , the control  $Z$  is nonconstant on  $[\tau - \varepsilon, \tau + \varepsilon]$ .

To restrict the class of extremal trajectories, we prove step by step the following:

- An extremal is bang-bang, and the associated control takes its values on the vertices of  $\mathcal{P}'_n$  (Lemma 3.4).
- An extremal control takes its values regularly on the vertices of  $\mathcal{P}'_n$  (Theorem 3.2).
- The number of switching points of an extremal control is finite (Theorem 3.3).
- The number of switching points of an extremal control is prescribed (Theorem 3.4).
- The distance between two consecutive switching points is constant (Proposition 4.1).

We first prove two lemmas which will be useful in proving Theorems 3.2 and 3.3.

**LEMMA 3.4.** Let  $W$  be an extremal trajectory of the system. Then the extremal control takes its values on the vertices of  $\mathcal{P}'_n$ .

*Proof.* First, we show that the extremal control takes its values on the vertices of  $\mathcal{P}'_n$ . By (3.5) and (3.14), the extremal control is a solution of the maximization problem

$$(3.15) \quad \max_{z \in \mathcal{P}'_n} \phi(z),$$

where  $\phi$  is defined on  $\mathcal{P}'_n$  by  $\phi(z) := -2\Re(\bar{z}W(\theta))$  and  $\theta \in [0, \delta]$  is fixed. Let  $z_0$  be a point where the maximum in (3.15) is obtained.

If  $W(\theta) = 0$ , then the maximum in (3.15) can be taken arbitrarily in  $\mathcal{P}'_n$  and, in particular, on a vertex of  $\mathcal{P}'_n$ . Let us now assume that  $W(\theta) \neq 0$ . The maximum of  $\phi$  is necessarily on the boundary of  $\mathcal{P}'_n$  because  $\nabla\phi(z_0) \neq 0$ . Hence,  $z_0$  is of the form  $z_0 = t_0\omega^j + (1 - t_0)\omega^{j+1}$ , where  $t_0 \in [0, 1]$  and  $0 \leq j \leq n - 1$ . If  $W(\theta)$  is orthogonal to  $\omega^{j+1} - \omega_j$ , then we can take  $z_0 = \omega^j$  or  $z_0 = \omega^{j+1}$ . If this is not the case, let us define the function  $\psi$  on  $[0, 1]$  by

$$\psi(t) = -2\Re((t\bar{\omega}^j + (1 - t)\bar{\omega}^{j+1})W(\theta)).$$

As we have  $\dot{\psi}(t_0) \neq 0$ , the maximum in (3.15) cannot be reached at  $t_0$ . Hence, the maximum in (3.15) is reached on a vertex of  $\mathcal{P}'_n$ , and this proves the lemma.  $\square$

LEMMA 3.5. *Let  $W$  be an extremal trajectory of the system and  $\tau_j$ ,  $j \in \mathbb{N}$ , a switching point of the extremal control  $Z$  such that  $Z(\tau_j^-) = \omega^{k_j}$  and  $Z(\tau_j^+) = \omega^{k_{j+1}}$  with  $(k_j, k_{j+1}) \in \mathbb{N}^2$ . Then there exists  $t_j \in \mathbb{R}$  such that*

$$(3.16) \quad W(\tau_j) = t_j \omega^{\frac{k_j + k_{j+1}}{2}}.$$

*Proof.* The Hamiltonian is constant along an extremal trajectory, and the functions  $\theta \mapsto |W(\theta)|^2$  and  $\theta \mapsto |W'(\theta)|^2$  are continuous. Hence, the function  $\theta \mapsto \Re(W(\theta)\overline{Z(\theta)})$  is continuous, and at a switching point  $\tau_j$ , we get

$$\Re(W(\tau_j)\overline{\omega^{k_j}}) = \Re(W(\tau_j)\overline{\omega^{k_{j+1}}}).$$

Geometrically speaking, the vector  $W(\tau_j)$  is orthogonal to the segment  $[\omega^{k_j}, \omega^{k_{j+1}}]$ ; hence it takes the form given by (3.16).  $\square$

By Lemma 3.4, an extremal trajectory is bang-bang: the extremal control associated with this trajectory takes the extremal values of the convex polygon  $\mathcal{P}'_n$ . We now show that the extremal control goes all over the vertices  $\omega^j$  clockwise or counterclockwise.

THEOREM 3.2. *Let  $W$  be an extremal trajectory of the system. There exists  $\varepsilon \in \{\pm 1\}$  such that if  $\tau_j$  is a switching point with  $Z(\tau_j^-) = \omega^{k_j}$  and  $Z(\tau_j^+) = \omega^{k_{j+1}}$ , then*

$$k_{j+1} - k_j = \varepsilon.$$

*Proof.* By Lemma 3.5, we have at a switching point  $\tau_j$

$$W(\tau_j) = t_j \omega^{\frac{k_j + k_{j+1}}{2}},$$

where  $t_j \in \mathbb{R}$ . Geometrically speaking, the vector  $W(\tau_j)$  is parallel to the median of the segment  $[\omega^{k_j}, \omega^{k_{j+1}}]$ , which is a side or a diagonal of the polygon  $\mathcal{P}'_n$ . The line  $\Delta$  directed by  $W(\tau_j)$  contains 0, 1, or 2 vertices of  $\mathcal{P}'_n$ .

First, assume that  $\Delta$  does not contain any vertex of  $\mathcal{P}'_n$ . If  $|k_j - k_{j+1}| \neq 1$ , there exists another vertex  $\omega^s := (U_s, V_s)$  of  $\mathcal{P}'_n$ , which is different from  $\omega^j$  and  $\omega^{j+1}$ , and such that

$$-2\Re(\overline{W(\tau_j)}\omega^s) > -2\Re(\overline{W(\tau_j)}\omega^j)$$

or

$$-2\Re(\overline{W(\tau_j)}\omega^s) > -2\Re(\overline{W(\tau_j)}\omega^{j+1}).$$

This means that the scalar product between  $W(\tau_j)$  and  $\omega^s$  is less than the scalar product between  $W(\tau_j)$  and  $\omega^{k_j}$  or  $\omega^{k_{j+1}}$ . Assume, for example, that the first inequality is satisfied by  $\omega^s$ . We obtain by (3.14)

$$H(W(\tau_j), \Pi(\tau_j), U_s, V_s, p_0) > H(W(\tau_j), \Pi(\tau_j), U(\tau_j^-), V(\tau_j^-), p_0).$$

This contradicts (3.5), that is, the maximality of the Hamiltonian along an extremal.

Now assume that  $\Delta$  contains only one vertex of  $\mathcal{P}'_n$  (in this case  $n$  is necessarily even) and  $|k_j - k_{j+1}| \neq 1$ . The segment  $[\omega^{k_j}, \omega^{k_{j+1}}]$  is parallel to a side  $[\omega^r, \omega^{r+1}]$  of  $\mathcal{P}'_n$ . Let us call  $\omega^l$  the vertex of  $\mathcal{P}'_n$  opposite to  $[\omega^r, \omega^{r+1}]$ . As in the previous case, we get a contradiction in (3.5). Indeed, one has

$$H(W(\tau_j), \Pi(\tau_j), U_s, V_s, p_0) > H(W(\tau_j), \Pi(\tau_j), U(\tau_j^-), V(\tau_j^-), p_0),$$

with  $s$  equal to  $r$ ,  $r + 1$ , or  $l$  and with  $\omega^s := (U_s, V_s)$ .

If  $\Delta$  contains two vertices  $\omega^s$  and  $\omega^l$  of  $\mathcal{P}_n$  and if  $|k_j - k_{j+1}| \neq 1$ , we get a similar contradiction in (3.5) by considering the vertex  $\omega^s$  or  $\omega^l$ .

We have thus proved that  $|k_{j+1} - k_j| = 1$  for any switching point  $\tau_j$ . To conclude the proof of the theorem, we have to show that the extremal control does not contain a subsequence of the form  $\{\omega^p, \omega^{p+1}, \omega^p, \dots\}$ , where  $p \in \mathbb{N}$ . Let us assume that an extremal control  $Z$  takes the form

$$Z(\theta) = \mathbb{1}_{[\tau_1, \tau_2[} + \omega \mathbb{1}_{[\tau_2, \tau_3[} + \mathbb{1}_{[\tau_3, \tau_4[} + \tilde{Z}(\theta), \quad \theta \in [0, \delta],$$

where  $\tau_1 < \tau_2 < \tau_3 < \tau_4$  and  $(\tau_2, \tau_3)$  are two consecutive switching points, and  $\tilde{Z}$  is the restriction of  $Z$  on  $[0, \delta] \setminus [\tau_1, \tau_4]$ :

$$\tilde{Z} = Z|_{[0, \delta] \setminus [\tau_1, \tau_4]}.$$

It is always possible to consider this case by multiplying  $Z$  by  $\overline{\omega}^p$ , since it does not change the extremality of  $(W, Z)$ . As  $Z$  is switching from 1 to  $\omega$  for  $\theta = \tau_2$ , we have by Lemma 3.5  $W(\tau_2) = t_2 \omega^{\frac{1}{2}}$ ,  $t_2 \in \mathbb{R}$ . Notice that by (3.14), we necessarily have  $t_1 < 0$ . Indeed, by the maximality condition, the value of the Hamiltonian on the extremal is greater than the value of the Hamiltonian obtained with  $(\tilde{U}, \tilde{V}) = (0, 0)$ . At the switching point  $\tau_3$ , we similarly have  $W(\tau_3) = t_3 \omega^{\frac{1}{2}}$ , where  $t_3 < 0$ . Hence, the vectors  $W(\tau_2)$  and  $W(\tau_3)$  are parallel. For  $\theta \in [\tau_2, \tau_3]$ , the function  $\theta \mapsto W(\theta)$  describes an arc of an ellipse whose center is the point  $\omega$ . Indeed, by (3.7), we have

$$W(\theta) = \omega + A_2 e^{i\theta} + B_2 e^{-i\theta}, \quad (A_2, B_2) \in \mathbb{C}^2.$$

Hence, the vectors  $W(\tau_2)$  and  $W(\tau_3)$  are equal or opposite because the line directed by  $W(\tau_2)$  crosses the ellipse in at most two points. But, as we have  $W(\tau_2) \cdot W(\tau_3) = t_2 t_3 > 0$ , we must have

$$W(\tau_2) = W(\tau_3).$$

This condition will bring a contradiction. Let  $\mathcal{E}$  be the ellipse of center  $\omega$  on which the function  $W$  takes its values for  $\theta \in [\tau_1, \tau_2]$ .

*First case.*  $\mathcal{E}$  is not degenerated. The function  $W$  satisfies  $W(\tau_2) = W(\tau_3)$ . As  $W$  is of class  $C^1$ , it must go all over the ellipse, and this is possible only if  $\tau_2 = \tau_1 + 2k\pi$ ,  $k \in \mathbb{N}^*$ . As  $(\tau_2, \tau_3)$  belong to the interval  $[0, \delta]$ , we get a contradiction.

*Second case.*  $\mathcal{E}$  is a segment which contains  $W(\tau_2)$  and  $\omega$ . For  $\theta \in [\tau_2, \tau_3]$ ,  $W(\theta)$  takes its values within this segment. For  $\theta \in [\tau_1, \tau_2]$ , the function  $\theta \mapsto W(\theta)$  takes its values within an ellipse  $\mathcal{E}'$  whose center is the point  $(1, 0)$ . By Lemma 3.5,  $W$  satisfies, for  $\theta = \tau_2$ ,  $W(\tau_2) = t_2 \omega^{\frac{1}{2}}$ . Hence, the function  $W$  cannot be of class  $C^1$  at the point  $\theta = \tau_2$ , since  $W(\theta)$  is parallel to  $W(\tau_2)$  for  $\theta \in [\tau_2, \tau_3]$ . We thus get a contradiction.

We have thus proved that for any switching point  $\tau_j$ ,  $k_{j+1} - k_j = \varepsilon$ , where  $\varepsilon = \pm 1$  is fixed by the rotation of  $Z$  clockwise or counterclockwise. This concludes the proof of the theorem.  $\square$

We now show that an extremal control switches a finite number of times on the interval  $[0, \delta]$ .

**THEOREM 3.3.** *Let  $W$  be an extremal trajectory of the system. Then there exists a subdivision  $(\tau_j)_{0 \leq j \leq r}$  of  $[0, \delta]$  with  $r \in \mathbb{N}^*$  such that  $\tau_0 = 0$  and  $\tau_{r+1} = \delta$  and such that on each  $[\tau_j, \tau_{j+1}[$  the extremal control  $(U, V)$  satisfies  $Z = \omega^{\varepsilon j + h}$ , where  $h \in \mathbb{N}$ ,  $\varepsilon = \pm 1$ .*

*Proof.* Let us prove that the number of switching points is finite on the interval  $[0, \delta]$ . Assume that there exists a sequence  $(\tau_j)$  of switching points in  $[0, \delta]$  that converges to a point  $\tau \in [0, \delta]$ . We will show that

$$(3.17) \quad W(\tau) = 0, \quad \dot{W}(\tau) = 0.$$

Assume that  $Z$  rotates clockwise, that is,  $\varepsilon = \pm 1$ . We have by Lemma 3.5

$$W(\tau_j) = t_j \omega^{j+\frac{1}{2}}.$$

As  $W$  is of class  $C^{1,1}$  on  $[0, \pi]$ , the sequence  $(t_j)$  is bounded. Consequently (up to a subsequence), we can assume that the sequence  $(t_j)$  converges to a real  $t \in \mathbb{R}$ . Assume that  $t \neq 0$ ; then there exists  $j_0 \in \mathbb{N}$  such that, for  $j \geq j_0$ , we have  $t_j \neq 0$ . Hence,  $\frac{W(\tau_j)}{W(\tau_{j+1})}$  converges to 1 and

$$\frac{W(\tau_j)}{W(\tau_{j+1})} = \frac{t_j}{t_{j+1}} \bar{\omega},$$

which converges to  $\bar{\omega}$ . Thus  $t = 0$  and  $W(\tau) = 0$ . Again, we get a contradiction if we assume that  $\dot{W}(\tau) \neq 0$ . This shows (3.17). The Hamiltonian  $H$  along this extremal is 0. By (3.5) and by (3.14), the value of  $H$  is greater than the value of  $H$  for  $(\tilde{U}, \tilde{V}) = (0, 0)$ . It follows that  $W \equiv 0$  and  $Z \equiv 0$ . This extremal represents the disc, which is not a minimizer. An extremal trajectory then has a finite number of switching points. Finally, if we consider  $\omega^h$ ,  $h \in \mathbb{N}$ , the initial value of the control, and  $\varepsilon = \pm 1$ , the rotation clockwise or counterclockwise of the control, then we get the theorem.  $\square$

We now compute the exact number of switching points of an extremal. We prove the following result.

**THEOREM 3.4.** *Let  $W$  be an extremal trajectory and  $Z$  the extremal control. Then we have*

$$(3.18) \quad Z = \sum_{0 \leq j \leq s} \omega^{\varepsilon j + h} \mathbb{1}_{[\tau_j, \tau_{j+1}[},$$

where  $\varepsilon \in \{\pm 1\}$ ,  $h \in \mathbb{N}$ , and  $\tau_0 = 0 < \tau_1 < \dots < \tau_s < \tau_{s+1} = \delta$ . Moreover, the number  $L$  of switching points of  $Z$  in the interval  $[0, \delta]$  is given by

$$(3.19) \quad L = s + 1 = ln - \varepsilon, \quad l \in \mathbb{N}^*.$$

*Proof.* By Theorem 3.3, an extremal control  $Z$  takes the values  $(\omega^{\varepsilon j + h})_{0 \leq j \leq n-1}$  with  $h \in \mathbb{N}$  and  $\varepsilon = \pm 1$  on a finite subdivision of  $[0, \delta]$  denoted by  $(\tau_j)_{0 \leq j \leq s+1}$  with  $\tau_0 = 0$  and  $\tau_{s+1} = \delta$ . Without loss of generality, we can assume that  $\varepsilon = +1$ . If  $Z = \omega^h$  for  $\theta = 0^+$ , by performing a rotation of the control, that is, by changing  $Z$  into  $Z\bar{\omega}^h$ , we can always assume that  $Z(0^+) = 1$ . By extending the function  $W$  to  $\mathbb{R}$  by the relation  $W(\theta + \delta) = \bar{\omega}W(\theta)$  (recall that  $W$  is in  $\Gamma$ ), we can assume that 0 is a switching point. The function  $Z$  is now given by

$$Z = \sum_{0 \leq j \leq s} \omega^j \mathbb{1}_{[\tau_j, \tau_{j+1}[},$$

with  $\tau_0 = 0 < \tau_1 < \dots < \tau_s < \tau_{s+1} = \delta$ . As  $Z$  is in  $\mathcal{Z}$ , we must have  $Z(\delta^+) = \bar{\omega}Z(0^+) = \bar{\omega}$ . On the interval  $[\tau_s, \delta]$ , we have  $Z = \omega^s$ . Consequently, the point  $\delta$  is

a switching point, and we must have  $\omega^{s+1} = \bar{\omega}$ . Thus,  $s+1$  is of the form  $s+1 = -1+ln$ ,  $l \in \mathbb{N}^*$ . The number of switching points in the interval  $[0, \delta]$  is  $s+1$ , as  $\delta$  is not considered as a switching point of this interval. We have proved the theorem in the case where  $\varepsilon = +1$ . When the control  $Z$  satisfies  $Z = \bar{\omega}^j$ , the proof is the same, and we must have  $\bar{\omega}^{s+1} = \bar{\omega}$ . Consequently,  $s$  is given by  $s = ln$ ,  $l \in \mathbb{N}^*$ . In this case the number of switching points is  $s+1 = ln+1$ . This ends the proof of the theorem.  $\square$

In the case of regular rotors  $O_n^{ln \pm 1}$ , the switching points are of the form  $j\tau$ ,  $j = 1, \dots, s = ln \pm 1 - 1$  with  $\tau = \frac{\delta}{s+1}$ , and the associated control is given by (2.39). In the next section, we show that the distance between two consecutive switching points  $\tau_j$  and  $\tau_{j+1}$  of an extremal is constant. This will prove that a minimizer is necessarily a regular rotor.

An extremal  $(W, Z)$  given by (3.18) satisfies on each interval  $[\tau_j, \tau_{j+1}]$

$$(3.20) \quad W(\theta) = A_j e^{i\theta} + B_j e^{-i\theta} + \omega^{\varepsilon j + h}.$$

A simple computation using (3.14) shows that the Hamiltonian along this trajectory is

$$(3.21) \quad H = 2|A_j|^2 + 2|B_j|^2 - 1 \quad \forall 0 \leq j \leq s,$$

and, as  $H$  is constant, we have

$$|A_j|^2 + |B_j|^2 \equiv cst \quad \forall 0 \leq j \leq s.$$

**4. Conserved quantities along the extremal trajectories.** In this section we prove by an extension of Noether's theorem in optimal control theory that the angular momentum is conserved along an extremal trajectory. Combining the two conserved quantities (Hamiltonian and angular momentum) we will show that extremal trajectories describe regular rotors. We use the results of Torres (see [29], [30]) in order to prove the conservation of the angular momentum.

**4.1. Conservation of the angular momentum.** Let  $M$  be the function defined on the interval  $[0, \delta]$  by

$$M(\theta) = \Im((\overline{W}(\theta) - \overline{Z}(\theta))\dot{W}(\theta)), \quad \theta \in [0, \delta],$$

where  $(W(\theta), Z(\theta))$  is an admissible trajectory of problem (3.2). This quantity is usually called the *angular momentum* in mechanics (cross product between the position and the velocity). If  $(W(\theta), Z(\theta))$  is an extremal trajectory of (3.2) given by (3.18), we have, for  $0 \leq j \leq s$ , and  $\theta \in [\tau_j, \tau_{j+1}[$ ,

$$M(\theta) = \Im((\overline{W}(\theta) - \overline{\omega}^{\varepsilon j + h})\dot{W}(\theta)).$$

By differentiating, we get

$$\dot{M}(\theta) = 0 \quad \forall \theta \in [\tau_j, \tau_{j+1}[.$$

This proves that the function  $M(\theta)$  is piecewise constant on each  $[\tau_j, \tau_{j+1}]$ . We now show a stronger result.

**THEOREM 4.1.** *Along an extremal trajectory of (3.2), the quantity  $M(\theta)$  is constant:*

$$\forall \theta \in [0, \delta], \quad \dot{M}(\theta) = 0.$$

*Proof.* Let us consider the  $C^1$  transformation  $h^\alpha : \mathbb{C} \times \mathbb{C} \rightarrow \mathbb{C}$ ,  $\alpha \in \mathbb{R}_+$ , defined by

$$(4.1) \quad h^\alpha(W, Z) = e^{i\alpha}(W - Z) + Z.$$

Geometrically speaking,  $h^\alpha(W, Z)$  is the image of  $W - Z$  by the rotation of angle  $\alpha$  and whose center is  $Z$ . For any  $(W, Z) \in \mathbb{C}^2$ , we have  $h^0(W, Z) = W$ . Now, given an extremal trajectory  $(W(\theta), Z(\theta))$  of (3.2), we denote by  $W^\alpha$  the image of  $(W(\theta), Z(\theta))$  by  $h^\alpha$ . We then have on  $[0, \delta]$

$$\ddot{W}^\alpha + W^\alpha = Z.$$

Consequently,  $W^\alpha$  satisfies the same equation as  $W$ , and the extremal control associated with  $W^\alpha$  is  $Z$ . Let  $L : \mathbb{C} \times \mathbb{C}$  be the  $C^1$  map defined by

$$L(W, Z) = \Re(W\overline{Z}).$$

If  $(W(\theta), Z(\theta))$  is an extremal trajectory, we have

$$L(W^\alpha, Z) = \cos(\alpha)L(W, Z) - \sin(\alpha)\Im(W\overline{Z}) + 1 - \cos(\alpha).$$

Considering the  $C^1$  map  $F : \mathbb{C} \times \mathbb{C} \times \mathbb{R}_+ \rightarrow \mathbb{R}$  defined by

$$F(W, \dot{W}, \alpha) = -\sin(\alpha)\Im(W\overline{\dot{W}}),$$

we then have along an extremal trajectory  $(W(\theta), Z(\theta))$

$$L(W^\alpha(\theta), Z(\theta)) = \cos(\alpha)L(W(\theta), Z(\theta)) + \frac{d}{d\theta}F(W(\theta), \dot{W}(\theta), \alpha) + 1 - \cos(\alpha) \quad \forall \theta \in [0, \delta].$$

By (3.12), the scalar product between the state variable  $W$  and the dual variable  $\Pi$  is

$$\langle W, \Pi \rangle = -\Re(W\overline{\Pi}) + \Re(\dot{W}\overline{\Pi}).$$

Now we are in position to derive consequences of the invariance theorem (see [29]). Let  $(W(\theta), Z(\theta))$  be an extremal trajectory of (3.2),  $H$  the Hamiltonian along this trajectory, and  $\Pi(\theta)$  the dual variable. We then have

$$(4.2) \quad p_0 \frac{\partial F(W(\theta), Z(\theta), \alpha)}{\partial \alpha} \Big|_{\alpha=0} + \left\langle \frac{\partial W^\alpha(\theta)}{\partial \alpha} \Big|_{\alpha=0}, \Pi(\theta) \right\rangle - H \equiv cst$$

for all  $\theta \in [0, \delta]$ . But, we have

$$p_0 \frac{\partial F(W(\theta), Z(\theta), \alpha)}{\partial \alpha} \Big|_{\alpha=0} = -\Im(\overline{W}(\theta)\dot{W}(\theta)) \quad \forall \theta \in [0, \delta],$$

and by Lemma 3.3, we can take  $\Pi = -W$  so that

$$\left\langle \frac{\partial W^\alpha(\theta)}{\partial \alpha} \Big|_{\alpha=0}, \Pi(\theta) \right\rangle = \Im(\overline{\dot{W}}(\theta)Z(\theta)) + 2\Im(\dot{W}(\theta)\overline{W}(\theta)) \quad \forall \theta \in [0, \delta].$$

As the Hamiltonian is constant along an extremal trajectory, we get by (4.2)

$$\Im((\overline{W} - \overline{Z})\dot{W}) \equiv cst.$$

This ends the proof of the theorem.  $\square$

#### 4.2. Conserved quantities and equidistance of the switching points.

Thanks to the two conserved quantities along a Pontryagin extremal, we are now in position to prove the equidistance of the switching points. We first show the following proposition.

**PROPOSITION 4.1.** *For an extremal trajectory given by (3.18), we have for  $0 \leq j \leq s$ ,  $\tau_{j+1} - \tau_j = \tau_1 - \tau_0$ .*

*Proof.* A simple computation shows that for an extremal given by (3.18) we have on each  $[\tau_j, \tau_{j+1}[$ ,  $0 \leq j \leq s$ ,

$$(4.3) \quad M(\theta) = |A_j|^2 - |B_j|^2, \quad \theta \in [\tau_j, \tau_{j+1}[.$$

Thus, by (3.21) and Theorem 4.1, we get, for  $0 \leq j \leq s$ ,

$$(4.4) \quad \begin{cases} |A_j| = |A_0|, \\ |B_j| = |B_0|. \end{cases}$$

Since  $W$  is of class  $C^1$  at each switching point  $\tau_j$ , the coefficients  $A_j$  and  $B_j$ ,  $1 \leq j \leq s$ , are given by

$$(4.5) \quad \begin{cases} A_j = A_{j-1} + \frac{1}{2}(\omega^{j-1} - \omega^j)e^{-i\tau_j}, \\ B_j = B_{j-1} + \frac{1}{2}(\omega^{j-1} - \omega^j)e^{i\tau_j}. \end{cases}$$

Combining (4.4) and (4.5), we get

$$(4.6) \quad \Re(A_j \overline{A_{j-1}}) \equiv cst, \quad 1 \leq j \leq s.$$

Geometrically speaking, the complex  $(A_j)_{0 \leq j \leq s}$  lie on a circle whose center is the origin and whose radius is  $|A_0|$ , and  $A_{j+1}$  is the image of  $A_j$  by a rotation of a fixed angle by (4.6). In terms of the switching point  $(\tau_j)_{1 \leq j \leq s}$ , the phase between  $A_{j+1} - A_j$  and  $A_j - A_{j-1}$  is  $\delta - (\tau_{j+1} - \tau_j)$  by (4.5). But using (4.4) and (4.6), the phase between these two complex numbers is the same as the phase between  $A_j$  and  $A_{j-1}$ . By (4.6), the phase between  $A_{j+1} - A_j$  and  $A_j - A_{j-1}$  is constant, which ends the proof of the proposition.  $\square$

**COROLLARY 4.1.** *Let  $W$  be an extremal trajectory of the system and  $Z$  the extremal control. Then the corresponding rotor is in the class  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*}$ , and the extremal control  $Z$  is given by (2.39).*

*Proof.* This is a consequence of the previous proposition, as two consecutive switching points of an extremal are equidistant. The corresponding rotor given by (3.18) satisfies  $\tau_{j+1} - \tau_j \equiv cst$ , and it is necessarily an element of  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*}$ .  $\square$

By Proposition 2.11, the rotor of minimal area in the class  $O_n^{ln\pm 1}$  is  $O_n^{n-1}$  (with the least number of arcs). As the rotor of minimal area necessarily belongs to this class (by the PMP), it is  $O_n^{n-1}$ . By (2.39) the optimal control  $Z_{min}$  corresponding to  $O_n^{n-1}$  is obtained for  $s+1 = n-1$  and is given by

$$(4.7) \quad Z_{min} = \sum_{0 \leq j \leq n-2} \omega^j \mathbb{1}_{[j \frac{\delta}{n-1}, (j+1) \frac{\delta}{n-1}[}.$$

This proves Goldberg's conjecture (Theorem 1.1). Note that there is no necessity of verifying the optimality of the extremal trajectories corresponding to  $(O_n^{ln\pm 1})_{l \in \mathbb{N}^*} \setminus \{O_n^{n-1}\}$ , as  $O_n^{n-1}$  is of minimal area in this class.

TABLE 1  
Values of the  $r_j$  for  $n = 3, 4, 5, 6$ .

$n$	$r_0$	$r_1$	$r_2$	$r_3$	$r_4$	$r_5$
3	0	$3r$	0			
4	0	$2r$	$2r$	0		
5	0	$r_1$	$r_2$	$r_1$	0	
6	0	$r$	$2r$	$2r$	$r$	0

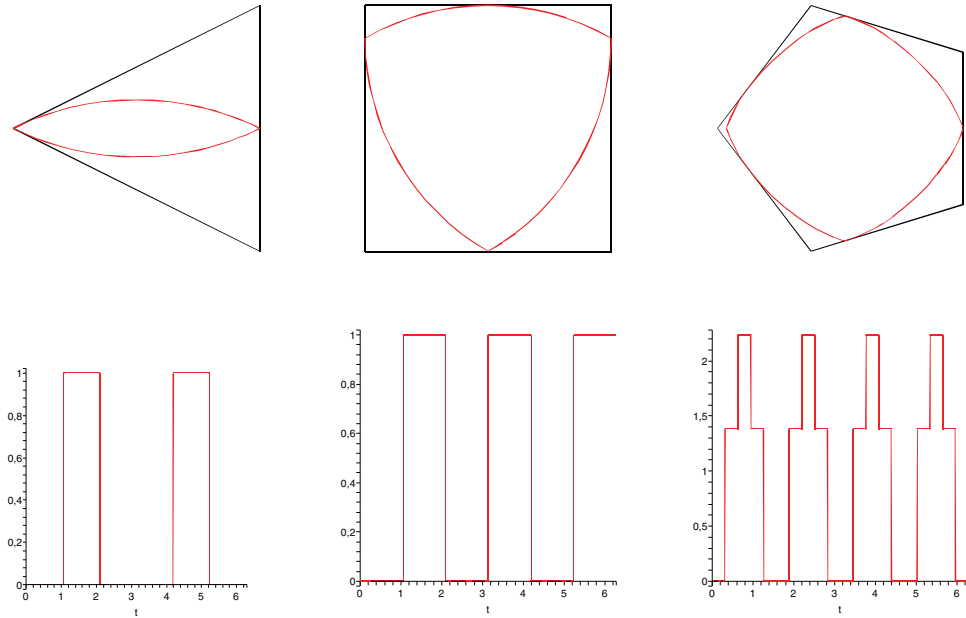

FIG. 3. The minimizers in the cases  $n = 3$  ( $\Delta$ -biangle),  $n = 4$  (Reuleaux triangle), and  $n = 5$  ( $O_5^4$ ) and their respective radii of curvature on the interval  $[0, 2\pi]$ .

Geometrically speaking, if we come back to the initial parameterization of a rotor by its support function  $p$ , the rotor  $O_n^{n-1}$  is the union of arcs of circles of radii  $r_j$ :

$$\begin{aligned} r_j &= \frac{r}{\cos\left(\frac{\delta}{2}\right)} \left( \cos\left(\frac{\delta}{2}\right) - \cos\left(\left(j + \frac{1}{2}\right)\delta\right) \right) \\ &= \frac{r}{\cos\left(\frac{\delta}{2}\right)} \Re(\omega^{1/2} - \omega^{j+1/2}), \quad j = 0, \dots, n-1. \end{aligned}$$

These values of the radii of curvature are precisely equal to the distances of the diagonals of the  $n$ -gon from the parallel sides (see [15], [16]), and the sectors are all equal to  $\frac{2\pi}{n(n-1)}$ , as the switching points are equidistant. In Table 1, we give the different values of the radii  $r_j$  for  $n = 3, 4, 5, 6$ . For  $n = 5$ , there are two different radii  $r_1 < r_2$ , and  $r$  denotes the radius of the inscribed circle. If  $n$  is even, there are exactly  $\frac{n-2}{2}$  values of the  $r_j$ , and if  $n$  is odd, there are exactly  $\frac{n-1}{2}$  values of the  $r_j$ . By (2.39), the radius of curvature of the boundary of  $O_n^{n-1}$  is  $\frac{2\pi}{n-1}$ -periodic (see [10]). We have represented in Figure 3 the minimizers of the area for  $n = 3$ ,  $n = 4$ , and  $n = 5$  and their respective radii of curvature.

## COMPOSITE SYSTEMS WITH UNCERTAIN COUPLINGS OF FIXED STRUCTURE: SCALED RICCATI EQUATIONS AND THE PROBLEM OF QUADRATIC STABILITY\*

DIEDERICH HINRICHSSEN<sup>†</sup> AND ANTHONY J. PRITCHARD<sup>‡</sup>

*Tony Pritchard, my friend and close collaborator of many years, died suddenly from a heart attack on the 12th of August 2007 while on holidays with his family. Some weeks before his death, we had agreed that after a final revision he would submit this paper to SICON as the corresponding author.—Diederich Hinrichsen.*

**Abstract.** We consider large scale systems consisting of a finite number of separate uncertain subsystems which interact via uncertain couplings of arbitrarily prescribed structure. The couplings are viewed as structured perturbations of the block-diagonal system representing the collection of the separate nominal subsystems (the “nominal system”). We define spectral value sets and stability radii for these time-invariant structured perturbations and derive formulas for their computation. Scaled Riccati equations are introduced to obtain explicit formulas for the stability radii with respect to time-varying and possibly nonlinear perturbations of the given structure. From these we derive necessary and sufficient conditions under which the stability radii with respect to time-invariant and time-varying perturbations are equal. These results are obtained by constructing joint quadratic Liapunov functions of optimal robustness. With their help we prove necessary and sufficient conditions for quadratic stability and sufficient conditions for the validity of a generalized Aizerman conjecture.

**Key words.** interconnected system, Riccati equation, structured perturbation, spectral value set, stability radius, time-varying perturbation, quadratic stability, Aizerman conjecture

**1. Introduction.** Composite systems play a role in many different areas of application. They arise naturally where large scale systems are composed of a finite number of separate interacting subsystems. Examples of such systems are traffic, biochemical [2], and power networks [6]; compartmental models in physiology and ecology [15]; and systems of cooperative robotic vehicles [10]; see also [3], [20]. Often in these composite systems the interconnection structure is fixed, but the magnitudes of the couplings between the subsystems are uncertain and may even change in time or be dependent on current states. The *interconnection structure* specifies for each subsystem  $\Sigma_i$  the set of subsystems  $\Sigma_j$  which can directly influence it. A structure of this type may be described by a graph, and tools from graph theory have been used by several authors to analyze such systems; see, e.g., [8], [22]. Due to economic costs, reliability, and availability of information flows, etc. there will also, in general, be structural constraints imposed on the control of composite systems. For instance, the subsystems may be separated geographically and for each one only local measurements may be available for feedback control. This leads to problems of *decentralized control* which have been studied extensively in the literature; see, e.g., [3], [21]. As a result of such structural constraints closed loop interconnected systems will also, in general, not be fully coupled but have a fixed interconnection structure.

<sup>‡</sup>Former address: Institute of Mathematics, University of Warwick, Coventry, UK.

In this paper we do not deal with control aspects, but our results may provide an aid to the design of decentralized feedback controls. We analyze stability properties of composite systems consisting of (possibly uncertain) subsystems interacting via uncertain couplings of a fixed structure. The couplings are viewed as structured perturbations of the block-diagonal system representing the collection of the disconnected nominal subsystems. This block-diagonal system will be regarded as the “nominal system”. We assume that the individual nominal subsystems are stable or have been stabilized (e.g., via decentralized control). Then a basic question is whether the overall system remains stable provided the uncertainties (possibly time-varying) are bounded in norm by some given realistic uncertainty level.

There is extensive literature on stability properties of composite systems. Various tools such as input-output methods [24], [3], passivity methods, scalar and vector Liapunov functions [17], [20], and (dynamic) graphs [22] have been used to obtain sufficient stability criteria. Our aim is to develop *nonconservative* results on the stability of uncertain composite systems with norm bounded couplings and an arbitrary fixed interconnection structure. If the interconnection structure is a priori known, then the application of robustness estimates for unstructured perturbations will, in general, lead to conservative results. On the other hand, it is well known from  $\mu$ -analysis that tight robustness margins for structured perturbations are not easily obtained.

In a first step we determine the *spectral value sets* [12] associated with uncertain composite systems of the above type, i.e., the set of eigenvalues of all the composite systems which are obtained from the block-diagonal nominal one by adding perturbations which preserve the prescribed interaction structure and are bounded in an appropriate norm by a given uncertainty level  $\delta > 0$ . We then derive computable formula for the *stability radius* [12] of the nominal system with respect to these (complex time-invariant) perturbations. Similar results, but with respect to different perturbation norms, have been obtained in the recent paper [16], and it has been shown there that for the special case of *one-dimensional* subsystems these results are closely related to classical spectral inclusion theorems of linear algebra due to Gershgorin, Brauer, and Brualdi. In fact, they can be used to show that the inclusion regions of Brauer and Brualdi (see [14], [23]) are tight for the corresponding perturbation structures.

In [16] *constant* variations of the coupling parameters were considered. However, time-varying couplings may often occur in practice. The notion of *connective stability* was introduced by Siljak [20] to determine conditions under which a composite system remains stable despite time-varying perturbations whereby subsystems are disconnected and again connected during the evolution of the system. It may also occur that some of the interconnected subsystems are nonlinear or time-varying, but for simplicity they have been modelled approximately by time-invariant ones. Then the “real” subsystems can be viewed as nonlinear or time-varying perturbations of the time-invariant nominal subsystems. In this paper we will focus on the establishment of nonconservative stability results for uncertain composite systems with such *time-varying and/or state-dependent* uncertainties, both in the couplings and in the individual subsystems.

In general, the determination of the stability radius with respect to time-varying structured perturbations is a difficult problem [7], [26]. But if no perturbation structure is prescribed and arbitrary complex matrix perturbations are allowed (“complex full block case”), then the situation is quite simple. It is known that in the complex full block case the stability radii with respect to time-invariant and time-varying perturbations coincide [12, section 5.6]. This result (which does *not* carry over to *real*

perturbations) has been obtained in [11] by characterizing the complex stability radius via a parametrized Riccati equation. By means of the Riccati equation a quadratic Liapunov function of maximal robustness can be constructed. The construction of such Liapunov functions for *structured* perturbations has been stated as an open problem in [16, Remark 3.2].

In this paper we will show that for uncertain block-diagonal systems with irreducible perturbation structures quadratic Liapunov functions of maximal robustness can be constructed by applying a scaling technique known from  $\mu$ -analysis. Via scaling, new parametrized algebraic Riccati equations are obtained whose Hermitian solutions provide us with quadratic Liapunov functions of approximately optimal robustness (optimality is achieved if the perturbation structure is irreducible). By means of these quadratic Liapunov functions one can derive computable formulas for the stability radius of uncertain block-diagonal systems with respect to *time-varying* perturbations of the prescribed structure. In general, the stability radii with respect to time-varying and time-invariant perturbations are different. We will derive necessary and sufficient conditions for them to be equal.

The robust stability problem with respect to time-varying perturbations is closely related to the more general stability problem for linear differential inclusions of the form  $\dot{x}(t) \in Ax(t)$ , where  $A$  is a compact set of  $n \times n$  matrices. Molchanov and Pyatnitskij [18] have shown that such a differential inclusion is asymptotically stable, if and only if there exists a joint convex positive homogeneous strict Liapunov function for all the time-invariant systems  $\dot{x} = Ax$ ,  $A \in A$ . This result shows a fundamental difference between robustness issues for time-varying and for time-invariant perturbations. In general, the stability of a set of time-invariant systems  $\dot{x} = Ax$ ,  $A \in A$ , does not guarantee the existence of a joint Liapunov function for all these systems. In contrast, if all the *time-varying* systems  $\dot{x}(t) = A(t)x(t)$ ,  $A(\cdot) : \mathbb{R}_+ \rightarrow A$  measurable, are uniformly asymptotically stable then, by Molchanov and Pyatnitskij's theorem, such a joint Liapunov function always exists.

A more specific problem is to characterize those sets of time-invariant linear systems for which a joint *quadratic* Liapunov function can be found. This is the problem of *quadratic stability*; see [5]. It is well known that for uncertain systems with full block perturbations, quadratic stability is equivalent to asymptotic stability; see [11]. Moreover, it is known that this equivalence does not, in general, hold for *structured perturbations* [19]. To the best of our knowledge, there are no general quadratic stability criteria available for structured perturbations besides reformulations of the problem in terms of linear matrix inequalities; see [1]. In this paper we consider block-diagonal systems under bounded perturbations of arbitrarily prescribed structure and derive explicit necessary and sufficient criteria for the quadratic stability of these systems. To check these criteria one only has to determine the spectral radius of a certain matrix; see Theorem 7.7.

The organization of this paper is as follows. In the next section we introduce the concepts of *spectral value set* and *stability radius* and for the special case of *full block* perturbations recall some characterizations of them via transfer functions and parametrized algebraic Riccati equations. The section concludes with the proof of a stability theorem for nonlinear time-varying full block perturbations. After fixing, in section 3, the terminology and notations for the analysis of composite systems, computable formulae for the corresponding spectral value sets and stability radii are presented in section 4. To derive these formulae, we apply the Perron–Frobenius theory of nonnegative matrices. We do not employ tools from  $\mu$ -analysis, but briefly express our results in terms of  $\mu$ -values. In section 5, we introduce scaled parametrized alge-

braic Riccati equations and show how they can be used to construct joint quadratic Liapunov functions of approximately optimal robustness (optimal robustness if the underlying perturbation structure is irreducible). The scaled Riccati equations introduced in section 5 will be the key tool for proving the main results of this paper. In section 6, we derive a computable formula for the stability radius of a block-diagonal system with respect to *time-varying* parameter perturbations. As a consequence we obtain necessary and sufficient conditions under which the stability radii with respect to time-invariant and time-varying perturbations of the prescribed structure coincide. In section 7, we show that this equality holds if the subsystems are either one-dimensional or positive. We then conclude this paper by applying our results to two classical robustness topics, the problems of *quadratic* and of *absolute* stability.

**2. Preliminaries.** In this section we introduce some basic concepts and fix the notation. The symbols  $\mathbb{N}, \mathbb{R}, \mathbb{R}_+, \mathbb{C}$  denote the sets of positive integers, real numbers, nonnegative real numbers, and complex numbers, respectively. For any  $N \in \mathbb{N}$  we set  $\underline{N} := \{1, 2, \dots, N\}$ . By  $\mathbb{K}^{n \times m}$  we denote the set of  $n$  by  $m$  matrices with entries in  $\mathbb{K}$ , where  $\mathbb{K} = \mathbb{R}$  or  $\mathbb{C}$ . If  $A = (a_{ij}) \in \mathbb{C}^{n \times m}$ , then we define  $|A| := (|a_{ij}|)$ , and for real matrices  $A = (a_{ij}), B = (b_{ij}) \in \mathbb{R}^{n \times m}$  we write  $A \leq B$  if  $a_{ij} \leq b_{ij}$  for all  $i \in \underline{n}, j \in \underline{m}$ . If  $A$  is square, then  $\sigma(A)$ ,  $\rho(A) = \mathbb{C} \setminus \sigma(A)$ , and  $\alpha(A) = \max\{\operatorname{Re} \lambda; \lambda \in \sigma(A)\}$  denote its *spectrum*, *resolvent set*, and *spectral abscissa*, respectively. By  $\mathbb{L}_{n,l,q}$  we denote the set of triples of matrices  $(A, B, C)$  with  $A \in \mathbb{C}^{n \times n}, B \in \mathbb{C}^{n \times l}, C \in \mathbb{C}^{q \times n}$ ,  $n, l, q \in \mathbb{N}$ . The open left half-plane is denoted by  $\mathbb{C}_- = \{s \in \mathbb{C}; \operatorname{Re} s < 0\}$ , and  $A \in \mathbb{C}^{n \times n}$  is called *Hurwitz stable* if  $\sigma(A) \subset \mathbb{C}_-$ . We use the conventions

$$(1) \quad 0^{-1} = \infty, \quad \infty^{-1} = 0, \quad \inf \emptyset = \infty.$$

In the following definitions we suppose that  $(A, B, C) \in \mathbb{L}_{n,l,q}$  and  $\Delta \subset \mathbb{K}^{l \times q}$  is a  $\mathbb{K}$ -linear subspace provided with a norm  $\|\cdot\|_\Delta$ . For a more detailed account of the definitions and some results presented in this section, see [12]. We consider perturbations of the form

$$(2) \quad A \rightsquigarrow A_\Delta = A + B\Delta C, \quad \Delta \in \Delta.$$

DEFINITION 2.1. The  $\mu$ -value of a matrix  $M \in \mathbb{C}^{q \times l}$  (with respect to the normed perturbation space  $(\Delta, \|\cdot\|_\Delta)$ ) is defined by

$$(3) \quad \mu_\Delta(M) := [\inf\{\|\Delta\|_\Delta; \Delta \in \Delta, \det(I_l - \Delta M)\}]^{-1}.$$

DEFINITION 2.2. Given a system  $(A, B, C) \in \mathbb{L}_{n,l,q}$  and the perturbation space  $(\Delta, \|\cdot\|_\Delta)$ , the spectral value set of  $A$  of level  $\delta > 0$ , with respect to perturbations of the form (2), is the following subset of the complex plane:

$$(4) \quad \sigma_\Delta(A, B, C; \delta) := \bigcup_{\Delta \in \Delta, \|\Delta\|_\Delta < \delta} \sigma(A + B\Delta C).$$

DEFINITION 2.3. Given a system  $(A, B, C) \in \mathbb{L}_{n,l,q}$  and the perturbation space  $(\Delta, \|\cdot\|_\Delta)$ , the stability radius of  $A$  with respect to perturbations of the form (2) is defined by

$$(5) \quad r_\Delta(A, B, C) = \inf\{\|\Delta\|_\Delta; \Delta \in \Delta, \sigma(A + B\Delta C) \not\subset \mathbb{C}_-\}.$$

It is easily seen that the infimum in (5) is in fact a minimum if  $r_{\Delta}(A, B, C)$  is finite. In this case the stability radius is the norm of a smallest perturbation in  $\Delta$  which destabilizes  $A$ .  $r_{\Delta}(A, B, C) = 0$  if and only if  $\sigma(A) \not\subset \mathbb{C}_-$ .  $r_{\Delta}(A, B, C) = \infty$  if and only if  $\sigma(A + B\Delta C) \subset \mathbb{C}_-$  for all  $\Delta \in \Delta$ .

Spectral value sets and stability radii can be characterized via  $\mu$ -values as follows; see [12].

PROPOSITION 2.4. *Let  $(A, B, C) \in \mathbb{L}_{n,l,q}$  be a given system and  $G(s) = C(sI_n - A)^{-1}B$  the associated transfer function. Then*

$$(6) \quad \sigma_{\Delta}(A, B, C; \delta) = \sigma(A) \cup \{s \in \rho(A); \mu_{\Delta}(G(s)) > \delta^{-1}\}, \quad \delta > 0;$$

$$(7) \quad r_{\Delta}(A, B, C) = \left( \sup_{\omega \in \mathbb{R}} \mu_{\Delta}(G(i\omega)) \right)^{-1} \quad \text{if } \sigma(A) \subset \mathbb{C}_-.$$

Specializing to *block-diagonal* and *full block* perturbations, further results are known if the perturbation norm  $\|\cdot\|_{\Delta}$  is an operator norm. Let  $\mathbb{C}^l, \mathbb{C}^q$  be endowed with arbitrary norms and  $\mathbb{C}^{l \times q}, \mathbb{C}^{q \times l}$  with the induced operator norms  $\|\cdot\|_{\mathcal{L}(\mathbb{C}^q, \mathbb{C}^l)}$  and  $\|\cdot\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)}$ . In the case where  $\mathbb{C}^l, \mathbb{C}^q$  are provided with 2-norms, we write  $\|\cdot\|_2$  for vector norms and the corresponding operator norms are denoted by  $\|\cdot\|_{2,2}$ . Suppose  $\Delta \subset \mathbb{C}^{l \times q}$  is the vector space of block-diagonal perturbations of the following form provided with the corresponding operator norm:

$$(8) \quad \Delta = \{\text{diag}(\Delta_1, \dots, \Delta_N); \Delta_i \in \mathbb{C}^{l_i \times q_i}, i \in \underline{N}\}, \quad \|\cdot\|_{\Delta} = \|\cdot\|_{\mathcal{L}(\mathbb{C}^q, \mathbb{C}^l)},$$

where  $N \geq 1$ ,  $l_i \geq 1$ ,  $q_i \geq 1$ ,  $i \in \underline{N}$  are given such that  $\sum_{i=1}^N l_i = l$ ,  $\sum_{i=1}^N q_i = q$ . Then estimates of the associated  $\mu$ -values, spectral value sets, and stability radii can be obtained by the following scaling method. For any scaling vector  $\gamma = (\gamma_1, \dots, \gamma_N)$ , where  $\gamma_i > 0$ ,  $i \in \underline{N}$ , we set  $L_{\gamma} = \text{diag}(\gamma_1 I_{l_1}, \dots, \gamma_N I_{l_N})$  and  $R_{\gamma} = \text{diag}(\gamma_1 I_{q_1}, \dots, \gamma_N I_{q_N})$ . Then  $L_{\gamma} \Delta R_{\gamma}^{-1} = \Delta$  for all  $\Delta \in \Delta$  and this fact implies (see [12, section 4.4]) that

$$(9) \quad \mu_{\Delta}(G) \leq \|R_{\gamma} G L_{\gamma}^{-1}\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)}, \quad G \in \mathbb{C}^{q \times l}.$$

As a consequence we have

$$(10) \quad \sigma_{\Delta}(A, B, C; \delta) \subset \sigma(A) \cup \{s \in \rho(A); \|R_{\gamma} G(s) L_{\gamma}^{-1}\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)} > \delta^{-1}\};$$

$$(11) \quad r_{\Delta}(A, B, C) \geq \left( \sup_{\omega \in \mathbb{R}} \|R_{\gamma} G(i\omega) L_{\gamma}^{-1}\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)} \right)^{-1} \quad \text{if } \sigma(A) \subset \mathbb{C}_-.$$

In the *full block case* where  $\Delta = \mathbb{K}^{l \times q}$  precise formulae are obtained without any scaling. For this case the spectral value sets and stability radii are denoted by  $\sigma_{\mathbb{K}}(A, B, C; \delta)$  and  $r_{\mathbb{K}}(A, B, C)$ , respectively, and are called the *complex* and *real* spectral value sets and stability radii according to whether  $\mathbb{K} = \mathbb{C}$  or  $\mathbb{K} = \mathbb{R}$ . For the complex case ( $\Delta = \mathbb{C}^{l \times q}$ ,  $\|\cdot\|_{\Delta} = \|\cdot\|_{\mathcal{L}(\mathbb{C}^q, \mathbb{C}^l)}$ ), one has  $\mu_{\mathbb{C}^{l \times q}}(G(s)) = \|G(s)\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)}$ , and therefore Proposition 2.4 implies

$$(12) \quad \sigma_{\mathbb{C}}(A, B, C; \delta) = \sigma(A) \cup \{s \in \rho(A); \|G(s)\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)} > \delta^{-1}\};$$

$$(13) \quad r_{\mathbb{C}}(A, B, C) = \left( \max_{\omega \in \mathbb{R}} \|G(i\omega)\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)} \right)^{-1} \quad \text{if } \sigma(A) \subset \mathbb{C}_-.$$

The formula for the real stability radius  $r_{\mathbb{R}}(A, B, C)$  (where  $A, B, C$  are supposed to be *real*) is more complicated; see [12, section 5.3.3].

In the following we will assume that both  $\mathbb{C}^l$  and  $\mathbb{C}^q$  are provided with the 2-norm  $\|\cdot\|_2$  so that the norms  $\|\cdot\|_{\mathcal{L}(\mathbb{C}^q, \mathbb{C}^l)}, \|\cdot\|_{\mathcal{L}(\mathbb{C}^l, \mathbb{C}^q)}$  are both spectral norms.<sup>1</sup> Then

$$(14) \quad r_{\mathbb{C}}(A, B, C) = \left( \max_{\omega \in \mathbb{R}} \|G(i\omega)\|_{2,2} \right)^{-1} = \|G(\cdot)\|_{H^\infty}^{-1} \quad \text{if } \sigma(A) \subset \mathbb{C}_-.$$

Throughout the rest of this paper we will reserve the notation  $r_{\mathbb{C}}(A, B, C)$  for the complex stability radius with respect to the spectral norm on  $\mathbb{C}^{l \times q}$ . This stability radius can be characterized in terms of the following parametrized algebraic Riccati equation:

$$(15) \quad PA + A^*P + \rho^2 C^*C + PBB^*P = 0,$$

where  $\rho \geq 0$ . We denote the real vector space of all the Hermitian matrices in  $\mathbb{C}^{n \times n}$  by  $\mathcal{H}_n(\mathbb{C})$  and the usual order relation on  $\mathcal{H}_n(\mathbb{C})$  by  $\preceq$ . The following results have been proved in [11].<sup>2</sup>

**THEOREM 2.5.** *Suppose that  $(A, B, C) \in \mathbb{L}_{n,l,q}$  is a given system with  $\sigma(A) \subset \mathbb{C}_-$ , and  $G(s) = C(sI_n - A)^{-1}B$  is the associated transfer matrix. Then (15) has a Hermitian solution if and only if  $\rho \leq r_{\mathbb{C}} := r_{\mathbb{C}}(A, B, C)$ . Moreover, the following statements are equivalent:*

- (i) *There exists a (unique) solution  $P_\rho \in \mathcal{H}_n(\mathbb{C})$  of (15) such that  $\sigma(A + BB^*P_\rho) \subset \mathbb{C}_-$ .*
- (ii)  *$\rho < r_{\mathbb{C}}$ .*

*If  $\rho = r_{\mathbb{C}}$ , then (15) has a unique solution  $P_{r_{\mathbb{C}}} \in \mathcal{H}_n(\mathbb{C})$  satisfying  $\sigma(A + BB^*P_{r_{\mathbb{C}}}) \subset \mathbb{C}_-$ . For each  $\rho \leq r_{\mathbb{C}}$ ,  $P_\rho$  is the smallest Hermitian solution of (15). If  $P$  is any Hermitian solution of (15), then  $P \succeq 0$ .  $P$  is positive definite if  $(A, C)$  is observable. If  $P$  is positive definite, then  $V_\rho(x) = \langle x, Px \rangle$  is a joint quadratic Liapunov function for all perturbed systems*

$$(16) \quad \dot{x} = A_\Delta x = (A + B\Delta C)x, \quad \Delta \in \mathbb{C}^{l \times q}, \quad \|\Delta\|_{2,2} \leq \rho.$$

Since there is no joint Liapunov function for all perturbed systems  $\dot{x} = A_\Delta x$  with  $\|\Delta\|_{2,2} < \rho$  if  $\rho > r_{\mathbb{C}}(A, B, C)$ , we may call the quadratic Liapunov function  $V_{r_{\mathbb{C}}}(x)$  (in case  $P \succ 0$ ) one of *maximal robustness* for the perturbation space  $\Delta = \mathbb{C}^{l \times q}$  endowed with the spectral norm.

We conclude this section with a theorem which extends Proposition 5.2 in [11] and will be useful for the treatment of time-varying nonlinear perturbations in section 6. Since the proof in [11] works only for time-invariant perturbations, we will give a full proof.

Let  $(A, B, C) \in \mathbb{L}_{n,l,q}$  be a given system with  $\sigma(A) \subset \mathbb{C}_-$ . We suppose that  $\Omega$  is an open neighborhood of 0 in  $\mathbb{C}^n$  and consider nonlinear time-varying perturbations of  $\dot{x} = Ax$  of “output feedback form”,

$$(17) \quad \dot{x} = Ax + B\Delta(x, t)y, \quad y = Cx, \quad \text{where } \Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega).$$

Here  $\Delta_{nt}(\Omega)$  is the vector space of all *bounded* matrix functions  $\Delta(\cdot, \cdot) : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{C}^{l \times q}$  with the *Carathéodory properties*; i.e.,  $\Delta(x, \cdot) : \mathbb{R}_+ \rightarrow \mathbb{C}^{l \times q}$  is measurable for each

<sup>1</sup>For any Hermitian matrix  $H$  we denote by  $\lambda_{\max}(H)$  the maximal eigenvalue of  $H$ . For any matrix  $M \in \mathbb{C}^{h \times k}$ ,  $h, k \in \mathbb{N}$ , we denote by  $\|M\|_{2,2} = [\lambda_{\max}(M^*M)]^{1/2} = [\lambda_{\max}(MM^*)]^{1/2}$  the spectral norm of  $M$ .

<sup>2</sup>Note that  $P$  is a solution of (15) if and only if  $-P$  satisfies (ARE) $_\rho$  in [11].

$x \in \Omega$ ,  $\Delta(\cdot, t) : \Omega \rightarrow \mathbb{C}^{l \times q}$  is continuous for each  $t \in \mathbb{R}_+$ , and for each compact product set  $K \times I \subset \Omega \times \mathbb{R}_+$  there exists an integrable  $k(\cdot) : I \rightarrow \mathbb{R}_+$  such that

$$\|\Delta(x, t)Cx - \Delta(\hat{x}, t)C\hat{x}\|_2 \leq k(t)\|x - \hat{x}\|_2, \quad (x, t), (\hat{x}, t) \in K \times I.$$

The norm on  $\Delta_{nt}(\Omega)$  is taken to be

$$(18) \quad \|\Delta(\cdot, \cdot)\| = \sup_{x \in \Omega, t \geq 0} \|\Delta(x, t)\|_{2,2}, \quad \Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega).$$

By Carathéodory's theorem for every  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$ , there exists a unique solution  $x(t) = x(t; t_0, x^0)$  of (17) with  $x(t_0) = x^0$  on some maximal semiopen interval  $[t_0, t_+(t_0, x^0))$ , where  $t_+(t_0, x^0) > t_0$ ; see [12, Theorem 2.1.14]. In the following theorem we will see that  $t_+(t_0, x^0) = \infty$  if  $\|\Delta(\cdot, \cdot)\| \leq r_{\mathbb{C}}(A, B, C)$  and  $x^0$  is sufficiently close to the equilibrium state  $\bar{x} = 0$ . Recall that a quadratic function  $V(x) = \langle x, Px \rangle$  is said to be a *Liapunov function* (respectively, *strict Liapunov function*) for the nonlinear time-varying system  $\dot{x} = Ax + B\Delta(x, t)Cx$  at the origin if  $P \succ 0$  and  $\dot{V}(x, t) \leq 0$  (respectively,  $\sup_{t \geq t_0} \dot{V}(x, t) < 0$  for  $x \neq 0$ ) on some neighborhood of the origin. The existence of a quadratic Liapunov function ensures that the origin is uniformly stable, whereas the existence of a strict quadratic Liapunov function implies uniform asymptotic stability; see [12, Theorem 3.2.17]. Unfortunately, these criteria are not applicable in the present situation where  $P$  is obtained as a solution of the algebraic Riccati equation (15), since the corresponding  $V(\cdot)$  is, in general, neither a strict Liapunov function for the system (17) nor need it be positive definite. Nevertheless, we will see in the following proof that  $V(\cdot)$  can be used to establish asymptotic stability. For simplicity, we call the system (17) *uniformly (asymptotically) stable* if  $\bar{x} = 0$  is a uniformly (asymptotically) stable equilibrium position of the system (17).

**THEOREM 2.6.** *Suppose  $(A, B, C) \in \mathbb{L}_{n,l,q}$  is a given system  $\sigma(A) \subset \mathbb{C}_-$ , and  $\Omega$  is an open neighborhood of 0 in  $\mathbb{C}^n$ . Then we have the following.*

- (i) *The nonlinear system (17) is asymptotically stable for all  $\Delta \in \Delta_{nt}(\Omega)$  satisfying  $\|\Delta(\cdot, \cdot)\| < r_{\mathbb{C}}(A, B, C)$ . Moreover, when this condition is satisfied we have  $x(t; t_0, x^0) \rightarrow 0$  as  $t \rightarrow \infty$  for all  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$  for which  $t_+(t_0, x^0) = \infty$ .*
- (ii) *Suppose  $\rho \leq r_{\mathbb{C}}(A, B, C)$ , and let  $P$  be a Hermitian solution of the algebraic Riccati equation (15). Then  $P \succeq 0$ . If  $\delta > 0$  satisfies  $D_\delta = \{x; x \in \mathbb{C}^n \text{ and } \langle x, Px \rangle < \delta\} \subset \Omega$ , then  $D_\delta$  is a joint domain of attraction of the equilibrium point  $\bar{x} = 0$  for all the systems (17) with  $\Delta \in \Delta_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\| < \rho$ .*
- (iii) *Suppose  $\rho \leq r_{\mathbb{C}}(A, B, C)$  and  $P$  is a Hermitian solution of (15). If  $r < \rho$ , then there exists a constant  $k > 0$  such that the derivative of the quadratic function  $V_\rho(x) = \langle x, Px \rangle$  along trajectories of (17) satisfies  $\dot{V}_\rho(x) \leq -k\|Cx\|^2$ ,  $x \in \Omega$ , for all  $\Delta \in \Delta_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\| \leq r$ . If  $(A, C)$  is observable,  $V_\rho(x)$  is a joint Liapunov function at  $\bar{x} = 0$  for all perturbed systems (87) with  $\Delta \in \Delta_{nt}(\Omega)$  satisfying  $\|\Delta(\cdot, \cdot)\| \leq \rho$ . In particular, (17) is uniformly stable if  $\Delta \in \Delta_{nt}(\Omega)$  and  $\|\Delta(\cdot, \cdot)\| \leq r_{\mathbb{C}}(A, B, C)$ .*

*Proof.* We first prove the third statement. Let  $\rho \leq r_{\mathbb{C}}(A, B, C)$ . Since  $A$  is Hurwitz stable, every Hermitian solution  $P$  of (15) is positive semidefinite. Multiplying (15) from the right by  $x \in \ker P$  and from the left by  $x^*$ , we see that  $\ker P \subset \ker C$ . Let  $x(t) = x(t; t_0, x^0)$ ,  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$ , be an arbitrary solution of (17). The derivative

of the time-invariant quadratic function  $V_\rho(x) = \langle x, Px \rangle$  along this solution is

$$\begin{aligned}
 \dot{V}_\rho(x(t)) &= [\langle (Ax(t) + B\Delta(x(t), t)Cx(t)), Px(t) \rangle \\
 &\quad + \langle x(t), P(Ax(t) + B\Delta(x(t), t)Cx(t)) \rangle] \\
 (19) \quad &= \langle (PA + A^*P)x(t), x(t) \rangle + 2\operatorname{Re} \langle B\Delta(x(t), t)Cx(t), Px(t) \rangle \\
 &= -\rho^2 \|y(t)\|_2^2 - \|B^*Px(t)\|_2^2 + 2\operatorname{Re} \langle \Delta(x(t), t)y(t), B^*Px(t) \rangle \\
 &= -\|\Delta(x(t), t)y(t) - B^*Px(t)\|_2^2 - [\rho^2 \|y(t)\|_2^2 - \|\Delta(x(t), t)y(t)\|_2^2] \\
 &\leq -[\rho^2 \|y(t)\|_2^2 - \|\Delta(x(t), t)y(t)\|_2^2], \quad t \in [t_0, t_+(t_0, x^0)],
 \end{aligned}$$

where  $y(t) = Cx(t)$ . Setting  $k = \rho^2 - r^2$  we obtain  $\dot{V}_\rho(x) \leq -k\|Cx\|^2$ ,  $x \in \Omega$ , for all  $\Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\| \leq r$ . If  $(A, C)$  is observable, then  $P \succ 0$  and so  $V_\rho$  is a time-invariant Liapunov function on  $\Omega$  for all perturbed systems (17) with  $\Delta \in \Delta_{nt}(\Omega)$  satisfying  $\|\Delta(\cdot, \cdot)\| \leq \rho$ . In particular, setting  $\rho = r_{\mathbb{C}}(A, B, C)$ , the system (17) is uniformly stable for all  $\Delta \in \Delta_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\| \leq r_{\mathbb{C}}(A, B, C)$  (see [12, Theorem 3.2.17]). This proves (iii).

We now abandon the observability assumption and prove (i). Suppose that  $\Delta \in \Delta_{nt}(\Omega)$  and  $\|\Delta(\cdot, \cdot)\| < \rho$ . Then

$$(20) \quad \dot{V}_\rho(x(t)) \leq 0, \quad t \in [t_0, t_+(t_0, x^0)], \quad \text{and} \quad \dot{V}_\rho(x(t)) = 0 \Rightarrow y(t) = Cx(t) = 0.$$

Consider the decomposition

$$x(t) = x_1(t) + x_2(t), \quad x_1(t) \in (\ker P)^\perp, \quad x_2(t) \in \ker P, \quad t \in [t_0, t_+(t_0, x^0)].$$

Since there exists  $\alpha > 0$  such that  $\langle x, Px \rangle = \langle x_1, Px_1 \rangle \geq \alpha \|x_1\|_2^2$  for all  $x \in \mathbb{C}^n$ , we have

$$(21) \quad \alpha \|x_1(t)\|_2^2 \leq \langle x_1(t), Px_1(t) \rangle \leq \langle x_1(t_0), Px_1(t_0) \rangle \leq \|P\|_{2,2} \|x_1(t_0)\|_2^2$$

for all  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$  and  $t \in [t_0, t_+(t_0, x^0)]$ . But  $\ker P \subset \ker C$ , so it follows that there exists a constant  $c > 0$ , independent of  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$ , such that

$$(22) \quad \|y(t)\|_2 = \|Cx(t)\|_2 = \|Cx_1(t)\|_2 \leq c \|x_1(t_0)\|_2, \quad t \in [t_0, t_+(t_0, x^0)].$$

Since  $\|e^{At}\| \leq Me^{-\omega t}$  with suitable  $M > 0$ ,  $\omega > 0$ , we have for all  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$

$$\begin{aligned}
 (23) \quad \|x(t)\|_2 &= \|e^{A(t-t_0)}x^0 + \int_{t_0}^t e^{A(t-s)}B\Delta(x(s), s)y(s)ds\|_2 \\
 &\leq Me^{-\omega(t-t_0)}\|x^0\|_2 + (M/\omega)\|B\|_{2,2}\|\Delta(\cdot, \cdot)\| \sup_{t \in [t_0, t_+(t_0, x^0)]} \|y(t)\|_2 \\
 &\leq Me^{-\omega(t-t_0)}\|x^0\|_2 + (M/\omega)\|B\|_{2,2}\|\Delta(\cdot, \cdot)\| c \|x_1(t_0)\|_2, \quad t \in [t_0, t_+(t_0, x^0)].
 \end{aligned}$$

Let  $\varepsilon > 0$  and  $B(0, \varepsilon) = \{x \in \mathbb{C}^n; \|x\|_2 < \varepsilon\}$  be such that the closed ball  $\overline{B(0, \varepsilon)}$  is contained in  $\Omega$ . Then by (23) there exists  $\delta' > 0$  so that

$$x^0 \in B(0, \delta'), \quad t_0 \in \mathbb{R}_+, \quad t \in [t_0, t_+(t_0, x^0)] \implies x(t) = x(t; t_0, x^0) \in B(0, \varepsilon).$$

Hence  $t_+(t_0, x^0) = \infty$  for  $(t_0, x^0) \in \mathbb{R}_+ \times B(0, \delta')$  and the system (17) is uniformly stable.

Now assume that  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$ ,  $t_+(t_0, x^0) = \infty$  and  $y(t) = Cx(t, t_0, x^0)$  does not tend to zero as  $t \rightarrow \infty$ . Then there exist  $\varepsilon_1 > 0$  and a sequence  $t_k \rightarrow \infty$  such that

$\|y(t_k)\|_2 > 2\varepsilon_1$  for  $k \in \mathbb{N}$ . Now  $\|x(t)\|_2$ ,  $t \geq t_0$  is bounded by (23), and so via (17) we see that  $\|\dot{x}(t)\|_2$ ,  $t \geq t_0$ , is also bounded. Hence there exists  $\eta > 0$  such that

$$\|y(t)\|_2 > \varepsilon_1 \quad \text{for } t \in [t_k, t_k + \eta], \quad k \in \mathbb{N}.$$

Let  $\gamma := \rho^2 - \|\Delta(\cdot, \cdot)\|^2 > 0$ . Then (19) implies for all  $k \in \mathbb{N}$

$$\begin{aligned} & V_\rho(x(t_k + \eta)) - V_\rho(x(t_k)) \\ &= \int_{t_k}^{t_k + \eta} \dot{V}_\rho(x(t)) dt \leq -\int_{t_k}^{t_k + \eta} (\rho^2 - \|\Delta(x(t), t)\|^2) \|y(t)\|_2^2 dt \leq -\gamma \eta \varepsilon_1^2. \end{aligned}$$

Since  $V_\rho(x(t))$  is not increasing in  $t$ , this contradicts the fact that  $V_\rho(x(t)) \geq 0$ ,  $t \geq t_0$ . Hence  $\lim_{t \rightarrow \infty} \|y(t)\|_2 = 0$ . Replacing  $t_0$  by a sufficiently large  $t'_0$ ,  $x^0$  by  $x(t'_0)$ , and  $t_+(t_0, x^0)$  by  $\infty$ , the first inequality in (23) becomes

$$\|x(t)\|_2 \leq M e^{-\omega(t-t'_0)} \|x(t'_0)\|_2 + (M/\omega) \|B\|_{2,2} \|\Delta(\cdot, \cdot)\| \sup_{t \in [t'_0, \infty)} \|y(t)\|_2, \quad t \in [t'_0, \infty).$$

We conclude that  $x(t) \rightarrow 0$  as  $t \rightarrow \infty$ . Since  $t_+(t_0, x^0) = \infty$  for all  $x^0 \in B(0, \delta')$ , setting  $\rho = r_{\mathbb{C}}(A, B, C)$  completes the proof of (i).

Now suppose that  $D_\delta = \{x \in \mathbb{C}^n; \langle x, Px \rangle < \delta\} \subset \Omega$  for some  $\delta > 0$  and  $\Delta \in \Delta_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\| < \rho$ . Let  $x^0 \in D_\delta$  and choose  $\delta_1 > 0$  such that  $\langle x^0, Px^0 \rangle < \delta_1 < \delta$ ; then  $\overline{D_{\delta_1}} \subset \Omega$  and  $\overline{D_{\delta_1}}$  is invariant for (17). Hence  $t_+(t_0, x^0) = \infty$ , and so, by (i),  $x(t) \rightarrow 0$  as  $t \rightarrow \infty$ . This proves (ii).  $\square$

*Remark 2.7.* (i) If  $P \succ 0$ , then there will always exist a  $\delta$  such that  $D_\delta \subset \Omega$ . However, this need not be the case if  $\ker P \neq \{0\}$  (e.g., for bounded  $\Omega$ ).

(ii) Suppose that  $\Delta \in \Delta_{nt}(\Omega)$  and there exist  $k > 0$  and a positive semidefinite  $P \in \mathcal{H}_n(\mathbb{C})$  with  $\ker P \subset \ker C$  such that the quadratic function  $V(x) = \langle x, Px \rangle$  satisfies  $\dot{V}(x) \leq -k\|Cx\|^2$  along the solutions of (17). Then by similar arguments as in the previous proof one can show that  $\bar{x} = 0$  is an asymptotically stable equilibrium point of (17).

**3. Composite systems.** Let us introduce some additional notation. In the following,  $\mathbf{q}, \mathbf{l}$  are finite  $N$ -tuples  $\mathbf{l} = (l_1, \dots, l_N)$ ,  $\mathbf{q} = (q_1, \dots, q_N)$ ,  $l_j, q_j, N \in \mathbb{N}$ , and we set  $q = |\mathbf{q}| = \sum_{i=1}^m q_i$ ,  $l = |\mathbf{l}| = \sum_{j=1}^m l_j$ . We denote by  $\mathbb{K}^{l \times \mathbf{q}}$  the set of  $N \times N$  block matrices

$$(24) \quad [\Delta_{ij}] = [\Delta_{ij}]_{i,j \in \underline{N}} = \begin{bmatrix} \Delta_{11} & \cdots & \Delta_{1N} \\ \vdots & & \vdots \\ \Delta_{N1} & \cdots & \Delta_{NN} \end{bmatrix}, \quad \Delta_{ij} \in \mathbb{K}^{l_i \times q_j} \text{ for } (i, j) \in \underline{N} \times \underline{N}.$$

For any positive integer  $k$  we denote by  $\mathbb{K}^{k \times \mathbf{q}}$  the set of all block rows  $[X_1, \dots, X_N]$ ,  $X_j \in \mathbb{K}^{k \times q_j}$ ,  $j \in \underline{N}$ , and by  $\mathbb{K}^{1 \times k}$  the set of block columns  $[Y_1^\top, \dots, Y_N^\top]^\top$ ,  $Y_i \in \mathbb{K}^{l_i \times k}$ ,  $i \in \underline{N}$ . The partitioned vectors in  $\mathbb{K}^{\mathbf{q}} := \mathbb{K}^{\mathbf{q} \times 1}$  are denoted by  $x = (x_i)$ , where  $x_i \in \mathbb{K}^{q_i}$  for  $i \in \underline{N}$ . The block-diagonal matrix with blocks  $\Delta_j \in \mathbb{K}^{l_j \times q_j}$ ,  $j \in \underline{N}$ , is denoted by

$$\Delta := \oplus_{j=1}^N \Delta_j = \text{diag}(\Delta_1, \dots, \Delta_N) = \begin{bmatrix} \Delta_1 & & & 0 \\ & \Delta_2 & & \\ & & \ddots & \\ 0 & & & \Delta_N \end{bmatrix} \in \mathbb{K}^{1 \times \mathbf{q}}.$$

Suppose that  $E \in \mathbb{R}^{N \times N}$  is a given nonnegative matrix with entries  $e_{ij} \geq 0$ , and let  $\mathcal{I} = \{(i, j) \in \underline{N} \times \underline{N}; e_{ij} > 0\}$ . For each  $i \in \underline{N}$  let  $\mathcal{I}_i = \{j \in \underline{N}; e_{ij} > 0\}$  denote the

set of positions of the positive entries of  $E$  in row  $i$ . We say that  $\Delta = (\Delta_{ij}) \in \mathbb{C}^{1 \times \mathbf{q}}$  is of structure  $E$  if  $e_{ij} = 0$  implies  $\Delta_{ij} = 0$ . Let  $\Delta_E \subset \mathbb{C}^{1 \times \mathbf{q}}$  be the vector space of all the block matrices  $\Delta \in \mathbb{C}^{1 \times \mathbf{q}}$  of structure  $E$ .

To describe the perturbations  $A \rightsquigarrow A_\Delta$  in a concise way we will make use of the *Hadamard product* of matrices. Given  $X = (x_{ij}), Y = (y_{ij}) \in \mathbb{C}^{h \times k}$ , where  $h, k$  are positive integers, the *Hadamard product* of  $X$  and  $Y$ , denoted by  $X \circ Y$ , is defined by  $X \circ Y = (x_{ij}y_{ij}) \in \mathbb{C}^{h \times k}$ . For  $k \in \mathbb{Z}$  the  $k$ th Hadamard power of  $X$  is defined by  $X^{\circ k} = (x_{ij}^{\circ k})$ , where  $x_{ij}^{\circ k} = x_{ij}^k$  if  $x_{ij} \neq 0$  and  $x_{ij}^{\circ k} = 0$  if  $x_{ij} = 0$ . Given a matrix  $X = (x_{ij}) \in \mathbb{C}^{N \times N}$  and a block matrix  $Y = [Y_{jk}]_{j,k \in \underline{N}} \in \mathbb{C}^{1 \times \mathbf{q}}$ , the *Hadamard block product* of  $X$  and  $Y$  is by definition the block matrix  $X \circ Y := [x_{ij}Y_{ij}]_{i,j \in \underline{N}}$ . Note that for every  $\Delta = (\Delta_{ij}) \in \mathbb{C}^{1 \times \mathbf{q}}$  we have  $E \circ \Delta = [e_{ij}\Delta_{ij}]_{i,j \in \underline{N}} \in \Delta_E$ .

Given  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ , the object of this paper is to study the variation of the spectrum of the block-diagonal matrix  $A = \oplus_{i=1}^N A_i \in \mathbb{C}^{n \times n}$  under perturbations of the form

$$(25) \quad A \rightsquigarrow A_\Delta := A + B(E \circ \Delta)C, \quad \Delta \in \Delta_E,$$

where  $\mathbf{n} = (n_1, \dots, n_N)$  is given,  $n := |\mathbf{n}|$ , and  $B, C$  are the block-diagonal matrices  $B = \oplus_{i=1}^N B_i \in \mathbb{C}^{n \times 1}$ ,  $C = \oplus_{i=1}^N C_i \in \mathbb{C}^{q \times n}$ . The nonnegative matrix  $E$  has a double role. On the one hand, it defines the *structure of the admissible perturbations*, i.e., the perturbation set  $\Delta_E$ . On the other hand, the positive entries  $e_{ij}$  of  $E$  provide *weights* for the blocks  $\Delta_{ij}$ . Note that since these weights cannot, in general, be absorbed by the matrices  $B_i$  and/or  $C_j$ , they provide an additional scaling flexibility. The scaled blocks  $e_{ij}\Delta_{ij}$  represent uncertain couplings between the subsystems described by the triplets  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ . In fact, consider the system

$$(26) \quad \Sigma : \quad \dot{x}(t) = Ax(t) + Bu(t), \quad y(t) = Cx(t),$$

which is the direct sum of the  $N$  subsystems

$$(27) \quad \Sigma_i : \quad \dot{x}_i(t) = A_i x_i(t) + B_i u_i(t), \quad y_i(t) = C_i x_i(t), \quad i \in \underline{N}.$$

The transfer matrix of  $\Sigma$  is the direct sum of the transfer matrices of the subsystems

$$(28) \quad G(s) = C(sI - A)^{-1}B = \oplus_{i=1}^m G_i(s), \quad G_i(s) := C_i(sI_{n_i} - A_i)^{-1}B_i, \quad i \in \underline{N}.$$

Introducing the couplings

$$(29) \quad u_i(t) = \sum_{j \in \mathcal{I}_i} e_{ij} \Delta_{ij} y_j(t), \quad i \in \underline{N},$$

one obtains the coupled subsystem equations

$$(30) \quad \dot{x}_i(t) = A_i x_i(t) + B_i \sum_{j \in \mathcal{I}_i} e_{ij} \Delta_{ij} C_j x_j(t), \quad i \in \underline{N},$$

which together describe the composite system

$$(31) \quad \Sigma_\Delta : \quad \begin{bmatrix} \dot{x}_1 \\ \vdots \\ \dot{x}_N \end{bmatrix} = (A + B(E \circ \Delta)C) \begin{bmatrix} x_1 \\ \vdots \\ x_N \end{bmatrix} = A_\Delta \begin{bmatrix} x_1 \\ \vdots \\ x_N \end{bmatrix}.$$

Thus the perturbed system  $\Sigma_\Delta$  with system matrix  $A_\Delta$  can be viewed as the composite system obtained by interconnecting the subsystems  $\Sigma_i$  via the uncertain couplings (29) determined by the unknown perturbation blocks  $\Delta_{ij}$ . The unperturbed (“nominal”) system  $\Sigma_0 : \dot{x} = Ax$  obtained by setting  $\Delta = 0$  is simply the direct sum of the subsystems  $\dot{x}_i = A_i x_i$ .

The interconnection structure of the composite system, determined by the matrix  $E$ , is best illustrated by drawing the associated graph  $\mathcal{G}(E)$  [13]. The node set of this directed graph is  $\underline{N}$  or alternatively, in the present context of interconnected systems, the set of subsystems  $\{\Sigma_i; i \in \underline{N}\}$ . The set of directed arcs is given by  $\mathcal{I} = \{(i, j); e_{ij} > 0\}$ , where the pair  $(i, j)$  denotes the arc from the node  $\Sigma_j$  to the node  $\Sigma_i$ .<sup>3</sup>

*Example 3.1.* Consider the following structure matrix  $E$  and the associated graph  $\mathcal{G}(E)$ .

The set of directed arcs of  $\mathcal{G}(E)$  is  $\mathcal{I} = \{(1, 2), (2, 1), (2, 3), (2, 4), (3, 1), (3, 4), (4, 4)\}$ . The diagonal entries of  $E$  portray a perturbation structure where the first three subsystems are unperturbed whereas the fourth one is subjected to perturbations of small weight. The off-diagonal entries model a situation where perturbation blocks of similar size will cause a strong interaction between the first two subsystems, a medium influence of the fourth on the second subsystem, a medium influence of the first on the third subsystem, a lesser influence of the fourth on the third subsystem, and a comparatively small influence of the third on the second subsystem.

**4. Stability radii and spectral value sets.** In this section we derive computable formulas for the spectral value sets and stability radii of the block-diagonal system  $\dot{x} = Ax$  with respect to structured perturbations of the form (25). We continue to use the set-up of the previous section and begin by extending the perturbation space from  $\Delta_E$  to  $\Delta = \mathbb{C}^{1 \times q} \supset \Delta_E$ . Let  $E^0$  be the  $N \times N$  matrix obtained from  $E$  by normalizing all of its nonzero entries to 1; i.e.,  $E^0 = (e_{ij}^0)$  with  $e_{ij}^0 = 1$  if  $e_{ij} > 0$  and  $e_{ij}^0 = 0$  if  $e_{ij} = 0$ . Clearly,  $E = E \circ E^0$  and we have for all  $\Delta \in \mathbb{C}^{1 \times q}$

$$(32) \quad \Delta_0 := E^0 \circ \Delta \in \Delta_E \quad \text{and} \quad E \circ \Delta = E \circ \Delta_0.$$

The block matrix  $\Delta_0 = [e_{ij}^0 \Delta_{ij}]$  is obtained from  $\Delta$  by replacing all of the blocks  $\Delta_{ij}$  in  $\Delta$  for which  $e_{ij} = 0$  by zero blocks of the same dimensions. Because of (32) the set of perturbed matrices  $A_\Delta$  is not extended if we extend the perturbation space from  $\Delta_E$  to  $\Delta = \mathbb{C}^{1 \times q}$ :

$$\{A_\Delta; \Delta \in \Delta_E\} = \{A_\Delta; \Delta \in \mathbb{C}^{1 \times q}\}.$$

<sup>3</sup>Note that this is the reverse of the standard notation in graph theory. We have used our notation in order to be in harmony with the system theoretic interpretation.

Since this leads to a substantial simplification in the notation we will henceforth allow  $\Delta$  to vary in  $\mathbb{C}^{1 \times \mathbf{q}}$  and consider perturbations of the form

$$(33) \quad A \rightsquigarrow A_\Delta := A + B(E \circ \Delta)C = A + B(E \circ \Delta_0)C, \quad \Delta \in \mathbf{\Delta} = \mathbb{C}^{1 \times \mathbf{q}}.$$

Let us introduce a norm on the extended perturbation space  $\mathbf{\Delta}$ . If  $\Delta_i = [\Delta_{i1}, \dots, \Delta_{iN}]$  is the  $i$ th block row of  $\Delta = [\Delta_{jk}] \in \mathbb{C}^{1 \times \mathbf{q}}$ ,  $i \in \underline{N}$ , then

$$(34) \quad \|\Delta_i\|_{2,2}^2 = \lambda_{\max}(\Delta_i \Delta_i^*) = \lambda_{\max} \left( \sum_{j \in \underline{N}} \Delta_{ij} \Delta_{ij}^* \right).$$

On the space of perturbation matrices  $\mathbf{\Delta} = \mathbb{C}^{1 \times \mathbf{q}}$  we introduce the mixed norm  $\|\cdot\|_{\mathbf{\Delta}}$  defined by

$$(35) \quad \|\Delta\|_{\mathbf{\Delta}} = \max_{i \in \underline{N}} \|\Delta_i\|_{2,2} = \max_{i \in \underline{N}} \left[ \lambda_{\max} \left( \sum_{j \in \underline{N}} \Delta_{ij} \Delta_{ij}^* \right) \right]^{1/2}, \quad \Delta = (\Delta_{ij}) \in \mathbf{\Delta}.$$

$\|\Delta\|_{\mathbf{\Delta}}$  is the operator norm of  $\Delta$  as a linear map from  $\mathbb{C}^{\mathbf{q}}$  provided with the 2-norm to  $\mathbb{C}^1$  provided with the  $(2|\infty)$ -Hölder norm  $\|\cdot\|_{2|\infty}$  defined by

$$\|u\|_{2|\infty} = \max_{i \in \underline{N}} \|u_i\|_2, \quad u = (u_i) \in \mathbb{C}^1, \quad u_i \in \mathbb{C}^{l_i}, \quad i \in \underline{N}.$$

The spectral value set (Definition 2.2) of the block-diagonal matrix  $A$  at uncertainty level  $\delta$  (with respect to the perturbations of the form (33)) is denoted by  $\sigma_{\mathbf{\Delta}}(A, B, C, E; \delta)$  and the corresponding stability radius (Definition 2.3) by  $r_{\mathbf{\Delta}}(A, B, C, E)$ . Since for every  $\Delta \in \mathbf{\Delta}$  we have  $\Delta = E^0 \circ \Delta \in \mathbf{\Delta}_E$  and  $\|\Delta_0\|_{\mathbf{\Delta}} \leq \|\Delta\|_{\mathbf{\Delta}}$ , we get from (32) and (33)

$$(36) \quad \begin{aligned} \sigma_{\mathbf{\Delta}}(A, B, C, E; \delta) &= \bigcup_{\Delta \in \mathbf{\Delta}, \|\Delta\|_{\mathbf{\Delta}} < \delta} \sigma(A_\Delta) = \bigcup_{\Delta \in \mathbf{\Delta}_E, \|\Delta\|_{\mathbf{\Delta}} < \delta} \sigma(A_\Delta) = \sigma_{\mathbf{\Delta}_E}(A, B, C, E; \delta), \\ r_{\mathbf{\Delta}}(A, B, C, E) &= \inf\{\|\Delta\|_{\mathbf{\Delta}}; \Delta \in \mathbf{\Delta}, \sigma(A_\Delta) \not\subset \mathbb{C}_-\} = r_{\mathbf{\Delta}_E}(A, B, C, E). \end{aligned}$$

Let  $\Pi_N$  be the group of permutations of the set  $\underline{N}$  and  $\pi \in \Pi_N$ . For every matrix  $X = (x_{ij}) \in \mathbb{C}^{N \times N}$  and every block matrix  $Y = [Y_{ij}]_{i,j \in \underline{N}} \in \mathbb{C}^{1 \times \mathbf{q}}$  we define the matrix (respectively, block matrix) obtained by simultaneous permutation  $\pi$  of its rows and columns (respectively, block rows and block columns) as follows:

$$(37) \quad \pi(X) = (x_{\pi(i)\pi(j)})_{i,j \in \underline{N}} \quad \text{and} \quad \pi(Y) = [Y_{\pi(i)\pi(j)}]_{i,j \in \underline{N}} \in \mathbb{C}^{\pi(1) \times \pi(\mathbf{q})},$$

where  $\pi(1) = (l_{\pi(1)}, \dots, l_{\pi(N)})$  and  $\pi(\mathbf{q}) = (q_{\pi(1)}, \dots, q_{\pi(N)})$ . Then

$$(38) \quad \pi(X) \circ \pi(Y) = \pi(X \circ Y), \quad X \in \mathbb{C}^{N \times N}, \quad Y \in \mathbb{C}^{1 \times \mathbf{q}}, \quad \pi \in \Pi_N.$$

In order to determine  $\sigma_{\mathbf{\Delta}}(A, B, C, E; \delta)$  and  $r_{\mathbf{\Delta}}(A, B, C, E)$  we will sometimes make the assumption that the structure matrix  $E$  is irreducible.  $E$  is said to be *irreducible* if it is not possible to find a perturbation  $\pi \in \Pi_N$  such that  $\pi(E) = \begin{bmatrix} E^{11} & 0 \\ E^{21} & E^{22} \end{bmatrix}$ , with  $E^{11} \in \mathbb{R}^{N_1 \times N_1}$ ,  $E^{22} \in \mathbb{R}^{(N-N_1) \times (N-N_1)}$  for some  $N_1 \in [1, N]$ . The irreducibility of  $E$  has a nice graph theoretical interpretation. Let  $\mathcal{G}(E)$  be the directed graph

corresponding to the matrix  $E$ ; see section 3. Then the matrix  $E$  is irreducible if and only if  $\mathcal{G}(E)$  is strongly connected; see [4, section 2.2]. If  $E$  is reducible, it is known (see [4, section 2.3]) that  $E$  can be reduced by a simultaneous row and column permutation  $\pi \in \Pi_N$  to a block-triangular form

$$(39) \quad \pi(E) = \begin{bmatrix} E_{11} & 0 & \cdots & 0 \\ E_{21} & E_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ E_{s1} & E_{s2} & \cdots & E_{ss} \end{bmatrix},$$

where each diagonal block  $E_{hh} \in \mathbb{R}^{N_h \times N_h}$ ,  $h \in \underline{s}$  is square and is either irreducible or a  $1 \times 1$  null matrix. Applying the permutation  $\pi$  to  $A + B(E \circ \Delta)C$  we obtain

$$(40) \quad \pi(A + B(E \circ \Delta)C) = \pi(A) + \pi(B)(\pi(E) \circ \pi(\Delta))\pi(C),$$

where

$$(41) \quad \begin{aligned} \pi(A) &= \oplus_{h=1}^s A_\pi^h, \quad \pi(B) = \oplus_{h=1}^s B_\pi^h, \quad \pi(C) = \oplus_{h=1}^s C_\pi^h, \\ \pi(\Delta) &= (\Delta_\pi^{hk})_{h,k \in \underline{s}} \in \mathbb{C}^{\pi(1) \times \pi(\mathbf{q})}. \end{aligned}$$

The superblocks  $A_\pi^h$ ,  $B_\pi^h$ ,  $C_\pi^h$ ,  $h \in \underline{s}$ , are block-diagonal matrices with  $N_h$  diagonal blocks on the diagonal and, for any  $\Delta \in \Delta_E$ ,  $\pi(\Delta)$  is a lower block-triangular matrix with the superblocks  $\Delta_\pi^{hk}$  consisting of  $N_h \times N_k$  blocks  $\Delta_{ij}$  of  $\Delta$ ,  $h, k \in \underline{s}$ . Clearly, the blocks on the diagonals of  $\pi(A)$ ,  $\pi(B)$ ,  $\pi(C)$  are a permutation of the diagonal blocks of  $A$ ,  $B$ ,  $C$ , respectively. Moreover, if  $\Delta \in \Delta_E$ , the superblocks  $\Delta_\pi^{hk}$  are of the structure  $E_{hk}$  in the sense that if an entry  $E_{hk}(i, j)$  of  $E_{hk}$  is zero, then the block  $\Delta_\pi^{hk}(i, j) = 0$ .

*Example 4.1.* Suppose we are given four subsystems  $(A_i, B_i, C_i) \in L_{n_i, l_i, q_i}$ ,  $i = 1, \dots, 4$ , and the interconnection matrix  $E \in \mathbb{R}^{4 \times 4}$  is as in Example 3.1. The graph  $\mathcal{G}(E)$  has two strongly connected components with node sets  $\{\Sigma_1, \Sigma_2, \Sigma_3\}$  and  $\{\Sigma_4\}$ . Choose  $\pi \in \Pi_4$  to be the permutation which maps 1, 2, 3, 4 to 4, 1, 2, 3, respectively. Then the permuted matrix  $\pi(E)$  is of the form (39) with  $s = 2$ :

$$\begin{aligned} \pi(E) &= \left[ \begin{array}{c|ccc} 0.1 & 0 & 0 & 0 \\ \hline 0 & 0 & 20 & 0 \\ 10 & 20 & 0 & 1 \\ 5 & 10 & 0 & 0 \end{array} \right] = \begin{bmatrix} E_{11} & 0 \\ E_{21} & E_{22} \end{bmatrix}, \\ E_{11} &= [0.1], \quad E_{21} = \begin{bmatrix} 0 \\ 10 \\ 5 \end{bmatrix}, \quad E_{22} = \begin{bmatrix} 0 & 20 & 0 \\ 20 & 0 & 1 \\ 10 & 0 & 0 \end{bmatrix}. \end{aligned}$$

The block-diagonal matrices  $\pi(A)$ ,  $\pi(B)$ ,  $\pi(C)$  each consist of two superblocks. For instance,  $\pi(A) = A_\pi^1 \oplus A_\pi^2$ , where  $A_\pi^1 = A_4$  and  $A_\pi^2 = A_1 \oplus A_2 \oplus A_3$ . The perturbation matrices  $\Delta \in \Delta_E$ , respectively,  $\pi(\Delta) \in \Delta_E^\pi = \pi(\Delta_E)$ , are of the following form:

$$\begin{aligned} \Delta &= \begin{bmatrix} 0 & \Delta_{12} & 0 & 0 \\ \Delta_{21} & 0 & \Delta_{23} & \Delta_{24} \\ \Delta_{31} & 0 & 0 & \Delta_{34} \\ 0 & 0 & 0 & \Delta_{44} \end{bmatrix}, \\ \pi(\Delta) &= \left[ \begin{array}{c|ccc} \Delta_{44} & 0 & 0 & 0 \\ \hline 0 & 0 & \Delta_{12} & 0 \\ \Delta_{24} & \Delta_{21} & 0 & \Delta_{23} \\ \hline \Delta_{34} & \Delta_{31} & 0 & 0 \end{array} \right] = \left[ \begin{array}{c|ccc} \Delta_\pi^{11} & 0 & & \\ \hline \Delta_\pi^{21} & & \Delta_\pi^{22} & \end{array} \right]. \end{aligned}$$

The spectrum and the perturbation norm remain invariant under the simultaneous permutation of block rows and block columns:

$$\begin{aligned}\sigma(A + B(E \circ \Delta)C) &= \sigma(\pi(A) + \pi(B)(\pi(E) \circ \pi(\Delta))\pi(C)), \\ \|\Delta\|_{\Delta} &= \max_{i \in \underline{N}} \left[ \lambda_{\max} \left( \sum_{j \in \underline{N}} \Delta_{ij} \Delta_{ij}^* \right) \right]^{1/2} \\ &= \max_{i \in \underline{N}} \left[ \lambda_{\max} \left( \sum_{j \in \underline{N}} \Delta_{\pi(i)\pi(j)} \Delta_{\pi(i)\pi(j)}^* \right) \right]^{1/2} = \|\pi(\Delta)\|_{\pi(\Delta)}.\end{aligned}$$

Hence

$$(42) \quad \begin{aligned}\sigma_{\Delta}(A, B, C, E; \delta) &= \sigma_{\pi(\Delta)}(\pi(A), \pi(B), \pi(C), \pi(E); \delta), \\ r_{\Delta}(A, B, C, E) &= r_{\pi(\Delta)}(\pi(A), \pi(B), \pi(C), \pi(E)),\end{aligned}$$

and we may therefore assume, wherever convenient, that  $E$  has the same block-triangular structure as  $\pi(E)$  in (39). Because of the block-triangular structure of  $\pi(A) + \pi(B)(\pi(E) \circ \pi(\Delta))\pi(C)$  the proof of the following lemma is straightforward.

LEMMA 4.2. Suppose that  $E$  is reduced to lower block-triangular form as in (39) by a permutation  $\pi \in \Pi_N$ , and  $\pi(A), \pi(B), \pi(C)$  and  $\pi(\Delta)$ ,  $\Delta \in \Delta$  are decomposed as in (41). If, for any pair  $(h, k) \in \underline{s} \times \underline{s}$ , we provide the space of superblocks  $\Delta_{\pi}^{hk} = \{\Delta_{\pi}^{hk}; \Delta \in \Delta\}$  with the norm

$$(43) \quad \|\Delta_{\pi}^{hk}\|_{\Delta_{\pi}^{hk}} = \max_{i \in \underline{N}_h} \left[ \lambda_{\max} \left( \sum_{j \in \underline{N}_k} \Delta_{ij}^{hk} (\Delta_{ij}^{hk})^* \right) \right]^{1/2}, \quad \Delta_{\pi}^{hk} = (\Delta_{ij}^{hk})_{i \in \underline{N}_h, j \in \underline{N}_k},$$

then

$$(44) \quad \sigma_{\Delta}(A, B, C, E; \delta) = \bigcup_{h \in \underline{s}} \sigma_{\Delta_{\pi}^{hh}}(A_{\pi}^h, B_{\pi}^h, C_{\pi}^h, E_{hh}; \delta), \quad \delta > 0,$$

and

$$(45) \quad r_{\Delta}(A, B, C, E) = \min_{h \in \underline{s}} r_{\Delta_{\pi}^{hh}}(A_{\pi}^h, B_{\pi}^h, C_{\pi}^h, E_{hh}).$$

Remark 4.3. If  $E_{hh}$  is a  $1 \times 1$  null matrix, then  $A_{\pi}^h = [A_i]$  for some  $i \in \underline{N}$ . It follows that the eigenvalues of  $A_i$  are fixed eigenvalues of all perturbed matrices  $A + B(E \circ \Delta)C$ ,  $\Delta \in \Delta$ , and  $r_{\Delta_{\pi}^{hh}}(A_{\pi}^h, B_{\pi}^h, C_{\pi}^h, E_{hh}) = \infty$  if  $A$  is asymptotically stable. Hence Lemma 4.2 shows that the analysis of the spectral perturbation problem under consideration can be reduced to the case where  $E$  is irreducible.

We illustrate Lemma 4.2 by applying it to the data of Example 4.1.

Example 4.4. Using the notation of Example 4.1 we obtain from (44) and (45) that

$$\sigma_{\Delta}(A, B, C, E; \delta) = \sigma_{\Delta_{\pi}^{11}}(A_{\pi}^1, B_{\pi}^1, C_{\pi}^1, E_{11}; \delta) \cup \sigma_{\Delta_{\pi}^{22}}(A_{\pi}^2, B_{\pi}^2, C_{\pi}^2, E_{22}; \delta),$$

$$r_{\Delta}(A, B, C, E) = \min\{r_{\Delta_{\pi}^{11}}(A_{\pi}^1, B_{\pi}^1, C_{\pi}^1, E_{11}), r_{\Delta_{\pi}^{22}}(A_{\pi}^2, B_{\pi}^2, C_{\pi}^2, E_{22})\},$$

where

$$A_\pi^1 = A_4, \quad A_\pi^2 = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix}, \quad E_{11} = [0.1], \quad E_{22} = \begin{bmatrix} 0 & 20 & 0 \\ 20 & 0 & 1 \\ 10 & 0 & 0 \end{bmatrix}$$

and the components  $B_\pi^i, C_\pi^i$ ,  $i = 1, 2$ , of the block-diagonal matrices  $B, C$  have a structure analogous to those of  $A$ . The perturbations of  $A_\pi^1$  are of the form

$$A_\pi^1 = A_4 \rightsquigarrow A_\pi^1 + 0.1B_\pi^1\Delta_\pi^{11}C_\pi^1 = A_4 + 0.1B_4\Delta_{44}C_4,$$

whereas the perturbations of  $A_\pi^2$  are of the form

$$A_\pi^2 = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \rightsquigarrow A_\pi^2 + B_\pi^2(E_{22} \circ \Delta_\pi^{22})C_\pi^2 = \begin{bmatrix} A_1 & 20\Delta_{12} & 0 \\ 20\Delta_{21} & A_2 & \Delta_{23} \\ 10\Delta_{11} & 0 & A_3 \end{bmatrix}.$$

Note that by the previous formulas the perturbation blocks  $\Delta_{24}, \Delta_{34}$  have no influence on  $\sigma_\Delta(A, B, C, E; \delta)$  and  $r_\Delta(A, B, C, E)$ . The spectrum of  $A_\Delta$  remains invariant if these blocks in the perturbation matrix  $\Delta$  are changed. In order to determine the stability radius  $r_\Delta(A, B, C, E)$  of  $A$  with respect to perturbations of the form (33) we will make use of the Perron–Frobenius theory of nonnegative matrices  $M \in \mathbb{R}_+^{N \times N}$ ; see [4], [13, Chapter 8].

LEMMA 4.5. Suppose  $M, M' \in \mathbb{R}_+^{N \times N}$ ,  $\alpha, \beta \in \mathbb{R}$ . Then we have the following.

- (i)  $\varrho(M) \in \sigma(M)$ , and there exists a nonnegative eigenvector  $z$  of  $M$  corresponding to the eigenvalue  $\varrho(M)$  (Perron vector). If  $M$  is irreducible, then the Perron vector is uniquely determined modulo multiplication by a positive scalar and all of its coordinates are positive.
- (ii) If there exists  $z \in \mathbb{R}_+^n$ ,  $z \neq 0$  such that  $Mz \geq \alpha z$ , then  $\varrho(M) \geq \alpha$ .
- (iii) If there exists  $z > 0$  such that  $Mz \leq \beta z$ , then  $\varrho(M) \leq \beta$ .
- (iv) If  $M \leq M'$ , then  $\varrho(M) \leq \varrho(M')$ . If  $M$  is irreducible and  $M \leq M'$ ,  $M \neq M'$ , then  $\varrho(M) < \varrho(M')$ .
- (v) If  $(M_k)$  is a sequence in  $\mathbb{R}_+^{N \times N}$  converging to  $M$ , then  $\varrho(M_k) \rightarrow \varrho(M)$  as  $k \rightarrow \infty$ .

*Proof.* (i)–(iv) follow from the Perron–Frobenius theory of nonnegative matrices; see [13, Theorem 8.3.1] and [13, Theorem 8.4.4] for (i), [13, Theorem 8.3.2] for (ii), [13, Corollary 8.1.29] for (iii), [13, Corollary 8.1.19] and [4, Corollary 1.3.29] for (iv).

(v) follows from the continuous dependence of the spectrum  $\sigma(M)$  on the matrix  $M$ .  $\square$

Remark 4.6. Let  $E$  be a nonnegative  $N \times N$  matrix,  $\mathcal{G}(E)$  the associated directed graph, and  $\mathcal{Z}_0(E)$  the set of cycles of this digraph. Then

$$\varrho(E) = 0 \quad \Leftrightarrow \quad E^N = 0 \quad \Leftrightarrow \quad \mathcal{Z}_0(E) = \emptyset.$$

The following theorem is the main result of this section and the key tool for determining  $\sigma_\Delta(A, B, C, E; \delta)$  and  $r_\Delta(A, B, C, E)$ .

THEOREM 4.7. Suppose  $E \in \mathbb{R}_+^{N \times N}$  and  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ , are given. If  $A = \oplus_{i=1}^N A_i$  is nonsingular,  $B = \oplus_{i=1}^N B_i$ ,  $C = \oplus_{i=1}^N C_i$ , and  $\Delta = \mathbb{C}^{1 \times \mathbf{q}}$  is provided with the norm (35), then the “distance of  $A$  from singularity” with respect to perturbations of the form (33) is given by

(46)

$$d_\Delta(A, B, C, E) := \inf\{\|\Delta\|_\Delta; \Delta \in \Delta \text{ and } \det(A + B(E \circ \Delta)C) = 0\} = 1/\sqrt{\varrho(D^2 E \circ^2)},$$

where  $D = \text{diag}(\|C_1 A_1^{-1} B_1\|_{2,2}, \dots, \|C_N A_N^{-1} B_N\|_{2,2})$ . If additionally  $A, B, C$  are real, then also

$$(47) \quad \inf\{\|\Delta\|_{\Delta}; \Delta \in \mathbf{\Delta} \cap \mathbb{R}^{1 \times \mathbf{q}} \text{ and } \det(A + B(E \circ \Delta)C) = 0\} = 1/\sqrt{\varrho(D^2 E^{\circ 2})}.$$

*Proof.* Suppose that  $A$  is nonsingular and  $(A + B(E \circ \Delta)C)x = 0$  for some  $\Delta = (\Delta_{ij}) \in \mathbf{\Delta}$ ,  $x = (x_i) \in \mathbb{C}^{\mathbf{n}}$ ,  $x_i \in \mathbb{C}^{n_i}$ ,  $x \neq 0$ . Then

$$(48) \quad -A_i x_i = B_i \sum_{j \in \underline{N}} e_{ij} \Delta_{ij} C_j x_j, \quad i \in \underline{N}.$$

Setting  $y_i = C_i x_i$  and  $z_i = \|y_i\|_2^2$ ,  $i \in \underline{N}$ , we obtain by (48) and (35)

$$y_i = -C_i A_i^{-1} B_i \sum_{j \in \underline{N}} e_{ij} \Delta_{ij} y_j \quad \text{and} \quad z_i \leq \|C_i A_i^{-1} B_i\|_{2,2}^2 \|\Delta\|_{\Delta}^2 \sum_{j \in \underline{N}} e_{ij}^2 z_j, \quad i \in \underline{N}.$$

The  $y_i$  cannot all be zero since otherwise  $Ax = 0$  by (48) and  $x \neq 0$  would imply that  $A$  is singular. Hence  $z = (z_i) \in \mathbb{R}_+^{\mathbf{N}}$  satisfies  $z \leq \|\Delta\|_{\Delta}^2 D^2 E^{\circ 2} z$ ,  $z \neq 0$ . By Lemma 4.5 this implies  $\|\Delta\|_{\Delta}^{-2} \leq \varrho(D^2 E^{\circ 2})$  and so the inequality  $\geq$  in (46). We also see that there cannot exist a  $\Delta \in \mathbf{\Delta}$  such that  $\det(A + B(E \circ \Delta)C) = 0$  if  $\varrho(D^2 E^{\circ 2}) = 0$ . So equality holds in (46) if  $\varrho(D^2 E^{\circ 2}) = 0$  (making use of the conventions (1)).

To prove the converse inequality  $\leq$  in (46) we may therefore assume  $\varrho(D^2 E^{\circ 2}) > 0$ . We construct a perturbation matrix  $\Delta \in \mathbf{\Delta}_E$  satisfying  $\|\Delta\|_{\Delta}^2 = 1/\varrho(D^2 E^{\circ 2})$  and a vector  $x \in \mathbb{C}^{\mathbf{n}}$ ,  $x \neq 0$ , such that  $(A + B(E \circ \Delta)C)x = 0$ . By the Perron–Frobenius theory there exists  $z = (z_1, \dots, z_N)^{\top} \geq 0$ ,  $z \neq 0$ , such that  $D^2 E^{\circ 2} z = \varrho(D^2 E^{\circ 2}) z$ ; that is

$$(49) \quad \|C_i A_i^{-1} B_i\|_{2,2}^2 \sum_{j \in \underline{N}} e_{ij}^2 z_j = \varrho(D^2 E^{\circ 2}) z_i, \quad i \in \underline{N}.$$

If  $\|C_i A_i^{-1} B_i\|_{2,2} = 0$ , then necessarily  $z_i = 0$  by (49). Hence there exists, for every  $i \in \underline{N}$ , a vector  $u_i \in \mathbb{C}^{q_i}$  such that  $y_i := C_i A_i^{-1} B_i u_i$  satisfies

$$(50) \quad \|y_i\|_2^2 = \|C_i A_i^{-1} B_i\|_{2,2}^2 \|u_i\|_2^2 \quad \text{and} \quad \|y_i\|_2^2 = z_i.$$

Here we can choose  $u_i = 0$  if  $z_i = 0$ . Setting  $x_i = A_i^{-1} B_i u_i$  for  $i \in \underline{N}$  we obtain that  $x_i = 0$  whenever  $z_i = 0$ . Now define, for  $i \in \underline{N}$ ,

$$(51) \quad \Delta_{ij} = \begin{cases} -\frac{e_{ij} u_i y_j^*}{\sum_{k \in \underline{N}} e_{ik}^2 \|y_k\|_2^2} & \text{if } j \in \mathcal{I}_i \text{ and } \sum_{k \in \underline{N}} e_{ik}^2 \|y_k\|_2^2 \neq 0, \\ 0 & \text{if } j \notin \mathcal{I}_i \text{ or } \sum_{k \in \underline{N}} e_{ik}^2 \|y_k\|_2^2 = 0. \end{cases}$$

If  $\sum_{k \in \underline{N}} e_{ik}^2 \|y_k\|_2^2 = \sum_{k \in \underline{N}} e_{ik}^2 z_k = 0$  for some  $i \in \underline{N}$ , then  $\Delta_{ij} = 0$  for all  $j \in \underline{N}$  by (51), and  $z_i = 0$  by (49) so that  $x_i = 0$  and

$$A_i x_i + B_i \sum_{j \in \underline{N}} e_{ij} \Delta_{ij} C_j x_j = B_i \sum_{j \in \underline{N}} e_{ij} \Delta_{ij} y_j = 0.$$

On the other hand, if  $\sum_{k \in \underline{N}} e_{ik}^2 \|y_k\|_2^2 \neq 0$ , then by (51)

$$\begin{aligned} A_i x_i + B_i \sum_{j \in \underline{N}} e_{ij} \Delta_{ij} C_j x_j &= A_i x_i - B_i u_i \left( \sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2 \right) / \left( \sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2 \right) \\ &= A_i x_i - B_i u_i = 0. \end{aligned}$$

We conclude that  $(A + B(E \circ \Delta)C)x = 0$ , where  $x := (x_i) \in \mathbb{C}^n$ ,  $x \neq 0$ . It remains to show that  $\|\Delta\|_{\Delta} = 1/\sqrt{\varrho(D^2 E^{\circ 2})}$ . Now, for every  $i \in \underline{N}$  such that  $\sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2 \neq 0$ , we have

$$\sum_{j=1}^N \Delta_{ij} \Delta_{ij}^* = \sum_{j \in \underline{N}} \frac{e_{ij}^2 u_i u_i^* \|y_j\|_2^2}{(\sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2)^2} = \frac{u_i u_i^*}{\sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2},$$

and so by (50) and (49)

$$\begin{aligned} \lambda_{\max} \left( \sum_{j \in \underline{N}} \Delta_{ij} \Delta_{ij}^* \right) &= \frac{\lambda_{\max}(u_i u_i^*)}{\sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2} \\ &= \frac{\|u_i\|_2^2}{\sum_{j \in \underline{N}} e_{ij}^2 z_j} = \begin{cases} \frac{z_i / \|C_i A_i^{-1} B_i\|_{2,2}^2}{\sum_{j \in \underline{N}} e_{ij}^2 z_j} = 1/\varrho(D^2 E^{\circ 2}), & z_i \neq 0, \\ 0, & z_i = 0. \end{cases} \end{aligned}$$

Since  $z \neq 0$  there exists  $i \in \underline{N}$  such that  $z_i \neq 0$  and hence by (49)  $\sum_{j \in \underline{N}} e_{ij}^2 \|y_j\|_2^2 \neq 0$ . It follows that  $\|\Delta\|_{\Delta}^2 = \max_{i \in \underline{N}} \lambda_{\max}(\sum_{j \in \underline{N}} \Delta_{ij} \Delta_{ij}^*) = 1/\varrho(D^2 E^{\circ 2})$ , and this concludes the proof of (46).

If  $A, B, C$  are real, the  $u_i$ ,  $i \in \underline{N}$ , can be chosen to be real and then the perturbation matrix  $\Delta$  constructed above is real, and (47) follows from the previous proof.  $\square$

*Remark 4.8.* If  $\varrho(D^2 E^{\circ 2}) = 0$ , then  $A + B(E \circ \Delta)C$  is nonsingular for all  $\Delta \in \Delta_E$ . If  $\varrho(D^2 E^{\circ 2}) > 0$ , then the above proof shows how to construct a perturbation  $\Delta \in \Delta_E$  (respectively,  $\Delta \in \Delta_E \cap \mathbb{R}^{1 \times \mathbf{q}}$ ) of minimum norm  $\|\Delta\|_{\Delta}$  such that  $A + B(E \circ \Delta)C$  is singular. In this case the “inf” can be replaced by “min” in (46).

**COROLLARY 4.9.** Suppose  $E \in \mathbb{R}_+^{N \times N}$  and  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ , are given. If  $A = \oplus_{i=1}^N A_i$ ,  $B = \oplus_{i=1}^N B_i$ ,  $C = \oplus_{i=1}^N C_i$ , and  $\Delta = \mathbb{C}^{1 \times \mathbf{q}}$  is provided with the norm (35), then we have the following.

- (i) For every  $\delta > 0$  the spectral value set of  $A$  of level  $\delta$  with respect to perturbations of the form (33) is

$$\begin{aligned} (52) \quad \sigma_{\Delta}(A, B, C, E; \delta) &= \bigcup_{\Delta \in \Delta, \|\Delta\|_{\Delta} < \delta} \sigma(A + B(E \circ \Delta)C) \\ &= \sigma(A) \cup \{s \in \rho(A); \varrho(D(s)^2 E^{\circ 2}) > \delta^{-2}\}, \end{aligned}$$

where  $D(s) = \text{diag}(\|G_1(s)\|_{2,2}, \dots, \|G_N(s)\|_{2,2})$ ,  $G_i(s) = C_i(sI_{n_i} - A_i)^{-1} B_i$ ,  $i \in \underline{N}$ .

- (ii) If  $A$  is Hurwitz stable, then its stability radius with respect to perturbations of the form (33) is

$$(53) \quad r_{\Delta}(A, B, C, E) = \left[ \max_{\omega \in \mathbb{R}} \varrho(D(i\omega)^2 E^{\circ 2}) \right]^{-1/2}.$$

*Proof.* (i) By definition we have  $\sigma(A) \subset \sigma_{\Delta}(A, B, C, E; \delta)$ . Now suppose  $s \in \rho(A)$ . Since  $s \in \sigma(A + B(E \circ \Delta)C)$  holds if and only if  $\det((sI_n - A) - B(E \circ \Delta)C) = 0$ , we obtain from (46) that  $s \in \sigma_{\Delta}(A, B, C, E; \delta)$  if and only if  $1/\sqrt{\varrho(D(s)^2 E^{\circ 2})} < \delta$ . This proves (52).

(ii) By the definition of  $r_{\Delta}(A, B, C, E)$ , the continuity of the spectrum, and by (52), we have for every  $\delta \geq 0$

$$\begin{aligned} \delta > r_{\Delta}(A, B, C, E) &\Leftrightarrow \sigma_{\Delta}(A, B, C, E; \delta) \cap i\mathbb{R} \neq \emptyset \\ &\Leftrightarrow \exists \omega \in \mathbb{R} : \varrho(D(i\omega)^2 E^{\circ 2}) > 1/\delta^2. \end{aligned}$$

Observing that the function  $\omega \mapsto \varrho(D(i\omega)^2 E^{\circ 2})$  admits a maximum on  $\mathbb{R}$  since  $\lim_{|\omega| \rightarrow \infty} \varrho(D(i\omega)^2 E^{\circ 2}) = 0$ , this proves (53).  $\square$

*Remark 4.10.* Suppose  $A, B, C$  are real and  $\omega \mapsto \varrho(D(i\omega)^2 E^{\circ 2})$  admits its maximum on  $\mathbb{R}_+$  at  $\omega = 0$ . Then  $D(0) = D$  and it follows from Theorem 4.7 that the stability radii of  $A$  with respect to complex and with respect to real perturbations of structure  $E$  are equal:

$$r_{\Delta}(A, B, C, E) = r_{\Delta_{\mathbb{R}}}(A, B, C, E) = [\varrho(D(0)^2 E^{\circ 2})]^{-1/2}.$$

As an illustration of Corollary 4.9 we consider an example where  $E$  is of “cyclic” structure.

*Example 4.11.* Suppose that  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ ,  $G_i(s) = C_i(sI_{n_i} - A_i)^{-1}B_i$ , and

$$(54) \quad E = \begin{bmatrix} 0 & e_{12} & 0 & \cdots & 0 \\ 0 & 0 & e_{23} & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e_{N-1, N} & 0 \\ e_{N, 1} & 0 & 0 & \cdots & 0 \end{bmatrix}, \quad D(s) = \text{diag}(\|G_1(s)\|_{2,2}, \dots, \|G_N(s)\|_{2,2}).$$

Then

$$\begin{aligned} \varrho(D(s)^2 E^{\circ 2}) &= \varrho \left( \begin{bmatrix} 0 & e_{12}^2 \|G_1(s)\|_{2,2}^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e_{N-1, N}^2 \|G_{N-1}(s)\|_{2,2}^2 \\ e_{N, 1}^2 \|G_N(s)\|_2^2 & 0 & \cdots & 0 \end{bmatrix} \right) \\ &= \sqrt[N]{e_{12}^2 \cdots e_{N-1, N}^2 e_{N, 1}^2 \|G_1(s)\|_{2,2}^2 \cdots \|G_N(s)\|_{2,2}^2}, \end{aligned}$$

and we obtain from (53) that

$$\begin{aligned} r_{\Delta}(A, B, C, E) &= \left[ \max_{\omega \in \mathbb{R}} \varrho(D(i\omega)^2 E^{\circ 2}) \right]^{-1/2} \\ &= \left[ \max_{\omega \in \mathbb{R}} \sqrt[N]{e_{12} \cdots e_{N-1, N} e_{N, 1} \|G_1(i\omega)\|_{2,2} \cdots \|G_N(i\omega)\|_{2,2}} \right]^{-1}. \end{aligned}$$

In particular, if we have, e.g.,

$$N = 2, \quad A = \begin{bmatrix} -1 + i & 0 \\ 0 & -2 + i \end{bmatrix}, \quad B = C = I_2, \quad E = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

then  $r_{\Delta} = r_{\Delta}(A, I_2, I_2, E)$  is given by

$$\begin{aligned} r_{\Delta} &= \left[ \max_{\omega \in \mathbb{R}} \sqrt{|1 + (\omega - 1)i|^{-1} \cdot |2 + (\omega - 1)i|^{-1}} \right]^{-1} \\ &= \left[ \min_{\omega \in \mathbb{R}} [1 + (\omega - 1)^2][4 + (\omega - 1)^2] \right]^{1/4} = \sqrt{2}. \end{aligned}$$

Although the perturbations (33) are structured, our approach does not make use of  $\mu$ -values. In order to explain how our results are related to  $\mu$ -analysis, we describe the perturbed system  $\dot{x} = A_{\Delta}x$  equivalently by an equation of the form

$$\dot{x} = Ax + B\tilde{\Delta}\tilde{C}x,$$

where  $\tilde{C}$  is a suitable matrix and  $\tilde{\Delta}$  is a block-diagonal counterpart of  $\Delta$  with spectral norm  $\|\tilde{\Delta}\|_{2,2} = \|\Delta\|_{\Delta}$ . Given  $\Delta = (\Delta_{ij}) \in \mathbf{\Delta}$ , we define  $\tilde{\Delta}$  by

$$(55) \quad \tilde{\Delta} = \text{diag}(\Delta^1, \dots, \Delta^N) \in \mathbb{C}^{1 \times Nq}, \quad \Delta^i = [\Delta_{i1}, \Delta_{i2}, \dots, \Delta_{iN}] \in \mathbb{C}^{l_i \times q}.$$

Note that the spectral norm of  $\tilde{\Delta}$  satisfies

$$(56) \quad \|\tilde{\Delta}\|_{2,2}^2 = \max_{i \in \underline{N}} \|\Delta^i\|_{2,2}^2 = \|\Delta\|_{\Delta}^2, \quad \Delta = (\Delta_{ij}) \in \mathbf{\Delta}.$$

Now define  $\tilde{C} \in \mathbb{C}^{Nq \times n}$  by

$$(57) \quad \tilde{C} = \begin{bmatrix} \tilde{C}^1 \\ \tilde{C}^2 \\ \vdots \\ \tilde{C}^N \end{bmatrix}, \quad \tilde{C}^i = \text{diag}(e_{i1}C_1, \dots, e_{iN}C_N) \in \mathbb{C}^{q \times n}.$$

Note that each block row of  $\tilde{C}$  contains at most one nonzero block and hence the nonzero blocks of any two different block columns of  $\tilde{C}$  occur at different positions. As a consequence  $\tilde{C}^* \tilde{C}$  is block-diagonal,

$$(58) \quad \tilde{C}^* \tilde{C} = \sum_{i \in \underline{N}} \tilde{C}^{i*} \tilde{C}^i = \text{diag} \left( \left( \sum_{i \in \underline{N}} e_{i1}^2 \right) C_1^* C_1, \dots, \left( \sum_{i \in \underline{N}} e_{iN}^2 \right) C_N^* C_N \right) \in \mathbb{C}^{n \times n}.$$

Moreover, we have

$$(59) \quad \Delta^i \tilde{C}^i = [e_{i1} \Delta_{i1} C_1, \dots, e_{iN} \Delta_{iN} C_N], \quad \tilde{\Delta} \tilde{C} = \begin{bmatrix} \Delta^1 \tilde{C}^1 \\ \vdots \\ \Delta^N \tilde{C}^N \end{bmatrix} = (E \circ \Delta) C,$$

and hence

$$(60) \quad A_{\Delta} = A + B(E \circ \Delta)C = A + B\tilde{\Delta}\tilde{C}, \quad \Delta \in \mathbf{\Delta}.$$

Defining  $\tilde{\mathbf{\Delta}} = \{\tilde{\Delta}; \Delta \in \mathbf{\Delta}\}$ , it follows from (60) and (56) that

$$\inf\{\|\Delta\|_{\Delta}; \Delta \in \mathbf{\Delta} \text{ and } \det(A_{\Delta}) = 0\} = \inf\{\|\tilde{\Delta}\|_{2,2}; \tilde{\Delta} \in \tilde{\mathbf{\Delta}} \text{ and } \det(A + B\tilde{\Delta}\tilde{C}) = 0\}.$$

On the other hand, since  $\det(I + UV) = \det(I + VU)$  for  $U \in \mathbb{C}^{h \times k}$ ,  $V \in \mathbb{C}^{k \times h}$ ,  $h, k \in \mathbb{N}$ , we have the equivalence

$$\det(A + B\tilde{\Delta}\tilde{C}) = 0 \Leftrightarrow \det(I + \tilde{\Delta}\tilde{C}A^{-1}B) = 0.$$

If we endow  $\tilde{\mathbf{\Delta}}$  with the spectral norm, we therefore obtain

$$(61) \quad d_{\mathbf{\Delta}}(A, B, C, E) = \inf\{\|\Delta\|_{\Delta}; \Delta \in \mathbf{\Delta} \text{ and } \det(A_{\Delta}) = 0\} = 1/\mu_{\tilde{\mathbf{\Delta}}}(\tilde{G}),$$

where  $\tilde{G} := \tilde{C}A^{-1}B$ .

*Remark 4.12.* Especially for sparse matrices  $E$  one can reduce the dimensions of  $\tilde{\Delta}$  and  $\tilde{C}$  a lot by eliminating in the rows of  $\Delta_i$  (see (55)) all of the blocks  $\Delta_{ij}$  for which  $e_{ij} = 0$  and removing in  $\tilde{C}^i$  (see (57)) all of the block rows for which  $e_{ij} = 0$ . However, this would considerably complicate the notation and not provide any computational advantage since the blown-up matrices  $\tilde{\Delta}$  and  $\tilde{C}$  will not be used in calculations.

The characterization (61) expresses the distance  $d_{\Delta}(A, B, C, E)$  in terms of the  $\mu$ -value of the blown-up matrix  $\tilde{G} := \tilde{C}A^{-1}B$  with respect to the set  $\tilde{\Delta}$  of blown-up block-diagonal perturbations  $\tilde{\Delta}$ . The question arises if it is possible to characterize  $d_{\Delta}(A, B, C, E)$  in terms of the  $\mu$ -value of the more natural “transfer function at  $s = 0$ ,”  $G = CA^{-1}B$ , and the given perturbation set  $\Delta_E$ . Since  $\Delta_E$  only reflects the structure of  $E$  but not the magnitude of its nonzero entries, such a characterization will only be possible, if the missing information is included in the set-up, e.g., via a suitable norm on  $\Delta_E$  depending on  $E$ . The following corollary shows how this can be done.

**COROLLARY 4.13.** *Suppose the conditions of Theorem 4.7 and let  $\Delta_E$  be provided with the norm*

$$(62) \quad \|\Delta\|_{\Delta_E} = \|E^{\circ-1} \circ \Delta\|_{\Delta}.$$

If  $G = CA^{-1}B$ , then  $\mu_{\Delta_E}(G) = \sqrt{\varrho(D^2E^{\circ 2})}$  and

$$(63) \quad \inf\{\|\Delta\|_{\Delta}; \Delta \in \Delta \text{ and } \det(A + B(E \circ \Delta)C) = 0\} = 1/\mu_{\Delta_E}(G).$$

*Proof.* For every  $\Delta \in \Delta_E$  define  $\Delta_E = E \circ \Delta \in \Delta_E$ . Then  $\|\Delta_E\|_{\Delta_E} = \|\Delta\|_{\Delta}$  for all  $\Delta \in \Delta_E$  and  $\Delta \mapsto \Delta_E$  is a norm preserving isomorphism from the normed space  $(\Delta_E, \|\cdot\|_{\Delta})$  onto  $(\Delta_E, \|\cdot\|_{\Delta_E})$ . Moreover, we obtain from (58) that for every  $\Delta \in \Delta$

$$(64) \quad \begin{aligned} \det(A + B(E \circ \Delta)C) = 0 &\Leftrightarrow \det(I + A^{-1}B(E \circ \Delta)C) = 0 \\ &\Leftrightarrow \det(I + \Delta_E G) = \det(I + (E \circ \Delta)CA^{-1}B) = 0. \end{aligned}$$

Now by definition  $\mu_{\Delta_E}(G)^{-1}$  equals

$$\inf\{\|\Delta_E\|_{\Delta_E}; \Delta_E \in \Delta_E, \det(I + \Delta_E G) = 0\} = \inf\{\|\Delta\|_{\Delta}; \Delta \in \Delta_E, \det(I + \Delta G) = 0\}.$$

Hence (63) follows from (64), and  $\mu_{\Delta_E}(G) = \sqrt{\varrho(D^2E^{\circ 2})}$  is a consequence of Theorem 4.7.  $\square$

*Remark 4.14.* There are many different possibilities for representing the perturbed matrices  $A_{\Delta} = A + B(E \circ \Delta)C$ ,  $\Delta \in \Delta$ , in the form  $A_{\Delta} = A + \tilde{B}\tilde{\Delta}\tilde{C}$ ,  $\tilde{\Delta} \in \tilde{\Delta}$ , where  $\tilde{\Delta}$  is a vector space of block-diagonal matrices. Equation (60) is just one of these representations, with  $\tilde{B} = B$ ,  $\tilde{C}$  defined by (57), and  $\tilde{\Delta}$  is the set of all block-diagonal perturbations  $\tilde{\Delta}$  of the form (55). Another representation of  $A_{\Delta}$  with block-diagonal perturbations  $\tilde{\Delta}$  is  $A_{\Delta} = A + \tilde{B}\tilde{\Delta}\tilde{C}$ , where

$$(65) \quad \tilde{B} = \oplus_{i \in \underline{N}} [B_{i1}, \dots, B_{iN}], \quad B_{ij} = B_i; \quad \tilde{\Delta} = \oplus_{i \in \underline{N}} \oplus_{j \in \underline{N}} \Delta_{ij}; \quad \tilde{C} = \begin{bmatrix} \oplus_{j \in \underline{N}} e_{1j} C_j \\ \vdots \\ \oplus_{j \in \underline{N}} e_{Nj} C_j \end{bmatrix}.$$

In order to relate this perturbation structure to the Riccati equation associated with the system  $(\tilde{A}, \tilde{B}, \tilde{C})$  via Theorem 2.5, we must provide  $\Delta$  with a norm  $\|\cdot\|_{\Delta}$  such

that  $\|\Delta\|_{\Delta} = \|\tilde{\Delta}\|_{2,2}$  for all  $\Delta \in \Delta_E$ . If we choose  $\tilde{B}, \tilde{C}, \tilde{\Delta}$  as in (65), then a suitable norm on  $\Delta$  would be  $\|\Delta\|_{\Delta} := \max_{i,j \in \underline{N}} \|\Delta_{ij}\|_{2,2}$ . If instead the weighted norm

$$\|\Delta\|_{\Delta_E} := \max_{(i,j) \in \mathcal{I}} e_{ij}^{-1} \|\Delta_{ij}\|_{2,2}$$

is introduced on  $\Delta_E$ , then

$$\|E \circ \Delta\|_{\Delta_E} = \|\Delta\|_{\Delta} = \|\tilde{\Delta}\|_{2,2}, \quad \Delta \in \Delta_E,$$

and one can prove that, with respect to the norms  $\|\cdot\|_{\Delta}$  and  $\|\cdot\|_{\Delta_E}$  just defined,

$$\inf\{\|\Delta\|_{\Delta}; \Delta \in \Delta \text{ and } \det(A + B(E \circ \Delta)C) = 0\} = 1/\mu_{\Delta_E}(G).$$

In [16, Theorem 4.2] the following formula for the  $\mu$ -value of any block-diagonal matrix  $G = \text{diag}(G_1, \dots, G_N) \in \mathbb{C}^{q \times l}$  (with respect to the norm  $\|\cdot\|_{\Delta_E}$  on  $\Delta_E$ ) was derived:

$$(66) \quad \mu_{\Delta_E}(G) = \varrho(ED), \quad \text{where} \quad D = \text{diag}(\|G_1\|_{2,2}, \dots, \|G_N\|_{2,2}).$$

An analysis of the corresponding Riccati equations and quadratic stability problem is more complicated and for lack of space cannot be dealt with in this article.

**5. Riccati equation.** We continue to use the set-up of section 3. There are various parametrized algebraic Riccati equations which can be used to construct joint quadratic Liapunov functions for perturbed systems of the form  $\dot{x} = A_{\Delta}x$  (31). If we neglected the structure matrix  $E$  and considered the full block case where  $A_{\Delta} = A + B\Delta C$ ,  $\Delta \in \mathbb{C}^{l \times q}$ , then the associated Riccati equation would be

$$(67) \quad PA + A^*P + \rho^2 C^*C + PBB^*P = 0.$$

If  $\sigma(A) \subset \mathbb{C}_-$ , then by Theorem 2.5 this Riccati equation has a Hermitian solution if and only if

$$(68) \quad \rho \leq \left[ \max_{\omega \in \mathbb{R}} \|G(i\omega)\|_{2,2} \right]^{-1} = \left[ \max_{\omega \in \mathbb{R}} \max_{i \in \underline{N}} \|G_i(i\omega)\|_{2,2} \right]^{-1} = \min_{i \in \underline{N}} g_i^{-1}, \quad g_i := \max_{\omega \in \mathbb{R}} \|G_i(i\omega)\|_{2,2},$$

where  $G(s)$  is the transfer function of the block-diagonal system  $(A, B, C)$ ; see (28).

If we take the perturbation structure into account, then different Riccati equations can be considered, depending on the representation of the perturbed system matrix  $A_{\Delta} = A + B(E \circ \Delta)C$  in the form  $A_{\Delta} = A + \tilde{B}\tilde{\Delta}\tilde{C}$ . In this section we will focus on the block-diagonal representation (60) where the matrices  $\tilde{B} = B, \tilde{C}$  and  $\tilde{\Delta}$  are given by (57) and (55). The parametrized algebraic Riccati equation associated with the system  $(A, B, \tilde{C})$  is given by

$$(69) \quad PA + A^*P + \rho^2 \tilde{C}^* \tilde{C} + PBB^*P = 0,$$

$$\tilde{C}^* \tilde{C} = \text{diag} \left( \left( \sum_{i \in \underline{N}} e_{i1}^2 \right) C_1^* C_1, \dots, \left( \sum_{i \in \underline{N}} e_{iN}^2 \right) C_N^* C_N \right).$$

We cannot expect to be able to characterize  $r_{\Delta}(A, B, C, E)$  by the solvability of this Riccati equation. In fact, by Theorem 2.5, (69) has a Hermitian solution if and only if

$$(70) \quad \rho \leq r_{\mathbb{C}}(A, B, \tilde{C}) = \inf\{\|\tilde{\Delta}\|_{2,2}; \tilde{\Delta} \in \mathbb{C}^{l \times Nq} \text{ and } \sigma(A + B\tilde{\Delta}\tilde{C}) \not\subset \mathbb{C}_-\} = \left[ \max_{\omega \in \mathbb{R}} \|\tilde{G}(i\omega)\|_{2,2} \right]^{-1},$$

where  $\tilde{G} = \tilde{C}(sI - A)^{-1}B$ . Thus (69) is related to a much larger class of perturbations than the block-diagonal perturbations of the form (55). We will therefore expect that, in general,  $r_{\mathbb{C}}(A, B, \tilde{C}) < r_{\Delta}(A, B, C, E)$ .

In order to get a better lower bound of  $r_{\Delta}(A, B, C, E)$  we use the scaling technique described in section 2. For any scaling vector  $\gamma = (\gamma_1, \dots, \gamma_N)$ , where  $\gamma_i > 0$ ,  $i \in \underline{N}$ , we set  $R_{\gamma} = \text{diag}(\gamma_1 I_{\mathbf{q}}, \dots, \gamma_N I_{\mathbf{q}})$  and  $L_{\gamma} = \text{diag}(\gamma_1 I_{l_1}, \dots, \gamma_N I_{l_N})$ . Then since  $\tilde{\Delta}$  is block-diagonal of the form (55) we have  $\tilde{\Delta} = L_{\gamma}^{-1} \tilde{\Delta} R_{\gamma}$ , and hence setting  $B_{\gamma} = B L_{\gamma}^{-1}$ ,  $\tilde{C}_{\gamma} = R_{\gamma} \tilde{C}$ , we obtain from (60) that

$$(71) \quad B(E \circ \Delta)C = B \tilde{\Delta} \tilde{C} = B_{\gamma} \tilde{\Delta} \tilde{C}_{\gamma}.$$

$\tilde{C}_{\gamma}$  has the same structure as  $\tilde{C}$  but with  $e_{ij}$  replaced by  $\gamma_i e_{ij}$ . More precisely,

$$(72) \quad \begin{aligned} B_{\gamma} &= \text{diag}(\gamma_1^{-1} B_1, \dots, \gamma_N^{-1} B_N), \\ \tilde{C}_{\gamma} &= \begin{bmatrix} \tilde{C}_{\gamma}^1 \\ \vdots \\ \tilde{C}_{\gamma}^N \end{bmatrix}, \quad \tilde{C}_{\gamma}^i = \text{diag}(\gamma_i e_{i1} C_1, \dots, \gamma_i e_{iN} C_N). \end{aligned}$$

The Riccati equation associated with the triple  $(A, B_{\gamma}, \tilde{C}_{\gamma})$  is

$$(73) \quad PA + A^*P + \rho^2 \tilde{C}_{\gamma}^* \tilde{C}_{\gamma} + PB_{\gamma} B_{\gamma}^* P = 0.$$

**THEOREM 5.1.** *Suppose that  $E \in \mathbb{R}_+^{N \times N}$ ,  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$ ,  $i \in \underline{N}$ , and a scaling vector  $\gamma = (\gamma_1, \dots, \gamma_N) > 0$  are given; then  $A = \oplus_{i=1}^N A_i$ ,  $\sigma(A) \subset \mathbb{C}_-$ ,  $B_{\gamma}$  and  $\tilde{C}_{\gamma}$  are defined by (72), and  $\Delta$  is provided with the norm (35). Then we have the following:*

- (i) *The algebraic Riccati equation (73) has a Hermitian solution if and only if*

$$(74) \quad \rho^2 \leq \rho_{\gamma}^2 := \left[ \max_{j \in \underline{N}} g_j^2 \sum_{i=1}^N \frac{\gamma_i^2 e_{ij}^2}{\gamma_j^2} \right]^{-1} = \min_{j \in \underline{N}} \frac{\gamma_j^2}{g_j^2 \sum_{i=1}^N \gamma_i^2 e_{ij}^2},$$

where  $g_i = \max_{\omega \in \mathbb{R}} \|G_i(i\omega)\|_{2,2}$  and  $G_i = C_i(sI - A_i)^{-1}B_i$ ,  $i \in \underline{N}$ .

- (ii) *If  $\rho \leq \rho_{\gamma}$ , then the smallest solution  $P(\rho, \gamma)$  of (73) (satisfying  $\sigma(A + B_{\gamma} B_{\gamma}^* P) \subset \overline{\mathbb{C}_-}$ ) is of the form  $P(\rho, \gamma) = \oplus_{j \in \underline{N}} P_j(\rho, \gamma)$ , where  $P_j(\rho, \gamma)$ ,  $j \in \underline{N}$ , is the smallest solution of the algebraic Riccati equation*

$$(75) \quad P_j A_j + A_j^* P_j + \rho^2 \left( \sum_{i=1}^N \gamma_i^2 e_{ij}^2 \right) C_j^* C_j + \gamma_j^{-2} P_j B_j B_j^* P_j = 0.$$

- (iii)  $\sigma(A + B(E \circ \Delta)C) \subset \mathbb{C}_-$  for all  $\Delta \in \Delta$  with  $\|\Delta\|_{\Delta} < \rho_{\gamma}$ .  
 (iv) *Suppose  $E$  does not have a zero column,  $\rho \leq \rho_{\gamma}$ , and  $P$  is a Hermitian solution of (73). If  $r < \rho$ , then there exists a constant  $k > 0$  such that the derivative of the quadratic function  $V_{\rho}(x) = \langle x, Px \rangle$  along trajectories of  $\dot{x} = A_{\Delta} x$  (31) satisfies  $\dot{V}_{\rho}(x) \leq -k \|Cx\|^2$ ,  $x \in \mathbb{C}^n$ , for all  $\Delta \in \Delta$ ,  $\|\Delta\|_{\Delta} \leq r$ . If the pairs  $(A_j, C_j)$ ,  $j \in \underline{N}$ , are observable, then the pair  $(A, \tilde{C}_{\gamma})$  is observable and  $V_{\rho}(x) = \langle x, Px \rangle$  is a joint Liapunov function for all perturbed systems  $\dot{x} = (A + B(E \circ \Delta)C)x$  with  $\Delta \in \Delta$ ,  $\|\Delta\|_{\Delta} \leq \rho$ .*

*Proof.* (i) It follows from (58) and (72) that  $\tilde{C}_\gamma^* \tilde{C}_\gamma$  is the block-diagonal matrix

$$(76) \quad \tilde{C}_\gamma^* \tilde{C}_\gamma = \text{diag} \left( \left( \sum_{i=1}^N \gamma_i^2 e_{i1}^2 \right) C_1^* C_1, \dots, \left( \sum_{i=1}^N \gamma_i^2 e_{iN}^2 \right) C_N^* C_N \right).$$

So if  $G_\gamma(s)$  is the transfer function of the system  $(A, B_\gamma, \tilde{C}_\gamma)$  and  $\Theta = \int_0^\infty e^{A^*t} \tilde{C}_\gamma^* \tilde{C}_\gamma e^{At} dt$  is the observability Gramian of the pair  $(A, \tilde{C}_\gamma)$ , then

$$(77) \quad \begin{aligned} G_\gamma(s)^* G_\gamma(s) \\ = \text{diag} \left( \left( \sum_{i=1}^N \gamma_i^2 e_{i1}^2 / \gamma_1^2 \right) G_1(s)^* G_1(s), \dots, \left( \sum_{i=1}^N \gamma_i^2 e_{iN}^2 / \gamma_N^2 \right) G_N(s)^* G_N(s) \right), \end{aligned}$$

$$(78) \quad \Theta = \text{diag} \left( \left( \sum_{i=1}^N \gamma_i^2 e_{i1}^2 \right) \Theta_1, \dots, \left( \sum_{i=1}^N \gamma_i^2 e_{iN}^2 \right) \Theta_N \right), \quad \Theta_j = \int_0^\infty e^{A_j^*t} C_j^* C_j e^{A_j t} dt.$$

By (77) we have  $\|G_\gamma(i\omega)\|_{2,2}^2 = \max_{j \in \underline{N}} \left( \sum_{i=1}^N \gamma_i^2 e_{ij}^2 / \gamma_j^2 \right) \|G_j(i\omega)\|_{2,2}^2$  and hence

$$(79) \quad \max_{\omega \in \mathbb{R}} \|G_\gamma(i\omega)\|_{2,2}^2 = \max_{j \in \underline{N}} \left[ \left( \sum_{i=1}^N \gamma_i^2 e_{ij}^2 / \gamma_j^2 \right) \max_{\omega \in \mathbb{R}} \|G_j(i\omega)\|_{2,2}^2 \right] = \max_{j \in \underline{N}} \left( g_j^2 \sum_{i=1}^N \gamma_i^2 e_{ij}^2 / \gamma_j^2 \right).$$

Therefore (i) follows from Theorem 2.5.

(ii) If  $\rho \leq \rho_\gamma$ , then  $\rho^2 \leq \left[ \left( \sum_{i=1}^N \gamma_i^2 e_{ij}^2 / \gamma_j^2 \right) \max_{\omega \in \mathbb{R}} \|G_j(i\omega)\|_{2,2}^2 \right]^{-1}$  for  $j \in \underline{N}$  and it follows from Theorem 2.5 that every Riccati equation (75),  $j \in \underline{N}$  has a smallest Hermitian solution  $P_j = P_j(\rho, \gamma)$  satisfying  $\sigma(A_j + \gamma_j^{-2} B_j B_j^* P_j) \subset \overline{\mathbb{C}_-}$ . Because of the block-diagonal structure of  $A$ ,  $\tilde{C}_\gamma^* \tilde{C}_\gamma$ , and  $B_\gamma B_\gamma^*$ , the block-diagonal Hermitian matrix  $P := \oplus_{j \in \underline{N}} P_j(\rho, \gamma)$  is a solution of (73) satisfying  $\sigma(A + B_\gamma B_\gamma^* P) \subset \overline{\mathbb{C}_-}$ . Since there exists only one such solution of (73) (which is the smallest one), (ii) follows.

(iii) Since  $\rho_\gamma = [\max_{\omega \in \mathbb{R}} \|G_\gamma(i\omega)\|_{2,2}]^{-1} = r_{\mathbb{C}}(A, B_\gamma, \tilde{C}_\gamma)$  by (79), (14),  $\|\Delta\|_{\Delta} = \|\tilde{\Delta}\|_{2,2}$ , by (56), and  $\sigma(A + B(E \circ \Delta)C) = \sigma(A + B_\gamma \tilde{\Delta} \tilde{C}_\gamma)$  by (71), (iii) follows from the definition of  $r_{\mathbb{C}}(A, B_\gamma, \tilde{C}_\gamma)$ .

(iv) If the pairs  $(A_j, C_j)$ ,  $j \in \underline{N}$ , are observable and  $E$  does not have a zero column, then  $\Theta_j \succ 0$  and it follows from (78) that  $\Theta \succ 0$ ; i.e.,  $(A, \tilde{C}_\gamma)$  is observable. This proves the observability assertion in (iv). As  $\rho_\gamma = r_{\mathbb{C}}(A, B_\gamma, \tilde{C}_\gamma)$ , the remaining statements in (iv) follow by applying Theorem 2.6(iii) to  $(A, B_\gamma, \tilde{C}_\gamma)$  and observing that by (76) there exist  $\alpha > 0$ ,  $\beta > 0$  such that  $\alpha C^* C \preceq \tilde{C}_\gamma^* \tilde{C}_\gamma \preceq \beta C^* C$  (since by assumption  $\forall j \in \underline{N} \exists i \in \underline{N} : e_{ij} \neq 0$ ).  $\square$

$\rho_\gamma$  is completely determined by the scaling vector  $\gamma > 0$ , the  $H_\infty$ -norms  $g_i$  of the transfer functions  $G_i(s)$  of the subsystems  $\Sigma_i$ , and by the structure matrix  $E$ . To indicate these dependencies we write  $\rho_\gamma = \rho_\gamma(D_g, E)$ , where  $D_g = \text{diag}(g_1, \dots, g_N)$ . Equation (74) implies that  $\rho_\gamma = \infty$  if and only if  $g_j^2 \sum_{i=1}^N \gamma_i^2 e_{ij}^2 = 0$  (i.e.,  $g_j = 0$  or the  $j$ th column of  $E$  is zero) for all  $j \in \underline{N}$ .

It follows from the third statement in Theorem 5.1 and the definition of the stability radius  $r_{\Delta} = r_{\Delta}(A, B, C, E)$  that  $\rho_\gamma \leq r_{\Delta}$ . But, in general, we will have  $\rho_\gamma < r_{\Delta}$ . It is an interesting question whether  $\hat{\rho} := \sup_{\gamma \in (0, \infty)^N} \rho_\gamma$  satisfies  $\hat{\rho} = r_{\Delta}$ .

and whether there exists a scaling vector  $\hat{\gamma} \in (0, \infty)^N$  such that  $\rho_{\hat{\gamma}} = \hat{\rho}$ . We will see that under certain conditions there exists an optimizing  $\gamma$ , but even in this case one has, in general,  $\hat{\rho} \neq r_{\Delta}$ .

First, we derive a formula for  $\hat{\rho}$ . Since the  $\rho_{\gamma}$  only depend upon the nonnegative matrix  $E$  and the diagonal matrix  $D_g$ , we formulate the result for these data.

**THEOREM 5.2.** *Suppose  $E \in \mathbb{R}_+^{N \times N}$ ,  $g_1, \dots, g_N \geq 0$  are given and, for any scaling vector  $\gamma = (\gamma_1, \dots, \gamma_N) > 0$ , the number  $\rho_{\gamma}$  is defined by (74). Then  $\hat{\rho} = \sup_{\gamma \in (0, \infty)^N} \rho_{\gamma}$  is determined by*

$$(80) \quad \hat{\rho}^2 = \varrho(E^{\circ 2} D_g^2)^{-1} = \varrho(D_g^2 E^{\circ 2})^{-1}, \text{ where } D_g = \text{diag}(g_1, \dots, g_N).$$

For the proof of this theorem we will make use of the following lemma.

**LEMMA 5.3.** *For every nonnegative matrix  $M = (m_{ij}) \in \mathbb{R}_+^{N \times N}$ ,*

$$(81) \quad \varrho(M) = \inf_{y > 0} \max_{j \in \underline{N}} \frac{(y^{\top} M)_j}{y_j} = \inf_{y > 0} \max_{j \in \underline{N}} \frac{1}{y_j} \sum_{i \in \underline{N}} y_i m_{ij}.$$

Moreover, the following conditions are equivalent:

- (i)  $\varrho(M) = \min_{y > 0} \max_{j \in \underline{N}} \frac{(y^{\top} M)_j}{y_j}$ .
- (ii) *There exists a positive row vector  $z > 0$  such that  $\max_{j \in \underline{N}} \frac{1}{z_j} \sum_{i \in \underline{N}} z_i m_{ij} = \varrho(M)$ .*
- (iii) *There exists a positive row vector  $z > 0$  such that  $zM \leq \varrho(M)z$ .*
- (iv) *Let  $\pi \in \Pi_N$  be a permutation such that  $\pi(M) = (M_{hk})_{h,k \in \underline{s}}$  is of block-triangular structure where each diagonal block  $M_{hh} \in \mathbb{R}_+^{\nu_h \times \nu_h}$ ,  $h \in \underline{s}$ , is square and is either irreducible or a  $1 \times 1$  null matrix. Then, for every  $k \in \underline{s}$ ,*

$$(82) \quad \varrho(M_{kk}) = \varrho(M) \Rightarrow M_{ik} = 0 \text{ for all } i = k + 1, \dots, s.$$

In particular, conditions (i)–(iii) hold if  $M$  is irreducible.

*Proof.* Let  $(M_k)$  be a decreasing sequence of positive matrices  $M_k > 0$  converging towards  $M$ . By [13, Corollary 8.1.31]

$$\varrho(M_k) = \min_{y > 0} \max_{j \in \underline{N}} \frac{(y^{\top} M_k)_j}{y_j}, \quad k \in \mathbb{N}.$$

Hence it follows by continuity and monotonicity of the spectral radius on  $\mathbb{R}_+^{N \times N}$  (see Lemma 4.5) that

$$\begin{aligned} \varrho(M) &= \inf_{k \in \mathbb{N}} \varrho(M_k) = \inf_{k \in \mathbb{N}} \min_{y > 0} \max_{j \in \underline{N}} \frac{(y^{\top} M_k)_j}{y_j} \\ &= \inf_{y > 0} \inf_{k \in \mathbb{N}} \max_{j \in \underline{N}} \frac{(y^{\top} M_k)_j}{y_j} = \inf_{y > 0} \max_{j \in \underline{N}} \frac{(y^{\top} M)_j}{y_j}. \end{aligned}$$

This proves (81). Let us now show the equivalence of the conditions (i)–(iv). (i)  $\Leftrightarrow$  (ii) follows directly from (81). The equivalence of (ii) and (iii) follows because  $zM \leq \varrho(M)z$  and  $z > 0$  imply  $\max_{j \in \underline{N}} (zM)_j / z_j = \varrho(M)$ , again by (81).

Since conditions (i)–(iii) hold for  $M$  if and only if they hold for any permutation  $\pi(M)$ , we may assume that  $M = (M_{ij})$  is already of the block-triangular form described in (iv).

(iii)  $\Rightarrow$  (iv). Suppose that  $z = (z_1, \dots, z_N) > 0$  satisfies  $zM \leq \varrho(M)z$  and  $\varrho(M_{kk}) = \varrho(M)$  for some  $k \in \underline{s}$ . If we partition  $z$  in a compatible way with  $M$ ,  $z = (z^1, \dots, z^s)$ ,  $z^i \in \mathbb{R}_+^{1 \times \nu_i}$ , then  $zM \leq \varrho(M)z$  implies

$$z^k M_{kk} \leq \sum_{i=k}^s z^i M_{ik} \leq \varrho(M)z^k = \varrho(M_{kk})z^k.$$

On the other hand, it follows from (81) applied to  $M_{kk}$  that  $z^k M_{kk} \geq \varrho(M_{kk})z^k$ . Therefore  $z^k M_{kk} = \sum_{i=k}^s z^i M_{ik}$  and so  $\sum_{i=k+1}^s z^i M_{ik} = 0$  which implies  $M_{ik} = 0$  for  $i = k+1, \dots, s$ .

(iv)  $\Rightarrow$  (iii) is proved by induction on  $s$ . If  $s = 1$ , then  $M$  is irreducible or  $N = 1$  and  $M = [0]$ . In the first case, (iii) holds by Lemma 4.5(i). In the second case,  $\varrho(M) = 0$  and (iii) holds for any  $z = (z_1) > 0$ . Now suppose the implication (iv)  $\Rightarrow$  (iii) has been proved for  $s = 1, \dots, k-1$  for some  $k \geq 2$  and  $M$  is of the form (39) with  $s = k$ . Assume that (iv) holds.  $M$  can be written as a triangular  $2 \times 2$  block matrix

$$(83) \quad M = \begin{bmatrix} M^{11} & 0_{\nu_1 \times (N-\nu_1)} \\ M^{21} & M^{22} \end{bmatrix}, \quad M^{11} = M_{11},$$

$$M^{21} = \begin{bmatrix} M_{21} \\ \vdots \\ M_{k1} \end{bmatrix}, \quad M^{22} = \begin{bmatrix} M_{22} & 0 & \cdots & 0 \\ M_{32} & M_{33} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ M_{k2} & M_{k3} & \cdots & M_{kk} \end{bmatrix}.$$

Let  $\varrho = \varrho(M)$ ,  $\varrho_1 = \varrho(M^{11})$ ,  $\varrho_2 = \varrho(M^{22})$ ,  $I_1 = \{1, \dots, \nu_1\}$ ,  $I_2 = \{\nu_1 + 1, \dots, N\}$ . Then  $\varrho = \max\{\varrho_1, \varrho_2\}$ . First, suppose  $\varrho_1 = \varrho$ . Then  $M^{11}$  is either irreducible or  $M^{11} = [0]$ ,  $\nu_1 = 1$ , and  $\varrho_1 = 0$ . In either case there exists a left Perron vector  $z^1 = (z_1, \dots, z_{\nu_1}) > 0$  such that  $z^1 M^{11} = \varrho_1 z^1$ . If  $\varrho_2 = \varrho$ , then  $M^{22}$  satisfies condition (iv) with  $M$  replaced by  $M^{22}$ . Therefore there exists, by assumption of induction, a row vector  $z^2 = (z_{\nu_1+1}, \dots, z_N) > 0$  such that  $z^2 M^{22} \leq \varrho_2 z^2$ . Since  $M_{i1} = 0$  for  $i = 2, \dots, k$  it follows that  $z = (z^1, z^2) = (z_1, \dots, z_N)$  satisfies  $zM \leq \varrho z$ . If  $\varrho_2 < \varrho$ , then we may apply (81) to conclude that there exists  $z^2 = (z_{\nu_1+1}, \dots, z_N) > 0$  such that  $z^2 M^{22} < \varrho z^2$ . Again we obtain  $zM \leq \varrho z$  for  $z = (z^1, z^2)$ .

Finally, suppose that  $\varrho_1 < \varrho$ . As above there exists a row vector  $z^1 = (z_1, \dots, z_{\nu_1}) > 0$  such that  $z^1 M^{11} = \varrho_1 z^1$ . On the other hand, we necessarily have  $\varrho_2 = \varrho$ . Hence  $M^{22}$  satisfies condition (iv) with  $M$  replaced by  $M^{22}$ . Therefore there exists, by assumption of induction, a row vector  $z^2 = (z_{\nu_1+1}, \dots, z_N) > 0$  such that  $z^2 M^{22} \leq \varrho_2 z^2$ . For any  $\alpha > 0$  define  $z(\alpha) = (z^1, \alpha z^2) = (z_1, \dots, z_{\nu_1}, \alpha z_{\nu_1+1}, \dots, \alpha z_N) > 0$ . Since  $\varrho_1 < \varrho$  we obtain  $z(\alpha)M \leq \varrho z(\alpha)$  if  $\alpha > 0$  is chosen sufficiently small. We conclude that in both cases,  $\varrho_1 = \varrho$  and  $\varrho_1 < \varrho$ , there exists a row vector  $z > 0$  such that  $zM \leq \varrho(M)z$ . This proves (iv)  $\Rightarrow$  (iii).  $\square$

*Proof of Theorem 5.2.* First, note that the second equality in (80) follows from the general fact that  $\varrho(ED) = \varrho(DE)$  for any pair of square matrices  $D, E$ . If  $\gamma > 0$  is any scaling vector, then we have by (74)

$$(84) \quad \rho_\gamma(D_g, E)^{-2} = \max_{j \in \underline{N}} \frac{1}{\gamma_j^2} \sum_{i=1}^N \gamma_i^2 e_{ij}^2 g_j^2 = \max_{j \in \underline{N}} \frac{(\gamma^2 E^{\circ 2} D_g^2)_j}{\gamma_j^2}.$$

Hence, applying (81) to  $M = E^{\circ 2} D_g^2$  with  $y = \gamma^2$  we obtain

$$\begin{aligned}\hat{\rho}^{-2} &= \left[ \sup_{\gamma \in (0, \infty)^N} \rho_\gamma(D_g, E) \right]^{-2} \\ &= \inf_{\gamma \in (0, \infty)^N} \rho_\gamma(D_g, E)^{-2} = \inf_{\gamma \in (0, \infty)^N} \max_{j \in \underline{N}} \frac{(\gamma^2 E^{\circ 2} D_g^2)_j}{\gamma_j^2} = \varrho(E^{\circ 2} D_g^2),\end{aligned}$$

and this proves (80).  $\square$

The following remark indicates that generically  $\hat{\rho} < r_\Delta(A, B, C, E)$ .

*Remark 5.4.* It follows from Corollary 4.9 and Theorem 5.2 that

$$(85) \quad r_\Delta(A, B, C, E) = \hat{\rho} \quad \Leftrightarrow \quad \max_{\omega \in \mathbb{R}} \varrho(E^{\circ 2} D(\omega)^2) = \varrho(E^{\circ 2} D_g^2).$$

Now suppose that  $E$  is irreducible and no  $G_i(s)$  vanishes identically. Then  $\hat{\rho}^2 = r_\Delta(A, B, C, E)$  if and only if there exists a joint maximum  $\omega_0 \in \mathbb{R}$  of the  $N$  functions  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ , i.e., such that  $\|G_i(\omega_0)\|_{2,2} = \max_{\omega \in \mathbb{R}} \|G_i(\omega)\|_{2,2}$  for all  $i \in \underline{N}$ . In fact, if this condition is not satisfied, then  $0 \leq D(\omega) \leq D_g$ ,  $D(\omega) \neq D_g$  and so  $\varrho(D(\omega)^2 E^{\circ 2}) = \varrho(E^{\circ 2} D(\omega)^2) < \varrho(E^{\circ 2} D_g^2)$  for all  $\omega \in \mathbb{R}$  by [4, Corollary 2.1.5] since  $E^{\circ 2} D_g^2$  is irreducible. Conversely, if the condition is satisfied, then the right-hand equality in (85) follows directly from  $\|G_i(\omega_0)\|_{2,2} = g_i$ ,  $i \in \underline{N}$ .

Now suppose that  $E$  is reducible. Then  $\hat{\rho} = r_\Delta(A, B, C, E)$  if and only if there exist a strongly connected component of  $\mathcal{G}_E$  with node set  $J \subset \underline{N}$  and a joint maximum  $\omega_0 \in \mathbb{R}$  such that  $\|G_i(\omega_0)\|_{2,2} = \max_{j \in \underline{N}} \max_{\omega \in \mathbb{R}} \|G_j(\omega)\|_{2,2}$  for all  $i \in J$ .

We will now investigate under which conditions there exists an *optimal* scaling vector, i.e.,  $\gamma > 0$  such that  $\rho_\gamma = \hat{\rho}$ .

**THEOREM 5.5.** *Suppose  $E \in \mathbb{R}_+^{N \times N}$ ,  $g_1, \dots, g_N \geq 0$  are given,  $D_g = \text{diag}(g_1, \dots, g_N)$ , and, for any scaling vector  $\gamma > 0$ , the number  $\rho_\gamma = \rho_\gamma(D_g, E)$  is defined by (74) and  $\hat{\rho}(D_g, E) = \sup_{\gamma \in (0, \infty)^N} \rho_\gamma$ . Then the following conditions are equivalent for every scaling vector  $\hat{\gamma} = (\hat{\gamma}_1, \dots, \hat{\gamma}_N) > 0$ :*

- (i)  $\hat{\gamma}$  is optimal; i.e.,  $\rho_{\hat{\gamma}}(D_g, E) = \hat{\rho}(D_g, E)$ .
- (ii)  $\hat{\gamma}^2 = (\hat{\gamma}_1^2, \dots, \hat{\gamma}_N^2)$  satisfies  $\max_{j \in \underline{N}} \frac{(\hat{\gamma}^2 E^{\circ 2} D_g^2)_j}{\hat{\gamma}_j^2} = \varrho(E^{\circ 2} D_g^2)$ .

*In particular, there exists an optimal scaling vector if and only if  $M = E^{\circ 2} D_g^2$  satisfies one of the equivalent conditions (i)–(iii) of Lemma 5.3.*

*Proof.* By (74) and (80) condition (i) holds if and only if  $\hat{\gamma}^2$  satisfies

$$\max_{j \in \underline{N}} \frac{1}{\hat{\gamma}_j^2} \sum_{i=1}^N \hat{\gamma}_i^2 e_{ij}^2 g_j^2 = \rho_{\hat{\gamma}}(D_g, E)^{-2} = \hat{\rho}(D_g, E)^{-2} = \varrho(E^{\circ 2} D_g^2).$$

This proves (i)  $\Leftrightarrow$  (ii). Setting  $z = \hat{\gamma}^2$ , condition (ii) is identical with condition (ii) of Lemma 5.3 for  $M = E^{\circ 2} D_g^2$  and this yields the last statement of the theorem.  $\square$

As a consequence of Theorem 5.5 there always exists an optimal scaling vector if  $E^{\circ 2} D_g^2$  is irreducible.

**6. Nonlinear and/or time-varying perturbations.** Throughout this section we suppose the following:

$$(86) \quad \begin{aligned} &(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}, \quad \sigma(A_i) \subset \mathbb{C}_-, \quad G_i(s) = C_i(sI - A_i)^{-1} B_i, \quad i \in \underline{N}, \\ &A = \oplus_{i=1}^N A_i, \quad B = \oplus_{i=1}^N B_i, \quad C = \oplus_{i=1}^N C_i, \quad D(s) = \oplus_{i=1}^N \|G_i(s)\|_{2,2}, \\ &g_i := \max_{\omega \in \mathbb{R}} \|G_i(\omega)\|_{2,2}, \quad i \in \underline{N}, \quad D_g = \text{diag}(g_1, \dots, g_N), \quad E \in \mathbb{R}_+^{N \times N}. \end{aligned}$$

Let  $\Omega$  be an open neighborhood of 0 in  $\mathbb{C}^n$ , and consider time-varying nonlinear perturbations of  $\dot{x} = Ax$  of the form

$$(87) \quad \dot{x} = Ax + B(E \circ \Delta(x, t))y, \quad y = Cx,$$

where  $\Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega)$ . Here  $\mathbf{\Delta}_{nt}(\Omega)$  is the vector space of all bounded block matrix valued functions  $\Delta(\cdot, \cdot) = (\Delta_{ij}(\cdot, \cdot)) : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{C}^{l \times q}$  with the Carathéodory properties (see section 2) provided with the norm

$$(88) \quad \|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} = \sup_{x \in \Omega, t \geq 0} \|\Delta(x, t)\|_{\mathbf{\Delta}}, \quad \Delta(\cdot, \cdot) = (\Delta_{ij}(\cdot, \cdot)) \in \mathbf{\Delta}_{nt}(\Omega).$$

Note that for every  $\Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega)$ ,  $\Delta^E(\cdot, \cdot) = E \circ \Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega)$  is of structure  $E$ ; i.e.,

$$\forall (x, t) \in \Omega \times \mathbb{R}_+ : \quad e_{ij} = 0 \quad \Rightarrow \quad \Delta_{ij}^E(x, t) = 0.$$

By Carathéodory's theorem, for every  $\Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega)$ ,  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$ , there exists a unique solution  $x_{\Delta}(t) = x_{\Delta}(t; t_0, x^0)$  of (87) with  $x_{\Delta}(t_0) = x^0$  on some maximal semiopen interval  $[t_0, t_+^{\Delta}(t_0, x^0))$ , where  $t_+^{\Delta}(t_0, x^0) > t_0$ ; see [12, Theorem 2.1.14]. In the following theorem we will see that  $t_+^{\Delta}(t_0, x^0) = \infty$  if  $\|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} < \hat{\rho}(D_g, E)$  and  $x^0$  is sufficiently close to the equilibrium state  $\bar{x} = 0$ . For simplicity, we call the nonlinear system (87) *uniformly (asymptotically) stable* if  $\bar{x} = 0$  is a uniformly (asymptotically) stable equilibrium position of the system (87).

**THEOREM 6.1.** *Suppose (86). Then we have the following.*

- (i) *The nonlinear system (87) is asymptotically stable for all  $\Delta \in \mathbf{\Delta}_{nt}(\Omega)$  satisfying*

$$(89) \quad \|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} < \hat{\rho}(D_g, E) = \sup_{\gamma > 0} \rho_{\gamma}(D_g, E).$$

*Moreover, if (89) holds, then every trajectory  $x_{\Delta}(t) = x_{\Delta}(t; t_0, x^0)$ ,  $(t_0, x^0) \in \mathbb{R}_+ \times \Omega$  of (87) with an infinite life span  $[t_0, \infty)$  tends to 0 as  $t \rightarrow \infty$ .*

- (ii) *Suppose  $\rho \leq \rho_{\gamma}(D_g, E)$  for some scaling vector  $\gamma > 0$  and  $P$  is a Hermitian solution of the associated algebraic Riccati equation (73). If  $\delta > 0$  is such that  $D_{\delta} = \{x \in \mathbb{C}^n; \langle x, Px \rangle < \delta\} \subset \Omega$ , then  $D_{\delta}$  is a joint domain of attraction of the equilibrium point  $\bar{x} = 0$  for all the systems (87) with  $\Delta \in \mathbf{\Delta}_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} < \rho$ .*
- (iii) *Suppose  $E$  does not have a zero column,  $\rho \leq \rho_{\gamma}(D_g, E)$  for some scaling vector  $\gamma > 0$ , and  $P$  is a Hermitian solution of (73). If  $r < \rho$ , then there exists a constant  $k > 0$  such that the derivative of the quadratic function  $V_{\rho}(x) = \langle x, Px \rangle$  along trajectories of (87) satisfies  $\dot{V}_{\rho}(x) \leq -k\|Cx\|^2$ ,  $x \in \Omega$ , for all  $\Delta \in \mathbf{\Delta}_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} \leq r$ . If the pairs  $(A_j, C_j)$ ,  $j \in \underline{N}$ , are observable, then  $V_{\rho}(x)$  is a joint Liapunov function at  $\bar{x} = 0$  for all perturbed systems (87) with  $\Delta \in \mathbf{\Delta}_{nt}(\Omega)$ ,  $\|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}} \leq \rho$ .*

*Proof.* For any  $\Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega)$  define  $\tilde{\Delta}(\cdot, \cdot) : \Omega \times \mathbb{R}_+ \rightarrow \mathbb{C}^{l \times Nq}$  by

$$\tilde{\Delta}(x, t) = \text{diag}(\Delta^1(x, t), \dots, \Delta^N(x, t)), \quad (x, t) \in \Omega \times \mathbb{R}_+,$$

where  $\Delta^i(x, t) \in \mathbb{C}^{l_i \times q}$ ,  $i \in \underline{N}$ , is the  $i$ th block row of  $\Delta(x, t)$ . We provide the vector space  $\tilde{\mathbf{\Delta}}_{nt}(\Omega)$  of all these  $\tilde{\Delta}(\cdot, \cdot)$  with the norm (see (56))

$$(90) \quad \begin{aligned} \|\tilde{\Delta}(\cdot, \cdot)\|_{\tilde{\mathbf{\Delta}}_{nt}} &:= \sup_{x \in \Omega, t \geq 0} \|\tilde{\Delta}(x, t)\|_{2,2} \\ &= \sup_{x \in \Omega, t \geq 0} \|\Delta(x, t)\|_{\mathbf{\Delta}} = \|\Delta(\cdot, \cdot)\|_{\mathbf{\Delta}_{nt}}, \quad \Delta(\cdot, \cdot) \in \mathbf{\Delta}_{nt}(\Omega). \end{aligned}$$

The map  $\Delta(\cdot, \cdot) \mapsto \tilde{\Delta}(\cdot, \cdot)$  is an (isometric) isomorphism from  $\Delta_{nt}(\Omega)$  onto  $\tilde{\Delta}_{nt}(\Omega)$ . By (59) we have  $B(E \circ \Delta(x, t))C = B\tilde{\Delta}(x, t)\tilde{C}$ , where  $\tilde{C}$  is as in (57). Since  $\tilde{\Delta}(x, t)$  is block-diagonal, we may apply scaling to obtain from (71) that, for all  $\gamma = (\gamma_1, \dots, \gamma_N) > 0$ ,

$$(91) \quad B(E \circ \Delta(x, t))C = B\tilde{\Delta}(x, t)\tilde{C} = B_\gamma\tilde{\Delta}(x, t)\tilde{C}_\gamma, \quad (x, t) \in \Omega \times \mathbb{R}_+, \quad \Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega),$$

where  $B_\gamma, \tilde{C}_\gamma$  are as in (72). Hence the uncertain time-varying nonlinear system (87) with  $\Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega)$  can equivalently be described by

$$(92) \quad \dot{x} = Ax + B_\gamma\tilde{\Delta}(x, t)\tilde{C}_\gamma x,$$

where  $\tilde{\Delta}(\cdot, \cdot) \in \tilde{\Delta}_{nt}(\Omega)$  is the associated block-diagonal perturbation.

The parametrized Riccati equation (73) is of the form (15) with  $(A, B, C)$  replaced by  $(A, B_\gamma, \tilde{C}_\gamma)$ . Hence, by Theorem 2.5, there exist Hermitian solutions  $P$  of (73) if

$$\rho \leq \rho_\gamma = \left[ \max_{\omega \in \mathbb{R}} \|G_\gamma(i\omega)\|_{2,2} \right]^{-1} = r_{\mathbb{C}}(A, B_\gamma, \tilde{C}_\gamma), \quad \text{where } G_\gamma(s) = \tilde{C}_\gamma(sI_n - A)^{-1}B_\gamma.$$

By (91) the perturbed system (87) is of the form (17) with  $(A, B, C)$  replaced by  $(A, B_\gamma, \tilde{C}_\gamma)$  and  $\Delta(\cdot, \cdot) \in \Delta_{nt}(\Omega)$  replaced by  $\tilde{\Delta}(\cdot, \cdot) \in \tilde{\Delta}_{nt}(\Omega)$ . By Theorem 5.1  $(A, \tilde{C}_\gamma)$  is observable if the pairs  $(A_j, C_j)$ ,  $j \in \underline{N}$ , are observable and  $E$  does not have a zero column. Hence (ii) and (iii) follow by application of Theorem 2.6 to  $(A, B_\gamma, \tilde{C}_\gamma)$  making use of (91) and the fact that there exist  $\alpha > 0, \beta > 0$  such that  $\alpha C^*C \preceq \tilde{C}_\gamma^* \tilde{C}_\gamma \preceq \beta C^*C$ . Finally (i) follows from Theorem 2.6(i) since for every  $\Delta \in \Delta_{nt}(\Omega)$  satisfying  $\|\Delta(\cdot, \cdot)\|_{\Delta_{nt}} < \hat{\rho}(D_g, E)$  there exists  $\gamma > 0$  such that  $\|\tilde{\Delta}(\cdot, \cdot)\|_{\tilde{\Delta}_{nt}} = \|\Delta(\cdot, \cdot)\|_{\Delta_{nt}} < \rho_\gamma(D_g, E) = r_{\mathbb{C}}(A, B_\gamma, \tilde{C}_\gamma)$ .  $\square$

We now examine whether or not (89) is a tight robustness estimate. In order to do this we introduce a stability radius with respect to time-varying linear and nonlinear perturbations. Consider the following time-varying linear system:

$$(93) \quad \dot{x}(t) = Ax(t) + B(E \circ \Delta(t))Cx(t),$$

where  $\Delta(\cdot) \in \Delta_{tv}$  and  $\Delta_{tv}$  is the vector space of all bounded measurable block matrix valued functions  $\Delta(\cdot): \mathbb{R}_+ \rightarrow \mathbb{C}^{l \times q}$ . We provide  $\Delta_{tv}$  with the  $tv$ -norm

$$(94) \quad \|\Delta(\cdot)\|_{\Delta_{tv}} = \sup_{t \geq 0} \|\Delta(t)\|_{\Delta}, \quad \Delta \in \Delta_{tv}.$$

Similarly, we denote by  $\Delta_n$  the vector space of all perturbations  $\Delta \in \Delta_n := \Delta_{nt}(\mathbb{C}^n)$  which are independent of time, i.e.,  $\Delta(x, t) = \Delta(x)$ , and provide it with the norm induced from  $\Delta_{nt}$ :

$$(95) \quad \|\Delta(\cdot)\|_n = \sup_{x \in \mathbb{C}^n} \|\Delta(x)\|_{\Delta}, \quad \Delta \in \Delta_n.$$

Note that, with the obvious embeddings  $\Delta \subset \Delta_{tv} \subset \Delta_{nt}$ , the norm  $\|\cdot\|_{\Delta_{tv}}$  is the restriction of the norm  $\|\cdot\|_{\Delta_{nt}}$  to  $\Delta_{tv}$  and the norm  $\|\cdot\|_{\Delta}$  is the restriction of the norm  $\|\cdot\|_{\Delta_{tv}}$  to  $\Delta$ .

DEFINITION 6.2. *Given  $A \in \mathbb{C}^{n \times n}$  the stability radius of  $A$  with respect to complex time-varying linear perturbations  $\Delta(\cdot) \in \Delta_{tv}$  is defined by*

$$r_{\Delta_{tv}}(A, B, C, E) = \inf\{\|\Delta(\cdot)\|_{\Delta_{tv}}; \Delta(\cdot) \in \Delta_{tv} \text{ and (93) is not asymptotically stable}\}.$$

The stability radius of  $A$  with respect to complex nonlinear (respectively, nonlinear time-varying) perturbations,  $r_{\Delta_n}(A, B, C, E)$  and  $r_{\Delta_{nt}}(A, B, C, E)$ , is defined analogously.

In the full block case we have (see [12, section 5.6])

$$r_{\Delta_{nt}}(A, B, C) = r_{\Delta_n}(A, B, C) = r_{\Delta_{tv}}(A, B, C) = r_{\Delta}(A, B, C).$$

We will see that for structured perturbations the last equality does, in general, not hold.

THEOREM 6.3. *Suppose the standing assumption of this section. Then*

$$(96) \quad r_{\Delta_{nt}}(A, B, C, E) = r_{\Delta_{tv}}(A, B, C, E) = \varrho(E^{\circ 2} D_g^2)^{-1/2} = \hat{\rho}(D_g, E).$$

*Proof.* It follows from the definitions and the isometric embeddings  $\Delta_{tv} \subset \Delta_{nt}$  that  $r_{\Delta_{nt}}(A, B, C, E) \leq r_{\Delta_{tv}}(A, B, C, E)$ . On the other hand, Theorem 6.1 (with  $\Omega = \mathbb{C}^n$ ) and Theorem 5.2 imply that  $r_{\Delta_{nt}}(A, B, C, E) \geq \hat{\rho}(D_g, E) = \sup_{\gamma > 0} \rho_{\gamma}(D_g, E) = \varrho(E^{\circ 2} D_g^2)^{-1/2}$ . To prove (96) it therefore suffices to show  $r_{\Delta_{tv}}(A, B, C, E) \leq \varrho(E^{\circ 2} D_g^2)^{-1/2}$ . Suppose

$$(97) \quad \omega_i \in \mathbb{R} \text{ is such that } \|C_i(\omega_i I_{n_i} - A_i)^{-1} B_i\|_{2,2} = g_i, \quad i \in \underline{N}.$$

Replacing  $A_i$  with  $A_i - \omega_i I_{n_i}$ ,  $i \in \underline{N}$ , in Theorem 4.7 we see that  $D$  is replaced by  $D_g = \text{diag}(g_1, \dots, g_N)$ . So just as in the proof of Theorem 4.7 one can find  $\Delta = (\Delta_{ij}) \in \Delta_E$  with  $\|\Delta\|_{\Delta} = \varrho(E^{\circ 2} D_g^2)^{-1/2}$  such that

$$(98) \quad \det(A_{\omega} + B(E \circ \Delta)C) = 0, \quad A_{\omega} = \text{diag}(A_1 - \omega_1 I_{n_1}, \dots, A_N - \omega_N I_{n_N}).$$

So there exists a nonzero  $x = (x_i)_{i \in \underline{N}} \in \mathbb{C}^n$

$$(99) \quad x = \begin{bmatrix} x_1 \\ \vdots \\ x_N \end{bmatrix} \text{ such that } \begin{bmatrix} \omega_1 x_1 \\ \vdots \\ \omega_N x_N \end{bmatrix} = (A + B(E \circ \Delta)C) \begin{bmatrix} x_1 \\ \vdots \\ x_N \end{bmatrix}.$$

Let

$$(100) \quad \Delta(t) = (\Delta_{ij}(t)), \quad \Delta_{ij}(t) = \Delta_{ij} e^{i(\omega_i - \omega_j)t}, \quad x(t) = \begin{bmatrix} x_1(t) \\ \vdots \\ x_N(t) \end{bmatrix} = \begin{bmatrix} e^{i\omega_1 t} x_1 \\ \vdots \\ e^{i\omega_N t} x_N \end{bmatrix}.$$

Then for each  $i \in \underline{N}$ ,

$$\begin{aligned} \dot{x}_i(t) &= \omega_i e^{i\omega_i t} x_i = e^{i\omega_i t} \left[ A_i x_i + B_i \sum_{j=1}^N e_{ij} \Delta_{ij} C_j x_j \right] \\ &= A_i x_i(t) + B_i \sum_{j=1}^N e_{ij} \Delta_{ij} e^{i(\omega_i - \omega_j)t} C_j e^{i\omega_j t} x_j = A_i x_i(t) + B_i \sum_{j=1}^N e_{ij} \Delta_{ij}(t) C_j x_j(t). \end{aligned}$$

Hence  $x(t)$  satisfies  $\dot{x}(t) = Ax(t) + B(E \circ \Delta(t))Cx(t)$  and  $\|\Delta(\cdot)\|_{\Delta_{tv}} = \|\Delta\|_{\Delta} = \varrho(E^{\circ 2} D_g^2)^{-1/2}$ . Since  $x(t)$  does not tend to 0 as  $t \rightarrow 0$ , it follows that  $\dot{x}(t) = Ax(t) + B(E \circ \Delta(t))Cx(t)$  is not asymptotically stable and so  $r_{\Delta_{tv}}(A) \leq \varrho(E^{\circ 2} D_g^2)^{-1/2}$ . This completes the proof.  $\square$

*Remark 6.4.* The previous theorem shows that the robustness bound (89) is tight. Moreover, we have seen in the proof that there exists a minimum norm perturbation in  $\Delta_{tv} \subset \Delta_{nt}$  which destroys asymptotic stability; that is, there is a  $\Delta(\cdot) \in \Delta_{tv}$  of tv-norm  $r_{\Delta_{tv}}(A, B, C, E) = r_{\Delta_{nt}}(A, B, C, E)$  for which the system (93) is not asymptotically stable.

Now suppose that there is a scaling vector  $\hat{\gamma} > 0$  satisfying  $\rho_{\hat{\gamma}} = \hat{\rho} = \hat{\rho}(D_g, E)$  and  $\hat{P} \succ 0$  is a Hermitian solution of the algebraic Riccati equation (73) with  $\rho = \hat{\rho}$ . Then  $V_{\hat{\rho}}(x) = \langle x, \hat{P}x \rangle$  is a joint Liapunov function of *maximal robustness* for the uncertain system (87):  $V_{\hat{\rho}}(x)$  is a Liapunov function for every system (87) with  $\Delta \in \Delta_{nt}$ ,  $\|\Delta(\cdot, \cdot)\|_{\Delta_{nt}} \leq \hat{\rho} = \varrho(E^{\circ 2} D_g^2)^{-1/2}$ , and one can prove for every  $\rho > \varrho(E^{\circ 2} D_g^2)^{-1/2}$  that there does not exist a Liapunov function for all the systems (87) with  $\Delta \in \Delta_{tv}$ ,  $\|\Delta(\cdot, \cdot)\|_{\Delta_{tv}} \leq \rho$ . The proof proceeds similarly to the proof of Theorem 6.3 showing that there exist a time-varying perturbation  $\Delta \in \Delta_{tv}$  with  $\varrho(E^{\circ 2} D_g^2)^{-1/2} < \|\Delta(\cdot, \cdot)\|_{\Delta_{tv}} < \rho$  and a solution  $x(t)$  of (93) such that  $\lim_{t \rightarrow \infty} \|x(t)\|_2 = \infty$ .

**COROLLARY 6.5.** *Suppose (86) and consider the following statements:*

- (i)  $r_{\Delta_{tv}}(A, B, C, E) = r_{\Delta}(A, B, C, E)$ .
- (ii)  $r_{\Delta_{nt}}(A, B, C, E) = r_{\Delta_n}(A, B, C, E) = r_{\Delta_{tv}}(A, B, C, E) = r_{\Delta}(A, B, C, E)$ .
- (iii)  $\max_{\omega \in \mathbb{R}} \varrho(E^{\circ 2} D(\omega)^2) = \varrho(E^{\circ 2} D_g^2)$ .
- (iv) *There exists a joint maximum  $\omega_0 \in \mathbb{R}$  of the  $N$  functions  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ ,  $i \in \underline{N}$ .*

Then (i)  $\Leftrightarrow$  (ii)  $\Leftrightarrow$  (iii)  $\Leftarrow$  (iv). If  $E$  is irreducible and  $g_i > 0$  for all  $i \in \underline{N}$ , then the four statements are all equivalent.

*Proof.* The equivalence (i)  $\Leftrightarrow$  (ii) follows from Theorem 6.3 because by definition  $r_{\Delta_{nt}}(A, B, C, E) \leq r_{\Delta_n}(A, B, C, E) \leq r_{\Delta}(A, B, C, E)$ . The equivalence (ii)  $\Leftrightarrow$  (iii) follows from Theorem 6.3 and (53).

(iv)  $\Rightarrow$  (i). Suppose that  $\omega_0 \in \mathbb{R}$  is a joint maximum of the  $N$  functions  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ ; i.e.,  $\|G_i(\omega_0)\|_{2,2} = g_i$ ,  $i \in \underline{N}$ . Then Theorem 6.3 and Lemma 4.5(iv) imply

$$r_{\Delta_{tv}}(A, B, C, E) = \varrho(E^{\circ 2} D_g^2)^{-1/2} = \varrho(E^{\circ 2} D(\omega_0)^2)^{-1/2} = \left[ \max_{\omega \in \mathbb{R}} \varrho(E^{\circ 2} D(\omega)^2) \right]^{-1/2}$$

and hence (i) by (53).

(i)  $\Rightarrow$  (iv). Now suppose that  $E$  is irreducible,  $g_i > 0$  for all  $i \in \underline{N}$ , and there does not exist a joint maximum of the functions  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ ,  $i \in \underline{N}$ . Let  $\omega_0 \in \mathbb{R}$  be a maximum of  $\omega \mapsto \varrho(E^{\circ 2} D(\omega)^2)$ . Then  $D(\omega_0) \leq D_g$  and  $D(\omega_0) \neq D_g$ . Since  $E$  and hence  $E^{\circ 2} D_g^2$  are irreducible, it follows from [4, Corollary 2.1.5] that

$$r_{\Delta}(A, B, C, E)^{-2} = \varrho(E^{\circ 2} D(\omega_0)^2) < \varrho(E^{\circ 2} D_g^2) = r_{\Delta_{tv}}(A, B, C, E)^{-2}.$$

This concludes the proof.  $\square$

*Remark 6.6.* (i) It is noteworthy that by the last statement in the previous corollary the equality  $r_{\Delta_{tv}}(A, B, C, E) = r_{\Delta}(A, B, C, E)$  depends only on the  $N$  isolated subsystems  $(A_i, B_i, C_i)$ ,  $i \in \underline{N}$ , and not on their specific interconnection, provided that  $E$  is irreducible.

(ii) Suppose  $A, B, C$  are real and each function  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ ,  $i \in \underline{N}$ , admits its maximum on  $\mathbb{R}_+$  at  $\omega = 0$ . Then  $\omega \mapsto \varrho(D(\omega)^2 E^{\circ 2})$  admits its maximum on  $\mathbb{R}_+$  at  $\omega = 0$ , and we conclude from Corollary 6.5, Theorem 6.3, and Remark 4.10 that

$$\begin{aligned} r_{\Delta_{nt}}(A, B, C, E) &= r_{\Delta_{tv}}(A, B, C, E) \\ &= r_{\Delta}(A, B, C, E) = r_{\Delta_{\mathbb{R}}}(A, B, C, E) = \varrho(E^{\circ 2} D_g^2)^{-1/2}. \end{aligned}$$

In particular, the stability radii of  $A$  with respect to *time-invariant* and *time-varying real* perturbations of structure  $E$  are equal.

In the following extended example we determine the stability radii of a system composed of two interacting oscillators with respect to time-invariant and time-varying complex perturbations. We also determine the stability radius with respect to time-invariant real perturbations of the same structure.

*Example 6.7.* Consider a composite system consisting of two harmonic oscillators

$$\Sigma_i : \quad \dot{x}_i(t) = \begin{bmatrix} 0 & 1 \\ -\nu_i^2 & -2\xi_i\nu_i \end{bmatrix} x_i(t) + \begin{bmatrix} 0 \\ b_i \end{bmatrix} u_i(t), \quad y_i(t) = \begin{bmatrix} c_i & 0 \end{bmatrix} x_i(t), \quad i = 1, 2,$$

interconnected via  $u_1 = \delta_{12}y_2$ ,  $u_2 = \delta_{21}y_1$ . We assume  $\nu_i, \xi_i > 0$ ,  $b_i, c_i \in \mathbb{R} \setminus \{0\}$ ,  $\delta_{12}, \delta_{21} \in \mathbb{C}$ . The coupled system is of the form (31) with  $N = 2$ ,  $\mathbf{l} = \mathbf{q} = (1, 1)$  and matrices

$$(101) \quad A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -\nu_1^2 & -2\xi_1\nu_1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -\nu_2^2 & -2\xi_2\nu_2 \end{bmatrix}, \quad B = \begin{bmatrix} 0 & 0 \\ b_1 & 0 \\ 0 & 0 \\ 0 & b_2 \end{bmatrix}, \quad C = \begin{bmatrix} c_1 & 0 & 0 & 0 \\ 0 & 0 & c_2 & 0 \end{bmatrix}, \quad E = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

The associated perturbation space  $\Delta_E$  is given by  $\Delta_E = \left\{ \begin{bmatrix} 0 & \delta_{12} \\ \delta_{21} & 0 \end{bmatrix}; \delta_{12}, \delta_{21} \in \mathbb{C} \right\}$  and provided with the norm  $\|\Delta\| := \|\Delta\|_{\Delta} = \max\{|\delta_{12}|, |\delta_{21}|\}$ ,  $\Delta \in \Delta_E$ . The transfer functions of the two subsystems  $\Sigma_i$  are  $G_i(s) = c_i b_i / (s^2 + 2\xi_i \nu_i s + \nu_i^2)$  and so

$$G_i(i\omega) = c_i b_i / (\nu_i^2 - \omega^2 + 2\xi_i \nu_i i\omega),$$

$$g_i = \max_{\omega \in \mathbb{R}} |G_i(i\omega)| = |c_i b_i| / \min_{\omega \in \mathbb{R}} [(\nu_i^2 - \omega^2)^2 + 4\xi_i^2 \nu_i^2 \omega^2]^{1/2}.$$

We conclude that  $r_{\Delta_{tv}} = r_{\Delta_{tv}}(A, B, C, E)$  and  $r_{\Delta} = r_{\Delta}(A, B, C, E)$  are determined by

$$r_{\Delta_{tv}} = \varrho(E^{\circ 2} D_g^2)^{-1/2} = \varrho \left( \begin{bmatrix} 0 & g_2^2 \\ g_1^2 & 0 \end{bmatrix} \right)^{-1/2} = \frac{1}{\sqrt{g_1 g_2}},$$

$$r_{\Delta} = \frac{1}{\max_{\omega \in \mathbb{R}} \sqrt{|G_1(i\omega)| |G_2(i\omega)|}}.$$

A simple calculation gives

$$|G_i(i\omega)| = \frac{|c_i b_i|}{\sqrt{(\nu_i^2 - \omega^2)^2 + 4\xi_i^2 \nu_i^2 \omega^2}}, \quad g_i = \begin{cases} |c_i b_i| / \nu_i^2 & \text{if } 1 \leq 2\xi_i^2, \\ \frac{|c_i b_i|}{2\nu_i^2 \xi_i \sqrt{1 - \xi_i^2}} & \text{if } 1 > 2\xi_i^2, \end{cases} \quad i = 1, 2.$$

Since  $E$  is irreducible, the equality  $r_{\Delta} = r_{\Delta_{tv}}$  holds if and only if there exists a joint minimum of the two even functions  $f_i : \omega \mapsto (\nu_i^2 - \omega^2)^2 + 4\xi_i^2 \nu_i^2 \omega^2$ ,  $i = 1, 2$ , on  $\mathbb{R}$ ; see Corollary 6.5. An easy calculation shows that  $f_i$  has a unique (local and global) minimum at  $\omega_0 = 0$  if  $1 \leq 2\xi_i^2$ , and has exactly two minima at  $\omega_{0i} = \pm \nu_i \sqrt{1 - 2\xi_i^2}$  if  $1 > 2\xi_i^2$ ,  $i = 1, 2$ . Hence  $r_{\Delta} = r_{\Delta_{tv}}$  holds if and only if either  $1 \leq 2\xi_1^2$  and  $1 \leq 2\xi_2^2$  or  $\nu_1^2(1 - 2\xi_1^2) = \nu_2^2(1 - 2\xi_2^2) > 0$ .

The frequencies  $\omega_{0i}$  maximize the amplitude (gain) responses of the two subsystems, so it is not surprising that they play critical roles in the stability analysis: We

have seen in the proof of Theorem 6.3 that periodic perturbations of these frequencies can be constructed which lead to nondecaying oscillations. The critical values  $\xi_i = \sqrt{1/2}$ ,  $i = 1, 2$ , are those values of the damping for which engineers regard the subsystems  $\Sigma_i$  as having only one significant overshoot.

We now consider *real* perturbations of the same structure; i.e.,  $\delta_{12}, \delta_{21} \in \mathbb{R}$ . Then

$$A + B(E \circ \Delta)C = A + B\Delta C = \begin{bmatrix} 0 & 1 & 0 & 0 \\ -\nu_1^2 & -2\xi_1\nu_1 & b_1\delta_{12}c_2 & 0 \\ 0 & 0 & 0 & 1 \\ b_2\delta_{21}c_1 & 0 & -\nu_2^2 & -2\xi_2\nu_2 \end{bmatrix},$$

$$\Delta = \begin{bmatrix} 0 & \delta_{12} \\ \delta_{21} & 0 \end{bmatrix} \in \mathbf{\Delta}_E \cap \mathbb{R}^{2 \times 2}.$$

$\Delta$  is marginally destabilizing if there exists  $\omega \in \mathbb{R}$  such that  $\det(\omega I - A - B\Delta C) = 0$ ; i.e.,

$$(102) \quad [(\nu_1^2 - \omega^2) + 2\xi_1\nu_1\omega][(\nu_2^2 - \omega^2) + 2\xi_2\nu_2\omega] = b_1b_2c_1c_2\delta_{12}\delta_{21}.$$

But this can only be the case if

$$2\xi_1\nu_1\omega(\nu_2^2 - \omega^2) + 2\xi_2\nu_2\omega(\nu_1^2 - \omega^2) = 0,$$

i.e., if  $\omega = 0$  or  $\omega^2(\xi_1\nu_1 + \xi_2\nu_2) = \nu_1\nu_2(\xi_1\nu_2 + \xi_2\nu_1)$ . We denote this latter value of  $\omega^2$  by  $\omega_c^2$ . In order to minimize  $\|\Delta\| = \max\{|\delta_{12}|, |\delta_{21}|\}$  in (102) we must choose  $\delta_{12} = \pm\delta_{21}$ . Hence if  $\omega = 0$ , then we have  $|b_1b_2c_1c_2|\|\Delta\|^2 = \nu_1^2\nu_2^2$  and if  $\omega^2 = \omega_c^2$ , we have

$$|b_1b_2c_1c_2|\|\Delta\|^2 = -(\nu_1^2 - \omega_c^2)(\nu_2^2 - \omega_c^2) + 4\xi_1\xi_2\nu_1\nu_2\omega_c^2.$$

It is easy to see that

$$(\xi_1\nu_1 + \xi_2\nu_2)(\nu_1^2 - \omega_c^2) = \xi_1\nu_1(\nu_1^2 - \nu_2^2), \quad (\xi_1\nu_1 + \xi_2\nu_2)(\nu_2^2 - \omega_c^2) = \xi_2\nu_2(\nu_2^2 - \nu_1^2).$$

Hence

$$(\xi_1\nu_1 + \xi_2\nu_2)^2|b_1b_2c_1c_2|\|\Delta\|^2 = \xi_1\xi_2\nu_1\nu_2[(\nu_2^2 - \nu_1^2)^2 + 4\nu_1\nu_2(\xi_1\nu_1 + \xi_2\nu_2)(\xi_1\nu_2 + \xi_2\nu_1)].$$

We conclude that

$$|b_1b_2c_1c_2|r_{\mathbf{\Delta}_{\mathbb{R}}}^2 = \min \left\{ \nu_1^2\nu_2^2, \frac{\xi_1\xi_2\nu_1\nu_2[(\nu_2^2 - \nu_1^2)^2 + 4\nu_1\nu_2(\xi_1\nu_1 + \xi_2\nu_2)(\xi_1\nu_2 + \xi_2\nu_1)]}{(\xi_1\nu_1 + \xi_2\nu_2)^2} \right\}.$$

As an example we consider two identical oscillators so that  $\xi_1 = \xi_2 = \xi$ ,  $\nu_1 = \nu_2 = \nu$  and for simplicity we choose  $b_1 = b_2 = c_1 = c_2 = 1$ . Then  $r_{\mathbf{\Delta}_{\mathbb{R}}} = \min\{\nu^2, 2\xi\nu^2\}$ . So  $r_{\mathbf{\Delta}_{\mathbb{R}}} = \nu^2$  if  $\xi \geq 1/2$  and  $r_{\mathbf{\Delta}_{\mathbb{R}}} = 2\xi\nu^2$  if  $\xi < 1/2$ . This is to be compared with the above results for complex perturbations that  $r_{\mathbf{\Delta}} = r_{\mathbf{\Delta}_{tv}} = \nu^2$  if  $2\xi^2 \geq 1$  and  $r_{\mathbf{\Delta}} = r_{\mathbf{\Delta}_{tv}} = 2\xi\nu^2\sqrt{1 - \xi^2}$  if  $2\xi^2 < 1$ . So we see that  $r_{\mathbf{\Delta}} < r_{\mathbf{\Delta}_{\mathbb{R}}}$  if  $\xi < 1/\sqrt{2}$ .

**7. Special cases and concluding remarks.** In this final section we illustrate our results by applying them to special classes of systems. In particular, we will prove that if the subsystems  $\Sigma_j$  are all real and one-dimensional or if they are all positive, then there is a joint maximum at  $\omega = 0$  of the  $N$  functions  $\omega \mapsto \|G_i(\omega)\|_{2,2}$ ,  $i \in \underline{N}$ , and consequently the stability radii with respect to time-varying and time-invariant parameter perturbations are equal. In a second part of this section we will discuss the relationship between our results and two classical problems of robust stability connected with the existence of joint Liapunov functions for a given set of time-invariant linear systems.

**One-dimensional subsystems.** Suppose that each subsystem  $\Sigma_i$  is one-dimensional; i.e.,  $l_i = n_i = q_i = 1$  and  $(A_i, B_i, C_i) = (a_i, b_i, c_i) \in \mathbb{L}_{1,1,1}$ ,  $i \in \underline{N}$ . Since  $B(E \circ \Delta)C = (b_i e_{ij} \delta_{ij} c_j) = (b_i e_{ij} c_j \delta_{ij})$  for  $\Delta = (\delta_{ij}) \in \mathbb{C}^{N \times N}$ , we can incorporate the diagonal entries of  $B = \text{diag}(b_1, \dots, b_N)$ ,  $C = \text{diag}(c_1, \dots, c_N)$  into  $E \in \mathbb{R}_+^{N \times N}$  and suppose  $B = C = I_N$  without restriction of generality. Hence let

$$(103) \quad A = \text{diag}(a_1, \dots, a_N) \in \mathbb{C}^{N \times N}, \quad B = I_N, \quad C = I_N, \quad E \in \mathbb{R}_+^{N \times N}.$$

We consider perturbations of the form

$$(104) \quad A \rightsquigarrow A_\Delta = A + E \circ \Delta, \quad \Delta \in \mathbf{\Delta} = \mathbb{C}^{N \times N}.$$

Note that  $E \circ \Delta \in \mathbf{\Delta}_E = \{(\delta_{ij}) \in \mathbb{C}^{N \times N}; \delta_{ij} = 0 \text{ if } e_{ij} = 0\}$  for every  $\Delta \in \mathbf{\Delta}$ .  $\mathbf{\Delta}$  is provided with the norm

$$\|\Delta\| = \max_{i \in \underline{N}} \left[ \sum_{j \in \underline{N}} |\delta_{ij}|^2 \right]^{1/2}, \quad \Delta = (\delta_{ij}) \in \mathbf{\Delta}.$$

We write  $\sigma_\Delta(A, E; \delta)$  for  $\sigma_\Delta(A, I_N, I_N, E; \delta)$ ,  $r_\Delta(A, E)$  for  $r_\Delta(A, I_N, I_N, E)$  and similarly for the other stability radii,  $r_{\Delta_{tv}}$ ,  $r_{\Delta_n}$ , and  $r_{\Delta_{nt}}$ . If  $\text{Re } a_i \neq 0$ ,  $i \in \underline{N}$ , then the transfer functions  $G_i(s)$ , the scalars  $g_i$  defined in (68), and the diagonal matrix  $D_g = \text{diag}(g_1, \dots, g_N)$  are given by

$$(105) \quad G_i(s) = (s - a_i)^{-1}, \quad g_i = \max_{\omega \in \mathbb{R}} |G_i(i\omega)| = |\text{Re } a_i|^{-1}, \quad i \in \underline{N}, \quad D_g = |\text{Re } A|^{-1}.$$

**THEOREM 7.1.** *Suppose (103). Then we have the following.*

- (i) *For every  $\delta > 0$  the spectral value set of  $A$  at level  $\delta > 0$  with respect to perturbations of the form (104) is*

$$(106) \quad \begin{aligned} \sigma_\Delta(A, E; \delta) &= \bigcup_{\Delta \in \mathbf{\Delta}, \|\Delta\| < \delta} \sigma(A + E \circ \Delta) \\ &= \sigma(A) \cup \{\lambda \in \rho(A); \varrho(|\lambda I_N - A|^{-2} E^{\circ 2}) > \delta^{-2}\}. \end{aligned}$$

- (ii) *If  $A$  is Hurwitz stable, then its stability radius with respect to perturbations of the form (104) is*

$$(107) \quad r_\Delta(A, E) = \left[ \max_{\omega \in \mathbb{R}} \varrho(|i\omega I_N - A|^{-2} E^{\circ 2}) \right]^{-1/2}.$$

*If, additionally,  $A$  is real, then*

$$(108) \quad \begin{aligned} r_{\Delta_{nt}}(A, E) &= r_{\Delta_n}(A, E) = r_{\Delta_{tv}}(A, E) \\ &= r_\Delta(A, E) = r_{\Delta_{\mathbb{R}}}(A, E) = \varrho(|A|^{-2} E^{\circ 2})^{-1/2}. \end{aligned}$$

- (iii) *If  $A$  is Hurwitz stable, then its stability radii with respect to time-varying linear or nonlinear perturbations of structure  $E$  are given by*

$$(109) \quad r_{\Delta_{nt}}(A, E) = r_{\Delta_{tv}}(A, E) = \varrho(|\text{Re } A|^{-2} E^{\circ 2})^{-1/2} = r_\Delta(\text{Re } A, E).$$

*Proof.* Part (i) and (107) follow from Corollary 4.9 since

$$D(s)^2 = [\text{diag}(|(s - a_1)^{-1}|, \dots, |(s - a_N)^{-1}|)]^2 = |(sI_N - A)^{-2}|, \quad s \in \rho(A).$$

If, additionally,  $A$  is real, then the functions  $\omega \mapsto |G_i(i\omega)| = |i\omega - a_i|^{-1}$  have a joint maximum at  $\omega = 0$  and  $D_g = |A|$ . Hence (108) follows directly from Remark 6.6(ii).

(iii) The first two equalities of (109) follow from Theorem 6.3 because of (105). The last equality follows from (108).  $\square$

**Remark 7.2.** Let  $A$  be any complex diagonal Hurwitz matrix and suppose that  $E$  is irreducible. The functions  $f_i : \omega \mapsto |G_i(i\omega)| = |i\omega - a_i|^{-1}$  have a unique maximum at  $\omega_i = \text{Im } a_i$ . Hence it follows from Corollary 6.5 that  $r_{\Delta_{tv}}(A, E) = r_{\Delta}(A, E)$  if and only if all the diagonal elements  $a_i$  of  $A$  have the same imaginary part,  $i \in \underline{N}$ . The “if” holds without the assumption that  $E$  is irreducible.

**Positive subsystems.** Positive systems occur frequently in the modelling of real processes where the state coordinates represent variables which cannot take negative values. They are used to model phenomena in such diverse fields as economics, population dynamics, and biology; see [9]. We will now show that positive block-diagonal systems have properties similar to those of the real scalar diagonal ones. A system  $(A, B, C) \in \mathbb{L}_{n,l,q}$  is called *positive* if  $B \geq 0$ ,  $C \geq 0$  and  $A$  is a Metzler matrix; i.e.,  $A + rI_n \geq 0$  for some  $r > 0$ . We use the same notation as in section 6.

**THEOREM 7.3.** Suppose (86) and that the subsystems  $(A_i, B_i, C_i) \in \mathbb{L}_{n_i, l_i, q_i}$  are positive. If  $\mathbf{n} = (n_1, \dots, n_N)$  and  $\Delta_{\mathbb{R}} = \Delta \cap \mathbb{R}^{\mathbf{n} \times \mathbf{n}}$ , then

$$\begin{aligned} r_{\Delta_{nt}}(A, B, C, E) &= r_{\Delta_{tv}}(A, B, C, E) \\ &= r_{\Delta}(A, B, C, E) = r_{\Delta_{\mathbb{R}}}(A, B, C, E) = \varrho(E \circ^2 D_g^2)^{-1/2}, \end{aligned}$$

where  $D_g = \text{diag}(\|C_1 A_1^{-1} B_1\|_{2,2}, \dots, \|C_N A_N^{-1} B_N\|_{2,2})$ .

*Proof.* Since  $(A_i, B_i, C_i)$  is positive, we have  $g_i = \max_{\omega \in \mathbb{R}} \|G_i(i\omega)\|_{2,2} = \|C_i A_i^{-1} B_i\|_{2,2}$  for  $i \in \underline{N}$ ; see [12, Example 5.3.22]. Thus the  $N$  functions  $\omega \mapsto \|G_i(i\omega)\|_{2,2}$ ,  $i \in \underline{N}$ , have a joint maximum at  $\omega_0 = 0$ . Hence the result follows from Remark 6.6(ii).  $\square$

**Quadratic and absolute stability.** We conclude this paper by applying our results to two classical robustness issues, the problems of *quadratic* and of *absolute* stability. As in the previous section we consider systems with structured norm-bounded uncertainties of the following kind:

$$(110) \quad \dot{x} = Ax + B(E \circ \Delta)y, \quad y = Cx, \quad \Delta \in \Delta(r),$$

$$(111) \quad \dot{x} = Ax + B(E \circ \Delta(t))y, \quad y = Cx, \quad \Delta \in \Delta_{tv}(r),$$

$$(112) \quad \dot{x} = Ax + B(E \circ \Delta(x))y, \quad y = Cx, \quad \Delta \in \Delta_n(r),$$

$$(113) \quad \dot{x} = Ax + B(E \circ \Delta(x, t))y, \quad y = Cx, \quad \Delta \in \Delta_{nt}(r),$$

where the data  $(A, B, C, E)$  are given as in (86),  $\Delta = \mathbb{C}^{1 \times \mathbf{q}}$ ,  $\Delta_{tv}$ ,  $\Delta_n$ ,  $\Delta_{nt}$  are defined as in the previous section, and for any uncertainty level  $r > 0$ ,  $\Delta$  varies within the following sets of norm bounded perturbations:

$$\begin{aligned} \Delta(r) &= \{\Delta \in \Delta; \|\Delta\| \leq r\}, \quad \Delta_n(r) = \{\Delta \in \Delta_n; \|\Delta\|_n \leq r\}, \\ \Delta_{tv}(r) &= \{\Delta \in \Delta_{tv}; \|\Delta\|_{tv} \leq r\}, \quad \Delta_{nt}(r) = \{\Delta \in \Delta_{nt}; \|\Delta\|_{nt} \leq r\}. \end{aligned}$$

The following definition specifies different concepts of robust stability.

**DEFINITION 7.4.** Let  $r > 0$ . The uncertain system  $(A, B, C, E)$  is said to be

- (i) asymptotically stable at level  $r$  if all the systems (110) are asymptotically stable,
- (ii) tv-stable at level  $r$  if all the systems (111) are asymptotically stable,
- (iii) absolutely stable at level  $r$  if all the systems (112) are asymptotically stable,
- (iv) nt-stable at level  $r$  if all the systems (113) are asymptotically stable.

For any uncertainty level  $r > 0$  the following implications are either trivial or easily proved:

$$(114) \quad \text{nt-stable} \Rightarrow \text{tv-stable} \Rightarrow \text{absolutely stable} \Rightarrow \text{asymptotically stable}.$$

In what follows we will discuss the relationship of these concepts with the notion of *quadratic stability*. Here we use a modification of the usual definition; compare [5].

**DEFINITION 7.5.** We say that the uncertain system  $(A, B, C, E)$  is quadratically stable at level  $r$  if there is a quadratic function  $V(x) = \langle x, Px \rangle$ , with a positive definite Hermitian matrix  $P$ , such that the derivative of  $V$  along the trajectories of (110)

$$(115) \quad \dot{V}(x) = \langle Px, Ax + B(E \circ \Delta)y \rangle + \langle Ax + B(E \circ \Delta)y, Px \rangle, \quad y = Cx$$

satisfies  $\dot{V}(x) \leq -k\|y\|^2$  for some  $k > 0$  and all  $\Delta \in \mathbf{\Delta}(r)$ .

The usual definition of quadratic stability requires that  $V(x)$  is a *strict* Liapunov function; i.e.,  $\dot{V}(x)$  is negative definite. Then it is well known that quadratic stability implies all the four properties of robust stability defined in the preceding definition. However, the quadratic Liapunov functions constructed from Riccati equations of the form (15) are usually not strict but only satisfy  $\dot{V}(x) \leq -k\|y\|^2$ . So as a direct consequence of Liapunov theory, we are only able to conclude stability but not asymptotic stability. However, a similar argument, as in the proof of Theorem 2.6, can be used to show that the condition  $\dot{V}(x) \leq -k\|y\|^2$  in fact suffices to prove asymptotic stability of the uncertain systems (110). This motivates our definition of a slightly weaker concept of quadratic stability.

In the following we will apply our previous results to the following two problems.

**Problem of quadratic stability.** Under what conditions does any one of the above properties of robust stability imply quadratic stability?

**Aizerman problem.** Under what conditions does the asymptotic stability of the uncertain system  $(A, B, C, E)$  at level  $r > 0$  imply that it is absolutely stable at level  $r$ ? (If this implication holds for every  $r > 0$ , we say that the *structured complex version of the generalized Aizerman conjecture* holds true for  $(A, B, C, E)$ .)

**Remark 7.6.** Note that the original Aizerman conjecture was stated for the *real* single input single output case where  $(A, B, C) \in \mathbb{L}_{n,1,1}$  is real and  $\mathbf{\Delta} = \mathbb{R}$ . In this real case the Aizerman conjecture is not true: there are counterexamples of  $(A, B, C) \in \mathbb{L}_{n,1,1}$  for which every matrix in the set  $\{A + B\Delta C; \Delta \in \mathbb{R}, |\Delta| \leq 1\}$  is asymptotically stable but  $(A, B, C)$  is not absolutely stable at level 1; see [25, section 7.3].

Assuming observability it is well known that in the full block case all of the above concepts of robust stability are equivalent. Note that the full block case is a very special case of the situation considered in this paper, namely  $N = 1$ ,  $\mathbf{n} = (n)$ ,  $\mathbf{l} = (l)$ ,  $\mathbf{q} = (q)$ ,  $(A, B, C) = (A_1, B_1, C_1) \in \mathbb{L}_{n,l,q}$ . In this special case we have that an uncertain *observable* system  $(A, B, C)$  is asymptotically stable at level  $r > 0$  if and only if it is quadratically stable at level  $r > 0$ ; see [12, section 5.6]. Moreover, the complex version of the Aizerman conjecture is true in the full block case [12, Theorem 5.6.22].

For structured perturbations these results, in general, no longer hold. Counterexamples have been given in [19]. Besides reformulations of the property in terms of linear matrix inequalities or  $\mu$ -analysis there are apparently no general necessary and sufficient criteria available for quadratic stability of systems with structured uncertainties; compare [1]. In our framework where the nominal system is block-diagonal and the perturbations  $E \circ \Delta \in \Delta_E$  have an arbitrarily prescribed zero structure (defined by  $E$ ), we can solve the problem of quadratic stability and establish its precise relationship with the other notions of robust stability. Moreover, we obtain computable tests for deciding whether a given uncertain system  $(A, B, C, E)$  is quadratically stable at level  $r$  or not. Finally, we obtain systematic procedures for the construction of counterexamples of uncertain systems which are asymptotically stable at a level  $r > 0$  but neither tv-stable nor quadratically stable at this level.

**THEOREM 7.7.** *Suppose (86). Then for any  $r > 0$  we have the following.*

- (i) *The uncertain system  $(A, B, C, E)$  at level  $r$  is tv-stable if and only if  $r < \varrho(E^{\circ 2} D_g^2)^{-1/2}$ . Moreover, it is tv-stable if and only if it is nt-stable.*
- (ii) *The asymptotic stability of the uncertain system  $(A, B, C, E)$  at level  $r$  implies the tv-stability at level  $r$  if and only if  $\max_{\omega \in \mathbb{R}} \varrho(D(i\omega)^2 E^{\circ 2}) = \varrho(E^{\circ 2} D_g^2)$ . In this case the structured complex version of the generalized Aizerman conjecture is valid for  $(A, B, C, E)$ .*
- (iii) *Suppose the pairs  $(A_j, C_j)$ ,  $j \in \underline{N}$ , are observable and  $E$  does not have a zero column. Then the uncertain system  $(A, B, C, E)$  is quadratically stable at level  $r$  if and only if it is tv-stable at level  $r$  (or, equivalently,  $r < \varrho(E^{\circ 2} D_g^2)$ ).*

*Proof.* In the proof of the three statements we implicitly make use of the fact that the uncertain system  $(A, B, C, E)$  at level  $r$  is tv-stable (respectively, nt-stable; respectively, asymptotically stable) if and only if  $r < r_{\Delta_{tv}}(A, B, C, E)$  (respectively,  $r < r_{\Delta_{nt}}(A, B, C, E)$ ; respectively,  $r < r_{\Delta}(A, B, C, E)$ ). This follows from the definitions of  $r_{\Delta_{nt}}$ ,  $r_{\Delta_{tv}}$ ,  $r_{\Delta}$  and the fact that there is a  $\Delta(\cdot) \in \Delta_{tv} \subset \Delta_{nt}$  with  $\|\Delta(\cdot)\|_{\Delta_{tv}} = r_{\Delta_{tv}} = r_{\Delta_{nt}}$  (respectively,  $\Delta \in \Delta$  with  $\|\Delta\|_{\Delta} = r_{\Delta}$ ) such that the corresponding perturbed system  $\dot{x} = Ax + B(E \circ \Delta(t))Cx$  (respectively,  $\dot{x} = Ax + B(E \circ \Delta)Cx$ ) is not asymptotically stable; see Remark 6.4.

(i) This follows directly from (96).

(ii) The asymptotic stability of the uncertain system  $(A, B, C, E)$  at level  $r$  implies the tv-stability at level  $r$  if and only if  $r_{\Delta_{tv}}(A, B, C, E) = r_{\Delta}(A, B, C, E)$ . Hence the first statement in (ii) follows from Corollary 6.5. Furthermore, if  $\max_{\omega \in \mathbb{R}} \varrho(D(i\omega)^2 E^{\circ 2}) = \varrho(E^{\circ 2} D_g^2)$ , then  $r_{\Delta_{nt}}(A, B, C, E) = r_{\Delta}(A, B, C, E)$  by Corollary 6.5 and therefore the structured complex version of the generalized Aizerman conjecture holds true for  $(A, B, C, E)$ .

(iii) Suppose that the uncertain system  $(A, B, C, E)$  at level  $r$  is tv-stable. Then  $r < r_{\Delta_{tv}}(A, B, C, E) = \hat{\rho}(D_g, E)$  by Theorem 6.3 and (80) and there exists a scaling vector  $\gamma > 0$  such that  $r < \rho_{\gamma}(D_g, E)$ . Let  $P$  be any Hermitian solution of the scaled algebraic Riccati equation (73) with  $\rho = \rho_{\gamma}(D_g, E)$ . By Theorem 6.1(iii)  $V(x) = \langle x, Px \rangle$  is a quadratic Liapunov function for (110) and there exists  $k > 0$  such that along the trajectories of (110) we have  $\dot{V}(x) \leq -k\|y\|^2$ ,  $y = Cx$  for all  $\Delta \in \Delta(r)$ . Hence the uncertain system (110) is quadratically stable. Conversely, if the uncertain system  $(A, B, C, E)$  is quadratically stable at level  $r$  and  $V(x) = \langle x, Px \rangle$  is the corresponding Liapunov function (see Definition 7.5), then for any solution  $x(\cdot) \neq 0$  of (111) on  $[t_0, \infty)$  we have  $V(x(t)) > 0$  and  $\dot{V}(x(t)) \leq -k\|Cx(t)\|^2$ ,  $t \geq t_0$  for some  $k > 0$ . So the origin is uniformly stable and just as in the last part of the proof of Theorem 2.6 we have  $x(t) \rightarrow 0$  as  $t \rightarrow \infty$ . Hence  $r < r_{\Delta_{tv}}$ , and this completes

the proof of (iv).  $\square$

Applying this theorem to the special cases described above, we see that the complex version of the Aizerman conjecture is valid if the subsystems  $(A_j, B_j, C_j)$ ,  $j \in \underline{N}$ , are either one-dimensional or positive. Moreover, the properties of asymptotic and quadratic stability are equivalent in these cases provided that the subsystems are observable and  $E$  does not have a zero column.

To illustrate Theorem 7.7 we return to Example 6.7 and construct a joint Liapunov function for the system consisting of two harmonic oscillators with uncertain couplings of norm  $< r_{\Delta_{tv}}(A, B, C, E)$ .

*Example 7.8.* As in Example 6.7 let

$$A_i = \begin{bmatrix} 0 & 1 \\ -\nu_i^2 & -2\xi_i\nu_i \end{bmatrix}, \quad B_i = \begin{bmatrix} 0 \\ b_i \end{bmatrix}, \quad C_i = [c_i \quad 0], \quad i = 1, 2; \quad E = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

$$\Delta_E = \left\{ \begin{bmatrix} 0 & \delta_{12} \\ \delta_{21} & 0 \end{bmatrix}; \delta_{12}, \delta_{21} \in \mathbb{C} \right\},$$

and consider the (four-dimensional) uncertain interconnected system described by

$$(116) \quad \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = [A + B(E \circ \Delta)C] \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} A_1 & B_1\delta_{12}C_2 \\ B_2\delta_{21}C_1 & A_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad \Delta \in \Delta_E;$$

see (101). For simplicity of presentation we assume that  $\nu_i = 1$ ,  $i = 1, 2$ . With  $\gamma = (\gamma_1, \gamma_2) > 0$  and  $\rho \leq \rho_\gamma$  the Riccati equations (75) take the form

$$(117) \quad P_1 A_1 + A_1^* P_1 + \rho^2 \gamma_2^2 C_1^* C_1 + \gamma_1^{-2} P_1 B_1 B_1^* P_1 = 0,$$

$$(118) \quad P_2 A_2 + A_2^* P_2 + \rho^2 \gamma_1^2 C_2^* C_2 + \gamma_2^{-2} P_2 B_2 B_2^* P_2 = 0.$$

In Example 6.7 we have shown that

$$r_{\Delta_{tv}} = \varrho \left( \begin{bmatrix} 0 & g_2^2 \\ g_1^2 & 0 \end{bmatrix} \right)^{-1/2} = \frac{1}{\sqrt{g_1 g_2}},$$

$$\text{where } g_i = \begin{cases} |c_i b_i| & \text{if } 1 \leq 2\xi_i^2, \\ \frac{|c_i b_i|}{2\xi_i \sqrt{1 - \xi_i^2}} & \text{if } 1 > 2\xi_i^2, \end{cases} \quad i = 1, 2.$$

By Theorem 5.2 we have  $\hat{\rho} = (g_1 g_2)^{-1/2}$ . To find an optimal scaling vector  $\hat{\gamma} > 0$  we determine a positive Perron vector  $\hat{\gamma}^2$  of  $E^{\circ 2} D_g^2$ :

$$E^{\circ 2} D_g^2 \begin{bmatrix} \hat{\gamma}_1^2 \\ \hat{\gamma}_2^2 \end{bmatrix} = \begin{bmatrix} 0 & g_2^2 \\ g_1^2 & 0 \end{bmatrix} \begin{bmatrix} \hat{\gamma}_1^2 \\ \hat{\gamma}_2^2 \end{bmatrix} = g_1 g_2 \begin{bmatrix} \hat{\gamma}_1^2 \\ \hat{\gamma}_2^2 \end{bmatrix}, \quad \text{i.e., } \hat{\gamma}_1^2 g_2 = \hat{\gamma}_2^2 g_1.$$

Choosing  $\hat{\gamma}_1 = \sqrt{g_1}$ ,  $\hat{\gamma}_2 = \sqrt{g_2}$ , we obtain  $\rho_\gamma = \hat{\rho}$  by Theorem 5.5. Then if  $P_1 = \begin{bmatrix} p_1 & p_2 \\ p_2 & p_3 \end{bmatrix}$ , the Riccati equation for the first subsystem with  $\rho = \hat{\rho}$  and  $\gamma = \hat{\gamma}$  takes the form

$$\begin{bmatrix} p_1 & p_2 \\ p_2 & p_3 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ -1 & -2\xi_1 \end{bmatrix} + \begin{bmatrix} 0 & -1 \\ 1 & -2\xi_1 \end{bmatrix} \begin{bmatrix} p_1 & p_2 \\ p_2 & p_3 \end{bmatrix} + g_1^{-1} \begin{bmatrix} c_1^2 & 0 \\ 0 & 0 \end{bmatrix} \\ + g_1^{-1} \begin{bmatrix} p_1 & p_2 \\ p_2 & p_3 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & b_1^2 \end{bmatrix} \begin{bmatrix} p_1 & p_2 \\ p_2 & p_3 \end{bmatrix} = 0.$$

A similar equation holds for  $P_2$  with  $\xi_1$  replaced by  $\xi_2$  and  $g_1$  replaced by  $g_2$ . Note that although the Riccati equations (117) and (118) are coupled through the parameters  $\rho$  and  $\gamma$ , they are decoupled at the optimal parameter values. The Riccati equation for  $P_1$  can be decomposed to

$$\begin{aligned} -2p_2 + g_1^{-1}c_1^2 + g_1^{-1}b_1^2p_2^2 &= 0, \\ p_1 - 2\xi_1p_2 - p_3 + g_1^{-1}b_1^2p_2p_3 &= 0, \\ 2p_2 - 4\xi_1p_3 + g_1^{-1}b_1^2p_3^2 &= 0. \end{aligned}$$

By solving the first quadratic equation for  $p_2$ , then the third quadratic equation for  $p_3$ , and finally the middle one for  $p_1$ , one obtains the following positive definite solution of (117) (with  $\rho = \hat{\rho}$  and  $\gamma = \hat{\gamma}$ ):

$$\begin{aligned} P_1 &= \frac{|c_1|}{|b_1|} \begin{bmatrix} 2\xi_1 & 1 \\ 1 & 2\xi_1 + \sqrt{4\xi_1^2 - 2} \end{bmatrix} \quad \text{if } 1 \leq 2\xi_1^2 \quad \text{and} \\ P_1 &= \frac{|c_1|}{|b_1|\sqrt{1 - \xi_1^2}} \begin{bmatrix} 1 & \xi_1 \\ \xi_1 & 1 \end{bmatrix} \quad \text{if } 1 > 2\xi_1^2. \end{aligned}$$

Replacing  $\xi_1$  by  $\xi_2$  and  $g_1$  by  $g_2$  one obtains an analogous formula for a solution  $P_2 \succ 0$  of (117) (with  $\rho = \hat{\rho}$  and  $\gamma = \hat{\gamma}$ ). By Theorem 5.1,  $V(x) = \langle x_1, P_1x_1 \rangle + \langle x_2, P_2x_2 \rangle$  is a joint Liapunov function for all the perturbed systems (116) with

$$\Delta = \begin{bmatrix} 0 & \delta_{12} \\ \delta_{21} & 0 \end{bmatrix} \in \mathbf{\Delta}_E, \quad \|\Delta\| = \max\{|\delta_{12}|, |\delta_{21}|\} \leq \rho_{\hat{\gamma}} = (g_1g_2)^{-1/2} = r_{\mathbf{\Delta}_{tv}}.$$

By Remark 6.4,  $V(\cdot)$  is a quadratic Liapunov function of maximal robustness for the uncertain system (116).

## A CLASS OF SINGULAR CONTROL PROBLEMS AND THE SMOOTH FIT PRINCIPLE\*

XIN GUO<sup>†</sup> AND PASCAL TOMECEK<sup>‡</sup>

**Abstract.** This paper analyzes a class of singular control problems for which value functions are not necessarily smooth. Necessary and sufficient conditions for the well-known smooth fit principle, along with the regularity of the value functions, are given. Explicit solutions for the optimal policy and for the value functions are provided. In particular, when payoff functions satisfy the usual Inada conditions, the boundaries between action and continuation regions are smooth and strictly monotonic, as postulated and exploited in the existing literature (see [A. K. Dixit and R. S. Pindyck, *Investment under Uncertainty*, Princeton University Press, Princeton, NJ, 1994]; [M. H. A. Davis et al., *Adv. in Appl. Probab.*, 19 (1987), pp. 156–176]; [T. Ø. Kobila, *Stochastics Stochastics Rep.*, 43 (1993), pp. 29–63]; [A. B. Abel and J. C. Eberly, *J. Econom. Dynam. Control*, 21 (1997), pp. 831–852]; [A. Øksendal, *Finance Stoch.*, 4 (2000), pp. 223–250]; [J. A. Scheinkman and T. Zariphopoulou, *J. Econom. Theory*, 96 (2001), pp. 180–207]; [A. Merhi and M. Zervos, *SIAM J. Control Optim.*, 46 (2007), pp. 839–876]; and [L. H. Alvarez, *A General Theory of Optimal Capacity Accumulation under Price Uncertainty and Costly Reversibility*, Working Paper, Helsinki Center of Economic Research, Helsinki, Finland, 2006]). Illustrative examples for both smooth and nonsmooth cases are discussed to emphasize the pitfall of solving singular control problems with a priori smoothness assumptions.

**Key words.** smooth fit, singular control, switching control, reversible investment

**DOI.** 10.1137/070685336

**1. Introduction.** Consider the following problem in reversible investment/capacity planning that arises naturally in resource extraction and power generation: Facing the risk of market uncertainty, a company extracts a resource (such as oil or gas) and chooses the capacity level in response to the random fluctuation of market price for the resources, subject to some capacity constraints and the associated cost for capacity expansion and contraction. The goal of the company is to maximize its long-term profit, subject to these constraints and the rate of resource extraction.

This kind of capacity planning with price uncertainty and partial (or no) reversibility originated from the economics literature and has since attracted the interest of the applied mathematics community. (See [16, 13, 11, 27, 1, 7, 32, 34, 35, 12, 20] and the references therein.) Mathematical analysis of such control problems has evolved considerably from the initial heuristics to the more sophisticated and standard stochastic control approach, and from the very special case to cases with general payoff functions. (See [22, 24, 25, 18, 19, 29, 14, 15, 10, 3, 4, 8, 9].) Most recently, Merhi and Zervos [31] analyzed this problem in great generality and provided explicit solutions for the *special case* where the payoff is of Cobb–Douglas type. Their method is to directly solve the HJB equations for the value function, assuming certain regularity conditions known as the smooth fit principle.

Indeed, this smooth fit principle is critical in most of the works involving explicit solutions for optimal stopping, optimal switching, and singular control problems. However, for many control problems in real options, queuing, and wireless communications (see [30, 5, 23, 6]), there is no regularity for *either the value function or the boundaries*. In fact, one can have very simple examples where neither the value function nor the boundary between the action and continuation regions is continuous. (See Examples 5.3 and 5.4 in section 5.)

In spite of the alternative and powerful viscosity solution approach for the issue of regularity for the value function, explicit characterization for structure of the optimal policy and the value function still relies heavily on the smooth fit principle or continuity of the boundary. In fact, the smooth fit principle is sometimes exploited in the applied literature even without the standard verification theorem argument. However, when there is no continuity in the boundary or no connectedness in the interior of the continuation region, it may be hard and even incorrect to directly apply the traditional “guess the boundary and verify” approach. (See again Examples 5.3, 5.4, and 5.5 and the discussion afterwards.)

Therefore, two fundamental mathematical issues remain: (1) sufficient and necessary conditions for regularity properties for *both* the value function *and* the boundaries, and (2) characterization for the value function and for the action and continuation regions when these regularity conditions fail. Understanding these issues is especially important in cases where only numerical solutions are available, and for which the assumption on the degree of the smoothness could be *wrong*. (See also the discussions in section 5.2.)

This paper addresses the above two issues, in particular the second one, via the study of a class of singular control problems. Our work combines the techniques of [21] and [28]. The former established a fundamental connection between singular controls and switching controls, and the latter used the viscosity solution approach to solve optimal switching problems. We establish *both necessary and sufficient conditions* on the differentiability of the value function and on the smooth fit principle. These conditions lead to a derivative-based characterization of the investment, disinvestment, and continuation regions even for nonsmooth value functions. In fact, for the case *when the payoff function is not smooth*, this paper is the first to rigorously characterize the action and continuation regions, and to explicitly construct both the optimal policy and the value function. We emphasize that the payoff function in our paper  $H(\cdot)$  is *any concave function* of the capacity and may be *neither monotonic nor differentiable*. This includes the special cases investigated by [20, 31, 21]. In particular, when  $H$  satisfies the well-known Inada conditions (i.e., continuously differentiable, strictly increasing, strictly concave, with  $H(0) = 0$ ,  $H'(0^+) = \infty$ ,  $H'(\infty) = 0$ ), our results show that the boundaries between regions are indeed continuous and strictly increasing, as postulated and exploited in previous works (see [16, 13, 27, 1, 32, 34, 31, 2]). Also note that our method can be applied to more general (diffusion) processes for the price dynamics, other than the geometric Brownian motion assumed for explicitness in this paper. Finally, the construction between the functional form of the boundaries and the payoff function itself is also novel, as the value function and the boundaries may be neither smooth nor strictly monotonic, as in the existing literature.

Another work relevant to this paper is [2], which provides a great deal of economic insight into the singular control problem. However, [2] handles only payoff functions satisfying the Inada conditions. Moreover, its derivation of the value function is dependent on these assumptions and seems valid only when the boundaries are of the

very particular form illustrated in [2, Figure 1]. (See Example 5.5 and the discussion afterwards in section 5.2.)

*Outline.* The control problem is formally stated with preliminary analysis in section 2. Details of the derivation and solution are in section 3. The analysis of the regularity of the value function and the region characterization is in section 4. Examples are provided in section 5, including cases for which the value function is not differentiable, the optimal controlled process not continuous, the boundaries of the action regions not smooth, and the interior of the continuation region not simply connected.

## 2. Mathematical problem and preliminary analysis.

**2.1. Problem.** Let  $(\Omega, \mathcal{F}, \mathbb{F}, \mathbb{P})$  be a filtered probability space, and assume a given bounded interval  $[a, b] \subset (-\infty, \infty)$ . Consider the following problem.

*Fundamental problem.*

$$(1) \quad V(x, y) := \sup_{(\xi^+, \xi^-) \in \mathcal{A}'_y} J(x, y; \xi^+, \xi^-),$$

with

$$J(x, y; \xi^+, \xi^-) := \mathbb{E} \left[ \int_0^\infty e^{-\rho t} H(Y_t) X_t^x dt - \int_0^\infty e^{-\rho t} K_1 d\xi_t^+ - \int_0^\infty e^{-\rho t} K_0 d\xi_t^- \right]$$

subject to

$$\begin{aligned} Y_t &:= y + \xi_t^+ - \xi_t^-, \quad y \in [a, b], \\ dX_t^x &:= \mu X_t^x dt + \sqrt{2\sigma} X_t^x dW_t, \quad X_0 := x > 0, \\ H : [a, b] &\rightarrow \mathbb{R} \text{ is concave with } H(y) = H(a) + \int_a^y h(z) dz, \\ K_1 + K_0 &> 0, \mu < \rho, \text{ and (without loss of generality) } K_1 > 0. \end{aligned}$$

The supremum is taken over all strategies  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , where

$$\begin{aligned} \mathcal{A}'_y &:= \left\{ (\xi^+, \xi^-) : \xi^\pm \text{ are left continuous, nondecreasing processes, } \xi_0^\pm = 0; \right. \\ &\quad y + \xi_t^+ - \xi_t^- \in [a, b]; \\ &\quad \left. \mathbb{E} \left[ \int_0^\infty e^{-\rho t} d\xi_t^+ + \int_0^\infty e^{-\rho t} d\xi_t^- \right] < \infty \right\}. \end{aligned}$$

This is a continuous time formulation of the aforementioned risk management problem. The capacity level  $Y$  is a controlled process represented by  $(\xi_t^+)_{t \geq 0}$  and  $(\xi_t^-)_{t \geq 0}$ , which are  $\mathbb{F}$ -adapted, nondecreasing càglàd processes and, respectively, stand for the cumulative capacity expansion and reduction by time  $t$ ; the market price  $X$  is modeled by a geometric Brownian motion; the rate of resource extraction is modeled by the function  $H(Y)$ ;  $K_0$  is the cost of capacity reduction with  $K_0 < 0$  representing a partial recovery of the initial investment;  $K_1$  is the cost of capacity increase. The goal of the company is to maximize its long-term profit with a payoff function that depends on both the resource extraction rate and the market price, with a form of  $H(Y)X$ .

*Remark 2.1.* We make a few remarks on the formulation here.

- First, the assumption of  $K_1 > 0$  is without loss of generality. Indeed, if  $K_1 \leq 0$ , then one considers the control problem on  $[0, b - a]$  for  $b - Y_t$  instead of  $Y_t$ .
- Second, the constraint that  $K_0 + K_1 > 0$  rules out the simple arbitrage opportunity and the condition  $\mu > \rho$  is necessary for the finiteness of the value function.
- Third, since  $h$  is clearly nonincreasing from the concavity of  $H$ , one can choose its left or right continuous versions without changing  $H$  or the value function of the control problem  $V$ .
- Finally, using a simple Ito's analysis for semimartingales, one can easily see that this formulation has several equivalent extensions. For example, one can replace  $H(Y_t)X_t$  by  $H(Y_t)(X_t) - C_0Y_t - C_1 \int_0^t Y_s ds$  to take into account possible running cost  $C_0$  and cumulating cost  $C_1$ ; one can also substitute  $H(Y_t)X_t$  with  $H(Y_t)X_t^\lambda$ .

To be consistent with the literature in (ir)reversible investment, the running payoff function in this paper is assumed to depend on the resource extraction rate and the market price in the form of  $H(Y)X$  (equivalent to  $H(Y)X^\lambda$ ), and we focus on this simple and most standard version of singular control problem (1).

**2.2. Preliminary.** Throughout the paper, we define  $m < 0 < 1 < n$  to be the roots of  $\sigma^2 x^2 + (\mu - \sigma^2)x - \rho = 0$ , so that

$$(2) \quad m, n = \frac{-(\mu - \sigma^2) \pm \sqrt{(\mu - \sigma^2)^2 + 4\sigma^2\rho}}{2\sigma^2}.$$

We also observe the identity  $\rho = -\sigma^2 mn$  and define the useful quantity  $\eta > 0$ :

$$(3) \quad \eta := \frac{1}{\rho - \mu} = \frac{-mn}{(n-1)(1-m)\rho} = \frac{1}{\sigma^2(n-1)(1-m)}.$$

Next, let  $R(x, y) := J(x, y; 0, 0)$  be the no-action expected payoff. Then,

$$(4) \quad R(x, y) := \mathbb{E} \left[ \int_0^\infty e^{-\rho t} H(y) X_t^x dt \right] = \eta H(y)x,$$

$$(5) \quad r(x, y) := R_y(x, y) = \mathbb{E} \left[ \int_0^\infty e^{-\rho t} h(y) X_t^x dt \right] = \eta h(y)x.$$

Moreover,  $|J(x, y; \xi^+, \xi^-)| < \infty$  for all  $(\xi^+, \xi^-) \in \mathcal{A}'_y$  from the boundedness of  $H$ . In fact, we have the following.

**PROPOSITION 2.2** (finiteness of value function).  $V(x, y) \leq \eta Mx + K_1(b - a)$ , where  $M = \sup_{y \in [a, b]} |H(y)| < \infty$ .

*Proof.* Let  $x > 0$  and  $y \in [a, b]$  be given. Since  $\rho > \mu$ , we have

$$\mathbb{E} \left[ \int_0^\infty e^{-\rho t} [H(Y_t)X_t^x] dt \right] \leq \mathbb{E} \left[ \int_0^\infty e^{-\rho t} [MX_t^x] dt \right] \leq \eta Mx.$$

Note that for any given  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , we have  $a - y \leq \xi_t^+ - \xi_t^- \leq b - y$ . From integration by parts, for any  $t > 0$ ,

$$(6) \quad - \int_{[0, T)} e^{-\rho t} d\xi_t^+ \leq - \int_{[0, T)} e^{-\rho t} d\xi_t^- + (y - a),$$

which, together with  $K_1 + K_0 > 0$  and  $K_1 > 0$ , implies

$$\begin{aligned} \mathbb{E} \left[ -K_1 \int_0^\infty e^{-\rho t} d\xi_t^+ - K_0 \int_0^\infty e^{-\rho t} d\xi_t^- \right] &\leq K_1(y - a) - (K_1 + K_0) \mathbb{E} \left[ \int_0^\infty e^{-\rho t} d\xi_t^- \right] \\ &\leq K_1(b - a). \end{aligned}$$

Since these bounds are independent of the control, we have

$$V(x, y) \leq \eta Mx + K_1(b - a) < \infty. \quad \square$$

**3. Deriving value function and optimal control.** Our solution approach is built on the general correspondence between singular controls and switching controls developed in [21]. For the reader's convenience, we recall here the most relevant concepts.

### 3.1. Key concepts.

**DEFINITION 3.1.** A switching control  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  consists of an increasing sequence of stopping times  $(\tau_n)_{n \geq 0}$  and a sequence of new regime values  $(\kappa_n)_{n \geq 0}$  that are assumed immediately after each stopping time.

**DEFINITION 3.2.** A switching control  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  is called admissible if the following hold almost surely:  $\tau_0 = 0$ ;  $\tau_{n+1} > \tau_n$  for  $n \geq 1$ ,  $\tau_n \rightarrow \infty$ ; and for all  $n \geq 0$ ,  $\kappa_n \in \{0, 1\}$  is  $\mathcal{F}_{\tau_n}$  measurable, with  $\kappa_n = \kappa_0$  for even  $n$  and  $\kappa_n = 1 - \kappa_0$  for odd  $n$ .

**PROPOSITION 3.3.** There is a one-to-one correspondence between admissible switching controls and the regime indicator function  $I_t(\omega)$ , which is an  $\mathbb{F}$ -adapted càglàd process of finite variation, so that  $I_t(\omega) : \Omega \times [0, \infty) \rightarrow \{0, 1\}$ , with

$$(7) \quad I_t := \sum_{n=0}^{\infty} \kappa_n 1_{\{\tau_n < t \leq \tau_{n+1}\}}, \quad I_0 = \kappa_0.$$

**DEFINITION 3.4.** Let  $y \in \bar{\mathcal{I}}$  be given, and for each  $z \in \mathcal{I}$ , let  $\alpha(z) = (\tau_n(z), \kappa_n(z))_{n \geq 0}$  be a switching control. The collection  $(\alpha(z))_{z \in \mathcal{I}}$  is consistent if

$$(8) \quad \alpha(z) \text{ is admissible for Lebesgue-almost every } z \in \mathcal{I},$$

$$(9) \quad I_0(z) := \kappa_0(z) = 1_{\{z \leq y\}} \text{ for Lebesgue-almost every } z \in \mathcal{I},$$

and for all  $t < \infty$ ,

$$(10) \quad \int_{\mathcal{I}} (I_t^+(z) + I_t^-(z)) dz < \infty, \text{ almost surely, and}$$

$$(11) \quad I_t(z) \text{ is decreasing in } z \text{ for } \mathbb{P} \otimes dz\text{-almost every } (\omega, z).$$

Here  $I_t^+(z)$  and  $I_t^-(z)$  are defined by

$$I_t^+ := \sum_{n > 0, \kappa_n = 1}^{\infty} 1_{\{\tau_n < t\}}, \quad I_0^+ = 0, \quad \text{and} \quad I_t^- := \sum_{n > 0, \kappa_n = 0}^{\infty} 1_{\{\tau_n < t\}}, \quad I_0^- = 0.$$

**LEMMA 3.5** (from switching controls to singular controls). Given  $y \in \bar{\mathcal{I}}$  and a consistent collection of switching controls  $(\alpha(z))_{z \in \mathcal{I}}$ , define two processes  $\xi^+$  and  $\xi^-$  by setting  $\xi_0^+ = 0$ ,  $\xi_0^- = 0$ , and for  $t > 0$ ,  $\xi_t^+ := \int_{\mathcal{I}} I_t^+(z) dz$ ,  $\xi_t^- := \int_{\mathcal{I}} I_t^-(z) dz$ . Then

1. the pair  $(\xi^+, \xi^-) \in \mathcal{A}_y$  is an admissible singular control;

2. up to indistinguishability,

$$Y_t = y + \int_y^\infty I_t(z) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y (I_t(z) - 1) 1_{\{z \in \mathcal{I}\}} dz; \quad \text{and}$$

3. for all  $t$ , we almost surely have

$$Y_t = \text{ess sup}\{z \in \mathcal{I} : I_t(z) = 1\} = \text{ess inf}\{z \in \mathcal{I} : I_t(z) = 0\},$$

where  $\text{ess sup } \emptyset := \inf \mathcal{I}$  and  $\text{ess inf } \emptyset := \sup \mathcal{I}$ .

DEFINITION 3.6. A singular control  $(\xi^+, \xi^-)$  is integrable if

$$(12) \quad \mathbb{E} \left[ \int_0^\infty e^{-\rho t} |H(Y_t) X_t^x| dt + \int_{[0, \infty)} e^{-\rho t} |K_1| d\xi_t^+ + \int_{[0, \infty)} e^{-\rho t} |K_0| d\xi_t^- \right] < \infty.$$

**3.2. Solving singular control via the switching problem.** Our derivation of the solution relies on the following connection between the value function of the singular control problem and that of a switching control problem [21, Theorem 3.7].

LEMMA 3.7. The value function in problem (1) is given by

$$(13) \quad V(x, y) = \eta H(a)x + \int_a^y v_1(x, z) dz + \int_y^b v_0(x, z) dz,$$

where  $v_0$  and  $v_1$  are solutions to the following optimal switching problems:

$$(14) \quad v_k(x, z) := \sup_{\substack{\alpha \in \mathcal{B} \\ \kappa_0 = k}} \mathbb{E} \left[ \int_0^\infty e^{-\rho t} [h(z) X_t^x] I_t dt - \sum_{n=1}^\infty e^{-\rho \tau_n} K_{\kappa_n} \right],$$

provided that the subsequent switching control is consistent and the resulting singular control is integrable. Here,  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  is an admissible switching control,  $\mathcal{B}$  is the subset of admissible switching controls  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  such that  $\mathbb{E}[\sum_{n=1}^\infty e^{-\rho \tau_n}] < \infty$ , and  $I_t$  is the regime indicator function for any given  $\alpha \in \mathcal{B}$ .

In light of Lemma 3.7, our derivation goes as follows: First, we shall solve the corresponding optimal switching problems; we shall then check that the corresponding collection of switching controls is consistent, which implies that it corresponds to an admissible singular control; and finally, we shall establish the existence of the corresponding integrable optimal singular control  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$  and derive the corresponding value function.

**3.2.1. Step 1: Solving the optimal switching problem.** In this section, we shall solve the switching problem (14),

$$v_k(x, z) := \sup_{\substack{\alpha \in \mathcal{B} \\ \kappa_0 = k}} \mathbb{E} \left[ \int_0^\infty e^{-\rho t} [h(z) X_t^x] I_t dt - \sum_{n=1}^\infty e^{-\rho \tau_n} K_{\kappa_n} \right].$$

First, according to [33, Theorem 1.4.1] and [28, Lemma 3.2], in addition to  $X$  being a geometric Brownian motion, we easily see the following.

PROPOSITION 3.8. For fixed  $z \in [a, b]$  and  $k \in \{0, 1\}$ ,  $v_k(x, z)$  is  $C^1$  in  $x$ . Moreover, for every  $x > 0$ ,  $|\frac{\partial}{\partial x} v_k(x, z)| \leq \eta |h(z)|$ .

Next, by modifying the argument in [28, Theorem 3.1] for  $h \geq 0$  to the case of  $h < 0$ , we obtain the following.

PROPOSITION 3.9.  $v_0$  and  $v_1$  are the unique viscosity solutions with linear growth condition to the following system of variational inequalities:

$$(15) \quad \min \{-\mathcal{L}v_0(x, z), v_0(x, z) - v_1(x, z) + K_1\} = 0,$$

$$(16) \quad \min \{-\mathcal{L}v_1(x, z) - h(z)x, v_1(x, z) - v_0(x, z) + K_0\} = 0,$$

with boundary conditions  $v_0(0^+, z) = 0$  and  $v_1(0^+, z) = \max\{-K_0, 0\}$ . Here  $\mathcal{L}$  is the generator of the diffusion  $X^x$ , killed at rate  $\rho$ , given by  $\mathcal{L}u(x, z) = \sigma^2 u_{xx}(x, z) + \mu u_x(x, z) - \rho u(x, z)$ .

*Solution to the optimal switching problem.* Finally, we explicitly solve  $v_0$  and  $v_1$  based on [28, Theorem 4.2]. We see the following cases.

*Case I:  $K_0 \geq 0$ .* For each  $z \in (a, b)$ , the switching regions are described in terms of  $F(z)$  and  $G(z)$ , which take values in  $(0, \infty]$ .

First, for each  $z \in (a, b)$  such that  $h(z) = 0$ , it is never optimal to switch, since  $K_0 \geq 0$  and  $K_1 > 0$ , and so we take  $F(z) = \infty = G(z)$ . For this case,  $v_0(x, z) = 0 = v_1(x, z)$ .

Second, for  $z$  such that  $h(z) > 0$ , we have  $G(z) < \infty$  and it is optimal to switch from regime 0 to regime 1 (to invest in the project at level  $z$ ) when  $X_t^x \in [G(z), \infty)$ . Since  $K_0 \geq 0$ , it is never optimal to switch from regime 1 to regime 0 (i.e.,  $F(z) = \infty$ ). Furthermore, we have

$$\begin{aligned} v_0(x, z) &= \begin{cases} A(z)x^n, & x < G(z), \\ \eta h(z)x - K_1, & x \geq G(z), \end{cases} \\ v_1(x, z) &= \eta h(z)x. \end{aligned}$$

Since  $v_0$  is  $C^1$  at  $G(z)$ , we get

$$\begin{cases} A(z)G(z)^n &= \eta h(z)G(z) - K_1, \\ nA(z)G(z)^{n-1} &= \eta h(z). \end{cases}$$

That is,

$$\begin{cases} G(z) &= \nu h(z)^{-1}, \\ A(z) &= \frac{K_1}{(n-1)} G(z)^{-n} = \frac{K_1}{(n-1)} \nu^{-n} h(z)^n, \end{cases}$$

where  $\nu = K_1 \sigma^2 n(1 - m)$ .

Finally, when  $h(z) < 0$ , it is optimal to switch from regime 1 to regime 0 (disinvest at level  $z$ ) when  $X_t^x \in [F(z), \infty)$ . Since  $K_1 > 0$ , it is never optimal to switch from regime 0 to regime 1 (i.e.,  $G(z) = \infty$ ). The derivation of the value function proceeds analogously to the derivation for the case of  $h(z) > 0$ .

*Case II:  $K_0 < 0$ .* First of all, for each  $z \in (a, b)$  such that  $h(z) \leq 0$ , it is always optimal to disinvest because  $K_0 < 0$ . That is,  $F(z) = \infty = G(z)$ . In this case, clearly  $v_0(x, z) = 0$  and  $v_1(x, z) = -K_0$ .

Next, for each  $z \in (a, b)$  such that  $h(z) > 0$ , it is optimal to switch from regime 0 to regime 1 (to invest in the project at level  $z$ ) when  $X_t^x \in [G(z), \infty)$ , and to switch from regime 1 to regime 0 (disinvest at level  $z$ ) when  $X_t^x \in (0, F(z)]$ , where  $0 < F(z) < G(z) < \infty$ .

Moreover,  $v_0$  and  $v_1$  are given by

$$\begin{aligned} v_0(x, z) &= \begin{cases} A(z)x^n, & x < G(z), \\ B(z)x^m + \eta x h(z) - K_1, & x \geq G(z), \end{cases} \\ v_1(x, z) &= \begin{cases} A(z)x^n - K_0, & x \leq F(z), \\ B(z)x^m + \eta x h(z), & x > F(z). \end{cases} \end{aligned}$$

Smoothness of  $v(x, z)$  at  $x = G(z)$  and  $x = F(z)$  from Proposition 3.8 leads to

$$(17) \quad \begin{cases} A(z)G(z)^n &= B(z)G(z)^m + \eta G(z)h(z) - K_1, \\ nA(z)G(z)^{n-1} &= mB(z)G(z)^{m-1} + \eta h(z), \\ A(z)F(z)^n &= B(z)F(z)^m + \eta F(z)h(z) + K_0, \\ nA(z)F(z)^{n-1} &= mB(z)F(z)^{m-1} + \eta h(z). \end{cases}$$

Eliminating  $A(z)$  and  $B(z)$  from (17) yields

$$(18) \quad \begin{cases} K_1 G(z)^{-m} + K_0 F(z)^{-m} &= \frac{-m}{(1-m)\rho} h(z) (G(z)^{1-m} - F(z)^{1-m}), \\ K_1 G(z)^{-n} + K_0 F(z)^{-n} &= \frac{n}{(n-1)\rho} h(z) (G(z)^{1-n} - F(z)^{1-n}). \end{cases}$$

Since the viscosity solutions to the variational inequalities are unique and  $C^1$  according to Proposition 3.9, for every  $z$  there is a unique solution  $F(z) < G(z)$  to (18). Let  $\kappa(z) = F(z)h(z)$ ,  $\nu(z) = G(z)h(z)$ ; then the following system of equations for  $\kappa(z)$  and  $\nu(z)$  is guaranteed to have a unique solution for each  $z$ :

$$\begin{cases} K_1 \nu(z)^{-m} + K_0 \kappa(z)^{-m} &= \frac{-m}{(1-m)\rho} (\nu(z)^{1-m} - \kappa(z)^{1-m}), \\ K_1 \nu(z)^{-n} + K_0 \kappa(z)^{-n} &= \frac{n}{(n-1)\rho} (\nu(z)^{1-n} - \kappa(z)^{1-n}). \end{cases}$$

Moreover, these equations depend on  $z$  only through  $\nu(z)$  and  $\kappa(z)$ , implying that there exist unique constants  $\kappa, \nu$  such that  $\kappa(z) \equiv \kappa$  and  $\nu(z) \equiv \nu$  for all  $z$ . Hence  $F(z) = \kappa h(z)^{-1}$ ,  $G(z) = \nu h(z)^{-1}$ , with  $\kappa < \nu$  being the unique solutions to

$$\begin{cases} \frac{1}{1-m} [\nu^{1-m} - \kappa^{1-m}] &= -\frac{\rho}{m} [K_1 \nu^{-m} + K_0 \kappa^{-m}], \\ \frac{1}{n-1} [\nu^{1-n} - \kappa^{1-n}] &= \frac{\rho}{n} [K_1 \nu^{-n} + K_0 \kappa^{-n}]. \end{cases}$$

Given  $F(z)$  and  $G(z)$ ,  $A(z)$  and  $B(z)$  are solved from (17),

$$\begin{cases} B(z) &= -\frac{G(z)^{-m}}{n-m} \left( \frac{G(z)h(z)}{\sigma^2(1-m)} - nK_1 \right) = -\frac{F(z)^{-m}}{n-m} \left( \frac{F(z)h(z)}{\sigma^2(1-m)} + nK_0 \right), \\ A(z) &= \frac{G(z)^{-n}}{n-m} \left( \frac{G(z)h(z)}{\sigma^2(n-1)} + mK_1 \right) = \frac{F(z)^{-n}}{n-m} \left( \frac{F(z)h(z)}{\sigma^2(n-1)} - mK_0 \right). \end{cases}$$

**3.2.2. Step 2: Corresponding switching controls.** Given the solution to the optimal switching problems, it is clear that the optimal switching control for any level  $z \in (a, b)$  is given by the following.

*Case I.* For  $z \in (a, b)$  and  $x > 0$ , let  $F$  and  $G$  be as given in Case I of Theorem 3.14. The switching control  $\hat{\alpha}_k(x, z) = (\hat{\tau}_n(x, z), \hat{\kappa}_n(z))_{n \geq 0}$ , starting from  $\hat{\tau}_0(x, z) = 0$  and  $\hat{\kappa}_0(z) = k$  is given as the following:

- for  $n \geq 1$  if  $k = 0$ ,  $\hat{\tau}_1(x, z) = \inf\{t > 0 : X_t^x \in [G(z), \infty)\}$ , and for  $n \geq 2$ ,  $\hat{\tau}_n(z) = \infty$ ;
- for  $n \geq 1$  if  $k = 1$ ,  $\hat{\tau}_1(x, z) = \inf\{t > 0 : X_t^x \in [F(z), \infty)\}$ , and for  $n \geq 2$ ,  $\hat{\tau}_n(z) = \infty$ .

*Case II.* For  $z \in (a, b)$  and  $x > 0$ ,  $F$  and  $G$  are as given in Case II of Theorem 3.14. The switching control  $\hat{\alpha}_k(x, z) = (\hat{\tau}_n(x, z), \hat{\kappa}_n(z))_{n \geq 0}$ , starting from  $\hat{\tau}_0(x, z) = 0$  and  $\hat{\kappa}_0(z) = k$  is given as the following:

- for  $n \geq 1$  if  $\hat{\kappa}_{n-1}(z) = 0$ ,  $\hat{\tau}_n(x, z) = \inf\{t > \tau_{n-1} : X_t^x \in [G(z), \infty)\}$ ,  $\hat{\kappa}_n(z) = 1$ ;
- for  $n \geq 1$  if  $\hat{\kappa}_{n-1}(z) = 1$ ,  $\hat{\tau}_n(x, z) = \inf\{t > \tau_{n-1} : X_t^x \in (0, F(z)]\}$ ,  $\hat{\kappa}_n(z) = 0$ .

**3.2.3. Step 3: Consistency of the switching controls.** Now, define the collection of admissible switching controls  $(\hat{\alpha}(x, z))_{z \in (a, b)}$  so that  $\hat{\alpha}(x, z) = \hat{\alpha}_0(x, z)$  for  $z > y$  and  $\hat{\alpha}(x, z) = \hat{\alpha}_1(x, z)$  for  $z \leq y$ . Then we have the following.

PROPOSITION 3.10. *The collection of switching controls  $(\hat{\alpha}(x, z))_{z \in (a, b)}$  is consistent.*

To prove the consistency, the following monotonicity properties of  $F$  and  $G$  are essential:  $F$  is nonincreasing and  $G$  is nondecreasing in Case I, and  $F$  is nondecreasing and  $G$  is nonincreasing in Case II.

To start, for each  $z \in (a, b)$ , denote  $\hat{I}_t(x, z)$  to be the regime indicator function of the optimal switching control  $\hat{\alpha}(x, z)$ . That is,  $\hat{I}_t(x, z) = \sum_{n=0}^{\infty} \hat{\kappa}_n(z) 1_{\{\hat{\tau}_n(x, z) < t \leq \hat{\tau}_{n+1}(x, z)\}}$ . Then the consistency follows from the following lemmas.

LEMMA 3.11. *For every  $x > 0$  and  $t > 0$ ,  $\hat{I}_t(x, \cdot)$  is nonincreasing.*

*Proof.* For simplicity, we omit the dependence on  $x$  from the notation.

- *Case I.* Fix  $x > 0$  and  $t > 0$ . Let  $w < z$  be given and suppose that  $\hat{I}_t(z) = 1$ . In the event that  $t \leq \hat{\tau}_1(z)$ , we have  $w < z \leq y$  and hence  $F(w) \geq F(z)$  since  $F$  is nonincreasing. So by definition,  $\hat{\tau}_1(w) \geq \hat{\tau}_1(z) \geq t$ . Thus,  $\hat{I}_t(w) = 1$  for  $w \leq y$ .

Now in the event that  $t > \hat{\tau}_1(z)$ ,  $\hat{I}_t(z) = 1$  implies that for some  $s < t$ ,  $X_s^x \in [G(z), \infty)$ , i.e.,  $\sup\{s \leq t : X_s^x \geq G(z)\} \geq G(z)$ . However, since  $G$  is nondecreasing,  $G(z) \geq G(w)$ . Hence  $\sup\{s \leq t : X_s^x \geq G(w)\} \geq G(w)$  and  $\hat{I}_t(w) = 1$ .

Since  $\hat{I}_t(z) = 1$  implies that  $\hat{I}_t(w) = 1$  for any  $w < z$ ,  $\hat{I}_t(x, \cdot)$  is nonincreasing.

- *Case II.* Fix  $x > 0$  and  $t > 0$ . Let  $w < z$  be given and suppose that  $\hat{I}_t(z) = 1$ . In the event that  $t \leq \hat{\tau}_1(z)$ , we have  $w < z \leq y$  and hence  $F(w) \leq F(z)$ . So by definition,  $\hat{\tau}_1(w) \geq \hat{\tau}_1(z) \geq t$ . Thus,  $\hat{I}_t(w) = 1$  for  $w \leq y$ .

Now in the event that  $t > \hat{\tau}_1(z)$ ,  $\hat{I}_t(z) = 1$  implies that for some  $s < t$ ,  $X_s^x \in [G(z), \infty)$  and also that  $X^x$  must have been in the set  $[G(z), \infty)$  more recently than in  $[0, F(z)]$ , i.e.,

$$\sup\{s \leq t : X_s^x \in [G(z), \infty)\} > \sup\{s \leq t : X_s^x \in (0, F(z)]\}.$$

However, since  $[G(z), \infty) \subset [G(w), \infty)$  and  $(0, F(w)] \subset (0, F(z)]$  for  $w < z$ , this implies

$$\begin{aligned} \sup\{s \leq t : X_s^x \in [G(w), \infty)\} &\geq \sup\{s \leq t : X_s^x \in [G(z), \infty)\} \\ &> \sup\{s \leq t : X_s^x \in (0, F(z)]\} \\ &\geq \sup\{s \leq t : X_s^x \in (0, F(w)]\}. \end{aligned}$$

Hence  $X^x$  was in  $[G(w), \infty)$  more recently than in  $(0, F(w)]$ , meaning that  $\hat{I}_t(w) = 1$ .

Since  $\hat{I}_t(z) = 1$  implies that  $\hat{I}_t(w) = 1$  for any  $w < z$ ,  $\hat{I}_t(x, \cdot)$  is nonincreasing.  $\square$

LEMMA 3.12. *For every  $x > 0$ ,  $t > 0$ ,  $\int_a^b (\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z)) dz < \infty$  almost surely.*

*Proof.*

- *Case I.* This is easy to prove by recalling that  $\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z)$  represents the number of switches at level  $z$  up to time  $t$ . Since there is at most one switch at each level  $z$ ,  $\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z) \leq 1$ . Hence  $\int_a^b (\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z)) dz \leq b - a < \infty$ .
- *Case II.* Since  $[a, b]$  is bounded, it suffices to show that for all  $(x, t)$ ,  $\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z)$  is almost surely bounded in  $z$ . Let  $x > 0$  and  $t > 0$  be given.

Recall that  $\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z)$  represents the number of switches at level  $z$  up to time  $t$ . When  $h(z) \leq 0$ , there is exactly one switch. When  $h(z) > 0$ ,  $0 < F(z) < G(z) < \infty$ ,  $G(z) = \nu h(z)^{-1}$ , and  $F(z) = \kappa h(z)^{-1}$ . Note that after the first switch, each subsequent switch requires that  $X^x$  move from  $(0, F(z))$  to  $[G(z), \infty)$  or vice versa.

Alternatively,  $\log(X^x)$  must move from  $(-\infty, \log(F(z)))$  to  $[\log(G(z)), \infty)$ , traveling a minimum distance of  $\log(G(z)) - \log(F(z)) = \log(\nu) - \log(\kappa) > 0$  for each switch. In particular, this quantity is independent of  $z$ .

Since  $\log(X^x)$  is a Brownian motion with drift, its sample paths are almost surely uniformly continuous on  $[0, t]$ . Thus, for almost all  $\omega \in \Omega$ , there exists some  $\delta(\omega) > 0$  such that for any  $x > 0$  and all  $s, r \in [0, t]$ , with  $|s - r| < \delta(\omega)$ ,

$$|\log(X_s^x(\omega)) - \log(X_r^x(\omega))| < \log(\nu) - \log(\kappa) = \log(G(z)) - \log(F(z)).$$

Hence, for any level  $z \in [a, b]$ , there is at least  $\delta(\omega)$  amount of time in between any two switches (after the first one). Hence there can be at most  $1 + \frac{t}{\delta(\omega)}$  switches at level  $z$  in  $[0, t]$ . Thus

$$\hat{I}_t^+(x, z) + \hat{I}_t^-(x, z) \leq 1 + \frac{t}{\delta} < \infty \quad \text{almost surely.} \quad \square$$

**3.2.4. Step 4: Corresponding optimal singular control.** It remains to check the integrability of the corresponding singular control, which is obvious from the following proposition due to [31].

**PROPOSITION 3.13.** *For any  $y \in [a, b]$  and any pair  $(\xi^+, \xi^-)$  of left continuous, nondecreasing processes, with  $\xi_0^\pm = 0$  and  $y + \xi_t^+ - \xi_t^- \in [a, b]$  for all  $t$ , either*

- A.  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , or
- B. *there exists an  $\mathbb{F}$ -adapted process  $Z$  such that  $U. \leq Z$ . almost surely,  $\mathbb{E}[|Z_T|] < \infty$  for all  $T \geq 0$ , and  $\limsup_{T \rightarrow \infty} \mathbb{E}[Z_T] = -\infty$ , where*

$$U_T(y, \xi^+, \xi^-) := \int_0^T e^{-\rho t} [H(Y_t) X_t^x] dt - K_1 \int_{[0, T)} e^{-\rho t} d\xi_t^+ - K_0 \int_{[0, T)} e^{-\rho t} d\xi_t^-.$$

Therefore, we conclude that there exists a corresponding integrable singular control  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$ , and define  $\hat{Y}_t = y + \hat{\xi}_t^+ - \hat{\xi}_t^-$ .

**3.2.5. Solution: Value function and optimal control.** In short, we summarize the solution for problem (1) as follows.

**THEOREM 3.14 (value function).** *The value function  $V(x, y)$  is given by*

$$(19) \quad V(x, y) = \eta H(a)x + \int_a^y v_1(x, z) dz + \int_y^b v_0(x, z) dz,$$

where  $v_0$  and  $v_1$  are given explicitly based on  $K_0$  as follows.

Case I:  $(K_0 \geq 0)$ .

- 1. For each  $z \in (a, b)$  such that  $h(z) = 0$ ,  $v_0(x, z) = v_1(x, z) = 0$ .
- 2. For each  $z \in (a, b)$  such that  $h(z) > 0$ ,

$$\begin{cases} v_0(x, z) &= \begin{cases} A(z)x^n, & x < G(z), \\ \eta h(z)x - K_1, & x \geq G(z), \end{cases} \\ v_1(x, z) &= \eta h(z)x, \end{cases}$$

where  $G(z) = \nu h(z)^{-1}$ , and  $A(z) = \frac{K_1}{(n-1)} \left(\frac{h(z)}{\nu}\right)^n$ , with  $\nu = K_1 \sigma^2 n(1 - m)$ .

FIG. 1. Illustration of Case I of Theorem 3.14 when boundaries are smooth.

FIG. 2. Illustration of Case I of Theorem 3.14 when boundaries are NOT smooth:  $h(z) = c/z$  for  $z < 1$  and  $h(z) = -d/(2-z)$  for  $z > 1$  with  $K_0/d < K_1/c$ .

3. For each  $z \in (a, b)$  such that  $h(z) < 0$ ,

$$\begin{cases} v_0(x, z) = 0, \\ v_1(x, z) = \begin{cases} B(z)x^n + \eta h(z)x, & x < F(z), \\ -K_0, & x \geq F(z), \end{cases} \end{cases}$$

where  $F(z) = -\frac{\kappa}{h(z)}$ , and  $B(z) = \frac{K_0}{(n-1)}\kappa^{-n}(-\frac{h(z)}{\kappa})^n$ , with  $\kappa = K_0\sigma^2n(1-m)$ .

See Figures 1 and 2.

Case II: ( $K_0 < 0$ ).

1. For each  $z \in (a, b)$  such that  $h(z) \leq 0$ ,  $v_0(x, z) = 0$ ,  $v_1(x, z) = -K_0$ .

2. For each  $z \in (a, b)$  such that  $h(z) > 0$ ,

$$(20) \quad v_0(x, z) = \begin{cases} A(z)x^n, & x < G(z), \\ B(z)x^m + \eta h(z)x - K_1, & x \geq G(z), \end{cases}$$

$$(21) \quad v_1(x, z) = \begin{cases} A(z)x^n - K_0, & x \leq F(z), \\ B(z)x^m + \eta h(z)x, & x > F(z). \end{cases}$$

FIG. 3. Illustration of Case II of Theorem 3.14 when boundaries are smooth.

FIG. 4. Example of Case II of Theorem 3.14 when boundaries are smooth.

Here

$$(22) \quad A(z) = \frac{h(z)^n}{(n-m)\nu^n} \left( \frac{\nu}{\sigma^2(n-1)} + mK_1 \right) = \frac{h(z)^n}{(n-m)\kappa^n} \left( \frac{\kappa}{\sigma^2(n-1)} - mK_0 \right),$$

$$(23) \quad B(z) = \frac{-h(z)^m}{(n-m)\nu^m} \left( \frac{\nu}{\sigma^2(1-m)} - nK_1 \right) = \frac{-h(z)^m}{(n-m)\kappa^m} \left( \frac{\kappa}{\sigma^2(1-m)} + nK_0 \right).$$

The functions  $F$  and  $G$  are nondecreasing with

$$(24) \quad F(z) = \frac{\kappa}{h(z)} \quad \text{and} \quad G(z) = \frac{\nu}{h(z)},$$

where  $\kappa < \nu$  are the unique solutions to

$$(25) \quad \frac{1}{1-m} [\nu^{1-m} - \kappa^{1-m}] = -\frac{\rho}{m} [K_1\nu^{-m} + K_0\kappa^{-m}],$$

$$(26) \quad \frac{1}{n-1} [\nu^{1-n} - \kappa^{1-n}] = \frac{\rho}{n} [K_1\nu^{-n} + K_0\kappa^{-n}].$$

See Figures 3 and 4.

**THEOREM 3.15** (optimal control). *The optimal singular control  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$  exists. For each  $z \in (a, b)$ , the optimal control is described in terms of  $F(z)$  and  $G(z)$  from Theorem 3.14 such that the following hold.*

- (Case I,  $K_0 \geq 0$ ): For  $z$  such that  $h(z) > 0$ , it is optimal to invest in the project past level  $z$  when  $X_t^x \in [G(z), \infty)$ , and never disinvest. When  $h(z) < 0$ , it is optimal to disinvest below level  $z$  when  $X_t^x \in [F(z), \infty)$ , and it is never optimal to invest. When  $h(z) = 0$ , it is optimal to neither invest nor disinvest (i.e.,  $F(z) = \infty = G(z)$ ).
- (Case II,  $K_0 < 0$ ): For  $z$  such that  $h(z) > 0$ , it is optimal to invest in the project past level  $z$  when  $X_t^x \in [G(z), \infty)$ , and to disinvest below level  $z$  when  $X_t^x \in (0, F(z)]$ . For  $z$  such that  $h(z) \leq 0$ , it is always optimal to disinvest.

**3.3. Optimally controlled process.** Having obtained the value function and the optimal control policy, now we can describe explicitly the optimally controlled process.

First, from Lemma 3.5 we clearly have the following.

LEMMA 3.16. *Given  $(x, y) \in (0, \infty) \times [a, b]$ , the optimally controlled process  $\hat{Y}$  is indistinguishable from  $\sup\{z \in (a, b) : \hat{I}_t(x, z) = 1\} = \inf\{z \in (a, b) : \hat{I}_t(x, z) = 0\}$ .*

Next we see the following.

LEMMA 3.17. *Let  $S \leq T$  be nonnegative random variables. Then with probability one,*

- $\hat{Y}$  is nondecreasing on  $(S, T]$  for  $(X^x, \hat{Y}) \in (\mathcal{S}_0)^c$  on  $(S, T)$ ;
- $\hat{Y}$  is nonincreasing on  $(S, T]$  for  $(X^x, \hat{Y}) \in (\mathcal{S}_1)^c$  on  $(S, T)$ ;
- $\hat{Y}$  is constant on  $(S, T]$  for  $(X^x, \hat{Y}) \in \mathcal{C}$  on  $(S, T)$ .

Consequently, with probability one,  $(X_t^x, \hat{Y}_t) \in \mathcal{C}$  for all  $t > 0$  and  $d\hat{Y}_t$  is supported on  $\partial\mathcal{C}$ .

*Proof.* We shall prove only the first claim. (The second one follows by a similar argument, and the last one is immediate from the definition of  $\mathcal{C}$  and the first two.) Take any  $x > 0$ . If  $(X^x, \hat{Y}) \in (\mathcal{S}_0)^c$  on  $(S, T)$ , then in light of Lemma 3.16 and the fact that  $h$  has at most countably many discontinuities, clearly it suffices to show that for any  $z \in (a, b)$  such that  $h$  is continuous at  $z$ ,  $\hat{I}_t(x, z)$  is almost surely nondecreasing on  $(S, T]$ .

Given  $z \in (a, b)$  where  $h$  is continuous, fix  $t > 0$  and consider the event that  $t \in (S, T)$  and  $\hat{I}_t(x, z) = 1$ . On this event  $\hat{Y}_t \geq z$  almost surely. Furthermore, for any  $s \in [t, T)$ , we have  $(X_s^x, \hat{Y}_s) \in \mathcal{C}$ , and hence  $X_s^x > F(\hat{Y}_s^-) \geq F(z^-) = F(z)$ , since  $z$  is a continuity point of  $h$ . This implies that there is no switching to regime 0 at level  $z$ , and hence with probability one,  $\hat{I}_s(x, z) = 1$  for all  $s \in [t, T)$ . By the left continuity of  $\hat{I}$ , this implies  $\hat{I}_T(x, z) = 1$  as well. Since  $\hat{I}_t(x, z) \in \{0, 1\}$ , this implies that  $\hat{I}_t(x, z)$  is indeed nondecreasing on  $(S, T]$ .  $\square$

Now, we have the next theorem.

THEOREM 3.18 (optimally controlled process). *The resulting optimal control process  $\hat{Y}_t$  is given by the following.*

Case I (up to indistinguishability). For  $t > 0$ ,

- if  $h(y^+) > 0$ , then  $\hat{Y}_t = \max\{G^\rightarrow(M_t), y\}$ ;
- if  $h(y^+) = 0$  or  $h(y^-) = 0$ , then  $\hat{Y}_t = y$ ;
- if  $h(y^-) < 0$ , then  $\hat{Y}_t = \min\{F^\rightarrow(M_t), y\}$ .

Here  $M_t = \max\{X_s^x : s \in [0, t]\}$ , and  $F^\rightarrow$  and  $G^\rightarrow$  are, respectively, the left continuous inverses of  $F$  (nonincreasing) and  $G$  (nondecreasing) such that

$$\begin{aligned} F^\rightarrow(x) &= \inf\{z \in (a, b) : F(z) < x\} = \sup\{z \in (a, b) : F(z) \geq x\}, \\ G^\rightarrow(x) &= \inf\{z \in (a, b) : G(z) \geq x\} = \sup\{z \in (a, b) : G(z) < x\}, \end{aligned}$$

with  $\inf \emptyset = b$  and  $\sup \emptyset = a$ .

Case II (up to indistinguishability). For  $t > 0$ ,

$$(27) \quad \hat{Y}_t = \begin{cases} G^\rightarrow(M_t^0) \vee y & \text{on } \{t \leq S_1\}, \\ F^\leftarrow(m_t^n) \wedge \hat{Y}_{S_n} & \text{on } \{S_n < t \leq T_n\}, \\ G^\rightarrow(M_t^n) \vee \hat{Y}_{T_n} & \text{on } \{T_n < t \leq S_{n+1}\}, \end{cases}$$

and  $\lim_{n \rightarrow \infty} S_n = \infty = \lim_{n \rightarrow \infty} T_n$  almost surely. Here  $F^\leftarrow(x)$  and  $G^\rightarrow(x)$  are, respectively, the right continuous inverse of  $F$  and the left continuous inverse of  $G$ , both of which are nondecreasing and are given by

$$\begin{aligned} F^\leftarrow(x) &= \inf\{z \in (a, b) : F(z) > x\} = \sup\{z \in (a, b) : F(z) \leq x\}, \\ G^\rightarrow(x) &= \inf\{z \in (a, b) : G(z) \geq x\} = \sup\{z \in (a, b) : G(z) < x\}, \end{aligned}$$

with  $\inf \emptyset = b$  and  $\sup \emptyset = a$ . Moreover, the stopping times  $(S_n)$  and  $(T_n)$  are given by

$$\begin{aligned} S_1 &= \inf\{t > 0 : (X_t^x, \hat{Y}_t) \in \mathcal{S}_0\}, & T_1 &= \inf\{t > S_1 : (X_t^x, \hat{Y}_t) \in \mathcal{S}_1\}, \\ S_n &= \inf\{t > T_{n-1} : (X_t^x, \hat{Y}_t) \in \mathcal{S}_0\}, & T_n &= \inf\{t > S_n : (X_t^x, \hat{Y}_t) \in \mathcal{S}_1\}. \end{aligned}$$

Lastly, the processes  $M_t^n$ ,  $m_t^n$  are defined by  $M_t^0 = \max\{X_t^x : 0 \leq s \leq t\}$  and

$$m_t^n = \min\{X_t^x : S_n \leq s \leq t\} 1_{\{S_n \leq t\}}, \quad M_t^n = \max\{X_t^x : T_n \leq s \leq t\} 1_{\{T_n \leq t\}}.$$

*Proof of Theorem 3.18.*

Case I. Recall the optimal switching controls for Case I. Suppose  $0 < h(y^+)$ ; then  $0 < h(y)$  since  $h$  is nonincreasing, and thus  $F(z) = \infty$  and  $G(z) < \infty$ . Let  $t > 0$  be fixed and observe that  $\hat{I}_t(z) \equiv 1$  for all  $z \leq y$  and for  $z > y$ ,  $\hat{I}_t(z) = 1_{\{\hat{\tau}_1(z) < t\}}$ . So  $\hat{I}_t(z) = 1$  if and only if  $z \leq y$  or  $t > \hat{\tau}_1(z)$ . Almost surely,  $t > \hat{\tau}_1(z)$  is equivalent to  $M_t > G(z)$ . Hence

$$\begin{aligned} \hat{Y}_t &= \sup\{z \in (a, b) : I_t(z) = 1\} = y \vee \sup\{z \in (a, b) : t > \hat{\tau}_1(z)\} \\ &= y \vee \sup\{z \in (a, b) : G(z) < M_t\} = \max\{G^\rightarrow(M_t), y\}. \end{aligned}$$

Now, since  $M$  is increasing,  $\max\{G^\rightarrow(M_t), y\}$  is also left continuous, and thus they are indistinguishable.

A similar argument proves the result for  $h(y-) < 0$ .

Suppose  $h(y+) = 0$  or  $h(y-) = 0$ . Then for all  $z > y$ , we have  $h(z) \leq 0$ , and hence it is never optimal to switch to regime 1. Since  $\hat{I}_t(0) = 0$ , this is true for all  $t$  and  $\hat{I}_t(z) \equiv 0$ . Similarly, for all  $z \leq y$ ,  $h(z) \leq 0$  and so  $\hat{I}_t(z) \equiv 1$ . Thus  $\hat{Y}_t = y$  for all  $t$ .

Case II. First, we show that  $\lim_{n \rightarrow \infty} S_n = \infty = \lim_{n \rightarrow \infty} T_n$  almost surely. Let  $\tilde{S}_n = \sup\{t < T_n : (X_t^x, \hat{Y}_t) \in \mathcal{S}_0\}$  be the last exit time of the process  $(X^x, \hat{Y})$  from  $\mathcal{S}_0$  before  $T_n$ . Then  $S_n \leq \tilde{S}_n \leq T_n$ , and  $(X_t^x, \hat{Y}_t) \in \mathcal{C}$  on  $(\tilde{S}_n, T_n)$ . By Lemma 3.17,  $\hat{Y}$  is constant on  $(\tilde{S}_n, T_n]$ . Thus, in between  $\tilde{S}_n$  and  $T_n$ , the process  $(X_t^x, \hat{Y}_{T_n})$  must travel between  $\mathcal{S}_0$  and  $\mathcal{S}_1$ . This means that between  $\tilde{S}_n$  and  $T_n$ ,  $\log(X^x)$  must travel between  $\log(F(\hat{Y}_{T_n}^-))$  and  $\log(G(\hat{Y}_{T_n}^+))$ .

Meanwhile, we have

$$\begin{aligned} \log(G(\hat{Y}_{T_n}^+)) - \log(F(\hat{Y}_{T_n}^-)) &= \log(\nu) - \log(h(\hat{Y}_{T_n}^+)) - \log(\kappa) + \log(h(\hat{Y}_{T_n}^-)) \\ &\geq \log(\nu) - \log(\kappa) > 0. \end{aligned}$$

Since this quantity is positive, and independent of  $n$ , and  $\log(X^x)$  is a Brownian motion, there exists a positive random variable  $\epsilon > 0$  such that  $\epsilon \leq T_n - \hat{S}_n \leq T_n - S_n \leq S_{n+1} - S_n$ . Hence  $\lim_{n \rightarrow \infty} S_n = \infty$  almost surely. Since  $T_n \geq S_n$  for all  $n$ ,  $\lim_{n \rightarrow \infty} T_n = \infty$  almost surely as well.

Next, fix  $t > 0$  and note that that almost surely  $t \in (T_n, S_{n+1}]$  or  $t \in (S_n, T_n]$ , for some  $n$ , where  $T_0 = 0$ . We consider the case that  $t \in (T_n, S_{n+1}]$  for some  $n \geq 0$ . The proof for the case  $t \in (S_n, T_n]$  is similar.

Note that  $(X^x, \hat{Y}) \in (\mathcal{S}_0)^c$  on  $(\hat{S}_n, S_{n+1})$ , and hence by Lemma 3.17,  $\hat{I}_s(x, z)$  is nondecreasing on  $[T_n, S_{n+1}] \subset (\hat{S}_n, S_{n+1})$  for all  $z \in (a, b)$  such that  $h$  is continuous at  $z$ .

Thus, in the event that  $t \in (T_n, S_{n+1}]$ , we know that  $\hat{I}_{T_n}(z) = 1$  for all  $z < \hat{Y}_{T_n}$  and  $\hat{I}_{T_n}(z) = 0$  for all  $z > \hat{Y}_t$ . Since  $\hat{I}$  is nondecreasing on  $[T_n, S_{n+1}]$ , this means that  $\hat{I}_t(x, z) = 1$  if and only if  $z < \hat{Y}_{T_n}$  or if  $X_s^x \geq G(z)$  for some  $s \in [T_n, t)$ . The latter condition is almost surely equivalent to  $G(z) < M_t^n$ . Thus, by Lemma 3.16, in the event that  $t \in (T_n, S_{n+1}]$ , we almost surely have

$$\begin{aligned} \hat{Y}_t &= \sup\{z \in (a, b) : I_t(z) = 1\} = \hat{Y}_{T_n} \vee \sup\{z \in (a, b) : G(z) < M_t^n\} \\ &= G^{-}(M_t^n) \vee \hat{Y}_{T_n}. \end{aligned}$$

A similar argument shows that in the event that  $t \in (S_n, T_n]$ , we almost surely have  $\hat{Y}_t = F^{-}(m_t^n) \wedge \hat{Y}_{S_n}$ . Hence, we have proved that for each  $t$ , the statement in (27) holds almost surely. Moreover, since  $M^n$  is increasing and  $G^{-}$  is left continuous,  $G^{-}(M_t^n)$  is left continuous in  $t$ . Similarly, since  $m^n$  is decreasing and  $F^{-}$  is right continuous,  $F^{-}(m_t^n)$  is left continuous in  $t$ . Thus, the right-hand side of (27) is left continuous in  $t$  and hence indistinguishable from  $\hat{Y}$ .  $\square$

**4. Regularity, smooth fit, and region characterization.** In this section, we shall establish necessary and sufficient conditions for the smooth fit principle by exploiting both the structure of the payoff function and the explicit solution of the value function. This analysis leads to the characterization for both the continuation and action regions.

#### 4.1. Regularity and smooth fit.

**THEOREM 4.1** (sufficient conditions).  *$V(x, y)$  is  $C^1$  in  $x$  for all  $(x, y) \in (0, \infty) \times [a, b]$ , and*

$$\frac{\partial}{\partial x} V(x, y) = \eta H(a) + \int_a^y \frac{\partial}{\partial x} v_1(x, z) dz + \int_y^b \frac{\partial}{\partial x} v_0(x, z) dz.$$

*Moreover, if  $H$  is  $C^1$  on an open interval  $\mathcal{J} \subset [a, b]$ , then  $V(x, y)$  is  $C^1$  in  $y$  on  $(0, \infty) \times \mathcal{J}$ ; that is,  $V(x, y)$  is  $C^{1,1}$  on  $(0, \infty) \times \mathcal{J}$ .*

*Proof.* First, by the representation of  $V(x, y)$  in (19), it suffices to check that for a fixed  $y \in [a, b]$ ,  $u'(x) = \int_a^y \frac{\partial}{\partial x} v_1(x, z) dz$  for all  $x > 0$ , where  $u(x) = \int_a^y v_1(x, z) dz$ .

Note that  $\int_a^y |v_1(x, z)| dz < \infty$ , and  $|\frac{\partial}{\partial x} v_1(x, z)|$  is locally bounded by a constant factor of  $h(z)$  by Proposition 3.8. Moreover, for every  $\delta > 0$  such that  $x - \delta > 0$ , there

exists a constant  $C$  such that

$$\int_a^y \int_{-\delta}^{\delta} \left| \frac{\partial}{\partial x} v_1(x + \theta, z) \right| d\theta dz \leq \int_a^y \int_{-\delta}^{\delta} C h(z) d\theta dz = 2\delta C [H(y) - H(a)] < \infty.$$

Hence, by the dominated convergence theorem,  $v$  is continuous, and by [17, Theorem A.9.1],  $u'(x) = \int_a^y \frac{\partial}{\partial x} v_1(x, z) dz$  for all  $x > 0$ .

Furthermore, suppose that  $H(y)$  is  $C^1$  in an open interval  $\mathcal{J} \subset [a, b]$ . Then for  $x > 0$  and  $y \in \mathcal{J}$ ,

$$\begin{aligned} \lim_{z \rightarrow y} \mathbb{E} \left[ \int_0^\infty |e^{-\rho t} h(z)(X_t^x) - e^{-\rho t} h(y) X_t^x| dt \right] &= \lim_{z \rightarrow y} \mathbb{E} \left[ \int_0^\infty e^{-\rho t} X_t^x dt \right] |h(z) - h(y)| \\ &= \eta x \lim_{z \rightarrow y} |h(z) - h(y)| = 0. \end{aligned}$$

So  $v_k(x, \cdot)$  is continuous at  $y$ , and hence  $V(x, y)$  is  $C^1$  in  $y$  for all  $(x, y) \in (0, \infty) \times \mathcal{J}$ . (See also Theorem 3.13 in [21].)  $\square$

To study the necessary conditions for the continuous differentiability of the value function on  $y$ , we start by defining  $d(x, y) = V_{y^+}(x, y) - V_{y^-}(x, y)$ .

First, note that  $v_1(x, \cdot) - v_0(x, \cdot) = \mathbb{E} \left[ \int_0^\infty e^{-\rho t} h(z) X_t^x dt \right]$ . Since  $h(y)$  is nonincreasing and hence  $\mathbb{E} \left[ \int_0^\tau e^{-\rho t} h(z) X_t^x dt \right]$  is nonincreasing in  $z$  for any stopping time  $\tau$ , we have the following.

**LEMMA 4.2.** *For  $x > 0$ ,  $v_1(x, \cdot) - v_0(x, \cdot)$  is decreasing. Therefore,  $d(x, \cdot)$  has only countably many discontinuities.*

This lemma, coupled with the variational inequalities in (15) and (16), leads to the following.

**PROPOSITION 4.3.**  *$V(x, y)$  is both left and right differentiable in  $y$ , with  $V_{y^+}$  and  $V_{y^-}$  decreasing in  $y$  and  $-K_0 \leq V_{y^+}(x, y) \leq V_{y^-}(x, y) \leq K_1$ . Thus,  $d(x, y) \leq 0$ .*

Note that the above results on regularity are based on the general properties of the payoff function  $H$  and on the relation between the value function  $V(x, y)$  of singular control problem (1) with the value functions  $v_k(x, z)$  of the corresponding optimal switching problems.

In the following, we exploit the explicit solutions of  $v_k(x, y)$  to establish further regularity properties of  $V(x, y)$  with respect to  $y$ .

**PROPOSITION 4.4.** *The left and right derivatives  $V_{y^-}(x, y)$  and  $V_{y^+}(x, y)$  are  $C^1$  in  $x$ . That is,  $d(x, y)$  is  $C^1$  in  $x$ .*

*Proof.* We provide the proof for  $V_{y^+}(x, y)$  in Case II with  $h(y^+) > 0$ , and other cases can be verified by similar arguments. Clearly, it suffices to verify that  $V_{y^+}(x, y)$  is continuous and differentiable (with zero derivative) at  $x = F(y^+)$  and  $x = G(y^+)$ .

In Case II,  $F$  and  $G$  are nondecreasing, and so taking limits of the difference between  $v_0$  and  $v_1$  in (21) and (20) gives

$$(28) \quad V_{y^+}(x, y) = \begin{cases} -K_0, & x \leq F(y^+), \\ B(y^+)x^m - A(y^+)x^n + \eta h(y^+)x, & F(y^+) < x \leq G(y^+), \\ K_1, & x > G(y^+), \end{cases}$$

$$(29) \quad V_{y^-}(x, y) = \begin{cases} -K_0, & x < F(y^-), \\ B(y^-)x^m - A(y^-)x^n + \eta h(y^-)x, & F(y^-) \leq x < G(y^-), \\ K_1, & x \geq G(y^-). \end{cases}$$

By the continuity of  $v_1$  and  $v_0$  in (20), we have

$$\begin{aligned} \lim_{x \downarrow G(y^+)} V_{y^+}(x, y) &= K_1 \\ \lim_{x \uparrow G(y^+)} V_{y^+}(x, y) &= B(y^+)G(y^+)^m - A(y^+)G(y^+)^n + \eta h(y^+)G(y^+) \\ &= \lim_{z \downarrow y} [B(z)G(z)^m - A(z)G(z)^n + \eta h(z)G(z)] \\ &= \lim_{z \downarrow y} [v_1(G(z), z) - v_0(G(z), z)] = K_1. \end{aligned}$$

Hence  $V_{y^+}(x, y)$  is continuous at  $G(y^+)$ .

Moreover, by the continuous differentiability of  $v_1$  and  $v_0$  in (20) and (21), we have

$$\begin{aligned} \lim_{h \downarrow 0} \frac{V_{y^+}(G(y^+) + h, y) - V_{y^+}(G(y^+), y)}{h} &= \lim_{h \downarrow 0} \frac{K_1 - K_1}{h} = 0 \\ \lim_{h \uparrow 0} \frac{V_{y^+}(G(y^+) + h, y) - V_{y^+}(G(y^+), y)}{h} &= mB(y^+)G(y^+)^{m-1} - nA(y^+)G(y^+)^{n-1} + \eta h(y^+) \\ &= \lim_{z \downarrow y} [mB(z)G(z)^{m-1} - nA(z)G(z)^{n-1} + \eta h(z)] \\ &= \lim_{z \downarrow y} \frac{\partial}{\partial x} [v_1(G(z), z) - v_0(G(z), z)] = 0. \end{aligned}$$

Hence  $V_{y^+}(x, y)$  is  $C^1$  at  $G(y^+)$  (and similarly at  $F(y^+)$ ).  $\square$

**THEOREM 4.5** (necessary and sufficient conditions for smooth fit).  *$V(x, y)$  is continuously differentiable in  $x$  for all  $(x, y) \in (0, \infty) \times [a, b]$ .  $V(x, y)$  is differentiable in  $y$  at the point  $(x, y)$  if and only if*

$$(x, y) \in \{(x, y) \in (0, \infty) \times (a, b) : H \text{ is differentiable at } y\} \cup \mathcal{S}_0 \cup \mathcal{S}_1,$$

where  $\mathcal{S}_0$  and  $\mathcal{S}_1$  are given as in (30). Alternatively, it is not differentiable in  $y$  at the point  $(x, y)$  if and only if

$$(x, y) \in \{(x, y) \in (0, \infty) \times (a, b) : H \text{ is not differentiable at } y\} \cap \mathcal{C}.$$

This theorem follows naturally from the following lemma and the proposition.

**LEMMA 4.6.** *If  $h$  is continuous at  $y$ , then for all  $x > 0$ ,  $d(x, y) = 0$ .*

**PROPOSITION 4.7.** *If  $h$  is not continuous at  $y$ , then in Case I,  $d(x, y) = 0$  for  $x \geq \min\{F(y^-), G(y^+)\}$  and  $d(x, y) < 0$  for  $x < \min\{F(y^-), G(y^+)\}$ . In Case II,  $d(x, y) = 0$  for  $x \leq F(y^-)$  and  $x \geq G(y^+)$  and  $d(x, y) < 0$  for  $x \in (F(y^-), G(y^+))$ .*

*Proof of Proposition 4.7.* Suppose that there exists  $y \in (a, b)$  where  $h$  is not continuous. We shall prove the result in Case II when  $h(y^+) > 0$ , and other cases can be verified by similar arguments.

First, since  $h$  is nonincreasing,  $\lim_{z \downarrow y} h(z) < \lim_{z \uparrow y} h(z)$ . This also implies that the switching boundaries  $F(z) = \kappa h(z)^{-1}$  and  $G(z) = \nu h(z)^{-1}$  are discontinuous at  $y$ . Clearly, by (28) and (29),  $d(x, y) = 0$  for  $x < F(y^-)$  and for  $x > G(y^+)$ . By the continuity of  $d$ , this is also true of  $x = F(y^-)$  and  $x = G(y^+)$ .

Next, without loss of generality, assume that  $h$  and hence  $G$  is right continuous. Then, pick  $x$  such that  $G(z^-) \leq x < G(y) = G(y^+)$ . Since  $x < G(y)$ , then  $v_1(x, y) - v_0(x, y) < K_1$  from the HJB equations (15) and (16). Furthermore, by Lemma 4.2,  $v_1(x, z) - v_0(x, z) \leq v_1(x, y) - v_0(x, y) < K_1$  for all  $z > y$ . Hence

$$\begin{aligned} V_{y+}(x, y) &= \lim_{z \downarrow y} v_1(x, z) - v_0(x, z) \leq v_1(x, y) - v_0(x, y) < K_1, \text{ and} \\ V_{y-}(x, y) &= \lim_{z \uparrow y} v_1(x, z) - v_0(x, z) = K_1, \end{aligned}$$

where the last equality follows from the fact that  $x \geq G(z)$  for all  $z < y$ . Thus,  $d(x, y) < 0$  for all  $x \in [G(y^-), G(y^+)]$ . A similar argument proves that in addition to the above,  $d(x, y) < 0$  for all  $x \in (F(y^-), F(y^+)]$ .

Finally, let  $x_0 \in (F(y^+), G(y^-))$  be given. We know that  $d(F(y^-), y) = 0 = d(G(y^+), y)$ ,  $d(x, y) \leq 0$  and that  $d$  is  $C^1$  in  $x$ . Suppose  $d(x_0, y) = 0$ , implying that  $x_0$  is a local maximum, and hence  $d_x(x_0, y) = 0$ . Furthermore, by the mean value theorem, there must be two points  $x_1 \in (F(y^-), x_0)$  and  $x_2 \in (x_0, G(y^+))$  such that  $d_x(x_1, y) = 0 = d_x(x_2, y)$ . In fact, since  $d(x, y) < 0$  for all  $x \in (F(y^-), F(y^+)]$  and  $x \in [G(y^-), G(y^+))$ , we must have  $x_1 \in (F(y^+), x_0)$  and  $x_2 \in (x_0, G(y^-))$ .

Let  $f(x) = x^{-(m-1)}d_x(x, y)$ . Since  $x_0, x_1, x_2 > 0$  and  $0 = d_x(x_0, y) = d_x(x_1, y) = d_x(x_2, y)$ , we must also have  $0 = f(x_0) = f(x_1) = f(x_2)$ . However, by (28) and (29), for  $x \in (F(y^+), G(y^-))$ ,  $d(x, y) = \Delta B(y)x^m - \Delta A(y)x^n + \eta\Delta h(y)x$ , with  $\Delta B(y) = B(y^+) - B(y^-)$ ,  $\Delta A(y) = A(y^+) - A(y^-)$ , and  $\Delta h(y) = h(y^+) - h(y^-)$ . So by differentiating, we have that for  $x \in (F(y^+), G(y^-))$ ,  $f(x) = x^{-(m-1)}d_x(x, y) = m\Delta B(y) - n\Delta A(y)x^{n-m} + \eta\Delta h(y)x^{1-m}$ .

Now,  $f$  is  $C^1$  on  $(F(y^+), G(y^-))$ ; hence by the mean value theorem again, there must be two points,  $\hat{x}_1 \in (x_1, x_0) \subset (F(y^+), G(y^-))$  and  $\hat{x}_2 \in (x_0, x_2) \subset (F(y^+), G(y^-))$  such that  $f_x(\hat{x}_1) = 0 = f_x(\hat{x}_2)$ . Thus  $f_x$  must have at least two positive roots. Differentiating again, we have, for  $x \in (F(y^+), G(y^-))$ ,

$$\begin{aligned} f_x(x) &= -n(n-m)\Delta A(y)x^{n-m-1} + (1-m)\eta\Delta h(y)x^{-m} \\ &= x^{-m}((1-m)\eta\Delta h(y) - n(n-m)\Delta A(y)x^{n-1}). \end{aligned}$$

Thus,  $f_x(x)$  can have at most one positive root, a contradiction. Thus  $d(x_0, y) < 0$ . Since  $x_0 \in (F(y^+), G(y^-))$  was arbitrary,  $d(x, y) < 0$  for all  $x \in (F(y^+), G(y^-))$ .  $\square$

Finally, we can explicitly compute  $V_{xy}$  and  $V_{yx}$  from the derivatives of  $v_k(x, y)$ .

**THEOREM 4.8.** *If  $V_y(x, \hat{y})$  exists in a neighborhood of  $\hat{x}$ , then  $V_{xy}$  and  $V_{yx}$  exist at  $(\hat{x}, \hat{y})$ , with  $V_{xy}(\hat{x}, \hat{y}) = V_{yx}(\hat{x}, \hat{y}) = \frac{\partial}{\partial x}[v_1(\hat{x}, \hat{y}) - v_0(\hat{x}, \hat{y})]$ .*

*Proof.* The existence of  $V_{yx}$  at  $(\hat{x}, \hat{y})$  is clear with  $V_{yx}(\hat{x}, \hat{y}) = \frac{\partial}{\partial x}[v_1(\hat{x}, \hat{y}) - v_0(\hat{x}, \hat{y})]$ . Moreover, by Theorem 4.5, the existence of  $V_y(\hat{x}, y)$  for all  $y$  in a neighborhood of  $\hat{y}$  means that either  $\hat{y}$  is a continuity point of  $h$ , or  $(\hat{x}, \hat{y})$  is in the interior of  $S_0 \cup S_1$ .

If  $\hat{y}$  is a continuity point of  $h$ , by the representation of  $V_x$  in Theorem 4.1, it is sufficient to show that  $u_1(y) := \frac{\partial}{\partial x}v_1(x, y)$  and  $u_0(y) := \frac{\partial}{\partial x}v_0(x, y)$  are continuous at  $\hat{y}$ .

We prove that  $u_0(y)$  is continuous at  $\hat{y}$  for Case II. (Similar arguments apply to other cases.) In this case,  $v_0$  is  $C^1$  in  $x$ , and from (20),

$$u_0(y) = \frac{\partial}{\partial x}v_0(x, z) = \begin{cases} nA(z)x^{n-1}, & x < G(z), \\ mB(z)x^{m-1} + \eta h(z), & x \geq G(z), \end{cases}$$

where  $nA(z)G(z)^{n-1} = mB(z)G(z)^{m-1} + \eta h(z)$ . Since  $h$  is continuous at  $\hat{y}$ , the continuity of  $A$ ,  $B$ , and  $G$  follows by their representation in Theorem 3.14, and hence the continuity of  $u_0(y)$  at  $\hat{y}$  follows from its expression.

If  $(\hat{x}, \hat{y})$  is in the interior of  $\mathcal{S}_1$ , then the explicit forms in Theorem 3.14 imply that for all  $(x, y)$  in a neighborhood of  $(\hat{x}, \hat{y})$ , we have  $\frac{\partial}{\partial x}v_0(x, y) = \frac{\partial}{\partial x}v_1(x, y)$ , and the limits in  $y$  from both the left and the right exist. Thus, by the representation in Theorem 4.1, the left and right derivatives of  $V_x(\hat{x}, \hat{y})$  exist and are given by

$$\begin{aligned} V_{xy^+}(\hat{x}, \hat{y}) &= \lim_{y \downarrow \hat{y}} \frac{\partial}{\partial x}v_1(\hat{x}, y) - \lim_{y \downarrow \hat{y}} \frac{\partial}{\partial x}v_0(\hat{x}, y) = \lim_{y \downarrow \hat{y}} \left( \frac{\partial}{\partial x}v_1(\hat{x}, y) - \frac{\partial}{\partial x}v_0(\hat{x}, y) \right) = 0, \\ V_{xy^-}(\hat{x}, \hat{y}) &= \lim_{y \uparrow \hat{y}} \frac{\partial}{\partial x}v_1(\hat{x}, y) - \lim_{y \uparrow \hat{y}} \frac{\partial}{\partial x}v_0(\hat{x}, y) = \lim_{y \uparrow \hat{y}} \left( \frac{\partial}{\partial x}v_1(\hat{x}, y) - \frac{\partial}{\partial x}v_0(\hat{x}, y) \right) = 0. \end{aligned}$$

Thus,  $V_{xy}$  exists, since the left and right derivatives are equal. Furthermore, it is easy to verify that for  $(\hat{x}, \hat{y})$  in the interior of  $\mathcal{S}_1$ ,  $V_{yx}(\hat{x}, \hat{y}) = \frac{\partial}{\partial x}[v_1(\hat{x}, \hat{y}) - v_0(\hat{x}, \hat{y})] = 0$ . A similar argument applies to  $(\hat{x}, \hat{y})$  in the interior of  $\mathcal{S}_0$ , thereby proving the claim.  $\square$

**COROLLARY 4.9.** *If  $H$  is  $C^1$  on an open interval  $\mathcal{J} \subset [a, b]$ , then  $V_{yx}$  and  $V_{xy}$  exist and are continuous with  $V_{xy}(x, y) = V_{yx}(x, y) = \frac{\partial}{\partial x}[v_1(x, y) - v_0(x, y)]$  on  $(0, \infty) \times \mathcal{J}$ .*

#### 4.2. Region characterization.

**THEOREM 4.10** (region characterization). *Under the optimal singular control  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$ , define the corresponding investment  $(\mathcal{S}_1)$ , disinvestment  $(\mathcal{S}_0)$ , and continuation  $(\mathcal{C})$  regions by*

$$(30) \quad \begin{cases} \mathcal{S}_0 &:= \begin{cases} \{(x, z) \in (0, \infty) \times [a, b] : x \geq \lim_{w \uparrow z} F(w)\} & \text{if } K_0 \geq 0 \text{ (Case I),} \\ \{(x, z) \in (0, \infty) \times [a, b] : x \leq \lim_{w \uparrow z} F(w)\} & \text{if } K_0 < 0 \text{ (Case II),} \end{cases} \\ \mathcal{S}_1 &:= \{(x, z) \in (0, \infty) \times [a, b] : x \geq \lim_{w \downarrow z} G(w)\}, \\ \mathcal{C} &:= (0, \infty) \times [a, b] \setminus (\mathcal{S}_0 \cup \mathcal{S}_1). \end{cases}$$

*Then, the action and continuation regions can be characterized as*

$$(31) \quad \begin{cases} \mathcal{S}_0 &= \{(x, y) \in (0, \infty) \times [a, b] : V_y(x, y) = -K_0\}, \\ \mathcal{S}_1 &= \{(x, y) \in (0, \infty) \times [a, b] : V_y(x, y) = K_1\}, \\ \mathcal{C} &= \{(x, y) \in (0, \infty) \times [a, b] : V_{y^-}(x, y) > -K_0, V_{y^+}(x, y) < K_1\}. \end{cases}$$

*Proof of Theorem 4.10.* Recall that  $V_{y^-}$  and  $V_{y^+}$  exist by Proposition 4.3 and that  $-K_0 \leq V_{y^+} \leq V_{y^-} \leq K_1$ .

Thus,  $V_y(x, y) = -K_0$  if and only if  $V_{y^-}(x, y) = -K_0$ , and from the expression for  $V_{y^-}$  in (29), we have that  $V_{y^-}(x, y) = -K_0$  for  $x < F(y^-)$  (in Case II). However, by the continuity of  $V_{y^-}$  in Proposition 4.4, we get  $V_{y^-}(x, y) = -K_0$  if and only if  $x \leq F(y^-)$ , which is true if and only if  $(x, y) \in \mathcal{S}_0$  by (30). Thus,  $V_y(x, y) = -K_0$  if and only if  $(x, y) \in \mathcal{S}_0$ .

The same argument applied to  $V_{y^+}(x, y) = K_1$  shows that  $V_y(x, y) = K_1$  if and only if  $(x, y) \in \mathcal{S}_1$ . Lastly, the claim for  $\mathcal{C}$  follows since it is the complement of  $\mathcal{S}_0 \cup \mathcal{S}_1$ .

A similar argument also applies in Case I.

**5. Examples and discussions.** By now, it is clear from our analysis that without sufficient smoothness of the payoff function, the value function may be non-differentiable and the boundaries may be nonsmooth or not strictly monotonic. Moreover, when the payoff function  $H$  is not continuously differentiable, the interior of  $\mathcal{C}$

may not be simply connected. Note, however, that the regions  $\mathcal{S}_0$ ,  $\mathcal{S}_1$ , and  $\mathcal{C}$  are mutually disjoint and simply connected by the monotonicity of  $F$  and  $G$ .

We elaborate on these points with some concrete examples.

**5.1. Examples.** Taking parameters  $\kappa, \nu, h$  as defined in the main results in section 3, we fix here  $[a, b] = [0, 2]$ ,  $K_0 < 0$ , and  $0 < \beta < 1$ . Recall that since  $K_0 < 0$ ,  $F(z) = \kappa h(z)^{-1}$  and  $G(z) = \nu h(z)^{-1}$ .

*Example 5.1* (the boundaries are  $C^1$  but NOT strictly increasing because  $H$  is not strictly concave).

$$H(z) = \begin{cases} z, & z \leq 1, \\ \arctan(z-1) + 1, & z > 1. \end{cases}$$

$$h(z) = \begin{cases} 1, & z \leq 1, \\ \frac{1}{1+(z-1)^2}, & z > 1. \end{cases}$$

See Figure 5.

*Example 5.2* ( $F, G$  are only  $C^0$  because  $H$  is not  $C^2$ ).

$$H(z) = \begin{cases} z, & z \leq 1, \\ \frac{z^\beta - 1}{\beta} + 1, & z > 1, \end{cases}$$

$$h(z) = \begin{cases} 1, & z \leq 1, \\ z^{\beta-1}, & z > 1. \end{cases}$$

See Figure 6.

*Example 5.3* (the value function is NOT  $C^{1,1}$ ;  $F, G$  are NOT continuous because  $H$  is not  $C^1$ ).

$$H(z) = \begin{cases} z, & z \leq 1, \\ \frac{2\kappa}{(\kappa+\nu)} \frac{z^\beta - 1}{\beta} + 1, & z > 1, \end{cases}$$

$$h(z) = \begin{cases} 1, & z \leq 1, \\ \frac{2\kappa}{\kappa+\nu} z^{\beta-1}, & z > 1. \end{cases}$$

See Figure 7.

*Example 5.4* (interior of continuation region NOT connected).

$$H(z) = \begin{cases} z, & z \leq 1, \\ \frac{\kappa}{2\nu} \frac{z^\beta - 1}{\beta} + 1, & z > 1, \end{cases}$$

$$h(z) = \begin{cases} 1, & z \leq 1, \\ \frac{\kappa}{2\nu} z^{\beta-1}, & z > 1. \end{cases}$$

See Figure 8.

Note that Examples 5.2–5.4 all have payoff functions of the form

$$H(z) = \begin{cases} z, & z \leq 1, \\ \phi \frac{z^\beta - 1}{\beta} + 1, & z > 1, \end{cases}$$

for some constant  $\phi$ . To ensure the concavity of  $H$ , we must have  $\phi \in [0, 1]$ . When  $\phi = 1$ , we recover Example 5.1 and Figure 6. For  $\frac{\kappa}{\nu} < \phi < 1$ , the regions are described by Figure 7. Lastly, for  $0 < \phi \leq \frac{\kappa}{\nu}$ , the interior of the continuation region is not connected, as in Figure 8.

FIG. 5.  $F, G$  are  $C^1$  but NOT strictly increasing because  $H$  is NOT strictly concave.

FIG. 6.  $F, G$  are only  $C^0$  because  $H$  is not  $C^2$ .

**5.2. Discussion.** The above examples demonstrate how the regularity assumptions typically assumed by the traditional HJB approach may fail.

First, according to that approach, the value function  $V(x, y)$  would satisfy some (quasi-)variational inequalities so that

$$\max\{\sigma^2 x^2 V_{xx}(x, y) + bxV_x(x, y) - rV(x, y) + H(y)x, V_y(x, y) - K_1, -V_y(x, y) - K_0\} = 0.$$

In general, while searching for a solution, one would assume a priori smoothness for the value function and the boundary. For example, in [2] and [31],  $V$  is derived from the class of  $C^{2,1}$ . However, Example 5.3 shows that although the HJB variational inequality may still hold, one should search for a solution in a larger class of functions, such as in  $C^{1,0}$ .

Furthermore, Example 5.3 shows that in general, one may not have the smoothness of the boundary, as the boundaries  $F$  and  $G$  are not necessarily continuous or not even strictly increasing. Indeed, in this example,  $F$  and  $G$  are inversely proportional to  $h$ , which may be neither.

Finally, we compare our results and method with those in [2].

*Example 5.5* (general case of [2] for geometric Brownian motion). Let  $x > 0$  and  $y \in [a, b]$ , with  $K_0 < 0$  and  $h > 0$  on  $[a, b]$ . Then  $F$  and  $G$  are nondecreasing and

FIG. 7. Value function NOT  $C^{1,1}$ ;  $F, G$  NOT continuous because  $H$  is not  $C^1$ .

FIG. 8. Interior of continuation region NOT connected.

given by (24). Define

$$y_0(x) = G^{\leftarrow}(x) \wedge b = \sup\{z : G(z) \leq x\} = \sup\{z : h(z) \leq (x/\nu)^{-1}\} \wedge b,$$

$$y_1(x) = F^{\rightarrow}(x) \vee a = \inf\{z : F(z) \geq x\} = \inf\{z : h(z) \geq (x/\kappa)^{-1}\} \vee a.$$

Then  $y_0(x) \leq y_1(x)$ , and

- $x \leq F(z)$  for  $z > y_1(x)$ ;
- $F(z) < x < G(z)$  for  $y_0(x) < z < y_1(x)$ ;
- $G(z) \leq x$  for  $z < y_0(x)$ .

When, in addition,  $H$  satisfies the Inada conditions, this example generalizes those in [2] when  $X$  is a geometric Brownian motion. Compared to the very special form appearing in [2], our results show that, in order to compute the value function, integration of  $v_k(x, z)$  is necessary, which we reduce to three possible cases as follows, depending on whether  $(x, y)$  is in  $\mathcal{S}_0$ ,  $\mathcal{S}_1$ , or  $\mathcal{C}$ .

1.  $(x, y) \in \mathcal{S}_0$ : Then  $y_1 \leq y$  and

$$V(x, y) = \eta H(y_1)x + x^m \int_a^{y_1} B(z)dz + x^n \int_{y_1}^b A(z)dz - K_0(y - y_1).$$

2.  $(x, y) \in \mathcal{C}$ : Then  $y_0 < y < y_1$  and

$$V(x, y) = \eta H(y)x + x^m \int_a^y B(z)dz + x^n \int_y^b A(z)dz.$$

3.  $(x, y) \in \mathcal{S}_1$ : Then  $y \leq y_0$  and

$$V(x, y) = \eta H(y_0)x + x^m \int_a^{y_0} B(z)dz + x^n \int_{y_0}^b A(z)dz - K_1(y_0 - y),$$

where  $A$  and  $B$  are as given by (22)–(23).

**Acknowledgments.** The authors thank the associate editor and the two anonymous referees for their constructive and detailed remarks, which led to a substantial improvement of the paper.

## STABILIZABILITY AND STABILITY ROBUSTNESS OF STATE DERIVATIVE FEEDBACK CONTROLLERS\*

WIM MICHIELS<sup>†</sup>, TOMÁŠ VYHLÍDAL<sup>‡</sup>, HENRI HUIJBERTS<sup>§</sup>, AND HENK NIJMEIJER<sup>¶</sup>

**Abstract.** We study the stabilizability of a linear controllable system using state derivative feedback control. As a special feature the stabilized system may be fragile, in the sense that arbitrarily small modeling and implementation errors may destroy the asymptotic stability. First, we discuss the pole placement problem and illustrate the fragility of stability with examples of a different nature. We also define a notion of stability, called  $p$ -stability, which explicitly takes into account the effect of small modeling and implementation errors. Next, we investigate the effect on the fragility of including a low-pass filter in the control loop. Finally, we completely characterize the stabilizability and  $p$ -stabilizability of linear controllable systems using state derivative feedback. In the stabilizability characterization the odd number limitation, well known in the context of the stabilization of unstable periodic orbits using Pyragas-type time-delayed feedback, plays a crucial role.

**1. Introduction.** We analyze the stabilizability and stabilization of the linear or linearized system

$$(1) \quad \dot{x}(t) = Ax(t) + Bu(t),$$

where  $x(t) \in \mathbb{R}^n$  is the system state vector and  $u(t) \in \mathbb{R}^m$  is the system input at time  $t$ , using state derivative feedback,

$$(2) \quad u(t) = K_d \dot{x}(t), \quad K_d \in \mathbb{R}^{n \times m}.$$

In this stabilizability study we explicitly take into account the effects of arbitrarily small modeling, approximation, and implementation errors, which may, for instance, be caused by feedback latency, unmodeled sensor and actuator dynamics, and approximations of the derivatives.

From a practical point of view, the motivation for using state derivative feedback (2) instead of conventional state feedback,  $u(t) = K_s x(t)$ , comes from applications

---

where accelerometers are used for measuring the system's motion. Typical applications are in vibration control of mechanical systems where the state variables are positions and velocities, while the accelerations, which are the sensed variables, are directly used for feedback; see [2, 3, 1]. In some applications, including vibration suppression, the fact that control law (2) keeps the steady state solutions of the uncontrolled system invariant might be considered as a positive feature.

From a theoretical point of view the stabilizability study of system (1) with control law (2) is a challenging problem if robustness aspects are taken into account. As will be addressed later in the text, the synthesis of the derivative feedback can be accomplished using modified pole placement methods under a controllability assumption. However, the achieved closed-loop dynamics may be *fragile* in the sense that the stability of the controlled system may lack robustness against *arbitrarily small* modeling and implementation errors. In other words, although the nominal system is asymptotically stable, some stability margins may be equal to zero. The main goals of the paper consist of studying this fragility problem and making a *complete* characterization of the stabilizability of (1) with (2) in the presence of any type of small modeling and implementation errors.

Other problems where a fragility of stability has been observed can be found in the literature. More specifically, a lack of robustness of stability against small feedback delays or against small delay changes has been observed for boundary controlled (hyperbolic) partial differential equations; see, e.g., [5, 6, 9, 12, 18, 22]; for feedback controlled descriptor systems see [11], and for neutral functional differential equations see [13, 14]. In [23] a model for gradient play dynamics is discussed where the discretization of a derivative may induce instability. In [15, 17] it was shown that the discretization of distributed delays in control laws, arising in the context of finite spectrum assignment of time-delay systems, may destabilize the system, even if the discretization stepsize is arbitrarily small.

The structure of the paper is as follows: In section 2 the pole placement problem for system (1) using control law (2) is first discussed. Next, a unified framework for studying the effect of small modeling and implementation errors is presented and a practical notion of stability is introduced. In section 3 two examples of a different nature are presented which illustrate that closed-loop stability may not be robust against small modeling and implementation errors. The observations on the instability mechanisms lead us to section 4, where we investigate to what extent the inclusion of a low-pass filter may solve the robustness problems. Finally, in sections 5 and 6 a full characterization of the stabilizability of (1) using (2) is given, with and without the effect of small modeling and implementation errors being taken into account. It will be shown that in the former case an important role is played by a condition that boils down to the so-called odd number limitation, well known in the context of the stabilization of unstable periodic solutions using Pyragas-type time-delayed controllers [21] and in the context of delay difference feedback [10]. Some concluding remarks end the paper.

The following notation and definitions will be adopted:  $\mathbb{C}$  ( $\mathbb{C}^+$ ,  $\mathbb{C}^-$ ) is the set of complex numbers (with strictly positive and strictly negative real parts), and  $j = \sqrt{-1}$ . For  $\lambda \in \mathbb{C}$ ,  $\bar{\lambda}$ ,  $\Re(\lambda)$ , and  $\Im(\lambda)$  define the complex conjugate, the real part, and the imaginary part of  $\lambda$ . For  $\Omega \subset \mathbb{C}$ ,  $\partial\Omega$  denotes the boundary of  $\Omega$  and  $\text{clos}(\Omega)$  its closure.  $\mathbb{R}$  ( $\mathbb{R}^+$ ,  $\mathbb{R}^-$ ) denotes the set of real numbers (larger than or equal to zero, smaller than or equal to zero).  $\mathbb{N}$  is the set of natural numbers and is assumed to include zero.  $\mathbb{Z}$  is the set of integers. For an operator or matrix  $A$ ,  $\sigma(A)$  and  $\rho(A)$

denote its spectrum and spectral radius, respectively. Throughout the paper we make the following assumption.

*Assumption 1.1.* The pair  $(A, B)$  is controllable.

## 2. Prerequisites.

**2.1. Pole placement using state derivative feedback.** Note that the closed-loop system (1)–(2) may be rewritten as

$$(3) \quad (I - BK_d)\dot{x}(t) = Ax(t).$$

Thus, the closed-loop system is well-posed if  $BK_d$  has no eigenvalue equal to one. The characteristic function of the closed-loop system is then given by

$$(4) \quad H_0(\lambda) := \det(\lambda I - A - BK_d\lambda).$$

We first give some preliminary results considering the stability of the closed-loop system.

**PROPOSITION 2.1.** *If  $\det(A) = 0$ , then the closed-loop system (1)–(2) has a zero characteristic root for all values of  $K_d$ .*

Conditions for arbitrary pole placement by state derivative feedback (2) are given in [1] as follows.

**PROPOSITION 2.2.** *If the pair  $(A, B)$  is controllable, then all characteristic roots of the closed-loop system can be assigned at arbitrarily positions in  $\mathbb{C} \setminus \{0\}$  using the control law (2) if and only if  $\det(A) \neq 0$ .*

The following result from [1] establishes relations with pole assignment using state feedback.

**PROPOSITION 2.3.** *Assume that  $\det(A) \neq 0$ . With the control law (2), the closed-loop system has the same characteristic roots as with the state feedback*

$$(5) \quad u(t) = K_s x(t)$$

if

$$K_d = K_s(A + BK_s)^{-1}.$$

Given the fact that algorithms for designing the controller (5) are widely available, this is an important result. However, algorithms have also been developed for a direct design of the state derivative feedback gain  $K_d$ . A general pole placement technique for state derivative feedback was proposed in [1] for single-input delay-free systems and in [2] for multiple-input systems. The same authors proposed a linear quadratic regulator for computing state derivative feedback in [3]. The application of acceleration feedback to vibration suppression problems has been discussed at length in [20] and [7].

*Remark 2.4.* If  $\det(-A) < 0$ , i.e., if the system (1) has an odd number of characteristic roots in  $\mathbb{C}^+$ , stabilization implies that an *odd* number of unstable roots need to be shifted to the left half plane, while a root cannot cross the imaginary axis at zero. This may sound counterintuitive but is always possible: if  $K_d$  is increased from zero to the stabilizing value, then some characteristic roots move to the right half plane via infinity, where for the critical value of  $K_d$  the system is not well-posed. For an example of this, one can consider the system

$$\dot{x}(t) = x(t) + u(t), \quad u(t) = k_d \dot{x}(t), \quad u, x \in \mathbb{R},$$

for which clearly the open-loop system has an odd number of characteristic roots in  $\mathbb{C}^+$ . Further, the closed-loop characteristic root  $\lambda$  satisfies

$$\lambda = \frac{1}{1 - k_d}, \quad k_d \neq 1.$$

It is straightforwardly seen that the closed-loop system is stable for  $k_d > 1$  and that  $\lambda \rightarrow \infty$  if  $k_d \uparrow 1$ .

**2.2. Framework for robustness analysis.** As we shall illustrate in the next section, the use of state derivative feedback may introduce some fragility in the sense that *arbitrarily small* modeling and implementation errors, e.g., arbitrarily small delays in the feedback loop, may change the system's behavior significantly and may even render an asymptotically stable nominal system unstable. To create a unifying framework to study this fragility problem, we assume that the modeling and implementation errors are such that the characteristic function of the actual system is given by

$$(6) \quad H(\lambda; p) := \det(\lambda I - \tilde{A}(p) - \tilde{B}(p) G_1(\lambda; p) K_d \lambda G_2(\lambda; p)),$$

where  $p \in (\mathbb{R}^+)^{n_p}$  denotes some parameters and the functions

$$(7) \quad \begin{aligned} \tilde{A} : (\mathbb{R}^+)^{n_p} &\rightarrow \mathbb{R}^{n \times n}, & p &\mapsto \tilde{A}(p), \\ \tilde{B} : (\mathbb{R}^+)^{n_p} &\rightarrow \mathbb{R}^{n \times m}, & p &\mapsto \tilde{B}(p), \\ G_1 : \mathbb{C} \times (\mathbb{R}^+)^{n_p} &\rightarrow \mathbb{C}^{m \times m}, & (\lambda, p) &\mapsto G_1(\lambda; p), \\ G_2 : \mathbb{C} \times (\mathbb{R}^+)^{n_p} &\rightarrow \mathbb{C}^{n \times n}, & (\lambda, p) &\mapsto G_2(\lambda; p), \end{aligned}$$

satisfy the following assumption.

*Assumption 2.5.*

1. The functions  $p \mapsto \tilde{A}(p)$  and  $p \mapsto \tilde{B}(p)$  are continuous;
2.  $\lim_{p \rightarrow 0} \tilde{A}(p) = A$ ;  $\lim_{p \rightarrow 0} \tilde{B}(p) = B$ ;
3. for every  $p \in (\mathbb{R}^+)^{n_p}$  and  $i = 1, 2$ , the functions  $G_i(\cdot; p)$  are meromorphic; for every  $\lambda \in \mathbb{C}$ , the functions  $G_i(\lambda; \cdot)$  are continuous;
4.  $G_i(\lambda; 0) = I$  for all  $\lambda \in \mathbb{C}$  and  $i = 1, 2$ ;
5. for every compact set  $\Omega \subset \mathbb{C}$ , we have

$$(8) \quad \lim_{p \rightarrow 0} \max_{\lambda \in \Omega} \|G_i(\lambda; p) - I\| = 0, \quad i = 1, 2;$$

6. there exist constants  $M, N, P > 0$  such that for all  $\lambda \in \mathbb{C}$  with  $\Re(\lambda) \geq -N$  and for all  $p \in (\mathbb{R}^+)^{n_p}$  with  $\|p\| \leq P$ ,

$$\|G_i(\lambda; p)\| \leq M, \quad i = 1, 2.$$

In Figure 1 a block diagram is drawn of the controlled system in the presence of modeling and implementation errors. For  $p = 0$ , the function (6) reduces to  $H_0$  in (4). It is clear that  $\tilde{A}(p)$  and  $\tilde{B}(p)$  model uncertainty on  $A$  and  $B$ . To motivate the inclusion of  $G_1$  and  $G_2$  in the control loop we present some examples of a different nature, which all satisfy Assumption 2.5.

- *Feedback delays.* The case where

$$\begin{aligned} n_p &= n + m, \quad p = (\tau_{u_1}, \dots, \tau_{u_n}, \tau_{x_1}, \dots, \tau_{x_n}), \\ G_1(\lambda; p) &= \text{diag}(e^{-\lambda \tau_{u_1}}, \dots, e^{-\lambda \tau_{u_m}}), \quad G_2(\lambda, p) = \text{diag}(e^{-\lambda \tau_{x_1}}, \dots, e^{-\lambda \tau_{x_n}}) \end{aligned}$$

FIG. 1. Feedback interpretation of the controlled system.

corresponds to the case where one assumes a time delay  $\tau_{u_k}$  in the  $k$ th component of the input  $u$  and a time delay  $\tau_{x_l}$  in the measurement of the  $l$ th component of  $\dot{x}$ , where  $1 \leq k \leq m$ ,  $1 \leq l \leq n$ .

- *Numerical computation of derivatives.* If, for example,

$$(9) \quad n_p = 1, \quad G_1(\lambda; p) = I, \quad G_2(\lambda; p) = g_2(\lambda; p)I,$$

with

$$g_2(\lambda; p) = \begin{cases} \frac{1-e^{-\lambda p}}{\lambda p}, & \lambda p \neq 0, \\ 1, & \lambda p = 0, \end{cases}$$

then we get

$$\lambda K_d G_2(\lambda; p) = K_d \frac{1 - e^{-\lambda p}}{p}.$$

Thus, this corresponds to the situation where  $\dot{x}(t)$  in control law (2) is not measured directly, but computed on-line from the measurements of  $x(t)$  using the finite-difference formula

$$(10) \quad \dot{x}(t) \approx \frac{x(t) - x(t-p)}{p}.$$

- *Unmodeled dynamics.*  $G_1$  and  $G_2$  may, for instance, model neglected actuator and sensor dynamics.

From a fragility point of view we are interested in the relationship between the stability properties for  $p = 0$  and those for small  $p \neq 0$ . For this, we first introduce the following practical notion of closed-loop stability.

**DEFINITION 2.6.** *The closed-loop system formed by the feedback interconnection of system (1) with output  $x$  and a controller with transfer function  $-C(\lambda)$  is  $p$ -stable if its null solution is asymptotically stable, and for every set of functions (7) satisfying Assumption 2.5, there is a constant  $\hat{p} > 0$  such that the zeros of*

$$\det(\lambda I - \tilde{A}(p) - \tilde{B}(p)G_1(\lambda; p)C(\lambda)G_2(\lambda; p))$$

are in  $\mathbb{C}^-$  for all  $p \in (\mathbb{R}^+)^{n_p}$  with  $\|p\| < \hat{p}$ .

In this way, requiring that (1), stabilized with (2), be robust against small modeling and implementation errors can be rephrased as requiring the  $p$ -stability of (1)–(2). Note that this concept of stability is closely related to the concept of  $w$ -stability defined in [8].

To conclude this section, we note that, for an arbitrary set of functions (7) that satisfy Assumption 2.5, the requirement that the roots of  $H_0$  in (4) be in  $\mathbb{C}^-$ , along

with Assumption 2.5, is in general not sufficient to guarantee that the zeros of  $H$  in (6) are in  $\mathbb{C}^-$  for sufficiently small  $p$ . However, an (approximate) matching of  $n$  zeros always takes place, as shown by the following result.

**PROPOSITION 2.7.** *Assume that  $\det(I - BK_d) \neq 0$  and let  $\mu_i \in \mathbb{C}$ ,  $1 \leq i \leq n$ , be the eigenvalues of  $(I - BK_d)^{-1}A$ . There exist a number  $\hat{p} > 0$  and  $n$  continuous functions*

$$\hat{\lambda}_i : [0, \hat{p}]^{n_p} \rightarrow \mathbb{C}, \quad p \mapsto \hat{\lambda}_i(p), \quad 1 \leq i \leq n,$$

which satisfy  $H(\hat{\lambda}_i(p); p) \equiv 0$  and

$$(11) \quad \lim_{p \rightarrow 0} \hat{\lambda}_i(p) = \mu_i, \quad 1 \leq i \leq n.$$

*Proof.* Let  $\mathcal{B} \subset \mathbb{C}$  be an open disk which contains all zeros of  $H_0$ . The function  $H(\lambda; p)$  uniformly converges on compact subsets of  $\mathbb{C}$  to  $H_0(\lambda)$  as  $p \rightarrow 0$ . This implies the existence of a number  $\hat{p}$  such that

$$\max_{\lambda \in \partial \mathcal{B}} |H_0(\lambda) - H(\lambda; p)| < \min_{\lambda \in \partial \mathcal{B}} |H_0(\lambda)| \quad \text{for all } p \in [0, \hat{p}]^{n_p}.$$

By Rouché's theorem one concludes that  $H(\lambda; p)$  and  $H_0(\lambda)$  both have  $n$  zeros in  $\mathcal{B}$  if  $p \in [0, \hat{p}]^{n_p}$ . The existence of the functions  $\hat{\lambda}_i$ ,  $1 \leq i \leq n$ , follows from the combination of this result with the continuity of the individual zeros of  $H$  with respect to (w.r.t.)  $p$ . The assertion (11) can be shown in a similar way by letting  $\mathcal{B}$  be a disk with arbitrarily small radius centered at a zero of  $H_0$ , and taking the same steps.  $\square$

In what follows, we focus on the behavior of the other zeros which may be introduced by the implementation or approximation.

**3. Sensitivity of stability to arbitrarily small modeling and implementation errors.** With two case studies we first show that even if all zeros of (4) are in  $\mathbb{C}^-$ , then (6) may have zeros in  $\mathbb{C}^+$  for *arbitrarily small* values of  $p$ . The first case study, inspired by [23], concerns a numerical approximation of the derivatives in the control law, and the second concerns the effect of a neglected time delay. In both cases the eigenvalue distribution of  $BK_d$  determines the position of the characteristic roots introduced by the approximation.

**3.1. Approximation of derivatives.** With the approximation (10) of the derivatives in control law (2), or, equivalently, with the transfer functions (9), the characteristic function of the closed-loop system becomes

$$I_1(\lambda; p) := \det \left( \lambda I - A - BK_d \frac{1 - e^{-\lambda p}}{p} \right).$$

We then have the following result.

**PROPOSITION 3.1.** *If  $BK_d$  has at least one eigenvalue which does not belong to  $\text{clos}(S)$ , where*

$$(12) \quad S := \left\{ \lambda \in \mathbb{C} : \Im(\lambda) \in (-\pi, \pi) \text{ and } \Re(\lambda) < \begin{cases} \Im(\lambda) \cotan(\Im(\lambda)), & \Im(\lambda) \in (-\pi, 0) \cup (0, \pi), \\ 1, & \Im(\lambda) = 0 \end{cases} \right\},$$

then there exist numbers  $\hat{p} > 0$ ,  $c > 0$  and a function  $\hat{\lambda} : (0, \hat{p}) \rightarrow \mathbb{C}$ ,  $p \mapsto \hat{\lambda}(p)$ , such that

$$I_1(\hat{\lambda}(p); p) = 0 \quad \text{and} \quad \Re(\hat{\lambda}(p)) > \frac{c}{p}$$

for all  $p \in (0, \hat{p})$ .

If all eigenvalues of  $BK_d$  belong to the set  $S$ , then there exist numbers  $\hat{p} > 0$  and  $c > 0$  such that for all  $0 < p \leq \hat{p}$ , the function  $I_1(\lambda; p)$  has exactly  $n$  zeros in the half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) > -\frac{c}{p}\}$ .

*Proof.* Let

$$G(\lambda; p) := p^n I_1\left(\frac{\lambda}{p}; p\right) = \det(\lambda I - Ap - BK_d(1 - e^{-\lambda})),$$

and let

$$\tilde{G}(\lambda) = \det(\lambda I - BK_d(1 - e^{-\lambda})).$$

It is clear that

$$(13) \quad \tilde{G}(\lambda) = 0 \iff \lambda - \lambda_i(1 - e^{-\lambda}) = 0, \quad i = 1, \dots, n,$$

where  $\lambda_i$ ,  $i = 1, \dots, m$ , are the eigenvalues of  $BK_d$ . In what follows we distinguish between two cases.

*Case 1:*  $\exists k \in \{1, \dots, n\} : \lambda_k \notin \text{clos}(S)$ . Following from expression (13) and Lemma A.1 in the appendix,  $\tilde{G}$  has a zero in  $\mathbb{C}^+$ . By the uniform convergence of  $G(\cdot; p)$  to  $\tilde{G}$  on compact sets as  $p \rightarrow 0$  and Rouché's theorem, there exist constants  $c_1 > 0$  and  $\hat{p}_1 > 0$  such that for all  $p \in (0, \hat{p}_1)$ ,  $G(\cdot; p)$  has a zero in the right half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) > c_1\}$ . Hence by (15),  $I_1(\cdot; p)$  has a zero in the half plane  $\{\lambda \in \mathbb{C} : \lambda > c_1/p\}$ .

*Case 2:*  $\lambda_i \in S$ ,  $1 \leq i \leq n$ . By expression (13) and Lemma A.1,  $\tilde{G}$  has a zero at the origin with multiplicity  $n$ , while all other zeros are confined to the open left half plane. Since the zeros of  $G(\cdot; p)$  belong to the set

$$(14) \quad \left\{ \lambda \in \mathbb{C} : |\lambda| \leq \|Ap\| + \|BK_d\|(1 + e^{-\Re(\lambda)}) \right\}$$

and  $G(\cdot; p)$  uniformly converges to  $\tilde{G}$  on compact sets as  $p \rightarrow 0$ , an application of Rouché's theorem allows us to conclude the existence of constants  $c > 0$  and  $\hat{p} > 0$  such that for all  $p \in (0, \hat{p})$ ,

1.  $G(\cdot; p)$  has exactly  $n$  zeros in the half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) > -c\}$ ;
2. all other zeros of  $G(\cdot; p)$  are in the half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) < -c\}$ .

This is equivalent to the assertion of the proposition when taking into account the equivalence

$$(15) \quad G(\lambda; p, 0) = 0 \iff I_1(\lambda p; p) = 0. \quad \square$$

*Remark 3.2.* In [23] the special case is treated where  $A$  and  $BK_d$  are multiples of each other, which stems from a gradient play dynamics application.

**COROLLARY 3.3.** *If  $BK_d$  has an eigenvalue outside  $\text{clos}(S)$  and control law (2) is stabilizing, then the closed-loop system is not  $p$ -stable. Furthermore,  $I_1(\lambda; p)$  has zeros in  $\mathbb{C}^+$  for arbitrarily small values of  $p$ .*

**3.2. Feedback delay.** We assume the presence of an unmodeled feedback delay  $p$  in all input channels, that is,

$$G_1(\lambda; p) = e^{-\lambda p} I, \quad G_2(\lambda; p) = I.$$

Then the characteristic function becomes

$$I_2(\lambda; p) := \det(\lambda I - A - BK_d \lambda e^{-\lambda p}).$$

As shown in the following result, the eigenvalue distribution of  $BK_d$  determines the behavior of the zeros thus introduced.

**PROPOSITION 3.4.** *If  $\rho(BK_d) > 1$ , there exist numbers  $\hat{p} > 0$ ,  $c > 0$  and a function  $\hat{\lambda}: (0, \hat{p}) \rightarrow \mathbb{C}$ ,  $p \mapsto \hat{\lambda}(p)$ , such that*

$$I_2(\hat{\lambda}(p); p) = 0 \quad \text{and} \quad \Re(\hat{\lambda}(p)) > \frac{c}{p}$$

for all  $p \in (0, \hat{p})$ .

*If  $\rho(BK_d) < 1$ , there exist numbers  $\hat{p} > 0$  and  $c > 0$  such that for all  $0 < p \leq \hat{p}$ , the function  $I_2(\lambda; p)$  has exactly  $n$  zeros in the half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) > -\frac{c}{p}\}$ .*

*Proof.* If  $\rho(BK_d) > 1$ , it follows from the theory developed in [4, 16] that for all  $p > 0$ , there exists a sequence of complex numbers  $\{\lambda_\nu\}_{\nu \geq 0}$  such that

$$I_2(\lambda_\nu; p) = 0, \quad \nu \geq 1, \\ \lim_{\nu \rightarrow \infty} \Im(\lambda_\nu) = +\infty, \quad \lim_{\nu \rightarrow \infty} \Re(\lambda_\nu) = \frac{\log(\rho(BK_d))}{p}.$$

By letting  $c = (\log(\rho(BK_d)))/2$  the statement of the proposition follows.

If  $\rho(BK_d) < 1$ , there exists a  $c > 0$  such that  $\rho(BK_d e^c) < 1$ . Next, we let  $\lambda_0$  be a zero of  $I_2(\cdot; p)$  satisfying  $\Re(\lambda) > -c/p$ . As the matrix  $(I - BK_d e^{-\lambda p})$  is invertible if  $\Re(\lambda) > -c/p$ , we get

$$\det(\lambda_0 I - (I - BK_d e^{-\lambda_0 p})^{-1} A) = 0.$$

This implies

$$(16) \quad |\lambda_0| \leq \max_{\Re(\lambda) \geq -c/p} \|(I - BK_d e^{-\lambda p})^{-1} A\| \leq M,$$

where

$$M := \max_{\Re(\lambda) \geq -c} \|(I - BK_d e^{-\lambda})^{-1} A\|.$$

Consequently, all zeros of  $I_2(\cdot; p)$  in the half plane  $\{\lambda \in \mathbb{C} : \Re(\lambda) \geq -c/p\}$  also lie in the disk  $\{\lambda \in \mathbb{C} : \|\lambda\| \leq M\}$ . Combining this result with Proposition 2.7 yields the assertion to be proven.  $\square$

**COROLLARY 3.5.** *If  $BK_d$  has an eigenvalue outside the unit disk and control law (2) is stabilizing, then the closed-loop system is not practically stable. Furthermore,  $I_2(\lambda; p)$  has zeros in  $\mathbb{C}^+$  for arbitrarily small values of  $p$ .*

**4. Filtered state derivative feedback.** Using Assumption 2.5 and Rouché-type arguments, all but  $n$  zeros of  $H(\lambda; p)$  move off to infinity as the parameter  $p$  tends to zero. An obstruction to  $p$ -stability occurs if some of these zeros move off to infinity *without* leaving the closed right half plane. Such situations are illustrated

with Propositions 3.1 and 3.4. A natural way to prevent the presence of zeros with a large modulus in the right half plane consists of including a *low-pass filter* in the control scheme. Note that such an approach has already been successfully applied to the discretization of distributed delay controllers in the context of finite spectrum assignment, where similar robustness problems occur [15, 17].

When applying a first order filter to the control law (2), the controller becomes

$$(17) \quad T\dot{u}(t) + u(t) = K_d\dot{x}(t),$$

where  $T = 1/\omega_f$  is the time constant of the filter, and  $\omega_f$  is its cutoff frequency.

The feedback system that consists of (1) and (17) is given by

$$(18) \quad \dot{z}(t) = \begin{bmatrix} A & B \\ 0 & -\frac{1}{T}I \end{bmatrix} z(t) + \begin{bmatrix} 0 & 0 \\ \frac{1}{T}K_d & 0 \end{bmatrix} \dot{z}(t),$$

where  $z(t) = [x(t)^T \ u(t)^T]^T$ . This system can be rewritten as

$$(19) \quad \dot{z}(t) = \begin{bmatrix} A & B \\ \frac{1}{T}K_dA & \frac{1}{T}(K_dB - I) \end{bmatrix} z(t).$$

Let  $J_0(\lambda; T)$  be the characteristic function of (18)–(19), that is,

$$(20) \quad J_0(\lambda; T) := \det \left( \lambda I - \begin{bmatrix} A & B \\ \frac{1}{T}K_dA & \frac{1}{T}(K_dB - I) \end{bmatrix} \right).$$

We perform the subsequent analysis in two steps. First, we discuss the effect of the introduction of the filter on the stability of the *nominal system*. Next, we investigate the effect of small approximation and implementation errors. We end the section with a brief discussion of the results.

**4.1. Filter design.** Intuitively, one might expect that the introduction of a filter with a sufficiently high cutoff frequency (i.e.,  $T$  is sufficiently small) has little influence on the dynamic behavior of the nominal system. However, this is not always the case, as shown by the following result.

**PROPOSITION 4.1.** *Assume that  $\det(I - BK_d) \neq 0$  and let  $\xi_i \in \mathbb{C}$ ,  $1 \leq i \leq n$ , be the eigenvalues of  $(I - BK_d)^{-1}A$ . There exist a number  $\hat{T}$  and  $n$  continuous functions*

$$\hat{\eta}_i : (0, \hat{T}) \rightarrow \mathbb{C}, \quad T \mapsto \hat{\eta}_i(T), \quad 1 \leq i \leq n,$$

*which satisfy  $J(\hat{\eta}_i(T); T) \equiv 0$  and*

$$(21) \quad \lim_{T \rightarrow 0+} \hat{\eta}_i(T) = \xi_i, \quad 1 \leq i \leq n.$$

*If  $(K_dB - I)$  is Hurwitz, then there exist numbers  $\hat{c} > 0$ ,  $\hat{T} > 0$  such that for all  $T \in (0, \hat{T})$ , the function  $J_0(\lambda; T)$  has exactly  $n$  zeros in the half plane*

$$\left\{ \lambda \in \mathbb{C} : \Re(\lambda) > -\frac{\hat{c}}{T} \right\}.$$

*If  $(K_dB - I)$  has an eigenvalue in the open right half plane, then there exist numbers  $\hat{c} > 0$  and  $\hat{T} > 0$  such that for all  $T \in (0, \hat{T})$ , the function  $J_0(\lambda; T)$  has a zero in the half plane*

$$\left\{ \lambda \in \mathbb{C} : \Re(\lambda) > \frac{\hat{c}}{T} \right\}.$$

FIG. 2. Feedback interpretation of the controlled system with a low-pass filter included in the feedback.

*Proof.* The proof follows the same steps as the proofs of Propositions 2.7 and 3.1, and it is therefore not developed in detail. We restrict ourselves to some consideration on the large eigenvalues introduced by the filter. From the normalized characteristic function

$$T^{n+m} J_0 \left( \frac{\mu}{T}; T \right) = \det \left( \mu I - \begin{bmatrix} AT & BT \\ K_d A & (K_d B - I) \end{bmatrix} \right),$$

where the argument of  $\det(\cdot)$  becomes triangular as  $T \rightarrow 0+$ , it is apparent that for small values of  $T$ , the eigenvalues of  $(K_d B - I)$  determine the large eigenvalues of the closed-loop system.  $\square$

From Proposition 4.1 one concludes that the presence of the filter may induce an additional stability constraint, namely, the Hurwitz stability of the matrix  $(K_d B - I)$ .

*Remark 4.2.* The above results can also be interpreted in terms of robustness of the unfiltered feedback system (1)–(2). If the nominal system (1)–(2) is asymptotically stable but  $(K_d B - I)$  is not Hurwitz, then the stability of the nominal system is not robust against arbitrarily small modeling error described by

$$(22) \quad n_p = 1; \quad G_1(\lambda; p) = I; \quad G_2(\lambda; p) = \frac{1}{1 + p\lambda}.$$

Note that (22) satisfies Assumption 2.5. In this way the above analysis can be seen as another illustration of the fragility, already illustrated in the previous section with two examples of a different nature.

**4.2. Effect of small modeling and implementation errors.** We consider the controller (17) and assume that  $T$  and  $K_d$  are such that the null solution of (18) is asymptotically stable.

In the presence of small modeling and approximation errors as described in section 2.1 the characteristic function (20) becomes

$$(23) \quad J(\lambda; T, p) := \det \left( \lambda I - \begin{bmatrix} \tilde{A}(p) & \tilde{B}(p) \\ \frac{1}{T} G_1(\lambda; p) K_d G_2(\lambda; p) \tilde{A}(p) & \frac{1}{T} (G_1(\lambda; p) K_d G_2(\lambda; p) \tilde{B}(p) - I) \end{bmatrix} \right),$$

where  $\tilde{A}, \tilde{B}, G_1, G_2$  satisfy Assumption 2.5. The corresponding block diagram of the closed-loop system is displayed in Figure 2.

Due to the low-pass filter in the control loop, the closed-loop system, described by (1) and (17), is  $p$ -stable in the sense of Definition 2.6, as can be concluded from the following proposition.

PROPOSITION 4.3. Assume that  $T > 0$  is fixed. Let  $\xi_i \in \mathbb{C}$ ,  $1 \leq i \leq n + m$ , be the zeros of  $J_0(\lambda; T)$ . There exist a number  $\hat{p}$  and  $n + m$  continuous functions

$$\hat{\eta}_i : [0, \hat{p})^{n_p} \rightarrow \mathbb{C}, \quad p \mapsto \hat{\eta}_i(p), \quad 1 \leq i \leq n + m,$$

which satisfy  $J(\hat{\eta}_i(p); T, p) \equiv 0$  and

$$(24) \quad \lim_{p \rightarrow 0} \hat{\eta}_i(p) = \xi_i, \quad 1 \leq i \leq n + m.$$

Furthermore, there exist numbers  $\tilde{p} > 0$  and  $c > 0$  such that for all  $p \in (\mathbb{R}^+)^{n_p}$  with  $\|p\| \leq \tilde{p}$ , the functions  $J(\lambda; T, p)$  and  $J_0(\lambda; T)$  have the same number of zeros in the half plane

$$(25) \quad \{\lambda \in \mathbb{C} : \Re(\lambda) \geq -c\}.$$

*Proof.* The proof of the first assertion is similar to the proof of Proposition 2.7, and is omitted. For the second assertion, choose numbers  $N$  and  $P$  according to item 6 of Assumption 2.5. Choose  $c \in (0, N)$  such that  $J_0$  has no zero with real part equal to  $c$ . Let  $\lambda_0$  be a zero of  $J(\cdot; T, p_0)$ , where  $\|p_0\| < P$ . If  $\Re(\lambda_0) \geq -c$ , then we get from (23) that

$$\lambda_0 \in \sigma \left( \begin{bmatrix} \tilde{A}(p) & \tilde{B}(p) \\ \frac{1}{T}G_1(\lambda_0; p)K_dG_2(\lambda_0; p)\tilde{A}(p) & \frac{1}{T}(G_1(\lambda_0; p)K_dG_2(\lambda_0; p)\tilde{B}(p) - I) \end{bmatrix} \right).$$

As  $\rho(\cdot) \leq \|\cdot\|$ , this implies that  $|\lambda_0| \leq R$ , where

$$(26) \quad R = \sup \left\{ \left\| \begin{bmatrix} \tilde{A}(p) & \tilde{B}(p) \\ \frac{1}{T}G_1(\lambda; p)K_dG_2(\lambda; p)\tilde{A}(p) & \frac{1}{T}(G_1(\lambda; p)K_dG_2(\lambda; p)\tilde{B}(p) - I) \end{bmatrix} \right\| : \lambda \in \mathbb{C}, p \in \mathbb{R}^{n_p}, \Re(\lambda) \geq -c, \|p\| \leq P \right\}.$$

Note that by Assumption 2.5 the right-hand side of (26) is finite. We conclude that if  $\|p\| \leq P$ , then all zeros of  $J(\cdot; T, p)$  in the half plane (25) are confined to the compact set

$$\Omega := \{\lambda \in \mathbb{C} : \Re(\lambda) \geq -c, |\lambda| \leq R\}.$$

Next, from Assumption 2.5 it follows that  $J(\lambda; T, p)$  converges to  $J_0(\lambda; T)$  uniformly on compact sets as  $p \rightarrow 0$ . Hence, we can choose  $\tilde{p} \in (0, P)$  such that for all  $p \in \mathbb{R}^{n_p}$  with  $\|p\| \leq \tilde{p}$  the following estimate holds:

$$\max_{\lambda \in \partial\Omega} |J_0(\lambda; T) - J(\lambda; T, p)| \leq \min_{\lambda \in \partial\Omega} |J_0(\lambda; T)|.$$

The second assertion of the proposition then follows from an application of Rouché's theorem.  $\square$

**4.3. Discussion.** In section 3 we have shown by construction that (unfiltered) state derivative feedback may lead to a fragile closed-loop system in the sense that the closed-loop system is stable but not  $p$ -stable. This was illustrated for a numerical

approximation of derivatives by a finite difference formula and for a small delay in the feedback loop. In both cases the eigenvalues of the matrix  $BK_d$  determine the robustness of stability. However, even if the resulting conditions on the gain  $K_d$  are satisfied, stability may still lack robustness against other types of perturbations satisfying Assumption 2.5.

In this section we have shown that if the filtered derivative feedback control law (17) is stabilizing, then the closed-loop system is  $p$ -stable. However, the existence of a stabilizing filtered derivative feedback for the nominal system may again impose restrictions on the gain, as expressed in Proposition 4.1. Summarizing, we have the following result.

**THEOREM 4.4.** *Assume that the control law (2) asymptotically stabilizes system (1).*

*If the matrix  $(BK_d - I)$  is Hurwitz, then the filtered control law (17) is stabilizing for small values of  $T$  and results in a  $p$ -stable closed-loop system.*

*If  $(BK_d - I)$  has an eigenvalue in  $\mathbb{C}^+$ , then the closed-loop system with control law (2) is not  $p$ -stable. Furthermore, the filtered control law (17) is not stabilizing for small values of  $T$ .*

*Proof.* The proof follows from Proposition 4.1, Remark 4.2, and Proposition 4.3.  $\square$

Further refinements will be made in the next section, where relations between stabilizing values of  $K_d$  and the eigenvalue distribution of  $(BK_d - I)$  will be taken into account.

**5. Conditions for  $p$ -stabilizability.** In this section we discuss the  $p$ -stabilizability problem and the design of stabilizing state derivative controllers of the form (2) or (17). As we shall see, the condition  $\det(-A) > 0$ , which is satisfied if  $A$  has no zero eigenvalue and an even number of eigenvalues in the closed right half plane, will play a crucial role.

Throughout this section we assume that  $(A, B)$  is controllable and that  $A$  is cyclic. Remarks on the noncyclic case will be made in the next section.

We start by stating a technical lemma.

**LEMMA 5.1.** *Assume that  $\det(-A) < 0$ . If the control law (2) is stabilizing, then the matrix  $BK_d$  has a real eigenvalue larger than one.*

*Proof.* The proof is based on a continuation argument. If we consider the feedback  $u = kK_d\dot{x}(t)$ , where  $k \in [0, 1]$  is a real parameter, then the closed-loop system becomes

$$(27) \quad (I - kBK_d)\dot{x}(t) = Ax(t).$$

Since  $\det(-A) < 0$ , for  $k = 0$  the system has an odd number of characteristic roots in the open right half plane. On the other hand, for  $k = 1$  it has an even number of characteristic roots in the open right half plane (zero) as it is assumed that (2) is stabilizing. Because the characteristic roots appear in complex conjugate pairs and depend continuously on  $k$ , there must be a value of  $k = \tilde{k} \in (0, 1)$  for which there is a characteristic root either at zero or “at infinity.” The former is not possible because a zero characteristic root is invariant w.r.t. changes of  $k$  and would contradict the stability for  $k = 1$ . The latter implies that  $\det(I - \tilde{k}BK_d) = 0$ . Consequently,  $\tilde{k}BK_d$  has an eigenvalues equal to one, or, equivalently,  $BK_d$  has a real eigenvalue equal to  $1/\tilde{k} > 1$ .  $\square$

The two following theorems are direct corollaries.

THEOREM 5.2. *If  $\det(-A) < 0$  and control law (2) is stabilizing, then the closed-loop system is not  $p$ -stable.*

*Proof.* This result can be shown in three different ways. As  $BK_d$  has an eigenvalue larger than one, an approximation of the derivative with a finite difference scheme (Proposition 3.1), a small feedback delay (Proposition 3.4), as well as a neglected first order lag (Proposition 4.1, Remark 4.2) destroy stability.  $\square$

THEOREM 5.3. *If  $\det(-A) < 0$ , then the system cannot be stabilized with a control law of the form (17). Moreover, every dynamic control law of the form*

$$(28) \quad \dot{\zeta}(t) = A_f \zeta(t) + B_f \dot{x}(t), \quad u(t) = C_f \zeta(t),$$

*with  $A_f$  Hurwitz, results in an unstable closed-loop system.*

*Proof.* The first assertion is a consequence of Theorem 4.4 and Lemma 5.1. The proof of the second assertion is by contradiction and employs a continuation argument. Assume that control law (28) is stabilizing. With the parameterized control law

$$\dot{\zeta}(t) = A_f \zeta(t) + k B_f \dot{x}(t), \quad u(t) = C_f \zeta(t),$$

with parameter  $k \in [0, 1]$ , the closed-loop system becomes

$$(29) \quad \left( I - \begin{bmatrix} 0 & 0 \\ k B_f & 0 \end{bmatrix} \right) \dot{\xi}(t) = \begin{bmatrix} A & B C_f \\ 0 & A_f \end{bmatrix} \xi(t),$$

where  $\xi(t) = [x(t)^T \quad \zeta^T(t)]^T$ . For  $k = 0$  the system has an odd number of characteristic roots in the open right half plane as  $\det(-A) \det(-A_f) < 0$ , while for  $k = 1$  it has an even number of characteristic roots in the open right half plane (zero) as it is assumed that (28) is stabilizing. Because the characteristic roots appear in complex conjugate pairs and depend continuously on  $k$ , there must be a value of  $k = \tilde{k} \in (0, 1)$  for which there is a characteristic root either at zero or “at infinity.” The former is not possible because a characteristic root at zero is invariant w.r.t. changes of  $k$ , which contradicts the stability for  $k = 1$ ; the latter is not possible because the matrix

$$I - \begin{bmatrix} 0 & 0 \\ k B_f & 0 \end{bmatrix}$$

is invertible for all values of  $k$ .  $\square$

Remark 5.4. This result is expected from the stabilization mechanism outlined in Remark 2.4 and the fact that a filter prevents characteristic roots with a large modulus.

Next, we consider the case where  $\det(-A) > 0$ . We first have the following lemma.

LEMMA 5.5. *If  $\det(-A) > 0$ , then there always exists a stabilizing control law of the form (2) for which all eigenvalues of  $BK_d$  are zero.*

*Proof.* The existence of such a control law is shown by construction in the proof of Theorem 2 of [10]. To make this paper self contained, we outline the main steps.

There exist a transformation of the state,  $z = T_x x$ , and of the input,  $w = T_u u$ , that put system (1) in the controller canonical form

$$(30) \quad \dot{z}(t) = A_c z(t) + B_c w(t),$$

with

$$A_c = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & & & 0 & 1 \\ -a_n & \cdots & \cdots & -a_2 & -a_1 \end{bmatrix}, \quad B_c = \begin{bmatrix} 0 \\ \vdots \\ \vdots \\ 0 \\ 1 \end{bmatrix} \left| \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \right| \cdots \left| \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \right| \begin{bmatrix} \tilde{B}_2 \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{bmatrix}.$$

The control law

$$(31) \quad w(t) = \tilde{K}_d \dot{z}(t),$$

where

$$\tilde{K}_d = \begin{bmatrix} -k_{n-1} & \cdots & -k_1 & 0 \\ 0 & \cdots & \cdots & 0 \\ \vdots & & & \vdots \\ 0 & \cdots & \cdots & 0 \end{bmatrix},$$

then results in a closed-loop system with characteristic equation

$$\lambda^n + \sum_{l=1}^{n-1} (a_l + k_l) \lambda^{n-l} + a_n = 0.$$

As  $a_n = \det(-A) > 0$ , there always exist stabilizing values of  $k_1, \dots, k_{n-1}$ . Furthermore, all eigenvalues of  $B_c \tilde{K}_d$  are equal to zero. In the original coordinates the control law (31) becomes

$$u(t) = T_u^{-1} \tilde{K}_d T_x \dot{x}(t) := K_d \dot{x}(t). \quad \square$$

By combining Lemma 5.5 with Theorem 4.4 we arrive at the following result.

**THEOREM 5.6.** *If  $\det(-A) > 0$ , then there always exists a stabilizing controller of the form (17) for which the closed-loop system is  $p$ -stable.*

The obtained stabilizability conditions are summarized in Table 1.

TABLE 1  
*p-stabilizability of the controllable system (1) using state derivative feedback. A is assumed cyclic.*

	$\det(-A) < 0$	$\det(-A) = 0$	$\det(-A) > 0$
stabilizable	yes	no	yes
$p$ -stabilizable	no (neither with (2) nor with (17) and (28))	no	yes (with (17))

**6. Remarks on the noncyclic case.** If the cyclic index<sup>1</sup> of  $A$  is  $k > 1$ , then there always exist transformations of the state,  $z = T_x x$ , and the input,  $w = T_u u$ , which transform (1) into

$$(32) \quad \dot{z}(t) = A_c z(t) + B_c w(t),$$

<sup>1</sup>The maximum of the geometric multiplicities of its eigenvalues.

where

$$A_c = \begin{bmatrix} A_{11} & & 0 \\ & \ddots & \\ 0 & & A_{kk} \end{bmatrix}, \quad B_c = \left[ \begin{array}{ccc|ccc} B_{11} & \cdots & B_{1k} & \cdots & B_{1m} \\ & & \vdots & & \vdots \\ 0 & & B_{kk} & \cdots & B_{km} \end{array} \right],$$

with  $A_{ii}$  cyclic and the pair  $(A_{ii}, B_{ii})$  controllable for each  $i = 1, \dots, k$ .

As their proofs do not depend on the cyclic index of  $A$ , Theorems 5.2 and 5.3 remain valid.

**THEOREM 6.1.** *If  $\det(-A) < 0$  and the control law (2) is stabilizing, then the closed-loop system is not  $p$ -stable. Furthermore, every dynamic control law of the form (28), with  $A_f$  Hurwitz, results in an unstable closed-loop system.*

Based on a decomposition into  $k$  subproblems induced by the canonical form (32), and an application of Theorem 5.6 to each subproblem, we arrive at the following result.

**THEOREM 6.2.** *If  $\det(-A_{ii}) > 0$ ,  $1 \leq i \leq k$ , then there always exists a stabilizing controller of the form (17) for which the closed-loop system is  $p$ -stable.*

When comparing Theorem 6.1 with Theorem 6.2, the stabilizability analysis is complete if one can make an assertion for the case where

$$(33) \qquad \det(-A) > 0, \quad \exists i \in \{1, \dots, k\} : \det(-A_{ii}) < 0.$$

This is still an open problem. The following example indicates that in such case a lack of practical stability may occur.

*Example 6.3.* The system

$$\begin{cases} \dot{x}_1(t) = x_1(t) + u_1(t), \\ \dot{x}_2(t) = x_2(t) + u_2(t) \end{cases}$$

is of the form (32) with  $A_c = I, B_c = I$ , and  $A_{11} = A_{22} = 1$ . Clearly, we have  $\det(-A_c) > 0$ , but  $\det(-A_{11}) = \det(-A_{22}) < 0$ .

The control law

$$u(t) = K_d \dot{x}(t), \quad K_d \in \mathbb{R}^{2 \times 2},$$

is stabilizing if and only if the eigenvalues of the matrix  $K_d$  have real part larger than one. By both Propositions 3.1 and 3.4, the closed-loop system is not  $p$ -stable.

If we apply the filtered control law

$$T\dot{u}(t) + u(t) = K_d \dot{x}(t), \quad T > 0, \quad K_d \in \mathbb{R}^{2 \times 2},$$

then the characteristic equation of the closed-loop is given by

$$\det \left( \lambda^2 I + \lambda \left( \frac{1}{T} (I - K_d) - I \right) - \frac{1}{T} I \right) = 0.$$

As this equation has a zero in  $\mathbb{C}^+$  for all values of  $T$  and  $K_d$ , stabilization is not possible.

**7. Concluding remarks.** The possible lack of stability robustness of the stabilized system (1)–(2) against arbitrarily small modeling and implementation errors, which was illustrated with several example case studies, led us to the practical notion

of  $p$ -stability. The stabilizability and  $p$ -stabilizability of system (1) with the (filtered) control law (2) was characterized.

For the generic case where  $A$  is cyclic, a *complete* characterization of stabilizability is described in Table 1. Surprisingly, if  $\det(-A) < 0$ , which is satisfied if  $A$  has an odd number of eigenvalues in the open right half plane, the system *is* stabilizable, but *not*  $p$ -stabilizable, using neither static feedback nor dynamic feedback. This shows that the so-called odd number condition,  $\det(-A) < 0$ , well known in the context of Pyragas-type time-delayed feedback controllers, is also a *fundamental obstruction* to stabilizability in this context, yet only appears at a second stage, where robustness aspects are considered.

For the case where  $A$  is noncyclic a full characterization of stabilizability and  $p$ -stabilizability was made, except when (33) holds, that is, in the canonical form there are subsystems which satisfy the odd number condition, but the whole systems does not. Example 6.3 illustrates that again a lack of robustness of stability may occur and suggests that the necessary and sufficient  $p$ -stabilizability condition in the noncyclic case is given by  $\det(-A_{ii}) > 0$  for all  $i = 1, \dots, k$ . Whether or not this is true is an open problem and a topic of further research.

Motivated by the large number of applications of sampled-data systems, which appear, for instance, in network controlled systems, it is also worthwhile to investigate to what extent the controller construction, observed phenomena, and robustness issues discussed in the paper carry over to the hybrid case where the controller is discrete and difference based. In the overview article [15], where one investigates the effect on stability of approximating distributed delays in a class of control laws for time-delay systems, it is shown that also with pure discrete approximations of control laws fragility problems may occur, and may lead to phenomena which are different from those observed for continuous approximations.

#### Appendix. A technical lemma.

LEMMA A.1. *Consider the equation*

$$(34) \quad \lambda - \mu(1 - e^{-\lambda}) = 0,$$

where  $\mu \in S$ , with  $S$  given by (12). Then all roots of (34) are in  $\mathbb{C}^-$ , except for a root at the origin with multiplicity one.

*Proof.* We distinguish two cases as below.

Case 1:  $\mu \notin \mathbb{R}$ . We first characterize the zeros of the auxiliary function

$$h(\lambda; \nu) := \lambda - \mu(1 - e^{-\lambda\nu})$$

as a function of the parameter  $\nu \geq 0$ . For  $\nu = 0$ , the function  $h$  has only one zero at the origin, which is invariant w.r.t. changes of  $\nu$ . If  $\nu$  is increased from zero, then the number of zeros in the closed right half plane can increase only if zeros cross the imaginary axis. To see this, note that  $h(\lambda; \nu) = 0$  implies

$$|\lambda| = |\mu| |1 - e^{-\lambda\nu}|$$

and

$$|\lambda| \leq |\mu| \left(1 + e^{-\Re(\lambda)\nu}\right).$$

Consequently, whatever the value of  $\nu \geq 0$ , the zeros of  $h(\cdot, \nu)$  in the closed right half plane (if any) have modulus smaller than or equal to  $2|\mu|$ . Thus by varying  $\nu$  the

number of zeros of  $h$  in the right half plane cannot be changed by zeros coming from infinity, only by zeros crossing the imaginary axis.

A zero at the origin with multiplicity larger than one cannot occur since

$$h'(0; \nu) = 1 - \mu\nu \neq 0.$$

If  $h$  has a zero  $j\omega$ ,  $\omega \in \mathbb{R} \setminus \{0\}$ , for some value of  $\nu$ , then we have

$$j\omega = \mu(1 - e^{-j\omega\nu}).$$

Solving this equation yields

$$(35) \quad \omega = \omega^* := 2\Im(\mu), \quad \nu = \nu_k^* := \frac{\angle(\mu) + \pi k}{\Im(\mu)}, \quad k \geq 1.$$

Next, we look at the crossing direction of a zero on the imaginary axis w.r.t. the parameter  $\nu$ . Taking the derivative of  $h(\lambda(\nu); \nu) = 0$  w.r.t.  $\nu$  at  $(\lambda, \nu) = (j\omega^*, \nu_k^*)$  yields

$$\lambda'(\nu^*) = \frac{j\omega^* \mu e^{-j\omega^* \nu^*}}{1 - \nu \mu e^{-j\omega^* \nu}},$$

from which we get

$$\begin{aligned} \Re(\lambda'(\nu^*)^{-1}) &= \Re\left(\frac{1}{j\omega^* \mu e^{-j\omega^* \nu^*}}\right) = \Re\left(\frac{1}{j\omega^* (\mu - j\omega^*)}\right) \\ &= \Re\left((2\Im(\mu)(\Im(\mu) + j\Re(\mu)))^{-1}\right) > 0 \end{aligned}$$

and

$$(36) \quad \Re(\lambda'(\nu^*)) > 0.$$

From (35) and (36) we can conclude that

1. if  $\nu \in [0, \nu_1^*)$ , then all zeros of  $h$  are in  $\mathbb{C}^-$ , except for a zero at the origin with multiplicity one;
2. if  $\nu > \nu_1^*$ , then  $h$  has zeros in  $\mathbb{C}^+$ .

The assertion of the proposition is straightforward when taking into account that  $\mu \in S$  ( $\mu \notin \text{clos}(S)$ ) is equivalent to  $\nu_1^* > 1$  ( $\nu_1^* < 1$ ).

*Case 2:*  $\mu \in \mathbb{R}$ . The equation  $h = 0$  is the characteristic equation of the system  $\dot{x}(t) = \mu x(t) - \mu x(t - \tau)$ . The stability of this system has been analyzed in, e.g., [19, 24], from which the statements of the proposition follow.  $\square$

## MEASURE-VALUED SOLUTIONS FOR A DIFFERENTIAL GAME RELATED TO FISH HARVESTING\*

ALBERTO BRESSAN<sup>†</sup> AND WEN SHEN<sup>†</sup>

**Abstract.** In this paper we consider a model for the harvesting of marine resources, described by an elliptic equation. Since the cost functionals have sublinear growth with respect to the pointwise intensity of fishing effort, optimal solutions are in general measure-valued. For the control problem in one space dimension, we prove the existence of optimal strategies. Uniqueness is established within a class of measures with small total mass. We also study the differential game, modeling the presence of several competing fishing companies, and prove the existence of a Nash equilibrium solution. This is obtained as a fixed point of a continuous transformation in a space of positive Radon measures.

**Key words.** differential games, optimal control, measured-valued solutions, fish harvest

**DOI.** 10.1137/07071007X

**1. Introduction.** This paper is concerned with a noncooperative differential game modeling the harvesting of marine resources. The general setting of the problem will be discussed for an  $N$ -dimensional domain. The main results, however, will be proved in the one-dimensional case. Consider a bounded domain  $\Omega \subset \mathbb{R}^N$  with smooth boundary. In practice,  $\Omega \subset \mathbb{R}^2$  will describe the region occupied by a lake or a sea. Denote by  $\phi = \phi(t, x)$  the density of fish at time  $t$  at the point  $x \in \Omega$ . In absence of fishing activity, assume that the fish population evolves according to the parabolic equations with source term

$$(1.1) \quad \phi_t = \Delta \phi + g(x, \phi), \quad x \in \Omega,$$

with Neumann boundary conditions

$$(1.2) \quad \nabla \phi \cdot \mathbf{n} = 0, \quad x \in \partial\Omega.$$

A natural choice for  $g$  is

$$(1.3) \quad g(x, \phi) = \alpha (h(x) - \phi) \phi.$$

Here the constant  $\alpha > 0$  is a growth rate, while  $h(x)$  denotes the maximum fish population that can be supported by the habitat at  $x$ . Let  $u_i = u_i(t, x)$  be the intensity of harvesting conducted by the  $i$ th fishing company, at time  $t$  at the location  $x \in \Omega$ . In the presence of this fishing activity, the fish population evolves according to

$$(1.4) \quad \phi_t = \Delta \phi + g(x, \phi) - \sum_{i=1}^m \phi u_i(t, x).$$

<sup>†</sup>Department of Mathematics, Penn State University, University Park, PA 16802 (bressan@math.psu.edu, shen\_w@math.psu.edu).

Throughout this paper, we consider steady state solutions. These satisfy the elliptic equation

$$(1.5) \quad \Delta\phi + g(x, \phi) = \sum_{i=1}^m \phi u_i(x),$$

together with the Neumann boundary conditions (1.2). The strategies  $u_i(x)$  are now assumed to be independent of time. We are interested in optimal fishing strategies for the various companies. At a steady fishing rate, the  $i$ th company will sustain a cost

$$(1.6) \quad \int_{\Omega} c_i(x) u_i(x) dx.$$

It is reasonable to assume that different companies will incur different costs  $c_i$  for fishing at a given location  $x$ . This is because their home bases may be located at coastal cities with different distances from  $x$ . In addition, there may be restrictions to the fishing activities of companies of various countries. For example, if there is an international treaty that does not allow the  $k$ th company to harvest fish in a subregion  $\Omega' \subset \Omega$ , this will be modeled by setting  $c_k(x) = \infty$  for  $x \in \Omega'$ . If a subregion  $\Omega_0$  is set aside as a marine park where no fishing is permitted, then  $c_i(x) = \infty$  for all  $x \in \Omega_0$ ,  $i = 1, \dots, m$ . The profit for the  $i$ th company will be proportional to the total fish caught:

$$(1.7) \quad p_i = \int_{\Omega} P \cdot \phi(x) u_i(x) dx.$$

Here  $P$  denotes the unit price of fish on the market. By a variable rescaling, it is not restrictive to take  $P = 1$ . The total payoff for the  $i$ th company is therefore

$$(1.8) \quad J_i = \int_{\Omega} (\phi(x) - c_i(x)) u_i(x) dx.$$

The function  $u_i = u_i(x)$  describes the strategy of the  $i$ th company. It is reasonable to assume that it satisfies the constraints

$$(1.9) \quad u_i(x) \geq 0, \quad \int_{\Omega} u_i(x) dx \leq M_i.$$

Here  $M_i$  denotes the maximum amount of fishing within the capabilities of the  $i$ th company. In practice, this may depend on the number of fishermen and on the size of fishing boats available.

*Remark 1.* The cost functionals given at (1.6) are linear with respect to (w.r.t.)  $u_i$ . More general, nonlinear cost functionals could take the form

$$(1.10) \quad \Psi_i \left( \int_{\Omega} c_i(x) u_i(x) dx \right),$$

where  $\Psi_i$  is a convex function, with  $\Psi_i(0) = 0$ ,  $\Psi'_i(0) > 0$ . This accounts for the fact that, as the total amount of harvesting increases, the cost increases superlinearly. On the other hand, a nonlinear cost functional of the form

$$(1.11) \quad G(u) \doteq \int_{\Omega} \psi(u(x)) dx,$$

with  $\psi'(s) \rightarrow \infty$  as  $s \rightarrow \infty$ , is not realistic. For example, assume  $\Omega \subset \mathbb{R}^2$  and choose any point  $\bar{x} \in \Omega$ . Consider the two strategies

$$u(x) \equiv \frac{1}{\text{meas}(\Omega)}, \quad u^{(r)}(x) = \begin{cases} 1/(\pi r^2) & \text{if } |x - \bar{x}| < r, \\ 0 & \text{otherwise.} \end{cases}$$

Notice that

$$\int_{\Omega} u(x) dx = \int_{\Omega} u^{(r)}(x) dx = 1.$$

For the functional (1.10), fishing over the entire domain or on a small part of it yields the same cost. However, for the cost functional  $G$ , as we reduce the fishing area more and more, the cost tends to infinity. Indeed

$$\lim_{r \rightarrow 0} \int_{\Omega} \varphi(u^{(r)}(x)) dx = \infty.$$

This feature is not supported by practical experience.

*Remark 2.* We also observe that integral constraints such as (1.9) are meaningful, while pointwise constraints of the form

$$(1.12) \quad |u_i(x)| \leq M$$

are not. Indeed, (1.12) models the presence of a “parking meter,” so that a fishing boat is allowed to stay in one place up to a maximum amount of time, then it must move elsewhere.

The above remarks indicate that in a realistic model, the cost of harvesting grows at most linearly w.r.t. the pointwise intensity  $u(x)$ . This has important implications for the corresponding optimization problem. Indeed, the existence of optimal strategies can now be obtained not in  $\mathbf{L}^1(\Omega)$  but in the space  $\mathcal{M}_+(\bar{\Omega})$  of nonnegative Radon measures supported on the closure of the domain  $\Omega$ .

This fact is actually consistent with practical experience. If an open subset  $\Omega' \subset \Omega$  is set aside as a marine reserve, the most profitable place to catch fish is right along the boundary of the reserve, i.e., on  $\Omega \cap \partial\Omega'$ . In an optimal strategy, a positive amount of harvesting thus takes place on a set of measure zero. This strategy is described by a measure  $\mu$ , singular w.r.t. Lebesgue measure on  $\Omega$ . We stress that the study of optimal strategies within a space of Radon measures is a major difference between the present paper and earlier literature on the subject [1, 7, 8, 9, 10, 11, 12, 13].

The remainder of the paper is organized as follows. In section 2 we review the definition of Nash equilibrium solution of the differential game. All subsequent analysis deals with the case of one space dimension. Results are expected to be qualitatively similar in more space dimensions. However, there are two features of one-dimensional problems which play a key role in our proofs:

- (i) The Green kernels of second order operators are Lipschitz continuous.
- (ii) Given a two-point boundary value problem on the interval  $[0, R]$  with a source involving a positive measure  $\mu$ , as in [6] one can introduce a new variable  $s$  such that  $s(x) \doteq x + \mu([0, x])$ . Rewriting the differential equation in terms of  $s$  as independent variable, the singularities are removed and classical ODE theory applies.

For given measures  $\mu_i$ , in section 3 we study the existence and uniqueness of strictly positive solutions to the boundary value problem (1.5), (1.2). The existence

and the uniqueness of measure-valued solutions to the optimal control problems for the various players are studied in sections 4 and 5, respectively. Our uniqueness result is obtained by proving the strict concavity of the payoff functional (1.8), as long as the measures  $\mu_i$  remain small. Finally, in section 6 we prove the existence of a Nash equilibrium solution to the differential game. This is obtained as a fixed point of a continuous transformation, in a space of measures.

**2. Nash equilibrium solutions.** From now on, we consider fishing strategies described by positive Radon measures  $\mu_i \in \mathcal{M}_+(\bar{\Omega})$ . The fish population will reach an equilibrium state  $\phi = \phi(x)$ , determined by the elliptic problem with measure-valued sources

$$(2.1) \quad \Delta\phi + g(x, \phi) = \phi \cdot \sum_{i=1}^m \mu_i,$$

and Neumann boundary conditions

$$(2.2) \quad \nabla\phi \cdot \mathbf{n} = 0, \quad x \in \partial\Omega.$$

For the analysis of elliptic equations with measure-valued source terms we refer to [2, 3, 4, 5].

Each company seeks a strategy  $\mu_i$  in order to maximize its payoff

$$(2.3) \quad J_i \doteq \int_{\Omega} \phi d\mu_i(x) - \Psi_i \left( \int_{\Omega} c_i d\mu_i \right),$$

subject to the constraints

$$(2.4) \quad \mu_i \geq 0, \quad \mu_i(\bar{\Omega}) \leq M_i.$$

**DEFINITION 1.** *We say that the  $(1+m)$ -tuple  $(\phi, \mu_1^*, \dots, \mu_m^*)$  is a Nash equilibrium solution of the noncooperative differential game (2.1)–(2.3) if the function  $\phi$  provides a solution to the elliptic boundary value problem (2.1)–(2.2) and, for each  $i = 1, \dots, m$ , the measure  $\mu = \mu_i^*$  achieves the maximum payoff for the optimal control problem*

$$(2.5) \quad \text{maximize: } J_i(\mu) \doteq \int_{\Omega} \phi d\mu(x) - \Psi_i \left( \int_{\Omega} c_i d\mu \right),$$

subject to

$$(2.6) \quad \Delta\phi(x) + g(x, \phi) - \phi \cdot \sum_{j \neq i} \mu_j^*(x) = \phi\mu,$$

with boundary conditions (2.2), and with the constraints

$$(2.7) \quad \mu \geq 0, \quad \mu(\bar{\Omega}) \leq M_i.$$

**3. Positive solutions of the boundary value problem.** From now on we focus on the case of one space dimension, so that our domain is a bounded interval:  $\Omega \doteq ]0, R[$ . In this section we study the uniqueness of nonnegative solutions to the boundary value problem

$$(3.1) \quad \phi'' + g(x, \phi) - \phi \cdot \mu = 0, \quad \phi'(0) = \phi'(R) = 0,$$

where primes denote derivatives w.r.t. the space variable  $x$ , while  $\mu \in \mathcal{M}(\bar{\Omega})$  is a positive Radon measure supported on the closed interval  $\bar{\Omega} = [0, R]$ . On the function  $g$  we impose the following assumptions:

(A1) One has  $g(x, \phi) = f(x, \phi) \phi$ , where the function  $f = f(x, \phi)$  is continuous w.r.t. both variables and twice continuously differentiable w.r.t.  $\phi$ . Moreover, for some continuous function  $h = h(x)$  one has

$$f(x, 0) > 0, \quad f_\phi(x, \phi) < 0, \quad f(x, h(x)) = 0 \quad \text{for all } x \in [0, R], \quad \phi \geq 0.$$

Here and in what follows, by  $f_\phi, f_{\phi\phi}$  we denote, respectively, the first and the second partial derivative of  $f$  w.r.t.  $\phi$ .

Since in (3.1)  $\mu$  can be a measure, a precise concept of solution should first be given.

DEFINITION 2. *By a solution of (3.1) we mean a Lipschitz continuous map  $x \mapsto \phi(x)$  such that*

(i) *the map  $x \mapsto \phi'(x)$  has bounded variation and satisfies*

$$(3.2) \quad \lim_{x \rightarrow 0+} \phi'(x) = \phi(0) \mu(\{0\}), \quad \lim_{x \rightarrow R-} \phi'(x) = -\phi(R) \mu(\{R\});$$

(ii) *for every test function  $\eta \in C_c^1([0, R])$  one has*

$$(3.3) \quad \int_0^R \left\{ -\phi' \eta' + g(x, \phi) \eta \right\} dx - \int_0^R \phi \eta d\mu = 0.$$

We notice that  $\phi \equiv 0$  is always a solution. The next two lemmas are concerned with the existence and uniqueness of strictly positive solutions. In the case where  $\mu$  has a positive density w.r.t. Lebesgue measure, these results are entirely standard. However, the case where  $\mu$  contains point masses must be handled with some care.

LEMMA 1. *Let the assumptions (A1) hold.*

(i) *Let  $\phi$  be a nonnegative solution to (3.1) with  $\phi(y) > 0$  for some  $y \in [0, R]$ . Then there exists  $\delta > 0$  such that*

$$(3.4) \quad \phi(x) \geq \delta \quad \text{for all } x \in [0, R].$$

(ii) *The problem (3.1) can have at most one nontrivial positive solution.*

*Proof.* 1. Consider the set

$$(3.5) \quad \mathcal{D} \doteq \{x \in ]0, R[; \quad \phi'(x) \text{ exists, } \mu(\{x\}) = 0\}.$$

Observe that

$$\text{meas}([0, R] \setminus \mathcal{D}) = 0.$$

Construct a standard mollifier  $\varphi : \mathbb{R} \mapsto [0, 1]$ , with

$$\varphi \in C_c^\infty, \quad \int_{-1}^1 \varphi(x) dx = 1, \quad \varphi(x) = 0 \quad \text{if } |x| \geq 1,$$

and set  $\varphi_\varepsilon(x) \doteq \varepsilon^{-1} \varphi(\varepsilon^{-1} x)$ . Given a couple of points  $x_1, x_2 \in \mathcal{D}$ , consider the test functions  $\eta_\varepsilon \doteq \chi_{[x_1, x_2]} * \varphi_\varepsilon$ , so that

$$\eta_\varepsilon(x) \doteq \int_{x_1}^{x_2} \varphi_\varepsilon(x - y) dy.$$

Inserting these test functions in (3.3) and letting  $\varepsilon \rightarrow 0$ , for every couple of points  $x_1, x_2$  such that  $\mu(\{x_1\}) = \mu(\{x_2\}) = 0$  we obtain

$$(3.6) \quad \phi'(x_2) - \phi'(x_1) = \int_{x_1}^{x_2} \phi \, d\mu - \int_{x_1}^{x_2} f(x, \phi) \phi \, dx.$$

In particular, for every point  $x \in ]0, R[$ , we have

$$(3.7) \quad \phi'(x+) - \phi'(x-) = \mu(\{x\}) \phi(x).$$

2. Assume  $\phi(\bar{x}) = 0$ , for some  $\bar{x} \in [0, R]$ . Recalling that  $\phi$  is nonnegative, we claim that

$$(3.8) \quad \phi'(\bar{x}) = 0$$

as well. Indeed, if  $\bar{x} = 0$  or  $\bar{x} = R$ , the boundary conditions (3.2) yield  $\phi'(0+) = 0$  or  $\phi'(R-) = 0$ , respectively. On the other hand, if  $0 < x < R$ , as  $x \rightarrow \bar{x}$  by (3.7) the left and right limits of  $\phi'(x)$  coincide. Therefore  $\phi'(\bar{x})$  exists. If this derivative were  $\neq 0$ , the function  $\phi$  would take values with opposite signs in a neighborhood of  $\bar{x}$ , against the nonnegativity assumption. Hence (3.8) must hold.

3. For notational convenience, define  $\psi(x) \doteq \phi'(x)$ . Introduce the variable

$$(3.9) \quad s \doteq x - \bar{x} + \mu([\bar{x}, x]).$$

The map  $x \mapsto s(x)$  is strictly increasing. It admits a nondecreasing inverse  $s \mapsto x(s)$  which is continuous with Lipschitz constant one. Namely,

$$(3.10) \quad \theta(s) \doteq \frac{d}{ds} x(s) \in [0, 1]$$

for almost every  $s$ . Observe that (3.9)–(3.10) formally yield  $ds = dx + d\mu = \theta ds + (1 - \theta)ds$ . To take care of points where  $\mu$  has a point mass, and  $\phi'$  thus has a jump, we set

$$s^+(s) \doteq \max \{ \sigma; \ x(\sigma) = x(s) \}, \quad s^-(s) \doteq \min \{ \sigma; \ x(\sigma) = x(s) \}$$

and define

$$\phi(s) \doteq \phi(x(s)), \quad \psi(s) \doteq \frac{s - s^-}{s^+ - s^-} \cdot \phi'(x(s) +) + \frac{s^+ - s}{s^+ - s^-} \cdot \phi'(x(s) -).$$

We observe that these maps provide a solution to the system of ODEs

$$(3.11) \quad \begin{cases} \frac{d}{ds} \phi(s) = \theta(s) \cdot \psi(s), \\ \frac{d}{ds} \psi(s) = (1 - \theta(s)) \cdot \phi(s) - \theta(s) \cdot f(x(s), \phi(s)) \phi(s), \end{cases}$$

with initial data

$$(3.12) \quad \phi(0) = \psi(0) = 0.$$

The right-hand side of (3.11) is bounded, Lipschitz continuous w.r.t.  $\phi, \psi$ , and measurable w.r.t.  $s$ . Therefore the only solution with initial data (3.12) is  $\phi(s) = \psi(s) = 0$  for every  $s$ .

4. Reverting to the original variables, in the previous step we have shown that if  $\phi(\bar{x}) = 0$  for some  $\bar{x} \in [0, R]$ , then  $\phi(x) \equiv 0$ . Equivalently, if  $\phi(y) > 0$  for some  $y$ , then  $\phi(x) > 0$  for all  $x \in [0, R]$ . Since the interval  $[0, R]$  is compact, this proves part (i) of the lemma.

5. To prove claim (ii) concerning uniqueness, let  $\phi_1, \phi_2$  be any two strictly positive solutions. Assume that  $\phi_1(y) < \phi_2(y)$  for some  $y \in [0, R]$ . Define

$$(3.13) \quad \lambda \doteq \max_{x \in [0, R]} \frac{\phi_2(x)}{\phi_1(x)} > 1.$$

We then have

$$(3.14) \quad \lambda \phi_1(x) \geq \phi_2(x) \quad \text{for all } x \in [0, R],$$

while

$$(3.15) \quad \lambda \phi_1(\bar{x}) = \phi_2(\bar{x})$$

for at least one point  $\bar{x} \in [0, R]$ . Define  $\varphi \doteq \lambda \phi_1 - \phi_2$ . This implies

$$(3.16) \quad \varphi(\bar{x}) = 0, \quad \varphi(x) \geq 0 \quad \text{for all } x \in [0, R].$$

Moreover,

$$(3.17) \quad \varphi'' + f(x, \phi_1(x)) \varphi - \mu \varphi = \left[ f(x, \phi_2(x)) - f(x, \phi_1(x)) \right] \phi_2(x).$$

Notice that, in a neighborhood of  $\bar{x}$ , the right-hand side of (3.17) is strictly negative, because  $f$  is strictly decreasing w.r.t.  $\phi$ . Using the auxiliary variable  $s$  as in (3.9), and setting  $\psi \doteq \varphi' = d\varphi/dx$ , we can represent  $\varphi$  as the solution to the Cauchy problem

$$(3.18) \quad \begin{cases} \frac{d}{ds} \varphi(s) = \theta(s) \cdot \psi(s), \\ \frac{d}{ds} \psi(s) = (1 - \theta(s)) \cdot \varphi(s) - \theta(s) \cdot f(x(s), \phi_1) \varphi + \theta(s) \kappa(s). \end{cases}$$

Here

$$\kappa(s) \doteq \left[ f(x(s), \phi_2(x(s))) - f(x(s), \phi_1(x(s))) \right] \phi_2(x(s)) < 0$$

as  $x(s)$  ranges in a neighborhood of the point  $\bar{x}$ .

6. Two cases should be considered. If  $0 < \bar{x} < R$ , since  $\varphi \geq 0$  we have

$$(3.19) \quad \lambda \phi_1'(\bar{x}-) - \phi_2'(\bar{x}-) \leq 0 \leq \lambda \phi_1'(\bar{x}+) - \phi_2'(\bar{x}+).$$

From the identities

$$\phi_2'(\bar{x}+) - \phi_2'(\bar{x}-) = \mu(\{\bar{x}\}) \cdot \phi_2(\bar{x}) = \mu(\{\bar{x}\}) \cdot \lambda \phi_1(\bar{x}) = \lambda \phi_1'(\bar{x}+) - \lambda \phi_1'(\bar{x}-),$$

it follows that the left- and right-hand sides of (3.19) are equal, and hence they both vanish. By the parametrization (3.9), at  $s = 0$  we have

$$(3.20) \quad \varphi(0) = \lambda \phi_1(\bar{x}) - \phi_2(\bar{x}) = 0, \quad \psi(0) = \lambda \phi_1'(\bar{x}) - \phi_2'(\bar{x}) \geq 0.$$

Since  $\kappa(s) < 0$  for  $s \in ]0, s_0]$ , with  $s_0 > 0$  small, from equations (3.18) and the initial conditions (3.20) it follows that  $\varphi(s) < 0$  for  $s > 0$  sufficiently small. This yields a contradiction with (3.16).

7. Finally, we consider the case where  $\bar{x} = 0$ . According to the boundary conditions (3.2), the identity  $\phi_2(0) = \lambda\phi_1(0)$  implies  $\phi'_2(0+) = \lambda\phi'_1(0+)$ . Therefore, for  $s = 0$  equations (3.18) should again be solved with the boundary conditions (3.20). As before, we conclude that  $\varphi(s) < 0$  for  $s > 0$  small, reaching a contradiction. The case where  $\bar{x} = R$  is entirely analogous.  $\square$

In the following, by a *subsolution* of problem (3.1) we mean a Lipschitz continuous function  $\phi$  which satisfies the following two conditions.

(i) The map  $x \mapsto \phi'(x)$  has bounded variation and satisfies

$$(3.21) \quad \lim_{x \rightarrow 0+} \phi'(x) \geq \phi(0) \mu(\{0\}), \quad \lim_{x \rightarrow R-} \phi'(x) \leq -\phi(R) \mu(\{R\}).$$

(ii) For every nonnegative test function  $\eta \in C_c^1([0, R])$  one has

$$(3.22) \quad \int_0^R \left\{ -\phi' \eta' + f(x, \phi) \phi \eta \right\} dx - \int_0^R \phi \eta d\mu \geq 0.$$

Repeating the previous analysis at (3.5)–(3.7), we see that  $\phi$  is a subsolution if and only if the boundary condition (3.21) holds and, moreover, for every  $x_1, x_2 \in ]0, R[$  such that  $\mu(\{x_1\}) = \mu(\{x_2\}) = 0$ , we have

$$(3.23) \quad \phi'(x_2) - \phi'(x_1) \geq \int_{x_1}^{x_2} \phi d\mu - \int_{x_1}^{x_2} f(x, \phi) \phi dx.$$

Supersolutions can be defined in an entirely similar way, reversing the inequalities in (3.21)–(3.22). The next result provides a necessary and sufficient condition for the existence of a strictly positive solution. Since it is an obvious extension of the corresponding result valid when  $\mu$  is absolutely continuous, we only sketch the main arguments of the proof.

LEMMA 2. *Let assumptions (A1) hold. Then the following are equivalent:*

(i) *The linear eigenvalue problem*

$$(3.24) \quad \phi'' + f(x, 0)\phi - \phi\mu = \lambda\phi, \quad \phi'(0) = \phi'(R) = 0$$

*has a strictly positive solution for some  $\lambda > 0$ .*

(ii) *The nonlinear problem (3.1) has a strictly positive solution.*

*Proof.* 1. Assume that (i) holds. Observe that the constant function

$$\phi^+(x) \equiv h_{\max} \doteq \max_{x \in [0, R]} h(x)$$

is a supersolution of (3.1). Indeed  $f(x, h_{\max}) \leq 0$  for all  $x \in [0, R]$ . On the other hand, let  $\phi_\lambda$  be a positive eigenfunction, corresponding to an eigenvalue  $\lambda > 0$ . Then, for all  $\varepsilon > 0$  sufficiently small, by the continuity of  $f$  we have

$$\varepsilon\phi_\lambda'' + f(x, \varepsilon\phi_\lambda(x)) \varepsilon\phi_\lambda - \varepsilon\phi_\lambda \mu \geq \varepsilon\phi_\lambda'' + [f(x, 0) - \lambda] \varepsilon\phi_\lambda - \varepsilon\phi_\lambda \mu = 0.$$

Hence the function  $\phi^-(x) \doteq \varepsilon\phi_\lambda(x)$  is a strictly positive subsolution of (3.1). By possibly reducing the size of  $\varepsilon$  we can assume that  $\phi^-(x) \leq h_{\max} = \phi^+(x)$ . Having constructed an upper and a lower solution, we conclude that there exists a solution  $\phi$

of (3.1) such that  $\phi^-(x) \leq \phi(x) \leq \phi^+(x)$  for all  $x \in [0, R]$ . Following a well-established technique, this solution  $\phi$  can be defined as the supremum of all subsolutions  $\leq \phi^+$ .

2. Conversely, assume that (3.1) admits a strictly positive solution  $\phi$ . In analogy with (3.9), define the new space variable

$$(3.25) \quad s = x + \mu([0, x])$$

and set  $\theta(s) = dx(s)/ds \in [0, 1]$ . We need to show that there exists  $\lambda > 0$  and a solution to the system

$$(3.26) \quad \begin{cases} \frac{d}{ds}\phi_\lambda(s) = \theta(s) \cdot \psi_\lambda(s), \\ \frac{d}{ds}\psi_\lambda(s) = (1 - \theta(s)) \cdot \phi_\lambda(s) - \theta(s) \cdot [f(x(s), 0) - \lambda] \phi_\lambda(s), \end{cases}$$

with  $\phi_\lambda > 0$  and with boundary conditions

$$(3.27) \quad \phi_\lambda(0) = 1, \quad \psi_\lambda(0) = \psi_\lambda(S) = 0.$$

Here  $S \doteq R + \mu([0, R])$ . Introducing the quotient function

$$(3.28) \quad \Phi_\lambda(s) \doteq \frac{\psi_\lambda(s)}{\phi_\lambda(s)},$$

from (3.26)–(3.27) we find that  $\Phi_\lambda$  must satisfy

$$(3.29) \quad \frac{d}{ds}\Phi_\lambda(s) = (1 - \theta(s)) - \theta(s)[f(x(s), 0) - \lambda] - \theta(s)\Phi_\lambda^2(s) \quad \text{for a.e. } s \in [0, S],$$

$$(3.30) \quad \Phi_\lambda(0) = 0,$$

together with the terminal condition  $\Phi_\lambda(S) = 0$ . For each  $\lambda \geq 0$ , consider the solution  $\Phi_\lambda$  of the Cauchy problem (3.29)–(3.30). As  $\lambda$  increases, we clearly have

$$\lim_{\lambda \rightarrow +\infty} \Phi_\lambda(S) = +\infty.$$

On the other hand, when  $\lambda = 0$  we have  $\Phi_0(S) < 0$ . Indeed, by assumption there exists a solution  $(\phi, \psi)$  of (3.11) with

$$\psi(0) = \psi(S) = 0, \quad \phi(s) > 0 \quad \text{for all } s \in [0, S].$$

Hence the function

$$\Phi(s) \doteq \psi(s)/\phi(s)$$

is well defined and satisfies

$$(3.31) \quad \frac{d}{ds}\Phi(s) = (1 - \theta(s)) - \theta(s)f(x(s), \phi(s)) - \theta(s)\Phi^2(s) \quad \text{for a.e. } s \in [0, S],$$

$$(3.32) \quad \Phi(0) = \Phi(S) = 0.$$

Recalling that  $f(x(s), \phi(s)) < f(x(s), 0)$  for every  $s \in [0, S]$ , by a standard comparison argument for first order ODEs we conclude that

$$\Phi_0(s) \leq \Phi(s) \quad \text{for all } s \in [0, S].$$

Moreover, at the terminal point we have the strict inequality  $\Phi_0(S) < \Phi(S)$ . Since the value  $\Phi_\lambda(S)$  depends continuously on  $\lambda$ , there exists a particular value  $\lambda^* > 0$  for which  $\Phi_{\lambda^*}(S) = 0$ . Returning to the original variables, this yields the desired solution to the linear boundary value problem (3.24).  $\square$

By the previous analysis, the nonlinear boundary value problem (3.1) has a strictly positive solution if and only if for  $\lambda = 0$  the solution  $\Phi_0$  of the Cauchy problem (3.29)–(3.30) satisfies  $\Phi_0(S) < 0$ . This yields the following.

**COROLLARY 1.** *A sufficient condition for problem (3.1) to have a strictly positive solution is that*

$$(3.33) \quad \mu([0, R]) < \int_0^R f(x, 0) dx.$$

Indeed, according to the proof of Lemma 2, a strictly positive solution exists if and only if the solution  $\Phi_0$  of the Cauchy problem

$$(3.34) \quad \frac{d}{ds} \Phi_0(s) = (1 - \theta(s)) - \theta(s) f(x(s), 0) - \theta(s) \Phi_0^2(s), \quad \Phi_0(0) = 0,$$

satisfies  $\Phi_0(S) < 0$ . Integrating (3.34) one obtains

$$\Phi_0(S) \leq \int_0^S (1 - \theta(s)) ds - \int_0^S \theta(s) f(x(s), 0) ds = \mu([0, R]) - \int_0^R f(x, 0) dx.$$

This establishes (3.33).

**4. The optimal control problem.** In this section we analyze the optimal control problem for one fishing company. This is formulated as an optimization problem within a space of nonnegative Radon measures for an elliptic PDE with Neumann boundary data. In one space dimension it takes the form

$$(4.1) \quad \text{maximize:} \quad J(\mu) = \int_0^R \phi(x) d\mu(x) - \Psi \left( \int_0^R c(x) d\mu(x) \right)$$

subject to

$$(4.2) \quad \phi''(x) + f(x, \phi) \phi - \phi \cdot \nu = \phi \cdot \mu, \quad x \in ]0, R[,$$

$$(4.3) \quad \phi'(0) = \phi'(R) = 0.$$

Here the measure  $\mu$  describes the fishing intensity for the particular company under consideration. This will be an element of the space  $\mathcal{M}([0, R])$  of Radon measures supported on the compact interval  $[0, R]$ . The measure  $\mu$  must be suitably chosen in order to maximize the profit  $J(\mu)$ . On the other hand,  $\nu$  is a given Radon measure, accounting for the combined intensity of fishing of all other companies. This situation is relevant in the study of differential games. Of course, if only one fishing company is active, we would simply take  $\nu \equiv 0$ .

On the cost functional  $J$  we make the following assumptions:

(A2) The cost function  $c : [0, R] \mapsto [c_0, \infty]$  is bounded from below by some constant  $c_0 > 0$  and is lower semicontinuous. The function  $\Psi$  is nondecreasing, convex, and lower semicontinuous and satisfies

$$(4.4) \quad \Psi(0) = 0, \quad \Psi'(0) = 1.$$

Finally,  $\nu$  is a nonnegative Radon measure on  $[0, R]$ .

Notice that the case  $c(x) = +\infty$  for every  $x$  in an open subset  $\Omega' \subset \Omega$  is allowed. Similarly, there may exist a value  $s_0 > 0$  such that  $\Psi(s) = +\infty$  for all  $s > s_0$ . Some preliminary observations are listed below.

*Remark 3.* For every nonnegative measures  $\mu, \nu \geq 0$ , the solution of (4.2)–(4.3) satisfies

$$(4.5) \quad 0 \leq \phi(x) \leq \max_{x \in [0, R]} h(x),$$

where  $h$  is the function introduced in assumption (A1).

*Remark 4.* Using the fact that the pointwise maximum of two solutions is a subsolution, we obtain the uniqueness of the maximal solution. Throughout the following, for a given control measure  $\mu$ , we shall always refer to this maximal solution. According to Lemma 1, this maximal solution is either identically zero or uniformly positive on the entire domain  $[0, R]$ .

*Remark 5.* Given two measures  $\mu, \tilde{\mu}$ , we write  $\tilde{\mu} \prec \mu$  if

$$\tilde{\mu}(A) \leq \mu(A)$$

for every open set  $A$ . In this case, the corresponding maximal solutions of (4.2)–(4.3) satisfy

$$(4.6) \quad \tilde{\phi}(x) \geq \phi(x), \quad x \in [0, R].$$

Indeed, the function  $\tilde{\phi}$  is then a supersolution of (4.2)–(4.3).

*Remark 6.* Let  $\phi_0$  be the equilibrium population of the fish if our specific company does no harvesting at all, so that

$$(4.7) \quad \phi_0''(x) + f(x, \phi_0)\phi_0 - \phi_0 \cdot \nu = 0, \quad x \in \Omega.$$

Then the optimal control strategy is  $\mu^* \equiv 0$  if and only if

$$(4.8) \quad \phi_0(x) \leq c(x) \quad \text{for all } x \in [0, R].$$

*Remark 7.* In the spatially homogeneous case  $c(x) \equiv \bar{c}$ ,  $d\nu = \bar{\nu} dx$ ,  $f(x, \phi) = (\bar{h} - \phi)$ , we expect to find a optimal solution  $\mu$  having constant density  $\bar{u}$  w.r.t. Lebesgue measure, so that  $d\mu = \bar{u} dx$ . In this case, the solution of (4.2)–(4.3) is explicitly computed:

$$(4.9) \quad \phi \equiv \bar{h} - \bar{\nu} - \bar{u};$$

otherwise  $\phi \equiv 0$  if the right-hand side of (4.9) is negative. The optimal value of  $\bar{u}$  is found by maximizing the scalar function

$$J(\bar{u}) = R(\bar{h} - \bar{\nu} - \bar{u}) - \Psi(R\bar{c}\bar{u}).$$

The main result of this section is the existence of an optimal strategy  $\mu^*$ , within the space of Radon measures. As we show in a subsequent section, this more general formulation cannot be avoided. Indeed, when the cost function  $c(\cdot)$  is discontinuous, the optimization problem may have no classical solution. The optimal strategy  $\mu^*$  is typically a measure which contains point masses and does not admit a density  $u^* \in \mathbf{L}^1([0, R])$  w.r.t. Lebesgue measure.

THEOREM 1. *Let assumptions (A1)–(A2) hold. Then the maximization problem (4.1)–(4.3) admits an optimal solution  $\mu^* \in \mathcal{M}_+([0, R])$  within the family of nonnegative Radon measures on  $[0, R]$ .*

*Proof.* 1. Let  $(\mu_n)_{n \geq 1}$  be a maximizing sequence, so that  $\mu_n \in \mathcal{M}_+([0, R])$  for all  $n \geq 1$  and

$$(4.10) \quad \lim_{n \rightarrow \infty} J(\mu_n) = \sup_{\mu} J(\mu).$$

Call  $\phi_n$  the corresponding maximal solution of (4.2)–(4.3). Notice that it is not restrictive to assume that the support of  $\mu_n$  is contained in the set

$$\Omega_n \doteq \{x \in [0, R]; \phi_n(x) \geq c_0\}.$$

Indeed, in the opposite case we can define a new measure  $\tilde{\mu}_n \prec \mu_n$  by setting

$$\tilde{\mu}_n(A) \doteq \mu_n(A \cap \Omega_n).$$

As in Remark 5, the corresponding solutions satisfy  $\tilde{\phi}_n \geq \phi_n$ , and hence  $J(\tilde{\mu}_n) \geq J(\mu_n)$ .

2. From (4.2)–(4.3) it now follows that

$$(4.11) \quad c_0 \mu_n([0, R]) \leq \int_0^R \phi_n d\mu_n \leq \int_0^R f(x, \phi_n) \phi_n dx \leq \int_0^R f(x, 0) h_{max} dx.$$

This proves that the sequence  $\mu_n$  is uniformly bounded.

3. By compactness, we can now select a subsequence, still called  $(\mu_n)$ , which converges weakly to a measure  $\mu^* \in \mathcal{M}_+([0, R])$ . Since the functions  $\phi_n$  are uniformly Lipschitz continuous and bounded on  $[0, R]$ , we have the uniform convergence  $\phi_n \rightarrow \phi^*$ , where  $\phi^*$  provides a solution to (4.2)–(4.3) with  $\mu = \mu^*$ . We now have

$$(4.12) \quad \lim_{n \rightarrow \infty} \int_0^R \phi_n d\mu_n = \int_0^R \phi^* d\mu^*.$$

Moreover, the lower semicontinuity of the functions  $c$  and  $\Psi$  implies

$$(4.13) \quad \begin{aligned} \int_0^R c d\mu^* &\leq \liminf_{n \rightarrow \infty} \int_0^R c d\mu_n, \\ \Psi \left( \int_0^R c d\mu^* \right) &\leq \liminf_{n \rightarrow \infty} \Psi \left( \int_0^R c d\mu_n \right). \end{aligned}$$

Together, (4.12)–(4.13) yield

$$\lim_{n \rightarrow \infty} J(\mu_n) \leq J(\mu^*).$$

Hence the strategy  $\mu^*$  is optimal.  $\square$

**5. Uniqueness of optimal solutions.** This section is concerned with the uniqueness of optimal solutions. We will show that, within a class of measures with small total mass, the optimal strategy is unique. This will follow from the strict concavity of the payoff functional  $J$ . Throughout the following, we denote by

$$(5.1) \quad \|\mu\| \doteq \sup \left\{ \int_0^R \varphi d\mu; \|\varphi\|_{C^0} \leq 1 \right\}$$

the total mass of a measure  $\mu$ . Notice that if  $\mu$  is nonnegative, one simply has  $\|\mu\| = \mu([0, R])$ . Given two distinct positive measures  $\mu, \tilde{\mu} \in \mathcal{M}_+([0, R])$ , define

$$\sigma \doteq \frac{\tilde{\mu} - \mu}{\|\tilde{\mu} - \mu\|}.$$

Of course,  $\sigma$  is a Radon measure, not necessarily positive, with unit norm.

For  $\epsilon \geq 0$  small, let  $\phi^\epsilon$  be the corresponding solution of boundary value problem (4.2)–(4.3), with  $\mu$  replaced by  $\mu^\epsilon \doteq \mu + \epsilon\sigma$ . We seek conditions which ensure that the scalar map

$$(5.2) \qquad \epsilon \mapsto J(\mu + \epsilon\sigma)$$

is strictly concave. It is clear that the map

$$\epsilon \mapsto \int_0^R c \, d\mu^\epsilon = \int_0^R c \, d\mu + \epsilon \int_0^R c \, d\sigma$$

is affine. Since we are assuming that the function  $s \mapsto \Psi(s)$  is convex, the same is true of the map

$$\epsilon \mapsto J^-(\mu^\epsilon) \doteq \Psi\left(\int_0^R c \, d\mu^\epsilon\right).$$

It thus suffices to study the concavity of the map

$$(5.3) \qquad \epsilon \mapsto J^+(\mu^\epsilon) \doteq \int_0^R \phi^\epsilon \, d\mu^\epsilon$$

for  $\epsilon \geq 0$  small. In the following analysis, we assume

$$(5.4) \qquad \|\nu\|, \|\mu\| << 1,$$

so that the corresponding solution of (4.2)–(4.3) will be close to the solution  $\psi_0$  of

$$(5.5) \qquad \psi_0'' + f(x, \psi_0) \psi_0 = 0, \qquad \psi_0'(0) = \psi_0'(R) = 0,$$

where no fishing occurs.

We begin with a formal analysis. Assume that at  $\epsilon \approx 0$ , the map  $\epsilon \mapsto \phi^\epsilon$  admits an asymptotic expansion

$$(5.6) \qquad \phi^\epsilon = \phi_0 + \epsilon\phi_1 + \epsilon^2\phi_2 + o(\epsilon^2).$$

Observe that each function  $\phi^\epsilon$  satisfies

$$(5.7) \qquad (\phi^\epsilon)'' + f(x, \phi^\epsilon)\phi^\epsilon = \phi^\epsilon(\nu + \mu + \epsilon\sigma),$$

with Neumann boundary conditions (4.3). Inserting (5.6) in (5.7) and expanding in powers of  $\epsilon$  we see that the functions  $\phi_0, \phi_1, \phi_2 : [0, R] \mapsto \mathbb{R}$  should provide solutions to the boundary value problems

$$(5.8) \quad \left\{ \begin{array}{l} \phi_0'' + f(x, \phi_0)\phi_0 = \phi_0(\nu + \mu), \\ \phi_1'' + f_\phi(x, \phi_0)\phi_0\phi_1 + f(x, \phi_0)\phi_1 = \phi_1(\nu + \mu) + \phi_0\sigma, \\ \phi_2'' + \frac{1}{2}f_{\phi\phi}(x, \phi_0)\phi_0\phi_1^2 + f_\phi(x, \phi_0)(\phi_0\phi_2 + \phi_1^2) + f(x, \phi_0)\phi_2 = \phi_2(\nu + \mu) + \phi_1\sigma, \end{array} \right.$$

with Neumann boundary conditions

$$(5.9) \quad \phi'_0(0) = \phi'_1(0) = \phi'_2(0) = 0, \quad \phi'_0(R) = \phi'_1(R) = \phi'_2(R) = 0.$$

Computing the second derivative at  $\epsilon = 0$ , we find

$$(5.10) \quad \begin{aligned} \frac{1}{2} \frac{d^2}{d\epsilon^2} J^+(\mu^\epsilon) &= \frac{1}{2} \frac{d^2}{d\epsilon^2} \int_0^R \phi^\epsilon d\mu^\epsilon \\ &= \frac{1}{2} \frac{d^2}{d\epsilon^2} \int_0^R (\phi_0 + \epsilon \phi_1 + \epsilon^2 \phi_2) d(\mu + \epsilon \sigma) \\ &= \int_0^R \phi_1 d\sigma + \int_0^R \phi_2 d\mu. \end{aligned}$$

We need to study the sign of the right-hand side of (5.10) and check if it is strictly negative. From the first two equations in (5.8) it follows that

$$(5.11) \quad \nu + \mu = \frac{\phi''_0}{\phi_0} + f(x, \phi_0),$$

$$(5.12) \quad \sigma = \frac{\phi''_1}{\phi_0} + f_\phi(x, \phi_0) \phi_1 - \phi_1 \frac{\phi''_0}{\phi_0^2}.$$

Integrating by parts and using the boundary conditions (5.9), we obtain

$$(5.13) \quad \begin{aligned} \int_0^R \phi_1 d\sigma &= \int_0^R \left( \frac{\phi''_1}{\phi_0} \phi_1 + f_\phi(x, \phi_0) \phi_1^2 - \phi_1^2 \frac{\phi''_0}{\phi_0^2} \right) dx \\ &= \int_0^R \left[ -\phi'_1 \left( \frac{\phi_1}{\phi_0} \right)' + f_\phi(x, \phi_0) \phi_1^2 + \left( \frac{\phi_1^2}{\phi_0^2} \right)' \phi'_0 \right] dx \\ &= \int_0^R \left[ -\frac{1}{\phi_0} (\phi'_1)^2 + 3 \frac{\phi'_0}{\phi_0^2} \phi'_1 \phi_1 + \left( f_\phi(x, \phi_0) - 2 \frac{(\phi'_0)^2}{\phi_0^3} \right) \phi_1^2 \right] dx. \end{aligned}$$

Since we always assume (5.4), in (5.8)–(5.9) we expect  $\phi_0 \approx \psi_0$ , where  $\psi_0$  is the solution of (5.5). On the other hand, the function  $\phi_1$  can be essentially arbitrary. In order to control the sign of the right-hand side of (5.13), on the Hilbert–Sobolev space  $H^1([0, R])$ , we consider the homogeneous quadratic functional

$$(5.14) \quad Q(v) = \int_0^R \left[ \frac{1}{\psi_0} (v')^2 - 3 \frac{\psi'_0}{\psi_0^2} v'v + \left( 2 \frac{(\psi'_0)^2}{\psi_0^3} - f_\phi(x, \psi_0) \right) v^2 \right] dx.$$

By an elementary inequality we see that if there exists  $\delta_0 > 0$  such that

$$(5.15) \quad f_\phi(x, \psi_0) + \frac{1}{4} \frac{[\psi'_0(x)]^2}{\psi_0^3(x)} \leq -\delta_0 < 0 \quad \text{for all } x \in [0, R],$$

then the functional  $Q$  is strictly positive definite. Namely,

$$(5.16) \quad Q(v) \geq 2\delta_1 \|v\|_{H^1}^2$$

for some constant  $\delta_1 > 0$  and all  $v \in H^1$ . For  $\nu, \mu \approx 0$  one has  $\phi_0 \approx \psi_0$ . Therefore the right-hand side of (5.13) will still be strictly negative definite. Concerning the second integral on the right-hand side of (5.10), we expect that it can be rendered arbitrarily

small by choosing the measure  $\mu$  small enough. These preliminary computations motivate the following.

**THEOREM 2.** *Let assumptions (A1)–(A2) hold. Moreover, assume that (5.15) holds, so that the quadratic functional  $Q$  in (5.14) is strictly positive definite. Then there exists a constant  $\delta^\sharp > 0$  such that, for any given measure  $\nu \in \mathcal{M}_+$ , the optimization problem (4.1)–(4.3) can have at most one solution within the set of measures  $\mu \in \mathcal{M}_+([0, R])$  which satisfy the additional condition*

$$(5.17) \qquad \qquad \qquad \|\mu\| + \|\nu\| \leq \delta^\sharp.$$

*In particular, if  $\nu = 0$  and*

$$(5.18) \qquad \qquad \qquad \frac{\Psi(c_0\delta^\sharp)}{\delta^\sharp} > h_{max},$$

*then the optimization problem has exactly one solution  $\mu \in \mathcal{M}_+$ .*

*Proof.* Assume that there exist two distinct optimal solutions  $\mu_1, \mu_2$ . To obtain a contradiction, we will show that the map

$$(5.19) \qquad \qquad \qquad \epsilon \mapsto J(\epsilon\mu_2 + (1 - \epsilon)\mu_1)$$

is strictly concave. This will be achieved in several steps.

1. Fix any  $\bar{\epsilon} \in [0, 1]$  and define

$$\mu \doteq \bar{\epsilon}\mu_2 + (1 - \bar{\epsilon})\mu_1, \qquad \sigma \doteq \frac{\mu_2 - \mu_1}{\|\mu_2 - \mu_1\|}.$$

We consider the map  $s \mapsto J(\mu + s\sigma)$  and check that, at  $s = 0$ ,

$$\frac{d^2}{ds^2} J(\mu + s\sigma) < 0.$$

Indeed, let  $\phi_0, \phi_1, \phi_2$  be the solutions of (5.8)–(5.9). Notice that, for  $\|\nu + \mu\|$  sufficiently small, these functions are uniquely defined. Call  $\phi^s$  the solution of (4.2)–(4.3) corresponding to the measure  $\mu + s\sigma$ . We then have

$$\lim_{s \rightarrow 0} \frac{1}{s^2} \|\phi^s - \phi_0 - s\phi_1 - s^2\phi_2\|_{C^0} = 0.$$

Hence

$$(5.20) \qquad \qquad \qquad \left. \frac{d^2}{ds^2} J(\mu + s\sigma) \right|_{s=0} = \int_0^R \phi_1 \, d\sigma + \int_0^R \phi_2 \, d\mu.$$

2. We now rewrite the third equation in (5.8) as

$$(5.21) \qquad \qquad \qquad \phi_2'' + \left( f_\phi(x, \phi_0)\phi_0 + f(x, \phi_0) - \nu - \mu \right) \phi_2 = \phi_1\sigma - \left( \frac{1}{2} f_{\phi\phi}(x, \phi_0)\phi_0 + f_\phi(x, \phi_0) \right) \phi_1^2.$$

This is a linear, nonhomogeneous equation for  $\phi_2$ . Recalling (5.12), its solution can be written in the form

$$(5.22) \qquad \qquad \qquad \begin{aligned} \phi_2(x) = \int_0^R K(x, y) \cdot & \left[ \left( \frac{\phi_1''}{\phi_0} + f_\phi(y, \phi_0)\phi_1 - \phi_1 \frac{\phi_0''}{\phi_0^2} \right) \phi_1 \right. \\ & \left. - \left( \frac{1}{2} f_{\phi\phi}(y, \phi_0)\phi_0 + f_\phi(y, \phi_0) \right) \phi_1^2 \right] dy. \end{aligned}$$

Here  $K(x, y)$  is a Green kernel and all terms inside the square brackets are evaluated at the point  $y$ . Integrating by parts we obtain

$$\begin{aligned}
 \phi_2(x) &= \int_0^R K(x, y) \cdot \left[ \phi_1'' \frac{\phi_1}{\phi_0} - \phi_0'' \frac{\phi_1^2}{\phi_0^2} - \frac{1}{2} f_{\phi\phi}(y, \phi_0) \phi_0 \phi_1^2 \right] dy \\
 &= - \int_0^R \left( K_y \frac{\phi_1}{\phi_0} + K \frac{\phi_1'}{\phi_0} - K \frac{\phi_1 \phi_0'}{\phi_0^2} \right) \phi_1' dy \\
 &\quad + \int_0^R \left( K_y \frac{\phi_1^2}{\phi_0^2} + K \frac{2\phi_1 \phi_1'}{\phi_0^2} - 2K \frac{\phi_1^2 \phi_0'}{\phi_0^3} \right) \phi_0' dy \\
 &\quad - \int_0^R \frac{1}{2} K f_{\phi\phi}(y, \phi_0) \phi_0 \phi_1^2 dy.
 \end{aligned}
 \tag{5.23}$$

We now observe that  $\phi_0$  is uniformly bounded and Lipschitz continuous, and bounded away from zero. Similarly, the kernel  $K$  is uniformly bounded and Lipschitz continuous w.r.t. both variables  $x, y$ . From (5.21) we thus derive an estimate of the form

$$\|\phi_2\|_{C^0} \leq C_2 \int_0^R [(\phi_1')^2 + \phi_1^2] dx
 \tag{5.24}$$

for some constant  $C_2$ .

3. Since the quadratic form  $Q$  in (5.14) by assumption is strictly positive definite, by continuity we can assume that, for all  $\|\mu\| \leq 2\delta^\sharp$ , the corresponding quadratic form is also strictly positive definite, namely,

$$\begin{aligned}
 Q^{\nu+\mu}(v) &\doteq \int_0^R \left( \frac{1}{\phi_0} (v')^2 - 3 \frac{\phi_0'}{\phi_0^2} v' v + \left( 2 \frac{(\phi_0')^2}{\phi_0^3} - f_\phi(x, \phi_0) \right) v^2 \right) dx \\
 &\geq \varepsilon_0 \int_0^R [(v')^2 + v^2] dx
 \end{aligned}
 \tag{5.25}$$

for some constant  $\varepsilon_0 > 0$ . Here  $\phi_0$  is the solution of the first equation in (5.8). Of course, as  $\nu + \mu \rightarrow 0$ , we have  $\phi_0 \rightarrow \psi_0$ .

Going back to the expression (5.10) for the second derivative, we obtain the estimate

$$\begin{aligned}
 \frac{d^2}{ds^2} J(\mu + s\sigma) \Big|_{s=0} &= \int_0^R \phi_1 d\sigma + \int_0^R \phi_2 d\mu \\
 &\leq -Q^{\nu+\mu}(\phi_1) + \|\phi_2\|_{C^0} \|\mu\| \\
 &\leq (-\varepsilon_0 + C_2 \|\mu\|) \int_0^R [(\phi_1')^2 + \phi_1^2] dx.
 \end{aligned}
 \tag{5.26}$$

If  $\|\mu\| < \varepsilon_0/C_2$ , then either  $\phi_1 \equiv 0$  or the left-hand side in (5.26) is strictly negative. We conclude that, at  $\epsilon = \bar{\epsilon}$ , either the first derivative  $dJ(\mu^\epsilon)/d\epsilon$  vanishes or else the second derivative is strictly negative. Since  $\bar{\epsilon} \in [0, 1]$  was arbitrary, this shows that there can be at most one optimal solution within the set of measures  $\mu$  such that  $\|\nu + \mu\| \leq \delta^\sharp$ .

4. To prove the last statement, assume that  $\nu = 0$  and (5.16) holds. In this case, we claim that any optimal solution  $\mu$  satisfies  $\|\mu\| \leq \delta^\sharp$ . Indeed, if  $\|\mu\| > \delta^\sharp$ , observing that  $\phi(x) \leq h_{max}$  and  $c(x) \geq c_0$  for all  $x \in [0, R]$ , and using the convexity

of the function  $\Psi$ , we compute

$$(5.27) \quad \int_0^R \phi(x) d\mu - \Psi \left( \int_0^R c(x) d\mu \right) \leq h_{\max} \|\mu\| - \Psi(c_0 \|\mu\|) \\ \leq h_{\max} \|\mu\| - \Psi(c_0 \delta^\#) \cdot \frac{\|\mu\|}{\delta^\#} < 0.$$

By (5.27) the measure  $\mu$  achieves a negative payoff and is not optimal, being worse than the zero measure, which achieves a null payoff.  $\square$

**6. Solutions to the differential game.** The aim of this section is to establish the existence of measure-valued, Nash equilibrium solutions to a differential game with  $m$  players. Denoting by  $\mu_i$  the intensity of fishing by the  $i$ th company, the density of fish population will satisfy

$$(6.1) \quad \phi'' + f(x, \phi)\phi = \phi \cdot \sum_{i=1}^m \mu_i, \quad \phi'(0) = \phi'(R) = 0.$$

We always assume that the function  $f$  satisfies assumptions (A1). The goal of the  $i$ th player is to maximize his payoff

$$(6.2) \quad J_i \doteq \int_0^R \phi(x) d\mu_i dx - \Psi \left( \int_0^R c_i(x) d\mu_i(x) \right)$$

among all nonnegative measures  $\mu_i \in \mathcal{M}_+$  on the closed interval  $[0, R]$ , subject to the constraint

$$(6.3) \quad \|\mu_i\| = \mu_i([0, R]) \leq \delta_i.$$

Notice that by (6.3) we impose an upper bound on the total amount of fishing activity carried out by the  $i$ th company. In practice, this limitation is due to the finite number of boats, fishermen, and working hours.

**DEFINITION 3.** *By a Nash equilibrium solution we mean an  $m$ -tuple of nonnegative Radon measures  $\mu = (\mu_1, \dots, \mu_m)$  such that, for each  $i = 1, \dots, m$ , the following holds. Setting  $\nu \doteq \sum_{j \neq i} \mu_j$ , the measure  $\sigma = \mu_i$  provides a solution to the optimization problem*

$$(6.4) \quad \text{maximize:} \quad J_i(\sigma) = \int_0^R \phi d\sigma - \Psi_i \left( \int_0^R c_i(x) d\sigma \right),$$

*subject to the bound (6.3) and with*

$$(6.5) \quad \phi''(x) + f(x, \phi)\phi - \phi \cdot \nu = \phi \cdot \sigma, \quad \phi'(0) = \phi'(R) = 0.$$

On the cost functionals  $J_i$  we make the following assumptions:

(A2) <sub>$i$</sub>  The cost function  $c_i : [0, R] \mapsto [c_0, \infty]$  is lower semicontinuous and strictly positive. Moreover, the function  $\Psi_i$  is convex and lower semicontinuous and satisfies

$$(6.6) \quad \Psi_i(0) = 0, \quad \Psi'_i(0) = 1.$$

THEOREM 3. *Let assumptions (A1) hold, together with (A2)<sub>i</sub>, for every  $i = 1, \dots, m$ . Moreover, assume that the solution  $\psi_0$  of (5.5) satisfies (5.15). Then there exists  $\delta > 0$  such that if*

$$(6.7) \quad \sum_{i=1}^m \delta_i \leq \delta,$$

*then the differential game (6.1)–(6.3) admits a Nash equilibrium solution.*

*Proof.* 1. By the analysis in section 4, for a given measure  $\nu$ , the optimization problem (6.3)–(6.5) for the  $i$ th player has at least one solution. The presence of the additional constraint (6.3) actually simplifies the proof, because the upper bound on  $\|\mu_i\|$  is now explicitly assumed. If

$$\|\mu_i\| + \|\nu\| = \|\mu_i\| + \sum_{j \neq i} \|\mu_j\| \leq \sum_{j=1}^m \delta_i$$

is sufficiently small, by Theorem 2 this optimal solution  $\mu_i$  is unique. We can thus write  $\mu_i = \mathcal{T}_i(\nu)$ , for a suitable transformation  $\mathcal{T}_i$  in the space of positive Radon measures.

2. Consider the compact set  $\mathcal{K}$  consisting of  $m$ -tuples of nonnegative measures  $\mu = (\mu_1, \dots, \mu_m)$  such that

$$\|\mu_i\| \leq \delta_i \quad i = 1, \dots, m.$$

Define the transformation  $\mathcal{T} : \mathcal{K} \mapsto \mathcal{K}$  by setting

$$\mathcal{T}(\mu) = (\mathcal{T}_1(\nu_1), \dots, \mathcal{T}_m(\nu_m)).$$

Here  $\mathcal{T}_i(\nu_i)$  is the measure providing the unique optimal solution to the problem (6.3)–(6.5), with  $\nu = \nu_i \doteq \sum_{j \neq i} \mu_j$ .

By the previous analysis, the map  $\mathcal{T}$  is a well-defined transformation of  $\mathcal{K}$  into itself. We claim that  $\mathcal{T}$  is continuous w.r.t. the weak convergence of measures. Indeed, consider a sequence of  $m$ -tuples of Radon measures  $(\mu_{1,n}, \dots, \mu_{m,n})_{n \geq 1}$ , and assume the weak convergence  $\mu_{i,n} \rightharpoonup \mu_i$  as  $n \rightarrow \infty$  for each  $i = 1, \dots, m$ . Of course, this implies the weak convergence

$$(6.8) \quad \nu_{i,n} \doteq \sum_{j \neq i} \mu_{j,n} \rightharpoonup \nu_i \doteq \sum_{j \neq i} \mu_j.$$

For each  $n \geq 1$ , let  $\sigma_{i,n} = \mathcal{T}_i(\nu_{i,n})$  be the unique measure that optimizes the corresponding problem (6.3)–(6.5), with  $\nu = \nu_{i,n}$ . Moreover, let  $\sigma_i$  be the measure which provides the optimal solution of (6.3)–(6.5) when  $\nu = \nu_i$ . We claim that the weak convergence  $\sigma_{i,n} \rightharpoonup \sigma_i$  holds. By a compactness argument, by possibly taking a subsequence we can assume that  $\sigma_{i,n} \rightharpoonup \sigma_{i,\infty}$  for some Radon measure  $\sigma_{i,\infty}$  with  $\|\sigma_{i,\infty}\| \leq \delta_i$ . To prove our claim, it suffices to show that  $\sigma_{i,\infty}$  provides an optimal solution to the problem of (6.3)–(6.5) when  $\nu = \nu_i$ . Indeed, the uniqueness result proved in section 5 will then imply  $\sigma_i = \sigma_{i,\infty}$ .

By the Ascoli–Arzelà theorem, we can assume the convergence  $\phi_n \rightarrow \phi_\infty$  of the corresponding solutions of (6.5), uniformly on  $[0, R]$ . Observe that  $\phi_\infty$  provides the solution of (6.5), with  $\nu = \nu_i$  and  $\sigma = \sigma_{i,\infty}$ . In particular,

$$(6.9) \quad \lim_{n \rightarrow \infty} \int_0^R \phi_n d\sigma_{i,n} = \int_0^R \phi_\infty d\sigma_{i,\infty}.$$

Using the assumptions of lower semicontinuity, we obtain

$$(6.10) \quad \Psi \left( \int_0^R c_i(x) d\sigma_{i,\infty} \right) \leq \liminf_{n \rightarrow \infty} \Psi \left( \int_0^R c_i(x) d\sigma_{i,n} \right).$$

Now let  $\hat{\phi}_n$  be the solution of (6.5) with  $\nu = \nu_{i,n}$  and  $\sigma = \sigma_i$ . Observe that  $\hat{\phi}_n \rightarrow \phi_\infty$  uniformly on  $[0, R]$ . Moreover, when  $\nu = \nu_{i,n}$  the measure  $\sigma_{i,n}$  performs better than  $\sigma_i$ . Therefore

$$\begin{aligned} & \int_0^R \phi_\infty d\sigma_{i,\infty} - \Psi \left( \int_0^R c_i(x) d\sigma_{i,\infty} \right) \\ & \geq \limsup_{n \rightarrow \infty} \left[ \int_0^R \phi_n d\sigma_{i,n} - \Psi \left( \int_0^R c_i(x) d\sigma_{i,n} \right) \right] \\ & \geq \lim_{n \rightarrow \infty} \left[ \int_0^R \hat{\phi}_n d\sigma_i - \Psi \left( \int_0^R c_i(x) d\sigma_i \right) \right] \\ & = \int_0^R \phi_\infty d\sigma_i - \Psi \left( \int_0^R c_i(x) d\sigma_i \right). \end{aligned}$$

The above inequalities show that the strategy  $\sigma_{i,\infty}$  achieves a payoff at least as good as  $\sigma_i$ . Hence it is optimal. By uniqueness, we conclude that  $\sigma_{i,\infty} = \sigma_i$ , as claimed. This establishes the continuity of the transformation  $\mathcal{T}$ , w.r.t. the topology of weak convergence of measures.

3. We now observe that  $\mathcal{T}$  is a continuous map from the compact, convex set  $\mathcal{K}$  into itself. By Schauder's fixed point theorem, it admits at least one fixed point  $\mu^* = (\mu_1^*, \dots, \mu_m^*)$ . By definition, this provides the required Nash equilibrium solution to the differential game.  $\square$

**7. Concluding remarks.** In this paper, we observed that a natural formulation of the optimal harvesting problem involves cost functionals with sublinear growth. As a consequence, the optimal strategies can be measure-valued. We expect that this optimal measure  $\mu^*$  will indeed be singular w.r.t. Lebesgue measure when the cost function  $c = c(x)$  is discontinuous. Results in this direction should be obtained by deriving necessary conditions for optimality.

Another issue that deserves further investigation is the range of validity of the uniqueness result. Here we established uniqueness of optimal strategies within a class of measures with small total mass. This result seems far from optimal. For applications, it would be useful to also cover the case of large-size control measures  $\mu^*$ . From our analysis, uniqueness appears to be related to the smallness of the gradient  $\nabla\phi$  of the solution. This might yield other forms of the uniqueness result. It would also be interesting to study the case of loss of uniqueness, looking for counterexamples in the case where  $\nabla\phi$  has large oscillations.

## LINEAR QUADRATIC DIFFERENTIAL GAMES: CLOSED LOOP SADDLE POINTS\*

MICHEL C. DELFOUR<sup>†</sup> AND OLIVIER DELLO SBARBA<sup>†</sup>

**Abstract.** The object of this paper is to revisit the results of Bernhard [*J. Optim. Theory Appl.*, 27 (1979), pp. 51–69] on two-person zero-sum linear quadratic differential games and generalize them to utility functions without positivity assumptions on the matrices acting on the state variable and to linear dynamics with bounded measurable data matrices. Our paper specializes to *state feedback* via Lebesgue measurable *affine closed loop strategies* with possible non- $L^2$ -integrable singularities. After sharpening the recent results of Delfour [*SIAM J. Control Optim.*, 46 (2007), pp. 750–774] on the characterization of the open loop lower and upper values of the game, it first deals with  $L^2$ -integrable closed loop strategies and then with the larger family of strategies that may have non- $L^2$ -integrable singularities. A new conceptually meaningful and mathematically precise definition of a closed loop saddle point is introduced to simultaneously handle state feedbacks of the  $L^2$  type and smooth locally bounded ones, except at most in the neighborhood of finitely many instants of time. A necessary and sufficient condition is that the free end problem be *normalizable almost everywhere*. This relaxation of the classical notion allows singularities in the feedback law at an infinite number of instants, including accumulation points that are not isolated. A complete classification of closed loop saddle points is given in terms of the convexity/concavity properties of the utility function, and connections are given with the open loop lower value, upper value, and value of the game.

**Key words.** linear quadratic differential game, two person, zero sum, saddle point, value of a game, Riccati differential equation, open loop and closed loop strategies, integrable singularities

**DOI.** 10.1137/070696593

**1. Introduction.** The object of this paper is to revisit the pioneering work of Bernhard [2, 3] on two-person zero-sum linear quadratic differential games and generalize it to utility functions without positivity assumptions on the matrices acting on the state variable and to linear dynamics with bounded measurable data matrices. Our paper specializes to *state feedback* via Lebesgue measurable *affine closed loop strategies* with possible non- $L^2$ -integrable singularities. After sharpening the recent results of Delfour [5] on the characterization of the open loop lower and upper values of the game in section 2, it first deals with  $L^2$ -integrable closed loop strategies and then with the larger family of strategies that may have non- $L^2$ -integrable singularities.

In section 3 several equivalent necessary and sufficient conditions are given for the existence of a closed loop saddle point with respect to  $L^2$ -integrable affine closed loop strategies, for instance, the *normality* of the problem; the existence of an  $H^1(0, T)$  solution to the associated matrix Riccati differential equation. It was shown in [5] that the existence of a solution to the coupled state-adjoint state system is a necessary condition for the existence of a finite open loop lower value, upper value, or value of the game, and that the difference essentially depends on the convexity of the utility function with respect to the control of the minimizing player and on its concavity with respect to the control of the maximizing player. This condition is also necessary

for the existence of a closed loop saddle point. It leads to a complete classification in terms of the convexity/concavity properties of the utility function.

Section 4 deals with two delicate issues. The first is the very definition of a closed loop saddle point in the presence of closed loop strategies with non- $L^2$ -integrable singularities. As was pointed out in [2, p. 68 and Remark 5.1] such strategies may lead to conflicting terms that simultaneously blow up in the utility function. Under the positivity assumptions, one may possibly get around this problem by setting the utility function equal to  $\pm\infty$ , but we do not have them here. So we had to introduce a new conceptually meaningful and mathematically precise definition (cf. Definition 4.5). It states that the original problem can be transformed via feedback in such a way that the resulting problem has an open loop saddle point at  $(0,0)$ . The second related issue is to specify the class of affine closed loop strategies (cf. Definition 4.3) in such a way that we can simultaneously handle, in the same framework,  $L^2$ -integrable closed loop strategies and smooth locally bounded ones, except at most in the neighborhood of finitely many instants of time as in [2].

It turns out that the classical definition of a closed loop saddle point (cf. Definition 3.2) can be an *undeterminate* or a *degenerate* one when either the open loop lower or upper value of the game is not finite (cf. Theorems 4.4 and 4.5). For instance, Berkovitz's equivalence [1] (see our Lemma 3.2) may not apply, as shown in Example 4.2. The proper point of view is that of Definition 4.1, which states that the two closed loop strategies cannot be chosen independently. They must be linked through the *admissibility condition* of Definition 4.3. This subtle difference fundamentally changes the nature of the problem and makes it different from the classical theory of saddle points with respect to two independent sets. We show that the slight relaxation of the definition of *normalizability* of the free end problem in the sense of [2, Definition 3.2] from isolated instants to a set of instants of zero measure is a necessary and sufficient condition for the existence of a closed loop saddle point. This relaxation of the classical notion allows singularities in the feedback law at an infinite number of instants, including accumulation points that are not isolated. This condition is also used to make sense of solutions with singularities to the matrix Riccati differential equation.

In section 4.7, we show that under the convexity-concavity condition, Definitions 3.2 and 4.5 of closed loop saddle points coincide and that closed loop strategies with non- $L^2$ -integrable singularities are useless. These singularities naturally occur when either the open loop lower or upper value of the game is not finite. We complete the classification of closed loop saddle points in section 4.8 along with conditions expressed in terms of the convexity/concavity properties of the utility function. We conclude in section 4.9 with an example of a nonnormalizable problem with finite open loop lower value that can be achieved by state feedback via a solution of the matrix Riccati differential equation.

## 2. Definitions, notation, and main results.

**2.1. System, utility function, values of the game.** Given a finite dimensional Euclidean space  $\mathbf{R}^d$  of dimension  $d \geq 1$ , the *norm* and *inner product* will be denoted by  $|x|$  and  $x \cdot y$ , respectively, and irrespective of the dimension  $d$  of the space. Given  $T > 0$ , the norm and inner product in  $L^2(0, T; \mathbf{R}^n)$  will be denoted  $\|f\|$  and  $(f, g)$ . The norm in the Sobolev space  $H^1(0, T; \mathbf{R}^n)$  will be written  $\|f\|_{H^1}$ .

Consider the following two-player zero-sum game over the finite time interval

$[0, T]$  characterized by the quadratic *utility function*

$$(2.1) \quad C_{x_0}(u, v) \stackrel{\text{def}}{=} Fx(T) \cdot x(T) + \int_0^T Q(t)x(t) \cdot x(t) + |u(t)|^2 - |v(t)|^2 dt,$$

where  $x$  is the solution of the linear differential system

$$(2.2) \quad x'(t) = A(t)x(t) + B_1(t)u(t) + B_2(t)v(t) \quad \text{a.e. in } [0, T], \quad x(0) = x_0,$$

$x_0 \in \mathbf{R}^n$  is the *initial state* at time  $t = 0$ ,  $u \in L^2(0, T; \mathbf{R}^m)$ ,  $m \geq 1$ , is the strategy of the first player, and  $v \in L^2(0, T; \mathbf{R}^k)$ ,  $k \geq 1$ , is the strategy of the second player. We assume that  $F$  is an  $n \times n$ -matrix and that  $A$ ,  $B_1$ ,  $B_2$ , and  $Q$  are matrix-functions of appropriate orders that are measurable and bounded almost everywhere in  $[0, T]$ . Moreover,  $Q(t)$  and  $F$  are symmetrical. It will be convenient to use the following compact notation and drop the a.e. in  $[0, T]$  wherever no confusion arises:

$$(2.3) \quad C_{x_0}(u, v) = Fx(T) \cdot x(T) + \int_0^T Qx \cdot x + |u|^2 - |v|^2 dt,$$

$$(2.4) \quad x' = Ax + B_1u + B_2v \quad \text{in } [0, T], \quad x(0) = x_0.$$

The above assumptions on  $F$ ,  $A$ ,  $B_1$ ,  $B_2$ , and  $Q$  will be used throughout this paper. The transpose of a matrix  $M$  will be denoted  $M^\top$ , the inverse of its transpose  $M^{-\top}$ , and  $R(t)$  will denote the matrix  $B_1(t)B_1(t)^\top - B_2(t)B_2(t)^\top$ .

DEFINITION 2.1. Let  $x_0$  be an initial state in  $\mathbf{R}^n$  at time  $t = 0$ .

(i) The game is said to achieve its open loop lower value (resp., upper value) if

$$(2.5) \quad v^-(x_0) \stackrel{\text{def}}{=} \sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v)$$

$$(2.6) \quad \left( \text{resp., } v^+(x_0) \stackrel{\text{def}}{=} \inf_{u \in L^2(0, T; \mathbf{R}^m)} \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v) \right)$$

is finite. By definition,  $v^-(x_0) \leq v^+(x_0)$ .

(ii) The game is said to achieve its open loop value if its open loop lower value  $v^-(x_0)$  and upper value  $v^+(x_0)$  are achieved and  $v^-(x_0) = v^+(x_0)$ . The open loop value of the game will be denoted by  $v(x_0)$ .

(iii) A pair  $(\bar{u}, \bar{v})$  in  $L^2(0, T; \mathbf{R}^m) \times L^2(0, T; \mathbf{R}^k)$  is an open loop saddle point of  $C_{x_0}(u, v)$  in  $L^2(0, T; \mathbf{R}^m) \times L^2(0, T; \mathbf{R}^k)$  if for all  $u$  in  $L^2(0, T; \mathbf{R}^m)$  and all  $v$  in  $L^2(0, T; \mathbf{R}^k)$ ,

$$(2.7) \quad C_{x_0}(\bar{u}, v) \leq C_{x_0}(\bar{u}, \bar{v}) \leq C_{x_0}(u, \bar{v}).$$

DEFINITION 2.2. Associate with  $x_0 \in \mathbf{R}^n$  the sets

$$(2.8) \quad V(x_0) \stackrel{\text{def}}{=} \left\{ v \in L^2(0, T; \mathbf{R}^k) : \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) > -\infty \right\},$$

$$(2.9) \quad U(x_0) \stackrel{\text{def}}{=} \left\{ u \in L^2(0, T; \mathbf{R}^m) : \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v) < +\infty \right\}.$$

**2.2. Properties of the utility function.** Recall from [5] that the utility function  $C_{x_0}(u, v)$  is infinitely differentiable and that its Hessian of second order derivatives is independent of  $(u, v)$ . Indeed,<sup>1</sup>

$$(2.10) \quad \frac{1}{2}dC_{x_0}(u, v; \bar{u}, \bar{v}) = Fx(T) \cdot \bar{y}(T) + (Qx, \bar{y}) + (u, \bar{u}) - (v, \bar{v}),$$

where  $x$  is the solution of (2.4) and  $\bar{y}$  is the solution of

$$(2.11) \quad \bar{y}' = A\bar{y} + B_1\bar{u} + B_2\bar{v}, \quad \bar{y}(0) = 0.$$

It is customary to introduce the *adjoint system*

$$(2.12) \quad p' + A^\top p + Qx = 0, \quad p(T) = Fx(T)$$

and rewrite expression (2.10) for the gradient in the form

$$(2.13) \quad \frac{1}{2}dC_{x_0}(u, v; \bar{u}, \bar{v}) = (B_1^\top p + u, \bar{u}) + (B_2^\top p - v, \bar{v}).$$

Hence  $dC_{x_0}(\hat{u}, \hat{v}; \bar{u}, \bar{v}) = 0$  for all  $\bar{u}$  and  $\bar{v}$  if and only if the *coupled system*

$$(2.14) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(0) = x_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T) \end{cases}$$

has a solution  $(\hat{x}, \hat{p})$  in  $H^1(0, T; \mathbf{R}^n)^2$  with  $(\hat{u}, \hat{v}) = (-B_1^\top \hat{p}, B_2^\top \hat{p})$ .

As expected, the Hessian is independent of  $(u, v)$ ,

$$(2.15) \quad \frac{1}{2}d^2C_{x_0}(u, v; \bar{u}, \bar{v}; \hat{u}, \hat{v}) = F\tilde{y}(T) \cdot \bar{y}(T) + (Q\tilde{y}, \bar{y}) + (\tilde{u}, \bar{u}) - (\tilde{v}, \bar{v}),$$

where  $\bar{y}$  is the solution of (2.11) and  $\tilde{y}$  is the solution of

$$(2.16) \quad \tilde{y}' = A\tilde{y} + B_1\tilde{u} + B_2\tilde{v}, \quad \tilde{y}(0) = 0.$$

In particular, for all  $x_0, u, v, \bar{u}$ , and  $\bar{v}$ ,  $d^2C_{x_0}(u, v; \bar{u}, \bar{v}; \bar{u}, \bar{v}) = 2C_0(\bar{u}, \bar{v})$ .

**2.3. Games with finite open loop lower or upper values.** We recall and sharpen the results of [5, Thms. 2.2, 2.3, and 2.4] when the open loop lower or upper value of the game is finite for a given initial state  $x_0$ . In each case, the global assumption of finiteness for *all* initial state  $x_0 \in \mathbf{R}^n$  yields the *uniqueness* of solution  $(x, p)$  of the coupled system (2.14) (cf. [5, Thms. 2.6, 2.7, and 2.8]).

**THEOREM 2.1.** *The following conditions are equivalent.*

(i) *There exist  $\hat{u}$  in  $L^2(0, T; \mathbf{R}^m)$  and  $\hat{v}$  in  $L^2(0, T; \mathbf{R}^k)$  such that*

$$(2.17) \quad C_{x_0}(\hat{u}, \hat{v}) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, \hat{v}) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v).$$

(ii) *The open loop lower value  $v^-(x_0)$  of the game is finite.*

<sup>1</sup>Given a real function  $f$  defined on a Banach space  $B$ , the *first directional semiderivative* at  $x$  in the direction  $v$  (when it exists) is defined as  $df(x; v) = \lim_{t \searrow 0} (f(x + tv) - f(x))/t$ . When the map  $v \mapsto df(x; v) : B \rightarrow \mathbf{R}$  is linear and continuous, it defines the *gradient*  $\nabla f(x)$  as an element of the dual  $B^*$  of  $B$ . The *second order bidirectional derivative* at  $x$  in the directions  $(v, w)$  (when it exists) is defined as  $d^2f(x; v, w) = \lim_{t \searrow 0} (df(x + tw; v) - df(x; v))/t$ . When the map  $(v, w) \mapsto d^2f(x; v, w) : B \times B \rightarrow \mathbf{R}$  is bilinear and continuous, it defines the *Hessian operator*  $Hf(x)$  as a continuous linear operator from  $B$  to  $B^*$ .

(iii) *There exists a solution in  $H^1(0, T; \mathbf{R}^n)^2$  of the coupled system*

$$(2.18) \quad \begin{cases} x' = Ax - Rp, & x(0) = x_0, \\ p' + A^\top p + Qx = 0, & p(T) = Fx(T), \end{cases}$$

*and the following identities are verified:*

$$(2.19) \quad \sup_{v \in V(0)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_0(u, v) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_0(u, 0) = C_0(0, 0).$$

*Under such conditions, the optimal controls and the open loop lower value are given by the expressions*

$$(2.20) \quad \hat{u} = -B_1^\top p, \quad \hat{v} = B_2^\top p, \quad \text{and} \quad C_{x_0}(\hat{u}, \hat{v}) = p(0) \cdot x_0.$$

*Remark 2.1.* The additional condition  $B_2^\top p \in V(x_0)$  that appeared in [5, Thms. 2.2 and 2.6] is redundant. To see that, recall that the last identity (2.19) is equivalent to the convexity of the mapping  $u \mapsto C_{x_0}(u, v)$ . By [5, Thm. 3.1] the convexity plus a solution of the coupled system (2.18) yields that

$$\inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, B_2^\top p) = C_{x_0}(-B_1^\top p, B_2^\top p) > -\infty \quad \Rightarrow \quad B_2^\top p \in V(x_0).$$

Similarly, the additional condition  $-B_1^\top p \in U(x_0)$  that appeared in [5, Thms. 2.3 and 2.7] is also redundant.

**THEOREM 2.2.** *The following conditions are equivalent.*

(i) *There exist  $\hat{u}$  in  $L^2(0, T; \mathbf{R}^m)$  and  $\hat{v}$  in  $L^2(0, T; \mathbf{R}^k)$  such that*

$$(2.21) \quad C_{x_0}(\hat{u}, \hat{v}) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(\hat{u}, v) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v).$$

(ii) *The open loop upper value  $v^+(x_0)$  of the game is finite.*

(iii) *There exists a solution  $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$  of the coupled system (2.18), and the following identities are verified:*

$$(2.22) \quad \inf_{u \in U(0)} \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_0(u, v) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_0(0, v) = C_0(0, 0).$$

*Under such conditions, the optimal controls and the open loop upper value are given by expressions (2.20).*

For the case when  $v^-(x_0)$  and  $v^+(x_0)$  are both finite, Zhang [9] proved that they are equal. So by combining this with the previous theorems, we get the complete picture.

**THEOREM 2.3.** *The following conditions are equivalent.*

(i) *There exist  $\hat{u}$  in  $L^2(0, T; \mathbf{R}^m)$  and  $\hat{v}$  in  $L^2(0, T; \mathbf{R}^k)$  such that*

$$(2.23) \quad \begin{aligned} C_{x_0}(\hat{u}, \hat{v}) &= \inf_{u \in L^2(0, T; \mathbf{R}^m)} \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v) \\ &= \sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) \end{aligned}$$

*(that is,  $C_{x_0}(u, v)$  has a saddle point).*

(ii) *The open loop value  $v(x_0)$  of the game is finite.*

- (iii) *There exists a solution  $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$  of the coupled system (2.18), and the following identities are verified:*

$$(2.24) \quad \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_0(u, 0) = C_0(0, 0) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_0(0, v).$$

- (iv) *The lower and upper open loop values,  $v^-(x_0)$  and  $v^+(x_0)$ , are finite. Under such conditions, the optimal controls and the value are given by expressions (2.20) and  $v(x_0) = v^-(x_0) = v^+(x_0)$ .*

There are six possible cases according to the fact that  $v^-(x_0)$  and  $v^+(x_0)$  are finite,  $-\infty$ , or  $+\infty$ . If either  $v^-(x_0)$  or  $v^+(x_0)$  is finite, there is a solution  $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$  of the coupled system (2.18), and we have the following three cases:

$$\begin{aligned} \text{(a)} \quad & \left| \begin{array}{l} v^-(x_0) \text{ finite} \\ v^+(x_0) \text{ finite} \end{array} \right| \left| \begin{array}{l} \inf_u C_0(u, 0) = C_0(0, 0) \\ \sup_v C_0(0, v) = C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ convex} \\ v \mapsto C_0(0, v) \text{ concave} \end{array} \right| \\ \text{(b)} \quad & \left| \begin{array}{l} v^-(x_0) \text{ finite} \\ v^+(x_0) = +\infty \end{array} \right| \left| \begin{array}{l} \inf_u C_0(u, 0) = C_0(0, 0) \\ \sup_v \inf_u C_0(u, v) = C_0(0, 0) \\ \sup_v C_0(0, v) > C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ convex} \\ v \mapsto \inf_u C_0(u, v) \text{ concave} \\ v \mapsto C_0(0, v) \text{ not concave} \end{array} \right| \\ \text{(c)} \quad & \left| \begin{array}{l} v^-(x_0) = -\infty \\ v^+(x_0) \text{ finite} \end{array} \right| \left| \begin{array}{l} \inf_u C_0(u, 0) < C_0(0, 0) \\ \inf_u \sup_v C_0(u, v) = C_0(0, 0) \\ \sup_v C_0(0, v) = C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ not convex} \\ u \mapsto \sup_v C_0(u, v) \text{ convex} \\ v \mapsto C_0(0, v) \text{ concave} \end{array} \right| \end{aligned}$$

There are three more cases as follows that can occur even if the coupled system (2.18) has a solution  $(x, p) \in H^1(0, T; \mathbf{R}^n)^2$  and neither  $v^-(x_0)$  nor  $v^+(x_0)$  is finite:

$$\begin{aligned} \text{(d)} \quad & \left| \begin{array}{l} v^-(x_0) = -\infty \\ v^+(x_0) = +\infty \end{array} \right| \left| \begin{array}{l} \inf_u C_0(u, 0) < C_0(0, 0) \\ \sup_v C_0(0, v) > C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ not convex} \\ v \mapsto C_0(0, v) \text{ not concave} \end{array} \right| \\ \text{(e)} \quad & \left| \begin{array}{l} v^-(x_0) = +\infty \\ v^+(x_0) = +\infty \end{array} \right| \left| \begin{array}{l} \inf_u C_0(u, 0) = C_0(0, 0) \\ \sup_v \inf_u C_0(u, v) > C_0(0, 0) \\ \sup_v C_0(0, v) > C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ convex} \\ v \mapsto \inf_u C_0(u, v) \text{ not concave} \\ v \mapsto C_0(0, v) \text{ not concave} \end{array} \right| \\ \text{(f)} \quad & \left| \begin{array}{l} v^-(x_0) = -\infty \\ v^+(x_0) = -\infty \end{array} \right| \left| \begin{array}{l} \inf_u \sup_v C_0(u, v) < C_0(0, 0) \\ \inf_u C_0(u, 0) < C_0(0, 0) \\ \sup_v C_0(0, v) = C_0(0, 0) \end{array} \right| \left| \begin{array}{l} u \mapsto C_0(u, 0) \text{ not convex} \\ u \mapsto \sup_v C_0(u, v) \text{ not convex} \\ v \mapsto C_0(0, v) \text{ concave} \end{array} \right| \end{aligned}$$

Case (d) can occur by combining a system of type (b) with a system of type (c) and a utility function equal to the sum of the two utility functions. Case (e) occurs for the following system and utility function:

$$(2.25) \quad \begin{aligned} x'(t) &= tu(t) + t^3v(t) \text{ in } [0, 2], \quad x(0) = x_0, \\ C_{x_0}(u, v) &= \frac{3}{8}x(2) \cdot x(2) + \int_0^2 |u(t)|^2 - |v(t)|^2 dt. \end{aligned}$$

Finally, by duality, case (f) can also occur.

**3.  $L^2$ -integrable closed loop strategies.** We generalize classical results to  $L^2$ -integrable affine closed loop feedback strategies for general  $F$  and  $Q(t)$  under the assumptions of section 2.1 on the matrix functions  $A$ ,  $B_1$ ,  $B_2$ ,  $Q$ , and  $F$ . We also give a classification of the possible cases in terms of the open loop properties of lower value, upper value, and value of the game and the convexity/concavity of the utility function.

### 3.1. Definitions and main results.

DEFINITION 3.1 ( $L^2$ -integrable affine closed loop strategies).

$$\Phi \stackrel{\text{def}}{=} \left\{ \phi : [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^m \left| \begin{array}{l} \text{such that } x \mapsto \phi(t, x) \text{ is affine and} \\ t \mapsto \phi(t, x) \text{ belongs to } L^2(0, T; \mathbf{R}^m) \end{array} \right. \right\}.$$

$$\Psi \stackrel{\text{def}}{=} \left\{ \psi : [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^k \left| \begin{array}{l} \text{such that } x \mapsto \psi(t, x) \text{ is affine and} \\ t \mapsto \psi(t, x) \text{ belongs to } L^2(0, T; \mathbf{R}^k) \end{array} \right. \right\}.$$

We say that  $\phi$  or  $\psi$  is linear if  $\phi(t, x)$  or  $\psi(t, x)$  is linear in  $x$ .

Remark 3.1. To each  $\phi \in \Phi$  (resp.,  $\psi \in \Psi$ ) we can associate an  $L^2(0, T; \mathbf{R}^m)$ -vector function  $u$  and an  $m \times n$ -matrix  $L^2$ -function  $U$  such that  $\phi(t, x) = u(t) + U(t)x$  (resp., an  $L^2(0, T; \mathbf{R}^k)$ -vector function  $v$  and a  $k \times n$ -matrix  $L^2$ -function  $V$  such that  $\psi(t, x) = v(t) + V(t)x$ ). The matrix functions  $U$  and  $V$  may have singularities, but they are globally  $L^2$ -integrable. As a result, the fundamental matrix associated with the  $L^2$ -matrix function  $A + B_1U + B_2V$  will be invertible everywhere in  $[0, T]$ . Therefore for all  $\phi \in \Phi$  and  $\psi \in \Psi$ , the closed loop system

$$(3.1) \quad \begin{aligned} x' &= Ax + B_1\phi(x) + B_2\psi(x), \quad x(0) = x_0, \\ x' &= (A + B_1U + B_2V)x + B_1u + B_2v, \quad x(0) = x_0 \end{aligned}$$

has a unique solution in  $H^1(0, T; \mathbf{R}^n)$  for all  $x_0 \in \mathbf{R}^n$ . This means that all pairs  $(\phi, \psi) \in \Phi \times \Psi$  are *admissible*, and, a fortiori, all pairs of the form  $(\phi, v)$  or  $(u, \psi)$  are admissible for all  $u \in L^2(0, T; \mathbf{R}^m)$  and  $v \in L^2(0, T; \mathbf{R}^k)$ .

DEFINITION 3.2.

- (i) Given  $x_0 \in \mathbf{R}^n$ , we say that  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable closed loop saddle point of  $C_{x_0}(\phi, \psi)$  in  $\Phi \times \Psi$  if for all  $\phi \in \Phi$  and  $\psi \in \Psi$ ,

$$(3.2) \quad C_{x_0}(\phi^*, \psi) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi, \psi^*).$$

- (ii) We say that  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable global closed loop saddle point of  $C_{x_0}(\phi, \psi)$  in  $\Phi \times \Psi$  if for all  $x_0 \in \mathbf{R}^n$  and for all  $\phi \in \Phi$  and  $\psi \in \Psi$  the inequalities (3.2) are verified.

By definition,  $C_{x_0}(\phi^*, \psi^*)$  is finite. Thus the saddle point is “nondegenerate” in the sense of [2]. The “global version” is better adapted to closed loop strategies. The interest in a closed loop strategy associated with a single initial state is rather limited.

Given any two pairs  $(\phi_1, \psi_1)$  and  $(\phi_2, \psi_2)$  achieving an  $L^2$ -integrable closed saddle point, the mixed pairs  $(\phi_1, \psi_2)$  and  $(\phi_2, \psi_1)$  are admissible and also achieve an  $L^2$ -integrable closed loop saddle point. Hence the value of the closed loop saddle point is unique (cf. [1]).

LEMMA 3.1. Given  $x_0 \in \mathbf{R}^n$ , for all pairs  $(\phi_1^*, \psi_1^*) \in \Phi \times \Psi$  and  $(\phi_2^*, \psi_2^*) \in \Phi \times \Psi$  verifying (3.2),  $C_{x_0}(\phi_1^*, \psi_1^*) = C_{x_0}(\phi_2^*, \psi_2^*)$ .

We quote Berkovitz’s equivalence lemma [1].

LEMMA 3.2. Given  $x_0 \in \mathbf{R}^n$ , the following statements are equivalent:

- (i)  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable closed loop saddle point of  $C_{x_0}(\phi, \psi)$ ;  
 (ii) there exists a pair  $(\phi^*, \psi^*) \in \Phi \times \Psi$  such that for all  $u \in L^2(0, T; \mathbf{R}^m)$  and all  $v \in L^2(0, T; \mathbf{R}^k)$ ,

$$(3.3) \quad C_{x_0}(\phi^*, v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(u, \psi^*).$$

THEOREM 3.1. *The following statements are equivalent.*

- (i)  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable global closed loop saddle point of  $C_{x_0}(\phi, \psi)$ .  
 (ii) There exists  $(\phi^*, \psi^*) \in \Phi \times \Psi$  such that for all  $x_0 \in \mathbf{R}^n$ ,  $u \in L^2(0, T; \mathbf{R}^m)$ , and  $v \in L^2(0, T; \mathbf{R}^k)$ ,

$$(3.4) \quad C_{x_0}(\phi^*, \psi^* + v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi^* + u, \psi^*).$$

- (iii) For all  $x_0 \in \mathbf{R}^n$  there exist a unique solution  $(\hat{x}, \hat{p}) \in H^1(0, T; \mathbf{R}^n)^2$  of

$$(3.5) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(0) = x_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T) \end{cases}$$

and  $L^2$ -integrable matrices  $U_*$  and  $V_*$  of appropriate orders such that for all  $x_0 \in \mathbf{R}^n$ ,

$$(3.6) \quad \hat{u} = -B_1^\top \hat{p} = U_* \hat{x}, \quad \hat{v} = B_2^\top \hat{p} = V_* \hat{x}.$$

- (iv) (Invariant embedding). For all initial times  $s \in [0, T]$ , there exists a unique  $H^1(s, T)$  solution of the coupled matrix system

$$(3.7) \quad \begin{cases} \hat{X}'_s = A\hat{X}_s - R\hat{\Lambda}_s, & \hat{X}_s(s) = I, \\ \hat{\Lambda}'_s + A^\top \hat{\Lambda}_s + Q\hat{X}_s = 0, & \hat{\Lambda}_s(T) = F\hat{X}_s(T). \end{cases}$$

By convention, set  $\hat{X}_T(T) = I$  and  $\hat{\Lambda}_T(T) = F$ .

- (v) (Normality).  $\det X(t) \neq 0$  everywhere in  $[0, T]$ , where  $(X, \Lambda)$  is the  $H^1(0, T)$  solution of the matrix differential system

$$(3.8) \quad \begin{cases} X' = AX - R\Lambda, & X(T) = I, \\ \Lambda' + A^\top \Lambda + QX = 0, & \Lambda(T) = F. \end{cases}$$

- (vi) There exists a symmetrical solution  $P$  with elements in  $H^1(0, T)$  to the matrix Riccati differential equation

$$(3.9) \quad P' + PA + A^\top P - PRP + Q = 0, \quad P(T) = F.$$

In particular  $C_{x_0}(\phi^*, \psi^*) = P(0)x_0 \cdot x_0$ , and the closed loop strategies are given by

$$(3.10) \quad \phi^*(t, x) = -B_1^\top(t)P(t)x = U_*(t)x \text{ and } \psi^*(t, x) = B_2^\top(t)P(t)x = V_*(t)x.$$

*Proof.* (i)  $\Rightarrow$  (ii). Let  $\hat{x}$  be the trajectory corresponding to the pair  $(\phi^*, \psi^*)$ , and denote by  $(\hat{u}, \hat{v}) = (\phi^*(x), \psi^*(x))$  the corresponding control pair. Let  $U_*(t)$  and  $V_*(t)$  be the respective matrices and  $u_*(t)$  and  $v_*(t)$  be the respective vectors such that  $\phi^*(t, x) = U_*(t)x + u_*(t)$  and  $\psi^*(t, x) = V_*(t)x + v_*(t)$ . Then

$$(3.11) \quad \hat{x}' = (A + B_1U_* + B_2V_*)\hat{x} + B_1u_* + B_2v_*, \quad \hat{x}(0) = x_0.$$

For all  $u \in L^2(0, T; \mathbf{R}^m)$  and  $v \in L^2(0, T; \mathbf{R}^k)$ , the pair  $(\phi^* + u, \psi^* + v) \in \Phi \times \Psi$  and

$$(3.12) \quad C_{x_0}(\phi^*, \psi^* + v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi^* + u, \psi^*).$$

(ii)  $\Rightarrow$  (iii). Introduce the notation  $c_{x_0}(u, v)$  for the utility function  $C_{x_0}(\phi^* + u, \psi^* + v)$ :

$$c_{x_0}(u, v) \stackrel{\text{def}}{=} Fx(T) \cdot x(T) + \int_0^T Qx \cdot x + |U_*x + u_* + u|^2 - |V_*x + v_* + v|^2 dt,$$

and denote by  $x$  the solution of the corresponding state equation

$$(3.13) \quad x' = (A + B_1U_* + B_2V_*)x + B_1(u_* + u) + B_2(v_* + v), \quad x(0) = x_0.$$

Then the closed loop saddle point inequalities (3.12) become open loop saddle point inequalities for system (3.13) and the new quadratic utility function  $c_{x_0}(u, v)$  satisfies the saddle point condition

$$(3.14) \quad \forall u \in L^2(0, T; \mathbf{R}^m) \text{ and } v \in L^2(0, T; \mathbf{R}^k), \quad c_{x_0}(0, v) \leq c_{x_0}(0, 0) \leq c_{x_0}(u, 0),$$

and the pair  $(0, 0)$  achieves that saddle point. By [5, Lemma 3.1]  $c_{x_0}(u, v)$  is convex-concave and  $dc_{x_0}(0, 0; u, v) = 0$  for all  $u$  and  $v$ . In particular, the coupled system

$$(3.15) \quad \begin{cases} \hat{x}' = (A + B_1U_* + B_2V_*)\hat{x} + B_1u_* + B_2v_*, & \hat{x}(0) = x_0, \\ \hat{p}' + (A + B_1U_* + B_2V_*)^\top \hat{p} + Q\hat{x} + U_*^\top (U_*\hat{x} + u_*) - V_*^\top (V_*\hat{x} + v_*) = 0, \\ \hat{p}(T) = F\hat{x}(T), \end{cases}$$

$$0 = -B_1^\top \hat{p} - (U_*\hat{x} + u_*) \text{ and } 0 = B_2^\top \hat{p} - (V_*\hat{x} + v_*)$$

has a solution  $(\hat{x}, \hat{p})$  in  $H^1(0, T; \mathbf{R}^n)^2$ . After substitution, it can be rewritten as

$$(3.16) \quad \begin{aligned} \hat{x}' &= A\hat{x} - R\hat{p}, & \hat{x}(0) &= x_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} &= 0, & \hat{p}(T) &= F\hat{x}(T). \end{aligned}$$

By assumption this is true for all  $x_0 \in \mathbf{R}^n$ . But, when system (3.16) has a solution for all  $x_0$ , its solution is unique (cf, [5, section 2.6, pp. 760–761]). As a result, for  $x_0 = 0$ , we have  $(\hat{x}, \hat{p}) = (0, 0)$ , and from identities (3.15),

$$0 = -B_1^\top \hat{p} - (U_*\hat{x} + u_*) \text{ and } 0 = B_2^\top \hat{p} - (V_*\hat{x} + v_*) \Rightarrow u_* = 0 \text{ and } v_* = 0.$$

Hence the feedback controls are of the form  $\hat{u} = U_*\hat{x} = -B_1^\top \hat{p}$  and  $\hat{v} = V_*\hat{x} = B_2^\top \hat{p}$ .

(iii)  $\Rightarrow$  (iv). By assumption for all  $x_0 \in \mathbf{R}^n$ , the coupled system (3.16) has a unique solution  $(\hat{x}, \hat{p})$ . By linearity of the solution of system (3.5) with respect to  $x_0$ , there exist  $H^1(0, T)$ -matrices  $(\hat{X}, \hat{\Lambda})$  solution of the matrix system

$$(3.17) \quad \begin{aligned} \hat{X}' &= A\hat{X} - R\hat{\Lambda}, & \hat{X}(0) &= I, \\ \hat{\Lambda}' + A^\top \hat{\Lambda} + Q\hat{X} &= 0, & \hat{\Lambda}(T) &= F\hat{X}(T). \end{aligned}$$

But the conditions  $U_*\hat{x} = -B_1^\top \hat{p}$  and  $V_*\hat{x} = B_2^\top \hat{p}$  for all  $x_0$  imply that  $U_*\hat{X} = -B_1^\top \hat{\Lambda}$  and  $V_*\hat{X} = B_2^\top \hat{\Lambda}$ , and  $\hat{X}$  is also the unique solution of the equation

$$(3.18) \quad \hat{X}' = (A + B_1U_* + B_2V_*)\hat{X}, \quad \hat{X}(0) = I.$$

Since the elements of the matrix function  $A + B_1U_* + B_2V_*$  are  $L^2$ -functions, the associated fundamental matrix solution  $\Phi(t, s)$  is invertible,  $\hat{X}(t)x_0 = \hat{x}(t) = \Phi(t, 0)x_0$ , and, a fortiori,  $\hat{X}(t) = \Phi(t, 0)$  is invertible in  $[0, T]$ . In particular, for all  $s \in [0, T[$ ,  $(\hat{X}_s(t), \hat{\Lambda}_s(t)) = (\hat{X}(t)\hat{X}(s)^{-1}, \hat{\Lambda}(t)\hat{X}(s)^{-1})$  is a solution of system (3.7).

(iv)  $\Rightarrow$  (v). First, observe that  $\hat{X}_s(T)$  is invertible for all  $s \in [0, T]$ . For  $s < T$ , let  $h \neq 0$  be such that  $\hat{X}_s(T)h = 0$ . The pair  $(x_s(t), p_s(t)) = (\hat{X}_s(t)h, \hat{\Lambda}_s(t)h)$  is a solution of the system  $x'_s = Ax_s - Rp_s$ ,  $x_s(s) = h$ , and  $p'_s + A^\top p_s + Qx_s = 0$ ,  $p_s(T) = Fx_s(T)$ , with  $(x_s(T), p_s(T)) = (0, 0)$ . Hence  $(x_s, p_s) = (0, 0)$  and  $h = x_s(s) = 0$ , a contradiction. For all  $0 \leq s \leq t \leq T$ ,  $\hat{X}_s(T) = \hat{X}_t(T)\hat{X}_s(t)$  and  $\det \hat{X}_s(t) \neq 0$ . Defining the matrix functions  $(X(t), \Lambda(t)) = (\hat{X}_0(t)\hat{X}_0(T)^{-1}, \hat{\Lambda}_0(t)\hat{X}_0(T)^{-1})$ , they are a solution of the matrix differential system (3.7), and necessarily,  $\det X(t) \neq 0$  everywhere in  $[0, T]$ .

(v)  $\Rightarrow$  (vi). Since  $X(t)$  is invertible for all  $t \in [0, T]$ , then  $P(t) = \Lambda(t)X(t)^{-1}$  is a matrix of  $H^1(0, T)$  functions. Moreover,  $P$  is symmetrical since  $\Lambda^\top X$  is by computing the derivative of  $\Lambda^\top X - X^\top \Lambda$ . Finally,  $P$  is a solution of the Riccati matrix differential equation (3.9). By uniqueness of the solution  $(x, p)$  of (3.5),  $(x(t), p(t)) = (\hat{X}_0(t)x_0, \hat{\Lambda}_0(t)x_0) = (X(t)\hat{X}_0(T)x_0, \Lambda(t)\hat{X}_0(T)x_0)$ . Hence  $p(t) = P(t)x(t)$ ,  $\hat{u}(t) = -B_1^\top p(t) = -B_1^\top P(t)x(t)$ , and  $\hat{v}(t) = B_2^\top p(t) = B_2^\top P(t)x(t)$ .

(vi)  $\Rightarrow$  (i). Let  $x \in H^1(0, T; \mathbf{R}^n)$  be the solution of

$$(3.19) \quad x' = Ax + B_1u + B_2v, \quad x(0) = x_0,$$

and let  $P$  be an  $H^1(0, T)$  solution of the matrix Riccati differential equation (3.9). By the classical argument of Bernhard [2], we get

$$C_{x_0}(u, v) = P(0)x_0 \cdot x_0 + \int_0^T |u + B_1^\top Px|^2 - |v - B_2^\top Px|^2 dt.$$

Choose the closed loop linear strategies  $\phi^*(t, x) = -B_1^\top(t)P(t)x$  and  $\psi^*(t, x) = B_2^\top(t)P(t)x$ . Then for all  $v \in L^2(0, T; \mathbf{R}^k)$  and all  $u \in L^2(0, T; \mathbf{R}^m)$ ,

$$\begin{aligned} C_{x_0}(\phi^*, \psi^*) &= P(0)x_0 \cdot x_0, \\ C_{x_0}(u, \psi^*) &= P(0)x_0 \cdot x_0 + \int_0^T |u + B_1^\top Px|^2 dt \geq P(0)x_0 \cdot x_0 = C_{x_0}(\phi^*, \psi^*), \\ C_{x_0}(\phi^*, v) &= P(0)x_0 \cdot x_0 - \int_0^T |v - B_2^\top Px|^2 dt \leq P(0)x_0 \cdot x_0 = C_{x_0}(\phi^*, \psi^*). \end{aligned}$$

By Lemma 3.2(ii), the linear pair  $(\phi^*, \psi^*)$  is a global closed loop saddle point. Finally, the pair of closed loop strategies  $\phi^*(t, x) = -B_1^\top(t)P(t)x = U_*(t)x$  and  $\psi^*(t, x) = B_2^\top(t)P(t)x = V_*(t)x$  yields the global closed loop saddle point  $P(0)x_0 \cdot x_0$ .  $\square$

**3.2. Classification of  $L^2$ -integrable closed loop saddle points.** One of the necessary conditions for the existence of a closed loop saddle point is the existence of a solution to the coupled system in  $(\hat{x}, \hat{p})$  that turns out to also be a necessary condition for the finiteness of the open loop lower value, upper value, or value of the game. The difference essentially depends on the convexity of the utility function with respect to  $u$  and on its concavity with respect to  $v$  that yields to the following classification.

**THEOREM 3.2.** *Assume that  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable closed loop saddle point of  $C_{x_0}(\phi, \psi)$ .*

(a)  $v(x_0)$  is finite if and only if  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ .

- (b)  $v^-(x_0)$  is finite and  $v^+(x_0) = +\infty$  if and only if  $C_{x_0}(u, v)$  is convex in  $u$  and not concave in  $v$ .
- (c)  $v^+(x_0)$  is finite and  $v^-(x_0) = -\infty$  if and only if  $C_{x_0}(u, v)$  is concave in  $v$  and not convex in  $u$ .
- (d)  $v^-(x_0) = -\infty$  and  $v^+(x_0) = +\infty$  if and only if  $C_{x_0}(u, v)$  is not convex in  $u$  and not concave in  $v$ .
- (e)  $v^-(x_0) = v^+(x_0) = +\infty$  cannot occur.
- (f)  $v^-(x_0) = v^+(x_0) = -\infty$  cannot occur.

In the first three cases,  $C_{x_0}(\phi^*, \psi^*)$  is equal to  $v(x_0)$ ,  $v^-(x_0)$ , and  $v^+(x_0)$ , respectively.

*Remark 3.2.* Case (d) can occur. An example can be constructed by using a first system of type (b) and a second system of type (c) without interconnection, with utility function equal to the sum of the two utility functions.

*Remark 3.3.* In Bernhard [2], the utility function was convex in  $u$  since  $F \geq 0$  and  $Q(t) \geq 0$ . Only cases (a) and (b) can occur, and case (e) is a degenerate one.

We need the following lemma.

LEMMA 3.3.

- (i) For all  $v \in L^2(0, T; \mathbf{R}^k)$ ,

$$(3.20) \quad \inf_{\phi \in \Phi} C_{x_0}(\phi, v) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v),$$

$$(3.21) \quad \sup_{\psi \in \Psi} \inf_{\phi \in \Phi} C_{x_0}(\phi, \psi) \geq \sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v).$$

- (ii) For all  $u \in L^2(0, T; \mathbf{R}^m)$ ,

$$(3.22) \quad \sup_{\psi \in \Psi} C_{x_0}(u, \psi) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v),$$

$$(3.23) \quad \inf_{\phi \in \Phi} \sup_{\psi \in \Psi} C_{x_0}(\phi, \psi) \leq \inf_{u \in L^2(0, T; \mathbf{R}^m)} \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(u, v).$$

*Proof of Lemma 3.3.* We need only prove (i). Since  $L^2(0, T; \mathbf{R}^m) \subset \Phi$ ,

$$\inf_{\phi \in \Phi} C_{x_0}(\phi, v) \leq \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v).$$

Conversely, given the pair  $(\phi, v)$ , let  $x \in H^1(0, T; \mathbf{R}^n)$  be the solution of the system

$$x' = Ax + B_1\phi(x) + B_2v, \quad x(0) = x_0,$$

and let  $u = \phi(x) \in L^2(0, T; \mathbf{R}^m)$ . This implies that

$$\begin{aligned} C_{x_0}(\phi, v) &= C_{x_0}(u, v) \geq \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) \\ \Rightarrow \inf_{\phi \in \Phi} C_{x_0}(\phi, v) &\geq \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) \Rightarrow \inf_{\phi \in \Phi} C_{x_0}(\phi, v) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v). \end{aligned}$$

The second inequality follows from the fact that  $L^2(0, T; \mathbf{R}^k) \subset \Psi$ .  $\square$

*Proof of Theorem 3.2.* From inequality (3.21),  $v^-(x_0) \leq C_{x_0}(\phi^*, \psi^*) < +\infty$  and case (e) cannot occur. Similarly, from inequality (3.23),  $v^+(x_0) \geq C_{x_0}(\phi^*, \psi^*) > -\infty$  and case (f) cannot occur. Therefore we are left with the first four cases.

(b) From the first part of the proof of Theorem 3.1, system (3.16) has a solution, and identities (3.15) are verified:

$$(3.24) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(0) = x_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T), \end{cases}$$

$$(3.25) \quad 0 = -B_1^\top \hat{p} - (U_* \hat{x} + u_*) \text{ and } 0 = B_2^\top \hat{p} - (V_* \hat{x} + v_*).$$

Using the controls  $(\hat{u}, \hat{v}) = (U_* \hat{x} + u_*, V_* \hat{x} + v_*) = (-B_1^\top \hat{p}, B_2^\top \hat{p})$ , the above system can be rewritten as

$$\begin{cases} \hat{x}' = A\hat{x} - B_1 B_1^\top \hat{p} + B_2 \hat{v}, & \hat{x}(0) = x_0, & \hat{u} = -B_1^\top \hat{p}, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T). \end{cases}$$

If  $C_{x_0}(u, v)$  is convex in  $u$ , this implies that  $\hat{u}$  is a minimizer of  $C_{x_0}(u, \hat{v})$  over  $u$  (cf., for instance, [5, Thm 3.1]). Therefore

$$\sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) \geq \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, \hat{v}) = C_{x_0}(\hat{u}, \hat{v}).$$

But, by construction of  $(\hat{u}, \hat{v})$ ,  $C_{x_0}(\phi^*, \psi^*) = C_{x_0}(\hat{u}, \hat{v})$ . Combining the above inequality with inequality (3.21) in Lemma 3.3, we get

$$v^-(x_0) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, v) = \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, \hat{v}) = C_{x_0}(\hat{u}, \hat{v})$$

and hence the finiteness of  $v^-(x_0)$ . If, in addition,  $C_{x_0}(u, v)$  was concave in  $v$ , then by [5, Thms. 2.5 and 2.4] the value of the game, and hence  $v^+(x_0)$ , would be finite, and this contradicts our assumption. Conversely, if  $v^-(x_0)$  is finite, then the mapping  $u \mapsto C_{x_0}(u, v)$  is convex ([5, Thm. 2.2(iii), last part of identity (2.35) and Remark 2.2]). If  $v^+(x_0)$  was also finite, then by [5, Thms. 2.5 and 2.4(iii)]  $C_{x_0}(u, v)$  would be concave in  $v$  in contradiction with our assumption.

The proof of (c) is dual to the proof of (b). The proof of (a) is similar to the proof of (b) and (c). Case (d) is the complement of all the other cases, so it can only occur when  $C_{x_0}(u, v)$  is neither convex in  $u$  nor concave in  $v$ .  $\square$

*Remark 3.4.* If the problem is normal and  $F \geq 0$  and  $Q(t) \geq 0$ , then  $v^-(x_0)$  is finite and  $v^-(x_0) \geq 0$  for all  $x_0 \in \mathbf{R}^n$ , and necessarily  $P(0)x_0 \cdot x_0 \geq 0$  for all  $x_0 \in \mathbf{R}^n$ .

#### 4. Not necessarily $L^2$ -integrable affine closed loop strategies.

**4.1. The curse of singularities.** We now extend the definitions and results of the previous section to Lebesgue measurable feedback matrices with singularities that are not necessarily  $L^2$ -integrable in any of its neighborhood. In order to accommodate such strategies, we first enlarge the sets of strategies  $\Phi$  and  $\Psi$ .

**DEFINITION 4.1.** *The class of affine closed loop strategies is defined as follows:*

$$\begin{aligned} \tilde{\Phi} &\stackrel{\text{def}}{=} \left\{ \phi : [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^m \left| \begin{array}{l} \text{such that } x \mapsto \phi(t, x) \text{ is affine,} \\ t \mapsto \phi(t, x) \text{ is Lebesgue measurable, and} \\ t \mapsto \phi(t, 0) \text{ belongs to } L^2(0, T; \mathbf{R}^m) \end{array} \right. \right\}, \\ \tilde{\Psi} &\stackrel{\text{def}}{=} \left\{ \psi : [0, T] \times \mathbf{R}^n \rightarrow \mathbf{R}^k \left| \begin{array}{l} \text{such that } x \mapsto \psi(t, x) \text{ is affine,} \\ t \mapsto \psi(t, x) \text{ is Lebesgue measurable, and} \\ t \mapsto \psi(t, 0) \text{ belongs to } L^2(0, T; \mathbf{R}^k) \end{array} \right. \right\}. \end{aligned}$$

We say that  $\phi$  (resp.,  $\psi$ ) is a linear closed loop strategy if  $\phi$  (resp.,  $\psi$ ) is linear in  $x$ .

To any  $(\phi, \psi) \in \tilde{\Phi} \times \tilde{\Psi}$  are associated measurable matrix functions  $U(t)$  and  $V(t)$  and  $L^2$ -vector functions  $u$  and  $v$  such that  $\phi(t, x) = U(t)x + u(t)$  and  $\psi(t, x) = V(t)x + v(t)$ . At that level of generality, an *admissibility condition* on the pair  $(\phi, \psi) \in \tilde{\Phi} \times \tilde{\Psi}$  is required to make sense of a solution of the underlying differential equation. How should the admissible affine closed loop strategies be chosen in order to preserve the assumption of *normalizability* of [2] that makes sense of a non- $H^1(0, T)$ -solution  $P$  to the matrix Riccati differential equation? It is clear that the choice of the space of solutions of the matrix Riccati differential equation and the specification of the families  $\Phi$  and  $\Psi$  are closely related.

It has been known that the solution of the scalar Riccati differential equation can exhibit singularities that are not *movable branch points*, at least when the coefficients are smooth functions of  $t$  (cf. Ince [6, section 12.51, p. 293]). Another interesting property is that “the general solution of the Riccati equation is expressible rationally in terms of any three distinct particular solutions, and also that the anharmonic ratio of any four solutions is constant. It also shows that the general solution is a rational function of the constant of integration (cf. Ince [6, section 2.15, p. 23 and section 12.51, p. 294]).”

This result was extended to the  $n \times n$  ( $n \geq 2$ ) solution of the matrix Riccati differential equation by Sorine and Winternitz [8], but with five particular solutions in the general case and four in the *symplectic case* that corresponds to our assumptions on the data matrices. They also give some thought to the space of solutions:<sup>2</sup> “For smooth coefficients  $A$ ,  $B$ ,  $C$ , and  $D$  in the MRE (6) the solution space consists of meromorphic matrices: the matrix elements may have first-order poles, the positions of which depends on the initial conditions. In other words, the MRE (6) has the Painlevé property [6]: the solutions have no moving critical points, i.e., no branch points or essential singularities, the positions of which depend on the initial conditions (cf. [8, pp. 271–272]).”

**4.2. Bernhard’s conditions [2] in the free end case.** In the free end case with  $F \geq 0$  and  $Q(t) \geq 0$ , the necessary and sufficient condition of Bernhard [2, Thm. 3.1] for the existence of a nondegenerate closed loop saddle point in the sense of [2, Definition 2.3 and Remark 5.1] reduces to the following three properties:

- (ii)  $X(t)$  is invertible except possibly at isolated points in  $[0, T]$ , where  $(X, \Lambda)$  is the unique  $H^1(0, T)$  matrix solution of

$$(4.1) \quad \begin{cases} X' = AX - R\Lambda, & X(T) = I, \\ \Lambda' + A^\top \Lambda + QX = 0, & \Lambda(T) = F; \end{cases}$$

- (iii)  $x_0 \in \text{Im } X(0)$ ;

- (iv) for all  $t \in [0, T]$ ,  $P(t) \geq 0$ ,

where  $P$  is defined in terms of  $\Lambda$  and the pseudoinverse of  $X$  as follows:

$$(4.2) \quad P(t) = \Lambda(t) X(t)^\dagger, \quad X(t)^\dagger \stackrel{\text{def}}{=} \begin{cases} [X(t)^\top X(t)]^{-1} X(t)^\top & \text{if } X(t) \neq 0, \\ \text{arbitrary} & \text{if } X(t) = 0, \end{cases}$$

and  $[X(t)^\top X(t)]^{-1}$  is the inverse of  $X(t)^\top X(t)$  as a matrix from  $\text{Im } X(t)^\top$  onto itself.

<sup>2</sup>Sorine and Winternitz [8] consider solutions  $W$  of the general matrix Riccati differential equation  $W' = A + WB + CW + WDW$ ,  $W(T) = W_0$ .

Condition (ii) defines the matrix function  $P(t)$  almost everywhere in  $[0, T]$  and gives meaning to a solution of the Riccati differential equation via the solution  $(\Lambda, X)$  of system (4.1). The positivity of  $F$  and  $Q(t)$  makes the utility function  $C_{x_0}(u, v)$  convex in  $u$  and this leads to the positivity of  $P(t)$  (cf. Remark 3.4). Our objective is to relax those positivity assumptions as in Theorem 3.1. Without them some of the competitive terms in the utility function may simultaneously blow up, making it difficult to set the utility function equal to  $\pm\infty$  (cf. [2, p. 68 and Remark 5.1]). Moreover, non- $L^2$ -integrable singularities in the closed loop strategies invalidate the equivalence (ii) of Lemma 3.2 when either the open loop lower or upper value of the game is not finite. So the very definition of a closed loop saddle point has to be properly revisited, and the family of pairs of admissible strategies is no longer  $\Phi \times \Psi$  but a subspace  $S$  of an enlarged product space  $\tilde{\Phi} \times \tilde{\Psi}$  containing  $\Phi \times \Psi$ .

**4.3. Normalizability and its consequences.** Given the matrices  $A$ ,  $B_1$ ,  $B_2$ ,  $Q$ , and  $F$  verifying the conditions of section 2.1, system (4.1) always has a unique solution  $(X, \Lambda)$  with elements in  $H^1(0, T)$ . Introduce the notation

$$(4.3) \quad Z \stackrel{\text{def}}{=} \{s \in [0, T] : \det X(s) = 0\}.$$

By definition,  $T \notin Z$  since  $X(T) = I$ . We now extend the definition of [2] (property (ii) in section 4.2) to a larger class of systems with bounded measurable coefficients.

**DEFINITION 4.2.** *The problem (2.1)–(2.2) is normalizable if  $\det X(t) \neq 0$  almost everywhere in  $[0, T]$ , where  $(X, \Lambda)$  is the  $H^1(0, T)$ -solution of the matrix differential system (4.1).*

Here  $Z$  is possibly infinite with accumulation points that are not isolated, as can be seen from the following example.

*Example 4.1.* Consider an extension of the example from [2, Example 5.1, p. 67]:

$$(4.4) \quad x'(t) = B_1(t)u(t) + B_2(t)v(t) \text{ a.e. in } [0, 2], \quad x(0) = x_0,$$

$$(4.5) \quad C_{x_0}(u, v) = \frac{1}{2}|x(2)|^2 + \int_0^2 |u(t)|^2 - |v(t)|^2 dt,$$

where

$$(4.6) \quad B_1(t) \stackrel{\text{def}}{=} \begin{cases} 2-t, & 1 < t \leq 2, \\ 2^{\frac{n}{2}+1} \left( \frac{1}{2^n} - t \right), & \frac{1}{2^{n+1}} < t \leq \frac{1}{2^n}, \quad n \geq 0, \end{cases}$$

$$(4.7) \quad B_2(t) \stackrel{\text{def}}{=} \begin{cases} t, & 1 < t \leq 2, \\ 2^{\frac{n}{2}+1} \left( t - \frac{1}{2^{n+1}} \right), & \frac{1}{2^{n+1}} < t \leq \frac{1}{2^n}, \quad n \geq 0. \end{cases}$$

It is readily seen that both  $B_1$  and  $B_2$  are measurable and bounded. Here  $A = 0$ ,  $F = 1/2$ ,  $Q = 0$ , and  $R = B_1 B_1^* - B_2 B_2^*$ ,

$$(4.8) \quad R(t) = \begin{cases} 4(1-t), & 1 < t \leq 2, \\ \left( \frac{3}{2^n} - 4t \right), & \frac{1}{2^{n+1}} < t \leq \frac{1}{2^n}, \quad n \geq 0. \end{cases}$$

The solution of system (4.1) is given by the expressions

$$(4.9) \quad \begin{aligned} X(t) &= \begin{cases} (1-t)^2, & 1 < t \leq 2, \\ \left(t - \frac{1}{2^n}\right) \left(t - \frac{1}{2^{n+1}}\right), & \frac{1}{2^{n+1}} < t \leq \frac{1}{2^n}, \quad n \geq 0, \\ 0, & t = 0, \end{cases} \\ \Lambda(t) &= \frac{1}{2}. \end{aligned}$$

Here  $Z = \{1/2^n : n \geq 0\} \cup \{0\}$  has an infinite number of isolated points plus the accumulation point 0 that is not isolated since  $1/2^n \rightarrow 0$ .

Thus Definition 4.2 is a natural extension of the normalizability in the sense of [2] to systems with bounded measurable coefficients.

LEMMA 4.1. *If problem (2.1)–(2.2) is normalizable in the sense of Bernhard [2], then  $Z$  contains a finite number of instants in  $[0, T[$ .*

*Proof.* If the compact set  $Z$  has an infinite number of points, then there exists a sequence of distinct points  $\{t_n\}$  in  $Z$  and an accumulation point  $t_0 \in Z$ ,  $t_n \neq t_0$ , such that  $t_n \rightarrow t_0$ . But this is impossible since each point of  $Z$  is an isolated point in  $[0, T]$ : there is an open interval  $(a, b)$  such that  $t_0 \in (a, b)$  and  $(a, b) \cap [0, T] \setminus \{t_0\} \subset [0, T] \setminus Z$ .  $\square$

Remark 4.1. Since  $Z$  has zero measure we know that it does not contain non-trivial intervals. One interesting issue that was raised by the referee is whether the set  $Z$  is countable or not. It is countable in our example, but can it be uncountable like the Cantor set? However, all the results of this paper are independent of that open issue.

The normalizability property relies on the fact that the state equation can be solved backward in finite dimension. In general, this would not be true for infinite dimensional evolution systems. Yet, in finite dimension, normalizability turns out to be equivalent to a weaker form of *invariant embedding with respect to the initial time* that would be more natural in infinite dimension. Denote by  $Z'$  the set of all initial times  $s \in [0, T[$  such that the matrix differential system

$$(4.10) \quad \begin{cases} \hat{X}'_s = A\hat{X}_s - R\hat{\Lambda}_s, & \hat{X}_s(s) = I, \\ \hat{\Lambda}'_s + A^\top \hat{\Lambda}_s + Q\hat{X}_s = 0, & \hat{\Lambda}_s(T) = F\hat{X}_s(T) \end{cases}$$

has a solution  $(\hat{X}_s, \hat{\Lambda}_s)$  with elements in  $H^1(s, T)$ .

LEMMA 4.2.

(i)  $Z = Z'$ .

(ii) For  $s \in [0, T[ \setminus Z'$ , the matrix differential system (4.10) has a unique solution  $(\hat{X}_s, \hat{\Lambda}_s)$  with elements in  $H^1(s, T)$  for all  $t \in [s, T[ \setminus Z'$ ,  $\det \hat{X}_s(t) \neq 0$ , and  $P(s) = \Lambda(s)X(s)^{-1} = \hat{\Lambda}_s(s)$ .

By convention we set  $\hat{X}_T(T) = I$  and  $\hat{\Lambda}_T(T) = F$ .

Remark 4.2. From part (i) of Lemma 4.2, normalizability is equivalent to invariant embedding with respect to almost all initial times. This equivalence should be compared with (iv) in Theorem 3.1. It says that the decoupling operator  $P(s)$  can be defined almost everywhere as  $\hat{\Lambda}_s(s)$  and that the invariant embedding with respect to almost all initial times can still be done as in [5]. This property was observed for the Riccati differential equation associated with Helmholtz equation<sup>3</sup> of waveguides.

<sup>3</sup>The author would like to thank Jacques Henry (INRIA) for bringing this work to his attention.

Due to a resonance phenomenon, the invariant embedding cannot be done at an at most countable set of initial times. This material can be found in the Ph.D. thesis of Champagne [4], where a sup-inf formulation is also introduced.

*Proof.* (i) For  $s \in [0, T[ \setminus Z$ , it is easy to check that the pair of matrices  $(\hat{X}_s(t), \hat{\Lambda}_s(t)) = (X(t)X(s)^{-1}, \Lambda(t)X(s)^{-1})$  is an  $H^1(s, T)$ -solution of system (4.10). Hence,  $[0, T[ \setminus Z \subset [0, T[ \setminus Z'$  and  $Z' \subset Z$ . Conversely, for all  $s \in [0, T[ \setminus Z'$ ,  $\hat{X}_s(T)$  is invertible. Indeed, if there exists  $h \neq 0$  such that  $\hat{X}_s(T)h = 0$ , then the pair  $(x, p) = (\hat{X}_s h, \hat{\Lambda}_s h)$  would be a solution of the system  $x' = Ax - Rp$ ,  $x(T) = 0$ ,  $p' + A^\top p + Qx = 0$ ,  $p(T) = Fx(T) = 0$ . Hence  $(x, p) = (0, 0)$  and  $0 = x(s) = \hat{X}_s(s)h = h \neq 0$ , a contradiction. Define for  $s \in [0, T[ \setminus Z'$  the new matrices  $(X_s(t), \Lambda_s(t)) = (\hat{X}_s(t)\hat{X}_s(T)^{-1}, \hat{\Lambda}_s(t)\hat{X}_s(T)^{-1})$ . They are a solution of system (4.1) in  $[s, T]$ . Hence  $X_s$  is the restriction of  $X$  to  $[s, T]$ ,  $X(t) = \hat{X}_s(t)\hat{X}_s(T)^{-1}$  on  $[s, T]$ ,  $X(s) = \hat{X}_s(T)^{-1}$ . Since  $\hat{X}_s(T)$  is invertible,  $X(s)$  is invertible,  $s \in [0, T[ \setminus Z$ ,  $[0, T[ \setminus Z' \subset [0, T[ \setminus Z$ , and  $Z \subset Z'$ . Therefore  $Z' = Z$ .

(ii) To prove that the solution of system (4.10) is unique for each  $s \in [0, T[ \setminus Z'$ , consider an arbitrary solution  $(\hat{X}_s, \hat{\Lambda}_s)$ . Define  $(\overline{X}_s(t), \overline{\Lambda}_s(t)) = (\hat{X}_s(t)X(s), \hat{\Lambda}_s(t)X(s))$ . It is readily seen that they are a solution of the system

$$\begin{cases} \overline{X}_s' = A\overline{X}_s - R\overline{\Lambda}_s, & \overline{X}_s(T) = \hat{X}_s(T)X(s), \\ \overline{\Lambda}_s' + A^\top \overline{\Lambda}_s + Q\overline{X}_s = 0, & \overline{\Lambda}_s(T) = F\hat{X}_s(T)X(s). \end{cases}$$

This matrix linear system with final conditions has the unique  $H^1$ -solution  $\overline{X}_s(t) = X(t)\hat{X}_s(T)X(s)$  and  $\overline{\Lambda}_s(t) = \Lambda(t)\hat{X}_s(T)X(s)$ . But we have shown in part (i) that  $\hat{X}_s(T)$  is invertible and that  $X(s) = \hat{X}_s(T)^{-1}$ . Therefore

$$(\hat{X}_s(t), \hat{\Lambda}_s(t)) = (X(t)X(s)^{-1}, \Lambda(t)X(s)^{-1})$$

is unique,  $P(s) = \Lambda(s)X(s)^{-1} = \hat{\Lambda}_s(s)$ , and  $\hat{X}_s(t)$  is invertible for all  $t \in [s, T] \setminus Z'$ .  $\square$

Starting with Definition 4.2 of normalizability, we now proceed in a constructive way to identify the appropriate definition of a closed loop saddle point in the presence of non- $L^2$ -integrable singularities in the closed loop strategies. The normalizability property gives a precise meaning to the *closed loop system* and to a solution of the matrix Riccati differential equation.

LEMMA 4.3. *Assume that the problem (2.1)–(2.2) is normalizable. Then*

- (i)  $P(s) = \Lambda(s)X(s)^{-1}$  is uniquely defined and symmetrical for all  $s \in [0, T] \setminus Z$ ,  $P$  verifies the matrix Riccati differential equation

$$P' + PA + A^\top P - PRP + Q = 0, \quad P(T) = F,$$

in  $[0, T] \setminus Z$ , and  $PX$  is the unique  $H^1(0, T)$ -solution of the matrix equation

$$(PX)' + A^\top(PX) + QX = 0, \quad (PX)(T) = F.$$

- (ii)  $X$  is an  $H^1(0, T)$  solution of the closed loop matrix equation

$$(4.11) \quad X' = (A - RP)X, \quad X(T) = I,$$

such that  $\det X(t) \neq 0$  in  $[0, T] \setminus Z$ , and  $-B_1^\top PX = -B_1^\top \Lambda$  and  $B_2^\top PX = B_2^\top \Lambda$  belong to  $L^2(0, T)$ .

- (iii) for all  $s \in [0, T] \setminus Z$ ,  $\hat{X}_s$  is an  $H^1(s, T)$ -solution of the closed loop matrix differential equation

$$(4.12) \quad \hat{X}'_s = (A - RP)\hat{X}_s, \quad \hat{X}_s(s) = I,$$

such that  $\det \hat{X}_s(t) \neq 0$  in  $[s, T] \setminus Z$ , and  $P\hat{X}_s$  is the unique  $H^1(s, T)$ -solution of the matrix equation

$$(P\hat{X}_s)' + A^\top(P\hat{X}_s) + Q\hat{X}_s = 0, \quad (P\hat{X}_s)(T) = F\hat{X}_s(T).$$

*Proof.* (i) It is easy to verify that the derivative of the matrix function  $X^\top \Lambda - \Lambda^\top X$  is null and that  $(X^\top \Lambda - \Lambda^\top X)(T) = 0$ . Hence  $X^\top \Lambda = \Lambda^\top X$  and  $P = \Lambda X^{-1} = (\Lambda X^{-1})^\top = X^{-\top} \Lambda^\top = P^\top$  almost everywhere in  $[0, T]$ . The second part follows by definition of  $P$  and the identity  $\Lambda = PX$ .

(ii) The second statement follows from the fact that, by definition of  $P$ ,  $X' = AX - R\Lambda = AX - R\Lambda X^{-1}X = (A - RP)X$ .

(iii) Equation (4.12) for  $\hat{X}_s$  follows from identity  $\hat{\Lambda}_s(t) = \hat{\Lambda}_t(t)\hat{X}_s(t) = P(t)\hat{X}_s(t)$ .  $\square$

**4.4. Admissible closed loop affine strategies.** The closed loop strategies  $(\phi, \psi) \in \tilde{\Phi} \times \tilde{\Psi}$  of Definition 4.1 with possible non- $L^2$ -integrable singularities need to be linked through an admissibility condition  $(\phi, \psi) \in S$  to make sense of a solution of the underlying differential equation. It fundamentally changes the nature of the problem. This subtle difference prevents the use of the nice classical results of the theory of saddle points with respect to two fixed independent sets  $\Phi$  and  $\Psi$ . For instance, two pairs  $(\phi_1, \psi_1) \in S$  and  $(\phi_2, \psi_2) \in S$  cannot be mixed:  $(\phi_1, \psi_2)$  and  $(\phi_2, \psi_1)$  need not belong to  $S$  as shown in Example 4.2 for the pairs  $(\phi^*, \psi^*) \in S$  and  $(0, 0) \in S$ . In particular, property (ii) of Berkovitz's equivalence, Lemma 3.2, is not verified for  $u = 0$  or  $v = 0$ .

*Example 4.2.* Consider the example from [2, Example 5.1, p. 67]:

$$(4.13) \quad x'(t) = (2 - t)u(t) + tv(t) \text{ a.e. in } [0, 2], \quad x(0) = x_0,$$

$$(4.14) \quad C_{x_0}(u, v) = \frac{1}{2}|x(2)|^2 + \int_0^2 |u(t)|^2 - |v(t)|^2 dt.$$

Here  $A = 0$ ,  $B_1(t) = 2 - t$ ,  $B_2(t) = t$ ,  $F = 1/2$ ,  $Q = 0$ , and  $R = B_1B_1^* - B_2B_2^* = 4(1 - t)$ . The Riccati equation reduces to

$$P' - 4(1 - t)P^2 = 0, \quad P(2) = \frac{1}{2} \Rightarrow P(t) = \frac{1}{2(t - 1)^2}.$$

Its solution is positive and blows up at  $t = 1$ . The open loop lower value of the game is  $v^-(x_0) = (x_0)^2/2$  and the open loop upper value of the game is  $v^+(x_0) = +\infty$  for all  $x_0 \in \mathbf{R}$ . The closed loop strategies have a singularity in  $t = 1$ :

$$(4.15) \quad \phi^*(t, x) = -\frac{2 - t}{2(t - 1)^2}x \quad \text{and} \quad \psi^*(t, x) = \frac{t}{2(t - 1)^2}x.$$

Yet the state  $x$  is an  $H^1(0, 2)$ -function and the controls  $\hat{u}$  and  $\hat{v}$  are  $L^2$ -functions:

$$(4.16) \quad x(t) = x_0(t - 1)^2, \quad \hat{u}(t) = -(2 - t)\frac{1}{2}x_0, \quad \text{and} \quad \hat{v}(t) = t\frac{1}{2}x_0.$$

Moreover,  $X(t) = (t - 1)^2$ .

In general for the pair  $(\phi^*, v)$ , both the resulting  $L^2$ -norms of the state  $x$  and the control  $u = \phi^*(x)$  will blow up even when  $v = 0$ :

$$(4.17) \quad x'(t) = -\frac{(2-t)^2}{2(t-1)^2}x(t) + tv(t) \text{ in } [0, 2], \quad x(0) = x_0,$$

$$(4.18) \quad \text{for } v = 0, \quad x(t) = e^{\frac{1}{2}[\frac{1}{t-1} - (t-1)]}|t-1|x_0,$$

where  $x(1^-) = 0$  and  $x(1^+) = \infty$ . So the equivalent condition (ii) of Berkovitz's Lemma 3.2 is not verified.

DEFINITION 4.3. *We say that the pair  $(\phi, \psi) \in \tilde{\Phi} \times \tilde{\Psi}$  belongs to  $S$  or simply that  $(\phi, \psi)$  is an admissible pair if the associated matrix differential equation*

$$(4.19) \quad X' = (A + B_1U + B_2V)X, \quad X(T) = I,$$

has an  $H^1(0, T)$ -solution such that  $\det X(t) \neq 0$  almost everywhere in  $[0, T]$ ,  $UX$  and  $VX$  are  $L^2(0, T)$  matrices,  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , and  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ .

Remark 4.3. Since  $A$ ,  $B_1$ , and  $B_2$  are  $L^\infty$ -matrix functions, it implies that the feedback matrix functions  $U$  and  $V$  will have properties similar to the ones of  $X'X^{-1}$ . As a consequence, given an admissible pair  $(\phi, \psi) \in S$  and  $y_0 \in \mathbf{R}^n$ ,  $x(t) = X(t)y_0$  is a solution in  $H^1(0, T; \mathbf{R}^n)$  of the equation

$$(4.20) \quad x' = [A + B_1U + B_2V]x, \quad x(0) = X(0)y_0,$$

(or  $x(T) = y_0$ ) such that

$$u = Ux = UXy_0 \in L^2(0, T; \mathbf{R}^m) \quad \text{and} \quad v = Vx = VXy_0 \in L^2(0, T; \mathbf{R}^k).$$

However, this solution of system (4.20) is not unique. Indeed, if  $x$  is a solution of system (4.20),  $t_i \in Z$ , and  $x_i$  in  $H^1(0, T; \mathbf{R}^n)$  is given by

$$x_i(t) = \begin{cases} 0, & 0 \leq t < t_i \\ X(t)z_i, & t_i \leq t \leq T \end{cases} \quad \forall z_i \in \ker X(t_i),$$

then  $X(t)y_0 + x_i(t)$  is also a solution of system (4.20).

The admissibility condition amounts to a change in the state variable via the associated transformation  $X(t)$ .

LEMMA 4.4. *Assume that  $(\phi, \psi) \in S$ ,  $\phi(t, x) = U(t)x + u_0(t)$ , and  $\psi(t, x) = V(t)x + v_0(t)$ . Let  $X$  be a solution of system (4.19) such that  $\det X(t) \neq 0$  almost everywhere in  $[0, T]$ .*

- (i) *For all  $y_0 \in \mathbf{R}^n$ ,  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , and  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ , the system*

$$(4.21) \quad y' = X^{-1}(B_1u + B_2v), \quad y(0) = y_0,$$

*has a unique solution in  $H^1(0, T; \mathbf{R}^n)$ ,  $x \stackrel{\text{def}}{=} Xy$  is the unique solution in*

$$(4.22) \quad H_X^1(0, T; \mathbf{R}^n) \stackrel{\text{def}}{=} \left\{ x \in H^1(0, T; \mathbf{R}^n) : \begin{array}{l} \exists y \in H^1(0, T; \mathbf{R}^n) \\ \text{such that } x = Xy \end{array} \right\}$$

of the system

$$(4.23) \quad x' = [A + B_1U + B_2V]x + B_1u + B_2v, \quad x(0) = X(0)y_0,$$

up to a function of the form  $X(t)z_0$  for some  $z_0 \in \ker X(0)$ , and all the solutions of (4.23) in  $H_X^1(0, T; \mathbf{R}^n)$  are given by the expression

$$(4.24) \quad x(t) = X(t) \left[ y_0 + z_0 + \int_0^t X^{-1}(B_1u + B_2v) ds \right] \quad \forall z_0 \in \ker X(0).$$

- (ii) The subspaces  $\mathcal{U} = \{u \in L^2(0, T; \mathbf{R}^m) : |X^{-1}|u \in L^2(0, T; \mathbf{R}^m)\}$  and  $\mathcal{V} = \{v \in L^2(0, T; \mathbf{R}^k) : |X^{-1}|v \in L^2(0, T; \mathbf{R}^k)\}$  are dense in  $L^2(0, T; \mathbf{R}^m)$  and  $L^2(0, T; \mathbf{R}^k)$ , respectively.

*Proof.* (i) By assumption on  $u$  and  $v$ , the right-hand side of (4.21) belongs to  $L^2(0, T; \mathbf{R}^n)$ , and its unique solution  $y$  belongs to  $H^1(0, T; \mathbf{R}^n)$ . By direct computation of the derivative of  $x = Xy$ , it is easy to check that  $x$  is a solution of system (4.23). Consider two solutions  $x_1$  and  $x_2$  of system (4.23). The difference  $z = x_2 - x_1$  is a solution in  $H_X^1(0, T; \mathbf{R}^n)$  of

$$z' = [A + B_1U + B_2V]z, \quad z(0) = 0.$$

Since  $z \in H_X^1(0, T; \mathbf{R}^n)$ , there exists  $y \in H^1(0, T; \mathbf{R}^n)$  such that  $z = Xy$ . The function  $y = X^{-1}z$  is the solution in  $H^1(0, T)$  of

$$y' = 0 \text{ in } (0, T), \quad y(T) = z(T).$$

Therefore  $y(t) = z(T)$  on  $[0, T]$ . This implies that  $z(t) = X(t)z(T)$  in  $[0, T]$ ,  $0 = z(0) = X(0)z(T)$ , and  $z(T) \in \ker X(0)$ . Therefore two solutions of system (4.23) can differ only by  $X(t)z_0$  for some  $z_0 \in \ker X(0)$ .

- (ii) Define  $w_n(t) = 1$  if  $|X(t)| \geq 1/n$  and  $0$  if  $|X(t)| < 1/n$ . For any  $u \in L^2(0, T; \mathbf{R}^m)$ , the sequence  $\{u_n = u w_n\} \subset \mathcal{U}$  converges to  $u$  in  $L^2(0, T; \mathbf{R}^m)$  by the Lebesgue dominated convergence theorem.  $\square$

As for normalizability, Definition 4.3 is equivalent to the following definition.

**DEFINITION 4.4.** We say that the pair  $(\phi, \psi) \in \tilde{\Phi} \times \tilde{\Psi}$  belongs to  $S$  or simply that  $(\phi, \psi)$  is an admissible pair if, for almost all  $s \in [0, T]$ , the matrix differential equation

$$(4.25) \quad X'_s = (A + B_1U + B_2V)X_s, \quad X_s(s) = I,$$

has an  $H^1(s, T)$ -solution,  $UX_s$  and  $VX_s$  are  $L^2(s, T)$  matrices,  $|X_s^{-1}|u \in L^2(s, T; \mathbf{R}^m)$ , and  $|X_s^{-1}|v \in L^2(s, T; \mathbf{R}^k)$ .

#### 4.5. Necessary and sufficient conditions for normalizability.

**LEMMA 4.5.** Assume that problem (2.1)–(2.2) is normalizable. Let  $(X, \Lambda)$  be the solution of system (4.1),  $Z = \{t \in [0, T] : \det X(t) = 0\}$ , and let  $P$  be defined by (4.2).

- (i)  $X$  is a solution in  $H^1(0, T)$  of the matrix equation (4.11),

$$X' = (A - RP)X, \quad X(T) = I,$$

such that  $\det X(t) \neq 0$  in  $[0, T] \setminus Z$ ,

$$(4.26) \quad \begin{aligned} U_*X &= -B_1^\top PX = -B_1^\top \Lambda \in L^2(0, T; \mathbf{R}^n)^n, \\ V_*X &= B_2^\top PX = B_2^\top \Lambda \in L^2(0, T; \mathbf{R}^n)^n \end{aligned}$$

for the matrices

$$(4.27) \quad U_*(t) \stackrel{\text{def}}{=} -B_1^\top(t)P(t) \text{ and } V_*(t) \stackrel{\text{def}}{=} B_2^\top(t)P(t)$$

and the pair  $(\phi^*, \psi^*) \in S$ , where  $(\phi^*(t, x), \psi^*(t, x)) = (U_*(t)x, V_*(t)x)$ .

- (ii) Given  $x_0 \in \text{Im } X(0)$ ,  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , and  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ , the system

$$(4.28) \quad x' = [A - RP]x + B_1u + B_2v, \quad x(0) = x_0,$$

has a solution  $x \in H_X^1(0, T; \mathbf{R}^n)$  unique up to an element  $X(t)z_0$  for some  $z_0 \in \ker X(0)$ . Moreover, for any solution  $x \in H_X^1(0, T; \mathbf{R}^n)^n$  of (4.28),

$$(4.29) \quad C_{x_0}(\phi^*(x) + u, \psi^*(x) + v) = \Lambda(0)y_0 \cdot x_0 + \int_0^T |u|^2 - |v|^2 dt,$$

$C_{x_0}(\phi^*, \psi^*) = \Lambda(0)y_0 \cdot x_0$  is independent of the choice of  $y_0$  such that  $X(0)y_0 = x_0$ , and  $C_{x_0}(\phi^*(x) + u, \psi^*(x) + v)$  is independent of the choice of the solution  $x$  in  $H_X^1(0, T; \mathbf{R}^n)$  to system (4.28).

- (iii) For all  $x_0 \in \text{Im } X(0)$ ,  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , and  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ ,

$$(4.30) \quad C_{x_0}(\phi^*, \psi^* + v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi^* + u, \psi^*).$$

*Remark 4.4.* In view of Lemma 4.4(ii), inequalities (4.30) are verified on dense subsets of  $L^2(0, T; \mathbf{R}^m)$  and  $L^2(0, T; \mathbf{R}^k)$ . They define an open loop saddle point in  $(0, 0) \in \mathcal{U} \times \mathcal{V}$  after a change of the state variable via the transformation  $X(t)$ .

*Proof.* (i) This follows from Lemma 4.3(ii).

(ii) Let  $x$  be a solution of system (4.28) in  $H_X^1(0, T; \mathbf{R}^n)$  and  $y_0$  be such that  $X(0)y_0 = x_0$ . By Lemma 4.4(i), the solutions  $x$  of system (4.28) in  $H_X^1(0, T; \mathbf{R}^n)$  are given by (4.24),

$$x(t) = X(t)y(t), \quad y(t) = y_0 + z_0 + \int_0^t X^{-1}(B_1u + B_2v) ds \quad \forall z_0 \in \ker X(0),$$

and, by definition of  $P(t)$ ,  $Px = \Lambda y$ . Hence  $Px$  is an  $H^1(0, T; \mathbf{R}^n)$ -function. Differentiate the inner product  $\Lambda y \cdot x$  as follows:

$$\begin{aligned} \frac{d}{dt} \Lambda y \cdot x &= \Lambda' y \cdot x + \Lambda y' \cdot x + \Lambda y \cdot x' \\ &= -[A^\top \Lambda + QX]y \cdot x + \Lambda X^{-1}(B_1u + B_2v) \cdot x + \Lambda y \cdot [(A - RP)x + B_1u + B_2v] \\ &= -[Qx \cdot x + | - B_1^\top Px + u|^2 + |B_2^\top Px + v|^2] + |u|^2 - |v|^2 \end{aligned}$$

and

$$\begin{aligned} C_{x_0}(\phi^* + u, \psi^* + v) &= \Lambda(0)(y_0 + z_0) \cdot x_0 + \int_0^T |u|^2 - |v|^2 dt \\ &\Rightarrow C_{x_0}(\phi^*, \psi^*) = \Lambda(0)(y_0 + z_0) \cdot x_0. \end{aligned}$$

But this last expression is dependent only on  $x_0$ . Assume that there exist  $y_0^1$  and  $y_0^2$  such that  $X(0)y_0^1 = x_0 = X(0)y_0^2$ . Let  $z_0^1$  and  $z_0^2$  be the respective elements of  $\ker X(0)$  associated with  $y_0^1$  and  $y_0^2$ . Then  $y_0^2 + z_0^2 - (y_0^1 - z_0^1) \in \ker X(0)$ . By the symmetry in

Lemma 4.3,  $X^\top(0)\Lambda(0)(y_0^2 + z_0^2 - (y_0^1 - z_0^1)) = \Lambda(0)^\top X(0)(y_0^2 + z_0^2 - (y_0^1 - z_0^1)) = 0$ . Hence

$$\begin{aligned} & \Lambda(0)(y_0^2 + z_0^2) \cdot x_0 - \Lambda(0)(y_0^1 + z_0^1) \cdot x_0 \\ &= \Lambda(0)(y_0^2 + z_0^2 - (y_0^1 - z_0^1)) \cdot x_0 = X(0)^\top \Lambda(0)(y_0^2 + z_0^2 - (y_0^1 - z_0^1)) \cdot y_0^1 = 0. \end{aligned}$$

The value of  $C_{x_0}(\phi^*, \psi^*)$  depends only on  $x_0$ .  $C_{x_0}(\phi^* + u, \psi^* + v)$  depends only on  $x_0$ ,  $u$ , and  $v$  and is independent of the choice of a solution  $x$  in  $H_X^1(0, T; \mathbf{R}^n)$  to system (4.28).

(iii) It is readily seen from part (ii) that

$$\forall u \in \mathcal{U}, \forall v \in \mathcal{V}, \quad C_{x_0}(\phi^*, \psi^* + v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi^* + u, \psi^*),$$

and  $(\hat{u}, \hat{v}) = (0, 0)$  is an open loop saddle point.  $\square$

We are now ready to prove the following result that sheds light on the choice of a definition of the closed loop saddle point in the presence of closed loop strategies with non- $L^2$ -integrable singularities.

THEOREM 4.1. *The following statements are equivalent.*

- (i) *Problem (2.1)–(2.2) is normalizable in the sense of Definition 4.2.*
- (ii) *There exists a pair of closed loop strategies  $(\phi^*, \psi^*) \in S$  that for all  $x_0 \in \text{Im } X(0)$ , all  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , and all  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ ,*

$$(4.31) \quad C_{x_0}(\phi^*, \psi^* + v) \leq C_{x_0}(\phi^*, \psi^*) \leq C_{x_0}(\phi^* + u, \psi^*).$$

- (iii) *There exists a pair of linear closed loop strategies  $(\phi^*, \psi^*) \in S$  (that is,  $\psi^*(t, x) = V_*(t)x$  and  $\phi^*(t, x) = U_*(t)x$ ) such that for all  $x_0 \in \text{Im } X(0)$ , there exists a solution  $(\hat{x}, \hat{p}) \in H_X^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)$  of*

$$(4.32) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(0) = x_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T), \end{cases}$$

and

$$(4.33) \quad -B_1^\top \hat{p} = U_* \hat{x}, \quad B_2^\top \hat{p} = V_* \hat{x}.$$

For all  $x_0 \in \text{Im } X(0)$  the feedback strategies associated with  $C_{x_0}$  are given by

$$(4.34) \quad \phi^*(t, x) = -B_1^\top(t)P(t)x \quad \text{and} \quad \psi^*(t, x) = B_2^\top(t)P(t)x,$$

where  $P$  is defined by (4.2), and the value of the closed loop saddle point by

$$(4.35) \quad C_{x_0}(\phi^*, \psi^*) = \Lambda(0)y_0 \cdot x_0$$

for some  $y_0 \in \mathbf{R}^n$  such that  $x_0 = X(0)y_0$ , and this value is independent of the choice of  $y_0$  such that  $x_0 = X(0)y_0$ .

*Proof.* (i)  $\Rightarrow$  (ii). This follows by Lemma 4.5.

(ii)  $\Rightarrow$  (iii). Denote by  $U_*$  and  $V_*$  and  $u_*$  and  $v_*$  the matrix and vector functions associated with the pair  $(\phi^*, \psi^*) \in S$ . By Definition 4.3 and Lemma 4.4, there exists a solution  $\bar{X}$  in  $H_X^1(0, T)$  to the matrix differential equation (4.19),

$$(4.36) \quad \bar{X}' = (A + B_1 U_* + B_2 V_*) \bar{X}, \quad \bar{X}(T) = I,$$

such that  $\det \bar{X}(t) \neq 0$  almost everywhere in  $[0, T]$ ,  $U_* \bar{X}$ , and  $V_* \bar{X}$  in  $L^2(0, T)$ ;  $u_* \in L^2(0, T; \mathbf{R}^m)$  such that  $|\bar{X}^{-1}|u_* \in L^2(0, T; \mathbf{R}^k)$ , and  $v_* \in L^2(0, T; \mathbf{R}^m)$  such that  $|\bar{X}^{-1}|v_* \in L^2(0, T; \mathbf{R}^k)$ .

We know that for all  $x_0 \in \text{Im } \bar{X}(0)$ ,  $(\hat{u}, \hat{v}) = (0, 0)$  is an open loop saddle point of  $C_{x_0}(\phi^*(x) + u, \psi^*(x) + v)$ , where  $x$  is a solution in  $H_{\bar{X}}^1(0, T; \mathbf{R}^n)$  of the state equation

$$x' = (A + B_1 U_* + B_2 V_*)x + B_1(u_* + u) + B_2(v_* + v), \quad x(0) = x_0.$$

To get around the nonuniqueness of solution, we start from the other state equation,

$$y' = \bar{X}^{-1}(B_1(u_* + u) + B_2(v_* + v)), \quad y(0) = y_0,$$

for all  $y_0 \in \mathbf{R}^n$  and  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|\bar{X}^{-1}|u \in L^2(0, T; \mathbf{R}^k)$ , and  $v \in L^2(0, T; \mathbf{R}^m)$  such that  $|\bar{X}^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ . By construction,  $x(t) = \bar{X}(t)y(t)$ , and we just substitute in the utility function to get it in terms of  $y$  rather than  $x$ :  $c_{y_0}(u, v) = C_{\bar{X}(0)y_0}(\phi^*(\bar{X}y) + u, \psi^*(\bar{X}y) + v)$ . This will take care of all  $x_0 \in \text{Im } \bar{X}(0)$ . From the closed loop saddle point inequalities,

$$(4.37) \quad c_{y_0}(0, v) \leq c_{y_0}(0, 0) \leq c_{y_0}(u, 0)$$

for all  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|\bar{X}^{-1}|u \in L^2(0, T; \mathbf{R}^k)$  and  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|\bar{X}^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ , the pair  $(0, 0)$  achieves an open loop saddle point. By [5, Lemma 3.1],  $c_{y_0}(u, v)$  is convex-concave and  $dc_{y_0}(0, 0; u, v) = 0$  for all  $u$  and  $v$ . A direct computation yields

$$(4.38) \quad \begin{aligned} \frac{1}{2}dc_{y_0}(0, 0; u, v) &= F\hat{y}(T) \cdot z(T) + \int_0^T Q\bar{X}\hat{y} \cdot \bar{X}z + (U_*\bar{X}\hat{y} + u_*) \cdot (U_*\bar{X}z + u) \\ &\quad - (V_*\bar{X}\hat{y} + v_*) \cdot (V_*\bar{X}z + v) dt, \\ \hat{y}' &= \bar{X}^{-1}(B_1 u_* + B_2 v_*), \quad \hat{y}(0) = y_0, \quad z' = \bar{X}^{-1}(B_1 u + B_2 v), \quad z(0) = 0. \end{aligned}$$

By introducing the solution  $\pi \in H^1(0, T; \mathbf{R}^n)$  of the adjoint equation

$$(4.39) \quad \begin{aligned} \pi' + \bar{X}^\top Q\bar{X}\hat{y} + \bar{X}^\top U_*^\top (U_*\bar{X}\hat{y} + u_*) - \bar{X}^\top V_*^\top (V_*\bar{X}\hat{y} + v_*) &= 0, \\ \pi(T) &= F\hat{y}(T), \end{aligned}$$

we get

$$0 = \frac{1}{2}dc_{y_0}(0, 0; u, v) = \int_0^T (B_1^\top \bar{X}^{-\top} \pi + U_* \bar{X} \hat{y} + u_*) \cdot u + (B_2^\top \bar{X}^{-\top} \pi - V_* \bar{X} \hat{y} - v_*) \cdot v dt.$$

By the density of  $\mathcal{U}$  in  $L^2(0, T; \mathbf{R}^m)$  and  $\mathcal{V}$  in  $L^2(0, T; \mathbf{R}^k)$  in Lemma 4.4(ii),

$$(4.40) \quad \begin{aligned} B_1^\top \bar{X}^{-\top} \pi + U_* \bar{X} \hat{y} + u_* &= 0 \text{ and } B_2^\top \bar{X}^{-\top} \pi - V_* \bar{X} \hat{y} - v_* = 0 \\ \Rightarrow -B_1^\top \bar{X}^{-\top} \pi &\in L^2(0, T; \mathbf{R}^m) \text{ and } B_2^\top \bar{X}^{-\top} \pi \in L^2(0, T; \mathbf{R}^k). \end{aligned}$$

Using the above identities (4.40) to eliminate  $u^*$  and  $v^*$ , we see that the pair  $(\hat{y}, \pi)$  is a solution in  $H^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)$  of the linear system

$$(4.41) \quad \begin{cases} \pi' + \bar{X}^\top Q\bar{X}\hat{y} - \bar{X}^\top (U_*^\top B_1^\top + V_*^\top B_2^\top) \bar{X}^{-\top} \pi = 0, & \pi(T) = F\hat{y}(T), \\ \hat{y}' = \bar{X}^{-1} [-R\bar{X}^{-\top} \pi - (B_1 U_* + B_2 V_*) \bar{X} \hat{y}], & \hat{y}(0) = y_0. \end{cases}$$

However, the solution of the equation for  $\pi$  is not unique as an element of  $H^1(0, T; \mathbf{R}^n)$ . Let  $\hat{p} \in H^1(0, T; \mathbf{R}^n)$  be the solution of the equation

$$(4.42) \quad \hat{p}' + A^\top \hat{p} + Q\bar{X}\hat{y} = 0, \quad \hat{p}(T) = F\hat{y}(T),$$

and consider the  $H^1(0, T; \mathbf{R}^n)$ -function  $\bar{X}^\top \hat{p}$ . A direct computation using equation (4.36) for  $\bar{X}$  shows that  $\bar{X}^\top \hat{p}$  is also a solution of the first equation of (4.41). So we can choose a solution  $\pi$  in the space

$$(4.43) \quad H_{\bar{X}^\top}^1(0, T; \mathbf{R}^n) \stackrel{\text{def}}{=} \left\{ q \in H^1(0, T; \mathbf{R}^n) : \begin{array}{l} \exists r \in H^1(0, T; \mathbf{R}^n) \\ \text{such that } q = \bar{X}^\top r \end{array} \right\}.$$

Moreover, by using  $\pi = \bar{X}^\top \hat{p}$  and by introducing the variable  $\hat{x} \stackrel{\text{def}}{=} \bar{X} \hat{y}$  in  $H_{\bar{X}}^1(0, T; \mathbf{R}^n)$ , we finally get that, for all  $y_0 \in \mathbf{R}^n$ , the pair  $(\hat{x}, \hat{p})$  is a solution in  $H_{\bar{X}}^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)$  of the system

$$(4.44) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(0) = X(0)y_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = F\hat{x}(T), \end{cases}$$

and from identity (4.40),

$$(4.45) \quad B_1^\top \hat{p} + U_* \hat{x} + u_* = 0, \quad B_2^\top \hat{p} - V_* \hat{x} - v_* = 0.$$

By linearity of system (4.44), the pair  $(2\hat{x}, 2\hat{p})$  is also a solution for the initial condition  $2y_0$ , and necessarily,

$$(4.46) \quad 2(B_1^\top \hat{p} + U_* \hat{x}) + u_* = 0, \quad 2(B_2^\top \hat{p} - V_* \hat{x}) - v_* = 0.$$

The last two sets of identities yield  $u_* = 0$ ,  $v_* = 0$ , and

$$(4.47) \quad -B_1^\top \hat{p} = U_* \hat{x}, \quad B_2^\top \hat{p} = V_* \hat{x}.$$

From this we conclude that the strategies  $(\phi^*, \psi^*) \in S$  are linear since  $\psi^*(t, x) = V_*(t)x$  and  $\phi^*(t, x) = U_*(t)x$ .

(iii)  $\Rightarrow$  (i). Let  $\bar{X}$  be an  $H^1(0, T)$ -solution of the matrix equation  $\bar{X}' = (A + B_1 U_* + B_2 V_*)\bar{X}$ ,  $\bar{X}(T) = I$ . By substituting identities (4.33) into the first equation of (4.32), we get for all  $x_0 \in \text{Im } \bar{X}(0)$ ,  $\hat{x}' = (A + B_1 U_* + B_2 V_*)\hat{x}$ ,  $\hat{x}(0) = x_0$ . By Lemma 4.4(i), the solutions of this equation in  $H_{\bar{X}}^1(0, T; \mathbf{R}^n)$  are  $\bar{X}(t)y_0$  for all  $y_0 \in \mathbf{R}^n$  such that  $x_0 = X(0)y_0$  and, in particular,  $\hat{x}(T) = y_0$ . As a consequence, for all  $y_0 \in \mathbf{R}^n$  the coupled system

$$(4.48) \quad \begin{cases} \hat{x}' = A\hat{x} - R\hat{p}, & \hat{x}(T) = y_0, \\ \hat{p}' + A^\top \hat{p} + Q\hat{x} = 0, & \hat{p}(T) = Fy_0 \end{cases}$$

has a solution  $(\hat{x}, \hat{p}) \in H_{\bar{X}}^1(0, T; \mathbf{R}^n) \times H^1(0, T; \mathbf{R}^n)$  such that  $\hat{x}(t) = \bar{X}(t)y_0$ . But the solution of system (4.48) with final conditions is unique. By linearity, there exists a unique  $H^1(0, T)$ -solution  $(X, \Lambda)$  to the matrix system

$$(4.49) \quad \begin{cases} X' = AX - R\Lambda, & X(T) = I, \\ \Lambda' + A^\top \Lambda + QX = 0, & \Lambda(T) = F, \end{cases}$$

such that  $\hat{x} = Xy_0$  and  $\hat{p} = \Lambda y_0$ . By uniqueness, for all  $y_0 \in \mathbf{R}^n$ ,  $\hat{x}(t) = \bar{X}(t)y_0$ . Hence  $X(t) = \bar{X}(t)$  and  $\det X(t) \neq 0$  for almost all  $t$  in  $[0, T]$ . This shows that the system is normalizable and completes the proof.  $\square$

**4.6. Definition of a closed loop saddle point.** In view of Theorem 4.1, we adopt the following definition that says that the original problem can be changed via feedback in such a way that the resulting problem has an open loop saddle point at  $(0, 0)$ . It will still be referred to as a *closed loop saddle point*, yet it is more a notion of *structural saddle point*.

DEFINITION 4.5.

- (i) Given  $x_0 \in \mathbf{R}^n$ ,  $(\phi^*, \psi^*) \in S$  is a closed loop saddle point of  $C_{x_0}$  if there exists a solution in  $H_X^1(0, T; \mathbf{R}^n)$  to the state equation

$$(4.50) \quad \hat{x}' = (A + B_1 U_* + B_2 V_*)\hat{x} + B_1 u_* + B_2 v_*, \quad \hat{x}(0) = x_0,$$

and for all solutions  $\hat{x} \in H_X^1(0, T; \mathbf{R}^n)$  of (4.50), all  $u \in L^2(0, T; \mathbf{R}^m)$  such that  $|X^{-1}|u \in L^2(0, T; \mathbf{R}^m)$ , all  $v \in L^2(0, T; \mathbf{R}^k)$  such that  $|X^{-1}|v \in L^2(0, T; \mathbf{R}^k)$ , and all solutions  $x_u, x_v \in H_X^1(0, T; \mathbf{R}^n)$  of the state equations

$$(4.51) \quad x'_u = (A + B_1 U_* + B_2 V_*)x_u + B_1(u_* + u) + B_2 v_*, \quad x_u(0) = x_0,$$

$$(4.52) \quad x'_v = (A + B_1 U_* + B_2 V_*)x_v + B_1 u_* + B_2(v_* + v), \quad x_v(0) = x_0,$$

the following inequalities are verified:

$$(4.53) \quad C_{x_0}(\phi^*(x_v), \psi^*(x_v) + v) \leq C_{x_0}(\phi^*(\hat{x}), \psi^*(\hat{x})) \leq C_{x_0}(\phi^*(x_u) + u, \psi^*(x_u)).$$

- (ii) We say that  $(\phi^*, \psi^*) \in S$  is an  $X(0)$ -global closed loop saddle point of  $C_{x_0}$  if for all  $x_0 \in \text{Im } X(0)$  the inequalities (4.53) are verified.

*Remark 4.5.* By definition of  $H_X^1(0, T; \mathbf{R}^n)$ , there exists  $y \in H^1(0, T; \mathbf{R}^n)$  such that  $\hat{x} = Xy$ ,  $x_0 = \hat{x}(0) = X(0)y(0)$ , and the existence of a solution to the state equation (4.50) implies that  $x_0 \in \text{Im } X(0)$ .

*Remark 4.6.* If  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable global closed loop saddle point in the sense of Definition 3.2(ii), it is an  $X(0)$ -global closed loop saddle point by the equivalence of parts (i) and (ii) of Theorem 3.1.

**4.7. Closed loop saddle points when  $v(x_0)$  is finite.** We first study closed loop saddle points when  $v(x_0)$  is finite.

THEOREM 4.2. Given  $x_0 \in \mathbf{R}^n$ , the following statements are equivalent.

- (i)  $C_{x_0}$  has a closed loop saddle point  $(\phi^*, \psi^*) \in S$ , and  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ .
- (ii)  $C_{x_0}$  has a closed loop saddle point  $(\phi^*, \psi^*) \in \Phi \times \Psi$ , and  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$  (case (a) of Theorem 3.2).
- (iii)  $C_{x_0}$  has an open loop saddle point.

*Proof.* (i)  $\Rightarrow$  (iii). By Remark 4.5,  $x_0 \in \text{Im } X(0)$ : there exists  $y_0$  such that  $x_0 = X(0)y_0$ . From part (ii) of the proof of Theorem 4.1, there exists a solution  $(\hat{x}, \hat{p})$  in  $H^1(0, T; \mathbf{R}^n)^2$  to the coupled system (4.48) with  $\hat{x}(0) = X(0)y_0$ . Since  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ ,  $C_{x_0}$  has an open loop saddle point by [5, Thm. 2.4].

(iii)  $\Rightarrow$  (ii). Denote by  $(\hat{u}, \hat{v})$  the pair achieving the open loop saddle point. By [5, Thm. 2.4],  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ . By definition of  $\Phi \times \Psi$ ,  $(\hat{u}, \hat{v}) \in \Phi \times \Psi$ . By inequalities (3.20) and (3.21) in Lemma 3.3,

$$\begin{aligned} \inf_{\phi \in \Phi} C_{x_0}(\phi, \hat{v}) &= \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, \hat{v}) = C_{x_0}(\hat{u}, \hat{v}), \\ \sup_{\psi \in \Psi} \inf_{\phi \in \Phi} C_{x_0}(\phi, \psi) &\geq v^-(x_0) \geq \inf_{\phi \in \Phi} C_{x_0}(\phi, \hat{v}) = C_{x_0}(\hat{u}, \hat{v}). \end{aligned}$$

By inequalities (3.22) and (3.23) in Lemma 3.3,

$$\begin{aligned} \sup_{\psi \in \Psi} C_{x_0}(\hat{u}, \psi) &= \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(\hat{u}, v) = C_{x_0}(\hat{u}, \hat{v}), \\ \inf_{\phi \in \Phi} \sup_{\psi \in \Psi} C_{x_0}(\phi, \psi) &\leq v^+(x_0) \leq \sup_{\psi \in \Psi} C_{x_0}(\hat{u}, \psi) = C_{x_0}(\hat{u}, \hat{v}). \end{aligned}$$

Hence, there exists  $(\hat{u}, \hat{v}) \in \Phi \times \Psi$  such that for all  $\phi \in \Phi$  and all  $\psi \in \Psi$ ,

$$C_{x_0}(\hat{u}, \psi) \leq C_{x_0}(\hat{u}, \hat{v}) \leq C_{x_0}(\phi, \hat{v}).$$

By Lemma 3.2,  $(\hat{u}, \hat{v})$  is a closed loop saddle point of  $C_{x_0}$  in  $\Phi \times \Psi$ .

(ii)  $\Rightarrow$  (i). By assumption,  $C_{x_0}$  is convex-concave. As in Remark 4.6, if  $(\phi^*, \psi^*) \in \Phi \times \Psi$  is an  $L^2$ -integrable closed loop saddle point in the sense of Definition 3.2(i), it is a closed loop saddle point in the sense of Definition 4.5(i). Hence this proof follows from the proof of (i)  $\Rightarrow$  (ii) of Theorem 3.1.  $\square$

We also have a global version of the previous theorem (case (a)).

**THEOREM 4.3.** *The following statements are equivalent.*

- (i)  $C_{x_0}$  has an  $X(0)$ -global closed loop saddle point  $(\phi^*, \psi^*) \in S$ ,  $X(0) = \mathbf{R}^n$ , and  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ .
- (ii)  $C_{x_0}$  has a global closed loop saddle point  $(\phi^*, \psi^*) \in \Phi \times \Psi$  and  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ .
- (iii) For all  $x_0 \in \mathbf{R}^n$ ,  $C_{x_0}$  has an open loop saddle point.

*Proof.* (i)  $\Rightarrow$  (iii). This follows from the equivalence of (i) and (iii) in Theorem 4.2.

(iii)  $\Rightarrow$  (ii). By [5, Thm. 2.4],  $C_{x_0}(u, v)$  is convex in  $u$  and concave in  $v$ . By [5, Thm. 2.9], there exists a unique symmetrical solution to the Riccati equation with elements in  $H^1(0, T)$ . By Theorem 3.1,  $C_{x_0}$  has a global closed loop saddle point  $(\phi^*, \psi^*) \in \Phi \times \Psi$ .

(ii)  $\Rightarrow$  (i). By Theorem 3.1(v),  $X(t)$  is invertible for all  $[0, T]$ ,  $\text{Im } X(0) = \mathbf{R}^n$ , and the problem is normalizable. By Theorem 4.1,  $C_{x_0}$  has an  $X(0)$ -global closed loop saddle point in  $S$  and  $X(0) = \mathbf{R}^n$ .  $\square$

**4.8. Closed loop saddle points when either  $v^-(x_0)$  or  $v^+(x_0)$  is not finite.** From Theorem 4.2, when the value of the game  $v(x_0)$  is finite, the closed loop strategy in  $S$  can be trivially chosen as  $(\phi^*(t, x), \psi^*(t, x)) = (\hat{u}(t), \hat{v}(t))$ ; from Theorem 4.3, when the value of the game  $v(x_0)$  is finite for all  $x_0 \in \mathbf{R}^n$ , the global closed loop strategy is equal to the  $L^2$ -integrable closed loop strategy  $(\phi^*, \psi^*) = (-B_1^\top P \hat{x}, B_2^\top P \hat{x}) \in \Phi \times \Psi$ , where  $P$  is the  $H^1(0, T)$  solution of the Riccati differential equation. The conclusion is that *closed loop strategies with non- $L^2$ -integrable singularities will only occur when either  $v^-(x_0)$  or  $v^+(x_0)$  is not finite.*

The new Definition 4.5 of a closed loop saddle point was introduced to accommodate closed loop strategies with non- $L^2$ -integrable singularities, but its relation to the open loop values is not as straightforward as in the  $L^2$ -integrable case of Theorem 3.2. Yet, a complete classification is obtained for the six cases along the lines of Theorem 3.2 in terms of the  $u$ -convexity and  $v$ -concavity of the utility function.

**THEOREM 4.4.** *Assume that  $C_{x_0}$  has a closed loop saddle point  $(\phi^*, \psi^*) \in S$ . Denote by  $(\hat{u}, \hat{v}) = (\phi^*, \psi^*)$  the associated controls.*

- (i) (case (b)).  $v^-(x_0)$  finite and  $v^+(x_0) = +\infty$  if and only if  $C_{x_0}(u, v)$  is convex in  $u$  and not concave in  $v$ , and  $v \mapsto \inf_v C_{x_0}(u, v)$  is concave. In that case,

$$(4.54) \quad v^-(x_0) = \inf_{u \in L^2(0, T; \mathbf{R}^n)} C_{x_0}(u, \hat{v}) = C_{x_0}(\hat{u}, \hat{v}) = C_{x_0}(\phi^*, \psi^*).$$

- (ii) (case (e)).  $v^-(x_0) = v^+(x_0) = +\infty$  if and only if  $C_{x_0}(u, v)$  is convex in  $u$  and not concave in  $v$ , and  $v \mapsto \inf_v C_{x_0}(u, v)$  is not concave. In that case,

$$\sup_{\psi \in \Psi} \inf_{\phi \in \Phi} C_{x_0}(\phi, \psi) = \inf_{\phi \in \Phi} \sup_{\psi \in \Psi} C_{x_0}(\phi, \psi) = +\infty.$$

*Proof.* From the proof of Theorem 4.1, there exists a solution  $(\hat{x}, \hat{p})$  in  $H^1(0, T; \mathbf{R}^n)^2$  to the coupled system (4.48) ( $x_0 \in \text{Im } X(0)$ ). Since  $C_{x_0}(u, v)$  is convex in  $u$ , we have

$$v^-(x_0) \geq \inf_{u \in L^2(0, T; \mathbf{R}^m)} C_{x_0}(u, \hat{v}) = C_{x_0}(\hat{u}, \hat{v}) > -\infty$$

for the pair  $(\hat{u}, \hat{v}) = (-B_1^\top \hat{p}, B_2^\top \hat{p})$ . Moreover, since  $C_{x_0}(u, v)$  is not concave in  $v$ , then  $v^+(x_0) = +\infty$ . As a result, only two cases can occur:  $v^-(x_0)$  finite and  $v^+(x_0) = +\infty$  or  $v^-(x_0) = v^+(x_0) = +\infty$ . The property in (ii) follows from Lemma 3.3.  $\square$

*Remark 4.7.* Contrarily to the  $L^2$ -integrable closed loop saddle point, case (e) can occur, as can be seen from the system and utility function (2.25).

Since the cases (c) and (f) are dual of cases (b) and (e), we have the dual result.

**THEOREM 4.5.** Assume that  $C_{x_0}$  has a closed loop saddle point  $(\phi^*, \psi^*) \in S$ . Denote by  $(\hat{u}, \hat{v}) = (\phi^*, \psi^*)$  the associated controls.

- (i) (case (c)).  $v^+(x_0)$  finite and  $v^-(x_0) = -\infty$  if and only if  $C_{x_0}(u, v)$  is concave in  $v$  and not convex in  $u$  and  $u \mapsto \sup_v C_{x_0}(u, v)$  is convex. In that case

$$(4.55) \quad v^+(x_0) = \sup_{v \in L^2(0, T; \mathbf{R}^k)} C_{x_0}(\hat{u}, v) = C_{x_0}(\hat{u}, \hat{v}) = C_{x_0}(\phi^*, \psi^*).$$

- (ii) (case (f)).  $v^-(x_0) = v^+(x_0) = -\infty$  if and only if  $C_{x_0}(u, v)$  is concave in  $v$  and not convex in  $u$  and  $u \mapsto \sup_v C_{x_0}(u, v)$  is not convex. In that case

$$\sup_{\psi \in \Psi} \inf_{\phi \in \Phi} C_{x_0}(\phi, \psi) = \inf_{\phi \in \Phi} \sup_{\psi \in \Psi} C_{x_0}(\phi, \psi) = -\infty.$$

*Remark 4.8.* Part (ii) of Theorems 4.4 and 4.5 justifies the terminology “degenerate” for cases (e) and (f), since what would be the candidate for a closed loop saddle point identity in  $\Phi \times \Psi$  is, respectively, equal to  $+\infty$  and  $-\infty$ . This is to be compared with [2, Definition 2.3 and Theorem 3.1]. If the problem is normalizable, then the conclusions of Theorems 4.4 and 4.5 hold for all  $x_0 \in \text{Im } X(0)$  (cf. Theorem 4.1).

Finally, by complementarity, we have the last case (d) of Theorem 3.2.

**THEOREM 4.6** (case (d)). Assume that  $C_{x_0}$  has a closed loop saddle point  $(\phi^*, \psi^*) \in S$ . Then  $v^-(x_0) = -\infty$  and  $v^+(x_0) = +\infty$  if and only if  $C_{x_0}(u, v)$  is not convex in  $u$  and not concave in  $v$ .

*Remark 4.9.* Case (d) can definitely occur, as all the other cases. Again, in the work of Bernhard [2], the utility function was convex in  $u$  since  $F \geq 0$  and  $Q(t) \geq 0$ . Hence, only cases (a) and (b) could occur, and case (e) is still a degenerate one in the sense of his definition.

**4.9. An example of a problem that is not normalizable.** We conclude with an example where  $\det X(t) = 0$  on an interval of nonzero length. Yet there are solutions to the matrix Riccati differential equation, and the open loop lower value of the game is finite for all initial conditions. The associated strategies can be obtained by feedback. So, the condition  $\det X(t) \neq 0$  almost everywhere in  $[0, T]$  might not be the most general one, and Definitions 4.3 and 4.5 might be further relaxed or generalized.

*Example 4.3.* Consider the dynamics and utility function in the time interval  $[0, 3]$ ,

$$(4.56) \quad x'(t) = b_1(t)u(t) + b_2(t)v(t), \text{ a.e. in } [0, 3], \quad x(0) = x_0,$$

$$(4.57) \quad C_{x_0}(u, v) = \frac{1}{2}|x(3)|^2 + \int_0^3 |u(t)|^2 - |v(t)|^2 dt,$$

where

$$(4.58) \quad b_1(t) = \begin{cases} 2-t, & 0 \leq t < 1, \\ 0, & 1 \leq t < 2, \\ 3-t, & 2 \leq t \leq 3, \end{cases} \quad b_2(t) = \begin{cases} t, & 0 \leq t < 1, \\ 0, & 1 \leq t < 2, \\ t-1, & 2 \leq t \leq 3. \end{cases}$$

Here  $A = 0$ ,  $B_1(t) = b_1(t)$ ,  $B_2(t) = b_2(t)$ ,  $F = 1/2$ ,  $Q = 0$ , and

$$(4.59) \quad R(t) = b_1(t)^2 - b_2(t)^2 = \begin{cases} 4(1-t), & 0 \leq t < 1, \\ 0, & 1 \leq t < 2, \\ 4(2-t), & 2 \leq t \leq 3. \end{cases}$$

We show that  $v^-(x_0) = (x_0)^2/2$  and  $v^+(x_0) = +\infty$ . For the open loop lower value of the game, the minimization with respect to  $u$  has a unique solution for all  $(x_0, v)$  since the utility function  $u \mapsto C_{x_0}(u, v)$  is convex and bounded below by  $-\|v\|_{L^2}^2$ . The minimizer is completely characterized by the coupled system

$$\begin{cases} x' = -b_1^2 p + b_2 v \text{ a.e. in } [0, 3], & x(0) = x_0, & \hat{u} = -b_1 p, \\ p' = 0 \text{ a.e. in } [0, 3], & p(3) = \frac{1}{2}x(3). \end{cases}$$

From this,

$$J_{x_0}^-(v) \stackrel{\text{def}}{=} \inf_{u \in L^2(0,2;\mathbf{R})} C_{x_0}(u, v) = C_{x_0}(\hat{u}, v) = \frac{1}{4} \left[ x_0 + \int_0^3 b_2 v ds \right]^2 - \int_0^3 |v|^2 dt.$$

It is readily seen that  $J_{x_0}^-$  is concave in  $v$  and that the supremum with respect to  $v$  of  $J_{x_0}^-(v)$  exists. Indeed, from the first order condition, for all  $v$ ,

$$\frac{1}{2} dJ_{x_0}^-(\hat{v}; v) = \frac{1}{4} \left[ x_0 + \int_0^3 b_2 \hat{v} ds \right] \int_0^3 b_2 v ds - \int_0^3 \hat{v} v(t) dt = 0,$$

there is a unique stationary point  $\hat{v}(t) = b_2(t)x_0/2$ , the Hessian is negative,

$$\frac{1}{2} d^2 J_{x_0}^-(\hat{v}; v; v) = \frac{1}{4} \left[ \int_0^3 b_2 v ds \right]^2 - \int_0^3 |v|^2 dt \leq -\frac{1}{3} \int_0^3 |v|^2 dt,$$

and the open loop lower value of the game is  $v^-(x_0) = J_{x_0}^-(\hat{v}) = (x_0)^2/2$ . Moreover,

$$(4.60) \quad \hat{u}(t) = \begin{cases} -(2-t)\frac{1}{2}x_0, & 0 \leq t < 1, \\ 0, & 1 \leq t < 2, \\ -(3-t)\frac{1}{2}x_0, & 2 \leq t \leq 3, \end{cases} \quad \hat{v}(t) = \begin{cases} t\frac{1}{2}x_0, & 0 \leq t < 1, \\ 0, & 1 \leq t < 2, \\ (t-1)\frac{1}{2}x_0, & 2 \leq t \leq 3. \end{cases}$$

However, the open loop upper value of the game is  $v^+(x_0) = +\infty$  for all  $x_0 \in \mathbf{R}$ . Indeed, pick the sequence of controls  $\{v_n\}$ ,  $n \geq 1$ ,  $v_n(t) = 0$  in  $[0, 2]$  and  $v_n(t) = n$  in  $[2, 3]$ . The corresponding sequence of states at time  $t = 3$  is

$$x_n(3) = x_0 + \int_0^3 b_1 u \, dt + n \int_2^3 (t-1) \, dt = \left[ x_0 + \int_0^3 b_1 u \, dt \right] + \frac{3}{2}n.$$

Denote by  $X$  the square bracket that does not depend on  $n$ . Then

$$\begin{aligned} C_{x_0}(u, v_n) &= \frac{1}{2} \left| X + \frac{3}{2}n \right|^2 + \int_0^3 |u|^2 \, dt - \int_2^3 n^2 \, dt \\ &= \frac{1}{8}n^2 + \frac{3}{2}nX + \frac{X^2}{2} + \int_0^3 |u|^2 \, dt \rightarrow +\infty \text{ as } n \rightarrow +\infty. \end{aligned}$$

Thus for all  $x_0 \in \mathbf{R}$  and  $u \in L^2(0, T; \mathbf{R})$ ,

$$\sup_{v \in L^2(0, T; \mathbf{R})} C_{x_0}(u, v) = +\infty \Rightarrow v^+(x_0) = +\infty.$$

Therefore,  $C_{x_0}(u, v)$  has no open loop saddle point. For all  $x_0$ , the coupled system

$$(4.61) \quad \hat{x}' = -R\hat{p}, \quad \hat{x}(0) = x_0 \quad \text{and} \quad \hat{p} = 0, \quad \hat{p} = \frac{1}{2}\hat{x}(3), \quad \hat{u} = -b_1\hat{p}, \quad \text{and} \quad \hat{v} = b_2\hat{p}$$

has a unique solution in  $H^1(0, 3)$ . The unique solution of system (4.1),

$$(4.62) \quad \begin{cases} X' = AX - R\Lambda, & X(T) = I, \\ \Lambda' + A^\top \Lambda + QX = 0, & \Lambda(T) = F, \end{cases}$$

is given by

$$(4.63) \quad \begin{aligned} X(t) &= \begin{cases} (t-1)^2, & 0 \leq t < 1 \\ 0, & 1 \leq t < 2 \\ (t-2)^2, & 2 \leq t \leq 3 \end{cases}, & P_c(t) &= \begin{cases} \frac{1}{2(t-1)^2}, & 0 \leq t < 1 \\ c \text{ (arbitrary)}, & 1 \leq t < 2 \\ \frac{1}{2(t-2)^2}, & 2 \leq t \leq 3 \end{cases}. \\ \Lambda(t) &= 1/2, \end{aligned}$$

The problem is not normalizable since  $X(t) = 0$  in  $[1, 2]$ . Yet, the associated optimal strategies are feedback strategies of the usual forms,  $\hat{u} = -b_1 P_c x$  and  $\hat{v} = b_2 P_c x$ , and the linear closed loop strategies are

$$\phi^*(t, x) = U_c(t)x = -b_1(t)P_c(t)x \quad \text{and} \quad \psi^*(t, x) = V_c(t)x = b_2(t)P_c(t)x.$$

The function  $X$  is also a solution of (4.19) in Definition 4.3,

$$X' = (b_1 U_c + b_2 V_c)X, \quad X(3) = I.$$

If we adopt the convention that a function  $u \in L^2(0, 3)$  such that  $|X^{-1}|u \in L^2(0, 3)$  implies that  $u = 0$  on  $Z = \{t \in [0, 3] : X(t) = 0\} = [1, 2]$  and adopt the same for the function  $v$ , it can be shown that  $dc_{x_0}(0, 0, : u, v) = 0$  for all  $u$  and  $v$ . However, we have not been able to prove the convexity-concavity of  $c_{x_0}(u, v)$  to conclude that the problem has a closed loop saddle point in the sense of Definitions 4.3 and 4.5.

Another issue is the meaning of a solution to the Riccati equation  $P' - RP^2 = 0$ , with final value  $P(3) = 1/2$  and a discontinuous function  $R$ . What is the effect of a discontinuity in  $R(t)$ ? For instance the following solutions are continuous in  $t = 1$ :

$$P(t) = \begin{cases} \bar{c}/(1 + 2\bar{c}(t-1)^2), & 0 \leq t < 1 \\ \bar{c}, & 1 \leq t < 2 \\ 1/(2(t-2)^2), & 2 \leq t \leq 3 \end{cases}$$

for some arbitrary constant  $\bar{c} \in \mathbf{R}$ . The singularity at  $t_2 = 2$  is independent of  $\bar{c}$ . For  $\bar{c} > -1/2$  it is the only singularity. For  $\bar{c} \leq -1/2$ , there is a second singularity at  $t_1 = 1 - \sqrt{1/(-2\bar{c})}$  in the interval  $[0, 1)$ . We also have the solutions  $P_c$  of (4.63) with a singularity in  $t_1 = 1$ . Therefore the solution of the Riccati equation is not unique.

# A UNIQUENESS RESULT FOR $p$ -MONOTONE VISCOSITY SOLUTIONS OF HAMILTON–JACOBI EQUATIONS IN BOUNDED DOMAINS\*

MARTIN V. DAY<sup>†</sup>

**Abstract.** We consider a class of Hamilton–Jacobi equations  $H(x, Du(x)) = 0$  with no  $u$ -dependence and with continuity properties consistent with recent applications in queueing theory. Continuous viscosity solutions are considered in a compact polyhedral domain, with oblique derivative (Neumann-type) boundary conditions. Comparison and uniqueness results are presented, which use monotonicity of  $H(x, p)$  in the  $p$  variable for values of  $p$  in the appropriate sub- and superdifferential sets of the solution  $u(x)$ . Several examples illustrate the results.

**Key words.** viscosity solution, Hamilton–Jacobi equation, uniqueness

**AMS subject classifications.** 49L25, 35D99, 35F30

**DOI.** 10.1137/070700401

**1. Introduction.** The theory of viscosity solutions to first order partial differential equations provides a satisfying approach to Hamilton–Jacobi equations for many types of optimal control problems and differential games. Bardi and Capuzzo-Dolcetta [4] give an extensive introduction to the basic theory and its application to a variety of optimization problems. At the heart of the theory are the fundamental comparison and uniqueness results, which identify the optimal value function as the unique viscosity solution of the appropriate Hamilton–Jacobi equation. Those comparison and uniqueness results generally depend on some monotonicity property of the Hamiltonian  $H$ . For instance, in the case of discounted infinite horizon problems, the Hamilton–Jacobi equation includes a term  $\lambda u$  ( $\lambda > 0$  being the discount rate). This provides monotonicity in  $u$  which is the key to the proof of the typical comparison result, such as [4, Theorem II.3.1].

In this paper we consider problems of the form

$$H(x, Du(x)) = 0,$$

in which the Hamiltonian  $H(x, p)$  has no  $u$ -dependence. It is well known that without some additional property, solutions may be nonunique. (See Example 6 in section 5, for instance.) Ishii [18] provides an approach which assumes convexity of  $p \mapsto H(x, p)$  and the existence of a special smooth subsolution  $\varphi$ . (See also [4, section II.5.3].) The idea is to perturb a given subsolution by a (small) convex combination with  $\varphi$  to obtain a “strict” subsolution. A basic comparison result (very like our Lemma 2) then implies the desired inequality. An elementary example is the eikonal equation

$$H(x, p) = |p| - h(x),$$

where  $h$  is continuous and strictly positive on the spatial domain  $\Omega$ . This category of problems can also be treated using the transformation of Kružkov. This can be applied generally when there is a strictly positive lower bound for the running cost  $L$

of (19) below. See Bardi and Soravia [5] and the references in [18]. Our  $p$ -monotone approach is also applicable to such problems; see Example 2 below.

Another approach is that of Camilli and Siconolfi [7]. They are interested in equations of the form

$$H(x, p) - f(x) = 0$$

and seek to identify maximal subsolutions. (In some control problems this is the standard characterization of the desired viscosity solution; see Soravia [21].) They obtain a definitive characterization of maximal subsolutions in terms of a special singular solution property. Their approach is rather technical, using convexity of the sets  $\{p : H(x, p) - f(x) \leq 0\}$  and a special topology in  $\Omega$  associated with them. Among their few simple hypotheses on the Hamiltonian is the assumption that  $t \mapsto H(x, tp)$  is strictly increasing in  $t \in [0, 1]$  for all  $p$ . We note that this is essentially the  $p$ -monotone property that we exploit below. We would comment that our results also provide a simple sufficient condition for a viscosity solution to be the maximal subsolution, namely that it be a  $p$ -monotone supersolution.

We are motivated by a growing body of work using control problems and differential games for asymptotic analysis of queueing networks. These problems often involve oblique-derivative boundary conditions on some part of  $\partial\Omega$ . (Although only Dirichlet conditions were considered in [18] and [7], presumably generalizations are possible.) These examples typically do not have the convexity needed for either the approach of [18] or [7]; see Examples 4 and 5 in section 5. However, the literature does contain some uniqueness results for certain problems of this type. The germ of our  $p$ -monotone argument can be found in the proof of Theorem 5 of Atar, Dupuis, and Schwartz [2] (see their equation (37)). Although it is not a viscosity solution result, the structured verification theorem of Day [12] uses a “positive storage condition” which is related to  $p$ -monotonicity (as we will see in Example 5). The essential feature underlying these results is monotonicity of  $t \mapsto H(x, tp)$ , not necessarily for all  $p$  but just for those  $p = \zeta \in D^\pm u(x)$  that are not accounted for by the boundary conditions. Our intent here is to develop comparison and uniqueness results based on this property for problems with oblique-derivative boundary conditions, such as are typical in queueing applications. This class of problems also motivates our regularity hypotheses on  $H$ .

There are a few other comparison results in the literature which employ properties of the  $p$ -dependence of  $H$ . For instance, the development in Crandall, Ishii, and Lions [8] assumes that a special test function  $\mu(x)$  exists for which  $\lambda \mapsto H(x, p + \lambda D\mu(x)) - H(x, p)$  satisfies a certain lower bound; see their (H2). We note that such a hypothesis is entirely a property of the Hamiltonian and depends on the existence of  $\mu(x)$ . In general our notion of a  $p$ -monotone solution depends on the specific solution  $u(x)$ , not solely on  $H$ .

In section 2 we pose the specific type of boundary value problem we will address, using oblique-derivative conditions on the boundary of a compact polyhedral domain. Section 3 presents a basic comparison result (Lemma 2) for sub- and supersolutions to a pair of “strictly separated” equations. (That strict separation generally implies a comparison result is well known; see Crandall, Ishii, and Lions [9].) The  $p$ -monotone results are then developed in section 4. Our main result (Theorem 4) implies that when a  $p$ -monotone solution exists it is the unique viscosity solution—the “complete solution” in the terminology of [4]. We conclude by looking at several examples in section 5.

**2. Preliminaries and hypotheses.** We consider a domain  $\Omega$  which is assumed to be a compact convex polyhedron in  $\mathbb{R}^n$ , defined by a finite collection of  $m$  linear constraints,

$$(1) \quad \Omega = \{x \in \mathbb{R}^n : n_i \cdot x \geq c_i \text{ for each } i = 1, \dots, m\}.$$

The  $n_i$  are unit vectors (inward normals) and the  $c_i$  are constants. For  $x \in \partial\Omega$  (the boundary of  $\Omega$ ) we define the set of active constraints as

$$I(x) = \{i : n_i \cdot x = c_i\}$$

and take  $I(x) = \emptyset$  for  $x \in \Omega^\circ$  (the interior of  $\Omega$ ). We consider a closed subset  $\mathcal{T} \subseteq \Omega$  on which Dirichlet data will be prescribed. This could be part of the boundary, but that it not necessary. Values for  $u$  are prescribed on  $\mathcal{T}$  by a continuous function  $g : \mathcal{T} \rightarrow \mathbb{R}$ ,

$$(2) \quad u(x) = g(x), \quad x \in \mathcal{T}.$$

It will be convenient to use the notation

$$\Omega_{\delta, \mathcal{T}} = \{x \in \Omega : \text{dist}(x, \mathcal{T}) > \delta\}$$

to refer to the part of  $\Omega$  at least  $\delta > 0$  away from  $\mathcal{T}$ . (We allow  $\mathcal{T} = \emptyset$ , in which case  $\Omega_{\delta, \mathcal{T}} = \Omega$ .) On the rest of the boundary,  $\partial\Omega \setminus \mathcal{T}$ , we want to require oblique-derivative boundary conditions using a collection of vectors  $d_i$ ,  $i = 1, \dots, m$ ,

$$(3) \quad -d_i \cdot Du(x) = 0, \quad i \in I(x).$$

In  $\Omega \setminus \mathcal{T}$  itself we consider a Hamilton–Jacobi equation,

$$(4) \quad H(x, Du(x)) = 0.$$

If  $\mathcal{T} = \partial\Omega$ , we have a standard Dirichlet problem. If  $\mathcal{T} = \emptyset$  we have a typical Neumann-type problem. In general the problem is a mixture of these two types.

**2.1. Continuity hypothesis on the Hamiltonian.** Appropriate continuity hypotheses for the Hamiltonian  $H$  are important. The examples we have in mind use a Hamiltonian of the form (19) below, with  $f = f(a, b)$  independent of state and running cost  $L = h(x) + \ell(a, b)$  with separate state and player components. This leads to a Hamiltonian of separated form,  $H(x, p) = H_0(p) - h(x)$ . But all we really need are continuity hypotheses consistent with that. We assume there exist  $m : [0, \infty) \rightarrow [0, \infty)$  with  $m(0) = 0$  and continuous at 0, and  $M : [0, \infty)^2 \rightarrow [0, \infty)$  with  $M(0, R) = 0$  and  $M(\cdot, R)$  continuous at 0 for each  $R < \infty$ , such that for all  $x, y \in \Omega$  and  $p, q \in \mathbb{R}^d$  with  $|p|, |q| \leq R$ , we have

$$(5) \quad |H(x, p) - H(y, q)| \leq m(|x - y|) + M(|p - q|, R).$$

**2.2. Technical hypotheses on  $\Omega$  and  $d_i$ .** The oblique-derivative boundary conditions (3) are closely associated with the Skorokhod problem for  $\Omega$ ; see Dupuis and Ishii [14]. Control problems for systems including a Skorokhod problem in their dynamics are common in queueing theory and lead to Hamilton–Jacobi equations with boundary conditions (3); see Lions [19], Dupuis and Ishii [15], and Day [11]. Although the Skorokhod problem does not appear in our results below, hypotheses from [14] regarding  $\Omega$  and the  $d_i$  of the boundary conditions are important ingredients for the proof of Lemma 2. For that purpose we assume the following.

• *B-hypothesis* [14, Assumption 2.1]. There exists a compact, convex  $B \subseteq \mathbb{R}^n$  with  $0 \in B^\circ$  and the following property: If  $z \in \partial B$  and  $|z \cdot n_i| < 1$ , then  $\nu \cdot d_i = 0$  for all unit outward normals to  $B$  at  $z$ . ( $\nu$  is an outward normal to  $B$  at  $z$  if  $\nu \cdot (z - x) \geq 0$  for all  $x \in B$ .) For further discussion of this hypothesis and an illustrative figure, see Dupuis and Ramanan [17].

• *Coercivity hypothesis*. For each  $x \in \partial\Omega$ , and any  $a_i \in \mathbb{R}$ ,

$$(6) \quad \left( \sum_{i \in I(x)} a_i d_i \right) \cdot \left( \sum_{i \in I(x)} a_i n_i \right) \geq 0,$$

with equality only if  $a_i = 0$  for all  $i \in I(x)$ . It is shown in Day [10] that this, together with the *B-hypothesis*, implies [14, Assumption 3.1] concerning the existence of a discrete projection map. Moreover, it implies that, for each  $x \in \partial\Omega$ , the  $d_i$ ,  $i \in I(x)$ , are linearly independent, which is needed for Lemma 1 below. We might have assumed [14, Assumption 3.1] along with this linear independence property, but (6) is a convenient sufficient condition for both and is easy to verify in examples, since it reduces to checking positive definiteness of a small number of matrices.

These hypotheses provide the following technical result, which will be needed for the proof of Lemma 2.

LEMMA 1. *Assume the B-hypothesis and the coercivity hypothesis.*

(a) *There exists a  $C^1$  function  $\mu : \Omega \rightarrow [0, 1]$  with the property that  $d_i \cdot D\mu(x) < 0$  whenever  $x \in \partial\Omega$  and  $i \in I(x)$ .*

(b) *There exists a  $C^1$  function  $\xi : \mathbb{R}^n \rightarrow [0, \infty)$  with the properties that*

(i)  *$\xi^{1/2}$  is a norm on  $\mathbb{R}^d$ , and*

(ii) *for any  $x \in \mathbb{R}^n$  and  $i = 1, \dots, m$ ,  $x \cdot n_i \geq 0$  [ $\leq 0$ ] implies  $d_i \cdot D\xi(x) \geq 0$  [ $\leq 0$ ].*

*Proof.* Part (a) is Lemma 3.2 of Dupuis and Ishii [15]. Their hypothesis (B.6) follows from the independence of  $d_i$ ,  $i \in I(x)$ , pointed out above. The other hypotheses are simple to check in our setting.

Part (b) follows from arguments given in Atar and Dupuis [1], which we outline. (See their remark on page 1109.) First, it is shown that the property of  $B$  is equivalent to an extended property, namely that if  $z \in \partial B$  and  $\nu$  is an outward normal to  $B$  at  $z$ , then

$$z \cdot n_i \geq -1 [\leq 1] \text{ implies } d_i \cdot \nu \geq 0 [\leq 0].$$

(Although [1] only considers  $\Omega = \mathbb{R}_+^n$ , the extension argument based on Dupuis and Ramanan [17] applies in general.) Next, given that the set  $B$  exists, it is argued that  $B$  can be assumed symmetric with a smooth boundary, in the sense that the unit outward normal  $\nu(x)$  is uniquely determined and continuous as a function of  $x \in \partial B$ . Such a  $B$  determines a (smooth) norm on  $\mathbb{R}^n$ , defined by

$$\|x\|_B = \inf\{r > 0 : x \in rB\}.$$

$B$  is the closed unit ball with respect to  $\|\cdot\|_B$ . We define  $\xi(x) = \|x\|_B^2$ . It follows that  $\xi$  is  $C^1$ , and for a given  $x$ ,

$$D\xi(x) = b\|x\|_B \nu,$$

where  $b = b(x) > 0$  is a scalar function and  $\nu$  the unit outward normal to  $B$  at  $z = x/\|x\|_B \in \partial B$ . Therefore if  $x \cdot n_i \geq 0$ , then  $-1 < 0 \leq z \cdot n_i$ , so that the extended

property of  $B$  above implies  $d_i \cdot \nu \geq 0$ , which in turn implies  $d_i \cdot D\xi(x) \geq 0$ . The other case is proven analogously, or by appeal to symmetry.  $\square$

As a consequence of (a), observe that there exists a constant  $\mu_0 > 0$  such that

$$(7) \quad \mu_0 < -d_i \cdot D\mu(x) \text{ for all } x \in \partial\Omega, i \in I(x).$$

**2.3. Viscosity solutions.** In the proof of Lemma 2 we will use the generalization of (3) to

$$(8) \quad C - d_i \cdot Du(x) = 0, i \in I(x),$$

where  $C$  is a constant. We want to state carefully what it means to be a viscosity sub- or supersolution of (4) with boundary conditions (8) on  $\Omega \setminus \mathcal{T}$ . Note that the definitions will not refer to (2) on  $\mathcal{T}$ ; we prefer to express that separately by referring to “subsolutions with  $u(x) \leq g(x)$  on  $\mathcal{T}$ ” as needed.

We will consider only continuous functions  $u : \Omega \rightarrow \mathbb{R}$  as possible solutions. For  $x \in \Omega$  the superdifferential set  $D^+u(x)$  consists of those  $\zeta \in \mathbb{R}^n$  which occur as the value  $\zeta = D\phi(x)$  for some  $C^1$  function  $\phi : \mathbb{R}^n \rightarrow \mathbb{R}$  with the property that  $u(x) - \phi(x) \geq u(y) - \phi(y)$  for all  $y \in \Omega$  sufficiently close to  $x$ . For the correct viscosity-sense understanding of (8) it is important to note that  $x$  is a local maximum of  $u - \phi$  *only relative to*  $\Omega$ . For  $x \in \partial\Omega$  this means that even if  $u$  is smooth,  $D^+u(x)$  can contain many  $\zeta$  other than  $Du(x)$  itself. (See Lemma 7 in section 5.) Similarly,  $D^-v(x)$  consists of  $\zeta$  arising as  $\zeta = D\phi(x)$  for some  $C^1$  function  $\phi(x)$  such that  $v - \phi$  has a local minimum at  $x$  relative to  $\Omega$ . The function  $u(x) \in C(\Omega)$  is called a *subsolution* of

$$(9) \quad H(x, Du(x)) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } C - d_i \cdot Du(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}$$

provided the following hold for all  $\zeta \in D^+u(x)$ :

- (i) if  $x \in \Omega^\circ \setminus \mathcal{T}$ , then  $H(x, \zeta) \leq 0$ ;
- (ii) if  $x \in \partial\Omega \setminus \mathcal{T}$ , then either  $H(x, \zeta) \leq 0$  or  $C - d_i \cdot \zeta \leq 0$  for some  $i \in I(x)$ .

In other words, at boundary points only one of the inequalities  $H(x, \zeta) \leq 0$ ,  $C - d_i \cdot \zeta \leq 0$  ( $i \in I(x)$ ) needs to hold. This is the, now standard, viscosity formulation of first order equations with “Neumann-type” boundary conditions (see Barles and Lions [6]), generalized to consider different boundary conditions  $C - d_i \cdot Du(x) = 0$  on the different planar faces of  $\partial\Omega$ . We can express this subsolution definition succinctly by writing

$$(10) \quad H(x, \zeta) \wedge \min_{i \in I(x)} (C - d_i \cdot \zeta) \leq 0 \text{ for all } x \in \Omega \setminus \mathcal{T} \text{ and } \zeta \in D^+u(x)$$

and using the convention that  $\min_{i \in I(x)} = +\infty$  if  $I(x) = \emptyset$ . The definition of a *supersolution* is obtained by reversing all the inequalities in (i) and (ii) and considering  $\zeta \in D^-u(x)$  instead. We would replace (10) by  $H(x, \zeta) \vee \max_{i \in I(x)} (C - d_i \cdot \zeta) \geq 0$ .

**3. A basic comparison result for strictly separated equations.** The task of this section is to establish a basic comparison result for oblique-derivative boundary conditions (3) analogous to that of Ishii [18, Lemma 1]. The comparison argument of Atar, Dupuis, and Schwartz [2] is close to ours and is the source of our approach to handling the boundary conditions. The use of a norm such as  $\xi$  in the function  $\Phi_\epsilon$  of the proof below originated in Dupuis, Ishii, and Soner [16].

LEMMA 2. Assume that  $g : \mathcal{T} \rightarrow \mathbb{R}$  is continuous and that  $u, v \in C(\Omega)$  with  $u \leq g \leq v$  on  $\mathcal{T}$  are such that

(a)  $u$  is a subsolution of  $H(x, Du(x)) + \eta_+(x) = 0$  on  $\Omega \setminus \mathcal{T}$ , with  $-d_i \cdot Du(x) = 0$  on  $\partial\Omega \setminus \mathcal{T}$ ; and

(b)  $v$  is a supersolution of  $H(x, Dv(x)) - \eta_-(x) = 0$  on  $\Omega \setminus \mathcal{T}$ , with  $-d_i \cdot Dv(x) = 0$  on  $\partial\Omega \setminus \mathcal{T}$ ,

where  $\eta_{\pm} : \Omega \rightarrow \mathbb{R}$  have the property that for each  $\delta > 0$ ,

$$(11) \quad \inf_{x \in \Omega_{\delta, \mathcal{T}}} \eta_+(x) + \inf_{x \in \Omega_{\delta, \mathcal{T}}} \eta_-(x) > 0.$$

Then  $u(x) \leq v(x)$  for all  $x \in \Omega$ .

We will say that the  $u$  and  $v$  of this lemma are viscosity sub- and supersolutions to a *strictly separated* pair of equations. Note that because of (11) this notion of strict separation depends on the choice of  $\mathcal{T}$ . Also observe that we have made no regularity assumption on the  $\eta_{\pm}$ . The inequality (11) is all the proof needs. An alternate hypothesis would be to assume that  $\inf_{\Omega_{\delta, \mathcal{T}}} [\eta_+(x) + \eta_-(x)] > 0$  along with continuity of (one of) the  $\eta_{\pm}$ .

*Proof.* Let  $0 < c_{\epsilon} < 1$  be a family of constants with  $c_{\epsilon} \rightarrow 0$  as  $\epsilon \downarrow 0$ . Near the end of the proof we will be more specific about how  $c_{\epsilon}$  should be chosen, but that detail is not needed yet. Given  $\epsilon > 0$ , define

$$u_{\epsilon}(x) = u(x) - c_{\epsilon}\mu(x), \quad v_{\epsilon}(x) = v(x) + c_{\epsilon}\mu(x),$$

where  $\mu(x)$  is as in Lemma 1 above. It follows that  $\zeta_{\epsilon} \in D^+u_{\epsilon}(x)$  iff  $\zeta = \zeta_{\epsilon} + c_{\epsilon}D\mu(x) \in D^+u(x)$ . Notice that

$$-d_i \cdot \zeta = -d_i \cdot (\zeta_{\epsilon} + c_{\epsilon}D\mu(x)) \geq -d_i \cdot \zeta_{\epsilon} + c_{\epsilon}\mu_0,$$

where  $\mu_0$  is as in (7). Therefore, the subsolution hypothesis of (a) implies that for all  $\zeta \in D^+u(x)$ ,

$$[H(x, \zeta_{\epsilon} + c_{\epsilon}D\mu(x)) + \eta_+(x)] \wedge \min_{i \in I(x)} (c_{\epsilon}\mu_0 - d_i \cdot \zeta_{\epsilon}) \leq 0.$$

In other words,  $u_{\epsilon}$  is a subsolution of

$$(12) \quad H(x, Du_{\epsilon}(x) + c_{\epsilon}D\mu(x)) + \eta_+(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } c_{\epsilon}\mu_0 - d_i \cdot Du_{\epsilon}(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}.$$

Similarly,  $v_{\epsilon}$  is a supersolution of

$$(13) \quad H(x, Dv_{\epsilon}(x) - c_{\epsilon}D\mu(x)) - \eta_-(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -c_{\epsilon}\mu_0 - d_i \cdot Dv_{\epsilon}(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}.$$

Now suppose that  $\sup_{\Omega}(u(x) - v(x)) > 0$ . Then because  $\mu(x)$  is bounded and  $c_{\epsilon} \rightarrow 0$ , there is a positive constant  $\rho$  so that for all sufficiently small  $\epsilon > 0$ ,

$$(14) \quad 0 < \rho < \sup_{\Omega}[u_{\epsilon}(x) - v_{\epsilon}(x)].$$

We now give a version of the usual argument leading to a contradiction. Define

$$\Phi_{\epsilon}(x, y) = u_{\epsilon}(x) - v_{\epsilon}(y) - \epsilon^{-1}\xi(x - y),$$

where  $\xi(\cdot)$  is as in Lemma 1, and let  $(x_{\epsilon}, y_{\epsilon}) \in \Omega \times \Omega$  be a maximizing pair for  $\Phi_{\epsilon}$ . By comparison to  $x = y$ , we have

$$(15) \quad \Phi_{\epsilon}(x_{\epsilon}, y_{\epsilon}) \geq \rho.$$

From  $\Phi_\epsilon(x_\epsilon, x_\epsilon) \leq \Phi_\epsilon(x_\epsilon, y_\epsilon)$  it follows that

$$(16) \quad \epsilon^{-1}\xi(x_\epsilon - y_\epsilon) \leq v_\epsilon(x_\epsilon) - v_\epsilon(y_\epsilon).$$

Since  $v$  and  $\mu$  are bounded, and  $0 < c_\epsilon < 1$ , it follows that  $v_\epsilon$  is bounded (independent of  $\epsilon$ ). We deduce that  $\xi(x_\epsilon - y_\epsilon) = O(\epsilon)$ . Since all norms on  $\mathbb{R}^n$  are equivalent, we have

$$(17) \quad \|x_\epsilon - y_\epsilon\| = O(\epsilon^{1/2}).$$

Next, we claim that none of the limit points of  $x_\epsilon$  (as  $\epsilon \downarrow 0$ ) can be in  $\mathcal{T}$ . Indeed, if (along a sequence of  $\epsilon \downarrow 0$ ) we had  $x_\epsilon \rightarrow z \in \mathcal{T}$ , then by (17)  $y_\epsilon \rightarrow z$  as well. It follows that

$$\lim_\epsilon [u_\epsilon(x_\epsilon) - v_\epsilon(y_\epsilon)] \leq g(z) - 0\mu(z) - [g(z) + 0\mu(z)] = 0.$$

Since  $v$  and  $\mu$  are continuous,  $v_\epsilon$  is equicontinuous with respect to  $\epsilon$ . This, together with (16), implies that  $\epsilon^{-1}\xi(x_\epsilon - y_\epsilon) \rightarrow 0$ . Therefore  $\Phi_\epsilon(x_\epsilon, y_\epsilon) \rightarrow 0$ , contrary to (15), and this proves our claim. The claim means that there exists  $\delta > 0$  so that  $x_\epsilon, y_\epsilon \in \Omega_{\delta, \mathcal{T}}$  for all sufficiently small  $\epsilon$ . By hypothesis (11), there exists  $\eta_0 > 0$  so that

$$\eta_0 \leq \eta_+(x_\epsilon) + \eta_-(y_\epsilon),$$

for all  $\epsilon > 0$  sufficiently small.

Now  $u_\epsilon(x) - [v_\epsilon(y_\epsilon) + \epsilon^{-1}\xi(x - y_\epsilon)]$  is maximized at  $x = x_\epsilon$ . Therefore  $\zeta_\epsilon \doteq \epsilon^{-1}D\xi(x_\epsilon - y_\epsilon) \in D^+u_\epsilon(x_\epsilon)$ . Since  $D\xi$  is continuous and  $\Omega$  is compact, it follows that

$$\zeta_\epsilon = O(\epsilon^{-1}).$$

If it were the case that  $x_\epsilon \in \partial\Omega$ , then by definition of  $\Omega$  we would have  $n_i \cdot (x_\epsilon - y_\epsilon) \leq 0$  for all  $i \in I(x_\epsilon)$ . By property (ii) of  $\xi$  in Lemma 1, it follows that  $d_i \cdot \zeta_\epsilon \leq 0$  for all  $i \in I(x_\epsilon)$ . Therefore,

$$c_\epsilon\mu_0 - d_i \cdot \zeta_\epsilon \geq c_\epsilon\mu_0 > 0.$$

Since we know  $x_\epsilon \notin \mathcal{T}$ , (12) implies that

$$H(x_\epsilon, \zeta_\epsilon + c_\epsilon D\mu(x_\epsilon)) + \eta_+(x_\epsilon) \leq 0.$$

Arguing in the same way, from the fact that  $y = y_\epsilon$  maximizes

$$v_\epsilon(y) - [u(x_\epsilon) - \epsilon^{-1}\xi(x_\epsilon - y)],$$

we are led to the conclusion that

$$H(y_\epsilon, \zeta_\epsilon - c_\epsilon D\mu(y_\epsilon)) - \eta_-(y_\epsilon) \geq 0.$$

Therefore,

$$0 < \eta_0 \leq \eta_+(x_\epsilon) + \eta_-(y_\epsilon) \leq H(y_\epsilon, \zeta_\epsilon - c_\epsilon D\mu(y_\epsilon)) - H(x_\epsilon, \zeta_\epsilon + c_\epsilon D\mu(x_\epsilon)).$$

Now we know that for some constant  $K$  (independent of  $\epsilon > 0$ ),  $|\zeta_\epsilon \pm c_\epsilon D\mu| \leq \epsilon^{-1}K$ . Our continuity hypotheses on  $H(x, p)$  imply that the right-hand side of the above expression is bounded above by

$$m(|x_\epsilon - y_\epsilon|) + M(2c_\epsilon|\mu|, \epsilon^{-1}K).$$

The first term converges to 0 because  $|x_\epsilon - y_\epsilon| \rightarrow 0$ . We can choose  $c_\epsilon \downarrow 0$  so that the second term  $\rightarrow 0$  as well. For such choices we have a contradiction to the positive lower bound  $\eta_0$ . This contradiction implies that  $\sup_\Omega [u(x) - v(x)] \leq 0$ , concluding the proof.  $\square$

**4.  $p$ -monotone uniqueness.** We want to use monotonicity properties of  $H$  in the  $p$  variable to produce the additional  $\eta_{\pm}(x)$  terms needed for application of Lemma 2. Intuitively, we want to use a property such as

$$H(x, s\zeta) < H(x, \zeta) \text{ for } 0 < s < 1 \quad \text{and} \quad H(x, \zeta) < H(x, s\zeta) \text{ for } 1 < s.$$

However, this is considerably stronger than needed for the proof. For the subsolution case,  $0 < s < 1$ , we don't really need  $H(x, s\zeta) < H(x, \zeta)$ , only  $H(x, s\zeta) < 0$ , but holding uniformly on compacts disjoint from  $\mathcal{T}$ . We express this as

$$H(x, s\zeta) + \eta_s(x) \leq 0$$

for some function  $\eta_s(x)$  which is uniformly positive on each  $\Omega_{\delta, \mathcal{T}}$ . Moreover, we only need these properties for those  $\zeta \in D^+u(x)$  such that the inequality (10) is not satisfied by virtue of the  $-d_i \cdot \zeta$  terms. This can be stated succinctly by saying that  $u(x)$  is a subsolution of

$$H(x, sDu(x)) + \eta_s(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -d_i \cdot Du(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T},$$

which is what we need to invoke Lemma 2. The following definition is based on this weakened monotonicity requirement.

DEFINITION 3. A viscosity subsolution  $u(x)$  of

$$(18) \quad H(x, Du(x)) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -d_i \cdot Du(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}$$

is called  $p$ -monotone if, for some  $\delta_0 > 0$  and each  $1 - \delta_0 < s < 1$ , there exists a function  $\eta_s : \Omega \rightarrow [0, \infty)$  with  $\inf_{\Omega_{\delta, \mathcal{T}}} \eta_s > 0$  for each  $\delta > 0$ , so that  $u(x)$  is a subsolution of

$$H(x, sDu(x)) + \eta_s(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -d_i \cdot Du(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}.$$

A viscosity supersolution  $v(x)$  of (18) is called  $p$ -monotone if, for some  $\delta_0 > 0$  and each  $1 < s < 1 + \delta_0$ , there exists a function  $\eta_s : \Omega \rightarrow [0, \infty)$  with  $\inf_{\Omega_{\delta, \mathcal{T}}} \eta_s > 0$  for each  $\delta > 0$ , so that  $v(x)$  is a supersolution of

$$H(x, sDv(x)) - \eta_s(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -d_i \cdot Dv(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}.$$

A viscosity solution which is both a  $p$ -monotone subsolution and a  $p$ -monotone supersolution is called a  $p$ -monotone solution.

We observe that  $p$ -monotonicity concerns  $s\zeta$  for  $s < 1$  in the case of a subsolution, but  $1 < s$  for a supersolution. It is possible for a viscosity solution to have the  $p$ -monotone property in the supersolution sense but not the subsolution sense. This would be a viscosity solution and a  $p$ -monotone supersolution, but not a  $p$ -monotone solution.

We are now ready for our main theorem. The basic idea is that if  $u(x)$  is a subsolution, then  $p$ -monotonicity will imply that  $su(x) + (s-1)c$  is a "strict" subsolution. (The constant term  $(s-1)c$  is to insure that  $su(x) + (s-1)c \leq g$  in case  $g(x) < 0$ . The fact that  $H$  has no  $u$ -dependence allows us to add such constants with impunity.) We then appeal to Lemma 2 and let  $s \uparrow 1$ .

THEOREM 4. Suppose  $u$  is a  $p$ -monotone subsolution of (9) with  $u \leq g$  on  $\mathcal{T}$ , and  $v$  is (any) supersolution with  $g \leq v$  on  $\mathcal{T}$ . Then  $u(x) \leq v(x)$  for all  $x \in \Omega$ . Likewise if  $u$  is (any) subsolution and  $v$  is a  $p$ -monotone supersolution with  $u \leq g \leq v$  on  $\mathcal{T}$ ,

then  $u(x) \leq v(x)$  for all  $x \in \Omega$ . If (9) has a  $p$ -monotone solution  $v$ , then  $v$  is the complete solution (i.e., it is the unique solution, the maximal subsolution, and the minimal supersolution).

COROLLARY 5. A viscosity solution which is a  $p$ -monotone supersolution is the maximal subsolution.

*Proof.* We focus on the  $p$ -monotone subsolution case. Let

$$-c = \min_{\mathcal{T}} g(x).$$

On  $\mathcal{T}$  we have  $u(x) + c \leq g(x) + c$ . Since  $0 \leq g(x) + c$ , it follows that (for any  $0 < s < 1$ )  $s(u(x) + c) \leq g(x) + c$  on  $\mathcal{T}$ . This is equivalent to

$$u_s(x) \doteq su(x) + (s - 1)c \leq g(x), \quad x \in \mathcal{T}.$$

Now  $\zeta_s \in D^+u_s(x)$  iff  $\zeta_s = s\zeta$  for some  $\zeta \in D^+u(x)$ . If  $x \in \partial\Omega \setminus \mathcal{T}$  and  $-d_i \cdot \zeta_s > 0$  for all  $i \in I(x)$ , then  $-d_i \cdot \zeta > 0$  for all  $i \in I(x)$ , so by the  $p$ -monotone subsolution property for  $u(x)$ ,

$$H(x, \zeta_s) + \eta_s(x) = H(x, s\zeta) + \eta_s(x) \leq 0.$$

The same inequality holds for  $x \in \Omega^\circ$ . We conclude that  $u_s$  is a viscosity subsolution of

$$H(x, Du_s(x)) + \eta_s(x) = 0 \text{ on } \Omega \setminus \mathcal{T} \text{ with } -d_i \cdot Du_s(x) = 0 \text{ on } \partial\Omega \setminus \mathcal{T}.$$

We can now apply Lemma 2 to  $u_s$  and  $v$ , using  $\eta_+(x) = \eta_s(x)$  for  $u_s$  and  $\eta_-(x) \equiv 0$  for  $v$ . The lemma implies that  $u_s(x) \leq v(x)$  all  $x \in \Omega$  as follows: for all  $1 - \delta_0 < s < 1$ ,

$$su(x) + (s - 1)c \leq v(x).$$

Letting  $s \uparrow 1$  implies  $u(x) \leq v(x)$ , as claimed. The supersolution case (using  $s \downarrow 1$ ) is analogous. The rest of the assertions of the theorem and corollary are now elementary.  $\square$

In general the  $p$ -monotone property may depend on the specific solution, since the definition only concerns  $\zeta \in D^\pm u(x)$ . However, for some Hamiltonians all (sub- or super-) solutions will be  $p$ -monotone. We consider in particular Hamiltonians associated with a running cost  $L(x, a, b)$ ,

$$(19) \quad H(x, p) = \inf_{b \in \mathcal{B}} \sup_{a \in \mathcal{A}} \{-p \cdot f(x, a, b) - L(x, a, b)\},$$

still assuming the continuity hypotheses of section 2.1 above. The next lemma shows that uniform positivity of the running cost provides a simple sufficient condition for all solutions to have the  $p$ -monotone property. (The argument is embedded in the proof of [2, Theorem 5].) When the lemma applies, Theorem 4 becomes a simple comparison and uniqueness theorem for *all* viscosity solutions.

LEMMA 6. Suppose that  $H(x, p)$  is given by (19), and that there exists a function  $\sigma : \Omega \rightarrow [0, \infty)$  with the property that  $0 < \inf_{\Omega_{\delta, \mathcal{T}}} \sigma(x)$  for each  $\delta > 0$  and for which

$$\sigma(x) \leq L(x, a, b)$$

for all  $a \in \mathcal{A}$ ,  $b \in \mathcal{B}$ ,  $x \in \Omega$ . Then every subsolution and every supersolution of (9) is  $p$ -monotone.

Note that since  $\sigma(x)$  is allowed to vanish on  $\mathcal{T}$ , the choice of  $\mathcal{T}$  may affect the applicability of the lemma.

*Proof.* Suppose that  $0 < s < 1$  and consider any  $\zeta \in \mathbb{R}^n$ . We have

$$\begin{aligned} -s\zeta \cdot f(a, b) - L(x, a, b) &= s[-\zeta \cdot f(a, b) - L(x, a, b)] - (1-s)L(x, a, b) \\ &\leq s[-\zeta \cdot f(a, b) - L(x, a, b)] - (1-s)\sigma(x). \end{aligned}$$

Taking  $\inf_{b \in \mathcal{B}} \sup_{a \in \mathcal{A}}$  yields  $H(x, s\zeta) \leq sH(x, \zeta) - (1-s)\sigma(x)$ . Let  $\eta_s(x) = (1-s)\sigma(x)$ . We have

$$H(x, s\zeta) + \eta_s(x) \leq sH(x, \zeta),$$

holding for all  $\zeta$ . It follows from this that any subsolution is a  $p$ -monotone subsolution.

The supersolution argument is analogous by using  $1 < s$ ,  $\eta_s(x) = (s-1)\sigma(x)$ , with the appropriate inequalities reversed.  $\square$

**5. Examples.** We now discuss several examples, most of which are taken from existing literature, which illustrate the applicability and limitations of the above results. In all the examples, the Hamiltonian has the form  $H(x, p) = H_0(p) - h(x)$ , for which the hypotheses (5) are easy to verify. We omit those details, as well as the confirmations of the  $B$ -hypothesis and the coercivity hypothesis.

Numerous optimal control or differential game problems have been posed for “fluid limits” of queueing networks. The most common domain for these examples is the nonnegative orthant  $\Omega = \mathbb{R}_+^d$ . Being unbounded, this is outside the scope of our results above. Our first example makes the point that our main result, Theorem 4, can fail in unbounded domains.

*Example 1.* In Day [11] an example in two dimensions was considered for the Hamiltonian

$$(20) \quad H(x, p) = \frac{1}{2}\|p\|^2 - \frac{1}{2}\|x\|^2.$$

This arises as in (19) using

$$(21) \quad L(x, a, b) = \frac{1}{2}\|x\|^2 + \frac{1}{2}\|a\|^2, \quad f(x, a, b) = a,$$

with  $\mathcal{A} = \mathbb{R}^2$ . ( $\mathcal{B}$  is irrelevant.) With  $\mathcal{T} = \{(0, 0)\}$  and  $\sigma(x) = \frac{1}{2}\|x\|^2$  we see that Lemma 6 applies, and therefore *all* viscosity solutions are  $p$ -monotone. The equation, however, was considered in the *unbounded* half-space  $\Omega = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 \leq 1\}$ , using  $d = (-1, 0)$  ( $= -\gamma(x)$  in the notation of [11]) for the boundary condition on  $\partial\Omega$ , and taking  $g(0, 0) = 0$ . If Theorem 4 were valid for unbounded domains, solutions would be unique. However, in [11] it was shown that both  $v(x) = \frac{1}{2}x_1^2 \pm \frac{1}{2}x_2^2$  are viscosity solutions.

The rest of our examples will use compact  $\Omega$  as hypothesized. Examples 2–4 illustrate the applicability of Lemma 6.

*Example 2.* The “eikonal” equation

$$|Du(x)| - h(x) = 0, \quad u(x) = g(x) \text{ on } \partial\Omega,$$

with  $h(x) > 0$  on  $\Omega$  was cited above in reference to the approach of Ishii [18]. We simply observe that  $H(x, p) = |p| - h(x)$  is obtained from (19) using  $f(x, a, b) = a$ ,  $a \in \mathcal{A} = \{a : |a| \leq 1\}$ , and  $L(x, a, b) = h(x)$ . ( $\mathcal{B}$  is irrelevant.) Lemma 6 applies, so

that all solutions are  $p$ -monotone, and Theorem 4 provides the usual comparison and uniqueness results for this Hamiltonian on bounded domains, for any choice of  $\mathcal{T}$ .

*Example 3.* The doctoral dissertation of Menendez [20] considers an example using dynamics of the form

$$(22) \quad f(x, a, b) = \lambda - Ga$$

in a bounded rectangle  $\Omega$  in two dimensions. The running cost  $L(x, a, b) = \frac{1}{2}|x|^2 + 1.1$  is strictly positive. The control set  $\mathcal{A}$  is compact and there is no dependence on  $b$ . This problem again falls within the scope of Lemma 6 (regardless of  $\mathcal{T}$ ), so that Theorem 4 applies to all viscosity solutions. Although [20] does not employ viscosity solution techniques, our results above show that they would be a viable alternative approach.

*Example 4.* A rather different problem is considered by Atar, Dupuis, and Schwartz [2]. Here a differential game is studied which provides an asymptotic description of a risk-sensitive stochastic control problem. In the stochastic control problem, reaching the target set  $\mathcal{T}$  ( $\partial_o G$  in their notation) is viewed as an event to be avoided, so the control attempts to maximize the time until this occurs. This becomes the maximizing player in the limiting game. The minimizing player emerges from the asymptotic analysis as the limiting representation of the random fluctuations.

The problem fits our format in the case that all the arrival parameters  $\lambda_i$  are positive. (If some  $\lambda_i = 0$ , then different boundary conditions are to be used on some parts of  $\partial\Omega \setminus \mathcal{T}$ .) We recast their problem in our notation.  $\Omega$  (their  $G$ ) is the rectangle  $\times_1^d [0, z_i]$  in  $\mathbb{R}^d$ .  $\mathcal{T}$  consists of the portion of the boundary where  $x_i = z_i$  for one or more coordinates. The  $d_i$  are the  $-\tilde{v}_i$  (below) for the respective faces  $\partial_i \Omega = \{x : x_i = 0\}$ . The maximizing player chooses the control  $b = (u_1, \dots, u_d)$  in a compact polygon  $\mathcal{B}$ . The minimizing player chooses a vector of rate perturbation factors  $a = (\alpha_i^\lambda, \alpha_i^\mu : i = 1, \dots, d)$ , with  $a \in \mathcal{A} = [0, \infty)^{2d}$ . The state dynamics are

$$f(x, a, b) = \sum_i \lambda_i \alpha_i^\lambda e_i + \sum_i u_i \mu_i \alpha_i^\mu \tilde{v}_i,$$

where  $e_i$  are the standard unit vectors in  $\mathbb{R}^d$ , and  $\tilde{v}_i$  are the *service event vectors*,  $\tilde{v}_i = e_{i'} - e_i$ , where  $i \rightarrow i'$  indicates the routing sequence in the network. The running cost is

$$L(x, a, b) = c + \sum_i \lambda_i \ell(\alpha_i^\lambda) + \sum_i u_i \mu_i \ell(\alpha_i^\mu),$$

$$\text{where } \ell(\alpha) = \alpha \log(\alpha) - \alpha + 1.$$

Here  $c > 0$  is a positive constant,  $\lambda_i > 0$ , and  $\mu_i \geq 0$ , so  $L(x, a, b) \geq c$ . Thus the hypotheses of Lemma 6 are satisfied once again, so that Theorem 4 applies to all viscosity solutions.

Our last two examples are beyond the scope of Lemma 6, and the details are more involved. The following lemma will assist us in checking the boundary conditions for (locally) smooth solutions.

LEMMA 7. Assume the coercivity condition (6). Suppose  $x \in \partial\Omega$  and  $u$  is continuously differentiable in a neighborhood of  $x$ .

(a)  $\zeta \in D^+u(x)$  iff  $\zeta = Du(x) + \sum_{i \in I(x)} \beta_i n_i$  for some choice of  $\beta_i \geq 0$ . Analogously,  $\zeta \in D^-u(x)$  iff  $\zeta = Du(x) - \sum_{i \in I(x)} \beta_i n_i$  for some  $\beta_i \geq 0$ .

(b) If  $-d_i \cdot Du(x) \leq 0$  for all  $i \in I(x)$ , then the viscosity subsolution property with boundary conditions holds as follows: for all  $\zeta \in D^+u(x)$ ,

$$H(x, \zeta) \wedge \min_{i \in I(x)} (-d_i \cdot \zeta) \leq 0.$$

Analogously, if  $-d_i \cdot Du(x) \geq 0$  for all  $i \in I(x)$ , then for all  $\zeta \in D^-u(x)$ ,

$$H(x, \zeta) \vee \max_{i \in I(x)} (-d_i \cdot \zeta) \geq 0.$$

*Proof.* The proof of (a) is the first paragraph of the proof of [12, Theorem 2.1]. For (b), suppose that  $-d_i \cdot Du(x) \leq 0$  for all  $i \in I(x)$  and consider any  $\zeta \in D^+u(x)$ . By (a) we know that  $\zeta = Du(x) + \sum_{i \in I(x)} \beta_i n_i$  with  $\beta_i \geq 0$ . We can assume some  $\beta_i > 0$  for some  $i \in I(x)$ ; else  $-d_i \cdot \zeta = -d_i \cdot Du(x) \leq 0$  follows directly. Observe that

$$\sum_{i \in I(x)} \beta_i d_i \cdot \zeta = \left( \sum_{i \in I(x)} \beta_i d_i \cdot Du(x) \right) + \left( \sum_{i \in I(x)} \beta_i d_i \right) \cdot \left( \sum_{i \in I(x)} \beta_i n_i \right).$$

By hypothesis, the first term on the right side is nonnegative. The last term is positive by the coercivity hypothesis and our assumption that  $\beta_i > 0$  for some  $i$ . Therefore the left side is positive. This implies that  $d_i \cdot \zeta > 0$  for some  $i \in I(x)$ . Consequently,

$$H(x, \zeta) \wedge \min_{i \in I(x)} (-d_i \cdot \zeta) \leq 0,$$

regardless of the value of  $H(x, \zeta)$ . The supersolution case in (b) is argued analogously.  $\square$

*Example 5.* The recent papers [3], [13], and [12] of Day and others explore a robust control approach to fluid queueing models, using state dynamics of the form

$$f(x, a, b) = b - Ga,$$

a compact control space  $\mathcal{A}$ , and opposing quadratic costs for the state and “disturbance”  $b \in \mathcal{B} = \mathbb{R}^n$  as follows:

$$(23) \quad L(x, a, b) = \frac{1}{2} \|x\|^2 - \frac{1}{2} \|b\|^2.$$

The resulting Hamiltonian is

$$(24) \quad \begin{aligned} H(x, p) &= \sup_{a \in \mathcal{A}} p \cdot Ga - \frac{1}{2} \|x\|^2 - \frac{1}{2} \|p\|^2 \\ &= \frac{1}{2} \sup_{a \in \mathcal{A}} (\|Ga\|^2 - \|p - Ga\|^2 - \|x\|^2). \end{aligned}$$

Since  $\|Ga\|$ ,  $a \in \mathcal{A}$  is bounded, we see from the second form that  $H(x, p) \geq 0$  implies a bound on  $\|x\|$ . Thus these problems are reasonable to consider *only* in bounded domains  $\Omega$ . The examples in the literature consider a bounded polygon  $\Omega$  consisting of  $x \in \mathbb{R}^d$  with  $x_i \geq 0$  and  $\eta \cdot x \leq c$  for a particular vector  $\eta$ . In [3] and [13] the boundary  $\eta \cdot x = c$  is omitted from  $\Omega$  and in its place an admissibility condition is imposed on controls, which prohibits the state from approaching this missing boundary. (See the “minimum performance criterion” and its discussion in section 2.4 of [13].) In [12] all of  $\partial\Omega$  is included, consistent with our formulation. Section 6 of [12] considers a

specific example of the type considered here. We will need to take advantage of certain explicit calculations, which would be cumbersome for that example. Instead, we will consider a simple instance of the example(s) of [3, sections 1–3], modified to include all of  $\partial\Omega$  in accordance with our hypotheses here.

We let  $G$  be the  $2 \times 2$  identity matrix. (In [3] this corresponds to  $s_i = \gamma = 1$ .) The control set is  $\mathcal{A} = \{(a_1, a_2) : 0 \leq a_i, a_1 + a_2 = 1\}$ . The Hamiltonian (24) simplifies to

$$(25) \quad H(x, p) = \max(p_1, p_2) - \frac{1}{2}\|x\|^2 - \frac{1}{2}\|p\|^2.$$

We consider the planar domain

$$\Omega = \{x \in \mathbb{R}_+^2 : x_1 + x_2 \leq r\}$$

for  $r < 1$ . If  $r = 1$ , then our  $\Omega$  would be (the closure of) the domain considered in [3]. With  $r < 1$  the domain here is slightly smaller. This reduction of the domain is important for the  $p$ -monotone property. We identify the faces and respective normal vectors as follows:

$$\begin{aligned} \partial_1\Omega &= \{x \in \Omega : x_1 = 0\}, & n_1 &= (1, 0), \\ \partial_2\Omega &= \{x \in \Omega : x_2 = 0\}, & n_2 &= (0, 1), \\ \partial_3\Omega &= \{x \in \Omega : x_1 + x_2 = r\}, & n_3 &= (-1/\sqrt{2}, -1/\sqrt{2}). \end{aligned}$$

We take  $d_i = n_i$  for all the faces. The target set will be the origin,  $\mathcal{T} = \{(0, 0)\}$ , with  $g(0, 0) = 0$ .

The constructions of [3] produce a  $C^1$  solution to  $H(x, Du(x)) = 0$ . We will see that this is a  $p$ -monotone solution, even though Lemma 6 does not apply. We will first indicate briefly how the viscosity solution properties are verified, and then turn our attention to  $p$ -monotonicity. The solution is symmetric about the diagonal  $x_1 = x_2$ . We confine our discussion to the lower-right half of  $\Omega$ :  $0 \leq x_2 \leq x_1 \leq r$ . The analysis on the other half follows by symmetry.

In the subregion  $0 \leq x_2 \leq x_1 \leq r$  the solution is most conveniently described in terms of the orthogonal basis,

$$\mu = (1/2, -1/2), \quad \eta = (1/2, 1/2).$$

(In the notation of [3, page 335],  $\mu = \mu_1 = \eta_{\{1\}} - \eta_{\{1,2\}}$  and  $\eta = \mu_2 = \eta_{\{1,2\}}$ .) The gradient  $Du(x)$  is related to  $x$  in terms of parameters  $0 \leq t_1 \leq t_2 \leq \pi/2$  by the expressions

$$(26) \quad x = \sin(t_1)\mu + \sin(t_2)\eta, \quad Du(x) = [1 - \cos(t_1)]\mu + [1 - \cos(t_2)]\eta.$$

The parameters can be eliminated to obtain the explicit expressions for  $0 \leq x_2 \leq x_1 \leq r$ ,

$$\begin{aligned} u(x) &= x_1 - \frac{1}{4} \left( \sqrt{1 - (x_1 - x_2)^2} (x_1 - x_2) + \sin^{-1}(x_1 - x_2) \right. \\ &\quad \left. + (x_1 + x_2) \sqrt{1 - (x_1 + x_2)^2} + \sin^{-1}(x_1 + x_2) \right), \\ \frac{\partial u}{\partial x_1} &= 1 - \frac{1}{2} \left( \sqrt{1 - (x_1 - x_2)^2} + \sqrt{1 - (x_1 + x_2)^2} \right), \\ \frac{\partial u}{\partial x_2} &= \frac{1}{2} \left( \sqrt{1 - (x_1 - x_2)^2} - \sqrt{1 - (x_1 + x_2)^2} \right). \end{aligned}$$

The parametric representation is more convenient for most purposes. For instance, observe that for  $p = Du(x)$ ,  $\max(p_1, p_2) = p_1$  is equivalent to  $p \cdot \mu = \frac{1}{2}[1 - \cos(t_1)] \geq 0$ , which does hold. Therefore,

$$(27) \quad H(x, p) = p_1 - \frac{1}{2}\|x\|^2 - \frac{1}{2}\|p\|^2 = p \cdot (\mu + \eta) - \frac{1}{2}\|x\|^2 - \frac{1}{2}\|p\|^2.$$

It is now straightforward to evaluate this, using the orthogonality of  $\mu$  and  $\eta$  to confirm that  $H(x, Du(x)) = 0$ . The explicit formulae provide the easiest way to check that

$$(28) \quad \partial u / \partial x_i \geq 0 \text{ for both } i,$$

because  $x_2 \leq x_1$ , and

$$(29) \quad \partial u / \partial x_2 = 0 \text{ when } x_2 = 0.$$

By Lemma 7(b), (29) implies that the viscosity boundary conditions are satisfied on  $\partial_2\Omega$ . On  $\partial_3\Omega$  we have from (28) that  $-d_3 \cdot Du(x) \geq 0$ , so that the supersolution boundary condition is satisfied there, as well as at the corner  $(r, 0)$ .

The subsolution property on  $\partial_3\Omega$  and at the corner takes more careful examination. For these  $x$  we need to identify the  $\zeta \in D^+u(x)$ , for which  $-d_i \cdot Du(x) > 0$  for all  $i \in I(x)$ , and for these we need to check that  $H(x, \zeta) \leq 0$  holds. Consider the corner  $x = (r, 0)$  specifically. From the explicit formulas,  $Du(x) = (1 - \sqrt{1 - r^2}, 0)$ . By Lemma 7, the  $\zeta \in D^+u(x)$  are

$$\zeta = Du(x) + \beta_2 n_2 + \beta_3 n_3, \quad \beta_i \geq 0.$$

One finds that the  $\zeta$  with  $\beta_i \geq 0$  and  $-d_i \cdot \zeta > 0$  comprise the triangle in the  $\zeta$ -plane with vertices  $(0, 0)$ ,  $Du(x) = [1 - \sqrt{1 - r^2}](1, 0)$ , and  $[1 - \sqrt{1 - r^2}](\frac{1}{2}, -\frac{1}{2})$ . For future reference, notice that all such  $\zeta$  satisfy

$$(30) \quad \|\zeta\| \leq \|Du(x)\|.$$

What we need at the moment is that  $\zeta_1 \leq 0 \leq \zeta_2$ , so that just as in (27),

$$H(x, \zeta) = \zeta \cdot (\mu + \eta) - \frac{1}{2}\|x\|^2 - \frac{1}{2}\|\zeta\|^2.$$

For the particular  $\zeta$  identified above, this works out to be

$$H(x, \zeta) = \frac{1}{2} \left( -\beta_2^2 + \sqrt{2}\beta_3\beta_2 - \beta_3 \left( \beta_3 + \sqrt{2}\sqrt{1 - r^2} \right) \right),$$

from which one may verify that  $H(x, \zeta) \leq 0$  for all  $\beta_i \geq 0$ . This confirms the viscosity subsolution property at the corner.

For  $x \in \partial_3\Omega$  with  $x_2 \leq x_1 < r$  the calculations are similar but simpler. The  $\zeta \in D^+u(x)$  with  $-d_3 \cdot \zeta > 0$  are  $\zeta = Du(x) + \beta_3 n_3$  with

$$(31) \quad 0 \leq \sqrt{2}\beta_3 < 1 - \cos(t_2).$$

Since  $n_3 = -\sqrt{2}\eta$ , we have

$$(32) \quad \zeta = [1 - \cos(t_1)]\mu + [1 - \cos(t_2) - \sqrt{2}\beta_3] \eta.$$

Notice that (32) implies that (30) again holds. Since  $\mu \cdot \zeta = \mu \cdot Du(x) \geq 0$ , we can again work out that

$$\begin{aligned} H(x, \zeta) &= \zeta \cdot (\mu + \eta) - \frac{1}{2} \|x\|^2 - \frac{1}{2} \|\zeta\|^2 \\ &= \frac{-1}{2} \beta_3 \left[ \sqrt{2} \cos(t_1) + \beta_3 \right] \leq 0 \text{ since } \beta_3 \geq 0. \end{aligned}$$

This completes the verification that  $u(x)$  is a viscosity solution to our problem.

We now consider  $p$ -monotonicity. Note that due to the  $-\|b\|^2$  term, there is no finite lower bound for the  $L$  of (23). Thus Lemma 6 does *not* apply. Even so, we will see that  $u(x)$  is a  $p$ -monotone solution. Observe that for any  $s > 0$ , we have  $\max(s\zeta_1, s\zeta_2) = s \max(\zeta_1, \zeta_2)$ . As a consequence we have the following identity:

$$(33) \quad H(x, s\zeta) = sH(x, \zeta) + (s-1) \left[ \frac{1}{2} \|x\|^2 - \frac{s}{2} \|\zeta\|^2 \right].$$

Consider the supersolution  $p$ -monotonicity property first. As observed above,  $-d_i \cdot Du(x) \geq 0$  on all boundary faces, so that only the interior points are involved in the  $p$ -monotonicity supersolution property. Since  $H(x, Du(x)) = 0$ , we see from (33) that  $p$ -monotonicity requires that

$$(34) \quad 0 < \frac{1}{2} \|x\|^2 - \frac{s}{2} \|Du(x)\|^2$$

for  $x \neq 0$  and  $s \approx 1$ . For  $s = 1$  this is the *positive storage condition* (see [3, (2.25)] and [12, (33)]), which was important for the verification results obtained in those papers. Here we are interested in  $1 < s$ . The parametric representation of  $Du(x)$  allows us to check (34) directly as follows:

$$\frac{1}{2} \|x\|^2 - \frac{s}{2} \|Du(x)\|^2 = \frac{1}{4} [\sin(t_1)^2 - s(1 - \cos(t_1))^2] + \frac{1}{4} [\sin(t_2)^2 - s(1 - \cos(t_2))^2].$$

Now  $0 \leq t_t \leq t_2$  and  $\frac{1}{2} \sin(t_2) = \eta \cdot x \leq \frac{r}{2}$ . Thus  $t_i \leq \sin^{-1}(r) < \frac{\pi}{2}$ , since  $r < 1$ . It is elementary to check that there exists  $\delta_0 > 0$ , so that

$$\sin(t)^2 - s(1 - \cos(t))^2 > 0$$

for all  $0 \leq t \leq \sin^{-1}(r)$  and all  $0 < s < 1 + \delta_0$ . This implies that (34) holds, and so  $u(x)$  is indeed a  $p$ -monotone supersolution, using

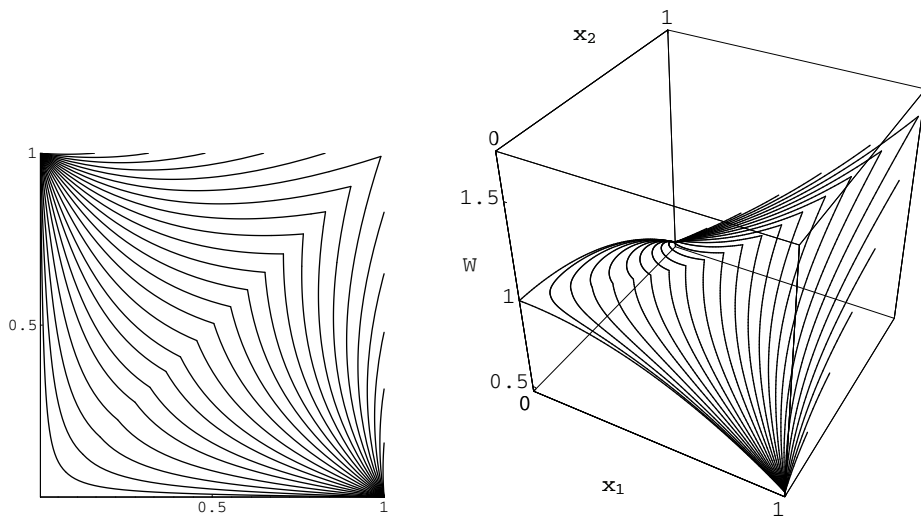

$$\eta_s(x) = (s-1) \left[ \frac{1}{2} \|x\|^2 - \frac{s}{2} \|Du(x)\|^2 \right].$$

Finally, consider the subsolution  $p$ -monotone property. Based on (33), for  $s-1 < 0$ , we need to know that, for  $\zeta \in D^+u(x)$  with  $-d_i \cdot \zeta > 0$  all  $i \in I(x)$ ,

$$0 < \frac{1}{2} \|x\|^2 - \frac{s}{2} \|\zeta\|^2.$$

But we observed in (30) above that for all such  $\zeta$ ,  $\|\zeta\| \leq \|Du(x)\|$ , and so

$$\frac{1}{2} \|x\|^2 - \frac{s}{2} \|\zeta\|^2 \geq \frac{1}{2} \|x\|^2 - \frac{s}{2} \|Du(x)\|^2.$$

FIG. 1.  $w(x)$ .

Thus we can again use

$$\eta_s(x) = (s-1) \left[ \frac{1}{2} \|x\|^2 - \frac{s}{2} \|Du(x)\|^2 \right],$$

which is strictly positive on  $\Omega \setminus \mathcal{T}$ , as shown above.

In summary,  $u(x)$  is a  $p$ -monotone viscosity solution and hence the complete solution of our problem.

Finally, we offer a new example which exhibits nonuniqueness of solutions when no  $p$ -monotone solution exists, but for which comparisons based on  $p$ -monotonicity properties are still possible.

*Example 6.* We return to the Hamiltonian (20) but consider the cube

$$\Omega = \{(x_1, x_2) : 0 \leq x_i \leq 1\}.$$

We number the boundary faces as

$$\begin{aligned} \partial_1 \Omega &= \{x \in \Omega : x_1 = 0\}, & \partial_2 \Omega &= \{x \in \Omega : x_2 = 0\}, \\ \partial_3 \Omega &= \{x \in \Omega : x_1 = 1\}, & \partial_4 \Omega &= \{x \in \Omega : x_2 = 1\}. \end{aligned}$$

The normals are  $n_1 = (1, 0)$ ,  $n_2 = (0, 1)$ ,  $n_3 = (-1, 0)$ , and  $n_4 = (0, -1)$ , and we take  $d_i = n_i$  for all faces. Consider the target set consisting of the two off-diagonal corners,  $\mathcal{T} = \{(1, 0), (0, 1)\}$ , taking  $g = \frac{1}{2}$  at both corners.

It is elementary to check that  $v(x) = \frac{1}{2}(x_1^2 + x_2^2)$  is a classical solution of  $0 = H(x, Dv(x))$  in the interior of  $\Omega$ . A second solution  $w$  is illustrated in Figure 1. It is symmetric about the diagonal line  $\Gamma = \{x \in \Omega : x_1 = x_2\}$ , but is nondifferentiable on  $\Gamma$  (and at the corners in  $\mathcal{T}$ ). In the upper left triangle,  $0 \leq x_1 \leq x_2 \leq 1$ , it is constructed from the family of characteristics (illustrated in the left pane of Figure 1),

$$\begin{aligned} \dot{x} &= H_p(x, p) = p; & x(0) &= (0, 1), \\ \dot{p} &= -H_x(x, p) = x; & p(0) &= (\cos(\theta), -\sin(\theta)), \quad 0 \leq \theta \leq \pi/2, \\ \dot{w} &= p \cdot \dot{x}; & w(0) &= 1/2 = g(x(0)), \end{aligned}$$

and extended by symmetry across  $\Gamma$ . It turns out that *both*  $v$  and  $w$  are viscosity solutions of  $H(x, Du(x)) = 0$  in  $\Omega \setminus \mathcal{T}$  with  $-d_i \cdot Du(x) = 0$  on  $\partial\Omega \setminus \mathcal{T}$  and  $u = g$  on  $\mathcal{T}$ . Moreover,  $v$  satisfies the oblique derivative boundary conditions at the points of  $\mathcal{T}$  as well. The verification of these assertions is similar to that of the previous example; we omit it for brevity.

In light of Theorem 4, neither  $v$  nor  $w$  can be a  $p$ -monotone solution. Lemma 6 does not apply here since  $x = (0, 0)$  does not belong to  $\mathcal{T}$  and  $L$  of (21) has no positive lower bound at this point. In fact, neither  $v$  nor  $w$  is a  $p$ -monotone solution in either the sub- or supersolution sense. In order for  $v$  to be a  $p$ -monotone subsolution we would need, for  $0 < s < 1$ , a function  $\eta_s(x) > 0$  (off  $\mathcal{T}$ ) with

$$H(x, sDv(x)) \leq -\eta_s(x), \quad x \in \Omega^\circ.$$

Now

$$H(x, sp) = s^2 \frac{1}{2} \|p\|^2 - \frac{1}{2} \|x\|^2 = s^2 H(x, p) + \frac{s^2 - 1}{2} \|x\|^2.$$

Since  $H(x, Dv(x)) = 0$ ,

$$H(x, sDv(x)) = \frac{s^2 - 1}{2} \|x\|^2.$$

Thus we would need  $\frac{s^2-1}{2} \|x\|^2 \leq -\eta_s(x)$  to be *uniformly* negative in a neighborhood of  $(0, 0)$ . This is clearly not possible. The same argument applies to  $w$  if we keep  $x$  off the diagonal. For the supersolution case, we would need  $\frac{s^2-1}{2} \|x\|^2 \geq \eta_s(x)$  to be uniformly positive in a neighborhood of  $(0, 0)$ , which is likewise impossible.

In Figure 2 we have plotted both solutions  $v$  and  $w$ . It is apparent that  $v \leq w$ . This can be deduced from Theorem 4 by considering the enlarged target set  $\mathcal{T}' = \{(0, 0), (0, 1), (1, 0)\}$ . Now Lemma 6 *does* apply; both  $v$  and  $w$  are  $p$ -monotone for this  $\mathcal{T}'$ . If we take  $g(0, 0) = 0 = v(0, 0)$ , then  $v$  is the complete solution of the

FIG. 2.  $v(x) \leq w(x)$ .

problem, but since  $w(0,0) = 1 > g(0,0)$ ,  $w$  is only a supersolution. Thus  $v \leq w$  follows from the comparison theorem. If instead we take  $g(0,0) = 1$ , then  $w$  is the complete solution. We obtain a supersolution by adding a constant to  $v$  as follows:  $\tilde{v}(x) = 1 + v(x)$ . In that case,  $\tilde{v} \geq g$  on  $\mathcal{T}$ , so that the comparison theorem implies  $v + 1 \geq w$ .

Also consider the target set  $\mathcal{T}'' = \{(0,0)\}$  consisting of the origin alone, with  $g(0,0) = 0$ . As above, Lemma 6 applies, so that  $v$  is the complete solution. According to Theorem 4, there can be no other viscosity solutions. Adding a constant,  $w - 1$  conforms to  $g$  at the origin. But investigation of the corners  $(0,1)$  and  $(1,0)$  shows that the supersolution condition fails there (details omitted). It is, however, a subsolution, which implies  $w - 1 \leq v$ , as we already deduced above.

## DELAY-INTEGRAL-QUADRATIC CONSTRAINTS AND ABSOLUTE STABILITY OF TIME-PERIODIC FEEDBACK SYSTEMS\*

D. A. ALTSHULLER†

**Abstract.** The paper considers the problem of absolute stability of systems with time-periodic nonlinear blocks. The approach presented in this paper is based on the so-called quadratic criterion and relies on integral-quadratic inequalities (constraints), which also involve time delays. The results are given in the frequency domain. The paper also includes geometric interpretation and numerical treatment of the new stability criteria.

**Key words.** absolute stability, frequency domain, nonlinear control systems, time-periodic systems

**AMS subject classifications.** 93D09, 93D10

**DOI.** 10.1137/070702758

**1. Introduction.** Consider a system consisting of a linear block represented by an integral equation

$$(1.1) \quad \sigma(t) = \alpha(t) + K_0 \xi(t) + \int_0^t K(t-s) \xi(s) ds$$

and a nonlinear block represented by the equation

$$(1.2) \quad \xi(t) = \varphi(\sigma(t), t).$$

Here  $\sigma(t) \in \mathbf{R}^m$ ;  $\xi(t) \in \mathbf{R}^p$ ; and  $K_0$  and  $K(t)$  are matrices of appropriate dimensions. It will always be assumed that  $\varphi(\sigma, t+T) = \varphi(\sigma, t)$ . Additional assumptions concerning this function, hereafter called the nonlinearity, will be stated in the hypotheses of the theorems.

Clearly, this system of equations can be combined into a single nonlinear Volterra integral equation. Existence theory for the equations of this type is well established under very broad assumptions about the functions involved (see, for example, [11]). Therefore, we are not going to concern ourselves with this aspect of the problem.

In this paper we are going to address the problem of absolute stability of the system (1.1)–(1.2). Roughly speaking, this problem is concerned with finding conditions involving only the linear block such that the system is stable for all nonlinearities belonging to a certain class.

Most of the research of the stability problem for the systems of this type has been confined to the case when the nonlinearity is a scalar function not depending explicitly on time. When the nonlinearity is monotone with respect to the state variable  $\sigma$  and its slope does not exceed a constant  $\mu$ , the most general results have the so-called multiplier form: The system is absolutely stable if for some constant  $\varepsilon > 0$  and for all  $\omega \in (-\infty, +\infty)$

$$(1.3) \quad \operatorname{Re}\{\mu^{-1} + W(i\omega)\}Z(i\omega) > \varepsilon > 0.$$

---

†Crane Aerospace and Electronics, 3000 Winona Ave., Burbank, CA 91510 (altshuller@ieee.org).

Here  $W(i\omega)$  is the frequency response of the linear block defined using the Fourier transform of its kernel:

$$(1.4) \quad W(i\omega) = -K_0 - \tilde{K}(i\omega) = -K_0 - \int_0^\infty K(t)e^{-i\omega t} dt.$$

The function  $Z(i\omega)$  is called the Zames–Falb multiplier after the classic paper by Zames and Falb [24], in which the most general form for  $Z(i\omega)$  has been given. The stability criteria written in this form have a convenient geometric interpretation [9].

For nonstationary systems, the problem of absolute stability was studied by Pyatnitsky and Molchanov [12, 13, 14, 16]. In [16] Pyatnitsky reduces the problem to the investigation of certain piecewise-linear systems and to variational problems. In [12, 13, 14] he and Molchanov focus on Lyapunov functions. Unfortunately, their criteria, unlike condition (1.3), are not easy to verify.

The objective of this paper is to obtain frequency-domain absolute stability criteria for systems with time-periodic nonlinearities. The early results for such systems go back to the book by Narendra and Taylor [15] and, for linear systems, to the two-volume classic by Yakubovich and Starzhinskii [23].

The method used in this paper is based on the so-called quadratic constraints. This method was used by Yakubovich [19] to prove some absolute stability criteria for systems similar in form to (1.1)–(1.2) but with stationary nonlinearities. The central concept of the method is to establish that the input and output signals of the nonlinear part of the system satisfy a certain set of integral-quadratic inequalities (constraints). These constraints may involve the values of these signals explicitly in time domain or, alternatively, their Fourier transforms. In the latter case, thoroughly investigated in the renown paper by Megretski and Rantzer [10] and further developed by Yakubovich [20, 21, 22], these constraints are said to be in the frequency domain.

The constraints used in this paper are in the time domain, but they also involve the values of the input and output signals at some earlier points in time (delays). Since they also involve integration over time, they are called delay-integral-quadratic constraints. They are, in fact, a special case of the constraints in frequency domain, but tend to arise more naturally from the properties of the input and output signals. For systems with stationary nonlinearities this method can be used [5] to prove the classical results of Zames and Falb [24].

In this paper the method will be extended to the case when the nonlinearities are periodic in time, and this periodicity, along with some other conditions, will play a crucial part in formulating the constraints.

The outline of the paper is as follows. First, for the sake of making the paper self-contained, we review the concept of the quadratic criterion of absolute stability (subsection 2.1). Then, in subsection 2.2, we shall prove two integral inequalities. The constraints will then follow naturally from these inequalities. The results will first be stated and proved for slope-restricted nonlinearities, thus extending the criteria of Zames and Falb to the case of time-periodic nonlinearities (subsection 3.1). We shall also give a geometric interpretation and numerical implementation of these new results (subsection 3.2). Next, in section 4, we consider the so-called quasimonotone nonlinearities (for the stationary case the corresponding result was proved by Barabanov [6]). In section 5 we shall prove a criterion for a class of MIMO linear time-periodic systems, which includes as a special case a SISO result by Yakubovich [22]. Finally, in section 6, we are going to obtain a criterion for a certain parametric class of nonlinearities, once again extending to the time-periodic case the result of Barabanov [6].

**2. Preliminaries.** In this section we present some background information on the so-called quadratic criterion of absolute stability. We also prove the integral inequalities needed for application of this criterion to the systems under consideration.

**2.1. Quadratic criterion for absolute stability.** For the sake of making this paper self-contained, we are going to restate the notation, definitions, and some lemmas (without proof) from the earlier paper [5].

Throughout the paper it will always be assumed that the linear block (1.1) satisfies the regularity conditions which we now define.

DEFINITION 2.1. *The linear block (1.1) satisfies the regularity conditions if*

$$(2.1) \quad |\alpha(\cdot)| \in L^2(0, +\infty) \cap L^\infty(0, +\infty)$$

and there exist positive constants  $C$  and  $\beta$ , such that

$$(2.2) \quad |K(t)| \leq Ce^{-\beta t}.$$

In this paper we are going to consider only locally square-integrable signals. In other words, it will be assumed that  $|\sigma(\cdot)|, |\xi(\cdot)| \in L^2_{loc}[0, +\infty]$ , where  $L^2_{loc}[0, +\infty]$  denotes the set of functions that are in  $L^2[0, t_0]$  for any  $t_0 > 0$ . Clearly, if the linear block satisfies the regularity conditions, then local square-integrability of the input signal implies local square-integrability of the output. Existence of such signals follows from the existence theorems for nonlinear integral equations.

For the purposes of this subsection, we let the nonlinear block of the system be represented instead of (1.2) by a more general form

$$(2.3) \quad [\sigma(\cdot), \xi(\cdot)] \in \mathcal{N}.$$

The set  $\mathcal{N}$  will be defined as follows: For any  $\sigma(\cdot) \in L^2_{loc}, \xi(\cdot) \in L^2_{loc}$  there exists a sequence  $t_k \rightarrow +\infty$ , possibly dependent on the functions  $\sigma(\cdot)$  and  $\xi(\cdot)$ , such that

$$(2.4) \quad \int_0^{t_k} \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t-\tau), \xi(t-\tau))dt \geq 0 \quad \forall \tau \in \mathcal{T}, j = 1, 2, \dots, N.$$

Here  $\mathcal{T}$  is a countable subset of nonnegative real numbers and  $\mathcal{F}_j(\sigma_1, \xi_1, \sigma_2, \xi_2)$  are given quadratic forms. If they depend on neither  $\sigma_2$  nor  $\xi_2$ , then condition (2.4) reduces to a set of ordinary integral-quadratic constraints in the time domain [19].

Let us define the following sets:

$$\mathcal{Z} = \{z(\cdot) = [\sigma(\cdot), \xi(\cdot)] : \sigma(t) \in \mathbb{R}^p, \xi(t) \in \mathbb{R}^m, |z(\cdot)| \in L^2_{loc}[0, +\infty]\},$$

$$\mathcal{Z}_s = \{z(\cdot) \in \mathcal{Z} : |z(\cdot)| \in L^2[0, +\infty]\},$$

$$\mathcal{L} = \{z(\cdot) \in \mathcal{Z} : \text{equation (1.1) holds}\},$$

$$\mathcal{L}_s = \mathcal{L} \cap \mathcal{Z}_s,$$

$$\mathcal{M} = \{z(\cdot) \in \mathcal{Z} : \text{equation (2.4) holds for some } t_k \rightarrow +\infty\}.$$

The elements of the set  $\mathcal{Z}$  are called processes, and the elements of the set  $\mathcal{Z}_s$  are called stable processes. We also need the set  $\mathcal{M}^\infty \subset \mathcal{Z}_s$  of stable processes satisfying

$$(2.5) \quad \int_0^\infty \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t-\tau), \xi(t-\tau))dt \geq 0 \quad \forall \tau \in \mathcal{T}, j = 1, 2, \dots, N.$$

The convergence of the integrals in (2.5) follows from the fact that the processes in the integrands are stable, i.e., globally square-integrable, and the integrands are quadratic forms.

The absolute stability, which is the main subject of this paper, is defined as follows.

**DEFINITION 2.2.** *The system defined by (1.1)–(2.3) is called absolutely stable if all processes  $z(\cdot) \in \mathcal{L} \cap \mathcal{N}$  are stable and there exists a constant  $\lambda$ , same for all processes, such that for all processes  $\|z(\cdot)\|^2 \leq \lambda \|\alpha(\cdot)\|^2$ .*

Here  $\|\cdot\|$  denotes the usual Euclidean norm in  $L^2[0, +\infty]$ . Note that existence of solutions of system (1.1)–(2.3) implies that  $\mathcal{L} \cap \mathcal{N} \neq \emptyset$ .

Each of the quadratic forms  $\mathcal{F}_j$  is extended to a Hermitian form  $\mathcal{F}_j(\tilde{\sigma}_1, \tilde{\sigma}_2, \tilde{\xi}_1, \tilde{\xi}_2)$ , where  $\tilde{\sigma}_1, \tilde{\sigma}_2 \in \mathbf{C}^p$  and  $\tilde{\xi}_1, \tilde{\xi}_2 \in \mathbf{C}^m$ . The Hermitian matrix  $\Pi_j(i\omega, \tau)$  is defined for  $\tau \in \mathcal{T}$  by the equation

$$(2.6) \quad \tilde{\xi}^* \Pi_j(i\omega, \tau) \tilde{\xi} = \mathcal{F}_j(-W(i\omega)\tilde{\xi}, \tilde{\xi}, -W(i\omega)\tilde{\xi}e^{-i\omega\tau}, \tilde{\xi}e^{-i\omega\tau}).$$

Here  $W(i\omega)$  is the frequency response of the linear block defined by (1.4).

The frequency condition (FC) is stated as follows: There exists a collection of  $N$  sequences  $\{\theta_n\}$  such that for some  $\varepsilon > 0$  we have

$$(2.7) \quad \sum_{j=1}^N \sum_{n=1}^{\infty} \Pi_j(i\omega, \tau_n) \theta_{nj} \leq -\varepsilon I_m, \quad \tau_n \in \mathcal{T}.$$

Here  $\theta_{nj}$  is the  $n$ th term of the  $j$ th sequence.

The FC in the paper [5] is stated differently: The Stieltjes integral is used instead of the infinite series. The reason is that in [5] the delay  $\tau$  can take any value. In this paper we need only the discrete set of values  $\tau_n = nT$ . The FC is adapted accordingly for our purposes.

We also need the notion of minimal stability. In order to define it we first need to introduce the stable continuations of processes.

**DEFINITION 2.3.** *A stable continuation of a process  $z(\cdot)$  in  $\mathcal{M}^\infty$  is a sequence of processes  $z_k(\cdot) \in \mathcal{L}_s \cap \mathcal{M}^\infty$  such that  $z_k(\cdot) = z(\cdot)$  for  $0 \leq t \leq t_k$  with  $t_k \rightarrow \infty$ .*

**DEFINITION 2.4.** *The system defined by (1.1), (2.3) is called minimally stable if every process  $z(\cdot) \in \mathcal{L} \cap \mathcal{N}$  has a stable continuation in  $\mathcal{M}^\infty$ .*

We are now in position to state the quadratic criterion for absolute stability, on which all the results of the paper will ultimately be based. It is an immediate consequence of Theorem 1 in [5].

**LEMMA 2.5.** *Suppose that the FC (2.7) is satisfied and system (1.1)–(2.3) is minimally stable. Then this system is absolutely stable.*

This lemma asserts that the minimal stability of a system is an essential ingredient of the absolute stability. Usually it is easy to verify by explicitly constructing the stable continuation required by Definition 2.4. To this end, it is often sufficient to construct a bounded continuation of a process, a concept which we now define.

**DEFINITION 2.6.** *A bounded continuation of a process  $z(\cdot)$  in  $\mathcal{M}$  is a sequence of processes  $z_k(\cdot) \in \mathcal{L} \cap \mathcal{M}$  such that  $|z_k(\cdot)| \in L^\infty[0, \infty]$  and  $z_k(\cdot) = z(\cdot)$  for  $0 \leq t \leq t_k$  with  $t_k \rightarrow \infty$ .*

The following lemma will be used throughout the paper to prove absolute stability of various systems under consideration. It is an immediate consequence of Lemma 2.5 and [5, Lemma 2].

**LEMMA 2.7.** *Suppose that the linear block (1.1) satisfies the regularity conditions (Definition 2.1) and the FC (2.7) holds. Then any bounded continuation of any process*

$z(\cdot) \in \mathcal{L}$  in  $\mathcal{M}$  is a stable continuation of  $z(\cdot)$  in  $\mathcal{M}^\infty$ . Furthermore, if every process  $z(\cdot) \in \mathcal{L} \cap \mathcal{N}$  has a bounded continuation in  $\mathcal{M}$ , then the system is absolutely stable.

The reader is referred to [5] for proofs and further details.

Lemma 2.7 asserts that the absolute stability of a system can be proved by showing that every process has a bounded continuation and that the appropriate FC is satisfied. The FC, in turn, will be derived from the constraints, which will naturally follow from the integral inequalities proved in the next subsection.

**2.2. Integral inequalities.** In this subsection we are going to prove two integral inequalities used later to derive the constraints needed for application of the quadratic criterion.

First, for a given function  $g(x, t)$ , continuous in each argument, we define

$$(2.8) \quad G(x, t) = \int_0^x g(x, t) dx.$$

The following lemma will be used in later sections. It extends the result of [18] to functions of two variables.

**LEMMA 2.8.** *Suppose that a function  $g(x, t)$ , continuous in each argument, is periodic in  $t$  with a period  $T$  and there exists a function  $H(u, v)$ , such that the following inequality holds for all  $x, y$ , and  $t$ :*

$$(2.9) \quad G(y, t) - G(x, t) + (x - y)g(x, t) \geq -H(x, g(x, t)) - H(y, g(y, t)).$$

*Suppose further that  $G(x, t) \geq 0$  for all  $x$  and  $t$ .*

*Then for any real number  $a$  and any measurable function  $x(t)$ , such that  $x(t) \equiv 0$  for  $t < 0$ , the following inequality holds:*

$$(2.10) \quad \int_0^a \{g(x(t), t)[x(t) - x(t - T)] + H(x(t), g(x(t), t))\} dt \\ + \int_0^a H(x(t - T), g(x(t - T), t)) dt \geq 0.$$

*If, in addition, the function  $g(x, t)$  is odd in  $x$ , the following inequality holds for any real number  $a$  and any measurable function  $x(t)$ , such that  $x(t) \equiv 0$  for  $t < 0$ :*

$$(2.11) \quad \int_0^a \{g(x(t), t)[x(t) + x(t - T)] + H(x(t), g(x(t), t))\} dt \\ + \int_0^a H(x(t - T), g(x(t - T), t)) dt \geq 0$$

*Proof.* Since the function  $g(x, t)$  is periodic in  $t$  with the period  $T$ , we have  $G(y, t - T) = G(y, t)$ . Using this we can replace inequality (2.9) with

$$(2.12) \quad G(y, t - T) - G(x, t) + (x - y)g(x, t) + H(x, g(x, t)) + H(y, g(y, t)) \geq 0.$$

Now we prove that inequality (2.12) implies inequality (2.10). In order to do that, we add to and subtract from the left-hand side of (2.10) the expression

$$\int_0^a [G(x(t - T), t - T) - G(x(t), t)] dt.$$

This yields

$$\begin{aligned}
 & \int_0^a \{g(x(t), t)[x(t) - x(t - T)] + H(x(t), g(x(t), t)) + H(x(t - T), g(x(t - T), t))\} dt \\
 &= \int_0^a \{g(x(t), t)[x(t) - x(t - T)] + H(x(t), g(x(t), t)) + H(x(t - T), g(x(t - T), t))\} dt \\
 & \quad + \int_0^a [G(x(t - T), t - T) - G(x(t), t)] dt \\
 & \quad + \int_0^a [G(x(t), t) - G(x(t - T), t - T)] dt \\
 &= \int_0^a \{G(x(t - T), t - T) - G(x(t), t) + g(x(t), t)[x(t) - x(t - T)]\} dt \\
 & \quad + \int_0^a [H(x(t), g(x(t), t)) + H(x(t - T), g(x(t - T), t))] dt \\
 & \quad + \int_{a-T}^a G(x(t), t) dt.
 \end{aligned}$$

The last integral is nonnegative because of the assumption that  $G(x, t) \geq 0$  for all  $x$  and  $t$ . By setting  $x = x(t)$ ,  $y = x(t - T)$ , and applying inequality (2.12) we conclude that the sum of the first two integrals is also nonnegative. Hence, the entire expression is nonnegative. This completes the proof of inequality (2.10).

Suppose now that the function  $g(x, t)$  is odd in  $x$ . Then the function  $G(x, t)$  is even in  $x$ , and we can replace  $G(y, t)$  with  $G(-y, t)$  in inequality (2.9). Inequality (2.11) can now be proved by repeating the above arguments, which completes the proof of the lemma.  $\square$

It is worth mentioning that this lemma can be proved if the assumption of the periodicity of the function  $g(x, t)$  in  $t$  is replaced with a weaker condition  $G(y, t - T) \geq G(y, t)$  for some number  $T$ . This fact can be used to derive stability conditions for some other classes of time-dependent nonlinearities [3].

**3. SISO systems with slope restricted nonlinearities.** In this section we are going to consider SISO systems (i.e.,  $p = m = 1$ ) with the nonlinearity satisfying the slope restriction inequality:

$$(3.1) \quad 0 \leq \frac{\varphi(\sigma_2, t) - \varphi(\sigma_1, t)}{\sigma_2 - \sigma_1} \leq \mu < \infty, \quad \varphi(0, t) \equiv 0.$$

Systems in which the nonlinearity does not depend explicitly on time have been well studied. The most general result is due to Zames and Falb [24]. However, for systems in which the nonlinearity is not stationary, the best known result is the celebrated circle criterion.

The method of delay-integral-quadratic constraints makes it possible to prove a stability criterion, similar in form to the result established by Zames and Falb for stationary systems.

**3.1. Stability multipliers.** In this subsection we are going to state and prove two results for this type of system.

The first result concerns the systems that satisfy the sector condition and the assumptions stated in the introduction.

THEOREM 3.1. Assume the following:

- I. The linear block (1.1) satisfies the regularity condition (Definition 2.1).
- II. The function  $\varphi(\sigma, t)$ , continuous in each variable, satisfies condition (3.1) and  $\varphi(\sigma, t + T) = \varphi(\sigma, t)$ .
- III. There exists a series  $\sum_{n=-\infty}^{n=+\infty} \vartheta_n < 1$  with nonnegative terms such that for all real values of  $\omega$

$$(3.2) \quad \operatorname{Re} \left\{ \left[ \mu^{-1} + W(i\omega) \right] \left[ 1 - \sum_{n=-\infty}^{\infty} \vartheta_n e^{-i\omega n T} \right] \right\} \geq \varepsilon > 0.$$

Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).

*Proof.* First, define the following quadratic form of the variables  $\xi_1$  and  $\sigma_1$ :

$$(3.3) \quad \mathcal{F}_1(\sigma_1, \xi_1) = \xi_1(\sigma_1 - \mu^{-1}\xi_1).$$

Condition (3.1) implies that

$$(3.4) \quad \mathcal{F}_1(\sigma_1(t), \xi_1(t)) \geq 0.$$

Define the quadratic forms

$$\begin{aligned} \mathcal{F}_2(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\xi_1 - \xi_2)(\sigma_1 - \mu^{-1}\xi_1), \\ \mathcal{F}_3(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\sigma_1 - \mu^{-1}\xi_1 - \sigma_2 + \mu^{-1}\xi_2)\xi_1. \end{aligned}$$

Condition (3.1) and Lemma 2.8 with  $H(u, v) \equiv 0$  together imply that the following inequality holds for any  $\tau = nT$  and any  $t_k > 0$ :

$$(3.5) \quad \int_0^{t_k} \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t - \tau), \xi(t - \tau)) dt \geq 0, \quad j = 2, 3.$$

Therefore, the FC (2.7) takes the following form: There exist sequences  $\theta_{1n}$ ,  $\theta_{2n}$ , and  $\theta_{3n}$ , all with nonnegative terms, such that for all real values of  $\omega$

$$(3.6) \quad \operatorname{Re} \left\{ \left[ \mu^{-1} + W(i\omega) \right] \left[ \Theta - \sum_{n=0}^{\infty} \theta_{2n} e^{i\omega n T} - \sum_{n=0}^{\infty} \theta_{3n} e^{-i\omega n T} \right] \right\} \geq \varepsilon > 0.$$

Here  $\Theta = \sum_{n=1}^{\infty} (\theta_{1n} + \theta_{2n} + \theta_{3n})$ .

It is easy to see that this condition is equivalent to condition III if we set  $\vartheta_n = \theta_{2n}/\Theta$  for  $n > 0$  and  $\vartheta_n = \theta_{3n}/\Theta$  for  $n < 0$ .

In order to complete the proof and use Lemma 2.7 we must show that every process has a bounded continuation. Let  $z(\cdot) = [\sigma(\cdot), \xi(\cdot)]$  be an arbitrary process, such that  $\xi(t) = \varphi(\sigma(t), t)$ . Let  $m_k$  be a number such that  $|\sigma(t)| \leq m_k$  for almost all  $0 \leq t \leq t_k$ . Define the following functions:

$$(3.7) \quad \varphi_k(\sigma, t) = \begin{cases} \varphi(-m_k, t) & \text{if } \sigma < -m_k, \\ \varphi(\sigma, t) & \text{if } |\sigma| \leq m_k, \\ \varphi(m_k, t) & \text{if } \sigma > m_k. \end{cases}$$

Consider a process  $z_k[\sigma_k(\cdot), \xi_k(\cdot)]$ , for which  $\xi_k(t) = \varphi_k(\sigma_k(t), t)$ . This process satisfies the constraints (3.4) and (3.5) and is, therefore, a bounded continuation of the process  $z(\cdot) = [\sigma(\cdot), \xi(\cdot)]$ . The proof is complete.  $\square$

If, in addition, the nonlinearity is odd, it is possible to weaken the condition that all terms of the series  $\sum_{n=-\infty}^{+\infty} \vartheta_n$  must be nonnegative.

**THEOREM 3.2.** *Suppose that conditions I and II of Theorem 3.1 are met and, in addition, the function  $\varphi(\sigma, t)$  is odd in  $\sigma$ . Suppose further that there exists an absolutely convergent series  $\sum_{n=-\infty}^{+\infty} \vartheta_n < 1$  such that for all real values of  $\omega$  condition (3.6) holds.*

*Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).*

*Proof.* The proof proceeds along the same steps as that of Theorem 3.1. We can define the same quadratic forms  $\mathcal{F}_1$ ,  $\mathcal{F}_2$ , and  $\mathcal{F}_3$ . Inequalities (3.4) and (3.5) hold.

Furthermore, we define the following two quadratic forms:

$$\begin{aligned}\mathcal{F}_4(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\xi_1 + \xi_2)(\sigma_1 - \mu^{-1}\xi_1), \\ \mathcal{F}_5(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\sigma_1 - \mu^{-1}\xi_1 + \sigma_2 - \mu^{-1}\xi_2)\xi_1.\end{aligned}$$

Since the function  $\varphi(\sigma, t)$  is odd in  $\sigma$ , Lemma 2.8 with  $H(u, v) \equiv 0$ , together with the condition (3.1), implies that inequality (3.5) holds for  $j = 4$  and  $j = 5$  for any  $\tau = nT$ .

Therefore, the FC takes the following form: There exist sequences  $\theta_{1n}, \theta_{2n}, \dots, \theta_{5n}$ , all with nonnegative terms, such that for all real values of  $\omega$

$$(3.8) \quad \operatorname{Re} \{ [\mu^{-1} + W(i\omega)] Z(i\omega) \} \geq \varepsilon > 0.$$

Here

$$\begin{aligned}Z(i\omega) &= \Theta - \sum_{n=0}^{\infty} \theta_{2n} e^{i\omega nT} - \sum_{n=0}^{\infty} \theta_{3n} e^{-i\omega nT} + \sum_{n=0}^{\infty} \theta_{4n} e^{i\omega nT} + \sum_{n=0}^{\infty} \theta_{5n} e^{-i\omega nT}, \\ \Theta &= \sum_{n=1}^{\infty} (\theta_{1n} + \theta_{2n} + \theta_{3n} + \theta_{4n} + \theta_{5n}).\end{aligned}$$

To show that this is equivalent to the FC of Theorem 3.2, define  $\vartheta_n = \theta_{2n} - \theta_{4n}/\Theta$  for  $n > 0$  and  $\vartheta_n = \theta_{3n} - \theta_{5n}/\Theta$  for  $n < 0$ .

Existence of the bounded continuations for every process is verified in exactly the same way as in the proof of Theorem 3.1. The functions, defined by (3.7), are odd in  $\sigma$  if the nonlinearity is odd in  $\sigma$ . Therefore, the system is absolutely stable by Lemma 2.7.  $\square$

**3.2. Geometric interpretation and numerical examples.** With a slight abuse of notation, the FC (3.2) in Theorems 3.1 and 3.2 can be rewritten in the form

$$(3.9) \quad [\mu^{-1} + \operatorname{Re} W(i\omega)] \operatorname{Re} Z(i\omega) - \operatorname{Im} W(i\omega) \operatorname{Im} Z(i\omega) > 0,$$

where

$$(3.10) \quad Z(i\omega) = 1 - \sum_{n=-\infty}^{\infty} \vartheta_n e^{-i\omega nT}$$

and the sequence  $\vartheta_n$  satisfies the conditions of either Theorem 3.1 or Theorem 3.2, depending on the context.

Let us define the following two functions:

$$\Phi(\omega) = \frac{\mu^{-1} + \operatorname{Re}W(i\omega)}{\operatorname{Im}W(i\omega)}, \quad \Psi(\omega) = \frac{\operatorname{Im}Z(i\omega)}{\operatorname{Re}Z(i\omega)}.$$

For the sake of simplicity let us assume that  $W(i\omega)$  is a proper rational function. Then it is easy to show [9] that the graph of the function  $\Phi(\omega)$  consists of branches with asymptotes. The ends of the branches point either to  $+\infty$  (called stalactites) or to  $-\infty$  (called stalagmites). The FC (3.2) holds if a function  $\Psi(\omega)$  can be found such that its graph separates the stalactites from the stalagmites. For the circle criterion,  $\Psi(\omega) \equiv 0$ , i.e., the stalactites must be separated from the stalagmites by the abscissa axis.

For the FC (3.2) we have

$$(3.11) \quad \Psi(\omega) = \frac{\sum_{n=-\infty}^{\infty} \vartheta_n \sin \omega n T}{\sum_{n=-\infty}^{\infty} \vartheta_n \cos \omega n T - 1}.$$

Furthermore,  $\sum_{n=-\infty}^{\infty} \vartheta_n < 1$  and there is an additional requirement that  $\vartheta_n \geq 0$  unless the nonlinearity is odd in  $\sigma$ .

It is often easier to use this approach if the infinite series in (3.11) are replaced with trigonometric polynomials as illustrated in the following numerical examples.

Consider a system with the linear block defined by the transfer function:

$$(3.12) \quad W(s) = 0.04 + \frac{s^2}{[(s + 0.5)^2 + 0.81][(s + 0.5)^2 + 1.21]}.$$

Let  $\mu = 20$ . For the function  $\Psi(\omega)$  we choose  $\vartheta_1 = 0.1$ ,  $\vartheta_2 = 0.5$ , and  $\vartheta_3 = 0.2$ . Figure 3.1 shows the plot for  $T = 0.25\pi$ , allowing us to conclude that the system is absolutely stable. The same is true for the case with  $T = 0.3\pi$  (Figure 3.2) and all the intermediate values of  $T$ .

FIG. 3.1. Functions  $\Phi(\omega)$  (solid line) and  $\Psi(\omega)$  (broken line) for  $T = 0.25\pi$ .

Now consider the case with an odd nonlinearity. This means we may use negative values for the coefficients in (3.11). Set  $\vartheta_1 = -0.25$ ,  $\vartheta_2 = 0.5$ , and  $\vartheta_3 = 0.2$ . Figure 3.3 shows the plot for the case of  $T = 0.21\pi$ . Hence, the system is absolutely stable for this value of the period. The same is, once again, true for the case with  $T = 0.3\pi$  (Figure 3.4) and all the intermediate values of  $T$ . Notice how including the additional

FIG. 3.2. Functions  $\Phi(\omega)$  (solid line) and  $\Psi(\omega)$  (broken line) for  $T = 0.3\pi$ .

FIG. 3.3. Functions  $\Phi(\omega)$  (solid line) and  $\Psi(\omega)$  (broken line) for  $T = 0.21\pi$  with odd nonlinearity.

FIG. 3.4. Functions  $\Phi(\omega)$  (solid line) and  $\Psi(\omega)$  (broken line) for  $T = 0.3\pi$  with odd nonlinearity.

requirement that the nonlinearity be odd (and thus relaxing the requirement that the coefficients in (3.11) must be nonnegative) allowed us to widen the range of periods, for which absolute stability of the system can be proved using this criterion.

It is worth noting that since the branches of the curve  $\Phi(\omega)$  intersect the abscissa axis, the circle criterion is not applicable.

**4. SISO systems with quasimonotone sector nonlinearities.** In this section we are going to replace the slope restriction inequality (3.1) with a weaker sector condition:

$$(4.1) \quad 0 \leq \frac{\varphi(\sigma, t)}{\sigma} \leq \mu < \infty, \quad \varphi(0, t) \equiv 0.$$

The requirement that the nonlinearity be nondecreasing in  $\sigma$  is relaxed to a weaker condition that it be quasimonotone. This concept is introduced by the following definition, paraphrased from [6].

**DEFINITION 4.1.** *A function  $g(x)$  is called quasimonotone if there exists a positive-semidefinite quadratic form  $B(r, w)$  such that for all  $x$  and  $y$*

$$(4.2) \quad G(y) - G(x) + (x - y)g(x) \geq -B(x, g(x)) - B(y, g(y)),$$

where

$$G(x) = \int_0^x g(x) dx.$$

The form  $B(r, w)$  is called a defining form of the quasimonotone function  $g(x)$ .

Clearly, if  $B(r, w) \equiv 0$ , condition (4.2) reduces to the concavity condition for the function  $G(x)$ , i.e., to the condition that the function  $g(x)$  is nondecreasing.

For this type of nonlinearity we have the following stability criterion.

**THEOREM 4.2.** *Assume the following:*

- I. *The linear block (1.1) satisfies the regularity conditions (Definition 2.1).*
- II. *The function  $\varphi(\sigma, t)$  is continuous in each argument, satisfies the sector condition (4.1), is quasimonotone in  $\sigma$  with a defining form  $B(r, w)$ , and  $\varphi(\sigma, t + T) = \varphi(\sigma, t)$ .*
- III. *There exists a series  $\sum_{n=-\infty}^{\infty} \vartheta_n < 1$  with nonnegative terms such that for all real values of  $\omega$*

$$(4.3) \quad \operatorname{Re} \left\{ [\mu^{-1} + W(i\omega)] \left[ 1 - \sum_{n=-\infty}^{n=+\infty} \vartheta_n e^{-i\omega n T} \right] - 2B(W(i\omega), 1) \right\} \geq \varepsilon > 0.$$

*Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).*

*Proof.* The proof of this theorem proceeds along the same steps as the results in the previous section. First, define the following quadratic form of the variables  $\xi$  and  $\sigma$ :

$$(4.4) \quad \mathcal{F}_1(\sigma_1, \xi_1) = \xi_1(\sigma_1 - \mu^{-1}\xi_1).$$

Condition (4.1) implies that

$$(4.5) \quad \mathcal{F}_1(\sigma_1(t), \xi_1(t)) \geq 0.$$

Next, define the following two quadratic forms:

$$\mathcal{F}_2(\sigma_1, \xi_1, \sigma_2, \xi_2) = (\xi_1 - \xi_2)(\sigma_1 - \mu^{-1}\xi_1) + B(\sigma_1, \xi_1) + B(\sigma_2, \xi_2),$$

$$\mathcal{F}_3(\sigma_1, \xi_1, \sigma_2, \xi_2) = (\sigma_1 - \mu^{-1}\xi_1 - \sigma_2 + \mu^{-1}\xi_2)\xi_1 + B(\sigma_1, \xi_1) + B(\sigma_2, \xi_2).$$

In order to apply Lemma 2.8 we set  $x(t) = \mu\sigma(t) + \varphi(\sigma(t), t)$  and  $H(u, v) = B(\sigma_0(u, t), v)$ , where  $\sigma_0(u, t)$  is a root of the equation  $u = \mu\sigma_0 + \varphi(\sigma_0, t)$ . We obtain for any  $\tau = nT$  and any  $t_k > 0$

$$(4.6) \quad \int_0^{t_k} \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t - \tau), \xi(t - \tau)) dt \geq 0, \quad j = 2, 3.$$

Therefore, the FC (2.7) takes the following form: There exist sequences  $\theta_{1n}$ ,  $\theta_{2n}$ , and  $\theta_{3n}$ , all with nonnegative terms, such that for all real values of  $\omega$

$$(4.7) \quad \operatorname{Re} \{ [\mu^{-1} + W(i\omega)] Z(i\omega) - 2B(W(i\omega), 1) \} \geq \varepsilon > 0.$$

Here

$$Z(i\omega) = \Theta - \sum_{n=0}^{\infty} \theta_{2n} e^{i\omega nT} - \sum_{n=0}^{\infty} \theta_{3n} e^{-i\omega nT},$$

$$\Theta = \sum_{n=1}^{\infty} (\theta_{1n} + \theta_{2n} + \theta_{3n}).$$

It is easy to see that this condition is equivalent to condition III if we set  $\vartheta_n = \theta_{2n}/\Theta$  for  $n > 0$  and  $\vartheta_n = \theta_{3n}/\Theta$  for  $n < 0$ .

In order to show that every process has a bounded continuation so that we can use Lemma 2.7, we use the same method as in the proof of Theorem 3.1. Suppose that  $t_k \rightarrow \infty$  is an arbitrary sequence. Let  $m_k = \max_{t \in [0, t_k]} |\sigma(t)|$  and let  $s_k$  be a real number, such that for all  $t$  and all  $\sigma \in [0, m_k]$  the following inequality holds:

$$(4.8) \quad |\varphi(s_k, t)| \geq |\varphi(\sigma, t)|.$$

Define the functions  $\varphi_k(\sigma, t)$  as follows:

$$(4.9) \quad \varphi_k(\sigma, t) = \begin{cases} \varphi(-s_k, t) & \text{if } \sigma < -m_k, \\ \varphi(\sigma, t) & \text{if } |\sigma| \leq m_k, \\ \varphi(s_k, t) & \text{if } \sigma > m_k. \end{cases}$$

Note that these functions may have discontinuities of the first kind in the argument  $\sigma$ , while the nonlinearity  $\varphi(\sigma, t)$  is assumed to be continuous in each argument. However, this is not a concern since the functions  $\varphi_k(\sigma, t)$  can be approximated by continuous functions with a level of precision sufficient for the relevant inequalities to hold.

Now we need to prove that the functions  $\varphi_k(\sigma, t)$  are quasimonotone in  $\sigma$  with the same defining form  $B(r, w)$  as  $\varphi(\sigma, t)$ . This means proving that for all  $u$  and  $v$  the following inequality holds:

$$(4.10) \quad \int_u^v \varphi_k(\sigma, t) d\sigma + (u - v)\varphi_k(u, t) \geq -B(u, \varphi_k(u, t)) - B(v, \varphi_k(v, t)).$$

For the sake of certainty suppose that  $0 < u < v$ . The arguments in other cases are similar. If  $u < v \leq m_k$ , then  $\varphi_k(\sigma, t) = \varphi(\sigma, t)$  on the entire interval of integration, and inequality (4.10) clearly holds. If  $m_k < u < v$ , the left-hand side of inequality (4.10) vanishes, while the right-hand side is nonpositive, and, therefore, it holds.

Consider the case when  $u < m_k < v$ . We have

$$\begin{aligned}
 & \int_u^v \varphi_k(\sigma, t) d\sigma + (u - v)\varphi_k(u, t) \\
 &= \int_u^{m_k} \varphi_k(\sigma, t) d\sigma + \int_{m_k}^v \varphi_k(\sigma, t) d\sigma + (u - m_k)\varphi_k(u, t) + (m_k - v)\varphi_k(u, t) \\
 &= \int_u^{m_k} \varphi_k(\sigma, t) d\sigma + (u - m_k)\varphi_k(u, t) + \int_{m_k}^v \varphi_k(\sigma, t) d\sigma + (m_k - v)\varphi_k(u, t) \\
 &\geq -B(u, \varphi_k(u, t)) - B(m_k, \varphi_k(m_k, t)) + (v - m_k)[\varphi(s_k, t) - \varphi(u, t)] \\
 &> -B(u, \varphi_k(u, t)) - B(m_k, \varphi_k(m_k, t)) \\
 &> -B(u, \varphi_k(u, t)) - B(v, \varphi_k(v, t)).
 \end{aligned}$$

Having proved that the functions  $\varphi_k(\sigma, t)$  are quasimonotone in  $\sigma$  with the same defining form as  $\varphi(\sigma, t)$ , we can now conclude that every process has a bounded continuation, which completes the proof of this theorem.  $\square$

Just as in the case of slope-restricted nonlinearities, the result can be strengthened if an additional requirement that the nonlinearity be odd in  $\sigma$  is imposed.

**THEOREM 4.3.** *Suppose that conditions I and II of Theorem 4.2 are met and, in addition, the function  $\varphi(\sigma, t)$  is odd in  $\sigma$ . Suppose further that there exists an absolutely convergent series  $\sum_{n=-\infty}^{\infty} \theta_n < 1$  such that for all real values of  $\omega$  condition (4.3) holds.*

*Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).*

*Proof.* The proof proceeds along the same steps as the other stability criteria. We can define the same quadratic forms  $\mathcal{F}_1$ ,  $\mathcal{F}_2$ , and  $\mathcal{F}_3$  as in the proof of Theorem 4.2. Inequalities (4.5) and (4.6) hold.

Further, we define the following two quadratic forms:

$$\begin{aligned}
 \mathcal{F}_4(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\xi_1 + \xi_2)(\sigma_1 - \mu^{-1}\xi_1) + B(\sigma_1, \xi_1) + B(\sigma_2, \xi_2), \\
 \mathcal{F}_5(\sigma_1, \xi_1, \sigma_2, \xi_2) &= (\sigma_1 - \mu^{-1}\xi_1 + \sigma_2 - \mu^{-1}\xi_2)\xi_1 + B(\sigma_1, \xi_1) + B(\sigma_2, \xi_2).
 \end{aligned}$$

Since the function  $\varphi(\sigma, t)$  is odd in  $\sigma$ , Lemma 2.8 implies that inequality (4.6) holds for  $j = 4$  and  $j = 5$  for any  $\tau = nT$ .

Therefore, the FC takes the following form: There exist sequences  $\theta_{1n}, \theta_{2n}, \dots, \theta_{5n}$ , all with nonnegative terms, such that for all real values of  $\omega$  inequality (4.7) holds with

$$\begin{aligned}
 Z(i\omega) &= \Theta - \sum_{n=0}^{\infty} \theta_{2n} e^{i\omega nT} - \sum_{n=0}^{\infty} \theta_{3n} e^{-i\omega nT} + \sum_{n=0}^{\infty} \theta_{4n} e^{i\omega nT} + \sum_{n=0}^{\infty} \theta_{5n} e^{-i\omega nT}, \\
 \Theta &= \sum_{n=1}^{\infty} (\theta_{1n} + \theta_{2n} + \theta_{3n} + \theta_{4n} + \theta_{5n}).
 \end{aligned}$$

To show that this is equivalent to the frequency condition of the theorem, define, just as before,  $\vartheta_n = \theta_{2n} - \theta_{4n}/\Theta$  for  $n > 0$  and  $\vartheta_n = \theta_{3n} - \theta_{5n}/\Theta$  for  $n < 0$ .

In order to exhibit bounded continuation for every process, we use the same functions  $\varphi_k(\sigma, t)$  defined by (4.9). They are odd in  $\sigma$ , and the proof can be completed by the same argument as that of Theorem 3.2.  $\square$

It is important to note here that the frequency conditions in these two theorems do not have the multiplier form. Therefore, the geometric interpretation from subsection 3.2 cannot be used directly. Numerical implementation of this result should be considered an open problem.

**5. Linear periodic MIMO systems.** In this section we turn our attention to linear MIMO systems. The function  $\varphi(\sigma, t)$  is assumed to have the form

$$(5.1) \quad \varphi(\sigma, t) = P(t)\sigma(t).$$

Here  $P(t)$  is a nonsingular  $m \times m$  matrix,  $P(t+T) = P(t)$ . Furthermore, it will be assumed that this matrix satisfies the MIMO analogue of the sector condition; i.e., for all  $t$  the following inequality holds:

$$(5.2) \quad \text{Sym} P^{-1}(t) - \mu^{-1} I_m \geq 0.$$

Here, for a real matrix  $X$ ,  $\text{Sym} X = (X + X^*)/2$ .

We also impose the following requirement: There exist constant matrices  $Q$  and  $S$ , such that for all values of  $t$

$$(5.3) \quad P^*(t)Q - SP(t) \equiv 0.$$

Clearly, (5.3) is fulfilled by setting  $P = Q = 0$ , which, as we shall see, yields the MIMO analogue of the circle criterion. Aside from this trivial possibility, this condition may at first glance appear rather restrictive. However, it is satisfied if  $P(t)$  is symmetric. It also holds if  $P(t) = GH(t)$ , where  $G$  is a constant nonsingular matrix and  $H(t)$  is either symmetric (set  $Q = S = G^{-1}$ ) or orthogonal (set  $Q = G$  and  $S = G^{-1}$ ).

The determination of existence of the required matrices  $G$  and  $H(t)$  can be made as follows. Recall that any matrix can be represented as a product of an orthogonal and a symmetric matrix. Thus we can always write  $P(t) = U(t)H(t)$ , where  $H^2(t) = P^*(t)P(t)$  and  $U(t) = P(t)H^{-1}(t)$ . If the matrix  $U(t)$  turns out to be constant, we set  $G = U(t)$ .

Let us illustrate this concept with a simple example. Let

$$P(t) = \begin{bmatrix} 1 & \sin t \\ \cos t & 1 \end{bmatrix}.$$

Performing the above computation, we find

$$U(t) = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

Therefore, in this case there exists the desired representation for the matrix  $P(t)$ . Another characterization of matrices satisfying (5.3) is given by the following statement.

**PROPOSITION 5.1.** *Suppose that there exists a constant matrix  $Q$ , such that*

$$(5.4) \quad [P'(t)P^{-1}(t)]^*Q \equiv QP^{-1}(t)P'(t).$$

*Then the matrix  $S = P^*(t)QP^{-1}(t)$  is constant.*

This proposition is proved by differentiating the matrix  $S$ . Condition (5.4) implies that its derivative is identically equal to zero.

Therefore, a determination of whether a given matrix  $P(t)$  satisfies the condition (5.3) can be made by attempting to solve (5.4). If a constant solution can be found, the question is answered affirmatively. The equation of this type is discussed in the book by Gantmacher [8].

Solving (5.4) for the matrix  $P(t)$  in the above example, we obtain the following two relationships for the components of the matrix  $Q$ :  $q_{11} = q_{22} \tan t$  and  $q_{12} = q_{21} - q_{22} \sec t$ . Set  $q_{11} = q_{22} = 0$  and  $q_{12} = q_{21} = 1$  to obtain the desired constant matrix  $Q$ .

The stability criterion for systems of this type is stated as follows.

THEOREM 5.2. *Assume the following:*

- I. *The linear block (1.1) satisfies the regularity conditions (Definition 2.1).*
- II. *The function  $\varphi(\sigma, t)$  is defined by  $\varphi(\sigma, t) = P(t)\sigma(t)$  with the nonsingular  $m \times m$  matrix  $P(t)$  satisfying the following conditions for all values of  $t$ :  $P(t+T) = P(t)$ ,  $\text{Sym}P^{-1}(t) - \mu^{-1}I_m \geq 0$ , and there exist constant matrices  $Q$  and  $S$ , such that for all values of  $t$  condition (5.4) is satisfied.*
- III. *There exists an odd periodic function  $q(\omega)$  with the period  $2\pi/T$  such that for all real values of  $\omega$  the following inequality holds:*

$$(5.5) \quad \text{Re}\{\mu^{-1}I_m + W(i\omega) + iq(\omega)[QW(i\omega) - W^*(i\omega)S]\} \geq \varepsilon I_m > 0.$$

*Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).*

*Proof.* As before, define the quadratic form

$$(5.6) \quad \mathcal{F}_1(\sigma_1, \xi_1) = \xi_1^*(\sigma_1 - \mu^{-1}\xi_1).$$

Condition (5.2) implies that

$$(5.7) \quad \mathcal{F}_1(\sigma_1, \xi_1) \geq 0.$$

Next, define the quadratic forms

$$\begin{aligned} \mathcal{F}_2(\sigma_1, \xi_1, \sigma_2, \xi_2) &= \xi_1^*Q\sigma_2 - \sigma_2^*S\xi_2, \\ \mathcal{F}_3(\sigma_1, \xi_1, \sigma_2, \xi_2) &= \sigma_2^*S\xi_1 - \xi_2^*Q\sigma_1. \end{aligned}$$

Now we show that condition (5.3) implies

$$(5.8) \quad \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t-nT), \xi(t-nT)) \equiv 0, \quad j = 2, 3.$$

Indeed, for  $j = 2$  we have

$$\begin{aligned} & \xi^*(t)Q\sigma(t-nT) - \sigma^*(t)S\xi(t-nT) \\ &= \sigma^*(t)P^*(t)Q\sigma(t-nT) - \sigma^*(t)SP(t-nT)\sigma(t-nT) \\ &= \sigma^*(t)[P^*(t)Q - SP(t-nT)]\sigma(t-nT) \\ &\equiv 0. \end{aligned}$$

The proof for  $j = 3$  is similar.

After some algebraic manipulations the FC takes the following form: There exists a sequence  $\theta_n$  such that for all real values of  $\omega$

$$(5.9) \quad \text{Re} \left\{ \mu^{-1}I_m + W(i\omega) + [QW(i\omega) - W^*(i\omega)S] \sum_{n=0}^{\infty} \theta_n \sin \omega nT \right\} \geq \varepsilon I_m > 0.$$

The series in this inequality is a Fourier series of an odd periodic function with period  $2\pi/T$ . Denoting this function by  $q(\omega)$ , we conclude that this FC is the same as condition III of the theorem.

Minimal stability can be verified by the same procedure as that in the paper [22]. By Lemma 2.5 the system is absolutely stable.  $\square$

It can be easily seen that if we set  $Q = S = 0$ , we obtain a MIMO analogue of the circle criterion.

If the matrix  $P(t)$  is symmetric (which also includes the case of  $m = 1$ ), we set  $Q = S = I_m$ . If, in addition, the matrix  $W(s)$  is Hermitian, then inequality (5.5) simplifies to

$$(5.10) \quad \operatorname{Re}\{\mu^{-1}I_m + W(i\omega)[1 + iq(\omega)]\} \geq \varepsilon I_m > 0.$$

This is a MIMO analogue of the result of Yakubovich [22].

**6. SISO systems with parametric class of nonlinearities.** In this section we are, again, going to consider the SISO systems satisfying the sector condition (4.1). In addition, it will be assumed that for all values of  $t$

$$(6.1) \quad \begin{aligned} |\sigma_1(t)\varphi(\sigma_2(t), t) - \sigma_2(t)\varphi(\sigma_1(t), t)| &\leq F(\sigma_1(t), \varphi(\sigma_1(t), t)) \\ &+ F(\sigma_2(t), \varphi(\sigma_2(t), t)). \end{aligned}$$

Here  $F(u, v)$  is a real quadratic form. Of particular interest is the case when  $F(u, v) = \gamma v(u - \mu^{-1}v)$ . Then if  $\gamma = 0$ , inequality (6.1) holds if and only if  $\varphi(\sigma, t)$  is a linear function in  $\sigma$ . For infinite value of  $\gamma$ , this inequality holds for all functions satisfying the sector condition (4.1). The stability criterion, however, can be proved for the general case.

**THEOREM 6.1.** *Assume the following:*

- I. *The linear block (1.1) satisfies the regularity conditions (Definition 2.1).*
- II. *The function  $\varphi(\sigma, t)$  is periodic in  $t$  with a period  $T$ , continuous in each argument, satisfies the sector condition (4.1) and inequality (6.1) for some real quadratic form  $F(u, v)$ .*
- III. *There exists an odd periodic function  $q(\omega)$  with a period  $2\pi/T$  such that for all real values of  $\omega$  the following inequality holds:*

$$(6.2) \quad \operatorname{Re}[\mu^{-1} + W(i\omega) - F(-W(i\omega), 1) + iq(\omega)W(i\omega)] \geq \varepsilon > 0.$$

*Then system (1.1)–(1.2) is absolutely stable (Definition 2.2).*

*Proof.* Define the quadratic form

$$(6.3) \quad \mathcal{F}_1(\sigma_1, \xi_1) = \xi_1(\sigma_1 - \mu^{-1}\xi_1).$$

Condition (4.1) implies that

$$(6.4) \quad \mathcal{F}_1(\sigma_1(t), \xi_1(t)) \geq 0.$$

Next, define the following two quadratic forms:

$$\begin{aligned} \mathcal{F}_2(\sigma_1, \xi_1, \sigma_2, \xi_2) &= F(\sigma_1, \xi_1) + F(\sigma_2, \xi_2) + \sigma_1\xi_2 - \sigma_2\xi_1, \\ \mathcal{F}_3(\sigma_1, \xi_1, \sigma_2, \xi_2) &= F(\sigma_1, \xi_1) + F(\sigma_2, \xi_2) + \sigma_2\xi_1 - \sigma_1\xi_2. \end{aligned}$$

Condition (6.1) implies

$$(6.5) \quad \mathcal{F}_j(\sigma(t), \xi(t), \sigma(t - nT), \xi(t - nT)) \equiv 0, \quad j = 2, 3.$$

The FC now takes the following form: There exists a sequence  $\theta_n$  such that for all real values of  $\omega$

$$\operatorname{Re} \left\{ [\mu^{-1} + W(i\omega) - F(-W(i\omega), 1)] \sum_{n=0}^{\infty} \theta_n + iW(i\omega) \sum_{n=0}^{\infty} \theta_n \sin \omega nT \right\} \geq \varepsilon > 0.$$

Just as in the previous section, this inequality includes a Fourier series of an odd periodic function with period  $2\pi/T$ . Denoting this function by  $q(\omega)$  we conclude that this FC is the same as condition III of the theorem.

Existence of a bounded continuation for every process is verified by introducing the same functions  $\varphi_m(\sigma, t)$  as in the proof of Theorem 3.1. It is easy to check that they satisfy both the sector condition and inequality (6.1). By Lemma 2.7 the system is absolutely stable.  $\square$

In the special case of  $F(u, v) = \gamma v(u - \mu^{-1}v)$  the FC (6.2) can, after some algebraic manipulations, be rewritten in the form

$$(6.6) \quad \operatorname{Re} \{ [\mu^{-1} + W(i\omega)][1 + \gamma + iq(\omega)] \} \geq \varepsilon > 0.$$

Several points are worth noting about this condition. First, it has a multiplier form, similar to the conditions in subsection 3.1, and is, therefore, amenable to the geometric interpretation and numerical procedure described in subsection 3.2.

If  $\gamma = 0$ , then the system reduces to the linear case described in section 5 with  $m = 1$ . The FC (6.6) then reduces to the form in Yakubovich's paper [22]. It is easy to see that if a multiplier exists for  $\gamma = 0$ , one can also be found for any  $\gamma > 0$ . On the other hand, as  $\gamma \rightarrow \infty$ , this inequality tends pointwise to the circle criterion, as the class of nonlinearities satisfying condition (6.1) expands to include all the functions satisfying the sector condition (3.1).

**7. Conclusions.** We have considered several types of systems with time-periodic feedback and, using the method of delay-integral-quadratic constraints, proved absolute stability criteria for each of them. Analogous results have previously been known for stationary systems.

It is of interest to note that some of the results have a multiplier form, similar to the corresponding results for stationary systems. The difference lies in the fact that for stationary systems the multipliers can be represented in the form of Fourier–Stieltjes integrals. For time-periodic systems these integrals are replaced with Fourier series.

This poses a significant difficulty in numerical implementation of the results. For stationary systems there usually exists a matrix realization of the multipliers. This makes it possible to express the frequency-domain conditions as linear matrix inequalities [7], which can be solved numerically. For time-periodic systems and the resulting multipliers such matrix realization may not exist. Therefore, numerical interpretation of these results is presently an open problem.

One possible approach is based on the fact that, just as in case of stationary systems, the multipliers can be interpreted geometrically. However, the interpretation differs in that the curve, separating stalactites from stalagmites, must be periodic in  $\omega$  with a period of  $2\pi/T$ . This is a significant restriction, compared to stationary systems. Nevertheless, numerical interpretation of the results is still possible as illustrated in subsection 3.2.

Future research may be directed at finding an algorithm for constructing multipliers, analogous to the one described for stationary systems by Safonov and Wyetznar [17], that would improve the applicability of the absolute stability criteria.

## PARTIAL STABILITY FOR A CLASS OF NONLINEAR SYSTEMS\*

EDUARDO F. COSTA<sup>†</sup> AND ALESSANDRO ASTOLFI<sup>‡</sup>

**Abstract.** This paper studies a nonlinear, discrete-time matrix system arising in the stability analysis of Kalman filters. These systems present an internal coupling between the state components that gives rise to complex dynamic behavior. The problem of partial stability, which requires that a specific component of the state of the system converge exponentially, is studied and solved. The convergent state component is strongly linked with the behavior of Kalman filters, since it can be used to provide bounds for the error covariance matrix under uncertainties in the noise measurements. We exploit the special features of the system—mainly the connections with linear systems—to obtain an algebraic test for partial stability. Finally, motivated by applications in which polynomial divergence of the estimates is acceptable, we study and solve a partial semistability problem.

**Key words.** stability, nonlinear systems, matrix analysis, Kalman filter stability

**DOI.** 10.1137/070708421

**1. Introduction.** Partial stability (PS) refers to the class of problems that deal with stability of some state components with respect to (w.r.t.) those same components or w.r.t. all state components, or even w.r.t. some (nonfixed) components. It has been studied for linear and nonlinear systems from different perspectives [2, 6, 9, 10, 14], and vector Lyapunov functions constitute one of the first and most common tools in the literature, which can be traced back to the fifties [12]. PS arises naturally in many applications, e.g., in situations where some of the variables are not important as far as the operation and performance are concerned, or are not essential at all (in a sense related to model order reduction problems); see [14] for a quite complete assessment of specific problems in PS literature.

In this paper we deal with a discrete-time matrix system arising in the analysis of the error covariance matrix  $V_k$  of Kalman filters under noise measurement uncertainties; see [3]. Therein it is shown that, assuming the filter gains are calculated taking into account an initial error covariance  $\Sigma$  that differs from the actual one  $V_0$ , if the “incorrect” calculated error covariances are bounded, then for each  $0 \leq \zeta < 1$  there exist  $\tau > 0$  and  $M = M' \geq 0$ , providing the bounds

$$(1 - \tau)Z_k - \zeta^{-k}M \leq V_k \leq (1 + \tau)Z_k + \zeta^{-k}M, \quad k \geq 0,$$

for the actual error  $V_k$ , where  $Z_k$  is a component of the state  $(Z_k, X_k)$  of the system

described by the equations

$$(1) \quad \Theta : \begin{cases} Z_{k+1} = H_k A Z_k A' H'_k, \\ X_{k+1} = A X_k A', \quad k \geq 0, \\ (Z_0, X_0) = (H_0 V_0 H'_0, \Sigma), \end{cases}$$

where  $Z_k$ ,  $X_k$ ,  $V_0$ , and  $\Sigma$  are symmetric positive semidefinite matrices and the square matrix  $A$  is assumed to be known.  $H_k$ ,  $k \geq 0$ , stands for the orthogonal projection onto the null space of  $X_k$ . For instance, when  $\ker\{\Sigma\} \subset \ker\{V_0\}$  (e.g., when  $\Sigma = V_0$  or  $\Sigma > 0$ ), we have  $H_0 V_0 H'_0 = 0$ , yielding  $Z_k = 0$ ,  $k \geq 0$ . We refer to  $H_k$  as the coupling projections, since it couples the dynamics of the  $Z$ -component with the trajectory of the  $X$ -component.

From the standpoint of the Kalman filter application, it is important to characterize, in terms of  $A$  and  $\Sigma$ , the existence, for each  $V_0$ , of  $0 \leq \beta < 1$  and  $\bar{Z}$  such that  $Z_k \leq \beta^k \bar{Z}$ ,  $k \geq 0$ , or, for each  $V_0$  and  $0 \leq \zeta < 1$ , of  $\bar{Z}$  such that  $\zeta^k Z_k \leq \bar{Z}$ , meaning that the  $Z$ -component cannot diverge exponentially. Moreover, since  $X_0 = \Sigma$  is fixed, we are interested only in the behavior of the  $Z$ -component w.r.t.  $V_0$ . We refer to these problems as PS and partial semistability<sup>1</sup> (PSS), respectively. PSS is relevant in situations where polynomial divergence of the Kalman estimates is acceptable.

Approaches for PS and PSS of general nonlinear systems can be employed, in principle. However, they are too general to yield an easy-to-test algebraic condition. The available results for PS of linear systems do not apply directly to  $\Theta$ , and it is worth mentioning that it is inappropriate to deal with the problem assuming that  $H_k$  are general projections, not connected with  $X$ , *in order to retrieve linearity*; in fact, in such a modified setting,  $Z_k$  can diverge exponentially, whereas  $A$  is stable<sup>2</sup> ( $A$  stable implies PS; see Remark 2). There is no available result specialized to system  $\Theta$ .

This paper exploits the special features of  $\Theta$ , for instance, the  $X$ -component obeys a linear difference equation and the coupling is via orthogonal projections; see other interesting properties in Proposition 1. We make use of a sequence of transformations  $W_k$ ,  $k \geq 0$ , playing the role of time-variant bases that allow one to characterize the convergence of the null space of  $X_k$ , as in Lemmas 6 and 7, and allow for adequate evaluations for the coupling projections in Lemma 9. Based on these evaluations, we show that  $\Theta$  is PSS if and only if the structural relation

$$(2) \quad \ker\{J\Sigma J^{-1}\} \cap \mathcal{J} = \{0\}$$

holds, where  $J$  is a similarity transformation such that  $JAJ^{-1}$  is in Jordan form and  $\mathcal{J}$  stands for the unstable subspace<sup>3</sup> of  $JAJ^{-1}$ . Recalling from linear systems theory that  $(A, \Sigma)$  semistabilizable can be interpreted as requiring that  $\Sigma$  excites the unstable space of  $A$ , the interpretation of (2) is that  $\Sigma$  has to “completely excite” the unstable space of  $A$ . Regarding PS, a similar condition holds, where  $\mathcal{J}$  is replaced with  $\mathcal{J}_S^\perp$  and  $\mathcal{J}_S$  is the stable space of  $A$ . These conditions are compared with classical notions of stabilizability and semistabilizability of  $(A, \Sigma)$ ; see Remark 2. Moreover, the conditions can be employed for “stabilization,” for instance, to obtain a  $\Sigma$  that provides PS or PSS; see Remark 3.

Apart from inherent theoretical significance, the derived conditions pave the way for obtaining sharp conditions for stability and semistability of Kalman filters [3, 4],

<sup>1</sup>Following the terminology of [1].

<sup>2</sup>For example, set  $A = \frac{3}{4} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$  and  $H_k = V_0 = \frac{1}{2} \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$ ,  $k \geq 0$ .  $A$  is stable and  $Z_k$  diverge.

<sup>3</sup>Please see section 2 for definitions.

which is a highly important issue, since existing conditions are conservative as they are either necessary or sufficient, or rely on additional assumptions, such as the existence of limiting stationary filters; see [7, 11, 13, 15].

The paper is organized as follows. Section 2 presents definitions and preliminary results. Section 3 introduces the sequence of transformations that allow us to derive a simple structure for  $A$  and to simplify the evaluation of the projections  $H_k$ . These results allow us to obtain testable conditions for PS and PSS in section 4. Finally, section 5 provides some conclusions.

**2. Definitions and preliminary results.** Let  $\mathbb{R}^n$  denote the  $n$ th dimensional Euclidean space. Let  $\mathbb{D}$  (respectively,  $\bar{\mathbb{D}}$ ) be the open (closed) unit disk. Let  $e_i$ ,  $i = 1, \dots, n$ , be the canonical basis of  $\mathbb{R}^n$ .  $[v_1, \dots, v_m]$  stands for the vector space spanned by  $v_1, \dots, v_m \in \mathbb{R}^n$ . For vector subspaces  $\mathcal{E}$  and  $\mathcal{F}$ ,  $\mathcal{E} \perp \mathcal{F}$  means that  $\mathcal{E}$  and  $\mathcal{F}$  are orthogonal,  $\mathcal{E}^\perp$  is such that  $\mathcal{E}^\perp \perp \mathcal{E}$ ,  $\mathcal{E} \oplus \mathcal{F}$  is the direct sum of  $\mathcal{E}$  and  $\mathcal{F}$ , and  $\mathcal{E} \ominus \mathcal{F} = \mathcal{E} \cap \mathcal{F}^\perp$ . Let  $\mathcal{R}^{r,s}$  (respectively,  $\mathcal{R}^r$ ) represent the normed linear space formed by all  $r \times s$  real matrices (respectively,  $r \times r$ ) and  $\mathcal{R}^{r*}$  ( $\mathcal{R}^{r0}$ ) the cone  $\{U \in \mathcal{R}^r : U = U'\}$  (the closed convex cone  $\{U \in \mathcal{R}^r : U = U' \geq 0\}$ ), where  $U'$  denotes the transpose of  $U$ . For  $U \in \mathcal{R}^n$ ,  $\lambda_i(U)$ ,  $i = 1, \dots, n$ , stands for an eigenvalue of  $U$ .  $\lambda_i(U)$  is referred to as a semistable (respectively, stable) eigenvalue when it lies in  $\bar{\mathbb{D}}$  ( $\mathbb{D}$ ). The associated eigenvector  $v \in \mathbb{R}^n$  is semistable (stable); otherwise it is unstable. The space spanned by all stable eigenvectors is referred to as the stable subspace of  $U$ , and similarly for semistable and unstable semispaces.

Regarding the system  $\Theta$  and its state trajectory  $(Z_k, X_k)$ ,  $k \geq 0$ , we employ the notation  $Z_k(V_0)$  and  $X_k(\Sigma)$  to emphasize the dependence on  $V_0$  and  $\Sigma$ ; when the dependence of  $Z_k$  on  $\Sigma$  (indirectly via the coupling projections) is relevant, we employ the notation  $Z_k(V_0, \Sigma)$ . The coupling projections  $H_k$  give rise to the nonlinearities of  $\Theta$ ; for example, with  $A = I$  and  $V_0 \neq 0$  we have  $Z_k(V_0, I) + Z_k(V_0, 0) = V_0 \neq 0 = Z_k(2V_0, I)$ ,  $k \geq 0$ . Some useful features of system  $\Theta$  are presented in what follows.

**PROPOSITION 1.** *Consider system  $\Theta$  and, for  $U \in \mathcal{R}^{n0}$ , let  $U^*$  stand for the pseudoinverse of  $U$ . The following statements hold:*

- (i)  $H_k = I - X_k^* X_k = I - (\zeta X_k)^*(\zeta X_k)$ ,  $k \geq 0$ ,  $\zeta \neq 0$ .
- (ii)  $(Z_k(\zeta U), X_k(\zeta \Sigma)) = (\zeta Z_k(U), \zeta X_k(\Sigma))$ ,  $k \geq 0$ ,  $\zeta \geq 0$ .
- (iii) If  $U_1 \geq U_0$ , then  $Z_k(U_1) \geq Z_k(U_0)$ ,  $k \geq 0$ .
- (iv) If  $\Sigma_1 \geq \Sigma_0$ , then  $X_k(\Sigma_1) \geq X_k(\Sigma_0)$  and  $Z_k(V_0, \Sigma_1) \leq Z_k(V_0, \Sigma_0)$ ,  $k \geq 0$ .

The stability notions considered in this paper are as follows.

**DEFINITION 1.** *Consider system  $\Theta$ . We say that  $(A, \Sigma)$  is partially semistable (PSS) if, for each  $0 \leq \zeta < 1$  and  $V \in \mathcal{R}^{n0}$ , there exists  $\bar{Z} \in \mathcal{R}^{n0}$  such that  $\zeta^k Z_k(V) \leq \bar{Z}$ ,  $k \geq 0$ . We say that  $(A, \Sigma)$  is partially stable (PS) if, for each  $V \in \mathcal{R}^{n0}$ , there exists  $0 \leq \beta < 1$  and  $\bar{Z} \in \mathcal{R}^{n0}$  such that  $Z_k \leq \beta^k \bar{Z}$ ,  $k \geq 0$ .*

*Example 1.* Consider the system  $\Theta$  with

$$(3) \quad A = \begin{bmatrix} d & 1 \\ 0 & d \end{bmatrix}, \quad \Sigma = \sigma \sigma'.$$

Set  $d = -1$  and  $\sigma = [0 \ 0]'$ . From (1) we have that  $X_k = 0$ ,  $k \geq 0$ . Direct inspection of PSS and PS via Definition 1 is virtually impossible, as it involves exhaustive searches for  $\bar{Z}$ , for each  $V$  and  $\zeta$ . Moreover, there is no evidence on how to modify the parameters (e.g.,  $\sigma$ ) in order to achieve PSS or PS. In Example 5 we shall see that  $(A, \Sigma)$  is PSS (and not PS), despite the fact that  $Z_k$  can diverge with polynomial rate;

for instance, with  $V = vv'$  and  $v = e_2$ , (1) yields

$$Z_k(V) = A^k V A'^k = \begin{bmatrix} k^2 & -k \\ -k & 1 \end{bmatrix}.$$

LEMMA 1. *Consider system  $\Theta$ . The following statements hold:*

- (i)  *$(A, \Sigma)$  is PSS if and only if, for each  $\rho > 1$ , there exists  $\bar{Z} \in \mathcal{R}^{n_0}$  such that  $Z_k(I) \leq \rho^k \bar{Z}$ ,  $k \geq 0$ .*
- (ii)  *$(A, \Sigma)$  is PS if and only if there exist  $\bar{Z} \in \mathcal{R}^{n_0}$  and  $0 \leq \gamma < 1$  such that  $Z_k(I) \leq \gamma^k \bar{Z}$ ,  $k \geq 0$ .*

*Proof of (i).* (Necessity.) It follows by setting  $V = I$  in Definition 1.

(Sufficiency.) For each  $V \in \mathcal{R}^{n_0}$  we can pick  $\kappa > 0$  such that  $\kappa V \leq I$  and Proposition 1 (iii) yields  $Z_k(\kappa V) \leq Z_k(I) \leq \rho^k \bar{Z}$ , which leads to  $\rho^{-k} Z_k(V) \leq \kappa^{-1} \bar{Z}$ .

*Proof of (ii).* It is similar to the proof of (i) and is not presented.  $\square$

Consider now the linear time-varying system related to the dynamics of the  $Z$ -component of  $\Theta$ , defined by

$$(4) \quad \Theta_Z : \begin{cases} z_{k+1} = H_k A z_k, & k \geq 0, \\ z_0 = H_0 z, \end{cases}$$

where  $z_k \in \mathbb{R}^n$  is the state and  $z \in \mathbb{R}^n$ . Not surprisingly, PSS and PS of  $(A, \Sigma)$  are strongly connected to semistability and stability of  $\Theta_Z$ , as stated in the following lemma.

LEMMA 2. *Consider systems  $\Theta$  and  $\Theta_Z$ . The following statements hold:*

- (i)  *$(A, \Sigma)$  is PSS if and only if, for each  $z \in \mathbb{R}^n$  and  $0 \leq \zeta < 1$ , there exist  $\alpha \geq 0$  and  $0 \leq \beta < 1$  such that  $\|\zeta^k z_k\| \leq \alpha \beta^k$ .*
- (ii)  *$(A, \Sigma)$  is PS if and only if for each  $z \in \mathbb{R}^n$  there exist  $\alpha \geq 0$  and  $0 \leq \beta < 1$  such that  $\|z_k\| \leq \alpha \beta^k$ .*

*Proof of (i).* We employ the notation  $z_k(z)$ ,  $\alpha_z$ , and  $\beta_z$  to emphasize the dependence on  $z$ .

(Necessity.) Let  $\iota > 1$  and, for each  $0 \leq \zeta < 1$ , let  $\rho = \zeta^{-2}\iota$ . From Lemma 1, there exists  $\bar{Z}$  such that  $Z_k(I) \leq (\zeta^{-2}\iota)^k \bar{Z}$ . Equivalently,

$$(5) \quad \zeta^{2k} Z_k(I) \leq \iota^k \bar{Z}.$$

Consider  $z$  such that  $\|z\| \leq 1$ . Note that  $Z_0(I) = H_0 H'_0 \geq H_0 z z' H'_0 = z_0 z'_0$  and that employing (1) and (4) recursively yields  $Z_k \geq z_k z'_k$ ,  $k \geq 0$ . Then (5) leads to  $\zeta^{2k} z_k z'_k \leq \zeta^{2k} Z_k \leq \iota^k \bar{Z}$ , and taking the trace we obtain

$$(6) \quad \|\zeta^k z_k\|^2 \leq \iota^k \text{tr}(\bar{Z}), \quad \|z\| \leq 1.$$

Now consider  $\|z\| > 1$ . Note from (4) that  $z_k(\|z\|^{-1}z) = \|z\|^{-1}z_k(z)$ , which allows us to employ (6) to evaluate

$$(7) \quad \|\zeta^k z_k\|^2 = \|\zeta^k z_k(\|z\|^{-1}z)\|^2 \|z\|^2 \leq \iota^k \text{tr}(\bar{Z}) \|z\|^2.$$

From (6) and (7) we have that, for each  $z \in \mathbb{R}^n$ ,  $\|\zeta^k z_k\|^2 \leq \iota^k \text{tr}(\bar{Z}) \max(1, \|z\|^2)$ .

(Sufficiency.) For each  $\gamma > 1$ , let  $\zeta = \sqrt{\gamma^{-1}}$  and note that for each  $z$ , by hypothesis,  $z_k(z) z_k(z)' \leq \zeta^{-2k} \beta_z^{2k} \alpha_z^2 I = \gamma^k \beta_z^{2k} \alpha_z^2 I$ . Then, for each  $z = e_i$ ,  $i = 1, \dots, n$ , we can write

$$(8) \quad z_k(e_i) z'_k(e_i) \leq \gamma^k \beta_{e_i}^{2k} \alpha_{e_i}^2 I.$$

Since  $H_k$  is an orthogonal projection, employing (1) we obtain  $Z_0(I) = H_0 H'_0 \leq I = z_0(e_1)z'_0(e_1) + \cdots + z_0(e_n)z'_0(e_n)$ , and it is simple to check by induction that

$$(9) \quad Z_k(I) \leq z_k(e_1)z'_k(e_1) + \cdots + z_k(e_n)z'_k(e_n).$$

Equations (8) and (9) lead to

$$(10) \quad Z_k(I) \leq \gamma^k \beta_{e_i}^{2k} \alpha_{e_1}^2 I + \cdots + \gamma^k \beta_{e_i}^{2k} \alpha_{e_n}^2 I \leq \gamma^k \bar{\beta}^{2k} n \bar{\alpha}^2 I,$$

where  $\bar{\alpha} = \max(\alpha_{e_1}, \dots, \alpha_{e_n})$  and  $\bar{\beta} = \max(\beta_{e_1}, \dots, \beta_{e_n})$ . Since  $\beta_{e_i} < 1$  and  $\bar{\beta} < 1$ , (10) leads to  $Z_k(I) \leq \gamma^k (n \bar{\alpha}^2 I)$  and Lemma 1 completes the proof.

*Proof of (ii).* It is similar to the proof of (i), replacing  $\iota > 1$ ,  $0 \leq \zeta < 1$ , and  $\gamma > 1$  with  $0 \leq \iota < 1$ ,  $\zeta = 1$ , and  $\gamma = 1$ , respectively.  $\square$

Similarly to the sequence  $z_k$  connected with the  $Z$ -component of  $\Theta$ , we introduce a vector sequence related to  $X$ , as follows. Consider the solution  $X_k = A^k \Sigma A^{k'}$  for the  $X$ -component. Introduce the rank-one decomposition

$$(11) \quad \Sigma = \sigma_1 \sigma'_1 + \cdots + \sigma_{r_\Sigma} \sigma'_{r_\Sigma},$$

where  $r_\Sigma$  stands for the rank of  $\Sigma$ , and the linear system defined by

$$\Theta_X : x_k(\sigma) = A^k \sigma.$$

It is simple to check that

$$X_k = x_k(\sigma_1)x_k(\sigma_1)' + \cdots + x_k(\sigma_{r_\Sigma})x_k(\sigma_{r_\Sigma})'$$

and  $H_k$  is the orthogonal projection onto  $[x_k(\sigma_1), \dots, x_k(\sigma_{r_\Sigma})]^\perp$ .

**3. Evaluations for the coupling projections.** The spaces spanned by the trajectory  $x_k = A^k \sigma$  play an important role in this paper, because they drive the projection  $H_k$ . We now present certain characterizations for convergence of these spaces. Note that, taking into account the original basis, there may be no convergence for  $[x_k]$ ; see Examples 2 and 4. In this paper we employ the bases introduced as follows, related to Jordan forms [8], in view of the fact that they lead to a simpler characterization for  $[x_k]$ , and despite the drawback of an inherent time dependence.

**PROPOSITION 2.** *For each  $A \in \mathcal{R}^n$  there is a sequence of transformations  $W_k$ ,  $k \geq 0$ , such that  $A = W_{k+1}^{-1} \bar{A} W_k$  and  $A^k = W_k^{-1} \bar{A}^k W_0$ ,  $k \geq 0$ , with*

$$\bar{A} = \text{diag}(\mathcal{A}(\eta_1), \dots, \mathcal{A}(\eta_j)),$$

where  $\mathcal{A}(\eta_i)$ ,  $0 \leq i \leq j \leq n$ , is an upper triangular Jordan block with eigenvalue  $\eta_i$ , and  $\eta_i$  is a real nonnegative number, corresponding to certain eigenvalues  $\lambda_\ell(A)$ ,  $0 \leq \ell \leq n$ , with  $|\lambda_\ell(A)| = \eta_i$ , ordered in such a manner that  $\eta_i \geq \eta_j$  whenever  $i \geq j$ . Moreover, there exists  $\kappa$ ,  $0 \leq \kappa < 1$ , such that  $(1 - \kappa) \leq \|W_k\| \leq (1 + \kappa)$ ,  $k \geq 0$ .

The bases of Proposition 2 are employed throughout the paper, hence we introduce the following notation. Unless otherwise stated, for any  $V \in \mathcal{R}^{n,r}$  and  $v \in \mathbb{R}^n$ , we define  $\bar{V} \in \mathcal{R}^{n,r}$  and  $\bar{v} \in \mathbb{R}^n$  as  $\bar{V} = W_0 V$  and  $\bar{v} = W_0 v$ . For instance, we denote  $W_0 \sigma$  simply by  $\bar{\sigma}$ . The matrix  $A$  associated with the transformation  $W_0$  is usually clear from the context; otherwise we employ the explicit notation  $W_0(A)$ . For  $\sigma, z \in \mathbb{R}^n$ , define  $\bar{z}_k, \bar{x}_k \in \mathbb{R}^n$ ,  $k \geq 0$ , by

$$(12) \quad \bar{z}_{k+1} = (\bar{H}_k \bar{A}) \bar{z}_k, \quad k \geq 1, \quad \bar{z}_0 = \bar{H}_0 \bar{z}, \quad \bar{x}_k(\sigma) = \bar{A}^k \bar{\sigma}, \quad k \geq 0,$$

where

$$(13) \quad \bar{H}_k = W_k H_k W_k^{-1}.$$

*Example 2.* Consider

$$(14) \quad A = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \bar{A} = I, W_{2\ell} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, W_{2\ell+1} = I, \ell \geq 0.$$

It is simple to check that the statements of Proposition 2 are satisfied. For  $\sigma = \begin{bmatrix} 1 & 1 \end{bmatrix}'$ ,  $x_k = A^k \sigma$  is in the form  $x_{2\ell} = \begin{bmatrix} 1 & 1 \end{bmatrix}'$  and  $x_{2\ell+1} = \begin{bmatrix} 1 & -1 \end{bmatrix}'$ ,  $\ell \geq 0$ ; hence the spaces spanned by  $[x_k]$  do not converge in any sense as  $k \rightarrow \infty$ . On the other hand,  $\bar{x}_k = \bar{A}^k \bar{\sigma} = W_0 \sigma = \begin{bmatrix} 1 & -1 \end{bmatrix}'$ ,  $k \geq 0$ . The matrix  $A$  is in Jordan form, making clear that the Jordan form is not convenient for the characterization of convergence of  $[x_k]$  that we seek. Note that  $\bar{A}$  is also in Jordan form, but is not similar to  $A$ .

Convergence of state trajectories is preserved, as stated in the next result.

LEMMA 3. *The following statements hold:*

- (i)  $z_k = W_{k-1}^{-1} \bar{z}_k$ ,  $x_k(\sigma) = W_k \bar{x}_k(\sigma)$ ,  $k \geq 0$ .
- (ii) *There exists  $\kappa$ ,  $0 \leq \kappa < 1$ , such that  $(1 + \kappa)^{-1} \|\bar{z}_k\| \leq \|z_k\| \leq (1 - \kappa)^{-1} \|\bar{z}_k\|$  and  $(1 - \kappa) \|\bar{x}_k(\sigma)\| \leq \|x_k(\sigma)\| \leq (1 + \kappa) \|\bar{x}_k(\sigma)\|$ ,  $k \geq 0$ .*

*Proof of (i).* We have from Proposition 2 that  $A = W_k^{-1} \bar{A} W_{k-1}$ ,  $k \geq 1$ ; substituting this equality and (13) in (4) yields

$$\begin{aligned} z_k &= (H_{k-1} A) \cdots (H_1 A) (H_0 v) = (W_{k-1}^{-1} \bar{H}_{k-1} W_{k-1} W_{k-1}^{-1} \bar{A} W_{k-2}) \cdots (W_0^{-1} \bar{H}_0 W_0 v) \\ &= W_{k-1}^{-1} (\bar{H}_{k-1} \bar{A}) \cdots (\bar{H}_1 \bar{A}) \bar{H}_0 (W_0 v) = W_{k-1}^{-1} \bar{z}_k. \end{aligned}$$

The proof for the second statement of (i) is analogous.

*Proof of (ii).* Accordingly to Proposition 2, there is a  $0 \leq \kappa < 1$  such that  $\|W_k\| \leq (1 + \kappa)$ ,  $k \geq 0$ , and assertion (i) allows us to write  $\|z_k\| \leq \|W_{k-1}^{-1}\| \|\bar{z}_k\| \leq (1 - \kappa)^{-1} \|\bar{z}_k\|$ . A similar evaluation yields  $\|z_k\| \geq (1 + \kappa)^{-1} \|\bar{z}_k\|$ . The proof for the second statement of (ii) is analogous.  $\square$

PROPOSITION 3. *Consider system  $\Theta_Z$  and the system  $\Theta_{\zeta Z}$  that arises by replacing the matrix  $A$  with  $(\zeta A)$ ,  $\zeta \geq 0$ , and let  $z_{\zeta,k}$  be the corresponding trajectory. Then  $\zeta^k z_k = z_{\zeta,k}$  and, similarly,  $\zeta^k \bar{z}_k = \bar{z}_{\zeta,k}$ .*

*Proof.* The first statement follows from Proposition 1 (i)–(ii). Moreover, the first statement and Lemma 3 (i) yield  $\zeta^k W_{k-1}^{-1}(A) \bar{z}_k = W_{k-1}^{-1}(\zeta A) \bar{z}_{\zeta,k}$ ; hence the second statement follows from the fact that one can always set  $W_k(\zeta A) = W_k(A)$  (even for  $\zeta = 0$ ).  $\square$

Consider now  $\bar{A}$  and let  $e_1, \dots, e_{q_u}$  and  $e_{q_u+1}, \dots, e_{q_s}$  be the associated unstable eigenvectors and semistable eigenvectors, respectively. Introduce the subspaces

$$(15) \quad \mathcal{U} = [e_1, \dots, e_{q_u}], \quad \mathcal{S} = [e_1, \dots, e_{q_s}].$$

Of course,  $\mathcal{U}^\perp = [e_{q_u+1}, \dots, e_n]$  and  $\mathcal{S}^\perp = [e_{q_s+1}, \dots, e_n]$ . The block structure of  $\bar{A}$  in Proposition 2 allows for the next invariance results.

LEMMA 4.  $\mathcal{U}, \mathcal{U}^\perp, \mathcal{S}$ , and  $\mathcal{S}^\perp$  are  $\bar{A}$ -invariant.

Note that  $\bar{A}$  is in Jordan form [8], leading to several links with available results for Jordan forms. For example, there are invariance results similar to the ones of Lemma 4; see, e.g., [1]. Another useful connection is as follows. Let  $J$  be the similarity matrix for which  $JAJ^{-1}$  is the Jordan form of  $A$  and let  $\mathcal{J}$  stand for the vector subspace spanned by the unstable eigenvectors of  $JAJ^{-1}$ . Then, for each  $\sigma \in \mathbb{R}^n$ , the

projection of  $J\sigma$  onto  $\mathcal{J}$  is zero if and only if the projection of  $\bar{\sigma} = W_0\sigma$  onto  $\mathcal{U}$  is zero, yielding the following result, given without proof, which is useful for representing the main results in terms of Jordan forms.

LEMMA 5.  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U} = \{0\}$  if and only if  $\ker\{J\Sigma J'\} \cap \mathcal{J} = \{0\}$ .

The spaces spanned by  $x_k$  may not converge in any sense (see Example 2), which implies that there may be no convergence for the projections  $H_k$ . However, the convenient structure of  $\bar{A}$  provides that  $[\bar{x}_k]$  always converge in a certain sense, allowing us to derive approximation results for  $\bar{H}$ . In order to make the convergence notion precise, we define, for the (nontrivial) vector subspaces  $\mathcal{U}$  and  $\mathcal{V}$ , the quantity

$$(16) \quad \theta_{\mathcal{V}}(\mathcal{U}) = \max_{v \in \mathcal{V}, v \neq 0} \min_{u \in \mathcal{U}, u \neq 0} 1 - (\|u\| \|v\|)^{-1} u'v.$$

Note from the structure of  $\bar{A}$  that if  $\sigma \in \mathbb{R}^n$  is such that  $\eta$  is the largest eigenvalue for which  $\sigma'\nu \neq 0$ , where  $\nu$  is an eigenvector associated with  $\eta$ , and assuming  $\eta$  unique (i.e., no other eigenvalue of  $\bar{A}$  equals  $\eta$ ), then there are  $\pi \geq 0$  and  $0 \leq \rho < 1$  such that  $\theta_{\mathcal{S}_\eta}([x_k(\sigma)]) \leq \pi\rho^k$ , where  $\mathcal{S}_\eta$  is the space spanned by the eigenvectors associated with  $\eta$ . This signifies that  $x_k(\sigma)$  and  $\mathcal{S}_\eta$  “align” with exponential rate. Moreover, there is a  $\varphi > 0$  such that  $\theta_{\mathbb{R}^n \ominus \mathcal{S}_\eta}([x_k(\sigma)]) \geq \varphi$  for a sufficiently large  $k$ . One can explore the convenient block structure of  $\bar{A}$  to obtain the more general characterization given in Lemmas 6 and 7 without proof; recall that  $\bar{\sigma} = W_0\sigma$  and  $\bar{x}_k(\sigma) = \bar{A}^k\bar{\sigma} = W_k A^k \sigma$ .

LEMMA 6. Consider  $\sigma_j \in \mathbb{R}^n$ ,  $j = 1, \dots, m$ , and assume  $\mathcal{S}$  is nontrivial. If  $\ker\{\bar{\sigma}_1\bar{\sigma}'_1 + \dots + \bar{\sigma}_m\bar{\sigma}'_m\} \cap \mathcal{S} = \{0\}$ , then there exist  $\pi \geq 0$  and  $0 \leq \rho < 1$  such that

$$\theta_{\mathcal{S}}([\bar{x}_k(\sigma_1), \dots, \bar{x}_k(\sigma_m)]) \leq \pi\rho^k.$$

Conversely to Lemma 6, if  $\sigma_j$  does not “completely excite” the subspace  $\mathcal{S}$ , then the space spanned by  $\bar{x}_k(\sigma_1)$  does not “align” with  $\mathcal{S}$ . It is convenient for later reference to formalize this in terms of  $\mathcal{U}$  rather than  $\mathcal{S}$ .

LEMMA 7. Consider  $\sigma_j \in \mathbb{R}^n$ ,  $\sigma_j \neq 0$ ,  $j = 1, \dots, m$ . If  $\ker\{\bar{\sigma}_1\bar{\sigma}'_1 + \dots + \bar{\sigma}_m\bar{\sigma}'_m\} \cap \mathcal{U} \neq \{0\}$ , then there exist  $\varphi > 0$  and a subspace  $\mathcal{F}$  spanned by eigenvectors of  $\bar{A}$  such that  $\mathcal{U} \ominus \mathcal{F}$  is nontrivial and

$$\begin{aligned} \theta_{\mathcal{F}}([\bar{x}_k(\sigma_1), \dots, \bar{x}_k(\sigma_m)]) &\leq o(k), \quad k \geq 0, \\ \theta_{\mathcal{U} \ominus \mathcal{F}}([\bar{x}_k(\sigma_1), \dots, \bar{x}_k(\sigma_m)]) &\geq \varphi, \quad k \geq 1, \end{aligned}$$

where  $o(\cdot)$  is a nonnegative-valued, strictly decreasing function.

Example 3. Consider the system  $\Theta$  of Example 1 with  $\sigma = e_2$ . The statements of Proposition 2 hold with  $\bar{A} = A$  and  $W_k = I$ ,  $k \geq 0$ , whenever  $d \geq 0$ , or

$$\bar{A} = -A, \quad W_{2\ell} = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}, \quad W_{2\ell+1} = -W_{2\ell}, \quad \ell \geq 0, \quad d < 0.$$

Consider  $d$  such that  $|d| > 1$ . Clearly,  $\bar{\sigma} = \sigma$  and  $\mathcal{U} = \mathbb{R}^n$  satisfy the hypothesis of Lemma 7. As  $k \rightarrow \infty$ ,  $\bar{x}_k(\sigma)$  “aligns” with  $\mathcal{F} = [e_1]$ . Figure 1 illustrates the behavior of  $\theta$ ; note from the detail presented in Figure 1 (ii), for  $d = 10$ , that the convergence is slower in the interval  $100 \leq t \leq 200$  than in the interval  $0 \leq t \leq 100$ , suggesting it is not exponential. The case when  $|d| \leq 1$  is not addressed by Lemmas 6 or 7 (note that  $\mathcal{U}$  is trivial; for  $|d| < 1$ ,  $\mathcal{S}$  is trivial and, for  $|d| = 1$ ,  $\sigma$  does not completely excite  $\mathcal{S} = \mathbb{R}^n$ ).

The coupling projections  $\bar{H}$  differ from  $H$  as they are not orthogonal, because of the “distortion” introduced by the new bases (see Example 4), but they are similar

FIG. 1. Behavior of  $\theta$  for system  $\Theta$  of Example 3.

to  $H$  in the sense that  $\bar{H}\bar{v} = 0$  whenever  $Hv = 0$ . We shall need the following related result.

LEMMA 8. Consider the rank-one decomposition (11) for  $\Sigma$ . The projections  $\bar{H}_k$ ,  $k \geq 0$ , are such that  $\bar{H}_k v = 0$  for  $v \in [\bar{x}_k(\sigma_1), \dots, \bar{x}_k(\sigma_{r_\Sigma})]$ .

Proof. Note that  $\bar{H}_k v = \bar{H}_k(\pi_1 \bar{x}_k(\sigma_1) + \dots + \pi_{r_\Sigma} \bar{x}_k(\sigma_{r_\Sigma}))$  for certain scalars  $\pi_j$ ,  $j = 0, \dots, r_\Sigma$ , and, for each term of this sum, one can employ Lemma 3 (i) to evaluate  $\bar{H}_k \bar{x}_k(\sigma_j) = W_k H_k W_k^{-1} W_k x_k(\sigma_j) = W_k H_k x_k(\sigma_j) = 0$ ,  $j = 0, \dots, r_\Sigma$ , since  $H_k x_k(\sigma_j) = 0$  by definition of  $H_k$ .  $\square$

As  $\bar{x}_k(\sigma_j)$ ,  $0 \leq j \leq r_\Sigma$ , aligns with  $\mathcal{S}$  ( $\mathcal{F}$ , respectively) as stated in Lemma 6 (Lemma 7, respectively), we have that the projections  $\bar{H}_k$  onto  $[\bar{x}(\sigma_1), \dots, \bar{x}(\sigma_{r_\Sigma})]$  “tend to align” with the orthogonal projection onto  $\mathcal{S}^\perp$  ( $\mathcal{F}^\perp$ , respectively), which allows us to obtain the approximation results that will be useful for section 4. We present these results in the next lemma, in which  $S$ ,  $T$ , and  $U$  denote the orthogonal projections onto  $\mathcal{S}^\perp$ ,  $\mathcal{F}^\perp$ , and  $\mathcal{U} \ominus \mathcal{F}$ , respectively.

LEMMA 9. If  $\ker\{W_0 \Sigma W_0'\} \cap \mathcal{S} = \{0\}$  and  $\ker\{W_0 \Sigma W_0'\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$ , then there exist  $\pi \geq 0$ ,  $0 \leq \rho < 1$ , such that, for  $k \geq 0$ ,

$$(i) \quad \|S(I - \bar{H}_k)v\| \leq \pi \rho^k \|v\| \text{ and } \|\bar{H}_k(I - S)v\| \leq \pi \rho^k \|v\|.$$

If  $\ker\{W_0 \Sigma W_0'\} \cap \mathcal{U} \neq \{0\}$ , then there exist  $\delta, \lambda > 0$  and a nonnegative-valued, strictly decreasing function  $o(\cdot)$  such that, for  $k \geq 0$ ,

$$(ii) \quad \|T(I - \bar{H}_k)v\| \leq o(k) \|v\| \text{ and } \|\bar{H}_k(I - T)v\| \leq o(k) \|v\|;$$

$$(iii) \quad \|(U\bar{A})^{k+1}Uv\| \geq (1 + \delta)\|Uv\|;$$

$$(iv) \quad T\bar{A}Uv = U\bar{A}Uv;$$

$$(v) \quad \|\bar{H}_k Uv\| \leq \lambda \|Uv\|.$$

Proof. (i). Lemma 6 leads to the result, provided  $\mathcal{S}$  is nontrivial; for trivial  $\mathcal{S}$  it is simple to check that  $S = H_k = I$  and the result holds with  $\pi = 0$ . (ii) Lemma 8 can be employed when  $\Sigma \neq 0$ . The case with trivial  $\Sigma$  leads to  $T = H_k = I$  and  $o(k) = 0$ ,  $k \geq 0$ . (iii) It follows from the fact that  $U$  is the projection onto  $\mathcal{U} \ominus \mathcal{F}$ , which is spanned by unstable eigenvectors of  $\bar{A}$ ; moreover,  $(1 + \delta)$  equals the minimal of these eigenvalues. (iv)  $\mathcal{U} \ominus \mathcal{F}$  is not necessarily  $\bar{A}$ -invariant in general, but one can easily check from the structure of  $\bar{A}$  that, for  $w \in \mathcal{U} \ominus \mathcal{F}$ ,  $\bar{A}w \in \mathcal{U}$ , in such a manner that the component of  $\bar{A}w$  in  $\mathcal{U}^\perp$  is zero and  $T\bar{A}w = U\bar{A}w$ . (v) It follows from the facts that  $\bar{H}_k = W_k H_k W_k^{-1}$  and  $(1 - \kappa) \leq \|W_k\| \leq (1 + \kappa)$  for some  $0 \leq \kappa < 1$ , as in Lemma 2.  $\square$

Remark 1 (condition  $\ker\{W_0 \Sigma_1 W_0'\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$  in Lemma 9). In order to show that  $\ker\{W_0 \Sigma W_0'\} \cap \mathcal{S} = \{0\}$  is a sufficient condition for PSS, we may initially consider a “modified”  $\Sigma_1$  such that  $\ker\{W_0 \Sigma_1 W_0'\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$  and then employ the inequality

$Z_k(V_0, \Sigma) \leq Z_k(V_0, \Sigma_1)$  of Proposition 1 (iv) to extend the result to the original  $\Sigma$ ; see the proof of Theorem 1. Since  $\Sigma_1$  does not excite  $\mathcal{S}^\perp$  and excites all  $\mathcal{S}$ , there is no need to consider excited and nonexcited subspaces of  $\mathcal{S}^\perp$  and  $\mathcal{S}$  (as opposed, e.g., to  $\mathcal{U} \cap \mathcal{F}$  and  $\mathcal{U} \cap \mathcal{F}^\perp$ ). However, the above inequality is not suitable for dealing with the necessary condition for PS. That is why we study the projection  $S$  in (i) of Lemma 9, and  $T$  and  $U$  in (ii) of the same lemma.

*Example 4.* Consider the systems  $\Theta$  and  $\Theta_X$  with

$$(17) \quad A = \begin{bmatrix} 1 & -0.1 & 0 \\ 0.2 & 1 & 0 \\ 0 & 0 & 0.99 \end{bmatrix}, \quad \Sigma = \sigma\sigma', \quad \sigma = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}.$$

Set  $W_k = \tilde{A}^{-k}$ , with

$$\tilde{A} \approx \begin{bmatrix} 0.9901 & -0.099 & 0 \\ 0.1980 & 0.9901 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad \bar{A} = \begin{bmatrix} \sqrt{1.02} & 0 & 0 \\ 0 & \sqrt{1.02} & 0 \\ 0 & 0 & 0.99 \end{bmatrix}.$$

Figure 2 (i) illustrates how simple the behavior of  $\bar{x}_k$  is when compared to  $x_k$ . The oscillatory behavior of  $x_k$  prevents convergence of  $\theta_V(x_k)$  for any fixed  $V$ . The hypothesis of Lemma 7 holds with  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U} = [e_2]$  and, in fact, for  $\mathcal{F} = [e_1]$ ,  $\theta_{\mathcal{F}^\perp \cap \mathcal{U}}(\bar{x}_k(\sigma)) \geq 1$ , and  $\theta_{\mathcal{F}}(\bar{x}_k(\sigma)) \leq 0.3 \times 0.96^k$ . We have checked that  $\bar{H}_k \bar{x}_k(\sigma) = 0$ ,  $k \geq 0$ , confirming Lemma 8. The statements of Lemma 9 (ii)–(iv) hold with  $\delta = 0.001$ ,  $\lambda = 1.031$ , and  $o(k) = 0.985^k$ ; Figure 2 (ii) and (iii) illustrate the behavior of the quantities  $\|T(I - \bar{H}_k)v\|$  and  $\|\bar{H}_k Uv\|$  for  $v = (\sqrt{3}/3) [1 \ 1 \ 1]'$ . Note that  $\|\bar{H}_k Uv\|$  presents an oscillation due to the fact that  $\bar{H}_k$  are *nonorthogonal* projections.

FIG. 2. Simulation results for system  $\Theta_X$  of Example 4. (i) State trajectory  $\bar{x}_k(\sigma)$ . (ii) and (iii) The quantities of Lemma 9 (ii) and (iv).

An important feature of the case with  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U} \neq \{0\}$  is that  $\text{Im}(\bar{H}) \cap \mathcal{U} \neq \{0\}$ , which follows from the fact that  $\bar{H}$  cannot “cover”  $\mathcal{U} \ominus \mathcal{F}$  as stated in Lemma 7. This fact, together with the structure of invariant spaces presented in Lemma 4, allows us to pick an initial condition  $\bar{z}$  for which the associated  $\bar{z}_k$  has a nontrivial projection onto  $\mathcal{U} \ominus \mathcal{F}$ , as stated in the next proposition, the proof of which is omitted.

**PROPOSITION 4.** *If  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U} \neq \{0\}$ , then there exists  $\bar{z} \in \mathcal{S}$  such that  $U\bar{z}_k \neq 0$ ,  $k \geq 0$ .*

**4. Testable condition for PS and PSS.** This section presents, initially, a sufficient condition for PS, with an extension to PSS. Then a necessary condition for PSS is presented and extended to PS. Finally, the results are gathered together in Theorem 1.

#### 4.1. Sufficient conditions.

LEMMA 10. Consider  $W_0$  as in Proposition 2, the subspace  $\mathcal{S}$  as in (15), and  $\bar{z}_k$  as in (12). If  $\ker\{W_0\Sigma W'_0\} \cap \mathcal{S} = \{0\}$  and  $\ker\{W_0\Sigma W'_0\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$ , then for each  $\bar{z}$  there exist  $\chi \geq 0$  and  $0 \leq \beta < 1$  such that  $\|\bar{z}_k\| \leq \chi\beta^k$ .

*Proof.* For ease of notation, in this proof we write  $\bar{z}$ ,  $\bar{A}$ , and  $\bar{H}$  as  $z$ ,  $A$ , and  $H$ , respectively; for  $\ell \geq 0$ ,  $w_{1,\ell}, w_{2,\ell}, w_{3,\ell}$  stand for vectors with  $\|w_{j,\ell}\| \leq 1$ . Recall the orthogonal projection  $S$  used in Lemma 9. From Lemma 4 we have that both  $\mathcal{S}^\perp$  and  $\mathcal{S}$  are  $A$ -invariant, in such a manner that  $ASz_{k+\ell} \in \mathcal{S}^\perp$  and  $A(I-S)z_{k+\ell} \in \mathcal{S}$ ,  $k, \ell \geq 0$ . Moreover,  $\ker\{W_0\Sigma W'_0\} \cap \mathcal{S} = \{0\}$ , and hence the conditions of Lemma 9 (i) hold, allowing us to evaluate, for  $k, \ell \geq 0$ ,

$$\begin{aligned}
 SH_{k+\ell+1}(ASz_{k+\ell}) &= S(ASz_{k+\ell}) + \pi\rho^{k+\ell+1}\|ASz_{k+\ell}\|w_{1,\ell} \\
 &= ASz_{k+\ell} + \pi\rho^{k+\ell+1}\|ASz_{k+\ell}\|w_{1,\ell}, \\
 (18) \quad H_{k+\ell+1}A(I-S)z_{k+\ell} &= H_{k+\ell+1}(I-S)(A(I-S)z_{k+\ell}) \\
 &= \pi\rho^{k+\ell+1}\|A(I-S)z_{k+\ell}\|w_{2,\ell},
 \end{aligned}$$

where  $\pi, \rho$  are as in Lemma 9. Now we shall show inductively that

$$\begin{aligned}
 (19) \quad z_{k+\ell+1} &= A^{\ell+1}Sz_k + (I-S)H_{k+\ell+1}A^{\ell+1}Sz_k \\
 &\quad + 2\pi\|A\|^{\ell+1}\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell+1})w_{3,\ell}, \quad \ell \geq 0.
 \end{aligned}$$

For  $\ell = 0$ , from (4) and (18) we have that

$$\begin{aligned}
 z_{k+1} &= H_{k+1}Az_k = H_{k+1}ASz_k + H_{k+1}A(I-S)z_k \\
 &= SH_{k+1}ASz_k + (I-S)H_{k+1}ASz_k + H_{k+1}A(I-S)z_k \\
 &= ASz_k + (I-S)H_{k+1}ASz_k \\
 &\quad + \pi\rho^{k+\ell+1}(\|ASz_k\|w_{1,0} + \|A(I-S)z_k\|w_{2,0}) \\
 &= ASz_k + (I-S)H_{k+1}ASz_k + \pi\rho^{k+\ell+1}(2\|A\|\|z_k\|w_{3,0}),
 \end{aligned}$$

and assuming (19) holds for  $\ell - 1$ , similarly to the above we evaluate from (4)

$$\begin{aligned}
 z_{k+\ell+1} &= H_{k+\ell+1}Az_{k+\ell} \\
 &= H_{k+\ell+1}A^{\ell+1}Sz_k \\
 &\quad + H_{k+\ell+1}A(I-S)H_{k+\ell}A^\ell Sz_k \\
 &\quad + H_{k+\ell+1}A(2\pi\|A\|^\ell\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell})w_{3,\ell-1}) \\
 &= SH_{k+\ell+1}A^{\ell+1}Sz_k + (I-S)H_{k+\ell+1}A^{\ell+1}Sz_k \\
 &\quad + H_{k+\ell+1}A(I-S)H_{k+\ell}A^\ell Sz_k \\
 &\quad + H_{k+\ell+1}A(2\pi\|A\|^\ell\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell})w_{3,\ell-1})
 \end{aligned}$$

and, from (18),

$$\begin{aligned}
 z_{k+\ell+1} &= A^{\ell+1}Sz_k + \pi\rho^{k+\ell+1}\|A^{\ell+1}Sz_k\|w_{1,k+\ell+1} \\
 &\quad + (I - S)H_{k+\ell+1}A^{\ell+1}Sz_k \\
 &\quad + \pi\rho^{k+\ell+1}\|A(I - S)H_{k+\ell}A^\ell Sz_k\|w_{2,k+\ell+1} \\
 &\quad + H_{k+\ell+1}A(2\pi\|A\|^\ell\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell})w_{3,\ell-1}) \\
 &= A^{\ell+1}Sz_k + (I - S)H_{k+\ell+1}A^{\ell+1}Sz_k \\
 &\quad + 2\pi\|A\|^{\ell+1}\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell} + \pi\rho^{k+\ell+1})w_{3,\ell},
 \end{aligned}$$

completing the inductive proof of (19). Then we can write, for  $k, \ell \geq 0$ ,

$$\begin{aligned}
 \|z_{k+\ell+1}\| &\leq \|A^{\ell+1}Sz_k\| + \|(I - S)H_{k+\ell+1}A^{\ell+1}Sz_k\| \\
 (20) \quad &\quad + 2\pi\|A\|^{\ell+1}\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell+1}) \\
 &\leq 2\|A^{\ell+1}Sz_k\| + 2\pi\|A\|^{\ell+1}\|z_k\|(\rho^{k+1} + \dots + \rho^{k+\ell+1}).
 \end{aligned}$$

Now consider the term  $A^\ell Sz_k$ ,  $\ell \geq 1$ . Since  $\mathcal{S}^\perp$  is  $A$ -invariant and corresponds to the subspace spanned by eigenvectors associated to eigenvalues (strictly) inside the unit disk, one has that  $\|A^\ell Sz_k\| \leq \eta\gamma^\ell\|Sz_k\| \leq \eta\gamma^\ell\|z_k\|$  for some scalars  $\eta \geq 0$  and  $0 \leq \gamma < 1$ . Then we set

$$\ell_0 : \eta\gamma^{\ell_0} \leq 1/4,$$

and from (20) with  $\ell = \ell_0 - 1$  we obtain

$$\begin{aligned}
 \|z_{k+\ell_0}\| &\leq (2\eta\gamma^{\ell_0} + 2\pi\|A\|^{\ell_0}(\rho^{k+1} + \dots + \rho^{k+\ell_0}))\|z_k\| \\
 (21) \quad &\leq (1/2 + 2\pi\|A\|^{\ell_0}(\rho^{k+1} + \dots + \rho^{k+\ell_0}))\|z_k\|, \quad k \geq 0.
 \end{aligned}$$

Now we set  $k_0$  such that  $2\pi\|A\|^{\ell_0}(\rho^{k_0+1} + \dots + \rho^{k_0+\ell_0}) < 1/2$ . From (21) with  $k = k_0$ , we obtain  $\|z_{k_0+\ell_0}\| \leq \bar{\beta}\|z_{k_0}\|$ , where  $\bar{\beta} = (1/2 + 2\pi\|A\|^{\ell_0}(\rho^{k_0+1} + \dots + \rho^{k_0+\ell_0})) < 1$ ; similarly, from (21) with  $k = k_0 + m\ell_0$ ,  $m \geq 0$ , we obtain

$$\|z_{k_0+m\ell_0+\ell_0}\| \leq \bar{\beta}\|z_{k_0+m\ell_0}\| \leq \bar{\beta}^2\|z_{k_0+(m-1)\ell_0}\| \leq \dots \leq \bar{\beta}^{m+1}\|z_{k_0}\|.$$

Finally, we have that each  $k \geq k_0$  can be written in the form  $k = k_0 + m\ell_0 + r$  for some  $0 \leq r < \ell_0$  and  $m$  with  $(k - k_0)/\ell_0 \leq m \leq (k - k_0)/\ell_0 + 1$ , leading to

$$\begin{aligned}
 \|z_k\| &\leq \|A\|^r\|z_{k_0+m\ell_0}\| \\
 &\leq \|A\|^{\ell_0}\bar{\beta}^m\|z_{k_0}\| \leq \|A\|^{\ell_0}\|z_{k_0}\|\bar{\beta}^{-1}(\pi^{1/\ell_0})^k, \quad k \geq k_0,
 \end{aligned}$$

and since  $\|z_k\| \leq \|A\|^k\|z_0\|$ ,  $k < k_0$ , it is a simple matter to check that we can set  $\beta = \bar{\beta}^{1/t_0} < 1$  and find  $\chi \geq 0$  for which  $\|z_k\| \leq \chi\beta^k$ ,  $k \geq 0$ .  $\square$

Lemma 10 can be easily extended to the context of semistability of the system  $\Theta_Z$  by employing  $\xi < 1$  as a scaling factor that “converts”  $\mathcal{U}$  associated with the matrix  $\bar{A}$  into  $\mathcal{S}_\xi$  associated with  $\xi\bar{A}$ .

**COROLLARY 1.** *Consider the system  $\Theta_Z$ ,  $W_0$  as in Proposition 2 and  $\mathcal{U}$  as in (15). If  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U} = \{0\}$  and  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{U}^\perp = \mathcal{U}^\perp$ , then for each  $z$  and  $0 \leq \zeta < 1$  there exist  $\alpha \geq 0$  and  $0 \leq \beta < 1$  such that  $\|\zeta^k z_k\| \leq \alpha\beta^k$ .*

*Proof.* Let  $\Theta_Z$ ,  $\mathcal{S}$ , and  $\mathcal{U}$  correspond to the matrix  $A$  and, for  $0 \leq \xi < 1$ , let  $\Theta_{\xi Z}$ ,  $\mathcal{S}_\xi$ , and  $\mathcal{U}_\xi$  correspond to the matrix  $\xi A$ . Note that the eigenvalues of  $\bar{A}$  lying in the unit disk are shifted to eigenvalues of  $\xi \bar{A}$  inside the disk, yielding  $\mathcal{U} \supset \mathcal{S}_\xi$  for a general  $0 \leq \xi < 1$ . Let  $\xi$  be sufficiently close to one, in such a manner that  $\xi \geq \zeta$  and  $\mathcal{U} = \mathcal{S}_\xi$ . This leads to  $(\ker\{W_0 \Sigma W'_0\} \cap \mathcal{S}_\xi) = (\ker\{W_0 \Sigma W'_0\} \cap \mathcal{U}) = \{0\}$ ; furthermore,  $\mathcal{S}_\xi^\perp = \mathcal{U}^\perp$  yields  $(\ker\{W_0 \Sigma W'_0\} \cap \mathcal{S}_\xi^\perp) = (\ker\{W_0 \Sigma W'_0\} \cap \mathcal{U}^\perp) = \mathcal{U}^\perp = \mathcal{S}_\xi^\perp$ . Employing the result of Lemma 10 for system  $\Theta_{\xi Z}$  yields that there exist  $\chi \geq 0$  and  $0 \leq \beta < 1$  for which

$$(22) \quad \|\bar{z}_{\xi,k}\| \leq \chi \beta^k.$$

From Proposition 3 we get that  $\bar{z}_{\xi,k} = \xi^k \bar{z}_k$ , allowing us to obtain from (22)

$$(23) \quad \|\xi^k \bar{z}_k\| = \|\bar{z}_{\xi,k}\| \leq \chi \beta^k,$$

and Lemma 3 (ii) provides  $\|\xi^k z_k\| \leq (1 - \kappa)^{-1} \|\xi^k \bar{z}_k\| \leq (1 - \kappa)^{-1} \chi \beta^k$ . Recalling that  $\zeta \leq \xi$ , we have  $\|\zeta^k z_k\| \leq \|\xi^k z_k\| \leq (1 - \kappa)^{-1} \chi \beta^k$ .  $\square$

**4.2. Necessary conditions.** Conversely to Corollary 1, if  $\Sigma$  does not completely excite  $\mathcal{U}$ , then exponential divergence takes place. It is convenient, for later reference, to formalize the result as follows.

LEMMA 11. *Consider the system  $\Theta_Z$ ,  $W_0$  as in Proposition 2 and  $\mathcal{U}$  as in (15). If  $\ker\{W_0 \Sigma W'_0\} \cap \mathcal{U} \neq \{0\}$ , then there exist  $z \in \mathbb{R}^n$  and  $0 \leq \zeta < 1$  such that for all  $\chi \geq 0$  and  $0 \leq \psi < 1$ ,  $\|\zeta^k z_k\| > \chi \psi^k$  for some  $k \geq 0$ .*

*Proof.* We start setting  $\zeta < 1$  sufficiently close to one, in such a manner that  $\zeta(1 + \delta) > 1$ , where  $\delta$  is as in Lemma 9, and, simultaneously,  $\lambda_i(\zeta A) \notin \bar{\mathbb{D}}$  if and only if  $\lambda_i(A) \notin \bar{\mathbb{D}}$ ,  $0 \leq i \leq n$  (the unstable space of  $\zeta A$  equals the unstable space of  $A$ ). For ease of notation, in what follows we write  $\bar{z}$ ,  $\bar{A}$ , and  $\bar{H}$  as  $z$ ,  $A$ , and  $H$ , respectively; for  $\ell \geq 0$ ,  $w_{1,\ell}$ ,  $w_{2,\ell}$ ,  $w_{3,\ell}$  stand for vectors with  $\|w_{j,\ell}\| \leq 1$ . We shall need an evaluation that is analogous to (19) of Lemma 10. In fact, (19) involves projections onto  $\mathcal{S}^\perp$  and  $\mathcal{S}$  via  $S$  and  $I - S$ , respectively, and now we consider projections onto  $\mathcal{U} \ominus \mathcal{F}$ ,  $\mathcal{F}$ , and  $\mathcal{U}^\perp \ominus \mathcal{F}$  via  $U$ ,  $(I - T)$ , and  $(I - U)T$ , respectively. Using Lemma 9 (ii) and (iii) yields

$$\begin{aligned} z_{k+\ell+1} &= (TA)^{\ell+1} U z_k + A^{\ell+1} (I - U) T z_k \\ &\quad + (I - T) H_{k+\ell+1} (TA)^{\ell+1} U z_k \\ &\quad + (I - T) H_{k+\ell+1} A^{\ell+1} (I - U) T z_k \\ &\quad + 4 \|A\|^{\ell+1} \|z_k\| (o(k+1) + \dots + o(k+\ell+1)) w_{3,\ell}, \quad \ell \geq 0, \end{aligned}$$

and, since Lemma 9 (v) provides  $(TA)^{\ell+1} U = (UA)^{\ell+1} U$ , this can be written as

$$\begin{aligned} z_{k+\ell+1} &= (UA)^{\ell+1} U z_k + A^{\ell+1} (I - U) T z_k \\ &\quad + (I - T) H_{k+\ell+1} (UA)^{\ell+1} U z_k \\ &\quad + (I - T) H_{k+\ell+1} A^{\ell+1} (I - U) T z_k \\ &\quad + 4 \|A\|^{\ell+1} \|z_k\| (o(k+1) + \dots + o(k+\ell+1)) w_{3,\ell}, \quad \ell \geq 0. \end{aligned} \tag{24}$$

Similarly to (18), we have from Lemma 9 (ii)

$$\begin{aligned} TH_{k+\ell+1} (UA)^{\ell+1} U z_k &= T(UA)^{\ell+1} U z_k + o(k+\ell+1) \|(UA)^{\ell+1} U z_k\| w_{1,\ell} \\ &= (UA)^{\ell+1} U z_k + o(k+\ell+1) \|(UA)^{\ell+1} U z_k\| w_{1,\ell}, \end{aligned}$$

which can be substituted in the third term on the right-hand side of (24), leading to

$$\begin{aligned}
 z_{k+\ell+1} &= H_{k+\ell+1}(UA)^{\ell+1}Uz_k - o(k+\ell+1)\|(UA)^{\ell+1}Uz_k\|w_{1,\ell} \\
 &\quad + A^{\ell+1}(I-U)Tz_k + (I-T)H_{k+\ell+1}A^{\ell+1}(I-U)Tz_k \\
 &\quad + 4\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1))w_{3,\ell} \\
 (25) \quad &= H_{k+\ell+1}(UA)^{\ell+1}Uz_k \\
 &\quad + A^{\ell+1}(I-U)Tz_k + (I-T)H_{k+\ell+1}A^{\ell+1}(I-U)Tz_k \\
 &\quad + 5\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1))w_{4,\ell}, \quad \ell \geq 0.
 \end{aligned}$$

Regarding the second and third terms on the right-hand side of (25), recall that  $(I-U)Tz_z \in (\mathcal{U}^\perp \ominus \mathcal{F}) \subset \mathcal{U}^\perp$ , yielding that  $A^k(I-U)Tz_z$  may present polynomial divergence, as  $k \rightarrow \infty$ ; hence we can write for each  $\gamma > 1$ , and in particular for  $\gamma$  such that  $\gamma\zeta < 1$ ,

$$\begin{aligned}
 &\|A^{\ell+1}(I-U)Tz_k + (I-T)H_{k+\ell+1}A^{\ell+1}(I-U)Tz_k\| \\
 (26) \quad &\leq \|A^{\ell+1}(I-U)Tz_k\| + \|(I-T)\| \|H_{k+\ell+1}\| \|A^{\ell+1}(I-U)Tz_k\| \\
 &= 2\|A^{\ell+1}(I-U)Tz_k\| \leq 2\eta\gamma^{\ell+1}\|z_k\|
 \end{aligned}$$

for some  $\eta \geq 0$ . Note that (25), (26), and Lemma 9 (v) lead to

$$\begin{aligned}
 \|z_{k+\ell+1}\| &\leq \|H_{k+\ell+1}(UA)^{\ell+1}Uz_k\| + 2\eta\gamma^{\ell+1}\|z_k\| \\
 &\quad + 5\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1)) \\
 (27) \quad &\leq \lambda\|(UA)^{\ell+1}Uz_k\| + 2\eta\gamma^{\ell+1}\|z_k\| \\
 &\quad + 5\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1)).
 \end{aligned}$$

On the other hand, premultiplying both sides of (24) by  $U$  and employing the fact that, for  $v \in \mathbb{R}^n$ ,  $(I-T)v \in \mathcal{F}$ , yielding  $(I-T)v \perp (\mathcal{F}^\perp \cap \mathcal{U})$  and hence  $U(I-T) = 0$ , evaluations similar to the above ones provide

$$\begin{aligned}
 \|Uz_{k+\ell+1}\| &= \|(UA)^{\ell+1}Uz_k + UA^{\ell+1}(I-U)Tz_k \\
 &\quad + 4\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1))Uw_{3,\ell}\| \\
 (28) \quad &\geq \|(UA)^{\ell+1}Uz_k\| - \eta\gamma^{\ell+1}\|z_k\| \\
 &\quad - 4\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1)).
 \end{aligned}$$

By substituting (28) in (27) we get that

$$\begin{aligned}
 \|z_{k+\ell+1}\| &\leq \lambda(\|Uz_{k+\ell+1}\| + \eta\gamma^{\ell+1}\|z_k\| \\
 &\quad + 4\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1))) \\
 &\quad + 2\eta\gamma^{\ell+1}\|z_k\| + 5\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1)) \\
 &= \lambda\|Uz_{k+\ell+1}\| + (2+\lambda)\eta\gamma^{\ell+1}\|z_k\| \\
 &\quad + (5+4\lambda)\|A\|^{\ell+1}\|z_k\|(o(k+1) + \cdots + o(k+\ell+1)), \quad \ell \geq 0,
 \end{aligned}$$

or equivalently, for  $\ell \geq 0$ ,

$$(29) \quad \begin{aligned} \|Uz_{k+\ell+1}\| &\geq \lambda^{-1}\|z_{k+\ell+1}\| - \lambda^{-1}(2+\lambda)\eta\gamma^{\ell+1}\|z_k\| \\ &\quad - \lambda^{-1}(5+4\lambda)\|A\|^{\ell+1}\|z_k\|(o(k+1) + \dots + o(k+\ell+1)). \end{aligned}$$

Now we employ the fact that  $\mathcal{U} \ominus \mathcal{F}^\perp$  is associated with unstable eigenvalues of  $A$ . We proceed similarly to the above, employing (24) with  $k$  replaced by  $k+\ell+1$  and  $\ell$  replaced by  $m-1$ , and Lemma 9 (ii)–(v), to evaluate

$$\begin{aligned} \|z_{k+\ell+m+1}\| &\geq \|(UA)^m Uz_{k+\ell+1} + (I-T)H_{k+\ell+m+1}(UA)^m Uz_{k+\ell+1} \\ &\quad + (I-T)H_{k+\ell+m+1}A^m(I-U)Tz_{k+\ell+1}\| - \|A^m(I-U)Tz_{k+\ell+1}\| \\ &\quad - 4\|A\|^m\|z_k\|(o(k+\ell+2) + \dots + o(k+\ell+m+1)). \end{aligned}$$

Recalling that  $(I-T)$  and  $U$  are orthogonal projections and employing Lemma 9 (iii) and an evaluation similar to (26) (with the same  $\gamma$  as in (26), such that  $\gamma\zeta < 1$ ), the above inequality leads to

$$\begin{aligned} \|z_{k+\ell+m+1}\| &\geq \|(UA)^m Uz_{k+\ell+1}\| - \|A^m(I-U)Tz_{k+\ell+1}\| \\ &\quad - 4\alpha\|A\|^m\|z_{k+\ell+1}\|(\beta^{k+\ell+2} + \dots + \beta^{k+\ell+m+1}) \\ &\geq (1+\delta)^m\|Uz_{k+\ell+1}\| - \eta\gamma^m\|z_{k+\ell+1}\| \\ &\quad - 4\|A\|^m\|z_{k+\ell+1}\|(o(k+\ell+2) + \dots + o(k+\ell+m+1)) \end{aligned}$$

and, from (29),

$$\begin{aligned} \|z_{k+\ell+m+1}\| &\geq (1+\delta)^m\lambda^{-1}\left(\|z_{k+\ell+1}\| - (2+\lambda)\eta\gamma^{\ell+1}\|z_k\| \right. \\ &\quad \left. - (5+4\lambda)\|A\|^{\ell+1}(o(k+1) + \dots + o(k+\ell+1))\|z_k\| \right) \\ &\quad - \eta\gamma^m\|z_{k+\ell+1}\| \\ &\quad - 4\|A\|^m(o(k+\ell+2) + \dots + o(k+\ell+m+1))\|z_{k+\ell+1}\|. \end{aligned}$$

Multiplying both sides of the above equation by  $\zeta^{k+\ell+m+1}$  and setting  $\xi = \gamma\zeta$  and  $z_{\zeta,k} = \zeta^k z_k$ ,  $\ell \geq 0$ , lead to

$$(30) \quad \begin{aligned} \|z_{\zeta,k+\ell+m+1}\| &\geq \zeta^m(1+\delta)^m\lambda^{-1}\left(\|z_{\zeta,k+\ell+1}\| - (2+\lambda)\eta\xi^{\ell+1}\|z_{\zeta,k}\| \right. \\ &\quad \left. - (5+4\lambda)\zeta^{\ell+1}\|A\|^{\ell+1}(o(k+1) + \dots + o(k+\ell+1))\|z_{\zeta,k}\| \right) \\ &\quad - \eta\xi^m\|z_{\zeta,k+\ell+1}\| \\ &\quad - 4\zeta^m\|A\|^m(o(k+\ell+2) + \dots + o(k+\ell+m+1))\|z_{\zeta,k+\ell+1}\|. \end{aligned}$$

Recall that  $\zeta(1+\delta) > 1$ ,  $\xi = \gamma\zeta < 1$ , and  $o(\cdot)$  is a decreasing function, allowing for the following settings. For an arbitrary  $\bar{m} > 0$ , let  $m$  be such that

$$(31) \quad \zeta^m(1+\delta)^m\lambda^{-1} - \eta\xi^m > 6\bar{m}.$$

Set  $\ell = \max(\ell_1, \ell_2)$ , where  $\ell_1$  is such that

$$(32) \quad \zeta^m(1+\delta)^m\lambda^{-1}(2+\lambda)\eta\xi^{\ell_1+1} < (1/2)\bar{m}$$

and  $\ell_2$  is such that  $4\zeta^m\|A\|^m(o(\ell_2+2)+\cdots+o(\ell_2+m+1))<3\bar{m}$ , yielding

$$(33) \quad 4\zeta^m\|A\|^m(o(k+\ell+2)+\cdots+o(k+\ell+m+1))<3\bar{m}, \quad k \geq 0.$$

Finally, let  $k$  be such that

$$(34) \quad \zeta^m(1+\delta)^m\lambda^{-1}(5+4\lambda)\zeta^{\ell+1}\|A\|^{\ell+1}(o(k+1)+\cdots+o(k+\ell+1))<(1/2)\bar{m}.$$

Substituting (31)–(34) in (30) provides

$$\begin{aligned} \|z_{\zeta,k+\ell+m+1}\| &\geq 6\bar{m}\|z_{\zeta,k+\ell+1}\| - (1/2)\bar{m}\|z_{\zeta,k}\| - (1/2)\bar{m}\|z_{\zeta,k}\| - 3\bar{m}\|z_{\zeta,k+\ell+1}\| \\ &= \bar{m}\|z_{\zeta,k+\ell+1}\| + 2\bar{m}\|z_{\zeta,k+\ell+1}\| - \bar{m}\|z_{\zeta,k}\|. \end{aligned}$$

Using this inequality in a recursive fashion, substituting  $k$  with  $k+qm$ ,  $q \geq 0$ , we obtain

$$(35) \quad \|z_{\zeta,k+\ell+1+(q+1)m}\| \geq \bar{m}^q\|z_{\zeta,k+\ell+1+m}\| + \sum_{j=0}^q (2\bar{m})^j\|z_{\zeta,k+\ell+1+jm}\| - \sum_{j=0}^q \bar{m}^j\|z_{\zeta,k+jm}\|.$$

The second term on the right-hand side of (35) dominates the third one, leading to exponential divergence; in particular, we can write for  $q \geq q_0$  for some  $q_0$  that  $\|z_{\zeta,k+\ell+1+(q+1)m}\| \geq \|z_{\zeta,k+\ell+1+m}\|$ , leading to

$$\zeta^{k+\ell+1+(q+1)m}\|z_{k+\ell+1+(q+1)m}\| \geq \zeta^{k+\ell+1+m}\|z_{k+\ell+1+m}\|$$

or, equivalently,  $\|z_{k+\ell+1+(q+1)m}\| \geq \zeta^{-q}\|z_{k+\ell+1+m}\|$ ,  $q \geq q_0$ . It is important to mention that we can pick an initial condition  $z$  for which  $z_{k+\ell+1+m} \neq 0$ ; see Proposition 4.  $\square$

Similarly to the proof of Corollary 1, we employ a “scaling factor”  $\xi < 1$  that converts  $\mathcal{S}$  associated with  $\bar{A}$  into  $\mathcal{U}_{\xi^{-1}}$  associated with  $\xi^{-1}\bar{A}$ , and extend the result of Lemma 11 to the context of PS. It is worth mentioning that Lemma 11 applied to matrix  $\xi^{-1}\bar{A}$  provides  $\|\zeta^k\xi^{-k}\bar{z}_k\| > \chi\psi^k$  (in analogy with (23)), or, equivalently,  $\|\bar{z}_k\| > \chi(\psi\xi^{-1})^k$ , and we can set both  $\zeta$  and  $\xi$  arbitrarily close to one, to obtain the next result, the proof of which is not presented.

**COROLLARY 2.** *Consider the system  $\Theta_Z$ ,  $W_0$  as in Proposition 2 and  $\mathcal{S}$  as in (15). If  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{S} \neq \{0\}$ , then there exist  $z \in \mathbb{R}^n$  such that for all  $\chi \geq 0$  and  $0 \leq \psi < 1$ ,  $\|z_k\| > \chi\psi^k$  for some  $k \geq 0$ .*

### 4.3. Main result.

**THEOREM 1.** *Consider the system  $\Theta$ . Let  $J$  represent the similarity transformation for which  $JAJ^{-1}$  is in Jordan form and let  $\mathcal{J}$  and  $\mathcal{J}_{\mathcal{S}}$  stand for the unstable space and the stable space of  $JAJ^{-1}$ , respectively.  $(A, \Sigma)$  is PSS if and only if*

$$(36) \quad \ker\{J\Sigma J'\} \cap \mathcal{J} = \{0\}.$$

*$(A, \Sigma)$  is PS if and only if*

$$(37) \quad \ker\{J\Sigma J'\} \cap \mathcal{J}_{\mathcal{S}}^{\perp} = \{0\}.$$

*Proof.* Regarding the first statement, consider  $W_0$  as in Proposition 2 and  $\mathcal{U}$  as in (15). Condition (36) holds if and only if

$$(38) \quad \ker\{W_0\Sigma W_0'\} \cap \mathcal{U} = \{0\};$$

see Lemma 5. Assume that  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$ . It follows from Corollary 1 and Lemma 11 that (38) is a necessary and sufficient condition for the existence, for each  $z \in \mathbb{R}^n$  and  $0 \leq \zeta < 1$ , of  $\alpha \geq 0$  and  $0 \leq \beta < 1$  such that  $\|\zeta^k z_k\| \leq \alpha\beta^k$ . Lemma 2 extends the result to PSS of  $(A, \Sigma)$ . Now we consider the case when  $\ker\{W_0\Sigma W_0'\} \cap \mathcal{S}^\perp \neq \mathcal{S}^\perp$ , that is,  $\Sigma$  also excites  $\mathcal{S}^\perp$ . In this situation, we can write  $\Sigma = \Sigma_1 + \Sigma_2$  with  $\Sigma_1, \Sigma_2 \in \mathcal{R}^{n0}$  and  $\ker\{W_0\Sigma_1 W_0'\} \cap \mathcal{S}^\perp = \mathcal{S}^\perp$ , to conclude that  $(A, \Sigma_1)$  is PSS, that is, for each  $0 \leq \zeta < 1$  and  $V \in \mathcal{R}^{n0}$ , there exists  $\bar{Z} \in \mathcal{R}^{n0}$  for which

$$(39) \quad Z_k(V, \Sigma_1) \leq \zeta^{-k} \bar{Z}.$$

Finally, since  $\Sigma - \Sigma_1 = \Sigma_2 \geq 0$ , Proposition 1 (iv) yields  $Z_k(V, \Sigma) \leq Z_k(V, \Sigma_1)$  and (39) provides  $Z_k(V, \Sigma) \leq \zeta^{-k} \bar{Z}$ , i.e.,  $(A, \Sigma)$  is PSS. The proof for the second statement follows from Corollary 2 and Lemma 10 in a similar manner as above.  $\square$

*Remark 2.* Either  $\Sigma > 0$  or semistable  $A$  imply  $(A, \Sigma)$  is PSS, which implies that  $(A, \Sigma)$  is semistabilizable. Indeed,  $\Sigma > 0$  provides  $\ker\{J\Sigma J'\} = \{0\}$  and semistable  $A$  yields  $\mathcal{J} = \{0\}$ , and in both cases (36) holds. Regarding the second implication,  $(A, \Sigma)$  not semistabilizable means that  $\Sigma$  does not excite an “entire” unstable mode of  $A$ , and (36) does not hold. PSS is not comparable to stabilizability of  $(A, \Sigma)$ ; indeed, Example 6 illustrates the situation when  $(A, \Sigma)$  is stabilizable but  $\Theta$  is not PSS, whereas system  $\Theta$  with  $A = 1$  and  $\Sigma = 0$  illustrates the opposite situation. Similarly, stable  $A$  imply that  $(A, \Sigma)$  is PS, which implies that  $(A, \Sigma)$  is stabilizable.

*Example 5.* Consider the system  $\Theta$  of Example 3 with  $|d| > 1$ . One has that  $J = I$ ,  $\ker\{J\Sigma J'\} = [e_1]$ , and  $\mathcal{J} = \mathcal{J}_S^\perp = \mathbb{R}^n$ . Neither (36) nor (37) holds, and from Theorem 1 we have that  $(A, \Sigma)$  is not PS or PSS. For  $|d| < 1$ ,  $\mathcal{J} = \mathcal{J}_S^\perp = \{0\}$ , and the system is PS and PSS. For  $|d| = 1$ ,  $\mathcal{J} = \{0\}$  and  $\mathcal{J}_S^\perp = \mathbb{R}^n$ , and hence only (36) holds and the system is “strictly” PSS; the same holds if  $\sigma = e_2$  is replaced with  $\sigma_2 = 0$ , as in Example 1.

*Example 6.* Consider the system  $\Theta$  of Example 4. It is simple to check that (36) is not satisfied and, according to Theorem 1,  $(A, \Sigma)$  is not PSS. See Figure 3 (i) for the behavior of the  $Z$ -component of the state trajectory. Note that  $(A, \Sigma)$  is stabilizable but the system is not PSS. Now, replace  $A$  with  $1.02^{-1/2}A$ , which leads to  $\lambda_i(A) \in \mathbb{D}$  and  $\mathcal{J} = \{0\}$ . In this situation, only (36) holds. Note via Figure 3 (ii) that the  $Z$ -component presents an oscillatory behavior, which is compatible with PSS.

FIG. 3. Behavior of the  $Z$ -component for the setups of Example 6.

*Remark 3.* The conditions of Theorem 1 can be employed in the problem of “stabilization” of the system  $\Theta$  via a suitable choice of  $\Sigma$ . For instance,  $\Sigma = \sigma_1\sigma_1' + \dots + \sigma_r\sigma_r'$  with  $r = \dim(\mathcal{J})$  is such that  $(A, \Sigma)$  is PSS if and only if  $\sigma_j$ ,  $0 \leq j \leq r$ ,

are linearly independent vectors with nontrivial projections onto  $\mathcal{J}$ , and a similar condition holds for PS. As illustration, for the system  $\Theta$  of Example 5, if we set  $\sigma_1 = e_1$  and  $\sigma_2 = e_2$ , we obtain both PS and PSS; the same is valid for the system of Example 6 (of course, now  $e_1, e_2 \in \mathbb{R}^3$  and  $\Sigma$  is rank deficient).

**5. Concluding remarks.** In this paper we have explored the structure of the system  $\Theta$  in (1), with special attention to the relations among the initial condition  $\Sigma$  of the  $X$ -component, its dynamics (governed by  $A$ ), and the coupling with the  $Z$ -component via the orthogonal projection  $H$ . We obtain the structural, testable condition (36) for PSS, with the interpretation that  $\Sigma$  has to completely excite the unstable modes of  $A$ . Similarly, the condition (37) for PS requires that  $\Sigma$  excite all modes of  $A$  except the stable ones. These interpretations are particularly meaningful in the scenario of Kalman filtering for linear time-invariant systems, meaning that the noise in the initial condition excites the unstable or the “semiunstable” dynamics of the plant; indeed, the derived conditions are essential to obtain, as discussed in [4], necessary and sufficient conditions for avoiding *actual* exponential divergence of estimates and bounded error estimates, under incorrect noise measurements, which is a significant result, taking into account the conservativeness of existing conditions. The results can also be employed in the problem of stabilization of the filter via a suitable choice of noise model; see Remark 3.

## THE CONTROL VARIATIONAL APPROACH FOR DIFFERENTIAL SYSTEMS\*

JÜRGEN SPREKELS<sup>†</sup> AND DAN TIBA<sup>‡</sup>

**Abstract.** In this work a new approach to generalized Naghdi shell and curved rod models is discussed. The method is based on optimal control theory and has a wide range of applications. Some abstract variants are also indicated.

**Key words.** curved rods, shells, variational methods, generalized Naghdi model, optimal control

**AMS subject classifications.** 49N90, 74K10, 74K25, 49S05

**DOI.** 10.1137/070710561

**1. Introduction.** The control variational method is a new variational approach for the solution of differential equations. It is based on the minimization of the usual energy via optimal control arguments. The method was introduced in a sequence of papers by Arnăutu et al. [1] and Sprekels and Tiba [8], [10] and has many variants. Due to its relationship to the energy functional, we consider that this approach is a generalization of the classical variational argument. We mention that already Glowinski and Pironneau [4], [3] noticed that for the biharmonic equation optimal control theory may be advantageously applied in the numerical approximation. The recent monograph of Neittaanmäki, Sprekels, and Tiba [7] includes a detailed discussion of the control variational approach in the case of Kirchhoff–Love arches and for simplified plate models. The method is very flexible and allows one to obtain new results, on a theoretical as well as a numerical level. We briefly recall here the example of the linear elasticity system, following Sprekels and Tiba [12]. If  $\Omega \subset \mathbb{R}^3$  is a bounded domain representing the elastic body, fixed on  $\Gamma \subset \partial\Omega$ , and if

$$V(\Omega) = \{\bar{v} \in H^1(\Omega)^3; \bar{v}|_{\Gamma} = 0\},$$

then the weak formulation of the isotropic linear elasticity system is

$$(1.1) \quad \int_{\Omega} [\lambda e_{pp}(\bar{u}) e_{qq}(\bar{v}) + 2\mu e_{ij}(\bar{u}) e_{ij}(\bar{v})] dx = \int_{\Omega} f_i v_i dx \quad \forall \bar{v} \in V(\Omega).$$

Here,  $\bar{u} = (u_1, u_2, u_3) \in V(\Omega)$  is the displacement vector,  $\bar{f} = (f_1, f_2, f_3) \in L^2(\Omega)^3$  is the load vector,  $\lambda \geq 0$ ,  $\mu > 0$  are the Lamé coefficients of the elastic material,  $e_{ij}(\cdot)$ ,  $i, j = \overline{1, 3}$ , denote the symmetrized gradients, and the summation convention is used.

The optimal control problem

$$(P) \quad \text{Min} \left\{ \int_{\Omega} \left\{ \mu |w|_{\mathbb{R}^9}^2 + \lambda |\operatorname{div} u|^2 + \mu \left[ \left( \frac{\partial u_1}{\partial x_1} \right)^2 + \left( \frac{\partial u_2}{\partial x_2} \right)^2 + \left( \frac{\partial u_3}{\partial x_3} \right)^2 \right] \right. \right. \\ \left. \left. + 2\mu \left( \frac{\partial u_1}{\partial x_2} \frac{\partial u_2}{\partial x_1} + \frac{\partial u_1}{\partial x_3} \frac{\partial u_3}{\partial x_1} + \frac{\partial u_2}{\partial x_3} \frac{\partial u_3}{\partial x_2} \right) \right\} dx \right\}$$

for all  $w \in L^2(\Omega)^9$  is associated to (1.1), subject to the state equation

$$(1.2) \quad \int_{\Omega} \nabla \bar{u} : \nabla \bar{v} dx = \int_{\Omega} w : \nabla \bar{v} dx + \frac{1}{\mu} \int_{\Omega} \bar{f} \cdot \bar{v} dx \quad \forall \bar{v} \in V(\Omega).$$

Here,  $\nabla \bar{u}$ ,  $\nabla \bar{v}$  denote the Jacobian matrices, and

$$\nabla \bar{u} : \nabla \bar{v} = \sum_{i,j=1}^3 \frac{\partial u_i}{\partial x_j} \frac{\partial v_i}{\partial x_j}, \quad f \cdot v = \sum_{i=1}^3 f_i v_i.$$

Problem (P) is an unconstrained optimal control problem whose state system (1.2) consists of three uncoupled Poisson equations for  $\{u_i\}_{i=1,3}$ . Therefore, problem (P) is particularly easy to solve and, according to Sprekels and Tiba [12], its optimal state  $u^*$  is the unique solution to (1.1).

In this paper, we demonstrate similar properties in the application of the control variational method to shell and curved rod models of generalized Naghdi type (see sections 2 and 3, respectively). The last section discusses some abstract variants of the method. Further examples and applications may be found in the preprints of Sprekels and Tiba [13] and Tiba [14], on which this paper is based.

**2. Naghdi shell models.** We first introduce the generalized Naghdi model for thin elastic shells, following Sprekels and Tiba [11]. Let  $\omega \in \mathbb{R}^2$  be a bounded Lipschitzian domain,  $\varepsilon > 0$  “small,” and  $\Omega = \omega \times ]-\varepsilon, \varepsilon[$ . We assume that  $\partial\omega = \bar{\gamma}_0 \cup \bar{\gamma}_1$ ,  $\gamma_0 \cap \gamma_1 = \emptyset$ , and we denote

$$\Gamma_0 = \gamma_0 \times ]-\varepsilon, \varepsilon[, \quad \Gamma_1 = \partial\Omega \setminus \Gamma_0, \quad V(\omega) = \{\bar{v} = (v_1, v_2, v_3) \in H^1(\omega)^3; \bar{v}|_{\gamma_0} = 0\}.$$

Let  $p : \omega \rightarrow \mathbb{R}$  be piecewise in  $C^2(\bar{\omega})$ , and let  $\bar{n} : \omega \rightarrow \mathbb{R}^3$ ,  $\bar{n} = (n_1, n_2, n_3)$ , be the unit normal vector to the graph of  $p$  in  $\mathbb{R}^3$ . We denote by  $\bar{\pi} = (\pi_1, \pi_2, \pi_3) = (x_1, x_2, p(x_1, x_2))$  this graph, which represents the midsurface of the shell. That is,  $\bar{n}$  is given by

$$(2.1) \quad \bar{n} = \frac{\frac{\partial \bar{\pi}}{\partial x_1} \wedge \frac{\partial \bar{\pi}}{\partial x_2}}{\left| \frac{\partial \bar{\pi}}{\partial x_1} \wedge \frac{\partial \bar{\pi}}{\partial x_2} \right|_{\mathbb{R}^3}} = \left( -\frac{p_1}{\sqrt{1 + p_1^2 + p_2^2}}, -\frac{p_2}{\sqrt{1 + p_1^2 + p_2^2}}, \frac{1}{\sqrt{1 + p_1^2 + p_2^2}} \right),$$

where  $p_1 = \frac{\partial p}{\partial x_1}$ ,  $p_2 = \frac{\partial p}{\partial x_2}$ .

We define the transformation  $F : \Omega \rightarrow F(\Omega) = \hat{\Omega} \subset \mathbb{R}^3$  by

$$(2.2) \quad F(\bar{x}) = F(x_1, x_2, x_3) = \bar{\pi}(x_1, x_2) + x_3 \bar{n}(x_1, x_2).$$

If  $\varepsilon > 0$  is small enough, it is one-to-one (see Ciarlet [2, Thm. 3.1-1]). Denote by  $J = \nabla F$  the Jacobian of  $F$ , and let  $(h_{ij}(\bar{x}))_{i,j=1,3} = J(\bar{x})^{-1}$ . Starting from the linear elasticity system (1.1), and using the assumption that the displacement has the form

$$(2.3) \quad \hat{y}(\hat{x}) = \bar{u}(x_1, x_2) + x_3 \bar{r}(x_1, x_2) \quad \forall \hat{x} \in \hat{\Omega}, \quad \bar{x} = F^{-1}(\hat{x}) \in \Omega,$$

one can deduce the generalized Naghdi model

$$\begin{aligned}
 (2.4) \quad & B([\bar{u}, \bar{r}], [\bar{\mu}, \bar{\rho}]) \\
 &= \lambda \int_{\Omega} \left\{ \sum_{i=1}^3 \left[ \left( \frac{\partial u_i}{\partial x_1} + x_3 \frac{\partial r_i}{\partial x_1} \right) h_{1i} + \left( \frac{\partial u_i}{\partial x_2} + x_3 \frac{\partial r_i}{\partial x_2} \right) h_{2i} + r_i h_{3i} \right] \right\} \\
 &\quad \cdot \left\{ \sum_{j=1}^3 \left[ \left( \frac{\partial \mu_j}{\partial x_1} + x_3 \frac{\partial \rho_j}{\partial x_1} \right) h_{1j} + \left( \frac{\partial \mu_j}{\partial x_2} + x_3 \frac{\partial \rho_j}{\partial x_2} \right) h_{2j} + \rho_j h_{3j} \right] \right\} \\
 &\quad \cdot |\det J(\bar{x})| d\bar{x} \\
 &\quad + 2\mu \int_{\Omega} \sum_{i=1}^3 \left[ \left( \frac{\partial u_i}{\partial x_1} + x_3 \frac{\partial r_i}{\partial x_1} \right) h_{1i} + \left( \frac{\partial u_i}{\partial x_2} + x_3 \frac{\partial r_i}{\partial x_2} \right) h_{2i} + r_i h_{3i} \right] \\
 &\quad \cdot \left[ \left( \frac{\partial \mu_i}{\partial x_1} + x_3 \frac{\partial \rho_i}{\partial x_1} \right) h_{1i} + \left( \frac{\partial \mu_i}{\partial x_2} + x_3 \frac{\partial \rho_i}{\partial x_2} \right) h_{2i} + \rho_i h_{3i} \right] |\det J(\bar{x})| d\bar{x} \\
 &\quad + \mu \int_{\Omega} \sum_{i < j} \left\{ \left[ \left( \frac{\partial u_i}{\partial x_1} + x_3 \frac{\partial r_i}{\partial x_1} \right) h_{1j} + \left( \frac{\partial u_i}{\partial x_2} + x_3 \frac{\partial r_i}{\partial x_2} \right) h_{2j} + r_i h_{3j} \right. \right. \\
 &\quad \left. \left. + \left( \frac{\partial u_j}{\partial x_i} + x_3 \frac{\partial r_j}{\partial x_1} \right) h_{1i} + \left( \frac{\partial u_j}{\partial x_2} + x_3 \frac{\partial r_j}{\partial x_2} \right) h_{2i} + r_j h_{3i} \right] \right. \\
 &\quad \cdot \left[ \left( \frac{\partial \mu_i}{\partial x_1} + x_3 \frac{\partial \rho_i}{\partial x_1} \right) h_{1j} + \left( \frac{\partial \mu_i}{\partial x_2} + x_3 \frac{\partial \rho_i}{\partial x_2} \right) h_{2j} + \rho_i h_{3j} \right. \\
 &\quad \left. \left. + \left( \frac{\partial \mu_j}{\partial x_1} + x_3 \frac{\partial \rho_j}{\partial x_1} \right) h_{1i} + \left( \frac{\partial \mu_j}{\partial x_2} + x_3 \frac{\partial \rho_j}{\partial x_2} \right) h_{2i} + \rho_j h_{3i} \right] \right\} \\
 &\quad \cdot |\det J(\bar{x})| d\bar{x} \\
 &= \sum_{i=1}^3 \left\{ \int_{\Omega} f_i(\mu_i + x_3 \rho_i) d\bar{x} + \int_{\Gamma_1} h_i(\mu_i + x_3 \rho_i) d\sigma \right\}, \\
 &\quad \forall \bar{\mu} = (\mu_1, \mu_2, \mu_3), \quad \forall \bar{\rho} = (\rho_1, \rho_2, \rho_3) \in V(\omega).
 \end{aligned}$$

Above,  $\bar{f} = (f_1, f_2, f_3)$  represents the body forces and  $\bar{h} = (h_1, h_2, h_3)$  the surface tractions. The shell is partially clamped along  $\Gamma_0$ . The existence of a unique solution  $\bar{u}, \bar{r} \in V(\omega)$  follows from the Lax–Milgram lemma and Korn’s inequality; see Sprekels and Tiba [11].

As in the case of (1.1), (1.2), we show that it is possible to solve directly the generalized Naghdi shell model (2.4) via a control problem governed by a finite number of independent Poisson equations. Usual gradient methods may be applied for its solution. Our choice is motivated by its simplicity; other choices are also possible, as the following sections will make clear.

We associate with (2.4) the following unconstrained control problem:

$$(2.5) \quad \min_{w \in L^2(\omega)^{12}} \left\{ L(w) = \frac{1}{2} B([\bar{u}, \bar{r}], [\bar{u}, \bar{r}]) + \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|w_1^i|_{\mathbb{R}^2}^2 + |w_2^i|_{\mathbb{R}^2}^2] dx_1 dx_2 \right. \\ \left. - \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|\nabla u_i|_{\mathbb{R}^2}^2 + |\nabla r_i|_{\mathbb{R}^2}^2] dx_1 dx_2 \right\},$$

subject to

$$(2.6) \quad \sum_{i=1}^3 \int_{\omega} [\nabla u_i \cdot \nabla \phi_i + \nabla r_i \cdot \nabla \psi_i] dx_1 dx_2 \\ = \sum_{i=1}^3 \int_{\omega} [w_1^i \cdot \nabla \phi_i + w_2^i \cdot \nabla \psi_i] dx_1 dx_2 \\ + \sum_{i=1}^3 \left\{ \int_{\Omega} f_i(\phi_i + x_3 \psi_i) d\bar{x} + \int_{\Gamma_1} h_i(\phi_i + x_3 \psi_i) d\tau \right\} \quad \forall \phi, \psi \in V(\omega).$$

**THEOREM 2.1.** *The gradient of the cost (2.5) in the point  $w = [w_1, w_2] \in L^2(\omega)^{12}$  has the form*

$$(2.7) \quad \langle \nabla L(w_1, w_2), [v_1, v_2] \rangle = \sum_{i=1}^3 \int_{\omega} [\langle w_1^i + \nabla p_i, \nabla \mu_i \rangle_{\mathbb{R}^2} + \langle w_2^i + \nabla q_i, \nabla \rho_i \rangle_{\mathbb{R}^2}] dx_1 dx_2$$

for  $v_1^i = \nabla \mu_i$ ,  $v_2^i = \nabla \rho_i$ ,  $i = \overline{1, 3}$ , and any  $[\bar{\mu}, \bar{\rho}] \in V(\omega)^2$ .

Here,  $\langle \cdot, \cdot \rangle$  is the scalar product in  $L^2(\omega)^{12}$ , and  $[p, q] \in V(\omega)^2$  satisfy the adjoint equation

$$(2.8) \quad \sum_{i=1}^3 \int_{\omega} [\langle \nabla p_i, \nabla \phi_i \rangle_{\mathbb{R}^2} + \langle \nabla q_i, \nabla \psi_i \rangle_{\mathbb{R}^2}] dx_1 dx_2 \\ = \mathcal{B}([\bar{u}, \bar{r}], [\phi, \psi]) - \sum_{i=1}^3 \int_{\omega} [\langle \nabla u_i, \nabla \phi_i \rangle_{\mathbb{R}^2} + \langle \nabla r_i, \nabla \psi_i \rangle_{\mathbb{R}^2}] dx_1 dx_2 \quad \forall \phi, \psi \in V(\omega).$$

If  $[u^*, r^*] \in V(\omega)^2$  denotes the optimal state corresponding to the optimal control  $[w_1^*, w_2^*] \in L^2(\omega)^{12}$  for the problem (2.6), (2.5), then  $[u^*, r^*]$  is the unique solution to (2.4).

*Proof.* We take variations around the optimal pair, given by any  $[\bar{\mu}, \bar{\rho}] \in V(\omega)^2$  and  $v_1^i = \nabla \mu_i$ ,  $v_2^i = \nabla \rho_i$ ,  $i = \overline{1, 3}$ , for the state, respectively, the control. Clearly,  $[u^*, r^*] + \lambda[\bar{\mu}, \bar{\rho}]$  and  $w^* + \lambda[v_1, v_2]$ ,  $\lambda \in \mathbb{R}$ , satisfy (2.6) and give an admissible pair for the control problem (2.5). Then the optimality of  $w^*$  yields that

$$(2.9) \quad 0 = \lim_{\lambda \rightarrow 0} \frac{L(w^* + \lambda[v_1, v_2]) - L(w^*)}{\lambda} \\ = \mathcal{B}([u^*, r^*], [\bar{\mu}, \bar{\rho}]) + \sum_{i=1}^3 \int_{\omega} [\langle (w_1^*)^i, v_1^i \rangle_{\mathbb{R}^2} + \langle (w_2^*)^i, v_2^i \rangle_{\mathbb{R}^2}] \\ - \sum_{i=1}^3 \int_{\omega} [\langle \nabla u_i^*, \nabla \mu_i \rangle_{\mathbb{R}^2} + \langle \nabla r_i^*, \nabla \rho_i \rangle_{\mathbb{R}^2}] \\ = \mathcal{B}([u^*, r^*], [\bar{\mu}, \bar{\rho}]) - \sum_{i=1}^3 \left\{ \int_{\omega} f_i(\mu_i + x_3 \rho_i) d\bar{x} + \int_{\Gamma_1} h_i(\mu_i + x_3 \rho_i) d\sigma \right\},$$

by the state equation (2.5) with  $\bar{\mu}, \bar{\rho}$  as test functions, and by fixing  $v_1^i = \nabla \mu_i$ ,  $v_2^i = \nabla \rho_i$ ,  $i = \overline{1, 3}$ . The first and last terms in (2.9) prove the last statement of the theorem.

The first equality in (2.9) and the adjoint system (2.8) give

$$\begin{aligned} \langle \nabla L(w), [v_1, v_2] \rangle &= \sum_{i=1}^3 \int_{\omega} [\langle w_1^i, v_1^i \rangle_{\mathbb{R}^2} + \langle w_2^i, v_2^i \rangle_{\mathbb{R}^2}] \, dx_1 \, dx_2 \\ &\quad + \sum_{i=1}^3 \int_{\omega} [\langle \nabla p_i, \nabla \mu_i \rangle_{\mathbb{R}^2} + \langle \nabla q_i, \nabla \rho_i \rangle_{\mathbb{R}^2}] \, dx_1 \, dx_2, \end{aligned}$$

which shows (2.7).  $\square$

*Remark.* The optimality system characterizing the solution of (2.6), (2.5) is given by (2.6), (2.8), and by the Pontryagin maximum principle

$$\sum_{i=1}^3 \int_{\omega} [\langle (w_1^*)^i + \nabla p_i^*, \nabla \mu_i \rangle_{\mathbb{R}^2} + \langle (w_2^*)^i + \nabla q_i^*, \nabla \rho_i \rangle_{\mathbb{R}^2}] \, dx_1 \, dx_2 = 0,$$

where  $[p_i^*, q_i^*]_{i=\overline{1,3}}$  are computed by (2.7), with  $\bar{u}^*, \bar{r}^*$  on the right-hand side. Both (2.6) and (2.8) are equivalent to a system of six Poisson equations.

*Remark.* If state constraints are added to the control problem (2.6), (2.5), then the optimal state will satisfy a variational inequality associated with (2.4). In Arnăutu et al. [1], a similar situation was discussed in the case of a simplified plate model.

**PROPOSITION 2.2.** *The optimal control problem (2.6), (2.5) has a unique optimal pair  $[u^*, r^*] \in V(\omega)^2$ ,  $[w_1^*, w_2^*] \in L^2(\omega)^{12}$ .*

*Proof.* We introduce the auxiliary mappings

$$(2.10) \quad \tau_i = \nabla u_i - w_1^i \in L^2(\omega)^2, \quad i = \overline{1, 3},$$

$$(2.11) \quad \theta_i = \nabla r_i - w_2^i \in L^2(\omega)^2, \quad i = \overline{1, 3}.$$

Then

$$(2.12) \quad |w_1^i|_{\mathbb{R}^2}^2 = |\nabla u_i|_{\mathbb{R}^2}^2 + |\tau_i|_{\mathbb{R}^2}^2 - 2 \langle \nabla u_i, \tau_i \rangle_{\mathbb{R}^2}, \quad i = \overline{1, 3},$$

and similarly for  $w_2^i$ . Relations (2.10)–(2.12) show that the cost functional (2.5) may be rewritten in the form

$$\begin{aligned} (2.13) \quad L(w) &= \frac{1}{2} \mathcal{B}([\bar{u}, \bar{r}], [\bar{u}, \bar{r}]) + \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|w_1^i|_{\mathbb{R}^2}^2 + |w_2^i|_{\mathbb{R}^2}^2] \, dx_1 \, dx_2 \\ &\quad - \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|\nabla u_i|_{\mathbb{R}^2}^2 + |\nabla r_i|_{\mathbb{R}^2}^2] \, dx_1 \, dx_2 \\ &= \frac{1}{2} \mathcal{B}([\bar{u}, \bar{r}], [\bar{u}, \bar{r}]) + \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|\tau_i|_{\mathbb{R}^2}^2 + |\theta_i|_{\mathbb{R}^2}^2] \, dx_1 \, dx_2 \\ &\quad - \sum_{i=1}^3 \int_{\omega} [\langle \nabla u_i, \tau_i \rangle_{\mathbb{R}^2} + \langle \nabla r_i, \theta_i \rangle_{\mathbb{R}^2}] \, dx_1 \, dx_2 \\ &= \frac{1}{2} \mathcal{B}([\bar{u}, \bar{r}], [\bar{u}, \bar{r}]) + \frac{1}{2} \sum_{i=1}^3 \int_{\omega} [|\tau_i|_{\mathbb{R}^2}^2 + |\theta_i|_{\mathbb{R}^2}^2] \, dx_1 \, dx_2 \\ &\quad - \sum_{i=1}^3 \left\{ \int_{\Omega} f_i(u_i + x_3 r_i) \, d\bar{x} + \int_{\Gamma_1} h_i(u_i + x_3 r_i) \, d\sigma \right\}, \end{aligned}$$

where we also use (2.6) with the test functions  $\phi_i = u_i$ ,  $\psi_i = r_i$ ,  $i = \overline{1, 3}$ .

If  $\{w_1^n, w_2^n\} \in L^2(\omega)^{12}$  is a minimizing sequence for the problem (2.6), (2.5), and  $\{\bar{u}_n, \bar{r}_n\} \in V(\omega)^2$  are the corresponding states, then the values of the associated cost are bounded from above by a constant, and (2.13) shows that  $\{\bar{\tau}^n\}, \{\bar{\theta}^n\}$  are bounded in  $L^2(\omega)^6$  and  $\{\bar{u}_n\}, \{\bar{r}_n\}$  are bounded in  $V(\omega)$ . Here, we also used that  $\mathcal{B}(\cdot, \cdot)$  is coercive in  $V(\omega)^2$  (cf. Sprekels and Tiba [11]) and that the linear terms in (2.13) are dominated by  $\mathcal{B}(\cdot, \cdot)$ .

Denoting by  $\tilde{\tau}, \tilde{\theta}, \tilde{u}, \tilde{r}, \tilde{w}_1, \tilde{w}_2$  the weak limits of the above quantities, on a suitable subsequence, we can pass to the limit in (2.6), (2.11), (2.10) to obtain similar relations between the limit points. In particular,  $\{\tilde{w}_1, \tilde{w}_2\} \in L^2(\omega)^{12}$  and  $\{\tilde{u}, \tilde{r}\} \in V(\omega)^2$  define an admissible pair for the control problem (2.6), (2.5). By (2.13), and owing to the weak lower semicontinuity of convex functionals, we can infer that

$$(2.14) \quad \begin{aligned} & \liminf_{n \rightarrow \infty} L([\bar{u}_n, \bar{r}_n], [w_1^n, w_2^n]) \\ & \geq \frac{1}{2} \mathcal{B}([\tilde{u}, \tilde{r}], [\tilde{u}, \tilde{r}]) + \frac{1}{2} \sum_{i=1}^3 \int_{\omega} \left[ |\tilde{\tau}_i|_{\mathbb{R}^2}^2 + |\tilde{\theta}_i|_{\mathbb{R}^2}^2 \right] dx_1 dx_2 \\ & \quad - \sum_{i=1}^3 \left\{ \int_{\Omega} f_i(\tilde{u}_i + x_3 \tilde{r}_i) d\bar{x} + \int_{\Gamma_1} h_i(\tilde{u}_i + x_3 \tilde{r}_i) d\sigma \right\}. \end{aligned}$$

By virtue of (2.14) and (2.13) (used in the converse sense), we deduce the optimality of  $[\tilde{w}_1, \tilde{w}_2]$ , which we redenote by  $[w_1^*, w_2^*]$ . Uniqueness is a consequence of the strict convexity of  $\mathcal{B}(\cdot, \cdot)$  and of (2.13).  $\square$

*Remark.* The form (2.13) of the cost functional also shows the connections with the energy minimization corresponding to the Naghdi shell model, as mentioned in the introduction.

**3. Curved rods.** The application to curved rod models exploits essentially the structure of the coefficients of the differential equations. We first indicate some details in this respect. To this end, denote by  $\bar{\theta} \in W^{2,\infty}(0, L)^3$ ,  $L > 0$ , the parametrization of a three-dimensional Jordan curve, which will represent the line of centroids of the curved rod. Let  $\omega \subset \mathbb{R}^2$  be some bounded Lipschitzian domain, not necessarily simply connected.

If  $\bar{t}, \bar{n}, \bar{b}$  denote the local orthonormal frame associated at each point  $x_3 \in [0, L]$  with the curve  $\bar{\theta}$ , we consider the geometric transformation

$$(3.1) \quad \begin{aligned} F : \Omega = \omega \times ]0, L[ & \rightarrow F(\Omega) = \hat{\Omega} \subset \mathbb{R}^3, \\ F(\bar{x}) = F(x_1, x_2, x_3) & = \bar{\theta}(x_3) + x_1 \bar{n}(x_3) + x_2 \bar{b}(x_3) \\ & \quad \forall (x_1, x_2) \in \Omega, \forall x_3 \in ]0, L[. \end{aligned}$$

In the following, the Jacobian of  $F$ ,  $J = \nabla F$ , and its inverse,  $J(\bar{x})^{-1} = (h_{ij}(\bar{x}))_{i,j=\overline{1,3}}$ , are needed. Elementary computations give

$$(3.2) \quad J(\bar{x})^{-1} = \begin{pmatrix} n_1 - \frac{c t_1 x_2}{\det J(\bar{x})} & n_2 - \frac{c t_2 x_2}{\det J(\bar{x})} & n_3 - \frac{c t_3 x_2}{\det J(\bar{x})} \\ b_1 + \frac{c t_1 x_1}{\det J(\bar{x})} & b_2 + \frac{c t_2 x_1}{\det J(\bar{x})} & b_3 + \frac{c t_3 x_1}{\det J(\bar{x})} \\ \frac{t_1}{\det J(\bar{x})} & \frac{t_2}{\det J(\bar{x})} & \frac{t_3}{\det J(\bar{x})} \end{pmatrix},$$

$$(3.3) \quad \det J(\bar{x}) = 1 - \beta x_1 - a x_2.$$

The coefficients  $a, \beta, c \in L^\infty(0, L)$  appearing in (3.2), (3.3) are similar to torsion and curvature known from classical differential geometry and may be obtained from the “equations of motion”

$$(3.4) \quad \begin{aligned} \bar{t}'(x_3) &= a(x_3) \bar{b}(x_3) + \beta(x_3) \bar{n}(x_3), \\ \bar{b}'(x_3) &= -a(x_3) \bar{t}(x_3) + c(x_3) \bar{n}(x_3), \\ \bar{n}'(x_3) &= -\beta(x_3) \bar{t}(x_3) - c(x_3) \bar{b}(x_3). \end{aligned}$$

We note that  $\bar{t}, \bar{n}, \bar{b}$  are not necessarily obtained as the Frenet or the Darboux local frames associated with  $\bar{\theta}$ . In Neittaanmäki, Sprekels, and Tiba [7, Chap. 6] such a local frame was constructed under the mere assumption that  $\bar{\theta} \in C^1[0, L]^3$ .

We also assume that the selection of axes in  $\omega \subset \mathbb{R}^2$  is such that

$$(3.5) \quad 0 = \int_{\omega} x_1 dx_1 dx_2 = \int_{\omega} x_2 dx_1 dx_2 = \int_{\omega} x_1 x_2 dx_1 dx_2,$$

which is usual in the literature on curved rods; cf. Murat and Sili [6]. If the diameter of  $\omega$  is sufficiently small, then  $|x_1|, |x_2|$  are small for  $(x_1, x_2) \in \omega$ , and since  $\beta, a \in L^\infty(0, L)$ , relation (3.3) shows that we may assume

$$(3.6) \quad \det J(\bar{x}) \geq c_0 > 0 \quad \forall \bar{x} \in \Omega.$$

Then it is known that  $F : \Omega \rightarrow \hat{\Omega}$  is a one-to-one transformation (see Ciarlet [2, Thm. 3.1.–1]), which justifies the definition (3.1) of the curved rod.

Starting from the linear elasticity system (1.1), and using the condition that the displacement of  $\hat{x} \in \hat{\Omega}$  has the form

$$(3.7) \quad \bar{y}(\hat{x}) = \bar{\tau}(x_3) + x_1 \bar{N}(x_3) + x_2 \bar{B}(x_3),$$

with  $\bar{x} = (x_1, x_2, x_3) = F^{-1}(\hat{x}) \in \Omega$ , we obtain the following model for the curved rod:

$$(3.8) \quad \begin{aligned} \mathcal{B}(\bar{y}, \bar{v}) &= \tilde{\lambda} \int_{\Omega} \sum_{i,j=1}^3 \left[ N_i(x_3) h_{1i}(\bar{x}) + B_i(x_3) h_{2i}(\bar{x}) + (\tau'_i(x_3) + x_1 N'_i(x_3) \right. \\ &\quad \left. + x_2 B'_i(x_3)) h_{3i}(\bar{x}) \right] \cdot \left[ M_j(x_3) h_{1j}(\bar{x}) + D_j(x_3) h_{2j}(\bar{x}) \right. \\ &\quad \left. + (\mu'_j(x_3) + x_1 M'_j(x_3) + x_2 D'_j(x_3)) h_{3j}(\bar{x}) \right] |\det J(\bar{x})| d\bar{x} \\ &\quad + \tilde{\mu} \int_{\Omega} \sum_{i < j} \left[ N_i(x_3) h_{1j}(\bar{x}) + B_i(x_3) h_{2j}(\bar{x}) + (\tau'_i(x_3) + x_1 N'_i(x_3) \right. \\ &\quad \left. + x_2 B'_i(x_3)) h_{3j}(\bar{x}) + N_j(x_3) h_{1i}(\bar{x}) + B_j(x_3) h_{2i}(\bar{x}) \right. \\ &\quad \left. + (\tau'_j(x_3) + x_1 N'_j(x_3) + x_2 B'_j(x_3)) h_{3i}(\bar{x}) \right] \\ &\quad \cdot \left[ M_i(x_3) h_{1j}(\bar{x}) + D_i(x_3) h_{2j}(\bar{x}) + (\mu'_i(x_3) + x_1 M'_i(x_3) \right. \\ &\quad \left. + x_2 D'_i(x_3)) h_{3j}(\bar{x}) + M_j(x_3) h_{1i}(\bar{x}) + D_j(x_3) h_{2i}(\bar{x}) \right. \\ &\quad \left. + (\mu'_j(x_3) + x_1 M'_j(x_3) + x_2 D'_j(x_3)) h_{3i}(\bar{x}) \right] |\det J(\bar{x})| d\bar{x} \end{aligned}$$

$$\begin{aligned}
& + 2 \tilde{\mu} \int_{\Omega} \sum_{i=1}^3 \left[ N_i(x_3) h_{1i}(\bar{x}) + B_i(x_3) h_{2i}(\bar{x}) + (\tau'_i(x_3) + x_1 N'_i(x_3) \right. \\
& \quad \left. + x_2 B'_i(x_3)) h_{3i}(\bar{x}) \right] \cdot \left[ M_i(x_3) h_{1i}(\bar{x}) + D_i(x_3) h_{2i}(\bar{x}) \right. \\
& \quad \left. + (\mu'_i(x_3) + x_1 M'_i(x_3) + x_2 D'_i(x_3)) h_{3i}(\bar{x}) \right] |\det J(\bar{x})| d\bar{x} \\
& = \sum_{\ell=1}^3 \int_{\Omega} f_{\ell}(\bar{x}) (\mu_{\ell}(x_3) + x_1 M_{\ell}(x_3) + x_2 D_{\ell}(x_3)) |\det J(\bar{x})| d\bar{x}
\end{aligned}$$

for any test functions  $\bar{\mu} = (\mu_1, \mu_2, \mu_3)$ ,  $\bar{M} = (M_1, M_2, M_3)$ ,  $\bar{D} = (D_1, D_2, D_3) \in H_0^1(0, L)^3$ . We denote by  $\bar{v} = (\bar{\mu}, \bar{M}, \bar{D}) \in H_0^1(0, L)^9$  and  $\bar{y} = (\tau_1, \tau_2, \tau_3, N_1, N_2, N_3, B_1, B_2, B_3) \in H_0^1(0, L)^9$  the vector of the unknowns. The bilateral null conditions, given by the choice of the space  $H_0^1(0, L)$ , correspond to the clamped curved rod.

The condition (3.7) and the choice of the test functions in a similar form are of the same type as (2.3), and that is why the model (3.8) was called a generalized Naghdi model for curved rods in [5] where it was studied. It consists of a system of nine ordinary differential equations for nine unknown functions.

It should be clear that  $\bar{\tau}$  describes the translation of the points on the line of centroids, and the vectors  $\bar{N} + \bar{n}$ ,  $\bar{B} + \bar{b}$  reflect the deformation of the orthogonal frame in the cross section (which remains plane but not necessarily orthogonal to the tangent of the deformed line of centroids, i.e., to  $\bar{\theta}' + \bar{\tau}'$ ). This allows for shear and for length or volume changes after the deformation. The vector  $\bar{f} = (f_1, f_2, f_3) \in L^2(0, L)^3$  represents the body forces acting on the curved rod, and  $\bar{\lambda} \geq 0$ ,  $\bar{\mu} > 0$  are the Lamé coefficients that characterize the elastic material. Note that the model is valid only for small deformations and for thin rods. As a special type of argument concerning the validity of such models and their stability with respect to iterative approaches, we quote [7, Chap. 6.1.2] (for Kirchhoff–Love arches) and [7, Chap. 6.2.3] (for three-dimensional curved rods). Especially relevant in this respect are [7, Ex. 6.1.11 and 6.2.13], where some experiments perfectly matching the physical interpretation are discussed for these models.

We associate with (3.8) the following optimal control problem with the basic properties (to be argued in what follows) that it solves (3.8) and has a very simple structure:

$$\begin{aligned}
(3.9) \quad \min \bigg\{ & \tilde{\lambda} \int_{\Omega} \sum_{i,j=1}^3 U_{ii}(\bar{x}) U_{jj}(\bar{x}) |\det J(\bar{x})| d\bar{x} \\
& + \tilde{\mu} \int_{\Omega} \sum_{i < j} [U_{ij}(\bar{x}) + U_{ji}(\bar{x})]^2 |\det J(\bar{x})| d\bar{x} \\
& + 2 \tilde{\mu} \int_{\Omega} \sum_{i=1}^3 U_{ii}^2(\bar{x}) |\det J(\bar{x})| d\bar{x} - 2 \sum_{i=1}^3 \int_{\Omega} f_i(\bar{x}) [\tau_i(x_3) + x_1 N_i(x_3) \\
& \quad + x_2 B_i(x_3)] |\det J(\bar{x})| d\bar{x} \bigg\},
\end{aligned}$$

subject to the state system

$$\begin{aligned}
(3.10) \quad & N_i(x_3) h_{1j}(\bar{x}) + B_i(x_3) h_{2j}(\bar{x}) + [\tau'_i(x_3) + x_1 N'_i(x_3) \\
& \quad + x_2 B'_i(x_3)] h_{3j}(\bar{x}) = U_{ij}(\bar{x}) \text{ in } \Omega,
\end{aligned}$$

$$(3.11) \quad N_i(0) = B_i(0) = \tau_i(0) = 0, \quad i = \overline{1, 3},$$

and to the control constraints

$$(3.12) \quad U = \{U_{ij}\}_{i,j=\overline{1,3}} \in \mathcal{V} \subset L^2(\Omega)^9.$$

Here,  $\mathcal{V} \neq \emptyset$  is the closed linear subspace in  $L^2(\Omega)^9$  generated from all functions in  $L^2(0, L)$  having zero mean value, used on the “position” of  $\tau'_i, N'_i, B'_i$ ,  $i = \overline{1, 3}$ , in (3.10). Clearly,  $N_i, B_i$  can be immediately computed using (3.11) and simple integration, which gives  $U_{ij}$  on the right-hand side of (3.10) and spans  $\mathcal{V}$ .

Note that in (3.10),  $(x_1, x_2) \in \omega$  appears as a parameter. The constraint (3.12) ensures that (3.10) has a unique solution and that

$$(3.13) \quad \tau_i(L) = N_i(L) = B_i(L) = 0, \quad i = \overline{1, 3}.$$

One could impose (3.13) instead of (3.12), but our choice is motivated by its explicit character with respect to the control unknown.

**THEOREM 3.1.** *The optimal control problem (3.9)–(3.12) has a unique optimal “pair”  $U^* = \{U_{ij}^*\} \in \mathcal{V}$ ,  $[\tau_i^*, B_i^*, N_i^*]_{i=\overline{1,3}} \in H_0^1(0, L)^9$ .*

*Proof.* Let  $L(U)$  denote the cost functional (3.9). Then there are  $\alpha > 0$ ,  $\bar{c} > 0$  such that

$$(3.14)$$

$$\alpha L(U) \geq \int_{\Omega} \sum_{i < j} [U_{ij}(\bar{x}) + U_{ji}(\bar{x})]^2 d\bar{x} + \int_{\Omega} \sum_{i=1}^3 U_{ii}^2(\bar{x}) - \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3,$$

where (3.3) and simple binomial inequalities have been used. Using (3.10) and (3.14), and again some binomial inequalities, we obtain (where we denote  $z_i = \tau'_i + x_1 N'_i + x_2 B'_i$ )

$$\begin{aligned} \alpha L(U) &\geq \int_{\Omega} \sum_{i < j} [N_i h_{1j} + B_i h_{2j} + z_i h_{3j} + N_j h_{1i} + B_j h_{2i} + z_j h_{3i}]^2 d\bar{x} \\ (3.15) \quad &+ \int_{\Omega} \sum_{i=1}^3 [N_i h_{1i} + B_i h_{2i} + z_i h_{3i}]^2 d\bar{x} - \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3 \\ &\geq \int_{\Omega} \sum_{i < j} (z_i h_{3j} + z_j h_{3i})^2 d\bar{x} + \int_{\Omega} \sum_{i=1}^3 z_i^2 h_{3i}^2 d\bar{x} - \hat{c} \sum_{i=1}^3 \int_0^L [N_i^2 + B_i^2] dx_3 \\ &\quad - \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3. \end{aligned}$$

Above, in the structure of the constant  $\hat{c} > 0$ , we also used that  $h_{ij} \in L^\infty(\Omega)$ ,  $i, j = \overline{1, 3}$ . In (3.15), we applied the following identities:

$$(3.16)$$

$$\frac{1}{2} \sum_{i < j} (z_i h_{3j} + z_j h_{3i})^2 + \frac{3}{2} \sum_{i=1}^3 z_i^2 h_{3i}^2 = \frac{1}{2} \sum_{i=1}^3 z_i^2 \sum_{j=1}^3 h_{3j}^2 + \frac{1}{2} \sum_{i < j} (z_i h_{3i} + z_j h_{3j})^2,$$

$$\begin{aligned}
 (3.17) \quad & \int_{\Omega} z_i^2 d\bar{x} = \int_{\Omega} [\tau'_i + x_1 N'_i + x_2 B'_i]^2 d\bar{x} \\
 &= \int_0^L \int_{\omega} (\tau'_i)^2 d\bar{x} + 2 \int_0^L \tau'_i N'_i dx_3 \int_{\omega} x_1 dx_1 dx_2 + 2 \int_0^L \tau'_i B'_i dx_3 \int_{\omega} x_2 dx_1 dx_2 \\
 &\quad + \int_0^L (N'_i)^2 dx_3 \int_{\omega} x_1^2 dx_1 dx_2 + \int_0^L (B'_i)^2 dx_3 \int_{\omega} x_2^2 dx_1 dx_2 \\
 &\quad + 2 \int_0^L N'_i B'_i dx_3 \int_{\omega} x_1 x_2 dx_1 dx_2 \geq \tilde{c} \int_0^L [(\tau'_i)^2 + (N'_i)^2 + (B'_i)^2] dx_3,
 \end{aligned}$$

with  $\tilde{c} := \min\{\text{meas}(\omega), \int_{\omega} x_1^2 dx_1 dx_2, \int_{\omega} x_2^2 dx_1 dx_2\} > 0$ ,

$$(3.18) \quad \sum_{j=1}^3 h_{3j}^2 = \frac{1}{\det J(\bar{x})} \sum_{j=1}^3 t_j^2 = \frac{1}{\det J(\bar{x})} \geq \check{c} > 0.$$

Relations (3.17), (3.18) are consequences of (3.5), respectively, of (3.2), (3.3), and of the assumption  $\bar{\theta} \in W^{2,\infty}(0, L)^3$ . From (3.15)–(3.18), we can infer that

$$\begin{aligned}
 (3.19) \quad & \alpha L(U) + \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3 \\
 & \geq \hat{c} \sum_{i=1}^3 \left[ |\tau_i|_{H_0^1(0,L)}^2 + |N_i|_{H_0^1(0,L)}^2 + |B_i|_{H_0^1(0,L)}^2 \right] \\
 & \quad - \hat{C} \sum_{i=1}^3 \left[ |N_i|_{L^2(0,L)}^2 + |B_i|_{L^2(0,L)}^2 \right]^2,
 \end{aligned}$$

where  $\hat{c}, \hat{C}, \bar{c}$  are positive constants that do not depend on  $\tau_i, N_i, B_i, U_{ij}$ ,  $i, j = \overline{1, 3}$ .  $\square$

LEMMA 3.2. *There is some  $\delta > 0$  such that*

$$\begin{aligned}
 (3.20) \quad & \alpha L(U) + \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3 \\
 & \geq \delta \sum_{i=1}^3 \left[ |\tau_i|_{H_0^1(0,L)}^2 + |N_i|_{H_0^1(0,L)}^2 + |B_i|_{H_0^1(0,L)}^2 \right]
 \end{aligned}$$

for all  $\tau_i, N_i, B_i \in H_0^1(0, L)$ ,  $i = \overline{1, 3}$ , obtained by (3.10) from some  $\{U_{ij}\}_{i,j=\overline{1,3}} \in \mathcal{V}$ .

*Proof.* Owing to (3.14), we have

$$\alpha L(U) + \bar{c} \sum_{i=1}^3 \int_0^L [\tau_i^2 + N_i^2 + B_i^2]^{\frac{1}{2}} dx_3 \geq 0.$$

Assume that (3.20) is false. Then for any  $\varepsilon > 0$  there are  $U^\varepsilon = \{U_{ij}^\varepsilon\}_{i,j=\overline{1,3}} \in \mathcal{V}$  and

$\{\tau_i^\varepsilon, N_i^\varepsilon, B_i^\varepsilon\}_{i=\overline{1,3}} \neq 0$ , associated with  $U_\varepsilon$  by (3.10), such that

$$\begin{aligned}
 (3.21) \quad & \varepsilon \sum_{i=1}^3 \left[ |\tau_i^\varepsilon|_{H_0^1(0,L)}^2 + |N_i^\varepsilon|_{H_0^1(0,L)}^2 + |B_i^\varepsilon|_{H_0^1(0,L)}^2 \right] \\
 & \geq \alpha L(U^\varepsilon) + \bar{c} \sum_{i=1}^3 \int_0^L [(\tau_i^\varepsilon)^2 + (N_i^\varepsilon)^2 + (B_i^\varepsilon)^2]^{\frac{1}{2}} dx_3 \\
 & \geq \int_\Omega \sum_{i < j} [U_{ij}^\varepsilon(\bar{x}) + U_{ji}^\varepsilon(\bar{x})]^2 d\bar{x} + \int_\Omega \sum_{i=1}^3 (U_{ii}^\varepsilon)^2 d\bar{x} \geq 0.
 \end{aligned}$$

Notice that we may assume that

$$\sum_{i=1}^3 \left[ |\tau_i^\varepsilon|_{H_0^1(0,L)}^2 + |N_i^\varepsilon|_{H_0^1(0,L)}^2 + |B_i^\varepsilon|_{H_0^1(0,L)}^2 \right] = 1$$

by scaling with the square root of this factor (if it differs from unity) in (3.10), and in the first and last terms of (3.21). Then we may assume without loss of generality that

$$\tau_i^\varepsilon \rightarrow \tau_i, \quad N_i^\varepsilon \rightarrow N_i, \quad B_i^\varepsilon \rightarrow B_i, \quad i = \overline{1,3},$$

weakly in  $H_0^1(0, L)$  and strongly in  $L^2(0, L)$ . By virtue of (3.10), we also see that  $U_{ij}^\varepsilon \rightarrow U_{ij}$  weakly in  $L^2(\Omega)$ . All the above convergences are valid for some subsequence. Also,  $\{\tau_i, N_i, B_i\}_{i=\overline{1,3}}$ , together with  $\{U_{ij}\}_{i,j=\overline{1,3}}$ , satisfy (3.10), while  $\{U_{ij}\} \in \mathcal{V}$ .

Passing to the limit in (3.21), we find that

$$(3.22) \quad \int_\Omega \sum_{i < j} [U_{ij}(\bar{x}) + U_{ji}(\bar{x})]^2 dx + \int_\Omega \sum_{i=1}^3 (U_{ii})^2 d\bar{x} = 0.$$

From (3.22) it follows that

$$(3.23) \quad N_i h_{1i} + B_i h_{2i} + z_i h_{3i} = 0, \quad i = \overline{1,3},$$

$$(3.24) \quad N_i h_{1j} + B_i h_{2j} + z_i h_{3j} + N_j h_{1i} + B_j h_{2i} + z_j h_{3i} = 0, \quad i \neq j.$$

Now fix  $j = j_0$  in (3.24), and let  $i_1, i_2$  be the two possible choices of indices  $i$  satisfying the condition in (3.24). We multiply (3.23), written for  $i = i_1$  or  $i = i_2$ , by  $h_{3j_0}$ , and subtract the result from (3.24) multiplied by  $h_{3i_1}$  or  $h_{3i_2}$ , respectively. Adding the results to (3.23) written for  $i = j$ , and multiplied by  $h_{3j_0}$ , we find that

$$(3.25) \quad z_{j_0} \sum_{i=1}^3 h_{3i}^2 = \tilde{\Gamma}_{j_0}(\bar{N}, \bar{B}),$$

where  $\tilde{\Gamma}_{j_0}$  is some linear expression of  $\bar{N}, \bar{B}$ . By (3.2), we obtain from (3.25) that

$$(3.26) \quad \tau'_i + x_1 N'_i + x_2 B'_i = \Gamma_i(\bar{N}, \bar{B}), \quad i = \overline{1,3},$$

where, again,  $\Gamma_i$  is linear in  $\bar{N}, \bar{B}$ .

Giving  $(x_1, x_2) \in \omega$  several independent values and taking into account (3.11), we conclude that all limit points  $\{\tau_i, N_i, B_i\}_{i=\overline{1,3}}$  are identically zero in their domains of definition. A similar conclusion follows for  $\{U_{ij}\}_{i,j=\overline{1,3}}$  by (3.10).

We combine the first inequality in (3.21) with (3.19):

$$\begin{aligned}
 (3.27) \quad & \varepsilon \sum_{i=1}^3 \left[ |\tau_i^\varepsilon|_{H_0^1(0,L)}^2 + |N_i^\varepsilon|_{H_0^1(0,L)}^2 + |B_i^\varepsilon|_{H_0^1(0,L)}^2 \right] \\
 & \geq \hat{c} \sum_{i=1}^3 \left[ |\tau_i^\varepsilon|_{H_0^1(0,L)}^2 + |N_i^\varepsilon|_{H_0^1(0,L)}^2 + |B_i^\varepsilon|_{H_0^1(0,L)}^2 \right] \\
 & \quad - \hat{C} \sum_{i=1}^3 \left[ |N_i^\varepsilon|_{L^2(0,L)}^2 + |B_i^\varepsilon|_{L^2(0,L)}^2 \right].
 \end{aligned}$$

Using the above scaling argument and its conclusion in (3.27), we arrive at the contradiction

$$0 \geq \hat{c} > 0,$$

since  $|N_i^\varepsilon|_{L^2(0,L)}^2 + |B_i^\varepsilon|_{L^2(0,L)}^2 \rightarrow 0$ . This completes the proof of (3.20).  $\square$

*Proof of Theorem 3.1 (continued).* Let  $\{U_{ij}^n\}_{i,j=\overline{1,3}}$ ,  $\{\tau_i^n, N_i^n, B_i^n\}_{i,j=\overline{1,3}}$  be a minimizing sequence in  $\mathcal{V} \times H_0^1(0,L)^9$  for the problem (3.9)–(3.12). Clearly,  $L(U^n)$  is majorized from above by a constant, and inequality (3.20) shows that  $\{\tau_i^n, N_i^n, B_i^n\}_{i=\overline{1,3}}$  is bounded in  $H_0^1(0,L)^9$ . Consequently, by (3.10),  $\{U_{ij}^n\}_{i,j=\overline{1,3}}$  are bounded in  $L^2(\Omega)^9$ . Let  $\{\tau_i^*, N_i^*, B_i^*\}_{i=\overline{1,3}}$  and  $\{U_{ij}^*\}_{i,j=\overline{1,3}}$  denote, respectively, their weak limits, on a subsequence. Then  $\{U_{ij}^*\}_{i,j=\overline{1,3}} \in \mathcal{V}$ , which is a closed linear space.

One can pass to the limit in (3.10) to see that  $\{\tau_i^*, N_i^*, B_i^*\}_{i=\overline{1,3}}$  and  $\{U_{ij}^*\}_{i,j=\overline{1,3}}$  form an admissible couple, and then, using the weak lower semicontinuity of cost functional (3.9), to conclude their optimality for the problem (3.9)–(3.12).

The uniqueness is an automatic consequence of the next result and of (3.10).  $\square$

**THEOREM 3.3.** *The optimal state  $\{\tau_i^*, N_i^*, B_i^*\}_{i=\overline{1,3}}$  is the unique solution to the system (3.8) that governs the generalized Naghdi model for curved rods.*

*Proof.* For any  $\{V_{ij}\}_{i,j=\overline{1,3}} \in \mathcal{V}$ , we define the system in variations by

$$\begin{aligned}
 (3.28) \quad & M_i(x_3) h_{1j}(\bar{x}) + D_i(x_3) h_{2j}(\bar{x}) + [\mu_i'(x_3) + x_1 M_i'(x_3) \\
 & + x_2 D_i'(x_3)] h_{3j}(\bar{x}) = V_{ij}(\bar{x}), \quad i, j = \overline{1,3},
 \end{aligned}$$

$$(3.29) \quad M_i(0) = D_i(0) = \mu_i(0) = 0, \quad i = \overline{1,3}.$$

Next, we perform admissible variations around the optimal pair of the following form:

$$\{\tau_i^*, N_i^*, B_i^*\}_{i=\overline{1,3}} + \lambda \{\mu_i, M_i, D_i\}_{i=\overline{1,3}}; \quad \{U_{ij}^*\}_{i,j=\overline{1,3}} + \lambda \{V_{ij}\}_{i,j=\overline{1,3}}.$$

By (3.28), (3.29), and (3.10)–(3.12), this couple is admissible for any  $\lambda \in \mathbb{R}$ . Subtracting the corresponding cost and the optimal cost, dividing by  $\lambda > 0$  or  $\lambda < 0$ , respectively, and taking the limits as  $\lambda \rightarrow 0$ , the minimum property of  $\{U_{ij}^*\}_{i,j=\overline{1,3}}$

yields the associated Euler equation,

(3.30)

$$\begin{aligned} 0 = & \tilde{\lambda} \int_{\Omega} \sum_{i,j=1}^3 [U_{ii}^* V_{jj} + U_{jj}^* V_{ii}] \det J(\bar{x}) d\bar{x} \\ & + 2\tilde{\mu} \int_{\Omega} \sum_{i < j} [U_{ij}^* + U_{ji}^*] [V_{ij} + V_{ji}] \det J(\bar{x}) d\bar{x} + 4\tilde{\mu} \int_{\Omega} \sum_{i=1}^3 U_{ii}^* V_{ii} \det J(\bar{x}) d\bar{x} \\ & - 2 \int_{\Omega} \sum_{i=1}^3 f_i [\mu_i + x_1 M_i + x_2 D_i] \det J(\bar{x}) d\bar{x}. \end{aligned}$$

If the  $V_{ij}$  are replaced as in (3.28), and if the  $U_{ij}^*$  are replaced as in (3.10), then a simple computation shows that (3.30) becomes (3.8), which is known to have a unique solution. This ends the proof.  $\square$

**PROPOSITION 3.4.** *If  $\{U_{ij}^*\}$  is known, then  $\{\tau_i^*, N_i^*, B_i^*\}_{i=\overline{1,3}}$  can be computed explicitly.*

*Proof.* Starting from (3.2), one can check the following orthogonality-type relations:

$$(3.31) \quad \sum_{j=1}^3 h_{1j} b_j = 0, \quad \sum_{j=1}^3 h_{3j} b_j = 0, \quad \sum_{j=1}^3 h_{2j} b_j = 1,$$

$$(3.32) \quad \sum_{j=1}^3 h_{1j} n_j = 1, \quad \sum_{j=1}^3 h_{2j} n_j = 0, \quad \sum_{j=1}^3 h_{3j} n_j = 0,$$

$$(3.33) \quad \sum_{j=1}^3 h_{1j} t_j = -\frac{c x_2}{\det J(\bar{x})}, \quad \sum_{j=1}^3 h_{2j} t_j = \frac{c x_1}{\det J(\bar{x})}, \quad \sum_{j=1}^3 h_{3j} t_j = \frac{1}{\det J(\bar{x})}.$$

Consequently, multiplying (3.10) by  $n_j$  (respectively, by  $b_j, t_j$ ) and adding for  $j = \overline{1,3}$ , the relations (3.31)–(3.33) yield that

$$(3.34) \quad B_i^* = \sum_{j=1}^3 U_{ij}^* b_j, \quad i = \overline{1,3},$$

$$(3.35) \quad N_i^* = \sum_{j=1}^3 U_{ij}^* n_j, \quad i = \overline{1,3},$$

$$\begin{aligned} (3.36) \quad (\tau_i^*)' + x_1 (N_i^*)' + x_2 (B_i^*)' = & \sum_{j=1}^3 U_{ij}^* t_j \det J(\bar{x}) + \sum_{j=1}^3 U_{ij}^* n_j c x_2 \\ & - \sum_{j=1}^3 U_{ij}^* b_j c x_1, \quad i = \overline{1,3}. \end{aligned}$$

Thus, integrating over  $[0, x_3]$  in (3.36) and subtracting (3.34), (3.35), we also obtain an explicit formula for  $\{\tau_i^*\}_{i=\overline{1,3}}$ , which completes the proof.  $\square$

*Remark.* Relations (3.34)–(3.36) may be extended to any admissible couple  $\{\tau_i, N_i, B_i\}_{i=\overline{1,3}}, \{U_{ij}\}_{i,j=\overline{1,3}}$ .

*Remark.* Let us denote by  $\Lambda_i(U_{ij})$  the right-hand side of (3.36). Then we can perform the following substitution in (3.9):

$$\begin{aligned}
 (3.37) \quad & \sum_{i=1}^3 \int_{\Omega} f_i [\tau_i + x_1 N_i + x_2 B_i] \det J \, d\bar{x} \\
 &= - \sum_{i=1}^3 \int_{\Omega} [\tau'_i + x_1 N'_i + x_2 B'_i] \int_0^{x_3} f_i(x_1, x_2, \rho) \det J(x_1, x_2, \rho) \, d\rho \, d\bar{x} \\
 &= - \sum_{i=1}^3 \int_{\Omega} \Lambda_i(U_{ij}) \int_0^{x_3} f_i(x_1, x_2, \rho) \det J(x_1, x_2, \rho) \, d\rho \, d\bar{x}.
 \end{aligned}$$

In this way, the optimal control problem (3.9)–(3.12) can be transformed into a mathematical programming problem defined on  $\mathcal{V} \subset L^2(\Omega)^9$ , since the state does not appear anymore in the cost functional. However, in order to recover the solution to (3.8), one has to solve (3.10) or use Proposition 3.4.

**PROPOSITION 3.5.** *The directional derivative at the point  $\{U_{ij}\}_{i,j=\overline{1,3}} \in \mathcal{V}$  and in the direction  $\{V_{ij}\}_{i,j=\overline{1,3}}$  is given by*

$$\begin{aligned}
 (3.38) \quad & \langle \nabla L(U_{ij}), \{V_{ij}\} \rangle = \tilde{\lambda} \int_{\Omega} \sum_{i,j=1}^3 [U_{ii} V_{jj} + U_{jj} V_{ii}] \det J(\bar{x}) \, d\bar{x} \\
 &+ 2\tilde{\mu} \int_{\Omega} \sum_{i < j} [U_{ij} + U_{ji}] [V_{ij} + V_{ji}] \det J(\bar{x}) \, d\bar{x} + 4\tilde{\mu} \int_{\Omega} \sum_{i=1}^3 U_{ii} V_{ii} \det J(\bar{x}) \, d\bar{x} \\
 &- 2 \int_{\Omega} \sum_{i=1}^3 \Lambda_i(V_{ij}) \int_0^{x_3} f_i(x_1, x_2, \rho) \det J(x_1, x_2, \rho) \, d\rho \, d\bar{x}.
 \end{aligned}$$

Here,  $\langle \cdot, \cdot \rangle$  is the scalar product in  $L^2(\Omega)^9$ .

*Proof.* It is similar to the deduction of the Euler equation (3.30). The last integral may be rewritten as in (3.37).  $\square$

*Remark.* By (3.38), one can solve (3.9)–(3.12) by standard gradient with projection methods.

**4. Abstract variants.** In this section, we briefly discuss two abstract variants of the control variational method. To this end, let  $V \subset H$  be two separable Hilbert spaces with dense and continuous embedding, endowed with scalar products  $(\cdot, \cdot)_V$  and  $(\cdot, \cdot)_H$ , respectively. Let  $V^*$  be the dual of  $V$  ( $H$  is identified with its own dual space), and let  $A_1, A_2 : V \rightarrow V^*$  be linear, continuous, symmetric operators, with  $A_1$  positively definite.

We consider the equation

$$(4.1) \quad (A_1 + A_2)y = f \in H,$$

and we assume the existence of a unique solution  $y \in V$  to (4.1).

The first optimal control problem associated with (4.1) that we take into account is

$$(4.2) \quad \min \left\{ \frac{1}{2} |w|_H^2 + \frac{1}{2} (A_2 y, y)_{V^* \times V} \right\},$$

subject to  $w \in H$  (no constraints) and

$$(4.3) \quad A_1^{1/2} y = g + w,$$

where  $g \in V$  is the unique solution of  $A_1^{1/2} g = f$ , and where  $A_1^{1/2} : V \rightarrow H$  is the square root of  $A_1$ , defined by the relation

$$(A_1^{1/2} y, A_1^{1/2} v)_H = (A_1 y, v)_{V^* \times V} \quad \forall y, v \in V.$$

Clearly,  $A_1^{1/2}$  is symmetric and positive definite, and (4.3) has a unique solution  $y \in V$  for any  $w \in H$ .

We denote by  $[w^*, y^*] \in H \times V$  an optimal pair for the unconstrained control problem (4.2), (4.3), which is assumed to exist. Now, take arbitrary variations of the form

$$y^* + \lambda z, \quad \lambda \in \mathbb{R}, \quad z \in V, \quad \text{and} \quad w^* + \lambda v, \quad v = A_1^{1/2} z \in H.$$

Then, as in (3.30), one may establish the Euler equation associated with (4.2), (4.3):

$$(4.4) \quad (w^*, v)_H + (A_2 y^*, z)_{V^* \times V} = 0$$

for any  $v \in H$ ,  $z \in V$  as above.

In (4.4), we replace  $v$  and  $w^*$ , and we infer that

$$(4.5) \quad \begin{aligned} 0 &= \left( A_1^{1/2} y^* - g, A_1^{1/2} z \right)_H + (A_2 y^*, z)_{V^* \times V} \\ &= (A_1 y^*, z)_{V^* \times V} + (A_2 y^*, z)_{V^* \times V} - \left( A_1^{-1/2} f, A_1^{1/2} z \right)_H \\ &= ((A_1 + A_2) y^*, z)_{V^* \times V} - (f, z)_H \quad \forall z \in V. \end{aligned}$$

Clearly, (4.5) shows that  $y^*$  is a solution to (4.1).

*Remark.* If also  $A_2$  is positive definite, then the control problem (4.2), (4.3) is coercive and strictly convex, and the existence of the optimal pair  $[w^*, y^*]$  is standard.

We consider now a second optimal control problem that may be associated with (4.1):

$$(4.6) \quad \min \left\{ (u, y)_{V^* \times V} - 3(u, \tilde{g})_{V^* \times V} + (A_2 y, y)_{V^* \times V} \right\},$$

subject to  $u \in V^*$  (again no constraints) and

$$(4.7) \quad A_1 y = u - f.$$

Here,  $\tilde{g} \in V$  is the unique solution to  $A_1 \tilde{g} = f$ , which exists under the assumptions imposed on  $A_1$ . The equation in variations associated with (4.7) is

$$(4.8) \quad A_1 \xi = \omega$$

for any  $\omega \in V^*$  (equivalently, for any  $\xi \in V$ , since  $A_1 : V \rightarrow V^*$  is an isomorphism). The Euler equation for the control problem (4.6), (4.7) is

$$(4.9) \quad 0 = (u^*, \xi)_{V^* \times V} + (\omega, y^*)_{V^* \times V} - 3(\omega, \tilde{g})_{V^* \times V} + 2(A_2 y^*, \xi)_{V^* \times V}$$

for any  $[\omega, \xi]$  satisfying (4.8). In (4.9),  $[u^*, y^*] \in V^* \times V$  denotes an optimal pair of (4.6), (4.7), which is assumed to exist. The argument for establishing (4.9) is the same as for (3.30). Combining (4.7)–(4.9), we obtain that

$$\begin{aligned} (4.10) \quad 0 &= (u^*, \xi)_{V^* \times V} + (A_1 \xi, y^*)_{V^* \times V} - 3(A_1 \xi, \bar{g})_{V^* \times V} + 2(A_2 y^*, \xi)_{V^* \times V} \\ &= (u^*, \xi)_{V^* \times V} + (A_1 y^*, \xi)_{V^* \times V} - 3(f, \xi)_{V^* \times V} + 2(A_2 y^*, \xi)_{V^* \times V} \\ &= 2(A_1 y^*, \xi) - 2(f, \xi)_{V^* \times V} + 2(A_2 y^*, \xi)_{V^* \times V} \end{aligned}$$

for any  $\xi \in V$ . Clearly, (4.10) shows that  $y^*$  satisfies (4.1). We thus have proved the following proposition.

**PROPOSITION 4.1.** *Any optimal state of either (4.2), (4.3) or (4.6), (4.7) is a solution to (4.1).*

*Remark.* The control variational method replaces (4.1) by (4.3) (alternatively by (4.7)). Both (4.3) and (4.7) involve just the inversion of  $A_1$ , and no invertibility properties are required for  $A_2$ . That is, one may choose  $A_1$  as the “nice and simple” part of (4.1) and solve (4.1) by inverting  $A_1$  (or  $A_1^{1/2}$ ) several times.

*Remark.* One could apply one of the above abstract approaches directly in section 2 or 3. However, we preferred simple and “adapted” direct approaches in the previous sections, in order to underline the flexibility of the control variational method. Further examples and applications concerning multiscale problems, hyperbolic equations, and singular and degenerate systems are briefly indicated in Tiba [14].

**Acknowledgment.** The authors thank the anonymous reviewers for suggestions that led to an improvement of the presentation.

## POSITIVE FORMS AND STABILITY OF LINEAR TIME-DELAY SYSTEMS\*

MATTHEW M. PEET<sup>†</sup>, ANTONIS PAPACHRISTODOULOU<sup>‡</sup>, AND SANJAY LALL<sup>§</sup>

**Abstract.** We consider the problem of constructing Lyapunov functions for linear differential equations with delays. For such systems it is known that exponential stability implies the existence of a positive Lyapunov function which is quadratic on the space of continuous functions. We give an explicit parameterization of a sequence of finite-dimensional subsets of the cone of positive Lyapunov functions using positive semidefinite matrices. This allows stability analysis of linear time-delay systems to be formulated as a semidefinite program.

**Key words.** Lyapunov stability, delay systems, semidefinite programming

**DOI.** 10.1137/070706999

**1. Summary of the paper.** In this paper we present an approach to the parameterization of Lyapunov functions for infinite-dimensional systems. In particular, we consider linear time-delay systems. These are systems which can be represented in the form

$$\dot{x}(t) = \sum_{i=0}^k A_i x(t - h_i),$$

where  $x(t) \in \mathbb{R}^n$ . In the simplest case we are given the delays  $h_0, \dots, h_k$  and the matrices  $A_0, \dots, A_k$  and we would like to determine whether the system is stable. For such systems it is known that if the system is stable, then there exists a Lyapunov function of the form

$$V(\phi) = \int_{-h}^0 \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix}^T M(s) \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix} ds + \int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt,$$

where  $h = \max\{h_0, \dots, h_k\}$  and  $M$  and  $N$  are piecewise continuous matrix-valued functions. Here  $\phi : [-h, 0] \rightarrow \mathbb{R}^n$  is an element of the state space, which in this case is the space of continuous functions mapping  $[-h, 0]$  to  $\mathbb{R}^n$ . The function  $V$  is thus a quadratic form on the state space. The derivative is also such a quadratic form, and the matrix-valued functions which define it depend linearly on  $M$  and  $N$ .

In this paper we develop an approach which uses semidefinite programming to construct piecewise continuous functions  $M$  and  $N$  such that the function  $V$  is positive and its derivative is negative. Roughly speaking, our contributions are as follows.

*Spacing functions.* In Theorem 5, we show that for any piecewise continuous function  $M$

$$V_1(\phi) = \int_{-h}^0 \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix}^T M(s) \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix} ds$$

is positive for all  $\phi$  if and only if there exists a piecewise continuous matrix-valued function  $T$  such that

$$M(t) + \begin{bmatrix} T(t) & 0 \\ 0 & 0 \end{bmatrix} \geq 0 \quad \text{for all } t,$$

$$\int_{-h}^0 T(t) dt = 0.$$

That is, we convert positivity of the integral to *pointwise* positivity of  $M$ . If we assume that  $M$  is polynomial, then pointwise positivity may be easily enforced, and in the case of positivity on the real line this is equivalent to a sum-of-squares constraint. The assumption that  $M$  is polynomial has recently been shown to be nonconservative. The constraint that  $T$  integrates to zero is a simple linear constraint on the coefficients of  $T$ . Notice that the sufficient condition that  $M(s)$  be pointwise nonnegative is conservative, and as the equivalence above shows it is easy to generate examples where  $V_1$  is nonnegative even though  $M(s)$  is not pointwise nonnegative.

*Positive polynomial kernels.* We give a sum-of-squares characterization of positive polynomial kernels. We consider the quadratic form

$$\int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt.$$

In Theorem 7, we show that the quadratic form is positive if and only if there exists a positive semidefinite matrix  $Q \succeq 0$  such that  $N(s, t) = Z(s)^T Q Z(t)$ , where  $Z$  is a vector of monomials. This condition allows us to test positivity of a polynomial kernel using semidefinite programming and implies the existence of a sum-of-squares-type representation. Note that pointwise positivity of  $N$  is not sufficient for positivity of the functional. The condition that the derivative of the Lyapunov function be negative is similarly enforced.

This paper is organized as follows. We begin with a discussion of the relevant history and prior work. We then give a definition of the system for which we will prove stability and a presentation of the class of Lyapunov functions we will construct. Following this section, we present our first result giving pointwise condition for positivity of the functional. Next, we give a parameterization of piecewise polynomial matrices. We use sum-of-squares techniques to parameterize matrices which are pointwise nonnegative, and we present a new result on the parameterization of kernel matrices which define positive quadratic forms. We then return to the problem of linear time-delay systems to document the derivative of the Lyapunov function along trajectories of the system. Finally, we use this derivative to define a semidefinite program for proving stability of linear time-delay systems.

**2. Background and prior work.** The use of Lyapunov functions on an infinite-dimensional space to analyze differential equations with delay originates with the work of [10]. For linear systems, quadratic Lyapunov functions were first considered by [19].

The book of [4] presents many useful results in this area, and further references may be found there as well as in [5, 9] and [13].

The idea of using semidefinite programming and sum of squares to solve polynomial optimization problems has many sources. Well-known examples include [11, 12] and [16]. Work on this problem continues actively, with recent results to be found in, e.g., [6] and [1].

An early example of using sum-of-squares polynomials together with semidefinite programming to construct polynomial Lyapunov functions for nonlinear ordinary differential equations can be found in [15]. Substantial work has been done in this area, with contributions from, e.g., [23] and [2].

The idea of constructing Lyapunov functions for linear time-delay systems using semidefinite programming is not original or new. A typical approach has been to examine subclasses of functions  $M$  and  $N$ , e.g., constant matrices, piecewise linear functions, etc. In practice, some of these approaches have been shown to be highly accurate.

The motivation for this paper is not exclusively the stability of linear time-delay systems. It is our hope, by investigating properties of a positive form known to be necessary and sufficient for stability of infinite-dimensional systems, and by using polynomial methods, that our results will also be useful in analysis of nonlinear and partial differential systems.

Building on the results of this paper, a treatment of nonquadratic Lyapunov functions for nonlinear time-delay systems appears in [14].

**2.1. Notation.** Let  $\mathbb{N}$  denote the set of nonnegative integers. Let  $\mathbb{S}^n$  be the set of  $n \times n$  real symmetric matrices, and for  $X \in \mathbb{S}^n$  we write  $X \succeq 0$  to mean that  $X$  is positive semidefinite. For two matrices  $A, B$ , we denote the Kronecker product by  $A \otimes B$ . For  $X$  any Banach space and  $I \subset \mathbb{R}$  any interval, let  $\Omega(I, X)$  be the space of all functions

$$\Omega(I, X) = \{f : I \rightarrow X\}$$

and let  $C(I, X)$  be the Banach space of bounded continuous functions

$$C(I, X) = \{f : I \rightarrow X \mid f \text{ is continuous and bounded}\}$$

equipped with the norm

$$\|f\| = \sup_{t \in I} \|f(t)\|_X.$$

We will omit the range space when it is clear from the context; for example we write  $C[a, b]$  to mean  $C([a, b], X)$ . A function is called  $C^n(I, X)$  if the  $i$ th derivative exists and is a continuous function for  $i = 0, \dots, n$ . A function  $f \in C[a, b]$  is called piecewise continuous if there exists a finite number of points  $a < h_1 < \dots < h_k < b$  such that  $f$  is continuous at all  $x \in [a, b] \setminus \{h_1, \dots, h_k\}$  and its right- and left-hand limits exist at  $\{h_1, \dots, h_k\}$ .

Define also the projection  $F_t : \Omega[-h, \infty) \rightarrow \Omega[-h, 0]$  for  $t \geq 0$  and  $h > 0$  by

$$(F_t x)(s) = x(t + s) \quad \text{for all } s \in [-h, 0].$$

We follow the usual convention and denote  $F_t x$  by  $x_t$ .

**3. Linear time-delay systems.** Suppose  $0 = h_0 < h_1 < \cdots < h_k = h$  and  $A_0, \dots, A_k \in \mathbb{R}^{n \times n}$ . We consider linear differential equations with delay, of the form

$$(1) \quad \dot{x}(t) = \sum_{i=0}^k A_i x(t - h_i) \quad \text{for all } t \geq 0,$$

where the trajectory  $x : [-h, \infty) \rightarrow \mathbb{R}^n$ . The boundary conditions are specified by a given function  $\phi : [-h, 0] \rightarrow \mathbb{R}^n$  and the constraint

$$(2) \quad x(t) = \phi(t) \quad \text{for all } t \in [-h, 0].$$

If  $\phi \in C[-h, 0]$ , then there exists a unique function  $x$  satisfying (1) and (2). The system is called *exponentially stable* if there exist  $\sigma > 0$  and  $a \in \mathbb{R}$  such that for every initial condition  $\phi \in C[-h, 0]$  the corresponding solution  $x$  satisfies

$$\|x(t)\| \leq ae^{-\sigma t} \|\phi\| \quad \text{for all } t \geq 0.$$

We write the solution as an explicit function of the initial conditions using the map  $G : C[-h, 0] \rightarrow \Omega[-h, \infty)$ , defined by

$$(G\phi)(t) = x(t) \quad \text{for all } t \geq -h,$$

where  $x$  is the unique solution of (1) and (2) corresponding to initial condition  $\phi$ . Also for  $s \geq 0$  define the *flow map*  $\Gamma_s : C[-h, 0] \rightarrow C[-h, 0]$  by

$$\Gamma_s \phi = F_s G \phi,$$

which maps the state of the system  $x_t$  to the state at a later time  $x_{t+s} = \Gamma_s x_t$ .

**3.1. Lyapunov functions.** Lyapunov theory for infinite-dimensional systems closely parallels that for finite-dimensional systems. The difference is that the state space is now a function space, and therefore Lyapunov functions are actually functions of functions. For linear time-delay systems, the Lyapunov functions we define here are functions of segments of the trajectory and, in particular, of the state  $x_t$ . For a given  $V : C[-h, 0] \rightarrow \mathbb{R}$ , we use the standard notion of the *Lie derivative* or derivative of a function on a vector field. The Lie derivative of  $V$  is defined by the flow map,  $\Gamma$ , as

$$\dot{V}(\phi) = \limsup_{r \rightarrow 0^+} \frac{1}{r} (V(\Gamma_r \phi) - V(\phi)).$$

In keeping with tradition, we will use the notation  $\dot{V}$  to denote the Lie derivative. We will consider the set  $X$  of quadratic functions, where  $V \in X$  if there exist piecewise continuous functions  $M : [-h, 0] \rightarrow \mathbb{S}^{2n}$  and  $N : [-h, 0] \times [-h, 0] \rightarrow \mathbb{R}^{n \times n}$  such that

$$(3) \quad V(\phi) = \int_{-h}^0 \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix}^T M(s) \begin{bmatrix} \phi(0) \\ \phi(s) \end{bmatrix} ds + \int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt.$$

The following result shows that for linear systems with delay the system is exponentially stable if and only if there exists a quadratic Lyapunov function. Define the sets  $H = \{-h_0, \dots, -h_k\}$  and  $H^c = [-h, 0] \setminus H$ .

**THEOREM 1.** *The linear system defined by (1) and (2) is exponentially stable if and only if there exists a Lie-differentiable function  $V \in X$  and  $\varepsilon > 0$  such that for all  $\phi \in C[-h, 0]$*

$$(4) \quad \begin{aligned} V(\phi) &\geq \varepsilon \|\phi(0)\|^2, \\ \dot{V}(\phi) &\leq -\varepsilon \|\phi(0)\|^2. \end{aligned}$$

Further  $V \in X$  may be chosen such that the corresponding functions  $M$  and  $N$  of (3) have the following smoothness property:  $M(s)$  and  $N(s, t)$  are continuous on  $s, t \in [-h, 0] \setminus \{-h_0, \dots, -h_k\}$ .

*Proof.* See [4] or [7] for a recent proof.  $\square$

The consequence of this theorem is that stability of a linear time-delay system is equivalent to the existence of a Lyapunov function which decreases along segments of the trajectory. In the next few sections, we will give results which will allow us to better understand the positivity of the function.

**4. Positivity of integral forms.** The goal of this section is to present results which enable us to characterize functions  $V \in X$  which satisfy the positivity conditions in (4) and have the form

$$V(y) = \int_{-h}^0 \begin{bmatrix} y(0) \\ y(t) \end{bmatrix}^T M(t) \begin{bmatrix} y(0) \\ y(t) \end{bmatrix} dt.$$

Before stating the main result in Theorem 5, we give a few necessary lemmas.

**LEMMA 2.** *Suppose  $f: [-h, 0] \rightarrow \mathbb{R}$  is piecewise continuous. Then the following are equivalent:*

- (i)  $\int_{-h}^0 f(t) dt \geq 0$ .
- (ii) *There exists a function  $g: [-h, 0] \rightarrow \mathbb{R}$  which is piecewise continuous and satisfies*

$$f(t) + g(t) \geq 0 \quad \text{for all } t,$$

$$\int_{-h}^0 g(t) dt = 0.$$

*Proof.* The direction (ii)  $\implies$  (i) is immediate. To show the other direction, suppose (i) holds, and let  $g$  be

$$g(t) = -f(t) + \frac{1}{h} \int_{-h}^0 f(s) ds \quad \text{for all } t.$$

Then  $g$  satisfies (ii).  $\square$

The next lemma shows that minimizing over continuous functions is as good as minimizing over piecewise continuous functions.

**LEMMA 3.** *Suppose  $H = \{-h_0, \dots, -h_k\}$ , and let  $H^c = [-h, 0] \setminus H$ . Let  $f: [-h, 0] \times \mathbb{R}^n \rightarrow \mathbb{R}$  be continuous on  $H^c \times \mathbb{R}^n$ , and suppose there exists a bounded function  $z: [-h, 0] \rightarrow \mathbb{R}$ , continuous on  $H^c$ , such that for all  $t \in [-h, 0]$*

$$f(t, z(t)) = \inf_x f(t, x).$$

Further suppose for each bounded set  $X \subset \mathbb{R}^n$  the set

$$\{f(t, x) \mid x \in X, t \in [-h, 0]\}$$

is bounded. Then

$$(5) \quad \inf_{y \in C[-h,0]} \int_{-h}^0 f(t, y(t)) dt = \int_{-h}^0 \inf_x f(t, x) dt.$$

*Proof.* Let

$$K = \int_{-h}^0 \inf_x f(t, x) dt.$$

It is easy to see that

$$\inf_{y \in C[-h,0]} \int_{-h}^0 f(t, y(t)) dt \geq K$$

since, if not, then there would exist some continuous function  $y$  and some interval on which

$$f(t, y(t)) < \inf_x f(t, x),$$

which is clearly impossible.

We now show that the left-hand side of (5) is also less than or equal to  $K$  and hence equals  $K$ . We need to show that for any  $\varepsilon > 0$  there exists  $y \in C[-h, 0]$  such that

$$\int_{-h}^0 f(t, y(t)) dt < K + \varepsilon.$$

To do this, for each  $n \in \mathbb{N}$  define the set  $H_n \subset \mathbb{R}$  by

$$H_n = \bigcup_{i=1}^{k-1} (h_i - \alpha/n, h_i + \alpha/n)$$

and choose  $\alpha > 0$  sufficiently small so that  $H_1 \subset (-h, 0)$ . Let  $z$  be as in the hypothesis of the lemma, and pick  $M$  and  $R$  so that

$$M > \sup_{t \in [-h, 0]} \|z(t)\|,$$

$$R = \sup\{|f(t, x)| \mid t \in [-h, 0], \|x\| \leq M\}.$$

For each  $n$  choose a continuous function  $x_n : [-h, 0] \rightarrow \mathbb{R}^n$  such that  $x_n(t) = z(t)$  for all  $t \notin H_n$  and

$$\sup_{t \in [-h, 0]} \|x_n(t)\| < M.$$

This is possible, for example, by linear interpolation. Now we have for the continuous function  $x_n$

$$\begin{aligned} \int_{-h}^0 f(t, x_n(t)) dt &= K + \int_{-h}^0 (f(t, x_n(t)) - f(t, z(t))) dt \\ &= K + \int_{H_n} (f(t, x_n(t)) - f(t, z(t))) dt \\ &\leq K + 4R\alpha(k-1)/n. \end{aligned}$$

This proves the desired result.  $\square$

The following lemma states that when the  $\arg \min_z f(t, z)$  is piecewise continuous in  $t$  we have the desired result.

LEMMA 4. Suppose  $f: [-h, 0] \times \mathbb{R}^n \rightarrow \mathbb{R}$  and the hypotheses of Lemma 3 hold. Then the following are equivalent:

(i) For all  $y \in C[-h, 0]$

$$\int_{-h}^0 f(t, y(t)) dt \geq 0.$$

(ii) There exists  $g: [-h, 0] \rightarrow \mathbb{R}$  which is piecewise continuous and satisfies

$$f(t, z) + g(t) \geq 0 \quad \text{for all } t, z,$$

$$\int_{-h}^0 g(t) dt = 0.$$

*Proof.* Again we need only show that (i) implies (ii). Suppose (i) holds; then

$$\inf_{y \in C[-h, 0]} \int_{-h}^0 f(t, y(t)) dt \geq 0,$$

and hence by Lemma 3 we have

$$\int_{-h}^0 r(t) dt \geq 0,$$

where  $r: [-h, 0] \rightarrow \mathbb{R}^n$  is given by

$$r(t) = \inf_x f(t, x) \quad \text{for all } t.$$

The function  $r$  is continuous on  $H^c$  since  $f$  is continuous on  $H^c \times \mathbb{R}^n$ . Hence, by Lemma 2, there exists  $g$  such that condition (ii) holds, as desired.  $\square$

We now specialize the result of Lemma 4 to the case of quadratic functions. It is shown that in this case, under certain conditions, the  $\arg \min_z f(t, z)$  is piecewise continuous.

THEOREM 5. Suppose  $M: [-h, 0] \rightarrow \mathbb{S}^{m+n}$  is piecewise continuous, and there exists  $\varepsilon > 0$  such that for all  $t \in [-h, 0]$  we have

$$M_{22}(t) \geq \varepsilon I,$$

where  $M$  is partitioned as

$$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix}$$

with  $M_{22}: [-h, 0] \rightarrow \mathbb{S}^n$ . Then the following are equivalent:

(i) For all  $x \in \mathbb{R}^m$  and continuous  $y: [-h, 0] \rightarrow \mathbb{R}^n$

$$(6) \quad \int_{-h}^0 \begin{bmatrix} x \\ y(t) \end{bmatrix}^T M(t) \begin{bmatrix} x \\ y(t) \end{bmatrix} dt \geq 0.$$

- (ii) *There exists a function  $T : [-h, 0] \rightarrow \mathbb{S}^m$  which is piecewise continuous and satisfies*

$$M(t) + \begin{bmatrix} T(t) & 0 \\ 0 & 0 \end{bmatrix} \geq 0 \quad \text{for all } t \in [-h, 0],$$

$$\int_{-h}^0 T(t) dt = 0.$$

*Proof.* Again we need only show that (i) implies (ii). Suppose  $x \in \mathbb{R}^n$ , and define

$$f(t, z) = \begin{bmatrix} x \\ z \end{bmatrix}^T M(t) \begin{bmatrix} x \\ z \end{bmatrix} \quad \text{for all } t, z.$$

Since by the hypothesis  $M_{22}$  has a lower bound, it is invertible for all  $t$  and its inverse is piecewise continuous. Therefore  $z(t) = -M_{22}(t)^{-1}M_{21}(t)x$  is the unique minimizer of  $f(t, z)$  with respect to  $z$ . By the hypothesis (i), we have that for all  $y \in C[-h, 0]$

$$\int_{-h}^0 f(t, y(t)) dt \geq 0.$$

Hence by Lemma 4 there exists a function  $g$  such that

$$g(t) + f(t, z) \geq 0 \quad \text{for all } t, z,$$

$$(7) \quad \int_{-h}^0 g(t) dt = 0.$$

The proof of Lemma 2 gives one such function as

$$g(t) = -f(t, z(t)) + \frac{1}{h} \int_{-h}^0 f(s, z(s)) dt.$$

We have

$$f(t, z(t)) = x^T (M_{11}(t) - M_{12}(t)M_{22}^{-1}(t)M_{21}(t))x,$$

and therefore  $g(t)$  is a quadratic function of  $x$ , say  $g(t) = x^T T(t)x$ , and  $T : [-h, 0] \rightarrow \mathbb{S}^m$  is continuous on  $H^c$ . Then (7) implies

$$x^T T(t)x + \begin{bmatrix} x \\ z \end{bmatrix}^T M(t) \begin{bmatrix} x \\ z \end{bmatrix} \geq 0 \quad \text{for all } t, z, x,$$

as required.  $\square$

Notice that the strict positivity assumption on  $M_{22}$  in Theorem 5 is implied by the existence of an  $\epsilon > 0$  such that

$$V(x) \geq \epsilon \|x\|_2^2,$$

where  $\|\cdot\|_2$  denotes the  $L_2$ -norm.

We have now shown that the convex cone of functions  $M$  such that the first term of (3) is nonnegative is exactly equal to the sum of the cone of pointwise nonnegative

functions and the linear space of functions whose integral is zero. The key benefit of this is that it is easy to parameterize the latter class of functions, and in particular when  $M$  is a polynomial these constraints are semidefinite representable constraints on the coefficients of  $M$ . Note that in (6) the vectors  $x$  and  $y$  are allowed to vary independently, whereas (3) requires that  $x = y(0)$ . It is, however, straightforward to show using the technique in the proof of Lemma 3 that this additional constraint does not change the result.

**5. Polynomial matrices and kernels.** In this paper we use piecewise polynomial matrices as a conveniently parameterized class of functions to represent the functions  $M$  and  $N$  defining the Lyapunov function (3) and its derivative. Theorem 5 has reduced nonnegativity of the first term of (3) to pointwise nonnegativity of a piecewise polynomial matrix in one variable.

We first make some definitions which we will use in this paper; some details on polynomial matrices may be found in [21] and [8]. We consider polynomials in  $n$  variables. As is standard, for  $\alpha \in \mathbb{N}^n$  define the monomial in  $n$  variables  $x^\alpha$  by  $x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$ . We say  $M$  is a real polynomial matrix in  $n$  variables if for some finite set  $W \subset \mathbb{N}^n$  we have

$$M(x) = \sum_{\alpha \in W} A_\alpha x^\alpha,$$

where  $A_\alpha$  is a real matrix for each  $\alpha \in W$ . A convenient representation of polynomial matrices is as a quadratic function of monomials. Suppose  $z$  is a vector of monomials in the variables  $x$ , such as

$$z(x) = \begin{bmatrix} 1 \\ x_1 \\ x_1 x_2^2 \\ x_3^4 \end{bmatrix}.$$

For convenience, assume the length of  $z$  is  $d + 1$ . Let  $Q \in \mathbb{S}^{n(d+1)}$  be a symmetric matrix. Then the function  $M$  defined by

$$(8) \quad M(x) = (I_n \otimes z(x))^T Q (I_n \otimes z(x))$$

is an  $n \times n$  symmetric polynomial matrix, and every real symmetric polynomial matrix may be represented in this way for some monomial vector  $z$ . If we partition  $Q$  as

$$Q = \begin{bmatrix} Q_{11} & \cdots & Q_{1n} \\ \vdots & & \vdots \\ Q_{n1} & \cdots & Q_{nn} \end{bmatrix},$$

where each  $Q_{ij} \in \mathbb{R}^{(d+1) \times (d+1)}$ , then the  $i, j$  entry of  $M$  is

$$M_{ij}(x) = z(x)^T Q_{ij} z(x).$$

Given a polynomial matrix  $M$ , it is called a *sum of squares* if there exist a vector of monomials  $z$  and a positive semidefinite matrix  $Q$  such that (8) holds. In this case,

$$M(x) \succeq 0 \quad \text{for all } x,$$

and therefore the existence of such a  $Q$  is a sufficient condition for the polynomial  $M$  to be globally pointwise positive semidefinite. A matrix polynomial in one variable is pointwise nonnegative semidefinite on the real line if and only if it is a sum of squares; see [3]. Given a matrix polynomial  $M(x)$ , we can test whether it is a sum of squares by testing whether there is a matrix  $Q$  such that

$$(9) \quad M(x) = (I_n \otimes z(x))^T Q (I_n \otimes z(x)),$$

$$Q \succeq 0,$$

where  $z$  is the vector of all monomials with degree half the degree of  $M$ . Equation (9) is interpreted as equality of polynomials, and equating their coefficients gives a finite set of linear constraints on the matrix  $Q$ . Therefore to find such a  $Q$  we need to find a positive semidefinite matrix subject to linear constraints, and this is therefore testable via semidefinite programming. See [25] for background on semidefinite programming.

**5.1. Piecewise polynomial matrices.** Define the intervals

$$H_i = \begin{cases} [-h_1, 0] & \text{if } i = 1, \\ [-h_i, -h_{i-1}) & \text{if } i = 2, \dots, k. \end{cases}$$

A matrix-valued function  $M : [-h, 0] \rightarrow \mathbb{S}^n$  is called a *piecewise polynomial matrix* if for each  $i = 1, \dots, k$  the function  $M$  restricted to the interval  $H_i$  is a polynomial matrix. We represent such piecewise polynomial matrices as follows. Define the vector of indicator functions  $g : [-h, 0] \rightarrow \mathbb{R}^k$  by

$$g_i(t) = \begin{cases} 1 & \text{if } t \in H_i, \\ 0 & \text{otherwise} \end{cases}$$

for all  $i = 1, \dots, k$  and all  $t \in [-h, 0]$ . Let  $z(t)$  be the vector of monomials

$$z(t) = \begin{bmatrix} 1 \\ t \\ t^2 \\ \vdots \\ t^d \end{bmatrix}$$

and for convenience also define the function  $Z_{n,d} : [-h, 0] \rightarrow \mathbb{R}^{nk(d+1) \times n}$  by

$$Z_{n,d}(t) = g(t) \otimes I_n \otimes z(t).$$

Then it is straightforward to show that  $M$  is a piecewise matrix polynomial if and only if there exist matrices  $Q_i \in \mathbb{S}^{n(d+1)}$  for  $i = 1, \dots, k$  such that

$$(10) \quad M(t) = Z_{n,d}(t)^T \text{diag}(Q_1, \dots, Q_k) Z_{n,d}(t).$$

The function  $M$  is pointwise positive semidefinite, i.e.,

$$M(t) \succeq 0 \quad \text{for all } t \in [-h, 0],$$

if there exist positive semidefinite matrices  $Q_i$  satisfying (10). We refer to such functions as *piecewise sum-of-squares matrices*, and we define the set of such functions

$$\Sigma_{n,d} = \{ Z_{n,d}^T(t) Q Z_{n,d}(t) \mid Q = \text{diag}(Q_1, \dots, Q_k), Q_i \in \mathbb{S}^{n(d+1)}, Q_i \succeq 0 \}.$$

If we are given a function  $M : [-h, 0] \rightarrow \mathbb{S}^n$  which is piecewise polynomial and want to know whether it is piecewise sum of squares, then this is computationally checkable using semidefinite programming. Naturally, the number of variables involved in this task scales as  $kn^2(d+1)^2$  when the degree of  $M$  is  $2d$ .

**5.2. Piecewise polynomial kernels.** We consider functions  $N$  of two variables  $s, t$  which we will use as a kernel in the quadratic form

$$(11) \quad \int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt$$

which appears in the Lyapunov function (3). A polynomial in two variables is referred to as a *binary* polynomial. A function  $N : [-h, 0] \times [-h, 0] \rightarrow \mathbb{S}^n$  is called a *binary piecewise polynomial matrix* if for each  $i, j \in \{1, \dots, k\}$  the function  $N$  restricted to the set  $H_i \times H_j$  is a binary polynomial matrix. It is straightforward to show that  $N$  is a symmetric binary piecewise polynomial matrix if and only if there exists a matrix  $Q \in \mathbb{S}^{nk(d+1)}$  such that

$$N(s, t) = Z_{n,d}^T(s) Q Z_{n,d}(t).$$

Here  $d$  is the degree of  $N$ , and recall that

$$Z_{n,d}(t) = g(t) \otimes I_n \otimes z(t).$$

We now proceed to characterize the binary piecewise polynomial matrices  $N$  for which the quadratic form (11) is nonnegative for all  $\phi \in C([-h, 0], \mathbb{R}^n)$ . We first state the following lemma.

LEMMA 6. *Suppose  $z$  is the vector of monomials*

$$z(t) = \begin{bmatrix} 1 \\ t \\ t^2 \\ \vdots \\ t^d \end{bmatrix}$$

*and the linear map  $A : C[0, 1] \rightarrow \mathbb{R}^{d+1}$  is given by*

$$A\phi = \int_0^1 z(t)\phi(t) dt.$$

*Then  $\text{rank } A = d + 1$ .*

*Proof.* Suppose for the sake of a contradiction that  $\text{rank } A < d + 1$ . Then  $\text{range } A$  is a strict subset of  $\mathbb{R}^{d+1}$ , and hence there exists a nonzero vector  $q \in \mathbb{R}^{d+1}$  such that  $q \perp \text{range } A$ . This means

$$\int_0^1 q^T z(t)\phi(t) dt = 0$$

for all  $\phi \in C[0, 1]$ . Since  $q^T z$  and  $\phi$  are continuous functions, define the function  $v : [0, 1] \rightarrow \mathbb{R}$  by

$$v(t) = \int_0^t q^T z(s) ds \quad \text{for all } t \in [0, 1].$$

Since  $v$  is absolutely continuous, we have for every  $\phi \in C[0, 1]$  that

$$\begin{aligned} \int_0^1 \phi(t) dv(t) &= \int_0^1 q^T z(t) \phi(t) dt \\ &= 0, \end{aligned}$$

where the integral on the left-hand side of the above equation is the Stieltjes integral. The function  $v$  is also of bounded variation, since its derivative is bounded. The Riesz representation theorem [20] implies that if  $v$  is of bounded variation and

$$\int_0^1 \phi(t) dv(t) = 0$$

for all  $\phi \in C[0, 1]$ , then  $v$  is constant on an everywhere dense subset of  $(0, 1)$ . Since  $v$  is continuous, we have that  $v$  is constant, and therefore  $q^T z(t) = 0$  for all  $t$ . Since  $q^T z$  is a polynomial, this contradicts the statement that  $q \neq 0$ .  $\square$

We now state the positivity result.

**THEOREM 7.** *Suppose  $N$  is a symmetric binary piecewise polynomial matrix of degree  $d$ . Then*

$$(12) \quad \int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt \geq 0$$

for all  $\phi \in C([-h, 0], \mathbb{R}^n)$  if and only if there exists  $Q \in \mathbb{S}^{nk(d+1)}$  such that

$$N(s, t) = Z_{n,d}^T(s) Q Z_{n,d}(t),$$

$$Q \succeq 0.$$

*Proof.* We need only show the *only if* direction. Suppose  $N$  is a symmetric binary piecewise polynomial matrix. Let  $d$  be the degree of  $N$ . Then there exists a symmetric matrix  $Q$  such that

$$N(s, t) = Z_{n,d}^T(s) Q Z_{n,d}(t).$$

Now suppose that the inequality (12) is satisfied for all continuous functions  $\phi$ . We will show that every such  $Q$  is positive semidefinite. To see this, define the linear map  $J : C([-h, 0], \mathbb{R}^n) \rightarrow \mathbb{R}^{nk(d+1)}$  by

$$J\phi = \int_{-h}^0 (g(t) \otimes I_n \otimes z(t)) \phi(t) dt.$$

Then

$$\int_{-h}^0 \int_{-h}^0 \phi(s)^T N(s, t) \phi(t) ds dt = (J\phi)^T Q (J\phi).$$

The result we desire holds if  $\text{rank } J = nk(d+1)$ , since in this case  $\text{range } J = \mathbb{R}^{nk(d+1)}$ . If  $Q$  has a negative eigenvalue with corresponding eigenvector  $q$ , then there exists  $\phi$  such that  $q = J\phi$  so that the quadratic form will be negative, contradicting the hypothesis.

To see that  $\text{rank } J = nk(d+1)$ , define for each  $i = 1, \dots, k$  the linear map  $L_i : C[H_i] \rightarrow \mathbb{R}^n$  by

$$L_i \phi = \int_{H_i} z(t) \phi(t) dt.$$

If we choose coordinates for  $\phi$  such that

$$\phi = \begin{bmatrix} \phi|_{H_1} \\ \phi|_{H_2} \\ \vdots \\ \phi|_{H_k} \end{bmatrix},$$

where  $\phi|_{H_j}$  is the restriction of  $\phi$  to the interval  $H_j$ , then we have in these coordinates that  $J$  is

$$J = \text{diag}(L_1, \dots, L_k) \otimes I_n.$$

Further, by Lemma 6 the maps  $L_i$  each satisfy  $\text{rank } L_i = d+1$ . Therefore  $\text{rank } J = nk(d+1)$ , as desired.  $\square$

The following corollary gives a tighter degree bound on the representation of  $N$ .

**COROLLARY 8.** *Let  $N$  be a binary piecewise polynomial matrix of degree  $2d$  which is positive in the sense of (12); then there exists  $Q \in \mathbb{S}^{nk(d+1)}$  such that*

$$N(s, t) = Z_{n,d}^T(s) Q Z_{n,d}(t),$$

$$Q \succeq 0.$$

*Proof.* The binary representation used in Theorem 7 had the form

$$N(s, t) = Z_{n,2d}^T(s) P Z_{n,2d}(t),$$

$$P \succeq 0,$$

where  $P \in \mathbb{S}^{nk(2d+1)}$ . However, in any such representation, it is clear that  $P_{ij,ij} = 0$  for  $i = d+2, \dots, 2d+1$  and  $j = 1, \dots, kn$ . Therefore, since  $P \succeq 0$ , these rows and columns are 0 and can be removed. Define  $Q$  to be the reduction of  $P$ .  $Z_{n,d}$  is the corresponding reduction of  $Z_{n,2d}$ . Then  $Q \in \mathbb{S}^{nk(d+1)}$ ,  $Q \succeq 0$ , and

$$N(s, t) = Z_{n,2d}^T(s) P Z_{n,2d}(t) = Z_{n,d}^T(s) Q Z_{n,d}(t). \quad \square$$

For convenience, we define the set of symmetric binary piecewise polynomial matrices which define positive quadratic forms by

$$\Gamma_{n,d} = \{ Z_{n,d}^T(s) Q Z_{n,d}(t) \mid Q \in \mathbb{S}^{nk(d+1)}, Q \succeq 0 \}.$$

As for  $\Sigma_{n,d}$ , if we are given a binary piecewise polynomial matrix  $N : [-h, 0] \times [-h, 0] \rightarrow \mathbb{S}^n$  of degree  $2d$  and want to know whether it defines a positive quadratic form, then this is computationally checkable using semidefinite programming. The number of variables involved in this task scales as  $(nk)^2(d+1)^2$ .

**6. Derivatives of the Lyapunov function.** In this section we will take the opportunity to define the relationship between the functions  $M$  and  $N$ , which define the Lyapunov function  $V$ , and the functions  $D$  and  $E$ , which define the derivative of the Lyapunov function along trajectories of the system. As the results are well known, we will not give detailed derivations for these derivatives. More expository explanations can be found in, e.g., [4] or [13].

**6.1. Single delay case.** We first present the single delay case, as it will illustrate the formulation in the more complicated case of several delays. Suppose that  $V \in X$  is given by (3), where  $M : [-h, 0] \rightarrow \mathbb{S}^{2n}$  and  $N : [-h, 0] \times [-h, 0] \rightarrow \mathbb{R}^{n \times n}$ . Since there is only one delay, if the system is exponentially stable, then there always exists a Lyapunov function of this form with continuous functions  $M$  and  $N$ . Then the Lie derivative of  $V$  is

$$\dot{V}(\phi) = \int_{-h}^0 \begin{bmatrix} \phi(0) \\ \phi(-h) \\ \phi(s) \end{bmatrix}^T D(s) \begin{bmatrix} \phi(0) \\ \phi(-h) \\ \phi(s) \end{bmatrix} ds + \int_{-h}^0 \int_{-h}^0 \phi(s)^T E(s, t) \phi(t) ds dt.$$

Partition  $D$  and  $M$  as

$$M(t) = \begin{bmatrix} M_{11} & M_{12}(t) \\ M_{21}(t) & M_{22}(t) \end{bmatrix}, \quad D(t) = \begin{bmatrix} D_{11} & D_{12}(t) \\ D_{21}(t) & D_{22}(t) \end{bmatrix}$$

so that  $M_{11} \in \mathbb{S}^n$  and  $D_{11} \in \mathbb{S}^{2n}$ . Without loss of generality we have assumed that  $M_{11}$  and  $D_{11}$  are constant. The functions  $D$  and  $E$  are linearly related to  $M$  and  $N$  by

$$\begin{aligned} D_{11} &= \begin{bmatrix} A_0^T M_{11} + M_{11} A_0 & M_{11} A_1 \\ A_1^T M_{11} & 0 \end{bmatrix} \\ &\quad + \frac{1}{h} \begin{bmatrix} M_{12}(0) + M_{21}(0) & -M_{12}(-h) \\ -M_{21}(-h) & 0 \end{bmatrix} \\ &\quad + \frac{1}{h} \begin{bmatrix} M_{22}(0) & 0 \\ 0 & -M_{22}(-h) \end{bmatrix}, \\ D_{12}(t) &= \begin{bmatrix} A_0^T M_{12}(t) - \dot{M}_{12}(t) + N(0, t) \\ A_1^T M_{12}(t) - N(-h, t) \end{bmatrix}, \\ D_{22}(t) &= -\dot{M}_{22}(t), \\ E(s, t) &= \frac{\partial N(s, t)}{\partial s} + \frac{\partial N(s, t)}{\partial t}. \end{aligned}$$

**6.2. Multiple-delay case.** Recall that we define the intervals

$$H_i = \begin{cases} [-h_1, 0] & \text{if } i = 1, \\ [-h_i, -h_{i-1}) & \text{if } i = 2, \dots, k. \end{cases}$$

We first give the complete class of functions which define the Lyapunov function,  $V$ , and its derivative:

$$\begin{aligned}
 Y_1 = \Big\{ & M : [-h, 0] \rightarrow \mathbb{S}^{2n} \mid \\
 & M_{11}(t) \text{ is constant} && \text{for all } t \in [-h, 0], \\
 & M \text{ is } C^1 \text{ on } H_i && \text{for all } i = 1, \dots, k \Big\}, \\
 Y_2 = \Big\{ & N : [-h, 0] \times [-h, 0] \rightarrow \mathbb{S}^n \mid \\
 & N(s, t) = N(t, s)^T && \text{for all } s, t \in [-h, 0], \\
 & N \text{ is } C^1 \text{ on } H_i \times H_j && \text{for all } i, j = 1, \dots, k \Big\},
 \end{aligned}$$

and, for its derivative, define

$$\begin{aligned}
 Z_1 = \Big\{ & D : [-h, 0] \rightarrow \mathbb{S}^{(k+2)n} \mid \\
 & D_{ij}(t) \text{ is constant} && \text{for all } t \in [-h, 0] \\
 & && \text{for } i, j = 1, \dots, 3, \\
 & D \text{ is } C^0 \text{ on } H_i && \text{for all } i = 1, \dots, k \Big\}, \\
 Z_2 = \Big\{ & E : [-h, 0] \times [-h, 0] \rightarrow \mathbb{S}^n \mid \\
 & E(s, t) = E(t, s)^T && \text{for all } s, t \in [-h, 0], \\
 & E \text{ is } C^0 \text{ on } H_i \times H_j && \text{for all } i, j = 1, \dots, k \Big\}.
 \end{aligned}$$

Here  $M \in Y_1$  is partitioned according to

$$(13) \quad M(t) = \begin{bmatrix} M_{11} & M_{12}(t) \\ M_{21}(t) & M_{22}(t) \end{bmatrix},$$

where  $M_{11} \in \mathbb{S}^n$  and  $D \in Z_1$  are partitioned according to

$$(14) \quad D(t) = \begin{bmatrix} D_{11} & D_{12} & D_{13} & D_{14}(t) \\ D_{21} & D_{22} & D_{23} & D_{24}(t) \\ D_{31} & D_{32} & D_{33} & D_{34}(t) \\ D_{41}(t) & D_{42}(t) & D_{43}(t) & D_{44}(t) \end{bmatrix},$$

where  $D_{11}, D_{33}, D_{44} \in \mathbb{S}^n$  and  $D_{22} \in \mathbb{S}^{(k-1)n}$ . Let  $Y = Y_1 \times Y_2$  and  $Z = Z_1 \times Z_2$ . Notice that if  $M \in Y_1$ , then  $M$  need not be continuous at  $h_i$  for  $1 \leq i \leq k-1$ ; however, we require it to be right continuous at these points. We also define the derivative  $\dot{M}(t)$  at these points to be the right-hand derivative of  $M$ . We define the continuity and derivatives of functions in  $Y_2, Z_1$ , and  $Z_2$  similarly.

We define the jump values of  $M$  and  $N$  at the discontinuities as follows:

$$\Delta M(h_i) = \lim_{t \rightarrow (-h_i)_+} M(t) - \lim_{t \rightarrow (-h_i)_-} M(t)$$

for each  $i = 1, \dots, k - 1$ , and similarly we define

$$\Delta N(h_i, t) = \lim_{s \rightarrow (-h_i)_+} N(s, t) - \lim_{s \rightarrow (-h_i)_-} N(s, t).$$

The derivative of a Lyapunov function can be defined as a linear map  $Y \mapsto Z$ . This is made explicit in the following definition.

DEFINITION 9. Define the map  $L : Y \rightarrow Z$  by  $(D, E) = L(M, N)$  if for all  $t, s \in [-h, 0]$  we have

$$\begin{aligned} D_{11} &= A_0^T M_{11} + M_{11} A_0 \\ &\quad + \frac{1}{h} (M_{12}(0) + M_{21}(0) + M_{22}(0)), \\ D_{12} &= [M_{11} A_1 \quad \cdots \quad M_{11} A_{k-1}] \\ &\quad - [\Delta M_{12}(h_1) \quad \cdots \quad \Delta M_{12}(h_{k-1})], \\ D_{13} &= \frac{1}{h} (M_{11} A_k - M_{12}(-h)), \\ D_{22} &= \frac{1}{h} \operatorname{diag}(-\Delta M_{22}(h_1), \dots, -\Delta M_{22}(h_{k-1})), \\ D_{23} &= 0, \\ D_{33} &= -\frac{1}{h} M_{22}(-h), \\ D_{14}(t) &= N(0, t) + A_0^T M_{12}(t) - \dot{M}_{12}(t), \\ D_{24}(t) &= \begin{bmatrix} \Delta N(-h_1, t) + A_1^T M_{12}(t) \\ \vdots \\ \Delta N(-h_{k-1}, t) + A_{k-1}^T M_{12}(t) \end{bmatrix}, \\ D_{34}(t) &= A_k^T M_{12}(t) - N(-h, t), \\ D_{44}(t) &= -\dot{M}_{22}(t) \end{aligned}$$

and

$$E(s, t) = \frac{\partial N(s, t)}{\partial s} + \frac{\partial N(s, t)}{\partial t}.$$

Here  $M$  is partitioned as in (13),  $D$  is partitioned as in (14), and the remaining entries are defined by symmetry.

The map  $L$  is the Lie derivative operator applied to the set of functions specified by (3); this is stated precisely below. Notice that this implies that  $L$  is a linear map.

LEMMA 10. Suppose  $M \in Y_1$  and  $N \in Y_2$  and  $V$  is given by (3). Let  $(D, E) = L(M, N)$ . Then the Lie derivative of  $V$  on the vector field of (1) is given by

$$(15) \quad \dot{V}(\phi) = \int_{-h}^0 \begin{bmatrix} \phi(-h_0) \\ \vdots \\ \phi(-h_k) \\ \phi(s) \end{bmatrix}^T D(s) \begin{bmatrix} \phi(-h_0) \\ \vdots \\ \phi(-h_k) \\ \phi(s) \end{bmatrix} ds + \int_{-h}^0 \int_{-h}^0 \phi(s)^T E(s, t) \phi(t) ds dt.$$

**7. Stability conditions.** We can now use the results of the paper and the linear map from Definition 9 to give stability conditions.

THEOREM 11. Suppose there exist  $d \in \mathbb{N}$  and piecewise matrix polynomials  $M, T, N, D, U, E$  such that

$$\begin{aligned} M + \begin{bmatrix} T & 0 \\ 0 & 0 \end{bmatrix} &\in \Sigma_{2n,d}, \\ -D + \begin{bmatrix} U & 0 \\ 0 & 0 \end{bmatrix} &\in \Sigma_{(k+2)n,d}, \\ N &\in \Gamma_{n,d}, \\ -E &\in \Gamma_{n,d}, \\ (D, E) &= L(M, N), \\ \int_{-h}^0 T(s) ds &= 0, \\ \int_{-h}^0 U(s) ds &= 0, \\ M_{11} &\succ 0, \\ D_{11} &\prec 0. \end{aligned}$$

Then the system defined by (1) and (2) is exponentially stable.

*Proof.* Assume  $M, T, N, D, U, E$  satisfy the above conditions, and define the function  $V$  by (3). Then Lemma 10 implies that  $\dot{V}$  is given by (15). The function  $V$  is the sum of two terms, each of which is nonnegative. The first is nonnegative by Theorem 5, and the second is nonnegative since  $N \in \Gamma_{n,d}$ . The same is true for  $\dot{V}$ . The strict positivity conditions of equations (4) hold since  $M_{11} \succ 0$  and  $-D_{11} \succ 0$ , and Theorem 1 then implies stability.  $\square$

The feasibility conditions specified in Theorem 11 are semidefinite representable. In particular the condition that a piecewise polynomial matrix lie in  $\Sigma$  is a set of linear and positive semidefinite constraints on its coefficients. Similarly, the condition that  $T$  and  $U$  integrate to zero is simply a linear equality constraint on its coefficients. Standard semidefinite programming codes may therefore be used to efficiently find such piecewise polynomial matrices. Most such codes will also return a dual certificate of infeasibility if no such polynomials exist.

As in the Lyapunov analysis of nonlinear systems using sum-of-squares polynomials, the set of candidate Lyapunov functions is parameterized by the degree  $d$ . This allows one to search first over polynomials of low degree and increase the degree if that search fails.

There are various natural extensions of this result. The first is to the case of uncertain systems, where we would like to prove stability for all matrices  $A_i$  in some given semialgebraic set. This is possible by extending Theorem 11 to allow Lyapunov functions which depend polynomially on unknown parameters. A similar approach may be used to check stability for systems with uncertain delays. Additionally, stability of systems with distributed delays defined by polynomial kernels can be verified. It is also straightforward to extend the class of Lyapunov functions, since it is not necessary that each piece of the piecewise sums-of-squares functions be nonnegative on the whole real line. To do this, one can use techniques for parameterizing polynomials nonnegative on an interval; for example, every polynomial  $p(x) = f(x) - (x-1)(x-2)g(x)$  where  $f$  and  $g$  are sums of squares is nonnegative on the interval  $[1, 2]$ .

**8. Numerical examples.** In this section we present the results of some example computations using the approach described above. The computations were performed using MATLAB software, together with the SOSTOOLS [18] toolbox and SeDuMi [22] code for solving semidefinite programming problems.

**8.1. Illustration.** Consider the process of proving stability using the results of this paper. The following system has well-known stability properties:

$$(16) \quad \dot{x}(t) = -x(t-1).$$

A MATLAB implementation of the algorithm in this paper has been developed and is available online, along with several tools for polynomial matrix manipulation [17]. This implementation returns the following Lyapunov function for system (16). For symmetric matrices, subdiagonal elements are suppressed:

$$V(x) = \int_{-1}^0 \begin{bmatrix} x(0) \\ x(s) \end{bmatrix}^T M(s) \begin{bmatrix} x(0) \\ x(s) \end{bmatrix} ds + \int_{-1}^0 \int_{-1}^0 x(s)^T R(s, t) x(t) ds dt,$$

where

$$M(s) = \begin{bmatrix} 27.3 & -16.8 + 2.74s \\ & 24.3 + 8.53s \end{bmatrix}$$

and

$$R(s, t) = 9.08.$$

Positivity is proven using the function

$$t(s) = -.915 + 1.83s$$

and the sum-of-squares functions

$$Q(s) = \begin{bmatrix} 13 & -3.3 \\ & 12.2 \end{bmatrix} \geq 0$$

and

$$V(s) = Z(s)^T L Z(s),$$

where

$$Z(s) = \begin{bmatrix} 1 & s & 0 & 0 \\ 0 & 0 & 1 & s \end{bmatrix}^T$$

and

$$L = \begin{bmatrix} 28.215 & 5.585 & -16.8 & -1.973 \\ & 13 & 1.413 & -3.3 \\ & & 24.3 & 10.365 \\ & & & 12.2 \end{bmatrix} \geq 0.$$

This is because  $-s(s+1) \geq 0$  for  $s \in [-1, 0]$  and

$$M(s) + \begin{bmatrix} t(s) & 0 \\ 0 & 0 \end{bmatrix} = -s(s+1)Q(s) + V(s).$$

Furthermore,

$$R(s) = 9.08 \geq 0.$$

Therefore, by Theorems 11 and 5, the Lyapunov function is positive.

The derivative of the function is given by

$$\dot{V}(x) = \int_{-1}^0 \begin{bmatrix} x(0) \\ x(-1) \\ x(s) \end{bmatrix}^T D(s) \begin{bmatrix} x(0) \\ x(-1) \\ x(s) \end{bmatrix} ds,$$

where

$$-D(s) = \begin{bmatrix} 9.3 & 7.76 & -6.34 \\ & 15.77 & -7.72 + 2.74s \\ & & 8.53 \end{bmatrix}.$$

Negativity of the function is proven using the function

$$U(s) = \begin{bmatrix} .0055 + .011s & -.272 - .544s \\ & -.458 - .916s \end{bmatrix},$$

where

$$\int_{-1}^0 U(s) ds = 0,$$

and the sum-of-squares functions

$$X(s) = \begin{bmatrix} 8.86 & 1.90 & -3.23 \\ & 11.54 & -3.71 \\ & & 7.74 \end{bmatrix}$$

and

$$Y(s) = Z(s)^T L Z(s),$$

where

$$Z(s) = \begin{bmatrix} 1 & s & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & s & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & s \end{bmatrix}^T$$

and

$$L = \begin{bmatrix} 9.3 & 4.43 & 7.76 & .61896 & -6.34 & -1.0371 \\ & 8.86 & 1.281 & 1.9 & -2.1929 & -3.23 \\ & & 15.77 & 5.77 & -7.72 & .01171 \\ & & & 11.54 & -.98171 & -3.71 \\ & & & & 8.53 & 3.87 \\ & & & & & 7.74 \end{bmatrix} \geq 0.$$

Negativity follows since

$$-D(s) + \begin{bmatrix} U(s) & 0 \\ 0 & 0 \end{bmatrix} = -s(s + 1)X(s) + Y(s).$$

Therefore, by Theorem 11, the derivative of the Lyapunov function is negative. Stability follows by Theorem 1.

**8.2. A single delay.** We consider the following instance of a system with a single delay:

$$\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ -2 & 0.1 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} x(t - h).$$

For a given  $h$ , we use semidefinite programming to search for a Lyapunov function of degree  $d$  that proves stability. Using a bisection search over  $h$ , we determine the maximum and minimum  $h$  for which the system may be shown to be stable. These are shown below.

$d$	$h_{\min}$	$h_{\max}$
1	.10017	1.6249
2	.10017	1.7172
3	.10017	1.71785

When the degree  $d = 3$ , the bounds  $h_{\min}$  and  $h_{\max}$  are tight [4]. For comparison, we include here the bounds obtained by Gu, Kharitonov, and Chen [4] using a piecewise linear Lyapunov function with  $n$  segments.

$n$	$h_{\min}$	$h_{\max}$
1	.1006	1.4272
2	.1003	1.6921
3	.1003	1.7161

**8.3. Multiple delays.** Consider the system with two delays below:

$$\dot{x}(t) = \begin{bmatrix} 0 & 1 \\ -1 & \frac{1}{10} \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\ -1 & 0 \end{bmatrix} x(t - \frac{h}{2}) + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} x(t - h).$$

As above, using a bisection search over  $h$ , we prove stability for the range of  $h$  below.

$d$	$h_{\min}$	$h_{\max}$
1	.20247	1.354
2	.20247	1.3722

Here for degree  $d = 2$ , the bounds obtained are tight. Again we include here bounds obtained by Gu, Kharitonov, and Chen [4] using a piecewise linear Lyapunov function with  $n$  segments.

$n$	$h_{\min}$	$h_{\max}$
1	.204	1.35
2	.203	1.372

**9. Summary.** In this paper we developed an approach for computing Lyapunov functions for linear systems with delay. In general this is a difficult computational problem, and certain specific classes of this problem are known to be NP-hard [24]. However, the set of Lyapunov functions is convex, and this enables us to effectively test feasibility of a subset of this set. Specifically, we parameterize a convex set of positive quadratic functions using the set of polynomials as a basis, and the main results here are Theorems 5 and 7. Combining these results with the well-known approach using sum-of-squares polynomials allows one to use standard semidefinite programming software to compute Lyapunov functions. This gives a nested sequence of computable sufficient conditions for stability of linear delay systems, indexed by the degree of the polynomial. In principle this enables searching over increasing degrees to find a Lyapunov function, although further work is needed to enhance existing semidefinite programming codes to make this more efficient in practice.

It is possible that Theorems 5 and 7 are applicable more widely, specifically to stability analysis of nonlinear and partial differential systems, as well as to controller synthesis. One specific extension that is possible is analysis of delay systems with uncertain parameters, for which sufficient conditions for existence of a Lyapunov function may be given using convex relaxations. It is also possible to analyze stability of nonlinear delay systems, in the case that the dynamics are defined by polynomial delay differential equations. Preliminary work has also been done on stability analysis of certain types of partial differential equations. Further extensions to allow synthesis of stabilizing controllers are of interest and may be possible.

## STABILITY AND ASYMPTOTIC OPTIMALITY OF GENERALIZED MAXWEIGHT POLICIES\*

SEAN MEYN†

**Abstract.** It is shown that stability of the celebrated MaxWeight or back pressure policies is a consequence of the following interpretation: either policy is myopic with respect to a surrogate value function of a very special form, in which the “marginal disutility” at a buffer vanishes for a vanishingly small buffer population. This observation motivates the *h*-MaxWeight policy, defined for a wide class of functions *h*. These policies share many of the attractive properties of the MaxWeight policy as follows: (i) Arrival rate data is not required in the policy. (ii) Under a variety of general conditions, the policy is stabilizing when *h* is a perturbation of a monotone linear function, a monotone quadratic, or a monotone Lyapunov function for the fluid model. (iii) A perturbation of the relative value function for a workload relaxation gives rise to a myopic policy that is approximately average-cost optimal in heavy traffic, with logarithmic regret. The first results are obtained for a general Markovian network model. Asymptotic optimality is established for a general Markovian scheduling model with a single bottleneck, and with homogeneous servers.

**Key words.** queueing networks, routing, scheduling, optimal control

**DOI.** 10.1137/06067746X

**1. Introduction.** While it is popular to cite the curse of dimensionality when discussing optimization of stochastic networks, there are many classes of effective policies that are easily implemented, require limited information, and have other attractive properties. A well-known example is the MaxWeight policy of Tassiulas and Ephremides [53]. This policy can be interpreted as a myopic policy for the associated fluid model with respect to a quadratic function,

$$(1) \quad h(x) = \frac{1}{2}x^T D x, \quad x \in \mathbb{R}^\ell,$$

with  $D > 0$  a diagonal matrix. Stability theory for this and similar classes of policies has been extended in multiple directions over the past 15 years [20, 52, 48, 17, 13], and in particular these policies are known to be approximately optimal in heavy traffic under certain conditions on the network; see [55, 49, 33] and the recent comprehensive results by Dai and Lin [14].

These results are fragile: Diagonal quadratics are one of a very few function classes for which the myopic policy is known to be stabilizing for general classes of network models. In contrast, stability of the fluid model under a myopic policy is virtually universal [10, 7, 35].

It is important to find broader classes of stabilizing policies for complex networks. It is known that the MaxWeight policy can perform poorly since it makes use of so little information [50].

To explain the gap between the stochastic and deterministic models, we consider some simple, well-known examples. The stochastic model favored in this paper is the controlled random walk (CRW) model in which the queue length process  $\mathbf{Q}$  evolves on  $\mathbb{Z}_+^\ell$  in discrete time according to the recursion,

$$(2) \quad Q(t+1) = Q(t) + B(t+1)U(t) + A(t+1), \quad t \geq 0, \quad Q(0) = x.$$

The allocation sequence  $\mathbf{U}$  evolves on  $\mathbb{Z}_+^{\ell_u}$  for some integer  $\ell_u$ ; the arrival sequence  $\mathbf{A}$  is  $\ell$ -dimensional, and  $\mathbf{B}$  is an  $\ell \times \ell_u$  matrix sequence; and each sequence has integer-valued entries.

The allocation sequence  $\mathbf{U}$  is subject to both integral and linear constraints of the form  $U(t) \in \mathbf{U}_\diamond$ ,  $t \geq 0$ , where

$$(3) \quad \mathbf{U}_\diamond := \{u \in \{0, 1\}^{\ell_u} : Cu \leq \mathbf{1}\}.$$

The  $\ell_m \times \ell_u$  matrix  $C$  is called the constituency matrix: Each of the rows of  $C$  corresponds to a “resource” in the network. Its entries are assumed to be binary.

The CRW model is a generalization of the network model of Lippman obtained via uniformization [31]. Versions of this model appear throughout the communications and operations research literature, and in particular appear in the paper [53] that introduced the MaxWeight policy.

The fluid model  $\mathbf{q} = \{q(t) : t \geq 0\}$  satisfies the linear equations

$$(4) \quad q(t) = x + Bz(t) + \alpha t, \quad t \geq 0,$$

where  $x \in \mathbb{R}_+^\ell$  is the initial condition,  $B$  and  $\alpha$  are the mean values of  $B(t)$  and  $A(t)$ , respectively, and  $\mathbf{z}$  is the cumulative allocation process evolving on  $\mathbb{R}_+^{\ell_u}$ . The constraints on  $\mathbf{z}$  are analogous to those on  $\mathbf{U}$ . We let  $\mathbf{U}$  denote the convex hull  $\mathbf{U} := \text{conv}(\mathbf{U}_\diamond)$  and assume that for each  $0 \leq t_0 < t_1$ ,

$$\frac{z(t_1) - z(t_0)}{t_1 - t_0} \in \mathbf{U}.$$

The fluid model (4) is also expressed as the ODE model,

$$(5) \quad \frac{d^+}{dt} q(t) = B\zeta(t) + \alpha, \quad t \geq 0,$$

where  $\zeta(t) \in \mathbf{U}$  denotes the allocation rate vector at time  $t$ , and the “+” denotes right derivative.

Suppose that  $h: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+$  is any  $C^1$  function that vanishes only at the origin. The *h-myopic policy* is defined for the fluid and stochastic models by the respective feedback laws,

$$(6) \quad \phi^F(x) = \arg \min_{\zeta \in \mathbf{U}(x)} \langle \nabla h(x), B\zeta + \alpha \rangle,$$

$$(7) \quad \phi^D(x) = \arg \min_{u \in \mathbf{U}_\diamond(x)} \mathbb{E}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x, U(t) = u],$$

where the “(x)” is used to capture boundary constraints,

$$(8) \quad \begin{aligned} \mathbf{U}_\diamond(x) &= \{u \in \mathbf{U} : (B(t)u)_i \geq 0 \text{ a.s. when } x_i = 0\}, \\ \mathbf{U}(x) &= \{u \in \mathbf{U} : v_i := (Bu + \alpha)_i \geq 0 \text{ when } x_i = 0\}. \end{aligned}$$

The MaxWeight policy coincides with the  $h$ -myopic policy for the fluid model when  $h$  is equal to the quadratic (1). This motivates an alternative policy for the stochastic model, the  $h$ -MaxWeight policy,

$$(9) \quad \phi^{\text{MW}}(x) = \arg \min_{u \in U_o(x)} \langle \nabla h(x), Bu + \alpha \rangle, \quad x \in \mathbb{Z}_+^\ell.$$

Note that  $\phi^{\text{MW}} = \phi^{\text{D}}$  when  $h$  is a linear function of  $x$ .

The policy (6) is stabilizing for the fluid model under mild assumptions on the function  $h$  (see [10] and [7, Thm. 12.5] for linear functions and [35, Proposition 11] for a smooth norm on  $\mathbb{R}^\ell$ ). The proof is based on establishing that the “drift” defined by

$$(10) \quad \frac{d^+}{dt} h(q(t)) = \left\langle \nabla h(q(t)), \frac{d^+}{dt} q(t) \right\rangle, \quad t \geq 0,$$

is strictly negative when  $q(t) \neq 0$ .

The  $h$ -myopic policy (7) for the stochastic model may or may not be stabilizing, depending upon the particular network and the structure of the function  $h$ . One difficulty is that the corresponding drift for the stochastic model,

$$(11) \quad \mathbb{E}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x, U(t) = u],$$

can be positive for certain values of  $x$  on the boundary of the state space. This important distinction between the two models is illustrated in the following two examples.

*Instability in the model of Rybko and Stolyar.* Consider the model of Kumar, Seidman, Rybko, and Stolyar shown in Figure 1 [27, 47]. A typical choice for  $h$  is a cost function  $c$ , and a typical cost function in network applications is the  $\ell_1$  norm,  $c(x) = |x| = \sum x_i$ . With  $h = c$ , the myopic policy for the fluid model gives priority to the exit buffers if no machine is starved of work. Suppose that the parameters satisfy

$$(12) \quad \mu_1 > \mu_2 \text{ and } \mu_3 > \mu_4.$$

If, for example,  $x_1 > 0$  and  $x_4 > 0$ , yet  $x_2 = x_3 = 0$ , we then have

$$\phi_1^{\text{F}}(x) = \mu_2 \mu_1^{-1}, \quad \phi_4^{\text{F}}(x) = 1 - \phi_1^{\text{F}}(x).$$

The  $h$ -myopic policy for the stochastic model is very different: The optimization (7) defines  $\phi_4^{\text{F}}(x) = 1$  if  $x_4 \geq 1$ , and  $\phi_2^{\text{F}}(x) = 1$  if  $x_2 \geq 1$ . This is precisely the policy found to be destabilizing in [47].

*Work stoppage under a myopic policy.* The  $h$ -myopic policy may be entirely irrational. Consider the pair of queues in tandem illustrated in Figure 2. Suppose that a linear cost function is given  $c(x) = c_1 x_1 + c_2 x_2$ , with  $c_2 > c_1$ . The  $h$ -myopic policy for the fluid model with  $h = c$  is nonidling at Station 2, while at Station 1,

$$(13) \quad \phi_1^{\text{F}}(x) = \begin{cases} 0 & \text{if } x_2 > 0, \\ \min(1, \mu_2 \mu_1^{-1}) & \text{if } x_2 = 0, x_1 > 0. \end{cases}$$

The  $h$ -myopic policy is pathwise optimal when  $\mu_1 \geq \mu_2$ .

FIG. 1. The Kumar–Seidman–Rybko–Stolyar model.

FIG. 2. *Tandem queues.*

For a CRW model defined consistently with the fluid model, we have for  $x \in \mathbb{Z}_+^2$ ,

$$\begin{aligned} \phi^{\text{MW}}(x) &= \phi^{\text{D}}(x) = \arg \min_{u \in \mathcal{U}_\diamond(x)} \mathbb{E}[c(Q(t+1)) \mid Q(t) = x, U(t) = u] \\ &= \arg \min_{u \in \mathcal{U}_\diamond(x)} (c_1(\alpha_1 - \mu_1 u_1) + c_2(\mu_1 u_1 - \mu_2 u_2)). \end{aligned}$$

At Station 2 this policy is nonidling, while at Station 1,

$$\phi_1^{\text{MW}}(x) = \arg \min_{u \in \mathcal{U}_\diamond(x)} ((c_2 - c_1)\mu_1 u_1).$$

That is, Station 1 is *always idle* under our assumption that  $c_2 > c_1$ !

Instability is a consequence of *additional constraints in the stochastic model*. The choices are limited in the CRW model, so from certain states on the boundary it is not possible to find an allocation  $u$  such that the drift in (11) is negative. Why then is this possible when  $h$  is a diagonal quadratic?

We show in this paper that the key property that is required is the derivative condition,

$$(14) \quad \frac{\partial}{\partial x_j} h(x) = 0 \quad \text{when } x_j = 0.$$

For a quadratic we have  $\nabla h(x) = Dx$ , and hence (14) does hold when  $D$  is diagonal. With  $h$  interpreted as an approximate value function, the derivative  $\frac{\partial}{\partial x_j} h(x)$  represents the “marginal disutility” of an additional increment of inventory at buffer  $j$ . If this marginal disutility is zero, then it is reasonable to shift inventory to this buffer when possible. Thus starvation of resources is avoided, which is the cause of instability in these two examples.

In this paper we make these informal observations precise. Moreover, to obtain a wide class of policies we describe a perturbation technique used to modify a given function so that (14) holds. Suppose that  $c$  is a norm on  $\mathbb{R}^\ell$ , such as  $c(x) = \sum |x_i|$ , and that  $h_0: \mathbb{R}^\ell \rightarrow \mathbb{R}_+$  is any  $C^1$  function that satisfies the dynamic programming *inequality* for the fluid model,

$$(15) \quad \min_{u \in \mathcal{U}(x)} \langle \nabla h_0(x), Bu + \alpha \rangle \leq -c(x), \quad x \in \mathbb{R}_+^\ell.$$

With  $\phi^{\text{F}}$  defined in (6) using  $h_0$ , and  $v := B\phi^{\text{F}}(x) + \alpha$ , the bound (15) is equivalent to the functional inequality  $\langle \nabla h_0, v \rangle \leq -c$ .

For example, if  $\|\cdot\|_h$  is any norm on  $\mathbb{R}^\ell$  that is monotone and  $C^1$  on  $\mathbb{R}_+^\ell$ , then (15) holds with  $h_0(x) = \frac{1}{2}\|x\|_h^2$  and  $c(\cdot) = \varepsilon_0\|\cdot\|_h$  for some  $\varepsilon_0 > 0$ . Another solution to the dynamic programming inequality is the quadratic (1), in which  $D$  is not necessarily diagonal but satisfies  $D_{ij} \geq 0$  and  $D_{ii} > 0$  for each  $i, j$ . In some cases a fluid value function is piecewise quadratic,  $C^1$ , and satisfies (15) with equality. An example is contained in section 2.2.2.

A perturbation of  $h_0$  is obtained through a change of variables: For fixed  $\theta \geq 1$ , we denote

$$(16) \quad \tilde{x}_i := x_i + \theta(e^{-x_i/\theta} - 1) \quad \text{for any } i \text{ and } x$$

and let  $\tilde{x}$  denote the corresponding vector  $\tilde{x} := (\tilde{x}_1, \dots, \tilde{x}_\ell)^\top \in \mathbb{R}_+^\ell$ . The function  $h$  is then defined by

$$(17) \quad h(x) = h_0(\tilde{x}), \quad x \in \mathbb{R}_+^\ell.$$

An application of the chain rule shows that (14) holds. The first main result of this paper is based on this observation.

**THEOREM 1.1.** *Consider the model (2) satisfying the following conditions:*

(i) *The independent and identically distributed (i.i.d.) process  $(\mathbf{A}, \mathbf{B})$  has integer entries, and a finite second moment.*

(ii)  *$B_{ij}(t) \geq -1$  for each  $i, j$ , and  $t$ , and for each  $j \in \{1, \dots, \ell_u\}$  there exists a unique value  $i_j \in \{1, \dots, \ell\}$  satisfying*

$$(18) \quad B_{ij}(t) \geq 0 \quad \text{a.s. } i \neq i_j.$$

(iii) *The function  $h_0: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+$  satisfies the following:*

(a) *Smoothness: The gradient  $\nabla h_0$  is Lipschitz continuous.*

(b) *Monotonicity:  $\nabla h_0(x) \in \mathbb{R}_+^\ell$  for  $x \in \mathbb{R}_+^\ell$ .*

(c) *The dynamic programming inequality (15) holds, with  $c$  a norm on  $\mathbb{R}^\ell$ .*

*Then, there exists  $\theta_0 < \infty$  and  $\bar{\eta}_h < \infty$  such that for any  $\theta \geq \theta_0$ , the following bound holds under the  $h$ -MaxWeight policy:*

$$(19) \quad \mathbb{E}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x] \leq -\frac{1}{2}c(x) + \frac{1}{2}\bar{\eta}_h.$$

*Consequently,*

$$(20) \quad n^{-1}\mathbb{E}\left[\sum_{t=0}^{n-1} c(Q(t)) \mid Q(t) = x\right] \leq 2n^{-1}h(x) + \bar{\eta}_h, \quad n \geq 1, \quad x \in \mathbb{Z}_+^\ell.$$

*Proof.* This is based on results obtained in section 2.2.2: Combining the bounds obtained in Lemmas 2.10 and 2.11 gives, under the  $h$ -MaxWeight policy, for each  $x \in \mathbb{Z}_+^\ell$ ,

$$\mathbb{E}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x] \leq -c(x) + k_{2,10} \log(1 + \|x\|) + k_{2,11}(1 + \theta^{-1}\|x\|),$$

where the constants are independent of  $\theta$ . Choosing  $\theta > 2k_{2,11}$ , we obtain the bound (19).

Equation (20) then follows from the comparison theorem, Theorem 2.2.  $\square$

Assumption (ii) implies that the matrix  $-B(t)$  is *Leontief* with probability one for each  $t$ , and that its expectation  $-B = -\mathbb{E}[B(t)]$  is also Leontief. Bramson and Williams [6] call a network *unitary* if assumption (ii) holds and, in addition, the rows of  $C$  are orthogonal (interpreted as the absence of “simultaneous resource possession”). Relaxations of assumption (ii) that imply stability of the MaxWeight policy are contained in [13, 14] (called *maximum pressure policies* in these papers).

For networks that are unitary, the  $h$ -MaxWeight policy has a simple representation in terms of the *generalized Klimov indices*,

$$(21) \quad \Theta_j(x) := -\sum_i B_{ij} \frac{\partial}{\partial x_i} h(x), \quad x \in \mathbb{Z}_+^\ell, \quad j \in \{1, \dots, \ell_u\}.$$

For a unitary model, for any  $j$  we denote by  $s(j) \in \{1, \dots, \ell_m\}$  the unique value of  $s$  satisfying  $C_{s,j} = 1$ .

PROPOSITION 1.2. *Suppose that the CRW model is unitary. Suppose, moreover, that  $h$  is  $C^1$ , monotone, and satisfies the boundary conditions (14). Then, the  $h$ -MaxWeight policy can be described as follows: For each  $s \in \{1, \dots, \ell_m\}$  and  $x \in \mathbb{Z}_+^\ell$ , denote  $\Theta_s^*(x) := \max\{\Theta_j(x) : s(j) = s\}$ . If  $\Theta_s^* < 0$ , then  $U_j(t) = 0$  whenever  $s(j) = s$ . Otherwise, priority is giving to buffers that achieve the maximum,*

$$\sum \{U_j(t) : s(j) = s, \Theta_j(x) = \Theta_s^*\} = 1.$$

*Proof.* For a unitary model, the optimization (9) decouples into  $\ell_m$  separate optimization problems, each with a single linear constraint obtained from the respective row of  $C$ . The proof is completed on noting that  $-\Theta_j$  is the coefficient of  $u_j$  in the objective function of (9).  $\square$

A drawback to Theorem 1.1 is that stability holds only for  $\theta > 0$  sufficiently large. Section 2.3 considers the alternative change of variables  $\tilde{x}_i := x_i \log(1 + x_i/\theta)$ ,  $i = 1, \dots, \ell$ . Theorem 2.14 shows that the resulting  $h$ -MaxWeight policy is stabilizing, for any fixed  $\theta > 0$ , in the sense that a version of (19) holds.

The inequality (19) is a *Lyapunov drift condition* of the form developed in [41, 18] and is also similar to the bounds used in [11, 4, 28, 26, 44] to obtain performance bounds for networks. Under natural assumptions on the model, the bound (19) implies that the controlled network is geometrically ergodic, so that the mean  $\mathbb{E}[c(Q(t))]$  converges to its steady-state value geometrically fast from each initial condition [41, 43, 40, 26, 35, 19]. Proposition 2.9 below contains sufficient conditions for geometric ergodicity for a particular version of the  $h$ -MaxWeight policy.

In section 3 we move to an asymptotic, heavy-traffic setting to obtain finer performance bounds. Dai and Lin's recent paper [14] contains a comprehensive survey on the theory of networks in heavy traffic. While the results in section 3 use language and some results from the heavy-traffic literature, the goals and conclusions are very different from those of [14] or any other papers from this literature.

A heavy-traffic analysis is based on the construction of a one-dimensional parameterized family of networks with increasing load. Let  $\kappa > 0$  denote the parameter, and assume that the load increases to one as  $\kappa \rightarrow \infty$ . Letting  $Q^\kappa(t; x)$  denote the queue-length process for the  $\kappa$ th network at time  $t$  with initial condition  $x$ , a “central limit” scaling is applied,

$$(22) \quad Q^{\kappa, \kappa}(t; x) = \frac{1}{\kappa} Q^\kappa(\kappa^2 t; \kappa x).$$

This is defined for all  $t \in \mathbb{R}_+$  via linear interpolation.

In virtually all of the asymptotic results contained in the literature it is assumed that there is a single bottleneck in heavy traffic or, more generally, *complete resource pooling* [2, 49, 33, 1, 14]. Let  $\xi \in \mathbb{R}^\ell$  denote the corresponding workload vector, and assume its entries are nonnegative. Then the workload process  $\widehat{W}^\kappa(t; x) = \xi^T Q^\kappa(t; x)$  evolves on  $\mathbb{R}_+$  and can be compared to a minimal workload process  $\widehat{W}^\kappa(t; x)$ . Section 3 restricts to a simplified setting in which a realization of the minimal process evolves as a simple queue,

$$(23) \quad \widehat{W}^\kappa(t+1) = \widehat{W}^\kappa(t) - S_1(t+1)\mathbb{1}\{\widehat{W}^\kappa(t) \geq 1\} + L_1(t+1), \quad t \geq 0,$$

where  $(S_1, L_1)$  is i.i.d. on  $\mathbb{Z}_+^2$ , and  $S_1$  is Bernoulli (see (83)). The load is given by  $\rho_\bullet = \mathbb{E}[L_1(t)]/\mathbb{E}[S_1(t)]$ .

For a convex cost function  $c: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+$ , the *effective cost*  $\bar{c}: \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is the value of the convex program,

$$(24) \quad \begin{aligned} \bar{c}(w) &= \min_x c(x) \\ \text{s.t.} \quad &\xi^\top x = w, \quad x \in \mathbb{R}_+^\ell. \end{aligned}$$

A sequence of policies is declared to have *heavy-traffic asymptotical optimality* (HTAO) if the following properties are verified.

**State space collapse.** For each  $t$ , the scaled queue-length process has asymptotically minimal cost, subject to its workload, in the sense that

$$\lim_{\kappa \rightarrow \infty} (c(Q^{\kappa, \kappa}(t; x)) - \bar{c}(W^{\kappa, \kappa}(t; x))) = 0,$$

where the convergence is in probability. This is called state space collapse because typically it implies that the queue-length processes converge to a one-dimensional subspace,

$$(25) \quad \lim_{\kappa \rightarrow \infty} \|Q^{\kappa, \kappa}(t; x) - \mathcal{X}^*(Q^{\kappa, \kappa}(t; x))\| = 0,$$

where  $\mathcal{X}^*$  denotes the projection. The vector  $\mathcal{X}^*(Q)$  is known as the *effective state* corresponding to  $Q$  (see (84)).

**Asymptotic minimality.** The scaled workload process  $W^{\kappa, \kappa}(t; x)$  and the scaled minimal workload process  $\widehat{W}^{\kappa, \kappa}(t; x)$ , defined as in (22), each converges in distribution to a reflected Brownian motion (RBM) with common drift and covariance.

A uniform version of HTAO is formulated in [36]. The paper considers multiclass networks with multiple bottlenecks and renewal inputs. Under the assumption that the effective cost is a monotone function of  $w$ , among other assumptions, the following uniform asymptotic bounds are obtained for a proposed policy: For any other policy, letting  $Q^{\kappa'}$  denote the resulting state process,

$$(26) \quad \begin{aligned} \frac{1}{T} \int_0^T c(Q^{\kappa}(t; x)) dt &\leq \frac{1}{T} \int_0^T c(Q^{\kappa'}(t; x)) dt + O(\log((1 - \rho_\bullet)^{-1})), \\ 0 \leq T &\leq \frac{1}{(1 - \rho_\bullet)^3}. \end{aligned}$$

The policies considered in [36] are based on those of [32], which are generalizations of the policy introduced in [2] for a particular example.

HTAO for MaxWeight and certain generalizations is established in the aforementioned papers [55, 49, 33, 14]. However, state space collapse for the MaxWeight policy is obtained with respect to an implicitly defined cost function [49]. In [14] an approximation is obtained: For a given linear cost function, the projection  $\mathcal{X}^*$  is of the form

$$\mathcal{X}^*(x) = (\xi^\top x) \frac{c_{i^*}}{\xi_{i^*}} \mathbf{1}^{i^*},$$

where  $i^* \in \arg \min \{c_i / \xi_i\}$ , and  $\mathbf{1}^i$  denotes the  $i$ th basis element in  $\mathbb{R}^\ell$ . For each  $\varepsilon > 0$ , the authors construct a version of the MaxWeight policy satisfying

$$(27) \quad \lim_{\kappa \rightarrow \infty} \mathbb{P}\{\|Q^{\kappa, \kappa}(t; x) - \mathcal{X}^*(Q^{\kappa, \kappa}(t; x))\| > \varepsilon \|Q^{\kappa, \kappa}(t; x)\|\} = 0.$$

The present paper is concerned with steady-state performance. The average cost is denoted

$$(28) \quad \eta = \lim_{T \rightarrow \infty} \frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E}[c(Q(t; x))],$$

where the limit is independent of  $x$  under the assumptions imposed in the main results. Note that HTAO as formulated above does not imply that the performance measured by average cost is approximately optimal, or even that  $\eta$  is finite. HTAO *suggests* a bound of the form

$$(29) \quad \eta \leq \hat{\eta}^* + o(\hat{\eta}^*),$$

where  $\hat{\eta}^* = \mathbb{E}[\bar{c}(\widehat{W}^\kappa(t))]$ ,  $\bar{c}$  denotes the effective cost, and the expectation is in steady state. This heuristic has been established rigorously only in special cases, based on the assumption of weak convergence of the scaled workload processes.

Suppose that the scaled workload processes converge in distribution to an RBM,

$$\widehat{W}^{\kappa, \kappa}(t; x) \xrightarrow{w} \widehat{W}^\infty(t; x), \quad \kappa \rightarrow \infty.$$

If, moreover, the scaled steady-state means are convergent,  $\mathbb{E}[\bar{c}(\widehat{W}^{\kappa, \kappa}(t; x))] \rightarrow \hat{\eta}^\infty = \mathbb{E}[\bar{c}(\widehat{W}^\infty(t))]$ ,  $\kappa \rightarrow \infty$ , then we can then reinterpret (29) as the limit

$$(30) \quad \lim_{\kappa \rightarrow \infty} \mathbb{E}[c(Q^{\kappa, \kappa}(t; x))] = \hat{\eta}^\infty,$$

where the expectations are all in steady state. The approximation (30) has been established for the single queue in the pioneering work of Kingman [24, 25], and for generalized Jackson networks by Gamarnik and Zeevi [19, Corollary 2, p. 73]. Stolyar conjectures in [49] that the invariant distributions for  $Q^{\kappa, \kappa}$  will converge weakly under the MaxWeight policy, provided there is complete resource pooling. This, together with uniform integrability, would imply the limit (30).

The limit (27) also suggests an asymptotic bound of the form

$$\eta \leq \hat{\eta}^* + O(\varepsilon \hat{\eta}^*),$$

but no such result is established in [14] or elsewhere.

Section 3 treats HTAO in an average-cost sense. The main result establishes *logarithmic regret*: For some fixed constant  $k_0 < \infty$ , independent of load,

$$(31) \quad \hat{\eta}^* \leq \eta \leq \hat{\eta}^* + k_0 \log(\hat{\eta}^*).$$

This is a significant refinement of (29) since  $\hat{\eta}^* \rightarrow \infty$  as the network load approaches unity. HTAO of the form (31) was obtained for the first time in [37] in several examples based on Lyapunov techniques similar to those used in this paper. The main idea is to take the optimal value function for the fluid model and introduce a penalty function to account for possible starvation when the state reaches the boundary of  $\mathbb{R}_+^\ell$ . In each example considered, a single policy is proposed that is independent of network load and is based on a switching curve with logarithmic growth. For example, for the tandem queues, the policy has the form

$$(32) \quad \text{serve buffer 1 if } x_2 \leq \beta \log(1 + x_1/\beta),$$

where  $\beta > 0$  is a sufficiently large constant.

The approach used in section 3 is similar: The function  $h_0$  is chosen as an approximation to a fluid value function. Rather than a penalty function, the change of variables (17) is used to construct a stabilizing  $h$ -MaxWeight policy and, under stronger conditions, HTAO with logarithmic regret.

The development is greatly simplified by imposing further structure on the model. The following assumptions are imposed in Theorem 3.1, the main result of section 3 that establishes logarithmic regret.

(HTAO 1). The network is described by a scheduling model with deterministic routing: For each  $i \in \{1, \dots, \ell\}$ , after processing at buffer  $i$  a customer either enters some buffer  $i_+ \in \{1, \dots, \ell\}$  or exits the system. The *routing matrix*  $R$  is the  $\ell \times \ell$  matrix defined for  $i, j \in \{1, \dots, \ell\}$  as  $R_{ij} = \mathbb{1}_{j=i_+}$ . The routing matrix satisfies  $R^\ell = 0_{\ell \times \ell}$ ; this ensures that each customer receives at most  $\ell$  services during its lifetime in the network. The CRW scheduling model is described by the recursion

$$(33) \quad Q(t+1) = Q(t) + \sum_{i=1}^{\ell} M_i(t+1)[-1^i + 1^{i_+}]U_i(t) + A(t+1), \quad Q(0) = x,$$

where  $M_i$  is a Bernoulli sequence for each  $i$ . The vector  $1^{i_+}$  is taken to be zero if customers exit the system following service at buffer  $i$ .

(HTAO 2). The network is of a generalized “Kelly type” in which service statistics are determined by the station, not the buffer. For each  $s \in \{1, \dots, \ell_m\}$ , Station  $s$  is said to be *homogeneous* if the random variables  $\{M_j(t) : s(j) = s\}$  are all identical. It is assumed that the network is homogeneous, meaning that each station satisfies this condition.

(HTAO 3). The cost function is linear.

(HTAO 4). There is a single bottleneck in heavy traffic, and the convex program (24) that defines the effective cost is assumed to possess a unique maximizer for each  $w \in \mathbb{R}_+$ .

We believe that many of these assumptions are nonessential. Potential extensions are surveyed in section 4.

The CRW scheduling model (33) is of the form (2) with

$$B(t) = -[I - R^T]M(t), \quad t \geq 1.$$

The Leontief condition (18) follows from the assumptions on  $M$  and  $R$ , where  $i_j = j$  for each  $j \in \{1, \dots, \ell\}$ . The vector load  $\rho \in \mathbb{R}_+^{\ell_m}$  is given by

$$(34) \quad \rho = CM^{-1}[I - R^T]^{-1}\alpha,$$

where  $M$  is a diagonal matrix, equal to the common mean of  $M(t)$ . The network load is the maximum,  $\rho_\bullet = \max_{1 \leq i \leq \ell} \rho_i$ .

Homogeneity is used to construct a one-dimensional workload relaxation satisfying the recursion (23). A one-dimensional workload process  $W$  corresponding to the most heavily loaded station is compared to its (minimal) relaxation  $\widehat{W}^*$ . For each  $t \geq 0$ , the lower bound holds with probability one,

$$(35) \quad W(t) \geq \widehat{W}^*(t), \quad t \geq 0,$$

under *any* policy for  $Q$ . This simplifies a proof of logarithmic regret since a lower bound on performance is explicit,  $\widehat{\eta}^* = \mathbb{E}[\widehat{c}(\widehat{W}^*(t))]$ .

A relaxation of the form (23) was introduced in the thesis of Laws [30] to obtain performance bounds (see also [29, 45]). Relaxations of this form and multidimensional extensions for the purposes of control synthesis and performance approximation are the subject of [9, 37, 23, 39].

Two significant contributions in the present paper are worth highlighting as follows:

(i) In each example considered in [37] the policy was explicitly constructed based on switching curves of the form (32). This requires considerable intuition for more complex models. In our two main results, Theorem 1.1 and Theorem 3.1, the policy is derived from the given value function via the minimization (9).

(ii) This is the first paper to give a completely general approach to HTAO for average cost, and in particular bounds of the form (31) for a general class of models.

The remainder of the paper is organized as follows. Section 2 concerns stability of  $h$ -MaxWeight policies. Asymptotic optimality is treated in section 3; Theorem 3.1 establishes a bound of the form (31) for a family of models with increasing load. Section 4 contains conclusions and possible extensions.

**2. MaxWeight policies.** In this section we consider the general CRW model (2) under the assumptions of Theorem 1.1: The sequence  $\{A(t), B(t)\}$  is i.i.d. with a finite second moment, and (18) holds for  $B(t)$ . This is a very general model, detailed as follows:

(i) Controlled routing from buffer  $i$  is modeled by allowing  $i_j = i$  for more than one  $j \in \{1, \dots, \ell_u\}$ . Then,  $U_j(t) = 1$  indicates that a customer at buffer  $i$  is routed to buffer  $i_j^+$ .

(ii) It is straightforward to model a flexible server, as found in the processor sharing models of [21, 22]; optimal policies for the fluid and CRW models are described in [35, p. 760] for a simple example.

(iii) Assembly-disassembly systems can be modeled. For example, following service completion at buffer  $i_j$ , a customer can spawn several new jobs. This is modeled by defining positive values of  $B_{ij}(t)$  for several values of  $i \neq i_j$ .

(iv) On interpreting an arrival as an increment of demand, the CRW model (2) can be used to model inventory systems. In this setting, an entry of  $U(t)$  can model an order for new raw material [8].

All of the policies considered in this paper are stationary and deterministic: For the CRW model it is assumed that there is a function  $\phi: \mathbb{Z}_+^\ell \rightarrow \mathcal{U}_\diamond$  such that

$$(36) \quad U(t) = \phi(Q(t)), \quad t \geq 0.$$

Hence  $\mathbf{Q}$  is a time-homogeneous Markov chain on  $\mathbb{Z}_+^\ell$ , with transition matrix denoted  $P$ . That is, for each  $x, y \in \mathbb{Z}_+^\ell$  and  $t \geq 0$ ,

$$P(x, y) = \mathbb{P}\{Q(t+1) = y \mid Q(t) = x\} = \mathbb{P}\{x + B(1)\phi(x) + A(1) = y\}.$$

For any function  $g: \mathbb{R}^\ell \rightarrow \mathbb{R}$ , the *generator*  $\mathcal{D}$  is defined as the difference operator,

$$\mathcal{D}g(x) := \mathbb{E}[g(Q(t+1)) - g(Q(t)) \mid Q(t) = x] = \sum_{y \in \mathbb{Z}_+^\ell} P(x, y)[g(y) - g(x)].$$

The analysis of the  $h$ -MaxWeight policy is based on bounds on the drift  $\mathcal{D}h$  for the stochastic model. The construction of these bounds is based on an analysis of the corresponding drift  $\langle B\phi^{\text{MW}}(x) + \alpha, \nabla h(x) \rangle$  for the fluid model. The first step is an

application of the mean value theorem, which implies the following representation for any  $Q(t) \in \mathbb{Z}_+^\ell$  and any  $t \geq 0$ :

$$(37) \quad \begin{aligned} h(Q(t+1)) - h(Q(t)) &= \langle \nabla h(\bar{Q}), \Delta(t+1) \rangle \\ &= \langle \nabla h(Q(t)), \Delta(t+1) \rangle \\ &\quad + \langle \nabla h(\bar{Q}) - \nabla h(Q(t)), \Delta(t+1) \rangle, \end{aligned}$$

where  $\Delta(t+1) := Q(t+1) - Q(t)$ , and  $\bar{Q} \in \mathbb{R}_+^\ell$  lies on the line connecting  $Q(t+1)$  and  $Q(t)$ . Consequently,

$$(38) \quad \mathcal{D}h(x) = \langle \nabla h(x), v \rangle + b_h,$$

where

$$(39) \quad v(x) = \mathbb{E}[\Delta(t+1) \mid Q(t) = x], \quad b_h(x) = \mathbb{E}[\langle \nabla h(\bar{Q}) - \nabla h(Q(t)), \Delta(t+1) \rangle \mid Q(t) = x].$$

To deduce stability based on (38) we obtain a bound on  $\langle \nabla h(x), v \rangle$  under the given policy. We then show that the second term  $b_h(x)$  is relatively small in magnitude.

We begin with a review of some Lyapunov theory for Markov and fluid models.

**2.1. Stochastic stability.** When does a stabilizing policy exist for a network model? How do we test for stability? To answer these questions we consider first the fluid model.

Denote the velocity set for the fluid model by

$$(40) \quad \mathbf{V} := \{v = B\zeta + \alpha : \zeta \in \mathbf{U}\}.$$

In the general setting of this section, the “load condition”  $\rho_\bullet < 1$  translates into the following:

$$(41) \quad \text{The origin is an interior point of } \mathbf{V}.$$

If (41) holds, then there exists  $\varepsilon > 0$  such that the vector  $v^x = -\varepsilon x/|x|$  lies in  $\mathbf{V}$  for each  $x \in \mathbb{R}_+^\ell$ . Setting  $\zeta = v^x$  from the initial condition  $q(0) = x$ , we have  $q(t) = q(0) - (\varepsilon/|x|)t$  for  $0 \leq t \leq |x|/\varepsilon$ . For a given policy for the fluid model, such as (7), we consider the value function,

$$(42) \quad J(x) = \int_0^\infty c(q(t; x)) dt.$$

We let  $J^*$  denote the minimum of (42) over all policies. Setting  $h = J$  in (6), we obtain the drift inequality,

$$\min_{u \in \mathbf{U}(x)} \langle \nabla J(x), Bu + \alpha \rangle \leq -c(x), \quad x \in \mathbb{R}_+^\ell,$$

and this inequality is an equality when  $J = J^*$ . We thereby obtain another class of functions that satisfy the dynamic programming inequality (15). The fluid value function is typically  $C^1$  in workload models [38].

We now turn to the CRW model. The general form of the Lyapunov condition considered here is condition (V3), or the special case known as Foster’s criterion [41]. All forms involve bounds on the generator applied to a function  $V: \mathbb{Z}_+^\ell \rightarrow \mathbb{R}_+$ .

(i) The controlled network satisfies *Foster's criterion* if there is a constant  $b < \infty$  and a finite set  $S \subset \mathbb{Z}_+^\ell$  such that

$$(V2) \quad \mathcal{D}V(x) \leq -1 + b\mathbb{1}_S(x), \quad x \in \mathbb{Z}_+^\ell.$$

(ii) The network satisfies condition (V3) if for a function  $f: \mathbb{Z}_+^\ell \rightarrow [1, \infty)$ ,

$$(V3) \quad \mathcal{D}V(x) \leq -f(x) + b\mathbb{1}_S(x), \quad x \in \mathbb{Z}_+^\ell,$$

where again  $b < \infty$  and  $S \subset \mathbb{Z}_+^\ell$  is a finite set.

We have the following simple but useful result relating the policies  $\phi^{\text{MW}}$  and  $\phi^{\text{D}}$ .

**PROPOSITION 2.1.** *Suppose that (V3) holds under the  $h$ -MaxWeight policy with  $V$  a constant multiple of  $h$ . Then the same bound holds for the  $h$ -myopic policy.*

*Proof.* If  $V = kh$  for some  $k < \infty$ , then we have under the  $h$ -myopic policy,

$$\begin{aligned} P_{\phi^{\text{D}}}V(x) &= k \arg \min_{u \in \mathcal{U}_\circ(x)} \mathbb{E}[h(Q(t+1)) \mid Q(t) = x, U(t) = u] \\ &\leq k\mathbb{E}[h(Q(t+1)) \mid Q(t) = x, U(t) = \phi^{\text{MW}}(x)] \\ &= P_{\phi^{\text{MW}}}V(x) \leq V(x) - f(x) + b\mathbb{1}_S(x). \quad \square \end{aligned}$$

The most common approach to establishing (V3) is to construct a function  $h: \mathbb{Z}_+^\ell \rightarrow (0, \infty)$  and a constant  $\bar{\eta} < \infty$  that solve the *Poisson inequality*,

$$(43) \quad \mathcal{D}h \leq -c + \bar{\eta}.$$

If  $c$  has bounded sublevel sets (e.g.,  $c$  defines a norm on  $\mathbb{R}^\ell$ ), then this implies (V3) with  $V = h$ ,  $f = 1 + c/2$ ,  $b = \bar{\eta} + 1$ , and  $S$  is the sublevel set  $S = \{x : c(x) \leq 2(\bar{\eta} + 1)\}$ . The comparison theorem implies that the steady-state mean of  $c$  is bounded by  $\bar{\eta}$  when (43) holds. Theorem 2.2 is also the most common approach to obtaining bounds on expectations involving stopping times. For a proof see [41].

**THEOREM 2.2** (comparison theorem). *Suppose that the nonnegative functions  $V, f, g$  satisfy the bound,*

$$(44) \quad \mathcal{D}V \leq -f + g.$$

*Then for each  $x \in \mathbb{Z}_+^\ell$  and any stopping time  $\tau$ , we have*

$$\mathbb{E}_x \left[ \sum_{t=0}^{\tau-1} f(Q(t)) \right] \leq V(x) + \mathbb{E}_x \left[ \sum_{t=0}^{\tau-1} g(Q(t)) \right].$$

The average cost is finite under (V3), provided  $f$  dominates the cost function. The following result follows from Theorems 14.0.1 and 17.0.1 of [41]. A sufficient condition for 0-irreducibility is given in Proposition 3.2.

**THEOREM 2.3.** *Consider the CRW model (2) controlled using a stationary policy. Suppose that there exists a solution to (V3) satisfying  $k_0^{-1}\|x\| \leq c(x) \leq k_0 f(x)$  for some  $k_0 < \infty$  and all  $x \in \mathbb{Z}_+^\ell$ . Suppose, moreover, that the controlled network is 0-irreducible: For each  $x \in \mathbb{Z}_+^\ell$ ,*

$$(45) \quad \sum_{t=0}^{\infty} \mathbb{P}\{Q(t) = \mathbf{0} \mid Q(0) = x\} > 0,$$

*and  $P(\mathbf{0}, \mathbf{0}) = \mathbb{P}\{A(t) = \mathbf{0}\} > 0$ . Then the following hold:*

(i)  $\mathbf{Q}$  is an aperiodic Markov chain with unique invariant measure  $\pi$ . The average cost defined in (28) is finite, is independent of initial condition, and coincides with the mean with respect to  $\pi$ :

$$\eta = \pi(c) := \sum \pi(x)c(x).$$

(ii) The law of large numbers holds: For each initial condition,

$$\eta(n) := n^{-1} \sum_{t=0}^{n-1} c(Q(t)) \rightarrow \eta, \quad n \rightarrow \infty \text{ a.s.}$$

(iii) The mean ergodic theorem holds: For each initial condition,

$$\mathbb{E}[c(Q(t))] \rightarrow \eta, \quad t \rightarrow \infty.$$

The simplest example is the CRW model for the single server queue defined by the recursion

$$(46) \quad Q(t+1) = Q(t) - S(t+1)U(t) + A(t+1), \quad t \in \mathbb{Z}_+,$$

with given initial condition  $Q(0) = x \in \mathbb{Z}_+$ . A solution to Poisson's inequality (43) is obtained with  $c(x) \equiv x$  and  $V = J^*$ , where the fluid value function is quadratic,

$$(47) \quad J^*(x) = \frac{1}{2} \frac{x^2}{\mu - \alpha}.$$

Theorem 2.4 establishes formulae for the steady-state mean as well as the associated solution to Poisson's equation with  $c$  the identity function ( $c(x) = x$  for  $x \in \mathbb{R}_+$ ),

$$(48) \quad \mathcal{D}h(x) = -x + \eta, \quad x \in \mathbb{Z}_+.$$

The formula (50) for the steady-state mean may be viewed as an analogue of the celebrated Pollaczek-Khintchine formula for the M/G/1 queue. The proof is based on refinements of the comparison theorem applied to the function  $V = J^*$  [37, 39].

THEOREM 2.4. Consider the CRW queueing model (46) satisfying  $\rho = \alpha/\mu < 1$ , and define

$$(49) \quad m^2 = \mathbb{E}[(S(1) - A(1))^2], \quad m_A^2 = \mathbb{E}[A(1)^2], \quad \sigma^2 = \rho m^2 + (1 - \rho)m_A^2.$$

Then

(i) there is a unique invariant probability measure  $\pi$  on  $\mathbb{Z}_+$ , with steady-state mean

$$(50) \quad \eta := \mathbb{E}_\pi[Q(0)] = \frac{1}{2} \frac{\sigma^2}{\mu - \alpha};$$

(ii) a solution to Poisson's equation (48) is the quadratic

$$(51) \quad h(x) = J^*(x) + \frac{1}{2} \mu^{-1} \left( \frac{m^2 - m_A^2}{\mu - \alpha} \right) x, \quad x \in \mathbb{Z}_+.$$

The MaxWeight policy is defined by (9) with  $h$  a quadratic,

$$(52) \quad \phi^{\text{MW}}(x) = \arg \min_{u \in \mathcal{U}_\diamond(x)} \langle Dx, Bu + \alpha \rangle, \quad x \in \mathbb{Z}_+^\ell,$$

where  $D > 0$  is a diagonal matrix. Proposition 2.5 implies that  $\phi^{\text{MW}}$  coincides with the  $h$ -myopic policy for the fluid model. This result is a special case of Proposition 2.8 that follows.

**PROPOSITION 2.5.** *Suppose that assumptions (i) and (ii) of Theorem 1.1 hold. Then, for each  $x \in \mathbb{Z}_+^\ell$ , the allocation  $\phi^{\text{MW}}(x)$  defined by the MaxWeight policy can be expressed as a solution to the linear program,*

$$(53) \quad \begin{aligned} \phi^{\text{MW}}(x) = \quad & \arg \max \quad x^\top D(I - R^\top)Mu \\ & \text{s.t.} \quad u \in \mathcal{U}. \end{aligned}$$

Proposition 2.5 easily leads to a proof of stability of the MaxWeight policy. Theorem 2.6 is essentially contained in earlier work [53, 13]. We present the short proof since the same ideas are used to prove Theorem 1.1 and generalizations that follow.

**THEOREM 2.6.** *Suppose that  $\rho_\bullet < 1$ , and that assumptions (i) and (ii) of Theorem 1.1 hold. Then, for any diagonal matrix  $D > 0$ , the network controlled under the MaxWeight policy has a solution to Poisson's inequality (43) with  $V = h$  the quadratic defined in (1), and  $c(x) \equiv \varepsilon_0|x|$  for some  $\varepsilon_0 > 0$ .*

*Proof.* Since (41) holds when  $\rho_\bullet < 1$ , there exists  $\varepsilon > 0$  such that the vector  $v$  with coefficients  $v_i = -\varepsilon$ ,  $i \geq 1$ , lies in  $\mathcal{V}$ . By definition there exists  $u \in \mathcal{U}$  such that  $Bu + \alpha = v$ , so that by Proposition 2.5,

$$\langle B\phi^{\text{MW}}(x) + \alpha, \nabla h(x) \rangle = \langle B\phi^{\text{MW}}(x) + \alpha, Dx \rangle \leq v^\top Dx = -\varepsilon \sum D_{ii}x_i \leq -\varepsilon_0|x|,$$

with  $\varepsilon_0 = \varepsilon(\min_i D_{ii})$ . We thus arrive at a version of the Poisson inequality,

$$\mathcal{D}_{\text{MW}}h(x) := \mathbf{E}_{\text{MW}}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x] \leq -\varepsilon_0|x| + \bar{\eta}_D,$$

with

$$\bar{\eta}_D := \frac{1}{2} \max_{x' \in \mathbb{Z}_+^\ell, u \in \mathcal{U}_\diamond(x)} \mathbf{E}[(Q(t+1) - Q(t))^\top D(Q(t+1) - Q(t)) \mid Q(t) = x', U(t) = u]. \quad \square$$

**2.2. Perturbed functions.** We now analyze the drift  $\mathcal{D}h$  represented in (38) to establish stability of the  $h$ -MaxWeight policy. We return to the general CRW model (2).

An application of the chain rule of differentiation shows the following.

**PROPOSITION 2.7.** *For any  $C^1$  function  $h_0$ , the function  $h$  defined in (17) satisfies the derivative conditions (14). We have the explicit representations as follows:*

(i) *The first derivative is given by*

$$(54) \quad \nabla h(x) = [I - M_\theta] \nabla h_0(\tilde{x}),$$

where

$$(55) \quad M_\theta = M_\theta(x) = \text{diag}(e^{-x_i/\theta}), \quad x \in \mathbb{R}_+^\ell.$$

(ii) *If  $h_0$  is  $C^2$ , then the Hessian of  $h$  is*

$$(56) \quad \nabla^2 h(x) = [I - M_\theta] \nabla^2 h_0(\tilde{x}) [I - M_\theta] + \theta^{-1} \text{diag}(M_\theta \nabla h_0(\tilde{x})).$$

Hence  $h$  is convex provided  $h_0$  is both convex and monotone.

A key step in the proof of Theorem 1.1 is to generalize Proposition 2.5.

PROPOSITION 2.8. *Suppose that assumptions (i) and (ii) of Theorem 1.1 hold, and that  $h$  is any  $C^1$  monotone function satisfying the derivative conditions (14). Then, for each  $x \in \mathbb{Z}_+^\ell$ , the allocation  $\phi^{\text{MW}}(x)$  defined by the  $h$ -MaxWeight policy can be expressed as a solution to the linear program,*

$$(57) \quad \begin{aligned} \phi^{\text{MW}}(x) = \quad & \arg \min \quad \langle Bu, \nabla h(x) \rangle \\ & \text{s.t.} \quad u \in \mathbf{U}. \end{aligned}$$

*Proof.* The proof requires that we demonstrate that the minimum in (9) can be relaxed to a minimum over all of  $\mathbf{U}$ .

Recall the definition of the generalized Klimov indices in (21), and the interpretation that  $-\Theta_j$  is the coefficient of  $u_j$  in the objective function of (9). Monotonicity of  $h$  implies that each partial derivative of  $h$  is nonnegative. This assumption, combined with (18), implies that

$$(58) \quad \Theta_j(x) \leq 0 \text{ whenever } x_{i_j} = 0.$$

It then follows that the optimizer  $u^*$  of the linear program (57) satisfies, without loss of generality,  $u_j^* = 0$  whenever  $x_{i_j} = 0$ . This shows that  $u^* \in \mathbf{U}(x)$  for  $x \in \mathbb{Z}_+^\ell$ , which proves (57).

To show that  $u^*$  can be chosen in  $\mathbf{U}_\diamond$  we argue that optimizers of linear programs can be chosen from among the extreme points in the constraint region. The extreme points for this linear program are contained in  $\mathbf{U}_\diamond$  because of the definition  $\mathbf{U} := \text{conv}(\mathbf{U}_\diamond)$ .  $\square$

Consider the special case in which  $h_0$  is linear.

**2.2.1. Perturbed linear function.** Suppose that  $h_0(x) = c^\top x$ , where the vector  $c \in \mathbb{R}_+^\ell$  has nonzero coefficients, so that the function  $h$  can be expressed as

$$(59) \quad h(x) = \sum_{i=1}^{\ell} c_i \tilde{x}_i, \quad x \in \mathbb{R}_+^\ell.$$

An application of Proposition 2.7 shows that the derivative condition (14) holds, and that the first and second derivatives are given by

$$(60) \quad \nabla h(x) = [I - M_\theta]c, \quad \nabla^2 h(x) = \theta^{-1} \text{diag}(M_\theta c).$$

Hence the function  $h$  is monotone and strictly convex.

We show in Proposition 2.9 that the  $h$ -MaxWeight policy is stabilizing provided  $\theta \geq 1$  is suitably large. Although the dynamic programming inequality (15) fails for the linear function  $h_0$ , it does hold for the function  $k_0 h_0^2$ , where  $k_0$  is a sufficiently large constant, and  $c(x) = c^\top x$ . Hence Proposition 2.9(ii) could be deduced from Theorem 1.1.

PROPOSITION 2.9. *Suppose that assumptions (i) and (ii) of Theorem 1.1 hold, along with the stabilizability condition (41). Then, there exists  $\theta_0 > 0$  such that the following hold under the  $h$ -MaxWeight policy with  $h_0$  linear, provided  $\theta \geq \theta_0$ :*

(i) *The controlled network satisfies Foster's criterion. The function  $V$  in (V2) can be taken as a constant multiple of  $h$ .*

(ii) Condition (V3) holds: There exists  $\varepsilon_2 > 0$ ,  $b_2 < \infty$ , and a finite set  $S$  satisfying

$$\mathcal{D}V \leq -f + b_2 \mathbb{1}_S$$

with  $V = 1 + \frac{1}{2}h^2$ ,  $f = 1 + \varepsilon_2 h$ .

(iii) Suppose that for some  $\varepsilon > 0$  the arrival process satisfies  $\mathbb{E}[\exp(\varepsilon \|A(t)\|)] < \infty$ . Then condition (V4) holds: For some  $\varepsilon_e > 0$ ,  $\delta_e > 0$ ,  $b_e < \infty$ , and a finite set  $S$ ,

$$\mathcal{D}V \leq -\delta_e V + b_e \mathbb{1}_S$$

with  $V = \exp(\varepsilon_e h)$ . Hence  $\mathbf{Q}$  is geometrically ergodic provided (45) holds [41].

*Proof.* We apply the second-order mean value theorem to obtain

$$(61) \quad \begin{aligned} h(Q(t+1)) - h(Q(t)) &= \langle \nabla h(Q(t)), \Delta(t+1) \rangle \\ &\quad + \frac{1}{2} \Delta(t+1)^\top [\nabla^2 h(\bar{Q})] \Delta(t+1), \end{aligned}$$

where again  $\bar{Q} \in \mathbb{R}_+^\ell$  lies on the line connecting  $Q(t+1)$  and  $Q(t)$ . This implies the identity (38) with  $b_h$  redefined as

$$b_h(x) = \frac{1}{2} \mathbb{E}[\Delta(t+1)^\top \nabla^2 h(\bar{Q}) \Delta(t+1) \mid Q(t) = x].$$

The expression for the second derivative in (60) then gives

$$\mathcal{D}h(x) = \langle \nabla h(x), v \rangle + \theta^{-1} b_\Delta,$$

where

$$b_\Delta = \frac{1}{2} \|c\| \sup_{x' \in \mathbb{Z}_+^\ell, u \in \mathcal{U}_\phi(x')} \mathbb{E}[\|\Delta(t+1)\|^2 \mid Q(t) = x', U(t) = u] < \infty.$$

We now obtain an upper bound on  $\langle \nabla h(x), v \rangle$  under the  $h$ -MaxWeight policy. The expression for the first derivative in (60) implies the bound

$$\frac{\partial}{\partial x_i} h(x) = c_i (1 - e^{-x_i/\theta}) \geq \underline{c} (1 - e^{-x_i/\theta}), \quad 1 \leq i \leq \ell,$$

with  $\underline{c} := \min_j c_j$ . Exactly as in the proof of Theorem 2.6, we can consider arbitrary  $v \in \mathbf{V}$  to obtain bounds on the value of (57). This is justified by Proposition 2.8. The stabilizability condition (41) implies that there exists  $\varepsilon > 0$  such that the vector with components  $v_i = -\varepsilon$ ,  $1 \leq i \leq \ell$ , lies in  $\mathbf{V}$  for each  $x \in \mathbb{R}_+^\ell$ . By definition, there exists  $u \in \mathcal{U}$  satisfying  $Bu + \alpha = v$ . Consequently, under the  $h$ -MaxWeight policy,

$$\mathcal{D}h(x) \leq -\varepsilon \underline{c} \max_i (1 - e^{-x_i/\theta}) + \theta^{-1} b_\Delta.$$

Suppose that  $|x| \geq \ell\theta$ . Then  $x_i \geq \theta$  for at least one  $i$ , and we obtain the bound

$$(62) \quad \mathcal{D}h(x) \leq -\frac{1}{2} \varepsilon \underline{c} + \theta^{-1} b_\Delta \quad \text{if } |x| \geq \ell\theta.$$

The right-hand side is negative provided  $\theta > 2b_\Delta/(\varepsilon \underline{c})$ . Fixing  $\theta$  satisfying this bound, we obtain the desired solution to (V2) with  $V = 2(\varepsilon \underline{c})^{-1} h$ , and  $S = \{x : |x| < \ell\theta\}$ . This establishes (i).

To establish (ii) we begin with the identity

$$\frac{1}{2}[h(Q(t+1))]^2 - \frac{1}{2}[h(Q(t))]^2 = h(Q(t))(h(Q(t+1)) - h(Q(t))) + \frac{1}{2}[h(Q(t+1)) - h(Q(t))]^2.$$

On taking conditional expectations of both sides, we obtain  $\mathcal{D}V(x) = h(x)[\mathcal{D}h(x)] + b_{\Delta 2}(x)$ , where

$$b_{\Delta 2} = \frac{1}{2} \sup_{x' \in \mathbb{Z}_+^{\ell}, u \in \mathcal{U}_{\diamond}(x')} \mathbb{E}[[h(Q(t+1)) - h(Q(t))]^2 \mid Q(t) = x', U(t) = u] < \infty.$$

Applying (i), we obtain a version of the Poisson inequality (43) with this  $V$ , which implies that (V3) also holds.

Part (iii) follows from (i) combined with [41, Theorem 16.3.1] (see also [35, Theorem 4]).  $\square$

In the next example we find that the  $h$ -MaxWeight policy considered in Proposition 2.9(i) mirrors the discounted-cost optimal policy.

*Tandem queues: Emergence of a threshold policy.* Suppose that we replace the linear cost function used in (13) with the convex cost function  $h: \mathbb{R}_+^2 \rightarrow \mathbb{R}_+$  defined in (59). Figure 3 shows a plot of the sublevel sets of this function.

The  $h$ -MaxWeight policy defined in (9) minimizes the inner product,

$$\langle Bu + \alpha, \nabla h(x) \rangle = -\mu_1 u_1 c_1 (1 - e^{-x_1/\theta}) + (\mu_1 u_1 c_1 - \mu_2 u_2 c_2)(1 - e^{-x_2/\theta}) + \langle \alpha, \nabla h(x) \rangle.$$

The  $h$ -MaxWeight policy is thus nonidling at Station 2, and at Station 1 the policy can be expressed as a switching curve,

$$\phi_1^{\text{MW}}(x) = \mathbb{1}\{-c_1(1 - e^{-x_1/\theta}) + c_2(1 - e^{-x_2/\theta}) \leq 0\}, \quad x_1 \geq 1.$$

For small values of  $x_1$ , a first-order Taylor series gives the approximation  $\phi_1^{\text{MW}}(x) \approx \mathbb{1}\{x_2 \leq (c_1/c_2)x_1\}$ . For large  $x_1$  there are three cases to consider, depending on the relative sizes of  $c_1$  and  $c_2$ . If  $c_1 = c_2$ , then the approximation is equality,  $\phi_1^{\text{MW}}(x) = \mathbb{1}\{x_2 \leq x_1\}$  for all  $x$ . If  $c_1 > c_2$ , then Station 1 does not idle for large  $x_1$ , exactly as in the  $c$ -myopic policy. The  $h$ -MaxWeight policy is most interesting when  $c_2 > c_1$ . In this case, for  $x_1 \gg \theta$  the policy can be approximated by a threshold policy,  $\phi_1^{\text{MW}}(x) \approx \mathbb{1}\{x_2 \leq \bar{q}_2\}$ , where the threshold  $\bar{q}_2$  is the solution to the equation  $c_2(1 - e^{-\bar{q}_2/\theta}) = c_1$ . That is,

$$(63) \quad \bar{q}_2 = \theta \left| \log \left( 1 - \frac{c_1}{c_2} \right) \right|.$$

FIG. 3. The perturbed cost function defined in (17) with  $h_0$  linear on  $\mathbb{R}^2$  satisfies  $\min_u \langle \nabla h(x), Bu + \alpha \rangle < 0$  for each nonzero  $x \in \mathbb{R}_+^2$ . This geometry is illustrated in this figure using the tandem queues. The contour plots shown are the level sets  $\{x : h(x) = r\}$  for  $r = 1, 2, \dots$ .

Figure 3 illustrates  $\phi^{\text{MW}}$  when  $c_1 = 1$ ,  $c_2 = 3$ , and  $\theta = 10$ . The asymptote (63) is  $\bar{q}_2 = 10 \log(3/2) \approx 4$  in this special case.

For comparison consider the discounted-cost optimal policy, minimizing

$$\sum_{t=0}^{\infty} (1 + \gamma)^{-t-1} \mathbb{E}[c(Q(t)) \mid Q(t) = x],$$

for a given  $\gamma > 0$ . Letting  $h_\gamma^*(x)$  denote the minimizing value, the optimal policy is expressed as the  $h_\gamma^*$ -myopic policy, and the discounted-cost dynamic programming equation holds:

$$\gamma h_\gamma^*(x) = c(x) + \min_{u \in U_\circ(x)} \mathbb{E}[h_\gamma^*(Q(t+1)) - h_\gamma^*(Q(t)) \mid Q(t) = x, U(t) = u].$$

Consider the CRW model described by the recursion

$$Q(t+1) = Q(t) + (-\mathbf{1}^1 + \mathbf{1}^2)U_1(t)M_1(t) - \mathbf{1}^2U_2(t)M_2(t) + \mathbf{1}^1A_1(t+1), \quad t \geq 0,$$

in which the statistics of  $\Phi(t) := (M_1(t), M_2(t), A_1(t))^T$ ,  $t \geq 1$ , are consistent with a model obtained through uniformization:  $\Phi$  is i.i.d., with marginal distribution defined by

$$(64) \quad \mathbb{P}\{\Phi(t) = \mathbf{1}^1\} = \mu_1, \quad \mathbb{P}\{\Phi(t) = \mathbf{1}^2\} = \mu_2, \quad \mathbb{P}\{\Phi(t) = \mathbf{1}^3\} = \alpha_1,$$

with  $\mu_1 + \mu_2 + \alpha_1 = 1$ . We take  $c_1 = 1$ ,  $c_2 = 3$ ,  $\rho_1 = 9/11$ , and  $\rho_2 = 9/10$ .

For any finite  $\gamma$ , the following approximation holds:

$$\lim_{r \rightarrow \infty} r^{-1} h_\gamma^*([rx]) = \gamma^{-1} c(x), \quad x \in \mathbb{R}_+^2,$$

where  $[\cdot]$  denotes the componentwise integer part of a vector. Hence for large  $x$  far from the boundary, the optimal policy coincides with the  $c$ -myopic policy. In fact, it can be shown that the optimal policy is approximated by a static threshold, as seen in the two examples shown in Figure 4 (see [39, Example 10.6.1]). Hence the optimal policy is similar in form to the  $h$ -myopic policy illustrated in Figure 3.

**2.2.2. Perturbed value function.** We now consider a function  $h_0$  that serves as a Lyapunov function for the fluid model. Our goal is to complete the proof of Theorem 1.1, which amounts to establishing (V3) in the form of the Poisson inequality (19) with  $V = 2h$ .

Before proving the theorem, we present an example to illustrate the structure of the  $h$ -MaxWeight policy with  $h_0 = J^*$ , the optimal fluid value function defined below (42). In simple examples it is approximated by a switching curve with logarithmic growth.

FIG. 4. Discounted-cost optimal policy for the tandem queues with cost parameters  $(c_1, c_2) = (1, 3)$ . The load parameters are  $\rho_1 = 9/10$  and  $\rho_2 = 9/11$ , and the linear cost is defined by  $c_1 = 1$ ,  $c_2 = 3$ . On the left  $\gamma = 0.01$  and on the right  $\gamma = 0.001$ .

*Tandem queues: Translation of the optimal policy.* If  $\rho_1 < \rho_2$  and  $c_1 < c_2$ , then the fluid value function is purely quadratic:

$$(65) \quad J^*(x) = \frac{1}{2} \frac{c_1}{\mu_2 - \alpha_1} (x_1 + x_2)^2 + \frac{1}{2} \frac{c_2 - c_1}{\mu_2} x_2^2, \quad x \in \mathbb{R}_+^2.$$

Letting  $h_0 = J^*$ , the dynamic programming inequality (15) is satisfied with equality:

$$\min_{u \in \mathcal{U}(x)} \langle \nabla h_0(x), Bu + \alpha \rangle = -c(x) \quad x \in \mathbb{R}_+^\ell.$$

The derivative conditions (14) fail, so we do not know if the  $h_0$ -MaxWeight policy is stabilizing for the CRW model.

To compute the  $h$ -MaxWeight policy, we write (65) as

$$h_0(x) = J^*(x) = \frac{1}{2} d_1 (x_1 + x_2)^2 + \frac{1}{2} d_2 x_2^2, \quad x \in \mathbb{R}_+^2,$$

so that the gradient of  $h(x) = h_0(\tilde{x})$  can be expressed as

$$\nabla h(x) = [I - M_\theta] \nabla h_0(\tilde{x}) = \begin{pmatrix} d_1(\tilde{x}_1 + \tilde{x}_2)(1 - e^{-x_1/\theta}) \\ (d_1(\tilde{x}_1 + \tilde{x}_2) + d_2\tilde{x}_2)(1 - e^{-x_2/\theta}) \end{pmatrix}.$$

Writing  $Bu + \alpha = (-\mu_1 u_1 + \alpha_1, \mu_1 u_1 + \mu_2 u_2)^\top$ , we obtain for any  $x \in \mathbb{Z}_+^\ell$ ,  $u \in \mathcal{U}(x)$ ,

$$\begin{aligned} \langle \nabla h(x), Bu + \alpha \rangle &= \mu_1 u_1 [d_1(e^{-x_1/\theta} - e^{-x_2/\theta})(\tilde{x}_1 + \tilde{x}_2) + d_2(1 - e^{-x_2/\theta})\tilde{x}_2] \\ &\quad - \mu_2 u_2 [d_1(1 - e^{-x_2/\theta})(\tilde{x}_1 + \tilde{x}_2) + d_2(1 - e^{-x_2/\theta})\tilde{x}_2] \\ &\quad + \alpha_1 d_1(1 - e^{-x_1/\theta})(\tilde{x}_1 + \tilde{x}_2). \end{aligned}$$

Minimizing over  $u$  we see that the policy is nonidling at Station 2. At Station 1 we have  $u_1 = 1$  if and only if  $x_1 \geq 1$  and the coefficient of  $u_1$  is nonpositive. That is, the policy at Station 1 is defined by the switching curve described by the equation

$$(66) \quad d_1(e^{-x_1/\theta} - e^{-x_2/\theta})(\tilde{x}_1 + \tilde{x}_2) + d_2(1 - e^{-x_2/\theta})\tilde{x}_2 = 0.$$

When  $x_1$  is large, we obtain the approximation

$$(67) \quad x_2 \approx s(x_1) := \theta \log \left( 1 + \frac{d_1}{d_2} x_1 \right),$$

where, by (65),

$$\frac{d_1}{d_2} = \left( \frac{c_2}{c_1} - 1 \right)^{-1} \frac{1}{1 - \rho_2}.$$

This is an approximation to (66) in the sense that for all sufficiently large  $x_1$  there is a unique  $x_2$  such that  $(x_1, x_2)$  solve (66), and the ratio  $x_2/s(x_1)$  tends to unity as  $x_1 \rightarrow \infty$ .

A policy defined by a switching curve  $s(x_1)$  of the form given in (67) is similar to the policy introduced in [37] to obtain HTAO (see (32) and the surrounding discussion).

Consider now the average-cost optimal policy for the CRW model, with statistics defined in (64) and linear cost with  $(c_1, c_2) = (1, 3)$ . It is known that the average-cost optimal policy exists, and that it is  $h^*$ -myopic with respect to the relative value

FIG. 5. Average-cost optimal policy for the tandem queues with  $c_1 = 1$ ,  $c_2 = 3$ ,  $\rho_1 = 9/11$ , and  $\rho_2 = 9/10$ .

function (see [5] and [39, Chapter 9]). Moreover, Theorem 7.2 of [34] implies that the following approximation holds:

$$\lim_{r \rightarrow \infty} r^{-2} h^*([rx]) = J^*(x), \quad x \in \mathbb{R}_+^2.$$

The average-cost optimal policy for the CRW model is shown in Figure 5 with  $\rho_1 = 9/11 < \rho_2$ . This policy can be represented by a switching curve  $s$  that is concave and unbounded in  $x_1$ , similar to (67).

The proof of Theorem 1.1 is organized in the following two lemmas.

LEMMA 2.10. *Under the assumptions of Theorem 1.1 we have, under the  $h$ -MaxWeight policy, for some constant  $k_{2.10}$ ,*

$$\langle \nabla h(x), v^{\text{MW}} \rangle \leq -c(x) + k_{2.10} \log(1 + \|x\|), \quad x \in \mathbb{Z}_+^\ell,$$

where  $v^{\text{MW}} = B\phi^{\text{MW}}(x) + \alpha$ .

*Proof.* Fix a constant  $\beta_- \geq \theta$ , and define

$$s_-(r) = \beta_- \log(1 + r/\beta_-), \quad r \geq 0.$$

To prove the lemma we compare  $v^{\text{MW}}$  with another velocity vector  $v \in \mathbb{V}$ , subject to the following constraints:

$$(68) \quad v_i \geq 0 \quad \text{whenever} \quad x_i < s_-(\|x\|), \quad i = 1, \dots, \ell.$$

The minimum of  $\langle \nabla h(x), v \rangle$  over  $v$  satisfying these constraints provides a bound under the  $h$ -MaxWeight policy. Proposition 2.8 is critical here so that we can ignore lattice constraints as we search for bounds on this inner product.

The purpose of (68) is to obtain the following bound:

$$(69) \quad -e^{-x_i/\theta} v_i \leq |v_i| (1 + \|x\|/\beta_-)^{-\beta_-/\theta}, \quad i = 1, \dots, \ell.$$

Since  $h_0$  is assumed monotone we have  $\nabla h_0: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+^\ell$ , and applying (54) we obtain

$$\langle \nabla h(x), v \rangle \leq \langle \nabla h_0(\tilde{x}), v \rangle + \|v\| \|\nabla h_0(\tilde{x})\| (1 + \|x\|/\beta_-)^{-\beta_-/\theta}.$$

Since  $\nabla h_0$  is also Lipschitz and  $\beta_- \geq \theta$ , this gives, for some constant  $k_0$ ,

$$(70) \quad \langle \nabla h(x), v \rangle \leq \langle \nabla h_0(\tilde{x}), v \rangle + k_0.$$

To bound (70) we shift  $\tilde{x}$  as follows: Let  $\tilde{x}^- \in \mathbb{Z}_+^\ell$  denote the vector with components

$$\tilde{x}_i^- = \lfloor (\tilde{x}_i - s_-(\|x\|))_+ \rfloor, \quad i = 1, \dots, \ell,$$

where  $\lfloor \cdot \rfloor$  denotes the integer part. In view of (15), there exists  $u \in \mathcal{U}(x)$  such that with  $v = Bu + \alpha$ ,

$$\langle \nabla h_0(\tilde{x}^-), v \rangle \leq -c(\tilde{x}^-).$$

Moreover, we have  $\tilde{x}_i^- = 0$  whenever the constraint on  $x_i$  in (68) is active. Since  $u \in \mathcal{U}(x)$ , this implies that the vector  $v = Bu + \alpha$  satisfies  $v_i \geq 0$ . That is,  $v$  satisfies the constraint (68).

Using this  $v$  in (70) gives

$$\begin{aligned} \langle \nabla h(x), v \rangle &\leq \langle \nabla h_0(\tilde{x}^-), v \rangle + \langle \nabla h_0(\tilde{x}) - \nabla h_0(\tilde{x}^-), v \rangle + k_0 \\ &\leq -c(\tilde{x}^-) + \|v\| \|\nabla h_0(\tilde{x}) - \nabla h_0(\tilde{x}^-)\| + k_0 \\ &\leq -c(x) + |c(x) - c(\tilde{x}^-)| + \|v\| \|\nabla h_0(\tilde{x}) - \nabla h_0(\tilde{x}^-)\| + k_0. \end{aligned}$$

This completes the proof since  $c$  and  $\nabla h_0$  are Lipschitz.  $\square$

LEMMA 2.11. *Under the assumptions of Theorem 1.1 we have, under the h-MaxWeight policy, for some constant  $k_{2.11}$ ,*

$$\mathcal{D}h(x) \leq \langle \nabla h(x), v^{\text{MW}} \rangle + k_{2.11}(1 + \theta^{-1}\|x\|), \quad x \in \mathbb{Z}_+^\ell,$$

where  $v^{\text{MW}} = B\phi^{\text{MW}}(x) + \alpha$ .

*Proof.* The first-order mean value theorem (37) results in the representation (38) for  $\mathcal{D}h$  with  $b_h$  defined in (39). The Cauchy–Schwarz inequality gives,

$$(71) \quad b_h(x) \leq \mathbb{E}[\|\nabla h(\bar{Q}) - \nabla h(Q(t))\|^2 \mid Q(t) = x]^{\frac{1}{2}} \mathbb{E}[\|\Delta(t+1)\|^2 \mid Q(t) = x]^{\frac{1}{2}}.$$

It remains to bound the right-hand side.

Given  $Q(t) = x$ , an application of Proposition 2.7 gives

$$\nabla h(\bar{Q}) - \nabla h(x) = [I - M_\theta(\bar{Q})](\nabla h_0(\tilde{\bar{Q}}) - \nabla h_0(\tilde{x})) + [M_\theta(x) - M_\theta(\bar{Q})]\nabla h_0(\tilde{x}),$$

where  $\tilde{\bar{Q}}$  is obtained from  $\bar{Q}$  via the pointwise transformation (16). The first expectation on the right-hand side of (71) is bounded through an application of the triangle inequality,

$$\begin{aligned} &\mathbb{E}[\|\nabla h(\bar{Q}) - \nabla h(Q(t))\|^2 \mid Q(t) = x]^{\frac{1}{2}} \\ &\leq \mathbb{E}[\|[I - M_\theta(\bar{Q})](\nabla h_0(\tilde{\bar{Q}}) - \nabla h_0(\tilde{x}))\|^2 \mid Q(t) = x]^{\frac{1}{2}} \\ (72) \quad &+ \mathbb{E}[\|[M_\theta(x) - M_\theta(\bar{Q})]\nabla h_0(\tilde{x})\|^2 \mid Q(t) = x]^{\frac{1}{2}}. \end{aligned}$$

To bound the first term on the right-hand side of (72) we apply the Lipschitz condition on  $h_0$ : For some constant  $k_0$ ,

$$\|\nabla h_0(\tilde{\bar{Q}}) - \nabla h_0(\tilde{x})\| \leq k_0 \|\tilde{\bar{Q}} - \tilde{x}\| \leq \|\Delta(t+1)\|.$$

Hence the first term is bounded over  $x$ .

The second term is bounded using the mean value theorem. The  $i$ th diagonal element of  $[M_\theta(x) - M_\theta(\bar{Q})]$  admits the bound

$$\begin{aligned} |e^{-x_i/\theta} - e^{-\bar{Q}_i/\theta}| &= e^{-x_i/\theta} |1 - e^{-(\bar{Q}_i - x_i)/\theta}| \\ &\leq e^{-x_i/\theta} (1 - e^{-\bar{\Delta}_i/\theta}) \mathbb{1}\{\bar{Q}_i > x_i\} \\ &\quad + e^{-x_i/\theta} (e^{\ell_u/\theta} - 1) \mathbb{1}\{\bar{Q}_i < x_i\}, \end{aligned}$$

where  $\bar{\Delta}_i = A_i(1) + \sum_j |B_{ij}(1)|$ , and we have used the fact that  $\sum_j B_{ij}(1) \geq -\ell_u$  under (18). The right-hand side can be bounded through a second application of the mean value theorem, giving

$$|e^{-x_i/\theta} - e^{-\bar{Q}_i/\theta}| \leq e^{-x_i/\theta} (e^{\ell_u/\theta} - e^{-\bar{\Delta}_i/\theta}) \leq \theta^{-1} e^{\ell_u/\theta} (\ell_u + \bar{\Delta}_i).$$

The Lipschitz condition on  $\nabla h_0$  and second moment conditions on  $(\mathbf{A}, \mathbf{B})$  then imply that for some  $k_3 < \infty$ ,

$$\begin{aligned} \mathbb{E}[\| [M_\theta(x) - M_\theta(\bar{Q})] \nabla h_0(\tilde{x}) \|^2 \mid Q(t) = x]^\frac{1}{2} &\leq \theta^{-1} e^{\ell_u/\theta} (\sqrt{\ell} \ell_u + \mathbb{E}[\|\bar{\Delta}\|^2]^\frac{1}{2}) \|\nabla h_0(\tilde{x})\| \\ &\leq k_3 \theta^{-1} (1 + \|x\|). \end{aligned}$$

This combined with (19), (71), and (72) completes the proof.  $\square$

**2.3. Universally stabilizing policies.** The policies described in the previous sections are stabilizing, provided the parameter  $\theta > 0$  is chosen sufficiently large. With a different change of variables we can construct a family of policies that are stabilizing regardless of the parameter.

In this subsection only we redefine  $\tilde{x}$  as

$$(73) \quad \tilde{x}_i := x_i \log(1 + x_i/\theta),$$

where  $\theta > 0$  is fixed but arbitrary. Theorem 1.1 and Proposition 2.9 can be generalized using this new definition of  $\tilde{x}$ . First we require derivative formulae.

**PROPOSITION 2.12.** *For any  $C^1$  function  $h_0$ , the function  $h$  defined in (17) with  $\tilde{x}$  defined componentwise in (73) satisfies the derivative conditions (14) as follows:*

(i) *The first derivative is given by*

$$(74) \quad \nabla h(x) = L_\theta \nabla h_0(\tilde{x}),$$

where

$$(75) \quad L_\theta(x) = \text{diag}(x_i/(\theta + x_i) + \log(1 + x_i/\theta)), \quad x \in \mathbb{R}_+^\ell.$$

(ii) *If  $h_0$  is  $C^2$ , then the Hessian of  $h$  is*

$$(76) \quad \nabla^2 h(x) = L_\theta \nabla^2 h_0(\tilde{x}) L_\theta + \theta^{-1} \text{diag}(N_\theta \nabla h_0(\tilde{x})),$$

where  $N_\theta(x) = \text{diag}(\theta/(\theta + x_i) + \theta^2/(\theta + x_i)^2)$ . In particular,  $h$  is convex provided  $h_0$  is both convex and monotone.

Proposition 2.13 establishes stability of the  $h$ -MaxWeight policy when  $h_0$  is linear. We omit the proof since it is similar to the proof of Proposition 2.9(i), applying Proposition 2.12 instead of Proposition 2.7.

**PROPOSITION 2.13.** *Suppose that assumptions (i) and (ii) of Theorem 1.1 hold, along with the stabilizability condition (41). Then, under the  $h$ -MaxWeight policy with  $h_0$  linear, and  $\tilde{x}$  defined in (73) with  $\theta > 0$ , there exists  $\varepsilon = \varepsilon(\theta) > 0$  such that condition (V3) holds with  $f(x) = 1 + \varepsilon \log(1 + \|x\|)$ .*

We now consider a version of Theorem 1.1. It is necessary to strengthen the  $L_2$  condition on the arrival process to a second moment bound on  $\tilde{\mathbf{A}}$ ,

$$(77) \quad \mathbb{E}[\|\tilde{\mathbf{A}}(t)\|^2] := \sum_{i=1}^{\ell} \mathbb{E}[(A_i(t) \log(1 + A_i(t)/\theta))^2] < \infty.$$

Moreover, it appears that the monotonicity assumption must be strengthened to

$$(78) \quad \frac{\partial}{\partial x_i} h_0(x) \geq \varepsilon_{78} x_i, \quad x \in \mathbb{R}_+^\ell, \quad i = 1, \dots, \ell,$$

where  $\varepsilon_{78} > 0$  is constant. For example, (78) holds for a quadratic (1) in which  $D_{ij} \geq 0$  and  $D_{ii} > 0$  for each  $i, j$ .

**THEOREM 2.14.** *Consider the  $h$ -MaxWeight policy in which the function  $h$  is based on the change of variables  $\tilde{x}$  defined in (73). The constant  $\theta > 0$  is fixed but arbitrary. The network model (2) and function  $h_0$  satisfy all of the assumptions of Theorem 1.1. In addition, the arrival process satisfies (77), and  $h_0$  satisfies the uniform bound (78) with  $\varepsilon_{78} > 0$ . Then, there exists  $\delta_h > 0$  and  $\bar{\eta}_h < \infty$  such that the following version of the Poisson inequality (43) holds under the  $h$ -MaxWeight policy:*

$$(79) \quad \mathcal{D}h(x) = \mathbb{E}[h(Q(t+1)) - h(Q(t)) \mid Q(t) = x] \leq -\delta_h \|x\| (\log(1 + \|x\|))^2 + \bar{\eta}_h.$$

*Proof.* We first obtain an extension of Lemma 2.10: There exists  $\delta_h^0 > 0$  such that

$$(80) \quad \langle \nabla h(x), v^{\text{MW}} \rangle \leq -\delta_h^0 \|x\| (\log(1 + \|x\|))^2, \quad x \in \mathbb{Z}_+^\ell.$$

As in the proof of Proposition 2.6, we have the bound  $\langle \nabla h(x), v^{\text{MW}} \rangle \leq \langle \nabla h(x), v \rangle$  with  $v_i = -\varepsilon$ ,  $i \geq 1$ , and  $\varepsilon > 0$  chosen so that  $v \in \mathbb{V}$ . Hence,

$$\langle \nabla h(x), v^{\text{MW}} \rangle \leq -\varepsilon \sum_{i=1}^{\ell} \frac{\partial}{\partial x_i} h(x) = -\varepsilon \sum_{i=1}^{\ell} (x_i/(\theta + x_i) + \log(1 + x_i/\theta)) \frac{\partial}{\partial x_i} h_0(\tilde{x}).$$

This combined with the bound (78) gives

$$\langle \nabla h(x), v^{\text{MW}} \rangle \leq -\varepsilon \varepsilon_{78} \sum_{i=1}^{\ell} \log(1 + x_i/\theta) \tilde{x}_i.$$

From the definition of  $\tilde{x}$  we obtain (80) for some  $\delta_h^0 > 0$ .

Based on (80) we complete the proof using an extension of Lemma 2.11. Combining (71) and (80) gives

$$(81) \quad \begin{aligned} \mathcal{D}h(x) &\leq -\delta_h^0 \|x\| (\log(1 + \|x\|))^2 \\ &\quad + \mathbb{E}[\|\nabla h(\bar{Q}) - \nabla h(Q(t))\|^2 \mid Q(t) = x]^{\frac{1}{2}} \mathbb{E}[\|\Delta(t+1)\|^2 \mid Q(t) = x]^{\frac{1}{2}}. \end{aligned}$$

Following the arguments used in the proof of Lemma 2.11, and using Proposition 2.12 in place of Proposition 2.7, we obtain the bound, for some constant  $k_0$ ,

$$\mathbb{E}[\|\nabla h(\bar{Q}) - \nabla h(Q(t))\|^2 \mid Q(t) = x]^{\frac{1}{2}} \leq k_0 \|x\| (\log(1 + \|x\|)).$$

This together with (81) completes the proof of (79), where the constant  $\delta_h$  can be chosen arbitrarily in the open interval  $(0, \delta_h^0)$ .  $\square$

**3. Relaxations and heavy traffic.** We now establish HTAO under the  $h$ -MaxWeight policy for a specifically chosen function  $h$ , and under further restrictions on the network model.

Throughout this section we consider the homogeneous scheduling model (33) subject to the following conventions. The load parameters defined in (34) are expressed as

$$\rho_i = \lambda_i / \mu_i, \quad 1 \leq i \leq \ell_m,$$

where  $\mu_i$  is the common mean of  $\{M_j(t) : s(j) = i\}$ , and  $\lambda_i$  is the  $i$ th component of  $C[I - R^T]^{-1}\alpha$ . It is assumed throughout this section that  $\rho_1 = \max_{1 \leq i \leq \ell} \rho_i$ , so that  $\rho_\bullet = \rho_1$ . This can be achieved by choice of indices. We let  $\xi \in \mathbb{Z}_+^\ell$  denote the first column of the  $\ell \times \ell_m$  matrix  $[I - R]^{-1}C^T$ , so that  $\xi^T \alpha = \lambda_1$ .

Homogeneity implies that the random variables  $\{M_j(t) : s(j) = 1\}$  are all identical; we let  $S_1(t)$  denote their common value, and we let  $L_1(t) = \xi^T A(t)$ . The one-dimensional workload process  $W(t) = \langle \xi, Q(t) \rangle$  evolves as

$$(82) \quad W(t+1) = W(t) - S_1(t+1) + S_1(t+1)\mathcal{L}(t) + L_1(t+1), \quad t \geq 0,$$

where  $\mathcal{L}(t) := 1 - [CU(t)]_1$ .

The one-dimensional relaxation is defined on the same probability space with  $Q$  and evolves as a controlled random walk analogous to (82):

$$(83) \quad \widehat{W}(t+1) = \widehat{W}(t) - S_1(t+1) + S_1(t+1)\widehat{\mathcal{L}}(t) + L_1(t+1), \quad t \geq 0.$$

The idleness process  $\{\widehat{\mathcal{L}}(t)\}$  is assumed nonnegative and adapted to  $\{\widehat{W}(t), S_1(t), L_1(t)\}$ . The relaxation is denoted  $\widehat{W}^*$  when controlled using the nonidling policy,  $\widehat{\mathcal{L}}^*(t) = \mathbb{1}\{\widehat{W}^*(t) \geq 1\}$ . In this case we have (35), provided each process has the common initialization  $\widehat{W}^*(0) = W(0) = \langle \xi, Q(0) \rangle$ , which we assume henceforth.

For a convex cost function  $c: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+$  the effective cost  $\bar{c}: \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is defined in (24). For each  $w \in \mathbb{R}_+$  an *effective state*  $\mathcal{X}^*(w)$  is defined to be any vector  $x^* \in \mathbb{R}_+^\ell$  that achieves the minimum in (24):

$$(84) \quad \mathcal{X}^*(w) = \arg \min_{x \in \mathbb{R}_+^\ell} \left( c(x) : \xi^T x = w \right).$$

It follows from the definitions that the following bound holds for all  $t$ :

$$(85) \quad c(Q(t)) \geq \bar{c}(W(t)) \geq \bar{c}(\widehat{W}^*(t)).$$

**3.1. Starvation and relaxations.** It is helpful to consider a workload relaxation to see how starvation arises under a myopic policy.

**3.1.1. Linear cost function.** If  $c(x) = c^T x$ ,  $x \in \mathbb{R}_+^\ell$ , then the effective state in a one-dimensional relaxation is given by

$$\mathcal{X}^*(w) = \left( \frac{1}{\xi_{i^*}} \mathbf{1}^{i^*} \right) w, \quad w \in \mathbb{R}_+,$$

where the index  $i^*$  is any solution to  $c_{i^*}/\xi_{i^*} = \min_{1 \leq i \leq \ell} (c_i/\xi_i)$ . The effective cost is given by the linear function  $\bar{c}(w) = c(\mathcal{X}^*(w)) = (c_{i^*}/\xi_{i^*})w$ ,  $w \in \mathbb{R}_+$ .

This underlines the conflict that arises frequently in network optimization: Optimization of an idealized model dictates zero inventory at various stations, while in a more realistic model, adopting a “zero-inventory policy” results in starvation of resources.

**3.1.2. Quadratic cost function.** If  $c: \mathbb{R}_+^\ell \rightarrow \mathbb{R}_+$  is quadratic, of the form  $c(x) = \frac{1}{2}x^\top D x$ ,  $x \in \mathbb{R}_+^\ell$  for a symmetric matrix  $D$ , then the effective state is again linear in the workload value in any one-dimensional relaxation.

For the scheduling model considered in this section the workload vector  $\xi$  has nonnegative entries. Suppose that  $D^{-1}$  also has nonnegative entries. In this case we have the explicit expression

$$\mathcal{X}^*(w) = \left( (\xi^\top D^{-1} \xi)^{-1} D^{-1} \xi \right) w, \quad w \in \mathbb{R}_+,$$

and the effective cost is the one-dimensional quadratic

$$\bar{c}(w) = \frac{1}{2} (\xi^\top D^{-1} \xi)^{-1} w^2, \quad w \in \mathbb{R}_+.$$

For example, if  $D > 0$  is diagonal, and  $\xi$  has strictly positive entries, then the effective state  $\mathcal{X}^*(w)$  has strictly positive entries for any  $w > 0$ . In conclusion, the conflict observed for linear cost functions does not arise when using a quadratic function satisfying these conditions.

**3.2. Logarithmic regret.** We now construct a policy satisfying (31) with  $c$  a linear cost function. The policy is defined as the  $h$ -MaxWeight policy for a specific function  $h$ .

We saw in section 3.1.1 that the effective state  $x^* = \mathcal{X}^*(w)$  can be constructed so that  $x_i^* = 0$  for all but one  $i \in \{1, \dots, \ell\}$ . By choice of indices we assume that  $x_i^* = 0$  for  $i \geq 2$  and any  $w \in \mathbb{R}_+$ . Consequently, the effective cost is given by

$$(86) \quad \bar{c}(w) = c(\mathcal{X}^*(w)) = \frac{c_1}{\xi_1} w, \quad w \in \mathbb{R}_+.$$

We assume, moreover, that the solution to (24) is unique, which amounts to the following strict bound:

$$(87) \quad \frac{c_i}{\xi_i} > \frac{c_1}{\xi_1}, \quad i = 2, \dots, \ell.$$

Theorem 2.4 implies the following formula for the steady-state cost for the relaxation:

$$(88) \quad \hat{\eta}^* = \frac{1}{2} \frac{\sigma_\kappa^2}{\mu_1 - \lambda_1} \frac{c_1}{\xi_1},$$

where  $\sigma_\kappa^2 := \rho_\bullet \mathbb{E}[(S_1(1) - L_1(1))^2] + (1 - \rho_\bullet) \mathbb{E}[(L_1(1))^2]$ . From (85) we evidently have  $\hat{\eta}^* \leq \eta^*$ . To establish (31) we require a bound in the reverse direction.

We now introduce a family of network models, parameterized by a scalar  $\kappa \in [1, \infty)$  that represents load. It is assumed that, for some fixed  $\kappa_0 \geq 1$ ,  $\bar{\rho} < 1$ , we have

$$(89) \quad \begin{aligned} \rho_\bullet &:= \rho_1 = 1 - 1/\kappa && \text{for each } \kappa \in [\kappa_0, \infty) \\ \text{and } \rho_i &\leq \bar{\rho} && \text{for each } \kappa \text{ and } i \geq 2. \end{aligned}$$

The one-dimensional workload process  $\mathbf{W}$  is given in (82), where we suppress the dependency of  $\{\mathbf{Q}, \mathbf{W}, \mathbf{S}, \mathbf{L}\}$  on the parameter  $\kappa$  to simplify notation.

The fluid model for the one-dimensional workload process is expressed as  $\frac{d^+}{dt} w(t) = -(\mu_1 - \lambda_1) + \iota(t)$  with  $\iota(t) \geq 0$ . Given the cost function  $\bar{c}$  given in (86), the fluid value function is given by

$$(90) \quad \hat{J}^*(w) = \frac{1}{2} \frac{c_1}{\xi_1} \frac{w^2}{\mu_1}, \quad w \geq 0.$$

The solution to Poisson's equation (51) is the sum of  $\widehat{J}^*$  and a linear function of  $w$ . We take the function  $h_0$  used to define the  $h$ -MaxWeight policy as a different perturbation of  $\widehat{J}^*$ : Fix a positive constant  $b > 0$ , and define

$$(91) \quad h_0(x) = \widehat{J}^*(\xi^\top x) + \frac{1}{2}b(c(x) - \bar{c}(\xi^\top x))^2.$$

This function is monotone since  $c(x) \geq \bar{c}(\xi^\top x)$  for each  $x$ . We then take  $h(x) = h_0(\tilde{x})$ , or

$$(92) \quad h(x) := \widehat{J}^*(\tilde{w}) + \frac{1}{2}b(c(\tilde{x}) - \bar{c}(\tilde{w}))^2, \quad x \in \mathbb{R}_+^\ell,$$

where  $\tilde{x}$  is the  $\ell$ -dimensional vector with components given in (16), and  $\tilde{w} := \sum \xi_i \tilde{x}_i$ .

For each  $\kappa$  we denote by  $\eta = \eta(\kappa)$  the steady-state cost under the policy for the CRW model, and  $\widehat{\eta}^*$  the optimal average cost for the one-dimensional relaxation. Applying (89), the representation (88) becomes

$$(93) \quad \widehat{\eta}^* = \frac{1}{2} \frac{\sigma_\kappa^2}{\mu_1} \frac{c_1}{\xi_1} \kappa.$$

Note that  $\eta$  and  $\widehat{\eta}^*$  are unbounded as the network load  $\rho_\bullet$  approaches unity, and  $\widehat{\eta}^*$  is of order  $\kappa$ . Hence (31) implies the bounds

$$(94) \quad \eta^* \leq \eta \leq \eta^* + k_{94} \log(\kappa), \quad \kappa \geq \kappa_0.$$

**THEOREM 3.1.** *Suppose that the following hold for the parameterized family of networks:*

(HTAO 1). *For each  $\kappa$ , the network is a CRW scheduling model with deterministic routing.*

(HTAO 2). *The network is homogeneous for each  $\kappa$ . Moreover,*

(a) *the random variables  $\{A^\kappa(t), S_s^\kappa(t) : t \geq 1, \kappa \in [1, \infty], s \geq 1\}$  are defined on a common probability space and are monotone in  $\kappa$ : For each  $s \in \{1, \dots, \ell_m\}$ ,*

$$S_s^\kappa(t) \downarrow S_s^\infty(t), \quad A^\kappa(t) \uparrow A^\infty(t), \quad \kappa \rightarrow \infty \text{ a.s. } t \geq 1.$$

(b) *the distribution of  $S_s^\kappa(t)$  is Bernoulli for each  $s$ , and  $\mathbb{E}[\|A^\infty(t)\|^2] < \infty$ .*

(c) *for some  $\varepsilon > 0$  independent of  $\kappa$  and  $s$ ,*

$$(95) \quad \mathbb{P}\{S_s^\kappa(t) = 1 \text{ and } A^\kappa(t) = 0\} \geq \varepsilon.$$

(HTAO 3). *Linear cost.*

(HTAO 4). *The load parameters satisfy (89). Hence  $\rho^\kappa \rightarrow \rho^\infty$  as  $\kappa \rightarrow \infty$ , where  $\rho_1^\infty = 1$  and  $\rho_i^\infty < 1$  for  $i \geq 2$ .*

*Moreover, the effective state is unique: Equation (87) holds.*

*Then, there exists  $\theta_0 > 0$  and  $b_0 > 0$  such that the following conclusions hold for the  $h$ -MaxWeight policy with  $h$  defined in (92), with  $\theta \geq \theta_0$  and  $b \geq b_0$ : There exists  $\kappa_0 > 0$  such that the controlled network is ergodic, in the sense that it is 0-irreducible and (V3) holds, for each  $\kappa \geq \kappa_0$ . Moreover, the family of controlled networks satisfies the bound (94) for some fixed  $k_{94} < \infty$ . That is, the policy has HTAO with logarithmic regret.*

The proof is based on the construction of a Lyapunov function  $V: \mathbb{Z}_+^\ell \rightarrow \mathbb{R}_+$  satisfying a refinement of (V3),

$$(96) \quad \mathbb{E}_x[V(Q(1))] \leq V(x) - c(x) + \widehat{\eta}^* + \mathcal{E}(x), \quad x \in \mathbb{Z}_+^\ell,$$

where the error  $\mathcal{E}$  has at most logarithmic growth,

$$(97) \quad \mathcal{E}(x) = k_{97} \left( \log(\kappa + c(x)) + \kappa / (1 + (\xi^T x)^2) \right), \quad x \in \mathbb{R}_+^\ell, \quad \kappa \geq 1.$$

This is achieved using the same steps used in section 2.2 to establish stability of the  $h$ -MaxWeight policy: First, we obtain a bound on the term  $\langle \nabla h(x), v \rangle$  appearing in (38). We then decompose the term  $b_h(x)$  into a bounded term, and a term whose mean is equal to  $\hat{\eta}^*$ .

**3.3. Proof of Theorem 3.1.** Throughout this section we assume that the assumptions of Theorem 3.1 hold. We let  $\mathcal{E}$  denote the function of  $x$  and  $\kappa$  given in (97). The constant  $k_{97}$  may differ in each appearance.

We first establish irreducibility.

**PROPOSITION 3.2.** *Under the assumptions of Theorem 3.1 the policy  $\phi^{\text{MW}}$  is 0-irreducible for each  $\kappa < \infty$ .*

*Proof.* Monotonicity of  $h$  implies that the  $h$ -MaxWeight policy is “weakly non-idling”: For any  $t$ ,

$$\sum_{i=1}^{\ell} U(t) \geq 1 \quad \text{whenever } Q(t) \neq \mathbf{0}.$$

Combining this with (95) we can conclude that for some  $\delta > 0$ , and any nonzero  $x \in \mathbf{X}_\diamond$ ,

$$\mathbb{P}\{\text{A service is completed at time } t \text{ and } A(t) = \mathbf{0} \mid Q(t-1) = x\} \geq \delta, \quad t \geq 1.$$

Since each customer in the network requires service at most  $\ell$  times, it follows that  $P^T(x, \mathbf{0}) \geq \delta^T$  for  $T = \ell|x|$ . This establishes 0-irreducibility.

Aperiodicity also follows from (95) since  $P(\mathbf{0}, \mathbf{0}) = \mathbb{P}\{A(t) = \mathbf{0}\} > 0$ .  $\square$

Recall that the proof of Theorem 1.1 was based on Lemmas 2.10 and 2.11. The following two propositions are refinements of these results.

**PROPOSITION 3.3.** *Under the  $h$ -MaxWeight policy, we have for some  $\varepsilon_{3.3} > 0$ , independent of  $b$  and  $x$ ,*

$$(98) \quad \langle \nabla h(x), v^{\text{MW}} \rangle \leq -\bar{c}(w) - \varepsilon \left( b|c(x) - \bar{c}(w)| + \|M_\theta(x)\xi\|\kappa w \right) + \mathcal{E}(x),$$

where  $w = \xi^T x$  and  $v^{\text{MW}} = B\phi^{\text{MW}}(x) + \alpha$ .

**PROPOSITION 3.4.** *Under the  $h$ -MaxWeight policy, we have for some  $k_{3.4} < \infty$ , independent of  $b$ ,  $\kappa$ , and  $x$ ,*

$$(99) \quad \mathcal{D}h(x) \leq \langle \nabla h(x), v^{\text{MW}} \rangle + \hat{\eta}^*(x) + k_{3.4} \theta^{-1} \left( b|c(x) - \bar{c}(w)| + \|M_\theta(x)\xi\|\kappa w \right) + \mathcal{E}(x),$$

where  $v^{\text{MW}} = B\phi^{\text{MW}}(x) + \alpha$  and

$$(100) \quad \hat{\eta}^*(x) := \frac{1}{2} \frac{\kappa}{\mu_1} \frac{c_1}{\xi_1} \sigma_\kappa^2(x), \quad \text{with} \quad \sigma_\kappa^2(x) := \mathbb{E}[(\xi^T \Delta(t+1))^2 \mid Q(t) = x].$$

We begin with the proof of Proposition 3.3. Note that

$$(101) \quad c(x) - \bar{c}(w) = \sum_{i=2}^{\ell} \left( c_i - (c_1/\xi_1)\xi_i \right) x_i,$$

which is nonnegative by (87). That is, we have  $|c(x) - \bar{c}(w)| = c(x) - \bar{c}(w)$ . To prove the proposition we first apply Proposition 2.7 to obtain a representation for the gradient of  $h$ ,

$$(102) \quad \nabla h(x) = \nabla \hat{J}^*(\tilde{w})[I - M_\theta]\xi + b(c(\tilde{x}) - \bar{c}(\tilde{w}))[I - M_\theta] \left( c - \frac{c_1}{\xi_1} \xi \right),$$

with

$$\nabla \hat{J}^*(w) = \frac{c_1}{\xi_1} \frac{w}{\mu_1 - \lambda_1} = \frac{c_1}{\xi_1} \frac{\kappa}{\mu_1} w, \quad w \geq 0.$$

A representation for the drift easily follows.

LEMMA 3.5. *For any  $v \in \mathbf{V}$ ,  $x \in \mathbb{R}_+^\ell$ , we have*

$$(103) \quad \begin{aligned} \langle \nabla h(x), v \rangle &= \nabla \hat{J}^*(\tilde{w}) \langle \xi, v \rangle - \nabla \hat{J}^*(\tilde{w}) \sum_{i=1}^{\ell} e^{-x_i/\theta} \xi_i v_i \\ &\quad + [c(\tilde{x}) - \bar{c}(\tilde{w})] \sum_{i=2}^{\ell} (1 - e^{-x_i/\theta}) b_i v_i \end{aligned}$$

with  $b_i = b(c_i - (c_1/\xi_1)\xi_i)$ ,  $i \geq 2$ .

Fix constants  $\beta_+ > \beta_- > 0$ , and define for  $r \geq 0$ ,

$$(104) \quad s_-(r) = \beta_- \log(1 + r/\beta_-), \quad s_+(r) = \beta_+ \log(1 + r/\beta_+).$$

It is assumed throughout that  $\beta_- \geq 3\theta^{-1}$ .

Similar to the proof of Lemma 2.10, to bound (103) we impose the following constraints on the velocity vector  $v$ :

$$(105) \quad v_i \geq 0 \quad \text{if } x_i \leq s_-(\xi^T x) - \beta_- \log(|\xi|) \text{ and } \xi_i > 0,$$

where  $|\xi| := \sum \xi_i$ . The minimum of  $\langle \nabla h(x), v \rangle$  over  $v$  satisfying (105) provides a bound under the  $h$ -MaxWeight policy. The following two results imply that (105) is feasible for a policy that is nonidling at Station 1.

LEMMA 3.6. *For each  $x \in \mathbb{R}_+^\ell$  we have  $\max\{x_i : \xi_i > 0\} \geq s_-(\xi^T x) - \beta_- \log(|\xi|)$ .*

*Proof.* Letting  $x^\infty = \max\{x_i : \xi_i > 0\}$ , we have  $\xi^T x \leq x^\infty |\xi|$ , and hence by concavity of the logarithm, with  $w = \xi^T x$ ,

$$\begin{aligned} s_-(w) &= \beta_- \log(1 + w/\beta_-) \leq \beta_- \log(1 + x^\infty |\xi|/\beta_-) \\ &\leq \beta_- \left( \log(|\xi|) + (1 + x^\infty |\xi|/\beta_- - |\xi|)/|\xi| \right). \end{aligned}$$

The right-hand side is bounded above by  $\beta_- \log(|\xi|) + x^\infty$  since  $|\xi| \geq 1$ . This gives the desired bound.  $\square$

We now establish a set of feasible values for  $v$ .

LEMMA 3.7. *There exists  $\kappa_v \geq 1$  and  $\varepsilon_v > 0$  such that for each  $\kappa \geq \kappa_v$  we have*

$$\{v : \|v\| \leq \varepsilon_v \quad \text{and} \quad \langle \xi, v \rangle \geq -(\mu_1 - \lambda_1)\} \subset \mathbf{V}.$$

*Proof.* The velocity space  $\mathbf{V}^\kappa$  is a polyhedron for each  $\kappa$ , and as  $\kappa \rightarrow \infty$  these sets converge to a polyhedron whose interior is nonempty, with a single face meeting the origin given by  $\{\xi^T v = 0\}$ .  $\square$

*Proof of Proposition 3.2.* To avoid trivialities we assume that  $\ell \geq 3$  (no less than three buffers), and that  $\xi_i > 0$  for at least three values of  $i$ .

The drift obtained with any  $v \in \mathbf{V}$  provides an upper bound on the drift obtained using the  $h$ -MaxWeight policy. We take  $v \in \mathbf{V}$  of the specific form  $v = v^* + v^0$  with  $v^* = -(\mu_1 - \lambda_1)\xi_1^{-1}\mathbf{1}^1$ , and  $v^0$  orthogonal to  $\xi$  so that  $\xi^T v = \xi^T v^* = -(\mu_1 - \lambda_1)$ . As in the proof of Lemma 2.10, we apply Proposition 2.8 to relax lattice constraints and boundary constraints in our construction of  $v$ .

Lemma 3.7 implies that we can find  $\varepsilon_{3.7} > 0$  such that the following inclusion holds for each  $\kappa \geq \kappa_v$ :

$$\{v = v^* + v^0 \in \mathbb{R}^\ell : \xi^T v^0 = 0 \text{ and } |v_i^0| \leq \varepsilon_{3.7} \text{ for each } i \geq 1\} \subset \mathbf{V}^\kappa.$$

With this value of  $\varepsilon_{3.7}$  fixed, we set  $v_i^0 = -\varepsilon_{3.7}$  for each  $i$  satisfying  $\xi_i = 0$ , and  $v_i^0 = 0$  for all but (at most) three indices satisfying  $\xi_i > 0$ . In Cases (ii) and (iii) below there are just two nonnull indices, denoted  $i_\ominus$  and  $i_\oplus$ , with  $v_{i_\ominus}^0 < 0$  and  $v_{i_\oplus}^0 > 0$ .

To complete the specification of  $v^0$  we introduce the index sets

$$\begin{aligned} I_\oplus &= \{i \geq 1 : \xi_i > 0, x_i \leq s_-(\xi^T x) - \beta_- \log(|\xi|)\}, \\ I_\ominus &= \{i \geq 2 : \xi_i > 0, x_i > s_+(\xi^T x)\}. \end{aligned}$$

The choice of  $v^0$  depends upon these sets as follows:

- (i) If  $I_\oplus = \emptyset$  and  $I_\ominus = \emptyset$ , then  $v_i^0 = 0$  for each  $i$  satisfying  $\xi_i > 0$ .
- (ii) If  $I_\oplus = \emptyset$  and  $I_\ominus \neq \emptyset$ , then we take  $i_\ominus \in I_\ominus$  arbitrary with  $v_{i_\ominus}^0 \xi_{i_\ominus} = -\varepsilon_{3.7}$ , and set  $v_1^0 \xi_1 = \varepsilon_{3.7}$ .
- (iii) If  $I_\oplus \neq \emptyset$  and  $I_\ominus = \emptyset$ , then we take

$$i_\oplus \in \arg \min\{x_i : i \geq 2, \xi_i > 0\}, \quad i_\ominus = 1,$$

and define  $v_{i_\oplus}^0 \xi_{i_\oplus} = \varepsilon_{3.7}^2$ ,  $v_{i_\ominus}^0 \xi_{i_\ominus} = -\varepsilon_{3.7}^2$ , and  $v_i^0 = 0$  for all other  $i$  satisfying  $\xi_i > 0$ .

- (iv) If  $I_\oplus \neq \emptyset$  and  $I_\ominus \neq \emptyset$ , then  $i_\ominus \in \arg \max\{x_i : i \geq 2, \xi_i > 0\}$ . To determine  $i_\oplus$  there are two subcases to consider.

- (a) If  $I_\oplus = \{1\}$ , then  $v_{i_\ominus}^0 \xi_{i_\ominus} = -\varepsilon_{3.7}$ , and  $i_\oplus = 1$  with  $v_1^0 \xi_1 = \varepsilon_{3.7}$ .
- (b) Otherwise,  $i_\oplus \in \arg \min\{x_i : i \geq 2, \xi_i > 0\}$ , and we take

$$v_{i_\oplus}^0 \xi_{i_\oplus} = \varepsilon_{3.7}^2, \quad v_{i_\ominus}^0 \xi_{i_\ominus} = -\varepsilon_{3.7}, \quad \text{and} \quad v_1^0 \xi_1 = \varepsilon_{3.7} - \varepsilon_{3.7}^2,$$

where again  $v_i = 0$  for all other  $i$  satisfying  $\xi_i > 0$ .

The added complexity in cases (iii) and (iv) is due to the positive drift induced by  $v_{i_\oplus}$ . By imposing the constraint that this is of order  $\varepsilon_{3.7}^2$  rather than  $\varepsilon_{3.7}$ , we can maintain a negative overall drift.

This choice of  $v$  satisfies (105). Moreover, under the assumption that  $\beta_- \geq 3\theta^{-1}$  and  $\beta_+ > \beta_-$ , we have for some constants  $k_{106}$ ,  $\varepsilon_{106}$ , and all  $x$ ,

$$\begin{aligned} |\nabla \hat{J}^*(\tilde{w}) e^{-x_i/\theta} \xi_i v_i| &\leq k_{106} \kappa (1 + w^2)^{-1} \leq \mathcal{E}(x), & i \notin I_\oplus, \\ (106) \quad -\nabla \hat{J}^*(\tilde{w}) e^{-x_{i_\oplus}/\theta} \xi_{i_\oplus} v_{i_\oplus} &\leq -\varepsilon_{106} \|M_\theta(x) \xi\| \kappa w & \text{if } I_\oplus \neq \emptyset, \\ \|M_\theta(x) \xi\| \kappa w &\leq \mathcal{E}(x) & \text{if } I_\oplus = \emptyset. \end{aligned}$$

Combining the bounds in (106) with Lemma 3.5 we obtain

$$\begin{aligned} \langle \nabla h(x), v \rangle &\leq -(\mu_1 - \lambda_1) \nabla \hat{J}^*(\tilde{w}) - \varepsilon_{106} \|M_\theta(x) \xi\| \kappa w + \mathcal{E}(x) \\ &\quad + [c(\tilde{x}) - \bar{c}(\tilde{w})] \sum_{i=2}^{\ell} (1 - e^{-x_i/\theta}) b_i v_i. \end{aligned}$$

To complete the proof we argue that the following bound holds: For some  $\varepsilon_{107} > 0$ ,

$$(107) \quad [c(\tilde{x}) - \bar{c}(\tilde{w})] \sum_{i=2}^{\ell} (1 - e^{-x_i/\theta}) b_i v_i \leq -\varepsilon_{107} b [c(\tilde{x}) - \bar{c}(\tilde{w})] + \mathcal{E}(x).$$

It is here that we require the fact that at most one value of  $v_i$  is positive for  $i \geq 2$ , and that for all such  $i$  we have the bound  $v_i \xi_i \leq \varepsilon_{3.7}^2$ .

If  $x_i > s_+(\xi^\top x)$  for some  $i \geq 2$  (not necessarily satisfying  $\xi_i > 0$ ), then  $v_i = -\varepsilon_{3.7}$  for some  $i \geq 2$ . In fact, with  $i_- \in \arg \max\{x_i : i \geq 2\}$  we have  $v_{i_-} = -\varepsilon_{3.7}$ , and from (101) we obtain  $c(x) - \bar{c}(w) \leq |c|x_{i_-}$ . Consequently,

$$\sum_{i=2}^{\ell} (1 - e^{-x_i/\theta}) b_i v_i \leq -(b_{i_-} \varepsilon_{3.7} - b_{i_{\oplus}} \varepsilon_{3.7}^2) + \varepsilon_{3.7} b_{i_-} e^{-[c(x) - \bar{c}(w)]/(|c|\theta)}.$$

The bound (107) follows for  $\varepsilon_{3.7} > 0$  sufficiently small: Fix  $\varepsilon_{3.7} < \min_{i,j \geq 2} b_i/b_j$  and set  $\varepsilon_{107} = \min_{i,j \geq 2} (b_i \varepsilon_{3.7} - b_j \varepsilon_{3.7}^2)/b$ . Note that the positive term  $b_{i_{\oplus}} \varepsilon_{3.7}^2$  is absent in cases (i) and (ii), so that we are considering the worst case in which  $I_{\oplus} \neq \emptyset$ .

If  $x_i \leq s_+(\xi^\top x)$  for each  $i \geq 2$ , then it may be impossible to guarantee the negative drift  $v_i = -\varepsilon_{3.7}$  for any  $i \geq 2$ . But this is irrelevant since in this case,

$$[c(\tilde{x}) - \bar{c}(\tilde{w})] \leq \mathcal{E}(x),$$

so that (107) follows trivially.  $\square$

*Proof of Proposition 3.3.* We begin with a representation of the form (38) based on a second-order mean value theorem of the form (61). We write  $h_0(x) = \frac{1}{2} x^\top H_0 x$ , with

$$H_0 = \frac{\kappa}{\mu_1} \frac{c_1}{\xi_1} \xi \xi^\top + b \left( c - \left( \frac{c_1}{\xi_1} \right) \xi \right) \left( c - \left( \frac{c_1}{\xi_1} \right) \xi \right)^\top.$$

Based on this expression combined with the mean value theorem, we obtain

$$(108) \quad \begin{aligned} \mathcal{D}h(x) &= \langle \nabla h(x), v \rangle + \frac{1}{2} \mathbb{E}[\Delta(t+1)^\top H_0 \Delta(t+1) \mid Q(t) = x] \\ &\quad + \frac{1}{2} \mathbb{E}[\Delta(t+1)^\top (\nabla^2 h(\bar{Q}) - H_0) \Delta(t+1) \mid Q(t) = x]. \end{aligned}$$

We also have, by definition of  $\hat{\eta}^*(x)$  in (100),

$$(109) \quad \begin{aligned} &\mathbb{E}[\Delta(t+1)^\top H_0 \Delta(t+1) \mid Q(t) = x] \\ &= \hat{\eta}^*(x) + b \mathbb{E}[(c - (c_1/\xi_1)\xi)^\top \Delta(t+1)]^2 \mid Q(t) = x. \end{aligned}$$

We apply Proposition 2.7 to bound the final term in (108):

$$(110) \quad \nabla^2 h(x) - H_0 = -[M_\theta H_0 + M_\theta H_0] + M_\theta H_0 M_\theta + \theta^{-1} \text{diag}(M_\theta \nabla h_0(\tilde{x})).$$

We have for any  $\Delta \in \mathbb{R}^\ell$ ,

$$\begin{aligned} &\Delta^\top [-[M_\theta H_0 + M_\theta H_0] + M_\theta H_0 M_\theta] \Delta \\ &= \kappa c_1 / (\mu_1 \xi_1) [-2(\Delta^\top \xi)(\Delta^\top M_\theta \xi) + (\Delta^\top M_\theta \xi)^2] + O(1) \\ &= \kappa c_1 / (\mu_1 \xi_1) [-(\Delta^\top M_\theta \xi) + 2(\Delta^\top M_\theta \xi)((\Delta^\top M_\theta \xi) - (\Delta^\top \xi))] + O(1) \\ &\leq \kappa c_1 / (\mu_1 \xi_1) [-(\Delta^\top M_\theta \xi) + 2\|\Delta\|^2 \|M_\theta \xi\| \|(I - M_\theta)\xi\|] + O(1), \end{aligned}$$

where terms that are independent of  $\kappa$  are suppressed using the “big O” notation. Applying the mean value theorem as in the proof of Lemma 2.11, we obtain the crude bound,  $\|(I - M_\theta)\xi\| \leq \theta^{-1}w$ , and hence for some  $k_0 < \infty$ ,

$$-[M_\theta H_0 + M_\theta H_0] + M_\theta H_0 M_\theta \leq k_0(\theta^{-1}\|M_\theta \xi\|\kappa w + 1)I.$$

Also, for a possibly larger constant  $k_0$ ,

$$\begin{aligned} \|M_\theta \nabla h_0(\tilde{x})\| &= \|M_\theta(\kappa\mu_1^{-1}\bar{c}(\tilde{w})\xi + b(c(\tilde{x}) - \bar{c}(\tilde{w}))(c - (c_1/\xi_1)\xi))\| \\ &\leq k_0(\|M_\theta \xi\|\kappa w + b|c(\tilde{x}) - \bar{c}(\tilde{w})|). \end{aligned}$$

Consequently, for some  $k_0 < \infty$ ,

$$\nabla^2 h(x) - H_0 \leq k_0\theta^{-1}(\kappa\|M_\theta \xi\|w + b|c(\tilde{x}) - \bar{c}(\tilde{w})|)I + k_0I.$$

This combined with (108) and (109) completes the proof.  $\square$

*Proof of Theorem 3.1.* Following Propositions 3.3 and 3.4, the proof of the theorem amounts to establishing the drift (96) for a function  $V$  derived from  $h$ . We define

$$V(x) = h(x) + \frac{1}{2} \frac{c_1}{\xi_1} \mu^{-1} \left( \frac{m^2 - m_L^2}{\mu - \alpha} \right) \xi^\top x, \quad x \in \mathbb{Z}_+^\ell,$$

where  $m^2 := \mathbb{E}[(S_1(1) - L_1(1))^2]$  and  $m_L^2 \mathbb{E}[(L_1(1))^2]$ . That is, we are re-introducing the linear term appearing in the solution to Poisson’s equation for the relaxation. Based on the definitions of  $\hat{\eta}^*$  and  $\hat{\eta}^*(x)$  in (88) and (100), we obtain the following identity for any policy:

$$\mathbb{E} \left[ \frac{1}{2} \frac{c_1}{\xi_1} \mu^{-1} \left( \frac{m^2 - m_L^2}{\mu - \alpha} \right) (W(t+1) - W(t)) \mid Q(t) = x \right] = \hat{\eta}^* - \hat{\eta}^*(x).$$

Hence the function  $V$  does satisfy (96).

This bound implies that (V3) holds, so that  $\pi(c)$  is finite for any finite  $\kappa$ . An application of the comparison theorem gives

$$\pi(c) \leq \hat{\eta}^* + \pi(\mathcal{E}).$$

From the form of  $\mathcal{E}$  given in (97), it follows that  $\pi(c)$  is bounded by a constant times  $\kappa$ . In fact, by the bound above, (97), and Jensen’s inequality, we obtain

$$\pi(c) \leq \hat{\eta}^* + k_{97} \log(\kappa + \pi(c)) + k_{97} \kappa \mathbb{E}_\pi[(1 + (\xi^\top Q(t))^2)^{-1}]$$

so that for a possibly larger constant,

$$\pi(c) \leq \hat{\eta}^* + k_{97} \log(\kappa) + k_{97} \kappa \mathbb{E}_\pi[(1 + (\xi^\top Q(t))^2)^{-1}].$$

Moreover, applying (35) we obtain,

$$\pi(c) \leq \hat{\eta}^* + k_{97} \log(\kappa) + k_{97} \kappa \mathbb{E}[(1 + (\widehat{W}^*(t))^2)^{-1}],$$

where the expectation is taken for the steady-state relaxation. Lemma A.2 of [37] implies that  $\kappa \mathbb{E}[(1 + (\widehat{W}^*(t))^2)^{-1}]$  is uniformly bounded in  $\kappa$ , so this final bound completes the proof.  $\square$

**4. Extensions, conjectures, and conclusions.** The generalized MaxWeight policies proposed in this paper can be designed to capture all of the desirable features observed in Tassiulus' original policy. Depending upon the structure of  $h$ , the policy can be designed to depend only on local information, as in the standard algorithm, or it can utilize more information, if available.

There remain many questions.

*Statistics.* Generalizations of Theorems 1.1 and 2.14 to network models with renewal arrivals and service are straightforward by applying fluid limit techniques [12, 15, 13]. It would be of interest to develop alternative methods to cope with these more complex models to obtain sharp performance estimates in heavy traffic. In particular, to date logarithmic regret has been established only for homogeneous Markovian models. To relax the homogeneity (Kelly-type) assumption, the workload process should be constructed in units of time rather than inventory as done here. It would be much more interesting to find a counterexample within the class of renewal models with finite second moment, though this is not likely to exist.

Of greater practical importance is the issue of memory: Long-range dependent models remain a frontier. It may be possible to extend fluid limit techniques to establish stability. New techniques are required to obtain performance bounds.

*Information.* Design of the function  $h_0$  requires stability considerations; e.g., monotonicity has been imposed as a blanket assumption in each of the main results. A second consideration is the amount of information required for implementation.

Consider the special case of the quadratic function (1). Monotonicity holds provided  $D_{ij} \geq 0$  for each  $i, j$ , and the dynamic programming inequality holds if in addition  $D_{ii} > 0$  for each  $i$ . In typical scheduling and routing models the MaxWeight policy in which  $D$  is diagonal requires only local information [53]. The main result of this paper shows that this can be relaxed through the introduction of a state transformation. If the matrix  $D$  that defines  $h_0$  is sparse, then the amount of information required for implementation of the  $h$ -MaxWeight policy will be limited.

Suppose that  $D$  is a band matrix with width  $n_0 \geq 1$  ( $D_{ij} = 0$  for each  $i, j$  satisfying  $|i - j| > n_0$ ). For the same scheduling and routing models considered in earlier work, the resulting  $h$ -MaxWeight policy will require “ $(n_0 + 1)$ -hop” local information. For example, for a network consisting of a sequence of  $N$  queues in tandem, for each integer  $i \in [n_0, N - n_0 - 1]$  the policy at Station  $i$  will require queue length information at buffers  $\{i \pm k, |k| \leq n_0\}$  and buffer  $i + n_0 + 1$ .

Another important class of quadratics is those with low rank. Suppose that for linearly independent vectors  $\{d^i : i = 1, \dots, n_1\} \subset \mathbb{R}_+^\ell$  we have

$$h_0(x) = \frac{1}{2} \sum_{i=1}^{n_1} d^i d^{i^\top}.$$

For example, the function (91) is of this form with  $n_1 = 2$ . This matrix is not banded in general, but the  $h$ -MaxWeight policy will again require limited information. For scheduling and routing models the required information is the same “one-hop” data required in the usual MaxWeight algorithm, along with values of the inner products  $\{d^{i^\top} Q(t) : i = 1, \dots, n_1\}$ . For small values of  $n_1$  this information might be distributed through message passing.

*Performance bounds for universally stabilizing policies.* The  $h$ -MaxWeight policy considered in Theorem 2.14 using the change of variables (73) is universally stabilizing, but its performance is not understood. It will be interesting to evaluate its

performance in the setting of section 3. It will not yield logarithmic regret in general under the assumptions of Theorem 3.1.

CONJECTURE 1. *Under the assumptions of Theorem 3.1, with  $\tilde{x}$  redefined via (73) and the  $L_2$  bound (77) satisfied for  $A^\infty(t)$ , the  $h$ -MaxWeight policy will result in asymptotic minimality of workload, with logarithmic regret, in the sense that*

$$\mathbb{E}[W(t; x)] \leq \mathbb{E}[\widehat{W}^*(t; x)] + k_1 \log(\kappa)$$

for some  $k_1$ , each  $\kappa$  sufficiently large, and each  $t$  an initial condition.

It is likely that minimality is not difficult to establish. It is also likely that state space collapse (25) will hold in some form, perhaps with  $\mathcal{X}^*$  defined with respect to the perturbed cost function,

$$\mathcal{X}^*(w) = \arg \min_{x \in \mathbb{R}_+^\ell} (c(\tilde{x}) : \xi^\top x = w).$$

*Linearity and logarithmic regret.* If  $c$  is an arbitrary norm on  $\mathbb{R}^\ell$ , then the average cost for the relaxation becomes

$$\widehat{\eta}^* = \frac{1}{2} \overline{c}(1) \frac{\sigma_\kappa^2}{\mu_1} \kappa,$$

where the definition of the effective cost is given in (24). This generalizes (93) since  $\overline{c}(1) = c_1/\xi_1$  under the assumptions of Theorem 3.1. A stability proof is simplified if the function  $h_0$  in (91) used to define the  $h$ -MaxWeight policy is redefined via

$$h_0(x) = \widehat{J}^*(\xi^\top x) + \frac{1}{2} b \|x - x^*\|^2.$$

CONJECTURE 2. *The conclusions of Theorem 3.1 remain valid when  $c$  is a general norm,  $h_0$  redefined as above, and with the remaining assumptions of the theorem maintained.*

*Multiple bottlenecks.* The generalization of Theorem 3.1 to multiple bottlenecks is a significant open problem. This is difficult because we do not have an explicit representation for the relative value function for the relaxation, and we do not know the optimal policy when the effective cost is not monotone.

To formulate a conjecture we again restrict to the homogeneous scheduling model with linear cost. If there are  $n$  bottlenecks in heavy traffic, we consider an  $n$ -dimensional relaxation, as formulated in [9]. Analysis of the usual MaxWeight policy based on a workload relaxation of dimension  $n \geq 2$  is contained in [39, Chapter 6].

The workload relaxation evolves in a positive cone  $W \subset \mathbb{R}^n$  according to a multi-dimensional recursion of the form (83). Let  $\widehat{\eta}^*$  denote the optimal average cost, and suppose that  $\hat{h}_* : W \rightarrow \mathbb{R}$  solves the average-cost optimality equations for the relaxation, perhaps approximately: For some finite constant  $k_3$  and all  $\kappa$ ,

$$\min \mathbb{E}[\hat{h}_*(\widehat{W}(t+1)) \mid \widehat{W}(t) = w, \mathcal{L}(t) = \iota] \leq \hat{h}_*(w) - \overline{c}(w) + \widehat{\eta}^* + k_3 \log(\kappa),$$

where  $\mathcal{L}(t)$  denotes the idleness at time  $t$ , and the minimum is over all  $\iota \geq 0$  such that  $\widehat{W}(t+1) \in W$  with probability one. The integer constraints are relaxed so that  $\hat{h}_*$  is defined on all of  $W$ . Based on the relative value function for the relaxation, the function  $h_0$  in (91) is redefined via

$$(111) \quad h_0(x) := \hat{h}_*(\xi^\top x) + \frac{1}{2} b [c(x) - \overline{c}(\xi^\top x)]^2, \quad x \in \mathbb{R}_+^\ell.$$

The function  $\hat{h}_*$  will depend upon  $\kappa$  in a parameterized model, but the constant  $b$  will be fixed as in Theorem 3.1.

CONJECTURE 3. *Theorem 3.1 can be extended to the case where there are precisely  $n$  bottlenecks as  $\kappa \rightarrow \infty$ , based on the  $h$ -MaxWeight policy with  $h_0$  as given in (111).*

If true, this provides a valuable tool for constructing an effective policy in a complex network setting.

A final topic of current research is to create a bridge between the concepts developed in this paper, and recent methodology that has emerged in the machine learning literature. Given a parameterized family of functions  $\{h_\alpha : \alpha \in \mathbb{R}^d\}$ , we seek the value of  $\alpha$  such that the  $h_\alpha$ -MaxWeight policy has the best performance in this class. There are a variety of methods for finding an optimizer based on simulation [3, 51, 54, 16, 46]. It is hoped that specialized algorithms can be constructed for networks based on the techniques introduced here.
