**PROPOSITION 6.** *Let  $\mathcal{S}_{sr}$  be any closed set of stochastic matrices which are all of the same size and whose graphs  $\gamma(S)$ ,  $S \in \mathcal{S}_{sr}$ , are all strongly rooted. As  $j \rightarrow \infty$ , any product  $S_j \cdots S_1$  of matrices from  $\mathcal{S}_{sr}$  converges exponentially fast to a matrix of the form  $\mathbf{1}c$  at a rate no slower than  $\lambda$ , where  $c$  is a nonnegative row vector depending on the sequence and  $\lambda$  is a nonnegative constant less than 1 depending only on  $\mathcal{S}_{sr}$ .*

*Proof of Theorem 2.* In view of (31),  $\theta(t) = F(t-1) \cdots F(0)\theta(0)$ . Thus to prove the theorem it suffices to prove that as  $t \rightarrow \infty$  the matrix product  $F(t) \cdots F(0)$  converges exponentially fast to a matrix of the form  $\mathbf{1}c$ .

By hypothesis, the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted by subsequences of length  $q$ . This means that each of the sequences  $\mathbb{N}(kq), \dots, \mathbb{N}((k+1)q-1)$ ,  $k \geq 0$ , is jointly rooted. Let  $\mathbb{D}(t) = \gamma(F(t))$ ,  $t \geq 0$ . In view of (29),  $\mathbb{N}(t) = Q(\mathbb{D}(t))$ ,  $t \geq 0$ . Thus each of the sequences  $Q(\mathbb{D}(kq)), \dots, Q(\mathbb{D}((k+1)q-1))$ ,  $k \geq 0$ , is jointly rooted, and so each composition  $Q(\mathbb{D}((k+1)q-1)) \circ \dots \circ Q(\mathbb{D}(kq))$  is a rooted graph. In view of Proposition 5, each graph  $Q(\mathbb{D}((k+1)q-1)) \circ \dots \circ \mathbb{D}(kq)$ ,  $k \geq 0$ , is also rooted.

Set  $p = (m(n-1)^2 + m - 1)q$ , where  $m$  is the largest integer in the set  $\{m_1, m_2, \dots, m_n\}$ . In view of Proposition 4, each of the graphs  $\mathbb{D}((k+1)p-1) \circ \dots \circ \mathbb{D}(kp)$ ,  $k \geq 0$ , is strongly rooted. Let  $\mathcal{F}(p)$  denote the set of all products of  $p$  matrices from  $\bar{\mathcal{F}}$  which have the additional property that each such product has a strongly rooted graph. Then  $\mathcal{F}(p)$  is finite and therefore compact, because  $\bar{\mathcal{F}}$  is.

For  $k \geq 0$ , define

$$(32) \quad S(k) = F((k+1)p-1) \cdots F(kp).$$

In view of (12) and the fact that  $\gamma(F(t)) = \mathbb{D}(t)$ ,  $t \geq 0$ , it must be true that  $\gamma(S(k)) = \mathbb{D}((k+1)p-1) \circ \dots \circ \mathbb{D}(kp)$ ,  $k \geq 0$ . Thus each  $S(k)$  has a strongly rooted graph. Moreover, each such  $S(k)$  is the product of  $p$  matrices from  $\bar{\mathcal{F}}$ . Therefore  $S(k) \in \mathcal{F}(p)$ ,  $k \geq 0$ . Therefore Proposition 6 applies with  $\mathcal{S}_{sr} = \mathcal{F}(p)$ , and so it can be concluded that the matrix product  $S(k) \cdots S(0)$  converges exponentially fast as  $k \rightarrow \infty$  to a matrix of the form  $\mathbf{1}c$  as  $k \rightarrow \infty$ .

In view of the definition of  $S(k)$  it is clear that for any  $t$ , there is an integer  $k(t)$  and a stochastic matrix  $\hat{S}(t)$  composed of the product of at most  $p-1$  matrices from  $\bar{\mathcal{F}}$  such that

$$F(t) \cdots F(1) = \hat{S}(t)S(k(t)) \cdots S(0).$$

Moreover,  $t \mapsto k(t)$  must be an unbounded, strictly increasing function; because of this the product  $S(k(t)) \cdots S(0)$  must converge exponentially fast as  $t \rightarrow \infty$  to a limit of the form  $\mathbf{1}c$ . Since  $\widehat{S}(t)\mathbf{1}c = \mathbf{1}c$ ,  $t \geq 0$ , the product  $F(t) \cdots F(1)$  must also converge exponentially fast as  $t \rightarrow \infty$  to the same limit  $\mathbf{1}c$ .  $\square$

**5. Asynchronous flocking.** In this section we consider a modified version of the consensus problem treated in [6] in which each agent independently updates its heading at times determined by its own clock.<sup>2</sup> We do not assume that the groups' clocks are synchronized or that the times any one agent updates its heading are evenly spaced. Updating of agent  $i$ 's heading is done as follows. At its  $k$ th *sensing event time*  $t_{ik}$ , agent  $i$  senses the headings  $\theta_j(t_{ik})$ ,  $j \in \mathcal{N}_i(t_{ik})$ , of its current neighbors (which includes itself) and from this data computes its  $k$ th "way-point"  $w_i(t_{ik})$ . In what follows we will consider way-points based on averaging. In particular, agent  $i$ 's  $k$ th *way-point* is defined by the rule

$$(33) \quad w_i(t_{ik}) = \frac{1}{n_i(t_{ik})} \left( \sum_{j \in \mathcal{N}_i(t_{ik})} \theta_j(t_{ik}) \right), \quad i \in \{1, 2, \dots, n\},$$

where  $n_i(t_{ik})$  is the number of neighbor elements in the neighbor index set  $\mathcal{N}_i(t_{ik})$ . After computing  $w_i(t_{ik})$ , agent  $i$  changes its heading from  $\theta_i(t_{ik})$  to  $w_i(t_{ik})$  on the interval  $(t_{ik}, t_{i(k+1)}]$ . In this paper we will consider the case when each agent updates its heading instantaneously at its own event times and holds its heading fixed between event times. More precisely, we will assume that agent  $i$ 's heading  $\theta_i(t)$  takes on its agent  $i$ 's  $k$ th way-point value  $w_i(t_{ik})$  immediately after its  $k$ th event time  $t_{ik}$  and that  $\theta_i(t)$  is constant on each continuous-time interval  $(t_{i(k-1)}, t_{ik}]$ ,  $k \geq 1$ , where  $t_{i0} = 0$  is agent  $i$ 's zeroth event time. In other words for  $k \geq 0$ , agent  $i$ 's heading satisfies

$$(34) \quad \theta_i(t_{i(k+1)}) = \frac{1}{n_i(t_{ik})} \left( \sum_{j \in \mathcal{N}_i(t_{ik})} \theta_j(t_{ik}) \right),$$

$$(35) \quad \theta_i(t) = \theta_i(t_{ik}), \quad t_{i(k-1)} < t \leq t_{ik}.$$

**5.1. Analytic synchronization.** To develop conditions under which all agents eventually move with the same heading requires the analysis of the asymptotic behavior of the *asynchronous* process which the  $2n$  heading equations of the form (34), (35) define. Despite the apparent complexity of this process, it is possible to capture its salient features using a suitably defined *synchronous* discrete-time, hybrid dynamical system  $\mathbb{S}$ . The sequence of steps involved in defining  $\mathbb{S}$  has been discussed before and is called *analytic synchronization* [12, 13]. Analytic synchronization is applicable to any finite family of continuous or discrete-time dynamical processes  $\{\mathbb{P}_1, \mathbb{P}_2, \dots, \mathbb{P}_n\}$  under the following conditions. First, each process  $\mathbb{P}_i$  must be a dynamical system whose inputs consist of functions of the states of the other processes as well as signals which are exogenous to the entire family. Second, each process  $\mathbb{P}_i$  must have associated with it an ordered sequence of event times  $\{t_{i1}, t_{i2}, \dots\}$  defined in such a way so that the state of  $\mathbb{P}_i$  at event time  $t_{i(k+1)}$  is uniquely determined by values of the exogenous signals and states of the  $\mathbb{P}_j$ ,  $j \in \{1, 2, \dots, n\}$ , at event times  $t_{jkj}$  which occur

<sup>2</sup>A preliminary version of the material in this section was presented at the 2005 IFAC congress [4].

prior to  $t_{i(k_i+1)}$  but in the finite past. Event time sequences for different processes need not be synchronized. Analytic synchronization is a procedure for creating a single synchronous process for purposes of analysis which captures the salient features of the original  $n$  asynchronously functioning processes. As a first step, all  $n$  event time sequences are merged into a single ordered sequence of event times  $\mathcal{T}$ . (This clever idea has been used before in [2] to study the convergence of totally asynchronous iterative algorithms.) The “synchronized” state of  $\mathbb{P}_i$  is then defined to be the original state of  $\mathbb{P}_i$  at  $\mathbb{P}_i$ ’s event times  $\{t_{i1}, t_{i2}, \dots\}$  plus possibly some additional variables; at values of  $t \in \mathcal{T}$  between event times  $t_{ik_i}$  and  $t_{i(k_i+1)}$ , the synchronized state of  $\mathbb{P}_i$  is taken to be the same as the value of its original state at time  $t_{ik}$ . Although it is not always possible to carry out all of these steps, when it is what ultimately results is a synchronous dynamical system  $\mathbb{S}$  evolving on the index set of  $\mathcal{T}$ , with the state composed of the synchronized states of the  $n$  individual processes under consideration. We now use these ideas to develop such a synchronous system  $\mathbb{S}$  for the asynchronous process under consideration.

**5.2. Definition of  $\mathbb{S}$ .** As a first step, let  $\mathcal{T}$  denote the set of all event times of all  $n$  agents. Relabel the elements of  $\mathcal{T}$  as  $t_0, t_1, t_2, \dots$  in such a way so that  $t_j < t_{j+1}$ ,  $j \in \{1, 2, \dots\}$ . Next define

$$(36) \quad \bar{\theta}_i(\tau) = \theta_i(t_\tau), \quad \tau \geq 0, \quad i \in \{1, 2, \dots, n\}.$$

In view of (34), it must be true that if  $t_\tau$  is an event time of agent  $i$ , then

$$\bar{\theta}_i(\tau') = \frac{1}{\bar{n}_i(\tau)} \left( \sum_{j \in \bar{\mathcal{N}}_i(\tau)} \bar{\theta}_j(\tau) \right),$$

where  $\bar{\mathcal{N}}_i(\tau) = \mathcal{N}_i(t_\tau)$ ,  $\bar{n}_i(\tau) = n_i(t_\tau)$ , and  $t_{\tau'}$  is the next event time of agent  $i$  after  $t_\tau$ . But  $\bar{\theta}_i(\tau') = \bar{\theta}_i(\tau + 1)$  because  $\theta_i(t)$  is constant for  $t_\tau < t \leq t_{\tau'}$  (approximately (35)). Therefore

$$(37) \quad \bar{\theta}_i(\tau + 1) = \frac{1}{\bar{n}_i(\tau)} \left( \sum_{j \in \bar{\mathcal{N}}_i(\tau)} \bar{\theta}_j(\tau) \right)$$

if  $t_\tau$  is an event time of agent  $i$ . Meanwhile if  $t_\tau$  is not an event time of agent  $i$ , then

$$(38) \quad \bar{\theta}_i(\tau + 1) = \bar{\theta}_i(\tau),$$

again because  $\theta_i(t)$  is constant between event times. Note that if we define  $\bar{\mathcal{N}}_i(\tau) = \{i\}$  and  $\bar{n}_i(\tau) = 1$  for every value of  $\tau$  for which  $t_\tau$  is not an event time of agent  $i$ , then (38) can be written as

$$(39) \quad \bar{\theta}_i(\tau + 1) = \frac{1}{\bar{n}_i(\tau)} \left( \sum_{j \in \bar{\mathcal{N}}_i(\tau)} \bar{\theta}_j(\tau) \right).$$

Doing this enables us to combine (37) and (39) into a single formula valid for all  $\tau \geq 0$ . In other words, agent  $i$ ’s heading satisfies

$$(40) \quad \bar{\theta}_i(\tau + 1) = \frac{1}{\bar{n}_i(\tau)} \left( \sum_{j \in \bar{\mathcal{N}}_i(\tau)} \bar{\theta}_j(\tau) \right), \quad \tau \geq 0,$$

where

$$(41) \quad \bar{\mathcal{N}}_i(\tau) = \begin{cases} \mathcal{N}_i(t_\tau) & \text{if } t_\tau \text{ is an event time of agent } i \\ \{i\} & \text{if } t_\tau \text{ is not an event time of agent } i \end{cases}$$

and  $\bar{n}_i(\tau) = 1$  if  $t_\tau$  is not an event time of agent  $i$ . Thus for all  $\tau$ ,  $\bar{n}_i(\tau)$  is the number of indices in  $\bar{\mathcal{N}}_i(\tau)$ . For purposes of analysis, it is useful to interpret (41) as meaning that between agent  $i$ 's event times, its only neighbor is itself. There are  $n$  equations of the form in (40), and together they define a synchronous system  $\mathbb{S}$  which models the evolutions of the  $n$  agents' headings at event times.

**5.3. State space model.** As before, we can represent the neighbor relationships associated with (41) using a directed graph  $\mathbb{N}$  with vertex set  $\mathcal{V} = \{1, 2, \dots, n\}$  and arc set  $\mathcal{A}(\mathbb{N}) \subset \mathcal{V} \times \mathcal{V}$  which is defined in such a way so that  $(i, j)$  is an arc from  $i$  to  $j$  just in case agent  $i$  is a neighbor of agent  $j$ . Thus as before,  $\mathbb{N}$  is a directed graph on  $n$  vertices with at most one arc from any vertex to another and with exactly one self-arc at each vertex. We continue to write  $\mathcal{G}_{sa}$  for the set of all such graphs.

For each graph  $\mathbb{N} \in \mathcal{G}_{sa}$  let  $F = D^{-1}A'$ , where  $A'$  is the transpose of the adjacency matrix of  $\mathbb{N}$  and  $D$  the diagonal matrix whose  $j$ th diagonal element is the in-degree of vertex  $j$  within the graph. The set of agent heading update rules defined by (41) can be written in state form as

$$(42) \quad \bar{\theta}(\tau + 1) = F(\tau)\bar{\theta}(\tau), \quad \tau \in \{0, 1, 2, \dots\},$$

where  $\bar{\theta}$  is the heading vector  $\bar{\theta} = [\bar{\theta}_1 \quad \bar{\theta}_2 \quad \dots \quad \bar{\theta}_n]'$ , and  $F(\tau)$  is the flocking matrix determined by neighbor graph  $\mathbb{N}(\tau)$  at event time  $t_\tau$ .

Up to this point the development is essentially the same as in the leaderless consensus problem discussed in section 2. But when one considers the type of graphs in  $\mathcal{G}_{sa}$  which are likely to be encountered along a given trajectory, things are quite different. Note, for example, that the only vertices of  $\mathbb{N}(\tau)$  which can have more than one incoming arc are those of agents for whom  $t_\tau$  is an event time. Thus in the most likely situation when distinct agents have only distinct event times, there will be at most one vertex in each graph  $\mathbb{N}(\tau)$  which has more than one incoming arc. It is this situation we want to explore further. Towards this end, let  $\mathcal{G}_{sa}^* \subset \mathcal{G}_{sa}$  denote the subclass of all graphs which have at most one vertex with more than one incoming arc. Note that for  $n > 2$ , there is no rooted graph in  $\mathcal{G}_{sa}^*$ . Nonetheless, in light of Theorem 1 it is clear that convergence to a common steady state heading will occur if the infinite sequence of graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted. This of course would require that there exist a jointly rooted sequence of graphs from  $\mathcal{G}_{sa}^*$ . We will now explain why such sequences do in fact exist.

Let us agree to call a graph  $\mathbb{G} \in \mathcal{G}_{sa}$  an *all neighbor graph centered at  $v$*  if every vertex of  $\mathbb{G}$  is a neighbor of  $v$ . Note that every all neighbor graph in  $\mathcal{G}_{sa}$  is also in  $\mathcal{G}_{sa}^*$ . Note also that all neighbor graphs are maximal in  $\mathcal{G}_{sa}^*$  with respect to the partial ordering of  $\mathcal{G}_{sa}^*$  by inclusion. Note also the composition of any all neighbor graph with itself is itself. On the other hand, because the union of two graphs in  $\mathcal{G}_{sa}$  is always contained in the composition of the two graphs, the composition of  $n$  all neighbor graphs with distinct centers must be a graph in which each vertex is a neighbor of every other, i.e., the complete graph. Thus the composition of  $n$  all neighbor graphs with distinct centers is strongly rooted. In summary, the hypothesis of Theorem 1 is not vacuous for the asynchronous problem under consideration. When that hypothesis is satisfied, convergence to a common steady state heading will occur.

**6. Leader following.** In this section we consider a modified version of the flocking problem for the same group of  $n$  agents as before but now with one of the group's members (say agent 1) acting as the group's *leader* [11, 8]. The remaining agents, henceforth called *followers* and labelled 2 through  $n$ , do not know who the leader is or even if there is a leader. Accordingly they continue to use the same heading update rule (1) as before. The leader, on the other hand, acting on its own, ignores update rule (1) and moves with a constant heading  $\theta_1(0)$ . Thus

$$(43) \quad \theta_1(t+1) = \theta_1(t).$$

The situation just described can be modelled as a state space system

$$(44) \quad \theta(t+1) = F(t)\theta(t), \quad t \geq 0,$$

just as before, except now agent 1 is constrained to have no neighbors other than itself. The neighbor graphs  $\mathbb{N}$  which model neighbor relations accordingly all have a distinguished *leader vertex* which has no incoming arcs other than its own.

Much like before, our goal here is to show for a large class of switching signals and for any initial set of follower agent headings that the headings of all  $n$  followers converge to the heading of the leader. Convergence in the leaderless case under the most general conditions required the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  encountered along a trajectory to be repeatedly jointly rooted. For the leader-follower case now under consideration, what is required is exactly the same. However, since the leader vertex has only one incoming arc which is a self-arc, the only way  $\mathbb{N}(0), \mathbb{N}(1), \dots$  can be repeatedly jointly rooted is that the sequence be “rooted at the leader vertex  $v = 1$ .” More precisely, an infinite sequence of graphs  $\mathbb{G}_1, \mathbb{G}_2$  in  $\mathcal{G}_{sa}$  is *repeatedly jointly rooted at  $v$*  if there is a positive integer  $m$  for which each finite sequence  $\mathbb{G}_{m(k-1)+1}, \dots, \mathbb{G}_{mk}, k \geq 1$ , is “jointly rooted at  $v$ ”; a finite sequence of directed graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_k$  is *jointly rooted at  $v$*  if the composition  $\mathbb{G}_k \circ \mathbb{G}_{k-1} \circ \dots \circ \mathbb{G}_1$  is rooted at  $v$ . Our main result on discrete-time leader following is next.

**THEOREM 3.** *Let  $\theta(0)$  be fixed. For any trajectory of the system determined by (1) along which the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted at vertex 1, there is a constant  $\theta_{ss}$ , depending only on  $\theta(0)$ , for which*

$$\lim_{t \rightarrow \infty} \theta(t) = \theta_1(0)\mathbf{1},$$

where the limit is approached exponentially fast.

*Proof of Theorem 3.* Since any sequence which is repeatedly jointly rooted at  $v$  is repeatedly jointly rooted, Theorem 1 is applicable. Therefore the headings of all  $n$  agents converge exponentially fast to a single common steady state heading  $\theta_{ss}$ . But since the heading of the leader is fixed,  $\theta_{ss}$  must be the leader's heading  $\theta_1(0)$ .  $\square$

**7. Concluding remarks.** The main goal of this paper has been to study various versions the flocking problem considered in [14, 16, 3, 11, 1] and elsewhere from a single point of view which emphasizes the underlying graphical structures for which consensus can be reached. The paper brings together in one place a number of results scattered throughout the literature and at the same time presents new results concerned with convergence rates, asynchronous operation, sensing delays, and graphical interpretations of several specially structured stochastic matrices appropriate to nonhomogeneous Markov chains.

The approach taken in this paper to analyze consensus in the face of measurement delays first goes through a lifting process and then focuses on the resulting state space

model. As we have explained, the lifting process determines stochastic matrices whose graphs do not have self-arcs at all vertices. Nonetheless the graphs which result, namely delay graphs, have special structure, which we have exploited. One is able to associate with each such graph two special graphs, namely a quotient graph and an agent subgraph. These graphs play roles in the analysis of the consensus problem with delays which are similar to the roles played by corresponding quotient graphs and the “injected subgraph” used in the analysis of the asynchronous flocking problem treated in [5]. Although the corresponding graphs which arise in the two problems are completely different, there does seem to be a general pattern of use appropriate to both problems. This suggests that quotient graphs and graphs similar to injected graphs or agent subgraphs may be useful in analyzing other problems as well.

## MIXING ENHANCEMENT BY OPTIMAL FLOW ADVECTION\*

WEIJIU LIU†

**Abstract.** We consider the problem of optimal mixing control. Our objective is to best enhance mixing by flow advection while the flow is optimized in the sense that it is almost steady and is of the least magnitude and the least rotation. For this we define a mixing efficiency functional by penalizing the average of variance of a diffusive scalar, the average of the flow, and the average of its acceleration and strain tensor. By variational principles, we prove the existence of an optimal flow and derive optimality conditions that consist of a system of nonlinear advection-diffusion equations, wave equations, and Laplace's equation.

**Key words.** mixing enhancement, optimal advection, optimal mixing control, advection-diffusion equation

**AMS subject classifications.** 76F25, 49J20

**DOI.** 10.1137/050647888

**1. Introduction.** A fluid mixture consists of diffusive physical quantities and a fluid in which the physical quantities are immersed. Typical examples of such a mixture include fuel and air in a combustor and chemical pollutants and water in the environment. These physical quantities can be mathematically regarded as scalars. If a scalar such as the fuel does not significantly influence the fluid motion, it is called a passive scalar. If chemical reactions can be neglected, then the scalar usually undergoes two processes: molecular diffusion and flow advection. These two processes can be mathematically modeled by the advection-diffusion equation

$$(1) \quad \frac{\partial c}{\partial t} + (\mathbf{v} \cdot \nabla)c = \kappa \nabla^2 c, \quad c(\mathbf{x}, 0) = c^0(\mathbf{x}) \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial c}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega$$

in the absence of a source or sink. In the above equation,  $c = c(\mathbf{x}, t)$  denotes the concentration of the scalar,  $c^0(\mathbf{x})$  is an initial concentration,  $\kappa > 0$  denotes the molecular diffusivity of the scalar,  $\Omega$  is a bounded domain in  $\mathbb{R}^n$ ,  $\frac{\partial}{\partial \mathbf{n}}$  denotes the normal derivative along the boundary  $\partial\Omega$ ,  $\mathbf{v} = \mathbf{v}(\mathbf{x}, t)$  denotes an incompressible velocity field ( $\nabla \cdot \mathbf{v} = 0$ ),  $\nabla = (\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n})$ , and  $\nabla^2 = \frac{\partial^2}{\partial x_1^2} + \dots + \frac{\partial^2}{\partial x_n^2}$ . We assume that  $\mathbf{v}$  satisfies no-penetration boundary conditions on the boundary  $\partial\Omega$  ( $\mathbf{n} \cdot \mathbf{v} = 0$  with  $\mathbf{n}$  denoting the unit normal on the boundary).

Often a certain level of homogeneity of a mixture is desired. For instance, before fuel is burned in a combustor, it is required to be well mixed so that the combustor can achieve its best efficiency. Hence, it is important to design efficient and practical mixing enhancement techniques.

Because a turbulent flow can greatly enhance mixing [4, 10, 11, 12, 13, 15, 22, 26], a useful mixing enhancement technique is to destabilize a flow so that it becomes as turbulent or chaotic as possible. In the design of a stainless cylindrical microcombustor,

a critical component for micropower systems using hydrogen and hydrocarbon fuels as an energy source, Yang et al. [28] used the backward facing step to provide a simple yet effective solution to enhance the mixing of the fuel mixture, prolong the residence time, control the position of the flame, and widen the operational range of the flow rate and  $H_2$ /air ratio. Charyulu et al. [7] studied mixing enhancement with two-dimensional (2D) lobed nozzles in a dual stream supersonic flow facility, and their results indicated an enormous enhancement in mixing when a 2D lobed nozzle was employed in comparison with a conventional plain 2D nozzle. The enhanced mixing performance could be attributed to the large-scale axial vortices observed in the flow field. In addition to the use of these passive control devices, a flow can be destabilized by open-loop active excitations through flaps, wall-jets, or other devices [14] so that the flow is separated and large-scale coherent structures are developed in the flow. Active feedback controllers were developed by Aamo, Krstic, and Bewley [1] for destabilization of 2D channel flows; by Balogh, Aamo, and Krstic [5] for destabilization of three-dimensional (3D) pipe flows; by Yuan, Krstic, and Bewley [29] for destabilization of jet nozzle flows; and by Wang et al. [27] for generation of flow separation in bluff body shear flows.

In these control designs, the optimization of control efforts is ignored. While we try to enhance mixing by destabilizing a flow, it is desirable to minimize this destabilization effort. For instance, after mixing has been enhanced, the destabilization should be stopped to save the control efforts. The goal of this paper is to characterize a flow that best enhances mixing and is optimized in some sense.

Mixing will be best enhanced if the scalar variance  $\|c(t; \mathbf{v}) - \langle c(t; \mathbf{v}) \rangle\|$  is made as small as possible [19], where  $c(\mathbf{x}, t; \mathbf{v})$  is the solution of (1) corresponding to the velocity  $\mathbf{v}$  and  $\langle c(t; \mathbf{v}) \rangle$  denotes the mean concentration. As for the control efforts, we could say that the flow velocity  $\mathbf{v}$  is optimal if the flow is almost steady and irrotational. This implies that the flow, its acceleration, and its strain tensor need to be minimized. Therefore we define a mixing efficiency functional by penalizing the average of variance of the scalar, the average of the flow velocity, the average of the strain tensor, and the average of the acceleration. We show that the functional is weakly lower semicontinuous and then it attains its minimum. The minimizer of the functional is called an optimal flow. By variational principles, we then derive optimality conditions that consist of a system of nonlinear partial differential equations.

There are different measures for mixing efficiency such as Lagrangian and Eulerian time averages of a flow [3], the mixing variance coefficient [6], and the Mix-Norm defined by Mathew, Mezić, and Petzold [20]. For the convenience of treatment of our optimal control problem, we use the  $L_2$  norm of a scalar variance as the mixing efficiency measurement.

The optimal mixing problem has been studied in the literature. Using the entropy of automorphisms of dynamical systems as the measure of mixing efficiency, D'Alessandro, Dahleh, and Mezic [2] formulated an optimal mixing problem by maximizing the entropy among all permissible periodic sequences composed of two shear flows orthogonal to each other. They derived the form of the protocol which maximizes the entropy by developing appropriate ergodic-theoretic tools. Another optimal mixing problem was defined by Noack et al. [21], who used the flux across a recirculation region as the measure of mixing efficiency and then maximized the flux among all permissible controlled vortex motions. These optimal mixing problems are different from the one discussed here. First, in our case, the advection-diffusion equation is used to describe the fluid mixing, while a system of ordinary differential equations was used in their studies. Second, the measures of mixing efficiency are different. Third,

the optimal objectives are different. While mixing and flow are both optimized in our case, the optimization of flow was not considered in their cases. Finally, because of these differences, the characterizations of the optimal flow are different. In our case, the optimal flow is characterized by a system of nonlinear partial differential equations, while, in their cases, the optimal sequence of flow is given by the sequence of period 2 of two matrices in [2], and the optimal vortex motion was identified in [21] by finding the optimal flat output trajectory which maximizes the flux.

The paper is organized as follows. We define a mixing efficiency functional in section 2 and prove the existence of an optimal flow in section 3. Optimality conditions are presented in section 4 and are proved in sections 5 and 6.

**2. Mixing efficiency functionals.** Throughout this paper,  $H^s(\Omega)$  denotes the usual Sobolev space [9] for any  $s \in \mathbb{R}$ . For  $s \geq 0$ ,  $H_0^s(\Omega)$  denotes the completion of  $C_0^\infty(\Omega)$  in  $H^s(\Omega)$ , where  $C_0^\infty(\Omega)$  denotes the space of all infinitely differentiable functions on  $\Omega$  with a compact support in  $\Omega$ .

We will need the following vector function spaces:

$$\begin{aligned}\mathbf{L}^2(\Omega) &= \{L^2(\Omega)\}^n, \\ \mathbf{H}^1(\Omega) &= \{H^1(\Omega)\}^n, \\ \mathbf{H}^2(\Omega) &= \{H^2(\Omega)\}^n, \\ \mathbf{H}_{div}^1(\Omega) &= \{\mathbf{v} \in \mathbf{H}^1(\Omega) : \operatorname{div}(\mathbf{v}) = 0 \text{ in } \Omega\}, \\ \mathbf{L}_{div}^2(\Omega) &= \text{the closure of } \mathbf{H}_{div}^1(\Omega) \text{ in } \mathbf{L}^2(\Omega).\end{aligned}$$

The  $\mathbf{L}^2$  norm of a function  $\mathbf{f}(\mathbf{x}) \in \mathbf{L}^2(\Omega)$  is denoted by

$$\|\mathbf{f}\| = \left( \int_{\Omega} |\mathbf{f}(\mathbf{x})|^2 dV \right)^{1/2}.$$

We will also need spaces involving time. Let  $X$  denote a Banach space with a norm  $\|\cdot\|$  and  $0 < T$ . The space  $L^2(0, T; X)$  consists of all measurable functions  $\mathbf{v} : [0, T] \rightarrow X$  with

$$\|\mathbf{v}\|_{L^2(0, T; X)} = \left( \int_0^T \|\mathbf{v}(t)\|^2 dt \right)^{1/2} < \infty.$$

The Sobolev space  $H^1(0, T; X)$  consists of all functions  $\mathbf{v} \in L^2(0, T; X)$  such that  $\mathbf{v}'$  exists in the weak sense and belongs to  $L^2(0, T; X)$ . The norm is defined by

$$\|\mathbf{v}\|_{H^1(0, T; X)} = \left( \int_0^T (\|\mathbf{v}(t)\|^2 + \|\mathbf{v}'(t)\|^2) dt \right)^{1/2}.$$

We denote

$$H_0^1(0, T; X) = \{\mathbf{v} \in H^1(0, T; X) \mid \mathbf{v}(0) = \mathbf{v}(T) = 0\}.$$

The space  $C([0, T]; X)$  consists of all continuous functions  $\mathbf{v} : [0, T] \rightarrow X$  with

$$\|\mathbf{v}\|_{C([0, T]; X)} = \max_{0 \leq t \leq T} \|\mathbf{v}(t)\| < \infty.$$

The strain tensor of the velocity  $\mathbf{v} = (v_1, v_2, v_3)$  is denoted by

$$\nabla \mathbf{v} = \begin{pmatrix} \frac{\partial v_1}{\partial x_1} & \frac{\partial v_1}{\partial x_2} & \frac{\partial v_1}{\partial x_3} \\ \frac{\partial v_2}{\partial x_1} & \frac{\partial v_2}{\partial x_2} & \frac{\partial v_2}{\partial x_3} \\ \frac{\partial v_3}{\partial x_1} & \frac{\partial v_3}{\partial x_2} & \frac{\partial v_3}{\partial x_3} \end{pmatrix}.$$

The mean concentration of  $c(\mathbf{x}, t; \mathbf{v})$  is defined by

$$\langle c(t; \mathbf{v}) \rangle = \frac{1}{\text{mes}(\Omega)} \int_{\Omega} c(\mathbf{x}, t; \mathbf{v}) dV.$$

Mixing will be best enhanced if the scalar variance  $\|c(t; \mathbf{v}) - \langle c(t; \mathbf{v}) \rangle\|$  is made as small as possible. While mixing is best enhanced, the velocity  $\mathbf{v}$  is desired to be optimized in the sense that it is almost steady and is of the least magnitude  $\|\mathbf{v}\|$  and the least rotation. The least magnitude ensures that the cost of generating the flow will be lowest, and the least rotation guarantees that the flow is not too turbulent and chaotic. A development of rotation in a flow requires shear stress to be present on a fluid particle surface. The shear stress depends on the strain tensor  $\nabla \mathbf{v}$  of the velocity  $\mathbf{v}$  [23]. Thus, to have the least rotation, the magnitude  $\|\nabla \mathbf{v}\|$  needs to be minimized. To make the flow almost steady, the acceleration magnitude  $\|\frac{\partial \mathbf{v}(t)}{\partial t}\|$  needs to be minimized. This motivates us to define the following mixing efficiency functional:

$$\begin{aligned} J(\mathbf{v}) = & \int_0^T \left( \|c(t; \mathbf{v}) - \langle c(t; \mathbf{v}) \rangle\|^2 + \alpha \|\mathbf{v}(t)\|^2 + \beta \|\nabla \mathbf{v}(t)\|^2 + \gamma \left\| \frac{\partial \mathbf{v}(t)}{\partial t} \right\|^2 \right) dt \\ (2) \quad & + \mu \|c(T; \mathbf{v}) - \langle c(T; \mathbf{v}) \rangle\|^2, \end{aligned}$$

where  $T > 0$  is some desired time, and  $\alpha > 0, \beta, \gamma, \mu \geq 0$  are weight constants. In optimal control theory, the first two terms  $\|c(t; \mathbf{v}) - \langle c(t; \mathbf{v}) \rangle\|^2, \alpha \|\mathbf{v}(t)\|^2$ , which penalize the averages of the scalar variance and the controlling cost, are standard [8, 16]. The variance  $\|c(T; \mathbf{v}) - \langle c(T; \mathbf{v}) \rangle\|^2$  at the final time is optional but included in this functional to ensure that the highest level of homogenization of the scalar will be achieved. Another standard functional in optimal control theory is the one over an infinite time interval for a regulator problem. For the problem of mixing enhancement, this functional is not appropriate since mixing needs to be enhanced in a desired finite time.

The weight constants in (2) play an important role in determining the control strength. For small values of  $\alpha, \beta, \gamma$ , the functional will result in an optimal solution with a small variance of the scalar but with big magnitudes of the velocity  $\mathbf{v}$ , of the strain tensor  $\nabla \mathbf{v}$ , and of the acceleration  $\frac{\partial \mathbf{v}}{\partial t}$ . This implies that the smaller the weights, the more turbulent the optimal flow, and then the better the mixing enhancement.

We note that the mean is conserved. In fact, integrating (1) over  $\Omega$  gives

$$\frac{d}{dt} \langle c \rangle = \frac{\kappa}{\text{mes}(\Omega)} \int_{\Omega} \nabla^2 c dV = 0,$$

where we have used the boundary conditions on  $\mathbf{v}$  and  $c$ . Therefore we can assume zero mean without loss of generality. With the zero-mean assumption, the cost functional reduces to

$$(3) \quad J(\mathbf{v}) = \int_0^T \left( \|c(t; \mathbf{v})\|^2 + \alpha \|\mathbf{v}(t)\|^2 + \beta \|\nabla \mathbf{v}(t)\|^2 + \gamma \left\| \frac{\partial \mathbf{v}(t)}{\partial t} \right\|^2 \right) dt + \mu \|c(T; \mathbf{v})\|^2.$$

Then the optimal control problem is to minimize  $J$  in an admissible velocity space  $\mathcal{V} = H_0^1(0, T; \mathbf{H}_{div}^1(\Omega))$ :

$$(4) \quad J(\mathbf{v}^*) = \min_{\mathbf{v} \in \mathcal{V}} J(\mathbf{v}).$$

The minimizer  $\mathbf{v}^*$  is called an *optimal flow*.

In deriving optimality conditions for the optimal flow below, control flows are required to satisfy the condition  $\mathbf{v}(0) = \mathbf{v}(T) = 0$ . This mathematical condition, in fact, is quite realistic because the control flows should start from the rest and return back to the rest at the final time when the mixing has been enhanced. For instance, before coffee is stirred, the flow is at rest.

In this theoretical study, we assume that an arbitrary unsteady flow can be generated. This may not be realistic. In a future work, we will consider specific velocity fields such as  $\mathbf{v} = \sum_{i=1}^N \mathbf{v}_i(\mathbf{x}) u_i(t)$ , where  $\mathbf{v}_i(\mathbf{x})$  ( $i = 1, \dots, N$ ) are given steady flows which prescribe how the control action is distributed in the flow field.

**3. Existence of optimal flows.** For convenience, we state a well-known estimate about the solution of (1) as follows.

**LEMMA 3.1.** *Let  $\mathbf{v} \in L^2(0, T; \mathbf{L}_{div}^2(\Omega))$ . Then the solution  $c$  of (1) satisfies the following estimate:*

$$(5) \quad \|c(t)\|^2 + 2\kappa \int_0^t \|\nabla c(s)\|^2 ds = \|c^0\|^2.$$

*Proof.* Multiplying (1) by  $c$  and using the boundary conditions, we obtain the equation

$$(6) \quad \frac{1}{2} \frac{d}{dt} \|c\|^2 = -\kappa \|\nabla c\|^2.$$

Integrating over  $[t_0, t]$  gives (5).  $\square$

To prove the existence of an optimal flow, we need the following weakly lower semicontinuity of the function  $J$ .

**LEMMA 3.2.** *The functional  $J$  defined by (3) is weakly lower semicontinuous. That is, if  $\mathbf{v}_n$  converges weakly to  $\mathbf{v}_0$  in  $H^1(0, T; \mathbf{H}_{div}^1(\Omega))$ , then*

$$J(\mathbf{v}_0) \leq \liminf_{n \rightarrow \infty} J(\mathbf{v}_n).$$

*Proof.* Let  $\mathbf{v}_n$  converge weakly to  $\mathbf{v}_0$  in  $H^1(0, T; \mathbf{H}_{div}^1(\Omega))$  and let  $c_n(\mathbf{x}, t; \mathbf{v}_n)$  be the solution of

$$(7) \quad \frac{\partial c_n}{\partial t} + (\mathbf{v}_n \cdot \nabla) c_n = \kappa \nabla^2 c_n, \quad c_n(\mathbf{x}, 0) = c^0(\mathbf{x}) \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial c_n}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega.$$

Then  $\mathbf{v}_n$  converges strongly to  $\mathbf{v}_0$  in  $L^2(0, T; \mathbf{L}_{div}^2(\Omega))$ . Moreover, it follows from (5) that there exists a subsequence of  $c_n(\mathbf{x}, t; \mathbf{v}_n)$ , still denoted by itself for convenience, that converges weakly to  $c_0^*$  in  $L^2(0, T; H^1(\Omega))$ . Therefore we can pass to the limit in (7) and obtain

$$\frac{\partial c_0^*}{\partial t} + (\mathbf{v}_0 \cdot \nabla) c_0^* = \kappa \nabla^2 c_0^*, \quad c_0^*(\mathbf{x}, 0) = c^0(\mathbf{x}) \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial c_0^*}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega.$$

Since any norm of a Banach space is weakly lower semicontinuous [17], it therefore follows that

$$\begin{aligned} \liminf_{n \rightarrow \infty} J(\mathbf{v}_n) &\geq \liminf_{n \rightarrow \infty} \int_0^T \left( \|c_n(t; \mathbf{v}_n)\|^2 + \alpha \|\mathbf{v}_n(t)\|^2 \right. \\ &\quad \left. + \beta \|\nabla \mathbf{v}_n(t)\|^2 + \gamma \left\| \frac{\partial \mathbf{v}_n(t)}{\partial t} \right\|^2 \right) dt \\ &\quad + \mu \liminf_{n \rightarrow \infty} \|c_n(T; \mathbf{v}_n)\|^2 \\ &\geq \int_0^T \left( \|c_0^*(t; \mathbf{v}_0)\|^2 + \alpha \|\mathbf{v}_0(t)\|^2 + \beta \|\nabla \mathbf{v}_0(t)\|^2 + \gamma \left\| \frac{\partial \mathbf{v}_0(t)}{\partial t} \right\|^2 \right) dt \\ &\quad + \mu \|c_0^*(T; \mathbf{v}_0)\|^2 \\ &= J(\mathbf{v}_0). \end{aligned}$$

So the functional  $J$  is weakly lower semicontinuous.  $\square$

From this lemma, we can readily prove the following existence theorem.

**THEOREM 3.1.** *If  $\beta, \gamma > 0$ , then there exists an optimal flow  $\mathbf{v}^* \in \mathcal{V} = H^1(0, T; \mathbf{H}_{div}^1(\Omega))$  such that*

$$(8) \quad J(\mathbf{v}^*) = \min_{\mathbf{v} \in \mathcal{V}} J(\mathbf{v}).$$

*Proof.* Let  $\mathbf{v}_n$  be the minimizing sequence in  $H^1(0, T; \mathbf{H}_{div}^1(\Omega))$ . That is,

$$\lim_{n \rightarrow \infty} J(\mathbf{v}_n) = \min_{\mathbf{v} \in \mathcal{V}} J(\mathbf{v}).$$

Then  $\mathbf{v}_n$  is bounded in  $H^1(0, T; \mathbf{H}_{div}^1(\Omega))$ . This implies that there exists a subsequence, still denoted by  $\mathbf{v}_n$ , that converges weakly to  $\mathbf{v}^*$  in  $H^1(0, T; \mathbf{H}_{div}^1(\Omega))$ . It therefore follows from Lemma 3.2 that

$$J(\mathbf{v}^*) \leq \lim_{n \rightarrow \infty} J(\mathbf{v}_n) = \min_{\mathbf{v} \in \mathcal{V}} J(\mathbf{v}),$$

which implies (8).  $\square$

If  $\beta = \gamma = 0$ , the existence is open. In this case, the minimizing sequence  $\mathbf{v}_n$  is bounded only in  $L^2(0, T; \mathbf{L}_{div}^2(\Omega))$  and then may not converge strongly to  $\mathbf{v}_0$  in  $L^2(0, T; \mathbf{L}_{div}^2(\Omega))$ . Thus passing to the limit in (7) cannot be guaranteed. Also the uniqueness of the optimal flow is open because we could not prove that the functional  $J$  is convex.

#### 4. Optimality conditions.

THEOREM 4.1. *If  $\mathbf{v}^*$  is an optimal flow under the cost functional  $J$  defined by (3), then it satisfies the following equations:*

$$(9) \quad \frac{\partial c}{\partial t} + (\mathbf{v}^* \cdot \nabla)c = \kappa \nabla^2 c,$$

$$(10) \quad \frac{\partial g}{\partial t} + (\mathbf{v}^* \cdot \nabla)g = -\kappa \nabla^2 g + c(\mathbf{v}^*),$$

$$(11) \quad \nabla^2 p(\mathbf{x}, t) = \nabla g(\mathbf{x}, t; \mathbf{v}^*) \cdot \nabla c(\mathbf{x}, t; \mathbf{v}^*) + g(\mathbf{x}, t; \mathbf{v}^*) \nabla^2 c(\mathbf{x}, t; \mathbf{v}^*),$$

$$(12) \quad -\alpha \mathbf{v}^* + \beta \nabla^2 \mathbf{v}^* + \gamma \frac{\partial^2 \mathbf{v}^*}{\partial t^2} = g(\mathbf{x}, t; \mathbf{v}^*) \nabla c(\mathbf{x}, t; \mathbf{v}^*) - \nabla p,$$

$$(13) \quad \frac{\partial c}{\partial \mathbf{n}} = \frac{\partial g}{\partial \mathbf{n}} = \frac{\partial p}{\partial \mathbf{n}} = 0, \quad \mathbf{v}^* = 0 \quad \text{on } \partial\Omega,$$

$$(14) \quad \mathbf{v}^*(\mathbf{x}, 0) = \mathbf{v}^*(\mathbf{x}, T) = 0 \quad \text{in } \Omega,$$

$$(15) \quad c(\mathbf{x}, 0) = c^0(\mathbf{x}), \quad g(\mathbf{x}, T) = -\mu c(\mathbf{x}, T; \mathbf{v}^*) \quad \text{in } \Omega.$$

We will prove this theorem in the next two sections.

If  $\beta = 0$ , we can solve (12) to obtain

$$\begin{aligned} \mathbf{v}^* &= \frac{1}{2} \sqrt{\frac{1}{\alpha\gamma}} \int_0^t (\nabla p(\mathbf{x}, s) - g(\mathbf{x}, s) \nabla c(\mathbf{x}, s)) \left( e^{\sqrt{\alpha/\gamma}(s-t)} - e^{\sqrt{\alpha/\gamma}(t-s)} \right) ds \\ &\quad + \frac{1}{2} \sqrt{\frac{1}{\alpha\gamma}} \frac{e^{-t\sqrt{\alpha/\gamma}} - e^{t\sqrt{\alpha/\gamma}}}{e^{-T\sqrt{\alpha/\gamma}} - e^{T\sqrt{\alpha/\gamma}}} \\ &\quad \times \int_0^T (\nabla p(\mathbf{x}, s) - g(\mathbf{x}, s) \nabla c(\mathbf{x}, s)) \left( e^{\sqrt{\alpha/\gamma}(T-s)} - e^{\sqrt{\alpha/\gamma}(s-T)} \right) ds. \end{aligned}$$

This control law shows that the optimal control flow depends on all the concentration gradients during the whole time period from 0 to  $T$ .

Solving the system (9)–(15) numerically or analytically is a challenging problem since it is highly nonlinear. As an initial attempt, we give a preliminary numerical result.

One potential method for solving (9)–(15) could be the iteration method. We first solve the advection-diffusion (9) with a given velocity  $\mathbf{v}_1$ . Then with this solution  $c(\mathbf{v}_1)$ , we solve (10) and then (11). Through (12), we obtain a new velocity  $\mathbf{v}_2$ . With this  $\mathbf{v}_2$ , we repeat the above procedure, and so on.

To test whether or not this iteration method works, we consider a simplified case where  $\beta = \gamma = \mu = 0$  and the system is considered in a 2D domain. Under this simplification, this testing could be purely numerical, as real mixing may take place only in the 3D space. Since  $\beta = \gamma = 0$ , the boundary condition (14) is not needed, and then  $\mathbf{v}^*(\mathbf{x}, 0)$  may not be equal to zero in this case.

In our computations, the domain  $\Omega = (0, 1) \times (0, 1)$ , the initial condition  $c^0(x, y) = \sin(2\pi x) \sin(2\pi y)$ , the diffusivity  $\kappa = 0.01$ , the starting velocity  $\mathbf{v}_1 = \mathbf{0}$ ,  $T = 2$ ,  $\alpha = 0.5$ , and  $\beta = \gamma = \mu = 0$ . All equations are solved by the finite element method developed in [25] (with some modifications for this particular problem).

FIG. 1. Starting with the velocity  $\mathbf{v}_1 = 0$ , the functional  $J$  reaches its minimum after a number of iterations and then stays there.

Figure 1 shows that the functional  $J$  reaches its minimum after a number of iterations and then stays there. The approximate optimal flow  $\mathbf{v}^*$  obtained via 20 iterations in this numerical experiment is shown in Figure 2. From this figure it can be seen that the flow is decreasing to zero. This could imply that after the scalar is well advected, no further advection is needed to save the control efforts.

To see how this optimal flow enhances mixing, we compare the variance decay in the case of  $\mathbf{v}_1 = 0$  with the variance decay in the case of the optimal flow, where the variance is defined by

$$V(t) = \|c(t; \mathbf{v}) - \langle c(t; \mathbf{v}) \rangle\|^2.$$

Figure 3 shows that the variance of the scalar advected by the optimal flow decays much faster than the one without advection.

To further test whether or not the functional  $J(\mathbf{v})$  really attains the minimum at the optimal flow obtained above, we consider a couple of other model flows. One of them is the following time-periodic velocity [18], denoted by  $\mathbf{v}_{p_1}$ :

$$(16) \quad \begin{aligned} v_1(x, y, t) &= \begin{cases} \sin(\pi x) \cos(\pi y) & \text{if } n \leq t < n + 0.5; \\ -\sin(2\pi x) \cos(\pi y) & \text{if } n + 0.5 \leq t < n + 1; \end{cases} \\ v_2(x, y, t) &= \begin{cases} -\cos(\pi x) \sin(\pi y) & \text{if } n \leq t < n + 0.5; \\ 2 \cos(2\pi x) \sin(\pi y) & \text{if } n + 0.5 \leq t < n + 1. \end{cases} \end{aligned}$$

As above, we can compute the value of the functional  $J(\mathbf{v}_{p_1})$  at this flow and obtain

$$J(\mathbf{v}_{p_1}) = 1.0429,$$

which is greater than the value of the functional at the above optimal flow:

$$J(\mathbf{v}^*) = 0.1731.$$

Another flow is the simplified model flow, denoted by  $\mathbf{v}_{p_2}$ , of time-aperiodic Rayleigh–Bénard convection. The velocity field of the flow is derived from the stream function

$$(17) \quad \Psi = \frac{A}{n} \sin(2\pi x) \sin\{n[x + B \sin(\omega t)]\} W(y),$$

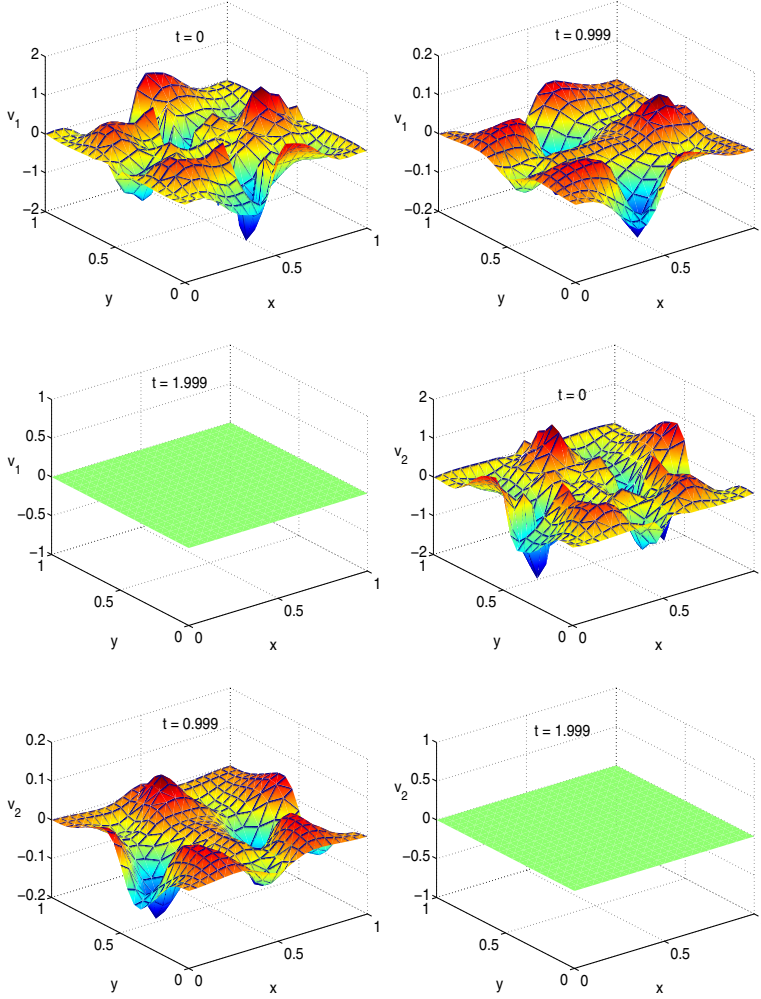

FIG. 2. The  $x$ -component  $v_1$  (top row and middle row (left)) and  $y$ -component  $v_2$  (middle row (right) and bottom row) of the optimal flow  $\mathbf{v}^*$  at  $t = 0, 0.999, 1.999$ , obtained via 20 iterations starting with the velocity  $\mathbf{v}_1 = 0$ .

where  $A$  is a positive constant,  $n$  is the wave number  $2\pi/\lambda$  with a constant  $\lambda$ , and  $W(y)$  is a function that satisfies the rigid boundary conditions at the top and bottom surfaces. Here we use the following function  $W(y)$ :

$$W(y) = (1 - y)y.$$

This stream function is obtained by adding the factor  $\sin(2\pi x)$  to a stream function used in [24] to make it satisfy the no-penetration boundary condition. In this computation,  $A = 1.8, B = 0.06, \omega = 2\pi$ , and  $\lambda = 2$ . The value of the functional at this flow is

$$J(\mathbf{v}_{p_2}) = 0.2801.$$

As before, it is also greater than  $J(\mathbf{v}^*) = 0.1731$ .

FIG. 3. The variance of a scalar advected by the optimal flow decays much faster than the one without advection.

The above is a very preliminary attempt. The complete resolution of the problem could require an extensive regularity analysis of solutions and applications of fixed point theorems.

The asymptotic behavior of solutions of the system (9)–(15) in the zero limit of the diffusivity  $\kappa$  is a singular perturbation problem. This problem is interesting but difficult. The resolution of the problem will require extensive asymptotic analysis such as the decomposition of inner and outer solutions and boundary layer analysis. This is beyond the reach of the paper.

**5. Gâteaux differentials.** The space  $C(\Omega)$  consists of all continuous functions  $f$  on  $\Omega$  with

$$\|f\|_{\infty} = \max_{\mathbf{x} \in \Omega} |f(\mathbf{x})| < \infty.$$

The function vector space  $\mathbf{C}(\Omega) = \{C(\Omega)\}^n$ .

**THEOREM 5.1.** *Let the functional  $J$  be defined by (3). If  $\mathbf{v} = (v_1, v_2, v_3) \in H^1(0, T; \mathbf{H}_{div}^1(\Omega))$  and  $\mathbf{u} = (u_1, u_2, u_3) \in H^1(0, T; \mathbf{H}_{div}^1(\Omega) \cap \mathbf{C}(\Omega))$ , then the Gâteaux differential of  $J$  is given by*

$$\begin{aligned} \langle J'(\mathbf{v}), \mathbf{u} \rangle &= \lim_{\varepsilon \rightarrow 0} \frac{J(\mathbf{v} + \varepsilon \mathbf{u}) - J(\mathbf{v})}{\varepsilon} \\ &= 2 \int_0^T \int_{\Omega} c(\mathbf{v}) h(\mathbf{v}, \mathbf{u}) dV dt + 2\mu \int_{\Omega} c(T; \mathbf{v}) h(T; \mathbf{v}, \mathbf{u}) dV \\ &\quad + 2 \int_0^T \int_{\Omega} \left( \alpha \mathbf{v} \cdot \mathbf{u} + \beta \nabla \mathbf{v} \cdot \nabla \mathbf{u} + \gamma \frac{\partial \mathbf{v}}{\partial t} \cdot \frac{\partial \mathbf{u}}{\partial t} \right) dV dt, \end{aligned} \quad (18)$$

where  $\nabla \mathbf{v} \cdot \nabla \mathbf{u} = \sum_{i,j=1}^3 \frac{\partial v_i}{\partial x_j} \frac{\partial u_i}{\partial x_j}$  and  $h$  is the solution of

$$\frac{\partial h}{\partial t} + (\mathbf{v} \cdot \nabla) h = \kappa \nabla^2 h - (\mathbf{u} \cdot \nabla) c(\mathbf{v}) \quad \text{in } \Omega, \quad (19)$$

$$h(\mathbf{x}, 0) = 0 \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial h}{\partial \mathbf{n}} = 0 \quad \text{on } \partial \Omega.$$

To prove this theorem, we need the following lemma. For a positive constant  $\varepsilon$  and  $\mathbf{v}, \mathbf{u} \in L^2(0, T; \mathbf{L}_{div}^2(\Omega))$ , we denote by  $c(\mathbf{v})$  and  $c_\varepsilon(\mathbf{v}, \mathbf{u})$  the solutions of (1) corresponding the velocities  $\mathbf{v}$  and  $\mathbf{v} + \varepsilon\mathbf{u}$ , respectively.

LEMMA 5.1. *Let  $\mathbf{u} \in L^2(0, T, \mathbf{L}_{div}^2(\Omega) \cap \mathbf{C}(\Omega))$  and denote  $h_\varepsilon(\mathbf{v}, \mathbf{u}) = c_\varepsilon(\mathbf{v}, \mathbf{u}) - c(\mathbf{v})$ . Then the  $h_\varepsilon$  satisfies the following estimates:*

$$(20) \quad \max_{0 \leq s \leq t} \|h_\varepsilon(s)\|^2 \leq \frac{2\varepsilon^2}{\kappa} \|c^0\|^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds,$$

$$(21) \quad \frac{1}{2} \|h_\varepsilon(t)\|^2 + \kappa \int_0^t \|\nabla h_\varepsilon(s)\|^2 ds \leq \frac{\varepsilon^2}{\kappa} \|c^0\|^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds,$$

$$(22) \quad \max_{0 \leq s \leq t} \left\| \frac{h_\varepsilon(s)}{\varepsilon} - h(s) \right\|^2 \leq \frac{4\varepsilon^2}{\kappa^2} \|c^0\|^2 \left( \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \right)^2.$$

*Proof.* A direct calculation shows that  $h_\varepsilon$  satisfies

$$(23) \quad \begin{aligned} \frac{\partial h_\varepsilon}{\partial t} + (\mathbf{v} \cdot \nabla) h_\varepsilon &= \kappa \nabla^2 h_\varepsilon - \varepsilon (\mathbf{u} \cdot \nabla) c_\varepsilon(\mathbf{v}, \mathbf{u}) \quad \text{in } \Omega, \\ h_\varepsilon(\mathbf{x}, 0) &= 0 \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial h_\varepsilon}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Multiplying (23) by  $h_\varepsilon$  and using the boundary conditions, we obtain the equation

$$(24) \quad \begin{aligned} \frac{1}{2} \frac{d}{dt} \|h_\varepsilon(t)\|^2 &= -\kappa \|\nabla h_\varepsilon\|^2 - \varepsilon \int_\Omega h_\varepsilon (\mathbf{u} \cdot \nabla) c_\varepsilon dV \\ &\leq \varepsilon \|\mathbf{u}(t)\|_\infty \|h_\varepsilon(t)\| \|\nabla c_\varepsilon(t)\|. \end{aligned}$$

Integrating over  $[t_0, t]$  gives

$$\begin{aligned} \|h_\varepsilon(t)\|^2 &\leq 2\varepsilon \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \int_0^t \|\mathbf{u}(s)\|_\infty \|\nabla c_\varepsilon(s)\| ds \\ &\leq 2\varepsilon \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \left( \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \right)^{1/2} \left( \int_0^t \|\nabla c_\varepsilon(s)\|^2 ds \right)^{1/2}, \end{aligned}$$

which implies that

$$\begin{aligned} \max_{0 \leq s \leq t} \|h_\varepsilon(s)\|^2 &\leq 2\varepsilon \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \left( \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \right)^{1/2} \left( \int_0^t \|\nabla c_\varepsilon(s)\|^2 ds \right)^{1/2} \\ &\leq \frac{1}{2} \left( \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \right)^2 + 2\varepsilon^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \int_0^t \|\nabla c_\varepsilon(s)\|^2 ds. \end{aligned}$$

It then follows from (5) that

$$(25) \quad \begin{aligned} \max_{0 \leq s \leq t} \|h_\varepsilon(s)\|^2 &\leq 4\varepsilon^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \int_0^t \|\nabla c_\varepsilon(s)\|^2 ds \\ &\leq \frac{2\varepsilon^2}{\kappa} \|c^0\|^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds. \end{aligned}$$

This proves (20).

To prove (21), we use (24) again and derive that

$$\begin{aligned}
 & \frac{1}{2} \|h_\varepsilon(t)\|^2 + \kappa \int_0^t \|\nabla h_\varepsilon(s)\|^2 ds \\
 & \leq \varepsilon \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \int_0^t \|\mathbf{u}(s)\|_\infty \|\nabla c_\varepsilon(s)\| ds \\
 & \leq \varepsilon \max_{0 \leq s \leq t} \|h_\varepsilon(s)\| \left( \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \right)^{1/2} \left( \int_0^t \|\nabla c_\varepsilon(s)\|^2 ds \right)^{1/2}.
 \end{aligned}$$

It then follows from (5) and (20) that

$$\begin{aligned}
 \frac{1}{2} \|h_\varepsilon(t)\|^2 + \kappa \int_0^t \|\nabla h_\varepsilon(s)\|^2 ds & \leq \varepsilon^2 \frac{\sqrt{2}}{\sqrt{\kappa}} \|c^0\| \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \frac{\|c^0\|}{\sqrt{2\kappa}} \\
 (26) \qquad \qquad \qquad & \leq \frac{\varepsilon^2}{\kappa} \|c^0\|^2 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds.
 \end{aligned}$$

To prove (22), we denote  $f_\varepsilon = \frac{h_\varepsilon}{\varepsilon} - h$ . A direct calculation shows that

$$\begin{aligned}
 (27) \qquad \frac{\partial f_\varepsilon}{\partial t} + (\mathbf{v} \cdot \nabla) f_\varepsilon & = \kappa \nabla^2 f_\varepsilon - (\mathbf{u} \cdot \nabla) h_\varepsilon \quad \text{in } \Omega, \\
 f_\varepsilon(\mathbf{x}, 0) & = 0 \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial f_\varepsilon}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega.
 \end{aligned}$$

In the same way as above, we can derive that

$$\begin{aligned}
 \max_{0 \leq s \leq t} \|f_\varepsilon(s)\|^2 & \leq 4 \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \int_0^t \|\nabla h_\varepsilon(s)\|^2 ds \\
 & \leq \frac{4\varepsilon^2}{\kappa^2} \|c^0\|^2 \left( \int_0^t \|\mathbf{u}(s)\|_\infty^2 ds \right)^2. \quad \square
 \end{aligned}$$

We are now ready to prove Theorem 5.1. Using the estimates (20) and (22), we derive that

$$\begin{aligned}
 & \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_0^T \int_\Omega [|c(\mathbf{v} + \varepsilon \mathbf{u})|^2 - |c(\mathbf{v})|^2] dV dt \\
 & = \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_0^T \int_\Omega [|c(\mathbf{v}) + h_\varepsilon(\mathbf{v}, \mathbf{u})|^2 - |c(\mathbf{v})|^2] dV dt \\
 & = \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_0^T \int_\Omega [2c(\mathbf{v})h_\varepsilon(\mathbf{v}, \mathbf{u}) + (h_\varepsilon(\mathbf{v}))^2] dV dt \\
 (28) \qquad \qquad \qquad & = 2 \int_0^T \int_\Omega c(\mathbf{v})h(\mathbf{v}, \mathbf{u}) dV dt.
 \end{aligned}$$

In the same way, we can show that

$$\begin{aligned}
& \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_{\Omega} [|c(T; \mathbf{v} + \varepsilon \mathbf{u})|^2 - |c(T; \mathbf{v})|^2] dV \\
&= \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_{\Omega} [|c(T; \mathbf{v}) + h_{\varepsilon}(T; \mathbf{v}, \mathbf{u})|^2 - |c(\mathbf{v})|^2] dV \\
&= \lim_{\varepsilon \rightarrow 0} \frac{1}{\varepsilon} \int_{\Omega} [2c(T; \mathbf{v})h_{\varepsilon}(T; \mathbf{v}, \mathbf{u}) + (h_{\varepsilon}(T; \mathbf{v}, \mathbf{u}))^2] dV \\
&= 2 \int_{\Omega} c(T; \mathbf{v})h(T; \mathbf{v}, \mathbf{u}) dV.
\end{aligned}$$

Using these limits, we then readily prove Theorem 5.1.

**6. Proof of Theorem 4.1.** If the flow  $\mathbf{v}^*$  is an optimal flow under the functional  $J$  defined by (3), then it satisfies

$$\langle J'(\mathbf{v}), \mathbf{u} \rangle = 0$$

for all  $\mathbf{u} \in H_0^1(0, T; \mathbf{H}_{div}^1(\Omega))$ . It then follows from (18) that

$$\begin{aligned}
(29) \quad & \int_0^T \int_{\Omega} c(\mathbf{x}, t; \mathbf{v}^*)h(\mathbf{x}, t; \mathbf{u}, \mathbf{v}^*) dV dt + \mu \int_{\Omega} c(\mathbf{x}, T; \mathbf{v}^*)h(\mathbf{x}, T; \mathbf{u}, \mathbf{v}^*) dV \\
& + \int_0^T \int_{\Omega} \left( \alpha \mathbf{v}^* \cdot \mathbf{u} + \beta \nabla \mathbf{v}^* \cdot \nabla \mathbf{u} + \gamma \frac{\partial \mathbf{v}^*}{\partial t} \cdot \frac{\partial \mathbf{u}}{\partial t} \right) dV dt = 0
\end{aligned}$$

for all  $\mathbf{u} \in H_0^1(0, T; \mathbf{H}_{div}^1(\Omega) \cap \mathbf{C}(\Omega))$ . Consider the adjoint equation

$$(30) \quad \frac{\partial g}{\partial t} + (\mathbf{v}^* \cdot \nabla)g = -\kappa \nabla^2 g + c(\mathbf{v}^*) \quad \text{in } \Omega,$$

$$g(\mathbf{x}, T) = -\mu c(\mathbf{x}, T; \mathbf{v}^*) \quad \text{in } \Omega, \quad \text{and} \quad \frac{\partial g}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega.$$

Multiplying (30) by  $h$  and (19) by  $g$  and integrating over  $\Omega \times [0, T]$ , we obtain

$$\begin{aligned}
(31) \quad & \int_0^T \int_{\Omega} c(\mathbf{x}, t; \mathbf{v}^*)h(\mathbf{x}, t; \mathbf{u}, \mathbf{v}^*) dV dt + \mu \int_{\Omega} c(\mathbf{x}, T; \mathbf{v}^*)h(\mathbf{x}, T; \mathbf{u}, \mathbf{v}^*) dV \\
& = \int_0^T \int_{\Omega} (\mathbf{u} \cdot \nabla c(\mathbf{x}, t; \mathbf{v}^*)) g(\mathbf{x}, t; \mathbf{v}^*) dV dt.
\end{aligned}$$

After integration by parts with respect to  $t$ , we deduce from (29) and (31) that

$$(32) \quad \int_0^T \int_{\Omega} \mathbf{u} \cdot \left( \alpha \mathbf{v}^* - \beta \nabla^2 \mathbf{v}^* - \gamma \frac{\partial^2 \mathbf{v}^*}{\partial t^2} + g(\mathbf{x}, t; \mathbf{v}^*) \nabla c(\mathbf{x}, t; \mathbf{v}^*) \right) dV dt = 0,$$

which implies that there exists a potential function  $p$  such that

$$(33) \quad \alpha \mathbf{v}^* - \beta \nabla^2 \mathbf{v}^* - \gamma \frac{\partial^2 \mathbf{v}^*}{\partial t^2} + g(\mathbf{x}, t; \mathbf{v}^*) \nabla c(\mathbf{x}, t; \mathbf{v}^*) = \nabla p.$$

To determine  $p$ , we apply the divergence operation to the above equation and then obtain

$$(34) \quad \nabla^2 p = \nabla g(\mathbf{x}, t; \mathbf{v}^*) \cdot \nabla c(\mathbf{x}, t; \mathbf{v}^*) + g(\mathbf{x}, t; \mathbf{v}^*) \nabla^2 c(\mathbf{x}, t; \mathbf{v}^*).$$

Thus we have proved Theorem 4.1.

**7. Conclusions.** We have studied the problem of optimal mixing control whose objective is to best enhance mixing by flow advection while the flow is optimized in the sense that it is almost steady and is of the least magnitude and the least rotation. In solving this problem, we defined a mixing efficiency functional by penalizing the average of variance of the scalar, the average of the flow, and the average of the strain tensor and acceleration of the flow. We showed that the functional is weakly lower semicontinuous and then it attains its minimum. By variational principles, we then derived optimality conditions that consist of a system of nonlinear partial differential equations.

A number of issues are left open. Solving the optimality partial differential equations numerically or analytically is challenging since nonlinearity is presented in the advection term, which, like in the study of Navier–Stokes equations, is difficult to estimate. The resolution of the problem could require the regularity analysis of solutions and applications of fixed point theorems. The uniqueness of the optimal flow is open because we could not prove that the efficiency functional  $J$  is convex. Another interesting problem is the singular perturbation problem for the optimality partial differential equations in the zero limit of diffusivity. The resolution of the problem will require an extensive asymptotic analysis such as the decomposition of inner and outer solutions and boundary layer analysis.

Results presented in this paper could have potential applications in aerospace engineering and mixing-related industry. Often a certain level of homogeneity of a fluid mixture is desired. For instance, before fuel is burned in a combustor, it is required to be well mixed so that the combustor has its best efficiency. Hence, optimality conditions derived in this paper could serve as guidelines in implementing an efficient and practical control technique for mixing enhancement.

**Acknowledgments.** The author thanks George Haller for introducing the mixing problem to the author and for constant discussions, thanks Enrique Zuazua for valuable comments on the weakly lower semicontinuity of the efficiency functional, and thanks the referees for their critical comments. One of the referees provided especially sharp insights into the mixing physics and English language comments which greatly improve the quality of presentation of the paper and make the author's Chinese style English close to native English. The author is grateful to his son, Xin Liu, for proofreading the text part of the manuscript.

## EFFECT OF INPUT NOISE ON A MAGNETOMETER WITH QUANTUM FEEDBACK\*

ZHIGANG ZHANG<sup>†</sup>

**Abstract.** This article investigates the effects of input noise on a magnetometer with quantum feedback. Previous research has shown that feedback makes the measurement robust to an unknown parameter, the number of atoms involved, with the assumption that the feedback is noise free. To evaluate the effects of the feedback noise, we extend the original model by an input noise term. We then analyze the steady state performance of the Kalman filter for both the closed-loop and open-loop cases and retrieve the second moment of the estimation error. The results are compared and criteria for evaluating the effects of input noise are obtained. Robust and optimal designs are also discussed. Computations and simulations show how quantitatively the input noise increases the estimation error and changes the region where the closed-loop case behaves better than the open-loop case.

**Key words.** quantum control, magnetometry, Kalman filter, LQG controller

**1. Introduction.** Several forces are driving the research of quantum control. The rapid development of optics and atomic physics has made it possible to now observe and manipulate small-scale quantum systems in laboratories, approaching the limitation allowed by quantum mechanics. The idea of controlling a quantum system is no longer impractical, and a steadily growing number of quantum control systems are now experimentally accessible. A particular area of interest in which quantum control is important is *quantum computing*. For many laser-driven, microscopically small quantum computing components, special control technologies are needed to make the quantum gates robust against uncertainties and reliable even under small disturbances. Quantum control also finds its applications in chemistry, metrology, and other fields. For example, substantial improvement can be made by quantum control in protein structure determination via nuclear magnetic resonance (NMR) [7].

To describe a quantum system, one requires knowledge of quantum mechanics. The model is usually a Schrödinger equation and may contain random factors to constitute a *quantum stochastic differential equation* (SDE) [19] or a *stochastic master equation* (SME) [18, 21, 20]. These models are mostly nonlinear and do not appear in the setting of classical control theory. Fortunately, a simplified model for control purposes is available in most cases, and the design of the controller and filter is analogous to that of a classical system [2]. Using the separation principle, we can normally separate the control system into a filter and a controller. The filter, combined with a continuous *quantum nondemolition measurement* (QND), covers all the quantum details and estimates the system state. This makes the controller design much easier. It is not surprising that many classical control methods find their way into the control of quantum systems. Examples include, but are not limited to, Bayesian estimation, the Kalman filter, bang-bang control, the linear quadratic Gaussian (LQG)

controller, and optimal control. Realization of nonclassical states [12], such as squeezed states [18, 21, 3] and Dicke-states [17], which had been difficult to achieve stably in the laboratory, now occurs frequently in the literature. Other applications, such as tracking a single molecule [1, 8], estimating the phase of a continuous beam of light [11], or even cooling a single atom with a laser [15], are also reported.

Measurement of basic physics quantities, such as a magnetic field, is fundamental for physics and for applications such as quantum computation. The system discussed in this article is a *magnetometer* with an ensemble of atomic spins as its probe. When put in a magnetic field, the collective spin rotates perpendicularly in the direction of the field. A light beam passing through experiences polarization changes due to the collective spin, and this polarization is then measured continuously to estimate the magnetic field. Feedback can be applied by adding another magnetic field controlled by a computer. The same system has been used to produce a squeezed spin state [3]. With the assumption that the applied feedback magnetic field has infinite accuracy, Stockton et al. [16] built a model for the system and showed that the measurement with feedback was robust to an unknown parameter in the model, which is the number of atoms in the ensemble. Molmer and Madsen [9] also present a theory for the estimation. Petersen, Madsen, and Molmer [10] extend the system setup to several ensembles to measure a vector field and gain precision, but the input noise has not yet been taken into account.

Our study here focuses on the effects of the input noise on the measurement. We begin from the SME model and prove that it is equivalent to a simple linear SDE model [16]. This model is extended with an input noise. We then proceed to find the steady state performances of the measurement and the second moments of the estimation error in both closed-loop and open-loop cases. As was done previously, we use the *Kalman filter* to estimate the system state and the *LQG controller* to find the compensative field. We also assume that the observer does not know the exact number of atoms.

This article is organized as follows. In section 2, we introduce the system setup and find the simplification of the SME model. In section 3, we determine the steady state performance when no feedback is applied (open-loop case). Similarly, the steady state performance with feedback (closed-loop case) is determined in section 4. In section 5, we compare the results between the open-loop and closed-loop cases, and in section 6, we look into the optimal and robust designs. Finally, in section 7, a conclusion is given.

**2. System setup and its model.** The system is designed to measure an unknown and possibly fluctuating magnetic field  $b(t)$  oriented along the  $y$ -axis. A schematic is given in Figure 2.1. It consists of a cloud of atoms, a linearly polarized off-resonant light beam, and a polarization detector formed by two photon detectors and one amplifier. When the control loop is closed, a compensative magnetic field  $u(t)$  is applied by a computer via a group of coils. The computer collects information from the polarization detector, estimates the state of the system, and decides the current through the coils. The atomic nuclei have nonzero spin. Originally initialized along the  $x$ -axis, the collective spin of the nuclei (hereafter we just call it the collective spin) will rotate in the  $x - z$  plane if  $b(t)$  is not completely compensated by  $u(t)$ . The  $z$ -component of the collective spin is measured with the light beam, which is linearly polarized and off-resonant to the atoms. While passing through the atomic cloud, the light beam experiences a Faraday rotation proportional to the magnetic field along its propagation direction, the  $z$ -axis. Because both  $u(t)$  and  $b(t)$  are along the  $y$ -axis,

FIG. 2.1. The setup of a magnetometer. The external magnetic field  $b(t)$  is directed along the  $y$ -axis, which is unknown and possibly fluctuating. To measure it, an ensemble of atoms with nonzero nuclear spin is put in the field and initially polarized along the  $x$ -axis. A linearly polarized light beam travels through the atomic cloud along the  $z$ -axis. The signal of the polarization change is picked up at the end by a pair of photodetectors. A spin ensemble is shown in (a) with spins polarized among a small angle of  $x$ -axis. The Kalman filter (estimator) and controller are shown in (b). The picture is excerpted from [16].

the rotation is purely an effect of the collective spin.

Let the state of a quantum system be given by its wavefunction  $|\psi\rangle$ , which lives in a finite dimensional  $\mathcal{L}^2$  space. According to quantum mechanics, every observable physics quantity,  $O$ , is associated with an operator on the  $\mathcal{L}^2$  space, denoted by  $\hat{O}$ . Let  $|\xi_i\rangle$  be an orthonormal basis of the space; the expectation of the quantity, denoted by  $\langle\hat{O}\rangle$ , is given by

$$E[O] = \langle\hat{O}\rangle = \langle\psi|\hat{O}|\psi\rangle = \text{Tr}(\hat{O}|\psi\rangle\langle\psi|) = \sum_i \langle\xi_i|\hat{O}|\psi\rangle\langle\psi|\xi_i\rangle,$$

where we have used the Dirac notation. For an ensemble of many identical quantum systems which are prepared similarly, we may not know the state of each system. Instead, as for the ensemble of atomic spins, only the probability distribution of possible states  $|\psi_j\rangle$ ,  $P_j$ , is available. The expectation of the quantity is then the average over all possible  $|\psi_j\rangle$  and is given by

$$(2.1) \quad \langle\hat{O}\rangle = \text{Tr}(\hat{O}\rho),$$

where  $\rho = \sum_j P_j |\psi_j\rangle\langle\psi_j|$  is called the *density matrix* or *density operator*. Similarly, the variance of  $O$  is given by

$$\text{Var}[O] = E[(O - E[O])^2] = \langle(\hat{O} - E[O])^2\rangle = \langle\Delta\hat{O}^2\rangle,$$

where  $\Delta\hat{O} = \hat{O} - \langle\hat{O}\rangle$ . When there is only one operator involved, we use  $\langle O \rangle$  and  $\langle\Delta O^2\rangle$  instead of  $\langle\hat{O}\rangle$  and  $\langle\Delta\hat{O}^2\rangle$ , respectively, without confusion.

The evolution of  $\rho$  can be derived using the Schrödinger equation of  $|\psi\rangle$ ,

$$(2.2) \quad \dot{\rho} = -\frac{i}{\hbar}[\hat{H}, \rho] = -\frac{i}{\hbar}(\hat{H}\rho - \rho\hat{H}),$$

where  $\hat{H}$  is the system Hamiltonian without interaction with its environment. This equation is called the Liouville or Von Neumann equation [13] or master equation. For the ensemble of spins we consider in this article, we have to take into account

the decay of the system due to its interaction with its environment (bath). Moreover, information from the measurement improves our knowledge about the system, and a density matrix conditioned on the measurement history fits our needs better. The evolution of this conditioned density matrix satisfies a more complicated SME [13, 18, 21]. In the system setup of this article, it is given by

$$(2.3) \quad d\rho_c(t) = -idt[\hat{H}(t), \rho_c(t)] + \mathcal{D}[\sqrt{M}\hat{J}_z]\rho_c(t)dt + \sqrt{\eta}\mathcal{H}[\sqrt{M}\hat{J}_z]\rho_c(t) \cdot 2\sqrt{M\eta}(y(t)dt - \langle\hat{J}_z\rangle(t)dt),$$

where  $\hat{H} = \gamma h \hat{J}_z$ ,  $\rho_c$  is the conditioned density matrix, and  $\hat{J}_z$  and  $\hat{J}_y$  are the operators associated with the  $z$ -component and  $y$ -component of the collective spin, respectively. Other symbols are defined below:  $\gamma$  is a constant called the gyromagnetic ratio,  $h = b(t) + u(t)$  is the total magnetic field,  $M$  is the measurement rate,  $\eta$  is the quantum efficiency of the detection, and  $y(t)$  is the photocurrent detected. Operators  $\mathcal{H}$  and  $\mathcal{D}$  are two superoperators defined by

$$(2.4) \quad \begin{aligned} \mathcal{D}(\hat{c})\rho &= \hat{c}\rho\hat{c}^\dagger - (\hat{c}^\dagger\hat{c}\rho + \rho\hat{c}^\dagger\hat{c})/2, \\ \mathcal{H}(\hat{c})\rho &= \hat{c}\rho + \rho\hat{c}^\dagger - \text{Tr}[(\hat{c} + \hat{c}^\dagger)\rho]\rho, \end{aligned}$$

where  $\hat{c}$  is an operator.

We define  $d\bar{W}(t) = \frac{1}{\sqrt{\sigma_m}}(y(t)dt - \langle J_z \rangle(t)dt)$ , where  $\sigma_m = \frac{1}{4M\eta}$ . The process  $\bar{W}$  is a stochastic quantity representing the shot noise in the photodetection process, and it is a Brownian motion. The SME model is first derived for an ensemble of atoms interacting with a single mode far-off resonant cavity [18]. However, Silberfarb and Deutsch lately show that it also applies to the free-space system we have [14]. When  $\eta = 0$ , we discard the measurement result and (2.3) changes into a deterministic master equation. In terms of  $d\bar{W}$ , the measurement result  $y(t)$  is also a stochastic process:

$$(2.5) \quad y(t)dt = \langle J_z \rangle(t)dt + \sqrt{\sigma_m}d\bar{W}(t).$$

According to its definition, the density matrix is another form describing the system state besides the wavefunction. When the measurement result is taken into account, the conditioned density matrix,  $\rho_c$ , gives us the best estimation of the system state. Its evolution is described by the SME models of (2.3) and (2.5). In this setup, to estimate the magnetic field we are concerned only with the current through the detector, and thus the  $z$ -component of the collective spin. It will be good enough for us to know the various moments of  $J_z$ , especially the first two.

Given  $\rho_c$ , the expectation and variance of  $J_z$ , denoted as  $\langle J_z \rangle$  and  $\langle \Delta J_z^2 \rangle$ , respectively, can be computed using (2.1):

$$(2.6) \quad \begin{cases} \langle J_z \rangle = \text{Tr}(\rho_c \hat{J}_z), \\ \langle \Delta J_z^2 \rangle = \text{Tr}(\rho_c (\hat{J}_z - \langle \hat{J}_z \rangle)^2). \end{cases}$$

The SDE of  $\langle J_z \rangle$  and its variance  $\langle \Delta J_z^2 \rangle$  can be derived from the SME [16]:

$$(2.7) \quad \begin{aligned} d\langle J_z \rangle(t) &= \gamma \langle J_x \rangle(t) h(t) dt + \frac{\langle \Delta J_z^2 \rangle(t)}{\sqrt{\sigma_m}} d\bar{W}(t), \\ d\langle \Delta J_z^2 \rangle(t) &= -\frac{\langle \Delta J_z^2 \rangle^2}{\sigma_m} dt - i\gamma \langle [\Delta \hat{J}_z^2, \hat{J}_y] \rangle(t) h(t) dt + \frac{\langle \Delta \hat{J}_z^3 \rangle(t)}{\sqrt{\sigma_m}} d\bar{W}(t). \end{aligned}$$

Clearly, both  $\langle J_z \rangle$  and  $\langle \Delta J_z^2 \rangle$  are scalar stochastic processes driven by  $d\bar{W}$  and  $h(t)$ . According to (2.6), it is actually the conditional expectation of  $J_z$  based on the measurement history, and thus the best estimation.

The above SDE, (2.7), is nonlinear and intractable. However, it can be simplified under certain conditions. First, we assume that the collective spin vector,  $\mathbf{J} = [J_x, J_y, J_z]$ , is a stochastic Gaussian process, which is called the *Gaussian assumption*; second, we assume that  $\mathbf{J}$  is kept around the  $x$ -axis, which is called the *small angle assumption*. Then a one-dimensional linear stochastic process whose optimal estimation is equivalent to  $\langle J_z \rangle$  can be found under these two assumptions.

**THEOREM 2.1.** *A linear stochastic process defined by*

$$(2.8) \quad \begin{cases} dz(t) &= \gamma J h(t) dt, \\ y(t) dt &= z(t) dt + \sqrt{\sigma_m} dw_2(t), \end{cases}$$

where  $w_2(t)$  is a Brownian motion, is equivalent to the system described by (2.3) and (2.5) under the small angle and Gaussian assumptions. The equivalence is in the meaning that its optimal estimator (Kalman filter) is the same as (2.7) by replacing  $\langle J_z \rangle$  by the optimal estimation of  $z(t)$  and replacing  $d\bar{W}$  by a multiple of the innovation process. Specifically, the optimal estimation of  $z(t)$  and  $\langle J_z \rangle$  satisfies the same SDE when  $d\bar{W}$  is replaced by  $\frac{N_t}{\sqrt{\sigma_m}}$ , where  $N_t$  is the innovation process of the Kalman filter.

*Proof.* Under the Gaussian assumption, both  $\langle \Delta \hat{J}_z^3 \rangle$ , the third order moment of  $J_z$ , and  $\langle [\Delta \hat{J}_z^2, \hat{J}_y] \rangle$  vanish. If the spin angle  $\langle J_z \rangle / \langle J_x \rangle$  is kept small (the small angle assumption),  $\langle J_x \rangle(t) \cong J e^{-Mt/2} \cong J$  when  $t \ll 1/M$ , where  $J$  is the amplitude of the vector  $\mathbf{J}$  or the number of atoms. Thus (2.7) can be simplified to

$$(2.9) \quad \begin{aligned} d\langle J_z \rangle(t) &= \gamma J h(t) dt + \frac{\langle \Delta J_z^2 \rangle(t)}{\sqrt{\sigma_m}} d\bar{W}(t), \\ d\langle \Delta J_z^2 \rangle(t) &= -\frac{\langle \Delta J_z^2 \rangle^2(t)}{\sigma_m} dt. \end{aligned}$$

The last differential equation can be solved analytically:

$$\langle \Delta J_z^2 \rangle(t) = \frac{\langle \Delta J_z^2 \rangle(0) \sigma_m}{\sigma_m + \langle \Delta J_z^2 \rangle(0) t},$$

where  $\langle \Delta J_z^2 \rangle(0) = J/2$  for an initially coherent spin state.

Now, if we think  $\langle J_z \rangle$  is the optimal estimation of  $J_z$  and  $\bar{W}(t)$  is a multiple of the innovation process, then (2.9) has the structure of an optimal estimator.

The following shows the optimal estimation  $\tilde{z}(t)$  of the linear system described by (2.8) satisfying an SDE:

$$(2.10) \quad \begin{aligned} d\tilde{z}(t) &= \gamma J h(t) dt + \frac{\Sigma}{\sigma_m} (y(t) dt - \tilde{z}(t) dt), \\ \frac{d}{dt} \Sigma(t) &= -\frac{\Sigma^2}{\sigma_m}. \end{aligned}$$

We note that it is a Kalman filter. Comparing (2.10) and (2.9), we obtain what we want.  $\square$

We have two notes about the above theorem. First, although the sample used is small, the number of atoms involved is still large. Thus the Gaussian assumption is practical. The term  $\langle [\Delta \hat{J}_z^2, \hat{J}_z] h(t) \rangle$  can be ignored also because  $h(t)$  is close to

zero when feedback control is applied. Second, the equivalence of these two models is based on the fact that we are interested only in  $\langle J_z \rangle$ , which connects  $h(t)$  and  $y(t)$ .

The above theorem shows that we can work on a simpler linear SDE model instead of the formidable SME in (2.3) and (2.5). Both  $b(t)$  and  $u(t)$  are classical. We assume that  $b(t)$  is fluctuating and can be described by a stochastic process:

$$(2.11) \quad db(t) = -r_b b(t)dt + \sqrt{\sigma_{bf}}dw_1,$$

where  $w_1$  is another Brownian motion independent of  $w_2$  and  $r_b$  defines the bandwidth of  $b(t)$ . Then a two-dimensional process combining (2.8) and (2.11) can be obtained:

$$(2.12) \quad d\mathbf{x}(t) = A\mathbf{x}(t)dt + \begin{bmatrix} 0 \\ \sqrt{\sigma_{bf}} \end{bmatrix} dw_1,$$

$$(2.13) \quad y(t)dt = C\mathbf{x}(t)dt + \sqrt{\sigma_m}dw_2,$$

where we use  $\mathbf{x}$  to denote the state,

$$\mathbf{x} = \begin{bmatrix} z(t) \\ b(t) \end{bmatrix}.$$

The matrices are given as

$$(2.14) \quad A = \begin{bmatrix} 0 & \gamma J \\ 0 & -r_b \end{bmatrix}, \quad C = [1, 0].$$

The initial variance matrix of the state is

$$(2.15) \quad \Sigma_0 = \begin{bmatrix} \sigma_{z0} & 0 \\ 0 & \sigma_{b0} \end{bmatrix}.$$

We also define  $\Sigma_1$  and  $\Sigma_2$  as follows:

$$(2.16) \quad \Sigma_1 = \begin{bmatrix} 0 & 0 \\ 0 & \sigma_{bf} \end{bmatrix}, \quad \Sigma_2 = \sigma_m = \frac{1}{4}M\eta.$$

### 3. Steady state performance without feedback.

**3.1. Methods without using the Kalman filter.** The magnetic field can be measured without using the Kalman filter. If  $b(t)$  is not compensated by another field, the collective spin will rotate around the  $y$ -axis. If the magnetic field is strong and constant, an oscillating signal can be obtained before the spin damps significantly. Since the oscillation frequency (Larmor frequency) is proportional to the magnetic field, the amplitude of the field can be found using the signal's Fourier transform. But this is not always the case. If the field is weak, only a noisy sloped line of a small angle rotation can be recorded. By fitting the curve with a line, we can find an estimation of its slope, denoted as  $s$ . If we know  $J$ , the field can be retrieved through identity  $\tilde{b} = b = s/\gamma J$ , where  $\tilde{b}$  is the estimation.

However, the above slope method doesn't work well when  $J$  is unknown. If a guess  $J'$  is used instead of the real  $J$ , the actual estimation satisfies  $\tilde{b} = s/\gamma J' = (J/J')b$ .

The second moment and expectation of the estimation error now depend on  $J'$ :

$$(3.1) \quad E[(b - \tilde{b})^2] = \left(1 - \frac{1}{f}\right)^2 E[b^2],$$

$$(3.2) \quad E[b - \tilde{b}] = \left(1 - \frac{J}{J'}\right) E[b] = \left(1 - \frac{1}{f}\right) E[b],$$

where  $f = J'/J$ . If the magnetic field is constant, the error is systematic and can be calibrated away. If both  $b$  and  $J$  are random, the error is no longer systematic and the slope does not make much sense.

**3.2. A method using the Kalman filter.** The Kalman filter gives us the best estimation for a linear stochastic process with Gaussian-type noise. In this section, we will find the steady state performance of the Kalman filter for any  $J'$  picked, using the SDE model formed by (2.12) and (2.13). Because the linearization requires a small angle assumption, we constrain  $b(t)$  to be weak and possibly fluctuating so that  $\langle J_z \rangle / \langle J_x \rangle$  is small. We also assume that the time scale is short enough, so that the damping effect can be ignored, and long enough so that the estimation reaches its steady state. The result sets a standard for future comparison.

Finding the Kalman gain vector involves solving a matrix Riccati equation

$$(3.3) \quad \frac{d}{dt} \Sigma(t) = A' \Sigma + \Sigma A'^T - \Sigma C^T (\Sigma_2)^{-1} C \Sigma + \Sigma_1$$

with initial condition

$$\Sigma(0) = E[(\mathbf{x}(0) - \tilde{\mathbf{x}}(0))(\mathbf{x}(0) - \tilde{\mathbf{x}}(0))^T] = \Sigma_0,$$

where  $A'$  is the same as  $A$  except that  $J$  is replaced by  $J'$ . The Kalman gain vector then is obtained from  $\Sigma$  using identity

$$(3.4) \quad K_o(t) = \Sigma C^T (\Sigma_2)^{-1}.$$

In this article, we are interested in only the steady state performance of the estimation. The above differential equation can be replaced by an algebraic equation,

$$(3.5) \quad A' \Sigma + \Sigma A'^T - \Sigma C^T (\Sigma_2)^{-1} C \Sigma + \Sigma_1 = 0,$$

and  $K_o$  becomes constant. Denoting the two entries of  $K_o$  as  $K_z$  and  $K_b$  and solving the above equation, we have

$$(3.6) \quad K_o = \begin{bmatrix} K_z \\ K_b \end{bmatrix} = \begin{bmatrix} -r_b + \sqrt{r_b^2 + 2\gamma J' \sqrt{\frac{\sigma_{bf}}{\sigma_m}}} \\ \sqrt{\frac{\sigma_{bf}}{\sigma_m}} - \frac{r_b}{\gamma J'} \left( \sqrt{r_b^2 + 2\gamma J' \sqrt{\frac{\sigma_{bf}}{\sigma_m}}} - r_b \right) \end{bmatrix} \approx \begin{bmatrix} \sqrt{2J'} \sigma_{bf}^{1/4} \sigma_m^{-1/4} \\ \sigma_{bf}^{1/2} \sigma_m^{-1/2} \end{bmatrix}.$$

Note that  $J'$  instead of  $J$  appears in (3.6). The observer actually chooses  $J'$  in the design of the Kalman filter. The approximation is based on the *large  $J$  assumption*:  $r_b^2 \ll \gamma J \sqrt{\sigma_{bf}/\sigma_m}$ . Although  $J'$  may be different from  $J$ , it is reasonable to assume that they have the same order because the observer does have some idea about  $J$ .

For simplicity, we define  $\mathbb{J} = \gamma J$  and  $\mathbb{J}' = \gamma J'$  because only the products,  $\gamma J$  and  $\gamma J'$ , appear in our matrices.

The combination of the linear stochastic system and its Kalman filter forms a four-dimensional system. By defining  $\Delta z = z - \tilde{z}$  and  $\Delta b = b - \tilde{b}$ , where  $\tilde{b}$  and  $\tilde{z}$  are the optimal estimations, we obtain a three-dimensional system:

$$(3.7) \quad d\boldsymbol{\theta} = G\boldsymbol{\theta}dt + \beta \begin{bmatrix} dw_1 \\ dw_2 \end{bmatrix}.$$

The matrices and vectors are defined as

$$(3.8) \quad \boldsymbol{\theta} = \begin{bmatrix} \Delta z \\ \Delta b \\ b \end{bmatrix}, \quad G = \begin{bmatrix} -K_z & \mathbb{J}' & \mathbb{J} - \mathbb{J}' \\ -K_b & -r_b & 0 \\ 0 & 0 & -r_b \end{bmatrix},$$

$$\beta = \begin{bmatrix} 0 & -K_z\sqrt{\sigma_m} \\ \sqrt{\sigma_{bf}} & -K_b\sqrt{\sigma_m} \\ \sqrt{\sigma_{bf}} & 0 \end{bmatrix}.$$

A total state covariance matrix  $\Theta$  is defined as

$$(3.9) \quad \Theta = E[\boldsymbol{\theta}\boldsymbol{\theta}^T] = \begin{bmatrix} \theta_{11} & \theta_{12} & \theta_{13} \\ \theta_{12} & \theta_{22} & \theta_{23} \\ \theta_{13} & \theta_{23} & \theta_{33} \end{bmatrix},$$

and its evolution satisfies

$$(3.10) \quad \frac{d\Theta}{dt} = G\Theta + \Theta G^T + \beta\beta^T.$$

The steady solution of  $\Theta$  satisfies an algebraic Riccati equation:

$$(3.11) \quad G\Theta + \Theta G^T + \beta\beta^T = 0.$$

The second moments of the estimation error can then be retrieved from  $\Theta$ :

$$(3.12) \quad \begin{aligned} \sigma_{bo} &= E[\Delta b^2] = \theta_{22}, \\ \sigma_{zo} &= E[\Delta z^2] = \theta_{11}. \end{aligned}$$

We use subscripts  $o$  and  $c$  to distinguish the open-loop case from the closed-loop case.

The solution of (3.11) gives us

$$(3.13) \quad \begin{aligned} \sigma_{zo} &= E[(z - \tilde{z})^2] = \theta_{11} \\ &= \frac{1}{4} \frac{4\sigma_{bf}\mathbb{J}^2 + K_z^2(3K_z^2 + 8K_z + 4r_b^2)\sigma_m}{K_z(K_z + r_b)(K_z + 2r_b)} \end{aligned}$$

and

$$(3.14) \quad \begin{aligned} \sigma_{bo} &= E[(b - \tilde{b})^2] = \theta_{22} \\ &= \frac{1}{8} \frac{K_z^4\sigma_m}{(K_z + r_b)\mathbb{J}'^2} + \frac{1}{2}\sigma_{bf} \left( \frac{K_z(K_z(\mathbb{J} - \mathbb{J}') - r_b\mathbb{J}')^2}{(K_z + r_b)(K_z + 2r_b)^2r_b\mathbb{J}'^2} + \frac{3K_z + 4r_b}{(K_z + 2r_b)^2} \right). \end{aligned}$$

We have used  $K_b = \frac{1}{2\mathbb{J}'} K_z^2$ .

The large  $J$  assumption implies that  $K_z \gg r_b$ , and this leads to an approximation of  $\sigma_{zo}$ :

$$\begin{aligned}
 \sigma_{zo} &= \frac{1}{4} \frac{4\sigma_m K_z^2 (K_z + r_b)^2 - \sigma_m K_z^4 + 4\sigma_{bf} \mathbb{J}^2}{K_z (K_z + 2r_b) (K_z + r_b)} \\
 (3.15) \quad &\approx \frac{3}{4} K_z \sigma_m + \sigma_{bf} \frac{\mathbb{J}^2}{K_z^3} \\
 &\approx \sigma_m^{3/4} \sigma_{bf}^{1/4} \left( \frac{3}{4} \sqrt{2\mathbb{J}'} + \frac{\mathbb{J}^2}{2\mathbb{J}' \sqrt{2\mathbb{J}'}} \right).
 \end{aligned}$$

THEOREM 3.1.  $\sigma_{zo}$  in (3.15) reaches its minimum when  $J = J'$ .

*Proof.* Let  $v = \sqrt{2\mathbb{J}'}$  and define  $g(v) = \frac{3}{4}v + \frac{\mathbb{J}^2}{v^3}$ . The first two derivatives of  $g$  can be computed as

$$(3.16) \quad g'(v) = \frac{3}{4} - \frac{3\mathbb{J}^2}{v^4}, \quad g''(v) = \frac{12\mathbb{J}^2}{v^5} > 0.$$

Equation  $g'(v) = 0$  has two solutions:  $v = \sqrt{2\mathbb{J}}$  and  $v = -\sqrt{2\mathbb{J}}$ . The last one can be discarded since  $v > 0$  according to its definition. Thus  $f$  obtains its minimum when  $v = \sqrt{2\mathbb{J}}$  since  $g''(v)$  is always positive. Identity  $v = \sqrt{2\mathbb{J}}$  implies  $\mathbb{J} = \mathbb{J}'$  and  $\sigma_z = \sqrt{2\mathbb{J}} \sigma_m^{3/4} \sigma_{bf}^{1/4}$ .  $\square$

Approximation of  $\sigma_{bo}$  can also benefit from the large  $J$  assumption:

$$(3.17) \quad \sigma_{bo} \approx \frac{K_z^3}{8\mathbb{J}'^2} \sigma_m + \frac{1}{2} \sigma_{bf} \left( \frac{3}{K_z} + \frac{(K_z(\mathbb{J} - \mathbb{J}') - r_b \mathbb{J}')^2}{K_z^2 \mathbb{J}'^2 r_b} \right).$$

By substituting  $K_z$  in terms of  $\sigma_{bf}$  and  $\sigma_m$ , we can further write  $\sigma_{bo}$  as

$$\sigma_{bo} \approx \sqrt{\frac{2}{\mathbb{J}'}} \sigma_{bf}^{3/4} \sigma_m^{1/4} + \frac{\sigma_{bf}}{2r_b} \left( \frac{1-f}{f} \right)^2 - \frac{\sigma_{bf}^{3/4} \sigma_m^{1/4}}{\sqrt{2\mathbb{J}'}} \left( \frac{1-f}{f} \right) + \frac{\sigma_{bf} r_b}{2K_z^2}.$$

The last term can be discarded as  $K_z \gg r_b$ , and the above expression becomes

$$(3.18) \quad \sigma_{bo} \approx \frac{\sigma_{bf}^{3/4} \sigma_m^{1/4}}{\sqrt{2\mathbb{J}'}} \left( \frac{3}{\sqrt{f}} - \frac{1}{f^{3/2}} \right) + \frac{\sigma_{bf}}{2r_b} \left( \frac{1-f}{f} \right)^2.$$

THEOREM 3.2. When  $J'$  is used in the design of the estimator (Kalman filter) and the control loop is open,  $\sigma_{bo}$  obtained for the linear system (2.12) can be approximated under the large  $J$  assumption by

$$(3.19) \quad \frac{1}{\sqrt{2\mathbb{J}'}} \sigma_{bf}^{3/4} \sigma_m^{1/4} \left( \frac{3}{\sqrt{f}} - \frac{1}{f^{3/2}} \right) + \frac{\sigma_{bf}}{2r_b} \left( \frac{1-f}{f} \right)^2,$$

where  $f = \mathbb{J}'/\mathbb{J}$ . Specifically, when  $\mathbb{J} = \mathbb{J}'$ ,

$$\begin{aligned}
 \sigma_{zo} &= \sqrt{2\mathbb{J}} \sigma_{bf}^{1/4} \sigma_m^{3/4}, \\
 (3.20) \quad \sigma_{bo} &= \sqrt{\frac{2}{\mathbb{J}}} \sigma_{bf}^{3/4} \sigma_m^{1/4}.
 \end{aligned}$$

*Proof.* We have already shown most of the theorem. For the specific case of  $\sigma_{bo}$  when  $\mathbb{J} = \mathbb{J}'$ , replacing  $f$  by 1 in (3.18), we obtain

$$\sigma_{bo} = \sqrt{\frac{2}{\mathbb{J}}} \sigma_{bf}^{3/4} \sigma_m^{1/4}. \quad \square$$

Because of the large  $J$  assumption,  $r_b^2 \ll \mathbb{J}\sqrt{\sigma_{bf}/\sigma_m}$ , the second term in (3.19) quickly dominates the first one when  $f$  is away from 1, which coincides with the result of the Caltech group. It vanishes only when  $f = 1$ , so  $\sigma_{bo}$  obtains its minimum near  $f = 1$ .

**4. Steady state performance with noised feedback.** When the control loop is closed and  $u(t)$  has infinite accuracy, feedback makes the measurement robust to an unknown parameter, the number of atoms involved. Choosing smaller  $J'$  in the design of filter and controller seems beneficial because the measurement is more robust with smaller  $J'$ .

Dropping the noise-free assumption raises concerns about the measurement. We need to know how much the input noise affects the measurement quantitatively and to find when the noise can be ignored. To investigate its effect, we extend the previous system by an input noise term, use a Kalman filter to estimate the magnetic field  $b(t)$ , and choose an LQG controller to find the compensative field  $u(t)$ . Then we proceed to derive the steady state performance of the magnetometer, i.e., the second moments of the estimation errors. As before, we reduce the system dimension, by defining  $\Delta z = z - \tilde{z}$  and  $\Delta b = b - \tilde{b}$ , and simplify the derivation by invoking the large  $J$  assumption and the large  $\lambda$  assumption. The last one will be explained later.

**4.1. The system, the Kalman filter, and the LQG controller.** Besides perturbation from external electromagnetic radiation, input noise arises also from inside the electric circuit in such forms as shot noise, thermal noise, truncation error in the computation, and quantization noise in the digital-to-analog (DA) converters. In practice, the input signal is always accompanied by uncertainty. This becomes serious especially when the input signal is small.

Magnitude varies from one kind of noise to another and highly depends on the specific equipment used. Thermal noise, the fluctuating charges across a resistor, for example, can be modeled as a combination of a noiseless resistor and a shunt current source connected in parallel. The mean square value of the current, a measurement of the magnitude of the noise [6], is

$$E[i^2] = 4KT\Delta fG,$$

where  $T$  is the absolute temperature in Kelvin,  $K$  is the Boltzmann's constant,  $G = 1/R$ , and  $\Delta f$  is the bandwidth of the circuit.

The driver circuit which provides current through the coil usually is a cascade of several amplifiers. The mean square value of the shot noise across a semiconductor junction is proportional to the direct current passing through it,  $I$ ,

$$E[i^2] = 2eI\Delta f,$$

where  $e$  is the electron charge. The shot noise in the first amplifier clearly is the most important since it is amplified in the following stages.

When discrete values are used to replace continuous values, truncation errors bring extra noise to the algorithm. Besides this, quantization error arises in the analog-to-digital (AD) and DA converters. It is nonlinear and signal dependent. The signal-to-noise ratio is low for low-resolution DA converters. Even for high-resolution converters, the signal-to-noise ratio deteriorates when the signal is small. This happens when the measured field is weak and the control loop maintains only a very small current.

There are also other sources of noise. Detailed evaluation of the noise level is time consuming and heavily depends on the specific equipment and its environment. Unfortunately, since this is a new research area and a new experiment setup is used, there is no detailed noise analysis available yet to our knowledge. Experiments published have shown that the signal is strongly polluted by noise, and deeper investigation is necessary.

The input noise appears in the  $h(t)$  term of (2.3) as a stochastic process. When the bandwidth of the noise is wide compared with that of the system, it is equivalent to an additional white noise added to  $u(t)$  in (2.12). Thus we introduce an input noise  $\sqrt{\sigma_{uf}}dw_3$  into the process where  $w_3$  is a Brownian motion independent of  $w_1$  and  $w_2$ , and this changes the original system described by (2.12) and (2.11) to

$$(4.1) \quad \begin{aligned} d\mathbf{x}(t) &= A\mathbf{x}(t)dt + Bu(t)dt + \begin{bmatrix} \sqrt{\sigma_{uf}} & 0 \\ 0 & \sqrt{\sigma_{bf}} \end{bmatrix} \begin{bmatrix} dw_3 \\ dw_1 \end{bmatrix}, \\ y(t)dt &= C\mathbf{x}(t)dt + \sqrt{\sigma_m}dw_2(t). \end{aligned}$$

The matrices are listed as

$$(4.2) \quad A = \begin{bmatrix} 0 & \mathbb{J} \\ 0 & -r_b \end{bmatrix}, \quad B = \begin{bmatrix} \mathbb{J} \\ 0 \end{bmatrix}, \quad C = [1, 0].$$

A constant feedback gain vector is used in our model:

$$(4.3) \quad u(t)dt = -K_c\tilde{x}(t)dt,$$

where  $K_c$  is the controller gain vector. Similarly, only the steady solution of the filter gain vector is used.

LEMMA 4.1. *The steady solution of the Kalman filter gain vector  $K_o$  of the linear system defined by (4.1) is*

$$(4.4) \quad \begin{aligned} K_z &= -r_b + \sqrt{r_b^2 + \sigma_{uf}\sigma_m^{-1} + 2\sqrt{\mathbb{J}'^2\sigma_{bf}\sigma_m^{-1} + r_b^2\sigma_{uf}\sigma_m^{-1}}}, \\ K_b &= \frac{1}{2\mathbb{J}'}(-\sigma_{uf}\sigma_m^{-1} + K_z^2) \end{aligned}$$

when  $J'$  instead of  $J$  is used in the design of the Kalman filter. Under the large  $J$  and  $\lambda$  assumption, the LQG controller gain vector  $K_c$  can be approximated by

$$(4.5) \quad K_c \approx [\lambda, 1],$$

where  $\lambda = \sqrt{q/r}$  for a cost function defined by

$$\mathcal{J} = \int_0^\infty (qz(t)^2 + ru(t)^2)dt.$$

*Proof.* We first find  $K_c$  [5, 4]. It satisfies

$$K_c \equiv r^{-1}B^TV,$$

where  $V$  is the solution of

$$(4.6) \quad P + A'^TV + VA' - \frac{1}{r}VB'B'^TV = 0.$$

The matrices  $A'$  and  $B'$  are the same as  $A$  and  $B$  except that  $J$  is replaced by  $J'$ . Matrix  $P$  is defined from the cost function:

$$P = \begin{bmatrix} q & 0 \\ 0 & 0 \end{bmatrix}.$$

The solution of (4.6) leads to

$$(4.7) \quad K_c = \left[ \lambda, \frac{\mathbb{J}'\lambda}{r_b + \mathbb{J}'\lambda} \right].$$

While the original large  $\lambda$  assumption in [16] implies that  $\lambda^2 \gg \sqrt{\sqrt{\sigma_{bf}/\sigma_m}/(2\mathbb{J})}$ , in this article, we change it to  $\lambda \gg \sqrt{\sqrt{\sigma_{bf}/\sigma_m}/(2\mathbb{J})}$ . This does not make a significant difference in the experiment but makes our derivation much easier. Combined with the large  $J$  assumption, our large  $\lambda$  assumption leads to  $\lambda\mathbb{J} \gg \sqrt{\sqrt{\sigma_{bf}/\sigma_m}\mathbb{J}} \gg r_b$ . Thus  $K_c$  can be approximated by

$$(4.8) \quad K_c \approx [\lambda, 1]$$

as we wanted.

Using the formulae of the Kalman filter, we obtain

$$K_o = \Sigma(t)C^T\Sigma_2^{-1}$$

and

$$\frac{d}{dt}\Sigma(t) = \Sigma_1 + A'\Sigma(t) + \Sigma(t)A'^T - \Sigma(t)C^T\Sigma_2^{-1}C\Sigma(t),$$

where  $\Sigma_2$  is defined in (2.16) as before, but  $\Sigma_1$  changes to

$$\Sigma_1 = \begin{bmatrix} \sigma_{uf} & 0 \\ 0 & \sigma_{bf} \end{bmatrix}.$$

Other matrices are defined as before. Let  $\Sigma(t)$  be constant and denoted as

$$\Sigma = \begin{bmatrix} \sigma_{zs} & \sigma_{cs} \\ \sigma_{cs} & \sigma_{bs} \end{bmatrix}.$$

We find a set of equations

$$(4.9) \quad \begin{cases} \sigma_{uf} + 2\mathbb{J}'\sigma_{cs} - \sigma_{zs}^2\sigma_m^{-1} = 0, \\ \mathbb{J}'\sigma_{bs} - r_b\sigma_{cs} - \sigma_{cs}\sigma_{zs}\sigma_m^{-1} = 0, \\ \sigma_{bf} - 2r_b\sigma_{bs} - \sigma_{cs}^2\sigma_m^{-1} = 0. \end{cases}$$

From among the three unknown entries, we need only  $\sigma_{zs}$  and  $\sigma_{cs}$ :

$$(4.10) \quad \begin{aligned} \sigma_{zs} &= -r_b\sigma_m + \sigma_m\sqrt{r_b^2 + \sigma_{uf}\sigma_m^{-1} + 2\sqrt{\mathbb{J}'^2\sigma_{bf}\sigma_m^{-1} + r_b^2\sigma_{uf}\sigma_m^{-1}}}, \\ \sigma_{cs} &= \frac{1}{2\mathbb{J}'}(-\sigma_{uf} + \sigma_{zs}^2\sigma_m^{-1}). \end{aligned}$$

The entries of  $K_o$  are then obtained from  $\sigma_{zs}$  and  $\sigma_{cs}$ :

$$(4.11) \quad \begin{aligned} K_z = \frac{\sigma_{zs}}{\sigma_m} &= -r_b + \sqrt{r_b^2 + \sigma_{uf}\sigma_m^{-1} + 2\sqrt{\mathbb{J}'^2\sigma_{bf}\sigma_m^{-1} + r_b^2\sigma_{uf}\sigma_m^{-1}}}, \\ K_b = \frac{\sigma_{cs}}{\sigma_m} &= \frac{1}{2\mathbb{J}'}(-\sigma_{uf}\sigma_m^{-1} + K_z^2). \quad \square \end{aligned}$$

There are several useful identities about  $K_z$  and  $K_b$ , and we list them in the following lemmas.

LEMMA 4.2.

$$(4.12) \quad \sigma_{uf} = K_z^2 \sigma_m - 2\mathbb{J}' K_b \sigma_m,$$

$$(4.13) \quad \mathbb{J}' \sigma_{bf} = (\mathbb{J}' K_b^2 + 2r_b^2 K_b + 2r_b K_b K_z) \sigma_m,$$

$$(4.14) \quad K_z r_b + K_b \mathbb{J}' = \sqrt{\mathbb{J}'^2 \sigma_{bf} \sigma_m^{-1} + r_b^2 \sigma_{uf} \sigma_m^{-1}}.$$

*Proof.* Identity (4.12) is just the first equation in (4.9) in terms of  $K_z$  and  $K_b$ . We need only prove (4.13) and (4.14). Using (4.12) and (4.11), we have

$$(4.15) \quad \begin{aligned} K_z r_b + K_b \mathbb{J}' &= \frac{1}{2} (2K_z r_b + K_z^2 - \sigma_{uf} \sigma_m^{-1}) \\ &= \frac{1}{2} ((K_z + r_b)^2 - r_b^2 - \sigma_{uf} \sigma_m^{-1}) \\ &= \sqrt{\mathbb{J}'^2 \sigma_{bf} \sigma_m^{-1} + r_b^2 \sigma_{uf} \sigma_m^{-1}}, \end{aligned}$$

and this proves (4.14). For (4.13), look into identity

$$(4.16) \quad \begin{aligned} \sigma_{bf} &= \sigma_{cs}^2 \sigma_m^{-1} + 2r_b \sigma_{bs} \\ &= \sigma_{cs}^2 \sigma_m^{-1} + 2r_b \frac{1}{\mathbb{J}'} (r_b \sigma_{cs} + \sigma_{cs} \sigma_{zs} \sigma_m^{-1}), \end{aligned}$$

which is equivalent to

$$\mathbb{J}' \sigma_{bf} = \mathbb{J}' K_b^2 \sigma_m + 2r_b^2 K_b \sigma_m + 2r_b K_b K_z \sigma_m. \quad \square$$

LEMMA 4.3.

$$(4.17) \quad \frac{(K_b^2 \sigma_m + \sigma_{bf})(r_b K_z + \mathbb{J}' K_b) + K_b^2 \sigma_{uf} + K_z^2 \sigma_{bf}}{2(K_z r_b + K_b \mathbb{J}')(K_z + r_b)} = \frac{K_b(K_z + r_b) \sigma_m}{\mathbb{J}'}.$$

*Proof.* Using Lemma 4.2, we have

$$(4.18) \quad \begin{aligned} &2(K_z r_b + K_b \mathbb{J}')(K_z + r_b)^2 K_b \sigma_m - \mathbb{J}'(\sigma_m K_b^2 + \sigma_{bf})(r_b K_z + \mathbb{J}' K_b) \\ &= (K_z r_b + \mathbb{J}' K_b)(2K_b(K_z + r_b)^2 \sigma_m - \mathbb{J}'(K_b^2 \sigma_m + \sigma_{bf})) \\ &= (K_z r_b + \mathbb{J}' K_b)(2K_b(K_z + r_b)^2 - 2(\mathbb{J}' K_b^2 + r_b^2 K_b + r_b K_b K_z)) \sigma_m \\ &= 2(K_z r_b + \mathbb{J}' K_b)(K_b(K_z^2 + K_z r_b - K_b \mathbb{J}')) \sigma_m \\ &= 2K_b(r_b K_z^3 + r_b^2 K_z^2 + \mathbb{J}' K_b K_z^2 - \mathbb{J}'^2 K_b^2) \sigma_m \end{aligned}$$

and

$$(4.19) \quad \begin{aligned} &K_b^2 \mathbb{J}' \sigma_{uf} + K_z^2 \mathbb{J}' \sigma_{bf} \\ &= \sigma_m (K_b^2 \mathbb{J}' (K_z^2 - 2\mathbb{J}' K_b) + K_z^2 (K_b^2 \mathbb{J}' + 2r_b^2 K_b + 2r_b K_b K_z)) \\ &= \sigma_m (\mathbb{J}' K_z^2 K_b^2 - 2\mathbb{J}'^2 K_b^3 + \mathbb{J}' K_z^2 K_b^2 + 2r_b^2 K_b K_z^2 + 2r_b K_b K_z^3) \\ &= 2K_b(r_b K_z^3 + r_b^2 K_z^2 + \mathbb{J}' K_b K_z^2 - \mathbb{J}'^2 K_b^2) \sigma_m. \end{aligned}$$

Thus

$$(4.20) \quad \begin{aligned} &2(K_z r_b + K_b \mathbb{J}')(K_z + r_b)^2 K_b \sigma_m - \mathbb{J}'(\sigma_m K_b^2 + \sigma_{bf})(r_b K_z + \mathbb{J}' K_b) \\ &= K_b^2 \mathbb{J}' \sigma_{uf} + K_z^2 \mathbb{J}' \sigma_{bf}, \end{aligned}$$

and that is equivalent to (4.17).  $\square$

LEMMA 4.4. If  $\mathbb{J} \gg r_b^2 \sqrt{\frac{\sigma_m}{\sigma_{bf}}}$  (large  $J$  assumption),  $K_z \gg r_b$ .

*Proof.* If  $\beta \gg \alpha > 0$ , then

$$\sqrt{\alpha + \beta} - \sqrt{\alpha} = \sqrt{\alpha}(\sqrt{1 + \beta/\alpha} - 1) \approx \sqrt{\beta} \gg \sqrt{\alpha}.$$

Letting  $\alpha = r_b^2$  and  $\beta = 2\sqrt{\mathbb{J}'^2 \sigma_{bf}/\sigma_m + r_b^2 \sigma_{uf}/\sigma_m} + \sigma_{uf}/\sigma_m$ , we obtain what we want.  $\square$

The large  $J$  assumption implies that  $r_b^2 \ll \sqrt{\mathbb{J}' \sigma_{bf} \sigma_m^{-1} + r_b^2 \sigma_{uf} \sigma_m^{-1}}$ , leading to an approximation of  $K_z$ :

$$(4.21) \quad K_z \approx \sqrt{\sigma_{uf} \sigma_m + 2\sqrt{\mathbb{J}'^2 \sigma_{bf} \sigma_m^3 + r_b^2 \sigma_{uf} \sigma_m^3}} \frac{1}{\sigma_m}$$

and an approximation of  $K_b$ :

$$(4.22) \quad K_b \approx \sqrt{\sigma_{bf} \sigma_m + r_b^2 \mathbb{J}'^{-2} \sigma_{uf} \sigma_m} \frac{1}{\sigma_m}.$$

**4.2. Derivation of the steady state performance.** In this subsection, we will find the steady state performance of the measurement under the influence of the input noise and simplify the results by invoking the large  $\lambda$  and  $J$  assumptions. We start with combining the system, the estimator, and the controller together to form a four-dimensional system:

$$(4.23) \quad d \begin{bmatrix} z(t) \\ b(t) \\ \tilde{z}(t) \\ \tilde{b}(t) \end{bmatrix} = \begin{bmatrix} 0 & \mathbb{J} & -\mathbb{J}\lambda & -\mathbb{J} \\ 0 & -r_b & 0 & 0 \\ K_z & 0 & -\mathbb{J}'\lambda - K_z & 0 \\ K_b & 0 & -K_b & -r_b \end{bmatrix} \begin{bmatrix} z(t) \\ b(t) \\ \tilde{z}(t) \\ \tilde{b}(t) \end{bmatrix} dt + \begin{bmatrix} \sqrt{\sigma_{uf}} & & & \\ & \sqrt{\sigma_{bf}} & & \\ & & K_z \sqrt{\sigma_m} & \\ & & K_b \sqrt{\sigma_m} & \end{bmatrix} \begin{bmatrix} dw_3 \\ dw_2 \\ dw_1 \end{bmatrix}.$$

As before, we define  $\Delta z = z - \tilde{z}$  and  $\Delta b = b - \tilde{b}$ , and a three-dimensional system is obtained as

$$(4.24) \quad d \begin{bmatrix} \Delta z \\ \Delta b \\ \tilde{z} \end{bmatrix} = \begin{bmatrix} -K_z & \mathbb{J} & \lambda(\mathbb{J}' - \mathbb{J}) \\ -K_b & -r_b & 0 \\ K_z & 0 & -\lambda\mathbb{J}' \end{bmatrix} \begin{bmatrix} \Delta z dt \\ \Delta b dt \\ \tilde{z} dt \end{bmatrix} + \begin{bmatrix} \sqrt{\sigma_{uf}} & 0 & -K_z \sqrt{\sigma_m} \\ 0 & \sqrt{\sigma_{bf}} & -K_b \sqrt{\sigma_m} \\ 0 & 0 & K_z \sqrt{\sigma_m} \end{bmatrix} \begin{bmatrix} dw_3 \\ dw_1 \\ dw_2 \end{bmatrix}.$$

The vector and matrices are defined as

$$(4.25) \quad \theta = \begin{bmatrix} \Delta z \\ \Delta b \\ \tilde{z} \end{bmatrix}, \quad \alpha = \begin{bmatrix} -K_z & \mathbb{J} & \lambda(\mathbb{J}' - \mathbb{J}) \\ -K_b & -r_b & 0 \\ K_z & 0 & -\lambda\mathbb{J}' \end{bmatrix},$$

$$\beta = \begin{bmatrix} \sqrt{\sigma_{uf}} & 0 & -K_z \sqrt{\sigma_m} \\ 0 & \sqrt{\sigma_{bf}} & -K_b \sqrt{\sigma_m} \\ 0 & 0 & K_z \sqrt{\sigma_m} \end{bmatrix}.$$

As before, the dynamic equation of the total state covariance satisfies

$$(4.26) \quad \frac{d\Theta}{dt} = \alpha\Theta + \Theta\alpha^T + \beta\beta^T,$$

where  $\Theta = E[\theta\theta^T]$ . Its steady solution can be found by solving

$$(4.27) \quad 0 = \alpha\Theta + \Theta\alpha^T + \beta\beta^T.$$

Because  $\Theta$  is symmetric, we can assume

$$\Theta = \begin{bmatrix} \theta_{11} & \theta_{12} & \theta_{13} \\ \theta_{12} & \theta_{22} & \theta_{23} \\ \theta_{13} & \theta_{23} & \theta_{33} \end{bmatrix},$$

and (4.27) is transformed into six linear equations:

$$(4.28) \quad \begin{cases} -K_z\theta_{11} + \mathbb{J}\theta_{12} + \lambda(\mathbb{J}' - \mathbb{J})\theta_{13} = -(\sigma_{uf} + K_z^2\sigma_m)/2, \\ -K_z\theta_{12} + \mathbb{J}\theta_{22} + \lambda(\mathbb{J}' - \mathbb{J})\theta_{23} - K_b\theta_{11} - r_b\theta_{12} = -K_zK_b\sigma_m, \\ -K_z\theta_{13} + \mathbb{J}\theta_{23} + \lambda(\mathbb{J}' - \mathbb{J})\theta_{33} + K_z\theta_{11} - \lambda\mathbb{J}'\theta_{13} = K_z^2\sigma_m, \\ K_b\theta_{12} + r_b\theta_{22} = (\sigma_{bf} + K_b^2\sigma_m)/2, \\ -K_b\theta_{13} - r_b\theta_{23} + K_z\theta_{12} - \lambda\mathbb{J}'\theta_{23} = K_zK_b\sigma_m, \\ K_z\theta_{13} - \lambda\mathbb{J}'\theta_{33} = -K_z^2\sigma_m/2. \end{cases}$$

We need only  $\sigma_{bc} = E[(\Delta b)^2] = \theta_{22}$ . Its solution can be written as a rational function:

$$(4.29) \quad \theta_{22} = \frac{Poly_N}{Poly_D},$$

where

$$(4.30) \quad Poly_D = 2\mathbb{J}(r_bK_z + \mathbb{J}'K_b)((\mathbb{J}'K_b + (K_z + \lambda\mathbb{J}')(r_b + \lambda\mathbb{J}'))(K_z + r_b) \\ + (\mathbb{J} - \mathbb{J}')(\lambda K_z(\lambda\mathbb{J}' + K_z) + K_b(r_b + K_z))),$$

and

$$(4.31) \quad \begin{aligned} Poly_N &= \mathbb{J}((\sigma_m K_b^2 + \sigma_{bf})(r_b K_z + \mathbb{J}'K_b) + K_b^2\sigma_{uf} + K_z^2\sigma_{bf}) \\ &\quad (\mathbb{J}'K_b + (K_z + \lambda\mathbb{J}')(r_b + \lambda\mathbb{J}')) \\ &\quad + (\mathbb{J} - \mathbb{J}')(\lambda\mathbb{J}\sigma_{bf}K_z^3 + \lambda\mathbb{J}\sigma_m r_b K_z^2 K_b^2 + \lambda^2\mathbb{J}'\sigma_{bf}K_z^2 \\ &\quad + r_b\mathbb{J}\sigma_m K_z K_b^3 + \lambda\mathbb{J}\mathbb{J}'\sigma_m K_z K_b^3 - \lambda\mathbb{J}'\sigma_{uf}K_z K_b^2 \\ &\quad + r_b\mathbb{J}\sigma_{bf}K_z K_b - \lambda\mathbb{J}\mathbb{J}'\sigma_{bf}K_z K_b + \mathbb{J}\mathbb{J}'\sigma_m K_b^4 + \mathbb{J}\mathbb{J}'\sigma_{bf}K_b^2 \\ &\quad - \lambda\mathbb{J}'\sigma_{uf}r_b K_b^2 - \lambda^2\mathbb{J}'^2\sigma_{uf}K_b^2) \\ &= \mathbb{J}(\dots) \\ &\quad + (\mathbb{J} - \mathbb{J}')(\mathbb{J}(K_b^2\sigma_m + \sigma_{bf})K_b(r_b K_z + \mathbb{J}'K_b) \\ &\quad - 2\lambda\frac{\mathbb{J}}{\mathbb{J}'}K_z K_b r_b (K_z + r_b)(r_b K_z + \mathbb{J}'K_b)\sigma_m \\ &\quad + \lambda(K_z + r_b + \lambda\mathbb{J}')(\mathbb{J}K_z^2\sigma_{bf} - \mathbb{J}'K_b^2\sigma_{uf})). \end{aligned}$$

Observing that

$$\frac{\alpha\mathcal{A} + \beta\mathcal{B}}{\alpha + \beta\mathcal{C}} = \mathcal{A} + \frac{\beta(\mathcal{B} - \mathcal{A}\mathcal{C})}{\alpha + \beta\mathcal{C}},$$

comparing it with (4.29)–(4.31), and using Lemma 4.3, we find

$$(4.32) \quad \theta_{22} = \frac{K_b(K_z + r_b)}{\mathbb{J}'} \sigma_m + \frac{(\mathbb{J} - \mathbb{J}') \text{Poly}_N^2}{\text{Poly}_D},$$

where

$$(4.33) \quad \begin{aligned} \text{Poly}_N^2 = & \mathbb{J}(K_b^2 \sigma_m + \sigma_{bf}) K_b(r_b K_z + \mathbb{J}' K_b) \\ & - 2\lambda \frac{\mathbb{J}}{\mathbb{J}'} K_z K_b r_b (K_z + r_b)(r_b K_z + K_b \mathbb{J}') \sigma_m \\ & + \lambda(K_z + r_b + \lambda \mathbb{J}')(\mathbb{J} K_z^2 \sigma_{bf} - \mathbb{J}' K_b^2 \sigma_{uf}) \\ & - \frac{K_b(K_z + r_b)}{\mathbb{J}'} \sigma_m (K_b r_b + K_b K_z + \lambda^2 \mathbb{J}' K_z + \lambda K_z^2) 2\mathbb{J}(K_z r_b + \mathbb{J}' K_b). \end{aligned}$$

Since

$$(4.34) \quad \begin{aligned} \mathbb{J}(K_b^2 \sigma_m + \sigma_{bf}) &= \frac{\mathbb{J}}{\mathbb{J}'} (K_b^2 \mathbb{J}' \sigma_m + \mathbb{J}' \sigma_{bf}) \\ &= \frac{2\mathbb{J}}{\mathbb{J}'} (K_b^2 \mathbb{J}' + r_b^2 K_b + r_b K_b K_z) \sigma_m, \end{aligned}$$

the first term in (4.33) can be rewritten in terms of  $\sigma_m$ . By collecting all  $\sigma_m$  terms together, we can rewrite  $\text{Poly}_N^2$  as

$$(4.35) \quad \begin{aligned} \text{Poly}_N^2 = & 2 \frac{\mathbb{J}}{\mathbb{J}'} \sigma_m K_b(r_b K_z + \mathbb{J}' K_b) (\lambda(K_z + r_b) K_z (-r_b - K_z - \lambda \mathbb{J}') \\ & + K_b^2 \mathbb{J}' - K_b K_z^2 - K_b K_z r_b) \\ & + \frac{\mathbb{J}}{\mathbb{J}'} (K_z + r_b + \lambda \mathbb{J}') \lambda \left( \mathbb{J}' K_z^2 \sigma_{bf} - \frac{\mathbb{J}^2}{\mathbb{J}} K_b^2 \sigma_{uf} \right). \end{aligned}$$

Using Lemma 4.2, we can further write  $\text{Poly}_N^2$  as a multiple of  $\sigma_m$ :

$$(4.36) \quad \begin{aligned} \frac{\text{Poly}_N^2}{\sigma_m} = & \lambda K_b^2 (K_z + r_b + \lambda \mathbb{J}') (2\mathbb{J}'^2 K_b - \mathbb{J}' K_z^2 - 2r_b \mathbb{J} K_z - \mathbb{J} K_z^2) \\ & + 2 \frac{\mathbb{J}}{\mathbb{J}'} K_b (K_b \mathbb{J}' + r_b K_z) (K_b^2 \mathbb{J}' - K_b K_z^2 - r_b K_z K_b). \end{aligned}$$

We can do the same for  $\theta_{22}$ :

$$(4.37) \quad \frac{\theta_{22}}{\sigma_m} = \frac{K_b(K_z + r_b)}{\mathbb{J}'} + \frac{(\mathbb{J} - \mathbb{J}') \text{Poly}_N^2}{\text{Poly}_D \sigma_m}.$$

Before we use the large  $\lambda$  and  $J$  assumptions to simplify (4.37), we first look into two identities:

$$(4.38) \quad \begin{aligned} & 2\mathbb{J}'^2 K_b - \mathbb{J}' K_z^2 - \mathbb{J} K_z^2 - 2r_b \mathbb{J} K_z \\ &= \mathbb{J}' (2\mathbb{J}' K_b - K_z^2) - \mathbb{J} K_z (K_z + 2r_b) \\ &= -\mathbb{J}' \sigma_{uf} \sigma_m^{-1} - \mathbb{J} K_z (K_z + 2r_b) \\ &= -(\mathbb{J} + \mathbb{J}') \sigma_{uf} \sigma_M^{-1} - 2\mathbb{J} \sqrt{T} \end{aligned}$$

and

$$\begin{aligned}
 & K_b^2 \mathbb{J}' - K_b K_z^2 - r_b K_z K_b \\
 &= K_b (\mathbb{J}' K_b - K_z^2 - r_b K_z) \\
 &= K_b \left( \frac{1}{2} (K_z^2 - \sigma_{uf} \sigma_m^{-1}) - K_z^2 - r_b K_z \right) \\
 (4.39) \quad &= K_b \left( -\frac{1}{2} (K_z^2 + 2r_b K_z + r_b^2) + \frac{r_b^2}{2} - \frac{\sigma_{uf}}{2\sigma_m} \right) \\
 &= \frac{K_b}{2} \left( -2 \frac{\sigma_{uf}}{\sigma_m} - 2\sqrt{T} \right),
 \end{aligned}$$

where  $T = \mathbb{J}'^2 \sigma_{bf} \sigma_m^{-1} + r_b^2 \sigma_{uf} \sigma_m^{-1}$ . Now (4.36) can be rewritten as

$$\begin{aligned}
 \frac{Poly_N^2}{\sigma_m} &= - \left( \lambda K_b^2 \mathbb{J} \left( \left( 1 + \frac{\mathbb{J}'}{\mathbb{J}} \right) \frac{\sigma_{uf}}{\sigma_m} + 2\sqrt{T} \right) (K_z + r_b + \lambda \mathbb{J}') \right. \\
 (4.40) \quad &\quad \left. + \frac{\mathbb{J}}{\mathbb{J}'} K_b^2 (r_b K_z + K_b \mathbb{J}') \left( 2 \frac{\sigma_{uf}}{\sigma_m} + 2\sqrt{T} \right) \right) \\
 &= -2K_b^2 \left( \frac{\sigma_{uf}}{\sigma_m} + \sqrt{T} \right) \left( \frac{1}{f} \sqrt{T} + \lambda \mathbb{J} (K_z + r_b + \lambda \mathbb{J}') \right) \\
 &\quad + (1-f) \lambda K_b^2 \mathbb{J} (K_z + r_b + \lambda \mathbb{J}') \frac{\sigma_{uf}}{\sigma_m},
 \end{aligned}$$

where  $f = \mathbb{J}'/\mathbb{J}$ .

The denominator  $Poly_D$  can be simplified by reorganizing its terms first:

$$\begin{aligned}
 Poly_D &= 2\mathbb{J} (K_z r_b + \mathbb{J}' K_b) ((K_z + r_b)(K_z r_b + \mathbb{J}' K_b) \\
 &\quad + \lambda \mathbb{J}' (K_z + r_b + \lambda \mathbb{J}') (K_z + r_b) \\
 &\quad + (\mathbb{J} - \mathbb{J}') (\lambda K_z (\lambda \mathbb{J}' + K_z) + K_b (r_b + K_z))) \\
 (4.41) \quad &= 2\mathbb{J} \sqrt{T} ((K_z + r_b) \sqrt{T} + \lambda \mathbb{J}' (K_z + r_b)^2 + \lambda^2 \mathbb{J}'^2 (K_z + r_b) \\
 &\quad + (\mathbb{J} - \mathbb{J}') (\lambda K_z (\lambda \mathbb{J}' + K_z) + K_b (r_b + K_z))) \\
 &= 2\mathbb{J} \sqrt{T} ((K_z + r_b) (\sqrt{T} + (\mathbb{J} - \mathbb{J}') K_b) \\
 &\quad + \lambda (\mathbb{J} K_z^2 + \lambda \mathbb{J}' (\mathbb{J} K_z + \mathbb{J}' r_b) + \mathbb{J}' r_b^2 + 2\mathbb{J}' r_b K_z)) \\
 &\approx 2\mathbb{J} \sqrt{T} \left( K_z \left( \sqrt{T} + \left( \frac{1}{f} - 1 \right) \sqrt{T} \right) + \lambda \mathbb{J} K_z (K_z + \lambda \mathbb{J}') \right) \\
 &\approx 2\mathbb{J} \sqrt{T} K_z \left( \frac{\mathbb{J}}{\mathbb{J}'} \sqrt{T} + \lambda \mathbb{J} (K_z + \lambda \mathbb{J}') \right).
 \end{aligned}$$

We have used (4.21) and the large  $J$  assumption in the above approximation.

Combining (4.40) and (4.41), we obtain

$$(4.42) \quad \frac{Poly_N^2}{Poly_D} = - \frac{K_b^2 (\sigma_{uf} + \sigma_m \sqrt{T})}{\mathbb{J} \sqrt{T} K_z} + (f-1) \frac{\lambda K_b^2 (K_z + r_b + \lambda \mathbb{J}') \sigma_{uf}}{2\mathbb{J} \sqrt{T} K_z (\frac{\sqrt{T}}{\mathbb{J}'} + \lambda (K_z + \lambda \mathbb{J}'))}.$$

The second term in the above equation can be made simpler if  $\lambda (K_z + \lambda \mathbb{J}') \gg \frac{\sqrt{T}}{\mathbb{J}'}$ :

$$(4.43) \quad \frac{\lambda K_b^2 (K_z + r_b + \lambda \mathbb{J}') \sigma_{uf}}{2\mathbb{J} \sqrt{T} K_z (\frac{\sqrt{T}}{\mathbb{J}'} + \lambda (K_z + \lambda \mathbb{J}'))} \approx \frac{K_b^2 \sigma_{uf}}{2\mathbb{J} \sqrt{T} K_z},$$

FIG. 5.1. Curves of  $\sigma_{bc}$  with respect to  $f$ , when  $\sigma_{uf}$  increases from  $10^{-4}$  to  $10^6$ . Curves are almost the same when  $\sigma_{uf} \leq 10^4$ . Parameters are chosen as in (5.1).

and  $\sigma_{bc}$  can be found by substituting (4.42) and (4.43) back into (4.33). We state this in a theorem.

**THEOREM 4.5.** *When  $J'$  is used in the design of the estimator (Kalman filter) and the controller,  $\sigma_{bc}$  obtained for the linear system (4.23) is approximated by*

$$(4.44) \quad \sigma_{bc}/\sigma_m \approx \frac{(K_z + r_b)K_b}{J'} - (1-f)\frac{K_b^2}{K_z} + \frac{K_b^2\sigma_{uf}\sigma_m^{-1}}{2\sqrt{T}K_z}(f^2 - 1).$$

The large  $\lambda$  and  $J$  assumptions are assumed to hold and so is  $\lambda(K_z + \lambda J') \gg \frac{\sqrt{T}}{J'}$ . Entries  $K_z$  and  $K_b$  are defined as before.

The inequality  $\lambda(K_z + \lambda J') \gg \frac{\sqrt{T}}{J'}$  is an extension of the large  $\lambda$  and  $J$  assumptions. According to the large  $\lambda$  assumption,  $\lambda^2$  is far larger than  $\sqrt{\frac{\sigma_{bf}}{\sigma_m} \frac{1}{2J'}}$ , and  $\frac{\sqrt{T}}{J'}$ , which is equal to  $\sqrt{\frac{\sigma_{bf}}{\sigma_m} + \frac{r_b^2\sigma_{uf}}{J'^2\sigma_m}}$ , is in the order of  $\sqrt{\frac{\sigma_{bf}}{\sigma_m}}$  if  $\sigma_{uf}$  is not too large. The condition about  $\sigma_{uf}$  is very reasonable if one considers the large  $J$  assumption.

**5. Effect of the input noise.** Equipped with Theorems 4.5 and 3.2, we can now compare  $\sigma_{bo}$  and  $\sigma_{bc}$ . When the compensative field is not applied with infinite accuracy, additional uncertainty is brought into the system. It influences and finally damages the measurement.

An example is useful. Figure 5.1 illustrates different  $\sigma_{bc}$  curves with respect to  $f$  for different  $\sigma_{uf}$ . Numbers are chosen as

$$(5.1) \quad \sigma_m = \sigma_{bf} = 10^{-4}, \quad J = 10^{10}, \quad \lambda = 0.5, \quad r_b = 10^3.$$

Figure 5.2 shows the three-dimensional mesh of  $\sigma_{bc}$  with respect to  $f$  and  $\sigma_{uf}$ . Additional input noise raises the estimation error, but its effect is not obvious when  $\sigma_{uf} \leq 10^5$ . For most  $\sigma_{uf}$ ,  $\sigma_{bc}$  obtains its minimum near  $f = 1$ .

A comparison between the open-loop and closed-loop results is shown in Figure 5.3 by drawing the ratio  $\sigma_{bc}/\sigma_{bo}$ . When  $\sigma_{uf}$  is small,  $\sigma_{bc}/\sigma_{bo} \leq 1$  for most  $J'$ . When  $\sigma_{uf}$  increases,  $\sigma_{bc}/\sigma_{bo}$  first becomes larger than 1 near  $f = 1$  and then the range of  $J'$ ,

FIG. 5.2. Three-dimensional mesh of  $\sigma_{bc}$  with respect to  $f$  and  $\sigma_{uf}$ . Parameters are chosen as in (5.1).

FIG. 5.3. Curves of  $\sigma_{bc}/\sigma_{bo}$  with respect to  $f$ , when  $\sigma_{uf}$  increases from  $10^{-4}$  to  $10^6$ . Curves are almost the same when  $\sigma_{uf} < 10^6$ . Parameters are chosen as in (5.1).

where  $\sigma_{bc}/\sigma_{bo} > 1$  expands towards both sides. Note that the figures are not accurate near  $f = 1$  because of simplifications in the computation and round-off errors.

Theorem 4.5 can be used to find a threshold of  $\sigma_{uf}$ . If we can assume that  $\frac{\sigma_{uf}}{\sigma_m} \ll \sqrt{T}$ ,  $K_z$  and  $K_b$  have a simpler form:

$$(5.2) \quad K_z \approx \sqrt{2\sqrt{T}}, \quad K_b \approx \frac{1}{\mathbb{J}'} \sqrt{T}.$$

Substituting (5.2) back into (4.44), we find an approximation of  $\sigma_{bc}$ :

$$(5.3) \quad \begin{aligned} \frac{\sigma_{bc}}{\sigma_m} &\approx \frac{K_z K_b}{\mathbb{J}'} + \frac{K_b^2}{K_z} (f - 1) \\ &\approx \left( \frac{\sigma_{bf}}{\sigma_m} + \frac{r_b^2 \sigma_{uf}}{\mathbb{J}'^2 \sigma_m} \right)^{3/4} \frac{\sqrt{2}}{2} \left( \frac{1}{\sqrt{\mathbb{J}'}} + \frac{\sqrt{\mathbb{J}'}}{\mathbb{J}} \right). \end{aligned}$$

FIG. 5.4. Three-dimensional mesh of  $\sigma_{bc}/\sigma_{bo}$  with respect to  $f$  and  $\sigma_{uf}$ . Parameters are chosen as in (5.1).

The last term in (4.44) is discarded because  $\frac{\sigma_{uf}}{\sigma_m} \ll \sqrt{T}$ .

When

$$\frac{r_b^2 \sigma_{uf}}{\mathbb{J}'^2 \sigma_m} \ll \frac{\sigma_{bf}}{\sigma_m} \text{ or } \sigma_{uf} \ll \frac{\mathbb{J}'^2 \sigma_{bf}}{r_b^2},$$

the  $\sigma_{uf}$  term can be further discarded and

$$(5.4) \quad \frac{\sigma_{bc}}{\sigma_m} \approx \left( \frac{\sigma_{bf}}{\sigma_m} \right)^{3/4} \frac{\sqrt{2}}{2} \left( \frac{1}{\sqrt{\mathbb{J}'}} + \frac{\sqrt{\mathbb{J}'}}{\mathbb{J}} \right),$$

which is the same as the noise-free case. Thus  $\sigma_{bc}$  obtains its minimum near  $\mathbb{J} = \mathbb{J}'$ . In our example,

$$\frac{\mathbb{J}'^2 \sigma_{bf}}{r_b^2} = 10^{10} \text{ and } \sigma_m \sqrt{\mathbb{J}'^2 \sigma_{bf} \sigma_m^{-1}} = 10^6,$$

which is a good approximation of  $\sigma_m \sqrt{T}$ . Thus when  $\sigma_{uf} \ll 10^6$ , the input noise can be ignored. This result coincides with the simulation in Figures 5.2 and 5.4, where  $10^5$  is a point below which  $\sigma_{uf}$  has no obvious effect.

**6. Robust and optimal choices of  $J'$  when  $\sigma_{uf}$  is negligible.** In this section, besides giving an explanation of the robust choice of  $J'$  by the Caltech group, we will further discuss its optimal choice when  $J$  is a random number. We assume that  $\sigma_{uf}$  is not too large so that we can use (5.4).

When  $\sigma_{uf}$  is small enough so that it can be neglected, let  $\mathbb{J} = a\mathbb{J}_0$  and  $\mathbb{J}' = b\mathbb{J}_0$ , where  $0.5 \leq a \leq 2.0$  and  $\mathbb{J}_0$  is some constant. We can rewrite (5.4) as

$$(6.1) \quad \sigma_{bc} \sigma_m^{-1} = c \left( \frac{1}{\sqrt{b}} + \frac{\sqrt{b}}{a} \right),$$

where

$$c = \left( \frac{\sigma_{bf}}{\sigma_m} \right)^{3/4} \cdot \frac{\sqrt{2}}{2} \cdot \frac{1}{\sqrt{\mathbb{J}_0}}.$$

Denote the minimum of  $a$  as  $\min(a)$ ; the worst result happens for a fixed  $b$  when  $a = \min(a)$ :

$$(6.2) \quad \sigma_b \sigma_m^{-1} \leq c \left( \frac{1}{\sqrt{b}} + \frac{\sqrt{b}}{\min(a)} \right).$$

The minimum of the right-hand side is obtained when  $b = \min(a)$  or  $J' = \min(a) \cdot J_0$ , corresponding to the result by the Caltech group [16]. Thus the Caltech design is robust in the maximum-minimum meaning.

When  $J$  is fixed, simulation in the previous section already shows that the optimal choice of  $J'$  to minimize  $\sigma_{bc}$  is still  $J$ . Thus the best  $J'$  is still the real  $J$ . If  $J$  is random, an optimal design can be found by choosing the optimal objective function as

$$\mathcal{J} = E[\sigma_{bc}],$$

where the expectation is taken with respect to  $J$ . From (6.1), we have

$$(6.3) \quad E[\sigma_{bc}] = \sigma_m c \left( \frac{1}{\sqrt{b}} + \sqrt{b} E \left[ \frac{1}{a} \right] \right) \geq 2c\sigma_m \sqrt{E \left[ \frac{1}{a} \right]},$$

and the identity is obtained only when  $J' = \frac{1}{E[1/J]}$ .

**7. Conclusion.** Extending the model proposed by the Caltech group by an input noise term, we have evaluated its effects on the measurement of a magnetic field using feedback. Large  $J$  and  $\lambda$  assumptions are repeatedly used in simplifying the results, especially the large  $J$  assumption. This implies that the number of atoms involved is relatively large. In our simulation, it is about  $10^6$ .

Both the closed-loop case and open-loop case are studied, but we have more interest in the closed-loop case and use the open-loop one for comparison. The input noise can be ignored if

$$\sigma_{uf} \ll \min \left( \sigma_m \sqrt{T}, \frac{J'^2 \sigma_{bc}}{r_b^2} \right).$$

When  $\sigma_{uf}$  is large,  $\sigma_{bc}$  is not always less than  $\sigma_{bo}$ , as it is when  $\sigma_{uf}$  is small enough. The region where  $\sigma_{bc} < \sigma_{bo}$  shrinks when  $\sigma_{uf}$  gets large. Although the computation is too tedious for us to give every detail, we have given all the main results. The quantitative results are helpful for explaining data collected in the experiment [16].

The best choice of  $J'$  is the actual  $J$  if we know  $J$  exactly. When we do not know  $J$  exactly or it is a random number, the optimal  $J'$  satisfies  $J' = 1/E[1/J]$  instead of  $J' = E[J]$ .

## STABLE SYNCHRONIZATION OF MECHANICAL SYSTEM NETWORKS\*

SUJIT NAIR<sup>†</sup> AND NAOMI EHRICH LEONARD<sup>†</sup>

**Abstract.** In this paper we address stabilization of a network of underactuated mechanical systems with unstable dynamics. The coordinating control law stabilizes the unstable dynamics with a term derived from the method of controlled Lagrangians and synchronizes the dynamics across the network with potential shaping designed to couple the mechanical systems. The coupled system is Lagrangian with symmetry, and energy methods are used to prove stability and coordinated behavior. Two cases of asymptotic stabilization are discussed; one yields convergence to synchronized motion staying on a constant momentum surface, and the other yields convergence to a relative equilibrium. We illustrate the results in the case of synchronization of  $n$  carts, each balancing an inverted pendulum.

**Key words.** coordinated control, mechanical systems, networks, synchronization, stabilization, energy shaping

**DOI.** 10.1137/050646639

**1. Introduction.** Coordinated motion and cooperative control have become important topics of late because of growing interest in the possibility of faster data processing and more efficient decision-making by a network of autonomous systems. For example, mobile sensor networks are expected to provide better data about a distributed environment if the sensors can be made to cooperate towards optimal coverage and efficient coordination.

Much of the recent work explores coordination and cooperative control with very simple dynamical systems, e.g., single or double integrator models (see, e.g., [10, 17, 18]) or nonholonomic models (see, e.g., [4]). For example, in some of these and related works, stabilization of coordinated group dynamics is studied in the case of limited, time-varying communication topologies. These authors deliberately choose to focus on the coordination issues independently of issues in the stabilization of individual dynamics.

However, for networks of autonomous systems such as unmanned helicopters or underwater vehicles, stability of individual dynamics can be important and challenging, and it may not always be possible (or desirable) to decouple the stabilization problem of individual dynamics from the coordination problem. In [22] the authors consider stability of a group with dynamics that satisfy a leader-to-formation stability (LFS) condition based on input-to-state stability [20]. Examples include linear dynamical systems and kinematic nonholonomic robots; in the latter case feedback linearization is used for stabilization. Using the LFS property, the authors are able to quantify how leader inputs and disturbances affect group stability. In [6], an extension to the previous work of [5] on unmanned aerial vehicle motion planning is presented

for identical multiple-vehicle stabilization and coordination. The single-vehicle motion planning is based on the interconnection of a finite number of suitably defined motion primitives. The problem is set in such a way that multiple-vehicle motion coordination primitives are obtained from the single-vehicle primitives. The technique is applied to motion planning for a group of small model helicopters.

Networks of rigid bodies are addressed in [8]. Reduction theory is applied in the case that control inputs depend only on relative configuration (relative orientation or position). The reduction results are used to study coordinated behavior of satellite and underwater vehicle network dynamics. Stability of a network of rotating rigid satellites and a network of coordinated underwater vehicles is proved in [14, 15].

In this paper, we investigate the problem of coordination of a network of underactuated mechanical systems with unstable dynamics. As a first step we make use of the method of controlled Lagrangians to stabilize the unstable dynamics of each mechanical system. The method of controlled Lagrangians and the equivalent interconnection and damping assignment passivity-based control (IDA-PBC) method use energy shaping for stabilization of underactuated mechanical systems (see [1, 19] and references therein). The method of controlled Lagrangians provides a control law for underactuated mechanical systems such that the closed-loop dynamics derive from a Lagrangian. The approach is to choose the control law to shape the controlled kinetic and potential energy for stability.

The class of underactuated mechanical systems we consider in this paper satisfies the *simplified matching conditions* (SMC) defined in [2, 1]. This class includes the planar or spherical inverted pendulum on a (controlled) cart. The goal of the development in this paper is to stabilize unstable dynamics for each individual mechanical system in the network and stably synchronize the actuated configuration variables across the network. For example, for a network of pendulum/cart systems, the problem is to stabilize each pendulum in the upright position while synchronizing the motion of the carts.

For stabilization of individual unstable dynamics we use the approach in [1]. To simultaneously synchronize the dynamics across the network, we show that potentials that couple the individual systems can be prescribed so that the complete coupled system still satisfies the SMC. Accordingly, we can choose potentials, find a Lagrangian for the coupled system, and prove Lyapunov stability of the stabilized and synchronized network. Since the controlled Lagrangian has a symmetry, we use Routh reduction and Routh criteria to prove stability.

We then design additional dissipative control terms and prove asymptotic stability. We show, on the one hand, how to apply a dissipative control term that yields convergence to synchronization staying on a constant momentum surface. In the pendulum/cart system example, this corresponds to a synchronized motion of the carts such that all the carts move together with a common velocity that is the sum of a constant plus an oscillation. Likewise, the pendula synchronize and oscillate at the same frequency as the carts. The oscillation frequency for the carts and pendula is determined by the control parameters. On the other hand, we show how to apply a dissipative control term that yields convergence to a relative equilibrium. In the example, this corresponds to steady, synchronized motion of  $n$  carts, each balancing its inverted pendulum.

In this paper we consider a homogeneous group of mechanical systems, i.e., no leaders, and a fixed, bidirectional, connected communication topology. Possibilities for extension include integration of the results with prior works cited above that

address time-varying and directed communication topologies and/or the presence of leaders in the group.

The organization of the paper is as follows. In section 2, we define notation and the different kinds of stabilization studied. In section 3, we give a brief background on the class of underactuated mechanical systems that satisfy the SMC defined in [2, 1]. We discuss how unstable dynamics are stabilized with feedback control that preserves Lagrangian structure. In section 4, we study a network of  $n$  systems, each of which satisfies the SMC. We choose coupling potentials in section 5, and we prove stability and coordination of the network. Asymptotic stabilization is investigated in sections 6 and 7. We illustrate the theory with the example of  $n$  planar, inverted pendulum/cart systems in section 8. In section 9 we conclude with a few remarks.

**2. Definitions.** In [1] the method of controlled Lagrangians is used to derive a control law that asymptotically stabilizes a class of underactuated mechanical systems with otherwise unstable dynamics. This class of systems satisfies a set of “simplified matching conditions” and we denote such systems as *SMC systems*. SMC systems lack gyroscopic forces; the planar inverted pendulum on a cart and the spherical inverted pendulum on a 2D cart are two such systems.

Consider an underactuated mechanical system with an  $(m + r)$ -dimensional configuration space. Let  $x^\alpha$  denote the coordinates for the unactuated directions with index  $\alpha$  going from 1 to  $m$ .  $\theta^a$  denotes the coordinates for the actuated directions with index  $a$  going from 1 to  $r$ . In the case of a network of  $n$  mechanical systems, each with the same  $(m + r)$ -dimensional configuration space,  $x_i^\alpha$  and  $\theta_i^a$  are the corresponding coordinates for the  $i$ th mechanical system,  $i = 1, \dots, n$ . Beginning in section 5, we will assume that the configuration space for the actuated variables for each individual system is  $\mathbb{R}^r$ . Note that we only require the configuration space for the individual mechanical systems to be the same and do not require that each system be identical, e.g., the individual systems can have different mass and inertia values. We will need to make the assumption of individual systems being identical only in section 6.

The goal of coordination is to synchronize the actuated variables  $\theta_i^a$  with the variables  $\theta_j^a$  for all  $i, j = 1, \dots, n$ . We define stable synchronization of these variables as stabilization of  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$ .

We define the following stability notions for the mechanical system network.

**DEFINITION 2.1 (SSRE).** *A relative equilibrium of the mechanical system network dynamics is a stable synchronized relative equilibrium (SSRE) if it is defined by  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$ ,  $x_i^\alpha = 0$  for all  $i$ , and if it is Lyapunov stable. This implies that the unactuated dynamics are stable and the actuated dynamics are stably synchronized.*

**DEFINITION 2.2 (ASSRE).** *A relative equilibrium of the mechanical system network dynamics is an asymptotically stable synchronized relative equilibrium (ASSRE) if it is SSRE and asymptotically stable.*

**DEFINITION 2.3 (ASSM).** *An asymptotically stable solution of the mechanical system network dynamics is an asymptotically stable synchronized motion (ASSM) if it is defined by  $x_i^\alpha - x_j^\alpha = 0$  and  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$  and the dynamics of the network evolve on a constant momentum surface.*

We note that an ASSRE is a special case of an ASSM. In the example of the network of pendulum/cart systems, the relative equilibrium of interest corresponds to the carts moving together at the same constant speed with each pendulum at rest in the upright position. In section 8 we asymptotically stabilize this synchronized relative equilibrium as well as a family of synchronized motions that exhibit a synchronized steady motion plus an oscillation of the carts and pendula.

**3. SMC.** Let the Lagrangian for an individual mechanical system be given by

$$L(x^\alpha, \theta^a, \dot{x}^\beta, \dot{\theta}^b) = \frac{1}{2}g_{\alpha\beta}\dot{x}^\alpha\dot{x}^\beta + g_{\alpha a}\dot{x}^\alpha\dot{\theta}^a + \frac{1}{2}g_{ab}\dot{\theta}^a\dot{\theta}^b - V(x^\alpha, \theta^a),$$

where summation over indices is implied,  $g$  is the kinetic energy metric, and  $V$  is the potential energy. It is assumed that the actuated directions are symmetry directions for the kinetic energy; that is, we assume  $g_{\alpha\beta}$ ,  $g_{\alpha a}$ ,  $g_{ab}$  are all independent of  $\theta^a$ . The equations of motion for the mechanical system with control inputs  $u_a$  are given by

$$\begin{aligned}\mathcal{E}_{x^\alpha}(L) &= 0, \\ \mathcal{E}_{\theta^a}(L) &= u_a,\end{aligned}$$

where  $\mathcal{E}_q(L)$  denotes the Euler–Lagrange expression corresponding to a Lagrangian  $L$  and generalized coordinates  $q$ , i.e.,

$$(3.1) \quad \mathcal{E}_q(L) = \frac{d}{dt} \frac{\partial L}{\partial \dot{q}} - \frac{\partial L}{\partial q}.$$

For such a system, following [1], the SMC are

- $g_{ab} = \text{constant}$ ;
- $\frac{\partial g_{\alpha a}}{\partial x^\beta} = \frac{\partial g_{\beta a}}{\partial x^\alpha}$ ;
- $\frac{\partial^2 V}{\partial x^\alpha \partial \theta^a} g^{ad} g_{\beta d} = \frac{\partial^2 V}{\partial x^\beta \partial \theta^a} g^{ad} g_{\alpha d}$ .

Satisfaction of these SMC allows for a structured feedback shaping of kinetic and potential energy. In particular, a control law  $u_a = u_a^{\text{cons}}$  is given in [1] such that the closed-loop system is a Lagrangian system. The controlled Lagrangian  $L_c$ , parametrized by constant parameters  $\kappa$  and  $\rho$  and by a potential term  $V_\epsilon$ , is given by

$$\begin{aligned}L_c(x^\alpha, \theta^a, \dot{x}^\beta, \dot{\theta}^b) &= \frac{1}{2} \left( g_{\alpha\beta} + \rho(\kappa + 1) \left( \kappa + \frac{\rho - 1}{\rho} \right) g_{\alpha a} g^{ab} g_{b\beta} \right) \dot{x}^\alpha \dot{x}^\beta + \rho(\kappa + 1) g_{\alpha a} \dot{x}^\alpha \dot{\theta}^a \\ &\quad + \frac{1}{2} \rho g_{ab} \dot{\theta}^a \dot{\theta}^b - V(x^\alpha, \theta^b) - V_\epsilon(x^\alpha, \theta^b),\end{aligned}$$

where  $V_\epsilon$  must satisfy

$$(3.2) \quad - \left( \frac{\partial V}{\partial \theta^a} + \frac{\partial V_\epsilon}{\partial \theta^a} \right) \left( \kappa + \frac{\rho - 1}{\rho} \right) g^{ad} g_{\alpha d} + \frac{\partial V_\epsilon}{\partial x^\alpha} = 0.$$

The results in [1] further give conditions on  $\rho$ ,  $\kappa$ , and  $V_\epsilon$  that ensure stability of the equilibrium in the full state space. Without loss of generality, we assume that the equilibrium of interest is the origin. We further assume that it is a *maximum* of the original potential energy  $V$  (the case when the origin is a minimum can be handled similarly). The inverted pendulum systems fall into this category. In this case,  $\kappa > 0$  and  $\rho < 0$  and the potential  $V_\epsilon$  can be chosen such that the energy function  $E_c$  for the controlled Lagrangian has a maximum at the origin of the full state space. Asymptotic stability is obtained by adding a dissipative term  $u_a^{\text{diss}}$  to the control law, i.e.,

$$u_a = u_a^{\text{cons}} + \frac{1}{\rho} u_a^{\text{diss}},$$

which drives the controlled system to the maximum value of the energy  $E_c$ .

In [1], it is also shown how to select new, useful coordinates  $(x^\alpha, y^a, \dot{x}^\alpha, \dot{y}^a)$ . In particular, for any SMC system, there exists a function  $h^a(x^\alpha)$  defined on an open subset of the configuration space of the unactuated variables such that

$$\frac{\partial h^a}{\partial x^\alpha} = \left( \kappa + \frac{\rho - 1}{\rho} \right) g^{\alpha c} g_{\alpha c}, \quad h^a(0) = 0.$$

The new coordinates are defined as

$$(x^\alpha, y^a) = (x^\alpha, \theta^a + h^a(x^\alpha)).$$

Note that if the origin is an equilibrium in the original coordinates, it is also an equilibrium in the new coordinates. In these coordinates, the closed-loop Lagrangian takes the form

$$(3.3) \quad L_c = \frac{1}{2} \left( g_{\alpha\beta} - \left( \kappa + \frac{\rho - 1}{\rho} \right) g_{\alpha a} g^{ab} g_{b\beta} \right) \dot{x}^\alpha \dot{x}^\beta + g_{\alpha a} \dot{x}^\alpha \dot{y}^a + \frac{1}{2} \rho g_{ab} \dot{y}^a \dot{y}^b \\ - V(x^\alpha, y^a - h^a(x^\alpha)) - V_\epsilon(y^a)$$

$$(3.4) \quad = \frac{1}{2} \tilde{g}_{\alpha\beta} \dot{x}^\alpha \dot{x}^\beta + \tilde{g}_{\alpha a} \dot{x}^\alpha \dot{y}^a + \frac{1}{2} \tilde{g}_{ab} \dot{y}^a \dot{y}^b - V(x^\alpha, y^a - h^a(x^\alpha)) - V_\epsilon(y^a),$$

where

$$(3.5) \quad \begin{aligned} \tilde{g}_{\alpha\beta} &= \left( g_{\alpha\beta} - \left( \kappa + \frac{\rho - 1}{\rho} \right) g_{\alpha a} g^{ab} g_{b\beta} \right), \\ \tilde{g}_{\alpha a} &= g_{\alpha a}, \\ \tilde{g}_{ab} &= \rho g_{ab}. \end{aligned}$$

Further, after adding dissipation  $u_a^{\text{diss}}$ , the Euler–Lagrange equations in the new coordinates become

$$\begin{aligned} \mathcal{E}_{x^\alpha}(L_c) &= 0, \\ \mathcal{E}_{y^a}(L_c) &= u_a^{\text{diss}}. \end{aligned}$$

**4. Matching for a network of SMC systems.** In this section we examine a network of  $n$  systems, each of which satisfies the SMC. We determine what control design freedom remains under the constraint that the complete network dynamics are Lagrangian and satisfy the simplified matching conditions.

Consider  $n$  SMC systems and let the  $i$ th system have dynamics described by Lagrangian  $L_i$ , where

$$(4.1) \quad L_i(x_i^\alpha, \theta_i^a, \dot{x}_i^\beta, \dot{\theta}_i^b) = \frac{1}{2} g_{\alpha\beta}^i \dot{x}_i^\alpha \dot{x}_i^\beta + g_{\alpha a}^i \dot{x}_i^\alpha \dot{\theta}_i^a + \frac{1}{2} g_{ab}^i \dot{\theta}_i^a \dot{\theta}_i^b - V_i(x_i^\alpha, \theta_i^a),$$

and the index  $i$  on every variable refers to the  $i$ th system.

The Lagrangian for the total (uncontrolled, uncoupled) system is  $L = \sum_{i=1}^n L_i = \frac{1}{2} \dot{\mathbf{x}}^T M \dot{\mathbf{x}} - \sum_{i=1}^n V_i(x_i^\alpha, \theta_i^a)$ , where  $\mathbf{x} = (x_1^\alpha, \dots, x_n^\beta, \theta_1^a, \dots, \theta_n^b)^T$ , and

$$M = \left( \begin{array}{cc|cc} g_{\alpha\beta}^1 & 0 & g_{\alpha a}^1 & 0 \\ & \ddots & & \ddots \\ 0 & g_{\alpha\beta}^n & 0 & g_{\alpha a}^n \\ \hline g_{a\alpha}^1 & 0 & g_{ab}^1 & 0 \\ & \ddots & & \ddots \\ 0 & g_{a\alpha}^n & 0 & g_{ab}^n \end{array} \right).$$

Since each system satisfies the SMC,  $g_{ab}^i = \text{constant}$  for each  $i = 1, \dots, n$ . It can be easily verified that the SMC are satisfied for the total system  $L$ , since they are satisfied for each individual system.

For the total system, the symmetry coordinates are  $(\theta_1^a, \dots, \theta_n^b)$ . As in [1], we can find a control law and a change of coordinates  $\mathbf{x} = (x_1^\alpha, \dots, x_n^\beta, \theta_1^a, \dots, \theta_n^b) \mapsto \mathbf{x}' = (x_1^\alpha, \dots, x_n^\beta, y_1^a, \dots, y_n^b)$  such that the closed-loop system is equivalent to another Lagrangian system with

$$(4.2) \quad L'_c = \frac{1}{2}(\dot{\mathbf{x}}')^T M_c \dot{\mathbf{x}}' - V'_\epsilon(\mathbf{x}')$$

and

$$(4.3) \quad M_c = \left( \begin{array}{cc|cc} \tilde{g}_{\alpha\beta}^1 & 0 & \tilde{g}_{\alpha a}^1 & 0 \\ & \ddots & & \ddots \\ 0 & \tilde{g}_{\alpha\beta}^n & 0 & \tilde{g}_{\alpha a}^n \\ \hline \tilde{g}_{a\alpha}^1 & 0 & \tilde{g}_{ab}^1 & 0 \\ & \ddots & & \ddots \\ 0 & \tilde{g}_{a\alpha}^n & 0 & \tilde{g}_{ab}^n \end{array} \right) := \left( \begin{array}{c|c} M_{11} & M_{12} \\ \hline M_{12}^T & M_{22} \end{array} \right),$$

$$V'_\epsilon = \sum_{i=1}^n \left( V_i(x_i^\alpha, y_i^a - h_i^a(x_i^\alpha)) + V_{\epsilon i}(x_i^\alpha, y_i^a) \right).$$

Here,  $\tilde{g}_{\alpha\beta}^i$ ,  $\tilde{g}_{\alpha a}^i$ , and  $\tilde{g}_{ab}^i$  are defined as in (3.5) with all variables replaced with those corresponding to the  $i$ th system, e.g.,  $\tilde{g}_{ab}^i = \rho_i g_{ab}^i$ , etc.

The control gains  $\kappa_i$  and  $\rho_i$  and control potentials  $V_{\epsilon i}$  can be chosen such that the mass matrix  $M_c$  is negative definite and the potential  $V'_\epsilon$  has a maximum when the configuration of each system, i.e.,  $(x_i^\alpha, \theta_i^a)$ , is at the origin. This means the control law brings each system independently to the origin without coordination.

To determine what additional freedom exists in the choice of the control, notably in the choice of control potentials  $V_{\epsilon i}$ , such that the network system satisfies the SMC, we specialize to a network of SMC systems which each satisfy the following condition.

**AS1.** *The potential energy for each system in the original coordinates satisfies  $V_i(x_i^\alpha, \theta_i^a) = V_{1i}(x_i^\alpha) + V_{2i}(\theta_i^a)$ .*

The inverted pendulum examples satisfy this assumption in the general case that the cart moves on an inclined plane. In the case that the cart moves in the horizontal plane,  $V_2 = 0$ .

As shown in [1], given the assumption **AS1**,  $V_{\epsilon i}$  in the new coordinates for  $i = 1, \dots, n$  can be chosen to take the form

$$V_{\epsilon i}(x_i^\alpha, y_i^a) = -V_{2i}(y_i^a - h_i^a(x_i^\alpha)) + \bar{V}_{\epsilon i}(y_i^a),$$

where  $\bar{V}_{\epsilon i}$  is an arbitrary function and  $h_i^a(x_i^\alpha)$  satisfies

$$(4.4) \quad \frac{\partial h_i^a}{\partial x_i^\alpha} = \left( \kappa_i + \frac{\rho_i - 1}{\rho_i} \right) g_i^{ac} g_{\alpha c}^i, \quad h_i^a(0) = 0.$$

We show next that a more general potential  $V_\epsilon$  can be used in  $V'_\epsilon$  in place of the sum of potentials  $V_{\epsilon i}(x_i^\alpha, y_i^a)$ .

PROPOSITION 4.1. *Under assumption **AS1**, the potential  $V'_\epsilon = V + V_\epsilon$  satisfies the SMC with*

$$(4.5) \quad \begin{aligned} V &= \sum_{i=1}^n (V_{1i}(x_i^\alpha)) + V_{2i}(y_i^a - h_i^a(x_i^\alpha)), \\ V_\epsilon &= - \left( \sum_{i=1}^n V_{2i}(y_i^a - h_i^a(x_i^\alpha)) \right) + \tilde{V}_\epsilon(y_1^a, \dots, y_n^a) \end{aligned}$$

and  $\tilde{V}_\epsilon$  an arbitrary function.

*Proof.* Recall that the potential  $V'_\epsilon = V + V_\epsilon$  given by (4.5) satisfies the SMC if (3.2) holds. Following [1], we can use the definition of  $h_i^a(x_i^\alpha)$  given by (4.4) to write the SMC (3.2) for the potential as

$$(4.6) \quad \frac{\partial V_\epsilon}{\partial x_i^\alpha} = \frac{\partial V}{\partial y_i^a} \frac{\partial h_i^a(x_i^\alpha)}{\partial x_i^\alpha}, \quad i = 1, \dots, n.$$

By a direct computation, one can check that each side of (4.6) is equal to  $\frac{\partial V_{2i}}{\partial v_i^a} \frac{\partial v_i^a}{\partial x_i^\alpha}$ , where  $v_i^a = y_i^a - h_i^a(x_i^\alpha)$ .  $\square$

Proposition 4.1 implies that *we can couple the  $n$  vehicles in the network using the freedom in our choice of  $\tilde{V}_\epsilon = \tilde{V}_\epsilon(y_1^a, \dots, y_n^a)$ , and the network dynamics will still satisfy the simplified matching conditions.* This result is completely independent of the degree of coupling; i.e., it extends from a network of uncoupled systems to a network of completely connected systems.

**5. Stable coordination of an SMC network.** In this section we make use of Proposition 4.1 to design coupling potentials  $\tilde{V}_\epsilon$  for stable coordination of the network of SMC systems. We prove that the relative equilibrium of interest is an SSRE. Recall from section 2 that to be an SSRE, a relative equilibrium should be defined by  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$  and  $x_i^\alpha = 0$  for all  $i$  and should be Lyapunov stable. We note that this is equivalent to showing that  $y_i^a - y_j^a = 0$  for all  $i \neq j$  and  $x_i^\alpha = 0$  for all  $i$  is Lyapunov stable. In the remainder of the paper we assume that the configuration space for the actuated variables for each individual system is  $\mathbb{R}^r$ .

To synchronize the actuated variables we use the results of Proposition 4.1 and design coupling potentials for stabilization of  $y_i^a - y_j^a = 0$  for all  $i \neq j$ . Note that the condition  $y_i^a - y_j^a = 0$  for all  $i \neq j$  by itself is necessary but not sufficient for  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$  and  $x_i^\alpha = 0$  for all  $i$ . We have  $y_i^a - y_j^a = 0$  for all  $i \neq j$  under more general conditions, e.g., if  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$  and  $h_i(x_i^\alpha) = h_j(x_j^\alpha) \neq 0$ ,  $i \neq j$ . This more general case makes possible interesting synchronized dynamics, when we add dissipation for asymptotic stability, as will be discussed in section 6.

We choose  $\tilde{V}_\epsilon$  such that the closed-loop potential  $V'_\epsilon$ , defined in Proposition 4.1, has a maximum when  $x_i^\alpha = 0$  and  $y_i^a - y_j^a = 0$  for all  $i \neq j$ . This is possible since from (4.5), the closed-loop potential is  $V'_\epsilon = \sum_{i=1}^n (V_{1i}(x_i)) + \tilde{V}_\epsilon(y_1^a, \dots, y_n^a)$  and the  $V_{1i}$  are assumed to already be maximized at  $x_i^\alpha = 0$ . We choose in this paper  $\tilde{V}_\epsilon$  to be quadratic in  $(y_i^a - y_j^a)$  with a maximum at  $y_i^a - y_j^a = 0$  for all  $i \neq j$ . In this case, consider a graph with one node corresponding to each individual system in the network. There is an (undirected) edge between nodes  $k$  and  $l$  if the term  $(y_k^a - y_l^a)$  appears in the quadratic function  $\tilde{V}_\epsilon$ . Then,  $V'_\epsilon$  has a strict maximum when  $x_i^\alpha = 0$  and  $y_i^a - y_j^a = 0$  for all  $i \neq j$  if the (undirected) graph is connected. Figure 5.1 illustrates an example of a connected, undirected communication graph for four vehicles.

FIG. 5.1. *Connected, undirected communication graph for four vehicles.*

With coupling of the individual systems using terms that depend only on  $y_i^a - y_j^a$ , the network system has a translational symmetry. Specifically, the system dynamics are invariant under translation of the center of mass of the network. Consider a new set of coordinates given by

$$(5.1) \quad \mathbf{x}_c = (x_1^\alpha, \dots, x_n^\beta, z_1^a, \dots, z_n^b)^T,$$

where

$$\begin{aligned} z_i^a &= y_1^a - y_{i+1}^a, \quad i = 1, \dots, n-1, \\ z_n^b &= y_1^b + \dots + y_n^b. \end{aligned}$$

In this coordinate system, the controlled Lagrangian for the total system (with abuse of notation for  $V'_\epsilon$ ) is

$$(5.2) \quad \tilde{L}_c = \frac{1}{2} \dot{\mathbf{x}}_c^T \tilde{M}_c \dot{\mathbf{x}}_c - V'_\epsilon(\mathbf{x}_r),$$

where  $\mathbf{x}_r = (x_1^\alpha, \dots, x_n^\beta, z_1^a, \dots, z_{n-1}^b)^T$  and

$$(5.3) \quad \tilde{M}_c = \begin{pmatrix} \tilde{M}_{11} & \tilde{M}_{12} \\ \tilde{M}_{12}^T & \tilde{M}_{22} \end{pmatrix}.$$

The transformation which takes the coordinates  $\mathbf{x}_c$  to the coordinates  $\mathbf{x}' = (x_1^\alpha, \dots, x_n^\beta, y_1^c, \dots, y_n^d)$  is given by the matrix

$$(5.4) \quad B = \begin{bmatrix} I_{mn \times mn} & 0 \\ 0 & B_{22} \end{bmatrix},$$

where

$$(5.5) \quad B_{22} = \frac{1}{n} \begin{bmatrix} I_{r \times r} & I_{r \times r} & \dots & I_{r \times r} \\ (1-n)I_{r \times r} & I_{r \times r} & \dots & I_{r \times r} \\ \vdots & \vdots & \dots & \vdots \\ I_{r \times r} & \dots & (1-n)I_{r \times r} & I_{r \times r} \end{bmatrix}$$

and  $I_{l \times l}$  denotes an  $l \times l$  identity matrix and  $B_{22}$  is an  $rn \times rn$  matrix. The expression for  $\tilde{M}_c$  in terms of  $M_c$  from (4.3) is

$$(5.6) \quad \tilde{M}_c = B^T M_c B.$$

We can compute the block elements in  $\tilde{M}_c$  to be

$$(5.7) \quad \tilde{M}_{11} = M_{11},$$

$$(5.8) \quad \tilde{M}_{12} = \frac{1}{n} \begin{pmatrix} \tilde{g}_{\alpha a}^1 & \tilde{g}_{\alpha a}^1 & \cdots & \tilde{g}_{\alpha a}^1 & \tilde{g}_{\alpha a}^1 \\ (1-n)\tilde{g}_{\alpha a}^2 & \tilde{g}_{\alpha a}^2 & \cdots & \tilde{g}_{\alpha a}^2 & \tilde{g}_{\alpha a}^2 \\ & & \ddots & & \\ \tilde{g}_{\alpha a}^{n-1} & \tilde{g}_{\alpha a}^{n-1} & \cdots & \tilde{g}_{\alpha a}^{n-1} & \tilde{g}_{\alpha a}^{n-1} \\ \tilde{g}_{\alpha a}^n & \tilde{g}_{\alpha a}^n & \cdots & (1-n)\tilde{g}_{\alpha a}^n & \tilde{g}_{\alpha a}^n \end{pmatrix},$$

$$(5.9) \quad \tilde{M}_{22} = \frac{1}{n^2} B_{22}^T M_{22} B_{22},$$

where  $M_{11}$  and  $M_{22}$  are as defined in (4.3). From (5.5) and (4.3), we can calculate the lowermost diagonal  $r \times r$  block of  $\tilde{M}_{22}$  to be

$$(5.10) \quad \tilde{g}_{ab} = \frac{1}{n^2} \sum_{i=1}^n (\tilde{g}_{ab}^i).$$

Thus, we can define  $\bar{M}_{22} = \tilde{g}_{ab}$  and  $\bar{M}_{11}$  and  $\bar{M}_{12}$  in terms of  $\tilde{M}_c$  such that

$$\begin{pmatrix} \bar{M}_{11} & \bar{M}_{12} \\ \bar{M}_{12}^T & \bar{M}_{22} \end{pmatrix} = \tilde{M}_c.$$

Then, we can rewrite (5.2) as

$$\tilde{L}_c = \frac{1}{2} \begin{pmatrix} \dot{\mathbf{x}}_r^T & \dot{\mathbf{z}}_n^T \end{pmatrix} \begin{pmatrix} \bar{M}_{11} & \bar{M}_{12} \\ \bar{M}_{12}^T & \bar{M}_{22} \end{pmatrix} \begin{pmatrix} \dot{\mathbf{x}}_r \\ \dot{\mathbf{z}}_n \end{pmatrix} - V'_\epsilon(\mathbf{x}_r),$$

where  $\mathbf{z}_n = (z_n^a)^T$ .

Note that in these coordinates  $z_n^a$  is the symmetry variable. We are interested in the relative equilibria given by

$$(5.11) \quad \mathbf{v}_{RE} := \begin{pmatrix} \mathbf{x}_r \\ \dot{\mathbf{x}}_r \\ \dot{\mathbf{z}}_n \end{pmatrix},$$

where

$$\mathbf{x}_r = \mathbf{0}, \quad \dot{\mathbf{x}}_r = \mathbf{0}, \quad \dot{z}_n^d = \zeta^d,$$

and  $\zeta^d$  corresponds to ( $n$  times) the constant velocity of the center of mass of the network.

**DEFINITION 5.1** (amended potential [13]). *The amended potential for the Lagrangian system with Lagrangian (5.2) is defined by*

$$V_\mu(\mathbf{x}_r) = V'_\epsilon(\mathbf{x}_r) + \frac{1}{2} \tilde{g}^{cd} \mu_c \mu_d,$$

where  $V'_\epsilon$  is given by (4.5) and  $\tilde{g}_{ab}$  is given by (5.10). If  $J_a$  is the momentum conjugate to  $z_n^a$ , then  $\mu_a$  is  $J_a$  evaluated at the relative equilibrium corresponding to  $\dot{z}_n^a = \zeta^a$ , i.e.,

$$(5.12) \quad J_a = \frac{\partial \tilde{L}_c}{\partial \dot{z}_n^a} = (\bar{M}_{12}^T \dot{\mathbf{x}}_r + \bar{M}_{22} \dot{\mathbf{z}}_n)_a, \quad \mu_a = \left. \frac{\partial \tilde{L}_c}{\partial \dot{z}_n^a} \right|_{\mathbf{x}_r=0, \dot{\mathbf{x}}_r=0, \dot{z}_n^a=\zeta^a} = \tilde{g}_{ab} \zeta^b.$$

By the Routh criteria, the relative equilibrium is stable if the second variation of

$$(5.13) \quad E_\mu := \frac{1}{2} \dot{\mathbf{x}}_r^T (\bar{M}_{11} - \bar{M}_{12} \bar{M}_{22}^{-1} \bar{M}_{12}^T) \dot{\mathbf{x}}_r + V_\mu(\mathbf{x}_r),$$

evaluated at the origin, is definite. Also, if  $R^\mu(\mathbf{x}_r, \dot{\mathbf{x}}_r)$  is defined as

$$(5.14) \quad R^\mu := \frac{1}{2} \dot{\mathbf{x}}_r^T (\bar{M}_{11} - \bar{M}_{12} \bar{M}_{22}^{-1} \bar{M}_{12}^T) \dot{\mathbf{x}}_r - V_\mu(\mathbf{x}_r),$$

then the reduced Euler–Lagrange equations can be written as

$$\mathcal{E}_{x_r^\alpha} R^\mu = 0.$$

The Routhian  $R^\mu$  plays the role of a Lagrangian for the reduced system in variables  $(\mathbf{x}_r, \dot{\mathbf{x}}_r)$ . Since  $\tilde{g}_{ab}^i$  is a constant for each  $i \in \{1, 2, \dots, n\}$ , the second term in the amended potential  $V_\mu$  does not contribute to the second variation. It follows that the relative equilibrium with momentum  $\mu_a$  is stable if the matrix  $(\bar{M}_{11} - \bar{M}_{12} \bar{M}_{22}^{-1} \bar{M}_{12}^T)$  evaluated at the origin is negative definite, since the potential  $V_\epsilon'$  is already maximum at the equilibrium. But  $(\bar{M}_{11} - \bar{M}_{12} \bar{M}_{22}^{-1} \bar{M}_{12}^T)$  is negative definite because it is the Schur complement of the negative definite matrix  $\bar{M}_c$  [9].

**THEOREM 5.2 (SSRE).** *Consider a network of  $n$  SMC systems, each satisfying assumption **AS1**. Suppose for each system that the origin is an equilibrium and that the original potential energy is maximum at the origin. Consider the kinetic energy shaping defined in section 4 and potential energy coupling defined above with a connected graph so that the closed-loop dynamics derive from the Lagrangian  $\tilde{L}_c$  given by (5.2) and the potential energy  $V_\epsilon'$  is maximized at the relative equilibrium (5.11). The corresponding control law for the  $i$ th mechanical system is*

$$(5.15) \quad \begin{aligned} u_{a,i} = u_{a,i}^{\text{cons}} = & -\kappa_i \left\{ g_{\beta a, \gamma}^i - g_{\delta a}^i A_i^{\delta \alpha} \left[ g_{\alpha \beta, \gamma}^i - \frac{1}{2} g_{\beta \gamma, \alpha}^i - (1 + \kappa_i) g_{\alpha d}^i g_{\beta a, \gamma}^i \right] \right\} \dot{x}_i^\beta \dot{x}_i^\gamma \\ & + \kappa_i g_{\delta a}^i A_i^{\delta \alpha} \frac{\partial V_i}{\partial x_i^\alpha} + \frac{\partial V_i}{\partial \theta_i^\alpha} - \frac{1}{\rho_i} (1 + \kappa_i g_{\delta a}^i A_i^{\delta \alpha} g_{\alpha d}^i g_{\beta a}^{db}) \frac{\partial V_\epsilon'}{\partial \theta_i^\alpha}, \end{aligned}$$

where  $A_{\alpha \beta}^i = g_{\alpha \beta}^i - (1 + \kappa_i) g_{\alpha d}^i g_{\beta a}^{da} g_{\beta a}^i$ ,  $\rho_i < 0$ , and

$$\kappa_i + 1 > \max \{ \lambda | \det (g_{\alpha \beta}^i - \lambda g_{\alpha a}^i g_{\beta b}^{ab} g_{\beta b}^i) |_{x_i^\alpha=0} = 0 \}.$$

Then, the relative equilibrium (5.11) is an SSRE for any  $\zeta^d$ .

*Proof.* Since  $(\bar{M}_{11} - \bar{M}_{12} \bar{M}_{22}^{-1} \bar{M}_{12}^T)$  evaluated at the origin is negative definite, the second variation of  $E_\mu$  evaluated at the origin is definite. Hence, the relative equilibrium (5.11) is stable for the total network system independent of momentum value  $\mu_a$ .  $\square$

**6. Asymptotic stability of the constant momentum solution.** In this section we investigate asymptotic stabilization of the coordinated network to a solution corresponding to a constant momentum  $J_a = \mu_a$ . We prove that the solution is an ASSM. Recall from section 2 that an ASSM is an asymptotically stable solution of the mechanical system network defined by  $x_i^\alpha = x_j^\alpha$  and  $\theta_i^a = \theta_j^a$  for all  $i \neq j$  and dynamics that evolve on a constant momentum surface. An ASSM describes a fully synchronized motion, i.e., one in which each degree of freedom is synchronized across

the whole network. If  $x_i^\alpha = x_j^\alpha = 0$ , then the solution is a relative equilibrium. However, in general, an ASSM is *not* a relative equilibrium. For example, in the case of a network of pendulum/cart systems presented in section 8, the ASSM corresponds to periodic solutions (synchronized oscillations of pendula and carts). In this section we prove a control law that yields ASSM where the constant value of the momentum is given by the initial conditions. Equivalently, given an arbitrary momentum value  $\mu_a$ , initial conditions on the corresponding momentum surface converge to the ASSM on the same momentum surface. In the pendulum/cart example of section 8, we show that control gains can be used to determine the frequency of the periodic solution (ASSM). We discuss at the end of the section a second case in which a momentum value is prescribed and a control term is added to drive the ASSM to the prescribed constant momentum surface.

In this section we apply no dissipative control in the  $x_i^\alpha$  directions for all  $i$  and as our Case I below we use no control in the  $z_n^a$  direction. Recall that for our closed-loop system,  $z_n^a$  is the symmetry direction. If there is no control applied in this direction,  $J_a$  remains a constant; i.e., the system evolves on a constant momentum surface. On this surface,  $E_\mu$  as defined in (5.13) is a conserved quantity and can be chosen as a Lyapunov function to prove stability. By choosing appropriate dissipation in the nonsymmetry directions  $z_1^a, \dots, z_{n-1}^b$ , we prove that solutions on a constant momentum surface, corresponding to  $x_i^\alpha - x_j^\alpha = 0$  and  $\theta_i^a - \theta_j^a = 0$  for all  $i \neq j$ , are asymptotically stable, i.e., they are ASSM.

Let the control input for the  $i$ th mechanical system be

$$(6.1) \quad u_{a,i} = u_{a,i}^{\text{cons}} + \frac{1}{\rho_i} u_{a,i}^{\text{diss}},$$

where  $u_{a,i}^{\text{cons}}$  is the “conservative” control term given by (5.15) and  $u_{a,i}^{\text{diss}}$  is the dissipative control term to be designed. The Euler–Lagrange equations in the original coordinates for the  $i$ th uncontrolled system are

$$\mathcal{E}_{x_i^\alpha}(L_i) = 0; \quad \mathcal{E}_{\theta_i^a}(L_i) = u_{a,i}^{\text{cons}} + \frac{1}{\rho_i} u_{a,i}^{\text{diss}},$$

where  $L_i$  is given by (4.1).

In the new coordinates given by (5.1), we have for  $i = 1, \dots, n$ ,

$$(6.2) \quad \mathcal{E}_{x_i^\alpha}(\tilde{L}_c) = 0; \quad \mathcal{E}_{z_i^a}(\tilde{L}_c) = \frac{1}{n} \tilde{u}_{a,i}^{\text{diss}},$$

where  $\tilde{L}_c$  is given by (5.2) and

$$\begin{aligned} \tilde{u}_{a,i}^{\text{diss}} &= \sum_{j=1, j \neq i+1}^n u_{a,j}^{\text{diss}} - (n-1)u_{a,i+1}^{\text{diss}}, \quad i = 1, \dots, n-1, \\ \tilde{u}_{a,n}^{\text{diss}} &= \sum_{j=1}^n u_{a,j}^{\text{diss}}. \end{aligned}$$

*Case I.*  $\tilde{u}_{a,n}^{\text{diss}} = 0$ .

Let  $\tilde{E}_c$  be the energy function for the Lagrangian  $\tilde{L}_c$ . Given momentum value  $\mu_a$ , let  $\xi^b = \tilde{g}^{ab} \mu_a$ . Then, the function  $\tilde{E}_c^\xi$  defined by

$$\tilde{E}_c^\xi = \tilde{E}_c - J_a \xi^a$$

has the property that its restriction to the level set  $J_a = \mu_a = \tilde{g}_{ab}\xi^b$  of the momentum gives  $E_\mu$  (5.13). We can use this fact to calculate the time derivative of  $E_\mu$  as follows. From (6.2), we get

$$(6.3) \quad \frac{d}{dt}\tilde{E}_c = \frac{1}{n} \sum_{i=1}^n (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}).$$

Using (6.3) and the fact that  $\frac{d}{dt}J_a = \frac{1}{n}\tilde{u}_{a,n}^{\text{diss}}$ , we get

$$(6.4) \quad \frac{d}{dt}\tilde{E}_c^\xi = \frac{1}{n} \sum_{i=1}^n (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}) - \left( \frac{1}{n} \tilde{u}_{a,n}^{\text{diss}} \xi^a \right).$$

The expression for the time derivative of  $E_\mu$  is obtained by restricting  $\frac{d}{dt}\tilde{E}_c^\xi$  to the set  $J_a = \mu_a$ . This and (5.12) give us

$$\begin{aligned} \frac{d}{dt}E_\mu &= \frac{1}{n} \sum_{i=1}^{n-1} (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}) + \frac{1}{n} \tilde{u}_{a,n}^{\text{diss}} (\dot{z}_n^a|_{J_b=\mu_b} - \xi^a) \\ &= \frac{1}{n} \sum_{i=1}^{n-1} (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}) + \frac{1}{n} \tilde{u}_{a,n}^{\text{diss}} (\tilde{g}^{ab}(\mu_b - (\bar{M}_{12}^T \dot{\mathbf{x}}_r)_b) - \xi^a) \\ &= \frac{1}{n} \sum_{i=1}^{n-1} (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}) + \frac{1}{n} \tilde{u}_{a,n}^{\text{diss}} (-\tilde{g}^{ab}(\bar{M}_{12}^T \dot{\mathbf{x}}_r)_b). \end{aligned}$$

Here,  $\bar{M}_{12}^T \dot{\mathbf{x}}_r$  is a covariant vector just like a momentum. Hence, its components are denoted by subscripts. Since  $\tilde{u}_{a,n}^{\text{diss}}$  is chosen to be zero, we get

$$(6.5) \quad \frac{d}{dt}E_\mu = \frac{1}{n} \sum_{i=1}^{n-1} (\dot{z}_i^a \tilde{u}_{a,i}^{\text{diss}}).$$

Expressing  $\tilde{u}_{a,i}^{\text{diss}}$  in terms of  $u_{a,i}^{\text{diss}}$ , we can write the expression for  $\dot{E}_\mu$  as

$$(6.6) \quad n \frac{d}{dt}E_\mu = u_{a,1}^{\text{diss}} \left( \sum_{j=1}^{n-1} \dot{z}_j^a \right) + \sum_{j=2}^{n-1} u_{a,j}^{\text{diss}} \left( -(n-1)\dot{z}_{j-1}^a + \sum_{k=1, k \neq j-1}^{n-1} \dot{z}_k^a \right)$$

and choose

$$\begin{aligned} u_{a,1}^{\text{diss}} &= d_{ab} \left( \sum_{j=1}^{n-1} \dot{z}_j^b \right), \\ u_{a,j}^{\text{diss}} &= d_{ab} \left( -(n-1)\dot{z}_{j-1}^b + \sum_{k=1, k \neq j-1}^{n-1} \dot{z}_k^b \right), \\ (6.7) \quad &j = 2, \dots, n-1, \end{aligned}$$

where  $d_{ab}$  is a positive definite control gain matrix, possibly dependent on  $x_i^\alpha$ ,  $i = 1, \dots, n$ , and  $z_i^a$ ,  $j = 1, \dots, n-1$ . With the dissipative control term (6.7),  $\frac{d}{dt}E_\mu \geq 0$ .

We note that this dissipative control term requires that each individual system can measure the variables  $\dot{z}_i^a$  of all other vehicles. Recall that for Lyapunov stability

the interconnection among individual systems need only be *connected* for the coupling potential  $\tilde{V}_\epsilon$  which is a function of the  $y_k^a$ ,  $k = 1, \dots, n$ . That is, for Lyapunov stability, each individual system need only measure its relative position with respect to some subset of the other individual systems. However, for ASSM we require *complete* interconnection in the dissipative control term which is a function of the variables  $\dot{z}_n$ . That is, each individual system feedbacks relative velocity with respect to every other individual system. Figure 6.1 illustrates a complete interconnected graph for the case of four vehicles. Complete interconnection is not needed for stabilization of group dynamics in the simpler dynamical models used more typically in the literature, as described in section 1. It is hoped that the interconnection limitation here in stabilization of networks of underactuated mechanical systems can likewise be overcome in future work.

FIG. 6.1. Complete interconnected communication graph for four vehicles.

We next study convergence of the system using the LaSalle invariance principle [11]. For  $c > 0$ , let  $\Omega_c = \{(\mathbf{x}_r, \dot{\mathbf{x}}_r) | E_\mu \geq c\}$ .  $\Omega_c$  is a compact and positive invariant set with integral curves starting in  $\Omega_c$  and staying in  $\Omega_c$  for all  $t \geq 0$ . Define the LaSalle surface

$$\mathcal{E} = \left\{ (\mathbf{x}_r, \dot{\mathbf{x}}_r) \left| \frac{d}{dt} E_\mu = 0 \right. \right\}.$$

On this surface,  $u_{a,j}^{\text{diss}} = 0$ ,  $i = 1, \dots, n$ , which implies that  $\dot{z}_i^a = 0$  for  $i = 1, \dots, n-1$ . Let  $\mathcal{M}$  be the largest invariant set contained in  $\mathcal{E}$ . By the LaSalle invariance principle, solutions that start in  $\Omega_c$  approach  $\mathcal{M}$ . The relative equilibrium (5.11) is contained in  $\mathcal{M}$ ; however, there are other solutions in this set.

We now proceed to analyze in more detail the structure of solutions on the LaSalle surface  $\mathcal{E}$ . Using the condition  $\dot{z}_i^a = 0$  for  $i = 1, \dots, n-1$ , we get  $\dot{y}_i^a = \dot{y}_j^a$  for all  $i, j \in \{1, \dots, n\}$ . This gives  $y_i^a - y_j^a = \text{constant}$ . Since we have chosen  $\tilde{V}_\epsilon$  to be a quadratic function of the terms  $y_i^a - y_j^a$ , we get  $\frac{\partial \tilde{V}_\epsilon}{\partial y_i^a} = \text{constant} =: \Delta_a^i$ . The equations of motion for the  $y_i^a$  restricted to the LaSalle surface are  $\mathcal{E}_{y_i^a}(L'_c) = 0$ , where  $L'_c$  is given by (4.2). Equivalently,

$$(6.8) \quad \ddot{y}_i^a + \frac{d}{dt} (\tilde{g}_i^{ab} g_{ab}^i \dot{x}_i^a) = -\tilde{g}_i^{ab} \frac{\partial \tilde{V}_\epsilon}{\partial y_i^b} = -\tilde{g}_i^{ab} \Delta_b^i.$$

As illustrated in [1], for SMC systems, there is a function  $l_i^a(x_i^\alpha)$  for each vehicle  $i$  defined on an open set of the configuration space for the  $i$ th vehicle's unactuated variables such that

$$(6.9) \quad \frac{\partial l_i^a}{\partial x_i^\alpha} = \tilde{g}_i^{ac} g_{ac}^i.$$

We can assume, by shrinking  $\Omega_c$  if necessary, that (6.9) holds in  $\Omega_c$ .

Let  $K_c$  be the projection of  $\Omega_c$  onto the coordinates  $(\mathbf{x}_n, \dot{\mathbf{x}}_n)$ , where  $\mathbf{x}_n = (x_1^\alpha, \dots, x_n^\alpha)$ . Then, since  $l_i^a$  is continuous and  $K_c$  is compact, there exist constants  $m_i$  and  $n_i$  such that

$$(6.10) \quad m_i \leq \|l_i(x_i)\| \leq n_i$$

for all  $x_i^\alpha$  such that  $\mathbf{x}_n \in \Omega_c$ . Using (6.8), (6.9), and the condition  $\dot{y}_i^a = \dot{y}_j^a$  on  $\mathcal{E}$ , we get

$$(6.11) \quad \frac{d}{dt}(l_i^a - l_j^a) = \tilde{g}_j^{ab} \Delta_b^j - \tilde{g}_i^{ab} \Delta_b^i.$$

Therefore, on  $\mathcal{E}$ ,

$$(6.12) \quad l_i^a - l_j^a = \frac{1}{2}(\tilde{g}_j^{ab} \Delta_b^j - \tilde{g}_i^{ab} \Delta_b^i)t^2 + \nu_1^a t + \nu_2^a$$

for some constant vectors  $\nu_1^a$  and  $\nu_2^a$ . The only way (6.10) can also be satisfied is if  $\tilde{g}_j^{ab} \Delta_b^j - \tilde{g}_i^{ab} \Delta_b^i = 0$  and  $\nu_1^a = 0$ .

To simplify our calculations, we assume that the  $n$  individual mechanical systems are identical. In this case,  $\tilde{g}_j^{ab} = \tilde{g}_i^{ab}$  for any  $i, j \in \{1, \dots, n\}$ . This gives  $\Delta_a^i = \Delta_a^j$  for any  $i, j \in \{1, \dots, n\}$ , and so for a connected network with potential  $V'_\epsilon$  having a maximum at  $x_i^\alpha = 0$  and  $y_i^a = y_j^a$  for all  $i \neq j$ , we get that  $y_i^a = y_j^a$  on  $\mathcal{E}$  for all  $i, j \in \{1, \dots, n\}$ .

Using the definition (6.9) and the assumption that the individual systems are identical, the fact that  $\dot{l}_i^a - \dot{l}_j^a = 0$  on  $\mathcal{E}$  yields

$$(6.13) \quad g_{\alpha b}^i \dot{x}_i^\alpha = g_{\alpha b}^j \dot{x}_j^\alpha,$$

where  $g_{\alpha b}^k = g_{\alpha b}(x_k^\alpha)$  for all  $k = 1, \dots, n$ . Therefore, on the LaSalle surface  $\mathcal{E}$ , we see that solutions are of the form  $(\mathbf{x}_n(t), \dot{\mathbf{x}}_n(t), y_1^a(t), \dots, y_n^b(t), \dot{y}_1^a(t), \dots, \dot{y}_n^b(t))$ , where  $y_i^a(t) = y_j^a(t)$  for any  $i, j \in \{1, \dots, n\}$ ,  $J_a = \mu_a$ , and condition (6.13) holds. Since  $z_n^a = \sum_{i=1}^n y_i^a$  and the individual systems are identical, we have

$$\begin{aligned} J_a &= \frac{\partial \tilde{L}_c}{\partial \dot{z}_n^a} = \sum_{i=1}^n (g_{\alpha a}^i \dot{x}_i^\alpha + \tilde{g}_{ab} \dot{y}_i^b) \\ &= \tilde{g}_{ab} \sum_{i=1}^n (\tilde{g}^{bc} g_{\alpha c}^i \dot{x}_i^\alpha + \dot{y}_i^b) \\ &= n \tilde{g}_{ab} (\tilde{g}^{bc} g_{\alpha c}^i \dot{x}_i^\alpha + \dot{y}_i^b) \end{aligned}$$

for any  $i \in \{1, \dots, n\}$ , where we have used the facts that  $\dot{y}_i^a = \dot{y}_j^a$  and (6.13) holds on  $\mathcal{E}$ . Therefore, for each  $i$  we get

$$(6.14) \quad \dot{y}_i^a = \frac{1}{n} \tilde{g}^{ab} \mu_b - \tilde{g}^{ab} g_{\alpha b}^i \dot{x}_i^\alpha.$$

Substituting (6.14) into the closed-loop equations for the Lagrangian  $L'_c$  (4.2), we get the following equations for the  $x_i^\alpha$  variables:

$$(6.15) \quad \frac{d}{dt} \frac{\partial L^\mu}{\partial \dot{x}_i^\alpha} = \frac{\partial L^\mu}{\partial x_i^\alpha},$$

where

$$\begin{aligned}
 L^\mu &= \sum_{i=1}^n \left( \frac{1}{2} (\tilde{g}_{\alpha\beta}^i - \tilde{g}^{ab} g_{\alpha a}^i g_{\beta b}^i) \dot{x}_i^\alpha \dot{x}_i^\beta - V_{1i}(x_i^\alpha) \right) \\
 (6.16) \quad &= \sum_{i=1}^n \left( \frac{1}{2} (g_{\alpha\beta}^i - (\kappa + 1) g^{ab} g_{\alpha a}^i g_{\beta b}^i) \dot{x}_i^\alpha \dot{x}_i^\beta - V_{1i}(x_i^\alpha) \right),
 \end{aligned}$$

and  $V_{1i}$  is defined by assumption **AS1**. Here,  $\kappa_i = \kappa$  for all  $i = 1, \dots, n$ .

$L^\mu$  is just the Routhian  $R^\mu$  for a mechanical system with abelian symmetry variables without a linear term in velocity and without the amended part of the potential. This follows because, for SMC systems, these latter terms do not contribute to the dynamics of the reduced system. We also see that the  $x_i^\alpha$  dynamics completely decouple from the  $x_j^\alpha$  dynamics on the LaSalle surface  $\mathcal{E}$  for all  $i$  and  $j$ . The  $y_i^a$  dynamics given by (6.14) can be thought of as a reconstruction of dynamics in the symmetry variables, obtained after solving the reduced dynamics in the  $x_i^\alpha$  variables. We now make the following assumption.

**AS2.** Consider two solutions  $(x^\alpha(t), y^a(t))$  and  $(\tilde{x}^\alpha(t), \tilde{y}^a(t))$  of the Euler–Lagrange equations corresponding to the Lagrangian given by (3.3). If  $y^a(t) = \tilde{y}^a(t)$  and  $g_{\alpha a}(x^\alpha(t))\dot{x}^\alpha(t) = g_{\alpha a}(\tilde{x}^\alpha(t))\dot{\tilde{x}}^\alpha(t)$ , then  $x^\alpha(t) = \tilde{x}^\alpha(t)$ .

Note that checking this condition does not require extensive computation since we already know the expression for the closed-loop Lagrangian. Consider two solutions  $x^\alpha(t)$  and  $\tilde{x}^\alpha(t)$  such that  $g_{\alpha a}(x^\alpha(t))\dot{x}^\alpha(t) = g_{\alpha a}(\tilde{x}^\alpha(t))\dot{\tilde{x}}^\alpha(t)$ . This is equivalent to  $l^a(x^\alpha) = l^a(\tilde{x}^\alpha) + c^a$ , where  $l^a$  is defined by (6.9) and  $c^a$  is a constant; i.e.,  $x^\alpha(t)$  and  $\tilde{x}^\alpha(t)$  are two solutions in  $(x^\alpha, \dot{x}^\alpha)$  space satisfying the Euler–Lagrange equation corresponding to the Lagrangian  $L^\mu$  given by (6.16) and differing by a constant. For mechanical systems with symmetries, it may be possible to prove that  $c^a$  is zero, as is done for the pendulum/cart case in section 8. Then, **AS2** is equivalent to assuming that the function  $l^a$  is injective, i.e.,  $g_{\alpha a}$  is one-to-one in a neighborhood about the equilibrium. For the pendulum/cart example in section 8, this holds in the neighborhood defined by pendulum angles which are above the horizontal plane. As mentioned in [1], **AS2** is equivalent to the (local) strong inertial coupling assumption in [21] and internal/external convertible system in [7].

Using (6.13) and the fact that  $y_i^a = y_j^a$  on the LaSalle surface, we get from **AS2** that  $x_i^\alpha = x_j^\alpha$  and  $\theta_i^a = \theta_j^a$  for all  $i, j \in \{1, \dots, n\}$ . So we get that the dissipation control law given by (6.7) yields asymptotic convergence to synchronized motion on a constant momentum surface.

**THEOREM 6.1 (ASSM).** Consider a network of  $n$  identical SMC systems that each satisfy **AS1** and **AS2**. Suppose for each individual system that the origin is an equilibrium and that the original potential energy is maximum at the origin. Consider the kinetic energy shaping defined in section 4 and potential energy coupling  $\tilde{V}_\epsilon$  defined in section 5, where the terms in  $\tilde{V}_\epsilon$  are quadratic in  $y_i^a - y_j^a$  and the corresponding interconnection graph is connected. The closed-loop dynamics (6.2) derive from the Lagrangian  $\tilde{L}_c$  given by (5.2), and the potential energy  $V'_\epsilon$  is maximized at the relative equilibrium (5.11). The control input takes the form (6.1), where  $u_{a,i}^{\text{cons}}$  is given by (5.15) and  $\rho_i = \rho$ ,  $\kappa_i = \kappa$ . The dissipative control term given by (6.7) asymptotically stabilizes the solution in which all the vehicles have synchronized dynamics such that  $\theta_i^a = \theta_j^a$  and  $x_i^\alpha = x_j^\alpha$  for all  $i$  and  $j$ , and each has the same constant momentum in the  $\theta_i^a$  direction. The system stays on the constant momentum surface determined by the initial conditions.

*Remark 6.2.* Consider a Case II in which we choose  $\tilde{u}_{a,n}^{\text{diss}} = -\lambda(J_a - \mu_a)$  and  $u_{a,i}$  for  $i = 1, \dots, n-1$  as in Case I. Then  $J_a = (J_a(0) - \mu_a) \exp(-\lambda t) + \mu_a$  and we can rewrite the reduced system in  $(\mathbf{x}_r, \dot{\mathbf{x}}_r)$  coordinates as follows:

$$(6.17) \quad \mathcal{E}_{\mathbf{x}_r}(R^\mu) = \begin{pmatrix} 0 \\ \frac{1}{n} \tilde{\mathbf{u}}^{\text{diss}} \end{pmatrix} + \lambda \bar{M}_{12} \bar{M}^{22} (\mathbf{J}(0) - \boldsymbol{\mu}) \exp(-\lambda t).$$

Here,  $\tilde{\mathbf{u}}^{\text{diss}} = (\tilde{u}_{a,1}^{\text{diss}}, \dots, \tilde{u}_{a,n-1}^{\text{diss}})$  is an  $rn$ -dimensional vector, and  $\mathbf{J}$  and  $\boldsymbol{\mu}$  are  $r$ -dimensional vectors with components  $J_a$  and  $\mu_b$ , respectively. When  $\lambda = 0$ , we get Case I. When  $\lambda \neq 0$ , the momentum  $J_a$  is no longer a conserved quantity. This case needs to be analyzed more carefully since we are pumping energy into the system now to drive it to a particular momentum value. Equation (6.17) can be considered to be a parameter dependent differential equation with the parameter being  $\lambda$ . When  $\lambda = 0$ , we already know the solution from Case I. From the continuity of dependence of solutions upon parameters, we get that when  $0 < \lambda < \delta$ , the solution stays within an  $\epsilon$ -tube of the solution in Case I for time  $t \in [0, t_1]$  for some  $t_1$  if the initial conditions are in a  $\delta$ -neighborhood. Our simulations for pendulum/cart systems suggest that this holds true for the infinite time interval. We plan to investigate this case further in our future work.

*Remark 6.3.* The simplifying requirement for Theorem 6.1 that all systems be identical is a weakness of the result and motivates the question of robustness to uncertainty in system parameters. Simulations suggest that the stability of Theorem 6.1 is robust to model parameter uncertainty, but a formal robustness analysis is warranted.

In section 8 we illustrate the result of Theorem 6.1 and the dynamics of (6.16) in more detail in the case of a network of inverted pendulum/cart systems. Solutions for this example correspond to synchronized balanced pendula on synchronized moving carts, where the motion of the carts is the sum of a constant velocity plus an oscillation and the motion of the pendula is oscillatory with the same frequency as the carts.

**7. Asymptotic stabilization of relative equilibria.** In the previous section, we proved asymptotic stability of the coordinated network in the case when the network asymptotically converges to the momentum surface  $J_a = \mu_a$ . This can lead to nontrivial and interesting synchronized group dynamics, as is discussed in section 8. Stabilization was proved using  $E_\mu$  as a Lyapunov function on the reduced space. The dynamics after adding a dissipative control term are given by  $\theta_i^a = \theta_j^a$  and  $x_i^\alpha = x_j^\alpha$  for all  $i, j = 1, \dots, n$ . The dissipative terms are chosen such that the momentum is preserved.

In this section, we demonstrate how to isolate and asymptotically stabilize the particular synchronized and constant momentum solutions corresponding to the relative equilibria given by (5.11). The value of the momentum  $\mu_a$  can be chosen arbitrarily. We use a different Lyapunov function from that used in section 6. We note that in the example of a network of inverted pendulum/cart systems, the relative equilibrium corresponds to the synchronized motion of all carts moving in unison at a steady speed with all pendula at rest in the upright position; i.e., it is the special case of the motion proved in Theorem 6.1 without the oscillation.

Consider the following function:

$$(7.1) \quad E_{RE} = \frac{1}{2} (\dot{\mathbf{x}}_c - \mathbf{v}_{RE})^T \tilde{M}_c (\dot{\mathbf{x}}_c - \mathbf{v}_{RE}) + V'_\epsilon,$$

where  $\mathbf{v}_{RE}$  is defined by (5.11).  $E_{RE}$  is a Lyapunov function in directions transverse to the group orbit of the relative equilibrium, i.e.,  $E_{RE} > 0$  in a neighborhood of the Euler–Lagrange solution given by  $(\mathbf{x}_r, \mathbf{z}_n, \dot{\mathbf{x}}_r, \dot{\mathbf{z}}_n)$ , where  $\mathbf{x}_r = \mathbf{0}$ ,  $\dot{\mathbf{x}}_r = \mathbf{0}$ ,  $\mathbf{z}_n^d = \zeta^d t$ ,  $\dot{\mathbf{z}}_n^d = \zeta^d$ , and  $\zeta^d$  corresponds to ( $n$  times) the constant velocity of the center of mass of the network.

The time derivative of  $E_{RE}$  along the flow given by (6.2) can be computed to be

$$\frac{d}{dt}E_{RE} = \frac{1}{n}(\dot{\mathbf{x}}_c - \mathbf{v}_{RE}) \cdot \begin{pmatrix} 0 \\ \tilde{\mathbf{u}}^{\text{diss}} \end{pmatrix}.$$

See [3] for the steps involved in proving this identity. Choose

$$(7.2) \quad \tilde{u}_{a,i}^{\text{diss}} = \begin{cases} n\sigma_i \dot{z}_i^a & \text{for } i = 1, \dots, n-1, \\ n\sigma_n(\dot{z}_n^a - \zeta^a) & \text{for } i = n, \end{cases}$$

where control parameters  $\sigma_i$  are positive constants. Then,

$$\frac{d}{dt}E_{RE} = \sum_{j=1}^{n-1} \sigma_j (\dot{z}_j^a)^2 + \sigma_n (\dot{z}_n^a - \zeta^a)^2 \geq 0.$$

We note here that, unlike the case of asymptotic stabilization in the previous section, where a complete interconnection was required to realize the dissipative control term (6.7), the dissipative control term (7.2) requires only a connected interconnection graph.

Let  $\Omega_c^{RE} = \{(\mathbf{x}_r, \dot{\mathbf{x}}_r, \dot{\mathbf{z}}_n^a) | E_{RE} \geq c\}$  for  $c > 0$ .  $\Omega_c^{RE}$  is a compact set, i.e.,  $E_{RE}$  is a proper Lyapunov function. Assume that the Euler–Lagrange system (6.2) satisfies the following controllability condition.

**AS3.** *The system (6.2) is linearly controllable at each point in a neighborhood of the relative equilibrium solution manifold.*

Note that checking this condition does not require extensive computation since we already know the expression for the closed-loop Lagrangian.

We now use a result from nonlinear control theory, which is stated in [3] as Lemma 2.1 and the remark following it, to conclude that the system (6.2) with dissipative control terms given by (7.2) converges exponentially to the set

$$\mathcal{E}_{RE} = \{(\mathbf{x}_r, \dot{\mathbf{x}}_r, \dot{\mathbf{z}}_n^a) | E_{RE} = 0\}.$$

On this set, the solution is given by (5.11). Thus, we have shown that the solutions of the controlled system will exponentially converge to  $(x_i^\alpha, \theta_i^\alpha, \dot{x}_i^\beta, \dot{\theta}_i^\beta) = (0, \frac{1}{n}\zeta^a t + \gamma^a, 0, \frac{1}{n}\zeta^b)$ , with  $\gamma^a$  constant.

**THEOREM 7.1 (ASSRE).** *Consider a network of  $n$  (not necessarily identical) individual SMC systems that each satisfy assumption **AS1**. Suppose for each individual system that the origin is an equilibrium and that the original potential energy is maximum at the origin. Consider the kinetic energy shaping defined in section 4 and potential energy coupling  $\tilde{V}_\epsilon$  defined in section 5, where the terms in  $\tilde{V}_\epsilon$  are quadratic in  $y_i^a - y_j^a$  and the corresponding interconnection graph is connected. The closed-loop dynamics (6.2) derive from the Lagrangian  $\tilde{L}_c$  given by (5.2) and the potential energy  $V'_\epsilon$  is maximized at the relative equilibrium (5.11). The control input takes the form (6.1), where  $u_{a,i}^{\text{cons}}$  is given by (5.15) and  $\rho_i = \rho$ . If (6.2) satisfies **AS3**, then the dissipative control term given by (7.2) exponentially stabilizes the relative equilibrium given by (5.11) in which  $x_i^\alpha = \dot{x}_i^\alpha = 0$  for all  $i = 1, \dots, n$  and  $\theta_i^a = \theta_j^a$  and  $\dot{\theta}_i^a = \dot{\theta}_j^a = \frac{1}{n}\zeta^a$  for all  $i$  and  $j$ .*

**8. Coordination of multiple inverted pendulum/cart systems.** As an illustration, we now consider the coordination of  $n$  identical planar inverted pendulum/cart systems. For the  $i$ th system, the pendulum angle relative to the vertical is  $x_i$  and the position of the cart is  $\theta_i$ . Let the Lagrangian for each system shown in Figure 8.1 be

$$L_i = \frac{1}{2}\alpha\dot{x}_i^2 + \beta\cos(x_i)\dot{x}_i\dot{\theta}_i + \frac{1}{2}\gamma\dot{\theta}_i^2 + D\cos(x_i); \quad i = 1, \dots, n,$$

where  $l, m, M$  are the pendulum length, pendulum bob mass, and cart mass, respectively.  $g$  is the acceleration due to gravity. The quantities  $\alpha, \beta, \gamma$ , and  $D$  are expressed in terms of  $l, m, M, g$  as follows:

$$\alpha = ml^2, \quad \beta = ml, \quad \gamma = m + M, \quad D = -mgl.$$

The equations of motion for the  $i$ th system are

$$\begin{aligned} \mathcal{E}_{x_i}(L_i) &= 0, \\ \mathcal{E}_{\theta_i}(L_i) &= u_i, \end{aligned}$$

where  $u_i$  is the control force applied to the  $i$ th cart.

One can see that  $\theta_i$  is a symmetry variable. Further, it can be easily verified that each pendulum/cart system satisfies the simplified matching conditions [1, 2]. The  $n$  inverted planar pendulum/cart systems lie on  $n$  parallel tracks corresponding to the  $\theta_i$  directions. The coordination problem is to prescribe control forces  $u_i$ ,  $i = 1, \dots, n$ , that asymptotically stabilize the solution where each pendulum is in the vertical upright position (in the case of ASSRE) or moving synchronously (in the case of ASSM) and the carts are moving at the same position along their respective tracks with the same common velocity. The relative equilibrium  $\mathbf{v}_{RE}$  (5.11) corresponds to  $x_i = \dot{x}_i = 0$  for all  $i$ ,  $\theta_i = \theta_j$  for all  $i \neq j$ , and  $\dot{\theta}_i = \frac{1}{n}\zeta$  for some constant scalar velocity  $\zeta$ .

Following (5.2), the closed-loop Lagrangian for the total system in the coordinates  $\mathbf{x}_c = (x_1, \dots, x_n, z_1, \dots, z_n)$ , where  $z_i = y_1 - y_{i+1}$  for  $i = 1, \dots, n-1$ ,  $z_n = y_1 + \dots + y_n$ ,  $y_i = \theta_i + p \sin x_i$ , and  $p = \frac{\beta}{\gamma}(\kappa + 1 - \frac{1}{\rho})$ , is

$$(8.1) \quad \tilde{L}_c = \frac{1}{2}\dot{\mathbf{x}}^T \tilde{M}_c \dot{\mathbf{x}} - V'_\epsilon(x_1, \dots, x_n, z_1, \dots, z_{n-1}).$$

$\tilde{M}_c$  is as in (5.6) and  $M_c$  is as in (4.3),

$$(8.2) \quad \begin{aligned} \tilde{g}_{\alpha\beta}^i &= \alpha - \left(\kappa + 1 - \frac{1}{\rho}\right) \frac{\beta^2}{\gamma} \cos^2(x_i), & \tilde{g}_{\alpha\alpha}^i &= \beta \cos(x_i), \\ \tilde{g}_{ab}^i &= \rho\gamma, & V'_\epsilon &= -D \sum_{i=1}^{n-1} \left( \cos(x_i) - \frac{1}{2}\epsilon \frac{\gamma^2}{\beta^2} z_i^2 \right) - D \cos(x_n) \end{aligned}$$

with  $\epsilon > 0$ . The control law (6.1) for the  $i$ th system is

$$(8.3) \quad u_i = \frac{\kappa\beta \left( \sin x_i \left( \alpha\dot{x}_i^2 + \cos(x_i)D \right) - B_i \left( \frac{\partial V'_\epsilon}{\partial \theta_i} - u_i^{\text{diss}} \right) \right)}{\alpha - \frac{\beta^2}{\gamma} (1 + \kappa) \cos^2(x_i)},$$

FIG. 8.1. The planar pendulum on a cart.

where

$$B_i = \frac{1}{\rho} \left( \alpha - \frac{\beta^2 \cos^2(x_i)}{\gamma} \right).$$

Note that we have chosen  $\rho_i = \rho$  and  $\kappa_i = \kappa$ . In the case  $u_i^{\text{diss}} = 0$ , by Theorem 5.2, we get stability of the relative equilibrium  $\mathbf{v}_{RE}$  (SSRE) if we choose  $\rho < 0$ ,  $\epsilon > 0$ , and  $\kappa$  such that  $m_\kappa := \alpha - (\kappa + 1) \frac{\beta^2}{\gamma} < 0$ . The choice of  $u_i^{\text{diss}}$  depends upon what kind of asymptotic stability we want, i.e., convergence to a synchronized constant momentum solution or to a relative equilibrium.

The dependence of  $V'_\epsilon$  on  $z_i^2$  in (8.2) implies that coupling between the pendulum/cart systems introduced by the control is a function of terms  $y_i - y_j$  rather than  $\theta_i - \theta_j$ . That is, our approach to simultaneous stabilization and synchronization of a network of planar pendulum/cart systems yields coupling not simply as a function of relative cart positions but, rather more subtly, as a function of the horizontal component of relative positions of pendulum bobs (where pendulum length is scaled by  $p$ ). Numerical simulations show that naively coupling the positions of the carts for the purpose of synchronization in fact destabilizes the network. This particular example illustrates the need to integrate synchronization and stabilization tasks.

### 8.1. Asymptotic stability on a constant momentum surface (ASSM).

Following (6.7), we let  $u_1^{\text{diss}}$  be

$$u_1^{\text{diss}} = d_1 \left( \sum_{k=1}^{n-1} (\dot{z}_k) \right)$$

and  $u_i^{\text{diss}}$  for  $i = 2, \dots, n$  be

$$u_i^{\text{diss}} = d_i \left( -(n-1)\dot{z}_{i-1} + \sum_{k=1, k \neq i-1}^{n-1} \dot{z}_k \right),$$

where coefficients  $d_i$  are constant positive scalars.

We now analyze the dynamics on the LaSalle surface. On this surface, we have  $\dot{y}_i = \dot{y}_j$  for all  $i, j \in \{1, \dots, n\}$  and  $J = \mu$ , where momentum  $\mu$  is determined by the initial conditions. From the calculations made in section 6, we also get  $y_i = y_j$  and  $\cos(x_i)\dot{x}_i = \cos(x_j)\dot{x}_j$ . The  $x_i$  dynamics are given by (6.15) with

$$(8.4) \quad L^\mu = \sum_{i=1}^n \left( \frac{1}{2} \left( \alpha - (\kappa + 1) \frac{\beta^2}{\gamma} \cos^2(x_i) \right) \dot{x}_i^2 + D \cos(x_i) \right).$$

FIG. 8.2. Simulation of a controlled network of pendulum/cart systems with dissipation designed for ASSM. The pendulum angle, cart position, and cart velocity are plotted as a function of time for each of the two pendulum/cart systems in the network.

To verify **AS2** we need to check that if  $\cos(x_i)\dot{x}_i = \cos(x_j)\dot{x}_j$  about the origin for a system corresponding to the Lagrangian  $L^\mu$ , then  $x_i = x_j$  identically. This condition can also be written as  $\sin(x_i) = \sin(x_j) + c$ , where  $c$  is a constant. Note that if  $x_i(t)$  is an Euler–Lagrange solution corresponding to  $L^\mu$  for the  $i$ th vehicle, then  $-x_i(t)$  is also a solution. Since we have a stable pendulum oscillation about the upright position,  $x_i(t)$  and therefore  $|\sin(x_i(t))|$  oscillates with mean zero for all  $i$ . This can also be concluded from the fact that the solution curves are closed level curves in the  $(x_i, \dot{x}_i)$  plane of  $L^\mu$  given by (8.4) and  $L^\mu$  is invariant under the sign change  $(x_i, \dot{x}_i) \mapsto -(x_i, \dot{x}_i)$ . Since  $|\sin(x_i)|$  oscillates with zero mean for all  $i$ , the constant  $c$  must be zero. Hence,  $x_i(t) = x_j(t)$  for all  $i, j$  identically and **AS2** is verified. Thus, by Theorem 6.1 the pendulum network asymptotically goes to an ASSM.

From (8.4), it can be seen that on the LaSalle surface, the dynamics of  $x_i$  are decoupled from the dynamics of  $x_j$  for all  $i \neq j$ . For small  $x_i$ , the dynamics of each individual term in  $L^\mu$  corresponds to the stable dynamics of a spring-mass system with a  $\kappa$ -dependent mass  $-m_\kappa > 0$  and spring constant  $-D > 0$ . The mass  $-m_\kappa$ , which determines the oscillation frequency of the pendulum for each individual cart, can be controlled by the choice of  $\kappa$ . For the nonlinear system also, constant energy curves are closed curves in the  $(x_i, \dot{x}_i)$  plane. Hence, we have a periodic orbit for the angle made by each pendulum with the vertical line with a  $\kappa$ -dependent frequency. On the LaSalle surface,  $J = \rho\gamma\dot{\theta}_i + (\beta + p\rho\gamma)\cos(x_i)\dot{x}_i = \text{constant}$ . Therefore, the velocity of the cart  $\dot{\theta}_i$  oscillates about a constant velocity with the same frequency as the pendulum oscillation.

Figure 8.2 shows the results of a MATLAB simulation for the controlled network of pendulum/cart systems using the following values for the system parameters. The pendulum/cart systems have identical pendulum bob masses, lengths, and cart masses. The pendulum bob mass is chosen to be  $m = 0.14$  kg, cart mass is  $M = 0.44$  kg, and pendulum length is  $l = 0.215$  m. The control gains are  $\rho = -0.27$ ,  $\kappa = 40$ ,  $d_i = d = 0.2$ , and  $\epsilon = 0.0005$ . We compute  $m_\kappa = -0.058 \text{ kgm}^2 < 0$  as required for

FIG. 8.3. Simulation of a controlled network of pendulum/cart systems with dissipation designed for ASSRE. The pendulum angle, cart position, and cart velocity are plotted as a function of time for each of the two pendulum/cart systems in the network.

stability. The initial conditions for the two systems shown are

$$\begin{pmatrix} x_1(0) & \dot{x}_1(0) & \theta_1(0) & \dot{\theta}_1(0) & x_2(0) & \dot{x}_2(0) & \theta_2(0) & \dot{\theta}_2(0) \end{pmatrix} \\ = ( 0.48 \quad 0.99 \quad 0.37 \quad 0.53 \quad 0.18 \quad 0.50 \quad 0.42 \quad 0.66 ).$$

Figure 8.2 shows plots of the pendulum angle, cart position, and cart velocity as a function of time for two of the coupled pendulum/cart systems. Convergence to an ASSM is evident. The frequency of oscillation of the pendula can be observed to be the same as the frequency of oscillation in the cart velocities. This frequency of oscillation can be computed as  $\omega = \sqrt{D/m_\kappa}$  and the period of oscillation as  $T = 2\pi/\omega = 2.8$  s, which is precisely the period of the oscillations observed in Figure 8.2.

**8.2. Asymptotic stability of relative equilibria (ASSRE).** In this case, we want to asymptotically stabilize the relative equilibrium  $\mathbf{v}_{RE}$ , i.e.,  $x_i = \dot{x}_i = 0$  for all  $i$ ,  $\theta_i = \theta_j$  for all  $i \neq j$ , and  $\dot{\theta}_i = \frac{1}{n}\zeta$  for all  $i$ , and any constant scalar velocity  $\zeta$ . Recall that this corresponds to each pendulum angle at rest in the upright position and all carts aligned and moving together with the same constant velocity  $\frac{1}{n}\zeta$ . Following (7.2), we let

$$u_i^{\text{diss}} = nd_i \dot{z}_i$$

for  $i = 1, \dots, n-1$  and

$$u_n^{\text{diss}} = nd_n(\dot{z}_n - \zeta),$$

where the control parameters  $d_i$  are positive constants.

Figure 8.3 shows the results of a MATLAB simulation for the controlled network of pendulum/cart systems with this dissipative control. We choose  $\zeta = 2n$  m/s, and

the remaining system and control parameters are as above in the ASSM case. The initial conditions for the two systems shown are

$$\begin{pmatrix} x_1(0) & \dot{x}_1(0) & \theta_1(0) & \dot{\theta}_1(0) & x_2(0) & \dot{x}_2(0) & \theta_2(0) & \dot{\theta}_2(0) \end{pmatrix} \\ = ( 0.53 \quad 1.12 \quad 0.56 \quad 0.50 \quad 1.02 \quad 0.63 \quad 0.24 \quad 0.81 ).$$

Figure 8.3 shows convergence to the relative equilibrium; the pendula are stabilized in the upright position, the cart positions become synchronized, and the cart velocities converge to 2 m/s.

**9. Final remarks.** We have derived control laws to stabilize and stably synchronize a network of mechanical systems with otherwise unstable dynamics. We have proved stability of relative equilibria corresponding to synchronization in all variables and common steady motion in the actuated directions. Using two different choices of a dissipative term in the control law, we prove two different kinds of asymptotic stability. In the first case of dissipation, we show how to drive the network to a synchronized motion on the constant momentum surface determined by the initial conditions. Such a synchronized motion can be interesting when examined in physical space. In our example of a network of planar pendulum/cart systems, we show that the synchronized motion is periodic and the period of the oscillation can be controlled with a control parameter. In the second case of dissipation, we show how to isolate and asymptotically stabilize the relative equilibrium for any choice of constant momentum. We illustrate all of our results for a network of pendulum/cart systems. For this example, our approach yields a subtle choice in the coupling variables: The coupling that leads to stable synchronization is a function of relative positions of pendulum bobs, not simply relative positions of carts. Indeed, coupling as a function of relative cart positions destabilizes the network.

For asymptotic stabilization of the relative equilibrium, we assume that the interconnection graph for the network is connected. However, for asymptotic stabilization of a synchronized motion on the constant momentum surface, we assume that the interconnection graph for the dissipative control is completely connected. It is of interest in future work to determine whether this latter condition can be relaxed.

In Theorem 6.1 we prove asymptotic stabilization of a synchronized motion on the constant momentum surface; however, we cannot select the value of the momentum because it is determined by the initial conditions. In Remark 6.2 we propose a control law to simultaneously drive the momentum to a desired value. This control law appears to work in simulation; however, the stability analysis is more subtle. It raises a number of interesting questions. For example, suppose we have a dynamical system depending upon a parameter  $\lambda$ , i.e., the Lagrangian is given by a function  $L(q, \dot{q}, \lambda)$ , where  $q$  is the state variable. Assume that for each  $\lambda \in [0, \epsilon]$ , the (controlled) system is Lyapunov stable. If we now let  $\lambda$  evolve in time such that it “slowly” goes to a value  $\bar{\epsilon} \in (0, \epsilon)$ , can we still conclude that the system is Lyapunov stable in the infinite time domain? See [12] for results in the case when the unperturbed system has a uniformly asymptotically stable equilibrium. We plan to build on these tools to study our parameter dependency problem in future work.

Another future direction is the inclusion of collision avoidance in our framework. For instance, in our example, the carts move on parallel tracks, and hence collision avoidance is not an issue. However, it is interesting to consider the case in which all of the carts are on the same track and the pendulum/cart systems can be controlled without collisions for stable synchronization.

## OPTIMAL STOPPING GAMES FOR MARKOV PROCESSES\*

ERIK EKSTRÖM<sup>†</sup> AND GORAN PESKIR<sup>†</sup>

**Abstract.** Let  $X = (X_t)_{t \geq 0}$  be a strong Markov process, and let  $G_1$ ,  $G_2$ , and  $G_3$  be continuous functions satisfying  $G_1 \leq G_3 \leq G_2$  and  $\mathbb{E}_x \sup_t |G_i(X_t)| < \infty$  for  $i = 1, 2, 3$ . Consider the optimal stopping game where the sup-player chooses a stopping time  $\tau$  to maximize, and the inf-player chooses a stopping time  $\sigma$  to minimize, the expected payoff  $M_x(\tau, \sigma) = \mathbb{E}_x[G_1(X_\tau)I(\tau < \sigma) + G_2(X_\sigma)I(\sigma < \tau) + G_3(X_\tau)I(\tau = \sigma)]$ , where  $X_0 = x$  under  $\mathbb{P}_x$ . Define the upper value and the lower value of the game by  $V^*(x) = \inf_\sigma \sup_\tau M_x(\tau, \sigma)$  and  $V_*(x) = \sup_\tau \inf_\sigma M_x(\tau, \sigma)$ , respectively, where the horizon  $T$  (the upper bound for  $\tau$  and  $\sigma$  above) may be either finite or infinite (it is assumed that  $G_1(X_T) = G_2(X_T)$  if  $T$  is finite and  $\liminf_{t \rightarrow \infty} G_2(X_t) \leq \limsup_{t \rightarrow \infty} G_1(X_t)$  if  $T$  is infinite). If  $X$  is right-continuous, then the *Stackelberg equilibrium* holds, in the sense that  $V^*(x) = V_*(x)$  for all  $x$  with  $V := V^* = V_*$  defining a measurable function. If  $X$  is right-continuous and left-continuous over stopping times (quasi-left-continuous), then the *Nash equilibrium* holds, in the sense that there exist stopping times  $\tau_*$  and  $\sigma_*$  such that  $M_x(\tau, \sigma_*) \leq M_x(\tau_*, \sigma_*) \leq M_x(\tau_*, \sigma)$  for all stopping times  $\tau$  and  $\sigma$ , implying also that  $V(x) = M_x(\tau_*, \sigma_*)$  for all  $x$ . Further properties of the value function  $V$  and the optimal stopping times  $\tau_*$  and  $\sigma_*$  are exhibited in the proof.

**1. Introduction.** Let  $X = (X_t)_{t \geq 0}$  be a strong Markov process, and let  $G_1$ ,  $G_2$ , and  $G_3$  be continuous functions satisfying  $G_1 \leq G_3 \leq G_2$  (for further details see section 2 below). Consider the optimal stopping game where the sup-player chooses a stopping time  $\tau$  to maximize, and the inf-player chooses a stopping time  $\sigma$  to minimize, the expected payoff

$$(1.1) \quad M_x(\tau, \sigma) = \mathbb{E}_x[G_1(X_\tau)I(\tau < \sigma) + G_2(X_\sigma)I(\sigma < \tau) + G_3(X_\tau)I(\tau = \sigma)],$$

where  $X_0 = x$  under  $\mathbb{P}_x$ .

Define the upper value and the lower value of the game by

$$(1.2) \quad V^*(x) = \inf_\sigma \sup_\tau M_x(\tau, \sigma) \quad \text{and} \quad V_*(x) = \sup_\tau \inf_\sigma M_x(\tau, \sigma),$$

respectively, where the horizon  $T$  (the upper bound for  $\tau$  and  $\sigma$  above) may be either finite or infinite (it is assumed that  $G_1(X_T) = G_2(X_T)$  if  $T$  is finite and  $\liminf_{t \rightarrow \infty} G_2(X_t) \leq \limsup_{t \rightarrow \infty} G_1(X_t)$  if  $T$  is infinite). Note that  $V_*(x) \leq V^*(x)$  for all  $x$ .

In this context one distinguishes: (i) the *Stackelberg equilibrium*, meaning that

$$(1.3) \quad V^*(x) = V_*(x)$$

for all  $x$  (in this case  $V := V^* = V_*$  unambiguously defines the value of the game), and (ii) the *Nash equilibrium*, meaning that there exist stopping times  $\tau_*$  and  $\sigma_*$  such

<sup>†</sup>School of Mathematics, The University of Manchester, Oxford Road, Manchester M13 9PL, UK (ekstrom@maths.man.ac.uk, [www.maths.man.ac.uk/ekstrom](http://www.maths.man.ac.uk/ekstrom), goran@maths.man.ac.uk, [www.maths.man.ac.uk/goran](http://www.maths.man.ac.uk/goran)).

that

$$(1.4) \quad M_x(\tau, \sigma_*) \leq M_x(\tau_*, \sigma_*) \leq M_x(\tau_*, \sigma)$$

for all stopping times  $\tau$  and  $\sigma$  and for all  $x$  (in other words  $(\tau_*, \sigma_*)$  is a saddle point). It is easily seen that the Nash equilibrium implies the Stackelberg equilibrium with  $V(x) = M_x(\tau_*, \sigma_*)$  for all  $x$ .

A variant of the problem above was first studied by Dynkin [5] using martingale methods similar to those of Snell [21]. Specific examples of the same problem were studied in [9] and [12] using Markovian methods (see also [13] for martingale methods). In parallel to that, Bensoussan and Friedman (cf. [10], [2], [3]) developed an analytic approach (for diffusions) based on variational inequalities. Martingale methods were further advanced in [18] (see also [23]), and Markovian setting was studied in [8] (via Wald–Bellman equations) and [22] (via penalty equations). More recent papers on optimal stopping games include [14], [16], [1], [11], [6], [7], and [15]. These papers study specific problems and often lead to explicit solutions. For optimal stopping games with randomized stopping times, see [17] and the references therein. For connections with singular stochastic control (forward/backward SDE), see [4] and the references therein.

The most general martingale result known to date assumes an upper/lower semi-continuity from the left (cf. [18, Theorem 15, p. 42]) so that it does not cover the case of Lévy processes, for example. The most general Markovian result known to date assumes an asymptotic condition uniformly over initial points (cf. [22, Condition (A3), p. 2]) so that it is not always easily verifiable. The present paper aims at closing these gaps.

The main result of the paper (Theorem 2.1) may be summarized as follows. If  $X$  is *right-continuous*, then the *Stackelberg equilibrium* holds with a measurable value function. If  $X$  is right-continuous and *left-continuous over stopping times* (quasi-left-continuous), then the *Nash equilibrium* holds (see also Example 3.1 and Theorem 3.2). These two sufficient conditions are known to be most general in optimal stopping theory (see, e.g., [19] and [20]). Further properties of the value function  $V$  and the optimal stopping times  $\tau_*$  and  $\sigma_*$  are exhibited in the proof.

**2. Result and proof.** 1. Throughout we will consider a strong Markov process  $X = (X_t)_{t \geq 0}$  defined on a filtered probability space  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P}_x)$  and taking values in a measurable space  $(E, \mathcal{B})$ , where  $E$  is a locally compact Hausdorff space with a countable base and  $\mathcal{B}$  is the Borel  $\sigma$ -algebra on  $E$ . It will be assumed that the process  $X$  starts at  $x$  under  $\mathbb{P}_x$  for  $x \in E$  and that the sample paths of  $X$  are (first) right-continuous and (then) left-continuous over stopping times. The latter condition is often referred to as quasi-left-continuity and means that  $X_{\tau_n} \rightarrow X_\tau$   $\mathbb{P}_x$ -a.s. whenever  $\tau_n$  and  $\tau$  are stopping times such that  $\tau_n \uparrow \tau$  as  $n \rightarrow \infty$ . (Stopping times are always referred to with respect to the filtration  $(\mathcal{F}_t)_{t \geq 0}$  given above.) It is also assumed that the filtration  $(\mathcal{F}_t)_{t \geq 0}$  is right-continuous (implying that the first entry times to open and closed sets are stopping times) and that  $\mathcal{F}_0$  contains all  $\mathbb{P}_x$ -null sets from  $\mathcal{F}_\infty^X = \sigma(X_t : t \geq 0)$  (implying also that the first entry times to Borel sets are stopping times). The main example we have in mind is when  $\mathcal{F}_t = \sigma(\mathcal{F}_t^X \cup \mathcal{N})$ , where  $\mathcal{F}_t^X = \sigma(X_s : 0 \leq s \leq t)$  and  $\mathcal{N} = \{A \subseteq \Omega : \exists B \in \mathcal{F}_\infty^X, A \subseteq B, \mathbb{P}_x(B) = 0\}$  for  $t \geq 0$  with  $\mathcal{F} = \mathcal{F}_\infty$ . In addition, it is assumed that the mapping  $x \mapsto \mathbb{P}_x(F)$  is (universally) measurable for each  $F \in \mathcal{F}$ . It follows that the mapping  $x \mapsto \mathbb{E}_x(Z)$  is (universally) measurable for each (integrable) random variable  $Z$ . Finally, without loss of generality we will assume that  $\Omega$  equals the canonical space  $E^{[0, \infty)}$  with  $X_t(\omega) = \omega(t)$  for  $\omega \in \Omega$ .

and  $t \geq 0$ , so that the shift operator  $\theta_t : \Omega \rightarrow \Omega$  is well defined by  $\theta_t(\omega)(s) = \omega(t+s)$  for  $\omega \in \Omega$  and  $t, s \geq 0$ .

2. Given continuous functions  $G_1, G_2, G_3 : E \rightarrow \mathbb{R}$  satisfying  $G_1 \leq G_3 \leq G_2$  and the following integrability condition:

$$(2.1) \quad \mathbb{E}_x \sup_t |G_i(X_t)| < \infty \quad (i = 1, 2, 3)$$

for all  $x \in E$ , we consider the *optimal stopping game* where the sup-player chooses a stopping time  $\tau$  to maximize, and the inf-player chooses a stopping time  $\sigma$  to minimize, the expected payoff

$$(2.2) \quad \mathbb{M}_x(\tau, \sigma) = \mathbb{E}_x[G_1(X_\tau)I(\tau < \sigma) + G_2(X_\sigma)I(\sigma < \tau) + G_3(X_\tau)I(\tau = \sigma)],$$

where  $X_0 = x$  under  $\mathbb{P}_x$ .

Define the upper value and the lower value of the game by

$$(2.3) \quad V^*(x) = \inf_{\sigma} \sup_{\tau} \mathbb{M}_x(\tau, \sigma) \quad \text{and} \quad V_*(x) = \sup_{\tau} \inf_{\sigma} \mathbb{M}_x(\tau, \sigma),$$

respectively, where the horizon  $T$  (the upper bound for  $\tau$  and  $\sigma$  above) may be either finite or infinite. If  $T < \infty$ , then it will be assumed that  $G_1(X_T) = G_2(X_T) = G_3(X_T)$ . In this case it is most interesting to assume that  $X$  is a time-space process  $(t, Y_t)$  for  $t \in [0, T]$ , so that  $G_i = G_i(t, y)$  will be functions of both time and space for  $i = 1, 2, 3$ . If  $T = \infty$ , then it will be assumed that  $\liminf_{t \rightarrow \infty} G_2(X_t) \leq \limsup_{t \rightarrow \infty} G_1(X_t)$ , and the common value for  $G_3(X_\infty)$  could formally be assigned as either of the preceding two values (if  $\tau$  and  $\sigma$  are allowed to take the value  $\infty$ ) yielding the same results as in Theorem 2.1 below. For simplicity of the exposition, however, we will assume that  $\tau$  and  $\sigma$  in (2.2) are finite valued.

3. The main result of the paper may now be stated as follows.

**THEOREM 2.1.** *Consider the optimal stopping game (2.3). If  $X$  is right-continuous, then the Stackelberg equilibrium (1.3) holds with  $V := V^* = V_*$  defining a measurable function. If  $X$  is right-continuous and left-continuous over stopping times, then the Nash equilibrium (1.4) holds with*

$$(2.4) \quad \tau_* = \inf \{t : X_t \in D_1\} \quad \text{and} \quad \sigma_* = \inf \{t : X_t \in D_2\},$$

where  $D_1 = \{V = G_1\}$  and  $D_2 = \{V = G_2\}$ .

*Proof.* Both finite and infinite horizons can be treated by slight modifications of the same method which we will therefore present without referring to the horizon.

(I) In the first part of the proof we will assume that  $X$  is right-continuous, and we will show that this hypothesis implies the Stackelberg equilibrium with  $V := V^* = V_*$  defining a measurable function. This will be done in a number of steps as follows.

1. Given  $\varepsilon > 0$  set

$$(2.5) \quad D_1^\varepsilon = \{V^* \leq G_1 + \varepsilon\} \quad \text{and} \quad D_2^\varepsilon = \{V_* \geq G_2 - \varepsilon\},$$

and consider the stopping times

$$(2.6) \quad \tau_\varepsilon = \inf \{t : X_t \in D_1^\varepsilon\} \quad \text{and} \quad \sigma_\varepsilon = \inf \{t : X_t \in D_2^\varepsilon\}.$$

The key is to show that

$$(2.7) \quad \mathbb{M}_x(\tau, \sigma_\varepsilon) - \varepsilon \leq V_*(x) \leq V^*(x) \leq \mathbb{M}_x(\tau_\varepsilon, \sigma) + \varepsilon$$

for all  $\tau, \sigma, x$ , and  $\varepsilon > 0$ . Indeed, suppose that (2.7) is valid. Then

$$(2.8) \quad V^*(x) \leq \inf_{\sigma} M_x(\tau_{\varepsilon}, \sigma) + \varepsilon \leq \sup_{\tau} \inf_{\sigma} M_x(\tau, \sigma) + \varepsilon = V_*(x) + \varepsilon$$

for all  $\varepsilon > 0$ . Letting  $\varepsilon \downarrow 0$  we see that  $V^* = V_*$ , and the claim follows (up to measurability which will be derived below).

Since the first inequality in (2.7) is analogous to the third one, and since the second inequality holds generally, we focus on establishing the third one, which states that

$$(2.9) \quad V^*(x) \leq M_x(\tau_{\varepsilon}, \sigma) + \varepsilon$$

for all  $\sigma, x$ , and  $\varepsilon > 0$ .

2. To prove (2.9) take any stopping time  $\sigma$ , and consider the optimal stopping problem

$$(2.10) \quad \hat{V}_{\sigma}^*(x) = \sup_{\tau} \hat{M}_x(\tau, \sigma),$$

where we set

$$(2.11) \quad \hat{M}_x(\tau, \sigma) = E_x[G_1(X_{\tau})I(\tau < \sigma) + G_2(X_{\sigma})I(\sigma \leq \tau)].$$

Note that the gain process  $G^{\sigma}$  in (2.10) is given by

$$(2.12) \quad G_t^{\sigma} = G_1(X_t)I(t < \sigma) + G_2(X_{\sigma})I(\sigma \leq t),$$

from which we see that  $G^{\sigma}$  is right-continuous and adapted (satisfying also a sufficient integrability condition which can be derived using (2.1)). Thus general optimal stopping results of the martingale approach (cf. [19]) are applicable to the problem (2.10). In order to make use of these results in the Markovian setting of the present theorem (where  $P_x$  forms a family of probability measures when  $x$  runs through  $E$ ), we will first verify a regularity property of the value function  $\hat{V}_{\sigma}^*$ .

3. We show that the function  $x \mapsto \hat{V}_{\sigma}^*(x)$  defined in (2.10) is measurable. The basic idea of the proof is to embed the problem (2.10) into a setting of the Wald–Bellman equations (cf. [19]) and then exploit the underlying Markovian structure in this context.

For this, let us first assume that the stopping times  $\tau$  in (2.10) take values in a finite set, and without loss of generality let us assume that this set equals  $\{0, 1, \dots, N\}$ . Introduce the auxiliary optimal stopping problems

$$(2.13) \quad V_n^N(x) = \sup_{n \leq \tau \leq N} E_x G_{\tau}^{\sigma}$$

for  $n = N, \dots, 1, 0$ , and recall that the Wald–Bellman equations in this setting read:

$$(2.14) \quad S_n^N = G_N^{\sigma} \quad \text{for } n = N,$$

$$(2.15) \quad S_n^N = G_n^{\sigma} \vee E_x(S_{n+1}^N | \mathcal{F}_n) \quad \text{for } n = N-1, \dots, 1, 0,$$

with  $V_n^N(x) = E_x S_n^N$  for  $n = N, \dots, 1, 0$  (see, e.g., [19, pp. 3–6]). In particular, since  $V_0^N = \hat{V}_{\sigma}^*$  we see that

$$(2.16) \quad \hat{V}_{\sigma}^*(x) = E_x S_0^N$$

for all  $x$ . Thus the problem is reduced to showing that  $x \mapsto \mathbf{E}_x S_0^N$  is measurable.

If  $\sigma$  is a hitting time, then by the strong Markov property of  $X$  it follows using (2.14)–(2.15) inductively that the following identity holds:

$$(2.17) \quad S_0^N = G_1(x)I(0 < \sigma) + F_N(x) + G_2(x)I(\sigma = 0)$$

under  $\mathbf{P}_x$ , where  $x \mapsto F_N(x)$  is a measurable function obtained by means of the following recursive relations:

$$(2.18) \quad F_n(x) = \mathbf{E}_x[G_1(X_1)I(1 < \sigma) \vee F_{n-1}(x)] + \mathbf{E}_x[G_2(X_\sigma)I(0 < \sigma \leq 1)]$$

for  $n = 1, 2, \dots, N$ , where  $F_0 \equiv -\infty$ . Taking  $\mathbf{E}_x$  in (2.17) and using (2.16) we get

$$(2.19) \quad \hat{V}_\sigma^*(x) = G_1(x)\mathbf{P}_x(0 < \sigma) + F_N(x) + G_2(x)\mathbf{P}_x(\sigma = 0)$$

for all  $x$ . Hence we see that  $x \mapsto \hat{V}_\sigma^*(x)$  is measurable as claimed. In the case of a general stopping time  $\sigma$  one can make use of the extended Radon–Nikodym theorem, which states that  $(x, \omega) \mapsto \mathbf{E}_x(Z_x | \mathcal{G})(\omega)$  is measurable when  $(x, \omega) \mapsto Z_x(\omega)$  is measurable and  $\mathcal{G} \subseteq \mathcal{F}$  is a  $\sigma$ -algebra. Applying this fact inductively in (2.15) and using (2.16) it follows that  $x \mapsto \hat{V}_\sigma^*(x)$  is measurable as claimed. [Note that this argument also applies when  $\sigma$  is a hitting time; however, the explicit formula (2.19) is no longer available if  $\sigma$  is a general stopping time.]

Let us now consider the general case when the stopping times  $\tau$  from (2.10) can take arbitrary values. Setting  $\tau_n = k/2^n$  on  $\{(k-1)/2^n < \tau \leq k/2^n\}$  one knows that each  $\tau_n$  is a stopping time with values in the set  $Q_n$  of dyadic rationals of the form  $k/2^n$ , and  $\tau_n \downarrow \tau$  as  $n \rightarrow \infty$ . Hence by right-continuity of  $G^\sigma$  and Fatou's lemma (using a needed integrability condition which is derived by means of (2.1) above), one gets

$$(2.20) \quad \mathbf{E}_x G_\tau^\sigma = \mathbf{E}_x \left( \lim_{n \rightarrow \infty} G_{\tau_n}^\sigma \right) \leq \liminf_{n \rightarrow \infty} \mathbf{E}_x G_{\tau_n}^\sigma \leq \sup_{n \geq 1} V_n(x),$$

where we set

$$(2.21) \quad V_n(x) = \sup_{\tau \in Q_n} \mathbf{E}_x G_\tau^\sigma.$$

Taking the supremum in (2.20) over all  $\tau$ , and using that  $V_n \leq \hat{V}_\sigma^*$  for all  $n \geq 1$ , it follows that

$$(2.22) \quad \hat{V}_\sigma^*(x) = \sup_{n \geq 1} V_n(x)$$

for all  $x$ . By the first part of the proof above we know that each function  $x \mapsto V_n(x)$  is measurable, so it follows from (2.22) that  $x \mapsto \hat{V}_\sigma^*(x)$  is measurable as claimed.

4. Since the function  $x \mapsto \hat{V}_\sigma^*(x)$  is measurable, it follows that

$$(2.23) \quad \hat{V}_\sigma^*(X_\rho) = \sup_{\tau} \hat{\mathbf{M}}_{X_\rho}(\tau, \sigma)$$

defines a random variable for any stopping time  $\rho$  which is given and fixed. On the other hand, by the strong Markov property we have

$$\begin{aligned}
 (2.24) \quad \hat{M}_{X_\rho}(\tau, \sigma) &= E_{X_\rho} [G_1(X_\tau) I(\tau < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau)] \\
 &= E_x [G_1(X_{\rho+\tau \circ \theta_\rho}) I(\rho + \tau \circ \theta_\rho < \rho + \sigma \circ \theta_\rho) \\
 &\quad + G_2(X_{\rho+\sigma \circ \theta_\rho}) I(\rho + \sigma \circ \theta_\rho \leq \rho + \tau \circ \theta_\rho) | \mathcal{F}_\rho].
 \end{aligned}$$

From (2.23) and (2.24) we see that

$$(2.25) \quad \hat{V}_\sigma^*(X_\rho) = \operatorname{ess\,sup}_\tau \hat{M}_x(\rho + \tau \circ \theta_\rho, \rho + \sigma \circ \theta_\rho | \mathcal{F}_\rho),$$

where we set

$$(2.26) \quad \hat{M}_x(\tau_\rho, \sigma_\rho | \mathcal{F}_\rho) = E_x [G_1(X_{\tau_\rho}) I(\tau_\rho < \sigma_\rho) + G_2(X_{\sigma_\rho}) I(\sigma_\rho \leq \tau_\rho) | \mathcal{F}_\rho],$$

with  $\tau_\rho = \rho + \tau \circ \theta_\rho$  and  $\sigma_\rho = \rho + \sigma \circ \theta_\rho$  (being stopping times).

5. By general optimal-stopping results of the martingale approach (cf. [19]), we know that the supermartingale

$$(2.27) \quad \hat{S}_t^\sigma = \operatorname{ess\,sup}_{\tau \geq t} \hat{M}_x(\tau, \sigma | \mathcal{F}_t)$$

admits a right-continuous modification (the Snell envelope) such that

$$(2.28) \quad \hat{V}_\sigma^*(x) = E_x \hat{S}_\rho^\sigma$$

for every stopping time  $\rho \leq \tau_\varepsilon^\sigma$ , where

$$(2.29) \quad \tau_\varepsilon^\sigma = \inf \{ t : \hat{S}_t^\sigma \leq G_t^\sigma + \varepsilon \}.$$

Moreover, by the well-known properties of the Snell envelope (stating that equality between the essential supremum and its right-continuous modification is preserved at stopping times and that the essential supremum is attained over hitting times), we see upon recalling (2.25) above that the following identity holds:

$$(2.30) \quad \hat{V}_\sigma^*(X_\rho) = \hat{S}_\rho^\sigma \quad \text{P}_x\text{-a.s.}$$

for every stopping time  $\rho \leq \sigma$ . The precise meaning of (2.30) is

$$(2.30') \quad \hat{V}_{\sigma^\rho(\omega, \cdot)}^*(X_\rho(\omega)) = \hat{S}_\rho^\sigma(\omega)$$

for  $\omega \in \Omega \setminus N$ , with  $P_x(N) = 0$ , where  $\sigma(\omega) = \rho(\omega) + \sigma^\rho(\omega, \theta_\rho(\omega))$  for a mapping  $(\omega, \omega') \mapsto \sigma^\rho(\omega, \omega')$  which is  $\mathcal{F}_\rho \otimes \mathcal{F}_\infty$ -measurable and  $\omega' \mapsto \sigma^\rho(\omega, \omega')$  is a stopping time for each  $\omega$  given and fixed. We will simplify the notation in what follows by dropping  $\rho$  and  $\omega$  from  $\sigma^\rho(\omega, \cdot)$  in (2.30') and simply writing  $\sigma$  instead. This also applies to the expression on the right-hand side of (2.23) above. [Note that, if  $\sigma$  is a hitting time, then  $\sigma^\rho(\omega, \omega') = \sigma(\omega')$  for all  $\omega$  and  $\omega'$ , and this simplification is exact.] In particular, using (2.30) with  $\rho = t$  and the fact that  $\hat{S}^\sigma$  and  $G^\sigma$  are right-continuous, we see that  $\tau_\varepsilon^\sigma$  from (2.29) can be equivalently defined as

$$(2.31) \quad \tau_\varepsilon^\sigma = \inf \{ t \in Q : \hat{V}_\sigma^*(X_t) \leq G_t^\sigma + \varepsilon \},$$

where  $Q$  is any (given and fixed) countable dense subset of the time set.

6. Setting

$$(2.32) \quad \hat{V}^*(x) = \inf_\sigma \sup_\tau \hat{M}_x(\tau, \sigma)$$

for  $x \in E$ , let us assume that the function  $x \mapsto \hat{V}^*(x)$  is measurable, and let us consider the stopping time  $\tau_\varepsilon$  from (2.6) above but defined over  $Q$  for  $\hat{V}^*$ , i.e.,

$$(2.33) \quad \tilde{\tau}_\varepsilon = \inf \{ t \in Q : X_t \in \hat{D}_1^\varepsilon \},$$

where  $\hat{D}_1^\varepsilon = \{ \hat{V}^* \leq G_1 + \varepsilon \}$ . Let a stopping time  $\beta$  be given and fixed, and let  $\sigma$  be any stopping time satisfying  $\sigma \geq \beta \wedge \tilde{\tau}_\varepsilon$ . Then, for any  $t \in Q$  such that  $t < \beta \wedge \tilde{\tau}_\varepsilon$ , we have

$$(2.34) \quad \begin{aligned} \hat{V}_\sigma^*(X_t) &\geq \hat{V}^*(X_t) > G_1(X_t) + \varepsilon \\ &= G_1(X_t) I(t < \sigma) + G_2(X_\sigma) I(\sigma \leq t) + \varepsilon \\ &= G_t^\sigma + \varepsilon, \end{aligned}$$

since  $t < \sigma$  so that  $I(\sigma \leq t) = 0$ . Hence we see by (2.31) that  $\beta \wedge \tilde{\tau}_\varepsilon \leq \tau_\varepsilon^\sigma$ . By (2.28) and (2.30) we can conclude that

$$(2.35) \quad \hat{V}_\sigma^*(x) = \mathbf{E}_x \hat{V}_\sigma^*(X_{\beta \wedge \tilde{\tau}_\varepsilon})$$

for any  $\sigma \geq \beta \wedge \tilde{\tau}_\varepsilon$ . Taking the infimum over all such  $\sigma$  we obtain

$$(2.36) \quad V^*(x) \leq \hat{V}^*(x) \leq \inf_{\sigma \geq \beta \wedge \tilde{\tau}_\varepsilon} \hat{V}_\sigma^*(x) = \inf_{\sigma \geq \beta \wedge \tilde{\tau}_\varepsilon} \mathbf{E}_x \hat{V}_\sigma^*(X_{\beta \wedge \tilde{\tau}_\varepsilon})$$

for every stopping time  $\beta$ . In the next step we will show that the infimum and the expectation in (2.36) can be interchanged.

7. We show that the family of random variables

$$(2.37) \quad \left\{ \sup_\tau \hat{M}_{X_\rho}(\tau, \sigma) : \sigma \text{ is a stopping time} \right\}$$

is downwards directed. Recall that a family of random variables  $\{Z_\sigma : \sigma \in I\}$  is downwards directed if for all  $\sigma_1, \sigma_2 \in I$  there exists  $\sigma_3 \in I$  such that  $Z_{\sigma_3} \leq Z_{\sigma_1} \wedge Z_{\sigma_2}$   $\mathbf{P}_x$ -a.s. for all  $x$ .

To prove the claim, recall that by the strong Markov property we have

$$(2.38) \quad \hat{M}_{X_\rho}(\tau, \sigma) = \hat{M}_x(\rho + \tau \circ \theta_\rho, \rho + \sigma \circ \theta_\rho | \mathcal{F}_\rho).$$

If  $\sigma_1$  and  $\sigma_2$  are two stopping times given and fixed, set  $\tau_\rho = \rho + \tau \circ \theta_\rho$ ,  $\sigma'_1 = \rho + \sigma_1 \circ \theta_\rho$ , and  $\sigma'_2 = \rho + \sigma_2 \circ \theta_\rho$ , and define

$$(2.39) \quad B = \left\{ \sup_\tau \hat{M}_x(\tau_\rho, \sigma'_1 | \mathcal{F}_\rho) \leq \sup_\tau \hat{M}_x(\tau_\rho, \sigma'_2 | \mathcal{F}_\rho) \right\}.$$

Then  $B \in \mathcal{F}_\rho$ , and the random variable

$$(2.40) \quad \sigma' := \sigma'_1 I_B + \sigma'_2 I_{B^c}$$

is a stopping time. For this, note that  $\{\sigma' \leq t\} = (\{\sigma'_1 \leq t\} \cap B) \cup (\{\sigma'_2 \leq t\} \cap B^c) = (\{\sigma'_1 \leq t\} \cap B \cap \{\rho \leq t\}) \cup (\{\sigma'_2 \leq t\} \cap B^c \cap \{\rho \leq t\}) \in \mathcal{F}_t$ , since  $B$  and  $B^c$  belong to  $\mathcal{F}_\rho$ , which verifies the claim.

Moreover, the stopping time  $\sigma'$  can be written as

$$(2.41) \quad \sigma' = \rho + \sigma \circ \theta_\rho$$

for some stopping time  $\sigma$ . Indeed, setting

$$(2.42) \quad A = \left\{ \sup_{\tau} \hat{M}_{X_0}(\tau, \sigma_1) \leq \sup_{\tau} \hat{M}_{X_0}(\tau, \sigma_2) \right\},$$

we see that  $A \in \mathcal{F}_0$  and  $B = \theta_{\rho}^{-1}(A)$  upon recalling (2.38). Hence from (2.40) we get

$$(2.43) \quad \begin{aligned} \sigma' &= (\rho + \sigma_1 \circ \theta_{\rho}) I_B + (\rho + \sigma_2 \circ \theta_{\rho}) I_{B^c} \\ &= \rho + [(\sigma_1 \circ \theta_{\rho})(I_A \circ \theta_{\rho}) + (\sigma_2 \circ \theta_{\rho})(I_{A^c} \circ \theta_{\rho})] \\ &= \rho + (\sigma_1 I_A + \sigma_2 I_{A^c}) \circ \theta_{\rho}, \end{aligned}$$

which implies that (2.41) holds with the stopping time  $\sigma = \sigma_1 I_A + \sigma_2 I_{A^c}$ . (The latter is a stopping time since  $\{\sigma \leq t\} = (\{\sigma_1 \leq t\} \cap A) \cup (\{\sigma_2 \leq t\} \cap A^c) \in \mathcal{F}_t$  due to the fact that  $A \in \mathcal{F}_0 \subseteq \mathcal{F}_t$  for all  $t$ .)

Finally, we have

$$(2.44) \quad \begin{aligned} \sup_{\tau} \hat{M}_{X_{\rho}}(\tau, \sigma) &= \sup_{\tau} \hat{M}_x(\tau_{\rho}, \sigma'_1 | \mathcal{F}_{\rho}) I_B + \sup_{\tau} \hat{M}_x(\tau_{\rho}, \sigma'_2 | \mathcal{F}_{\rho}) I_{B^c} \\ &= \sup_{\tau} \hat{M}_x(\tau_{\rho}, \sigma'_1 | \mathcal{F}_{\rho}) \wedge \sup_{\tau} \hat{M}_x(\tau_{\rho}, \sigma'_2 | \mathcal{F}_{\rho}) \\ &= \sup_{\tau} \hat{M}_{X_{\rho}}(\tau, \sigma_1) \wedge \sup_{\tau} \hat{M}_{X_{\rho}}(\tau, \sigma_2), \end{aligned}$$

which proves that the family (2.37) is downwards directed as claimed.

8. It is well-known (see, e.g., [19, pp. 6–7]) that, if a family  $\{Z_{\sigma} : \sigma \in I\}$  of random variables is downwards directed, there exists a countable subset  $J = \{\sigma_n : n \geq 1\}$  of  $I$  such that

$$(2.45) \quad \operatorname{ess\,inf}_{\sigma \in I} Z_{\sigma} = \lim_{n \rightarrow \infty} Z_{\sigma_n} \quad \mathbb{P}_x\text{-a.s.},$$

where  $Z_{\sigma_1} \geq Z_{\sigma_2} \geq \dots$   $\mathbb{P}_x$ -a.s. In particular, if there exists a random variable  $Z$  such that  $\mathbb{E}_x Z < \infty$  and  $Z_{\sigma} \leq Z$  for all  $\sigma \in I$ , then

$$(2.46) \quad \mathbb{E}_x \operatorname{ess\,inf}_{\sigma \in I} Z_{\sigma} = \lim_{n \rightarrow \infty} \mathbb{E}_x Z_{\sigma_n} = \inf_{\sigma \in I} \mathbb{E}_x Z_{\sigma};$$

i.e., the order of the infimum and the expectation can be interchanged.

Applying the preceding general fact to the family in (2.37) upon returning to (2.36) we can conclude that

$$(2.47) \quad V^*(x) \leq \hat{V}^*(x) \leq \inf_{\sigma \geq \beta \wedge \tilde{\tau}_{\varepsilon}} \mathbb{E}_x \hat{V}_{\sigma}^*(X_{\beta \wedge \tilde{\tau}_{\varepsilon}}) = \mathbb{E}_x \hat{V}^*(X_{\beta \wedge \tilde{\tau}_{\varepsilon}}).$$

In the next step we will relate the process  $\hat{V}^*(X_{\tilde{\tau}_{\varepsilon}})$  to yet another right-continuous modification which will play a useful role in what follows.

9. We show that the process

$$(2.48) \quad \hat{S}_{t \wedge \tilde{\tau}_{\varepsilon}} = \operatorname{ess\,inf}_{\sigma \geq t \wedge \tilde{\tau}_{\varepsilon}} \hat{S}_{\sigma}^{\sigma}$$

admits a right-continuous modification. For this, simplify the notation by setting

$$(2.49) \quad \hat{S}_t^{\varepsilon} = \hat{S}_{t \wedge \tilde{\tau}_{\varepsilon}} \quad \text{and} \quad M_t^{\sigma} = \hat{S}_{t \wedge \tilde{\tau}_{\varepsilon}}^{\sigma},$$

and note that the (stopped) process  $M^{\sigma}$  is a martingale. Indeed, recalling the conclusion in relation to (2.34) above that if  $\sigma \geq t \wedge \tilde{\tau}_{\varepsilon}$ , then  $t \wedge \tilde{\tau}_{\varepsilon} \leq \tau_{\varepsilon}^{\sigma}$ , we see that

the martingale property follows by (2.28) above (this is a well-known property of the Snell envelope).

Moreover, since by (2.30) we have

$$(2.50) \quad \hat{S}_{t \wedge \tilde{\tau}_\varepsilon}^\sigma = \sup_\tau \hat{M}_{X_{t \wedge \tilde{\tau}_\varepsilon}}(\tau, \sigma)$$

when  $\sigma \geq t \wedge \tilde{\tau}_\varepsilon$ , it follows by (2.37) and (2.48) that there exists a sequence of stopping times  $\{\sigma_n : n \geq 1\}$  satisfying  $\sigma_n \geq t \wedge \tilde{\tau}_\varepsilon$  such that

$$(2.51) \quad \hat{S}_t^\varepsilon = \lim_{n \rightarrow \infty} M_t^{\sigma_n} \quad \mathbb{P}_x\text{-a.s.},$$

where  $M_t^{\sigma_1} \geq M_t^{\sigma_2} \geq \dots$   $\mathbb{P}_x$ -a.s. Hence by the conditional monotone convergence theorem (using the integrability condition (2.1) above), we find for  $s < t$  that

$$(2.52) \quad \mathbb{E}_x(\hat{S}_t^\varepsilon | \mathcal{F}_s) = \lim_{n \rightarrow \infty} \mathbb{E}_x(M_t^{\sigma_n} | \mathcal{F}_s) = \lim_{n \rightarrow \infty} M_s^{\sigma_n} \geq \hat{S}_s^\varepsilon,$$

where the martingale property of  $M^{\sigma_n}$  and the definition of  $\hat{S}_s^\varepsilon$  are used. This shows that  $\hat{S}^\varepsilon$  is a submartingale.

A well-known result in martingale theory states that the submartingale  $\hat{S}^\varepsilon$  admits a right-continuous modification if and only if

$$(2.53) \quad t \mapsto \mathbb{E}_x \hat{S}_t^\varepsilon \text{ is right-continuous.}$$

To verify (2.53) note that by the submartingale property of  $\hat{S}^\varepsilon$  we have  $\mathbb{E}_x \hat{S}_t^\varepsilon \leq \dots \leq \mathbb{E}_x \hat{S}_{t_2}^\varepsilon \leq \mathbb{E}_x \hat{S}_{t_1}^\varepsilon$ , so that  $L := \lim_{n \rightarrow \infty} \mathbb{E}_x \hat{S}_{t_n}^\varepsilon$  exists and  $\mathbb{E}_x \hat{S}_t^\varepsilon \leq L$  whenever  $t_n \downarrow t$  as  $n \rightarrow \infty$  is given and fixed. To prove the reverse inequality, fix  $N \geq 1$ , and by means of (2.51) and the monotone convergence theorem choose  $\sigma \geq t \wedge \tilde{\tau}_\varepsilon$  such that

$$(2.54) \quad \mathbb{E}_x M_t^\sigma \leq \mathbb{E}_x \hat{S}_t^\varepsilon + 1/N.$$

Fix  $\delta > 0$ , and note that there is no restriction to assume that  $t_n \in [t, t + \delta]$  for all  $n \geq 1$ . Define a stopping time  $\sigma_n$  by setting

$$(2.55) \quad \sigma_n = \begin{cases} \sigma & \text{if } \sigma > t_n \wedge \tilde{\tau}_\varepsilon, \\ t \wedge \tilde{\tau}_\varepsilon + \delta & \text{if } \sigma \leq t_n \wedge \tilde{\tau}_\varepsilon \end{cases}$$

for  $n \geq 1$ . Then for all  $n \geq 1$  we have

$$(2.56) \quad \mathbb{E}_x M_t^{\sigma_n} = \mathbb{E}_x M_{t_n}^{\sigma_n} \geq \mathbb{E}_x \hat{S}_{t_n}^\varepsilon$$

by the martingale property of  $M^{\sigma_n}$  and the definition of  $\hat{S}_{t_n}^\varepsilon$  using that  $\sigma_n \geq t_n \wedge \tilde{\tau}_\varepsilon \geq t \wedge \tilde{\tau}_\varepsilon$ .

Since  $\{\sigma > t_n \wedge \tilde{\tau}_\varepsilon\}$  and  $\{\sigma \leq t_n \wedge \tilde{\tau}_\varepsilon\}$  belong to  $\mathcal{F}_{t_n \wedge \tilde{\tau}_\varepsilon}$ , it is easily verified using (2.30) above that  $M_{t_n}^{\sigma_n} I(\sigma > t_n \wedge \tilde{\tau}_\varepsilon) = M_{t_n}^\sigma I(\sigma > t_n \wedge \tilde{\tau}_\varepsilon)$  and  $M_{t_n}^{\sigma_n} I(\sigma \leq t_n \wedge \tilde{\tau}_\varepsilon) = M_{t_n}^{t \wedge \tilde{\tau}_\varepsilon + \delta} I(\sigma \leq t_n \wedge \tilde{\tau}_\varepsilon)$  for all  $n \geq 1$ . Hence

$$(2.57) \quad \mathbb{E}_x M_{t_n}^{\sigma_n} = \mathbb{E}_x [M_{t_n}^\sigma I(\sigma > t_n \wedge \tilde{\tau}_\varepsilon) + M_{t_n}^{t \wedge \tilde{\tau}_\varepsilon + \delta} I(\sigma \leq t_n \wedge \tilde{\tau}_\varepsilon)]$$

for all  $n \geq 1$ . Letting  $n \rightarrow \infty$  in (2.56) and using (2.57) we get

$$(2.58) \quad \mathbb{E}_x [M_t^\sigma I(\sigma > t \wedge \tilde{\tau}_\varepsilon) + M_t^{t \wedge \tilde{\tau}_\varepsilon + \delta} I(\sigma \leq t \wedge \tilde{\tau}_\varepsilon)] \geq L$$

for all  $\delta > 0$ .

By (2.30) (recall also (2.30')) we have

$$\begin{aligned}
 (2.59) \quad M_t^{t \wedge \tilde{\tau}_\varepsilon + \delta} &= \hat{S}_{t \wedge \tilde{\tau}_\varepsilon}^{t \wedge \tilde{\tau}_\varepsilon + \delta} = \hat{V}_{t \wedge \tilde{\tau}_\varepsilon + \delta}^*(X_{t \wedge \tilde{\tau}_\varepsilon}) = \sup_{\tau} M_{X_{t \wedge \tilde{\tau}_\varepsilon}}(\tau, \delta) \\
 &= \sup_{\tau} \mathbb{E}_{X_{t \wedge \tilde{\tau}_\varepsilon}} [G_1(X_\tau) I(\tau < \delta) + G_2(X_\delta) I(\delta \leq \tau)] \\
 &\leq \sup_{\tau} \mathbb{E}_{X_{t \wedge \tilde{\tau}_\varepsilon}} [G_2(X_{\tau \wedge \delta})] \rightarrow G_2(X_{t \wedge \tilde{\tau}_\varepsilon}) = M_t^{t \wedge \tilde{\tau}_\varepsilon},
 \end{aligned}$$

where the convergence relation follows by

$$(2.60) \quad \left| \sup_{\tau} \mathbb{E}_x G_2(X_{\tau \wedge \delta}) - G_2(x) \right| \leq \mathbb{E}_x \sup_{0 \leq t \leq \delta} |G_2(X_t) - G_2(x)| \rightarrow 0$$

as  $\delta \downarrow 0$  upon using that  $X$  is right-continuous (at zero) and that the integrability condition (2.1) holds. Inserting (2.59) in (2.58) and using that  $\sigma \geq t \wedge \tilde{\tau}_\varepsilon$ , it follows that

$$(2.61) \quad \mathbb{E}_x M_t^\sigma \geq L.$$

Combining this with (2.54) we see that  $L \leq \mathbb{E}_x \hat{S}_t^\varepsilon$  and thus  $L = \mathbb{E}_x \hat{S}_t^\varepsilon$ . This establishes (2.53), and hence  $\hat{S}^\varepsilon$  admits a right-continuous modification (denoted by the same symbol) as claimed.

Moreover, from (2.48) and (2.50) upon using (2.37) it is easily verified that equality between the process in (2.48) and its right-continuous modification extends from deterministic times to all stopping times (via discrete stopping times upon using that each stopping time is the limit of a decreasing sequence of discrete stopping times). Hence by (2.30)+(2.32) and (2.48)+(2.49) we find that

$$(2.62) \quad \hat{V}^*(X_{\beta \wedge \tilde{\tau}_\varepsilon}) = \hat{S}_\beta^\varepsilon \quad \text{P}_x\text{-a.s.}$$

for every stopping time  $\beta$ .

10. We claim that

$$(2.63) \quad \hat{S}_{\tilde{\tau}_\varepsilon} \leq G_1(X_{\tilde{\tau}_\varepsilon}) + \varepsilon \quad \text{P}_x\text{-a.s.}$$

To verify this note first that  $\tilde{\tau}_{\varepsilon_2} \leq \tilde{\tau}_{\varepsilon_1}$  for  $\varepsilon_1 < \varepsilon_2$ , so that the right-continuous modification of (2.48) extends by letting  $\varepsilon \downarrow 0$  to become a right-continuous modification of the process

$$(2.64) \quad \hat{S}_{t \wedge \tilde{\tau}_{0-}} = \operatorname{ess\,inf}_{\sigma \geq t \wedge \tilde{\tau}_{0-}} \hat{S}_\sigma^\sigma,$$

where  $\tilde{\tau}_{0-} = \lim_{\varepsilon \downarrow 0} \tilde{\tau}_\varepsilon$  is a stopping time. But then by right-continuity of  $\hat{S}$  and  $G_1(X)$  on  $[0, \tau_{0-})$  it follows that on  $\{\tilde{\tau}_\varepsilon < \tilde{\tau}_{0-}\}$  we have the inequality (2.63) satisfied. Note that  $\tilde{\tau}_{0-} \leq \tilde{\tau}_0$ , where  $\tilde{\tau}_0$  is defined as in (2.33) with  $\varepsilon = 0$ .

To see what happens on  $\{\tilde{\tau}_\varepsilon = \tilde{\tau}_{0-}\}$ , let us consider the process

$$(2.65) \quad \hat{S}_t = \operatorname{ess\,inf}_{\sigma \geq t} \hat{S}_t^\sigma.$$

We claim that, if  $\rho_n$  and  $\rho$  are stopping times such that  $\rho_n \downarrow \rho$  as  $n \rightarrow \infty$ , then

$$(2.66) \quad \mathbb{E}_x \hat{S}_\rho \leq \liminf_{n \rightarrow \infty} \mathbb{E}_x \hat{S}_{\rho_n}.$$

Indeed, for this note first (since the families are downwards and upwards directed) that

$$(2.67) \quad \mathbb{E}_x \hat{S}_\rho = \inf_{\sigma \geq \rho} \sup_{\tau \geq \rho} \hat{M}_x(\tau, \sigma) \leq \inf_{\sigma > \rho_n} \sup_{\tau \geq \rho} \hat{M}_x(\tau, \sigma).$$

Taking  $\sigma > \rho_n$  we find that

$$(2.68) \quad \begin{aligned} \hat{M}_x(\tau, \sigma) &= \mathbb{E}_x [(G_1(X_\tau) I(\tau < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau)) I(\tau < \rho_n)] \\ &\quad + \mathbb{E}_x [(G_1(X_{\tau \vee \rho_n}) I(\tau \vee \rho_n < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau \vee \rho_n)) I(\tau \geq \rho_n)] \\ &= \mathbb{E}_x [G_1(X_\tau) I(\tau < \rho_n)] \\ &\quad + \mathbb{E}_x [G_1(X_{\tau \vee \rho_n}) I(\tau \vee \rho_n < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau \vee \rho_n)] \\ &\quad - \mathbb{E}_x [(G_1(X_{\tau \vee \rho_n}) I(\tau \vee \rho_n < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau \vee \rho_n)) I(\tau < \rho_n)] \\ &= \mathbb{E}_x [G_1(X_\tau) I(\tau < \rho_n) - G_1(X_{\rho_n}) I(\tau < \rho_n)] \\ &\quad + \mathbb{E}_x [G_1(X_{\tau \vee \rho_n}) I(\tau \vee \rho_n < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau \vee \rho_n)] \\ &= \mathbb{E}_x [G_1(X_{\tau \wedge \rho_n}) - G_1(X_{\rho_n})] + \hat{M}_x(\tau \vee \rho_n, \sigma). \end{aligned}$$

From (2.67) and (2.68) we get

$$(2.69) \quad \begin{aligned} \mathbb{E}_x \hat{S}_\rho &\leq \mathbb{E}_x \sup_{\rho \leq t \leq \rho_n} |G_1(X_t) - G_1(X_{\rho_n})| + \inf_{\sigma > \rho_n} \sup_{\tau \geq \rho_n} \hat{M}_x(\tau, \sigma) \\ &= \mathbb{E}_x \sup_{\rho \leq t \leq \rho_n} |G_1(X_t) - G_1(X_{\rho_n})| + \inf_{\sigma \geq \rho_n} \sup_{\tau \geq \rho_n} \hat{M}_x(\tau, \sigma) \\ &= \mathbb{E}_x \sup_{\rho \leq t \leq \rho_n} |G_1(X_t) - G_1(X_{\rho_n})| + \mathbb{E}_x \hat{S}_{\rho_n}, \end{aligned}$$

where the first equality can easily be justified by using that each  $\sigma$  is the limit of a strictly decreasing sequence of discrete stopping times  $\sigma_m$  as  $m \rightarrow \infty$  yielding

$$(2.70) \quad \sup_{\tau \geq \rho_n} \hat{M}_x(\tau, \sigma) \geq \limsup_{m \rightarrow \infty} \sup_{\tau \geq \rho_n} \hat{M}_x(\tau, \sigma_m),$$

which is obtained directly from (2.93) below. Letting  $n \rightarrow \infty$  in (2.69) and using that the second-last expectation tends to zero since  $G_1(X)$  is right-continuous and the integrability condition (2.1) holds, we get (2.66) as claimed.

Returning to the question of  $\{\tilde{\tau}_\varepsilon = \tilde{\tau}_0 -\}$ , consider the Borel set  $\hat{D}_1^0 = \{\hat{V}^* = G_1\}$ , and choose compact sets  $K_1 \subseteq K_2 \subseteq \dots \subseteq \hat{D}_1^0$  such that  $\tau_n := \inf\{t : X_t \in K_n\}$  satisfy  $\tau_n \downarrow \tilde{\tau}_0$   $\mathbb{P}_x$ -a.s. as  $n \rightarrow \infty$ . (The latter is a well-known consequence of the fact that each probability measure on  $E$  is tight.) Since each  $K_n$  is closed, we have  $\hat{S}_{\tau_n} = \hat{V}^*(X_{\tau_n}) = G_1(X_{\tau_n})$  by right-continuity of  $X$  for all  $n \geq 1$ . Hence by (2.66) we find

$$(2.71) \quad \mathbb{E}_x \hat{S}_{\tilde{\tau}_0} \leq \liminf_{n \rightarrow \infty} \mathbb{E}_x \hat{S}_{\tau_n} = \liminf_{n \rightarrow \infty} \mathbb{E}_x G_1(X_{\tau_n}) = \mathbb{E}_x G_1(X_{\tilde{\tau}_0})$$

by right-continuity of  $G_1(X)$  using also the integrability condition (2.1) above. Since  $\hat{S}_{\tilde{\tau}_0} \geq G_1(X_{\tilde{\tau}_0})$   $\mathbb{P}_x$ -a.s. by definition, we see from (2.71) that  $\hat{S}_{\tilde{\tau}_0} = G_1(X_{\tilde{\tau}_0})$   $\mathbb{P}_x$ -a.s. Moreover, if we consider the Borel set  $\hat{D}_1^\varepsilon = \{\hat{V}^* \leq G_1 + \varepsilon\}$  and likewise choose stopping times  $\tau_n^\varepsilon$  satisfying  $\tau_n^\varepsilon \downarrow \tilde{\tau}_\varepsilon$   $\mathbb{P}_x$ -a.s., then the same arguments as in (2.71) show that

$$\begin{aligned}
(2.72) \quad \mathbb{E}_x G_1(X_{\tilde{\tau}_0-}) &= \mathbb{E}_x \lim_{\varepsilon \downarrow 0} G_1(X_{\tilde{\tau}_\varepsilon}) \leq \mathbb{E}_x \liminf_{\varepsilon \downarrow 0} \hat{S}_{\tilde{\tau}_\varepsilon} \leq \liminf_{\varepsilon \downarrow 0} \mathbb{E}_x \hat{S}_{\tilde{\tau}_\varepsilon} \\
&\leq \liminf_{\varepsilon \downarrow 0} \left( \liminf_{n \rightarrow \infty} \mathbb{E}_x \hat{S}_{\tau_n^\varepsilon} \right) \leq \liminf_{\varepsilon \downarrow 0} \left( \liminf_{n \rightarrow \infty} \mathbb{E}_x G_1(X_{\tau_n^\varepsilon}) + \varepsilon \right) \\
&= \mathbb{E}_x G_1(X_{\tilde{\tau}_0-})
\end{aligned}$$

upon using that  $G_1(X_{\tilde{\tau}_\varepsilon}) \leq \hat{S}_{\tilde{\tau}_\varepsilon}$   $\mathbb{P}_x$ -a.s. and applying Fatou's lemma. Hence all of the inequalities in (2.72) are equalities, and thus

$$(2.73) \quad G_1(X_{\tilde{\tau}_0-}) = \liminf_{\varepsilon \downarrow 0} \hat{S}_{\tilde{\tau}_\varepsilon} \quad \mathbb{P}_x\text{-a.s.}$$

Since  $\tilde{\tau}_\varepsilon \uparrow \tilde{\tau}_0-$  as  $\varepsilon \downarrow 0$ , we see from (2.73) that  $G_1(X_{\tilde{\tau}_0-}) = \hat{S}_{\tilde{\tau}_0-}$   $\mathbb{P}_x$ -a.s. on  $\{\tilde{\tau}_\varepsilon = \tilde{\tau}_0-\}$ . This implies that  $\tilde{\tau}_0 \leq \tilde{\tau}_0-$  and thus  $\tilde{\tau}_0 = \tilde{\tau}_0-$  both  $\mathbb{P}_x$ -a.s. on  $\{\tilde{\tau}_\varepsilon = \tilde{\tau}_0-\}$ . Recalling also that  $\hat{S}_{\tilde{\tau}_0} = G_1(X_{\tilde{\tau}_0})$   $\mathbb{P}_x$ -a.s. we finally see that on  $\{\tilde{\tau}_\varepsilon = \tilde{\tau}_0-\}$  one has  $\hat{S}_{\tilde{\tau}_\varepsilon} = \hat{S}_{\tilde{\tau}_0} = G_1(X_{\tilde{\tau}_0}) = G_1(X_{\tilde{\tau}_\varepsilon}) \leq G_1(X_{\tilde{\tau}_\varepsilon}) + \varepsilon$   $\mathbb{P}_x$ -a.s. so that (2.63) holds as claimed. [Note that (2.63) can also be obtained by showing that  $\hat{S}$  defined in (2.65) admits a right-continuous modification. This proof can be used instead of parts 9 and 10 above, which focused on exploiting the submartingale characterization (2.53) above.]

11. Inserting (2.62) into (2.47) and using (2.63) we get

$$\begin{aligned}
(2.74) \quad V^*(x) &\leq \hat{V}^*(x) \leq \mathbb{E}_x \hat{S}_\beta^\varepsilon = \mathbb{E}_x [\hat{S}_{\tilde{\tau}_\varepsilon} I(\tilde{\tau}_\varepsilon \leq \beta) + \hat{S}_\beta I(\beta < \tilde{\tau}_\varepsilon)] \\
&\leq \mathbb{E}_x [(G_1(X_{\tilde{\tau}_\varepsilon}) + \varepsilon) I(\tilde{\tau}_\varepsilon < \beta) + G_2(X_\beta) I(\beta < \tilde{\tau}_\varepsilon) \\
&\quad + (G_3(X_{\tilde{\tau}_\varepsilon}) + \varepsilon) I(\tilde{\tau}_\varepsilon = \beta)] \\
&\leq M_x(\tilde{\tau}_\varepsilon, \beta) + \varepsilon
\end{aligned}$$

for every stopping time  $\beta$ . Proceeding as in (2.8) above we find that  $\hat{V}^* = V^* = V_*$ , and thus (2.63) yields (2.9) with  $\tilde{\tau}_\varepsilon$  in place of  $\tau_\varepsilon$ .

12. To derive (2.9) with  $\tau_\varepsilon$  from (2.6), first note that  $\tau_\varepsilon \leq \tilde{\tau}_\varepsilon$ , and recall from (2.47) that

$$(2.75) \quad V^*(x) \leq \mathbb{E}_x V^*(X_{\beta \wedge \tilde{\tau}_\varepsilon})$$

for every stopping time  $\beta$ . From general theory of Markov processes (upon using that  $t \mapsto X_{t \wedge \tilde{\tau}_\varepsilon}$  is right-continuous and adapted) it is known that (2.75) implies that  $V^*$  is finely lower-semicontinuous up to  $\tilde{\tau}_\varepsilon$  in the sense that

$$(2.76) \quad V^*(x) \leq \liminf_{t \downarrow 0} V^*(X_{t \wedge \tilde{\tau}_\varepsilon}) \quad \mathbb{P}_x\text{-a.s.}$$

This in particular implies (since  $X^{\tilde{\tau}_\varepsilon}$  is a strong Markov process) that

$$(2.77) \quad V^*(X_\tau) \leq \liminf_{t \downarrow 0} V^*(X_{\tau+t}) \quad \mathbb{P}_x\text{-a.s. on } \{\tau < \tilde{\tau}_\varepsilon\}$$

for every stopping time  $\tau$ . Indeed, setting  $Y_t = X_{t \wedge \tilde{\tau}_\varepsilon}$ ,

$$(2.78) \quad A = \{V^*(x) \leq \liminf_{t \downarrow 0} V^*(Y_t)\} \quad \text{and} \quad B = \{V^*(Y_\tau) \leq \liminf_{t \downarrow 0} V^*(Y_{\tau+t})\}$$

we see that  $B = \theta_\tau^{-1}(A)$  and  $B^c = \theta_\tau^{-1}(A^c)$  so that the strong Markov property of  $Y$  implies

$$(2.79) \quad \begin{aligned} P_x(B^c) &= P_x(\theta_\tau^{-1}(A^c)) = E_x[E_x(I_{A^c} \circ \theta_\tau | \mathcal{F}_\tau)] \\ &= E_x E_{X_\tau}(I_{A^c}) = E_x P_{X_\tau}(A^c) = 0, \end{aligned}$$

since  $P_y(A^c) = 0$  for all  $y$ . Hence (2.77) holds as claimed. In particular, if (2.77) is applied to  $\tau_\varepsilon$ , we get

$$(2.80) \quad V^*(X_{\tau_\varepsilon}) \leq G_1(X_{\tau_\varepsilon}) + \varepsilon \quad P_x\text{-a.s. on } \{\tau_\varepsilon < \tilde{\tau}_\varepsilon\}.$$

With this new information we can now revisit (2.74) via (2.75) upon using (2.63) and (2.80). This gives

$$(2.81) \quad \begin{aligned} V^*(x) &\leq E_x V^*(X_{\beta \wedge \tau_\varepsilon}) = E_x[V^*(X_{\tau_\varepsilon})I(\tau_\varepsilon \leq \beta) + V^*(X_\beta)I(\beta < \tau_\varepsilon)] \\ &= E_x[V^*(X_{\tau_\varepsilon})I(\tau_\varepsilon \leq \beta, \tau_\varepsilon < \tilde{\tau}_\varepsilon) + \hat{S}_{\tilde{\tau}_\varepsilon} V^*(X_{\tau_\varepsilon})I(\tau_\varepsilon \leq \beta, \tau_\varepsilon = \tilde{\tau}_\varepsilon) \\ &\quad + V^*(X_\beta)I(\beta < \tau_\varepsilon)] \\ &\leq E_x[(G_1(X_{\tau_\varepsilon}) + \varepsilon)I(\tau_\varepsilon \leq \beta, \tau_\varepsilon < \tilde{\tau}_\varepsilon) + (G_1(X_{\tilde{\tau}_\varepsilon}) + \varepsilon)I(\tau_\varepsilon \leq \beta, \tau_\varepsilon = \tilde{\tau}_\varepsilon) \\ &\quad + G_2(X_\beta)I(\beta < \tau_\varepsilon)] \\ &\leq E_x[(G_1(X_{\tau_\varepsilon}) + \varepsilon)I(\tau_\varepsilon < \beta) + G_2(X_\beta)I(\beta < \tau_\varepsilon) \\ &\quad + (G_3(X_{\tau_\varepsilon}) + \varepsilon)I(\tau_\varepsilon = \beta)] \\ &\leq M_x(\tau_\varepsilon, \beta) + \varepsilon \end{aligned}$$

for every stopping time  $\beta$ . This completes the proof of (2.9) when the function  $x \mapsto \hat{V}^*(x)$  from (2.32) is assumed to be measurable.

13. If  $x \mapsto \hat{V}^*(x)$  is not assumed to be measurable, then the proof above can be repeated with reference only to  $\hat{S}^\sigma$  and  $\hat{S}$  under  $P_x$  with  $x$  given and fixed. In exactly the same way as above, this gives the identity  $\hat{V}^*(x) = V^*(x) = V_*(x)$  for this particular and thus all  $x$ . But then the measurability follows from the following general fact: If  $V^* = V_*$ , then  $V := V^* = V_*$  defines a measurable function.

To derive this fact consider the optimal stopping game (2.2)+(2.3) when  $X$  is a discrete-time Markov chain, so that  $\tau$  and  $\sigma$  (without loss of generality) take values in  $\{0, 1, 2, \dots\}$ . The horizon  $N$  (the upper bound for  $\tau$  and  $\sigma$  in (2.2)+(2.3) above) can be either finite or infinite. When  $N$  is finite, the most interesting case is when  $G_i = G_i(x, n)$  for  $i = 1, 2, 3$ , with  $G_1(x, N) = G_2(x, N) = G_3(x, N)$  for all  $x$ . When  $N$  is infinite, then

$$(2.82) \quad \liminf_{n \rightarrow \infty} G_2(X_n) \leq \limsup_{n \rightarrow \infty} G_1(X_n)$$

as stipulated following (2.3) above, and the common value for  $G_3(X_\infty)$  could formally be assigned as either of the two values in (2.82) (if  $\tau$  and  $\sigma$  are allowed to take the value  $\infty$ ).

Then the following Wald–Bellman equations are valid:

$$(2.83) \quad V_n(x) = G_1(x) \vee TV_{n-1}(x) \wedge G_2(x)$$

for  $n = 1, 2, \dots$ , where  $V_0$  is set to be either  $G_1$  or  $G_2$ . This yields  $V_N = V^* = V_*$ , with  $V_\infty = \lim_{n \rightarrow \infty} V_n$  if  $N = \infty$  (see [8] for details).

Recalling that  $T$  denotes the transition operator defined by

$$(2.84) \quad TF(x) = E_x F(X_1),$$

one sees that  $x \mapsto TF(x)$  is measurable whenever  $F$  is so (and  $E_x F(X_1)$  is well defined for all  $x$ ). Applying this argument inductively in (2.83) we see that  $x \mapsto V_N(x)$  is a measurable function. Thus, optimal stopping games for discrete-time Markov chains always lead to measurable value functions.

To treat the case of general  $X$ , let  $Q_n$  denote the set of all dyadic rationals  $k/2^n$  in the time set, and for a given stopping time  $\tau$  let  $\tau_n$  be defined by setting  $\tau_n = k/2^n$  on  $\{(k-1)/2^n < \tau \leq k/2^n\}$ . Then each  $\tau_n$  is a stopping time taking values in  $Q_n$ , and the following inequality is valid:

$$(2.85) \quad M_x(\tau, \sigma) \leq M_x(\tau_n, \sigma) + E_x |G_1(X_\tau) - G_1(X_{\tau_n})|$$

for every stopping time  $\sigma \in Q_n$  (meaning that  $\sigma$  takes values in  $Q_n$ ). Indeed, this can be derived as follows:

$$\begin{aligned} (2.86) \quad & M_x(\tau, \sigma) - M_x(\tau_n, \sigma) \\ &= E_x [G_1(X_\tau) I(\tau < \sigma) + G_2(X_\sigma) I(\sigma < \tau) + G_3(X_\tau) I(\tau = \sigma, \tau \neq \tau_n) \\ &\quad - G_1(X_{\tau_n}) I(\tau_n < \sigma) - G_2(X_\sigma) I(\sigma < \tau_n) - G_3(X_{\tau_n}) I(\tau_n = \sigma, \tau_n \neq \tau)] \\ &\leq E_x [(G_1(X_\tau) - G_1(X_{\tau_n})) I(\tau < \sigma) \\ &\quad + G_1(X_{\tau_n}) (I(\tau < \sigma) - I(\tau_n < \sigma) - I(\tau_n = \sigma, \tau_n \neq \tau)) \\ &\quad + G_2(X_\sigma) (I(\sigma < \tau) + I(\tau = \sigma, \tau \neq \tau_n) - I(\sigma < \tau_n))] \\ &= E_x [(G_1(X_\tau) - G_1(X_{\tau_n})) I(\tau < \sigma) + (G_1(X_{\tau_n}) - G_2(X_\sigma)) I(\tau < \sigma < \tau_n)] \end{aligned}$$

being true for any stopping times  $\tau, \sigma$ , and  $\tau_n$  such that  $\tau \leq \tau_n$ . In particular, if  $\sigma \in Q_n$  (and  $\tau_n$  is defined as above), then  $\{\tau < \sigma < \tau_n\} = \emptyset$ , so that (2.86) becomes

$$\begin{aligned} (2.87) \quad & M_x(\tau, \sigma) \leq M_x(\tau_n, \sigma) + E_x [(G_1(X_\tau) - G_1(X_{\tau_n})) I(\tau < \sigma)] \\ &\leq M_x(\tau_n, \sigma) + E_x |G_1(X_\tau) - G_1(X_{\tau_n})| \end{aligned}$$

as claimed in (2.85) above.

Let  $\tau_n^*$  and  $\sigma_n^*$  denote the optimal stopping times (in the Nash sense) for the optimal stopping game (2.2)+(2.3) with the time set  $Q_n$ , and let  $V_n(x)$  denote the corresponding value of the game, i.e.,

$$(2.88) \quad V_n(x) = M_x(\tau_n^*, \sigma_n^*)$$

for all  $x$ . (From (2.83) one sees that such optimal stopping times always exist in the discrete-time setting.) By the first part above (applied to the Markov chain  $(X_t)_{t \in Q_n}$ ) we know that  $x \mapsto V_n(x)$  is measurable.

Setting  $\varepsilon_n(x, \tau) = E_x |G_1(X_\tau) - G_1(X_{\tau_n})|$  we see that (2.85) reads

$$(2.89) \quad M_x(\tau, \sigma) \leq M_x(\tau_n, \sigma) + \varepsilon_n(x, \tau)$$

for every  $\tau$  and every  $\sigma \in Q_n$ . Hence we find that

$$\begin{aligned} (2.90) \quad & M_x(\tau, \sigma_n^*) \leq M_x(\tau_n, \sigma_n^*) + \varepsilon_n(x, \tau) \\ &\leq M_x(\tau_n^*, \sigma_n^*) + \varepsilon_n(x, \tau) = V_n(x) + \varepsilon_n(x, \tau). \end{aligned}$$

This implies that

$$(2.91) \quad \inf_{\sigma} M_x(\tau, \sigma) \leq \liminf_{n \rightarrow \infty} V_n(x),$$

since  $\varepsilon_n(x, \tau) \rightarrow 0$  by right-continuity of  $X$  and the fact that  $\tau_n \downarrow \tau$  as  $n \rightarrow \infty$  (using also the integrability condition (2.1) above). Taking the supremum over all  $\tau$  we conclude that

$$(2.92) \quad V_*(x) \leq \liminf_{n \rightarrow \infty} V_n(x)$$

for all  $x$ .

On the other hand, similarly to (2.86) one finds that

$$(2.93) \quad \begin{aligned} M_x(\tau, \sigma) - M_x(\tau, \sigma_n) &\geq E_x[(G_2(X_\sigma) - G_2(X_{\sigma_n})) I(\sigma < \tau) \\ &\quad + (G_2(X_{\sigma_n}) - G_1(X_\tau)) I(\sigma < \tau < \sigma_n)] \end{aligned}$$

for any stopping times  $\tau, \sigma$ , and  $\sigma_n$  such that  $\sigma \leq \sigma_n$ . If  $\sigma_n$  is defined analogously to  $\tau_n$  above (with  $\sigma$  in place of  $\tau$ ), then (2.93) yields the following analogue of (2.89) above:

$$(2.94) \quad M_x(\tau, \sigma) \geq M_x(\tau, \sigma_n) - \delta_n(x, \sigma),$$

where  $\delta_n(x, \sigma) = E_x|G_2(X_\sigma) - G_2(X_{\sigma_n})| \rightarrow 0$  as  $n \rightarrow \infty$  for the same reasons as above. This analogously yields

$$(2.95) \quad \limsup_{n \rightarrow \infty} V_n(x) \leq V^*(x)$$

for all  $x$ . Thus, if  $V^* = V_*$ , then by (2.92) and (2.95) we see that  $V := V^* = V_*$  satisfies

$$(2.96) \quad V(x) = \lim_{n \rightarrow \infty} V_n(x)$$

for all  $x$ . Since each  $V_n$  is measurable, we see that  $V$  is measurable as claimed. This completes the first part of the proof.

(II) In the second part of the proof we will assume that  $X$  is right-continuous and left-continuous over stopping times, and we will show that these hypotheses imply the Nash equilibrium (1.4) with  $\tau_*$  and  $\sigma_*$  from (2.4).

1. Since  $X$  is right-continuous we know by the first part of the proof above that  $V^* = V_*$ , with  $V := V^* = V_*$  defining a measurable function which by (2.7) satisfies

$$(2.97) \quad M_x(\tau, \sigma_\varepsilon) - \varepsilon \leq V(x) \leq M_x(\tau_\varepsilon, \sigma) + \varepsilon$$

for all  $\tau, \sigma, x$ , and  $\varepsilon > 0$ . Recalling from (2.5)+(2.6) that

$$(2.98) \quad \tau_\varepsilon = \inf \{ t : X_t \in D_1^\varepsilon \},$$

where  $D_1^\varepsilon = \{ V \leq G_1 + \varepsilon \}$ , we will now show that the second inequality in (2.97) implies

$$(2.99) \quad V(x) \leq M_x(\tau_0, \sigma)$$

for all  $\sigma$  and  $x$ , where  $\tau_0 = \inf \{ t : X_t \in D_1^0 \}$ , with  $D_1^0 = \{ V = G_1 \}$ . (Note that  $\tau_0$  coincides with  $\tau_*$  in the notation above.)

2. It is clear from the definitions that  $\tau_\varepsilon \uparrow \tau_{0-}$  as  $\varepsilon \downarrow 0$ , where  $\tau_{0-}$  is a stopping time satisfying  $\tau_{0-} \leq \tau_0$ . We will now show that  $\tau_{0-} = \tau_0$  P<sub>x</sub>-a.s. For this, let us first

establish the following general fact: If  $\rho_n$  and  $\rho$  are stopping times such that  $\rho_n \uparrow \rho$  as  $n \rightarrow \infty$ , then

$$(2.100) \quad \mathbb{E}_x V(X_\rho) \leq \liminf_{n \rightarrow \infty} \mathbb{E}_x V(X_{\rho_n}).$$

To see this recall from the first part of the proof above that  $V(X_\beta) = \hat{V}(X_\beta) = \hat{S}_\beta = \check{V}(X_\beta) = \check{S}_\beta$  for every stopping time  $\beta$ , where  $\check{V}$  and  $\check{S}$  are defined analogously to  $\hat{V}$  and  $\hat{S}$  but with  $\hat{M}_x(\tau, \sigma) = \mathbb{E}_x[G_1(X_\tau) I(\tau \leq \sigma) + G_2(X_\sigma) I(\sigma < \tau)]$  in place of  $\hat{M}_x(\tau, \sigma)$  and with the order of the supremum and the infimum being interchanged. Hence we find that

$$(2.101) \quad \mathbb{E}_x V(X_{\rho_n}) = \mathbb{E}_x \hat{S}_{\rho_n} = \sup_{\tau \geq \rho_n} \inf_{\sigma \geq \rho_n} \hat{M}_x(\tau, \sigma) \geq \sup_{\tau \geq \rho} \inf_{\sigma \geq \rho_n} \hat{M}_x(\tau, \sigma).$$

Taking  $\tau \geq \rho$  we find that

$$(2.102) \quad \begin{aligned} \hat{M}_x(\tau, \sigma) &= \mathbb{E}_x[(G_1(X_\tau) I(\tau < \sigma) + G_2(X_\sigma) I(\sigma \leq \tau)) I(\sigma \leq \rho)] \\ &\quad + \mathbb{E}_x[(G_1(X_\tau) I(\tau < \sigma \vee \rho) + G_2(X_{\sigma \vee \rho}) I(\sigma \vee \rho \leq \tau)) I(\sigma > \rho)] \\ &= \mathbb{E}_x[G_2(X_\sigma) I(\sigma \leq \rho)] \\ &\quad + \mathbb{E}_x[G_1(X_\tau) I(\tau < \sigma \vee \rho) + G_2(X_{\sigma \vee \rho}) I(\sigma \vee \rho \leq \tau)] \\ &\quad - \mathbb{E}_x[(G_1(X_\tau) I(\tau < \sigma \vee \rho) + G_2(X_{\sigma \vee \rho}) I(\sigma \vee \rho \leq \tau)) I(\sigma \leq \rho)] \\ &= \mathbb{E}_x[G_2(X_\sigma) I(\sigma \leq \rho) - G_2(X_\rho) I(\sigma \leq \rho)] \\ &\quad + \mathbb{E}_x[G_1(X_\tau) I(\tau < \sigma \vee \rho) + G_2(X_{\sigma \vee \rho}) I(\sigma \vee \rho \leq \tau)] \\ &= \mathbb{E}_x[G_2(X_{\sigma \wedge \rho}) - G_2(X_\rho)] + \hat{M}_x(\tau, \sigma \vee \rho). \end{aligned}$$

From (2.101) and (2.102) we get

$$(2.103) \quad \begin{aligned} \mathbb{E}_x V(X_{\rho_n}) &\geq \inf_{\sigma \geq \rho_n} \mathbb{E}_x[G_2(X_{\sigma \wedge \rho}) - G_2(X_\rho)] + \sup_{\tau \geq \rho} \inf_{\sigma \geq \rho} \hat{M}_x(\tau, \sigma) \\ &= \mathbb{E}_x V(X_\rho) + \inf_{\rho_n \leq \sigma \leq \rho} \mathbb{E}_x[G_2(X_\sigma) - G_2(X_\rho)]. \end{aligned}$$

Letting  $n \rightarrow \infty$  and using that the final expectation tends to zero, since  $X$  is left-continuous over stopping times and the integrability condition (2.1) holds, we get (2.100) as claimed.

Applying (2.100) to  $\tau_\varepsilon$  and  $\tau_{0-}$ , and recalling from the first part of the proof above that  $V(X_{\tau_\varepsilon}) \leq G_1(X_{\tau_\varepsilon}) + \varepsilon$   $\mathbb{P}_x$ -a.s., it follows that

$$(2.104) \quad \mathbb{E}_x V(X_{\tau_{0-}}) \leq \liminf_{\varepsilon \downarrow 0} \mathbb{E}_x V(X_{\tau_\varepsilon}) \leq \liminf_{\varepsilon \downarrow 0} \mathbb{E}_x[G_1(X_{\tau_\varepsilon}) + \varepsilon] = \mathbb{E}_x G_1(X_{\tau_{0-}})$$

upon using that  $G_1(X)$  is left-continuous over stopping times (as well as the integrability condition (2.1) above). Since, on the other hand, we have  $V(X_{\tau_{0-}}) \geq G_1(X_{\tau_{0-}})$ , we see from (2.104) that  $V(X_{\tau_{0-}}) = G_1(X_{\tau_{0-}})$  and thus  $\tau_0 \leq \tau_{0-}$   $\mathbb{P}_x$ -a.s., proving that  $\tau_0 = \tau_{0-}$   $\mathbb{P}_x$ -a.s. as claimed.

3. Motivated by passing to the limit in (2.97) for  $\varepsilon \downarrow 0$ , we will now establish the following general fact: If  $\tau_n$  and  $\tau$  are stopping times such that  $\tau_n \uparrow \tau$ , then

$$(2.105) \quad \limsup_{n \rightarrow \infty} M_x(\tau_n, \sigma) \leq M_x(\tau, \sigma)$$

for every stopping time  $\sigma$  given and fixed. To see this, note that

$$\begin{aligned}
 (2.106) \quad & M_x(\tau, \sigma) - M_x(\tau_n, \sigma) \\
 &= \mathbb{E}_x [G_1(X_\tau) I(\tau < \sigma) + G_2(X_\sigma) I(\sigma < \tau) + G_3(X_\tau) I(\tau = \sigma, \tau \neq \tau_n) \\
 &\quad - G_1(X_{\tau_n}) I(\tau_n < \sigma) - G_2(X_\sigma) I(\sigma < \tau_n) \\
 &\quad - G_3(X_{\tau_n}) I(\tau_n = \sigma, \tau_n \neq \tau)] \\
 &\geq \mathbb{E}_x [(G_1(X_\tau) - G_1(X_{\tau_n})) I(\tau < \sigma) \\
 &\quad + G_1(X_{\tau_n}) (I(\tau < \sigma) + I(\tau = \sigma, \tau \neq \tau_n) - I(\tau_n < \sigma)) \\
 &\quad + G_2(X_\sigma) (I(\sigma < \tau) - I(\sigma < \tau_n) - I(\tau_n = \sigma, \tau_n \neq \tau))] \\
 &= \mathbb{E}_x [(G_1(X_\tau) - G_1(X_{\tau_n})) I(\tau < \sigma) \\
 &\quad + (G_2(X_\sigma) - G_1(X_{\tau_n})) I(\tau_n < \sigma < \tau)] \\
 &\geq -\mathbb{E}_x |G_1(X_\tau) - G_1(X_{\tau_n})| \\
 &\quad - \mathbb{E}_x [(\sup_t |G_2(X_t)| + \sup_t |G_1(X_t)|) I(\tau_n < \sigma < \tau)].
 \end{aligned}$$

Letting  $n \rightarrow \infty$  and using the fact that the final two expectations tend to zero, since  $G_1(X)$  is left-continuous over stopping times and the integrability condition (2.1) holds, we see that (2.105) follows as claimed.

Applying (2.105) to  $\tau_\varepsilon$  and  $\tau_0$  upon letting  $\varepsilon \downarrow 0$  in (2.97), we get (2.99). The inequality

$$(2.107) \quad M_x(\tau, \sigma_0) \leq V(x)$$

can be established analogously. Combining (2.99) and (2.107), we get (1.4), and the proof is complete.  $\square$

**3. Concluding remarks.** The following example shows that the Nash equilibrium (1.4) may fail when  $X$  is right-continuous but not left-continuous over stopping times.

*Example 3.1.* Let the state space  $E$  of the process  $X$  be  $[-1, 1]$ . If  $X$  starts at  $x \in (-1, 1)$ , let  $X$  be a standard Brownian motion until it hits either  $-1$  or  $1$ ; at this time let  $X$  start afresh from  $0$  as an independent copy of  $B$  until it hits either  $-1$  or  $1$ ; and so on. If  $X$  starts at  $x \in \{-1, 1\}$ , let  $X$  stay at the same  $x$  for the rest of time.

It follows that  $X$  is a right-continuous strong Markov process which is not left-continuous over stopping times. Indeed, if we consider the first hitting time  $\rho_\varepsilon$  of  $X$  to  $b_\varepsilon$  under  $\mathbb{P}_x$  for  $x \in (-1, 1)$  given and fixed, where  $b_\varepsilon$  equals either  $-1 + \varepsilon$  or  $1 - \varepsilon$  for all  $\varepsilon > 0$  sufficiently small, then  $\rho_\varepsilon \uparrow \rho$  as  $\varepsilon \downarrow 0$  so that  $\rho$  is a stopping time; however, the value  $X_{\rho_\varepsilon} = b_\varepsilon$  does not converge to  $X_\rho = 0$  as  $\varepsilon \downarrow 0$ , implying the claim.

Let  $G_1(x) = x(x+1)-1$  and  $G_2(x) = -x(x-1)+1$  for  $x \in [-1, 1]$ , and let  $G_3$  be equal to  $G_1$  on  $[-1, 1]$ . Note that  $G_i(-1) = -1$  and  $G_i(1) = 1$  for  $i = 1, 2, 3$ . To include stopping times  $\tau$  and  $\sigma$  which are allowed to take the value  $\infty$  below, let us set  $G_3(X_\infty) = \limsup_{t \rightarrow \infty} G_1(X_t)$ . Note that  $G_3(X_\infty) \equiv 1$  under  $\mathbb{P}_x$  when  $x \in (-1, 1]$  and  $G_3(X_\infty) \equiv -1$  under  $\mathbb{P}_x$  when  $x = -1$ .

It is then easily seen (using the first part of Theorem 2.1 above) that  $V^*(x) = V_*(x) = x$  for all  $x \in [-1, 1]$  with  $\tau_\varepsilon = \inf \{t : X_t \leq a_\varepsilon^1 \text{ or } X_t \geq b_\varepsilon^1\}$  (where  $a_\varepsilon^1 < b_\varepsilon^1$  satisfy  $G_1(a_\varepsilon^1) = a_\varepsilon^1 - \varepsilon$  and  $G_1(b_\varepsilon^1) = b_\varepsilon^1 - \varepsilon$ ) and  $\sigma_\varepsilon = \inf \{t : X_t \leq a_\varepsilon^2 \text{ or } X_t \geq b_\varepsilon^2\}$  (where  $a_\varepsilon^2 < b_\varepsilon^2$  satisfy  $G_2(a_\varepsilon^2) = a_\varepsilon^2 + \varepsilon$  and  $G_2(b_\varepsilon^2) = b_\varepsilon^2 + \varepsilon$ ), being approximate stopping times satisfying (2.7) above. (Note that  $a_\varepsilon^i \downarrow -1$  and  $b_\varepsilon^i \uparrow 1$  as  $\varepsilon \downarrow 0$  for  $i = 1, 2$ .)

Thus the Stackelberg equilibrium (1.3) holds with  $V(x) = x$  for all  $x \in [-1, 1]$ . It is clear, however, that the Nash equilibrium fails as it is impossible to find stopping times  $\tau_*$  and  $\sigma_*$  satisfying (1.4) above. [Note that the natural candidates  $\tau \equiv \infty$  and  $\sigma \equiv \infty$  are ruled out, since  $M_x(\infty, \infty) = 1$  for  $x \in (-1, 1]$  and  $M_x(\infty, \infty) = -1$  for  $x = -1$ .]

The methodology used in the proof of Theorem 2.1 above (second part) extends from the Markovian approach to the martingale approach for optimal stopping games. For the sake of completeness we will formulate the analogous results of the martingale approach.

Let  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$  be a filtered probability space such that  $(\mathcal{F}_t)_{t \geq 0}$  is right-continuous and  $\mathcal{F}_0$  contains all  $\mathbb{P}$ -null sets from  $\mathcal{F}$ . Given adapted stochastic processes  $G^1, G^2, G^3$  on  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})$  satisfying  $G_t^1 \leq G_t^2 \leq G_t^3$  for all  $t$  and the integrability condition

$$(3.1) \quad \mathbb{E} \sup_t |G_t^i| < \infty \quad (i = 1, 2, 3),$$

consider the optimal stopping game where the sup-player chooses a stopping time  $\tau$  to maximize, and the inf-player chooses a stopping time  $\sigma$  to minimize, the expected payoff

$$(3.2) \quad M(\tau, \sigma | \mathcal{F}_t) = \mathbb{E}[G_\tau^1 I(\tau < \sigma) + G_\sigma^2 I(\sigma < \tau) + G_\tau^3 I(\tau = \sigma) | \mathcal{F}_t]$$

for each  $t$  given and fixed. Note that, if  $\mathcal{F}_0$  is trivial (in the sense that  $\mathbb{P}(F)$  equals either 0 or 1 for all  $F \in \mathcal{F}_0$ ), then  $M(\tau, \sigma | \mathcal{F}_0)$  equals  $\mathbb{E}[G_\tau^1 I(\tau < \sigma) + G_\sigma^2 I(\sigma < \tau) + G_\tau^3 I(\tau = \sigma)]$ , and this expression is then denoted by  $M(\tau, \sigma)$  for all  $\tau$  and  $\sigma$ .

Define the upper value and the lower value of the game by

$$(3.3) \quad V_t^* = \operatorname{ess\,inf}_{\sigma \geq t} \operatorname{ess\,sup}_{\tau \geq t} M(\tau, \sigma | \mathcal{F}_t) \quad \text{and} \quad V_t^t = \operatorname{ess\,sup}_{\tau \geq t} \operatorname{ess\,inf}_{\sigma \geq t} M(\tau, \sigma | \mathcal{F}_t),$$

respectively, where the horizon  $T$  (the upper bound for  $\tau$  and  $\sigma$  above) may be either finite or infinite. If  $T < \infty$ , then it is assumed that  $G_T^1 = G_T^2 = G_T^3$ . If  $T = \infty$ , then it is assumed that  $\liminf_{t \rightarrow \infty} G_t^2 \leq \limsup_{t \rightarrow \infty} G_t^1$ , and the common value for  $G_\infty^3$  could formally be assigned as either of the preceding two values (if  $\tau$  and  $\sigma$  are allowed to take the value  $\infty$ ).

**THEOREM 3.2.** *Consider the optimal stopping game (3.3). If  $G_i$  is right-continuous for  $i = 1, 2, 3$ , then the Stackelberg equilibrium holds in the sense that*

$$(3.4) \quad V_t^* = V_t^t \quad \mathbb{P}\text{-a.s.},$$

with  $V_t := V_t^* = V_t^t$  defining a right-continuous process (modification) for  $t \geq 0$ . Moreover, the stopping times

$$(3.5) \quad \tau_\varepsilon = \inf \{ t : V_t \leq G_t^1 + \varepsilon \} \quad \text{and} \quad \sigma_\varepsilon = \inf \{ t : V_t \geq G_t^2 - \varepsilon \}$$

satisfy the following inequalities:

$$(3.6) \quad M(\tau, \sigma_\varepsilon | \mathcal{F}_t) - \varepsilon \leq M(\tau_\varepsilon, \sigma_\varepsilon | \mathcal{F}_t) \leq M(\tau_\varepsilon, \sigma | \mathcal{F}_t) + \varepsilon$$

for each  $t$  and every  $\varepsilon > 0$ . If  $G_i$  is right-continuous and left-continuous over stopping times for  $i = 1, 2, 3$ , then the Nash equilibrium holds in the sense that the stopping times

$$(3.7) \quad \tau_* = \inf \{ t : V_t = G_t^1 \} \quad \text{and} \quad \sigma_* = \inf \{ t : V_t = G_t^2 \}$$

satisfy the following inequalities:

$$(3.8) \quad M(\tau, \sigma_* | \mathcal{F}_t) \leq M(\tau_*, \sigma_* | \mathcal{F}_t) \leq M(\tau_*, \sigma | \mathcal{F}_t)$$

for each  $t$  and all stopping times  $\tau$  and  $\sigma$ .

*Proof.* The first part of the theorem (Stackelberg equilibrium) was established in [18] (under slightly more restrictive conditions on integrability and the common value at the end of time but the same method extends to cover the present case without major changes). The second part of the theorem (Nash equilibrium) can be derived using the same arguments as in the second part of the proof of Theorem 2.1 above.  $\square$

Note that the second part of Theorem 3.2 (Nash equilibrium) is applicable to all Lévy processes (without additional hypotheses on the jump structure).

## ON THE OPTIMAL STOCHASTIC IMPULSE CONTROL OF LINEAR DIFFUSIONS\*

LUIS H. R. ALVAREZ<sup>†</sup> AND JUKKA LEMPA<sup>†</sup>

**Abstract.** We consider a class of stochastic impulse control problems of linear diffusions arising in studies considering the determination of optimal dividend policies. This class of problems appears also in studies analyzing the optimal management of renewable resources. We state a set of weak conditions guaranteeing both existence and uniqueness of the boundary characterizing the optimal policy and its value. We also analyze two associated stochastic control problems and establish a general ordering for both the values and the marginal values of the considered stochastic control problems. In this way we extend previous findings obtained by relying on linear payoff characterizations.

**Key words.** stochastic impulse and singular control, optimal stopping, diffusions

**DOI.** 10.1137/060659375

**1. Introduction.** A stochastic impulse control policy can be characterized by two factors, namely, by the sequence of random dates at which the policy is exercised and by the sequence of impulses describing the magnitude of the applied policies. Thus, solving an impulse control problem typically involves the consideration of two endogenously determined variables: the timing and size of an impulse policy. For example, in most forest economic applications of stochastic impulse control the implemented impulse size is constrained by an exogenously determined generic initial state at which the underlying stochastic process is restarted after the forest has been harvested (see, for example, [3], [4], [5], [6], [37], and [39]). Hence, in those models the only endogenous variable determining the size of the optimal policy is the single boundary at which the irreversible policy is optimally exercised. On the other hand, most capital theoretic and cash flow management applications of impulse control are based on models where both the exercise boundary at which the impulse policy is exercised and the generic initial state at which the controlled process is restarted after the irreversible policy has been exerted have to be simultaneously determined (see, for example, [7], [9], [10], [18], [29], [34]; see also [26] for an excellent survey on stochastic impulse control applications in finance). Given the general applicability of stochastic impulse control models in various fields, it is not surprising that the mathematical analysis of such problems is well established (see, for example, [16], [17], [21], [28], [30], [32]; see also [12] for a seminal textbook on quasi-variational inequalities and impulse control). In most cases the impulse control problem is studied by relying on a combination of variational and quasi-variational inequalities. Even though that approach is general and applies in the multidimensional setting as well, it typically results into functional inequalities which, depending naturally on the explicit form of

the considered problem, may be relatively difficult to analyze and in that way difficult to interpret in terms of the particular application.

Given the arguments mentioned above, we consider in this study a class of stochastic impulse control problems of linear time-homogenous diffusion processes arising, among others, in various cash flow management applications and in studies on the rational management of renewable resources. As usual, we assume that the decision maker has to choose both the timing and the size of the optimal policy affecting the dynamics of the underlying diffusion. We generalize the analysis of the study [7] in two ways. First, instead of relying on a simple linear and state-independent exercise payoff, we introduce a state-dependent and potentially nonlinear cash flow term measuring the revenue flow accrued from continuing operation (in capital theoretic applications of impulse control this flow can be interpreted either as the short-run profit flow or as a continuous dividend stream, and in forest economics this flow term is typically interpreted as the flow of revenues accrued from amenity services; cf. [5]). This extension is of interest, since, as our analysis clearly demonstrates, in the presence of a state-dependent and potentially nonlinear cash flow, no strong concavity requirements are needed in order to guarantee both existence and uniqueness of an optimal policy. This is a result which is in sharp contrast with the findings of the linear state-independent exercise payoff case studied in [7]. Second, in order to model the potential imperfect controllability of the underlying stochastic dynamics, we also consider situations where an arbitrary admissible impulse may result in a jump discontinuity which is either greater or smaller than the size of the actual impulse (such configurations typically arise in models considering the effects of taxation or other financial frictions on rational cash flow management). We model the imperfect controllability as scalar multiplication of the applied impulse control policy. Our analysis shows that small (linear) changes in the controllability of the system result in nonlinear and possibly dramatic changes in the required rate of return and, consequently, in both the optimal policy and its value.

Instead of analyzing the considered class of stochastic impulse control problems directly by relying on the ordinary Hamilton–Jacobi–Bellman approach, we follow the approach introduced in [3] and [4] and first derive the value accrued from applying a potentially suboptimal stochastic impulse control policy characterized by a sequence of constant-sized impulses exerted every time the underlying diffusion hits a predetermined and constant exercise threshold. By relying on standard nonlinear programming techniques we then state the ordinary first order necessary conditions characterizing both the exercise threshold and the impulse size of a potentially optimal policy maximizing the value of the associated class of Markovian functionals (for a recent study utilizing a similar idea, see [10]). The advantage of this approach is that it simplifies the economic analysis of the optimal policy and its value by admitting the application of standard marginalistic interpretations familiar from ordinary microeconomic theory. We present a set of relatively weak sufficient conditions under which a unique pair satisfying the necessary first order conditions exists. We establish that this pair constitutes the optimal impulse control policy in terms of both the size of the optimal impulse and the threshold at which the irreversible policy should be optimally exerted. In accordance with these observations, we then find that given the policy mentioned above the iteratively defined Markovian functional actually constitutes the value of the optimal stochastic impulse control policy.

We also consider two associated stochastic control problems (namely, a singular stochastic control and an optimal stopping problem) and study the boundary value

problem connecting the values (including the value of the stochastic impulse control problem). Both of these associated classical problems have been studied extensively (for singular control cf., e.g., [11], [22], [8], [25], [3], and [38]; for optimal stopping we refer the reader to the recent textbook [35]), and it is well known from this literature that singular stochastic control problems and optimal stopping problems are closely connected. More precisely, for a large class of singular stochastic control problems the derivative of the optimal value (i.e., the marginal value) coincides with the value of an associated optimal stopping problem of a certain transformed diffusion (cf. [23], [24], [14], [13]; see also [2]). The results of the current study connecting the problems differ from the previous characterizations in two ways. First, in all three of the considered separate stochastic control problems, the underlying dynamics are the same in the absence of control. Second, we study how, on the one hand, the optimal values and, on the other hand, the marginal values are interrelated. As is intuitively clear, we find that the value of the associated singular stochastic control problem dominates the value of the stochastic impulse control problem, which, in turn, dominates the value of the associated optimal stopping problem. Somewhat surprisingly, we also find that the same ordering is satisfied by the marginal values of the optimal policies as well. More precisely, we establish that the marginal value of the associated singular stochastic control problem dominates the marginal value of the stochastic impulse control problem, which, in turn, dominates the marginal value of the associated optimal stopping problem. This finding is important from the point of view of economic and financial applications, since our results demonstrate that increased policy flexibility unambiguously increases the *Tobin's marginal  $q$*  (i.e., marginal value) associated with the considered stochastic control problems as well. In this way our results extend the findings of [7] by demonstrating that the positivity of the relationship between the (marginal) value and the flexibility of the admissible policy is satisfied in the presence of a state-dependent and potentially nonlinear cash flow as well.

The contents of this study are as follows. In section 2 we present the considered class of stochastic impulse control problems. In section 3 we then state a set of auxiliary results and analyze the two associated stochastic control problems. In section 4 we then analyze the considered stochastic impulse control problem and state our main results. Finally, our results are explicitly illustrated in section 5 in a model based on geometric Brownian motion.

## 2. The impulse control problem.

**2.1. General setup.** It is our purpose in this study to analyze a class of stochastic impulse control problems of linear diffusions arising in many financial and economical applications of stochastic control theory. In order to accomplish this task, let  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t \geq 0}, \mathbb{P})$  denote a complete filtered probability space satisfying the usual conditions and assume that the dynamics of the underlying controlled diffusion process are given by the generalized Itô equation

$$(2.1) \quad X_t^\nu = x + \int_0^t \mu(X_s^\nu) ds + \int_0^t \sigma(X_s^\nu) dW_s - \sum_{\tau_k \leq t} \beta \zeta_k, \quad 0 \leq t \leq H_0^\nu,$$

where  $\beta > 0$  is an exogenously given constant,  $H_0^\nu = \inf\{t \geq 0 : X_t^\nu \leq 0\}$  denotes the possibly finite first exit time of the controlled diffusion  $X^\nu$  from the state-space  $\mathbb{R}_+$ , and  $\mu : \mathbb{R}_+ \rightarrow \mathbb{R}$  and  $\sigma : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  are known sufficiently smooth mappings (at least continuous) guaranteeing the existence of a solution for the stochastic differential

equation

$$(2.2) \quad dX_t = \mu(X_t)dt + \sigma(X_t)dW_t, \quad X_0 = x,$$

characterizing the dynamics of the underlying diffusion in the absence of interventions (cf. [15, pp. 46–47]). In a rational cash flow management application, the uncontrolled diffusion  $X$  represents the evolution of cash reserve in the absence of dividend payments and the impulse  $\zeta_k$  represent the amount paid out as dividends to stock holders at the corresponding time  $\tau_k$ ; hence the sum  $\sum_{\tau_k \leq t} \beta \zeta_k$  represents the total amount of dividends paid out until time  $t$  (or the cumulative portfolio wealth consumed by the decision maker up to time  $t$ ). The parameter  $\beta$  can be interpreted as a measure of the *imperfect controllability* of the underlying stochastic dynamics, since whenever  $\beta \neq 1$  an arbitrary admissible impulse results in a jump discontinuity which is either greater or smaller than the size of the actual impulse  $\zeta_k$ . As in [32], an admissible impulse control policy for the system (2.1) is a potentially infinite joint sequence  $\nu = \{(\tau_k, \zeta_k)\}_{k=1}^N$ ,  $N \leq \infty$ , where  $\{\tau_k\}_{k=1}^N$  denotes an increasing sequence of  $\mathcal{F}_t$ -stopping times for which  $\tau_1 \geq 0$  and  $\{\zeta_k\}_{k=1}^N$  denotes a sequence of nonnegative,  $\mathcal{F}_{\tau_k}$ -measurable impulses exerted at the corresponding intervention dates  $\{\tau_k\}_{k=1}^N$ , respectively. We denote as  $\mathcal{V}$  the class of admissible impulse controls  $\nu$  and assume that  $\tau_k \rightarrow H_0^\nu$  almost surely for all  $\nu \in \mathcal{V}$  and  $x \in \mathbb{R}_+$ . This convergence should be understood as follows: If  $N = \infty$ , then the convergence is typical almost sure convergence. However, if  $N < \infty$ , then we augment the control  $\nu$  with a pair  $(\tau_{N+1}, \zeta_{N+1}) := (H_0^\nu, 0)$ . As usual, we denote as  $\mathcal{A} = \frac{1}{2}\sigma^2(x)\frac{d^2}{dx^2} + \mu(x)\frac{d}{dx}$  the differential operator associated with  $X$ . For the diffusion  $X$ , the densities of scale function  $S$  and the speed measure  $m$  are defined as  $S'(x) = \exp(-\int^x \frac{2\mu(y)}{\sigma^2(y)} dy)$  and  $m'(x) = 2/(\sigma^2(x)S'(x))$ , respectively, for all  $x \in \mathbb{R}$ .

Denote as  $\mathcal{L}_1$  the class of measurable mappings  $f: \mathbb{R}_+ \rightarrow \mathbb{R}$  satisfying the condition

$$\mathbf{E}_x \left[ \int_0^{H_0} e^{-rs} |f(X_s)| ds \right] < \infty,$$

where  $r > 0$  is a given constant and  $H_0 = \inf\{t \geq 0 : X_t \leq 0\}$  is the first, potentially infinite, exit time for the uncontrolled diffusion  $X$  from  $\mathbb{R}_+$ . For a given  $f \in \mathcal{L}_1$ , define the resolvent  $(R_r f): \mathbb{R}_+ \rightarrow \mathbb{R}$  as

$$(R_r f)(x) = \mathbf{E}_x \left[ \int_0^{H_0} e^{-rs} f(X_s) ds \right].$$

The resolvent  $(R_r f)$  measures the expected cumulative present value of the cash flow  $f(X_t)$  from the present up to  $H_0$ . It is well known from the literature on linear diffusions that  $(R_r f)$  can be rewritten as (cf. [31])

$$(2.3) \quad (R_r f)(x) = B^{-1}\varphi(x) \int_0^x \psi(y)f(y)m'(y)dy + B^{-1}\psi(x) \int_x^\infty \varphi(y)f(y)m'(y)dy,$$

where  $\psi$  denotes the increasing and  $\varphi$  the decreasing fundamental solutions of the linear differential equation  $\mathcal{A}u = ru$  and  $B = (\psi'(x)\varphi(x) - \varphi'(x)\psi(x))/S'(x)$  denotes the Wronskian determinant of  $X$  (for a characterization of the fundamental solutions and the Green function of a linear diffusion, see [15, pp. 18–20]). The fundamental solutions  $\psi$  and  $\varphi$  constitute the *minimal  $r$ -excessive functions* for  $X$  since any non-trivial  $r$ -excessive function for  $X$  can be expressed in terms of  $\psi$  and  $\varphi$  via an integral expression (the so-called Martin integral representation theorem; cf. [15, p. 33]).

**2.2. Formulation of the impulse control problem.** Given the stochastic dynamics in (2.1) and the assumptions presented above on the dynamics of the controlled system, define the *expected cumulative net present value of the revenues from the present up to a potentially infinite future* as

$$(2.4) \quad J_c^\nu(x) = \mathbf{E}_x \left[ \int_0^{H_0^\nu} e^{-rs} \pi(X_s^\nu) ds + \sum_{k=1}^N e^{-r\tau_k} (\lambda \zeta_k - c) \right],$$

where  $r > 0$  is the discount rate,  $\lambda > 0$  is an exogenously given constant,  $c > 0$  is a known constant measuring a lump-sum sunk cost associated with the irreversible policy, and  $\pi : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is a given continuous, nondecreasing and nonnegative mapping measuring the *revenue flow accrued from continuing the operation*. This type of objective functional arise frequently in studies considering rational cash flow management (optimal dividend policy) and in studies considering the rational harvesting of renewable resources. In cash flow management application, the right-hand side of (2.4) represents the expected cumulative present value of the revenues accrued from the present up to the potentially infinite horizon at which the firm is liquidated. Along the lines of our interpretation of  $\beta$ , the parameter  $\lambda$  can be interpreted as another measure of imperfect controllability, since whenever  $\lambda \neq 1$  the realized revenue is strictly smaller or larger than the size of the actual impulse  $\zeta_k$  (in most economic and financial applications this parameter arises due to either taxes or subsidies).

Given the definition of  $J_c^\nu$  we plan to study the stochastic impulse control problem

$$(2.5) \quad V_c(x) = \sup_{\nu \in \mathcal{V}} J_c^\nu(x), \quad x \in \mathbb{R}_+,$$

and to determine an admissible impulse control  $\nu^*$  for which the maximum  $J_c^{\nu^*}(x) = V_c(x)$  is attained for all  $x \in \mathbb{R}_+$ . We will analyze the problem (2.5) under the following standing assumptions.

ASSUMPTION 2.1. (1) *We assume that the upper boundary  $\infty$  is natural and that the lower boundary 0 is natural, exit, or regular for the uncontrolled diffusion  $X$  in the absence of interventions. In the case when the origin is regular, we assume that it is killing.*

(2) *Define the mapping  $\theta : \mathbb{R}_+ \rightarrow \mathbb{R}$  as*

$$(2.6) \quad \theta(x) = \beta\pi(x) + \lambda\rho(x),$$

where  $\rho(x) = \mu(x) - rx$ . Throughout the study, we assume that  $\theta \in \mathcal{L}_1(\mathbb{R}_+)$  and that there is a unique state  $x^* \geq 0$  for which  $\theta$  is increasing on  $(0, x^*)$  and decreasing on  $(x^*, \infty)$ . Moreover, we assume that  $0 \leq \lim_{x \rightarrow 0+} \theta(x) < \infty$  and that  $\lim_{x \rightarrow \infty} \theta(x) < 0$ .

We prove all our main results under Assumption 2.1. First, we prove that under Assumption 2.1 the impulse control problem (2.5) has a unique solution. We characterize the optimal admissible impulse control policy explicitly as a threshold policy with a constant threshold and a constant impulse and derive a closed form expression of the optimal value function (Theorem 4.2). Moreover, we consider two associated control problems, namely, the associated singular control problem (3.6) and the optimal stopping problem (3.12), where the uncontrolled underlying dynamics follow the same diffusion  $X$  given by (2.2) as in the impulse control problem. This allows us to study the effect of flexibility of the control on the optimal value. We also show that these associated problems are solvable under Assumption 2.1 (Lemmas 3.4 and 3.6). We establish that the value functions of all three problems can be presented as

solutions of a certain free-boundary problem (see (4.16)). Finally, we prove a strong ordering of both the values and the marginal values of the control problems (Theorem 4.6). Informally, this ordering can be expressed as follows: *Increased flexibility of the control increases not only the value but also the rate at which the value grows.*

The assumption (1) characterizes the boundary behavior of the underlying diffusion. In line with most financial and economical applications, the upper boundary is assumed to be natural. Hence, even though the underlying controlled diffusion process may be expected to drift toward infinity, it is never expected to attain it in finite time. In the context of cash flow management applications, this assumption can be interpreted as a requirement that the retained profits from which dividends are paid out to the shareholders cannot become infinitely large in finite time. On the other hand, the assumed behavior of the underlying diffusion at the lower boundary is in line with the concept of liquidation and essentially guarantees that no dividends can be paid from negative reserves (since the time horizon is defined up to  $H_0^v$ ). From a mathematical point of view, the minimal  $r$ -harmonic functions  $\psi$  and  $\varphi$  satisfy useful limiting conditions depending on the boundary behavior of  $X$  (see [15, p. 19]). More precisely, if the lower boundary 0 is natural, then  $\lim_{x \rightarrow 0+} \psi(x) = 0$ ,  $\lim_{x \rightarrow 0+} \psi'(x)/S'(x) = 0$ ,  $\lim_{x \rightarrow 0+} \varphi(x) = \infty$ , and  $\lim_{x \rightarrow 0+} \varphi'(x)/S'(x) = -\infty$ . Analogous conditions hold also for the upper boundary  $\infty$  (which was assumed to be natural). If the origin is an exit boundary, then the second and third conditions are replaced by  $\lim_{x \rightarrow 0+} \psi'(x)/S'(x) > 0$  and  $\lim_{x \rightarrow 0+} \varphi(x) < \infty$ . In the case of a killing boundary, we have a limiting condition only for  $\psi$ , namely, that  $\lim_{x \rightarrow 0+} \psi(x) = 0$ .

The assumption (2) is also quite reasonable from the point of view of financial and economical applications. In a cash flow management application, the function  $\theta$  measures the expected net return (the sum of the continuous dividend flow and the expected capital gain) accrued from postponing the dividend payment into the future instead of paying out dividends instantaneously. Hence, the assumed limiting behavior of the net return guarantees that the rate of return earned from a retained unit dominates its opportunity cost (i.e., the return from a safe investment) when the reserves are low and that the opposite argument is valid when the reserves are large. In this respect our assumption (2) characterizes a set of sufficient conditions under which the decision maker has incentives to distribute part of the reserves when they become sufficiently large without liquidating the corporation instantaneously. The absence of speculative bubbles condition  $\theta \in \mathcal{L}_1$  guarantees that the expected cumulative present value of the net returns accrued from the present up to the liquidation date is finite.

In order to proceed in the analysis of the considered class of stochastic control problems, we first establish the following verification theorem.

LEMMA 2.1. *Assume that there is a mapping  $F : \mathbb{R}_+ \mapsto \mathbb{R}_+$  satisfying the following conditions.*

- (a) *The function  $F(x) - (R_r\pi)(x)$  is nonnegative and  $r$ -superharmonic for  $X_t$ .*
- (b)  *$F$  satisfies the inequality*

$$(2.7) \quad F(x) \geq \sup_{\beta\zeta \in [0, x]} [\lambda\zeta - c + F(x - \beta\zeta)]$$

for all  $x \in \mathbb{R}_+$ . Then,  $F(x) \geq V_c(x)$  for all  $x \in \mathbb{R}_+$ .

*Proof.* Let  $\nu \in \mathcal{V}$  be an admissible stochastic impulse control. Since  $\{\tau_j\}_{j=1}^N$  is an increasing sequence of stopping times, we first observe that the assumed

$r$ -superharmonicity of the function  $F(x) - (R_r\pi)(x)$  implies that (cf. [33, Lemma 10.1.3, p. 207])

$$(2.8) \quad \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ e^{-r\tau_{j+1}} (F(X_{\tau_{j+1}-}^\nu) - (R_r\pi)(X_{\tau_{j+1}-}^\nu)) \right] \leq e^{-r\tau_j} (F(X_{\tau_j}^\nu) - (R_r\pi)(X_{\tau_j}^\nu)).$$

Since  $((\mathcal{A} - r)(R_r\pi))(x) = -\pi(x)$  for all  $x \in \mathbb{R}_+$ , application of Dynkin's theorem to  $(R_r\pi)$  yields

$$\mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ e^{-r\tau_{j+1}} (R_r\pi)(X_{\tau_{j+1}-}^\nu) \right] = e^{-r\tau_j} (R_r\pi)(X_{\tau_j}^\nu) - \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ \int_{\tau_j}^{\tau_{j+1}-} e^{-rs} \pi(X_s^\nu) ds \right],$$

implying that inequality (2.8) can be re-expressed as

$$e^{-r\tau_j} F(X_{\tau_j}^\nu) - \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ e^{-r\tau_{j+1}} F(X_{\tau_{j+1}-}^\nu) \right] \geq \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ \int_{\tau_j}^{\tau_{j+1}-} e^{-rs} \pi(X_s^\nu) ds \right].$$

Taking expectations and invoking the tower property of conditional expectations then yield

$$\mathbf{E}_x \left[ e^{-r\tau_j} F(X_{\tau_j}^\nu) \right] - \mathbf{E}_x \left[ e^{-r\tau_{j+1}} F(X_{\tau_{j+1}-}^\nu) \right] \geq \mathbf{E}_x \left[ \int_{\tau_j}^{\tau_{j+1}-} e^{-rs} \pi(X_s^\nu) ds \right].$$

Letting  $\tau_0 = 0$ , summing terms from  $j = 0$  to  $j = n \wedge N$ , and applying the nonnegativity of the mapping  $F(x)$  result in

$$F(x) \geq \sum_{j=1}^{n \wedge N} \mathbf{E}_x \left[ e^{-r\tau_j} F(X_{\tau_j-}^\nu) - F(X_{\tau_j}^\nu) \right] + \mathbf{E}_x \left[ \int_0^{\tau_{n \wedge N+1}-} e^{-rs} \pi(X_s^\nu) ds \right].$$

Since  $X_{\tau_j} = X_{\tau_j-} - \beta\zeta_j$  for any admissible strategy and  $F$  satisfies the quasi-variational inequality  $F(x) \geq \sup_{\beta\zeta \in [0, x]} [\lambda\zeta - c + F(x - \beta\zeta)]$  for all  $x \in \mathbb{R}_+$ , we find that

$$F(x) \geq \mathbf{E}_x \left[ \int_0^{\tau_{n \wedge N+1}-} e^{-rs} \pi(X_s^\nu) ds + \sum_{j=1}^{n \wedge N} e^{-r\tau_j} (\lambda\zeta_j - c) \right].$$

Letting  $n \rightarrow \infty$  and invoking dominated convergence then finally imply that

$$F(x) \geq \mathbf{E}_x \left[ \int_0^{H_0^\nu} e^{-rs} \pi(X_s^\nu) ds + \sum_{j=1}^N e^{-r\tau_j} (\lambda\zeta_j - c) \right].$$

Since this inequality is valid for any admissible impulse control, it has to be valid for the optimal as well, from which the alleged result follows.  $\square$

Lemma 2.1 states a set of considerably weak sufficient conditions which can be applied in the verification of the optimality of a value attained by applying an admissible policy. An interesting implication of Lemma 2.1 stating a set of more easily applicable sufficient conditions is now summarized in the following.

**COROLLARY 2.2.** *Assume that the mapping  $F: \mathbb{R}_+ \mapsto \mathbb{R}_+$  satisfies the conditions  $F \in C^1(\mathbb{R}_+) \cap C^2(\mathbb{R}_+ \setminus \mathcal{D})$ , where  $\mathcal{D}$  is a set of measure zero and  $F''(x \pm) < \infty$  for all  $x \in \mathcal{D}$ . Assume also that  $F$  satisfies the quasi-variational inequality (2.7) for all*

$x \in \mathbb{R}_+$  and the variational inequality  $(\mathcal{A}F)(x) - rF(x) + \pi(x) \leq 0$  for all  $x \notin \mathcal{D}$ . Then,  $F(x) \geq V_c(x)$  for all  $x \in \mathbb{R}_+$ .

*Proof.* As was established in Theorem D.1. in [33, pp. 315–318] the conditions of our corollary guarantee that there exists a sequence  $\{F_n\}_{n=1}^\infty$  of mappings  $F_n \in C^2(\mathbb{R}_+)$  such that

- (i)  $F_n \rightarrow F$  uniformly on compact subsets of  $\mathbb{R}_+$  as  $n \rightarrow \infty$ ;
- (ii)  $(\mathcal{A}F_n) - rF_n \rightarrow (\mathcal{A}F) - rF$  uniformly on compact subsets of  $\mathbb{R}_+ \setminus \mathcal{D}$  as  $n \rightarrow \infty$ ;
- and
- (iii)  $\{(\mathcal{A}F_n) - rF_n\}_{n=1}^\infty$  is locally bounded on  $\mathbb{R}_+$ .

Applying Itô's theorem to the mapping  $(t, x) \mapsto e^{-rt} \Delta_n(x)$ , where  $\Delta_n(x) = F_n(x) - (R_r \pi)(x)$ , taking expectations, and reordering terms yield

$$\begin{aligned} e^{-r\tau_j} \Delta_n(X_{\tau_j}^\nu) &= \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ e^{-r\tau_{j+1}} \Delta_n(X_{\tau_{j+1}-}^\nu) \right] \\ &\quad - \mathbf{E}_{\mathcal{F}_{\tau_j}} \left[ \int_{\tau_j}^{\tau_{j+1}-} e^{-rs} ((\mathcal{A}F_n)(X_s^\nu) - rF_n(X_s^\nu) + \pi(X_s^\nu)) ds \right]. \end{aligned}$$

Letting  $n \rightarrow \infty$ , applying Fatou's theorem, and invoking the variational inequality  $(\mathcal{A}F)(x) - rF(x) + \pi(x) \leq 0$  then result in inequality (2.8). The alleged result now follows from Lemma 2.1.  $\square$

### 3. Auxiliary results.

**3.1. Some associated functionals.** In subsection 2.2 we made a standing assumption that the upper boundary  $\infty$  is natural and the lower boundary 0 is natural, exit, or killing. It is important to point out that in all of these cases we have that  $\lim_{x \rightarrow 0+} \psi(x) = \lim_{x \rightarrow \infty} \varphi(x) = 0$  (cf. [15, p. 19]). These conditions will be used in this subsection without explicit indication. Recall the definition (2.6) of  $\theta$  and consider the expected cumulative present value  $(R_r \theta)$ . By invoking the representation (2.3), differentiating the equation sidewise, and dividing the resulting identity with  $\psi'(x)$ , we find that

$$(3.1) \quad \frac{(R_r \theta)'(x)}{\psi'(x)} = B^{-1} \frac{\varphi'(x)}{\psi'(x)} \int_0^x \psi(y) \theta(y) m'(y) dy + B^{-1} \int_x^\infty \varphi(y) \theta(y) m'(y) dy.$$

Differentiating (3.1) and noticing that  $\varphi''(x)\psi'(x) - \varphi'(x)\psi''(x) = 2rBS'(x)/\sigma^2(x)$  now yield

$$\frac{d}{dx} \left[ \frac{(R_r \theta)'(x)}{\psi'(x)} \right] = \frac{2S'(x)}{\sigma^2(x)\psi'^2(x)} L(x),$$

where the functional  $L : \mathbb{R}_+ \rightarrow \mathbb{R}$  is defined as

$$L(x) = r \int_0^x \psi(y) \theta(y) m'(y) dy - \theta(x) \frac{\psi'(x)}{S'(x)}.$$

The functional  $L$  will prove to be the principal determinant of the optimal policies in all the considered stochastic control problems. Our first auxiliary result is now summarized in the following.

**LEMMA 3.1.** *Let Assumption 2.1 be satisfied. Then there is a unique state  $\hat{x} = \operatorname{argmin}\{\frac{(R_r \theta)'(x)}{\psi'(x)}\} \in (x^*, \infty)$  satisfying the condition  $L(\hat{x}) = 0$ .*

*Proof.* Assume first that  $x^* < x < z$ . Since the mapping  $\theta$  is decreasing on  $(x^*, \infty)$  and

$$r \int_a^b \psi(y) m'(y) dy = \frac{\psi'(b)}{S'(b)} - \frac{\psi'(a)}{S'(a)}$$

for any  $0 < a < b < \infty$ , we have that

$$\begin{aligned} \frac{1}{r} [L(z) - L(x)] &= \int_x^z \psi(y) \theta(y) m'(y) dy - \frac{\theta(z)}{r} \frac{\psi'(z)}{S'(z)} + \frac{\theta(x)}{r} \frac{\psi'(x)}{S'(x)} \\ &> \frac{\theta(z)}{r} \left[ \frac{\psi'(z)}{S'(z)} - \frac{\psi'(x)}{S'(x)} \right] - \frac{\theta(z)}{r} \frac{\psi'(z)}{S'(z)} + \frac{\theta(x)}{r} \frac{\psi'(x)}{S'(x)} \\ &= \frac{[\theta(x) - \theta(z)]}{r} \frac{\psi'(x)}{S'(x)} > 0, \end{aligned}$$

proving that  $L$  is monotonically increasing on  $(x^*, \infty)$ . Analogously, we find that whenever  $z < x < x^*$

$$\begin{aligned} \frac{1}{r} [L(x) - L(z)] &= \int_z^x \psi(y) \theta(y) m'(y) dy - \frac{\theta(x)}{r} \frac{\psi'(x)}{S'(x)} + \frac{\theta(z)}{r} \frac{\psi'(z)}{S'(z)} \\ &< \frac{[\theta(z) - \theta(x)]}{r} \frac{\psi'(z)}{S'(z)} < 0 \end{aligned}$$

showing that  $L$  is monotonically decreasing on  $(0, x^*)$ .

Since the boundary 0 is assumed to be natural, exit, or killing, we find that  $\lim_{x \rightarrow 0+} L(x) \leq 0$ . Moreover, since  $x^*$  is the global maximum of  $\theta$ , we find that

$$\begin{aligned} L(x^*) &= r \int_0^{x^*} \psi(y) \theta(y) m'(y) dy - \theta(x^*) \frac{\psi'(x^*)}{S'(x^*)} \\ &< \theta(x^*) \left[ \frac{\psi'(x^*)}{S'(x^*)} - \frac{\psi'(0)}{S'(0)} \right] - \theta(x^*) \frac{\psi'(x^*)}{S'(x^*)} \leq 0. \end{aligned}$$

Assumption 2.1 implies that there is a unique state  $x_0 \in (x^*, \infty)$  such that  $\theta(x_0) = 0$  and that  $\theta(x) > 0$  on  $(0, x_0)$ . Hence,

$$L(x_0) = r \int_0^{x_0} \psi(y) \theta(y) m'(y) dy > 0.$$

Since  $L$  is increasing on  $(x^*, \infty)$ , we find there is a unique state  $\hat{x} \in (x^*, \infty)$  such that  $L(\hat{x}) = 0$ .  $\square$

Along with the functional  $L$ , two additional functionals will be important in the subsequent study of the considered stochastic control problems. These functionals, which are denoted as  $I : \mathbb{R}_+ \rightarrow \mathbb{R}$  and  $J : \mathbb{R}_+ \rightarrow \mathbb{R}$ , are defined as

$$(3.2) \quad I(x) = \frac{\beta(R_r \pi)'(x) - \lambda}{\psi'(x)}$$

and as

$$(3.3) \quad J(x) = \beta(R_r \pi)(x) - \lambda x - I(x) \psi(x).$$

Note that  $J'(x) = -\psi(x)I'(x)$  for all  $x \in \mathbb{R}_+$ . The functional  $J$  has an alternative representation which will be used later. More precisely, since

$$\frac{\psi(x)}{\psi'(x)} - x = \frac{S'(x)}{\psi'(x)} \int_0^x \psi(y)\rho(y)m'(y)dy$$

(cf. [7, Lemma 3.3]), we find by using the representation (2.3) for  $(R_r\pi)$  that

$$(3.4) \quad J(x) = \frac{S'(x)}{\psi'(x)} \int_0^x \psi(y)\theta(y)m'(y)dy.$$

We will now demonstrate that the behavior of  $L$  dictates the monotonicity properties of the associated functionals  $I$  and  $J$ . This is accomplished in the following.

LEMMA 3.2. *Let Assumption 2.1 be satisfied. Then  $I'(x) \gtrless 0$  and  $J'(x) \lesseqgtr 0$  when  $x \gtrless \hat{x}$ .*

*Proof.* First note that since  $\rho \in \mathcal{L}_1$ , the expression

$$\frac{d}{dx} \left[ \frac{(R_r\rho)'(x)}{\psi'(x)} \right] = \frac{2S'(x)}{\sigma^2(x)\psi'^2(x)} \left[ r \int_0^x \psi(y)\rho(y)m'(y)dy - \rho(x) \frac{\psi'(x)}{S'(x)} \right]$$

holds. On the other hand, we have that

$$\psi''(x) = \frac{2S'(x)}{\sigma^2(x)} \left[ r \int_0^x \psi(y)\rho(y)m'(y)dy - \rho(x) \frac{\psi'(x)}{S'(x)} \right]$$

(cf. [3, Lemma 2.1]), which in turn implies that

$$\frac{d}{dx} \left[ \frac{(R_r\rho)'(x)}{\psi'(x)} \right] = \frac{\psi''(x)}{\psi'^2(x)}.$$

Combining this observation with the findings of Lemma 3.1 now yields

$$I'(x) = \frac{d}{dx} \left[ \frac{\beta(R_r\pi)'(x) - \lambda}{\psi'(x)} \right] = \frac{d}{dx} \left[ \frac{(R_r\theta)'(x)}{\psi'(x)} \right] = \frac{2S'(x)}{\sigma^2(x)\psi'^2(x)} L(x),$$

from which the first alleged inequality follows. The remaining part of the proof follows now from the equation  $J'(x) = -\psi(x)I'(x)$ .  $\square$

Lemma 3.2 essentially demonstrates that under our Assumption 2.1 the threshold  $\hat{x}$  constitutes the global minimum of the functional  $I(x)$  and the global maximum of the functional  $J(x)$ . To close the subsection, we present a lemma determining the limiting properties of  $I$  and  $J$ .

LEMMA 3.3. *Let Assumption 2.1 be satisfied. Then*

$$\lim_{x \rightarrow 0+} J(x) \geq 0, \lim_{x \rightarrow 0+} I(x) \geq 0, \lim_{x \rightarrow \infty} I(x) \leq 0, \text{ and } \lim_{x \rightarrow \infty} J(x) = -\infty.$$

*Proof.* If the origin is attainable, then the representation (3.4) implies that  $J(0) = 0$ , since  $\lim_{x \rightarrow 0+} \frac{\psi'(x)}{S'(x)} > 0$ . On the other hand, if the origin is unattainable, then  $\lim_{x \rightarrow 0+} \frac{\psi'(x)}{S'(x)} = 0$ . In this case l'Hôpital's rule yields

$$\lim_{x \rightarrow 0+} J(x) = \lim_{x \rightarrow 0+} \frac{\psi(x)\theta(x)m'(x)}{\frac{d}{dx} \left[ \frac{\psi'(x)}{S'(x)} \right]} = \lim_{x \rightarrow 0+} \frac{\psi(x)\theta(x)m'(x)}{r\psi(x)m'(x)} = \lim_{x \rightarrow 0+} \frac{\theta(x)}{r} \geq 0.$$

To prove the alleged behavior of  $J$  at infinity, note that

$$\lim_{x \rightarrow \infty} \int_0^x \psi(y) \theta(y) m'(y) dy = -\infty$$

and that  $\lim_{x \rightarrow \infty} \frac{\psi'(x)}{S'(x)} = \infty$ . Thus  $\lim_{x \rightarrow \infty} J(x) = \lim_{x \rightarrow \infty} \frac{\theta(x)}{r} = -\infty$ .

We showed in Lemma 3.1 that the state  $\hat{x} = \operatorname{argmax}\{J(x)\} = \operatorname{argmin}\{I(x)\}$  lies in the interval  $(x^*, \infty)$ , i.e., where  $\theta$  is monotonically decreasing. Hence for  $x > \hat{x}$ , we have that

$$\begin{aligned} I(x) &= B^{-1} \frac{\varphi'(x)}{\psi'(x)} \left[ \int_0^{\hat{x}} \psi(y) \theta(y) m'(y) dy + \int_{\hat{x}}^x \psi(y) \theta(y) m'(y) dy \right] \\ &\quad + B^{-1} \int_x^\infty \varphi(y) \theta(y) m'(y) dy \\ &= B^{-1} \frac{\varphi'(x)}{\psi'(x)} \left[ \frac{\theta(\hat{x})}{r} \frac{\psi'(\hat{x})}{S'(\hat{x})} + \int_{\hat{x}}^x \psi(y) \theta(y) m'(y) dy \right] + B^{-1} \int_x^\infty \varphi(y) \theta(y) m'(y) dy \\ &\leq B^{-1} \frac{\varphi'(x)}{\psi'(x)} \left[ \frac{\theta(\hat{x})}{r} \frac{\psi'(\hat{x})}{S'(\hat{x})} + \frac{\theta(\hat{x})}{r} \left( \frac{\psi'(x)}{S'(x)} - \frac{\psi'(\hat{x})}{S'(\hat{x})} \right) \right] + B^{-1} \int_x^\infty \varphi(y) \theta(y) m'(y) dy \\ &= B^{-1} \frac{\varphi'(x)}{S'(x)} \frac{\theta(\hat{x})}{r} + B^{-1} \int_x^\infty \varphi(y) \theta(y) m'(y) dy. \end{aligned}$$

By letting  $x$  tend to infinity in the inequality above, we discover that  $\lim_{x \rightarrow \infty} I(x) \leq 0$ , since  $\lim_{x \rightarrow \infty} \frac{\varphi'(x)}{S'(x)} = 0$ . The property  $\lim_{x \rightarrow 0+} I(x) \geq 0$  is still left to prove. To prove this, observe that the condition  $I(x) \geq I(\hat{x})$  implies that

$$\lim_{x \rightarrow 0+} \frac{(R_r \theta)'(x)}{S'(x)} = \lim_{x \rightarrow 0+} I(x) \frac{\psi'(x)}{S'(x)} \geq \lim_{x \rightarrow 0+} I(\hat{x}) \frac{\psi'(x)}{S'(x)} = 0;$$

hence  $\lim_{x \rightarrow 0+} (R_r \theta)'(x) \geq 0$ . Now the desired result

$$\lim_{x \rightarrow 0+} I(x) = \lim_{x \rightarrow 0+} \frac{(R_r \theta)'(x)}{\psi'(x)} \geq 0$$

follows, since  $\psi'(x) > 0$ .  $\square$

**3.2. The associated singular control problem.** Before proceeding to the analysis of the stochastic impulse control problem, we first consider an associated singular stochastic control problem. To this end, consider the associated controlled diffusion process  $X^Z$  on  $\mathbb{R}_+$  given by the generalized Itô stochastic differential equation

$$(3.5) \quad dX_t^Z = \mu(X_t^Z) dt + \sigma(X_t^Z) dW_t - \beta dZ_t, \quad X_0^Z = x,$$

where the process  $Z_t$  is an *admissible control*, meaning a nonnegative, nondecreasing, right-continuous, and  $\{\mathcal{F}_t\}$ -adapted process. We denote the class of such processes as  $\Lambda$  and assume that  $\mu$  and  $\sigma$  satisfy the same regularity conditions as in the impulse control case. Given these assumptions, we will consider the associated singular control problem

$$(3.6) \quad K(x) = \sup_{Z \in \Lambda} \mathbf{E}_x \left[ \int_0^{H_0^Z} e^{-rs} (\pi(X_s^Z) ds + \lambda dZ_s) \right],$$

where  $H_0^Z = \inf\{t \geq 0 : X_t^Z \leq 0\}$  denotes the first exit time of the controlled diffusion  $X^Z$  from  $\mathbb{R}_+$ . It is important to emphasize that since the value accumulates only up to the first exit time  $H_0^Z$ , we are actually considering only such controls  $Z$  that keep the process  $X^Z$  positive. Moreover, it is worth observing that applying the generalized Itô theorem to the linear mapping  $x \mapsto \lambda x/\beta$  yields

$$\mathbf{E}_x \int_0^{\tau_N} e^{-rs} \lambda dZ_s = \frac{\lambda x}{\beta} + \mathbf{E}_x \int_0^{\tau_N} e^{-rs} \frac{\lambda}{\beta} \rho(X_s^Z) ds - \mathbf{E}_x \left[ e^{-r\tau_N} \frac{\lambda}{\beta} X_{\tau_N}^Z \right],$$

where  $\rho(x) = \mu(x) - rx$  and  $\tau_N = H_0^Z \wedge N \wedge \inf\{t \geq 0 : X_t^Z \geq N\}$  is an almost surely finite stopping time. The nonnegativity of the controlled process then results by letting  $N$  tend to infinity and invoking monotone convergence to the inequality

$$(3.7) \quad K(x) \leq \beta^{-1} \left[ \lambda x + \sup_{Z \in \Lambda} \mathbf{E}_x \int_0^{H_0^Z} e^{-rs} \theta(X_s^Z) ds \right].$$

It is clear that if the implemented admissible policy is such that

$$\lim_{N \rightarrow \infty} \mathbf{E}_x [e^{-r\tau_N} X_{\tau_N}^Z] = 0,$$

then the inequality (3.7) becomes an equality. In that case the value of the optimal policy can be decomposed into a part measuring the value of the instantaneous liquidation policy and the expected cumulative present value of the excess return accrued from following the optimal policy and postponing the immediate liquidation of the underlying process.

The Hamilton–Jacobi–Bellman equation for (3.6) can be written as

$$(3.8) \quad \max \{ \mathcal{A}K(x) - rK(x) + \pi(x), K'(x) - \lambda/\beta \} = 0$$

for all  $x \in \mathbb{R}_+$ . In the next lemma we will establish the value and the optimal policy for the problem (3.6). These results will later turn out to be useful in the analysis of the impulse control problem (2.5) as well.

LEMMA 3.4. *Let Assumption 2.1 be satisfied. Then the optimal singular stochastic control exists and is given by*

$$(3.9) \quad Z_t^* = \begin{cases} (x - \hat{x})^+, & t = 0, \\ \mathcal{L}(t, \hat{x}), & t > 0, \end{cases}$$

where the threshold  $\hat{x} \in (x^*, \infty)$  is the unique root of the first order condition  $L(\hat{x}) = 0$  and  $\mathcal{L}(t, \hat{x})$  is the local time of  $X$  at  $\hat{x}$  (cf. [15, pp. 21–24]). Moreover, the value function  $K$  reads as

$$(3.10) \quad K(x) = \begin{cases} \beta^{-1} \left( \lambda x + \frac{\theta(\hat{x})}{r} \right), & x \geq \hat{x}, \\ (R_r \pi)(x) - \beta^{-1} I(\hat{x}) \psi(x), & x < \hat{x}, \end{cases}$$

implying that the marginal value  $K'$  can be expressed as

$$(3.11) \quad \begin{aligned} K'(x) &= (R_r \pi)'(x) + \beta^{-1} \psi'(x) \sup_{y \geq x} \left[ \frac{\lambda - \beta (R_r \pi)'(y)}{\psi'(y)} \right] \\ &= \begin{cases} \lambda \beta^{-1}, & x \geq \hat{x}, \\ (R_r \pi)'(x) - \beta^{-1} I(\hat{x}) \psi'(x), & x < \hat{x}. \end{cases} \end{aligned}$$

The value function  $K$  satisfies also the smooth pasting condition  $\lim_{x \rightarrow \hat{x}} K''(x) = 0$ .

*Proof.* Denote the function defined in (3.10) as  $\hat{K}(x)$ . We will now demonstrate that  $K(x) = \hat{K}(x)$  for all  $x \in \mathbb{R}_+$ . Since  $\hat{K}(x)$  is attained by the admissible local time push policy (3.9) (i.e., reflection at  $\hat{x}$ ), it is clear that  $\hat{K}(x) \leq K(x)$  for all  $x \in \mathbb{R}_+$  (cf. section 1.6 in [19]). In order to establish the opposite inequality, we first observe by ordinary differentiation that

$$\hat{K}'(x) = \begin{cases} \lambda\beta^{-1}, & x \geq \hat{x}, \\ \beta^{-1} [\lambda + \psi'(x) (I(x) - I(\hat{x}))], & x < \hat{x}. \end{cases}$$

Since the state  $\hat{x}$  is the global minimum of the functional  $I$ , we find that  $\hat{K}'(x) \geq \lambda\beta^{-1}$  for all  $x \in \mathbb{R}_+$ . Moreover,

$$(\mathcal{A}\hat{K})(x) - r\hat{K}(x) + \pi(x) = \begin{cases} \beta^{-1} (\theta(x) - \theta(\hat{x})), & x \geq \hat{x}, \\ 0, & x < \hat{x}. \end{cases}$$

Since the state  $\hat{x}$  is on the set where  $\theta$  is strictly decreasing, we find that  $(\mathcal{A}\hat{K})(x) - r\hat{K}(x) + \pi(x) \leq 0$  for all  $x \in \mathbb{R}_+$ . Finally, since  $\hat{x}$  minimizes  $I$ , first order optimality conditions imply that  $\psi''(\hat{x})\beta(R_r\pi)''(\hat{x}) = \psi''(\hat{x})(\beta(R_r\pi)'(\hat{x}) - \lambda)$ . Therefore,  $\lim_{x \rightarrow \hat{x}} \hat{K}''(x) = 0$ , implying that  $\hat{K} \in C^2(\mathbb{R}_+)$ . The function  $K$  now satisfies the conditions of Lemma 1 in [1]. Thus  $\hat{K}(x) \geq K(x)$  for all  $x \in \mathbb{R}_+$ .  $\square$

Lemma 3.4 demonstrates that under Assumption 2.1 the associated singular control problem (3.6) is solvable and that the optimal value is attained by utilizing a local time push policy at the threshold  $\hat{x}$  (cf. [20]). The optimal control policy  $Z_t^*$  does not exhibit jumps at time  $H_0^Z$  and, therefore, does not produce interior singularities into the value function  $K$  (see (3.6)). Moreover, Lemma 3.4 also shows that the smooth pasting property holds for (3.6), and we notice from the proof that it is an implication of our approach to the problem. In particular, Lemma 3.4 shows that the value function  $K$  defined in (3.10) is a  $C^2$ -solution of the Hamilton–Jacobi–Bellman equation (3.8). A set of interesting comparative static results implied by Lemma 3.4 are now summarized in the following.

**COROLLARY 3.5.** *Let Assumption 2.1 be satisfied. Then the following hold.*

- (i) *The value  $K$  and the marginal value  $K'$  of the optimal policy are decreasing functions of the parameter  $\beta$ .*
- (ii) *The value  $K$  and the marginal value  $K'$  of the optimal policy are increasing functions of the parameter  $\lambda$ .*
- (iii) *The optimal exercise threshold  $\hat{x}$  is an increasing mapping of the parameter  $\beta$  and a decreasing mapping of the parameter  $\lambda$ .*
- (iv) *If  $\lambda = \beta$ , then the optimal exercise threshold  $\hat{x}$  is independent of  $\lambda$  and  $\beta$ .*

*Proof.* (i) Denote the value associated with the parameter  $\beta_i$  as  $K_i$ ,  $i = 1, 2$ . It is now clear from the proof of Lemma 3.4 that  $K_2$  satisfies the sufficient variational inequalities  $(\mathcal{A}K_2)(x) - rK_2(x) + \pi(x) \leq 0$  and  $K_2'(x) \geq \lambda/\beta_2 > \lambda/\beta_1$  for all  $x \in \mathbb{R}_+$ . Hence,  $K_2(x) \geq K_1(x)$  for all  $x \in \mathbb{R}_+$ . In order to establish that  $K_2'(x) \geq K_1'(x)$  for all  $x \in \mathbb{R}_+$ , we observe that the mapping  $x \mapsto (\lambda - \beta(R_r\pi)'(x))/(\beta\psi'(x))$  is a decreasing function of the parameter  $\beta$  from which the alleged result follows by invoking the representation (3.11). Proving part (ii) is entirely analogous. It remains to consider the sensitivity of the optimal exercise threshold  $\hat{x}$  with respect to parametric changes. To this end, consider the mapping

$$\bar{L}(x, \lambda, \beta) = r \int_0^x \psi(y)(\beta\pi(y) + \lambda\rho(y))m'(y)dy - (\beta\pi(x) + \lambda\rho(x)) \frac{\psi'(x)}{S'(x)}.$$

If  $\beta_1 > \beta_2$ , then

$$\bar{L}(x, \lambda, \beta_1) - \bar{L}(x, \lambda, \beta_2) = (\beta_1 - \beta_2) \left[ r \int_0^x \psi(y) \pi(y) m'(y) dy - \pi(x) \frac{\psi'(x)}{S'(x)} \right] \leq 0$$

since

$$r \int_0^x \psi(y) \pi(y) m'(y) dy - \pi(x) \frac{\psi'(x)}{S'(x)} \leq -\pi(x) \frac{\psi'(0)}{S'(0)} \leq 0$$

by the assumed monotonicity and nonnegativity of  $\pi$ . Therefore, if  $\hat{x}_i$  denotes the optimal exercise threshold associated with  $\beta_i$ ,  $i = 1, 2$ , we observe that  $0 = \bar{L}(\hat{x}_1, \lambda, \beta_1) \leq \bar{L}(\hat{x}_1, \lambda, \beta_2)$ , which, in turn, implies that  $\hat{x}_1 \geq \hat{x}_2$ . Establishing that  $\hat{x}$  is a decreasing mapping of the parameter  $\lambda$  is entirely analogous. Finally, if  $\lambda = \beta$ , then

$$L(x) = \beta \left[ r \int_0^x \psi(y) (\pi(y) + \rho(y)) m'(y) dy - (\pi(x) + \rho(x)) \frac{\psi'(x)}{S'(x)} \right],$$

from which the alleged result follows.  $\square$

Corollary 3.5 characterizes the impact of parametric changes on the value, the marginal value, and the optimal exercise threshold of the irreversible policy. We observe that an increase in  $\beta$  decreases both the value and the marginal value of the optimal policy and, therefore, postpones exercise by increasing the optimal exercise threshold and, therefore, expanding the continuation region where waiting is optimal. The contrary happens when the parameter  $\lambda$  increases. An interesting implication of these comparative static results is that parametric changes are neutral (i.e., do not affect the optimal exercise threshold  $\hat{x}$ ) as long as the ratio  $\lambda/\beta$  is held constant. As usual in models considering cash flow management in the presence of taxation, Corollary 3.5 shows that when  $\lambda = \beta$  the optimal policy is independent of the parameters  $\lambda$  and  $\beta$  (i.e., the *harmonization of tax rates implies the tax neutrality of the optimal policy*).

**3.3. The associated optimal stopping problem.** In this subsection we consider another associated control problem, namely, an optimal stopping problem. Let  $X$  be the diffusion evolving on  $\mathbb{R}_+$  according to the ordinary Itô stochastic differential equation (2.2), and assume that the infinitesimal coefficients  $\mu$  and  $\sigma$  satisfy the same regularity conditions as in the impulse control case. Given these assumptions, consider the corresponding optimal stopping problem

$$(3.12) \quad G_c(x) = \sup_{\tau < H_0} \mathbf{E}_x \left[ \int_0^\tau e^{-rs} \pi(X_s) ds + e^{-r\tau} (\lambda \beta^{-1} X_\tau - c) \right],$$

where  $c \geq 0$  is an arbitrary constant and  $\tau$  is an arbitrary  $\mathcal{F}_t$ -stopping time satisfying the constraint  $\tau < H_0$  stating that the stopping time problem is defined up to the first exit time from  $\mathbb{R}_+$ . Following the reasoning of (3.7), we find by applying Dynkin's theorem to the mapping  $x \mapsto \lambda x/\beta - c$  (or by applying Itô's theorem to the process  $t \mapsto e^{-rt}(\lambda \beta^{-1} X_t - c)$ ) that

$$G_c(x) = \frac{\lambda}{\beta} x - c + \frac{1}{\beta} \sup_{\tau < H_0} \mathbf{E}_x \int_0^\tau e^{-rs} (\theta(X_s) + \beta c r) ds,$$

demonstrating how the value of the optimal policy can in this case be decomposed into the sum of the exercise payoff and the early exercise premium. Our main findings on this associated stopping problem are now summarized in the following.

LEMMA 3.6. *Let Assumption 2.1 be satisfied. Then an optimal stopping policy is to stop at the Markov time  $\tau_{\bar{x}_c} = \inf\{t \geq 0 : X_t \geq \bar{x}_c\}$ , where  $\bar{x}_c$ , denoting the optimal stopping threshold, is the unique root of the equation  $J(\bar{x}_c) = -\beta c$ , where  $J$  is as defined in (3.3). Moreover, the value can be written as*

$$(3.13) \quad \begin{aligned} G_c(x) &= (R_r\pi)(x) + \beta^{-1}\psi(x) \sup_{y \geq x} \left[ \frac{\lambda y - \beta(R_r\pi)(y) - \beta c}{\psi(y)} \right] \\ &= \begin{cases} \beta^{-1}\lambda x - c, & x \geq \bar{x}_c, \\ (R_r\pi)(x) - \beta^{-1}I(\bar{x}_c)\psi(x), & x < \bar{x}_c, \end{cases} \end{aligned}$$

and it satisfies the smooth-pasting condition  $\lim_{x \rightarrow \bar{x}_c-} G'_c(x) = \beta^{-1}\lambda$ .

*Proof.* In order to establish (3.13), denote as  $x_0$  the unique interior state at which  $\theta(x_0) = 0$ . The expression (3.4) implies that

$$\frac{d}{dx} \left[ \frac{\psi'(x)}{S'(x)} J(x) \right] = \psi(x)\theta(x)m'(x) \geq 0, \quad x \leq x_0.$$

Thus  $J(x) > 0$  for all  $x \in (0, x_0)$ , since  $\lim_{x \rightarrow 0+} \frac{\psi'(x)}{S'(x)} J(x) \geq 0$ . On the other hand, we proved in Lemma 3.3 that  $\lim_{x \rightarrow \infty} J(x) = -\infty$ . Together with the monotonicity properties of  $J$ , this implies that there is a unique state  $\bar{x}_c \in \theta^{-1}(\mathbb{R}_-)$  at which the condition  $J(\bar{x}_c) = -\beta c$  is satisfied. Since

$$\frac{d}{dx} \left[ \frac{\lambda x - \beta(R_r\pi)(x) - \beta c}{\psi(x)} \right] = \frac{\psi'(x)}{\psi^2(x)} (J(x) + \beta c),$$

we find that  $\bar{x}_c = \operatorname{argmax} \{(\lambda x - \beta(R_r\pi)(x) - \beta c)/\psi(x)\}$ . The first order optimality condition now implies that

$$\frac{\lambda \bar{x}_c - \beta(R_r\pi)(\bar{x}_c) - \beta c}{\psi(\bar{x}_c)} = \frac{\lambda - \beta(R_r\pi)'(\bar{x}_c)}{\psi'(\bar{x}_c)} = -I(\bar{x}_c),$$

which gives us the expression (3.13) and proves the smooth-pasting condition

$$\lim_{x \rightarrow \bar{x}_c} G'_c(x) = \beta^{-1}\lambda.$$

Given these observations, denote the function defined in (3.13) as  $\hat{G}_c(x)$ . Since

$$\hat{G}_c(x) = \mathbf{E}_x \left[ \int_0^{\tau_{\bar{x}_c}} e^{-rs} \pi(X_s) ds + e^{-r\tau_{\bar{x}_c}} (\lambda \beta^{-1} X_{\tau_{\bar{x}_c}} - c) \right],$$

where  $\tau_{\bar{x}_c} = \inf\{t \geq 0 : X_t \geq \bar{x}_c\}$ , we find that  $\hat{G}_c(x) \leq G_c(x)$  for all  $x \in \mathbb{R}_+$ . On the other hand, we also observe that  $\hat{G}_c$  is continuously differentiable on  $\mathbb{R}_+$ , is twice continuously differentiable on  $\mathbb{R}_+ \setminus \{\bar{x}_c\}$ , satisfies the inequalities  $|\hat{G}_c''(\bar{x}_c \pm)| < \infty$ , and satisfies the variational inequality  $\min\{r\hat{G}_c(x) - (\mathcal{A}\hat{G}_c)(x) - \pi(x), \hat{G}_c(x) - \lambda\beta^{-1}x + c\} = 0$ . Thus  $\hat{G}_c(x) \geq G_c(x)$  for all  $x \in \mathbb{R}_+$ .  $\square$

Lemma 3.6 establishes that under Assumption 2.1 the optimal stopping problem (3.12) is solvable and that an optimal stopping policy is a threshold policy requiring that the underlying process should be stopped once it hits the constant boundary  $\bar{x}_c$  at which the expected present value of the exercise payoff is maximized. At the optimal exercise threshold  $\bar{x}_c$  the standard balance identity holds and the value of

the project  $\bar{x}_c$  coincides with the sum of the sunk cost  $c$  and the lost option value  $G_c(\bar{x}_c)$ . Moreover, following the reasoning of our findings on the associated singular stochastic control problem, we find that the smooth-pasting principle holds for the problem (3.12) as well. We also note that  $G_c''(\bar{x}_c-) \neq 0$ ; in other words,  $G_c$  is not twice continuously differentiable over the boundary  $\bar{x}_c$ . A set of interesting comparative static results implied by Lemma 3.6 are now summarized in the following.

**COROLLARY 3.7.** *Let Assumption 2.1 be satisfied. Then the following hold.*

- (i) *The value  $G_c$  is a decreasing function of both the parameter  $\beta$  and the sunk cost  $c$  and an increasing function of the parameter  $\lambda$ .*
- (ii) *The optimal exercise threshold  $\bar{x}_c$  is an increasing mapping of both the parameter  $\beta$  and the sunk cost  $c$  and a decreasing mapping of the parameter  $\lambda$ .*
- (iii) *If  $\lambda = \beta$ , then the optimal exercise threshold  $\bar{x}_c$  is independent of  $\lambda$  and  $\beta$ .*

*Proof.* The claim of part (i) of our corollary follows directly from the definition of the exercise payoff. Thus, it is sufficient to consider the sensitivity of the optimal threshold  $\bar{x}_c$  to changes in  $\lambda$ ,  $\beta$ , or  $c$ . To this end, consider the mapping

$$\tilde{L}(x, \lambda, \beta, c) = \int_0^x \psi(y)(\beta\pi(y) + \lambda\rho(y))m'(y)dy + \beta c \frac{\psi'(x)}{S'(x)}$$

and denote as  $\bar{x}_c(\beta_i)$  the optimal exercise threshold associated with the parameter  $\beta_i$ . If  $\beta_1 > \beta_2$ , then

$$\tilde{L}(x, \lambda, \beta_1, c) - \tilde{L}(x, \lambda, \beta_2, c) = (\beta_1 - \beta_2) \left[ \int_0^x \psi(y)\pi(y)m'(y)dy + c \frac{\psi'(x)}{S'(x)} \right] > 0,$$

which implies that  $0 = \tilde{L}(\bar{x}_c(\beta_1), \lambda, \beta_1, c) > \tilde{L}(\bar{x}_c(\beta_1), \lambda, \beta_2, c)$  and, therefore, that  $\bar{x}_c(\beta_1) > \bar{x}_c(\beta_2)$ . The analysis of the impact of changes in either  $\lambda$  or  $c$  on the optimal exercise threshold is entirely analogous. Finally, if  $\lambda = \beta$ , then

$$\bar{x}_c = \operatorname{argmax} \{ (x - (R_r\pi)(x) - c)/\psi(x) \},$$

from which the alleged result follows.  $\square$

Corollary 3.7 extends the findings of Corollary 3.5 to the present example. More precisely, we observe that an increase in  $\beta$  postpones rational exercise by expanding the continuation region where stopping is suboptimal. The opposite is shown to happen when  $\lambda$  increases. Interestingly, we again find that parametric changes are neutral (i.e., do not affect the optimal exercise threshold  $\bar{x}_c$ ) as long as the ratio  $\lambda/\beta$  is held constant. Following the reasoning of our findings on the associated singular control problem, we again find that if  $\lambda = \beta$ , the optimal exercise strategy is independent of the parameters  $\lambda$  and  $\beta$  (i.e., *harmonization results in neutrality*). Moreover, as is intuitively clear, our findings indicate that increased sunk costs decrease the value and postpone rational exercise by expanding the continuation region.

#### 4. Optimal impulse control policy.

**4.1. Necessary conditions.** The stochastic impulse control problems of type (2.5) are typically tackled by relying on a combination of the classical Hamilton–Jacobi–Bellman approach and quasi-variational inequalities. In this study, we plan to adopt an alternative approach which results in more easily interpretable conditions characterizing a potentially optimal policy. Instead of considering all the admissible impulse controls at once, we restrict our attention to the subclass  $\nu_{(\zeta, y)}$  of impulse

controls characterized by the sequence of intervention times  $\tau_0^y = 0$ ,  $\tau_k^y = \inf\{t \geq \tau_{k-1}^y : X_t^{\nu(\zeta, y)} \geq y\}$  and the sequence of interventions  $\zeta_k^y = \zeta + (x - y)^+$  for all  $k \geq 1$ . That is, we restrict our attention to control policies consisting of sequence of constant-sized impulses (with the exception of the initial impulse, which depends on the initial state) exerted every time the underlying diffusion hits a predetermined, constant exercise threshold  $y$ . Given this class of admissible impulse controls, define the value  $F_c : \mathbb{R}_+ \rightarrow \mathbb{R}$  accrued from applying the impulse control  $\nu_{(\zeta, y)}$  as  $F_c(x) = J_c^{(\zeta, y)}(x)$ . Since  $X_{\tau_k^y+}^{\nu(\zeta, y)} = X_{\tau_k^y-}^{\nu(\zeta, y)} - \beta\zeta = y - \beta\zeta$  for all  $k$  and the controlled diffusion evolves as the linear diffusion  $X$  between any two successive intervention dates, we observe that for all  $x < y$  the value satisfies the functional relation (a so-called *running present value formulation*)

$$(4.1) \quad F_c(x) = \mathbf{E}_x \left[ \int_0^{\tau_y} e^{-rs} \pi(X_s) ds + e^{-r\tau_y} (\lambda(X_{\tau_y} - (y - \zeta)) - c + F_c(y - \beta\zeta)) \right],$$

where  $\tau_y = \inf\{t \geq 0 : X_t \geq y\}$ . Invoking the strong Markov property of diffusions now implies that the value  $F_c(x)$  can be represented as

$$(4.2) \quad F_c(x) = \begin{cases} F_c(y - \beta\zeta) + \lambda(x - y + \zeta) - c, & x \geq y, \\ (R_r\pi)(x) + (\lambda\zeta - c - (R_r\pi)(y) + F_c(y - \beta\zeta)) \frac{\psi(x)}{\psi(y)}, & x < y. \end{cases}$$

First, note that letting  $x$  tend to  $y$  in (4.2) yields the *value-matching condition*  $F_c(y) = F_c(y - \beta\zeta) + \lambda\zeta - c$ , which can be re-expressed in the more familiar form  $F_c(y - \beta\zeta) + \lambda\zeta = F_c(y) + c$  stating that *the value of the investment opportunity has to coincide with its full costs (lost option value + sunk cost)*. On the other hand, letting  $x$  tend to  $y - \beta\zeta$  yields

$$(4.3) \quad F_c(y - \beta\zeta) = \frac{\psi(y)(R_r\pi)(y - \beta\zeta) + [\lambda\zeta - c - (R_r\pi)(y)]\psi(y - \beta\zeta)}{\psi(y) - \psi(y - \beta\zeta)}.$$

Now, inserting (4.3) into (4.2) implies that the value can be expressed as

$$(4.4) \quad F_c(x) = \begin{cases} (R_r\pi)(y - \beta\zeta) + h(\zeta, y)\psi(y - \beta\zeta) + \lambda(x - y + \zeta) - c, & x \geq y, \\ (R_r\pi)(x) + h(\zeta, y)\psi(x), & x < y, \end{cases}$$

where the mapping  $h : \mathbb{R}_+^2 \rightarrow \mathbb{R}$  is defined as

$$(4.5) \quad h(\zeta, y) = \frac{(R_r\pi)(y - \beta\zeta) - (R_r\pi)(y) + \lambda\zeta - c}{\psi(y) - \psi(y - \beta\zeta)}.$$

In order to prove the existence and uniqueness of the optimal impulse control policy, we will consider the constrained nonlinear programming problem

$$(4.6) \quad \sup_{\substack{\beta\zeta \in [0, y], \\ y \in \mathbb{R}_+}} \frac{(R_r\pi)(y - \beta\zeta) - (R_r\pi)(y) + \lambda\zeta - c}{\psi(y) - \psi(y - \beta\zeta)}.$$

To ease the subsequent analysis, introduce a linear change of variables  $z := y - \beta\zeta$ . Thus  $\zeta = \beta^{-1}(y - z)$ . Since the parameter  $\beta$  is assumed to be positive, the programming problem (4.6) can now be rewritten as

$$(4.7) \quad \sup_{\substack{z \in [0, y], \\ y \in \mathbb{R}_+}} \frac{(R_r\pi)(z) - (R_r\pi)(y) + \lambda\beta^{-1}(y - z) - c}{\psi(y) - \psi(z)}.$$

If an interior pair maximizing the mapping  $h$  exists, denote the associated mapping of the form (4.1) as  $F_c^*$ . More precisely, if an interior pair  $(z_c^*, y_c^*)$  satisfying the problem (4.7) exists, define the mapping  $F_c^* : \mathbb{R} \rightarrow \mathbb{R}$  as

$$(4.8) \quad F_c^*(x) = \begin{cases} (R_r\pi)(z_c^*) + h(z_c^*, y_c^*)\psi(z_c^*) + \gamma(x) - c, & x \geq y_c^*, \\ (R_r\pi)(x) + h(z_c^*, y_c^*)\psi(x), & x < y_c^*, \end{cases}$$

where  $\gamma(x) = \lambda(x - y_c^* - \beta^{-1}(y_c^* - z_c^*))$ . Since  $h$  is differentiable, it is clear that if an interior pair  $(z_c^*, y_c^*)$  satisfying the problem (4.7) exists, then this pair satisfies the ordinary necessary first order conditions  $\frac{\partial h}{\partial z}(z_c^*, y_c^*) = \frac{\partial h}{\partial y}(z_c^*, y_c^*) = 0$ . More precisely, if an optimal pair exists, it must satisfy the conditions

$$(4.9) \quad \begin{cases} (\psi(y_c^*) - \psi(z_c^*)) (\lambda\beta^{-1} - (R_r\pi)'(y_c^*)) = r(z_c^*, y_c^*)\psi'(y_c^*), \\ (\psi(y_c^*) - \psi(z_c^*)) (\lambda\beta^{-1} - (R_r\pi)'(z_c^*)) = r(z_c^*, y_c^*)\psi'(z_c^*), \end{cases}$$

where  $r(z, y) = (R_r\pi)(z) - (R_r\pi)(y) + \lambda\beta^{-1}(y - z) - c$ . This immediately yields the condition

$$\frac{\lambda - \beta(R_r\pi)'(z_c^*)}{\psi'(z_c^*)} = \frac{\lambda - \beta(R_r\pi)'(y_c^*)}{\psi'(y_c^*)}.$$

Using the definition (3.2), this can be rewritten as

$$(4.10) \quad I(y_c^*) - I(z_c^*) = 0.$$

On the other hand, since

$$\frac{\psi'(z_c^*)}{\psi(y_c^*) - \psi(z_c^*)} = \frac{(R_r\pi)'(z_c^*) - \lambda\beta^{-1}}{r(z_c^*, y_c^*)},$$

we find by invoking condition (4.10) and reordering the terms that

$$[\beta(R_r\pi)(y_c^*) - I(y_c^*)\psi(y_c^*) - \lambda y_c^*] - [\beta(R_r\pi)(z_c^*) - I(z_c^*)\psi(z_c^*) - \lambda z_c^*] = -\beta c.$$

Using the definition (3.3), this can be expressed as

$$(4.11) \quad J(y_c^*) - J(z_c^*) = -\beta c.$$

Conditions (4.10) and (4.11) are standard necessary first order conditions for the existence of the solution of the problem (4.7). In a recent paper [10], a similar idea is used to solve another impulse control problem, where first order optimality conditions are derived for an associated functional reminiscent of (4.8) (see [10, equation 2.17]). However, our control problem differs from the problem of [10] on a fundamental level (we will comment on this in the next subsection). Moreover, the actual solution methods are also different.

**4.2. Existence and sufficiency.** Having the necessary conditions (4.10) and (4.11) at our disposal, we will now study their solvability under Assumption 2.1.

**LEMMA 4.1.** *Let Assumption 2.1 be satisfied. Then there exists a unique interior pair  $(z_c^*, y_c^*)$  for which the necessary conditions (4.10) and (4.11) are satisfied.*

*Proof. Existence.* Define the mappings  $\tilde{J} : (0, \hat{x}) \rightarrow (\tilde{J}(0), \tilde{J}(\hat{x}))$  and  $\hat{J} : [\hat{x}, \infty) \rightarrow (-\infty, \hat{J}(\hat{x}))$  as restrictions of the mapping  $J$  and the mapping  $k : \mathbb{R} \rightarrow \mathbb{R}$  as

FIG. 4.1. A prototype figure of the functions  $I$  (solid curve) and  $J$  (dashed curve). The vertical solid line marks the state  $\hat{x}$ .

$k(x) = x - \beta c$ . It is clear that both  $\check{J}$  and  $\hat{J}$  are continuous and monotonic. Define now the mapping  $\hat{y} : (0, \hat{x}) \rightarrow (\hat{y}(\hat{x}), \hat{y}(0))$  as  $\hat{y}(x) = (\hat{J}^{-1} \circ k \circ \check{J})(x)$ . By the definitions of  $\check{J}$ ,  $\hat{J}$ , and  $k$ , we observe that  $\hat{y}$  is well defined. Moreover, the mapping  $\hat{y}$  is continuous as a composition of continuous mappings. Finally, since  $\hat{y}(z) = \hat{J}^{-1}(\check{J}(z) - \beta c)$ , we find that the equation  $J(\hat{y}(z)) - J(z) = -\beta c$  holds for all  $z \in (0, \hat{x})$ .

Analogously, define the mappings  $\check{I} : (0, \hat{x}) \rightarrow (\check{I}(\hat{x}), \check{I}(0))$  and  $\hat{I} : [\hat{x}, \infty) \rightarrow [\hat{I}(\hat{x}), \hat{I}(0))$  as restrictions of the mapping  $I$ . It is clear that both  $\check{I}$  and  $\hat{I}$  are continuous and monotonic. Define the mapping  $Y : (0, \hat{x}) \rightarrow (\check{I}^{-1}(\hat{I}(\hat{y}(\hat{x}))), \check{I}^{-1}(\hat{I}(\hat{y}(0))))$  as  $Y(x) = (\check{I}^{-1} \circ \hat{I} \circ \hat{y})(x)$ . Since  $0 < \beta c < \infty$  and  $\hat{J}$  is decreasing, we find that  $\hat{y}(\hat{x}) = \hat{J}^{-1}(\check{J}(\hat{x}) - \beta c) > \hat{J}^{-1}(\check{J}(\hat{x})) = \hat{x}$  and  $\hat{y}(0) = \hat{J}^{-1}(\check{J}(0) - \beta c) \leq \hat{J}^{-1}(-\beta c) < \infty$ . First, these inequalities together with monotonicity of  $\check{I}$  and  $\hat{I}$  guarantee that  $Y$  is well defined. Moreover, coupled with Lemma 3.3 they imply that

$$\left( \check{I}^{-1}(\hat{I}(\hat{y}(\hat{x}))), \check{I}^{-1}(\hat{I}(\hat{y}(0))) \right) \subsetneq \left( \check{I}^{-1}(\hat{I}(\hat{x})), \check{I}^{-1}(\hat{I}(x)) \right) \Big|_{x=\infty} \subseteq (0, \hat{x}).$$

In other words, we find that the image of  $Y$  is strictly included in the domain of  $Y$ . This observation coupled with the fact that  $Y$  is continuous implies that  $Y$  has a fixed point. In other words, there is a state  $z_c^* \in (0, \hat{x})$  for which  $I(z_c^*) = \check{I}(z_c^*) = \hat{I}(\hat{y}(z_c^*)) = I(\hat{y}(z_c^*))$ . Moreover, since  $z_c^* \in (0, \hat{x})$  the equation  $J(\hat{y}(z_c^*)) - J(z_c^*) = -\beta c$  also holds.

*Uniqueness.* Assume that  $z^*$  is a fixed point for the mapping  $Y$ . Since  $J'(x) = -\psi(x)I'(x)$ , we find that

$$Y'(z^*) = \frac{J'(z^*)}{I'(z^*)} \frac{I'(\hat{y}(z^*))}{J'(\hat{y}(z^*))} = \frac{\psi(z^*)}{\psi(\hat{y}(z^*))} < 1.$$

In other words we find that the curve  $Y(x)$  intersects the diagonal always from above. Continuity of  $Y$  yields now the desired uniqueness.  $\square$

Lemma 4.1 demonstrates that Assumption 2.1 is sufficient for both the existence and uniqueness of a solution for the typically highly nonlinear (cf. Figure 4.1) necessary conditions (4.10) and (4.11). It is worth pointing out that since the existence result of Lemma 4.1 is based on a fixed point argument, the existence of a potentially

optimal pair is guaranteed for a considerably broad class of problems. In comparison to the recent paper [10], Lemma 4.1 is analogous to the main result of [10], where the original impulse control problem is defined over threshold policies described by single open interval. We will now proceed by proving that the optimal threshold policy determined by Lemma 4.1 is optimal over the class  $\mathcal{V}$  defined in (2.5), which is much wider than the class of threshold policies.

**THEOREM 4.2.** *Let Assumption 2.1 be satisfied. Then the optimal impulse control policy is to instantaneously take the controlled diffusion  $X_t^\nu$  to the state  $y_c^* - \beta\zeta_c^*$  whenever it hits the state  $y_c^*$  (i.e., the size of the impulse is  $\beta\zeta_c^*$ ). If the initial state  $x \geq y_c^*$ , then  $\tau_1 = 0$  and  $\zeta_1 = \beta^{-1}(x - (y_c^* - \beta\zeta_c^*))$ . Moreover, the value of the optimal impulse control policy reads as*

$$(4.12) \quad V_c(x) = F_c^*(x) = \begin{cases} \beta^{-1}(\lambda x + J(y_c^*)), & x \geq y_c^*, \\ (R_r\pi)(x) - \beta^{-1}I(y_c^*)\psi(x), & x < y_c^*, \end{cases}$$

and the optimal intervention times are given by  $\tau_{i+1} = \inf\{t \geq \tau_i : X_t^\nu \geq y_c^*\}$ ,  $i \geq 1$ .

*Proof.* Since the policy described above is admissible, it is clear that  $F_c^*(x) \leq V_c(x)$  for all  $x \in \mathbb{R}_+$ . To prove the opposite inequality, we first observe that  $F_c^* \in C^1(\mathbb{R}_+) \cap C^2(\mathbb{R}_+ \setminus \{y_c^*\})$  and that  $F_c^{*''}(y_c^*+) = 0 \leq |(R_r\pi)''(y_c^*) - \beta^{-1}I(y_c^*)\psi''(y_c^*)| = |F_c^{*''}(y_c^*-)| < \infty$  implying that  $F_c^*$  is stochastically  $C^2(\mathbb{R}_+)$ . Moreover, we find that  $((\mathcal{A} - r)F_c^*)(x) + \pi(x) = 0$  on  $(0, y_c^*)$  and that  $((\mathcal{A} - r)F_c^*)(x) + \pi(x) = \beta^{-1}(\theta(x) - rJ(y_c^*))$  on  $(y_c^*, \infty)$ . On the other hand, (3.4) implies that

$$I'(x) = \frac{2(rJ(x) - \theta(x))}{\sigma^2(x)\psi'(x)}.$$

Since  $I$  is nondecreasing on  $(\hat{x}, \infty)$  and  $\hat{x} < y_c^*$ , we find that  $\theta(x) \leq rJ(x)$  on  $(y_c^*, \infty)$ . This implies that  $((\mathcal{A} - r)F_c^*)(x) + \pi(x) \leq r\beta^{-1}(J(x) - J(y_c^*)) \leq 0$  for all  $x \in (y_c^*, \infty)$ , since  $J$  is nonincreasing on  $(y_c^*, \infty)$ . Hence  $((\mathcal{A} - r)F_c^*)(x) + \pi(x) \leq 0$  for all  $x \in \mathbb{R}_+ \setminus \{y_c^*\}$ .

Our next task is to show that  $F_c^*$  satisfies the quasi-variational inequality

$$F_c^*(x) \geq \sup_{\beta\zeta \in [0, x]} [F_c^*(x - \beta\zeta) + \lambda\zeta - c]$$

for all  $x \in \mathbb{R}_+$ . Note that this quasi-variational inequality can also be written in the form  $F_c^*(x) \geq \beta^{-1}(\lambda x - \beta c) + \sup_{y \in [0, x]} [F_c^*(y) - \lambda\beta^{-1}y]$ . Define now the mapping  $A : \mathbb{R}_+ \rightarrow \mathbb{R}$  as

$$A(x) = F_c^*(x) - \beta^{-1}(\lambda x - \beta c) - \sup_{y \in [0, x]} [F_c^*(y) - \lambda\beta^{-1}y].$$

Utilizing (4.10) we find that

$$F_c^{*'}(x) = \begin{cases} \lambda\beta^{-1}, & x \geq y_c^*, \\ \beta^{-1}(\lambda + \psi'(x)(I(x) - I(y_c^* - \beta\zeta_c^*))), & x < y_c^*. \end{cases}$$

Since  $I$  is nonincreasing on  $(0, \hat{x})$  and  $y_c^* - \beta\zeta_c^* < \hat{x}$ , we find that  $F_c^{*'}(x) > \lambda\beta^{-1}$  on  $(0, y_c^* - \beta\zeta_c^*)$ . Moreover, the condition (4.10) implies that  $I(x) - I(y_c^*) < 0$  for all  $x \in (y_c^* - \beta\zeta_c^*, y_c^*)$ . Therefore,  $F_c^{*'}(x) \leq \lambda\beta^{-1}$  on  $(y_c^* - \beta\zeta_c^*, y_c^*)$ . Finally, since

$F_c^{*'}(x) = \lambda\beta^{-1}$  on  $(y_c^*, \infty)$ , we find that the function  $x \mapsto F_c^*(x) - \lambda\beta^{-1}x$  attains a global maximum at  $y_c^* - \beta\zeta_c^*$ . Therefore,

$$\sup_{y \in [0, x]} [F_c^*(y) - \lambda\beta^{-1}y] = \begin{cases} F_c^*(y_c^* - \beta\zeta_c^*) - \lambda\beta^{-1}(y_c^* - \beta\zeta_c^*), & x > y_c^* - \beta\zeta_c^*, \\ F_c^*(x) - \lambda\beta^{-1}x, & x \leq y_c^* - \beta\zeta_c^*. \end{cases}$$

Using (4.11) the mapping  $A$  can now be written in the form

$$A(x) = \begin{cases} 0, & x \geq y_c^*, \\ (R_r\pi)(x) - I(y_c^*)\psi(x) - \lambda\beta^{-1}x - J(y_c^*), & x \in (y_c^* - \beta\zeta_c^*, y_c^*), \\ c, & x \leq y_c^* - \beta\zeta_c^*. \end{cases}$$

Since  $\lim_{x \rightarrow y_c^* -} A(x) = 0$  and  $A'(x) = (R_r\pi)(x) - I(y_c^*)\psi'(x) - \lambda\beta^{-1} = \psi'(x)(I(x) - I(y_c^*)) < 0$  for all  $x \in (y_c^* - \beta\zeta_c^*, y_c^*)$ , we find that  $A(x) \geq 0$  on  $(y_c^* - \beta\zeta_c^*, y_c^*)$ ; hence  $A(x) \geq 0$  for all  $x \in \mathbb{R}_+$ .

Finally, given the continuity of  $F_c^*$  and the fact that the state-space  $(0, y_c^*)$  of the controlled diffusion  $X_t^\nu$  is bounded, we observe that  $\mathbf{E}_x[e^{-rt}F_c^*(X_t^\nu)] \rightarrow 0$  for all  $x \in \mathbb{R}_+$  as  $t \rightarrow \infty$ . Thus  $F_c^*(x) \geq V_c(x)$  for all  $x \in \mathbb{R}_+$  and  $\nu^* = \nu_{(\zeta_c^*, y_c^*)}$ .  $\square$

Theorem 4.2 demonstrates that the admissible policy  $\nu^* = \nu_{(\zeta_c^*, y_c^*)}$  is optimal and  $F_c^*$  is the value of the optimal policy under Assumption 2.1. This observation is of interest since it emphasizes the role of the mapping  $\theta$  as the principal determinant of both the existence and uniqueness of an optimal policy. In comparison to [7], it is worth emphasizing that the conditions of Theorem 4.2 are relatively weak since no concavity assumptions are needed and only the monotonicity and continuity properties of the mapping  $\theta$  are required for guaranteeing the validity of our results.

Having studied the existence and uniqueness of an optimal impulse control policy, we now plan to analyze the comparative static properties of the optimal policy and its value. In accordance with our earlier findings in Corollaries 3.5 and 3.7 we can now establish the following corollary.

**COROLLARY 4.3.** *Let Assumption 2.1 be satisfied. Then the value  $V_c$  is a decreasing function of both the parameter  $\beta$  and the sunk cost  $c$  and an increasing function of the parameter  $\lambda$ . In particular, if  $\lambda = \beta$ , then  $\partial\zeta_c^*/\partial\lambda = -\zeta_c^*/\lambda < 0$  and both the optimal exercise boundary  $y_c^*$  and the optimal generic initial state  $z_c^* = y_c^* - \lambda\zeta_c^*$  are independent of  $\lambda$  and  $\beta$ .*

*Proof.* Denote as  $V_{c, \lambda_i}$  the value of the optimal policy associated with the parameter  $\lambda_i$ ,  $i = 1, 2$ , and assume that  $\lambda_1 > \lambda_2$ . It is now clear from the proof of Theorem 4.2 that the value  $V_{c, \lambda_1}$  satisfies the variational inequality  $(\mathcal{A}V_{c, \lambda_1})(x) - rV_{c, \lambda_1}(x) + \pi(x) \leq 0$  for all  $x \in \mathbb{R}_+ \setminus \{y_{c, \lambda_1}^*\}$ , where  $y_{c, \lambda_1}^*$  denotes the optimal exercise threshold associated with the parameter  $\lambda_1$ . Moreover, since  $V_{c, \lambda_1}$  also satisfies the sufficient quasi-variational inequality

$$V_{c, \lambda_1}(x) \geq \sup_{y \in [0, x]} \left[ V_{c, \lambda_1}(y) + \frac{\lambda_1}{\beta}(x - y) \right] - c \geq \sup_{y \in [0, x]} \left[ V_{c, \lambda_1}(y) + \frac{\lambda_2}{\beta}(x - y) \right] - c,$$

we find that  $V_{c, \lambda_1}(x) \geq V_{c, \lambda_2}(x)$ . Proving that  $V_c$  is a decreasing function of both the parameter  $\beta$  and the sunk cost  $c$  is entirely analogous. Finally, if  $\lambda = \beta$ , then the necessary conditions (4.9) imply that  $y_c^*$  and  $z_c^*$  are independent of  $\lambda$  and  $\beta$ . However, since  $z_c^* = y_c^* - \lambda\zeta_c^*$ , we find that  $\partial\zeta_c^*/\partial\lambda = -\zeta_c^*/\lambda < 0$  by partial differentiation.  $\square$

Corollary 4.3 summarizes the impact of parametric changes on the value of the optimal policy. Interestingly, and in contrast to our findings on the associated control

problems, Corollary 4.3 proves that even though the optimal exercise boundary and generic initial state are independent of the parameters  $\lambda$  and  $\beta$  whenever  $\lambda = \beta$ , the optimal impulse  $\zeta_c^*$  is a decreasing function of  $\lambda$ . Thus, the harmonization of the parameters  $\lambda$  and  $\beta$  does not result in the neutrality of the optimal policy. Unfortunately, it is difficult to explicitly characterize the impact of parametric changes in either  $\lambda$  or  $\beta$  on the optimal exercise boundary  $y_c^*$  and the optimal generic initial state  $y_c^* - \beta\zeta_c^*$ . Fortunately, the impact of changes in the sunk cost  $c$  can be explicitly characterized by studying the behavior of the implicit curves  $I(y_c^*) - I(y_c^* - \beta\zeta_c^*) = 0$  and  $J(y_c^*) - J(y_c^* - \beta\zeta_c^*) = -\beta c$ . Implicit differentiation of these curves with respect to  $c$  together with the relation  $J'(x) = -\psi(x)I'(x)$  yield the conditions

$$(4.13) \quad \frac{d(y_c^* - \beta\zeta_c^*)}{dc} = -\frac{\beta}{I'(y_c^* - \beta\zeta_c^*)[\psi(y_c^* - \beta\zeta_c^*) - \psi(y_c^*)]} < 0$$

and

$$(4.14) \quad \frac{dy_c^*}{dc} = -\frac{\beta}{I'(y_c^*)[\psi(y_c^* - \beta\zeta_c^*) - \psi(y_c^*)]} > 0.$$

In other words, the optimal threshold  $y_c^*$  decreases, the regeneration state  $y_c^* - \beta\zeta_c^*$  increases, and, therefore, the optimal impulse  $\zeta_c^*$  decreases as the fixed intervention cost  $c$  decreases. This observation is intuitively clear, since the proof of Lemma 4.1 implies that  $\lim_{c \rightarrow 0+} y_c^* = \hat{x}$  and  $\lim_{c \rightarrow 0+} \zeta_c^* = 0$ . Moreover, by continuity of the increasing fundamental solution  $\psi$ , we discover that  $\lim_{c \rightarrow 0+} \frac{dy_c^*}{dc} = \infty$  and  $\lim_{c \rightarrow 0+} \frac{d\zeta_c^*}{dc} = -\infty$ . Finally, by ordinary differentiation we find that

$$\frac{dV_c}{dc}(x) = \begin{cases} \beta^{-1} J'(y_c^*) \frac{dy_c^*}{dc}, & x \geq y_c^* \\ -\beta^{-1} \psi(x) I'(y_c^*) \frac{dy_c^*}{dc}, & x < y_c^* \end{cases} < 0.$$

Summarizing, we formulate the following lemma characterizing the impact of the transaction cost  $c$  on the value of the optimal policy (see, for example, [32] for a similar observation).

LEMMA 4.4. *Let Assumption 2.1 be satisfied. Then,  $d(y_c^* - \beta\zeta_c^*)/dc < 0$ ,  $dy_c^*/dc > 0$ , and  $d\zeta_c^*/dc > 0$ . Moreover,*

$$\lim_{c \rightarrow 0+} y_c^* = \hat{x}, \lim_{c \rightarrow 0+} \zeta_c^* = 0, \lim_{c \rightarrow 0+} \frac{dy_c^*}{dc} = \infty, \lim_{c \rightarrow 0+} \frac{d\zeta_c^*}{dc} = -\infty, \text{ and } \lim_{c \rightarrow 0+} \frac{dV_c}{dc}(x) = -\infty$$

for all  $x \in \mathbb{R}_+$ .

In light of our general findings and the explicit characterization of the value of the optimal impulse policy, it would be of interest to analyze how increased volatility affects the optimal boundary  $y_c^*$  and the optimal impulse  $\zeta_c^*$ . Unfortunately, as our results indicated, the value function is neither concave nor convex on the entire state-space of the controlled process. Thus, presenting a set of easily verifiable general conditions under which the sign of the relationship between increased volatility and the optimal policy could be unambiguously characterized is extremely difficult, if possible at all.

**4.3. Ordering of the values.** We have established in Lemmas 3.4 and 3.6 and in Theorem 4.2 that all three control problems (3.6), (3.12), and (2.5) are solvable under Assumption 2.1. In this subsection we study how the value functions as well as the marginal values of these associated stochastic control problems can be ordered. To

this end, recall first the expression (3.10) for the value of the singular control problem (3.6). This value can be rewritten as

$$(4.15) \quad K(x) = \begin{cases} \beta^{-1}(\lambda x + J(\hat{x})), & x \geq \hat{x}, \\ (R_r\pi)(x) - \beta^{-1}I(\hat{x})\psi(x), & x < \hat{x}. \end{cases}$$

In the next lemma we show that the value (4.15) has an interesting maximality property. This lemma extends the results obtained in [7] to a model subject to a linear exercise payoff.

LEMMA 4.5. *Define the continuously differentiable mapping  $H : \mathbb{R}_+^2 \rightarrow \mathbb{R}_+$  as*

$$H(x, y) = \begin{cases} \beta^{-1}(\lambda x + J(y)), & x \geq y, \\ (R_r\pi)(x) - \beta^{-1}I(y)\psi(x), & x < y, \end{cases}$$

*and let Assumption 2.1 be satisfied. Then  $K(x) = H(x, \hat{x}) > H(x, y)$  and  $K'(x) = H_x(x, \hat{x}) > H_x(x, y)$  for all  $(x, y) \in \mathbb{R}_+ \times \mathbb{R} \setminus \{\hat{x}\}$ . Moreover,  $H_y(x, y) < 0$ , for all  $(x, y) \in \mathbb{R}_+ \times (\hat{x}, \infty)$ .*

*Proof.* We first find that

$$H_y(x, y) = \begin{cases} -\beta^{-1}I'(y)\psi(y), & x \geq y, \\ -\beta^{-1}I'(y)\psi(x), & x < y. \end{cases}$$

By the monotonicity properties of the function  $I$ , this implies that  $H_y(x, y) \geq 0$ ,  $y \leq \hat{x}$ . This observation coupled with the identity  $K(x) = H(x, \hat{x})$  proves that  $K(x) = H(x, \hat{x}) > H(x, y)$  for all  $(x, y) \in \mathbb{R}_+ \times \mathbb{R} \setminus \{\hat{x}\}$ . Moreover, since

$$H_{xy}(x, y) = \begin{cases} 0, & x \geq y, \\ -\beta^{-1}I'(y)\psi'(x), & x < y, \end{cases}$$

the monotonicity properties of  $I$  imply that  $K'(x) = H_x(x, \hat{x}) > H_x(x, y)$  for all  $(x, y) \in \mathbb{R}_+ \times \mathbb{R} \setminus \{\hat{x}\}$ .  $\square$

Lemma 4.5 shows that the value of the associated singular stochastic control problem not only dominates but also grows faster than any other solution of the associated free-boundary value problem

$$(4.16) \quad \begin{cases} (\mathcal{A}u)(x) - ru(x) + \pi(x) = 0, & x < y, \\ u'(x) = \lambda/\beta, & x \geq y. \end{cases}$$

This result is of interest since it emphasizes the role of the flexibility of the admissible policy as the main determinant of both the actual value and its growth rate. As we will later observe, it is these variational inequalities which relate the considered stochastic impulse control problem to both the associated singular stochastic control problem and to the associated optimal stopping problem.

Our main characterization of the impact of the flexibility of the applied policy on the values and the marginal values of the considered stochastic control problems is now summarized in the following (cf. [7] for a similar observation in the linear payoff case).

THEOREM 4.6. *Let Assumption 2.1 be satisfied. Then*

$$K(x) \geq V_c(x) \geq G_c(x) \quad \text{and} \quad K'(x) \geq V'_c(x) \geq G'_c(x)$$

*for all  $x \in \mathbb{R}_+$ . Moreover,  $\bar{x}_c > y_c^* > \hat{x}$  for all  $c > 0$ .*

*Proof.* In order to prove that  $K(x) \geq G_c(x)$  for all  $x \in \mathbb{R}_+$ , observe that  $K$  satisfies the variational inequality  $(\mathcal{A}K)(x) - rK(x) + \pi(x) \leq 0$  for all  $x \in \mathbb{R}_0$ . Moreover, since  $I$  is decreasing on  $(0, \hat{x})$ , we find that the inequality  $K(x) - (\lambda\beta^{-1}x - c) \geq \beta^{-1}J(\min(x, \hat{x})) \geq 0$  holds for all  $x \in \mathbb{R}_+$ . Thus  $K$  satisfies the sufficient variational inequalities, guaranteeing that  $K(x) \geq G_c(x)$  for all  $x \in \mathbb{R}_+$ . The inequality  $K'(x) \geq G'_c(x)$  for all  $x \in \mathbb{R}_+$  is now a straightforward consequence of the representation (3.11) and Lemma 4.5.

Inequality  $K(x) \geq V_c(x)$  for all  $x \in \mathbb{R}_+$  follows directly from Lemma 4.5 and the representation (4.12). On the other hand, as was established in the proof of Theorem 4.2, the value function  $V_c$  is continuously differentiable on the whole of  $\mathbb{R}_+$ , is twice continuously differentiable on  $\mathbb{R}_+ \setminus \{y_c^*\}$ , and satisfies the variational inequality  $(\mathcal{A}V_c)(x) - rV_c(x) + \pi(x) \leq 0$  for all  $x \in \mathbb{R}_+ \setminus \{y_c^*\}$ . Moreover, since

$$V_c(x) \geq \sup_{\beta\zeta \leq x} [\lambda\zeta - c + V_c(x - \beta\zeta)] \geq \lambda\beta^{-1}x - c$$

for all  $x \in \mathbb{R}_+$ , we observe that  $V_c$  satisfies the sufficient quasi-variational inequalities guaranteeing that  $V_c(x) \geq G_c(x)$  for all  $x \in \mathbb{R}_+$ .

It is clear from the proof of Lemma 4.1 that  $y_c^* > \hat{x}$ . Moreover, since

$$0 \leq V_c(x) - G_c(x) = \beta^{-1}\psi(x)(I(\bar{x}_c) - I(y_c^*))$$

for all  $x \in (0, \min(y_c^*, \bar{x}_c))$  and both of the thresholds  $\bar{x}_c$  and  $y_c^*$  are attained on the set where  $I(x)$  is nondecreasing, we find that  $\bar{x}_c \geq y_c^*$ .

It remains to establish that  $K'(x) \geq V'_c(x) \geq G'_c(x)$  for all  $x \in \mathbb{R}_+$ . Again, the inequality  $K'(x) \geq V'_c(x)$  for all  $x \in \mathbb{R}_+$  follows directly from Lemma 4.5. Since  $\bar{x}_c \geq y_c^* \geq \hat{x}$ , we find that

$$V'_c(x) - G'_c(x) \geq \begin{cases} \beta^{-1}J(y_c^* - \beta\zeta_c^*), & y_c^* < \bar{x}_c \leq x, \\ \beta^{-1}\psi(x)[I(\bar{x}_c) - I(x)], & y_c^* \leq x < \bar{x}_c \text{ or } x < y_c^* < \bar{x}_c. \end{cases}$$

Consequently, we find that  $V'_c(x) - G'_c(x) \geq 0$  for all  $x \in \mathbb{R}_+$  since both of the thresholds  $y_c^*$  and  $\bar{x}_c$  are attained on the set where  $I$  is nondecreasing.  $\square$

Theorem 4.6 states a strong ordering for the stochastic control problems in terms of their values, marginal values, and continuation regions. Interestingly, Theorem 4.6 proves that increased policy flexibility increases not only the value of the optimal stochastic control but also its marginal value. This observation is interesting from the point of view of financial and economical applications since essentially it implies that increased cash flow management flexibility increases not only the value of a rationally managed corporation but also the rate at which this value grows and, therefore, *Tobin's marginal q* associated to the particular cash flow management problem.

The proof of Theorem 4.6 relies on Lemma 4.5. However, it is of interest to notice that the ordering of the optimal values can be justified by a direct inclusion argument. More precisely, it is clear that within our problem specifications, an admissible stopping policy is also an admissible impulse control policy corresponding to a single impulse  $\zeta = (X_\tau/\beta)\chi_{\tau < H_0}$  which takes the underlying diffusion to 0 at the stopping time. On the other hand, since an admissible impulse control policy is nonnegative, nondecreasing, right-continuous, and  $\{\mathcal{F}_t\}$ -adapted, we find that since the value of the associated singular stochastic control problem constitutes the largest attainable value within this class of policies, it, in turn, dominates the value of an admissible impulse control policy, thus resulting in the desired ordering of the values. However, we

emphasize that this simple argument cannot be used for the ordering of the marginal values, which is an essentially more delicate result.

**5. Illustration: Controlled geometric Brownian motion.** In order to illustrate our results explicitly, we now assume that the underlying controlled geometric Brownian motion evolves according to the dynamics characterized by the stochastic differential equation

$$(5.1) \quad X_t^\nu = x + \int_0^t \mu X_s^\nu ds + \int_0^t \sigma X_s^\nu dW_s - \sum_{\tau_k \leq t} \beta \zeta_k, \quad 0 \leq t \leq \tau_0^\nu,$$

where  $\mu > 0$  and  $\sigma > 0$  are exogenously determined known parameters. For the sake of the finiteness of the value of the considered stochastic control problems, we assume that  $r > \mu$ , that is, that the discount rate dominates the expected per capita growth rate of the controlled GBM. It is well known that in this case the fundamental solutions read as  $\psi(x) = x^\kappa$  and  $\varphi(x) = x^\phi$ , where

$$\kappa = \frac{1}{2} - \frac{\mu}{\sigma^2} + \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}} > 1$$

and

$$\phi = \frac{1}{2} - \frac{\mu}{\sigma^2} - \sqrt{\left(\frac{1}{2} - \frac{\mu}{\sigma^2}\right)^2 + \frac{2r}{\sigma^2}} < 0.$$

Given the considered controlled process, we now assume that the revenue flow accrued from continuing operation reads as  $\pi(x) = x^\alpha$ , where  $\alpha \in (0, 1)$ . Hence, we observe that  $\theta(x) = \beta x^\alpha - (r - \mu)\lambda x$ , implying that the conditions of Lemma 3.1 are satisfied and that

$$x^* = \operatorname{argmax}\{\theta(x)\} = \left(\frac{\alpha\beta}{(r - \mu)\lambda}\right)^{1/(1-\alpha)}.$$

Moreover, standard integration implies that  $(R_r\pi)(x) = x^\alpha/(r - \delta(\alpha))$ , where  $\delta(\alpha) = \alpha\mu + \sigma^2\alpha(\alpha - 1)/2$ .

The value of the optimal singular stochastic control policy reads as

$$(5.2) \quad K(x) = \begin{cases} \frac{\lambda}{\beta}(x - \hat{x}) + \frac{1}{r}\left(\hat{x}^\alpha + \frac{\lambda\mu}{\beta}\hat{x}\right), & x \geq \hat{x}, \\ \frac{x^\alpha}{(r - \delta(\alpha))} + \frac{1}{\kappa}\left(\frac{\lambda}{\beta}\hat{x} - \frac{\alpha\hat{x}^\alpha}{(r - \delta(\alpha))}\right)\left(\frac{x}{\hat{x}}\right)^\kappa, & x < \hat{x}, \end{cases}$$

where the optimal threshold  $\hat{x}$  reads as

$$\hat{x} = \left(\frac{\alpha\beta(\kappa - \alpha)}{(r - \delta(\alpha))(\kappa - 1)\lambda}\right)^{1/(1-\alpha)} = \left(1 + \frac{1 - \alpha}{\alpha - \phi}\right)^{1/(1-\alpha)}.$$

Since

$$\frac{\partial\phi}{\partial\sigma} = \frac{2\phi(\phi - 1)}{\sigma(\kappa - \phi)} > 0,$$

FIG. 5.1. The optimal exercise boundary  $\hat{x}(\sigma)$ .

we immediately find that

$$\frac{\partial \hat{x}}{\partial \sigma} = \left( \frac{1 - \phi}{\alpha - \phi} \right)^{\alpha/(1-\alpha)} \frac{x^*}{(\alpha - \phi)^2} \frac{\partial \phi}{\partial \sigma} > 0.$$

Hence, we find that increased volatility increases the optimal threshold at which the irreversible policy should be exercised. Moreover, standard differentiation also yields that

$$\frac{\partial \hat{x}}{\partial \beta} = \frac{\hat{x}}{(1 - \alpha)\beta} > 0 \quad \text{and} \quad \frac{\partial \hat{x}}{\partial \lambda} = -\frac{\hat{x}}{(1 - \alpha)\lambda} < 0,$$

demonstrating along the lines of our Corollary 3.5 that the optimal exercise threshold is an increasing function of the parameter  $\beta$  and a decreasing function of the parameter  $\lambda$ . The optimal exercise boundary is illustrated as a function of the underlying volatility in Figure 5.1 for  $\beta = 0.9, 1, 1.1$  under the assumption that  $r = 0.045, \mu = 0.025, \alpha = 0.5$ , and  $\lambda = 10$ .

The value of the associated optimal stopping problem reads as

$$(5.3) \quad G_c(x) = \begin{cases} \frac{\lambda}{\beta}x - c, & x \geq \bar{x}_c, \\ \frac{x^\alpha}{(r - \delta(\alpha))} + \left( \frac{\lambda}{\beta}\bar{x}_c - \frac{\bar{x}_c^\alpha}{(r - \delta(\alpha))} - c \right) \left( \frac{x}{\bar{x}_c} \right)^\kappa, & x < \bar{x}_c, \end{cases}$$

where the optimal stopping boundary  $\bar{x}_c > \hat{x}$  is the unique root of the equation

$$\bar{x}_c^\alpha - \frac{(\kappa - 1)(r - \delta(\alpha))\lambda}{\beta(\kappa - \alpha)}\bar{x}_c + \frac{\kappa c(r - \delta(\alpha))}{\kappa - \alpha} = 0.$$

The optimal exercise boundary  $\bar{x}_c$  is illustrated as a function of the underlying volatility in Figure 5.2 for  $\beta = 0.9, 1, 1.1$  under the assumption that  $r = 0.045, \mu = 0.025, \alpha = 0.5, c = 1$ , and  $\lambda = 10$ .

The value of the considered stochastic impulse control problem reads as

$$(5.4) \quad V_c(x) = \begin{cases} \frac{\lambda}{\beta}(x - y_c^*) + \frac{1}{\kappa} \left( \frac{(\kappa - \alpha)y_c^{*\alpha}}{(r - \delta(\alpha))} + \frac{\lambda}{\beta}y_c^* \right), & x \geq y_c^*, \\ \frac{x^\alpha}{(r - \delta(\alpha))} - \frac{1}{\kappa} \left( \frac{\alpha y_c^{*\alpha}}{r - \delta(\alpha)} - \frac{\lambda}{\beta}y_c^* \right) \left( \frac{x}{y_c^*} \right)^\kappa, & x < y_c^*, \end{cases}$$

where the optimal impulse threshold  $y_c^*$  and generic initial state  $z_c^* = y_c^* - \beta\zeta_c^*$  are the unique roots of the optimality conditions

$$\alpha\beta(y_c^{*\alpha-\kappa} - z_c^{*\alpha-\kappa}) = (r - \delta(\alpha))\lambda(y_c^{*1-\kappa} - z_c^{*1-\kappa})$$

FIG. 5.2. The optimal exercise boundary  $\bar{x}_c(\sigma)$ .TABLE 1  
The impact of increased volatility.

$\sigma$	0.01	0.05	0.1	0.15	0.2	0.25

$y_c^* - \zeta_c^*$	4.482	4.656	5.124	5.749	6.443	7.147

TABLE 2  
The impact of increased volatility.

$\sigma$	0.01	0.05	0.1	0.15	0.2	0.25
$y_c^*$	11.562	12.122	13.641	15.727	18.138	20.725
$\zeta_c^*$	6.091	6.437	7.382	8.699	10.257	11.977
$\zeta_c^*/y_c^*$	0.5268	0.5310	0.5412	0.5532	0.5655	0.5779
$y_c^* - \zeta_c^*$	5.471	5.685	6.259	7.027	7.881	8.747

and

$$\beta(\kappa - \alpha)(y_c^{*\alpha} - z_c^{*\alpha}) - \lambda(r - \delta(\alpha))(\kappa - 1)(y_c^* - z_c^*) = -\kappa\beta(r - \delta(\alpha))c.$$

Unfortunately, solving these nonlinear equations explicitly is difficult (if possible at all). Hence, we numerically illustrate the optimal exercise threshold  $y_c^*$ , the optimal impulse  $\zeta_c^*$ , the ratio  $\zeta_c^*/y_c^*$ , and the optimal generic initial state  $y_c^* - \zeta_c^*$  in Table 1 under the assumption that  $r = 0.045$ ,  $\mu = 0.025$ ,  $\alpha = 0.5$ ,  $c = 1$ ,  $\beta = 1$ , and  $\lambda = 10$ .

Table 1 clearly indicates that increased volatility not only increases the optimal threshold at which the impulse policy is irreversibly exercised but also simultaneously increases both the size of the optimal policy and the optimal generic initial state. This result is of interest from the point of view of risk management since it clearly demonstrates that increased volatility will result in both larger but less frequent dividends and a larger generic initial capital protecting the rationally managed corporation from future unfavorable yet uncertain events (i.e., a larger capital buffer). It is also worth emphasizing that our results indicate that the optimal dividend-capital-ratio  $\zeta_c^*/y_c^*$  is also an increasing function of volatility. Consequently, even though increased volatility increases the generic initial state  $y_c^* - \zeta_c^*$ , it simultaneously decreases the ratio between the buffers and the optimal capital.

The impact of a change in the parameter  $\beta$  on the risk sensitivity of the optimal impulse control policy is numerically illustrated in Table 2 under the assumption that  $r = 0.045$ ,  $\mu = 0.025$ ,  $\alpha = 0.5$ ,  $c = 1$ ,  $\beta = 1.1$ , and  $\lambda = 10$  and in Table 3 under the assumption that  $r = 0.045$ ,  $\mu = 0.025$ ,  $\alpha = 0.5$ ,  $c = 1$ ,  $\beta = 0.9$ , and  $\lambda = 10$ . Along the lines of our previous findings on both the associated optimal stopping problem and the associated singular stochastic control problem, our numerical illustrations seem

TABLE 3  
*The impact of increased volatility.*

$\sigma$	0.01	0.05	0.1	0.15	0.2	0.25
$y_c^*$	7.989	8.377	9.429	10.876	12.55	14.35
$\zeta_c^*$	4.394	4.643	5.323	6.272	7.394	8.635
$\zeta_c^*/y_c^*$	0.55	0.5542	0.5646	0.5767	0.5892	0.6017
$y_c^* - \zeta_c^*$	3.595	3.734	4.106	4.604	5.155	5.715

to indicate that the optimal variables are increasing as functions of the parameter  $\beta$  and decreasing as functions of the parameter  $\lambda$ .

**6. Concluding comments.** In this article, we considered a broad class of stochastic impulse control problems arising in the literature on rational cash flow management and optimal harvesting. We presented a set of weak conditions guaranteeing the existence and uniqueness of an optimal pair characterizing the state at which the impulse policy should be exerted and the size of the optimal impulse policy. We derived the value of the optimal policy and characterized its sensitivity with respect to changes in the cost parameters. We also studied two associated stochastic control problems and presented a general ordering for the values as well as for the marginal values of the considered problems. In line with economic intuition, our findings supported the view according to which increased policy flexibility should increase the value of a rationally managed corporation. Moreover, our results indicated that the sign of the relationship between policy flexibility and the rate at which the value of the optimal policy is increasing as a function of the controlled diffusion is unambiguously positive as well.

Even though our results are relatively general in the sense that the controlled diffusion was assumed only to be one-dimensional, they are based on the idea that the admissible bounded variation control policy is one-sided. It would, therefore, be of interest to study whether our findings could be extended to a more general setting where the applied impulse control policy can drive the underlying diffusion both upward and downward (as in the recent study by Weerasinghe [38]). Unfortunately, such extension is outside the scope of the present study and, therefore, left for future research.

# AN INVERSE PROBLEM FOR A PARABOLIC VARIATIONAL INEQUALITY WITH AN INTEGRO-DIFFERENTIAL OPERATOR\*

YVES ACHDOU†

**Abstract.** We consider the calibration of a Lévy process with American vanilla options. The price of an American vanilla option as a function of the maturity and the strike satisfies a forward in time linear complementarity problem involving a partial integro-differential operator. It leads to a variational inequality in a suitable weighted Sobolev space. Calibrating the Lévy process amounts to solving an inverse problem where the state variable satisfies the previously mentioned variational inequality. We propose a regularized least square method. After studying the variational inequality carefully, we find necessary optimality conditions for the least square problem. In this work, we focus on the case when the volatility is bounded away from zero.

**Key words.** Lévy process, American options, model calibration, inverse problem, variational inequality, optimality conditions

**1. Introduction.** Consider an arbitrage-free market described by a probability measure  $\mathbb{P}$  on a scenario space  $(\Omega, \mathcal{A})$ . There is a risk-free asset whose price at time  $\tau$  is  $e^{r\tau}$ ,  $r \geq 0$ , and a risky asset whose price at time  $\tau$  is  $S_\tau$ . Specifying an arbitrage-free option pricing model necessitates the choice of a risk-neutral measure, i.e., a probability  $\mathbb{P}^*$  equivalent to  $\mathbb{P}$  such that the discounted price  $(e^{-r\tau}S_\tau)_{\tau \in [0, T]}$  is a martingale under  $\mathbb{P}^*$ . Such a probability measure  $\mathbb{P}^*$  allows for the pricing of European options; consider a European option with payoff  $\overline{P}_o$  at maturity  $t \leq T$ : its price at time  $\tau \leq t$  is  $P_\tau = e^{-r(t-\tau)}\mathbb{E}^{\mathbb{P}^*}(\overline{P}_o(S_t)|\mathcal{F}_\tau)$ , where  $(\mathcal{F}_\tau)_{\tau \in [0, T]}$  is the natural filtration. Similarly, consider an American option with payoff  $\overline{P}_o$  and maturity  $t \leq T$ : the price of this option at time  $\tau$  is

$$(1.1) \quad P_\tau = \sup_{s \in \mathcal{T}_{\tau, t}} \mathbb{E}^{\mathbb{P}^*} \left( e^{-r(s-\tau)} \overline{P}_o(S_s) \mid \mathcal{F}_\tau \right),$$

where  $\mathcal{T}_{\tau, t}$  denotes the set of stopping times in  $[\tau, t]$ .

The pricing model  $\mathbb{P}^*$  must be compatible with the prices of the options observed on the market, whose number may be large. *Model calibration* consists of finding  $\mathbb{P}^*$  such that the discounted price  $(e^{-r\tau}S_\tau)_{\tau \in [0, T]}$  is a martingale and such that the option prices computed by, e.g., (1.1) in the case of American options coincide with the observed option prices. This is an *inverse problem*. We focus on the case when the observed prices  $(\bar{p}_i)_{i \in I}$  are those of a family of American vanilla put options indexed by  $i \in I$ , with maturities  $t_i$  (assuming for simplicity that  $T = \max_{i \in I} t_i$ ) and strikes  $x_i$ .

The Black–Scholes model assumes that  $(S_\tau)_{\tau \in [0, T]}$  is a geometric Brownian motion under  $\mathbb{P}^*$ :  $dS_\tau = S_\tau(r d\tau + \sigma dW_\tau)$ , where the volatility  $\sigma$  is a constant. Unfortu-

nately, this model is often too simple to match the observed option prices and must be replaced by more involved models.

(1) Black–Scholes models with local volatility. The volatility is assumed to be a function of time and of the price of the underlying asset. This volatility function is calibrated by observing the option prices available on the markets and solving inverse problems involving either partial differential equations or inequalities; see [3, 7, 24] for volatility calibration with European options and [2, 5] with American options;

(2) Models where the volatility is also a stochastic process; see, e.g., [21]. The option price is then found as a function of time, the price of the underlying asset, and the volatility. These models also lead to parabolic partial differential equations or inequalities with possible degeneracies when the volatility vanishes; stochastic volatility calibration has been performed in [32].

(3) Models with Lévy driven underlying assets. Lévy processes are processes with stationary and independent increments which are continuous in probability; see the book by Cont and Tankov [13] and the references therein—for example, [19, 20]. The option price is found by solving partial integro-differential (PID) equations or inequalities. Calibration of Lévy models with European options has been discussed in [14, 15]. The present work is devoted to the calibration of Lévy processes with American options. At this stage, it is not yet necessary to discuss Lévy processes in detail. For the moment, we just assume that the model is characterized by parameters  $\theta$  in a suitable class  $\Theta$ .

The last two classes of models describe incomplete markets: the knowledge of the historical price process alone does not allow us to compute the option prices in a unique manner. When the option prices do not determine the model completely, additional information may be introduced into the problem by specifying a *prior* model. If the historical price process has been estimated statistically from the time series of the underlying asset, this knowledge has to be injected in the inverse problem; calling  $\mathbb{P}_0$  the prior probability measure obtained as an estimation of  $\mathbb{P}$ , we are going to focus on least square formulations of the following type: find  $\theta \in \Theta$  which minimizes

$$(1.2) \quad \sum_{i \in I} \omega_i \left( P^\theta(0, S_o, t_i, x_i) - \bar{p}_i \right)^2 + \rho J_2(\mathbb{P}^\theta, \mathbb{P}_0),$$

where

- $\omega_i$  are suitable positive weights,
- $S_o$  is the price of the underlying asset today,
- $P^\theta(0, S_o, t_i, x_i)$  is the price of the option with maturity  $t_i$  strike  $x_i$ , computed with the pricing model associated with  $\theta$ , and
- $\rho J_2(\mathbb{P}^\theta, \mathbb{P}_0)$  is a regularization term which measures the closedness of the model  $\mathbb{P}^\theta$  to the prior. The number  $\rho > 0$  is called the regularization parameter. This functional has two roles: (1) it stabilizes the inverse problem; for that,  $\rho$  should be large enough and  $J_2$  should be convex or at least convex in a large enough region; (2) it guarantees that  $\mathbb{P}^\theta$  remains close to  $\mathbb{P}_0$  in some sense. The choice of  $J_2$  is very important:  $J_2(\mathbb{P}^\theta, \mathbb{P}_0)$  is often chosen as the relative entropy of the pricing measure  $\mathbb{P}^\theta$  w.r.t. the prior model  $\mathbb{P}_0$  (see [8]) because the relative entropy becomes infinite if  $\mathbb{P}^\theta$  is not equivalent to  $\mathbb{P}_0$ . Some authors have argued that such a choice may be too conservative in some cases for two reasons: (a) the historical data which determine the prior may be missing or partially available; (b) in the context of, e.g., volatility calibration, once the volatility is specified under  $\mathbb{P}_0$ , then the volatility under

$\mathbb{P}^\theta$  must be the same for the relative entropy to be finite. In [9] a different approach was considered which allowed for volatility calibration.

Note that evaluating the functional in (1.2) requires solving  $\#I$  linear complementarity problems (LCPs) involving PID operators in the variables  $\tau$  and  $S$ ; see section 2.1 below. This approach was chosen in [2, 5] for calibrating local volatility with American options.

In the present case (Lévy driven assets), we show that there is a better approach which consists of computing the prices  $P^\theta(0, S_o, t_i, x_i)$ ,  $i \in I$ , by using a single forward in time LCP with a PID operator in the variables maturity  $t$  and strike  $x$ . This LCP is introduced in section 2.2; see (2.9)–(2.11) below. It is reminiscent of the forward equation (known as Dupire’s equation in the finance community) which is often used for local volatility calibration with vanilla European options; see [4, 18].

We then find a new least square problem where the functional is evaluated by solving a single LCP involving a PID operator. The main goal of the paper is to study this least square problem theoretically for a rather general parameterization of the Lévy density  $k$  (see (2.14) below), with the volatility  $\sigma$  bounded away from 0, and to give necessary optimality conditions. This problem has connections with some optimal control problems for variational inequalities studied in [11, 23, 31]. The article of Hintermüller [22] on an inverse problem for an elliptic variational inequality has inspired [2] and the present work.

As far as we know, this is the first attempt at calibrating Lévy processes with American options, so comparison with other methods is difficult. The results below can be used in practice because they have their discrete counterparts when finite elements or finite differences are used. The accuracy is expected to be similar to that observed in [5].

The paper is organized as follows. In section 2, we obtain the forward LCP (2.9)–(2.11) and make some assumptions on the Lévy density. In section 3, we introduce a family of fractional weighted Sobolev spaces and give preliminary results on the nonlocal operator in (2.9). In section 4 we carefully study the variational inequality stemming from (2.9)–(2.11). For the analysis, we must first study a regularized nonlinear problem posed in a bounded domain and then let the regularization parameter tend to 0 and the domain’s boundary tend to infinity. The sensitivity of the solution to variations of  $\sigma$  and  $k$  is discussed in section 5. Finally, the inverse problem is studied in section 6: necessary optimality conditions are given. Some technical proofs are postponed in Appendices A and B.

For the reader’s convenience, let us point out the main results of this work:

- The forward complementarity problem is written in (2.9)–(2.11), and the assumptions on  $k$  are described in section 2.3.
- Theorem 4.9 contains a result of existence and uniqueness for the variational inequality associated to (2.9)–(2.11) in suitable Sobolev spaces. It is also proved that the related free boundary stays in a bounded region. Note that, by using the theory presented in [10], it is possible to study the variational inequality in Sobolev spaces with decaying weights as  $x \rightarrow 0$  and  $x \rightarrow +\infty$  (actually the variable  $\log(x)$  was used instead of  $x$  in [10]). Here, we show that these weights can be avoided. Another advantage of the present analysis is that it can be extended to the case when  $\sigma = 0$  by singular perturbation arguments if the Lévy measure is chosen to keep the problem parabolic. This will be done in a forthcoming work [1].
- The sensitivity of solutions w.r.t. variations of the Lévy process is studied in section 5.

- Theorem 6.6 contains the necessary optimality conditions for the least square inverse problem. These conditions are obtained by first studying a modified inverse problem whose state variable satisfies the above-mentioned regularized nonlinear problem and then by passing to the limit as the regularization parameter tends to zero.

## 2. Description of the model.

**2.1. The backward LCP.** For a Lévy process  $(X_\tau)_{\tau \geq 0}$  on a filtered probability space, the Lévy–Khintchine formula says that there exists a function  $\chi : \mathbb{R} \rightarrow \mathbb{C}$  such that  $\mathbb{E}(e^{iuX_\tau}) = e^{\tau\chi(u)}$ , with

$$\chi(u) = -\frac{\sigma^2 u^2}{2} + i\beta u + \int_{|z| < 1} (e^{iuz} - 1 - iuz)\nu(dz) + \int_{|z| > 1} (e^{iuz} - 1)\nu(dz)$$

for  $\sigma \geq 0$ ,  $\beta \in \mathbb{R}$ , and a positive measure  $\nu$  on  $\mathbb{R} \setminus \{0\}$  such that  $\int_{\mathbb{R}} \min(1, z^2)\nu(dz) < +\infty$ . The measure  $\nu$  is called the Lévy measure of  $(X_\tau)_{\tau \geq 0}$ .

We assume that the discounted price of the risky asset is a martingale obtained as the exponential of a Lévy process:  $e^{-r\tau}S_\tau = S_0 e^{\tilde{X}_\tau}$ . The fact that the discounted price is a martingale is equivalent to

$$\int_{|z| > 1} e^z \nu(dz) < \infty \quad \text{and} \quad \beta = -\frac{\sigma^2}{2} - \int_{\mathbb{R}} (e^z - 1 - z1_{|z| \leq 1})\nu(dz).$$

We also assume that  $\int_{|z| > 1} e^{2z}\nu(dz) < \infty$ , so the discounted price is a square integrable martingale.

In what follows, we assume that the Lévy measure has a density,  $\nu(dz) = k(z)dz$ , with  $k$  possibly singular at  $z = 0$ . Doing so, we exclude the simplest Lévy processes obtained as the sum of Brownian motions and Poisson processes. This is not a fundamental restriction in the sense that the methods proposed below could be extended (and even simplified) to calibrate the previously mentioned processes. The restriction is mainly done in order to focus on the difficulties posed by the possible singularities of  $k$  at  $z = 0$ .

We denote  $\bar{B}$  the integral operator:

$$(\bar{B}v)(S) = \int_{\mathbb{R}} \left( v(Se^z) - v(S) - S(e^z - 1) \frac{\partial}{\partial S} v(S) \right) k(z) dz.$$

Consider an American option with payoff  $\bar{P}_o$  and maturity  $t$ . In [10], Bensoussan and Lions assume  $\sigma > 0$  and study the variational inequality stemming from the LCP:  $P(t, S) = \bar{P}_o(S)$ , and for  $\tau < t$  and  $S > 0$ ,

$$(2.1) \quad \frac{\partial P}{\partial \tau}(\tau, S) + \frac{\sigma^2 S^2}{2} \frac{\partial^2 P}{\partial S^2}(\tau, S) + rS \frac{\partial P}{\partial S}(\tau, S) - rP(\tau, S) + (\bar{B}P)(\tau, S) \leq 0,$$

$$(2.2) \quad P(\tau, S) \geq \bar{P}_o(S),$$

$$(2.3) \quad \left( \frac{\partial P}{\partial \tau}(\tau, S) + \frac{\sigma^2 S^2}{2} \frac{\partial^2 P}{\partial S^2}(\tau, S) + rS \frac{\partial P}{\partial S}(\tau, S) - rP(\tau, S) + (\bar{B}P)(\tau, S) \right) (P(\tau, S) - \bar{P}_o(S)) = 0$$

in suitable Sobolev spaces with decaying weights near  $+\infty$  and 0. They prove that the price of the American option is  $P_\tau = P(\tau, S_\tau)$ . Other approaches with viscosity solutions are possible (see [34]), especially in the case  $\sigma = 0$ . One advantage of the variational methods is that they provide stability estimates. For numerical methods for options on Lévy driven assets; see [4, 16, 17, 28, 29, 30].

**2.2. The forward LCP.** As already explained, we aim at finding a forward LCP in the variables maturity/strike; a single solution of this problem will be needed for evaluating the cost function in (1.2).

Hereafter, since the observed prices are those of vanilla American put options, we use the notation

$$(2.4) \quad P_{\circ}(x) = (x - S)_{+}.$$

If  $\bar{P}_{\circ}(S) = (x - S)_{+}$ , it can be seen that the solution of (2.1)–(2.3) is of the form

$$(2.5) \quad P(\tau, S, t, x) = xg(\xi, y), \quad y = S/x \in \mathbb{R}_{+}, \quad \xi = t - \tau \in (0, t),$$

where  $g$  is the solution of the complementarity problem independent of  $x$ ,  $g(0, y) = (1 - y)_{+}$ , and for  $0 < \xi \leq t$ ,  $y \in \mathbb{R}_{+}$ ,

$$(2.6) \quad -\frac{\partial g}{\partial \xi}(\xi, y) + \frac{\sigma^2 y^2}{2} \frac{\partial^2 g}{\partial y^2}(\xi, y) + ry \frac{\partial g}{\partial y}(\xi, y) - rg(\xi, y) + (\check{B}g)(\xi, y) \leq 0,$$

$$(2.7) \quad g(\xi, y) \geq (1 - y)_{+},$$

$$(2.8) \quad \left( \begin{array}{c} -\frac{\partial g}{\partial \xi}(\xi, y) + \frac{\sigma^2 y^2}{2} \frac{\partial^2 g}{\partial y^2}(\xi, y) + ry \frac{\partial g}{\partial y}(\xi, y) \\ -rg(\xi, y) + (\check{B}g)(\xi, y) \end{array} \right) (g(\xi, y) - (1 - y)_{+}) = 0,$$

where  $(\check{B}v)(y) = \int_{\mathbb{R}} (v(ye^z) - v(y) - y(e^z - 1) \frac{\partial}{\partial y} v(y)) k(z) dz$ . From this observation and the identities  $x \frac{\partial g}{\partial \xi} = -\frac{\partial P}{\partial t}$ ,  $xy \frac{\partial g}{\partial y} = -x \frac{\partial P}{\partial x} + P$ , and  $xy^2 \frac{\partial^2 g}{\partial y^2} = x^2 \frac{\partial^2 P}{\partial x^2}$ , we deduce that, as a function of  $t$  and  $x$ ,  $P(0, S, t, x)$  satisfies the following forward problem:  $P(t = 0) = P_{\circ}$  and for  $t \in (0, T]$  and  $x > 0$ ,

$$(2.9) \quad \left( \frac{\partial P}{\partial t} - \frac{\sigma^2 x^2}{2} \frac{\partial^2 P}{\partial x^2} + rx \frac{\partial P}{\partial x} + BP \right) \geq 0,$$

$$(2.10) \quad P(t, x) \geq P_{\circ}(x),$$

$$(2.11) \quad \left( \frac{\partial P}{\partial t} - \frac{\sigma^2 x^2}{2} \frac{\partial^2 P}{\partial x^2} + rx \frac{\partial P}{\partial x} + BP \right) (P - P_{\circ}) = 0,$$

where the integral operator  $B$  is defined by

$$(2.12) \quad (Bu)(x) = - \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \frac{\partial u}{\partial x}(x) + e^z (u(xe^{-z}) - u(x)) \right) dz.$$

Note that the arguments yielding (2.9)–(2.11) are much easier than those used for getting Dupire's equation (see [4, 18]), because (2.5) does not hold with local volatility. Problem (2.9)–(2.11) can also be obtained by probabilistic arguments. Note also that finding a forward LCP in the variables  $t$  and  $x$  is not possible in the case of American options with local volatility, because the arguments in [4, 18] do not apply to nonlinear problems. This explains why, in [2, 5], the evaluation of the least square cost functional necessitates the solution of  $\#I$  LCP instead of one here. In this respect, we may say that with American options, the calibration of Lévy processes is easier than the calibration of local volatility.

**2.3. Choice of the Lévy process.** We have already discussed our choice to take  $\nu(dz) = k(z)dz$ , with

$$(2.13) \quad \max \left( \int_{\mathbb{R}} \min(1, z^2) k(z) dz, \int_1^{+\infty} e^{2z} k(z) dz \right) < \infty.$$

We need to make further restrictions on the Lévy process for several reasons:

1. In practice, we need to specify a class of Lévy densities  $k$  in order to define the inverse problem.
2. The analysis below will need problem (2.16)–(2.19) to be parabolic. This implies restrictions on the pair  $(\sigma, k)$ .

As will appear in section 3.2 below, the restrictions in order to have a parabolic problem are

1. either  $\sigma > 0$  and  $k$  satisfies (2.13),
2. or  $\sigma = 0$  and  $k$  satisfies (2.13) and is sufficiently singular near  $z = 0$ . The result in section 3.2 will imply that choosing  $k(z) \sim |z|^{-1-2\alpha}$  with  $1/2 < \alpha < 1$  yields a parabolic problem. To keep the length of this article reasonable, this case will be discussed elsewhere.

ASSUMPTION 1. *For this reason, we assume that  $k$  is of the form*

$$(2.14) \quad k(z) = \psi(z)|z|^{-(1+2\alpha)},$$

where  $\psi$  is a nonnegative function in  $L^\infty(\mathbb{R})$  such that  $\psi(z) \geq \underline{\psi} > 0$  in a fixed neighborhood of  $z = 0$ , and  $\alpha$  is such that  $-1/2 \leq \alpha < 1$ . We assume furthermore that (2.13) is satisfied.

For practical purposes, one can impose further restrictions on  $\psi$ , for example, let  $\psi$  belong to a finite dimensional function space, but this need not be discussed at this stage.

Assumption 1 holds for models of jump-diffusion type, for example, the Merton model ( $\sigma > 0$  and the jumps in the log-price have a Gaussian distribution) or some Kou models ( $\sigma > 0$  and the distribution of jumps is an asymmetric exponential with a fast enough decay at infinity); see [13, p. 111]. Indeed, these models can be obtained by taking  $\alpha = -1/2$  and choosing  $\psi$  properly. Assumption 1 also holds for some variance gamma processes ( $\sigma > 0$ ,  $\alpha = 0$ ) and normal inverse Gaussian processes ( $\sigma > 0$ ,  $\alpha = 1/2$ ) (see [13, p. 117]), with a fast enough decay of the jump density at infinity. It also holds for some tempered stable processes (see [13, p. 119]) or some parabolic CGMY models discussed by Carr et al. [12]. These last two models usually take  $\sigma = 0$ . Allowing  $\sigma > 0$  in the analysis can be seen as a step toward  $\sigma = 0$ .

REMARK 1. *The assumption  $\psi(z) \geq \underline{\psi} > 0$  near 0 avoids ambiguities in the definition of the singularity of  $k$  at  $z = 0$ . It is a bit restrictive since, for example, a logarithmic singularity of  $k$  at  $z = 0$  is ruled out. However, this assumption is unessential and most of the results below hold without it.*

**2.4. Change of unknown function in the forward problem.** In order to have a datum with a compact support in  $x$ , it is helpful to change the unknown function: we set

$$(2.15) \quad u_o(x) = (S - x)_+; \quad u(t, x) = P(t, x) - x + S.$$

The function  $u$  satisfies, for  $t \in (0, T]$  and  $x > 0$ ,

$$(2.16) \quad \frac{\partial u}{\partial t} - \frac{\sigma^2 x^2}{2} \frac{\partial^2 u}{\partial x^2} + rx \frac{\partial u}{\partial x} + Bu \geq -rx,$$

$$(2.17) \quad u(t, x) \geq u_o(x),$$

$$(2.18) \quad \left( \frac{\partial u}{\partial t} - \frac{\sigma^2 x^2}{2} \frac{\partial^2 u}{\partial x^2} + rx \frac{\partial u}{\partial x} + Bu + rx \right) (u - u_o) = 0.$$

The initial condition for  $u$  is

$$(2.19) \quad u(t = 0, x) = u_o(x), \quad x > 0.$$

For writing the variational inequalities stemming from (2.16)–(2.19), we need to introduce suitable weighted Sobolev spaces. In particular, fractional order weighted Sobolev spaces will be useful for studying the nonlocal part of the operator.

### 3. Preliminary results.

#### 3.1. Functional setting.

**3.1.1. Sobolev spaces on  $\mathbb{R}$ .** For a real number  $s$ , let the Sobolev space  $H^s(\mathbb{R})$  be defined as follows: the distribution  $w$  defined on  $\mathbb{R}$  belongs to  $H^s(\mathbb{R})$  if and only if its Fourier transform  $\widehat{w}$  satisfies  $\int_{\mathbb{R}} (1 + \xi^2)^s |\widehat{w}(\xi)|^2 d\xi < +\infty$ . The spaces  $H^s(\mathbb{R})$  are Hilbert spaces, with the inner product and norm:

$$(w_1, w_2)_{H^s(\mathbb{R})} = \int_{\mathbb{R}} (1 + \xi^2)^s \widehat{w}_1(\xi) \overline{\widehat{w}_2(\xi)} d\xi, \quad \|w\|_{H^s(\mathbb{R})} = \sqrt{(w, w)_{H^s(\mathbb{R})}}.$$

For two real numbers  $s_1, s_2$ ,  $s_1 \leq s_2$ ,  $H^{s_2}(\mathbb{R}) \subset H^{s_1}(\mathbb{R})$  with a continuous injection. It can be seen that  $H^0(\mathbb{R}) = L^2(\mathbb{R})$  and that if  $s$  is a positive integer,  $H^s(\mathbb{R})$  is the space of all the functions whose derivatives up to order  $s$  are square integrable. If  $s$  is a non-negative integer, the norm  $\|\cdot\|_{H^s(\mathbb{R})}$  is equivalent to the norm  $v \mapsto \sqrt{\sum_{\ell=0}^s \|\frac{d^\ell v}{dy^\ell}\|_{L^2(\mathbb{R})}^2}$ . If  $s > 0$  is not an integer, the norm  $\|\cdot\|_{H^s(\mathbb{R})}$  is equivalent to

$$(3.1) \quad v \mapsto \sqrt{\sum_{\ell=0}^m \left\| \frac{d^\ell v}{dy^\ell} \right\|_{L^2(\mathbb{R})}^2 + \int_{\mathbb{R}} \int_{\mathbb{R}} |y - z|^{2(m-s)-1} \left( \frac{d^m v}{dy^m}(y) - \frac{d^m v}{dy^m}(z) \right)^2 dy dz},$$

where  $m$  is the integer part of  $s$ . For  $s \geq 0$ , the space  $\mathcal{D}(\mathbb{R})$  is dense in  $H^s(\mathbb{R})$ .

It is well known (see [27, 6]) that if  $0 < s < 1$ , then  $H^s(\mathbb{R})$  can be obtained by real or complex interpolation between the spaces  $H^1(\mathbb{R})$  and  $L^2(\mathbb{R})$  (the parameter for the real interpolation is  $\nu = 1/2 - s$ ; see [6, p. 204]), and that the norm obtained by the interpolation process is equivalent to the one defined in (3.1).

For  $s \geq 0$ ,  $H^{-s}(\mathbb{R})$  is the dual of  $H^s(\mathbb{R})$ , and for  $s > 0$ , the norm  $\|\cdot\|_{H^{-s}(\mathbb{R})}$  is equivalent to the norm  $v \mapsto \sup_{w \in H^s(\mathbb{R}), w \neq 0} \frac{|\langle v, w \rangle|}{\|w\|_{H^s(\mathbb{R})}}$ . If  $s$  is a nonnegative integer, we define the seminorm  $|v|_{H^s(\mathbb{R})} = \sqrt{\sum_{\ell=1}^s \|\frac{d^\ell v}{dy^\ell}\|_{L^2(\mathbb{R})}^2}$ . If  $s > 0$  is not an integer, we define  $|v|_{H^s(\mathbb{R})}$  by  $|v|_{H^s(\mathbb{R})}^2 = \sum_{\ell=1}^m \|\frac{d^\ell v}{dy^\ell}\|_{L^2(\mathbb{R})}^2 + \int_{\mathbb{R}} \int_{\mathbb{R}} \frac{(\frac{d^m v}{dy^m}(y) - \frac{d^m v}{dy^m}(z))^2}{|y - z|^{1+2s}}$ , where  $m$  is the integer part of  $s$ .

**3.1.2. Some weighted Sobolev spaces on  $\mathbb{R}_+$ .** Let  $V^1$  be the weighted Sobolev space

$$V^1 = \left\{ v \in L^2(\mathbb{R}_+), \quad x \frac{\partial v}{\partial x} \in L^2(\mathbb{R}_+) \right\},$$

which is a Hilbert space with the norm  $\|v\|_{V^1} = \sqrt{\|v\|_{L^2(\mathbb{R}_+)}^2 + \|x \frac{\partial v}{\partial x}\|_{L^2(\mathbb{R}_+)}^2}$ . It is proved in [4] that  $\mathcal{D}(\mathbb{R}_+)$  is a dense subspace of  $V^1$ , and that the following Poincaré inequality is true: for all  $v \in V^1$ ,

$$(3.2) \quad \|v\|_{L^2(\mathbb{R}_+)} \leq 2 \|x \frac{dv}{dx}\|_{L^2(\mathbb{R}_+)}.$$

Therefore, the seminorm  $|\cdot|_{V^1}: |v|_{V^1} = \|x \frac{dv}{dx}\|_{L^2(\mathbb{R}_+)}$  is a norm equivalent to  $\|\cdot\|_{V^1}$ .

For a function  $v$  defined on  $\mathbb{R}_+$ , call  $\tilde{v}$  the function defined on  $\mathbb{R}$  by

$$(3.3) \quad \tilde{v}(y) = v(\exp(y)) \exp(y/2).$$

By using the change of variable  $y = \log(x)$ , it can be seen that the mapping  $v \mapsto \tilde{v}$  is a topological isomorphism from  $L^2(\mathbb{R}_+)$  onto  $L^2(\mathbb{R})$ , and from  $V^1$  onto  $H^1(\mathbb{R})$ . This leads to defining the space  $V^s$  for  $s \in \mathbb{R}$  by

$$V^s = \{v : \tilde{v} \in H^s(\mathbb{R})\},$$

which is a Hilbert space with the norm  $\|v\|_{V^s} = \|\tilde{v}\|_{H^s(\mathbb{R})}$ . Using the interpolation theorem given in, e.g., [6, Theorem 7.17], one can prove that if  $0 < s < 1$ , then  $V^s$  can be obtained by real interpolation between the spaces  $V^1$  and  $L^2(\mathbb{R}_+)$  (the parameter for the real interpolation is  $\nu = 1/2 - s$ ), and that the norm obtained by the interpolation process is equivalent to the one defined above.

For  $s > 0$ , the space  $V^{-s}$  is the topological dual of  $V^s$ .

For  $s > 0$ , we introduce the seminorm  $|v|_{V^s} = |\tilde{v}|_{H^s(\mathbb{R})}$ .

LEMMA 3.1. *Let  $s$  be a real number such that  $1/2 < s \leq 1$ . Then for all  $v \in V^s$ ,  $v$  is continuous on  $(0, +\infty)$  and there exists a constant  $C > 0$  such that*

$$(3.4) \quad \sqrt{x}|v(x)| \leq C\|v\|_{V^s} \quad \forall x \in [1, +\infty).$$

*Proof.* From the Sobolev continuous imbedding  $H^s(\mathbb{R}) \subset L^\infty(\mathbb{R}) \cap C^0(\mathbb{R})$  for  $s > 1/2$ , we see that  $V^s \subset C^0((0, +\infty))$  and there exists a constant  $C$  such that  $|v(x)| = |\tilde{v}(\log(x))|/\sqrt{x} \leq C\|\tilde{v}\|_{H^s(\mathbb{R})}/\sqrt{x} = C\|v\|_{V^s}/\sqrt{x}$  for all  $v \in V^s$ , for all  $x \geq 1$ .  $\square$

For a continuous and nonnegative function  $\phi$  defined on  $\mathbb{R}$  and a measurable function  $v$  on  $\mathbb{R}_+$ , consider

$$|v|_{\phi,s}^2 = \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} \frac{\phi(z)}{|z|^{1+2s}} (v(xe^{-z}) - v(x))^2 dz, \text{ and } \|v\|_{\phi,s} = \sqrt{|v|_{\phi,s}^2 + \|v\|_{L^2(\mathbb{R}_+)}^2}.$$

LEMMA 3.2. *Let  $\phi$  be a continuous and nonnegative function defined on  $\mathbb{R}$ . If  $\phi(0) > 0$  and if the function  $z \mapsto \phi(z) \max(e^z, 1)$  is bounded, then for any  $s \in (0, 1)$ ,  $\|\cdot\|_{\phi,s}$  is a norm on  $V^s$  equivalent to the norm  $\|\cdot\|_{V^s}$ .*

*Proof.* For the reader's ease, the proof is postponed to Appendix A.  $\square$

REMARK 2. *Lemma 3.2 remains true if  $\phi$  is a function in  $L^\infty(\mathbb{R})$  and if for a given positive constant  $\underline{\phi}$ ,  $\phi \geq \underline{\phi} > 0$  a.e. in a neighborhood of 0.*

REMARK 3. *If the assumption  $\phi(0) > 0$  is not satisfied, then the conclusion of Lemma 3.2 becomes  $\exists C > 0$  such that  $|u|_{\phi,s} \leq C\|u\|_{V^s}$  for all  $u \in V^s$ .*

## 3.2. The integro-differential operator.

### 3.2.1. The integral operator.

We study the operator  $B$  defined in (2.12).

LEMMA 3.3. *Let  $(\alpha, \psi)$  satisfy Assumption 1. For each  $s \in \mathbb{R}$ , the following hold:*

- if  $\alpha > 1/2$ , then the operator  $B$  is continuous from  $V^s$  to  $V^{s-2\alpha}$ ,
- if  $\alpha < 1/2$ , then the operator  $B$  is continuous from  $V^s$  to  $V^{s-1}$ , and
- if  $\alpha = 1/2$ , then the operator  $B$  is continuous from  $V^s$  to  $V^{s-1-\epsilon}$  for any  $\epsilon > 0$ .

*Proof.* See Appendix A.  $\square$

COROLLARY 3.4. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $1/2 < \alpha < 1$ , then the operator  $B$  is continuous from  $V^\alpha$  to  $V^{-\alpha}$ .*

LEMMA 3.5. *If  $(\alpha, \psi)$  satisfy Assumption 1 and  $1/2 < \alpha < 1$ , then for all  $v, w \in V^\alpha$ ,*

$$(3.5) \quad \langle Bu, v \rangle + \langle Bv, u \rangle = \begin{cases} \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z (u(x) - u(xe^{-z})) (v(x) - v(xe^{-z})) dx dz \\ + (\int_{\mathbb{R}} k(z) (2e^z - e^{2z} - 1) dz) \int_{\mathbb{R}_+} u(x) v(x) dx, \end{cases}$$

where  $\langle \cdot, \cdot \rangle$  stands for the duality pairing between  $V^{-\alpha}$  and  $V^\alpha$ .

If  $-1/2 \leq \alpha \leq 1/2$ , then (3.5) is true for  $u, v \in V^s$ ,  $s > 1/2$ , defining  $\langle \cdot, \cdot \rangle$  as the duality pairing between  $V^{-s}$  and  $V^s$ .

*Proof.* See Appendix A.  $\square$

REMARK 4. *If  $(\alpha, \psi)$  satisfy Assumption 1, the operator  $B^T$  defined by*

$$(3.6) \quad B^T u(x) = \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \frac{\partial u}{\partial x}(x) - e^{2z} u(xe^z) + (2e^z - 1) u(x) \right) dz$$

*is a continuous operator from  $V^s$  to  $V^{s-2\alpha}$  if  $\alpha > 1/2$ , is a continuous operator from  $V^s$  to  $V^{s-1}$  if  $\alpha < 1/2$ , and is a continuous operator from  $V^s$  to  $V^{s-1-\epsilon}$  for any  $\epsilon > 0$  if  $\alpha = 1/2$ .*

*If  $\alpha > 1/2$ , then for all  $u, v \in V^\alpha$ ,  $\langle B^T u, v \rangle = \langle Bv, u \rangle$ . This identity holds for all  $u, v \in V^s$  with  $s > 1/2$  if  $\alpha \leq 1/2$ .*

LEMMA 3.6. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if*

- *either  $\alpha < 1/2$ ,*
- *or  $\psi$  is continuous near 0 and there exists a bounded function  $\omega : \mathbb{R} \rightarrow \mathbb{R}$  and two positive numbers  $\zeta$  and  $C$  such that  $\psi(z)e^{3/2z} - \psi(0)e^{-3/2z} = z\omega(z)$ , with  $|\omega(z)| \leq C|z|e^{-\zeta|z|}$ , for all  $z \in \mathbb{R}$ ,*

*then for any  $s \in \mathbb{R}$ , the operator  $B - B^T$  is continuous from  $V^s$  to  $V^{s-1}$ .*

*Proof.* See Appendix A.  $\square$

PROPOSITION 3.7 (Gårding inequality). *Let  $(\alpha, \psi)$  satisfy Assumption 1. If  $1/2 < \alpha < 1$ , there exist two constants  $\underline{C} > 0$  and  $\lambda \geq 0$  such that, for all  $v \in V^\alpha$ ,*

$$(3.7) \quad \langle Bv, v \rangle \geq \underline{C} \|v\|_{V^\alpha}^2 - \lambda \|v\|_{L^2(\mathbb{R}_+)}^2.$$

*If  $\alpha \leq 1/2$ , then (3.7) holds for any  $v \in V^s$ ,  $s > 1/2$  ( $\langle \cdot, \cdot \rangle$  standing for the duality pairing between  $V^{-s}$  and  $V^s$ ), with  $\underline{C} = 0$  if  $\alpha < 0$ .*

*Proof.* If  $0 < \alpha < 1$ , the function  $\phi : z \mapsto e^z \psi(z)$  satisfies the assumptions of Remark 2. Therefore,  $u \mapsto \sqrt{\|u\|_{L^2(\mathbb{R}_+)}^2 + \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z (u(x) - u(xe^{-z}))^2 dx dz}$  is a norm on  $V^\alpha$  equivalent to the norm  $\|\cdot\|_{V^\alpha}$ . From this and (3.5), we deduce (3.7).  $\square$

Consider the following two situations:

- $1/2 < \alpha < 1$ ,  $\psi$  and  $u \in V^\alpha$ : It can be shown (using the interpolation theorem 7.17 in [6]) that the functions  $u_+$  and  $u_-$  belong to  $V^\alpha$ .
- $\alpha \leq 1/2$  and  $u \in V^s$ ,  $s > 1/2$ .

In both cases,  $\int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z u_-(xe^{-z}) u_+(x) dx dz$  is well defined because

$$\begin{aligned} \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z u_-(xe^{-z}) u_+(x) dx dz &= \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z (u_-(xe^{-z}) - u_-(x)) u_+(x) dx dz \\ &\leq C \|u_+\|_{L^2(\mathbb{R}_+)} \sqrt{\int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z (u_-(xe^{-z}) - u_-(x))^2 dx dz} \end{aligned}$$

and is nonnegative. Therefore,

$$\begin{aligned}\langle Bu, u_+ \rangle &= \langle Bu_+, u_+ \rangle - \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z (u(xe^{-z}) - u_+(xe^{-z})) u_+(x) dx dz \\ &= \langle Bu_+, u_+ \rangle + \int_{\mathbb{R}_+} \int_{\mathbb{R}} k(z) e^z u_-(xe^{-z}) u_+(x) dx dz \geq \langle Bu_+, u_+ \rangle.\end{aligned}$$

We have proved the following lemma.

LEMMA 3.8. *If  $(\alpha, \psi)$  satisfy Assumption 1, then there exist two constants  $\underline{C} > 0$  and  $\lambda \geq 0$  such that, for all  $u \in V^\alpha$ , if  $\alpha > 1/2$ , or for all  $u \in V^s$ ,  $s > 1/2$ , if  $\alpha \leq 1/2$ ,*

$$(3.8) \quad \langle Bu, u_+ \rangle \geq \underline{C} |u_+|_{V^\alpha}^2 - \lambda \|u_+\|_{L^2(\mathbb{R}_+)}^2,$$

with  $\underline{C} = 0$  if  $\alpha < 0$ .

**3.2.2. The integro-differential operator.** With  $B$  defined in (2.12), we introduce the integro-differential operator  $A$ ,

$$(3.9) \quad Av = -\frac{\sigma^2 x^2}{2} \frac{\partial^2 v}{\partial x^2} + rx \frac{\partial v}{\partial x} + Bv,$$

where  $\sigma$  and  $r$  are nonnegative real numbers. In this work, we limit ourselves to the case  $\sigma > 0$ . The case  $\sigma = 0$ ,  $\alpha > 1/2$  requires working in the fractional Sobolev spaces described above and will be treated in [1]. Since the space  $V^1$  will play a special role, we use the shorter notation  $V = V^1$ .

If  $\sigma > 0$  and if  $(\alpha, \psi)$  satisfy Assumption 1, then the following hold:

- $A$  is a continuous operator from  $V$  to  $V^{-1}$ .
- We have the Gårding inequalities: there exist  $\underline{c} > 0$  and  $\lambda \geq 0$  such that

$$(3.10) \quad \langle Av, v \rangle \geq \underline{c} |v|_V^2 - \lambda \|v\|_{L^2(\mathbb{R}_+)}^2 \quad \forall v \in V,$$

$$(3.11) \quad \langle Av, v_+ \rangle \geq \underline{c} |v_+|_V^2 - \lambda \|v_+\|_{L^2(\mathbb{R}_+)}^2 \quad \forall v \in V.$$

- The operator  $A + \lambda I$  is one-to-one and continuous from  $V^2$  onto  $L^2(\mathbb{R}_+)$ , with a continuous inverse.

REMARK 5. *The assumption that  $\psi > 0$  near  $z = 0$  is not necessary for  $A$  to have the above properties. Its role is to allow a clear identification of the kernel's singularity at  $z = 0$ .*

**3.3. The variational inequalities.** We are ready to write the variational inequalities corresponding to the LCP (2.16)–(2.19).

We introduce the closed subspace of  $V$ :

$$(3.12) \quad K = \{v \in V, v(x) \geq u_\circ(x) \text{ in } \mathbb{R}_+\}.$$

The variational problem will consist of looking for  $u \in L^2(0, T; V) \cap C^0([0, T]; L^2(\mathbb{R}_+))$ , with  $\frac{\partial u}{\partial t} \in L^2((0, T) \times \mathbb{R}_+)$ , such that the following hold:

1. There exists a constant  $X_T > S$  such that  $u(t, x) = 0$  for all  $t \in [0, T]$ , for all  $x \geq X_T$ .
2.  $u(t) \in K$  for almost every  $t \in (0, T)$ .
3. For almost every  $t \in (0, T)$ , for any  $v \in K$  with bounded support,

$$(3.13) \quad \left\langle \frac{\partial u}{\partial t} + Au + rx, v - u \right\rangle \geq 0,$$

where  $\langle \cdot, \cdot \rangle$  stands for the duality pairing between  $V'$  (the dual of  $V$ ) and  $V$ .

4.  $u(t = 0) = u_\circ$ .

Hereafter, this problem will be referred to as (VIP). The goal of section 4 below is to prove that (VIP) has a unique solution and to study its properties.

#### 4. Analysis of the variational inequalities.

**4.1. Orientation.** Hereafter, we assume that  $\sigma > 0$ . Problem (2.16)–(2.19) is posed in an unbounded domain. This is a technical difficulty in order to use variational methods, and we first have to replace this problem by a similar one posed in a bounded domain. Therefore, the program is to

1. approximate (2.16)–(2.19) by a similar problem posed in  $[0, T] \times [0, X]$ , for some given positive parameter  $X > S$ , and write the related variational problem, which will be called  $(VIP_X)$  below;
2. solve first a penalized version of  $(VIP_X)$  by introducing a semilinear monotone operator, and pass to the limit as the penalty parameter tends to zero;
3. prove that the free boundary of  $(VIP_X)$  stays in a bounded domain as  $X$  tends to infinity; this will show that for  $X$  large enough a solution of  $(VIP_X)$  is actually a solution of (VIP); and
4. obtain estimates for the solution of (VIP) independent of the parameters  $(\sigma, \alpha, \psi)$ , when these parameters vary in a suitably defined set.

**4.2. Approximation of (VIP) in a bounded domain.** Let  $X$  be a positive number greater than  $S$ . Hereafter, for a function  $v \in L^2((0, X))$  we call  $\mathcal{E}_X(v)$  the function in  $L^2(\mathbb{R}_+)$  obtained by extending  $v$  by 0 outside  $(0, X)$ . We introduce the Sobolev spaces  $W_X^1 = \{v \in L^2((0, X)), x \frac{\partial v}{\partial x} \in L^2((0, X))\}$  and  $W_X^2 = \{v \in W_X^1, x^2 \frac{\partial^2 v}{\partial x^2} \in L^2((0, X))\}$ . For  $\beta, 0 < \beta < 1$ ,  $W_X^\beta$  is the space obtained by real interpolation between  $W_X^1$  and  $L^2(0, X)$  with parameter  $\nu = 1/2 - \beta$  (see [6, p. 204], [27]), and  $W_X^{1+\beta} = \{v \in W_X^1, x \frac{\partial v}{\partial x} \in W_X^\beta\}$ .

For  $\beta, 0 \leq \beta < 3/2$ , we introduce  $V_X^\beta = \{v \in L^2(0, X), \mathcal{E}(v) \in V^\beta\}$ , endowed with the norm  $\|v\|_{V_X^\beta} = \|\mathcal{E}_X(v)\|_{V^\beta}$ . Note that for  $\beta, 0 \leq \beta < 1/2$ ,  $V_X^\beta = W_X^\beta$ . Let  $V_X^{-\beta}$  be the dual of  $V_X^\beta$ . Thanks to Lemma 3.1, we know that for  $\beta > 1/2$ , a function  $v \in V_X^\beta$  is continuous in  $[0, X]$  and vanishes at  $X$ .

Since the space  $V_X^1$  will often be used, we introduce the special notation

$$(4.1) \quad V_X = \{v \in L^2(0, X), \mathcal{E}_X(v) \in V\},$$

and  $\|v\|_{V_X} = \|\mathcal{E}_X(v)\|_V$ . We define the operators  $A_X$  and  $B_X, V_X \rightarrow V_X'$ :

$$(4.2) \quad \langle A_X v, w \rangle = \langle A \mathcal{E}_X(v), \mathcal{E}_X(w) \rangle \quad \text{and} \quad \langle B_X v, w \rangle = \langle B \mathcal{E}_X(v), \mathcal{E}_X(w) \rangle.$$

A Gårding inequality for  $A_X$  is deduced from (3.10), with constants independent of  $X$ . We define

$$(4.3) \quad D_X = \{v \in V_X : A_X v \in L^2((0, X))\}.$$

It follows from the Gårding inequality that  $(A_X, D_X)$  is the infinitesimal generator of an analytic semigroup [33]. Proposition 4.1 below contains information on  $D_X$ .

**PROPOSITION 4.1.** *If  $v \in D_X$ , then for any number  $X' < X$ ,  $v|_{(0, X')} \in W_{X'}^2$ .*

*For  $\alpha, 0 < \alpha < 3/4$ ,  $D_X = W_X^2 \cap V_X$ . For  $\alpha, 3/4 \leq \alpha < 1$ , there exists  $\epsilon > 0$  such that  $D_X \subset W_X^{3/2+\epsilon} \cap V_X$ . In any case, if  $v \in D_X$ , then  $\frac{\partial v}{\partial x} \in C^0((0, X])$ .*

*Proof.* See Appendix B.  $\square$

REMARK 6. *It can be proved by lengthy calculations that if  $v(x) = X - x$  (note that  $v \in W_X^2 \cap V_X$ ), then  $A_X v$  behaves like  $(X - x)^{1-2\alpha}$  near  $x = X$ , so  $A_X v \notin L^2((0, X))$  if  $\alpha > 3/4$ .*

We introduce

$$(4.4) \quad K_X = \{v \in V_X, v(x) \geq u_o(x) \text{ in } (0, X)\}.$$

We are going to look for  $u_X \in L^2(0, T; V_X) \cap C^0([0, T]; L^2((0, X)))$ , with  $\frac{\partial u_X}{\partial t} \in L^2((0, T) \times (0, X))$ , such that the following hold:

1.  $u_X(t) \in K_X$  for almost every  $t \in (0, T)$ .
2. For almost every  $t \in (0, T)$ ,

$$(4.5) \quad \left\langle \frac{\partial u_X}{\partial t} + A_X u_X + rx, v - u_X \right\rangle \geq 0$$

for any  $v \in K_X$ . Here  $\langle \cdot, \cdot \rangle$  stands for the duality pairing between  $V_X'$  (the dual of  $V_X$ ) and  $V_X$ .

3.  $\mathcal{E}_X(u_X)(t=0) = u_o$ .

Hereafter, this problem will be referred to as  $(VIP_X)$ . In order to prove that  $(VIP_X)$  has a unique solution, we follow [25] and introduce first a sequence of monotone problems which can be seen as penalized versions of (4.5): find  $u_{X,\epsilon}$  such that

$$(4.6) \quad \begin{aligned} \frac{\partial u_{X,\epsilon}}{\partial t} + A_X u_{X,\epsilon} + rx(1 - 1_{\{x>S\}} \mathcal{V}_\epsilon(u_{X,\epsilon})) &= 0, \quad t \in (0, T], \quad 0 < x < X, \\ u_{X,\epsilon}(t=0, x) &= u_o(x), \quad 0 < x < X, \\ u_{X,\epsilon}(t, X) &= 0, \quad t \in (0, T]. \end{aligned}$$

where  $\mathcal{V}_\epsilon(u) = \mathcal{V}(u/x\epsilon)$  and  $\mathcal{V}$  is a smooth nonincreasing convex function such that

$$\mathcal{V}(0) = 1, \quad \mathcal{V}(u) = 0 \quad \text{for } u \geq 1, \quad 0 \geq \mathcal{V}'(u) \geq -2 \quad \text{for } 0 \leq u \leq 1.$$

In what follows, we call  $u_X^{(E)}$  and  $\underline{u}_X^{(E)}$  the solutions to the linear problems:

$$\begin{aligned} \frac{\partial u_X^{(E)}}{\partial t} + A_X u_X^{(E)} &= 0, \quad \frac{\partial \underline{u}_X^{(E)}}{\partial t} + A_X \underline{u}_X^{(E)} = -rx, \quad t \in (0, T], \quad 0 < x < X, \\ u_X^{(E)}(t=0, x) &= \underline{u}_X^{(E)}(t=0, x) = u_o(x), \quad 0 < x < X, \\ u_X^{(E)}(t, X) &= \underline{u}_X^{(E)}(t, X) = 0, \quad t \in (0, T]. \end{aligned}$$

It can be seen that  $\underline{u}_X^{(E)}(t, 0) = S$  for all  $t \in [0, T]$  and that

$$(4.7) \quad \underline{u}_X^{(E)}(t, x) > S - x \quad \forall (t, x) \in (0, T] \times (0, X].$$

Let  $u^{(E)}$  be the solution of the linear problem:

$$\frac{\partial u^{(E)}}{\partial t} + Au^{(E)} = 0, \quad t \in (0, T], \quad x > 0, \quad u^{(E)}(t=0, x) = u_o(x), \quad x > 0.$$

The function  $u^{(E)}$  is smooth near  $x = 0$  and  $\frac{\partial u^{(E)}}{\partial x}(t, 0) = -1$  for all  $t \geq 0$ .

THEOREM 4.2. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , then (4.6) has a unique weak solution  $u_{X,\epsilon} \in L^2(0, T; V_X) \cap C^0([0, T]; L^2(0, X))$ . It satisfies*

$$(4.8) \quad \underline{u}_X^{(E)} \leq u_{X,\epsilon} \leq u_X^{(E)} \leq u^{(E)}.$$

The function  $u_{X,\epsilon}$  belongs to  $C^0([0, T]; K_X) \cap L^2(0, T; D_X)$  and is continuous and nondecreasing w.r.t.  $t$ . For two positive numbers  $\epsilon' < \epsilon$ , we have

$$(4.9) \quad u_{X,\epsilon'} \leq u_{X,\epsilon} \leq u_{X,\epsilon'} + \epsilon.$$

The quantities  $\|u_{X,\epsilon}\|_{L^\infty(0,T;V_X)}$ ,  $\|u_{X,\epsilon}\|_{L^2(0,T;D_X)}$ , and  $\|\frac{\partial u_{X,\epsilon}}{\partial t}\|_{L^2((0,T)\times(0,X))}$  are bounded independently of  $\epsilon$ . The quantities  $\|u_{X,\epsilon}\|_{L^\infty(0,T;L^2(0,X))}$  and  $\|u_{X,\epsilon}\|_{L^2(0,T;V_X)}$  are bounded independently of  $X$ .

*Proof.* See Appendix B.  $\square$

**THEOREM 4.3.** The function  $x \frac{\partial u_{X,\epsilon}}{\partial x}$  is the sum of  $\tilde{z}_{X,\epsilon} \in C^0([0, T]; L^2(0, X))$  and of  $\hat{z}_{X,\epsilon} \in L^2(0, T; V_X)$  such that  $\tilde{z}_{X,\epsilon} \leq 0$  and  $\lim_{\epsilon \rightarrow 0} \|\hat{z}_{X,\epsilon}\|_{L^2(0,T;V_X)} = 0$ .

Finally, for two numbers  $X$  and  $X'$  such that  $S < X < X'$ , for any  $\epsilon > 0$ ,

$$(4.10) \quad \mathcal{E}_X(u_{X,\epsilon}) \leq \mathcal{E}_{X'}(u_{X',\epsilon}).$$

*Proof.* See Appendix B.  $\square$

**THEOREM 4.4.** If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ ,  $(VIP_X)$  has a unique solution  $u_X \in C^0([0, T]; K_X) \cap L^2(0, T; D_X)$ , with  $\frac{\partial u_X}{\partial t} \in L^2((0, T) \times (0, X))$ .

The function  $u_X$  is continuous in  $[0, T] \times [0, X]$ , with  $u_X(t, 0) = S$  for all  $t \in [0, T]$ ,  $\underline{u}_X^{(E)} \leq u_X \leq u_X^{(E)} \leq u^{(E)}$ , and  $u_X(t, x) > u_o(x)$  for  $0 < t \leq T$  and  $0 < x \leq S$ .

The function  $u_X$  is nondecreasing w.r.t.  $t$  and nonincreasing w.r.t.  $x$ . The quantities  $\|\mathcal{E}_X(u_X)\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$  and  $\|\mathcal{E}_X(u_X)\|_{L^2(0,T;V)}$  are bounded independently of  $X$ .

For  $\epsilon > 0$ , we have the bounds

$$(4.11) \quad u_X \leq u_{X,\epsilon} \leq u_X + \epsilon,$$

and the sequence  $u_{X,\epsilon}$  converges to  $u_X$  uniformly as  $\epsilon \rightarrow 0$ .

For two numbers  $X$  and  $X'$  such that  $S < X < X'$ ,  $\mathcal{E}_X(u_X) \leq \mathcal{E}_{X'}(u_{X'})$ .

*Proof.* The proof consists mainly of passing to the limit in (4.6) as  $\epsilon \rightarrow 0$ . It uses the Minty trick; see [25]. We skip it since it is rather classical.  $\square$

**LEMMA 4.5.** If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , there exists a nondecreasing function  $\gamma_X : (0, T] \rightarrow (S, X]$ , such that the set  $\{(t, x) : u_X(t, x) = u_o(x)\}$  coincides with the set  $\{(t, x) : x \geq \gamma_X(t)\}$ . Calling

$$(4.12) \quad \mu_X = \frac{\partial u_X}{\partial t} + A_X u_X + r x,$$

we have a.e.

$$(4.13) \quad 0 \leq \mu_X \leq r x 1_{\{u_X=0\}} = r x 1_{\{x \geq \gamma_X(t)\}}.$$

*Proof.* We know that for all  $t \in [0, T]$ ,  $u_X(t, X) = u_o(X) = 0$ . Thus, at each time  $t$ , the set where  $u_X(t, x)$  coincides with  $u_o$  is nonempty. It is closed since  $u_X$  and  $u_o$  are continuous. We also know that  $u_X(t, x) > u_o(x)$  for  $t > 0$  and  $x \leq S$ ; thus,  $\{x > 0$  such that  $u_X(t, x) = u_o(x)\} \subset (S, X]$  for  $t > 0$ . On the other hand, for all  $t \in (0, T]$ , the function  $u_X(t)$  is nonincreasing w.r.t.  $x$ , so  $\{x > 0$  such that  $u_X(t, x) = u_o(x)\}$  is an interval  $[\gamma_X(t), X]$ , with  $\gamma_X(t) > S$ . Since  $u_X$  is nondecreasing w.r.t.  $t$ , the function  $\gamma_X$  is nondecreasing.

With  $\mu_X \in L^2((0, T) \times \mathbb{R}_+)$  given by (4.12), we have  $\mu_X = 0$  a.e. in the open region where  $u_X > 0$ . Now,  $\mu_X$  is the weak limit of  $r x 1_{x>S} \mathcal{V}_\epsilon(u_{X,\epsilon})$  in  $L^2((0, T) \times (0, X))$ . From (4.11), we deduce that  $r x 1_{x>S} \mathcal{V}_\epsilon(u_{X,\epsilon}) \leq r x 1_{x>S} \mathcal{V}_\epsilon(u_X)$ , and  $1_{x>S} \mathcal{V}_\epsilon(u_X)$  converges pointwise to  $1_{\{u_X=0\}}$ . Therefore,  $\mu_X \leq r x 1_{\{u_X=0\}}$ .  $\square$

PROPOSITION 4.6. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , the function  $\gamma_X$  is nondecreasing and lower semicontinuous. The graph of  $\gamma_X$  has measure 0 (Lebesgue measure in  $\mathbb{R}^2$ ) and*

$$(4.14) \quad \begin{aligned} \mu_X(t, x) &= 1_{\{u_X(t, x)=0\}}(rx + B_X u_X(t, x)) \\ &= 1_{\{u_X(t, x)=0\}} \left( rx - \int_{\mathbb{R}} k(z) e^z u_X(t, x e^{-z}) dz \right) \quad \text{for a.a. } t, x. \end{aligned}$$

*Proof.* We have already seen that  $\gamma_X$  is nondecreasing. The epigraph of  $\gamma_X$  is the set where  $u_X$  vanishes. This region is closed since  $u_X$  is continuous.

Since  $\gamma_X$  has left and right limits at each point  $t$ , the graph of  $\gamma_X$  has measure 0 (Lebesgue measure in  $\mathbb{R}^2$ ); see Theorem 3.7 in [2] for the proof. As a consequence, the boundary of the coincidence set  $\{u_X = 0\}$  has measure 0 (Lebesgue measure in  $\mathbb{R}^2$ ). From this and since the identity  $\mu_X(t, x) = rx - \int_{\mathbb{R}} k(z) e^z u_X(t, x e^{-z}) dz$  is true in the set  $\{x > \gamma_X(t)\}$ , we obtain (4.14).  $\square$

REMARK 7. *We will not try to obtain further regularity results on  $\gamma_X$ . Yet, this is certainly an interesting topic on which little seems to be known.*

Let  $T_X$  be defined by

$$(4.15) \quad T_X = \sup\{t, 0 < t \leq T, \gamma_X(t) < X\}.$$

Since  $\gamma_X$  is nondecreasing, we know that if  $T_X < T$ , then for all  $t \in [T_X, T]$ ,  $\gamma_X(t) = X$ .

Note that  $\mathcal{E}_X(u_X)$  is a solution of (2.16)–(2.19) in  $(0, T_X) \times \mathbb{R}_+$ , so for all  $X' > X$ ,  $\mathcal{E}_X(u_X)$  coincides with  $\mathcal{E}_{X'}(u_{X'})$  for  $0 < t < T_X$ . In particular, this implies that  $X \mapsto T_X$  is a nondecreasing function.

LEMMA 4.7. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , there exists  $X_T > S$  such that for all  $X \geq X_T$ ,  $T_X = T$ . For  $X > X_T$ ,  $u_X \in L^2(0, T; W_X^2)$ .*

*Proof.* The proof is by contradiction: if  $X_T$  does not exist, then  $\lim_{X \rightarrow \infty} T_X = \underline{T} < T$ . We have  $\frac{\partial u_X}{\partial t} + A_X u_X = -rx$  in  $[\underline{T}, T] \times (0, X)$  for all  $X > S$ . We choose a smooth and nonnegative function  $\phi$  defined on  $\mathbb{R}$  with compact support, and for  $y > 0$ , we call  $\phi_y$  the function  $\phi_y(x) = \phi(x - y)/\sqrt{y}$ . Then we take  $\phi_y$  as a test function in (4.12). We have

$$\int_0^X (u_X(T, x) - u_X(\underline{T}, x)) \phi_y(x) + \int_{\underline{T}}^T \langle A_X u_X(t), \phi_y \rangle dt = -r \int_{\underline{T}}^T \int_0^X x \phi_y(x) dx.$$

Take  $y = X/2$  and let  $X$  tend to  $\infty$ . From the bounds on  $u_X$ , the left-hand side in the identity above remains bounded, whereas the right-hand side tends to infinity. We have obtained the desired contradiction. The last statement of Lemma 4.7 follows easily from the first statement of Proposition 4.1.  $\square$

PROPOSITION 4.8. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , the function  $\mu_{X, \epsilon} = rx 1_{\{x > S\}} \mathcal{V}_{\epsilon}(u_{X, \epsilon})$ , converges to  $\mu_X$  in  $L^p((0, T) \times (0, X))$  for  $p, 1 \leq p < +\infty$ . The sequence  $u_{X, \epsilon}$  converges to  $u_X$  strongly in  $L^2(0, T; D_X)$  and in  $L^\infty(0, T; V_X)$ .*

*Proof.* See Appendix B.  $\square$

**4.3. The problem (VIP).** From Theorem 4.4, Proposition 4.6, and Lemma 4.7, we can pass to the limit as  $X \rightarrow \infty$ .

THEOREM 4.9. *If  $(\alpha, \psi)$  satisfy Assumption 1 and if  $\sigma > 0$ , there exists a unique solution of problem (VIP), i.e., a function  $u \in C^0([0, T]; K) \cap L^2(0, T; V^2)$ , with  $\frac{\partial u}{\partial t} \in L^2((0, T) \times \mathbb{R}_+)$ , such that  $u(t = 0) = u_\circ$ ,*

$$(4.16) \quad u(t, x) = 0 \quad \forall t \in [0, T], x \geq X_T,$$

where  $X_T$  is defined in Lemma 4.7, and satisfying the variational inequality (3.13) for all  $v \in K$  with bounded support in  $x$ . The function  $u$  coincides with  $u_X$  for  $X \geq X_T$ . There exists a nondecreasing and lower semicontinuous function  $\gamma : (0, T] \rightarrow (S, X_T)$ , such that for all  $t \in (0, T)$ ,  $\{x > 0 \text{ such that } u(t, x) = u_o(x)\} = [\gamma(t), +\infty)$ . Calling

$$(4.17) \quad \mu = \frac{\partial u}{\partial t} + Au + rx,$$

we have a.e.  $0 \leq \mu \leq rx1_{\{u=0\}} = rx1_{\{x \geq \gamma(t)\}}$ .

**PROPOSITION 4.10.** *The function  $\mu$  defined in (4.17) is nondecreasing w.r.t.  $x$  (i.e., the distribution  $\frac{\partial \mu}{\partial x}$  is negative) and nonincreasing w.r.t.  $t$ , (i.e., the distribution  $\frac{\partial \mu}{\partial t}$  is positive). For any  $X > X_T$ , the total variation of  $\mu$  in  $(0, T) \times (0, X)$  is bounded by  $rX(T + X)$ .*

*Proof.* Consider  $X > X_T$ . The function  $\mu$  coincides with  $\mu_X$  on  $(0, T) \times (0, X)$ . The monotone character of  $\mu$  w.r.t. the two variables stems from (4.14) and from the fact that  $u$  is nonincreasing w.r.t.  $x$  and nondecreasing w.r.t.  $t$ .

The same result can be proved by observing that  $\mu_X$  is the weak limit in  $L^2((0, T) \times (0, X))$  of the sequence  $rx1_{x>S}\mathcal{V}_\epsilon(u_{X,\epsilon})$  and using the properties of  $rx1_{x>S}\mathcal{V}_\epsilon(u_{X,\epsilon})$ .

The bound on the total variation of  $\mu$  on  $(0, T) \times (0, X)$  comes from the fact that  $\mu$  is nondecreasing w.r.t.  $x$  and nonincreasing w.r.t.  $t$  and that  $0 \leq \mu \leq rX$  a.e. in  $(0, T) \times (0, X)$ .  $\square$

**PROPOSITION 4.11.** *A.e. in the coincidence set  $\{(t, x) : u(t, x) = 0\}$ ,  $\mu > 0$ .*

*Proof.* We know from Proposition 4.6 that the boundary of the coincidence set has measure 0 (Lebesgue measure in  $\mathbb{R}^2$ ). Assume that  $\mu = 0$  in some subset of  $x > \gamma(t)$  with positive measure. In view of the monotone behavior of  $\mu$ , this implies that  $\mu = 0$  in a rectangle contained in the set  $x > \gamma(t)$ . From Proposition 4.6, this implies that  $\int_{\mathbb{R}} k(z)e^z u(t, xe^{-z}) dz = rx$  in this rectangle. Taking the derivative w.r.t.  $x$ , we obtain that  $\int_{\mathbb{R}} k(z) \frac{\partial u}{\partial x}(t, xe^{-z}) dz = r$  in the rectangle. But this is impossible, since  $u(t, x)$  is nonincreasing w.r.t.  $x$  and nonidentically 0.  $\square$

**REMARK 8.** *Proposition 4.11 tells us that there is a.e. strict complementarity: the reaction term  $\mu$  is positive at almost every point where  $u = 0$ .*

**4.4. Further bounds.** Let us choose some constants  $\underline{\sigma}, \bar{\sigma}, \underline{\alpha}, b_1, b_2, \underline{\psi}, \bar{\psi}$ , and  $\bar{z}$  such that  $0 < \underline{\sigma} \leq \bar{\sigma}$ ,  $0 < \underline{\alpha} < 1/2$ ,  $b_1 > 1$ ,  $b_2 > 1$ ,  $\bar{\psi} \geq \underline{\psi} > 0$ , and  $\bar{z} > 0$ . Let us define the subset  $\mathcal{F}$  of  $\mathbb{R}_+ \times \mathbb{R} \times L^\infty(\mathbb{R})$  by

$$(4.18) \quad \mathcal{F} = [\underline{\sigma}, \bar{\sigma}] \times [-1/2, 1 - \underline{\alpha}] \times \left\{ \psi : \begin{array}{l} \|\max(e^{2b_1 z}, |z|^{b_2}, 1)\psi\|_{L^\infty(\mathbb{R})} \leq \bar{\psi}; \\ \psi \geq 0, \psi \geq \underline{\psi} \text{ a.e. in } [-\bar{z}, \bar{z}] \end{array} \right\}.$$

We can make the following three observations:

1. The norm of  $A$  as an operator from  $V$  to  $V'$  is bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .
2. The constants in (3.10)–(3.11) can be taken independent of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .
3. With  $\lambda$  in (3.10) independent of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ , the operator  $A + \lambda I$  is one-to-one and continuous from  $V^2$  onto  $L^2(\mathbb{R}_+)$  and  $(A + \lambda I)^{-1} : L^2(\mathbb{R}_+) \mapsto V^2$  is bounded with constants independent of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .

By carefully inspecting the proofs of Theorems 4.2, 4.4, and 4.9, we see that

1. the quantities  $\|u_{X,\epsilon}\|_{L^\infty(0,T;L^2(0,X))}$  and  $\|u_{X,\epsilon}\|_{L^2(0,T;V_X)}$  are bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ ,
2. the quantities  $\|\mathcal{E}_X(u_X)\|_{L^\infty(0,T;L^2(\mathbb{R}_+)})$  and  $\|\mathcal{E}_X(u_X)\|_{L^2(0,T;V)}$  are bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ , and

3. the quantities  $\|u\|_{L^\infty(0,T;L^2(\mathbb{R}_+))}$  and  $\|u\|_{L^2(0,T;V)}$  are bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .

**PROPOSITION 4.12.** *The function  $\gamma$  is bounded in  $[0, T]$  by some constant  $\bar{X}$  independent of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ . The quantities  $\|u\|_{L^\infty(0,T;V)}$ ,  $\|u\|_{L^2(0,T;V^2)}$ , and  $\|\frac{\partial u}{\partial t}\|_{L^2((0,T)\times\mathbb{R}_+)}$  are bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .*

*Proof.* For a sequence  $(\sigma_n, \alpha_n, \psi_n)$  in  $\mathcal{F}$ , let us call  $u_n$  the corresponding solution of problem (VIP) and  $\gamma_n$  the function such that  $u_n(t, x) = 0 \Leftrightarrow x \geq \gamma_n(t)$ . Assume that  $\lim_{n \rightarrow \infty} \gamma_n(T/2) = +\infty$ . Then, we can use the same arguments as in the proof of Lemma 4.7 and reach a contradiction. Therefore,  $\gamma|_{[0,T/2]}$  is bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ . Since (VIP) can always be solved in  $(0, 2T) \times \mathbb{R}_+$  instead of  $(0, T) \times \mathbb{R}_+$ , and since for the solution  $u$ ,  $\|u\|_{L^2(0,2T;V)} + \|\frac{\partial u}{\partial t}\|_{L^2(0,2T;V')}$  is bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ , we can use the same arguments and prove that  $\gamma|_{[0,T]}$  is bounded independently of  $(\sigma, \alpha, \psi)$  in  $\mathcal{F}$ .

Therefore, it is possible to choose  $\bar{X}$  such that, for any  $(\sigma, \alpha, \psi) \in \mathcal{F}$ ,  $\gamma < \bar{X}$ , and  $u$  coincides with  $\mathcal{E}_{\bar{X}}(u_{\bar{X}})$ , where  $u_{\bar{X}}$  is the solution of (VIP) $_{\bar{X}}$ . For  $x > \bar{X}$ ,

$$\mu(t, x) = rx - \int_{z > \log(x/\bar{X})} k(z) e^z u(xe^{-z}) dz.$$

Thus, for  $x$  large enough such that, for example,  $\log(x/\bar{X}) > 1$ ,

$$\begin{aligned} 0 \leq rx - \mu(t, x) &\leq S \int_{z > \log(x/\bar{X})} k(z) e^z dz \leq S \int_{z > \log(x/\bar{X})} \psi(z) e^{2z} e^{-z} dz \\ (4.19) \quad &\leq S \bar{\psi} \int_{z > \log(x/\bar{X})} e^{-z} dz = \bar{\psi} S \frac{\bar{X}}{x}. \end{aligned}$$

Therefore,  $\|\frac{\partial u}{\partial t} + Au\|_{L^2(0,T;L^2(\mathbb{R}_+))}$  is bounded by a constant independent of  $(\sigma, \alpha, \psi)$ . This implies that the quantities  $\|u\|_{L^\infty(0,T;V)}$ ,  $\|u\|_{L^2(0,T;V^2)}$ , and  $\|\frac{\partial u}{\partial t}\|_{L^2((0,T)\times\mathbb{R})}$  are bounded independently of  $(\sigma, \alpha, \psi) \in \mathcal{F}$ .  $\square$

**REMARK 9.** *It may be possible to impose weaker conditions on  $\psi$ , and other choices of  $\mathcal{F}$  could be made.*

**5. Sensitivity analysis.** Here, we aim at understanding the sensitivity of the solution  $u$  of (VIP) and of  $\mu$  given by (4.17) to the variations of  $(\sigma, \alpha, \psi) \in \mathcal{F}$ . Let us introduce  $\mathcal{B} = \{f : z \mapsto f(z) \max(1, |z|^{b_2}, e^{2b_1 z}) \in L^\infty(\mathbb{R})\}$  endowed with the norm  $\|f\|_{\mathcal{B}} = \|f(\cdot) \max(1, |\cdot|^{b_2}, e^{2b_1 \cdot})\|_{L^\infty(\mathbb{R})}$ . For  $(\sigma, \alpha, \psi) \in \mathcal{F}$ , let  $u(\sigma, \alpha, \psi)$  be the corresponding solution of (VIP). Accordingly, let  $\mu(\sigma, \alpha, \psi)$  be given by (4.17) and  $\gamma(\sigma, \alpha, \psi)$  be the function defining the free boundary.

**PROPOSITION 5.1.** *There exists  $C > 0$  such that  $(\sigma, \alpha, \psi) \in \mathcal{F}$ ,  $(\tilde{\sigma}, \tilde{\alpha}, \tilde{\psi}) \in \mathcal{F}$ ,*

$$(5.1) \quad \|u - \tilde{u}\|_{L^2(0,T;V)} + \|u - \tilde{u}\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} \leq C \left( |\sigma - \tilde{\sigma}| + |\alpha - \tilde{\alpha}| + \|\psi - \tilde{\psi}\|_{\mathcal{B}} \right),$$

$$(5.2) \quad \int_0^T \int_{\mathbb{R}} (\mu(\tilde{u} - u_o) + \tilde{\mu}(u - u_o)) \leq C \left( |\sigma - \tilde{\sigma}| + |\alpha - \tilde{\alpha}| + \|\psi - \tilde{\psi}\|_{\mathcal{B}} \right)^2,$$

calling  $u = u(\sigma, \alpha, \psi)$ ,  $\mu = \mu(\sigma, \alpha, \psi)$ ,  $\tilde{u} = u(\tilde{\sigma}, \tilde{\alpha}, \tilde{\psi})$ , and  $\tilde{\mu} = \mu(\tilde{\sigma}, \tilde{\alpha}, \tilde{\psi})$ .

*Proof.* We skip the proof since its arguments are well known.  $\square$

**PROPOSITION 5.2.** *Consider  $(\sigma, \alpha, \psi) \in \mathcal{F}$  and let  $(\sigma_n, \alpha_n, \psi_n)_{n \in \mathbb{N}}$  be a sequence of coefficients in  $\mathcal{F}$  such that  $\lim_{n \rightarrow \infty} (|\sigma - \sigma_n| + |\alpha - \alpha_n| + \|\psi - \psi_n\|_{\mathcal{B}}) = 0$ . Calling*

$$(5.3) \quad \lim_{n \rightarrow +\infty} \|u_n - u\|_{L^\infty((0,T) \times \mathbb{R}_+)} = 0, \quad \lim_{n \rightarrow +\infty} \|\mu_n - \mu\|_{L^p((0,T) \times \mathbb{R}_+)} = 0$$

for all  $p$ ,  $1 < p < +\infty$ , and

$$(5.4) \quad \|u_n - u\|_{L^\infty(0,T;V^1)} + \|u_n - u\|_{L^2(0,T;V^2)} + \left\| \frac{\partial(u_n - u)}{\partial t} \right\|_{L^2((0,T) \times \mathbb{R}_+)} \rightarrow 0.$$

*Proof.* From the facts that

- $u(t, x) = u_n(t, x) = 0$  for  $x > \bar{X}$  (where  $\bar{X}$  is given in Proposition 4.12 and does not depend of  $(\sigma, \alpha, \psi) \in \mathcal{F}$ ), and
- for all  $n$ ,  $S - x \leq u_n(t, x) \leq S$  and  $S - x \leq u(t, x) \leq S$ , which implies that  $u - u_n$  is arbitrarily small as  $x \rightarrow 0$  uniformly w.r.t.  $n$ ,

it is enough to prove that for all  $\epsilon > 0$ ,

$$(5.5) \quad \lim_{n \rightarrow +\infty} \|u_n - u\|_{L^\infty((0,T) \times (\epsilon, \bar{X}))} = 0.$$

From (5.1), we see that  $\lim_{n \rightarrow \infty} \|u_n - u\|_{L^\infty(0,T;L^2(\mathbb{R}_+))} = 0$ . On the other hand, we know that  $\|u_n - u\|_{L^\infty(0,T;V)}$  is bounded independently of  $n$ . These two observations imply (5.5), and the first part of (5.3) is proved.

Let us prove the second part of (5.3): from the fact that  $\mu_n - rx$  is bounded  $L^2((0, T) \times \mathbb{R}_+)$ , one can extract a subsequence converging weakly in  $L^2((0, T) \times \mathbb{R}_+)$ . The limit is nothing else but  $\mu - rx$ , and the whole sequence  $\mu_n - rx$  converges to  $\mu - rx$  weakly in  $L^2((0, T) \times \mathbb{R}_+)$ . Thanks to (4.19) with  $\bar{X}$  independent of  $(\sigma, \alpha, \psi) \in \mathcal{F}$ , it is enough to prove that  $\mu_n$  strongly converges to  $\mu$  in  $L^p((0, T) \times (0, X))$ , for any  $X > S$ , and  $1 < p < +\infty$ . But, from Proposition 4.10, we know that the sequence  $(\mu_n)_n$  is bounded in  $BV((0, T) \times (0, X))$  and in  $L^\infty((0, T) \times (0, X))$ , and therefore relatively compact in  $L^p((0, T) \times (0, X))$ ,  $1 \leq p < +\infty$ . Therefore, a subsequence of  $(\mu_n)_n$  converges in  $L^p((0, T) \times (0, X))$ , and the limit is nothing but  $\mu$ , from the observation above. The whole sequence  $(\mu_n)_n$  converges to  $\mu$  in  $L^p((0, T) \times (0, X))$ . We have proved that  $\mu_n - rx$  converges to  $\mu - rx$  in  $L^p((0, T) \times \mathbb{R}_+)$ ,  $1 < p < +\infty$ .

Finally, (5.4) follows from (5.3).  $\square$

**6. The least square inverse problem.** Let us introduce a Hilbert space  $H_\psi$  endowed with the norm  $\|\cdot\|_{H_\psi}$  and such that the bounded subsets of  $H_\psi$  are relatively compact in  $\mathcal{B}$ .

Consider  $\mathcal{H}_\psi$  a closed and convex subset of  $H_\psi$ . We assume that  $\mathcal{H}_\psi$  is contained in  $\{\psi : \|\psi\|_{\mathcal{B}} \leq \bar{\psi}; \psi \geq 0\}$  and that (a) the functions  $\psi \in \mathcal{H}_\psi$  are continuous near 0, (b) there exist two positive constants  $\underline{\psi}$  and  $\bar{z}$  such that  $\psi(z) \geq \underline{\psi}$  for all  $z$  such that  $|z| \leq \bar{z}$ , and (c) there exist two constants  $\zeta > 0$  and  $C \geq 0$  such that for all  $\psi \in \mathcal{H}_\psi$ ,  $\psi(z)e^{3/2z} - \psi(0)e^{-3/2z} = z\omega(z)$ , with  $|\omega(z)| \leq C|z|e^{-\zeta|z|}$ , for all  $z \in \mathbb{R}$ . This choice of  $\mathcal{H}_\psi$  will allow us to use the results stated in Lemma 3.6.

Finally, consider the set  $\mathcal{H} = [\underline{\sigma}, \bar{\sigma}] \times [-1/2, 1 - \underline{\alpha}] \times \mathcal{H}_\psi$ . Let  $J_R$  be a convex, coercive, and  $\mathcal{C}^1$  function defined on  $[\underline{\sigma}, \bar{\sigma}] \times [-1/2, 1 - \underline{\alpha}] \times H_\psi$ . It is well known that  $J_R$  is also weakly lower semicontinuous. The functional  $J_R$  may depend on suitable prior parameters  $\sigma_0$ ,  $\alpha_0$ , and  $\psi_0$ . It is the analogue of the function  $\rho J_2$  discussed in section 1.

### 6.1. Toward the calibration problem.

**6.1.1. Orientation.** For calibrating the Lévy process, one observes the spot price  $S$  and the prices  $(\bar{p}_i)_{i \in I}$  of a family of American put options with maturities/ strikes given by  $(T_i, x_i)$ , and we call  $\bar{u}_i = \bar{p}_i - x_i + S$ ,  $i \in I$ . The parameters of the

Lévy process, i.e., the volatility  $\sigma$ , the exponent  $\alpha$ , and the function  $\psi$  will be found as solutions of a least square problem, where the functional to be minimized is the sum of a suitable Tychonoff regularization functional and of

$$J(u) = \sum_{i \in I} \omega_i (u(T_i, x_i) - \bar{u}_i)^2,$$

where  $\omega_i$  are positive weights, and  $u = u(\sigma, \alpha, \psi)$  is a solution of (VIP).

We aim at finding some necessary optimality conditions satisfied by the solutions of the least square problem. The main difficulty comes from the fact that the derivability of the functional  $J(u)$  w.r.t. the parameter  $(\sigma, \alpha, \psi)$  is not guaranteed. To obtain some necessary optimality conditions, we shall consider first a least square problem where  $u$  is the solution of the penalized problem (4.6) rather than (VIP), obtain the necessary optimality conditions for this new problem, and then have the penalty parameter  $\epsilon$  tend to 0 and pass to the limit in the optimality conditions. Such a program has already been applied in [2] for calibrating the local volatility with American options; see also [4, 5] for a related numerical method and results. The idea originally comes from Hintermüller [22] and Ito and Kunisch [23], who applied a similar program for elliptic variational inequalities. Let us also mention Mignot and Puel [31], who applied a nice method for finding the optimality conditions of a special control problem with a parabolic variational inequality.

In order to simplify the notation, we are going to consider first a toy problem where only one price is observed. Of course, observing only one price is not enough. However, finding the optimality conditions for this simplified calibration problem presents the same difficulties as for the original one.

**6.1.2. The least square problem and its penalized version.** A first step toward the calibration problem is to consider the functional  $J$ ,

$$(6.1) \quad J : \mathcal{C}^0([0, T] \times \mathbb{R}_+) \rightarrow \mathbb{R}, \quad J(u) = (u(T, x_{ob}) - \bar{u})^2,$$

where  $x_{ob}$  and  $\bar{u}$  are positive numbers. We fix  $\bar{X}$  (independent of  $(\sigma, \alpha, \psi) \in \mathcal{H}$ ) as in Proposition 4.12 and assume that  $x_{ob} < \bar{X}$ . Consider the least square problem:

$$(6.2) \quad \text{Minimize } J(u) + J_R(\sigma, \alpha, \psi) \quad \left| \quad (\sigma, \alpha, \psi) \in \mathcal{H}, u = u(\sigma, \alpha, \psi) \text{ satisfies (VIP)} \right|.$$

Fixing  $X \geq \bar{X}$ , we know that  $u|_{[0, T] \times [0, X]} = u_X$ , where  $u_X$  is the solution of (VIP<sub>X</sub>). Therefore, (6.2) is equivalent to the least square problem:

$$(6.3) \quad \text{Minimize } J(u) + J_R(\sigma, \alpha, \psi) \quad \left| \quad (\sigma, \alpha, \psi) \in \mathcal{H}, u \text{ satisfies (VIP}_X\text{)} \right|.$$

We will also consider the least square problem related to the penalized problem:

$$(6.4) \quad \text{Minimize } J(u_\epsilon) + J_R(\sigma, \alpha, \psi) \quad \left| \quad (\sigma, \alpha, \psi) \in \mathcal{H}, u_\epsilon \text{ satisfies (4.6)} \right|.$$

**LEMMA 6.1.** *Let  $(\epsilon_n)_n$  be a sequence of penalty parameters such that  $\epsilon_n \rightarrow 0$  as  $n \rightarrow \infty$ , and let  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*), u_{\epsilon_n}^*$  be a solution of problem (6.4). Consider a subsequence such that  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*)$  converges to  $(\sigma^*, \alpha^*, \psi^*)$  in  $\mathcal{F}$ ,  $\psi_{\epsilon_n}^*$  weakly converges to  $\psi^*$  in  $H_\psi$ , and  $u_{\epsilon_n}^* \rightarrow u^*$  weakly in  $L^2(0, T; V_X)$ , where  $V_X$  is defined in (4.1). Then  $(\sigma^*, \alpha^*, \psi^*), u^*$  is a solution of (6.3). We have that*

- $u_{\epsilon_n}^*$  converges to  $u^*$  uniformly in  $[0, T] \times [0, X]$ , and in  $L^2(0, T; V_X)$ ,
- $1_{\{x>S\}}rx\mathcal{V}_{\epsilon_n}(u_{\epsilon_n}^*)$  converges to  $\mu^*$  strongly in  $L^2((0, T) \times (0, X))$ , and
- for all smooth functions  $\chi$  with compact support contained in  $[0, X]$ ,  $\chi\mathcal{E}_X(u_{\epsilon_n}^*)$  converges to  $\chi\mathcal{E}_X(u^*)$  strongly in  $L^2(0, T; V^2)$  and in  $L^\infty(0, T; V)$ .

*Proof.* For brevity, the proof is outlined only. We skip the proof that  $u^*$  satisfies (VIP<sub>X</sub>) with  $(\sigma, \alpha, \psi) = (\sigma^*, \alpha^*, \psi^*)$  and the proofs of the first two points above, since they are in the same spirit as the proofs of Theorem 4.4 and Proposition 4.8. The third point above is proved by writing the boundary value problems satisfied by  $y_n = \chi\mathcal{E}_X(u_{\epsilon_n}^*)$  and  $y = \chi\mathcal{E}_X(u^*)$ , with the PID equations

$$\frac{\partial y_n}{\partial t} + A_n y_n = f_n, \quad \frac{\partial y}{\partial t} + Ay = f,$$

where  $A$  (resp.,  $A_n$ ) is given by (3.9) and (2.12) with  $(\sigma, \alpha, \psi) = (\sigma^*, \alpha^*, \psi^*)$  (resp.,  $(\sigma, \alpha, \psi) = (\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*)$ ) and where the right-hand side  $f$  (resp.,  $f_n$ ) can be written in terms of  $\chi$ ,  $u^*$ , and  $\mu^*$  (resp.,  $\chi$  and  $u_{\epsilon_n}^*$ ). By using the first two points above and the same arguments as in the proofs of Propositions 5.1 and 5.2, it can be proved that  $f_n$  converges to  $f$  in  $L^2((0, T) \times \mathbb{R}_+)$  and that  $y_n$  converges to  $y$  in  $L^2(0, T; V^2)$  and in  $L^\infty(0, T; V)$ .

As a consequence of the first point above,  $J(u_{\epsilon_n}^*) \rightarrow J(u^*)$ . Moreover, from the assumptions on  $J_R$ ,  $J_R(\sigma^*, \alpha^*, \psi^*) \leq \liminf_{n \rightarrow \infty} J_R(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*)$ .

Since  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*)$  is a solution of (6.4),

$$J(u_{\epsilon_n}^*) + J_R(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*) \leq J(u_{\epsilon_n}(\sigma, \alpha, \psi)) + J_R(\sigma, \alpha, \psi) \quad \forall (\sigma, \alpha, \psi) \in \mathcal{H},$$

where  $u_{\epsilon_n}(\sigma, \alpha, \psi)$  is the solution of (4.6) with  $\epsilon = \epsilon_n$ . This implies that

$$J(u^*) + J_R(\sigma^*, \alpha^*, \psi^*) \leq J(u(\sigma, \alpha, \psi)) + J_R(\sigma, \alpha, \psi) \quad \forall (\sigma, \alpha, \psi) \in \mathcal{H},$$

where  $u(\sigma, \alpha, \psi)$  satisfies (VIP<sub>X</sub>) and  $(\sigma^*, \alpha^*, \psi^*), u^*$  is a solution of (6.3).  $\square$

**REMARK 10.** Let  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*), u_{\epsilon_n}^*$  be a subsequence converging to  $(\sigma^*, \alpha^*, \psi^*), u^*$  as in Lemma 6.1. It is clear from the continuity of  $u^*$  and from the uniform convergence of  $u_{\epsilon_n}^*$  that if  $u^*(T, x_{ob}) > u_o(x_{ob})$ , then there exist a constant  $a > 0$  and an integer  $N$  such that for  $n > N$ ,  $u_{\epsilon_n}^*(t, x) > u_o(x) + \epsilon_n$  for all  $(t, x)$  with  $|x - x_{ob}| < a$  and  $t > T - a$ .

**6.1.3. First order necessary optimality conditions for (6.4).** We take  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*), u_{\epsilon_n}^*$  and  $(\sigma^*, \alpha^*, \psi^*), u^*$  as in Lemma 6.1. We assume that  $u^*(T, x_{ob}) > u_o(x_{ob})$ , and we take  $N$  and  $a$  as in Remark 10. For  $n > N$ , we wish to find necessary optimality conditions for the solution  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*), u_{\epsilon_n}^*$  of (6.4). In order to simplify the notation, we drop the index  $n$ ; below,  $\epsilon$  means  $\epsilon_n$ .

We shall need to solve an adjoint problem. Since the cost functional involves pointwise values of  $u$ , the adjoint problem will have a singular data. In that context, the notion of very weak solution of boundary value problems will be relevant: we introduce the space  $Z_\epsilon = \{v \in \tilde{Z}_\epsilon; v(t = 0) = 0\}$ , where

$$\tilde{Z}_\epsilon = \left\{ v \in L^2(0, T; V_X); \frac{\partial v}{\partial t} + A_{\epsilon, X} v - rx1_{\{x>S\}}\mathcal{V}'(u_\epsilon^*)v \in L^2((0, T) \times (0, X)) \right\}$$

and  $A_{\epsilon, X}$  is the operator defined by (4.2), with  $(\sigma, \alpha, \psi) = (\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*)$ . The space  $Z_\epsilon$  endowed with the graph norm is a Banach space.

LEMMA 6.2. Assume that  $u^*(T, x_{ob}) > u_o(x_{ob})$  and take  $N$  and  $a$  as in Remark 10. There exists a unique  $p_\epsilon^* \in L^2((0, T) \times (0, X))$  such that, for all  $v \in Z_\epsilon$ ,

$$(6.5) \quad \int_0^T \int_0^X \left( \frac{\partial v}{\partial t} + A_{\epsilon, X} v - r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*) v \right) p_\epsilon^* = 2(u_\epsilon^*(T, x_{ob}) - \bar{u}) v(T, x_{ob}),$$

and  $\|p_\epsilon^*\|_{L^2((0, T) \times (0, X))}$  is bounded by a constant independent of  $\epsilon$  in the subsequence. For a fixed smooth function  $\phi$  taking the value 1 for  $|x - x_{ob}| \geq a/2$ ,  $T - t \geq a/2$  and vanishing in a neighborhood of  $(T, x_{ob})$ , we have that  $\phi p_\epsilon^* \in L^2(0, T; V_X) \cap C^0([0, T]; L^2((0, X)))$ , with norms bounded independently of  $\epsilon$ .

*Proof.* See Appendix B.  $\square$

REMARK 11. Problem (6.5) is a very weak formulation of

$$(6.6) \quad \begin{aligned} \frac{\partial p_\epsilon^*}{\partial t} - A_{\epsilon, X}^T p_\epsilon^* + r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* &= 0, \quad (t, x) \in [0, T) \times (0, X), \\ p_\epsilon^*(t, X) &= 0, \quad t \in (0, T), \\ p_\epsilon^*(T) &= -2(u_\epsilon^*(T, x_{ob}) - \bar{u}) \delta_{x_{ob}}, \end{aligned}$$

where  $A_{\epsilon, X}^T v(x) = -\frac{(\sigma_\epsilon^*)^2}{2} \frac{\partial^2}{\partial x^2} (x^2 v) + B_{\epsilon, X}^T v(x) - \frac{\partial}{\partial x} (r x v)$  with

$$B_{\epsilon, X}^T v(x) = \int_{\mathbb{R}} k_\epsilon^*(z) \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) - 1_{z < \log \frac{x}{x}} e^{2z} v(xe^z) + (2e^z - 1)v(x) \right) dz,$$

and  $k_\epsilon^*(z) = |z|^{-(2\alpha_\epsilon^* + 1)} \psi_\epsilon^*(z)$ .

REMARK 12. Similarly,  $\left\| \frac{\partial(\phi p_\epsilon^*)}{\partial t} - A_{\epsilon, X}^T(\phi p_\epsilon^*) + r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*)(\phi p_\epsilon^*) \right\|_{L^2((0, T) \times (0, X))}$  is bounded independently of  $\epsilon$ .

From Lemma 6.2, we see that  $\int_0^T \langle x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2}, \phi p_\epsilon^* \rangle$  is well defined, where  $\langle \cdot, \cdot \rangle$  is the duality pairing between  $(V_X)'$  and  $V_X$ . On the other hand,  $\int_0^T \int_0^X ((1 - \phi) x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2}) p_\epsilon^*$  is well defined since both  $((1 - \phi) x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2})$  and  $p_\epsilon^*$  are square integrable. Moreover, the sum  $\int_0^T \langle x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2}, \phi p_\epsilon^* \rangle + \int_0^T \int_0^X ((1 - \phi) x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2}) p_\epsilon^*$  does not depend on the choice of  $\phi$ . Therefore, we call  $\mathcal{G}^{(\sigma)}(u_\epsilon^*, p_\epsilon^*)$  the quantity

$$(6.7) \quad \mathcal{G}^{(\sigma)}(u_\epsilon^*, p_\epsilon^*) = \int_0^T \left\langle x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2}, \phi p_\epsilon^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) x^2 \frac{\partial^2 u_\epsilon^*}{\partial x^2} \right) p_\epsilon^*.$$

Let us introduce the operator  $B_{\epsilon, X}^{(\alpha)}$ :

$$(6.8) \quad \begin{aligned} B_{\epsilon, X}^{(\alpha)} v(x) &= - \int_{\mathbb{R}} k_\epsilon^*(z) \log(|z|) \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) \right. \\ &\quad \left. + e^z (1_{\{z > -\log(\frac{x}{x})\}} v(xe^{-z}) - v(x)) \right) dz, \end{aligned}$$

where  $k_\epsilon^*(z) = |z|^{-2\alpha_\epsilon^* - 1} \psi_\epsilon^*(z)$ . From Lemma 6.2, the quantity  $\int_0^T \langle B_{\epsilon, X}^{(\alpha)} u_\epsilon^*, \phi p_\epsilon^* \rangle$  is well defined, where  $\langle \cdot, \cdot \rangle$  is the duality pairing between  $(V_X)'$  and  $V_X$ . On the other hand, the quantity  $\int_0^T \int_0^X ((1 - \phi) B_{\epsilon, X}^{(\alpha)} u_\epsilon^*) p_\epsilon^*$  is well defined since both  $p_\epsilon^*$  and  $((1 - \phi) B_{\epsilon, X}^{(\alpha)} u_\epsilon^*)$  are square integrable. Moreover, the sum  $\int_0^T \langle B_{\epsilon, X}^{(\alpha)} u_\epsilon^*, \phi p_\epsilon^* \rangle + \int_0^T \int_0^X ((1 - \phi) B_{\epsilon, X}^{(\alpha)} u_\epsilon^*) p_\epsilon^*$  does not depend on  $\phi$ . Therefore, we denote  $\mathcal{G}_\epsilon^{(\alpha)}(u_\epsilon^*, p_\epsilon^*)$

the quantity

$$(6.9) \quad \mathcal{G}_\epsilon^{(\alpha)}(u_\epsilon^*, p_\epsilon^*) = \int_0^T \left\langle B_{\epsilon, X}^{(\alpha)} u_\epsilon^*, \phi p_\epsilon^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) B_{\epsilon, X}^{(\alpha)} u_\epsilon^* \right) p_\epsilon^*.$$

Similarly, for  $\kappa \in H_\psi$ , we introduce the operator  $B_{\epsilon, X}^{(\psi, \kappa)}$ :

$$B_{\epsilon, X}^{(\psi, \kappa)} v(x) = \int_{\mathbb{R}} \frac{\kappa(z)}{|z|^{1+2\alpha_\epsilon^*}} \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) + e^z (1_{\{z > -\log(\frac{x}{\epsilon})\}} v(xe^{-z}) - v(x)) \right) dz,$$

and the quantity

$$(6.10) \quad \left\langle \mathcal{G}_\epsilon^{(\psi)}(u_\epsilon^*, p_\epsilon^*), \kappa \right\rangle = \int_0^T \left\langle B_{\epsilon, X}^{(\psi, \kappa)} u_\epsilon^*, \phi p_\epsilon^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) B_{\epsilon, X}^{(\psi, \kappa)} u_\epsilon^* \right) p_\epsilon^*,$$

which does not depend on  $\phi$ . We are now ready to give necessary optimality for the least square problem (6.4).

PROPOSITION 6.3. *The optimality conditions for problem (6.4) are as follows: for all  $(\sigma, \alpha, \psi) \in \mathcal{H}$ ,*

$$(6.11) \quad (\sigma - \sigma_\epsilon^*) \left( D_\sigma J_R(\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*) + \sigma_\epsilon^* \mathcal{G}^{(\sigma)}(u_\epsilon^*, p_\epsilon^*) \right) \geq 0,$$

$$(6.12) \quad (\alpha - \alpha_\epsilon^*) \left( D_\alpha J_R(\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*) + 2\mathcal{G}_\epsilon^{(\alpha)}(u_\epsilon^*, p_\epsilon^*) \right) \geq 0,$$

$$(6.13) \quad \langle D_\psi J_R(\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*), \psi - \psi_\epsilon^* \rangle + \left\langle \mathcal{G}_\epsilon^{(\psi)}(u_\epsilon^*, p_\epsilon^*), \psi - \psi_\epsilon^* \right\rangle \geq 0.$$

*Proof.* The proof is quite standard. It is omitted for brevity.  $\square$

**6.1.4. First order necessary optimality conditions for (6.3).** In order to obtain optimality conditions for (6.3), we wish to pass to the limit in the optimality conditions for (6.4). Let  $\epsilon_n$  be sequence of penalty parameters converging to zero, and let  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*, u_{\epsilon_n}^*)$  be a sequence of solutions to (6.4) converging to  $(\sigma^*, \alpha^*, \psi^*, u^*)$  as in Lemma 6.1. Assume that there exists a positive number  $a$  such that  $u_{\epsilon_n}^*(t, x) > u_o(x) + \epsilon_n$  for all  $(t, x)$  with  $|x - x_{ob}| \leq a$  and  $T - t \leq a$ . Let  $p_{\epsilon_n}^*$  be the adjoint state defined by Lemma 6.2. There exists a subsequence denoted  $n_k$  such that  $p_{\epsilon_{n_k}}^*$  weakly converges to  $p^*$  in  $L^2((0, T) \times (0, X))$  and  $\phi p_{\epsilon_{n_k}}^*$  weakly converges to  $\phi p^*$  in  $L^2(0, T; V_X)$ , where  $\phi$  is given in Lemma 6.2.

We call  $\tilde{Z}$  and  $Z$  the spaces

$$(6.14) \quad \begin{aligned} \tilde{Z} &= \left\{ v \in L^2(0, T; V_X); \frac{\partial v}{\partial t} + A_X v \in L^2((0, T) \times (0, X)) \right\}, \\ Z &= \left\{ v \in \tilde{Z}; v(t = 0) = 0 \right\}, \end{aligned}$$

where  $A_X$  is the operator given by (4.2), (3.9), and (2.12), with the parameter  $(\sigma^*, \alpha^*, \psi^*)$ . These spaces, endowed with the graph norm, are Banach spaces.

PROPOSITION 6.4. *There exists a Radon measure  $\xi^*$  such that for all  $v \in Z$ ,*

$$(6.15) \quad \int_0^T \int_0^X \left( \frac{\partial v}{\partial t} + A_X v \right) p^* + \langle \xi^*, v \rangle = 2(u^*(T, x_{ob}) - \bar{u})v((T, x_{ob})).$$

*The function  $p^*$  satisfies*

$$(6.16) \quad \frac{\partial p^*}{\partial t} - A_X^T p^* - \xi^* = 0$$

in the sense of distributions. Furthermore, with  $u^*, \mu^*$  defined as in Lemma 6.1,

$$(6.17) \quad \mu^*|p^*| = 0,$$

$$(6.18) \quad |u^*|\xi^* = 0.$$

*Proof.* For simplicity, we drop the index  $n$  in  $\epsilon_n$ . In what follows,  $\epsilon$  means  $\epsilon_n$ . For a positive parameter  $\delta$ , we introduce the nondecreasing function  $\rho_\delta : \mathbb{R} \rightarrow \mathbb{R}$ ,

$$\rho_\delta(p) = -1 \text{ for } p \leq -\delta, \quad \rho_\delta(p) = p/\delta \text{ for } -\delta \leq p \leq \delta, \quad \rho_\delta(p) = 1 \text{ for } p \geq \delta,$$

and the nonnegative function  $R_\delta(p) = \int_0^p \rho_\delta(q) dq$ .

In what follows,  $\delta$  will be the generic term of a decreasing sequence of positive parameters which converges to 0.

For  $\phi$  introduced in Lemma 6.2, we use Remark 12: there exists a function  $g_\epsilon \in L^2((0, T) \times (0, X))$  with a norm bounded independently of  $\epsilon$  such that  $\phi p_\epsilon^*$  is the weak solution to

$$\frac{\partial(\phi p_\epsilon^*)}{\partial t} - A_{\epsilon, X}^T(\phi p_\epsilon^*) + r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*)(\phi p_\epsilon^*) = g_\epsilon$$

with the Cauchy condition  $(\phi p_\epsilon^*)(T, \cdot) = 0$  and the boundary condition  $(\phi p_\epsilon^*)(\cdot, X) = 0$ . Therefore,  $\|\phi p_\epsilon^*\|_{L^2(0, T; V_X)}$  is bounded uniformly in  $\epsilon$ . Moreover, from the properties of  $\phi$  (see Lemma 6.2), we have  $\mathcal{V}'_\epsilon(u_\epsilon^*)(\phi p_\epsilon^*) = \mathcal{V}'_\epsilon(u_\epsilon^*)p_\epsilon^*$ .

Multiplying the last equation by  $\rho_\delta(\phi p_\epsilon^*)$ , we obtain that there exists a constant  $C$  independent of  $\delta$  and  $\epsilon$  such that

$$(6.19) \quad \begin{aligned} & \int_0^X R_\delta(\phi p_\epsilon^*)(0, x) dx + \int_0^T \int_0^X \frac{(\sigma_\epsilon^*)^2 x^2}{2} \rho'_\delta(\phi p_\epsilon^*) \left( \frac{\partial(\phi p_\epsilon^*)}{\partial x} \right)^2 \\ & - r \int_0^T \int_S^X x \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* \rho_\delta(p_\epsilon^*) + \int_0^T \langle (B_{\epsilon, X}^T(\phi p_\epsilon^*)), \rho_\delta(\phi p_\epsilon^*) \rangle \leq C. \end{aligned}$$

Let us focus on the last term in the sum above: we can write it as

$$(6.20) \quad \begin{aligned} & \int_0^T \int_{\mathbb{R}_+} (B_\epsilon^T(\mathcal{E}_X(\phi p_\epsilon^*))) \rho_\delta(\mathcal{E}_X(\phi p_\epsilon^*)) = \frac{1}{2} \int_0^T \langle (B_\epsilon + B_\epsilon^T)(\mathcal{E}_X(\phi p_\epsilon^*)), \rho_\delta(\mathcal{E}_X(\phi p_\epsilon^*)) \rangle \\ & - \frac{1}{2} \int_0^T \langle (B_\epsilon - B_\epsilon^T)(\mathcal{E}_X(\phi p_\epsilon^*)), \rho_\delta(\mathcal{E}_X(\phi p_\epsilon^*)) \rangle. \end{aligned}$$

From Lemma 3.6 and the choice of  $\mathcal{H}_\psi$ , there exists a constant  $C$  independent of  $(\sigma, \alpha, \psi) \in \mathcal{H}$  and of  $\delta$  such that

$$(6.21) \quad \begin{aligned} & \left| \int_0^T \langle (B_\epsilon - B_\epsilon^T)(\mathcal{E}_X(\phi p_\epsilon^*)), \mathcal{E}_X(\rho_\delta(\phi p_\epsilon^*)) \rangle \right| \\ & \lesssim \|\phi p_\epsilon^*\|_{L^2((0, T); V_X)} \|\rho_\delta(\phi p_\epsilon^*)\|_{L^2((0, T) \times (0, X))} \leq C. \end{aligned}$$

On the other hand, from Lemma 3.5,

$$(6.22) \quad \begin{aligned} & \left| \int_0^T \langle (B_\epsilon + B_\epsilon^T)(\mathcal{E}_X(\phi p_\epsilon^*)), \mathcal{E}_X(\rho_\delta(\phi p_\epsilon^*)) \rangle \right. \\ & \left. - \int_0^T \int_0^X \int_{\mathbb{R}} k_\epsilon(z) e^z ((\phi p_\epsilon^*)(x) - (\phi p_\epsilon^*)(x e^{-z})) (\rho_\delta(\phi p_\epsilon^*)(x) - \rho_\delta(\phi p_\epsilon^*)(x e^{-z})) \right| \\ & \lesssim \|\phi p_\epsilon^*\|_{L^2((0, T) \times (0, X))} \|\rho_\delta(\phi p_\epsilon^*)\|_{L^2((0, T) \times (0, X))} \leq C. \end{aligned}$$

From (6.19), (6.20), (6.21), and (6.22), we see that

$$\begin{aligned} & \int_0^X R_\delta(\phi p_\epsilon^*)(0, x) dx + \int_0^T \int_0^X \int_{\mathbb{R}} k_\epsilon(z) e^z ((\phi p_\epsilon^*)(x) - (\phi p_\epsilon^*)(x e^{-z})) \\ & \quad \cdot (\rho_\delta(\phi p_\epsilon^*)(x) - \rho_\delta(\phi p_\epsilon^*)(x e^{-z})) \\ & + \int_0^T \int_0^X \frac{(\sigma_\epsilon^*)^2 x^2}{2} \rho'_\delta(\phi p_\epsilon^*) \left( \frac{\partial(\phi p_\epsilon^*)}{\partial x} \right)^2 - r \int_0^T \int_S^X x \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* \rho_\delta(p_\epsilon^*) \leq C. \end{aligned}$$

Since  $p \mapsto p \rho_\delta(p)$  is a nonnegative function and since  $\rho_\delta$  is nondecreasing, all the terms in the sum above are nonnegative. Therefore, for a constant  $C$  independent of the parameters,  $-r \int_0^T \int_S^X x \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* \rho_\delta(p_\epsilon^*) \leq C$ .

On the other hand we know that  $-x \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* \rho_\delta(p_\epsilon^*)$  defines an increasing (as  $\delta$  decreases) sequence of nonnegative functions, which converges almost everywhere to  $x |\mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^*|$  as  $\delta$  tends to 0. Thus, Beppo Levi's theorem tells us that  $-r \int_0^T \int_S^X x \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* \rho_\delta(p_\epsilon^*)$  tends to  $r \int_0^T \int_S^X x |\mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^*|$  as  $\delta \rightarrow 0$ . Therefore, for a positive constant  $C$ ,

$$(6.23) \quad r \int_0^T \int_S^X x |\mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^*| \leq C.$$

It is thus possible to extract a subsequence  $\epsilon_{n_k}$ , such that  $p_{\epsilon_{n_k}}^* \rightarrow p^*$  weakly in  $L^2((0, T) \times (0, X))$ ,  $\phi p_{\epsilon_{n_k}}^* \rightarrow \phi p^*$  weakly in  $L^2(0, T; V_X)$ , and  $-r x 1_{\{x > S\}} \mathcal{V}'_{\epsilon_{n_k}}(u_{\epsilon_{n_k}}^*) p_{\epsilon_{n_k}}^*$  converges to  $\xi^*$  weakly\* in  $(L^\infty((0, T) \times (0, X)))^*$ . In order to simplify the notation, we omit the indexes  $n_k$ ; now  $\epsilon$  means  $\epsilon_{n_k}$ .

From this, (6.15) is obtained as well by passing to the limit in (6.5), and (6.16) is satisfied in the sense of distributions.

For proving (6.17), we use the convexity of  $\mathcal{V}_\epsilon$  (still dropping the index  $n_k$  in  $\epsilon_{n_k}$ ): since  $\mathcal{V}_\epsilon(\epsilon) = 0$ , we have that for all  $u \in [0, \epsilon]$ ,  $\mathcal{V}_\epsilon(u) \leq -\mathcal{V}'_\epsilon(u)(\epsilon - u) \leq -\epsilon \mathcal{V}'_\epsilon(u)$ . This implies that  $\mathcal{V}_\epsilon(u_\epsilon^*) \leq -\epsilon \mathcal{V}'_\epsilon(u_\epsilon^*)$  because we also know that  $\mathcal{V}_\epsilon(u_\epsilon^*) = 0$  if  $u_\epsilon^* \geq \epsilon$ . Thus, calling  $\mu_\epsilon^* = r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*)$ , (6.23) implies that

$$(6.24) \quad 0 \leq \int_0^T \int_0^X \mu_\epsilon^* |p_\epsilon^*| \leq -\epsilon r \int_0^T \int_S^X x \mathcal{V}'_\epsilon(u_\epsilon^*) |p_\epsilon^*| \rightarrow 0.$$

But we also know that  $p_\epsilon^* \rightarrow p^*$  weakly in  $L^2((0, T) \times (0, X))$  and that  $\mu_\epsilon^* \rightarrow \mu^*$  strongly in  $L^2((0, T) \times (0, X))$  from Lemma 6.1. Hence,  $\int_0^T \int_0^X \mu_\epsilon^* |p_\epsilon^*| \rightarrow \int_0^T \int_0^X \mu^* |p^*|$ , and (6.17) is proved.

Let us call  $\xi_\epsilon^* = -r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*) p_\epsilon^* = -r x 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_\epsilon^*) \phi p_\epsilon^*$ ; for  $\chi$  a continuous function in  $[0, T] \times [0, X]$ , we have

$$\int_0^T \int_0^X |\xi_\epsilon^*| \chi u_\epsilon^* \leq r \left( \int_0^T \int_S^X |x \mathcal{V}'_\epsilon(u_\epsilon^*)| |\phi p_\epsilon^*|^2 \right)^{\frac{1}{2}} \left( \int_0^T \int_S^X |x \mathcal{V}'_\epsilon(u_\epsilon^*)| |\chi u_\epsilon^*|^2 \right)^{\frac{1}{2}}$$

from the Cauchy-Schwarz inequality. But it can be checked that  $|\mathcal{V}'_\epsilon(u_\epsilon^*)| u_\epsilon^* \chi^2 \leq C \epsilon$ , which yields  $\int_0^T \int_S^X |x \mathcal{V}'_\epsilon(u_\epsilon^*)| u_\epsilon^* \chi^2 \leq C \epsilon$ . On the other hand, it is easy to check that  $\int_0^T \int_S^X |x \mathcal{V}'_\epsilon(u_\epsilon^*)| |\phi p_\epsilon^*|^2 \leq C$ . Therefore,  $\int_0^T \int_{\mathbb{R}_+} \xi_\epsilon^* |u_\epsilon^*| \chi \rightarrow 0$  as  $\epsilon \rightarrow 0$ . We know that  $\xi_\epsilon^* \rightarrow \xi^*$  weakly in  $(L^\infty)^*$  and that  $|u_\epsilon^*| \chi \rightarrow |u^*| \chi$  in  $C^0([0, T] \times [0, X])$  from Lemma 6.1. We can pass to the limit as  $\epsilon \rightarrow 0$  and (6.18) is proved.  $\square$

Proceeding as in (6.7), (6.9), and (6.10), we introduce the quantities

$$(6.25) \quad \mathcal{G}^{(\sigma)}(u^*, p^*) = \int_0^T \left\langle x^2 \frac{\partial^2 u^*}{\partial x^2}, \phi p^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) x^2 \frac{\partial^2 u^*}{\partial x^2} \right) p^*,$$

$$(6.26) \quad \mathcal{G}^{(\alpha)}(u^*, p^*) = \int_0^T \left\langle B_X^{(\alpha)} u^*, \phi p^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) B_X^{(\alpha)} u^* \right) p^*,$$

$$(6.27) \quad \left\langle \mathcal{G}^{(\psi)}(u^*, p^*), \kappa \right\rangle = \int_0^T \left\langle B_X^{(\psi, \kappa)} u^*, \phi p^* \right\rangle + \int_0^T \int_0^X \left( (1 - \phi) B_X^{(\psi, \kappa)} u^* \right) p^*,$$

where  $\phi$  is chosen as in Lemma 6.2, and where

$$B_X^{(\alpha)} v(x) = - \int_{\mathbb{R}} k^*(z) \log(|z|) \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) + e^z (1_{\{z > -\log(\frac{x}{x_0})\}} v(xe^{-z}) - v(x)) \right),$$

$$B_X^{(\psi, \kappa)} v(x) = \int_{\mathbb{R}} \frac{\kappa(z)}{|z|^{1+2\alpha^*}} \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) + e^z (1_{\{z > -\log(\frac{x}{x_0})\}} v(xe^{-z}) - v(x)) \right) dz.$$

One can check exactly as above that  $\mathcal{G}^{(\sigma)}(u^*, p^*)$ ,  $\mathcal{G}^{(\alpha)}(u^*, p^*)$ , and  $\langle \mathcal{G}^{(\psi)}(u^*, p^*), \kappa \rangle$  are well defined and do not depend of the particular choice of  $\phi$ . We are now ready to give necessary optimality for the least square problem (6.4).

**PROPOSITION 6.5.** *Let  $(\sigma^*, \alpha^*, \psi^*, u^*)$  be a solution to problem (6.3) obtained in Lemma 6.1. Assume that  $u^*(T, x_{ob}) > u_0(x_{ob})$  and take  $a$  as in Remark 10. There exist  $p^* \in L^2((0, T) \times (0, X))$  and a Radon measure  $\xi^*$  satisfying (6.15), (6.17), (6.18), and such that, for all  $(\sigma, \alpha, \psi) \in \mathcal{H}$ ,*

$$(6.28) \quad (\sigma - \sigma^*) \left( D_\sigma J_R(\sigma^*, \alpha^*, \psi^*) + \sigma^* \mathcal{G}^{(\sigma)}(u^*, p^*) \right) \geq 0,$$

$$(6.29) \quad (\alpha - \alpha^*) \left( D_\alpha J_R(\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*) + 2\mathcal{G}^{(\alpha)}(u^*, p^*) \right) \geq 0,$$

$$(6.30) \quad \langle D_\psi J_R(\sigma_\epsilon^*, \alpha_\epsilon^*, \psi_\epsilon^*), \psi - \psi^* \rangle + \langle \mathcal{G}^{(\psi)}(u^*, p^*), \psi - \psi^* \rangle \geq 0.$$

*Proof.* We consider a sequence of parameters  $\epsilon_n$  such that

- (1)  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*, u_{\epsilon_n}^*)$  is a sequence of solutions to (6.4) converging to  $(\sigma^*, \alpha^*, \psi^*, u^*)$  as in Lemma 6.1,
- (2)  $u_{\epsilon_n}^*(t, x) > u_0(x) + \epsilon_n$  for all  $(t, x)$  with  $|x - x_{ob}| \leq a$  and  $T - t \leq a$ ,
- (3) for the adjoint states  $p_\epsilon^*$  defined by Lemma 6.2,  $p_{\epsilon_n}^*$  weakly converges to  $p^*$  in  $L^2((0, T) \times (0, X))$  and  $\phi p_{\epsilon_n}^*$  weakly converges to  $\phi p^*$  in  $L^2(0, T; V_X)$ , where  $\phi$  is given in Lemma 6.2.

We drop the index  $n$  in  $\epsilon_n$ . We have to prove that  $\lim_{\epsilon \rightarrow 0} \mathcal{G}^{(\sigma)}(u_\epsilon^*, p_\epsilon^*) = \mathcal{G}^{(\sigma)}(u^*, p^*)$ . Since  $u_\epsilon^* \rightarrow u^*$  strongly in  $L^2(0, T; V_X)$  (see Lemma 6.1) and  $\phi p_\epsilon^* \rightarrow \phi p^*$  weakly in  $L^2(0, T; V_X)$ , we deduce that

$$\lim_{\epsilon \rightarrow 0} \int_0^T \left\langle \frac{\partial^2 u_\epsilon^*}{\partial x^2}, \phi p_\epsilon^* \right\rangle = \int_0^T \left\langle \frac{\partial^2 u^*}{\partial x^2}, \phi p^* \right\rangle.$$

On the other hand,  $(1 - \phi) \frac{\partial^2 u_\epsilon^*}{\partial x^2}$  strongly converges to  $(1 - \phi) \frac{\partial^2 u^*}{\partial x^2}$  in  $L^2((0, T) \times (0, X))$  from Lemma 6.1, and  $p_\epsilon^*$  weakly converges to  $p^*$  in  $L^2((0, T) \times (0, X))$ . Thus

$$\lim_{\epsilon \rightarrow 0} \int_0^T \int_0^X \left( (1 - \phi) \frac{\partial^2 u_\epsilon^*}{\partial x^2} \right) p_\epsilon^* = \int_0^T \int_0^X \left( (1 - \phi) \frac{\partial^2 u^*}{\partial x^2} \right) p^*.$$

From the two points above, we see that  $\lim_{\epsilon \rightarrow 0} \mathcal{G}^{(\sigma)}(u_\epsilon^*, p_\epsilon^*) = \mathcal{G}^{(\sigma)}(u^*, p^*)$ ; we can pass to the limit in (6.11) and obtain (6.28).

We have to prove that  $\lim_{\epsilon \rightarrow 0} \mathcal{G}_\epsilon^{(\alpha)}(u_\epsilon^*, p_\epsilon^*) = \mathcal{G}^{(\alpha)}(u^*, p^*)$ . The fact that  $u_\epsilon^* \rightarrow u^*$  strongly in  $L^2(0, T; V_X)$  (see Lemma 6.1) implies that  $B_{\epsilon, X}^{(\alpha)} u_\epsilon^*$  converges to  $B_X^{(\alpha)} u^*$  in  $L^2(0, T, (V_X)')$ . On the other hand,  $\phi p_\epsilon^* \rightarrow \phi p^*$  weakly in  $L^2(0, T; V_X)$ . This implies that

$$\lim_{\epsilon \rightarrow 0} \int_0^T \left\langle B_{\epsilon, X}^{(\alpha)} u_\epsilon^*, \phi p_\epsilon^* \right\rangle = \int_0^T \left\langle B_X^{(\alpha)} u^*, \phi p^* \right\rangle.$$

It can also be checked that  $(1 - \phi)B_{\epsilon, X}^{(\alpha)} u_\epsilon^*$  strongly converges to  $(1 - \phi)B_X^{(\alpha)} u^*$  in  $L^2((0, T) \times (0, X))$ . From the weak convergence of  $p_\epsilon^*$  to  $p^*$  in  $L^2((0, T) \times (0, X))$ , we deduce that

$$\lim_{\epsilon \rightarrow 0} \int_0^T \int_0^X \left( (1 - \phi)B_{\epsilon, X}^{(\alpha)} u_\epsilon^* \right) p_\epsilon^* = \int_0^T \int_0^X \left( (1 - \phi)B_X^{(\alpha)} u^* \right) p^*.$$

The two points above yield that  $\lim_{\epsilon \rightarrow 0} \mathcal{G}_\epsilon^{(\alpha)}(u_\epsilon^*, p_\epsilon^*) = \mathcal{G}^{(\alpha)}(u^*, p^*)$ . This and (6.12) yield (6.29). The last condition (6.30) is obtained in the same manner.  $\square$

**6.2. Conclusion: Optimality condition for the calibration problem.** For calibrating the Lévy process, one observes the spot price  $S$  and the prices  $(\bar{p}_i)_{i \in I}$  of a family of American put options with maturities/strikes given by  $(T_i, x_i)$ , and we call  $\bar{u}_i = \bar{p}_i - x_i + S$ ,  $i \in I$ . We assume that

$$\bar{u}_i > u_o(x_i) \quad \text{for all } i \in I.$$

Call  $T = \max_{i \in I} T_i$ . Let  $\bar{X}$  be such that for all  $(\sigma, \alpha, \psi) \in \mathcal{H}$ , the exercise price  $\gamma(t)$  is smaller than  $\bar{X}$  for all  $t \leq T$ , and take  $X \geq \bar{X}$ . The calibration problem has the form (6.3) with the new definition of  $J$ :

$$J(u) = \sum_{i \in I} \omega_i (u(T_i, x_i) - \bar{u}_i)^2,$$

where  $\omega_i$  are positive weights.

As above, we can also define the modified least square problem (6.4) and have  $\epsilon$  tend to 0. Let a subsequence  $(\sigma_{\epsilon_n}^*, \alpha_{\epsilon_n}^*, \psi_{\epsilon_n}^*, u_{\epsilon_n}^*)$  of solutions of (6.4) converge to  $(\sigma^*, \alpha^*, \psi^*, u^*)$  as in Lemma 6.1; then  $(\sigma^*, \alpha^*, \psi^*, u^*)$  is a solution of (6.3).

We assume that  $u^*(T_i, x_i) > u_o(x_i)$  for all  $i \in I$ . It is clear from the continuity of  $u^*$  and from the uniform convergence of  $u_{\epsilon_n}^*$  that there exist a positive real number  $a$  and an integer  $N$  such that for  $n > N$ ,  $u_{\epsilon_n}^*(t, x) > u_o(x) + \epsilon_n$  for all  $(t, x)$  such that  $|t - T_i| < a$  and  $|x - x_i| < a$  for some  $i \in I$ . We may fix a smooth function  $\phi$  taking the value 1 for all  $x$  such that  $|x - x_i| \geq a/2$ ,  $|T_i - t| \geq a/2$  for all  $i \in I$ , and vanishing in neighborhoods of  $(T_i, x_i)$ ,  $i \in I$ .

Calling  $A_X$  the operator defined by (4.2), (3.9), and (2.12) with the parameters  $(\sigma, \alpha, \psi) = (\sigma^*, \alpha^*, \psi^*)$ , we obtain the optimality conditions exactly as in section 6.1.4.

**THEOREM 6.6.** *Under the assumptions made at the beginning of section 6.2, there exist a function  $p^* \in L^2((0, T) \times (0, X))$  and a Radon measure  $\xi^*$  satisfying (6.17), (6.18) and for all  $v \in Z$  ( $Z$  is defined by (6.14)),*

$$(6.31) \quad \int_0^T \int_0^X \left( \frac{\partial v}{\partial t} + A_X v \right) p^* + \langle \xi^*, v \rangle = 2 \sum_{i \in I} \omega_i (u^*(T_i, x_i) - \bar{u}_i) v((T_i, x_i)),$$

equation (6.31) which remains unchanged and which I do not write and such that (6.28), (6.29), and (6.30) hold for all  $(\sigma, \alpha, \psi) \in \mathcal{H}$ , with  $\mathcal{G}^{(\sigma)}$ ,  $\mathcal{G}^{(\alpha)}$ , and  $\mathcal{G}^{(\psi)}$  defined, respectively, by (6.25), (6.26), and (6.27) (with the new choice of  $\phi$ ).

*Proof.* The proof follows exactly the same lines as that of Proposition 6.5.  $\square$

### Appendix A.

*Proof of Lemma 3.2.* By the change of variable  $y = \log(x)$ ,

$$\begin{aligned} |v|_{\phi,s}^2 &= \int_{\mathbb{R}} e^y dy \int_{\mathbb{R}} \frac{\phi(z)}{|z|^{1+2s}} (v(e^{y-z}) - v(e^y))^2 dz \\ &= \int_{\mathbb{R}} dy \int_{\mathbb{R}} \frac{\phi(z)}{|z|^{1+2s}} (e^{\frac{z}{2}} \tilde{v}(y-z) - \tilde{v}(y))^2 dz. \end{aligned}$$

By Fubini's theorem,  $|v|_{\phi,s}^2 = \int_{\mathbb{R}} dz \phi(z) |z|^{-(1+2s)} \int_{\mathbb{R}} (e^{\frac{z}{2}} \tilde{v}(y-z) - \tilde{v}(y))^2 dy$ ; after a Fourier transform w.r.t. the variable  $y$ ,

$$\begin{aligned} |v|_{\phi,s}^2 &= \int_{\mathbb{R}} dz \phi(z) |z|^{-(1+2s)} \int_{\mathbb{R}} \left| e^{z(\frac{1}{2}-i\xi)} \widehat{\tilde{v}}(\xi) - \widehat{\tilde{v}}(\xi) \right|^2 d\xi \\ &= \int_{\mathbb{R}} dz \phi(z) |z|^{-(1+2s)} \int_{\mathbb{R}} (e^z + 1 - 2e^{\frac{z}{2}} \cos(\xi z)) |\widehat{\tilde{v}}(\xi)|^2 d\xi \\ &= \int_{\mathbb{R}} dz \phi(z) |z|^{-(1+2s)} \int_{\mathbb{R}} \left( (e^{\frac{z}{2}} - 1)^2 + 4e^{\frac{z}{2}} \sin^2\left(\frac{\xi z}{2}\right) \right) |\widehat{\tilde{v}}(\xi)|^2 d\xi \\ &= \left( \int_{\mathbb{R}} \frac{\phi(z)}{|z|^{1+2s}} (e^{\frac{z}{2}} - 1)^2 dz \right) \|v\|_{L^2(\mathbb{R}_+)}^2 + 4 \int_{\mathbb{R}} dz \frac{\phi(z) e^{\frac{z}{2}}}{|z|^{1+2s}} \int_{\mathbb{R}} \sin^2\left(\frac{\xi z}{2}\right) |\widehat{\tilde{v}}(\xi)|^2 d\xi. \end{aligned}$$

But  $4 \int_{\mathbb{R}} dz \frac{\phi(z) e^{\frac{z}{2}}}{|z|^{1+2s}} \int_{\mathbb{R}} \sin^2\left(\frac{\xi z}{2}\right) |\widehat{\tilde{v}}(\xi)|^2 d\xi = 4 \int_{\mathbb{R}} |\xi|^{2s} |\widehat{\tilde{v}}(\xi)|^2 \int_{\mathbb{R}} \frac{\phi(z) e^{\frac{z}{2}}}{|\xi z|^{1+2s}} \sin^2\left(\frac{\xi z}{2}\right) |\xi| dz$ . Define

$$C_1 = \int_{\mathbb{R}} \phi(z) |z|^{-(1+2s)} (e^{\frac{z}{2}} - 1)^2 dz,$$

which is a real number since  $z \mapsto \phi(z) \max(e^z, 1)$  is bounded. Similarly, there exists a constant  $\beta > 0$  such that

$$4 \int_{\mathbb{R}} \frac{\phi(z) e^{\frac{z}{2}}}{|\xi z|^{1+2s}} \sin^2\left(\frac{\xi z}{2}\right) |\xi| dz \leq 4\beta \int_{\mathbb{R}} \frac{\sin^2\left(\frac{\xi z}{2}\right)}{|\xi z|^{1+2s}} |\xi| dz = 4\beta \int_{\mathbb{R}} \frac{\sin^2\left(\frac{u}{2}\right)}{|u|^{1+2s}} du,$$

and we introduce  $C_2 = 4\beta \int_{\mathbb{R}} \frac{\sin^2\left(\frac{u}{2}\right)}{|u|^{1+2s}} du$ . We have obtained that

$$|v|_{\phi,s}^2 \leq C_1 \|v\|_{L^2(\mathbb{R}_+)}^2 + C_2 \int_{\mathbb{R}} |\xi|^{2s} |\widehat{\tilde{v}}(\xi)|^2 d\xi.$$

On the other hand,

$$\begin{aligned} \int_{\mathbb{R}} \frac{\phi(z) e^{\frac{z}{2}}}{|\xi z|^{1+2s}} \sin^2\left(\frac{\xi z}{2}\right) |\xi| dz &= \int_{\mathbb{R}} \phi\left(\frac{u}{|\xi|}\right) e^{\frac{u}{2|\xi|}} \frac{\sin^2\left(\frac{u}{2}\right)}{|u|^{1+2s}} du \\ &\geq \int_{-1}^1 \phi\left(\frac{u}{|\xi|}\right) e^{\frac{u}{2|\xi|}} \frac{\sin^2\left(\frac{u}{2}\right)}{|u|^{1+2s}} du \end{aligned}$$

implies that

$$\liminf_{|\xi| \rightarrow \infty} \int_{\mathbb{R}} \phi(z) e^{\frac{z}{2}} |\xi z|^{-(1+2s)} \sin^2\left(\frac{\xi z}{2}\right) |\xi| dz \geq \phi(0) \int_{-1}^1 \sin^2\left(\frac{u}{2}\right) |u|^{-(1+2s)} du,$$

which shows that there exists a constant  $M > 0$  such that for  $|\xi| \geq M$ ,

$$4 \int_{\mathbb{R}} \phi(z) e^{\frac{z}{2}} |\xi z|^{-(1+2s)} \sin^2 \left( \frac{\xi z}{2} \right) |\xi| dz \geq 2\phi(0) \int_{-1}^1 \sin^2 \left( \frac{u}{2} \right) |u|^{-(1+2s)} du,$$

and we introduce  $C_4 = 2\phi(0) \int_{-1}^1 \frac{\sin^2(\frac{u}{2})}{|u|^{1+2s}} du$ . Thus

$$|v|_{\phi,s}^2 \geq C_1 \|v\|_{L^2(\mathbb{R}_+)}^2 + C_4 \int_{|\xi| > M} |\xi|^{2s} |\widehat{v}(\xi)|^2 d\xi \geq \frac{C_1}{2} \|v\|_{L^2(\mathbb{R}_+)}^2 + C_3 \int_{\mathbb{R}} |\xi|^{2s} |\widehat{v}(\xi)|^2 d\xi,$$

with  $C_3 = \min(C_1/(2M^{2s}), C_4)$ .  $\square$

*Proof of Lemma 3.3.* It is enough to prove that  $B|_{\mathcal{D}(\mathbb{R}_+)}$  is continuous from  $\mathcal{D}(\mathbb{R}_+)$  endowed with the norm of  $V^s$  to  $V^{s-\max(2\alpha,1)}$  if  $\alpha \neq 1/2$ , and to  $V^{s-1-\epsilon}$  if  $\alpha = 1/2$ . For that, we use the change of variable  $y = \log(x)$  and call  $\tilde{u}$  the function defined on  $\mathbb{R}$  by  $\tilde{u}(y) = u(e^y) e^{\frac{y}{2}}$ . This yields that  $\langle Bu, v \rangle = \langle \tilde{B}\tilde{u}, \tilde{v} \rangle$ , where

$$\begin{aligned} \tilde{B}\tilde{u}(y) &= - \int_{\mathbb{R}} k(z) e^z \left( (1 - e^{-z}) \left( \frac{\partial \tilde{u}}{\partial y}(y) - \frac{1}{2} \tilde{u}(y) \right) + (e^{\frac{z}{2}} \tilde{u}(y - z) - \tilde{u}(y)) \right) dz \\ &= - \int_{\mathbb{R}} k(z) e^z \left( (1 - e^{-z}) \frac{\partial \tilde{u}}{\partial y}(y) + \left( \frac{1}{2} e^{-z} - \frac{3}{2} \right) \tilde{u}(y) + e^{\frac{z}{2}} \tilde{u}(y - z) \right) dz. \end{aligned}$$

The Fourier transform of  $\tilde{B}\tilde{u}$  is

$$\hat{b} = -\widehat{\tilde{u}}(\xi) \int_{\mathbb{R}} k(z) e^z \left( (1 - e^{-z}) i\xi + \frac{1}{2} e^{-z} - \frac{3}{2} + e^{\frac{z}{2}} e^{-i\xi z} \right) dz.$$

We make out three cases.

(1)  $\alpha > 1/2$ . In this case, one sees that

$$\begin{aligned} (1 - e^{-z}) i\xi + \frac{1}{2} e^{-z} - \frac{3}{2} + e^{\frac{z}{2}} e^{-i\xi z} &= \frac{1}{2} (e^{-z} + 2e^{\frac{z}{2}} - 3) + e^{\frac{z}{2}} (e^{-i\xi z} - 1 + iz\xi) \\ &\quad - i\xi (e^{-z} - 1 + ze^{\frac{z}{2}}). \end{aligned}$$

Therefore,

$$(A.1) \quad \hat{b} = -\widehat{\tilde{u}}(\xi) \left( \begin{aligned} &\int_{\mathbb{R}} \frac{k(z)}{2} (1 + 2e^{\frac{3z}{2}} - 3e^z) + \int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{-i\xi z} - 1 + iz\xi) \\ &- i\xi \int_{\mathbb{R}} k(z) e^z (e^{-z} - 1 + ze^{\frac{z}{2}}) \end{aligned} \right).$$

From the assumption on  $\psi$ , the first integral is a real number independent of  $\xi$ .

As in Lemma 3.2, by introducing  $\theta = \xi/|\xi|$  for  $\xi \neq 0$ , and writing that

$$\int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{-i\xi z} - 1 + iz\xi) dz = |\xi|^{2\alpha} \int_{\mathbb{R}} |y|^{-(1+2\alpha)} \psi \left( \frac{y}{|\xi|} \right) e^{\frac{3y}{2|\xi|}} (e^{-iy\theta} - 1 + iy\theta) dy,$$

we see from the assumptions on  $\psi$  that there exists a positive constant  $C_1$  such that  $|\int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{-i\xi z} - 1 + iz\xi) dz| \leq C_1 |\xi|^{2\alpha}$ , because  $y \mapsto \psi(y) \exp(3y/2)$  is a real bounded function and  $\int_{\mathbb{R}} |e^{-iy\theta} - 1 + iy\theta| |y|^{-(1+2\alpha)} dy$  can be bounded independently of  $\xi$ . The third integral in (A.1) is a real number independent of  $\xi$ . Therefore,

$$|\hat{b}| \lesssim (1 + |\xi| + |\xi|^{2\alpha}) |\widehat{\tilde{u}}(\xi)| \lesssim (1 + |\xi|^{2\alpha}) |\widehat{\tilde{u}}(\xi)|.$$

(2)  $\alpha < 1/2$ . We can still split  $\hat{b}$  as in (A.1). From the assumption on  $\psi$ , the first integral is a real number independent of  $\xi$ . The second integral can be split into the sum of  $\int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{-i\xi z} - 1) dz$  and  $i\xi \int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} z dz$ , which are both bounded by  $C_1|\xi|$ . The third integral is a real number independent of  $\xi$ , so

$$|\hat{b}| \lesssim (1 + |\xi|)|\hat{u}(\xi)|.$$

(3)  $\alpha = 1/2$ . The only change w.r.t. the previous two cases concerns the second integral: we write it as

$$(A.2) \quad |\xi| \int_{\mathbb{R}} \psi \left( \frac{y}{|\xi|} \right) e^{\frac{3y}{2|\xi|}} \frac{(e^{-iy\theta} - 1 + iy1_{|y|<1}\theta)}{|y|^2} dy + i\theta|\xi| \int_{|z\xi|>1} \psi(z) e^{\frac{3z}{2}} \frac{z}{|z|^2} dz.$$

The first integral in (A.2) is bounded by a constant independent of  $\xi$ , because  $z \mapsto \psi(z) \exp(3z/2)$  is a bounded function and  $\int_{\mathbb{R}} |y|^{-2} |e^{-iy\theta} - 1 + iy1_{|y|<1}\theta|$  can be bounded independently of  $\xi$ . For the second integral in (A.2), we have, if  $\xi > 1$ ,

$$\left| \int_{|z\xi|>1} \psi(z) e^{\frac{3z}{2}} \frac{z}{|z|^2} dz \right| \leq \int_{|z|>1} \frac{\psi(z) e^{\frac{3z}{2}}}{|z|} dz + \int_{|\xi|^{-1} \leq |z| \leq 1} \frac{\psi(z) e^{\frac{3z}{2}}}{|z|} dz \lesssim (1 + \log(\xi))$$

$$|\hat{b}| \lesssim (1 + |\xi| + |\xi \log(|\xi|)|)|\hat{u}(\xi)|. \quad \square$$

*Proof of Lemma 3.5.* It is enough to prove the result for  $u, v \in \mathcal{D}(\mathbb{R}_+)$ :

$$\langle Bu, v \rangle = - \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \frac{\partial u}{\partial x}(x) + e^z (u(xe^{-z}) - u(x)) \right) v(x) dz = I + II + III,$$

where

$$\begin{aligned} I &= \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) e^z (u(x) - u(xe^{-z})) (v(x) - v(xe^{-z})) dz, \\ II &= - \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) x(e^z - 1) \frac{\partial u}{\partial x}(x) v(x) dz, \\ III &= \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) e^z (u(x) - u(xe^{-z})) v(xe^{-z}) dz. \end{aligned}$$

But

$$II = \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) x(e^z - 1) \frac{\partial v}{\partial x}(x) u(x) dz + \int_{\mathbb{R}_+} dx \int_{\mathbb{R}} k(z) (e^z - 1) u(x) v(x) dz.$$

From this,

$$\begin{aligned} II + III &= \int_{\mathbb{R}_+} \left( \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \frac{\partial v}{\partial x}(x) + e^z (v(xe^{-z}) - v(x)) \right) dz \right) u(x) dx \\ &\quad + \left( \int_{\mathbb{R}} k(z) (2e^z - e^{2z} - 1) dz \right) \int_{\mathbb{R}_+} u(x) v(x) dx. \end{aligned}$$

The desired result is obtained.  $\square$

*Proof of Lemma 3.6.* The assertion is already proved in the case  $\alpha < 1/2$ , thanks to Lemma 3.3 and Remark 4. Thus, let us focus on the case when  $\alpha \geq 1/2$ : after a few calculations, one sees that

$$(B^T u - Bu)(x) = \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \left( 2 \frac{\partial u}{\partial x}(x) + u(x) \right) + e^z u(xe^{-z}) - e^{2z} u(xe^{-z}) \right) dz.$$

The same change of variables as in the proof of Lemma 3.3 leads to  $\langle (B - B^T)u, v \rangle = \langle (\tilde{B} - \tilde{B}^T)\tilde{u}, \tilde{v} \rangle$ , where

$$(\tilde{B}\tilde{u} - \tilde{B}^T\tilde{u})(y) = - \int_{\mathbb{R}} k(z) \left( 2(e^z - 1) \frac{\partial \tilde{u}}{\partial y}(y) + e^{\frac{3z}{2}} (\tilde{u}(y - z) - \tilde{u}(y + z)) \right) dz.$$

The Fourier transform of  $(\tilde{B} - \tilde{B}^T)\tilde{u}$  is

$$\begin{aligned} & -\widehat{\tilde{u}}(\xi) \int_{\mathbb{R}} k(z) \left( 2i\xi(e^z - 1) - e^{\frac{3z}{2}} (e^{i\xi z} - e^{-i\xi z}) \right) dz \\ &= -2i\xi \widehat{\tilde{u}}(\xi) \int_{\mathbb{R}} k(z) (e^z - 1 - ze^{\frac{3z}{2}}) dz + \widehat{\tilde{u}}(\xi) \int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{i\xi z} - e^{-i\xi z} - 2i\xi z) dz. \end{aligned}$$

From the assumptions, the first integral in the sum above is a real number. Let us focus on the second integral: since the function  $z \mapsto e^{i\xi z} - e^{-i\xi z} - 2i\xi z$  is odd,  $\psi(0) \int_{\mathbb{R}} |z|^{-(1+2\alpha)} e^{\frac{-3|z|}{2}} (e^{i\xi z} - e^{-i\xi z} - 2i\xi z) dz = 0$ , and

$$\begin{aligned} & \int_{\mathbb{R}} k(z) e^{\frac{3z}{2}} (e^{i\xi z} - e^{-i\xi z} - 2i\xi z) dz = \int_{\mathbb{R}} |z|^{-(1+2\alpha)} z \omega(z) (e^{i\xi z} - e^{-i\xi z} - 2i\xi z) dz \\ & \lesssim \int_{\mathbb{R}} |z|^{-2\alpha} e^{-\zeta|z|} (e^{i\xi z} - e^{-i\xi z} - 2i\xi z) dz \lesssim |\xi|^{2\alpha-1} \lesssim (1 + |\xi|), \end{aligned}$$

where, in the case  $\alpha = 1/2$ , we have used the fact that  $|\sin(\xi z)|/|z| \leq |\xi|$ . This concludes the proof.  $\square$

## Appendix B.

*Proof of Proposition 4.1.* Consider  $X'$ ,  $0 < X' < X$  and let  $\phi$  be a smooth cut-off function taking the value 1 in  $[0, 3/4X' + \frac{1}{4}X]$  and 0 in  $[3/4X + \frac{1}{4}X', X]$ . It is possible to prove that  $A_X(\mathcal{E}_X(\phi v)) \in L^2((\mathbb{R}_+))$ , which yields that  $\mathcal{E}_X(\phi v) \in V^2$  and  $\phi v \in W_X^2$ . This yields the first statement of Proposition 4.1.

Assume that  $v \in V_X$  is such that  $A_X v \in L^2((0, X))$ . Then there exists  $f \in L^2((0, X))$  such that

$$(B.1) \quad -\sigma x^2 \frac{\partial^2 v}{\partial x^2} = f - B_X v.$$

If  $0 \leq \alpha < 1/2$ , then, from Lemma 3.3,  $B_X v \in L^2((0, X))$ , and (B.1) implies that  $v \in W_X^2 \cap V_X$ .

If  $\alpha > 1/2$ , then, from Lemma 3.3,  $B_X v \in V_X^{1-2\alpha}$ . From this and (B.1), one immediately deduces that  $v \in V_X \cap W_X^{3-2\alpha}$ . A boot-strap argument is needed for improving this result.

If  $1/2 < \alpha < 3/4$ , then for all  $\epsilon > 0$ ,  $v \in W_X^{3/2-\epsilon}$ , and  $\mathcal{E}_X(v) \in V^{3/2-\epsilon}$ . Note that we cannot give a better regularity result for  $\mathcal{E}_X(v)$  (for example,  $\mathcal{E}_X(v) \in V^{3/2+\epsilon}$ ), because this would require the condition  $\frac{\partial v}{\partial x}(x = X) = 0$ , which is not proved. Then Lemma 3.3 yields that  $B_X v \in L^2((0, X))$  and that  $v \in W_X^2 \cap V_X$  from (B.1). In the

case  $\alpha = 1/2$ , we obtain from Lemma 3.3 that  $v \in W_X^2 \cap V_X$  as well. If  $\alpha = 3/4$ , the same argument shows that  $v \in W_X^{2-\epsilon} \cap V_X$  for all  $\epsilon > 0$ .

On the contrary, if  $3/4 < \alpha < 1$ , we have to keep on boot-strapping:  $v \in V_X \cap W_X^{3-2\alpha}$  implies that  $B_X v \in V_X^{3-4\alpha}$ , and from (B.1),  $v \in W_X^{5-4\alpha}$ . Either  $3/4 < \alpha < 7/8$ , and we see that there exists  $\epsilon > 0$  such that  $v \in W_X^{3/2+\epsilon}$ , or  $7/8 \leq \alpha < 1$ , and we keep on boot-strapping. After a finite number of steps, we obtain the first two statements of Proposition 4.1.

Then we obtain that  $\frac{\partial v}{\partial x} \in \mathcal{C}^0((0, X))$  from Sobolev imbeddings.  $\square$

*Proof of Theorem 4.2.* For brevity, and since the proof uses rather classical arguments, we shall omit some details. By using results on parabolic equations with monotone operators [26, p. 156], it is possible to prove that (4.6) has a unique weak solution in  $L^2(0, T; V_X) \cap C^0([0, T]; L^2(0, X))$ , with  $\frac{\partial u_{X,\epsilon}}{\partial t} \in L^2(0, T; V'_X)$ . Note that for all  $t_0$ ,  $0 < t_0 < T$ ,  $u_{X,\epsilon}$  is smooth in  $(t_0, T] \times [a, b]$ , where  $[a, b]$  is any interval strictly contained in  $(0, S)$  or in  $(S, X)$ . From (3.11), the weak maximum principle may be used. It yields that, a.e.,  $u_{X,\epsilon}$  is nonnegative on the one hand and greater than or equal to  $x \mapsto S - x$  on the other hand. Therefore, for almost every time  $t$ ,  $u_{X,\epsilon}(t) \in K_X$ . This implies that  $0 \leq rx(1 - 1_{\{x>S\}}) \leq rx(1 - 1_{\{x>S\}}) \mathcal{V}_\epsilon(u_{X,\epsilon}) \leq rx$ .

From this and (4.6),  $u_{X,\epsilon}$  belongs to  $C^0([0, T]; V_X) \cap L^2(0, T; D_X)$ ,  $\frac{\partial u_{X,\epsilon}}{\partial t} \in L^2((0, T) \times (0, X))$ , and the norms  $\|u_{X,\epsilon}\|_{L^\infty(0, T; V_X)}$ ,  $\|u_{X,\epsilon}\|_{L^2(0, T; D_X)}$ , and  $\|\frac{\partial}{\partial t} u_{X,\epsilon}\|_{L^2((0, T) \times (0, X))}$  are bounded independently of  $\epsilon$ .

Since  $V \subset \mathcal{C}^0((0, +\infty))$  and since for any  $t$ ,  $\lim_{x \rightarrow 0} u_{X,\epsilon}(t, x) = S$  (because  $S - x \leq u_X(t, x) \leq S$ ), we see that  $\mathcal{E}_X(u_{X,\epsilon}) \in \mathcal{C}^0([0, T] \times [0, +\infty))$ .

The maximum principle yields (4.8) and (4.9). From the bounds  $u_o(x) \leq u_{X,\epsilon}(t, x) \leq u^{(E)}(t, x)$ , and from the fact that  $\frac{\partial u^{(E)}}{\partial x}(t, 0) = -1$ , we see that  $u_{X,\epsilon}(t, x)$  has a derivative w.r.t.  $x$  at  $x = 0$  and that  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, 0) = -1$  for all  $t \geq 0$ .

By calling  $y_{X,\epsilon}$  the time derivative of  $u_{X,\epsilon}$ , we see that

$$(B.2) \quad \begin{aligned} \frac{\partial y_{X,\epsilon}}{\partial t} + A_X y_{X,\epsilon} - rx 1_{\{x>S\}} \mathcal{V}'_\epsilon(u_{X,\epsilon}) y_{X,\epsilon} &= 0, \quad t \in (0, T], \quad 0 < x < X, \\ y_{X,\epsilon}(t, X) &= 0 \quad t \in (0, T]. \end{aligned}$$

Note that

$$(B.3) \quad -rx 1_{\{x>S\}} \mathcal{V}'_\epsilon(u_{X,\epsilon}) \geq 0.$$

Since  $y_{X,\epsilon} \in \mathcal{C}^0([0, T], V'_X)$ , we have that  $y_{X,\epsilon}(t = 0) = -A_X u_o|_{(0, X)} + rx 1_{x < S} = \frac{\sigma^2 S^2}{2} \delta_{x=S} - B_X u_o|_{(0, X)}$ . It can be seen that  $-B_X u_o|_{(0, X)}$  is a positive distribution in  $V'_X$ , because  $u_o$  is convex: to prove it, one can approximate  $u_o$  in  $V_X$  by a sequence  $u_{o,n}$  of smooth convex functions with bounded support such that  $-B_X u_{o,n} \geq 0$ , and pass to the limit. Therefore,  $y_{X,\epsilon}(t = 0) \geq 0$  in  $V'_X$ . From this, and from (B.2), (B.3), we deduce that  $y_{X,\epsilon} \geq 0$  a.e.. Therefore,  $u_{X,\epsilon}$  is nondecreasing w.r.t.  $t$ .

Finally, the quantities  $\|u_{X,\epsilon}\|_{L^\infty(0, T; L^2(0, X))}$  and  $\|u_{X,\epsilon}\|_{L^2(0, T; V_X)}$  can be bounded independently of  $X$  by taking  $u_{X,\epsilon}$  as a test function in the weak formulation of (4.6) and by observing that the constants in Gårding's inequality for  $A_X$  do not depend of  $X$ .  $\square$

*Proof of Theorem 4.3.* We know that  $u_{X,\epsilon}$  belongs to  $\mathcal{C}^0([\tau, T]; D_X)$  for all  $\tau$ ,  $0 < \tau < T$ . Therefore, from Proposition 4.1,  $u_{X,\epsilon} \in \mathcal{C}^0([\tau, T]; W_X^{3/2+\epsilon})$  for some positive  $\epsilon$ . This yields that for each time  $t > 0$ ,  $u_{X,\epsilon} \in \mathcal{C}^1((0, X])$ . On the other hand, we know that  $u_{X,\epsilon}(t, X) = 0$  for  $t \in [0, T]$ , and  $u_{X,\epsilon} \geq 0$  in  $[0, T] \times [0, X]$ . From the last three observations, we see that for all  $t$ ,  $0 < t \leq T$ ,  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, X) \leq 0$ .

We aim at proving that for each  $t > 0$  there exists a number  $\xi(t)$ ,  $0 \leq \xi(t) < X$ , such that  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, x) \leq 0$  if  $\xi(t) < x < X$ . Indeed, if this were not the case, we would be in one of the following two situations.

(1)  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, x) > 0$  in some interval  $[y(t), X)$ ,  $y(t) < X$ . This implies that  $u_{X,\epsilon}(t, x) < 0$  in  $(y(t), X)$ , which is impossible since  $u(t, \cdot) \geq u_0$ .

(2) There exists a strictly increasing sequence of numbers  $y_n$ ,  $0 < y_n < y_{n+1} < X$ , such that  $\lim_{n \rightarrow \infty} y_n = X$  and  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, y_n) = 0$ , and  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, x)$  is positive for  $x$  in  $(y_{2n}, y_{2n+1})$  and negative for  $x$  in  $(y_{2n+1}, y_{2n+2})$ . The numbers  $y_{2n}$ ,  $n \in \mathbb{N}$ , are local minima of  $u_{X,\epsilon}(t, \cdot)$ . Let us consider the terms entering (4.6) at  $x = y_{2n}$ : we have  $\frac{\partial u_{X,\epsilon}}{\partial t}(t, y_{2n}) \geq 0$  and  $\lim_{n \rightarrow \infty} \frac{\partial u_{X,\epsilon}}{\partial t}(t, y_{2n}) = 0$ . It is clear that  $-\frac{\sigma^2 y_{2n}^2}{2} \frac{\partial^2 u_{X,\epsilon}}{\partial x^2}(t, y_{2n}) \leq 0$  and  $ry_{2n} \frac{\partial u_{X,\epsilon}}{\partial x}(t, y_{2n}) = 0$  because  $y_{2n}$  is a local minimum. We also know that  $ry_{2n}(1 - 1_{\{y_{2n} > S\}}) \mathcal{V}_\epsilon(u_{X,\epsilon}(t, y_{2n})) \geq 0$  and that  $\lim_{n \rightarrow \infty} ry_{2n}(1 - 1_{\{y_{2n} > S\}}) \mathcal{V}_\epsilon(u_{X,\epsilon}(t, y_{2n})) = 0$ . Therefore,

$$\liminf_{n \rightarrow \infty} B_X u_{X,\epsilon}(t, y_{2n}) \geq 0,$$

and, since  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, y_{2n}) = 0$ ,

$$\limsup_{n \rightarrow \infty} \int_{\mathbb{R}} k(z) \left( e^z (1_{z > \log \frac{y_{2n}}{X}} u_{X,\epsilon}(t, y_{2n} e^{-z}) - u_{X,\epsilon}(t, y_{2n})) \right) dz \leq 0.$$

This yields  $\int_{z > 0} k(z) e^z u_{X,\epsilon}(t, X e^{-z}) dz \leq 0$ , which is impossible since  $u_{X,\epsilon} \geq u_0$ .

Therefore, for all  $t > 0$ , the function  $x \mapsto \frac{\partial u_{X,\epsilon}}{\partial x}(t, x)$  is nonpositive in a neighborhood of  $X$ , and  $(\frac{\partial u_{X,\epsilon}}{\partial x}(t, \cdot))_+$  is zero near  $X$ .

Moreover, since  $u_{X,\epsilon}$  is nondecreasing and  $u_{X,\epsilon}(\cdot, X) = 0$ , the function  $t \mapsto \frac{\partial u_{X,\epsilon}}{\partial x}(t, X)$  is nonincreasing. Therefore, there exists  $\tau_0$ ,  $0 \leq \tau_0 \leq T$ , such that  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, X) < 0$  for  $\tau_0 < t \leq T$  and  $\frac{\partial u_{X,\epsilon}}{\partial x}(t, X) = 0$  for  $0 \leq t \leq \tau_0$ .

By taking the derivative of (4.6) w.r.t.  $x$  and multiplying by  $x$ , we see that  $z_{X,\epsilon} = x \frac{\partial u_{X,\epsilon}}{\partial x}$  satisfies

$$\begin{aligned} (B.4) \quad & \frac{\partial z_{X,\epsilon}}{\partial t} + A_X z_{X,\epsilon} - rx 1_{\{x > S\}} \mathcal{V}'_\epsilon(u_{X,\epsilon}) z_{X,\epsilon} \\ & = -rx(1 - 1_{x > S} \mathcal{V}_\epsilon(u_{X,\epsilon})) + rS \mathcal{V}_\epsilon(u_{X,\epsilon}) \delta_{x=S}, \quad t \in (0, T], \quad 0 < x < X, \\ & z_{X,\epsilon}(t = 0, x) = -x 1_{0 < x < S}, \quad 0 < x < X. \end{aligned}$$

Since  $z_{X,\epsilon}(t, X) = 0$  for  $t \in [0, \tau_0]$  ( $\tau_0$  is defined above), the function  $z_{X,\epsilon}|_{t \in (0, \tau_0)} \in L^2(0, \tau_0; V_X)$ . On the other hand,  $z_{X,\epsilon}(t, \cdot) \notin V_X$  for  $t \in (\tau_0, T]$ . In (B.4), for  $t > \tau_0$ ,  $A_X z_{X,\epsilon}(t)$ , i.e.,

$$\begin{aligned} & A_X z_{X,\epsilon}(t, x) = -\frac{\sigma^2 x^2}{2} \frac{\partial^2 z_{X,\epsilon}}{\partial x^2}(t, x) + rx \frac{\partial z_{X,\epsilon}}{\partial x}(t, x) \\ & - \int_{\mathbb{R}} k(z) \left( x(e^z - 1) \frac{\partial z_{X,\epsilon}}{\partial x}(t, x) + e^z (1_{\{z > -\log(X/x)\}} z_{X,\epsilon}(t, x e^{-z}) - z_{X,\epsilon}(t, x)) \right) dz, \end{aligned}$$

has a sense as a distribution and for all  $X' < X$ , belongs to the dual of  $\{v \in V_X, v = 0 \text{ in } (X', X)\}$ .

We split the function  $z_{X,\epsilon}$  into the sum of two functions  $\tilde{z}_{X,\epsilon} \in \mathcal{C}^0([0, T]; L^2(0, X))$

and  $\hat{z}_{X,\epsilon} \in L^2(0, T; V_X)$  which satisfy

$$(B.5) \quad \begin{aligned} & \frac{\partial \hat{z}_{X,\epsilon}}{\partial t} + A_X \hat{z}_{X,\epsilon} - rx 1_{\{x>S\}} \mathcal{V}'_\epsilon(u_{X,\epsilon}) \hat{z}_{X,\epsilon} = rS \mathcal{V}_\epsilon(u_{X,\epsilon}) \delta_{x=S}, \\ & \hat{z}_{X,\epsilon}(t=0, x) = 0, \quad 0 < x < X, \\ & \hat{z}_{X,\epsilon}(t, X) = 0, \quad 0 < t < T, \end{aligned}$$

and

$$(B.6) \quad \begin{aligned} & \frac{\partial \tilde{z}_{X,\epsilon}}{\partial t} + A_X \tilde{z}_{X,\epsilon} - rx 1_{\{x>S\}} \mathcal{V}'_\epsilon(u_{X,\epsilon}) \tilde{z}_{X,\epsilon} = -rx(1 - 1_{x>S} \mathcal{V}_\epsilon(u_{X,\epsilon})), \\ & \tilde{z}_{X,\epsilon}(t=0, x) = -x 1_{0<x<S}, \quad 0 < x < X, \\ & \tilde{z}_{X,\epsilon}(t, X) \leq 0, \quad 0 < t < T. \end{aligned}$$

From the fact that  $u_{X,\epsilon} \geq \underline{u}_X^{(E)}$  and from (4.7), we know that

$$\lim_{\epsilon \rightarrow 0} \|\mathcal{V}_\epsilon(u_{X,\epsilon}(S)) \delta_{x=S}\|_{L^2(0,T;V')} = 0.$$

Thus,  $\lim_{\epsilon \rightarrow 0} \|\hat{z}_{X,\epsilon}\|_{L^2(0,T;V)} = 0$ . One can also prove that  $\hat{z}_{X,\epsilon}(t, 0) = 0$  and that  $\hat{z}_{X,\epsilon} \geq 0$ .

From the last observation and since  $z_{X,\epsilon}(t, 0) = 0$ , we see that for all  $t \in [0, T]$ ,  $\tilde{z}_{X,\epsilon}(t, 0) = 0$ .

We know that  $\tilde{z}_{X,\epsilon}|_{(0,\tau_0)} \in L^2(0, \tau_0, V_X)$ : in  $(0, \tau_0) \times (0, X)$ , we can take  $e^{-Mt}(\tilde{z}_{X,\epsilon})_+$  as a test-function in the equation satisfied by  $\tilde{z}_{X,\epsilon}$ . From Gårding's inequality, choosing  $M$  large enough yields that  $\tilde{z}_{X,\epsilon}(t, \cdot)_+ = 0$  for  $t \in [0, \tau_0]$ .

On the other hand, for  $\tau_1 > \tau_0$ , there exists a constant  $\underline{z} > 0$  such that  $\tilde{z}_{X,\epsilon}(t, X) \leq -\underline{z}$  for  $t \in [\tau_1, T]$ . This and the continuity of  $\tilde{z}_{X,\epsilon}$  imply that there exists  $\underline{X}_{\tau_1}$ ,  $S < \underline{X}_{\tau_1} < X$ , such that  $\tilde{z}_{X,\epsilon} \leq 0$  in  $[\tau_1, T] \times [\underline{X}_{\tau_1}, X]$ . Therefore, in the time interval  $[\tau_1, T]$ , we can take  $(\tilde{z}_{X,\epsilon}(t, x))_+ e^{-Mt}$  as a test-function in the equation satisfied by  $\tilde{z}_{X,\epsilon}$ , even if  $\tilde{z}_{X,\epsilon}$  does not belong to  $V_X$ , (indeed  $(\tilde{z}_{X,\epsilon}(t, \cdot))_+$  does not see the singular behavior of  $z_{X,\epsilon}(t, \cdot)$  near  $X$ ). From Gårding's inequality, we have that for  $M$  large enough,  $t \mapsto e^{-Mt} \int_0^X ((\tilde{z}_{X,\epsilon})_+)^2(t, x) dx$  is nonincreasing in  $(\tau_1, T)$ . We can have  $\tau_1$  tend to  $\tau_0$ . This yields that  $(\tilde{z}_{X,\epsilon})_+ = 0$  in  $(\tau_0, T) \times (0, X)$ . We have proved that  $\tilde{z}_{X,\epsilon} \leq 0$  in  $(0, T) \times (0, X)$ .

Finally, let  $X$  and  $X'$  be two numbers such that  $S < X < X'$ . Call  $\tilde{u}_{X,\epsilon}$  the function obtained by extending  $u_{X,\epsilon}$  by 0 in  $[0, T] \times [X, X']$ . Clearly,  $\tilde{u}_{X,\epsilon} \in C^0([0, T]; K_{X'})$ . It can be seen from (4.6) and from  $\frac{\partial u_{X,\epsilon}}{\partial x}(x = X) \leq 0$  that  $\frac{\partial \tilde{u}_{X,\epsilon}}{\partial t} + A_{X'} \tilde{u}_{X,\epsilon} + rx(1 - 1_{\{x>S\}} \mathcal{V}_\epsilon(\tilde{u}_{X,\epsilon}))$  is a negative distribution in  $(0, T) \times (0, X')$ . This and the maximum principle imply (4.10).  $\square$

*Proof of Proposition 4.8.* It is enough to prove that  $\mu_{X,\epsilon}$  converges to  $\mu_X$  in  $L^1((0, T) \times (0, X))$  because  $0 \leq \mu_{X,\epsilon} \leq rx$ . For that, we make two observations.

- (a) Since  $u_{X,\epsilon}$  is nondecreasing w.r.t.  $t$ ,  $\mu_{X,\epsilon}$  is nonincreasing w.r.t.  $t$ .
- (b)

$$\begin{aligned} \frac{\partial \mu_{X,\epsilon}}{\partial x} &= r 1_{x>S} \mathcal{V}_\epsilon(u_{X,\epsilon}) + rS \mathcal{V}_\epsilon(u_{S,\epsilon}) \delta_{x=S} + r 1_{x>S} \mathcal{V}'_\epsilon(u_{X,\epsilon}) \tilde{z}_{X,\epsilon} \\ &\quad + r 1_{x>S} \mathcal{V}'_\epsilon(u_{X,\epsilon}) \hat{z}_{X,\epsilon}, \end{aligned}$$

where  $\tilde{z}_{X,\epsilon}$  and  $\hat{z}_{X,\epsilon}$  are respectively defined in (B.6) and (B.5). The first three terms in the right-hand side are positive distributions. Let us study the

last term more carefully: we call  $g_\epsilon = r1_{\{x>S\}}\mathcal{V}'_\epsilon(u_{X,\epsilon})\hat{z}_{X,\epsilon}$ . We know that  $\hat{z}_{X,\epsilon}$  is nonnegative and tends to 0 in  $L^2(0,T;V_X)$ . Hence,  $g_\epsilon$  is a nonpositive function. Moreover, let  $\phi_\eta$  be a smooth function defined on  $[0,X]$  such that  $0 \leq \phi_\eta \leq 1$ ,  $\phi_\eta = 1$  for  $0 \leq x \leq X - \eta$ , and  $\phi_\eta(x) = 0$  for  $X - \eta/2 \leq x \leq X$ . Taking  $\phi_\eta$  as a test function in (B.5) yields

$$\lim_{\epsilon \rightarrow 0} \left( \int_0^X \hat{z}_{X,\epsilon}(T,x)\phi_\eta(x)dx + \int_0^T \langle A_X \hat{z}_{X,\epsilon}, \phi_\eta \rangle - \int_0^T \int_0^X g_\epsilon(t,x)\phi_\eta(x)dxdt \right) = 0.$$

This proves that  $\lim_{\epsilon \rightarrow 0} \|g_\epsilon\|_{L^1((0,T) \times (0,X-\eta))} = 0$ .

To summarize,  $\mu_{X,\epsilon}|_{\{x < X-\eta\}}$  is the sum of a nondecreasing function and of  $\tilde{\mu}_{X,\epsilon} = \int_0^x g_\epsilon(t,y)dy$ , and  $\tilde{\mu}_{X,\epsilon}$  and its derivative w.r.t.  $x$  tend to 0 in  $L^1((0,T) \times (0,X-\eta))$ .

From (a) and (b), one sees that the total variation of  $\mu_{X,\epsilon}$  on  $(0,T) \times (0,X-\eta)$  is bounded. Therefore, we can extract a subsequence of  $\mu_{X,\epsilon}|_{\{x < X-\eta\}}$  converging strongly in  $L^1((0,T) \times (0,X-\eta))$ . The limit cannot be anything but  $\mu_X|_{\{x < X-\eta\}}$ , so the whole sequence converges to  $\mu_X|_{\{x < X-\eta\}}$ . Since  $\eta$  is arbitrarily small and  $\mu_{X,\epsilon}$  is bounded, we have that  $\lim_{\epsilon \rightarrow 0} \|\mu_{X,\epsilon} - \mu_X\|_{L^1((0,T) \times (0,X))} = 0$ .

The convergence results for  $u_{X,\epsilon}$  are an easy consequence of the strong convergence of  $\mu_{X,\epsilon}$  to  $\mu_X$ .  $\square$

*Proof of Lemma 6.2.* The proof is similar to an argument given in [2]. For brevity, we shall omit some details. We call  $\mathcal{Q}_\epsilon$  the bilinear form on  $L^2((0,T) \times (0,X)) \times Z_\epsilon$ :

$$\mathcal{Q}_\epsilon(q,v) = \int_0^T \int_0^X \left( \frac{\partial v}{\partial t} + A_{\epsilon,X}v - rx1_{\{x>S\}}\mathcal{V}'_\epsilon(u_\epsilon^*)v \right) q.$$

It is clear that  $\mathcal{Q}_\epsilon$  is continuous. Moreover, there exists a positive constant  $c$ , independent of  $\epsilon$ , such that

$$\inf_{q \in L^2((0,T) \times (0,X))} \sup_{v \in Z_\epsilon} \frac{\mathcal{Q}_\epsilon(q,v)}{\|q\|_{L^2((0,T) \times (0,X))} \|v\|_{Z_\epsilon}} \geq c.$$

To prove this inf-sup condition, take  $v \in L^2(0,T;V_X) \cap H^1(0,T;L^2((0,X)))$  as the weak solution of

$$\frac{\partial v}{\partial t} + A_{\epsilon,X}v - rx1_{\{x>S\}}\mathcal{V}'_\epsilon(u_\epsilon^*)v = q \quad t > 0, \quad v(0,\cdot) = 0.$$

and observe that  $\|v\|_{Z_\epsilon} \leq C\|q\|_{L^2((0,T) \times (0,X))}$  for a constant  $C$  independent of  $\epsilon$ .

Therefore, calling  $Q_\epsilon$  the linear and continuous operator from  $L^2((0,T) \times (0,X))$  to the dual of  $Z_\epsilon$  defined by  $\langle Q_\epsilon p, v \rangle = \mathcal{Q}_\epsilon(p,v)$ , the range of  $Q_\epsilon$  is closed and  $Q_\epsilon$  is injective. On the other hand,  $\mathcal{Q}_\epsilon(q,v)$  for all  $q \in L^2((0,T) \times (0,X))$  implies that  $v = 0$ . Therefore,  $Q_\epsilon^T$  is injective. We have proved that  $Q_\epsilon$  is an isomorphism from  $L^2((0,T) \times (0,X))$  onto the dual of  $Z_\epsilon$  and that its inverse is continuous with a norm independent of  $\epsilon$ .

From this and since  $z \mapsto 2(u_\epsilon^*(T,x_{ob}) - \bar{u})z((T,x_{ob}))$  is a continuous linear form on  $Z_\epsilon$  with a continuity constant independent of  $\epsilon$ , there exists a unique  $p_\epsilon^* \in L^2((0,T) \times (0,X))$  such that for all  $v \in Z_\epsilon$ ,  $\mathcal{Q}_\epsilon(p_\epsilon^*,v) = 2(u_\epsilon^*(T,x_{ob}) - \bar{u})v((T,x_{ob}))$  and  $\|p_\epsilon^*\|_{L^2((0,T) \times (0,X))}$  is bounded independently of  $\epsilon$ . The first part of the lemma is proved.

To prove the second part of the lemma, consider  $G_\epsilon \in L^2((0, T) \times \mathbb{R}_+)$  the solution of the backward Cauchy problem:

$$(B.7) \quad \frac{\partial G_\epsilon}{\partial t} + \frac{(\sigma_\epsilon^*)^2}{2} \frac{\partial^2}{\partial x^2} (x^2 G_\epsilon) - B_\epsilon^T G_\epsilon + \frac{\partial}{\partial x} (rx G_\epsilon) = 0, \quad (t, x) \in [0, T] \times \mathbb{R}_+,$$

$$G_\epsilon(t = T) = -2(u_\epsilon^*(T, x_{ob}) - \bar{u})\delta_{x=x_{ob}},$$

where  $B_\epsilon^T$  is given by (3.6). One can check that  $G_\epsilon$  is smooth for  $t < T$  and that for any integer  $k$  and for any compact  $\omega$  in  $[0, T] \times [0, +\infty)$  which does not contain  $(T, x_{ob})$ , the norm of  $G_\epsilon$  in  $\mathcal{C}^k(\omega)$  is bounded independently of  $\epsilon$ . Also, for the function  $\phi$  defined in Lemma 6.2,  $\phi G_\epsilon \in L^2(0, T; V)$ , with a norm bounded by a constant independent of  $\epsilon$ .

Let  $\chi$  be a smooth function with a compact support contained in  $(0, T] \times [0, X)$ , taking the value 1 in a neighborhood of  $(T, x_{ob})$ , and whose support does not intersect the support of  $\mathcal{V}_\epsilon(u_\epsilon^*)$  for all  $\epsilon$ . For example,  $\chi = 1 - \phi$  can be chosen. With  $A_{\epsilon, X}^T$  defined in Remark 11, it may be checked that  $\|\chi A_\epsilon^T G_\epsilon - A_{\epsilon, X}^T(\chi G_\epsilon)\|_{L^2((0, T) \times (0, X))}$  is bounded independently of  $\epsilon$ . The reason for that is that  $\chi$  is constant near the point where  $G_\epsilon$  is singular.

One sees that  $q_\epsilon^* = p_\epsilon^* - \chi G_\epsilon$  is the unique solution (in the very weak sense defined above, i.e. by duality with the functions in  $Z^\epsilon$ ) of a boundary value problem in  $(0, T] \times (0, X)$ , of the form

$$\begin{aligned} \frac{\partial q_\epsilon^*}{\partial t} - A_{\epsilon, X}^T q_\epsilon^* + rx 1_{\{x > S\}} \mathcal{V}_\epsilon'(u_\epsilon^*) q_\epsilon^* &= g_\epsilon^*, & (t, x) \in [0, T] \times (0, X), \\ q_\epsilon^*(t, X) &= 0, & t \in (0, T), \\ q_\epsilon^*(T, x) &= 0, & x \in (0, X), \end{aligned}$$

where  $g^* = \frac{\partial \chi}{\partial t} G_\epsilon + \chi A_\epsilon^T G_\epsilon - A_{\epsilon, X}^T(\chi G_\epsilon) \in L^2((0, T) \times (0, X))$ . This last boundary value problem has a unique weak solution in  $L^2(0, T; V_X)$ , with a norm bounded independently of  $\epsilon$ . The weak and the very weak solutions coincide. Therefore,  $p_\epsilon^* - \chi G_\epsilon \in L^2(0, T; V_X)$  and  $\|p_\epsilon^* - \chi G_\epsilon\|_{L^2(0, T; V_X)}$  is bounded by a constant independent of  $\epsilon$ . Therefore,  $\phi p_\epsilon^* \in L^2(0, T; V_X)$ , with a norm bounded independently of  $\epsilon$ .  $\square$

**Acknowledgment.** It is a pleasure to thank Rama Cont for introducing me to the topic and for helpful discussions.

## A QUADRATIC REGULATOR PROBLEM RELATED TO IDENTIFICATION PROBLEMS AND SINGULAR SYSTEMS\*

A. FAVINI<sup>†</sup> AND L. PANDOLFI<sup>‡</sup>

**Abstract.** In this paper we study a new form of the quadratic regulator problem which is suggested by recent applications to singular systems and to identification problems. The new feature of the quadratic regulator problem under study is the penalization of the values taken by the control at individual instants of time.

**Key words.** quadratic regulator problems, identification problems, singular systems

**AMS subject classification.** 49J27

**DOI.** 10.1137/050637248

**1. Introduction.** The quadratic regulator problem has a key role in control theory and it has been studied from many different points of view. We study here a new version which is encountered in the study of singular systems and in the solution of an inverse problem. The system that we study is described by

$$(1) \quad \dot{x} = Ax + Bu, \quad y(t) = Gu(t), \quad s < t \leq T, \quad x(s) = x_0.$$

We note that  $y(t)$  depends on  $u(t)$ .

The operators  $A$ ,  $B$ , and  $G$  in (1) satisfy the following:

- The operator  $A$  generates a  $C_0$ -semigroup on a Hilbert space  $X$ ;
- the operators  $B$  and  $G$  are linear and continuous,  $B \in \mathcal{L}(U, X)$ ,  $G \in \mathcal{L}(U, Y)$ , where  $U$  and  $Y$  are Hilbert spaces;
- we assume  $\ker G^* = 0$ . This is usually not restrictive, but see Remark 2.

The quadratic cost we consider is nonstandard. It has the following form:

$$(2) \quad J_s(x_0; u) = \int_s^T F(x(t) - \xi(t), u(t)) dt + \left\langle \begin{bmatrix} x(\tau_0) - \xi_0 \\ y(\tau_0) \end{bmatrix}, \tilde{M} \begin{bmatrix} x(\tau_0) - \xi_0 \\ y(\tau_0) \end{bmatrix} \right\rangle + \left\langle \begin{bmatrix} x(T) - \xi_T \\ y(T) \end{bmatrix}, M \begin{bmatrix} x(T) - \xi_T \\ y(T) \end{bmatrix} \right\rangle.$$

Here  $\tau_0 \leq T$  and

$$(3) \quad F(x, u) = \langle x, Qx \rangle + \|u\|^2,$$

while  $\xi$ ,  $\xi_0$ ,  $\xi_T$  are given reference signals. We *do not* assume that  $\xi_0$  and  $\xi_T$  are the values of the function  $\xi$  at the corresponding time instants.

The “initial time”  $s$  belongs to an interval on the left of  $T$ ,  $s \in [0, T)$  for definiteness. Note that  $\tau_0 < s$  is possible. In this case the penalization at  $\tau_0$  has to be ignored.

\*Received by the editors August 1, 2005; accepted for publication (in revised form) October 9, 2007; published electronically February 15, 2008. This paper fits the research programs of GNAMPA-INDAM.

The goal of this paper is the study of the properties of the infimum, possibly the minimum, of the quadratic cost when the input  $u$  belongs to a subspace of  $L^2(s, T; U)$  which is specified below. However, we mention here the fact that we shall also consider the case that the functions  $u(t)$  are forced to be zero on a subinterval  $(T_0, T)$  of the interval  $(s, T)$  on which the quadratic cost is computed. This is required by the application described in section 2.1.

The novelty of this problem stems from the intermediate and final penalization of the control. Due to these terms, the quadratic functional is neither continuous nor closed (according to [11, p. 313]) on  $L^2(0, T; U)$ .

In order to simplify the notation we shall put

$$(4) \quad \begin{aligned} \Phi_{\tau_0}^1(x, y) &= \left\langle \begin{bmatrix} x - \xi_0 \\ y \end{bmatrix}, \tilde{M} \begin{bmatrix} x - \xi_0 \\ y \end{bmatrix} \right\rangle, \quad \Phi_T^1(x, y) = \left\langle \begin{bmatrix} x - \xi_T \\ y \end{bmatrix}, M \begin{bmatrix} x - \xi_T \\ y \end{bmatrix} \right\rangle, \\ \Phi_{\tau_0}(x, u) &= \Phi_{\tau_0}^1(x, Gu), \quad \Phi_T(x, u) = \Phi_T^1(x, Gu), \\ J_{s, \text{int}}(x_0; u) &= \int_s^T F(x(t) - \xi(t), u(t)) \, dt, \quad J_{\text{fin}}(x_0; u) = \begin{cases} \Phi_{\tau_0}(x, u) + \Phi_T(x, u) & \text{if } s \leq \tau_0, \\ \Phi_T(x, u) & \text{if } s > \tau_0. \end{cases} \end{aligned}$$

Standing assumptions:  $Q$  and  $M$  and  $\tilde{M}$  are symmetric nonnegative continuous linear operators. We assume furthermore that

$$M = \begin{bmatrix} M_{11} & M_{12} \\ M_{12}^* & M_{22} \end{bmatrix}, \quad M_{22} > cI > 0, \quad \tilde{M} = \begin{bmatrix} \tilde{M}_{11} & \tilde{M}_{12} \\ \tilde{M}_{12}^* & \tilde{M}_{22} \end{bmatrix}, \quad \tilde{M}_{22} > cI > 0.$$

This setup is encountered in particular in the study of important classes of singular control systems, as documented in [8]. Moreover, recently in [1, 10] similar quadratic control problems have been studied for the solution of identification (inverse) problems. See section 2 for details.

*Remark 1.* As we said, the novelty of this problem consists in the presence of the penalization of the final and intermediate values of the control. We have been stimulated to study this problem by identification problems and by the theory of singular control systems. These applications require that we study the problem in an infinite dimensional Hilbert space. This kind of problem has rarely been studied even for finite dimensional systems; see [4]. The problem with  $s = 0$ ,  $\tau_0 = 0$ , and null matrices  $\tilde{M}_{12}$ ,  $\tilde{M}_{22}$  is studied in [13], in the context of Kalman filtering for lumped systems.

Now we comment on apparently more general versions of our problem.

It may seem that  $y = Hx + Gu$  gives a more general problem than (1) and (2). However, it is easily seen that this case can be treated as below. This is left to the reader.

Finally, let us consider the general case

$$F(x, u) = F_0(x, u) + \langle u, u \rangle, \quad F_0(x, u) = \langle x, Qx \rangle + 2\Re \langle x, Q_{12}Gu \rangle + \langle Gu, Q_{22}Gu \rangle \geq 0$$

(see section 2.2 concerning the application to singular systems). This can be reduced to the form (3) as follows: First we absorb  $\langle y, Q_{22}y \rangle = \langle u, G^*Q_{22}Gu \rangle$  into the last term which takes the form  $\langle u, (I + G^*Q_{22}G)u \rangle$ . A coordinate transformation in  $U$  reduces this to  $\langle u, u \rangle$  again. We then apply a feedback  $u = -Q_{12}x + v$  in order to absorb the mixed term. This changes the operator  $A$  to  $A - BQ_{12}$  and does not

change the value of the infimum. We assume that these transformations have been already performed.  $\square$

We are going to study our quadratic regulator problem with  $u \in L^2(s, T; U)$ . Clearly, the quadratic cost is not well defined for every  $u \in L^2(s, T; U)$ . So, we introduce a suitable domain over which the quadratic cost makes sense.

Let

$$\operatorname{ess} \lim_{t \rightarrow \tau_0} u(t) = l$$

when for every  $\epsilon > 0$  there exists  $\delta > 0$  such that the following set has zero Lebesgue measure:

$$\{t, \text{ such that } \|u(t) - l\| > \epsilon, |t - \tau_0| < \delta\}.$$

Analogous definition for the left limits.

If two functions  $u$  and  $u'$  belong to the same equivalence class  $[u] \in L^2(s, T; U)$ , then the  $\operatorname{ess} \lim$  exists for the first if it exists for the second, and the limit itself is the same.

We introduce the linear space  $\mathcal{U}_{\operatorname{ess}}$  of those equivalent classes in  $L^2(s, T; U)$  identified by a representative  $u$  such that the essential limits for  $t \rightarrow T-$  and  $t \rightarrow \tau_0$  exist, and we define for  $u \in \mathcal{U}_{\operatorname{ess}}$ ,

$$u(\tau_0) = \operatorname{ess} \lim_{t \rightarrow \tau_0} u(t), \quad u(T) = \operatorname{ess} \lim_{t \rightarrow T-} u(t).$$

The subspace over which we study our quadratic regulator problem is

$$\mathcal{U} = \mathcal{U}_{\operatorname{ess}} \bigcap \mathcal{U}_0,$$

where  $\mathcal{U}_0 \subseteq L^2(s, T; U)$  is

$$\mathcal{U}_0 = \{u \in L^2(s, T; U), u(t) = 0 \text{ for } t > T_0\}, \quad T_0 > 0.$$

Here  $T_0 > 0$  is fixed. Of course, if  $T_0 < s$ , then  $\mathcal{U}_0 = \{0\}$ .

As already noted, the introduction of the space  $\mathcal{U}_0$  is required by the identification problem described in section 2, while the definition of the subspace  $\mathcal{U}_{\operatorname{ess}}$  is suggested in [12, Chap. 1].

If  $T_0 > T$ , then we intend that  $\mathcal{U} = \mathcal{U}_{\operatorname{ess}}$ . If  $\tau_0 = T$  or if  $\tau_0 < s$ , then we simply ignore the term  $\Phi_{\tau_0}$ .

In general, the quadratic cost we are studying does not admit an optimal control. The optimal control might exist for special initial conditions  $x_0$ . An initial condition which admits an optimal control will be called "optimizable" and  $\mathcal{O}$  is the set of all the optimizable initial conditions.

We already said that, in general, the optimal control does not exist. We define

$$I_s(x_0; \xi_0, \xi_T, \xi) = \inf_{u \in \mathcal{U}} J_s(x_0; u).$$

The most important case in the applications to singular control systems is when the reference signals are equal to zero. In this case we use the simpler notation  $I_s(x_0)$ .

It is convenient to introduce the following additional notation:

- The solution of (1) (initial time is  $s$  and initial value  $x_0$ ) is denoted  $x(t; s, x_0, u)$ .

- When it exists, the optimal control on  $[s, T]$  which corresponds to the initial condition  $x_0$  (at the initial time  $s$ ) is denoted  $u_s^+(\cdot; x_0)$ . The corresponding optimal trajectory is  $x_s^+(\cdot; x_0)$ . We shall see uniqueness of the optimal control, so that the notation is unambiguous.
- An *optimal pair* is the pair of an optimal control and the corresponding trajectory for a given initial condition  $x_0$  at the initial time  $s$ .
- In order to use lighter notation, the index  $s$  is omitted in those sections in which  $s$  is kept fixed, i.e.,  $s = 0$  without restriction; hence we shall write  $J(x_0; u)$  instead of  $J_s(x_0; u)$ , and similarly we shall write  $x^+(\cdot; x_0)$ ,  $u^+(\cdot; x_0)$ ,  $I(x_0; \xi_0, \xi_T, \xi)$ ,  $I(x_0)$ .

The organization of the paper is as follows. In section 2 we present two applications of the problem we are studying and we derive a preliminary characterization of the optimal controls. We shall see that optimal controls will exist only for special initial conditions. But, the infimum of the cost is always finite (and nonnegative). The properties of the infimum are studied in section 3, where it is proved that the infimum is always a continuous quadratic form of the parameters  $x_0, \xi_0, \xi_T$  in  $X$  and  $\xi(\cdot)$  in  $L^2(s, T; X)$ . The infimum of the cost as a function of the initial time  $s \geq 0$  is studied in section 3.2. If, in particular,  $T_0 \geq T = \tau_0$ , we prove that the infimum of the cost is a continuous function of the initial time. With the application to singular systems in mind, this should be contrasted with the result in [3], where it is proved that when the cost is singular but the system is regular, the infimum of the cost is not a continuous function of the “initial time”  $s$ ; it is an upper semicontinuous function of  $s$ .

In section 4 we concentrate on the problem which is most important for the applications to singular systems, that is, the problem with  $\tau_0 = T < T_0$  and reference signals equal to zero. Also in this case the optimal control exists only for suitable initial conditions. The set  $\mathcal{O}$  of the optimizable initial conditions and the corresponding optimal controls are characterized in section 4, where we also clarify the relation of the optimal control with the Riccati equation. A noteworthy result is that the set of the optimizable initial conditions is a closed subspace of  $X$  which is characterized as the kernel of a continuous linear operator.

**2. Examples, applications, and the optimal control.** We present two examples in this section which justify our study. We then characterize the optimal controls and we see that, for a given  $x_0$ , the optimal control, now characterized by a “multipoint problem,” in general does not exist. This justifies our analysis of the properties of the infimum of the cost.

**2.1. An identification problem.** This example is taken from [1]. In applications, delay systems are often used as simple models of more complex distributed parameter systems. Let a signal  $\tilde{y}$  be measured and let us assume that we guessed a delay system

$$(5) \quad y' = Ay + By(t - h)$$

( $y \in \mathbb{R}^n$ ) which could be used as an approximation of the device which produces  $\tilde{y}$ . The solution  $y$  depends on the initial condition  $\phi(\cdot)$ ,  $y(t) = \phi(t)$ ,  $t \in [-h, 0)$  and the approximation is “tuned” by choosing  $\phi$  in the “best possible” way. In [1] the index

to be minimized for the choice of  $\phi$  is a quadratic index,

$$(6) \quad \frac{\alpha}{2} \int_{-h}^0 \|\phi(t) - \tilde{\phi}(t)\|^2 dt + \frac{1}{2} \int_0^T \|y(t) - \tilde{y}(t)\|^2 dt \\ + \frac{\beta}{2} \|\phi(0) - \tilde{\phi}(0)\|^2 + \frac{\gamma}{2} \|y(0) - \tilde{y}(0)\|^2.$$

We show that the previous problem fits into the framework described in section 1. First of all we rewrite (5) as

$$(7) \quad y' = Ay + By(t-h) + Bu(t), \quad y(t) = 0 \text{ if } t < 0, \quad y(0) = y_0.$$

Note that  $y(t) = 0$  for  $t < 0$  since the action of the initial condition  $\phi(\cdot)$  on  $[-h, 0)$  is taken into account by the “control”  $u$  which is

$$u(t) = \begin{cases} \phi(t-h) & \text{if } t \leq T_0 = h, \\ 0 & \text{if } t > T_0 = h. \end{cases}$$

Note that the introduction of  $T_0$  is now required by the very essence of the problem: The initial condition  $\phi$  acts only on a time interval of length  $h$ :  $T_0 = h$ .

After that, we use a standard idea in order to represent the system as a semigroup system on the Hilbert space  $M^2 = \mathbb{R}^n \times L^2(-h, 0; \mathbb{R}^n)$ . We refer to [2, 5] for the technical details and we informally present the idea which leads to this representation: We note that  $y(t-h) = \theta(t, -1)$  if  $\theta(t, s)$  solves

$$\theta_t = \theta_s, \quad \theta(t, 0) = y(t).$$

Combining this equation and (7) suggests the introduction of the following operators:

$$\mathcal{B} : \mathbb{R}^n \rightarrow M^2, \quad \mathcal{B}u = \begin{bmatrix} B \\ 0 \end{bmatrix} u,$$

and  $\mathcal{A}$  from  $M^2$  to itself,

$$\text{dom } \mathcal{A} = \left\{ \begin{bmatrix} y \\ \theta \end{bmatrix}, \theta \in W^{1,2}(-h, 0; \mathbb{R}^n), \theta(0) = y \right\}, \quad \mathcal{A} \begin{bmatrix} y \\ \theta \end{bmatrix} = \begin{bmatrix} Ay + B\theta(-h) \\ \theta'(s) \end{bmatrix}.$$

It is possible to prove that the operator  $\mathcal{A}$  generates a  $C_0$ -semigroup on  $M^2$  and that a solution  $Y(t) = \text{col} \begin{bmatrix} y(t) & \theta(t, \cdot) \end{bmatrix}$  of

$$(8) \quad Y' = \mathcal{A}Y + \mathcal{B}u, \quad Y(0) = \begin{bmatrix} y_0 \\ 0 \end{bmatrix}$$

has the form  $Y(t) = \text{col} \begin{bmatrix} y(t) & y(t+s) \end{bmatrix}$ ,  $s \in (-h, 0)$ , if and only if  $y(t)$  solves (7). Hence, the pair of the quadratic cost (6) and system (8) gives an optimization problem of the same form as described in section 1, when the reference signal  $\tilde{\phi}(t)$  is zero. The presence of the reference signal  $\tilde{\phi}(t)$  to the control  $u$ , as in the cost (6), is not really a more general problem than that described in section 1 since if we replace  $v(t) = u(t) - \tilde{\phi}(t)$ , then  $x(t)$  is replaced by

$$x(t) + \xi_1(t), \quad \xi_1(t) = \int_0^t e^{A(t-s)} B \tilde{\phi}(s) ds,$$

and  $\xi_1(t)$  can be absorbed by the reference signals  $\tilde{y}(t)$  for the state function.

A more interesting observation is in the next remark.

*Remark 2.* Let us consider the case that there are signals that  $y(\tau_0)$  and  $y(T)$  should track, which do not belong to  $\text{im } G$ ; i.e., for example, we want the intermediate penalization at  $\tau_0$  to have the form  $\|Gu(\tau_0) - \omega\|^2$  and  $\omega$  to not be in the closure of the image of  $G$ . In this case it is not possible to replace  $Y$  with the closure of  $\text{im } G$ ; i.e., the condition  $\ker G^* = 0$  is restrictive in this case.

**2.2. Application to singular systems.** Let  $m(x)$  be a continuous nonnegative function defined on a Jordan region  $\Omega$  bounded by a smooth curve, for example, of class  $C^2$  (as we are giving an example, we don't need to use the most general assumptions).

We explicitly assume that  $m(x)$  is zero on a subset of  $\Omega$  of positive measure, so that the following equation is degenerate:

$$(9) \quad \frac{\partial}{\partial t}[m(x)\eta(t, x)] = \mathcal{A}\eta + \mathcal{B}u.$$

The operator  $\mathcal{A}$  is the Laplacian on  $\Omega$ , with Dirichlet homogeneous conditions, and  $\mathcal{B}u$  is given by

$$\mathcal{B}u = \sum_{j=1}^m b_j u_j, \quad b_j \in H^{-1}(\Omega).$$

Hence, the control is finite dimensional,

$$u = \text{col} \begin{bmatrix} u_1 & u_2 & \dots & u_m \end{bmatrix}, \quad m \geq 1.$$

A regularity assumption on the vectors  $b_j$  is shown below.

We impose the initial condition

$$\lim_{t \rightarrow 0+} m(x)\eta(t, x) = m(x)\eta_0(x), \quad \eta_0 \in H_0^1(\Omega).$$

The cost functional most often associated to the problem under study is the cost (2) with  $\tau_0 = T < T_0$  and reference signals equal to zero, i.e., a functional of the form

$$(10) \quad \int_0^T [\|Q\eta(t)\|^2 + \|u(t)\|_{\mathbb{R}^m}^2] dt + \|\eta(T)\|^2$$

(see below for the norms used).

Let  $M$  be the multiplication operator by  $m(x)$ . It is proved in [7, 8] that

$$(11) \quad \|M(\lambda M - \mathcal{A})^{-1}\|_{\mathcal{L}(H^{-1}(\Omega))} \leq \frac{C}{1 + |\lambda|}, \quad \Re \lambda \geq 0.$$

This inequality and the fact that  $\mathcal{A}^{-1} \in \mathcal{L}(H^{-1}(\Omega), H_0^1(\Omega))$  suggest that we choose  $H^{-1}(\Omega)$  as a space for the solution  $\eta$  and for the vectors  $b_j$ . Hence,  $Q$  must be a continuous function on  $H^{-1}(\Omega)$  and, for definiteness, we assume that it takes values in  $H^{-1}(\Omega)$ . Hence, the norms of  $Q\eta(t)$  and  $\eta(T)$  in (10) are the norms of  $H^{-1}(\Omega)$ .

Let us introduce the operator  $\mathcal{T} = M\mathcal{A}^{-1}$  and let us split

$$X = (\ker \mathcal{T}) \oplus \left( \overline{(\text{im } \mathcal{T})} \right).$$

Note that this decomposition is nontrivial when the multiplication operator  $M$  has a nontrivial kernel, i.e., in the case that  $m(x)$  is zero on a subset of  $\Omega$  of positive measure, as we assumed.

We shall assume the following regularity assumption on the vectors  $b_j$ : The vectors  $b_j$  belong to  $(\ker \mathcal{T}) \oplus (\operatorname{im} \mathcal{T})$ .

Using condition (11), it is possible to prove that the restriction  $\tilde{\mathcal{T}}$  of  $\mathcal{T}$  to  $[(\operatorname{im} \mathcal{T})]$  has an inverse (let it be denoted  $\tilde{\mathcal{T}}^{-1}$ ), which generates a holomorphic semigroup.

Let  $P$  denote the projection of  $X$  onto  $\ker \mathcal{T}$  along  $[(\operatorname{im} \mathcal{T})]$ . Then, it turns out that the system can be split as

$$\begin{cases} x' = \tilde{\mathcal{T}}^{-1}x + \tilde{\mathcal{T}}^{-1}(I - P)\mathcal{B}u, \\ y(t) = -P\mathcal{B}u. \end{cases}$$

In order to see this, we perform the following transformation: We define

$$\tilde{x} = \mathcal{A}\eta$$

so that our equation takes the form

$$\frac{d}{dt}(\mathcal{T}\tilde{x}) = \tilde{x} + \mathcal{B}u, \quad \text{i.e.,} \quad \begin{cases} \frac{d}{dt}(\tilde{\mathcal{T}}(I - P))\tilde{x} &= (I - P)\tilde{x} + (I - P)\mathcal{B}u, \\ 0 &= P\tilde{x} + P\mathcal{B}u. \end{cases}$$

We now introduce

$$x = (I - P)\tilde{x}, \quad y = P\tilde{x}.$$

We get a (nontrivial) system of the form (1) when  $P\mathcal{B} \neq 0$ .

Now we choose the space  $Y$ . We note that the equations force  $y = P\tilde{x} = -P\mathcal{B}u$  to belong to the finite dimensional subspace  $(\operatorname{im} P\mathcal{B}) \subseteq \operatorname{im} P$  of  $H^{-1}(\Omega)$ . So, we shall take this finite dimensional subspace as the output space  $Y$ . The reason for this will appear below.

We examine the effects of these transformations on the cost functional (10).

We replace  $\eta = \mathcal{A}^{-1}[x + y]$ ,  $y = -P\mathcal{B}u$ , in the quadratic cost. Norms and inner products being taken in  $H^{-1}(\Omega)$ , we obtain

$$\begin{aligned} \|\eta(T)\|^2 &= \|\mathcal{A}^{-1}x(T)\|^2 + 2\langle \mathcal{A}^{-2}x(T), y(T) \rangle + \|\mathcal{A}^{-1}y(T)\|^2 \\ &= \|\mathcal{A}^{-1}x(T)\|^2 - 2\langle \mathcal{A}^{-2}x(T), P\mathcal{B}u(T) \rangle + \langle \mathcal{A}^{-2}P\mathcal{B}u(T), P\mathcal{B}u(T) \rangle. \end{aligned}$$

Analogously we find that  $\|Q\eta(t)\|^2$  takes the following form, where  $Z = (Q\mathcal{A}^{-1})^*Q\mathcal{A}^{-1}$ :

$$\langle Zx, x \rangle - 2\langle Z\mathcal{B}u, x \rangle + \|Q\mathcal{A}^{-1}\mathcal{B}u\|^2.$$

We get the form of the functionals examined in Remark 1, where we have seen that this seemingly more general functional can be reduced to the form (2).

The system in the form we have obtained does not seem to fit the assumptions in this paper since  $M_{22} = P^*\mathcal{A}^{-2}P$  is not a coercive operator. However, we did not yet use the fact that  $y$  is forced to belong to the finite dimensional space  $Y$ . Taking this into account, coercivity can be recovered. Let  $\mathbf{R}$  denote restriction to  $Y$ ,  $H\mathbf{R}y = Hy$  for every  $y \in Y$ , and every operator  $H$  defined on a linear space which contains  $Y$ . Then

$$\langle P^*\mathcal{A}^{-2}Py(T), y(T) \rangle = \langle \mathbf{R}^*P^*\mathcal{A}^{-2}P\mathbf{R}y(T), y(T) \rangle$$

(an analogous operation is performed on the mixed term of the inner product which defines  $\|\eta(T)\|^2$ ). Hence,

$$M_{22} = \mathbf{R}^* P^* \mathcal{A}^{-2} P \mathbf{R}.$$

This is now a selfadjoint positive operator on a finite dimensional space, whose kernel is 0, because  $y \in Y$  takes values in  $\text{im } P$ ,  $y = Ph$ , so that

$$P \mathbf{R} y = P P h = P h = y$$

and of course  $A^{-2}$  is boundedly invertible. Hence,  $M_{22}$  is coercive, as wanted.

**2.3. The optimal control.** In this section,  $s$  is a fixed value so that we put  $s = 0$  without restriction and we don't explicitly indicate the dependence on  $s$ . An optimality condition is easily obtained, provided that the optimal control exists. We present this condition now and we deduce that in general the optimal control *does not exist*. This justifies our interest in the properties of the infimum of the cost.

Let the optimal control  $u^+(\cdot; x_0)$  exist for a fixed initial condition  $x_0$ . As  $x_0$  is now fixed, we shall simply denote it as  $u^+$ , and  $x^+$  is the corresponding trajectory. Moreover, we introduce the error  $e^+(t) = x^+(t) - \xi(t)$ . If  $t = \tau_0$  or  $t = T$ , we introduce  $e_{\tau_0}^+ = x^+(\tau_0) - \xi_0$ ,  $e_T^+ = x^+(T) - \xi_T$ . In general, these vectors are not the values of  $e^+(t)$  for  $t = \tau_0$  or  $t = T$ .

We compute the Gâteaux derivative of the cost at  $u^+$ . Standard computations give that the following conditions must hold:

$$(12) \quad \begin{aligned} & \int_0^T \langle u^+(t) + B^* p_0(t) + B^* e^{A^*(T-s)} [M_{11} e_T^+ + M_{12} G u^+(T)], v(s) \rangle \, ds \\ & + \int_0^{\tau_0} \langle B^* e^{A^*(\tau_0-s)} [\tilde{M}_{11} e_{\tau_0}^+ + \tilde{M}_{12} G u^+(\tau_0)], v(s) \rangle \, ds = 0 \end{aligned}$$

and

$$(13) \quad \begin{cases} \langle G^* \tilde{M}_{22} G u^+(\tau_0) + G^* \tilde{M}_{12}^* e_{\tau_0}^+, v(\tau_0) \rangle = 0, \\ \langle G^* M_{22} G u^+(T) + G^* M_{12}^* e_T^+, v(T) \rangle = 0, \end{cases}$$

where

$$p_0(t) = \int_t^T e^{A^*(s-t)} Q e^+(s) \, ds.$$

Here  $v$  is *every admissible* input, i.e., every  $v \in \mathcal{U}$ . From (13) we obtain that the following conditions must hold (here we use  $\ker G^* = 0$ . If this condition does not hold, then the equalities below are replaced by inclusions in  $\ker G^*$  of the values taken by suitable functions):

$$(14) \quad \begin{cases} \tilde{M}_{22} G u^+(\tau_0) = -\tilde{M}_{12}^* e_{\tau_0}^+ & \text{if } T_0 > \tau_0, \\ M_{22} G u^+(T) = -M_{12}^* e_T^+ & \text{if } T_0 > T. \end{cases}$$

Condition (12) shows that the optimal control might be discontinuous at  $\tau_0$  and the following relations must hold:

$$(15) \quad u^+(t) = -B^* p(t), \quad 0 \leq t \leq T_0, \quad u(t) = 0, \quad t > T_0,$$

where

$$(16) \quad \begin{aligned} p(t) = & p_0(t) + \mathbf{1}(\tau_0 - t)e^{A^*(\tau_0 - t)} \left\{ \tilde{M}_{11}e_{\tau_0}^+ + \tilde{M}_{12}Gu^+(\tau_0) \right\} \\ & + e^{A^*(T-t)} \left\{ M_{11}e_T^+ + M_{12}Gu^+(T) \right\}. \end{aligned}$$

The function  $\mathbf{1}(t)$  is the Heaviside function, equal to 1 for  $t \geq 0$ , and equal to 0 otherwise (used formally to say that the corresponding term does not appear if the argument of  $\mathbf{1}$  is negative; strictly speaking, in this case this term might be meaningless).

We can use the compatibility conditions (14) in order to replace  $Gu^+(\tau_0)$  and  $Gu^+(T)$  in this last expression, and we find

$$\begin{aligned} p(t) = & p_0(t) + \mathbf{1}(\tau_0 - t)e^{A^*(\tau_0 - t)} \left\{ \tilde{M}_{11} - \tilde{M}_{12}\tilde{M}_{22}^{-1}\tilde{M}_{12}^* \right\} e_{\tau_0}^+ \\ & + e^{A^*(T-t)} \left\{ M_{11} - M_{12}M_{22}^{-1}M_{12}^* \right\} e_T^+. \end{aligned}$$

It is easily seen that when  $G = 0$  and  $T_0 > \tau_0 = T$  these conditions are the usual two-point problem for the proposed cost.

It is now possible to see that the optimal control does not exist, even in the simplest cases. Let  $X = \mathbb{R}$ ,  $A = 0$ ,  $B = 1$ ,  $T_0 = \tau_0 = T = 1$ . Let  $M_{22} = 1$ ,  $M_{11} = 1$ ,  $M_{12} = 0$ ,  $Q = 0$ ,  $G = 1$ . Let the reference signals be zero. The optimality system takes the form

$$\dot{x} = -p, \quad x(0) = 1, \quad \dot{p} = 0, \quad p(1) = x(1)$$

together with the “compatibility condition”

$$0 = M_{22}Gu^+(1) = -M_{22}GB^*p(1), \quad \text{i.e., } p(1) = 0,$$

which cannot be met since if  $p(1) = 0$ , then  $p(t) \equiv 0$  and  $x(t) \equiv 1$ , in contrast with the compatibility condition.

The previous relations have been derived as conditions which an optimal control must satisfy. The converse holds; see the next theorem.

**THEOREM 3.** *If  $x_0$  is an optimizable initial condition, then the optimal control is unique.*

*Let the functions  $x$  and  $p$  solve (1) and (16) when  $u$  is given by (15), and furthermore let conditions (14) be satisfied. Then,  $x_0$  is an optimizable initial condition and the control  $u$  in (15) is the optimal control.*

*Proof.* We prove uniqueness first. Let  $u_1$  and  $u_2$  be different optimal controls for the same initial condition  $x_0$  and let  $v = [u_1 + u_2]/2$ . Then,  $J_{\text{int}}(x_0; v) < J_{\text{int}}(x_0; u_i)$  while  $J_{\text{fin}}(x_0; v) \leq J_{\text{fin}}(x_0; u_i)$  so that  $v$  gives a smaller value of the cost if  $u_1 \neq u_2$ . This is not possible, and thus  $u_1 = u_2$ .

The second part follows because if we replace  $u$  with  $u + v$  and the functions  $x$ ,  $p$ , and  $u$  satisfy the stated condition, we get a quadratic form in  $v$ , which has a minimum when  $v = 0$ .  $\square$

As we said already, this uniqueness result justifies the notation  $u^+(t; x_0)$  chosen to denote the unique optimal control.

The infimum of the cost is always nonnegative. As the optimal control does not exist, we construct a minimizing sequence  $\{\hat{u}_n\}$ , i.e., a sequence such that  $J(x_0; \hat{u}_n)$  converges to the infimum. We define

$$(17) \quad \tilde{u} = \arg \min \{ J_{\text{int}}(x_0; u) + \langle M_{11}[x(T) - \xi_T], x(T) - \xi_T \rangle \}$$

( $\tilde{x}$  is the corresponding solution). Note that this functional is coercive in  $u(\cdot) \in L^2(0, T; U)$  so that the minimum point exists and is unique.

Consider now

$$\tilde{y}_{\tau_0} = \arg \min \Phi_{\tau_0}^1(\tilde{x}(\tau_0), y), \quad \tilde{y}_T = \arg \min \Phi_T^1(\tilde{x}(T), y).$$

The existence of the minima is clear since  $\tilde{M}_{22}$  and  $M_{22}$  are coercive, but the minima do not belong to  $\text{im } G$  in general. As we assumed  $\ker G^* = 0$ , we can find sequences  $\{\hat{u}_{\tau_0}^n\}$  and  $\{\hat{u}_T^n\}$  such that  $G\hat{u}_{\tau_0}^n \rightarrow \tilde{y}_{\tau_0}$  and  $G\hat{u}_T^n \rightarrow \tilde{y}_T$ . These sequences need not be bounded. We choose a sequence  $\{\sigma_n\}$  such that  $\sigma_n \|\hat{u}_{\tau_0}^n\|^2 \rightarrow 0$ , and  $\sigma_n \|\hat{u}_T^n\|^2 \rightarrow 0$  and we define

$$(18) \quad \hat{u}_n(t) = \begin{cases} \tilde{u}(t), & t \notin [\tau_0 - 1/\sigma_n, \tau_0 + 1/\sigma_n] \cup [T - 1/\sigma_n, T], \\ \hat{u}_{\tau_0}^n, & t \in (\tau_0 - 1/\sigma_n, \tau_0 + 1/\sigma_n), \\ \hat{u}_T^n, & t \in [T - 1/\sigma_n, T]. \end{cases}$$

It is easy to check that  $\{\hat{u}_n\}$  is a minimizing sequence.

The limit of  $\{\hat{u}_n\}$  exists in  $L^2(0, T; U)$  but in general is not the optimal control.

A robustness property of this minimizing sequence will be given in section 3.1.

**3. The infimum of the quadratic cost.** In this section the initial time  $s$  is kept fixed,  $s = 0$  for definiteness, and we study the dependence of  $I(x_0; \xi_0, \xi_T, \xi) = I_{s=0}(x_0; \xi_0, \xi_T, \xi)$  on the parameters  $x_0, \xi_0, \xi_T, \xi(\cdot)$ . We shall prove that  $I(x_0; \xi_0, \xi_T, \xi)$  is a continuous quadratic form of its arguments, even in the case  $\ker G \neq 0$ ; see Remark 2 for the interest of this case.

We easily see that the following inequalities hold:

$$(19) \quad \begin{aligned} J(x_0; u) &\geq \|u\|_2^2, \\ \inf_{u \in \mathcal{U}} J(x_0; u) &\leq J(x_0; 0) \leq K \{ \|x_0\|^2 + \|\xi_0\|^2 + \|\xi_T\|^2 + \|\xi(\cdot)\|_2^2 \}. \end{aligned}$$

Here and below,  $\|\cdot\|$  denotes the norms in the spaces  $X, U$ , or  $Y$ , while  $\|\cdot\|_2$  will be used to denote the norm in either  $L^2(0, T; X)$  (as above) or in  $L^2(0, T; U)$ . Moreover, we have the following lemma.

**LEMMA 4.** *Let  $x_0$  be fixed and let  $\{u_n\} \in \mathcal{U}$  be a minimizing sequence. The sequences  $\{Gu_n(\tau_0)\}$  and  $\{Gu_n(T)\}$  are bounded.*

*Proof.* The first inequality (19) shows that  $\{u_n\}$  is bounded in  $L^2(0, T; U)$  so that the sequences  $\{x(\cdot; x_0, u_n)\}$ ,  $\{x(T; x_0, u_n)\}$  are bounded, respectively, in  $C(0, T; X)$  and in  $X$ .

We prove boundedness of the second sequence  $\{Gu_n(T)\}$ . The first sequence is treated analogously.

By contradiction, let  $\lim \|Gu_n(T)\| = +\infty$ . In this case,

$$2\Re \langle x_n(T) - \xi_T, M_{12}Gu_n(T) \rangle + \langle Gu_n(T), M_{22}Gu_n(T) \rangle$$

is unbounded since  $\{x_n(T)\}$  is bounded and  $M_{22}$  is coercive. Hence,  $\{u_n\}$  cannot be a minimizing sequence, which is a contradiction.  $\square$

So, every minimizing sequence  $\{u_n(\cdot)\}$  is bounded in  $L^2(0, T; U)$ , and the sequences  $\{Gu_n(\tau_0)\}$ ,  $\{Gu_n(T)\}$  are bounded in  $U$ . Weak compactness follows. However,  $\mathcal{U}$  is not closed and we cannot use this observation to deduce the existence of the minimum. In spite of this we have the following result, which shows the dependence of the infimum on  $(x_0, \xi_0, \xi_T) \in X^3$  and on  $\xi \in L^2(0, T; X)$ .

THEOREM 5. *The nonnegative functional  $I(x_0; \xi_0, \xi_T, \xi)$  is continuous and quadratic; i.e., there exists  $\mathbf{P} = \mathbf{P}^* \geq 0$ ,  $\mathbf{P} \in \mathcal{L}(X^3 \times L^2(0, T; X))$  such that*

$$I(x_0; \xi_0, \xi_T, \xi) = \langle (x_0, \xi_0, \xi_T, \xi), \mathbf{P}(x_0, \xi_0, \xi_T, \xi) \rangle.$$

*Proof.* For simplicity of notation, we give the proof in the case  $\xi_0 = \xi_T = 0$  and  $\xi = 0$ . Hence, the infimum will be denoted  $I(x_0)$ . The proof can easily be repeated in general; see also Remark 6.

In order to prove the theorem we must show that

1. the transformation  $x \rightarrow I(x)$  is continuous;
2. the parallelogram identity holds for  $I(x)$ ;

see [9, section 9.2].

We prove continuity first. By contradiction, let there exist a sequence  $\{x_n\}$  such that

$$\lim x_n = x_0, \quad \lim I(x_n) \neq I(x_0).$$

This means that there exists  $\epsilon > 0$  such that

$$\text{either (1a) } \limsup I(x_n) > I(x_0) + \epsilon \quad \text{or (1b) } \liminf I(x_n) < I(x_0) - \epsilon.$$

We consider separately (1a) and (1b).

(1a) Let  $\tilde{u}$  be such that

$$|I(x_0) - J(x_0; \tilde{u})| < \epsilon$$

so that

$$\limsup I(x_n) > J(x_0; \tilde{u}) + \epsilon/2.$$

Hence, for a suitable subsequence still denoted  $\{x_n\}$ , we have for every  $n$

$$I(x_n) > J(x_0; \tilde{u}) + \epsilon/3$$

and for every  $u \in \mathcal{U}$  we have

$$J(x_n; u) > J(x_0; \tilde{u}) + \epsilon/3.$$

In particular when  $u = \tilde{u}$ ,

$$J(x_n; \tilde{u}) > J(x_0; \tilde{u}) + \epsilon/3.$$

This cannot be since, with  $\tilde{u}$  fixed,

$$\lim J(x_n; \tilde{u}) = J(x_0; \tilde{u}).$$

Hence, case (1a) is impossible.

If (1b) holds, then we can find  $\{u_n\}$  such that

$$J(x_n; u_n) < I(x_0) - \epsilon/2 < J(x_0; u_n) - \epsilon/2.$$

As already noted, the sequences  $\{u_n\}$ ,  $\{Gu_n(\tau_0)\}$ , and  $\{Gu_n(T)\}$  are bounded. Hence, it is not restrictive to assume

$$u_n \rightharpoonup \tilde{u}, \quad Gu_n(\tau_0) \rightharpoonup \tilde{\eta}, \quad Gu_n(T) \rightharpoonup \eta.$$

Now we use the representation

$$(20) \quad J(x_0; u) = J_{\text{int}}(x_0; u) + J_{\text{fin}}(x_0; u)$$

as in (4). We have

$$J(x_n; u_n) - J(x_0; u_n) < -\epsilon/2$$

so that (with  $x_n(t) = x(t; x_0, u_n)$ )

$$(21) \quad -\frac{\epsilon}{2} > \{J_{\text{int}}(x_n; u_n) - J_{\text{int}}(x_0; u_n)\} \\ + \{[\langle e^{A\tau_0} x_n, \tilde{M}_{11} e^{A\tau_0} x_n \rangle - \langle e^{A\tau_0} x_0, \tilde{M}_{11} e^{A\tau_0} x_0 \rangle] + 2\langle e^{A\tau_0} (x_n - x_0), \tilde{M}_{11} \Lambda_{\tau_0} u_n \rangle \\ (22) \quad + 2\langle e^{A\tau_0} (x_n - x_0), \tilde{M}_{12} G u_n(\tau_0) \rangle\} \\ + \{[\langle e^{AT} x_n, M_{11} e^{AT} x_n \rangle - \langle e^{AT} x_0, M_{11} e^{AT} x_0 \rangle] + 2\langle e^{AT} (x_n - x_0), M_{11} \Lambda_T u_n \rangle \\ (23) \quad + 2\langle e^{AT} (x_n - x_0), M_{12} G u_n(T) \rangle\},$$

where

$$\Lambda_t u = \int_0^t e^{A(t-s)} B u(s) \, ds.$$

The brace in (23) converges to zero because the sequences  $\{u_n\}$  and  $\{G u_n(T)\}$  are bounded and

$$\lim x_n = x_0.$$

Analogously it is seen that the brace in (22) converges to zero.

The terms which contain solely  $u_n$  in the brace (21) cancel out and, as we noted,  $x_n \rightarrow x_0$ ,  $u_n(\cdot) \rightarrow u_0(\cdot)$  so that the limit of the brace in (21) is zero. This is a contradiction and proves continuity of  $I(x)$ .

We now prove the parallelogram identity

$$I(x+y) + I(x-y) = 2[I(x) + I(y)].$$

It is known that the parallelogram identity holds for  $J$ :

$$J(x+y; u+v) + J(x-y; u-v) = 2[J(x; u) + J(y; v)]$$

for every  $x, y$  in  $X$  and  $u, v$  in  $\mathcal{U}$ .

We fix  $x$  and  $y$  and  $\epsilon > 0$  and choose  $u_x$  and  $u_y$  such that

$$J(x; u_x) < I(x) + \epsilon/2, \quad J(y; u_y) < I(y) + \epsilon/2$$

so that

$$J(x+y; u_x + u_y) + J(x-y; u_x - u_y) = 2J(x; u_x) + 2J(y; u_y) < 2[I(x) + I(y)] + 2\epsilon.$$

This proves the inequality

$$I(x+y) + I(x-y) \leq 2[I(x) + I(y)].$$

We prove that the inequality cannot be strict. We prove that if  $\epsilon$  satisfies

$$(24) \quad I(x+y) + I(x-y) \leq 2[I(x) + I(y)] - \epsilon,$$

then  $\epsilon = 0$ .

If (24) holds, then we can find  $\tilde{u}$  and  $\tilde{v}$  such that

$$J(x + y; \tilde{u}) + J(x - y; \tilde{v}) \leq 2[I(x) + I(y)] - \epsilon/2.$$

We define

$$u_0 = \frac{\tilde{u} + \tilde{v}}{2}, \quad v_0 = \frac{\tilde{u} - \tilde{v}}{2}$$

so that

$$2[J(x; u_0) + J(y; v_0)] = J(x + y; u_0 + v_0) + J(x - y; u_0 - v_0) \leq 2[I(x) + I(y)] - \epsilon/2.$$

However, we also have

$$I(x) + I(y) \leq J(x; u_0) + J(y; v_0) \leq [I(x) + I(y)] - \epsilon/2.$$

This shows  $\epsilon = 0$  so that the parallelogram identity holds.

The operator  $\mathbf{P}$  is now constructed by polarization,

$$(25) \quad 4\langle x, \mathbf{P}y \rangle = I(x + y) - I(x - y).$$

*Remark 6.* The previous proof can be repeated verbatim in the case when  $\xi(\cdot)$ ,  $\xi_0$ , and  $\xi_T$  are not zero, but this is not really needed since the cost  $J$  does not depend on these quantities separately but on the triple of the differences  $(\Gamma x_0)(\cdot) - \xi(\cdot)$ ,  $(\Gamma x_0)(\tau_0) - \xi_0$ ,  $(\Gamma x_0)(T) - \xi_T$ , where  $(\Gamma x_0)(t) = e^{At}x_0$ . This triple can be chosen as the “new parameter  $x_0$ ” in the previous proof. See Corollary 11 for a use of this fact.

**3.1. Robustness of the minimizing sequence.** Also in this section the value of the initial time  $s$  is kept fixed,  $s = 0$ , without restriction.

The nonexistence of the optimal control forces us in general to relay on minimizing sequences, i.e., sequences  $\{u_n\}$  such that  $\{J(x_0; u_n)\}$  converges to the infimum. Note that, in general, a minimizing sequence is not convergent.

In this section we prove that the minimizing sequence constructed in (18) is robust under perturbations, in the sense that we explain now.

In practice the parameters which define the cost, i.e., the reference signals and the time  $\tau_0$ , are never exactly equal to their nominal value. The discrepancy between the nominal and actual values of the parameters is usually modeled as follows: Let  $\epsilon \geq 0$  be a parameter whose nominal value should be 0, and let  $\xi_{\tau_0}^\epsilon$ ,  $\xi_T^\epsilon$ ,  $\xi^\epsilon$ ,  $\tau_0^\epsilon$  depend continuously on  $\epsilon$  (respectively, in  $X$ ,  $L^2(0, T; X)$ , and  $[0, T]$ ), with the nominal values taken for  $\epsilon = 0$  (so, the exponent  $\epsilon$  denotes functional dependence and not a power).

We recall the definition of  $\hat{u}_n$  from (18) and denote by  $\{\hat{u}_n^\epsilon\}$  the minimizing sequence constructed as in (18), but for the case when the reference signals and intermediate penalization time are those which correspond to a certain value  $\epsilon > 0$ . Let  $J^\epsilon$ ,  $J_{\text{int}}^\epsilon$ ,  $\Phi_{\tau_0}^\epsilon$ ,  $\Phi_T^\epsilon$  be the functionals in (4), computed with the parameters which correspond to the value  $\epsilon \geq 0$ .

We compare the values of  $J(x_0; \hat{u}_n)$  and  $J(x_0; \hat{u}_n^\epsilon)$  and prove that  $J(x_0; \hat{u}_n^\epsilon)$  approximates  $I(x_0; \xi_0, \xi_T, \xi)$  when  $n$  is large and  $\epsilon$  sufficiently close to zero.

In this sense we say that the construction of the minimizing sequence is *robust* under the action of the perturbations.

We prove the following.

THEOREM 7. *Let  $\delta > 0$ . There exists  $\eta_\delta > 0$  such that if  $0 \leq \epsilon < \eta_\delta$ , then we have*

$$(26) \quad \|J(x_0; \hat{u}_n) - J^\epsilon(x_0; \hat{u}_n^\epsilon)\| < \delta.$$

*Proof.* As a preliminary observation we note that if  $\eta^\epsilon$  depends continuously on  $\epsilon$  and  $M$  is fixed and coercive, the minimum point  $v^\epsilon$  of

$$\langle Mv, v \rangle + \langle \eta^\epsilon, v \rangle, \quad \text{i.e.,} \quad v^\epsilon = -M^{-1}\eta^\epsilon,$$

is a continuous function of  $\epsilon$ . Also the minimum value is a continuous function of  $\epsilon$ .

We apply to the perturbed data the construction for the minimizing sequence described in section 2.3. The construction is in two steps. In the first step we use (17) and construct  $\tilde{u}^\epsilon$ . This does not depend on  $n$ ; it is a continuous function of  $\epsilon$ , and also the corresponding solution  $\tilde{x}^\epsilon(\cdot)$  is a  $C(0, T; X)$  continuous function of  $\epsilon$  thanks to the observation above. Moreover,

$$\{J_{\text{int}}^\epsilon(x_0; \tilde{u}^\epsilon) + \langle [\tilde{x}^\epsilon(T) - \xi_T^\epsilon], M_{11}[\tilde{x}^\epsilon(T) - \xi_T^\epsilon] \rangle\}$$

is a continuous function of  $\epsilon$ . Hence, in order to prove the theorem it is sufficient to consider the remaining terms.

We consider sequences  $\{\hat{u}_{\tau_0}^{\epsilon, n}\}$  and  $\{\hat{u}_T^{\epsilon, n}\}$  and  $\sigma_n^\epsilon$  such that for every  $\epsilon$ , we have

$$\lim_n G\hat{u}_{\tau_0}^{\epsilon, n} = \tilde{y}_{\tau_0}^\epsilon, \quad \lim_n G\hat{u}_T^{\epsilon, n} = \tilde{y}_T^\epsilon,$$

and  $\sigma_n^\epsilon$  such that for each  $\epsilon$  fixed, we have

$$\lim_n \sigma_n^\epsilon \|\hat{u}_{\tau_0}^{\epsilon, n}\|^2 = 0, \quad \lim_n \sigma_n^\epsilon \|\hat{u}_T^{\epsilon, n}\|^2 = 0.$$

We then define  $\hat{u}_n^\epsilon(t)$  with a formula analogous to (18). Thanks to the choice of  $\sigma_n^\epsilon$ , the contribution to the cost of the restriction of  $\hat{u}_n^\epsilon(t)$  to the intervals  $(\tau_0^\epsilon - \sigma_n^\epsilon, \tau_0^\epsilon + \sigma_n^\epsilon)$  and  $(T - \sigma_n^\epsilon, T]$  tends to zero uniformly with respect to  $\epsilon$  so that we have (26).  $\square$

**3.2. The function  $s \rightarrow I_s(x_0; \xi_0, \xi_T, \xi)$ .** In this section the parameters  $x_0, \xi_0, \xi_T, \xi$  are kept fixed while  $s$  varies on the interval  $[0, T]$ . We are going to study the regularity properties of the function  $s \rightarrow I_s(x_0; \xi_0, \xi_T, \xi)$ .

We recall that  $x(t; s, x_0, u)$  is the solution of (1).

We need the following lemma, which is analogous to Lemma 4.

LEMMA 8. *Let  $s_n \rightarrow \hat{\chi}$  and let  $\{u_n\}$  be a sequence in  $L^2(s_n, T; U)$  such that  $J_{s_n}(x_0; u_n) < \beta$  ( $\beta$  is a fixed number). Then the sequences  $\{Gu_n(\tau_0)\}$  and  $\{Gu_n(T)\}$  are bounded (of course the sequence  $\{Gu_n(\tau_0)\}$  is considered only if  $\hat{\chi} \leq \tau_0$ ).*

*Proof.* We see from (19) that  $\{u_n\}$  is a bounded sequence in  $L^2(0, T; U)$  so that the sequence  $\{x(T; s_n, x_0, u_n)\}$  is bounded in  $X$ . The result now follows as in Lemma 4.  $\square$

THEOREM 9. *The function  $s \rightarrow I_s(x_0; \xi_0, \xi_T, \xi)$  is continuous for every  $x_0$  and  $s \neq \tau_0$ . For  $s = \tau_0$ , it is left continuous and upper semicontinuous from the right.*

*Proof.* As above, we prove the result for  $I_s(x_0)$ . The general case when  $\xi_0, \xi_T$ , and  $\xi(\cdot)$  are nonzero is completely analogous. We prove separately upper and lower semicontinuity at every  $\hat{\chi} \in [0, T]$ ,  $\hat{\chi} \neq \tau_0$ . The arguments we present hold also for  $\hat{\chi} = \tau_0$  but only from the left, while only the argument concerning upper semicontinuity holds at  $\tau_0$  from the right.

We prove first

$$\limsup_{s \rightarrow \hat{\chi}} I_s(x_0) \leq I_{\hat{\chi}}(x_0).$$

Let us fix  $\alpha > I_{\hat{\chi}}(x_0)$ . We prove

$$\limsup_{s \rightarrow \hat{\chi}} I_s(x_0) \leq \alpha.$$

Let  $u$  satisfy

$$I_{\hat{\chi}}(x_0) < J_{\hat{\chi}}(x_0; u) < \alpha.$$

Now we distinguish the two limits for  $s \rightarrow \hat{\chi}+$  and  $s \rightarrow \hat{\chi}-$ .

If  $s \rightarrow \hat{\chi}+$ , we use

$$x(t; s, x_0, u) = \left\{ e^{A(t-s)} x_0 + \int_s^t e^{A(t-r)} B u(r) \, dr \right\} \longrightarrow x(t; \hat{\chi}, x_0, u)$$

uniformly on every  $[r, T]$ ,  $r > \hat{\chi}$ , and it remains bounded. Hence,

$$\lim_{s \rightarrow \hat{\chi}+} J_s(x_0; u|_{[s, T]}) = \begin{cases} J_{\hat{\chi}}(x_0; u), & \hat{\chi} \neq \tau_0, \\ J_{\tau_0}(x_0; u) - \Phi_{\tau_0}(x(\tau_0), u(\tau_0)), & \hat{\chi} = \tau_0. \end{cases}$$

In both cases, the expression on the right-hand side is less than or equal to  $J_{\hat{\chi}}(x_0; u) \leq \alpha$ .

For every  $s$ , we have

$$I_s(x_0) \leq J_s(x_0; u|_{[s, T]}).$$

Hence, we have

$$\limsup_{s \rightarrow \hat{\chi}+} I_s(x_0) \leq \alpha.$$

Analogously, let  $s \rightarrow \hat{\chi}-$ . The input  $u$  is as above, and for every  $s$  we introduce  $u_s$ :

$$u_s(t) = \begin{cases} u(t) & \text{if } t > \hat{\chi}, \\ u(\tau_0) & \text{if } s < t < \hat{\chi} \end{cases}$$

so that we still have

$$\lim_{s \rightarrow \hat{\chi}-} x(t; s, x_0, u) = x(t; \hat{\chi}, x_0, u).$$

The limit is uniform on  $[\hat{\chi}, T]$ . The result follows as above (and we don't need to single out the case  $\hat{\chi} = \tau_0$ ).

We prove now lower semicontinuity,

$$\liminf_{s \rightarrow \hat{\chi}} I_s(x_0) \geq I_{\hat{\chi}}(x_0).$$

We prove this for  $\hat{\chi} \neq \tau_0$ , and when  $\hat{\chi} = \tau_0$  we prove the result only for the left limit. We choose any  $\beta$  and  $\beta'$  such that  $\beta < \beta' < I_{\hat{\chi}}(x_0)$  and we prove

$$\liminf_{s \rightarrow \hat{\chi}} I_s(x_0) \geq \beta.$$

By contradiction, let  $\liminf_{s \rightarrow \hat{\chi}} I_s(x_0) < \beta$  and let  $s_n \rightarrow \hat{\chi}$ ,  $\{u_n\}$  be sequences such that

$$J_{s_n}(x_0; u_n) < \beta'.$$

If  $\hat{\chi} = \tau_0$ , we assume  $s_n < \tau_0$ . Lemma 8 shows that  $\{u_n(\cdot)\}$  is bounded in  $L^2(0, T; U)$  and that  $\{Gu_n(\tau_0)\}$ ,  $\{Gu_n(T)\}$  are bounded. We first consider the case  $s \rightarrow \hat{\chi}-$ . We shall prove below that

$$(27) \quad |J_{\hat{\chi}}(x_0; u_n) - J_{s_n}(x_0; u_n)| \longrightarrow 0.$$

Accepting this, there exists  $N_\epsilon$  such that for  $n > N_\epsilon$  we have

$$I_{\hat{\chi}}(x_0) \leq J_{\hat{\chi}}(x_0; u_n) < \beta'$$

and this is a contradiction because we assumed  $\beta' < I_{\hat{\chi}}(x_0)$ .

In order to complete this argument, we give an estimate of the absolute value in (27) (recall  $s \rightarrow \hat{\chi}-$ ). We represent

$$(28) \quad J_{\hat{\chi}}(x_0; u_n) - J_{s_n}(x_0; u_n)$$

$$(29) \quad = \int_{\hat{\chi}}^T \left\{ \left\langle \begin{bmatrix} x(t; \hat{\chi}, x_0, u_n) \\ u_n(t) \end{bmatrix}, Q \begin{bmatrix} x(t; \hat{\chi}, x_0, u_n) \\ u_n(t) \end{bmatrix} \right\rangle + |u_n(t)|^2 \right\} dt$$

$$(30) \quad + \Phi_{\tau_0}(x(\tau_0; \hat{\chi}, x_0, u), u(\tau_0)) + \Phi_T(x(T; \hat{\chi}, x_0, u), u(T))$$

$$- \int_{s_n}^T \left\{ \left\langle \begin{bmatrix} x(t; s_n, x_0, u_n) \\ u_n(t) \end{bmatrix}, Q \begin{bmatrix} x(t; s_n, x_0, u_n) \\ u_n(t) \end{bmatrix} \right\rangle + |u_n(t)|^2 \right\} dt$$

$$- \Phi_{\tau_0}(x(\tau_0; s_n, x_0, u), u(\tau_0)) - \Phi_T(x(T; s_n, x_0, u), u(T)).$$

Now we represent the sum of the integrals in (29) and in (30) as

$$\int_{\hat{\chi}}^T = \int_{s_n}^{\hat{\chi}} + \int_{\hat{\chi}}^T.$$

We note that the quadratic terms which contain only  $u_n$  cancel out. Boundedness of the integrand (in the square norm) proves that the first integral on the right-hand side converges to zero. The second integral converges to zero because  $\{u_n\}$  is bounded in  $L^2(0, T; U)$ , while

$$\|x(\cdot; \hat{\chi}, x_0, u_n) - x(\cdot; s, x_0, u_n)\|_2$$

converges to zero uniformly.

Analogous arguments prove that the contributions of the final and intermediate costs, represented by the  $\Phi$ 's, tend to zero. We stress the fact that the purely quadratic terms in  $u(\cdot)$ ,  $Gu(\tau_0)$ , and  $Gu(T)$  cancel out.

If  $s_n \rightarrow \hat{\chi}_+$ , an analogous argument holds, provided that  $\hat{\chi} \neq \tau_0$ , by using

$$\tilde{u}_n(t) = \begin{cases} u_n(t) & \text{if } s_n \leq t \leq T, \\ 0 & \text{if } \hat{\chi} \leq t \leq s_n. \end{cases}$$

We cannot repeat this last argument for  $\hat{\chi} = \tau_0$  because if  $s > \tau_0$ , the contribution of  $\Phi_{\tau_0}$  is not accounted for.  $\square$

Note that the condition  $\ker G^* = 0$  has not been used in the previous proof and that the previous result holds for every  $T_0$ . Of course, if  $T_0 < \tau_0$ , the control is not penalized at  $\tau_0$  and we have continuity also at  $\tau_0$ .

Moreover, we have the following.

COROLLARY 10. *Let  $\tau_0 = 0$ . The function  $s \rightarrow I_s(x_0)$  is continuous on  $(0, T]$ .*

COROLLARY 11. *Let  $\tau_0 < T$ . We have that  $I_T(x_0)$  is a quadratic function of  $(x_0 - \xi_T)$ ; i.e., there exists  $N = N^* \geq 0$  in  $\mathcal{L}(X)$  such that*

$$(31) \quad I_T(x_0) = \inf_u \left\langle \begin{bmatrix} x_0 - \xi_T \\ Gu \end{bmatrix}, M \begin{bmatrix} x_0 - \xi_T \\ Gu \end{bmatrix} \right\rangle = \langle (x_0 - \xi_T), N(x_0 - \xi_T) \rangle.$$

We note that  $G^*M_{22}G$  is not assumed coercive, so that the infimum in (31) is not generally a minimum or realized by a unique minimum point. However, we note the following.

LEMMA 12. *Let  $x_0$  be an optimizable initial condition. Then, the optimal control is unique. Furthermore, if the optimal control  $u^+(\cdot; x_0) \in \mathcal{U}$  exists for the initial condition  $x_0$ , then we have*

$$(32) \quad \begin{cases} u^+(\tau_0; x_0) = \arg \min_{u \in \mathcal{U}} \left\langle \begin{bmatrix} x^+(\tau_0; x_0) \\ Gu \end{bmatrix}, \tilde{M} \begin{bmatrix} x^+(\tau_0; x_0) \\ Gu \end{bmatrix} \right\rangle, \\ u^+(T; x_0) = \arg \min_{u \in \mathcal{U}} \left\langle \begin{bmatrix} x^+(T; x_0) \\ Gu \end{bmatrix}, M \begin{bmatrix} x^+(T; x_0) \\ Gu \end{bmatrix} \right\rangle. \end{cases}$$

*Proof.* Unicity was already proved in Theorem 3. Conditions (32) might be proved from (13). Instead, we give an independent proof. We consider the optimal control and  $t = T$ . We recall that  $u(\cdot) \rightarrow x(\cdot; x_0, u)$  is a linear continuous transformation from  $L^2(0, T; U)$  to  $C(0, T; X)$ . By contradiction,  $u(\cdot)$  does not satisfy the second condition in (32). Then, we can find  $\tilde{u}_0 \in U$  such that

$$\left\langle \begin{bmatrix} x^+(T; x_0) \\ G\tilde{u}_0 \end{bmatrix}, M \begin{bmatrix} x^+(T; x_0) \\ G\tilde{u}_0 \end{bmatrix} \right\rangle < \left\langle \begin{bmatrix} x^+(T; x_0) \\ Gu^+(T) \end{bmatrix}, M \begin{bmatrix} x^+(T; x_0) \\ Gu^+(T) \end{bmatrix} \right\rangle - \epsilon_0, \quad \epsilon_0 > 0.$$

We change the definition of  $u^+(\cdot)$  in a short time interval  $[T - \sigma, T]$ ,

$$\tilde{u}(t) = \begin{cases} u^+(t; x_0) & \text{if } t < T - \sigma, \\ \tilde{u}_0 & \text{if } T - \sigma \leq t \leq T. \end{cases}$$

Clearly we can find  $\sigma$  so small that

$$|J_{\text{int}}(x_0, \tilde{u}) - J_{\text{int}}(x_0, u^+)| < \epsilon_0/8,$$

$$\left| \left\langle \begin{bmatrix} x^+(T; x_0) \\ \tilde{u}_0 \end{bmatrix}, M \begin{bmatrix} x^+(T; x_0) \\ \tilde{u}_0 \end{bmatrix} \right\rangle - \left\langle \begin{bmatrix} x(T; x_0, \tilde{u}) \\ \tilde{u}_0 \end{bmatrix}, M \begin{bmatrix} x(T; x_0, \tilde{u}) \\ \tilde{u}_0 \end{bmatrix} \right\rangle \right| < \epsilon_0/8$$

so that

$$J(x_0; \tilde{u}) < J(x_0; u) - \epsilon_0/2.$$

Hence,  $u(\cdot)$  is not the optimal control of  $x_0$ . The proof of the first equality in (32) is similar.  $\square$

**4. Optimal control, Riccati equation, and dissipation inequality.** In this section we consider the case which is most important for the applications to singular systems,  $T_0 > \tau_0 = T$ , and zero reference signals. The initial time of interest is  $s = 0$ , but we shall use dynamic programming arguments so that we have to consider also the general case  $s \in [0, T]$ : If  $x_0$  is optimizable with initial time 0, then dynamic programming shows that the restriction of  $u^+(t; x_0)$  to  $[s, T]$  is optimal for the “initial condition”  $x^+(s; x_0)$  assigned at the initial time  $s$ . Moreover, we recall from section 3.2:

$$(33) \quad I_s(x_0) = \langle P(s)x_0, x_0 \rangle \quad \text{and} \quad P(s) = P^*(s) \in \mathcal{L}(\mathcal{X}), \quad P(s) \geq 0.$$

Due to the fact that reference signals are now equal to zero, we can derive the properties of the functional  $I_s(x_0)$  using an auxiliary (standard) quadratic regulator problem, and we can characterize the optimizable initial conditions and the optimal controls.

We rewrite the characterization of the optimal controls in the special case we are studying now: Theorem 3 takes the following form (the solutions of the differential equations must be intended in the weak sense. In particular,  $p(t)$  is now a continuous function).

**THEOREM 13.** *Let  $x_0 \in X$  and let us consider the following two-point problem:*

$$(34) \quad \begin{cases} x(0) = x_0, \\ \dot{x} = Ax(t) + Bu, & u(t) = -B^*p(t), \\ \dot{p} = -A^*p - Qx, \\ p(T) = \{M_{11} - M_{12}M_{22}^{-1}M_{12}^*\}x(T), \end{cases}$$

*and let us consider the compatibility condition*

$$(35) \quad Gu(T; x_0) = -M_{22}^{-1}M_{12}^*x(T; x_0).$$

*The initial condition  $x_0$  is optimizable if and only if problem (34) has a solution  $(x(\cdot), p(\cdot))$  such that the function  $u(t) = -B^*p(t)$  satisfies the compatibility condition (35). In this case, the function  $-B^*p(t)$  is the optimal control.*

Now we note that the two-point problem (34) (without the compatibility condition (35)) is always solvable as follows.

**THEOREM 14.** *We have*

$$(36) \quad M_{11} - M_{12}M_{22}^{-1}M_{12}^* \geq 0$$

*so that the two-point problem (34) is solvable. Moreover, the vector  $x(T)$  is a linear and continuous function of  $x_0$ .*

*Proof.* The positivity condition (36) follows from  $M \geq 0$ .

The two-point problem (34) (without the compatibility condition (35)) is the two-point problem of the standard quadratic cost

$$(37) \quad \tilde{J}_s(x_0; u) = \int_s^T \{ \langle Qx(t), x(t) \rangle + \langle u(t), u(t) \rangle \} dt + \langle \mathcal{M}x(T), x(T) \rangle,$$

where (see the first line in (34)) the initial time is  $s = 0$  and  $\mathcal{M} = M_{11} - M_{12}M_{22}^{-1}M_{12}^* \geq 0$  (below we shall write  $\tilde{J}(x_0; u)$  when  $s = 0$ ). This is our “auxiliary” cost function.

The functional (37) admits a unique optimal control  $\tilde{u}(t; x_0)$  for every  $x_0$ . Furthermore, if  $\tilde{x}(t; x_0)$  is the optimal trajectory of  $x_0$ , then the transformation  $x_0 \rightarrow \tilde{x}(t; x_0)$  is linear and continuous.  $\square$

We use the last statement of the theorem as follows: The compatibility condition (35) can be written as

$$(38) \quad \begin{aligned} \mathcal{L}x(T) &= 0, \\ \mathcal{L} &= -M_{22}GB^* [M_{11} - M_{12}M_{22}^{-1}M_{12}^*] - M_{12}^*. \end{aligned}$$

Hence, we have the following.

**THEOREM 15.** *The initial condition  $x_0$  is optimizable if and only if  $\mathcal{L}x(T) = 0$ . In particular, the set  $\mathcal{O}$  of the optimizable initial conditions is a closed subspace of  $X$ .*

The second assertion follows since we already noted continuity of the transformation  $x_0 \rightarrow x(T)$  when  $(x(\cdot), p(\cdot))$  solves (34).

Of course, the optimal control  $\tilde{u}(t; x_0)$  for  $\tilde{J}(x_0; u)$  is given by

$$\tilde{u}(\cdot; x_0) = -B^*p(\cdot).$$

It always exists, while  $u^+(\cdot; x_0)$  exists only if  $x_0$  is optimizable. The previous considerations show the following.

**THEOREM 16.** *If  $x_0$  is optimizable, then  $\tilde{u}(\cdot; x_0) = u^+(\cdot; x_0)$ .*

The Riccati equation is an important tool in the quadratic regulator problem. Hence we now relate our problem to a differential Riccati equation. It is known that the component  $p$  of the two-point problem (34) is expressed as

$$p(t) = \mathcal{P}(t)x(t),$$

where  $\mathcal{P}(t)$  solves the Riccati equation

$$\begin{aligned} \frac{d}{dt} \langle \mathcal{P}(t)x, y \rangle &= -\langle Ax, \mathcal{P}(t)y \rangle - \langle \mathcal{P}(t)x, Ay \rangle - \langle Qx, y \rangle \\ &\quad + \langle B^*\mathcal{P}(t)x, B^*\mathcal{P}(t)y \rangle \quad \forall x, y \in \text{dom} A; \quad \mathcal{P}(T) = \mathcal{M}, \end{aligned}$$

so that the optimal control of the auxiliary functional  $\tilde{J}(x_0; u)$  in (37) is

$$(39) \quad \tilde{u}(t) = -B^*\mathcal{P}(t)x(t),$$

where  $x$  solves the closed loop equation

$$(40) \quad \dot{x} = (A - BB^*\mathcal{P}(t))x, \quad x(0) = x_0.$$

As we noted, this is also the optimal control of  $J(x_0; u)$  when  $x_0$  is optimizable. Hence, we have the next theorem.

**THEOREM 17.** *Let  $x_0$  be optimizable. Then, the optimal control has the feedback form*

$$u^+(t; x_0) = -B^*\mathcal{P}(t)x^+(t; x_0).$$

We recall that

$$(41) \quad \min_{u \in L^2(s, T)} \tilde{J}_s(x_0; u) = \langle x_0, \mathcal{P}(s)x_0 \rangle, \quad \min_{u \in L^2(0, T)} \tilde{J}(x_0; u) = \langle x_0, \mathcal{P}(0)x_0 \rangle.$$

Using this equality and the previous formulas which do depend on the assumption  $\ker G^* = 0$ , we can now prove the next theorem.

**THEOREM 18.** *Let the reference signals  $\xi(\cdot)$ ,  $\xi_0$ ,  $\xi_T$  be zero and let  $\ker G^* = 0$ . For every  $s \in [0, T]$ , we have*

$$(42) \quad P(s) = \mathcal{P}(s),$$

where  $P(s)$  is the operator of the quadratic form  $I_s(x_0)$ .

*Proof.* We note that

$$(43) \quad J(x_0; u) = \tilde{J}(x_0; u) + \{ \Phi_T(x(T; x_0, u), u(T)) - \langle x(T; x_0, u), \mathcal{M}x(T; x_0, u) \rangle \},$$

$$\mathcal{M} = [M_{11} - M_{12}M_{22}^{-1}M_{12}^*].$$

The cost  $\tilde{J}(x_0; u)$  is the auxiliary cost defined in (37) and the brace is nonnegative. Hence,

$$P(s) \geq \mathcal{P}(s).$$

We use the same idea as that used to derive the minimizing sequence (18) in order to prove that the inequality cannot be strict. We consider the optimal control  $\tilde{u}(t)$  in (39) and, for every  $n$ , we define the sequence

$$u_n(t) = \begin{cases} \tilde{u}(t) & \text{if } t < T_n, \\ u_{n,T} & \text{if } T_n < t < T, \end{cases}$$

where  $u_{n,T}$  satisfies

$$\|Gu_{n,T} - \tilde{y}\| < \frac{1}{n}, \quad \text{where } \tilde{y} = \arg \min \left\langle \begin{bmatrix} \tilde{x}(T; s, x_0) \\ y \end{bmatrix}, M \begin{bmatrix} \tilde{x}(T; s, x_0) \\ y \end{bmatrix} \right\rangle.$$

It is easily seen that letting  $T_n \rightarrow T$  we have constructed a minimizing sequence for  $J$ , so that the inequality cannot be strict.  $\square$

*Remark 19.* The referees stimulated us to try to understand whether

$$(44) \quad \min_{L^2(0,T;U)} \tilde{J}(x_0; u) = \inf_{\mathcal{U}} J(x_0; u)$$

in every case. Combining equalities (33), (41), and (42), we see that (44) holds if  $\ker G^* = 0$ . Taking into account the observation in Remark 2, it is interesting to see that equality (44) does not hold in general if  $\ker G^* \neq 0$ .

We present the following finite dimensional counterexample:  $T = 1 = \tau_0 < T_0$ ,  $X = U = \mathbb{R}$ , while  $Y = \mathbb{R}^2$ . The system is

$$\dot{x} = u, \quad y = \begin{bmatrix} 0 \\ 1 \end{bmatrix} u,$$

and the cost is

$$J(x_0; u) = \int_0^1 u^2(s) \, ds + \left\langle \begin{bmatrix} x(1) \\ y(1) \end{bmatrix}, \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x(1) \\ y(1) \end{bmatrix} \right\rangle$$

(no intermediate penalization and  $F(x, u) = u^2$ ) so that  $M_{11} - M_{12}M_{22}^{-1}M_{12}^* = 0$  and the auxiliary cost is

$$\tilde{J}(x_0; u) = \int_0^1 u^2(s) \, ds.$$

Of course the minimum of  $\tilde{J}$  is zero for every initial condition  $x_0$ . The original cost is

$$\begin{aligned} J(x_0; u) &= \int_0^1 u^2(s) \, ds + x(1)^2 + u(1)^2 \\ &= \int_0^1 u^2(s) \, ds + \left[ x_0 + \int_0^1 u(s) \, ds \right]^2 + u(1)^2. \end{aligned}$$

If the infimum is zero, then we must find a sequence  $\{u_n\}$  in  $L^2(0, 1)$  such that

$$\|u_n\|_{L^2(0,1)} \rightarrow 0, \quad \int_0^1 u_n(s) \, ds \rightarrow -x_0.$$

Of course this is possible only if  $x_0 = 0$ . So the two functionals do not have the same infimum if  $x_0 \neq 0$ .

It is interesting to note that  $x_0 = 0$  is the unique optimizable initial condition for this problem.

We note that in this counterexample  $\tau_0 = T < T_0$ ; hence, the counterexample is valid even in the case that the optimal control is characterized by the “usual” two-point problem (plus the compatibility conditions at  $T$ ). In general the minimum point of the functional  $J$  is characterized by the “multipoint” problem in section 2.3. This problem is nonstandard, and we can interpret the results in this paper as a first step toward a variational investigation of this nonstandard multipoint problem. In this regard we note that *the condition  $\ker G^* = 0$  has not been used in the proofs of Theorems 5 and 9.*

The counterexample just presented shows that if  $\ker G^* \neq 0$ , then the functional  $\tilde{J}(x_0; u)$  is not the relaxed functional of  $J(x_0; u)$  (see [6] for the definition). Further insight into our problem is given by the observation that if, instead,  $\ker G^* = 0$ , then the relaxed functional of  $J(x_0; u)$  is  $\tilde{J}(x_0; u)$ . In order to see this, it is sufficient to note that the brace in (43) is nonnegative since the second addendum in that brace is

$$\min \left\{ \left\langle \begin{bmatrix} x(T) \\ v \end{bmatrix}, M \begin{bmatrix} x(T) \\ v \end{bmatrix} \right\rangle, \quad v \in U \right\}.$$

The minimum is realized by  $v = [-M_{22}^{-1}M_{12}^*x(T)]$ . Now let  $\hat{u}$  be any element in  $L^2(0, T; U)$  and let  $\hat{x} = x(T; \hat{u})$ . Using the fact that  $\ker G^* = 0$  we can construct a sequence  $\{u_n\}$  in  $\mathcal{U}$  which converges to  $\hat{u}$  in  $L^2(0, T; U)$  and such that  $Gu_n(T) \rightarrow [-M_{22}^{-1}M_{12}^*\hat{x}]$  so that when  $n \rightarrow +\infty$  the brace, with this particular sequence, converges to 0.

Finally, we prove that  $P(s)$ , the operator of the quadratic form  $I_s(x_0)$ , and any input  $u$  are related by the usual dissipation inequality.

**THEOREM 20.** *For every  $s > s_0$  and every  $u \in \mathcal{U}$ , we have*  
(45)

$$\langle x(s; s_0, x_0, u), P(s)x(s; s_0, x_0, u) \rangle - \langle x_0, P(s_0)x_0 \rangle + \int_{s_0}^s F(x(r; s_0, x_0, u), u(r)) \, dr \geq 0.$$

Let  $x_0$  be an initial condition which admits the optimal control  $u^+(\cdot; x_0)$ . If  $u^+(\cdot; x_0)$  is replaced with  $u$  in (45), then equality holds for every  $s_0$  and every  $s > s_0$ .

Conversely, let  $x_0$  be given and  $P(s)$  be a solution of the dissipation inequality, which satisfies condition

$$\langle x_0, P(T)x_0 \rangle = \inf_v \left\langle \begin{bmatrix} x_0 \\ Gv \end{bmatrix}, M \begin{bmatrix} x_0 \\ Gv \end{bmatrix} \right\rangle = \langle x_0, Nx_0 \rangle$$

(the operator  $N$  is the same one appearing in (31)). Let  $u(\cdot)$  be an input such that the dissipation inequality (with  $s_0 = 0$ ) holds as an equality along  $x(\cdot; x_0, u)$  and  $u(\cdot)$  and, furthermore, let  $u(T)$  satisfy

$$(46) \quad u(T) = \arg \min_{v \in U} \left\langle \begin{bmatrix} x(T; x_0, u) \\ Gv \end{bmatrix}, M \begin{bmatrix} x(T; x_0, u) \\ Gv \end{bmatrix} \right\rangle = \langle x(T; x_0, u), Nx(T; x_0, u) \rangle$$

(i.e., the second condition in (32)). Then,  $u(\cdot) = u^+(\cdot; x_0)$  is the optimal control of  $x_0$ .

This can be repeated for each initial time  $s_0$ .

*Proof.* In fact, it is known from the theory of the (standard) quadratic regulator problem that  $\mathcal{P}(s)$  solves the dissipation inequality and that  $\tilde{u}$  is characterized as the control which realizes equality in the dissipation inequality. Hence, the statement follows from Theorems 18 and 16.  $\square$

It is known that  $\mathcal{P}(s)$  is maximal among the selfadjoint nonnegative operator functions which solve the dissipation inequality. Hence, we have the following.

**THEOREM 21.** *Let  $P(s)$  be the operator of the quadratic form  $I_s$ . Then,  $P(s)$  is maximal among the nonnegative selfadjoint solutions of the dissipation inequality which satisfy the final condition (31).*

*Remark 22.* Following the suggestion of one referee, we derived Theorems 20 and 21 from the known properties of  $\mathcal{P}(s)$  in order to stress the role of the auxiliary cost  $\tilde{J}$ . In view of the counterexample presented in Remark 19, we note that it is possible to prove Theorems 20 and 21 from first principles, using arguments which resemble those in [3], thanks to the fact that if  $x_0$  is optimizable, then the restriction of  $u^+(t; x_0)$  to  $[s, T]$  is optimal for the initial condition at  $s$  given by  $x^+(s; x_0)$ . This proof holds even if  $\ker G^* \neq 0$ .

**5. Conclusions.** In this paper we have shown two applications which force us to study a quadratic control problem which penalizes the value taken by the control at the final time  $T$  and at an intermediate time  $\tau_0$  (of course similar arguments can be repeated if the values of the control at a finite number of intermediate instants are penalized). An obvious approach to this problem is to assume that  $u \in W^{1,2}(0, T)$  and to take as a “new control” the derivative  $u' \in L^2(0, T; U)$ . The examples we have presented, however, show that the regularity assumption on  $u$  is not natural, and that we must assume solely that  $u$  is square integrable.

The optimal control for the problem under study in general does not exist. We characterized the initial conditions which admit an optimal control (which is unique) and we characterized the optimal control in terms of a two-point problem and compatibility conditions. In the important case that the reference signal is zero, we expressed the optimal control in terms of a suitable Riccati equation.

The optimal control, however, in general does not exist. So, we studied the value function and we proved that it is a continuous function of the initial datum and the reference signal, and also a continuous function of the initial time, except at the intermediate points at which the control is penalized. Moreover, we gave a construction for a minimizing sequence and we proved that this construction is robust with respect to the reference signal and the time at which the value of the control is penalized.

**Acknowledgments.** We thank the referees for the careful reading of the paper, which led to an improved presentation and, in particular, to a more precise analysis of the role of the auxiliary cost function.

## GLOBAL OPTIMIZATION OF LINEAR HYBRID SYSTEMS WITH VARYING TRANSITION TIMES\*

C. K. LEE<sup>†</sup> AND P. I. BARTON<sup>†</sup>

**Abstract.** Open loop optimal control problems with linear hybrid (discrete/continuous) systems embedded are often approximated as dynamic optimization problems. We propose a deterministic global optimization algorithm for linear hybrid systems with varying transition times. First, the control parametrization enhancing transform is used to transform the problem from a linear hybrid system with scaled discontinuities and varying transition times into a nonlinear one with stationary discontinuities and fixed transition times. Next, a theory is developed for constructing convex relaxations of arbitrary Bolza-type functionals subject to the transformed hybrid system. Finally, the convex relaxations are utilized in a branch-and-bound framework to obtain the solution to  $\epsilon$  global optimality within a finite number of iterations.

**Key words.** multistage dynamic optimization, nonconvex dynamic optimization, hybrid optimal control

**AMS subject classifications.** 34A30, 90C26

**DOI.** 10.1137/050625539

**1. Introduction.** Hybrid systems exhibit both discrete state and continuous state dynamics and have become indispensable for modeling systems exhibiting discontinuities in their dynamics [4]. This article focuses on the global solution of a specific class of dynamic optimization problems with linear time varying (LTV) hybrid systems embedded: problems in which the temporal sequence of modes is fixed, but the transition times between modes are allowed to vary. This is motivated by the fact that many practical problems can be expressed as open loop optimal control problems with hybrid systems embedded, which in turn can be approximated by dynamic optimization problems with hybrid systems embedded [4]. The latter transformation is carried out via control parametrization [29, 35], a partial discretization method where the controls are approximated by a finite series of piecewise continuous basis functions over the time horizon. The numerical solution of the resulting parameter optimization problem can then be obtained to local optimality by iterating finitely between the following subproblems:

1. An initial value (IVP) subproblem in which the hybrid system model is simulated for given values of the real valued variables parameterizing the controls using robust hybrid simulation technology, e.g., DAEPACK [37].
2. A nonlinear programming (NLP) Master problem that searches in the Euclidean parameter space using function and gradient information furnished by the IVP subproblem. Smoothness of the objective and constraint functionals are crucial for the application of existing gradient based algorithms, e.g., SNOPT [16].

Clearly, the practicality of such a method hinges on the existence and uniqueness of the parametric sensitivities of the hybrid system (or the related adjoints), which are

---

employed to calculate the gradients of the objective and constraint functionals used by the Master problem [10, 38]. Sufficient conditions for the existence and uniqueness of these sensitivities have been developed in [14], and these results indicate that the sensitivity trajectories of a hybrid system will usually exist a.e. in the parameter space. Subject to the key restriction that the temporal sequence of modes visited by executions of the hybrid system is unchanged throughout the parameter space (the timing of switches and jumps may still vary), the resulting Master NLP is smooth under mild assumptions and existing gradient based methods may be used to find local solutions [13, 3]. On the other hand, if the temporal sequence of modes varies as a function of the optimization parameters, then most resulting Master NLPs will exhibit some degree of nonsmoothness [13, 3]. These critical observations explicate the requirement of fixing the sequence of modes, a key issue. The restriction to a fixed sequence of modes reduces the embedded hybrid system to a *multistage* dynamic system. The extension of classical control parametrization of single-stage dynamic systems [29, 35] to multistage systems has been previously studied in [25, 39], where gradient based solvers were used to obtain local solutions of the NLP Master problem.

More recent research in the hybrid systems community has focused on optimal control problems where the switching times of an embedded hybrid system with a fixed sequence of modes are allowed to vary. In [41], the timings of the transitions are parameterized, and the gradients to the local NLP solver are obtained by solving the Hamilton–Jacobi–Bellman (HJB) equations using a dynamic programming approach. This problem (of determining the optimal switching times) constitutes the Stage 1 subproblem of a two stage optimization algorithm described in [42]. One of the methods presented in [42] involves obtaining the gradients of the participating functionals through formulating the costate equations, and this is further expanded upon by a different group of authors in [8], in which they derive the gradient of the cost functional for an especially simple form (special structure on the costate equations; the problem considered has no controls and has only the switching times as variables). However, this body of research has only focused on obtaining local solutions to the optimization problem (with no guarantees to the global optimality of the transition times). In this respect this body of research proves to be very similar in vein to the aforementioned work on multistage dynamic optimization.

In the context of global optimization, a deterministic branch-and-bound framework has been developed for the global optimization of linear hybrid systems with fixed transition times and a fixed sequence of modes [19]. This work has been extended to determine the optimal mode sequence using a mixed-integer optimization approach [5]. The final, missing piece of the puzzle for linear hybrid systems is to obtain the globally optimal switching times for a fixed sequence of modes. This problem is difficult because it is inherently nonconvex (see, e.g., [5]).

Many current deterministic approaches for global optimization rely on the ability to construct convex relaxations of the participating functionals, e.g., branch-and-bound algorithms [17, 28] and decomposition algorithms (outer approximation and generalized Benders decomposition) [12, 18, 15]. For static problems in mathematical programming, these functionals are provided by the convex envelope, McCormick’s composition technique [23], or  $\alpha$ BB by Adjiman, et al. [1]. The extension to systems for optimal control problems is nontrivial and has only been recently developed for both linear and nonlinear ODE systems [32, 34]. In addition, the extension to linear hybrid systems has also only recently been proposed [19, 5]. Unfortunately, these dynamic extensions can handle only problems for which the switching times are fixed in the optimal control problem. Currently, no satisfactory method exists for

constructing convex relaxations when the switching times are allowed to vary.

Bearing the aforementioned issues in mind, it is thus very desirable to have a method for transforming a problem with variable switching times into one with fixed switching times, which can then be solved using standard control parametrization algorithms. The control parametrization enhancing transform (CPET) [20] is a natural transform to use for this purpose. Unfortunately, this transformation comes with an associated difficulty: the right-hand sides of the differential equations become multiplied by the enhancing control. Thus, the resulting dynamic system no longer has the special structure exploited by methods specific to linear systems. While this is not significant for local optimization, it poses a considerable obstacle for global optimization because global optimization of nonlinear dynamic systems is much more challenging than that for linear systems. In this article, we will present an extension of the methods proposed in [34, 19] to solve the transformed problem, establishing a relaxation theory for the global optimization of general, nonlinear hybrid systems with a fixed sequence of modes and fixed transition times, i.e., nonlinear multistage systems with fixed switching times.

The rest of this article is organized as follows. Section 2 introduces the hybrid system modeling framework. Section 3 presents the formulation of the problem. It also includes a discussion on nonsmoothness of the problem when the objective function or constraints are evaluated at fixed points in time, which has profound implications on the type of discontinuities permitted in the dynamics of each mode. The transformed problem is constructed in section 4, while the theory for solving the transformed problem is presented in section 5. Finally, section 6 contains some examples illustrating the proposed approach, and section 7 concludes the article.

**2. Hybrid systems: Notation.** The modeling framework of [4] is used as a basis to define the following hybrid system of interest.

DEFINITION 2.1. *The hybrid system considered is the 10-tuple  $\mathcal{H} = (\mathcal{M}, \mathcal{E}, T_\mu, \sigma_1, \delta, \mathbf{p}, \mathbf{x}, \mathcal{F}, \mathcal{T}^0, \mathcal{T})$ , where*

- $\mathcal{M} = \{1, \dots, n_m\}$ ,  $1 \leq n_m < +\infty$ ,
- $\mathcal{E} = \{1, \dots, n_e\}$ ,  $1 \leq n_e < +\infty$ ,
- $T_\mu = \{m_i\}_{i \in \mathcal{E}}$ ,  $m_i \in \mathcal{M} \ \forall i \in \mathcal{E}$ ,
- $\sigma_1 \in \mathbb{R}$ ,
- $\delta \in \Delta \subset \mathbb{R}_+^{n_e}$ ,
- $\mathbf{p} \in P \subset \mathbb{R}^{n_p}$ ,
- $\mathbf{x} : \mathcal{E} \times P \times \Delta \times \mathbb{R} \rightarrow \mathbb{R}^{n_x}$ ,
- $\mathcal{F} : \mathcal{M} \times \mathbb{R}^{n_x} \times P \times \Delta \times \mathbb{R} \rightarrow \mathbb{R}^{n_x}$ ,
- $\mathcal{T}^0 : P \times \Delta \rightarrow \mathbb{R}^{n_x}$ , and
- $\mathcal{T} : \mathcal{E} \setminus \{n_e\} \times \mathbb{R}^{n_x} \times P \times \Delta \rightarrow \mathbb{R}^{n_x}$ .

The elements of  $\mathcal{M}$  are called the *modes* of  $\mathcal{H}$ .  $T_\mu$  is called the *hybrid mode trajectory* and is the discrete state variable of  $\mathcal{H}$ .  $\sigma_1$  is the initial time.  $\delta$  is the vector of nonnegative durations, and  $\mathbf{p}$  is the vector of parameters.  $\mathbf{x}$  is the vector of continuous state variables, and  $\mathcal{F}$  is the vector field for  $\mathbf{x}$ .  $\mathcal{T}^0$  are the initial conditions, and  $\mathcal{T}$  are the *transition functions*.  $\mathcal{E}$  is the index set for the *epochs*, which are defined in the following definition.

DEFINITION 2.2. *The hybrid time trajectory of  $\mathcal{H}$  is a finite sequence of intervals  $T_\tau = \{I_i\}_{i \in \mathcal{E}}$ , where  $I_i = [\sigma_i, \tau_i]$ ,  $\tau_i = \sigma_i + \delta_i$  for  $i \in \mathcal{E}$  and  $\sigma_i = \tau_{i-1}$  for  $i = 2, \dots, n_e$ . The  $I_i$  are called *epochs*.*

DEFINITION 2.3. *Consider the epoch  $I_i = [\sigma_i, \tau_i]$  and its corresponding scaled time interval  $\hat{I}_i = [\hat{\sigma}_i, \hat{\tau}_i] = [i - 1, i]$ . A scaled simple discontinuity occurring at time*

$t \in I_i$  is one that occurs at a fixed (stationary) point  $s \in \hat{I}_i$  such that

$$\frac{s - \hat{\sigma}_i}{\hat{\tau}_i - \hat{\sigma}_i} = s - i + 1 = \frac{t - \sigma_i}{\tau_i - \sigma_i}.$$

It is clear from Definition 2.3 that there is a stationary simple discontinuity [32, Definition 2.1] at  $s^*$  in  $\hat{I}_i$  iff there is a scaled simple discontinuity at  $t^*$  in  $I_i$ .

We will impose the following assumptions to make the optimization problem (introduced later) well posed:

A1.  $\Delta = [\delta^L, \delta^U]$  and  $P = [\mathbf{p}^L, \mathbf{p}^U]$  are nondegenerate interval vectors. The vector field  $\mathcal{F}(m, \cdot)$  for each  $m \in \mathcal{M}$  is affine in the continuous state variables  $\mathbf{x}$  and the parameters  $\mathbf{p}$  so that for each epoch  $I_{i \in \mathcal{E}}$  the continuous state variables evolve according to the LTV ODE system

$$\dot{\mathbf{x}}(i, \mathbf{p}, \delta, t) \equiv \left. \frac{d\mathbf{x}}{dt} \right|_{i, \mathbf{p}, \delta, t} = \mathbf{A}(m, \delta, t)\mathbf{x}(i, \mathbf{p}, \delta, t) + \mathbf{B}(m, \delta, t)\mathbf{p} + \mathbf{q}(m, \delta, t) \quad \forall t \in (\sigma_i, \tau_i].$$

Moreover, for all  $(m, i, \delta) \in \mathcal{M} \times \mathcal{E} \times \Delta$ ,  $\mathbf{A}(m, \delta, \cdot)$ ,  $\mathbf{B}(m, \delta, \cdot)$ , and  $\mathbf{q}(m, \delta, \cdot)$  are piecewise continuous on epoch  $I_i$  with a finite number of scaled simple discontinuities and are defined at any point of discontinuity.

A2. The initial conditions  $\mathcal{T}^0$  are affine functions so that the initial conditions for epoch  $I_1$  are given by

$$\mathbf{x}(1, \mathbf{p}, \delta, \sigma_1) = \mathbf{E}(0)\mathbf{p} + \mathbf{J}(0)\delta + \mathbf{k}(0).$$

A3. The transition functions  $\mathcal{T}(i, \cdot)$  for each  $i \in \mathcal{E} \setminus \{n_e\}$  are affine functions so that the initial conditions for epochs  $I_{i \in \mathcal{E} \setminus \{1\}}$  are given by

$$(2.1) \quad \mathbf{x}(i, \mathbf{p}, \delta, \sigma_i) = \mathbf{D}(i-1)\mathbf{x}(i-1, \mathbf{p}, \delta, \tau_{i-1}) + \mathbf{E}(i-1)\mathbf{p} + \mathbf{J}(i-1)\delta + \mathbf{k}(i-1).$$

DEFINITION 2.4. *Given values for  $\mathbf{p}$  and  $\delta$ , the solution, or execution, of a hybrid system  $\mathcal{H}$  subject to assumptions A1–A3 is  $\mathbf{x}(i, \mathbf{p}, \delta, t)$ ,  $t \in I_i$ ,  $i \in \mathcal{E}$ , where  $\mathbf{x}(i, \mathbf{p}, \delta, t)$  is the solution of the ODE system in A1 with initial conditions A2 if  $i = 1$ , and A3 otherwise.*

We shall now describe an execution of the hybrid system in time. The finite time horizon is partitioned into contiguous intervals called epochs. Starting from the initial conditions given by  $\mathcal{T}^0$ , the continuous state variables  $\mathbf{x}(1, \mathbf{p}, \delta, \cdot)$  evolve in time,  $t$ , according to the differential equations defined by the vector field  $\mathcal{F}(m_1, \cdot)$  for a (possibly trivially zero) duration of  $\delta_1$ . At time  $\tau_1$ , a *transition* is made from mode  $m_1$  to mode  $m_2$ . The transition functions in (2.1) map the value of the continuous state at  $\tau_1$  in epoch  $I_1$  to an initial condition for epoch  $I_2$  at time  $\sigma_2$ . The hybrid system then evolves according to the differential equations defined by the vector field  $\mathcal{F}(m_2, \cdot)$  for a duration of  $\delta_2$ , and so on and so forth. Note that for epoch  $I_i$ , the system evolves continuously in time if  $\delta_i > 0$ , and it evolves discretely by making an instantaneous transition if  $\delta_i = 0$ . We would like to emphasize that throughout this article, the hybrid mode trajectory  $T_\mu$  is known a priori and is fixed in the sense that it is not a decision variable in the optimization problem.

THEOREM 2.5. *A solution  $\mathbf{x}(i, \mathbf{p}, \delta, t)$ ,  $t \in I_i$ ,  $i \in \mathcal{E}$  to the hybrid system defined by Definition 2.1 and assumptions A1–A3 exists and is unique for each  $(\mathbf{p}, \delta) \in P \times \Delta$ .*

*Proof.* Consider any arbitrary  $(\mathbf{p}^*, \delta^*) \in P \times \Delta$  and the first epoch  $I_1$ . Since  $(\mathbf{p}^*, \delta^*)$  is fixed, the form of the LTV ODE system in the first epoch satisfies the

nonhomogenous linear system in [6, Chapter 3, p. 74]. Hence, there exists a unique solution of the hybrid system in the first epoch. At the transition to the second epoch, the initial conditions for the second epoch are clearly bounded by (2.1). Thus, the form of the LTV ODE system in the second epoch satisfies the nonhomogenous linear system in [6, Chapter 3, p. 74]. Therefore, a unique solution of the hybrid system in the second epoch exists. By induction, a unique solution of the hybrid system exists for all epochs  $I_{i \in \mathcal{E}}$ . Since  $(\mathbf{p}^*, \delta^*)$  was arbitrary, we obtain the desired result.  $\square$

*Remark 2.6.* It is possible to transcribe a problem in which  $\sigma_1$  is a decision variable bounded by the interval  $[\sigma_1^L, \sigma_1^U]$  into one where the initial time is fixed by prepending an additional mode to the hybrid system:

1. Introduce a new mode  $m_0$ .
2. Increase the number of durations (and epochs) by one,  $\delta^\dagger = (\delta_0, \delta)$ , where  $\delta_0 \in [0, \sigma_1^U - \sigma_1^L]$ .
3. The new mode trajectory becomes  $T_\mu^\dagger = m_0, T_\mu$ .
4. The dynamics of the initial mode  $m_0$  is given by  $\dot{\mathbf{x}}(t) = \mathbf{0}$  with initial conditions  $\mathbf{x}(0, \mathbf{p}, \delta^\dagger, \sigma_1^L) = \mathbf{E}(0)\mathbf{p} + \mathbf{J}(0)\delta + \mathbf{k}(0)$ .
5. The transition from mode  $m_0$  to  $m_1$  occurs at  $\sigma_1^L + \delta_0$  with state continuity as the transition function,  $\mathbf{x}(1, \mathbf{p}, \delta^\dagger, \sigma_1) = \mathbf{x}(0, \mathbf{p}, \delta^\dagger, \sigma_1^L + \delta_0)$  (*state continuity* means that the state variables are continuous at the transition, i.e., the transition function is the identity mapping).

*Remark 2.7.* In general, it is very difficult to characterize the exact image of  $P \times \Delta$  in the solution of the hybrid system (the *implied state bounds* in [32, 19]) when the transition times are varying (i.e., the durations of the epochs are decision variables in the optimization problem), thus we will work with relaxations of the image set.

**DEFINITION 2.8** (implied state bounds). *Define the following convex sets for all  $i \in \mathcal{E}$ , where  $\mathcal{S}_i \equiv [\sigma_1 + \sum_{j=1}^i \delta_j^L, \sigma_1 + \sum_{j=1}^i \delta_j^U]$ . For any fixed  $\underline{t} \in \mathcal{S}_i$ ,*

$$X(i, \underline{t}; P, \Delta) \equiv [\mathbf{x}^L(\underline{t}), \mathbf{x}^U(\underline{t})] \mid \mathbf{x}^L(\underline{t}) \leq \mathbf{x}(i, \mathbf{p}, \delta, \underline{t}) \leq \mathbf{x}^U(\underline{t}) \quad \forall (\mathbf{p}, \delta) \in P \times \Delta.$$

In addition,  $X(i, P, \Delta) \equiv [\mathbf{x}^L, \mathbf{x}^U] \mid X(i, \underline{t}; P, \Delta) \subset [\mathbf{x}^L, \mathbf{x}^U] \quad \forall \underline{t} \in \mathcal{S}_i$ .

**3. Problem formulation.** Consider the following problem.

**PROBLEM 3.1.**

$$\min_{\mathbf{p} \in P, \delta \in \Delta} F(\mathbf{p}, \delta) = \sum_{i=1}^{n_e} \left\{ \sum_{j=1}^{n_{\phi i}} \phi_{ij}(\mathbf{x}(i, \mathbf{p}, \delta, \alpha_{ij}(\delta)), \mathbf{p}, \delta) + \int_{\sigma_i(\delta)}^{\tau_i(\delta)} f_i(\mathbf{x}, \mathbf{p}, \delta, t) dt \right\},$$

subject to the following point and isoperimetric constraints,

$$\mathbf{G}(\mathbf{p}, \delta) = \sum_{i=1}^{n_e} \left\{ \sum_{j=1}^{n_{\eta i}} \eta_{ij}(\mathbf{x}(i, \mathbf{p}, \delta, \beta_{ij}(\delta)), \mathbf{p}, \delta) + \int_{\sigma_i(\delta)}^{\tau_i(\delta)} \mathbf{g}_i(\mathbf{x}, \mathbf{p}, \delta, t) dt \right\} \leq \mathbf{0},$$

where  $\mathbf{x}(i, \mathbf{p}, \delta, t)$  is given by the solution of the embedded hybrid system in Definition 2.1 subject to assumptions A1–A3;  $f_i$  and  $\mathbf{g}_i$  are piecewise continuous mappings  $f_i : X(i, P, \Delta) \times P \times \Delta \times \mathcal{S}_i \rightarrow \mathbb{R}$  and  $\mathbf{g}_i : X(i, P, \Delta) \times P \times \Delta \times \mathcal{S}_i \rightarrow \mathbb{R}^{n_c}$  for all  $i \in \mathcal{E}$ , where only a finite number of scaled simple discontinuities are allowed;  $n_{\phi i}$  is an arbitrary number of scaled point objectives in epoch  $I_i$ ,  $\alpha_{ij}(\delta) \in I_i$  such that  $\alpha_{ij}(\delta) = \sigma_i + \delta_i(\hat{\alpha}_{ij} - i + 1)$  for some fixed  $\hat{\alpha}_{ij} \in \hat{I}_i$ , and  $\phi_{ij}$  is a continuous mapping  $\phi_{ij} : X(i, P, \Delta) \times P \times \Delta \rightarrow \mathbb{R}$  for all  $j = 1, \dots, n_{\phi i}$  and  $i \in \mathcal{E}$ ; and  $n_{\eta i}$  is an

arbitrary number of scaled point constraints in epoch  $I_i$ ,  $\beta_{ij} \in I_i$  such that  $\beta_{ij}(\delta) = \sigma_i + \delta_i(\hat{\beta}_{ij} - i + 1)$  for some fixed  $\hat{\beta}_{ij} \in \hat{I}_i$ , and  $\eta_{ij}$  is a continuous mapping  $\eta_{ij} : X(i, P, \Delta) \times P \times \Delta \rightarrow \mathbb{R}^{n_c}$  for all  $j = 1, \dots, n_{\eta_i}$  and  $i \in \mathcal{E}$ . Additionally, we require that the set  $G = \{(\mathbf{p}, \delta) \in P \times \Delta \mid \mathbf{G}(\mathbf{p}, \delta) \leq \mathbf{0}\}$  is nonempty.

*Remark 3.2.* Problem 3.1 is a finite dimensional optimization problem in the Euclidean space  $P \times \Delta$ . Under the control parametrization framework (see, e.g., [29, 35]) the function and gradient information for the objective and constraint functionals are furnished by the solution of the embedded hybrid system as an IVP. More specifically, it is easy to show that Problem 3.1 encompasses open loop optimal control problems where the controls,  $\mathbf{u}$ , appear linearly in the dynamics of the system

$$\dot{\mathbf{x}}(i, \mathbf{p}, \delta, t) = \tilde{\mathbf{A}}(m, \delta, t)\mathbf{x}(\mathbf{p}, \delta, t) + \tilde{\mathbf{B}}(m, \delta, t)\mathbf{p} + \tilde{\mathbf{C}}(m, \delta, t)\mathbf{u}(\mathbf{p}, \delta, t) + \tilde{\mathbf{q}}(m, \delta, t)$$

for all  $i \in \mathcal{E}$ , where  $\tilde{\mathbf{A}}(m, \delta, \cdot)$ ,  $\tilde{\mathbf{B}}(m, \delta, \cdot)$ ,  $\tilde{\mathbf{C}}(m, \delta, \cdot)$ , and  $\tilde{\mathbf{q}}(m, \delta, \cdot)$  are piecewise continuous on epoch  $I_i$  with a finite number of scaled simple discontinuities and defined at any point of discontinuity for all  $(m, i) \in \mathcal{M} \times \mathcal{E}$ ; and the bounded real valued controls are parameterized linearly:

$$\begin{aligned} \mathbf{u}(\mathbf{p}, \delta, t) &= \tilde{\mathbf{S}}(m, \delta, t)\mathbf{p} + \tilde{\mathbf{v}}(m, \delta, t), \\ \mathbf{u}^L(t) \leq \mathbf{u}(\mathbf{p}, \delta, t) \leq \mathbf{u}^U(t) \quad \forall t \in \left[ \sigma_1, \sigma_1 + \sum_{j=1}^{n_e} \delta_j^U \right], \end{aligned}$$

where  $\mathbf{u}^L(t)$  and  $\mathbf{u}^U(t)$  are known bounds on the control variables  $\mathbf{u}(\mathbf{p}, \delta, t)$  that define the set  $U$ , and  $\tilde{\mathbf{S}}(m, \delta, \cdot)$ ,  $\tilde{\mathbf{v}}(m, \delta, \cdot)$  are piecewise continuous on epoch  $I_i$  with a finite number of scaled simple discontinuities and defined at any point of discontinuity for all  $(m, i) \in \mathcal{M} \times \mathcal{E}$ . Note that the latter parametrization of the control variables includes the cases where the controls are approximated by piecewise Lagrange polynomials, e.g., piecewise constant, linear, or quadratic approximations.

*Remark 3.3.* It is possible to cast the optimization decision variables as the transition times  $\tau$  instead of the epoch durations  $\delta$ . The equivalence between the two is established by the following:

$$\tau_i = \sigma_1 + \sum_{j=1}^i \delta_j \quad \forall i \in \mathcal{E}.$$

However, it is advantageous to work in terms of the epoch durations for the following reasons: (a) it is the natural formulation that facilitates the application of the CPET; and (b) the implicit constraints for feasible simulation trajectories using transition times,

$$\tau_{i-1} \leq \tau_i \quad \forall i = 2, \dots, n_e$$

need to be added explicitly to the Master NLP problem, whereas the same constraints with the duration formulation are handled by the simple bound constraints  $\delta^L \geq \mathbf{0}$ . This subtle difference is important in the control parametrization framework, as the decision variables passed to the IVP solver have to effect feasible simulations. For the majority of NLP solvers, this is handled much more robustly as simple bound constraints rather than as explicit constraints (i.e., simple bound constraints are satisfied throughout the solution process).

Comparing this problem formulation with that in [19], the main difference lies in the type of discontinuities allowed: the participating functionals and hybrid system now include scaled simple discontinuities rather than stationary simple discontinuities. The following examples illustrate how fixed-time point objectives, stationary simple discontinuities in the integrand of the objective function and stationary simple discontinuities in the dynamics of the hybrid system, can cause nonsmoothness in the problem. A discussion of sufficient conditions for the smoothness of the problem is deferred to the next section.

*Example 3.4* (fixed-time point objective). Consider the problem

$$\min_{\delta_1 \in [0.5, 1.5]} F(\delta_1) = x(1, \delta_1, 1) + x(2, \delta_1, 2),$$

subject to the hybrid system

$$\text{Mode 1 : } \dot{x}(i, \delta_1, t) = 0, \quad \text{Mode 2 : } \dot{x}(i, \delta_1, t) = 1$$

for all  $i \in \mathcal{E} = \{1, 2\}$ , with  $\sigma_1 = 0$ ,  $x(1, \delta_1, 0) = 0$ ,  $\delta_2 = 2 - \delta_1$ ,  $t \in [0, 2]$ ,  $T_\mu = 1, 2$ , and state continuity as the transition function  $x(2, \delta_1, \sigma_2) = x(1, \delta_1, \tau_1)$ . The nonsmooth objective function is given by

$$F(\delta_1) = \begin{cases} 3 - 2\delta_1 & \text{if } \delta_1 < 1, \\ 2 - \delta_1 & \text{if } \delta_1 \geq 1. \end{cases}$$

*Example 3.5* (integrand with stationary simple discontinuity). Consider the problem

$$\min_{\delta_1 \in [0.5, 1.5]} F(\delta_1) = \int_{\sigma_1}^{\tau_1(\delta_1)} f_1(x(1, \delta_1, t)) \, dt + \int_{\sigma_2(\delta_1)}^{\tau_2(\delta_1)} f_2(x(2, \delta_1, t)) \, dt,$$

where

$$f_1(x(1, \delta_1, t)) = \begin{cases} 0 & \text{if } t < 1, \\ x(1, \delta_1, t) + 1 & \text{if } t \geq 1, \end{cases}$$

$$f_2(x(2, \delta_1, t)) = \begin{cases} 0 & \text{if } t < 1, \\ x(2, \delta_1, t) + 1 & \text{if } t \geq 1, \end{cases}$$

subject to the hybrid system

$$\text{Mode 1 : } \dot{x}(i, \delta_1, t) = 0,$$

for all  $i \in \mathcal{E} = \{1, 2\}$ , with  $\sigma_1 = 0$ ,  $x(1, \delta_1, 0) = 0$ ,  $\delta_2 = 2 - \delta_1$ ,  $t \in [0, 2]$ ,  $T_\mu = 1, 1$ , and the transition function  $x(2, \delta_1, \sigma_2) = x(1, \delta_1, \tau_1) + 1$ . The nonsmooth objective function is given by

$$F(\delta_1) = \begin{cases} 2 & \text{if } \delta_1 < 1, \\ 4 - 2\delta_1 & \text{if } \delta_1 \geq 1. \end{cases}$$

*Example 3.6* (piecewise continuous dynamic system with stationary simple discontinuity). Consider the problem

$$\min_{\delta_1 \in [0.5, 1.5]} F(\delta_1) = x(2, \delta_1, 2),$$

subject to the hybrid system

$$\text{Mode 1 : } \dot{x}(i, \delta_1, t) = \begin{cases} 0 & \text{if } t < 1, \\ 1 & \text{if } t \geq 1, \end{cases} \quad \text{Mode 2 : } \dot{x}(i, \delta_1, t) = 0$$

for all  $i \in \mathcal{E} = \{1, 2\}$ , with  $\sigma_1 = 0$ ,  $x(1, \delta_1, 0) = 0$ ,  $\delta_2 = 2 - \delta_1$ ,  $t \in [0, 2]$ ,  $T_\mu = 1, 2$ , and state continuity as the transition function. The nonsmooth objective function is given by

$$F(\delta_1) = \begin{cases} 0 & \text{if } \delta_1 < 1, \\ \delta_1 - 1 & \text{if } \delta_1 \geq 1. \end{cases}$$

**4. The transform.** The CPET (see, e.g., [20, 36, 21] for details) is implemented as follows. Consider the original independent variable time ( $t$ ) in Problem 3.1. We now wish to construct a new time scale in which the varying epoch durations (transition times) are fixed,  $s \in [0, n_e]$ . The transformation (CPET) from  $t \in [\sigma_1, \sigma_1 + \sum_{i=1}^{n_e} \delta_i^U]$  to  $s \in [0, n_e]$  is defined by

$$(4.1) \quad \frac{dt}{ds} = v(\boldsymbol{\delta}, s), \quad t(\boldsymbol{\delta}, 0) = \sigma_1,$$

where the function  $v : \Delta \times [0, n_e] \rightarrow \mathbb{R}$  is called the *enhancing control*. It is a piecewise constant function with possible simple discontinuities at the prefixed knots  $1, \dots, n_e - 1$ ,

$$v(\boldsymbol{\delta}, s) = \sum_{i=1}^{n_e} \delta_i \chi_i(s),$$

where  $\chi_i(s)$  is the indicator function defined by

$$\chi_i(s) = \begin{cases} 1 & \text{if } s \in [i-1, i], \\ 0 & \text{otherwise.} \end{cases}$$

Clearly,

$$(4.2) \quad t(\boldsymbol{\delta}, s) = \sigma_1 + \int_0^s v(\boldsymbol{\delta}, z) dz = \sigma_1 + \delta_i(s - (i-1)) + \sum_{j=1}^{i-1} \delta_j = (s - i + 1)\delta_i + \sigma_i$$

for  $s \in [i-1, i]$ ,  $i \in \mathcal{E}$ , where the value of the enhancing control in the transformed time interval  $(i-1, i)$  corresponds to the value of the duration of epoch  $I_i$  in the original time scale. In addition, the scaled simple discontinuities, point objectives, and point constraints in Problem 3.1 become stationary simple discontinuities, point objectives, and point constraints in the new time scale, according to Definition 2.3. Finally, let  $\mathbf{x}' \equiv \frac{d\mathbf{x}}{ds}$ . It follows from the CPET that

$$\begin{aligned} \frac{\mathbf{x}'(i, \mathbf{p}, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s))}{v(\boldsymbol{\delta}, s)} = & \left( \mathbf{A}(m, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s)) \mathbf{x}(i, \mathbf{p}, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s)) + \mathbf{B}(m, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s)) \mathbf{p} \right. \\ & \left. + \mathbf{q}(m, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s)) \right), \end{aligned}$$

where  $t$  is an additional differential state variable that has to satisfy (4.1). We can substitute for the explicit form of  $t(\boldsymbol{\delta}, s)$  to obtain

$$(4.3) \quad \hat{\mathbf{x}}'(i, \mathbf{p}, \boldsymbol{\delta}, s) = v(\boldsymbol{\delta}, s) \left( \hat{\mathbf{A}}(m, \boldsymbol{\delta}, s) \hat{\mathbf{x}}(\mathbf{p}, \boldsymbol{\delta}, s) + \hat{\mathbf{B}}(m, \boldsymbol{\delta}, s) \mathbf{p} + \hat{\mathbf{q}}(m, \boldsymbol{\delta}, s) \right),$$

where  $\hat{\mathbf{x}}(i, \mathbf{p}, \delta, s) \equiv \mathbf{x}(i, \mathbf{p}, \delta, t(\delta, s))$ ,  $\hat{\mathbf{x}}' \equiv \frac{d\hat{\mathbf{x}}}{ds}$ ,  $\hat{\mathbf{A}}(m, \delta, s) \equiv \mathbf{A}(m, \delta, t(\delta, s))$ ,  $\hat{\mathbf{B}}(m, \delta, s) \equiv \mathbf{B}(m, \delta, t(\delta, s))$ ,  $\hat{\mathbf{q}}(m, \delta, s) \equiv \mathbf{q}(m, \delta, t(\delta, s))$ , and  $t(\delta, s)$  is given by (4.2). Consider now any  $i \in \mathcal{E}$ . It is clear that  $v = \delta_i$  is continuous on  $\Delta \times (i-1, i)$  and defined at the points of discontinuity  $s = i-1$  and  $s = i$ . Also,  $t$  is continuous on  $\Delta \times [i-1, i]$  from (4.2). Let the epoch  $I_i$  be split into a finite number of contiguous intervals (*subepochs*) where  $\mathbf{A}(m, \delta, \cdot)$ ,  $\mathbf{B}(m, \delta, \cdot)$ , and  $\mathbf{q}(m, \delta, \cdot)$  are continuous internal to each subepoch. From Definition 2.3, the scaled simple discontinuities (in  $t$ ) for  $\mathbf{A}(m, \delta, \cdot)$ ,  $\mathbf{B}(m, \delta, \cdot)$ , and  $\mathbf{q}(m, \delta, \cdot)$  become stationary simple discontinuities (in  $s$ ) for  $\hat{\mathbf{A}}(m, \delta, \cdot)$ ,  $\hat{\mathbf{B}}(m, \delta, \cdot)$ , and  $\hat{\mathbf{q}}(m, \delta, \cdot)$ . Internal to any arbitrary, transformed subepoch in  $\hat{I}_i$ ,  $\hat{\mathbf{A}}(m, \delta, \cdot)$ ,  $\hat{\mathbf{B}}(m, \delta, \cdot)$ , and  $\hat{\mathbf{q}}(m, \delta, \cdot)$  are continuous (this follows from the fact that the composition of continuous functions is also continuous [27, Theorems 9.15 and 4.7]). The right-hand side of (4.3) is thus piecewise continuous in  $s$  with a finite number of stationary simple discontinuities, defined at each point of discontinuity. The objective function and constraints after the CPET are given by

$$(4.4) \quad \hat{F}(\mathbf{p}, \delta) = \sum_{i=1}^{n_e} \left\{ \sum_{j=1}^{n_{\phi i}} \phi_{ij}(\hat{\mathbf{x}}(i, \mathbf{p}, \delta, \hat{\alpha}_{ij}), \mathbf{p}, \delta) + \int_{i-1}^i f_i(\hat{\mathbf{x}}, \mathbf{p}, \delta, t(\delta, s)) v(\delta, s) ds \right\},$$

$$(4.5) \quad \hat{\mathbf{G}}(\mathbf{p}, \delta) = \sum_{i=1}^{n_e} \left\{ \sum_{j=1}^{n_{\eta i}} \eta_{ij}(\hat{\mathbf{x}}(i, \mathbf{p}, \delta, \hat{\beta}_{ij}), \mathbf{p}, \delta) + \int_{i-1}^i \mathbf{g}_i(\hat{\mathbf{x}}, \mathbf{p}, \delta, t(\delta, s)) v(\delta, s) ds \right\}.$$

Note that  $\hat{\alpha}_{ij}$  and  $\hat{\beta}_{ij}$  are no longer a function of  $\delta$ . Henceforth, we shall use the superscript prime notation to denote the transformed time derivative, i.e.,  $' \equiv \frac{d}{ds}$ . We are now able to formally state the transformed hybrid system and problem.

DEFINITION 4.1. A CPET hybrid system is the 8-tuple  $\hat{\mathcal{H}} = (\mathcal{M}, \mathcal{E}, T_\mu, \hat{\mathbf{p}}, \hat{\mathbf{x}}, \mathcal{F}, \mathcal{T}^0, \mathcal{T})$ , where  $\mathcal{M}$ ,  $\mathcal{E}$ , and  $T_\mu$  are as defined in Definition 2.1, and

- $\hat{\mathbf{p}} = (\mathbf{p}, \delta) \in \hat{P} = P \times \Delta \subset \mathbb{R}^{n_p + n_e}$ ,
- $\hat{\mathbf{x}} : \mathcal{E} \times \hat{P} \times \mathbb{R} \rightarrow \mathbb{R}^{n_x}$ ,
- $\mathcal{F} : \mathcal{M} \times \mathbb{R}^{n_x} \times \hat{P} \times \mathbb{R} \rightarrow \mathbb{R}^{n_x}$ ,
- $\mathcal{T}^0 : \hat{P} \rightarrow \mathbb{R}^{n_x}$ , and
- $\mathcal{T} : \mathcal{E} \setminus \{n_e\} \times \mathbb{R}^{n_x} \times \hat{P} \rightarrow \mathbb{R}^{n_x}$ .

As before, the elements of  $\mathcal{M}$  are called the modes of  $\hat{\mathcal{H}}$ .  $T_\mu$  is called the hybrid mode trajectory and is the discrete state variable of  $\hat{\mathcal{H}}$ .  $\hat{\mathbf{p}}$  is the vector of parameters.  $\hat{\mathbf{x}}$  is the vector of continuous state variables, and  $\mathcal{F}$  is the vector field for  $\mathbf{x}$ .  $\mathcal{T}^0$  are the initial conditions, and  $\mathcal{T}$  are the transition functions.  $\mathcal{E}$  remains the index set for the epochs, which are defined in the following definition.

DEFINITION 4.2. The hybrid time trajectory of  $\hat{\mathcal{H}}$  is a finite sequence of intervals  $T_\tau = \{\hat{I}_i\}_{i \in \mathcal{E}}$ , where  $\hat{I}_i = [\hat{\sigma}_i, \hat{\tau}_i] = [i-1, i]$ . The  $\hat{I}_i$  are called epochs.

From the previous analysis, the CPET transform of  $\mathcal{H}$  subject to assumptions A1–A3 will result in a CPET hybrid system  $\hat{\mathcal{H}}$  subject to the following assumptions.

B1.  $\hat{P} = [\hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U] = [(\mathbf{p}^L, \delta^L), (\mathbf{p}^U, \delta^U)]$  is a nondegenerate interval vector. The vector field  $\mathcal{F}(m, \cdot)$  for each  $m \in \mathcal{M}$  is nonlinear in the continuous state variables  $\hat{\mathbf{x}}$  and the parameters  $\hat{\mathbf{p}}$  so that for each epoch  $\hat{I}_{i \in \mathcal{E}}$  the continuous state variables evolve according to the nonlinear system in (4.3), written as

$$(4.6) \quad \hat{\mathbf{x}}'(i, \hat{\mathbf{p}}, s) = \mathcal{F}(m, \hat{\mathbf{x}}, \hat{\mathbf{p}}, s) \quad \forall s \in (i-1, i].$$

Moreover, for all  $(m, i, \hat{\mathbf{p}}, \hat{x}) \in \mathcal{M} \times \mathcal{E} \times \hat{P} \times \mathbb{R}^{n_x}$ ,  $\mathcal{F}(m, \hat{\mathbf{x}}, \hat{\mathbf{p}}, \cdot)$  is piecewise continuous on epoch  $\hat{I}_i$  with a finite number of stationary simple discontinuities and is defined at any point of discontinuity.

B2. The initial conditions  $\mathcal{T}^0$  are functions so that the initial conditions for epoch  $\hat{I}_1$  are given by

$$\hat{\mathbf{x}}(1, \hat{\mathbf{p}}, 0) = \mathbf{E}(0)\mathbf{p} + \mathbf{J}(0)\boldsymbol{\delta} + \mathbf{k}(0).$$

B3. The transition functions  $\mathcal{T}(i, \cdot)$  for each  $i \in \mathcal{E} \setminus \{n_e\}$  are functions so that the initial conditions for epochs  $\hat{I}_{i \in \mathcal{E} \setminus \{1\}}$  are given by

$$(4.7) \quad \hat{\mathbf{x}}(i, \hat{\mathbf{p}}, i-1) = \mathbf{D}(i-1)\hat{\mathbf{x}}(i-1, \hat{\mathbf{p}}, i-1) + \mathbf{E}(i-1)\mathbf{p} + \mathbf{J}(i-1)\boldsymbol{\delta} + \mathbf{k}(i-1).$$

DEFINITION 4.3. *Given a value for  $\hat{\mathbf{p}}$ , the solution, or execution, of a CPET hybrid system  $\hat{\mathcal{H}}$  subject to assumptions B1–B3 is  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s)$ ,  $s \in \hat{I}_i$ ,  $i \in \mathcal{E}$ , where  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s)$  is the solution of the ODE system in B1 with initial conditions B2 if  $i = 1$  and B3 otherwise.*

The major differences between a CPET hybrid system  $\hat{\mathcal{H}}$  subject to assumptions B1–B3 and a hybrid system  $\mathcal{H}$  subject to assumptions A1–A3 are (a) the initial time for  $\hat{\mathcal{H}}$  is fixed at  $s = 0$ , and the durations of all epochs are 1, and (b) the form of the underlying differential equations for each mode. The corresponding relaxations for the implied state bounds are given by the following definition.

DEFINITION 4.4 (implied state bounds). *Define the following convex sets for all  $i \in \mathcal{E}$ . For any fixed  $\underline{s} \in \hat{I}_i$ ,*

$$\hat{X}(i, \underline{s}; \hat{P}) \equiv [\hat{\mathbf{x}}^L(\underline{s}), \hat{\mathbf{x}}^U(\underline{s})] \mid \hat{\mathbf{x}}^L(\underline{s}) \leq \hat{\mathbf{x}}(\hat{\mathbf{p}}, \underline{s}) \leq \hat{\mathbf{x}}^U(\underline{s}) \quad \forall \hat{\mathbf{p}} \in \hat{P}.$$

In addition,

$$\hat{X}(i, \hat{P}) \equiv [\hat{\mathbf{x}}^L, \hat{\mathbf{x}}^U] \mid \hat{X}(i, \underline{s}; \hat{P}) \subset [\hat{\mathbf{x}}^L, \hat{\mathbf{x}}^U] \quad \forall \underline{s} \in \hat{I}_i.$$

PROBLEM 4.5. *The transformed problem is given by*

$$\begin{aligned} & \min_{\hat{\mathbf{p}} \in \hat{P}} \hat{F}(\hat{\mathbf{p}}) \\ & \text{s.t. } \hat{\mathbf{G}}(\hat{\mathbf{p}}) \leq \mathbf{0}, \end{aligned}$$

where  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s)$  is given by the solution of the embedded nonlinear hybrid system in Definition 4.1 subject to assumptions B1–B3;  $\hat{F}(\hat{\mathbf{p}})$  and  $\hat{\mathbf{G}}(\hat{\mathbf{p}})$  are given by (4.4) and (4.5), respectively;  $\hat{f}_i$  and  $\hat{\mathbf{g}}_i$  are piecewise continuous mappings  $\hat{f}_i : \hat{X}(i, \hat{P}) \times \hat{P} \times \hat{I}_i \rightarrow \mathbb{R}$ , and  $\hat{\mathbf{g}}_i : \hat{X}(i, \hat{P}) \times \hat{P} \times \hat{I}_i \rightarrow \mathbb{R}^{n_e}$  for all  $i \in \mathcal{E}$ , with a finite number of stationary simple discontinuities;  $n_{\phi i}$  is the number of fixed point objectives in epoch  $\hat{I}_i$ ,  $\hat{\alpha}_{ij} \in \hat{I}_i$ ,  $\hat{\phi}_{ij}$  is a continuous mapping  $\hat{\phi}_{ij} : \hat{X}(i, \hat{\alpha}_{ij}; \hat{P}) \times \hat{P} \rightarrow \mathbb{R}$  for all  $j = 1, \dots, n_{\phi i}$ , and  $i \in \mathcal{E}$ ; and  $n_{\eta i}$  is the number of fixed point constraints in epoch  $\hat{I}_i$ ,  $\hat{\beta}_{ij} \in \hat{I}_i$ ,  $\hat{\eta}_{ij}$  is a continuous mapping  $\hat{\eta}_{ij} : \hat{X}(i, \hat{\beta}_{ij}; \hat{P}) \times \hat{P} \rightarrow \mathbb{R}^{n_e}$  for all  $j = 1, \dots, n_{\eta i}$ , and  $i \in \mathcal{E}$ . Additionally, we require that the set  $\hat{G} = \{\hat{\mathbf{p}} \in \hat{P} \mid \hat{\mathbf{G}}(\hat{\mathbf{p}}) \leq \mathbf{0}\}$  be nonempty.

LEMMA 4.6. *Consider  $\mathcal{H}$  subject to A1–A3 and  $\hat{\mathcal{H}}$  subject to B1–B3. Then, for any  $(\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_i$ ,  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s) = \mathbf{x}(i, \mathbf{p}, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s))$  for all  $i \in \mathcal{E}$ , where  $t(\boldsymbol{\delta}, s)$  is given by (4.2).*

*Proof.* Consider any arbitrary  $\hat{\mathbf{p}}^* = (\mathbf{p}^*, \boldsymbol{\delta}^*) \in \hat{P}$  and the first epoch in the transformed time scale,  $\hat{I}_1$ . From (4.2),  $t(\boldsymbol{\delta}^*, \hat{\sigma}_1) = \sigma_1$ . Hence, from the initial

conditions in assumptions A2 and B2,  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1) = \mathbf{x}(1, \mathbf{p}^*, \boldsymbol{\delta}^*, \sigma_1)$ . Integrating (4.3), we obtain

$$\int_0^s \hat{\mathbf{x}}' dz = \int_0^s \left( \hat{\mathbf{A}}(m_1, \boldsymbol{\delta}, z) \hat{\mathbf{x}}(1, \hat{\mathbf{p}}, z) + \hat{\mathbf{B}}(m_1, \boldsymbol{\delta}, z) \mathbf{p} + \hat{\mathbf{q}}(m_1, \boldsymbol{\delta}, z) \right) v(\boldsymbol{\delta}, z) dz,$$

and with the change of variables  $t(\boldsymbol{\delta}^*, s)$  given by (4.2),

$$\int_0^s \hat{\mathbf{x}}' dz = \int_{\sigma_1}^{t(\boldsymbol{\delta}^*, s)} \left( \mathbf{A}(m_1, \boldsymbol{\delta}, w) \mathbf{x}(1, \mathbf{p}, \boldsymbol{\delta}, z) + \mathbf{B}(m_1, \boldsymbol{\delta}, w) \mathbf{p} + \mathbf{q}(m_1, \boldsymbol{\delta}, w) \right) dw$$

or

$$\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s) - \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1) = \mathbf{x}(1, \mathbf{p}^*, \boldsymbol{\delta}^*, t(\boldsymbol{\delta}^*, s)) - \mathbf{x}(1, \mathbf{p}^*, \boldsymbol{\delta}^*, \sigma_1).$$

Therefore, for all  $s \in \hat{I}_1$ ,  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s) = \mathbf{x}(1, \mathbf{p}^*, \boldsymbol{\delta}^*, t(\boldsymbol{\delta}^*, s))$ . At the transition to epoch 2, from (4.2),  $t(\boldsymbol{\delta}^*, \hat{\tau}_1) = \tau_1$ , thus  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\tau}_1) = \mathbf{x}(1, \mathbf{p}^*, \boldsymbol{\delta}^*, \tau_1)$ . Applying the transition functions in assumptions A3 and B3, we obtain  $\hat{\mathbf{x}}(2, \hat{\mathbf{p}}^*, \hat{\sigma}_2) = \mathbf{x}(2, \mathbf{p}^*, \boldsymbol{\delta}^*, \sigma_2)$ . Since the choice of  $\mathbf{p}^*$  was arbitrary, induction on all epochs gives  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s) = \mathbf{x}(i, \mathbf{p}, \boldsymbol{\delta}, t(\boldsymbol{\delta}, s))$  for all  $i \in \mathcal{E}$ , for any  $(\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_i$ .  $\square$

*Remark 4.7.* A solution,  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s)$ ,  $s \in \hat{I}_{i \in \mathcal{E}}$  will exist and be unique for all  $\hat{\mathbf{p}} \in \hat{P}$ . This follows directly from Theorem 2.5 and Lemma 4.6.

**THEOREM 4.8.** *Problem 3.1 has the solution  $(\mathbf{p}^*, \boldsymbol{\delta}^*)$  iff  $(\mathbf{p}^*, \boldsymbol{\delta}^*)$  is a solution to Problem 4.5.*

*Proof.* Consider any arbitrary  $\hat{\mathbf{p}}^* = (\mathbf{p}^*, \boldsymbol{\delta}^*) \in \hat{P}$  and any arbitrary epoch  $i \in \mathcal{E}$ . For any  $j \in \{1, \dots, n_{\phi i}\}$ , from Lemma 4.6 and (4.2), we have

$$\phi_{ij}(\hat{\mathbf{x}}(i, \hat{\mathbf{p}}^*, \hat{\alpha}_{ij}), \hat{\mathbf{p}}^*) = \phi_{ij}(\mathbf{x}(i, \mathbf{p}^*, \boldsymbol{\delta}^*, \alpha_{ij}(\boldsymbol{\delta}^*)), \mathbf{p}^*, \boldsymbol{\delta}^*).$$

Similarly,

$$\int_{\hat{\sigma}_i}^{\hat{\tau}_i} f_i(\hat{\mathbf{x}}(i, \hat{\mathbf{p}}^*, s), \hat{\mathbf{p}}^*, t(\boldsymbol{\delta}^*, s)) v(\boldsymbol{\delta}^*, s) ds = \int_{\sigma_i(\boldsymbol{\delta}^*)}^{\tau_i(\boldsymbol{\delta}^*)} f_i(\mathbf{x}(i, \mathbf{p}^*, \boldsymbol{\delta}^*, t), \mathbf{p}^*, \boldsymbol{\delta}^*, t) dt.$$

Hence, we have  $\hat{F}(\hat{\mathbf{p}}^*) = F(\mathbf{p}^*, \boldsymbol{\delta}^*)$ . Applying the same analysis to the constraints, we have  $\hat{\mathbf{G}}(\hat{\mathbf{p}}^*) = \mathbf{G}(\mathbf{p}^*, \boldsymbol{\delta}^*)$ . Since  $\hat{\mathbf{p}}^*$  was arbitrary, we have shown the equivalence of Problems 3.1 and 4.5.  $\square$

*Remark 4.9.* A consequence of the CPET transform is the destruction of the linear structure of the original hybrid system.

The following theorem presents sufficient conditions for the objective function (and analogously the constraints) to be smooth, and will be assumed to hold for the transformed problem.

**THEOREM 4.10.** *Let  $\hat{P}^o \supset \hat{P}$ ,  $\hat{X}^o(i, \hat{\alpha}_{ij}) \supset \hat{X}(i, \hat{\alpha}_{ij}; \hat{P}^o)$  and  $\hat{X}^o(i) \supset \hat{X}(i, \hat{P}^o)$  be open subsets of  $\mathbb{R}^{n_p + n_e}$ ,  $\mathbb{R}^{n_x}$ , and  $\mathbb{R}^{n_x}$ , respectively, for all  $j = 1, \dots, n_{\phi i}$ ,  $i \in \mathcal{E}$ . If the following conditions are satisfied, then the objective function  $\hat{F}$  is continuously differentiable on  $\hat{P}^o$ .*

- C1.  $\frac{\partial \phi_{ij}}{\partial \mathbf{x}}$  and  $\frac{\partial \phi_{ij}}{\partial \mathbf{p}}$  exist and are continuous on  $\hat{X}^o(i, \hat{\alpha}_{ij}) \times \hat{P}^o$  for all  $j = 1, \dots, n_{\phi i}$ ,  $i \in \mathcal{E}$ .
- C2.  $\frac{\partial f_i}{\partial \mathbf{x}}$  and  $\frac{\partial f_i}{\partial \mathbf{p}}$  exist and are piecewise continuous on  $\hat{X}^o(i) \times \hat{P}^o \times \hat{I}_i$  for all  $i \in \mathcal{E}$ , where only a finite number of stationary simple discontinuities in  $s$  are allowed.

*Proof.* Consider an arbitrary epoch  $\hat{I}_i$ . First, we show that the parametric sensitivities exist and are unique. We have a finite number of stationary discontinuities (in  $s$ ) in (4.6). Let there be  $k$  such discontinuities in  $\hat{I}_i$  found at points  $s = \zeta_l$ ,  $l = 1, \dots, k$ . Construct a sequence of  $k + 1$  subepochs  $[\xi_1, \zeta_1], \dots, [\xi_{k+1}, \zeta_{k+1}]$ , where  $\xi_1 = \hat{\sigma}_i$ ,  $\zeta_{k+1} = \hat{\tau}_i$ , and  $\xi_{l+1} = \zeta_l$ ,  $l = 1, \dots, k$ . Extend the function  $\mathcal{F}(m_i, \cdot)$  to be continuous on all subepochs,

$$\mathcal{F}(m_i, \cdot, \xi_l) \equiv \lim_{s \rightarrow \xi_l^+} \mathcal{F}(m_i, \cdot, s), \quad \mathcal{F}(m_i, \cdot, \zeta_l) \equiv \lim_{s \rightarrow \zeta_l^-} \mathcal{F}(m_i, \cdot, s),$$

for  $l = 1, \dots, k + 1$ , and impose state continuity for each transition between subepochs. A CPET hybrid system is thus defined within the epoch  $\hat{I}_i$ . Now consider an arbitrary subepoch  $[\xi_l, \zeta_l]$ . From (4.3), it is clear that the partial derivatives  $\frac{\partial \mathcal{F}(m_i, \cdot)}{\partial \mathbf{x}}$  and  $\frac{\partial \mathcal{F}(m_i, \cdot)}{\partial \mathbf{p}}$  exist and are continuous internal to this subepoch. At the transition  $\zeta_l$ , it is easy to verify that the remaining assumptions of [14, Theorem 1] are satisfied, which provides the existence and uniqueness result. Since the discontinuities are stationary, the transition times in the interior of the epoch are independent of the parameters, and the sensitivities are continuous everywhere interior to the epoch.

Consider now an arbitrary  $v \in \{1, \dots, n_p + n_e\}$ . For the point objectives, since  $\hat{P}^o$  is an open set, the parametric sensitivities exist and condition C1 holds, the summation term  $\sum_{j=1}^{n_{\phi i}} \frac{\partial \phi_{ij}}{\partial p_v}$  exists and is continuous on  $\hat{P}^o$  by the chain rule and linearity of the derivative operator. Next, consider the integral objectives. We have a finite number of stationary discontinuities (in  $s$ ) in the integrand  $f_i$ ,  $\mathcal{F}(m_i, \cdot)$ , the parametric sensitivities and the derivatives in condition C2. Let there be  $\hat{k}$  such discontinuities found at points  $s = \hat{\zeta}_{\hat{l}}$ ,  $\hat{l} = 1, \dots, \hat{k}$ . Partition the integral into the following:

$$\hat{F}_i(\hat{\mathbf{p}}) = \sum_{\hat{l}=0}^{\hat{k}} \hat{F}_{i\hat{l}}(\hat{\mathbf{p}}) = \sum_{\hat{l}=0}^{\hat{k}} \int_{\zeta_{\hat{l}}}^{\zeta_{\hat{l}+1}} f_i(\hat{\mathbf{x}}, \hat{\mathbf{p}}, s) \, ds,$$

where  $\zeta_0 = \hat{\sigma}_i$  and  $\zeta_{\hat{k}+1} = \hat{\tau}_i$ . Now, consider an arbitrary  $\hat{l} \in \{1, \dots, \hat{k}\}$ . Extend  $f_i$ ,  $\frac{\partial f_i}{\partial \mathbf{x}}$ , and  $\frac{\partial f_i}{\partial \mathbf{p}}$  to be continuous on  $\hat{X}^o(i) \times \hat{P}^o \times [\zeta_{\hat{l}}, \zeta_{\hat{l}+1}]$ , and  $\frac{\partial \hat{\mathbf{x}}(i, \cdot)}{\partial \mathbf{p}}$  and  $\hat{\mathbf{x}}(i, \cdot)$  to be continuous on  $\hat{P}^o \times [\zeta_{\hat{l}}, \zeta_{\hat{l}+1}]$ . At most, these functions are discontinuous at their endpoints in time. Removing these discontinuities does not alter the value of the integral because the endpoints comprise a set of measure zero. As above, applying the chain rule on the partial derivative  $\frac{\partial f_i}{\partial p_v}$ , we obtain continuity of said derivative on  $\hat{P}^o \times [\zeta_{\hat{l}}, \zeta_{\hat{l}+1}]$ . These continuity conditions enable us to differentiate under the integral sign [7, p. 308] to obtain

$$\frac{\partial \hat{F}_{i\hat{l}}}{\partial p_v} = \int_{\zeta_{\hat{l}}}^{\zeta_{\hat{l}+1}} \frac{\partial f_i}{\partial p_v} \, ds.$$

We can then apply [32, Proposition 2.1] to yield  $\frac{\partial \hat{F}_{i\hat{l}}}{\partial p_v}$  continuous on  $\hat{P}^o$ . Since  $\hat{l}$  was arbitrary,  $\frac{\partial \hat{F}_i}{\partial p_v}$  is continuous on  $\hat{P}^o$  as the sum of continuous functions is continuous. Since  $i$  was arbitrary,  $\frac{\partial \hat{F}}{\partial p_v}$  is continuous on  $\hat{P}^o$ . Since  $v$  was arbitrary, it follows that  $\hat{F}$  is continuously differentiable on  $\hat{P}^o$ .  $\square$

**5. Relaxation theory.** In this section, we will present the theory required for constructing convex relaxations of Problem 4.5. This theory is an extension of that developed in [30, Chapter 6] and [33] for (single-stage) nonlinear dynamic systems. The main idea behind the theorems presented below will consist of breaking down the multistage hybrid system into contiguous intervals in time, verifying that the hypotheses of the theorems in [30, Chapter 6] and [33] hold for each of these intervals, and applying the theorems sequentially for each interval via finite induction.

The ultimate goal of this section is condensed into constructing a convex relaxation for the objective function (4.4), subject to the transformed nonlinear hybrid system. The exact same theory is applied for the point and isoperimetric constraints in (4.5). The ability to construct convex relaxations for the objective function and constraints then enables a convex relaxation of the problem to be solved. Finally, it is shown that the constructed convex relaxations possess the same consistent bounding properties of the convex relaxation techniques used in their construction, so that their incorporation into a branch-and-bound framework [9, 23] leads to an infinitely convergent algorithm [17]. This implies  $\varepsilon$  global optimality within a finite number of iterations.

The steps for constructing the convex relaxation are outlined below:

1. Estimating the implied state bounds,  $\hat{X}(i, \underline{s}; \hat{P})$  in Definition 4.4.
2. Constructing convex and concave relaxations for the states.
3. Applying convex relaxation techniques on subsets of Euclidean spaces to construct the required convex relaxation.

**DEFINITION 5.1.** Let  $\hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s)$  be the solution of  $\hat{\mathcal{H}}$  subject to assumptions B1–B3, and let  $\hat{x}_j(i, \hat{\mathbf{p}}, s) \in \hat{X}_j(i, \hat{\mathbf{p}}, s)$  for each  $\hat{\mathbf{p}} \in \hat{P}$ ,  $i \in \mathcal{E}$ ,  $j = 1, \dots, n_x$ , where  $\hat{X}_j(i, \hat{\mathbf{p}}, s) \subset \mathbb{R}$  is a bounding set that is known independently. For each fixed  $\underline{s} \in \hat{I}_{i \in \mathcal{E}}$ , let  $\varrho_j(i, \mathbf{r}, \underline{s}) = \inf \hat{X}_j(i, \mathbf{r}, \underline{s})$  and  $\varsigma_j(i, \mathbf{r}, \underline{s}) = \sup \hat{X}_j(i, \mathbf{r}, \underline{s})$  for each  $\mathbf{r} \in \hat{P}$ ,  $j = 1, \dots, n_x$ . Furthermore, let  $\hat{X}(i, \underline{s})$  be defined pointwise in (transformed) time for each  $i \in \mathcal{E}$  by  $\hat{X}(i, \underline{s}) = [\mathbf{z}^L, \mathbf{z}^U]$  such that

$$z_j^L = \inf_{\mathbf{r} \in \hat{P}} \varrho_j(i, \mathbf{r}, \underline{s}), \quad z_j^U = \sup_{\mathbf{r} \in \hat{P}} \varsigma_j(i, \mathbf{r}, \underline{s}) \quad \forall j = 1, \dots, n_x,$$

where  $z_j^L$  and  $z_j^U$  are in the extended real number system.

**THEOREM 5.2.** Consider  $\hat{\mathcal{H}}$  subject to assumptions B1–B3. If the following conditions are satisfied for all  $i \in \mathcal{E}$  and  $j = 1, \dots, n_x$ ,

$$\text{D1. } v_j(\hat{\sigma}_i) < \min_{\mathbf{r} \in \hat{P}} \hat{x}_j(i, \mathbf{r}, \hat{\sigma}_i),$$

$$\text{D2. } w_j(\hat{\sigma}_i) > \max_{\mathbf{r} \in \hat{P}} \hat{x}_j(i, \mathbf{r}, \hat{\sigma}_i),$$

and, additionally, for all  $\mathbf{v}(s), \mathbf{w}(s) \in H(s)$ ,  $s \in [i-1, i]$ ,

$$\text{D3. } v'_j = \underline{h}_j(m_i, \mathbf{v}, \mathbf{w}, s; \hat{P}) < \inf_{\substack{\mathbf{z} \in \hat{X}(i, s) \cap H(s), \mathbf{r} \in \hat{P} \\ z_j = v_j(s)}} \mathcal{F}_j(m_i, \mathbf{z}, \mathbf{r}, s),$$

$$\text{D4. } w'_j = \bar{h}_j(m_i, \mathbf{v}, \mathbf{w}, s; \hat{P}) > \sup_{\substack{\mathbf{z} \in \hat{X}(i, s) \cap H(s), \mathbf{r} \in \hat{P} \\ z_j = w_j(s)}} \mathcal{F}_j(m_i, \mathbf{z}, \mathbf{r}, s),$$

where  $H(s) \equiv \{\mathbf{z} \mid \mathbf{v}(s) \leq \mathbf{z} \leq \mathbf{w}(s)\}$ ; then

$$\mathbf{v}(s) < \hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s) < \mathbf{w}(s) \quad \forall (\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_i, \quad i \in \mathcal{E}.$$

It is also assumed that the solutions, in the sense of Carathéodory, to the differential systems in  $\mathbf{v}$  and  $\mathbf{w}$  exist and are unique for all  $i \in \mathcal{E}$ .

*Proof.* From assumption B2, Theorem 4.10 (treating  $\hat{\mathbf{x}}(i, \cdot, \hat{\tau}_i)$  as the objective function) and the form of (4.7),  $\hat{\mathbf{x}}(i, \cdot, \hat{\sigma}_i)$  is continuous on  $\hat{P}$  for all  $i \in \mathcal{E}$ . Hence, the extrema in conditions D1 and D2 exist.

Consider now the first epoch  $\hat{I}_1$ . From assumption B1,  $\mathcal{F}(m_1, \cdot)$  is piecewise continuous with a finite number of stationary simple discontinuities in  $s$ . Let  $\gamma$  be the number of discontinuities occurring at  $\tilde{\tau}_k \in \hat{I}_1$ ,  $k = 1, \dots, \gamma$ . Then, the first epoch can be further subdivided into  $\gamma + 1$  contiguous subepochs, for which we have transitions at the subepoch boundaries, state continuity at each transition, and  $\mathcal{F}(m_1, \cdot)$  is continuous for each subepoch. Let the sequence of subepochs be given by  $\{\tilde{I}_k\}$ ,  $k = 1, \dots, \gamma + 1$ , where  $\tilde{I}_k = [\tilde{\sigma}_k, \tilde{\tau}_k]$ ,  $\tilde{\sigma}_1 = 0$ ,  $\tilde{\tau}_{\gamma+1} = \hat{\tau}_1$ , and  $\tilde{\sigma}_{k+1} = \tilde{\tau}_k$  for  $k = 1, \dots, \gamma$ . Consider now the first subepoch  $\tilde{I}_1$ .

The initial condition at time  $s = 0$  given by assumption B2 is clearly continuous on  $\hat{P}$ . The form of the nonlinear ODE system in the first subepoch, and the conditions D1–D4 clearly satisfy the conditions of [33, Corollary 2.6], which gives

$$(5.1) \quad \mathbf{v}(s) < \hat{\mathbf{x}}(1, \hat{\mathbf{p}}, s) < \mathbf{w}(s)$$

for all  $(\hat{\mathbf{p}}, s) \in \hat{P} \times \tilde{I}_1$ . At the transition  $\tilde{\tau}_1$ , state continuity ensures

$$(5.2) \quad \mathbf{v}(\tilde{\sigma}_2) = \mathbf{v}(\tilde{\tau}_1) < \hat{\mathbf{x}}(1, \hat{\mathbf{p}}, \tilde{\sigma}_2) < \mathbf{w}(\tilde{\tau}_1) = \mathbf{w}(\tilde{\sigma}_2) \quad \forall \hat{\mathbf{p}} \in \hat{P}.$$

From Theorem 4.10,  $\hat{\mathbf{x}}(1, \cdot, \tilde{\sigma}_2)$  is continuous on  $\hat{P}$  (simply treat  $\hat{\mathbf{x}}(1, \cdot, \tilde{\sigma}_2)$  as the objective function). The form of the nonlinear ODE system in the second subepoch, (5.2), and the conditions D3 and D4 thus satisfy the conditions of [33, Corollary 2.6], which implies that (5.1) holds for all  $(\hat{\mathbf{p}}, s) \in \hat{P} \times \tilde{I}_2$ . By induction on all subepochs, (5.1) holds for all  $(\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_1$ . Consider now the second epoch  $\hat{I}_2$ . From Theorem 4.10 and (4.7),  $\hat{\mathbf{x}}(2, \cdot, \hat{\sigma}_2)$  is continuous on  $\hat{P}$ . The analysis carried out for the first epoch is thus valid for the second. By induction on all epochs, we have the desired result.  $\square$

By asserting uniqueness of the solution of the bounding differential equations, the conditions of the above theorem may be relaxed to

$$\text{D1. } v_j(\hat{\sigma}_i) \leq \min_{\mathbf{r} \in \hat{P}} \hat{x}_j(\mathbf{r}, \hat{\sigma}_i),$$

$$\text{D2. } w_j(\hat{\sigma}_i) \geq \max_{\mathbf{r} \in \hat{P}} \hat{x}_j(\mathbf{r}, \hat{\sigma}_i),$$

$$\text{D3. } v'_j = \underline{h}_j(m_i, \mathbf{v}, \mathbf{w}, s; \hat{P}) \leq \inf_{\substack{\mathbf{z} \in \hat{\mathcal{X}}(i, s) \cap H(s), \mathbf{r} \in \hat{P} \\ z_j = v_j(s)}} \mathcal{F}_j(m_i, \mathbf{z}, \mathbf{r}, s),$$

$$\text{D4. } w'_j = \bar{h}_j(m_i, \mathbf{v}, \mathbf{w}, s; \hat{P}) \geq \sup_{\substack{\mathbf{z} \in \hat{\mathcal{X}}(i, s) \cap H(s), \mathbf{r} \in \hat{P} \\ z_j = w_j(s)}} \mathcal{F}_j(m_i, \mathbf{z}, \mathbf{r}, s),$$

i.e., replacing the strict inequalities with regular inequalities (see [40, Remark 12.X]). Furthermore, by asserting regular inequalities, the result of the theorem also permits

$$\mathbf{v}(s) \leq \hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s) \leq \mathbf{w}(s) \quad \forall (\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_i, \quad i \in \mathcal{E}.$$

For the remainder of this article, we will assume that the uniqueness of the constructed bounding differential equations hold for all  $\hat{\mathbf{p}} \in \hat{P}$ ,  $s \in [0, n_e]$ , and so it is understood that reference to Theorem 5.2 also refers to the regular inequalities just described.

*Remark 5.3.* The bounding set  $\hat{\mathcal{X}}(i, \hat{\mathbf{p}}, s)$  makes it possible to tighten the implied state bounds obtained when physical insight from the problem in the form of invariants (e.g., conservation laws) and bounds is available; see [30, 33] for examples.

Theorem 5.2 enables a hybrid system of bounding differential equations to be constructed to obtain the set:

$$(5.3) \quad \hat{X}(i, \underline{s}; \hat{P}) \equiv \{\mathbf{z} \mid \mathbf{v}(\underline{s}) \leq \mathbf{z} \leq \mathbf{w}(\underline{s})\}.$$

The most difficult aspect of applying the theorem lies in obtaining the extrema in conditions D1–D4. As stated in [33], while computing the exact solution to the optimization problem would yield the tightest bounds possible from the theorem, actually solving the optimization problems at each integration step in a numerical integration would be a prohibitively expensive task. Hence, in practice, the solutions to the optimization problems are estimated by interval arithmetic [24] pointwise in time. Before we proceed, we will briefly introduce the metric topology for the set of intervals (see [24] for more details). By an *interval* we mean a compact set of real numbers  $[x^L, x^U] = \{x \mid x^L \leq x \leq x^U\}$ . As in [24], we will not distinguish between the degenerate interval  $[a, a]$  and the real number  $a$ . Define the distance  $d(X, Y) = \max(|x^L - y^L|, |x^U - y^U|)$  for the intervals  $X \equiv [x^L, x^U]$ ,  $Y \equiv [y^L, y^U]$ . The absolute value of an interval  $X \equiv [x^L, x^U]$  is given by  $|X| = \max(|x^L|, |x^U|)$ . The vector norm  $\|Z\| = \max(|Z_1|, \dots, |Z_n|)$  is used for interval vectors. An interval valued function  $F: Z \rightarrow \mathbb{IR}$ ,  $Z \subset \mathbb{IR}^n$ , is said to be *continuous* in the usual  $\varepsilon - \delta$  fashion with the metric  $d(X, Y)$ , where  $\mathbb{IR}$  is the set of all intervals. We say that an interval valued function  $F$  of the interval variables  $X_1, \dots, X_n$  is *inclusion monotonic* if  $Y_i \subseteq X_i, i = 1, \dots, n$  implies  $F(Y_1, \dots, Y_n) \subseteq F(X_1, \dots, X_n)$ . Let  $f$  be a real valued function of  $n$  real variables  $x_1, \dots, x_n$ . By an *interval extension* of  $f$ , we mean an interval valued function  $F$  of  $n$  interval variables  $X_1, \dots, X_n$  with the property  $F(x_1, \dots, x_n) = f(x_1, \dots, x_n)$  for real arguments; i.e., an interval extension of  $f$  is an interval valued function which has real values when the arguments are all real (degenerate intervals) and coincides with  $f$ .

Consider now the vector  $\mathbf{z} \in \mathbb{R}^n$ . We will introduce the following notation: for any fixed  $j \in \{1, \dots, n\}$ , let  $\mathbf{z}_{k \neq j}$  denote the vector  $\tilde{\mathbf{z}} \in \mathbb{R}^{n-1}$ , where

$$\tilde{z}_k = \begin{cases} z_k & \text{if } k < j, \\ z_{k+1} & \text{if } k \geq j. \end{cases}$$

If  $\mathbf{z} \in Z = [\mathbf{z}^L, \mathbf{z}^U]$ , then the corresponding interval vector  $Z_{k \neq j} = [\mathbf{z}_{k \neq j}^L, \mathbf{z}_{k \neq j}^U]$ . For convenience, we will also introduce the following (elementwise) maximization and minimization operations: consider the  $n$ -dimensional vectors  $\mathbf{x}$  and  $\mathbf{y}$  whose elements are in the extended real number system. Let the vector valued operation  $\text{cmin}(\mathbf{x}, \mathbf{y})$  return the  $n$ -dimensional vector  $\mathbf{z}$  whose elements are in the extended real number system where

$$z_i = \min(x_i, y_i) \quad \forall i = 1, \dots, n.$$

Similarly, let  $\text{cmax}(\mathbf{x}, \mathbf{y})$  return the  $n$ -dimensional vector  $\mathbf{z}$  in the extended real number system where

$$z_i = \max(x_i, y_i) \quad \forall i = 1, \dots, n.$$

**COROLLARY 5.4.** Consider  $\hat{\mathcal{H}}$  subject to assumptions B1–B3. Define the following interval valued functions:

$$(5.4) \quad Y(\hat{\sigma}_1) = [\mathbf{y}^L(\hat{\sigma}_1), \mathbf{y}^U(\hat{\sigma}_1)] = \mathbf{E}(0)P + \mathbf{J}(0)\Delta + \mathbf{k}(0),$$

$$(5.5) \quad \begin{aligned} Y(\hat{\sigma}_{l+1}) &= [\mathbf{y}^L(\hat{\sigma}_{l+1}), \mathbf{y}^U(\hat{\sigma}_{l+1})] \\ &= \mathbf{D}(l)[\mathbf{v}(\hat{\tau}_l), \mathbf{w}(\hat{\tau}_l)] + \mathbf{E}(l)P + \mathbf{J}(l)\Delta + \mathbf{k}(l) \quad \forall l = 1, \dots, n_e - 1, \end{aligned}$$

and let  $\Gamma_j(m_i, v_j, Z(j, i, s), \hat{P}, s) = [\gamma_j^L(m_i), \gamma_j^U(m_i)]$  and  $\Lambda_j(m_i, w_j, Z(j, i, s), \hat{P}, s) = [\lambda_j^L(m_i), \lambda_j^U(m_i)]$  be inclusion monotonic interval extensions of  $\mathcal{F}_j(m_i, \hat{x}_j, \hat{\mathbf{x}}_{k \neq j}, \hat{\mathbf{p}}, s)$   $\forall i \in \mathcal{E}, j = 1, \dots, n_x$ , where

$$Z(j, i, s) = \{\mathbf{z}_{k \neq j} \mid \text{cmax}(\mathbf{v}_{k \neq j}(s), \boldsymbol{\varphi}_{k \neq j}(i, s)) \leq \mathbf{z}_{k \neq j} \leq \text{cmin}(\mathbf{w}_{k \neq j}(s), \boldsymbol{\psi}_{k \neq j}(i, s))\},$$

and  $\hat{X}(i, s; \hat{P}) = [\boldsymbol{\varphi}(i, s), \boldsymbol{\psi}(i, s)]$  is defined in (5.3) and obtained from Theorem 5.2. Then,  $\forall j = 1, \dots, n_x, s \in [i-1, i]$ , and  $i \in \mathcal{E}$ , the system of differential equations and initial conditions

$$(5.6) \quad v_j' = \gamma_j^L(m_i, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s), \quad v_j(\hat{\sigma}_i) = y_j^L(\hat{\sigma}_i),$$

$$(5.7) \quad w_j' = \lambda_j^U(m_i, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s), \quad w_j(\hat{\sigma}_i) = y_j^U(\hat{\sigma}_i),$$

bounds the transformed hybrid system,

$$\mathbf{v}(s) \leq \hat{\mathbf{x}}(i, \hat{\mathbf{p}}, s) \leq \mathbf{w}(s) \quad \forall (\hat{\mathbf{p}}, s) \in \hat{P} \times \hat{I}_i, i \in \mathcal{E}.$$

*Proof.* The rational interval functions (5.4) and (5.5) are inclusion monotonic [24, p. 21]. Together with the inclusion monotonicity of the interval extensions of  $\mathcal{F}_j(m_i, \cdot)$ , (5.6) and (5.7) thus satisfy conditions D1–D4 of Theorem 5.2.  $\square$

It is important to note that the implied state bounds are obtained given a particular parameter set  $\hat{P}$ ; in order to ensure convergence of the branch-and-bound framework, these bounds must converge as  $\hat{P}$  becomes degenerate in the limit.

LEMMA 5.5. Let  $H(X_1, \dots, X_n) = [h^L, h^U]$  be an interval valued function, where  $X_i = [\mathbf{x}_i^L, \mathbf{x}_i^U]$  are  $n_{x_i}$ -dimensional interval vectors for all  $i = 1, \dots, n$ . Consider the following real valued functions:

$$g_1(\mathbf{x}_1^L, \dots, \mathbf{x}_n^L, \mathbf{x}_1^U, \dots, \mathbf{x}_n^U) = h^L, \quad g_2(\mathbf{x}_1^L, \dots, \mathbf{x}_n^L, \mathbf{x}_1^U, \dots, \mathbf{x}_n^U) = h^U.$$

If  $H$  is continuous on  $Y = Y_1 \times \dots \times Y_n$ , where  $Y_i = [\mathbf{y}_i^L, \mathbf{y}_i^U] \subset \mathbb{R}^{n_{x_i}}$  for all  $i = 1, \dots, n$ , then  $g_1$  and  $g_2$  are continuous on  $Y \times Y$ , and bounded by a constant  $M$  there.

*Proof.* The proof of continuity is elementary, employing the metric topology for intervals defined in [24] and the max norm. That the functions are bounded follows from continuity on the compact set  $Y \times Y$ .  $\square$

THEOREM 5.6. Let  $\{\hat{P}_k\}$  be a convergent sequence of interval vectors such that

$$(5.8) \quad \lim_{k \rightarrow \infty} \hat{P}_k = \hat{P}^* = [\hat{\mathbf{p}}^*, \hat{\mathbf{p}}^*],$$

where  $\hat{P}^* \in \hat{P}$ . Let Corollary 5.4 be used to construct (5.3). For all  $i \in \mathcal{E}$ , let the epoch  $\hat{I}_i$  be split into a finite number  $(\pi_i)$  of contiguous subepochs  $\tilde{I}_l = [\tilde{\sigma}_l, \tilde{\tau}_l]$ , where  $\tilde{\sigma}_1 = i-1$ ,  $\tilde{\tau}_{\pi_i} = i$ , and  $\tilde{\sigma}_{l+1} = \tilde{\tau}_l$  for all  $l = 1, \dots, \pi_i - 1$ . If the interval extensions  $\Gamma_j(m_i, \cdot)$  and  $\Lambda_j(m_i, \cdot)$  are continuous on  $\hat{X}_j(i, \hat{P}) \times \hat{X}_{n \neq j}(i, \hat{P}) \times \hat{P} \times [\tilde{\sigma}_l, \tilde{\tau}_l]$  for all  $i \in \mathcal{E}, j = 1, \dots, n_x$ , and  $l = 1, \dots, \pi_i$ , then

$$\lim_{k \rightarrow \infty} \hat{X}(i, \underline{s}; \hat{P}_k)_k = [\hat{\mathbf{x}}(i, \hat{\mathbf{p}}^*, \underline{s}), \hat{\mathbf{x}}(i, \hat{\mathbf{p}}^*, \underline{s})] \quad \forall \underline{s} \in \hat{I}_i, i \in \mathcal{E}.$$

*Proof.* Consider the first subepoch of the first epoch,  $\tilde{I}_1$ . By definition, interval extensions have real values when their arguments are all real (degenerate interval vectors). Hence, with the degenerate interval vector  $\hat{P}^*$  as argument, the natural

interval extension (5.4) becomes  $Y(\check{\sigma}_1) = [\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1), \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1)]$ . Thus, the initial conditions for the bounding ODE system becomes

$$\mathbf{v}(\check{\sigma}_1) = \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1) = \mathbf{w}(\check{\sigma}_1).$$

This implies that the interval vector  $Z(j, 1, s)$  defined in Corollary 5.4 is degenerate at  $s = \check{\sigma}_1$ , which implies

$$\begin{aligned} v'_j(\check{\sigma}_1) &= \gamma_j^L(m_1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^*, \hat{\mathbf{p}}^*, \check{\sigma}_1) = \mathcal{F}_j(m_1, \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \check{\sigma}_1), \hat{\mathbf{p}}^*, \check{\sigma}_1), \\ w'_j(\check{\sigma}_1) &= \lambda_j^U(m_1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^*, \hat{\mathbf{p}}^*, \check{\sigma}_1) = \mathcal{F}_j(m_1, \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \check{\sigma}_1), \hat{\mathbf{p}}^*, \check{\sigma}_1) \end{aligned}$$

for all  $j = 1, \dots, n_x$ . We have thus defined an initial value problem in  $\mathbf{v}(s)$  and  $\mathbf{w}(s)$ . Since the solution trajectory  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s)$  is unique (Remark 4.7), this implies that the interval vector  $Z(j, 1, s)$  is degenerate for all  $j = 1, \dots, n_x$ ,  $s \in \check{I}_1$  and equal to the value  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s)$ . Hence, (5.6) and (5.7) become

$$(5.9) \quad \mathbf{v}'(s) = \mathcal{F}(m_1, \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s), \hat{\mathbf{p}}^*, s) = \mathbf{w}'(s), \quad \mathbf{v}(\check{\sigma}_1) = \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \hat{\sigma}_1) = \mathbf{w}(\check{\sigma}_1).$$

For convenience, let  $\mathbf{z}(s) = (\mathbf{v}(s), \mathbf{w}(s))$  and  $\mathbf{y} = (\hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U)$ . The system of ODEs in (5.6) and (5.7) can then be expressed as

$$\mathbf{z}' = \mathbf{f}(\mathbf{z}, \mathbf{y}, s),$$

where a solution  $\mathbf{z}(\mathbf{y}^*, s)$  exists and is unique for  $\mathbf{y}^* = (\hat{\mathbf{p}}^*, \hat{\mathbf{p}}^*)$  (since the solution  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s)$  exists and is unique). Since the interval extensions  $\Gamma_j(m_1, \cdot)$  and  $\Lambda_j(m_1, \cdot)$  are continuous for all  $j = 1, \dots, n_x$ , an application of Lemma 5.5 (treating  $x_j$  and  $s$  as degenerate intervals) gives  $\mathbf{f}$  continuous on  $\hat{X}(1, \hat{P})^2 \times \hat{P}^2 \times \check{I}_1$  and bounded by a constant  $M$  there. With  $\mathbf{z}(\mathbf{y}^*, s)$  as the unique trajectory, we can then apply [6, Theorem 4.3] to obtain  $\mathbf{z}(s) \rightarrow (\hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s), \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s))$  uniformly over  $\check{I}_1$  as  $\hat{\mathbf{p}}^L \rightarrow \hat{\mathbf{p}}^*$  and  $\hat{\mathbf{p}}^U \rightarrow \hat{\mathbf{p}}^*$  (or  $\hat{P}_k \rightarrow \hat{P}^*$ ). Consider now the transition at  $\check{\tau}_1$ . Clearly, state continuity preserves the form of (5.9),

$$\mathbf{v}' = \mathcal{F}(m_1, \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, s), \hat{\mathbf{p}}^*, s) = \mathbf{w}', \quad \mathbf{v}(\check{\sigma}_2) = \hat{\mathbf{x}}(1, \hat{\mathbf{p}}^*, \check{\sigma}_2) = \mathbf{w}(\check{\sigma}_2).$$

We can then perform the same analysis to obtain uniform convergence of the bounds over the second subepoch. By induction on all subepochs, we obtain uniform convergence over the first epoch. Consider now the transition to the second epoch at  $\hat{\tau}_1$ . With the degenerate interval vector  $\hat{P}^*$  as argument, it is clear from the preceding analysis that the natural interval extension (5.5) becomes  $Y(\hat{\sigma}_2) = [\hat{\mathbf{x}}(2, \hat{\mathbf{p}}^*, \hat{\sigma}_2), \hat{\mathbf{x}}(2, \hat{\mathbf{p}}^*, \hat{\sigma}_2)]$ . The same analysis made for  $\check{I}_1$  in  $\hat{I}_1$  thus applies, and (5.9) becomes

$$\mathbf{v}' = \mathcal{F}(m_2, \hat{\mathbf{x}}(2, \hat{\mathbf{p}}^*, s), \hat{\mathbf{p}}^*, s) = \mathbf{w}', \quad \mathbf{v}(\hat{\sigma}_2) = \hat{\mathbf{x}}(2, \hat{\mathbf{p}}^*, \hat{\sigma}_2) = \mathbf{w}(\hat{\sigma}_2).$$

The analysis carried out for the first epoch is thus valid for the second. By induction on all epochs, we have the desired result.  $\square$

*Remark 5.7.* Note that the requirement of  $\Gamma_j(m_i, \cdot)$  and  $\Lambda_j(m_i, \cdot)$  to be inclusion monotonic and continuous for all  $j = 1, \dots, n_x$  and  $i \in \mathcal{E}$  is not a strong one. For linear time invariant hybrid systems, it is automatically satisfied since (4.3) becomes a rational function (in the sense of interval analysis [24]). For time varying hybrid systems, inclusion monotonic interval extensions of the time varying matrices in (4.3) can be constructed for most functions in computing provided that no division by an interval containing zero occurs (see, e.g., [24, Chapters 3 and 4] and [26, Chapter

1]). In addition, since the functions of interest are continuous in each subepoch, the constructed interval extensions will also be continuous (see, e.g., [2, Theorem 4 and Corollary 5]).

Next, we will show how convex and concave relaxations for the states of the transformed hybrid system can be constructed.

**DEFINITION 5.8.** *Consider the functions  $f : Z \times \hat{P} \times S \rightarrow \mathbb{R}$  and  $\mathbf{z} : S \rightarrow Z$ , where  $Z \subset \mathbb{R}^{n_x}$ ,  $\hat{P} \subset \mathbb{R}^{n_p+n_e}$ ,  $S \subset \mathbb{R}$ , and  $f(\cdot, \underline{s})$  is differentiable on some suitable open set containing  $Z \times \hat{P}$  for each  $\underline{s} \in S$ . Define the function  $\mathcal{L}_f|_{\zeta^*(s)} : Z \times \hat{P} \times S \rightarrow \mathbb{R}$  to be a linearization of  $f$  at the point  $\zeta^*(s) = (\mathbf{z}^*(s), \hat{\mathbf{p}}^*)$ , where  $(\mathbf{z}^*(s), \hat{\mathbf{p}}^*) \in Z \times \hat{P}$ , and given by the following:*

$$\begin{aligned} \mathcal{L}_f|_{\zeta^*(s)}(\mathbf{z}, \hat{\mathbf{p}}, s) = & f(\mathbf{z}^*, \hat{\mathbf{p}}^*, s) + \sum_{k=1}^{n_x} \frac{\partial f}{\partial z_k} \bigg|_{(\zeta^*(s), s)} (z_k(s) - z_k^*(s)) \\ & + \sum_{k=1}^{n_p} \frac{\partial f}{\partial \hat{p}_k} \bigg|_{(\zeta^*(s), s)} (\hat{p}_k - \hat{p}_k^*). \end{aligned}$$

**THEOREM 5.9.** *For  $i \in \mathcal{E}$  and  $j = 1, \dots, n_x$ , define the functions  $u_j(m_i, \cdot, \underline{s}) : \hat{X}(i, s; \hat{P}) \times \hat{P} \rightarrow \mathbb{R}$  and  $o_j(m_i, \cdot, \underline{s}) : \hat{X}(i, s; \hat{P}) \times \hat{P} \rightarrow \mathbb{R}$  for each fixed  $\underline{s} \in \hat{I}_i$ . Let the following conditions be satisfied for all  $i \in \mathcal{E}$ ,  $j = 1, \dots, n_x$  and each fixed  $\underline{s} \in \hat{I}_i$ :*

- E1.  $u_j(m_i, \cdot, \underline{s})$  is a convex underestimator and  $o_j(m_i, \cdot, \underline{s})$  is a concave overestimator for  $\mathcal{F}_j(m_i, \cdot, \underline{s})$  on  $\hat{X}(i, \underline{s}; \hat{P}) \times \hat{P}$ .
- E2.  $u_j(m_i, \cdot, \underline{s})$  and  $o_j(m_i, \cdot, \underline{s})$  are differentiable on some suitable open set containing  $\hat{X}(i, s; \hat{P}) \times \hat{P}$  along some reference trajectory  $\zeta^*(s) = (\mathbf{z}^*(s), \hat{\mathbf{p}}^*) \in \hat{X}(i, s; \hat{P}) \times \hat{P}$ .

Therefore the following ODE system can be constructed:

$$\begin{aligned} c'_j = h_{c,j}(m_i, \mathbf{c}, \mathbf{C}, \hat{\mathbf{p}}, s) &= \inf_{\substack{\mathbf{z} \in \mathcal{C}(\hat{\mathbf{p}}, s) \\ z_j = c_j(s)}} \mathcal{L}_{u_j(m_i, \cdot)}(\mathbf{z}, \hat{\mathbf{p}}, s) \big|_{(\zeta^*(s), s)}, \quad s \in (i-1, i], \\ C'_j = h_{C,j}(m_i, \mathbf{c}, \mathbf{C}, \hat{\mathbf{p}}, s) &= \sup_{\substack{\mathbf{z} \in \mathcal{C}(\hat{\mathbf{p}}, s) \\ z_j = C_j(s)}} \mathcal{L}_{o_j(m_i, \cdot)}(\mathbf{z}, \hat{\mathbf{p}}, s) \big|_{(\zeta^*(s), s)}, \quad s \in (i-1, i], \end{aligned}$$

with initial conditions for each epoch  $\hat{I}_i$  given by

$$(5.10) \quad \mathbf{c}(\hat{\mathbf{p}}, 0) = \mathbf{C}(\hat{\mathbf{p}}, 0) = \mathbf{E}(0)\mathbf{p} + \mathbf{J}(0)\boldsymbol{\delta} + \mathbf{k}(0),$$

$$(5.11) \quad [\mathbf{c}(\hat{\mathbf{p}}, \hat{\sigma}_{l+1}), \mathbf{C}(\hat{\mathbf{p}}, \hat{\sigma}_{l+1})] = \mathbf{D}(l)[\mathbf{c}(\hat{\mathbf{p}}, \hat{\tau}_l), \mathbf{C}(\hat{\mathbf{p}}, \hat{\tau}_l)] + \mathbf{E}(l)\mathbf{p} + \mathbf{J}(l)\boldsymbol{\delta} + \mathbf{k}(l),$$

for  $l = 1, \dots, n_e - 1$ , where  $\mathcal{C}(\hat{\mathbf{p}}, s) = \{\mathbf{z} \mid \mathbf{c}(\hat{\mathbf{p}}, s) \leq \mathbf{z} \leq \mathbf{C}(\hat{\mathbf{p}}, s)\}$ . Then, for each fixed  $\underline{s} \in \hat{I}_i$ ,  $\mathbf{c}(\cdot, \underline{s})$  is a convex underestimator and  $\mathbf{C}(\cdot, \underline{s})$  is a concave overestimator for  $\hat{\mathbf{x}}(i, \cdot, \underline{s})$  on  $\hat{P}$  for all  $i \in \mathcal{E}$ .

*Proof.* We proceed as in the proof of Theorem 5.2 by subdividing the epochs into contiguous subepochs. Consider now the first subepoch  $\tilde{I}_1$ . The initial condition given by (5.10) is clearly affine on  $\hat{P}$  and satisfies  $\mathbf{c}(\hat{\mathbf{p}}, 0) \leq \hat{\mathbf{x}}(1, \hat{\mathbf{p}}, 0) \leq \mathbf{C}(\hat{\mathbf{p}}, 0)$ . The conditions for [30, Theorem 6.16] are thus satisfied, and applying said theorem,  $\mathbf{c}(\cdot, \underline{s})$  is a convex underestimator and  $\mathbf{C}(\cdot, \underline{s})$  is a concave overestimator for  $\hat{\mathbf{x}}(1, \cdot, \underline{s})$  for

each fixed  $\underline{s} \in \hat{I}_1$ . At the transition  $\tilde{\tau}_1$ , state continuity of the hybrid system gives  $\hat{x}(1, \hat{\mathbf{p}}, \tilde{\sigma}_2) = \hat{x}(1, \hat{\mathbf{p}}, \tilde{\tau}_1)$ , which implies that

$$\mathbf{c}(\hat{\mathbf{p}}, \tilde{\sigma}_2) = \mathbf{c}(\hat{\mathbf{p}}, \tilde{\tau}_1) \leq \hat{x}(1, \hat{\mathbf{p}}, \tilde{\sigma}_2) \leq \mathbf{C}(\hat{\mathbf{p}}, \tilde{\tau}_1) = \mathbf{C}(\hat{\mathbf{p}}, \tilde{\sigma}_2) \quad \forall \hat{\mathbf{p}} \in \hat{P}.$$

From [30, Theorem 6.16], we know that  $\mathbf{c}(\cdot, \tilde{\sigma}_2)$  and  $\mathbf{C}(\cdot, \tilde{\sigma}_2)$  are affine in  $\hat{\mathbf{p}}$ . The conditions for [30, Theorem 6.16] are thus satisfied for the second subepoch. By induction on all subepochs, the desired result holds for each fixed  $\underline{s} \in \hat{I}_1$ . Consider now the second epoch  $\hat{I}_2$ . From (5.11),

$$\mathbf{c}(\hat{\mathbf{p}}, \hat{\sigma}_2) \leq \hat{\mathbf{x}}(2, \hat{\mathbf{p}}, \hat{\sigma}_2) \leq \mathbf{C}(\hat{\mathbf{p}}, \hat{\sigma}_2) \quad \forall \hat{\mathbf{p}} \in \hat{P},$$

where  $\mathbf{c}(\cdot, \hat{\sigma}_2)$  and  $\mathbf{C}(\cdot, \hat{\sigma}_2)$  are clearly affine in  $\hat{\mathbf{p}}$ . The conditions for [30, Theorem 6.16] are thus satisfied for the second epoch, and by induction on all epochs, we obtain the desired result.  $\square$

Note that the infima and suprema in Theorem 5.9 are attained at the vertices of the set  $\mathcal{C}(\hat{\mathbf{p}}, s)$  due to the properties of the linearizations, and are easily computed; see [30, Theorem 6.16]. The next theorem demonstrates the convergence properties of the convex relaxations constructed using the relaxation techniques presented in this section.

**THEOREM 5.10.** *Consider the following convex relaxation of (4.4):*

$$(5.12) \quad \hat{U}(\hat{\mathbf{p}}; \hat{P}) = \sum_{i=1}^{n_e} \left\{ \sum_{j=1}^{n_{\phi i}} \hat{\psi}_{ij} \left( \mathbf{c}(\hat{\mathbf{p}}, \hat{\alpha}_{ij}), \mathbf{C}(\hat{\mathbf{p}}, \hat{\alpha}_{ij}), \hat{\mathbf{p}}; \hat{X}(i, \hat{\alpha}_{ij}; \hat{P}), \hat{P} \right) + \int_{i-1}^i \hat{u}_i \left( \mathbf{c}, \mathbf{C}, \hat{\mathbf{p}}, s; \hat{X}(i, s; \hat{P}), \hat{P} \right) v(\delta, s) \, ds \right\},$$

where  $\hat{\psi}_{ij}$  and  $\hat{u}_i$  are constructed using any relaxation technique that possesses a consistent bounding operation [17, Definition IV.4, p. 128], the convex and concave relaxations for the state and derivatives are constructed using Theorem 5.9, and the estimation of the state bounds constructed using Corollary 5.4. If the interval vector  $\hat{P}_k$  in any partition on  $\hat{P}$  approaches degeneracy  $\hat{P}^*$ , then the lower bound on this partition  $\hat{U}(\hat{\mathbf{p}}; \hat{P}_k)$  converges pointwise to the objective function value  $\hat{F}(\hat{\mathbf{p}})$  in this same partition.

*Proof.* Choose any arbitrary partition and any fixed  $\underline{s}$  in any epoch  $\hat{I}_i$ . From Theorem 5.6, as  $\hat{P}_k \rightarrow \hat{P}^*$ , the interval vector  $\hat{X}(i, \underline{s}; \hat{P}_k)_k$  approaches the degenerate value of  $\hat{\mathbf{x}}^*(i, \hat{\mathbf{p}}^*, \underline{s})$ . To be valid, the convex and concave overestimators ( $u_j(m_i, \cdot)$  and  $o_j(m_i, \cdot)$ ) from Theorem 5.9 must themselves possess a consistent bounding operation for all  $j = 1, \dots, n_x$ . Hence, as  $\hat{X}(i, \underline{s}; \hat{P}_k)_k \times \hat{P}_k$  shrinks to degeneracy,  $u_j(m_i, \cdot, \underline{s}) \uparrow \mathcal{F}_j(m_i, \cdot, \underline{s})$  and  $o_j(m_i, \cdot, \underline{s}) \downarrow \mathcal{F}_j(m_i, \cdot, \underline{s})$  for  $j = 1, \dots, n_x$ . The right-hand sides of the equations defining  $c'_i$  and  $C'_i$  are linearizations on  $u_j(m_i, \cdot)$  and  $o_j(m_i, \cdot)$ , respectively. Since  $u_j(m_i, \cdot, \underline{s})$  and  $o_j(m_i, \cdot, \underline{s})$  are each approaching  $\mathcal{F}_j(m_i, \cdot, \underline{s})$ ,  $h_{c,j}(m_i, \cdot, \underline{s}) \uparrow \mathcal{F}_j(m_i, \cdot, \underline{s})$ , and  $h_{C,j}(m_i, \cdot, \underline{s}) \downarrow \mathcal{F}_j(m_i, \cdot, \underline{s})$  because the linearization approaches the value of the function it approximates at the point of linearization. Thus, as  $k \rightarrow \infty$ ,

$$(5.13) \quad \hat{\psi}_{ij} \left( \mathbf{c}(\hat{\mathbf{p}}, \hat{\alpha}_{ij}), \mathbf{C}(\hat{\mathbf{p}}, \hat{\alpha}_{ij}), \hat{\mathbf{p}}; \hat{X}(i, \hat{\alpha}_{ij}; \hat{P}_k), \hat{P} \right) \uparrow \phi_{ij} \left( \hat{\mathbf{x}}(i, \hat{\mathbf{p}}, \hat{\alpha}_{ij}), \hat{\mathbf{p}} \right)$$

for all  $j = 1, \dots, n_{\phi i}$  and  $\hat{u}_i(\mathbf{c}, \mathbf{C}, \hat{\mathbf{p}}, \underline{s}; \hat{X}(i, \underline{s}; \hat{P}_k), \hat{P}_k) \uparrow f_i(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \underline{s})$  for all  $\underline{s} \in \hat{I}_i$ , where the convergence arises because the convex relaxations  $\hat{\psi}_{ij}$  and  $\hat{u}_i$  possess consistent

bounding operations as  $\hat{P}_k$  approaches degeneracy. Because  $\underline{s}$  is fixed arbitrarily, the convergence for the integrand is true for all  $\underline{s} \in \hat{I}_i$ . An application of the monotone convergence theorem [27, Theorem 11.28] for the integral term then gives

$$(5.14) \quad \lim_{k \rightarrow \infty} \int_{i-1}^i \hat{u}_i(\mathbf{c}, \mathbf{C}, \hat{\mathbf{p}}, s; \hat{X}(i, s; \hat{P}_k), \hat{P}_k) v(\boldsymbol{\delta}, s) \, ds = \int_{i-1}^i f_i(\hat{\mathbf{x}}, \hat{\mathbf{p}}^*, s) v(\boldsymbol{\delta}, s) \, ds.$$

Since the partition and epoch was arbitrarily chosen, (5.13) and (5.14) imply that  $\lim_{k \rightarrow \infty} \hat{U}(\hat{\mathbf{p}}; \hat{P}_k) = \hat{F}(\hat{\mathbf{p}}^*)$ .  $\square$

**6. Results and discussion.** In the first example, we walk through a procedure for bounding the solution of the transformed hybrid system using Corollary 5.4. In the second example, we present an interesting problem from chemical reaction engineering that can be posed in the form of Problem 3.1 and solved using the techniques developed in this article.

*Example 6.1.* Consider the following linear hybrid system:

$$\begin{aligned} \text{Mode 1: } & \begin{cases} \dot{x}_1 &= 0.5x_1 + x_2 + p_1, \\ \dot{x}_2 &= -x_1 + x_2 + p_1, \end{cases} \\ \text{Mode 2: } & \begin{cases} \dot{x}_1 &= x_1 + x_2 - p_2, \\ \dot{x}_2 &= -x_1 + p_2, \end{cases} \end{aligned}$$

$\mathcal{E} = \{1, 2\}$ ,  $T_\mu = 1, 2$ ,  $P \equiv [0, 1]^2$ ,  $\Delta \equiv [0, 1]^2$ , and we have state continuity as the transition functions with initial condition  $\mathbf{x}(1, \mathbf{p}, \boldsymbol{\delta}, 0) = (0, 2)$ .

Applying the CPET, we obtain the following transformed nonlinear hybrid system:

$$\begin{aligned} \text{Mode 1: } & \begin{cases} \hat{x}'_1 &= v(0.5\hat{x}_1 + \hat{x}_2 + p_1), \\ \hat{x}'_2 &= v(-\hat{x}_1 + \hat{x}_2 + p_1), \end{cases} \\ \text{Mode 2: } & \begin{cases} \hat{x}'_1 &= v(\hat{x}_1 + \hat{x}_2 - p_2), \\ \hat{x}'_2 &= v(-\hat{x}_1 + p_2), \end{cases} \end{aligned}$$

$\mathcal{E} = \{1, 2\}$ ,  $T_\mu = 1, 2$ ,  $\hat{P} \equiv [0, 1]^2 \times [0, 1]^2$ , and we have state continuity as the transition functions with initial condition  $\hat{\mathbf{x}}(1, \hat{\mathbf{p}}, 0) = (0, 2)$ .

We now apply Corollary 5.4 to obtain bounds for the transformed hybrid system. For this example, we assume that we do not have additional bounding information, and so the user defined set  $\hat{\mathcal{X}}(i, \hat{\mathbf{p}}, s)$  is set to  $\mathbb{R}^2$ . From (5.4),  $Y(0) = [\mathbf{k}(0), \mathbf{k}(0)]$ , where  $\mathbf{k}(0) = (0, 2)$  since  $\mathbf{E}(0)$  and  $\mathbf{J}(0)$  are zero matrices. Expanding the right-hand sides of the nonlinear ODEs in epoch  $\hat{I}_1$  (note that  $v = \delta_1$  for epoch  $\hat{I}_1$ ), and taking the natural interval extensions, we obtain the following forms for  $\Gamma(1, \cdot)$  and  $\Lambda(1, \cdot)$  in Corollary 5.4:

$$\begin{aligned} \Gamma_1(1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_1^L, \delta_1^U] \cdot (0.5v_1(s) + [v_2(s), w_2(s)] + [p_1^L, p_1^U]), \\ \Gamma_2(1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_1^L, \delta_1^U] \cdot (-[v_1(s), w_1(s)] + v_2(s) + [p_1^L, p_1^U]), \\ \Lambda_1(1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_1^L, \delta_1^U] \cdot (0.5w_1(s) + [v_2(s), w_2(s)] + [p_1^L, p_1^U]), \\ \Lambda_2(1, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_1^L, \delta_1^U] \cdot (-[v_1(s), w_1(s)] + w_2(s) + [p_1^L, p_1^U]). \end{aligned}$$

At the transition, state continuity gives  $Y(1) = [\mathbf{v}(1), \mathbf{w}(1)]$  for (5.5) since  $\mathbf{D}(1)$  is the identity matrix,  $\mathbf{E}(1)$  and  $\mathbf{J}(1)$  are zero matrices, and  $\mathbf{k}(1)$  is a zero vector. Similarly, expanding and taking the natural interval extensions of right-hand sides of the nonlinear ODEs in epoch  $\hat{I}_2$  (and noting that  $v = \delta_2$  for epoch  $\hat{I}_2$ ), we obtain

$$\begin{aligned}\Gamma_1(2, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_2^L, \delta_2^U] \cdot (v_1(s) + [v_2(s), w_2(s)] - [p_2^L, p_2^U]), \\ \Gamma_2(2, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_2^L, \delta_2^U] \cdot (-[v_1(s), w_1(s)] + [p_2^L, p_2^U]), \\ \Lambda_1(2, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_2^L, \delta_2^U] \cdot (w_1(s) + [v_2(s), w_2(s)] - [p_2^L, p_2^U]), \\ \Lambda_2(2, \mathbf{v}, \mathbf{w}, \hat{\mathbf{p}}^L, \hat{\mathbf{p}}^U, s) &= [\delta_2^L, \delta_2^U] \cdot (-[v_1(s), w_1(s)] + [p_2^L, p_2^U]).\end{aligned}$$

Applying Corollary 5.4, the following ODE system bounds the transformed hybrid system,  $\mathbf{v}(s) \leq \mathbf{x}(s) \leq \mathbf{w}(s)$ :

$$\text{Epoch } \hat{I}_1: \left\{ \begin{array}{l} v_1'(s) = \min \left( \delta_1^L(0.5v_1(s) + v_2(s) + p_1^L), \delta_1^L(0.5v_1(s) + w_2(s) + p_1^U), \right. \\ \quad \left. \delta_1^U(0.5v_1(s) + v_2(s) + p_1^L), \delta_1^U(0.5v_1(s) + w_2(s) + p_1^U) \right), \\ v_2'(s) = \min \left( \delta_1^L(-w_1(s) + v_2(s) + p_1^L), \delta_1^L(-v_1(s) + v_2(s) + p_1^U), \right. \\ \quad \left. \delta_1^U(-w_1(s) + v_2(s) + p_1^L), \delta_1^U(-v_1(s) + v_2(s) + p_1^U) \right), \\ w_1'(s) = \max \left( \delta_1^L(0.5w_1(s) + v_2(s) + p_1^L), \delta_1^L(0.5w_1(s) + w_2(s) + p_1^U), \right. \\ \quad \left. \delta_1^U(0.5w_1(s) + v_2(s) + p_1^L), \delta_1^U(0.5w_1(s) + w_2(s) + p_1^U) \right), \\ w_2'(s) = \max \left( \delta_1^L(-w_1(s) + w_2(s) + p_1^L), \delta_1^L(-v_1(s) + w_2(s) + p_1^U), \right. \\ \quad \left. \delta_1^U(-w_1(s) + w_2(s) + p_1^L), \delta_1^U(-v_1(s) + w_2(s) + p_1^U) \right), \end{array} \right.$$

with initial conditions  $\mathbf{v}(0) = \mathbf{w}(0) = (0, 2)$ , and

$$\text{Epoch } \hat{I}_2: \left\{ \begin{array}{l} v_1'(s) = \min \left( \delta_2^L(v_1(s) + v_2(s) - p_2^U), \delta_2^L(v_1(s) + w_2(s) - p_2^L), \right. \\ \quad \left. \delta_2^U(v_1(s) + v_2(s) - p_2^U), \delta_2^U(v_1(s) + w_2(s) - p_2^L) \right), \\ v_2'(s) = \min \left( \delta_2^L(-w_1(s) + p_2^L), \delta_2^L(-v_1(s) + p_2^U), \right. \\ \quad \left. \delta_2^U(-w_1(s) + p_2^L), \delta_2^U(-v_1(s) + p_2^U) \right), \\ w_1'(s) = \max \left( \delta_2^L(w_1(s) + v_2(s) - p_2^U), \delta_2^L(w_1(s) + w_2(s) - p_2^L), \right. \\ \quad \left. \delta_2^U(w_1(s) + v_2(s) - p_2^U), \delta_2^U(w_1(s) + w_2(s) - p_2^L) \right), \\ w_2'(s) = \max \left( \delta_2^L(-w_1(s) + p_2^L), \delta_2^L(-v_1(s) + p_2^U), \right. \\ \quad \left. \delta_2^U(-w_1(s) + p_2^L), \delta_2^U(-v_1(s) + p_2^U) \right), \end{array} \right.$$

with initial conditions  $\mathbf{v}(1) = \mathbf{v}^*$ ,  $\mathbf{w}(1) = \mathbf{w}^*$ , where  $\mathbf{v}^*$  and  $\mathbf{w}^*$  are the final values of the bounding ODE system for the first epoch at  $s = 1$ .

This bounding ODE system can be integrated efficiently with an integrator that supports the rigorous detection of events, due to the min and max functions in the right-hand sides. The following results are obtained using the JACOBIAN Dynamic Modeling and Optimization Software [22] release 2.1A with the default options.

Figure 6.1 shows the bounding trajectories obtained for  $P \equiv [0, 1]^2$  and  $\Delta \equiv [0, 1]^2$ . To illustrate that the trajectories actually bound the transformed system, 20

FIG. 6.1. Bounding trajectories (dashed lines) and random state trajectories (solid lines) with  $P \equiv [0, 1]^2$  and  $\Delta \equiv [0, 1]^2$  for (a)  $\hat{x}_1(s)$  and (b)  $\hat{x}_2(s)$ .

FIG. 6.2. Bounding trajectories (dashed lines) and random state trajectories (solid lines) with  $P \equiv [0, 0.25] \times [0.25, 0.5]$  and  $\Delta \equiv [0.5, 0.75] \times [0.75, 1]$  for (a)  $\hat{x}_1(s)$  and (b)  $\hat{x}_2(s)$ .

random points were generated in  $P \times \Delta$ , and the state trajectories of the transformed system were plotted alongside the bounding trajectories. It can be seen that the bounds indeed enclose the solution of the transformed system, as should be expected with the application of Corollary 5.4. Figure 6.2 shows what happens when the bounds on  $(\mathbf{p}, \delta)$  are changed to  $P \equiv [0, 0.25] \times [0.25, 0.5]$ ,  $\Delta \equiv [0.5, 0.75] \times [0.75, 1]$ . Again, 20 random points of  $(\mathbf{p}, \delta)$  were generated in  $P \times \Delta$  and plotted together with the new bounding trajectories. Besides bounding the state trajectories, it can be seen from the scales of the vertical axis that the bounding trajectories are closer together than those in Figure 6.1. Finally, Figure 6.3 illustrates the convergence of the bounding trajectories in Theorem 5.6 as  $P$  and  $\Delta$  become degenerate. Note that for the degenerate intervals  $P \equiv \Delta \equiv [0.5, 0.5]^2$  (case (f)), the bounding trajectories become the same, i.e.,  $\mathbf{v}(s) = \mathbf{w}(s) = \hat{\mathbf{x}}(i, 0.5, 0.5, s)$ .

*Example 6.2.* Consider an isothermal plug flow reactor (PFR) operating at steady state with three sections into which the catalyst can be loaded. It has been determined that catalysts 1, 2, and 3 will be loaded in that order into the reactor. The optimization decision variables are the lengths of the catalyst sections. Table 6.1 lists the associated rate constants of the following kinetic model:

$$\begin{aligned} \dot{x}_1(t) &= -(k_1 + k_2)x_1, & \dot{x}_2(t) &= k_2x_1, & \dot{x}_3(t) &= k_1x_1 - (k_3 + k_4)x_3, \\ \dot{x}_4(t) &= k_4x_3, & \dot{x}_5(t) &= k_3x_3, \end{aligned}$$

FIG. 6.3. Bounding trajectories with  $P \equiv \Delta \equiv Z^2$ , where  $Z$  is given by (a)  $[0, 1]$ , (b)  $[0.1, 0.9]$ , (c)  $[0.2, 0.8]$ , (d)  $[0.3, 0.7]$ , (e)  $[0.4, 0.6]$ , and (f)  $[0.5, 0.5]$ . The plot on the left is for  $\hat{x}_1(s)$ , while the one on the right is for  $\hat{x}_2(s)$ .

TABLE 6.1  
Rate constants for each catalyst.

Catalyst	$k_1$	$k_2$	$k_3$	$k_4$
1	2.098	1.317	0.021	0.033
2	29.53	110.2	0.295	0.079
3	182.6	2325	1.826	0.143

where  $x_i$  represents the molar concentration of component  $i$  ( $\text{mol m}^{-3}$ ), and  $k_j$  represents the rate constant of reaction  $j$  ( $\text{min}^{-1}$ ). The PFR has a uniform cross-sectional area of  $0.05 \text{ m}^2$ , and a constant volumetric flow rate of  $0.05 \text{ m}^3 \text{ min}^{-1}$ . In this example, the independent variable  $t$  is the distance,  $l$ , along the reactor. The objective function,  $F$  (\$k), is to maximize the profit from the process, which is the value of the product  $x_5$  minus the treatment costs of the byproducts  $x_2$  and  $x_4$ ,

$$\min_{\delta \in \Delta} -F = 0.01x_2(1) + 0.1x_4(1) - x_5(1).$$

After applying the CPET, the transformed problem is given by

$$\min_{\delta \in \Delta} 0.01\hat{x}_2(\delta, 3) + 0.1\hat{x}_4(\delta, 3) - \hat{x}_5(\delta, 3),$$

subject to the point constraint,

$$(6.1) \quad \delta_1 + \delta_2 + \delta_3 = 1,$$

where  $\hat{\mathbf{x}}(i, \delta, s)$  is given by the solution of the following CPET hybrid system:

$$\text{Mode } m: \left\{ \begin{array}{l} \hat{x}'_1(s) = v \left( -(k_1(i) + k_2(i))\hat{x}_1 \right), \\ \hat{x}'_2(s) = v \left( k_2(i)\hat{x}_1 \right), \\ \hat{x}'_3(s) = v \left( k_1(i)\hat{x}_1 - (k_3(i) + k_4(i))\hat{x}_3 \right), \\ \hat{x}'_4(s) = v \left( k_4(i)\hat{x}_3 \right), \\ \hat{x}'_5(s) = v \left( k_3(i)\hat{x}_3 \right) \end{array} \right\} m = 1, 2, 3,$$

$\mathcal{E} = \{1, 2, 3\}$ ,  $T_\mu = 1, 2, 3$ ,  $\hat{P} \equiv \Delta \equiv [0, 1]^3$ , and we have state continuity as the transition functions with initial condition  $\hat{\mathbf{x}}(1, \boldsymbol{\delta}, 0) = (1000, 0, 0, 0, 0)$ .

The convex relaxations for this example are constructed directly using Theorem 5.9 as the original objective function comprises an affine function of the state variables at the final time. Since the right-hand sides of the nonlinear hybrid system exhibit a bilinear structure, the convex and concave relaxations in Theorem 5.9 can be calculated from the convex envelope of a bilinear term [9]. However, since the convex envelope is composed of two intersecting hyperplanes and thus not continuously differentiable everywhere, there is no guarantee that condition E2 will be satisfied for a particular choice of a reference trajectory. Fortunately, it is clear that the condition can be relaxed to accommodate the nonsmoothness in the intersection of the two hyperplanes by constructing the linearizations using any subgradient at the point of nonsmoothness. In practice, we have implemented a heuristic that either chooses one or the other hyperplane (which are both valid convex relaxations and supply valid subgradients), where the effects of any possible chattering in the numerical integration can be mitigated; see [30, Chapter 7].

It is also possible to remove a degree of freedom,  $\delta_3$ , from the optimization problem by substituting it with  $1 - \delta_1 - \delta_2$  and eliminating the constraint (6.1) from the problem. This is attractive because it reduces the dimension of the parameter space in the branch-and-bound framework. The numerical implementation used for solving this problem is as follows: the convex relaxations constructed using Theorem 5.9 and the natural interval extensions of Corollary 5.4 were generated automatically based on an operator-overloading approach using C++; the local dynamic optimizations were performed using the code DYNO [11], which implements the control parametrization approach; and the branch-and-bound framework used was libBandB 3.2 [31]. Using a Pentium 4 2.6 GHz machine with 1 GB RAM running SuSE Linux 9.2, a reference trajectory of  $(\hat{\mathbf{x}}, \boldsymbol{\delta})_k = (\hat{\mathbf{x}}^L, \boldsymbol{\delta}^L)_k$ , a relative tolerance for libBandB of  $10^{-3}$ , relative and absolute tolerances for the numerical integrator in DYNO of  $10^{-7}$ , and an optimality tolerance for the NLP solver in DYNO of  $10^{-5}$ , an optimal solution value of 314.2 was obtained, at the point  $\boldsymbol{\delta}^* = (0.3626, 0.0196, 0.6178)$ . There was a total of 483 nodes visited in the branch-and-bound tree, with a total CPU time of 560 seconds. For comparison, if the problem only involved two sections with the mode sequence  $T_\mu = 1, 3$ , then an optimal solution value of 296.9 was obtained, at the point  $\boldsymbol{\delta}^* = (0.4181, 0.5819)$ , with a total of 17 nodes and a total CPU time of 8 seconds.

**7. Conclusion.** The global optimization problem with continuous time linear hybrid systems embedded has been considered where the embedded systems have varying time transitions. Sufficient conditions have been proposed for these problems to be smooth in the control parametrization framework. The CPET has been utilized to transform the problem into a global optimization problem with nonlinear hybrid systems embedded where the transitions are now fixed in time. A method of constructing convex relaxations for the transformed problem has been developed that is shown to be convergent within a branch-and-bound framework.

# THE MAX-PLUS FINITE ELEMENT METHOD FOR SOLVING DETERMINISTIC OPTIMAL CONTROL PROBLEMS: BASIC PROPERTIES AND CONVERGENCE ANALYSIS\*

MARIANNE AKIAN<sup>†</sup>, STÉPHANE GAUBERT<sup>†</sup>, AND ASMA LAKHOUE<sup>‡</sup>

**Abstract.** We introduce a max-plus analogue of the Petrov–Galerkin finite element method to solve finite horizon deterministic optimal control problems. The method relies on a max-plus variational formulation. We show that the error in the sup-norm can be bounded from the difference between the value function and its projections on max-plus and min-plus semimodules when the max-plus analogue of the stiffness matrix is exactly known. In general, the stiffness matrix must be approximated: this requires approximating the operation of the Lax–Oleinik semigroup on finite elements. We consider two approximations relying on the Hamiltonian. We derive a convergence result, in arbitrary dimension, showing that for a class of problems, the error estimate is of order  $\delta + \Delta x(\delta)^{-1}$  or  $\sqrt{\delta} + \Delta x(\delta)^{-1}$ , depending on the choice of the approximation, where  $\delta$  and  $\Delta x$  are, respectively, the time and space discretization steps. We compare our method with another max-plus based discretization method previously introduced by Fleming and McEneaney. We give numerical examples in dimensions 1 and 2.

**Key words.** max-plus algebra, tropical semiring, Hamilton–Jacobi equation, weak formulation, residuation, projection, idempotent semimodules, finite element method

**DOI.** 10.1137/060655286

**1. Introduction.** We consider the following optimal control problem:

$$(1a) \quad \text{maximize} \quad \int_0^T \ell(\mathbf{x}(s), \mathbf{u}(s)) ds + \phi(\mathbf{x}(T))$$

over the set of trajectories  $(\mathbf{x}(\cdot), \mathbf{u}(\cdot))$  satisfying

$$(1b) \quad \dot{\mathbf{x}}(s) = f(\mathbf{x}(s), \mathbf{u}(s)), \quad \mathbf{x}(s) \in X, \quad \mathbf{u}(s) \in U$$

for all  $0 \leq s \leq T$  and

$$(1c) \quad \mathbf{x}(0) = x.$$

Here the *state space*  $X$  is a subset of  $\mathbb{R}^n$ , the set of *control values*  $U$  is a subset of  $\mathbb{R}^m$ , the *horizon*  $T > 0$  and the *initial condition*  $x \in X$  are given, and we assume that the map  $\mathbf{u}(\cdot)$  is measurable and that the map  $\mathbf{x}(\cdot)$  is absolutely continuous. We also assume that the *instantaneous reward* or *Lagrangian*  $\ell : X \times U \rightarrow \mathbb{R}$  and the *dynamics*  $f : X \times U \rightarrow \mathbb{R}^n$  are sufficiently regular maps and that the *terminal reward*  $\phi$  is a map  $X \rightarrow \mathbb{R} \cup \{-\infty\}$ .

We are interested in the numerical computation of the *value function*  $v$  which associates with any  $(x, t) \in X \times [0, T]$  the supremum  $v(x, t)$  of  $\int_0^t \ell(\mathbf{x}(s), \mathbf{u}(s)) ds + \phi(\mathbf{x}(t))$ , under the constraints (1b), for  $0 \leq s \leq t$  and (1c). It is known that, under certain regularity assumptions,  $v$  is solution of the Hamilton–Jacobi equation

$$(2a) \quad -\frac{\partial v}{\partial t} + H\left(x, \frac{\partial v}{\partial x}\right) = 0, \quad (x, t) \in X \times (0, T],$$

with initial condition

$$(2b) \quad v(x, 0) = \phi(x), \quad x \in X,$$

where  $H(x, p) = \sup_{u \in U} \ell(x, u) + p \cdot f(x, u)$  is the *Hamiltonian* of the problem (see, for instance, [Lio82], [FS93], [Bar94]).

Several techniques have been proposed in the literature to solve this problem. We mention, for example, finite difference schemes and the method of the vanishing viscosity [CL84], the antidiffusive schemes for advection [BZ07], the finite element approach [GR85a], [GR85b] (in the case of the stopping time problem), the so-called discrete dynamic programming method or semi-Lagrangian method [CD83], [CDI84], [Fal87a], [Fal87b], [FF94], [FG99], [CFF04], and the Markov chain approximations [BD99]. Other schemes have been obtained by integration from the essentially nonoscillatory schemes for the hyperbolic conservation laws (see, for instance, [OS91]). Recently, max-plus methods have been proposed to solve first-order Hamilton–Jacobi equations [McE06], [MH98], [MH99], [FM00], [McE02], [McE03], [CM04], [McE04].

Recall that the *max-plus semiring*,  $\mathbb{R}_{\max}$ , is the set  $\mathbb{R} \cup \{-\infty\}$ , equipped with the addition  $a \oplus b = \max(a, b)$  and the multiplication  $a \otimes b = a + b$ . In what follows, let  $S^t$  denote the *evolution semigroup* of (2), or Lax–Oleinik semigroup, which associates with any map  $\phi$  the function  $v^t := v(\cdot, t)$ , where  $v$  is the value function of the optimal control problem (1). Maslov [Mas73] observed that the semigroup  $S^t$  is *max-plus linear*, meaning that for all maps  $f, g$  from  $X$  to  $\mathbb{R}_{\max}$ , and for all  $\lambda \in \mathbb{R}_{\max}$ , we have

$$S^t(f \oplus g) = S^t f \oplus S^t g,$$

$$S^t(\lambda f) = \lambda S^t f,$$

where  $f \oplus g$  denotes the map  $x \mapsto f(x) \oplus g(x)$ , and  $\lambda f$  denotes the map  $x \mapsto \lambda \otimes f(x)$ . Linear operators over max-plus-type semirings have been widely studied; see, for instance, [CG79], [MS92], [BCOQ92], [KM97], [GM01], [Fat].

In [FM00], Fleming and McEneaney introduced a max-plus-based discretization method to solve a subclass of Hamilton–Jacobi equations (with a Lagrangian  $\ell$  quadratic with respect to  $u$  and a dynamics  $f$  affine with respect to  $u$ ). They use the max-plus linearity of the semigroup  $S^t$  to approximate the value function  $v^t$  by a function  $v_h^t$  of the form

$$(3) \quad v_h^t = \sup_{1 \leq i \leq p} \{\lambda_i^t + w_i\},$$

where  $\{w_i\}_{1 \leq i \leq p}$  is a given family of functions (a max-plus “basis”) and  $\{\lambda_i^t\}_{1 \leq i \leq p}$  is a family of scalars (the “coefficients” of  $v_h^t$  on the max-plus “basis”), which must be determined. They proposed a discretization scheme in which  $\lambda^t$  is computed inductively by applying a max-plus linear operator to  $\lambda^{t-\delta}$ , where  $\delta$  is the time discretization step. Thus, their scheme can be interpreted as the dynamic programming equation of a discrete control problem.

In this paper, we introduce a max-plus analogue of the finite element method, the “MFEM,” to solve the deterministic optimal control problem (1). We still look for an approximation  $v_h^t$  of the form (3). However, to determine the “coefficients”  $\lambda_i^t$ , we use a max-plus analogue of the notion of variational formulation, which originates from the notion of generalized solution of Hamilton–Jacobi equations of Maslov and Kolokoltsov [KM88], [KM97, Section 3.2]. We choose a family  $\{z_j\}_{1 \leq j \leq q}$  of test functions and define  $v_h^t$  inductively to be the maximal function of the form (3) satisfying

$$(4) \quad \langle v_h^t \mid z_j \rangle \leq \langle S^\delta v_h^{t-\delta} \mid z_j \rangle \quad \forall 1 \leq j \leq q,$$

where  $\langle \cdot \mid \cdot \rangle$  denotes the max-plus scalar product (see section 3 for details). We show that the corresponding vector of coefficients  $\lambda^t$  can be obtained by applying to  $\lambda^{t-\delta}$  a nonlinear operator, which can be interpreted as the dynamic programming operator of a deterministic zero-sum two player game, with finite action and state spaces. Indeed,

$$\lambda_i^t = \min_{1 \leq j \leq q} \left( - (M_h)_{ji} + \max_{1 \leq k \leq p} ((K_h)_{jk} + \lambda_k^{t-\delta}) \right),$$

where the matrices  $M_h$  and  $K_h$  are max-plus analogues of the mass and stiffness matrices, respectively (see (20) and (21) for the definitions of  $M_h$  and  $K_h$  and Remark 5 for details on the game interpretation).

One interest of the MFEM is to provide, as in the case of the classical finite element method, a systematic way to compute error estimates, which can be interpreted geometrically as “projection” errors. In the classical finite element method, orthogonal projectors with respect to the energy norm must be used. In the max-plus case, projectors on semimodules must be used (note that these projectors minimize an additive analogue of Hilbert projective metric [CGQ04]).

We shall see that when the value function is nonsmooth, the space of test functions must be different from the space in which the solution is represented, so that our discretization is indeed a max-plus analogue of the Petrov–Galerkin finite element method. A convenient choice of finite elements and test functions includes quadratic functions (also considered by Fleming and McEneaney [FM00]) and norm-like functions; see section 5.

In the MFEM, we need to compute the value of the max-plus scalar product  $\langle z \mid S^\delta w \rangle$  for each finite element  $w$  and each test function  $z$ . In some special cases,  $\langle z \mid S^\delta w \rangle$  can be computed analytically. In general, we need to approximate this scalar product. Here we consider the approximation  $S^\delta w(x) = w(x) + \delta H(x, \nabla w(x))$ , for  $x \in X$ , which is also used in [MH99]. Our main result, Theorem 22, provides for the resulting discretization of the value function an error estimate of order  $\delta + \Delta x(\delta)^{-1}$ , where  $\Delta x$  is the “space discretization step,” under classical assumptions on the control problem and the additional assumption that the value function  $v^t$  is semiconvex for all  $t \in [0, T]$ . This is comparable with the order obtained in the simplest discrete dynamic programming method; see [CDI84], [Fal87a], [Fal87b], [CDF89]. To avoid solving a difficult (nonconvex) optimization problem, we propose a further approximation of the max-plus scalar product  $\langle z \mid S^\delta w \rangle$ , for which we obtain an error estimate of order  $\sqrt{\delta} + \Delta x(\delta)^{-1}$ , which is yet comparable to the order of the existing discretization methods [CDI84], [Fal87a], [Fal87b], [CDF89], [CL84].

Note that the discretization grid need not be regular: in Theorem 22,  $\Delta x$  is defined for an arbitrary grid in terms of Voronoi tessellations.

The paper is organized as follows. In section 2, we recall some basic tools and notions: residuation, semimodules, and projection. In section 3, we present the formulation of the max-plus finite element method. In section 4, we compare our method

with the method proposed by Fleming and McEneaney in [FM00]. In section 5, we state an error estimate and give the main convergence theorem. Finally, in section 6, we illustrate the method by numerical examples in dimensions 1 and 2. Preliminary results of this paper appeared in [AGL04].

**2. Preliminaries on residuation and projections over semimodules.** In this section we recall some classical residuation results (see, for example, [DJLC53], [Bir67], [BJ72], [BCOQ92]) and their application to linear maps on idempotent semimodules (see [LMS01], [CGQ04]). We also review some results of [CGQ96], [CGQ04] concerning projectors over semimodules. Other results on projectors over semimodules appeared in [Gon96], [GM01].

**2.1. Residuation, semimodules, and linear maps.** If  $(S, \leq)$  and  $(T, \leq)$  are (partially) ordered sets, we say that a map  $f : S \rightarrow T$  is *monotone* if  $s \leq s' \implies f(s) \leq f(s')$ . We say that  $f$  is *residuated* if there exists a map  $f^\sharp : T \rightarrow S$  such that

$$(5) \quad f(s) \leq t \iff s \leq f^\sharp(t).$$

The map  $f$  is residuated if and only if, for all  $t \in T$ ,  $\{s \in S \mid f(s) \leq t\}$  has a maximum element in  $S$ . Then

$$f^\sharp(t) = \max\{s \in S \mid f(s) \leq t\} \quad \forall t \in T.$$

Moreover, in that case, we have

$$(6) \quad f \circ f^\sharp \circ f = f \quad \text{and} \quad f^\sharp \circ f \circ f^\sharp = f^\sharp.$$

In what follows, we shall consider situations where  $S$  (or  $T$ ) is equipped with an idempotent monoid law  $\oplus$  (*idempotent* means that  $a \oplus a = a$ ). Then the *natural order* on  $S$  is defined by  $a \leq b \iff a \oplus b = b$ . The supremum law for the natural order, which is denoted by  $\bigvee$ , coincides with  $\oplus$ , and the infimum law for the natural order, when it exists, will be denoted by  $\bigwedge$ . We say that  $S$  is *complete* as a naturally ordered set if any subset of  $S$  has a least upper bound for the natural order. When  $S$  and  $T$  are complete, it is known that the map  $f : S \rightarrow T$  is residuated if and only if it preserves arbitrary sups [BCOQ92, Theorem 4.50].

If  $\mathcal{K}$  is an idempotent semiring, i.e., a semiring whose addition is idempotent, we say that the semiring  $\mathcal{K}$  is *complete* if it is complete as a naturally ordered set and if the left and right multiplications  $\mathcal{K} \rightarrow \mathcal{K}$ ,  $x \mapsto ax$ , and  $x \mapsto xa$  are residuated. Here and in what follows, semiring multiplication is denoted by concatenation.

The max-plus semiring,  $\mathbb{R}_{\max} = (\mathbb{R} \cup \{-\infty\}, \max, +)$ , defined in the introduction, is an idempotent semiring. It is not complete, but it can be embedded into the complete idempotent semiring  $\overline{\mathbb{R}}_{\max}$  obtained by adjoining  $+\infty$  to  $\mathbb{R}_{\max}$ , with the convention that  $-\infty$  is absorbing for the multiplication. The map  $x \mapsto -x$  from  $\overline{\mathbb{R}}$  to itself yields an isomorphism from  $\overline{\mathbb{R}}_{\max}$  to the complete idempotent semiring  $\overline{\mathbb{R}}_{\min}$ , obtained by replacing  $\max$  by  $\min$  and by exchanging the roles of  $+\infty$  and  $-\infty$  in the definition of  $\overline{\mathbb{R}}_{\max}$ .

Semimodules over semirings are defined like modules over rings, mutatis mutandis; see [LMS01], [CGQ04]. When  $\mathcal{K}$  is a complete idempotent semiring, we say that a (right)  $\mathcal{K}$ -semimodule  $\mathcal{X}$  is *complete* if it is complete as an idempotent monoid and if, for all  $u \in \mathcal{X}$  and  $\lambda \in \mathcal{K}$ , the right and left multiplications,  $R_\lambda^\mathcal{X} : \mathcal{X} \rightarrow \mathcal{X}$ ,  $v \mapsto v\lambda$  and  $L_u^\mathcal{X} : \mathcal{K} \rightarrow \mathcal{X}$ ,  $\mu \mapsto u\mu$ , are residuated (for the natural order). In a complete semimodule  $\mathcal{X}$ , we define, for all  $u, v \in \mathcal{X}$ ,

$$u \setminus v \stackrel{\text{def}}{=} (L_u^\mathcal{X})^\sharp(v) = \max\{\lambda \in \mathcal{K} \mid u\lambda \leq v\}.$$

We shall use *semimodules of functions*: when  $X$  is a set and  $\mathcal{K}$  is a complete idempotent semiring, the set of functions  $\mathcal{K}^X$  is a complete  $\mathcal{K}$ -semimodule for the componentwise addition  $(u, v) \mapsto u \oplus v$  (defined by  $(u \oplus v)(x) = u(x) \oplus v(x)$ ) and the componentwise multiplication  $(\lambda, u) \mapsto u\lambda$  (defined by  $(u\lambda)(x) = u(x)\lambda$ ). In fact, we shall need only the case where  $\mathcal{K} = \overline{\mathbb{R}}_{\max}$  or  $\overline{\mathbb{R}}_{\min}$  when applying these notions. In particular, when  $\mathcal{K} = \overline{\mathbb{R}}_{\max}$ ,  $\mathcal{K}^X$  is the set of functions from  $X$  to  $\mathbb{R} \cup \{\pm\infty\}$ , equipped with the pointwise supremum and with the action  $(\lambda, u) \mapsto \lambda + u$ , where  $(\lambda + u)(x) = \lambda + u(x)$ , for all  $x \in X$ , again with the convention that  $(-\infty) + \infty = -\infty$ .

If  $\mathcal{K}$  is an idempotent semiring, and if  $\mathcal{X}$  and  $\mathcal{Y}$  are  $\mathcal{K}$ -semimodules, we say that a map  $A : \mathcal{X} \rightarrow \mathcal{Y}$  is *linear*, or is a *linear operator*, if for all  $u, v \in \mathcal{X}$  and  $\lambda, \mu \in \mathcal{K}$ ,  $A(u\lambda \oplus v\mu) = A(u)\lambda \oplus A(v)\mu$ . Then, as in classical algebra, we use the notation  $Au$  instead of  $A(u)$ . When  $A$  is residuated and  $v \in \mathcal{Y}$ , we use the notation  $A \setminus v$  or  $A^\sharp v$  instead of  $A^\sharp(v)$ . So

$$A \setminus v = A^\sharp v = \max\{w \in \mathcal{X} \mid Aw \leq v\}.$$

We denote by  $L(\mathcal{X}, \mathcal{Y})$  the set of linear operators from  $\mathcal{X}$  to  $\mathcal{Y}$  which is a complete semimodule as soon as  $\mathcal{K}$  and  $\mathcal{Y}$  are complete. If  $\mathcal{K}$  is a complete idempotent semiring, if  $\mathcal{X}, \mathcal{Y}, \mathcal{Z}$  are complete  $\mathcal{K}$ -semimodules, and if  $A \in L(\mathcal{X}, \mathcal{Y})$  is residuated, then the map  $L_A : L(\mathcal{Z}, \mathcal{X}) \rightarrow L(\mathcal{Z}, \mathcal{Y})$ ,  $B \mapsto A \circ B$  is residuated and we set  $A \setminus C := (L_A)^\sharp(C)$  for all  $C \in L(\mathcal{Z}, \mathcal{Y})$ .

If  $X$  and  $Y$  are two sets,  $\mathcal{K}$  is a complete idempotent semiring, and  $a \in \mathcal{K}^{X \times Y}$ , we construct the linear operator  $A$  from  $\mathcal{K}^Y$  to  $\mathcal{K}^X$  which associates with any  $u \in \mathcal{K}^Y$  the function  $Au \in \mathcal{K}^X$  such that  $Au(x) = \bigvee_{y \in Y} a(x, y)u(y)$ . We say that  $A$  is the *kernel operator* with *kernel* or *matrix*  $a$ . We shall often use the same notation  $A$  for the operator and the kernel (so  $A(x, y) = a(x, y)$ ). In particular, when  $\mathcal{K} = \overline{\mathbb{R}}_{\max}$ , we have

$$(7) \quad Au(x) = \sup_{y \in Y} (A(x, y) + u(y)).$$

As is well known (see, for instance, [BCOQ92]), the kernel operator  $A$  is residuated, and

$$(A \setminus v)(y) = \bigwedge_{x \in X} A(x, y) \setminus v(x).$$

When  $\mathcal{K} = \overline{\mathbb{R}}_{\max}$ ,  $A \setminus v$  is given by

$$(8) \quad (A \setminus v)(y) = \inf_{x \in X} (-A(x, y) + v(x)) = [-A^*(-v)](y),$$

where  $A^*$  denotes the *transposed operator*  $\mathcal{K}^X \rightarrow \mathcal{K}^Y$ , which is associated with the kernel  $A^*(y, x) = A(x, y)$ . (In (8), we use the convention that  $+\infty$  is absorbing for addition.)

**2.2. Projectors on semimodules.** Let  $\mathcal{K}$  be a complete idempotent semiring and  $\mathcal{V}$  denote a *complete subsemimodule* of a complete semimodule  $\mathcal{X}$ , i.e., a subset of  $\mathcal{X}$  that is stable by arbitrary sups and by the action of scalars. We call *canonical projector* on  $\mathcal{V}$  the map

$$(9) \quad P_{\mathcal{V}} : \mathcal{X} \rightarrow \mathcal{X}, \quad u \mapsto P_{\mathcal{V}}(u) = \max\{v \in \mathcal{V} \mid v \leq u\}.$$

Let  $W$  denote a *generating family* of a complete subsemimodule  $\mathcal{V}$ , which means that any element  $v \in \mathcal{V}$  can be written as  $v = \bigvee \{w\lambda_w \mid w \in W\}$  for some  $\lambda_w \in \mathcal{K}$ . It is known that

$$P_{\mathcal{V}}(u) = \bigvee_{w \in W} w(w \setminus u)$$

(see, for instance, [CGQ04]). If  $B : \mathcal{U} \rightarrow \mathcal{X}$  is a residuated linear operator, then when  $\mathcal{U}$  and  $\mathcal{X}$  are complete semimodules over  $\mathcal{K}$ , the image  $\text{im } B$  of  $B$  is a complete subsemimodule of  $\mathcal{X}$ , and

$$(10) \quad P_{\text{im } B} = B \circ B^{\sharp}.$$

The max-plus finite element methods relies on the notion of projection on an image, parallel to a kernel, which was introduced by Cohen, Gaubert, and Quadrat in [CGQ96]. The following theorem, of which Corollary 3 below is an immediate corollary, is a variation on the results of [CGQ96, Section 6].

**THEOREM 1** (projection on an image parallel to a kernel). *Let  $\mathcal{U}$ ,  $\mathcal{X}$ , and  $\mathcal{Y}$  be complete semimodules over  $\mathcal{K}$ . Let  $B : \mathcal{U} \rightarrow \mathcal{X}$  and  $C : \mathcal{X} \rightarrow \mathcal{Y}$  be two residuated linear operators over  $\mathcal{K}$ . Let  $\Pi_B^C = B \circ (C \circ B)^{\sharp} \circ C$ . We have  $\Pi_B^C = \Pi_B \circ \Pi^C$ , where  $\Pi_B = B \circ B^{\sharp}$  and  $\Pi^C = C^{\sharp} \circ C$ . Moreover,  $\Pi_B^C$  is a projector, meaning that  $(\Pi_B^C)^2 = \Pi_B^C$ , and for all  $x \in \mathcal{X}$*

$$\Pi_B^C(x) = \max\{y \in \text{im } B \mid Cy \leq Cx\}.$$

*Proof.* The first assertion follows from  $(C \circ B)^{\sharp} = B^{\sharp} \circ C^{\sharp}$ . For the second assertion, we have

$$\begin{aligned} (\Pi_B^C)^2 &= (B \circ (C \circ B)^{\sharp} \circ C) \circ (B \circ (C \circ B)^{\sharp} \circ C) \\ &= B \circ (C \circ B)^{\sharp} \circ C \quad (\text{using (6)}) \\ &= \Pi_B^C. \end{aligned}$$

To prove the last assertion, we use that  $\Pi_B = P_{\text{im } B}$  and (5), and we deduce that

$$\begin{aligned} \Pi_B^C(x) &= P_{\text{im } B} \circ C^{\sharp} \circ C(x) \\ &= \max\{y \in \text{im } B \mid y \leq C^{\sharp} \circ C(x)\} \\ &= \max\{y \in \text{im } B \mid Cy \leq Cx\}. \quad \square \end{aligned}$$

The results of [CGQ96] characterize the existence and uniqueness, for all  $x \in X$ , of  $y \in \text{im } B$  such that  $Cy = Cx$ . In that case,  $y = \Pi_B^C(x)$ .

When  $\mathcal{K} = \overline{\mathbb{R}}_{\max}$ , and  $C : \overline{\mathbb{R}}_{\max}^X \rightarrow \overline{\mathbb{R}}_{\max}^Y$  is a kernel operator,  $\Pi^C = C^{\sharp} \circ C$  has an interpretation similar to (10):

$$\Pi^C(v) = C^{\sharp} \circ C(v) = -P_{\text{im } C^*}(-v) = P^{-\text{im } C^*}(v),$$

where  $-\text{im } C^*$  is thought of as a  $\overline{\mathbb{R}}_{\min}$ -subsemimodule of  $\overline{\mathbb{R}}_{\min}^X$  and  $P^{\mathcal{V}}$  denotes the projector on a  $\overline{\mathbb{R}}_{\min}$ -semimodule  $\mathcal{V}$ , so that

$$P^{-\text{im } C^*}(v) = \min\{w \in -\text{im } C^* \mid w \geq v\},$$

FIG. 1. Example illustrating max-plus and min-plus projectors.

where  $\leq$  denotes here the usual order on  $\overline{\mathbb{R}}^X$ . When  $B : \overline{\mathbb{R}}_{\max}^U \rightarrow \overline{\mathbb{R}}_{\max}^X$  is also a kernel operator, we have

$$\Pi_B^C = P_{\text{im } B} \circ P^{-\text{im } C^*}.$$

This factorization will be instrumental in the geometrical interpretation of the finite element algorithm.

*Example 2.* We take  $U = \{1, \dots, p\}$ ,  $X = \mathbb{R}$ , and  $Y = \{1, \dots, q\}$ . Consider the linear operators  $B : \overline{\mathbb{R}}_{\max}^U \rightarrow \overline{\mathbb{R}}_{\max}^X$  and  $C : \overline{\mathbb{R}}_{\max}^X \rightarrow \overline{\mathbb{R}}_{\max}^Y$  such that

$$B\lambda(x) = \sup_{1 \leq i \leq p} \left\{ -\frac{c}{2}(x - \hat{x}_i)^2 + \lambda_i \right\} \quad \forall \lambda \in \overline{\mathbb{R}}_{\max}^U$$

and

$$(Cf)_i = \sup_{x \in \mathbb{R}} \{-a|x - \hat{y}_i| + f(x)\} \quad \forall f \in \overline{\mathbb{R}}_{\max}^X.$$

The image of  $B$ ,  $\text{im } B$ , is the semimodule generated in the max-plus sense by the functions  $x \mapsto -\frac{c}{2}(x - \hat{x}_i)^2$  for  $i = 1, \dots, p$ . We have

$$C^\sharp \mu(x) = \inf_{1 \leq i \leq q} \{a|x - \hat{y}_i| + \mu_i\} \quad \forall \mu \in \overline{\mathbb{R}}_{\max}^Y,$$

and the image of  $C^\sharp$ , which coincides with  $-\text{im } C^*$ , is the semimodule generated in the min-plus sense by the functions  $x \mapsto a|x - \hat{y}_i|$  for  $i = 1, \dots, q$ .

In Figure 1(a), we represent a function  $v$  and its projection  $P^{-\text{im } C^*}(v)$  (in bold). In Figure 1(b), we represent (in bold) the projection  $P_{\text{im } B}(P^{-\text{im } C^*}(v)) = \Pi_B^C(v)$ .

### 3. The max-plus finite element method.

**3.1. Max-plus variational formulation.** We now describe the max-plus finite element method to solve problem (1). Let  $\mathcal{V}$  be a complete semimodule of functions from  $X$  to  $\overline{\mathbb{R}}_{\max}$ . Let  $S^t : \mathcal{V} \rightarrow \mathcal{V}$  and  $v^t$  be defined as in the introduction. Using the semigroup property  $S^{t+t'} = S^t \circ S^{t'}$ , for  $t, t' > 0$ , we get

$$(11) \quad v^{t+\delta} = S^\delta v^t, \quad t = 0, \delta, \dots, T - \delta,$$

with  $v^0 = \phi$  and  $\delta = \frac{T}{N}$  for some positive integer  $N$ . Let  $\mathcal{W} \subset \mathcal{V}$  be a complete  $\overline{\mathbb{R}}_{\max}$ -semimodule of functions from  $X$  to  $\overline{\mathbb{R}}_{\max}$  such that for all  $t \geq 0$ ,  $v^t \in \mathcal{W}$ . We choose a “dual” semimodule  $\mathcal{Z}$  of “test functions” from  $X$  to  $\overline{\mathbb{R}}_{\max}$ . Recall that the max-plus scalar product is defined by

$$\langle u | v \rangle = \sup_{x \in X} u(x) + v(x)$$

for all functions  $u, v : X \rightarrow \overline{\mathbb{R}}_{\max}$ . We replace (11) by

$$(12) \quad \langle z | v^{t+\delta} \rangle = \langle z | S^\delta v^t \rangle \quad \forall z \in \mathcal{Z}$$

for  $t = 0, \delta, \dots, T - \delta$ , with  $v^\delta, \dots, v^T \in \mathcal{W}$ . Equation (12) can be seen as the analogue of a *variational* or *weak formulation*. Kolokoltsov and Maslov used this formulation in [KM88] and [KM97, Section 3.2] to define a notion of generalized solution of Hamilton–Jacobi equations. We use it in the next section to construct an approximation algorithm for the value function, which is obtained by taking for  $\mathcal{W}$  and  $\mathcal{Z}$  finitely generated semimodules (whereas in the work of Kolokoltsov and Maslov, the semimodules  $\mathcal{W}$  and  $\mathcal{Z}$  are “infinite dimensional” spaces consisting, for instance, of continuous or convex functions).

**3.2. Ideal max-plus finite element method.** We consider a semimodule  $\mathcal{W}_h \subset \mathcal{W}$  generated by the family  $\{w_i\}_{1 \leq i \leq p}$ . We call *finite elements* the functions  $w_i$ . We approximate  $v^t$  by  $v_h^t \in \mathcal{W}_h$ , that is,

$$v^t \simeq v_h^t = \bigvee_{1 \leq i \leq p} w_i \lambda_i^t,$$

where  $\lambda_i^t \in \overline{\mathbb{R}}_{\max}$ . We also consider a semimodule  $\mathcal{Z}_h \subset \mathcal{Z}$  with generating family  $\{z_j\}_{1 \leq j \leq q}$ . The functions  $z_1, \dots, z_q$  will act as test functions. We replace (12) by

$$(13) \quad \langle z | v_h^{t+\delta} \rangle = \langle z | S^\delta v_h^t \rangle \quad \forall z \in \mathcal{Z}_h$$

for  $t = 0, \delta, \dots, T - \delta$ , with  $v_h^\delta, \dots, v_h^T \in \mathcal{W}_h$ . The function  $v_h^0$  is a given approximation of  $\phi$ . Since  $\mathcal{Z}_h$  is generated by  $z_1, \dots, z_q$ , (13) is equivalent to

$$(14) \quad \langle z_j | v_h^{t+\delta} \rangle = \langle z_j | S^\delta v_h^t \rangle \quad \forall 1 \leq j \leq q$$

for  $t = 0, \delta, \dots, T - \delta$ , with  $v_h^t \in \mathcal{W}_h$ ,  $t = 0, \delta, \dots, T$ .

Since (14) need not have a solution, we look for its maximal subsolution, i.e., the maximal solution  $v_h^{t+\delta} \in \mathcal{W}_h$  of

$$(15a) \quad \langle z_j | v_h^{t+\delta} \rangle \leq \langle z_j | S^\delta v_h^t \rangle \quad \forall 1 \leq j \leq q.$$

We also take for the approximate value function  $v_h^0$  at time 0 the maximal solution  $v_h^0 \in \mathcal{W}_h$  of

$$(15b) \quad v_h^0 \leq v^0.$$

Let us denote by  $W_h$  the max-plus linear operator from  $\overline{\mathbb{R}}_{\max}^p$  to  $\mathcal{W}$  with matrix  $W_h = \text{col}(w_i)_{1 \leq i \leq p}$  and by  $Z_h^*$  the max-plus linear operator from  $\mathcal{W}$  to  $\overline{\mathbb{R}}_{\max}^q$  whose transposed matrix is  $Z_h = \text{col}(z_j)_{1 \leq j \leq q}$ . This means that  $W_h \lambda = \bigvee_{1 \leq i \leq p} w_i \lambda_i$  for all  $\lambda = (\lambda_i)_{i=1, \dots, p} \in \overline{\mathbb{R}}_{\max}^p$ , and  $(Z_h^* v)_j = \langle z_j | v \rangle$  for all  $v \in \mathcal{W}$  and  $j = 1, \dots, q$ .

Applying Theorem 1 to  $B = W_h$  and  $C = Z_h^*$  and noting that  $\mathcal{W}_h = \text{im } W_h$ , we get the following corollary.

COROLLARY 3. *The maximal solution  $v_h^{t+\delta} \in \mathcal{W}_h$  of (15a) is given by  $v_h^{t+\delta} = S_h^\delta(v_h^t)$ , where*

$$S_h^\delta = \Pi_{W_h}^{Z_h^*} \circ S^\delta.$$

Note that  $\Pi_{W_h}^{Z_h^*} = P_{\mathcal{W}_h} \circ P^{-Z_h}$ . The following proposition provides a recursive equation verified by the vector of coordinates of  $v_h^t$ .

PROPOSITION 4. *Let  $v_h^t \in \mathcal{W}_h$  be the maximal solution of (15) for  $t = 0, \delta, \dots, T$ . Then, for every  $t = 0, \delta, \dots, T$ , there exists a maximal  $\lambda^t \in \mathbb{R}_{\max}^p$  such that  $v_h^t = W_h \lambda^t$ ,  $t = 0, \delta, \dots, T$ , which can be determined recursively from*

$$(16a) \quad \lambda^{t+\delta} = (Z_h^* W_h) \setminus (Z_h^* S^\delta W_h \lambda^t)$$

for  $t = 0, \dots, T - \delta$  with the initial condition

$$(16b) \quad \lambda^0 = W_h \setminus \phi.$$

*Proof.* Since  $v_h^t \in \mathcal{W}_h$ ,  $v_h^t = W_h \lambda^t$  for some  $\lambda^t \in \overline{\mathbb{R}}_{\max}^p$  and the maximal  $\lambda^t$  satisfying this condition is  $\lambda^t = W_h^\#(v_h^t)$  for all  $t = 0, \delta, \dots, T$ . Since  $v_h^0$  is the maximal solution of (15b), then by (9) and (10),  $v_h^0 = P_{\mathcal{W}_h}(\phi) = W_h \circ W_h^\#(\phi)$ , and hence  $\lambda^0 = W_h^\# \circ W_h \circ W_h^\#(\phi) = W_h^\#(\phi)$ . Let  $t = \delta, \dots, T$ . Using Corollary 3, Theorem 1, (6), and the property that  $(f \circ g)^\# = g^\# \circ f^\#$  for all residuated maps  $f$  and  $g$ , we get

$$\begin{aligned} \lambda^{t+\delta} &= W_h^\# \circ \Pi_{W_h}^{Z_h^*} \circ S^\delta(W_h \lambda^t) \\ &= W_h^\# \circ W_h \circ W_h^\# \circ (Z_h^*)^\# \circ Z_h^* \circ S^\delta(W_h \lambda^t) \\ &= W_h^\# \circ (Z_h^*)^\# \circ Z_h^* \circ S^\delta(W_h \lambda^t) \\ &= (Z_h^* W_h)^\#(Z_h^* S^\delta W_h \lambda^t), \end{aligned}$$

which yields (16a).  $\square$

For  $1 \leq i \leq p$  and  $1 \leq j \leq q$ , we define

$$(17) \quad (M_h)_{ji} = \langle z_j \mid w_i \rangle,$$

$$(18) \quad (K_h)_{ji} = \langle z_j \mid S^\delta w_i \rangle,$$

$$(19) \quad = \langle (S^*)^\delta z_j \mid w_i \rangle,$$

where  $S^*$  is the *transposed semigroup* of  $S$ , which is the evolution semigroup associated with the optimal control problem (1) in which the sign of the dynamics is changed. The matrices  $M_h$  and  $K_h$ , which represent, respectively, the max-plus linear operators  $Z_h^* W_h$  and  $Z_h^* S^\delta W_h$ , may be thought of as the max-plus analogues of the mass and stiffness matrices, respectively.

The ideal max-plus finite element method (Algorithm 1) is the algorithm derived from Proposition 4, assuming that the “mass” and “stiffness” matrices  $M_h$  and  $K_h$  are computed by oracles. We shall discuss in the next section the approximations of the matrices  $M_h$  and  $K_h$ , which will allow us to implement the method.

**Algorithm 1** IDEAL MAX-PLUS FINITE ELEMENT METHOD

- 
- 1: Choose the finite elements  $(w_i)_{1 \leq i \leq p}$  and  $(z_j)_{1 \leq j \leq q}$ . Choose the time discretization step  $\delta = \frac{T}{N}$ .
  - 2: Compute the matrix  $M_h$  and the matrix  $K_h$  defined in (17), (18), or (19).
  - 3: Compute  $\lambda^0 = W_h \setminus \phi$  and  $v_h^0 = W_h \lambda^0$ .
  - 4: For  $t = \delta, 2\delta, \dots, T$ , compute  $\lambda^t = M_h \setminus (K_h \lambda^{t-\delta})$  and  $v_h^t = W_h \lambda^t$ .
- 

For the convenience of the reader, we rewrite the elements of Algorithm 1 with the usual notation:

$$(20) \quad (M_h)_{ji} = \sup_{x \in X} (z_j(x) + w_i(x)),$$

$$(21) \quad \begin{aligned} (K_h)_{ji} &= \sup_{x \in X} (z_j(x) + S^\delta w_i(x)), \\ &= \sup_{x \in X} (w_i(x) + (S^*)^\delta z_j(x)). \end{aligned}$$

Equation (16a) may be written explicitly, using (7) and (8), for  $1 \leq i \leq p$ , as

$$\lambda_i^{t+\delta} = \min_{1 \leq j \leq q} \left( - (M_h)_{ji} + \max_{1 \leq k \leq p} ((K_h)_{jk} + \lambda_k^t) \right).$$

*Remark 5.* This recursion may be interpreted as the dynamic programming equation of a deterministic zero-sum two player game, with finite action and state spaces. Here the state space of the game is the finite set  $\{1, \dots, p\}$  (to each finite element corresponds a state of the game). To each test function corresponds one possible action  $j \in \{1, \dots, q\}$  of the first player, and to each finite element corresponds one possible action  $k \in \{1, \dots, p\}$  of the second player. Given these actions at the state  $i \in \{1, \dots, p\}$ , the cost of the first player, which is the reward of the second player, is  $-(M_h)_{ji} + (K_h)_{jk}$ .

Finally, we have, for all  $x \in X$  and  $t = 0, \delta, \dots, T - \delta$ ,

$$v_h^{t+\delta} = \sup_{1 \leq i \leq p} (w_i(x) + \lambda_i^{t+\delta}).$$

*Remark 6.* Since  $v_h^t \in \mathcal{W}_h$  for all  $t = 0, \dots, T$ , the dynamics of  $v_h^t$  can be written as a function of the matrices  $M_h$  and  $K_h$ :

$$(22) \quad v_h^{t+\delta} = W_h \circ M_h^\# \circ K_h \circ W_h^\#(v_h^t).$$

**3.3. Effective max-plus finite element method.** In the ideal max-plus finite element method, we assume that the matrices  $M_h$  and  $K_h$  are exactly known. We shall see in section 5 that for natural choices of finite elements and test functions, computing every entry of the matrix  $M_h$  is equivalent to solving a maximization problem in which the objective function is concave and the feasible set is convex. This problem can be approached by standard optimization methods. When the domain  $X$  has a “simple” shape, for instance when  $X$  is a hypercube, the entries of the matrix  $M_h$  can even be computed analytically. Hence, the assumption that  $M_h$  is accurately known is not a restrictive one. The same is not true for  $K_h$ . Indeed, evaluating every scalar product  $\langle z \mid S^\delta w \rangle$  leads to a new optimal control problem since

$$\langle z \mid S^\delta w \rangle = \max z(\mathbf{x}(0)) + \int_0^\delta \ell(\mathbf{x}(s), \mathbf{u}(s)) ds + w(\mathbf{x}(\delta)),$$

where the maximum is taken over the set of trajectories  $(\mathbf{x}(\cdot), \mathbf{u}(\cdot))$  satisfying (1b). This problem is simpler to approximate than problem (1), because the horizon  $\delta$  is small, and the functions  $z$  and  $w$  have a regularizing effect.

We call “the effective max-plus finite element method” the method obtained by replacing in Algorithm 1 the matrix  $K_h$  by an approximation.

We first discuss the approximation of  $S^\delta w$  for every finite element  $w$ . The Hamilton–Jacobi equation (2a) suggests approximating  $S^\delta w$  by the function  $[S^\delta w]_H$  such that

$$(23) \quad [S^\delta w]_H(x) = w(x) + \delta H(x, \nabla w(x)) \quad \forall x \in X.$$

Let  $[S^\delta W_h]_H$  denote the max-plus linear operator from  $\mathbb{R}_{\max}^p$  to  $\mathcal{W}$  with matrix  $[S^\delta W_h]_H = \text{col}([S^\delta w_i]_H)_{1 \leq i \leq p}$ , which means that

$$[S^\delta W_h]_H \lambda = \bigvee_{1 \leq i \leq p} [S^\delta w_i]_H \lambda_i$$

for all  $\lambda = (\lambda_i)_{1 \leq i \leq p} \in \mathbb{R}_{\max}^p$ . The above approximation of  $S^\delta w$  yields an approximation of the matrix  $K_h$  by the matrix  $K_{H,h} := Z_h^* [S^\delta W_h]_H$ , whose entries are given, for  $1 \leq i \leq p$  and  $1 \leq j \leq q$ , by

$$(24) \quad (K_{H,h})_{ji} = \sup_{x \in X} \left( z_j(x) + w_i(x) + \delta H(x, \nabla w_i(x)) \right).$$

Let  $A_{ji}$  denote the set where the optimum of the function  $x \mapsto z_j(x) + w_i(x)$  is attained. Computing  $(K_{H,h})_{ji}$  in (24) requires solving an optimization problem, which is nothing but a perturbation of the optimization problem associated with the computation of  $(M_h)_{ji}$ . We may exploit this observation by approximating  $K_{H,h}$  by the matrix  $\tilde{K}_{H,h}$  with entries

$$(25) \quad \begin{aligned} (\tilde{K}_{H,h})_{ji} &= \sup_{x \in A_{ji}} \left( z_j(x) + w_i(x) \right) + \sup_{x \in A_{ji}} H(x, \nabla w_i(x)) \\ &= \langle z_j \mid w_i \rangle + \delta \sup_{x \in A_{ji}} H(x, \nabla w_i(x)) \end{aligned}$$

for  $1 \leq i \leq p$  and  $1 \leq j \leq q$ . When  $A_{ji}$  has only one element, (25) yields a convenient approximation of  $K_h$ .

Of course,  $w_i$  must be differentiable for the approximation (23) to make sense. When  $w_i$  is nondifferentiable, but  $z_j$  is differentiable, the dual formula (19) suggests approximating  $(K_h)_{ji}$  by

$$\sup_{x \in X} \left( z_j(x) + \delta H(x, -\nabla z_j(x)) + w_i(x) \right).$$

We may also use the dual formula of (25), where  $\nabla w_i(x)$  is replaced by  $-\nabla z_j(x)$ .

We shall see in section 5 that the approximation (24) yields an error of order  $O(\delta^2)$  and that the further approximation (25) yields a more important error of order  $O(\delta^{\frac{3}{2}})$ .

**4. Comparison with the method of Fleming and McEneaney.** Fleming and McEneaney proposed a max-plus based method [FM00], which also uses a space  $\mathcal{W}_h$  generated by finite elements,  $w_1, \dots, w_p$ , together with the linear formulation (11).

Their method approaches the value function at time  $t$ ,  $v^t$ , by  $W_h\mu^t$ , where  $W_h = \text{col}(w_i)_{1 \leq i \leq p}$  as above, and  $\mu^t$  is defined inductively by

$$(26a) \quad \mu^0 = W_h \setminus \phi,$$

$$(26b) \quad \mu^{t+\delta} = (W_h \setminus (S^\delta W_h)) \mu^t$$

for  $t = 0, \delta, \dots, T - \delta$ . This can be compared with the limit case of our finite element method, in which the space of test functions  $\mathcal{Z}_h$  is the set of all functions. This limit case corresponds to replacing  $Z_h^*$  by the identity operator in (16a), so that

$$(27) \quad \lambda^{t+\delta} = W_h \setminus (S^\delta W_h \lambda^t).$$

**PROPOSITION 7.** *Let  $(\mu^t)$  be the sequence of vectors defined by the algorithm of Fleming and McEneaney, (26); let  $(\lambda^t)$  be the sequence of vectors defined by the max-plus finite element method in the limit case (27); and let  $v^t$  denote the value function at time  $t$ . Then*

$$(28) \quad W_h \mu^t \leq W_h \lambda^t \leq v^t \quad \text{for } t = 0, \delta, \dots, T.$$

*Proof.* We first prove that  $W_h \lambda^t \leq v^t$  for  $t = 0, \delta, \dots, T$ . This can be proved by induction. For  $t = 0$ , we have  $W_h \lambda^0 \leq v^0$  by (15b). We assume that  $W_h \lambda^t \leq v^t$ . Using (27), we have

$$\begin{aligned} W_h \lambda^{t+\delta} &= W_h W_h^\dagger S^\delta (W_h \lambda^t) \\ &= \Pi_{W_h} (S^\delta (W_h \lambda^t)). \end{aligned}$$

Using the monotonicity of the semigroup  $S^\delta$ , we obtain

$$\begin{aligned} W_h \lambda^{t+\delta} &\leq \Pi_{W_h} (S^\delta v^t) \\ &\leq S^\delta v^t \\ &= v^{t+\delta}. \end{aligned}$$

The second inequality is also proved by induction. For  $t = 0$ , we have  $\mu^0 = \lambda^0 = W_h \setminus \Phi$ . Suppose that  $\mu^t \leq \lambda^t$ . By definition of  $W_h \setminus (S^\delta W_h)$ , we have

$$W_h (W_h \setminus S^\delta W_h) \leq S^\delta W_h,$$

and hence

$$\begin{aligned} W_h \mu^{t+\delta} &= W_h (W_h \setminus S^\delta W_h) \mu^t \\ &\leq (S^\delta W_h) \mu^t \\ &\leq S^\delta W_h \lambda^t. \end{aligned}$$

Since

$$\begin{aligned} \lambda^{t+\delta} &= W_h \setminus (S^\delta W_h \lambda^t) \\ &= \max\{\lambda \in \overline{\mathbb{R}}_{\max}^p \mid W_h \lambda \leq S^\delta W_h \lambda^t\}, \end{aligned}$$

we get that  $\mu^{t+\delta} \leq \lambda^{t+\delta}$ . Then  $\mu^t \leq \lambda^t$  for  $t = 0, \delta, \dots, T$ . Since  $W_h$  is monotone, we deduce (28).  $\square$

An approximation of (26b) using formulae of the same type as (23) is also discussed in [MH99].

## 5. Error analysis.

**5.1. General error estimates.** In what follows we denote by  $\|v\|_\infty = \sup_{i \in I} |v(i)| \in \mathbb{R} \cup \{+\infty\}$  the sup-norm of any function  $v : I \rightarrow \mathbb{R}$ . We also use the same notation  $\|v\|_\infty = \sup_{i \in I} |v_i|$  for a vector  $v = (v_i)_{i \in I}$ . For any two sets  $I$  and  $J$ , a map  $\Phi : \mathbb{R}^I \rightarrow \mathbb{R}^J$  is said to be monotone and homogeneous if it is monotone for the natural order and if for all  $u \in \mathbb{R}^I$  and  $\lambda \in \mathbb{R}$ ,  $\Phi(u + \lambda) = \Phi(u) + \lambda$  with  $(u + \lambda)(i) = u(i) + \lambda$ . Monotone homogeneous maps are nonexpansive for the sup-norm:  $\|\Phi(u) - \Phi(v)\|_\infty \leq \|u - v\|_\infty$ ; see [CT80]. In particular, max-plus or min-plus linear operators are nonexpansive for the sup-norm. This property will be frequently used in what follows. In order to simplify notation, we denote  $\bar{\tau}_\delta = \{0, \delta, \dots, T\}$ ,  $\tau_\delta^+ = \bar{\tau}_\delta \setminus \{0\}$ , and  $\tau_\delta^- = \bar{\tau}_\delta \setminus \{T\}$ .

*Remark 8.* To establish the main result of the paper (Theorem 22 below), we shall need only to take the norm of finite valued functions. However, we wish to emphasize that all the computations that follow are valid for functions with values in  $\bar{\mathbb{R}}$  if one replaces every occurrence of a term of the form  $\|u - v\|_\infty$  by  $d_\infty(u, v) = \inf\{\lambda \geq 0 \mid -\lambda + v \leq u \leq \lambda + v\}$ . Observe that  $d_\infty(u, v)$  is a semidistance and that  $d_\infty(u, v) = \|u - v\|_\infty$  if  $u - v$  takes finite values. Observe also that if a map  $\Phi : \bar{\mathbb{R}}^I \rightarrow \bar{\mathbb{R}}^J$  is monotone and homogeneous,  $d_\infty(\Phi(u), \Phi(v)) \leq d_\infty(u, v)$  for all  $u, v \in \bar{\mathbb{R}}^I$ .

The following lemma shows that the error of the ideal max-plus finite element method is controlled by the projection errors  $\|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty$ . This lemma may be thought of as an analogue of Cea's lemma in the classical analysis of the errors of the finite element method. Projectors over semimodules in the MFEM correspond to orthogonal projectors in the classical finite element method.

**LEMMA 9.** *For  $t \in \bar{\tau}_\delta$ , let  $v^t$  be the value function at time  $t$  and  $v_h^t$  be its approximation given by the ideal max-plus finite element method. We have*

$$(29) \quad \|v_h^T - v^T\|_\infty \leq \|\Pi_{W_h}(v^0) - v^0\|_\infty + \sum_{t \in \tau_\delta^+} \|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty.$$

*Proof.* For all  $t \in \tau_\delta^-$ , we have

$$\begin{aligned} \|v_h^{t+\delta} - v^{t+\delta}\|_\infty &\leq \|v_h^{t+\delta} - S_h^\delta(v^t)\|_\infty + \|S_h^\delta(v^t) - v^{t+\delta}\|_\infty \\ &\leq \|S_h^\delta(v_h^t) - S_h^\delta(v^t)\|_\infty + \|\Pi_{W_h}^{Z_h^*} \circ S_h^\delta(v^t) - v^{t+\delta}\|_\infty. \end{aligned}$$

Since  $S_h^\delta$  is a nonexpansive operator, we deduce that

$$\|v_h^{t+\delta} - v^{t+\delta}\|_\infty \leq \|v_h^t - v^t\|_\infty + \|\Pi_{W_h}^{Z_h^*}(v^{t+\delta}) - v^{t+\delta}\|_\infty.$$

The result is obtained by induction on  $t$ , using the fact that  $v_h^0 = P_{W_h}(v^0) = \Pi_{W_h}(v^0)$ .  $\square$

To obtain an error estimate, we need to bound  $\|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty$  for all  $t \in \tau_\delta^+$ . Since  $\Pi_{W_h}^{Z_h^*} = \Pi_{W_h} \circ \Pi^{Z_h^*}$ , we have

$$\begin{aligned} \|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty &= \|\Pi_{W_h} \circ \Pi^{Z_h^*}(v^t) - v^t\|_\infty \\ &\leq \|\Pi_{W_h} \circ \Pi^{Z_h^*}(v^t) - \Pi_{W_h}(v^t)\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty, \end{aligned}$$

and since  $\Pi_{W_h}$  is a nonexpansive operator, we get

$$(30) \quad \|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty \leq \|\Pi^{Z_h^*}(v^t) - v^t\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty.$$

Using this inequality together with Lemma 9, we deduce the following corollary.

**COROLLARY 10.** *For  $t \in \bar{\tau}_\delta$ , let  $v^t$  be the value function at time  $t$  and  $v_h^t$  be its approximation given by the ideal max-plus finite element method. We have*

$$\|v_h^T - v^T\|_\infty \leq \left(1 + \frac{T}{\delta}\right) \left(\sup_{t \in \bar{\tau}_\delta} (\|\Pi^{Z_h^*}(v^t) - v^t\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty)\right).$$

The following general lemma shows that the error of the effective finite element method is controlled by the projection errors and the errors resulting from the approximation of the matrix  $K_h$  by a matrix  $\tilde{K}_h$ .

**LEMMA 11.** *For  $t \in \bar{\tau}_\delta$ , let  $v^t$  be the value function at time  $t$  and  $v_h^t$  be its approximation given by the effective max-plus finite element method, where  $K_h$  is approximated by  $\tilde{K}_h$ . We have*

$$\begin{aligned} \|v_h^T - v^T\|_\infty &\leq \left(1 + \frac{T}{\delta}\right) \left(\sup_{t \in \bar{\tau}_\delta} (\|\Pi^{Z_h^*}(v^t) - v^t\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty) \right. \\ &\quad \left. + \|\tilde{K}_h - K_h\|_\infty\right). \end{aligned}$$

*Proof.* Since  $v_h^t$  is computed with the approximation  $\tilde{K}_h$  of  $K_h$ , we have  $v_h^t = W_h \lambda^t$ ,  $t \in \bar{\tau}_\delta$ , with

$$\lambda^{t+\delta} = M_h^\# \circ (\tilde{K}_h \lambda^t) = W_h^\# \circ (Z_h^*)^\# \circ (\tilde{K}_h \lambda^t).$$

We have

$$\begin{aligned} \|v_h^{t+\delta} - v^{t+\delta}\|_\infty &\leq \|v_h^{t+\delta} - S_h^\delta v_h^t\|_\infty + \|S_h^\delta v_h^t - S_h^\delta v^t\|_\infty + \|S_h^\delta v^t - v^{t+\delta}\|_\infty \\ &\leq \|\Pi_{W_h} \circ (Z_h^*)^\# \circ (\tilde{K}_h \lambda^t) - \Pi_{W_h} \circ (Z_h^*)^\# \circ Z_h^* \circ S_h^\delta W_h \lambda^t\|_\infty \\ &\quad + \|v_h^t - v^t\|_\infty + \|\Pi_{W_h}^{Z_h^*}(v^{t+\delta}) - v^{t+\delta}\|_\infty \\ &\leq \|\tilde{K}_h \lambda^t - K_h \lambda^t\|_\infty + \|v_h^t - v^t\|_\infty + \|\Pi_{W_h}^{Z_h^*}(v^{t+\delta}) - v^{t+\delta}\|_\infty \\ &\leq \max_{\substack{1 \leq j \leq q \\ 1 \leq i \leq p}} |(\tilde{K}_h)_{ji} - (K_h)_{ji}| + \|v_h^t - v^t\|_\infty + \|\Pi_{W_h}^{Z_h^*}(v^{t+\delta}) - v^{t+\delta}\|_\infty. \end{aligned}$$

We deduce that

$$\|v_h^T - v^T\|_\infty \leq \|\Pi_{W_h}(v^0) - v^0\|_\infty + \sum_{t \in \tau_\delta^+} \left(\|\Pi_{W_h}^{Z_h^*}(v^t) - v^t\|_\infty + \|\tilde{K}_h - K_h\|_\infty\right),$$

and so

$$\begin{aligned} \|v_h^T - v^T\|_\infty &\leq \left(1 + \frac{T}{\delta}\right) \left(\sup_{t \in \bar{\tau}_\delta} (\|\Pi^{Z_h^*}(v^t) - v^t\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty) \right. \\ &\quad \left. + \|\tilde{K}_h - K_h\|_\infty\right). \quad \square \end{aligned}$$

COROLLARY 12. For  $t \in \bar{\tau}_\delta$ , let  $v^t$  be the value function at time  $t$  and  $v_h^t$  be its approximation given by the effective max-plus finite element method, implemented with the approximation  $K_{H,h}$  of  $K_h$ , given by (24). We have

$$\begin{aligned} \|v_h^T - v^T\|_\infty &\leq \left(1 + \frac{T}{\delta}\right) \left( \sup_{t \in \bar{\tau}_\delta} (\|\Pi^{Z_h^*}(v^t) - v^t\|_\infty + \|\Pi_{W_h}(v^t) - v^t\|_\infty) \right. \\ &\quad \left. + \max_{1 \leq i \leq p} \|[S^\delta w_i]_H - S^\delta w_i\|_\infty \right). \end{aligned}$$

*Proof.* Using the same technique as in the precedent lemma and using that  $K_{H,h} = Z_h^*[S^\delta W_h]_H$  and  $K_h = Z_h^*S^\delta W_h$ , we have

$$\begin{aligned} \|K_{H,h} - K_h\|_\infty &\leq \|[S^\delta W_h]_H - S^\delta W_h\|_\infty \\ (31) \qquad \qquad \qquad &= \max_{1 \leq i \leq p} \|[S^\delta w_i]_H - S^\delta w_i\|_\infty, \end{aligned}$$

which ends the proof.  $\square$

COROLLARY 13. For  $t \in \bar{\tau}_\delta$ , let  $v^t$  be the value function at time  $t$  and  $v_h^t$  be its approximation given by the effective max-plus finite element method, implemented with the approximation  $\tilde{K}_{H,h}$  of  $K_h$ , given by (25). We have

$$\begin{aligned} \|v_h^T - v^T\|_\infty &\leq \left(1 + \frac{T}{\delta}\right) \left( \sup_{t \in \bar{\tau}_\delta} (\|\Pi^{Z_h^*}v^t - v^t\|_\infty + \|\Pi_{W_h}v^t - v^t\|_\infty) \right. \\ &\quad \left. + \max_{1 \leq i \leq p} \|[S^\delta w_i]_H - S^\delta w_i\|_\infty + \|\tilde{K}_{H,h} - K_{H,h}\|_\infty \right). \end{aligned}$$

*Proof.* We use Lemma 11, together with (31) and

$$\|\tilde{K}_{H,h} - K_h\|_\infty \leq \|\tilde{K}_{H,h} - K_{H,h}\|_\infty + \|K_{H,h} - K_h\|_\infty. \quad \square$$

**5.2. Projection errors.** In this section, we estimate the projection errors resulting from different choices of finite elements. Recall that a function  $f$  is *c-semiconvex* if  $f(x) + \frac{c}{2}\|x\|_2^2$ , where  $\|\cdot\|_2$  is the standard euclidean norm of  $\mathbb{R}^n$ , is convex. A function  $f$  is *c-semiconcave* if  $-f$  is *c-semiconvex*. Spaces of semiconvex functions were intensively used in the max-plus based approximation method of Fleming and McEneaney [FM00]; see also [MH98], [MH99], [McE02], [McE03], [McE04], [Fal87a], [Fal87b], [CDI84], [CDF89].

We shall use the following finite elements.

DEFINITION 14 ( $P_1$  finite elements). We call the  $P_1$  finite element or Lipschitz finite element centered at point  $\hat{x} \in X$ , with constant  $a > 0$ , the function  $w(x) = -a\|x - \hat{x}\|_1$ , where  $\|x\|_1 = \sum_{i=1}^n |x_i|$  is the  $l^1$ -norm of  $\mathbb{R}^n$ .

The family of Lipschitz finite elements of constant  $a$  generates, in the max-plus sense, the semimodule of Lipschitz continuous functions from  $X$  to  $\bar{\mathbb{R}}$  of Lipschitz constant  $a$  with respect to  $\|\cdot\|_1$ .

DEFINITION 15 ( $P_2$  finite elements). We call the  $P_2$  finite element or quadratic finite element centered at point  $\hat{x} \in X$ , with Hessian  $c > 0$ , the function  $w(x) = -\frac{c}{2}\|x - \hat{x}\|_2^2$ .

When  $X = \mathbb{R}^n$ , the family of quadratic finite elements with Hessian  $c$  generates, in the max-plus sense, the semimodule of l.s.c. *c*-semiconvex functions with values in  $\bar{\mathbb{R}}$ .

FIG. 2. Voronoi tessellation.

*Notation.* Let  $Y$  be a subset of  $\mathbb{R}^n$  and  $f$  be a function from  $Y$  to  $\overline{\mathbb{R}}$ . We will denote by  $\text{Conv}Y$  the convex hull of  $Y$ ,  $\text{ri}Y$  the relative interior of  $Y$ ,  $\text{dom}f$  the effective domain of  $f$ , and  $\partial f(x)$  the subdifferential of  $f$  at  $x \in \text{dom}f$ .

When  $C$  is a nonempty convex subset of  $\mathbb{R}^n$  and  $c > 0$ , a function is said to be  $c$ -strongly convex on  $C$  if and only if  $f - \frac{1}{2}c\|\cdot\|_2^2$  is convex on  $C$ . A function  $f$  is  $c$ -strongly concave on  $C$  if  $-f$  is  $c$ -strongly convex on  $C$ .

Let  $P$  be a finite subset of  $\mathbb{R}^n$ . The Voronoi cell of a point  $p \in P$  is defined by

$$V(p) = \{x \in \mathbb{R}^n \mid \|x - p\|_2 \leq \|x - q\|_2 \forall q \in P\}.$$

The family  $\{V(p)\}_{p \in P}$  constitutes a subdivision of  $\mathbb{R}^n$ , which is called a Voronoi tessellation (see [SU00] for an introduction to Voronoi tessellations). We define the restriction of  $V(p)$  to  $X$  to be

$$V_X(p) = V(p) \cap X.$$

We define  $\rho_X(P)$  to be the maximal radius of the restriction to  $X$  of the Voronoi cells of the points of  $P$ :

$$\rho_X(P) := \sup_{p \in P} \sup_{x \in V_X(p)} \|x - p\|_2.$$

Observe that

$$\rho_X(P) := \sup_{x \in X} \inf_{p \in P} \|x - p\|_2.$$

The previous definitions are illustrated in Figure 2. The set  $X$  is in light gray,  $P = \{p_1, \dots, p_{10}\}$ ,  $V_X(p_9)$  is in dark gray, and  $\rho_X(P)$  is indicated by a bidirectional arrow.

The next two lemmas bound the projection error in term of the radius of Voronoi cells.

**LEMMA 16** (primal projection error). *Let  $X$  be a compact convex subset of  $\mathbb{R}^n$ . Let  $v : X \rightarrow \mathbb{R}$  be a  $c$ -semiconvex and Lipschitz continuous function with Lipschitz constant  $L_v$  with respect to the euclidean norm. Let  $v_c(x) = v(x) + \frac{c}{2}\|x\|_2^2$ . Let  $\hat{X} = X + B_2(0, \frac{L_v}{c})$ , let  $\hat{X}_h$  be a finite subset of  $\mathbb{R}^n$ , and let  $\mathcal{W}_h$  denote the complete subsemimodule of  $\overline{\mathbb{R}}_{\max}^X$  generated by the family  $(w_{\hat{x}_h})_{\hat{x}_h \in \hat{X}_h}$ , where  $w_{\hat{x}_h}(x) = -\frac{c}{2}\|x - \hat{x}_h\|_2^2$ . Then*

$$\|v - P_{\mathcal{W}_h} v\|_\infty \leq c \text{diam } X \rho_{\hat{X}}(\hat{X}_h).$$

*Proof.* Let  $\mathcal{W}$  denote the complete subsemimodule of  $\overline{\mathbb{R}}_{\max}^X$  generated by the family  $(w_{\hat{x}})_{\hat{x} \in \hat{X}}$ . We will first prove that for all  $x \in X$ ,  $P_{\mathcal{W}}v(x) = v(x)$ . It is obvious that for all  $x \in X$ ,  $v(x) \geq P_{\mathcal{W}}v(x)$ . Using that  $P_{\mathcal{W}} = W \circ W^\sharp$ , with  $W = \text{col}(w_{\hat{x}})_{\hat{x} \in \hat{X}}$ , we obtain

$$\begin{aligned} P_{\mathcal{W}}v(x) &= \sup_{\hat{x} \in \hat{X}} \left( -\frac{c}{2}\|x - \hat{x}\|_2^2 + \inf_{y \in X} \left( \frac{c}{2}\|y - \hat{x}\|_2^2 + v(y) \right) \right) \\ &= \sup_{\hat{x} \in \hat{X}} \left( -\frac{c}{2}\|x\|_2^2 + c\hat{x} \cdot x - \sup_{y \in X} (c\hat{x} \cdot y - v_c(y)) \right) \\ &= -\frac{c}{2}\|x\|_2^2 + \sup_{\hat{x} \in \hat{X}} (c\hat{x} \cdot x - v_c^*(c\hat{x})), \end{aligned}$$

where  $v_c^*$  denotes the Fenchel transform of  $v_c$ . Since  $v_c$  is l.s.c., convex, and proper, we have for all  $x \in X$

$$(32) \quad v_c(x) = v_c^{**}(x) = \sup_{\theta \in \mathbb{R}^n} (\theta \cdot x - v_c^*(\theta)).$$

Using Theorem 23.4 of [Roc70], for all  $x \in \text{ri}(\text{dom}v_c)$ , the subdifferential of  $v_c$  at  $x$ ,  $\partial v_c(x) = \{\theta \in \mathbb{R}^n \mid v_c(y) - v_c(x) \geq \theta \cdot (y - x) \forall y \in X\}$ , is nonempty. Then  $\theta \in \partial v_c(x)$  if and only if  $v_c^*(\theta) = \theta \cdot x - v_c(x)$  and, consequently, the supremum of (32) is attained for all elements  $\theta$  of  $\partial v_c(x)$ .

Set  $q(x) = \frac{c}{2}\|x\|_2^2$ . Using the fact that  $q(y) - q(x) = q'(x) \cdot (y - x) + O(\|y - x\|_2^2)$  and that  $v$  is Lipschitz continuous with Lipschitz constant  $L_v$ , we obtain  $\partial v_c(x) \subset B_2(cx, L_v)$  for all  $x \in \text{ri}X$ . Therefore, for all  $x \in \text{ri}X$ ,

$$(33) \quad v_c(x) = \sup_{\hat{x} \in \hat{X}} (c\hat{x} \cdot x - v_c^*(c\hat{x})).$$

By continuity in the members of (33), we have the equality for all  $x \in X$ , and so

$$\begin{aligned} P_{\mathcal{W}}v(x) &= -\frac{c}{2}\|x\|_2^2 + \sup_{\hat{x} \in \hat{X}} (c\hat{x} \cdot x - v_c^*(c\hat{x})) \\ &= -\frac{c}{2}\|x\|_2^2 + v_c(x) \\ &= v(x) \end{aligned}$$

for all  $x \in X$ .

Now fix  $x \in X$ . For  $\hat{x} \in \hat{X}$ , we set  $\varphi(\hat{x}) = c\hat{x} \cdot x - v_c^*(c\hat{x})$ . Since  $P_{\mathcal{W}_h}v \leq P_{\mathcal{W}}v \leq v$ , we have for all  $x \in X$

$$\begin{aligned} 0 \leq v(x) - P_{\mathcal{W}_h}v(x) &= P_{\mathcal{W}}v(x) - P_{\mathcal{W}_h}v(x) \\ &= \sup_{\hat{x} \in \hat{X}} \varphi(\hat{x}) - \sup_{\hat{x}_h \in \hat{X}_h} \varphi(\hat{x}_h) \\ &= \sup_{\hat{x} \in \hat{X}} \inf_{\hat{x}_h \in \hat{X}_h} \varphi(\hat{x}) - \varphi(\hat{x}_h). \end{aligned}$$

We have  $\partial(-\varphi)(\hat{x}) = -cx + c\partial v_c^*(c\hat{x})$ . Since  $\partial v_c^* \subset X$ , we have  $\partial(-\varphi)(\hat{x}) \subset c(X - x) \subset B_2(0, c \text{diam} X)$ . Hence,  $\varphi$  is Lipschitz continuous with Lipschitz constant

$L_\varphi = c \operatorname{diam} X$ . Then for all  $x \in X$

$$\begin{aligned} v(x) - P_{\mathcal{W}_h} v(x) &\leq \sup_{\hat{x} \in \hat{X}} \inf_{\hat{x}_h \in \hat{X}_h} L_\varphi \|\hat{x} - \hat{x}_h\|_2 \\ &= c \operatorname{diam} X \rho_{\hat{X}}(\hat{X}_h). \quad \square \end{aligned}$$

LEMMA 17 (dual projection error). *Let  $X$  be a bounded subset of  $\mathbb{R}^n$  and  $X_h$  a finite subset of  $\mathbb{R}^n$ . Let  $v : X \rightarrow \mathbb{R}$  be a given Lipschitz continuous function with Lipschitz constant  $L_v$  with respect to the euclidean norm. Let  $\mathcal{Z}_h$  denote the complete semimodule of  $\overline{\mathbb{R}}_{\max}^X$  generated by the  $P_1$  finite elements  $(z_{x_h})_{x_h \in X_h}$  centered at the points of  $X_h$  with constant  $a \geq L_v$ . Then*

$$\|v - P^{-\mathcal{Z}_h} v\|_\infty \leq n(a + L_v) \rho_X(X_h).$$

*Proof.* It is clear that  $P^{-\mathcal{Z}_h} v \geq v$ , and using that  $P^{-\mathcal{Z}_h} = (Z^*)^\# \circ Z^*$ , with  $Z = \operatorname{col}(z_{x_h})_{x_h \in X_h}$ , we obtain

$$P^{-\mathcal{Z}_h} v(x) - v(x) = \inf_{x_h \in X_h} \left( a \|x - x_h\|_1 + \sup_{y \in X} (-a \|y - x_h\|_1 + v(y) - v(x)) \right)$$

for all  $x \in X$ . Since  $v$  is  $L_v$ -Lipschitz continuous, we have

$$\begin{aligned} P^{-\mathcal{Z}_h} v(x) - v(x) &\leq \inf_{x_h \in X_h} \left( a \|x - x_h\|_1 + \sup_{y \in X} (-a \|y - x_h\|_1 + L_v \|y - x\|_2) \right) \\ &\leq \inf_{x_h \in X_h} \left( a \|x - x_h\|_1 + \sup_{y \in X} (-a \|y - x_h\|_1 + L_v \|y - x\|_1) \right) \\ &\leq \inf_{x_h \in X_h} \left( a \|x - x_h\|_1 + \sup_{y \in X} (-a \|y - x_h\|_1 + L_v \|y - x_h\|_1 \right. \\ &\quad \left. + L_v \|x - x_h\|_1) \right) \\ &= \inf_{x_h \in X_h} \left( (a + L_v) \|x - x_h\|_1 + \sup_{y \in X} (L_v - a) \|y - x_h\|_1 \right). \end{aligned}$$

Since  $a \geq L_v$ , we deduce that

$$P^{-\mathcal{Z}_h} v(x) - v(x) \leq (a + L_v) \sup_{x \in X} \inf_{x_h \in X_h} \|x - x_h\|_1 \leq n(a + L_v) \rho_X(X_h). \quad \square$$

**5.3. The approximation errors.** To state an error estimate, we make the following standard assumptions (see [Bar94], for instance):

- (H1)  $f : X \times U \rightarrow \mathbb{R}^n$  is bounded and Lipschitz continuous with respect to  $x$ , meaning that there exist  $L_f > 0$  and  $M_f > 0$  such that

$$\begin{aligned} \|f(x, u) - f(y, u)\|_2 &\leq L_f \|x - y\|_2 & \forall x, y \in X, u \in U, \\ \|f(x, u)\|_2 &\leq M_f & \forall x \in X, u \in U. \end{aligned}$$

- (H2)  $\ell : X \times U \rightarrow \mathbb{R}$  is bounded and Lipschitz continuous with respect to  $x$ , meaning that there exist  $L_\ell > 0$  and  $M_\ell > 0$  such that

$$\begin{aligned} |\ell(x, u) - \ell(y, u)| &\leq L_\ell \|x - y\|_2 & \forall x, y \in X, u \in U, \\ |\ell(x, u)| &\leq M_\ell & \forall x \in X, u \in U. \end{aligned}$$

We shall also need the further assumptions:

- (H3) The domain  $X$  is invariant by the dynamics: for all  $\mathbf{u} : [0, T] \rightarrow U$  and for all  $x \in X$ , the solution  $\mathbf{x}_{\mathbf{u},x}$  of  $\dot{\mathbf{x}}_{\mathbf{u},x}(s) = f(\mathbf{x}_{\mathbf{u},x}(s), u(s))$ ,  $s \geq 0$ , and  $\mathbf{x}_{\mathbf{u},x}(0) = x$  satisfies  $\mathbf{x}_{\mathbf{u},x}(s) \in X$  for all  $s \geq 0$ .
- (H4) The domain  $X$  is invariant by the discretized dynamics in time  $\delta > 0$ : for all  $u \in U$  and for all  $x \in X$ ,  $x + \delta f(x, u) \in X$ .

In the main results, the domain will be also assumed to be convex. Then assumption (H4) implies (H3).

### 5.3.1. Approximation of $S^\delta w$ .

LEMMA 18. *Let  $X$  be a convex subset of  $\mathbb{R}^n$ . We make assumptions (H1), (H2), (H3), and (H4). Let  $w : x \rightarrow \mathbb{R}$  be such that  $w$  is  $C^1$  on a neighborhood of  $X$ , Lipschitz continuous with Lipschitz constant  $L_w$  with respect to the euclidean norm,  $c_1$ -semiconvex, and  $c_2$ -semiconcave. Then there exists  $K_1 > 0$  such that  $\|[S^\delta w]_H - S^\delta w\|_\infty \leq K_1 \delta^2$ , for  $\delta > 0$ , where  $[S^\delta w]_H$  is given by (23).*

*Proof.* We first show that there exists  $K_1 > 0$  such that

$$[S^\delta w]_H(x) - S^\delta w(x) \geq -K_1 \delta^2 \quad \forall x \in X.$$

For all  $x \in X$  and  $u \in U$ , define  $\mathbf{x}_{u,x}$  to be the trajectory such that  $\dot{\mathbf{x}}_{u,x}(s) = f(\mathbf{x}_{u,x}(s), u)$ ,  $s \geq 0$ , and  $\mathbf{x}_{u,x}(0) = x$ . In other words, we apply a constant control  $u$ . From (H3),  $\mathbf{x}_{u,x}(s) \in X$ ,  $s \geq 0$ , for all  $u \in U$  and  $x \in X$ . Hence

$$(S^\delta w)(x) \geq \sup \left\{ \int_0^\delta \ell(\mathbf{x}_{u,x}(s), u) ds + w(\mathbf{x}_{u,x}(\delta)) \mid u \in U \right\}.$$

Since  $\ell$  is Lipschitz continuous and  $f$  is bounded, we have

$$\begin{aligned} \left| \int_0^\delta [\ell(\mathbf{x}_{u,x}(s), u) - \ell(x, u)] ds \right| &\leq L_\ell \int_0^\delta \|\mathbf{x}_{u,x}(s) - x\|_2 ds \\ &\leq L_\ell \int_0^\delta M_f s ds; \end{aligned}$$

then

$$(34) \quad \left| \int_0^\delta [\ell(\mathbf{x}_{u,x}(s), u) - \ell(x, u)] ds \right| \leq \frac{1}{2} L_\ell M_f \delta^2.$$

Therefore,

$$(S^\delta w)(x) \geq -\frac{1}{2} L_\ell M_f \delta^2 + \sup \{ \delta \ell(x, u) + w(\mathbf{x}_{u,x}(\delta)) \mid u \in U \}.$$

Since  $w$  is Lipschitz continuous,  $X$  is invariant by the discretized dynamics in time  $\delta$ , and  $f$  is bounded and Lipschitz continuous, we have

$$\begin{aligned}
 \left| w(\mathbf{x}_{u,x}(\delta)) - w(x + \delta f(x, u)) \right| &\leq L_w \|\mathbf{x}_{u,x}(\delta) - x - \delta f(x, u)\|_2 \\
 &\leq L_w \int_0^\delta \|f(\mathbf{x}_{u,x}(s), u) - f(x, u)\|_2 ds \\
 &\leq L_w \int_0^\delta L_f \|\mathbf{x}_{u,x}(s) - x\|_2 ds \\
 &\leq L_w L_f \int_0^\delta M_f s ds,
 \end{aligned}$$

and so

$$(35) \quad \left| w(\mathbf{x}_{u,x}(\delta)) - w(x + \delta f(x, u)) \right| \leq \frac{1}{2} L_w L_f M_f \delta^2.$$

Moreover, since  $w$  is  $c_1$ -semiconvex, we have

$$(36) \quad w(x + \delta f(x, u)) \geq w(x) + \delta \nabla w(x) \cdot f(x, u) - \frac{c_1}{2} M_f^2 \delta^2.$$

We deduce from (34), (35), and (36) that

$$\begin{aligned}
 (S^\delta w)(x) &\geq -(L_\ell M_f + L_w L_f M_f + c_1 M_f^2) \frac{\delta^2}{2} + w(x) \\
 &\quad + \sup_{u \in U} \{ \delta \ell(x, u) + \delta \nabla w(x) \cdot f(x, u) \} \\
 &\geq -(L_\ell M_f + L_w L_f M_f + c_1 M_f^2) \frac{\delta^2}{2} + w(x) + \delta H(x, \nabla w(x)).
 \end{aligned}$$

This ends the first part of the proof.

We now prove an opposite inequality. For all  $x \in X$  and for all measurable functions  $\mathbf{u} : [0, \delta] \rightarrow U$ , define  $\mathbf{x}_{\mathbf{u},x}$  to be the trajectory such that  $\dot{\mathbf{x}}_{\mathbf{u},x}(s) = f(\mathbf{x}_{\mathbf{u},x}(s), \mathbf{u}(s))$  and  $\mathbf{x}_{\mathbf{u},x}(0) = x$ . From (H3),  $\mathbf{x}_{\mathbf{u},x}(s) \in X$ ,  $s \geq 0$ , for all  $\mathbf{u} : [0, \delta] \rightarrow U$  and  $x \in X$ . Since  $\ell(x, u) \leq H(x, p) - p \cdot f(x, u)$ , for all  $p \in \mathbb{R}^n$ ,  $x \in X$ , and  $u \in U$ , we deduce that

$$\begin{aligned}
 (S^\delta w)(x) &\leq \sup \left\{ \int_0^\delta H(\mathbf{x}_{\mathbf{u},x}(s), \nabla w(x)) ds + w(\mathbf{x}_{\mathbf{u},x}(\delta)) \right. \\
 &\quad \left. - \nabla w(x) \cdot \int_0^\delta f(\mathbf{x}_{\mathbf{u},x}(s), \mathbf{u}(s)) ds \mid \mathbf{u} : [0, \delta] \rightarrow U \right\} \\
 &= \sup \left\{ \int_0^\delta H(\mathbf{x}_{\mathbf{u},x}(s), \nabla w(x)) ds \right. \\
 &\quad \left. + w(\mathbf{x}(\delta)) - \nabla w(x) \cdot (\mathbf{x}_{\mathbf{u},x}(\delta) - x) \mid \mathbf{u} : [0, \delta] \rightarrow U \right\}.
 \end{aligned}$$

Using the fact that  $\ell$  and  $f$  are Lipschitz continuous with respect to  $x$ , we have for all  $x, x' \in X$ ,  $p \in \mathbb{R}^n$

$$\left| H(x, p) - H(x', p) \right| \leq (L_\ell + L_f \|p\|_2) \|x - x'\|_2;$$

therefore

$$\begin{aligned} (S^\delta w)(x) &\leq \sup \left\{ (L_\ell + L_f L_w) \int_0^\delta \|\mathbf{x}_{\mathbf{u},x}(s) - x\|_2 ds + \delta H(x, \nabla w(x)) \right. \\ &\quad \left. + w(\mathbf{x}_{\mathbf{u},x}(\delta)) - \nabla w(x) \cdot (\mathbf{x}_{\mathbf{u},x}(\delta) - x) \mid \mathbf{u} : [0, \delta] \rightarrow U \right\} \\ &\leq (L_\ell + L_f L_w) M_f \frac{\delta^2}{2} + \delta H(x, \nabla w(x)) \\ &\quad + \sup \left\{ w(\mathbf{x}_{\mathbf{u},x}(\delta)) - \nabla w(x) \cdot (\mathbf{x}_{\mathbf{u},x}(\delta) - x) \mid \mathbf{u} : [0, \delta] \rightarrow U \right\}. \end{aligned}$$

Since  $w$  is  $c_2$ -semiconcave, we have

$$w(\mathbf{x}_{\mathbf{u},x}(\delta)) \leq w(x) + \nabla w(x) \cdot (\mathbf{x}_{\mathbf{u},x}(\delta) - x) + \frac{c_2}{2} M_f^2 \delta^2.$$

We obtain

$$(S^\delta w)(x) \leq (L_\ell + L_f L_w + c_2 M_f) M_f \frac{\delta^2}{2} + w(x) + \delta H(x, \nabla w(x)).$$

To end the proof, we take  $K_1 = \frac{1}{2} (L_\ell M_f + L_f L_w M_f + \max(c_1, c_2) M_f^2)$ .  $\square$

### 5.3.2. Approximation of the matrix $K_h$ by the matrix $\tilde{K}_H$ .

LEMMA 19. Let  $X$  be a compact subset of  $\mathbb{R}^n$ . We consider an u.s.c. function  $\varphi : X \rightarrow \mathbb{R}$  and a Lipschitz continuous function  $\psi : X \rightarrow \mathbb{R}$  with Lipschitz constant  $L_\psi$  with respect to a norm  $\|\cdot\|$ . For  $\varepsilon \geq 0$ , we define

$$(37a) \quad F_\varepsilon = \left\{ x \in X \mid \varphi(x) \geq \sup_{x' \in X} \varphi(x') - \varepsilon \right\},$$

$$(37b) \quad g(\varepsilon) = \sup_{x \in F_\varepsilon} d(x, F_0),$$

where  $d(x, F_0) = \inf_{y \in F_0} \|y - x\|$ . We have

$$\left| \sup_{x \in X} (\varphi(x) + \delta \psi(x)) - \left[ \sup_{x \in X} \varphi(x) + \delta \sup_{x \in \arg \max \varphi} \psi(x) \right] \right| \leq L_\psi \delta g(\delta M),$$

where  $M = \sup_{x \in X} \psi(x) - \inf_{x \in X} \psi(x)$ .

*Proof.* Since  $\varphi$  is u.s.c. and  $X$  is compact,  $F_0 = \arg \max \varphi$  and

$$(38) \quad \sup_{x \in X} (\varphi(x) + \delta \psi(x)) \geq \sup_{x \in X} \varphi(x) + \delta \sup_{x \in F_0} \psi(x).$$

For  $\varepsilon > 0$ , we have

$$\sup_{x \in X} (\varphi(x) + \delta \psi(x)) = \max \left[ \sup_{x \in F_\varepsilon} (\varphi(x) + \delta \psi(x)), \sup_{x \in X \setminus F_\varepsilon} (\varphi(x) + \delta \psi(x)) \right].$$

Let  $\varepsilon = \delta(\sup_{x \in X} \psi(x) - \inf_{x \in X} \psi(x)) = M\delta$  (which is finite since  $\psi$  is continuous and  $X$  is compact). We have

$$\begin{aligned} \sup_{x \in X \setminus F_\varepsilon} (\varphi(x) + \delta\psi(x)) &\leq -\varepsilon + \sup_{x \in X} \varphi(x) + \delta \sup_{x \in X} \psi(x) \\ &= \sup_{x \in F_\varepsilon} \varphi(x) + \delta \inf_{x \in X} \psi(x) \\ &\leq \sup_{x \in F_\varepsilon} [\varphi(x) + \delta\psi(x)]. \end{aligned}$$

Therefore,

$$\begin{aligned} \sup_{x \in X} (\varphi(x) + \delta\psi(x)) &= \sup_{x \in F_\varepsilon} (\varphi(x) + \delta\psi(x)) \\ (39) \qquad \qquad \qquad &\leq \sup_{x \in X} \varphi(x) + \delta \sup_{x \in F_\varepsilon} \psi(x). \end{aligned}$$

We deduce from (38) and (39) that

$$0 \leq \sup_{x \in X} (\varphi(x) + \delta\psi(x)) - \left[ \sup_{x \in X} \varphi(x) + \delta \sup_{x \in F_0} \psi(x) \right] \leq \delta \left[ \sup_{x \in F_\varepsilon} \psi(x) - \sup_{x \in F_0} \psi(x) \right].$$

Since  $\psi$  is Lipschitz continuous, we have

$$\begin{aligned} \sup_{x \in F_\varepsilon} \psi(x) - \sup_{x \in F_0} \psi(x) &= \sup_{x \in F_\varepsilon} \inf_{y \in F_0} (\psi(x) - \psi(y)) \\ &\leq \sup_{x \in F_\varepsilon} \inf_{y \in F_0} L_\psi \|x - y\| \\ &= L_\psi \sup_{x \in F_\varepsilon} d(x, F_0) \\ &= L_\psi g(\varepsilon). \quad \square \end{aligned}$$

**COROLLARY 20.** *Let  $X$  be a compact convex subset of  $\mathbb{R}^n$ . We consider an u.s.c. and strongly concave function  $\varphi : X \rightarrow \mathbb{R}$  with modulus  $c > 0$  and a Lipschitz continuous function  $\psi : X \rightarrow \mathbb{R}$  with Lipschitz constant  $L_\psi$  with respect to the euclidean norm. Then the maximum of  $\varphi$  on  $X$  is attained at a unique point  $x_0 \in X$ , i.e.,  $\arg \max_X \varphi = \{x_0\}$  and*

$$\left| \sup_{x \in X} (\varphi(x) + \delta\psi(x)) - (\varphi(x_0) + \delta\psi(x_0)) \right| \leq L_\psi \delta \sqrt{\frac{2\delta M}{c}},$$

where  $M = \sup_{x \in X} \psi(x) - \inf_{x \in X} \psi(x)$ .

*Proof.* Define  $\Phi(x) = \varphi(x_0) - \varphi(x)$  for  $x \in X$  and  $\Phi(x) = +\infty$  elsewhere. We have  $\Phi(x) \geq 0$  for all  $x \in \mathbb{R}^n$  and  $\Phi(x_0) = 0$ . Since  $\Phi$  is l.s.c. and convex on  $\mathbb{R}^n$ , then  $0 \in \partial\Phi(x_0)$ . Moreover,  $\Phi$  is strongly convex with modulus  $c$ . Then, using Theorem 6.1.2 of [HUL93, Chapter VI], we have for all  $x, x' \in X$

$$\Phi(x) \geq \Phi(x') + \langle s \mid x - x' \rangle + \frac{c}{2} \|x - x'\|_2^2 \quad \forall s \in \partial\Phi(x').$$

Taking  $x' = x_0$  and  $s = 0$  we obtain for all  $x \in X$

$$\Phi(x) \geq \frac{c}{2} \|x - x_0\|_2^2,$$

which implies that

$$\varphi(x) \leq \varphi(x_0) - \frac{c}{2} \|x - x_0\|_2^2 \quad \forall x \in X.$$

Using the notation of Lemma 19, we get easily (see also Proposition 4.32 of [BS00]) for all  $x \in F_\varepsilon$ ,  $d(x, F_0) \leq \sqrt{\frac{2\varepsilon}{c}}$ , where  $\varepsilon = \delta(\sup_{x \in X} \psi(x) - \inf_{x \in X} \psi(x))$ .  $\square$

*Remark 21.* To have an error estimate of the approximation of the matrix  $K_{H,h}$  by the matrix  $\tilde{K}_{H,h}$ , we apply Corollary 20 in the case where

$$\varphi(x) = w_i(x) + z_j(x) \quad \text{and} \quad \psi(x) = H(x, \nabla w_i(x))$$

for a suitable choice of the finite elements  $w_i$  and test functions  $z_j$ . Using assumptions (H1) and (H2), we have that, for all  $x \in X$ ,  $|\psi(x)| \leq M_f \|\nabla w\|_\infty + M_\ell$ , where  $\|\nabla w\|_\infty = \|\nabla w\|_2$  and  $\nabla w = (\nabla w_i)_{1 \leq i \leq p}$ . We deduce that

$$\sup \psi - \inf \psi \leq 2(M_f \|\nabla w\|_\infty + M_\ell).$$

Moreover,  $H(\cdot, p)$  and  $H(x, \cdot)$  are Lipschitz continuous with Lipschitz constants  $L_f \|p\|_2 + L_\ell$  and  $M_f$ , respectively. Hence,  $\psi$  is Lipschitz continuous with Lipschitz constant

$$L_\psi = L_f \|\nabla w\|_\infty + L_\ell + M_f \|D^2 w_i\|_\infty.$$

**5.4. Final estimation of the error of the MFEM.** We now state our main convergence result, which holds for quadratic finite elements and Lipschitz test functions.

**THEOREM 22.** *Let  $X$  be a compact convex subset of  $\mathbb{R}^n$  with nonempty interior and  $\hat{X} = X + B_2(0, \frac{L}{c})$ , where  $L > 0$ ,  $c > 0$ . Choose any finite sets of discretization points  $X_h \subset \mathbb{R}^n$  and  $\hat{X}_h \subset \mathbb{R}^n$ . Let*

$$\Delta x = \max(\rho_X(X_h), \rho_{\hat{X}}(\hat{X}_h)).$$

*We make assumptions (H1), (H2), (H3), and (H4) and assume that the value function at time  $t$ ,  $v^t$ , is  $c$ -semiconvex and Lipschitz continuous with constant  $L$  with respect to the euclidean norm for all  $t \geq 0$ . Let us choose quadratic finite elements  $w_{\hat{x}_h}$  of Hessian  $c$ , centered at the points  $\hat{x}_h$  of  $\hat{X}_h$ . Let us choose, as test functions, the Lipschitz finite elements  $z_{x_h}$  with constant  $a \geq L$ , centered at the points  $x_h$  of  $X_h$ . For  $t = 0, \delta, \dots, T$ , let  $v_h^t$  be the approximation of  $v^t$  given by the max-plus finite element method implemented with the approximation  $K_{H,h}$  of  $K_h$  given by (24). Then there exists a constant  $C_1 > 0$  such that*

$$\|v_h^T - v^T\|_\infty \leq C_1 \left( \delta + \frac{\Delta x}{\delta} \right).$$

*When the approximation  $K_{H,h}$  is replaced by  $\tilde{K}_{H,h}$ , given by (25), this inequality becomes*

$$\|v_h^T - v^T\|_\infty \leq C_2 \left( \sqrt{\delta} + \frac{\Delta x}{\delta} \right)$$

*for some constant  $C_2 > 0$ .*

*Proof.* Let  $\mathcal{W}_h$  and  $\mathcal{Z}_h$  denote the complete semimodules of  $\overline{\mathbb{R}}_{\max}^X$  generated by the families  $(w_{\hat{x}_h})_{\hat{x}_h \in \hat{X}_h}$  and  $(z_{x_h})_{x_h \in X_h}$ , respectively. We index the elements of  $\hat{X}_h$  and  $X_h$  by  $\hat{x}_{h_1}, \dots, \hat{x}_{h_p}$  and  $x_{h_1}, \dots, x_{h_q}$ , respectively. Using Corollary 12, we have

$$\begin{aligned} \|v_h^T - v^T\|_\infty &\leq \left(1 + \frac{T}{\delta}\right) \left( \sup_{t \in \bar{\tau}_\delta} (\|P^{-\mathcal{Z}_h}(v^t) - v^t\|_\infty + \|P_{\mathcal{W}_h}(v^t) - v^t\|_\infty) \right. \\ &\quad \left. + \max_{1 \leq i \leq p} \|[S^\delta w_i]_H - S^\delta w_i\|_\infty \right). \end{aligned}$$

To estimate the projection error  $\|P_{\mathcal{W}_h}(v^t) - v^t\|_\infty$ , we apply Lemma 16. We obtain, for  $t \in \bar{\tau}_\delta$ ,  $\|P_{\mathcal{W}_h}(v^t) - v^t\|_\infty \leq c \operatorname{diam} X \Delta x$ . Applying Lemma 17 we obtain, for  $t \in \bar{\tau}_\delta$ ,  $\|P^{-\mathcal{Z}_h}(v^t) - v^t\|_\infty \leq n(a + L)\Delta x$ . Finally, using Lemma 18, we get

$$\|v_h^T - v^T\|_\infty \leq C_1 \left( \delta + \frac{\Delta x}{\delta} \right),$$

where

$$C_1 > (T + 1) \max \left( c \operatorname{diam} X + n(a + L), \frac{M_f}{2} \left( L_\ell + cL_f \left( \operatorname{diam} X + \frac{L}{c} \right) + cM_f \right) \right).$$

To prove the second inequality, we use Corollary 13 together with Remark 21. Using the notation of Corollary 20 and Remark 21, we have  $\sup \psi - \inf \psi \leq 2(M_\ell + M_f c(\operatorname{diam} X + \frac{L}{c}))$  and  $L_\psi = L_\ell + cM_f + L_f c(\operatorname{diam} X + \frac{L}{c})$ . Since  $\varphi = w_i + z_j$  is  $c$ -strongly concave, we deduce that

$$\begin{aligned} |(\tilde{K}_{H,h})_{ji} - (K_{H,h})_{ji}| \\ \leq 2 \left( L_\ell + cM_f + L_f c \left( \operatorname{diam} X + \frac{L}{c} \right) \right) \sqrt{\frac{M_\ell}{c} + M_f \left( \operatorname{diam} X + \frac{L}{c} \right)} \delta \sqrt{\delta} \end{aligned}$$

for  $i = 1, \dots, p$  and  $j = 1, \dots, q$ . Hence, there exists  $C_2 > 0$  such that

$$\|v_h^T - v^T\|_\infty \leq C_2 \left( \sqrt{\delta} + \frac{\Delta x}{\delta} \right)$$

when  $\delta$  is small enough.  $\square$

A variant of this theorem, with a stronger assumption, was proved in [Lak03].

*Remark 23.* When  $X_h$  is a rectangular grid of step  $h > 0$ , meaning that  $X_h$  is the intersection of  $(\mathbb{Z}h)^n$  with a Cartesian product of bounded intervals, we have

$$\rho_X(X_h) \leq \sqrt{n}h.$$

Hence, when  $X_h$  and  $\hat{X}_h$  are both rectangular grids of step  $h$ , we have  $\Delta x \leq \sqrt{n}h = O(h)$  in Theorem 22.

**6. Numerical results.** This section presents the results of numerical experiments with the MFEM described in section 3. We consider optimal control problems in dimensions 1 and 2 whose value functions are known or can be computed by solving the Riccati equation (in the case of linear quadratic problems).

FIG. 3. *Max-plus approximation (Example 24).*

**6.1. Implementation.** We implemented the MFEM using the max-plus toolbox of Scilab [Plu98] (in dimension 1) and specific programs written in C (in dimension 2). We used the approximation  $\tilde{K}_{H,h}$  of the matrix  $K_h$ . The matrix  $M_h$  can always be computed analytically. In all the examples below, the Hamiltonian  $H$ , and thus the stiffness matrix  $\tilde{K}_{H,h}$ , have been computed analytically. We avoided storing the (full) matrices  $M_h$  and  $\tilde{K}_{H,h}$  when the number of discretization points was large.

**6.2. Examples in dimension 1.** The next two examples are inspired by those proposed by M. Falcone in [BCD97].

*Example 24.* We consider the case where  $T = 1$ ,  $\phi \equiv 0$ ,  $X = [-1, 1]$ ,  $U = [0, 1]$ ,  $\ell(x, u) = x$ , and  $f(x, u) = -xu$ . Assumptions (H1) and (H2) are satisfied. The optimal choice is to take  $u^* = 0$  whenever  $x > 0$  and to move on the right with maximum speed ( $u^* = 1$ ) whenever  $x \leq 0$ . For all  $t \in [0, T]$ , the value function is

$$v(x, t) = \begin{cases} xt & \text{if } x > 0, \\ x(1 - e^{-t}) & \text{otherwise.} \end{cases}$$

We choose quadratic finite elements  $w_i$  of Hessian  $c$  centered at the points of the regular grid  $(\mathbb{Z}\Delta x) \cap [-2, 2]$  and Lipschitz finite elements  $z_j$  with constant  $a \geq 1$  centered at the points of the regular grid  $(\mathbb{Z}\Delta x) \cap X$ . We represent in Figure 3 the solution given by our algorithm in the case where  $\delta = 0.01$ ,  $\Delta x = 0.005$ ,  $a = 1.5$ , and  $c = 1$ . We obtain an  $L_\infty$ -error of order  $10^{-2}$ .

*Example 25.* We consider the case where  $T = 1$ ,  $\Phi \equiv 0$ ,  $X = [-1, 1]$ ,  $U = [-1, 1]$ ,  $\ell(x, u) = -3(1 - |x|)$ , and  $f(x, u) = u(1 - |x|)$ . It is clear that  $\ell$  and  $f$  are bounded and Lipschitz continuous functions. The optimal choice is to take  $u^* = -1$  whenever  $x > 0$  and  $u^* = 1$  whenever  $x < 0$ . Therefore, all the trajectories lie in  $X$ . For all  $t \in [0, T]$ , the value function is

$$v(x, t) = -3(1 - |x|)(1 - e^{-t}).$$

We choose quadratic finite elements  $w_i$  of Hessian  $c$  and Lipschitz finite elements  $z_j$  with constant  $a$ . We represent in Figure 4 the solution given by our algorithm in the case where  $\delta = 0.02$ ,  $\Delta x = 0.01$ ,  $a = 2$ , and  $c = 8$ . We obtain an  $L_\infty$ -error of order  $7.66 \cdot 10^{-3}$ .

*Example 26* (linear quadratic problem). We consider the case where  $U = \mathbb{R}$ ,  $X = \mathbb{R}$ ,

$$\ell(x, u) = -\frac{1}{2}(x^2 + u^2), \quad f(x, u) = u, \quad \text{and } \phi \equiv 0.$$

FIG. 4. *Max-plus approximation (Example 25).*

FIG. 5. *Max-plus approximation of a linear quadratic control problem (Example 26).*

The Hamiltonian is  $H(x, p) = -\frac{x^2}{2} + \frac{p^2}{2}$ . This problem can be solved analytically. For  $x \in X$ , the value function at time  $t$  is

$$v(x, t) = -\frac{1}{2} \tanh(t) x^2.$$

The domain  $X$  is unbounded, and  $\ell$  and  $f$  are unbounded and locally Lipschitz continuous. We will restrict  $X$  to the set  $[-5; 5]$  so that  $\ell$  and  $f$  satisfy assumptions (H1) and (H2).

We choose quadratic finite elements  $w_i$  and  $z_j$  of Hessian  $c = 1$ , centered at the points of the regular grid  $(\mathbb{Z}\Delta x) \cap [-6, 6]$ . We represent in Figure 5 the solution given by our algorithm in the interval  $[-1; 1]$  in the case where  $T = 5$ ,  $\delta = 0.5$ ,  $\Delta x = 0.05$ , and  $L = 1$ . We obtain an  $L_\infty$ -error of  $4.54 \cdot 10^{-5}$ .

*Example 27* (distance problem). We consider the case where  $T = 1$ ,  $\phi \equiv 0$ ,  $X = [-1, 1]$ ,  $U = [-1, 1]$ ,

$$\ell(x, u) = \begin{cases} -1 & \text{if } x \in (-1, 1), \\ 0 & \text{if } x \in \{-1, 1\}, \end{cases} \quad \text{and} \quad f(x, u) = \begin{cases} u & \text{if } x \in (-1, 1), \\ 0 & \text{if } x \in \{-1, 1\}. \end{cases}$$

Putting  $\ell = 0$  and  $f = 0$  on  $\partial X$  keeps the trajectories in the domain  $X$ , but we lose the Lipschitz continuity of  $\ell$  and  $f$ . For  $x \in X$ , the value function at time  $t$  of this

FIG. 6. A bad choice of test functions for the distance problem (Example 27).

FIG. 7. A good choice of test functions for the distance problem (Example 27).

problem is

$$v(x, t) = \max(-t, |x| - 1).$$

Consider first quadratic finite elements  $w_i$  and  $z_j$  of Hessian  $c$ , centered at the points of the regular grid  $(\mathbb{Z}\Delta x) \cap (X + B_\infty(0, \frac{L}{c}))$ . In Figure 6, we represent the solution given by our algorithm in the case where  $\delta = 0.02$ ,  $\Delta x = 0.01$ ,  $c = 2$ , and  $L = 1$ . Since  $\Pi^{Z_h^*}$  is a projector on a subsemimodule of the  $\bar{\mathbb{R}}_{\min}$ -semimodule of  $c$ -semiconcave functions, and since the solution is not  $c$ -semiconcave for any  $c$ , the error of projection  $\|\Pi^{Z_h^*}(v^t) - v^t\|_\infty$  does not converge to zero when  $\Delta x$  goes to zero, which explains the magnitude of the error.

To solve this problem, it suffices to replace the test functions  $z_j$  by the Lipschitz finite elements with constant  $a \geq 1$ , centered at the points of the regular grid  $(\mathbb{Z}\Delta x) \cap [-1, 1]$ . This is illustrated in Figure 7 in the case where  $\delta = 0.02$ ,  $\Delta x = 0.01$ ,  $c = 2$ , and  $a = 1.1$ . We obtain an  $L_\infty$ -error of  $1.05 \cdot 10^{-2}$ .

### 6.3. Examples in dimension 2.

*Example 28* (linear quadratic problem in dimension 2). We consider the case where  $U = \mathbb{R}^2$ ,  $X = \mathbb{R}^2$ ,  $\phi \equiv 0$ ,

$$\ell(x, u) = -\frac{x_1^2 + x_2^2}{2} - \frac{u_1^2 + u_2^2}{2}, \quad \text{and} \quad f(x, u) = u.$$

FIG. 8. *Max-plus approximation of a linear quadratic control problem (Example 28).*

For  $x \in X$ , the value functions at time  $t$  is

$$v(x, t) = -\frac{1}{2} \tanh(t)(x_1^2 + x_2^2).$$

As in Example 26, the domain  $X$  is unbounded; therefore  $\ell$  and  $f$  do not satisfy assumptions (H1) and (H2). We will restrict the domain to the set  $[-5; 5]^2$ . We choose quadratic finite elements  $w_i$  and  $z_j$  of Hessian  $c$  centered at the points of the regular grid  $((\mathbb{Z}\Delta x) \cap [-6, 6])^2$ . We represent in Figure 8 the solution given by our algorithm in the case where  $T = 5$ ,  $\delta = 0.5$ ,  $\Delta x = 0.1$ , and  $c = 1$ . The  $L_\infty$ -error is  $9 \cdot 10^{-5}$ .

*Example 29* (distance problem in dimension 2). We consider the case where  $T = 1$ ,  $\phi \equiv 0$ ,  $X = [-1, 1]^2$ ,  $U = [-1, 1]^2$ ,

$$\ell(x, u) = \begin{cases} -1 & \text{if } x \in \text{int}X, \\ 0 & \text{if } x \in \partial X, \end{cases}$$

and

$$f(x, u) = 7 \begin{cases} u & \text{if } x \in \text{int}X, \\ 0 & \text{if } x \in \partial X. \end{cases}$$

For  $x \in X$ , the value function at time  $t$  is

$$v(x, t) = \max(-t, \max(|x_1|, |x_2|) - 1).$$

We choose quadratic finite elements  $w_i$  of Hessian  $c$  centered at the points of the regular grid  $((\mathbb{Z}\Delta x) \cap [-3, 3])^2$  and Lipschitz finite elements  $z_j$  with constant  $a$  centered at the points of the regular grid  $((\mathbb{Z}\Delta x) \cap [-1, 1])^2$ . We represent in Figure 9 the solution given by our algorithm in the case where  $T = 1$ ,  $\delta = 0.05$ ,  $\Delta x = 0.025$ ,  $a = 3$ , and  $c = 1$ . The  $L_\infty$ -error is of order 0.05.

FIG. 9. *Max-plus approximation of the distance problem (Example 29).*FIG. 10. *Max-plus approximation of the rotating problem (Example 30).*

*Example 30* (rotating problem). We consider here the Mayer problem where  $T = 1$ ,  $X = B_2(0, 1)$ ,  $U = \{0\}$ ,  $\phi(x) = -\frac{1}{2}x_1^2 - \frac{3}{2}x_2^2$ ,  $\ell(x, u) = 0$ , and  $f(x, u) = (-x_2, x_1)$ . For  $x \in X$ , the value function at time  $t$  is

$$v(x, t) = -\frac{1}{2}(-x_2 \sin(t) + x_1 \cos(t))^2 - \frac{3}{2}(x_2 \cos(t) + x_1 \sin(t))^2.$$

We choose quadratic finite elements  $w_i$  and  $z_j$  of Hessians  $c_w$  and  $c_z$ , respectively, centered at the points of the regular grid  $((\mathbb{Z}\Delta x) \cap [-2, 2])^2$ . We represent in Figure 10 the solution given by our algorithm in the case where  $\delta = \Delta x = 0.05$ ,  $c_w = 4$ , and  $c_z = 3$ . The  $L_\infty$ -error is 0.046.

FIG. 11. Max-plus approximation of the solution of the control problem of Example 31.

*Example 31.* We consider the case where  $U = \mathbb{R}$ ,  $X = \mathbb{R}^2$ ,  $\phi(x) = -x_1^2 - 2x_2^2$ ,

$$\ell(x, u) = -x_1^2 - \frac{u^2}{2}, \quad \text{and} \quad f(x, u) = (x_2, u)^T.$$

We choose quadratic finite elements  $w_i$  and  $z_j$  of Hessian  $c_w$  and  $c_z$ , respectively, centered at the points of the grids  $((\mathbb{Z}\Delta x) \cap [-2, 2])^2$  and  $((\mathbb{Z}\Delta x) \cap [-11, 11])^2$ , respectively. We represent in Figure 11 the solution given by our algorithm in the case where  $T = 1$ ,  $\delta = 0.05$ ,  $\Delta x = 0.025$ ,  $c_w = 10$ , and  $c_z = 1$ . The  $L_\infty$ -error is 0.11. (We compared the max-plus approximation with the solution of the problem given by the Riccati equation.)

**6.4. Conclusion.** We have tested our method on examples that fulfill the assumptions of Theorem 22 (see Examples 24, 25, 30) but also on problems that do not fulfill these assumptions. The method is efficient even in the second case. The only difficulty comes from the full character of the matrices  $M_h$  and  $K_h$ , which limits the number of discretization points. To treat higher dimensional examples, we need higher-order approximations (when the value function is regular enough). This is the object of a subsequent work.

**Acknowledgment.** We thank Henda El Fekih for advice and suggestions throughout the development of the present work.

## NONUNIFORM SMALL-GAIN THEOREMS FOR SYSTEMS WITH UNSTABLE INVARIANT SETS\*

IVAN TYUKIN<sup>†</sup>, ERIK STEUR<sup>‡</sup>, HENK NIJMEIJER<sup>‡</sup>, AND CEES VAN LEEUWEN<sup>§</sup>

**Abstract.** We consider the problem of asymptotic convergence to invariant sets in interconnected nonlinear dynamical systems. Standard approaches often require that the invariant sets be uniformly attracting, e.g., stable in the Lyapunov sense. This, however, is neither a necessary requirement nor is always useful. Systems may, for instance, be inherently unstable (e.g., intermittent, itinerant, meta-stable) or the problem statement may include requirements that cannot be satisfied with stable solutions. This is often the case in general optimization problems and in nonlinear parameter identification or adaptation. Conventional techniques for these cases either rely on detailed knowledge of the system's vector-fields or require boundedness of its states. The presently proposed method relies only on estimates of the input-output maps and steady-state characteristics. The method requires the possibility of representing the system as an interconnection of a stable and contracting part with an unstable and exploratory part. We illustrate with examples how the method can be applied to problems of analyzing the asymptotic behavior of locally unstable systems as well as to problems of parameter identification and adaptation in the presence of nonlinear parametrizations. The relation of our results to conventional small-gain theorems is discussed.

**Key words.** nonuniform convergence, weakly attracting sets, small-gain theorems, input-output stability

**DOI.** 10.1137/060672546

**1. Notation.** Throughout the paper we use the following notational conventions. The symbol  $\mathbb{R}$  denotes the field of real numbers; symbol  $\mathbb{R}_+$  stands for the following subset of  $\mathbb{R}$ :  $\mathbb{R}_+ = \{x \in \mathbb{R} \mid x \geq 0\}$ ; and  $\mathbb{N}$  and  $\mathbb{Z}$  denote the set of natural numbers and its extension to the negative domain, respectively.

Let  $\Omega$  be a set; by the symbol  $\mathcal{S}\{\Omega\}$  we denote the set of all subsets of  $\Omega$ . The symbol  $\mathcal{C}^k$  denotes the space of functions that are at least  $k$  times differentiable;  $\mathcal{K}$  denotes the class of all strictly increasing functions  $\kappa : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  such that  $\kappa(0) = 0$ . If, in addition,  $\lim_{s \rightarrow \infty} \kappa(s) = \infty$ , we say that  $\kappa \in \mathcal{K}_\infty$ . Further,  $\mathcal{K}_e$  (or  $\mathcal{K}_{e,\infty}$ ) denotes the class of functions of which the restriction to the interval  $[0, \infty)$  belongs to  $\mathcal{K}$  (or  $\mathcal{K}_\infty$ ). The symbol  $\mathcal{KL}$  denotes the class of functions  $\beta : \mathbb{R}_+ \times \mathbb{R}_+ \rightarrow \mathbb{R}_+$  such that  $\beta(\cdot, s) \in \mathcal{K}$  and  $\beta(r, \cdot)$  is monotonically decreasing for each  $s, r \in \mathbb{R}_+$ .

Let  $\mathbf{x} \in \mathbb{R}^n$ , and  $\mathbf{x}$  can be partitioned into two vectors  $\mathbf{x}_1 \in \mathbb{R}^q$ ,  $\mathbf{x}_1 = (x_{11}, \dots, x_{1q})^T$ ,  $\mathbf{x}_2 \in \mathbb{R}^p$ ,  $\mathbf{x}_2 = (x_{21}, \dots, x_{2p})^T$  with  $q + p = n$ ; then  $\oplus$  denotes their concatenation:  $\mathbf{x} = \mathbf{x}_1 \oplus \mathbf{x}_2$ .

The symbol  $\|\mathbf{x}\|$  denotes the Euclidian norm in  $\mathbf{x} \in \mathbb{R}^n$ . By  $L_\infty^n[t_0, T]$  we denote the space of all functions  $\mathbf{f} : \mathbb{R}_+ \rightarrow \mathbb{R}^n$  such that  $\|\mathbf{f}\|_{\infty, [t_0, T]} = \sup\{\|\mathbf{f}(t)\|, t \in [t_0, T]\} < \infty$ , and  $\|\mathbf{f}\|_{\infty, [t_0, T]}$  stands for the  $L_\infty^n[t_0, T]$  norm of  $\mathbf{f}(t)$ . Let  $\mathcal{A}$  be a set in  $\mathbb{R}^n$  and  $\|\cdot\|$  be the usual Euclidian norm in  $\mathbb{R}^n$ . By the symbol  $\|\cdot\|_{\mathcal{A}}$  we denote the following induced norm:

$$\|\mathbf{x}\|_{\mathcal{A}} = \inf_{\mathbf{q} \in \mathcal{A}} \{\|\mathbf{x} - \mathbf{q}\|\}.$$

Let  $\Delta \in \mathbb{R}_+$ ; then the notation  $\|\mathbf{x}\|_{\mathcal{A}_\Delta}$  stands for the following equality:

$$\|\mathbf{x}\|_{\mathcal{A}_\Delta} = \begin{cases} \|\mathbf{x}\|_{\mathcal{A}} - \Delta, & \|\mathbf{x}\|_{\mathcal{A}} > \Delta, \\ 0, & \|\mathbf{x}\|_{\mathcal{A}} \leq \Delta. \end{cases}$$

The symbol  $\|\cdot\|_{\mathcal{A}_\infty, [t_0, t]}$  is defined as follows:

$$\|\mathbf{x}(\tau)\|_{\mathcal{A}_\infty, [t_0, t]} = \sup_{\tau \in [t_0, t]} \|\mathbf{x}(\tau)\|_{\mathcal{A}}.$$

**2. Introduction.** In many fields of science, such as systems and control theory, physics, chemistry, and biology, it is of fundamental importance to analyze the asymptotic behavior of dynamical systems. Most of these analyses are based around the concept of Lyapunov stability [15], [33], [32], i.e., continuity of the flow  $\mathbf{x}(t, \mathbf{x}_0) : \mathbb{R}_+ \times \mathbb{R}^n \rightarrow L_\infty^n[t_0, \infty]$  with respect to  $\mathbf{x}_0$  [18], in combination with the standard notion of an *attracting set* [9], defined as follows.

DEFINITION 1. A set  $\mathcal{A}$  is an *attracting set* iff it is

- (i) *closed, invariant, and*
- (ii) *for some neighborhood  $\mathcal{V}$  of  $\mathcal{A}$  and for all  $\mathbf{x}_0 \in \mathcal{V}$  the following conditions hold:*

$$(1) \quad \mathbf{x}(t, \mathbf{x}_0) \in \mathcal{V} \quad \forall t \geq 0;$$

$$(2) \quad \lim_{t \rightarrow \infty} \|\mathbf{x}(t, \mathbf{x}_0)\|_{\mathcal{A}} = 0.$$

Condition (1) in Definition 1 stipulates the existence of a trapping region  $\mathcal{V}$  which is a neighborhood of  $\mathcal{A}$ . Condition (2) assures convergence to  $\mathcal{A}$ . Due to condition (1), convergence to  $\mathcal{A}$  is uniform with respect to  $\mathbf{x}_0$  in the neighborhood of  $\mathcal{A}$ ; i.e., every trajectory which starts in  $\mathcal{V}$  remains in  $\mathcal{V}$  for  $t \geq 0$  and converges to  $\mathcal{A}$  at  $t \rightarrow \infty$ .

Although the conventional concepts of attracting set and Lyapunov stability are powerful in tandem in various applications, some problems cannot be solved within this framework. Condition (1), for example, could be violated in systems with intermittent, itinerant, or meta-stable dynamics. In general the condition does not hold when the system dynamics, loosely speaking, is exploring rather than contracting. Such systems appear naturally in the context of global optimization. For instance, in [22] finding the global minimum of a differentiable cost function  $Q : \mathbb{R}^n \rightarrow \mathbb{R}_+$  in a bounded subset  $\Omega_x \subset \mathbb{R}^n$  is achieved by splitting the search procedure into a locally attracting gradient  $\mathcal{S}_a$  and a wandering part  $\mathcal{S}_w$ :

$$(3) \quad \begin{aligned} \mathcal{S}_a : \dot{\mathbf{x}} &= -\mu_x \frac{\partial Q(\mathbf{x})}{\partial \mathbf{x}} + \mu_t T(t), \quad \mu_x, \mu_t \in \mathbb{R}_+, \\ \mathcal{S}_w : T(t) &= h\{t, \mathbf{x}(t)\}, \quad h : \mathbb{R}_+ \times L_\infty^n[t_0, t] \rightarrow L_\infty^n[t_0, t]. \end{aligned}$$

The trace function,  $T(t)$ , in (3) is supposed to cover (i.e., be dense in) the whole searching domain  $\Omega_x$ . Even though the results in [22] are purely simulation studies,

they illustrate the superior performance of algorithms (3) in a variety of benchmark problems compared to standard local minimizers and classical methods of global optimization. Abandoning Lyapunov stability is likewise advantageous in problems of identification and adaptation in the presence of general nonlinear parametrization [28], in maneuvering and path searching [26], and in decision making in intelligent systems [30], [31]. Systems with attracting, yet unstable, invariant sets are relevant for modeling complex behavior in biological and physical systems [2]. Last but not least, Lyapunov-unstable attracting sets are relevant in problems of synchronization [5], [19], [27].<sup>1</sup>

Even when it is appropriate to consider a system as stable, we may be limited in our success in meeting the requirement to identify a proper Lyapunov function. This is the case, for instance, when the system's dynamics is only partially known. Trading stability requirements for the sake of convergence might be a possible remedy. Known results in this direction can be found in [11], [21].<sup>2</sup>

In all the cases that are problematic under condition (1) of Definition 1, condition (2)—convergence of  $\mathbf{x}(t, \mathbf{x}_0)$  to an invariant set  $\mathcal{A}$ —is still a requirement that has to be met. In order to treat these cases analytically we shall, first of all, move from the standard concept of attracting sets in Definition 1 to one that does not assume that the basin of attraction is necessarily a neighborhood of the invariant set  $\mathcal{A}$ . In other words we shall allow convergence which is not uniform in initial conditions. This requirement is captured by the concept of weak, or Milnor, attraction [17], defined as follows.

DEFINITION 2. *A set  $\mathcal{A}$  is weakly attracting, or Milnor attracting, iff*

- (i) *it is closed, invariant, and*
- (ii) *for some set  $\mathcal{V}$  (not necessarily a neighborhood of  $\mathcal{A}$ ) with strictly positive measure and for all  $\mathbf{x}_0 \in \mathcal{V}$  limiting relation (2) holds.*

Conventional methods such as La Salle's invariance principle [14] or center manifold theory [7] can, in principle, address the issue of convergence to weak equilibria. They do so, however, at the expense of requiring detailed knowledge of the vector-fields of the ordinary differential equations of the model. When such information is not available the system can be thought of as a mere interconnection of input-output maps. Small-gain theorems [34], [12] are usually efficient in this case. These results, however, apply only under the assumption of stability of each component in the interconnection.

In the present study we aim to find a proper balance between the generality of input-output approaches [34], [12] in the analysis of convergence and the specificity of the fundamental notions of limit sets and invariance that play a central role in [14], [7]. The object of our study is a class of systems that can be decomposed into an attracting, or stable, component  $\mathcal{S}_a$  and an exploratory, generally unstable, part  $\mathcal{S}_w$ . Typical systems of this class are nonlinear systems in cascaded form

$$(4) \quad \begin{aligned} \mathcal{S}_a : \quad \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, \mathbf{z}), \\ \mathcal{S}_w : \quad \dot{\mathbf{z}} &= \mathbf{q}(\mathbf{z}, \mathbf{x}), \end{aligned}$$

where the zero solution of the  $\mathbf{x}$ -subsystem is asymptotically stable in the absence of

<sup>1</sup>See also [20], where the striking difference between stable and “almost stable” synchronization in terms of the coupling strengths for a pair of the Lorenz oscillators is demonstrated analytically.

<sup>2</sup>In Examples 1 and 2 in section 6, we demonstrate how explorative dynamics can solve the problem of simultaneous state and parameter observation for a system which cannot be transformed into a canonical adaptive observer form [3].

input  $\mathbf{z}$ , and the state of the  $\mathbf{z}$ -subsystem consists of functions of the type  $\int_{t_0}^t \|\mathbf{x}(\tau)\| d\tau$ . Even when both subsystems in (4) are stable and the  $\mathbf{x}$ -subsystem does not depend on state  $\mathbf{z}$ , the cascade can still be unstable [1]. We show, however, that for unstable interconnections (4), under certain conditions that involve only input-to-state properties of  $\mathcal{S}_a$  and  $\mathcal{S}_w$ , there is a set  $\mathcal{V}$  in the system state space such that trajectories starting in  $\mathcal{V}$  remain bounded. The result is formally stated in Theorem 3. In the case when an additional measure of invariance is defined for  $\mathcal{S}_a$  (in our case a steady-state characteristic), a weak, Milnor attracting set emerges. Its location is completely determined by the zeros of the steady-state response of system  $\mathcal{S}_a$ .

We demonstrate how this basic result can be used in problems of design and analysis of control systems and identification/adaptation algorithms. In particular, we present an adaptive observer of state and parameter values for uncertain systems which cannot be transformed into a canonic adaptive observer form [3]. In Examples 1 and 2 in section 6 we present an application of this result to the problem of reconstructing a dynamic model of neuronal cell activity.

The paper is organized as follows. In section 3 we formally state the problem and provide specific assumptions for the class of systems under consideration. Section 4 contains the main results of our present study. In section 5 we provide several corollaries of the main result that apply to specific problems. Section 6 contains examples, and section 7 concludes the paper. Proofs of all lemmas, theorems, and corollaries are provided in the appendix.

**3. Problem formulation.** Consider a system that can be decomposed into two interconnected subsystems,  $\mathcal{S}_a$  and  $\mathcal{S}_w$ :

$$(5) \quad \begin{aligned} \mathcal{S}_a &: (u_a, \mathbf{x}_0) \mapsto \mathbf{x}(t), \\ \mathcal{S}_w &: (u_w, \mathbf{z}_0) \mapsto \mathbf{z}(t), \end{aligned}$$

where  $u_a \in \mathcal{U}_a \subseteq L_\infty[t_0, \infty]$ ,  $u_w \in \mathcal{U}_w \subseteq L_\infty[t_0, \infty]$  are the spaces of inputs to  $\mathcal{S}_a$  and  $\mathcal{S}_w$ , respectively,  $\mathbf{x}_0 \in \mathbb{R}^n$ ,  $\mathbf{z}_0 \in \mathbb{R}^m$  represent initial conditions, and  $\mathbf{x}(t) \in \mathcal{X} \subseteq L_\infty^n[t_0, \infty]$ ,  $\mathbf{z}(t) \in \mathcal{Z} \subseteq L_\infty^m[t_0, \infty]$  are the system states.

System  $\mathcal{S}_a$  represents the contracting dynamics. More precisely, we require that  $\mathcal{S}_a$  is input-to-state stable<sup>3</sup> [23] with respect to a compact set  $\mathcal{A}$ .

ASSUMPTION 1 (contracting dynamics).

$$(6) \quad \mathcal{S}_a : \|\mathbf{x}(t)\|_{\mathcal{A}} \leq \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, t - t_0) + c\|u_a(t)\|_{\infty, [t_0, t]} \quad \forall t_0 \in \mathbb{R}_+, t \geq t_0,$$

where the function  $\beta(\cdot, \cdot) \in \mathcal{KL}$ , and  $c > 0$  is some positive constant.

The function  $\beta(\cdot, \cdot)$  in (6) specifies the contraction property of the unperturbed dynamics of  $\mathcal{S}_a$ . In other words it models the rate with which the system forgets its initial conditions  $\mathbf{x}_0$ , if left unperturbed. Propagation of the input to output is estimated in terms of a continuous mapping,  $c\|u_a(t)\|_{\infty, [t_0, t]}$ , which, in our case, is chosen for simplicity to be linear. Notice that this mapping should not necessarily be contracting. In what follows we will assume that the function  $\beta(\cdot, \cdot)$  and constant  $c$  are known or can be estimated a priori.

For systems  $\mathcal{S}_a$ , of which a model is given by a system of ordinary differential equations

$$(7) \quad \dot{\mathbf{x}} = \mathbf{f}_x(\mathbf{x}, u_a), \quad \mathbf{f}_x(\cdot, \cdot) \in \mathcal{C}^1,$$

<sup>3</sup>In general, as will be demonstrated with examples, our analysis can be carried out for (integral) input-to-output/input-to-state stable systems as well.

Assumption 1 is equivalent, for instance, to the combination of the following properties:<sup>4</sup>

1. Let  $u_a(t) \equiv 0$  for all  $t$ ; then the set  $\mathcal{A}$  is Lyapunov stable and globally attracting for (7).
2. For all  $u_a \in \mathcal{U}_a$  and  $\mathbf{x}_0 \in \mathbb{R}^n$  there exists a nondecreasing function  $\kappa : \mathbb{R}_+ \rightarrow \mathbb{R}_+ : \kappa(0) = 0$  such that

$$\inf_{t \in [0, \infty)} \|\mathbf{x}(t)\|_{\mathcal{A}} \leq \kappa(\|u_a(t)\|_{\infty, [t_0, \infty)}).$$

The system  $\mathcal{S}_w$  stands for the searching or wandering dynamics. We will consider  $\mathcal{S}_w$  subject to the following conditions.

ASSUMPTION 2 (wandering dynamics). *The system  $\mathcal{S}_w$  is forward-complete:*

$$u_w(t) \in \mathcal{U}_w \Rightarrow \mathbf{z}(t) \in \mathcal{Z} \quad \forall t \geq t_0, \quad t_0 \in \mathbb{R}_+,$$

and there exists an “output” function  $h : \mathbb{R}^m \rightarrow \mathbb{R}$ , and two “bounding” functions  $\gamma_0 \in \mathcal{K}_{\infty, e}$ ,  $\gamma \in \mathcal{K}_{\infty, e}$  such that the following integral inequality holds:

$$(8) \quad \mathcal{S}_w : \int_{t_0}^t \gamma_1(u_w(\tau)) d\tau \leq h(\mathbf{z}(t_0)) - h(\mathbf{z}(t)) \leq \int_{t_0}^t \gamma_0(u_w(\tau)) d\tau$$

$$\forall t \geq t_0, \quad t_0 \in \mathbb{R}_+.$$

In the case when system  $\mathcal{S}_w$  is specified in terms of vector-fields

$$(9) \quad \dot{\mathbf{z}} = \mathbf{f}_z(\mathbf{z}, u_w), \quad \mathbf{f}_z(\cdot, \cdot) \in \mathcal{C}^1,$$

Assumption 2 can be viewed, for example, as postulating the existence of a function  $h : \mathbb{R}^m \rightarrow \mathbb{R}_+$  of which the evolution in time is a mere integration of the input  $u_w(t)$ . In general, for  $u_w : u_w(t) \geq 0$  for all  $t \in \mathbb{R}_+$ , inequality (8) implies *monotonicity* of function  $h(\mathbf{z}(t))$  in  $t$ . Regarding the function  $\gamma_0(\cdot)$  in (8), we assume that for any  $M \in \mathbb{R}_+$  there exists a function  $\gamma_{0,1} : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  and a *nondecreasing* function  $\gamma_{0,2} : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  such that

$$(10) \quad \gamma_0(a \cdot b) \leq \gamma_{0,1}(a) \cdot \gamma_{0,2}(b) \quad \forall a, b \in [0, M].$$

Requirement (10) is a technical assumption which will be used in the formulation and proof of the main results of the paper. Yet, it is not too restrictive; it holds, for instance, for a wide class of locally Lipschitz functions  $\gamma_0(\cdot) : \gamma_0(a \cdot b) \leq L_0(M) \cdot (a \cdot b)$ ,  $L_0(M) \in \mathbb{R}_+$ . Another example for which the assumption holds is the class of polynomial functions  $\gamma_0(\cdot) : \gamma_0(a \cdot b) = (a \cdot b)^p = a^p \cdot b^p$ ,  $p > 0$ . No further restrictions will be imposed a priori on  $\mathcal{S}_a, \mathcal{S}_w$ .

Now consider the interconnection of (6), (8) with coupling  $u_a(t) = h(\mathbf{z}(t))$  and  $u_s(t) = \|\mathbf{x}(t)\|_{\mathcal{A}}$ . Equations for the combined system can be written as

$$(11) \quad \begin{aligned} \|\mathbf{x}(t)\|_{\mathcal{A}} &\leq \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, t - t_0) + c\|h(\mathbf{z}(t))\|_{\infty, [t_0, t]}, \\ \int_{t_0}^t \gamma_1(\|\mathbf{x}(\tau)\|_{\mathcal{A}}) d\tau &\leq h(\mathbf{z}(t_0)) - h(\mathbf{z}(t)) \leq \int_{t_0}^t \gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}}) d\tau. \end{aligned}$$

<sup>4</sup>For a comprehensive characterization of the input-to-state stability and detailed mathematical arguments we refer to the paper by Sontag and Wang [24].

FIG. 1. The class of interconnected systems  $S_a$  and  $S_w$  (diagram (a)). System  $S_a$ , the “contracting system,” has an attracting invariant set  $A$  in its state space. System  $S_w$  does not necessarily have an attracting set. This system represents the “wandering” dynamics. A typical example of such behavior is the dynamics of the flow in a neighborhood of a saddle point in three-dimensional space (diagram (b)).

A diagram illustrating the general structure of the entire system (11) is given in Figure 1.

Equations (11) capture the relevant interplay between contracting,  $S_a$ , and wandering,  $S_w$ , dynamics inherent in a variety of searching strategies in the realm of optimization, (3), and interconnections, (4), in general systems theory. In addition, this kind of interconnection describes the behavior of systems which undergo transcritical or saddle-node bifurcations. Consider, for instance, the following system:

$$(12) \quad \begin{aligned} \dot{x}_1 &= -x_1 + x_2, \\ \dot{x}_2 &= \varepsilon + \gamma x_1^2, \gamma > 0, \end{aligned}$$

where the parameter  $\varepsilon$  varies from negative to positive values. At  $\varepsilon = 0$  stable and unstable equilibria collide, leading to the cascade satisfying (11). An alternative bifurcation scenario could be represented by the system

$$(13) \quad \begin{aligned} \dot{x}_1 &= -x_1 + x_2, \\ \dot{x}_2 &= \varepsilon + \gamma x_2^2, \gamma > 0. \end{aligned}$$

In this case, however, the dynamics of the variable  $x_2$  is *independent* of  $x_1$ , and analysis of the asymptotic behavior of (13) reduces to the analysis of each equation separately. Thus systems such as (13) are easier to deal with than (12). This constitutes an additional motivation for the present approach.

When analyzing the asymptotic behavior of interconnection (11) we will address the following question: Is there a set (a weak trapping set in the system state space) such that the trajectories which start in this set are bounded? It is natural to expect that the existence of such a set depends on the specific functions  $\gamma_0(\cdot)$ ,  $\gamma_1(\cdot)$  in (11), on properties of  $\beta(\cdot, \cdot)$ , and on values of  $c$ . In the case when such a set exists and could be defined, the next questions are, therefore, where will the trajectories converge and how can these domains be characterized?

**4. Main results.** In this section we provide a formal statement of the main results of our present study. In section 4.1, we formulate conditions ensuring that

FIG. 2. Emergence of a weak (Milnor) attracting set  $\Omega_\infty$ . Panel (a) depicts the target invariant set  $\Omega_\infty$  as a filled circle. First (see Theorem 3), we investigate whether a domain  $\Omega_\gamma \subset \mathbb{R}^n \times \mathbb{R}^m$  exists such that  $\|\mathbf{x}(t)\|_{\mathcal{A}}, h(\mathbf{z}(t))$  are bounded for all  $\mathbf{x}_0 \oplus \mathbf{z}_0 \in \Omega_\gamma$ . In the text we refer to this set as a weak trapping region or simply a trapping region. The trapping region is shown as a grey domain in panel (b). In principle, the system's states can eventually leave the domain  $\Omega_\gamma$ . They must, however, satisfy (14), ensuring boundedness of  $\|\mathbf{x}(t)\|_{\mathcal{A}}, h(\mathbf{z}(t))$ . As a result they will dwell within the region shown as a circle in panel (b). Notice that neither this domain nor the previous need be neighborhoods of  $\Omega_\infty$ . Second (see Lemmas 6 and 7 and Corollary 8), we provide conditions which lead to the emergence of a weak attracting set in the trapping region  $\Omega_\gamma$ . This is illustrated in panel (c).

there exists a point  $\mathbf{x}_0 \oplus \mathbf{z}_0$  such that the  $\omega$ -limit set of  $\mathbf{x}_0 \oplus \mathbf{z}_0$ <sup>5</sup> is bounded in the following sense:

$$(14) \quad \|\omega_{\mathbf{x}}(\mathbf{x}_0 \oplus \mathbf{z}_0)\|_{\mathcal{A}} < \infty, \quad |h(\omega_{\mathbf{z}}(\mathbf{x}_0 \oplus \mathbf{z}_0))| < \infty.$$

These conditions and a specification of the set  $\Omega_\gamma$  of points  $\mathbf{x}' \oplus \mathbf{z}'$  for which the  $\omega$ -limit set satisfies property (14) are provided in Theorem 3.

In order to verify whether an attracting set exists in  $\omega(\Omega_\gamma)$  that is a subset of  $\omega(\Omega_\gamma)$  we use an additional characterization of the contracting system  $\mathcal{S}_a$ . In particular, we introduce the intuitively clear notion of the input-to-state *steady-state characteristics*<sup>6</sup> of a system. It is possible to show that in the case when system  $\mathcal{S}_a$  has a steady-state characteristic, there exists an attracting set in  $\omega(\Omega_\gamma)$ , and this set is uniquely defined by the zeros of the steady-state characteristics of  $\mathcal{S}_a$ . A diagram illustrating the steps of our analysis is provided in Figure 2, along with the sequence of conditions leading to the emergence of the attracting set in (11).

**4.1. Emergence of the trapping region. Small-gain conditions.** Before we formulate the main results of this section let us first comment briefly on the machinery of our analysis. First, we introduce three sequences

$$\begin{aligned} \mathcal{S} &= \{\sigma_i\}_{i=0}^\infty, \quad \sigma_i \in \mathbb{R}_+, \\ \Xi &= \{\xi_i\}_{i=0}^\infty, \quad \xi_i \in \mathbb{R}_+, \\ \mathcal{T} &= \{\tau_i\}_{i=0}^\infty, \quad \tau_i \in \mathbb{R}_+. \end{aligned}$$

The first sequence,  $\mathcal{S}$ , partitions the interval  $[0, h(\mathbf{z}_0)]$ ,  $h(\mathbf{z}_0) > 0$ , into the union of shrinking subintervals  $H_i$ :

$$(15) \quad [0, h(\mathbf{z}_0)] = \cup_{i=0}^\infty H_i, \quad H_i = [\sigma_{i+1}h(\mathbf{z}_0), \sigma_i h(\mathbf{z}_0)].$$

<sup>5</sup>Recall that in our current notation a point  $\mathbf{p} \in \mathbb{R}^{m+n}$  is an  $\omega$ -limit point of  $\mathbf{x}' \oplus \mathbf{z}'$  if there exists a sequence  $\{t_i\}$ ,  $i = 1, 2, \dots$ , such that  $\lim_{i \rightarrow \infty} t_i = \infty$  and  $\lim_{t_i \rightarrow \infty} \mathbf{x}(t_i, \mathbf{x}' \oplus \mathbf{z}') \oplus \mathbf{z}(t_i, \mathbf{x}' \oplus \mathbf{z}') = \mathbf{p}$ , where  $\mathbf{x}(t, \mathbf{x}' \oplus \mathbf{z}') \oplus \mathbf{z}(t, \mathbf{x}' \oplus \mathbf{z}')$  denotes the flow of interconnection (11). A set of all  $\omega$ -limit points of  $\mathbf{x}' \oplus \mathbf{z}'$  is an  $\omega$ -limit set of  $\mathbf{x}' \oplus \mathbf{z}'$ .

<sup>6</sup>A more precise definition of the steady-state characteristics is given in section 4.2.

For the sake of clarity, let us define this property formally in the form of Property 1 as follows.

PROPERTY 1 (partition of  $\mathbf{z}_0$ ). *The sequence  $\mathcal{S}$  is strictly monotone and converging:*

$$(16) \quad \{\sigma_n\}_{n=0}^\infty : \lim_{n \rightarrow \infty} \sigma_n = 0, \sigma_0 = 1.$$

Sequences  $\Xi$  and  $\mathcal{T}$  will specify the desired rates  $\xi_i \in \Xi$  of the contracting dynamics (6) in terms of function  $\beta(\cdot, \cdot)$  and  $\tau_i \in \mathcal{T}$ . Let us, therefore, impose the following constraint on the choice of  $\Xi, \mathcal{T}$ .

PROPERTY 2 (rate of contraction, part 1). *Sequences  $\Xi$  and  $\mathcal{T}$  are such that for the given function  $\beta(\cdot, \cdot) \in \mathcal{KL}$  in (6) the following inequality holds:*

$$(17) \quad \beta(\cdot, T) \leq \xi_i \beta(\cdot, 0) \quad \forall T \geq \tau_i.$$

Property 2 states that for the given, yet arbitrary, factor  $\xi_i$  and time instant  $t_0$ , time  $\tau_i$  is needed for the state  $\mathbf{x}$  in order to reach the domain:

$$\|\mathbf{x}\|_{\mathcal{A}} \leq \xi_i \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, 0).$$

In order to specify the desired convergence rates  $\xi_i$ , it will be necessary to define another measure in addition to (17). This is a measure of the propagation of initial conditions  $\mathbf{x}_0$  and input  $h(\mathbf{z}_0)$  to the state  $\mathbf{x}(t)$  of the contracting dynamics (6) when the system travels in  $h(\mathbf{z}(t)) \in [0, h(\mathbf{z}_0)]$ . For this reason we introduce two systems of functions,  $\Phi$  and  $\Upsilon$ :

$$(18) \quad \Phi : \begin{aligned} \phi_j(s) &= \phi_{j-1} \circ \rho_{\phi,j}(\xi_{i-j} \cdot \beta(s, 0)), \quad j = 1, \dots, i, \\ \phi_0(s) &= \beta(s, 0), \end{aligned}$$

$$(19) \quad \Upsilon : \begin{aligned} v_j(s) &= \phi_{j-1} \circ \rho_{v,j}(s), \quad j = 1, \dots, i, \\ v_0(s) &= \beta(s, 0), \end{aligned}$$

where the functions  $\rho_{\phi,j}, \rho_{v,j} \in \mathcal{K}$  satisfy the following inequality:

$$(20) \quad \phi_{j-1}(a + b) \leq \phi_{j-1} \circ \rho_{\phi,j}(a) + \phi_{j-1} \circ \rho_{v,j}(b).$$

Notice that in the case when  $\beta(\cdot, 0) \in \mathcal{K}_\infty$ , the functions  $\rho_{\phi,j}(\cdot), \rho_{v,j}(\cdot)$  will always exist [12]. The properties of sequence  $\Xi$  which ensure the desired propagation rate of the influence of initial condition  $\mathbf{x}_0$  and input  $h(\mathbf{z}_0)$  to the state  $\mathbf{x}(t)$  are specified in Property 3.

PROPERTY 3 (rate of contraction, part 2). *The sequences*

$$\sigma_n^{-1} \cdot \phi_n(\|\mathbf{x}_0\|_{\mathcal{A}}), \quad \sigma_n^{-1} \cdot \left( \sum_{i=0}^n v_i(c|h(\mathbf{z}_0)|\sigma_{n-i}) \right), \quad n = 0, \dots, \infty,$$

*are bounded from above; e.g., there exist functions  $B_1(\|\mathbf{x}_0\|), B_2(|h(\mathbf{z}_0)|, c)$  such that*

$$(21) \quad \sigma_n^{-1} \cdot \phi_n(\|\mathbf{x}_0\|_{\mathcal{A}}) \leq B_1(\|\mathbf{x}_0\|_{\mathcal{A}}),$$

$$(22) \quad \sigma_n^{-1} \cdot \left( \sum_{i=0}^n v_i(c|h(\mathbf{z}_0)|\sigma_{n-i}) \right) \leq B_2(|h(\mathbf{z}_0)|, c)$$

*for all  $n = 0, 1, \dots, \infty$ .*

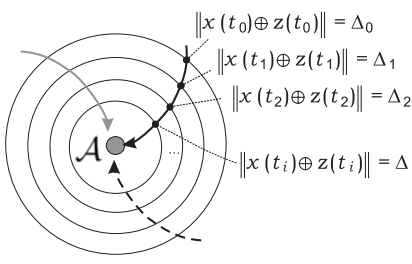

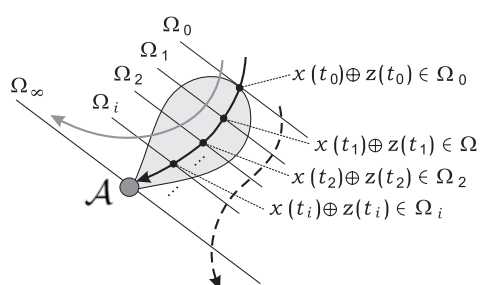

Standard	Proposed
1) Domain of attraction is a neighborhood  2) Implies Lyapunov stability  	1) Domain of attraction is a set of positive measure (not necessarily a neighborhood)  2) Allows us to analyze convergence in Lyapunov-unstable systems  
Given: a sequence of diverging time instances $t_i$	Given: a sequence of sets $\Omega_i$ whose distance $\Delta_i$ to $\mathcal{A}$ is converging to zero
Prove: convergence of norms $\ \mathbf{x}(t_i) \oplus \mathbf{z}(t_i)\  = \Delta_i$ to zero	Prove: divergence of $\{t_i\}$ , where $t_i : \mathbf{x}(t_i) \oplus \mathbf{z}(t_i) \in \Omega_i$

FIG. 3. Key differences between the conventional concept of convergence (left panel) and the concept of weak, nonuniform convergence (right panel). In the uniform case, trajectories which start in a neighborhood of  $\mathcal{A}$  remain in a neighborhood of  $\mathcal{A}$  (solid and dashed lines). In the nonuniform case, only a fraction of the initial conditions in a neighborhood of  $\mathcal{A}$  will produce trajectories which remain in a neighborhood of  $\mathcal{A}$  (solid black line). In the most general case a necessary condition for this to happen is that the sequence  $\{t_i\}$  diverges. In our current problem statement divergence of  $\{t_i\}$  implies boundedness of  $\|\mathbf{x}(t)\|_{\mathcal{A}}$ . To show state boundedness and convergence of  $\mathbf{x}(t)$  to  $\mathcal{A}$ , additional information on the system dynamics will be required.

For a large class of functions  $\beta(s, 0)$ , for instance those that are Lipschitz in  $s$ , these conditions reduce to more transparent ones which can always be satisfied by an appropriate choice of sequences  $\Xi$  and  $\mathcal{S}$ . This case is considered in detail as a corollary of our main results in section 4.3.

The main differences between the standard and the presently proposed approaches for the analysis of asymptotic behavior of dynamical systems are illustrated in Figure 3. In order to prove the emergence of the trapping region we consider the following collection of volumes induced by the sequence  $\mathcal{S}_i$  and the corresponding partition (15) of the interval  $[0, h(\mathbf{z}_0)]$ :

$$(23) \quad \Omega_i = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid h(\mathbf{z}(t)) \in H_i\}.$$

For the given initial conditions  $\mathbf{x}_0 \in \mathcal{X}$ ,  $\mathbf{z}_0 \in \mathcal{Z}$  two alternative possibilities exist. First, there exists an  $i$  such that the trajectory  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  enters  $\Omega_i$  and stays there forever. Hence for  $t \rightarrow \infty$  the state will converge into

$$(24) \quad \Omega_a = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid \|\mathbf{x}\|_{\mathcal{A}} \leq c \cdot h(\mathbf{z}_0), \mathbf{z} : h(\mathbf{z}) \in [0, h(\mathbf{z}_0)]\}.$$

The second alternative is that for each  $i = 0, 1, \dots$  the trajectory  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  enters  $\Omega_i$  and leaves some time later. Let  $t_i$  be the time instances when it hits

the hypersurfaces  $h(\mathbf{z}(t)) = h(\mathbf{z}_0)\sigma_i$ . Then the state of the coupled system stays in  $\cup_{i=0}^{\infty} \Omega_i$  only if the sequence  $\{t_i\}_{i=0}^{\infty}$  diverges. Theorem 3 provides sufficient conditions specifying the latter case in terms of the properties of sequences  $\mathcal{S}$ ,  $\Xi$ ,  $\mathcal{T}$  and function  $\gamma_0(\cdot)$  in (11). For a large class of interconnections (11) it is possible to formulate these conditions in terms of the input-output properties of systems  $\mathcal{S}_a$  and  $\mathcal{S}_w$  explicitly, i.e., in terms of functions  $\beta(\cdot, \cdot)$  and  $\gamma_0(\cdot)$  and the values of  $c$ . The results are presented as immediate corollaries of Theorem 3 in sections 4.3 and 5.1.

**THEOREM 3** (nonuniform small-gain theorem). *Let systems  $\mathcal{S}_a$ ,  $\mathcal{S}_w$  be given and satisfy Assumptions 1, 2. Consider their interconnection (11) and suppose there exist sequences  $\mathcal{S}$ ,  $\Xi$ , and  $\mathcal{T}$  satisfying Properties 1–3. In addition, suppose that the following conditions hold:*

1. *There exists a positive number  $\Delta_0 > 0$  such that*

$$(25) \quad \frac{1}{\tau_i} \frac{(\sigma_i - \sigma_{i+1})}{\gamma_{0,1}(\sigma_i)} \geq \Delta_0 \quad \forall i = 0, 1, \dots, \infty.$$

2. *The set  $\Omega_\gamma$  of all points  $\mathbf{x}_0, \mathbf{z}_0$  satisfying the inequality*

$$(26) \quad \gamma_{0,2}(B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) + B_2(|h(\mathbf{z}_0)|, c) + c|h(\mathbf{z}_0)|) \leq h(\mathbf{z}_0)\Delta_0$$

*is not empty.*

3. *Partial sums of elements from  $\mathcal{T}$  diverge:*

$$(27) \quad \sum_{i=0}^{\infty} \tau_i = \infty.$$

*Then for all  $\mathbf{x}_0, \mathbf{z}_0 \in \Omega_\gamma$  the state  $\mathbf{x}(t, \mathbf{z}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  of system (11) converges into the set specified by (24):*

$$\Omega_a = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid \|\mathbf{x}\|_{\mathcal{A}} \leq c \cdot h(\mathbf{z}_0), \mathbf{z} : h(\mathbf{z}) \in [0, h(\mathbf{z}_0)]\}.$$

The proofs of Theorem 3 and subsequent results are provided in the appendix.

The major difference between the conditions of Theorem 3 and those of conventional small-gain theorems [34], [12] is that the latter involve only input-output or input-state mappings. Formulating conditions for state boundedness of the interconnection in terms of input-output or input-state mappings is possible in the traditional case because the interconnected systems are assumed to be input-to-state stable. Hence their internal dynamics can be neglected. In our case, however, the dynamics of  $\mathcal{S}_w$  is generally unstable in the Lyapunov sense. Hence, in order to ensure boundedness of  $\mathbf{x}(t, \mathbf{x}_0)$  and  $h(\mathbf{z}(t, \mathbf{z}_0))$ , the rate/degree of stability of  $\mathcal{S}_a$  should be taken into account. Roughly speaking, system  $\mathcal{S}_a$  should ensure a sufficiently high degree of contraction in  $\mathbf{x}_0$  while the input-output response of  $\mathcal{S}_w$  should be sufficiently small. The rate of contraction in  $\mathbf{x}_0$  of  $\mathcal{S}_a$ , according to (6), is specified in terms of the function  $\beta(\cdot, \cdot)$ . Properties of this function that are relevant for convergence are explicitly accounted for in Property 3 and (27). The domain of admissible initial conditions, and actually the small-gain condition (input-state-output properties of  $\mathcal{S}_w$  and  $\mathcal{S}_a$ ), are defined by (25), (26), respectively. Notice also that  $\Omega_\gamma$  is not necessarily a neighborhood of  $\Omega_a$ ; thus the convergence ensured by Theorem 3 is allowed to be nonuniform in  $\mathbf{x}_0, \mathbf{z}_0$ .

**4.2. Characterization of the attracting set.** Even for interconnections of Lyapunov-stable systems, small-gain conditions usually are effective merely for establishing boundedness of states or outputs. Yet, even in the setting of Theorem 3 it is still possible to derive estimates (such as, for instance, (24)) of the domains to which the state will converge. These estimates, however, are often too conservative. If a more precise characterization of these domains is required, additional information on the dynamics of systems  $\mathcal{S}_a$  and  $\mathcal{S}_w$  will be needed. The question, therefore, is how detailed this information should be. It appears that some additional knowledge of the steady-state characteristics of system  $\mathcal{S}_a$  is sufficient to improve the estimates (24) substantially.

Let us formally introduce the notion of steady-state characteristic as follows.

**DEFINITION 4.** *We say that system (6) has steady-state characteristic  $\chi : \mathbb{R} \rightarrow \mathcal{S}\{\mathbb{R}_+\}$  with respect to the norm  $\|\mathbf{x}\|_{\mathcal{A}}$  iff for each constant  $\bar{u}_a$  the following holds:*

$$(28) \quad \forall u_a(t) \in \mathcal{U}_a : \lim_{t \rightarrow \infty} u_a(t) = \bar{u}_a \Rightarrow \lim_{t \rightarrow \infty} \|\mathbf{x}(t)\|_{\mathcal{A}} \in \chi(\bar{u}_a).$$

The key property captured by Definition 4 is that there exists a limit of  $\|\mathbf{x}(t)\|_{\mathcal{A}}$  as  $t \rightarrow \infty$ , provided that the limit for  $u_a(t)$ ,  $t \rightarrow \infty$ , is defined and constant. Notice that the mapping  $\chi$  is set-valued. This means that for each  $\bar{u}_a$  there is a set  $\chi(\bar{u}_a) \subset \mathbb{R}_+$  such that  $\|\mathbf{x}(t)\|_{\mathcal{A}}$  converges to an element of  $\chi(\bar{u}_a)$  as  $t \rightarrow \infty$ . Therefore, our definition allows a fairly large amount of uncertainty for  $\mathcal{S}_a$ . It will be of essential importance, however, that such a characterization exists for the system  $\mathcal{S}_a$ .

Clearly, not every system obeys a steady-state characteristic  $\chi(\cdot)$  of Definition 4. There are relatively simple systems of which the state does not converge even in the “norm” sense for constant converging inputs (condition (28)). In mechanics, physics, and biology such systems encompass the large class of nonlinear oscillators which can be excited by constant inputs. In order to take such systems into consideration, we introduce a weaker notion, that of a steady-state characteristic *on average*, defined as follows.

**DEFINITION 5.** *We say that system (6) has steady-state characteristic on average  $\chi_T : \mathbb{R} \rightarrow \mathcal{S}\{\mathbb{R}_+\}$  with respect to the norm  $\|\mathbf{x}\|_{\mathcal{A}}$  iff for each constant  $\bar{u}_a$  and some  $T > 0$  the following holds:*

$$(29) \quad \forall u_a(t) \in \mathcal{U}_a : \lim_{t \rightarrow \infty} u_a(t) = \bar{u}_a \Rightarrow \lim_{t \rightarrow \infty} \int_t^{t+T} \|\mathbf{x}(\tau)\|_{\mathcal{A}} d\tau \in \chi_T(\bar{u}_a).$$

Steady-state characterizations of system  $\mathcal{S}_a$  allow us to further specify the asymptotic behavior of interconnection (11). These results are summarized in Lemmas 6 and 7 below.

**LEMMA 6.** *Let system (11) be given and  $h(\mathbf{z}(t, \mathbf{z}_0))$  be bounded for some  $\mathbf{x}_0, \mathbf{z}_0$ . Let, furthermore, system (6) have steady-state characteristic  $\chi(\cdot) : \mathbb{R} \rightarrow \mathcal{S}\{\mathbb{R}_+\}$ . Then the following limiting relations hold:<sup>7</sup>*

$$(30) \quad \lim_{t \rightarrow \infty} \|\mathbf{x}(t, \mathbf{x}_0)\|_{\mathcal{A}} = 0, \quad \lim_{t \rightarrow \infty} h(\mathbf{z}(t, \mathbf{z}_0)) \in \chi^{-1}(0).$$

As follows from Lemma 6, in the case when the steady-state characteristic of  $\mathcal{S}_a$  is defined, the asymptotic behavior of interconnection (11) is characterized by the zeros

<sup>7</sup>The symbol  $\chi^{-1}(0)$  in (30) denotes the set  $\chi^{-1}(0) = \bigcup_{\bar{u}_a \in \mathbb{R}_+} \bar{u}_a : \chi(\bar{u}_a) \ni 0$ .

of the steady-state mapping  $\chi(\cdot)$ . For the steady-state characteristics on average a slightly modified conclusion can be derived.

LEMMA 7. *Let system (11) be given,  $h(\mathbf{z}(t, \mathbf{z}_0))$  be bounded for some  $\mathbf{x}_0, \mathbf{z}_0$ ,  $h(\mathbf{z}(t, \mathbf{z}_0)) \in [0, h(\mathbf{z}_0)]$ , and system (6) have steady-state characteristic  $\chi_T(\cdot) : \mathbb{R} \rightarrow \mathcal{S}\{\mathbb{R}_+\}$  on average. Furthermore, let there exist a positive constant  $\bar{\gamma}$  such that the function  $\gamma_1(\cdot)$  in (8) satisfies the following constraint:*

$$(31) \quad \gamma_1(s) \geq \bar{\gamma} \cdot s \quad \forall s \in [0, \bar{s}], \bar{s} \in \mathbb{R}_+ : \bar{s} > c \cdot h(\mathbf{z}_0).$$

*In addition, suppose that  $\chi_T(\cdot)$  has no zeros in the positive domain, i.e.,  $0 \notin \chi_T(\bar{u}_a)$  for all  $\bar{u}_a > 0$ . Then*

$$(32) \quad \lim_{t \rightarrow \infty} \|\mathbf{x}(t, \mathbf{x}_0)\|_{\mathcal{A}} = 0, \quad \lim_{t \rightarrow \infty} h(\mathbf{z}(t, \mathbf{z}_0)) = 0.$$

An immediate outcome of Lemmas 6 and 7 is that in the case when the conditions of Theorem 3 are satisfied and system (6) has steady-state characteristic  $\chi(\cdot)$  or  $\chi_T(\cdot)$ , the domain of convergence  $\Omega_a$  becomes

$$(33) \quad \Omega_a = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid \|\mathbf{x}\|_{\mathcal{A}} = 0, \mathbf{z} : h(\mathbf{z}) \in [0, h(\mathbf{z}_0)]\}.$$

It is possible, however, to improve estimate (33) further under additional hypotheses on system  $\mathcal{S}_a$  and  $\mathcal{S}_w$  dynamics. This result is formulated in the corollary below.

COROLLARY 8. *Let system (11) be given and satisfy the assumptions of Theorem 3. Let, in addition,*

(C1) *the flow  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  be generated by a system of autonomous differential equations with a locally Lipschitz right-hand side;*

(C2) *subsystem  $\mathcal{S}_w$  be practically integral-input-to-state stable:*

$$(34) \quad \|\mathbf{z}(\tau)\|_{\infty, [t_0, t]} \leq C_z + \int_0^t \gamma_1(u_w(\tau)) d\tau,$$

*and let function  $h(\cdot) \in \mathcal{C}^0$  in (8);*

(C3) *system  $\mathcal{S}_a$  have steady-state characteristic  $\chi(\cdot)$ .*

*Then for all  $\mathbf{x}_0, \mathbf{z}_0 \in \Omega_\gamma$  the state of the interconnection converges to the set*

$$(35) \quad \Omega_a = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid \|\mathbf{x}\|_{\mathcal{A}} = 0, h(\mathbf{z}) \in \chi^{-1}(0)\}.$$

As follows from Corollary 8, zeros of the steady-state characteristic of system  $\mathcal{S}_a$  actually “control” the domains to which the state of interconnection (11) might potentially converge. This is illustrated in Figure 4. Notice also that in the case when condition C3 in Corollary 8 is replaced with the alternative,

(C3)' *system  $\mathcal{S}_a$  has a steady-state characteristic on average  $\chi_T(\cdot)$ ,*

*and then it is possible to show that the state converges to*

$$(36) \quad \Omega_a = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid \|\mathbf{x}\|_{\mathcal{A}} = 0, h(\mathbf{z}) = 0\}.$$

The proof follows straightforwardly from the proof of Corollary 8 and is therefore omitted.

FIG. 4. Control of the attracting set by means of the system's steady-state characteristics.

**4.3. Systems with contracting dynamics separable in space-time.** In the previous sections we have presented convergence tests and estimates of the trapping region, and also characterized the attracting sets of interconnection (11) under assumptions of uniform asymptotic stability of  $\mathcal{S}_a$  and input-output properties (8), (34) of system  $\mathcal{S}_w$ . The conditions are given for rather general functions  $\beta(\cdot, \cdot) \in \mathcal{KL}$  in (6) and  $\gamma_0(\cdot)$ ,  $\gamma_1(\cdot)$  in (8). It appears, however, that these conditions can be substantially simplified if additional properties of  $\beta(\cdot, \cdot)$  and  $\gamma_0(\cdot)$  are available. This information is, in particular, the separability of function  $\beta(\cdot, \cdot)$  or, equivalently, the possibility of factorization:

$$(37) \quad \beta(\|\mathbf{x}\|_{\mathcal{A}}, t) \leq \beta_x(\|\mathbf{x}\|_{\mathcal{A}}) \cdot \beta_t(t),$$

where  $\beta_x(\cdot) \in \mathcal{K}$  and  $\beta_t(\cdot) \in \mathcal{C}^0$  is strictly decreasing<sup>8</sup> with

$$(38) \quad \lim_{t \rightarrow \infty} \beta_t(t) = 0.$$

In principle, as shown in [8], factorization (37) is achievable for a large class of uniformly asymptotically stable systems under an appropriate coordinate transformation. An immediate consequence of factorization (37) is that the elements of sequence  $\Xi$  in Property 2 are independent of  $\|\mathbf{x}(t_i)\|_{\mathcal{A}}$ . As a result, verification of Properties 2, 3 becomes easier. The most interesting case, however, occurs when the function  $\beta_x(\cdot)$  in the factorization (37) is Lipschitz. For this class of functions the conditions of Theorem 3 reduce to a single and easily verifiable inequality. Let us consider this case in detail.

Without loss of generality, we assume that the state  $\mathbf{x}(t)$  of system  $\mathcal{S}_a$  satisfies the equation

$$(39) \quad \|\mathbf{x}(t)\|_{\mathcal{A}} \leq \|\mathbf{x}(t_0)\|_{\mathcal{A}} \cdot \beta_t(t - t_0) + c \cdot \|h(\mathbf{z}(\tau, \mathbf{z}_0))\|_{\infty, [t_0, t]},$$

where  $\beta_t(0)$  is greater than or equal to one. Given that  $\beta_t(t)$  is strictly decreasing, the mapping  $\beta_t : [0, \infty) \mapsto [0, \beta_t(0)]$  is injective. Moreover  $\beta_t(t)$  is continuous, and then it is surjective and, therefore, bijective. In other words there is a (continuous) mapping  $\beta_t^{-1} : [0, \beta_t(0)] \mapsto \mathbb{R}_+$ :

$$(40) \quad \beta_t^{-1} \circ \beta_t(t) = t \quad \forall t > 0.$$

Conditions for emergence of the trapping region for interconnection (11) with dynamics of system  $\mathcal{S}_a$  governed by (39) are summarized below:

<sup>8</sup>If  $\beta_t(\cdot)$  is not strictly monotone, it can always be majorized by a strictly decreasing function.

COROLLARY 9. *Let the interconnection (11) be given, system  $\mathcal{S}_a$  satisfy (39), and function  $\gamma_0(\cdot)$  in (8) be Lipschitz:*

$$(41) \quad |\gamma_0(s)| \leq D_{\gamma,0} \cdot |s|.$$

*Domain*

$$(42) \quad \Omega_\gamma : D_{\gamma,0} \leq \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa - 1}{\kappa} \times \frac{h(\mathbf{z}_0)}{\beta_t(0) \|\mathbf{x}_0\|_{\mathcal{A}} + \beta_t(0) \cdot c \cdot |h(\mathbf{z}_0)| \left( 1 + \frac{\kappa}{1-d} \right) + c|h(\mathbf{z}_0)|}$$

is not empty for some  $d < 1$ ,  $\kappa > 1$ . Then for all initial conditions  $\mathbf{x}_0, \mathbf{z}_0 \in \Omega_\gamma$  the state  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  of interconnection (11) converges into the set  $\Omega_a$  specified by (24). If, in addition, conditions (C1)–(C3) of Corollary 8 hold, then the domain of convergence is given by (33).

A practically important consequence of this corollary concerns systems  $\mathcal{S}_a$  which are exponentially stable:

$$(43) \quad \|\mathbf{x}(t)\|_{\mathcal{A}} \leq \|\mathbf{x}(t_0)\|_{\mathcal{A}} D_\beta \exp(-\lambda t) + c \cdot \|h(\mathbf{z}(t, \mathbf{z}_0))\|_{\infty, [t_0, t]}, \lambda > 0, D_\beta \geq 1.$$

In this case the domain (42) of initial conditions ensuring convergence into  $\Omega_a$  is defined as

$$D_{\gamma,0} \leq \max_{\kappa > 1, d \in (0,1)} -\lambda \left( \ln \frac{d}{\kappa} \right)^{-1} \frac{\kappa - 1}{\kappa} \times \frac{h(\mathbf{z}_0)}{D_\beta \|\mathbf{x}_0\|_{\mathcal{A}} + D_\beta \cdot c \cdot |h(\mathbf{z}_0)| \left( 1 + \frac{\kappa}{1-d} \right) + c|h(\mathbf{z}_0)|}.$$

**5. Discussion.** In this section we discuss some practically relevant outcomes of the results of Theorem 3 and Corollaries 8, 9 and their potential applications to problems of analysis of asymptotic behavior in nonlinear dynamic systems.

First, in section 5.1 we specify conditions for existence of a trapping region of nonzero volume in  $\mathbb{R}^n \oplus \mathbb{R}^m$  in terms of the parameters of system (11) without invoking dependence on  $\mathbf{x}(t_0), \mathbf{z}(t_0)$ , as was done in Theorem 3. The resulting criterion has a form similar to the standard small-gain conditions [34]. The differences and similarities between this new result and standard small-gain theorems are illustrated with an example.

Second, in section 5.2 we demonstrate how the results of our present contribution can be applied to address the problem of output nonlinear identification for systems which cannot be transformed into a canonic observer form and/or with nonlinear parametrization.

**5.1. Relation to conventional small-gain theorems.** Conditions specifying state boundedness formulated in Theorem 3 and Corollaries 8, 9 depend explicitly on initial conditions  $\mathbf{x}(t_0), \mathbf{z}(t_0)$ . Such dependence is inevitable when the convergence is allowed to be nonuniform. But if the mere existence of a trapping region is asked for, dependence on initial conditions may be removed from the statements of the results. The next corollary presents such modified conditions.

COROLLARY 10. *Consider interconnection (11), where the system  $\mathcal{S}_a$  satisfies inequality (39) and the function  $\gamma_0(\cdot)$  obeys (41). Then there exists a set  $\Omega_\gamma$  of initial*

conditions corresponding to the trajectories converging to  $\Omega_a$  if the following condition is satisfied:

$$(44) \quad D_{\gamma,0} \cdot c \cdot \mathcal{G} < 1,$$

where

$$\mathcal{G} = \beta_t^{-1} \left( \frac{d}{\kappa} \right) \frac{k}{k-1} \left( \beta_t(0) \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right)$$

for some  $d \in (0, 1)$ ,  $\kappa \in (1, \infty)$ . In particular,  $\Omega_\gamma$  contains the following domain:

$$\|\mathbf{x}(t_0)\|_{\mathcal{A}} \leq \frac{h(\mathbf{z}(t_0))}{\beta_t(0)} \left[ \frac{1}{D_{\gamma,0}} \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{k-1}{k} - c \left( \beta_t(0) \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right) \right].$$

In the case when the function  $h(\mathbf{z})$  in (11) is continuous, the volume of the set  $\Omega_\gamma$  is nonzero in  $\mathbb{R}^n \oplus \mathbb{R}^m$ .

Notice that in the case when the dynamics of the contracting subsystem  $\mathcal{S}_a$  is exponentially stable, i.e., it satisfies inequality (43), the term  $\mathcal{G}$  in condition (44) reduces to

$$(45) \quad \mathcal{G} = \frac{1}{\lambda} \cdot \ln \left( \frac{\kappa}{d} \right) \frac{k}{k-1} \left( D_\beta \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right).$$

For  $D_\beta = 1$  the minimal value of  $\mathcal{G}$  in (45) can be estimated as

$$(46) \quad \mathcal{G}^* = \frac{1}{\lambda} \cdot \min_{d \in (0,1), \kappa \in (1,\infty)} \ln \left( \frac{\kappa}{d} \right) \frac{k}{k-1} \left( 2 + \frac{\kappa}{1-d} \right) \approx \frac{15.6886}{\lambda} < \frac{16}{\lambda},$$

which leads to an even more simple formulation of (45):

$$D_{\gamma,0} \cdot \frac{c}{\lambda} \leq \frac{1}{16}.$$

Corollary 10 provides an explicit and easy-to-check condition for existence of a trapping region in the state space of a class of Lyapunov unstable systems. In addition, it allows us to specify explicitly points  $\mathbf{x}(t_0)$ ,  $\mathbf{z}(t_0)$  which belong to the emergent trapping region. Notice also that the existence condition, inequality (44), has the flavor of conventional small-gain constraints. Yet, it is substantially different from these classical results. This is because the input-output gain for the wandering subsystem,  $\mathcal{S}_w$ , may not be finite or need not even be defined.

To elucidate these differences as well as the similarities between conditions of conventional small-gain theorems and those formulated in Corollary 10 we provide an example. Consider the following systems:

$$(47a) \quad \begin{cases} \dot{x}_1 = -\lambda_1 x_1 + c_1 x_2, \\ \dot{x}_2 = -\lambda_2 x_2 - c_2 |x_1|, \end{cases}$$

$$(47b) \quad \begin{cases} \dot{x}_1 = -\lambda_1 x_1 + c_1 x_2, \\ \dot{x}_2 = -c_2 |x_1|. \end{cases}$$

System (47a) can be viewed as an interconnection of two input-to-state stable systems,  $x_1$  and  $x_2$ , with input-output  $L_\infty$ -gains  $c_1/\lambda_1$  and  $c_2/\lambda_2$ , respectively. Therefore, in order to prove state boundedness of (47a) we can, in principle, invoke the conventional small-gain theorem. The small-gain condition in this case is as follows:

$$(48a) \quad \frac{c_1}{\lambda_1} \cdot \frac{c_2}{\lambda_2} < 1.$$

The theorem, however, does not apply to system (47b) because the input-output gain of its second subsystem,  $x_2$ , is infinite. Yet, by invoking Corollary 10 it is still possible to show existence of a weak attracting set in the state space of system (47b) and specify its basin of attraction. As follows from Corollary 10, condition

$$(48b) \quad \frac{c_1}{\lambda_1} \cdot \frac{c_2}{\lambda_1} < \frac{1}{16}$$

ensures existence of the trapping region, and the trapping region itself is given by

$$|x_1(t_0)| \leq \left[ \frac{1}{c_2} \lambda_1 \left( \ln \frac{\kappa}{d} \right)^{-1} \frac{k-1}{k} - \frac{c_1}{\lambda_1} \left( 2 + \frac{\kappa}{1-d} \right) \right] x_2(t_0).$$

**5.2. Output nonlinear identification problem.** In the literature on adaptive control, observation, and identification a few classes of systems are referred to as *canonic forms* because they guarantee existence of a solution to the problem and because a large variety of physical models can be transformed into this class. Among these, perhaps the most widely known is the *adaptive observer canonical form* [3]. Necessary and sufficient conditions for transformation of the original system into this canonical form can be found, for example, in [16]. These conditions, however, include restrictive requirements of linearization of uncertainty-independent dynamics by output injection, and they also require linear parametrization of the uncertainty. Alternative approaches [4] heavily rely on knowledge of the proper Lyapunov function for the uncertainty-independent part and still assume linear parametrization.

We now demonstrate how these restrictions can be lifted by application of our result to the problem of state and parameter observation. Let us consider systems which can be transformed by means of static or dynamic feedback<sup>9</sup> into the following form:

$$(49) \quad \dot{\mathbf{x}} = \mathbf{f}_0(\mathbf{x}, t) + \mathbf{f}(\boldsymbol{\xi}(t), \boldsymbol{\theta}) - \mathbf{f}(\boldsymbol{\xi}(t), \hat{\boldsymbol{\theta}}) + \boldsymbol{\varepsilon}(t),$$

where

$$\boldsymbol{\varepsilon}(t) \in L_\infty^m[t_0, \infty], \quad \|\boldsymbol{\varepsilon}(\tau)\|_{\infty, [t_0, t]} \leq \Delta_\varepsilon$$

is an external perturbation with known  $\Delta_\varepsilon$ , and  $\mathbf{x} \in \mathbb{R}^n$ . The function  $\boldsymbol{\xi} : \mathbb{R}_+ \rightarrow \mathbb{R}^\xi$  is a function of time, which possibly includes available measurements of the state, and  $\boldsymbol{\theta}, \hat{\boldsymbol{\theta}} \in \Omega_\theta \subset \mathbb{R}^d$  are the unknown and estimated parameters of the function  $\mathbf{f}(\cdot)$ , respectively, and the set  $\Omega_\theta$  is bounded. We assume that uniformly in  $\boldsymbol{\xi}$ , the function  $\mathbf{f}(\boldsymbol{\xi}(t), \boldsymbol{\theta})$  is locally bounded in  $\boldsymbol{\theta}$ :

$$\|\mathbf{f}(\boldsymbol{\xi}(t), \boldsymbol{\theta}) - \mathbf{f}(\boldsymbol{\xi}(t), \hat{\boldsymbol{\theta}})\| \leq D_f \|\boldsymbol{\theta} - \hat{\boldsymbol{\theta}}\| + \Delta_f$$

<sup>9</sup>Notice that conventional observers in control theory could be viewed as dynamic feedbacks.

and the values of  $D_f \in \mathbb{R}_+$ ,  $\Delta_f$  are available. The function  $\mathbf{f}_0(\cdot)$  in (49) is assumed to satisfy the following condition.

ASSUMPTION 3. *The system*

$$(50) \quad \dot{\mathbf{x}} = \mathbf{f}_0(\mathbf{x}, t) + \mathbf{u}(t)$$

is forward-complete. Furthermore, for all  $\mathbf{u}(t)$  such that

$$\|\mathbf{u}(t)\|_{\infty, [t_0, t]} \leq \Delta_u + \|\mathbf{u}_0(\tau)\|_{\infty, [t_0, t]}, \quad \Delta_u \in \mathbb{R}_+,$$

there exists a bounded set  $\mathcal{A}$ ,  $c > 0$  and a function  $\Delta : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  satisfying the following inequality:

$$\|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta(\Delta_u)}} \leq \beta(t - t_0) \|\mathbf{x}(t_0)\|_{\mathcal{A}_{\Delta(\Delta_u)}} + c \|\mathbf{u}_0(\tau)\|_{\infty, [t_0, t]},$$

where  $\beta(\cdot) : \mathbb{R}_+ \rightarrow \mathbb{R}_+$ ,  $\lim_{t \rightarrow \infty} \beta(t) = 0$  is a strictly decreasing function.

Consider the following auxiliary system:

$$(51) \quad \dot{\lambda} = S(\lambda), \quad \lambda(t_0) = \lambda_0 \in \Omega_\lambda \subset \mathbb{R}^\lambda,$$

where  $\Omega_\lambda \subset \mathbb{R}^\lambda$  is a compact set,  $\lambda(t, \lambda_0) \in \Omega_\lambda$  for all  $t \geq t_0$ , and  $S(\lambda)$  is locally Lipschitz. Furthermore, suppose that the following assumption holds for system (51).

ASSUMPTION 4. *System (51) is Poisson stable in  $\Omega_\lambda$ , that is,*

$$\forall \lambda' \in \Omega_\lambda, \quad t' \in \mathbb{R}_+ \Rightarrow \exists t'' > t : \|\lambda(t'', \lambda') - \lambda'\| \leq \epsilon,$$

where  $\epsilon$  is an arbitrary small positive constant. Moreover, the trajectory  $\lambda(t, \lambda_0)$  is dense in  $\Omega_\lambda$ :

$$\forall \lambda' \in \Omega_\lambda, \quad \epsilon \in \mathbb{R}_{>0} \Rightarrow \exists t \in \mathbb{R}_+ : \|\lambda' - \lambda(t, \lambda_0)\| < \epsilon.$$

Now we are ready to formulate the following statement.

COROLLARY 11. *Consider system (49) and suppose that the following conditions hold:*

- (C4) *the vector-field  $\mathbf{f}_0(\mathbf{x}, t)$  in (49) satisfies Assumption 3;*
- (C5) *there exists a (known) system (51) satisfying Assumption 4;*
- (C6) *there exists a locally Lipschitz  $\eta : \mathbb{R}^\lambda \rightarrow \mathbb{R}^d$ :*

$$\|\eta(\lambda') - \eta(\lambda'')\| \leq D_\eta \|\lambda' - \lambda''\|$$

such that the set  $\eta(\Omega_\lambda)$  is dense in  $\Omega_\theta$ ;

- (C7) *system (49) has a steady-state characteristic with respect to the norm*

$$\|\cdot\|_{\mathcal{A}_{\Delta(M)}}, \quad M = 2\Delta_f + \Delta_\varepsilon + \delta,$$

and input  $\hat{\theta}$ , where  $\delta$  is some positive (arbitrarily small) constant.

Consider the following interconnection of (49), (51):

$$(52) \quad \begin{aligned} \dot{\mathbf{x}} &= \mathbf{f}_0(\mathbf{x}, t) + \mathbf{f}(\xi(t), \theta) - \mathbf{f}(\xi(t), \hat{\theta}) + \varepsilon(t), \\ \dot{\hat{\theta}} &= \eta(\lambda), \\ \dot{\lambda} &= \gamma \|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta(M)}} S(\lambda), \end{aligned}$$

where  $\gamma > 0$  satisfies the following inequality:

$$(53) \quad \gamma \leq \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa - 1}{\kappa} \frac{1}{D_\lambda \left( \beta_t(0) \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right)},$$

$$D_\lambda = c \cdot D_f \cdot D_\eta \cdot \max_{\lambda \in \Omega_\lambda} \|S(\lambda)\|$$

for some  $d \in (0, 1)$ ,  $\kappa \in (1, \infty)$ . Then, for  $\lambda(t_0) = \lambda_0$ , some  $\theta' \in \Omega_\theta$ , and all  $\mathbf{x}(t_0) = \mathbf{x}_0 \in \mathbb{R}^n$ , the following holds:

$$(54) \quad \lim_{t \rightarrow \infty} \|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta(M)}} = 0, \quad \lim_{t \rightarrow \infty} \hat{\theta}(t) = \theta' \in \Omega_\theta.$$

Notice that, as has been pointed out in the previous section, in the case when the dynamics of (50) is exponentially stable with a rate of convergence equal to  $\rho$  and  $\beta(0) = D_\beta$ , condition (53) will have the following form:

$$\gamma \leq -\rho \left( \ln \frac{d}{\kappa} \right)^{-1} \frac{\kappa - 1}{\kappa} \frac{1}{D_\lambda \left( D_\beta \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right)}.$$

According to Corollary 11, for the rather general class of systems (49) it is possible to design an estimator  $\hat{\theta}(t)$  which guarantees not only that the “error” vector  $\mathbf{x}(t)$  reaches a neighborhood of the origin, but also that the estimates  $\hat{\theta}(t)$  converge to some  $\theta'$  in  $\Omega_\theta$ . Both these facts, together with additional nonlinear persistent excitation conditions [6], [29]

$$\begin{aligned} & \exists T > 0, \rho \in \mathcal{K} : \forall \mathcal{T} = [t, t + T], t \in \mathbb{R}_+ \\ & \Rightarrow \exists \tau \in \mathcal{T} : |\mathbf{f}(\xi(\tau), \theta) - \mathbf{f}(\xi(\tau), \theta')| \geq \rho(\|\theta - \theta'\|), \end{aligned}$$

in principle allow us to estimate the domain of convergence for  $\hat{\theta}(t)$ .

Concluding this section we mention that statements of Theorem 3 and Corollaries 8–11 constitute additional theoretical tools for the analysis of asymptotic behavior of systems in cascaded form. In particular they are complementary to the results of [1], where *asymptotic stability* of systems of the following type:

$$\begin{aligned} \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}), \\ \dot{\mathbf{z}} &= \mathbf{q}(\mathbf{x}, \mathbf{z}), \quad \mathbf{f} : \mathbb{R}^n \rightarrow \mathbb{R}^n, \quad \mathbf{q} : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^m \end{aligned}$$

was considered under the assumption that the  $\mathbf{x}$ -subsystem is globally asymptotically stable and the  $\mathbf{z}$ -subsystem is integral input-to-state stable. In contrast to this, our results apply to establishing *asymptotic convergence* for systems with the following structure:

$$\begin{aligned} \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, \mathbf{z}), \\ \dot{\mathbf{z}} &= \mathbf{q}(\mathbf{x}, \mathbf{z}), \quad \mathbf{f} : \mathbb{R}^n \times \mathbb{R}^m \rightarrow \mathbb{R}^n, \end{aligned}$$

where the  $\mathbf{x}$ -subsystem is input-to-state stable, and the  $\mathbf{z}$ -subsystem could be practically integral input-to-state stable (see Corollary 8), although in general no stability assumptions are imposed on it.

**6. Examples.** In this section we provide two examples of parameter identification in nonlinearly parametrized systems that cannot be transformed into the canonical adaptive observer form.

The first example is merely an academical illustration of Corollary 11, where only one parameter is unknown and the system itself is a first-order differential equation. The second example illustrates a possible application of our results to the problem of identifying the dynamics in living cells.

*Example 1.* Consider the following system:

$$(55) \quad \dot{x} = -kx + \sin(x\theta + \theta) + u, \quad k > 0, \quad \theta \in [-a, a],$$

where  $\theta$  is an unknown parameter and  $u$  is the control input. Without loss of generality we let  $a = 1, k = 1$ . The problem is to estimate the parameter  $\theta$  from measurements of  $x$  and steer the system to the origin. Clearly, the choice  $u = -\sin(x\hat{\theta} + \hat{\theta})$  transforms (55) into

$$(56) \quad \dot{x} = -kx + \sin(x\theta + \theta) - \sin(x\hat{\theta} + \hat{\theta}),$$

which satisfies Assumption 3. Moreover, the system

$$\begin{aligned} \dot{\lambda}_1 &= \lambda_1, \\ \dot{\lambda}_2 &= -\lambda_2, \quad \lambda_1^2(t_0) + \lambda_2^2(t_0) = 1 \end{aligned}$$

with mapping  $\eta = (1, 0)^T \lambda$  satisfies Assumption 4 and therefore

$$(57) \quad \begin{aligned} \dot{\lambda}_1 &= \gamma|x|\lambda_1, \\ \dot{\lambda}_2 &= -\gamma|x|\lambda_2, \quad \lambda_1^2(t_0) + \lambda_2^2(t_0) = 1 \end{aligned}$$

would be a candidate for the control and parameter estimation algorithm. According to Corollary 11, the goal will be reached if the parameter  $\gamma$  in (57) obeys the following constraint:

$$\gamma \leq -\rho \left( \ln \frac{d}{\kappa} \right)^{-1} \frac{\kappa - 1}{\kappa} \frac{1}{D_\lambda \left( D_\beta \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right)}, \quad \rho = k = 1, \quad D_\beta = 1, \quad D_\lambda = 1$$

for some  $d \in (0, 1), \kappa \in (1, \infty)$ . Hence, choosing, for example,  $d = 0.5, \kappa = 2$  we obtain that choice

$$0 < \gamma < -\ln \left( \frac{0.5}{2} \right)^{-1} \frac{1}{2} \cdot \frac{1}{6} = 0.0601$$

suffices to ensure that

$$\lim_{t \rightarrow \infty} x(t) = 0, \quad \lim_{t \rightarrow \infty} \hat{\theta}(t) = \theta.$$

We simulated system (56), (57) with  $\theta = 0.3, \gamma = 0.05$  and initial conditions  $x(t_0)$  randomly distributed in the interval  $[-1, 1]$ . Results of the simulation are illustrated in Figure 5, where the phase plots of system (56), (57) as well as the trajectories of  $\hat{\theta}(t)$  are given.

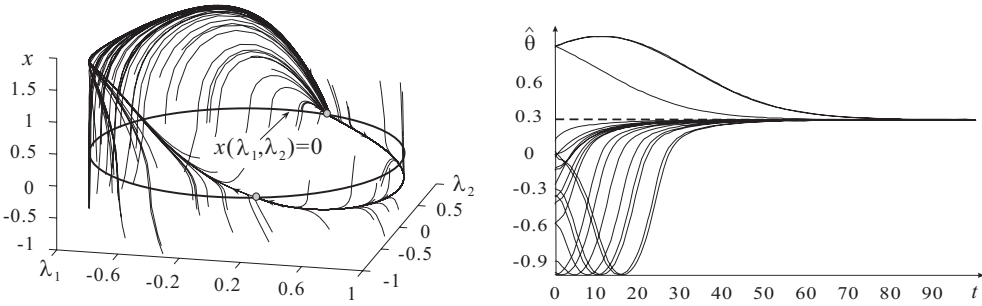

FIG. 5. Trajectories of system (56), (57) (left panel) and the family of estimates  $\hat{\theta}(t)$  of parameter  $\theta$  as functions of time  $t$  (right panel).

*Example 2.* Consider the problem of modeling electrical activity in biological cells from the input-output data in current clamp experiments. The simplest mathematical model, which captures a fairly large variety of phenomena such as periodic bursting in response to constant stimulation, is the classical Hindmarsh and Rose model neuron without adaptation currents [10]:

$$(58) \quad \begin{aligned} \dot{x}_1 &= -ax_1^3 + bx_1^2 + x_2 + \alpha u, \\ \dot{x}_2 &= c - \beta x_2 - dx_1^2, \end{aligned}$$

where variable  $x_1$  is the membrane potential,  $x_2$  stands for the ionic currents in the cell,  $u$  is the input current, and  $a, b, c, d, \alpha, \beta \in \mathbb{R}$  are parameters. While the parameters of the first equation can, in principle, be identified experimentally by blocking the ionic channels in the cells and measuring the membrane conductance, identification of parameters  $\beta, d$  is a difficult problem, as information about ionic currents  $x_2$  is rarely available.

Conventional techniques [3] cannot be applied directly to this problem as the model (58) is not in canonical adaptive observer form. Let us illustrate how our results can be used to derive the unknown parameters of (58) such that the reconstructed model fits the observed data. Assume, first, that parameters  $a, b, c, \alpha$  in the first equation of (58) are known, whereas parameters  $\beta, d$  in the second equation are unknown. This corresponds to the realistic case, where the time constant of current  $x_2$  and coupling between  $x_1$  and  $x_2$  are uncertain. In our example we assumed that

$$\beta \in \Omega_\beta = [0.3, 0.7], \quad d \in \Omega_d = [2, 3], \quad a = 1, \quad b = 3, \quad \alpha = 0.7, \quad c = 0.5.$$

As a candidate for the observer we select the following system:

$$(59) \quad \dot{\hat{x}} = \rho(x_1 - \hat{x}) - ax_1^3 + bx_1^2 + \alpha u + f(\hat{\beta}, \hat{d}, t), \quad \rho \in \mathbb{R}_{>0},$$

where  $\hat{\beta}, \hat{d}$  are parameters to be adjusted and the function  $f(\hat{\beta}, \hat{d}, t)$  is specified as

$$f(\hat{\beta}, \hat{d}, t) = \int_{t_0}^t e^{-\hat{\beta}(t-\tau)} (\hat{d}x_1^2(\tau) + c) d\tau.$$

Then the dynamics of  $\tilde{x}(t) = x(t) - \hat{x}(t)$  satisfies the following differential equation:

$$\dot{\tilde{x}} = -\rho\tilde{x} + f(\beta, d, t) - f(\hat{\beta}, \hat{d}, t).$$

The function  $f(\beta, d, t)$  satisfies the following inequality:

$$\begin{aligned} |f(\beta, d, t) - f(\hat{\beta}, \hat{d}, t)| &\leq |f(\beta, d, t) - f(\hat{\beta}, d, t)| + |f(\hat{\beta}, d, t) - f(\hat{\beta}, \hat{d}, t)| \\ &\leq D_{f,\beta}|\beta - \hat{\beta}| + D_{f,d}|d - \hat{d}| + \epsilon(t), \end{aligned}$$

where  $\epsilon(t)$  is an exponentially decaying term, and

$$(60) \quad D_{f,\beta} = \max_{\hat{\beta}, \beta \in \Omega_\beta, d \in \Omega_d} \left\{ \frac{1}{\beta \hat{\beta}} (d \|x_1(\tau)\|_{\infty, [t_0, \infty]} + c) \right\}, \quad D_{f,d} = \max_{\hat{\beta} \in \Omega_\beta} \left\{ \frac{1}{\hat{\beta}} \|x_1(\tau)\|_{\infty, [t_0, \infty]} \right\}.$$

Furthermore, Assumption 3 is satisfied for system

$$(61) \quad \dot{\tilde{x}} = -\rho \tilde{x} + v(t),$$

with

$$\Delta(\Delta_u) = \frac{\Delta_u}{\rho}.$$

In particular, for all  $v(t) : \|v(\tau)\|_{\infty, [t_0, t]} \leq \Delta_u + \|v_0(\tau)\|_{\infty, [t_0, t]}$  the following inequality holds:

$$(62) \quad \|\tilde{x}(t)\|_{\Delta(\Delta_u)} \leq e^{-\rho(t-t_0)} \|\tilde{x}(t_0)\|_{\Delta(\Delta_u)} + \frac{1}{\rho} \|v_0(\tau)\|_{\infty, [t_0, t]}.$$

To see this consider the general solution of (61):

$$\tilde{x}(t) = e^{-\rho(t-t_0)} \tilde{x}(t_0) + e^{-\rho t} \int_{t_0}^t e^{\rho \tau} v(\tau) d\tau$$

and derive an estimate of  $|\tilde{x}(t)|$ . This estimate has the following form:

$$\begin{aligned} |\tilde{x}(t)| &\leq e^{-\rho(t-t_0)} |\tilde{x}(t_0)| + \frac{1}{\rho} (1 - e^{-\rho(t-t_0)}) \|v(\tau)\|_{\infty, [t_0, t]} \\ &\leq e^{-\rho(t-t_0)} \left( |\tilde{x}(t_0)| - \frac{1}{\rho} \Delta_u \right) + \frac{1}{\rho} (\|v_0(\tau)\|_{\infty, [t_0, t]} + \Delta_u) \\ &\leq e^{-\rho(t-t_0)} \|\tilde{x}(t_0)\|_{\Delta(\Delta_u)} + \frac{1}{\rho} (\|v_0(\tau)\|_{\infty, [t_0, t]} + \Delta_u). \end{aligned}$$

Hence

$$|\tilde{x}(t)| - \frac{1}{\rho} \Delta_u \leq e^{-\rho(t-t_0)} \|\tilde{x}(t_0)\|_{\Delta(\Delta_u)} + \frac{1}{\rho} \|v_0(\tau)\|_{\infty, [t_0, t]},$$

which automatically implies (62).

Let us define subsystem (51). Consider the following system of differential equations:

$$(63) \quad \begin{aligned} \dot{\lambda}_1 &= \lambda_2, \\ \dot{\lambda}_2 &= -\omega_1^2 \lambda_1, \\ \dot{\lambda}_3 &= \lambda_4, \\ \dot{\lambda}_4 &= -\omega_2^2 \lambda_3, \quad \lambda_0 = (1, 0, 1, 0)^T, \end{aligned}$$

where  $\Omega_\lambda$  is the  $\omega$ -limit set of the point  $\lambda_0$ , and  $\omega_1, \omega_2 \in \mathbb{R}$ . System (63), therefore, satisfies Assumption 4. Given that domains  $\Omega_\beta, \Omega_d$  are known, select

(64)

$$\boldsymbol{\eta} : \mathbb{R}^n \rightarrow \mathbb{R}^2, \quad \boldsymbol{\eta} = (\eta_1(\boldsymbol{\lambda}), \eta_2(\boldsymbol{\lambda})),$$

$$\hat{\beta} = \eta_1(\boldsymbol{\lambda}) = \frac{1}{2} \left( \frac{2 \arcsin(\lambda_1)}{\pi} + 1 \right) \cdot 0.4 + 0.3, \quad \hat{d} = \eta_2(\boldsymbol{\lambda}) = \frac{1}{2} \left( \frac{2 \arcsin(\lambda_3)}{\pi} + 1 \right) + 2.$$

Choosing

$$\frac{\omega_1}{\omega_2} = \pi$$

we ensure that  $\boldsymbol{\eta}(\Omega_\lambda)$  is dense in  $\Omega_\beta \times \Omega_d$ . Given that  $\hat{\beta}, \hat{d}$  are bounded and  $\hat{\beta} \geq 0.3$ , the values of  $D_{f,\beta}, D_{f,d}$  are bounded since the signal  $x_1(t)$  is always bounded for any  $t \geq t_0$  for the given range of parameters. Hence, according to Corollary 11, interconnection of (59), (64), and

$$\begin{aligned} \dot{\lambda}_1 &= \gamma \|\tilde{x}(t)\|_{\Delta(\delta)} \cdot \lambda_2, \\ \dot{\lambda}_2 &= -\gamma \|\tilde{x}(t)\|_{\Delta(\delta)} \cdot \omega_1^2 \lambda_1, \\ \dot{\lambda}_3 &= \gamma \|\tilde{x}(t)\|_{\Delta(\delta)} \cdot \lambda_4, \\ \dot{\lambda}_4 &= -\gamma \|\tilde{x}(t)\|_{\Delta(\delta)} \cdot \omega_2^2 \lambda_3, \quad \boldsymbol{\lambda}_0 = (1, 0, 1, 0)^T, \end{aligned}$$

with arbitrary small  $\delta > 0$  and properly chosen  $\gamma > 0$ , ensures that

$$\lim_{t \rightarrow \infty} \|\tilde{x}(t)\|_{\Delta(\delta)} = 0, \quad \lim_{t \rightarrow \infty} \hat{\beta}(t) = \beta' \in \Omega_\beta, \quad \lim_{t \rightarrow \infty} \hat{d}(t) = d' \in \Omega_d.$$

This in turn implies a successful fit of the model to the observations.

We simulated the system with  $\rho = 10$  and  $\gamma = 3 \cdot 10^{-4}$  for  $\beta = 0.5, d = 2.5$ . The results of the simulations are provided in Figure 6. It can be seen from this figure that the reconstruction is successful and that the parameters converge into a small neighborhood of the actual values. Further details explaining how this technique can be applied to model the dynamics of the evoked membrane potentials in real neural cells from input-output measurements in vitro are discussed in [25].

**7. Conclusion.** We proposed tools for the analysis of asymptotic behavior of a class of dynamical systems. In particular, we consider an interconnection of an input-to-state stable system with an unstable or integral input-to-state dynamics. Our results allow us to address a variety of problems in which convergence may not be uniform with respect to initial conditions. It is necessary to notice that the proposed method does not require complete knowledge of the dynamical systems in question. Only qualitative information such as, for instance, characterization of input-to-state stability is necessary for application of our results. We demonstrated how our analysis can be used in the problems of synthesis and design—in particular for problems of nonlinear regulation and parameter identification of nonlinear parametrized systems. The examples show the relevance of our approach in those domains where application of the standard techniques is either not possible or too complicated.

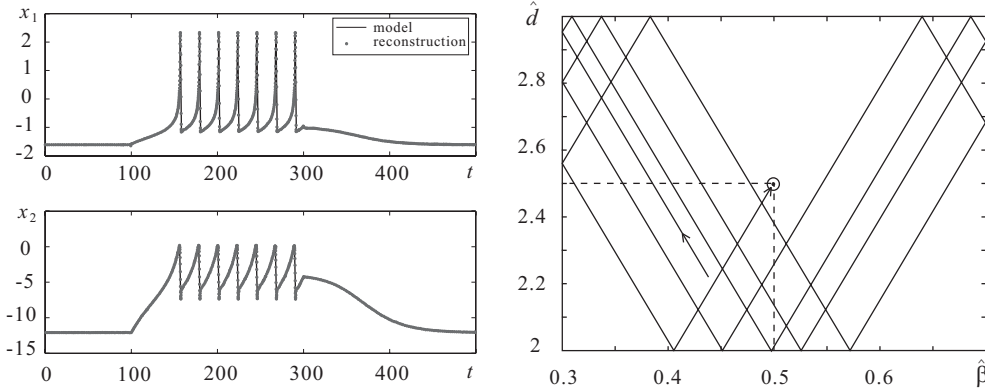

FIG. 6. Left panel: trajectories  $x_1(t)$ ,  $x_2(t)$  of system (58) plotted for the nominal values of parameters  $\beta = 0.5$ ,  $d = 2.5$  (model), and for the values  $\beta = \hat{\beta}(t_0 + T)$ ,  $d = \hat{d}(t_0 + T)$ , where  $T$  is the total simulation time (reconstruction). Input  $u(t)$  is a rectangular impulse with amplitude 0.7 starting at  $t = 100$  and ending at  $t = 300$ . Right panel: searching dynamics in the bounded parameter space (a segment of the trajectory  $\hat{\beta}(t)$ ,  $\hat{d}(t)$  towards the end of the simulation).

## Appendix. Proofs of Theorem 3, lemmas, and corollaries.

**A.1. Proof of Theorem 3.** Let the conditions of the theorem be satisfied for given  $t_0 \in \mathbb{R}_+$ :  $\mathbf{x}(t_0) = \mathbf{x}_0$ ,  $\mathbf{z}(t_0) = \mathbf{z}_0$ . Notice that in this case  $h(\mathbf{z}_0) \geq 0$ ; otherwise requirement (26) will be violated. Consider the sequence (23) of volumes  $\Omega_i$  induced by  $\mathcal{S}$ :

$$\Omega_i = \{\mathbf{x} \in \mathcal{X}, \mathbf{z} \in \mathcal{Z} \mid h(\mathbf{z}(t)) \in H_i\}.$$

To prove the theorem we show that  $0 \leq h(\mathbf{z}(t)) \leq h(\mathbf{z}_0)$  for all  $t \geq t_0$ . For the given partition (23) we consider two alternatives.

First, in the degenerative case, the state  $\mathbf{x}(t) \oplus \mathbf{z}(t)$  enters some  $\Omega_j$ ,  $j \geq 0$ , and stays there afterward, which automatically guarantees that  $0 \leq |h(\mathbf{z})| \leq h(\mathbf{z}_0)$ . Then, according to (6) the trajectory  $\mathbf{x}(t)$  satisfies the following inequality:

$$(65) \quad \|\mathbf{x}(t)\|_{\mathcal{A}} \leq \beta(\|\mathbf{x}_0\|_{\mathcal{A}}, t - t_0) + c\|h(\mathbf{z}(t))\|_{\infty, [t_0, t]} \leq \beta(\|\mathbf{x}_0\|_{\mathcal{A}}, t - t_0) + c|h(\mathbf{z}_0)|.$$

Taking into account that  $\beta(\cdot, \cdot) \in \mathcal{KL}$  we can conclude that (65) implies that

$$(66) \quad \limsup_{t \rightarrow \infty} \|\mathbf{x}(t)\|_{\mathcal{A}} \leq c|h(\mathbf{z}_0)|.$$

Therefore the statements of the theorem hold.

Let us consider the second alternative, where the state  $\mathbf{x}(t) \oplus \mathbf{z}(t)$  enters each  $\Omega_j$  and leaves later. Given that  $h(\mathbf{z}(t))$  is monotone and nonincreasing in  $t$ , this implies that there exists an ordered sequence of time instants  $t_j$ :

$$(67) \quad t_0 < t_1 < t_2 \cdots t_j < t_{j+1} \cdots$$

such that

$$(68) \quad h(\mathbf{z}(t_i)) = \sigma_i h(\mathbf{z}_0).$$

Hence in order to prove the theorem we must show that the sequence  $\{t_i\}_{i=0}^{\infty}$  does not converge. In other words, the boundary  $\sigma_{\infty} h(\mathbf{z}_0) = 0$  will not be reached in finite time.

In order to do this let us estimate the upper bounds for the following differences:

$$T_i = t_{i+1} - t_i.$$

Taking into account inequality (8) and the fact that  $\gamma_0(\cdot) \in \mathcal{K}_e$ , we can derive that

$$(69) \quad h(\mathbf{z}(t_i)) - h(\mathbf{z}(t_{i+1})) \leq T_i \max_{\tau \in [t_i, t_{i+1}]} \gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}}) \leq T_i \gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]}).$$

According to the definition of  $t_i$  in (68) and noticing that the sequence  $\mathcal{S}$  is strictly decreasing, we have

$$h(\mathbf{z}(t_i)) - h(\mathbf{z}(t_{i+1})) = (\sigma_i - \sigma_{i+1})h(\mathbf{z}_0) > 0.$$

Hence  $h(\mathbf{z}_0) > 0$  implies that  $\gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]}) > 0$  and, therefore, (69) results in the following estimate of  $T_i$ :

$$(70) \quad T_i \geq \frac{h(\mathbf{z}(t_i)) - h(\mathbf{z}(t_{i+1}))}{\gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]})} = \frac{h(\mathbf{z}_0)(\sigma_i - \sigma_{i+1})}{\gamma_0(\|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]})}.$$

Taking into account that  $h(\mathbf{z}(t))$  is nonincreasing over  $[t_i, t_{i+1}]$  and using (6) we can bound the norm  $\|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]}$  as follows:

$$(71) \quad \begin{aligned} \|\mathbf{x}(\tau)\|_{\mathcal{A}_{\infty}, [t_i, t_{i+1}]} &\leq \beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, 0) + c\|h(\mathbf{z}(\tau))\|_{\infty, [t_i, t_{i+1}]} \\ &\leq \beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, 0) + c \cdot \sigma_i h(\mathbf{z}_0). \end{aligned}$$

Hence, combining (70) and (71), we obtain that

$$T_i \geq \frac{h(\mathbf{z}_0)(\sigma_i - \sigma_{i+1})}{\gamma_0(\sigma_i(\sigma_i^{-1}\beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0)))}.$$

Then, using property (10) of function  $\gamma_0$  we can derive that

$$(72) \quad T_i \geq \frac{h(\mathbf{z}_0)(\sigma_i - \sigma_{i+1})}{\gamma_{0,1}(\sigma_i)} \frac{1}{\gamma_{0,2}(\sigma_i^{-1}\beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0)))}.$$

Taking into account condition (27) of the theorem, the theorem will be proved if we ensure that

$$(73) \quad T_i \geq \tau_i$$

for all  $i = 0, 1, 2, \dots, \infty$ . We prove this claim by induction with respect to the index  $i = 0, 1, \dots, \infty$ . We start with  $i = 0$ , and then show that for all  $i > 0$  the following implication holds:

$$(74) \quad T_i \geq \tau_i \Rightarrow T_{i+1} \geq \tau_{i+1}.$$

Let us prove that (73) holds for  $i = 0$ . For this purpose consider the term  $(\sigma_i - \sigma_{i+1})/\gamma_{0,1}(\sigma_i)$ . As follows immediately from condition (25) of the theorem, we have that

$$(75) \quad \frac{\sigma_i - \sigma_{i+1}}{\gamma_{0,1}(\sigma_i)} \geq \tau_i \Delta_0 \quad \forall i \geq 0.$$

In particular

$$\frac{\sigma_0 - \sigma_1}{\gamma_{0,1}(\sigma_0)} \geq \tau_0 \Delta_0.$$

Therefore, inequality (72) reduces to

$$(76) \quad T_0 \geq \tau_0 \Delta_0 \frac{h(\mathbf{z}_0)}{\gamma_{0,2}(\sigma_0^{-1} \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0))}.$$

Moreover, taking into account Property 3 and (18), (19), we can derive the following estimate:

$$\begin{aligned} \sigma_0^{-1} \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, 0) &\leq \sigma_0^{-1} \phi_0(\|\mathbf{x}(t_0)\|_{\mathcal{A}}) + \sigma_0^{-1} v_0(c \cdot |h(\mathbf{z}_0)| \sigma_0) \\ &\leq B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) + B_2(|h(\mathbf{z}_0)|, c). \end{aligned}$$

According to the theorem conditions,  $\mathbf{x}_0$  and  $\mathbf{z}_0$  satisfy inequality (26). This in turn implies that

$$(77) \quad \begin{aligned} &\gamma_{0,2}(\sigma_0^{-1} \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0)) \\ &\leq \gamma_{0,2}(B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) + B_2(|h(\mathbf{z}_0)|, c) + c \cdot h(\mathbf{z}_0)) \leq \Delta_0 \cdot h(\mathbf{z}_0). \end{aligned}$$

Combining (76) and (77), we obtain the desired inequality

$$T_0 \geq \tau_0 \Delta_0 \frac{h(\mathbf{z}_0)}{\gamma_{0,2}(\sigma_0^{-1} \beta(\|\mathbf{x}(t_0)\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0))} \geq \tau_0 \frac{\Delta_0 h(\mathbf{z}_0)}{\Delta_0 h(\mathbf{z}_0)} = \tau_0.$$

Thus the basis of induction is proved.

Let us assume that (73) holds for all  $i = 0, \dots, n$ ,  $n \geq 0$ . We shall prove now that implication (74) holds for  $i = n + 1$ . Consider the term  $\beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0)$ :

$$\begin{aligned} \beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0) &\leq \beta(\beta(\|\mathbf{x}(t_n)\|_{\mathcal{A}}, T_n) + c \|h(\mathbf{z}(\tau))\|_{\infty, [t_n, t_{n+1}]}, 0) \\ &\leq \beta(\beta(\|\mathbf{x}(t_n)\|_{\mathcal{A}}, T_n) + c \cdot \sigma_n \cdot h(\mathbf{z}_0), 0). \end{aligned}$$

Taking into account Property 2 (specifically, inequality (17)) and (18)–(20) we can derive that

$$(78) \quad \begin{aligned} \beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0) &\leq \beta(\xi_n \cdot \beta(\|\mathbf{x}(t_n)\|_{\mathcal{A}}, 0) + c \cdot \sigma_n \cdot h(\mathbf{z}_0), 0) \\ &\leq \phi_1(\|\mathbf{x}(t_n)\|_{\mathcal{A}}) + v_1(c \cdot |h(\mathbf{z}_0)| \cdot \sigma_n). \end{aligned}$$

Notice that, according to the inductive hypothesis ( $T_i \geq \tau_i$ ), the following holds:

$$(79) \quad \|\mathbf{x}(t_{i+1})\|_{\mathcal{A}} \leq \beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, T_i) + c \cdot \sigma_i \cdot h(\mathbf{z}_0) \leq \xi_i \beta(\|\mathbf{x}(t_i)\|_{\mathcal{A}}, 0) + c \cdot \sigma_i \cdot h(\mathbf{z}_0)$$

for all  $i = 0, \dots, n$ . Then (78), (79), and (18)–(20) imply that

$$(80) \quad \begin{aligned} &\beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0) \leq \phi_1(\xi_n \beta(\|\mathbf{x}(t_{n-1})\|_{\mathcal{A}}, 0) + c \cdot \sigma_{n-1} \cdot h(\mathbf{z}_0)) \\ &\quad + v_1(c \cdot |h(\mathbf{z}_0)| \cdot \sigma_n) \leq \phi_2(\|\mathbf{x}(t_{n-1})\|_{\mathcal{A}}) + v_2(c \cdot |h(\mathbf{z}_0)| \cdot \sigma_{n-1}) \\ &\quad + v_1(c \cdot |h(\mathbf{z}_0)| \cdot \sigma_n) \leq \phi_{n+1}(\|\mathbf{x}_0\|_{\mathcal{A}}) + \sum_{i=1}^{n+1} v_i(c \cdot |h(\mathbf{z}_0)| \sigma_{n+1-i}) \\ &\leq \phi_{n+1}(\|\mathbf{x}_0\|_{\mathcal{A}}) + \sum_{i=0}^{n+1} v_i(c \cdot |h(\mathbf{z}_0)| \sigma_{n+1-i}). \end{aligned}$$

According to Property 3, the term

$$\sigma_{n+1}^{-1} \left( \phi_{n+1}(\|\mathbf{x}_0\|_{\mathcal{A}}) + \sum_{i=0}^{n+1} v_i(c \cdot |h(\mathbf{z}_0)|\sigma_{n+1-i}) \right)$$

is bounded from above by the sum

$$B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) + B_2(|h(\mathbf{z}_0)|, c).$$

Therefore, monotonicity of  $\gamma_{0,2}$ , estimate (80), and inequality (26) lead to the following inequality:

$$\begin{aligned} \gamma_{0,2}(\sigma_{n+1}^{-1}\beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0)) &\leq \gamma_{0,2}(B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) + B_2(|h(\mathbf{z}_0)|, c) + c \cdot h(\mathbf{z}_0)) \\ &\leq h(\mathbf{z}_0)\Delta_0. \end{aligned}$$

Hence, according to (72) and (75) we have

$$\begin{aligned} T_{n+1} &\geq \frac{(\sigma_{n+1} - \sigma_{n+2})}{\gamma_{0,1}(\sigma_{n+1})} \frac{h(\mathbf{z}_0)}{\gamma_{0,2}(\sigma_{n+1}^{-1}\beta(\|\mathbf{x}(t_{n+1})\|_{\mathcal{A}}, 0) + c \cdot h(\mathbf{z}_0))} \\ &\geq \tau_{n+1} \frac{\Delta_0 h(\mathbf{z}_0)}{\Delta_0 h(\mathbf{z}_0)} = \tau_{n+1}. \end{aligned}$$

Thus implication (74) is proved. This implies that  $h(\mathbf{z}(t)) \in [0, h(\mathbf{z}_0)]$  for all  $t \geq t_0$  and, consequently, that (66) holds.  $\square$

**A.2. Proof of Lemma 6.** As follows from the assumptions,  $h(\mathbf{z}(t, \mathbf{z}_0))$  is bounded. Assume it belongs to the interval  $[a, h(\mathbf{z}_0)]$ ,  $a \leq h(\mathbf{z}_0)$ . Taking into account that  $h(\mathbf{z}(t, \mathbf{z}_0))$  is bounded and monotone in  $t$  (every subsequence of which is again monotone) and applying the Bolzano–Weierstrass theorem we can conclude that  $h(\mathbf{z}(t, \mathbf{z}_0))$  converges in  $[a, h(\mathbf{z}_0)]$ . In particular, there exists  $\bar{h} \in [a, h(\mathbf{z}_0)]$  such that

$$(81) \quad \lim_{t \rightarrow \infty} h(\mathbf{z}(t, \mathbf{z}_0)) = \bar{h}.$$

Therefore, as follows from (8) we can conclude that

$$\begin{aligned} (82) \quad 0 &\leq \lim_{t \rightarrow \infty} \int_{t_0}^t \gamma_1(\|\mathbf{x}(\tau, \mathbf{x}_0)\|_{\mathcal{A}}) d\tau \leq \lim_{t \rightarrow \infty} (h(\mathbf{z}_0) - h(\mathbf{z}(t, \mathbf{z}_0))) \\ &= h(\mathbf{z}_0) - \bar{h} \leq h(\mathbf{z}_0) - a < \infty. \end{aligned}$$

According to the lemma assumptions, system  $\mathcal{S}_a$  has steady-state characteristics. This means that there exists a constant  $\bar{x} \in \mathbb{R}_+$  such that

$$(83) \quad \lim_{t \rightarrow \infty} \|\mathbf{x}(t, \mathbf{x}_0)\|_{\mathcal{A}} = \bar{x}.$$

Suppose that  $\bar{x} > 0$ . Then it follows from (83) that there exists time instant  $t_1$ ,  $t_0 \leq t_1 < \infty$  and some constant  $0 < \delta < \bar{x}$  such that

$$\|\mathbf{x}(t)\|_{\mathcal{A}} \geq \delta \quad \forall t \geq t_1.$$

Hence using (82) and noticing that  $\gamma_1 \in \mathcal{K}_e$  we obtain

$$\infty > h(\mathbf{z}_0) - \bar{h} \geq \lim_{t \rightarrow \infty} \int_{t_0}^t \gamma_1(\|\mathbf{x}(\tau, \mathbf{x}_0)\|_{\mathcal{A}}) d\tau \geq \lim_{t \rightarrow \infty} \int_{t_1}^t \gamma_1(\delta) d\tau = \infty.$$

Thus we obtained a contradiction. Hence  $\bar{x} = 0$  and, consequently,

$$\lim_{t \rightarrow \infty} \|\mathbf{x}(t)\|_{\mathcal{A}} = 0.$$

Then, according to the notion of steady-state characteristic in Definition 4, this is possible only if  $\bar{h} \in \chi^{-1}(0)$ .  $\square$

**A.3. Proof of Lemma 7.** Analogously to the proof of Lemma 6 we notice that (82) holds. This, however, implies that for any constant and positive  $T$ , the limit

$$\lim_{t \rightarrow \infty} \int_t^{t+T} \gamma_1(\|\mathbf{x}(\tau)\|_{\mathcal{A}}) d\tau$$

exists and equals zero. Furthermore,  $h(\mathbf{z}(t, \mathbf{z}_0)) \in [0, h(\mathbf{z}_0)]$  for all  $t \geq t_0$ . Hence there exists a time instant  $t'$  such that

$$\|\mathbf{x}(t)\|_{\mathcal{A}} \leq c \cdot h(\mathbf{z}_0) + \varepsilon \quad \forall t \geq t',$$

where  $\varepsilon > 0$  is arbitrarily small. Then taking into account (31) we can conclude that

$$(84) \quad \lim_{t \rightarrow \infty} \int_t^{t+T} \gamma_1(\|\mathbf{x}(\tau)\|_{\mathcal{A}}) d\tau \geq \bar{\gamma} \int_t^{t+T} \|\mathbf{x}(\tau)\|_{\mathcal{A}} d\tau = 0.$$

Given that (81) holds, system (6) has the steady-state characteristic on average, and given that  $\chi_T(\cdot)$  has no zeros in the positive domain, limiting relation (84) is possible only if  $\bar{h} = 0$ . Then, according to (6),  $\lim_{t \rightarrow \infty} \|\mathbf{x}(t)\|_{\mathcal{A}} = 0$ .  $\square$

**A.4. Proof of Corollary 8.** As follows from Theorem 3, state  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  converges to the set  $\Omega_a$  specified by (24). Hence  $h(\mathbf{z}(t, \mathbf{z}_0))$  is bounded. Then, according to (8), estimate (82) holds. This, in combination with condition (34), implies that  $\mathbf{z}(t, \mathbf{z}_0)$  is bounded. In other words,

$$\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0) \in \Omega' \quad \forall t \geq t_0,$$

where  $\Omega'$  is a bounded subset in  $\mathbb{R}^n \times \mathbb{R}^m$ . Applying the Bolzano–Weierstrass theorem we can conclude that for every point  $\mathbf{x}_0 \oplus \mathbf{z}_0 \in \Omega_\gamma$  there is an  $\omega$ -limit set  $\omega(\mathbf{x}_0 \oplus \mathbf{z}_0) \subseteq \Omega'$  (nonempty).

As follows from (C3) and Lemma 6, the following holds:

$$\lim_{t \rightarrow \infty} h(\mathbf{z}(t, \mathbf{z}_0)) \in \chi^{-1}(0).$$

Therefore, given that  $h(\cdot) \in \mathcal{C}^0$ , we can obtain that

$$\lim_{t_i \rightarrow \infty} (\mathbf{z}(t_i, \mathbf{z}_0)) = h \left( \lim_{t_i \rightarrow \infty} \mathbf{z}(t_i, \mathbf{z}_0) \right) = h(\omega_z(\mathbf{x}_0 \oplus \mathbf{z}_0)) \in \chi^{-1}(0).$$

In other words,

$$\omega_z(\mathbf{x}_0 \oplus \mathbf{z}_0) \subseteq \Omega_h = \{\mathbf{x} \in \mathbb{R}^n, \mathbf{z} \in \mathbb{R}^m \mid h(\mathbf{z}) \in \chi^{-1}(0)\}.$$

Moreover,

$$\omega_x(\mathbf{x}_0 \oplus \mathbf{z}_0) \subseteq \Omega_a = \{\mathbf{x} \in \mathbb{R}^n, \mathbf{z} \in \mathbb{R}^m \mid \|\mathbf{x}\|_{\mathcal{A}} = 0\}.$$

According to assumption (C1), the flow  $\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0)$  is generated by a system of autonomous differential equations with a locally Lipschitz right-hand side. Then, as follows from [13, Lemma 4.1, page 127],

$$\lim_{t \rightarrow \infty} \text{dist}(\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0), \omega(\mathbf{x}_0 \oplus \mathbf{z}_0)) = 0.$$

Noticing that

$$\text{dist}(\mathbf{x}(t, \mathbf{x}_0) \oplus \mathbf{z}(t, \mathbf{z}_0), \omega(\mathbf{x}_0 \oplus \mathbf{z}_0)) \geq \text{dist}(\mathbf{x}(t, \mathbf{x}_0), \Omega_a) + \text{dist}(\mathbf{z}(t, \mathbf{z}_0), \Omega_h),$$

we can finally obtain that

$$\lim_{t \rightarrow \infty} \text{dist}(\mathbf{x}(t, \mathbf{x}_0), \Omega_a) = 0, \quad \lim_{t \rightarrow \infty} \text{dist}(\mathbf{z}(t, \mathbf{z}_0), \Omega_h) = 0. \quad \square$$

**A.5. Proof of Corollary 9.** As follows from Theorem 3, the corollary will be proved if Properties 1–3 are satisfied and also if (25), (26), and (27) hold. In order to satisfy Property 1 we select the following sequence  $\mathcal{S}$ :

$$(85) \quad \mathcal{S} = \{\sigma_i\}_{i=0}^{\infty}, \quad \sigma_i = \frac{1}{\kappa^i}, \quad \kappa \in \mathbb{R}_+, \quad \kappa > 1.$$

Let us choose sequences  $\mathcal{T}$  and  $\Xi$  as follows:

$$(86) \quad \mathcal{T} = \{\tau_i\}_{i=0}^{\infty}, \quad \tau_i = \tau^*,$$

$$(87) \quad \Xi = \{\xi_i\}_{i=0}^{\infty}, \quad \xi_i = \xi^*,$$

where  $\tau^*, \xi^*$  are positive constants yet to be defined. Notice that choosing  $\mathcal{T}$  as in (86) automatically fulfills condition (27) of Theorem 3. On the other hand, taking into account (17), (39), and that  $\beta_t(t)$  is monotonically decreasing in  $t$ , this choice defines a constant  $\xi^*$  as follows:

$$(88) \quad \beta_t(\tau^*) \leq \xi^* \beta_t(0) < \beta_t(0), \quad 0 \leq \xi^* < 1.$$

Given that the inverse  $\beta_t^{-1}$  exists, (40), this choice is always possible. In particular, (88) will be satisfied for the following values of  $\tau^*$ :

$$(89) \quad \tau^* \geq \beta_t^{-1}(\xi^* \beta_t(0)).$$

Let us now find the values for  $\tau^*$  and  $\xi^*$  such that Property 3 is also satisfied. For this purpose consider systems of functions  $\Phi, \Upsilon$  specified by (18), (19). Notice that function  $\beta(s, 0)$  in (18), (19) is linear for system (39),

$$\beta(s, 0) = s \cdot \beta_t(0),$$

and therefore the functions  $\rho_{\phi, j}(\cdot), \rho_{v, j}$  are identity maps. Hence  $\Phi, \Upsilon$  reduce to the following:

$$(90) \quad \Phi : \begin{aligned} \phi_j(s) &= \phi_{j-1} \cdot \xi^* \cdot \beta(s, 0) = \xi^* \cdot \beta_t(0) \cdot \phi_{j-1}(s), \quad j = 1, \dots, i, \\ \phi_0(s) &= \beta_t(0) \cdot s, \end{aligned}$$

$$(91) \quad \Upsilon : \begin{aligned} v_j(s) &= \phi_{j-1}(s), \quad j = 1, \dots, i, \\ v_0(s) &= \beta_t(0) \cdot s. \end{aligned}$$

Taking into account (85), (90), and (91), let us explicitly formulate requirements (21), (22) in Property 3. These conditions are equivalent to the boundedness of the following functions:

$$(92) \quad \|\mathbf{x}(t_0)\|_{\mathcal{A}} \cdot \beta_t(0) \cdot \kappa^n (\xi^* \cdot \beta_t(0))^n;$$

$$(93) \quad \begin{aligned} & \kappa^n \left( \beta_t(0) \frac{c|h(\mathbf{z}_0)|}{\kappa^n} + \frac{\beta_t(0)c|h(\mathbf{z}_0)|}{\kappa^{n-1}} + \beta_t(0) \sum_{i=2}^n c|h(\mathbf{z}_0)| \frac{1}{\kappa^{n-i}} (\xi^* \cdot \beta_t(0))^{i-1} \right) \\ &= \beta_t(0)c|h(\mathbf{z}_0)| + \beta_t(0)c|h(\mathbf{z}_0)|\kappa \left( 1 + \sum_{i=2}^n \kappa^{i-1} (\xi^* \cdot \beta_t(0))^{i-1} \right). \end{aligned}$$

Boundedness of the functions  $B_1(\|\mathbf{x}_0\|_{\mathcal{A}})$  and  $B_2(|h(\mathbf{z}_0)|, c)$  is ensured if  $\xi^*$  satisfies the inequality

$$(94) \quad \xi^* \leq \frac{d}{\kappa \cdot \beta_t(0)}$$

for some  $0 \leq d < 1$ . Notice that  $\kappa > 1$ ,  $\beta_t(0) \geq 1$  imply that  $\xi^* \leq 1$ , and therefore constant  $\tau^*$  satisfying (89) will always be defined. Hence according to (92) and (93), the functions  $B_1(\|\mathbf{x}_0\|_{\mathcal{A}})$  and  $B_2(|h(\mathbf{z}_0)|, c)$  satisfying Property 3 can be chosen as

$$(95) \quad B_1(\|\mathbf{x}_0\|_{\mathcal{A}}) = \beta_t(0) \|\mathbf{x}_0\|_{\mathcal{A}}; \quad B_2(|h(\mathbf{z}_0)|, c) = \beta_t(0) \cdot c \cdot |h(\mathbf{z}_0)| \left( 1 + \frac{\kappa}{1-d} \right).$$

In order to apply Theorem 3 we have to check the remaining conditions (25) and (26). This requires the possibility of factorization (10) for the function  $\gamma_0(\cdot)$ . According to assumption (41) of the corollary the function  $\gamma_0(\cdot)$  is Lipschitz:

$$|\gamma_0(s)| \leq D_{\gamma,0} \cdot |s|.$$

This allows us to choose functions  $\gamma_{0,1}(\cdot)$  and  $\gamma_{0,2}(\cdot)$  as follows:

$$(96) \quad \gamma_{0,1}(s) = s, \quad \gamma_{0,2}(s) = D_{\gamma,0} \cdot s.$$

Condition (25), therefore, is equivalent to solvability of the following inequality:

$$(97) \quad \left( \frac{1}{\kappa^i} - \frac{1}{\kappa^{i+1}} \right) \frac{\kappa^i}{\tau^*} \geq \Delta_0.$$

Taking into account inequalities (89) and (94), we can derive that solvability of

$$(98) \quad \Delta_0 = \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa - 1}{\kappa}$$

implies existence of  $\Delta_0 > 0$  satisfying (97) and, consequently, condition (25) of Theorem 3. Given that  $d < 1$ ,  $\kappa > 1$ , and  $\beta_t(0) \geq 1$ , a positive solution to (98) is always defined. Hence the proof will be complete and the claim is nonvacuous if the domain

$$(99) \quad \begin{aligned} & D_{\gamma,0} \leq \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa - 1}{\kappa} \\ & \times \frac{h(\mathbf{z}_0)}{\beta_t(0) \|\mathbf{x}_0\|_{\mathcal{A}} + \beta_t(0) \cdot c \cdot |h(\mathbf{z}_0)| \left( 1 + \frac{\kappa}{1-d} \right) + c|h(\mathbf{z}_0)|} \end{aligned}$$

is not empty.  $\square$

**A.6. Proof of Corollary 10.** It follows from Corollary 9 that the state of the interconnection converges into  $\Omega_a$  for all initial conditions  $\mathbf{x}_0, \mathbf{z}_0$  satisfying (99). In other words, the following inequality should hold:

$$(100) \quad \begin{aligned} & D_{\gamma,0} \left( \beta_t(0) \|\mathbf{x}_0\|_{\mathcal{A}} + \beta_t(0) \cdot c \cdot |h(\mathbf{z}_0)| \left( 1 + \frac{\kappa}{1-d} \right) + c|h(\mathbf{z}_0)| \right) \\ & \leq \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa-1}{\kappa} \cdot h(\mathbf{z}_0). \end{aligned}$$

Hence assuming that  $h(\mathbf{z}_0) > 0$ , we can rewrite (100) in the following way:

$$(101) \quad \begin{aligned} & D_{\gamma,0} \cdot \beta_t(0) \|\mathbf{x}_0\|_{\mathcal{A}} \\ & \leq \left( \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa-1}{\kappa} - D_{\gamma,0} \cdot c \left( \beta_t(0) \cdot \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right) \right) h(\mathbf{z}_0). \end{aligned}$$

Solutions to (101) exist, however, if the inequality

$$\left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa-1}{\kappa} \geq D_{\gamma,0} \cdot c \left( \beta_t(0) \cdot \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right)$$

or, equivalently,

$$(102) \quad D_{\gamma,0} \cdot c \cdot \left( \beta_t(0) \cdot \left( 1 + \frac{\kappa}{1-d} \right) + 1 \right) \cdot \beta_t^{-1} \left( \frac{d}{\kappa} \right) \frac{\kappa}{\kappa-1} < 1$$

is satisfied. The estimate of the trapping region follows from (101).

Let us finally show that continuity of  $h(\mathbf{z})$  implies that the volume of  $\Omega_\gamma$  is nonzero in  $\mathbb{R}^n \oplus \mathbb{R}^m$ . For the sake of compactness we rewrite inequality (101) in the following form:

$$(103) \quad \|\mathbf{x}_0\|_{\mathcal{A}} \leq C_\gamma h(\mathbf{z}_0),$$

where  $C_\gamma$  is a constant depending on  $d, \kappa, \beta_t(0)$ , and  $D_{\gamma,0}$ . Given that (102) holds we can conclude that  $C_\gamma > 0$ . According to (103), domain  $\Omega_\gamma$  contains the following set:

$$\{\mathbf{x}_0 \in \mathbb{R}^n, \mathbf{z}_0 \in \mathbb{R}^m \mid h(\mathbf{z}_0) > D_z \in \mathbb{R}_+, \|\mathbf{x}_0\|_{\mathcal{A}} \leq C_\gamma D_z\}.$$

Consider the following domain:  $\Omega_{\mathbf{x},\gamma} = \{\mathbf{x}_0 \in \mathbb{R}^n \mid \|\mathbf{x}_0\|_{\mathcal{A}} \leq C_\gamma D_z\}$ . Clearly, it contains a point  $\mathbf{x}_{0,1} \in \mathbb{R}^n : \|\mathbf{x}_{0,1}\|_{\mathcal{A}} = \frac{C_\gamma D_z}{2}$ . For the point  $\mathbf{x}_{0,1}$  and for all  $\boldsymbol{\varepsilon}_1 \in \mathbb{R}^n : \|\boldsymbol{\varepsilon}_1\| \leq \frac{C_\gamma D_z}{4}$  we have that  $\|\mathbf{x}_{0,1} + \boldsymbol{\varepsilon}_1\|_{\mathcal{A}} = \inf_{\mathbf{q} \in \mathcal{A}} \|\mathbf{x}_{0,1} + \boldsymbol{\varepsilon}_1 - \mathbf{q}\| \leq \inf_{\mathbf{q} \in \mathcal{A}} \{\|\mathbf{x}_{0,1} - \mathbf{q}\| + \|\boldsymbol{\varepsilon}_1\|\} \leq \frac{3C_\gamma D_z}{4}$ . On the other hand,  $\|\mathbf{x}_{0,1} + \boldsymbol{\varepsilon}_1\|_{\mathcal{A}} = \inf_{\mathbf{q} \in \mathcal{A}} \|\mathbf{x}_{0,1} + \boldsymbol{\varepsilon}_1 - \mathbf{q}\| \geq \inf_{\mathbf{q} \in \mathcal{A}} \{\|\mathbf{x}_{0,1} - \mathbf{q}\| - \|\boldsymbol{\varepsilon}_1\|\} \geq \frac{C_\gamma D_z}{4}$ . This implies that there exists a set of points  $\mathbf{x}_{0,2} = \mathbf{x}_{0,1} + \boldsymbol{\varepsilon}_1 \in \mathbb{R}^n : \|\mathbf{x}_{0,1} - \mathbf{x}_{0,2}\| \leq \frac{C_\gamma D_z}{4}, \mathbf{x}_{0,2} \notin \mathcal{A}, \|\mathbf{x}_{0,2}\|_{\mathcal{A}} \leq C_\gamma D_z$ .

Consider now the following domain:  $\Omega_{\mathbf{z},\gamma} = \{\mathbf{z}_0 \in \mathbb{R}^m \mid h(\mathbf{z}_0) > D_z\}$ . Let us pick  $\mathbf{z}_{0,1} \in \Omega_{\mathbf{z},\gamma} : h(\mathbf{z}_{0,1}) = 2D_z$ . Because  $h(\cdot)$  is continuous we have that

$$\forall \varepsilon > 0, \exists \delta > 0 : \|\mathbf{z}_{0,1} - \mathbf{z}_{0,2}\| < \delta \Rightarrow |h(\mathbf{z}_{0,1}) - h(\mathbf{z}_{0,2})| < \varepsilon.$$

Let  $\varepsilon = D_z$ ; then  $-D_z < h(\mathbf{z}_{0,1}) - h(\mathbf{z}_{0,2}) < D_z$  and therefore  $h(\mathbf{z}_{0,2}) > D_z$ . Hence there exists a set of points  $\mathbf{z}_{0,2} \in \mathbb{R}^m : \|\mathbf{z}_{0,1} - \mathbf{z}_{0,2}\| < \delta, \mathbf{z}_{0,2} \in \Omega_{\mathbf{z},\gamma}$ .

Consider the following set:

$$\Omega_{\mathbf{xz},\gamma} = \left\{ \mathbf{x}' \in \mathbb{R}^n, \mathbf{z}' \in \mathbb{R}^m \mid \|\mathbf{x}_{0,1} - \mathbf{x}'\|^2 + \|\mathbf{z}_{0,1} - \mathbf{z}'\|^2 \leq r^2, r = \min \left\{ \delta, \frac{C_\gamma D_z}{4} \right\} \right\}.$$

For all  $\mathbf{x}_0, \mathbf{z}_0 \in \Omega_{\mathbf{xz},\gamma}$  we have that  $\mathbf{x}_0 \in \Omega_{\mathbf{x},\gamma}$ ,  $\mathbf{z}_0 \in \Omega_{\mathbf{z},\gamma}$ . Hence inequality (103) holds, and  $\mathbf{x}_0 \oplus \mathbf{z}_0 \in \Omega_\gamma$ . The volume of the set  $\Omega_{\mathbf{xz},\gamma}$  is defined by the volume of the interior of a sphere in  $\mathbb{R}^{n+m}$  with nonzero radius. Thus the volume of  $\Omega_\gamma \supset \Omega_{\mathbf{xz},\gamma}$  is also nonzero.  $\square$

**A.7. Proof of Corollary 11.** Let  $\lambda(\tau, \lambda_0)$  be a solution of system (51). Consider it as a function of variable  $\tau$ . Let us pick some monotone, strictly increasing function  $\sigma$  such that the following holds:

$$\tau = \sigma(t), \sigma : \mathbb{R}_+ \rightarrow \mathbb{R}_+.$$

Given that  $\eta(\Omega_\lambda)$  is dense in  $\Omega_\theta$ , for any  $\theta \in \Omega_\theta$  there always exists a vector  $\lambda_\theta \in \Omega_\lambda$  such that  $\eta(\lambda_\theta) = \theta + \epsilon_\theta$ , where  $\|\epsilon_\theta\|$  is arbitrarily small. Furthermore,  $\lambda(\tau)$  is dense in  $\Omega_\lambda$ , and hence there is a point  $\lambda^* = \lambda(\tau^*, \lambda_0)$  which is arbitrarily close to  $\lambda_\theta$ . Consider the following difference:

$$\mathbf{f}(\xi(t), \theta) - \mathbf{f}(\xi(t), \hat{\theta}) = \mathbf{f}(\xi(t), \theta) - \mathbf{f}(\xi(t), \eta(\lambda^*)) + \mathbf{f}(\xi, \eta(\lambda^*)) - \mathbf{f}(\xi, \eta(\lambda(\sigma(t)))).$$

The function  $\mathbf{f}(\cdot)$  is locally bounded and  $\eta(\cdot)$  is Lipschitz, and then

$$\|\mathbf{f}(\xi, \theta) - \mathbf{f}(\xi, \eta(\lambda^*))\| \leq D_f \|\epsilon_\theta\| + \Delta_f = \Delta_\theta + \Delta_f,$$

where  $\Delta_\theta$  is arbitrarily small. Hence

$$(104) \quad \begin{aligned} \|\mathbf{f}(\xi, \eta(\lambda^*)) - \mathbf{f}(\xi, \eta(\lambda(\sigma(t))))\| &\leq D_f \|\eta(\lambda^*) - \eta(\lambda(\sigma(t)))\| + \Delta_f + \Delta_\theta \\ &\leq D_f \cdot D_\eta \|\lambda^* - \lambda(\sigma(t))\| + \Delta_f + \Delta_\theta. \end{aligned}$$

Noticing that  $\lambda^* = \lambda(\tau^*, \lambda_0) = \lambda(\sigma(\tau^*), \lambda_0)$  and taking into account the Poisson stability of (51), we can always choose  $\lambda^*(\sigma^*, \lambda_0)$  such that  $\sigma^* > \sigma(t_0) = \tau_0$  for any  $\tau_0 \in \mathbb{R}_+$ . Hence, according to (104) the following estimate holds:

$$(105) \quad \begin{aligned} \|\mathbf{f}(\xi, \eta(\lambda^*)) - \mathbf{f}(\xi, \eta(\lambda(\sigma(t))))\| &\leq D_f \cdot D_\eta \left\| \int_{\sigma(t)}^{\sigma^*} S(\lambda(\sigma(\tau))) d\tau \right\| + \Delta_f + \Delta_\theta \\ &\leq D_f \cdot D_\eta \cdot \max_{\lambda \in \Omega_\lambda} \|S(\lambda)\| |\sigma^* - \sigma(t)| = \mathcal{D} \cdot |\sigma^* - \sigma(t)| + \Delta_f + \Delta_\theta, \\ \mathcal{D} &= D_f \cdot D_\eta \cdot \max_{\lambda \in \Omega_\lambda} \|S(\lambda)\|. \end{aligned}$$

Denoting  $\mathbf{u}(t) = \mathbf{f}(\xi(t), \theta) - \mathbf{f}(\xi(t), \hat{\theta}) + \varepsilon(t)$  we can now conclude that

$$(106) \quad \begin{aligned} \|\mathbf{u}(t)\| &\leq \Delta_\epsilon + \Delta_f + \|\mathbf{f}(\xi(t), \theta) - \mathbf{f}(\xi(t), \eta(\lambda^*))\| + \mathcal{D} \cdot |\sigma^* - \sigma(t)| \\ &\leq \Delta_\epsilon + 2\Delta_f + \Delta_\theta + D_f \|\theta - \eta(\lambda^*)\| + \mathcal{D} \cdot |\sigma^* - \sigma(t)|. \end{aligned}$$

Notice that due to the denseness of  $\lambda(t, \lambda_0)$  in  $\Omega_\lambda$  it is always possible to choose  $\lambda^*$  such that

$$D_f \|\theta - \eta(\lambda^*)\| = D_f \|\eta(\lambda_\theta) - \eta(\lambda^*)\| \leq D_f D_\eta \|\lambda_\theta - \eta(\lambda^*)\| \leq \Delta_\lambda.$$

Hence, according to (106), we have

$$\|\mathbf{u}(t)\|_{\infty, [t_0, t]} \leq 2\Delta_f + \Delta_\varepsilon + \delta + \mathcal{D} \cdot \|\sigma^* - \sigma(t)\|_{\infty, [t_0, t]},$$

where the term  $\delta > \Delta_\theta + \Delta_\lambda$  can be made arbitrarily small.

Therefore Assumption 3 implies that the following inequality holds:

$$(107) \quad \|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta(M)}} \leq \beta(t - t_0) \|\mathbf{x}(t_0)\|_{\mathcal{A}_{\Delta(M)}} + c \cdot \mathcal{D} \cdot \|\sigma^* - \sigma(t)\|_{\infty, [t_0, t]}.$$

Let us now define  $\sigma(t)$  as follows:

$$(108) \quad \sigma(t) = \int_{t_0}^t \gamma \|\psi(\mathbf{x}(\tau))\|_{\mathcal{A}_{\Delta(M)}} d\tau.$$

Moreover, let us introduce the following notation:

$$h(t) = \sigma^* - \sigma(t) = \sigma^* - \int_{t_0}^t \gamma \|\psi(\mathbf{x}(\tau))\|_{\mathcal{A}_{\Delta(M)}} d\tau;$$

then for all  $t', t \geq t_0$ ,  $t \geq t'$  we have that

$$h(t') - h(t) = \int_{t'}^t \gamma \|\psi(\mathbf{x}(\tau))\|_{\mathcal{A}_{\Delta(M)}} d\tau.$$

Taking into account (104), (105), equality

$$\frac{\partial \boldsymbol{\lambda}(\sigma(t), \boldsymbol{\lambda}_0)}{dt} = \frac{\partial \sigma(t)}{dt} S(\boldsymbol{\lambda}(\sigma(t), \boldsymbol{\lambda}_0)) = \gamma \|\psi(\mathbf{x}(\tau))\|_{\mathcal{A}_{\Delta(M)}} S(\boldsymbol{\lambda}(\sigma(t), \boldsymbol{\lambda}_0)),$$

and (107), and denoting  $D_\lambda = c\mathcal{D}$ , we can conclude that the following holds along the trajectories of (52):

$$(109) \quad \begin{aligned} \|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta(M)}} &\leq \beta(t - t_0) \|\mathbf{x}(t_0)\|_{\mathcal{A}_{\Delta(M)}} + D_\lambda \|h(t)\|_{\infty, [t_0, t]}, \\ h(t_0) - h(t) &= \int_{t_0}^t \gamma \|\psi(\mathbf{x}(\tau))\|_{\mathcal{A}_{\Delta(M)}} d\tau. \end{aligned}$$

Hence, according to Corollary 8, the limit relation (54) holds for all  $|h(t_0)|$ ,  $\|\mathbf{x}(t_0)\|_{\mathcal{A}_{\Delta(M)}}$  which belong to the domain

$$\begin{aligned} \Omega_\gamma : \gamma &\leq \left( \beta_t^{-1} \left( \frac{d}{\kappa} \right) \right)^{-1} \frac{\kappa - 1}{\kappa} \\ &\times \frac{h(t_0)}{\beta_t(0) \|\mathbf{x}(t_0)\|_{\mathcal{A}_{\Delta+\delta}} + \beta_t(0) \cdot D_\lambda \cdot |h(t_0)| \left( 1 + \frac{\kappa}{1-d} \right) + D_\lambda |h(t_0)|} \end{aligned}$$

for some  $d < 1$ ,  $\kappa > 1$ . Notice, however, that  $\|\mathbf{x}(t)\|_{\mathcal{A}_{\Delta+\delta}}$  is always bounded, as  $\mathbf{f}(\cdot)$  is Lipschitz in  $\theta$  and both  $\boldsymbol{\theta}$  and  $\hat{\boldsymbol{\theta}}$  are bounded ( $\boldsymbol{\eta}(\cdot)$  is Lipschitz and  $\boldsymbol{\lambda}(t, \boldsymbol{\lambda}_0)$  is bounded according to assumptions of the corollary). Moreover, due to the Poisson stability of (51) it is always possible to choose a point  $\boldsymbol{\lambda}^*$  such that  $h(t_0) = \sigma^*$  is arbitrarily large. Hence the choice of  $\gamma$  in (109), as (53) suffices to ensure that  $h(t)$  is bounded. Moreover, it follows that  $h(t)$  converges to a limit as  $t \rightarrow \infty$ . This implies

that  $\gamma \int_{t_0}^t \|\mathbf{x}(\tau)\|_{\mathcal{A}_{\Delta(M)}}$  also converges as  $t \rightarrow \infty$  and, consequently,  $\boldsymbol{\lambda}(t, \boldsymbol{\lambda}_0)$  converges to some  $\boldsymbol{\lambda}' \in \Omega_{\lambda}$ . Hence the following holds:

$$\lim_{t \rightarrow \infty} \hat{\boldsymbol{\theta}}(t) = \boldsymbol{\theta}'$$

for some  $\boldsymbol{\theta}' \in \Omega_{\theta}$ . According to the corollary conditions, system (50) has steady-state characteristics with respect to  $\hat{\boldsymbol{\theta}}$ . Then, in the same way as in the proof of Lemma 6, we can show that (54) holds.  $\square$

## A SET-VALUED EKELAND'S VARIATIONAL PRINCIPLE IN VECTOR OPTIMIZATION\*

C. GUTIÉRREZ<sup>†</sup>, B. JIMÉNEZ<sup>‡</sup>, AND V. NOVO<sup>‡</sup>

**Abstract.** This paper deals with Ekeland's variational principle for vector optimization problems. By using a set-valued metric, a set-valued perturbed map, and a cone-boundedness concept based on scalarization, we introduce an original approach to extending the well-known scalar Ekeland's principle to vector-valued maps. As a consequence of this approach, we obtain an Ekeland's variational principle that does not depend on any approximate efficiency notion. This result is related to other Ekeland's principles proved in the literature, and the finite-dimensional case is developed via an  $\varepsilon$ -efficiency notion that we introduced in [*Math. Methods Oper. Res.*, 64 (2006), pp. 165–185; *SIAM J. Optim.*, 17 (2006), pp. 688–710].

**Key words.** Ekeland's variational principle,  $\varepsilon$ -efficiency, set-valued metric, normal based cone, cone-boundedness

**DOI.** 10.1137/060672868

**1. Introduction.** Ekeland's variational principle (EVP) [6] has been used extensively in subjects such as fixed point theorems, geometry of Banach spaces, mathematical programming, control theory, etc. (See [3, p. 183] and [7] for other applications.) So, EVP is one of the most popular tools in nonlinear analysis and optimization theory.

Motivated by this wide usefulness, during the last two decades different authors have been interested in obtaining EVP for vector-valued maps (see, for instance, [2, 5, 9, 10, 15, 16, 17, 19, 21, 23, 25] and the recent survey by Chen, Huang, and Yang in [3, Chapter 4]).

Broadly speaking, one can find in the literature four different approaches to obtaining EVP for vector-valued maps: by using a scalarization process [5, 19, 23]; by transfinite induction arguments such as Zorn's lemma, the axiom of choice, the Hausdorff maximality principle, etc. [2, 21, 25]; by existence theorems of critical points in dynamic systems such as the Dancs–Hegedus–Medvegyev theorem [15]; or by means of particular classes of cones such as nuclear, well-based, or Daniell cones [9, 10, 16, 17].

A lot of EVPs proved in the literature for vector-valued maps have the same statements as the classical EVP for a scalar functional, since they give necessary conditions for  $\varepsilon$ -efficient (approximate) solutions of vector optimization problems via efficient (exact) solutions of vector-valued perturbed maps. Let us remark that several  $\varepsilon$ -efficiency concepts have been used to this end (see [11, 12] for a unified approach on the  $\varepsilon$ -efficiency notion).

The EVP obtained in this work is stronger than these previous EVPs from two points of view. First, because a set-valued perturbed map is considered, and second, because, in a certain sense, it does not depend on any  $\varepsilon$ -efficiency concept. Both improvements are attained by considering a set-valued metric notion, which is new to our knowledge, and a cone-boundedness concept based on scalarization.

In proving our results, we follow the fourth previous approach. Specifically, we consider normal and based cones. Let us observe that this is a broad class of cones. Moreover, the normalness and basedness of the order cone are mild hypotheses in the framework of the vector optimization problems when the final space is a Hausdorff locally convex space.

This paper is structured as follows. In section 2, the vector optimization problem and several notations used in what follows are fixed. Moreover, some definitions and technical results are recalled. In section 3, two general set-valued EVPs for vector-valued maps are proved. In section 4, we show several conditions in order to check the assumptions of these set-valued EVPs. In particular, the cone-boundedness concept based on scalarization is related to other well-known cone-boundedness notions, and some specific conditions for the finite-dimensional case are given. In section 5, we relate the EVP attained in section 3 to similar results in the literature. Let us observe that the finite-dimensional case is studied via a new  $\varepsilon$ -efficiency notion. Finally, in section 6 various conclusions are presented which summarize this work.

**2. Preliminaries.** Let  $(X, d)$  be a nontrivial complete metric space and let  $Y$  be a Hausdorff locally convex space. As usual, the topological dual space of  $Y$  is denoted by  $Y^*$ , and for all  $y^* \in Y^*$  and  $y \in Y$  the value  $y^*(y)$  is written as  $\langle y, y^* \rangle$ .

In this work, the following vector optimization problem is considered:

$$(1) \quad \text{Min}\{f(x) : x \in S\},$$

where  $f : X \rightarrow Y$  and  $S$  is a nonempty closed subset of  $X$ . The partial order in  $Y$  is given via a convex cone  $D$  by the relation

$$y_1, y_2 \in Y, \quad y_1 \leq y_2 \iff y_1 - y_2 \in -D.$$

We assume that  $D$  is pointed ( $D \cap (-D) = \{0\}$ ) and nontrivial ( $D \neq \{0\}$ ). Let us recall that  $x_0 \in S$  is an efficient solution of (1) if there is not a feasible point  $x \in S$  such that  $f(x) \leq f(x_0)$ ,  $f(x) \neq f(x_0)$ .

The positive (resp., strict positive) polar cone of  $D$  is denoted by  $D^+$  (resp.,  $D^{+s}$ ). We denote the nonnegative orthant of  $\mathbb{R}^p$  by  $\mathbb{R}_+^p$  and  $\mathbb{R}_+ := [0, \infty)$ . Moreover, the interior, the closure, the convex hull, the affine hull, and the conical hull of a set  $A \subset Y$  are denoted by  $\text{int}(A)$ ,  $\text{cl}(A)$  ( $\text{cl}^w(A)$  if the weak topology is considered),  $\text{conv}(A)$ ,  $\text{aff}(A)$ , and  $\text{cone}(A)$ , respectively. We say that  $D$  is a solid cone if  $\text{int}(D) \neq \emptyset$ .

If  $A, B \subset Y$  and  $\alpha \in \mathbb{R}$ , the sets  $A + B$  and  $\alpha A$  are defined as follows:

$$\begin{aligned} A + B &= \{z \in Y : z = x + y, x \in A, y \in B\}, \\ \alpha A &= \{z \in Y : z = \alpha x, x \in A\}. \end{aligned}$$

For a scalar optimization problem, there exist several equivalent versions of the EVP (see, for instance, [1]), but the first and most popular statement is based on approximate solutions of the problem (see [6, Theorem 1.1]). In the literature, several EVPs for vector optimization problems have been proposed following this approach and this fact has motivated different EVPs for vector-valued maps, since the  $\varepsilon$ -efficiency notion is not unique.

In this paper, the  $(C, \varepsilon)$ -efficiency concept due to Gutiérrez, Jiménez, and Novo [11, 12] is considered, because it extends and unifies several  $\varepsilon$ -efficiency notions (see [11, 12] for more details).

DEFINITION 2.1. A nonempty set  $C \subset Y$  is coradial if  $\cup_{\beta \geq 1} \beta C = C$ .

Let us refer to [24] and the references therein for further details on this class of sets.

DEFINITION 2.2. Let  $C \subset D \setminus \{0\}$  be a coradial set and  $\varepsilon > 0$ . A point  $x_0 \in S$  is a  $(C, \varepsilon)$ -efficient solution of problem (1) if  $(f(S) - f(x_0)) \cap (-\varepsilon C) = \emptyset$ .

In [11, 12] the reader can find several  $\varepsilon$ -efficiency concepts given by different coradial sets. The set of  $(C, \varepsilon)$ -efficient solutions of (1) is denoted by  $AE(C, \varepsilon)$ . It is easy to prove that if  $C$  is a coradial set, then  $\varepsilon_2 C \subset \varepsilon_1 C \ \forall \varepsilon_1, \varepsilon_2 > 0, \varepsilon_1 < \varepsilon_2$ . Therefore,

$$(2) \quad AE(C, \varepsilon_1) \subset AE(C, \varepsilon_2) \quad \forall \varepsilon_1, \varepsilon_2 > 0, \quad \varepsilon_1 < \varepsilon_2.$$

In obtaining an EVP for vector optimization problems, different conditions on the order cone  $D$  are usually required (see section 5). In this paper we assume that  $D$  is  $w$ -normal, and a nontrivial based convex cone  $K \subset D$  is considered.

DEFINITION 2.3. A convex cone  $D \subset Y$  is normal if for all nets  $(x_i), (y_i) \subset Y$  such that  $0 \leq x_i \leq y_i$  for all  $i$  and  $(y_i) \rightarrow 0$ , then one has  $(x_i) \rightarrow 0$ .

A convex cone  $D \subset Y$  is called  $w$ -normal if it verifies Definition 2.3 when the weak topology is considered (and so  $\rightarrow$  is changed by the weak convergence  $\xrightarrow{w}$ ).

DEFINITION 2.4. A convex cone  $K \subset Y$  is based (well-based) if there exists a (bounded) convex set  $B \subset K$ , called base of  $K$ , such that  $0 \notin \text{cl}(B)$  and  $\mathbb{R}_+ B = K$ .

The following results are well known. The reader can find more details about normal and based cones in [9].

PROPOSITION 2.5 (see [9, Proposition 2.2.9]). Let  $D \subset Y$  be a convex cone. Then  $D$  is  $w$ -normal if and only if  $Y^* = D^+ - D^+$ .

PROPOSITION 2.6 (see [9, Theorem 2.2.12]). A convex cone  $K \subset Y$  is based if and only if  $K^{+s} \neq \emptyset$ .

**3. A set-valued EVP for vector optimization problems.** In this section, a set-valued EVP for (1) is obtained, which extends several given in the literature (see section 5). To attain this goal, a set-valued  $D$ -metric concept is introduced.

DEFINITION 3.1. A set-valued map  $F : X \times X \rightarrow 2^D$  is called a set-valued  $D$ -metric (sv- $D$ -metric) if it satisfies the following conditions:

- (a)  $F(x, y) \neq \emptyset$  and  $F(x, x) = \{0\} \ \forall x, y \in X$ , and  $0 \notin F(x, y) \ \forall x \neq y$ .
- (b)  $F(x, y) = F(y, x) \ \forall x, y \in X$ .
- (c)  $F(x, y) + F(y, z) \subset F(x, z) + D \ \forall x, y, z \in X$ .

Example 3.2.

- (a) Let  $r : X \times X \rightarrow D$  be a vector-valued  $D$ -metric (see, for instance, [21, p. 673]). The set-valued map  $F(x, y) = \{r(x, y)\} \ \forall x, y \in X$  is an sv- $D$ -metric, and so Definition 3.1 extends to set-valued maps the vector concept of a  $D$ -metric.
- (b) Let  $H \subset D \setminus \{0\}$  be a nonempty  $D$ -convex set (i.e.,  $H + D$  is a convex set). It follows that  $F(x, y) = d(x, y)H$  is an sv- $D$ -metric.
- (c) If  $F$  is an sv- $D$ -metric, then the set-valued map  $G : X \times X \rightarrow 2^D$  defined by

$$G(x, y) = \begin{cases} F(x, y) + D & \text{if } x \neq y, \\ \{0\} & \text{if } x = y \end{cases}$$

is an sv- $D$ -metric.

Let us denote  $K_F := \text{cone}(\text{conv}(\cup\{F(x, y) : \forall x, y \in X\}))$  and

$$(3) \quad D_F := (K_F \setminus \{0\} + D) \cup \{0\}.$$

Let us observe that  $D_F$  is a convex cone.

Next, a cone-boundedness notion is introduced, which will be required in what follows. In Proposition 4.6 the reader can find some relations between different cone-boundedness concepts.

**DEFINITION 3.3.** *Let  $K \subset Y$  be a convex cone. A set  $M \subset Y$  is said to be  $K$ -bounded by scalarizations ( $K$ -bounded) if*

$$\inf\{\langle y, \xi \rangle : y \in M\} > -\infty \quad \forall \xi \in K^+.$$

In order to prove the announced set-valued EVP, several assumptions on problem (1), a constant  $\gamma > 0$ , an sv- $D$ -metric  $F$ , and a point  $x_0 \in S$  will be considered:

- (A1)  $D$  is  $w$ -normal and  $D_F$  is based.
- (B1)  $D$  is  $w$ -normal and based.
- (A2)  $0 \notin \text{cl}^w(\cup_{d(x,y) \geq \delta} F(x, y)) \forall \delta > 0$ .
- (A3) Let us denote

$$A_x^{\gamma F} := \{z \in X : (f(z) + \gamma F(z, x) - f(x)) \cap (-D) \neq \emptyset\} \quad \forall x \in S.$$

For each  $x \in S$  and  $(z_n) \subset A_x^{\gamma F}$ ,  $(z_n) \rightarrow z$  such that  $f(z_n) \leq f(z_m) \forall n > m$ , it follows that  $z \in A_x^{\gamma F}$ .

- (A4) The set  $(f(S) - f(x_0)) \cap (-D_F)$  is  $D$ -bounded.
- (B4) The set  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded.

*Remark 3.4.*

- (a) If  $D$  is  $w$ -normal (in particular, when (A1) or (B1) is satisfied), then  $\text{cl}(D)$  is pointed. Indeed, according to [9, Corollary 2.1.23],  $\text{cl}^w(D)$  is pointed, and as  $\text{cl}(D)$  is a convex closed set, one has  $\text{cl}(D) = \text{cl}^w(D)$ .
- (b) It is clear that (B1) implies (A1). However, assumption (A1) is weaker than (B1). Indeed, suppose that  $D$  is closed and take a Banach space  $X$ ,  $d_0 \in D \setminus \{0\}$ , and the sv- $D$ -metric  $F(x, y) = \{\|x - y\|d_0\} \forall x, y \in X$ . Then we have that

$$D_F \setminus \{0\} = \{\alpha d_0 + d : \forall \alpha > 0, \forall d \in D\}.$$

As  $\{-d_0\} \cap D = \emptyset$ , by the separation theorem, there exists  $\lambda \in D^+ \setminus \{0\}$  such that  $\lambda(d_0) > 0$ . It follows that

$$\lambda(\alpha d_0 + d) = \alpha \lambda(d_0) + \lambda(d) \geq \alpha \lambda(d_0) > 0 \quad \forall \alpha > 0, \forall d \in D$$

and so  $D_F^{+s} \neq \emptyset$ , since  $\lambda \in D_F^{+s}$ . Consequently, if  $D$  is  $w$ -normal and  $D^{+s} = \emptyset$ , then (A1) holds and (B1) is not satisfied. Next, we show two examples in which  $D$  is closed and  $w$ -normal and  $D^{+s} = \emptyset$ .

- (i) Let  $Y = B([a, b])$  be the Banach space of all bounded real functions on the compact interval  $[a, b]$  endowed with the supremum norm, and consider the cone  $D = \{y \in Y : y(t) \geq 0 \forall t \in [a, b]\}$  (see [22, p. 27]).
- (ii) Let  $Y = \ell^2(\mathbb{R})$  be the Hilbert space of all square summable functions  $y : \mathbb{R} \rightarrow \mathbb{R}$  endowed with the norm associated to the usual scalar product  $\langle y, z \rangle = \sum_{t \in \mathbb{R}} y(t)z(t) \forall y, z \in Y$ , and consider the cone  $D = \{y \in Y : y(t) \geq 0 \forall t \in \mathbb{R}\}$ . Let us check that  $D^{+s} = \emptyset$ . If  $v \in D^{+s}$ , then  $\langle v, y \rangle > 0$

$\forall y \in D \setminus \{0\}$ . In particular, for each  $\alpha \in \mathbb{R}$  define  $y_\alpha : \mathbb{R} \rightarrow \mathbb{R}$  by  $y_\alpha(\beta) = 1$  if  $\beta = \alpha$  and  $y_\alpha(\beta) = 0$  if  $\beta \neq \alpha$ . It is clear that  $y_\alpha \in D \ \forall \alpha \in \mathbb{R}$ , and  $\langle v, y_\alpha \rangle = v(\alpha) > 0 \ \forall \alpha \in \mathbb{R}$ , but this is a contradiction because if  $v \in \ell^2(\mathbb{R})$ , then  $\{\alpha \in \mathbb{R} : v(\alpha) \neq 0\}$  is countable.

- (c) The convex cones  $D$  and  $D_F$  are very close: one has  $\text{cl}(D) = \text{cl}(D_F)$  and so  $D^+ = D_F^+$ . As a consequence, by Proposition 2.5,  $D$  is  $w$ -normal if and only if  $D_F$  is  $w$ -normal, and a set  $M$  is  $D$ -bounded if and only if  $M$  is  $D_F$ -bounded. Indeed, as  $X$  is nontrivial, there exists  $q \in D \setminus \{0\}$  such that

$$(0, \infty)q + D \subset D_F.$$

Therefore,  $D \subset \text{cl}(D_F)$  and so  $\text{cl}(D) = \text{cl}(D_F)$ .

- (d) It is obvious that (B4) implies (A4). However, hypothesis (A4) is weaker than (B4). Indeed, consider  $X = Y = \mathbb{R}^2$ ,  $D = \mathbb{R}_+^2$ ,  $S = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 x_2 = 0\}$ ,  $f(x) = x \ \forall x \in \mathbb{R}^2$ ,  $F(x, u) = \{\|x - u\|(1, 1)\} \ \forall x, u \in \mathbb{R}^2$ , and  $x_0 = (0, 0)$ . We have that  $(f(S) - f(x_0)) \cap (-\mathbb{R}_+^2)$  is not  $\mathbb{R}_+^2$ -bounded. However,  $D_F = \text{int}(\mathbb{R}_+^2) \cup \{0\}$  and so  $(f(S) - f(x_0)) \cap (-D_F) = \{0\}$ , which is  $\mathbb{R}_+^2$ -bounded.

Next we give some useful conditions to check if  $D_F$  is based. The proof of Lemma 3.5 is immediate and so it is omitted. Lemma 3.6(b)–(d) extends Lemma 4.20 in [3].

LEMMA 3.5. *Let  $D_F$  be the convex cone given by (3). Then*

- (a)  $D_F^{+s} = K_F^{+s} \cap D^+$ ,  
 (b)  $D_F$  is based if and only if  $K_F^{+s} \cap D^+ \neq \emptyset$ .

LEMMA 3.6. *Let  $K \subset D$  be a nonempty convex cone. The following statements all hold.*

- (a) *If there exists a  $D$ -convex set  $B_K$  such that  $\mathbb{R}_+ B_K = K$  and  $0 \notin \text{cl}(B_K + D)$ , then  $K^{+s} \cap D^+ \neq \emptyset$ .*  
 (b) *If  $D$  is closed and there exists a  $D$ -convex compact set  $B_K$  such that  $\mathbb{R}_+ B_K = K$  and  $0 \notin B_K$ , then  $K^{+s} \cap D^+ \neq \emptyset$ .*  
 (c) *If  $D$  is normal and there exists a  $D$ -convex set  $B_K$  such that  $\mathbb{R}_+ B_K = K$  and  $0 \notin \text{cl}(B_K)$ , then  $K^{+s} \cap D^+ \neq \emptyset$ .*  
 (d) *If  $D$  is solid and  $K \setminus \{0\} \subset \text{int}(D)$ , then  $D^+ \setminus \{0\} \subset K^{+s}$ .*

*Proof.* Part (a). It is clear that

$$(\mathbb{R}_+(B_K + D))^{+s} = (\mathbb{R}_+ B_K)^{+s} \cap D^+ = K^{+s} \cap D^+.$$

Then, the conclusion follows since  $\mathbb{R}_+(B_K + D)$  is based.

Part (b). The set  $B_K + D$  is closed because it is the sum of a compact set and a closed set, and  $B_K + D \subset D \setminus \{0\} + D \subset D \setminus \{0\}$ . Therefore, the result follows from part (a).

Part (c). Since  $D$  is normal and  $B_K \subset D$  we deduce that  $0 \in \text{cl}(B_K)$  whenever  $0 \in \text{cl}(B_K + D)$ . Therefore,  $0 \notin \text{cl}(B_K + D)$  and the result follows from part (a).

Part (d) is well known (see, for instance, [3, Lemma 4.20(xiii)]).  $\square$

The next lemma is useful to prove Theorem 3.8. Consider  $x \in S$ ,  $\gamma > 0$ , an sv-D-metric  $F$ , and

$$(4) \quad S_x := \{z \in S \setminus \{x\} : (f(z) + \gamma F(z, x) - f(x)) \cap (-D) \neq \emptyset\}.$$

LEMMA 3.7. *The following properties are satisfied:*

- (a)  $S_z \subset S_x \ \forall z \in S_x$ .

- (b) Let  $x_0 \in S$  and suppose that (A4) holds. Then  $\xi \circ f$  is bounded from below on  $S_x \forall x \in S_{x_0} \cup \{x_0\}$  and  $\forall \xi \in D^+$ , and for each  $x \in S$  such that  $S_x \neq \emptyset$  it follows that

$$\langle f(x), \lambda \rangle > \inf_{z \in S_x} \{\langle f(z), \lambda \rangle\} > -\infty \quad \forall \lambda \in D_F^{+s}.$$

*Proof.* Part (a). If  $z \in S_x$  and  $u \in S_z$ , there exists  $d \in F(u, z)$  such that  $f(u) \leq f(z) - \gamma d$ . As  $z \in S_x$  there exists  $q \in F(z, x)$  such that  $f(z) \leq f(x) - \gamma q$ . By adding these relations we see that

$$(5) \quad f(u) \leq f(x) - \gamma(d + q).$$

From Definition 3.1 it follows that  $d + q \in F(u, x) + D$  and by (5) we derive that  $(f(u) + \gamma F(u, x) - f(x)) \cap (-D) \neq \emptyset$ . If  $u = x$ , then  $q = 0$ , which is a contradiction since  $q \in F(z, x)$  and  $z \neq x$ . Then  $u \neq x$  and  $u \in S_x$ .

Part (b). Let  $x \in S_{x_0} \cup \{x_0\}$ . By part (a) it is clear that

$$\inf\{\langle f(z), \xi \rangle : z \in S_x\} \geq \inf\{\langle f(z), \xi \rangle : z \in S_{x_0}\} \quad \forall \xi \in D^+.$$

Moreover, from the definitions of the sets  $S_{x_0}$  and  $D_F$  we see that  $f(S_{x_0}) - f(x_0) \subset -D_F$ . Then, by (A4) we have that

$$\begin{aligned} \inf\{\langle f(z), \xi \rangle : z \in S_{x_0}\} &= \langle f(x_0), \xi \rangle + \inf\{\langle f(z) - f(x_0), \xi \rangle : z \in S_{x_0}\} \\ &= \langle f(x_0), \xi \rangle + \inf\{\langle y, \xi \rangle : y \in (f(S_{x_0}) - f(x_0)) \cap (-D_F)\} \\ &\geq \langle f(x_0), \xi \rangle + \inf\{\langle y, \xi \rangle : y \in (f(S) - f(x_0)) \cap (-D_F)\} > -\infty \quad \forall \xi \in D^+ \end{aligned}$$

and  $\xi \circ f$  is bounded from below on  $S_x \forall \xi \in D^+$ .

For the second part of (b), let  $u \in S_x$ . Then  $u \neq x$  and there exist  $q \in F(u, x)$ ,  $d \in D$  such that  $f(u) + \gamma q - f(x) = -d$ . As  $F$  is an sv- $D$ -metric we see that  $q \neq 0$  and so  $\gamma q + d \in D_F \setminus \{0\}$ . Therefore,

$$\langle f(x), \lambda \rangle > \langle f(u), \lambda \rangle \geq \inf_{z \in S_x} \{\langle f(z), \lambda \rangle\} > -\infty \quad \forall \lambda \in D_F^{+s},$$

where the last inequality is a consequence of the first part of (b) and Lemma 3.5(a).  $\square$

**THEOREM 3.8.** Consider  $\gamma > 0$ , an sv- $D$ -metric  $F$ , and a point  $x_0 \in S$  satisfying assumptions (A1)–(A4). Then, there exists  $\hat{x} \in S$  such that

- (a)  $(f(\hat{x}) + \gamma F(\hat{x}, x_0) - f(x_0)) \cap (-D) \neq \emptyset$ ,  
 (b)  $(f(\hat{x}) - f(x) - \gamma F(x, \hat{x})) \cap D = \emptyset \quad \forall x \in S \setminus \{\hat{x}\}$ .

*Proof.* By Proposition 2.6 we see that  $D_F^{+s} \neq \emptyset$  and then a functional  $\lambda \in D_F^{+s}$  can be fixed. For this functional, a sequence  $(x_n) \subset S$  is attained via an iterative process.

Suppose that  $x_1, x_2, \dots, x_n$  are defined in such a way that  $x_1 = x_0$  and for each  $i = 2, 3, \dots, n$ ,  $x_i \in S_{x_{i-1}}$ , where the sets  $S_{x_i}$  are given by (4). The point  $x_{n+1}$  is defined as follows. If  $S_{x_n} = \emptyset$ , then  $x_{n+1} := x_n$  and so  $(x_n)$  is stationary.

If  $S_{x_n} \neq \emptyset$ , then by Lemma 3.7(b) we deduce that

$$(6) \quad \langle f(x_n), \lambda \rangle > \inf_{x \in S_{x_n}} \{\langle f(x), \lambda \rangle\} > -\infty.$$

Then, in view of (6) the point  $x_{n+1} \in S_{x_n}$  can be chosen such that

$$(7) \quad \langle f(x_{n+1}), \lambda \rangle - \inf_{x \in S_{x_n}} \{\langle f(x), \lambda \rangle\} \leq (1/2) \left( \langle f(x_n), \lambda \rangle - \inf_{x \in S_{x_n}} \{\langle f(x), \lambda \rangle\} \right).$$

Let us prove that  $(x_n)$  is a Cauchy sequence. Indeed, suppose that there exists  $\delta > 0$  such that  $\forall k \in \mathbb{N}$  there exists  $n_k \in \mathbb{N}$ ,  $n_k > k$ , verifying  $d(x_{n_k}, x_k) \geq \delta$ . From Lemma 3.7(a) we see that  $S_{x_{n_k-1}} \subset S_{x_k}$ , and as  $x_{n_k} \in S_{x_{n_k-1}}$  we have that there exists  $d_{n_k} \in F(x_{n_k}, x_k)$  such that  $f(x_{n_k}) \leq f(x_k) - \gamma d_{n_k}$ . By Lemma 3.7(a), (b) we deduce that the real-valued sequence  $(\langle f(x_k), \xi \rangle)$  is lower bounded  $\forall \xi \in D^+$  because  $x_k \in S_{x_0}$ . Moreover,  $f(x_{k+1}) \in f(x_k) - D_F \forall k$  and so  $(\langle f(x_k), \xi \rangle)$  is nonincreasing. Thus,  $(\langle f(x_k), \xi \rangle)$  has a limit and it follows that

$$0 \leq \gamma \langle d_{n_k}, \xi \rangle \leq \langle f(x_k), \xi \rangle - \langle f(x_{n_k}), \xi \rangle \rightarrow 0 \quad \forall \xi \in D^+.$$

By Proposition 2.5 we deduce that  $(d_{n_k}) \xrightarrow{w} 0$ , which is a contradiction to (A2).

Therefore,  $(x_n)$  is a Cauchy sequence and so there exists a point  $\hat{x} \in S$  such that  $(x_n) \rightarrow \hat{x} \in S$ . Let us prove that  $\hat{x}$  verifies properties (a) and (b).

As  $x_m \in S_{x_n} \forall m \geq n+1$  and  $f(x_k) \leq f(x_m) \forall k > m \geq n+1$ , it follows that  $\hat{x} \in S_{x_n} \cup \{x_n\} \forall n$ , since assumption (A3) is satisfied. In particular,  $\hat{x} \in S_{x_0} \cup \{x_0\}$  and so

$$(f(\hat{x}) + \gamma F(\hat{x}, x_0) - f(x_0)) \cap (-D) \neq \emptyset.$$

Next, let us suppose, contrary to part (b), that there exists  $x \in S_{\hat{x}}$ , i.e.,  $f(x) = f(\hat{x}) - \gamma d - d'$  for some  $x \in S \setminus \{\hat{x}\}$ ,  $d \in F(x, \hat{x})$ , and  $d' \in D$ . As  $\gamma d + d' \in K_F \setminus \{0\} + D = D_F \setminus \{0\}$  and  $\lambda \in D_F^{+s}$  we deduce that

$$(8) \quad \langle f(x), \lambda \rangle < \langle f(\hat{x}), \lambda \rangle.$$

As  $x \in S_{\hat{x}}$  and  $\hat{x} \in S_{x_n} \cup \{x_n\} \forall n$  by Lemma 3.7(a) we deduce that  $x \in S_{x_n} \forall n \geq 1$ . Thus, from (7) we see that

$$2\langle f(x_{n+1}), \lambda \rangle - \langle f(x_n), \lambda \rangle \leq \inf_{z \in S_{x_n}} \{\langle f(z), \lambda \rangle\} \leq \langle f(x), \lambda \rangle \quad \forall n$$

and  $\lim \langle f(x_n), \lambda \rangle \leq \langle f(x), \lambda \rangle$ . As  $\hat{x} \in S_{x_n} \cup \{x_n\}$ , we have that  $\langle f(\hat{x}), \lambda \rangle \leq \langle f(x_n), \lambda \rangle \forall n$  and it follows that  $\langle f(\hat{x}), \lambda \rangle \leq \lim \langle f(x_n), \lambda \rangle$ . Therefore,  $\langle f(\hat{x}), \lambda \rangle \leq \langle f(x), \lambda \rangle$ , contrary to (8), and the proof is finished.  $\square$

*Remark 3.9.* Let us observe from Remark 3.4(b), (d) that Theorem 3.8 is also true if assumptions (A1) and (A4) are changed to (B1) and (B4), respectively.

*Remark 3.10.* Let us observe that Theorem 3.8(b) can be rewritten by saying that  $(\hat{x}, f(\hat{x}))$  is a minimizer of the following set-valued optimization problem (see [18, Definition 14.2] for more details):

$$\text{Min}\{f(x) + \gamma F(x, \hat{x}) : x \in S\}.$$

Moreover,  $(\hat{x}, f(\hat{x}))$  is a strong minimizer, since it is a minimizer and  $f(x) + \gamma d \neq f(\hat{x}) \forall x \in S \setminus \{\hat{x}\}$ ,  $\forall d \in F(x, \hat{x})$ . Therefore, as usual in the context of EVP, part (b) of Theorem 3.8 consists of perturbing the objective function  $f$  by a map  $g := \gamma F(\cdot, \hat{x})$  in such a way that  $f + g$  attains a strong minimum on  $S$  at  $\hat{x}$ . The advantage of Theorem 3.8(b) as opposed to similar principles in the literature is that the perturbation  $g$  is a set-valued map (see Example 5.2).

Next, motivated by the results obtained in [1] for scalar optimization problems, we present a different version of Theorem 3.8 based on  $(C, \varepsilon)$ -efficient solutions. Previously, a simple relation between  $D$ -bounded sets and  $(C, \varepsilon)$ -efficient points is established, from which one can easily deduce if a feasible point is an approximate efficient

solution of (1). In this sense, let us observe that if (1) is a scalar optimization problem ( $Y = \mathbb{R}$ ), then all feasible points are approximate solutions if and only if the problem is lower bounded, and the problem is lower bounded if and only if there exists some approximate solution. However,  $(C, \varepsilon)$ -efficient and not  $(C, \varepsilon)$ -efficient feasible points are possible in the same vector (nonscalar) optimization problem, or it is even possible to find a  $(C, \varepsilon)$ -efficient solution  $x_0$  whose section  $(f(x_0) - D) \cap f(S)$  is not bounded.

LEMMA 3.11. *Let us consider a coradial set  $C \subset D \setminus \{0\}$ .*

- (a) *Suppose that  $K \subset Y$  is a  $w$ -normal convex cone such that  $C \subset K$  and let  $x_0 \in S$ . If  $0 \notin \text{cl}^w(C)$  and  $(f(S) - f(x_0)) \cap (-K)$  is  $K$ -bounded, then there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$ .*
- (b) *Let  $K \subset Y$  be a convex cone and suppose that there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$ . Then  $(f(S) - f(x_0)) \cap (-K)$  is  $K$ -bounded if and only if  $(f(S) - f(x_0)) \cap (-\varepsilon(K \setminus C))$  is  $K$ -bounded.*

*Proof.* Part (a). Let us suppose that  $(f(S) - f(x_0)) \cap (-K)$  is  $K$ -bounded and  $x_0 \notin \text{AE}(C, \varepsilon) \forall \varepsilon > 0$ . Then, for each  $n \in \mathbb{N}$  there exists  $c_n \in C$  such that  $-nc_n \in (f(S) - f(x_0)) \cap (-K)$ . By the  $K$ -boundedness of this set we deduce for each  $\xi \in K^+$  that there exists  $m_\xi \in \mathbb{R}$  such that

$$m_\xi \leq -n \langle c_n, \xi \rangle \quad \forall n.$$

Therefore  $(\langle c_n, \xi \rangle) \rightarrow 0 \forall \xi \in K^+$ . By Proposition 2.5 it follows that  $(c_n) \xrightarrow{w} 0$  and so  $0 \in \text{cl}^w(C)$ , which is a contradiction.

Part (b). It is clear that

$$K = (K \setminus (\varepsilon C)) \cup (K \cap \varepsilon C) = (\varepsilon(K \setminus C)) \cup (K \cap \varepsilon C).$$

As  $x_0 \in \text{AE}(C, \varepsilon)$ , we have that

$$(f(S) - f(x_0)) \cap (-K) = (f(S) - f(x_0)) \cap (-\varepsilon(K \setminus C)),$$

and the result follows.  $\square$

The assumption  $0 \notin \text{cl}^w(C)$  is important in order to consider appropriate approximate efficiency concepts. Let us observe that in the other case, it is possible to obtain minimizing sequences  $(x_n)$  such that  $f(x_{n+1}) - f(x_n) \in -\varepsilon C \forall n$ ; i.e., there could be feasible sequences that tend to efficient points and whose elements are not  $(C, \varepsilon)$ -efficient solutions for a fixed precision  $\varepsilon > 0$ .

COROLLARY 3.12. *Let  $C \subset D \setminus \{0\}$  be a coradial set and suppose that  $-(D \setminus C)$  is  $D$ -bounded. If there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$ , then  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded. In particular, the assumption on the boundedness of  $-(D \setminus C)$  is satisfied if there exists  $B \subset D$  such that  $-B$  is  $D$ -bounded,  $D = \mathbb{R}_+ B$ , and  $C = [1, \infty)B$ .*

*Proof.* It is clear that  $(f(S) - f(x_0)) \cap (-\varepsilon(D \setminus C))$  is  $D$ -bounded, since

$$(f(S) - f(x_0)) \cap (-\varepsilon(D \setminus C)) \subset -\varepsilon(D \setminus C)$$

and  $-(D \setminus C)$  is  $D$ -bounded. Then, by Lemma 3.11(b) with  $K = D$  we deduce that  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded.

Next, let us suppose that  $D = \mathbb{R}_+ B$  and  $C = [1, \infty)B$ , where  $-B$  is  $D$ -bounded. It is obvious that

$$-(D \setminus C) \subset \bigcup_{0 \leq \beta < 1} (-\beta B),$$

and the result follows since  $-B$  is  $D$ -bounded.  $\square$

In some vector optimization problems, the order cone  $D$  is well-based (see Definition 2.4). In this case, if  $B$  is a base of  $D$ , by defining  $C = B + D$  we obtain that a feasible point  $x_0$  is a  $(C, \varepsilon)$ -efficient solution for some  $\varepsilon > 0$  if and only if the section  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded. This fact is established in the following corollary. Unfortunately, the well-based property is not verified for several usual order cones (see [4, section 3] for more details).

**COROLLARY 3.13.** *Suppose that  $D$  is well-based with respect to the weak topology through the base  $B$ . Consider  $C = B + D$  and  $x_0 \in S$ . Then, there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$  if and only if the section  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded.*

*Proof.* It is well known that  $D$  is  $w$ -normal when  $D$  is well-based (see, for example, [9, Proposition 2.2.15]). Moreover,  $C$  is a coradial set and  $0 \notin \text{cl}^w(C)$  since  $C = B + D$ ,  $D$  is  $w$ -normal, and  $0 \notin \text{cl}^w(B)$ . Therefore, by Lemma 3.11(a) with  $K = D$ , if  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded, then there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$ .

Reciprocally, as  $B$  is bounded with respect to the weak topology, it follows that  $-B$  is  $D$ -bounded. Moreover, from the convexity of  $B$  and the relation  $D = \mathbb{R}_+ B$  we have that  $C = [1, \infty)B$ . Thus, by Corollary 3.12 we deduce that the section  $(f(S) - f(x_0)) \cap (-D)$  is  $D$ -bounded if there exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$ .  $\square$

Let us consider the following assumptions on problem (1), an  $sv$ - $D$ -metric  $F$ , a coradial set  $C \subset D \setminus \{0\}$ , and a feasible point  $x_0 \in S$ :

(A5)  $\bigcup_{x, y \in X} F(x, y) \subset \text{cone}(C)$  and  $C + D = C$ .

(A6) There exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$  and  $(f(S) - f(x_0)) \cap (-\varepsilon(D_F \setminus C))$  is  $D$ -bounded.

(B6) There exists  $\varepsilon > 0$  such that  $x_0 \in \text{AE}(C, \varepsilon)$  and  $(f(S) - f(x_0)) \cap (-\varepsilon(D \setminus C))$  is  $D$ -bounded.

**THEOREM 3.14.** *If assumptions (A1)–(A3), (A5), and (A6) are satisfied, then there exists  $x_\varepsilon \in S$  such that*

(a)  $(f(x_\varepsilon) + \gamma F(x_\varepsilon, x_0) - f(x_0)) \cap (-D) \neq \emptyset$  (and so  $f(x_\varepsilon) \leq f(x_0)$ ),

(b)  $F(x_\varepsilon, x_0) \cap (\text{cone}(C) \setminus ((\varepsilon/\gamma)C)) \neq \emptyset$ ,

(c)  $(f(x_\varepsilon) - f(x) - \gamma F(x, x_\varepsilon)) \cap D = \emptyset \ \forall x \in S \setminus \{x_\varepsilon\}$ .

*Proof.* By Remark 3.4(c) and Lemma 3.11(b) with  $D_F$  instead of  $K$ , it follows that assumption (A4) is also satisfied. Then, by applying Theorem 3.8 one obtains  $x_\varepsilon \in S$ , satisfying parts (a) and (c).

Part (b) is trivial if  $x_\varepsilon = x_0$ . If  $x_\varepsilon \neq x_0$ , then by part (a) we deduce that there exist  $d \in F(x_\varepsilon, x_0)$  and  $d' \in D$  such that  $f(x_\varepsilon) - f(x_0) = -\gamma d - d'$ . Since  $x_0 \in \text{AE}(C, \varepsilon)$  we have that  $\gamma d + d' \notin \varepsilon C$ . If  $d \in (\varepsilon/\gamma)C$ , then  $\gamma d + d' \in \varepsilon C + D = \varepsilon C$ , a contradiction. Hence  $d \in \text{cone}(C) \setminus ((\varepsilon/\gamma)C)$ , that is, (b) holds.  $\square$

**Remark 3.15.** Let us notice that Theorem 3.14 is also true if assumptions (A1) and (A6) are changed to (B1) and (B6), respectively.

In the proof of Theorem 3.14 it was deduced that the hypotheses of Theorem 3.8 hold when the hypotheses of Theorem 3.14 are satisfied, and so the former hypotheses are weaker than the latter. However, by Lemma 3.11 with  $D_F$  instead of  $K$  and Remark 3.4(c), both collections of hypotheses are equivalent when statement (A5) is satisfied,  $0 \notin \text{cl}^w(C)$ , and  $C \subset D_F$ . This fact motivates the following definition.

**DEFINITION 3.16.** *Let  $D$  be a nontrivial pointed convex cone, let  $C \subset D \setminus \{0\}$  be a coradial set such that  $0 \notin \text{cl}^w(C)$ , and let  $F$  be an  $sv$ - $D$ -metric. We say that  $D$ ,  $C$ , and  $F$  are compatible if statement (A5) is satisfied and  $C \subset D_F$ .*

Theorem 3.14 has been proved by using Theorem 3.8. Reciprocally, it is obvious that Theorem 3.8 can be proved via Theorem 3.14 when  $D$ ,  $C$ , and  $F$  are compatible.

This fact is shown in the following proposition by saying that both theorems are equivalent.

**PROPOSITION 3.17.** *Assume that  $D$ ,  $C$ , and  $F$  are compatible. Then Theorems 3.8 and 3.14 are equivalent.*

*Remark 3.18.* In Proposition 3.17, we have extended to vector optimization problems an equivalence between two versions of the original (scalar) EVP (see [1, pp. 345–346] for more details). Indeed, let us suppose that (1) is a scalar optimization problem. In this problem,  $D = \mathbb{R}_+$  and the usual concept of approximate solution is obtained by considering  $C = [1, \infty)$ . By taking  $F(x, y) = \{d(x, y)\}$  it is clear that  $D$ ,  $C$ , and  $F$  are compatible, and so Theorems 3.8 and 3.14 are equivalent. Let us observe that (A1) and (A2) are satisfied, and if  $f$  is lower semicontinuous, then (A3) is verified too. Finally,

$$(A4) \iff (A6) \iff \inf_{x \in S} \{f(x)\} > -\infty.$$

**4. On the assumptions of the set-valued EVP.** In this section we show some conditions from which one can check if a vector optimization problem satisfies the hypotheses of Theorems 3.8 and 3.14.

The reader can deduce from Remark 3.18 that hypothesis (A3) is a kind of cone lower semicontinuity of the map  $f$ . Next, we give a condition from which one can prove that hypothesis.

**DEFINITION 4.1** (see [9, Definition 2.5.7(iv)]). *Let  $G : X \rightarrow 2^Y$  be a set-valued map.  $G$  is said to be (sequentially) compact at  $x \in X$  if for every sequence  $(x_n, y_n) \subset X \times Y$  such that  $y_n \in G(x_n) \forall n$  and  $(x_n) \rightarrow x$ , there exists a subsequence  $(y_{n_k})$  converging to some  $y \in G(x)$ .  $G$  is said to be compact if it is compact at every  $x \in X$ .*

*Remark 4.2.* Let  $g : X \rightarrow \mathbb{R}$  be a continuous functional and let  $H \subset Y$  be a sequentially compact set. It is easy to check that the set-valued map  $G : X \rightarrow 2^Y$  defined by  $G(x) = g(x)H \forall x \in X$  is compact.

**DEFINITION 4.3** (see [21, p. 674]). *A vector-valued map  $f : X \rightarrow Y$  is said to be sequentially submonotone with respect to  $D$  (submonotone) if for every  $x \in X$  and for each sequence  $(x_n)$  such that  $(x_n) \rightarrow x$  and  $f(x_n) \leq f(x_m) \forall n > m$ , it follows that  $f(x) \leq f(x_n) \forall n$ .*

Let us observe that a  $D$ -lower semicontinuous vector-valued map  $f : X \rightarrow Y$  (i.e., a vector-valued map  $f$  such that the sets  $\{x \in X : f(x) \leq y\}$  are closed  $\forall y \in Y$ ) is submonotone.

**THEOREM 4.4.** *If  $D$  is closed, the set-valued map  $F(\cdot, x)$  is compact  $\forall x \in X$ , and the map  $f$  is submonotone, then (A3) is satisfied.*

*Proof.* Let us consider  $x \in S$  and a sequence  $(z_n) \subset A_x^{\gamma F}$  such that  $(z_n) \rightarrow z$  and  $f(z_m) \leq f(z_n) \forall m > n$ . Then there exists a sequence  $(d_n)$  such that  $d_n \in F(z_n, x)$  and  $f(z_n) \in -\gamma d_n + f(x) - D \forall n$ . As  $f$  is submonotone, we deduce that

$$f(z) \leq f(z_n) \leq -\gamma d_n + f(x) \quad \forall n.$$

Since the set-valued map  $F(\cdot, x)$  is compact, we see that there exist a point  $d \in Y$  and a subsequence  $(d_{n_k})$  such that  $(d_{n_k}) \rightarrow d \in F(z, x)$ . Therefore, taking the limit when  $n_k \rightarrow \infty$ , it follows that

$$f(z) + \gamma d \in f(x) - D,$$

since  $D$  is closed. Thus  $z \in A_x^{\gamma F}$  and the proof is completed.  $\square$

Next, some simple relations between different  $D$ -boundedness concepts are introduced, which show that the notion stated in Definition 3.3 is weaker than others more usual in the literature.

DEFINITION 4.5. *Let  $M$  be a subset of  $Y$ .*

- (a) (See [20, Definition 3.1, p. 13].)  *$M$  is called topologically  $D$ -bounded if for each neighborhood  $V \subset Y$  of zero there exists  $\alpha > 0$  such that  $M \subset \alpha V + D$ . In what follows we say that  $M$  is strong (resp., weak)  $D$ -bounded if  $M$  is topologically  $D$ -bounded with respect to the strong (resp., weak) topology on  $Y$ .*
- (b) (See [9, p. 15].)  *$M$  is called lower order bounded if there exists  $y \in Y$  such that  $M \subset y + D$ .*

PROPOSITION 4.6. *Consider a set  $M \subset Y$ . Then*

- (a) *if  $M$  is lower order bounded, then  $M$  is strong  $D$ -bounded.*
- (b) *if  $M$  is strong  $D$ -bounded, then  $M$  is weak  $D$ -bounded.*
- (c) *if  $M$  is weak  $D$ -bounded, then  $M$  is  $D$ -bounded by scalarization.*
- (d) *assuming that  $M \subset -D$  and  $D$  is  $w$ -normal, if  $M$  is  $D$ -bounded by scalarization, then  $M$  is weak  $D$ -bounded.*

*Proof.* Part (a) is clear because every neighborhood of zero in  $Y$  is absorbing. Part (b) is obvious.

Part (c). Let us suppose that  $M$  is weak  $D$ -bounded. For each  $\xi \in D^+$ , the set

$$V_\xi = \{y \in Y : |\langle y, \xi \rangle| < 1\}$$

is a weak neighborhood of zero. As  $M$  is weak  $D$ -bounded, there exists  $\alpha_\xi > 0$  such that  $M \subset \alpha_\xi V_\xi + D$ . Thus,

$$\begin{aligned} \inf\{\langle y, \xi \rangle : y \in M\} &\geq \inf\{\langle \alpha_\xi z + d, \xi \rangle : z \in V_\xi, d \in D\} \\ &= \alpha_\xi \inf\{\langle z, \xi \rangle : z \in V_\xi\} \geq -\alpha_\xi, \end{aligned}$$

and so  $M$  is  $D$ -bounded by scalarization.

Part (d). To obtain a contradiction, consider  $\xi \in Y^*$  and suppose that

$$M \not\subset \{y \in Y : |\langle y, \xi \rangle| < r\} + D \quad \forall r > 0.$$

Then there exists  $(y_n) \subset M$  such that  $|\langle y_n, \xi \rangle| \geq n \quad \forall n$ . Since  $D$  is  $w$ -normal, by Proposition 2.5 we deduce that  $\xi = \xi_1 - \xi_2$  for some  $\xi_1, \xi_2 \in D^+$ . Thus,  $|\langle y_n, \xi_1 - \xi_2 \rangle| \geq n \quad \forall n$ , and we can suppose (by taking a subsequence and by changing  $\xi_1$  to  $\xi_2$  and  $\xi_2$  to  $\xi_1$  if necessary) that

$$\langle y_n, \xi_1 \rangle - \langle y_n, \xi_2 \rangle \geq n \quad \forall n.$$

Then, as  $M \subset -D$  we deduce that

$$\langle y_n, \xi_2 \rangle \leq \langle y_n, \xi_1 \rangle - n \leq -n \quad \forall n,$$

and so

$$\inf\{\langle y, \xi_2 \rangle : y \in M\} = -\infty,$$

which is a contradiction because  $M$  is  $D$ -bounded by scalarization. Therefore,  $M$  is weak  $D$ -bounded and the proof is finished.  $\square$

To finish this section, we focus on finite-dimensional vector optimization problems. In this framework, an  $sv$ - $D$ -metric is proposed from which hypotheses (A1)–(A3) are satisfied if the objective function  $f$  is submonotone.

THEOREM 4.7. Assume that  $Y$  is finite-dimensional.

- (a) If  $\text{cl}(D)$  is pointed, then  $D$  is normal,  $D^{+s} \neq \emptyset$ , and  $D_F^{+s} \neq \emptyset \forall \text{sv-}D\text{-metric } F$ .
- (b) (A1) is satisfied if and only if  $\text{cl}(D)$  is pointed.
- (c) Assume that  $D$  is closed. Then  $D$  is well-based through each set

$$B_\xi = \{d \in D : \langle d, \xi \rangle = 1\} \quad \forall \xi \in D^{+s}.$$

- (d) If there exists a bounded set  $B \subset D$  such that  $D = \mathbb{R}_+ B$  and  $0 \notin \text{cl}(\text{conv}(B))$ , then  $\text{cl}(D)$  is pointed.

*Proof.* Part (a). By [9, Corollary 2.2.11 and Example 1.1.2] we see that  $D$  is normal and  $D^{+s} \neq \emptyset$ . Then  $D_F^{+s} \neq \emptyset$  since  $D_F \subset D \forall \text{sv-}D\text{-metric } F$ .

Part (b) is a consequence of part (a) and Remark 3.4(a).

Part (c). By part (a) we see that  $D^{+s} \neq \emptyset$ . For each  $\xi \in D^{+s}$  it is obvious that  $B_\xi$  is convex,  $0 \notin \text{cl}(B_\xi)$ , and  $D = \mathbb{R}_+ B_\xi$ . Then the proof is completed if we prove that  $B_\xi$  is bounded. Suppose that  $B_\xi$  is not bounded for some  $\xi \in D^{+s}$ ; then there exists  $(b_n) \subset B_\xi$  with  $\|b_n\| \rightarrow \infty$ . Taking a subsequence if necessary, we have  $\|b_n\|^{-1} b_n \rightarrow y \in \text{cl}(D) \setminus \{0\} = D \setminus \{0\}$ . Since  $\|b_n\|^{-1} = \xi(\|b_n\|^{-1} b_n)$  we get the contradiction  $\xi(y) = 0$ .

Part (d). Set  $B_1 = \text{cl}(\text{conv}(B))$ . Then  $B_1$  is a compact convex set with  $0 \notin B_1$ , and the convex cone  $D_1 = \mathbb{R}_+ B_1$  is closed (see, for instance, [14, Proposition 1.4.7, p. 102]) and based. Thus, it is pointed (see [9, Example 1.1.2]). As  $\text{cl}(D) \subset D_1$ , it follows that  $\text{cl}(D)$  is pointed.  $\square$

Let  $\mathcal{D}$  be the family of nonempty finite sets  $\Delta \subset D^{+s}$ , let  $\varphi_\Delta : Y \rightarrow \mathbb{R}$  be the functional defined by  $\varphi_\Delta(y) = \min_{\xi \in \Delta} \{\langle y, \xi \rangle\} \forall y \in Y$ , and denote

$$B_\Delta := \{y \in D : \varphi_\Delta(y) = 1\}.$$

The following facts are clear:  $\varphi_\Delta$  is positively homogeneous and concave,  $\mathbb{R}_+ B_\Delta = D = \{y \in D : \varphi_\Delta(y) \geq 0\}$ , and

$$(9) \quad B_\Delta + D = \{y \in D : \varphi_\Delta(y) \geq 1\}.$$

Moreover,  $B_\Delta \subset \cup_{\xi \in \Delta} B_\xi$ , and by Theorem 4.7(c) it is clear that  $B_\Delta$  is compact when  $\dim Y < \infty$  and  $D$  is closed.

COROLLARY 4.8. Assume that  $Y$  is finite-dimensional. If  $D$  is closed, then the family  $\mathcal{D}$  is not empty and for each  $\Delta \in \mathcal{D}$ , the map  $F_{B_\Delta}(x, y) = d(x, y)B_\Delta$  is an sv- $D$ -metric such that hypotheses (A1)–(A2) are satisfied. If, in addition,  $f$  is submonotone, then (A3) is also satisfied.

*Proof.* By Theorem 4.7(a) we have that  $D^{+s} \neq \emptyset$ . Therefore the family  $\mathcal{D}$  is not empty. Moreover, by Example 3.2(b) the map  $F_{B_\Delta}$  is an sv- $D$ -metric  $\forall \Delta \in \mathcal{D}$ , since  $0 \notin B_\Delta$  and the sets  $B_\Delta$  are  $D$ -convex, taking into account (9) and that  $\varphi_\Delta$  is concave.

Condition (A1) is satisfied by Theorem 4.7(b). Fix  $\Delta \in \mathcal{D}$  and  $\delta > 0$ ; then

$$(10) \quad \cup \{F_{B_\Delta}(x, y) : d(x, y) \geq \delta\} \subset [\delta, \infty)B_\Delta = \{y \in D : \varphi_\Delta(y) \geq \delta\},$$

where the last equality is true because  $\varphi_\Delta$  is positively homogeneous. Since  $\varphi_\Delta$  is continuous, the last set in (10) is closed, and therefore (A2) holds.

From Remark 4.2 we see that the set-valued map  $F_{B_\Delta}(\cdot, z)$  is compact  $\forall z \in X$ . Thus, by Theorem 4.4 we deduce that hypothesis (A3) is satisfied, and the proof is finished.  $\square$

### 5. Relations between several EVPs for vector optimization problems.

We begin this section by giving a set-valued EVP for finite-dimensional vector optimization problems. In order to deal with  $(C, \varepsilon)$ -efficient solutions of this problem, we consider the following coradiant set  $C_\Delta$  introduced in [11, Remark 4.6]:

$$C_\Delta = \{d \in D : \varphi_\Delta(d) \geq 1\},$$

where  $\Delta \in \mathcal{D}$ .

**PROPOSITION 5.1.** *Consider problem (1) with the following data:  $Y = \mathbb{R}^p$ ,  $D$  closed,  $f$  submonotone,  $\gamma, \varepsilon > 0$ , and  $x_0 \in \text{AE}(C_\Delta, \varepsilon)$ . Then there exists a point  $x_\varepsilon \in S$  such that*

- (a)  $f(x_\varepsilon) \leq f(x_0)$ ,
- (b)  $d(x_\varepsilon, x_0) < \varepsilon/\gamma$ ,
- (c)  $\forall d \in D$  such that  $\varphi_\Delta(d) = 1$  it follows that

$$(11) \quad f(x_\varepsilon) \notin f(x) + \gamma d(x, x_\varepsilon)d + D \quad \forall x \in S \setminus \{x_\varepsilon\}.$$

*Proof.* From (9) we see that  $C_\Delta = B_\Delta + D$ . It is clear that  $\text{cone}(C_\Delta) = D$ , and as  $X$  is not a singleton we have that  $D = D_{F_\Delta}$ . So  $D$ ,  $C_\Delta$ , and  $F_\Delta$  are compatible. Moreover,  $B_\Delta$  is bounded since it is compact,  $D = \mathbb{R}_+ B_\Delta$ , and  $C_\Delta = [1, \infty) B_\Delta$  by (10). Then, the result follows by Corollary 4.8, Corollary 3.12, and Theorem 3.14.  $\square$

In particular, if  $D = \mathbb{R}_+^p$  (i.e., (1) is a Pareto problem),  $(\varepsilon_1, \varepsilon_2, \dots, \varepsilon_p) \in \mathbb{R}_+^p \setminus \{0\}$ ,  $\varepsilon = \sum_{i=1}^p \varepsilon_i$ ,  $\gamma = \sqrt{\varepsilon}$ ,  $\Delta = \{(1, 1, \dots, 1)\}$ , and statement (11) is evaluated at  $d = (1/\varepsilon)(\varepsilon_1, \varepsilon_2, \dots, \varepsilon_p)$ , then Proposition 5.1 collapses to the first EVP proved in the literature for a vector optimization problem ([19, Proposition 4.2]).

In the literature, the reader can find several EVPs for vector optimization problems proved via different notions of approximate efficiency (see, for instance, [2, 3, 5, 8, 9, 10, 15, 16, 17, 19, 21, 23, 25]). These EVPs are “vector-valued” because they relate approximate solutions of (1) with efficient solutions of vector optimization problems. In other words, they use vector-valued perturbation functions. Specifically, the perturbation function is as follows (see [2, Corollary 2.1], [3, Corollary 4.17, Theorem 4.32], [5, Theorem 3.3], [8, Theorem 8], [9, Proposition 3.10.3], [10, Corollary 2, Corollary 9], [15, Theorem 4], [16, Theorem 11], [17, Theorem 10], [19, Proposition 4.2], [23, Corollary 4.1], and [25, section 4]):

$$f_q(x) := f(x) + \gamma d(x, x_\varepsilon)q \quad \forall x \in X,$$

where  $q \in D \setminus \{0\}$ ,  $\gamma > 0$ , and  $x_\varepsilon$  is a feasible point. Let us observe that some EVPs (see, for instance, [2, Theorem 2.1], [3, Theorem 4.15], [9, Corollary 3.10.19], [10, Corollary 12], and [21, Theorem 6.1]) consider the following more general perturbation function:

$$f_q(x) := f(x) + \gamma r(x, x_\varepsilon) \quad \forall x \in X,$$

where  $r : X \times X \rightarrow D$  is a vector-valued  $D$ -metric,  $\gamma > 0$ , and  $x_\varepsilon$  is a feasible point. However, in practice, this vector-valued  $D$ -metric is defined by  $r(x, y) = d(x, y)q \quad \forall x, y \in X$ , where  $q \in D \setminus \{0\}$  (see, for instance, [2, Lemma 2.1], [3, Lemma 4.16], [9, p. 209], and [10, p. 919]) and so the previous perturbation function is obtained.

In our approach, the perturbation function is set-valued, and this feature is important because in (1), the objective can be improved by using any vector  $d \in D \setminus \{0\}$ .

Next, we give an example which shows that the EVP is stronger if the perturbation function is set-valued.

*Example 5.2.* Let us consider problem (1) with the following data:  $X = Y = \mathbb{R}^2$ ,  $f(x) = x \ \forall x \in \mathbb{R}^2$ ,  $D = \mathbb{R}_+^2$ ,  $S_1 = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 \geq 0, x_2 = 0\}$ ,  $S_2 = \{(x_1, x_2) \in \mathbb{R}^2 : x_1 = 0, x_2 \geq 0\}$ ,  $S = S_1 \cup S_2$ ,  $\xi = (1, 1)$ , and  $\text{AE}(B_\xi + \mathbb{R}_+^2, 1/2)$  as an approximate efficiency set.

In order to identify  $(B_\xi + \mathbb{R}_+^2, 1/2)$ -efficient solutions via the EVP and  $\gamma = 1/2$ , one can use two approaches. The first is to apply the usual vector-valued version of this principle (see, for instance, Theorem 5.4 following). Indeed, it is obvious that

$$(12) \quad \text{AE}(B_\xi + \mathbb{R}_+^2, 1/2) = \bigcap_{q \in B_\xi} \text{AE}(q + \mathbb{R}_+^2, 1/2).$$

Then, from statements (a)–(c) of Theorem 5.4, the following necessary conditions are derived:

$$(13) \quad \{(0, x_2) : 1/2 < x_2\} \cap \text{AE}((0, 1) + \mathbb{R}_+^2, 1/2) = \emptyset,$$

$$(14) \quad \{(x_1, 0) : 1/2 < x_1\} \cap \text{AE}((1, 0) + \mathbb{R}_+^2, 1/2) = \emptyset,$$

and no information is obtained regarding any vector  $q \in \text{int}(\mathbb{R}_+^2)$  because in this case statements (a)–(c) are fulfilled  $\forall x \in S$ . In summary, from (12)–(14) (and so, by considering an sv- $D$ -metric!) it follows that

$$(15) \quad \{(x_1, x_2) \in S : x_1 + x_2 > 1/2\} \cap \text{AE}(B_\xi + \mathbb{R}_+^2, 1/2) = \emptyset.$$

The reader can observe that if the EVP is applied by considering a single vector  $q \in \mathbb{R}_+^2$ , then the information on the set  $\text{AE}(B_\xi + \mathbb{R}_+^2, 1/2)$  is incomplete (or even trivial, if  $q \in \text{int}(\mathbb{R}_+^2)$ ).

Of course, one can deduce (15) directly by means of Theorem 3.14 and the sv- $D$ -metric

$$F(x, z) := \|x - z\|_{B_\xi} \quad \forall x, z \in \mathbb{R}^2.$$

Another consequence of considering a vector-valued perturbation functional is that various EVPs in the literature, based on different  $\varepsilon$ -efficiency concepts, are particular cases of Theorem 5.4. This result is well known and has been proved under different hypotheses on the objective function and the order cone (see Remark 5.5). Here, by using an approach introduced in [23], we show that the result works for any pointed convex order cone  $D$ .

The following lemma can be proved in a way similar to [9, Theorem 2.3.1].

LEMMA 5.3. *Consider  $q \in D \setminus \{0\}$ , the functional  $\varphi_q : Y \rightarrow \mathbb{R} \cup \{\pm\infty\}$  defined by*

$$(16) \quad \varphi_q(y) := \begin{cases} \inf\{t \in \mathbb{R} : y \in tq - D\} & \text{if } y \in \mathbb{R}q - D, \\ \infty & \text{if } y \notin \mathbb{R}q - D, \end{cases}$$

and the set  $\text{dom}(\varphi_q) = \{y \in Y : |\varphi_q(y)| < \infty\}$ . Then

(a) *for each  $y \in Y$ ,  $y \in \text{dom}(\varphi_q)$  if and only if  $y + \mathbb{R}q \subset \text{dom}(\varphi_q)$  and*

$$(17) \quad \varphi_q(y + \alpha q) = \varphi_q(y) + \alpha \quad \forall y \in Y, \quad \forall \alpha \in \mathbb{R};$$

(b)  *$\{y \in Y : \varphi_q(y) < 0\} = (-\infty, 0)q - D$ ;*

(c)  $\varphi_q$  is  $D$ -monotone, i.e.,

$$\forall y_1, y_2 \in Y, \quad y_1 \in y_2 - D \Rightarrow \varphi_q(y_1) \leq \varphi_q(y_2).$$

Let us consider the following assumption on problem (1),  $q \in D \setminus \{0\}$ , and a feasible point  $x_0 \in S$ :

(B3) The sets  $\{x \in X : f(x) \leq f(x_0) + rq\}$  are closed  $\forall r \in \mathbb{R}$ .

THEOREM 5.4. *Let  $q \in D \setminus \{0\}$ ,  $\gamma > 0$ ,  $\varepsilon > 0$ ,  $C_q := q + D \setminus \{0\}$ , and  $x_0 \in \text{AE}(C_q, \varepsilon)$ . Assume that (B3) is satisfied. Then there exists  $x_\varepsilon \in S$  such that*

- (a)  $f(x_\varepsilon) \leq f(x_0)$  and  $f(x_\varepsilon) \neq f(x_0)$  if  $x_\varepsilon \neq x_0$ ,
- (b)  $d(x_\varepsilon, x_0) \leq \gamma$ ,
- (c)  $f(x) + (\varepsilon/\gamma)d(x, x_\varepsilon)q \notin f(x_\varepsilon) - D \setminus \{0\} \quad \forall x \in S \setminus \{x_\varepsilon\}$ .

*Proof.* Let us define a functional  $g_{q,\varepsilon} : S \subset X \rightarrow \mathbb{R} \cup \{\pm\infty\}$  as follows:

$$g_{q,\varepsilon}(x) := \varphi_q(f(x) - f(x_0) + \varepsilon q) \quad \forall x \in S.$$

From Definition 2.2 is clear that  $(f(S) - f(x_0)) \cap (-\varepsilon C_q) = \emptyset$  and so

$$(f(S) - f(x_0) + \varepsilon q) \cap (-D \setminus \{0\}) = \emptyset,$$

since  $\varepsilon C_q = \varepsilon q + D \setminus \{0\}$ . Then, from Lemma 5.3(b) we see that

$$(18) \quad g_{q,\varepsilon}(x) = \varphi_q(f(x) - f(x_0) + \varepsilon q) \geq 0 \quad \forall x \in S.$$

Moreover, it is easy to check that  $\varphi_q(0) = 0$ . Thus, by (17) it follows that

$$g_{q,\varepsilon}(x_0) = \varphi_q(0 + \varepsilon q) = \varphi_q(0) + \varepsilon = \varepsilon,$$

and from (18) we have that

$$g_{q,\varepsilon}(x_0) - \varepsilon \leq g_{q,\varepsilon}(x) \quad \forall x \in S.$$

Therefore, the functional  $g_{q,\varepsilon}$  is lower bounded and proper. Moreover, by reasoning similar to the proof of [5, Lemma 3.1] we deduce that  $g_{q,\varepsilon}$  is lower semicontinuous. Then, by applying the scalar EVP (see, for example, [6, Theorem 1.1 and statement (1.18)]) we deduce that there exists a point  $x_\varepsilon \in S$  such that

- (i)  $g_{q,\varepsilon}(x_\varepsilon) \leq g_{q,\varepsilon}(x_0) - (\varepsilon/\gamma)d(x_\varepsilon, x_0)$ ,
- (ii)  $d(x_\varepsilon, x_0) \leq \gamma$ ,
- (iii)  $g_{q,\varepsilon}(x_\varepsilon) < g_{q,\varepsilon}(x) + (\varepsilon/\gamma)d(x, x_\varepsilon) \quad \forall x \in S \setminus \{x_\varepsilon\}$ ,

and so part (b) is verified. Part (a) is obvious if  $x_\varepsilon = x_0$ . From (i) and (17) we have that

$$\varphi_q(f(x_\varepsilon) - f(x_0)) + (\varepsilon/\gamma)d(x_\varepsilon, x_0) \leq 0,$$

and if  $x_\varepsilon \neq x_0$ , it follows that

$$\varphi_q(f(x_\varepsilon) - f(x_0)) < 0.$$

Then, by Lemma 5.3(b) we see that  $f(x_\varepsilon) \in f(x_0) - D \setminus \{0\}$  and so part (a) is completed.

In order to prove part (c), let us suppose that there exists  $x \in S \setminus \{x_\varepsilon\}$  such that  $f(x) + (\varepsilon/\gamma)d(x, x_\varepsilon)q \in f(x_\varepsilon) - D \setminus \{0\}$ . Then

$$f(x) - f(x_0) + \varepsilon q + (\varepsilon/\gamma)d(x, x_\varepsilon)q \in f(x_\varepsilon) - f(x_0) + \varepsilon q - D \setminus \{0\},$$

and by the  $D$ -monotonicity of  $\varphi_q$  and property (17) we obtain that

$$\begin{aligned} g_{q,\varepsilon}(x) + (\varepsilon/\gamma)d(x, x_\varepsilon) &= \varphi_q(f(x) - f(x_0) + \varepsilon q + (\varepsilon/\gamma)d(x, x_\varepsilon)q) \\ &\leq \varphi_q(f(x_\varepsilon) - f(x_0) + \varepsilon q) = g_{q,\varepsilon}(x_\varepsilon), \end{aligned}$$

which is contrary to (iii), and part (c) is verified.  $\square$

Property (B3) is called the lower semicontinuity of  $f$  at  $x_0$  along  $q$  (or in the direction  $q$ ) and has been used by some authors in obtaining EVPs for vector-valued maps (see, for example, [9, Corollary 3.10.14], [10, Corollary 9], [23, Corollary 4.1]).

*Remark 5.5.*

- (a) In the literature, Theorem 5.4 has been proved by assuming additional hypotheses such as  $D$  solid (see [3, Theorem 4.32], [9, Proposition 3.10.3], [23, Corollary 4.1]),  $D$  normal (see [15, Theorem 4]),  $D$  closed (see [9, Proposition 3.10.3], [10, Corollary 9], [17, Theorem 10]), or  $f(S)$  lower order bounded (see [3, Theorem 4.32], [8, Theorem 8], [10, Corollary 2], [16, Theorem 11], [17, Theorem 10], [19, Proposition 4.2], [23, Corollary 4.1]).
- (b) The conclusions of Theorem 5.4 could be obtained from Theorem 3.14 via the sv- $D$ -metric  $F(x, y) = d(x, y)q$ , but by considering stronger hypotheses. In particular, let us observe that Theorem 5.4 does not include any boundedness condition. However, Theorem 5.4 is weaker than Theorem 3.14 because it deals with a specific  $\varepsilon$ -efficiency notion and the perturbed map is vector valued.

As was pointed out, one drawback of considering EVPs with vector-valued perturbation functionals for vector optimization problems is that the conclusions are equal whatever the  $(C, \varepsilon)$ -efficiency notion considered in the hypotheses. For example, parts (7)–(9) of [2, Corollary 2.1], parts (vi)–(viii) of [3, Corollary 4.17], parts (a), (c), and (d) of [5, Theorem 3.3], and, by considering the vector-valued metric  $r(u, v) = d(u, v)q$ , part (viii) of [2, Theorem 2.1], part (viii) of [3, Theorem 4.13], and parts (ii) and (iii) of [21, Theorem 6.1] are consequences of our Theorem 5.4. This fact is shown in the following proposition and has been suggested in [10, p. 919]. Previously, two concepts of approximate efficiency due to Németh [21] and Dentcheva and Helbig [5] are recalled.

DEFINITION 5.6.

- (a) (See Németh [21].) Let  $H \subset D \setminus \{0\}$  and  $\varepsilon > 0$ . A point  $x_0 \in S$  is said to be an  $\varepsilon$ -efficient solution of (1) in the sense of Németh (with respect to  $H$ ) if  $(f(x_0) - \varepsilon H - D) \cap f(S) = \emptyset$ .
- (b) (See Dentcheva and Helbig [5].) Let  $q \in D \setminus \{0\}$ ,  $\varepsilon > 0$ , and consider a strictly  $D$ -monotone functional  $h : Y \rightarrow \mathbb{R}$ , i.e., such that  $h(y_1) < h(y_2) \forall y_1, y_2 \in Y, y_1 \in y_2 - D \setminus \{0\}$ . A point  $x_0 \in S$  is said to be an  $\varepsilon$ -efficient solution of (1) in the sense of Dentcheva and Helbig (with respect to  $h$  and  $q$ ) if  $h(f(x_0)) \leq h(f(x) + \varepsilon q) \forall x \in S$  such that  $f(x) \in f(x_0) - D \setminus \{0\}$ .

PROPOSITION 5.7. Consider  $q \in D \setminus \{0\}$ ,  $\gamma > 0$ ,  $\varepsilon > 0$ ,  $x_0 \in S$  and assume that (B3) is satisfied. Suppose that  $x_0$  is an  $\varepsilon$ -efficient solution of (1) in the sense of Dentcheva and Helbig with respect to  $h$  and  $q$  or in the sense of Németh with respect to  $H$ , where  $q \in H$ . Then, parts (a)–(c) of Theorem 5.4 are verified.

*Proof.* First, let us suppose that  $x_0$  is an  $\varepsilon$ -efficient solution in the sense of Németh with respect to  $H$  and  $q \in H$ . Then it is clear that  $x_0 \in \text{AE}(C_q, \varepsilon)$ , and so parts (a)–(c) of Theorem 5.4 hold since the hypotheses of this theorem are satisfied.

If  $x_0$  is an  $\varepsilon$ -efficient solution in the sense of Dentcheva and Helbig with respect to  $h$  and  $q$  and we see that  $x_0 \in \text{AE}(C_q, \varepsilon)$ , then the result follows from Theorem 5.4. Let us suppose that  $x_0 \notin \text{AE}(C_q, \varepsilon)$ . Then there exists  $x \in S$  and  $d \in D \setminus \{0\}$  such that  $f(x) = f(x_0) - \varepsilon q - d$ , and as  $h$  is strictly  $D$ -monotone, it follows that

$$h(f(x_0)) = h(f(x) + \varepsilon q + d) > h(f(x) + \varepsilon q),$$

which is a contradiction since  $f(x) \in f(x_0) - D \setminus \{0\}$  and  $x_0$  is an  $\varepsilon$ -efficient solution in the sense of Dentcheva and Helbig with respect to  $h$  and  $q$ .  $\square$

*Remark 5.8.* Let us observe from Proposition 5.7 that if hypothesis (B3) holds for all  $x_0 \in S$ , then parts (a)–(c) of Theorem 5.4 are verified for each  $(C, \varepsilon)$ -efficient solution if  $\text{AE}(C, \varepsilon) \subset \text{AE}(C_q, \varepsilon)$ . For example, let us consider the  $(C_h, \varepsilon)$ -efficiency notion given by the set

$$C_h = \{d \in D : h(d) > 1\},$$

where  $h \in D^+$  and  $h(q) = 1$  (see [11, Example 3.4] for more details). If  $h \in D^{+s}$ , then it is easy to check that  $\text{AE}(C_h, \varepsilon) \subset \text{AE}(C_q, \varepsilon)$ , and so we deduce that parts (a)–(c) of Theorem 5.4 are true if (B3) is verified and  $x_0 \in \text{AE}(C_h, \varepsilon)$ .

In Theorems 5.11 and 5.15 two set-valued EVPs for  $\varepsilon$ -efficient solutions in the senses of Németh and Dentcheva and Helbig are obtained, which improve the vector-valued versions proved in [21, Theorem 6.1] and [5, Theorem 3.3]. To this end, Theorem 3.14 is applied.

In what follows, a nonempty  $D$ -convex set  $H \subset D \setminus \{0\}$  and the sv- $D$ -metric  $F_H(x, y) := d(x, y)H \forall x, y \in X$  are considered. Let us denote  $C_H := H + D$ .

LEMMA 5.9. *The following statements are satisfied:*

- (a)  $K_{F_H} = (\bigcup_{\alpha > 0} \alpha \text{conv}(H)) \cup \{0\}$ .
- (b)  $D_{F_H} = \text{cone}(C_H)$ .
- (c)  $x_0 \in \text{AE}(C_H, \varepsilon)$  if and only if  $x_0$  is an  $\varepsilon$ -efficient solution of (1) in the sense of Németh with respect to  $H$ .
- (d) If  $0 \notin \text{cl}^w(H)$ , then  $F_H$  satisfies (A2).
- (e)  $F_H$  and  $C_H$  verify (A5).

*Proof.* Part (a). As  $X$  is nontrivial, it follows that

$$(\bigcup_{\alpha > 0} \alpha \text{conv}(H)) \cup \{0\} \subset \text{cone}(\text{conv}(\bigcup_{x \neq y} d(x, y)H)).$$

The reciprocal inclusion is obvious since  $\bigcup_{\alpha \geq 0} \alpha \text{conv}(H)$  is a convex cone, and so part (a) is completed.

Part (b). As  $H$  is  $D$ -convex, we have that

$$H + D \subset \text{conv}(H) + D \subset \text{conv}(H + D) + D = H + D.$$

Therefore,

$$\begin{aligned} D_{F_H} &= ((\bigcup_{\alpha > 0} \alpha \text{conv}(H)) + D) \cup \{0\} \\ &= \bigcup_{\alpha \geq 0} \alpha (\text{conv}(H) + D) = \bigcup_{\alpha \geq 0} \alpha (H + D) = \text{cone}(C_H). \end{aligned}$$

Part (c) is immediate since  $\varepsilon C_H = \varepsilon H + D$ .

Part (d). Fix  $\delta > 0$ . Then  $\bigcup \{d(x, y)H : d(x, y) \geq \delta\} \subset [\delta, \infty)H$ . If  $0 \in \text{cl}^w([\delta, \infty)H)$ , then,  $\alpha_i z_i \xrightarrow{w} 0$  for some nets  $(\alpha_i) \subset [\delta, \infty)$  and  $(z_i) \subset H$ . We can assume that  $\alpha_i \rightarrow \alpha \in [\delta, \infty]$ . It follows that  $z_i = \alpha_i^{-1}(\alpha_i z_i) \xrightarrow{w} 0$ , which is a contradiction because  $0 \notin \text{cl}^w(H)$ .

Part (e) is trivial, and so the proof is finished.  $\square$

*Remark 5.10.* If  $D$  is based, then from Lemma 5.9(b) we deduce that there exists a convex set  $B$  such that  $F(x, y) := d(x, y)B$  is an sv- $D$ -metric and  $D_{F_B} = D$ .

THEOREM 5.11. *Suppose that  $D$  is  $w$ -normal,  $\text{cone}(C_H)$  is based,  $0 \notin \text{cl}^w(H)$ , and assumption (A3) is verified by considering the sv- $D$ -metric  $F_H$ . Let  $x_0$  be an  $\varepsilon$ -efficient solution of (1) in the sense of Németh with respect to  $H$  and assume that the set  $(f(S) - f(x_0)) \cap (-\varepsilon(\text{cone}(C_H) \setminus C_H))$  is  $D$ -bounded. Then there exists  $x_\varepsilon \in S$*

such that

- (a)  $(f(x_\varepsilon) + \gamma d(x_\varepsilon, x_0)H - f(x_0)) \cap (-D) \neq \emptyset$ ,
- (b)  $d(x_\varepsilon, x_0)H \cap (\varepsilon/\gamma)(\text{cone}(C_H) \setminus C_H) \neq \emptyset$ ,
- (c)  $(f(x_\varepsilon) - f(x) - \gamma d(x, x_\varepsilon)H) \cap D = \emptyset \ \forall x \in S \setminus \{x_\varepsilon\}$ .

*Proof.* By Lemma 5.9(b) we see that  $D_{F_H} = \text{cone}(C_H)$ , and from the hypotheses we have that assumptions (A1) and (A3) hold. Moreover, by parts (c), (d), and (e) of Lemma 5.9 we deduce that assumptions (A6), (A2), and (A5) are verified, respectively. Then, the result follows from Theorem 3.14.  $\square$

Let us observe that the assumptions of Theorem 5.11 describe properties about the cone  $D_F \subset D$  and the boundedness and cone lower semicontinuity of problem (1). In the next theorem we show a particular case in which these properties are verified.

**THEOREM 5.12.** *Let us consider that  $D$  is well-based and has a compact base  $B$  such that  $0 \notin \text{aff}(B)$ . Suppose that the objective map  $f$  is submonotone with respect to  $D$ . Consider that  $x_0$  is an  $\varepsilon$ -efficient solution of (1) in the sense of Németh with respect to  $B$ . Then there exists  $x_\varepsilon \in S$  such that*

- (a)  $(f(x_\varepsilon) + \gamma d(x_\varepsilon, x_0)B - f(x_0)) \cap (-D) \neq \emptyset$ ,
- (b)  $d(x_\varepsilon, x_0) < \varepsilon/\gamma$ ,
- (c)  $(f(x_\varepsilon) - f(x) - \gamma d(x, x_\varepsilon)B) \cap D = \emptyset \ \forall x \in S \setminus \{x_\varepsilon\}$ .

*Proof.* Let us define  $H := B$ . Then  $\text{cone}(C_H) = D$ , and so  $\text{cone}(C_H)$  is based and  $0 \notin B = \text{cl}^w(H)$ . Moreover,  $D$  is  $w$ -normal (see [9, Proposition 2.2.15]) and closed, since  $D$  has a compact base. Therefore, by Remark 4.2 and Theorem 4.4 it follows that assumption (A3) is satisfied by considering the  $sv$ - $D$ -metric  $F_H$ .

By Corollary 3.13, Lemma 3.11, and Remark 5.10, we deduce that the set

$$(f(S) - f(x_0)) \cap (-\varepsilon(\text{cone}(C_H) \setminus C_H))$$

is  $D$ -bounded. Then parts (a)–(c) of Theorem 5.11 hold and the result is obtained if we prove that  $d(x_\varepsilon, x_0) < \varepsilon/\gamma$ . Indeed, from the convexity of  $B$  it is clear that  $C_H = B + D = [1, \infty)B$ ,  $D = [0, \infty)B$ , and so  $\text{cone}(C_H) \setminus C_H = [0, 1)B$ . Thus,

$$d(x_\varepsilon, x_0)H \cap (\varepsilon/\gamma)(\text{cone}(C_H) \setminus C_H) \neq \emptyset \iff d(x_\varepsilon, x_0)B \cap [0, \varepsilon/\gamma)B \neq \emptyset$$

and this last statement is satisfied if and only if  $d(x_\varepsilon, x_0) < \varepsilon/\gamma$ , since the condition  $0 \notin \text{aff}(B)$  implies that the representation of a vector of  $D$  as an element of the set  $\mathbb{R}_+ B$  is unique (see [9, Theorem 2.1.15]).  $\square$

To prove a set-valued EVP for approximate solutions of (1) in the sense of Dentcheva and Helbig, the following lemma is necessary. In what follows, we consider a vector  $q \in D \setminus \{0\}$  and a continuous positively homogeneous  $D$ -monotone functional  $h : Y \rightarrow \mathbb{R}$  such that

$$(19) \quad h(y_1 - y_2) \leq 0 \Rightarrow h(y_1) \leq h(y_2) \quad \forall y_1, y_2 \in Y.$$

For instance, any functional  $\xi \in D^+ \setminus \{0\}$  satisfies these properties. In general, if  $\xi_i \in D^+ \setminus \{0\} \ \forall i = 1, 2, \dots, m$ , then the functional

$$g(y) = \max_{1 \leq i \leq m} \{\langle y, \xi_i \rangle\}$$

verifies those properties too. Property (19) is satisfied for any subadditive functional.

Let us define  $C_{q,h} := \{d \in D : h(-q + d) > 0\}$ ,  $[h = 0] := \{d \in D : h(d) = 0\}$  and  $D_h := (D \setminus [h = 0]) \cup \{0\}$ .

**LEMMA 5.13.** *Let  $\varepsilon > 0$ . The following statements are true:*

- (a)  $C_{q,h}$  is a coradiant set and if  $[h = 0] \neq D$ , then  $C_{q,h}$  is nonempty.
- (b)  $\varepsilon C_{q,h} = \{d \in D : h(-\varepsilon q + d) > 0\}$ .
- (c) If  $x_0 \in \text{AE}(C_{q,h}, \varepsilon)$  and  $h$  is strictly  $D$ -monotone, then  $x_0$  is an  $\varepsilon$ -efficient solution of (1) in the sense of Dentcheva and Helbig.
- (d)  $\text{cone}(C_{q,h}) = D_h$  and  $D_h$  is convex.

*Proof.* Parts (a) and (b) follow easily since  $h$  is  $D$ -monotone and positively homogeneous.

Part (c). Let us suppose that  $x_0 \in \text{AE}(C_{q,h}, \varepsilon)$  and consider a point  $x \in S$  such that  $f(x) \leq f(x_0)$ . Then  $f(x_0) - f(x) \notin \varepsilon C_{q,h}$  and by property (19) we have that  $h(f(x_0)) \leq h(f(x) + \varepsilon q)$ ; i.e.,  $x_0$  is an  $\varepsilon$ -efficient solution of (1) in the sense of Dentcheva and Helbig.

Part (d). Let  $d \in \text{cone}(C_{q,h})$ ,  $d \neq 0$ . Then there exists  $\alpha > 0$  such that  $h(-\alpha q + d) > 0$ , and as  $h$  is  $D$ -monotone we have that  $h(d) > 0$ . Therefore,  $\text{cone}(C_{q,h}) \subset (D \setminus [h = 0]) \cup \{0\}$ .

Reciprocally, if  $d \in D \setminus [h = 0]$ , then  $h(d) > 0$  and so, by the continuity of  $h$ ,  $h(d - \alpha q) > 0$  for some  $\alpha > 0$ . Hence  $d \in \text{cone}(C_{q,h})$ . Moreover, it is easy to check that  $C_{q,h} + D \subset C_{q,h}$ , and then  $\alpha_1 d_1 + \alpha_2 d_2 = \alpha_1(d_1 + \alpha_1^{-1} \alpha_2 d_2) \in \text{cone}(C_{q,h})$ , since  $d_1 + \alpha_1^{-1} \alpha_2 d_2 \in C_{q,h}$  for  $d_1, d_2 \in C_{q,h}$ , and  $\alpha_1, \alpha_2 > 0$ . Therefore,  $D_h$  is convex and the proof is finished.  $\square$

*Remark 5.14.* The reader can deduce from the previous proof that  $h \in D^{+s}$  and  $h(q) = 1$  imply that  $x_0 \in \text{AE}(C_{q,h}, \varepsilon)$  if and only

$$h(f(x_0)) \leq h(f(x)) + \varepsilon \quad \forall x \in S, f(x) \leq f(x_0).$$

This notion is due to Helbig (see [13]) and was introduced by considering (not necessarily linear)  $D$ -monotone functionals.

The following result is a direct consequence of Theorem 3.14 and so its proof is omitted.

**THEOREM 5.15.** *Suppose that  $D$  is  $w$ -normal and  $D_h$  is nontrivial and based through a set  $B$ . Define  $F_B(x, y) = d(x, y)B$  and suppose that assumption (A3) is verified by the  $sv$ - $D$ -metric  $F_B$ . Consider that  $x_0 \in \text{AE}(C_{q,h}, \varepsilon)$  and assume that the set  $(f(S) - f(x_0)) \cap (-\varepsilon(D_h \setminus C_{q,h}))$  is  $D$ -bounded. Then there exists  $x_\varepsilon \in S$  such that*

- (a)  $(f(x_\varepsilon) + \gamma d(x_\varepsilon, x_0)B - f(x_0)) \cap (-D) \neq \emptyset$ ,
- (b)  $d(x_\varepsilon, x_0)B \cap (\varepsilon/\gamma)(D_h \setminus C_{q,h}) \neq \emptyset$ ,
- (c)  $(f(x_\varepsilon) - f(x) - \gamma d(x, x_\varepsilon)B) \cap D = \emptyset \quad \forall x \in S \setminus \{x_\varepsilon\}$ .

**COROLLARY 5.16.** *Consider that  $D$  is  $w$ -normal and based. For  $\xi_0 \in D^{+s}$  define  $B = \{d \in D : \langle d, \xi_0 \rangle = 1\}$  and  $F_B(x, y) = d(x, y)B$ . Suppose that assumption (A3) is verified by considering the  $sv$ - $D$ -metric  $F_B$ . Let  $q \in B$  and  $x_0 \in \text{AE}(C_{q,g}, \varepsilon)$ , where  $g = \max\{\xi_0, \xi_1, \xi_2, \dots, \xi_m\}$  and  $\xi_i \in D^+ \quad \forall i = 1, 2, \dots, m$ ,  $m \geq 0$ , and assume that the set  $(f(S) - f(x_0)) \cap (-\varepsilon(D \setminus C_{q,g}))$  is  $D$ -bounded. Then there exists  $x_\varepsilon \in S$  such that*

- (a)  $(f(x_\varepsilon) + \gamma d(x_\varepsilon, x_0)B - f(x_0)) \cap (-D) \neq \emptyset$ ;
- (b)  $d(x_\varepsilon, x_0) \leq \varepsilon/\gamma$ , and if  $m > 0$ , then there exists  $b \in B$  such that

$$d(x_\varepsilon, x_0)\langle b, \xi_i \rangle \leq (\varepsilon/\gamma)\langle q, \xi_i \rangle \quad \forall i = 1, 2, \dots, m;$$

- (c)  $(f(x_\varepsilon) - f(x) - \gamma d(x, x_\varepsilon)B) \cap D = \emptyset \quad \forall x \in S \setminus \{x_\varepsilon\}$ .

*Proof.* It is easy to check that  $[g = 0] = \{0\}$ . Then, by applying Theorem 5.15 to  $h = g$  we deduce that there exists  $x_\varepsilon \in S$ , verifying parts (a) and (c) of this corollary and the relation

$$d(x_\varepsilon, x_0)B \cap (\varepsilon/\gamma)(D \setminus C_{q,g}) \neq \emptyset.$$

Therefore, there is  $b \in B$  such that  $d(x_\varepsilon, x_0)b \notin (\varepsilon/\gamma)C_{q,g}$ , i.e.,

$$g(-(\varepsilon/\gamma)q + d(x_\varepsilon, x_0)b) \leq 0.$$

Thus,

$$\begin{aligned} \langle -(\varepsilon/\gamma)q + d(x_\varepsilon, x_0)b, \xi_0 \rangle &\leq 0, \\ \langle -(\varepsilon/\gamma)q + d(x_\varepsilon, x_0)b, \xi_i \rangle &\leq 0 \quad \forall i = 1, 2, \dots, m, \end{aligned}$$

and the result follows since  $b, q \in B$ .  $\square$

**6. Conclusions.** In this work, an original approach is introduced to extending the well-known Ekeland's variational principle to vector optimization problems. This new approach is based on considering a concept of a set-valued  $D$ -metric, a notion of cone-boundedness, and a set-valued perturbed map. The notions of an sv- $D$ -metric (which is new to our knowledge) and a cone-bounded set by scalarizations are fundamental tools in developing this approach.

In section 5 we have given several results and examples in order to show that this new approach is stronger than the usual vector-valued EVP proved in the literature. In particular let us point out that in the context of vector optimization, where the preferences of the decision-maker are given by a cone, the perturbed map can use various directions, and in this sense the principle is stronger when a set of directions is considered.

The EVP obtained in Theorem 3.8 does not depend on any  $\varepsilon$ -efficient concept. However, the EVP proved in Theorem 3.14 could be applied to several  $\varepsilon$ -efficient notions, since it has been obtained for  $(C, \varepsilon)$ -efficient solutions. In section 5 these results have been applied to different contexts such as the finite-dimensional case or the consideration of various  $\varepsilon$ -efficiency concepts.

## JUMP DIFFUSION OVER FEATURE SPACE FOR OBJECT RECOGNITION\*

SÉBASTIEN GADAT†

**Abstract.** We present a dynamical model for a population of tests in pattern recognition. Taking a preprocessed initialization of a feature set, we apply a stochastic algorithm based on an efficiency criterion and a Gaussian noise to recursively build and improve the feature space. This algorithm simulates a Markov chain which estimates a probability distribution  $\mathbb{P}$  on the set of features. The features are structured as binary trees and we show that such random forests are a good way to represent the evolution of the feature set. We then obtain properties on the dynamic of the features space before applying this algorithm to practical examples such as face detection and microarray analysis. Lastly, we identify the weak limit of our process as a jump-diffusion process defined using the Skorokhod map over simplices.

**Key words.** Markov processes, jump-diffusion algorithms, stochastic approximation, Skorokhod map, feature selection, pattern recognition

**DOI.** 10.1137/060656759

**1. Introduction.** In this paper, we study a learning algorithm designed for the construction of features in pattern recognition tasks. This algorithm is constructed as the stochastic approximation of a constrained jump-diffusion process, for which we provide an asymptotic analysis.

The algorithm originates from the following issue. A pattern recognition problem corresponds to the classification of *input data* into two or more classes. To solve this, an algorithm, called a *classifier*, is used to design a function which associates a class prediction to an observation of the input variables. There exists several types of competing approaches for building classifiers. Our goal is not to build a new one, but to optimize and improve the prediction by feeding the algorithm with the “best” input variables. Poorly informative variables indeed act like noise in a dataset and reduce the quality of learning algorithms, and fewer variables generally is a guarantee for robustness and reduced generalization ability. Also, a good understanding of the features which have more impact in the classification is critical in some subjects such as biology or text categorization: In microarray analysis, for example, it is important to identify the genes which express a pathology, and in spam detection, one can expect that the presence of some special chain of words enables better detection of nondesirable spam for some classical algorithms such as support vector machines (SVMs), classification trees (CART), or random forests, for instance.

Denote by  $\mathcal{F}_0$  the initial set of variables; in the machine learning community, these are also called *features* and this is the word we will use in this paper. In several recent interesting applications,  $\mathcal{F}_0$  is a large set, which contains hundreds, maybe thousands, of elements. Given that what we want to consider are not only a few useful elements of  $\mathcal{F}_0$ , but also useful combinations of them, we face an overwhelming space of possible explanatory variables that we need to explore in the selection process. Our goal will

†Institut Mathématiques de Toulouse, Université Paul Sabatier, 118 Route de Narbonne, 31062 Toulouse, France (sebastien.gadat@math.ups-tlse.fr).

be to provide a suboptimal stochastic approach to recursively explore and build new composed features space.

For simplicity, the only combinations we consider in this paper are products of variables. If we denote  $\mathcal{P}(\mathcal{F}_0)$  parts of  $\mathcal{F}_0$ , we estimate, from a training set of samples, a subset  $\mathcal{F}$  of  $\mathcal{P}(\mathcal{F}_0)$  of “useful” variables, those which are the most important for the classification task. This set will be estimated as a jump process which will be denoted  $(\mathcal{F}_t)_{t \geq 0}$ .<sup>1</sup>

This jump process will in fact be driven by an auxiliary process, denoted  $\mathbb{P}_t$ , such that, at all times  $t$ ,  $\mathbb{P}_t$  is a probability measure supported by  $\mathcal{F}_t$ . We will define the pair  $(\mathbb{P}_t, \mathcal{F}_t)$  as a jump-diffusion process, designed to maximize the efficiency of the variables belonging to  $\mathcal{F}_t$ . The practical implementation will be a stochastic approximation of this process. The primary goal of this paper is to provide a convergence study of both algorithms, the diffusion, and its approximation.

Since there are important motivations and applications from feature extraction, finding a universal alphabet of features has intrigued researchers in computer vision, and the construction of feature sets has become an active research domain. Direct methods, based on principal (or discriminant) components analysis (PCA) or independent components analysis (ICA) [24], can be used for reduction of dimension, but are not able to create new variables by composition and do not help us to easily understand the selection. Methods based on hierarchically structured variables have also been developed: Amit and Geman [2] and Fleuret and Geman [16] build recursive sets of binary decision trees using coarse to fine procedures. These recursive algorithms combine statistical and geometric properties to assemble discriminative sequential testing and reach very low rates of error in many image classification problems. But in most cases for these algorithms, the amount of features constructed is not limited and can regularly increase if the learning procedure is not stopped [25] and conclusions about optimization results are not inferred. Our approach to the feature space structure will be largely inspired from this sequential testing method, based on statistical correlation [16], entropy [20], or mutual information [15].

Finally, methods based on the optimization of margin of support vector machines have been recently proposed to make recursive feature elimination (RFE [31], [10]). These methods use exact expressions of margin separation of SVM and optimize weights on features to keep only those with high influence on the margin formula. This yielded interesting results on several classification tasks, such as pedestrian detection and cancer morphology classification, with a quantity of features. However, all these methods perform only backward selections from an initial fixed set of features, while adding new features obtained from composition of initial ones could improve efficiency of classification.

Building a set of features derived from an initial set, which contains a reduced number of variables, and complex combinations of variables, is at this point a largely open issue. Our objective will be to handle this problem using simultaneously upward and backward stochastic strategies. Such evolutionary algorithms are commonly used in the framework of regression, adding and removing variables with respect to any information criterion (AIC (Akaike information criterion), MSE (mean square error), etc.). We show here how one can think about similar ideas for the framework of pattern classification without using logistic regression, which may be considered somewhat artificial. Moreover, contrary to most variable selection procedures for linear analysis, we provide a theoretical background for our stochastic exploration of

---

<sup>1</sup>The construction will in fact be slightly more complex, involving trees instead of subsets.

features subsets dedicated to an optimization criterion. Lastly, our method can be used with any classification algorithm. This is an important point since for the commonly investigated classification problems, there does not exist a best classifier among all methods developed by statisticians.

Our paper will be organized as follows. In the next section, we give a precise description of our framework and introduce notation. The third section is devoted to the theoretical model of our jump-diffusion Markov process. Then, section 4 gives exact rules to enable features space to evolve over time. These rules use a Metropolis–Hastings evolution based on an energy  $\mathcal{E}$  to be minimized over time. Section 5 gives dynamic properties of the model previously defined, whereas section 6 provides a statistical implementation and approximation method to simulate the jump-diffusion process of section 3. Finally, we conclude our work with experiments on synthetic data and real classification problems (face detection and leukemia classification) before giving future developments and applications to other situations in pattern recognition. Lastly, note that we choose to formalize our work in a continuous setting (Markov processes) rather than in a discrete form (Markov chains). One motivation will be to provide an understanding of the limit behavior of our exploration/extraction algorithm. Continuous setup will make it easier to precisely describe the dynamic of our constrained optimization method (section 5.1), while the formalism of the martingale problem and generator for Markov processes will be very powerful in identifying the asymptotic measure of our algorithm (Theorems 6.3 and 7.2). In fact, one can also describe our algorithm in a discrete setting (it is, moreover, the way it is numerically implemented) but the identification of the asymptotic behavior requires a time continuous approach with the use of the Skorokhod map. We thus choose to directly present the algorithm in the continuous framework to avoid some additional notation and repetitions.

## 2. Notation and settings.

**2.1. Classes and features.** We address the following pattern recognition problem. Given a large integer  $d$  which will denote the initial number of features, an input signal  $I \in \mathbb{R}^d$  must be classified into a fixed number of classes denoted  $\mathcal{C} = \{C_1, \dots, C_N\}$ . Each input  $I$  is described by its coordinates  $(X^1(I), \dots, X^d(I))$ .  $\mathcal{F}_0$  is the set of initial coordinates maps:

$$\mathcal{F}_0 = \{X^1, \dots, X^d\}.$$

In our experiments, the  $X^j$  will be the projection to the  $j$ th component, it can be binary (values in  $\{0, 1\}$ ) or ternary (values in  $\{-1, 0, 1\}$ ) for the image processing problem of section 8, or more generally, real-valued coordinates can also be considered (see the microarray analysis experiments of section 8).

A classification algorithm is a function which assigns a class  $C_i$  of the finite set  $\mathcal{C}$  to an observed signal  $I$ . This function is estimated on the basis of a training set, which is a finite family of correctly labeled signals. However, for obvious dimensional complexity, the algorithm assumes a specific parametric form for the classification function: it could be, for instance, CART, SVMs, linear discriminant analysis, nearest neighbor, etc. In the two-class problem, the simplest classification rule is based on linear separation: Compute the sum  $\beta_0 + \sum_{j=1}^d \beta_j X^j$ , and decide for the first class if it is negative and for the second otherwise. The parameters  $(\beta_0, \beta_j, j \in \{1 \dots p\})$  are estimated so that this rule is as consistent as possible with the training data. Various definitions of the consistency criterion, variants on the functional form of the decision

rule and of the optimization algorithms, yield a very large family of classifiers, as provided by the literature. We will use in our applications an SVM with a linear kernel because of the generalization ability of this algorithm. Note that the previous linear separation rule assumes that *all* the features are used *as monomials*. Our goal in this context is twofold:

- Selection: Use less than the total family of features, which can be very large ( $d > 1000$ , for instance).
- Composition: Use more complex expressions than monomials by combining the features, and thus define one way to combine them.

This last point implies heuristic or stochastic exploration of the several compositions we can produce starting from  $\mathcal{F}_0$ : simplest ones are  $X^j X^k, (j, k) \in \{1 \dots d\}$ , and  $X^j X^k X^l, (j, k) \in \{1 \dots d\}$ . One can see the exponential growth of the size of possible composition space, and our algorithm proposes a stochastic approach of this exploration step.

*Example 2.1.* Consider the following synthetic example that will be used first in the experiments section. We deal with 3 classes of signals described by 100 ternary features. We thus have  $\mathcal{F}_0 = \{X^1, \dots, X^{100}\}$ . One can imagine that these 3 classes behave differently on several subset of features  $\mathcal{G}_1, \mathcal{G}_2$ , and  $\mathcal{G}_3$  (which may overlap or not) and follow exactly the same distribution on variables in  $\mathcal{F}_0 \setminus \mathcal{G}_1 \cup \mathcal{G}_2 \cup \mathcal{G}_3$ . This is the case for most signal processing situations, where some variables act as independent noise whatever the class of the signal is, although different statistic distributions are located on some other special set of variables for each corresponding class ( $\mathcal{G}_1$  for  $C_1$ ,  $\mathcal{G}_2$  for  $C_2$ , and  $\mathcal{G}_3$  for  $C_3$ ).

We are interested in the problem of detecting interactions of features encoded in all  $\mathcal{G}_i$ , filtering out noisy features in  $\mathcal{F}_0 \setminus \mathcal{G}_1 \cup \mathcal{G}_2 \cup \mathcal{G}_3$ , and forming new compositional variables corresponding to each subset  $\mathcal{G}_i$ . We will provide more details on practical examples in section 8.

**2.2. Composition of features.** We introduce notation regarding the composition of features. Individual features from the original set will be denoted  $\mathcal{F}_0$ , while the set of features obtained at time  $t$  will be naturally named  $\mathcal{F}_t$ . In the definition of the jump diffusion, there will be many advantages in ensuring that the jumps are *reversible*. To obtain such a property, it will be necessary (see section 4.2) for each element of  $\mathcal{F}_t$  to remember how it has been constructed. For this reason, we introduce trees on the set of features as follows.

To an elementary feature  $X^j$  in  $\mathcal{F}_0$  we associate the elementary tree (and keep the same notation “ $X^j$ ”):

$$(1) \quad X^j := \begin{array}{c} X^j \\ \wedge \\ \emptyset \quad \emptyset \end{array} .$$

A tree feature  $\mathcal{A}$  is a binary tree such that each node contains a composition of elementary features, and terminal nodes (leaves) are elementary features of  $\mathcal{F}_0$ . Moreover, each nonterminal node in  $\mathcal{A}$  must be the concatenation (union) of its descendants so that one can easily infer how any tree has been formed. The root of  $\mathcal{A}$ , denoted  $r(\mathcal{A})$ , is the main node associated to the tree. Tree features  $\mathcal{A}, \mathcal{B}$  are aggregated with the construction rule “ $::$ ”

$$(2) \quad \mathcal{A} :: \mathcal{B} = \begin{array}{c} r(\mathcal{A}) \cup r(\mathcal{B}) \\ \wedge \\ \mathcal{A} \quad \mathcal{B} \end{array} .$$

Note that we do not take into account any order or repetition of elementary features taken in  $r(\mathcal{A}) \cup r(\mathcal{B})$ .

*Example 2.2.* For instance, in the operation

$$\begin{array}{c} X^1 X^2 \\ \swarrow \quad \searrow \\ X^1 \quad X^2 \\ \underbrace{\hspace{1.5cm}}_{Al} \end{array} \quad :: \quad \begin{array}{c} X^1 X^3 \\ \swarrow \quad \searrow \\ X^1 \quad X^3 \\ \underbrace{\hspace{1.5cm}}_{Ar} \end{array} = \begin{array}{c} X^1 X^2 X^3 \\ \swarrow \quad \searrow \\ \begin{array}{c} X^1 X^2 \\ \swarrow \quad \searrow \\ X^1 \quad X^2 \end{array} \quad \begin{array}{c} X^1 X^3 \\ \swarrow \quad \searrow \\ X^1 \quad X^3 \end{array} \\ \underbrace{\hspace{3cm}}_{Bl} \end{array} := A,$$

we can reform left and right sons ( $Ar$  and  $Al$ ) from  $A$  by cutting  $A$ 's main node. It is manifest here that without this tree structure of features, the same composition will be

$$\underbrace{X^1 X^2}_{Bl} :: \underbrace{X^1 X^3}_{Bl} = X^1 X^2 X^3 := B$$

but we cannot directly obtain from  $B$  the way it has been formed since some sons could be  $\{(X^1 X^2); (X^1 X^3)\}$  or  $\{(X^2 X^3); (X^2 X^1)\}$ .

To restrict the number of notations, we will keep again the notation  $\mathcal{F}_0$  for the set of elementary trees over the initial set of variables created by operation (1). Similarly,  $\mathcal{F}_t$  will be the set of features handled at time  $t$  by our algorithm. We will denote by  $\mathbf{F}^\sharp$  the set of all trees over  $\mathcal{F}_0$  defined by (1) using (2). Technically,  $\mathcal{F}_t$  will be a jump process on  $\mathbf{F}^\sharp$  (we will call them forests), and  $\mathbb{P}_t$  will be a jump diffusion process with values in the set of probability distributions on  $\mathbf{F}^\sharp$ , which will be supported by a subset of the process  $\mathcal{F}_t$ .

We use the map  $\mathcal{A} \rightarrow r(\mathcal{A})$  only for the computation of trees over input signals since each value of any tree  $\mathcal{A}$  will naturally be defined on any signal  $I$  by

$$r(\mathcal{A})(I) = X^{i_1}(I) \times \cdots \times X^{i_p}(I)$$

if  $r$  is written as  $r(\mathcal{A}) = X^{i_1} \dots X^{i_p}$ .

**2.3. Base classification algorithm  $\mathbb{A}$ .** In this paper, we consider a classification algorithm, denoted  $\mathbb{A}$ , as a “black box” with the following functionalities. We assume that  $\mathbb{A}$  can be conditioned by any subset  $\omega \subset \mathbf{F}^\sharp$  of *active variables*. In training mode,  $\mathbb{A}$  uses a database to build an optimal classifier  $\mathbb{A}_\omega : \mathcal{I} \rightarrow \mathcal{C}$ , such that  $\mathbb{A}_\omega(I)$  depends only on variables  $\omega(I)$ . The test mode simply consists in the instantiation of  $\mathbb{A}_\omega$  on a given signal of the test set.

We work with a randomized version of  $\mathbb{A}$ , in which the randomization is on the set of variables. This randomization of features spaces has been introduced by Amit and Geman [1] and Breiman [8] who build accurate random classifiers with very low dependence to outliers and noise. In the training phase, this works as follows: First, extract a collection  $\{\omega^{(1)}, \dots, \omega^{(N)}\}$  of subsets of  $\mathbf{F}^\sharp$ , and build the classifiers  $\mathbb{A}_{\omega^{(1)}}, \dots, \mathbb{A}_{\omega^{(N)}}$ . Then, derive the classification in the test phase using a majority rule within these  $N$  classifiers. This final algorithm will be denoted  $\bar{\mathbb{A}} = \bar{\mathbb{A}}(\omega^{(1)}, \dots, \omega^{(N)})$ . In test mode, it is run with fixed  $\omega^{(i)}$ 's, which have been obtained in the learning phase.

In addition to being an auxiliary process that we use for variable selection, the probability  $\mathbb{P}_t$  will also be used for sampling the  $\omega^{(k)}$  in the construction of randomized algorithms. Note that the present paper focuses on the way to construct an automatic process creating the random subsets of  $\mathbf{F}^\sharp$  and not designing the classification algorithm  $\mathbb{A}$ , for which we use standard procedures.

We will construct a process  $(\mathcal{F}_t, \mathbb{P}_t)$ , where  $\mathcal{F}_t$  is a jump process over forests (subsets of  $\mathbf{F}^\sharp$ ) and between jumps, and  $\mathbb{P}_t$  is a diffusion process, constrained to the set of probabilities on  $\mathcal{F}_t$ , designed to optimize the performance of the classification algorithm. We start by describing the diffusion process. We will then consider the transition probabilities at jump times, both for  $\mathcal{F}_t$  and  $\mathbb{P}_t$ .

### 3. Constrained diffusion.

*Important notation.* From now on, we will denote with capital letters the Markov process  $(\mathcal{F}_t)$  among the forests;  $(\mathbb{P}_t)$  will denote the Markov process among the probabilities although  $F$  (and  $F_1, F_2, \dots$ ) or  $P$  ( $P_1, P_2, \dots$ ) will be some possible realizations of these two processes. This distinction will be important to the understanding of settings of the next sections.

*Description of the dynamic.* Between jumping times, the probability will essentially evolve according to the diffusion

$$(3) \quad d\mathbb{P}_t = -\nabla \mathcal{E}_{err}(\mathbb{P}_t)dt + \sigma dW_t,$$

where  $\mathcal{E}_{err}(P)$  is a cost function measuring the quality of the classifier using variables sampled from  $P$ ; this will be precisely defined in the following paragraph. Such a process classically stabilizes around probabilities  $P$  with low cost  $\mathcal{E}_{err}$ .

This process must, however, be modified in order to ensure that  $\mathbb{P}_t$  is a probability supported by  $\mathcal{F}_t$ . If  $\mathcal{F}$  is a subset of  $\mathbf{F}^\sharp$ , we denote by  $\mathcal{H}_{\mathcal{F}}$  the hyperplane in  $\mathbb{R}^{\mathcal{F}}$  of equation  $\sum_{\delta \in \mathcal{F}} P(\delta) = 1$ . Let  $\pi_{\mathcal{F}}$  be the affine orthogonal projection onto  $\mathcal{H}_{\mathcal{F}}$  (which is  $\pi_{\mathcal{F}}(U) = U - \sum_{\delta \in \mathcal{F}} U(\delta)/|\mathcal{F}|$ ). We denote  $\nabla^{\mathcal{F}} \mathcal{E}_{err}(P) = \pi_{\mathcal{F}} \nabla \mathcal{E}_{err}(P)$ . We can restrict (3) to  $\mathcal{H}_{\mathcal{F}}$  by replacing  $\nabla$  by  $\nabla^{\mathcal{F}}$  and using a Brownian motion on  $\mathcal{H}_{\mathcal{F}}$ , or equivalently, using

$$(4) \quad d\mathbb{P}_t = -\nabla \mathcal{E}_{err}(\mathbb{P}_t)dt + \Sigma^{\mathcal{F}} dW_t,$$

where  $W$  is a Brownian motion on  $\mathbb{R}^{\mathbf{F}^\sharp}$  and  $\Sigma^{\mathcal{F}} = \sigma \pi_{\mathcal{F}}$ .

Denoting  $\mathcal{S}_{\mathcal{F}}$  for the set of all such probability distributions on  $\mathcal{F}$ , we need to modify (4) to ensure that  $\mathbb{P}_t$  belongs to  $\mathcal{S}_{\mathcal{F}_t}$  at all times. This is done using a constrained diffusion process, which is here a reflected diffusion process:

$$d\mathbb{P}_t = -\nabla \mathcal{E}_{err}(\mathbb{P}_t)dt + \Sigma^{\mathcal{F}_t} dW_t + dZ_t,$$

where  $Z_t$  acts as a correction to ensure that the positivity constraints are satisfied at all times. This means that  $d|Z_t|$  is positive only when  $\mathbb{P}_t$  hits  $\partial \mathcal{S}_{\mathcal{F}}$ .

**3.1. Cost function.** We now define two costs functions for our system forest  $F$  +probability  $P$ . The first function  $\mathcal{E}_{err}(P)$  measures the average performance of the classifier based on random feature selection according to  $P$ . The second measures a structural cost of the set of features  $F$  and does not depend on  $P$ . These two functions enable us to form the global cost for the pairwise process  $(\mathcal{F}_t, \mathbb{P}_t)$ .

**3.1.1. Measuring the mean performance of  $\mathbb{A}$ : The energy  $\mathcal{E}_{err}$ .** Consider a set of trees  $F \subset \mathbf{F}^\sharp$  and a probability distribution  $P$  on  $\mathbf{F}^\sharp$  supported by  $F$ . The algorithm  $\mathbb{A}$  provides a different classifier  $\mathbb{A}_\omega$  for each choice of a subset  $\omega$  of  $k$  features  $\omega = (\omega_1, \dots, \omega_k) \subset F$ . We let  $\eta$  be the classification error,  $\eta(\omega) = \mathbf{P}(\mathbb{A}_\omega(I) \neq \mathcal{C}(I))$ , which will be estimated by

$$g(\omega) = \hat{\mathbf{P}}(\mathbb{A}_\omega(I) \neq \mathcal{C}(I)),$$

where  $\hat{\mathbf{P}}$  is the empirical probability on the training set. As we want to use a small number of features, we fix an integer  $k$ ; the distribution  $P^{\otimes k}$  corresponds to  $k$  independent trials with replacement with respect to the distribution  $P$ . We define the cost function  $\mathcal{E}_{err}$  by

$$\mathcal{E}_{err}(P) = \mathbb{E}_{P^{\otimes k}} g(\omega) = \sum_{\omega \in F^k} g(\omega) P^{\otimes k}(\omega) = \sum_{\omega \in F^k} g(\omega) P(\omega_1) \dots P(\omega_k).$$

One can thus remark that minimizing  $\mathcal{E}_{err}$  according to the control parameter  $P$  will drive us to a distribution with important weights on useful features for the classification (low error rate induced by  $\mathbb{A}$ ).

**3.1.2. Global cost function on  $(F, P)$ : The energy  $\mathcal{E}$ .** We now describe the global cost function, denoted by  $\mathcal{E}$ . It will take the form

$$\mathcal{E}(F, P) = \mathcal{E}_{err}(P) + \mathcal{E}_{struct}(F),$$

where  $\mathcal{E}_{struct}$  is a structural energy on the forest. More precisely,

$$(5) \quad \mathcal{E}_{struct}(F) = \underbrace{\sum_{\mathcal{A} \in F} |\mathcal{A}|}_{\mathcal{E}_s^1(F)} - \underbrace{\sum_{\mathcal{A} \in F} \hat{I}(\mathcal{A}.g, \mathcal{A}.d)}_{\mathcal{E}_s^2(F)}$$

and  $\hat{I}(\mathcal{A}.g, \mathcal{A}.d)$  is the empirical mutual information function between the left and right subtrees of  $\mathcal{A}$ . The first term  $\mathcal{E}_s^1$  limits the size of the forest and comes from the minimum description length principle of information theory [28]. The last term  $\mathcal{E}_s^2$  is of a compositional nature and favors the concatenation of correlated trees (or trees with high mutual information) [16]. Our goal is now to minimize  $\mathcal{E}$  over the space  $\mathbf{F}^\# \times \mathbf{S}_{\mathbf{F}^\#}$ , which has a discrete component and a continuous one.

**4. Jumps.** We first introduce the notion of *weak reversibility* of a jump process since this property will have critical importance in the stochastic dynamic search  $(\mathcal{F}_t, \mathbb{P}_t)$ .

**4.1. General rule.** The time differences between jumps are assumed to be mutually independent, and independent from the rest of the process. Jumps occur as a Poisson process (interjump times are independent and identically distributed (i.i.d.) exponential). Coupled with the constrained diffusion process, this allows the inference algorithm to visit  $\mathbf{F}^\# \times \mathbf{S}_{\mathbf{F}^\#}$ . This accomodates the discrete nature of the problem. At jump times, the transitions  $\mathcal{F}_t \rightarrow \mathcal{F}_{t+dt}$  will correspond to deletion, addition, or combination of elements of  $\mathcal{F}_t$ . Each of these rules will be designed using an accept/reject scheme (Hastings) as follows. We handle here the complete cost function,  $\mathcal{E}(\mathcal{F}_t, \mathbb{P}_t)$  defined by (5). Below, we review some general notions on the Metropolis–Hastings method (this section may be skipped).

**4.1.1. Generality on the Metropolis–Hastings algorithm.** The situation is as follows: Let  $\Omega$  be a measurable set with a measure  $m$  and let  $\mu$  be a measure on  $\Omega$  with density (also denoted  $\mu$ ) w.r.t.  $m$ . The Metropolis–Hastings transitions follow a two-step rule:

- From state  $x \in \Omega$ , first propose a state  $y$  with probability  $Q_0(x, dy)$ ;
- then, accept the transition with a probability which is adjusted so that  $\mu$  is invariant.

We assume the following property: For all  $x \in \Omega$ , there exists a measure  $\rho_x$  such that

- (A1)  $Q_0(x, \cdot)$  has a density  $q(x, \cdot)$  w.r.t.  $\rho_x$ .
- (A2)  $q(x, y) > 0 \Leftrightarrow q(y, x) > 0$ .
- (A3) the measure  $\rho_x(dy) \otimes m(dx)$  is symmetrical: For any function  $f$  on  $\Omega^2$ ,

$$\int_{\Omega} f(x, y) \rho_x(dy) m(dx) = \int_{\Omega} f(y, x) \rho_x(dy) m(dx).$$

The transition  $Q$  is then defined by

$$(6) \quad \begin{aligned} Q(x, dy) = & \min \left( \frac{\mu(y)q(y, x)}{\mu(x)q(x, y)}, 1 \right) Q_0(x, dy) \\ & + \left( 1 - \int_{\Omega} \min \left( \frac{\mu(z)q(z, x)}{\mu(x)q(x, z)}, 1 \right) Q_0(x, dz) \right) \mathbb{1}_x(dy). \end{aligned}$$

The distribution of two consecutive states is then  $Q(x, dy) \otimes m(dx)$ , and to ensure the reversibility we need to verify that it is symmetrical. But

$$\begin{aligned} Q(x, dy) \otimes m(dx) = & \min(\mu(y)q(y, x), \mu(x)q(x, y)) \rho_x(dy) \otimes m(dx) \\ & + \left( 1 - \int_{\Omega} \min(\mu(z)q(z, x), \mu(x)q(x, z)) \rho_x(dz) \right) \mathbb{1}_x(dy) \otimes m(dx). \end{aligned}$$

The second line takes the form  $g(x) \mathbb{1}_x(dy) m(dx)$  and is obviously symmetric, although the first one is symmetric thanks to our assumption on  $\rho_x$ . Consequently, we need to give a transitions rule satisfying the previous assumptions (A1), (A2), and (A3) for our framework on weighted forests.

*Remark 4.1* (necessity of weak reversibility). It is important here to underline why the building process of  $(\mathcal{F}_t)$  must be weakly reversible (assumptions (A1), (A2), and (A3)). We can present at least two reasons for this imperative condition:

- First, note that our exploration process of  $\mathbf{F}^\sharp$  has a stochastic nature and may be mistaken for some iteration because of the Metropolis–Hastings acceptance strategy. We thus need to cancel the decision taken at this step (assumption (A2)), and weak reversibility guarantees this possibility in only one reverse jump.
- Furthermore, the Metropolis–Hastings acceptance rate computation (6) involves the ratio  $q(x, y)/q(y, x)$  because of assumptions (A1), (A3) applied to  $q(x, \cdot)$  and  $q(y, \cdot)$ . Obviously, if the features are not structured as a tree, one cannot compute this ratio since we do not have from any set of variables  $x$  the unique pair of its antecedents.

**4.1.2. Metropolis–Hastings transitions on weighted forests.** We denote by  $m_F$  the Lebesgue measure on  $\mathcal{S}_F$  and consider  $m$  as the global measure on  $\mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}$  defined by

$$m = \sum_{F \subset \mathbf{F}^\sharp} \mathbb{1}_F \otimes m_F,$$

which means that

$$\int f(F, P) dm(F, P) = \sum_{F \subset \mathbf{F}^\sharp} \int_{\mathcal{S}_F} f(F, P) dm_F(P).$$

Here,  $\mathbb{1}_F$  is the Dirac measure at a forest  $F$ . Consider any forest  $F_1$  and an element  $P_1$  of  $\mathcal{S}_{F_1}$ . The transitions are defined as follows: Choose a new forest  $F_2 \in V_{F_1}$ , where  $V_{F_1}$  is the set of forests which are reachable in one jump, and then choose an element of  $\mathcal{S}_{F_2}$  according to a probability which depends on  $F_1$ ,  $F_2$ , and  $P_1$ . Assume that this probability has a positive density w.r.t. some measure denoted  $\psi_{F_1, F_2}(P_1, \cdot)$  on  $\mathcal{S}_{F_2}$ . This implies that the measures, w.r.t. which the densities of the transitions are computed, are

$$\rho_{F_1, P_1}(F_2, \cdot) = \mathbb{1}_{V_{F_1}}(F_2) \psi_{F_1, F_2}(P_1, \cdot),$$

where  $\rho_{F_1, P_1} = \rho_x$  is the measure defined in the former paragraph. Therefore, we need to construct  $\rho$ ,  $\psi$ , and a neighborhood  $V$  in order to satisfy assumptions (A1)–(A3). We design in the next section transitions satisfying (A1) and (A2). Next, we will show that the symmetry requirement is true. Since in the framework of a weighted forest we have

$$m_{F_1}(dP_1) \rho_{F_1, F_2}(P_1, dP_2) = \mathbb{1}_{V_{F_1}}(F_2) \psi_{F_1, F_2}(P_1, \cdot) m_{F_1}(dP_1),$$

it will be sufficient to establish

$$m_{F_1}(dP_1) \psi_{F_1, F_2}(P_1, dP_2) = m_{F_2}(dP_2) \psi_{F_2, F_1}(P_2, dP_1).$$

**4.2. Transitions between forests.** We first construct a set  $\mathcal{T}$  of compositional rules before showing the *weak reversibility* (assumptions (A1), (A2), and (A3)) of our system. This set of transitions does not seem standard and is different from what is done in genetic algorithms. However, to satisfy the *weak reversibility* needed by the Metropolis sampling scheme, this set of transitions  $\mathcal{T}$  will be necessary.

**DEFINITION 4.2** (transition rules  $\mathcal{T}$ ).  *$\mathcal{T}$  is the set of applications from  $\mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}$  to  $\mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}$  formed by buddings, cuttings, suppressions, or rebirths. By  $(F, P) \in \mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}$  we enumerate the states which are reachable in one jump from  $(F, P)$ . For convenience of notation,  $U$  will denote the set of active variables in  $F$  with their associated weights in  $P$ . The quantities  $p_b, p_c, p_s$ , and  $p_r$  will represent the nonnegative probability at each jump time of choosing budding, cutting, suppression, or rebirth. We first enumerate the **budding transitions**:*

Transition	Symbol	Antecedents	Changes in $U$	Probability
Budding without suppression	$\mathcal{B}$	$(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)$	Add $(\mathcal{A}_1 :: \mathcal{A}_2, p)$ Change the weights: $(\mathcal{A}_1, p_1 - p + x)$ $(\mathcal{A}_2, p_2 - x)$ where $p \sim \mathcal{U}_{[0; p_1 + p_2]}$ $x \sim \mathcal{U}_{[p - p_1; p_2]}$	$p_b/4$
Budding with left suppression	$\mathcal{B}_l$	$(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)$	Add $(\mathcal{A}_1 :: \mathcal{A}_2, p_1)$ Leave $(\mathcal{A}_2, p_2)$ Remove $(\mathcal{A}_1, p_1)$	$p_b/4$
Budding with right suppression	$\mathcal{B}_r$	$(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)$	Add $(\mathcal{A}_1 :: \mathcal{A}_2, p_2)$ Leave $(\mathcal{A}_1, p_1)$ Remove $(\mathcal{A}_2, p_2)$	$p_b/4$
Budding with both suppressions	$\mathcal{B}_{lr}$	$(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)$	Add $(\mathcal{A}_1 :: \mathcal{A}_2, p_1 + p_2)$ Remove $(\mathcal{A}_1, p_1)$ Remove $(\mathcal{A}_2, p_2)$	$p_b/4$

We present next the **cut transitions**:

Transition	Notation	Antecedents	Changes in $U$	Probability
Cut without creation	$\mathcal{C}$	$(\mathcal{A}_1 :: \mathcal{A}_2, p)$ $(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)$	Remove $(\mathcal{A}_1 :: \mathcal{A}_2, p)$ Change the weights: $(\mathcal{A}_1, p_1 + p - x)$ $(\mathcal{A}_2, p_2 + x)$ where $x \sim \mathcal{U}_{[-p_2; p_1 + p]}$	$p_c/4$
Cut with left creation	$\mathcal{C}_l$	$(\mathcal{A}_1 :: \mathcal{A}_2, p)$ $(\mathcal{A}_2, p_2)$	Remove $(\mathcal{A}_1 :: \mathcal{A}_2, p)$ Add $(\mathcal{A}_1, p)$ Leave $(\mathcal{A}_2, p_2)$	$p_c/4$
Cut with right creation	$\mathcal{C}_r$	$(\mathcal{A}_1 :: \mathcal{A}_2, p)$ $(\mathcal{A}_1, p_1)$	Remove $(\mathcal{A}_1 :: \mathcal{A}_2, p)$ Add $(\mathcal{A}_2, p)$ Leave $(\mathcal{A}_1, p_1)$	$p_c/4$
Cut with both creation	$\mathcal{C}_{lr}$	$(\mathcal{A}_1 :: \mathcal{A}_2, p)$	Remove $(\mathcal{A}_1 :: \mathcal{A}_2, p)$ Add $(\mathcal{A}_1, x)$ Add $(\mathcal{A}_2, p - x)$ where $x \sim \mathcal{U}_{[0; p]}$	$p_c/4$

Lastly, we have the **suppression and rebirth transitions**:

Transition	Notation	Antecedents	Changes in $U$	Probability
Suppression	$\mathcal{S}$	$(\mathcal{A}, p)$	Remove $(\mathcal{A}, p)$ Change the weights $\forall (\mathcal{B}, q) \in U \Rightarrow (\mathcal{B}, q/(1-p))$	$p_s$
Rebirth	$\mathcal{S}$	$\mathcal{A} \in \mathcal{F}_0 \setminus F$	Add $(\mathcal{A}, x)$ Change the weights $\forall (\mathcal{B}, q) \Rightarrow (\mathcal{B}, q(1-x))$	$p_r$

With these former transition rules, it is now possible to establish the *weak reversibility conditions*.

PROPOSITION 4.3 (weak reversibility of  $\mathcal{T}$ ). *Assumptions (A1), (A2), and (A3) are true under the dynamic of  $(\mathcal{F}_t, \mathbb{P}_t)$  induced by  $\mathcal{T}$ .*

*Proof.* Take a forest  $F$  in  $\mathcal{P}(\mathcal{F}^\#)$  and define  $V_F$  as the set of reachable forests using one (and only one) transition of  $\mathcal{T}$ . We first remark that if we enumerate all transitions between two forests, we have for any couples of forests  $(F_1, F_2)$ :

$$F_2 \in V_{F_1} \iff F_1 \in V_{F_2}.$$

Roughly speaking, if one tree is created, cut, or deleted using  $\mathcal{T}$ , it is instantaneously possible to flashback and cancel this transition using another rule in  $\mathcal{T}$ . This point is also true if we study weights over forests. For instance, the inverse of budding without suppression is a cut without creation, and if

$$\{(\mathcal{A}_1, p_1); (\mathcal{A}_2, p_2)\} \mapsto \{(\mathcal{A}_1, q_1 = p_1 - p + x); (\mathcal{A}_2, q_2 = p_2 - x); (\mathcal{A}_1 :: \mathcal{A}_2, q_3 = p)\},$$

one can see easily that  $q_1$  takes all values in  $[0; p_1 + p_2]$  and  $q_2$  in  $[0; p_1 + p_2]$  with, in addition,  $q_1 + q_2 + q_3 = p_1 + p_2$ . Consequently, cut without creation from such  $\{(\mathcal{A}_1, q_1); (\mathcal{A}_2, q_2); (\mathcal{A}_1 :: \mathcal{A}_2, q_3)\}$  can reach the initial state. We can verify that this

point is true for all transitions given in the three former arrays while enumerating all possible transitions.

If we then denote by  $\rho_{F,P}$  the uniform measure among reachable sets from  $(F, P)$  using  $\mathcal{T}$ , and by  $q((F, P), \cdot)$  the density of proposition law  $Q_0$  defined in section 4.1.1, we naturally obtain that (A1) and (A2) are true.

We now study assumption (A3). Denote first  $(F_1, P_1)$  as a weighted forest and  $(F_2, P_2)$  as reachable from  $(F_1, P_1)$  using  $\mathcal{T}$ . We must compare  $m_{F_1}(dP_1)\psi_{F_1, F_2}(P_1, dP_2)$  with  $m_{F_2}(dP_2)\psi_{F_2, F_1}(P_2, dP_1)$ . We must then number all transitions of  $\mathcal{T}$  and verify the symmetrical relation. This point is more or less complicated according to the relation considered. For instance, take again the case of budding without creation (remember that  $m_{F_1}$  is the Lebesgue measure defined on the simplex  $S_{F_1}$ ), and denote by  $N$  the length of vector  $P_1 = (p_1, p_2, \dots, p_N)$ . Without loss of generality, we can suppose that we choose to bud trees 1 and 2 so that other weighted trees of  $F_1$  remain unchanged. The length of  $P_2$  is consequently  $N + 1$ , and we have thus  $P_2 = (q_1, q_2, \dots, q_N, q_{N+1})$ .

Hence, to one side we have

$$m_{F_1}(dP_1)\psi_{F_1, F_2}(P_1, dP_2) = \prod_{i=1}^N m_{F_1}(dp_i) \otimes \prod_{i=3}^N \mathbb{1}_{p_i}(q_i) \otimes \mathcal{U}_{X^{p_1, p_2}}(q_1, q_2, q_{N+1}),$$

and  $\psi_{F_1, F_2}(P_1, \cdot)$  is a Dirac for all coordinates in  $P_1$  which are not modified by the bud and

$$X^{p_1, p_2} = \{(a, b, c) \in \mathbb{R}_+^3 \mid a + b + c = p_1 + p_2\}.$$

On the other hand, we can equally write the transition measure

$$m_{F_2}(dP_2)\psi_{F_2, F_1}(P_2, dP_1) = \prod_{i=1}^{N+1} m_{F_2}(dq_i) \otimes \prod_{i=3}^N \mathbb{1}_{q_i}(p_i) \otimes \mathcal{U}_{X^{q_1, q_2, q_{N+1}}}(p_1, p_2).$$

The symmetrical claim is satisfied since, for all measurable functions  $f$  on  $\mathcal{S}_{F_1} \times \mathcal{S}_{F_2}$ ,

$$\begin{aligned} & \langle m_{F_1}(dP_1)\psi_{F_1, F_2}(P_1, dP_2); f \rangle \\ &= \iint_{\mathcal{S}_{F_1} \times \mathcal{S}_{F_2}} f(p_1, \dots, p_N, q_1, \dots, q_{N+1}) m_{F_1}(dP_1)\psi_{F_1, F_2}(P_1, dP_2) \\ &= \int \prod_{i=1}^N dp_i \int_0^{p_1+p_2} dp \int_{p-p_1}^{p_2} dx f(P_1, p_1-p+x, p_2-x, p_3, \dots, p_N, p) \\ &= \int \prod_{i=1}^{N+1} dq_i \int_{-q_2}^{q_1+q_{N+1}} dx \int_{q_1+q_{N+1}-x}^{q_2+x} f(P_2, q_1+p-x, q_2+x, q_3, \dots, q_N) \\ &= \langle m_{F_2}(dP_2)\psi_{F_2, F_1}(P_2, dP_1); f \rangle. \end{aligned}$$

A similar change of variables can be done for all other types of transitions of  $\mathcal{T}$ , and we can conclude that the symmetrical assumption (A3) is also true.  $\square$

**4.3. Decision steps of the Markovian dynamic of jumps.** Taking a jump time  $t_j$  and any state of our process  $(\mathcal{F}_{t_j}, \mathbb{P}_{t_j})$ , we use rules taken from  $\mathcal{T}$  to modify  $\mathcal{F}_{t_j}$  and  $\mathbb{P}_{t_j}$  to  $\mathcal{F}_{t_j+dt}$  and  $\mathbb{P}_{t_j+dt}$ . There are exactly three steps for the choice of which transition of  $\mathcal{T}$  is applied.

- Step 1.* We first choose which kind of transition is proposed in  $\mathcal{T}$  (bud, cut, suppression, or rebirth) according to the probability distribution specified in the last columns of arrays of section 4.2.
- Step 2.* When the rule is chosen, select the trees to which the rule is applied. One can make this decision regardless of whether it is dependent on  $\mathbb{P}_{t_j}$ . The simpler method is to choose uniformly among all trees in  $\mathcal{F}_{t_j}$  or in  $\mathcal{F}_0 \setminus \mathcal{F}_{t_j}$ .
- Step 3.* Accept (or not) the transition according to a differential energy criterion,

$$(7) \quad Q((\mathcal{F}_{t_j}, \mathbb{P}_{t_j}); (F, P)) = \min \left( 1, e^{\mathcal{E}(\mathcal{F}_{t_j}, \mathbb{P}_{t_j}) - \mathcal{E}(F, P)} \times R \right),$$

where

$$R = \frac{Q_0((F, P); (\mathcal{F}_{t_j}, \mathbb{P}_{t_j}))q((F, P); (\mathcal{F}_{t_j}, \mathbb{P}_{t_j}))}{Q_0((\mathcal{F}_{t_j}, \mathbb{P}_{t_j}); (F, P))q((F, P); (\mathcal{F}_{t_j}, \mathbb{P}_{t_j}))}.$$

The computation of the first step is easy with a discrete probability distribution on the rules constituting  $\mathcal{T}$ . At Step 2, the choice of which trees to apply the rule can depend on the distribution  $\mathbb{P}_{t_j}$ . The main idea is to favor trees with high probability for *budding* and low probability for *cuts*. Trees selected for *rebirth* are chosen uniformly in the feature space  $\mathcal{F}_0 \setminus \mathcal{F}_{t_j}$ . More details can be found in [17].

**5. Existence of the jump-diffusion process.** From the beginning of this section, special attention will be dedicated to the indexing of our random processes. They will be described first (up to and including section 6) using a continuous setting  $(\mathcal{F}_t, \mathbb{P}_t)$ , which looks somewhat artificial since in section 7 the algorithm works in a discrete framework with  $(\mathcal{F}_n, \mathbb{P}_n)$ . Moreover, the description of the continuous setup will be much more complicated than the discretized one mainly owing to the projection term in the set of probability distributions.

Actually, the asymptotic behavior of the Markov chain  $(\mathcal{F}_n, \mathbb{P}_n)$  will be presented following a classical scheme of compactness/identification. The compactness is studied in section 7, although the identification of the stationary measure in section 7 will critically use uniqueness of the stationary measure for the continuous process. Thus, the heavy use of the Skorokhod map is highly motivated by this asymptotic study since the identification of the stationary measure is easily deduced from the Markov generator of the process. Since we will need this continuous approach for this last identification, we directly describe the learning process in a continuous setting. Lastly, the weak limit of our discrete Markov chain will be the continuous reflected jump diffusion, and the description of this last process will need the Skorokhod map.

But the Skorokhod map can be skipped to intuitively make the understanding easier in this section, and one can replace the continuous processes by the discretized ones using a simple convex projection to keep  $\mathbb{P}_n$  in a set of probability measures.

**5.1. Existence of the reflected diffusion between jump times.** We work in this section with fixed  $\mathcal{F}_t = F$  of size  $S$  and discuss the existence of a Markovian reflected diffusion process which drives the evolution in the absence of jumps:

$$(8) \quad d\mathbb{P}_t = - \underbrace{\nabla}_{(=\nabla^F)} \mathcal{E}_{err}(\mathbb{P}_t) dt + \sigma dW_t + dZ_t.$$

The construction of solutions of (8) relies on the Skorokhod map  $\Gamma$  associated to  $\mathcal{S}_F$  and a set of unit vectors  $d_c(x)$  for all  $x$  on the boundary  $\partial\mathcal{S}_F$ . This map associates

FIG. 1. Directions of reflection vectors for  $x$  in  $\partial\mathcal{S}_F$ .

to any càdlàg trajectory a constrained càdlàg trajectory that satisfies some boundary conditions based on  $d_c(\cdot)$ . We refer to [12] and [13] for further precise technical definitions on this construction. For the sake of completeness, we provide only the constraint vectors we used. The important fact is thus that  $\Gamma$  will exist and define a Lipschitz function on càdlàg trajectories.

DEFINITION 5.1 (directions of constraints  $d_c(\cdot)$ ). We call  $\vec{n}_i$  the unit vectors belonging to the hyperplane supporting  $\mathcal{S}_F$  that normally enter the  $i$ th face of the simplex. The directions of constraints are given by

$$\forall x \in \partial\mathcal{S}_F, \quad d_c(x) = \left\{ \gamma = \sum_{i \mid x_i=0} \alpha_i \vec{n}_i \mid \alpha_i \geq 0, \|\gamma\| = 1 \right\}.$$

These directions of reflection on  $\partial\mathcal{S}_F$  can be expressed easily in a different way as follows.

PROPOSITION 5.2 (directions of constraints  $d_c(\cdot)$ ). For any point  $x$  in  $\partial\mathcal{S}_F$ , vectors  $d_c(x)$  coincide exactly with the sets of unit vectors:

$$d_c(x) = \{ \vec{\gamma} \text{ with } \|\vec{\gamma}\|_2 = 1 \mid \exists y \in \mathcal{H}_F \quad y - \pi_F(y) = \alpha \gamma, \quad \alpha \leq 0, x = \pi_F(y) \},$$

where  $\pi_F$  is the natural convex projection on the simplex  $\mathcal{S}_F$ .

Figure 1 summarizes this natural property. One can remark that directions  $d_c(x)$  are strongly connected to convex projections on  $\mathcal{S}_F$ : they correspond exactly to the unitary vectors that can be used to project any exterior point to  $\mathcal{S}_F$ . In stochastic approximation algorithms, it is the usual way of introducing convex constraints. This yields a set of possible callback vectors shown in Figure 1.

The Skorokhod map allows us to formalize the reflected diffusion (8) as a system of integral equations:

$$\begin{cases} X_t = \mathbb{P}_0 - \int_0^t \nabla \mathcal{E}_{err}(\mathbb{P}_s) ds + \sigma dW(s), \\ \mathbb{P}_t = \Gamma(X)_t. \end{cases}$$

This system is equivalent to the stochastic differential equation (8) [3, 12]. Strong (and obviously weak) existence and uniqueness of such an integral system is standard using a fixed point method [30], Lipschitz regularity of  $\Gamma$ , and Lipschitz continuity of the drift  $\nabla \mathcal{E}_{err}$ . Indeed, for  $\omega \in F^k$  and  $\delta \in F$ , denote by  $C(\omega, \delta)$  the number of occurrences of  $\delta$  in  $\omega$ :

$$C(\omega, \delta) = |\{i \in \{1, \dots, k\} \mid \omega_i = \delta\}|.$$

Since the drift term is polynomial in variables  $P(\delta)$ , it is obviously Lipschitz continuous. Its exact expression is for any  $P \in \mathcal{S}_F$ ; then

$$(9) \quad \forall \delta \in F, \quad \nabla_P \mathcal{E}_{err}(\delta) = \sum_{\omega \in F^k} \frac{C(\omega, \delta) P^{\otimes k}(\omega)}{P(\delta)} g(\omega).$$

We can thus infer the following result.

**THEOREM 5.3** (existence and uniqueness of (8)). *Let  $(\Omega, \mathcal{T}, Q)$  be a probability space with an increasing filtration  $\mathcal{T}_t$ , let  $W_t$  be standard Brownian motion on  $\mathbb{R}^{|\mathcal{F}|}$ , and let  $\mathbb{P}$  be a random variable  $\mathcal{T}_0$ -measurable. Then there exists a unique pair  $(\mathbb{P}_t, Z_t)$   $\mathcal{T}_t$ -measurable satisfying (8) with*

1.

$$\forall T > 0, \quad |Z_T| < +\infty \quad \mathcal{T}_T\text{-a.s.}$$

2.

$$\forall t \geq 0, \quad |Z|_t = \int_0^t \mathbb{1}_{\mathbb{P}_s \in \partial \mathcal{S}_{\mathcal{F}}} d|Z|_s.$$

3.

$$\forall t \geq 0, \quad dZ_t \in d_c(\mathbb{P}_t).$$

*Proof.* See [30, Chapter 5].  $\square$

**5.2. Existence of the complete process.** Since the jump time is a Poisson process independent of the rest, the previous result, combined with the Markov transitions at jump times, trivially implies the existence and uniqueness of the complete jump-diffusion process. An example of the evolution of such a stochastic process is summarized in Figure 2 using a sequence of four different simplices and jumping times. Each simplex corresponds to a features space while the a.s. continuous trajectory points to the evolution of our extraction method  $\mathbb{P}_s$ . We represent here one reflection on  $\mathcal{S}_{\mathcal{F}_{t_{s_2}}}$  and several jumps between several (i.e., 4) simplices. Note that if it is possible to jump from  $\mathcal{S}_{\mathcal{F}_{t_{s_2}}}$  to  $\mathcal{S}_{\mathcal{F}_{t_{s_3}}}$ , it is equally possible to jump from  $\mathcal{S}_{\mathcal{F}_{t_{s_3}}}$  to  $\mathcal{S}_{\mathcal{F}_{t_{s_2}}}$  (weak reversibility).

We will denote by  $\Phi$  the stationary solution of the stochastic differential equation of the reflected jump diffusion based on reflected diffusion on each simplex and jumps between subspaces of features. This solution is defined as follows.

**DEFINITION 5.4** (stationary solution  $\Phi$ ). *Let  $(\Omega, \mathcal{T}, Q)$  be a probability space with an increasing filtration  $\mathcal{T}_t$ . Let  $(W_t)_{t \geq 0}$  be a standard Brownian motion on  $\mathbb{R}^{|\mathcal{F}|}$  and  $(N_t)_{t \geq 0}$  be a Poisson jump process, both adapted to filtration  $\mathcal{T}$ . Suppose likewise that  $W$  and  $N$  are independent. We call  $\Phi = (\mathbb{P}, \mathcal{F})$  the stationary solution of the*

FIG. 2. General form of the stochastic jump-diffusion process.

stochastic differential equation with jumps:

$$d\left(\begin{matrix} \mathbb{P}_t \\ \mathcal{F}_t \end{matrix}\right) = - \begin{pmatrix} \nabla^{\mathcal{F}_t} \mathcal{E}(\mathbb{P}_t) dt + \Sigma^{\mathcal{F}_t} dW_t + dZ_t \\ 0 \end{pmatrix} + \int_{\mathcal{F} \subset \mathbf{F}^\sharp, \mathbb{P} \in \mathcal{S}_{\mathcal{F}}} Q\left[\begin{pmatrix} \mathcal{F}_t \\ \mathbb{P}_t \end{pmatrix}; \begin{pmatrix} \mathcal{F} \\ \mathbb{P} \end{pmatrix}\right] N\left(d\left(\begin{matrix} \mathbb{P} \\ \mathcal{F} \end{matrix}\right); dt\right).$$

**6. Dynamical properties of the algorithm.** In this section, we briefly summarize the dynamical properties of the unique solution of the reflected jump-diffusion process. Our goal is to prove that the process is positive recurrent with a unique stationary measure, given by the the density

$$(10) \quad \mu(F, P) = \frac{e^{-\mathcal{E}(F, P)}}{Z},$$

with respect to the measure on  $\mathcal{P}_{\mathbf{F}^\sharp} \times \mathcal{S}_{\mathbf{F}^\sharp}$ ,

$$m = \sum_{F \subset \mathbf{F}^\sharp} \mathbb{1}_F \otimes m_F.$$

We first give the expression of the infinitesimal generator of the process, then establish that  $(\mathbb{P}_s, X_s)_{s \geq 0}$  is positive recurrent and prove that its stationary measure is the Gibbs field  $\mu$  associated to  $\mathcal{E}$ .

**6.1. Infinitesimal generator of  $(\mathcal{F}_s, \mathbb{P}_s)_{s \geq 0}$ .** Our Markov process is a combination of a reflected diffusion process and a jump process. A generic function on  $\mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}$  can be decomposed as

$$f(F, P) = \sum_{F' \subset \mathbf{F}^\sharp} \mathbb{1}_{F'}(F) f_{F'}(P).$$

The generator  $A$  of this process can be decomposed into a diffusion part and a jump part, yielding  $Af = A^d f + A^j f$ , with

$$A^d f(P, F) = -\langle \nabla_P^F \mathcal{E}_{err} | \nabla_P^F f_F \rangle + \frac{1}{2} \Delta^F f_F(x)$$

and

$$A^j f(P, F) = \int_{\mathcal{P}(\mathbf{F}^\sharp) \times \mathcal{S}_{\mathbf{F}^\sharp}} [f_{F'}(P') - f_F(P)] Q[(F, P), (F', P')] dm(F', P'),$$

where  $Q$  is the transition probability at jump times.

**6.2. Positive recurrence.** The main result of this section uses the positive definite nature of  $\Sigma_F$  on  $\mathcal{H}_F$  and a result of [23, Theorem 1, section 7] ensuring a positive recurrence of the reflected process (without any jump). For any reachable simplex  $\mathcal{S}_F$ , the unique process solution of

$$d\mathbb{P}_t = -\nabla \mathcal{E}_\epsilon(\mathbb{P}_t) dt + \sigma dW_t + dZ_t$$

satisfies the following for all compact sets  $S \subset \mathcal{S}_{\mathcal{F}}$  of nonnegative Lebesgue measure  $\lambda(S) > 0$  (if  $P_p$  is the probability of one event for which initialization of our process is taken at point  $p$ ):

$$(11) \quad \inf_{p \in \mathcal{S}_{\mathcal{F}}} P_p [\tau_S \leq 1] > 0,$$

where

$$\tau_S = \inf \{t / \mathbb{P}_t \in S\}.$$

Equation (11) means that starting at any point  $p$  of simplex  $\mathcal{S}_F$ , one can reach  $S$  in less time than with a probability strictly positive. This implies in particular (see [4, Theorem 2.8]) the positive recurrence of (8) without a jump, and the existence of a unique invariant measure. The extension of the results to the jump-diffusion process now requires only the following fact. Denote

$$p_{F,T}(S) = \inf_{p \in \mathcal{S}_F} P_p [\tau_S \leq T]$$

for  $S \subset \mathcal{S}_F$ , where  $\tau_S$  is the hitting time of  $S$ . We have the following result.

COROLLARY 6.1.

$$p_{F,T}(S) > 0,$$

and the general reflected process with jumps is positive recurrent.

*Proof.* The jumps have been designed so that there exists an integer  $N$  such that for any  $F$  and  $F'$ , and for any  $P \in \mathcal{S}_F$ , the transition  $(F, P) \rightarrow F'$  in  $N$  steps has a probability strictly larger than some positive constant,  $\eta$ . Since the probability of making  $N$  jumps before  $T$ , and no other jump after, is strictly positive, the result is a direct consequence of the positive recurrence of the process without a jump.  $\square$

**6.3. Invariant measure of the process.** Properties of the invariant measure can be inferred from the positive recurrence of  $(\mathbb{P}_t, \mathcal{F}_t)_{t \geq 0}$ . First, note that for any initialization  $(\mathbb{P}_0, \mathcal{F}_0)$  of the process, the family of occupation measures  $(\mu_t)_{t \geq 0}$ , defined by

$$\mu_t(A) = \frac{1}{t} \int_0^t P_{(\mathbb{P}_0, \mathcal{F}_0)}[(\mathbb{P}_s, \mathcal{F}_s) \in A] ds,$$

is tight and any weak limit is an invariant measure of  $(\mathbb{P}_t, X_t)_{t \geq 0}$  since the process is Feller–Markov. Uniqueness is derived from the nondegeneracy of the diffusion of the process into each simplex and the weak reversibility between each simplex of  $(\mathbb{P}_t, \mathcal{F}_t)$ . Identification of this measure from the characterization of [14] is used, for example, in [29].

We use here the well-posedness of the associated martingale problem. Define first the core of this generator as

$$\mathbb{D} = \left\{ f = \sum_{F \subset \mathcal{F}^\#} \mathbb{1}_{\mathcal{S}_F}(P) f_F(P) \mid \forall F \subset \mathcal{F}^\# \quad \forall P \in \partial \mathcal{S}_F \quad \nabla f_F(P) = 0 \right\}.$$

We start noticing that for any function in  $\mathbb{D}$ , the mean effect of generator  $A$  with distribution  $\mu$  given by (10) is null.

PROPOSITION 6.2. *Assume  $f$  is an element of  $\mathbb{D}$ ; then we have*

$$\int A f d\mu = 0.$$

*Proof.* This result is proved by integration by parts, using the Neumann conditions on each simplex  $\mathcal{S}_F$ , where  $F \subset \mathbf{F}^\#$ , the Ostrogradski formula, and the stability equation on the transition acceptance threshold (7). Similar arguments can be found in [29].  $\square$

We are now able to prove the next theorem.

THEOREM 6.3. *The Gibbs field  $\mu$  given by (10) is the unique invariant measure of the global reflected jump-diffusion process, and the martingale problem associated to  $A$  on  $\mathbb{D}$  is well-posed.*

*Proof.* We first apply Echeverria’s theorem (see [14, Theorem 9.17, Chapter 9]) to show that  $\mu$  is stationary. Denote by  $E$  the compact set  $\{(F, P) \mid F \subset \mathbf{F}^\#, P \in \mathcal{S}_F\}$ ; note first that  $\mathbb{D}$  is dense in  $\mathcal{C}(E)$  by the Uryshon lemma applied in each simplex  $\mathcal{S}_F$ . Now,  $A$  satisfies the positive maximum principle on  $\mathbb{D}$  ( $A$  is a classical jump-diffusion generator) and the measure  $\mu$  satisfies

$$\forall f \in \mathbb{D}, \quad \int_E A f d\mu = 0.$$

Consequently  $\mu$  is stationary for  $A$ . Since  $A$  satisfies the maximum principle,  $A$  is dissipative on  $\mathcal{C}(E)$  and  $E$  is separable. Denote then by  $\nu$  a measure on  $E$ ; we can apply the result of [14, Theorem 4.1, Chapter 4] to conclude that uniqueness holds for the martingale problem  $(A, \nu)$  and every solution of the martingale problem is Markov. The martingale problem is well-posed on  $\mathcal{C}(E)$ , every solution of the martingale problem is a weak solution of the stochastic differential equation of jump diffusion, and  $\mu$  is the unique stationary distribution of  $(\mathcal{F}_t, \mathbb{P}_t)$ .  $\square$

**7. Stochastic approximations.** We now address the computational part of the algorithm, which is not trivial because the drift term involves a sum over an untractable number of terms. Fortunately, this sum can be interpreted as an expectation, which allows us to replace it by a stochastic approximation of Robbins–Monro type. Before passing to the drift term, we first address the time discretization issues.

**7.1. Time discretization.** To solve (8), we use a time discretization scheme with a discretization step  $\alpha$ ,

$$\forall n \in \mathbb{N}, \quad \mathbb{P}_{n+1} = \mathbb{P}_n - \alpha \nabla^{\mathcal{F}} \mathcal{E}_{err}(\mathbb{P}_n) + \sqrt{\alpha} \sqrt{\sigma} d\xi_n + dz_n,$$

where  $d\xi_n$  is a centered normal  $|\mathcal{F}|$  dimensional vector and  $dz_n$  is the smaller vector that is added to make  $\mathbb{P}_{n+1} \in \mathcal{S}_{\mathcal{F}}$ . In other words,

$$\forall n \in \mathbb{N}, \quad \mathbb{P}_{n+1} = \pi_{\mathcal{F}} \left( \mathbb{P}_n - \alpha \nabla^{\mathcal{F}} \mathcal{E}_{err}(\mathbb{P}_n) + \sqrt{\alpha} \sqrt{\sigma} d\xi_n \right).$$

However, the computational issue comes from the gradient of  $\mathcal{E}_{err}$ , given in (9), which requires a sum over all  $\omega$  in  $\mathcal{F}^p$ . This is an untractable sum, since  $|\mathcal{F}|$  is typically thousands and  $p$  hundreds. However, it can be replaced by the stochastic approximation defined in the next section.

**7.2. Stochastic differential equation method for approximation.** Stochastic approximation can be seen as noisy discretizations of stochastic differential equations ([26]). They are generally expressed under the form

$$(12) \quad X_{n+1} = X_n + \alpha_n F(X_n, \zeta_{n+1}) + \sqrt{\alpha_n} \sqrt{\sigma} \xi_n + \alpha_n z_n + \alpha_n^2 T_n,$$

where  $X_n$  is the current state of the process,  $\zeta_{n+1}$  a random perturbation,  $\xi_n$  a random perturbation of known distribution,  $z_n$  a random variable designed to ensure the constraints, and  $T_n$  a secondary error term. If the distribution of  $\zeta_{n+1}$  depends only on the current value of  $X_n$ , then one defines an average drift  $X \mapsto G(X)$  by

$$G(X) = \mathbb{E}[F(X, \zeta)|X],$$

and (12) can be shown to evolve similarly to the stochastic differential equation:  $dX_t = G(X)dt + \sqrt{\sigma}dw_t + dz_t$ , in the sense that the trajectories coincide when  $(\epsilon_n)_{n \in \mathbb{N}}$  goes to 0 (a more precise statement is given below).

To implement our reflected diffusion equations (8) in this framework, we need to design a random variable  $d_n$  (identified as  $F(X_n, \zeta_n)$  in (12)) such that

$$(13) \quad \mathbb{E}[d_n] = -\nabla^{\mathcal{F}} \mathcal{E}_{err}(\mathbb{P}_n) = -\Pi_{\overrightarrow{\mathcal{H}_{\mathcal{F}}}}[\nabla \mathcal{E}_{err}(\mathbb{P}_n)],$$

where  $\Pi_{\overrightarrow{\mathcal{H}_{\mathcal{F}}}}$  is the vectorial projection on the hyperplane supporting  $\mathcal{S}_{\mathcal{F}}$ . We will then define

$$\mathbb{P}_{n+1} = \mathbb{P}_n - \alpha_n d_n + \sqrt{\alpha_n} \sqrt{\sigma} \xi_n + dz_n = \pi_{\mathcal{F}} \left( \mathbb{P}_n - \alpha_n d_n + \sqrt{\alpha_n} \sqrt{\sigma} \xi_n \right).$$

From (9), we obtain

$$\nabla \mathcal{E}_{err}(\mathbb{P})(\delta) = \mathbb{E}_{\mathbb{P}^{\otimes k}} \left[ \frac{C(\omega, \delta)g(\omega)}{\mathbb{P}(\delta)} \right].$$

Using the linearity of the projection  $\Pi_{\overrightarrow{\mathcal{H}_{\mathcal{F}}}}$ , we get

$$\Pi_{\overrightarrow{\mathcal{H}_{\mathcal{F}}}}(\nabla \mathcal{E}(\mathbb{P}))(\delta) = \mathbb{E}_{\mathbb{P}^{\otimes k}} \left[ \Pi_{\overrightarrow{\mathcal{H}_{\mathcal{F}}}} \left( \frac{C(\omega, \cdot)g(\omega)}{\mathbb{P}(\cdot)} \right) (\delta) \right].$$

Consequently, following (13), it is now natural to define the approximation term of the reflected diffusion (8) by

$$d_n(\delta) = \Pi_{\mathcal{H}_{\mathcal{F}}} \left( \frac{C(\omega_n, \cdot)}{\mathbb{P}_n(\cdot)} \right) (\delta),$$

where the set of  $k$  features  $\omega_n$  is a random variable extracted from  $\mathcal{F}$  with law  $\mathbb{P}_n^{\otimes k}$ .

This results in the following numerical simulation scheme:

1. Step 0: Initialization: Set  $\mathbb{P}_0 = \mathcal{U}_{\mathcal{F}}$ .
2. Step  $n$ : Draw a sample  $\omega_n$  in  $\mathcal{F}^k$  with respect to  $\mathbb{P}_n^{\otimes k}$ .
3. Step  $n$ : Compute  $g(\omega_n)$ .
4. Step  $n$ : Update  $\mathbb{P}_{n+1}$  with

$$(14) \quad \begin{aligned} \mathbb{P}_{n+1} &= \pi_{\mathcal{F}} \left( \mathbb{P}_n - \alpha_n \left[ \frac{C(\omega_n, \cdot)}{\mathbb{P}_n} \right] + \sqrt{\alpha_n} \sqrt{\sigma} d\xi_n \right) \\ &= \mathbb{P}_n - \alpha_n \left[ \frac{C(\omega_n, \cdot)}{\mathbb{P}_n} \right] + \sqrt{\alpha_n} \sqrt{\sigma} d\xi_n + dz_n, \end{aligned}$$

where  $-\alpha_n C(\omega_n, \cdot)/\mathbb{P}_n$  is the approximated value of  $-\nabla \mathcal{E}_{err}(\mathbb{P}_n)$  and  $d\xi_n$  is a centered normal  $|\mathcal{F}|$  dimensional vector.

To simulate the stochastic approximation of the jump-diffusion algorithm, (14) must be combined with transitions of  $(\mathcal{F}, \mathcal{P})$  at jump times. This results in the following new complete scheme:

1. Step 0: Initialization: Set  $\mathbb{P}_0 = \mathcal{U}_{\mathcal{F}_0}$ . Sample the first jumping time  $t^1$  with an exponential distribution, set  $t = 0$ , and set  $n = 0$ .
2. Step  $j$  ( $j \geq 1$ ): While  $t < t^j$ , run the previous discretization scheme (for the reflected diffusion),  $t$  being iteratively computed by  $t = \alpha_0 + \dots + \alpha_n$ .
3. When  $t > t_j$ : Update  $\mathcal{F}_t$  and  $\mathbb{P}_t$  according to the Markov transition rules.
4. Compute the next jump time with  $t^{j+1}$  by adding an exponential variable to  $t^j$  and return to 2.

**7.3. Weak convergence of the numerical scheme.** In the following paragraphs, we will define  $(\mathbb{P}^n(t)_{t \geq 0})_{n \in \mathbb{N}}$  as a sequence of continuous processes that interpolates the behavior of the discrete sequence of  $(\mathbb{P}_n)_{n \in \mathbb{N}}$ .

**7.3.1. Interpolated approximations.** Following classic notation of [26], we set up the time parameter  $\tau_n$  as

$$\tau_n = \sum_{i \leq n} \alpha_i,$$

and set up the map  $m$  permitting the association of continuous time and discrete iteration as

$$m(t) = \sup_{\tau_n \leq t} \{n \in \mathbb{N}\}.$$

Given that the  $j$ th jump occurs at time  $\nu_j$ , we construct its values according to the distribution  $Q((\mathcal{F}_{\nu_j-}, \mathbb{P}_{\nu_j-}), \cdot)$  to obtain  $(\mathcal{F}_{\nu_j}, \mathbb{P}_{\nu_j})$ . It is thus possible to define the discrete jump term in the discrete case as

$$q_j = \mathbb{P}_{m(\nu_j)+1} - \mathbb{P}_{m(\nu_j)},$$

which corresponds to the term we add to compute the jump from  $\nu_j-$  to  $\nu_j$ .

We now define the sequence of right continuous interpolation processes  $(\mathbb{P}^n(t))_{t \geq 0}$  initialized at  $\mathbb{P}_n$ .

**DEFINITION 7.1** (processes  $(\mathbb{P}^n(\cdot), Y^n(\cdot), W^n(\cdot), Z^n(\cdot))_{n \in \mathbb{N}}$ ). *We define the processes  $(\mathbb{P}^n, Y^n, W^n, Z^n)$  valued in  $\mathbb{R}^{\mathbf{F}^\sharp}$  by*

$$\forall n \in \mathbb{N}, \quad \forall t \in \mathbb{R}_+, \quad Y^n(t) = \sum_{i=n}^{m(\tau_n+t)} \alpha_i y_i,$$

where the term  $y_i$  satisfies

$$\forall \delta \in \mathcal{F}, \quad y_i(\delta) = -\frac{C(\omega_i, \delta)g(\omega_i)}{\mathbb{P}_i(\delta)} \text{ if } \mathbb{P}_i(\delta) \neq 0 \text{ and } y_i(\delta) = 0 \text{ if } \mathbb{P}_i(\delta) = 0.$$

Likewise, we define

$$W^n(t) = \sum_{i=n}^{m(\tau_n+t)} \sqrt{\alpha_i} d\xi_i,$$

where  $d\xi_i$  is considered as an element of  $\mathbb{R}^{\mathbf{F}^\sharp}$ ,

$$Z^n(t) = \sum_{i=n}^{m(\tau_n+t)} dz_i.$$

Finally,

$$\mathbb{P}^n(t) = \mathbb{P}_n + Y^n(t) + W^n(t) + Z^n(t) + \sum_{\tau_n \leq \nu_j \leq \tau_n+t} q_j.$$

With these definitions, it is obvious that  $\mathbb{P}^n$  is a process on  $\mathcal{S}_{\mathbf{F}^\sharp}$ , which is right continuous with left limits (in the space  $\mathcal{D}$  of càdlàg trajectories). To get theoretical convergence results on these sequence of processes, we will now classically choose  $(\alpha_n)$  such that  $\sum \alpha_i = \infty$  and  $\sum \alpha_i^2 < \infty$  (see [5], [26], for instance).

**7.3.2. Convergence of  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$ .** We will show that the family of processes  $(\mathbb{P}^n(\cdot), Y^n(\cdot), W^n(\cdot), Z^n(\cdot))_{n \in \mathbb{N}}$  is weakly compact in the space  $\mathcal{D}$ . The associated topology on this space is derived from the Skorokhod distance [6], [26] and we consider weak convergence of trajectories of  $\mathcal{D}([0; \infty[)$ .

**THEOREM 7.2.** *The processes  $(\mathbb{P}^n, Z^n)_{n \in \mathbb{N}}$ , which are stepwise constant, weakly converge toward the unique invariant solution of the stochastic differential equation without jumps and  $(\mathbb{P}_n, \mathcal{F}_n)_{n \in \mathbb{N}}$  converges toward the stationary measure  $\mu$ .*

The proof of Theorem 7.2 includes three steps: First, prove the tightness of the family  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$ , then identify the unique possible weak limit, and finally show the convergence toward the stationary measure  $\mu$ .

**7.3.3. Tightness.** To show tightness, we use the following criterion.

**THEOREM 7.3** (see [26], [6]). *Let  $X^n$  be a sequence in  $\mathcal{D}$ ;  $(X^n)_{n \in \mathbb{N}}$  is tight iff*

1. *for any time  $T$  and  $\epsilon > 0$ , there exist an integer  $n_0$  and a real  $K$  satisfying*

$$(15) \quad \forall n \geq n_0, \quad P \left[ \sup_{t \leq T} |X^n(t)| \geq K \right] \leq \epsilon.$$

2.

$$(16) \quad \forall \epsilon > 0, \quad \lim_{\delta \rightarrow 0} \limsup_n P[w'_{X^n}(\delta) \geq \epsilon] = 0.$$

We establish successively (15) and (16) for our family of processes  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$ . The next proposition shows that (15) is true for  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$  and consequently guarantees the tightness of the family  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$ .

PROPOSITION 7.4. *The sequence of processes  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$  satisfies (15).*

*Proof.* The result is obvious for  $\mathbb{P}^n$ , since it is compactly supported. To get the result for  $(Y^n)_{n \in \mathbb{N}}$ , we define the sequence  $\tilde{y}_n$  as

$$\tilde{y}_n = y_n - \underbrace{\mathbb{E}_{\mathbb{P}^n}[y_n]}_{=h_n}.$$

Fix any real time  $T$  and a real number  $\epsilon > 0$ . We define the sequence of processes

$$\tilde{Y}^n(t) = \sum_{i=n}^{m(\tau_n+t)} \alpha_i \tilde{y}_i.$$

Since  $\mathbb{E}_{\mathbb{P}^n}[y_n]$  is bounded by  $M$ , the first tightness criterion is true for processes  $H^n$ :

$$H^n(t) = \sum_{i=n}^{m(\tau_n+t)} \alpha_i h_i,$$

and we study the sequence of  $(\tilde{Y}^n)_{n \in \mathbb{N}}$ . Now the sum  $M_p^n$  given by

$$M_p^n = \sum_{i=n}^{n+p} \alpha_i \tilde{y}_i$$

is a martingale for the filtration generated by  $\mathbb{F}_p^n = \sigma(\mathbb{P}_i, \xi_i, w_{i-1}, i \leq n+p)$ . We can use Doob's inequality to show that

$$P\left(\sup_{q \leq p} |M_q^n| > K\right) \leq \frac{1}{K} \mathbb{E}(|M_p^n|).$$

Now,

$$\mathbb{E}(|M_p^n|) \leq \sum_{i=n}^p \alpha_i \mathbb{E}[|\tilde{y}_i|] \leq \sup_i \mathbb{E}[|\tilde{y}_i|] \sum_{i=n}^p \alpha_i.$$

Finally,  $\mathbb{E}[|\tilde{y}_i|] = \mathbb{E}(\mathbb{E}[|\tilde{y}_i| | \mathbb{F}_i^n])$ , and  $\mathbb{E}[|\tilde{y}_i| | \mathbb{F}_i^n]$  is bounded by  $2M$ . We have  $\sum_{i=n}^p \alpha_i \leq T$  and we can deduce from these upper-bounds that

$$\lim_{K \rightarrow \infty} P\left(\sup_{q \leq p} |M_q^n| > K\right) = 0.$$

The fact that

$$\lim_{K \rightarrow \infty} \sup_{n \in \mathbb{N}} P\left[\sup_{t \leq T} |W^n(t)| \geq K\right] = 0$$

is standard and can be found in [26], [17]. Finally, since  $Z^n = \mathbb{P}^n - Y^n - W^n$ ,  $(Z^n)_{n \in \mathbb{N}}$  obviously satisfies (15).  $\square$

We must now establish condition (16) to achieve tightness of  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$ .

**PROPOSITION 7.5** (condition (16)). *Each of the processes  $(\mathbb{P}^n, Y^n, W^n, Z^n)_{n \in \mathbb{N}}$  satisfies (16).*

*Proof.* We first establish (16) for  $(Y^n)_{n \in \mathbb{N}}$ . Note that

$$\mathbb{E}[Y^n(t+s) - Y^n(t)] = \sum_{i=m(\tau_n+t)}^{m(\tau_n+t+s)} \alpha_i \mathbb{E}[\mathbb{E}[y_i | \mathbb{F}_0^i]].$$

Then, use the fact that the expectations of  $y_k$  are bounded by  $M$  to obtain

$$\mathbb{E}[|Y^n(t+s) - Y^n(t)|] \leq Ms.$$

We thus conclude that (16) is true for  $(Y^n)_{n \in \mathbb{N}}$  using the Markov inequality. The argument is standard to get a similar result for  $(W^n)_{n \in \mathbb{N}}$  by Doob's inequality (see [26]). The jump component involved by terms  $q_j$  defines also a sequence of processes:

$$J^n(t) = \sum_{\tau_n \leq \nu_j \leq \tau_n+t} q_j.$$

Inequality (16) for  $(J^n)_{n \in \mathbb{N}}$  is here clearly satisfied since jumps occur exponentially as each term  $q_j$  is bounded. Consequently, we have

$$\limsup_n P[w'_{J^n}(\delta) \geq \epsilon] = o(\delta).$$

To deal with the processes  $(Z^n)_{n \in \mathbb{N}}$ , it is important to note that

$$|Z^n(t+s) - Z^n(t)| \leq C \sum_{i=m(\tau_n+t)}^{m(\tau_n+t+s)} |\alpha_i y_i + \sqrt{\alpha_i} d\xi_i|,$$

since

$$(17) \quad |z_i| \leq C|\alpha_i y_i + \sqrt{\alpha_i} d\xi_i|.$$

Using inequality (16) for  $(Y^n)_{n \in \mathbb{N}}$  and  $(W^n)_{n \in \mathbb{N}}$ , and (17), we obtain the second tightness inequality needed on the processes  $(Z^n)_{n \in \mathbb{N}}$ . The conclusion is immediate for  $(\mathbb{P}^n)_{n \in \mathbb{N}}$ .  $\square$

**7.3.4. Proof of Theorem 7.2.** We end the proof of Theorem 7.2 using compactness of the trajectories. Note first that if  $(\mathbb{P}^n, Y^n, W^n, Z^n)$  is weakly convergent toward  $(\mathbb{P}, Y, W, Z)$ , then  $(\mathbb{P}, Y, W, Z)$  is a solution of the reflected jump diffusion  $\Phi$  initialized to the weak limit of  $(\mathbb{P}^n(0), Y^n(0), W^n(0), Z^n(0))$  using the same argument of [26, Theorem 2.3].

While replacing  $(\mathbb{P}^n, \mathcal{F}^n)$  by  $\mathbb{P}^n$  and taking any sequence extracted from  $(\mathbb{P}^n)_{n \in \mathbb{N}}$ , we note  $(N_k)_{k \in \mathbb{N}}$  this extraction procedure and show that  $(\mathbb{P}^{N_k})_{k \in \mathbb{N}}$  is weakly convergent to the unique invariant measure  $\mu$ . Denote by  $\nu_\infty$  the weak limit of  $(\mathbb{P}^{N_k}(0))_{k \in \mathbb{N}}$ ; it is then sufficient to show that for any measurable function  $\phi$ ,

$$\mathbb{E}_{\nu_\infty} \phi = \mathbb{E}_\mu \phi.$$

Denote by  $P_\nu^t$  the law of our process at time  $t$  initialized by measure  $\nu$ , since  $\mu$  is the unique stationary measure we have for any compact set of measures  $K$ :

$$(18) \quad \forall \nu \in K \quad \forall \epsilon > 0, \quad \exists T > 0 \quad \forall t \geq T, \quad \left| \int \phi(y) dP_\nu^t - \int \phi(y) d\mu(y) \right| \leq \epsilon.$$

Taking  $\epsilon$  strictly positive and applying (18) to the family of measures  $K$  formed by the law of  $(\mathbb{P}^{N_k})_{k \in \mathbb{N}}$ , which is tight and thus compact, we find  $T$  such that

$$\forall t \geq T, \quad \left| \int \phi(y) dP_\nu^t - \int \phi(y) d\mu(y) \right| \leq \epsilon.$$

Now, if  $\nu'_\infty$  is the weak limit of the sequence of processes  $(\mathbb{P}^{N_k}(\cdot - T))_{k \in \mathbb{N}}$ , which is also the weak limit of  $(\mathbb{P}(\tau_{N_k} - T))_{k \in \mathbb{N}}$ , we have

$$\begin{aligned} \left| \int \phi(y) d\nu_\infty(y) - \int \phi(y) d\mu(y) \right| &\leq \left| \int \phi(y) d\nu_\infty(y) - \mathbb{E}[\phi(\mathbb{P}(\tau_{N_k}))] \right| \\ &\quad + \left| \mathbb{E}[\phi(\mathbb{P}(\tau_{N_k}))] - \int \phi(y) dP_{\nu'_\infty}^T(y) \right| \\ &\quad + \left| \int \phi(y) dP_{\nu'_\infty}^T(y) - \int \phi(y) d\mu(y) \right|. \end{aligned}$$

Making  $N_k \mapsto \infty$ , then  $\tau_{N_k} \mapsto \infty$ , and under our hypotheses on  $T$ ,  $\nu_\infty$ , and  $\nu'_\infty$ , we obtain

$$\left| \int \phi(y) d\nu_\infty(y) - \int \phi(y) d\mu(y) \right| \leq \epsilon.$$

Finally, we conclude that  $\nu_\infty = \mu$  and this fact ensures that  $(\mathbb{P}^n)_{n \in \mathbb{N}}$  and  $(\mathbb{P}^n(0))_{n \in \mathbb{N}}$  weakly converge toward  $\mu$ .

**8. Experiments.** We present here three experiments. The first one is a synthetic mixture model, and we compare our result with standard algorithms. The other databases are real problems on image processing and microarray data. In these last two cases, we use Fisher rule selection, random forest selection (see [8]), forward/backward selection, and OFW (optimal feature weighting) (see [18]) to draw comparisons with our method. In each of these cases, the number of selected features is computed using an internal cross-validation step.

### 8.1. Synthetic data.

**8.1.1. Description of the database.** We first test our algorithm on a simple synthetic example. We consider  $f = 100$  ternary variables ( $|\mathcal{F}| = 100$ ) and three classes (similar results can be obtained with more classes and variables). We let  $I \in \{-1; 0; 1\}^{100}$  and let  $\mathcal{G}$  be a subset of  $\mathcal{F}$ . We define the probability distribution  $\mu(\cdot; \mathcal{G})$  on  $\mathcal{I}$  to be the one for which all  $X^j$  in  $\mathcal{G}$  are independent,  $X^j(I)$  follows a uniform distribution on  $\{-1; 0; 1\}$  if  $X^j \notin \mathcal{G}$ , and  $X^j(I) = 1$  if  $X^j \in \mathcal{G}$ . We model each class by a mixture of such a distribution, including a small proportion of noise. More precisely, for a class  $C_i$ ,  $i = 1, 2, 3$ , we define

$$\mu_i(I) = \frac{q}{3} (\mu(I; \mathcal{G}_i^1) + \mu(I; \mathcal{G}_i^2) + \mu(I; \mathcal{G}_i^3)) + (1 - q)\mu(I; \emptyset),$$

with  $q = 0.9$  and

$$\begin{aligned} \mathcal{G}_1^1 &= \{X^1; X^3; X^5; X^7\}, & \mathcal{G}_1^2 &= \{X^1; X^5\}, & \mathcal{G}_1^3 &= \{X^3; X^7\}, \\ \mathcal{G}_2^1 &= \{X^2; X^4; X^6; X^8\}, & \mathcal{G}_2^2 &= \{X^2; X^4\}, & \mathcal{G}_2^3 &= \{X^6; X^8\}, \\ \mathcal{G}_3^1 &= \{X^1; X^4; X^8; X^9\}, & \mathcal{G}_3^2 &= \{X^1; X^8\}, & \mathcal{G}_3^3 &= \{X^4; X^9\}. \end{aligned}$$

We sample with this mixture model enough data to obtain well-conditioned statistical problems. We expect our learning algorithm to put large weights on features that compose the sets  $\mathcal{G}_i^j$  and to filter out the other noisy ones. The algorithm  $\mathbb{A}$  we use in this case is a  $p$  nearest neighbor classification algorithm, with distance given by

$$d(I_1, I_2) = \sum_j \mathbb{1}_{X^j(I_1) \neq X^j(I_2)}.$$

This synthetic example is interesting because it makes it possible to compute the exact gradient of  $\mathcal{E}$  for small values of  $M$  and  $k = |\omega|$ . See [17] and [18] for more details on this experiment when the set of features is fixed.

### 8.1.2. Results and comparisons with existing methods.

*OFW and jump algorithm.* We compare first the reflected diffusion (OFW of [18]) with our jump algorithm. Performances obtained with the jump algorithm are better than the ones without any jump as shown in Figure 3. The trees constructed by our algorithm are deeper than elementary ones since the mean depth achieved by our algorithm is 3. We compute the mean occupation measure of each tree in the process  $\mathcal{F}_t$  as

$$\mu_t(\mathcal{A}) = \frac{1}{t} \int_0^t \mathbb{1}_{\mathcal{A} \in \mathcal{F}_{ts}} ds.$$

We can then infer from this measure the importance of a tree while looking at the real numbers  $\mu_t(\mathcal{A})$ . We rank the nodes of these trees by decreasing importance of  $\mu_t(\mathcal{A})$  and we give the main roots detected by our algorithm below:

$$\{X^2; X^4\}, \{X^1; X^5\}, \{X^4; X^9\}, \{X^1; X^8\}, \{X^6; X^8\}, \{X^3; X^7\}, X^1, X^4, X^8.$$

It is important to remark that the nodes selected by our jump-diffusion algorithm are very similar to the sources  $\mathcal{G}_i^j$ , while the favored nodes are those which are *reusable features*.

One can, however, consider using standard feature selection techniques such as anova coupled with the logistic regression method or the more recent random forests feature selection.

FIG. 3. Evolution of the mean error rate for the reflected diffusion (crosses) and the reflected jump diffusion (dashed line).

*Backward selection, random forest, and Fisher selection.* We run first a ternary (three classes) logistic regression coupled with a backward selection based on the anova criterion. In this particular case, the selected features cannot be composed and interactions with features are completely missed. We logically obtain the subset of selected variables  $\{X^1; X^2; X^3; X^4; X^5; X^6; X^7; X^8; X^9\}$  with small  $p$ -value. This result is not surprising and is coherent with the selected features of the OFW [18] (diffusion algorithm without the jump process). Note also that the selected features here are the same while running the random forest selection method and we are convinced that in this simple example, several other classical criteria, such as PLS (partial least square method), AIC, etc., achieve the same result. Lastly, we remark that we do not run a forward selection method with the logistic regression because of the high number of features, which make this greedy method numerically costly.

*Learning composition: The forward/backward selection.* Next, we use the classical forward/backward selection method combined with logistic regression [21] since other feature selection methods, such as random forest, do not provide any composed features. In this very simple example (there are “only” 100 variables although typical real applications will use thousands of variables), the computational time to run this forward/backward selection is much more important (it takes several hours to stabilize the model). In addition to each singleton  $X^i$ , we obtain all subsets  $\mathcal{G}_i^j$  given in the description of the way we construct our synthetic example.

*Comparison.* To conclude this section on the synthetic data, we observe that many other feature selection algorithms achieve the identification of useful variables.

Only one of them (the forward/backward method coupled with detection of interactions) can also compose features. This method has an important numerical cost. If this method succeeds in locating the interactions between features, it does not provide a selection as small as our method does.

Moreover, the main drawback in this framework is that the forward/backward criterion can be performed only with a sufficiently large database (we need to have

FIG. 4. Sample of images taken from [27] database.

more observations than initial number of variables). This point is very annoying in some real applications such as microarray analysis, where standard situations are described with thousands of variables for less than 100 observations.

Lastly, the forward/backward algorithm is dedicated only to very special classification algorithms such as logistic regression, although we can apply our approach to every classification algorithm  $\mathbb{A}$ . It is an important point too since there does not exist a universal classifier that beats all other algorithms. It can thus be helpful to run our meta-jump algorithm to the more appropriate  $\mathbb{A}$  regarding the database which is studied.

## 8.2. Face recognition.

**8.2.1. Description of the database.** We use in this section the face database from [27], which contains  $19 \times 19$  grayscale images. The elementary features in  $\mathcal{F}_0$  are simply edge detectors constructed by Amit and Geman in [2]. The initial number of elementary features in  $\mathcal{F}_0$  is nearly 2000. The number of observations in this database is 7000 in the training set and 23,000 in the test set. Figure 4 presents some examples of images taken in this database.

### 8.2.2. Results and comparisons.

*OFW and jump algorithm.* Efficiency of the reflected diffusion (OFW algorithm) is already described in [18]. In this paper, our approach permits largely improved error rates on the same datasets and we can easily give an interpretation of features constructed by our jump-diffusion process. To illustrate these advantages, we can plot first in Figures 5 and 6 the evolution of the number of trees selected by our algorithm with time  $t$ .

The decreasing of the number of trees is consequently important since starting with almost 2000 features, we reduce the amount of variables to below 800. Even if this number seems to be strictly decreasing in Figure 5, this is not the case if we “zoom” the evolution of the cardinal  $t \mapsto |\mathcal{F}_t|$ , as shown in Figure 6.

Moreover, by using a linear SVM and a voting procedure with the subsets  $\omega^{(i)}$  extracted with the process  $\mathbb{P}_t$ , we obtain a null false positive rate (images taken from the font class are perfectly classified) and the global misclassification rate is improved

FIG. 5. Evolution of the number of trees in the forest  $\mathcal{F}_t$  with time for the face recognition problem.

FIG. 6. Microscopic evolution of the number of trees in the forest  $\mathcal{F}_t$  for the faces experiment.

since we get 1.2% misclassified test samples using only 650 features (3.5% error rate with the OFW approach without jump and the same amount of features).

*Comparison with random forest, Fisher selection, and forward/backward selection.* Without features composition, the random forest classifier provides more than 1000 useful features and gives a general misclassification rate of 1%; note also that this rate has been achieved using 1000 trees in the random forest. The Fisher selection method combined with a linear SVM algorithm yields an error rate of 4% with a selection

FIG. 7. Representation of the main aggregation of edge detectors selected by our process.

of more than 1000 features. Lastly, the logistic regression algorithm combined with forward/backward selection and composition performs poorly (more than 1000 useful features and 12% of misclassified signals). It seems here that the classifier  $\mathbb{A}$  used by the forward/backward (logistic regression) is not adequate for this database. This illustrates the fact that it is important to have a meta-algorithm to select features in order to apply any classifier which seems adapted to the problem. It is not the case with the forward/backward selection method.

In this case, the better global misclassification rate is obtained using the random forest selection method. Our method obtains good results too since only 1.2% of signals are misclassified. Lastly, the selection obtained using our jump algorithm is much more compact than the one obtained by random forest.

*Selected features.* We show in Figure 7 the main composition of edges selected by our process of jump diffusion. The important fact is that complex features (as well as elementary ones) are constructed and used by our algorithm. It is this point that permits us to obtain the perfect false positive rate since these complex compositions of features filter out the background images.

### 8.3. Leukemia microarray classification.

*Description of the database.* Finally, we benchmark our selection of features on the standard leukemia cancer dataset available online from the NCI.<sup>2</sup> Data are preprocessed and transformed into a collection of 3859 genes of 72 leukemia samples. They are divided into 47 samples of Acute Lymphoblastic Leukemia (ALL) and 25 samples of Acute Myeloblastic Leukemia (AML). As we cannot provide a simple meaning of concatenation of real variables, we only permit suppression ( $\mathcal{S}$ ) and rebirth ( $\mathcal{R}$ ) of some genes in  $\mathcal{F}_t$ . As this database does not contain any train or test sets, we estimate the misclassification rate using a tenfold cross-validation method. The cross-validation method is a good way to estimate performances of our algorithm [7].

<sup>2</sup>National Cancer Institute, <http://www.cancer.gov>.

FIG. 8. Mean error rate on the training set of the ALL-AML database with time  $t$ .

TABLE 1  
Rate of misclassified samples using several number of genes selected by our algorithm.

Number of genes	OFW	Reflected jump diffusion	Random forest	F-test
4-9	6.9%	4.8%	4%	5.5%
10-19	5.5%	4.3%	3.8%	4.2%
20-24	4.1%	2.1%	4.5%	4.1%
25-45	3.5%	0.9%	4.5%	4.8%

*Comparison with random forest, Fisher selection, and forward/backward selection.* After a learning procedure, we then ranked genes by a decreasing importance criterion based on the probability distribution  $\mathbb{P}_t$ . For the jump-diffusion method, we do not run a tenfold cross validation because of the time of computation needed by this method, and we then employ a more simple three-fold cross validation.

We use for  $\mathbb{A}$  a linear SVM classifier, and  $k = 100$  genes are extracted at each step. The evolution of the error rate all along our learning algorithm is shown in Figure 8. We obtain in [9] interesting results on classification rates on this database applying other algorithms such as CART to the OFW meta-algorithm.

We present in Table 1 results obtained using our jump process. We cannot run here a logistic regression coupled with a forward/backward algorithm because of the small number of signals in the database. The several selection methods used highlight the good performance of our jump algorithm, comparing it to standard methods such as Fisher tests.

Our results improve those referred to in [22], and the genes selected by our algorithm are consistent with some of the genes selected in other works (such as Zyxin in [11]). However, our selected features are nearly similar to those reported in [19]. One can again note the improvement using the jump process (second and third columns of Table 1).

Figure 9 represents the evolution of the number of genes selected at time  $t$ . In this case, we note again the good dimensionality reduction that permits our algorithm.

Finally, we can extract from the set of variables the names of genes most selected by our algorithm. We do not obtain exactly the same results for the 10 most important

genes listed in Figure 10 whether we use the OFW or the jump-diffusion approach.

**9. Conclusion.** From a theoretical point of view, we provide in this paper a mathematical algorithm to select variables in a large amount of features dealing with the general untractable problems using full data. This is not the case of filter methods (forward/backward, for instance) that use a heuristic strategy to compose features, and these methods are not useful in some situations. Our approach is based on a jump-diffusion stochastic differential equation, where jumps are transitions between spaces of features. We have seen that the structure of trees is convenient to deal with Markov processes since this enables us to identify the dynamical structure of our method. This method is highly motivated by real problems and we have shown (Theorem 7.2) the “optimality” of our algorithm since it converges toward the unique Gibbs field measure inferred from an energy  $\mathcal{E}$ .

From a practical point of view, we have reached interesting results in real data such as face recognition and microarray analysis, even if we do not perform any composition rule with this last database. We have obtained similar results as other standard methods on the synthetic example and have clearly overcome the forward/backward algorithm in the face recognition problem, which is the only other method known to permit features composition. On this last point, one can consider two hypotheses. Either the selected features are not so good with the forward/backward strategy

(it would be surprising) or (and it is the more likely) the classifier used after this selection is powerless compared to the SVM used with our method. This stresses the fact that our approach is usable with any classification algorithm: One can use for  $\mathbb{A}$  SVMs, linear discriminant analysis, random forests, etc., and it is well known that at the moment there does not exist one algorithm which performs best on all pattern recognition problems.

In a forthcoming paper, we will present several computational results on this algorithm applied to several databases described by thousands of variables. Numerically, it would be interesting to use our composition strategy with real variables (instead of binary or ternary ones) since we have not used it on the leukemia database, for instance.

Similarly, it would be useful to interpret the composition of real variables as a process to learn a kernel for the SVM. We believe that using a Rademacher penalty term in energy  $\mathcal{E}$  will improve the generalization ability of the algorithm and could permit us to obtain Oracle's inequality. Another improvement can be made using a simulated annealing strategy to fix the selected features to a deterministic version in the end of the algorithm.

**Acknowledgments.** This paper contains research performed during my thesis and I am glad to thank my Ph.D. advisor Laurent Younes for the numerous and helpful discussions we had on this occasion.

## STABILITY ANALYSIS OF SWITCHED TIME DELAY SYSTEMS\*

PENG YAN<sup>†</sup> AND HITAY ÖZBAY<sup>‡</sup>

**Abstract.** This paper addresses the asymptotic stability of switched time delay systems with heterogeneous time invariant time delays. Piecewise Lyapunov–Razumikhin functions are introduced for the switching candidate systems to investigate the stability in the presence of an infinite number of switchings. We provide sufficient conditions in terms of the minimum dwell time to guarantee asymptotic stability under the assumptions that each switching candidate is delay-independently or delay-dependently stable. Conservatism analysis is also provided by comparing with the dwell time conditions for switched delay-free systems. Finally, a numerical example is given to validate the results.

**Key words.** asymptotic stability, switched systems, time delay, dwell time

**1. Introduction.** Switching control offers a new look into the design of complex control systems (e.g., nonlinear systems, parameter varying systems, and uncertain systems) [1, 8, 9, 19, 21, 27]. Unlike the conventional adaptive control techniques that rely on continuous tuning, the switching control method updates the controller parameters in a discrete fashion based on the switching logic. The resulting closed-loop systems have hybrid behaviors (e.g., continuous dynamics, discrete time dynamics, and jump phenomena). One of the most challenging issues in the area of hybrid systems is the stability analysis in the presence of control switching. We refer to [9] for a general review on switching control methods.

In particular, we are interested in the stability analysis of switched time delay systems. In fact, time delay systems are ubiquitous in chemical processes, aerodynamics, and communication networks [3, 14]. To further complicate the situation, the time delays are usually time varying and uncertain [24, 26]. It has been shown that robust  $\mathcal{H}^\infty$  controllers can be designed for such infinite-dimensional plants, where robustness can be guaranteed within some uncertainty bounds [4]. In order to incorporate a larger operating range or better robustness, controller switching can be introduced, which results in switched closed-loop systems with time delays. For delay-free systems, stability analysis and design methodology have been investigated recently in the framework of hybrid dynamical systems [1, 2, 8, 11, 19, 21, 25]. In particular, [21] provided sufficient conditions on the stability of the switching control systems based on Filippov solutions to discontinuous differential equations and Lyapunov functionals; [19] proposed a dwell-time-based switching control, where a sufficiently large dwell time can guarantee system stability. A more flexible result was obtained in [10], where the average dwell time was introduced for switching control. In [25] the results of [10] were extended to linear parameter varying (LPV) systems. LaSalle’s invariance

principle was extended to a class of switched linear systems for stability analysis [8]. Despite the variety and significance of the many results on hybrid system stability, stability of switched time delay systems hasn't been adequately addressed due to the general difficulty of infinite-dimensional systems [7].

Two important approaches in the stability analysis of time delay systems are the (1) Lyapunov–Krasovskii method and (2) Lyapunov–Razumikhin method [6, 20]. Various sufficient conditions with respect to the stability of time delay systems have been given using Riccati-type inequalities or linear matrix inequalities (LMIs) [3, 12, 14, 24]. Meanwhile, stability analysis in the presence of switching has been discussed in some recent works [16, 18, 22]. In [18] stability and stabilizability were discussed for discrete time switched time delay systems; [16] considered a similar stability problem in a continuous time domain. Note that [18] and [16] produce *trajectory-dependent* results without taking admissible switching signals into consideration.

The main contribution of this paper is a collection of results on the *trajectory-independent* stability of continuous time switched time delay systems using piecewise Lyapunov–Razumikhin functions. The dwell time of the switching signals is constructively given, which guarantees asymptotic stability for the delay-independent case and the delay-dependent case, respectively. Note that the asymptotic stability of finite-dimensional linear systems indicates exponential stability, while this is not the case for infinite-dimensional systems [7, 15]. This poses the key challenge in the analysis of switched time delay systems, where we do not assume exponential convergence of the switching candidates, as opposed to most of the results in the literature [8, 10, 17, 19].

The paper is organized as follows. The problem is defined in section 2. In section 3, the main results on the stability of switched time delay systems are presented in terms of the dwell time of the switching signals. Conservatism analysis is provided by comparing with the dwell-time conditions for switching delay-free systems in section 4. The results are illustrated with a numerical example in section 5, followed by concluding remarks in section 6.

**2. Problem definition.** For convenience, we would like to employ the following notation. The general retarded functional differential equations (RFDEs) with time delay  $r$  can be described as

$$(2.1) \quad \dot{x}(t) = f(t, x_t)$$

with initial condition  $\phi(\cdot) \in C([-r, 0], \mathbb{R}^n)$ , where  $x_t$  denotes the state defined by  $x_t(\theta) = x(t + \theta)$ ,  $-r \leq \theta \leq 0$ . We use  $\|\cdot\|$  to denote the Euclidean norm of a vector in  $\mathbb{R}^n$ , and  $\|f\|_{[t-r, t]}$  for the  $\infty$ -norm of  $f$ , i.e.,

$$\|f\|_{[t-r, t]} := \sup_{t-r \leq \theta \leq t} \|f(\theta)\|,$$

where  $f$  is an element of the Banach space  $C([t-r, t], \mathbb{R}^n)$ .

Consider the following switched time delay systems:

$$(2.2) \quad \Sigma_t : \begin{cases} \dot{x}(t) = A_{q(t)}x(t) + \bar{A}_{q(t)}x(t - \tau_{q(t)}), & t \geq 0, \\ x_0(\theta) = \phi(\theta) \quad \forall \theta \in [-\tau_{max}, 0], \end{cases}$$

where  $x(t) \in \mathbb{R}^n$  and  $q(t)$  is a piecewise switching signal taking values on the set  $\mathcal{F} := \{1, 2, \dots, l\}$ , i.e.,  $q(t) = k_j$ ,  $k_j \in \mathcal{F} \quad \forall t \in [t_j, t_{j+1})$ , where  $t_j$ ,  $j \in \mathbb{Z}^+ \cup \{0\}$ , is the  $j$ th switching time instant. It is clear that the trajectory of  $\Sigma_t$  in any arbitrary

switching interval  $t \in [t_j, t_{j+1})$  obeys

$$(2.3) \quad \Sigma_{k_j} : \begin{cases} \dot{x}(t) = A_{k_j}x(t) + \bar{A}_{k_j}x(t - \tau_{k_j}), & t \in [t_j, t_{j+1}), \\ x_{t_j}(\theta) = \phi_j(\theta) \quad \forall \theta \in [-\tau_{k_j}, 0], \end{cases}$$

where  $\phi_j(\theta)$  is defined as

$$(2.4) \quad \phi_j(\theta) = \begin{cases} x(t_j + \theta), & -\tau_{k_j} \leq \theta < 0, \\ \lim_{h \rightarrow 0^-} x(t_j + h), & \theta = 0. \end{cases}$$

We introduce the triplet  $\Sigma_i := (A_i, \bar{A}_i, \tau_i) \in \mathbb{R}^{n \times n} \times \mathbb{R}^{n \times n} \times \mathbb{R}^+$  to describe the  $i$ th candidate system of (2.2). Thus  $\forall t \geq 0$ , we have  $\Sigma_t \in \mathcal{A} := \{\Sigma_i : i \in \mathcal{F}\}$ , where  $\mathcal{A}$  is the family of candidate systems of (2.2). In (2.2),  $\phi(\cdot) : [-\tau_{max}, 0] \rightarrow \mathbb{R}^n$  is a continuous and bounded vector-valued function, where  $\tau_{max} = \max_{i \in \mathcal{F}} \{\tau_i\}$  is the maximal time delay of the candidate systems in  $\mathcal{A}$ .

Similar to [8], we say that the switched time delay system  $\Sigma_t$  described by (2.2) is *stable* if there exists a function  $\bar{\alpha}$  of class  $\mathcal{K}^1$  such that

$$(2.5) \quad \|x(t)\| \leq \bar{\alpha}(\|x\|_{[t_0 - \tau_{max}, t_0]}) \quad \forall t \geq t_0 \geq 0$$

along the trajectory of (2.2). Furthermore,  $\Sigma_t$  is *asymptotically stable* when  $\Sigma_t$  is stable and  $\lim_{t \rightarrow +\infty} x(t) = 0$ .

LEMMA 2.1 (see [3, 14]). *Suppose for a given triplet  $\Sigma_i \in \mathcal{A}$ ,  $i \in \mathcal{F}$ , there exists symmetric and positive-definite  $P_i \in \mathbb{R}^{n \times n}$ , such that the following LMI with respect to  $P_i$  is satisfied for some  $p_i > 1$  and  $\alpha_i > 0$ :*

$$(2.6) \quad \begin{bmatrix} P_i A_i + A_i^T P_i + p_i \alpha_i P_i & P_i \bar{A}_i \\ \bar{A}_i^T P_i & -\alpha_i P_i \end{bmatrix} < 0.$$

*Then  $\Sigma_i$  is asymptotically stable independent of delay.*

If all candidate systems of (2.2),  $\Sigma_i \in \mathcal{A}$ , are delay-independently asymptotically stable satisfying (2.6), we denote  $\mathcal{A}$  by  $\tilde{\mathcal{A}}$ .

LEMMA 2.2 (see [3, 14]). *Suppose for a given triplet  $\Sigma_i \in \mathcal{A}$ ,  $i \in \mathcal{F}$ , there exists symmetric and positive-definite  $P_i \in \mathbb{R}^{n \times n}$ , and a scalar  $p_i > 1$ , such that*

$$(2.7) \quad \begin{bmatrix} \tau_i^{-1} \Omega_i & P_i \bar{A}_i M_i \\ M_i^T \bar{A}_i^T P_i & -R_i \end{bmatrix} < 0,$$

where

$$\begin{aligned} \Omega_i &= (A_i + \bar{A}_i)^T P_i + P_i (A_i + \bar{A}_i) + \tau_i p_i (\alpha_i + \beta_i) P_i, \\ M_i &= [A_i \quad \bar{A}_i], \\ R_i &= \text{diag}(\alpha_i P_i, \beta_i P_i), \end{aligned}$$

*and  $\alpha_i > 0$ ,  $\beta_i > 0$  are scalars. Then  $\Sigma_i$  is asymptotically stable dependent on delay.*

Similarly we denote  $\mathcal{A}$  by  $\tilde{\mathcal{A}}_d$  if all candidate systems of (2.2) are delay-dependently asymptotically stable satisfying (2.7).

<sup>1</sup>A continuous function  $\bar{\alpha}(\cdot) : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  is a class  $\mathcal{K}$  function if it is strictly increasing and  $\bar{\alpha}(0) = 0$ .

In what follows, we will establish sufficient conditions to guarantee stability of switched system (2.2) for the delay-independent case and the delay-dependent case. Therefore, we will assume that  $\mathcal{A} = \tilde{\mathcal{A}}$  and  $\mathcal{A} = \tilde{\mathcal{A}}_d$ , respectively, in the corresponding sections in this paper. An important method in stability analysis of switched systems is based on the construction of the common Lyapunov function (CLF), which allows for arbitrary switching. However, this method is too conservative from the perspective of controller design because it is usually difficult to find the CLF for all the candidate systems, particularly for time delay systems whose stability criteria are only sufficient in most of the circumstances. A recent paper [28] explored the CLF method for switched time delay systems with three very strong assumptions: (i) each candidate system has the same time delay  $\tau$ ; (ii) each candidate is assumed to be delay-independently stable; (iii) the  $A$ -matrix is always symmetric and the  $\bar{A}$ -matrix is always in the form of  $\delta I$ . In the present paper, we consider an alternative method using piecewise Lyapunov–Razumikhin functions for a general class of systems (2.2) and obtain stability conditions in terms of the dwell time of the switching signal. This method can be used for the case with delay-independent criterion (2.6) and the case with delay-dependent criterion (2.7).

**3. Main results on dwell-time-based switching.** For a given positive constant  $\tau_D$ , the switching signal set based on the dwell time  $\tau_D$  is denoted by  $S[\tau_D]$ , where for any switching signal  $q(t) \in S[\tau_D]$ , the distance between any consecutive discontinuities of  $q(t)$ ,  $t_{j+1} - t_j$ ,  $j \in \mathbb{Z}^+ \cup \{0\}$ , is larger than  $\tau_D$  [10, 19]. A sufficient condition on the minimum dwell time to guarantee the stable switching will be given using piecewise Lyapunov–Razumikhin functions. Note that the dwell-time-based switching is trajectory independent [8].

Before presenting the main result of this paper, we recall the following lemma [7] for general RFDEs (2.1).

LEMMA 3.1 (see [7]). *Suppose  $u, v, w, p : \mathbb{R}^+ \rightarrow \mathbb{R}^+$  are continuous, nondecreasing functions,  $u(0) = v(0) = 0$ ,  $u(s), v(s), w(s), p(s)$  positive for  $s > 0$ ,  $p(s) > s$ , and  $v(s)$  strictly increasing. If there is a continuous function  $V : \mathbb{R} \times \mathbb{R}^n \rightarrow \mathbb{R}$  such that*

$$(3.1) \quad u(\|x(t)\|) \leq V(t, x) \leq v(\|x(t)\|), \quad t \in \mathbb{R}, x \in \mathbb{R}^n,$$

and

$$(3.2) \quad \dot{V}(t, x(t)) \leq -w(\|x(t)\|)$$

if

$$(3.3) \quad V(t + \theta, x(t + \theta)) < p(V(t, x(t))) \quad \forall \theta \in [-r, 0],$$

then the solution  $x = 0$  of the RFDE is uniformly asymptotically stable.

A particular case of (2.1) is a linear time delay system  $\Sigma_i$ ,  $i \in \mathcal{F}$ , where we can construct the corresponding Lyapunov–Razumikhin function in the quadratic form

$$(3.4) \quad V_i(t, x) = x^T(t) P_i x(t), \quad P_i = P_i^T > 0.$$

Apparently  $V_i$  can be bounded by

$$(3.5) \quad u_i(\|x(t)\|) \leq V_i(t, x) \leq v_i(\|x(t)\|) \quad \forall x \in \mathbb{R}^n,$$

where

$$(3.6) \quad u_i(s) := \kappa_i s^2, \quad v_i(s) := \bar{\kappa}_i s^2,$$

in which  $\kappa_i := \sigma_{\min}[P_i] > 0$  denotes the smallest singular value of  $P_i$  and  $\bar{\kappa}_i := \sigma_{\max}[P_i] > 0$  the largest singular value of  $P_i$ .

PROPOSITION 3.2. *For each time delay system  $\Sigma_i$  with Lyapunov–Razumikhin function defined by (3.4), assume that (3.2) and (3.3) are satisfied for some  $w_i(s)$ . Then we have*

$$(3.7) \quad |x|_{[t_m - \tau_i, t_m]} \leq \left( \frac{\bar{\kappa}_i}{\kappa_i} \right)^{1/2} |x|_{[t_n - \tau_i, t_n]} \quad \forall t_m \geq t_n \geq 0.$$

*Proof.* Define

$$(3.8) \quad \bar{V}_i(t, x) := \sup_{-\tau_i \leq \theta \leq 0} V_i(t + \theta, x(t + \theta))$$

for  $t \geq 0$ . We have

$$(3.9) \quad \kappa_i(|x|_{[t - \tau_i, t]})^2 \leq \bar{V}_i(t, x) \leq \bar{\kappa}_i(|x|_{[t - \tau_i, t]})^2, \quad t \geq 0.$$

The definition of  $\bar{V}_i(t, x)$  implies  $\exists \theta_0 \in [-\tau_i, 0]$ , such that  $\bar{V}_i(t, x) = V(t + \theta_0, x(t + \theta_0))$ . Introduce the upper right-hand derivative of  $\bar{V}_i(t, x)$  as

$$\dot{\bar{V}}_i^+ = \limsup_{h \rightarrow 0^+} \frac{1}{h} [\bar{V}_i(t + h, x(t + h)) - \bar{V}_i(t, x(t))].$$

We have the following:

- (i) If  $\theta_0 = 0$ , i.e.,  $V_i(t + \theta, x(t + \theta)) \leq V_i(t, x(t)) < p(V_i(t, x(t)))$ , we have  $\dot{\bar{V}}_i(t, x) < 0$  by (3.2). Therefore  $\dot{\bar{V}}_i^+ \leq 0$ .
- (ii) If  $-\tau_i < \theta_0 < 0$ , we have  $\bar{V}_i(t + h, x(t + h)) = \bar{V}_i(t, x)$  for  $h > 0$  sufficiently small, which results in  $\dot{\bar{V}}_i^+ = 0$ .
- (iii) If  $\theta_0 = -\tau_i$ , the continuity of  $V_i(t, x)$  implies  $\dot{\bar{V}}_i^+ \leq 0$ .

The above analysis shows that

$$(3.10) \quad \bar{V}_i(t_m) \leq \bar{V}_i(t_n) \quad \forall t_m \geq t_n \geq 0.$$

Recalling (3.9), we have

$$(3.11) \quad \kappa_i(|x|_{[t_m - \tau_i, t_m]})^2 \leq \bar{V}_i(t_m) \leq \bar{V}_i(t_n) \leq \bar{\kappa}_i(|x|_{[t_n - \tau_i, t_n]})^2$$

for any  $t_m \geq t_n \geq 0$ . This implies (3.7) and proves the result.  $\square$

Suppose all of the conditions of Lemma 3.1 are satisfied for general RFDEs (2.1). We also have the following result.

LEMMA 3.3 (see [7]). *Suppose  $|\phi|_{[t_0 - r, t_0]} \leq \bar{\delta}_1$ ,  $\bar{\delta}_1 > 0$ , and  $\bar{\delta}_2 > 0$  such that  $v(\bar{\delta}_1) = u(\bar{\delta}_2)$ . For all  $\eta$  satisfying  $0 < \eta \leq \bar{\delta}_2$ , we have*

$$(3.12) \quad V(t, x) \leq u(\eta) \quad \forall t \geq t_0 + T.$$

Here

$$(3.13) \quad T = \frac{Nv(\bar{\delta}_1)}{\gamma}$$

is defined by  $\gamma = \inf_{v^{-1}(u(\eta)) \leq s \leq \bar{\delta}_2} w(s)$  and  $N = \lceil (v(\bar{\delta}_1) - u(\eta))/a \rceil$ , where  $\lceil \cdot \rceil$  is the ceiling integer function and  $a > 0$  satisfies  $p(s) - s > a$  for  $u(\eta) \leq s \leq v(\bar{\delta}_1)$ .

**3.1. The case with delay-independent criterion.** Consider the switched time delay systems  $\Sigma_t$  defined by (2.2) and assume each candidate system  $\Sigma_i$ ,  $i \in \mathcal{F}$ , delay-independently asymptotically stable satisfying (2.6) (i.e.,  $\mathcal{A} = \tilde{\mathcal{A}}$ ). A sufficient condition on the minimum dwell time to guarantee the asymptotic stability can be derived using multiple piecewise Lyapunov–Razumikhin functions. In order to state the main result we make some preliminary definitions.

For the switched delay systems (2.2), first assume  $\tau_D > \tau_{max}$ . Consider an arbitrary switching interval  $[t_j, t_{j+1})$  of the piecewise switching signal  $q(t) \in S[\tau_D]$ , where  $q(t) = k_j$ ,  $k_j \in \mathcal{F} \forall t \in [t_j, t_{j+1})$  and  $t_j$  is the  $j$ th switching time instant for  $j \in \mathbb{Z}^+ \cup \{0\}$  and  $t_0 = 0$ . The state variable  $x_j(t)$  defined on this interval obeys (2.3). For the convenience of using “sup”, we define  $x_j(t_{j+1}) = \lim_{h \rightarrow 0^-} x_j(t_{j+1} + h) = x_{j+1}(t_{j+1})$  based on the fact that  $x(t)$  is continuous for  $t \geq 0$ . Therefore  $x_j(t)$  is now defined on a compact set  $[t_j, t_{j+1}]$ . Recall (2.4); the initial condition  $\phi_j(t)$  of  $\Sigma_{k_j}$  is  $\phi_j(t) = x(t) = x_{j-1}(t)$ ,  $t \in [t_j - \tau_{k_j}, t_j]$  for  $j \in \mathbb{Z}^+$ , which is true because  $\tau_D > \tau_{max}$ .

Construct the Lyapunov–Razumikhin function

$$(3.14) \quad V_{k_j}(x_j, t) = x_j^T(t) P_{k_j} x_j(t), \quad t \in [t_j, t_{j+1}],$$

for (2.3). Then we have

$$(3.15) \quad \kappa_{k_j} \|x_j(t)\|^2 \leq V_{k_j}(t, x_j) \leq \bar{\kappa}_{k_j} \|x_j(t)\|^2 \quad \forall x_j \in \mathbb{R}^n.$$

A straightforward calculation gives the time derivative of  $V_{k_j}(t, x_j(t))$  along the trajectory of (2.3),

$$(3.16) \quad \dot{V}_{k_j}(t, x_j) = x_j^T (A_{k_j}^T P_{k_j} + P_{k_j} A_{k_j}) x_j + 2x_j^T(t) P_{k_j} \bar{A}_{k_j} x_j(t - \tau_{k_j}),$$

where

$$\begin{aligned} & 2x_j^T(t) P_{k_j} \bar{A}_{k_j} x_j(t - \tau_{k_j}) \\ & \leq \alpha_{k_j} x_j^T(t - \tau_{k_j}) P_{k_j} x_j(t - \tau_{k_j}) \\ & \quad + \alpha_{k_j}^{-1} x_j^T(t) P_{k_j} \bar{A}_{k_j} P_{k_j}^{-1} \bar{A}_{k_j}^T P_{k_j} x_j(t) \quad \forall \alpha_{k_j} > 0. \end{aligned}$$

Applying the Razumikhin condition with  $p(s) = p_{k_j} s$ ,  $p_{k_j} > 1$ , we obtain

$$(3.17) \quad x_j^T(t - \tau_{k_j}) P_{k_j} x_j(t - \tau_{k_j}) \leq p_{k_j} x_j^T(t) P_{k_j} x_j(t)$$

for

$$V_{k_j}(t + \theta, x_j(t + \theta)) < p_{k_j} V_{k_j}(t, x_j(t)) \quad \forall \theta \in [-\tau_{k_j}, 0].$$

Let

$$(3.18) \quad S_{k_j} := -(A_{k_j}^T P_{k_j} + P_{k_j} A_{k_j} + p_{k_j} \alpha_{k_j} P_{k_j} + \alpha_{k_j}^{-1} P_{k_j} \bar{A}_{k_j} P_{k_j}^{-1} \bar{A}_{k_j}^T P_{k_j}).$$

We have

$$(3.19) \quad \dot{V}_{k_j}(t, x_j) \leq -x_j^T(t) S_{k_j} x_j(t).$$

Because  $\Sigma_t \in \tilde{\mathcal{A}}$ , we have  $S_{k_j} > 0$  from Lemma 2.1. Furthermore we can select  $w(s) = w_{k_j} s^2$  in Lemma 3.1, such that (3.2) is satisfied, where  $w_{k_j} := \sigma_{min}[S_{k_j}] > 0$ .

Define

$$(3.20) \quad \lambda := \max_{i \in \mathcal{F}} \frac{\bar{\kappa}_i}{\kappa_i}$$

and

$$(3.21) \quad \mu := \max_{i \in \mathcal{F}} \frac{\bar{\kappa}_i}{w_i}.$$

Now we are ready to state the main result.

**THEOREM 3.4.** *Let the dwell time be defined by  $\tau_D := T^* + \tau_{max}$ , where*

$$(3.22) \quad T^* := \lambda\mu \left\lfloor \frac{\lambda - 1}{\bar{p} - 1} + 1 \right\rfloor,$$

with  $\bar{p} := \min_{i \in \mathcal{F}} \{p_i\} > 1$ , and  $\lfloor \cdot \rfloor$  being the floor integer function. Then the system (2.2) with  $\Sigma_t \in \bar{\mathcal{A}}$  is asymptotically stable for any switching rule  $q(t) \in S[\tau_D]$ .

*Proof.* First we claim that  $\forall \tau > \tau_D$ , there exist  $0 < \beta < 1$  and  $0 < \alpha < 1$ , such that  $\tau \geq \bar{T} + \tau_{max}$ , where

$$(3.23) \quad \bar{T} := \frac{\lambda\mu}{\alpha^2} \left\lfloor \frac{\lambda - \alpha^2}{\alpha^2\beta(\bar{p} - 1)} \right\rfloor.$$

For a given  $\tau$ , to find such  $\alpha$  and  $\beta$  define  $\tilde{T} + \tau_{max} := \tau > \tau_D = T^* + \tau_{max}$ , and consider the two cases below.

- (1) If  $\lfloor (\lambda - 1)/(\bar{p} - 1) \rfloor =: k < (\lambda - 1)/(\bar{p} - 1) < k + 1$ , then we can find  $\Delta_1 > 0$  and  $\Delta_2 > 0$  small enough, such that

$$\left\lfloor \frac{\lambda - \alpha_1^2}{\alpha_1^2\beta(\bar{p} - 1)} \right\rfloor = \left\lfloor \frac{\lambda - 1}{\bar{p} - 1} \right\rfloor = k + 1 = \left\lfloor \frac{\lambda - 1}{\bar{p} - 1} + 1 \right\rfloor$$

with  $\alpha_1 = (1 + \Delta_1)^{-\frac{1}{2}} < 1$  and  $\beta = (1 + \Delta_2)^{-\frac{1}{2}} < 1$ . Let  $\tilde{T} = T^* + \epsilon$ ,  $\epsilon > 0$ . It is easy to check that

$$(3.24) \quad \frac{\lambda\mu}{\alpha_2^2} \left\lfloor \frac{\lambda - \alpha_1^2}{\alpha_1^2\beta(\bar{p} - 1)} \right\rfloor = \frac{\lambda\mu}{\alpha_2^2} (k + 1) \leq (k + 1)\lambda\mu + \epsilon = \tilde{T},$$

where  $0 < \alpha_2 = (1 + \Delta_3)^{-\frac{1}{2}} < 1$  with  $0 < \Delta_3 \leq \frac{\epsilon}{(k+1)\lambda\mu}$ . Now choosing  $0 < \alpha = \max\{\alpha_1, \alpha_2\} < 1$ , we have  $\bar{T} \leq \tilde{T}$ , which is straightforward from (3.23) and (3.24).

- (2) If  $(\lambda - 1)/(\bar{p} - 1) = k > 0$  is an integer, then we can similarly find  $0 < \alpha_1 < 1$  and  $0 < \beta < 1$  such that

$$\left\lfloor \frac{\lambda - \alpha_1^2}{\alpha_1^2\beta(\bar{p} - 1)} \right\rfloor = \left\lfloor \frac{\lambda - 1}{\bar{p} - 1} + 1 \right\rfloor = k + 1 = \left\lfloor \frac{\lambda - 1}{\bar{p} - 1} + 1 \right\rfloor.$$

In the same fashion as (1), we can constructively have  $0 < \alpha < 1$  and  $0 < \beta < 1$  such that  $\bar{T} \leq \tilde{T}$ .

This proves the first claim.

The second claim we make is that  $\|x_j(t)\| \leq \alpha\delta_j$  for any  $t \geq t_j + \bar{T}$ ,  $t \in [t_j, t_{j+1}]$ , where we assume  $|\phi_j(t)|_{[t_j - \tau_{k_j}, t_j]} \leq \delta_j$ . To show this fact, we can choose  $\delta_1 = \delta_j$ ,

$\bar{\delta}_2 = \bar{\delta}_1 \sqrt{\bar{\kappa}_{k_j}/\kappa_{k_j}} \geq \bar{\delta}_1$ , and select  $\eta = \alpha \bar{\delta}_1$  in Lemma 3.3. It is straightforward that  $0 < \eta < \bar{\delta}_1 \leq \bar{\delta}_2$ . Recalling (3.12) and (3.13), we have

$$(3.25) \quad V_{k_j}(t, x_j) \leq \kappa_{k_j} \eta^2 \quad \text{for } t \geq t_j + T,$$

where

$$(3.26) \quad \begin{aligned} T &= \frac{Nv(\bar{\delta}_1)}{\gamma} \frac{[(v(\bar{\delta}_1) - u(\eta))/a]v(\bar{\delta}_1)}{\inf_{v^{-1}(u(\eta)) \leq s \leq \bar{\delta}_2} w(s)} \\ &= \frac{\bar{\kappa}_{k_j}^2 [(v(\bar{\delta}_1) - u(\eta))/a]}{\alpha^2 w_{k_j} \kappa_{k_j}}. \end{aligned}$$

Combining (3.15) and (3.25) yields

$$(3.27) \quad \|x_j(t)\| \leq \alpha \delta_j \quad \text{for } t \geq t_j + T.$$

Now choosing  $a = \beta(p_{k_j} - 1)\kappa_{k_j}\eta^2$ , we have

$$(3.28) \quad T = \frac{\bar{\kappa}_{k_j}^2 \left[ \frac{(\bar{\kappa}_{k_j}/\kappa_{k_j}) - \alpha^2}{\alpha^2 \beta(p_{k_j} - 1)} \right]}{\alpha^2 w_{k_j} \kappa_{k_j}} \leq \bar{T}.$$

Therefore from (3.27) and (3.28) we have

$$(3.29) \quad |x_j|_{[t_j + \bar{T}, t_{j+1}]} \leq \alpha \delta_j,$$

as claimed.

Now recall that  $t_{j+1} - t_j > \tau_D$ . Therefore  $t_{j+1} - t_j \geq \bar{T} + \tau_{max} \geq \bar{T} + \tau_{k_{j+1}}$ . Also notice that  $\phi_{j+1}(t) = x_j(t)$ ,  $t \in [t_{j+1} - \tau_{k_{j+1}}, t_{j+1}]$ . We have

$$(3.30) \quad \begin{aligned} |\phi_{j+1}|_{[t_{j+1} - \tau_{k_{j+1}}, t_{j+1}]} &= |x_j|_{[t_{j+1} - \tau_{k_{j+1}}, t_{j+1}]} \\ &\leq |x_j|_{[t_j + \bar{T}, t_{j+1}]} \leq \alpha \delta_j := \delta_{j+1} \end{aligned}$$

and  $\delta_0$  is defined as  $\delta_0 := |\phi|_{[-\tau_{max}, 0]} \geq |\phi|_{[-\tau_{k_0}, 0]}$ . Therefore we obtain a convergent sequence  $\{\delta_i\}$ ,  $i = 0, 1, 2, \dots$ , where  $\delta_i = \alpha^i \delta_0$ .

Meanwhile, (3.7) implies

$$(3.31) \quad |x_j|_{[t - \tau_{k_j}, t]} \leq \sqrt{\frac{\bar{\kappa}_{k_j}}{\kappa_{k_j}}} |x_j|_{[t_j - \tau_{k_j}, t_j]} \quad \forall t \in [t_j, t_{j+1}].$$

Hence

$$(3.32) \quad \begin{aligned} &\sup_{t \in [t_j, t_{j+1}]} \|x_j(t)\| \\ &\leq \sup_{t \in [t_j, t_{j+1}]} |x_j|_{[t - \tau_{k_j}, t]} \leq \sqrt{\lambda} |x_j|_{[t_j - \tau_{k_j}, t_j]} \\ &\leq \sqrt{\lambda} \delta_j = \alpha^j \sqrt{\lambda} \delta_0, \end{aligned}$$

which implies the asymptotic stability of the switched time delay system  $\Sigma_t$  with the switching signal  $q(t) \in S_{[\tau_D]}$ .  $\square$

**3.2. The case with delay-dependent criterion.** In a similar fashion, we can investigate the stability of the switched time delay system  $\Sigma_t$  of (2.2) under the assumption that  $\Sigma_t \in \bar{\mathcal{A}}_d$ . Hence each candidate system  $\Sigma_i$ ,  $i \in \mathcal{F}$ , is delay-dependently asymptotically stable satisfying (2.7). We assume  $\tau_D^d > 2\tau_{max}$  in this scenario. Similar to the proof of Theorem 3.4, we consider an arbitrary switching interval  $[t_j, t_{j+1})$  of the piecewise switching signal  $q(t) \in S[\tau_D^d]$ , where the state variable  $x_j(t)$  defined on this interval obeys (2.3). The first order model transformation [7] of (2.3) results in

$$(3.33) \quad \begin{aligned} \dot{x}_j(t) = & (A_{k_j} + \bar{A}_{k_j})x_j(t) \\ & - \bar{A}_{k_j} \int_{-\tau_{k_j}}^0 [A_{k_j}x_j(t+\theta) + \bar{A}_{k_j}x(t+\theta-\tau_{k_j})]d\theta, \end{aligned}$$

where the initial condition  $\psi_j(t)$  is defined as  $\psi_j(t) = x_{j-1}(t)$ ,  $t \in [t_j - 2\tau_{k_j}, t_j]$ , for  $j \in \mathbb{Z}^+$ , and  $\psi_0(t)$  defined by

$$\psi_0(t) = \begin{cases} \phi(t), & t \in [-\tau_{max}, 0], \\ \phi(-\tau_{max}), & t \in [-2\tau_{max}, -\tau_{max}). \end{cases}$$

By using the Lyapunov–Razumikhin function (3.14), we obtain the time derivative of  $V_{k_j}(t, x_j(t))$  along the trajectory of (3.33),

$$\begin{aligned} \dot{V}_{k_j}(t, x_j) = & x_j^T(t)[P_{k_j}(A_{k_j} + \bar{A}_{k_j}) + (A_{k_j} + \bar{A}_{k_j})^T P_{k_j}]x_j(t) \\ & - \int_{-\tau_{k_j}}^0 [2x_j^T(t)P_{k_j}\bar{A}_{k_j}(A_{k_j}x_j(t+\theta) + \bar{A}_{k_j}x_j(t+\theta-\tau_{k_j}))]d\theta. \end{aligned}$$

Assume  $V_{k_j}(t+\theta, x_j(t+\theta)) < p(V_{k_j}(t, x_j(t))) \quad \forall \theta \in [-2\tau_{k_j}, 0]$ , where  $p(s) = p_{k_j}s$ ,  $p_{k_j} > 1$ . We have [3, 14]

$$(3.34) \quad \dot{V}_{k_j}(t, x_j) \leq -x_j^T(t)S_{k_j}^d x_j(t),$$

where

$$(3.35) \quad \begin{aligned} S_{k_j}^d := & - \left\{ P_{k_j}(A_{k_j} + \bar{A}_{k_j}) + (A_{k_j} + \bar{A}_{k_j})^T P_{k_j} \right. \\ & + \tau_{k_j} \left[ \alpha_{k_j}^{-1} P_{k_j} \bar{A}_{k_j} A_{k_j} P_{k_j}^{-1} \bar{A}_{k_j}^T A_{k_j}^T P_{k_j} \right. \\ & \left. \left. + \beta_i^{-1} P_{k_j} (\bar{A}_{k_j})^2 P_{k_j}^{-1} (\bar{A}_{k_j}^T)^2 P_{k_j} + p_{k_j}(\alpha_{k_j} + \beta_{k_j}) P_{k_j} \right] \right\}. \end{aligned}$$

Because  $\Sigma_t \in \tilde{\mathcal{A}}_d$ , we have  $S_{k_j}^d > 0$  from Lemma 2.2. Therefore we can select  $w(s) = w_{k_j}^d s^2$  in Lemma 3.1, such that (3.2) holds, where  $w_{k_j}^d := \sigma_{min}[S_{k_j}^d] > 0$ .

**THEOREM 3.5.** *Let the dwell time be  $\tau_D^d := T_d^* + 2\tau_{max}$ , where*

$$(3.36) \quad T_d^* := \lambda \mu_d \left[ \frac{\lambda - 1}{\bar{p} - 1} + 1 \right],$$

with

$$(3.37) \quad \mu_d := \max_{i \in \mathcal{F}} \frac{\bar{\kappa}_i}{w_i^d}$$

and the other parameters are the same as those defined in Theorem 3.4. Then system (2.2) with  $\Sigma_t \in \tilde{\mathcal{A}}_d$  is asymptotically stable for any switching rule  $q(t) \in S[\tau_D^d]$ .

*Proof.* We can apply arguments similar to those used in the proof of Theorem 3.4 to obtain the following inequality:

$$(3.38) \quad \sup_{t \in [t_j, t_{j+1}]} \|x_j(t)\| \leq \sqrt{\lambda} \delta_j^d,$$

where  $|\psi_j(t)|_{[t_j - 2\tau_{k_j}, t_j]} \leq \delta_j^d$  and  $\delta_{j+1}^d = \alpha \delta_j^d$ . Note that  $\delta_0^d$  can be selected as

$$\delta_0^d := |\psi|_{[-2\tau_{max}, 0]} = |\phi|_{[-\tau_{max}, 0]} = \delta_0.$$

It is clear that  $|\psi|_{[-2\tau_{k_0}, 0]} \leq \delta_0^d$ , which further implies  $\delta_j^d = \delta_j$ ,  $j \in \mathbb{Z}^+ \cup \{0\}$ . The upper bound of the state variable  $x(t)$  of the switched time delay systems  $\Sigma_t$  is bounded by a decreasing sequence  $\{\delta_i\}$ ,  $i = 0, 1, 2, \dots$ , converging to zero, which implies the asymptotic stability and proves this theorem.  $\square$

The dwell-time-based stability analysis proposed in this paper is general in the sense that it can be used for other stability results based on Razumikhin theorems as long as the correspondingly Lyapunov functions are in quadratic forms. Particularly, Theorem 3.5 can be extended easily to the case where  $\Sigma_t$  has time-varying time delays and parameter uncertainties, which has important applications such as TCP (transmission control protocol) congestion control of computer networks [13, 26].

*Remark 3.6.* Note that the Lyapunov–Krasovskii method has been used to analyze the stability of time delay systems, with which some less conservative stability conditions have been provided [5]. However, it is difficult to employ piecewise Lyapunov–Krasovskii functionals for dwell-time-based analysis similar to Theorems 3.4 and 3.5. Recall the general form of Lyapunov–Krasovskii functional  $V(t, x_t)$  [20] for delay system (2.1), such that

$$u(\|x(t)\|) \leq V(t, x_t) \leq v(|x|_{[t-\tau, t]}), \quad t \in \mathbb{R}, \quad x \in \mathbb{R}^n,$$

and

$$\dot{V}(t, x(t)) \leq -w(\|x(t)\|).$$

The upper bound of  $V(t, x_t)$  is dependent on the  $\infty$ -norm of the trajectory, while other bounds on  $V(t, x_t)$  and  $\dot{V}(t, x_t)$  are on the Euclidean norm of the trajectory, which poses the technical challenge of estimating the trajectory bound and decaying rate for the switched delay systems (2.2).

**4. Conservatism analysis.** The dwell-time-based stability results had been obtained for switched linear systems free of delays [10, 19]. It is interesting to compare the conservatism of the results presented in this paper with those for delay-free systems.

In fact, one extreme case of the switched system  $\Sigma_t$  is  $\tau_i = 0$  and  $\bar{A}_i = 0$  for  $i \in \mathcal{A}$ , which corresponds to the delay-free scenario. For each candidate system  $\dot{x} = A_i x$ , a sufficient and necessary condition to guarantee asymptotic stability is  $\exists P_i = P_i^T > 0$ , such that  $Q_i := -(A_i^T P_i + P_i A_i) > 0$ . Correspondingly a dwell-time-based stability for such a switched delay-free system is  $q(t) \in S[\tilde{\tau}_D]$ , where

$$(4.1) \quad \tilde{\tau}_D = \tilde{\mu} \ln \lambda,$$

where  $\lambda$  is defined by (3.20) and

$$(4.2) \quad \tilde{\mu} := \max_{i \in \mathcal{F}} \frac{\bar{\kappa}_i}{\tilde{w}_i},$$

where  $\tilde{w}_i := \sigma_{\min}[Q_i] > 0$ .

On the other hand, in our case for  $\tau_i = 0$  and  $\bar{A}_i = 0$ , we observe that

$$(4.3) \quad \lim_{\alpha_i \rightarrow 0^+} S_i = \lim_{\alpha_i, \beta_i \rightarrow 0^+} S_i^d = Q_i, \quad i \in \mathcal{F},$$

from (3.18) and (3.35), which indicates  $\mu = \mu_d = \tilde{\mu}$  by (3.21), (3.37), and (4.2). Accordingly we can select  $p_i > 1$ ,  $i \in \mathcal{F}$ , sufficiently large such that  $\lfloor \frac{\lambda-1}{p-1} + 1 \rfloor = 1$  in (3.22) and (3.36) and obtain

$$(4.4) \quad \tau_D = T^* = \lambda\mu = \lambda\mu_d = T_d^* = \tau_D^d.$$

Therefore

$$(4.5) \quad \tau_D = \tau_D^d = \lambda\tilde{\mu} > \tilde{\mu} \ln \lambda = \tilde{\tau}_D.$$

The dwell times derived for switched time delay systems are proportional to  $\lambda$ , in contrast to the logarithm of  $\lambda$  for switched delay-free systems. This gap is due to the fact that asymptotic stability for linear delay-free systems implies exponential stability. However, for time delay systems, the sufficient stability conditions based on the Lyapunov–Razumikhin theorem do not guarantee exponential stability. As a matter of fact, the exponential estimates for time delay systems require additional assumptions besides asymptotic stability [15].

It should be noted that stability conditions for switched time delay systems are also considered in [22, 23], where the authors give a sufficient condition to guarantee *uniform* stability (see Theorem 6.1 of [22] for notation and details):  $\Gamma e^{L(\Lambda+h)} \leq 1$ . Apparently, this condition does not hold for the switched system (2.2) because in our case  $\Gamma = 1$ , and hence

$$\Gamma e^{L(\Lambda+h)} = e^{L(\Lambda+h)} > 1 \quad \forall \Lambda > 0, L > 0, h > 0.$$

**5. Numerical example.** In this section, we use an illustrative example to demonstrate the results in section 3.

*Example.* Consider the following switched time delay system with 2 candidates:

$$(5.1) \quad \Sigma_t : \begin{cases} \dot{x} = A_{q(t)}x(t) + \bar{A}_{q(t)}x(t - \tau_{q(t)}), & t \geq 0, \\ x(t) = \phi(t) & \forall t \in [-\tau_{\max}, 0], \\ q(t) \in \{1, 2\}, \end{cases}$$

where the switching candidate systems  $\Sigma_1 := (A_1, \bar{A}_1, \tau_1)$  and  $\Sigma_2 := (A_2, \bar{A}_2, \tau_2)$  are determined by

$$A_1 = \begin{bmatrix} -2 & 0 \\ 0 & -0.9 \end{bmatrix}, \quad \bar{A}_1 = \begin{bmatrix} -1 & 0 \\ -0.5 & -1 \end{bmatrix};$$

$$A_2 = \begin{bmatrix} -1 & 0.5 \\ 0 & -1 \end{bmatrix}, \quad \bar{A}_2 = \begin{bmatrix} -1 & 0 \\ 0.1 & -1 \end{bmatrix};$$

TABLE 5.1

Parameters calculated with respect to switched time delay system  $\Sigma_t$  and switched delay-free system  $\bar{\Sigma}_t$ .

Parameters	$\Sigma_t$ (with delay)	$\bar{\Sigma}_t$ (delay free)
$\lambda$	1.7224	1.7224
$\mu_d$	1.5216	N/A
$\bar{\mu}_d$	N/A	0.7056
$\bar{p}$	1.4	N/A
$T_d^*$	5.3147	N/A
Dwell time	$\tau_D^d = 6.5147$	$\tilde{\tau}_D = 0.3836$

FIG. 5.1. The state trajectory of  $\Sigma_t$  in the presence of switching.

and  $\tau_1 = 0.3, \tau_2 = 0.6$ . The initial condition of (5.1) is chosen as

$$\phi(t) = \begin{bmatrix} 5 \cos\left(\frac{\pi}{2.4}t + \frac{\pi}{6}\right) \\ 5 \sin\left(\frac{\pi}{2.4}t + \frac{\pi}{6}\right) \end{bmatrix} \quad \forall t \in [-0.6, 0].$$

It is clear that  $\Sigma_1$  and  $\Sigma_2$  are delay-dependently stable, which can be verified by Lemma 2.2. Applying Theorem 3.5 gives the dwell time  $\tau_D^d = 6.52$ , which guarantees the asymptotic stability of the switched time delay system (5.1). For the purpose of comparison, we also calculate the dwell time  $\tilde{\tau}_D$  of the delay-free system  $\bar{\Sigma}_t : \dot{x} = A_{q(t)}x(t), q(t) \in \{1, 2\}$ . The results are shown in Table 5.1.

The switched time delay system  $\Sigma_t$  described by (5.1) is simulated in MATLAB, where we start with  $\Sigma_2$  and perform switching every  $\tau_D^d$  seconds. The state trajectory is depicted in Figure 5.1, where we clearly see the asymptotic convergence in the presence of switching. Also, we provide the phase portrait in Figure 5.2 with respect to  $x_1(t)$  and  $x_2(t)$ , which better illustrates the switching and the stability of the switched system.

It is also interesting to investigate the relation between time delays of (2.2) and the corresponding dwell time  $\tau_D^d$ . For this purpose, we took  $\tau_1 = \tau_2 = \tau$  in (5.1) with  $\tau$  varying from 0.1 to 0.7. The results are shown in Table 5.2. We should also indicate that the free parameters  $\alpha_i, \beta_i$ , and  $p_i$  can be further optimized to reduce the values of  $\tau_D^d$  given in the table. However, this is an open problem deserving a

FIG. 5.2. Phase portrait of the switched time delay system  $\Sigma_t$ .

TABLE 5.2  
Dwell time values versus time delays of  $\Sigma_t$ .

$\tau$	0.1	0.2	0.3	0.4	0.5	0.6	0.7
$\tau_D^d$	0.93	1.49	3.36	4.83	9.14	106.23	950.58

separate study. Nevertheless, the results given in the table suggest an exponentially increasing behavior of  $\tau_D^d$  with the delay. Similar behavior is observed for the  $\mathcal{H}^\infty$  optimal cost in weighted sensitivity minimization for systems with delays [4].

**6. Concluding remarks.** We provided stability analysis for switched linear systems with time delays, where each candidate system is assumed to be delay-independently or delay-dependently asymptotically stable. We showed the existence of a dwell time of the switching signal, such that the switched time delay system is asymptotically stable independent of the trajectory. The dwell time values for both scenarios are constructively given. The results are compared with the dwell-time conditions for switched delay-free systems. Optimization of the minimum dwell times that we have derived, in terms of the free parameters appearing in the LMI conditions, is an interesting open problem. An interesting extension of this work is to investigate stability and controller synthesis for switched interval time delay systems, which will potentially offer a hybrid control method for large time delay systems and time varying delay systems.

## OUTPUT FEEDBACK $H_\infty$ CONTROL OF CONTINUOUS-TIME INFINITE MARKOVIAN JUMP LINEAR SYSTEMS VIA LMI METHODS\*

MARCOS G. TODOROV<sup>†</sup> AND MARCELO D. FRAGOSO<sup>†</sup>

**Abstract.** The output feedback  $H_\infty$  control is addressed for a class of continuous-time Markov jump linear systems with the Markov process taking values in an infinite countable set  $\mathcal{S}$ . We consider that only an output and the jump parameters are available to the controller. Via a certain bounded real lemma, together with some extensions of Schur complements and of the projection lemma, a theorem which characterizes whether there exists a full-order solution to the disturbance attenuation problem is devised in terms of two different linear matrix inequality (LMI) feasibility problems. This result connects a certain projection approach to an LMI problem which is more amenable to computer solution, and hence for design. We conclude the paper with some design algorithms for the construction of such controllers and an illustrative example.

**Key words.** continuous-time linear systems, Markov jump parameter, bounded real lemma, linear matrix inequalities, output feedback,  $H_\infty$  control

**1. Introduction.** It is a well-known fact that in order to treat adequately problems related to a wide class of dynamical systems, we do need to characterize adequately the uncertainties in the mathematical description of these systems, which can be, for instance, of an environmental and/or modeling nature. These uncertainties have many sources: noise in communications systems, atmospheric fluctuation, volatility in the economic scenario, *failures* (abrupt change in the system structure), parametric uncertainty, etc. In this paper we shall be interested in a class of linear dynamical systems which are subjected to uncertainty (change) in their structures as a consequence of abrupt phenomena. The uncertainties are characterized in the model via a Markov process. These systems are known in the literature as Markov jump linear systems (MJLS) and constitute an important class of hybrid systems.

MJLS provide a powerful framework for modeling and analyzing systems which are subject to abrupt changes in their structure [6]. They are seen as a real alternative to reaching failure tolerance behavior in control systems, and consequently are highly relevant for control theory; i.e., MJLS belong to what is known in the specialized literature as safety-critical and high-integrity systems (e.g., aircraft, chemical plants, nuclear power station, robotic manipulator systems, large scale flexible structures for space stations such as antenna, solar arrays, etc.).

This class of systems (MJLS) has been the subject of intensive research over the last few decades and the associated literature is now fairly extensive. The last 25 years have seen significant development in the nature and scope of this subject. This

period has witnessed exciting development in creating new directions of study and understanding a great deal of subtleties in this field (see, e.g., [6] and [12] for an up-to-date discussion on this subject). While the study of MJLS is mature in many ways, a great variety of interesting problems of this field are still wide open. This is the case, for instance, with the output feedback  $H_\infty$  control problem for the class of continuous-time infinite MJLS (including many aspects of the finite case). *Infinite*, or *finite*, here refers to the state space of the Markov process.

In this paper we address the output feedback  $H_\infty$  control for the case in which the state space of the Markov chain is *infinite countable*. We consider that only an output and the jump parameters are available to the controller. A theorem which characterizes whether there exists a full-order solution to the disturbance attenuation problem is devised in terms of two different linear matrix inequality (LMI) feasibility problems. Our result establishes the connection between a certain projection approach and an LMI problem which is more suitable for design. A certain infinite Markov jump bounded real lemma (JBRL) is employed for the first time, illustrating the importance of this recent result (see [21]). In addition, we provide some *design algorithms* leading to a series of tools that, among other things, may be readily applied to the finite setting. This includes an LMI algorithm, which allows one to check, by two different ways, whether there exists a solution for the disturbance attenuation (DA) problem (Algorithm 4.10); a two-step design method (Algorithm 5.3) which provides explicit formulas for the construction of a suboptimal controller; and an alternative three-step design method (Algorithm 5.4). The main difference between Algorithms 5.3 and 5.4 is that, in the latter, one can first check if a smaller (projected) LMI problem is feasible by means of Algorithm 4.10. This amounts to verifying whether or not the DA problem has a solution, before proceeding further. Finally, in order to provide a rather complete design framework and hence bring our results to a more applicable basis, the  $H_\infty$  optimization problem is also treated from this viewpoint. A simple bisectional algorithm (Algorithm 5.5) is employed, in a parallel to [2] and [6, Algorithm 8.9], yielding a tractable way of computing the optimal  $H_\infty$  performance that may be achieved with our results.

An important issue here is that some fundamental tools such as Schur complements and the projection lemma cannot be directly applied in the *infinity* setting. Since, to the best of the authors' knowledge, this is the first time the LMI approach is employed for the infinite case, we had to solve this problem by devising extended versions of these results. We notice that, as the breadth of applicability of these tools is not restricted to the jump setting, they represent potentially powerful tools for handling a variety of LMI problems (for instance, in time-varying systems [9, 20]). Furthermore, it seems that these are new results not previously found in the literature (for a discussion on some differences in the treatment of the infinite case, readers are referred, e.g., to [11], [10], and [12]).

When reduced to the *finite case*, a closely related paper is [7]. One important aspect which distinguishes our work from [7] is that the starting point here is a novel bounded real lemma, recently devised in [21], which allows us to ignore the bounds of sufficiency conditions as used in [7]. The bounded real lemma enables us to stray into the more general realm of the  $H_\infty$  problem, providing not only *necessary* and sufficient conditions at each step, but also allowing us to decouple the existence problem from the design. We should perhaps mention here that no *regularity assumptions* are made, as, for example, in [8] and [17].

It is perhaps worth noting here that, besides being interesting in their own right,

matrices with complex coefficients are also interesting from an application point of view. As pointed out in [16] and [1], in several engineering applications, such as communication application of signals systems, whirling shafts, and vibrational systems, complex coefficients come into play. In [16] some systems with complex coefficients that naturally arise in mechanics and signal processing are presented, motivating the study of equations with complex coefficients and illustrating more general situations as in, for instance, satellite and cosmic vehicles control. We refer the reader to these papers and the references therein for further examples and results on systems with complex coefficients.

Finally, it is too early to predict the full extent to which the theory developed here, for the case of a countably infinite state space of the Markov chain, will be applied. However, a few situations where model (3.2) seems to be naturally applied are mentioned in the introduction of [10] (see also [5]).

The paper is organized as follows. In section 2 we provide the bare essentials of notation and some auxiliary results. Section 3 introduces the basic model together with the bounded real lemma, which will be important in section 4, where the  $H_\infty$  problem is dealt with. Some tools for the design of *full-order*  $H_\infty$  compensators are given in section 5, together with a nominal example. The paper is concluded in section 6 with a highlight of the main contributions. Some proofs and auxiliary results are presented in the appendix.

**2. Notation and auxiliary results.** Let  $\|\cdot\|$  denote the euclidean norm in the complex  $n$ -space  $\mathbb{C}^n$ . We define  $\mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$  as the Banach space of all complex matrices  $M \in \mathbb{C}^{n \times m}$ , equipped with the standard induced matrix norm, also denoted by  $\|\cdot\|$ . Let us also define the infinite-dimensional Banach space  $\mathbb{H}_{\text{sup}}^{m,n}$  of all matrices of the form  $H = (H_1, H_2, \dots)$ , where  $H_i \in \mathbb{M}(\mathbb{C}^m, \mathbb{C}^n)$  for every  $i \in \mathcal{S} := \{1, 2, \dots\}$ , such that  $\|H\|_{\text{sup}} := \sup_{i \in \mathcal{S}} \|H_i\| < \infty$ . We also write  $\mathbb{H}_{\text{sup}}^n$  in place of  $\mathbb{H}_{\text{sup}}^{n,n}$  and define  $\mathbb{H}_{\text{sup}}^{n*}$  as the subset of  $\mathbb{H}_{\text{sup}}^n$  whose elements  $H = (H_1, H_2, \dots)$  exhibit the additional property that  $H_i = H_i^*$  for all  $i \in \mathcal{S}$  ( $H = H^*$  for short), with  $*$  denoting the conjugate transpose (we denote plain transposition by  $'$ ). Next, we define  $\tilde{\mathbb{H}}_{\text{sup}}^{n+}$  as the set composed by all *uniformly positive* matrices  $H \gg 0$ , i.e., such that  $H = (H_1, H_2, \dots) \in \mathbb{H}_{\text{sup}}^{n*}$  and  $H_i \geq \varepsilon I_n$  for all  $i \in \mathcal{S}$  and some  $\varepsilon > 0$  independent of  $i$  (here  $I_n$  stands for the  $n \times n$  identity matrix). Accordingly, we say that  $L \in \tilde{\mathbb{H}}_{\text{sup}}^{n-}$  (or is *uniformly negative*,  $L \ll 0$ ) whenever  $-L \gg 0$ . For short, we write that such  $H_i \gg 0$  and  $L_i \ll 0$  for all  $i \in \mathcal{S}$ . Finally, given  $R = (R_1, R_2, \dots) \in \mathbb{H}_{\text{sup}}^{n*}$  and  $S = (S_1, S_2, \dots) \in \mathbb{H}_{\text{sup}}^{n,m}$ , we shall write that  $R_i \gg 0$  over  $\mathcal{N}(S_i)$  whenever there exist  $\varepsilon > 0$  such that  $R_i \geq \varepsilon I_n$  over  $\mathcal{N}(S_i)$  for all  $i \in \mathcal{S}$ , where  $\mathcal{N}(\cdot)$  stands for the null space associated to a given complex matrix. (Accordingly,  $\mathcal{R}(\cdot)$  is the range of complex matrices. We refer to Proposition 2.3, in which an extension of  $\mathcal{N}(\cdot)$  and  $\mathcal{R}(\cdot)$  to the infinite case is stated.)

For  $H \in \mathbb{H}_{\text{sup}}^{p,m}$  and  $L \in \mathbb{H}_{\text{sup}}^{n,p}$  we have, in a natural way, that  $\|HL\|_{\text{sup}} \leq \|H\|_{\text{sup}} \|L\|_{\text{sup}}$  and thus  $HL := (H_1 L_1, H_2 L_2, \dots) \in \mathbb{H}_{\text{sup}}^{n,m}$ . Moreover, given  $F \in \mathbb{H}_{\text{sup}}^{\ell,m}$  we have that  $[H \ F] := ([H_1 \ F_1], [H_2 \ F_2], \dots) \in \mathbb{H}_{\text{sup}}^{(p+\ell),m}$  (the analogous holding for vertical or diagonal block concatenation). We denote by  $0_{\ell \times m}$  the zero matrix in either  $\mathbb{C}^{\ell,m}$  or  $\mathbb{H}_{\text{sup}}^{m,\ell}$ , the same holding for the identity matrices  $I_\ell \in \mathbb{C}^{\ell \times \ell}$ ,  $I_\ell \in \tilde{\mathbb{H}}_{\text{sup}}^{\ell+}$ . Whenever the size of any of those matrices has no importance or may be easily deduced by the context, it will be omitted. In addition, we define  $\text{Her}(H) := H + H^*$ ,  $\mathfrak{C}(H, L) := L^* H L$ , and sometimes represent off-diagonal blocks of a given self-adjoint matrix (that is, a matrix in a set such as  $\mathbb{H}_{\text{sup}}^{n*}$ ) by  $*$ , while entries with absolutely

no importance are denoted by  $\star$ . Furthermore, the Kronecker product of complex matrices is denoted by  $\otimes$ , in the usual way (see [4]).

With respect to the infinite countable set  $\mathcal{S}$  consider two infinite sequences  $\mathbf{m} = (m_1, m_2, \dots)$ ,  $\mathbf{n} = (n_1, n_2, \dots)$ , where  $(m_i, n_i) \in \{1, 2, \dots, M\}^2$  for some finite integer  $M$  and every  $i \in \mathcal{S}$ . Then define the infinite-dimensional Banach space  $\mathbb{H}_{\text{sup}}^{\mathbf{m}, \mathbf{n}}$  of all *bounded matrices*, which are objects of the form  $H = (H_1, H_2, \dots)$ , such that  $H_i \in \mathbb{M}(\mathbb{C}^{m_i}, \mathbb{C}^{n_i})$  for every  $i \in \mathcal{S}$ , where  $\|H\|_{\text{sup}} := \sup_{i \in \mathcal{S}} \|H_i\| < \infty$ . Let us also define the set  $\tilde{\mathbb{H}}_{\text{sup}}^{n+} \subset \mathbb{H}_{\text{sup}}^{\mathbf{n}, \mathbf{n}}$  analogously as before, where  $H \gg 0$  once more stands for uniform positivity,  $H \in \tilde{\mathbb{H}}_{\text{sup}}^{n+}$ . In particular, whenever  $\mathbf{m} = (m, m, \dots)$  and  $\mathbf{n} = (n, n, \dots)$  we simply have that  $\mathbb{H}_{\text{sup}}^{\mathbf{m}, \mathbf{n}} \equiv \mathbb{H}_{\text{sup}}^{m, n} \equiv \mathbb{H}_{\text{sup}}^{\mathbf{m}, n} \equiv \mathbb{H}_{\text{sup}}^{m, n}$ .

Concerning the random objects, fix a complete probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  carrying a right-continuous filtration  $\mathcal{F}_t \subset \mathcal{F}$  on  $t \in \mathbb{R}_+ := [0, \infty)$ . In addition, let  $E(\cdot)$  denote the usual mathematical expectation and define  $L_2^n$  as the space of all second order random variables  $(\Omega, \mathcal{F}) \mapsto \mathbb{C}^n$ . We also define the Lebesgue space  $L_2^n(\mathbb{R}_+)$  of all stochastic processes  $y = \{(y(t), \mathcal{F}_t); t \in \mathbb{R}_+, y(\cdot) \in \mathbb{C}^n\}$  such that  $\|y\|_{\mathbb{R}_+} := (\int_0^\infty E[\|y(t)\|^2] dt)^{1/2}$  is finite.

**2.1. Some auxiliary results.** This subsection contains some independent tools which will be necessary later on, including *extended versions* of Schur complements and of the projection lemma. The reader is referred to the appendix for the proofs.

The following proposition states that if uniform positive definiteness of the identity element in  $\mathbb{H}_{\text{sup}}^{n+}$  is preserved under application of a congruence transformation, then, in particular, both this entire set and its negative counterpart are invariant by such operation. This easy-to-check condition will be employed throughout the paper.

**PROPOSITION 2.1.** *Suppose  $Q = (Q_1, Q_2, \dots) \in \mathbb{H}_{\text{sup}}^{m, n}$  is such that  $Q^*Q \gg 0$ . Then the following statements are true:*

- (i)  $X \in \tilde{\mathbb{H}}_{\text{sup}}^{n+}$  implies  $Q^*XQ \gg 0$ ;
- (ii)  $Y \in \tilde{\mathbb{H}}_{\text{sup}}^{n-}$  implies  $Q^*YQ \ll 0$ .

*Proof.* See the appendix.  $\square$

The following result extends the well-known result on Schur complements to our setting.

**THEOREM 2.2** (uniform Schur complements). *Given  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\text{sup}}^{p, p}$ ,  $V = (V_1, V_2, \dots) \in \mathbb{H}_{\text{sup}}^{q, p}$ , and  $W = (W_1, W_2, \dots) \in \mathbb{H}_{\text{sup}}^{q, q}$ , the following are equivalent:*

- (i)  $\begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \gg 0$ ;
- (ii)  $U \gg 0$  and  $W - V^*U^{-1}V \gg 0$ ;
- (iii)  $W \gg 0$  and  $U - VW^{-1}V^* \gg 0$ .

Moreover, the same holds replacing  $\gg$  by  $\ll$ .

*Proof.* See the appendix.  $\square$

The following proposition introduces the notion of range and null spaces to the infinite case, besides defining what we will refer to later as an “orthonormal basis.”

**PROPOSITION 2.3.** *Suppose  $\Psi = (\Psi_1, \Psi_2, \dots) \in \mathbb{H}_{\text{sup}}^{p, \ell}$  is such that  $1 \leq p_i := \dim(\mathcal{N}(\Psi_i))$  for any  $i \in \mathcal{S}$ . Then, defining  $\mathbf{p} = (p_1, p_2, \dots)$ , there exists  $\Phi = (\Phi_1, \Phi_2, \dots) \in \mathbb{H}_{\text{sup}}^{\mathbf{p}, \mathbf{p}}$  such that, for all  $i \in \mathcal{S}$ ,*

- (i)  $\mathcal{N}(\Phi_i) = \{0\}$  and  $\mathcal{R}(\Phi_i) = \mathcal{N}(\Psi_i)$ ;
- (ii)  $\Phi_i^* \Phi_i = I_{p_i}$ .

Moreover, we use the notation  $\mathcal{N}(\Psi) = \mathcal{R}(\Phi)$  and say that such  $\Phi$  is an orthonormal basis for these spaces.

*Proof.* See the appendix.  $\square$

The following result is an immediate consequence of the two previous results.

COROLLARY 2.4. Suppose  $\Psi = (\Psi_1, \Psi_2, \dots) \in \mathbb{H}_{\text{sup}}^{p,\ell}$  is such that  $\dim(\mathcal{N}(\Psi_i)) \geq 1$  for any  $i \in \mathcal{S}$ . Then the following are equivalent for any  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\text{sup}}^{p,*}$ ,  $V = (V_1, V_2, \dots) \in \mathbb{H}_{\text{sup}}^{q,p}$ , and  $W = (W_1, W_2, \dots) \in \mathbb{H}_{\text{sup}}^{q,*}$ :

- (i)  $\begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \gg 0$  over  $\mathcal{N}([\Psi \ 0])$ ;
- (ii)  $U - VW^{-1}V^* \gg 0$  over  $\mathcal{N}(\Psi)$  and  $W \gg 0$ .

*Proof.* See the appendix.  $\square$

The following lemma is an extension from the one depicted in [15] and is of major importance in what follows.

LEMMA 2.5 (uniform projection lemma). Assume  $N = (N_1, N_2, \dots) \in \mathbb{H}_{\text{sup}}^{p,q}$ ,  $M = (M_1, M_2, \dots) \in \mathbb{H}_{\text{sup}}^{p,r}$ , and  $H = (H_1, H_2, \dots) \in \mathbb{H}_{\text{sup}}^{p,*}$ . Then the LMI

$$(2.1) \quad H + N^* X^* M + M^* X N \gg 0$$

has a solution  $X \in \mathbb{H}_{\text{sup}}^{q,r}$  if and only if  $H$  is uniformly positive over  $\mathcal{N}(N) \cup \mathcal{N}(M)$ .

*Proof.* See the appendix.  $\square$

**3. Model setting and preliminaries.** Consider in  $(\Omega, \mathcal{F}, \mathbb{P})$  a homogeneous Markov process  $\theta = \{(\theta_t, \mathcal{F}_t), t \in \mathbb{R}_+\}$ , with right-continuous sample paths and countably infinite state space  $\mathcal{S} = \{1, 2, \dots\}$ , such that

$$(3.1) \quad \mathbb{P}(\theta_{t+dt} = j | \theta_t = i) = \begin{cases} \lambda_{ij} dt + o(dt), & i \neq j, \\ 1 + \lambda_{ii} dt + o(dt), & i = j, \end{cases}$$

where  $0 \leq \lambda_{ij}$  for  $i \neq j$ , and  $0 \leq \lambda_i := -\lambda_{ii} = \sum_{j \in \mathcal{S} \setminus \{i\}} \lambda_{ij} \leq \varrho$  for some  $\varrho < \infty$  and all  $i \in \mathcal{S}$ . We assume that  $\theta_0 : (\Omega, \mathcal{F}) \rightarrow \mathcal{S}$  is a random variable with distribution  $\nu_0$ , and that  $\theta_t$  is available for every  $t \in \mathbb{R}_+$  (this last assumption reflects the fact that the control laws we shall seek are  $\theta_t$ -dependent).

In order to introduce the bounded real lemma (JBRL), it suffices to consider now a simple version of the MJLS which will be stated in the next section (see (4.1)).

$$(3.2) \quad \Sigma : \begin{cases} \dot{\hat{x}}(t) = \hat{A}_{\theta_t} \hat{x}(t) + \hat{B}_{\theta_t} v(t), & \hat{x}(0) = \hat{x}_0, \\ z(t) = \hat{C}_{\theta_t} \hat{x}(t) + \hat{D}_{\theta_t} v(t), & t \in \mathbb{R}_+, \end{cases}$$

for  $\hat{x}_0 \in L_2^{\hat{n}}$ , where  $\hat{A} = (\hat{A}_1, \hat{A}_2, \dots) \in \mathbb{H}_{\text{sup}}^{\hat{n}}$  in the same way as  $\hat{B} \in \mathbb{H}_{\text{sup}}^{n_v, \hat{n}}$ ,  $\hat{C} \in \mathbb{H}_{\text{sup}}^{\hat{n}, n_z}$ , and  $\hat{D} \in \mathbb{H}_{\text{sup}}^{n_v, n_z}$ . In what follows we shall point out some fundamental facts regarding this model, including a modified version of the JBRL [21].

Denoting by  $\hat{x}(\cdot, \hat{x}_0, \theta_0, v)$  the *state response* of system  $\Sigma$  when subjected to arbitrary initial conditions  $(\hat{x}_0, \theta_0)$  and input  $v \in L_2^{n_v}(\mathbb{R}_+)$ , we begin with the following definition.

DEFINITION 3.1. For an initial condition  $\hat{x}(0) = 0$  and arbitrary  $\theta_0$  we define the zero-state response of (3.2) as  $\hat{x}_{zs}(\cdot) = \hat{x}(\cdot, 0, \theta_0, v)$ . On the other hand, for arbitrary initial conditions but an identically zero input, we have the zero-input response,  $\hat{x}_{zi}(\cdot) = \hat{x}(\cdot, \hat{x}_0, \theta_0, 0)$ .

Preserving the terminology, often used in the literature for MJLS, in this paper we deal exclusively with stability in the following internal sense.

DEFINITION 3.2. System (3.2) is said to be stochastically stable (SS) if, for any initial condition  $\hat{x}_0 \in L_2^{\hat{n}}$  and initial distribution  $\nu_0$ , we have that  $\|\hat{x}_{zi}\|_{\mathbb{R}_+} < \infty$ .

Concerning SS for this class of systems, an extensive series of results may be found in the recent paper [12]. In particular, it has been proved that SS of (3.2) implies  $z \in L_2^{n_z}(\mathbb{R}_+)$  for any  $v \in L_2^{n_v}(\mathbb{R}_+)$ . That is, SS leads to some kind of *external*  $L_2$  input-output stability for this system (see also [21, Remark 2]).

If  $\Sigma$  is SS, we may define, in the spirit of  $H_\infty$  theory, the following *perturbation operator*  $\mathbb{L} : L_2^{n_v}(\mathbb{R}_+) \rightarrow L_2^{n_z}(\mathbb{R}_+)$ :

$$(3.3) \quad \mathbb{L}v(t) = \hat{C}_{\theta_t} \hat{x}_{zs}(t) + \hat{D}_{\theta_t} v(t),$$

which describes how input disturbances affect the output of system  $\Sigma$ , in such a way that  $z(\cdot) = \mathbb{L}v(\cdot)$  whenever  $\hat{x}_0 = 0$ . The worst-case effect of such disturbances is measured by the induced norm of  $\mathbb{L}$  from  $L_2^{n_v}(\mathbb{R}_+)$  into  $L_2^{n_z}(\mathbb{R}_+)$ :

$$(3.4) \quad \|\mathbb{L}\| = \sup_{v \in L_2^{n_v}(\mathbb{R}_+), \|v\|_{\mathbb{R}_+} \neq 0} \frac{\|\mathbb{L}v\|_{\mathbb{R}_+}}{\|v\|_{\mathbb{R}_+}}.$$

We conclude this section by presenting one important tool which we shall be employing in the remainder of this paper. The so-called JBRL is the starting point towards a characterization of  $H_\infty$  controllers for the class of MJLS under consideration, when it comes to an LMI approach.

**LEMMA 3.3 (JBRL).** *System (3.2) is SS with  $\|\mathbb{L}\| < \gamma$  if and only if there exist  $P = (P_1, P_2, \dots) \in \tilde{\mathbb{H}}_{\sup}^{\hat{n}-}$  such that, for all  $i \in \mathcal{S}$ ,*

$$(3.5) \quad \begin{bmatrix} \hat{A}_i^* P_i + P_i \hat{A}_i + \sum_{j \in \mathcal{S}} \lambda_{ij} P_j & P_i \hat{B}_i & \hat{C}_i^* \\ \hat{B}_i^* P_i & \gamma^2 I_{n_v} & \hat{D}_i^* \\ \hat{C}_i & \hat{D}_i & I_{n_z} \end{bmatrix} \gg 0.$$

*Proof.* The proof follows directly from [21], in view of Theorem 2.2.  $\square$

**4. Disturbance attenuation.** In this section we shall establish the disturbance attenuation (DA) problem in the jump setting and apply the JBRL in order to characterize the existence of solutions in terms of LMIs.

**4.1. Problem setting.** Bearing in mind the definition of  $\{\theta_t\}$ , consider the MJLS

$$(4.1) \quad \Sigma_u : \begin{cases} \dot{x}(t) = A_{\theta_t} x(t) + B_{\theta_t} v(t) + G_{\theta_t} u(t), \\ z(t) = C_{\theta_t} x(t) + D_{\theta_t} v(t) + H_{\theta_t} u(t), \\ y(t) = \Gamma_{\theta_t} x(t) + L_{\theta_t} v(t) \end{cases}$$

for  $t \in \mathbb{R}_+$  and  $x(0) = x_0 \in L_2^n$ , where  $A = (A_1, A_2, \dots) \in \mathbb{H}_{\sup}^n$  in the same way as  $B \in \mathbb{H}_{\sup}^{n_v, n}$ ,  $G \in \mathbb{H}_{\sup}^{n_u, n}$ ,  $C \in \mathbb{H}_{\sup}^{n_u, n_z}$ ,  $D \in \mathbb{H}_{\sup}^{n_v, n_z}$ ,  $H \in \mathbb{H}_{\sup}^{n_u, n_z}$ ,  $\Gamma \in \mathbb{H}_{\sup}^{n_u, n_y}$ , and  $L \in \mathbb{H}_{\sup}^{n_v, n_y}$ .

We refer to  $x(t)$  as the state variable for a given  $t \in \mathbb{R}_+$  and to  $(x(t), \theta_t)$  as an augmented state variable. Just as before, we assume  $v \in L_2^{n_v}(\mathbb{R}_+)$  is any finite energy stochastic disturbance acting on the system; the specific structure of the  $n_u$ -dimensional control input  $u$  will be defined soon.

We call  $z$  and  $y$  the *error* and *measurement* outputs, respectively. The former represents some adversely disturbed output, which should be relatively insensitive to input disturbances. In addition, the processes  $x$  and  $z$  may only be observed through the measurement  $y$  (which without any loss of generality is not directly fed by  $u$ ), which makes this model rather general for both practical and theoretical reasons. Sometimes we refer to the system (4.1) simply as  $\Sigma_u$ .

To meet the ends of the  $H_\infty$  control problem, it is natural to ask the following question about  $\Sigma_u$ : *How does one characterize a class of (suboptimal) controllers  $\mathcal{K}$*

which guarantee not only stability, but also that the worse-case effect caused by the disturbance ( $v$ ) on the error output ( $z$ ) is smaller than some prescribed attenuation level? (In what follows it will be meaningful to measure such effect through (3.4).)

In our approach, we consider the class of dynamic compensators that map the augmented measurement process  $(y, \theta)$  into control policies  $u$  according to the following ( $k$ -dimensional) model:

$$(4.2) \quad \mathcal{K} : \begin{bmatrix} \dot{x}_{\mathcal{K}}(t) \\ u(t) \end{bmatrix} = \begin{bmatrix} \mathcal{K}_{\theta_t}^{11} & \mathcal{K}_{\theta_t}^{12} \\ \mathcal{K}_{\theta_t}^{21} & \mathcal{K}_{\theta_t}^{22} \end{bmatrix} \begin{bmatrix} x_{\mathcal{K}}(t) \\ y(t) \end{bmatrix}, \quad x_{\mathcal{K}}(0) = 0.$$

The above compensator is completely defined through the matrix  $\mathcal{K} = (\mathcal{K}_1, \mathcal{K}_2, \dots) \in \mathbb{H}_{\text{sup}}^{(k+n_y), (k+n_u)}$ , where  $\mathcal{K}_i = [\mathcal{K}_i^{\bullet\bullet}]$ ,  $i \in \mathcal{S}$ . For this reason, the same symbol is used to denote both the system and the matrix in question without confusion.

It is possible to incorporate both systems,  $\Sigma_u$  and  $\mathcal{K}$ , into a *closed-loop* system  $\Sigma_{\mathcal{K}}$ , with the augmented state variable  $(\hat{x}(t), \theta_t) = (x(t), x_{\mathcal{K}}(t), \theta_t)$  for any  $t \in \mathbb{R}_+$ . Defining  $\hat{n} = n + k$  and  $\hat{x}_0 = (x_0, 0)$  we have that the state and output equations for this  $\hat{n}$ -dimensional system may be written as an instance of (3.2):

$$(4.3) \quad \Sigma_{\mathcal{K}} : \begin{cases} \dot{\hat{x}}(t) = \hat{A}_{\theta_t} \hat{x}(t) + \hat{B}_{\theta_t} v(t), & \hat{x}(0) = \hat{x}_0, \\ z(t) = \hat{C}_{\theta_t} \hat{x}(t) + \hat{D}_{\theta_t} v(t), & t \in \mathbb{R}_+, \end{cases}$$

where  $\hat{A} = (\hat{A}_1, \hat{A}_2, \dots) \in \mathbb{H}_{\text{sup}}^{\hat{n}}$ ,  $\hat{B} = (\hat{B}_1, \hat{B}_2, \dots) \in \mathbb{H}_{\text{sup}}^{n_v, \hat{n}}$ ,  $\hat{C} = (\hat{C}_1, \hat{C}_2, \dots) \in \mathbb{H}_{\text{sup}}^{\hat{n}, n_z}$ ,  $\hat{D} = (\hat{D}_1, \hat{D}_2, \dots) \in \mathbb{H}_{\text{sup}}^{n_v, n_z}$ , and, for  $i \in \mathcal{S}$ ,

$$\begin{aligned} \hat{A}_i &= \begin{bmatrix} A_i + G_i \mathcal{K}_i^{22} \Gamma_i & G_i \mathcal{K}_i^{21} \\ \mathcal{K}_i^{12} \Gamma_i & \mathcal{K}_i^{11} \end{bmatrix}, & \hat{B}_i &= \begin{bmatrix} B_i + G_i \mathcal{K}_i^{22} L_i \\ \mathcal{K}_i^{12} L_i \end{bmatrix}, \\ \hat{C}_i &= [C_i + H_i \mathcal{K}_i^{22} \Gamma_i \quad H_i \mathcal{K}_i^{21}], & \hat{D}_i &= D_i + H_i \mathcal{K}_i^{22} L_i, \end{aligned}$$

or, equivalently,

$$\begin{aligned} \hat{A}_i &= A_i^0 + \hat{G}_i \mathcal{K}_i \hat{\Gamma}_i, & \hat{B}_i &= B_i^0 + \hat{G}_i \mathcal{K}_i \hat{L}_i, \\ \hat{C}_i &= C_i^0 + \hat{H}_i \mathcal{K}_i \hat{\Gamma}_i, & \hat{D}_i &= D_i^0 + \hat{H}_i \mathcal{K}_i \hat{L}_i, \end{aligned}$$

with

$$\begin{bmatrix} A_i^0 & B_i^0 & \hat{G}_i \\ C_i^0 & D_i^0 & \hat{H}_i \\ \hat{\Gamma}_i & \hat{L}_i & \star \end{bmatrix} = \left[ \begin{array}{cc|cc|cc} A_i & 0 & B_i & 0 & G_i & \\ 0 & 0_k & 0_{k \times n_v} & I_k & 0 & \\ \hline C_i & 0_{n_z \times k} & D_i & 0 & H_i & \\ 0 & I_k & 0 & \star & \star & \\ \hline \Gamma_i & 0 & L_i & \star & \star & \end{array} \right],$$

where  $\star$  denotes an entry which has no importance in the rest of this paper (see section 2). For the sake of simplicity we also introduce the following definition.

**DEFINITION 4.1.** A compensator  $\mathcal{K} \in \mathbb{H}_{\text{sup}}^{(k+n_y), (k+n_u)}$  such as (4.2) is said to be  $H_{\infty}$  of level  $\gamma$  whenever the closed-loop system  $\Sigma_{\mathcal{K}}$  is SS and  $\|\mathbb{L}\| < \gamma$ , in accordance with (3.3)–(3.4).

**4.2. Characterization results (general case).** In this subsection we shall derive conditions which relate the existence of  $H_{\infty}$  controllers of a given level  $\gamma$  to the solvability of LMIs. The main results here will be further explored in the next section, where the full-order case is dealt with.

The first result we prove shows that a given compensator  $\mathcal{K}$  guarantees SS of system  $\Sigma_{\mathcal{K}}$  with a desired DA level  $\gamma$  if and only if a specific LMI feasibility problem in the variable  $P$  possesses an adequate solution. It should be noted that *any*  $H_\infty$  controller must satisfy this condition in order to solve the DA problem at hand.

PROPOSITION 4.2. *Given a compensator  $\mathcal{K}$  and a desired disturbance attenuation level  $\gamma > 0$  to be achieved, the following are equivalent:*

- (i) *System  $\Sigma_{\mathcal{K}}$  is SS with  $\|\mathbb{L}\| < \gamma$ .*
- (ii) *There exists  $P = (P_1, P_2, \dots) \in \tilde{\mathbb{H}}_{\sup}^{\hat{n}-}$  such that*

$$(4.4) \quad \mathcal{M}^0 + (\mathcal{H}\mathcal{P})^* \mathcal{K} \mathcal{J} + \mathcal{J}^* \mathcal{K}^* (\mathcal{H}\mathcal{P}) \gg 0,$$

where  $\mathcal{M}^0 = (\mathcal{M}_1^0, \mathcal{M}_2^0, \dots) \in \mathbb{H}_{\sup}^{(\hat{n}+n_v+n_z)^*}$ , with

$$\mathcal{M}_i^0 = \begin{bmatrix} P_i A_i^0 + (A_i^0)^* P_i + \sum_{j \in \mathcal{S}} \lambda_{ij} P_j & P_i B_i^0 & (C_i^0)^* \\ (B_i^0)^* P_i & \gamma^2 I_{n_v} & D_i^* \\ C_i^0 & D_i & I_{n_z} \end{bmatrix}, \quad i \in \mathcal{S},$$

and  $\mathcal{P} \in \mathbb{H}_{\sup}^{(\hat{n}+n_v+n_z)^*}$ ,  $\mathcal{H} \in \mathbb{H}_{\sup}^{(\hat{n}+n_v+n_z), (k+n_u)}$ , and  $\mathcal{J} \in \mathbb{H}_{\sup}^{(\hat{n}+n_v+n_z), (k+n_y)}$  given by

$$\mathcal{P} = \begin{bmatrix} P & 0 & 0 \\ 0 & I_{n_v} & 0 \\ 0 & 0 & I_{n_z} \end{bmatrix}, \quad \mathcal{H} = \begin{bmatrix} \hat{G}^* & 0_{(k+n_u) \times n_v} & \hat{H}^* \end{bmatrix},$$

$$\mathcal{J} = \begin{bmatrix} \hat{\Gamma} & \hat{L} & 0_{(k+n_y) \times n_z} \end{bmatrix}.$$

*Proof.* The proof relies on straightforward manipulations of (3.5), which is equivalent to condition (i) above (Lemma 3.3). It turns out that (i) holds if and only if, for some  $P = (P_1, P_2, \dots) \in \tilde{\mathbb{H}}_{\sup}^{\hat{n}-}$  and every  $i \in \mathcal{S}$ ,

$$\mathcal{M}_i^0 + \text{Her} \begin{bmatrix} P_i \hat{G}_i \mathcal{K}_i \hat{\Gamma}_i & P_i \hat{G}_i \mathcal{K}_i \hat{L}_i & 0_{\hat{n} \times n_z} \\ 0_{n_v \times \hat{n}} & 0_{n_v} & 0_{n_v \times n_z} \\ \hat{H}_i \mathcal{K}_i \hat{\Gamma}_i & \hat{H}_i \mathcal{K}_i \hat{L}_i & 0_{n_z} \end{bmatrix} \gg 0,$$

which corresponds to (ii),  $\mathcal{M}^0 + \text{Her}\{(\mathcal{H}\mathcal{P})^* \mathcal{K} \mathcal{J}\} \gg 0$ .  $\square$

The following proposition states that the existence of any compensator *at all* which is  $H_\infty$  of level  $\gamma$  depends on the feasibility of two specific sets of matrix inequalities.

PROPOSITION 4.3. *There exists a compensator  $\mathcal{K}$  which is  $H_\infty$  of level  $\gamma$  if and only if the following conditions are satisfied for some  $P = (P_1, P_2, \dots) \in \tilde{\mathbb{H}}_{\sup}^{\hat{n}-}$ :*

- (i)  $\mathcal{M}^0 \gg 0$  over  $\mathcal{N}(\mathcal{J})$ ;
- (ii)  $\mathcal{P}^{-1} \mathcal{M}^0 \mathcal{P}^{-1} \gg 0$  over  $\mathcal{N}(\mathcal{H})$ .

*Proof.* (Necessity.) Suppose that such  $\mathcal{K}$  exists. Then, from Proposition 4.2, there must exist  $P \in \tilde{\mathbb{H}}_{\sup}^{\hat{n}-}$  such that (4.4) is satisfied. From Lemma 2.5, condition (i) is just a consequence of this fact, along with the following, for some  $\mu > 0$ :

$$(4.5) \quad y_i^* \mathcal{M}_i^0 y_i \geq \mu y_i^* y_i \text{ whenever } \mathcal{H}_i \mathcal{P}_i y_i = 0.$$

Now notice that the linear map  $\mathcal{N}(\mathcal{H}_i \mathcal{P}_i) \ni y_i \mapsto \mathcal{P}_i y_i = x_i \in \mathcal{N}(\mathcal{H}_i)$  is a bijection between  $\mathcal{N}(\mathcal{H}_i \mathcal{P}_i)$  and  $\mathcal{N}(\mathcal{H}_i)$ . Thus, the above condition holds if and only if, for all  $i \in \mathcal{S}$ ,

$$(4.6) \quad (\mathcal{P}_i^{-1} x_i)^* \mathcal{M}_i^0 (\mathcal{P}_i^{-1} x_i) \geq \mu (\mathcal{P}_i^{-1} x_i)^* (\mathcal{P}_i^{-1} x_i)$$

$$= \mu x_i^* \mathcal{P}_i^{-2} x_i$$

holds true for every such  $x_i$ . But since  $P \in \tilde{\mathbb{H}}_{\text{sup}}^{\hat{n}-}$ , it follows that  $P^2 \in \tilde{\mathbb{H}}_{\text{sup}}^{\hat{n}+}$ ; thus, there must exist positive bounds  $\varepsilon_1, \varepsilon_2$  such that

$$(4.7) \quad \varepsilon_1 I \leq P^2 \leq \varepsilon_2 I \quad \Leftrightarrow \quad \varepsilon_1^{-1} I \geq P^{-2} \geq \varepsilon_2^{-1} I,$$

that is,  $P^{-2} \in \tilde{\mathbb{H}}_{\text{sup}}^{\hat{n}+}$  also. Then we have that the congruence transformation  $\mathfrak{C}(\cdot, \mathcal{P}^{-1})$  (see section 2) satisfies the conditions described in Proposition 2.1, from which (4.6) implies that, for some  $\varepsilon > 0$  sufficiently small and every  $x_i \in \mathcal{N}(\mathcal{H}_i)$ ,

$$(\mathcal{P}_i^{-1} x_i)^* \mathcal{M}_i^0 (\mathcal{P}_i^{-1} x_i) \geq \mu x_i^* \mathcal{P}_i^{-2} x_i > \varepsilon x_i^* x_i,$$

which corresponds to (ii), since the existence of a norm bound for  $\mathfrak{C}(\mathcal{M}^0, \mathcal{P}^{-1})$  is ensured by Proposition 2.1.

(Sufficiency.) Since condition (ii) is equivalent to (4.5) holding for all  $i \in \mathcal{S}$ , it follows that the existence of such  $P \in \tilde{\mathbb{H}}_{\text{sup}}^{\hat{n}-}$  guarantees (again from Lemma 2.5) that there is  $\mathcal{K}$  such that (4.4) is satisfied, which from Proposition 4.2 implies that this controller meets the desired condition.  $\square$

It should be noted that, even though the first condition of the last proposition corresponds to an LMI feasibility problem, the same doesn't hold for the second one. Besides, it will be shown that the restrictions on  $\mathcal{N}(\mathcal{J})$  and  $\mathcal{N}(\mathcal{H})$  can be expressed under simpler forms. With the aid of Corollary 2.4 we shall restate the last result in a more suitable way in what follows.

PROPOSITION 4.4. For  $X = (X_1, X_2, \dots)$ ,  $Y = (Y_1, Y_2, \dots) \in \mathbb{H}_{\text{sup}}^{n*}$ ,  $P_2 = (P_{21}, P_{22}, \dots)$ ,  $S_2 = (S_{21}, S_{22}, \dots) \in \mathbb{H}_{\text{sup}}^{k,n}$ ,  $P_3 = (P_{31}, P_{32}, \dots) \in \mathbb{H}_{\text{sup}}^k$ , and  $S_3 = (S_{31}, S_{32}, \dots) \in \mathbb{H}_{\text{sup}}^k$ , let

$$P_i := \begin{bmatrix} X_i & P_{2i} \\ P_{2i}^* & P_{3i} \end{bmatrix}, \quad S_i := P_i^{-1} = \begin{bmatrix} Y_i & S_{2i} \\ S_{2i}^* & S_{3i} \end{bmatrix}, \quad i \in \mathcal{S}.$$

Then

(i)  $\mathcal{M}^0 \gg 0$  over  $\mathcal{N}(\mathcal{J})$  if and only if

$$(4.8) \quad \begin{bmatrix} A_i^* X_i + X_i A_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & X_i B_i & C_i^* \\ B_i^* X_i & \gamma^2 I_{n_v} & D_i^* \\ C_i & D_i & I_{n_z} \end{bmatrix} \gg 0$$

over  $\mathcal{N} \left[ \begin{array}{ccc} \Gamma_i & L_i & 0_{n_y \times n_z} \end{array} \right];$

(ii)  $\mathcal{P}^{-1} \mathcal{M}^0 \mathcal{P}^{-1} \gg 0$  over  $\mathcal{N}(\mathcal{H})$  if and only if

$$(4.9) \quad \begin{bmatrix} Y_i A_i^* + A_i Y_i + \lambda_{ii} Y_i + \sum_{j \neq i} \lambda_{ij} (S_i S_j^{-1} S_i)_{11} & Y_i C_i^* & B_i \\ C_i Y_i & I_{n_z} & D_i \\ B_i^* & D_i^* & \gamma^2 I_{n_v} \end{bmatrix} \gg 0$$

over  $\mathcal{N} \left[ \begin{array}{ccc} G_i^* & H_i^* & 0_{n_u \times n_v} \end{array} \right],$

where  $(S_i S_j^{-1} S_i)_{11} = Y_i X_j Y_i + Y_i P_{2j} S_{2i}^* + S_{2i} P_{2j}^* Y_i + S_{2i} P_{3j} S_{2i}^*$ .

*Proof.* First of all, notice that  $\mathcal{N}(\mathcal{J}_i)$  may be rewritten as

$$\mathcal{N} \left[ \begin{array}{ccc} \hat{\Gamma}_i & \hat{L}_i & 0_{(k+n_y) \times n_z} \end{array} \right] = \mathcal{N} \left[ \begin{array}{cccc} 0 & I_k & 0 & 0 \\ \Gamma_i & 0 & L_i & 0_{n_y \times n_z} \end{array} \right] = \mathcal{R} \left[ \begin{array}{cc} \Phi_{1i} & 0 \\ 0 & 0_k \\ \Phi_{2i} & 0 \\ 0 & I_{n_z} \end{array} \right]$$

whenever  $\mathcal{N} \begin{bmatrix} \Gamma_i & L_i \end{bmatrix} = \mathcal{R} \begin{bmatrix} \Phi_{1i} \\ \Phi_{2i} \end{bmatrix}$ . Thus, noticing that  $(P_i A_i^0)_{11} = X_i A_i$ , we have that the first condition of Proposition 4.3 is equivalent to

$$\begin{aligned} 0 &\ll \mathfrak{C} \left( \begin{bmatrix} A_i^* X_i + X_i A_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & \star & X_i B_i & C_i^* \\ \star & \star & \star & \star \\ B_i^* X_i & \star & \gamma^2 I_{n_v} & D_i^* \\ C_i & \star & D_i & I_{n_z} \end{bmatrix}, \begin{bmatrix} \Phi_{1i} & 0 \\ 0 & 0 \\ \Phi_{2i} & 0 \\ 0 & I \end{bmatrix} \right) \\ &= \mathfrak{C} \left( \begin{bmatrix} A_i^* X_i + X_i A_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & X_i B_i & C_i^* \\ B_i^* X_i & \gamma^2 I_{n_v} & D_i^* \\ C_i & D_i & I_{n_z} \end{bmatrix}, \begin{bmatrix} \Phi_{1i} & 0 \\ \Phi_{2i} & 0 \\ 0 & I_{n_z} \end{bmatrix} \right), \end{aligned}$$

from which (i) follows. With respect to the second condition of Proposition 4.3 we have that

$$\begin{aligned} &\mathcal{P}_i^{-1} \mathcal{M}_i^0 \mathcal{P}_i^{-1} \\ &= \mathfrak{C} \left( \begin{bmatrix} (A_i^0)^* P_i + P_i A_i^0 + \sum_{j \in \mathcal{S}} \lambda_{ij} P_j & \star & \star \\ (B_i^0)^* P_i & \gamma^2 I_{n_v} & \star \\ C_i^0 & D_i & I_{n_z} \end{bmatrix}, \begin{bmatrix} P_i^{-1} & 0 & 0 \\ 0 & I_{n_v} & 0 \\ 0 & 0 & I_{n_z} \end{bmatrix} \right) \\ &= \begin{bmatrix} S_i (A_i^0)^* + A_i^0 S_i + \sum_{j \in \mathcal{S}} \lambda_{ij} S_i S_j^{-1} S_i & B_i^0 & S_i (C_i^0)^* \\ (B_i^0)^* & \gamma^2 I_{n_v} & D_i^* \\ C_i^0 S_i & D_i & I_{n_z} \end{bmatrix}, \end{aligned}$$

which clearly corresponds to (ii). Moreover, we have that  $\mathcal{N}(\mathcal{H}_i)$  may be rewritten as

$$\mathcal{N}(\mathcal{H}_i) = \mathcal{N} \left( \begin{bmatrix} \hat{G}_i^* & 0_{(k+n_u) \times n_v} & \hat{H}_i^* \end{bmatrix} \right) = \mathcal{R} \begin{bmatrix} \hat{\Psi}_{1i} & 0 \\ 0 & I_{n_v} \\ \hat{\Psi}_{2i} & 0 \end{bmatrix}$$

whenever  $\mathcal{R} \begin{bmatrix} \hat{\Psi}_{1i} \\ \hat{\Psi}_{2i} \end{bmatrix} = \mathcal{N} \begin{bmatrix} \hat{G}_i^* & \hat{H}_i^* \end{bmatrix}$ . We rewrite condition (ii) as

$$\begin{aligned} 0 &\ll \mathfrak{C} \left( \begin{bmatrix} S_i (A_i^0)^* + A_i^0 S_i + \sum_{j \in \mathcal{S}} \lambda_{ij} S_i S_j^{-1} S_i & \star & \star \\ (B_i^0)^* & \gamma^2 I_{n_v} & \star \\ C_i^0 S_i & D_i & I_{n_z} \end{bmatrix}, \begin{bmatrix} \hat{\Psi}_{1i} & 0 \\ 0 & I \\ \hat{\Psi}_{2i} & 0 \end{bmatrix} \right) \\ &= \mathfrak{C} \left( \begin{bmatrix} S_i (A_i^0)^* + A_i^0 S_i + \sum_{j \in \mathcal{S}} \lambda_{ij} S_i S_j^{-1} S_i & \star & \star \\ C_i^0 S_i & I_{n_z} & \star \\ (B_i^0)^* & D_i^* & \gamma^2 I_{n_v} \end{bmatrix}, \begin{bmatrix} \hat{\Psi}_{1i} & 0 \\ \hat{\Psi}_{2i} & 0 \\ 0 & I_{n_v} \end{bmatrix} \right). \end{aligned}$$

But

$$\mathcal{R} \begin{bmatrix} \hat{\Psi}_{1i} \\ \hat{\Psi}_{2i} \end{bmatrix} = \mathcal{N} \begin{bmatrix} \hat{G}_i^* & \hat{H}_i^* \end{bmatrix} = \mathcal{N} \begin{bmatrix} 0 & I_k & 0 \\ G_i^* & 0 & H_i^* \end{bmatrix} = \mathcal{R} \begin{bmatrix} \Psi_{1i} & 0 \\ 0 & 0_k \\ \Psi_{2i} & 0 \end{bmatrix}$$

whenever  $\mathcal{N} \begin{bmatrix} G_i^* & H_i^* \end{bmatrix} = \mathcal{R} \begin{bmatrix} \Psi_{1i} \\ \Psi_{2i} \end{bmatrix}$ . By substituting into the previous expression we get the equivalence to

$$\begin{aligned} 0 &\ll \mathfrak{C} \left( \begin{bmatrix} Y_i A_i^* + A_i Y_i + \sum_{j \in \mathcal{S}} \lambda_{ij} (S_i S_j^{-1} S_i)_{11} & \star & Y_i C_i^* & B_i \\ \star & \star & \star & \star \\ C_i Y_i & \star & I_{n_z} & D_i \\ B_i^* & \star & D_i^* & \gamma^2 I_{n_v} \end{bmatrix}, \begin{bmatrix} \Psi_{1i} & 0 \\ 0 & 0_{k \times n_v} \\ \Psi_{2i} & 0 \\ 0 & I_{n_v} \end{bmatrix} \right) \\ &= \mathfrak{C} \left( \begin{bmatrix} Y_i A_i^* + A_i Y_i + \sum_{j \neq i} \lambda_{ij} (S_i S_j^{-1} S_i)_{11} & \star & \star \\ C_i Y_i & I_{n_z} & \star \\ B_i^* & D_i^* & \gamma^2 I_{n_v} \end{bmatrix}, \begin{bmatrix} \Psi_{1i} & 0 \\ \Psi_{2i} & 0 \\ 0 & I_{n_v} \end{bmatrix} \right), \end{aligned}$$

and (ii) follows directly.  $\square$

*Remark 4.5.* In the single-mode case (when  $\mathcal{S} = \{1\}$ ) the above result reconciles with the LMI characterization results stated, for instance, in [14], [15], and [18].

Although the last result applies to the general-order case (when  $k$  is arbitrary), it has two major drawbacks:

- (i) Relation (4.9) depends on every entry of  $S$  (and  $P$ , consequently) through the term  $S_i S_j^{-1} S_i$ .
- (ii) The equality  $S = P^{-1}$  leads to the coupling condition  $X = (Y - S_2 S_3^{-1} S_2^*)^{-1}$ , which is nonlinear and conservative in excess.

In an effort to overcome such drawbacks, we consider in the next subsection the full-order case. The main idea is that, by restricting ourselves to a specific class of Lyapunov functions, a fairly complete LMI characterization may be derived along the lines of Proposition 4.4.

**4.3. Characterization results (full-order case).** This subsection deals with the so-called *full-order case*, in which  $k = n$  (that is, we consider controllers of the same order as the to-be-controlled system). The main result (Theorem 4.8) states an equivalent condition to the existence of  $H_\infty$  controllers of such type in terms of two distinct LMI problems (see also Algorithm 4.10).

The basic idea here is to restrict ourselves to the class of quadratic Lyapunov functions parametrized by

$$(4.10) \quad P_i = \begin{bmatrix} X_i & Y_i^{-1} - X_i \\ Y_i^{-1} - X_i & X_i - Y_i^{-1} \end{bmatrix}, \quad i \in \mathcal{S}.$$

Notice that, in this case,  $S_i := P_i^{-1} = \begin{bmatrix} Y_i & Y_i \\ Y_i & \star \end{bmatrix}$  for every such  $i$ , and hence

$$(4.11) \quad S_i S_j^{-1} S_i = \begin{bmatrix} Y_i Y_j^{-1} Y_i & \star \\ \star & \star \end{bmatrix}.$$

In what follows we shall investigate what conditions  $X, Y \in \mathbb{H}_{\text{sup}}^{n*}$  must satisfy so that a quadratic Lyapunov function may be defined with the aid of (4.10). First, we derive a sufficient condition in terms of LMIs. This result, in conjunction with an auxiliary lemma, will be germane to the proof of Theorem 4.8, which shows that the sufficient condition is also necessary.

**THEOREM 4.6.** *There exists a full-order  $H_\infty$  compensator  $\mathcal{K}$  of level  $\gamma$  whenever there exist  $X, Y \in \mathbb{H}_{\text{sup}}^{n*}$  such that the following set of LMIs is satisfied for every  $i \in \mathcal{S}$ :*

$$(4.12a) \quad \begin{bmatrix} A_i^* X_i + X_i A_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & X_i B_i & C_i^* \\ B_i^* X_i & \gamma^2 I_{n_v} & D_i^* \\ C_i & D_i & I_{n_z} \end{bmatrix} \gg 0$$

over  $\mathcal{N} \begin{bmatrix} \Gamma_i & L_i & 0_{n_y \times n_z} \end{bmatrix},$

$$(4.12b) \quad \begin{bmatrix} Y_i A_i^* + A_i Y_i + \lambda_{ii} Y_i & Y_i C_i^* & B_i & \underline{\lambda}'_i \otimes Y_i \\ C_i Y_i & I_{n_z} & D_i & 0 \\ B_i^* & D_i^* & \gamma^2 I_{n_v} & 0 \\ \underline{\lambda}_i \otimes Y_i & 0 & 0 & \mathbb{D}_i(Y) \end{bmatrix} \gg 0$$

over  $\mathcal{N} \begin{bmatrix} G_i^* & H_i^* & 0_{n_u \times n_v} & 0_{n_u \times \infty} \end{bmatrix},$

and

$$(4.12c) \quad \begin{bmatrix} Y_i & I \\ I & X_i \end{bmatrix} \ll 0,$$

where  $\underline{\lambda}_i = (\sqrt{\lambda_{i1}}, \dots, \sqrt{\lambda_{i(i-1)}}, \sqrt{\lambda_{i(i+1)}}, \dots)$ ,  $\mathbb{D}_i(Y) := -\text{diag}(Y_1, \dots, Y_{i-1}, Y_{i+1}, \dots)$  for any such  $i$ , and  $0_{\bullet \times \infty}$  is a zero matrix with an infinite number of columns.

*Proof.* The idea behind this proof is to further improve the previous result (Proposition 4.4) by choosing  $P$  as in (4.10). Notice that (4.12c) implies  $X - Y^{-1} \ll 0$  and

$$(4.13) \quad X - (Y^{-1} - X)(X - Y^{-1})^{-1}(Y^{-1} - X) = Y^{-1} \ll 0,$$

which guarantees that this particular choice satisfies  $P \ll 0$ .

Since (4.8) depends only on the first diagonal block of  $P$  this condition remains unchanged, (4.12a). Hence, it remains only to prove that (4.12b) yields (4.9).

Let  $\Phi = (\Phi_1, \Phi_2, \dots)$  be an orthonormal basis for  $\mathcal{N} \begin{bmatrix} G_i^* & H_i^* & 0_{n_u \times n_v} \end{bmatrix}$  and, for any such  $i \in \mathcal{S}$ , define

$$\left[ \begin{array}{c|c} \frac{U_i}{V_i^*} & \frac{V_i}{W_i} \end{array} \right] := \left[ \begin{array}{c|c} \Phi_i^* \begin{pmatrix} \text{Her}(A_i Y_i) + \lambda_{ii} Y_i & Y_i C_i^* & B_i \\ C_i Y_i & I_{n_z} & D_i \\ B_i^* & D_i^* & \gamma^2 I_{n_v} \end{pmatrix} \Phi_i & \Phi_i^* \begin{pmatrix} \underline{\lambda}'_i \otimes Y_i \\ 0 \\ 0 \end{pmatrix} \\ \hline \begin{pmatrix} \underline{\lambda}_i \otimes Y_i & 0 & 0 \end{pmatrix} \Phi_i & \mathbb{D}_i(Y) \end{array} \right].$$

Then, bearing in mind (A.5) and (A.9), it is not difficult to see that application of the transformation  $\mathfrak{C}\{\cdot, [-W_i^{-1} V_i^*]\}$ ,  $i \in \mathcal{S}$ , to both sides of (4.12b) yields

$$(4.14) \quad \left[ \begin{array}{c|c} Y_i A_i^* + A_i Y_i + \lambda_{ii} Y_i + \sum_{j \neq i} \lambda_{ij} Y_i Y_j^{-1} Y_i & Y_i C_i^* & B_i \\ C_i Y_i & I_{n_z} & D_i \\ B_i^* & D_i^* & \gamma^2 I_{n_v} \end{array} \right] \gg 0$$

over  $\mathcal{N} \begin{bmatrix} G_i^* & H_i^* & 0_{n_u \times n_v} \end{bmatrix}$ .

In fact, assume the left-hand side (LHS) of (4.12b) is  $\varepsilon$ -positive; then, in a similar way to (A.5), we have

$$(4.15) \quad U_i - V_i W_i^{-1} V_i^* = \mathfrak{C} \left\{ \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix}, \begin{bmatrix} I \\ -W_i^{-1} V_i^* \end{bmatrix} \right\} \geq \varepsilon I$$

for every  $i \in \mathcal{S}$ . Finally, we have from (A.9) that

$$\|U_i - V_i W_i^{-1} V_i^*\| \leq (1 + \|V_i W_i^{-1}\|)^2 \left\| \begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \right\|_{\sup},$$

in which, for every such  $i \in \mathcal{S}$ ,

$$(4.16) \quad \begin{aligned} \|V_i W_i^{-1}\| &\leq \|\Phi_i\| \|(\underline{\lambda}'_i \otimes Y_i) \mathbb{D}_i(Y^{-1})\| \leq \|\underline{\lambda}_i\| \|Y\|_{\sup} \|Y^{-1}\|_{\sup} \\ &= \left( \sum_{j \in \mathcal{S} \setminus \{i\}} \lambda_{ij} \right)^{1/2} \|Y\|_{\sup} \|Y^{-1}\|_{\sup} \\ &\leq \sqrt{\varrho} \|Y\|_{\sup} \|Y^{-1}\|_{\sup} \end{aligned}$$

with  $\varrho$  as defined in the beginning of section 3. This concludes the proof, since (4.14) is just a restatement of (4.9) with  $P$  given by (4.10).  $\square$

Before presenting our main result, we state the following lemma. It is proven that the feasibility of a specific LMI problem is necessary for the existence of full-order controllers, in the spirit of [20, Theorem 4].

LEMMA 4.7. *Suppose there exists a full-order  $H_\infty$  compensator  $\mathcal{K}$  of level  $\gamma$ . Then there exist  $X = (X_1, X_2, \dots)$ ,  $Y = (Y_1, Y_2, \dots) \in \mathbb{H}_{\sup}^{n_y, n}$ ,  $J = (J_1, J_2, \dots) \in \mathbb{H}_{\sup}^{n_y, n}$ ,  $F = (F_1, F_2, \dots) \in \mathbb{H}_{\sup}^{n, n_u}$ , and  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\sup}^{n_y, n_u}$  such that the following LMIs are satisfied for every  $i \in \mathcal{S}$ :*

$$(4.17a) \quad \begin{bmatrix} \text{Her}(X_i A_i + J_i \Gamma_i) + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & * & * \\ (X_i B_i + J_i L_i)^* & \gamma^2 I_{n_v} & * \\ C_i + H_i U_i \Gamma_i & D_i + H_i U_i L_i & I_{n_z} \end{bmatrix} \gg 0,$$

$$(4.17b) \quad \begin{bmatrix} \text{Her}(A_i Y_i + G_i F_i) + \lambda_{ii} Y_i & * & * & * \\ (B_i + G_i U_i L_i)^* & \gamma^2 I_{n_v} & * & * \\ C_i Y_i + H_i F_i & D_i + H_i U_i L_i & I_{n_z} & * \\ \underline{\lambda}_i \otimes Y_i & 0 & 0 & \mathbb{D}_i(Y) \end{bmatrix} \gg 0,$$

$$(4.17c) \quad \begin{bmatrix} Y_i & I \\ I & X_i \end{bmatrix} \ll 0.$$

*Proof.* From the hypothesis there must exist  $P = (P_1, P_2, \dots) \ll 0$  satisfying (3.5). For later use, let us write such  $P$  and  $S := P^{-1}$  under the following compatible form:

$$(4.18) \quad P = \begin{bmatrix} X & P_2 \\ P_2^* & P_3 \end{bmatrix}, \quad S = \begin{bmatrix} Y & S_2 \\ S_2^* & S_3 \end{bmatrix}.$$

Introducing now  $\mathcal{I} = \begin{bmatrix} 0_n & I_n \end{bmatrix}$ , let us make explicit the affine dependence of  $\hat{A}$  on  $\mathcal{K}^{11}$ :

$$(4.19) \quad \hat{A}_i = \begin{bmatrix} A_i + G_i \mathcal{K}_i^{22} \Gamma_i & G_i \mathcal{K}_i^{21} \\ \mathcal{K}_i^{12} \Gamma_i & 0_n \end{bmatrix} + \begin{bmatrix} 0_n & 0 \\ 0 & \mathcal{K}_i^{11} \end{bmatrix} =: \underline{\hat{A}}_i + \mathcal{I}' \mathcal{K}_i^{11} \mathcal{I}.$$

Next, define  $\mathcal{J} = \begin{bmatrix} I_n & 0_n \end{bmatrix}'$  and notice that  $\mathcal{N}(\text{diag}(\mathcal{J}, I_{n_v}, I_{n_z})) = \{0\}$ , so uniform definiteness is preserved under application of  $\mathfrak{C}(\cdot, \text{diag}(\mathcal{J}, I_{n_v}, I_{n_z}))$  on (3.5). Moreover, since  $\mathcal{I}\mathcal{J} = 0$  the hypothesis yields

$$(4.20) \quad \begin{bmatrix} \mathcal{J}'(\underline{\hat{A}}_i^* P_i + P_i \underline{\hat{A}}_i + \sum_{j \in \mathcal{S}} \lambda_{ij} P_j) \mathcal{J} & * & * \\ \hat{B}_i^* P_i \mathcal{J} & \gamma^2 I_{n_v} & * \\ \hat{C}_i \mathcal{J} & \hat{D}_i & I_{n_z} \end{bmatrix} \gg 0.$$

By defining  $U := \mathcal{K}^{22}$ ,  $J := XGU + P_2 \mathcal{K}^{12}$  and performing the indicated calculations, the equivalence between (4.20) and (4.17a) follows immediately.

Proceeding further, we have that the transformation  $\mathfrak{C}(\cdot, \text{diag}(S_i, I_{n_v}, I_{n_z})) \equiv \mathfrak{C}(\cdot, \mathcal{P}^{-1})$ , which also preserves uniform definiteness (see the proof of Proposition 4.3), leaves (3.5) as

$$(4.21) \quad \begin{bmatrix} S_i \hat{A}_i^* + \hat{A}_i S_i + \sum_{j \in \mathcal{S}} \lambda_{ij} S_i S_j^{-1} S_i & * & * \\ \hat{B}_i^* & \gamma^2 I_{n_v} & * \\ \hat{C}_i S_i & \hat{D}_i & I_{n_z} \end{bmatrix} \gg 0.$$

In the spirit of Theorem 2.2, let us now define

$$(4.22) \quad \mathcal{U}_i - \mathcal{V}_i \mathcal{W}_i^{-1} \mathcal{V}_i^* := \begin{bmatrix} S_i \hat{A}_i^* + \hat{A}_i S_i + \lambda_{ii} S_i & * & * \\ \hat{B}_i^* & \gamma^2 I_{n_v} & * \\ \hat{C}_i S_i & \hat{D}_i & I_{n_z} \end{bmatrix} - \begin{bmatrix} \underline{\lambda}_i' \otimes S_i \\ 0 \\ 0 \end{bmatrix} \mathbb{D}_i(S)^{-1} \begin{bmatrix} \underline{\lambda}_i' \otimes S_i \\ 0 \\ 0 \end{bmatrix}^*$$

for each  $i \in \mathcal{S}$ . Then (4.21) implies that

$$\begin{bmatrix} \mathcal{U}_i & \mathcal{V}_i \\ \mathcal{V}_i^* & \mathcal{W}_i \end{bmatrix} = \begin{bmatrix} I & \mathcal{V}_i \mathcal{W}_i^{-1} \\ 0 & I \end{bmatrix} \begin{bmatrix} \mathcal{U}_i - \mathcal{V}_i \mathcal{W}_i^{-1} \mathcal{V}_i^* & 0 \\ 0 & \mathcal{W}_i \end{bmatrix} \begin{bmatrix} I & 0 \\ \mathcal{W}_i^{-1} \mathcal{V}_i^* & I \end{bmatrix} \gg 0$$

on  $\mathcal{S}$ , which may be rewritten more explicitly as

$$(4.23) \quad \begin{bmatrix} S_i \hat{A}_i^* + \hat{A}_i S_i + \lambda_{ii} S_i & * & * & * \\ \hat{B}_i^* & \gamma^2 I_{n_v} & * & * \\ \hat{C}_i S_i & \hat{D}_i & I_{n_z} & * \\ \underline{\lambda}_i \otimes S_i & 0 & 0 & \mathbb{D}_i(S) \end{bmatrix} \gg 0.$$

To see why this is true, we rely on two facts. First, that  $\mathcal{X}_i := \mathcal{W}_i^{-1} \mathcal{V}_i^*$  is such that

$$(4.24) \quad \sup \sigma \{ \mathcal{X}_i^* \mathcal{X}_i \} = \|\mathcal{V}_i \mathcal{W}_i^{-1}\|^2 \leq (\sqrt{\varrho} \|P\|_{\sup} \|S\|_{\sup})^2 < \infty$$

for all  $i \in \mathcal{S}$ ; this can be verified directly from (4.22), in the same vein as (4.16) (here  $\sigma\{\cdot\}$  denotes the spectrum of an infinite matrix, and  $\varrho$  is as defined in the beginning of section 3). Hence, by performing a minor modification to (A.4) and bearing in mind (A.2)–(A.3), it follows that a uniform lower bound must be attained on (4.23). Finally, the other fact to be observed is that, in the spirit of (A.8), the estimate (4.24) should guarantee the existence of a norm bound to the LHS of (4.23) over all  $i \in \mathcal{S}$ .

At this point, we already know that (4.23) is necessary for the existence of compensators. But since  $\mathcal{N}(\mathcal{J}) = \{0\}$  it follows that uniform positivity is not affected by  $\mathfrak{C}\{\cdot, \text{diag}(\mathcal{J}, I_{n_v}, I_{n_z}, \text{diag}(\mathcal{J}, \dots))\}$ . Thus, defining  $F := UTY + \mathcal{K}^{21} S_2^*$  we have (4.23) reduced to (4.17b) by such transformation.

To complete the proof, notice that  $P_2$  may be assumed invertible without loss of generality: given any admissible  $P \ll 0$ , just perturb it to  $\tilde{P} \ll 0$  in such a way that  $\tilde{P}_2$  is invertible and (3.5) continues to hold true. By a classical argument, there always exists such  $\tilde{P} \in \tilde{\mathbb{H}}_{\sup}^{n-}$  arbitrarily close to  $P$ . In light of this, the congruence transformation associated to  $\begin{bmatrix} Y & I \\ -P_3^{-1} P_2^* Y & 0 \end{bmatrix}$  leaves  $P_i \ll 0$  as (4.17c).  $\square$

The following main result of this section unifies the results obtained so far by giving equivalent conditions to the existence of full-order  $H_\infty$  compensators.

**THEOREM 4.8** (full-order characterization). *The following statements are equivalent:*

- (i) *There exists a full-order  $H_\infty$  compensator  $\mathcal{K}$  of level  $\gamma$ .*
- (ii) *There exist suitable  $X, Y$  such that (4.12) is satisfied for every  $i \in \mathcal{S}$ .*
- (iii) *There exist suitable  $X, Y, J, F$ , and  $U$  such that (4.17) is satisfied for every  $i \in \mathcal{S}$ .*

Moreover, given any  $X, Y$  satisfying (ii) there always exist suitable  $J, F$ , and  $U$  such that (iii) is satisfied.

*Proof.* First assume (ii) holds; then Theorem 4.6 guarantees that (i) is satisfied. Next, notice that (i) yields (iii) according to Lemma 4.7 (the fact that such  $X$  and  $Y$  satisfying (iii) may be chosen by (ii) will be proved last). Thus it remains only to prove (iii)  $\Rightarrow$  (ii).

Assume (iii) is true. Since relations (4.17c) and (4.12c) are the same, it remains only to prove that such  $X, Y$  satisfy (4.12a) and (4.12b), respectively. We have that (4.17a) may be written

$$(4.25) \quad \begin{bmatrix} X_i A_i + A_i^* X_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j & * & * \\ B_i^* X_i & \gamma^2 I & * \\ C_i & D_i & I \end{bmatrix} + \text{Her} \left( \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & H_i^* \end{bmatrix}^* \begin{bmatrix} J_i \\ 0 \\ U_i \end{bmatrix} \begin{bmatrix} \Gamma_i & L_i & 0 \end{bmatrix} \right) \gg 0.$$

Moreover, the transformation

$$\mathfrak{C} \left( \cdot, \begin{bmatrix} I & 0 & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & I & 0 & 0 \\ 0 & 0 & 0 & I \end{bmatrix} \right)$$

leaves (4.17b) equivalent to

$$(4.26) \quad \begin{bmatrix} \text{Her}(A_i Y_i) + \sum_{j \in \mathcal{S}} \lambda_{ij} Y_i Y_j^{-1} Y_i & * & * \\ C_i Y_i & I & * \\ B_i^* & D_i^* & \gamma^2 I \end{bmatrix} + \text{Her} \left( \begin{bmatrix} G_i \\ H_i \\ 0 \end{bmatrix} \begin{bmatrix} F_i & 0 & U_i \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & L_i \end{bmatrix} \right) \gg 0$$

(this is proved just as (4.12b)  $\Rightarrow$  (4.14) in Theorem 4.6). Further on, we have that

$$(4.27) \quad \mathcal{N} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & H_i^* \end{bmatrix} = \mathcal{R} \begin{bmatrix} 0 \\ 0 \\ \Psi_{H_i^*} \end{bmatrix}, \quad \mathcal{N} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & L_i \end{bmatrix} = \mathcal{R} \begin{bmatrix} 0 \\ 0 \\ \Psi_{L_i} \end{bmatrix}$$

for some adequate  $\Psi_{H_i^*}, \Psi_{L_i}$ . These facts, along with the uniform projection lemma (Lemma 2.5), lead to the fulfillment of statement (ii).

Finally, we prove that any  $X$  and  $Y$  satisfying (ii) may be fed into (iii) and suitable  $J, F$ , and  $U$  will always exist. In fact, just assume (ii) holds. Then (i) follows, and Lemma 4.7 guarantees that  $U = \mathcal{K}_{22}$ ,  $J = XGU + (Y^{-1} - X)\mathcal{K}^{12}$ , and  $F = UTY + \mathcal{K}^{21}Y$  are such that (4.17a)–(4.17c) are satisfied, completing the proof.  $\square$

*Remark 4.9.* In case  $D$  and  $\mathcal{K}^{22} = U$  are identically zero, all data are real, and the state space of the underlying Markov chain is finite, the LMIs (4.17a)–(4.17c) coincide with those pointed out in Theorem 4.2 of [7]. In addition, notice that here it is stated that such conditions are not only sufficient but also necessary for the existence of  $\mathcal{K}$ , with the class of Lyapunov functions taken into consideration.

Bearing in mind the above characterization result we present the following algorithm as a solution to the *existence* problem. It is noteworthy that each of the design

procedures we present in the next subsection (Algorithms 5.3, 5.4, and 5.5) depend on it to some extent.

**ALGORITHM 4.10** (existence of compensators). *The existence of some  $H_\infty$  compensator of given level  $\gamma > 0$  is guaranteed by solving either one of the following convex feasibility problems:*

**e<sub>1</sub>**: Find  $X = (X_1, X_2, \dots)$ ,  $Y = (Y_1, Y_2, \dots) \in \mathbb{H}_{\sup}^{n*}$ ,  $J = (J_1, J_2, \dots) \in \mathbb{H}_{\sup}^{n_y, n}$ ,  $F = (F_1, F_2, \dots) \in \mathbb{H}_{\sup}^{n, n_u}$ , and  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\sup}^{n_y, n_u}$  such that (4.17) is satisfied for every  $i \in \mathcal{S}$ .

**e<sub>2</sub>**: Find  $X = (X_1, X_2, \dots)$ ,  $Y = (Y_1, Y_2, \dots) \in \mathbb{H}_{\sup}^{n*}$  such that (4.12) is satisfied for every  $i \in \mathcal{S}$ .

On the other hand, whenever it may be proved that either of these problems doesn't have a solution, then such a compensator does not exist at all.

Finally, we would like to point out that the above algorithm is of immediate practical interest when it comes to the finite case, in the sense that it can be efficiently implemented by widely available convex programming software (see, for instance, [3], [19], and the references therein). The following remark closes this subsection with one last consideration in this direction.

**Remark 4.11.** Some evident differences between procedures **e<sub>1</sub>** and **e<sub>2</sub>** are the larger number of variables in the former and the projection-like restrictions in the latter. It would be interesting to determine under which conditions each of these aspects is more critical when aiming for practical implementation.

**5. Design.** In this section we present some tools for the design of full-order  $H_\infty$  compensators. Both the suboptimal and optimal synthesis problems are discussed.

The main theoretical result of this section, whose *statement* has been inspired in [7, Theorem 4.2] (see also [14]), provides the aforementioned formulas for construction of full-order  $H_\infty$  compensators, as follows.

**THEOREM 5.1.** *Suppose that suitable  $X$ ,  $Y$ ,  $J$ ,  $F$ , and  $U$  satisfying the conditions of Theorem 4.8 may be found. Then the following full-order compensator guarantees that SS of the closed-loop system  $\Sigma_K$  is achieved along with a DA level  $\gamma$ :*

$$(5.1) \quad K^{12} = (Y^{-1} - X)^{-1} (J - XGU),$$

$$(5.2) \quad K^{21} = (F - UTY)Y^{-1},$$

$$(5.3) \quad K^{22} = U,$$

and, for every  $i \in \mathcal{S}$ ,

$$(5.4) \quad \begin{aligned} K_i^{11} = & -(Y_i^{-1} - X_i)^{-1} \left\{ X_i(A_i Y_i + G_i F_i) + (J_i - X_i G_i U_i) \Gamma_i Y_i + \tilde{A}_i^* \right. \\ & + \sum_{j \in \mathcal{S}} \lambda_{ij} Y_j^{-1} Y_i - \tilde{C}_i^* (C_i Y_i + H_i F_i) - [X_i B_i + J_i L_i - \tilde{C}_i^* \tilde{D}_i] \\ & \left. \times (\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} [\tilde{B}_i - (C_i Y_i + H_i F_i)^* \tilde{D}_i] \right\} Y_i^{-1}, \end{aligned}$$

where

$$(5.5) \quad \begin{bmatrix} \tilde{A}_i & \tilde{B}_i \\ \tilde{C}_i & \tilde{D}_i \end{bmatrix} = \begin{bmatrix} A_i & B_i \\ C_i & D_i \end{bmatrix} + \begin{bmatrix} G_i \\ H_i \end{bmatrix} U_i \begin{bmatrix} \Gamma_i & L_i \end{bmatrix}.$$

*Proof.* First of all, notice that such  $X$  and  $Y$  (which are known by hypothesis) satisfy the conditions of Theorem 4.6; moreover, it has been proved there that  $P = (P_1, P_2, \dots)$  given by

$$(5.6) \quad P_i = \begin{bmatrix} X_i & Y_i^{-1} - X_i \\ Y_i^{-1} - X_i & X_i - Y_i^{-1} \end{bmatrix}, \quad i \in \mathcal{S},$$

ensures the existence of some  $H_\infty$  compensator  $\mathcal{K}$  of level  $\gamma$ , and hence it remains only to explicitly present one such compensator. Also notice that, in this case,  $S_i = P_i^{-1} = \begin{bmatrix} Y_i & Y_i \\ Y_i & \star \end{bmatrix}$  for every such  $i$ .

From Theorem 4.8 we have that such  $X, Y, J, F$ , and  $U$  (all of which are known) correspond to a solution of (4.17). Now, from Lemma 4.7 we have that such  $J, F$ , and  $U$  are related to the controller matrices (and to the Lyapunov variable  $P$ ) as

$$(5.7) \quad J = XGU + P_2\mathcal{K}^{12}, \quad F = U\Gamma Y + \mathcal{K}^{21}S_2^*, \quad U = \mathcal{K}^{22},$$

which, in accordance with (4.18) and (5.6), yields (5.1), (5.2), and (5.3).

To complete the proof we have to present some  $\mathcal{K}^{11}$  in order to solve the LMI problem (3.5); from Theorem 2.2, however, this is equivalent to  $0 \ll N^\gamma(P) = (N_1^\gamma(P), N_2^\gamma(P), \dots)$ , where

$$(5.8) \quad \begin{aligned} N_i^\gamma(P) := & \hat{A}_i^* P_i + P_i \hat{A}_i + \sum_{j \in \mathcal{S}} \lambda_{ij} P_j - \hat{C}_i^* \hat{C}_i \\ & - (P_i \hat{B}_i - \hat{C}_i^* \tilde{D}_i)(\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} (\hat{B}_i^* P_i - \tilde{D}_i^* \hat{C}_i) \end{aligned}$$

for every such  $i$ , since (4.17a) guarantees that  $\gamma^2 I - \tilde{D}_i^* \tilde{D}_i \gg 0$  (bearing in mind  $\tilde{D}_i := D_i + H_i U_i L_i$ ). Now define  $\mathfrak{R} = (\mathfrak{R}_1, \mathfrak{R}_2, \dots)$  by

$$(5.9) \quad \mathfrak{R}_i = \begin{bmatrix} \mathfrak{R}_i^{11} & \mathfrak{R}_i^{21*} \\ \mathfrak{R}_i^{21} & \mathfrak{R}_i^{22} \end{bmatrix} = \begin{bmatrix} Y_i & I \\ Y_i & 0 \end{bmatrix}^* N_i^\gamma(P) \begin{bmatrix} Y_i & I \\ Y_i & 0 \end{bmatrix}$$

for  $i \in \mathcal{S}$ , with each block dimension according to  $\hat{A}_i$ . Since the above congruence transformation satisfies the conditions of Proposition 2.1, we have that the uniform positivity of  $\mathfrak{R}_i$  on  $i \in \mathcal{S}$  is actually equivalent to that of  $N^\gamma(P)$ .

A sketch of the rest of the proof is as follows. First, we shall prove that  $\mathfrak{R}^{11} \gg 0$  and  $\mathfrak{R}^{22} \gg 0$  regardless of what choice is made on  $\mathcal{K}^{11}$ . Next, we claim that it is possible to choose  $\mathcal{K}^{11}$  in such a way that the off-diagonal element  $\mathfrak{R}^{21}$  is zero, which in fact will correspond to (5.4) for all  $i \in \mathcal{S}$ . Notice, however, that  $\mathfrak{R}^{21} = 0$  is only a sufficient but not a necessary condition (because different controllers could be sought at this point).

Moving further, let us define  $\mathcal{Y}_i = \begin{bmatrix} Y_i & I \\ Y_i & 0 \end{bmatrix}$ ,  $\Xi_i = X_i(A_i Y_i + G_i F_i) + (J_i - X_i G_i U_i) \Gamma_i Y_i + (Y_i^{-1} - X_i) \mathcal{K}_i^{11} Y_i$  and calculate each entry of  $\mathfrak{R}_i$  separately. We have

$$\mathcal{Y}_i^* P_i \hat{A}_i \mathcal{Y}_i = \begin{bmatrix} A_i Y_i + G_i F_i & A_i + G_i U_i \Gamma_i \\ \Xi_i & X_i A_i + J_i \Gamma_i \end{bmatrix} \quad \text{and} \quad \mathcal{Y}_i^* P_j \mathcal{Y}_i = \begin{bmatrix} Y_i Y_j^{-1} Y_i & Y_i Y_j^{-1} \\ Y_j^{-1} Y_i & X_j \end{bmatrix}.$$

Moreover, we have that

$$\mathcal{Y}_i^* \hat{C}_i^* \hat{C}_i \mathcal{Y}_i = \begin{bmatrix} (C_i Y_i + H_i F_i)^* (C_i Y_i + H_i F_i) & (C_i Y_i + H_i F_i)^* (C_i + H_i U_i \Gamma_i) \\ * & (C_i + H_i U_i \Gamma_i)^* (C_i + H_i U_i \Gamma_i) \end{bmatrix},$$

because  $\{C_i + H_i(U_i\Gamma_i + \mathcal{K}_i^{21})\}Y_i = C_iY_i + H_iF_i$ . Finally,

$$\mathcal{Y}_i^* P_i \hat{B}_i = \begin{bmatrix} B_i + G_i U_i L_i \\ X_i B_i + J_i L_i \end{bmatrix} \quad \text{and} \quad \mathcal{Y}_i^* \hat{C}_i^* \tilde{D}_i = \begin{bmatrix} (C_i Y_i + H_i F_i)^* \\ (C_i + H_i U_i \Gamma_i)^* \end{bmatrix} (D_i + H_i U_i L_i).$$

Now substitute the above results back into the definition of  $\mathfrak{R}$  to obtain that

$$\begin{aligned} \mathfrak{R}_i^{\ell m} &= \text{Her}(\mathcal{Y}_i^* P_i \hat{A}_i \mathcal{Y}_i)_{\ell m} + \sum_{j \in \mathcal{S}} \lambda_{ij} (\mathcal{Y}_i^* P_j \mathcal{Y}_i)_{\ell m} - (\mathcal{Y}_i^* \hat{C}_i^* \hat{C}_i \mathcal{Y}_i)_{\ell m} \\ &\quad - \mathcal{Y}_i^* (P_i \hat{B}_i - \hat{C}_i^* \tilde{D}_i)_{\ell \bullet} (\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} (\hat{B}_i^* P_i - \tilde{D}_i^* \hat{C}_i)_{\bullet m}, \\ &\quad \text{where } (\ell, m) \in \{1, 2\} \times \{1, 2\}, \\ \Rightarrow \mathfrak{R}_i^{11} &= A_i Y_i + Y_i A_i^* + \sum_{j \in \mathcal{S}} \lambda_{ij} Y_i Y_j^{-1} Y_i + G_i F_i + F_i^* G_i^* - (C_i Y_i + H_i F_i)^* (C_i Y_i + H_i F_i) \\ &\quad - (B_i + G_i U_i L_i - (C_i Y_i + H_i F_i)^* (D_i + H_i U_i L_i)) (\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} \\ &\quad \times (B_i + G_i U_i L_i - (C_i Y_i + H_i F_i)^* (D_i + H_i U_i L_i))^*, \\ \mathfrak{R}_i^{22} &= X_i A_i + A_i^* X_i + \sum_{j \in \mathcal{S}} \lambda_{ij} X_j + J_i \Gamma_i + \Gamma_i^* J_i^* - (C_i + H_i U_i \Gamma_i)^* (C_i + H_i U_i \Gamma_i) \\ &\quad - (X_i B_i + J_i L_i - (C_i + H_i U_i \Gamma_i)^* \tilde{D}_i) (\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} \\ &\quad \times (X_i B_i + J_i L_i - (C_i + H_i U_i \Gamma_i)^* \tilde{D}_i)^*, \end{aligned}$$

and

$$\begin{aligned} \mathfrak{R}_i^{21} &= X_i (A_i Y_i + G_i F_i) + (J_i - X_i G_i U_i) \Gamma_i Y_i + (Y_i^{-1} - X_i) \mathcal{K}_i^{11} Y_i \\ &\quad + (A_i + G_i U_i \Gamma_i)^* + \sum_{j \in \mathcal{S}} \lambda_{ij} Y_j^{-1} Y_i - (C_i + H_i U_i \Gamma_i)^* (C_i Y_i + H_i F_i) \\ &\quad - \{X_i B_i + J_i L_i - (C_i + H_i U_i \Gamma_i)^* \tilde{D}_i\} (\gamma^2 I - \tilde{D}_i^* \tilde{D}_i)^{-1} \\ &\quad \times \{B_i + G_i U_i L_i - (C_i Y_i + H_i F_i)^* \tilde{D}_i\}^*. \end{aligned}$$

Just as mentioned before, we have from a repeated application of uniform Schur complements (Theorem 2.2, aiming for dimension reduction) that (4.17a) and (4.17b) are equivalent to  $\mathfrak{R}^{11} \gg 0$  and  $\mathfrak{R}^{22} \gg 0$ , respectively, and regardless of what choice is made with respect to  $\mathcal{K}^{11}$ .

Finally, we have that the unique solution  $\mathcal{K}^{11}$  to the algebraic equation  $\mathfrak{R}_i^{21} = 0$ ,  $i \in \mathcal{S}$ , is given by (5.4), concluding the proof.  $\square$

*Remark 5.2.* Suppose  $D$  and  $\mathcal{K}^{22} = U$  are identically zero. Then (5.4) reduces to

$$\begin{aligned} \mathcal{K}_i^{11} &= -(Y_i^{-1} - X_i)^{-1} \left\{ X_i (A_i Y_i + G_i F_i) + J_i \Gamma_i Y_i + A_i^* + \sum_{j \in \mathcal{S}} \lambda_{ij} Y_j^{-1} Y_i \right. \\ (5.10) \quad &\quad \left. - C_i^* (C_i Y_i + H_i F_i) - \gamma^{-2} (X_i B_i + J_i L_i) B_i^* \right\} Y_i^{-1}, \end{aligned}$$

which, together with (5.1) and (5.2), coincides with the result from Theorem 4.2 in [7], in case all data are real and the set  $\mathcal{S}$  is finite.

**5.1. Some algorithms.** In what follows we shall present some design procedures in order to put our results on a more practical basis. It should be noted that this whole

design framework provides a collection of tools which may be readily implemented on convex programming software, at least in the finite case.

The next algorithm provides one possible way of computing a full-order controller such as the one presented in Theorem 5.1.

**ALGORITHM 5.3** (two-step design procedure). *An  $H_\infty$  compensator of given level  $\gamma > 0$  may be constructed according to Theorem 5.1 by the following steps:*

**d<sub>1</sub>:** *Solve the existence problem by means of  $\mathbf{e}_1$ ;*

$\hookrightarrow$  *If such a solution can't be found, then **stop**.*

**d<sub>2</sub>:** *Bearing in mind  $X, Y, J, F$ , and  $U$  from the previous step, build a compensator by means of relations (5.1)–(5.4).*

Looking back at Theorem 4.8 it is possible to propose the following alternative to Algorithm 5.3. The main advantage here is that the existence of solutions depends on the feasibility of a problem of relatively smaller dimension.

**ALGORITHM 5.4** (three-step design procedure). *An  $H_\infty$  compensator of given level  $\gamma > 0$  may be constructed according to Theorem 5.1 by the following steps:*

**D<sub>1</sub>:** *Solve the existence problem by means of  $\mathbf{e}_2$ ;*

$\hookrightarrow$  *If such a solution can't be found, then **stop**.*

**D<sub>2</sub>:** *Bearing in mind such  $X$  and  $Y$  from the above step, find  $J = (J_1, J_2, \dots) \in \mathbb{H}_{\text{sup}}^{n_y, n}$ ,  $F = (F_1, F_2, \dots) \in \mathbb{H}_{\text{sup}}^{n, n_u}$ , and  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\text{sup}}^{n_y, n_u}$  such that (4.17a) and (4.17b) are satisfied (from Theorem 4.8 we have that there always exists a solution to this problem).*

**D<sub>3</sub>:** *With  $X, Y, J, F$ , and  $U$  obtained from the previous steps, build a compensator by means of relations (5.1)–(5.4).*

We now consider the  $H_\infty$  optimization problem—that of computing the smallest DA level possible. The next algorithm provides, by means of a bisectional procedure (see [2] or [6, Algorithm 8.9], for instance), two different ways to compute the optimal DA level that may be achieved by a full-order controller such as  $\mathcal{K}$ , by solving each one of the following semidefinite programs [22]:

$$\begin{array}{ll} \mathbf{SDP}_1 : & \text{minimize } \gamma \\ & \text{subject to } (4.12), i \in \mathcal{S}, \quad \gamma > 0, \end{array}$$

and

$$\begin{array}{ll} \mathbf{SDP}_2 : & \text{minimize } \gamma \\ & \text{subject to } (4.17), i \in \mathcal{S}, \quad \gamma > 0. \end{array}$$

**ALGORITHM 5.5** ( $H_\infty$  optimization). *The smallest DA level  $\gamma = \gamma_*$  that can be achieved by a controller such as (4.2) in the full-order case may be computed, with arbitrary precision  $\varepsilon > 0$ , by the following steps (where  $\iota \in \{1, 2\}$ ):*

**B<sub>1</sub><sup>sec</sup>:** *Let  $\gamma_{\min} = 0$  and choose  $\gamma_{\max} > 2\varepsilon$  so large that  $\mathbf{e}_\iota$  is feasible for  $\gamma = \gamma_{\max}$ .*

**B<sub>2</sub><sup>sec</sup>:** *Let  $\gamma \leftarrow (\gamma_{\min} + \gamma_{\max})/2$  and solve the existence problem by means of  $\mathbf{e}_\iota$ ;*

$\hookrightarrow$  *If a solution to  $\mathbf{e}_\iota$  can be found, then let  $\gamma_{\max} \leftarrow \gamma$ ;*

$\hookrightarrow$  *otherwise, let  $\gamma_{\min} \leftarrow \gamma$ .*

**B<sub>3</sub><sup>sec</sup>:** *Repeat **B<sub>2</sub><sup>sec</sup>** until  $(\gamma_{\max} - \gamma_{\min})/2 < \varepsilon$ .*

**B<sub>4</sub><sup>sec</sup>:** *Return  $\gamma \approx \gamma_*$ .*

An explicit implementation of the above design procedures is presented in what follows. It is worth noting that the example under consideration does not satisfy the simplifying assumptions of [7] and, by consequence, cannot be tackled by current methods in the literature.

**5.1.1. A nominal example.** Let  $\mathcal{S} = \{1, 2\}$ ,  $n = 1$ , and consider system (4.1) in the form

$$\begin{bmatrix} A_1 & B_1 & G_1 \\ C_1 & D_1 & H_1 \\ \Gamma_1 & L_1 & \star \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & -1 & \star \end{bmatrix}, \quad \begin{bmatrix} A_2 & B_2 & G_2 \\ C_2 & D_2 & H_2 \\ \Gamma_2 & L_2 & \star \end{bmatrix} = \begin{bmatrix} 1 & -1 & -1 \\ 1 & 1 & 1 \\ 1 & 1 & \star \end{bmatrix},$$

with Markov switching governed by

$$\begin{bmatrix} \lambda_{11} & \lambda_{12} \\ \lambda_{21} & \lambda_{22} \end{bmatrix} = \begin{bmatrix} -1 & +1 \\ +1 & -1 \end{bmatrix}.$$

Notice that the results of [7] do not apply here, since  $D_2 \neq 0$ . In what follows we shall design a controller which ensures stochastic stability of the closed-loop system together with a prescribed DA level  $\gamma$ .

Let  $\gamma = 5$ . By employing Algorithm 4.10, we obtain that a feasible solution to (4.12)–(4.17) is given by

$i$	$X_i$	$Y_i$	$J_i$	$F_i$	$U_i$
1	-4.1633	-0.5227	19.9958	1.5509	-0.0727
2	-5.0761	-0.2459	19.4919	-0.7369	-1.0000

either by performing  $\mathbf{d}_1$  (in Algorithm 5.3) or  $\mathbf{D}_1$ – $\mathbf{D}_2$  (Algorithm 5.4). A suboptimal controller is then given by

$$\begin{bmatrix} \mathcal{K}_1^{11} & \mathcal{K}_1^{12} \\ \mathcal{K}_1^{21} & \mathcal{K}_1^{22} \end{bmatrix} = \begin{bmatrix} -9.3202 & 8.7519 \\ -2.8944 & -0.0727 \end{bmatrix}, \quad \begin{bmatrix} \mathcal{K}_2^{11} & \mathcal{K}_2^{12} \\ \mathcal{K}_2^{21} & \mathcal{K}_2^{22} \end{bmatrix} = \begin{bmatrix} -28.4562 & 24.3391 \\ 3.9967 & -1.0000 \end{bmatrix}.$$

Finally, by running Algorithm 5.5 with initial condition  $\gamma_{\max} = 5$ , we obtain, after 22 iterations and with precision  $\varepsilon = 10^{-6}$ , the optimal  $H_\infty$  performance  $\gamma_* \approx 3.42735$ .

One final remark goes as follows. For the example under consideration, the obtained results for the optimal case ( $\gamma$  close to  $\gamma_*$ ) are such that  $XY \approx 1$ , which gives rise to unbounded controller entries in (5.1) and (5.4). Although this is a drawback of the presented method, we remark that the same kind of problem arises in the LTI case (see [13] or [15, section 9.4], for example).

**6. Conclusions.** In this paper, the output feedback  $H_\infty$  control has been addressed for a class of continuous-time Markov jump linear systems with the Markov process taking values in an infinite countable set  $\mathcal{S}$ . We have obtained the following results:

- A theorem which characterizes whether there exists a full-order solution to the disturbance attenuation problem in terms of two distinct sets of LMIs (Theorem 4.8). This result connects a certain projection approach to an LMI problem which is more suitable for design.
- Extensions of Schur complements and of the projection lemma to a wider context. We remark here that one is faced with the same *uniformity* problems if dealing with, say, time-variant systems (as, e.g., in [9] or [20]), considering the case where the system parameters are time functions with uniform bounds.
- The JBRL was employed for the first time and valuable results could be obtained, thus illustrating the importance of this recent result and accomplishing an important step in the development of an  $H_\infty$ -like theory for the class of systems considered.
- An LMI algorithm (Algorithm 4.10), which allows one to check whether there exists a solution for the DA problem.

- A two-step design method (Algorithm 5.3) which provides explicit formulas for the construction of a controller.
- An alternative three-step design method, Algorithm 5.4. The main issue here is that one can first check if a smaller (projected) LMI problem is feasible, which amounts to verifying whether the DA problem has a solution or not. This partial solution is then fed into the two-step procedure.
- A bisectional procedure for  $H_\infty$  optimization of infinite Markov jump systems (Algorithm 5.5).
- A nominal example, for the finite case, which illustrates how the obtained results may be employed in a situation where the hypotheses of [7] are not satisfied.

**Appendix.** We present now some of the proofs omitted in the core of the text.

*Proof of Proposition 2.1.* Let us first prove (i). From the hypothesis, there must exist  $\eta > 0$  such that  $Q_i^* Q_i \geq \eta I$  for every  $i \in \mathcal{S}$ . Additionally, since  $X \gg 0$  there must exist  $\varepsilon_0 > 0$  such that  $X_i \geq \varepsilon_0 I_n$  for every such  $i$ . Thus

$$Q_i^* X_i Q_i \geq \varepsilon_0 Q_i^* Q_i \geq (\varepsilon_0 \eta) I = \varepsilon I$$

for some suitable  $\varepsilon > 0$ , and

$$\|Q_i^* X_i Q_i\| \leq \|Q_i\|^2 \|X_i\| \leq \|Q\|_{\sup}^2 \|X\|_{\sup},$$

from which the result follows. To prove (ii), just replace  $X$  by  $-X$ .  $\square$

*Remark A.1.* Two important issues in the above proof are the need to ensure uniform definiteness on the relations and the norm-bound invariance. It highlights two important features which come up when the state space of the Markov chain is assumed to be infinite vis-à-vis the finite case.

Before we proceed to the proof of Theorem 2.2, let us state the following auxiliary result.

**PROPOSITION A.2.** *Given  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\sup}^{p*}$ ,  $V = (V_1, V_2, \dots) \in \mathbb{H}_{\sup}^{q,p}$ , and  $W = (W_1, W_2, \dots) \in \mathbb{H}_{\sup}^{q*}$ , the following are equivalent:*

- (i)  $\begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \geq \varepsilon I$  for every  $i \in \mathcal{S}$  and some  $\varepsilon > 0$ ;
- (ii)  $U_i \geq \mu I$  and  $W_i - V_i^* U_i^{-1} V_i \geq \mu I$  for every  $i \in \mathcal{S}$  and some  $\mu > 0$ ;
- (iii)  $W_i \geq \nu I$  and  $U_i - V_i W_i^{-1} V_i^* \geq \nu I$  for every  $i \in \mathcal{S}$  and some  $\nu > 0$ .

*Proof.* Assume (iii) holds. Thus, defining  $X = -W^{-1} V^* \in \mathbb{H}_{\sup}^{p,q}$  we have that, for every such  $i$ ,

$$(A.1) \quad \nu I \leq \begin{bmatrix} U_i - V_i W_i^{-1} V_i^* & 0 \\ 0 & W_i \end{bmatrix} = \begin{bmatrix} I & -X_i^* \\ 0 & I \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} I & 0 \\ -X_i & I \end{bmatrix}.$$

Notice that  $\begin{bmatrix} -I & 0 \\ -X_i & I \end{bmatrix}^{-1} = \begin{bmatrix} I & 0 \\ X_i & I \end{bmatrix}$ ; then the above expression is equivalent to

$$(A.2) \quad \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \geq \nu \begin{bmatrix} I & X_i^* \\ 0 & I \end{bmatrix} \begin{bmatrix} I & 0 \\ X_i & I \end{bmatrix} = \nu \begin{bmatrix} I + X_i^* X_i & X_i^* \\ X_i & I \end{bmatrix}.$$

But notice that, for some  $\alpha \in (0, 1)$  and every  $i \in \mathcal{S}$ ,

$$(A.3) \quad \begin{aligned} & \begin{bmatrix} I + X_i^* X_i & X_i^* \\ X_i & I \end{bmatrix} - \alpha \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix} \\ &= \mathfrak{C} \left\{ \begin{bmatrix} (1-\alpha)I - \frac{\alpha}{1-\alpha} X_i^* X_i & 0 \\ 0 & (1-\alpha)I \end{bmatrix}, \begin{bmatrix} I & 0 \\ \frac{1}{1-\alpha} X_i & I \end{bmatrix} \right\} \\ &> 0. \end{aligned}$$

This is due to the fact that  $\mathcal{N} \begin{bmatrix} I & 0 \\ \frac{1}{1-\alpha} X_i & I \end{bmatrix} \equiv \{0\}$ , together with  $(1-\alpha)I > 0$  and

$$\begin{aligned} (1-\alpha)I - \frac{\alpha}{1-\alpha} X_i^* X_i &\geq (1-\alpha)I - \frac{\alpha}{1-\alpha} \lambda_{\max}(X_i^* X_i)I = (1-\alpha)I - \frac{\alpha}{1-\alpha} \|X_i\|^2 I \\ &\geq I - \alpha \left\{ 1 + \frac{1}{1-\alpha} \|X\|_{\sup}^2 \right\} I \\ (A.4) \quad &> 0, \end{aligned}$$

bearing in mind that  $\|X\|_{\sup} \leq \|W^{-1}\|_{\sup} \|V\|_{\sup} < \infty$ , and  $\alpha \in (0, 1)$  may be as small as desired. Hence, (i) follows straight from (A.2)–(A.3) by choosing  $\varepsilon < \alpha\nu$ .

Now assume (i) holds. Then it is immediate that, for every  $i \in \mathcal{S}$ ,

$$\begin{aligned} U_i - V_i W_i^{-1} V_i^* &= \begin{bmatrix} I & -X_i^* \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} I \\ -X_i \end{bmatrix} \\ &\geq \varepsilon \begin{bmatrix} I & -X_i^* \end{bmatrix} \begin{bmatrix} I \\ -X_i \end{bmatrix} = \varepsilon(I + X_i^* X_i) \\ (A.5) \quad &\geq \varepsilon I \end{aligned}$$

and

$$(A.6) \quad W_i = \begin{bmatrix} 0 & I \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} 0 \\ I \end{bmatrix} \geq \varepsilon \begin{bmatrix} 0 & I \end{bmatrix} \begin{bmatrix} 0 \\ I \end{bmatrix} = \varepsilon I,$$

so that (iii) should hold with  $\nu \equiv \varepsilon$ .

Finally, to prove the equivalence between (i) and (ii), one has to notice only that

$$(A.7) \quad \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} 0 & I \\ I & 0 \end{bmatrix} = \begin{bmatrix} W_i & V_i^* \\ V_i & U_i \end{bmatrix}$$

and that Proposition 2.1 guarantees that the indicated transformation preserves uniform definiteness. Hence, the result follows immediately if we replace  $(U, V, V^*, W)$  by  $(W, V^*, V, U)$  in the first part of the proof.  $\square$

*Proof of Theorem 2.2.* Suppose (iii) holds. From Proposition A.2 we have the positivity in (i) guaranteed, and it remains only to prove that boundedness is preserved. From (A.1) we have that

$$\begin{aligned} \left\| \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \right\| &= \left\| \begin{bmatrix} I & X_i^* \\ 0 & I \end{bmatrix} \begin{bmatrix} U_i - V_i W_i^{-1} V_i^* & 0 \\ 0 & W_i \end{bmatrix} \begin{bmatrix} I & 0 \\ X_i & I \end{bmatrix} \right\| \\ &\leq \left\| \begin{bmatrix} I & 0 \\ X_i & I \end{bmatrix} \right\|^2 \left\| \begin{bmatrix} U_i - V_i W_i^{-1} V_i^* & 0 \\ 0 & W_i \end{bmatrix} \right\| \\ &\leq \left\{ 1 + \left\| \begin{bmatrix} 0 & 0 \\ X_i & 0 \end{bmatrix} \right\| \right\}^2 (\|U_i - V_i W_i^{-1} V_i^*\| + \|W_i\|) \\ (A.8) \quad &\leq (1 + \|X\|_{\sup})^2 (\|U - VW^{-1}V^*\|_{\sup} + \|W\|_{\sup}) \end{aligned}$$

for every  $i \in \mathcal{S}$ , which immediately yields (i).

Assuming now (i), relation (A.1) guarantees that, for every  $i \in \mathcal{S}$ ,

$$\begin{aligned} \|U_i - V_i W_i^{-1} V_i^*\| &= \left\| \begin{bmatrix} I & -X_i^* \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} I \\ -X_i \end{bmatrix} \right\| \\ (A.9) \quad &\leq \left\| \begin{bmatrix} I & -X_i^* \end{bmatrix} \right\|^2 \left\| \begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \right\|_{\sup} \end{aligned}$$

and

$$(A.10) \quad \|W_i\| = \left\| \begin{bmatrix} 0 & I \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} 0 \\ I \end{bmatrix} \right\| \leq \left\| \begin{bmatrix} 0 & I \end{bmatrix} \right\|^2 \left\| \begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \right\|_{\sup},$$

which, similarly to (A.8), implies (iii).

Equivalence between (i) and (ii) is proven with the aid of (A.7), as we did in the proof of Proposition A.2. Finally, we have that the negative case benefits from the above proof, in the sense that some given  $Q \ll 0$  if and only if  $-Q \gg 0$ .  $\square$

The following proposition further extends Theorem 2.2 to the wider context of *bounded matrices* (see the beginning of section 2); this natural extension will be employed in the proof of the uniform projection lemma (Lemma 2.5) below.

**PROPOSITION A.3.** *Let  $\mathbf{p} = (p_1, p_2, \dots)$  and  $\mathbf{q} = (q_1, q_2, \dots)$  be such that  $(p_i, q_i) \in \{1, 2, \dots, M\}^2$  for some finite integer  $M$  and every  $i \in \mathcal{S}$ . Then the following statements are equivalent for all  $U = (U_1, U_2, \dots) \in \mathbb{H}_{\sup}^{\mathbf{p}+}$ ,  $V = (V_1, V_2, \dots) \in \mathbb{H}_{\sup}^{\mathbf{q}, \mathbf{p}}$  and  $W = (W_1, W_2, \dots) \in \mathbb{H}_{\sup}^{\mathbf{q}+}$ :*

- (i)  $\begin{bmatrix} U & V \\ V^* & W \end{bmatrix} \gg 0$ ;
- (ii)  $U \gg 0$  and  $W - V^*U^{-1}V \gg 0$ ;
- (iii)  $W \gg 0$  and  $U - VW^{-1}V^* \gg 0$ .

*Proof.* The proof is straightforward. Just notice that Proposition 2.1, as well as Proposition A.2 and Theorem 2.2, may be extended to the case where  $m, n, p$ , and  $q$  are replaced by bounded and arbitrarily chosen sequences of integers  $\mathbf{m}, \mathbf{n}, \mathbf{p}$ , and  $\mathbf{q}$ , respectively, by quite the same proofs.  $\square$

*Proof of Proposition 2.3.* Just notice that, for any  $i \in \mathcal{S}$ , we have that  $p_i \leq \min\{\ell, p\}$ . Then define  $\Phi_i = [\phi_{i,1} \ \dots \ \phi_{i,p_i}] \in \mathbb{C}^{p \times p_i}$ , where the set  $\{\phi_{i,j}\}_{j=1}^{p_i} \subset \mathbb{C}^p$  forms an orthonormal basis for  $\mathcal{N}(\Psi_i)$ , and the proof follows immediately.  $\square$

*Proof of Corollary 2.4.* From Theorem 2.2 we have that the boundedness of the LHS of each of these expressions is equivalent, so it remains only to prove that uniform definiteness is preserved.

Define  $\Phi$  to be an orthonormal basis for  $\mathcal{N}(\Psi)$  (see Proposition 2.3). Then (ii) is equivalent to the existence of some  $\varepsilon > 0$  such that  $W_i > \varepsilon I$  for all  $i \in \mathcal{S}$  and

$$(A.11) \quad 0 < \Phi_i^*(U_i - \varepsilon I - V_i W_i^{-1} V_i^*) \Phi_i = \Phi_i^*(U_i - V_i W_i^{-1} V_i^*) \Phi_i - \varepsilon I,$$

which, due to Theorem 2.2, is equivalent to the inequality

$$\begin{aligned} & \begin{bmatrix} \Phi_i^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} U_i & V_i \\ V_i^* & W_i \end{bmatrix} \begin{bmatrix} \Phi_i & 0 \\ 0 & I \end{bmatrix} \\ &= \begin{bmatrix} \Phi_i^* U_i \Phi_i & \Phi_i^* V_i \\ V_i^* \Phi_i & W_i \end{bmatrix} \\ &> \varepsilon \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix} = \varepsilon \begin{bmatrix} \Phi_i^* \Phi_i & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} \Phi_i^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} \varepsilon I & 0 \\ 0 & \varepsilon I \end{bmatrix} \begin{bmatrix} \Phi_i & 0 \\ 0 & I \end{bmatrix}, \end{aligned}$$

which is equivalent to (i), since  $\mathcal{R} \begin{bmatrix} \Phi_i & 0 \\ 0 & I \end{bmatrix} = \mathcal{N} \begin{bmatrix} \Psi_i & 0 \end{bmatrix}$  for all  $i \in \mathcal{S}$ :

$$\begin{bmatrix} \Phi_i^* & 0 \\ 0 & I \end{bmatrix} \begin{bmatrix} U_i - \varepsilon I & V_i \\ V_i^* & W_i - \varepsilon I \end{bmatrix} \begin{bmatrix} \Phi_i & 0 \\ 0 & I \end{bmatrix} > 0. \quad \square$$

*Proof of Lemma 2.5.* The proof of necessity is straightforward. Just assume that such  $X$  exists and notice that (2.1) must hold, in particular, on the indicated set.

The proof of sufficiency goes as follows. For  $\iota \in \{1, 2, 3, 4\}$  and  $i \in \mathcal{S}$  let  $W_{\iota i}$  of adequate dimensions be an orthonormal basis for  $\mathbb{W}_{\iota i}$ , where

$$\begin{aligned}\mathbb{W}_{1i} &= \mathcal{N}(M_i) \cap \mathcal{N}(N_i), & \mathbb{W}_{3i} &= \mathcal{N}(M_i)^\perp \cap \mathcal{N}(N_i), \\ \mathbb{W}_{2i} &= \mathcal{N}(M_i) \cap \mathcal{N}(N_i)^\perp, & \mathbb{W}_{4i} &= \mathcal{N}(M_i)^\perp \cap \mathcal{N}(N_i)^\perp.\end{aligned}$$

Thus, defining  $T = (T_1, T_2, \dots) \in \mathbb{H}_{\text{sup}}^p$  by  $T_i = [W_{1i} \ W_{2i} \ W_{3i} \ W_{4i}]$ ,  $i \in \mathcal{S}$ , we have that  $T^*T = I_p \gg 0$ . Then from Proposition 2.1 it follows that (2.1) is equivalent to

$$(A.12) \quad T^*HT + (NT)^*X^*(MT) + (MT)^*X(NT) \gg 0.$$

Now, similarly to [15, Lemma 3.1], we partition each component of (A.12) just as  $T_i$ . This yields equivalence of (2.1) to

$$(A.13) \quad \begin{bmatrix} \Phi_1 & \Phi_2 & \Phi_3 & \Phi_4 \\ \Phi_2^* & \Phi_5 & \Phi_6 + \mathcal{X}_{11}^* & \Phi_7 + \mathcal{X}_{21}^* \\ \Phi_3^* & \Phi_6^* + \mathcal{X}_{11} & \Phi_8 & \Phi_9 + \mathcal{X}_{12} \\ \Phi_4^* & \Phi_7^* + \mathcal{X}_{21} & \Phi_9^* + \mathcal{X}_{12}^* & \Phi_{10} + \mathcal{X}_{22} + \mathcal{X}_{22}^* \end{bmatrix} \gg 0,$$

where  $[\Phi_\bullet] := T^*HT$  and

$$\begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & \mathcal{X}_{11} & 0 & \mathcal{X}_{12} \\ 0 & \mathcal{X}_{21} & 0 & \mathcal{X}_{22} \end{bmatrix} := \begin{bmatrix} 0 \\ 0 \\ Q_1^* \\ Q_2^* \end{bmatrix} X \begin{bmatrix} 0 & R_1 & 0 & R_2 \end{bmatrix} = (MT)^*X(NT),$$

in which  $Q = [Q_1 \ Q_2]$  and  $R = [R_1 \ R_2]$  are defined by the full column rank matrices  $[Q_{1i} \ Q_{2i}]$  and  $[R_{1i} \ R_{2i}]$  for which  $M_i T_i = [0 \ 0 \ Q_{1i} \ Q_{2i}]$  and  $N_i T_i = [0 \ R_{1i} \ 0 \ R_{2i}]$ . Then from Proposition A.3 we have that (A.12) is equivalent to the two following relations being satisfied for some quadruple  $\mathcal{X} = (\mathcal{X}_{11}, \mathcal{X}_{12}, \mathcal{X}_{21}, \mathcal{X}_{22})$  of bounded matrices:

$$(A.14) \quad \Upsilon(\mathcal{X}_{11}) := \begin{bmatrix} \Phi_1 & \Phi_2 & \Phi_3 \\ \Phi_2^* & \Phi_5 & \Phi_6 + \mathcal{X}_{11}^* \\ \Phi_3^* & \Phi_6^* + \mathcal{X}_{11} & \Phi_8 \end{bmatrix} \gg 0,$$

$$(A.15) \quad \Phi_{10} + \mathcal{X}_{22} + \mathcal{X}_{22}^* - \begin{bmatrix} \Phi_4 \\ \Phi_7 + \mathcal{X}_{21}^* \\ \Phi_9 + \mathcal{X}_{12} \end{bmatrix}^* \Upsilon(\mathcal{X}_{11})^{-1} \begin{bmatrix} \Phi_4 \\ \Phi_7 + \mathcal{X}_{21}^* \\ \Phi_9 + \mathcal{X}_{12} \end{bmatrix} \gg 0.$$

Finally, after some calculations analogous to [15, Lemma 3.1], we have that (A.14) holds if and only if

$$(A.16) \quad \begin{bmatrix} \Phi_1 & \Phi_2 \\ \Phi_2^* & \Phi_5 \end{bmatrix} \gg 0 \quad \text{together with} \quad \begin{bmatrix} \Phi_1 & \Phi_3 \\ \Phi_3^* & \Phi_8 \end{bmatrix} \gg 0,$$

which from the definition of  $\Phi$  yields immediately the desired result.  $\square$

**Acknowledgment.** The authors would like to express their gratitude to the referees for their suggestions and comments, which have certainly improved the paper.

## ON STABILITY AND ROBUST STABILITY OF POSITIVE LINEAR VOLTERRA EQUATIONS\*

PHAM HUU ANH NGOC<sup>†</sup>, TOSHIKI NAITO<sup>†</sup>, JONG SON SHIN<sup>†</sup>, AND  
SATORU MURAKAMI<sup>‡</sup>

**Abstract.** We first introduce the notion of positive linear Volterra integrodifferential equations. Then we give some characterizations of these positive equations. An explicit criterion and a Perron–Frobenius-type theorem for positive linear Volterra integrodifferential equations are given. Then we offer a new criterion for uniformly asymptotic stability of positive equations. Finally, we study stability radii of positive linear Volterra integrodifferential equations. It is proved that complex, real, and positive stability radii of positive linear Volterra equations under structured perturbations (or affine perturbations) coincide and can be computed by explicit formulae. To the best of our knowledge, most of the results of this paper are new.

**Key words.** linear Volterra equation, positive system, uniformly asymptotic stability, stability radius

**1. Introduction.** Generally speaking, a dynamical system is called *positive* if for any nonnegative initial condition, the corresponding solution of the system is also nonnegative. In particular, a dynamical system with state space  $\mathbb{R}^n$  is positive if any trajectory of the system starting at an initial state in the positive orthant  $\mathbb{R}_+^n$  remains forever in  $\mathbb{R}_+^n$ . Positive dynamical systems play an important role in the modeling of dynamical phenomena whose variables are restricted to be nonnegative. This model class is used in many areas such as economics, population dynamics, and ecology; see [2], [25]. They are often encountered in applications, for example, networks of reservoirs, industrial processes involving chemical reactors, heat exchangers, distillation columns, storage systems, hierarchical systems, compartmental systems used for modeling transport and accumulation phenomena of substances, etc. The mathematical theory of positive systems is based on the theory of nonnegative matrices founded by Perron and Frobenius. As references we mention [2], [5].

Problems of positive systems have attracted a lot of attention from researchers for a long time; see, e.g., [5], [6], [8], [9], [10], [14], [15], [17], [18], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [43], [44], [45], [46]. In the literature, there are some criteria for familiar positive linear systems such as positive linear invariant-time differential (difference) systems, and positive linear time-delay systems of retarded type. For example, it is well known that a linear time-delay system of the form  $\dot{x}(t) = A_0x(t) + A_1x(t-h)$ ,  $t \geq 0$ , is positive if and only if  $A_0$  is a Metzler matrix and  $A_1$  is a nonnegative matrix, and a linear discrete time system of the form  $x(k+1) = A_0x(k) + A_1x(k-h)$ ,  $k \in \mathbb{N}$ ,  $k \geq h$ , is positive if and only if  $A_0, A_1$  are nonnegative matrices; see, e.g., [33], [34], [45].

Recently, we developed a theory of positive systems for some new classes of linear systems such as positive linear functional differential equations [37], [35], [32], positive linear functional difference equations [38], and positive linear Volterra integral equations [29]. More precisely, we introduced various notions of positive systems for these classes of systems. Then we offered explicit criteria for them in terms of positivity of system matrices. Furthermore, we gave some extensions of the classical Perron–Frobenius theorems which are important tools for analyzing stability and robust stability of these positive systems. Finally, we obtained new criteria for asymptotic stability of positive systems. For example, in the recent paper [37], we showed that a linear functional differential equation of the form

$$(1) \quad \dot{x}(t) = Ax(t) + \int_{-h}^0 d[\eta(\theta)]x(t+\theta), \quad x(t) \in \mathbb{R}^n, \quad t \geq 0,$$

is positive (meaning that its solution semigroup is positive) if and only if  $A$  is a Metzler matrix and  $\eta$  is an increasing matrix function. Then such a positive equation is exponentially stable if and only if the spectral abscissa of the matrix  $A + \eta(0)$  is strictly less than zero. Moreover, stability radius problems of positive linear functional differential equations (1) under multiperturbations or affine perturbations have been studied in [35], where the explicit formulae for the stability radii are given.

In the present paper, we first introduce the notion of positive linear Volterra integrodifferential equations. Then we give an explicit criterion for equations of this class. Finally, we study stability and robust stability of positive equations. It is important to note that Volterra equations are studied extensively in many various areas such as control theory, optimization, probability and statistics, economics, etc. In particular, problems of stability and robust stability of Volterra equations have been studied quite some time; see, e.g., [3], [4], [11], [19], [20], [26], [27], [47], [48]. However, to the best of our knowledge, aspects of positivity of problems of Volterra equations have not been exploited yet in the literature and the main purpose of this paper is to fill this gap. This paper is motivated by a series of our works on the problems of stability and robust stability of positive linear systems; see, e.g., [15], [29], [30], [31], [32], [33], [34], [35], [36], [37], [38], [45], [46].

The organization of the paper is as follows. In the next section, we summarize some notation and preliminary results which will be used in what follows. In section 3, we give an explicit criterion and a Perron–Frobenius theorem for positive linear Volterra integrodifferential equations. In the next section, we offer a new criterion for uniformly asymptotic stability of positive equations. In section 5, we study stability radii of positive linear Volterra integrodifferential equations. It is proved that complex, real, and positive stability radii of positive linear Volterra equations under structured perturbations (or affine perturbations) coincide and can be computed by explicit formulae. Finally, in section 6, we briefly summarize the obtained results and give a suggestion for further research of positive Volterra differential equations with delays and positive Volterra–Stieltjes differential equations.

**2. Preliminaries.** In this section we shall define some notation and recall some well-known results which will be used in subsequent sections. Let  $\mathbb{K} = \mathbb{C}$  or  $\mathbb{R}$ , where  $\mathbb{C}$  and  $\mathbb{R}$  denote the sets of all complex and all real numbers, respectively. Let us denote  $\Re z$  the real part of  $z \in \mathbb{C}$ . For an integer  $l, q \geq 1$ ,  $\mathbb{K}^l$  denotes the  $l$ -dimensional vector space over  $\mathbb{K}$ ,  $(\mathbb{K}^l)^*$  is its dual, and  $\mathbb{K}^{l \times q}$  stands for the set of all  $l \times q$  matrices with entries in  $\mathbb{K}$ . Inequalities between real matrices or vectors will be understood componentwise; i.e., for two real matrices  $A = (a_{ij})$  and  $B = (b_{ij})$

in  $\mathbb{R}^{l \times q}$ , we write  $A \geq B$  if and only if  $a_{ij} \geq b_{ij}$  for  $i = 1, \dots, l$ ,  $j = 1, \dots, q$ . In particular, if  $a_{ij} > b_{ij}$  for  $i = 1, \dots, l$ ,  $j = 1, \dots, q$ , then we write  $A \gg B$  instead of  $A \geq B$ . We denote by  $\mathbb{R}_+^{l \times q}$  the set of all nonnegative matrices  $A \geq 0$ . A similar notation is adopted for vectors. For  $x \in \mathbb{K}^n$  and  $P \in \mathbb{K}^{l \times q}$  we define  $|x| = (|x_i|)$  and  $|P| = (|p_{ij}|)$ . For any matrix  $A \in \mathbb{K}^{n \times n}$  the *spectral radius* and *spectral abscissa* of  $A$  are denoted by  $\rho(A) = \max\{|\lambda|; \lambda \in \sigma(A)\}$  and  $\mu(A) = \max\{\Re \lambda; \lambda \in \sigma(A)\}$ , where  $\sigma(A) := \{s \in \mathbb{C}; \det(sI_n - A) = 0\}$  is the spectrum of  $A$ . A matrix  $A \in \mathbb{R}^{n \times n}$  is called a *Metzler matrix* if all off-diagonal elements of  $A$  are nonnegative or, equivalently,  $tI_n + A \geq 0$  for some  $t \geq 0$ . It is clear that any  $A \in \mathbb{R}_+^{n \times n}$  is a Metzler matrix and, moreover,  $\rho(A) = \mu(A)$ .

A norm  $\|\cdot\|$  on  $\mathbb{K}^n$  is said to be *monotonic* if  $\|x\| \leq \|y\|$  whenever  $|x| \leq |y|$ ,  $x, y \in \mathbb{K}^n$ . Every  $p$ -norm on  $\mathbb{K}^n$ ,  $1 \leq p \leq \infty$ , is monotonic. Throughout the paper, if not otherwise stated, the norm of a matrix  $P \in \mathbb{K}^{l \times q}$  is understood as its operator norm associated with a given pair of monotonic vector norms on  $\mathbb{K}^l$  and  $\mathbb{K}^q$ , that is,  $\|P\| = \max\{\|Py\|; \|y\| = 1\}$ . We note that the operator norm is in general not monotonic norm on  $\mathbb{K}^{l \times q}$  even if  $\mathbb{K}^l, \mathbb{K}^q$  are provided with monotonic norms. However, such monotonicity holds for nonnegative matrices. Moreover, we have (see, e.g., [44])

$$(2) \quad P \in \mathbb{K}^{l \times q}, Q \in \mathbb{R}_+^{l \times q}, |P| \leq Q \quad \Rightarrow \quad \|P\| \leq \| |P| \| \leq \|Q\|.$$

The following theorem summarizes some existing results on properties of Metzler matrices which will be used in what follows (see, e.g., [44]).

**THEOREM 2.1.** *Suppose that  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix. Then*

- (i) (Perron–Frobenius)  $\mu(A)$  is an eigenvalue of  $A$  and there exists a nonnegative eigenvector  $x \geq 0$ ,  $x \neq 0$  such that  $Ax = \mu(A)x$ ;
- (ii) given  $\alpha \in \mathbb{R}$ , there exists a nonzero vector  $x \geq 0$  such that  $Ax \geq \alpha x$  if and only if  $\mu(A) \geq \alpha$ ;
- (iii)  $(tI_n - A)^{-1}$  exists and is nonnegative if and only if  $t > \mu(A)$ ;
- (iv) given  $B \in \mathbb{R}_+^{n \times n}$ ,  $C \in \mathbb{C}^{n \times n}$ , then

$$(3) \quad |C| \leq B \quad \Rightarrow \quad \mu(A + C) \leq \mu(A + B).$$

For  $\phi \in C([\alpha, \beta], \mathbb{R}^{m \times n})$ , the notation  $\phi \geq 0$  means that  $\phi(\theta) \geq 0$  for every  $\theta \in [\alpha, \beta]$ . To make the presentation self-contained we present here some basic facts on vector functions of bounded variation and relative ones.

A matrix function  $\eta(\cdot) : [\alpha, \beta] \rightarrow \mathbb{R}^{l \times q}$  is called an increasing matrix function if

$$\eta(\theta_2) \geq \eta(\theta_1) \quad \text{for } \alpha \leq \theta_1 \leq \theta_2 \leq \beta.$$

A matrix function  $\eta(\cdot) : [\alpha, \beta] \rightarrow \mathbb{K}^{m \times n}$  is said to be of bounded variation if

$$(4) \quad \text{Var}(\eta; \alpha, \beta) := \sup_{P[\alpha, \beta]} \sum_k \|\eta(\theta_k) - \eta(\theta_{k-1})\| < +\infty,$$

where the supremum is taken over the set of all finite partitions of the interval  $[\alpha, \beta]$ . The set  $BV([\alpha, \beta], \mathbb{K}^{m \times n})$  of all matrix functions  $\eta(\cdot)$  of bounded variation on  $[\alpha, \beta]$  satisfying  $\eta(\alpha) = 0$  is a Banach space endowed with the norm  $\|\eta\| = \text{Var}(\eta; \alpha, \beta)$ . Since all matrix norms on  $\mathbb{K}^{m \times n}$  are equivalent, it follows that the matrix function  $\eta(\cdot) = (\eta_{ij}(\cdot)) \in \mathbb{K}^{m \times n}$  is of bounded variation if and only if each  $\eta_{ij}(\cdot)$  is of bounded variation. Moreover, it is easy to show that if  $\mathbb{K}^{m \times n}$  is provided with the  $\infty$ -norm, then

$$(5) \quad \max_{1 \leq i \leq m} \sum_{j=1}^n \text{Var}(\eta_{ij}; \alpha, \beta) \leq \|\eta\| = \text{Var}(\eta; \alpha, \beta) \leq \sum_{i=1}^m \sum_{j=1}^n \text{Var}(\eta_{ij}; \alpha, \beta).$$

Given  $\eta(\cdot) \in BV([\alpha, \beta], \mathbb{K}^{m \times n})$ , then for any continuous functions  $\gamma \in C([\alpha, \beta], \mathbb{K})$  and  $\phi \in C([\alpha, \beta], \mathbb{K}^n)$ , the integrals

$$\int_{\alpha}^{\beta} \gamma(\theta) d[\eta(\theta)] \quad \text{and} \quad \int_{\alpha}^{\beta} d[\eta(\theta)] \phi(\theta)$$

exist and are defined, respectively, as the limits of  $S_1(P) := \sum_{k=1}^p \gamma(\zeta_k)(\eta(\theta_k) - \eta(\theta_{k-1}))$  and  $S_2(P) := \sum_{k=1}^p (\eta(\theta_k) - \eta(\theta_{k-1}))\phi(\zeta_k)$  as  $d(P) := \max_k |\theta_k - \theta_{k-1}| \rightarrow 0$ , where  $P = \{\theta_1 = \alpha \leq \theta_2 \leq \dots \leq \theta_p = \beta\}$  is any finite partition of the interval  $[\alpha, \beta]$  and  $\zeta_k \in [\theta_{k-1}, \theta_k]$ . It is immediate from the definition that

$$(6) \quad \left\| \int_{\alpha}^{\beta} \gamma(\theta) d[\eta(\theta)] \right\| \leq \max_{\theta \in [\alpha, \beta]} |\gamma(\theta)| \|\eta\|,$$

$$\left\| \int_{\alpha}^{\beta} d[\eta(\theta)] \phi(\theta) \right\| \leq \max_{\theta \in [\alpha, \beta]} \|\phi(\theta)\| \|\eta\|.$$

Let  $\mathbb{K}^n$  be endowed with a vector norm  $\|\cdot\|$  and let  $C([\alpha, \beta], \mathbb{K}^n)$  be the Banach space of all continuous functions on  $[\alpha, \beta]$  with values in  $\mathbb{K}^n$  normed by the maximum norm  $\|\phi\| = \max_{\theta \in [\alpha, \beta]} \|\phi(\theta)\|$ . Let  $L : C([\alpha, \beta], \mathbb{K}^n) \rightarrow \mathbb{K}^n$  be a linear bounded operator. Then, by the Riesz representation theorem, there exists a unique matrix function  $\eta = (\eta_{ij}(\cdot)) \in BV([\alpha, \beta], \mathbb{K}^{n \times n})$  which is *continuous from the left* (c.f.l.) on  $(\alpha, \beta)$  such that

$$(7) \quad L\phi = \int_{\alpha}^{\beta} d[\eta(\theta)] \phi(\theta) \quad \forall \phi \in C([\alpha, \beta], \mathbb{K}^n).$$

For any vector norm on  $\mathbb{K}^n$ , we have by (6),  $\|L\| \leq \|\eta\|$ . Moreover, if  $\mathbb{K}^n$  is provided with the  $\infty$ -norm so that  $\forall x \in \mathbb{K}^n$  and  $\forall \theta \in [\alpha, \beta]$

$$\|x\| = \max_{1 \leq i \leq n} |x_i| \quad \text{and} \quad \|\eta(\theta)\| = \max_{1 \leq i \leq n} \sum_{j=1}^n |\eta_{ij}(\theta)|,$$

then it can be shown immediately that  $\|L\| = \|\eta\|$ . Let  $X$  be a subspace of  $C([\alpha, \beta], \mathbb{R}^n)$ . Then the operator  $L$  is called positive on  $X$  if  $L\phi \geq 0$  for every  $\phi \in X$ ,  $\phi \geq 0$ .

In subsequent sections the following subspace of  $BV([\alpha, \beta], \mathbb{K}^{m \times n})$  will be used:  $NBV([\alpha, \beta], \mathbb{K}^{m \times n}) := \{\eta \in BV([\alpha, \beta], \mathbb{K}^{m \times n}) : \eta \text{ is c.f.l. on } [\alpha, \beta]\}$ . It is clear that  $NBV([\alpha, \beta], \mathbb{K}^{m \times n})$  is closed in  $BV([\alpha, \beta], \mathbb{K}^{m \times n})$  and thus it is a Banach space with the norm  $\|\delta\| = \text{Var}(\delta; \alpha, \beta)$ .

To end this section, we give below a list of notation:

$\mathbb{R}$	$(-\infty, +\infty)$ ;
$\mathbb{C}$	the complex plane;
$\mathbb{K}$	either $\mathbb{R}$ or $\mathbb{C}$ ;
$\mathbb{N}$	the set of all natural numbers;
$\mathbb{R}^n$	the set of $n$ -dimensional column vectors with real entries;
$\mathbb{C}^n$	the set of $n$ -dimensional column vectors with complex entries;
$\mathbb{R}_+^n$	the set of $n$ -dimensional column vectors with nonnegative entries;
$\mathbb{R}^{m \times n}$	the set of $m \times n$ -dimensional matrices with real entries;
$\mathbb{C}^{m \times n}$	the set of $m \times n$ -dimensional matrices with complex entries;
$\mathbb{R}_+^{m \times n}$	the set of $m \times n$ -dimensional matrices with nonnegative entries;
$\Re z$	the real part of $z \in \mathbb{C}$ ;
$A, B, C$ , etc.	matrices;

$I_n$	the identity of $\mathbb{C}^{n \times n}$ ;
$x, y, z, \text{ etc.}$	column vectors;
$\mu(A)$	the spectral abscissa of $A \in \mathbb{C}^{n \times n}$ ;
$A \geq B$	$A, B \in \mathbb{R}^{m \times n}$ and $A - B \in \mathbb{R}_+^{m \times n}$ for some $m, n \in \mathbb{N}$ ;
$C([0, +\infty), \mathbb{K}^{m \times n})$	the vector space of all continuous functions on $[0, +\infty)$ with values in $\mathbb{K}^{m \times n}$ ;
$C([\alpha, \beta], \mathbb{K}^{m \times n})$	the Banach space of all continuous functions on $[\alpha, \beta]$ with values in $\mathbb{K}^{m \times n}$ , endowed with the maximum norm;
$BV([\alpha, \beta], \mathbb{K}^{m \times n})$	the Banach space of all matrix functions $\eta(\cdot)$ of bounded variation on $[\alpha, \beta]$ with values in $\mathbb{K}^{m \times n}$ satisfying $\eta(\alpha) = 0$ , endowed with the norm $\ \eta\  = \text{Var}(\eta; \alpha, \beta)$ ;
$NBV([\alpha, \beta], \mathbb{K}^{m \times n})$	functions in $BV([\alpha, \beta], \mathbb{K}^{m \times n})$ that are c.f.l. on $[\alpha, \beta]$ ;
$L^1([0, +\infty), \mathbb{K}^{m \times n})$	the Banach space of $L^1$ -integrable matrix functions on $[0, +\infty)$ , with values in $\mathbb{K}^{m \times n}$ and endowed with the $L^1$ -norm;
$\mu(A, B(\cdot))$	the spectral abscissa of a Volterra differential equation of convolution type defined by $A \in \mathbb{C}^{n \times n}$ and $B(\cdot) \in C([0, +\infty), \mathbb{C}^{n \times n})$ .

### 3. Positive linear Volterra integrodifferential equations.

**3.1. Explicit criterion for positive linear Volterra integrodifferential equations.** Consider a linear Volterra integrodifferential equation of convolution type

$$(8) \quad \dot{x}(t) = Ax(t) + \int_0^t B(t-s)x(s)ds,$$

where  $A \in \mathbb{R}^{n \times n}$  is a given matrix and  $B : [0, +\infty) \rightarrow \mathbb{R}^{n \times n}$  is a given continuous matrix function.

**DEFINITION 3.1.** Let  $\sigma \geq 0$  and  $\phi \in C([0, \sigma], \mathbb{R}^n)$  be given. A function  $x : [0, +\infty) \rightarrow \mathbb{R}^n$  such that

$$(9) \quad x(t) = \phi(t), \quad t \in [0, \sigma],$$

and fulfilling (8) for every  $t \geq \sigma$  is called a solution of (8) with the initial condition (9).

It is well known that for every  $\sigma \geq 0$  and  $\phi \in C([0, \sigma], \mathbb{R}^n)$ , (8) has a unique solution satisfying the initial condition (9); see, e.g., [4, p. 177]. We denote it by  $x(t, \sigma, \phi), t \geq 0$ .

**DEFINITION 3.2.** We say that (8) is positive if for every  $\sigma \geq 0$  and every  $\phi \in C([0, \sigma], \mathbb{R}^n)$ , with  $\phi \geq 0$ , the corresponding solution  $x(t, \sigma, \phi)$  satisfies  $x(t, \sigma, \phi) \geq 0 \forall t \geq \sigma$ .

**Remark 3.3.** The notion of positive linear Volterra equations given in Definition 3.2 is similar to that of positive linear functional differential equations of the form (1); see, e.g., [35], [37]. However, it is worth noting that in general a Volterra equation of the form (8) cannot convert into a linear functional differential equation of the form (1).

We believe that positive linear Volterra equations are interesting objects not only in mathematics but also in other sciences such as economics, physics, and biology. To prove a criterion for positive linear Volterra equations, we need the following technical lemmas.

**LEMMA 3.4.** Let  $T > 0$  and  $C_0([0, T], \mathbb{R}^n) := \{\phi \in C([0, T], \mathbb{R}^n) : \phi(T) = 0\}$ . Suppose that the linear operator  $L$  is defined by

$$L : C_0([0, T], \mathbb{R}^n) \rightarrow \mathbb{R}^n, \quad \phi \mapsto L\phi = \int_0^T d[\eta(\theta)]\phi(\theta),$$

where  $\eta \in NBV([0, T], \mathbb{R}^{n \times n})$  is given. Then  $L$  is a positive operator if and only if  $\eta$  is an increasing matrix function.

*Proof.* Let  $\eta$  be an increasing matrix function. Then by the definition of Riemann–Stieltjes integrals, we have

$$L\phi = \lim_{d(P) \rightarrow 0} \sum_{k=1}^p (\eta(\theta_k) - \eta(\theta_{k-1}))\phi(\zeta_k) \geq 0$$

for every  $\phi \in C_0([0, T], \mathbb{R}^n)$ ,  $\phi \geq 0$ . This means that  $L$  is positive.

Conversely, assume that  $L$  is positive on  $C_0([0, T], \mathbb{R}^n)$ . Let  $\eta(\cdot) = (\eta_{ij}(\cdot))$ . We show that  $\eta_{ij}(\cdot) \in NBV([0, T], \mathbb{R})$  is an increasing scalar function for every  $i, j \in \{1, 2, \dots, n\}$ . Since  $L$  is positive, it is easy to see that the operator

$$L_{ij} : C_0([0, T], \mathbb{R}) \rightarrow \mathbb{R}, \quad \phi \mapsto L_{ij}\phi := \int_0^T \phi(\theta) d[\eta_{ij}(\theta)]$$

is also positive for every  $i, j \in \{1, 2, \dots, n\}$ . Fix  $\theta_1, \theta_2 \in (0, T)$ ,  $\theta_1 < \theta_2$  and  $k \in \mathbb{N}$ ,  $k > \max\{\frac{1}{\theta_1}, \frac{1}{\theta_2}, \frac{1}{\theta_2 - \theta_1}\}$ , and consider the continuous function  $\phi_k$  defined by

$$(10) \quad \phi_k(\theta) := \begin{cases} 0 & \text{if } \theta \in [0, \theta_1 - \frac{1}{k}], \\ k\theta + 1 - k\theta_1 & \text{if } \theta \in (\theta_1 - \frac{1}{k}, \theta_1], \\ 1 & \text{if } \theta \in (\theta_1, \theta_2 - \frac{1}{k}], \\ -k\theta + k\theta_2 & \text{if } \theta \in (\theta_2 - \frac{1}{k}, \theta_2], \\ 0 & \text{if } \theta \in (\theta_2, T]. \end{cases}$$

Since  $\phi_k$  is a continuous on  $[0, T]$ , it follows from a standard property of Riemann–Stieltjes integrals that

$$\int_0^T \phi_k(\theta) d[\eta_{ij}(\theta)] = \left( \int_0^{\theta_1 - \frac{1}{k}} + \int_{\theta_1 - \frac{1}{k}}^{\theta_1} + \int_{\theta_1}^{\theta_2 - \frac{1}{k}} + \int_{\theta_2 - \frac{1}{k}}^{\theta_2} + \int_{\theta_2}^T \right) \phi_k(\theta) d[\eta_{ij}(\theta)];$$

see, e.g., [41]. This gives

$$\int_{\theta_1 - \frac{1}{k}}^{\theta_1} \phi_k(\theta) d[\eta_{ij}(\theta)] + \eta_{ij}\left(\theta_2 - \frac{1}{k}\right) - \eta_{ij}(\theta_1) + \int_{\theta_2 - \frac{1}{k}}^{\theta_2} \phi_k(\theta) d[\eta_{ij}(\theta)] \geq 0$$

for every  $k \in \mathbb{N}$  large enough. Taking into account that  $\eta_{ij}$  is c.f.l. at  $\theta_1, \theta_2$  and letting  $k \rightarrow +\infty$ , we have  $\eta_{ij}(\theta_2) \geq \eta_{ij}(\theta_1)$  for every  $\theta_1, \theta_2 \in (0, T)$ ,  $\theta_2 \geq \theta_1$ . In the case of  $\theta_1 = 0 < \theta_2 < T$ , in a similar way we also get  $\eta_{ij}(\theta_2) \geq \eta_{ij}(\theta_1)$ . Finally, since  $\eta_{ij}$  is c.f.l. at  $T$ , we have  $\eta_{ij}(T) \geq \eta_{ij}(\theta)$  for  $\theta \in [0, T]$ . This completes our proof.  $\square$

Let  $h : [0, +\infty) \rightarrow \mathbb{R}$ . Then the Laplace transform of  $h$  is formally defined to be

$$\hat{h}(s) := \int_0^{+\infty} e^{-st} h(t) dt.$$

If  $\beta \in \mathbb{R}$  and  $\int_0^{+\infty} e^{-\beta t} |h(t)| dt < +\infty$ , then  $\hat{h}(s)$  exists for  $s \in \mathbb{C}$ ,  $\Re s \geq \beta$ . Furthermore,  $\hat{h}(s)$  is an analytic function in the domain  $\{s \in \mathbb{C} : \Re s > \beta\}$ . If  $D(t) = (d_{ij}(t))$  is a matrix function, then we define

$$\hat{D} := (\hat{d}_{ij}).$$

In the rest of this paper, we always assume that

$$(11) \quad B(\cdot) \in L^1([0, +\infty), \mathbb{R}^{n \times n}).$$

Let  $Z(t)$  be the matrix whose columns are solutions of (8) with  $Z(0) = I_n$ . Then  $Z(t)$  satisfies the resolvent equation

$$(12) \quad \frac{d}{dt}Z(t) = AZ(t) + \int_0^t B(t-s)Z(s)ds, \quad Z(0) = I_n.$$

LEMMA 3.5. *Suppose that for every  $x_0 \in \mathbb{R}_+^n$ , the corresponding solution  $x(t, 0, x_0)$ ,  $t \geq 0$ , satisfies  $x(t, 0, x_0) \geq 0 \forall t \geq 0$ . Then  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix and  $(sI_n - A - \hat{B}(s))^{-1} \geq 0$  for  $s \in \mathbb{R}$  large enough.*

*Proof.* By the assumption,  $Z(t) \geq 0 \forall t \geq 0$ . It is well known that  $Z(\cdot)$  is of exponential order; see [3, p. 29]. Therefore, taking the Laplace transform of both sides of (12), we get

$$[sI_n - A - \hat{B}(s)]\hat{Z}(s) = Z(0) = I_n$$

for  $s \in \mathbb{R}$  large enough. From  $Z(t) \geq 0 \forall t \geq 0$ , it follows that  $\hat{Z}(s) = (sI_n - A - \hat{B}(s))^{-1} \geq 0$  for  $s \in \mathbb{R}$  large enough. It remains only to show that  $A$  is a Metzler matrix. Let  $A = (a_{ij})$  and assume to the contrary that  $a_{i_0 j_0} < 0$  for some  $i_0 \neq j_0$ . Since  $B(t) \in L^1([0, +\infty), \mathbb{R}^{n \times n})$ , it is easy to see that  $\hat{B}(s) \rightarrow 0$  as  $s \rightarrow +\infty$ . This implies that the spectral radius of the matrix  $s^{-1}(A + \hat{B}(s))$  is strictly less than 1 for  $s > 0$  large enough. Therefore, we can represent

$$\begin{aligned} (sI_n - A - \hat{B}(s))^{-1} &= s^{-1} \left( I_n - s^{-1}(A + \hat{B}(s)) \right)^{-1} \\ &= s^{-1}I_n + s^{-2}(A + \hat{B}(s)) + \sum_{k=2}^{+\infty} s^{-(k+1)}(A + \hat{B}(s))^k \end{aligned}$$

for  $s > 0$  large enough. We thus get

$$(13) \quad sI_n + (A + \hat{B}(s)) + \sum_{k=2}^{+\infty} s^{-(k-1)}(A + \hat{B}(s))^k \geq 0$$

for  $s > 0$  large enough. It is important to note that

$$\lim_{s \rightarrow +\infty} \sum_{k=2}^{+\infty} s^{-(k-1)}(A + \hat{B}(s))^k = 0.$$

Then from (13) it follows that the entry  $\tilde{b}_{i_0 j_0}$  of the matrix on the left-hand side of (13) is negative for  $s > 0$  large enough. This is a contradiction. Hence,  $A$  must be a Metzler matrix. This completes our proof.  $\square$

LEMMA 3.6. (see [3, p. 24]) *Let  $0 < \alpha \leq +\infty$  and suppose that  $f : [0, \alpha) \rightarrow \mathbb{R}^n$  is continuous and that  $D(t, s)$  is an  $n \times n$  matrix of functions continuous for  $0 \leq s \leq t < \alpha$ . If  $0 < T < \alpha$ , then there exists a unique solution  $y(t)$  of the integral equation*

$$(14) \quad y(t) = f(t) + \int_0^t D(t, s)y(s)ds$$

on  $[0, T]$ . Moreover,  $y(t)$  is the limit in  $C([0, T], \mathbb{R}^n)$  of the sequence of Picard's successive approximations  $(y_n(t))_n$ , given by

$$(15) \quad y_1(t) = f(t); \quad y_{n+1}(t) = f(t) + \int_0^t D(t, s)y_n(s)ds, \quad t \in [0, T], n \geq 1.$$

We are now in the position to prove the first main result of this paper.

**THEOREM 3.7.** *Equation (8) is positive if and only if  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix and  $B(t) \geq 0$  for every  $t \geq 0$ .*

*Proof.* Assume that  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix and  $B(t) \geq 0$  for every  $t \geq 0$ . Let  $\sigma \geq 0$  and  $\phi \in C([0, \sigma], \mathbb{R}^n)$ ,  $\phi \geq 0$ . Denote  $x(t) = x(t, \sigma, \phi)$ ,  $t \geq 0$ . Then  $x(t)$  satisfies

$$x(t) = e^{A(t-\sigma)}\phi(\sigma) + \int_{\sigma}^t e^{A(t-s)}g(s)ds, \quad t \geq \sigma,$$

where  $g(s) := \int_0^s B(s-\tau)x(\tau)d\tau$ ,  $s \in [\sigma, t]$ . This is equivalent to

$$x(t+\sigma) = e^{At}\phi(\sigma) + \int_0^t e^{A(t-s)}g(s+\sigma)ds, \quad t \geq 0.$$

Therefore,

$$x(t+\sigma) = e^{At}\phi(\sigma) + \int_0^t e^{A(t-s)} \left( \int_0^{\sigma} B(s+\sigma-\tau)\phi(\tau)d\tau + \int_{\sigma}^{\sigma+s} B(s+\sigma-\tau)x(\tau)d\tau \right) ds, \quad t \geq 0.$$

This gives

$$(16) \quad x(t+\sigma) = f(t) + \int_0^t \left( e^{A(t-s)} \int_0^s B(s-\tau)x(\tau+\sigma)d\tau \right) ds, \quad t \geq 0,$$

where

$$f(t) = e^{At}\phi(\sigma) + \int_0^t \left( e^{A(t-s)} \int_0^{\sigma} B(s+\sigma-\tau)\phi(\tau)d\tau \right) ds, \quad t \geq 0.$$

Set  $y(t) = x(t+\sigma)$ ,  $t \geq 0$ . Then (16) can be rewritten in the form

$$y(t) = f(t) + \int_0^t \left( e^{A(t-s)} \int_0^s B(s-\tau)y(\tau)d\tau \right) ds, \quad t \geq 0.$$

Interchanging the order of integration in the last term, we get

$$(17) \quad y(t) = f(t) + \int_0^t \left( \int_s^t e^{A(t-\tau)}B(\tau-s)d\tau \right) y(s)ds, \quad t \geq 0.$$

Since  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix, it follows that  $A + \alpha I_n \geq 0$  for some  $\alpha > 0$ . This implies that  $e^{(A+\alpha I_n)t} = e^{\alpha t}e^{At} \geq 0 \quad \forall t \geq 0$ . Thus,  $e^{At} \geq 0 \quad \forall t \geq 0$ . From  $e^{At}$ ,  $B(t) \geq 0$  for every  $t \geq 0$ , it follows that  $f(t) \geq 0 \quad \forall t \geq 0$  and  $D(t, s) := \int_s^t e^{A(t-\tau)}B(\tau-s)d\tau \geq 0$ ,  $0 \leq s \leq t \leq T$ . Furthermore, the functions  $y_n(t)$ ,  $n \in \mathbb{N}$ , defined by (15) in Lemma 3.6 are also nonnegative for every  $t \geq 0$ . Applying Lemma 3.6 to (17), we conclude that the solution  $y(t)$ ,  $t \in [0, T]$ , of integral equation (17) is nonnegative on  $[0, T]$ . Since  $T > 0$  is arbitrary, it implies that  $y(t) \geq 0 \quad \forall t \geq 0$ . Thus,  $x(t) \geq 0 \quad \forall t \geq 0$ .

Conversely, assume that (8) is positive. By Lemma 3.5, it remains only to show that  $B(t) \geq 0$  for every  $t \geq 0$ . Fix  $T > 0$  and let  $\phi \in C_0([0, T], \mathbb{R}^n)$ ,  $\phi \geq 0$ . Since (8) is positive, it follows that

$$\frac{d}{dt}x(t)\Big|_{t=T} = \lim_{t \rightarrow T+0} \frac{x(t) - x(T)}{t - T} = \lim_{t \rightarrow T+0} \frac{x(t)}{t - T} \geq 0.$$

This implies that

$$\frac{d}{dt}x(t)\Big|_{t=T} = Ax(T) + \int_0^T B(T-s)x(s)ds = \int_0^T B(T-s)\phi(s)ds \geq 0$$

for every  $\phi \in C_0([0, T], \mathbb{R}^n)$ ,  $\phi \geq 0$ . Thus, the linear operator defined by

$$L : C_0([0, T], \mathbb{R}^n) \rightarrow \mathbb{R}^n, \quad \phi \mapsto L\phi := \int_0^T B(T-s)\phi(s)ds$$

is a positive operator. Applying Lemma 3.4 to the positive operator  $L$ , we conclude that the function

$$\eta(t) = \int_0^t B(T-s)ds, \quad t \in [0, T],$$

is an increasing matrix function. This gives  $B(t) \geq 0$  for every  $t \in [0, T]$ . Since  $T > 0$  is arbitrary, it follows that  $B(t) \geq 0$  for every  $t \geq 0$ . This completes our proof.  $\square$

**3.2. A Perron–Frobenius theorem for positive linear Volterra integro-differential equations.** It is well known that Perron–Frobenius-type theorems are principal tools for analysis of stability and robust stability of positive linear time-invariant systems. To our knowledge, there is a large number of extensions of classical Perron–Frobenius theorems; see; e.g., [1], [6], [21], [31], [32], [36], [42], and the references therein.

Recall that a linear time-invariant differential system of the form  $\dot{x}(t) = Ax(t)$ ,  $t \geq 0$ , is positive if and only if the system matrix  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix. Therefore, the classical Perron–Frobenius theorem (Theorem 2.1) can be seen as the Perron–Frobenius theorem for the class of these positive systems. From this dynamic point of view, we recently presented some extensions of the classical Perron–Frobenius theorem such as the Perron–Frobenius theorem for positive linear higher order difference equations [36], the Perron–Frobenius theorem for positive linear time-delay systems [31], and the Perron–Frobenius theorem for positive linear functional differential equations [32].

In this subsection, we give a new Perron–Frobenius theorem for positive linear Volterra integrodifferential equations of the form (8). Let us denote

$$(18) \quad H(s) := (sI_n - A - \hat{B}(s)) = \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t)dt \right)$$

for appropriate  $s \in \mathbb{C}$ . Let us define

$$(19) \quad \mu(A, B(\cdot)) := \sup \left\{ \Re s : \int_0^{+\infty} e^{-\Re st} \|B(t)\|dt < +\infty, \det H(s) = 0 \right\},$$

where  $\mu(A, B(\cdot)) := -\infty$  if  $\det H(s) \neq 0 \forall s \in \mathbb{C}$ ,  $\int_0^{+\infty} e^{-\Re st} \|B(t)\|dt < +\infty$ . Then  $\mu(A, B(\cdot))$  is called *spectral abscissa* of the Volterra equation (8).

**THEOREM 3.8.** *Suppose that the Volterra equation (8) is positive. Let  $\beta := \inf\{\gamma \in \mathbb{R} : \int_0^{+\infty} e^{-\gamma t} \|B(t)\| dt < +\infty\}$  and  $\alpha \in (\beta, +\infty)$  be given. Denote by  $\mu_0 := \mu(A, B(\cdot))$ . If  $\mu_0 > -\infty$ , then*

- (i) *(Perron–Frobenius theorem for positive linear Volterra integrodifferential equations)  $\mu_0$  is a root of the characteristic equation, that is,  $\det H(\mu_0) = 0$ ; moreover, there exists a nonzero vector  $x \geq 0$  such that*

$$\left(A + \int_0^{+\infty} e^{-\mu_0 t} B(t) dt\right)x = \mu_0 x;$$

- (ii) *there exists a nonzero vector  $x \geq 0$  such that  $(A + \int_0^{+\infty} e^{-\alpha t} B(t) dt)x \geq \alpha x$  if and only if  $\mu_0 \geq \alpha$ ;*

- (iii) *the matrix  $H(\alpha)^{-1} = (\alpha I_n - A - \int_0^{+\infty} e^{-\alpha t} B(t) dt)^{-1}$  exists and is nonnegative if and only if  $\alpha > \mu_0$ .*

*Proof.* We first show that  $\mu_0$  is finite. Since (8) is positive, it follows that  $A$  is a Metzler matrix and  $B(t) \in \mathbb{R}_+^{n \times n} \forall t \geq 0$ . Assume that  $\beta > -\infty$  and  $\det H(s) = 0$  for some  $s \in \mathbb{C}, \Re s \geq \beta + 1$ . Then, by Theorem 2.1(iv),  $\Re s \leq \mu(A + \int_0^{+\infty} e^{-st} B(t) dt) \leq \mu(A + \int_0^{+\infty} e^{-\Re s t} B(t) dt) \leq \mu(A + \int_0^{+\infty} e^{-(\beta+1)t} B(t) dt)$ . It follows that

$$\mu_0 \leq \max \left\{ \beta + 1, \mu \left( A + \int_0^{+\infty} e^{-(\beta+1)t} B(t) dt \right) \right\}.$$

If  $\beta = -\infty$ , then by a similar argument, we get  $\mu_0 \leq \mu(A + \int_0^{+\infty} B(t) dt)$ . Next, we prove that

$$(20) \quad \mu_0 \leq \mu \left( A + \int_0^{+\infty} e^{-\mu_0 t} B(t) dt \right).$$

In fact, by the assumption  $\mu_0 > -\infty$ , there exists  $s_0 \in \mathbb{C}$  such that  $\det H(s_0) = 0$ ,  $\beta \leq \Re s_0 \leq \mu_0$ . If  $\Re s_0 = \mu_0$ , then, using Theorem 2.1(iv) again, we get (20). If  $\beta \leq \Re s_0 < \mu_0$ , then there exists a sequence  $(s_k)_k$  such that  $\det H(s_k) = 0$ ,  $\beta < \Re s_k < \mu_0 \forall k \in \mathbb{N}$  and  $\Re s_k \rightarrow \mu_0$  as  $k \rightarrow \infty$ . Then by Theorem 2.1(iv), we get

$$(21) \quad \Re s_k \leq \mu \left( A + \int_0^{+\infty} e^{-\Re s_k t} B(t) dt \right).$$

Letting  $k \rightarrow \infty$  in (21), we also get (20). We now consider the continuous real function

$$(22) \quad f(\theta) := \theta - \mu \left( A + \int_0^{+\infty} e^{-\theta t} B(t) dt \right),$$

where  $\theta \in [\beta, +\infty)$  if  $\int_0^{+\infty} e^{-\beta t} \|B(t)\| dt < +\infty$ ; otherwise  $\theta \in (\beta, +\infty)$ . Then  $f(\mu_0) \leq 0$  by (20). Assume that  $f(\mu_0) < 0$ . Since, clearly,  $\lim_{\theta \rightarrow +\infty} f(\theta) = +\infty$ , we derive that  $f(\theta_0) = 0$  for some  $\theta_0 > \mu_0$ . This gives  $\theta_0 = \mu(A + \int_0^{+\infty} e^{-\theta_0 t} B(t) dt)$ . By Theorem 2.1(i), it implies that  $\det(\theta_0 I_n - A - \int_0^{+\infty} e^{-\theta_0 t} B(t) dt) = 0$ . However, this conflicts with the definition of  $\mu_0$ . Thus  $f(\mu_0) = 0$ , or, equivalently,  $\mu_0 = \mu(A + \int_0^{+\infty} e^{-\mu_0 t} B(t) dt)$ . Then Theorem 3.8(i) now follows from Theorem 2.1(i).

Moreover, by Theorem 2.1(iv), we get

$$\mu \left( A + \int_0^{+\infty} e^{-\theta_2 t} B(t) dt \right) \leq \mu \left( A + \int_0^{+\infty} e^{-\theta_1 t} B(t) dt \right), \quad \beta < \theta_1 \leq \theta_2.$$

Therefore,  $f$  is strictly increasing on  $(\beta, +\infty)$ . Moreover,  $f(\mu_0) = 0$ . Now, it is easy to see that Theorem 3.8(ii), (iii) follow from Theorem 2.1(ii), (iii), respectively.  $\square$

**4. An explicit criterion for uniformly asymptotic stability of positive linear Volterra integrodifferential equations.** In this section, we offer a new and novel criterion for uniformly asymptotic stability of positive linear Volterra integrodifferential equations of the form (8). First, we quote here the various notions of stability of zero solution of (8) which are taken from the standard books on theory of Volterra equations; see [3], [4].

DEFINITION 4.1. *The zero solution of (8) is (Lyapunov) stable if, for each  $\epsilon > 0$  and each  $t_0 \geq 0$ , there exists  $\delta > 0$  such that*

$$\phi \in C([0, t_0], \mathbb{R}^n), \quad \|\phi\| < \delta,$$

*implies that  $\|x(t, t_0, \phi)\| < \epsilon \quad \forall t \geq t_0$ .*

DEFINITION 4.2. *The zero solution of (8) is uniformly stable if, for each  $\epsilon > 0$ , there exists  $\delta > 0$  such that*

$$t_0 \geq 0, \phi \in C([0, t_0], \mathbb{R}^n), \quad \|\phi\| < \delta,$$

*implies that  $\|x(t, t_0, \phi)\| < \epsilon \quad \forall t \geq t_0$ .*

DEFINITION 4.3. *The zero solution of (8) is asymptotically stable (AS) if it is stable and if, for each  $t_0 \geq 0$ , there exists  $\delta > 0$  such that  $\phi \in C([0, t_0], \mathbb{R}^n)$ ,  $\|\phi\| < \delta$ , implies that  $x(t, t_0, \phi) \rightarrow 0$  as  $t \rightarrow +\infty$ .*

DEFINITION 4.4. *The zero solution of (8) is uniformly asymptotically stable (UAS) if it is uniformly stable and if there exists  $\delta > 0$  such that, for each  $\epsilon > 0$ , there is a  $T > 0$  such that*

$$t_0 \geq 0, \phi \in C([0, t_0], \mathbb{R}^n), \quad \|\phi\| < \delta,$$

*implies that  $\|x(t, t_0, \phi)\| < \epsilon \quad \forall t \geq t_0 + T$ .*

If the zero solution of (8) is AS (UAS), then we say that (8) is AS (UAS), respectively. Recall that we continue to assume that (11) holds true, that is,  $B(\cdot) \in L^1([0, \infty), \mathbb{R}^{n \times n})$ . Let us denote by  $\sigma(A, B(\cdot))$  the set of all root of the characteristic equation of (8). That is,  $\sigma(A, B(\cdot)) := \{s \in \mathbb{C} : \det H(s) = 0\}$ . Denote  $\mathbb{C}^- := \{s \in \mathbb{C} : \Re s < 0\}$ .

THEOREM 4.5 (see [7]). *Let assumption (11) hold true. Then (8) is UAS if and only if  $\sigma(A, B(\cdot)) \subset \mathbb{C}^-$ .*

The following theorem provides an explicit criterion for uniformly asymptotic stability of positive linear Volterra equations (8).

THEOREM 4.6. *Suppose that (8) is positive. Then (8) is UAS if and only if  $\mu(A + \int_0^{+\infty} B(t)dt) < 0$ .*

*Proof.* Assume on the contrary that (8) is UAS but  $\mu(A + \int_0^{+\infty} B(t)dt) \geq 0$ . Since  $B(\cdot)$  is integrable on  $[0, \infty)$ , it follows that the real function given by (22) is continuous on  $[0, +\infty)$ . By our assumption,  $f(0) \leq 0$ . Since, clearly,  $\lim_{\theta \rightarrow +\infty} f(\theta) = +\infty$ , we have  $f(\theta_0) = 0$  for some  $\theta_0 \geq 0$ . This gives  $\theta_0 = \mu(A + \int_0^{+\infty} e^{-\theta_0 t} B(t)dt)$ . Since  $A + \int_0^{+\infty} e^{-\theta_0 t} B(t)dt$  is a Metzler matrix, it follows from Theorem 2.1(i) that  $\det(\theta_0 I_n - A - \int_0^{+\infty} e^{-\theta_0 t} B(t)dt) = 0$ ,  $\theta_0 \geq 0$ . However, by Theorem 4.5, this conflicts with the fact that (8) is UAS.

Conversely, let  $\mu(A + \int_0^{+\infty} B(t)dt) < 0$ . Assume on the contrary that there exists  $s \in \mathbb{C}$ ,  $\Re s \geq 0$  such that  $\det H(s) = 0$ . This implies that  $\Re s \leq \mu(A + \int_0^{+\infty} e^{-st} B(t)dt)$ . By  $\Re s \geq 0$ , we have

$$\left| \int_0^{+\infty} e^{-st} B(t)dt \right| \leq \int_0^{+\infty} e^{-\Re s t} B(t)dt \leq \int_0^{+\infty} B(t)dt.$$

Then it follows from Theorem 2.1(iv) that

$$0 \leq \mu \left( A + \int_0^{+\infty} e^{-st} B(t) dt \right) \leq \mu \left( A + \int_0^{+\infty} e^{-\Re st} B(t) dt \right) \leq \mu \left( A + \int_0^{+\infty} B(t) dt \right).$$

We reach a contradiction. This completes our proof.  $\square$

*Remark 4.7.* We encountered a scalar version of Theorem 4.6 in some standard books on Volterra equations (see, e.g., [3], [23]), where it was proven by using a Lyapunov function. However, to the best of our knowledge, there is not such a result for  $k$ -dimensional systems with  $k \geq 2$ . As a consequence of the above theorem, we have the following.

**THEOREM 4.8.** *Suppose that (8) is positive and  $b \in \mathbb{R}^n, b \gg 0$ . Then the following statements are equivalent:*

- (i) *equation (8) is AS;*
- (ii) *equation (8) is UAS;*
- (iii)  $\mu(A + \int_0^{+\infty} B(t) dt) < 0$ ;
- (iv) *if  $x(t)$  is a solution of (8) on  $[0, +\infty)$ , then  $x \in L^1([0, +\infty), \mathbb{R}^n)$ ;*
- (v) *there exists a nonzero vector  $p \in \mathbb{R}_+^n$  such that*

$$(23) \quad \left( A + \int_0^{+\infty} B(t) dt \right) p = -b.$$

Moreover, under one of the above conditions, each solution  $y(t)$  of

$$(24) \quad \dot{y}(t) = Ay(t) + \int_0^t B(t-s)y(s)ds + b$$

satisfies  $\lim_{t \rightarrow +\infty} y(t) = p$ .

*Proof.* (i)  $\Leftrightarrow$  (ii) was proved in [7]. By Theorem 4.6, we have (ii)  $\Leftrightarrow$  (iii). Moreover, (ii)  $\Leftrightarrow$  (iv) was found in [26]. We now show that (i)  $\Leftrightarrow$  (v). In fact, the implication (i)  $\Rightarrow$  (v) follows from Theorem 2.1(iii). Conversely, assume on the contrary that (23) holds true but we have  $\mu_0 := \mu(A + \int_0^{+\infty} B(t) dt) \geq 0$ . By Theorem 2.1(i), we get

$$\left( A + \int_0^{+\infty} B(t) dt \right)^T p_0 = \mu_0 p_0$$

for some nonzero vector  $p_0 \in \mathbb{R}_+^n$ . Then it follows from (23) that

$$\mu_0 p^T p_0 + b^T p_0 = 0.$$

However, this conflicts with  $p, p_0 \geq 0$ ,  $p, p_0 \neq 0$ ,  $b \gg 0$ , and  $\mu_0 \geq 0$ . We now assume that (8) is UAS. Then each solution  $y$  of (24) satisfying  $y(0) = y_0$  is given by

$$y(t) = Z(t)y_0 + \int_0^t Z(s)b ds, \quad t \geq 0.$$

It follows that  $\lim_{t \rightarrow +\infty} y(t) = \left( \int_0^{+\infty} Z(t) dt \right) b = \hat{Z}(0)b = \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} b = p$ . This completes our proof.  $\square$

We illustrate the obtained result by a simple example.

*Example 4.9.* Consider a linear positive Volterra integrodifferential equation in  $\mathbb{R}^2$  given by

$$(25) \quad \dot{x}(t) = Ax(t) + \int_0^t B(t-\tau)x(\tau)d\tau, \quad x(t) \in \mathbb{R}^2, t \geq 0,$$

where

$$(26) \quad A = \begin{pmatrix} a & 1 \\ 0 & a \end{pmatrix}; \quad B(t) = \begin{pmatrix} e^{-pt} & 0 \\ \frac{1}{(t+1)^2} & e^{-pt} \end{pmatrix}, \quad t \geq 0,$$

and  $a, p \in \mathbb{R}, p > 0$  are parameters. From  $p > 0$ , it follows that the condition (11) is satisfied. By Theorem 4.6, (25) is UAS if and only if

$$\mu \left( A + \int_0^{+\infty} B(t) dt \right) = \mu \left( \begin{bmatrix} a + 1/p & 1 \\ 1 & a + 1/p \end{bmatrix} \right) = a + 1 + 1/p < 0.$$

Taking into account that  $p > 0$ , it is easy to see that this is equivalent to  $a < -1$ ,  $p > -1/(a+1)$ .

**5. Stability radius of positive linear Volterra integrodifferential equations.** Motivated by many applications in control engineering, researchers have focused much attention on problems of robust stability of dynamical systems over the last twenty years. In the study of these problems, the notion of the stability radius was proved to be an effective tool. By definition, the stability radius of an AS linear differential system  $\dot{x}(t) = Ax(t), t \geq 0$ , is the *maximal*  $r > 0$  for which all systems of the form

$$\dot{x}(t) = (A + D\Delta E)x(t), \quad \|\Delta\| < r,$$

are AS. Here,  $\Delta$  is an unknown disturbance matrix, and  $D$  and  $E$  are given matrices defining the structure of the perturbations. Depending upon whether complex or real disturbances  $\Delta$  are considered, this maximal  $r$  is called a complex or real stability radius, respectively. The basic problem in the study of robustness of stability of the system is to characterize and compute these radii in terms of given matrices  $A, D, E$ . It is important to note that these two stability radii are in general distinct. The analysis and computation of the complex stability radius for systems under structured perturbations was first shown in [12] and extended later in many subsequent papers (see [13] for a survey up till 1990), while the computation of the real stability radius, being a much more difficult problem, has been solved only quite recently; see, e.g., [40]. The situation is much simpler for the class of positive systems. It had been shown in [14], [43] that if  $A$  is a Metzler matrix (i.e.,  $\dot{x}(t) = Ax(t), t \geq 0$ , is a positive system) and  $D, E$  are nonnegative matrices, then the complex and the real stability radii coincide and can be computed directly by a simple formula. These results have been extended recently to many various classes of positive systems such as positive linear time-delay differential systems [34], [30], [45], positive linear discrete time-delay systems [15], [33], and positive linear functional differential equations [35], [46].

Although there have been many works dedicated to studying the stability radius problems of linear dynamical systems, the problem of computing stability radii of linear Volterra integrodifferential equations has not yet been studied in the literature. In this section, we deal with the stability radii of positive linear Volterra integrodifferential equation (8) under structured perturbations and affine perturbations.

**5.1. Stability radius of positive linear Volterra integrodifferential equation under structured perturbations.** We now assume that (8) is UAS and consider the following perturbed equations of the form

$$(27) \quad \dot{x}(t) = (A + D_0\Delta E)x(t) + \int_0^t (B(s) + D_1\delta(s)E)x(t-s)ds,$$

where  $D_i \in \mathbb{R}^{n \times l_i}$  ( $i \in I := \{0, 1\}$ ),  $E \in \mathbb{R}^{q \times n}$  are given matrices determining the *structure* of perturbations, and  $\Delta \in \mathbb{K}^{l_0 \times q}$ ,  $\delta(\cdot) \in L^1([0, +\infty), \mathbb{K}^{l_1 \times q}) \cap C([0, +\infty), \mathbb{K}^{l_1 \times q})$ , ( $\mathbb{K} = \mathbb{R}, \mathbb{C}$ ) are unknown disturbances. In this case, we say that  $A, B(\cdot)$  are subjected to *structured perturbations* of the form

$$(28) \quad A \rightsquigarrow A + D_0 \Delta E; \quad B(\cdot) \rightsquigarrow B(\cdot) + D_1 \delta(\cdot) E.$$

We shall measure the size of each perturbation  $(\Delta, \delta(\cdot)) \in \mathbb{K}^{l_0 \times q} \times L^1([0, +\infty), \mathbb{K}^{l_1 \times q})$  by the norm

$$(29) \quad \|(\Delta, \delta(\cdot))\| := \|\Delta\| + \int_0^{+\infty} \|\delta(t)\| dt.$$

The main problem here is to find the maximal  $r > 0$  for which the perturbed equations (27) remain UAS whenever  $\|(\Delta, \delta(\cdot))\| < r$ .

Let  $\sigma(A + D_0 \Delta E, B(\cdot) + D_1 \delta(\cdot) E)$  be the set of all roots of the characteristic equation of a perturbed equation (27). Recall that, by Theorem 4.5, the perturbed equation (27) is UAS if and only if  $\sigma(A + D_0 \Delta E, B(\cdot) + D_1 \delta(\cdot) E) \subset \mathbb{C}^-$ . Denote

$$\mathcal{D}_{\mathbb{C}} := \{(\Delta, \delta(\cdot)) : \Delta \in \mathbb{C}^{l_0 \times q}, \delta(\cdot) \in L^1([0, +\infty), \mathbb{C}^{l_1 \times q}) \cap C([0, +\infty), \mathbb{C}^{l_1 \times q})\},$$

$$\mathcal{D}_{\mathbb{R}} := \{(\Delta, \delta(\cdot)) : \Delta \in \mathbb{R}^{l_0 \times q}, \delta(\cdot) \in L^1([0, +\infty), \mathbb{R}^{l_1 \times q}) \cap C([0, +\infty), \mathbb{R}^{l_1 \times q})\},$$

$$\mathcal{D}_+ := \{(\Delta, \delta(\cdot)) : \Delta \in \mathbb{R}_+^{l_0 \times q}, \delta(\cdot) \in L^1([0, +\infty), \mathbb{R}_+^{l_1 \times q}) \cap C([0, +\infty), \mathbb{R}_+^{l_1 \times q})\}.$$

Then  $\mathcal{D}_{\mathbb{C}}, \mathcal{D}_{\mathbb{R}}, \mathcal{D}_+$  are called, respectively, the *class of complex, real, and nonnegative perturbations*. In what follows, we always define  $\inf \emptyset = +\infty, 0^{-1} = +\infty$ . To study robustness of stability of the linear Volterra equation (8), we introduce the following.

**DEFINITION 5.1.** *Let (8) be UAS. Then the complex, real, and positive stability radii of the equation under structured perturbations (28) are defined, respectively, by*

$$r_{\mathbb{C}} = \inf\{\|(\Delta, \delta(\cdot))\| : (\Delta, \delta(\cdot)) \in \mathcal{D}_{\mathbb{C}}, \sigma(A + D_0 \Delta E, B(\cdot) + D_1 \delta(\cdot) E) \not\subset \mathbb{C}^-\},$$

$$r_{\mathbb{R}} = \inf\{\|(\Delta, \delta(\cdot))\| : (\Delta, \delta(\cdot)) \in \mathcal{D}_{\mathbb{R}}, \sigma(A + D_0 \Delta E, B(\cdot) + D_1 \delta(\cdot) E) \not\subset \mathbb{C}^-\},$$

$$r_+ = \inf\{\|(\Delta, \delta(\cdot))\| : (\Delta, \delta(\cdot)) \in \mathcal{D}_+, \sigma(A + D_0 \Delta E, B(\cdot) + D_1 \delta(\cdot) E) \not\subset \mathbb{C}^-\}.$$

From the above definition, it is easy to see that

$$(30) \quad 0 < r_{\mathbb{C}} \leq r_{\mathbb{R}} \leq r_+ \leq +\infty.$$

To get characterizations of the stability radii for the class of positive equations, we need the following technical lemmas.

**LEMMA 5.2.** *Suppose that (8) is positive and UAS and  $D \in \mathbb{R}_+^{n \times l}, E \in \mathbb{R}_+^{q \times n}$ . Then*

$$(31) \quad \left| \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t) dt \right)^{-1} x \right| \leq \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} |x|, \quad x \in \mathbb{C}^n,$$

for every  $s \in \mathbb{C}, \Re s \geq 0$ . Moreover, we have

$$(32) \quad \max_{s \in \mathbb{C}, \Re s \geq 0} \left\| E \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t) dt \right)^{-1} D \right\| = \left\| E \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} D \right\|.$$

*Proof.* (i) Since (8) is positive, it follows that  $A$  is a Metzler matrix and  $B(t) \geq 0 \forall t \geq 0$ . For every  $s \in \mathbb{C}, \Re s \geq 0$ , by Theorem 2.1(iv), we get

$$\mu \left( A + \int_0^{+\infty} e^{-st} B(t) dt \right) \leq \mu \left( A + \int_0^{+\infty} e^{-\Re s t} B(t) dt \right) \leq \mu \left( A + \int_0^{+\infty} B(t) dt \right).$$

On the other hand, by Theorem 4.6, we have  $\mu(A + \int_0^{+\infty} B(t) dt) < 0$ . Therefore,  $\mu(A + \int_0^{+\infty} e^{-st} B(t) dt) < 0$  for every  $s \in \mathbb{C}, \Re s \geq 0$ . For a fixed  $s \in \mathbb{C}, \Re s \geq 0$ , we can represent

$$(33) \quad \left( sI_n - \left( A + \int_0^{+\infty} e^{-st} B(t) dt \right) \right)^{-1} x = \int_0^{+\infty} e^{-s\theta} e^{\theta(A + \int_0^{+\infty} e^{-st} B(t) dt)} x d\theta, \quad x \in \mathbb{C}^n,$$

for every  $s \in \mathbb{C}, \Re s \geq 0$ ; see [28, p. 8] or [39]. Since  $A$  is a Metzler matrix, there exists a real number  $\alpha_0 > 0$  such that  $(A + \alpha_0 I_n) \geq 0$ . From  $(A + \alpha_0 I_n)$  and  $B(t) \geq 0 \forall t \geq 0$ , it follows that

$$e^{\alpha_0 \theta} |e^{\theta(A + \int_0^{+\infty} e^{-st} B(t) dt)}| = |e^{\alpha_0 \theta} e^{\theta(A + \int_0^{+\infty} e^{-st} B(t) dt)}| = |e^{\alpha_0 \theta I_n} e^{\theta(A + \int_0^{+\infty} e^{-st} B(t) dt)}| \\ = |e^{\theta((A + \alpha_0 I_n) + \int_0^{+\infty} e^{-st} B(t) dt)}| \leq e^{\theta((\alpha_0 I_n + A) + \int_0^{+\infty} B(t) dt)} = e^{\alpha_0 \theta} e^{\theta(A + \int_0^{+\infty} B(t) dt)}, \quad \theta \geq 0.$$

This implies that

$$(34) \quad |e^{\theta(A + \int_0^{+\infty} e^{-st} B(t) dt)}| \leq e^{\theta(A + \int_0^{+\infty} B(t) dt)}, \quad \theta \geq 0, \quad s \in \mathbb{C}, \Re s \geq 0.$$

Taking (33), (34) into account, we get

$$\left| \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t) dt \right)^{-1} x \right| \leq \int_0^{+\infty} e^{\theta(A + \int_0^{+\infty} B(t) dt)} d\theta |x| \\ = \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} |x|$$

for every  $s \in \mathbb{C}, \Re s \geq 0$ . Furthermore, since  $D, E$  are the nonnegative matrices, it follows that

$$\left| E \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t) dt \right)^{-1} D x \right| \leq E \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} D |x|, \quad x \in \mathbb{C}^n,$$

for every  $s \in \mathbb{C}, \Re s \geq 0$ . By the monotonicity property of the vector norm and the definition of the operator norm, we get

$$\left\| E \left( sI_n - A - \int_0^{+\infty} e^{-st} B(t) dt \right)^{-1} D \right\| \leq \left\| E \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} D \right\|$$

for every  $s \in \mathbb{C}, \Re s \geq 0$ . This completes our proof.  $\square$

LEMMA 5.3. Suppose that (8) is positive and UAS and  $D_i \in \mathbb{R}_+^{n \times l_i}$ ,  $i \in I$ ,  $E \in \mathbb{R}_+^{q \times n}$ . If  $\max_{i \in I} \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_i\| \neq 0$ , then there exists a nonnegative perturbation  $(\Delta_0, \delta_1(\cdot)) \in \mathcal{D}_+$  such that

$$(35) \quad \|(\Delta_0, \delta_1(\cdot))\| = \frac{1}{\max_{i \in I} \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_i\|}$$

and

$$(36) \quad 0 \in \sigma(A + D_0 \Delta_0 E, B(\cdot) + D_1 \delta_1(\cdot) E).$$

*Proof.* Since (8) is UAS, it follows from Theorem 4.6 that  $\mu(A + \int_0^{+\infty} B(t)dt) < 0$ . By Theorem 2.1(iii), we get  $E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_i \in \mathbb{R}_+^{q \times l_i}$ ,  $i \in I$ . Assume that

$$\max_{i \in I} \left\{ \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_i \right\| \right\} = \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_{i_0} \right\|, \quad i_0 \in I.$$

Then  $\|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0}\| = \max_{u \in \mathbb{R}_+^{l_{i_0}}, \|u\|=1} \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u\|$ ; see, e.g., [16]. Therefore, we can choose  $u_0 \in \mathbb{R}_+^{l_{i_0}}$  such that  $\|u_0\| = 1$  and  $\|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u_0\| = \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0}\|$ . By a theorem of Krein and Rutman [22], from  $E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u_0 \geq 0$ , there exists a positive linear form  $y^* \in (\mathbb{C}^q)^*$  of dual norm  $\|y^*\| = 1$  such that  $y^* E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u_0 = \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u_0\|$ . Define  $\Delta := \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0}\|^{-1} u_0 y^* \in \mathbb{R}_+^{l_{i_0} \times q}$ . It is easy to see that  $\|\Delta\| = \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0}\|^{-1}$ . Set  $x_0 := (-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} u_0$ . This implies that  $\Delta E x_0 = u_0$ . Therefore,  $x_0 \neq 0$  and  $x_0 = (-A - \int_0^{+\infty} B(t)dt)^{-1} D_{i_0} \Delta E x_0$ . It follows that

$$\begin{aligned} \left( (A + D_{i_0} \Delta E) + \int_0^{+\infty} B(t)dt \right) x_0 &= \left( A + \int_0^{+\infty} (B(t) + D_{i_0} \delta(t) E) dt \right) x_0 = 0, \\ x_0 &\in \mathbb{R}^n, x_0 \neq 0, \end{aligned}$$

where  $\delta(t) := e^{-t} \Delta \in L^1([0, +\infty), \mathbb{R}_+^{l_{i_0} \times q}) \cap C([0, +\infty), \mathbb{R}_+^{l_{i_0} \times q})$ . We consider two separate cases as follows:

- If  $i_0 = 0$ , then we set  $\Delta_0 = \Delta$  and  $\delta_1(\cdot) = 0$ . Then it is easy to see that  $(\Delta_0, \delta_1(\cdot)) \in \mathcal{D}_+$  satisfies (35)–(36).
- If  $i_0 = 1$ , then we set  $\Delta_0 = 0$  and  $\delta_1(\cdot) = \delta(\cdot)$ . Then  $(\Delta_0, \delta_1(\cdot)) \in \mathcal{D}_+$  satisfies (35)–(36).

This completes our proof.  $\square$

The following theorem shows that for the class of positive equations, the complex, real, and positive stability radii coincide and can be computed by an explicit formula.

THEOREM 5.4. Suppose that (8) is positive and UAS and  $D_i \in \mathbb{R}_+^{n \times l_i}$  ( $i \in I$ ),  $E \in \mathbb{R}_+^{q \times n}$ . Then

$$r_{\mathbb{C}} = r_{\mathbb{R}} = r_+ = \frac{1}{\max_{i \in I} \|E(-A - \int_0^{+\infty} B(t)dt)^{-1} D_i\|}.$$

*Proof.* Suppose that  $r_{\mathbb{C}} < +\infty$ , as otherwise there is nothing to show. Let  $(\Delta, \delta(\cdot)) \in \mathcal{D}_{\mathbb{C}}$  be a destabilizing complex disturbance. That is,  $\sigma(A + D_0 \Delta E, B(\cdot) +$

$D_1\delta(\cdot)E) \not\subset \mathbb{C}^-$ . Then there exist  $s \in \mathbb{C}$ ,  $\Re s \geq 0$ , and a nonzero vector  $x \in \mathbb{C}^n$  such that

$$\left( A + D_0\Delta E + \int_0^{+\infty} e^{-st}(B(t) + D_1\delta(t)E)dt \right) x = sx.$$

Since (8) is UAS, it follows that

$$\left( sI_n - A - \int_0^{+\infty} e^{-st}B(t)dt \right)^{-1} \left( D_0\Delta E + D_1 \int_0^{+\infty} e^{-st}\delta(t)dt E \right) x = x.$$

Therefore,  $Ex \neq 0$  and we thus get

$$E \left( sI_n - A - \int_0^{+\infty} e^{-st}B(t)dt \right)^{-1} \left( D_0\Delta E + D_1 \int_0^{+\infty} e^{-st}\delta(t)dt E \right) x = Ex.$$

This implies that

$$\begin{aligned} & \left\| E \left( sI_n - A - \int_0^{+\infty} e^{-st}B(t)dt \right)^{-1} D_0 \right\| \|\Delta\| \|Ex\| \\ & + \left\| E \left( sI_n - A - \int_0^{+\infty} e^{-st}B(t)dt \right)^{-1} D_1 \right\| \left\| \int_0^{+\infty} e^{-st}\delta(t)dt \right\| \|Ex\| \geq \|Ex\|. \end{aligned}$$

Hence,

$$\max_{i \in I} \left\{ \left\| E \left( sI_n - A - \int_0^{+\infty} e^{-st}B(t)dt \right)^{-1} D_i \right\| \right\} \left( \|\Delta\| + \int_0^{+\infty} \|\delta(t)\|dt \right) \geq 1.$$

Using Lemma 3.6, we get

$$\max_{i \in I} \left\{ \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_i \right\| \right\} \|(\Delta, \delta(\cdot))\| \geq 1.$$

This is equivalent to

$$\|(\Delta, \delta(\cdot))\| \geq \frac{1}{\max_{i \in I} \left\{ \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_i \right\| \right\}}.$$

Since this inequality holds true for an arbitrary destabilizing complex perturbation, we conclude that

$$r_{\mathbb{C}} \geq \frac{1}{\max_{i \in I} \left\{ \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_i \right\| \right\}}.$$

Taking into account the inequalities (30), it remains only to show that

$$r_+ \leq \frac{1}{\max_{i \in I} \left\{ \left\| E \left( -A - \int_0^{+\infty} B(t)dt \right)^{-1} D_i \right\| \right\}}.$$

However, this is immediate from Lemma 5.3. This completes our proof.  $\square$

*Example 5.5.* We revisit the linear positive Volterra integrodifferential equation in  $\mathbb{R}^2$  defined by (25)–(26) in Example 4.9. Assume that the matrix  $A$  and the matrix function  $B(\cdot)$  are subjected to the structured perturbations of the form (28), where

$$D_1 = \begin{pmatrix} 2 \\ 0 \end{pmatrix}, \quad D_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad \text{and} \quad E = I_2.$$

By an easy computation, we get

$$\begin{aligned} E \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} D_1 &= \begin{pmatrix} \frac{-2b}{b^2-1} \\ \frac{2}{b^2-1} \end{pmatrix}, \\ E \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} D_2 &= \begin{pmatrix} \frac{1}{b^2-1} \\ \frac{-b}{b^2-1} \end{pmatrix}, \end{aligned}$$

where  $b := a + 1/p < -1$ . Therefore, if  $\mathbb{R}^2$  is endowed, respectively, with the 1-norm, 2-norm, and  $\infty$ -norm, then by Theorem 5.4, we have

$$r_{\mathbb{C}} = r_{\mathbb{R}} = r_+ = \frac{-1-b}{2}, \quad \frac{(b^2-1)\sqrt{(b^2+1)}}{2(b^2+1)}, \quad \frac{b^2-1}{-2b},$$

respectively.

**5.2. Stability radius of positive linear Volterra integrodifferential equations under affine perturbations.** We now deal with the problem of computing the stability radius of positive linear Volterra equation (8) under affine perturbations. To do this, we assume that (8) is UAS and the system matrices  $A, B(\cdot)$  are subjected to *affine perturbation* of the form

$$(37) \quad A \rightsquigarrow A + \sum_{i=1}^N \alpha_i A_i, \quad B(\cdot) \rightsquigarrow B(\cdot) + \sum_{i=1}^N \beta_i B_i(\cdot),$$

where  $A_i \in \mathbb{R}^{n \times n}$ ,  $B_i(\cdot) \in L^1([0, +\infty), \mathbb{R}^{n \times n}) \cap C([0, +\infty), \mathbb{R}^{n \times n})$ ,  $i \in \underline{N} := \{1, 2, \dots, N\}$  are given and  $\alpha_i, \beta_i \in \mathbb{K}$  ( $\mathbb{K} = \mathbb{R}, \mathbb{C}$ ),  $i \in \underline{N}$ , are unknown scalars.

We assume that  $A$  is a Metzler matrix and  $B(t) \geq 0 \ \forall t \geq 0$ , under which the linear Volterra equation (8) is positive. In view of positivity of the equation under consideration, we assume that  $A_i \in \mathbb{R}_+^{n \times n}$  and  $B_i(t) \geq 0 \ \forall t \geq 0, \forall i \in \underline{N}$ . We define the complex and the real stability radii of the linear Volterra equation (8) under affine parameter perturbations (37) by setting, for  $\mathbb{K} = \mathbb{C}$  and, respectively,  $\mathbb{K} = \mathbb{R}$ ,

$$\begin{aligned} r_{\mathbb{K}}^a &= \inf \left\{ \max \left( \max_{i \in \underline{N}} |\alpha_i|; \max_{i \in \underline{N}} |\beta_i| \right) : \right. \\ &\quad \left. \alpha_i, \beta_i \in \mathbb{K}, \sigma \left( A + \sum_{i=1}^N \alpha_i A_i, B(\cdot) + \sum_{i=1}^N \beta_i B_i(\cdot) \right) \not\subset \mathbb{C}^- \right\}. \end{aligned}$$

Similarly, the positive stability radius  $r_+^a$  is obtained by restricting, in the above definition, the disturbances  $(\alpha, \beta) := ((\alpha_i)_{i \in \underline{N}}, (\beta_j)_{j \in \underline{N}})$  to be nonnegative.

It is clear that

$$(38) \quad 0 < r_{\mathbb{C}}^a \leq r_{\mathbb{R}}^a \leq r_+^a.$$

The following theorem proves that the equalities in (38) hold true and provides computable formulae for the stability radii  $r_{\mathbb{K}}^a, r_+^a$  ( $\mathbb{K} = \mathbb{C}, \mathbb{R}$ ).

**THEOREM 5.6.** *Suppose that the linear Volterra equation (8) is UAS and  $A, B(\cdot)$  are subjected to multi-affine perturbations of the form (37). If the stability radii of the equation are given by (38), then*

$$(39) \quad r_{\mathbb{C}}^a = r_{\mathbb{R}}^a = r_+^a = \frac{1}{\mu[(-A - \int_0^{+\infty} B(t)dt)^{-1}(\sum_{i=1}^N A_i + \sum_{i=1}^N \int_0^{+\infty} B_i(t)dt)]}.$$

*Proof.* We first prove that

$$r_+^a = \frac{1}{\mu[(-A - \int_0^{+\infty} B(t)dt)^{-1}(\sum_{i=1}^N A_i + \sum_{i=1}^N \int_0^{+\infty} B_i(t)dt)]}.$$

Let  $(\alpha, \beta) = ((\alpha_i)_{i \in \underline{N}}, (\beta_i)_{i \in \underline{N}})$  be an arbitrary nonnegative destabilizing perturbation, that is,

$$\sigma\left(A + \sum_{i=1}^N \alpha_i A_i, B(\cdot) + \sum_{i=1}^N \beta_i B_i(\cdot)\right) \not\subset \mathbb{C}^-.$$

Then there exist a complex number  $s, \Re s \geq 0$  and a nonzero vector  $x \in \mathbb{C}^n$  such that

$$\left(\left(A + \sum_{i=1}^N \alpha_i A_i\right) + \int_0^{+\infty} e^{-st} \left(B(t) + \sum_{i=1}^N \beta_i B_i(t)\right) dt\right) x = sx.$$

Since (8) is UAS, this implies that

$$\left(sI_n - A - \int_0^{+\infty} e^{-st} B(t)dt\right)^{-1} \left(\sum_{i=1}^N \alpha_i A_i + \sum_{i=1}^N \beta_i \int_0^{+\infty} e^{-st} B_i(t)dt\right) x = x.$$

Using (31), we obtain the estimates

$$\begin{aligned} |x| &= \left| \left(sI_n - A - \int_0^{+\infty} e^{-st} B(t)dt\right)^{-1} \left(\sum_{i=1}^N \alpha_i A_i + \sum_{i=1}^N \beta_i \int_0^{+\infty} e^{-st} B_i(t)dt\right) x \right| \\ &\leq \left(-A - \int_0^{+\infty} B(t)dt\right)^{-1} \left| \left(\sum_{i=1}^N \alpha_i A_i + \sum_{i=1}^N \beta_i \int_0^{+\infty} e^{-st} B_i(t)dt\right) x \right| \\ &\leq \left(-A - \int_0^{+\infty} B(t)dt\right)^{-1} \left(\sum_{i=1}^N \alpha_i A_i + \sum_{i=1}^N \beta_i \int_0^{+\infty} B_i(t)dt\right) |x| \\ &\leq \gamma \left[ \left(-A - \int_0^{+\infty} B(t)dt\right)^{-1} \left(\sum_{i=1}^N A_i + \sum_{i=1}^N \int_0^{+\infty} B_i(t)dt\right) \right] |x|, \end{aligned}$$

where  $\gamma := \max\{\max_{i \in \underline{N}} \alpha_i, \max_{i \in \underline{N}} \beta_i\}$ . Since  $B := [(-A - \int_0^{+\infty} B(t)dt)^{-1}(\sum_{i=1}^N A_i + \sum_{i=1}^N \int_0^{+\infty} B_i(t)dt)]$  is a nonnegative matrix, it follows from Theorem 2.1(ii) that

$$\mu(B) \geq \frac{1}{\gamma} > 0.$$

Hence,

$$\gamma \geq \frac{1}{\mu(B)}.$$

Since this holds for arbitrary destabilizing nonnegative perturbation  $(\alpha, \beta)$ , we conclude that

$$r_+^a \geq \frac{1}{\mu(B)}.$$

We shall prove that the converse inequality holds true. In fact, by Theorem 2.1(i) (Perron–Frobenius), there exists a nonzero vector  $y \in \mathbb{R}_+^n$  such that  $By = \mu(B)y$ . This implies that

$$\left( \left( A_0 + \sum_{i=1}^N \frac{1}{\mu(B)} A_i \right) + \int_0^{+\infty} \left( B(t) + \sum_{i=1}^N \frac{1}{\mu(B)} B_i(t) \right) dt \right) y = 0.$$

This means that the nonnegative perturbation  $(\alpha^*, \beta^*)$  defined by  $\alpha_i^* = 1/\mu(B)$ ,  $\beta_i^* = 1/\mu(B)$ ,  $i \in \underline{N}$ , is destabilizing. By the definition of  $r_+^a$ , we have

$$r_+^a \leq \frac{1}{\mu(B)}.$$

Thus, we obtain

$$r_+^a = \frac{1}{\mu(B)} = \frac{1}{\mu \left[ \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} \left( \sum_{i=1}^N A_i + \sum_{i=1}^N \int_0^{+\infty} B_i(t) dt \right) \right]}.$$

We are now ready to show that  $r_{\mathbb{C}}^a = r_{\mathbb{R}}^a = r_+^a$ . Suppose  $(\alpha, \beta) = ((\alpha_i)_{i \in \underline{N}}, (\beta_j)_{j \in \underline{N}})$  is an arbitrary complex destabilizing perturbation. By an argument similar to the above, we get

$$(40) \quad \left[ \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} \left( \sum_{i=1}^N |\alpha_i| A_i + \sum_{i=1}^N |\beta_i| \int_0^{+\infty} B_i(t) dt \right) \right] |x_0| \geq |x_0|$$

for some  $x_0 \in \mathbb{C}^n$ ,  $x_0 \neq 0$ . By Theorem 2.1(ii),

$$\mu \left[ \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} \left( \sum_{i=1}^N |\alpha_i| A_i + \sum_{i=1}^N |\beta_i| \int_0^{+\infty} B_i(t) dt \right) \right] \geq 1.$$

Since  $C := \left( -A - \int_0^{+\infty} B(t) dt \right)^{-1} \left( \sum_{i=1}^N |\alpha_i| A_i + \sum_{i=1}^N |\beta_i| \int_0^{+\infty} B_i(t) dt \right)$  is nonnegative, using Theorem 2.1(i) again, we have  $Cx_1 = \mu(C)x_1$  for some nonzero vector  $x_1 \in \mathbb{R}_+^n$ . This gives

$$\left( \left( A_0 + \sum_{i=1}^N \frac{|\alpha_i|}{\mu(C)} A_i \right) + \int_0^{+\infty} \left( B(t) + \sum_{i=1}^N \frac{|\beta_i|}{\mu(C)} B_i(t) \right) dt \right) x_1 = 0,$$

which means that

$$(|\alpha|, |\beta|) := \left( \left( \frac{|\alpha_i|}{\mu(C)} \right)_{i \in \underline{N}}, \left( \frac{|\beta_i|}{\mu(C)} \right)_{i \in \underline{N}} \right)$$

is a nonnegative destabilizing perturbation. Hence, it follows from the definition of  $r_+^a$  that

$$\max \left( \max_{i \in \underline{N}} \left( \frac{|\alpha_i|}{\mu(C)} \right), \max_{i \in \underline{N}} \left( \frac{|\beta_i|}{\mu(C)} \right) \right) \geq r_+^a,$$

or, equivalently,  $\max(\max_{i \in \underline{N}} |\alpha_i|, \max_{i \in \underline{N}} |\beta_i|) \geq \mu(C)r_+^a \geq r_+^a$ , which implies that  $r_{\mathbb{C}}^a \geq r_+^a$ . Combined with the inequalities  $r_{\mathbb{C}}^a \leq r_{\mathbb{R}}^a \leq r_+^a$ , this implies that  $r_{\mathbb{C}}^a = r_{\mathbb{R}}^a = r_+^a$ . In addition, from the above arguments, we observe that  $r_{\mathbb{C}}^a = r_{\mathbb{R}}^a = r_+^a = +\infty$  if and only if  $\mu(B) = 0$ . This completes our proof.  $\square$

**6. Concluding remarks.** A new class of positive linear systems (namely, positive linear Volterra integrodifferential equations) is introduced and an explicit criterion for equations of this class is presented. A new Perron–Frobenius theorem for positive linear Volterra integrodifferential equations is given. Furthermore, explicit criteria for uniformly asymptotic stability of positive equations are provided. Finally, two explicit formulae for the stability radii of positive equations under structured perturbations and affine perturbations are given.

The proposed approach can be extended to study positive linear Volterra integrodifferential equations with delay and positive linear Volterra–Stieltjes differential equations. These works will be done in the future.

## PERTURBATION METHODS IN STABILITY AND NORM ANALYSIS OF SPATIALLY PERIODIC SYSTEMS\*

MAKAN FARDAD<sup>†</sup> AND BASSAM BAMIEH<sup>‡</sup>

**Abstract.** We consider systems governed by partial differential equations with spatially periodic coefficients over unbounded domains. These spatially periodic systems are considered as perturbations of spatially invariant ones, and we develop perturbation methods to study their stability and  $\mathcal{H}^2$  system norm. The operator Lyapunov equations characterizing the  $\mathcal{H}^2$  norm are studied by using a special frequency representation, and formulas are given for the perturbation expansion of their solution. The structure of these equations allows for a recursive method of solving for the expansion terms. Our analysis provides conditions that capture possible resonances between the periodic coefficients and the spatially invariant part of the system. These conditions can be regarded as useful guidelines when spatially periodic coefficients are to be designed to increase or decrease the  $\mathcal{H}^2$  norm of a spatially distributed system. The developed perturbation framework also gives simple conditions for checking whether a spatially periodic operator generates a holomorphic  $C_0$  semigroup and thus satisfies the spectrum-determined growth condition.

**Key words.** PDE with periodic coefficients, perturbation analysis,  $\mathcal{H}^2$  norm, sectorial operator, spectrum-determined growth condition

**1. Introduction.** The terms distributed-parameter and infinite-dimensional are used to describe those systems in which the state belongs to an infinite-dimensional vector space [1]. Such systems include, but are not limited to, time-delay (retarded) and spatially distributed systems [2]. The latter includes systems in which the dynamics are governed by partial differential equations (PDEs) and it is a subclass of these systems that will be the subject of this study. More specifically, we will analyze certain properties of spatially distributed systems in which the underlying PDEs have spatially periodic coefficients. We refer to such systems as *spatially periodic*. Spatially periodic systems have many real life applications, for example, in boundary layer and channel flow problems with corrugated walls and in nonlinear optics.

Our motivation for this work is to study the effect of spatially periodic coefficients on stability and system norms of spatially distributed systems. This can be thought of as using the periodic coefficients as static feedback controls for spatially distributed systems. For example, in flow control problems where corrugated wall geometries or spatially periodic body forces are introduced, the PDEs that describe the resulting flow dynamics have periodic coefficients that are related to either the wall shape or the spatially distributed body force. An important objective is to “design” such wall shapes or body forces to obtain certain stability or instability properties of the resulting dynamics. There are currently no systematic methods for achieving this.

An analogy can be made between the present work and the use of time-periodic coefficients in ordinary differential equations (ODEs). It is known that the introduction

of time-periodic coefficients in ODEs with constant coefficients can change the stability properties of the linear time invariant (LTI) system described by the original ODE. A useful picture is to think of an ODE with periodic coefficients as an LTI system modified by time-periodic (memoryless) feedback. It is known that certain unstable LTI systems can be stabilized by being put in feedback with periodic gains of properly designed amplitudes and frequencies [3]. This can be roughly considered as an example of “vibrational control” [4]. On the other hand, certain stable or neutrally stable LTI systems can be destabilized by periodic feedback gains. This is sometimes referred to as “parametric resonance” in the dynamical systems literature [3]. In the above scenarios, the stabilization/destabilization process depends in subtle ways on “resonances” between the natural modes of the LTI subsystem and the frequency and amplitude of the periodic feedback. Although Floquet analysis can be used to ascertain stability of the resulting periodic systems, it is cumbersome to use for *designing* the periodic coefficients. This requires an exhaustive search over frequencies and amplitudes of the periodic coefficients. Alternatively, simple resonance conditions can be derived by using a perturbation analysis [3], which in turn can be used for a preliminary selection of the coefficient’s frequency. In this way, perturbation analysis serves as a useful design tool.

In related recent work [5] we developed computational tools to study stability and system norms for spatially periodic systems. However, for problems where the spatially periodic coefficients are to be designed, using these tools involves a computationally expensive search over spatial frequencies and amplitudes of the coefficients. Therefore, our aim in the present work is to develop a *perturbation analysis* that can be used to derive resonance conditions and provide a useful design tool in a similar manner to the case of ODEs discussed earlier. These resonance conditions can then identify candidate spatial frequencies to be used for the periodic coefficients. The exact behavior with respect to amplitudes can then be ascertained by using the full analysis of [5]. In this manner we reduce the dimension of the search space required for design problems.

Another challenging problem is checking the stability of a spatially periodic or, in general, any infinite-dimensional system. It is well known that, for a finite-dimensional LTI system, the spectrum of the infinitesimal generator (i.e., the  $A$ -matrix) being contained in the open left half of the complex plane is equivalent to exponential stability. In this sense the spectrum of the infinitesimal generator determines stability. Therefore it is said that the system satisfies the *spectrum-determined growth condition* (SDGC). But the SDGC may not hold for some infinite-dimensional LTI systems; indeed the evolution can grow exponentially even though the infinitesimal generator (i.e., the  $A$ -operator) has its spectrum inside the left half of the complex plane [6, 7, 8]. In the present work we use perturbation analysis to find simple conditions under which the spatially periodic system satisfies the SDGC and is exponentially stable.

Our presentation is organized as follows. Section 2 outlines the main results of the paper. Section 3 briefly reviews the frequency representation of spatially periodic operators. Section 4 introduces the problem setup. Section 5 discusses the analytic perturbation of the  $\mathcal{H}^2$  norm, and section 6 provides related illustrative examples. Section 7 studies conditions under which a spatially periodic system is exponentially stable. Many proofs and technical details have been relegated to the appendix to improve readability.

**Notation.** We use  $k \in \mathbb{R}$  to characterize the spatial-frequency variable, also known as the *wave number*.  $\Sigma(T)$  is the spectrum of the operator  $T$ ,  $\Sigma_p(T)$  its point spectrum, and  $\rho(T)$  its resolvent set.  $\mathbb{C}^-$  denotes all complex numbers with real part

less than zero, and  $j := \sqrt{-1}$ . “\*” denotes the complex-conjugate transpose and also the adjoint of a linear operator.  $\overline{\mathfrak{S}}$  is the closure of the set  $\mathfrak{S} \subset \mathbb{C}$ . The function  $\hat{u}(t, k)$  denotes the Fourier transform (in the spatial variable  $x$ ) of the spatiotemporal function  $u(t, x)$ . Similarly, the operator  $\hat{A}$  is the Fourier domain representation of the spatial operator  $A$ . We will use the same symbol for a linear operator and its kernel representation. Where there is no chance of confusion, we use the same notation for a spatially invariant operator and its Fourier symbol.

**Terminology.** Throughout the paper, we use the terms *spatial “operators”* and *spatial “systems.”* By the former we mean a *purely spatial* operator with no temporal dynamics (i.e., a memoryless operator that acts on a spatial function and yields a spatial function), whereas by the latter we refer to a *spatiotemporal* system (a system with an internal state which evolves on some spatial domain; i.e., for every time  $t$  the state is a function on a spatial domain). By a *scalar system*, we mean that the Euclidean dimension of the state is equal to one. When spatially periodic feedback operators are small in norm, we will use the phrases *periodic feedback* and *periodic perturbation* interchangeably. Finally, in the case of doubly infinite matrices we will use the phrases biinfinite matrix and (biinfinite or lifted) operator interchangeably.

**2. Main results.** We consider systems described by linear, time-invariant, integro partial differential equations defined on an unbounded one-dimensional domain. We use a standard state-space representation of the form

$$\begin{aligned} [\partial_t \psi](t, x) &= [A \psi](t, x) + [B u](t, x), \\ (1) \quad y(t, x) &= [C \psi](t, x), \end{aligned}$$

where  $t \in [0, \infty)$  and  $x \in \mathbb{R}$ ,  $\psi$ ,  $u$ ,  $y$  are spatiotemporal functions, and  $A$ ,  $B$ ,  $C$  are spatial integrodifferential operators with coefficients that are periodic functions with a common period  $X$ . We refer to (1) as a *spatially periodic system*.

It is often physically meaningful to regard the spatially periodic operators as additive or multiplicative perturbations of spatially invariant ones (and by spatially invariant we mean integrodifferential operators with constant coefficients). For example, the infinitesimal generator  $A$  in (1) can often be decomposed as  $A = A^\circ + \epsilon E$ , where  $A^\circ$  is a spatially invariant operator and  $E$  is an operator that includes multiplication by periodic functions. In some control application the operator  $E$  is something to be “designed.” Therefore it is desirable to have easily verifiable conditions for stability and norms of such systems. This would then allow for the selection of the spatial period and amplitude of periodic functions in  $E$  to achieve the desired behavior. The perturbation analysis we present, though limited to small values of  $\epsilon$ , provides useful guidelines for selecting candidate “periods” for  $E$ .

Our results are derived by using a special frequency representation. We show that the spatial periodicity of the operators  $A$ ,  $B$ , and  $C$  implies that (1) can be rewritten as

$$\begin{aligned} [\partial_t \psi_\theta](t) &= [\mathcal{A}_\theta \psi_\theta](t) + [\mathcal{B}_\theta u_\theta](t), \\ (2) \quad y_\theta(t) &= [\mathcal{C}_\theta \psi_\theta](t), \end{aligned}$$

where  $\theta \in [0, 2\pi/X)$ . For every value of  $\theta$ ,  $\psi_\theta$ ,  $u_\theta$ ,  $y_\theta$  are *biinfinite vectors*, and  $\mathcal{A}_\theta$ ,  $\mathcal{B}_\theta$ ,  $\mathcal{C}_\theta$  are *biinfinite matrices*. The systems (2) and (1) are related through a unitary transformation, and in particular quadratic forms are preserved by this transformation. Consequently, the stability and quadratic norm properties of (2) and (1) are equivalent. With this transformation the analysis of the original system (1) is reduced to that

of the family of systems (2) that are *decoupled* in the parameter  $\theta$ . In particular, perturbation analysis for (2) is easier and less technical than for the original system (1).

To make for easier reading, both in this section and in the body of the paper, we first present the results on perturbation analysis of the  $\mathcal{H}^2$  norm and then deal with the issue of stability.

The first set of results concerns  $\mathcal{H}^2$  norm analysis. For a large class of infinite-dimensional systems, computing the  $\mathcal{H}^2$  norm involves solving an *operator* algebraic Lyapunov equation

$$AP + PA^* = -BB^*.$$

In general this is a difficult task that must be done by using appropriate discretization techniques. However, if  $A$  and  $B$  are spatially periodic operators, then so is the solution  $P$ . Then the special frequency representation described above allows this operator Lyapunov equation to be rewritten as a  $\theta$ -decoupled family of Lyapunov equations

$$(3) \quad \mathcal{A}_\theta \mathcal{P}_\theta + \mathcal{P}_\theta \mathcal{A}_\theta^* = -\mathcal{B}_\theta \mathcal{B}_\theta^*,$$

where  $\mathcal{A}_\theta$ ,  $\mathcal{B}_\theta$ , and  $\mathcal{P}_\theta$  are the *biinfinite matrix* representations of  $A$ ,  $B$ , and  $P$ . Once  $\mathcal{P}_\theta$  is found, the  $\mathcal{H}^2$  norm of the system can be computed from [5]

$$\frac{1}{2\pi} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta \mathcal{C}_\theta^*] d\theta, \quad \Omega = 2\pi/X.$$

Solving (3) is still a difficult problem in general, since it involves biinfinite matrices. We use perturbation analysis as follows: The infinitesimal generator  $\mathcal{A}_\theta$  is expressed as  $\mathcal{A}_\theta = \mathcal{A}_\theta^0 + \epsilon \mathcal{E}_\theta$ , where  $\mathcal{A}_\theta^0$  and  $\mathcal{E}_\theta$  correspond to the spatially invariant and spatially periodic components of  $\mathcal{A}_\theta$ , respectively. It follows that the solution  $\mathcal{P}_\theta$  is analytic in  $\epsilon$ , and the terms of its power series expansion  $\mathcal{P}_\theta^{(i)}$  satisfy a sequence of forward coupled Lyapunov equations. Furthermore, the terms  $\mathcal{P}_\theta^{(i)}$  are banded matrices with the number of bands increasing with the index  $i$ . These Lyapunov equations can then be solved recursively for  $i = 0, 1, 2, \dots$ . Formulas for these Lyapunov equations are derived in section 5. In some examples that we present in section 6, these formulas reveal simple “resonance” conditions for stabilization or destabilization of PDEs by using spatially periodic feedback.

The second set of results concerns the problem of stability. As mentioned in the introduction, when the infinitesimal generator  $A$  is an infinite-dimensional operator it is possible that its spectrum  $\Sigma(A)$  lies inside  $\mathbb{C}^-$  and yet  $\|e^{At}\|$  grows exponentially [6, 7, 8]. In such cases it is said that the *spectrum-determined growth condition* is not satisfied [8]. Yet there exists a wide range of infinite-dimensional systems for which the spectrum-determined growth condition *is* satisfied. These include, but are not limited to, systems for which the infinitesimal generator is *sectorial* (also known as an operator which generates a *holomorphic* or *analytic* semigroup) [9, 10, 11] or the infinitesimal generator is a *Riesz-spectral* operator [2]. In this paper we focus on sectorial operators.

Therefore, to establish exponential stability of a system, one possibility would be to show simultaneously that

- (i) the operator  $A$  is sectorial (and thus its spectrum determines stability) and
- (ii) the spectrum  $\Sigma(A)$  lies in  $\mathbb{C}^-$ .

The problem is that proving an infinite-dimensional operator is sectorial and finding its spectrum can in general be extremely difficult.

FIG. 1. Left: Pictorial representation of  $\hat{\phi}(\bar{k}) = \int_{\mathbb{R}} \hat{A}(\bar{k}, \kappa) \hat{\psi}(\kappa) d\kappa$ . Right: The frequency kernel  $\hat{A}$  of a spatially periodic operator  $A$ .

Once again we use perturbation methods to show (i) and (ii). We consider  $A$  to have the form  $A = A^\circ + \epsilon E$ , where  $A^\circ$  is a spatially invariant operator,  $E$  is a spatially periodic operator, and  $\epsilon$  is a small complex scalar. By using the biinfinite matrix representation, we first find conditions on the spatially invariant operator  $A^\circ$  such that (i) and (ii) are satisfied. We then show that (i) and (ii) will *remain* satisfied if  $\epsilon$  is small enough and if the spatially periodic operator  $E$  is “weaker” than  $A^\circ$  (in the sense that  $E$  is *relatively bounded* with respect to  $A^\circ$ ). The advantage of this approach is that (i) and (ii) are much easier to check for a spatially invariant operator than they are for a spatially periodic one.

**3. Frequency representation of periodic operators.** In this section we briefly discuss the frequency domain representation of spatially periodic operators. We then show how this representation can be used to convert a spatially periodic system into a family of matrix-valued LTI systems. For a detailed account the reader is referred to [5, 12].

Let  $\hat{\psi}(k)$  and  $\hat{\phi}(k)$  denote the Fourier transforms of two spatial functions  $\psi(x)$  and  $\phi(x)$ , respectively. If  $\psi$  and  $\phi$  are related by a linear operator  $A$  which admits a kernel representation, then  $\hat{\psi}$  and  $\hat{\phi}$  too are related by a linear operator  $\hat{A}$  which admits a kernel representation, and we have

$$(4) \quad \phi(x) = \int_{\mathbb{R}} A(x, \chi) \psi(\chi) d\chi \quad \xleftrightarrow{\mathcal{F}_x} \quad \hat{\phi}(k) = \int_{\mathbb{R}} \hat{A}(k, \kappa) \hat{\psi}(\kappa) d\kappa,$$

where  $A(\cdot, \cdot)$  and  $\hat{A}(\cdot, \cdot)$  are the *kernel functions* corresponding to the operators  $A$  and  $\hat{A}$ , respectively, and  $\mathcal{F}_x$  denotes the Fourier transform. Figure 1 (left) shows a cartoon way of picturing the equation  $\hat{\phi} = \hat{A} \hat{\psi}$ .

A linear operator is called *spatially periodic* with period  $X$  if its kernel has the property

$$A(x + Xm, \chi + Xm) = A(x, \chi) \quad \text{for all } x, \chi \in \mathbb{R}, m \in \mathbb{Z}.$$

**PROPOSITION 1.** *Let  $A$  be a spatially periodic operator with spatial period  $X = 2\pi/\Omega$ . Then its Fourier transform  $\hat{A}$  has the kernel representation*

$$(5) \quad \hat{A}(k, \kappa) = \sum_{l \in \mathbb{Z}} \hat{A}_l(k) \delta(k - \kappa - \Omega l).$$

*Proof.* See [12, Appendix to Chapter 2].  $\square$

Thus the kernel function corresponding to  $\hat{A}$  is composed of parallel and equally spaced “impulse sheets” which can be visualized in Figure 1 (right). References [5, 12] further describe how the particular structure (5) of  $\hat{A}$  allows the right-hand equation in (4) to be given a biinfinite<sup>1</sup> matrix representation

$$(6) \quad \begin{bmatrix} \vdots \\ \hat{\phi}(\theta - \Omega) \\ \hat{\phi}(\theta) \\ \hat{\phi}(\theta + \Omega) \\ \vdots \end{bmatrix} = \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \ddots \\ \cdots & \hat{A}_0(\theta - \Omega) & \hat{A}_{-1}(\theta - \Omega) & \hat{A}_{-2}(\theta - \Omega) & \cdots \\ \cdots & \hat{A}_1(\theta) & \hat{A}_0(\theta) & \hat{A}_{-1}(\theta) & \cdots \\ \cdots & \hat{A}_2(\theta + \Omega) & \hat{A}_1(\theta + \Omega) & \hat{A}_0(\theta + \Omega) & \cdots \\ \ddots & \vdots & \vdots & \vdots & \ddots \end{bmatrix} \begin{bmatrix} \vdots \\ \hat{\psi}(\theta - \Omega) \\ \hat{\psi}(\theta) \\ \hat{\psi}(\theta + \Omega) \\ \vdots \end{bmatrix}$$

for which we adopt the notation

$$\phi_\theta = \mathcal{A}_\theta \psi_\theta, \quad \theta \in [0, \Omega).$$

In other words, a general spatially periodic operator  $A$  can be described by a family of biinfinite matrices  $\mathcal{A}_\theta$  parameterized by a variable  $\theta$ .

*Remark 1.* We emphasize that the functions  $\hat{A}_l(\cdot)$ ,  $l \in \mathbb{Z}$ , in (5) and (6) can be matrix-valued. Thus, in general,  $\mathcal{A}_\theta$  has a “block” structure. But throughout this paper and for the sake of brevity we choose not to explicitly refer to this block structure, even though all of our results are derived for matrix-valued  $\hat{A}_l(k)$ . Similarly, we do not refer explicitly to the Euclidean dimension of the vectors  $\hat{\psi}(k)$  and  $\hat{\phi}(k)$  for a given  $k \in \mathbb{R}$ .

*Spatially invariant* [13] and *spatially periodic pure multiplication* operators constitute special subclasses of spatially periodic operators. In the framework established above,  $\mathcal{A}_\theta$  is *diagonal* for spatially invariant operators and *Toeplitz* for periodic pure multiplication operators.

*Example 1.* The operators  $A = \partial_x$  and  $F(x) = \cos(\Omega x)$  have the following biinfinite representations

$$\mathcal{A}_\theta = \text{diag}\{j(\theta + \Omega n)\}_{n \in \mathbb{Z}}, \quad \mathcal{F} = \text{toep}\left\{\dots, 0, \frac{1}{2}, \boxed{0}, \frac{1}{2}, 0, \dots\right\},$$

where the boxed element corresponds to the main diagonal of the biinfinite Toeplitz operator  $\mathcal{F}$ . Notice that since  $A$  is spatially invariant it is fully described by its *Fourier symbol*  $\hat{A}_0(k) = jk$ ,  $k \in \mathbb{R}$ , and it is the samples of  $\hat{A}_0(\cdot)$  at  $k = \theta + \Omega n$ ,  $n \in \mathbb{Z}$ , that make up the diagonal of  $\mathcal{A}_\theta$  for a given  $\theta$ . We have dropped the  $\theta$  subscript in  $\mathcal{F}$  because it is independent of this variable.

*Remark 2.* It is possible to define a unitary operator  $\mathcal{M}_\theta$ ,  $\theta \in [0, \Omega)$ , such that  $\psi_\theta = \mathcal{M}_\theta \hat{\psi}$ ,  $\phi_\theta = \mathcal{M}_\theta \hat{\phi}$ , and thus  $\mathcal{A}_\theta = \mathcal{M}_\theta \hat{A} \mathcal{M}_\theta^*$  [12].  $\mathcal{M}_\theta$  is equivalent to a *frequency domain lifting* operation [14, 15, 16] which breaks an  $L^2(\mathbb{R})$  function into a family of  $\ell^2$  vectors. By the unitary property of the lifting operator it follows that

$$(7) \quad \int_0^\Omega \|\mathcal{A}_\theta\|_{\text{HS}}^2 d\theta = \int_0^\Omega \text{trace}[\mathcal{A}_\theta \mathcal{A}_\theta^*] d\theta = \sum_{l \in \mathbb{Z}} \int_{\mathbb{R}} \text{trace}[\hat{A}_l(k) \hat{A}_l^*(k)] dk,$$

with  $\|T\|_{\text{HS}}^2 := \text{trace}[T T^*]$  being the square of the Hilbert–Schmidt norm<sup>2</sup> of  $T$ .

<sup>1</sup>Sometimes referred to as doubly infinite.

<sup>2</sup>The Hilbert–Schmidt norm of an operator is a generalization of the Frobenius norm of finite-dimensional matrices  $\|A\|_{\text{F}}^2 = \sum_{m,n} |a_{mn}|^2 = \text{trace}[A A^*]$ .

Finally, given a spatially periodic system in state-space form (1) with spatially periodic operators  $A$ ,  $B$ , and  $C$ , one can replace each of these operators with its biinfinite matrix representation to obtain the family of LTI systems (2).

*Example 2.* Consider the spatially periodic heat equation on the real line

$$(8) \quad \begin{aligned} \partial_t \psi(t, x) &= (\partial_x^2 - \alpha \cos(\Omega x)) \psi(t, x) + u(t, x), \\ y(t, x) &= \psi(t, x), \end{aligned}$$

with real  $\alpha \neq 0$  and  $\Omega > 0$ .<sup>3</sup> Clearly  $A = \partial_x^2 + \alpha \cos(\Omega x)$  with domain

$$\mathcal{D} = \left\{ \phi \in L^2(\mathbb{R}) \mid \phi, \frac{d\phi}{dx} \text{ absolutely continuous, } \frac{d^2\phi}{dx^2} \in L^2(\mathbb{R}) \right\},$$

and  $B$  and  $C$  are equal to the identity operator on  $L^2(\mathbb{R})$ . Rewriting the system in its lifted representation, we have

$$(9) \quad \begin{aligned} \partial_t \psi_\theta(t) &= \mathcal{A}_\theta \psi_\theta(t) + u_\theta(t), \\ y_\theta(t) &= \psi_\theta(t), \end{aligned}$$

where  $\mathcal{B}_\theta$  and  $\mathcal{C}_\theta$  are equal to the identity operator on  $\ell^2$  and  $\mathcal{A}_\theta$  can be found from Example 1

$$\mathcal{A}_\theta = - \begin{bmatrix} \ddots & \vdots & \vdots & \vdots & \ddots \\ \cdots & (\theta + \Omega(n-1))^2 & \alpha/2 & 0 & \cdots \\ \cdots & \alpha/2 & (\theta + \Omega n)^2 & \alpha/2 & \cdots \\ \cdots & 0 & \alpha/2 & (\theta + \Omega(n+1))^2 & \cdots \\ \ddots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}.$$

Notice that (9) is now fully decoupled in the variable  $\theta$ . In other words, (8) is equivalent to the family of state-space representations (9) parameterized by  $\theta \in [0, \Omega)$ .

**4. Problem setup.** In this section we set the stage for the analysis that will follow in the proceeding sections. We first describe the class of spatially periodic LTI systems that we will be considering in this paper. We then review some facts and definitions regarding the spectrum of the infinitesimal generators of such systems, their exponential stability, and conditions under which the spectrum determines exponential stability. Finally, we introduce the notion of the  $\mathcal{H}^2$  norm for exponentially stable spatially periodic systems and give a procedure for computing this norm.

Let us consider a distributed system of the form

$$(10) \quad \begin{aligned} \partial_t \psi(t, x) &= A \psi(t, x) + B u(t, x) \\ &= (A^\circ + B^\circ \epsilon F C^\circ) \psi(t, x) + B u(t, x), \\ y(t, x) &= C \psi(t, x), \end{aligned}$$

where  $t \in [0, \infty)$  and  $x \in \mathbb{R}$  with the following assumptions. The (possibly unbounded) operators  $A^\circ$ ,  $B^\circ$ , and  $C^\circ$  are spatially invariant, and the bounded operators  $B$  and  $C$  are spatially periodic with period  $X = 2\pi/\Omega$ .  $F(x) = 2L \cos(\Omega x)$ , with  $L$  a constant

<sup>3</sup>By  $\partial_t \psi(t, x)$  and  $\partial_x^2 \psi(t, x)$  we mean the spatiotemporal functions  $\partial_t \psi$  and  $\partial_x^2 \psi$ , respectively, evaluated at the point  $(t, x)$ .

matrix, and  $\epsilon$  is a complex scalar.  $A^\circ$ ,  $B^\circ$ ,  $C^\circ$ , and  $E := B^\circ F C^\circ$  are all defined on a common dense domain  $\mathcal{D} \subset L^2(\mathbb{R})$ .  $A = A^\circ + \epsilon E$  is closed and generates a *strongly continuous* semigroup (also known as a  $C_0$  semigroup)  $e^{At}$  [2]. We will refer to  $A$  as the *infinitesimal generator* of the system. The functions  $u$ ,  $y$ , and  $\psi$  are, respectively, the spatiotemporal input, output, and state of the system and belong to  $L^2(\mathbb{R})$  for all  $t$ .

**Comment on notation.** To avoid clutter, we henceforth drop the “ $\wedge$ ” from the representation of frequency domain functions. For example, we use  $A_0(\cdot)$  [instead of  $\hat{A}_0(\cdot)$ ] to represent the Fourier symbol of the spatially invariant operator  $A^\circ$ .

As shown in [12, 5, 17], system (10) can be represented in the (spatial) frequency domain by the family of systems

$$\begin{aligned} \partial_t \psi_\theta(t) &= (\mathcal{A}_\theta^\circ + \epsilon \mathcal{B}_\theta^\circ \mathcal{F} \mathcal{C}_\theta^\circ) \psi_\theta(t) + \mathcal{B}_\theta u_\theta(t) \\ (11) \quad &= (\mathcal{A}_\theta^\circ + \epsilon \mathcal{E}_\theta) \psi_\theta(t) + \mathcal{B}_\theta u_\theta(t), \\ y_\theta(t) &= \mathcal{C}_\theta \psi_\theta(t), \end{aligned}$$

parameterized by  $\theta \in [0, \Omega)$ . The vectors  $u_\theta$ ,  $y_\theta$ , and  $\psi_\theta$  belong to  $\ell^2$  for all  $t$ .  $\mathcal{B}_\theta$  and  $\mathcal{C}_\theta$  have no particular structure and can be any bounded operators on  $\ell^2$ .  $\mathcal{F}$  has the form given in Example 1 with  $\frac{1}{2}$  replaced by the matrix  $L$ .  $\mathcal{A}_\theta^\circ$ ,  $\mathcal{B}_\theta^\circ$ , and  $\mathcal{C}_\theta^\circ$  are (possibly unbounded) block diagonal operators on  $\ell^2$ ,

$$\begin{aligned} \mathcal{A}_\theta^\circ &= \begin{bmatrix} \ddots & & \\ & A_0(\theta_n) & \\ & & \ddots \end{bmatrix}, \quad \mathcal{B}_\theta^\circ = \begin{bmatrix} \ddots & & \\ & B^\circ(\theta_n) & \\ & & \ddots \end{bmatrix}, \quad \mathcal{C}_\theta^\circ = \begin{bmatrix} \ddots & & \\ & C^\circ(\theta_n) & \\ & & \ddots \end{bmatrix}, \\ (12) \quad \mathcal{E}_\theta &:= \mathcal{B}_\theta^\circ \mathcal{F} \mathcal{C}_\theta^\circ = \begin{bmatrix} \ddots & & \ddots & & \\ & \ddots & & 0 & A_{-1}(\theta_n) \\ & & A_1(\theta_{n+1}) & 0 & \ddots \\ & & & \ddots & \ddots \end{bmatrix}, \end{aligned}$$

with  $\theta_n := \theta + \Omega n$ ,  $n \in \mathbb{Z}$ , and<sup>4</sup>

$$(13) \quad A_1(\cdot) := B^\circ(\cdot) L C^\circ(\cdot - \Omega), \quad A_{-1}(\cdot) := B^\circ(\cdot) L C^\circ(\cdot + \Omega).$$

$A_0(\cdot)$ ,  $B^\circ(\cdot)$ , and  $C^\circ(\cdot)$  denote the Fourier symbols of the spatially invariant operators  $A^\circ$ ,  $B^\circ$ , and  $C^\circ$ , respectively.

In sections 7 and 5 we will establish conditions for exponential stability of system (10) and compute its  $\mathcal{H}^2$  norm. We will see that the biinfinite representation (11)–(12) will play a key role in simplifying the perturbation analysis of system (10).

*Remark 3.* Taking  $F(x)$  to be a pure cosine is not restrictive. The results obtained here can be easily extended to problems where  $F(x)$  is any periodic function with absolutely convergent Fourier series coefficients.

*Remark 4.* The system (10) can be considered as the linear fractional transformation [18] of a spatially periodic system  $G^\circ$  with *spatially invariant* infinitesimal

<sup>4</sup>We emphasize that the notational convention used in the elements of  $\mathcal{E}_\theta$  is the same as that used in (6); the  $n$ th row of  $\mathcal{E}_\theta$  is  $\{\dots, 0, A_1(\theta_n), 0, A_{-1}(\theta_n), 0, \dots\}$ .

generator  $A^\circ$ ,

$$G^\circ = \left[ \begin{array}{c|cc} A^\circ & B & B^\circ \\ \hline C & 0 & 0 \\ \hline C^\circ & 0 & 0 \end{array} \right],$$

and the (memoryless and bounded) spatially periodic pure multiplication operator  $\epsilon F(x) = \epsilon 2L \cos(\Omega x)$ .

**Sectorial operators and exponential stability.** We introduce the class of *sectorial* operators. These operators generate *holomorphic* (also known as *analytic*) semigroups  $e^{At}$ . Sectorial operators have the important property that their spectrum determines the decay or growth rate of their semigroup; i.e., they satisfy the spectrum-determined growth condition.

Suppose  $A$  is densely defined,  $\rho(A)$  contains a sector of the complex plane  $|\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma$ ,  $\gamma > 0$ ,  $\alpha \in \mathbb{R}$ , and there exists some  $M > 0$  such that

$$(14) \quad \|(zI - A)^{-1}\| \leq \frac{M}{|z - \alpha|} \quad \text{for } |\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma.$$

Then  $A$  generates a holomorphic semigroup, and we write  $A \in \mathcal{H}(\gamma, \alpha, M)$  [11, 9]. We say that  $A$  is *sectorial* if  $A$  belongs to some  $\mathcal{H}(\gamma, \alpha, M)$ .

A semigroup is called exponentially stable if there exist positive constants  $M$  and  $\varrho$  such that [2]

$$\|e^{At}\| \leq M e^{-\varrho t} \quad \text{for } t \geq 0.$$

The following theorem constitutes the reason for our interest in sectorial operators and forms the foundation of our analysis in section 7.

**THEOREM 2.** *Assume that  $A$  is sectorial. Then  $A$  generates an exponentially stable  $C_0$  semigroup if and only if  $\Sigma(A) \subset \mathbb{C}^-$ .*

*Proof.* If  $A$  is sectorial, it defines a holomorphic  $C_0$  semigroup and  $e^{At}$  is differentiable for  $t > 0$  [10, 19]. Then [8] shows that this is sufficient for the spectrum-determined growth condition to hold. Since  $\Sigma(A) \subset \mathbb{C}^-$  and  $\Sigma(A)$  belongs to a left sector, it follows that  $\Sigma(A)$  is bounded away from the imaginary axis. Let  $\omega_\sigma = \sup_{z \in \Sigma(A)} \operatorname{Re}(z)$ . Then  $\omega_\sigma < 0$ , and  $A$  generates an exponentially stable  $C_0$  semigroup. Clearly  $\Sigma(A) \subset \mathbb{C}^-$  is also a necessary condition for exponential stability, and the proof is complete.  $\square$

**Spectrum of spatially periodic operators.** We show how the spectrum of  $A$  relates to the spectrum of the  $\theta$ -parameterized family of operators  $\mathcal{A}_\theta$ . We will use this in section 7 to find the spectrum of  $A$ , as needed in Theorem 2 to establish exponential stability.

Since the spatially periodic operator  $A$  and the family of biinfinite matrices  $\mathcal{A}_\theta$ ,  $\theta \in [0, \Omega)$ , are related via a unitary transformation, it follows that [5]

$$(15) \quad \Sigma(A) = \overline{\bigcup_{\theta \in [0, \Omega)} \Sigma(\mathcal{A}_\theta)}.$$

In the case where  $A$  is spatially invariant (and thus  $\mathcal{A}_\theta = \operatorname{diag}\{\dots, A_0(\theta_n), \dots\}$ ), (15) further simplifies to

$$(16) \quad \Sigma(A) = \overline{\bigcup_{k \in \mathbb{R}} \Sigma_p(A_0(k))}.$$

FIG. 2. Left: The symbol  $A_0(\cdot)$  of Example 3 in “complex-plane  $\times$  spatial-frequency” space. Center: The spectrum  $\Sigma(A)$  in the complex plane. Right: For spatially invariant  $A$ , the (diagonal) elements of  $A_\theta$  are samples of the Fourier symbol  $A_0(\cdot)$ .

Example 3. Let  $A = -(\partial_x^2 + \varkappa^2)^2$  with domain

$$(17) \quad \mathcal{D} = \left\{ \phi \in L^2(\mathbb{R}) \mid \phi, \frac{d\phi}{dx}, \frac{d^2\phi}{dx^2}, \frac{d^3\phi}{dx^3} \text{ absolutely continuous, } \frac{d^4\phi}{dx^4} \in L^2(\mathbb{R}) \right\}.$$

Integration by parts shows that  $A$  is a self-adjoint operator and thus closed. The function  $A_0(k) = -(k^2 - \varkappa^2)^2$  is the Fourier symbol of  $A$ ; see Figure 2 (left). Since  $A_0(\cdot)$  is scalar, we have  $\Sigma_p(A_0(k)) = A_0(k)$  for every  $k$ . It is easy to see that  $A_0(\cdot)$  takes every real negative value, and thus from (16)  $A$  has continuous spectrum  $\Sigma(A) = (-\infty, 0]$ ; see Figure 2 (center).

Remark 5. When  $A$  is spatially invariant, a helpful way to think about  $\Sigma(A)$  in terms of the symbol  $A_0(\cdot)$  of  $A$  is suggested by the previous example. First plot  $\Sigma_p(A_0(\cdot))$  in the “complex-plane  $\times$  spatial-frequency” space, as in Figure 2 (left). Then the orthogonal projection onto the complex plane of this plot would give  $\Sigma(A)$ . This can be considered as a geometric interpretation of (16). In Example 3, since  $A_0(\cdot)$  is real scalar and takes all negative values, this projection yields the negative real axis. But, in general, if  $A_0(\cdot) \in \mathbb{C}^{q \times q}$ , this projection would lead to  $q$  curves in the complex plane. Notice also that in this setting  $\Sigma(A_\theta)$  is the projection onto the complex plane of samples of  $\Sigma_p(A_0(\cdot))$  taken at  $k = \theta + \Omega n$ ,  $n \in \mathbb{Z}$ , in the complex-plane  $\times$  spatial-frequency space. As  $\theta$  varies in  $[0, \Omega)$  these projections trace out  $\Sigma(A)$  in the complex plane. This can be considered as a geometric interpretation of (15). Figure 2 (right) shows the said samples in the complex-plane  $\times$  spatial-frequency space for a scalar  $A$ .

**$\mathcal{H}^2$  norm of spatially periodic systems.** We define the  $\mathcal{H}^2$  norm of an exponentially stable spatially periodic system  $G$  as

$$\|G\|_{\mathcal{H}^2}^2 = \frac{1}{2\pi} \int_0^\Omega \int_0^\infty \text{trace}[\mathcal{G}_\theta(t) \mathcal{G}_\theta^*(t)] dt d\theta,$$

where  $\mathcal{G}_\theta(t) = C_\theta e^{A_\theta t} B_\theta$  is the impulse response of the system (11). The proof of the following theorem can be found in [5, 12].

THEOREM 3. Consider the exponentially stable spatially periodic LTI system  $G$ , with spatial period  $X = 2\pi/\Omega$  and state-space realization (10)–(11). Then

$$\|G\|_{\mathcal{H}^2}^2 = \frac{1}{2\pi} \int_0^\Omega \text{trace}[C_\theta \mathcal{P}_\theta C_\theta^*] d\theta = \frac{1}{2\pi} \int_0^\Omega \text{trace}[B_\theta^* \mathcal{Q}_\theta B_\theta] d\theta,$$

where  $\mathcal{P}_\theta$  and  $\mathcal{Q}_\theta$  are the solutions of the  $\theta$ -parameterized algebraic Lyapunov equations

$$\mathcal{A}_\theta \mathcal{P}_\theta + \mathcal{P}_\theta \mathcal{A}_\theta^* = -\mathcal{B}_\theta \mathcal{B}_\theta^*, \quad \mathcal{A}_\theta^* \mathcal{Q}_\theta + \mathcal{Q}_\theta \mathcal{A}_\theta = -\mathcal{C}_\theta^* \mathcal{C}_\theta.$$

**5. Perturbation analysis of the  $\mathcal{H}^2$  norm.** The difficulty in calculating the  $\mathcal{H}^2$  norm using Theorem 3 is that, unless  $\mathcal{A}_\theta$ ,  $\mathcal{B}_\theta$ , and  $\mathcal{C}_\theta$  are diagonal, the operators  $\mathcal{P}_\theta$  and  $\mathcal{Q}_\theta$  are “full,” meaning that they possess *all* of their (infinite number of) subdiagonals. This makes the computation of the  $\mathcal{H}^2$  norm numerically expensive. Namely, one has to solve an *infinite-dimensional* algebraic Lyapunov equation to find the operator  $\mathcal{P}_\theta$  (or  $\mathcal{Q}_\theta$ ) for every value of  $\theta \in [0, \Omega)$ . In this section we will see how one can use analytic perturbation techniques to compute the  $\mathcal{H}^2$  norm in a simple and numerically efficient way and without having to explicitly find the full  $\mathcal{P}_\theta$  and  $\mathcal{Q}_\theta$  operators. Such a perturbation analysis is very useful in predicting general trends and extracting valuable information about the  $\mathcal{H}^2$  norm, as needed in the design of periodic feedback.

Consider the general setup of (10), where we take  $\epsilon$  to be a small *real* scalar. We assume that  $A = A^\circ + \epsilon E$  defines an exponentially stable  $C_0$  semigroup on  $L^2(\mathbb{R})$  with finite  $\mathcal{H}^2$  norm for small enough  $\epsilon$  and that  $B$  and  $C$  are spatially invariant operators. We are interested in the changes in the  $\mathcal{H}^2$  norm of this system for small magnitudes of  $\epsilon$  and different values of the frequency  $\Omega$ .

Let

$$\mathcal{P}_\theta(\epsilon) = \mathcal{P}_\theta^{(0)} + \epsilon \mathcal{P}_\theta^{(1)} + \epsilon^2 \mathcal{P}_\theta^{(2)} + \dots,$$

with  $\mathcal{P}_\theta^*(\epsilon) = \mathcal{P}_\theta(\epsilon)$ . This implies that  $\mathcal{P}_\theta^{(m)*} = \mathcal{P}_\theta^{(m)}$  for all  $m = 0, 1, 2, \dots$ ; i.e.,  $\mathcal{P}_\theta^{(m)}$  are self-adjoint operators for all  $m$ . The proof of convergence of the above series is relegated to the appendix. Our aim is to find  $\mathcal{P}_\theta^{(m)}$  by solving the Lyapunov equation

$$(18) \quad \mathcal{A}_\theta(\epsilon) \mathcal{P}_\theta(\epsilon) + \mathcal{P}_\theta(\epsilon) \mathcal{A}_\theta^*(\epsilon) = -\mathcal{B}_\theta \mathcal{B}_\theta^*$$

$\Downarrow$

$$(19) \quad (\mathcal{A}_\theta^\circ + \epsilon \mathcal{E}_\theta) (\mathcal{P}_\theta^{(0)} + \epsilon \mathcal{P}_\theta^{(1)} + \epsilon^2 \mathcal{P}_\theta^{(2)} + \dots) + (\mathcal{P}_\theta^{(0)} + \epsilon \mathcal{P}_\theta^{(1)} + \epsilon^2 \mathcal{P}_\theta^{(2)} + \dots) (\mathcal{A}_\theta^\circ + \epsilon \mathcal{E}_\theta)^* = -\mathcal{B}_\theta \mathcal{B}_\theta^*$$

and to compute the  $\mathcal{H}^2$  norm of the system by using Theorem 3 and

$$\|G\|_{\mathcal{H}^2}^2 = \frac{1}{2\pi} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta(\epsilon) \mathcal{C}_\theta^*] d\theta.$$

By equating equal powers of  $\epsilon$  on both sides of (19), we have

$$(20) \quad \mathcal{A}_\theta^\circ \mathcal{P}_\theta^{(0)} + \mathcal{P}_\theta^{(0)} \mathcal{A}_\theta^{\circ*} = -\mathcal{B}_\theta \mathcal{B}_\theta^*,$$

$$(21) \quad \mathcal{A}_\theta^\circ \mathcal{P}_\theta^{(1)} + \mathcal{P}_\theta^{(1)} \mathcal{A}_\theta^{\circ*} = -(\mathcal{E}_\theta \mathcal{P}_\theta^{(0)} + \mathcal{P}_\theta^{(0)} \mathcal{E}_\theta^*),$$

$$(22) \quad \mathcal{A}_\theta^\circ \mathcal{P}_\theta^{(2)} + \mathcal{P}_\theta^{(2)} \mathcal{A}_\theta^{\circ*} = -(\mathcal{E}_\theta \mathcal{P}_\theta^{(1)} + \mathcal{P}_\theta^{(1)} \mathcal{E}_\theta^*),$$

$\vdots$

The existence of a unique solution to each of these equations is guaranteed by the exponential stability of the unperturbed system. Furthermore, in (20) since the operators  $\mathcal{A}_\theta^\circ$  and  $\mathcal{B}_\theta \mathcal{B}_\theta^*$  are diagonal, so is  $\mathcal{P}_\theta^{(0)}$ . In (21) the right-hand side operator has

the structure of being nonzero only on the first upper and lower subdiagonals, and hence  $\mathcal{P}_\theta^{(1)}$  inherits the same structure since  $\mathcal{A}_\theta^o$  is diagonal. In the same manner, the operator  $\mathcal{P}_\theta^{(2)}$  is nonzero only on the main diagonal and on the second upper and lower subdiagonals. This type of argument can be applied to all other  $\mathcal{P}_\theta^{(m)}$ ,  $m = 3, 4, \dots$ , and we have

$$\mathcal{P}_\theta^{(0)} = \begin{bmatrix} \ddots & & & \\ & P_0(\theta_n) & & \\ & & \ddots & \end{bmatrix}, \quad \mathcal{P}_\theta^{(1)} = \begin{bmatrix} \ddots & \ddots & & \\ \ddots & 0 & P_1^*(\theta_n) & \\ & P_1(\theta_n) & 0 & \ddots \\ & & \ddots & \ddots \end{bmatrix},$$

$$\mathcal{P}_\theta^{(2)} = \begin{bmatrix} \ddots & \ddots & \ddots & & \\ \ddots & \ddots & 0 & P_2^*(\theta_{n+1}) & \\ \ddots & 0 & Q_0(\theta_n) & 0 & \ddots \\ & P_2(\theta_{n+1}) & 0 & \ddots & \ddots \\ & & \ddots & \ddots & \ddots \end{bmatrix}, \quad \dots,$$

where we have used the self-adjointness of these operators in writing the elements of their upper subdiagonals.

*Remark 6.* Note that not only is  $\mathcal{P}_\theta^{(m)}$  not a full operator, it has at most  $m$  nonzero upper and lower subdiagonals. Furthermore, all  $\mathcal{P}_\theta^{(m)}$  for odd  $m$  have zero diagonal and are thus trace-free operators.

*Remark 7.* Although  $\mathcal{A}_\theta = \mathcal{A}_\theta^o + \epsilon \mathcal{E}_\theta$  has only one nonzero subdiagonal, the operator  $\mathcal{P}_\theta(\epsilon) = \mathcal{P}_\theta^{(0)} + \epsilon \mathcal{P}_\theta^{(1)} + \dots$  possesses all of its subdiagonals. This is precisely the reason why direct calculation of  $\mathcal{P}_\theta$  in Theorem 3 is computationally difficult.

From (20)–(22) the operators  $\mathcal{P}_\theta^{(0)}$ ,  $\mathcal{P}_\theta^{(1)}$ , and  $\mathcal{P}_\theta^{(2)}$  are found by equating, element by element, the biinfinite matrices on both sides of these equations. For example, (20) leads to

$$A_0(\theta + \Omega n) P_0(\theta + \Omega n) + P_0(\theta + \Omega n) A_0^*(\theta + \Omega n) = -B(\theta + \Omega n) B^*(\theta + \Omega n)$$

for every  $n \in \mathbb{Z}$  and  $\theta \in [0, \Omega)$ . But as  $n$  takes all integer values and  $\theta$  changes in  $[0, \Omega)$ , the variable  $k = \theta + \Omega n$  takes all real values, and one can rewrite the above equation as

$$A_0(k) P_0(k) + P_0(k) A_0^*(k) = -B(k) B^*(k),$$

with  $k \in \mathbb{R}$ . By applying the same procedure to (21)–(22) one arrives at

$$(23) \quad A_0(k) P_0(k) + P_0(k) A_0^*(k) = -B(k) B^*(k),$$

$$(24) \quad A_0(k) P_1(k) + P_1(k) A_0^*(k - \Omega) = -(A_1(k) P_0(k - \Omega) + P_0(k) A_{-1}^*(k - \Omega)),$$

$$(25) \quad \begin{aligned} A_0(k) Q_0(k) + Q_0(k) A_0^*(k) &= -(A_1(k) P_1^*(k) + P_1(k) A_1^*(k) \\ &\quad + A_{-1}(k) P_1(k + \Omega) + P_1^*(k + \Omega) A_{-1}^*(k)), \end{aligned}$$

and so on for all nonzero diagonals of  $\mathcal{P}_\theta^{(m)}$ ,  $m = 3, 4, \dots$ . The existence of a unique solution to each of these equations is guaranteed by the exponential stability of the unperturbed system.

From the above equations one first finds  $P_0(\cdot)$  from (23), then  $P_1(\cdot)$  from (24), and so on. In other words, computing the subdiagonals of  $\mathcal{P}_\theta$  becomes *decoupled in one direction*. This decoupling would not have been possible had we not employed a perturbation approach and had attempted to solve (18) directly.

Returning to the calculation of the  $\mathcal{H}^2$  norm, let us first separate the diagonal part of  $\mathcal{P}_\theta^{(2)}$  by rewriting it as  $\mathcal{P}_\theta^{(2)} = \overline{\mathcal{P}}_\theta^{(2)} + \widetilde{\mathcal{P}}_\theta^{(2)}$ , where

$$\overline{\mathcal{P}}_\theta^{(2)} := \begin{bmatrix} \ddots & & \\ & Q_0(\theta_n) & \\ & & \ddots \end{bmatrix}$$

and  $\widetilde{\mathcal{P}}_\theta^{(2)}$  contains the rest of  $\mathcal{P}_\theta^{(2)}$ . Clearly  $\text{trace}[\mathcal{C}_\theta \widetilde{\mathcal{P}}_\theta^{(2)} \mathcal{C}_\theta^*] = 0$ . Also recall that

$$(26) \quad \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta^{(2m+1)} \mathcal{C}_\theta^*] = 0, \quad m = 0, 1, 2, \dots$$

Therefore

$$\begin{aligned} \|G\|_{\mathcal{H}^2}^2 &= \frac{1}{2\pi} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta(\epsilon) \mathcal{C}_\theta^*] d\theta \\ &= \frac{1}{2\pi} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta^{(0)} \mathcal{C}_\theta^* + \epsilon^2 \mathcal{C}_\theta \mathcal{P}_\theta^{(2)} \mathcal{C}_\theta^*] d\theta + O(\epsilon^4) \\ &= \frac{1}{2\pi} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta^{(0)} \mathcal{C}_\theta^* + \epsilon^2 \mathcal{C}_\theta \overline{\mathcal{P}}_\theta^{(2)} \mathcal{C}_\theta^*] d\theta + O(\epsilon^4), \end{aligned}$$

where the absence of odd powers of  $\epsilon$  is due to (26) and the last equation follows from the fact that  $\text{trace}[\mathcal{C}_\theta \widetilde{\mathcal{P}}_\theta^{(2)} \mathcal{C}_\theta^*] = 0$ . By using the unitary property of the lifting transform we have

$$\begin{aligned} \int_0^\Omega \text{trace}[\mathcal{C}_\theta \mathcal{P}_\theta^{(0)} \mathcal{C}_\theta^*] d\theta &= \int_{-\infty}^\infty \text{trace}[C(k) P_0(k) C^*(k)] dk, \\ \int_0^\Omega \text{trace}[\mathcal{C}_\theta \overline{\mathcal{P}}_\theta^{(2)} \mathcal{C}_\theta^*] d\theta &= \int_{-\infty}^\infty \text{trace}[C(k) Q_0(k) C^*(k)] dk, \end{aligned}$$

and we arrive at the final result

$$(27) \quad \|G\|_{\mathcal{H}^2}^2 = \frac{1}{2\pi} \int_{-\infty}^\infty \text{trace}[C(k) P_0(k) C^*(k) + \epsilon^2 C(k) Q_0(k) C^*(k)] dk + O(\epsilon^4).$$

We have thus proved the following theorem, which is the main result of this section.

**THEOREM 4.** *Consider the exponentially stable spatially periodic LTI system  $G$  with finite  $\mathcal{H}^2$  norm, spatial period  $X = 2\pi/\Omega$ , and state-space realization (10). Then for small values of  $|\epsilon|$  the  $\mathcal{H}^2$  norm of the system (10) can be computed from (27), where  $P_0(\cdot)$  and  $Q_0(\cdot)$  are solutions of the family of finite-dimensional Lyapunov and Sylvester equations described by (23)–(25).*

The described procedure can be continued to find higher-order terms in the perturbation series of the  $\mathcal{H}^2$  norm. The interested can refer to [20] for details.

**6. Examples.** As an application of the perturbation results of the previous section, we first investigate the occurrence of “parametric resonance” for a class of spatially periodic systems. Parametric resonance occurs when a specific frequency  $\Omega_{\text{res}}$

FIG. 3. *Top: Plot of  $P_0(\cdot)$ . Bottom: Plot of  $P_0(\cdot - \Omega)$  and  $P_0(\cdot + \Omega)$  (dashed line).*

of the periodic perturbation resonates with some “natural frequency”  $\varkappa$  of the unperturbed system, leading to a local (in  $\Omega$ ) change in system behavior [3]. In the systems we consider in this section this change in behavior is captured by the value of the  $\mathcal{H}^2$  norm.

*Example 4.* We consider the Swift–Hohenberg equation, which is of interest in hydrodynamics [21, 22, 23] and nonlinear optics [24, 25] as well as in other branches of physics [23]. The linearization of the Swift–Hohenberg equation around its time-independent spatially periodic solution leads to a PDE with spatially periodic coefficients of the form [26]

$$\begin{aligned} \partial_t \psi &= -(\partial_x^2 + \varkappa^2)^2 \psi - c\psi + f\psi + u, \\ y &= \psi, \end{aligned} \quad (28)$$

with  $0 \neq \varkappa \in \mathbb{R}$ ,  $c > 0$ , and  $f(x) = f(x + 2\pi/\Omega)$ . We assume here that  $f(x) = \epsilon \cos(\Omega x)$ , with  $\epsilon \in \mathbb{R}$  small. By comparing (28) and (10) we have

$$A_0(k) = -(k^2 - \varkappa^2)^2 - c, \quad B^o(k) = 1, \quad C^o(k) = 1, \quad B(k) = 1, \quad C(k) = 1, \quad L = \frac{1}{2}.$$

For this system the functions  $P_0(k)$  and  $Q_0(k)$  of the previous section simplify to<sup>5</sup>

$$\begin{aligned} (29) \quad P_0(k) &= \frac{-1}{2A_0(k)}, \\ Q_0(k) &= \frac{1}{(A_0(k))^2} \left( \frac{-1}{2A_0(k - \Omega)} + \frac{-1}{2A_0(k + \Omega)} \right) \\ (30) \quad &= 4(P_0(k))^2 (P_0(k - \Omega) + P_0(k + \Omega)), \end{aligned}$$

and our aim is to find the  $\mathcal{H}^2$  norm

$$(31) \quad \|G\|_{\mathcal{H}^2}^2 = \frac{1}{2\pi} \int_{-\infty}^{\infty} (P_0(k) + \epsilon^2 Q_0(k)) dk + O(\epsilon^4)$$

for different values of the parameter  $\Omega > 0$ . More specifically, we are interested in the values of  $\Omega$  for which the  $\mathcal{H}^2$  norm is maximized.

From (29) we have  $P_0(k) = (1/2)/[(k^2 - \varkappa^2)^2 + c]$ . The first plot of Figure 3 shows  $P_0(\cdot)$ , while the second shows  $P_0(\cdot - \Omega)$  and  $P_0(\cdot + \Omega)$  [dashed line] for a given value of  $\Omega \neq 0$ . As  $\Omega$  is increased,  $P_0(\cdot - \Omega)$  slides to the right and  $P_0(\cdot + \Omega)$  to the left. From (30) it is clear that, to find  $Q_0(\cdot)$  for a given  $\Omega$ , one would sum the two functions in the second plot and multiply the result by the square of the first

<sup>5</sup>To find  $Q_0(k)$  one needs to first find  $P_1(k)$ , but we have omitted the details for brevity.

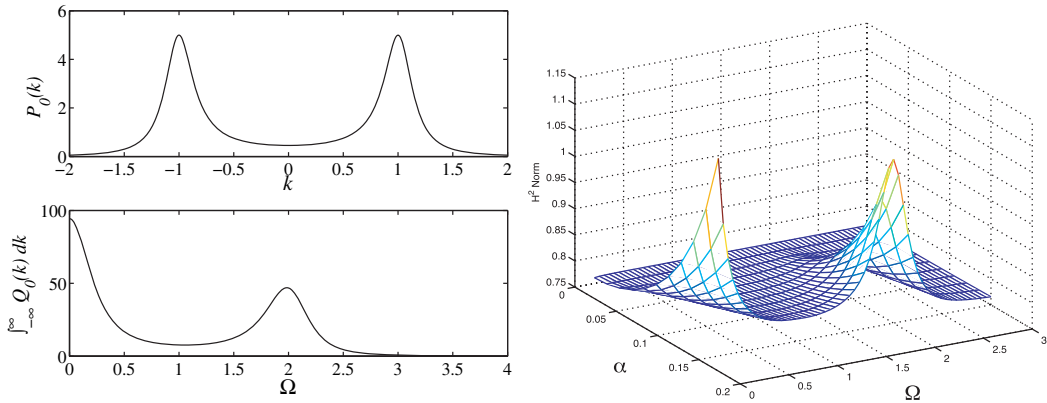

FIG. 4. Left: Plots of Example 4 for  $\kappa = 1$  and  $c = 0.1$ . Notice that the first graph is plotted against  $k$  and the second against  $\Omega$ . Right: The plot of the  $\mathcal{H}^2$  norm of the same example but calculated by taking large truncations of the  $\mathcal{A}_\theta$ ,  $\mathcal{B}_\theta$ , and  $\mathcal{C}_\theta$  matrices and using Theorem 3.

plot. The interesting question now is for what value(s) of  $\Omega \in (0, \infty)$  the  $\mathcal{H}^2$  norm in (31) would be maximized.

One can easily see that as  $\Omega \rightarrow 0$  the peaks of  $P_0(\cdot - \Omega)$  and  $P_0(\cdot + \Omega)$  merge toward those of  $(P_0(\cdot))^2$ . Thus  $\int_{-\infty}^{\infty} Q_0(k) dk$  grows, and hence  $\|G\|_{\mathcal{H}^2}^2$  grows.<sup>6</sup> This is not surprising; as  $\Omega \rightarrow 0$  the perturbation is tending toward a constant function  $F(x) = \cos(\Omega x) \rightarrow 1$ . This results in shifting the whole spectrum of  $A^0$  toward the right half of the complex plane, thus increasing the  $\mathcal{H}^2$  norm of the perturbed system.

But we are more interested in frequencies  $\Omega \gg 0$  that lead to a local (in  $\Omega$ ) increase in the  $\mathcal{H}^2$  norm. Notice that a different alignment of the peaks can also occur, which leads to another local maximum of the  $\mathcal{H}^2$  norm as a function of  $\Omega$ . This happens when the peak of  $P_0(\cdot - \Omega)$  at  $k = -\kappa + \Omega$  becomes aligned with the peak of  $(P_0(\cdot))^2$  at  $k = \kappa$  and, simultaneously, the peak of  $P_0(\cdot + \Omega)$  at  $k = \kappa - \Omega$  becomes aligned with the peak of  $(P_0(\cdot))^2$  at  $k = -\kappa$ . Clearly this occurs when

$$-\kappa + \Omega_{\text{res}} = \kappa \implies \Omega_{\text{res}} = 2\kappa.$$

This result agrees exactly with that obtained in [27], where in the analysis of the same problem it is shown that the part of the spectrum of  $A$  closest to the imaginary axis “resonates” with perturbations whose frequency satisfies the relation  $\Omega = 2\kappa$ .

Consider (28) with  $\kappa = 1$  and  $c = 0.1$ . For this system  $\int_{-\infty}^{\infty} P_0(k) dk \approx 4.74$ . Figure 4 (left) shows the graphs of  $P_0(\cdot)$  plotted against  $k$  and  $\int_{-\infty}^{\infty} Q_0(k) dk$  plotted against  $\Omega$ . The peak at  $\Omega = 2$  in the lower plot verifies the relation  $\Omega_{\text{res}} = 2\kappa$  obtained previously.

Figure 4 (right) shows the  $\mathcal{H}^2$  norm of this system computed by taking large enough truncations [5] of the  $\mathcal{A}_\theta$ ,  $\mathcal{B}_\theta$ , and  $\mathcal{C}_\theta$  matrices and then applying Theorem 3. The figure shows that the trends were indeed correctly predicted by the perturbation analysis and the peaks at  $\Omega = 0, 2$  correspond to the peaks of  $\int_{-\infty}^{\infty} Q_0(k) dk$ .

Now consider (28) with  $\kappa = 1$  and  $c = 0.1$  but with  $\epsilon$  replaced by  $\epsilon j$ . This would correspond to  $L = j/2$  in the notation of (10). Obviously the unperturbed system

<sup>6</sup>Remember that  $P_0(k)$  is independent of  $\Omega$ , and thus  $\int_{-\infty}^{\infty} P_0(k) dk$  remains constant for different  $\Omega$ .

FIG. 5. The plot of Example 4 for  $\varkappa = 1$ ,  $c = 0.1$ , and a purely imaginary perturbation.FIG. 6. Plot of Example 5 for  $\varkappa = 1$  and  $c = 0.1$ .

remains the same as before, and hence  $\int_{-\infty}^{\infty} P_0(k) dk \approx 4.74$ . Figure 5 shows the graph of  $\int_{-\infty}^{\infty} Q_0(k) dk$  which demonstrates that for this system the purely imaginary perturbation reduces the  $\mathcal{H}^2$  norm at all frequencies. The physical interpretation of such a perturbation is investigated in [17].

*Example 5.* We consider a slightly different version of the Swift–Hohenberg equation in the previous example [5]

$$\begin{aligned} \partial_t \psi &= -(\partial_x^2 + \varkappa^2) \psi - c \psi + \epsilon \cos(\Omega x) \partial_x \psi + u, \\ y &= \psi. \end{aligned} \quad (32)$$

By comparing (32) and (10) we have

$$(33) \quad A_0(k) = -(k^2 - \varkappa^2)^2 - c, \quad B^o(k) = 1, \quad C^o(k) = jk, \quad B(k) = 1, \quad C(k) = 1, \quad L = \frac{1}{2}.$$

The difference between this system and (28) is that here  $C^o$  is a spatial derivative. The plot of Figure 6 demonstrates  $\int_{-\infty}^{\infty} Q_0(k) dk$  for  $\varkappa = 1$  and  $c = 0.1$ . Notice that the peak at  $\Omega_{\text{res}} = 2$  remains the same as in Figure 4, but we now have a decrease at small frequencies. This is due to the derivative operator  $C^o = \partial_x$ . These results are in agreement with the (nonperturbation) calculations for the same system in Example B, section VII of [5]. Our perturbation methods correctly predict the increase at  $\Omega = 2$  and the decrease around  $\Omega \approx 0.4$  of the  $\mathcal{H}^2$  norm.

*Example 6.* The system in this example is inspired by boundary layer and channel flow problems, where the introduction of corrugated walls or periodic body forces influences drag reduction or enhancement in such geometries. The following PDE has an analogous structure to the linearized Navier–Stokes equations in these geometries. Consider

$$A_0(k) = \begin{bmatrix} -\frac{1}{R}(k^2 + c) & 0 \\ jk & -\frac{1}{R}(k^2 + c) \end{bmatrix},$$

$$B^o(k) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C^o(k) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad B(k) = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad C(k) = \begin{bmatrix} 0 & 1 \end{bmatrix}, \quad L = \frac{1}{2} \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}.$$

 FIG. 7. Plots of Example 6 for  $R = 6$  and  $c = 1$ .

Numerical calculations for  $R = 6$ ,  $c = 1$  give  $\int_{-\infty}^{\infty} \text{trace}[C(k)P_0(k)C^*(k)] dk \approx 20.72$ . Figure 7 shows that the  $\mathcal{H}^2$  norm can be decreased by the application of periodic perturbations with frequency  $\Omega \approx 0.7$ . It is interesting that, if one uses the locations of the peaks in the first plot of Figure 7 to find  $\varkappa = 0.75$ , then from the peak at  $\Omega_{\text{res}} = 1.6$  in the second plot it seems that the relationship  $\Omega_{\text{res}} \approx 2\varkappa = 1.5$  (see Example 4) still holds with an acceptable error even for this matrix-valued system.

**7. Stability and the spectrum-determined growth condition.** In the literature on semigroups there exist examples in which  $\Sigma(A)$  lies entirely inside  $\mathbb{C}^-$  but  $\|e^{At}\|$  does not decay exponentially; see [6] and more recently [7]. In such cases it is said that the semigroup does not satisfy the *spectrum-determined growth condition* [8]. The determining factor in the examples presented in [6, 7] is the accumulation of the eigenvalues of  $\mathcal{A}_\theta$  around  $\pm j\infty - c$ ,  $c > 0$ , in the form of Jordan blocks of ever-increasing size (i.e., as the eigenvalues tend to  $\pm j\infty - c$ , their algebraic multiplicity increases while their geometric multiplicity stays finite). But such cases are ruled out when one deals with semigroups generated by *sectorial* operators.

Our ultimate aim in this section is to verify exponential stability. From Theorem 2, in order to prove exponential stability of a holomorphic  $C_0$  semigroup generated by a sectorial operator  $A$ , it is necessary and sufficient to verify that  $\Sigma(A) \subset \mathbb{C}^-$ . Hence in the first part of this section we give conditions under which the infinitesimal generator  $A$  in (10) is a sectorial operator. In the second part we find conditions which guarantee  $\Sigma(A) \subset \mathbb{C}^-$ .

Once again, the setup is that of (10) where  $\epsilon$  is a small complex scalar. In addition, assume that  $A_0(k) \in \mathbb{C}^{q \times q}$  is diagonalizable for every  $k \in \mathbb{R}$ .

**Conditions for sectorial infinitesimal generator.** To find conditions under which an infinitesimal generator  $A$  is sectorial, we have to verify (14), i.e., verify whether  $\|(zI - A)^{-1}\| \leq M/|z - \alpha|$  for all  $z$  belonging to some sector of  $\mathbb{C}$ . This involves finding the inverse of the operator  $zI - A$  and then calculating its norm. Such a computation can in general be very difficult. On the other hand, finding  $\|(zI - A^\circ)^{-1}\|$  is easy because of the spatial invariance of  $A^\circ$ . Indeed, from the norm-preserving property of the Fourier transform, it follows that  $\|(zI - A^\circ)^{-1}\| = \sup_{k \in \mathbb{R}} \|(zI - A_0(k))^{-1}\|$ .

Thus to establish conditions for  $A$  to be sectorial we again use perturbation theory. We first find conditions under which  $A^\circ$  is sectorial. We then show that  $A = A^\circ + \epsilon E$

remains sectorial if  $E$  is “weaker” than  $A^\circ$  in a certain sense we will describe and if  $\epsilon$  is small enough.

In the next theorem we present a condition for a spatially invariant operator  $A^\circ$  with Fourier symbol  $A_0(\cdot)$  to be sectorial.

**THEOREM 5.** *Let  $A_0(k)$  be diagonalizable for every  $k \in \mathbb{R}$ , and let  $U(k)$  be the transformation that diagonalizes  $A_0(k)$ , i.e.,  $A_0(k) = U(k) \Lambda(k) U^{-1}(k)$ , with  $\Lambda(k)$  diagonal. Let  $\kappa(k) := \|U(k)\| \|U^{-1}(k)\|$  denote the condition number of  $U(k)$ . If  $\sup_{k \in \mathbb{R}} \kappa(k) < \infty$ , and for every  $k \in \mathbb{R}$  the resolvent set  $\rho(A_0(k))$  contains a sector of the complex plane  $|\arg(z - \alpha)| < \frac{\pi}{2} + \gamma$ , with  $\gamma > 0$  and  $\alpha \in \mathbb{R}$  both independent of  $k$ , then  $A^\circ$  is sectorial.*

*Proof.* See the appendix.  $\square$

This theorem has a particularly simple interpretation when  $A_0(\cdot)$  is scalar. In this case  $\kappa(k) = 1$  for all  $k \in \mathbb{R}$ . Since  $A_0(\cdot)$  traces a curve in the complex plane, by Theorem 5 if this curve stays outside some sector  $|\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma$ ,  $\gamma > 0$ , of the complex plane, then  $A^\circ$  is sectorial.

The following theorem is the main result of this section and uses the notion of *relative boundedness* of one unbounded operator with respect to another unbounded operator [9] to prove that  $A = A^\circ + \epsilon E$  is sectorial.

**THEOREM 6.** *Let  $A^\circ$  with domain  $\mathcal{D}$  be a closed operator, and  $A^\circ \in \mathcal{H}(\gamma, \alpha, M)$ . Let  $E = B^\circ F C^\circ$  with domain  $\mathcal{D}' \supset \mathcal{D}$  be relatively bounded with respect to  $A^\circ$  such that*

$$(34) \quad \|E\psi\| \leq a \|\psi\| + b \|A^\circ \psi\|, \quad \psi \in \mathcal{D},$$

with  $0 \leq a < \infty$  and  $0 \leq b|\epsilon| < 1/(1 + M)$ . Then  $A = A^\circ + \epsilon E$  is sectorial, closed, and generates a  $C_0$  semigroup.

*Proof.* From (34) we have

$$\|\epsilon E \psi\| \leq a |\epsilon| \|\psi\| + b |\epsilon| \|A^\circ \psi\|.$$

Then from [11, Theorem 4.5.7] it follows that  $A = A^\circ + \epsilon E$  is sectorial for all  $\epsilon$  such that  $0 \leq b|\epsilon| < 1/(1 + M)$ . Since  $M > 0$  we have  $b|\epsilon| < 1$ , and [9, Theorem IV.1.1] gives that  $A$  is closed. Finally, it follows from [19, p. 100] that  $A$  is the generator of a  $C_0$  semigroup.  $\square$

This theorem says that if  $A^\circ$  is sectorial and closed, then so is  $A = A^\circ + \epsilon E$  if  $E$  is weaker than  $A^\circ$  in the sense of (34) and if  $|\epsilon|$  is small enough. Notice that at this point condition (34) cannot be reduced to a condition in terms of Fourier symbols as in Theorem 5 (i.e., a condition that can be checked pointwise in  $k$ ). This is because  $E$  is not spatially invariant. But once the exact form of the operators  $B^\circ$  and  $C^\circ$  is known, (34) can be simplified to a condition on the Fourier symbols of  $A^\circ$ ,  $B^\circ$ , and  $C^\circ$ . Let us clarify this statement with the aid of an example.

*Example 7.* Consider the spatially periodic system

$$\begin{aligned} \partial_t \psi &= -(\partial_x^2 + \varkappa^2)^2 \psi - c \psi + \epsilon \partial_x \cos(\Omega x) \psi + u, \\ y &= \psi, \end{aligned}$$

where  $\psi \in \mathcal{D}$ , and  $\mathcal{D}$  is defined as in (17). It is easy to see that  $A^\circ = -(\partial_x^2 + \varkappa^2)^2 - c$  is sectorial by Theorem 5 and closed by Example 3, and  $E = \partial_x \cos(\Omega x)$ . By formal differentiation we have

$$E \psi = \partial_x \cos(\Omega x) \psi = -\Omega \sin(\Omega x) \psi + \cos(\Omega x) \partial_x \psi.$$

By using the triangle inequality and  $\|\sin(\Omega x)\| = \|\cos(\Omega x)\| = 1$ , we have

$$(35) \quad \|E\psi\| \leq |\Omega| \|\psi\| + \|\partial_x \psi\|.$$

Thus we have effectively commuted out the bounded spatially periodic component of  $E$  and are left with only spatially invariant operators on the right of (35). Hence after applying a Fourier transformation to the right side of (35), a sufficient condition for (34) to hold is that

$$|\Omega| + |k| \leq a + b|(k^2 - \varkappa^2)^2 + c|, \quad k \in \mathbb{R},$$

which can be shown to be satisfied for large enough  $a > 0$  and  $b > 0$ . By using Theorem 6 we get that  $A$  is sectorial, closed, and the generator of a  $C_0$  semigroup.

*Remark 8.* The above example makes clear the notion of  $E$  being “weaker” than  $A^\circ$  that we mentioned at the beginning of this subsection. If in Example 7 we had  $B^\circ = \partial_x^\nu$ ,  $C^\circ = \partial_x^\mu$ , and  $\nu + \mu = 5$ , then  $E$  would contain a 5th-order derivative, whereas the highest order of  $\partial_x$  in  $A^\circ$  is 4. This would mean that (34) cannot be satisfied for any choice of  $a$  and  $b$ .

**Conditions for infinitesimal generator with spectrum in  $\mathbb{C}^-$ .** The final step in establishing exponential stability is to check whether  $\Sigma(A) \subset \mathbb{C}^-$ . Since this is, in general, a difficult problem, we proceed as follows. We consider the (block) diagonal operators  $\mathcal{A}_\theta^\circ$  and extend Geršgorin-type methods to find bounds on the location of  $\Sigma(\mathcal{A}_\theta)$ ,  $\mathcal{A}_\theta = \mathcal{A}_\theta^\circ + \epsilon \mathcal{E}_\theta$ . We then use this to find conditions on  $\epsilon \mathcal{E}_\theta$  that yield  $\Sigma(\mathcal{A}_\theta) \subset \mathbb{C}^-$  for all  $\theta \in [0, \Omega]$ .

In locating the spectrum of a finite-dimensional matrix  $T \in \mathbb{C}^{q \times q}$ , the theory of Geršgorin circles [28] provides us with a region of the complex plane that contains the eigenvalues of  $T$ . This region is composed of the union of  $q$  disks, the centers of which are the diagonal elements of  $T$ , and their radii depend on the magnitude of the off-diagonal elements [28]. This theory has also been extended to the case of finite-dimensional *block* matrices (i.e., matrices whose elements are themselves matrices) in [29]. We will further extend this theory to include biinfinite block matrices  $\mathcal{A}_\theta$ .

Take  $\mathfrak{B}_k$  to be the set of complex numbers  $z$  that satisfy

$$(36) \quad \sigma_{\min}(zI - A_0(k)) \leq |\epsilon| (\|A_{-1}(k)\| + \|A_1(k)\|),$$

where  $\sigma_{\min}(zI - A_0(k))$  denotes the smallest singular value of the matrix  $zI - A_0(k)$ .

LEMMA 7. *For every  $\theta$  we have  $\Sigma(\mathcal{A}_\theta) \subseteq \mathfrak{S}_\theta$ , where*

$$\mathfrak{S}_\theta = \overline{\bigcup_{n \in \mathbb{Z}} \mathfrak{B}_{\theta_n}}.$$

*Proof.* See the appendix.  $\square$

*Example 8.* Let us consider again the spatially periodic system in Example 5,

$$\begin{aligned} \partial_t \psi &= -(\partial_x^2 + \varkappa^2)^2 \psi - c\psi + \epsilon \cos(\Omega x) \partial_x \psi + u, \\ y &= \psi. \end{aligned}$$

From (33) and (13) we have  $A_1(k) = \frac{i}{2}(k - \Omega)$ ,  $A_{-1}(k) = \frac{i}{2}(k + \Omega)$ , and thus  $\|A_{-1}(k)\| + \|A_1(k)\| = \frac{1}{2}(|k - \Omega| + |k + \Omega|)$ . Hence (36) leads to

$$\sigma_{\min}(zI - A_0(k)) = |zI - A_0(k)| \leq \frac{|\epsilon|}{2} (|k - \Omega| + |k + \Omega|) = \begin{cases} \Omega |\epsilon| & |k| \leq \Omega, \\ |k| |\epsilon| & |k| \geq \Omega, \end{cases}$$

FIG. 8. Left: The  $\mathfrak{B}_{\theta_n}$  regions viewed in the complex-plane  $\times$  spatial-frequency space (the disks are parallel to the complex plane). Center:  $\Sigma(\mathcal{A}_\theta)$  is contained inside the union of the regions  $\mathfrak{B}_{\theta_n}$ . Right: The bold line shows  $\Sigma(A^\circ)$ , and the dotted region contains  $\Sigma(A)$ ,  $A = A^\circ + \epsilon E$ .

which means that the set  $\mathfrak{S}_\theta$  is composed of the union of disks with centers at  $A_0(\theta_n)$  and radii  $\frac{|\epsilon|}{2}(|\theta_n - \Omega| + |\theta_n + \Omega|)$ . This is nothing but an extension of the classical Geršgorin disks to biinfinite matrices. Figure 8 (left and center) show  $\mathfrak{S}_\theta$  in the complex-plane  $\times$  spatial-frequency space and in  $\mathbb{C}$ , respectively.<sup>7</sup>

*Remark 9.* The set

$$\begin{aligned}
 \Sigma_\varepsilon(T) &:= \{z \in \mathbb{C} \mid \sigma_{\min}(zI - T) \leq \varepsilon\} \\
 &= \{z \in \mathbb{C} \mid \|(zI - T)\varphi\| \leq \varepsilon \text{ for some } \|\varphi\| = 1\} \\
 (37) \quad &= \{z \in \mathbb{C} \mid z \in \Sigma_p(T + Z) \text{ for some } \|Z\| \leq \varepsilon\}
 \end{aligned}$$

is called the  $\varepsilon$ -pseudospectrum of the matrix  $T$  [30, 31]. Clearly  $\Sigma_{\varepsilon'}(T) \subseteq \Sigma_\varepsilon(T)$  if  $\varepsilon' \leq \varepsilon$ , and  $\Sigma_\varepsilon(T) = \Sigma_p(T)$  for  $\varepsilon = 0$ . The pseudospectrum is composed of small sets around the eigenvalues of  $T$ . For instance, if  $T$  has simple eigenvalues then for small enough values of  $\varepsilon$  the pseudospectrum consists of disjoint compact and convex neighborhoods of each eigenvalue [32]. By comparing (37) and the definition of  $\mathfrak{B}_k$  in (36), it is clear that  $\mathfrak{B}_k = \Sigma_\varepsilon(A_0(k))$ , with  $\varepsilon = |\epsilon|(\|A_{-1}(k)\| + \|A_1(k)\|)$ . Thus for every  $k \in \mathbb{R}$ , the inequality (36) defines a closed region of  $\mathbb{C}$  that includes the eigenvalues of  $A_0(k)$ .

We now employ Lemma 7 to determine whether  $\Sigma(A)$  resides completely inside  $\mathbb{C}^-$ , as needed to assess system stability. Take  $\mathfrak{D}_\varepsilon$  to be the closed disk of radius  $\varepsilon$  and center at the origin and  $\mathfrak{B}_k$  to be the region described by (36). Define the sum of sets by  $\mathfrak{U}_1 + \mathfrak{U}_2 = \{z \mid z = z_1 + z_2, z_1 \in \mathfrak{U}_1, z_2 \in \mathfrak{U}_2\}$ . For every  $k \in \mathbb{R}$  let  $\lambda_{\max}(k)$  represent the eigenvalue of  $A_0(k)$  with the maximum real part, and let  $\kappa(k)$  be defined as in Theorem 5.

**THEOREM 8.** For a given  $k$  the set  $\mathfrak{B}_k$  is contained inside  $\Sigma_p(A_0(k)) + \mathfrak{D}_{r(k)}$ , with

$$r(k) = |\epsilon|(\|A_{-1}(k)\| + \|A_1(k)\|)\kappa(k).$$

In particular, if  $\Sigma(A^\circ) \subset \mathbb{C}^-$  and

$$(38) \quad r(k) < |\operatorname{Re}(\lambda_{\max}(k))| + \beta$$

for every  $k \in \mathbb{R}$  and some  $\beta < 0$  independent of  $k$ , then  $\Sigma(A) \subset \mathbb{C}^-$ .

<sup>7</sup>We point out that Figure 8 (left) is technically incorrect; once the spatially invariant system is perturbed by a spatially periodic perturbation, it is no longer spatially invariant and thus cannot be represented by a Fourier symbol. Hence its spectrum can no longer be demonstrated in the complex-plane  $\times$  spatial-frequency space. Figure 8 (center) demonstrates the correct representation of the Geršgorin disks for  $\mathcal{A}_\theta$ .

*Proof.* See the appendix.  $\square$

*Example 9.* Consider the system of Example 8.  $\kappa(k) = 1$  since  $A_0(k)$  is scalar,  $|\operatorname{Re}(\lambda_{\max}(k))| = |(k^2 - \varkappa^2)^2 + c|$ , and

$$\|A_{-1}(k)\| + \|A_1(k)\| = \frac{1}{2} (|k - \Omega| + |k + \Omega|).$$

Thus condition (38) becomes

$$\frac{|\epsilon|}{2} (|k - \Omega| + |k + \Omega|) < |(k^2 - \varkappa^2)^2 + c| + \beta.$$

If this condition is satisfied for some  $\beta < 0$ , the dotted region in Figure 8 (right) will remain inside  $\mathbb{C}^-$ , and thus  $\Sigma(A) \subset \mathbb{C}^-$ .

In summary, to assess exponential stability we first find sufficient conditions on the infinitesimal generator  $A$  such that it belongs to the class of sectorial operators, for which the spectrum-determined growth condition holds. We then find sufficient conditions for  $A$  to have  $\mathbb{C}^-$  spectrum. We do this via an extension of Geršgorin circles to biinfinite (block) matrices.

**8. Conclusions and future work.** We use perturbation analysis to find a computationally efficient way of revealing trends in the  $\mathcal{H}^2$  norm of spatially periodic systems. We show that for certain classes of systems the periodicity can be chosen so as to increase the  $\mathcal{H}^2$  norm and induce parametric resonance. An application of this would be in fluid mixing problems. It is also shown that the  $\mathcal{H}^2$  norm can be made to decrease for an appropriate choice of the frequency of the perturbation. This would be the desired scenario, for example, in the design of the body of an aircraft. We demonstrate that for certain scalar systems the value of the spatial period that achieves the desired increase or decrease of the  $\mathcal{H}^2$  norm can be characterized exactly based on the description of the nominal system.

We also study the problem of verifying the exponential stability of a spatially periodic system. We do this by (i) finding conditions under which its infinitesimal generator is a sectorial operator (i.e., generates a holomorphic  $C_0$  semigroup) and thus satisfies the spectrum-determined growth condition and (ii) deriving conditions which guarantee that the infinitesimal generator has its spectrum contained inside the open left half of the complex plane.

The methods presented here can also be used in systems with many spatial directions. For example, consider the PDE

$$\psi_t = \psi_{yy} + \psi_{xx} + c\psi + \epsilon \cos(\Omega x)\psi,$$

with  $y \in [-1, 1]$  and  $x \in R$ . To put this system into the developed framework one would only have to perform a discrete approximation of the operator  $\partial_y^2$  with the appropriate boundary conditions. Furthermore, the techniques developed in this paper can be applied to spatially periodic systems defined on a torus with minor changes.

Future research in this direction would include an exact (analytical) characterization of the frequencies for which the  $\mathcal{H}^2$  norm is most increased or decreased for the general case of matrix-valued  $A_0(\cdot)$ . The perturbation methods presented here could also be generalized to biinfinite Sylvester equations which arise frequently in fluids problems.

### Appendix.

**Convergence of the perturbation series.** For the series expansion

$$\mathcal{P}_\theta(\epsilon) = \mathcal{P}_\theta^{(0)} + \epsilon \mathcal{P}_\theta^{(1)} + \epsilon^2 \mathcal{P}_\theta^{(2)} + \dots$$

to be valid, we must show that all elements of the biinfinite matrix  $\mathcal{P}_\theta(\epsilon)$  converge for  $\epsilon$  contained in some small enough neighborhood of the origin. Let us assume that  $B^\circ$  and  $C^\circ$  are bounded operators and (without loss of generality) that  $\sup_{k \in \mathbb{R}} \|B(k)\| = 1$ . Assume that  $\|e^{A_0(k)t}\| \leq M_k e^{\varrho_k t}$ , and define

$$M := \sup_{k \in \mathbb{R}} M_k < \infty, \quad -\alpha_0 := \sup_{k \in \mathbb{R}} \varrho_k < 0,$$

$$\alpha_1 := \max\{\sup_{k \in \mathbb{R}} \|A_1(k)\|, \sup_{k \in \mathbb{R}} \|A_{-1}(k)\|\}.$$

Notice that the finiteness of  $M$  and the negativity of  $-\alpha_0$  follow from the exponential stability of the unperturbed system. Now from (23) we have

$$P_0(k) = \int_0^\infty e^{A_0(k)t} B(k) B^*(k) e^{A_0^*(k)t} dt,$$

and therefore

$$\sup_{k \in \mathbb{R}} \|P_0(k)\| \leq \frac{M^2}{2\alpha_0} =: \mu.$$

Similarly, from (24) we have

$$P_1(k) = \int_0^\infty e^{A_0(k)t} (A_1(k) P_0(k - \Omega) + P_0(k) A_{-1}^*(k - \Omega)) e^{A_0^*(k - \Omega)t} dt,$$

and therefore

$$\sup_{k \in \mathbb{R}} \|P_1(k)\| \leq \frac{M^2}{2\alpha_0} (2\alpha_1 \mu) \leq \mu (4\alpha_1 \mu) = 4\alpha_1 \mu^2.$$

From (25) we have

$$Q_0(k) = \int_0^\infty e^{A_0(k)t} (A_1(k) P_1^*(k) + \dots + P_1^*(k + \Omega) A_{-1}^*(k)) e^{A_0^*(k)t} dt,$$

and therefore

$$\sup_{k \in \mathbb{R}} \|Q_0(k)\| \leq \frac{M^2}{2\alpha_0} (4\alpha_1 (4\alpha_1 \mu^2)) \leq \mu (4\alpha_1)^2 \mu^2 = (4\alpha_1)^2 \mu^3.$$

In fact it is possible to show that any element of  $\mathcal{P}_\theta^{(m)}$  is bounded by

$$(4\alpha_1)^m \mu^{(m+1)}.$$

Thus for all  $|\epsilon| < 4\alpha_1 \mu = 2M^2 \alpha_1 / \alpha_0$  the series expansion of  $\mathcal{P}_\theta(\epsilon)$  converges.

*Proof of Theorem 5.* Recall that  $A^\circ$  is a sectorial operator if  $\rho(A^\circ)$  contains a (right) sector of the complex plane  $|\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma$ ,  $\gamma > 0$ ,  $\alpha \in \mathbb{R}$ , and there exists some  $M > 0$  such that

$$|z - \alpha| \|(zI - A^\circ)^{-1}\| \leq M \quad \text{for} \quad |\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma.$$

Since  $A_0(k) \in \mathbb{C}^{q \times q}$  is diagonalizable for every  $k$ , there exists a matrix  $U(k)$  such that  $A_0(k) = U(k) \Lambda(k) U^{-1}(k)$ , with  $\Lambda(k)$  a diagonal matrix. Let  $\lambda_i(k)$ ,  $i = 1, \dots, q$ , denote the diagonal elements of  $\Lambda(k)$ , which are also the eigenvalues of  $A_0(k)$ . Then

$$\begin{aligned} |z - \alpha| \|(zI - A^\circ)^{-1}\| &\leq \sup_{k \in \mathbb{R}} \left( |z - \alpha| \|(zI - A_0(k))^{-1}\| \right) \\ &\leq \sup_{k \in \mathbb{R}} \left( |z - \alpha| \|U(k)\| \|U^{-1}(k)\| \|(zI - \Lambda(k))^{-1}\| \right) \\ &= \sup_{k \in \mathbb{R}} \left( \kappa(k) \frac{|z - \alpha|}{\text{dist}[z, \Sigma_p(A_0(k))]} \right) \\ &\leq \kappa_{\max} \sup_{k \in \mathbb{R}} \left( \frac{|z - \alpha|}{\text{dist}[z, \Sigma_p(A_0(k))]} \right), \end{aligned}$$

where  $\kappa_{\max} := \sup_{k \in \mathbb{R}} \kappa(k)$ .

Set  $M = (M' + 1) \kappa_{\max}$ , with  $M' > 0$ . Consider for a given  $k$  the region of the complex plane defined by

$$\kappa_{\max} \frac{|z - \alpha|}{\text{dist}[z, \Sigma_p(A_0(k))]} \geq M.$$

This region (which contains the eigenvalues  $\lambda_i(k)$ ) is contained inside the union of the disks

$$\kappa_{\max} \frac{|z - \alpha|}{|z - \lambda_i(k)|} \geq M, \quad i = 1, \dots, q,$$

which are themselves contained inside the larger disks

$$(A1) \quad |z - \lambda_i(k)| \leq \frac{|\lambda_i(k) - \alpha|}{M'}, \quad i = 1, \dots, q.$$

Notice that (A1) describes disks whose radii increase like  $|\lambda_i(k) - \alpha|/M'$ ,  $M' > 0$ , as their centers  $\lambda_i(k)$  grow distant from the point  $\alpha$ . A sufficient condition for these disks to belong to some open (left) sector of the complex plane  $|\arg(z - \alpha)| > \frac{\pi}{2} + \gamma$ ,  $\gamma > 0$ , for all  $k \in \mathbb{R}$  and large enough  $M'$  is that  $\Sigma_p(A_0(k))$ ,  $k \in \mathbb{R}$ , reside inside some open (left) sector of the complex plane  $|\arg(z - \alpha)| > \frac{\pi}{2} + \gamma'$ ,  $\gamma' > \gamma$ .

Finally, if the conditions of the previous paragraph are satisfied then for  $z \in \mathbb{C}$  that belong to the sector  $|\arg(z - \alpha)| \leq \frac{\pi}{2} + \gamma$  we have  $z \in \rho(A_0(k))$  and

$$\kappa_{\max} \sup_{k \in \mathbb{R}} \left( \frac{|z - \alpha|}{\text{dist}[z, \Sigma_p(A_0(k))]} \right) \leq M.$$

Thus  $|z - \alpha| \|(zI - A^\circ)^{-1}\| \leq M$ , and  $A^\circ$  is sectorial.  $\square$

*Proof of Lemma 7.* We use  $\Pi_N T \Pi_N$  to denote the  $(2N + 1) \times (2N + 1)$  [block] truncation of an operator  $T$  on  $\ell^2$ , where  $\Pi_N$  is the projection defined by

$$\text{diag} \left\{ \dots, 0, \underbrace{I, \dots, I}_{2N+1 \text{ times}}, \dots, I, 0, \dots \right\},$$

center  
↓

and  $I$  is the identity matrix. Notice that  $\Pi_N T \Pi_N$  is still an operator on  $\ell^2$ ; it is made from the biinfinite matrix  $T$  by replacing all entries outside the center  $(2N+1) \times (2N+1)$

block with zeros. We now form the finite-dimensional matrix  $\Pi_N \mathcal{A}_\theta \Pi_N|_{\Pi_N \ell^2}$  by restricting  $\Pi_N \mathcal{A}_\theta \Pi_N$  to the finite-dimensional space  $\Pi_N \ell^2$ . Clearly  $\Pi_N \mathcal{A}_\theta \Pi_N|_{\Pi_N \ell^2}$  has pure point spectrum. Hence, using a generalized form of the Gershgorin circle theorem [29] for finite-dimensional (block) matrices, we conclude that

$$\Sigma(\Pi_N \mathcal{A}_\theta \Pi_N|_{\Pi_N \ell^2}) \subset \bigcup_{|n| \leq N} \mathfrak{B}_{\theta_n} \subseteq \overline{\bigcup_{n \in \mathbb{Z}} \mathfrak{B}_{\theta_n}},$$

where  $\mathfrak{B}_{\theta_n}$  are regions of  $\mathbb{C}$  defined by (36). Since this holds for all  $N \geq 0$ , we have  $\Sigma(\mathcal{A}_\theta) \subseteq \mathfrak{S}_\theta$ .  $\square$

*Proof of Theorem 8.* If  $U(k)$  diagonalizes  $A_0(k)$ ,  $A_0(k) = U(k) \Lambda(k) U^{-1}(k)$ , and  $\kappa(k) = \|U(k)\| \|U^{-1}(k)\|$  denotes the condition number of  $U(k)$ , then from [33] the pseudospectrum of  $A_0(k)$  satisfies

$$(A2) \quad \Sigma_p(A_0(k)) + \mathfrak{D}_\varepsilon \subseteq \Sigma_\varepsilon(A_0(k)) \subseteq \Sigma_p(A_0(k)) + \mathfrak{D}_{\varepsilon \kappa(k)}$$

for all  $\varepsilon \geq 0$ . Thus the first statement of the theorem follows immediately from (A2) and the fact that  $\mathfrak{B}_k = \Sigma_\varepsilon(A_0(k))$ , with  $\varepsilon = |\epsilon| (\|A_{-1}(k)\| + \|A_1(k)\|)$  [see Remark 9].

To prove the second statement, let  $\mathbb{C}_\beta^-$  denote all complex numbers with a real part less than  $\beta \in \mathbb{R}$ . It follows from  $\Sigma(A^\circ) \subset \mathbb{C}^-$  that  $\Sigma(\mathcal{A}_\theta^\circ) \subset \mathbb{C}^-$  for every  $\theta$ . If (38) holds, then

$$\mathfrak{B}_{\theta_n} \subseteq \Sigma_p(A_0(\theta_n)) + \mathfrak{D}_{r(\theta_n)} \subset \mathbb{C}_\beta^-$$

for every  $n \in \mathbb{Z}$ , and from Lemma 7 we have  $\Sigma(\mathcal{A}_\theta) \subseteq \mathfrak{S}_\theta = \overline{\bigcup_{n \in \mathbb{Z}} \mathfrak{B}_{\theta_n}} \subset \mathbb{C}_{\beta'}^-$  for some  $\beta < \beta' < 0$  and every  $\theta$ . Thus  $\Sigma(A) \subset \mathbb{C}^-$ .

# A VISCOSITY SOLUTION APPROACH TO THE INFINITE-DIMENSIONAL HJB EQUATION RELATED TO A BOUNDARY CONTROL PROBLEM IN A TRANSPORT EQUATION\*

GIORGIO FABBRI†

**Abstract.** The paper concerns the infinite-dimensional Hamilton–Jacobi–Bellman equation related to an optimal control problem regulated by a linear transport equation with boundary control. A suitable viscosity solution approach is needed in view of the presence of the unbounded control-related term in the state equation in the Hilbert setting. An existence-and-uniqueness result is obtained.

**Key words.** Hamilton–Jacobi–Bellman equation, viscosity solution, boundary control

**AMS subject classifications.** 49J20, 49L25

**DOI.** 10.1137/050638813

**1. Introduction.** We study the Hamilton–Jacobi–Bellman (HJB) equation related to the infinite-dimensional formulation of an optimal control problem whose state equation is a PDE of transport type.

More precisely we consider the PDE

$$(1) \quad \begin{cases} \frac{\partial}{\partial s}x(s, r) + \beta \frac{\partial}{\partial r}x(s, r) = -\mu x(s, r) + \alpha(s, r), & (s, r) \in (0, +\infty) \times (0, \bar{s}), \\ x(s, 0) = a(s) & \text{if } s > 0, \\ x(0, r) = x^0(r) & \text{if } r \in [0, \bar{s}], \end{cases}$$

where  $\bar{s}, \beta$  are positive constants,  $\mu \in \mathbb{R}$ , the initial data  $x^0$  is in  $L^2(0, \bar{s})$ , and we consider two controls: A boundary control  $a$  is in  $L^2_{loc}([0, +\infty); \mathbb{R})$  and a distributed control  $\alpha \in L^2_{loc}([0, +\infty) \times [0, \bar{s}]; \mathbb{R})$ .<sup>1</sup>

By using the approach and the references described in section 2, the above equation can be written as an ordinary differential equation in the Hilbert space  $\mathcal{H} = L^2(0, \bar{s})$  as follows:

$$(2) \quad \begin{cases} \frac{d}{ds}x(s) = Ax(s) - \mu x(s) + \alpha(s) + \beta \delta_0 a(s), \\ x(0) = x^0, \end{cases}$$

where  $A$  is the generator of a suitable  $C_0$  semigroup and  $\delta_0$  is the Dirac delta in 0. Such an unbounded contribution in the Hilbert formulation comes from the presence in the PDE of a boundary control (see [8]). Besides we consider the problem of minimizing the cost functional

$$(3) \quad J(x, \alpha(\cdot), a(\cdot)) = \int_0^\infty e^{-\rho s} L(x(s), \alpha(s), a(s)) ds,$$

where  $\rho > 0$  and  $L$  is globally bounded and satisfies some Lipschitz-type condition, as better described in section 2. The HJB equation related to the control problem with

†Dipartimento di Scienze Economiche ed Aziendali, Università LUISS - Guido Carli, Roma, Italy (gfabbri@luiss.it).

<sup>1</sup>We write “ $-\mu x$ ” instead of “ $\mu x$ ” because it is the standard way to write the equation in the economic literature, where  $-\mu$  has the meaning of a depreciation factor (and only the case  $\mu \geq 0$  is used). Here we consider a generic  $\mu \in \mathbb{R}$ .

state equation (2) and target functional (3) is

$$(4) \quad \rho u(x) - \langle \nabla u(x), Ax \rangle - \langle \nabla u(x), -\mu x \rangle_{L^2(0, \bar{s})} \\ - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \langle \beta \delta_0(\nabla u(x)), a \rangle_{\mathbb{R}} + \langle \nabla u(x), \alpha \rangle_{L^2(0, \bar{s})} + L(x, \alpha, a) \right) = 0.$$

The sets  $\Gamma$  and  $\Sigma$  will be introduced in section 2; they are suitable subsets, respectively, of  $\mathbb{R}$  and  $\mathcal{H}$ . If we define the value function of the control problem as

$$V(x) \stackrel{\text{def}}{=} \inf_{(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}} J(x, \alpha(\cdot), a(\cdot)),$$

we wish to prove that  $V(\cdot)$  is the unique solution, in a suitable sense, of the HJB equation.

We use the viscosity approach. Our main problem is to write a suitable definition of the viscosity solution, so that an existence and uniqueness theorem can be derived for such a solution. The main difficulties we encounter, with respect to the existing literature, are in dealing with the boundary term and the nonanalyticity of the semigroup. We substantially follow the original idea of Crandall and Lions [14], [15]—with some changes, as the reader will rate in Definitions 2.14 and 2.15—of writing test functions as the sum of a “good part” as it is a regular function with differential in  $D(A^*)$  and a “bad part” represented by some radial function. The main problems arise from the evaluation of the boundary term on the radial part.

In order to write a working definition in our case, some further requirements are needed, such as a  $C^2$  regularity of the test functions, the presence of a “remainder term” in the definition of a sub/supersolution, and the  $B$ -Lipschitz continuity (see Definition 2.10) of the solution. This last feature guarantees that the maxima and the minima in the definition of a sub/supersolution remain in  $D(A^*)$  (see Proposition 4.1). Some other comments on the definition of solution (Definitions 2.14 and 2.15) need some technical details and can be found in Remark 2.17.

The technique used cannot be easily extended to treat a general nonlinear problem because we use the explicit form of the PDE that we give in (6). A nontrivial generalization would be also that of replacing the constant  $\mu$  with a function  $\mu(r)$  in  $L^\infty(0, \bar{s})$  (see Remark 4.9 for details). Nevertheless, the problem remains challenging.

**A brief summary of the literature.** Hamilton–Jacobi equations in infinite dimensions, especially when arising from optimal control problems in Hilbert spaces, were first studied by Barbu and Da Prato [3], [4] with a strong solutions approach. The viscosity method, introduced in the study of finite-dimensional HJ equations in [13], was generalized by the same authors in a series of works: The most important for our approach are [14] and [15]. Moreover new variants of the notion of a viscosity solution for HJB equations in Hilbert spaces were given in [28], [34], [35], [33], [16].

The study of viscosity solutions for HJB equations associated to boundary control in PDE is more recent. In this research field there is not an organic and complete theory but some works that adapt the ideas and the techniques of viscosity solutions to problems for particular PDEs, by exploiting their peculiarities (as we do in this work for the problem regulated by a transport equation). For the first order HJB equations see [9], [12] (see also [10], [11]), where some classes of parabolic equations are treated, and [24], where the authors study the HJB equation related to a two-dimensional Navier–Stokes equation (see also [32]). It must be noted that all of these works treat the case of analytic  $A$ .

A HJB equation like (4) was treated, but only in the case of a convex objective functional, with a strong solutions approach by adapting Barbu and Da Prato's technique of convex regularization in [20], [19].

**A motivating economic problem.** Transport equations are used to model a large variety of phenomena. They are used, for example, in age-structured population models (see, for instance, [26], [2], [27]), in population economics [23], epidemiologic studies, socioeconomic science, and transport phenomena in physics.

Problems such as (1) can be used to describe, in economics, capital accumulation processes where an heterogeneous capital is involved, and this is the reason why the study of the infinite-dimensional control problem is of growing interest in the economic fields. For instance, in the vintage capital models  $x(t, s)$  may be regarded as the stock of capital goods differentiated with respect to the time  $t$  and the age  $s$ . Heterogeneous capital, in both the finite- and infinite-dimensional approaches, is used to study depreciation and obsolescence of physical capital, geographical difference in growth, innovation, and R&D.

Regarding problems modeled by a transport equation where an infinite-dimensional setting is used, we cite the following papers: [5], [7] on optimal technology adoption in a vintage capital context (in the case of a quadratic cost functional), [25] on capital accumulation, [6] on optimal advertising, and [19], [21] on the case of a general objective convex functional with a strong solutions approach. See also [22].

Moreover, we mention that the infinite-dimensional approach may apply to problems such as issuance of public debt (see [1] for a description of the problem). In that problem a stochastic setting and simple state-control constraints appear, but hopefully the present work can be a first step in this direction.

**Plan of the paper.** The work is organized as follows: In the first section we recall some results on the state equation, we introduce some preliminary remarks on the main operators involved in the problem, we explain some notations, we define the HJB equation, and we give the definition of solution. The second section regards some properties of the value function (in particular, some regularity properties) that will be used in the third section to prove that it is the unique (viscosity) solution of the HJB equation.

## 2. Notation and preliminary results.

**2.1. State equation.** In this subsection we will see some properties of the state equation: We write it in three different (and equivalent) forms that point out different properties of the solution. We will use all three forms in the following proofs.

We consider the PDE on  $[0, +\infty) \times [0, \bar{s}]$  given by

$$(5) \quad \begin{cases} \frac{\partial}{\partial s} x(s, r) + \beta \frac{\partial}{\partial r} x(s, r) = -\mu x(s, r) + \alpha(s, r), & (s, r) \in (0, +\infty) \times (0, \bar{s}), \\ x(s, 0) = a(s) & \text{if } s > 0, \\ x(0, r) = x^0(r) & \text{if } r \in [0, \bar{s}]. \end{cases}$$

Given an initial datum  $x^0 \in L^2((0, \bar{s}); \mathbb{R})$  (from now on simply  $L^2(0, \bar{s})$ ), a boundary control  $a(\cdot) \in L^2_{loc}([0, +\infty); \mathbb{R})$ , and a distributed control  $\alpha(\cdot) \in L^2_{loc}([0, +\infty) \times [0, \bar{s}]; \mathbb{R})$ , (5) has a unique solution in  $L^2_{loc}([0, +\infty) \times [0, \bar{s}]; \mathbb{R})$  given by

$$(6) \quad x(s, r) = \begin{cases} e^{-\mu s} x^0(r - \beta s) + \int_0^s e^{-\mu \tau} \alpha(s - \tau, r - \beta \tau) d\tau, & r \in [\beta s, \bar{s}], \\ e^{-\frac{\mu}{\beta} r} a(s - r/\beta) + \int_0^{r/\beta} e^{-\mu \tau} \alpha(s - \tau, r - \beta \tau) d\tau, & r \in [0, \beta s]. \end{cases}$$

In the following  $x(s, r)$  is the function defined in (6).

We can rewrite such an equation in a suitable Hilbert space setting. We take the Hilbert space  $\mathcal{H} \stackrel{\text{def}}{=} L^2(0, \bar{s})$  and the  $C_0$  semigroup  $S(t)$  given by

$$S(s)f[r] \stackrel{\text{def}}{=} \begin{cases} f(r - \beta s) & \text{for } r \in [\beta s, \bar{s}], \\ 0 & \text{for } r \in [0, \beta s]. \end{cases}$$

The generator of  $S(s)$  is the operator  $A$  given by

$$\begin{cases} D(A) = \{f \in H^1[0, \bar{s}] : f(0) = 0\}, \\ A(f)[r] = -\beta \frac{d}{dr} f(r) \end{cases}$$

(see [7] for a proof in the case where  $\beta = 1$ ; the proof in our case can be obtained by simply taking  $s' = \beta s$ ). In the following we will use the notation  $e^{sA}$  instead of  $S(s)$ .

*Remark 2.1.* To avoid confusion if  $x \in L^2(0, \bar{s})$  we will use  $[\cdot]$  to denote the pointwise evaluation, so  $x[r]$  is the value of  $x$  in  $r \in [0, \bar{s}]$ . On the other hand,  $x(s)$  will denote the evolution of the solution of the state equation (in the Hilbert space) at time  $s$  (as in (7)). That is,  $x(s)$  is an element of  $\mathcal{H}$ , while  $x[r]$  is a real number.

We want to write an infinite-dimensional formulation of (5), but in  $L^2(0, \bar{s})$  it should appear like

$$(7) \quad \begin{cases} \frac{d}{ds} x(s) = Ax(s) - \mu x(s) + \alpha(s) + \beta \delta_0 a(s), \\ x(0) = x^0, \end{cases}$$

where  $\alpha(s) \in L^2(0, \bar{s})$  is the function  $r \mapsto \alpha(s, r)$ . Such an expression does not make sense in  $L^2(0, \bar{s})$  for the presence of the unbounded term  $\beta \delta_0 a(s)$ . We can anyway apply formally the variation of constants method to (7) and obtain a mild form of (7) that is continuous from  $[0, +\infty)$  to  $L^2(0, \bar{s})$ . This is what we do in the next definition.

**DEFINITION 2.2.** Given  $x^0 \in L^2(0, \bar{s})$ ,  $a(\cdot) \in L^2_{loc}([0, +\infty); \mathbb{R})$ , and  $\alpha(\cdot) \in L^2_{loc}([0, +\infty); L^2(0, \bar{s}))$ , the function in  $C([0, +\infty); L^2(0, \bar{s}))$  given by

$$(8) \quad x(s) = e^{-\mu s} e^{sA} x^0 - A \int_0^s e^{-\mu(s-\tau)} e^{(s-\tau)A} (a(\tau)\nu) d\tau + \int_0^s e^{-\mu(s-\tau)} e^{(s-\tau)A} \alpha(\tau) d\tau,$$

where

$$\begin{aligned} \nu: [0, \bar{s}] &\rightarrow \mathbb{R}, \\ \nu: r &\mapsto e^{-\frac{\mu}{\beta} r}, \end{aligned}$$

is called the mild solution of (7).

*Remark 2.3.* We could include the term  $-\mu x$  in the generator of the semigroup  $A$  taking a  $\tilde{A} = A - \mu \mathbb{1}$  as done in [7]. The problem of this approach is that often we will use, in the estimates, the dissipativity of the generator, and  $\tilde{A}$  is dissipative only if  $\mu \geq 0$ .

**PROPOSITION 2.4.** Given  $x(s)$  the function from  $\mathbb{R}^+$  to  $L^2(0, \bar{s})$  given by (8) and  $x(s, r)$  the function from  $\mathbb{R}^+ \times [0, \bar{s}]$  to  $\mathbb{R}$  given by (6), we have  $x(s)[r] = x(s, r)$ .

*Proof.* See [7].  $\square$

Eventually we observe that (7) can be rewritten in a precise way in a larger space in which  $\beta \delta_0$  belongs. To this extent, we consider the adjoint operator  $A^*$ , whose explicit expression is given by

$$\begin{cases} D(A^*) \stackrel{\text{def}}{=} \{f \in H^1(0, \bar{s}) : f(\bar{s}) = 0\}, \\ A^*(f)[r] = \beta \frac{d}{dr} f(r). \end{cases}$$

We endow, in all of the paper,  $D(A^*)$  with the graph norm and the related Hilbert structure. We consider the inclusion

$$i: D(A^*) \hookrightarrow L^2(0, \bar{s})$$

and its continuous adjoint

$$i^*: L^2(0, \bar{s}) \rightarrow D(A^*)',$$

where we have identified  $L^2$  with its dual.

We can extend  $A$  to a generator of a  $C_0$  semigroup on  $D(A^*)'$  (the domain of the extension will contain  $L^2(0, \bar{s})$ ), and we observe that Dirac's measure  $\delta_0 \in D(A^*)'$  (see [20, Proposition 4.5, page 60] for details).

**PROPOSITION 2.5.** *Given  $T > 0$ ,  $x^0 \in L^2(0, \bar{s})$ ,  $a(\cdot) \in L^2(0, T)$ ,  $\alpha(\cdot) \in L^2([0, T]; L^2(0, \bar{s}))$ , (8) is the unique solution of*

$$(9) \quad \begin{cases} \frac{d}{ds} i^* x(s) = Ax(s) - \mu x(s) + \alpha(s) + \beta \delta_0 a(s), \\ x(0) = x^0 \end{cases}$$

in  $W^{1,2}(0, T; D(A^*)') \cap C(0, T, \mathcal{H})$ . Moreover, if  $a(\cdot) \in W^{1,2}(0, T)$ , then such a solution will belong to  $C^1(0, T; D(A^*)') \cap C(0, T; \mathcal{H})$ .

*Proof.* See [8, Chapter 3.2] (in particular, Theorem 3.1, page 173).  $\square$

**2.2. The definition of the operator  $B$ .** In this subsection we give the definition of the operator  $B$  that will have a fundamental role.<sup>2</sup>

Note that  $A^*$  and  $A$  are negative operators. We take  $\phi \in D(A^*)$ , so that  $\phi(\bar{s}) = 0$ , and then

$$\langle A^* \phi, \phi \rangle = \int_0^{\bar{s}} \beta \phi'(r) \phi(r) dr = \frac{-\beta \phi(0)^2}{2}$$

and for  $\phi \in D(A)$  (so that  $\phi(0) = 0$ )

$$\langle A \phi, \phi \rangle = \int_0^{\bar{s}} -\beta \phi'(r) \phi(r) dr = \frac{-\beta \phi(\bar{s})^2}{2}.$$

Therefore, given a  $\lambda > 0$ , the operators  $(A - \lambda I)$  and  $(A^* - \lambda I)$  are strongly negative:  $\langle (A - \lambda I)x, x \rangle \leq -\lambda |x|_{\mathcal{H}}^2$  for all  $x \in D(A)$  and  $\langle (A^* - \lambda I)x, x \rangle \leq -\lambda |x|_{\mathcal{H}}^2$  for all  $x \in D(A^*)$ .

We can also directly prove that

$$(A - \lambda I)^{-1}: \mathcal{H} \rightarrow D(A)$$

is a continuous negative linear operator whose explicit expression is given by

$$(A - \lambda I)^{-1}(\phi)[r] = \frac{1}{\beta} \left( -e^{-\frac{\lambda}{\beta} r} \int_0^r e^{\frac{\lambda}{\beta} \tau} \phi(\tau) d\tau \right).$$

The continuity can be proved directly with not difficult estimates, and the negativity can be proved directly by using an integration by part argument.

<sup>2</sup>We could use an abstract approach, noting that  $A$  and  $A^*$  are both generators of  $C_0$  semigroups of contractions, and then both are negative (see [17, page 424]), and the set  $\{\lambda \in \mathbb{C} : \operatorname{Re}(\lambda) > 0\}$  is in the resolvent of both  $A$  and  $A^*$  (Hille–Yosida theorem; see [29, page 53]). Here we can also follow a more direct approach that allows us to find the explicit form of the operator.

In the same way we can prove that

$$(A^* - \lambda I)^{-1}: \mathcal{H} \rightarrow D(A^*)$$

is a continuous and negative linear operator and that its explicit expression is given by

$$(A^* - \lambda I)^{-1}(\phi)[r] = \frac{1}{\beta} \left( -e^{\frac{\lambda}{\beta}r} \int_r^{\bar{s}} e^{-\frac{\lambda}{\beta}\tau} \phi(\tau) d\tau \right).$$

Eventually we can define  $B \stackrel{\text{def}}{=} (A^* - \lambda I)^{-1}(A - \lambda I)^{-1} = ((A - \lambda I)^{-1})^*(A - \lambda I)^{-1}$  that is continuous, positive, and self-adjoint.<sup>3</sup> Moreover

$$(A^* - \lambda I)B = (A - \lambda I)^{-1} \leq 0,$$

and so

$$A^*B = (A - \lambda I)^{-1} + \lambda B \leq \lambda B;$$

then  $A^*B$  is continuous, and if we choose  $\lambda < 1$ , we have

$$(10) \quad A^*B \leq B.$$

Thus  $B$  satisfies all requirements of the so-called “weak case” of [14].

*Remark 2.6.* Note that  $B^{1/2}$  is a particular case of the operator that Renardy found in more generality in [31], and so  $B^{1/2}: \mathcal{H} \rightarrow D(A^*)$  continuously and in particular  $\mathcal{R}(B^{1/2}) \subseteq D(A^*)$ .

*Notation 2.7.* For every  $x \in \mathcal{H}$  we will indicate with  $|x|_B$  the  $B$ -norm that is  $\sqrt{\langle Bx, x \rangle_{\mathcal{H}}}$ . We will write  $\mathcal{H}_B$  for the completion of  $\mathcal{H}$  with respect to the  $B$ -norm.

*Remark 2.8.* Thanks to the definition of  $A^*$ , the graph norm on  $D(A^*)$  is equivalent to the  $H^1(0, \bar{s})$ -norm. In particular  $D(A^*)$  is the completion of

$$K = \{f|_{[0, \bar{s}]} : f \in C_c^\infty(\mathbb{R}) \text{ with } \text{supp}(f) \subseteq (-\infty, \bar{s})\}$$

with respect to the  $H^1(0, \bar{s})$ -norm. So, since  $H^1(0, \bar{s}) \hookrightarrow C([0, \bar{s}]; \mathbb{R})$ , we can apply  $\beta\delta_0$  on the elements of  $D(A^*)$  and  $\delta_0 \in D(A^*)'$ .

*Notation 2.9.* The notation  $\langle x, y \rangle_H$  will indicate the inner product in the Hilbert space  $H$  (for example,  $H = \mathcal{H} \equiv L^2(0, \bar{s})$  or  $H = \mathbb{R}$  or  $D(A^*) \dots$ ). Otherwise, if  $Z$  is a Banach space (possibly a Hilbert space) and  $Z'$  its dual, the notation  $\langle x, y \rangle_{Z \times Z'}$  will indicate the duality pairing. Eventually  $\langle x, y \rangle \equiv \langle x, y \rangle_{L^2(0, \bar{s})}$ .

**2.3. The control problem and the HJB equation.** In this subsection we describe the optimal control problem, state the hypotheses, define the HJB equation of the system, and give a suitable definition of solution of the HJB equation.

We consider the optimal control problem governed by the state equation

$$(11) \quad \begin{cases} \frac{d}{ds} i^* x(s) = Ax(s) - \mu x(s) + \alpha(s) + \beta\delta_0 a(s), \\ x(0) = x \end{cases}$$

that has a unique solution in the sense described in section 2.1. Given two compact subsets  $\Gamma$  and  $\Lambda$  of  $\mathbb{R}$ , we consider the set of admissible boundary controls given by

$$\mathcal{A} \stackrel{\text{def}}{=} \{a: [0, +\infty) \rightarrow \Gamma \subseteq \mathbb{R} : a(\cdot) \text{ is measurable}\}.$$

<sup>3</sup>See [36, Proposition 2, page 273] for a proof of the equality  $(A^* - \lambda I)^{-1} = ((A - \lambda I)^{-1})^*$ .

Moreover we call

$$\Sigma \stackrel{def}{=} \{\gamma: [0, \bar{s}] \rightarrow \Lambda \subseteq \mathbb{R} : \gamma(\cdot) \text{ is measurable}\}.$$

In view of the compactness of  $\Lambda$  we have  $\Sigma \subseteq L^2(0, \bar{s})$ . We define the set of admissible distributed controls as

$$\mathcal{E} \stackrel{def}{=} \{\alpha: [0, +\infty) \rightarrow \Sigma \subseteq L^2(0, \bar{s}) : \alpha(\cdot) \text{ is measurable}\}.$$

In view of the compactness of  $\Gamma$  and  $\Lambda$ , we have  $\mathcal{A} \subseteq L^2_{loc}([0, +\infty); \mathbb{R})$  and  $\mathcal{E} \subseteq L^2_{loc}([0, +\infty) \times [0, \bar{s}]; \mathbb{R})$ . We call  $\|\Gamma\| \stackrel{def}{=} \sup_{a \in \Gamma}(|a|)$ ,  $\|\Lambda\| \stackrel{def}{=} \sup_{b \in \Lambda}(|b|)$ , and  $\|\Sigma\| \stackrel{def}{=} \sup_{\alpha \in \Sigma}(\|\alpha\|_{\mathcal{H}})$  (they are bounded thanks to the boundedness of  $\Gamma$  and  $\Lambda$ ).

We call *admissible control* a couple  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$ . The cost functional will be of the form

$$J(x, \alpha(\cdot), a(\cdot)) = \int_0^\infty e^{-\rho s} L(x(s), \alpha(s), a(s)) ds,$$

where  $L$  is uniformly continuous and satisfies the following conditions: There exists a  $C_L \geq 0$  with

$$((L1)) \quad |L(x, \alpha, a) - L(y, \alpha, a)| \leq C_L \langle B(x - y), (x - y) \rangle_{\mathcal{H} \times \mathcal{H}} \forall (\alpha, a) \in \Sigma \times \Gamma,$$

$$((L2)) \quad |L| \leq C_L < +\infty.$$

We define formally the HJB equation of the system as

$$(HJB) \quad \rho u(x) - \langle \nabla u(x), Ax \rangle - \langle \nabla u(x), -\mu x \rangle - H(x, \nabla u(x)) = 0,$$

where  $H$  is the Hamiltonian of the system and is defined as

$$\begin{cases} H: \mathcal{H} \times D(A^*) \rightarrow \mathbb{R}, \\ H(x, p) \stackrel{def}{=} \inf_{(\alpha, a) \in \Sigma \times \Gamma} (\langle \beta \delta_0(p), a \rangle_{\mathbb{R}} + \langle p, \alpha \rangle_{\mathcal{H}} + L(x, \alpha, a)). \end{cases}$$

Before introducing a suitable definition of the (viscosity) solution of the HJB equation, we give some preliminary definitions.

DEFINITION 2.10. A function  $v \in C(\mathcal{H})$  is *Lipschitz with respect to the B-norm*, or *B-Lipschitz*, if there exists a constant  $C$  such that

$$|v(x) - v(y)| \leq C|(x - y)|_B \stackrel{def}{=} C|B^{1/2}(x - y)|_{\mathcal{H}}$$

for every choice of  $x$  and  $y$  in  $\mathcal{H}$ . In the same way we can give the definition of a *locally B-Lipschitz function*.

DEFINITION 2.11. A function  $v \in C(\mathcal{H})$  is said to be *B-continuous* at a point  $x \in \mathcal{H}$  if for every  $x_n \in \mathcal{H}$ , with  $x_n \rightarrow x$  and  $|B(x_n - x)| \rightarrow 0$ , it holds that  $v(x_n) \rightarrow v(x)$ . In the same way we can define the *B-upper/lower semicontinuity*.

DEFINITION 2.12. We say that a function  $\phi$  such that  $\phi \in C^1(\mathcal{H})$  and  $\phi$  is *B-lower semicontinuous* is a *test function of type 1*, and we write  $\phi \in \text{test1}$ , if  $\nabla \phi(x) \in D(A^*)$  for all  $x \in \mathcal{H}$  and  $A^* \nabla \phi: \mathcal{H} \rightarrow \mathcal{H}$  is continuous.

DEFINITION 2.13. We say that  $g \in C^2(\mathcal{H})$  is a *test function of type 2*, and we write  $g \in \text{test2}$ , if  $g(x) = g_0(|x|)$  for some nondecreasing function  $g_0: \mathbb{R}^+ \rightarrow \mathbb{R}$ .

DEFINITION 2.14. A function  $u \in C(\mathcal{H})$  bounded and Lipschitz with respect to the  $B$ -norm, is a subsolution of the HJB equation (or simply a “subsolution”) if for every  $\phi \in \text{test1}$ ,  $g \in \text{test2}$ , and local maximum point  $x$  of  $u - (\phi + g)$  we have

$$(12) \quad \begin{aligned} & \rho u(x) - \langle A^* \nabla \phi(x), x \rangle - \langle \nabla \phi(x) + \nabla g(x), -\mu x \rangle \\ & - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \langle \beta \delta_0(\nabla \phi(x), a) \rangle_{\mathbb{R}} + \langle \nabla \phi(x) + \nabla g(x), \alpha \rangle_{\mathcal{H}} + L(x, \alpha, a) \right) \\ & \leq \frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2}. \end{aligned}$$

DEFINITION 2.15. A function  $v \in C(\mathcal{H})$  bounded and Lipschitz with respect to the  $B$ -norm is a supersolution of the HJB equation (or simply a “supersolution”) if for every  $\phi \in \text{test1}$ ,  $g \in \text{test2}$ , and local minimum point  $x$  of  $v + (\phi + g)$  we have

$$(13) \quad \begin{aligned} & \rho v(x) + \langle A^* \nabla \phi(x), x \rangle + \langle \nabla \phi(x) + \nabla g(x), -\mu x \rangle \\ & - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( -\langle \beta \delta_0(\nabla \phi(x), a) \rangle_{\mathbb{R}} - \langle \nabla \phi(x) + \nabla g(x), \alpha \rangle_{\mathcal{H}} + L(x, \alpha, a) \right) \\ & \geq -\frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2}. \end{aligned}$$

DEFINITION 2.16. A function  $v \in C(\mathcal{H})$  bounded and Lipschitz with respect to the  $B$ -norm is a solution of the HJB equation if it is at the same time a supersolution and a subsolution.

Remark 2.17. In the definition of viscosity solution we have used two kinds of test functions: those in *test1* and those in *test2*, which, as usual in the literature, play a different role. In view of their properties the functions of the first set (*test1*) represent the “good part.” More difficult is to deal with the functions of the set *test2*, which have the role of localizing the problem. A difficulty of our case is the following: The trajectory is not Lipschitz with respect to the  $\mathcal{H}$ -norm, and so, given a function  $g \in \text{test2}$ , the term

$$(14) \quad \frac{g(x(s)) - g(x)}{s}$$

(where  $x(s)$  is a trajectory starting from  $x$ ) cannot be treated with standard arguments. The idea then is to consider only a  $B$ -Lipschitz solution so that the maxima/minima considered in Definitions 2.14 and 2.15 are in  $D(A^*)$ . If the starting point  $x$  is in  $D(A^*)$ , there are some advantages in the estimate of (14), but some problems remain: In such a case we will prove in Proposition 4.5 that (if  $\alpha(\cdot)$  is continuous in 0)

$$\left| \frac{g(x(s)) - g(x)}{s} - \langle \nabla g(x), -\mu x + \alpha(0) \rangle \right| \leq \frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2} + O(s),$$

where the rest  $O(s) \xrightarrow{s \rightarrow 0} 0$  and does not depend on the control. So the most challenging case is the one described in the definition.

**3. The value function and its properties.** The value function is, as usual, the candidate unique solution of the HJB equation. In this section we define the value function  $V(\cdot)$  of the problem, and then we verify that it has the regularity properties

required to be a solution. Namely, we will check that  $V(\cdot)$  is  $B$ -Lipschitz (Proposition 3.4). To obtain such a result we prove an approximation result (Proposition 3.1) and then a suitable estimate for the solution of the state equation (Proposition 3.3).

The value function of our problem is defined as

$$V(x) \stackrel{\text{def}}{=} \inf_{(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}} J(x, \alpha(\cdot), a(\cdot)).$$

We consider the functions

$$\begin{cases} \eta_n: [0, \bar{s}] \rightarrow \mathbb{R}, \\ \eta_n(r) \stackrel{\text{def}}{=} [2n - 2n^2 r]^+ \end{cases}$$

(where  $[\cdot]^+$  is the positive part). We then define

$$\begin{cases} \mathcal{C}_n^*: \mathbb{R} \rightarrow \mathcal{H}, \\ \mathcal{C}_n^*: \gamma \mapsto \gamma \eta_n. \end{cases}$$

Such functions are linear and continuous, and their adjoints are

$$(15) \quad \begin{cases} \mathcal{C}_n: \mathcal{H} \rightarrow \mathbb{R}, \\ \mathcal{C}_n: x \mapsto \langle x, \eta_n \rangle. \end{cases}$$

The functions  $\mathcal{C}_n$  approximate the delta measure in some sense. The approximating state equations we consider are

$$(16) \quad \begin{cases} \frac{d}{ds} x_n(s) = Ax_n(s) - \mu x_n(s) + \alpha(s) + \beta \mathcal{C}_n^* a(s), \\ x_n(0) = x. \end{cases}$$

In the following proofs we will use (8) together with the mild form of the approximating state equations (that can be found in [30, page 105, equation (2.3)]):

$$(17) \quad x_n(s) = e^{-\mu s} e^{sA} x + \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} \alpha(\tau) d\tau + \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} \beta \mathcal{C}_n^* a(\tau) d\tau.$$

PROPOSITION 3.1. For  $T > 0$  and  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$

$$\lim_{n \rightarrow \infty} \sup_{s \in [0, T]} |x_n(s) - x(s)|_{\mathcal{H}} = 0.$$

*Proof.* By using (8) and (17) we find

$$(18) \quad |x(s) - x_n(s)| = \left| -A \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} (a(\tau) \nu) d\tau - \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} \beta \mathcal{C}_n^* (a(\tau)) d\tau \right|.$$

To estimate such an expression we will use the explicit expression of the two terms (as a two-variable function). We simplify the notation by using the extension  $\tilde{a}(\cdot)$  of  $a(\cdot)$  on all  $\mathbb{R}$  given by

$$\tilde{a}(s) = \begin{cases} 0 & \text{if } s < 0, \\ a(s) & \text{if } s \geq 0. \end{cases}$$

So

$$\begin{aligned}
 y(s, r) &\stackrel{def}{=} \left( -A \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} (a(\tau)\nu) d\tau \right) [r] = e^{-\frac{\mu}{\beta}r} \tilde{a}(s - r/\beta), \\
 (19) \quad y_n(s, r) &\stackrel{def}{=} \left( \int_0^s e^{-(s-\tau)\mu} e^{(s-\tau)A} \beta \mathcal{C}_n^*(a(\tau)) d\tau \right) [r] \\
 &= \int_0^{r \wedge (1/n)} e^{-\frac{\mu}{\beta}(r-\theta)} [2n - 2n^2\theta]^+ \tilde{a} \left( \frac{\theta - r}{\beta} + s \right) d\theta.
 \end{aligned}$$

Now for all  $s \in [0, T]$  we have

$$\begin{aligned}
 (20) \quad &|y(s, \cdot) - y_n(s, \cdot)|_{\mathcal{H}}^2 \\
 &\leq \left( \int_{1/n}^{\bar{s}} \left| e^{-\frac{\mu}{\beta}r} \tilde{a}(s - r/\beta) - \int_0^{1/n} e^{-\frac{\mu}{\beta}(r-\theta)} [2n - 2n^2\theta]^+ \tilde{a} \left( \frac{\theta - r}{\beta} + s \right) d\theta \right|^2 dr \right) \\
 &\quad + \left( \int_0^{1/n} \left| e^{-\frac{\mu}{\beta}r} \tilde{a}(s - r/\beta) - \int_0^r e^{-\frac{\mu}{\beta}(r-\theta)} [2n - 2n^2\theta]^+ \tilde{a} \left( \frac{\theta - r}{\beta} + s \right) d\theta \right|^2 dr \right) \\
 &\quad (\text{for } \bar{s} \leq T)
 \end{aligned}$$

$$\begin{aligned}
 (21) \quad &\leq \left( e^{|\mu|s} \int_0^T \left| e^{-\mu(\frac{r}{\beta}-s)} \tilde{a}(s - r/\beta) \right. \right. \\
 &\quad \left. \left. - \int_0^{1/n} e^{-\mu(\frac{r-\theta}{\beta}-s)} [2n - 2n^2\theta]^+ \tilde{a} \left( s + \frac{\theta - r}{\beta} \right) d\theta \right|^2 dr \right) + \left( \frac{1}{n} e^{|\mu|/\beta T} 2\|\Gamma\| \right).
 \end{aligned}$$

Such an estimate does not depend on  $s$ ; the integral term goes to zero because it is the convolution of a function in  $L^2(0, T)$  with an approximate unit, and the second goes to zero for  $n \rightarrow \infty$ .  $\square$

**PROPOSITION 3.2.** *Let  $\phi \in C^1(\mathcal{H})$  be such that  $\nabla\phi: \mathcal{H} \rightarrow D(A^*)$  is continuous. Then, for an admissible control  $(\alpha(\cdot), a(\cdot))$ , if we call  $x(\cdot)$  the trajectory starting from  $x$  and subject to the control  $(\alpha(\cdot), a(\cdot))$ , we have that, for every  $s > 0$ ,*

$$\begin{aligned}
 (22) \quad \phi(x(s)) &= \phi(x) + \int_0^s [\langle A^* \nabla\phi(x(\tau)), x(\tau) \rangle + \langle \beta\delta_0(\nabla\phi(x(\tau))), a(\tau) \rangle_{\mathbb{R}} \\
 &\quad + \langle \nabla\phi(x(\tau)), \alpha(\tau) \rangle + \langle \nabla\phi(x(\tau)), -\mu x(\tau) \rangle] d\tau.
 \end{aligned}$$

*Proof.* In the approximating state equation (16) the unbounded term  $\beta\delta_0$  does not appear ( $\beta\mathcal{C}_n^*$  are continuous), and then (see [29, Proposition 5.5, page 67]) for every  $\phi(\cdot) \in C^1(\mathcal{H})$  such that  $A^*\nabla\phi(\cdot) \in C(\mathcal{H})$  we have

$$\begin{aligned}
 (23) \quad \phi(x_n(s)) &= \phi(x) + \int_0^s [\langle A^* \nabla\phi(x_n(\tau)), x_n(\tau) \rangle + \langle \nabla\phi(x_n(\tau)), \beta\mathcal{C}_n^* a(\tau) \rangle \\
 &\quad + \langle \nabla\phi(x_n(\tau)), \alpha(\tau) \rangle + \langle \nabla\phi(x_n(\tau)), -\mu x_n(\tau) \rangle] d\tau \\
 &= \phi(x) + \int_0^s [\langle A^* \nabla\phi(x_n(\tau)), x_n(\tau) \rangle + \langle \beta\mathcal{C}_n \nabla\phi(x_n(\tau)), a(\tau) \rangle \\
 &\quad + \langle \nabla\phi(x_n(\tau)), \alpha(\tau) \rangle + \langle \nabla\phi(x_n(\tau)), -\mu x_n(\tau) \rangle] d\tau,
 \end{aligned}$$

where we passed to the adjoint in view of the continuity of the operator  $\mathcal{C}_n^*$  (see (15) for the explicit form of  $\mathcal{C}_n$ ).

Now we prove that every integral term of (23) converges to the corresponding term of (22). This fact, together with the pointwise convergence of  $\phi(x_n(s))$  to  $\phi(x(s))$  (due to Proposition 3.1), will imply the claim.

First we note that, in view of Proposition 3.1 and of the continuity of  $x$ ,  $x_n(\tau)$  is bounded uniformly in  $n$  and  $\tau \in [0, s]$ , and, in view of the continuity of  $\nabla\phi$ ,  $\nabla\phi(x_n(\tau))$  is bounded uniformly in  $n$  and  $\tau \in [0, s]$ . So we can apply the Lebesgue theorem (the pointwise convergence is given by Proposition 3.1 and  $|\alpha(\tau)| \leq \|\Sigma\|$ ), and we derive that

$$(24) \quad \int_0^s [\langle \nabla\phi(x_n(\tau)), \alpha(\tau) \rangle + \langle \nabla\phi(x_n(\tau)), -\mu x_n(\tau) \rangle] d\tau \\ \xrightarrow{n \rightarrow \infty} \int_0^s [\langle \nabla\phi(x(\tau)), \alpha(\tau) \rangle + \langle \nabla\phi(x(\tau)), -\mu x(\tau) \rangle] d\tau.$$

Next we observe that, in view of the continuity of  $A^*\nabla\phi$  and of Proposition 3.1, the term  $A^*\nabla\phi(x_n(\tau))$  is bounded uniformly in  $n$  and  $\tau \in [0, s]$ , so the same is true for

$$|A^*\nabla\phi(x_n(\tau)) - A^*\nabla\phi(x(\tau))|.$$

Therefore we can use the Lebesgue theorem (the pointwise convergence is given by Proposition 3.1) to conclude that

$$\int_0^s \langle A^*\nabla\phi(x_n(\tau)), x_n(\tau) \rangle d\tau \rightarrow \int_0^s \langle A^*\nabla\phi(x(\tau)), x(\tau) \rangle d\tau.$$

We now have to prove that

$$(25) \quad \int_0^s \langle \beta \mathcal{C}_n \nabla\phi(x_n(\tau)), a(\tau) \rangle d\tau \rightarrow \int_0^s \langle \beta \delta_0(\nabla\phi(x(\tau))), a(\tau) \rangle_{\mathbb{R}} d\tau.$$

We first note that  $\mathcal{C}_n \xrightarrow{n \rightarrow \infty} \delta_0$  in  $H^{-1}(0, \bar{s})$  and then in  $D(A^*)'$ . Indeed given  $z \in H^1(0, \bar{s})$  we have

$$(26) \quad |(\mathcal{C}_n - \delta_0)z| = \left| \int_0^{\bar{s}} z[\tau] \eta_n[\tau] d\tau - z[0] \right| \\ = \left| \int_0^{1/n} \left( z[0] + \int_0^\tau \partial_\omega z[r] dr \right) \eta_n[\tau] d\tau - z[0] \right|$$

( $\partial_\omega z$  is the weak derivative of  $z$ ), and integrating by parts

$$(27) \quad = \left| \left( z[0] + \int_0^{1/n} \partial_\omega z[r] dr \right) \left( \int_0^{1/n} \eta_n[r] dr \right) \right. \\ \left. - \int_0^{1/n} \partial_\omega z[\tau] \int_0^\tau \eta_n[r] dr d\tau - z[0] \right|$$

and then, writing  $\eta_n$  in explicit form (note that  $\int_0^{1/n} \eta_n[r] dr = 1$ ),

$$\leq \left| \int_0^{\bar{s}} \chi_{[0, 1/n]}[\tau] |\partial_\omega z[\tau]| d\tau \right| \leq \frac{1}{\sqrt{n}} \|z\|_{H^1(0, \bar{s})}.$$

In summary, by Proposition 3.1,  $x_n(\cdot) \xrightarrow{n \rightarrow \infty} x(\cdot)$  in  $C([0, T]; \mathcal{H})$ , then (by hypothesis on  $\phi$ )  $\nabla \phi(x_n(\cdot)) \xrightarrow{n \rightarrow \infty} \nabla \phi(x(\cdot))$  in  $C([0, T]; D(A^*))$ , and then, by the last estimate,  $\beta \mathcal{C}_n(\nabla \phi(x_n(\cdot))) \xrightarrow{n \rightarrow \infty} \beta \delta_0(\nabla \phi(x(\cdot)))$  in  $C([0, T]; \mathbb{R})$ . Then (25) follows by Cauchy–Schwartz inequality.  $\square$

PROPOSITION 3.3. *Given  $T > 0$  and a control  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$ , there exists  $c_T$  such that for every  $x, y \in \mathcal{H}$*

$$\sup_{s \in [0, T]} |x_x(s) - x_y(s)|_B^2 \leq c_T |x - y|_B^2,$$

where  $x_y(\cdot)$  is the solution of

$$\begin{cases} \frac{d}{ds} i^* x(s) = Ax(s) + \alpha(s) - \mu x(s) + \beta \delta_0 a(s), \\ x(0) = y \end{cases}$$

and  $x_x(\cdot)$  the solution with initial data  $x$ .

*Proof.* We use Proposition 3.2 with  $\phi(x) = \langle Bx, x \rangle$  so that  $\nabla \phi(x) = 2Bx$ . Moreover  $x_x(\cdot) - x_y(\cdot)$  satisfies the equation

$$\begin{cases} \frac{d}{ds} i^* (x_x(s) - x_y(s)) = A(x_x(s) - x_y(s)) - \mu(x_x(s) - x_y(s)), \\ (x_x - x_y)(0) = x - y \end{cases}$$

(the one of Proposition 3.2 with control identically 0), and then by (10)

$$\begin{aligned} (28) \quad |x_x(s) - x_y(s)|_B^2 &= |x - y|_B^2 + 2 \int_0^s \langle A^* B(x_x(r) - x_y(r)), (x_x(r) - x_y(r)) \rangle \\ &\quad - \mu \langle B(x_x(s) - x_y(s)), x_x(s) - x_y(s) \rangle dr \\ &\leq |x - y|_B^2 + 2(1 + |\mu|) \int_0^s \langle B(x_x(r) - x_y(r)), (x_x(r) - x_y(r)) \rangle dr. \end{aligned}$$

Finally we can use Gronwall's lemma to obtain the claim.  $\square$

PROPOSITION 3.4. *The value function  $V$  is Lipschitz with respect to the  $B$ -norm.*

*Proof.* Assume  $V(y) > V(x)$ ,  $\varepsilon > 0$ , and  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$  an  $\varepsilon$ -optimal control for  $x$ . We have

$$|V(y) - V(x)| - \varepsilon \leq \int_0^\infty e^{-\rho t} |L(x_y(s), \alpha(s), a(s)) - L(x_x(s), \alpha(s), a(s))| ds.$$

If we look, the explicit form of  $x_x(\cdot)$  and  $x_y(\cdot)$  as two-variable functions depends on the initial data only for  $s \in [0, \frac{\bar{s}}{\beta}]$  and afterwards only on the control. Indeed, for  $s > \frac{\bar{s}}{\beta}$ ,  $x_x(s) = x_y(s)$ , and the previous integral is equal to

$$\int_0^{\bar{s}/\beta} e^{-\rho t} |L(x_y(s), \alpha(s), a(s)) - L(x_x(s), \alpha(s), a(s))| ds$$

by (L1) and Proposition 3.3

$$\leq \int_0^{\bar{s}/\beta} e^{-\rho t} C_L |x_y(s) - x_x(s)|_B ds \leq \frac{\bar{s}}{\beta} c_{\bar{s}} C_L |x - y|_B.$$

By letting  $\varepsilon \rightarrow 0$  we have the thesis.  $\square$

**4. Existence and uniqueness of a solution.** In this section we will prove that the value function is a viscosity solution of the HJB equation (Theorem 4.7) and that the HJB equation admits at most one solution (Theorem 4.8).

We remind the reader that we use  $\mathcal{H}_B$  to denote the completion of  $\mathcal{H}$  in the  $B$ -norm. This notation will be used in the next propositions.

**PROPOSITION 4.1.** *Let  $u \in C(\mathcal{H})$  be a locally  $B$ -Lipschitz function. Let  $\psi \in C^1(\mathcal{H})$ , and let  $x$  be a local maximum (or a local minimum) of  $u - \psi$ . Then  $\nabla\psi(x) \in \mathcal{R}(B^{1/2}) \subseteq D(A^*)$ .*

*Proof.* We give the proof only when  $x$  is a local maximum, as the case of the minima is similar.

We take  $\omega \in \mathcal{H}$ , with  $|\omega| = 1$  and  $h \in (0, 1)$ . Then for every  $h$  small enough

$$\frac{(u(x - h\omega) - \psi(x - h\omega))}{h} \leq \frac{u(x) - \psi(x)}{h},$$

so that

$$\frac{\psi(x) - \psi(x - h\omega)}{h} \leq C|\omega|_B,$$

and by passing to the limit we have  $\langle \nabla\psi(x), \omega \rangle \leq C|\omega|_B$ . Likewise

$$\frac{(u(x + h\omega) - \psi(x + h\omega))}{h} \leq \frac{u(x) - \psi(x)}{h},$$

so that

$$\frac{\psi(x) - \psi(x + h\omega)}{h} \leq C|\omega|_B,$$

and by passing to the limit we have  $-\langle \nabla\psi(x), \omega \rangle \leq C|\omega|_B$ .

The two inequalities together then give

$$|\langle \nabla\psi(x), \omega \rangle| \leq C|\omega|_B$$

for all  $\omega \in \mathcal{H}$ . Then we can consider the linear extension to  $\mathcal{H}_B$  of the continuous linear functional  $\omega \mapsto \langle \nabla\psi(x), \omega \rangle$  that we denote with  $\Phi_x$ . By the Riesz representation theorem, we can find  $z_x \in \mathcal{H}_B$  such that

$$\Phi_x(\omega) = \langle z_x, \omega \rangle_{\mathcal{H}_B} \quad \forall \omega \in \mathcal{H}_B$$

and note afterwards that

$$\begin{aligned} (29) \quad \langle z_x, \omega \rangle_{\mathcal{H}_B} &= \left\langle B^{1/2}(z_x), B^{1/2}(\omega) \right\rangle_{\mathcal{H}} \\ &= \left\langle B^{1/2}(B^{1/2}(z_x)), \omega \right\rangle_{(\mathcal{H}_B)' \times (\mathcal{H}_B)} = \left\langle B^{1/2}(m_x), \omega \right\rangle_{(\mathcal{H}_B)' \times (\mathcal{H}_B)}, \end{aligned}$$

where  $m_x \stackrel{\text{def}}{=} (B^{1/2}(z_x)) \in \mathcal{H}$ . Now for  $\omega \in \mathcal{H}$

$$\left\langle B^{1/2}(m_x), \omega \right\rangle_{(\mathcal{H}_B)' \times (\mathcal{H}_B)} = \left\langle B^{1/2}(m_x), \omega \right\rangle_{\mathcal{H}},$$

and therefore  $\nabla\psi(x) = B^{1/2}(m_x) \in \mathcal{R}(B^{1/2}) \subseteq D(A^*)$ , where the last inclusion follows from Remark 2.6.  $\square$

**4.1. Existence.** We start by proving a lemma and two propositions that will be used to prove the existence theorem (Theorem 4.7). We will use the notation introduced in Remark 2.1 on “ $x(s)$ ” and “ $x[r]$ .” Moreover we will continue to use the symbol  $\delta_0$  in the text so that  $x[0] = \delta_0 x$  if  $x \in D(A^*)$ .

LEMMA 4.2. *Let  $x$  be a function of  $H^1(0, \bar{s})$ , and then*

$$(30) \quad (i) \lim_{s \rightarrow 0^+} \left( \int_s^{\bar{s}} \frac{(x[r] - x[r-s])^2}{s} dr \right) = 0,$$

$$(31) \quad (ii) \lim_{s \rightarrow 0^+} \left( \int_s^{\bar{s}-s} \frac{(x[r+s] - x[r])}{s} x[r] dr \right) = \frac{x^2[\bar{s}] - x^2[0]}{2}.$$

*Proof.* Part (i): We have

$$\int_s^{\bar{s}} \frac{(x[r] - x[r-s])^2}{s} dr = \int_0^{\bar{s}} \psi_s[r] dr,$$

where  $\psi_s: [0, \bar{s}] \rightarrow \mathbb{R}$  is defined in the following way:

$$\psi_s[r] = \begin{cases} 0 & \text{if } r \in [0, s), \\ \frac{(x[r] - x[r-s])^2}{s} & \text{if } r \in [s, \bar{s}]. \end{cases}$$

We prove the thesis by means of the Lebesgue theorem. First we show that  $\psi_s$  converges a.e. to zero. For  $r > s$ :

$$\psi_s[r] \leq \frac{\left| \int_{r-s}^r \partial_\omega x[\tau] d\tau \right|}{s} |x[r] - x[r-s]|,$$

where  $\partial_\omega x$  is the weak derivative of  $x$ . Now almost every  $r$  is a Lebesgue point, which implies that

$$\frac{\left| \int_{r-s}^r \partial_\omega x(\tau) d\tau \right|}{s} \xrightarrow{s \rightarrow 0^+} |\partial_\omega x[r]| \quad \text{a.e. in } r \in (0, \bar{s}),$$

while the term  $|x[r] - x[r-s]|$  goes uniformly to 0.

In order to dominate the convergence we note that by Morrey's theorem ([18, Theorem 4, page 266]) every  $x \in H^1(0, \bar{s})$  is 1/2-Holder continuous, and then there exists a positive constant  $C$  such that for every  $s \in (0, \bar{s})$  and every  $r \in [s, \bar{s}]$  we have

$$\frac{|x[r] - x[r-s]|}{\sqrt{s}} \leq C.$$

Then

$$|\psi_s[r]| \leq \frac{|x[r] - x[r-s]|^2}{s} \leq C^2,$$

and the proof of part (i) is complete.

Now we prove part (ii):

$$\begin{aligned}
 (32) \quad I(s) &\stackrel{\text{def}}{=} \int_s^{\bar{s}-s} \frac{(x[r+s] - x[r])}{s} x[r] dr \\
 &= \int_s^{\bar{s}-s} \frac{(x[r+s]x[r])}{s} dr - \int_0^{\bar{s}-2s} \frac{(x[r+s]x[r+s])}{s} dr \\
 &= - \int_s^{\bar{s}-2s} \frac{(x[r+s] - x[r])}{s} x[r+s] dr + \int_{\bar{s}-2s}^{\bar{s}-s} \frac{(x[r+s]x[r])}{s} dr \\
 &\quad + \int_0^s - \frac{(x[r+s])^2}{s} dr \stackrel{\text{def}}{=} -I_1(s) + I_2(s) + I_3(s).
 \end{aligned}$$

By the continuity of  $x$  we see that

$$I_2(s) \xrightarrow{s \rightarrow 0^+} x^2[\bar{s}]$$

and

$$I_3(s) \xrightarrow{s \rightarrow 0^+} -x^2[0].$$

Moreover, by using arguments similar to those in (i), we find that

$$\begin{aligned}
 (33) \quad \lim_{s \rightarrow 0^+} (I(s) - I_1(s)) &= \lim_{s \rightarrow 0^+} \int_s^{\bar{s}-2s} - \frac{(x[r+s] - x[r])^2}{s} dr \\
 &\quad + \lim_{s \rightarrow 0^+} \int_{\bar{s}-2s}^{\bar{s}-s} \frac{(x[r+s] - x[r])}{s} x[r] dr = 0,
 \end{aligned}$$

so, since  $I(s) + I_1(s) = I_2(s) + I_3(s)$ , the limit  $\lim_{s \rightarrow 0^+} I(s)$  exists if and only if there exists the limit  $\lim_{s \rightarrow 0^+} \frac{I_1(s) + I(s)}{2}$ , and in such a case they have the same value. As

$$\frac{I_1(s) + I(s)}{2} = \frac{I_2(s) + I_3(s)}{2} \xrightarrow{s \rightarrow 0^+} \frac{x^2[\bar{s}] - x^2[0]}{2},$$

then

$$\lim_{s \rightarrow 0^+} \left( \int_s^{\bar{s}-s} \frac{(x[r+s] - x[r])}{s} x[r] dr \right) = \frac{x^2[\bar{s}] - x^2[0]}{2}. \quad \square$$

*Notation 4.3.* We will call from now on  $O(s)$  a generic function  $O(\cdot): [0, +\infty) \rightarrow [0, +\infty)$  such that  $O(s) \xrightarrow{s \rightarrow 0^+} 0$  and  $O(0) = 0$ . In what follows such notation will be used to express in particular the estimates that do not depend on the control.

**LEMMA 4.4.** *Given  $x \in D(A^*)$ , there exists an  $O(s)$ , independent of the control, such that, for every control  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$ , we have that*

$$|x(s) - x| \leq O(s)$$

(where we called  $x(s)$  the trajectory that starts from  $x$  and subject to the control  $(\alpha(\cdot), a(\cdot))$ ).

*Proof.* We consider  $s \in (0, 1]$ . By means of (6) we have

$$\begin{aligned}
 (34) \quad \|x(s) - x\|_{\mathcal{H}}^2 &= \int_{\beta s}^{\bar{s}} \left| e^{-\mu s} x[r - \beta s] + \int_0^s e^{-\mu \tau} \alpha(s - \tau, r - \beta \tau) d\tau - x[r] \right|^2 dr \\
 &+ \int_0^{\beta s} \left| e^{-\frac{\mu}{\beta} r} a(s - r/\beta) + \int_0^{r/\beta} e^{-\mu \tau} \alpha(s - \tau, r - \beta \tau) d\tau - x[r] \right|^2 dr \\
 &\leq 2 \int_{\beta s}^{\bar{s}} |e^{-\mu s} x[r - \beta s] - x[r]|^2 dr + 2 \int_{\beta s}^{\bar{s}} \left| \int_0^s e^{|\mu|} \|\Lambda\| d\tau \right|^2 dr \\
 &\quad + \int_0^{\beta s} \left| e^{|\mu|/\beta} \|\Gamma\| + \int_0^{r/\beta} e^{|\mu|} \|\Lambda\| d\tau + |x|_{L^\infty(0, \bar{s})} \right|^2 dr,
 \end{aligned}$$

where we have used that  $x \in D(A^*) \subseteq W^{1,2}(0, \bar{s}) \subseteq L^\infty(0, \bar{s})$

$$\begin{aligned}
 (35) \quad &\leq 2 \int_0^{\bar{s}} |e^{-\mu s} x[(r - \beta s) \wedge 0] - x[r]|^2 dr + 2s^2 \bar{s} \left( e^{|\mu|} \|\Lambda\| \right)^2 \\
 &\quad + s\beta \left( e^{|\mu|/\beta} \|\Gamma\| + |x|_{L^\infty} + se^{|\mu|} \|\Lambda\| \right)^2.
 \end{aligned}$$

Observe that in this estimate the control  $(\alpha(\cdot), a(\cdot))$  does not appear. The second and the third terms go to zero for  $s \rightarrow 0$ , while for the first we can use the Lebesgue theorem by observing that

$$|e^{-\mu s} x[(r - \beta s) \wedge 0] - x[r]| \leq e^{|\mu|} |x|_{L^\infty} + |x|_{L^\infty} \quad \forall (s, r) \in (0, 1] \times [0, \bar{s}]$$

and that  $|e^{-\mu s} x[(r - \beta s) \wedge 0] - x[r]| \xrightarrow{s \rightarrow 0} 0$  pointwise.  $\square$

**PROPOSITION 4.5.** *Given  $x \in D(A^*)$  and  $g \in \text{test2}$ , there exists an  $O(s)$ , independent of the control, such that, for every control  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$ , with  $a(\cdot)$  continuous, we have that*

$$\left| \frac{g(x(s)) - g(x)}{s} - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle}{s} - \langle \nabla g(x), -\mu x \rangle \right| \leq \frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2} + O(s)$$

(where we called  $x(s)$  the trajectory that starts from  $x$  and subject to the control  $(\alpha(\cdot), a(\cdot))$ ).

*Proof.* First we observe

$$\begin{aligned}
 (36) \quad &\frac{g(x(s)) - g(x)}{s} - \langle \nabla g(x), -\mu x \rangle - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle}{s} \\
 &= \frac{g(x(s)) - g(y(s)) + g(y(s)) - g(x)}{s} - \langle \nabla g(x), -\mu x \rangle - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle}{s},
 \end{aligned}$$

where  $y(\cdot)$  is the mild solution of

$$(37) \quad \begin{cases} \dot{y}(s) = Ay(s) + \beta \delta_0 a(s), \\ y(0) = x \end{cases}$$

corresponding to (11) with  $\mu = 0$  and  $\alpha(\cdot) = 0$ . The difference  $x(s) - y(s)$  can be expressed in the mild form as

$$x(s) - y(s) = \int_0^s e^{(s-\tau)A}(\alpha(\tau) - \mu x(\tau))d\tau.$$

Now we come back to (36), and we have

$$(38) \quad \left| \frac{g(x(s)) - g(x)}{s} - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle dr}{s} - \langle \nabla g(x), -\mu x \rangle \right| \\ \leq \left| \frac{g(x(s)) - g(y(s))}{s} - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle dr}{s} - \langle \nabla g(x), -\mu x \rangle \right| + \left| \frac{g(y(s)) - g(x)}{s} \right|.$$

In order to estimate the first addendum we use the Taylor expansion as follows:

$$(39) \quad \frac{g(x(s)) - g(y(s))}{s} = \left\langle \nabla g(y(s)), \frac{x(s) - y(s)}{s} \right\rangle \\ + \left\langle \nabla g(\xi(s)) - \nabla g(y(s)), \frac{x(s) - y(s)}{s} \right\rangle,$$

where  $\xi(s)$  is a point between  $x(s)$  and  $y(s)$

$$(40) \quad = \left\langle \nabla g(y(s)), \frac{\int_0^s e^{(s-\tau)A}(\alpha(\tau) - \mu x(\tau))d\tau}{s} \right\rangle \\ + \left\langle \nabla g(\xi(s)) - \nabla g(y(s)), \frac{\int_0^s e^{(s-\tau)A}(\alpha(\tau) - \mu x(\tau))d\tau}{s} \right\rangle.$$

We know by Lemma 4.4 that  $x(s) \xrightarrow{s \rightarrow 0} x$  and  $y(s) \xrightarrow{s \rightarrow 0} x$  uniformly in the control  $(\alpha(\cdot), a(\cdot))$ , and then  $\nabla g(y(s)) \xrightarrow{s \rightarrow 0} \nabla g(x)$  uniformly in the control and  $|\nabla g(y(s)) - \nabla g(\xi(s))| \xrightarrow{s \rightarrow 0} 0$  uniformly in the control. Moreover, since in addition the control is bounded and  $x(s) \xrightarrow{s \rightarrow 0} x$  uniformly in the control, we infer that the term

$$\left| \frac{\int_0^s e^{(s-\tau)A}(\alpha(\tau) - \mu x(\tau))d\tau}{s} \right|_{\mathcal{H}}$$

is bounded uniformly in the control  $\alpha(\cdot)$  and in  $s$ . From this we conclude that the second term in (40) goes to zero uniformly in  $(\alpha(\cdot), a(\cdot))$  and that

$$(41) \quad \left| \frac{g(x(s)) - g(y(s))}{s} - \frac{\int_0^s \langle \nabla g(x), \alpha(r) \rangle dr}{s} - \langle \nabla g(x), -\mu x \rangle \right| \leq O(s)$$

for some function  $O(s)$  independent of the control.

Now we estimate the second term of (38).

We first note that

$$\nabla g(x) = g'_0(|x|) \frac{x}{|x|}$$

and

$$D^2g(x) = g_0''(|x|)\frac{x}{|x|} \otimes \frac{x}{|x|} + g_0'(|x|)\left(\frac{\mathbf{I}}{|x|} - \frac{x \otimes x}{|x|^3}\right).$$

We consider the Taylor's expansion of  $g$  at  $x$ :

$$\begin{aligned} (42) \quad \frac{g(y(s)) - g(x)}{s} &= \frac{\langle \nabla g(x), y(s) - x \rangle}{s} + \frac{1}{2} \frac{(y(s) - x)^T (D^2g(x))(y(s) - x)}{s} \\ &\quad + \frac{o(|y(s) - x|^2)}{s} \\ &= \frac{g_0'(|x|)}{|x|} \left( \left\langle x, \frac{y(s) - x}{s} \right\rangle + \frac{1}{2} \frac{\langle y(s) - x, y(s) - x \rangle}{s} \right) \\ &\quad + \frac{1}{2} \left( \frac{g_0''(|x|)}{|x|^2} - \frac{g_0'(|x|)}{|x|^3} \right) \frac{\langle x, y(s) - x \rangle^2}{s} + \frac{o(|y(s) - x|^2)}{s} \\ &\stackrel{def}{=} P1 + P2 + P3. \end{aligned}$$

First we prove that  $P2$  and  $P3$  go to zero uniformly in  $(\alpha(\cdot), a(\cdot))$ , and then we estimate  $P1$ . We proceed in three steps.

*Step 1.* There exists a constant  $C$  such that for every admissible control  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$  with  $a(\cdot)$  continuous, and every  $s \in (0, 1]^4$

$$\left| \frac{\langle x, y(s) - x \rangle}{s} \right| \leq C.$$

We observe first that the explicit solution of  $y(s)[r]$  can be found by taking  $\mu = 0$  and  $\alpha = 0$  in (6). We have

$$y(s, r) = \begin{cases} x[r - \beta s], & r \in [\beta s, \bar{s}], \\ a(s - r/\beta), & r \in [0, \beta s), \end{cases}$$

so

$$\begin{aligned} (43) \quad \frac{\langle x, y(s) - x \rangle}{s} &= \int_{\beta s}^{\bar{s}} x[r] \frac{(x[r - \beta s] - x[r])}{s} dr + \frac{\int_0^{\beta s} x[r](a(s - r/\beta) - x[r]) dr}{s} \\ &= \int_{\beta s}^{\bar{s} - \beta s} x[r] \frac{(x[r + \beta s] - x[r])}{s} dr + \frac{\int_{\bar{s} - \beta s}^{\bar{s}} -x^2[r] dr}{s} + \frac{\int_0^{\beta s} x[r]x[r + \beta s] dr}{s} \\ &\quad + \frac{\int_0^{\beta s} x[r]a(s - r/\beta) dr}{s} - \frac{\int_0^{\beta s} x^2[r] dr}{s}. \end{aligned}$$

When  $s \rightarrow 0$ , the third and the fifth terms have opposite limits, while the second goes to zero as  $x$  is continuous and  $x(\bar{s}) = 0$ . The first term goes to  $-\frac{\beta}{2}x^2[0] = \langle A^*x, x \rangle$  in view of Lemma 4.2. The control appears only in the fourth term that we estimate as follows:

$$\left| \frac{\int_0^{\beta s} x[r]a(s - r/\beta) dr}{s} \right| \leq \frac{\int_0^{\beta s} |x[r]| \|\Gamma\| dr}{s} \leq \beta \max_{r \in [0, \bar{s}]} |x[r]| \|\Gamma\|.$$

<sup>4</sup>In the expression of  $y(\cdot)$  the distributed control  $\alpha(\cdot)$  does not appear, so we will speak from now on only of the boundary control  $a(\cdot)$

*Step 2.* There exists a constant  $C$  such that for every admissible control  $a(\cdot) \in \mathcal{A}$ , with  $a(\cdot)$  continuous, and every  $s \in (0, 1]$

$$\frac{|y(s) - x|^2}{s} \leq C.$$

Indeed

$$(44) \quad \left| \frac{\langle y(s) - x, y(s) - x \rangle}{s} \right| = \left| \int_{\beta s}^{\bar{s}} \frac{(x[r - \beta s] - x[r])^2}{s} dr \right| + \left| \frac{\int_0^{\beta s} (a(s - r/\beta) - x[r])^2 dr}{s} \right|,$$

since  $x \in D(A^*) \subseteq H^1(0, \bar{s})$  and Lemma 4.2 holds; then the first term goes to zero. Moreover the second term is less than or equal to

$$(45) \quad \frac{\int_0^{\beta s} \|\Gamma\|^2 dr}{s} + \frac{\int_0^{\beta s} 2|x[r]||\|\Gamma\| dr}{s} + \frac{\int_0^{\beta s} |x[r]|^2 dr}{s} \leq C.$$

This completes Step 2.

From Step 2 it follows that

$$\frac{o(|y(s) - x|^2)}{s} = \frac{o(|y(s) - x|^2)}{|y(s) - x|^2} \frac{|y(s) - x|^2}{s} \xrightarrow{s \rightarrow 0^+} 0$$

uniformly in  $a(\cdot)$ . Thus  $|P3| \xrightarrow{s \rightarrow 0} 0$  uniformly in  $a(\cdot)$ . Moreover

$$\frac{\langle x, y(s) - x \rangle^2}{s} \leq \frac{|\langle x, y(s) - x \rangle|}{s} |x| |y(s) - x|,$$

and then, from Step 1 and Lemma 4.4,  $|P2| \xrightarrow{s \rightarrow 0} 0$  uniformly in  $a(\cdot)$ .

*Step 3. (Conclusion.)* We now estimate  $P1$ . We can write a more explicit form of  $P1$  as in the proofs of Steps 1 and 2 ((43), (44), and (45)), and by using the same arguments we can see that there exists a function  $O(s)$  (depending only on  $x$  and independent of the control) such that for every continuous control  $a(\cdot)$

$$(46) \quad P1 = \frac{g'_0(|x|)}{|x|} \left( \langle A^* x, x \rangle + \frac{\int_0^{\beta s} x[s] a(s - r/\beta) dr}{s} + \frac{1}{2} \frac{\int_0^{\beta s} (a(s - r/\beta))^2 dr}{s} \right. \\ \left. + \frac{1}{2} \frac{\int_0^{\beta s} x^2[r] dr}{s} + \frac{1}{2} \frac{\int_0^{\beta s} -2x[r] a(s - r/\beta) dr}{s} \right) + O(s).$$

The fourth term above does not depend on the control and converges to  $\beta \frac{x[0]^2}{2}$  that is the opposite of the first term. The second and the fifth terms are opposite. Then we have that

$$P1 = O(s) + \frac{g'_0(|x|)}{|x|} \left( \frac{1}{2} \frac{\int_0^{\beta s} (a(s - r/\beta))^2 dr}{s} \right) \leq O(s) + \frac{1}{2} \frac{g'_0(|x|)}{|x|} \beta \|\Gamma\|^2.$$

Now, by using the estimates on  $P1$ ,  $P2$ , and  $P3$ , we see that

$$\left| \frac{g(y(s)) - g(x)}{s} \right| \leq O(s) + \frac{1}{2} \frac{g'_0(|x|)}{|x|} \beta \|\Gamma\|^2.$$

By using this fact and (41) in (38), we have proved the proposition.  $\square$

**PROPOSITION 4.6.** *If  $x \in D(A^*)$  and  $\phi \in \text{test1}$ , then there exists an  $O(s)$ , independent of the control, such that, for every control  $(\alpha(\cdot), a(\cdot)) \in \mathcal{E} \times \mathcal{A}$ , with  $a(\cdot)$  continuous, we have that*

$$(47) \quad \left| \frac{\phi(x(s)) - \phi(x)}{s} - \frac{\int_0^s \langle \nabla \phi(x), \alpha(r) \rangle dr}{s} - \langle \nabla \phi(x), -\mu x \rangle - \langle A^* \nabla \phi(x), x \rangle - \frac{\int_0^s \langle \beta \delta_0(\nabla \phi(x)), a(r) \rangle_{\mathbb{R}} dr}{s} \right| \leq O(s)$$

(where we called  $x(s)$  the trajectory that starts from  $x$  and subject to the control  $(\alpha(\cdot), a(\cdot))$ ).

*Proof.* We proceed as in the proof of Proposition 4.5 by observing that

$$\frac{\phi(x(s)) - \phi(x)}{s} = \frac{\phi(x(s)) - \phi(y(s))}{s} + \frac{\phi(y(s)) - \phi(x)}{s},$$

where  $y(\cdot)$  is the solution of (37). It is possible to prove, by using exactly the same arguments in the proof of Proposition 4.5, that

$$\left| \frac{\phi(x(s)) - \phi(y(s))}{s} - \langle \nabla \phi(x), -\mu x \rangle - \frac{\int_0^s \langle \nabla \phi(x), \alpha(r) \rangle dr}{s} \right| \leq O(s),$$

where  $O(s)$  does not depend on the control. What is left to show is

$$\left| \frac{\phi(y(s)) - \phi(x)}{s} - \langle A^* \nabla \phi(x), x \rangle - \frac{\int_0^s \beta \langle \delta_0 \nabla \phi(x), a(r) \rangle_{\mathbb{R}} dr}{s} \right| \leq O(s),$$

where  $O(s)$  does not depend on the control.

We write

$$(48) \quad \frac{\phi(y(s)) - \phi(x)}{s} = I_0 + I_1 \stackrel{\text{def}}{=} \left\langle \nabla \phi(x), \frac{y(s) - x}{s} \right\rangle + \left\langle \nabla \phi(\xi(s)) - \nabla \phi(x), \frac{y(s) - x}{s} \right\rangle,$$

where  $\xi(s)$  is a point between  $x$  and  $y(s)$ . In view of Lemma 4.4,  $|y(s) - x| \xrightarrow{s \rightarrow 0} 0$  uniformly in the control, so that  $|\xi(s) - x| \xrightarrow{s \rightarrow 0} 0$  uniformly in  $a(\cdot)$ . By hypothesis  $\nabla \phi: \mathcal{H} \rightarrow D(A^*)$  is continuous so that

$$(49) \quad |\nabla \phi(\xi(s)) - \nabla \phi(x)|_{D(A^*)} \xrightarrow{s \rightarrow 0} 0$$

uniformly in  $a(\cdot)$ .

If we read (37) in  $D(A^*)'$  it appears as an equation of the form

$$\begin{cases} \dot{u}(t) = \bar{A}u(t) + f(t), \\ u(0) = x, \end{cases}$$

where  $f(t)$  is a bounded measurable function, with  $|f(t)|_{D(A^*)'} \leq \beta|\delta_0|_{D(A^*)'}\|\Gamma\|$ , and  $\bar{A}$  is an extension of  $A$  that generates a  $C_0$ -semigroup on  $D(A^*)'$ . So<sup>5</sup> we can choose a constant  $C$  that depends on  $x$  such that, for all admissible continuous control  $a(\cdot)$  and all  $s \in (0, 1]$ ,

$$(50) \quad \frac{|y(s) - x|_{D(A^*)'}}{s} \leq C.$$

Thus from (49) and (50), we can say that  $|I_1| \xrightarrow{s \rightarrow 0} 0$  uniformly in  $a(\cdot)$ . Therefore

$$\left| \frac{\phi(y(s)) - \phi(x)}{s} - \frac{\langle \nabla \phi(x), y(s) - x \rangle}{s} \right| \xrightarrow{s \rightarrow 0} 0$$

uniformly in  $a(\cdot)$ . We now write

$$\begin{aligned} (51) \quad \frac{\langle \nabla \phi(x), y(s) - x \rangle}{s} &= \int_{\beta s}^{\bar{s}} \nabla \phi(x)[r] \frac{(x[r - \beta s] - x[r])}{s} dr \\ &\quad + \frac{\int_0^{\beta s} \nabla \phi(x)[r] (a(s - r/\beta) - x[r]) dr}{s} \\ &= \int_{\beta s}^{\bar{s} - \beta s} x[r] \frac{\nabla \phi(x)[r + \beta s] - \nabla \phi(x)[r]}{s} dr + \int_{\bar{s} - \beta s}^{\bar{s}} \frac{(-\nabla \phi(x)[r] x[r])}{s} dr \\ &\quad + \frac{\int_0^{\beta s} (\nabla \phi(x)[r + \beta s] x[r]) dr}{s} + \frac{\int_0^{\beta s} \nabla \phi(x)[r] a(s - r/\beta) dr}{s} \\ &\quad + \frac{\int_0^{\beta s} -\nabla \phi(x)[r] x[r] dr}{s}. \end{aligned}$$

The third and the fifth terms, which do not depend on the control, have opposite limits, the second goes to zero because  $\nabla \phi(x)$  and  $x$  are in  $D(A^*)$ , and then  $x[\bar{s}] = 0 = \nabla \phi(x)[\bar{s}]$ . The first term tends to  $\langle A^* \nabla \phi(x), x \rangle$ . Finally we observe that the only term that depends on the control is the fourth and

$$\left| \frac{\int_0^{\beta s} \nabla \phi(x)[r] a(s - r/\beta) dr}{s} - \beta \frac{\int_0^s \nabla \phi(x)[0] a(s - r') dr'}{s} \right| \xrightarrow{s \rightarrow 0} 0$$

uniformly in  $a(\cdot)$  and, since  $\phi(x)[0]$  is a constant,

$$\beta \frac{\int_0^s \nabla \phi(x)[0] a(s - r) dr}{s} = \frac{\int_0^s \langle \beta \delta_0 \nabla \phi(x), a(r) \rangle_{\mathbb{R}} dr}{s}.$$

This complete the proof.  $\square$

We can now prove that the value function is a solution of the HJB equation.

**THEOREM 4.7.** *The value function  $V$  is bounded and  $B$ -Lipschitz, and it is a solution of the HJB equation.*

<sup>5</sup>In view of the fact that  $x$  is in  $\mathcal{H} \subseteq D(\bar{A}) \subseteq D(A^*)'$ ; see [20] for a proof.

*Proof.* The boundedness of  $V$  follows from the boundedness of  $L$  (assumption (L2)). The  $B$ -Lipschitz property is the result of Proposition 3.4. It remains to verify that  $V$  is a solution of the HJB equation.

**$V$  is a subsolution:** Let  $x$  be a local maximum of  $V - (\phi + g)$  for  $\phi \in \text{test1}$  and  $g \in \text{test2}$ . Due to Proposition 4.1 we know that  $\nabla(\phi + g)(x) \in D(A^*)$ . Moreover we know that  $\nabla\phi(x) \in D(A^*)$  for the definition of the set  $\text{test1}$ . So  $\nabla g(x) = g'_0(|x|) \frac{x}{|x|} \in D(A^*)$ , which implies that  $x \in D(A^*)$ . We can assume that  $V(x) - (\phi + g)(x) = 0$ . We consider the constant control  $(\alpha(\cdot), a(\cdot)) \equiv (\alpha, a) \in \Sigma \times \Gamma$  and  $x(s)$  the trajectory starting from  $x$  and subject to  $(\alpha, a)$ . Then for  $s$  small enough

$$V(x(s)) - (\phi + g)(x(s)) \leq V(x) - (\phi + g)(x),$$

and thanks to Bellman's principle of optimality we know that

$$V(x) \leq e^{-\rho s} V(x(s)) + \int_0^s e^{-\rho r} L(x(r), \alpha, a) dr,$$

so that

$$(52) \quad \frac{1 - e^{-\rho s}}{s} V(x(s)) - \frac{\phi(x(s)) - \phi(x)}{s} - \frac{g(x(s)) - g(x)}{s} - \frac{\int_0^s e^{-\rho r} L(x(r), \alpha, a) dr}{s} \leq 0.$$

By using Propositions 4.5 and 4.6 and letting  $s \rightarrow 0$ , we obtain

$$(53) \quad \begin{aligned} & \rho V(x) - \langle \nabla\phi(x), -\mu x \rangle - \langle \nabla g(x), -\mu x \rangle \\ & - \left( \langle A^* \nabla\phi(x), x \rangle + \langle \beta \delta_0(\nabla\phi(x)), a \rangle_{\mathbb{R}} + \langle \nabla\phi(x), \alpha \rangle + \langle \nabla g(x), \alpha \rangle + L(x, \alpha, a) \right) \\ & \leq \frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2}. \end{aligned}$$

By taking the  $\inf_{(\alpha, a) \in \Sigma \times \Gamma}$  we obtain the subsolution inequality.

**$V$  is a supersolution:** Let  $\phi \in \text{test1}$  and  $g \in \text{test2}$  and  $x$  be a minimum for  $V + (\phi + g)$  and such that  $V + (\phi + g)(x) = 0$ . Then as observed above  $x \in D(A^*)$ . For some  $\varepsilon > 0$  let  $(\alpha_\varepsilon(\cdot), a_\varepsilon(\cdot))$  be an  $\varepsilon^2$ -optimal strategy. With no loss of generality we can assume  $a_\varepsilon(\cdot)$  continuous. We call  $x(s)$  the trajectory starting from  $x$  and subject to  $(\alpha_\varepsilon(\cdot), a_\varepsilon(\cdot))$ . Now for  $s$  small enough

$$V(x(s)) + (\phi + g)(x(s)) \geq V(x) + (\phi + g)(x),$$

and due to the  $\varepsilon^2$ -optimality and Bellman's principle we know that

$$V(x) + \varepsilon^2 \geq e^{-\rho s} V(x(s)) + \int_0^s e^{-\rho r} L(x(r), \alpha_\varepsilon(r), a_\varepsilon(r)) dr.$$

Then for  $s = \varepsilon$  we have

$$(54) \quad \frac{1 - e^{-\rho \varepsilon}}{\varepsilon} V(x(\varepsilon)) + \frac{\phi(x(\varepsilon)) - \phi(x)}{\varepsilon} + \frac{g(x(\varepsilon)) - g(x)}{\varepsilon} - \frac{\int_0^\varepsilon e^{-\rho r} L(x(r), \alpha_\varepsilon(r), a_\varepsilon(r)) dr}{\varepsilon} + \frac{\varepsilon^2}{\varepsilon} \geq 0.$$

In view of Propositions 4.5 and 4.6 we can choose, independently of the control  $(\alpha_\varepsilon(\cdot), a_\varepsilon(\cdot))$ , an  $O(s)$  such that:

$$(55) \quad \rho V(x) + \langle A^* \nabla \phi(x), x \rangle + \langle \nabla \phi(x) + \nabla g(x), -\mu x \rangle \\ - \left( \frac{\int_0^\varepsilon \langle -\beta \delta_0(\nabla \phi(x), a_\varepsilon(r)) \rangle_{\mathbb{R}} + e^{-\rho r} L(x, \alpha_\varepsilon(r), a_\varepsilon(r)) dr}{\varepsilon} \right. \\ \left. - \frac{\int_0^\varepsilon \langle \nabla \phi(x) + \nabla g(x), \alpha_\varepsilon(r) \rangle dr}{\varepsilon} \right) \geq O(\varepsilon) - \frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2}.$$

Next we take the infimum as  $\alpha$  and  $a$  varying in  $\Sigma \times \Gamma$  inside the integral and let  $\varepsilon \rightarrow 0$  to obtain that

$$(56) \quad \rho V(x) + \langle A^* \nabla \phi(x), x \rangle + \langle \nabla \phi(x) + \nabla g(x), -\mu x \rangle \\ - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( -\langle \beta \delta_0(\nabla \phi(x)), a \rangle_{\mathbb{R}} + L(x, \alpha, a) - \langle \nabla \phi(x) + \nabla g(x), \alpha \rangle \right) \\ \geq -\frac{g'_0(|x|)}{|x|} \beta \frac{\|\Gamma\|^2}{2}$$

(we observe again that the fact that  $O(s) \xrightarrow{\varepsilon \rightarrow 0} 0$  uniformly in the control is essential). Therefore  $V$  is a solution of the HJB equation.  $\square$

**4.2. Uniqueness.** Now we prove a uniqueness result in the case  $\mu \neq 0$ . The proof of the case  $\mu = 0$  is similar with minor changes.

**THEOREM 4.8.** *Given a supersolution  $v$  of the HJB equation and a subsolution  $u$  we have*

$$u(x) \leq v(x) \text{ for every } x \in \mathcal{H}.$$

*In particular there exists at most one solution of the HJB equation.*

*Proof.* We proceed by contradiction. Assume that  $u$  is a subsolution of the HJB equation and  $v$  a supersolution, and suppose that there exists  $\tilde{x} \in \mathcal{H}$  and  $\gamma > 0$  such that

$$(u(\tilde{x}) - v(\tilde{x})) > \frac{3\gamma}{\rho} > 0.$$

We choose  $\gamma < 1$ . Given  $\vartheta > 0$  small enough we have

$$(57) \quad u(\tilde{x}) - v(\tilde{x}) - \vartheta |\tilde{x}|^2 > \frac{2\gamma}{\rho} > 0.$$

We consider  $\varepsilon > 0$  and  $\psi: \mathcal{H} \times \mathcal{H} \rightarrow \mathbb{R}$  given by

$$\psi(x, y) \stackrel{def}{=} u(x) - v(y) - \frac{1}{2\varepsilon} |B^{1/2}(x - y)|^2 - \frac{\vartheta}{2} |x|^2 - \frac{\vartheta}{2} |y|^2.$$

Thanks to the boundedness of  $u$  and  $v$ , chosen  $\vartheta > 0$ , there exist  $R_\vartheta > 0$  such that

$$(58) \quad \psi(0, 0) \geq \left( \sup_{(|x| \geq R_\vartheta) \text{ or } (|y| \geq R_\vartheta)} (\psi(x, y)) \right) + 1.$$

We set

$$S = \{(x, y) \in \mathcal{H} \times \mathcal{H} : |x| \leq R_\vartheta \text{ and } |y| \leq R_\vartheta\}.$$

If we choose  $R_\vartheta$  big enough  $\tilde{x} \in S$ . By standard techniques (see [29, page 252]), given  $\sigma > 0$ , we can find  $p$  and  $q$  in  $\mathcal{H}$ , with  $|p| < \sigma$  and  $|q| < \sigma$ , and such that

$$(x, y) \mapsto \psi(x, y) - \langle Bp, x \rangle - \langle Bq, y \rangle$$

attains a maximum  $(\bar{x}, \bar{y})$  in  $\bar{S}$ . If we choose  $\sigma$  small enough (for example, such that  $\sigma \|B\| R_\vartheta < \frac{1}{4} \frac{\gamma}{\rho}$ ), we know from (58) that such a maximum is in the interior of  $S$  and, thanks to (57), that

$$\psi(\bar{x}, \bar{y}) - \langle Bp, \bar{x} \rangle - \langle Bq, \bar{y} \rangle > \frac{3\gamma}{2\rho}.$$

Moreover

$$(59) \quad \psi(\bar{x}, \bar{y}) > \frac{\gamma}{\rho} \quad \text{and so} \quad u(\bar{x}) - v(\bar{y}) > \frac{\gamma}{\rho}.$$

In order to find an estimate in contradiction with (59) we prove some preliminary estimates.

**Estimates 1 (on  $\varepsilon$ ):** We observe that

$$\begin{cases} M: (0, 1] \rightarrow \mathbb{R}, \\ M: \varepsilon \mapsto \sup_{(x, y) \in \mathcal{H} \times \mathcal{H}} \left( u(x) - v(y) - \frac{1}{2\varepsilon} |B^{1/2}(x - y)|^2 \right) \end{cases}$$

is nonincreasing and bounded and so it admits a limit for  $\varepsilon \rightarrow 0^+$ . So there exists a  $\bar{\varepsilon} > 0$  such that for every  $\varepsilon_1, \varepsilon_2 \in (0, \bar{\varepsilon}]$  we have that

$$(60) \quad |M(\varepsilon_1) - M(\varepsilon_2)| < \left( \frac{\gamma}{16(1 + |\mu|)} \right)^2.$$

We choose now  $\varepsilon$  that will be fixed in the proof:

$$(61) \quad \varepsilon := \min \left\{ \bar{\varepsilon}, \frac{1}{32C_L^2} \right\}$$

( $C_L$  is the constant introduced in hypotheses (L1) and (L2)). This concludes the estimates on  $\varepsilon$ .

Now we state and prove a claim that we will use in the estimate on  $\sigma$  and  $\vartheta$ .

*Claim.* If  $\tilde{x} \in \mathcal{H}$  and  $\tilde{y} \in \mathcal{H}$  satisfy

$$(62) \quad u(\tilde{x}) - v(\tilde{y}) - \frac{1}{2\varepsilon} |B^{1/2}(\tilde{x} - \tilde{y})|^2 \geq M(\varepsilon) - \left( \frac{\gamma}{16(1 + |\mu|)} \right)^2,$$

then

$$(63) \quad \frac{1}{\varepsilon} |B^{1/2}(\tilde{x} - \tilde{y})|^2 \leq \frac{1}{32} \left( \frac{\gamma}{(1 + |\mu|)} \right)^2.$$

*Proof of the claim.* (We follow the idea used in Lemma 3.2 of [16])

$$\begin{aligned}
 (64) \quad M(\varepsilon/2) &\geq u(\tilde{x}) - y(\tilde{y}) - \frac{1}{4\varepsilon} \left| B^{1/2}(\tilde{x} - \tilde{y}) \right|^2 \\
 &= u(\tilde{x}) - y(\tilde{y}) - \frac{1}{2\varepsilon} \left| B^{1/2}(\tilde{x} - \tilde{y}) \right|^2 + \frac{1}{4\varepsilon} \left| B^{1/2}(\tilde{x} - \tilde{y}) \right|^2 \\
 &\geq M(\varepsilon) - \left( \frac{\gamma}{16(1+|\mu|)} \right)^2 + \frac{1}{4\varepsilon} \left| B^{1/2}(\tilde{x} - \tilde{y}) \right|^2,
 \end{aligned}$$

so that

$$\begin{aligned}
 (65) \quad \frac{1}{4\varepsilon} \left| B^{1/2}(\tilde{x} - \tilde{y}) \right|^2 &\leq M(\varepsilon/2) - M(\varepsilon) + \left( \frac{\gamma}{16(1+|\mu|)} \right)^2 \\
 &\leq \left( \frac{\gamma}{16(1+|\mu|)} \right)^2 + \left( \frac{\gamma}{16(1+|\mu|)} \right)^2 = 2 \left( \frac{\gamma}{16(1+|\mu|)} \right)^2,
 \end{aligned}$$

where the inequality  $M(\varepsilon/2) - M(\varepsilon) < \left( \frac{\gamma}{16(1+|\mu|)} \right)^2$  follows from the definition of  $\varepsilon$  (61) that implies  $\varepsilon \leq \bar{\varepsilon}$  and then (60). The claim follows.

Note that from (61) we have

$$\frac{1}{\sqrt{\varepsilon}} \geq 4\sqrt{2}C_L,$$

and then, if  $\tilde{x}, \tilde{y}$  satisfy the hypothesis (62) of the claim, we have

$$(66) \quad C_L |\tilde{x} - \tilde{y}|_B \leq \frac{\gamma}{32(1+|\mu|)}.$$

**Estimates 2 (on  $\sigma$ ):** We have already imposed  $\sigma < \frac{\gamma/\rho}{4\|B\|R_\vartheta}$  we set here and in the following

$$(67) \quad \sigma = \min \left\{ \frac{\gamma}{8\rho\|B\|R_\vartheta}, \vartheta, \frac{\vartheta}{R_\vartheta} \right\},$$

so that

$$(68) \quad \sigma \xrightarrow{\vartheta \rightarrow 0} 0$$

and

$$(69) \quad \sigma R_\vartheta \xrightarrow{\vartheta \rightarrow 0} 0.$$

We recall that we have already fixed  $\varepsilon$  in (61). From the choice of  $\sigma$  (67) follows that

$$(70) \quad |\langle Bp, \bar{x} \rangle| \leq \|B\|\sigma R_\vartheta \xrightarrow{\vartheta \rightarrow 0} 0, \quad |\langle Bq, \bar{y} \rangle| \leq \|B\|\sigma R_\vartheta \xrightarrow{\vartheta \rightarrow 0} 0.$$

Moreover, in view of the continuity of the linear operator  $A^*B: \mathcal{H} \rightarrow \mathcal{H}$  with norm  $\|A^*B\|$ , we have

$$(71) \quad |\langle A^*Bp, \bar{x} \rangle| \leq \|A^*B\|\sigma R_\vartheta \xrightarrow{\vartheta \rightarrow 0} 0, \quad |\langle A^*Bq, \bar{y} \rangle| \leq \|B\|\sigma R_\vartheta \xrightarrow{\vartheta \rightarrow 0} 0.$$

This concludes the estimates on  $\sigma$ .

**Estimates 3 (on  $\vartheta$ ):** One can prove that with fixed  $\varepsilon$  we have

$$(72) \quad \vartheta |\bar{x}|^2 \xrightarrow{\vartheta \rightarrow 0} 0, \quad \vartheta |\bar{y}|^2 \xrightarrow{\vartheta \rightarrow 0} 0$$

(it is a quite standard fact; see, for example, [16]). So

$$(73) \quad \lim_{\vartheta \rightarrow 0} (\psi(\bar{x}, \bar{y}) - \langle Bp, \bar{x} \rangle - \langle Bq, \bar{y} \rangle) \\ = \sup_{(x,y) \in \mathcal{H} \times \mathcal{H}} \left( x(x) - v(y) - \frac{1}{2\varepsilon} \left| B^{1/2}(x-y) \right|^2 \right) > 2\frac{\gamma}{\rho}$$

(where the last inequality follows from (57)). In (67) we chose  $\sigma$  as a function of  $\vartheta$ , and now we fix  $\vartheta$ . We begin by taking

$$\vartheta < \frac{\gamma}{64\beta\|\Gamma\|^2}$$

so that

$$(74) \quad \beta\vartheta\|\Gamma\|^2 < \frac{\gamma}{64}.$$

We know from (70) and (71) that, if we choose  $\vartheta$  small enough, we have

$$(75) \quad |\mu| |\langle Bp, \bar{x} \rangle| < \frac{\gamma}{16}, \quad |\mu| |\langle Bq, \bar{y} \rangle| < \frac{\gamma}{16}, \\ |\langle A^*Bp, \bar{x} \rangle| < \frac{\gamma}{16}, \quad |\langle A^*Bq, \bar{y} \rangle| < \frac{\gamma}{16}.$$

From (72) we know that, if we choose  $\vartheta$  small enough, we have

$$(76) \quad |\mu|\vartheta |\bar{x}|^2 < \frac{\gamma}{32}, \quad |\mu|\vartheta |\bar{y}|^2 < \frac{\gamma}{32}.$$

Moreover (72) implies also that

$$\vartheta |\bar{x}| \xrightarrow{\vartheta \rightarrow 0} 0, \quad \vartheta |\bar{y}| \xrightarrow{\vartheta \rightarrow 0} 0,$$

and then, if we choose  $\vartheta$  small enough, we have

$$(77) \quad \vartheta \|\Sigma\| (|\bar{x}| + |\bar{y}|) < \frac{\gamma}{32}.$$

Moreover in view of (73) we know that, if we choose  $\vartheta$  small enough, then  $\bar{x}$  and  $\bar{y}$  satisfy the hypothesis (62) of the claim, and then, from (63), we have

$$(78) \quad \frac{1}{\varepsilon} \left| B^{1/2}(\bar{x} - \bar{y}) \right|^2 \leq \frac{1}{32} \left( \frac{\gamma}{(1+|\mu|)} \right)^2 \leq \frac{1}{32} \frac{\gamma}{(1+|\mu|)} \leq \frac{\gamma}{32}$$

(we took  $0 < \gamma < 1$  and then  $\gamma^2 < \gamma$ ). From (63) in the same way we obtain

$$(79) \quad \frac{|\mu|}{\varepsilon} \left| B^{1/2}(\bar{x} - \bar{y}) \right|^2 \leq \frac{\gamma}{32}$$

and, from (66),

$$(80) \quad C_L \left| B^{1/2}(\bar{x} - \bar{y}) \right| \leq \frac{\gamma}{32}.$$

Eventually, if we choose  $\vartheta$  small enough in (68), we have

$$(81) \quad 2\|B\|\|p\|\|\Sigma\| \leq 2\|B\|\|\sigma\|\|\Sigma\| \leq \frac{\gamma}{64}$$

and

$$(82) \quad 2\sigma\beta\|\delta_0 \circ B\|\|\Gamma\| \leq \frac{\gamma}{32},$$

where  $\|\delta_0 \circ B\|$  is the norm of the linear continuous functional  $\delta_0 \circ B: \mathcal{H} \rightarrow \mathbb{R}$ .

Finally we fix  $\vartheta > 0$  small enough to satisfy (75), (76), (77), (78), (79) (80), (81), and (82).

Now we proceed with the proof of the theorem. The map

$$x \mapsto u(x) - \left( \frac{1}{2\varepsilon} |B^{1/2}(x - \bar{y})|^2 + \frac{\vartheta}{2} |x|^2 + \langle Bp, x \rangle \right)$$

attains a maximum at  $\bar{x}$ , and

$$y \mapsto v(y) + \left( \frac{1}{2\varepsilon} |B^{1/2}(\bar{x} - y)|^2 + \frac{\vartheta}{2} |y|^2 + \langle Bq, y \rangle \right)$$

attains a minimum at  $\bar{y}$ .

Note that, due to Proposition 4.1,  $\bar{x}$  and  $\bar{y}$  are in  $D(A^*)$ . We can now use the definition of sub- and supersolution to obtain

$$(83) \quad \begin{aligned} & \rho u(\bar{x}) - \frac{1}{\varepsilon} \langle A^* B(\bar{x} - \bar{y}), \bar{x} \rangle - \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), -\mu \bar{x} \rangle - \langle A^* Bp, \bar{x} \rangle \\ & - \langle Bp, -\mu \bar{x} \rangle - \vartheta \langle \bar{x}, -\mu \bar{x} \rangle - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} + \langle \beta \delta_0(Bp), a \rangle_{\mathbb{R}} \right. \\ & \left. + \vartheta \langle \bar{x}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle + \langle Bp, \alpha \rangle + L(\bar{x}, \alpha, a) \right) \leq \frac{\vartheta \beta \|\Gamma\|^2}{2} \end{aligned}$$

and

$$(84) \quad \begin{aligned} & \rho v(\bar{y}) - \frac{1}{\varepsilon} \langle A^* B(\bar{x} - \bar{y}), \bar{y} \rangle - \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), -\mu \bar{y} \rangle + \langle A^* Bq, \bar{y} \rangle \\ & + \langle Bq, -\mu \bar{y} \rangle + \vartheta \langle \bar{y}, -\mu \bar{y} \rangle - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} - \langle \beta \delta_0(Bq), a \rangle_{\mathbb{R}} \right. \\ & \left. - \vartheta \langle \bar{y}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle - \langle Bq, \alpha \rangle + L(\bar{y}, \alpha, a) \right) \geq -\frac{\vartheta \beta \|\Gamma\|^2}{2}. \end{aligned}$$

The two estimates together give

$$\begin{aligned}
 (85) \quad & \rho u(\bar{x}) - \rho v(\bar{y}) - \frac{1}{\varepsilon} \langle A^* B(\bar{x} - \bar{y}), (\bar{x} - \bar{y}) \rangle \\
 & - \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), -\mu(\bar{x} - \bar{y}) \rangle - \langle A^* Bp, \bar{x} \rangle - \langle A^* Bq, \bar{y} \rangle \\
 & - \langle Bp, -\mu\bar{x} \rangle - \langle Bq, -\mu\bar{y} \rangle - \vartheta \langle \bar{x}, -\mu\bar{x} \rangle - \vartheta \langle \bar{y}, -\mu\bar{y} \rangle \\
 & - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} + \langle \beta \delta_0(Bp), a \rangle_{\mathbb{R}} \right. \\
 & \left. + \vartheta \langle \bar{x}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle + \langle Bp, \alpha \rangle + L(\bar{x}, \alpha, a) \right) \\
 & + \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} - \langle \beta \delta_0(Bq), a \rangle_{\mathbb{R}} \right. \\
 & \left. - \vartheta \langle \bar{y}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle - \langle Bq, \alpha \rangle + L(\bar{y}, \alpha, a) \right) \leq \beta \vartheta \|\Gamma\|^2.
 \end{aligned}$$

We now note that from (10)  $A^* B \leq B$ , and then we have

$$(86) \quad -\frac{1}{\varepsilon} \langle A^* B(\bar{x} - \bar{y}), (\bar{x} - \bar{y}) \rangle \geq -\frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), (\bar{x} - \bar{y}) \rangle = -\frac{1}{\varepsilon} |\bar{x} - \bar{y}|_B^2.$$

Moreover we observe that

$$\begin{aligned}
 (87) \quad & - \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} + \langle \beta \delta_0(Bp), a \rangle_{\mathbb{R}} \right. \\
 & \left. + \vartheta \langle \bar{x}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle + \langle Bp, \alpha \rangle + L(\bar{x}, \alpha, a) \right) \\
 & + \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( \frac{1}{\varepsilon} \langle \beta \delta_0(B(\bar{x} - \bar{y})), a \rangle_{\mathbb{R}} - \langle \beta \delta_0(Bq), a \rangle_{\mathbb{R}} \right. \\
 & \left. - \vartheta \langle \bar{y}, \alpha \rangle + \frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), \alpha \rangle - \langle Bq, \alpha \rangle + L(\bar{y}, \alpha, a) \right) \\
 & \geq \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( - \langle \beta \delta_0(Bp), a \rangle_{\mathbb{R}} - \langle \beta \delta_0(Bq), a \rangle_{\mathbb{R}} + L(\bar{y}, \alpha, a) - L(\bar{x}, \alpha, a) \right. \\
 & \quad \left. - \vartheta \langle \bar{y}, \alpha \rangle - \vartheta \langle \bar{x}, \alpha \rangle - \langle Bq, \alpha \rangle - \langle Bp, \alpha \rangle \right) \\
 & \geq \inf_{(\alpha, a) \in \Sigma \times \Gamma} \left( L(\bar{y}, \alpha, a) - L(\bar{x}, \alpha, a) \right) \\
 & \quad - \sup_{(\alpha, a) \in \Sigma \times \Gamma} \left( \langle \beta \delta_0(Bp), a \rangle_{\mathbb{R}} + \langle \beta \delta_0(Bq), a \rangle_{\mathbb{R}} \right) \\
 & - \sup_{(\alpha, a) \in \Sigma \times \Gamma} \left( \vartheta \langle \bar{y}, \alpha \rangle + \vartheta \langle \bar{x}, \alpha \rangle \right) - \sup_{(\alpha, a) \in \Sigma \times \Gamma} \left( \langle Bq, \alpha \rangle + \langle Bp, \alpha \rangle \right) \\
 & \geq -C_L |\bar{x} - \bar{y}|_B - 2\sigma\beta \|\delta_0 \circ B\| \|\Gamma\| - \|\Sigma\| \vartheta(|\bar{x}| + |\bar{y}|) - 2\|B\| \sigma \|\Sigma\|.
 \end{aligned}$$

Thus by using (86) and (87) in (85) we derive

$$\begin{aligned}
 (88) \quad & \rho(u(\bar{x}) - v(\bar{y})) - \frac{1}{\varepsilon} |\bar{x} - \bar{y}|_B^2 \\
 & - \frac{\mu}{\varepsilon} \langle B(\bar{x} - \bar{y}), -(\bar{x} - \bar{y}) \rangle - \langle A^* Bp, \bar{x} \rangle - \langle A^* Bq, \bar{y} \rangle \\
 & - \langle Bp, -\mu\bar{x} \rangle - \langle Bq, -\mu\bar{y} \rangle - \vartheta \langle \bar{x}, -\mu\bar{x} \rangle - \vartheta \langle \bar{y}, -\mu\bar{y} \rangle \\
 & - C_L |\bar{x} - \bar{y}|_B - 2\sigma\beta \|\delta_0 \circ B\| \|\Gamma\| - \|\Sigma\| \vartheta(|\bar{x}| + |\bar{y}|) - 2\|B\| \sigma \|\Sigma\| - \beta\vartheta \|\Gamma\|^2 \leq 0,
 \end{aligned}$$

and from the preceding and from (78), (79), (75), (76), (80), (82), (77), (81), and (74) we obtain

$$(89) \quad \rho(u(\bar{x}) - v(\bar{y})) - 2\left(\frac{\gamma}{32}\right) - 4\left(\frac{\gamma}{16}\right) - 2\left(\frac{\gamma}{32}\right) - \frac{\gamma}{32} - \frac{\gamma}{32} - \frac{\gamma}{32} - \frac{\gamma}{64} - \frac{\gamma}{64} \leq 0;$$

that is,

$$(90) \quad \rho(u(\bar{x}) - v(\bar{y})) - \frac{1}{2}\gamma \leq 0.$$

Now we recall that from (59) we have  $\rho(u(\bar{x}) - v(\bar{y})) > \gamma$ , and then we obtain from (90)

$$\frac{1}{2}\gamma = \gamma - \frac{1}{2}\gamma < \rho(u(\bar{x}) - v(\bar{y})) - \frac{1}{2}\gamma \leq 0,$$

which yields a contradiction because  $\gamma > 0$ . The theorem is proved.  $\square$

**Remark 4.9.** Now we can better explain the remark in the introduction saying that it is difficult to treat the case of a nonconstant coefficient. We can estimate the term  $\frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), -\mu(\bar{x} - \bar{y}) \rangle$  because we use the term  $\frac{1}{\varepsilon} |\bar{x} - \bar{y}|_B^2$  to penalize the doubling of the variables with respect to the  $B$ -norm. If  $\mu$  is a function of  $r$ , such a term is replaced by  $\frac{1}{\varepsilon} \langle B(\bar{x} - \bar{y}), -\mu(\cdot)(\bar{x} - \bar{y}) \rangle$ , where  $-\mu(\cdot)(\bar{x} - \bar{y})$  is the pointwise product of the  $L^\infty(0, \bar{s})$  function  $\mu(\cdot)$  and the  $L^2(0, \bar{s})$  function  $(\bar{x} - \bar{y})$ , which cannot be estimated by using similar arguments.

**Acknowledgments.** The author thanks Prof. Andrzej Świąch for his hospitality, his great kindness, many useful suggestions, and stimulating conversations. Thanks to Silvia Faggian for the invaluable advice.

## STABILITY AND ERGODICITY OF PIECEWISE DETERMINISTIC MARKOV PROCESSES\*

O. L. V. COSTA<sup>†</sup> AND F. DUFOUR<sup>‡</sup>

**Abstract.** The main goal of this paper is to establish some equivalence results on stability, recurrence, and ergodicity between a piecewise deterministic Markov process (PDMP)  $\{X(t)\}$  and an embedded discrete-time Markov chain  $\{\Theta_n\}$  generated by a Markov kernel  $G$  that can be explicitly characterized in terms of the three local characteristics of the PDMP, leading to tractable criterion results. First we establish some important results characterizing  $\{\Theta_n\}$  as a sampling of the PDMP  $\{X(t)\}$  and deriving a connection between the probability of the first return time to a set for the discrete-time Markov chains generated by  $G$  and the resolvent kernel  $R$  of the PDMP. From these results we obtain equivalence results regarding irreducibility, existence of  $\sigma$ -finite invariant measures, and (positive) recurrence and (positive) Harris recurrence between  $\{X(t)\}$  and  $\{\Theta_n\}$ , generalizing the results of [F. Dufour and O. L. V. Costa, *SIAM J. Control Optim.*, 37 (1999), pp. 1483–1502] in several directions. Sufficient conditions in terms of a modified Foster–Lyapunov criterion are also presented to ensure positive Harris recurrence and ergodicity of the PDMP. We illustrate the use of these conditions by showing the ergodicity of a capacity expansion model.

**Key words.** piecewise deterministic Markov process, recurrence, ergodicity

**1. Introduction.** Piecewise deterministic Markov processes (PDMPs) were introduced in the literature by Davis [6] as a general class of stochastic models. PDMPs are a family of Markov processes involving deterministic motion punctuated by random jumps. The motion of the PDMP  $\{X(t)\}$  depends on three local characteristics, namely, the flow  $\Phi$ , the jump rate  $\lambda$ , and the transition measure  $Q$ , which specifies the postjump location. Starting from  $x$  the motion of the process follows the flow  $\Phi(x, t)$  until the first jump time  $T_1$ , which occurs either spontaneously in a Poisson-like fashion with rate  $\lambda$  or when the flow  $\Phi(x, t)$  hits the boundary of the state space. In either case the location of the process at the jump time  $T_1$  is selected by the transition measure  $Q(\Phi(x, T_1), \cdot)$  and the motion restarts from this new point as before. A suitable choice of the state space and the local characteristics  $\Phi$ ,  $\lambda$ , and  $Q$  provide stochastic models covering a great number of problems in operations research [6].

Over the past decades a great deal of attention has been given to the stability properties and related ergodic theory of Markov processes. One of the main approaches to dealing with these problems is to show that the recurrence properties of the Markov process under consideration are related to the recurrence properties of an associated discrete-time Markov chain obtained from a sampling of the original process, so that the well-known discrete-time Markov chains results could be used (see, for example, the books [12, 17, 18] and the references therein).

In the continuous-time context, Azéma, Duflo, and Revuz [1, 2] showed that a general Markov process and its associated resolvent admit the same recurrence properties. It was proved by Tuominen and Tweedie [19] that the recurrence structure of a Markov process  $\{X(t)\}$  with transition semigroup  $\{P^t\}$  and the Markov chain with kernel  $K_F = \int P^t F(dt)$ , where  $F$  is a distribution on  $[0, \infty)$ , are essentially equivalent, provided that a continuity assumption on  $\{P^t\}$  is satisfied, an assumption later suppressed in a fundamental paper by Meyn and Tweedie [11]. It must be pointed out that these results are related to the sampling of a continuous-time process  $\{X(t)\}$ , sampled at random times defined by an independent undelayed renewal process. This idea of randomized sampling was generalized to state-dependent sampling to provide some more powerful state-dependent drift criteria in order to ensure stability of the original Markov process. Within this context, Malyšev and Men'sikov [9] derived a modified Foster–Lyapunov criterion to establish recurrence properties for discrete-time Markov chains with countable state space. Meyn and Tweedie [15] generalized this work to discrete-time Markov chains with a general state space and furthermore obtained state-dependent drift conditions to get geometric ergodic properties. The generalization to continuous-time models was established by Dai and Meyn [5] in the context of general state space Markovian queuing models. In particular, they provided sufficient conditions for the existence of bounds on the long-run average moments and rates of convergence of the  $p$ th moments to their steady-state values. Another paper related to this subject is [4].

The main goal of this paper is to establish equivalence results on stability, recurrence, and ergodicity between a PDMP and a discrete-time Markov chain generated by a kernel  $G$  (see (2.2)–(2.4) for its definition) that can be explicitly characterized in terms of the three local characteristics of the PDMP leading to tractable criterion results. From a practical point of view, it should be noted that the results developed in [2, 11, 19] would be hard to apply for PDMPs because the transition semigroup of the PDMP as well as its associated resolvent kernel cannot be explicitly calculated from its local characteristics, which is not the case regarding the kernel  $G$ . As shown in Theorem 3.1 below,  $G$  generates a Markov chain that corresponds to a state-dependent sampling of the PDMP  $\{X(t)\}$ , providing an interesting parallel between our work in the continuous-time context and the results obtained in [15] in the discrete-time setting. However, it must be stressed that [15] provides general sufficient conditions to ensure that stability of the sampled chain implies stability of the Markov process, but not the converse. One of the main goals of our paper is to show the converse for PDMPs and, in fact, that the PDMP and the discrete-time Markov chain generated by this tractable kernel  $G$  have an equivalent recurrence structure. This is an important feature that distinguishes our work from [15]. We show that the following equivalence results hold:

- (i) The PDMP  $\{X(t)\}$  is irreducible if and only if the Markov chain  $\{\Theta_n\}$  associated to  $G$  is irreducible; see Proposition 4.1.
- (ii) There is a one-to-one correspondence between the set of invariant measures for the PDMP  $\{X(t)\}$  and for the Markov chain  $\{\Theta_n\}$  associated to  $G$ ; see Theorem 4.2.
- (iii) The PDMP  $\{X(t)\}$  is recurrent if and only if the Markov chain  $\{\Theta_n\}$  associated to  $G$  is recurrent; see Theorem 4.4.
- (iv) The PDMP is Harris recurrent if and only if the Markov chain associated to  $G$  is Harris recurrent; see Theorem 4.6.
- (v) The PDMP is positive recurrent (respectively, positive Harris recurrent) if and

only if the Markov chain associated to  $G$  is recurrent (respectively, Harris recurrent) with invariant measure satisfying a boundedness condition; see Corollary 4.5 (respectively, Corollary 4.7).

It is interesting to note that (v) also highlights some differences between our approach and some general results in the literature [2, 11, 15, 19]. Indeed, as shown in [11, Theorem 3.1], the Markov chain generated by  $K_F$  is positive Harris recurrent if and only if the process  $\{X(t)\}$  is positive Harris recurrent, while in our case the PDMP is positive Harris recurrent if and only if the Markov chain associated to  $G$  is Harris recurrent with its unique invariant measure satisfying a boundedness condition, which is far less demanding than positive Harris recurrence.

It should be pointed out that the proof of the Harris recurrence equivalence (item (iv)) requires two important results. One of them, Theorem 3.3, establishes a connection between the probability of the first return time to a set considering the Markov kernels generated by  $G$  and the resolvent kernel  $R$ . From this result we obtain the first part of the equivalence; if the process  $\{X(t)\}$  is Harris recurrent, then so is the Markov chain  $\{\Theta_n\}$ . The other result is presented in Theorem 3.1, which provides the sample path characterization of the Markov chain generated by  $G$  through the PDMP  $\{X(t)\}$ . From this result we get the second part of the equivalence; if the Markov chain  $\{\Theta_n\}$  is Harris recurrent, then so is the PDMP  $\{X(t)\}$ .

After we obtain the recurrence structure for PDMPs in terms of  $G$ , a natural question that would arise is what could be said about tractable ergodicity conditions for the PDMPs. As shown in [13, Theorem 6.1], if  $\{X(t)\}$  is positive Harris recurrent, then it is ergodic if and only if some skeleton chain is irreducible. Again, the problem is that the transition semigroup and consequently the skeleton chain for  $\{X(t)\}$  cannot be explicitly calculated from the local characteristics of the PDMP. We provide a tractable and equivalent condition to ensure that a skeleton chain is irreducible.

We conclude the paper by presenting sufficient conditions in a modified Foster–Lyapunov criterion form, written in terms of  $G$ , to ensure the following for the PDMP: the existence of an invariant probability measure, positive Harris recurrence, and ergodicity.

The paper is organized as follows. In section 2 we present some basic definitions related to the motion of a PDMP, introduce the Markov kernel  $G$ , and recall some classical definitions related to Markov processes both in the discrete-time and continuous-time contexts. Some preliminary results are derived in section 3 that will be important to obtain the equivalence properties for the stability of the PDMPs and the Markov kernel  $G$ . In section 4, it will be established that the stability and ergodic properties are equivalent for the PDMPs and the kernel  $G$ . In section 5 we establish some sufficient conditions to ensure various concepts of stability of the PDMP through a Foster–Lyapunov criterion for the kernel  $G$ . Section 6 illustrates the use of these conditions by showing the ergodicity of a capacity expansion model. The last two sections (7 and 8) are devoted to the proofs of Theorems 3.1 and 3.3.

**2. Definition of the PDMP and the Markov kernel  $G$ .** In this section we first present some standard notation and some basic definitions related to the motion of a PDMP  $\{X(t)\}$ . For further details the reader is referred to [6]. Afterwards we introduce the Markov kernel  $G$ , which we will use for characterizing the recurrence and the Harris recurrence structure of the PDMP  $\{X(t)\}$ . At the end of this section, we recall some classical definitions related to Markov processes both in the discrete-time and continuous-time contexts. For a complete exposition on the subject, the reader is referred to the works of Meyn and Tweedie [12, 10, 14, 13]. We follow closely the

notation in Meyn and Tweedie [12].

Let  $\mathbb{R}_+$  be the set of nonnegative real numbers. The set of natural numbers is denoted by  $\mathbb{N}$ , and  $\mathbb{N}^* \doteq \mathbb{N} - \{0\}$ . For any metric space  $H$ , the Borel  $\sigma$ -field of  $H$  is denoted by  $\mathcal{B}(H)$ . The indicator of a set  $A$  is denoted by  $\mathbf{1}_A$  ( $\mathbf{1}_A(x) = 1$  if  $x \in A$ ,  $\mathbf{1}_A(x) = 0$  if  $x \notin A$ ). Let  $E$  and  $F$  be two metric spaces. A kernel  $K$  on  $E \times \mathcal{B}(F)$  is a map  $K : E \times \mathcal{B}(F) \longrightarrow \mathbb{R}_+ \cup \{+\infty\}$  such that for  $x \in E$ ,  $K(x, \cdot)$  is a nonnegative  $\sigma$ -finite measure on  $(F, \mathcal{B}(F))$  and for any  $A \in \mathcal{B}(F)$ ,  $K(\cdot, A)$  is a measurable function on  $E$ . The kernel  $I_A$  on  $(E, \mathcal{B}(E))$  is defined for any set  $A \in \mathcal{B}(E)$  by  $I_A(x, B) = \mathbf{1}_{A \cap B}(x)$ . For two kernels  $K_1$  and  $K_2$  defined on  $E \times (\mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+))$ , the convolution  $K_1 * K_2$  is again a kernel on  $E \times (\mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+))$  defined as

$$K_1 * K_2(x, A \times \Gamma) \doteq \int_E \int_{\mathbb{R}_+} K_1(x, dy \times dt) K_2(y, A \times (\Gamma - t)),$$

where  $A \in \mathcal{B}(E)$ ,  $\Gamma \in \mathcal{B}(\mathbb{R}_+)$ , and  $\Gamma - t = \{u - t : u \in \Gamma\}$ . The notation  $K^{*n}$  represents the  $n$ -fold convolution  $K * \cdots * K$ . For a positive real-valued measurable function  $f$  defined on  $E \times \mathbb{R}_+$  the convolution  $K_1 * f$  is defined for  $x \in E$ ,  $t \in \mathbb{R}_+$  as

$$K_1 * f(x, t) \doteq \int_E \int_0^t f(y, t - s) K_1(x, dy \times ds).$$

For a substochastic kernel  $D$  we define  $U^D$  as  $U^D \doteq \sum_{k=1}^{\infty} D^k$ .

We denote by  $\gamma$  the Lebesgue measure on  $(\mathbb{R}_+, \mathcal{B}(\mathbb{R}_+))$ .

We present next the definition of the motion of a PDMP. Let  $E^0$  be an open subset of  $\mathbb{R}^n$  and let  $\partial E^0$  be its boundary. A PDMP is determined by its local characteristics  $(\mathfrak{X}, \lambda, Q)$  where the following hold:

- $\mathfrak{X}$  is a Lipschitz continuous vector field.  $\mathfrak{X} : \mathbb{R}^n \longrightarrow \mathbb{R}^n$ , which determines a flow  $\Phi(x, t)$  such that  $\frac{\partial}{\partial t} \Phi(x, t) = \mathfrak{X}(\Phi(x, t))$  and  $\Phi(x, 0) = x$  for all  $x \in \mathbb{R}^n$ .

Define

$$\Gamma^+ \doteq \{x \in \partial E^0 : x = \Phi(y, t) \text{ for some } y \in E^0, t > 0, \text{ and } \Phi(y, s) \in E^0 \forall s \in [0, t]\},$$

and

$$\Gamma^- \doteq \{x \in \partial E^0 : x = \Phi(y, -t) \text{ for some } y \in E^0, t > 0, \text{ and } \Phi(y, -s) \in E^0 \forall s \in [0, t]\}.$$

$\Gamma^+ \subset \partial E^0$  represents the boundary points at which the flow exits from  $E^0$ .  $\Gamma^- \subset \partial E^0$  is characterized by the fact that the flow starting from a point in  $\Gamma^-$  will not leave  $E^0$  immediately. Therefore it is natural to define the state space for the PDMP by  $E \doteq E^0 \cup \Gamma^- - \Gamma^- \cap \Gamma^+$ . For all  $x$  in  $E$ , let us denote  $t_*(x) \doteq \inf\{t > 0 : \Phi(x, t) \in \partial E^0\}$ , with the convention  $\inf \emptyset = \infty$ .

- The jump rate  $\lambda : E \rightarrow \mathbb{R}_+$  is assumed to be a measurable function satisfying  $(\forall x \in E) (\exists \varepsilon > 0)$  such that  $\int_0^\varepsilon \lambda(\Phi(x, s)) ds < \infty$ .

- $Q : E \cup \Gamma^+ \times \mathcal{B}(E) \rightarrow [0, 1]$  is a transition measure satisfying the following property:  $(\forall x \in E \cup \Gamma^+) Q(x, E - \{x\}) = 1$ .

From these characteristics, it can be shown [6, pp. 62–66] that there exists a filtered probability space  $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}, \{P_x\}_{x \in E})$  such that the motion of the process  $\{X(t)\}$  starting from a point  $x \in E$  may be constructed as follows. Take a random variable  $T_1$  such that

$$P_x(T_1 > t) \doteq \begin{cases} e^{-\Lambda(x, t)} & \text{for } t < t_*(x), \\ 0 & \text{for } t \geq t_*(x), \end{cases}$$

where for  $x \in E$  and  $t \in [0, t_*(x)[$

$$(2.1) \quad \Lambda(x, t) \doteq \int_0^t \lambda(\Phi(x, s)) ds.$$

If  $T_1$  generated according to the above probability is equal to infinity, then for  $t \in \mathbb{R}_+$ ,  $X(t) = \Phi(x, t)$ . Otherwise select independently an  $E$ -valued random variable (labeled  $X_1$ ) having distribution  $Q(\Phi(x, T_1), \cdot)$ . The trajectory of  $\{X(t)\}$  starting at  $x$ , for  $t \leq T_1$ , is given by

$$X(t) \doteq \begin{cases} \Phi(x, t) & \text{for } t < T_1, \\ X_1 & \text{for } t = T_1. \end{cases}$$

Starting from  $X(T_1) = X_1$ , we now select the next interjump time  $T_2 - T_1$  and post-jump location  $X(T_2) = X_2$  in a similar way.

This gives a strong Markov process  $\{X(t)\}$  with jump times  $\{T_k\}_{k \in \mathbb{N}}$  (where  $T_0 \doteq 0$ ). The transition semigroup of the process  $\{X(t)\}$  is denoted by  $\{P^t\}_{t \in \mathbb{R}_+}$ . We denote by  $\{\mathcal{F}_t^X\}_{t \in \mathbb{R}_+}$  the filtration generated by the process  $\{X(t)\}$ .

It is assumed throughout that for all  $(t, x) \in \mathbb{R}_+ \times E$ ,  $E_x[\sum_k \mathbf{1}_{\{T_k \leq t\}}] < \infty$ , implying in particular that  $T_k \rightarrow \infty$  as  $k \rightarrow \infty$ . This is a standard assumption; see, for example, (24.4) or (24.8) in [6].

Now let us introduce the substochastic kernels  $H$  and  $J$  and the Markov kernel  $G$ :

$$(2.2) \quad H(x, A) \doteq \int_0^{t_*(x)} e^{-\{s+\Lambda(x,s)\}} \mathbf{1}_A(\Phi(x, s)) ds,$$

$$(2.3) \quad \begin{aligned} J(x, A) &\doteq \int_0^{t_*(x)} \lambda(\Phi(x, s)) e^{-\{s+\Lambda(x,s)\}} Q(\Phi(x, s), A) ds \\ &\quad + e^{-\{t_*(x)+\Lambda(x, t_*(x))\}} Q(\Phi(x, t_*(x)), A), \end{aligned}$$

$$(2.4) \quad G(x, A) \doteq J(x, A) + H(x, A).$$

In [8], it was shown that  $G$  as defined in (2.4) is a Markov kernel.

The resolvent kernel associated to the process  $\{X(t)\}_{t \in \mathbb{R}_+}$  is denoted by

$$(2.5) \quad R(x, A) \doteq \int_0^\infty P^t(x, A) e^{-t} dt.$$

As shown in [8],  $R$  can be written in terms of  $H$  and  $J$  as follows:

$$(2.6) \quad R = \sum_{j=0}^\infty J^j H.$$

Let  $\{\Theta_n\}$  (respectively,  $\{\Upsilon_n\}$ ) be the Markov chain associated to the Markov kernel  $G$  (respectively,  $R$ ). In Theorem 3.1 below it will be shown how the Markov chain  $\{\Theta_n\}$  can be generated from the sample paths of the PDMP  $\{X(t)\}$ .

In what follows we will present some definitions considering a discrete-time Markov chain  $\{\chi_n\}$  with Markov kernel  $S$  that could be either  $\{\Theta_n\}$  (with  $S = G$ ) or  $\{\Upsilon_n\}$  (with  $S = R$ ). The first return time of a set  $A \in \mathcal{B}(E)$  for the PDMP  $\{X(t)\}$  and for the Markov chain  $\{\chi_n\}$  are defined, respectively, as follows:

$$\tau_A^X \doteq \inf\{t > 0 : X(t) \in A\}, \quad \tau_A^S \doteq \inf\{n \geq 1 : \chi_n \in A\}.$$

Associated to these first return times are the return time probability of a set  $A \in \mathcal{B}(E)$  for the PDMP  $\{X(t)\}$  and for the Markov chain  $\{\chi_n\}$ , given, respectively, by

$$L^X(x, A) \doteq P_x(\tau_A^X < \infty), \quad L^S(x, A) \doteq P_x(\tau_A^S < \infty).$$

The number of visits to a set  $A$  is defined for the PMDP  $\{X(t)\}$  and for the Markov chain  $\{\chi_n\}$ , respectively, as

$$\eta_A^X \doteq \int_0^\infty \mathbf{1}_A(X(t))dt, \quad \eta_A^S \doteq \sum_{n=1}^\infty \mathbf{1}_A(\chi_n).$$

If  $F$  is a probability distribution on  $\mathbb{R}_+$  (respectively,  $b$  is a probability on  $\mathbb{N}^*$ ), then the stochastic kernel  $K_F^X$  (respectively,  $K_b^S$ ) associated to  $\{X(t)\}$  (respectively,  $\{\chi_n\}$ ) is defined on  $E \times \mathcal{B}(E)$  by

$$(2.7) \quad (\forall x \in E) \quad (\forall A \in \mathcal{B}(E)) \quad K_F^X(x, A) \doteq \int_0^\infty P^t(x, A)F(dt),$$

$$(2.8) \quad (\forall x \in E) \quad (\forall A \in \mathcal{B}(E)) \quad K_b^S(x, A) \doteq \sum_{k=0}^\infty b(k)S^k(x, A).$$

A set  $C \in \mathcal{B}(E)$  is called a petite set for  $\{X(t)\}$  (respectively,  $\{\chi_n\}$ ) if there exist a probability distribution  $F$  on  $\mathbb{R}_+$  (respectively, a probability  $b$  on  $\mathbb{N}^*$ ) and a non-trivial measure  $\nu$  on  $(E, \mathcal{B}(E))$  such that  $(\forall A \in \mathcal{B}(E)) \quad (\forall x \in C) \quad K_F^X(x, A) \geq \nu(A)$  (respectively,  $(\forall A \in \mathcal{B}(E)) \quad (\forall x \in C) \quad K_b^S(x, A) \geq \nu(A)$ ).

A positive measure  $\mu$  (respectively,  $\pi$ ) is called an invariant for the PMDP  $\{X(t)\}$  (respectively, for the Markov chain  $\{\chi_n\}$ ) if it is a  $\sigma$ -finite measure satisfying  $\mu = \mu P^t$  for all  $t \geq 0$  (respectively,  $\pi = \pi S$ ). The PDMP  $\{X(t)\}$  is said to be ergodic if it has an invariant probability measure  $\mu$  such that

$$(\forall x \in E) \quad \lim_{t \rightarrow \infty} \|P^t(x, \cdot) - \mu(\cdot)\| = 0,$$

where  $\|\cdot\|$  denotes the total variation norm.

The following definitions apply for both the continuous-time as well as the discrete-time processes, and therefore we suppress the superscript  $X$  or  $S$ . A Markov process is called  $\varphi$ -irreducible (and  $\varphi$  is an irreducibility measure) if for some  $\sigma$ -finite measure  $\varphi$  we have that  $E_x(\eta_A) > 0$  for all  $x \in E$  whenever  $\varphi(A) > 0$ . A set  $A \in \mathcal{B}(E)$  is said to be full if  $\varphi(A^c) = 0$ . An irreducibility measure  $\psi$  is called maximal irreducible if for any other  $\varphi$  irreducibility measure we have that  $\psi \gg \varphi$ . A Markov process is called recurrent if for some  $\sigma$ -finite measure  $\varphi$  we have that  $E_x(\eta_A) = \infty$  for all  $x \in E$  whenever  $\varphi(A) > 0$ , and is called Harris recurrent if  $E_x(\eta_A) = \infty$  is replaced by  $P_x(\eta_A = \infty) = 1$ . If the Markov process is Harris recurrent, then there exists a unique (up to constant multiples) invariant measure. The Markov process is said to be positive Harris recurrent if it is Harris recurrent and the invariant measure is finite.

**3. Preliminary results.** In this section we present some preliminary results that will be very important in characterizing the recurrence and Harris recurrence structure of the PDMP  $\{X(t)\}$ . First, in Theorem 3.1 the Markov chain  $\{\Theta_n\}$  generated by the kernel  $G$  is shown to be related to the sample path of the PDMP. Since the proof of Theorem 3.1 is rather long and technical, it is presented in an independent section near the end of the paper (see section 7). It is interesting to note that  $\{\Theta_n\}$  corresponds to a sampling of the continuous-time process  $\{X(t)\}$  at random

times that depends on a combination of a sequence of independent and identically distributed exponential times with the sequence  $\{T_k\}$  of jump times of the PDMP  $\{X(t)\}$ . Moreover it must be pointed out that the Markov kernel  $G$  does not correspond to a generalized resolvent, as studied in the fundamental paper of Meyn and Tweedie [11]. An easy consequence of Theorem 3.1 presented in Corollary 3.2 is that if the first return time of the Markov chain  $\{\Theta_n\}$  to a set  $A$  is finite, then the first return time of the PDMP  $\{X(t)\}$  to the same set  $A$  is finite. Consequently, it will be easy to deduce from this result that if the Markov chain  $\{\Theta_n\}$  is Harris recurrent, then so is the process  $\{X(t)\}$ . The last two theorems of this section show that

- the probability of the first return time of  $\{\Theta_n\}$  to a set  $A$  to be finite is bounded below by the probability of the first return time of  $\{\Upsilon_n\}$  to the same set  $A$  to be finite (see Theorem 3.3);
- the average number of visits of  $\{\Theta_n\}$  to a set  $A$  is bounded below by the average number of visits of the Markov chain  $\{\Upsilon_n\}$  (generated by the resolvent) to the same set  $A$  (see Theorem 3.4).

Theorem 3.4 will be used in the next section to show that if the process  $\{X(t)\}$  is recurrent, then so is the Markov chain  $\{\Theta_n\}$ . An important consequence of Theorem 3.3 is that if the process  $\{X(t)\}$  is Harris recurrent, then so is the Markov chain  $\{\Theta_n\}$ . Theorem 3.3 is surprising and far from trivial to show. The last section of the paper (see section 8) is devoted to its proof.

We have the following result, which shows how the Markov chain  $\{\Theta_n\}$  could be generated from the sample path realizations of  $\{X(t)\}$ .

**THEOREM 3.1.** *On the probability space  $(\Omega, \mathcal{F}_t^X, \mathcal{F}, P_x)$  let  $\{s_n\}_{n \geq 0}$  be a sequence of independent and identically distributed  $\mathbb{R}_+$ -valued random variables with exponential distribution with parameter equal to 1 such that  $\forall_{t \geq 0} \mathcal{F}_t^X$  and  $\sigma\{s_k : k \geq 0\}$  are independent. Let the sequence of stopping times  $\{\tau_n\}_{n \in \mathbb{N}}$  be defined as follows:  $\tau_0 = 0$  and*

$$(3.1) \quad \tau_{n+1} \doteq \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \left[ (\tau_n + s_{n+1}) \wedge T_{k+1} \right].$$

*Then  $\{X(\tau_n)\}$  is a Markov chain with transition probability given by  $G$ .*

The proof of this result is presented in section 7.

**Remark 3.1.** Roughly speaking the sequence  $\{\tau_n\}_{n \in \mathbb{N}}$  is defined as

$$\begin{aligned} \tau_1 &= \mathbf{1}_{\{T_0 \leq \tau_0 < T_1\}} \left[ (\tau_0 + s_1) \wedge T_1 \right] \\ &= \begin{cases} s_1 & \text{if } s_1 < T_1, \\ T_1 & \text{otherwise,} \end{cases} \end{aligned}$$

$$\begin{aligned} \tau_2 &= \mathbf{1}_{\{T_0 \leq \tau_1 < T_1\}} \left[ (\tau_1 + s_2) \wedge T_1 \right] + \mathbf{1}_{\{T_1 \leq \tau_1 < T_2\}} \left[ (\tau_1 + s_2) \wedge T_2 \right] \\ &= \begin{cases} \tau_1 + s_2 & \text{if } \tau_1 < T_1 \text{ (equivalently } s_1 < T_1), \text{ and } \tau_1 + s_2 < T_1, \\ T_1 & \text{if } \tau_1 < T_1 \text{ (equivalently } s_1 < T_1), \text{ and } \tau_1 + s_2 \geq T_1, \\ T_1 + s_2 & \text{if } \tau_1 = T_1 \text{ (equivalently } s_1 \geq T_1), \text{ and } T_1 + s_2 < T_2, \\ T_2 & \text{otherwise,} \end{cases} \end{aligned}$$

and so on.

Without loss of generality, it can be considered that  $\Theta_n = X(\tau_n)$ , since  $\{\Theta_n\}$  was defined in section 2 as a Markov chain generated by  $G$ , and, from the previous theorem, that  $\{\Theta_n\}$  and  $\{X(\tau_n)\}$  have the same probability distribution. An important corollary of the previous theorem is the following inclusion for the first return times of the Markov chain  $\{\Theta_n\}$  and the process  $\{X(t)\}$ .

COROLLARY 3.2. *For any set  $A \in \mathcal{B}(E)$ ,*

$$(3.2) \quad \{\tau_A^G < \infty\} \subset \{\tau_A^X < \infty\}.$$

*Proof.* This is a straightforward consequence from the fact that we can consider  $\Theta_n = X(\tau_n)$ , as shown in Theorem 3.1.  $\square$

We have the following important theorem establishing a link between the probability of the first return time to a set for the Markov chains  $\{\Theta_n\}$  and  $\{\Upsilon_n\}$ .

THEOREM 3.3. *For every  $x \in E$  and for  $A \in \mathcal{B}(E)$ ,*

$$(3.3) \quad L^G(x, A) \geq L^R(x, A).$$

The proof of this result is presented in section 8.

Combining (3.2) and (3.3) we have, for every  $x \in E$  and  $A \in \mathcal{B}(E)$ , the following important inequalities:

$$L^R(x, A) \leq L^G(x, A) \leq L^X(x, A).$$

We conclude this section with the following theorem, providing a link between the average numbers of visits for the Markov chains generated by the kernel  $G$  and  $R$ .

THEOREM 3.4. *For every  $x \in E$  and for  $A \in \mathcal{B}(E)$ ,*

$$(3.4) \quad U^G(x, A) \geq U^R(x, A).$$

*Proof.* From Lemma 4.1 in [17], we have  $G^n = (J+H)^n = J^n + \sum_{j=1}^n J^{j-1} H G^{n-j}$  for any  $n \in \mathbb{N}^*$ . Consequently, it follows that

$$\begin{aligned} U^G &= U^J + \sum_{n=1}^{\infty} \sum_{j=1}^{\infty} J^{j-1} H G^{n-j} \mathbf{1}_{\{j \leq n\}} \\ &= U^J + R + R U^G, \end{aligned}$$

where the last equality follows from (2.6). Hence, by iteration on  $n$  in the previous equation, we get that for all  $n \geq 1$ ,

$$U^G = U^J + \sum_{j=1}^{n-1} R^j U^J + \sum_{j=1}^n R^j + R^n U^G \geq \sum_{j=1}^n R^j.$$

Taking the limit as  $n$  goes to  $\infty$ , we get the result.  $\square$

**4. Characterization of the recurrence and Harris recurrence structures of the PDMP in terms of the Markov kernel  $G$ .** The aim of this section is to characterize the (Harris) recurrence properties between the PMDP  $\{X(t)\}$  and the Markov chain  $\{\Theta_n\}$  generated by the kernel  $G$ . First, it is proved in Proposition 4.1 that  $\{X(t)\}$  is irreducible if and only if  $\{\Theta_n\}$  is irreducible. Then a generalization of Theorem 3.5 in [8] is presented in Theorem 4.2 giving a one-to-one correspondence between the invariant (positive and  $\sigma$ -finite) measures for the PDMP  $\{X(t)\}$  and the

Markov chain  $\{\Theta_n\}$ . Using the preliminary results derived in the previous section, it is shown in Theorems 4.4 and 4.6 that the PDMP  $\{X(t)\}$  is recurrent (respectively, Harris recurrent) if and only if the Markov chain  $\{\Theta_n\}$  is recurrent (respectively, Harris recurrent). One would expect a natural generalization of such equivalence results for positivity between the processes  $\{X(t)\}$  and  $\{\Theta_n\}$ . In fact, this result does not hold. Indeed, it is shown in Corollary 4.5 that the positive recurrence of the process  $\{X(t)\}$  is equivalent to a weaker form of stability for the Markov chain  $\{\Theta_n\}$ . Namely,  $\{X(t)\}$  is positive recurrent if and only if  $\{\Theta_n\}$  is recurrent and its unique invariant measure  $\pi$  satisfies the condition given by  $\pi H(E) < \infty$ , which is far less demanding than positive recurrence for  $\{\Theta_n\}$ . A similar result will be proved for the positive Harris recurrence of  $\{X(t)\}$  (see Corollary 4.7).

We have the following proposition characterizing the irreducibility of the process  $\{X(t)\}$  and the Markov chain  $\{\Theta_n\}$ .

**PROPOSITION 4.1.** *The PDMP  $\{X(t)\}$  is irreducible if and only if the Markov chain  $\{\Theta_n\}$  is irreducible.*

*Proof.* Suppose that the Markov chain  $\{\Theta_n\}$  is  $\varphi$ -irreducible. From Proposition 4.2.1 in [12, p. 87], whenever  $\varphi(A) > 0$  for any  $A \in \mathcal{B}(E)$  we have that  $L^G(x, A) > 0$  for all  $x \in E$ . From (3.2) we have that  $L^X(x, A) > 0$  for all  $x \in E$  whenever  $\varphi(A) > 0$  for  $A \in \mathcal{B}(E)$ . By using Proposition 2.1 in [13], it follows that the PDMP  $\{X(t)\}$  is  $\mu$ -irreducible with  $\mu = \varphi R$ , where we recall that  $R$  is the resolvent defined in (2.5).

Now suppose that  $\{X(t)\}$  is  $\Psi$ -irreducible. Then for  $A \in \mathcal{B}(E)$  with  $\Psi(A) > 0$ , we have, for all  $x \in E$ ,  $E_x[\eta_A^X] > 0$ . Since  $E_x[\eta_A^X] = U^R(x, A)$  (see, for instance, [19]), it implies that  $L^R(x, A) > 0$ . From Theorem 3.3, we get the result.  $\square$

Recall that by definition an invariant measure is always  $\sigma$ -finite and positive. The next result shows that there exists a one-to-one correspondence between the set of invariant measures for the PDMP  $\{X(t)\}$  and the set of invariant measures for the Markov chain  $\{\Theta_n\}$  generated by  $G$ . It extends Theorem 3.5 in [8], which was restricted to the set of invariant probability measures for the PDMPs.

**THEOREM 4.2.** (i) *If  $\mu$  is an invariant measure for  $\{X(t)\}$ , then  $\mu \sum_{j=0}^{\infty} J^j$  is invariant for  $\{\Theta_n\}$  and  $\mu \sum_{j=0}^{\infty} J^j H = \mu$ .*

(ii) *If  $\pi$  is an invariant measure for  $\{\Theta_n\}$ , then  $\pi H$  is invariant for  $\{X(t)\}$  and  $\pi H \sum_{j=0}^{\infty} J^j = \pi$ .*

*Proof.* Let us show (i). Let  $\mu$  be an invariant measure for  $\{X(t)\}$  and set  $\pi = \sum_{j=0}^{\infty} \mu J^j$ . Let us show that  $\pi$  is  $\sigma$ -finite. Since  $\mu$  is  $\sigma$ -finite, there exists a partition  $\{A_i\}$  of  $E$  such that  $\mu(A_i) < \infty$ . Define  $C_n = \bigcup_{i=1}^n A_i$  and  $B_{n,m} = \{y \in E : H(y, C_n) > \frac{1}{m}\}$  for  $m \in \mathbb{N}^*$ . Notice now that for every  $x \in E$ , we have that  $0 < H(x, E) < 1$ , and so  $\bigcup_{n,m} B_{n,m} = E$ . From (2.6) we have that  $\mu = \mu R = \sum_{j=0}^{\infty} \mu J^j H = \pi H$ , so that

$$\infty > \mu(C_n) = \int_E H(y, C_n) \pi(dy) \geq \int_{B_{n,m}} H(y, C_n) \pi(dy) \geq \frac{1}{m} \pi(B_{n,m}),$$

showing that  $\pi$  is  $\sigma$ -finite. Finally notice from (2.4) and (2.6) that

$$\pi G = \pi J + \pi H = \sum_{j=1}^{\infty} \mu J^j + \mu R = \sum_{j=1}^{\infty} \mu J^j + \mu = \sum_{j=0}^{\infty} \mu J^j = \pi,$$

showing that  $\pi$  is invariant for  $\{\Theta_n\}$ . Moreover,

$$\mu \sum_{j=0}^{\infty} J^j H = \mu R = \mu,$$

completing the proof of (i).

Let us now show (ii). Let  $\pi$  be an invariant measure for  $\{\Theta_n\}$ . For any  $n \in \mathbb{N}^*$ , we have

$$\pi \sum_{j=1}^n J^j H + \pi H = \pi G \sum_{j=0}^n J^j H = \pi \sum_{j=1}^n J^j H + \pi J^{n+1} H + \pi H \sum_{j=0}^n J^j H.$$

In order to cancel out the identical term  $\pi \sum_{j=1}^n J^j H$  on both sides of the previous equation, one must first check that all the measures under consideration are  $\sigma$ -finite. Since  $\pi = \pi G = \pi H + \pi J$ , it can be shown easily by induction that  $\pi J^j H \leq \pi$  and so  $\pi J^j H$  is  $\sigma$ -finite for all  $j \in \mathbb{N}$ . Consequently, for all  $j \in \mathbb{N}^*$ , the measures  $\pi \sum_{j=1}^n J^j H$ ,  $\pi H$ ,  $\pi J^{n+1} H$ , and  $\pi H \sum_{j=0}^n J^j H$  are  $\sigma$ -finite, implying that

$$(4.1) \quad \pi H = \pi J^{n+1} H + \pi H \sum_{j=0}^n J^j H.$$

Moreover, it can be shown that  $J^n(x, A) = E_x[e^{-T_n} \mathbf{1}_A[X(T_n)]]$  for all  $n \in \mathbb{N}^*$ ,  $x \in E$ , and  $A \in \mathcal{B}(E)$ . By using the dominated convergence theorem and the fact that  $\lim_{n \rightarrow \infty} T_n = +\infty$ , it follows that for all  $A \in \mathcal{B}(E)$

$$(4.2) \quad \lim_{n \rightarrow \infty} \pi J^n(A) = 0.$$

Combining (4.1) and (4.2), we have that  $\mu = \pi H = \pi H \sum_{j=0}^{\infty} J^j H = \mu R$ , and from Lemma 1 in [1] it follows that  $\mu$  is an invariant measure for  $\{X(t)\}$ . Now we have that

$$\pi H \sum_{j=0}^n J^j + \pi J^{n+1} + \pi \sum_{j=1}^n J^j = \pi + \pi \sum_{j=1}^n J^j.$$

It follows that  $\pi H \sum_{j=0}^n J^j + \pi J^{n+1} = \pi$  by using the same arguments as above. Equation (4.2) yields that  $\lim_{n \rightarrow \infty} \pi H \sum_{j=0}^n J^j = \pi$ , showing (ii).  $\square$

*Remark 4.1.* A straightforward consequence of Theorem 4.2 is the following result: There exists a *finite* invariant measure for  $\{X(t)\}$  if and only if there exists an invariant measure  $\pi$  for  $\{\Theta_n\}$  satisfying  $\pi H(E) < \infty$ . Note that this result was already proved in Theorem 3.5 in [8].

The next two results show that if the PDMP is recurrent, then so is the Markov chain generated by  $G$ , and vice versa.

**PROPOSITION 4.3.** *If  $H \in \mathcal{B}(E)$  is recurrent for the process  $\{X(t)\}$ , then  $H$  is recurrent for the Markov chain  $\{\Theta_n\}$ .*

*Proof.* If  $H \in \mathcal{B}(E)$  is recurrent for  $\{X(t)\}$ , then there exists a measure  $\nu$  on  $(H, \mathcal{B}(H))$  such that for all  $A \in \mathcal{B}(H)$  with  $\nu(A) > 0$ ,  $E_x[\eta_A^X] = U^R(x, A) = \infty$  for every  $x \in H$ . From Theorem 3.4, it follows that  $U^G(x, A) = \infty$ , showing the result.  $\square$

**THEOREM 4.4.** *The PDMP  $\{X(t)\}$  is recurrent if and only if the Markov chain  $\{\Theta_n\}$  associated to  $G$  is recurrent.*

*Proof.* Suppose that  $\{X(t)\}$  is transient and  $\{\Theta_n\}$  is recurrent. Let  $\varphi$  be a maximal irreducibility measure for  $\{\Theta_n\}$ . Then from Proposition 9.0.1 in [12],  $E = H \cup T$ , where  $T \in \mathcal{B}(E)$  is  $\varphi$ -null and transient for  $\{\Theta_n\}$ ,  $H \in \mathcal{B}(E)$  is nonempty and absorbing for  $\{\Theta_n\}$ , and every subset of  $H$  in  $\mathcal{B}(E)^+ \doteq \{A \in \mathcal{B}(E) : \varphi(A) > 0\}$

is Harris recurrent. On the other hand, since  $\{X(t)\}$  is transient, it follows that  $E = \cup_{i=1}^{\infty} E_i$  with  $E_x[\eta_{E_i}^X] \leq M_i < \infty$  for every  $x \in E$ . Define  $A_n \doteq \cup_{i=1}^n E_i \cap H$ . Consider  $k \in \mathbb{N}^*$  such that  $\varphi(A_k) > 0$ . For every  $x \in E$ , we have

$$E_x[\eta_{A_k}^X] \leq \sum_{i=1}^k E_x[\eta_{E_i}^X] \leq M,$$

with  $M \doteq \sum_{i=1}^k M_i$ . However, since  $A_k$  is a subset of  $H$  and belongs to  $\mathcal{B}(E)^+$ , the set  $A_k$  is Harris recurrent for  $\{\Theta_n\}$ . Consequently, by using (3.2), we have that for every  $x \in A_k$ ,  $1 = L^G(x, A) \leq L^X(x, A)$ , contradicting the fact that  $E_x[\eta_{A_k}^X] \leq M$ . Therefore, if  $\{\Theta_n\}$  is recurrent, then  $\{X(t)\}$  is recurrent.

The converse follows from Proposition 4.3, giving the result.  $\square$

The next corollary emphasizes a split with the previous equivalence results. Indeed it is shown that the process is positive recurrent if and only if  $\{\Theta_n\}$  satisfies a weaker condition: recurrence and a technical condition for its unique ( $\sigma$ -finite) invariant measure.

**COROLLARY 4.5.** *The PDMP  $\{X(t)\}$  is positive recurrent if and only if the Markov chain  $\{\Theta_n\}$  associated to  $G$  is recurrent with invariant measure  $\pi$  satisfying  $\pi H(E) < \infty$ .*

*Proof.* The result easily follows from Remark 4.1 and Theorem 4.4.  $\square$

We prove now that the Harris recurrent properties are equivalent for  $\{X(t)\}$  and  $\{\Theta_n\}$ .

**THEOREM 4.6.** *The PDMP  $\{X(t)\}$  is Harris recurrent if and only if the Markov chain  $\{\Theta_n\}$  is Harris recurrent.*

*Proof.* Suppose that the Markov chain  $\{\Theta_n\}$  is Harris recurrent. Denote by  $\Psi^G$  a maximal irreducibility measure for the Markov chain  $\{\Theta_n\}$ . Then for any set  $A \in \mathcal{B}(E)$  satisfying  $\Psi^G(A) > 0$  it follows from Corollary 3.2 that  $1 = L^G(x, A) \leq L^X(x, A)$  for all  $x \in E$ . Therefore,  $\{X(t)\}$  is Harris recurrent by using Theorem 1.1 in [11].

Now assume that the PDMP  $\{X(t)\}$  is Harris recurrent. From the equivalence results in [19], if the PDMP  $\{X(t)\}$  is Harris recurrent, then the Markov chain  $\{\Upsilon_n\}$  associated to the resolvent  $R$  is Harris recurrent. Moreover, by using Proposition 4.1  $\{\Theta_n\}$  is irreducible. Let us denote by  $\Psi^G$  (respectively,  $\Psi^R$ ) a maximal irreducible measure for  $\{\Theta_n\}$  (respectively,  $\{\Upsilon_n\}$ ). According to the definition of Harris recurrence (see [12, p. 200]), we want to show that if  $\Psi^G(A) > 0$ , then  $P_x(\cap_{j=1}^{\infty} \cup_{n=j}^{\infty} \{\Theta_n \in A\}) = 1$  for all  $x \in E$ . From (ii) and (iii) of Proposition 5.5.5 in [12], it follows that there exists an increasing sequence of petite sets  $\{C_k\}_{k \in \mathbb{N}}$  for  $\{\Theta_n\}$  such that  $E = \cup_{k \in \mathbb{N}} C_k$  with  $\Psi^G(C_k) > 0$  and  $\Psi^R(C_k) > 0$  for all  $k \in \mathbb{N}$ . Since  $\{\Upsilon_n\}$  is Harris recurrent we have for all  $k \in \mathbb{N}$  that  $L^R(x, C_k) = 1$  for all  $x \in C_k$ . From Theorem 3.3 we have that  $L^G(x, C_k) = 1$  for all  $x \in C_k$ , and from Proposition 9.1.1 in [12], it follows that  $C_k$  is Harris recurrent for  $\{\Theta_n\}$ . The remainder of the proof now follows the same steps as the end of the proof of Theorem 9.1.4 in [12], and it will be presented for the sake of completeness. From Lemma 5.5.1 in [12], we have that for all  $A \in \mathcal{B}(E)$  with  $\Psi^G(A) > 0$  there exists  $\delta > 0$  such that  $\inf_{x \in C_k} L^G(x, A) > \delta$ . However,  $C_k$  is Harris recurrent for  $\{\Theta_n\}$ , and from Theorem 9.1.3(i) in [12], we have that for all  $x \in C_k$ ,  $P_x(\cap_{j=1}^{\infty} \cup_{n=j}^{\infty} \{\Theta_n \in A\}) = 1$ . The result follows after recalling that  $E = \cup_{k \in \mathbb{N}} C_k$ .  $\square$

**Remark 4.2.** In the previous proof note that if  $A$  is a set such that  $\psi^G(A) > 0$ , then it does not necessarily imply that  $\psi^R(A) > 0$ . That is why we needed to proceed

through the tool of petite sets.

As for the positive recurrence property, the following result points out the split with the previous theorem by showing that the positive Harris recurrence is equivalent to a weaker form of stability for the chain  $\{\Theta_n\}$ .

**COROLLARY 4.7.** *The PDMP  $\{X(t)\}$  is positive Harris recurrent if and only if the Markov chain  $\{\Theta_n\}$  associated to  $G$  is Harris recurrent with invariant measure  $\pi$  satisfying  $\pi H(E) < \infty$ .*

*Proof.* Combining Remark 4.1 and Theorem 4.6, we obtain the result.  $\square$

The final result of this section gives a condition for the PDMP to be ergodic. As shown in [13, Theorem 6.1], if  $\{X(t)\}$  is positive Harris recurrent, then it is ergodic if and only if some skeleton chain is irreducible. Thus from Corollary 4.7 it remains only to obtain a tractable and equivalent condition to show that some skeleton chain is irreducible. Let  $N$  be the kernel defined on  $E \times \mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+)$  by

$$(4.3) \quad \begin{aligned} N(x, A \times \Gamma) &= \int_0^{t_*(x)} \mathbf{1}_\Gamma(s) \lambda(\Phi(x, s)) e^{-\Lambda(x, s)} Q(\Phi(x, s), A) ds \\ &+ \mathbf{1}_\Gamma(t_*(x)) e^{-\Lambda(x, t_*(x))} Q(\Phi(x, t_*(x)), A), \end{aligned}$$

where  $A \in \mathcal{B}(E)$ ,  $\Gamma \in \mathcal{B}(\mathbb{R}_+)$ . Define  $M : E \times \mathcal{B}(E) \times \mathbb{R}_+ \rightarrow \mathbb{R}$  by

$$(4.4) \quad M^t(x, A) \doteq \mathbf{1}_{\{t < t_*(x)\}} \mathbf{1}_A(\Phi(x, t)) e^{-\Lambda(x, t)}$$

for  $A \in \mathcal{B}(E)$ ,  $t \in \mathbb{R}_+$ , and  $x \in E$ . For  $x \in E$  and  $k \in \mathbb{N}$ , define the measure  $\alpha^k(x, \cdot)$  on  $(E \times \mathbb{R}_+, \mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+))$  by

$$\alpha^k(x, B) \doteq \int_B N^{*k} * M^t(x, dy) \gamma(dt)$$

for  $B \in \mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+)$ .

**THEOREM 4.8.** *Suppose that the Markov chain  $\{\Theta_n\}$  is positive Harris recurrent and denote by  $\Psi^G$  a maximal irreducibility measure for  $\{\Theta_n\}$ . The following propositions are equivalent:*

- (i) *There exist a set  $C \in \mathcal{B}(E)$  with  $\Psi^G H(C) > 0$  such that for all  $x \in C$  there exists  $k \in \mathbb{N}$  for which the measure  $\alpha^k(x, \cdot)$  is nonsingular with respect to the measure  $\Psi^G H \otimes \gamma$ .*
- (ii) *The PDMP  $\{X(t)\}$  is ergodic.*

*Proof.* From Lemma (27.3) in [6], it is easy to obtain that for all  $x \in E$  and for  $A \in \mathcal{B}(E)$ ,

$$(4.5) \quad P^t(x, A) = \sum_{k=0}^{\infty} N^{*k} * M^t(x, A).$$

Consequently, for any  $B \in \mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+)$ , we have

$$(4.6) \quad \int_B P^t(x, dy) \gamma(dt) = \sum_{k=0}^{\infty} \alpha^k(x, B).$$

From Corollary 4.7, the PDMP  $\{X(t)\}$  is positive Harris recurrent. Denote by  $\mu$  the invariant probability measure for  $\{X(t)\}$  and by  $\Psi^X$  a maximal irreducibility measure for  $\{X(t)\}$ . From Proposition 4.1 there exists a positive  $\sigma$ -finite measure

(labeled  $\pi$ ) invariant for  $G$  satisfying  $\pi H = \mu$ . By hypothesis, we also have that  $G$  is irreducible. From Theorem 10.4.9 in [12] we obtain that  $\mu \sim \Psi^X$  and  $\pi \sim \Psi^G$ , and thus  $\Psi^G H \sim \Psi^X$ .

According to Proposition 6.2 of Niemi and Nummelin [16] and by using (4.6), a skeleton chain is irreducible if and only if there exists a set  $C$  satisfying  $\Psi^X(C) > 0$  and such that for all  $x \in C$  there exists an integer  $k$  for which the measure  $\alpha^k(x, \cdot)$  is nonsingular with respect to the measure  $\Psi^X \otimes \gamma$ . However, from Theorem 6.1 in [13] and by using the fact that  $\Psi^G H \sim \Psi^X$ , we have that the PDMP  $\{X(t)\}$  is ergodic if and only if item (i) is satisfied, showing the result.  $\square$

**5. Sufficient conditions for stability and ergodicity of PDMPs.** Based on the results derived in the previous section we now present some sufficient conditions for the existence of an invariant probability measure, positive Harris recurrence, and ergodicity for the PDMP  $\{X(t)\}$ . These various stability conditions are inspired by the results obtained in [12, 15] and are based on modified Foster–Lyapunov criteria through the Markov kernel  $G$ . As mentioned before, this will lead to tractable criteria since the kernel  $G$  can be explicitly characterized in terms of the three local characteristics of the PDMP. It must be pointed out that the results derived in [12, 15] are not directly applicable to our case mainly because we need to obtain a criterion ensuring the existence of  $\sigma$ -finite invariant measure for  $G$  satisfying  $\pi H(E) < \infty$ .

We present next a Foster–Lyapunov criterion, based on the stochastic kernel  $G$ , for obtaining an invariant probability measure  $\mu$  for the PDMP  $\{X(t)\}$  satisfying  $\int_E f(x)\mu(dx) < \infty$ , for any measurable function  $f \geq 1$ . This result generalizes Corollary 4.5 in [8] by relaxing the hypotheses on the Lyapunov function  $V$  and the test set  $D$ , and allowing us to consider the measurable function  $f \geq 1$ .

**PROPOSITION 5.1.** *Let  $f : E \rightarrow [1, \infty)$  be a measurable function. Suppose that the Markov kernel  $G$  is recurrent and that the following Foster–Lyapunov criterion is satisfied:*

$$(5.1) \quad (\forall x \in E) \quad GV(x) \leq V(x) - Hf(x) + bI_D(x),$$

where  $D$  is a petite set for the Markov chain associated to  $G$ , and  $V : E \rightarrow [0, \infty]$  is a measurable function (with  $V(x_0) < +\infty$  for at least one  $x_0 \in E$ ). Then there exists a unique invariant probability measure  $\mu$  for the PDMP  $\{X(t)\}$  and moreover  $\int_E f(x)\mu(dx) < \infty$ .

*Proof.* Let  $\Psi^G$  be a maximal irreducibility measure for  $G$ . From Proposition 5.5.5 in [12], there exists a sequence of petite sets, say  $\{C_n\}$ , such that  $C_n \uparrow E$ . Define  $B_n = C_n \cap \{x \in E : V(x) \leq n\}$ . Notice that the set  $A = \{x \in E : V(x) < +\infty\}$  is absorbing (indeed, from (5.1), if  $x \in A$ , then  $GV(x) < \infty$  and thus  $G(x, A) = 1$ ), and thus from Proposition 4.2.3 in [12], it is full. It follows that there exists  $k \in \mathbb{N}$  such that  $\Psi^G(B_k) > 0$ . Clearly,  $B_k$  is a petite set for  $G$ , and  $V$  is bounded in  $B_k$ . Now applying Theorem 14.2.3 in [12] we obtain that  $\sup_{x \in B_k} E_x \left[ \sum_{j=0}^{\tau_{B_k}-1} Hf(\Theta_j) \right] < +\infty$ . By using the same arguments as in Theorem 4.4 of [8], it follows that there exists a unique invariant measure  $\pi$  of  $G$  which, moreover, satisfies  $\int_E f(x)\pi H(dx) < \infty$ . Consequently, it follows from Theorem 4.2 and Remark 4.1 that the measure  $\mu$  defined by  $\pi H$  is finite, invariant for the PDMP, and satisfies  $\int_E f(x)\mu(dx) < \infty$ . We get the uniqueness by using Proposition 4.1 since  $G$  is irreducible, showing the result.  $\square$

Next we present a theorem that requires only  $\varphi$ -irreducibility of the Markov kernel  $G$ , replacing the recurrence condition by another Lyapunov criterion. Moreover this result shows that the PDMP  $\{X(t)\}$  is positive Harris recurrent.

THEOREM 5.2. *Let  $f : E \rightarrow [1, \infty)$  be a measurable function. Suppose that the Markov kernel  $G$  is irreducible and satisfies the following Lyapunov criterion:*

$$(5.2) \quad (\forall x \in C^c) \quad GW(x) \leq W(x),$$

$$(5.3) \quad (\forall x \in E) \quad GV(x) \leq V(x) - Hf(x) + bI_D(x),$$

where  $C$  and  $D$  are petite sets for the Markov chain associated to  $G$ ,  $V : E \rightarrow [0, \infty]$  is a measurable function (with  $V(x_0) < +\infty$  for at least one  $x_0 \in E$ ), and  $W$  is a function unbounded off petite sets. Then the PDMP  $\{X(t)\}$  is positive Harris recurrent and its unique invariant probability measure  $\mu$  satisfies  $\int_E f(x)\mu(dx) < \infty$ .

*Proof.* From Theorem 9.1.8 in [12], inequality (5.2) implies that  $G$  is Harris recurrent, showing that the PDMP is Harris recurrent from Theorem 4.6. From Proposition 5.1 we get the result.  $\square$

Next we present a state-dependent criterion based on Theorem 2.2 of [15]. For this consider a random variable  $\varsigma_x$  on  $\mathbb{N}^*$  for each  $x \in E$ , independent of  $\{\Theta_k\}$ , and with distribution  $a_x(k)$ ,  $k \in \mathbb{N}^*$ . Recall that  $K_{a_x}^G(x, A) = \sum_{k=1}^{\infty} a_x(k)G^k(x, A)$  for any  $A \in \mathcal{B}(E)$ . Suppose that  $\sum_{i>k} a_x(i) \leq B_x a_x(k)$ . We have the following theorem.

THEOREM 5.3. *Let  $f : E \rightarrow [1, \infty)$  be a measurable function. Suppose that the Markov kernel  $G$  is  $\varphi$ -irreducible and satisfies the following Lyapunov criterion:*

$$(5.4) \quad (\forall x \in C^c) \quad K_{a_x}^G W(x) \leq W(x),$$

$$(5.5) \quad (\forall x \in E) \quad K_{a_x}^G V(x) \leq V(x) - Hf(x) + bI_D(x),$$

where  $C$  and  $D$  are petite sets for the Markov chain associated to  $G$ ,  $V : E \rightarrow [0, \infty]$  is a measurable function bounded on  $D$ , and  $W$  is a nonnegative function unbounded off petite sets. Then the PDMP  $\{X(t)\}$  is positive Harris recurrent and its unique invariant probability measure  $\mu$  satisfies  $\int_E f(x)\mu(dx) < \infty$ .

*Proof.* From Theorem 2.2(i) in [15], inequality (5.4) implies that  $G$  is Harris recurrent. From (5.5) and the proof of Theorem 2.2(i) in [15, p. 158], we have that for some nonnegative function  $W(x)$ , with  $W(x) < \infty$  for all  $x \in E$ , that  $GW(x) \leq W(x) - Hf(x) + bI_D(x)$  for all  $x \in E$ . From Theorem 5.2 we get the desired result.  $\square$

Finally we present a sufficient tractable condition for the PDMP to be ergodic.

THEOREM 5.4. *Suppose that the hypotheses of Theorem 5.2 and item (i) of Theorem 4.8 are satisfied. Then the PDMP  $\{X(t)\}$  is ergodic.*

*Proof.* The result follows by combining Theorems 4.8 and 5.2.  $\square$

REMARK 5.1. The results have been developed considering the stochastic kernel  $G$  defined on the measurable state space  $(E, \mathcal{B}(E))$ . It may be convenient in some applications to consider the extended state space  $E \cup \Gamma^+$  instead of  $E$ , with the stochastic kernel  $G$  extended to include the points in  $\Gamma^+$ . Let us define the kernel  $\overline{G}$  on  $(E \cup \Gamma^+, \mathcal{B}(E \cup \Gamma^+))$  (corresponding to an extension of  $G$ ) by  $(\forall x \in E \cup \Gamma^+) (\forall A \in \mathcal{B}(E \cup \Gamma^+))$

$$\overline{G}(x, A) \doteq \mathbf{1}_E(x)G(x, A \cap E) + \mathbf{1}_{\Gamma^+}(x)Q(x, A \cap E).$$

It is easy to see that  $\overline{G}$  is a stochastic kernel on  $(E \cup \Gamma^+, \mathcal{B}(E \cup \Gamma^+))$ . Moreover, it can be easily shown that  $\overline{G}$  has the following important properties:

- (a)  $\varphi$  is an irreducibility measure for  $G$  if and only if  $\varphi$  is an irreducibility measure for  $\overline{G}$ .
- (b)  $\pi$  is an invariant measure for  $G$  if and only if  $\pi$  is an invariant measure for  $\overline{G}$ .

(c)  $G$  is Harris recurrent if and only if  $\bar{G}$  is Harris recurrent. Consequently, the result presented in Theorem 5.4 remains valid if the Markov kernel  $G$  is replaced by the Markov kernel  $\bar{G}$ .

**6. Example.** This example is based on the capacity expansion model, analyzed in [7], [6, Example (34.45)], and [3, section 7]. The existence of an invariant probability measure for a generalized version of this model was studied in [8]. In the present work this example is revisited and the result of [8] is strengthened: Proposition 6.1 gives sufficient conditions to ensure that this general capacity expansion model is ergodic.

Capacity expansions are general processes of adding facilities to meet a rising demand. The demand for some utility is modeled as a random point process; i.e., it increases by one unit at random times. This demand is met by consecutive construction of expansion projects. Each project meets  $K_i$  units of demand when completed, where  $i$  corresponds the present level of excess demand. We assume that if there is an excess demand of at least  $p$  units, then the construction of a new project is started at a rate  $r_i$  per unit of time and is completed after a lead time of  $\mathcal{L}_i$  units of time. If the excess demand is less than  $p$ , then no construction takes place. New demand occurs with rate  $\lambda_i(u)$ , where  $u$  is the time spent by the current project. This problem can be modeled as a PDMP  $\{x_t\}$  with state space

$$(6.1) \quad E \doteq \{ \{p - K_p, \dots, p - 1\} \times \{0\} \} \cup \bigcup_{n=p}^{\infty} \{n, [0, \mathcal{L}_n[ \},$$

where  $p \in \mathbb{N}$  and  $(K_i)_{i \geq p}$  is a sequence of integers, and  $(\mathcal{L}_i)_{i \geq p}$  is an increasing sequence of strictly positive real numbers.  $\mathbb{N}_p$  denotes the set of integers greater than or equal to  $p$ . The local characteristics are given by

$$(6.2) \quad \lambda((i, u)) \doteq \lambda_i(u),$$

$$(6.3) \quad \Phi((i, u), t) = \begin{cases} (i, 0) & \text{for } i \in \{p - K_p, \dots, p - 1\}, \\ (i, u + r_i t) & \text{for } i \geq p, \end{cases}$$

$$(6.4) \quad Q((i, u), \{(i + 1, u)\}) = 1 \quad \text{and} \quad Q((i, \mathcal{L}_i), \{(i - K_i, 0)\}) = 1.$$

Consequently, we have  $\Gamma^+ = \{(n, \mathcal{L}_n) : n \geq p\}$ . Let us introduce the following assumptions:

- (H1) There exists  $r > 0$  such that for all  $i$ ,  $r_i \geq r$ .
- (H2) For  $i \geq p$ ,  $i - K_i \geq p - K_p > 0$  and  $\lim_{i \rightarrow \infty} i - K_i = \infty$ .
- (H3) There exists an integer  $k_0$  such that for all  $i \geq k_0$ ,  $\frac{K_i}{\mathcal{L}_i} \leq \frac{K_{i+1}}{\mathcal{L}_{i+1}}$ .
- (H4) For  $i \geq p$ ,  $\lambda_i(u)$  is a continuous real-valued function on  $[0, \mathcal{L}_i]$ .
- (H5) For  $i \in \{p - K_p, \dots, p - 1\}$ ,  $\lambda_i > 0$ .
- (H6)  $\limsup_{i \rightarrow \infty} \frac{\mathcal{L}_i}{K_i r_i} \max_{u \in [0, \mathcal{L}_i]} \lambda_i(u) < 1$ .

We have the following result.

**PROPOSITION 6.1.** *If (H1)–(H6) hold, then the PDMP  $\{X(t)\}$  is ergodic.*

*Proof.* Following the proof of Proposition 5.1 in [8], we have that the Markov kernel  $\bar{G}$  defined on  $(E \cup \Gamma^+, \mathcal{B}(E \cup \Gamma^+))$  is weak Feller and for the real-valued function defined on  $E \cup \Gamma^+$  by

$$V((i, u)) = i - \frac{K_i}{\mathcal{L}_i} u,$$

there exist  $(\varepsilon, b) \in \mathbb{R}_+^2$  and an integer  $k_0$  such that

$$\bar{G}V(i, u) - V(i, u) \leq -\varepsilon H((i, u), E) + b \mathbf{1}_{C_{k_0}}((i, u)),$$

where  $C_{k_0} \doteq \{\{p - K_p, \dots, p - 1\} \times \{0\}\} \cup \bigcup_{n=p}^{k_0} \{n, [0, \mathcal{L}_n]\}$ .

Using the hypotheses, it can be shown that  $\delta_{\{(p-1,0)\}}$  is an irreducibility measure for  $\{X(t)\}$ . The support of  $\delta_{\{(p-1,0)\}}$  clearly has a nonempty interior. It follows from item (ii) of Theorem 3.4 in [13] that all compact subsets of  $E \cup \Gamma^+$  are petite sets. Therefore,  $C_{k_0}$  is a petite set and the function  $V$  is unbounded off petite sets. Consequently, the hypotheses of Theorem 5.2 are satisfied.

Now let us show that item (i) of Theorem 4.8 is satisfied for the Markov kernel  $\overline{G}$ . Define  $C \doteq \{(p-1, 0)\}$ . Clearly,  $\delta_{\{(p-1,0)\}}(C) > 0$  and

$$(\forall x \in C) (\forall A \in \mathcal{B}(E) \otimes \mathcal{B}(\mathbb{R}_+)) \quad \alpha^0(x, A) = \int_A \delta_{\{(p-1,0)\}}(dy) e^{-\lambda_{p-1}(0)s} \gamma(ds),$$

since  $t_*(p-1, 0) = +\infty$  and  $\Phi((p-1, 0), s) = (p-1, 0)$ . Using assumption (H5), we obtain that

$$(6.5) \quad (\forall x \in C) \quad \alpha^0(x, \cdot) \sim \delta_{\{(p-1,0)\}} \otimes \gamma(\cdot).$$

Consequently, for all  $x \in C$ ,  $\alpha^0(x, \cdot)$  is nonsingular with respect to the measure  $\delta_{\{(p-1,0)\}} \otimes \gamma$ . However, if  $\Psi^{\overline{G}}$  denotes an irreducibility measure for  $\overline{G}$ , then  $\Psi^{\overline{G}}H$  is a maximal irreducibility for  $\{X(t)\}$  and so  $\delta_{\{(p-1,0)\}} \ll \Psi^{\overline{G}}H$ . Consequently, item (i) of Theorem 4.8 is satisfied for the Markov kernel  $\overline{G}$ . Combining Remark 5.1 and Theorem 5.4, we obtain the result.  $\square$

**7. Proof of Theorem 3.1.** In this section we present the proof of Theorem 3.1. First, Lemma 7.1 gives another expression for the Markov kernel  $G$ . The following results (see Lemmas 7.2 and 7.4 and Proposition 7.3) will give some relations between the sequence of stopping times  $\{\tau_n\}$  and the jump times of the PDMP  $\{T_n\}$  that will be used in what follows. The filtration generated by the PDMP stopped at times  $\{\tau_n\}$  and at times  $\{T_n\}$  are studied in Lemma 7.5. Finally, the proof of Theorem 3.1 follows by combining Proposition 7.6 and the previous results.

LEMMA 7.1. Assume that  $\bigvee_{t \geq 0} \mathcal{F}_t^x$  and  $\sigma\{s_k : k \geq 0\}$  are independent. Then

$$G(x, A) = E_x \left[ \mathbf{1}_A [X(T_1 \wedge s_0)] \right].$$

*Proof.* From the definition of  $G$  it follows by a straightforward calculation that  $G(x, A) = \int_0^{+\infty} E_x [\mathbf{1}_A [X(T_1 \wedge t)]] e^{-t} dt$ , showing the result.  $\square$

LEMMA 7.2. For any  $x \in E$  and for all  $n \in \mathbb{N}$ , we have

$$(7.1) \quad P_x(\tau_n \leq T_n) = 1,$$

$$(7.2) \quad P_x(\tau_n < \tau_{n+1}) = 1,$$

$$(7.3) \quad P_x \left( \sum_{j=n}^{\infty} \mathbf{1}_{\{\tau_j = T_n\}} = 1 \right) = 1.$$

For all  $n \in \mathbb{N}^*$ ,  $k < n$ ,  $j \in \{k, k+1, \dots, n-1\}$ , and  $x \in E$ ,

$$(7.4) \quad \tau_n = T_k + \sum_{i=j+1}^n s_i,$$

$P_x$ -a.s. on  $\{T_k \leq \tau_n < T_{k+1}\} \cap \{\tau_j = T_k\}$ .

*Proof.* These results can be shown easily by induction on the definition of  $\tau_n$ . The proof is therefore omitted.  $\square$

PROPOSITION 7.3. For all  $n \in \mathbb{N}_*$ ,  $k < n$ ,

$$(7.5) \quad \tau_n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = \sum_{j=k}^{n-1} \mathbf{1}_{\{\tau_j = T_k\}} \left[ T_k + \sum_{i=j+1}^n s_i \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} + \mathbf{1}_{\{T_k = \tau_n\}} T_k.$$

*Proof.* From (7.3), we have

$$(7.6) \quad \tau_n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = \tau_n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \left[ \sum_{j=k}^n \mathbf{1}_{\{\tau_j = T_k\}} + \sum_{j=n+1}^{\infty} \mathbf{1}_{\{\tau_j = T_k\}} \right],$$

and from (7.2), we get  $\{T_k \leq \tau_n < T_{k+1}\} \cap \{\tau_j = T_k\} = \emptyset$  for  $j \geq n+1$ . Consequently, the last term in (7.6) cancels out, and, by using (7.4), the result follows.  $\square$

It is important to point out that in the next lemma the function  $H_{k,p}(\tau_{p-1}, T_1, \dots, T_k, s_1, \dots, s_p)$  does not depend on  $T_{k+1}$ .

LEMMA 7.4. For all  $(k, p, n) \in \mathbb{N}_*^3$  such that  $p \leq n$  and  $k < n$ , there exists a measurable function  $H_{k,p}$  such that

$$\tau_p \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = H_{k,p}(T_1, \dots, T_k, s_1, \dots, s_p) \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}.$$

*Proof.* For  $p \leq n$  and  $k < n$  and from the definition of  $\tau_p$ , we have

$$(7.7) \quad \tau_p \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = \sum_{j=0}^{p-1} \mathbf{1}_{\{T_j \leq \tau_{p-1} < T_{j+1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_{j+1} \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}.$$

However, if  $k < p-1$ , then  $\{T_j \leq \tau_{p-1} < T_{j+1}\} \cap \{T_k \leq \tau_n < T_{k+1}\} = \emptyset$  for  $j \in \{k+1, \dots, p-1\}$  by using (7.2). Consequently, it follows from (7.7) that

$$\begin{aligned} \tau_p \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} &= \sum_{j=0}^{k \wedge (p-1)} \mathbf{1}_{\{T_j \leq \tau_{p-1} < T_{j+1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_{j+1} \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \\ &= \sum_{j=0}^{(k-1) \wedge (p-2)} \mathbf{1}_{\{T_j \leq \tau_{p-1} < T_{j+1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_{j+1} \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \\ &\quad + \mathbf{1}_{\{p-1 < k\}} \mathbf{1}_{\{T_{p-1} \leq \tau_{p-1} < T_p\}} \left[ (\tau_{p-1} + s_p) \wedge T_p \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \\ (7.8) \quad &+ \mathbf{1}_{\{p-1 \geq k\}} \mathbf{1}_{\{T_k \leq \tau_{p-1} < T_{k+1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_{k+1} \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}. \end{aligned}$$

However, by using (7.1) we have  $\{T_{p-1} \leq \tau_{p-1} < T_p\} = \{T_{p-1} = \tau_{p-1}\}$ , and  $\{T_k \leq \tau_{p-1} < T_{k+1}\} \cap \{T_k \leq \tau_n < T_{k+1}\} = \{T_k \leq \tau_{p-1}\} \cap \{T_k \leq \tau_n < T_{k+1}\}$ . On the set  $\{T_k \leq \tau_{p-1} < T_{k+1}\} \cap \{T_k \leq \tau_n < T_{k+1}\}$ , we get  $(\tau_{p-1} + s_p) \wedge T_{k+1} = \tau_{p-1} + s_p$ . Taking these remarks into consideration, (7.8) becomes

$$\begin{aligned} \tau_p \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} &= \left\{ \sum_{j=0}^{(k-1) \wedge (p-2)} \mathbf{1}_{\{T_j \leq \tau_{p-1} < T_{j+1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_{j+1} \right] \right. \\ &\quad + \mathbf{1}_{\{p-1 < k\}} \mathbf{1}_{\{T_{p-1} = \tau_{p-1}\}} \left[ (\tau_{p-1} + s_p) \wedge T_p \right] \\ &\quad \left. + \mathbf{1}_{\{p-1 \geq k\}} \mathbf{1}_{\{T_k \leq \tau_{p-1}\}} (\tau_{p-1} + s_p) \right\} \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}. \end{aligned}$$

Consequently, there exists a measurable function  $H_{p,k}$  such that

$$\tau_p \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = H_{k,p}(\tau_{p-1}, T_1, \dots, T_k, s_1, \dots, s_p) \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}.$$

Now repeating the same arguments for  $\tau_{p-1} \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}$ , the result follows by induction.  $\square$

LEMMA 7.5. Define  $\mathcal{G}_n = \sigma\{X(t \wedge \tau_n) : t \in \mathbb{R}_+\} \vee \sigma\{\tau_j : j \leq n\}$ , and  $\mathcal{S}_n = \sigma\{s_j : j \leq n\}$ . For  $n \in \mathbb{N}_*$  and  $k < n$ , we have that

$$\left[ \mathcal{G}_n \cap \{T_k \leq \tau_n < T_{k+1}\} \right] \subset \left[ \left( \mathcal{S}_n \vee \sigma\{X(t \wedge T_k) : t \in \mathbb{R}_+\} \right) \cap \{T_k \leq \tau_n < T_{k+1}\} \right].$$

*Proof.* For all  $t \in \mathbb{R}_+$ , it follows from Lemma 7.4 that for all  $p \leq n$ ,

$$\{\tau_p \leq t\} \cap \{T_k \leq \tau_n < T_{k+1}\} \in \left( \mathcal{S}_n \vee \sigma\{X(t \wedge T_k) : t \in \mathbb{R}_+\} \right) \cap \{T_k \leq \tau_n < T_{k+1}\}.$$

Now, from Proposition 7.3, we have on the set  $\{t \geq T_k\} \cap \{T_k \leq \tau_n < T_{k+1}\}$

$$X(t \wedge \tau_n) = \sum_{j=k}^{n-1} \mathbf{1}_{\{\tau_j = T_k\}} \Phi \left( X(T_k), (t - T_k) \wedge \sum_{i=j+1}^n s_i \right) + \mathbf{1}_{\{\tau_n = T_k\}} \Phi(X(T_k), 0).$$

Therefore, for any  $B \in \mathcal{B}(\mathbb{R})$  and for all  $t \in \mathbb{R}_+$ , we have

$$\begin{aligned} \{X(t \wedge \tau_n) \in B\} \cap \{T_k \leq \tau_n < T_{k+1}\} &= \left( \left[ \{t < T_k\} \cap \{X(t \wedge T_k) \in B\} \right] \right. \\ &\quad \cup \left[ \bigcup_{j=k}^{n-1} \left[ \{\tau_j = T_k\} \cap \left\{ \Phi \left( X(T_k), (t - T_k) \wedge \sum_{i=j+1}^n s_i \right) \in B \right\} \cap \{T_k \leq t\} \right] \right] \\ &\quad \left. \cup \left[ \{\tau_n = T_k\} \cap \{X(T_k) \in B\} \cap \{T_k \leq t\} \right] \right) \cap \{T_k \leq \tau_n < T_{k+1}\}. \end{aligned}$$

Using again Lemma 7.4, it follows that

$$\{X(t \wedge \tau_n) \in B\} \cap \{T_k \leq \tau_n < T_{k+1}\} \in \left( \mathcal{S}_n \vee \sigma\{X(t \wedge T_k) : t \geq 0\} \right) \cap \{T_k \leq \tau_n < T_{k+1}\},$$

showing the result.  $\square$

PROPOSITION 7.6. Assume that  $\forall_{t \geq 0} \mathcal{F}_t^x$  and  $\sigma\{s_k : k \geq 0\}$  are independent. For  $n \in \mathbb{N}_*$  and  $k \leq n$ , we have that

$$E_x \left[ \mathbf{1}_{\{t + \tau_n < T_{k+1}\}} | \mathcal{G}_n \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = F(t, \Theta_n) \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}},$$

where  $F(t, x) = \mathbf{1}_{\{t < t_*(x)\}} e^{-\int_0^t \lambda(\Phi(x, s)) ds}$ .

*Proof.* Denote  $S_{k+1} = T_{k+1} - T_k$ . Consider first the case where  $n \in \mathbb{N}_*$  and  $k = n$ . From (7.1) and by Theorem 25.5 in [6] and its proof, it follows that

$$E_x \left[ \mathbf{1}_{\{t + \tau_n < T_{k+1}\}} | \mathcal{G}_n \right] \mathbf{1}_{\{T_k \leq \tau_k < T_{k+1}\}} = F(t, X(\tau_k)) \mathbf{1}_{\{T_k \leq \tau_k < T_{k+1}\}}.$$

Now consider the case where  $n \in \mathbb{N}_*$  and  $k < n$ . From Proposition 7.3, we have

$$(7.9) \quad \begin{aligned} E_x \left[ \mathbf{1}_{\{t+\tau_n < T_{k+1}\}} | \mathcal{G}_n \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} &= \left[ \sum_{j=k}^{n-1} E_x \left[ \mathbf{1}_{\{\tau_j = T_k\}} \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} | \mathcal{G}_n \right] \right. \\ &\quad \left. + E_x \left[ \mathbf{1}_{\{\tau_n = T_k\}} \mathbf{1}_{\{S_{k+1} > t\}} | \mathcal{G}_n \right] \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}}. \end{aligned}$$

From Lemma 7.5, we obtain that for any  $A \in \mathcal{G}_n$ , there exists  $B \in \mathcal{S}_n \vee \sigma\{X(t \wedge T_k) : t \in \mathbb{R}_+\}$  such that

$$A \cap \{T_k \leq \tau_n < T_{k+1}\} = B \cap \{T_k \leq \tau_n < T_{k+1}\}.$$

By denoting  $\mathcal{H}_k = \sigma\{s_j : j \geq 0\} \vee \sigma\{X(t \wedge T_k) : t \in \mathbb{R}_+\}$ , we have for  $j \leq n-1$

$$\begin{aligned} \int_A \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \mathbf{1}_{\{\tau_j = T_k\}} dP \\ = \int_B \mathbf{1}_{\{\tau_j = T_k\}} E_x \left[ \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} | \mathcal{H}_k \right] dP. \end{aligned}$$

However, since  $\vee_{t \geq 0} \mathcal{F}_t^X$  and  $\sigma\{s_k : k \geq 0\}$  are independent, we have that

$$E_x \left[ \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} | \mathcal{H}_{n,k} \right] = F \left( \sum_{i=j+1}^n s_i + t, X(T_k) \right).$$

Therefore, by using the semigroup property of  $\Phi$ , we obtain

$$\begin{aligned} \int_A \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \mathbf{1}_{\{\tau_j = T_k\}} dP \\ = \int_A \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \mathbf{1}_{\{\tau_j = T_k\}} F(t, X(\tau_n)) dP. \end{aligned}$$

Consequently, it follows that for  $j \leq n-1$

$$(7.10) \quad E_x \left[ \mathbf{1}_{\{S_{k+1} > \sum_{i=j+1}^n s_i + t\}} | \mathcal{G}_n \right] = F(t, X(\tau_n))$$

on the set  $\{\tau_j = T_k\} \cap \{T_k \leq \tau_n < T_{k+1}\}$ . Similarly, we have that

$$(7.11) \quad \mathbf{1}_{\{\tau_n = T_k\}} E_x \left[ \mathbf{1}_{\{S_{k+1} > t\}} | \mathcal{G}_n \right] = \mathbf{1}_{\{\tau_n = T_k\}} F(t, X(\tau_n)).$$

Combining (7.9), (7.10), and (7.11), we have that

$$E_x \left[ \mathbf{1}_{\{t+\tau_n < T_{k+1}\}} | \mathcal{G}_n \right] \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} = \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} F(t, X(\tau_n)) \sum_{j=k}^n \mathbf{1}_{\{\tau_j = T_k\}},$$

showing the result.  $\square$

Using the previous results, we now present the proof of Theorem 3.1.

*Proof.* Consider  $n \in \mathbb{N}_*$  and denote  $\sigma\{X(\tau_k) : k \leq n\}$  by  $\mathcal{F}_n^\Theta$ . From the definition of  $\tau_n$  (see (3.1)), we have

$$E_x \left[ \mathbf{1}_A(\Theta_{n+1}) | \mathcal{F}_n^\Theta \right] = E_x \left[ \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \mathbf{1}_A[X((\tau_n + s_{n+1}) \wedge T_{k+1})] | \mathcal{F}_n^\Theta \right].$$

However, by using the facts that  $\vee_{t \geq 0} \mathcal{F}_t^X$  and  $\sigma\{s_k : k \geq 0\}$  are independent and that  $\{s_n\}_{n \geq 0}$  is a sequence of independent and identically distributed  $\mathbb{R}_+$ -valued random variables with exponential distribution, we obtain

$$\begin{aligned} E_x \left[ \mathbf{1}_A(\Theta_{n+1}) | \mathcal{F}_n^\Theta \right] &= \int_0^{+\infty} E_x \left[ \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} \mathbf{1}_A[X((\tau_n + t) \wedge T_{k+1})] | \mathcal{F}_n^\Theta \right] e^{-t} dt \\ (7.12) \quad &= \int_0^{+\infty} E_x \left[ \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} E_x \left[ \mathbf{1}_A[X((\tau_n + t) \wedge T_{k+1})] | \mathcal{G}_n \right] | \mathcal{F}_n^\Theta \right] e^{-t} dt, \end{aligned}$$

where for the last equality we have used  $\{T_k \leq \tau_n < T_{k+1}\} \in \mathcal{G}_n$  and  $\mathcal{F}_n^\Theta \subset \mathcal{G}_n$ . For  $k \leq n$ , by using Proposition 7.6 we have that on the set  $\{T_k \leq \tau_n < T_{k+1}\}$

$$(7.13) \quad E_x \left[ \mathbf{1}_A[X((\tau_n + t) \wedge T_{k+1})] | \mathcal{G}_n \right] = E_{X(\tau_n)} \left[ \mathbf{1}_A[X(T_1 \wedge t)] \right].$$

Combining (7.12) and (7.13), it follows that

$$\begin{aligned} E_x \left[ \mathbf{1}_A(\Theta_{n+1}) | \mathcal{F}_n^\Theta \right] &= \int_0^{+\infty} E_x \left[ \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} E_{X(\tau_n)} \left[ \mathbf{1}_A[X(T_1 \wedge t)] \right] | \mathcal{F}_n^\Theta \right] e^{-t} dt \\ &= \int_0^{+\infty} E_{X(\tau_n)} \left[ \mathbf{1}_A[X(T_1 \wedge t)] \right] E_x \left[ \sum_{k=0}^n \mathbf{1}_{\{T_k \leq \tau_n < T_{k+1}\}} | \mathcal{F}_n^\Theta \right] e^{-t} dt \\ &= G(X(\tau_n), A), \end{aligned}$$

showing the result.  $\square$

**8. Proof of Theorem 3.3.** In this section we present the proof of Theorem 3.3. Propositions 8.1 and 8.2 show how we can represent  $L^R$  as an infinite sum of substochastic kernels. Proposition 8.3 presents iterative equations for  $L^R$  and  $L^G$ , which, combined with the previous propositions and some limit convergence proved in Proposition 8.4, yield the proof of Theorem 3.3.

**PROPOSITION 8.1.** *Let  $f$  be an  $\mathbb{R}_+$ -valued measurable function defined on  $E$ . For  $B \in \mathcal{B}(E)$  and  $n \in \mathbb{N}$ ,*

$$(8.1) \quad (HI_B)^{n+1} f(x) = E_x \left[ \int_0^{T_1} v_{n,B}(x, s) e^{-s} f(X(s)) \mathbf{1}_B(X(s)) ds \right],$$

$$(8.2) \quad (HI_B)^n Jf(x) = E_x \left[ v_{n,B}(x, T_1) e^{-T_1} f(X(T_1)) \right],$$

where

$$(8.3) \quad v_{n,B}(x, s) = \frac{1}{n!} \left[ \int_0^s \mathbf{1}_B(\Phi(x, u)) du \right]^n.$$

*Proof.* Notice that for  $s \geq t$  we have that

$$v_{n,B}(\Phi(x, t), s - t) = \frac{1}{n!} \left[ \int_0^{s-t} \mathbf{1}_B(\Phi(x, u + t)) du \right]^n = \frac{1}{n!} \left[ \int_t^s \mathbf{1}_B(\Phi(x, u)) du \right]^n$$

and thus

$$(8.4) \quad \frac{dv_{n,B}(\Phi(x, t), s - t)}{dt} = -v_{n-1,B}(\Phi(x, t), s - t) \mathbf{1}_B(\Phi(x, t)).$$

Let us first show (8.1) by induction on  $n$ . For  $n = 1$  the result follows from the fact that

$$(8.5) \quad H(x, A) = E_x \left[ \int_0^{T_1} e^{-s} \mathbf{1}_A(X(s)) ds \right].$$

Suppose it holds for  $n$ . Note that for any  $\mathbb{R}_+$ -valued measurable function  $h$  defined on  $\mathbb{R}$ , we have

$$(8.6) \quad E_x \left[ \int_0^{T_1} h(s) ds \right] = \int_0^{t_*(x)} h(s) e^{-\Lambda(x,s)} ds.$$

Combining (8.5) and (8.6), we have

$$(8.7) \quad \begin{aligned} (HI_B)^{n+1} f(x) &= HI_B (HI_B)^n f(x) \\ &= \int_0^{t_*(x)} \mathbf{1}_B(\Phi(x, s)) (HI_B)^n f(\Phi(x, s)) e^{-\{s+\Lambda(x,s)\}} ds. \end{aligned}$$

However, from the induction hypothesis and (8.6), we have

$$(HI_B)^n f(x) = \int_0^{t_*(x)} v_{n-1,B}(x, u) \mathbf{1}_B(\Phi(x, u)) f(\Phi(x, u)) e^{-\{u+\Lambda(x,u)\}} du.$$

Using the semigroup property of  $\Phi$ , it follows that

$$(8.8) \quad \begin{aligned} (HI_B)^n f(\Phi(x, s)) &= e^{\{s+\Lambda(x,s)\}} \int_s^{t_*(x)} v_{n-1,B}(\Phi(x, s), u-s) \mathbf{1}_B(\Phi(x, u)) \\ &\quad \times f(\Phi(x, u)) e^{-\{u+\Lambda(x,u)\}} du. \end{aligned}$$

Combining (8.7) and (8.8), we obtain that

$$\begin{aligned} (HI_B)^{n+1} f(x) &= \int_0^{t_*(x)} \mathbf{1}_B(\Phi(x, u)) f(\Phi(x, u)) e^{-\{u+\Lambda(x,u)\}} \\ &\quad \times \int_0^{t_*(x)} v_{n-1,B}(\Phi(x, s), u-s) \mathbf{1}_B(\Phi(x, s)) \mathbf{1}_{[0,u]}(s) ds du. \end{aligned}$$

Now from (8.4), we have

$$\int_0^u v_{n-1,B}(\Phi(x, s), u-s) \mathbf{1}_B(\Phi(x, s)) ds = v_{n,B}(x, u),$$

and so

$$(HI_B)^{n+1} f(x) = \int_0^{t_*(x)} v_{n,B}(x, u) \mathbf{1}_B(\Phi(x, u)) f(\Phi(x, u)) e^{-\{u+\Lambda(x,u)\}} du.$$

Finally, using (8.6), we obtain

$$(HI_B)^{n+1} f(x) = E_x \left[ \int_0^{T_1} v_{n,B}(x, s) e^{-s} f(X(s)) \mathbf{1}_B(X(s)) ds \right],$$

showing the first part of the result.

The second part of the result can be obtained by using the same arguments and the fact that

$$\begin{aligned} E_x[g(T_1)f(X(T_1))] &= \int_0^{t_*(x)} \lambda(\Phi(x, s))e^{-\Lambda(x, s)}g(s)Qf(\Phi(x, s))ds \\ &\quad + e^{-\Lambda(x, t_*(x))}g(t_*(x))Qf(\Phi(x, t_*(x))) \end{aligned}$$

for any  $\mathbb{R}_+$ -valued measurable function  $f$  (respectively,  $g$ ) defined on  $\mathbb{R}$  (respectively,  $E$ ). Indeed, for  $n = 0$  the result follows from the fact that

$$J(x, A) = E_x[e^{-T_1}\mathbf{1}_A(X(T_1))].$$

Now, suppose it holds for  $n$ . Then

$$(HI_B)^{n+1}Jf(x) = \int_0^{t_*(x)} \mathbf{1}_B(\Phi(x, s))(HI_B)^nJf(\Phi(x, s))e^{-\{s+\Lambda(x, s)\}}ds$$

and

$$\begin{aligned} (HI_B)^nJf(\Phi(x, t)) &= \left[ e^{-\Lambda(x, t_*(x))}Qf(\Phi(x, t_*(x)))v_{n,B}(\Phi(x, t), t_*(x) - t) \right. \\ &\quad \left. + \int_t^{t_*(x)} \lambda(\Phi(x, s))e^{-\Lambda(x, s)}Qf(\Phi(x, s))v_{n,B}(\Phi(x, t), s - t)ds \right] e^{\{t+\Lambda(x, t)\}}. \end{aligned}$$

Combining the two previous equations and (8.4) gives

$$\begin{aligned} (HI_B)^{n+1}Jf(x) &= \int_0^{t_*(x)} \lambda(\Phi(x, s))e^{-\{s+\Lambda(x, s)\}}Qf(\Phi(x, s))v_{n+1,B}(x, s)ds \\ &\quad + e^{-\{t_*(x)+\Lambda(x, t_*(x))\}}Qf(\Phi(x, t_*(x)))v_{n+1,B}(x, t_*(x)). \end{aligned}$$

From (8.9) we have  $(HI_B)^{n+1}Jf(x) = E_x[v_{n,B}(x, T_1)e^{-T_1}f(X(T_1))]$ , completing the proof.  $\square$

PROPOSITION 8.2. *For any  $A \in \mathcal{B}(E)$  define the kernel  $\mathbb{H}_A$  on  $(E, \mathcal{B}(E))$  as*

$$\mathbb{H}_A = \sum_{n=0}^{\infty} (HI_{A^c})^n.$$

Then

$$(8.9) \quad L^R(x, A) = \sum_{n=0}^{\infty} (\mathbb{H}_AJ)^n \mathbb{H}_AH\mathbf{1}_A(x).$$

*Proof.* From Proposition 8.1 we have that for any  $\mathbb{R}_+$ -valued measurable function  $g$  defined on  $E$

$$\begin{aligned} \mathbb{H}_Ag(x) &= g(x) + E_x \left[ \int_0^{T_1} \sum_{n=0}^{\infty} v_{n,A^c}(x, s)e^{-s}g(X(s))\mathbf{1}_{A^c}(X(s))ds \right] \\ &= g(x) + E_x \left[ \int_0^{T_1} e^{-s+\int_0^s \mathbf{1}_{A^c}(\Phi(x, u))du} g(\Phi(x, s))\mathbf{1}_{A^c}(\Phi(x, s))ds \right] \\ &= g(x) + \int_0^{t_*(x)} e^{-\int_0^s \mathbf{1}_A(\Phi(x, u))du} g(\Phi(x, s))\mathbf{1}_{A^c}(\Phi(x, s))e^{-\Lambda(x, s)}ds. \end{aligned}$$

However,  $H\mathbf{1}_A(\Phi(x, s)) = \int_t^{t_*(x)} \mathbf{1}_A(\Phi(x, s))e^{-[s+\Lambda(x, s)]}ds e^{t+\Lambda(x, t)}$ . Consequently,

$$\begin{aligned}
 \mathbb{H}_A H\mathbf{1}_A(x) &= \int_0^{t_*(x)} \mathbf{1}_A(\Phi(x, s))e^{-[s+\Lambda(x, s)]} \int_0^s e^{t-\int_0^t \mathbf{1}_A(\Phi(x, u))du} \mathbf{1}_{A^c}(\Phi(x, t))dt ds \\
 &\quad + H\mathbf{1}_A(x) \\
 &= \int_0^{t_*(x)} \mathbf{1}_A(\Phi(x, s))e^{-[s+\Lambda(x, s)]} \left[ e^{-\int_0^s \mathbf{1}_{A^c}(\Phi(x, u))du} - 1 \right] ds + H\mathbf{1}_A(x) \\
 &= \int_0^{t_*(x)} \mathbf{1}_A(\Phi(x, s))e^{-\Lambda(x, s)} e^{-\int_0^s \mathbf{1}_A(\Phi(x, u))du} ds \\
 (8.10) \quad &= E_x \left[ \int_0^{T_1} e^{-\int_0^t \mathbf{1}_A(X(u))du} \mathbf{1}_A(X(t))dt \right].
 \end{aligned}$$

Using Proposition 8.1, we have that for any  $\mathbb{R}_+$ -valued measurable function  $f$  defined on  $E$

$$\begin{aligned}
 \mathbb{H}_A Jf(x) &= E_x \left[ \sum_{n=0}^{\infty} v_{n, A^c}(x, T_1) e^{-T_1} f(X(T_1)) \right] \\
 &= E_x \left[ e^{-T_1 + \int_0^{T_1} \mathbf{1}_{A^c}(\Phi(x, u))du} f(X(T_1)) \right] \\
 (8.11) \quad &= E_x \left[ e^{-\int_0^{T_1} \mathbf{1}_A(\Phi(x, u))du} f(X(T_1)) \right].
 \end{aligned}$$

From (8.10), (8.11), and the Markov property of the process  $\{X(t)\}$ , we get by induction

$$(8.12) \quad (\mathbb{H}_A J)^n \mathbb{H}_A H\mathbf{1}_A(x) = E_x \left[ \int_{T_n}^{T_{n+1}} e^{-\int_0^t \mathbf{1}_A(X(u))du} \mathbf{1}_A(X(t))dt \right].$$

Taking the sum over  $n$  in (8.12) and recalling that a.s.  $T_n \rightarrow \infty$  as  $n \rightarrow \infty$ , it follows that

$$\begin{aligned}
 \sum_{n=0}^{\infty} (\mathbb{H}_A J)^n \mathbb{H}_A H\mathbf{1}_A(x) &= E_x \left[ \int_0^{\infty} e^{-\int_0^t \mathbf{1}_A(X(u))du} \mathbf{1}_A(X(t))dt \right] \\
 &= 1 - E_x \left[ e^{-\int_0^{\infty} \mathbf{1}_A(X(u))du} \right] \\
 &= 1 - E_x \left[ e^{-\eta_A^x} \right] = L^R(x, A),
 \end{aligned}$$

where the last equality follows from, for instance, Theorem 2.3(ii) of [11].  $\square$

PROPOSITION 8.3. *We have that*

$$(8.13) \quad L^R(x, A) = \mathbb{H}_A H(x, A) + \mathbb{H}_A J L^R(x, A),$$

$$(8.14) \quad L^G(x, A) = \mathbb{H}_A G(x, A) + \mathbb{H}_A J I_{A^c} L^G(x, A).$$

*Proof.* Note that  $L^R(x, A) = \sum_{n=1}^{\infty} (R I_{A^c})^{(n-1)} R(x, A)$ . Since  $R = \sum_{j=0}^{\infty} J^j H$  we have that  $R = H + JR$ . Therefore, from [17, Lemma 4.1], it follows that for any  $n \in \mathbb{N}^*$

$$\begin{aligned}
 (R I_{A^c})^n &= (H I_{A^c} + J R I_{A^c})^n \\
 &= (H I_{A^c})^n + \sum_{j=1}^n (H I_{A^c})^{j-1} J (R I_{A^c}) (R I_{A^c})^{n-j} \\
 &= (H I_{A^c})^n + \sum_{j=1}^n (H I_{A^c})^{j-1} J (R I_{A^c})^{n+1-j}.
 \end{aligned}$$

Taking the sum over  $n$  and using the fact that  $R = H + JR$ , we get that

$$\begin{aligned} L^R(x, A) &= \sum_{n=0}^{\infty} (HI_{A^c})^n R(x, A) + \sum_{n=1}^{\infty} \sum_{j=1}^{\infty} (HI_{A^c})^{j-1} J(RI_{A^c})^{n+1-j} R(x, A) I_{\{j \leq n\}} \\ &= \mathbb{H}_A R(x, A) + \sum_{j=1}^{\infty} (HI_{A^c})^{j-1} J \sum_{n=j}^{\infty} (RI_{A^c})^{n+1-j} R(x, A) \\ &= \mathbb{H}_A H(x, A) + \mathbb{H}_A JR(x, A) + \mathbb{H}_A J \sum_{n=1}^{\infty} (RI_{A^c})^n R(x, A), \end{aligned}$$

giving (8.13). Similarly for  $G$ , we have  $L^G(x, A) = \sum_{n=1}^{\infty} (GI_{A^c})^{(n-1)} G(x, A)$  and so

$$\begin{aligned} L^G(x, A) &= \sum_{n=0}^{\infty} (HI_{A^c})^n G(x, A) + \sum_{n=1}^{\infty} \sum_{j=1}^{\infty} (HI_{A^c})^{j-1} JI_{A^c} (GI_{A^c})^{n-j} G(x, A) I_{\{j \leq n\}} \\ &= \mathbb{H}_A G(x, A) + \sum_{j=1}^{\infty} (HI_{A^c})^{j-1} JI_{A^c} \sum_{n=j}^{\infty} (GI_{A^c})^{n-j} GI_{A^c}(x), \end{aligned}$$

showing the last part of the result.  $\square$

PROPOSITION 8.4. *For every  $x \in E$  and for  $A \in \mathcal{B}(E)$ , we have that*

$$\lim_{n \rightarrow \infty} (\mathbb{H}_A J)^n L^R(x, A) = 0$$

and the limit

$$\lim_{n \rightarrow \infty} (\mathbb{H}_A JI_{A^c})^n L^G(x, A)$$

exists.

*Proof.* From (8.13) we have that for every  $x \in E$  and all  $n \in \mathbb{N}^*$ ,

$$(8.15) \quad \sum_{k=0}^n (\mathbb{H}_A J)^k \mathbb{H}_A H \mathbf{1}_A(x) + (\mathbb{H}_A J)^{n+1} G^R(x, A) = L^R(x, A).$$

Taking the limit as  $n \rightarrow \infty$  in (8.15), the first part of the result follows from (8.9).

Similarly, from (8.14) we have that every  $x \in E$  and all  $n \in \mathbb{N}^*$

$$(8.16) \quad \sum_{k=0}^n (\mathbb{H}_A JI_{A^c})^k \mathbb{H}_A G \mathbf{1}_A(x) + (\mathbb{H}_A JI_{A^c})^{n+1} L^G(x, A) = L^G(x, A).$$

Since  $\sum_{k=0}^n (\mathbb{H}_A JI_{A^c})^k \mathbb{H}_A G \mathbf{1}_A(x) \geq 0$ , and  $(\mathbb{H}_A JI_{A^c})^{n+1} L^G(x, A) \geq 0$  for all  $x \in E$  and all  $n \in \mathbb{N}^*$ , it follows that  $\lim_{n \rightarrow \infty} \sum_{k=0}^n (\mathbb{H}_A JI_{A^c})^k \mathbb{H}_A G \mathbf{1}_A(x)$  exists in  $\mathbb{R}_+$ , implying the existence of  $\lim_{n \rightarrow \infty} (\mathbb{H}_A JI_{A^c})^n L^G(x, A)$ , completing the proof.  $\square$

Using the previous results, we now present the proof of Theorem 3.3.

*Proof.* From (8.13) and (8.14), it follows that for all  $x \in E$ ,

$$\begin{aligned} L^G(x, A) - L^R(x, A) &= \mathbb{H}_A (G(x, A) - H(x, A)) + \mathbb{H}_A JI_{A^c} U^G(x, A) \\ &\quad - \mathbb{H}_A J (I_{A^c} + I_A) L^R(x, A) \\ &= \mathbb{H}_A J(x, A) - \mathbb{H}_A JI_{A^c} L^R(x, A) \\ &\quad + \mathbb{H}_A JI_{A^c} [L^G(x, A) - L^R(x, A)] \\ &= \mathbb{H}_A JI_{A^c} [\mathbf{1}_E(x) - L^R(x, A)] \\ &\quad + \mathbb{H}_A JI_{A^c} [L^G(x, A) - L^R(x, A)]. \end{aligned}$$

Consequently, for all  $x \in E$  and all  $n \in \mathbb{N}^*$ ,

$$\begin{aligned} L^G(x, A) - L^R(x, A) &= \sum_{k=0}^n [\mathbb{H}_A J I_{A^c}]^k \mathbb{H}_A J I_A [\mathbf{1}_E(x) - L^R(x, A)] \\ &\quad + [\mathbb{H}_A J I_{A^c}]^{n+1} [L^G(x, A) - L^R(x, A)]. \end{aligned}$$

From Proposition 8.4, and using the fact that  $\lim_{n \rightarrow \infty} (\mathbb{H}_A J \mathbf{1}_{A^c})^n L^G(x, A)$  is non-negative, it follows that

$$L^G(x, A) - L^R(x, A) \geq \sum_{k=0}^{\infty} [\mathbb{H}_A J I_{A^c}]^k \mathbb{H}_A J I_A [\mathbf{1}_E(x) - L^R(x, A)].$$

Since for all  $x \in E$ ,  $A \in \mathcal{B}(E)$ ,  $L^R(x, A) \leq \mathbf{1}_E(x)$ , the result follows.  $\square$

## SINGULAR TRAJECTORIES OF CONTROL-AFFINE SYSTEMS\*

YACINE CHITOUR<sup>†</sup>, FRÉDÉRIC JEAN<sup>‡</sup>, AND EMMANUEL TRÉLAT<sup>§</sup>

**Abstract.** When applying methods of optimal control to motion planning or stabilization problems, we see that some theoretical or numerical difficulties may arise, due to the presence of specific trajectories, namely, minimizing singular trajectories of the underlying optimal control problem. In this article, we provide characterizations for singular trajectories of control-affine systems. We prove that, under generic assumptions, such trajectories share nice properties, related to computational aspects; more precisely, we show that, for a generic system—with respect to the Whitney topology—all nontrivial singular trajectories are of minimal order and of corank one. These results, established both for driftless and for control-affine systems, extend results of [Y. Chitour, F. Jean, and E. Trélat, *Comptes Rendus Math.*, 337 (2003), pp. 49–52 (in French); Y. Chitour, F. Jean, and E. Trélat, *J. Differential Geom.*, 73 (2006), pp. 45–73]. As a consequence, for generic control-affine systems (with or without drift) defined by more than two vector fields, and for a fixed cost, there do not exist minimizing singular trajectories. Besides, we prove that, given a control-affine system satisfying the Lie algebra rank condition (LARC), singular trajectories are strictly abnormal, generically with respect to the cost. We then show how these results can be used to derive regularity results for the value function and in the theory of Hamilton–Jacobi equations, which in turn have applications for stabilization and motion planning, from both theoretical and implementational points of view.

**Key words.** singular trajectory, control-affine system, genericity, optimal control

**1. Introduction.** When addressing standard issues of control theory such as motion planning and stabilization, one may adopt an approach based on optimal control, e.g., Hamilton–Jacobi type methods and shooting algorithms. One is then immediately facing intrinsic difficulties due to the possible presence of singular trajectories. It is therefore important to characterize these trajectories by studying, in particular, their existence, their optimality status, and the related computational aspects. In this paper, we provide solutions to the aforementioned difficulties for control-affine systems, under generic assumptions, and then investigate consequences in optimal control and its applications.

Let  $M$  be a smooth (i.e.,  $C^\infty$ ) manifold of dimension  $n$ . Consider the control-affine system

$$(\Sigma) \quad \dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x),$$

where  $x \in M$ ,  $m$  is a positive integer,  $(f_0, \dots, f_m)$  is an  $(m+1)$ -tuple of smooth vector fields on  $M$ , and the control  $u = (u_1, \dots, u_m)$  takes values in an open subset  $\Omega$  of  $\mathbb{R}^m$ . For  $x_0 \in M$  and  $T > 0$ , a control  $u \in L^\infty([0, T], \Omega)$  is said to be *admissible* if the trajectory  $x(\cdot, x_0, u)$  of  $(\Sigma)$  associated to  $u$  and starting at  $x_0$  is well defined on

$[0, T]$ . On the set  $\mathcal{U}_{x_0, T}$  of admissible controls, define the *end-point mapping* by

$$E_{x_0, T}(u) := x(T, x_0, u).$$

It is classical that  $\mathcal{U}_{x_0, T}$  is an open subset of  $L^\infty([0, T], \Omega)$  and that  $E_{x_0, T} : \mathcal{U}_{x_0, T} \rightarrow M$  is a smooth map.

DEFINITION 1.1. A control  $u \in \mathcal{U}_{x_0, T}$  is said to be *singular* if  $u$  is a critical point of the end-point mapping  $E_{x_0, T}$ ; i.e., its differential at  $u$ ,  $DE_{x_0, T}(u)$ , is not surjective. A trajectory  $x(\cdot, x_0, u)$  is said to be *singular* if  $u$  is singular and of corank one if the codimension in the tangent space of the range of  $E_{x_0, T}(u)$  is equal to one.

In other words, a control  $u \in \mathcal{U}_{x_0, T}$  is singular if the linearized system along the trajectory  $x(\cdot, x_0, u)$  is not controllable on  $[0, T]$ . Singular trajectories appear as singularities in the set of trajectories of  $(\Sigma)$  joining two given points, and hence, they play a crucial role in variational problems associated to  $(\Sigma)$  and in optimal control, as described next.

Let  $x_0$  and  $x_1$  be two points of  $M$ , and let  $T > 0$ . Consider the following optimal control problem: From among all the trajectories of  $(\Sigma)$  steering  $x_0$  to  $x_1$ , determine a trajectory minimizing the *cost*

$$(1.1) \quad C_{U, \alpha, g}(T, u) = \int_0^T \left( \frac{1}{2} u(t)^T U(x(t)) u(t) + \alpha(x(t))^T u(t) + g(t, x(t)) \right) dt,$$

where  $\alpha = (\alpha_1, \dots, \alpha_m) \in C^\infty(M, \mathbb{R}^m)$ ,  $g \in C^\infty(\mathbb{R} \times M)$ , and  $U$  takes values in the set of symmetric positive definite  $m \times m$  matrices.

According to the Pontryagin maximum principle (see [21]), for every optimal trajectory  $x(\cdot) := x(\cdot, x_0, u)$ , there exists a nonzero pair  $(\lambda(\cdot), \lambda^0)$ , where  $\lambda^0$  is a nonpositive real number and  $\lambda(\cdot)$  is an absolutely continuous function on  $[0, T]$  (called *adjoint vector*) with  $\lambda(t) \in T_{x(t)}^* M$  such that, almost everywhere on  $[0, T]$ ,

$$(1.2) \quad \begin{aligned} \dot{x}(t) &= \frac{\partial H}{\partial \lambda}(t, x(t), \lambda(t), \lambda^0, u(t)), \\ \dot{\lambda}(t) &= -\frac{\partial H}{\partial x}(t, x(t), \lambda(t), \lambda^0, u(t)), \\ \frac{\partial H}{\partial u}(t, x(t), \lambda(t), \lambda^0, u(t)) &= 0, \end{aligned}$$

where

$$H(t, x, \lambda, \lambda^0, u) := \sum_{i=1}^m u_i \langle \lambda, f_i(x) \rangle + \lambda^0 \left( \frac{1}{2} u^T U(x) u + \alpha(x)^T u + g(t, x) \right)$$

is the *Hamiltonian* of the system. An *extremal* is a 4-tuple  $(x(\cdot), \lambda(\cdot), \lambda^0, u(\cdot))$  solution of the system of equations (1.2). The extremal is said to be *normal* if  $\lambda^0 \neq 0$  and *abnormal* if  $\lambda^0 = 0$ .

The relevance of singular trajectories in optimal control lies in the fact that they are exactly the projections of abnormal extremals. Note that a singular trajectory may be the projection of several abnormal extremals, and also of a normal extremal. A singular trajectory is said to be *strictly abnormal* if it is not the projection of a normal extremal. Notice that a singular trajectory is of corank one if and only if it admits a unique (up to scalar normalization) abnormal extremal lift; it is strictly abnormal and of corank one if and only if it admits a unique extremal lift which is abnormal.

For a normal extremal, it is standard to adopt the normalization  $\lambda^0 = -1$  and to derive the control  $u$  as the feedback function of  $(x, \lambda)$ ,

$$(1.3) \quad u(t) = \begin{pmatrix} u_1(t) \\ \vdots \\ u_m(t) \end{pmatrix} = U(x(t))^{-1} \begin{pmatrix} h_1(t) - \alpha_1(x(t)) \\ \vdots \\ h_m(t) - \alpha_m(x(t)) \end{pmatrix},$$

for every  $t \in [0, T]$ , where  $h_i(t) := \langle \lambda(t), f_i(x(t)) \rangle$ , for  $i = 1, \dots, m$ . In particular, normal extremals are smooth on  $[0, T]$ .

For abnormal extremals, the situation is much more involved, since system (1.2) does not provide directly an expression for abnormal controls. Abnormal extremals may be nonsmooth, and it is not always possible to determine an explicit expression for singular controls. Indeed, it follows from (1.2) that

$$(1.4) \quad h_i(\cdot) \equiv 0 \text{ on } [0, T], \quad i = 1, \dots, m,$$

along every abnormal extremal. At that point, in order to compute the singular control, one usually differentiates iteratively (1.4) with respect to  $t$  until the control appears explicitly (in an affine way). To recover the control, an invertibility property is then required, which may not hold in general.

In this paper, we prove that, in a generic context, such an invertibility property is obtained with a minimal number of differentiations (cf. Theorem 2.6). This is the concept of *minimal order*, defined in Definition 2.5. Here, genericity means that the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to an open and dense subset of the set of vector fields equipped with the Whitney topology. The corank one property is also proved to hold generically. We obtain similar results in the driftless case for generic  $m$ -tuples  $(f_1, \dots, f_m)$  (cf. Theorem 2.17).

Note that the latter result can be directly derived from [14] under the additional assumption that the  $m$ -tuples  $(f_1, \dots, f_m)$  are everywhere linearly independent. Such a geometric assumption is not adapted for control applications, e.g., whenever the state space is a product of manifolds involving a sphere of even dimension. One of the main novelties of this paper consists in dropping that assumption. As pointed out in [12], this raises serious technical difficulties, which furthermore cannot be treated by the methods of [14].

In a preliminary step for deriving the above theorems, we establish two results of independent interest, asserting that any trajectory of a generic control-affine system satisfies  $\dot{x} = 0$  almost everywhere on the set where the vector fields are linearly dependent (cf. Theorems 2.1 and 2.13).

When considering optimal control problems, we see that minimizing singular trajectories may exist, and play a major role, since they are not dependent on the specific minimization problem. The issue of such minimizing trajectories was already well known in the classical theory of calculus of variations (see, for instance, [9, 32]) and proved to be a major focus, during the 1940s, when the whole domain eventually developed into optimal control theory (cf. [10]). The optimality status of singular trajectories was chiefly investigated in [11, 30] in relation to control-affine systems with  $m = 1$ , in [1, 18, 19, 30] regarding driftless systems with  $m = 2$ , and in [2, 27] for general nonlinear control systems.

In this paper, we prove that, for generic systems with  $m \geq 2$  (and  $m \geq 3$  in the driftless case) and for a fixed cost  $C_{U,\alpha,g}$ , there does not exist minimizing singular trajectories (cf. Corollaries 2.9 and 2.20). We also prove that, given a fixed system

( $\Sigma$ ), singular trajectories are strictly abnormal, generically with respect to the cost (1.1) (cf. Propositions 2.12 and 2.22). We then show how the above mentioned results can be used to derive regularity results for the value function and in the theory of Hamilton–Jacobi equations, which in turn have applications for stabilization and motion planning.

This paper is organized as follows. Section 2 is devoted to the statement of the main results, first in the control-affine case, and second in the driftless case. The consequences are detailed in section 3, and proofs are provided in section 4.

**2. Statement of the main results.** Let  $M$  be a smooth,  $n$ -dimensional manifold. Throughout the paper,  $VF(M)$  denotes the set of smooth vector fields on  $M$ , endowed with the  $C^\infty$  Whitney topology.

**2.1. Trajectories of control-affine systems.** Let  $T$  be a positive real number. Consider the control-affine system

$$(2.1) \quad \dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t) f_i(x(t)),$$

where  $(f_0, \dots, f_m)$  is an  $(m+1)$ -tuple of smooth vector fields on  $M$ , and the set of admissible controls  $u = (u_1, \dots, u_m)$  is an open subset of  $L^\infty([0, T], \Omega)$ .

For every trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of (2.1), define  $I_{\text{dep}}(x(\cdot))$  as the closed subset of  $[0, T]$ ,

$$(2.2) \quad I_{\text{dep}}(x(\cdot)) := \{t \in [0, T] \mid \text{rank}\{f_0(x(t)), \dots, f_m(x(t))\} < m+1\}.$$

Note that, on the open subset of  $\mathbb{R}^n$ , where  $\text{rank}\{f_0, \dots, f_m\} = m+1$ , there is a one-to-one correspondence between trajectories and controls. In contrast, on  $I_{\text{dep}}(x(\cdot))$ , there is no uniqueness of the control associated to  $x(\cdot)$ ; in particular,  $x(\cdot)$  may be associated to both singular and nonsingular controls. This fact emphasizes the following result, which describes, in a generic context, trajectories on the subset of  $\mathbb{R}^n$ , where  $\text{rank}\{f_0, \dots, f_m\} < m+1$ .

**THEOREM 2.1.** *Let  $m < n$  be a nonnegative integer. There exists an open and dense subset  $O_{m+1}$  of  $VF(M)^{m+1}$  so that, if the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to  $O_{m+1}$ , then every trajectory  $x(\cdot)$  of the associated control-affine system  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$  verifies*

$$(2.3) \quad \dot{x}(t) = 0, \text{ for almost every } t \in I_{\text{dep}}(x(\cdot)).$$

*In addition, for every integer  $N$ , the set  $O_{m+1}$  can be chosen so that its complement has codimension greater than  $N$ .*

**Remark 2.2.** In light of the previous result, one can choose the admissible control  $u$  on  $I_{\text{dep}}(x(\cdot))$  such that, for every  $t \in I_{\text{dep}}(x(\cdot))$ ,  $u(t)$  consists of any  $m$ -tuple  $(\alpha_1, \dots, \alpha_m)$  so that

$$f_0(x(t)) + \sum_{i=1}^m \alpha_i f_i(x(t)) = 0.$$

In particular, on any subinterval of  $I_{\text{dep}}(x(\cdot))$ , the trajectory  $x(\cdot)$  is constant, and the control can be chosen constant as well.

**Remark 2.3.** A trajectory  $x(\cdot)$  is said to be *trivial* if it reduces to a point; otherwise it is said to be *nontrivial*. It is clear that, if  $I_{\text{dep}}(x(\cdot)) \neq [0, T]$ , then  $\dot{x}(t) \neq 0$  for  $t \notin I_{\text{dep}}(x(\cdot))$  and  $x(\cdot)$  is nontrivial.

Let  $x(\cdot)$  be a trajectory of a control-affine system associated to an  $(m+1)$ -tuple of  $O_{m+1}$ . As a consequence of Theorem 2.1,  $x(\cdot)$  is trivial if and only if  $I_{\text{dep}}(x(\cdot)) = [0, T]$ .

**2.2. Singular trajectories.** Recall that a singular trajectory  $x(\cdot)$  is the projection of an abnormal extremal  $(x(\cdot), \lambda(\cdot))$ . For  $t \in [0, T]$  and  $i, j \in \{0, \dots, m\}$ , we define

$$h_i(t) := \langle \lambda(t), f_i(x(t)) \rangle, \quad h_{ij}(t) := \langle \lambda(t), [f_i, f_j](x(t)) \rangle.$$

Along an abnormal extremal, we have for every  $t \in [0, T]$ ,

$$(2.4) \quad h_0(t) = \text{constant}, \quad h_i(t) = 0, \quad i = 1, \dots, m.$$

Differentiating (2.4), one gets, almost everywhere on  $[0, T]$ ,

$$(2.5) \quad h_{i0}(t) + \sum_{j=1}^m h_{ij}(t) u_j(t) = 0, \quad i \in \{0, \dots, m\}.$$

DEFINITION 2.4. *Along an abnormal extremal  $(x(\cdot), \lambda(\cdot), u(\cdot))$  of the system (2.1), the Goh matrix  $G(t)$  at time  $t \in [0, T]$  is the  $m \times m$  skew-symmetric matrix given by*

$$(2.6) \quad G(t) := (h_{ij}(t))_{1 \leq i, j \leq m}.$$

Since  $G(t)$  is skew-symmetric, rank  $G(t)$  is even, and (2.5) is rewritten as, almost everywhere on  $[0, T]$ ,

$$(2.7) \quad G(t)u(t) = b(t),$$

with  $b(t) := -(h_{i0}(t))_{1 \leq i \leq m}$ .

Note that, if  $G(t)$  is invertible, then  $u(t)$  is uniquely determined by (2.7). This only occurs for  $m$  even.

If  $m$  is odd,  $G(t)$  is never invertible. However, a similar construction is derived as follows. Define

$$(2.8) \quad \overline{G}(t) := (h_{ij}(t))_{0 \leq i, j \leq m}.$$

Since  $\overline{G}(t)$  is skew-symmetric, the determinant of  $\overline{G}(t)$  is the square of a polynomial  $\overline{P}(t)$  in the  $h_{ij}(t)$  with degree  $(m+1)/2$ , called the *Pfaffian* of  $\overline{G}(t)$  (see [6]). From (2.5),  $\overline{G}(t)$  is not invertible, and thus, along the extremal,  $\overline{P}(t) = 0$ . After differentiation, one gets, almost everywhere on  $[0, T]$ ,

$$(2.9) \quad \{\overline{P}, h_0\}(t) + \sum_{i=1}^m u_i(t) \{\overline{P}, h_i\}(t) = 0.$$

Define the  $(m+1) \times m$  matrix  $\tilde{G}(t)$  as  $G(t)$  augmented with the row  $(\{\overline{P}, h_j\}(t))_{1 \leq j \leq m}$ , and the  $(m+1)$ -dimensional vector  $\tilde{b}(t)$  as  $b(t)$  augmented with the coefficient  $-\{\overline{P}, h_0\}(t)$ . Then, from (2.7) and (2.9), there holds, almost everywhere on  $[0, T]$ ,

$$(2.10) \quad \tilde{G}(t)u(t) = \tilde{b}(t).$$

If  $\tilde{G}(t)$  is of rank  $m$ , then  $u(t)$  is uniquely determined by (2.10).

These facts, combined with Remark 2.2, motivate the following definition.

DEFINITION 2.5. *If  $m$  is even (resp., odd), a singular trajectory  $x(\cdot)$  is said to be of minimal order if*

- (i)  $\dot{x}(t) = 0$  for almost every  $t \in I_{\text{dep}}(x(\cdot))$ ;
- (ii) it admits an abnormal extremal lift such that, for almost every  $t \in [0, T] \setminus I_{\text{dep}}$ ,  
 $\text{rank } G(t) = m$  if  $m$  is even, resp.,  $\text{rank } \tilde{G}(t) = m$  if  $m$  is odd.

On the opposite side, for arbitrary  $m$ , a singular trajectory is said to be a *Goh trajectory* if it admits an abnormal extremal lift along which the Goh matrix is identically equal to 0.

**THEOREM 2.6.** *Let  $m < n$  be a positive integer. There exists an open and dense subset  $O_{m+1}$  of  $VF(M)^{m+1}$  so that, if the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to  $O_{m+1}$ , then every nontrivial singular trajectory of the associated control-affine system  $\dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t)f_i(x(t))$  is of minimal order and of corank one. In addition, for every integer  $N$ , the set  $O_{m+1}$  can be chosen so that its complement has codimension greater than  $N$ .*

**COROLLARY 2.7.** *With the notation of Theorem 2.6 and if  $m \geq 2$ , there exists an open and dense subset  $O_{m+1}$  of  $VF(M)^{m+1}$  so that every control-affine system defined with an  $(m+1)$ -tuple of  $O_{m+1}$  does not admit nontrivial Goh singular trajectories.*

**2.3. Minimizing singular trajectories.** We keep here the notation of the previous sections. Consider the control-affine system

$$(2.11) \quad \dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t)f_i(x(t)),$$

and the quadratic cost given by

$$(2.12) \quad C_{U,g}(T, u) = \frac{1}{2} \int_0^T \left( u(t)^T U(x(t)) u(t) + g(t, x(t)) \right) dt,$$

where  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ . Here,  $\mathcal{S}_m^+(M)$  denotes the set of smooth mappings  $x \mapsto U(x)$  on  $M$ , taking values in the set  $\mathcal{S}_m^+$  of  $m \times m$  real positive definite matrices.

For  $x_0 \in M$  and  $T > 0$ , define the optimal control problem

$$(2.13) \quad \inf \{ C_{U,g}(T, u) \mid E_{x_0, T}(u) = x \}.$$

We next state two sets of genericity results, which depend, resp., on whether the cost or the control system is fixed.

### 2.3.1. Genericity with respect to the control system, with a fixed cost.

**PROPOSITION 2.8.** *Fix  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ . There exists an open and dense subset  $O_{m+1}$  of  $VF(M)^{m+1}$  such that every nontrivial singular trajectory of a control-affine system defined by an  $(m+1)$ -tuple of  $O_{m+1}$  is strictly abnormal for the optimal control problem (2.13).*

Corollary 2.7, together with Proposition 2.8, yields the next corollary.

**COROLLARY 2.9.** *Fix  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ . Let  $m \geq 2$  be an integer. There exists an open and dense subset  $O_{m+1}$  of  $VF(M)^{m+1}$  so that the optimal control problem (2.13) defined with an  $(m+1)$ -tuple of  $O_{m+1}$  does not admit nontrivial minimizing singular trajectories.*

**Remark 2.10.** In both previous results, the set  $O_{m+1}$  can be chosen so that its complement has an arbitrary codimension.

### 2.3.2. Genericity with respect to the cost, with a fixed control system.

We endow  $\mathcal{S}_m^+(M)$  with the Whitney topology. An  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  of

$VF(M)^{m+1}$  is said to verify the *Lie algebra rank condition* (LARC) if the Lie algebra generated by  $f_0, \dots, f_m$  is of dimension  $n$  at every point of  $M$ .

**PROPOSITION 2.11.** *Fix  $(f_0, \dots, f_m) \in VF(M)^{m+1}$  so that the LARC is satisfied and the zero control  $u \equiv 0$  is not singular. Let  $g \in C^\infty(\mathbb{R} \times M)$ . Then, there exists an open and dense subset  $\mathcal{A}_m$  of  $\mathcal{S}_m^+(M)$  such that every nontrivial singular trajectory of the control-affine system associated to the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  is strictly abnormal for the optimal control problem (2.13) defined with  $U \in \mathcal{A}_m$  and  $g$ .*

Assuming that the zero control  $u \equiv 0$  is not singular is a necessary hypothesis. Indeed, the fact that a control  $u$  is singular is a property of the sole  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  and is independent of the cost. On the other hand, every trajectory  $x := x(\cdot, x_0, 0)$  associated to the zero control is always the projection of the normal extremal  $(x(\cdot), 0, -1, 0)$  of any optimal control problem (2.13). As a consequence, if the zero control is singular, such a trajectory  $x(\cdot, x_0, 0)$  cannot be strictly abnormal.

In order to handle the case of a singular zero control, it is therefore necessary to consider more general quadratic costs such as

$$(2.14) \quad C_{U,\alpha,g}(T, u) = \int_0^T \left( \frac{1}{2} u(t)^T U(x(t)) u(t) + \alpha(x(t))^T u(t) + g(t, x(t)) \right) dt,$$

where  $U \in \mathcal{S}_m^+(M)$ ,  $\alpha \in C^\infty(M, \mathbb{R}^m)$  and  $g \in C^\infty(\mathbb{R} \times M)$ .

**PROPOSITION 2.12.** *Fix  $(f_0, \dots, f_m) \in VF(M)^{m+1}$  satisfying the LARC and  $g \in C^\infty(\mathbb{R} \times M)$ . Then, there exists an open and dense subset  $\mathcal{B}_m$  of  $\mathcal{S}_m^+(M) \times C^\infty(M, \mathbb{R}^m)$  such that every nontrivial singular trajectory of the control-affine system associated to the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  is strictly abnormal for the optimal control problem (2.11)–(2.14) defined with  $(U, \alpha) \in \mathcal{B}_m$  and  $g$ .*

**2.4. Driftless control-affine systems.** Let  $T$  be a positive real number. Consider the driftless control-affine system

$$(2.15) \quad \dot{x}(t) = \sum_{i=1}^m u_i(t) f_i(x(t)),$$

where  $(f_1, \dots, f_m)$  is an  $m$ -tuple of smooth vector fields on  $M$ , and the set of admissible controls  $u = (u_1, \dots, u_m)$  is an open subset of  $L^\infty([0, T], \Omega)$ .

For every trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of (2.1), define  $I_{\text{dep}}(x(\cdot))$  as the closed subset of  $[0, T]$ ,

$$I_{\text{dep}}(x(\cdot)) := \{t \in [0, T] \mid \text{rank}\{f_1(x(t)), \dots, f_m(x(t))\} < m\}.$$

**THEOREM 2.13.** *Let  $m \leq n$  be a positive integer. There exists an open and dense subset  $O_m$  of  $VF(M)^m$  so that, if the  $m$ -tuple  $(f_1, \dots, f_m)$  belongs to  $O_m$ , then every trajectory  $x(\cdot)$  of the associated driftless control-affine system  $\dot{x} = \sum_{i=1}^m u_i f_i(x)$  verifies*

$$\dot{x}(t) = 0 \text{ for almost every } t \in I_{\text{dep}}(x(\cdot)).$$

*In addition, for every integer  $N$ , the set  $O_m$  can be chosen so that its complement has codimension greater than  $N$ .*

**Remark 2.14.** As a consequence, one can simply choose the admissible control  $u$  on  $I_{\text{dep}}(x(\cdot))$  such that, for every  $t \in I_{\text{dep}}(x(\cdot))$ ,  $u(t) = 0$ . This choice induces a one-to-one correspondence between trajectories and controls.

**2.4.1. Singular trajectories.** Let  $x(\cdot)$  be a singular trajectory; it is the projection of an abnormal extremal  $(x(\cdot), \lambda(\cdot))$ . Similarly to the previous section, we define, for  $t \in [0, T]$  and  $i, j \in \{1, \dots, m\}$ ,

$$h_i(t) := \langle \lambda(t), f_i(x(t)) \rangle, \quad h_{ij}(t) := \langle \lambda(t), [f_i, f_j](x(t)) \rangle.$$

For every  $t \in [0, T]$ ,

$$(2.16) \quad h_i(t) = 0, \quad i = 1, \dots, m.$$

Differentiating (2.16), one gets, almost everywhere on  $[0, T]$ ,

$$(2.17) \quad \sum_{j=1}^m h_{ij}(t) u_j(t) = 0, \quad i \in \{1, \dots, m\}.$$

DEFINITION 2.15. *Along an abnormal extremal  $(x(\cdot), \lambda(\cdot), u(\cdot))$  of the system (2.1), the Goh matrix  $G(t)$  at time  $t \in [0, T]$  is the  $m \times m$  skew-symmetric matrix given by*

$$(2.18) \quad G(t) := (h_{ij}(t))_{1 \leq i, j \leq m}.$$

Since  $G(t)$  is skew-symmetric,  $\text{rank } G(t)$  is even, and (2.17) is rewritten, almost everywhere on  $[0, T]$ , as

$$(2.19) \quad G(t)u(t) = 0.$$

Note that, if  $\text{rank } G(t) = m - 1$ , one can deduce from (2.19) an expression for  $u(t)$ , up to time reparameterization. This only occurs for  $m$  odd.

If  $m$  is even,  $\text{rank } G(t)$  is always smaller than  $m - 1$ . However, a similar construction is derived as follows. The determinant of  $G(t)$  is the square of the Pfaffian  $P(t)$ , and, along the extremal,  $P(t) \equiv 0$ . After differentiation, one gets, almost everywhere on  $[0, T]$ ,

$$(2.20) \quad \sum_{i=1}^m u_i(t) \{P, h_i\}(t) = 0.$$

Define the  $(m+1) \times m$  matrix  $\tilde{G}(t)$  as  $G(t)$  augmented with the row  $(\{P, h_j\}(t))_{1 \leq j \leq m}$ . Then, from (2.19) and (2.20), there holds, almost everywhere on  $[0, T]$ ,

$$(2.21) \quad \tilde{G}(t)u(t) = 0.$$

If  $\tilde{G}(t)$  is of rank  $m - 1$ , one can deduce from (2.21) an expression for  $u(t)$ , up to time reparameterization.

DEFINITION 2.16. *If  $m$  is odd (resp., even), a singular trajectory  $x(\cdot)$  is said to be of minimal order if*

- (i)  $\dot{x}(t) = 0$  for almost every  $t \in I_{\text{dep}}(x(\cdot))$ ;
- (ii) it admits an abnormal extremal lift such that, for almost every  $t \in [0, T] \setminus I_{\text{dep}}$ ,  $\text{rank } G(t) = m - 1$  if  $m$  is odd, resp.,  $\text{rank } \tilde{G}(t) = m - 1$  if  $m$  is even.

On the opposite side, for arbitrary  $m$ , a singular trajectory is said to be a *Goh trajectory* if it admits an abnormal extremal lift along which the Goh matrix is identically equal to 0.

**THEOREM 2.17.** *Let  $m$  be an integer such that  $2 \leq m \leq n$ . There exists an open and dense subset  $O_m$  of  $VF(M)^m$  so that, if the  $m$ -tuple  $(f_1, \dots, f_m)$  belongs to  $O_m$ , then every nontrivial singular trajectory of the associated driftless control-affine system  $\dot{x}(t) = \sum_{i=1}^m u_i(t)f_i(x(t))$  is of minimal order and of corank one. In addition, for every integer  $N$ , the set  $O_m$  can be chosen so that its complement has codimension greater than  $N$ .*

**COROLLARY 2.18.** *With the notation of Theorem 2.17 and if  $m \geq 3$ , there exists an open and dense subset  $O_m$  of  $VF(M)^m$  so that every driftless control-affine system defined with an  $m$ -tuple of  $O_m$  does not admit nontrivial Goh singular trajectories.*

**2.4.2. Minimizing singular trajectories.** Consider the optimal control problem associated to the driftless control-affine system

$$(2.22) \quad \dot{x}(t) = \sum_{i=1}^m u_i(t)f_i(x(t)),$$

with the quadratic cost given by

$$(2.23) \quad C_{U,g}(T, u) = \frac{1}{2} \int_0^T \left( u(t)^T U(x(t)) u(t) + g(t, x(t)) \right) dt,$$

where  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ .

For  $x_0 \in M$  and  $T > 0$ , define the optimal control problem

$$(2.24) \quad \inf \{ C_{U,g}(T, u) \mid E_{x_0, T}(u) = x \}.$$

We next state genericity results with respect to the control system, with a fixed cost.

**PROPOSITION 2.19.** *Fix  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ . There exists an open and dense subset  $O_m$  of  $VF(M)^m$  such that every nontrivial singular trajectory of a driftless control-affine system defined by an  $m$ -tuple of  $O_m$  is strictly abnormal for the optimal control problem (2.24).*

Corollary 2.18, together with Proposition 2.19, yields the next corollary.

**COROLLARY 2.20.** *Fix  $U \in \mathcal{S}_m^+(M)$  and  $g \in C^\infty(\mathbb{R} \times M)$ . Let  $m \geq 3$  be an integer. There exists an open and dense subset  $O_m$  of  $VF(M)^m$  so that the optimal control problem (2.24) defined with an  $m$ -tuple of  $O_m$  does not admit nontrivial minimizing singular trajectories.*

**Remark 2.21.** In both previous results, the set  $O_m$  can be chosen so that its complement has an arbitrary codimension.

We also have a genericity result with respect to the cost, with a fixed control system.

**PROPOSITION 2.22.** *Fix  $(f_1, \dots, f_m) \in VF(M)^m$  so that the LARC is satisfied. Let  $g \in C^\infty(\mathbb{R} \times M)$ . Then, there exists an open and dense subset  $\mathcal{A}_m$  of  $\mathcal{S}_m^+(M)$  such that every nontrivial singular trajectory of the driftless control-affine system associated to the  $m$ -tuple  $(f_1, \dots, f_m)$  is strictly abnormal for the optimal control problem (2.24) defined with  $U \in \mathcal{A}_m$  and  $g$ .*

**Remark 2.23.** In the driftless case, the control  $u \equiv 0$  is always singular but corresponds to a trivial trajectory. Therefore, in opposition to the control-affine case, it is not necessary to add the linear term  $\alpha(x)^T u$  in the cost.

### 3. Consequences.

**3.1. Regularity of the value function.** Consider the optimal control problem (2.13), associated to the control-affine system (2.11) and the cost (2.12). The value function is defined by

$$(3.1) \quad S_{x_0,T}(x) := \inf\{C_{U,g}(T, u) \mid E_{x_0,T}(u) = x\}$$

for every  $x \in \mathbb{R}^n$  (with, as usual,  $\inf \emptyset := -\infty$ ). We assume in what follows that all data are analytic.

The regularity of  $S_{x_0,T}$  is closely related to the existence of nontrivial minimizing singular trajectories starting from  $x_0$ . It is proved in [29] that, in the absence of minimizing singular trajectories, the value function is continuous and subanalytic (see, e.g., [16] for a definition of a subanalytic function). For driftless control-affine systems and  $g \equiv 0$ , the value function coincides with the square of a sub-Riemannian distance (see [7] for an introduction to sub-Riemannian geometry). In particular, in this case, the value function is always continuous, but the trivial trajectory  $x(\cdot) \equiv x_0$  is always minimizing and singular. Moreover, if there is no nontrivial minimizing singular trajectories, then the value function is subanalytic outside  $x_0$  (see [3, 4]). This situation holds for generic distributions of rank greater than or equal to three (see [5, 14]).

The results of section 2.3 have the following consequence on the regularity of  $S_{x_0,T}$ .

**COROLLARY 3.1.** *With the notation of Corollary 2.9, and if in addition the functions  $g$ ,  $U$  and the vector fields of the  $(m+1)$ -tuple in  $O_{m+1}$  are analytic, then the associated value function  $S_{x_0,T}$  is continuous and subanalytic on its domain of definition.*

**Remark 3.2.** If there exists a nontrivial minimizing singular trajectory, the value function may fail to be subanalytic or even continuous. For example, consider the control-affine system in  $\mathbb{R}^2$  given by

$$\dot{x}(t) = 1 + y(t)^2, \quad \dot{y}(t) = u(t),$$

and the cost  $C(T, u) = \int_0^T u(t)^2 dt$ . The trajectory  $(x(t) = t, y(t) = 0)$ , associated to the control  $u = 0$ , is a nontrivial minimizing singular trajectory, and the value function  $S_{(0,0),T}$  has the asymptotic expansion, near the point  $(T, 0)$ ,

$$S_{(0,0),T}(x, y) = \frac{1}{4} \frac{y^4}{x - T} + \frac{y^4}{x - T} \exp\left(-\frac{y^2}{x - T}\right) + o\left(\frac{y^4}{x - T} \exp\left(-\frac{y^2}{x - T}\right)\right)$$

(see [29] for details). Hence, it is neither continuous nor subanalytic at the point  $(T, 0)$ .

In the driftless control-affine case, by using the results of section 2.4.2, we derive the following similar consequence.

**COROLLARY 3.3.** *With the notation of Corollary 2.20, and if in addition the functions  $g$ ,  $U$  and the vector fields of the  $m$ -tuple in  $O_m$  are analytic, then the associated value function  $S_{x_0,T}$  is subanalytic outside  $x_0$ .*

### 3.2. Regularity of viscosity solutions of Hamilton–Jacobi equations.

Assume that the assumptions of the previous subsection hold. It is standard (see [15, 17]) that the value function  $v(t, x) = S_{x_0,t}(x)$  is a viscosity solution of the

Hamilton–Jacobi equation

$$(3.2) \quad \frac{\partial v}{\partial t} + \mathcal{H}\left(x, \frac{\partial v}{\partial x}\right) = g(t, x),$$

where  $\mathcal{H}(x, p) = \langle p, f_0(x) \rangle + \frac{1}{2} \sum_{i,j=1}^m (U^{-1}(x))_{ij} \langle p, f_i(x) \rangle \langle p, f_j(x) \rangle$ .

Conversely, the viscosity solution of (3.2) with analytic Dirichlet-type conditions is subanalytic, as soon as the corresponding optimal control problem does not admit minimizing singular trajectories (see [31]). Using the results of the previous sections, this situation holds generically if  $m \geq 2$  (and, similarly for driftless control-affine systems, if  $m \geq 3$ ).

As a consequence, the analytic singular set  $\text{Sing}(v)$  of the viscosity solution  $v$ , i.e., the subset of  $\mathbb{R}^n$  where  $v$  is not analytic, is a (subanalytic) stratified manifold of codimension greater than or equal to one (see [28] for more details on the subject). Since  $\text{Sing}(v)$  is also the locus where characteristic curves intersect, the above mentioned property turns out to be instrumental for the global convergence of numerical schemes for (3.2) (see [15]). Indeed, the analytic singular set must be as “nice” as possible in order to integrate energy functions on the set of characteristic curves.

**3.3. Applications to stabilization and motion planning.** For a driftless control-affine system verifying the LARC, there exist general stabilizing strategies stemming from dynamic programming. As usual, the stabilizing feedback is computed using the gradient of the value function  $S$  for a suitable optimal control problem. Of course this is only possible outside the singular set  $\text{Sing}(S)$ , and one must devise another construction for the feedback on  $\text{Sing}(S)$ . Let us mention two such strategies, the first one providing a hybrid feedback (see [22]) and the second one a smooth repulsive stabilizing (SRS) feedback (see [23, 24]). Both strategies crucially rely on the fact that  $\text{Sing}(S)$  is a stratified manifold of codimension greater than or equal to one.

As seen before, the latter fact holds generically in the analytic category for  $m \geq 3$ .

On the other hand, the absence of minimizing singular trajectories is the basic requirement for the convergence of usual algorithms in optimal control (such as direct or indirect methods; see, e.g., [8, 20]). We have proved that this situation holds generically for control-affine systems if  $m \geq 2$  and for driftless control-affine systems if  $m \geq 3$ .

As a final application, consider a driftless control-affine system verifying the LARC. According to Proposition 2.22, it is possible to choose a (generic) cost function  $C_{U,g}$  such that all singular trajectories are strictly abnormal. Combining that fact with [25, Theorem 1.1], we deduce that there exists a dense subset  $N$  of  $\mathbb{R}^n$  such that every point of  $N$  is reached by a unique minimizing trajectory, which is, moreover, nonsingular. As a consequence, a shooting method with a target in  $N$  will converge. That fact may be used for solving (at least approximately) motion planning problems.

## 4. Proofs of the results.

**4.1. Proofs of Theorems 2.1 and 2.13.** Every trajectory of the control-affine system  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$  is also a trajectory of the driftless control system  $\dot{x} = \sum_{i=0}^m u_i f_i(x)$ , with  $u_0 \equiv 1$ . Therefore, Theorem 2.1 follows from Theorem 2.13, whose proof is provided next.

Let  $x(\cdot) = x(\cdot, x_0, u)$  be a trajectory of the driftless control system  $\dot{x} = \sum_{i=1}^m u_i f_i(x)$ , with  $2 \leq m \leq n$ . Consider the set  $I_{\text{dep}}(x(\cdot))$  defined by (2.2). We argue by contraposition and assume that  $I_{\text{dep}}(x(\cdot))$  contains a subset  $I$  of positive

measure such that  $\dot{x}(t) \neq 0$  for  $t \in I$ . Since Lebesgue points of  $u$  are of full Lebesgue measure, we assume that  $u$  is continuous on  $I$ .

Up to considering a subset of  $I$ , and relabeling the  $f_i$ 's, we assume that, for every  $t \in I$ , that

- (i) there exists  $1 \leq k < m$  such that

$$\text{rank}\{f_1(x(t)), \dots, f_m(x(t))\} = k;$$

- (ii)  $f_1(x(t)), \dots, f_k(x(t))$  are linearly independent, and thus, there exist real numbers  $\alpha_i^j(t)$ ,  $i = 1, \dots, k$ ,  $j = k+1, \dots, m$ , such that

$$f_j(x(t)) = \sum_{i=1}^k \alpha_i^j(t) f_i(x(t)), \quad j = k+1, \dots, m.$$

Therefore,  $\dot{x}(t) = \sum_{i=1}^k \delta_i(t) f_i(x(t))$ , where  $\delta_i(t) := u_i(t) + \sum_{j=k+1}^m \alpha_i^j(t) u_j(t)$ ;

- (iii)  $\delta_1(t) \neq 0$ .

*Remark 4.1.* Up to reducing  $I$ , we furthermore assume that  $I$  is contained in an open interval  $\mathcal{I}$  on which  $\text{rank}\{f_1(x(t)), \dots, f_k(x(t))\} = k$ .

Set  $\text{ad}^0 g(h) = h$ , where  $g, h \in \text{VF}(M)$ , and  $\text{ad}^k g(h) = [g, \text{ad}^{k-1} g(h)]$  for  $k \geq 1$ . The length of the iterated Lie bracket  $[f_{i_1}, [f_{i_2}, [\dots, f_{i_k}]\dots]]$  of  $f_1, \dots, f_m$  is the integer  $k$ .

**PROPOSITION 4.2.** *Let  $N$  be a positive integer. There exists a subset  $J_N \subset I$  of positive measure such that, for every  $t \in J_N$  and every  $\ell \in \{1, \dots, N\}$ ,*

$$(4.1) \quad \delta_1(t)^{\ell-1} \text{ad}^{\ell-1} f_1(f_m)(x(t)) = h_t^\ell(x(t)) + R_t^\ell(x(t)),$$

where

- $h_t^\ell(x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\}$ ;
- $R_t^\ell$  is a linear combination of iterated Lie brackets of  $f_1, \dots, f_m$ , of length smaller than  $\ell-1$ , and of iterated Lie brackets of  $f_1, \dots, f_k$ , of length smaller than or equal to  $\ell$ .

*Proof.* For  $t \in I$ , let  $F_t \in \text{VF}(M)$  be the vector field defined by

$$F_t(x) := \sum_{i=1}^k \delta_i(t) f_i(x).$$

Notice that  $\dot{x}(t) = F_t(x(t))$  for  $t \in I$ . For the argument of Proposition 4.2, we need the following lemma.

**LEMMA 4.3.** *Consider a set  $J \subset I$  of positive measure and  $h \in \text{VF}(M)$  so that  $h(x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\}$  on  $J$ ; i.e., for every  $t \in J$ , there exist real numbers  $\beta_i(t)$ ,  $i = 1, \dots, k$ , such that*

$$(4.2) \quad h(x(t)) = \sum_{i=1}^k \beta_i(t) f_i(x(t)).$$

For  $t \in J$ , define  $g_t \in \text{VF}(M)$  by

$$g_t(x) := h(x) - \sum_{i=1}^k \beta_i(t) f_i(x).$$

Then, there exists a set  $J' \subset J$  of positive measure such that

$$(4.3) \quad [F_t, g_t](x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\} \quad \text{on } J'.$$

*Proof of Lemma 4.3.* Using Remark 4.1, we see that there exist  $e_j \in VF(M)$ ,  $k+1 \leq j \leq n$ , so that, for every  $t \in \mathcal{I}$ , the vectors  $f_1(x(t)), \dots, f_k(x(t)), e_{k+1}(x(t)), \dots, e_n(x(t))$  span  $T_{x(t)}M$ . Thus, there exist  $n$  smooth functions  $b_i$ ,  $1 \leq i \leq n$ , defined on  $M$ , such that

$$h(x) = \sum_{i=1}^k b_i(x) f_i(x) + \sum_{i=k+1}^n b_i(x) e_i(x),$$

for  $x$  in an open neighborhood of  $x(\mathcal{I})$ . For  $i = 1, \dots, n$ , define  $\beta_i(t) := b_i(x(t))$  for  $t \in \mathcal{I}$  (this notation is consistent with (4.2)). The  $\beta_i$ 's are absolutely continuous on  $\mathcal{I}$  and differentiable everywhere on  $J$ . For  $i = k+1, \dots, n$ , there holds  $\beta_i \equiv 0$  on  $J$  and therefore, it follows that  $\dot{\beta}_i \equiv 0$  on a subset  $J' \subset J$  of full measure (cf. [26, Lemma p. 177]).

For  $t \in J$ , using that  $g_t(x(t)) = 0$  and  $F_t(x(t)) = \dot{x}(t)$ , it holds that

$$\begin{aligned} [F_t, g_t](x(t)) &= dg_t \circ F_t(x(t)) \\ &= \sum_{i=1}^k (db_i(x(t)) \cdot \dot{x}(t)) f_i(x(t)) + \sum_{i=k+1}^n (db_i(x(t)) \cdot \dot{x}(t)) e_i(x(t)) \\ &= \sum_{i=1}^k \dot{\beta}_i(t) f_i(x(t)) + \sum_{i=k+1}^n \dot{\beta}_i(t) e_i(x(t)). \end{aligned}$$

On  $J'$ , the second sum of the right-hand side of the last equation vanishes, and the lemma follows.  $\square$

Applying Lemma 4.3 to  $h = f_m$  and  $J = I$ , we get

$$[F_t, g_t^1](x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\} \quad \text{on } J_1,$$

where  $J_1 \subset I$  and  $g_t^1 := f_m - \sum_{i=1}^k \alpha_i^m(t) f_i$ .

Set  $h_t^1 = [F_t, g_t^1]$ . We next iterate the above procedure for  $1 \leq \ell \leq N$ . Assume that the vector fields  $h_t^\ell$ ,  $g_t^\ell$  and the set  $J_\ell$  of positive measure are defined such that  $h_t^\ell(x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\}$  on  $J_\ell$ . For every  $t \in J_\ell$ , let  $\beta_i^\ell(t)$ ,  $i = 1, \dots, k$ , be the real numbers such that

$$h_t^\ell(x(t)) = \sum_{i=1}^k \beta_i^\ell(t) f_i(x(t)),$$

and define  $g_t^{\ell+1} \in VF(M)$  by  $g_t^{\ell+1} := h_t^\ell - \sum_{i=1}^k \beta_i^\ell(t) f_i$ . Set  $h_t^{\ell+1} := [F_t, g_t^{\ell+1}]$ . Applying Lemma 4.3, there exists a subset  $J_{\ell+1} \subset J_\ell$  of positive measure such that  $h_t^{\ell+1}(x(t)) \in \text{Span}\{f_1(x(t)), \dots, f_k(x(t))\}$  on  $J_{\ell+1}$ .

For  $t \in J_N$ , and for  $\ell = 1, \dots, N$ , we express  $h_t^\ell(x(t))$  using iterated Lie brackets of  $f_1, \dots, f_m$ , and an easy induction yields (4.1).  $\square$

Combining Proposition 4.2 with routine transversality arguments (see, for instance, [12] and [14]), it follows that the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to a closed subset of  $VF(M)^{m+1}$  of codimension greater than or equal to  $N$ . Theorem 2.13 follows.

*Remark 4.4.* The fact that  $f_1(x(t)) \neq 0$  is essential in order to derive, from (4.1), an infinite number of independent relations, and then to apply the above mentioned transversality arguments.

**4.2. Proof of Theorem 2.6.** The minimal order and corank one properties are proved separately in the following lemmas.

LEMMA 4.5. *There exists an open and dense subset  $O_{m+1}^1$  of  $VF(M)^{m+1}$  so that, if the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to  $O_{m+1}^1$ , then every singular trajectory of the associated control-affine system  $\dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t)f_i(x(t))$  is of minimal order. In addition, for every integer  $N$ , the set  $O_{m+1}^1$  can be chosen so that its complement has codimension greater than  $N$ .*

LEMMA 4.6. *There exists an open and dense subset  $O_{m+1}$  of  $O_{m+1}^1$  so that, if the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to  $O_{m+1}$ , then every nontrivial singular trajectory of the associated control-affine system  $\dot{x}(t) = f_0(x(t)) + \sum_{i=1}^m u_i(t)f_i(x(t))$  is of corank one. In addition, for every integer  $N$ , the set  $O_{m+1}$  can be chosen so that its complement has codimension greater than  $N$ .*

The conclusion of Theorem 2.6 follows.

**4.2.1. Proof of Lemma 4.5.** From Theorem 2.1, there exists an open and dense subset  $O_{m+1}^{11}$  of  $VF(M)^{m+1}$  such that, if  $(f_0, \dots, f_m) \in O_{m+1}^{11}$ , then every trajectory  $x(\cdot)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$  verifies item (i) of Definition 2.5.

It is therefore enough to show the existence of an open and dense subset  $O_{m+1}^{12}$  of  $VF(M)^{m+1}$  such that, if  $(f_0, \dots, f_m) \in O_{m+1}^{12}$ , then every singular trajectory  $x(\cdot)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$  verifies item (ii) of Definition 2.5. Then, by choosing  $O_{m+1}^1 := O_{m+1}^{11} \cap O_{m+1}^{12}$ , the conclusion of Lemma 4.5 follows.

Consider a singular trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$ , admitting an abnormal extremal  $(x(\cdot), \lambda(\cdot))$ . Assume that there exists  $J \subset [0, T] \setminus I_{\text{dep}}(x(\cdot))$  of positive measure such that  $G(t)$  is not of rank  $m$  if  $m$  is even, resp.,  $\tilde{G}(t)$  is not of rank  $m$  if  $m$  is odd. We will show that the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to a subset of arbitrary codimension in  $VF(M)^{m+1}$  whose complement contains an open and dense subset.

Note that, on  $[0, T] \setminus I_{\text{dep}}(x(\cdot))$ , the vector fields  $f_0(x(t)), \dots, f_m(x(t))$  are linearly independent. The remaining part of the argument consists of reformulating the problem in order to follow the chain of arguments in the proof of [14, Theorem 2.4] concerning the case of everywhere linearly independent vector fields. For that purpose, we distinguish the cases  $m$  even and  $m$  odd.

Assume first that  $m$  is even. As in (2.8), define, for  $t \in J$ ,  $\overline{G}(t) := (h_{ij}(t))_{0 \leq i, j \leq m}$ . From (2.7), we have, for  $t \in J$ ,

$$\overline{G}(t) = \begin{pmatrix} 0 & (G(t)u(t))^T \\ -G(t)u(t) & G(t) \end{pmatrix}.$$

Since the ranks of both  $\overline{G}(t)$  and  $G(t)$  are even, they must be equal, for  $t \in J$ , and hence, the rank of  $\overline{G}(t)$  is smaller than  $m$  on  $J$ . This is exactly the starting point of the proof of [14, Lemma 3.8]. The machinery of [14] then applies and we deduce that the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to a subset of arbitrary codimension in  $VF(M)^{m+1}$  whose complement contains an open and dense subset  $O_{m+1}^2$  of  $VF(M)^{m+1}$ .

Assume next that  $m$  is odd. Define the  $(m+2) \times (m+1)$  matrix  $\widehat{G}(t)$  as  $\overline{G}(t)$  augmented in the last row with  $(\{P, h_j\}(t))_{0 \leq j \leq m}$ .

LEMMA 4.7. *With the notation above,  $\text{rank } \widehat{G}(t) \leq \text{rank } \tilde{G}(t) + 1$ .*

*Proof.* It amounts to showing that  $\xi \in \ker \tilde{G}(t)$  implies  $(0, \xi) \in \ker \widehat{G}(t)$ . This follows from the fact that if  $\tilde{G}(t)\xi = 0$ , then  $G(t)\xi = 0$ , and thus  $\xi$  is orthogonal to the range of  $G(t)$  since  $G(t)$  is skew-symmetric.  $\square$

Using Lemma 4.7, we see that the rank of  $\widehat{G}(t)$  is less than  $m + 1$  on  $J$ . This is exactly the starting point of the proof of [14, Lemma 3.9]. The machinery of [14] then applies and we deduce that the  $(m + 1)$ -tuple  $(f_0, \dots, f_m)$  belongs to a subset of arbitrary codimension in  $VF(M)^{m+1}$  whose complement contains an open and dense subset  $O_{m+1}^{12}$  of  $VF(M)^{m+1}$ .

**4.2.2. Proof of Lemma 4.6.** We argue by contraposition. Consider a nontrivial singular trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$ , with  $(f_0, \dots, f_m) \in O_{m+1}^1$ . Assume  $x(\cdot)$  admits two abnormal extremal lifts  $(x(\cdot), \lambda^{[1]}(\cdot))$  and  $(x(\cdot), \lambda^{[2]}(\cdot))$  such that, for some  $t_0 \in [0, T]$ ,  $\lambda^{[1]}(t_0)$  and  $\lambda^{[2]}(t_0)$  are linearly independent. By linearity,  $\lambda^{[1]}(\cdot)$  and  $\lambda^{[2]}(\cdot)$  are linearly independent everywhere on  $[0, T]$ . Since  $x(\cdot)$  is nontrivial, it follows from Remark 2.3 that there exists a nonempty subinterval  $J$  of  $[0, T] \setminus I_{\text{dep}}(x(\cdot))$ . We are now in a position to exactly follow the arguments of [14] corresponding to the corank one property, i.e., [14, Lemma 4.4].

**4.3. Proof of Theorem 2.17.** We start with the proof of the statement dealing with the minimal order property.

From Theorem 2.13, there exists an open and dense subset  $O_m^1$  of  $VF(M)^m$  such that, if  $(f_1, \dots, f_m) \in O_m^1$ , then every trajectory  $x(\cdot)$  of  $\dot{x} = \sum_{i=1}^m u_i f_i(x)$  verifies item (i) of Definition 2.16.

It is therefore enough to show the existence of an open and dense subset  $O_m^2$  of  $VF(M)^m$  such that, if  $(f_1, \dots, f_m) \in O_m^2$ , then every singular trajectory  $x(\cdot)$  of  $\dot{x} = \sum_{i=1}^m u_i f_i(x)$  verifies item (ii) of Definition 2.16. Then, by choosing  $O_m := O_m^1 \cap O_m^2$ , the statement dealing with the minimal order property in Theorem 2.17 follows.

Consider a singular trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of  $\dot{x} = \sum_{i=1}^m u_i f_i(x)$  admitting an abnormal extremal  $(x(\cdot), \lambda(\cdot))$ . Assume that there exists  $J \subset [0, T] \setminus I_{\text{dep}}(x(\cdot))$  of positive measure such that  $G(t)$  is not of rank  $m - 1$  if  $m$  is odd, resp.,  $\widetilde{G}(t)$  is not of rank  $m - 1$  if  $m$  is even. Following exactly the proofs of Lemmas 3.8 and 3.9 in [14], the  $m$ -tuple  $(f_1, \dots, f_m)$  belongs to a subset of arbitrary codimension in  $VF(M)^m$  whose complement contains an open and dense subset.

We proceed similarly for an argument of the statement dealing with the corank one property.

**4.4. Proofs of Propositions 2.8 and 2.19.** We only treat the control-affine case, as the argument for the driftless control-affine case is identical. We argue by contraposition. Consider a nontrivial singular trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$ , with  $(f_0, \dots, f_m) \in VF(M)^{m+1}$ . Assume that  $x(\cdot)$  admits on the one part a normal extremal lift  $(x(\cdot), \lambda^{[n]}(\cdot))$  and on the other part an abnormal extremal lift  $(x(\cdot), \lambda^{[a]}(\cdot))$ .

Let us introduce some notation. For  $k \in \mathbb{N}$ , let  $L = l_1 \cdots l_k$  be a multi-index of  $\{0, \dots, m\}$ . The length of  $L$  is  $|L| = k$  and  $f_L$  is the vector field defined by

$$f_L := [[\cdots [f_{l_1}, f_{l_2}], \cdots], f_{l_k}].$$

A multi-index  $L = jl \cdots l$  with  $k$  consecutive occurrences of the index  $l$  is denoted as  $L = j l^k$ .

For every multi-index  $L$  of  $\{0, \dots, m\}$  and  $t \in [0, T]$ , set

$$h_L^{[n]}(t) = \langle \lambda^{[n]}(t), f_L(x(t)) \rangle \text{ and } h_L^{[a]}(t) = \langle \lambda^{[a]}(t), f_L(x(t)) \rangle.$$

After time differentiation, we have on  $[0, T]$ ,

$$(4.4) \quad \frac{d}{dt} h_L^{[n]}(t) = \sum_{l=1}^m u_l(t) h_{Ll}^{[n]}(t),$$

$$(4.5) \quad \frac{d}{dt} h_L^{[a]}(t) = \sum_{l=1}^m u_l(t) h_{Ll}^{[a]}(t).$$

Recall that, according to the Pontryagin maximum principle, there holds

$$(4.6) \quad u(t) = \begin{pmatrix} u_1(t) \\ \vdots \\ u_m(t) \end{pmatrix} = U(x(t))^{-1} \begin{pmatrix} h_1^{[n]}(t) \\ \vdots \\ h_m^{[n]}(t) \end{pmatrix},$$

and, for every  $t \in [0, T]$ ,

$$(4.7) \quad h_0^{[a]}(t) = \text{constant}, \quad h_i^{[a]}(t) = 0,$$

for every  $l \in \{1, \dots, m\}$ , and  $t \in [0, T]$ . Since the trajectory  $x(\cdot)$  is nontrivial, there exists an open interval  $J \subset [0, T]$  and  $i \in \{0, \dots, m\}$  such that  $u_i(\cdot) f_i(x(\cdot))$  is never vanishing (with the convention  $u_0 \equiv 1$ ). Fix  $j \in \{0, \dots, m\} \setminus \{i\}$ . Differentiating  $s$  times (with  $s \geq 1$ ) the relation  $h_j^{[a]}(t) = \text{constant}$  with respect to  $t \in J$ , one gets, by using (4.4), (4.5), and (4.6), that

$$(4.8) \quad 0 = \frac{d^s}{dt^s} h_j^{[a]}(t) = (u_i(t))^s h_{ji^s}^{[a]}(t) + R_s(t),$$

where  $R_s(t)$  is polynomial in  $h_L^{[n]}(t)$  and  $h_K^{[a]}(t)$ ,  $|L| \leq s$ ,  $|K| \leq s+1$ , with  $K$  different from  $ji^s$  and  $iji^{s-1}$ . Fix  $t \in J$ . Since  $u_i(t) \neq 0$  and  $f_i(x(t)) \neq 0$ , we are in a position to apply routine transversality arguments. It follows that the  $(m+1)$ -tuple  $(f_0, \dots, f_m)$  belongs to a closed subset of  $VF(M)^{m+1}$  of arbitrary codimension. Proposition 2.8 follows.

**4.5. Proofs of Propositions 2.11, 2.12, and 2.22.** We first prove Proposition 2.12 and argue by contraposition. Consider a nontrivial singular trajectory  $x(\cdot) := x(\cdot, x_0, u)$  of  $\dot{x} = f_0(x) + \sum_{i=1}^m u_i f_i(x)$ . Assume that  $x(\cdot)$  admits on the one part a normal extremal lift  $(x(\cdot), \lambda^{[n]}(\cdot))$  and on the other part an abnormal extremal lift  $(x(\cdot), \lambda^{[a]}(\cdot))$ .

From the Pontryagin maximum principle, there holds, for  $l = 1, \dots, m$ ,

$$u_l(t) = \sum_{p=1}^m Q^{lp}(x(t)) \beta_p(x(t)), \quad \beta_p(x(t)) := h_p^{[n]}(t) - \alpha_p(x(t)),$$

where the  $Q^{lp}(x)$  and the  $\alpha_p(x)$  are, resp., the coefficients of  $U^{-1}(x)$  and of  $\alpha(x)$ . Note that the  $u_l$ 's are smooth functions of the time.

Since the trajectory  $x(\cdot)$  is nontrivial, there exists an open interval  $J \subset [0, T]$  such that  $\dot{x}$  is never vanishing on  $J$  and one of the two following cases holds.

*Case 1.*  $u \equiv 0$  on  $J$ .

In that case,  $\dot{x}(t) = f_0(x(t))$  for  $t \in J$ , and  $f_0(x(\cdot))$  is never vanishing on  $J$ . Moreover, for  $p = 1, \dots, m$ ,  $\beta_p \equiv 0$  on  $J$ , i.e.,  $\alpha_p(x(t)) = h_p^{[n]}(t)$  for  $t \in J$ . By differentiating the latter relation with respect to the time, we deduce that, for all  $N \geq 0$ ,  $t \in J$ , and  $p = 1, \dots, m$ ,

$$L_{f_0}^N \alpha_p(x(t)) = L_{f_0}^N h_p^{[n]}(x(t)),$$

where  $L_{f_0}$  denotes the Lie derivative with respect to the vector field  $f_0$ . Applying routine transversality arguments, it follows that  $\alpha$  belongs to a closed subset of  $C^\infty(M, \mathbb{R}^m)$  of arbitrary codimension.

*Case 2.*  $u$  is never vanishing on  $J$ .

Using (2.4) and the LARC, there exist a multi-index  $L$ , an index  $j_0 \in \{0, \dots, m\}$ , and a subinterval of  $J$  (still denoted  $J$ ), such that

$$h_L^{[a]}(t) = \text{constant and } h_{L_{j_0}}^{[a]}(t) \neq 0$$

for every  $t \in J$ . Differentiating  $h_L^{[a]}$  on  $J$ , one gets

$$\begin{aligned} 0 &= \frac{d}{dt} h_L^{[a]}(t) = h_{L_0}^{[a]}(t) + \sum_{l=1}^m u_l(t) h_{L_l}^{[a]}(t) \\ (4.9) \quad &= h_{L_0}^{[a]}(t) + \sum_{1 \leq l \leq p \leq m} c_{lp}(t) Q^{lp}(x(t)), \end{aligned}$$

where  $c_{ll}(t) := \beta_l(t) h_{L_l}^{[a]}(t)$ , and  $c_{lp}(t) := \beta_p(t) h_{L_l}^{[a]}(t) + \beta_l(t) h_{L_p}^{[a]}(t)$  if  $l < p$ .

LEMMA 4.8. *Up to reducing the interval  $J$ , there exist indices  $j$  and  $l$  in  $\{1, \dots, m\}$  such that  $c_{lj}(t)$  or  $c_{jl}(t)$  is never vanishing on  $J$ .*

*Proof.* If  $j_0 = 0$ , then  $h_{L_0}^{[a]}(t) \neq 0$ , and it follows from (4.9) that there exist  $l, j \in \{1, \dots, m\}$  such that  $c_{lj}(t) \neq 0$ . Otherwise, take  $j := j_0$ . In that case, one of the  $\beta_p$ 's does not vanish on  $J$  since  $u$  is not zero. First, assume that  $\beta_j(t)$  is not identically equal to zero on  $J$ ; then, up to reducing  $J$ ,  $c_{jj}(t)$  is never vanishing on  $J$ . Otherwise, there exists  $l \neq j$  such that, up to reducing  $J$ ,  $\beta_l$  is never vanishing on  $J$  and thus similarly for  $c_{lj}$  (or  $c_{jl}$ ).  $\square$

For  $t \in J$ , let  $F_t \in VF(M)$  be the vector field defined by

$$F_t(x) := f_0(x) + \sum_{i=1}^m u_i(t) f_i(x).$$

Notice that  $F_t(x(t)) = \dot{x}(t) \neq 0$ . For all  $N \geq 0$  and  $t \in J$ , we get, by taking the  $(N+1)$ th time derivative of  $h_L^{[a]}$  on  $J$ ,

$$0 = \frac{d^{N+1}}{dt^{N+1}} h_L^{[a]}(t) = c_{lj}(t) L_{F_t}^N Q^{jl}(x(t)) + R_N(t),$$

where  $R_N(t)$  is a linear combination of  $L_{F_t}^s Q^{pi}(x(t))$  with  $s \leq N$ ,  $p \leq i$  in  $\{1, \dots, m\}$ , and  $s < N$  if  $(p, i) = (j, l)$ , and of  $L_{f_r}^s Q^{pi}(x(t))$  with  $s < N$ ,  $p \leq i$  in  $\{1, \dots, m\}$ , and  $r \in \{0, \dots, m\}$ . Applying routine transversality arguments, it follows that  $(U, \alpha)$  belongs to a closed subset of  $\mathcal{S}_m^+(M) \times C^\infty(M, \mathbb{R}^m)$  of arbitrary codimension. Proposition 2.12 is proved.

To show Propositions 2.11 and 2.22, we simply note that the argument of Case 2 with  $\alpha = 0$  applies with suitable modifications.

## TIME-VARYING REGULAR BILINEAR SYSTEMS\*

HAMID BOUNITH<sup>†</sup> AND ABDELALI IDRISSE<sup>‡</sup>

**Abstract.** The theory of infinite-dimensional systems introduced and developed by Salamon [*Trans. Amer. Math. Soc.*, 300 (1987), pp. 383–431] and Weiss [*SIAM J. Control Optim.*, 27 (1989), pp. 527–545] has been recently applied for various systems; see, e.g., the Jacob–Partington survey [*Current Trends in Operator Theory and its Applications*, Birkhäuser, Boston, 2004]. In the same spirit, Schnaubelt, in his recent work [*SIAM J. Control Optim.*, 41 (2002), pp. 1141–1165], has extended their approach to the time-varying linear systems. In this paper, we follow this spirit and prove that one can extend the results recently obtained for infinite-dimensional time-invariant bilinear systems to the time-varying setting. In particular, we show that the absolute regularity and detectability assumptions ensure the existence of an observer for this kind of systems.

**Key words.** evolution family, well-posed bilinear systems, Lebesgue extension, representation, feedback bilinear systems, detectability, observer

**AMS subject classifications.** 34K35, 34K17, 47D06, 93C23

**DOI.** 10.1137/050632245

**1. Introduction.** In this paper, we deal with the large class of infinite-dimensional time-varying bilinear systems which allow some degree of unboundedness in control and observation. These systems are of the following form:

$$(1.1) \quad \begin{cases} \dot{x}(t) &= A(t)x(t) + u(t)B(t)x(t), \quad t \geq s \geq 0, \\ y(t) &= C(t)x(t), \quad x(s) = x_0, \end{cases}$$

where  $A(t)$ ,  $t \geq 0$ , generate an evolution family  $\mathbb{T}(\cdot, \cdot)$  on  $X$ . The inputs  $u(\cdot)$  are  $L^2_{loc}$ -integrable scalar functions. The Banach spaces  $X$  and  $Y$  are state space and output space, respectively. The linear operators  $B(t)$  are bounded from  $X$  to its extension  $\bar{X}_t$ , which is a Banach space, and  $C(t)$  are densely defined linear operators from  $\underline{X}_t$  to  $Y$ , with  $\underline{X}_t \subset X \subset \bar{X}_t$ . Such operators, called “unbounded,” arise from the modeling of point or boundary control and sensing; see, e.g., [6]. The bilinear systems can be considered as an intermediate subclass between the linear and nonlinear systems. Their relation to several phenomena, especially in engineering areas (see, e.g., [7, 26]) justify their importance. The system (1.1) is a generalized time-varying version of the systems considered recently in [6].

If we consider the particular case  $\underline{X}_t = X = \bar{X}_t$ , then the state  $x$  and the output  $y$  of the system (1.1) can be interpreted by the following functional equations:

$$(1.2) \quad x(t) = \mathbb{T}(t, s)x_0 + \Phi_{t,s}(u, x) \quad \text{for } t \geq s,$$

$$(1.3) \quad y = \Psi_s x_0 + \mathbb{F}_s(u, x) \quad \text{on } [0, t],$$

where  $\Phi_{t,s}(u, x) := \int_s^t \mathbb{T}(t, \tau)u(\tau)B(\tau)x(\tau)d\tau$  (the bilinear input-state operator),  $(\Psi_s x_0)(t) := C(t)\mathbb{T}(t, s)x_0$  (the linear state-output operator), and  $\mathbb{F}_s(u, x)(t) := C(t)$

$\Phi_{t,s}(u, x)$  (the bilinear input-output operator). In our setting, where the unboundedness of control and observation operators is considered, we just conserve, in an abstract formulation, the algebraic relations interconnecting the operators  $\mathbb{T}$ ,  $\Phi$ ,  $\Psi$ , and  $\mathbb{F}$ . These also interpret the different relations between the three components of the time-varying bilinear systems: input, state, and output. This approach was first introduced by Salamon [29] and developed by Weiss [36] for time-invariant linear systems. Later, many studies of time-varying linear systems have proposed different generalizations of this approach; see, e.g., [19, 21, 22, 25, 31].

In the present work we combine the notion of well-posed time-varying linear systems due to Schnaubelt [31] and that of well-posed time-invariant bilinear systems (i.e.,  $A(t) = A, B(t) = B$  and  $C(t) = C$ ), which we have introduced in [6]. The main motivation of our framework is the study of the observer design problem for the well-posed time-varying bilinear system constituted by the quadruple  $\Sigma := (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  (see section 4).

By setting up our abstract framework, we give some topological properties of the bilinear input-state operator  $\Phi$  and the bilinear input-output operator  $\mathbb{F}$  (see Lemmas 3.3 and 3.4). This will be used to give a representation of the abstract system  $\Sigma$  in terms of some control and observation operators. More precisely, we prove that the bilinear input-state operator  $\Phi$  is still “approximately” represented by some bounded operators  $B_n(\cdot)$  (see Proposition 3.9), and under regularity assumptions, which assume a certain smoothness of  $\mathbb{F}_s$  at initial time  $s$  (see Definition 3.10), we also prove that  $\mathbb{F}_s$  can be represented via some unbounded observation operator  $C(\cdot)$  (see Theorem 3.12). This later is extracted by means of the Lebesgue points of the functions  $\Psi_s x_0$  (the output of  $\Sigma$  with  $u = 0$  and initial state  $x_0$ ). This technique was used by Weiss [35] for time-invariant linear systems and later by Schnaubelt [31] for the time-varying situation. We have to mention that in the time-invariant setting we can give, by means of the extrapolation theory, a representation of the bilinear input-state operators  $\Phi$  as convolutions of the semigroups with some unbounded control operators  $B$  (see [20, Cor. 3.11]). The extrapolation theory developed for semigroups (see, e.g., [15, sect. VI.9]) shows that the approximation leads to the existence of the unbounded admissible control operator  $B$ , and if  $X$  is reflexive, the operator  $B$  has to be bounded (see [20, Cor. 4.8]). This theory, however, has no counterpart for evolution families. But the approximation procedure still holds, in our setting, for the convolutions associated with  $\mathbb{T}$  and  $B_n(\cdot)$ . A similar result has been also established by Schnaubelt for time-varying linear systems [31, Prop. 3.5].

In Theorem 3.14 we show that the state trajectory  $x(\cdot)$  of the well-posed time-varying bilinear system  $\Sigma$  exists and is unique by solving the equation (1.2). Further, for any input  $u \in L^2(s, \infty)$  the associated state is given by  $x(t) = \mathbb{T}_u(t, s)x_0$ , where the evolution family  $\mathbb{T}_u$  satisfies the “variation of constants formula”

$$\mathbb{T}_u(t, s)x_0 = \mathbb{T}(t, s)x_0 + \Phi_{t,s}(u, \mathbb{T}_u(\cdot, s)x_0)$$

for  $t \geq s$  and  $x_0 \in X$  (see Theorem 3.14). On the other hand, the regularity gives sense to the output function  $y$  of  $\Sigma$  given by (1.3), since  $x(t)$  fits in  $D(C(t))$  for a.e.  $t \geq s$  (see Theorem 3.15). We show also that the unbounded observation operators  $C(\cdot)$  issued from  $\Sigma$  are still admissible for the evolution family  $\mathbb{T}_u$  whence  $u \in L^2(s, \infty) \cup L^\infty(s, \infty)$ ; i.e., the linear state-output operator  $\Psi_u$  associated with  $C(\cdot)$  and  $\mathbb{T}_u$  can map any initial state  $x_0 \in X$  to an  $L^2_{loc}$ -function which coincides with the output of  $\Sigma$  (see Proposition 3.17).

The results thus obtained in section 3 will serve us to study the observer design problem for the well-posed time-varying bilinear systems  $\Sigma$ . In contrast to the linear systems, the existence and the type of the observer depend on the injected inputs and this even for time-invariant bilinear systems. In the finite-dimensional situation we can cite, e.g., the works by Funahashi [16] and Hara and Furuta [18], who have been interested in the inputs which make the system unobservable called “bad” inputs. Bornard, Couenne, and Celle [2] and Celle et al. [8] were interested in the observer design exited by a class of inputs called “regularly persistent” inputs. In the infinite-dimensional case there are the works by Gauthier, Xu, and Bounabat [17] and Bounit and Hammouri [5], who have adapted the notion of regular persistent input to the infinite-dimensional skew-adjoint bilinear systems. In [4] Bounit and Hammouri have also proposed an exponential observer for bilinear systems when the semigroup is contractive on Hilbert space  $X$ , and the control and observation operators are supposed bounded. Recently, we have given some generalization of the previous results to the regular time-invariant bilinear systems on Banach spaces [6]. We have proved the existence of a Luenberger-like observer for such systems without restrictive conditions on the semigroup [6, Thm. 5.7].

In this paper, we investigate the problem of observer design for the well-posed time-varying bilinear systems  $\Sigma$ . We establish, in Theorem 4.5, the existence of the so-called “feedback” bilinear systems  $\Sigma^K := (\mathbb{T}^K, \Phi^K, \Psi^K, \mathbb{F}^K)$  which describe exactly the estimation error and inherit the absolute regularity. In Proposition 4.7, we prove that the system  $\Sigma^K$  can be represented by the same control and observation operators issued from the observed system  $\Sigma$ . The main result in section 4 (Theorem 4.9) gives the existence of an exponential Luenberger-like observer for the systems  $\Sigma$ . This extends the results of [4, 6] to the present setting. Our condition on the pair  $(\mathbb{T}, \Psi)$ —detectability (see Definition 4.8)—is somewhat stronger than that introduced by Schnaubelt [31, Def. 5.8], but it coincides with that considered by Rebarber [28, Def. 1.5] for time-invariant linear systems.

The article is organized as follows: In section 2 we review the notions of well-posed and regular time-varying linear systems and collect necessary tools for our study. In section 3 we introduce and develop the notions of well-posed and regular time-varying bilinear systems. Section 4 is devoted to designing an observer for absolutely regular time-varying bilinear systems. We give a time-varying version of the results already obtained for this kind of system. Finally, in section 5 we present an example of a system with boundary control and unbounded observation which can be written as an absolutely regular time-varying bilinear systems. We show also the existence of exponential observers for this system.

**2. Well-posed and regular time-varying linear systems: Review.** In this section we recall the necessary background on time-varying linear systems which allow some unboundedness in controls and observations. These systems were initially introduced and studied by Curtain and Pritchard [10], Hinrichsen and Pritchard [19], Jacob [22, 23], and Jacob, Dragan, and Pritchard [25]. Here we recall some notions and collect recent results due to Schnaubelt [31]. The proofs will be omitted and will be referenced.

We begin, first, by fixing some notations which will be used throughout the paper. For a complex Banach space  $E$  and  $p \in [1, +\infty]$  we set  $E^p := L^p([0, \infty), E)$ , and for  $s \geq 0$  we denote by  $E_{loc}^{p,s}$  and  $E_{loc}^p := E_{loc}^{p,0}$  the spaces  $L_{loc}^p([s, \infty); E)$  and  $L_{loc}^p([0, \infty); E)$ , respectively, endowed with their standard Fréchet topology.  $L^\infty([0, \infty),$

$\mathcal{L}_s(E, F)$  is the space of (essentially) bounded strongly measurable operator-valued functions. For  $f \in E_{loc}^{p,s}$  we denote by  $f|_J$  the restriction of  $f$  to the interval  $J$ . We say that  $t \in \mathbb{R}_+$  is a  $p$ -Lebesgue point of  $f \in E_{loc}^p$  if

$$\lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} \|f(t) - f(\sigma)\|^p d\sigma = 0.$$

It is known (see, e.g., [14, sect. I.1.8], [37, Lem. 6.1]) that almost every  $t \in \mathbb{R}_+$  is a Lebesgue point of  $f$ . We use  $\chi_I$  to denote the characteristic function of the interval  $I$ . For a vector  $z \in E$  we shall use the tensor notation  $\chi_{\mathbb{R}_+} \otimes z$  to denote the function defined by  $(\chi_{\mathbb{R}_+} \otimes z)(t) = z$ . For Banach spaces  $E$ ,  $F$ , and  $G$ ,  $\mathcal{L}(E, F)$  denotes the space of bounded linear operators from  $E$  into  $F$  ( $\mathcal{L}(E) := \mathcal{L}(E, E)$ ), and  $\mathcal{BL}(E \times F, G)$  is the space of bounded bilinear operators from  $E \times F$  to  $G$ .

DEFINITION 2.1. Let  $X$  be a Banach space and  $\Delta := \{(t, s), 0 \leq s \leq t\}$ . An evolution family is a set  $\mathbb{T} := (\mathbb{T}(t, s))_{(t,s) \in \Delta}$  of bounded linear operators on  $X$  such that

- (i)  $\mathbb{T}(s, s) = I$ ;
- (ii)  $\mathbb{T}(t, s) = \mathbb{T}(t, r)\mathbb{T}(r, s)$  for all  $0 \leq s \leq r \leq t$ ;
- (iii)  $(t, s) \mapsto \mathbb{T}(t, s)$  is strongly continuous on  $X$ .

We define the exponential growth bound of evolution family  $\mathbb{T}$  by

$$\omega_0(\mathbb{T}) := \inf\{\omega \in \mathbb{R} : \exists M_\omega \geq 1 \text{ with } \|\mathbb{T}(t, \tau)\| \leq M_\omega e^{\omega(t-\tau)} \text{ for } (t, \tau) \in \Delta\}.$$

In contrast to strongly continuous semigroups, the evolution family may not be exponentially bounded (i.e.  $\omega_0(\mathbb{T}) = +\infty$ ). For this reason and in order to obtain some estimations, we need to deal with the exponentially bounded evolution family. If  $\omega_0(\mathbb{T}) < 0$ , we say that the evolution family  $\mathbb{T}$  is *exponentially stable*. For more details on evolution families and the associated time-varying Cauchy problems, we refer to [9], [15, sect. VI.9], and [30].

We now recall some properties of well-posed and regular time-varying linear systems as introduced by Schnaubelt [31]. Those systems are necessary for studying the problem of observer design for the introduced time-varying bilinear systems; see section 4.

DEFINITION 2.2. Let  $U, X$ , and  $Y$  be Banach spaces. A well-posed time-varying linear system on  $(X, U, Y)$  for state space  $X$ , control space  $U$ , and output space  $Y$  is the quadruple  $\Gamma := (\mathbb{T}, \mathbb{K}, \Psi, \mathbb{L})$ , where

- (i)  $\mathbb{T} := (\mathbb{T}(t, s))_{(t,s) \in \Delta}$  is an evolution family on  $X$ ;
- (ii)  $\mathbb{K} := (\mathbb{K}_{t,s})_{(t,s) \in \Delta}$  is a family of operators in  $\mathcal{L}(U_{loc}^{2,s}, X)$  such that

$$(2.1) \quad \mathbb{K}_{t,s}u = \mathbb{K}_{t,r}(u|_{[r,\infty)}) + \mathbb{T}(t, r)\mathbb{K}_{r,s}(u), \quad s \leq r \leq t, \text{ and}$$

$$(2.2) \quad \|\mathbb{K}_{t,s}(u)\|_X \leq \beta \|u\|_{L^2([s,t], U)}, \quad s \leq t \leq s + t_0,$$

for  $u \in U_{loc}^{2,s}$  and some/all  $t_0$  and  $\beta = \beta(t_0) > 0$ . The pair  $(\mathbb{T}, \mathbb{K})$  is called a time-varying linear control system on  $(X, U)$ ;

- (iii)  $\Psi := (\Psi_s)_{s \geq 0}$  is a family of operators in  $\mathcal{L}(X, Y_{loc}^{2,s})$  such that

$$(2.3) \quad \Psi_s x = \Psi_t \mathbb{T}(t, s)x, \quad \text{on } [t, \infty), \text{ and}$$

$$(2.4) \quad \int_s^{s+t_0} \|(\Psi_s x)(t)\|^2 dt \leq \delta^2 \|x\|^2,$$

for  $(t, s) \in \Delta$ ,  $x \in X$ , and some/all  $t_0$  and constant  $\delta = \delta(t_0) > 0$ . The pair  $(\mathbb{T}, \Psi)$  is called a time-varying linear observation system on  $(X, Y)$ ;

(iv)  $\mathbb{L} := (\mathbb{L}_s)_{s \geq 0}$  is a family of operators in  $\mathcal{L}(U_{loc}^{2,s}, Y_{loc}^{2,s})$  such that

$$(2.5) \quad \mathbb{L}_s u = \Psi_t \mathbb{K}_{t,s} u + \mathbb{L}_t(u|_{[t,\infty)}) \quad \text{on } [t, \infty), \text{ and}$$

$$(2.6) \quad \|\mathbb{L}_s u\|_{L^2([s, s+t_0], Y)} \leq \kappa \|u\|_{L^2([s, s+t_0], U)}$$

for  $u \in U_{loc}^{2,s}$ ,  $(t, s) \in \Delta$ , and some/all  $t_0$  and constant  $\kappa = \kappa(t_0) > 0$ . The operators  $\mathbb{L}_s$ ,  $s \geq 0$ , are called input-output operators.

The above definition can be extended to the case of  $p \in [1, \infty)$  instead of  $p = 2$ . As for time-invariant linear observation systems, it was shown [31] that time-varying observation systems are typically given by some unbounded operators which we define as follows.

DEFINITION 2.3. Let  $\mathbb{T}$  be an evolution family on  $X$  and  $C(s) : X \supset D(C(s)) \rightarrow Y$ ,  $s \geq 0$ , be densely defined linear operators. We say that  $C(\cdot)$  are  $\mathbb{T}$ -admissible observation operators if

$$(i) \quad \mathbb{T}(\cdot, s)x \in \mathcal{D}_s(C(\cdot)),$$

$$(ii) \quad \int_s^{s+t_0} \|C(t)\mathbb{T}(t, s)x\|^2 dt \leq \delta^2 \|x\|^2$$

for  $s \geq 0$ ,  $x \in D(C(s))$ , and some constants  $\delta, t_0 > 0$ .

Here  $\mathcal{D}_s(C(\cdot)) := \{f \in X_{loc}^{2,s} : f(t) \in D(C(t)) \text{ for a.e. } t \geq s, C(\cdot)f(\cdot) \in Y_{loc}^{2,s}\}$ .

By the above admissibility, the mapping

$$(2.7) \quad \begin{aligned} \Psi_s : D(C(s)) &\longrightarrow Y_{loc}^{2,s}, \quad s \geq 0, \\ x &\longmapsto \Psi_s x := C(\cdot)\mathbb{T}(\cdot, s)x \end{aligned}$$

has a unique extension (again noted by  $\Psi_s$ ) to linear bounded operators from  $X$  to  $Y_{loc}^{2,s}$ , and the pair  $(\mathbb{T}, \Psi)$  is a time-varying linear observation system represented by  $C(\cdot)$ . Conversely, it was shown [31] that a time-varying observation system  $(\mathbb{T}, \Psi)$  can be represented by admissible observation operators. This extends the time-invariant case given in [35]. In fact, we define the operators  $C(\cdot)$  as follows:

$$(2.8) \quad D(C(s)) = \underline{X}_s := \left\{ x \in X : \exists C(s)x := Y - \lim_{\tau \searrow 0} \frac{1}{\tau} \int_s^{s+\tau} (\Psi_s x)(\sigma) d\sigma \right\},$$

equipped with the norm

$$\|x\|_{\underline{X}_s} := \|x\| + \sup_{0 < \tau \leq 1} \left\| \frac{1}{\tau} \int_s^{s+\tau} (\Psi_s x)(\sigma) d\sigma \right\|_Y$$

for  $x \in \underline{X}_s$ . Then  $(\underline{X}_s, \|\cdot\|_s)$ ,  $s \geq 0$ , are Banach spaces,  $\underline{X}_s \subset X$ , and  $C(s)$  is linear continuous. It was shown (see [31, Thm. 2.7]) that the operators  $C(\cdot)$  are admissible and  $(\Psi_s x)(t) = C(t)\mathbb{T}(t, s)x$  for all Lebesgue points  $t$  of  $\Psi_s x$ .

A more important subclass of well-posed linear systems is those which are regular. This concept was first introduced by Weiss [37] and generalized latter by Schnaubelt [31] to the time-varying systems.

DEFINITION 2.4. Let  $\Gamma = (\mathbb{T}, K, \Psi, \mathbb{L})$  be a time-varying linear system. Then  $\Gamma$  is called a regular linear system (with feedthrough  $D = 0$ ) if for  $v \in U, t \geq 0$  the following limit exists in  $Y$ :

$$(2.9) \quad \lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} \mathbb{L}_t(\chi_{\mathbb{R}_+} \otimes v)(\sigma) d\sigma = 0,$$

and absolutely regular if

$$\lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} \|\mathbb{L}_t(\chi_{\mathbb{R}_+} \otimes v)(\sigma)\|^2 d\sigma = 0.$$

One can remark that  $\Gamma = (\mathbb{T}, K, \Psi, \mathbb{L})$  is regular if the step response  $\mathbb{L}_t(\chi_{\mathbb{R}_+} \otimes v)$  has a Lebesgue point at  $t$  equal to zero for all  $t \geq 0$ .

**3. Well-posed and regular time-varying bilinear systems.** In this section, we follow what we have presented in the previous section. We give the time-varying analogue of the well-posed bilinear systems introduced in [6].

**DEFINITION 3.1.** *Let  $X$  and  $Y$  be Banach spaces. A well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$ , for state space  $X$ , control space  $\mathbb{C}$ , and output space  $Y$ , is the quadruple  $\Sigma := (\mathbb{T}, \Phi, \Psi, \mathbb{F})$ , where*

- (i)  $\mathbb{T}$  and  $\Psi$  satisfy (i) and (iii) of Definition 2.2, respectively;
- (ii)  $\Phi := (\Phi_{t,s})_{(t,s) \in \Delta}$  is a family of operators in  $\mathcal{BL}(\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}, X)$  satisfying

$$(3.1) \quad \Phi_{t,s}(u, x) = \Phi_{t,r}(u|_{[r,\infty)}, x|_{[r,\infty)}) + \mathbb{T}(t, r)\Phi_{r,s}(u, x), \quad s \leq r \leq t, \text{ and}$$

$$(3.2) \quad \|\Phi_{t,s}(u, x)\|_X \leq \beta \|u\|_{L^2[s,t]} \|x\|_{L^2([s,t], X)}, \quad s \leq t \leq s + t_0,$$

for  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ , and constants  $t_0, \beta = \beta(t_0) > 0$ . Then the pair  $(\mathbb{T}, \Phi)$  is called a time-varying bilinear control system on  $X$ ;

- (iii)  $\mathbb{F} := (\mathbb{F}_s)_{s \geq 0}$  is a family of operators in  $\mathcal{BL}(\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}, Y_{loc}^{2,s})$  such that

$$(3.3) \quad \mathbb{F}_s(u, x) = \Psi_t \Phi_{t,s}(u, x) + \mathbb{F}_t(u|_{[t,\infty)}, x|_{[t,\infty)}) \quad \text{on } [t, \infty) \text{ and}$$

$$(3.4) \quad \|\mathbb{F}_s(u, x)\|_{L^2([s, s+t_0], Y)} \leq \kappa \|u\|_{L^2[s, s+t_0]} \|x\|_{L^2([s, s+t_0], X)}$$

for  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ ,  $(t, s) \in \Delta$ , and constants  $t_0, \kappa = \kappa(t_0) > 0$ .

**Remark 3.2.**

- (i) The property (3.3) shows that the operator  $\mathbb{F}_s$  is causal, i.e.,  $\mathbb{F}_s(u, x)|_{[t,\infty)} = \mathbb{F}_t(u|_{[t,\infty)}, x|_{[t,\infty)})$ . Thus, one can define the restriction

$$\mathbb{F}_{t,s} := \mathbb{F}_s : L^2[s, t] \times L^2([s, t], X) \rightarrow L^2([s, t], Y).$$

- (ii) If  $(\mathbb{T}, \Phi)$  is a well-posed time-varying bilinear control system on  $X$ , then  $(\mathbb{T}, \Phi(\chi_{\mathbb{R}_+}, \cdot))$  is a well-posed time-varying linear control system on  $(X, U := X)$ . Conversely, let  $X = U$ , and assume that the pair  $(\mathbb{T}, \varphi)$  is a linear control system for  $p = 1$ ; then  $(\mathbb{T}, \Phi)$  is a bilinear control system on  $(X, U)$  for all  $p \in (1, \infty)$  where  $\Phi_{t,s}(u, x) := \varphi_{t,s}(u \cdot x)$ . Moreover, if  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  is a well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$ , then the associated quadruple  $\Gamma_\Sigma = (\mathbb{T}, \Phi(\chi_{\mathbb{R}_+}, \cdot), \Psi, \mathbb{F}(\chi_{\mathbb{R}_+}, \cdot))$  is a time-varying linear system on  $(X, X, Y)$ .

We start with some lemmas which will be used in the subsequent developments.

**LEMMA 3.3.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$  with  $\omega_0(\mathbb{T}) < \infty$ . Then*

$$(3.5) \quad \|\Phi_{t,s}(u, x)\|_X \leq d(\omega, t - s) \|u\|_{L^2[s,t]} \|x\|_{L^2([s,t], X)},$$

$$(3.6) \quad \|\Phi_{\cdot,s}(u, x)\|_{L^2([s,t], X)} \leq d(\omega, t - s) \|u\|_{L^2[s,t]} \|x\|_{L^2([s,t], X)},$$

$$(3.7) \quad \|\mathbb{F}_s(u, x)\|_{L^2([s, s+t_1], Y)} \leq d(\omega, t_1) \|u\|_{L^2[s, s+t_1]} \|x\|_{L^2([s, s+t_1], X)}$$

for  $t_1 \geq 0$ ,  $t \geq s \geq 0$ ,  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ , where  $\omega > \omega_0(\mathbb{T})$ ,

$$d(\omega, t) := \begin{cases} d_0(w)e^{\omega t} & \text{if } \omega > 0, \\ d_0(w) \left(1 + \frac{t}{t_0}\right)^{\frac{1}{2}} & \text{if } \omega = 0, \\ d_0(\omega)e^{\omega t_0} & \text{if } \omega < 0, \end{cases}$$

and  $d_0, t_0$  are positive constants.

*Proof.* Let  $t_0$  be the constant given in Definition 3.1(ii). For  $s \leq t \leq s + t_0$ , the assertion (3.5) is clear. Now let  $t > s + t_0$  and  $n := [\frac{t-s}{t_0}]$  (the integer part of  $\frac{t-s}{t_0}$ ), and set  $s_k := s + kt_0$  for  $k \in \mathbb{N} := \{0, 1, \dots\}$ . Then  $t \in I_n := [s_n, s_{n+1}]$ . Let  $u_k$  and  $x_k$  be the restriction of  $u$  and  $x$  to  $I_k \cap [s, t]$  for  $k = 0, \dots, n$ , respectively. By using (3.1) and proceeding by induction we obtain

$$\Phi_{t,s}(u, x) = \Phi_{t,s_n}(u_n, x_n) + \sum_{k=1}^n \mathbb{T}(t, s_k) \Phi_{s_k, s_{k-1}}(u_{k-1}, x_{k-1}).$$

That means

$$\begin{aligned} \|\Phi_{t,s}(u, x)\| &\leq \beta(t_0) \|u_n\|_{L^2[s,t]} \|x_n\|_{L^2([s,t], X)} \\ &\quad + M\beta(t_0) \sum_{k=1}^n e^{\omega(t-s_k)} \|u_{k-1}\|_{L^2[s,t]} \|x_{k-1}\|_{L^2([s,t], X)} \\ &\leq M\beta(t_0) e^{\omega^- t_0} \left( \sum_{k=0}^{\infty} e^{\omega t_0(n-k)} \|u_k\|_{L^2[s,t]} \|x_k\|_{L^2([s,t], X)} \right) \\ &= M\beta(t_0) e^{\omega^- t_0} \left( \sum_{k=0}^{\infty} e_{(n-k)} \|u_k\|_{L^2[s,t]} \|x_k\|_{L^2([s,t], X)} \right), \end{aligned}$$

where  $\omega^- := \min\{\omega, 0\}$  and  $e_k := e^{\omega t_0 k}$  if  $k = 0, \dots, n$  and  $e_k := 0$  elsewhere. Thus, Young's and Hölder's inequalities yield estimation (3.5). Estimation (3.6) is straightforward.

The assertion (3.7) is clear for  $t_1 \leq t_0$ . Assume, now that  $t_1 > t_0$ , as in (i) that there is  $n \in \mathbb{N}^* := \mathbb{N} - \{0\}$  such that  $t_1 \in I_n := [s_n, s_{n+1}]$ . By using (3.1) and (3.3) we obtain

$$\begin{aligned} \mathbb{F}_s(u, x) &= \Psi_{s_k} \Phi_{s_k, s}(u, x) + \mathbb{F}_{s_k}(u_k, x_k) \quad \text{on } I_k \\ &= \mathbb{F}_{s_k}(u_k, x_k) + \sum_{j=1}^k \Psi_{s_k} \mathbb{T}(s_k, s_j) \Phi_{s_j, s_{j-1}}(u_{j-1}, x_{j-1}). \end{aligned}$$

Hence

$$\begin{aligned} \|\mathbb{F}_s(u, x)\|_{L^2(I_k, Y)} &\leq \kappa(t_0) \|u_k\|_{L^2(I_k)} \|x_k\|_{L^2(I_k, X)} \\ &\quad + M\kappa(t_0) \delta(t_0) \sum_{j=1}^k e^{\omega t_0(k-j)} \|u_{j-1}\|_{L^2(I_{j-1})} \|x_{j-1}\|_{L^2(I_{j-1}, X)} \\ &\leq c(t_0) e^{\omega^- t_0} \sum_{j=1}^k e^{\omega t_0(k-j)} \|u_{j-1}\|_{L^2(I_{j-1})} \|x_{j-1}\|_{L^2(I_{j-1}, X)}, \end{aligned}$$

where  $c(t_0) := \max\{\kappa(t_0)M\kappa(t_0)\delta(t_0)\}$ . Therefore it follows that

$$\begin{aligned} \|\mathbb{F}_s(u, x)\|_{L^2([s, s+t_1], Y)} &\leq \left( \sum_{k=0}^n \|\mathbb{F}_s(u, x)\|_{L^2(I_k, Y)}^2 \right)^{1/2} \\ &\leq c(t_0)e^{\omega^- t_0} \left( \sum_{k=0}^n \left( \sum_{j=0}^k e^{\omega(k-j)} \|u_j\|_{L^2(I_j)} \|x_j\|_{L^2(I_j, X)} \right)^2 \right)^{\frac{1}{2}} \\ &\leq c(t_0)e^{\omega^- t_0} \left( \sum_{k=0}^{\infty} \left( \sum_{j=0}^k e^{\omega(k-j)} \|u_j\|_{L^2(I_j)} \|x_j\|_{L^2(I_j, X)} \right)^2 \right)^{\frac{1}{2}}. \end{aligned}$$

By applying once again Young's and Hölder's inequalities, we then obtain

$$\|\mathbb{F}_s(u, x)\|_{L^2([s, s+t_1], Y)} \leq c(t_0)e^{\omega^- t_0} \left( \sum_{k=0}^n e^{2\omega t_0 k} \right)^{\frac{1}{2}} \|u\|_{L^2[s, s+t_1]} \|x\|_{L^2([s, s+t_1], X)}.$$

Thus the asserted estimate follows.  $\square$

LEMMA 3.4. *Let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$  with  $\omega_0(\mathbb{T}) < \infty$ . If  $u \in \mathbb{C}_{loc}^{2,s}$  and  $x \in X_{loc}^{2,s}$ , then the following properties hold:*

- (i)  $t \mapsto \Phi_{t,s}(u, x) \in X$  is continuous from the right for  $t \geq s$ ;
- (ii)  $s \mapsto \Phi_{t,s}(u, x) \in X$  is continuous for  $s \in [0, t]$  (locally uniformly in  $t$ );
- (iii)  $(t, s) \mapsto \Phi_{t,s}(u, x)$  is measurable in  $X$ .

*Proof.* In view of (3.1), we get

$$\begin{aligned} \Phi_{t',s}(u, x) - \Phi_{t,s}(u, x) &= \Phi_{t',t}(u, x) + (\mathbb{T}(t', t) - I)\Phi_{t,s}(u, x) \text{ and} \\ \Phi_{t,s}(u, x) - \Phi_{t,s'}(u, x) &= \mathbb{T}(t, s')\Phi_{s',s}(u, x) \end{aligned}$$

for all  $t' \geq t \geq s' \geq s \geq 0$ . Thus, we can estimate

$$\begin{aligned} \|\Phi_{t',s}(u, x) - \Phi_{t,s}(u, x)\| &\leq \kappa \|u\|_{L^2[t, t']} \|x\|_{L^2([t, t'], X)} + \|(\mathbb{T}(t', t) - I)\Phi_{t,s}(u, x)\| \text{ and} \\ \|\Phi_{t,s}(u, x) - \Phi_{t,s'}(u, x)\| &\leq M\kappa e^{|\omega|(t-s)} \|u\|_{L^2[s, s']} \|x\|_{L^2([s, s'], X)}. \end{aligned}$$

Thus the lemma is proved.  $\square$

DEFINITION 3.5. *Let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$ ,  $(\mathbb{T}, \Psi)$  be a time-varying linear observation system on  $(X, Y)$ , and  $C(\cdot)$  be the observation operator associated with  $(\mathbb{T}, \Psi)$  given by (2.8). We say that the bilinear triple  $(\mathbb{T}, \Phi, \Psi)$  is admissible on  $(X, \mathbb{C}, Y)$  if for all  $s \geq 0$ ,  $u \in \mathbb{C}_{loc}^{2,s}$ , and  $x \in X_{loc}^{2,s}$*

- (i)  $\Phi_{\cdot,s}(u, x) \in \mathcal{D}_s(C(\cdot))$  and

$$(ii) \|C(\cdot)\Phi_{\cdot,s}(u, x)\|_{L^2([s, s+t_0], Y)} \leq \kappa \|u\|_{L^2[s, s+t_0]} \|x\|_{L^2([s, s+t_0], X)}$$

for some constants  $\kappa, t_0 > 0$ .

PROPOSITION 3.6. *Let  $(\mathbb{T}, \Phi, \Psi)$  be an admissible triple on  $(X, \mathbb{C}, Y)$ . Define  $\mathbb{F}_s(u, x) := C(\cdot)\Phi_{\cdot,s}(u, x)$ . Then  $(\mathbb{T}, \Phi, \Psi, \mathbb{F})$  is a well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$ .*

*Proof.* We have only to verify (3.3) for all  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ , and  $(t, s) \in \Delta$ . By definition, we have

$$\begin{aligned}\mathbb{F}_s(u, x)(\tau) &= C(\tau)\Phi_{\tau,s}(u, x) \\ &= C(\tau)(\Phi_{\tau,t}(u|_{[t,\infty)}, x|_{[t,\infty)}) + \mathbb{T}(\tau, t)\Phi_{t,s}(u, x)) \\ &= C(\tau)\Phi_{\tau,t}(u|_{[t,\infty)}, x|_{[t,\infty)}) + C(\tau)\mathbb{T}(\tau, t)\Phi_{t,s}(u, x) \\ &= \mathbb{F}_t(u|_{[t,\infty)}, x|_{[t,\infty)})(\tau) + (\Psi_t\Phi_{t,s}(u, x))(\tau)\end{aligned}$$

for a.e.  $\tau \geq t$ .  $\square$

Let  $\overline{X}_t$ ,  $t \geq 0$ , be Banach spaces in which  $X$  is densely and continuously embedded. We assume that  $\mathbb{T}(t, s)$  has a locally uniformly bounded extension  $\overline{\mathbb{T}}(t, s) : \overline{X}_s \rightarrow \overline{X}_t$  verifying (i) and (ii) of Definition 2.1. We assume that  $\overline{\mathbb{T}}(t, \cdot)$  is strongly continuous. The following definition of admissible control operators is a simple extension of that given in [20] for the time-invariant case. For  $(t, s) \in \Delta$  and  $f \in L_{loc}^1([s, \infty), X)$  we define

$$(\mathbb{V}_s^{\overline{\mathbb{T}}}f)(t) := \int_s^t \overline{\mathbb{T}}(t, \tau)f(\tau) d\tau.$$

DEFINITION 3.7. We say that  $B(t) \in \mathcal{L}(X, \overline{X}_t)$ ,  $t \geq 0$ , is  $\mathbb{T}$ -admissible control operators if the following hold:

- (i) The function  $\overline{\mathbb{T}}(t, \cdot)u(\cdot)B(\cdot)x(\cdot)$  is integrable in  $\overline{X}_t$  and

$$(3.8) \quad [\mathbb{V}_s^{\overline{\mathbb{T}}}(uB(\cdot))x](t) := \int_s^t \overline{\mathbb{T}}(t, \tau)u(\tau)B(\tau)x(\tau) d\tau \in X.$$

- (ii) There are constants  $t_0, \beta > 0$  such that

$$(3.9) \quad \|[\mathbb{V}_s^{\overline{\mathbb{T}}}(uB(\cdot))x](t)\|_X \leq \beta \|u\|_{L^2(s,t)} \|x\|_{L^2([s,t], X)}$$

for all  $0 \leq s \leq t \leq s + t_0$ ,  $u \in L^2[s, t]$ , and  $x \in L^2([s, t], X)$ .

Remark 3.8.

- (i) By means of the admissible control operators  $B(\cdot)$  we can define a time-varying bilinear control system  $(\mathbb{T}, \Phi)$  on  $X$  by setting

$$(3.10) \quad \Phi_{t,s}(u, x) := [\mathbb{V}_s^{\overline{\mathbb{T}}}(uB(\cdot))x](t), \quad (t, s) \in \Delta.$$

Let us mention that every time-invariant bilinear control system on  $X$  is given by a  $\mathbb{T}$ -admissible control operator due to [20, Thm. 3.9], where  $\overline{X}_t$  coincides with the extrapolation space  $X_{-1}$  associated with  $\mathbb{T}$ . However, one can extend this result only to the time-dependent setting in the “approximate” sense because we have not an extrapolation theory for evolution families.

- (ii) If  $B(s)$  and  $C(s)$ ,  $s \geq 0$ , are  $\mathbb{T}$ -admissible control and observation operators, then the triple  $(\mathbb{T}, B(\cdot), C(\cdot))$  is called admissible if  $(\mathbb{T}, \Phi, \Psi)$  is admissible, where  $\Phi$  and  $\Psi$  are given by (3.10) and (2.7), respectively. Moreover, an admissible triple  $(\mathbb{T}, B(\cdot), C(\cdot))$  on  $(X, \mathbb{C}, Y)$  gives rise to a well-posed time-varying bilinear system  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$ , on  $(X, \mathbb{C}, Y)$ , where  $\mathbb{F}_s = C(\cdot)\mathbb{V}_s^{\overline{\mathbb{T}}}(uB(\cdot))x$  (via Proposition 3.6).

Let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$ . Let  $(u, x) \in \mathbb{C}_{loc}^2 \times X_{loc}^2$ ,  $z \in X$ , and  $n \in \mathbb{N}^*$ . We define

$$(3.11) \quad B_n(u, x)(t) := \begin{cases} n\Phi_{t, t-\frac{1}{n}}(u, x) & \text{if } t - \frac{1}{n} \geq 0, \\ n\Phi_{t, 0}(u, x) & \text{if } t - \frac{1}{n} < 0, \end{cases} \quad \text{and}$$

$$(3.12) \quad B_n(t)z := B_n(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes z)(t) \quad \text{for } t \geq 0.$$

Due to Lemma 3.4,  $B_n(u, x) \in X_{loc}^1$  and  $B_n(t) \in \mathcal{L}(X)$ . The following result shows that the input operator  $\Phi_{t,s}$  can be approximated by the convolutions:

$$(3.13) \quad \Phi_{t,s}^n(u, x) := [\mathbb{V}_s^{\mathbb{T}} B_n(u, x)](t), \quad (t, s) \in \Delta.$$

**PROPOSITION 3.9.** *Let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$ ,  $0 \leq t - s \leq t_0$ ,  $z \in X$ ,  $u \in \mathbb{C}_{loc}^2$ , and  $x \in X_{loc}^2$ . Then the following hold:*

(i)  $\Phi_{t,s}^n(u, x) \rightarrow \Phi_{t,s}(u, x)$  in  $X$  as  $n \rightarrow \infty$ , and

$$\|\Phi_{t,s}^n(u, x)\|_X \leq \beta \|u\|_{L^2[s,t]} \|x\|_{L^2([s,t], X)} \quad (\text{with } \beta > 0).$$

(ii)  $(t, s) \mapsto \Phi_{t,s}(u, x)$  and  $B_n(\cdot)z$  are continuous in  $X$ .

(iii)  $[\mathbb{V}_s^{\mathbb{T}}(uB_n(\cdot)x)](t) \rightarrow \Phi_{t,s}(u, x)$  as  $n \rightarrow \infty$  if  $u \in W_{loc}^{1,2}(\mathbb{R})$  and  $x \in W_{loc}^{1,2}(\mathbb{R}, X)$ .

(iv)  $\|[\mathbb{V}_s^{\mathbb{T}}(uB_n(\cdot)x)](t)\|_X \leq \beta \|u \cdot x\|_{L^2([s,t], X)}$  if  $u \cdot x \in L^2([s,t], X)$ .

The limits in (i) and (iv) are taken in  $X$  and locally uniform in  $(t, s) \in \Delta$ .

*Proof.* The assertions (i)–(ii) can be obtained by proceeding as in the proof of [31, Prop. 3.5]. We now concentrate on the claims in (iii) and (iv). To prove (iii) we proceed by steps.

(iii) *Step 1.* We first show that  $\Xi_k(u, x) := B_k(u, x) - uB_k(\cdot)x \rightarrow 0$  as  $k \rightarrow \infty$  in  $X_{loc}^1$ . Take  $u \in W_{loc}^{1,2}(\mathbb{R})$  and  $x \in W_{loc}^{1,2}(\mathbb{R}, X)$ . Then, via (3.2), we have

$$\begin{aligned} & \|\Xi_k(u, x)\|_{L^1([s, s+t_0], X)} \\ & \leq k \int_s^{s+t_0} \|\Phi_{\tau, \tau-\frac{1}{k}}(u, x) - u(\tau)\Phi_{\tau, \tau-\frac{1}{k}}(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes x(\tau))\| d\tau \\ & \leq k \int_s^{s+t_0} (\|\Phi_{\tau, \tau-\frac{1}{k}}(u - \chi_{\mathbb{R}_+} \otimes u(\tau), x)\| + \|\Phi_{\tau, \tau-\frac{1}{k}}(\chi_{\mathbb{R}_+} \otimes u(\tau), x - \chi_{\mathbb{R}_+} \otimes x(\tau))\|) d\tau \\ & \leq \beta k \int_s^{s+t_0} \left( \int_{\tau-\frac{1}{k}}^{\tau} |u(\sigma) - u(\tau)|^2 d\sigma \right)^{1/2} \left( \int_{\tau-\frac{1}{k}}^{\tau} \|x(\sigma)\|^2 d\sigma \right)^{1/2} d\tau \\ & \quad + \beta k^{1/2} \int_s^{s+t_0} |u(\tau)| \left( \int_{\tau-\frac{1}{k}}^{\tau} \|x(\sigma) - x(\tau)\|^2 d\sigma \right)^{1/2} d\tau. \end{aligned}$$

This can be also decomposed as

$$\begin{aligned} & \|\Xi_k(u, x)\|_{L^1([s, s+t_0], X)} \\ & \leq \beta k \int_s^{s+t_0} \left( \int_{\tau-\frac{1}{k}}^{\tau} |u(\sigma) - u(\tau)|^2 d\sigma \right)^{1/2} \left( \int_{\tau-\frac{1}{k}}^{\tau} \|x(\sigma) - x(\tau)\|^2 d\sigma \right)^{1/2} d\tau \\ & \quad + \beta k^{1/2} \int_s^{s+t_0} \|x(\tau)\| \left( \int_{\tau-\frac{1}{k}}^{\tau} |u(\sigma) - u(\tau)|^2 d\sigma \right)^{1/2} d\tau \\ & \quad + \beta k^{1/2} \int_s^{s+t_0} |u(\tau)| \left( \int_{\tau-\frac{1}{k}}^{\tau} \|x(\sigma) - x(\tau)\|^2 d\sigma \right)^{1/2} d\tau. \end{aligned}$$

Therefore, one can write

$$\begin{aligned} \|\Xi_k(u, x)\|_{L^1([s, s+t_0], X)} &\leq \beta k \int_s^{s+t_0} |u_k(\tau)| \|x_k(\tau)\| d\tau + c_u \beta k^{1/2} \int_s^{s+t_0} \|x_k(\tau)\| d\tau \\ &\quad + c_x \beta k^{1/2} \int_s^{s+t_0} |u_k(\tau)| d\tau, \end{aligned}$$

where  $f_k(\tau) := (\int_{\tau-\frac{1}{k}}^{\tau} \|f(\sigma) - f(\tau)\|^2 d\sigma)^{1/2}$  and  $c_f := \sup_{s \leq \sigma \leq s+t_0} \|f(\sigma)\|_E$  for  $f \in W_{loc}^{1,2}(\mathbb{R}, E)$ .

*Step 2.* We have to show that

$$(3.14) \quad \lim_{k \rightarrow \infty} k \int_s^{s+t_0} \|f_k(\tau)\|^2 d\tau = 0$$

for all  $f \in W_{loc}^{1,2}(\mathbb{R}, E)$ . In fact, we have

$$\begin{aligned} \int_s^{s+t_0} \|f_k(\tau)\|^2 d\tau &= \int_s^{s+t_0} \int_{\tau-\frac{1}{k}}^{\tau} \|f(\sigma) - f(\tau)\|^2 d\sigma d\tau \\ &= \int_s^{s+t_0} \int_{\tau-\frac{1}{k}}^{\tau} \left\| \int_{\sigma}^{\tau} f'(\mu) d\mu \right\|^2 d\sigma d\tau \\ &\leq \int_s^{s+t_0} \int_{\tau-\frac{1}{k}}^{\tau} \left( \int_{\sigma}^{\tau} \|f'(\mu)\| d\mu \right)^2 d\sigma d\tau \\ &\leq \frac{1}{k} \int_s^{s+t_0} \left( \int_{\tau-\frac{1}{k}}^{\tau} \|f'(\mu)\| d\mu \right)^2 d\tau. \end{aligned}$$

By using Hölder's inequality and interchanging integrals we obtain

$$\begin{aligned} \int_s^{s+t_0} \|f_k(\tau)\|^2 d\tau &\leq \frac{1}{k^2} \int_s^{s+t_0} \int_0^{\frac{1}{k}} \|f'(\tau - \mu)\|^2 d\mu d\tau \\ &\leq \frac{1}{k^2} \int_0^{\frac{1}{k}} \int_s^{s+t_0} \|f'(\tau - \mu)\|^2 d\tau d\mu. \end{aligned}$$

It follows that

$$k \int_s^{s+t_0} \|f_k(\tau)\|^2 d\tau \leq \frac{1}{k} \int_0^{\frac{1}{k}} \int_s^{s+t_0} \|f'(\tau - \mu)\|^2 d\tau d\mu.$$

Therefore by the fact that

$$k \int_s^{s+t_0} |u_k(\tau)| \|x_k(\tau)\| d\tau \leq \frac{k}{2} \int_s^{s+t_0} |u_k(\tau)|^2 d\tau + \frac{k}{2} \int_s^{s+t_0} \|x_k(\tau)\|^2 d\tau$$

we obtain the limit (3.14).

(iv) Consider now  $u \in L^2([s, t])$ ,  $x \in L^2([s, t], X)$ ,  $t > s \geq 0$ , and extend  $u$  and  $x$  by zero to  $\mathbb{R}$ . By making a straightforward computation based on (3.1) we get

$$\begin{aligned} (\mathbb{V}_s^T u B_n(\cdot)x)(t) &= n \int_{s-\frac{1}{n}}^t \left( \Phi_{t,\tau} \left( \chi_{\mathbb{R}_+} \otimes u \left( \tau + \frac{1}{n} \right), \chi_{\mathbb{R}_+} \otimes x \left( \tau + \frac{1}{n} \right) \right) \right. \\ &\quad \left. - \Phi_{t,\tau}(\chi_{\mathbb{R}_+} \otimes u(\tau), \chi_{\mathbb{R}_+} \otimes x(\tau)) \right) d\tau \\ &= \lim_{k \rightarrow \infty} n \int_{s-\frac{1}{n}}^t \int_{\tau}^t \mathbb{T}(t, \mu) B_k(\mu) \left( u \left( \tau + \frac{1}{n} \right) \cdot x \left( \tau + \frac{1}{n} \right) \right. \\ &\quad \left. - u(\tau) \cdot x(\tau) \right) d\mu d\tau \\ &= \lim_{k \rightarrow \infty} n \int_{s-\frac{1}{n}}^t \mathbb{T}(t, \mu) B_k(\mu) \int_{s-\frac{1}{n}}^{\mu} \left( u \left( \tau + \frac{1}{n} \right) \cdot x \left( \tau + \frac{1}{n} \right) \right. \\ &\quad \left. - u(\tau) \cdot x(\tau) \right) d\mu d\tau. \end{aligned}$$

Observe that  $B_k(\cdot)$  are exactly the control operators associated with time-varying linear control system  $(\mathbb{T}, \Phi(\chi_{\mathbb{R}_+}, \cdot))$  on  $(X, X)$ ; see Remark 3.2. It follows from [31, Prop. 3.15(iii)] that

$$(\mathbb{V}_s^T u B_n(\cdot)x)(t) = \Phi_{t, s-\frac{1}{n}}(\chi_{\mathbb{R}_+}, (u \cdot x)^{(n)}),$$

with

$$(u \cdot x)^{(n)}(\sigma) = n \int_{\sigma}^{\sigma + \frac{1}{n}} (u \cdot x)(\tau) d\tau$$

satisfying the estimate

$$\|(u \cdot x)^{(n)}\|_{L^2([s, t], X)} \leq \|u \cdot x\|_{L^2([s, t], X)}.$$

Finally, by means of the latter and (2.2) we then obtain

$$\|(\mathbb{V}_s^T u B_n(\cdot)x)(t)\| \leq \beta(t_0 + 1) \|u \cdot x\|_{L^2([s, t], X)}. \quad \square$$

As for the time-invariant setting, to show that the converse of Proposition 3.6 holds we need the following concepts of regularity.

**DEFINITION 3.10.** *A well-posed time-varying bilinear system  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  is called regular (with feedthrough  $D = 0$ ) if the following limit exists in  $Y$ :*

$$(3.15) \quad \lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} [\mathbb{F}_t(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes x)](\sigma) d\sigma = 0,$$

and absolutely regular if

$$(3.16) \quad \lim_{\tau \searrow 0} \frac{1}{\tau} \int_t^{t+\tau} \|\mathbb{F}_t(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes x)(\sigma)\|_Y^2 d\sigma = 0$$

for all  $t \geq 0$  and  $x \in X$ .

**Remark 3.11.** One can remark that the (absolute) regularity of time-varying bilinear system  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  is equivalent to that of time-varying linear system  $\Gamma_{\Sigma} :=$

$(\mathbb{T}, \Phi(\chi_{\mathbb{R}_+}, \cdot), \Psi, \mathbb{F}(\chi_{\mathbb{R}_+}, \cdot))$ ; see Remark 3.2. Trivially, the triple  $(\mathbb{T}, B(\cdot), C(\cdot) := I)$  gives rise to an absolutely regular well-posed time-varying bilinear control system where  $B(\cdot)$  is an admissible control operator for  $\mathbb{T}$ ; see Remark 3.8.

We say that  $(\mathbb{T}, \Phi, \Psi)$  is an admissible (absolutely) regular triple if the associated well-posed time-varying bilinear system (see Proposition 3.6) is (absolutely) regular. For the time-invariant case, the regularity of  $\Sigma$  has been characterized by that of  $\Gamma_\Sigma$  (cf. [6, Thm. 4.8]).

Now we show a time-varying version of the representation theorem (see [6, Thm. 4.11]).

**THEOREM 3.12.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a regular time-varying bilinear system and  $C(s)$  be given by (2.8). Then  $\Phi_{\cdot, s}(u, x) \in \mathcal{D}_s(C(\cdot))$  and  $\mathbb{F}_s(u, x) = C(\cdot)\Phi_{\cdot, s}(u, x)$  for all  $s \geq 0, u \in \mathbb{C}_{loc}^{2, s}$ , and  $x \in X_{loc}^{2, s}$ .*

*Proof.* Set  $\epsilon_f(\sigma, t) := f(\sigma) - f(t)$ ,  $\sigma \geq t$ . Let  $(u, x) \in \mathbb{C}_{loc}^{2, s} \times X_{loc}^{2, s}$  and  $t \geq s$ , where  $t \in P_u \cap P_x \cap P_{\mathbb{F}_s(u, x)}$  such that the regularity condition (3.15) holds at  $t$ . Here  $P_f$  is the set of 2-Lebesgue points of  $f$ ; see section 2. These intersections are not void, since its complement in  $[s, \infty)$  is negligible. Then, by invoking (3.3), we obtain

$$\mathbb{F}_s(u, x) = \Psi_t \Phi_{t, s}(u, x) + \mathbb{F}_t(\epsilon_u(\cdot, t) + \chi_{\mathbb{R}_+} \otimes u(t), \epsilon_x(\cdot, t) + \chi_{\mathbb{R}_+} \otimes x(t)) \quad \text{on } [t, \infty). \quad (3.17)$$

Set  $I(\tau, t) := \frac{1}{\tau} \left\| \int_t^{t+\tau} \mathbb{F}_t(\epsilon_u(\cdot, t) + \chi_{\mathbb{R}_+} \otimes u(t), \epsilon_x(\cdot, t) + \chi_{\mathbb{R}_+} \otimes x(t))(\sigma) d\sigma \right\|$ . We get

$$\begin{aligned} I(\tau, t) &\leq \frac{1}{\tau} \left\| \int_t^{t+\tau} \mathbb{F}_t(\epsilon_u(\cdot, t), \epsilon_x(\cdot, t) + \chi_{\mathbb{R}_+} \otimes x(t))(\sigma) d\sigma \right\| \\ &\quad + \frac{1}{\tau} \left\| \int_t^{t+\tau} \mathbb{F}_t(\chi_{\mathbb{R}_+} \otimes u(t), \epsilon_x(\cdot, t))(\sigma) d\sigma \right\| \\ &\quad + \frac{1}{\tau} \left\| \int_t^{t+\tau} \mathbb{F}_t(\chi_{\mathbb{R}_+} \otimes u(t), \chi_{\mathbb{R}_+} \otimes x(t))(\sigma) d\sigma \right\| \\ &=: I_1(\tau, t) + I_2(\tau, t) + I_3(\tau, t). \end{aligned}$$

By regularity of  $\Sigma$ , it follows that  $I_3(\tau, t)$  goes to zero when  $\tau \rightarrow 0$ . By means of Hölder's inequality and (3.4) we obtain

$$\begin{aligned} I_1^2(\tau, t) &\leq \frac{1}{\tau^2} \left( \int_t^{t+\tau} \|\mathbb{F}_t(\epsilon_u(\cdot, t), x)(\sigma)\| d\sigma \right)^2 \\ &\leq \frac{\kappa^2}{\tau} \int_t^{t+\tau} \|u(\sigma) - u(t)\|^2 d\sigma \int_t^{t+\tau} \|x(\sigma)\|^2 d\sigma. \end{aligned}$$

Thus,  $I_1(\tau, t)$  goes to zero when  $\tau \rightarrow 0$ . Similarly, we can also show that  $I_2(\tau, t)$  goes to zero when  $\tau \rightarrow 0$ . Therefore we conclude, via (3.17) and (2.8), that  $\Phi_{\cdot, s}(u, x) \in \mathcal{D}_s(C(\cdot))$  and  $\mathbb{F}_s(u, x)(\cdot) = C(\cdot)\Phi_{\cdot, s}(u, x)$  for a.e.  $t \geq s$ .  $\square$

**Remark 3.13.** By adopting a technique from the proof of [31, Prop. 3.12], it is easy to show that for an absolutely regular time-varying bilinear system

$$C(\cdot)\Phi_{\cdot, s}^n(u, x) \rightarrow \mathbb{F}_s(u, x) \quad \text{in } Y_{loc}^{2, s} \quad \text{as } n \rightarrow \infty$$

for all  $u \in \mathbb{C}_{loc}^{2, s}$ ,  $x \in X_{loc}^{2, s}$ , and  $s \geq 0$ .

Now let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$ , and consider the equation

$$(3.18) \quad x(t) = \mathbb{T}(t, s)x_0 + \Phi_{t, s}(u, x), \quad (t, s) \in \Delta,$$

for a given  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x_0 \in X$ , and  $s \geq 0$ . So we are looking for the function (called the state trajectory of  $(\mathbb{T}, \Phi)$ )  $x(\cdot) \in \mathcal{C}([s, \infty), X)$  solution of (3.18). In particular, if  $\Phi_{\cdot,s}(u, z) = \mathbb{V}_s^\mathbb{T} u B(\cdot) z$  for admissible control operators  $B(\cdot)$ , then  $x(\cdot)$  is a solution of the following variation of constants formula:

$$(3.19) \quad x(t) = \mathbb{T}(t, s)x_0 + \int_s^t \mathbb{T}(t, \tau)u(\tau)B(\tau)x(\tau)d\tau, \quad (t, s) \in \Delta.$$

Equation (3.19) can also be related to the absolutely regular time-varying linear system  $(\mathbb{T}, \phi, \Psi, \mathbb{L})$  on  $(X, X, X)$  where

$$\phi_{t,s} x := [\mathbb{V}_s^\mathbb{T}(B(\cdot)x)](t), \quad \Psi_s x_0 := \mathbb{T}(\cdot, s)x_0 \text{ (i.e., } C(\cdot) = I) \quad \text{and} \quad \mathbb{L}_s x := \mathbb{V}_s^\mathbb{T} B(\cdot)x$$

for  $x \in X_{loc}^{2,s}$ ,  $x_0 \in X$ , and  $(t, s) \in \Delta$ . Thus, if the input  $u \in \mathbb{C}^\infty$ , then one can apply [31, Thm. 4.4, Rem. 4.6(a)], with admissible feedback operators  $\Delta(\cdot) := u(\cdot)I$  (see [31, Def. 4.1] or Remark 4.4(ii) for definition), to show the existence of a solution to (3.19). Yet, for inputs  $u \in \mathbb{C}_{loc}^{2,s}$  one cannot apply this result since, in this case, the feedback operators  $\Delta(\cdot)$  do not fit in the setting of [31, Thm. 4.4]. Here we show that (3.18) admits a unique solution and is given by an evolution family on  $X$ .

**THEOREM 3.14.** *Let  $(\mathbb{T}, \Phi)$  be a time-varying bilinear control system on  $X$  with  $\omega_0(\mathbb{T}) < \infty$ . Then for every  $u \in \mathbb{C}_{loc}^{2,s}$  and  $x_0 \in X$  there exists an evolution family  $\mathbb{T}_u := (\mathbb{T}_u(t, s))_{t \geq s}$  on  $X$  such that  $x(\cdot) := \mathbb{T}_u(\cdot, s)x_0$  is the unique solution of the functional equation*

$$(3.20) \quad x(t) = \mathbb{T}(t, s)x_0 + \Phi_{t,s}(u, x), \quad (t, s) \in \Delta.$$

*Proof: Existence.* Define a sequence  $\mathbb{T}_u^n(t, s)$  for  $(t, s) \in \Delta$  by

$$\mathbb{T}_u^0(t, s) := \mathbb{T}(t, s) \quad \text{and} \quad \mathbb{T}_u^{n+1}(t, s)x_0 := \Phi_{t,s}(u, \mathbb{T}_u^n(\cdot, s)x_0).$$

The operators  $\mathbb{T}_u^n(t, s) \in \mathcal{L}(X)$ . By using Proposition 3.9 and Lemma 3.3, we obtain by induction

$$(3.21) \quad \|\mathbb{T}_u^n(t, s)\| \leq c_1 \left( \frac{(c_2 \|u\|_{L^2[s,t]}(t-s))^n}{n!} \right)^{\frac{1}{2}}$$

for some positive constants  $c_1$  and  $c_2$ . It follows from (3.21) that  $\sum_{n=0}^\infty \mathbb{T}_u^n(t, s)$  converges with respect to the  $\mathcal{L}(X)$ -norm and uniformly on any compact subset of  $\Delta$ . The operators  $\mathbb{T}_u(t, s) := \sum_{n=0}^\infty \mathbb{T}_u^n(t, s) \in \mathcal{L}(X)$  are strongly continuous in  $X$ , since  $(t, s) \mapsto \mathbb{T}_u^n(t, s)x_0 \in X$  is continuous.

Now let us show that  $\mathbb{T}_u(\cdot, s)x_0$  satisfies (3.18). In fact, we can write

$$(3.22) \quad \begin{aligned} \sum_{k=0}^n \mathbb{T}_u^k(t, s)x_0 &= \mathbb{T}(t, s)x_0 + \sum_{k=1}^n \mathbb{T}_u^k(t, s)x_0 \\ &= \mathbb{T}(t, s)x_0 + \sum_{k=0}^{n-1} \Phi_{t,s}(u, \mathbb{T}_u^k(\cdot, s)x_0) \\ &= \mathbb{T}(t, s)x_0 + \Phi_{t,s} \left( u, \sum_{k=0}^{n-1} \mathbb{T}_u^k(\cdot, s)x_0 \right). \end{aligned}$$

Since  $S_u^n(\cdot, s) := \sum_{k=0}^n \mathbb{T}_u^k(\cdot, s)$  and  $\mathbb{T}_u(\cdot, s)$  are strongly continuous on  $X$ , it follows that  $S_u^n(\cdot, s)x_0 \rightarrow \mathbb{T}_u(\cdot, s)x_0$  in  $X_{loc}^{2,s}$  as  $n \rightarrow \infty$ . By (3.22) and Lemma 3.3 we can show that  $\mathbb{T}_u(t, s)x_0$  verifies (3.18). Clearly property (i) of Definition 2.1 is satisfied by  $\mathbb{T}_u$ . To prove the evolution property (ii), let  $T \geq t \geq r \geq s \geq 0$ . By invoking (3.18) and (3.1) we get

$$\begin{aligned} & \mathbb{T}_u(t, r)\mathbb{T}_u(r, s)x_0 \\ &= \mathbb{T}(t, r)\mathbb{T}_u(r, s)x_0 + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0) \\ &= \mathbb{T}(t, r)\mathbb{T}(r, s)x_0 + \mathbb{T}(t, r)\Phi_{r,s}(u, \mathbb{T}_u(\cdot, s)x_0) + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0) \\ &= \mathbb{T}(t, s)x_0 + \mathbb{T}(t, r)\Phi_{r,s}(u, \mathbb{T}_u(\cdot, s)x_0) + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, s)x_0) \\ &\quad + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(\cdot, s)x_0) \\ &= \mathbb{T}(t, s)x_0 + \Phi_{t,s}(u, \mathbb{T}_u(\cdot, s)x_0) + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(\cdot, s)x_0) \\ &= \mathbb{T}_u(t, s)x_0 + \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(\cdot, s)x_0), \end{aligned}$$

which implies that

$$(3.23) \quad \mathbb{T}_u(t, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(t, s)x_0 = \Phi_{t,r}(u, \mathbb{T}_u(\cdot, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(\cdot, s)x_0).$$

Set  $\varphi_r(\tau) := \mathbb{T}_u(\tau, r)\mathbb{T}_u(r, s)x_0 - \mathbb{T}_u(\tau, s)x_0$  for  $\tau \in [r, t]$ . Then (3.23) and (3.2) give

$$\begin{aligned} \|\varphi_r(\tau)\|^2 &= \|\Phi_{t,r}(u, \varphi_r)\|^2 \\ &\leq c(u, T) \int_r^t \|\varphi_r(\tau)\|^2 d\tau. \end{aligned}$$

By Gronwall's lemma we obtain  $\varphi_r(\tau) = 0$  on  $[r, t]$  and  $\mathbb{T}_u(t, r)\mathbb{T}_u(r, s)x_0 = \mathbb{T}_u(t, s)x_0$ . Since  $T > 0$  and  $x_0 \in X$  are arbitrariness, we have (ii) for  $\mathbb{T}_u$ .

*Uniqueness.* Suppose that  $\tilde{x}(\cdot) \in \mathcal{C}([s, \infty), X)$  is another solution of (3.18), and set  $\xi(t) := x(t) - \tilde{x}(t)$ ; then we have  $\xi(t) = \Phi_{t,s}(u, \xi)$ . By using Lemma 3.3, we obtain

$$\|\xi(t)\|^2 \leq \text{const} \|u\|_{L^2[s,t]}^2 \int_s^t \|\xi(\tau)\|^2 d\tau.$$

Again, from Gronwall's lemma we deduce that  $\xi(t) = 0$  for all  $t \geq s$ .  $\square$

The following result shows that the regularity allows an explicit expression of the output function  $y(\cdot)$  in terms of the observation operators  $C(\cdot)$  issued from the system  $(\mathbb{T}, \Psi)$ . This extends the representation theorem obtained for time-invariant bilinear systems; see [6, Thm. 11].

**THEOREM 3.15.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$  and  $\omega_0(\mathbb{T}) < \infty$ . Let  $C(\cdot)$  be the observation operator associated with  $(\mathbb{T}, \Psi)$  given by (2.8). Then, for any  $s \geq 0$ ,  $x_0 \in X$ , and  $u \in \mathbb{C}_{loc}^{2,s}$ , there is a unique solution  $(x_\Sigma, y_\Sigma) \in \mathcal{C}([s, \infty), X) \times Y_{loc}^{2,s}$  of the functional equations*

$$(3.24) \quad \begin{cases} x_\Sigma(t) = \mathbb{T}(t, s)x_0 + \Phi_{t,s}(u, x_\Sigma), & t \geq s, \\ y_\Sigma = \Psi_s x_0 + \mathbb{F}_s(u, x_\Sigma). \end{cases}$$

If, furthermore,  $\Sigma$  is regular, then  $x_\Sigma(\cdot) \in \mathcal{D}_s(C(\cdot))$ , and the output  $y_\Sigma$  satisfies

$$(3.25) \quad y_\Sigma(t) = C(t)x_\Sigma(t) \quad \text{for a.e. } t \geq s.$$

*Proof.* The existence and the uniqueness of the  $x_\Sigma(\cdot)$  solution of the first equation in (3.24) have been proved in Theorem 3.14 and that  $y_\Sigma \in Y_{loc}^{2,s}$  is trivial. Now assume

that  $\Sigma$  is regular, and let us show that  $x_\Sigma(\cdot) \in \mathcal{D}_s(C(\cdot))$  and  $y_\Sigma$  satisfies (3.25). By [31, Thm. 2.7], we have

$$(3.26) \quad \mathbb{T}(\cdot, s)x_0 \in \mathcal{D}_s(C(\cdot)) \quad \text{and} \quad (\Psi_s x_0)(\cdot) = C(\cdot)\mathbb{T}(\cdot, s)x_0.$$

By using (3.26) and applying Theorem 3.12 we obtain that  $x_\Sigma(\cdot) \in \mathcal{D}_s(C(\cdot))$  and

$$\begin{aligned} y_\Sigma(t) &= C(t)\mathbb{T}(t, s)x_0 + C(t)\Phi_{t,s}(u, x_\Sigma) \\ &= C(t)x_\Sigma(t) \end{aligned}$$

for a.e.  $t \geq s$ .  $\square$

*Remark 3.16.* If we consider a regular time-varying bilinear system  $\Sigma$ , Theorems 3.14–3.15 give us some additional information: The evolution family  $\mathbb{T}_u$  is such that  $\mathbb{T}_u(\cdot, s)x_0 \in \mathcal{D}_s(C(\cdot))$  for all  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x_0 \in X$ , and  $s \geq 0$ . Then we ask under what condition  $C(\cdot)$  is still an admissible observation operator for the evolution  $\mathbb{T}_u$  and that the observation system  $(\mathbb{T}_u, \Psi_u)$  is also represented by  $C(\cdot)$ , where  $\Psi_u$  is given by  $(\Psi_u)_s x_0 := C(\cdot)\mathbb{T}_u(\cdot, s)x_0$ .

The following proposition provides a sufficient condition for the invariance of admissibility of observation for a perturbed evolution family in terms of input  $u$ .

**PROPOSITION 3.17.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a regular time-varying bilinear system on  $(X, \mathbb{C}, Y)$  and  $\omega_0(\mathbb{T}) < \infty$ . Let  $C(\cdot)$  be the observation operator associated with  $(\mathbb{T}, \Psi)$  given by (2.8). If  $u \in \mathbb{C}^2 \cup \mathbb{C}^\infty$ , then the pair  $(\mathbb{T}_u, \Psi_u)$  ( $\Psi_u$  is defined in Remark 3.16) is a time-varying observation system which is represented by  $C(\cdot)$ .*

*Proof.* By taking into account Theorems 3.14 and 3.15, we have only to verify (ii) in Definition 2.3. So, let  $x_0 \in X$  and  $t_0, s \geq 0$ ; then in view of the result above we have

$$\begin{aligned} \int_s^{s+t_0} \|[(\Psi_u)_s x_0](t)\|^2 dt &= \int_s^{s+t_0} \|y_\Sigma(t)\|^2 dt \\ &= \int_s^{s+t_0} \|(\Psi_s x_0)(t) + (\mathbb{F}_s(u, \mathbb{T}_u(\cdot, s)x_0))(t)\|^2 dt \\ &\leq 2 \int_s^{s+t_0} \left( \|(\Psi_s x_0)(t)\|^2 + \|(\mathbb{F}_s(u, \mathbb{T}_u(\cdot, s)x_0))(t)\|^2 \right) dt \\ &\leq 2 \left( \gamma^2 \|x_0\|^2 + \kappa^2 \|u\|_{L^2[s, s+t_0]}^2 \int_s^{s+t_0} \|\mathbb{T}_u(t, s)x_0\|^2 dt \right). \end{aligned}$$

By making a straightforward computation based on the fact that  $u \in \mathbb{C}^2 \cup \mathbb{C}^\infty$  and (3.21), we can show that the evolution family  $\mathbb{T}_u$  is exponentially bounded. Therefore, we obtain

$$\int_s^{s+t_0} \|[(\Psi_u)_s x_0](t)\|^2 dt \leq 2 \left( \gamma^2 + \kappa^2 M_u \frac{(e^{2\omega_u t_0} - 1)}{2\omega_u} \|u\|_{\mathbb{C}^2}^2 \right) \|x\|^2$$

for some positive constants  $M_u$  and  $\omega_u$ .

It remains to show that  $\Psi_u$  is represented by  $C(\cdot)$ . Let  $s \geq 0, t > 0$ , and  $x \in X$ . Then

$$(3.27) \quad \frac{1}{t} \int_s^{s+t} [(\Psi_u)_s x](\tau) d\tau - \frac{1}{t} \int_s^{s+t} (\Psi_s x)(\tau) d\tau = \frac{1}{t} \int_s^{s+t} [\mathbb{F}_s(u, \mathbb{T}_u(\cdot, s)x)](\tau) d\tau.$$

By using (3.7) and Hölder's inequality we obtain

$$\left\| \frac{1}{t} \int_s^{s+t} [\mathbb{F}_s(u, \mathbb{T}_u(\cdot, s)x)](\tau) d\tau \right\| \leq d(\omega, t) \|u\|_{L^2[s, s+t]} \|\mathbb{T}_u(\cdot, s)x\|_{L^2([s, s+t], X)}. \quad (3.28)$$

As the right-hand side of (3.28) tends to zero as  $t \rightarrow 0$ , identity (3.27) shows that

$$\lim_{t \rightarrow 0} \frac{1}{t} \int_s^{s+t} [(\Psi_u)_s x](\tau) d\tau = \lim_{t \rightarrow 0} \frac{1}{t} \int_s^{s+t} (\Psi_s x)(\tau) d\tau,$$

which ends the proof.  $\square$

Proposition 3.17 means that a regular time-varying (or -invariant) bilinear system  $\Sigma$  has the same state and output as the linear time-varying observation system  $(\mathbb{T}_u, \Psi_u)$  whenever the input  $u \in \mathbb{C}^2 \cup \mathbb{C}^\infty$ . Consequently, an input  $u \in \mathbb{C}^2 \cup \mathbb{C}^\infty$  is universal on  $[s, t]$  for a well-posed time-varying bilinear system  $\Sigma$  if the associated time-varying linear observation system  $(\mathbb{T}_u, \Psi_u)$  is observable on  $[s, t]$  (see the comment after Definition 4.1 about these notions). Based on this, the author in [3] gives some topological properties for observers input extending the results given in [2, 8] and in [4, 5, 17] in infinite dimensions to absolutely regular time-varying bilinear systems.

**4. Observer design.** Motivated by the results obtained for time-invariant bilinear systems [6], this section deals with the problem of synthesis of observers for more general systems, namely, for the absolutely regular time-varying bilinear systems introduced in section 3. Thus, the problem of approximating the state of an absolutely regular time-varying bilinear system is solved by a Luenberger-like observer whenever the system is detectable. Contrary to the linear case, this observer has the property that the dynamics of the error estimation depend on the inputs being applied.

**DEFINITION 4.1.** Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system. An observer for  $\Sigma$  is given by a system  $(\tilde{\mathcal{O}})$  (not necessarily bilinear) controlled by the inputs and the outputs of  $\Sigma$ :

$$(\tilde{\mathcal{O}}) \quad \begin{cases} \zeta(t) &= \Omega(\zeta, u, y_\Sigma), & \zeta(s) = \zeta_0 \in X, \\ \hat{x}(t) &= \Xi(\zeta(t)) \end{cases}$$

such that the output  $\hat{x}$  is an approximation to the state  $x_\Sigma$  for any initial states of  $\Sigma$  and  $(\tilde{\mathcal{O}})$ . That means

$$(4.1) \quad \lim_{t \rightarrow +\infty} \|\hat{x}(t, \zeta_0, u, y_\Sigma) - x_\Sigma(t, x_0, u)\| = 0 \text{ for any } \zeta_0, x_0 \in X.$$

Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system on  $(X, \mathbb{C}, Y)$ . A pair of points  $x_0$  and  $\bar{x}_0$  ( $x_0 \neq \bar{x}_0$ ) is *indistinguishable* if for every input  $u \in L^2[s, t]$  the associated outputs  $y_\Sigma$  and  $\bar{y}_\Sigma$  are identically equal on  $[s, t]$ . The system  $\Sigma$  with an input  $u \in \mathbb{C}_{loc}^{2,s}$  is called *observable* on  $[s, t]$  if every pair of points  $x_0$  and  $\bar{x}_0$  is distinguishable on  $[s, t]$ . In this case we say that  $u$  is a universal input for  $\Sigma$  on  $[s, t]$ .

If the time-varying linear observation system  $(\mathbb{T}, \Psi)$  is observable on  $[s, t]$  (i.e.,  $\Psi_{t,s} := \chi_{[s,t]} \Psi_s$  is injective), then automatically the null input is universal for  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  on  $[s, t]$ . It is worth mentioning that, when a well-posed time-varying (or -invariant) linear system is observable, any input distinguishes any two distinct states, while for a bilinear (generally nonlinear) system this is no longer true. Even if the system is observable, some inputs cannot distinguish between states. Furthermore,

these “bad” inputs give rise to singularities in the observation design. The study of universal inputs has been initiated by Sontag [32] for the discrete case. For finite-dimensional bilinear systems, universal inputs do exist and are generic in the analytic case [34]. Now we give a definition of a Luenberger-like observer for the well-posed time-varying bilinear systems.

DEFINITION 4.2. *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system, let  $x_\Sigma$  and  $y_\Sigma$  be the corresponding state trajectory and the output given by (3.24), respectively, let  $u \in \mathbb{C}_{loc}^{2,s}$ , and let  $\mathbb{K} := (\mathbb{K}_{t,s})_{(t,s) \in \Delta} \in \mathcal{L}(Y_{loc}^{2,s}, X)$ . The system*

$$(\mathcal{O}) \quad \begin{cases} \zeta(t) &= \mathbb{T}(t,s)\zeta_0 + \Phi_{t,s}(u, \zeta) + \mathbb{K}_{t,s}(C(\cdot)\zeta(\cdot) - y_\Sigma), & t \geq s, \quad \zeta_0 \in X, \\ \hat{x}(t) &= \zeta(t), & t \geq s, \end{cases}$$

*is called an exponential Luenberger-like observer for  $\Sigma$  if  $\zeta(\cdot) \in \mathcal{C}([s, \infty), X) \cap \mathcal{D}_s(C(\cdot))$  and*

$$\|\hat{x}(t) - x_\Sigma(t)\| \leq d \|\zeta_0 - x_0\| e^{-\delta t}, \quad t \geq s,$$

*for any  $\zeta_0, x_0 \in X$  with constants  $d, \delta > 0$ .*

As in the finite-dimensional case, the observer system is obtained as an output injection of the original system where the difference  $\hat{y} - y_\Sigma$  (with  $\hat{y} := C(\cdot)\zeta(\cdot)$ ) is another input used to correct the estimated state  $\hat{x}(\cdot)$ .

Notice that, by taking the difference between the equations  $(\mathcal{O})$  and (3.24), we formally obtain the system which describes the estimation error

$$(4.2) \quad \varepsilon_{\Sigma^K}(t) = \mathbb{T}(t,s)\varepsilon_0 + \Phi_{t,s}(u, \varepsilon_{\Sigma^K}) + \mathbb{K}_{t,s}(\hat{y} - y_\Sigma)$$

for a.e.  $t \geq s$ , where  $\varepsilon_0 := \zeta_0 - x_0$ .

Contrary to the observer system  $(\mathcal{O})$ , we can show that the system (4.2) augmented by the output  $h_{\Sigma^K} := \hat{y} - y_\Sigma$  generates a well-posed time-varying bilinear system  $\Sigma^K$  in the sense of Theorem 3.15; i.e., the solution  $\varepsilon_{\Sigma^K}(\cdot)$  and the output function  $h_{\Sigma^K}$  associated with  $\Sigma^K$ , as in (3.24), are given by

$$\begin{cases} \varepsilon_{\Sigma^K}(t) &= \mathbb{T}^K(t,s)\varepsilon_0 + \Phi_{t,s}^K(u, \varepsilon_{\Sigma^K}), \\ h_{\Sigma^K} &= \Psi_s^K \varepsilon_0 + \mathbb{F}_s^K(u, \varepsilon_{\Sigma^K}) \end{cases}$$

for  $t \geq s$ .

DEFINITION 4.3. *Let  $(\mathbb{T}, \Psi)$  be a time-varying observation system. The family  $\mathbb{K} = (\mathbb{K}_{t,s})_{(t,s) \in \Delta} \in \mathcal{L}(Y_{loc}^{2,s}, X)$  is called admissible for  $(\mathbb{T}, \Psi)$  if the following hold:*

- (i)  *$(\mathbb{T}, \mathbb{K}, \Psi)$  is an admissible regular linear triple, and*
- (ii)  *$I$  is an admissible feedback for the time-varying linear system  $(\mathbb{T}, \mathbb{K}, \Psi, \mathbb{L}^K)$  where the notions in (i) and (ii) are defined and commented in the following remark.*

Remark 4.4.

- (i) As for the bilinear case (see Remark 3.11), condition (i) means that the system  $(\mathbb{T}, \mathbb{K}, \Psi, \mathbb{L}^K)$ , where  $\mathbb{L}_s^K y := C(\cdot)\mathbb{K}_{\cdot,s}y$ ,  $y \in Y_{loc}^{2,s}$ , is a time-varying regular linear system (see Definition 2.4), with  $C(\cdot)$  is defined by (2.8).
- (ii) Condition (ii) of Definition 4.3 means that there exists  $t_0 > 0$  such that the operators  $I - \mathbb{L}_{s+t_0,s}^K$ ,  $s \geq 0$ , are invertible on  $L^2([s, s+t_0], Y)$  and have uniformly bounded inverses. This is equivalent to the invertibility of  $I - \mathbb{L}_{s+t_1,s}^K$  on  $L^2([s, s+t_1], Y)$  for all  $t_1 > 0$  [31, Lem. 4.2]. A time-invariant version of this result was given in the paper of Staffans and Weiss [33] about the flow inversion of abstract linear systems.

Now we state the following result on the existence of the so-called feedback bilinear system without any regularity assumption on the open-loop system.

**THEOREM 4.5.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be a well-posed time-varying bilinear system. If a family  $\mathbb{K} = (\mathbb{K}_{t,s})_{(t,s) \in \Delta}$  is admissible for  $(\mathbb{T}, \Psi)$ , then the quadruple  $\Sigma^K := (\mathbb{T}^K, \Phi^K, \Psi^K, \mathbb{F}^K)$  defined by*

$$(4.3) \quad \begin{aligned} \mathbb{F}_s^K &:= (I - \mathbb{L}_s^K)^{-1} \mathbb{F}_s, & \Psi_s^K &:= (I - \mathbb{L}_s^K)^{-1} \Psi_s, \\ \Phi_{t,s}^K &:= \Phi_{t,s} + \mathbb{K}_{t,s} \mathbb{F}_s^K, & \mathbb{T}^K(t, s) &:= \mathbb{T}(t, s) + \mathbb{K}_{t,s} \Psi_s^K \end{aligned}$$

for all  $(t, s) \in \Delta$  is a well-posed time-varying bilinear system, where  $\mathbb{L}_s^K$  is the linear input-output map defined in Remark 4.4(i). Moreover, if  $\Sigma$  is absolutely regular, then  $\Sigma^K$  is so as well.

*Proof.* Let us prove that the four operators in (4.3) satisfy the conditions of Definition 3.1. Thus, the two upper identities in (4.3) give

$$(4.4) \quad \mathbb{F}_s^K(u, x) = \mathbb{F}_s(u, x) + \mathbb{L}_s^K \mathbb{F}_s^K(u, x) \quad \text{and} \quad \Psi_s^K x_0 = \Psi_s x_0 + \mathbb{L}_s^K \Psi_s^K x_0$$

for all  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ ,  $x_0 \in X$ , and  $s \geq 0$ . By combining the first identity in (4.4) with the properties (2.5) and (3.3), we obtain

$$(4.5) \quad \begin{aligned} \mathbb{F}_s^K(u, x) &= \mathbb{F}_t(u, x) + \Psi_t \Phi_{t,s}(u, x) + \mathbb{L}_t^K \mathbb{F}_s^K(u, x) + \Psi_t \mathbb{K}_{t,s} \mathbb{F}_s^K(u, x) \\ &= \mathbb{F}_t(u, x) + \Psi_t (\Phi_{t,s}(u, x) + \mathbb{K}_{t,s} \mathbb{F}_s^K(u, x)) + \mathbb{L}_t^K \mathbb{F}_s^K(u, x) \\ &= \mathbb{F}_t(u, x) + \Psi_t \Phi_{t,s}^K + \mathbb{L}_t^K \mathbb{F}_s^K(u, x) \end{aligned}$$

on  $[t, \infty)$ , which implies that

$$(I - \mathbb{L}_t^K) \mathbb{F}_s^K(u, x) = \mathbb{F}_t(u, x) + \Psi_t \Phi_{t,s}^K \quad \text{on } [t, \infty).$$

Thus, the definitions of  $\mathbb{F}_t^K$  and  $\Psi_t^K$  in (4.3) give the equation required in (3.3) for  $\mathbb{F}_s^K$ .

Now, by using the second identity in (4.4) and applying (2.5) and (2.3), we obtain

$$(4.6) \quad \begin{aligned} \Psi_s^K x_0 &= \Psi_t \mathbb{T}(t, s) x_0 + \mathbb{L}_t^K \Psi_s^K x_0 + \Psi_t \mathbb{K}_{t,s} \Psi_s^K x_0 \\ &= \Psi_t (\mathbb{T}(t, s) + \mathbb{K}_{t,s} \Psi_s^K) x_0 + \mathbb{L}_t^K \Psi_s^K x_0 \end{aligned}$$

on  $[t, \infty)$  for  $(t, s) \in \Delta$  and  $x_0 \in X$ .

Therefore, the equation required in (2.3) for  $\Psi_s^K$  follows from the definitions of  $\mathbb{T}^K(t, s)$  and  $\Psi_t^K$  in (4.3).

By combining now (2.1) and (3.1) we obtain

$$\begin{aligned} \Phi_{t,s}^K(u, x) &= \Phi_{t,s}(u, x) + \mathbb{K}_{t,s} \mathbb{F}_s^K(u, x) \\ &= \Phi_{t,l}(u, x) + \mathbb{T}(t, l) \Phi_{l,s}(u, x) + \mathbb{K}_{t,l} \mathbb{F}_s^K(u, x) + \mathbb{T}(t, l) \mathbb{K}_{l,s} \mathbb{F}_s^K(u, x) \end{aligned}$$

for  $t \geq l \geq s$ . By using (3.3) for  $\mathbb{F}_s^K$  and definitions of  $\Phi^K$  and  $\mathbb{T}^K$  in (4.3), it follows that

$$(4.7) \quad \begin{aligned} \Phi_{t,s}^K(u, x) &= \Phi_{t,l}(u, x) + \mathbb{T}(t, l) \Phi_{l,s}(u, x) + \mathbb{K}_{t,l} (\mathbb{F}_l^K(u, x) \\ &\quad + \Psi_l^K \Phi_{l,s}^K(u, x)) + \mathbb{T}(t, l) \mathbb{K}_{l,s} \mathbb{F}_s^K(u, x) \\ &= \Phi_{t,l}^K(u, x) + \mathbb{T}(t, l) (\Phi_{l,s}(u, x) + \mathbb{K}_{l,s} \mathbb{F}_s^K(u, x)) + \mathbb{K}_{t,l} \Psi_l^K \Phi_{l,s}^K(u, x) \\ &= \Phi_{t,l}^K(u, x) + (\mathbb{T}(t, l) + \mathbb{K}_{t,l} \Psi_l^K) \Phi_{l,s}^K(u, x) \\ &= \Phi_{t,l}^K(u, x) + \mathbb{T}^K(t, l) \Phi_{l,s}^K(u, x) \end{aligned}$$

for  $t \geq l \geq s$ , which proves (3.1) for  $\Phi_{t,s}^K$ . Since  $(I - \mathbb{L}_s^K)^{-1}$  is uniformly bounded on  $L^2([s, s+t], Y)$  and  $\Sigma$  is a well-posed time-varying bilinear system, the estimations (2.4), (3.2), and (3.4) hold for  $\Psi_s^K$ ,  $\Phi_{t,s}^K$ , and  $\mathbb{F}_s^K$ , respectively. It remains to show that  $\mathbb{T}^K$  is an evolution family on  $X$ . Due to the fact that  $\mathbb{K}_{t,t} = 0$  and  $\mathbb{T}(t, t) = I$ , we obtain  $\mathbb{T}^K(t, t) = I$ . By applying (2.1) and (2.3) for  $(\mathbb{T}, \mathbb{K})$  and  $(\mathbb{T}^K, \Psi^K)$ , respectively, we get

$$\begin{aligned} \mathbb{T}^K(t, s)x_0 &= \mathbb{T}(t, s)x_0 + \mathbb{K}_{t,s}\Psi_s^K x_0 \\ &= \mathbb{T}(t, r)\mathbb{T}(r, s)x_0 + \mathbb{K}_{t,r}\Psi_r^K x_0 + \mathbb{T}(t, r)\mathbb{K}_{r,s}\Psi_s^K x_0 \\ &= \mathbb{T}(t, r)(\mathbb{T}(r, s) + \mathbb{K}_{r,s}\Psi_s^K)x_0 + \mathbb{K}_{t,r}\Psi_r^K x_0 \\ &= \mathbb{T}(t, r)\mathbb{T}^K(r, s)x_0 + \mathbb{K}_{t,r}\Psi_r^K \mathbb{T}^K(r, s)x_0 \\ &= \mathbb{T}^K(t, r)\mathbb{T}^K(r, s)x_0 \end{aligned}$$

for all  $(t, s) \in \Delta$  and  $x_0 \in X$ . The strong continuity of  $\mathbb{T}^K$  is obtained as in [31, Thm. 4.4].

Finally, the definition of  $\mathbb{F}^K$  in (4.3) yields

$$\int_t^{t+\tau} \|\mathbb{F}_t^K(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes x)(\sigma)\|^2 d\sigma \leq \text{const} \int_t^{t+\tau} \|\mathbb{F}_t(\chi_{\mathbb{R}_+}, \chi_{\mathbb{R}_+} \otimes x)(\sigma)\|^2 d\sigma.$$

Thus  $\Sigma^K$  is a well-posed bilinear system, and if  $\Sigma$  is absolutely regular, then  $\Sigma^K$  is so as well.  $\square$

*Remark 4.6.* In the time-invariant setting (see [6, sect. 5]) we have proved that the regularity is even conserved by the systems  $\Sigma^K$ . This was established by means of the transfer functions introduced for well-posed time-invariant bilinear systems  $\Sigma^K$  and its relation with that of  $\Sigma$ ; see [6, Rem. 6(ii)]. But the proof is essentially based on the Laplace transform of the input-output maps and the use of [6, Prop. 4.9], which has no version in our setting.

We now show more representation of  $\Sigma^K$ . We begin by giving the expressions of  $\Psi^K$ ,  $\mathbb{F}^K$ , and the observation operators  $C^K(\cdot)$  associated with  $(\mathbb{T}^K, \Psi^K)$ . This requires the initial observation operators associated with  $(\mathbb{T}, \Psi)$ . We show that, if  $\Phi$  is represented by an admissible control operators,  $\Phi^K$  has a representation by the same control operators. This is the time-varying analogue of the result given in [6, Prop. 5.5].

**PROPOSITION 4.7.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be an absolutely regular time-varying bilinear system and  $\omega_0(\mathbb{T}) < \infty$ . Let  $C(\cdot)$  be the observation operator associated with  $(\mathbb{T}, \Psi)$  and  $\mathbb{K}$  is admissible for  $(\mathbb{T}, \Psi)$ , and let  $\Sigma^K$  be the absolutely regular time-varying bilinear system given in Theorem 4.5. Then the following hold:*

- (i)  $\mathbb{T}^K(\cdot, s)x_0$  and  $\Phi_{\cdot,s}^K(u, x)$  belong to  $\mathcal{D}_s(C(\cdot))$ , and we have

$$(4.8) \quad \Psi_s^K x_0 = C(\cdot)\mathbb{T}^K(\cdot, s)x_0, \quad \mathbb{F}_s^K(u, x) = C(\cdot)\Phi_{\cdot,s}^K(u, x)$$

for all  $x_0 \in X, u \in \mathbb{C}_{loc}^{2,s}$ , and  $x \in X_{loc}^{2,s}$ .

- (ii) For any  $z_0 \in X, u \in \mathbb{C}_{loc}^{2,s}$ , the unique solutions  $(z_{\Sigma^K}, h_{\Sigma^K}) \in \mathcal{C}([s, \infty), X) \times Y_{loc}^{2,s}$  of the functional equations

$$(4.9) \quad \begin{cases} z_{\Sigma^K}(t) = \mathbb{T}^K(t, s)z_0 + \Phi_{t,s}^K(u, z_{\Sigma^K}), \\ h_{\Sigma^K} = \Psi_s^K z_0 + \mathbb{F}_s^K(u, z_{\Sigma^K}) \end{cases}$$

are such that  $z_{\Sigma^K} \in \mathcal{D}_s(C(\cdot)) \cap \mathcal{D}_s(C^K(\cdot))$  and  $h_{\Sigma^K}(t) = C(t)z_{\Sigma^K}(t)$  for a.e.  $t \geq s$ .

- (iii) Let  $\overline{X}$  be a Banach space in which  $X$  is dense and continuously embedded. Assume that  $\Phi_{t,s}$  is represented by admissible control operators  $B(\cdot) \in L^\infty(\mathbb{R}_+, \mathcal{L}_s(X, \overline{X}))$  (see Remark 3.8(i)) and  $\mathbb{T}^K(t, s)$  has a locally uniformly bounded extension  $\overline{\mathbb{T}}^K(t, s) : \overline{X} \rightarrow \overline{X}$ . Thus,  $\overline{\mathbb{T}}^K$  satisfies (i) and (ii) of Definition 2.1. Then

$$(4.10) \quad \Phi_{\cdot,s}^K(u, x) = \mathbb{V}_s^{\overline{\mathbb{T}}^K}(uB(\cdot)x) \quad \text{and} \quad \mathbb{F}_s^K(u, x) = C(\cdot)\mathbb{V}_s^{\overline{\mathbb{T}}^K}(uB(\cdot)x)$$

for all  $(u, x) \in \mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$ .

*Proof.* (i) From identity (4.4) we have, for all  $x_0 \in X$ ,

$$\begin{aligned} \Psi_s^K x_0 &= \Psi_s x_0 + \mathbb{L}_s^K \Psi_s^K x_0 \\ &= C(\cdot)\mathbb{T}(\cdot, s)x_0 + C(\cdot)\mathbb{K}_{\cdot,s}\Psi_s^K x_0 && \text{(by Remark 4.4(i))} \\ &= C(\cdot)(\mathbb{T}(\cdot, s) + \mathbb{K}_{\cdot,s}\Psi_s^K)x_0 \\ &= C(\cdot)\mathbb{T}^K(\cdot, s)x_0 && \text{(by (4.3)),} \end{aligned}$$

and this shows that  $\mathbb{T}^K(\cdot, s)x_0 \in \mathcal{D}_s(C(\cdot))$ .

By using again (4.4) and Remark 4.4(i) and applying Theorem 3.12, we obtain

$$\begin{aligned} \mathbb{F}_s^K(u, x) &= \mathbb{F}_s(u, x) + \mathbb{L}_s^K \mathbb{F}_s^K(u, x) \\ &= C(\cdot)\Phi_{\cdot,s}(u, x) + C(\cdot)\mathbb{K}_{\cdot,s}\mathbb{F}_s^K(u, x) \\ &= C(\cdot)(\Phi_{\cdot,s}(u, x) + \mathbb{K}_{\cdot,s}\mathbb{F}_s^K(u, x)) \\ &= C(\cdot)\Phi_{\cdot,s}^K(u, x) && \text{(by (4.3))} \end{aligned}$$

for all  $u \in \mathbb{C}_{loc}^{2,s}$  and  $x \in X_{loc}^{2,s}$ . Therefore  $\Phi_{\cdot,s}^K(u, x) \in \mathcal{D}_s(C(\cdot))$ .

(ii) As  $\omega_0(\mathbb{T}) < \infty$  we deduce from [31, Thm. 4.4] that  $\omega_0(\mathbb{T}^K) < \infty$ . Then, according to Theorems 4.5 and 3.15, the functional equations (4.9) have a unique solution  $(z_{\Sigma^K}, h_{\Sigma^K})$  such that  $z_{\Sigma^K} \in \mathcal{D}_s(C^K(\cdot))$  and  $h_{\Sigma^K}(t) = C^K(t)z_{\Sigma^K}(t)$  for a.e.  $t \geq s$ . From (i) it follows that  $z_{\Sigma^K}(\cdot) \in \mathcal{D}_s(C(\cdot))$ , and, for a.e.  $t \geq s$ , we obtain

$$\begin{aligned} h_{\Sigma^K}(t) &= (\Psi_s^K z_0)(t) + \mathbb{F}_s^K(u, z_{\Sigma^K})(t) \\ &= C(t)\mathbb{T}^K(t, s)z_0 + C(t)\Phi_{t,s}^K(u, z_{\Sigma^K}) \\ &= C(t)z_{\Sigma^K}(t). \end{aligned}$$

(iii) By [31, Prop. 2.11] we can see that  $\mathbb{V}_s^{\mathbb{T}} B_k(u, x) \in \mathcal{D}_s(C(\cdot))$ , and by proceeding as in the proof of [31, Form. (4.14)] we can obtain

$$(4.11) \quad \mathbb{V}_s^{\mathbb{T}^K} B_k(u, x) = \mathbb{V}_s^{\mathbb{T}} B_k(u, x) + \mathbb{K}_{\cdot,s}(I - \mathbb{L}_{s+t_1,s}^K)^{-1} C(\cdot) \mathbb{V}_s^{\mathbb{T}} B_k(u, x)$$

for all  $u \in \mathbb{C}_{loc}^{2,s}$ ,  $x \in X_{loc}^{2,s}$ , and  $t_1$  large enough. By using Proposition 3.9 and Remark 3.13 and taking the limit in (4.11) on  $\mathcal{C}([s, s+t_1], X)$ , we obtain

$$(4.12) \quad \begin{aligned} \Phi_{t,s}^K(u, x) &= \lim_{k \rightarrow \infty} [\mathbb{V}_s^{\mathbb{T}^K} B_k(u, x)](t) \\ &= \Phi_{t,s}(u, x) + \mathbb{K}_{t,s}(I - \mathbb{L}_{s+t_1,s}^K)^{-1} \mathbb{F}_s(u, x). \end{aligned}$$

Hence, it follows from Remark 4.4(i) that  $\Phi_{\cdot,s}^K(u, x) \in \mathcal{D}_s(C(\cdot))$ . Our aim now is to show that for all  $(u, x) \in \mathcal{A}^{2,s} := \{(u, x) \in \mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s} \mid u.x \in X_{loc}^{2,s}\}$

$$(4.13) \quad B_k(u, x) \rightarrow uB(\cdot)x \quad \text{as } k \rightarrow \infty \quad \text{in } \overline{X}_{loc}^{2,s},$$

where the operator  $B_k$  is defined in (3.11). Let  $(u, x) \in \mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$ , and set  $D_k(u, x) := B_k(u, x) - uB(\cdot)x$ . Then  $D_k(u, x) \in \overline{X}_{loc}^{2,s}$  if  $(u, x) \in \mathcal{A}^{2,s}$ . By means of Hölder's inequality and Fubini's theorem we estimate

$$\begin{aligned} \|D_k(u, x)\|_{L^2([0,T], \overline{X})} &= k^2 \int_0^T \left\| \int_{\tau-\frac{1}{k}}^\tau \overline{\mathbb{T}}(\tau, \mu) u(\mu) B(\mu) x(\mu) d\mu - u(\tau) B(\tau) x(\tau) \right\|^2 d\tau \\ &\leq k \int_0^{\frac{1}{k}} \int_0^T \|\overline{\mathbb{T}}(\tau + \mu, \tau) u(\tau) B(\tau) x(\tau) - u(\tau + \mu) B(\tau + \mu) x(\tau + \mu)\|^2 d\tau d\mu, \end{aligned}$$

which gives (4.13). By combining now (4.12) and (4.13) we obtain

$$(4.14) \quad \mathbb{V}_s^{\mathbb{T}^K} B_k(u, x)(t) = \mathbb{V}_s^{\overline{\mathbb{T}}^K} B_k(u, x)(t) \rightarrow (\mathbb{V}_s^{\overline{\mathbb{T}}^K} uB(\cdot)x)(t) \text{ as } k \rightarrow \infty.$$

Thus  $\Phi_{\cdot, s}^K(u, x) = \mathbb{V}_s^{\overline{\mathbb{T}}^K} (uB(\cdot)x)$  for all  $(u, x) \in \mathcal{A}^{2,s}$ .

Let  $\mathcal{E} := \mathcal{C}_c([s, \infty), \mathbb{C}) \times \mathcal{C}_c([s, \infty), X)$ , where  $\mathcal{C}_c([s, \infty), X)$  is the space of continuous functions with compact support in  $[s, \infty)$ . Since the space  $\mathcal{E}$  is dense in  $\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$  and is included in  $\mathcal{A}^{2,s}$ , we deduce that this latter is also dense in  $\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$ . Thus, by the continuity of both sides of (4.14) we obtain the first equality in (4.10). The second equality in (4.10) is immediate from the first equality.  $\square$

We now turn back to the problem of the observer. This leads us to introduce the following concept of detectability.

**DEFINITION 4.8.** *Let  $(\mathbb{T}, \Psi)$  be a time-varying observation system. We say that  $(\mathbb{T}, \Psi)$  is admissibly detectable if there exists a family  $\mathbb{K}$  such that:*

- (i)  $\mathbb{K}$  is admissible for  $(\mathbb{T}, \Psi)$  (see Definition 4.3);
- (ii) the evolution family  $\mathbb{T}^K$  on  $X$  defined in (4.3) is such that  $\omega_0(\mathbb{T}^K) < 0$ .

For the time-invariant Hilbert space setting, Rebarber [28, Def. 1.5] has introduced a somewhat general version of detectability. However, in the time-varying Banach space setting, Schnaubelt [31, Def. 5.8] has proposed a more general definition of detectability with no regularity assumption on the system. But one can remark that if the pair  $(\mathbb{T}, \Psi)$  is detectable in the sense of Definition 4.8, then, by Theorem 4.5, the closed-loop evolution family

$$\mathbb{T}^K(t, s) = \mathbb{T}(t, s) + \mathbb{K}_{t,s}(I - \mathbb{L}_s^K)^{-1} \Psi_s, \quad (t, s) \in \Delta,$$

is exponentially stable on  $X$ . By letting  $\phi_{t,s}^K := \mathbb{K}_{t,s}(I - \mathbb{L}_s^K)^{-1}$ , it is easy to see that the pair  $(\mathbb{T}^K, \phi^K)$  is a linear control system on  $X$  which implies that  $(\mathbb{T}, \Psi)$  is detectable in the sense of [31, Def. 5.8]. It is not known if Schnaubelt's definition is genuinely more general; i.e., there exists a pair  $(\mathbb{T}, \Psi)$  which is detectable in the sense of [31, Def. 5.8] but it is not in the sense of Definition 4.8.

The problem to design an observer for any input holds even in the finite-dimensional case; see, e.g., [16, 18]. The following result gives sufficient conditions for the existence of a Luenberger-like observer for an absolutely regular time-varying bilinear system.

**THEOREM 4.9.** *Let  $\Sigma = (\mathbb{T}, \Phi, \Psi, \mathbb{F})$  be an absolutely regular time-varying bilinear system and  $\omega_0(\mathbb{T}) < \infty$ . If  $(\mathbb{T}, \Psi)$  is admissibly detectable by  $\mathbb{K}$ , then the system  $(\mathcal{O})$  is an exponential Luenberger-like observer for  $\Sigma$  working for some small inputs.*

*Proof.* First, for  $\varepsilon_0 \in X$  and  $s \geq 0$ , we are looking for a function  $\varepsilon_{\Sigma^K}(\cdot) \in \mathcal{D}_s(C(\cdot)) \cap \mathcal{D}_s(C^K(\cdot))$  satisfying (4.2). So let  $\Sigma^K$  be the absolutely regular time-varying bilinear systems associated with  $\Sigma$  as defined in Theorem 4.5 and consider

the system

$$(4.15) \quad \begin{cases} \varepsilon_{\Sigma^K}(t) &= \mathbb{T}^K(t, s)\varepsilon_0 + \Phi_{t,s}^K(u, \varepsilon_{\Sigma^K}), \\ h_{\Sigma^K} &= \Psi_s^K \varepsilon_0 + \mathbb{F}_s^K(u, \varepsilon_{\Sigma^K}) \end{cases}$$

for  $u \in \mathbb{C}_{loc}^{2,s}$ . According to Theorem 3.15, the solution  $\varepsilon_{\Sigma^K}(\cdot)$  of  $\Sigma^K$  associated with  $u$  exists in  $\mathcal{C}([s, \infty), X)$ , and, via Proposition 4.7(i), it fits in  $\mathcal{D}_s(C(\cdot)) \cap \mathcal{D}_s(C^K(\cdot))$ . Therefore, we have  $h_{\Sigma^K}(t) = C^K(t)\varepsilon_{\Sigma^K}(t) = C(t)\varepsilon_{\Sigma^K}(t)$  for a.e.  $t \geq s$ . Again by Theorem 3.15, the solution  $x_{\Sigma}(\cdot)$  of  $\Sigma$  associated with  $u$  exists in  $\mathcal{C}([s, \infty), X) \cap \mathcal{D}_s(C^K(\cdot))$ . Thus,  $\zeta(\cdot) := x_{\Sigma}(\cdot) + \varepsilon_{\Sigma^K}(\cdot) \in \mathcal{C}([s, \infty), X) \cap \mathcal{D}_s(C(\cdot))$ , and the output function is then given by

$$(4.16) \quad \begin{aligned} h_{\Sigma^K}(t) &= C^K(t)\varepsilon_{\Sigma^K}(t) \\ &= C(t)(\zeta(t) - x_{\Sigma}(t)) \\ &= \hat{y}(t) - y_{\Sigma}(t) \end{aligned}$$

for a.e.  $t \geq s$ . On the other hand, by using the first equation in (4.15) and (4.3), we can write

$$\begin{aligned} \varepsilon_{\Sigma^K}(t) &= \mathbb{T}(t, s)\varepsilon_0 + \Phi_{t,s}(u, \varepsilon_{\Sigma^K}) + \mathbb{K}_{t,s}(\Psi_s^K \varepsilon_0 + \mathbb{F}_s^K(u, \varepsilon_{\Sigma^K})) \\ &= \mathbb{T}(t, s)\varepsilon_0 + \Phi_{t,s}(u, \varepsilon_{\Sigma^K}) + \mathbb{K}_{t,s}h_{\Sigma^K}. \end{aligned}$$

By combining this with (4.16), we deduce that  $\varepsilon_{\Sigma^K}(\cdot)$  is the unique solution of (4.2) and that  $\zeta(\cdot)$  is the unique solution of the observer  $(\mathcal{O})$ . Now, by detectability and Lemma 3.3,  $\delta := \sup_{(t,s) \in \Delta} \|\Phi_{t,s}^K\|_{\mathcal{BL}(L^2(s,t) \times L^2(s,t;X), X)}$  is finite, and, via (4.15), we have

$$\|\varepsilon_{\Sigma^K}(t)\| \leq M e^{-\theta(t-s)} \|\varepsilon_0\| + \delta \|u\|_{\mathbb{C}^{2,s}} \left( \int_s^t \|\varepsilon_{\Sigma^K}(\sigma)\|^2 d\sigma \right)^{\frac{1}{2}},$$

where  $\omega := \omega_0(\mathbb{T}^K) < 0$ ,  $\theta \in ]0, -\omega[$ , and  $M \geq 1$ . By taking the square of both terms of the above inequality and using Gronwall's lemma, it then follows that

$$\|\varepsilon_{\Sigma^K}(t)\| \leq M\sqrt{2} e^{(\delta^2 \|u\|_{\mathbb{C}^{2,s}}^2 - \epsilon)(t-s)} \|\varepsilon_0\|.$$

Thus, the system  $(\mathcal{O})$  is an exponential observer for  $\Sigma$  for all inputs satisfying  $\|u\|_{\mathbb{C}^{2,s}} < \varrho$ , with  $\varrho := \frac{\sqrt{-\omega}}{\delta}$ .  $\square$

**5. Application.** We consider the following partial differential equation with mixed boundary conditions:

$$(5.1) \quad \begin{cases} \partial_t^1 \phi(t, \xi) = \alpha(t) \partial_{\xi}^2 \phi(t, \xi) & \text{for } t \geq s, \xi \in [0, 1], \\ \phi(t, 0) = 0, \quad \partial_{\xi}^1 \phi(t, 1) + u(t) \int_0^1 \pi(\xi) \phi(t, \xi) d\xi = 0 & \text{for } t \geq s, \\ \phi(s, \xi) = \varphi(\xi) & \text{for } \xi \in [0, 1], \end{cases}$$

where  $\partial_{\xi}^i := \frac{\partial^i}{\partial \xi^i}$ ,  $i = 1, 2$ ,  $\varphi \in X := L^1(0, 1)$ , the input function  $u \in L_{loc}^2(\mathbb{R}_+)$ , and the coefficient  $\alpha \in \mathcal{C}(\mathbb{R}_+)$  is a strictly positive function such that  $0 < \alpha_0 \leq \alpha(t) \leq \alpha_m$  for all  $t \geq 0$ . For simplicity, we assume that the boundary coefficient  $\pi \in L^\infty(0, 1)$ . Let  $A := \partial_{\xi}^2$  with  $D(A) := \{f \in W^{2,1}[0, 1], f(0) = f'(1) = 0\}$ . It is known that  $(A, D(A))$  generates an analytic semigroup  $(S(t))_{t \geq 0}$  on the space  $X$ . For the

reformulation of our system in bilinear form we define the space  $X_{-1}$  as the completion of  $X$  with respect to the new norm  $\|x\|_{-1} := \|(\lambda I - A)^{-1}x\|$  for some  $\lambda$  fixed in  $\rho(A)$ . This space is independent of the choice of  $\lambda$  and is called the *extrapolation space* of  $X$  with respect to  $A$ . The semigroup  $(S(t))_{t \geq 0}$  can be extended to a  $C_0$ -semigroup  $(S_{-1}(t))_{t \geq 0}$  on  $X_{-1}$ , with the generator denoted by  $(A_{-1}, D(A_{-1}))$ . Notice that  $A_{-1}$  is an extension of  $A$  to  $X$ , with  $D(A_{-1}) = X$ , and the norm of  $X$  is equivalent to the graph norm of  $A_{-1}$ . On the other hand, let  $X_a$  (respectively,  $X_{b-1}$ ) be the domain of the fractional power  $(\lambda - A)^a$  (respectively,  $(\lambda - A_{-1})^b$ ), endowed with the graph norm, with  $a, b \in [0, 1]$ . Then it is known that

$$(5.2) \quad S_{-1}(t) \in \mathcal{L}(X_{b-1}, X_a) \quad \text{and}$$

$$(5.3) \quad \|S(t)(\lambda - A)^b x\|_{X_a} \leq h e^{\omega t} \max\{1, t^{-(a+b)}\} \|x\|$$

for all  $t \geq 0$  and  $x \in X$ , where  $h = h(\lambda) > 0$ ,  $\omega \geq 0$ , and  $a, b \in [0, 1]$ . For more details we can see, e.g., [15, sect. II.5] and [1].

Here we suppose that our system (5.1) is coupled with the output function

$$(5.4) \quad y(t) = \int_0^1 \xi^\theta \phi(t, \xi) d\xi$$

for  $t \geq s$ , where  $\theta \in ]-1, 0[$ . We will show that (5.1) and (5.4) can be reformulated as a well-posed time-varying bilinear system  $\Sigma$ .

Let  $t \geq 0$  and  $\lambda > 0$ . We first remark that the solution of the elliptic problem

$$(5.5) \quad (\lambda - \alpha(t)\partial_\xi^2)\beta_{\lambda,t} = 0, \quad \text{with} \quad \beta_{\lambda,t}(0) = 0 \quad \text{and} \quad \partial_\xi^1 \beta_{\lambda,t}(1) = 1,$$

exists, and it is explicitly given by

$$(5.6) \quad \beta_{\lambda,t}(\xi) = \sqrt{\frac{\alpha(t)}{\lambda}} \frac{\sinh(\sqrt{\frac{\lambda}{\alpha(t)}} \xi)}{\cosh(\sqrt{\frac{\lambda}{\alpha(t)}})}.$$

In what follows, we fix  $\lambda > 0$ , and we introduce the time-varying operators

$$A(t) := \alpha(t)A_{-1}, \quad \text{with} \quad D(A(t)) := D(A_{-1}) = X, \quad t \geq 0,$$

and

$$B_\lambda(t) := (\lambda - A(t))(\beta_{\lambda,t} \otimes L),$$

where

$$L(f) := \int_0^1 \pi(\xi) f(\xi) d\xi \quad \text{and} \quad (\beta_{\lambda,t} \otimes L)f := L(f)\beta_{\lambda,t}, \quad f \in X.$$

Thus, we obtain the following result, which shows that the system (5.1) is equivalent to some time-varying bilinear system.

**PROPOSITION 5.1.** *If  $z$  is a solution of (5.1), i.e.,  $z \in \mathcal{C}^1([s, \infty), X) \cap \mathcal{C}([s, \infty), \mathcal{C}^2[0, 1])$  and verifies (5.1), then  $x(t) := z(t, \cdot)$  is a solution of the bilinear system*

$$(5.7) \quad \dot{x}(t) = A(t)x(t) + u(t)B_\lambda(t)x(t), \quad x(s) = \varphi, \quad t \geq s.$$

Conversely, if  $x \in \mathcal{C}^1([s, \infty), X) \cap \mathcal{C}([s, \infty), \mathcal{C}^2[0, 1])$  is a solution of (5.7) and verifies (5.8)

$$x(t) - u(t)(\beta_{\lambda,t} \otimes L)x(t) \in D(A)$$

for all  $t \geq s$ , then  $z(t, \cdot) := x(t)$  is a solution of (5.1).

*Proof.* Let  $z$  be a solution of (5.1). Then, from the boundary conditions, we deduce that  $x(t) := z(t, \cdot)$  verifies the condition (5.8). By invoking (5.5) together with (5.8), we get

$$\begin{aligned} \dot{x}(t) &= \lambda x(t) - \left( \lambda - \alpha(t) \frac{\partial^2}{\partial \xi^2} \right) x(t) \\ &= \lambda x(t) - (\lambda - \alpha(t)A)(x(t) + u(t)(\beta_{\lambda,t} \otimes L)x(t)) \\ &= \lambda x(t) - (\lambda - A(t))(x(t) + u(t)(\beta_{\lambda,t} \otimes L)x(t)) \\ &= A(t)x(t) + u(t)B_\lambda(t)x(t). \end{aligned}$$

It is straightforward to see that the converse also holds.  $\square$

We know that the evolution family generated by  $\alpha(\cdot)A$  is given by  $\mathbb{T}(t, s) := S(\int_s^t \alpha(\tau) d\tau)$ ,  $(t, s) \in \Delta$ . This family can be extended on the extrapolated space  $X_{-1}$  to the evolution family  $\overline{\mathbb{T}}(t, s) := S_{-1}(\int_s^t \alpha(\tau) d\tau)$  which is generated by  $A(\cdot)$ . Let us define the operator

$$\Phi_{t,s}(u, x) := \int_s^t \overline{\mathbb{T}}(t, \sigma) u(\sigma) B_\lambda(\sigma) x(\sigma) d\sigma$$

for  $(u, x) \in \mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$  and  $(t, s) \in \Delta$ . We show that the pair  $(\mathbb{T}, \Phi)$  is a time-varying bilinear control system on  $X$ . We proceed by steps.

*Step 1.* We show that the operator  $\Phi_{t,s} \in \mathcal{BL}(\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}, X)$ : For each  $(s, t) \in \Delta$  and  $(u, x) \in \mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}$  we define the functions

$$\gamma(\sigma) := \int_\sigma^t \alpha(\tau) d\tau \quad \text{and} \quad f(\sigma) := u(\sigma)(\lambda - A(t))L(x(\sigma))\beta_{\lambda,\sigma}, \quad \sigma \in [s, t].$$

The function  $\gamma \in C^1([s, t])$  and is strictly decreasing and hence bijective. Thus, by changing variables, one can write

$$\begin{aligned} \Phi_{t,s}(u, x) &= \int_s^t S_{-1}(\gamma(\sigma)) f(\sigma) d\sigma \\ &= \int_0^{\gamma(s)} S_{-1}(r) \frac{f(\gamma^{-1}(r))}{\alpha(\gamma^{-1}(r))} dr \\ (5.9) \quad &= \int_0^{\gamma(s)} S_{-1}(\gamma(s) - r) g(\gamma(s) - r) dr, \end{aligned}$$

where  $g(\cdot) := \frac{f(\gamma^{-1}(\cdot))}{\alpha(\gamma^{-1}(\cdot))}$ .

We now introduce the Favard space associated with a semigroup  $(V(t))_{t \geq 0}$  (with generator  $G$ ) on some Banach space  $E$  which is defined by

$$F_G := \left\{ x \in E : \sup_{t > 0} \frac{1}{t} \|e^{-\omega t} V(t)x - x\| < \infty \right\},$$

with  $\omega > \omega_0$  fixed ( $\omega_0$  is the growth bound of the semigroup  $(V(t))_{t \geq 0}$ ). The space  $F_G$  endowed with the norm  $\|x\|_{F_G} := \sup_{t > 0} \frac{1}{t} \|e^{-\omega t} V(t)x - x\|$  is a Banach space;

see, e.g., [15, sect. II.5] for further properties. We have to note that in our case  $F_{\alpha(t)A} = F_A$  for all  $t \geq 0$ .

PROPOSITION 5.2. *We have the following properties:*

- (i) *The function  $\beta_{\lambda,t} \in F_A$  for each  $t \geq 0$ .*
- (ii) *The function  $t \mapsto \beta_{\lambda,t}$  is continuous from  $\mathbb{R}_+$  to  $F_A$ .*
- (iii) *The function  $g$  defined in (5.9) is locally integrable with values in  $F_{A_{-1}}$ .*

*Proof.* (i) In fact, a simple computation gives

$$(5.10) \quad \|\beta_{\lambda,t}\|_X \leq \frac{\alpha_m}{\lambda}$$

for all  $\lambda > 0$ , and then by applying [13, Thm. 16] we obtain our claim.

(ii) The estimate (5.10) implies that the space  $X_m := \{f \in W^{1,2}(0,1), f(0) = 0\}$ , endowed with the  $W^{1,2}$ -norm, is continuously embedded in the Favard space  $F_A$ ; see [11, Prop. 4.1]. Hence, via (i) and (5.5), we can write

$$\begin{aligned} \|\beta_{\lambda,t} - \beta_{\lambda,t_0}\|_{F_A} &\leq \text{const } \|\beta_{\lambda,t} - \beta_{\lambda,t_0}\|_{X_m} \\ &\leq \text{const } (1 + \lambda) \|\beta_{\lambda,t} - \beta_{\lambda,t_0}\|_X. \end{aligned}$$

Thus, it is enough to prove the continuity of  $\beta_{\lambda,\cdot}$  with respect to the topology of  $X$ . For this we can simply use (5.6) and the fact that the function  $\cosh$  is locally Lipschitz.

(iii) Remark that  $\lambda_0 - A_{-1} \in \mathcal{L}(F_A, F_{A_{-1}})$  for all  $\lambda_0 \in \rho(A) = \rho(A_{-1})$ ; see, e.g., [15, sect. II.5]. Then the function  $g$  takes values in  $F_{A_{-1}}$ . To obtain our aim we show that the function  $(\lambda - \alpha(\cdot)A_{-1})\beta_{\lambda,\cdot}$  is continuous from  $\mathbb{R}_+$  to  $F_{A_{-1}}$ . In fact, let  $t, t' \geq 0$  and  $\lambda_0 \in \rho(A)$ . Then by the estimate

$$\begin{aligned} \|(\lambda - \alpha(t)A_{-1})\beta_{\lambda,t} - (\lambda - \alpha(t')A_{-1})\beta_{\lambda,t'}\|_{F_{A_{-1}}} &\leq \alpha(t) \left| \frac{\lambda}{\alpha(t)} - \frac{\lambda}{\alpha(t')} \right| \|\beta_{\lambda,t}\|_{F_A} \\ &\quad + \left\{ \left| \frac{\lambda}{\alpha(t')} - \lambda_0 \right| + \|\lambda_0 - A_{-1}\|_{\mathcal{L}(F_A, F_{A_{-1}})} \right\} \|\alpha(t)\beta_{\lambda,t} - \alpha(t')\beta_{\lambda,t'}\|_{F_A} \end{aligned}$$

together with the continuity of the function  $\alpha$  and (ii), we obtain (iii).

To conclude this step, we apply the Nagel–Sinestrari result (see [27, Prop. 3.1]) and use (iii) to obtain that the range of  $\Phi_{t,s}$  is contained in  $X$ . Therefore, by using the fact that  $X (= D(A_{-1}))$  is continuously injected in  $X_{-1}$  and the open mapping theorem for bilinear operators, we can deduce that  $\Phi_{t,s} \in \mathcal{BL}(\mathbb{C}_{loc}^{2,s} \times X_{loc}^{2,s}, X)$ .  $\square$

*Step 2.* We prove the estimate (3.2): By applying again [27, Prop. 3.1] and using (5.9) we obtain

$$(5.11) \quad \|\Phi_{t,s}(u, x)\| \leq N e^{\omega\gamma(s)} \|g\|_{L^1(0, \gamma(s); F_{A_{-1}})},$$

with constants  $\omega, N \geq 0$  independent of  $s$  and  $t$ . Now, by using successively Hölder's

inequality and changing variables we can estimate

$$\begin{aligned}
 \|g\|_{L^1(0,\gamma(s);F_{A_{-1}})} &\leq \left( \int_0^{\gamma(s)} \frac{1}{\alpha(\gamma^{-1}(r))} |u(\gamma^{-1}(r))|^2 dr \right)^{\frac{1}{2}} \\
 &\quad \times \left( \int_0^{\gamma(s)} (|Lx(\gamma^{-1}(r))| \|(\lambda - \alpha(\gamma^{-1}(r))A_{-1})\beta_{\lambda,\gamma^{-1}(r)}\|_{F_{A_{-1}}})^2 dr \right)^{\frac{1}{2}} \\
 &\leq \frac{\alpha_m^2}{\alpha_0} \|\pi\|_{L^\infty} \left( \int_s^t |u(r)|^2 dr \right)^{\frac{1}{2}} \left( \int_s^t \left( \|x(r)\| \left\| \left( \frac{\lambda}{\alpha(r)} - A_{-1} \right) \beta_{\lambda,r} \right\|_{F_{A_{-1}}} \right)^2 dr \right)^{\frac{1}{2}}.
 \end{aligned}
 \tag{5.12}$$

On the other hand, we have the following continuous injection  $X_m \hookrightarrow F_{A_{-1}}$  ( $X_m$  is defined in (ii)). Thus, by using the fact that  $\|\beta_{\lambda,r}\|_{X_m} \leq \text{const } (1 + \lambda)\|\beta_{\lambda,r}\|_X$  and (5.10), we obtain

$$\begin{aligned}
 \left\| \left( \frac{\lambda}{\alpha(r)} - A_{-1} \right) \beta_{\lambda,r} \right\|_{F_{A_{-1}}} &\leq \left\| \left( \frac{\lambda}{\alpha(r)} - \lambda_0 \right) \beta_{\lambda,r} \right\|_{F_{A_{-1}}} + \|(\lambda_0 - A_{-1})\beta_{\lambda,r}\|_{F_{A_{-1}}} \\
 &\leq \text{const } \alpha_m \frac{1 + \lambda}{\lambda} \left( \frac{\lambda}{\alpha_0} + \lambda_0 + 1 \right).
 \end{aligned}
 \tag{5.13}$$

Therefore, the estimate (3.2) can be deduced from (5.11) and (5.13) with the constant

$$\beta(t_0) = \text{const } \left\{ \frac{\alpha_m^3}{\alpha_0} N \|\pi\|_{L^\infty} \frac{1 + \lambda}{\lambda} \left( \frac{\lambda}{\alpha_0} + \lambda_0 + 1 \right) \right\} e^{\omega \alpha_m t_0}.$$

Finally, the property of composition (3.1) is immediate, and then the pair  $(\mathbb{T}, \Phi)$  is a time-varying bilinear control system on  $X$ .

Our observation operator  $C_\theta f := \int_0^1 \xi^\theta f(\xi) d\xi$  is unbounded with maximal domain  $D(C_\theta) = L^r(0, 1)$ ,  $r > \frac{1}{1+\theta}$ . But one can prove by using the change of variables in (5.9) and [12, Lem. 6.5] that  $C_\theta$  is a  $\mathbb{T}$ -admissible observation operator. Remark also that the operator  $C_\theta$  is bounded on  $X_a$ , where  $a \in ]0, \frac{1}{2}[$ . Hence, according to (5.2), the output map  $\Psi$  is given by  $\Psi_s(x) = C_\theta \mathbb{T}(\cdot, s)x$  for  $x \in X$ .

Since the Favard space  $F_A$  is continuously embedded in  $X_a$  when  $a \in [0, 1[$  and due to Proposition 5.2, we have that  $\bar{\mathbb{T}}(t, s)B_\lambda(t) \in \mathcal{L}(X, X_a)$ , which is continuous w.r.t.  $t \geq s$ . On the other hand, by using (5.3) we can easily deduce that

$$\|\bar{\mathbb{T}}(t, s)B_\lambda(t)\|_{\mathcal{L}(X, X_a)} \leq \hbar_1 e^{\omega(t-s)}(t-s)^{(b-a-1)},
 \tag{5.14}$$

where  $a \in ]0, 1[$ ,  $b \in ]0, \frac{3}{4}[$ , and  $\hbar_1 = \hbar_1(L, a, b, \alpha) > 0$ . This proves that  $\Phi_{t,s}(u, x) \in X_a$ , and if  $a \in ]0, \frac{1}{2}[$  and  $b \in ]0, \frac{3}{4}[$ , then we estimate

$$|C_\theta \Phi_{t,s}(u, x)| \leq \hbar_2 \int_s^t e^{\omega(\tau-s)}(\tau-s)^{(b-a-1)} u(\tau) x(\tau) d\tau,$$

where  $\hbar_2 := \hbar_1 \|C_\theta\|_{\mathcal{L}(X_a, \mathbb{C})}$ . This implies that

$$\|C_\theta \Phi_{t,s}(u, x)\|_{L^2(s, s+t_0)}^2 \leq \hbar_2 \int_s^{s+t_0} \left( \int_s^t e^{\omega(\tau-s)}(\tau-s)^{(b-a-1)} u(\tau) x(\tau) d\tau \right)^2 dt.$$

By applying successively Young and Hölder inequalities and assuming that  $b-a > 1/2$ , we have

$$(5.15) \quad \|C_\theta \Phi_{\cdot,s}(u, x)\|_{L^2(s, s+t_0)} \leq \hbar_3 e^{\omega t_0} t_0^{(b-a-\frac{1}{2})} \|u\|_{L^2(s, s+t_0)} \|x\|_{L^2([s, s+t_0], X)},$$

where  $\hbar_3 = \hbar_3(a, b, \hbar_2) > 0$ .

Thus we have proved that, if  $a \in ]0, \frac{1}{2}[$ ,  $b \in ]0, \frac{3}{4}[$ , and  $b-a > 1/2$ , the triple  $(\mathbb{T}, \Phi, \Psi)$  is admissible on  $(L^1(0,1), \mathbb{C}, \mathbb{C})$ , which means that the system  $\Sigma := (\mathbb{T}, \Phi, \Psi, \mathbb{F})$ , where  $\mathbb{F}_s(u, x) := C_\theta \Phi_{\cdot,s}(u, x)$ , is a well-posed time-varying bilinear system on  $(L^1(0,1), \mathbb{C}, \mathbb{C})$ ; see Proposition 3.6. Under the same condition we can also deduce from (5.15) that our system is absolutely regular.

Now it remains to prove that the pair  $(\mathbb{T}, \Psi)$  is detectable. Since the spectral bound  $s(A) = -\pi^2/4$  and  $S(\cdot)$  is an analytic semigroup, then via the spectral mapping theorem the semigroup  $S(\cdot)$  is exponentially stable. Hence the evolution family  $\mathbb{T}$  is so as well. Therefore  $(\mathbb{T}, \Psi)$  is detectable by the operator  $\mathbb{K} = 0$ . However, one can see that this pair is still detectable by nontrivial, but not “too greater,” operators. In fact, let  $k \in X_{loc}^2$ , and set

$$(5.16) \quad \mathbb{K}_{t,s}(y) := \int_s^t \mathbb{T}(t, \sigma) y(\sigma) k(\sigma) d\sigma,$$

where  $y \in \mathbb{C}_{loc}^{2,s}$  and  $t \geq s \geq 0$ .

**PROPOSITION 5.3.** *There is a constant  $k_0 > 0$  such that the pair  $(\mathbb{T}, \Psi)$  is admissibly detectable by  $\mathbb{K}$  for all functions  $k \in X^\infty$ , with  $\|k\|_{X^\infty} < k_0$ .*

*Proof.* The time-varying linear observation system  $(\mathbb{T}, \Psi)$  is represented by  $C_\theta$ ; then by [31, Prop. 2.11],  $\mathbb{K}_{t,s}y \in D(C_\theta)$  for all  $t \geq s$ , and the time-varying linear system  $\Gamma := (\mathbb{T}, \mathbb{K}, \Psi, \mathbb{L}^K)$ , where  $\mathbb{L}_s^K := C_\theta \mathbb{K}_{\cdot,s}$ , is well-posed. The system  $\Gamma$  is also regular since  $k \in X^\infty$ . Similarly, the time-varying linear system  $\Gamma^I := (\mathbb{T}, \mathbb{K}^I, \Psi, \mathbb{L}^I)$ , where  $\mathbb{K}_{t,s}^I f := (\mathbb{V}_s^\mathbb{T} f)(t)$  for  $f \in X_{loc}^{2,s}$ , and  $\mathbb{L}_s^I := C_\theta \mathbb{K}_{\cdot,s}^I$ , is well-posed and regular. On the other hand,  $I$  is an admissible feedback for  $\Gamma$ , since the constant  $\kappa(t_0) = \kappa_0 t_0^{1/2}$  (see (2.6)) tends to 0 when  $t_0$  tends to 0. Similarly, the operators  $k(\cdot) \in L^\infty([0, \infty), \mathcal{L}_s(\mathbb{C}, X))$  are admissible feedback for  $\Gamma^I$ . This means that there exists  $t_0 > 0$  such that the operators  $I - \mathbb{L}_{s+t_0,s}^I k(\cdot)$ ,  $s \geq 0$ , are invertible on  $L^2[s, s+t_0]$  and have uniformly bounded inverses. Therefore, according to [31, Thm. 5.6], there exists a constant  $k_0 > 0$  such that for all  $k \in X^\infty$ , with  $\|k\|_{X^\infty} < k_0$ , the feedback evolution family  $\mathbb{T}^K$ , associated with  $\Gamma^I$  and the feedback  $k$ , is exponentially stable. Finally, it is easy to see that the feedback evolution family  $\mathbb{T}^K$  coincides with that of the feedback bilinear system  $\Sigma^K$ .  $\square$

From this result and Theorem 4.9 we can deduce that, with  $\mathbb{K}$  given in (5.16) and under conditions in Proposition 5.3, the system  $(\mathcal{O})$  is an exponential Luenberger-like observer for  $\Sigma$  with some small inputs.

## OPTIMAL TRANSPORTATION PROBLEM BY STOCHASTIC OPTIMAL CONTROL\*

TOSHIO MIKAMI<sup>†</sup> AND MICHÈLE THIEULLEN<sup>‡</sup>

**Abstract.** We address an optimal mass transportation problem by means of optimal stochastic control. We consider a stochastic control problem which is a natural extension of the Monge–Kantorovich problem. Using a vanishing viscosity argument we provide a probabilistic proof of two fundamental results in mass transportation: the Kantorovich duality and the graph property for the support of an optimal measure for the Monge–Kantorovich problem. Our key tool is a stochastic duality result involving solutions of the Hamilton–Jacobi–Bellman PDE.

**1. Introduction.** Our goal in the present paper is to show that stochastic optimal control theory can be used efficiently to study deterministic optimal mass transportation problems. Let us recall that optimal transportation theory consists of the following two minimization problems, where  $P_0$  and  $P_1$  are given Borel probability measures on  $\mathbf{R}^d$  and the cost function  $c : \mathbf{R}^d \times \mathbf{R}^d \rightarrow \mathbf{R}^+ \cup \{+\infty\}$  is measurable. In this paper the cost function has the form

$$(1.1) \quad c(x, y) = L(y - x)$$

with  $L(u) : \mathbf{R}^d \rightarrow [0, \infty)$  convex in  $u$ . In the Monge problem the object of study is

$$(1.2) \quad T_M(P_0, P_1) := \inf \left\{ \int_{\mathbf{R}^d} L(g(x) - x) P_0(dx) \right\},$$

and the infimum is taken over all measurable maps  $g : \mathbf{R}^d \mapsto \mathbf{R}^d$  such that the image of  $P_0$  by  $g$  is  $P_1$ . In the Monge–Kantorovich problem (MKP), one considers

$$(1.3) \quad T_{MK}(P_0, P_1) := \inf \left\{ \int_{\mathbf{R}^d \times \mathbf{R}^d} L(y - x) \mu(dxdy) \right\}$$

on the set of probability measures  $\mu$  on  $\mathbf{R}^d \times \mathbf{R}^d$  with marginals  $P_0$  and  $P_1$  (namely, such that  $\mu(A \times \mathbf{R}^d) = P_0(A)$  and  $\mu(\mathbf{R}^d \times B) = P_1(B)$ ). The resolution of (1.2) is a difficult problem. Kantorovich introduced the relaxed version (1.3) as a step to solve (1.2). It is easy to check that

$$(1.4) \quad T_{MK}(P_0, P_1) \leq T_M(P_0, P_1).$$

Indeed, any measurable mapping  $g : \mathbf{R}^d \mapsto \mathbf{R}^d$  such that the image measure of  $P_0$  by  $g$  is  $P_1$  satisfies

$$(1.5) \quad \int_{\mathbf{R}^d} L(g(x) - x) P_0(dx) = \int_{\mathbf{R}^d \times \mathbf{R}^d} L(y - x) \mu_g(dxdy),$$

where  $\mu_g$  is the image measure of  $P_0$  by the mapping

$$(1.6) \quad \mathbf{R}^d \mapsto \mathbf{R}^d \times \mathbf{R}^d,$$

$$(1.7) \quad x \mapsto (x, g(x)).$$

Inequality (1.4) follows since  $\mu_g$  is a probability measure on  $\mathbf{R}^d \times \mathbf{R}^d$  with marginals  $P_0$  and  $P_1$ . Moreover, an optimal measure for (1.3) always exists (cf. [14]). If any such measure is supported by the graph of a measurable map, we say that the *graph property* holds; that is, if for any  $\mu^*$  optimal for (1.3), there exists a set  $\Gamma$  satisfying  $\mu^*(\Gamma) = 1$  and

$$(1.8) \quad \Gamma = \{(x, \theta(x)); x \in \mathbf{R}^d\}$$

for some measurable mapping  $\theta$ . If the graph property holds, it provides a solution to Monge problem (1.2). Indeed, in this case  $T_{MK}(P_0, P_1) = \int_{\mathbf{R}^d \times \mathbf{R}^d} L(y - x) \mu^*(dxdy) = \int_{\mathbf{R}^d} L(\theta(x) - x) P_0(dx)$ . Using (1.4), we see that the mapping  $\theta$  minimizes Monge problem (1.2). In order to check whether the graph property is satisfied, *Kantorovich duality* for (1.3) plays a fundamental role. It was first proved by Kantorovich (cf. [7]) when the cost function is a distance and later generalized by Kellerer (cf. [8]). It runs as follows:

$$(1.9) \quad T_{MK}(P_0, P_1) = \sup \left\{ \int_{\mathbf{R}^d} \psi(y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(x) P_0(dx) \right\},$$

where the supremum is taken over all pairs  $(\varphi, \psi) \in L^1(P_0) \times L^1(P_1)$  satisfying  $\psi(y) - \varphi(x) \leq L(y - x)$ . To go from Kantorovich duality to the graph property, two types of arguments have been used: differentiability properties of convex functions for the quadratic cost (cf. [1]) and geometrical properties of cyclically monotone sets for general costs (cf. [6]).

In the present paper we show that Kantorovich duality and the graph property can be proved by stochastic optimal control combined with a vanishing viscosity argument. It is not clear a priori that stochastic optimal control theory is well suited to studying problems such as  $T_{MK}$  or  $T_M$ , where the initial and the final distributions are both imposed. However, for the case when the cost is  $L(u) = |u|^2$ , one of us (cf. [10]) addressed (1.2) directly without using (1.3) and gave a probabilistic proof of existence and uniqueness of a solution to (1.2). The proof in [10] relies on h-path processes and cyclically monotone sets. In the present paper, on the contrary, we focus on (1.3) and on duality arguments. We rely on a stochastic duality result which we proved in [11]. The basis of this result is the correspondence between solutions of the Hamilton–Jacobi–Bellman (HJB) partial differential equation (PDE) and value functions of stochastic control. We do not use cyclically monotone sets. By *vanishing viscosity* we prove Kantorovich duality and we recover the graph property. Thus the present paper together with [11] provides a global treatment of these two building blocks of optimal transportation theory by stochastic optimal control. Let us mention that here  $L$  is more general than  $|u|^2$  and our method greatly simplifies the arguments

of [10]. Classically (cf. [14]) the graph property is proved for  $L$  satisfying a cone-type condition which is easy to check only for radial  $L$ . We prove the graph property without any additional cone condition when  $L$  is not necessarily radial such that  $L(u) \sim |u|^2$  at infinity.

In our approach by vanishing viscosity there are still open questions left. One question is the convergence of the optimal process for the stochastic control problem (see section 2 below) to the optimal trajectory for (1.2). It is known that when  $L(u) = |u|^2$ , each optimal process is an h-path process, which is a rather explicit property. Using this information, it was proved in [10] that these optimal h-path processes converge to the deterministic optimal trajectory of (1.2) when their diffusion part tends to zero. To prove an analogous convergence when  $L(u) \sim |u|^2$  at infinity, we may be willing to use the following result obtained in [11] which can be compared to the h-path process property: when  $L(u) \sim |u|^2$  at infinity, the optimal process of the stochastic control problem solves a forward-backward system (cf. [11] Theorem 2.2).

The paper is organized as follows. In section 2 we review the stochastic duality theorem that we have proved in [11]. Sections 3 and 4 present two applications of this stochastic duality combined with a vanishing viscosity argument: Kantorovich duality in section 3 as well as the graph property in section 4 are proved using this method.

**2. A stochastic duality result.** We will be working under the following assumptions:  $L(u) : \mathbf{R}^d \rightarrow [0, \infty)$  is convex in  $u$ ,

(A.1) for some  $\delta > 1$ ,

$$\liminf_{|u| \rightarrow \infty} \frac{L(u)}{|u|^\delta} > 0.$$

(A.2) (i)  $L \in C^3(\mathbf{R}^d)$ ,

(ii)  $D_u^2 L(u)$  is positive definite for all  $u \in \mathbf{R}^d$ .

We denote by  $H$  the Legendre transform of  $L$ :

$$(2.1) \quad H(z) := \sup_{u \in \mathbf{R}^d} \{ \langle z, u \rangle - L(u) \},$$

for  $z \in \mathbf{R}^d$ ;  $\nabla := (\partial/\partial x_i)_{i=1}^d$  and  $\langle \cdot, \cdot \rangle$  denotes the inner product in  $\mathbf{R}^d$ .

**2.1. The stochastic control problem.** We consider the following stochastic optimization problem. For  $\epsilon > 0$ , let

$$(2.2) \quad V_\epsilon(P_0, P_1) := \inf \left\{ E \left[ \int_0^1 L(\beta_X(t, X)) dt \right] \mid \forall X \in \mathcal{A}^\epsilon \text{ such that } PX_0^{-1} = P_0, PX_1^{-1} = P_1 \right\},$$

where  $\mathcal{A}^\epsilon$  is the set of all  $\mathbf{R}^d$ -valued, continuous semimartingales  $\{X(t)\}_{0 \leq t \leq 1}$  on a probability space  $(\Omega, \mathbf{B}, P)$  such that there exists a Borel measurable  $\beta_X : [0, 1] \times C([0, 1]) \mapsto \mathbf{R}^d$  for which

(i)  $\omega \mapsto \beta_X(t, X(\omega))$  is  $\mathcal{B}_t(C)_+$ -measurable for all  $t \in [0, 1]$ , where  $\mathcal{B}_t(C)$  denotes the Borel  $\sigma$ -field of  $C([0, t])$ ;

(ii)  $\{X(t) - X(0) - \int_0^t \beta_X(s, X) ds := \sqrt{\epsilon} W_X(t)\}_{0 \leq t \leq 1}$ , where  $W_X$  is a  $\sigma[X(s) : 0 \leq s \leq t]$ -Brownian motion.

Results about existence and uniqueness of a minimizer for  $V_\epsilon$  are gathered in the following statement.

**THEOREM 2.1.** *Let  $\epsilon > 0$ . Let us assume that  $V_\epsilon(P_0, P_1) < +\infty$  and that assumptions (A.1) and (A.2) hold. Then*

- (i)  $V_\epsilon(P_0, P_1)$  admits a minimizer.
- (ii) if assumption (A.1) holds with  $\delta = 2$ ,  $V_\epsilon(P_0, P_1)$  admits a Markovian minimizer.
- (iii) if  $L$  is strictly convex and assumption (A.1) holds with  $\delta = 2$ , then  $V_\epsilon(P_0, P_1)$  admits a unique minimizer (which is Markovian from (ii)).

Actually statements (ii) and (iii) will be of no use in the present paper. They were important in [11] in order to characterize the minimizer of (2.2) as the solution of a forward-backward system which consists of the coupling of a usual stochastic differential equation (SDE) with a backward one (we refer the reader to [2] for a study of such systems).

**2.2. Stochastic duality.** We now recall (Theorem 2.3 below) the stochastic duality result we obtained in [11]. In order to set the framework, we first quote a fundamental result of optimal stochastic control theory.

In the same way as  $\mathcal{A}^\epsilon$ , we define the set of semimartingales  $\mathcal{A}_t^\epsilon$  in  $C([t, 1])$  and we notice that (A.2)(ii) implies the strict convexity of  $u \mapsto L(u)$ . Moreover, the HJB equation with diffusion coefficient (or viscosity)  $\epsilon$  is the following PDE with given terminal value  $\varphi(1, \cdot) = f(\cdot)$ :

$$(2.3) \quad \frac{\partial \varphi(t, x)}{\partial t} + \frac{\epsilon}{2} \Delta \varphi(t, x) + H(\nabla \varphi(t, x)) = 0 \quad ((t, x) \in (0, 1) \times \mathbf{R}^d),$$

where  $\Delta := \sum_{i=1}^d \partial^2 / \partial x_i^2$  and  $\nabla := (\frac{\partial}{\partial x_i}; 1 \leq i \leq d)$ .

**THEOREM 2.2** (cf. [5]). *Suppose that (A.1) and (A.2) hold. Then for any  $f \in C_b^\infty(\mathbf{R}^d)$ , the HJB equation (2.3) with  $\varphi(1, \cdot) = f$  has a unique solution  $\varphi \in C^{1,2}([0, 1] \times \mathbf{R}^d) \cap C_b^{0,1}([0, 1] \times \mathbf{R}^d)$ , which can be written as follows (as a value function):*

$$(2.4) \quad \varphi(t, x) = \sup_{X \in \mathcal{A}_t^\epsilon} \left\{ E[f(X(1)) | X(t) = x] - E \left[ \int_t^1 L(\beta_X(s, X)) ds \middle| X(t) = x \right] \right\},$$

and for the minimizer  $X \in \mathcal{A}_t^\epsilon$ , the following holds:

$$\beta_X(s, X) = D_x H(\nabla \varphi(s, X(s))).$$

In other words, this theorem establishes a one-to-one correspondence between classical solutions of (2.3) and value functions of stochastic control problems with smooth terminal cost. Actually it is a duality result since the supremum in (2.4) involves  $L$ , while (2.3) involves its Legendre transform  $H$ .

In [11] we proved the following duality theorem for the minimization problem (2.2).

**THEOREM 2.3** (stochastic duality). *Let  $\epsilon > 0$  be fixed and  $V_\epsilon(P_0, P_1)$  be as defined in (2.2). Let us assume that (A.1), (A.2) are satisfied and*

$$(2.5) \quad V_\epsilon(P_0, P_1) < +\infty.$$

Then, the following identity holds:

$$(2.6) \quad V_\epsilon(P_0, P_1) = \nu_\epsilon(P_0, P_1)$$

with  $\nu_\epsilon(P_0, P_1)$  defined by

$$(2.7) \quad \nu_\epsilon(P_0, P_1) := \sup \left\{ \int_{\mathbf{R}^d} \varphi(1, y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(0, x) P_0(dx) \right\},$$

where the supremum is taken over all classical solutions  $\varphi$ , to HJB equation (2.3) for which  $\varphi(1, \cdot) \in C_b^\infty(\mathbf{R}^d)$ .

*Remark 2.1.* Actually a stronger version of Theorem 2.3 is proved in [11]: (2.6) holds true without assuming that  $V_\epsilon(P_0, P_1) < +\infty$ ; moreover, this identity still holds when the supremum in  $\nu_\epsilon$  is taken over all bounded, uniformly Lipschitz continuous viscosity solutions  $\varphi$  of (2.3).

Before proceeding further we check that the right-hand side of (2.6) is finite when  $V_\epsilon(P_0, P_1) < +\infty$  and give an outline of the proof of this theorem. For the detailed proof we refer the reader to [11].

Let us first notice that Theorem 2.2 recalled above ensures, in particular, that given  $f \in C_b^\infty(\mathbf{R}^d)$ , a classical solution of HJB PDE (2.3) exists with  $f$  as a terminal value and belongs to  $C^{1,2}([0, 1] \times \mathbf{R}^d) \cap C_b^{0,1}([0, 1] \times \mathbf{R}^d)$ . For more details we refer the reader to [5, p. 206, Theorem 11.1 and p. 210, Remark 11.2]. Therefore the set on which the supremum in (2.7) is taken is not empty.

Let us now assume that  $V_\epsilon(P_0, P_1) < +\infty$ . For all  $X \in \mathcal{A}^\epsilon$  and  $\varphi$  solution of (2.3) satisfying  $\varphi(1, \cdot) \in C_b^\infty(\mathbf{R}^d)$ , the constraints on the marginals of  $X$  combined with the Ito formula imply the following identities:

$$(2.8) \quad \int_{\mathbf{R}^d} \varphi(1, y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(0, x) P_0(dx) = E(\varphi(1, X_1) - \varphi(0, X_0))$$

$$(2.9) \quad = E \int_0^1 \left( \frac{\partial \varphi(s, X_s)}{\partial t} + \frac{\epsilon}{2} \Delta \varphi(s, X_s) + \beta_X(s, X) \nabla \varphi(s, X_s) \right) ds.$$

Since  $\varphi$  solves (2.3) and  $H$  is the Legendre transform of  $L$ , it follows that

$$(2.10) \quad \int_{\mathbf{R}^d} \varphi(1, y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(0, x) P_0(dx) \leq E \int_0^1 L(\beta_X(s, X)) ds.$$

Hence

$$(2.11) \quad \int_{\mathbf{R}^d} \varphi(1, y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(0, x) P_0(dx) \leq V_\epsilon(P_0, P_1)$$

since  $\varphi$  and  $X$  have been chosen independently.

The scheme of the proof of Theorem 2.3 proceeds as follows. We show first that the function  $Q \mapsto V_\epsilon(P_0, Q)$  is lower semicontinuous and convex on the set of probability measures on  $\mathbf{R}^d$ . Therefore it coincides with its double dual, in particular at point  $P_1$ ; namely,

$$(2.12) \quad V_\epsilon(P_0, P_1) = \sup_{f \in C_b(\mathbf{R}^d)} \left\{ \int_{\mathbf{R}^d} f(x) P_1(dx) - V_\epsilon(P_0, \cdot)^*(f) \right\},$$

where for  $f \in C_b(\mathbf{R}^d)$ ,

$$(2.13) \quad V_\epsilon(P_0, \cdot)^*(f) := \sup_{Q \in \mathcal{M}_1(\mathbf{R}^d)} \left\{ \int_{\mathbf{R}^d} f(x) Q(dx) - V_\epsilon(P_0, Q) \right\}.$$

In this identity,  $Q$  plays the role of a terminal law and is arbitrary. Hence we are back in the framework of classical stochastic control; in particular, we can use Theorem 2.2. For all of the details, see [11].

**3. Kantorovich duality by vanishing viscosity.** We start with a precise statement of Kantorovich duality mentioned in the introduction. For the sake of coherence we keep a cost function of the form  $c(x, y) = L(y - x)$ , but this result holds true for general costs (cf. [12] or [14]).

**THEOREM 3.1** (cf. [7], [8]). *Let  $L : \mathbf{R}^d \rightarrow \mathbf{R}^+ \cup \{+\infty\}$  be a lower semicontinuous function. Let  $P_0$  and  $P_1$  be given Borel probability measures on  $\mathbf{R}^d$ . Let us keep the notation  $T_{MK}(P_0, P_1)$  for the MKP as in (1.3) and define*

$$(3.1) \quad \mathcal{T}(P_0, P_1) = \sup \left\{ \int_{\mathbf{R}^d} \psi(y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(x) P_0(dx) \right\},$$

where the supremum is taken over all pairs  $(\varphi, \psi) \in L^1(P_0) \times L^1(P_1)$  satisfying  $\psi(y) - \varphi(x) \leq L(y - x)$ . Then

$$(3.2) \quad T_{MK}(P_0, P_1) = \mathcal{T}(P_0, P_1).$$

We now apply our stochastic duality (Theorem 2.3) in order to prove *Kantorovich duality* with the help of a vanishing viscosity argument. The first part of the following statement is our key tool to go from  $\epsilon > 0$  to  $\epsilon = 0$ . Remember that  $\mathcal{T}(P_0, P_1)$  is defined by (3.1).

**THEOREM 3.2.** *Let us assume that  $T_{MK}(P_0, P_1) < +\infty$  and that assumptions (A.1)–(A.2) hold. Let us recall that  $V_\epsilon$  (resp.,  $\nu_\epsilon$ ) has been defined in (2.2) (resp., (2.7)). We denote by  $g_\epsilon \star P_1$  the convolution of  $P_1$  with the Gaussian kernel  $g_\epsilon(x) = (2\pi\epsilon)^{-\frac{d}{2}} \exp(-\frac{|x|^2}{2\epsilon})$ . Then*

(1.i) *for all  $\epsilon > 0$ ,*

$$(3.3) \quad \nu_\epsilon(P_0, g_\epsilon \star P_1) \leq \mathcal{T}(P_0, P_1).$$

(1.ii) *Moreover,*

$$(3.4) \quad T_{MK}(P_0, P_1) \leq \liminf_{\epsilon \rightarrow 0} V_\epsilon(P_0, g_\epsilon \star P_1).$$

(2) *As a consequence we recover the Kantorovich duality,*

$$(3.5) \quad T_{MK}(P_0, P_1) = \mathcal{T}(P_0, P_1).$$

*Proof of Theorem 3.2.* The only thing to prove is  $T_{MK}(P_0, P_1) \leq \mathcal{T}(P_0, P_1)$ . Indeed, the converse inequality is easy, as we now check. Let  $(u, v) \in L^1(P_0) \times L^1(P_1)$  be such that  $v(y) - u(x) \leq L(y - x)$  and  $\mu$  with marginals  $P_0$  and  $P_1$ . Then

$$\begin{aligned} \int_{\mathbf{R}^d} v(y) P_1(dy) - \int_{\mathbf{R}^d} u(x) P_0(dx) &= \int_{\mathbf{R}^d \times \mathbf{R}^d} (v(y) - u(x)) \mu(dxdy) \\ &\leq \int_{\mathbf{R}^d \times \mathbf{R}^d} L(y - x) \mu(dxdy), \end{aligned}$$

which yields

$$(3.6) \quad \mathcal{T}(P_0, P_1) \leq T_{MK}(P_0, P_1).$$

Let us now prove the converse.

(1.i) Take  $\epsilon > 0$  and let  $\varphi(t, x)$  denote a solution to the HJB PDE (2.3) with  $\varphi(1, \cdot) \in C_b^\infty(\mathbf{R}^d)$ , which implies that  $\varphi \in C^{1,2}([0, 1] \times \mathbf{R}^d) \cap C_b^{0,1}([0, 1] \times \mathbf{R}^d)$ . Let us define

$$(3.7) \quad u_\epsilon(x) := \varphi(0, x),$$

$$(3.8) \quad v_\epsilon(y) := E(\varphi(1, y + \sqrt{\epsilon}W_1)).$$

The pair  $(u_\epsilon, v_\epsilon)$  belongs to  $L^1(P_0) \times L^1(P_1)$  and satisfies

$$\begin{aligned} & \int_{\mathbf{R}^d} \varphi(1, y) g_\epsilon \star P_1(dy) - \int_{\mathbf{R}^d} \varphi(0, x) P_0(dx) \\ &= \int_{\mathbf{R}^d} v_\epsilon(y) P_1(dy) - \int_{\mathbf{R}^d} u_\epsilon(x) P_0(dx). \end{aligned}$$

Moreover, by definition

$$(3.9) \quad v_\epsilon(y) - u_\epsilon(x) = E(\varphi(1, X_1^{x,y}) - \varphi(0, X_0^{x,y})),$$

where  $X_t^{x,y} := x + t(y - x) + \sqrt{t}W_t$ . Using the Ito formula and the fact that  $\varphi$  solves (2.3), we obtain

$$(3.10) \quad E(\varphi(1, X_1^{x,y}) - \varphi(0, X_0^{x,y})) = E \int_0^1 (\langle y - x, \nabla \varphi \rangle - H(\nabla \varphi))(s, X_s^{x,y}) ds,$$

which implies  $v_\epsilon(y) - u_\epsilon(x) \leq L(y - x)$ . Inequality (3.3) follows.

(1.ii) Let us first notice that

$$(3.11) \quad 0 \leq \liminf_{\epsilon \rightarrow 0} V_\epsilon(P_0, g_\epsilon \star P_1)$$

since by definition  $V_\epsilon$  is positive. Moreover,

$$(3.12) \quad \liminf_{\epsilon \rightarrow 0} V_\epsilon(P_0, g_\epsilon \star P_1) < +\infty.$$

Indeed, (3.6) and (1.i) imply  $V_\epsilon(P_0, g_\epsilon \star P_1) \leq T_{MK}(P_0, P_1) < +\infty$ , and stochastic duality applied to the pair  $(P_0, g_\epsilon \star P_1)$  yields (3.12). Let us now consider a sequence  $(\epsilon_n)$  which converges to 0 such that  $V_{\epsilon_n}(P_0, g_{\epsilon_n} \star P_1)$  converges to  $\liminf_{\epsilon \rightarrow 0} V_\epsilon(P_0, g_\epsilon \star P_1)$ . Let us denote by  $X^n$  a minimizer of  $V_{\epsilon_n}(P_0, g_{\epsilon_n} \star P_1)$  (cf. Theorem 2.1). For each  $n$ ,  $X^n \in \mathcal{A}^{\epsilon_n}$ . In particular, with the notation of (2.2),

$$(3.13) \quad \lim_{n \rightarrow +\infty} E \int_0^1 L(\beta_{X^n}(s, X^n)) ds = \liminf_{\epsilon \rightarrow 0} V_\epsilon(P_0, g_\epsilon \star P_1).$$

The superlinearity of  $L$  (namely,  $L(u) \geq |u|^\delta$  with  $\delta > 1$ ) ensures that the sequence of semimartingales  $(X^n)$  is tight and any converging subsequence converges to an absolutely continuous process (cf. [15]). Let  $X_t = X_0 + \int_0^t b_X(s) ds$  be the limit of a converging subsequence. From the convexity property of  $L$ ,

$$(3.14) \quad E \int_0^1 L(b_X(s)) ds \geq E(L(X_1 - X_0)).$$

The law of  $X_1$  is equal to  $P_1$  since it is the limit in distribution of a subsequence of  $g_\epsilon \star P_1$ . Using Fatou's lemma we obtain (3.4).

(2) By combining inequalities (3.3), (3.4), and (3.6) with stochastic duality applied to the pair  $(P_0, g_\epsilon \star P_1)$ , we recover *Kantorovich duality*.  $\square$

#### 4. Graph property by vanishing viscosity.

**4.1. Graph property.** We sketch the argument briefly, for the quadratic cost. For a complete exposition we refer the reader to [14].

So, let us assume for a short while that  $L(y - x) = \frac{1}{2}|y - x|^2$ . In this case,

$$(4.1) \quad T_{MK}(P_0, P_1) := \inf \left\{ \int_{\mathbf{R}^d \times \mathbf{R}^d} \frac{1}{2} |y - x|^2 \mu(dx dy) \right\}$$

on the set of probability measures  $\mu$  on  $\mathbf{R}^d \times \mathbf{R}^d$  with marginals  $P_0$  and  $P_1$  satisfying  $\int_{\mathbf{R}^d} |y|^2 P_1(dy) < +\infty$  (resp.,  $\int_{\mathbf{R}^d} |x|^2 P_0(dx) < +\infty$ ). *Kantorovich duality* (3.2) takes the form

$$(4.2) \quad T_{MK}(P_0, P_1) = \sup \left\{ \int_{\mathbf{R}^d} \psi(y) P_1(dy) - \int_{\mathbf{R}^d} \varphi(x) P_0(dx) \right\},$$

where the supremum is taken over all pairs  $(\varphi, \psi) \in L^1(P_0) \times L^1(P_1)$  satisfying  $\psi(y) - \varphi(x) \leq \frac{1}{2}|y - x|^2$ . Using the identity  $\int_{\mathbf{R}^d \times \mathbf{R}^d} \frac{1}{2} |y|^2 \mu(dx dy) = \int_{\mathbf{R}^d} \frac{1}{2} |y|^2 P_1(dy)$  (resp.,  $\int_{\mathbf{R}^d \times \mathbf{R}^d} \frac{1}{2} |x|^2 \mu(dx dy) = \int_{\mathbf{R}^d} \frac{1}{2} |x|^2 P_0(dx)$ ), and setting  $u(x) := \varphi(x) + \frac{1}{2}|x|^2$  (resp.,  $v(y) := \frac{1}{2}|y|^2 - \psi(y)$ ), identity (4.2) can be rewritten as

$$(4.3) \quad \sup \int_{\mathbf{R}^d \times \mathbf{R}^d} \langle x, y \rangle \mu(dx dy) = \inf \int_{\mathbf{R}^d} v(y) P_1(dy) + \int_{\mathbf{R}^d} u(x) P_0(dx),$$

where the supremum on the left-hand side is taken over all probabilities with marginals  $P_0$  and  $P_1$  with finite second order moments, and the infimum on the right-hand side is over pairs  $(u, v) \in L^1(P_0) \times L^1(P_1)$  satisfying

$$(4.4) \quad \langle x, y \rangle \leq u(x) + v(y) \quad \forall (x, y) \in \mathbf{R}^d \times \mathbf{R}^d.$$

This simple remark has an important consequence (cf. [14]): On the right-hand side of (4.3) it is sufficient to consider pairs  $(u, v)$  such that  $u$  is convex and  $v$  is the Legendre transform of  $u$ . Now let  $\mu^*$  be optimal for (1.3) and  $(u^*, v^*)$  be optimal for the right-hand side of (4.3) (cf. [14] for the respective existence of these optima). Then

$$(4.5) \quad \langle x, y \rangle = u^*(x) + v^*(y) \quad \text{for } \mu^*\text{-a.a. } (x, y).$$

Let us assume, moreover, that  $P_0$  is absolutely continuous w.r.t. Lebesgue measure. Then, differentiability properties of convex functions imply that  $u^*$  is differentiable  $P_0$ -a.s. on  $\mathbf{R}^d$ . Let us consider  $x_0 \in \mathbf{R}^d$  such that  $(x_0, y_0) \in \text{Supp} \mu^*$  for some  $y_0$ . Let  $u^*$  be differentiable at  $x_0$ . Comparison of identity (4.4), written for  $(u^*, v^*)$  valid for all  $(x, y_0), x \in \mathbf{R}^d$  on the one hand and (4.5) at  $(x_0, y_0)$  on the other hand, implies that  $y_0 = \nabla u^*(x_0)$ . We conclude that  $\mu^*$  is indeed supported on a graph, which is the graph of  $\nabla u^*$ : the *graph property* holds.

We now come back to general costs and recall precise statements on the *graph property* obtained, respectively, by Brenier and Benamou (quadratic cost) and Gangbo and McCann (more general costs). The proof of Gangbo and McCann relies on cyclically monotone sets. These authors assume that  $L$  has the following property: For  $(p, \theta, r) \in \mathbf{R}^d \times ]0, \pi[ \times ]0, +\infty[$ , when the norm of  $p$  is large enough, there exists a  $z \in \mathbf{R}^d$  such that the restriction of  $L$  to the set

$$(4.6) \quad K(p, z, \theta, r) := \left\{ x \in \mathbf{R}^d; \quad |x - p| |z| \cos \left( \frac{\theta}{2} \right) \leq \langle z, x - p \rangle \leq r |z| \right\}$$

attains its maximum at  $p$ . Let us notice that  $K(p, z, \theta, r)$  is a truncated cone (with vertex  $p$ , angle  $\frac{1}{2}\theta$ , direction  $z$ ); for this reason we call this condition the cone condition. A drawback of the cone condition is that it can be easily checked only for radial functions  $L$ .

**THEOREM 4.1** (cf. [1], [6]). *Let us assume that  $T_{MK}(P_0, P_1) < +\infty$  and  $P_0$  is absolutely continuous w.r.t. the Lebesgue measure on  $\mathbf{R}^d$ .*

(1) *Let  $L(u) = \frac{1}{2}|u|^2$ . There exists a unique  $\mu^*$  minimizing (1.3). The support of  $\mu^*$  is the graph of  $\nabla u$ , where  $u$  is convex.*

(2) *Let  $L$  be superlinear ( $\lim_{|u| \rightarrow \infty} \frac{L(u)}{|u|} = +\infty$ ) and strictly convex, satisfying the cone condition. Let  $H$  denote the Legendre transform of  $L$ . Then there exists a unique  $\mu^*$  minimizing (1.3). There exists  $\phi$ ,  $L$ -concave, such that the support of  $\mu^*$  is the graph of the mapping*

$$(4.7) \quad g(x) = x + \nabla H(-\nabla \phi(x)).$$

Let us recall that a function  $\gamma : \mathbf{R}^d \rightarrow \mathbf{R} \cup \{-\infty\}$  is  $L$ -concave if there exists  $\beta : \mathbf{R}^d \rightarrow \mathbf{R} \cup \{-\infty\}$  with  $\beta \not\equiv -\infty$  such that

$$(4.8) \quad \forall x \in \mathbf{R}^d \quad \gamma(x) = \inf_{y \in \mathbf{R}^d} (L(y - x) - \beta(y)).$$

**4.2. Vanishing viscosity method.** In this section we apply stochastic duality to recover the fact that an optimal measure for (1.3) is supported on a graph when  $P_0$  is absolutely continuous w.r.t. the Lebesgue measure on  $\mathbf{R}^d$ . More precisely, stochastic duality will enable us to reach a weak form of the situation just described for the quadratic cost, where we had at the same time identities (4.4) and (4.5). However, this weak form will turn out to be sufficient to conclude. In what follows we denote by  $\mu^*$  an optimal measure for (1.3). The following statement exhibits a set  $S$  which supports  $\mu^*$ .

**THEOREM 4.2.** *Let us assume that (A.1)–(A.2) hold true. Let  $\mu^*$  be optimal for the MKP (1.3). There exists a sequence  $(\epsilon_n, \varphi_{\epsilon_n})$  such that  $\epsilon_n \rightarrow 0$ ,*

$$(4.9) \quad \frac{\partial \varphi_{\epsilon_n}(t, x)}{\partial t} + \frac{\epsilon_n}{2} \Delta \varphi_{\epsilon_n}(t, x) + H(\nabla \varphi_{\epsilon_n}(t, x)) = 0,$$

as well as  $\varphi_{\epsilon_n}(1, \cdot) \in C_b^\infty(\mathbf{R}^d)$  for all  $n$ , and  $\mu^*(S) = 1$ , where

$$(4.10) \quad S := \left\{ (x, y); \lim_{n \rightarrow +\infty} E(\varphi_{\epsilon_n}(1, y + \sqrt{\epsilon_n} W_1)) - \varphi_{\epsilon_n}(0, x) = L(y - x) \right\}.$$

*Proof.* For each  $\epsilon > 0$ , by the definition of  $\nu_\epsilon(P_0, g_\epsilon \star P_1)$ , we can choose  $\varphi_\epsilon(t, x)$  such that

$$(4.11) \quad \frac{\partial \varphi_\epsilon(t, x)}{\partial t} + \frac{\epsilon}{2} \Delta \varphi_\epsilon(t, x) + H(\nabla \varphi_\epsilon(t, x)) = 0,$$

and choose  $\varphi_\epsilon(1, \cdot) \in C_b^\infty(\mathbf{R}^d)$  as well as

$$(4.12) \quad \nu_\epsilon(P_0, g_\epsilon \star P_1) - \epsilon \leq \int_{\mathbf{R}^d} \varphi_\epsilon(1, y) g_\epsilon \star P_1(dy) - \int_{\mathbf{R}^d} \varphi_\epsilon(0, x) P_0(dx).$$

Since  $\mu^*$  has marginals  $P_0$  and  $P_1$ , the right-hand side of this inequality can be written as

$$(4.13) \quad \int_{\mathbf{R}^d \times \mathbf{R}^d} (E(\varphi_\epsilon(1, y + \sqrt{\epsilon} W_1)) - \varphi_\epsilon(0, x)) \mu^*(dxdy).$$

Let us subtract  $T_{MK}(P_0, P_1) = \int_{\mathbf{R}^d \times \mathbf{R}^d} L(y-x) \mu^*(dxdy)$  from both sides of (4.12). We know that  $L(y-x) - (E(\varphi_\epsilon(1, y + \sqrt{\epsilon}W_1)) - \varphi_\epsilon(0, x))$  always remains nonnegative and  $\lim_{\epsilon \rightarrow 0} \nu_\epsilon(P_0, g_\epsilon \star P_1) = T_{MK}(P_0, P_1)$  (cf. Theorem 3.2 and its proof). Therefore

$$(4.14) \quad E(\varphi_\epsilon(1, y + \sqrt{\epsilon}W_1)) - \varphi_\epsilon(0, x) - L(y-x)$$

converges to 0 in  $L^1(\mu^*)$  when  $\epsilon$  goes to 0, which implies  $\mu^*$ -a.s. convergence for a subsequence  $(\epsilon_n)$ .  $\square$

At this stage, let us assume that both sequences of functions  $(\varphi_{\epsilon_n}(0, \cdot))$  and  $(E(\varphi_{\epsilon_n}(1, \cdot + \sqrt{\epsilon_n}W_1)))$  admit limits when  $n \rightarrow +\infty$  which we denote, respectively, by  $u(\cdot)$  and  $v(\cdot)$ . The pair  $(u, v)$  then satisfies

$$(4.15) \quad v(y) - u(x) \leq L(y-x) \quad \forall (x, y) \in \mathbf{R}^d \times \mathbf{R}^d$$

with equality on  $S$ . If we know that  $u(\cdot)$  is differentiable at any interior point  $(x_0, y_0)$  of  $S$ , we can conclude, as we did for the quadratic cost, that the following holds:

$$(4.16) \quad \nabla u(x_0) = \nabla L(y_0 - x_0)$$

and consequently  $y_0 = x_0 + \nabla H(\nabla u(x_0))$ . The *graph property* will hold if this argument is applicable at any  $(x_0, y_0)$  in  $S$ . Unfortunately neither separate convergence nor differentiability holds true in general; we also do not know whether interior points exist. Moreover, in the quadratic example, differentiability of  $u(\cdot)$  was a consequence of its convexity; actually existence of partial derivatives  $\frac{\partial u}{\partial x_i}$  would have been sufficient to conclude. In what follows we will approach the ideal quadratic situation by taking advantage of semiconvexity properties of value functions under relevant assumptions.

**DEFINITION 4.1.** *Let  $\Phi$  be a function defined on a convex subset of  $\mathbf{R}^d$  with values in  $\mathbf{R} \cup \{+\infty\}$ . The function  $\Phi$  is semiconvex with constant  $C$  if there exists  $C > 0$  such that  $x \mapsto \Phi(x) + C\frac{|x|^2}{2}$  is convex.*

**PROPOSITION 4.1** (cf. [5, p. 229]). *Let  $G$  be a compact subset of  $\mathbf{R}^d$  and  $\Phi$  a semiconvex function on  $G$ . Let us assume that  $x_0$  maximizes  $\Phi$  on  $G$  and belongs to the interior of  $G$ . Then  $\Phi$  is differentiable at  $x_0$  with  $D\Phi(x_0) = 0$ .*

**THEOREM 4.3.** *Let us assume that  $L$  satisfies*

$$(4.17) \quad \exists \quad C > 0, \quad D_u^2 L \leq C.$$

*Let  $\varphi(t, x)$  be a value function given by (2.4). Then,  $\varphi(0, \cdot)$  is semiconvex with constant  $C$ .*

The proofs of Theorem 4.3 and Proposition 4.1 are given in the appendix. For other sufficient conditions which guarantee that the value function is semiconvex we refer the reader to [5]. Definition 4.1 is equivalent to the requirement

$$(4.18) \quad \forall (x, z) \quad \Phi(x+z) + \Phi(x-z) - 2\Phi(x) \geq -C|z|^2$$

**Note.** From now on we will be working under assumption (4.17). We do *not* require  $L$  to satisfy the cone condition.

**DEFINITION 4.2.** *Let  $(\epsilon_n)$  denote a sequence given by Theorem 4.2. For  $a \in \mathbf{R}^d$ ,*

$$(4.19) \quad \psi_a(x) := \limsup_{n \rightarrow +\infty} (\varphi_{\epsilon_n}(0, x) - \varphi_{\epsilon_n}(0, a)).$$

**PROPOSITION 4.2.** *Under assumption (4.17), the set  $D_a := \{x \in \mathbf{R}^d; \psi_a(x) < +\infty\}$  is a convex set independent of  $a \in \pi_1(S) := \{x \in \mathbf{R}^d; \exists y \in \mathbf{R}^d, (x, y) \in S\}$ . Moreover,  $\psi_a$  is semiconvex on  $D_a$ .*

PROPOSITION 4.3. *Let us denote by  $(\mathbf{e}_i, 1 \leq i \leq n)$  the canonical basis of  $\mathbf{R}^d$  and assume that  $L \in C^1(\mathbf{R}^d)$ . Let  $a$  belong to  $\pi_1(S)$  and  $(a, b) \in S$ . If for some  $i \in \{1, \dots, d\}$  there exist sequences  $(h_n^{(i)})$  and  $(y_n^{(i)})$  such that  $h_n^{(i)} \rightarrow 0$ ,  $y_n^{(i)} \rightarrow b$ , and for all  $n$ ,  $(a + h_n^{(i)} \mathbf{e}_i, y_n^{(i)}) \in S$ , then  $\lim_{n \rightarrow +\infty} \frac{1}{h_n^{(i)}} \psi_a(a + h_n^{(i)} \mathbf{e}_i)$  exists and coincides with  $\partial_i L(b - a)$ .*

*Proof of Proposition 4.2.* Since  $(a, b) \in S$  for all  $(u, c) \in \mathbf{R}^d \times \mathbf{R}^d$ ,

$$(4.20) \quad \psi_a(u) \geq L(b - a) - L(b - u),$$

$$(4.21) \quad \psi_a(u) \geq \psi_c(u) + L(b - a) - L(b - c).$$

Indeed, since  $\varphi_{\epsilon_n}(0, c) - E(\varphi_{\epsilon_n}(1, b + \sqrt{\epsilon_n} W_1)) \geq -L(b - c)$ , the following holds:

$$\begin{aligned} \varphi_{\epsilon_n}(0, u) - \varphi_{\epsilon_n}(0, a) \\ \geq \varphi_{\epsilon_n}(0, u) - \varphi_{\epsilon_n}(0, c) + E(\varphi_{\epsilon_n}(1, b + \sqrt{\epsilon_n} W_1)) - \varphi_{\epsilon_n}(0, a) - L(b - c). \end{aligned}$$

To obtain (4.21) it remains to let  $n$  go to  $+\infty$  and apply Theorem 4.2. Inequality (4.20) follows when  $u$  equals  $c$ . Semiconvexity of  $\psi_a$  on its domain  $D_a$  follows from Theorem 4.3 and the fact that if  $(\Phi_n)$  is a sequence of semiconvex functions with the same constant  $C$ , then  $\limsup \Phi_n$  is itself semiconvex with this same constant. Therefore the set  $D_a$  is convex since it coincides with the domain of the convex function  $\psi_a + \frac{C}{2} |\cdot|^2$ . Moreover, let  $a$  and  $a'$  in  $\pi_1(S)$ . By applying (4.21) twice, to  $(a, a')$  and to  $(a', a)$ , we conclude that  $D_a = D_{a'}$ .  $\square$

*Proof of Proposition 4.3.* Take  $i \in \{1, \dots, d\}$ ,  $a \in \pi_1(S)$  and  $b$  such that  $(a, b) \in S$ . Inequality (4.21) implies

$$(4.22) \quad L(b - a) - L(b - (a + h_n^{(i)} \mathbf{e}_i)) \leq \psi_a(a + h_n^{(i)} \mathbf{e}_i) \leq L(y_n^{(i)} - a) - L(y_n^{(i)} - (a + h_n^{(i)} \mathbf{e}_i)).$$

The desired statement follows since  $L$  is  $C^1$  by letting  $n \rightarrow +\infty$ .  $\square$

For  $a \in \pi_1(S)$  and  $b$  such that  $(a, b)$  belongs to  $S$ , we see that the function  $x \mapsto L(b - a) - \psi_a(x)$  plays the same role as  $x \mapsto v(b) - u(x)$  in (4.15):  $L(b - a) - \psi_a(x) \leq L(b - x)$  on  $\mathbf{R}^d$  with equality when  $x = a$ . We cannot apply Proposition 4.1 since we do not know whether  $\pi_1(S)$  has interior points. However, suppose that the assumptions of Proposition 4.3 are satisfied for all  $i \in \{1, \dots, d\}$ . Then we can set  $\nabla \psi_a$  to be the vector

$$(4.23) \quad \nabla \psi_a := \left( \lim_{n \rightarrow +\infty} \frac{1}{h_n^{(i)}} \psi_a(a + h_n^{(i)} \mathbf{e}_i); \quad i = 1 \leq d \right).$$

Hence  $b$  is uniquely given by  $a + \nabla H(\nabla \Psi_a)$ .

Let us now assume that  $P_0$  is absolutely continuous w.r.t. the Lebesgue measure on  $\mathbf{R}^d$ . We prove below that the set of points  $a \in \pi_1(S)$ , where  $\nabla \psi_a(a)$  does not exist, has Lebesgue measure 0. It suffices to show that the set  $\Pi := \{a \in \pi_1(S); \partial_1 \psi_a(a) \text{ does not exist}\}$  has Lebesgue measure 0. Let us first make the following remark: For  $\alpha \in \pi_1(S)$  and  $\beta$  such that  $(\alpha, \beta) \in S$ , consider

$$\begin{aligned} U_n^+(\alpha, \beta) &= \{(x, y) \in \mathbf{R}^d \times \mathbf{R}^d; x = \alpha + h \mathbf{e}_1, h > 0, |h|^2 + |y - \beta|^2 < n^{-2}\}, \\ U_n^-(\alpha, \beta) &= \{(x, y) \in \mathbf{R}^d \times \mathbf{R}^d; x = \alpha + h \mathbf{e}_1, h < 0, |h|^2 + |y - \beta|^2 < n^{-2}\}; \end{aligned}$$

if  $U_n^+(\alpha, \beta) \cap S \neq \emptyset$  or  $U_n^-(\alpha, \beta) \cap S \neq \emptyset$  for a sequence of integers  $n$  going to  $+\infty$ , then  $\partial_1 \psi_\alpha(\alpha)$  exists as a consequence of Proposition 4.3. Take now  $a \in \Pi$  and  $(a, b) \in S$ .

There exists  $N = N(a, b) \geq 1$  such that  $U_N^+(a, b) \cap S = U_N^-(a, b) \cap S = \emptyset$ . Therefore the set  $\sigma := \{x \in \mathbf{R}; a + x\mathbf{e}_1 \in \mathbf{\Pi}\}$  is at most countable and thus has Lebesgue measure 0. We have just proved the following theorem.

**THEOREM 4.4.** *Let  $P_0(dx) \ll dx$  and  $T_{MK}(P_0, P_1) < +\infty$ . Under assumption (4.17), the graph property holds.*

### 5. Appendix.

*Proof of Theorem 4.3.* Let  $(X_t^x; t \in [0, 1])$  in  $\mathcal{A}_\epsilon$  be optimal for (2.4); namely,  $X_t^x = x + \int_0^t \nabla H(\nabla \varphi(s, X_s^x)) ds + \sqrt{\epsilon} W_t$  and

$$(5.1) \quad \varphi(0, x) = E \left[ f(X_1^x) - \int_0^1 L(\nabla H(\nabla \varphi(s, X_s^x))) ds \right]$$

with  $\varphi(1, \cdot) = f(\cdot)$ . For  $z \in \mathbf{R}^d$  let us set  $X_t^1 := X_t^x + (1-t)z$  and  $X_t^2 := X_t^x - (1-t)z$ ; these processes both belong to  $\mathcal{A}_\epsilon$  and satisfy  $X_0^1 = x + z$ ,  $X_0^2 = x - z$ , and  $X_1^1 = X_1^2 = X_1^x$ . Let  $\beta_t^x := \nabla H(\nabla \varphi(t, X_t^x))$ . From the definition of  $\varphi$  in (2.4) it follows that

$$(5.2) \quad \begin{aligned} & \varphi(0, x+z) + \varphi(0, x-z) - 2\varphi(0, x) \\ & \geq E \int_0^1 (2L(\beta_t^x) - L(\beta_t^x + z) - L(\beta_t^x - z)) dt. \end{aligned}$$

The conclusion follows from assumption (4.17).  $\square$

*Proof of Proposition 4.1.* Let  $\mathbf{B}$  be an open ball centered at  $x_0$  included in  $G$ . Such a ball exists since  $x_0$  is an interior point of  $G$ . The function  $x \mapsto \Psi(x) := \Phi(x) + C \frac{|x-x_0|^2}{2}$  is convex on  $\mathbf{B}$  for some constant  $C > 0$ . Therefore there exists a vector  $b \in \mathbf{R}^d$  such that, for all  $x \in \mathbf{B}$ ,  $\Psi(x) \geq \Psi(x_0) + \langle b, x - x_0 \rangle$ . Moreover, since  $x_0$  maximizes  $\Phi$  on  $\mathbf{B}$ ,

$$(5.3) \quad \langle b, x - x_0 \rangle \leq C \frac{|x - x_0|^2}{2} \quad \forall x \in \mathbf{B}.$$

For  $\epsilon > 0$  small enough, the point  $x = x_0 + \epsilon b$  belongs to  $\mathbf{B}$ . We conclude that  $b = 0$  since it must satisfy  $\epsilon|b|^2 \leq \frac{C}{2} \epsilon^2 |b|^2$  for all  $\epsilon$  small enough.  $\square$

**Acknowledgments.** We thank two anonymous referees for their comments and suggestions which helped us to improve the first version of this paper. This work was done during the visit of the second author (M. Thieullen) to the University of Hokkaido. She would like to thank this university for its hospitality.

## CONTROLLABILITY OF LINEAR DISCRETE SYSTEMS WITH CONSTANT COEFFICIENTS AND PURE DELAY\*

JOSEF DIBLÍK<sup>†</sup>, DENYS YA. KHUSAINOV<sup>‡</sup>, AND M. RŮŽIČKOVÁ<sup>§</sup>

**Abstract.** The purpose of this contribution is to develop a controllability method for linear discrete systems with constant coefficients and with pure delay. To do this, a representation of solutions with the aid of a discrete matrix delayed exponential is used. Such an approach leads to new conditions of controllability. Except for a criterion of relative controllability, a control function is constructed as well.

**Key words.** discrete system, delay, discrete matrix delayed exponential, relative controllability, control function

**AMS subject classifications.** 39A10, 39A11, 93B05

**DOI.** 10.1137/070689085

**1. Introduction.** In control theory, one of the best solved problems is the problem of controllability of linear time-independent differential systems with one input,

$$(1.1) \quad \dot{x}(t) = Ax(t) + bu(t),$$

where  $x: R_+ := [0, \infty) \rightarrow R^n$  is continuously differentiable,  $A$  is an  $n \times n$  constant matrix,  $b$  is a constant vector, and input  $u: R_+ \rightarrow R$  (see, e.g., [9, 11]). As usual, system (1.1) is called controllable if, for arbitrary finite initial state  $x(0) = x_0$  and terminal state  $x(t_1) = x_1$  with finite  $t_1 > 0$ , there exists a control  $u^*(t)$  such that the system

$$\dot{x}(t) = Ax(t) + bu^*(t)$$

has a solution  $x = x^*(t)$  satisfying  $x^*(0) = x_0$  and  $x^*(t_1) = x_1$ .

A much more complicated situation occurs if we deal with differential equations with an aftereffect having, e.g., the form

$$\begin{aligned} \dot{x}(t) &= Bx(t - \tau) + bu(t), \quad t > 0, \\ x(t) &= \varphi(t), \quad -\tau \leq t \leq 0, \quad \tau > 0, \end{aligned}$$

where  $x: [-\tau, \infty) \rightarrow R^n$  is continuously differentiable on  $(0, \infty)$ ,  $B$  is an  $n \times n$  constant matrix,  $b$  is a constant vector, and input  $u: R_+ \rightarrow R$ ,  $\tau = \text{const}$  and  $\varphi: [-\tau, 0] \rightarrow R^n$ . We refer to [6], where various classes of control for delayed differential systems are considered and different variants of controllability are developed.

We use the following notation: For integers  $s, q$ ,  $s \leq q$  we define  $Z_s^q := \{s, s+1, \dots, q\}$ , where either  $s = -\infty$  or  $q = \infty$  is admitted, too. Throughout this paper, using notation  $Z_s^q$  (perhaps with another pair of integers), we always assume  $s \leq q$ .

In the present paper we consider discrete controlled systems with pure delay,

$$(1.2) \quad \Delta x(k) = Bx(k-m) + bu(k),$$

where  $m \geq 1$  is a fixed integer,  $k \in Z_0^\infty$ ,  $B$  is a constant  $n \times n$  matrix,  $\Delta x(k) = x(k+1) - x(k)$ ,  $x: Z_{-m}^\infty \rightarrow R^n$  is an unknown solution,  $b \in R^n$  is a given nonzero vector, and  $u: Z_0^\infty \rightarrow R$  is the input scalar function. Following the standard terminology (used, e.g., in [1, 2]) we refer to (1.2) as a delayed discrete system if  $m \geq 1$  and as a nondelayed discrete system if  $m = 0$ . Discrete systems containing only one delay are often called *systems with pure delay*.

Together with (1.2) we consider an initial (Cauchy) problem

$$(1.3) \quad x(k) = \varphi(k)$$

with a given initial function  $\varphi: Z_{-m}^0 \rightarrow R^n$ . The *existence* and *uniqueness* of the solution of the initial problem (1.2), (1.3) on  $Z_{-m}^\infty$  are obvious. We recall that a *solution*  $x: Z_{-m}^\infty \rightarrow R^n$  of initial Cauchy problem (1.2), (1.3) is defined as an *infinite sequence*

$$\{x(-m) = \varphi(-m), x(-m+1) = \varphi(-m+1), \dots, x(0) = \varphi(0), x(1), x(2), \dots, x(k), \dots\}$$

such that, for any  $k \in Z_0^\infty$ , equality (1.2) holds.

Throughout the paper we adopt the customary notation for the sum and the product:  $\sum_{i=k+s}^k \circ(i) = 0$  and  $\prod_{i=k+s}^k \circ(i) = 1$ , where  $k$  is an integer,  $s$  is a positive integer, and “ $\circ$ ” denotes the function considered independently of whether it is defined for indicated arguments or not. For  $\varphi: Z_s^q \rightarrow R^n$  we define  $\|\varphi\|_{sq} := \max_{j=s, \dots, q} \|\varphi(j)\|$  with  $\|\varphi(j)\| := \max_{i=1, \dots, n} |\varphi_i(j)|$ .

**1.1. Description of the problem considered.** Problems of control in discrete systems are considered, e.g., in [5, 7, 10, 12]. In [10] attention is paid to discrete delayed systems as well. Unlike the given recommendation to transform delayed systems into systems without delay but with greater dimensionality, we perform direct investigation using a new technique.

We will consider controllability on finite intervals. In this paper we deal with the so-called relatively controllable discrete systems (1.2) within the meaning of the following definition.

**DEFINITION 1.1.** *System (1.2) is relatively controllable if for any initial function  $\varphi: Z_{-m}^0 \rightarrow R^n$ , any finite terminal state  $x = x^* \in R^n$ , and any finite terminal point  $k_1$  greater than or equal to a fixed integer  $k^* \in Z_1^\infty$  there exists a discrete function  $u^*: Z_0^{k_1-1} \rightarrow R$  such that the system (1.2) with the input  $u = u^*$ , i.e., the system*

$$\Delta x(k) = Bx(k-m) + bu^*(k),$$

*has a solution  $x^*: Z_{-m}^{k_1} \rightarrow R^n$  such that  $x^*(k_1) = x^*$  and  $x^*(k) = \varphi(k)$  if  $k \in Z_{-m}^0$ .*

In this paper we will derive not only conditions for relative controllability of system (1.2), but also an explicit form of a possible control function  $u^*$ .

**2. Preliminaries.** In investigating relative controllability we use an auxiliary result, which is an analogy of the well-known basic lemma of variational calculus.

LEMMA 2.1. *Let a function  $\Phi: Z_s^q \rightarrow R$  be given. Then the equality*

$$(2.1) \quad \sum_{k=s}^q \Phi(k) \eta(k) = 0$$

*with an arbitrary function  $\eta: Z_s^q \rightarrow R$  holds if and only if  $\Phi(k) = 0$  on  $Z_s^q$ .*

The proof of the lemma is obvious and we omit it.

The known proof of controllability for linear differential systems with one input (Kalman's criterion) is based on two important results. The first is the formula for integral representation of a solution of a Cauchy problem for nonhomogeneous system (1.1),

$$x(t) = e^{At}x_0 + b \int_0^t e^{A(t-s)}u(s)ds,$$

where  $\exp(At)$  is the matrix exponential defined as

$$e^{At} = I + \frac{1}{1!}At + \frac{1}{2!}(At)^2 + \cdots + \frac{1}{k!}(At)^k + \cdots$$

with a unit  $n \times n$  matrix  $I$ . The second is the Cayley–Hamilton theorem, which states that every power  $A^i$ ,  $i = n, n+1, \dots$ , of a given  $n \times n$  constant matrix  $A$  can be expressed as a linear combination of a finite number of matrices  $I, A, A^2, \dots, A^{n-1}$ . Concerning these facts (which serve as motivation in our research) we refer the reader to, e.g., [8].

In this paper we will use what is called a discrete matrix delayed exponential  $\exp_m(Bk)$ . Its definition was given in [3, 4]. We reproduce this definition. Let a constant  $n \times n$  matrix  $B$  be given. Then

$$e_m^{Bk} := \begin{cases} \Theta & \text{if } k \in Z_{-\infty}^{-m-1}, \\ I & \text{if } k \in Z_{-m}^0, \\ I + B \cdot \binom{k}{1} & \text{if } k \in Z_1^{m+1}, \\ I + B \cdot \binom{k}{1} + B^2 \cdot \binom{k-m}{2} & \text{if } k \in Z_{(m+1)+1}^{2(m+1)}, \\ I + B \cdot \binom{k}{1} + B^2 \cdot \binom{k-m}{2} + B^3 \cdot \binom{k-2m}{3} & \text{if } k \in Z_{2(m+1)+1}^{3(m+1)}, \\ \dots & \\ I + B \cdot \binom{k}{1} + B^2 \cdot \binom{k-m}{2} + \dots + B^\ell \cdot \binom{k-(\ell-1)m}{\ell} & \\ \text{if } k \in Z_{(\ell-1)(m+1)+1}^{\ell(m+1)}, \quad \ell = 0, 1, 2, \dots, \end{cases}$$

where  $\Theta$  is an  $n \times n$  null matrix.

The following result is proved in [4].

LEMMA 2.2. *Let  $B$  be a constant  $n \times n$  matrix. Then*

$$(2.2) \quad \Delta e_m^{Bk} = B e_m^{B(k-m)}$$

*for  $k \in Z_{-m}^\infty$ .*

The discrete matrix delayed exponential  $\exp_m(Bk)$  of the  $n \times n$  constant matrix  $B$  can be successfully used for representing the solutions of discrete systems. In [4] a formula expressing the solution of an initial Cauchy problem with the aid of a discrete matrix exponential was given. In the case of the problem (1.2), (1.3) it takes the form

$$(2.3) \quad x(k) = e_m^{Bk} \varphi(-m) + \sum_{j=-m+1}^0 e_m^{B(k-m-j)} \Delta \varphi(j-1) \\ + \sum_{j=1}^k e_m^{B(k-m-j)} bu(j-1),$$

where  $k \in Z_1^\infty$ .

**DEFINITION 2.3.** Let a positive number  $r$  be given. We define a class of bounded discrete functions  $\Omega_r(s, q)$  as

$$\Omega_r(s, q) := \{\omega: Z_s^q \rightarrow R, \|\omega\|_{sq} \leq r\}.$$

**DEFINITION 2.4.** We define a domain of reachability  $Q_\varphi \subseteq R^n$  as a set of all points  $x(k_1)$ , where  $x$  is a solution of the system (1.2) corresponding to fixed initial data (1.3) and to an arbitrary control  $u \in \Omega_r(0, k_1 - 1)$ .

**3. Main results.** We obtain conditions for relative controllability and we find the control function  $u = u^*(k)$ ,  $k \in Z_0^{k_1-1}$ , for the problem

$$(3.1) \quad \Delta x(k) = Bx(k-m) + bu(k), \quad k \in Z_0^{k_1-1},$$

$$(3.2) \quad x(k) = \varphi(k), \quad k \in Z_{-m}^0,$$

$$(3.3) \quad x(k_1) = x^*.$$

We define an auxiliary  $n \times n$  matrix

$$S := (b, Bb, B^2b, \dots, B^{n-1}b)$$

and the vector

$$(3.4) \quad \xi := x^* - e_m^{Bk_1} \varphi(-m) - \sum_{j=-m+1}^0 e_m^{B(k_1-m-j)} \Delta \varphi(j-1).$$

Moreover, we define a number

$$(3.5) \quad k^* := (n-1)(m+1) + 1.$$

### 3.1. Criterion of relative controllability of the problem (3.1)–(3.3).

**THEOREM 3.1.** Problem (3.1)–(3.3) is relatively controllable if and only if assumptions

$$(3.6) \quad \text{rank } S = n$$

and

$$(3.7) \quad k_1 \geq k^*$$

hold simultaneously.

*Proof.* (a) Let the system (3.1) be relatively controllable. Then, in accordance with Definition 1.1 for any arbitrary initial function  $\varphi: Z_{-m}^0 \rightarrow R^n$ , arbitrary finite terminal state  $x = x^* \in R^n$ , and arbitrary finite terminal point  $k_1$  greater than or equal to a fixed integer  $k^* \in Z_1^\infty$ , there exists a discrete function  $u^*: Z_0^{k_1-1} \rightarrow R$  such that the system (3.1) has a solution  $x^*: Z_{-m}^{k_1} \rightarrow R^n$  satisfying assumption (3.3). We show that, in this case, (3.6) and (3.7) with  $k^*$  defined by (3.5) hold. We use the formula (2.3) to represent the solution  $x^*$  of the problem (3.1)–(3.3). At the moment  $k = k_1$  we have

$$(3.8) \quad x^* = x^*(k_1) = e_m^{Bk_1} \varphi(-m) + \sum_{j=-m+1}^0 e_m^{B(k_1-m-j)} \Delta \varphi(j-1) + \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} bu^*(j-1).$$

We rewrite (3.8) (using (3.4)) as

$$(3.9) \quad \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} bu^*(j-1) = \xi.$$

The discrete matrix delayed exponential  $\exp_m(Bk)$  contains the same maximal degree  $p(k)$  of the matrix  $B$  for every set of values

$$k = (\ell - 1)(m + 1) + 1, (\ell - 1)(m + 1) + 2, \dots, \ell(m + 1)$$

with fixed  $\ell = 0, 1, 2, \dots$ . It is easy to see (the function  $[\cdot]$  is the greatest integer function) that

$$p(k) = \begin{cases} \left[ \frac{k-1}{m+1} \right] + 1 & \text{if } k = 1, 2, \dots, \\ 0 & \text{if } k < 1. \end{cases}$$

Consequently, the definition of a discrete matrix delayed exponential can be shortened to

$$e_m^{Bk} = \begin{cases} 0 & \text{if } k \in Z_{-\infty}^{-m}, \\ I + \sum_{i=1}^{p(k)} B^i \cdot \binom{k - (i-1)m}{i} & \text{if } k \in Z_{-m}^{\infty}. \end{cases}$$

Since  $k_1 \geq 1$ , the relation (3.9) becomes

$$(3.10) \quad \sum_{j=1}^{k_1} \left[ I + \sum_{i=1}^{p(k_1-m-j)} B^i \cdot \binom{k_1 - m - j - (i-1)m}{i} \right] bu^*(j-1) = \xi.$$

The left-hand side is a linear combination of  $q + 1$  vectors

$$(3.11) \quad b, Bb, \dots, B^q b$$

with

$$(3.12) \quad q = p(k_1 - m - 1) = \left[ \frac{k_1 - m - 1 - 1}{m + 1} \right] + 1 = \left[ \frac{k_1 - 1}{m + 1} \right].$$

In other words, (3.10) can be written in the form

$$(3.13) \quad C_1 \cdot b + C_2 \cdot Bb + \cdots + C_{q+1} \cdot B^q b = \xi$$

with “constants”  $C_1, C_2, \dots, C_{q+1}$  (being functions of  $u^*(0), u^*(1), \dots, u^*(k_1 - 1)$ ). We conclude that, for  $q + 1 < n$ , system (3.13) is, in general, overdetermined and its solution (for arbitrary  $\xi$ ) does not always exist. Therefore, a necessary condition for the solvability of (3.13) is the inequality  $q + 1 \geq n$ . Then, the solution of (3.13) always exists. Finally, we have that (see (3.12))

$$q = \left\lceil \frac{k_1 - 1}{m + 1} \right\rceil \geq n - 1$$

or

$$k_1 \geq (n - 1)(m + 1) + 1 = k^*.$$

The validity of inequality (3.7) is now obvious. By the Cayley–Hamilton theorem, any matrix  $B^i$  with  $i \geq n$  can be expressed as a linear combination of matrices

$$I, B, B^2, \dots, B^{n-1}.$$

If  $q \geq n$ , then the linear combination (3.13) of vectors of system (3.11) can be reduced to a linear combination of vectors of the following system:

$$b, Bb, \dots, B^{n-1}b.$$

Thus, the above-mentioned system (3.13) of  $n$  linear equations is solvable for any arbitrary right-hand side  $\xi$  if and only if  $\det S \neq 0$ , i.e.,  $\text{rank } S = n$ . Consequently, condition (3.6) holds.

(b) Let (3.6), (3.7) be valid. We show that the system (3.1) is relatively controllable. First, we prove that the dimension of the domain of reachability equals  $n$ . Suppose the contrary, i.e.,  $\dim Q_\varphi < n$ . Then there exists a nontrivial constant vector  $y = (y_1, y_2, \dots, y_n)^T \in R^n$  such that, for any control  $u \in \Omega_r(0, k_1 - 1)$  and the corresponding solution  $x = x(k; u, \varphi)$  of the problem (3.1), (3.2), we have

$$(3.14) \quad y^T x(k_1) = 0.$$

We choose the zero initial function  $\varphi(k) = 0$ ,  $k \in Z_{-m}^0$ . Then, with the aid of formula (2.3), we get

$$(3.15) \quad x(k_1) = \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b u(j-1),$$

and (3.14) becomes

$$(3.16) \quad y^T \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b u(j-1) = 0.$$

Since (3.16) holds for arbitrary control  $u \in \Omega_r(0, k_1 - 1)$  then, by Lemma 2.1,

$$(3.17) \quad y^T e_m^{B(k_1-m-j)} b = 0, \quad j \in Z_0^{k_1}.$$

Now we apply (2.2) to (3.17). We obtain

$$\Delta \left[ y^T e_m^{B(k_1-m-j)} b \right] = y^T \Delta \left[ e_m^{B(k_1-m-j)} \right] b = y^T B e_m^{B(k_1-2m-j)} b = 0$$

or

$$(3.18) \quad y^T B e_m^{B(k_1-2m-j)} b = 0, \quad j \in Z_0^{k_1}.$$

We repeatedly apply the operator  $\Delta$  to (3.18) for a total  $(n-2)$  times. Then, in accordance with (2.2),

$$(3.19) \quad y^T B^2 e_m^{B(k_1-3m-j)} b = 0, \quad j \in Z_0^{k_1},$$

$$(3.20) \quad y^T B^3 e_m^{B(k_1-4m-j)} b = 0, \quad j \in Z_0^{k_1},$$

...

$$(3.21) \quad y^T B^{n-1} e_m^{B(k_1-nm-j)} b = 0, \quad j \in Z_0^{k_1}.$$

We put  $j = k_1$  in (3.17),  $j = k_1 - m$  in (3.18) and, step by step,

$$j = k_1 - 2m, j = k_1 - 3m, \dots, j = k_1 - (n-1)m$$

in (3.19), (3.20), and (3.21). Since, due to (3.7), inequality  $k_1 \geq (n-1)(m+1) + 1$  holds, we get  $k_1 - (n-1)m \geq n \geq 1$ , and all choices of indices  $j$  are admissible. Since  $e_m^{B(-m)} \equiv I$ , system (3.17)–(3.21) (with respect to  $b$ ) reduces to

$$(3.22) \quad y^T b = 0, y^T B b = 0, \dots, y^T B^{n-1} b = 0.$$

We use the definition of the matrix  $S$  and rewrite (3.22) as

$$(3.23) \quad y^T S = 0.$$

The homogeneous system (3.23) has a nontrivial solution if and only if its matrix is singular. This means  $\det S = 0$ . We get a contradiction with (3.6). Consequently, the inequality  $\dim Q_\varphi < n$  does not hold and the dimension of the domain of reachability equals  $n$ .

Since the domain of reachability  $Q_\varphi$  contains the point  $-x(k_1)$  corresponding to a control  $-u \in \Omega_r(0, k_1 - 1)$  together with a point  $x(k_1)$  corresponding to a control  $u \in \Omega_r(0, k_1 - 1)$  (in view of the choice of a zero initial function and in view of representation (3.15)), we conclude that  $Q_\varphi$  is symmetric. Moreover, the domain of reachability contains the segment connecting the point  $x(k_1)$  with the point  $-x(k_1)$ . Consequently, due to the linearity of the problem considered, it contains a ball of a radius  $\delta$ :

$$U_\delta := \{x \in R^n, \|x\| < \delta\}$$

with positive  $\delta$ . Obviously, if  $r \rightarrow \infty$  in  $\Omega_r(0, k_1 - 1)$ , then, due to the finiteness of the interval  $Z_0^{k_1-1}$ , we conclude that  $\delta \rightarrow \infty$  in the definition of  $U_\delta$ . Therefore, the domain  $Q_\varphi$  coincides with the whole space  $R^n$ . Simultaneously it says that, for every point  $x^* \in R^n$ , there exists a control  $u = u^*$  solving the problem (3.1)–(3.3). This conclusion remains valid even in the case of the nonzero initial function  $\varphi$ . Indeed, a simple transformation  $x(k) = x_\varphi(k) + z(k)$ , where  $x_\varphi(k)$  is a solution of the homogeneous problem

$$\begin{aligned} \Delta x_\varphi(k) &= Bx_\varphi(k-m), \quad k \in Z_0^{k_1-1}, \\ x_\varphi(k) &= \varphi(k), \quad k \in Z_{-m}^0, \end{aligned}$$

leads to the same problem with respect to  $z$  with a zero initial function.  $\square$

**3.2. A control function for the problem (3.1)–(3.3).** In this section we construct a control function  $u = u^*$  for the problem (3.1)–(3.3). To do this, we need some auxiliary results.

DEFINITION 3.2. We say that the pair  $(B, b)$  is controlled if  $\text{rank } S = n$ .

LEMMA 3.3. Let the pair  $(B, b)$  be controlled and  $k_1 \geq k^*$ . Then the elements  $(e_m^{Bk}b)_i$ ,  $i = 1, 2, \dots, n$ , of the vector  $e_m^{Bk}b$  are linearly independent on  $Z_{-m}^{k^*-1}$ , i.e., no nontrivial constant vector  $l = (l_1, l_2, \dots, l_n)^T$  exists such that

$$(3.24) \quad l^T e_m^{Bk}b = 0 \quad \text{for } k \in Z_{-m}^{k^*-1}.$$

*Proof.* Suppose that, on the contrary, there exists a nontrivial vector  $l$  such that (3.24) holds. Itemizing (3.24) in accordance with the definition of the discrete matrix exponential  $\exp_m(Bk)$  and noting that  $k^* - 1 = (n - 1)(m + 1)$ , we get

$$(3.25) \quad 0 = l^T e_m^{Bk}b = \begin{cases} l^T b & \text{if } k \in Z_{-m}^0, \\ l^T \left[ I + B \cdot \binom{k}{1} \right] b & \text{if } k \in Z_1^{m+1}, \\ l^T \left[ I + B \cdot \binom{k}{1} + B^2 \cdot \binom{k-m}{2} \right] b & \text{if } k \in Z_{(m+1)+1}^{2(m+1)}, \\ \dots \\ l^T \left[ I + B \cdot \binom{k}{1} + \dots + B^{n-1} \cdot \binom{k-(n-2)m}{n-1} \right] b \\ \text{if } k \in Z_{(n-2)(m+1)+1}^{(n-1)(m+1)}, \text{ where } (n-1)(m+1) = k^* - 1. \end{cases}$$

From (3.25) we get (due to formula (2.2))

$$(3.26) \quad \begin{aligned} 0 &= \Delta [l^T e_m^{Bk}b] = l^T \Delta [e_m^{Bk}] b = l^T B e_m^{B(k-m)} b, \\ &= \begin{cases} 0 & \text{if } k \in Z_{-m}^1, \\ l^T B b & \text{if } k \in Z_0^m, \\ l^T B \left[ I + B \cdot \binom{k}{1} \right] b & \text{if } k \in Z_{m+1}^{2m+1}, \\ \dots \\ l^T \left[ I + B \cdot \binom{k}{1} + \dots + B^{n-2} \cdot \binom{k-(n-3)m}{n-2} \right] b \\ \text{if } k \in Z_{(n-2)(m+1)}^{(n-1)(m+1)-1}, \text{ where } (n-1)(m+1) - 1 = k^* - 2. \end{cases} \end{aligned}$$

We continue to compute further differences up to those of order  $(n - 1)$ . Finally, we get from (3.26) (due to formula (2.2))

$$(3.27) \quad \begin{aligned} 0 &= \Delta^{n-1} [l^T e_m^{Bk}b] = l^T B^{n-1} e_m^{B(k-(n-1)m)} b \\ &= \begin{cases} 0 & \text{if } k \in Z_{-m}^{(n-2)m-1}, \\ l^T B^{n-1} b = 0 & \text{if } k \in Z_{(n-2)m}^{(n-1)m}, \text{ where } (n-1)m = k^* - n. \end{cases} \end{aligned}$$

Now we select the equation  $l^T b = 0$  from (3.25), the equation  $l^T B b = 0$  from (3.26), and, proceeding similarly up to the last formula (3.27), we finally select the equality  $l^T B^{n-1} b = 0$ . We get the system of equations

$$l^T S = 0.$$

This is a system of homogeneous equations and its nontrivial solution can exist only in the case of  $\det S = 0$ . This is a contradiction with our supposition, and the components of the vector  $e_m^{Bk}b$  in (3.24) are linearly independent on the interval  $Z_{-m}^{k^*-1}$ .  $\square$

LEMMA 3.4. *Let  $k_1 \geq k^*$ . Then the matrix*

$$G = \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b b^T \left( e_m^{B(k_1-m-j)} \right)^T$$

*is nonsingular.*

*Proof.* Since the components  $(e_m^{Bk}b)_i$ ,  $i = 1, 2, \dots, n$ , of the vector  $e_m^{Bk}b$  are linearly independent on interval  $Z_{-m}^{k^*-1}$  by Lemma 3.3, we have

$$\left( e_m^{B(k_1-m-j)} b \right)^T l = \sum_{i=1}^n l_i \left( e_m^{B(k_1-m-j)} b \right)_i \neq 0$$

for arbitrary nontrivial vectors  $l = (l_1, l_2, \dots, l_n)^T$  and for  $j = k_1 - n(m+1) + 1, \dots, k_1$  (note that  $k_1 - m - j \in Z_{-m}^{k^*-1}$ ), or

$$\sum_{j=1}^{k_1} \left[ \left( e_m^{B(k_1-m-j)} b \right)^T l \right]^2 > 0$$

since  $k_1 \geq n$ . Let us transform the expression on the left-hand side of the last inequality. We have

$$\begin{aligned} \sum_{j=1}^{k_1} \left[ \left( e_m^{B(k_1-m-j)} b \right)^T l \right]^2 &= \sum_{j=1}^{k_1} \left[ \left( e_m^{B(k_1-m-j)} b \right)^T l \right] \left[ \left( e_m^{B(k_1-m-j)} b \right)^T l \right] \\ &= \sum_{j=1}^{k_1} \left[ l^T e_m^{B(k_1-m-j)} b \right] \left[ b^T \left( e_m^{B(k_1-m-j)} \right)^T l \right] \\ &= l^T \left[ \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b b^T \left( e_m^{B(k_1-m-j)} \right)^T \right] l \\ &= l^T G l. \end{aligned}$$

Thus,  $l^T G l > 0$  and therefore  $\det G \neq 0$ .  $\square$

Using the assertions given by Lemmas 3.3 and 3.4, it is easy to prove the final result.

THEOREM 3.5. *Let the conditions of relative controllability (3.6), (3.7) be valid. Then a control function  $u = u^*$  for the problem (3.1)–(3.3) can be expressed in the form*

$$(3.28) \quad u^*(k) = b^T \left( e_m^{B(k_1-m-k-1)} \right)^T G^{-1} \xi,$$

where the vector  $\xi$  is defined by formula (3.4) and  $k \in Z_0^{k_1-1}$ .

*Proof.* Since the control function  $u^*(j)$ ,  $j \in Z_0^{k_1-1}$ , should satisfy (3.8), it is necessary to prove that the system

$$(3.29) \quad \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b u(j-1) = \xi$$

has a solution  $u(j-1) = u^*(j-1)$ ,  $j \in Z_1^{k_1}$ . Let us try to find the control function in the form of a linear combination

$$(3.30) \quad u(j-1) = \left( e_m^{B(k_1-m-j)} b \right)^T D,$$

where  $D = (D_1, D_2, \dots, D_n)^T$  is an unknown vector. We apply representation (3.30) to (3.29). Then we get a linear homogeneous system with respect to  $D_1, D_2, \dots, D_n$ :

$$\left[ \sum_{j=1}^{k_1} e_m^{B(k_1-m-j)} b b^T \left( e_m^{B(k_1-m-j)} \right)^T \right] D = \xi$$

or, in a matrix form,

$$GD = \xi.$$

By Lemma 3.4, the matrix  $G$  is nonsingular and it is clear that  $D = G^{-1}\xi$ . From (3.30) we get

$$u(j-1) = \left( e_m^{B(k_1-m-j)} b \right)^T G^{-1}\xi,$$

which is equivalent to (3.28).  $\square$

# A PRIORI ERROR ESTIMATES FOR SPACE-TIME FINITE ELEMENT DISCRETIZATION OF PARABOLIC OPTIMAL CONTROL PROBLEMS PART I: PROBLEMS WITHOUT CONTROL CONSTRAINTS\*

DOMINIK MEIDNER<sup>†</sup> AND BORIS VEXLER<sup>‡</sup>

**Abstract.** In this paper we develop a priori error analysis for Galerkin finite element discretizations of optimal control problems governed by linear parabolic equations. The space discretization of the state variable is done using usual conforming finite elements, whereas the time discretization is based on discontinuous Galerkin methods. For different types of control discretizations we provide error estimates of optimal order with respect to both space and time discretization parameters. The paper is divided into two parts. In the first part we develop some stability and error estimates for space-time discretization of the state equation and provide error estimates for optimal control problems without control constraints. In the second part of the paper, the techniques and results of the first part are used to develop a priori error analysis for optimal control problems with pointwise inequality constraints on the control variable.

**Key words.** optimal control, parabolic equations, error estimates, finite elements

**1. Introduction.** In this paper we develop a priori error analysis for space-time finite element discretizations of parabolic optimization problems. We consider the following linear-quadratic optimal control problem for the state variable  $u$  and the control variable  $q$ :

$$(1.1a) \quad \text{Minimize } J(q, u) = \frac{1}{2} \int_0^T \int_{\Omega} (u(t, x) - \hat{u}(t, x))^2 dx dt + \frac{\alpha}{2} \int_0^T \int_{\Omega} q(t, x)^2 dx dt$$

subject to

$$(1.1b) \quad \begin{aligned} \partial_t u - \Delta u &= f + q && \text{in } (0, T) \times \Omega, \\ u(0) &= u_0 && \text{in } \Omega, \end{aligned}$$

combined with either homogeneous Dirichlet or homogeneous Neumann boundary conditions on  $(0, T) \times \partial\Omega$ . A precise formulation of this problem including a functional analytic setting is given in the next section.

While the a priori error analysis for finite element discretization of optimal control problems governed by elliptic equations is discussed in many publications (see, e.g., [12, 15, 1, 16, 22, 4]), there are only a few published results on this topic for parabolic problems; see [20, 28, 17, 19, 24].

In this paper, we will use discontinuous finite element methods for time discretization of the state equation (1.1b), as proposed, e.g., in [7, 10]. The spatial discretization will be based on usual  $H^1$ -conforming finite elements. In [2] this type of discretization is shown to allow for a natural translation of the optimality conditions from the continuous to the discrete level. This gives rise to exact computation of the derivatives required in the optimization algorithms on the discrete level. In [21] a posteriori error estimates for this type of discretization are derived and an adaptive algorithm is developed.

Throughout, we will use a general discretization parameter  $\sigma$  consisting of three discretization parameters  $\sigma = (k, h, d)$ , where  $k$  corresponds to the time discretization of the state variable,  $h$  to the space discretization of the state variable, and  $d$  to the discretization of the control variable  $q$ , respectively. The space and time discretizations of the control variable may differ from the discretizations of the state. Therefore, the discretization parameter  $d$  consists of the discretization parameters  $k_d$  and  $h_d$  for the time and space discretizations of the control variable. In this paper we will derive a priori error estimates of optimal order with respect to all discretization parameters, where the influences of different parts of the discretization are clearly separated. Moreover, the temporal and spatial regularity properties of the solution to the continuous problem (1.1) are separated as well.

For the discretization error between the solution of the continuous optimization problem  $(\bar{q}, \bar{u})$  and the solution of the discretized problem  $(\bar{q}_\sigma, \bar{u}_\sigma)$ , we will prove error estimates of the following structure:

$$(1.2) \quad \|\bar{q} - \bar{q}_\sigma\|_{L^2((0,T) \times \Omega)} \leq C_1(\bar{u}, \bar{z}) k^{r+1} + C_2(\bar{u}, \bar{z}) h^{s+1} + C_3(\bar{q}) k_d^{r_d+1} + C_4(\bar{q}) h_d^{s_d+1},$$

where  $r, r_d$  are the highest degrees of the polynomials in the time discretization of the state and the control variable, respectively, and  $s, s_d$  are the highest degree of the polynomials in the space discretization of the control and the state variable. The constants  $C_1(\bar{u}, \bar{z})$  and  $C_2(\bar{u}, \bar{z})$  depend on the temporal and the spatial regularity of the optimal state  $\bar{u}$  and the corresponding adjoint state  $\bar{z}$ , respectively; cf. Theorem 6.1. The temporal and spatial regularity of the optimal control  $\bar{q}$  determines the constants  $C_3(\bar{q})$  and  $C_4(\bar{q})$ , respectively.

In [19] a similar result is proved for the case  $r = 0, s = 1$ , and under the assumption  $k \approx h^2$ . We would like to emphasize that the discretization parameters  $k, h, k_d, h_d$  in estimate (1.2) can be chosen independently of each other.

The purpose of this paper is twofold. The first goal is to derive a priori error estimates for optimal control problem (1.1) of the above structure. The second goal is to provide techniques which will be used in the second part of the paper for derivation of a priori error estimates for problems involving pointwise inequality constraints on the control variable.

The paper is organized as follows. In the next section we recall the function analytic setting and optimality conditions for the optimal control problem under consideration. In section 3 the space-time finite element discretization is presented. Based on stability estimates developed in section 4, we provide a priori error analysis for the state equation in section 5. The main result on the error analysis for the considered optimal control problem is given in section 6. In this section error estimates for the error in the control, state, and adjoint variables are developed. In the last section we present a numerical example illustrating our results.

**2. Optimization.** In this section we briefly discuss the precise formulation of the optimization problem under consideration. Furthermore, we recall theoretical results

on existence, uniqueness, and regularity of optimal solutions as well as optimality conditions.

To set up a weak formulation of the state equation (1.1b), we introduce the following notation: For a convex polygonal domain  $\Omega \subset \mathbb{R}^n$ ,  $n \in \{2, 3\}$ , we denote  $V$  to be either  $H^1(\Omega)$  or  $H_0^1(\Omega)$  depending on the prescribed type of boundary conditions (homogeneous Neumann or homogeneous Dirichlet). Together with  $H = L^2(\Omega)$ , the Hilbert space  $V$  and its dual  $V^*$  build a Gelfand triple  $V \hookrightarrow H \hookrightarrow V^*$ . Here and in what follows, we employ the usual notion for Lebesgue and Sobolev spaces.

For a time interval  $I = (0, T)$  we introduce the state space

$$X := \{v \mid v \in L^2(I, V) \text{ and } \partial_t v \in L^2(I, V^*)\}$$

and the control space

$$Q = L^2(I, L^2(\Omega)).$$

In addition, we use the following notation for the inner products and norms on  $L^2(\Omega)$  and  $L^2(I, L^2(\Omega))$ :

$$\begin{aligned} (v, w) &:= (v, w)_{L^2(\Omega)}, & (v, w)_I &:= (v, w)_{L^2(I, L^2(\Omega))}, \\ \|v\| &:= \|v\|_{L^2(\Omega)}, & \|v\|_I &:= \|v\|_{L^2(I, L^2(\Omega))}. \end{aligned}$$

In this setting, a standard weak formulation of the state equation (1.1b) for given control  $q \in Q$ ,  $f \in L^2(I, H)$ , and  $u_0 \in V$  reads as follows: Find a state  $u \in X$  satisfying

$$\begin{aligned} (2.1) \quad & (\partial_t u, \varphi)_I + (\nabla u, \nabla \varphi)_I = (f + q, \varphi)_I \quad \forall \varphi \in X, \\ & u(0) = u_0. \end{aligned}$$

For simplicity of notation, we skip here and throughout the paper the dependence of the solution variable on  $x$  and  $t$ .

For this formulation of the state equation, we recall the following result on existence and regularity.

**PROPOSITION 2.1.** *For fixed control  $q \in Q$ ,  $f \in L^2(I, H)$ , and  $u_0 \in V$  there exists a unique solution  $u \in X$  of problem (2.1). Moreover, the solution exhibits the improved regularity*

$$u \in L^2(I, H^2(\Omega) \cap V) \cap H^1(I, L^2(\Omega)) \hookrightarrow C(\bar{I}, V).$$

*It holds the stability estimate*

$$\|\partial_t u\|_I + \|\nabla^2 u\|_I \leq C\{\|f + q\|_I + \|\nabla u_0\|\}.$$

*Proof.* The proof of existence and uniqueness is given, e.g., in [18] and [29]. The improved regularity relies on the fact that  $\Omega$  is polygonal and convex and is proved, e.g., in [11]. The embedding of  $L^2(I, H^2(\Omega) \cap V) \cap H^1(I, L^2(\Omega))$  into  $C(\bar{I}, V)$  can be found, for instance, in [6].  $\square$

The weak formulation of the optimal control problem (1.1) is given as follows:

$$(2.2) \quad \text{Minimize } J(q, u) := \frac{1}{2}\|u - \hat{u}\|_I^2 + \frac{\alpha}{2}\|q\|_I^2 \text{ subject to (2.1) and } (q, u) \in Q \times X,$$

where  $\hat{u} \in L^2(I, H)$  is a given desired state and  $\alpha > 0$  is the regularization parameter.

PROPOSITION 2.2. *For given  $f, \hat{u} \in L^2(I, H)$ ,  $u_0 \in V$ , and  $\alpha > 0$ , the optimal control problem (2.2) admits a unique solution  $(\bar{q}, \bar{u}) \in Q \times X$ . The optimal control  $\bar{q}$  possesses the regularity*

$$\bar{q} \in L^2(I, H^2(\Omega)) \cap H^1(I, L^2(\Omega)).$$

*Proof.* For existence and uniqueness we refer to [18]. First order necessary optimality conditions and Proposition 2.1 imply the stated regularity of the optimal control.  $\square$

The existence result for the state equation in Proposition 2.1 ensures the existence of a control-to-state mapping  $q \mapsto u = u(q)$  defined through (2.1). By means of this mapping we introduce the reduced cost functional  $j: Q \rightarrow \mathbb{R}$ :

$$j(q) := J(q, u(q)).$$

The optimal control problem (2.2) can then be equivalently reformulated as follows:

$$(2.3) \quad \text{Minimize } j(q) \text{ subject to } q \in Q.$$

The first order necessary optimality condition for (2.3) reads as

$$(2.4) \quad j'(\bar{q})(\delta q) = 0 \quad \forall \delta q \in Q.$$

Due to the linear-quadratic structure of the optimal control problem this condition is also sufficient for optimality.

Utilizing the adjoint state equation for  $z = z(q) \in X$  given by

$$(2.5) \quad \begin{aligned} -(\varphi, \partial_t z)_I + (\nabla \varphi, \nabla z)_I &= (\varphi, u(q) - \hat{u})_I \quad \forall \varphi \in X, \\ z(T) &= 0, \end{aligned}$$

the first derivative of the reduced cost functional can be expressed as

$$(2.6) \quad j'(q)(\delta q) = (\alpha q + z(q), \delta q)_I.$$

**3. Discretization.** In this section we describe the space-time finite element discretization of the optimal control problem (2.2).

**3.1. Semidiscretization in time.** At first, we present the semidiscretization in time of the state equation by discontinuous Galerkin methods. We consider a partitioning of the time interval  $\bar{I} = [0, T]$  as

$$(3.1) \quad \bar{I} = \{0\} \cup I_1 \cup I_2 \cup \cdots \cup I_M$$

with subintervals  $I_m = (t_{m-1}, t_m]$  of size  $k_m$  and time points

$$0 = t_0 < t_1 < \cdots < t_{M-1} < t_M = T.$$

We define the discretization parameter  $k$  as a piecewise constant function by setting  $k|_{I_m} = k_m$  for  $m = 1, 2, \dots, M$ . Moreover, we denote by  $k$  the maximal size of the time steps, i.e.,  $k = \max k_m$ .

The semidiscrete trial and test space is given as

$$X_k^r = \left\{ v_k \in L^2(I, V) \mid v_k|_{I_m} \in \mathcal{P}_r(I_m, V), \ m = 1, 2, \dots, M \right\}.$$

Here,  $\mathcal{P}_r(I_m, V)$  denotes the space of polynomials up to order  $r$  defined on  $I_m$  with values in  $V$ . On  $X_k^r$  we use the notation

$$(v, w)_{I_m} := (v, w)_{L^2(I_m, L^2(\Omega))} \quad \text{and} \quad \|v\|_{I_m} := \|v\|_{L^2(I_m, L^2(\Omega))}.$$

To define the discontinuous Galerkin (dG( $r$ )) approximation using the space  $X_k^r$  we employ the following definitions for functions  $v_k \in X_k^r$ :

$$v_{k,m}^+ := \lim_{t \rightarrow 0^+} v_k(t_m + t), \quad v_{k,m}^- := \lim_{t \rightarrow 0^+} v_k(t_m - t) = v_k(t_m), \quad [v_k]_m := v_{k,m}^+ - v_{k,m}^-$$

and define the bilinear form  $B(\cdot, \cdot)$  for  $u_k, \varphi \in X_k^r$  by

$$(3.2) \quad B(u_k, \varphi) := \sum_{m=1}^M (\partial_t u_k, \varphi)_{I_m} + (\nabla u_k, \nabla \varphi)_I + \sum_{m=2}^M ([u_k]_{m-1}, \varphi_{m-1}^+) + (u_{k,0}^+, \varphi_0^+).$$

Then, the dG( $r$ ) semidiscretization of the state equation (2.1) for a given control  $q \in Q$  reads as follows: Find a state  $u_k = u_k(q) \in X_k^r$  such that

$$(3.3) \quad B(u_k, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_k^r.$$

The existence and uniqueness of solutions to (3.3) can be shown by using Fourier analysis; see [27] for details.

*Remark 3.1.* Using a density argument, it is possible to show that the exact solution  $u = u(q) \in X$  also satisfies the identity

$$B(u, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_k^r.$$

Thus, we have here the property of Galerkin orthogonality

$$B(u - u_k, \varphi) = 0 \quad \forall \varphi \in X_k^r,$$

although the dG( $r$ ) semidiscretization is a nonconforming Galerkin method ( $X_k^r \not\subset X$ ).

The semidiscrete optimization problem for the dG( $r$ ) time discretization has the following form:

$$(3.4) \quad \text{Minimize } J(q_k, u_k) \text{ subject to (3.3) and } (q_k, u_k) \in Q \times X_k^r.$$

**PROPOSITION 3.2.** *The semidiscrete optimal control problem (3.4) admits for  $\alpha > 0$  a unique solution  $(\bar{q}_k, \bar{u}_k) \in Q \times X_k^r$ .*

*Proof.* The proof is done by translating standard arguments from the proof in the continuous case and by employing the continuity of the mapping  $q \mapsto u_k(q)$  provided by the stability estimates derived in the next section (cf. Theorem 4.3).  $\square$

Note that the optimal control  $\bar{q}_k$  is searched for in the continuous space  $Q$  and the subscript  $k$  indicates the usage of the semidiscretized state equation.

Similar to the continuous case, we introduce the semidiscrete reduced cost functional  $j_k: Q \rightarrow \mathbb{R}$ :

$$j_k(q) := J(q, u_k(q))$$

and reformulate the semidiscrete optimal control problem (3.4) as follows:

$$\text{Minimize } j_k(q_k) \text{ subject to } q_k \in Q.$$

The first order necessary optimality condition reads as

$$(3.5) \quad j'_k(\bar{q}_k)(\delta q) = 0 \quad \forall \delta q \in Q,$$

and the derivative of  $j_k$  can be expressed as

$$(3.6) \quad j'_k(q)(\delta q) = (\alpha q + z_k(q), \delta q)_I.$$

Here,  $z_k = z_k(q) \in X_k^r$  denotes the solution of the semidiscrete adjoint equation

$$(3.7) \quad B(\varphi, z_k) = (\varphi, u_k(q) - \hat{u})_I \quad \forall \varphi \in X_k^r.$$

Note that by using integration by parts in time, the bilinear form  $B(\cdot, \cdot)$  defined by (3.2) can equivalently be expressed as

$$(3.8) \quad B(\varphi, z_k) = - \sum_{m=1}^M (\varphi, \partial_t z_k)_{I_m} + (\nabla \varphi, \nabla z_k)_I - \sum_{m=1}^{M-1} (\varphi_m^-, [z_k]_m) + (\varphi_M^-, z_{k,M}^-).$$

**3.2. Discretization in space.** To define the finite element discretization in space, we consider two or three dimensional shape-regular meshes; see, e.g., [5]. A mesh consists of quadrilateral or hexahedral cells  $K$ , which constitute a non-overlapping cover of the computational domain  $\Omega$ . The corresponding mesh is denoted by  $\mathcal{T}_h = \{K\}$ , where we define the discretization parameter  $h$  as a cellwise constant function by setting  $h|_K = h_K$  with the diameter  $h_K$  of the cell  $K$ . We use the symbol  $h$  also for the maximal cell size, i.e.,  $h = \max h_K$ .

On the mesh  $\mathcal{T}_h$  we construct a conforming finite element space  $V_h \subset V$  in a standard way:

$$V_h^s = \{v \in V \mid v|_K \in \mathcal{Q}_s(K) \text{ for } K \in \mathcal{T}_h\}.$$

Here,  $\mathcal{Q}_s(K)$  consists of shape functions obtained via (bi-/tri-)linear transformations of polynomials in  $\widehat{\mathcal{Q}}_s(\widehat{K})$  defined on the reference cell  $\widehat{K} = (0, 1)^n$ , where

$$\widehat{\mathcal{Q}}_s(\widehat{K}) = \text{span} \left\{ \prod_{j=1}^n x_j^{\alpha_j} \mid \alpha_j \in \mathbb{N}_0, \alpha_j \leq s \right\}.$$

*Remark 3.3.* The definition of  $V_h^s$  can be extended to the case of triangular meshes in the obvious way.

To obtain the fully discretized versions of the time discretized state equation (3.3), we utilize the space-time finite element space

$$X_{k,h}^{r,s} = \left\{ v_{kh} \in L^2(I, V_h^s) \mid v_{kh}|_{I_m} \in \mathcal{P}_r(I_m, V_h^s) \right\} \subset X_k^r.$$

*Remark 3.4.* Here, the spatial mesh and, therefore, also the space  $V_h^s$  is fixed for all time intervals. We refer to [25] for a discussion of treatment of different meshes  $\mathcal{T}_h^m$  for each of the subintervals  $I_m$ .

The so-called cG( $s$ )dG( $r$ ) discretization of the state equation for given control  $q \in Q$  has the following form: Find a state  $u_{kh} = u_{kh}(q) \in X_{k,h}^{r,s}$  such that

$$(3.9) \quad B(u_{kh}, \varphi) = (f + q, \varphi)_I + (u_0, \varphi_0^+) \quad \forall \varphi \in X_{k,h}^{r,s}.$$

*Remark 3.5.* The notation  $\text{cG}(s)\text{dG}(r)$  is taken from [7] and describes a method with conforming (continuous) discretization in space of order  $s$  and discontinuous discretization in time of order  $r$ .

Then, the corresponding optimal control problem is given as follows:

$$(3.10) \quad \text{Minimize } J(q_{kh}, u_{kh}) \text{ subject to (3.9) and } (q_{kh}, u_{kh}) \in Q \times X_{k,h}^{r,s},$$

and by means of the discrete reduced cost functional  $j_{kh}: Q \rightarrow \mathbb{R}$ ,

$$j_{kh}(q) := J(q, u_{kh}(q)),$$

it can be reformulated as follows:

$$\text{Minimize } j_{kh}(q_{kh}) \text{ subject to } q_{kh} \in Q.$$

The uniquely determined optimal solution of (3.10) is denoted by  $(\bar{q}_{kh}, \bar{u}_{kh}) \in Q \times X_{k,h}^{r,s}$ .

The optimal control  $\bar{q}_{kh} \in Q$  fulfills the first order optimality condition

$$(3.11) \quad j'_{kh}(\bar{q}_{kh})(\delta q) = 0 \quad \forall \delta q \in Q,$$

where  $j'_{kh}(q)(\delta q)$  is given by

$$(3.12) \quad j'_{kh}(q)(\delta q) = (\alpha q + z_{kh}(q), \delta q)_I$$

with the discrete adjoint solution  $z_{kh} = z_{kh}(q) \in X_{k,h}^{r,s}$  of

$$(3.13) \quad B(\varphi, z_{kh}) = (\varphi, u_{kh}(q) - \hat{u})_I \quad \forall \varphi \in X_{k,h}^{r,s}.$$

**3.3. Discretization of the controls.** To obtain the fully discrete optimal control problem we restrict the control space  $Q$  to a finite dimensional subspace  $Q_d \subset Q$ . The optimal control problem on this level of discretization is given as follows:

$$(3.14) \quad \text{Minimize } J(q_\sigma, u_\sigma) \text{ subject to (3.9) and } (q_\sigma, u_\sigma) \in Q_d \times X_{k,h}^{r,s}.$$

The unique optimal solution of (3.14) is denoted by  $(\bar{q}_\sigma, \bar{u}_\sigma) \in Q_d \times X_{k,h}^{r,s}$ , where the subscript  $\sigma$  collects the discretization parameters  $k$ ,  $h$ , and  $d$ . The optimality condition is given using the discrete reduced cost functional  $j_{kh}$  introduced in the previous section by

$$(3.15) \quad j'_{kh}(\bar{q}_\sigma)(\delta q) = 0 \quad \forall \delta q \in Q_d.$$

Most of our results presented below hold true independently of the choice of the control discretization; see Theorem 6.1. However, we present here some possibilities for construction of the discrete control space  $Q_d$ , which will play a role in the discussion of the error in the state and adjoint variables (see section 6.2) and which will be employed for the numerical example in section 7.

For the construction of  $Q_d$  it is possible to use spatial and temporal meshes, which are different from those employed for the discretization of the state variable. However, for simplicity of notation we will use the same time-partitioning (3.1). Using a spatial mesh  $\mathcal{T}_{h_d}$  we consider two corresponding finite element spaces:

$$V_{h_d}^{s_d} = \{v \in C(\bar{\Omega}) \mid v|_K \in \mathcal{Q}_{s_d}(K) \text{ for } K \in \mathcal{T}_{h_d}\}$$

and

$$\tilde{V}_{h_d}^{s_d} = \{v \in L^2(\Omega) \mid v|_K \in \mathcal{Q}_{s_d}(K) \text{ for } K \in \mathcal{T}_{h_d}\}.$$

The space  $V_{h_d}^{s_d}$  consists of continuous cellwise polynomial functions of order  $s_d$ , whereas the functions in the space  $\tilde{V}_{h_d}^{s_d}$  are discontinuous. Using these spaces we define two possibilities for the choice of  $Q_d$ .

The first possibility is similar to the construction of the state space  $X_{k,h}^{r,s}$ , consisting of functions which are continuous in space and discontinuous in time, and results in the following definition:

$$Q_d = \left\{ v_{kh} \in L^2(I, V_{h_d}^{s_d}) \mid v_{kh}|_{I_m} \in \mathcal{P}_{r_d}(I_m, V_{h_d}^{s_d}) \right\}.$$

We will refer to this control discretization as  $\text{cG}(s_d)\text{dG}(r_d)$ . If the control mesh  $\mathcal{T}_{h_d}$  coincides with the state mesh  $\mathcal{T}_h$  and one chooses the same order of polynomials ( $r = r_d, s = s_d$ ), then the state space  $X_{k,h}^{r,s}$  coincides with the control space  $Q_d$  in case of homogeneous Neumann boundary conditions and is a subspace of it, i.e.,  $X_{k,h}^{r,s} \subset Q_d$  in the presence of homogeneous Dirichlet boundary conditions. In this case one can show (cf. the discussion in section 6) that  $\bar{q}_{kh} = \bar{q}_\sigma$ . This means that a complete discretization of the optimal control problem is achieved already after discretization of the state equation; cf. [16].

For the second possibility we employ the space  $\tilde{V}_{h_d}^{s_d}$  of discontinuous cellwise polynomials and obtain the following definition:

$$Q_d = \left\{ v_{kh} \in L^2(I, \tilde{V}_{h_d}^{s_d}) \mid v_{kh}|_{I_m} \in \mathcal{P}_{r_d}(I_m, \tilde{V}_{h_d}^{s_d}) \right\}.$$

We will refer to this control discretization as  $\text{dG}(s_d)\text{dG}(r_d)$ . The special choice  $s_d = 0$  leads to cellwise constant discretization in space.

**4. Stability estimates for the state and adjoint equations.** The first step in proving the desired a priori estimate is to prove stability estimates for the solution of the semidiscrete (3.3) and the fully discretized (3.9) state equation. Throughout this section we discuss the uncontrolled situation and set therefore  $q = 0$ .

In the following theorem we provide a stability estimate for semidiscretization in time, which has a structure similar to the estimate on the continuous level given in Proposition 2.1. A comparable estimate is shown in [8, 9] for the case  $f = 0$ .

**THEOREM 4.1.** *For the solution  $u_k \in X_k^r$  of the  $\text{dG}(r)$  semidiscretized state equation (3.3) with right-hand side  $f \in L^2(I, H)$ , initial condition  $u_0 \in V$ , and  $q = 0$ , the stability estimate*

$$\sum_{m=1}^M \|\partial_t u_k\|_{I_m}^2 + \|\Delta u_k\|_I^2 + \sum_{m=1}^M k_m^{-1} \|[u_k]_{m-1}\|^2 \leq C \{ \|f\|_I^2 + \|\nabla u_0\|^2 \}$$

*holds. The constant  $C$  depends only on the polynomial degree  $r$  and the domain  $\Omega$ . The jump term  $[u_k]_0$  at  $t = 0$  is defined as  $u_{k,0}^+ - u_0$ .*

*Proof.* By means of the definition  $[u_k]_0 = u_{k,0}^+ - u_0$ , the solution  $u_k \in X_k^r$  of (3.3) fulfills for all  $\varphi \in \mathcal{P}_r(I_m, V)$  the following system of equations:

$$(4.1) \quad (\partial_t u_k, \varphi)_{I_m} + (\nabla u_k, \nabla \varphi)_{I_m} + ([u_k]_{m-1}, \varphi_{m-1}^+) = (f, \varphi)_{I_m}, \quad m = 1, 2, \dots, M.$$

The proof of the desired estimate consist of three steps—one for each term of the left-hand side of (4.1). The steps are based on consecutively testing with  $\varphi = -\Delta u_k$ ,  $\varphi = (t - t_{m-1})\partial_t u_k$ , and  $\varphi = [u_k]_{m-1}$ .

*Step* (i). At first, we want to choose  $\varphi = -\Delta u_k$ . For applying integration by parts in space to (4.1), it is necessary to prove  $\Delta u_k|_{I_m} \in \mathcal{P}_r(I_m, H)$ . This assertion follows immediately from applying elliptic regularity theory (cf. [11]) to the transformed time stepping equation

$$(\nabla u_k, \nabla \varphi)_{I_m} = (f - \partial_t u_k, \varphi)_{I_m} - ([u_k]_{m-1}, \varphi_{m-1}^+).$$

The fact that  $u_k|_{I_m}$  is polynomial in time with values in  $V \subseteq H$  implies that the right-hand side is in  $H$  for almost all  $t \in I_m$ . Thus,  $\Delta u_k|_{I_m}$  is also in  $H$  for almost all  $t \in I_m$ , and since  $u_k|_{I_m}$  is polynomial with respect to time, this yields  $\Delta u_k|_{I_m} \in \mathcal{P}_r(I_m, H)$ .

Consequently, it is feasible to integrate (4.1) by parts in space to obtain the formulation

$$(4.2) \quad (\partial_t u_k, \varphi)_{I_m} - (\Delta u_k, \varphi)_{I_m} + ([u_k]_{m-1}, \varphi_{m-1}^+) = (f, \varphi)_{I_m}, \quad m = 1, 2, \dots, M.$$

The arising boundary terms vanish for both homogeneous Neumann and homogeneous Dirichlet boundary conditions.

Since there are no spatial derivatives on the test function  $\varphi$  anymore, formulation (4.2) holds not only for all  $\varphi \in \mathcal{P}_r(I_m, V)$  but by the density of  $V$  in  $H$  also for all  $\varphi \in \mathcal{P}_r(I_m, H)$ . Hence, we may choose  $\varphi = -\Delta u_k$  as a test function and get, by applying integration by parts in space a second time,

$$(\partial_t \nabla u_k, \nabla u_k)_{I_m} + (\Delta u_k, \Delta u_k)_{I_m} + ([\nabla u_k]_{m-1}, \nabla u_{k,m-1}^+) = (f, -\Delta u_k)_{I_m}.$$

Again, the arising boundary terms vanish due to the prescribed homogeneous boundary conditions of Neumann or Dirichlet type.

By means of the identities

$$(4.3a) \quad (\partial_t v, v)_{I_m} = \frac{1}{2} \|v_m^-\|^2 - \frac{1}{2} \|v_{m-1}^+\|^2,$$

$$(4.3b) \quad ([v]_{m-1}, v_{m-1}^+) = \frac{1}{2} \|v_{m-1}^+\|^2 + \frac{1}{2} \|[v]_{m-1}\|^2 - \frac{1}{2} \|v_{m-1}^-\|^2,$$

we achieve

$$\frac{1}{2} \|\nabla u_{k,m}^-\|^2 + \frac{1}{2} \|[\nabla u_k]_{m-1}\|^2 - \frac{1}{2} \|\nabla u_{k,m-1}^-\|^2 + \|\Delta u_k\|_{I_m}^2 = (f, -\Delta u_k)_{I_m}.$$

Summation of the equations for  $m = 1, 2, \dots, M$  leads to

$$\frac{1}{2} \|\nabla u_{k,M}^-\|^2 + \frac{1}{2} \sum_{m=1}^M \|[\nabla u_k]_{m-1}\|^2 + \|\Delta u_k\|_I^2 = (f, -\Delta u_k)_I + \frac{1}{2} \|\nabla u_0\|^2.$$

Using Young's inequality for the right-hand side, we obtain the first intermediary result

$$(4.4) \quad \|\Delta u_k\|_I^2 \leq \|f\|_I^2 + \|\nabla u_0\|^2.$$

Step (ii). To bound the time derivative  $\partial_t u_k$ , we will use the inverse estimate

$$(4.5) \quad \|v_k\|_{I_m}^2 \leq C k_m^{-1} \int_{I_m} (t - t_{m-1}) \|v_k\|^2 dt,$$

which holds true for all  $v_k \in \mathcal{P}_r(I_m, V)$ . To obtain this estimate one transforms both sides of the inequality into the reference time interval  $[0, 1]$ , uses equivalence of norms for finite dimensional spaces, and transforms the inequality back into the real interval  $I_m$ .

We choose  $\varphi = (t - t_{m-1}) \partial_t u_k$  and obtain, utilizing the fact that  $\varphi_{m-1}^+ = 0$ ,

$$\begin{aligned} \int_{I_m} (t - t_{m-1}) \|\partial_t u_k\|^2 dt &= \int_{I_m} (t - t_{m-1}) (f + \Delta u_k, \partial_t u_k) dt \\ &\leq \left( \int_{I_m} (t - t_{m-1}) \|f + \Delta u_k\|^2 dt \right)^{\frac{1}{2}} \left( \int_{I_m} (t - t_{m-1}) \|\partial_t u_k\|^2 dt \right)^{\frac{1}{2}}. \end{aligned}$$

The inverse estimate (4.5) yields, by means of Hölder's inequality,

$$\|\partial_t u_k\|_{I_m}^2 \leq C k_m^{-1} \int_{I_m} (t - t_{m-1}) \|f + \Delta u_k\|^2 dt \leq C \{ \|f\|_{I_m}^2 + \|\Delta u_k\|_{I_m}^2 \}.$$

Then, (4.4) implies the second intermediary result

$$(4.6) \quad \sum_{m=1}^M \|\partial_t u_k\|_{I_m}^2 \leq C \{ \|f\|_I^2 + \|\nabla u_0\|^2 \}.$$

Step (iii). It remains to estimate the jump terms. To this end, we choose  $\varphi = [u_k]_{m-1}$  constant in time on  $I_m$  and obtain

$$\begin{aligned} \|[u_k]_{m-1}\|^2 &= (f + \Delta u_k - \partial_t u_k, [u_k]_{m-1})_{I_m} \\ &\leq \frac{k_m}{2} \|f + \Delta u_k - \partial_t u_k\|_{I_m}^2 + \frac{1}{2k_m} \|[u_k]_{m-1}\|_{I_m}^2. \end{aligned}$$

Since  $[u_k]_{m-1}$  is constant in time, we have  $\|[u_k]_{m-1}\|_{I_m}^2 = k_m \|[u_k]_{m-1}\|^2$ . This implies

$$k_m^{-1} \|[u_k]_{m-1}\|^2 \leq \|f + \Delta u_k - \partial_t u_k\|_{I_m}^2.$$

The results (4.4) and (4.6) yield the remaining estimate

$$\sum_{m=1}^M k_m^{-1} \|[u_k]_{m-1}\|^2 \leq C \{ \|f\|_I^2 + \|\nabla u_0\|^2 \}. \quad \square$$

The result of the previous theorem will also be applied to dual (adjoint) equations. Let  $g \in L^2(I, H)$  be a given right-hand side and  $z_T \in V$  a given terminal condition; then the corresponding semidiscretized dual equation is given by

$$(4.7) \quad B(\varphi, z_k) = (\varphi, g)_I + (\varphi_M^-, z_T) \quad \forall \varphi \in X_k^r.$$

Note that the semidiscrete adjoint solution defined in (3.7) can be obtained by setting  $g = u_k(q) - \hat{u}$  and  $z_T = 0$ .

**COROLLARY 4.2.** *For the solution  $z_k \in X_k^r$  of the semidiscrete dual equation (4.7) with right-hand side  $g \in L^2(I, H)$  and terminal condition  $z_T \in V$ , the estimate from Theorem 4.1 reads as*

$$\sum_{m=1}^M \|\partial_t z_k\|_{I_m}^2 + \|\Delta z_k\|_I^2 + \sum_{m=1}^M k_m^{-1} \|[z_k]_m\|^2 \leq C \{\|g\|_I^2 + \|\nabla z_T\|^2\}.$$

Here, the jump term  $[z_k]_M$  at  $t = T$  is defined as  $z_T - z_{k,M}^-$ .

*Proof.* Let  $z_k \in X_k^r$  be the solution of (4.7). Then formula (3.8) implies that it also fulfills for all  $\varphi \in \mathcal{P}_r(I_m, V)$  the following system of equations:

$$-(\varphi, \partial_t z_k)_{I_m} + (\nabla \varphi, \nabla z_k)_{I_m} - (\varphi_m^-, [z_k]_m) = (g, \varphi)_{I_m}, \quad m = 1, 2, \dots, M.$$

Based on this representation, all steps of the proof of Theorem 4.1 can be repeated similarly to obtain the stated result.  $\square$

For proving a priori estimates for the control problem (2.2), we will additionally need stability estimates for the  $L^2(I, H)$ -norm of the solution  $\|u_k\|_I$  and of its gradient  $\|\nabla u_k\|_I$ , which are given in the following theorem.

**THEOREM 4.3.** *For the solution  $u_k \in X_k^r$  of the dG(r) semidiscretized state equation (3.3) with right-hand side  $f \in L^2(I, H)$ , initial condition  $u_0 \in V$ , and  $q = 0$ , the stability estimate*

$$\|u_k\|_I^2 + \|\nabla u_k\|_I^2 \leq C \{\|f\|_I^2 + \|\nabla u_0\|^2 + \|u_0\|^2\}$$

holds true with a constant  $C$  that depends only on the polynomial degree  $r$ , the domain  $\Omega$ , and the final time  $T$ .

*Remark 4.4.* In the case of homogeneous Dirichlet boundary conditions, the estimate can be proved by means of Poincaré's inequality with a constant independent of  $T$ .

*Proof.* The proof is done using a duality argument: Let  $\tilde{z} \in X$  be the solution of

$$-(\varphi, \partial_t \tilde{z})_I + (\nabla \varphi, \nabla \tilde{z})_I = (\varphi, u_k)_I \quad \forall \varphi \in X$$

together with the terminal condition  $\tilde{z}(T) = \tilde{z}_T = 0$ . Thus, due to Remark 3.1, which applies similarly to dual or adjoint equations,  $\tilde{z}$  also fulfills

$$B(\varphi, \tilde{z}) = (\varphi, u_k)_I \quad \forall \varphi \in X_k^r.$$

By means of this equality, we write

$$\begin{aligned} \|u_k\|_I^2 &= B(u_k, \tilde{z}) \\ &= \sum_{m=1}^M (\partial_t u_k, \tilde{z})_{I_m} + (\nabla u_k, \nabla \tilde{z})_I + \sum_{m=2}^M ([u_k]_{m-1}, \tilde{z}(t_{m-1})) + (u_{k,0}^+, \tilde{z}(0)). \end{aligned}$$

Using the setting  $[u_k]_0 = u_{k,0}^+ - u_0$  we obtain

$$\|u_k\|_I^2 = \sum_{m=1}^M (\partial_t u_k, \tilde{z})_{I_m} + (\nabla u_k, \nabla \tilde{z})_I + \sum_{m=1}^M ([u_k]_{m-1}, \tilde{z}(t_{m-1})) + (u_0, \tilde{z}(0)),$$

from which we get, with integration by parts in space and Hölder's inequality,

$$\begin{aligned} \|u_k\|_I^2 &\leq \left( \sum_{m=1}^M \|\partial_t u_k\|_{I_m}^2 \right)^{\frac{1}{2}} \|\tilde{z}\|_I + \|\Delta u_k\|_I \|\tilde{z}\|_I \\ &\quad + \left( \sum_{m=1}^M k_m^{-1} \|[u_k]_{m-1}\|^2 \right)^{\frac{1}{2}} \left( \sum_{m=1}^M k_m \|\tilde{z}(t_{m-1})\|^2 \right)^{\frac{1}{2}} + \|u_0\| \|\tilde{z}(0)\|. \end{aligned}$$

The stability estimate for the continuous solution  $\tilde{z} \in X$

$$\max_{t \in \bar{I}} \|\tilde{z}(t)\| \leq C \|u_k\|_I,$$

which makes use of the continuity of the mapping  $u_k \mapsto \tilde{z}$  (cf. [18]) and the continuous embedding of  $X$  into  $C(\bar{I}, H)$ , implies

$$\begin{aligned} \|u_k\|_I &\leq C\sqrt{T} \left( \sum_{m=1}^M \|\partial_t u_k\|_{I_m}^2 \right)^{\frac{1}{2}} + C\sqrt{T} \|\Delta u_k\|_I \\ &\quad + C\sqrt{T} \left( \sum_{m=2}^M k_m^{-1} \|[u_k]_{m-1}\|^2 \right)^{\frac{1}{2}} + C\|u_0\|, \end{aligned}$$

from which the desired estimate for  $\|u_k\|_I^2$  follows by application of Theorem 4.1.

To prove the estimate for  $\|\nabla u_k\|_I^2$ , we proceed similarly to the proof of Theorem 4.1 and test (4.1) with  $\varphi = u_k$ . We obtain for  $m = 1, 2, \dots, M$

$$(\partial_t u_k, u_k)_{I_m} + (\nabla u_k, \nabla u_k)_{I_m} + ([u_k]_{m-1}, u_{k,m-1}^+) = (f, u_k)_{I_m}.$$

The identities (4.3) lead to

$$\frac{1}{2} \|u_{k,m}^-\|^2 + \frac{1}{2} \|[u_k]_{m-1}\|^2 - \frac{1}{2} \|u_{k,m-1}^-\|^2 + \|\nabla u_k\|_{I_m}^2 = (f, u_k)_{I_m}.$$

After summing up these equations for  $m = 1, 2, \dots, M$  and by application of Young's inequality, we have

$$\|\nabla u_k\|_I^2 \leq \frac{1}{2} \{ \|f\|_I^2 + \|u_k\|_I^2 + \|u_0\|^2 \}.$$

Insertion of the already proved estimate for  $\|u_k\|_I^2$  completes the proof.  $\square$

**COROLLARY 4.5.** *For the solution  $z_k \in X_k^r$  of the semidiscrete dual equation (4.7) with right-hand side  $g \in L^2(I, H)$  and terminal condition  $z_T \in V$ , the estimate from Theorem 4.3 reads as*

$$\|z_k\|_I^2 + \|\nabla z_k\|_I^2 \leq C \{ \|g\|_I^2 + \|\nabla z_T\|^2 + \|z_T\|^2 \}.$$

*Proof.* The proof is done similarly to the proof of Theorem 4.3.  $\square$

All the estimates proved in this section hold true also for the fully discrete cG(s)dG(r) solutions  $u_{kh}$ ,  $z_{kh} \in X_{k,h}^{r,s}$  almost without any changes. Only two differences have to be regarded: We have to replace the continuous Laplacian  $\Delta$  by a discrete analogue  $\Delta_h: V_h^s \rightarrow V_h^s$  defined by

$$(\Delta_h u, \varphi) = -(\nabla u, \nabla \varphi) \quad \forall \varphi \in V_h^s,$$

and the jump terms  $[u_{kh}]_0$  and  $[z_{kh}]_M$  are given here by means of the spatial  $L^2$ -projection  $\Pi_h: V \rightarrow V_h^s$  as

$$[u_{kh}]_0 = u_{kh,0}^+ - \Pi_h u_0 \quad \text{and} \quad [z_{kh}]_M = \Pi_h z_T - z_{kh,M}^-.$$

Here,  $z_{kh} \in X_{k,h}^{r,s}$  is the solution of the fully discretized dual equation with given right-hand side  $g \in L^2(I, H)$  and terminal condition  $z_T \in V$  given by

$$(4.8) \quad B(\varphi, z_{kh}) = (\varphi, g)_I + (\varphi_M^-, z_T) \quad \forall \varphi \in X_{k,h}^{r,s}.$$

For convenience of the reader, we state here the estimates for the fully discrete solutions.

**THEOREM 4.6.** *For the solution  $u_{kh} \in X_{k,h}^{r,s}$  of the discrete state equation (3.9) with right-hand side  $f \in L^2(I, H)$ , initial condition  $u_0 \in V$ , and  $q = 0$ , the stability estimate*

$$\sum_{m=1}^M \|\partial_t u_{kh}\|_{I_m}^2 + \|\Delta_h u_{kh}\|_I^2 + \sum_{m=1}^M k_m^{-1} \|[u_{kh}]_{m-1}\|^2 \leq C \{ \|f\|_I^2 + \|\nabla \Pi_h u_0\|^2 \}$$

*holds. The constant  $C$  depends only on the polynomial degree  $r$  and the domain  $\Omega$ . The jump term  $[u_{kh}]_0$  at  $t = 0$  is defined as  $u_{kh,0}^+ - \Pi_h u_0$ . Furthermore, the estimate*

$$\|u_{kh}\|_I^2 + \|\nabla u_{kh}\|_I^2 \leq C \{ \|f\|_I^2 + \|\nabla \Pi_h u_0\|^2 + \|\Pi_h u_0\|^2 \}$$

*holds true with a constant  $C$  that depends only on the polynomial degree  $r$ , the domain  $\Omega$ , and the final time  $T$ .*

**COROLLARY 4.7.** *For the solution  $z_{kh} \in X_{k,h}^{r,s}$  of the discrete dual equation (4.8) with right-hand side  $g \in L^2(I, H)$  and terminal condition  $z_T \in V$ , the estimates from Theorem 4.6 read as*

$$\sum_{m=1}^M \|\partial_t z_{kh}\|_{I_m}^2 + \|\Delta_h z_{kh}\|_I^2 + \sum_{m=1}^M k_m^{-1} \|[z_{kh}]_m\|^2 \leq C \{ \|g\|_I^2 + \|\nabla \Pi_h z_T\|^2 \}$$

*and*

$$\|z_{kh}\|_I^2 + \|\nabla z_{kh}\|_I^2 \leq C \{ \|g\|_I^2 + \|\nabla \Pi_h z_T\|^2 + \|\Pi_h z_T\|^2 \}.$$

*Here, the jump term  $[z_{kh}]_M$  at  $t = T$  is defined as  $\Pi_h z_T - z_{kh,M}^-$ .*

**5. Analysis of the discretization error for the state equation.** The goal of this section is to prove an a priori error estimate for the discretization error of the (uncontrolled) state equation. Due to the choice of the control space  $Q = L^2(I, L^2(\Omega))$ , we will need error estimates for the error in the state (and adjoint) variable with respect to the norm of  $L^2(I, L^2(\Omega))$ ; cf. the discussion in section 6. Similar error estimates with respect to the  $L^\infty(I, L^2(\Omega))$ -norm can be found in [8, 9], and with respect to the  $L^2(I, H^1(\Omega))$ -norm in [13].

Let  $u \in X$  be the solution of the state equation (2.1) for  $q = 0$ ,  $u_k \in X_k^r$  be the solution of the corresponding semidiscretized equation (3.3), and  $u_{kh} \in X_{k,h}^{r,s}$  be the solution of the fully discretized state equation (3.9). To separate the influences of the space and time discretizations, we split the total discretization error  $e := u - u_{kh}$  into its temporal part  $e_k := u - u_k$  and its spatial part  $e_h := u_k - u_{kh}$ . The temporal

discretization error will be estimated in the following subsection, and the spatial discretization error is treated in section 5.2.

Throughout this section we will assume that the solutions  $u \in X$  and  $u_k \in X_k^r$  possess the regularity  $\partial_t^{r+1}u \in L^2(I, L^2(\Omega))$  and  $\nabla^{s+1}u_k \in L^2(I, L^2(\Omega))$ . Note that Proposition 2.1 and Theorem 4.1 ensure this assumption for  $s = 1$  and  $r = 0$  for convex polygonal domains  $\Omega$ . Better regularity results ( $r > 0$ ,  $s > 1$ ) usually require stronger assumptions on the domain  $\Omega$  and additional compatibility relations.

**5.1. Analysis of the temporal discretization error.** In this section, we will prove the following error estimate for the temporal discretization error  $e_k$ .

**THEOREM 5.1.** *For the error  $e_k := u - u_k$  between the continuous solution  $u \in X$  of (2.1) and the  $dG(r)$  semidiscretized solution  $u_k \in X_k^r$  of (3.3), we have the error estimate*

$$\|e_k\|_I \leq Ck^{r+1}\|\partial_t^{r+1}u\|_I,$$

where the constant  $C$  is independent of the size of the time steps  $k$ .

For clarity of presentation, we divide the proof of this theorem into several steps, which are discussed in the following lemmas.

Before doing so, we define a semidiscrete projection  $\pi_k: C(\bar{I}, V) \rightarrow X_k^r$  for  $m = 1, 2, \dots, M$  by  $\pi_k u|_{I_m} \in \mathcal{P}_r(I_m, V)$  and

$$(5.1a) \quad (\pi_k u - u, \varphi)_{I_m} = 0 \quad \forall \varphi \in \mathcal{P}_{r-1}(I_m, V) \quad \text{for } r > 0,$$

$$(5.1b) \quad \pi_k u(t_m^-) = u(t_m^-).$$

In the case  $r = 0$ ,  $\pi_k u$  is defined solely by condition (5.1b). The projection  $\pi_k$  is well-defined by these conditions; see, for instance, [27] or [26]. By Proposition 2.1 the solution  $u$  of (2.1) belongs to  $C(\bar{I}, V)$ , and therefore  $\pi_k$  is applicable to the state  $u$ .

To shorten the notation in the following analysis, we introduce the abbreviations

$$\eta_k := u - \pi_k u \quad \text{and} \quad \xi_k := \pi_k u - u_k$$

and split the error  $e_k$  as

$$e_k = \eta_k + \xi_k.$$

**LEMMA 5.2.** *For the projection error  $\eta_k$  defined above, the identity*

$$B(\eta_k, \varphi) = (\nabla \eta_k, \nabla \varphi)_I$$

holds for all  $\varphi \in X_k^r$ .

*Proof.* By means of (3.8), we have

$$B(\eta_k, \varphi) = - \sum_{m=1}^M (\eta_k, \partial_t \varphi)_{I_m} + (\nabla \eta_k, \nabla \varphi)_I - \sum_{m=1}^{M-1} (\eta_{k,m}^-, [\varphi]_m) + (\eta_{k,M}^-, \varphi_{k,M}^-).$$

The term  $(\eta_k, \partial_t \varphi)_{I_m}$  vanishes due to (5.1a), and  $\eta_{k,m}^- = 0$  for all  $m$  due to (5.1b). This completes the proof.  $\square$

**LEMMA 5.3.** *The temporal discretization error  $e_k = u - u_k$  is bounded by the projection error  $\eta_k$  with respect to the  $L^2(I, L^2(\Omega))$ -norm, that is,*

$$\|e_k\|_I \leq C\|\eta_k\|_I.$$

*Proof.* We define  $\tilde{z}_k \in X_k^r$  to be the solution of

$$B(\varphi, \tilde{z}_k) = (\varphi, e_k)_I \quad \forall \varphi \in X_k^r.$$

Thus, we obtain by Galerkin orthogonality the relation  $B(\xi_k + \eta_k, \tilde{z}_k) = 0$  (cf. Remark 3.1) which implies

$$\|e_k\|_I^2 = (\xi_k, e_k)_I + (\eta_k, e_k)_I = B(\xi_k, \tilde{z}_k) + (\eta_k, e_k)_I = -B(\eta_k, \tilde{z}_k) + (\eta_k, e_k)_I.$$

Using Lemma 5.2 and integration by parts in space, and the stability estimate from Corollary 4.2, it follows that

$$-B(\eta_k, \tilde{z}_k) = -(\nabla \eta_k, \nabla \tilde{z}_k)_I = (\eta_k, \Delta \tilde{z}_k)_I \leq \|\eta_k\|_I \|\Delta \tilde{z}_k\|_I \leq C \|\eta_k\|_I \|e_k\|_I.$$

Note that the arising boundary terms vanish for both homogeneous Neumann and homogeneous Dirichlet boundary conditions. This leads, by means of Cauchy's inequality, to the desired assertion.  $\square$

LEMMA 5.4. *For the projection error  $\eta_k = u - \pi_k u$  the following estimate holds:*

$$\|\eta_k\|_{I_m} \leq C k_m^{r+1} \|\partial_t^{r+1} u\|_{I_m}.$$

*Proof.* Similarly to [27], the proof is done by standard arguments utilizing the Bramble–Hilbert lemma from [3].  $\square$

After these preparations, we are able to give the proof of Theorem 5.1.

*Proof of Theorem 5.1.* From the Lemmas 5.3 and 5.4 we directly obtain

$$\|e_k\|_I^2 \leq C \|\eta_k\|_I^2 = C \sum_{m=1}^M \|\eta_k\|_{I_m}^2 \leq C \sum_{m=1}^M k_m^{2r+2} \|\partial_t^{r+1} u\|_{I_m}^2 \leq C k^{2r+2} \|\partial_t^{r+1} u\|_I^2,$$

which implies the stated result.  $\square$

**5.2. Analysis of the spatial discretization error.** In this section we give a proof of the following result.

THEOREM 5.5. *For the error  $e_h := u_k - u_{kh}$  between the  $dG(r)$  semidiscretized solution  $u_k \in X_k^r$  of (3.3) and the fully  $cG(s)dG(r)$  discretized solution  $u_{kh} \in X_{k,h}^{r,s}$  of (3.9), we have the error estimate*

$$\|e_h\|_I \leq C h^{s+1} \|\nabla^{s+1} u_k\|_I,$$

where the constant  $C$  is independent of the mesh size  $h$  and the size of the time steps  $k$ .

Similar to the previous subsection, the proof is divided into several steps which are collected in the following lemmas.

We define the projection  $\pi_h: X_k^r \rightarrow X_{k,h}^{r,s}$  by means of the spatial  $L^2$ -projection  $\Pi_h: V \rightarrow V_h^s$  pointwise in time as

$$(\pi_h u_k)(t) = \Pi_h u_k(t).$$

For the solutions of the semidiscrete and fully discretized state equations  $u_k \in X_k^r$  and  $u_{kh} \in X_{k,h}^{r,s}$ , and for  $\tilde{z}_k \in X_k^r$  being the solution of the dual equation (4.7) with right-hand side  $g = e_h$  and terminal condition  $\tilde{z}_T = 0$ , we use the abbreviations

$$\eta_h := u_k - \pi_h u_k, \quad \xi_h := \pi_h u_k - u_{kh}, \quad \text{and} \quad \eta_h^* := \tilde{z}_k - \pi_h \tilde{z}_k,$$

and split the error  $e_h$  as

$$e_h = \eta_h + \xi_h.$$

LEMMA 5.6. *For the projection errors  $\eta_h$  and  $\eta_h^*$  defined above, the identities*

$$B(\eta_h, \varphi) = (\nabla \eta_h, \nabla \varphi)_I \quad \text{and} \quad B(\varphi, \eta_h^*) = (\nabla \varphi, \nabla \eta_h^*)_I$$

hold for all  $\varphi \in X_{k,h}^{r,s}$ .

*Proof.* As in the proof of Lemma 5.2 we obtain

$$\begin{aligned} B(\eta_h, \varphi) &= - \sum_{m=1}^M (\eta_h, \partial_t \varphi)_{I_m} + (\nabla \eta_h, \nabla \varphi)_I - \sum_{m=1}^{M-1} (\eta_{h,m}^-, [\varphi]_m) + (\eta_{h,M}^-, \varphi_M^-) \\ &= (\nabla \eta_h, \nabla \varphi)_I \end{aligned}$$

by means of the definition of  $\pi_h$ . The assertion for  $B(\varphi, \eta_h^*)$  follows directly when employing representation (3.2) instead of (3.8).  $\square$

LEMMA 5.7. *For the error  $\xi_h$  and the projection error  $\eta_h$ , the estimate*

$$\|\nabla \xi_h\|_I \leq \|\nabla \eta_h\|_I$$

holds.

*Proof.* As in [13], we have for all  $v \in X_k^r$  by (3.2) and (3.8)

$$\begin{aligned} B(v, v) &= \sum_{m=1}^M (\partial_t v, v)_{I_m} + (\nabla v, \nabla v)_I + \sum_{m=1}^{M-1} ([v]_m, v_m^+) + (v_0^+, v_0^+), \\ B(v, v) &= - \sum_{m=1}^M (v, \partial_t v)_{I_m} + (\nabla v, \nabla v)_I + \sum_{m=1}^{M-1} (-v_m^-, [v]_m) + (v_M^-, v_M^-). \end{aligned}$$

We arrive at

$$B(v, v) \geq (\nabla v, \nabla v)_I$$

by adding these two identities. Utilizing the Galerkin orthogonality of the space discretization, we obtain

$$\|\nabla \xi_h\|_I^2 = (\nabla \xi_h, \nabla \xi_h)_I \leq B(\xi_h, \xi_h) = -B(\eta_h, \xi_h) = -(\nabla \eta_h, \nabla \xi_h)_I \leq \|\nabla \eta_h\|_I \|\nabla \xi_h\|_I.$$

Division by  $\|\nabla \xi_h\|_I$  leads to the asserted result.  $\square$

LEMMA 5.8. *For the projection errors  $\eta_h$  and  $\eta_h^*$  we have the intermediary result*

$$B(\eta_h, \eta_h^*) \leq \|\nabla \eta_h\|_I \|\nabla \eta_h^*\|_I + C \|\eta_h\|_I \|e_h\|_I.$$

*Proof.* Since  $\pi_h \tilde{z}_k \in X_{k,h}^{r,s}$ , it holds by (3.8) and the definition of  $\pi_h$  that

$$B(\eta_h, \eta_h^*) = - \sum_{m=1}^M (\eta_h, \partial_t \tilde{z}_k)_{I_m} + (\nabla \eta_h, \nabla \eta_h^*)_I - \sum_{m=1}^{M-1} (\eta_{h,m}^-, [\tilde{z}_k]_m) + (\eta_{h,M}^-, \tilde{z}_{k,M}^-).$$

Using  $\tilde{z}_T = 0$ , we subtract the term  $(\eta_{h,M}^-, \tilde{z}_T)$  and obtain by means of the definition  $[\tilde{z}_k]_M = \tilde{z}_T - \tilde{z}_{k,M}^-$

$$(5.2) \quad B(\eta_h, \eta_h^*) = - \sum_{m=1}^M (\eta_h, \partial_t \tilde{z}_k)_{I_m} + (\nabla \eta_h, \nabla \eta_h^*)_I - \sum_{m=1}^M (\eta_{h,m}^-, [\tilde{z}_k]_m).$$

Now, we separately treat the three terms on the right-hand side above: For the term containing spatial derivatives, we have immediately

$$(5.3) \quad (\nabla \eta_h, \nabla \eta_h^*)_I \leq \|\nabla \eta_h\|_I \|\nabla \eta_h^*\|_I.$$

For the term containing the time derivatives, we achieve by Cauchy's inequality and with the stability estimate from Corollary 4.2

$$(5.4) \quad - \sum_{m=1}^M (\eta_h, \partial_t \tilde{z}_k)_{I_m} \leq \|\eta_h\|_I \left( \sum_{m=1}^M \|\partial_t \tilde{z}_k\|_{I_m}^2 \right)^{\frac{1}{2}} \leq C \|\eta_h\|_I \|e_h\|_I.$$

For the jump terms, we obtain again by Cauchy's inequality

$$- \sum_{m=1}^M (\eta_{h,m}^-, [\tilde{z}_k]_m) \leq \left( \sum_{m=1}^M k_m \|\eta_{h,m}^-\|^2 \right)^{\frac{1}{2}} \left( \sum_{m=1}^M k_m^{-1} \|[\tilde{z}_k]_m\|^2 \right)^{\frac{1}{2}}.$$

Utilizing the inverse estimate (cf. [8])

$$k_m \|\eta_{h,m}^-\|^2 \leq C \|\eta_h\|_{I_m}^2,$$

which holds true for polynomials in time, and the stability estimate from Corollary 4.2, we finally obtain

$$(5.5) \quad - \sum_{m=1}^M (\eta_{h,m}^-, [\tilde{z}_k]_m) \leq C \|\eta_h\|_I \|e_h\|_I.$$

We complete the proof by inserting the three estimates (5.3), (5.4), and (5.5) into (5.2).  $\square$

We are now prepared to give the proof of Theorem 5.5.

*Proof of Theorem 5.5.* The solution  $\tilde{z}_k \in X_k^r$  defined above satisfies

$$B(\varphi, \tilde{z}_k) = (\varphi, e_h)_I \quad \forall \varphi \in X_k^r.$$

Due to Galerkin orthogonality, which is applicable for  $\pi_h \tilde{z}_k \in X_{k,h}^{r,s}$ , the identity

$$\|e_h\|_I^2 = B(e_h, \tilde{z}_k) = B(e_h, \tilde{z}_k - \pi_h \tilde{z}_k) = B(\xi_h, \eta_h^*) + B(\eta_h, \eta_h^*)$$

is fulfilled. For the first term we obtain, using Lemma 5.6 and Lemma 5.7,

$$B(\xi_h, \eta_h^*) = (\nabla \xi_h, \nabla \eta_h^*)_I \leq \|\nabla \xi_h\|_I \|\nabla \eta_h^*\|_I \leq \|\nabla \eta_h\|_I \|\nabla \eta_h^*\|_I.$$

This yields, together with Lemma 5.8,

$$(5.6) \quad \|e_h\|_I^2 \leq 2 \|\nabla \eta_h\|_I \|\nabla \eta_h^*\|_I + C \|\eta_h\|_I \|e_h\|_I.$$

Due to the definition of  $\pi_h$ , well-known a priori estimates for the spatial  $L^2$ -projection  $\Pi_h$  can be employed to directly obtain estimates for  $\eta_h$  and  $\eta_h^*$ . We have

$$\|\eta_h\|_I \leq Ch^{s+1} \|\nabla^{s+1} u_k\|_I, \quad \|\nabla \eta_h\|_I \leq Ch^s \|\nabla^{s+1} u_k\|_I, \quad \|\nabla \eta_h^*\|_I \leq Ch \|\nabla^2 \tilde{z}_k\|_I.$$

These estimates applied to (5.6) lead to

$$\|e_h\|_I^2 \leq Ch^{s+1} \|\nabla^{s+1} u_k\|_I \{ \|\nabla^2 \tilde{z}_k\|_I + \|e_h\|_I \}.$$

Due to the fact that the domain  $\Omega$  is polygonal and convex, elliptic regularity theory yields

$$\|\nabla^2 z_k\|_I \leq C \|\Delta z_k\|_I,$$

and we obtain the stated result by the stability estimate from Corollary 4.2.  $\square$

**6. Error analysis for the optimal control problem.** In this section, we prove the main results of this article, namely, an estimate of the error between the solution  $(\bar{q}, \bar{u})$  of the continuous optimal control problem (2.2) and the solution  $(\bar{q}_\sigma, \bar{u}_\sigma)$  of the discretized problem (3.14).

Throughout this section, we will indicate the dependence of the state and the adjoint state on the specific control  $q \in Q$  by the notation introduced in section 2 and section 3, that is,  $u(q)$ ,  $z(q)$  on the continuous level,  $u_k(q)$ ,  $z_k(q)$  on the semidiscrete and  $u_{kh}(q)$ ,  $z_{kh}(q)$  on the discrete level.

**6.1. Error in the control variable.** In this section we analyze the error with respect to the control variable and prove the following result.

**THEOREM 6.1.** *The error between the solution  $\bar{q} \in Q$  of the continuous optimization problem (2.2) and the solution  $\bar{q}_\sigma \in Q_d$  of the discrete optimization problem (3.14) can be estimated as*

$$\begin{aligned} \|\bar{q} - \bar{q}_\sigma\|_I &\leq \frac{C}{\alpha} k^{r+1} \{ \|\partial_t^{r+1} u(\bar{q})\|_I + \|\partial_t^{r+1} z(\bar{q})\|_I \} \\ &\quad + \frac{C}{\alpha} h^{s+1} \{ \|\nabla^{s+1} u_k(\bar{q})\|_I + \|\nabla^{s+1} z_k(\bar{q})\|_I \} + \left( 2 + \frac{C}{\alpha} \right) \inf_{p_d \in Q_d} \|\hat{q} - p_d\|_I, \end{aligned}$$

where  $\hat{q} \in Q$  can be chosen either as the continuous solution  $\bar{q}$  or as the solution  $\bar{q}_{kh}$  of the purely state discretized problem (3.10). The constants  $C$  are independent of the mesh size  $h$ , the size of the time steps  $k$ , and the choice of the discrete control space  $Q_d \subset Q$ .

We first discuss the infimum term appearing on the right-hand side of the error estimate above. Thereby, we make use of the two possible formulations of this term for  $\hat{q} = \bar{q}$  or  $\hat{q} = \bar{q}_{kh}$ : From the optimality conditions (3.11) for the optimal control problem (3.10) obtained after the discretization of the state equation in space and time, we get

$$(\bar{q}_{kh}, \delta q)_I = \frac{1}{\alpha} (z_{kh}(\bar{q}_{kh}), \delta q)_I \quad \forall \delta q \in Q,$$

and therefore  $\bar{q}_{kh} = \frac{1}{\alpha} z_{kh}(\bar{q}_{kh}) \in X_{k,h}^{r,s} \subset Q$ . Thus, if  $Q_d$  is chosen such that  $Q_d \supset X_{k,h}^{r,s}$ , the term

$$\inf_{p_d \in Q_d} \|\bar{q}_{kh} - p_d\|_I$$

vanishes. In this case, the solution  $\bar{q}_\sigma$  of the fully discretized optimal control problem (3.14) coincides with the solution  $\bar{q}_{kh}$ ; cf. [16]. Consequently, it is reasonable to discretize the control at most as fine as the adjoint state. The same conclusion can be drawn by inspection of the a posteriori error estimates developed in [21].

If the discrete control space  $Q_d$  does not fulfill the condition  $Q_d \supset X_{k,h}^{r,s}$ , it is desirable to choose  $\hat{q} = \bar{q}$  in the above theorem to obtain an estimate for the infimum term. For both choices of the space  $Q_d$  described in section 3.3 we obtain the following estimate using interpolation theory:

$$\inf_{p_d \in Q_d} \|\bar{q} - p_d\|_I \leq Ck^{r_d+1} \|\partial_t^{r_d+1} \bar{q}\|_I + Ch_d^{s_d+1} \|\nabla^{s_d+1} \bar{q}\|_I.$$

Here,  $h_d$  is the discretization parameter corresponding to the spatial mesh employed for the control discretization.

The proof of Theorem 6.1 makes use of the assertions of the following lemmas and will be given at the end of this section.

LEMMA 6.2. *Let  $q \in Q$  be a given control. The error between the continuous state  $u = u(q) \in X$  determined by (2.1) and the discrete state  $u_{kh} = u_{kh}(q) \in X_{k,h}^{r,s}$  determined by (3.9) can be estimated as*

$$\|u(q) - u_{kh}(q)\|_I \leq Ck^{r+1} \|\partial_t^{r+1} u(q)\|_I + Ch^{s+1} \|\nabla^{s+1} u_k(q)\|_I.$$

For the error between the continuous adjoint state  $z = z(q) \in X$  determined by (2.5) and the discrete adjoint state  $z_{kh} = z_{kh}(q) \in X_{k,h}^{r,s}$  determined by (3.13), the following estimate holds:

$$\begin{aligned} \|z(q) - z_{kh}(q)\|_I &\leq Ck^{r+1} \{ \|\partial_t^{r+1} u(q)\|_I + \|\partial_t^{r+1} z(q)\|_I \} \\ &\quad + Ch^{s+1} \{ \|\nabla^{s+1} u_k(q)\|_I + \|\nabla^{s+1} z_k(q)\|_I \}. \end{aligned}$$

*Proof.* The estimate for the error in terms of the state variable is immediately obtained by Theorems 5.1 and 5.5 since for  $q \in Q$  the right-hand side  $f + q$  of the state equation (2.1) is in  $L^2(I, H)$  and thus fulfills the assumptions of Proposition 2.1.

For estimating the error in  $z$ , we introduce additionally the solutions  $\tilde{z}_k \in X_k^r$  and  $\tilde{z}_{kh} \in X_{k,h}^{r,s}$  which solve

$$\begin{aligned} B(\varphi, \tilde{z}_k) &= (\varphi, u(q) - \hat{u})_I \quad \forall \varphi \in X_k^r \quad \text{and} \\ B(\varphi, \tilde{z}_{kh}) &= (\varphi, u_k(q) - \hat{u})_I \quad \forall \varphi \in X_{k,h}^{r,s}. \end{aligned}$$

Since the adjoint solution  $z(q) \in X$  is determined by (2.5), we may apply Theorem 5.1 to obtain

$$\|z(q) - \tilde{z}_k\|_I \leq Ck^{r+1} \|\partial_t^{r+1} z(q)\|_I.$$

Correspondingly, due to the definition of the semidiscrete adjoint solution  $z_k(q) \in X_k^r$  by (3.7), Theorem 5.5 yields the estimate

$$\|z_k(q) - \tilde{z}_{kh}\|_I \leq Ch^{s+1} \|\nabla^{s+1} z_k(q)\|_I.$$

Using (3.7) for  $z_k(q)$ , we obtain that the difference  $\tilde{z}_k - z_k(q)$  solves

$$B(\varphi, \tilde{z}_k - z_k(q)) = (\varphi, u(q) - u_k(q))_I \quad \forall \varphi \in X_k^r.$$

Then, the stability estimate from Corollary 4.2 yields

$$\|\tilde{z}_k - z_k(q)\|_I \leq C\|u(q) - u_k(q)\|_I.$$

Similarly, using (3.13) for  $z_{kh}(q)$ , we obtain for the difference  $\tilde{z}_{kh} - z_{kh}(q)$  the identity

$$B(\varphi, \tilde{z}_{kh} - z_{kh}(q)) = (\varphi, u_k(q) - u_{kh}(q))_I \quad \forall \varphi \in X_{k,h}^{r,s},$$

and the stability estimate from Corollary 4.7 implies

$$\|\tilde{z}_{kh} - z_{kh}(q)\|_I \leq C\|u_k(q) - u_{kh}(q)\|_I.$$

Finally, the triangle inequality and the error estimates from Theorems 5.1 and 5.5 for the error in the state variable lead to the proposed result.  $\square$

LEMMA 6.3. *For given controls  $q, r \in Q$ , the difference between the derivatives of the continuous reduced functional  $j$  and the discrete reduced functional  $j_{kh}$  can be estimated by*

$$|j'(q)(r) - j'_{kh}(q)(r)| \leq \|z(q) - z_{kh}(q)\|_I \|r\|_I.$$

*Proof.* The representations (2.6) and (3.12) for  $j'$  and  $j'_{kh}$ , respectively, imply directly the assertion

$$|j'(q)(r) - j'_{kh}(q)(r)| = |(z(q) - z_{kh}(q), r)_I| \leq \|z(q) - z_{kh}(q)\|_I \|r\|_I. \quad \square$$

LEMMA 6.4. *The derivatives of the discrete reduced functional  $j_{kh}$  are Lipschitz continuous on  $Q$ . That is, for arbitrary  $p, q, r \in Q$ , the estimate*

$$|j'_{kh}(q)(r) - j'_{kh}(p)(r)| \leq (C + \alpha)\|q - p\|_I \|r\|_I$$

*holds true.*

*Proof.* By means of (3.12), we have

$$\begin{aligned} |j'_{kh}(q)(r) - j'_{kh}(p)(r)| &\leq \alpha|(q - p, r)_I| + |(z_{kh}(q) - z_{kh}(p), r)_I| \\ &\leq \alpha\|q - p\|_I \|r\|_I + \|z_{kh}(q) - z_{kh}(p)\|_I \|r\|_I. \end{aligned}$$

Since  $z_{kh}(q) - z_{kh}(p)$  solves

$$B(\varphi, z_{kh}(q) - z_{kh}(p)) = (\varphi, u_{kh}(q) - u_{kh}(p))_I \quad \forall \varphi \in X_{k,h}^{r,s},$$

and  $u_{kh}(q) - u_{kh}(p)$  satisfies

$$B(u_{kh}(q) - u_{kh}(p), \varphi) = (q - p, \varphi)_I \quad \forall \varphi \in X_{k,h}^{r,s},$$

the stability estimates for  $z_{kh}$  from Corollary 4.7 and for  $u_{kh}$  from Theorem 4.6 yield

$$\|z_{kh}(q) - z_{kh}(p)\|_I \leq C\|u_{kh}(q) - u_{kh}(p)\|_I \leq C\|q - p\|_I,$$

which implies the desired result.  $\square$

With the aid of these preliminary results, we now prove Theorem 6.1.

*Proof of Theorem 6.1.* To obtain the asserted result, we split the error to be estimated in two different ways:

$$(6.1) \quad \|\bar{q} - \bar{q}_\sigma\|_I \leq \|\bar{q} - p_d\|_I + \|p_d - \bar{q}_\sigma\|_I,$$

$$(6.2) \quad \|\bar{q} - \bar{q}_\sigma\|_I \leq \|\bar{q} - \bar{q}_{kh}\|_I + \|\bar{q}_{kh} - p_d\|_I + \|p_d - \bar{q}_\sigma\|_I.$$

Here,  $p_d$  is an arbitrary element of  $Q_d$  and  $\bar{q}$ ,  $\bar{q}_{kh}$ , and  $\bar{q}_\sigma$  are the optimal solutions on the different levels of discretization.

Due to the linear-quadratic structure of the optimal control problem under consideration, we have for all  $p, r \in Q$ ,

$$j''_{kh}(p)(r, r) \geq \alpha \|r\|_I^2,$$

and  $j''_{kh}(p)$  does not depend on  $p$ . This implies, for arbitrary  $p, p_d \in Q_d$ ,

$$\alpha \|p_d - \bar{q}_\sigma\|_I^2 \leq j''_{kh}(p)(p_d - \bar{q}_\sigma, p_d - \bar{q}_\sigma) = j'_{kh}(p_d)(p_d - \bar{q}_\sigma) - j'_{kh}(\bar{q}_\sigma)(p_d - \bar{q}_\sigma).$$

Since  $\bar{q}$ ,  $\bar{q}_{kh}$ , and  $\bar{q}_\sigma$  are the optimal solutions of the continuous, semidiscrete, and discrete optimization problems, we have by (2.4), (3.11), and (3.15),

$$j'_{kh}(\bar{q}_\sigma)(p_d - \bar{q}_\sigma) = j'_{kh}(\bar{q}_{kh})(p_d - \bar{q}_\sigma) = j'(\bar{q})(p_d - \bar{q}_\sigma) = 0.$$

Using these identities, we obtain for the separation (6.1) (which we use to prove the theorem in the case  $\hat{q} = \bar{q}$ ) the estimate

$$\begin{aligned} \alpha \|p_d - \bar{q}_\sigma\|_I^2 &\leq j'_{kh}(p_d)(p_d - \bar{q}_\sigma) - j'(\bar{q})(p_d - \bar{q}_\sigma) \\ &= j'_{kh}(p_d)(p_d - \bar{q}_\sigma) - j'_{kh}(\bar{q})(p_d - \bar{q}_\sigma) + j'_{kh}(\bar{q})(p_d - \bar{q}_\sigma) - j'(\bar{q})(p_d - \bar{q}_\sigma). \end{aligned}$$

By means of Lemmas 6.3 and 6.4, we achieve

$$\alpha \|p_d - \bar{q}_\sigma\|_I^2 \leq (C + \alpha) \|p_d - \bar{q}\|_I \|p_d - \bar{q}_\sigma\|_I + \|z(\bar{q}) - z_{kh}(\bar{q})\|_I \|p_d - \bar{q}_\sigma\|_I.$$

Using (6.1) we get the estimate

$$(6.3) \quad \|\bar{q} - \bar{q}_\sigma\|_I \leq \frac{1}{\alpha} \|z(\bar{q}) - z_{kh}(\bar{q})\|_I + \left(2 + \frac{C}{\alpha}\right) \|\bar{q} - p_d\|_I.$$

To use separation (6.2) for proving the theorem in the case  $\hat{q} = \bar{q}_{kh}$ , we estimate alternatively by means of Lemma 6.4,

$$\alpha \|p_d - \bar{q}_\sigma\|_I^2 \leq j'_{kh}(p_d)(p_d - \bar{q}_\sigma) - j'_{kh}(\bar{q}_{kh})(p_d - \bar{q}_\sigma) \leq (C + \alpha) \|p_d - \bar{q}_{kh}\|_I \|p_d - \bar{q}_\sigma\|_I.$$

In the same manner as before, we can estimate  $\|\bar{q} - \bar{q}_{kh}\|_I$  by Lemma 6.3 as

$$\begin{aligned} \alpha \|\bar{q} - \bar{q}_{kh}\|_I^2 &\leq j''_{kh}(p)(\bar{q} - \bar{q}_{kh}, \bar{q} - \bar{q}_{kh}) \\ &= j'_{kh}(\bar{q})(\bar{q} - \bar{q}_{kh}) - j'_{kh}(\bar{q}_{kh})(\bar{q} - \bar{q}_{kh}) \\ &= j'_{kh}(\bar{q})(\bar{q} - \bar{q}_{kh}) - j'(\bar{q})(\bar{q} - \bar{q}_{kh}) \\ &\leq \|z(\bar{q}) - z_{kh}(\bar{q})\|_I \|\bar{q} - \bar{q}_{kh}\|_I. \end{aligned}$$

Then, the two latter estimates imply

$$(6.4) \quad \|\bar{q} - \bar{q}_\sigma\|_I \leq \frac{1}{\alpha} \|z(\bar{q}) - z_{kh}(\bar{q})\|_I + \left(2 + \frac{C}{\alpha}\right) \|\bar{q}_{kh} - p_d\|_I.$$

Finally, the inequalities (6.3) and (6.4) prove the assertion by means of the estimate for  $\|z(\bar{q}) - z_{kh}(\bar{q})\|_I$  from Lemma 6.2.  $\square$

To concretize the result of Theorem 6.1, we consider the following choice of discretizations: The state space is discretized by the cG(1)dG(0) method, that is, we consider the case when  $r = 0$  and  $s = 1$ . Using for simplicity the same triangulation of the spatial domain ( $h_d = h$ ) and the same distribution of the time steps ( $k_d = k$ ) as for the discretization of the state, we discuss the following two possibilities for the

control discretization (cf. section 3.3):

1. *cG(1)dG(0) discretization, i.e., cellwise (bi-/tri-)linear in space and piecewise constant in time:* In this case the infimum term in the estimate in Theorem 6.1 vanishes, since  $Q_d \supset X_{k,h}^{r,s}$ ; see the above discussion. Thus, Theorem 6.1 implies that the discretization error is of order

$$\|\bar{q} - \bar{q}_\sigma\|_I = \mathcal{O}(k + h^2).$$

2. *dG(0)dG(0) discretization, i.e., cellwise constant in space and piecewise constant in time:* In this case the infimum term of the error estimation from Theorem 6.1 has to be taken into account, leading to the discretization error of order

$$\|\bar{q} - \bar{q}_\sigma\|_I = \mathcal{O}(k + h).$$

Note that the regularity of the optimal solutions required for these estimates is ensured by Propositions 2.1 and 2.2 for the continuous solutions  $q$ ,  $u$ , and  $z$ , and by Theorem 4.1 and Corollary 4.2 for the time-discrete solutions  $u_k$  and  $z_k$ . A numerical validation of these estimates will be given in section 7.

**6.2. Error in the state and in the adjoint variable.** In this subsection we prove error estimates for the state and adjoint state variables. That is, we consider the discretization errors

$$\|\bar{u} - \bar{u}_\sigma\|_I = \|u(\bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I \quad \text{and} \quad \|\bar{z} - \bar{z}_\sigma\|_I = \|z(\bar{q}) - z_{kh}(\bar{q}_\sigma)\|_I.$$

By means of the stability estimates derived in section 4, one simply obtains the following result.

**THEOREM 6.5.** *Let  $(\bar{q}, \bar{u})$  be the solution of the continuous optimal control problem (2.2) and  $\bar{z} = z(\bar{q})$  be the corresponding adjoint state. Let, moreover,  $(\bar{q}_\sigma, \bar{u}_\sigma)$  be the solution of the discrete optimal control problem (3.14) with the corresponding discrete adjoint state  $\bar{z}_\sigma = z_{kh}(\bar{q}_\sigma)$ . Then, the following estimates hold:*

- (i)  $\|\bar{u} - \bar{u}_\sigma\|_I \leq \|u(\bar{q}) - u_{kh}(\bar{q})\|_I + C\|\bar{q} - \bar{q}_\sigma\|_I,$
- (ii)  $\|\bar{z} - \bar{z}_\sigma\|_I \leq \|z(\bar{q}) - z_{kh}(\bar{q})\|_I + C\|\bar{q} - \bar{q}_\sigma\|_I.$

*Proof.* Using the fact that  $\bar{u} = u(\bar{q})$  and  $\bar{u}_\sigma = u_{kh}(\bar{q}_\sigma)$ , we have

$$(6.5) \quad \|\bar{u} - \bar{u}_\sigma\|_I \leq \|u(\bar{q}) - u_{kh}(\bar{q})\|_I + \|u_{kh}(\bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I.$$

By means of the stability result from Theorem 4.6, we obtain

$$\|u_{kh}(\bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I \leq C\|\bar{q} - \bar{q}_\sigma\|_I.$$

This proves the first assertion. The second assertion follows in the same way utilizing the stability of the adjoint state given by Corollary 4.7.  $\square$

Employing the discretization of the control by cG(1)dG(0), the above theorem leads to the optimal order of convergence using Lemma 6.2 and Theorem 6.1. That is, we have

$$\begin{aligned} \|u(\bar{q}) - u_{kh}(\bar{q})\|_I &= \mathcal{O}(k + h^2), & \|z(\bar{q}) - z_{kh}(\bar{q})\|_I &= \mathcal{O}(k + h^2), \\ \|\bar{q} - \bar{q}_\sigma\|_I &= \mathcal{O}(k + h^2), \end{aligned}$$

and thus

$$\|\bar{u} - \bar{u}_\sigma\|_I = \mathcal{O}(k + h^2) \quad \text{and} \quad \|\bar{z} - \bar{z}_\sigma\|_I = \mathcal{O}(k + h^2).$$

However, in the case of dG(0)dG(0) discretization, this theorem does not lead to the optimal order of convergence: In this case, we have indeed as before,

$$\|u(\bar{q}) - u_{kh}(\bar{q})\|_I = \mathcal{O}(k + h^2) \quad \text{and} \quad \|z(\bar{q}) - z_{kh}(\bar{q})\|_I = \mathcal{O}(k + h^2)$$

since the discretization of the state space is unaffected by the discretization of the controls, but we have only

$$\|\bar{q} - \bar{q}_\sigma\|_I = \mathcal{O}(k + h)$$

due to the first order discretization of the control space. This would lead to  $\mathcal{O}(k + h)$  for the state and the adjoint variable.

Utilizing a more detailed analysis, we can prove also in this case the optimal order of convergence  $\mathcal{O}(k + h^2)$  for the errors  $\|\bar{u} - \bar{u}_\sigma\|_I$  and  $\|\bar{z} - \bar{z}_\sigma\|_I$ .

For both choices of the space  $Q_d$  described in section 3.3 the following results hold.

**THEOREM 6.6.** *Let  $(\bar{q}, \bar{u})$  be the solution of the continuous optimal control problem (2.2) and  $\bar{z} = z(\bar{q})$  be the corresponding adjoint state. Let, moreover,  $(\bar{q}_\sigma, \bar{u}_\sigma)$  be the solution of the discrete optimal control problem (3.14) with the corresponding discrete adjoint state  $\bar{z}_\sigma = z_{kh}(\bar{q}_\sigma)$ . In addition we assume  $r = r_d$ , i.e., the same discretization of the state and control variable in time. Then, the following estimates hold:*

$$\begin{aligned} \text{(i)} \quad & \|\bar{u} - \bar{u}_\sigma\|_I \leq \|u(\bar{q}) - u_{kh}(\bar{q})\|_I + Ch_d \left(1 + \frac{1}{\alpha}\right) \|\bar{q} - \pi_d \bar{q}\|_I + \frac{C}{\alpha} \|z(\bar{q}) - z_{kh}(\bar{q})\|_I, \\ \text{(ii)} \quad & \|\bar{z} - \bar{z}_\sigma\|_I \leq Ch_d \left(1 + \frac{1}{\alpha}\right) \|\bar{q} - \pi_d \bar{q}\|_I + C \left(1 + \frac{1}{\alpha}\right) \|z(\bar{q}) - z_{kh}(\bar{q})\|_I, \end{aligned}$$

where  $\pi_d: Q \rightarrow Q_d$  is the space-time  $L^2$ -projection on  $Q_d$ .

*Proof.* For proving (i) we split the error  $\|\bar{u} - \bar{u}_\sigma\|_I$  as follows:

$$(6.6) \quad \|\bar{u} - \bar{u}_\sigma\|_I \leq \|u(\bar{q}) - u_{kh}(\bar{q})\|_I + \|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I + \|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I.$$

The second term on the right-hand side of (6.6) is estimated using the following duality argument: Let  $\tilde{z}_{kh} \in X_{k,h}^{r,s}$  be the solution of

$$B(\varphi, \tilde{z}_{kh}) = (\varphi, u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q}))_I \quad \forall \varphi \in X_{k,h}^{r,s}.$$

By means of the discrete state equation (3.9) for  $u_{kh}(\bar{q})$  and  $u_{kh}(\pi_d \bar{q})$ , we obtain

$$\|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I^2 = B(u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q}), \tilde{z}_{kh}) = (\bar{q} - \pi_d \bar{q}, \tilde{z}_{kh})_I.$$

Since  $\pi_d$  is the  $L^2$ -projection, we have

$$(6.7) \quad \|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I^2 = (\bar{q} - \pi_d \bar{q}, \tilde{z}_{kh} - \pi_d \tilde{z}_{kh})_I \leq \|\bar{q} - \pi_d \bar{q}\|_I \|\tilde{z}_{kh} - \pi_d \tilde{z}_{kh}\|_I.$$

Using the fact that  $r = r_d$  and that therefore the same time discretization is employed for the control and state variable, the space-time  $L^2$ -projection  $\pi_d$  applied to  $\tilde{z}_{kh}$  can be expressed as spatial  $L^2$ -projection  $\Pi_{h_d} \tilde{z}_{kh}$ .

Applying an interpolation estimate and the stability estimate from Corollary 4.7 we obtain

$$\|\tilde{z}_{kh} - \pi_d \tilde{z}_{kh}\|_I = \|\tilde{z}_{kh} - \Pi_{h_d} \tilde{z}_{kh}\|_I \leq Ch_d \|\nabla \tilde{z}_{kh}\|_I \leq Ch_d \|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I.$$

Plugging this estimate into (6.7) yields

$$(6.8) \quad \|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I \leq Ch_d \|\bar{q} - \pi_d \bar{q}\|_I.$$

For the third term in (6.6) we obtain, using Theorem 4.6,

$$\|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I \leq C \|\pi_d \bar{q} - \bar{q}_\sigma\|_I.$$

For estimating the term  $\|\pi_d \bar{q} - \bar{q}_\sigma\|_I$  we proceed as in the proof of Theorem 6.1 for the term  $\|p_d - \bar{q}_\sigma\|_I$ :

$$\alpha \|\pi_d q - q_\sigma\|_I^2 \leq j'_{kh}(\pi_d q)(\pi_d q - q_\sigma) - j'(q)(\pi_d q - q_\sigma).$$

Using representation (3.12) of  $j'_{kh}$  and (2.6) of  $j'$  we have

$$\alpha \|\pi_d \bar{q} - \bar{q}_\sigma\|_I^2 \leq \alpha (\pi_d \bar{q} - \bar{q}, \pi_d \bar{q} - \bar{q}_\sigma)_I + (z_{kh}(\pi_d \bar{q}) - z(\bar{q}), \pi_d \bar{q} - \bar{q}_\sigma)_I.$$

Since  $\pi_d \bar{q} - \bar{q}_\sigma \in Q_d$ , the term  $(\pi_d \bar{q} - \bar{q}, \pi_d \bar{q} - \bar{q}_\sigma)_I$  vanishes, and due to Corollary 4.7, we end up with

$$\begin{aligned} \alpha \|\pi_d \bar{q} - \bar{q}_\sigma\|_I &\leq \|z_{kh}(\pi_d \bar{q}) - z(\bar{q})\|_I \\ &\leq \|z_{kh}(\pi_d \bar{q}) - z_{kh}(\bar{q})\|_I + \|z_{kh}(\bar{q}) - z(\bar{q})\|_I \\ &\leq C \|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q})\|_I + \|z_{kh}(\bar{q}) - z(\bar{q})\|_I, \end{aligned}$$

which implies, by using (6.8), the estimate

$$\begin{aligned} (6.9) \quad \|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I &\leq \frac{C}{\alpha} \|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q})\|_I + \frac{C}{\alpha} \|z_{kh}(\bar{q}) - z(\bar{q})\|_I \\ &\leq \frac{C}{\alpha} h_d \|\bar{q} - \pi_d \bar{q}\|_I + \frac{C}{\alpha} \|z_{kh}(\bar{q}) - z(\bar{q})\|_I. \end{aligned}$$

Plugging (6.8) and (6.9) into (6.6) we complete the proof of (i). The assertion (ii) follows using (6.8), (6.9), and the following estimate exploiting the stability result from Corollary 4.7:

$$\begin{aligned} \|\bar{z} - \bar{z}_\sigma\|_I &\leq \|z(\bar{q}) - z_{kh}(\bar{q})\|_I + \|z_{kh}(\bar{q}) - z_{kh}(\pi_d \bar{q})\|_I + \|z_{kh}(\pi_d \bar{q}) - z_{kh}(\bar{q}_\sigma)\|_I \\ &\leq \|z(\bar{q}) - z_{kh}(\bar{q})\|_I + C \|u_{kh}(\bar{q}) - u_{kh}(\pi_d \bar{q})\|_I + C \|u_{kh}(\pi_d \bar{q}) - u_{kh}(\bar{q}_\sigma)\|_I. \quad \square \end{aligned}$$

For the case of dG(0)dG(0) discretization of the control space with  $h_d = h$  and  $k_d = k$  this theorem leads to the improved (optimal) order of convergence

$$\|\bar{u} - \bar{u}_\sigma\|_I = \mathcal{O}(k + h^2) \quad \text{and} \quad \|\bar{z} - \bar{z}_\sigma\|_I = \mathcal{O}(k + h^2).$$

**7. Numerical results.** In this section, we are going to validate the a priori error estimates for the error in the control, state, and adjoint state numerically. To this end, we consider the following concretization of the model problem (2.2) with known analytical exact solution on  $\Omega \times I = (0, 1)^2 \times (0, 0.1)$  and homogeneous Dirichlet boundary conditions. The right-hand side  $f$ , the desired state  $\hat{u}$ , and the initial condition  $u_0$  are given in terms of the eigenfunctions

$$w_a(t, x_1, x_2) := \exp(a\pi^2 t) \sin(\pi x_1) \sin(\pi x_2), \quad a \in \mathbb{R},$$

of the operator  $\pm \partial_t - \Delta$  as

$$f(t, x_1, x_2) := -\pi^4 w_a(T, x_1, x_2),$$

$$\hat{u}(t, x_1, x_2) := \frac{a^2 - 5}{2 + a} \pi^2 w_a(t, x_1, x_2) + 2\pi^2 w_a(T, x_1, x_2),$$

$$u_0(x_1, x_2) := \frac{-1}{2 + a} \pi^2 w_a(0, x_1, x_2).$$

For this choice of data and with the regularization parameter  $\alpha$  chosen as  $\alpha = \pi^{-4}$ , the optimal solution triple  $(\bar{q}, \bar{u}, \bar{z})$  of the optimal control problem (2.2) is given by

$$\bar{q}(t, x_1, x_2) := -\pi^4 \{w_a(t, x_1, x_2) - w_a(T, x_1, x_2)\},$$

$$\bar{u}(t, x_1, x_2) := \frac{-1}{2 + a} \pi^2 w_a(t, x_1, x_2),$$

$$\bar{z}(t, x_1, x_2) := w_a(t, x_1, x_2) - w_a(T, x_1, x_2).$$

We are going to validate the estimates developed in the previous section by separating the discretization errors. That is, we consider at first the behavior of the error for a sequence of discretizations with decreasing size of the time steps and a fixed spatial triangulation with  $N = 1089$  nodes. Second, we examine the behavior of the error under refinement of the spatial triangulation for  $M = 2048$  time steps.

The state discretization is chosen as cG(1)dG(0), i.e.,  $r = 0$ ,  $s = 1$ . For the control discretization we use the same temporal and spatial meshes as for the state variable and present the result for two choices of the discrete control space  $Q_d$ : cG(1)dG(0) and dG(0)dG(0). For the following computations, we choose the free parameter  $a$  to be  $-\sqrt{5}$ . For this choice the right-hand side  $f$  and the desired state  $\hat{u}$  do not depend on time which avoids side effects introduced by numerical quadrature.

The optimal control problems are solved by the optimization library RoDoBo [23] and the finite element toolkit GASCOIGNE [14] using a conjugate gradient method applied to the reduced problem (3.14).

Figure 7.1(a) depicts the development of the error under refinement of the temporal step size  $k$ . Up to the spatial discretization error it exhibits the proven convergence order  $\mathcal{O}(k)$  for both kinds of spatial discretization of the control space. For piecewise constant control (dG(0)dG(0) discretization), the discretization error is already reached at 128 time steps, whereas in the case of bilinear control (cG(1)dG(0) discretization), the number of time steps could be increased up to  $M = 4096$  until reaching the spatial accuracy.

FIG. 7.1. Discretization error  $\|\bar{q} - \bar{q}_\sigma\|_I$ .FIG. 7.2. Discretization error  $\|\bar{u} - \bar{u}_\sigma\|_I$ .

FIG. 7.3. Discretization error  $\|\bar{z} - \bar{z}_\sigma\|_I$ .

In Figure 7.1(b) the development of the error in the control variable under spatial refinement is shown. The expected order  $\mathcal{O}(h)$  for piecewise constant control (dG(0)dG(0) discretization) and  $\mathcal{O}(h^2)$  for bilinear control (cG(1)dG(0) discretization) is observed.

Figures 7.2 and 7.3 show the errors in the state and the adjoint variables,  $\|\bar{u} - \bar{u}_\sigma\|_I$  and  $\|\bar{z} - \bar{z}_\sigma\|_I$ , for separate refinement of the time and space discretization. Thereby, we observe convergence of order  $\mathcal{O}(k + h^2)$  regardless of the type of spatial discretization used for the controls. This is consistent with the results proven in the previous section.

## THE “PRINCESS AND MONSTER” GAME ON AN INTERVAL\*

STEVE ALPERN<sup>†</sup>, ROBERT FOKKINK<sup>‡</sup>, ROY LINDELAUF<sup>‡</sup>, AND  
GEERT-JAN OLSDER<sup>‡</sup>

**Abstract.** A minimizing searcher  $S$  and a maximizing hider  $H$  move at unit speed on a closed interval until the first (*capture*, or *payoff*) time  $T = \min\{t : S(t) = H(t)\}$  that they meet. This zero-sum *princess and monster game* or less colorfully *search game with mobile hider* was proposed by Rufus Isaacs for general networks  $Q$ . While the existence and finiteness of the value  $V = V(Q)$  has been established for such games, only the circle network has been solved (value and optimal mixed strategies). It seems that the interval network  $Q = [-1, 1]$  had not been studied because it was assumed to be trivial, with value  $3/2$  and “obvious” searcher mixed strategy going equiprobably from one end to the other. We establish that this game is in fact nontrivial by showing that  $V < 3/2$ . Using a combination of continuous and discrete mixed strategies for both players, we show that  $15/11 \leq V \leq 13/9$ . The full solution of this very simple game is still open and appears difficult, though many properties of the optimal strategies are derived here.

**Key words.** differential game, search game, zero-sum game, interval

**1. Introduction.** In the final chapter of his classic book *Differential Games* [15], Rufus Isaacs introduced search games with mobile hiders, which he also called princess and monster games (see also [7], Example 1.4). A searcher (monster) and a hider (princess) move about a space  $Q$ , which we take to be a network (and later specialize to an interval). The searcher chooses as his pure strategy a path  $S = S(t)$  of known speed, which we take to be 1. He says, “We permit the princess full freedom of locomotion,” which we take to be any continuous path  $H = H(t)$ . (We will establish for the interval that she need never go faster than the searcher.) The payoff for this zero-sum game  $\Gamma(Q)$  is the capture time

$$(1) \quad T = T(S, H) = \min\{t : S(t) = H(t)\}.$$

Taking the topology of uniform convergence on compact subsets, the payoff function  $T$  is upper semicontinuous and the searcher mixed strategy space is compact Hausdorff. Consequently the minimax theorem of Alpern and Gal [4] can be used, as shown in Appendix A of [6] or [11] to establish the existence of the value  $V(Q)$ , an optimal mixed searcher strategy, and an  $\varepsilon$ -optimal hider mixed strategy. Recall that a strategy is  $\varepsilon$ -optimal if the expected payoff is at least  $V - \varepsilon$  against any strategy of the opponent. Upper bounds on  $V = V(Q)$  in terms of the structure of  $Q$  (and hence the finiteness of  $V$ ) are derived in [3]. For general networks  $Q$ , it is sometimes advantageous for the searcher to wait for a while at a node, a so-called *ambush strategy*, and these games are known to be difficult—none have been solved. So the only networks that might appear

possible to solve are those with no nodes (of degree greater than 2)—namely, the circle and the interval. The game  $\Gamma(Q)$  when  $Q$  is a circle was indeed a problem suggested by Isaacs [15, Example 12.4.2] and was solved a long time ago [20], [1]. The solution, for both players, is the *cohatu* strategy: start randomly (uniform distribution); flip a coin; if head (tails) go to antipodal point half way around circle clockwise (anticlockwise), at unit speed. No one seems to have considered this problem for the other network without nodes, the interval. It seems to have generally been believed that the game on the interval was trivial. The searcher should simply start at a random end and go directly to the other end. (Against this, the hider waits at 0 until time  $1 - \epsilon$ , then goes equiprobably to either end.)

It should be noted that this “simple” search strategy, of starting at a random end and going to the other, is indeed optimal in the related *search game with immobile hider*, also introduced by Isaacs [15, section 12.3]. Indeed, for trees [9] and trees with Eulerian networks attached [2], an optimal search strategy is to traverse a Chinese postman path (minimal covering path) equiprobably in either direction [10, 12]. Of course this is obvious for the interval, where the hider can hide uniformly or equiprobably at the ends (or many other optimal strategies—the full class has not been determined). The value is 1 for this game on an interval of length 2. A related problem on the interval, also with two mobile agents (they both have unit speed), was analyzed by Howard [14] and by Chester and Tutuncu [8]. In this rendezvous version of the problem, both players wish to *minimize* the meeting time  $T$ . Related problems have been analyzed in [13, 16, 18].

The paper is organized as follows. In section 2 we establish some elementary lemmas which restrict the strategies we need to consider in the rest of the paper. In section 3 we show that the game  $\Gamma(I)$  is not trivial by using some finitely supported mixed strategies to obtain estimates on its value  $V$ . In section 4 we obtain the bound  $V \leq 13/9$  by using a continuous mixed searcher strategy. In section 5 we obtain the bound  $V \geq 15/11$  by using a continuous mixed hider strategy.

**2. Properties of optimal strategies.** In this section we present results which restrict the strategies (pure and mixed) that we will need to consider in the remainder of the paper. We begin by noting that the pure strategy space for the hider is the space  $\mathcal{H}$  consisting of all continuous paths  $H : [0, \infty) \rightarrow I = [-1, 1]$ . For the searcher the pure strategy space  $\mathcal{S}$  consists of all paths in  $\mathcal{H}$  with Lipschitz constant 1, that is

$$(2) \quad \mathcal{S} = \{S : [0, \infty) \rightarrow I ; |S(t) - S(t')| \leq |t - t'| \quad \forall t, t' \geq 0\}.$$

If a searcher chooses paths that do not cover the entire interval, then hiding at some end gives a payoff that is infinite. This is absurd, so we may assume that searcher paths are onto. We show that once the searcher reaches an end, he should go directly to the other end, but if the hider reaches an end, he should stay there. The hider, while unrestricted in speed, need never go faster than speed 1 (the searcher’s maximum speed). We show that both players can optimally use mixed strategies which respect the symmetry of the interval, that is, the reflection  $\phi(x) = -x$ , and that in an optimal hider mixed strategy, the pure strategies do not intersect. Finally, we give some properties of optimal response searcher strategies.

We say that a pure strategy  $S$  is *end-reflecting* if whenever  $S(t_0) = \pm 1$ , we have  $|S(t) - S(t_0)| = t - t_0$  for  $t_0 \leq t \leq t_0 + 1$ . We say that a pure strategy  $H$  is *end-absorbing* if  $H(t_0) = \pm 1$  implies  $H(t) = H(t_0)$  for  $t \geq t_0$ . We say that a mixed strategy (for either player) is *symmetric* if it is invariant under the reflection  $\phi(x) = -x$ .

The first three lemmas concern pure strategies which we may ignore in our subsequent analysis because they are dominated.

**PROPOSITION 1.** *Every pure searcher strategy  $S \in \mathcal{S}$  is dominated by one which is end-reflecting.*

*Proof.* Suppose  $S$  is not end-reflecting and reaches, say,  $+1$  at first time  $t_0$ . Define  $S^*$  as  $S$  up to time  $t_0$  and then equal to  $1+t_0-t$ . Consider any  $H \in \mathcal{H}$ . If  $T(S, H) \leq t_0$ , then  $T(S^*, H) = T(S, H)$ . If  $T(S, H) = t_1 > t_0$ , then  $H(t_1) - S^*(t_1) \geq 0$ , and since  $H$  is continuous and  $H(t_0) - S^*(t_0) = H(t_0) - 1 \leq 0$  the intermediate value theorem implies that  $T(S^*, H) = t_2$  for some  $t_2$  with  $t_0 \leq t_2 \leq t_1$ . Thus in all cases the end-reflecting strategy  $S^*$  satisfies  $T(S^*, H) \leq T(S, H)$ .  $\square$

**PROPOSITION 2.** *Every pure hider strategy  $H$  is dominated by one which is end-absorbing.*

*Proof.* Assume that  $H$  is not end-absorbing and arrives at, say,  $+1$  at first time  $t_0$ . Let  $H^*$  be the end-absorbing strategy that agrees with  $H$  up to  $t_0$  and then stays at  $+1$ . Consider any  $S \in \mathcal{S}$  and assume, as we may, that  $T(S, H^*) = t_1 > t_0$ . Then  $S(t_1) = 1 \geq H(t_1)$  and  $S(t_0) < 1 = H(t_0)$  so the searcher meets the hider  $H$  between  $t_0$  and  $t_1$  by the intermediate value theorem. It follows that  $T(S, H) \leq T(S, H^*)$  for any pure searcher strategy.  $\square$

We say that a continuously differentiable function is *smooth*. By reasons that will become clear below, we may restrict the pure hider strategies to any subset that is dense in  $\mathcal{S}$ . In particular, we may consider smooth paths only, without changing the value of the game.

**PROPOSITION 3.** *Every smooth hider strategy in  $\mathcal{H}$  is dominated by one in  $\mathcal{S}$ , that is, one with speed bounded by 1.*

*Proof.* Essentially, the idea is that if  $H$  is any smooth hider and if  $H^*$  is a hider that follows  $H$  but has speed bounded by 1, then  $H^*$  cannot be caught from behind since the searcher has the same speed limit. Let  $t_0 = \inf\{t \in [0, \infty): |H'(t)| > 1\}$  and assume, as we may, that  $t_0$  is finite. Define  $H^*(t) = H(t)$  for  $t \leq t_0$ . For  $t > t_0$  the hider  $H^*$  continues to move at speed 1. Since the interval is bounded,  $H^*$  meets  $H$  at some time  $\tau > t_0$ . Now let  $t_1 = \inf\{t \in [\tau, \infty): |H'(t)| > 1\}$  and repeat the construction inductively.

Suppose that a searcher  $S$  finds  $H$  at a time  $T = T(S, H)$  when the hiders  $H$  and  $H^*$  are in different locations. So suppose that  $t_0 < T < \tau$ . By symmetry, we may assume as well that  $H'(t_0) = +1$ . Then  $H^*$  has velocity  $+1$  and  $H^*(t) < H(t)$  for all  $t \in (t_0, t_1)$ . Since  $S(T) = H(T) > H^*(T)$  and since the searcher moves with bounded speed,  $S(t) > H^*(t)$  for all  $t \in (t_0, T)$ . This implies that  $T(S, H^*) > T(S, H)$ .  $\square$

From now on, we shall only consider hider paths of speed  $\leq 1$ . We say that a hider or a searcher runs at time  $t$  if  $|H'(t)| = 1$  or  $|S'(t)| = 1$ , respectively. We now consider mixed strategies, i.e., probability measures on the Borel  $\sigma$ -algebra of  $\mathcal{S}$ .

**PROPOSITION 4.** *There is an optimal searcher mixed strategy and (for any  $\varepsilon$ ) an  $\varepsilon$ -optimal hider mixed strategy, which are invariant under the reflection  $\phi(x) = -x$ .*

*Proof.* The proof is just a special case of Theorem 3 of Alpern and Asic [3], where the existence of such strategies invariant under the isometry group (distance-preserving homeomorphisms) of a network  $Q$  is established. In the case of  $Q = I$ , this group consists just of the identity and  $\phi$ .  $\square$

The capture time  $T(S, H)$  is upper semicontinuous as a function on the pure strategies  $H \in \mathcal{H}$  and  $S \in \mathcal{S}$ . This implies that for any  $\varepsilon$  there exists a  $\varepsilon$ -optimal finite mixed strategy and in principle it is possible to determine the value of the game by considering finite mixed strategies only.

FIG. 1. The searcher strategy for  $V < 47/32$  in a space–time diagram.

**PROPOSITION 5.** Suppose the hider is using a mixed strategy concentrated on a finite number of pure strategies  $H_j \in \mathcal{S}$ ,  $j = 1, \dots, J$ . Then the optimal response by the searcher is concentrated on a finite number of strategies as well. In particular, the searcher picks a random permutation  $\sigma$  of  $1, \dots, J$  and runs towards  $H_{\sigma(j+1)}$  as soon as he has met  $H_{\sigma(j)}$ .

*Proof.* Let  $S$  be any optimal response to the hider mixed strategy. The searcher  $S$  meets the  $H_j$  in a certain order and this defines a permutation  $\sigma$  of  $1, \dots, J$ . Now it is obviously optimal for the searcher to run toward  $H_{\sigma(j+1)}$  after he has met  $H_{\sigma(j)}$ .  $\square$

This result is a simplified version of a similar observation for rendezvous on the line due to Alpern and Gal [5] (repeated as Theorem 16.10 of [6]). It follows that we can restrict our attention to pure strategies in which the searcher runs all the time. In a space–time diagram  $[-1, 1] \times [0, \infty)$ , such search paths are depicted as broken lines of slope  $\pm 1$  with finitely many turning points; see Figure 1.

**DEFINITION 6.** A pair of pure hider strategies  $H_1, H_2$  is called noncrossing if (possibly after reordering) we have  $H_1(t) \leq H_2(t)$  for all  $t \geq 0$ . If the inequality holds strictly, we say that they are nonintersecting.

For pure hider strategies  $H_1$  and  $H_2$ , define new pure strategies  $H_1 \wedge H_2(t) = \min\{H_1(t), H_2(t)\}$  and  $H_1 \vee H_2(t) = \max\{H_1(t), H_2(t)\}$ . Obviously,  $H_1 \wedge H_2$  and  $H_1 \vee H_2$  are noncrossing.

**PROPOSITION 7.** The hider strategy that mixes two pure strategies  $H_1, H_2$  with equal probability is dominated by the noncrossing hider strategy that mixes  $H_1 \wedge H_2, H_1 \vee H_2$  with equal probability. Consequently, any finite mixed hider strategy may be assumed to consist of noncrossing pure strategies.

*Proof.* Note that at for all  $t$  the sets  $\{H_1(t), H_2(t)\}$  and  $\{H_1 \wedge H_2(t), H_1 \vee H_2(t)\}$  are the same. So if  $S$  catches the first of the two original hiders  $H_1, H_2$ , then at the same time he catches the first of the noncrossing hiders  $H_1 \wedge H_2, H_1 \vee H_2$ . Denote this time by  $t_1$ . By renumbering indices or reflecting the interval we may assume that  $S(t_1) = H_1(t_1)$  and that  $H_1(t_1) \leq H_2(t_1)$ . Now under these assumptions,  $H_2$  and  $H_1 \vee H_2$  are in the same location at time  $t_1$  and the searcher is to their left. Since  $H_1 \vee H_2(t) \geq H_2(t)$  for all  $t$ , the searcher cannot catch  $H_1 \vee H_2$  before he catches  $H_2$ .  $\square$

It follows from Proposition 4 that there exist noncrossing  $\varepsilon$ -optimal hider strategies that are symmetric. Any finite collection of noncrossing paths can be approximated arbitrarily closely by a collection of nonintersecting paths. So, there exist  $\varepsilon$ -optimal mixed hider strategies that are finite, symmetric and nonintersecting.

**PROPOSITION 8.** *Any pure strategy  $H$  in a nonintersecting symmetric hider strategy is contained in half of the interval, that is,  $H(t) \in [-1, 0]$  or  $H(t) \in [0, 1]$  for all  $t$ .*

*Proof.* If the pure strategy  $H$  is used in a symmetric mixed strategy, then so is  $-H$ . If  $H(t) = 0$ , then  $H$  and  $-H$  intersects  $-H(t)$ , but the mixed strategy is nonintersecting. So either  $H(t) \neq 0$  for all  $t$  or  $H$  is immobile and remains in 0. In both cases,  $H$  is contained in half of the interval.  $\square$

**3. The interval game is not trivial.** The interval game has some fairly obvious strategies for each player that appear like they might be optimal. If any of these were indeed optimal, we would consider the game to be trivial. The purpose of this section is to show that none of these strategies are in fact optimal. For the searcher, the obvious strategy is to start at a random end and run to the other end; this gives an estimate  $V \leq 3/2$  and the bound can be obtained if the hider waits at the center until time  $1 - \varepsilon$  and then runs to a random end. For the hider, the two stationary strategies may be considered that are optimal in the immobile version of the game: one of these is to wait at a random end; the other is to wait randomly along the interval. Both guarantee  $V \geq 1$ , where 1 is the value of the immobile hider game. We show that the game is not trivial by exhibiting fairly simple strategies establishing that

$$1 < \frac{97}{75} < V < \frac{47}{32} < \frac{3}{2}.$$

Suppose that the hider starts out with the strategy of hiding at an end point  $E(t) = 1$  and symmetrically  $-E(t) = -1$ . According to Lemma 5 the optimal response of the searcher is to start at an end point and run to the other end  $A(t) = 1 - t$ , or symmetrically  $-A(t) = -1 + t$ . The strategies  $A$  and  $-A$  are what Howard [14] called the *sweepers* in his rendezvous version. The expected meeting time for this optimal response is 1 and this is a lower bound on  $V$ . Similarly, suppose that the searcher adopts the sweeper strategies  $A$  and  $-A$ . Against any hider path  $H$  either  $V(A, H) \leq 1$  or  $V(-A, H) \leq 1$ . So if the searcher adopts the sweeping strategy, then the payoff is  $\leq 3/2$  against any mixed hider strategy and this puts an upper bound on  $V$ . The game would be trivial if  $V = 1$  or  $V = 3/2$ , but it is not. In this section we show that  $1 < V < 3/2$ . It is  $\varepsilon$ -optimal against the sweeping strategy to loiter around 0 until time  $1 - \varepsilon$  and then run to one of the end points. The searcher can ambush such loiterers by adding a search path that patrols the center. More specifically, strategy  $B$  starts at 0; runs to the left; joins sweeper  $-A$  from the time  $(1/2)$  when he meets him, until reaching  $-1$ ; then (by Lemma 1) goes to  $-1$ . Strategies  $\pm A$  are each used with probability  $7/16$ , while  $\pm B$  are each used with probability  $1/16$ . The searcher strategies  $\pm A, \pm B$  are drawn in a space-time diagram in Figure 1.

We show that this mixed strategy ensures a meeting time less than  $3/2$ , though admittedly not much less.

THEOREM 9.  $V \leq \frac{47}{32} = 1.4688$ .

*Proof.* Consider the mixed strategy  $s$  in which the searcher uses  $\pm A$  each with probability  $7/16$  and  $\pm B$  each with probability  $1/16$ . Let  $H$  be *any* hiding strategy. Let  $P(t)$  denote the probability that  $T \leq t$ . There are two cases: (1)  $|H(1/2)| \leq 1/2$ , and (2)  $|H(1/2)| > 1/2$ .

- (i) In this case  $P(1/2) \geq 1/16$  (because  $B$  or  $-B$  has been met) and  $P(1) \geq 8/16$  (because also  $A$  or  $-A$  has been met). Furthermore  $P(2) = 1$ . Thus

$$T \leq \frac{1}{16} \cdot \frac{1}{2} + \frac{7}{16} \cdot 1 + \frac{1}{2} \cdot 2 = \frac{47}{32}.$$

- (ii) By symmetry we may assume  $H(1/2) > 1/2$ . Then  $P(1/2) \geq 7/16$  ( $A$  has been met),  $P(2) \geq 15/16$  ( $A, -A, B$  have been met), and  $P(4) = 1$  (all met). Hence

$$(3) \quad T \leq \frac{7}{16} \cdot \frac{1}{2} + \frac{8}{16} \cdot 2 + \frac{1}{16} \cdot 4 = \frac{47}{32}. \quad \square$$

We now consider the lower bound on  $V$ . In the search game with an immobile hider, the hider has two particular mixed strategies that guarantee him an expected capture time of half the length of the interval: (1) Hide equiprobably at the ends (end-hiding is optimal on trees for such games [9], and symmetry implies the equiprobability), or (2) hide uniformly (this is optimal for all networks with Eulerian paths [2]). Mobility usually helps the hider, for example, when  $Q$  is the circle of circumference  $c$  an immobile hider can be found (by a random tour) in mean time  $c/2$ , while a mobile hider can be found with best play on both ends in time  $3c/4$  [1]. The intuitive explanation is usually that when the hider is immobile, the searcher does not have to search again any part of  $Q$  already searched (and hence can employ a minimal, Chinese postman, search path)—but a *mobile* hider might not be met by such a path. However this explanation does not apply to the interval (though to all other networks), since a Chinese postman path on an interval will indeed find a mobile hider—it has search number 1 in the sense of Parsons [17].

Mobility helps the hider, since  $V > 1$  if the hider is mobile. To prove that this is true, we select hider strategies by considering the searcher strategies  $A$  and  $B$ . The optimal hider strategy against  $A, B$  is to loiter around  $\pm \frac{1}{2}$  and just before time  $\frac{1}{2}$  run either to the middle and back, or to the end. These two possible paths  $G, H$  and their symmetric counterparts are depicted in thick lines in the left-hand diagram in Figure 2 (the paths do not cross the center). We combine these with the two other hider strategies that we considered above:  $E$ , hiding at an end, or  $F$ , loitering in the center  $F(t) = \max\{0, t + \varepsilon - 1\}$ . Then we get a mixed strategy in which the hider uses  $\{E, F, G, H\}$  and their symmetric counterparts. According to Lemma 5 the searcher adopts strategies that start at  $0, \pm \frac{1}{2} \pm 1$  and then run between hider paths. If the searcher starts out from an end, then by Proposition 1 it is optimal to adopt strategy  $A$ . If he starts out in  $0$ , then the searcher runs to  $\pm \frac{1}{2}$  at which point he may turn, “strategy  $B$ ,” or continue to an end and run back, “strategy  $M$ ” in Figure 2. Starting from  $\pm \frac{1}{2}$  the searcher either runs to the near end, “strategy  $C$ ,” or to the remote end, “strategy  $D$ .” So the optimal optimal response to a mixed hider strategy on  $G$  and  $H$  is a mixed searcher strategy on  $\{A, B, C, D, M\}$  and their symmetric counterparts.

FIG. 2. *Hide paths are bold. Left: the pure paths in an optimal mixed hide strategy against A, B in a space-time diagram are E, F, G, H. Right: the searcher's response to {E, F, G, H}. Apart from A and B the only relevant paths, up to symmetry, are C, D, M.*

Ignoring  $\varepsilon$  these strategies give the zero-sum game matrix:

$$(4) \quad \begin{array}{c} A \\ B \\ C \\ D \\ M \end{array} \begin{array}{c} E \quad F \quad G \quad H \\ \left[ \begin{array}{cccc} 1 & \frac{3}{2} & \frac{3}{2} & \frac{5}{4} \\ 3 & 0 & \frac{5}{4} & 3 \\ \frac{3}{2} & \frac{15}{8} & \frac{5}{4} & \frac{5}{4} \\ \frac{5}{2} & \frac{1}{2} & \frac{3}{8} & \frac{3}{4} \\ 2 & 0 & \frac{7}{4} & 2 \end{array} \right] \end{array}$$

The value of this matrix game  $\frac{97}{75}$  puts a lower bound on  $V$ .

THEOREM 10.  $V \geq \frac{97}{75} = 1.29\bar{3}$ .

In principle, it is possible to compute the value of the game in the following iterative manner. Give finitely many pure strategies to the hider; according to Proposition 5 the searcher needs finitely many pure strategies to optimize his response to the hider. From the space-time diagram it is obvious that the hider can now optimize his response to the searcher by a finite number of additional pure strategies, etc. In this way we get an ever-increasing set of pure strategies for the hider and the searcher, but the convergence is slow and the increase is exponential. The convergence to the value of the game appears to be slow and not effectively computable.

**4. A searcher strategy with a continuous initial distribution.** To improve on the upper bound  $V < 47/32$  of Theorem 9, we extend the mixed searcher strategy which uses  $\{A, B\}$ . We replace the pure strategy  $B$  by a continuous mixed strategy  $s_\Phi$ . In this strategy  $s_\Phi$  the searcher picks a point  $x$  according to a continuous distribution function on the interval  $\Phi(x)$  and runs to the right until he meets the sweeper  $A$ , then joins the sweeper until he reaches  $-1$  and runs back to the other end. The symmetric strategy  $-s_\Phi$  starts according to  $\Phi(-x)$  and the searcher runs to the left until he meets the sweeper  $-A$ , etc.

LEMMA 11. *Suppose that the searcher uses the mixed strategy  $s_\Phi$ . Let  $H$  be a pure hider strategy and let  $y = y(H)$  be the first time that the hider meets a sweeper. Then the searcher finds the hider before time  $y$  if and only if he starts in  $(H(y) - y, H(0)]$  and runs to the right, or if he starts in  $[H(0), H(y) + y)$  and runs to the left.*

*Proof.* By Proposition 8 we may assume that  $H \geq 0$ , so  $H$  meets the right sweeper  $A$  first and  $H(y) = 1 - y$ . We consider only the case that the searcher  $S$  initially runs to the right until he meets  $A$ . If  $S$  runs to the left the argument is the same. Suppose that  $S$  starts in  $(1 - 2y, H(0)]$ , so  $S$  meets  $A$  at time  $t = \frac{1-S(0)}{2} < y$ . Then  $S(0) < H(0)$  and  $S(t) > H(t)$  since  $H(t) < A(t)$  for  $t < y$ . Therefore  $S$  finds  $H$  in between time 0 and time  $t$ . Now suppose that  $S$  does not start in the interval  $(1 - 2y, H(0)]$ , so either  $S(0) > H(0)$  or  $S(0) < 1 - 2y$ . In the first case,  $S$  runs toward  $A$  and finds the hider at time  $y$ . In the second case, the searcher cannot meet  $A$  at time  $y$ , while the hider can. So the paths of  $S$  and  $H$  cannot cross before time  $y$ .  $\square$

LEMMA 12. *Let  $f = \Phi'$  be the probability density. Searchers that start in  $(H(y) - y, H(0)]$  and run to the right catch the hider with expected time*

$$(5) \quad \int_0^y t f(H(t) - t) (1 - H'(t)) dt.$$

*Searchers that start in  $[H(0), H(y) + y)$  and run to the left catch the hider with expected time*

$$(6) \quad \int_0^y t f(-H(t) - t) (1 + H'(t)) dt.$$

*Proof.* Consider a small time interval  $[t, t + \Delta t]$  when the hider moves from  $H(t)$  to  $H(t) + \Delta H$ . Searchers that meet the hider in that time interval and that have started out from the right have started in  $[H(t) - t + \Delta H - \Delta t, H(t) - t]$ . Here we use that  $|\Delta H| \leq \Delta t$  since we may assume that a hider moves at no greater speed than 1. The probability of a hider starting out in that interval is  $f(H(t) - t)(\Delta H - \Delta t)$  up to first order. The time of capture is  $t$  up to first order. By taking the limit of  $\Delta t \rightarrow 0$  we obtain the integral in (5). By symmetry we obtain (6).  $\square$

If a hider has chosen  $x = H(0)$  and  $y$ , then he maximizes the expected time of capture, which comes down to maximizing

$$(7) \quad \int_0^y t [f(H(t) - t) (1 - H'(t)) + f(-H(t) - t) (1 + H'(t))] dt.$$

This integral can be simplified by partial integration, which gives the sum of a constant  $-y\Phi(1 - 2y)$  and the integral in (8).

LEMMA 13. *Let  $y$  be the first time that the hider meets a sweeper. The optimal hider path from  $H(0)$  to  $H(y)$  maximizes*

$$(8) \quad \int_0^y \Phi(-t + H(t)) + \Phi(-t - H(t)) dt.$$

This is a variational problem. Its Euler–Lagrange equation is  $f(-t + H(t)) = f(-t - H(t))$ , where as before  $f$  is the probability density. A stationary value is  $H(t) = 0$  and this makes sense, since  $s_\Phi$  is designed against loitering hiders and  $H(t) = 0$  is a minimum. If  $\Phi$  is the uniform distribution, then the Euler–Lagrange equation is satisfied by any path and the integral does not depend on  $H$ : it is equal to  $y(1 - y/2)$ .

The integral in (8) represents the payoff against the searchers that start in  $(H(0) - y, H(0) + y)$  and run toward  $H(0)$ . Once the hider has met a sweeper, he should run to the end since if the searcher uses  $s_\Phi$  he joins the sweeper. So we can determine the payoff  $V(s_\Phi, H)$ . Denote  $x = H(0)$ ; then this payoff is

$$(9) \quad 1 - \Phi(-x) + 2\Phi(1 - 2y) + \frac{y}{2}(1 - \Phi(x)) - \frac{y}{2}\Phi(1 - 2y) + \frac{1}{2} \int_0^y \Phi(-t + H(t)) + \Phi(-t - H(t)) dt.$$

This equation is derived as follows. A searcher starts out left from  $x$  and runs to the left with probability  $(1 - \Phi(-x))/2$ . Such a searcher catches  $H$  at time 2. This gives the first term. A searcher starts out left from  $1 - 2y$  and runs to the right with probability  $\Phi(1 - 2y)/2$ . Such a searcher catches  $H$  at time 4 and this gives the second term. A searcher starts out right from  $x$  and runs right with probability  $(1 - \Phi(x))/2$ . Such a searcher catches  $H$  at time  $T$ . This gives the third term. The fourth term  $-y\Phi(1 - 2y)$  turns up in the partial integration and the final term is the variational integral.

We consider a mixed strategy  $\sigma$  for the searcher, as follows. Use the sweeper strategy  $\pm A$  with probability  $p$  and use the continuous mixed strategy  $s_\Phi$  with probability  $1 - p$ . If  $\Phi$  is the uniform distribution then (9) is equal to

$$(10) \quad \frac{10 + 2x - (7 + x)y + y^2}{4},$$

which is maximal at  $x = 1$  for any  $0 \leq y \leq 1$  and decreasing in  $y$ . If the searcher takes  $p = 7/9$ , then  $V(\sigma, H) = 13/9 - y/18 + y^2/18$  which is maximal at  $y = 0$  and  $y = 1$ . So against  $\sigma$ , the hider optimizes in either of two ways: stick to an end, or run from an end to the middle and back. The payoff is  $13/9$ , which puts an upper bound on the value of the game that is sharper than the bound  $47/32$  that we found in the previous section. We summarize this in a theorem.

**THEOREM 14.** *If the searcher uses the mixed strategy  $\sigma$ , then the optimal response of the hider gives a matrix game with value  $13/9$ . In particular  $V \leq 13/9$ .*

Now the obvious way to try to improve on this bound is by varying the distribution  $\Phi$ . Our computer experiments indicated that the bound of  $13/9$  can be improved only marginally in this way. To prove that there is only room for marginal improvement, we consider a specific noncrossing hider strategy:  $H_x$  starts in  $H(0) = x \geq 0$  and runs toward the sweeper  $A$ ; turning just  $\varepsilon$  in front of the sweeper; then  $H_x$  runs back toward the middle but turns once again at time  $y$ , before reaching the middle, to run to the end. So, ignoring  $\varepsilon$  we can describe this path by  $H_x(t) = x + t$  if  $t \leq (1 - x)/2$  and  $H_x(t) = 1 - t$  if  $(1 - x)/2 \leq t \leq y$  for  $x \geq 0$ . The variational integral (8) over this path is

$$(11) \quad \frac{1}{2} \left( \Phi(x)(1 - x) + \int_0^{-x} \Phi(t) dt + \int_{1-2y}^x \Phi(t) dt \right)$$

Suppose that  $y = 1$ . Then the payoff  $V(H_x, A)$  against the sweeper strategy is  $3/2$ . Against the continuous strategy it is

$$(12) \quad V(H_x, s_\Phi) = \frac{3}{2} - \Phi(-x) - \Phi(x) \frac{(1+x)}{4} + \frac{1}{4} \int_{-1}^{-x} \Phi(t) dt + \frac{1}{4} \int_{-1}^x \Phi(t) dt.$$

Suppose that the searcher uses a mixed strategy  $\sigma_\Phi$  on  $\{A, s_\Phi\}$ . Suppose that the hider uses a mixed strategy  $\gamma$  on  $\{E, H_1, H_{\frac{1}{2}}, H_0\}$ , where  $E$  is the end point strategy. The integrals in (12) can be bounded from below by finite sums such as  $\int_{-1}^0 \Phi(t) dt \geq \frac{1}{2}\Phi(-\frac{1}{2}) + \frac{1}{2}\Phi(0)$ . Bounding the integrals in this way we get a  $4 \times 2$  zero-sum matrix game, the value of which is a lower bound on  $V(\gamma, \sigma_\Phi)$ :

$$\begin{bmatrix} 1 & \frac{3}{2} & \frac{3}{2} & \frac{3}{2} \\ 3 & 1 + \frac{1}{8}\Phi(-\frac{1}{2}) + \frac{1}{8}\Phi(0) + \frac{1}{8}\Phi(\frac{1}{2}) & \frac{3}{2} + \frac{1}{4}\Phi(-\frac{1}{2}) - \frac{5}{4}\Phi(0) & \frac{3}{2} - \frac{7}{8}\Phi(-\frac{1}{2}) + \frac{1}{8}\Phi(0) - \frac{3}{8}\Phi(\frac{1}{2}) \end{bmatrix}.$$

By linear programming we find that the value of the matrix game is  $\frac{337}{237} = 1.4219\dots$ , which is only marginally smaller than  $13/9$ .

**THEOREM 15.** *If the searcher uses a mixed strategy  $\sigma_\Phi$  on  $\{A, s_\Phi\}$  for any distribution  $\Phi$ , then the hider can respond by a strategy  $\gamma_\Phi$  such that  $V(\sigma_\Phi, \gamma) > 1.421$ .*

**5. A hider strategy with a continuous initial distribution.** To improve on the lower bound  $V > 97/75$  of Theorem 10, we extend the mixed hider strategy which uses  $\{E, F, G\}$ . We replace the loitering strategies  $F$  and  $G$  by a continuous mixed strategy  $h_\Phi$ . In this strategy the hider picks a point  $x \in [\varepsilon, 1 - \varepsilon]$  according to a distribution function  $\Phi(x)$  and he waits at  $x$  until the sweeper  $A$  is  $\varepsilon$  close. Then the hider runs to  $\varepsilon$ , turns, and runs back to 1. In the symmetric strategy  $-h_\Phi$  the hider picks a point in  $[-1 + \varepsilon, -\varepsilon]$ .

It follows from Proposition 5 that the searcher  $S$  either starts at an end, in which case the  $S$  is a sweeper, or starts in  $[-1 + \varepsilon, -\varepsilon] \cup [\varepsilon, 1 - \varepsilon]$ . Let  $y$  be the first time that  $S$  gets  $\varepsilon$  close to a sweeper. By symmetry we may assume that this sweeper is  $A$ . Since  $A$  runs all the time  $S(t) < A(t)$  for  $t < y$ . We conclude that  $S$  approaches  $A$  from the left, so up to time  $y$  he catches hidens that have remained immobile. Clearly, the searcher should maximize the interval  $[S(0), S(y)]$  to catch as many immobile hidens as possible. So  $S$  starts in  $1 - 2T - \varepsilon$  and runs to  $1 - T - \varepsilon$ . At time  $y$  the searcher catches all the loitering hidens that have started out from  $x > S(0)$  and are running  $\varepsilon$  in front of  $A$ . The searcher now effectively has two possibilities, and we leave it to the reader to check this: either he turns and runs to  $-1$  and back to  $+1$ , let's call this  $S_1$ , or he continues and runs to  $+1$  and then back to  $-1$ , let's call this  $S_2$ . Against the end point strategy the payoffs are  $V(S_1, E) = 3$  and  $V(S_2, E) = 1 + 2T$ . Ignoring  $\varepsilon$  the payoffs of these two strategies against  $h_\Phi$  are

$$\begin{aligned} V(S_1, h_\Phi) &= (1 - \Phi(2y - 1)) + \frac{1}{2} \int_0^{2y-1} f(t) dt \\ &\quad + \frac{y(1 - \Phi(1 - y)) + \Phi(1 - 2y) + \int_{1-2y}^{1-y} f(t) dt}{2}, \\ V(S_2, h_\Phi) &= (1 + y)(1 - \Phi(2y - 1)) + \frac{1}{2} \int_0^{2y-1} f(t) dt \\ &\quad + \frac{y(1 - \Phi(1 - y)) + (1 + y)\Phi(1 - 2y) + \int_{1-2y}^{1-y} f(t) dt}{2}, \end{aligned}$$

FIG. 3.  $V(S_1, h_\Phi)$  as a function of  $y$ .

where, as before,  $f$  denotes the density of  $\Phi$ . To see why this is true, note that the first two terms in  $V(S_1, h_\Phi)$  concern loitering hidiers that start out from  $x < 0$ : the term first represents the hidiers that start from  $x < 0$  and that are found at the end point  $-1$ ; the second term represents the hidiers that start from  $1 - 2y < x < 0$ , which are caught before time  $y$ . The third term represents hidiers that start from  $x > 0$ . In the same way we obtain  $V(S_2, h_\Phi)$ . Both payoffs are functions of  $y$ .

We simplify the analysis and consider only the case that  $\Phi$  is the uniform distribution. Let  $\gamma$  be the mixed strategy in which the hider uses  $\{E, h_\Phi\}$  with  $\Phi$  equal to the uniform distribution.

Since  $V(S_1, E)$  does not depend on  $T$  it is optimal for the searcher to choose  $y$  such that  $V(S_1, h_\Phi)$  is minimal.

**THEOREM 16.** *If the hider uses the mixed strategy  $\gamma$ , then the optimal response of the searcher gives a matrix game with value  $15/11$ . In particular  $V \geq 15/11$ .*

*Proof.* Since  $V(S_1, E)$  does not depend on  $y$ , the searcher should choose  $y$  such that  $V(S_1, h_\Phi)$  is minimal. As is shown in Figure 3, the minimum is at  $y = 1$ . So the searcher  $S_1$  runs  $\varepsilon$  ahead of the sweeper and the payoff is  $\frac{3}{4}$ . If the searcher only uses a mixed strategy on  $\{A, S_1\}$ , then we get a  $2 \times 2$  matrix game  $\begin{bmatrix} 1 & 3/2 \\ 3 & 3/4 \end{bmatrix}$  which has value  $15/11$ . In this game it is optimal for the hider to choose the end point strategy  $E$  with probability  $\frac{3}{11}$  and the loitering strategy  $h_\Phi$  with probability  $\frac{8}{11}$ . It turns out that the searcher cannot decrease the value of the game by including the strategy  $S_2$ :  $\frac{3}{11}V(S_2, E) + \frac{8}{11}V(S_2, h_\Phi) \geq \frac{15}{11}$  as illustrated in Figure 4. So if the hider uses the mixed strategy  $\gamma$  in which he chooses  $E$  with probability  $\frac{3}{11}$  then the searcher cannot do better than expected capture time  $15/11$ .  $\square$

**6. Conclusions.** This paper introduces the apparently easy problem of how best to search for a mobile hider who is restricted to a known interval. The existence of

FIG. 4.  $\frac{3}{11}V(S_2, h_\Phi) + \frac{8}{11}V(S_2, h_\Phi)$  as a function of  $y$ .

a Value for this game, and of  $\varepsilon$ -optimal strategies for the searcher and the hider, follows from a minimax theorem by Alpern and Gal. However, the determination of the value  $V$ , much less optimal strategies, seems difficult. The problem has resisted our attempts to solve it, but we have made significant progress in that direction. We have established many properties of optimal searcher and hider paths, that is, those that can be used in optimal mixed strategies. We have established bounds  $15/11 \leq V \leq 13/9$  on the value of the game by developing a variational theory that can be used to evaluate certain mixed strategies which start according to a continuous distribution on the interval. We present this problem, the princess and monster game on an interval as a challenge to the zero-sum game community. We conjecture that its value is 1.4.

## A DIRECT SOLUTION METHOD FOR STOCHASTIC IMPULSE CONTROL PROBLEMS OF ONE-DIMENSIONAL DIFFUSIONS\*

MASAHIKO EGAMI<sup>†</sup>

**Abstract.** We consider stochastic impulse control problems where the process is driven by one-dimensional diffusions. Impulse control problems are widely applied to financial engineering and decision-making problems including the dividend payout problem, portfolio optimization with transaction costs, and inventory control. We shall show a new mathematical characterization of the value function in the continuation region as a linear function in a certain transformed space. The merits of our approach are as follows: (1) One does not have to guess optimal strategies or verify the optimality via a verification lemma, (2) the method of finding the solution (based on the new characterization of the value function) is simple and direct, and thereby (3) one can handle a broader class of reward and cost functions than the conventional methods that use quasi-variational inequalities.

**Key words.** stochastic impulse control, diffusions, optimal stopping, concavity

**1. Introduction.** This paper proposes a general solution method of stochastic impulse control problems for one-dimensional diffusion processes. Stochastic impulse control problems have attracted a growing interest of many researchers for the past two decades. Under a typical setting, the controller faces some underlying process and reward/cost structure. There exist continuous and instantaneous components of reward/cost functions. By exercising impulse controls, the controller moves the underlying process from one point to another. At the same time, the controller receives rewards associated with the instantaneous shifts of the process. Then the controller's objective is to maximize the total discounted expected net income.

The mathematical framework to these types of problems is in Bensoussan and Lions [4]. Impulse control has been studied widely in inventory control (Harrison, Sellke, and Taylor [15]), the exchange rate problem (Jeanblanc-Piqué [17], Mundaca and Øksendal [23], Cadenillas and Zapatero [7]), dividend payout problems (for example, Jeanblanc-Piqué and Shiryaev [18]), and portfolio optimization with transaction costs (Korn [19], Morton and Pliska [22]). It is worth mentioning that Korn [20] surveys the applications in mathematical finance. Also see Chancelier, Øksendal, and Sulem [10] for a combination of optimal stopping and impulse control problems. In many economic and financial applications where the controlled process is described as an Itô diffusion, the solution to the problem demands a thorough study of a related Hamilton–Jacobi–Bellman equation and quasi-variational inequalities. The method based on quasi-variational inequalities is the following: One guesses the form of (a) the continuation region and the intervention region, (b) the associated optimal policy, and (c) the value function. Then one specifies the value function by using appropriate boundary conditions and verifies optimality of the candidate policy. Both steps are

often very difficult, and success depends heavily on the form of the controlled process, reward, and cost functions.

Alternatively, an impulse control problem can be viewed as a sequence of optimal stopping problems. The connection between impulse control and optimal stopping has been investigated by Davis [12] and Øksendal and Sulem [25] among others. In this setting, the value functions of a sequence of optimal stopping problems converge to the value function of the impulse control problem under suitable conditions. In this regard, we utilize the results of Dynkin [14] (see, e.g., Theorem 16.4) about the functional concavity characterization of  $\alpha$ -excessive mappings and Dayanik and Karatzas [13] that give a general characterization of optimal stopping times of one-dimensional diffusions. We use these results to identify a new and useful characterization of the solution of the original impulse control problem. At the end, we get rid of the sequence of optimal stopping problems altogether and directly find the value function: The new characterization allows us to propose a new direct solution method for impulse control problems. Other works similar to our approach include Alvarez [1], Alvarez and Lempa [3], and Alvarez and Virtanen [2].

Similar recursive formulations for one-dimensional diffusions appear in multiple stopping problems in the context of swing options; see, for example, Carmona and Dayanik [8]. See also Carmona and Touzi [9] and Dahlgren and Korn [11] for the valuation of swing options. It is worth pointing out the differences of this article from Carmona and Dayanik [8], where, given a reward function, the controller can exercise their options  $n$  times under the condition that the controller has to wait at least certain units of time between two exercising times. By using a recursive formulation, we are able to obtain the result that the value function has to be linear in the continuation region of the transformed space. This linear characterization enables us to present the three-step optimization procedure (described in section 3.3) that does not require us to use the recursive stopping scheme, while Carmona and Dayanik [8] do not have this kind of geometric specification due to the nature of their problem; one needs to solve multiple stopping problems.

In the next section, we briefly go over the solution method for optimal stopping problems of one-dimensional diffusions. We describe the impulse control problem and its solution in section 3. Examples are presented in section 4. Finally, extensions and concluding remarks are in section 5.

**2. Summary of the key results of optimal stopping.** Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a complete probability space with a standard Brownian motion  $W = \{W_t; t \geq 0\}$ , and consider the diffusion process  $X^0$  with state space  $\mathcal{I} \subseteq \mathbb{R}$  and dynamics

$$(2.1) \quad dX_t^0 = \mu(X_t^0)dt + \sigma(X_t^0)dW_t$$

for some Borel functions  $\mu : \mathcal{I} \rightarrow \mathbb{R}$  and  $\sigma : \mathcal{I} \rightarrow (0, \infty)$ . We emphasize here that  $X^0$  is an uncontrolled process. We assume that  $\mathcal{I}$  is an interval with end points  $-\infty \leq c < d \leq +\infty$  and that  $X^0$  is regular in  $(c, d)$ ; in other words,  $X^0$  reaches  $y$  with positive probability starting at  $x$  for every  $x$  and  $y$  in  $(c, d)$ . We shall denote by  $\mathbb{F} = \{\mathcal{F}_t\}$  the natural filtration generated by  $X^0$  and assume that the usual condition is satisfied.

Let  $\alpha \geq 0$  be a real constant and  $h(\cdot)$  a Borel function such that  $\mathbb{E}^x[e^{-\alpha\tau}h(X_\tau^0)]$  is well-defined for every  $\mathbb{F}$ -stopping time  $\tau$  and  $x \in \mathcal{I}$ . We first consider

$$(2.2) \quad V(x) \triangleq \sup_{\tau \in \mathcal{S}} \mathbb{E}^x[e^{-\alpha\tau}h(X_\tau^0)], \quad x \in \mathcal{I},$$

the value function of the optimal stopping problem with the reward function  $h(\cdot) : \mathcal{I} \rightarrow \mathbb{R}$  where the supremum is taken over the class  $\mathcal{S}$  of all  $\mathbb{F}$ -stopping times.

Let  $z \in \mathcal{I}$  be a fixed point of the state space and  $\tau_z$  be the first hitting time of  $z \in \mathcal{I}$  by  $X^0$ . Let us denote the infinitesimal generator of  $X^0$  by  $\mathcal{A}$  and consider the ODE  $(\mathcal{A} - \alpha)v(x) = 0$ . This equation has two fundamental solutions:  $\psi(\cdot)$  and  $\varphi(\cdot)$ . We set  $\psi(\cdot)$  to be the increasing and  $\varphi(\cdot)$  to be the decreasing solution. They are linearly independent positive solutions and uniquely determined up to multiplication. It is well known that

$$\mathbb{E}^x[e^{-\alpha\tau_z}] = \begin{cases} \frac{\psi(x)}{\psi(z)}, & x \leq z, \\ \frac{\varphi(x)}{\varphi(z)}, & x \geq z. \end{cases}$$

For the complete characterization of  $\psi(\cdot)$  and  $\varphi(\cdot)$  corresponding to various types of boundary behavior, refer to Itô and McKean [16]. Let us now define

$$(2.3) \quad F(x) \triangleq \frac{\psi(x)}{\varphi(x)}, \quad x \in \mathcal{I}.$$

Then  $F(\cdot)$  is continuous and strictly increasing. Next, following Dynkin [14, pp. 238], we define concavity of a function with respect  $F$  as follows: A real-valued function  $u$  is called  $F$ -concave on  $\mathcal{I}$  if, for every  $x \in [l, r] \subseteq \mathcal{I}$ ,

$$u(x) \geq u(l) \frac{F(r) - F(x)}{F(r) - F(l)} + u(r) \frac{F(x) - F(l)}{F(r) - F(l)}.$$

We will use the notion of  $F$ -concavity to provide a new characterization of the value function of stochastic impulse control problems. Before doing that, the first step is to present the following results of optimal stopping problems, the proofs of which we refer to Dayanik and Karatzas [13].

**PROPOSITION 2.1.** *The value function  $V(\cdot)$  of (2.2) is the smallest nonnegative majorant of  $h(\cdot)$  such that  $V(\cdot)/\varphi(\cdot)$  is  $F$ -concave on  $\mathcal{I}$ .*

**PROPOSITION 2.2.** *Let  $W(\cdot)$  be the smallest nonnegative concave majorant of  $H \triangleq (h/\varphi) \circ F^{-1}$  on  $[F(c), F(d)]$ , where  $F^{-1}(\cdot)$  is the inverse of the strictly increasing function  $F(\cdot)$  in (2.3). Then  $V(x) = \varphi(x)W(F(x))$  for every  $x \in \mathcal{I}$ .*

**PROPOSITION 2.3.** *Define*

$$(2.4) \quad S \triangleq \{x \in [c, d] : V(x) = h(x)\} \quad \text{and} \quad \tau^* \triangleq \inf\{t \geq 0 : X_t^0 \in S\}.$$

*If  $h(\cdot)$  is continuous on  $\mathcal{I}$ , then  $\tau^*$  is an optimal stopping rule.*

**3. Impulse control problem and its solution.** Suppose that, at any time  $t \in \mathbb{R}_+$  and any state  $x \in \mathcal{I}$ , we can intervene and give the system an impulse  $\xi \in \mathbb{R}$ . Once the system gets intervened, the point moves from  $x$  to  $y \in \mathbb{R}$ . An impulse control for the system is a double sequence:

$$\nu = (T_1, T_2, \dots, T_i, \dots; \xi_1, \xi_2, \dots, \xi_i, \dots),$$

where  $0 \leq T_1 < T_2 < \dots$  are an increasing sequence of  $\mathbb{F}$ -stopping times and  $\xi_1, \xi_2, \dots$  are  $\mathcal{F}_{T_i}$ -measurable random variables representing impulses exercised at the corresponding intervention times  $T_i$ , with  $\xi_i \in Z$  for all  $i$ , where  $Z \in \mathbb{R}$  is a given

set of admissible impulse amounts. The controlled process is, in general, described as follows:

$$(3.1) \quad dX_t = \mu(X_t)dt + \sigma(X_t)dW_t, \quad T_{i-1} \leq t < T_i,$$

$$(3.2) \quad X_{T_i} = \Gamma(X_{T_i-}, \xi_i)$$

with some mapping  $\Gamma : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ .

Let 0 be the absorbing state, without loss of generality, and  $\tau_0 \triangleq \inf\{t : X_t = 0\}$  the ruin time. With the absorbing state at 0, it is natural to consider a set of problems where  $Z \in \mathbb{R}_+$  (i.e.,  $\xi_i = x_i - y_i > 0$  for all  $i$ ) and  $X_{T_i} = X_{T_i-} - \xi_i$ . (We shall comment on cases where interventions are allowed in both positive and negative directions in section 5.)

With each pair  $(T_i, \xi_i)$ , we associate the intervention reward

$$(3.3) \quad K(X_{T_i-}, X_{T_i}),$$

where  $K(x, y) : \mathcal{I} \times \mathbb{R} \rightarrow \mathbb{R}$  is a given function continuous in the first and second arguments. Our result below does not depend on the specification of  $K(\cdot)$ . We assume that, for any point  $x \in \mathcal{I}$ ,

$$(3.4) \quad K(x, x) < 0$$

due to the existence of fixed costs. We consider the following performance measure with  $\nu \in \mathcal{V}$ , a collection of admissible strategies:

$$(3.5) \quad J^\nu(x) = \mathbb{E}^x \left[ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P + \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right],$$

where  $P \in \mathbb{R}_-$  is a constant penalty<sup>1</sup> at the ruin time and  $f : \mathbb{R} \rightarrow \mathbb{R}$  is a continuous function, satisfying:

$$(3.6) \quad \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} |f(X_s)| ds \right] < \infty.$$

We also assume the standard polynomial growth condition on  $f(\cdot)$  and  $K(x, y) = K(z)$  by setting  $z := x - y$ : That is, there exist constants  $C_i$  and  $m_i$  ( $i = 1, 2$ ) such that, for all  $x, z \in \mathbb{R}$ ,

$$(3.7) \quad |f(x)| \leq C_1(1 + |x|^{m_1}) \quad \text{and} \quad |K(z)| \leq C_2(1 + |z|^{m_2}).$$

Our goal is to find the optimal strategy  $\nu^*(T_i, \xi_i)_{i \geq 0}$  and the corresponding value function

$$(3.8) \quad v(x) \triangleq \sup_{\nu \in \mathcal{V}} J^\nu(x) = J^{\nu^*}(x).$$

Let us briefly go over our plan. In section 3.1, we introduce a recursive optimal stopping scheme that eventually solves the original impulse control problem as in Øksendal and Sulem [25]. In section 3.2, we consider a special case where the mapping

<sup>1</sup>Equation (3.5) can be rewritten as  $J^\nu(x) = P + \mathbb{E}^x[\int_0^{\tau_0} e^{-\alpha s} (f(X_s) - \alpha P) ds + \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i})]$ . Hence we could define  $\tilde{f}(x) \triangleq f(x) - \alpha P$  to get rid of  $P$ . We, however, maintain the original formulation to make the penalty term explicit.

$x \rightarrow \frac{K}{\varphi}(x) : \mathcal{I} \rightarrow \mathbb{R}$  is  $F$ -concave. We show, under this assumption, that the optimal intervention times  $T_i$  are characterized as exit times from an interval, say,  $(0, b^*)$ , for every  $i$ . Then we characterize the value function for impulse control problems and present a solution method based on the characterization of the intervention times and value function. In section 3.4, we consider the general case where the  $F$ -concavity assumption above does not hold.

**3.1. A sequence of optimal stopping problems.** In this subsection, we consider a recursive optimal stopping with a view to characterizing intervention times for the impulse control problems. Here we assume that no absorbing boundary exists. As we will see in the next subsection, the existence of an absorbing state is easily incorporated. Hence by using the same  $v(x)$ , we consider the problem

$$(3.9) \quad v(x) = \sup_{\nu \in \mathcal{V}} \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + \sum_i e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right].$$

Let us also define the set  $S_n$  and the objective function  $v_n$  as follows:

$$S_n \triangleq \{\nu \in S; \nu = (T_1, T_2, \dots, T_{n+1}; \xi_1, \xi_2, \dots, \xi_n); T_{n+1} = +\infty\}$$

and

$$(3.10) \quad v_n(x) \triangleq \sup_{\nu \in S_n} \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + \sum_{T_i} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right].$$

In other words, we are allowed to make at most  $n$  interventions. For this recursive approach, see, for example, Davis [12] and Øksendal and Sulem [25]. We use the following notation for convenience:

$$(3.11) \quad g(x) \triangleq \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s^0) ds \right].$$

Let  $\mathcal{H}$  denote the space of all Borel functions. Define the two operators  $\mathcal{M} : \mathcal{H} \rightarrow \mathcal{H}$  and  $\mathcal{L} : \mathcal{H} \rightarrow \mathcal{H}$  as follows:

$$(3.12) \quad \mathcal{M}u(x) \triangleq \sup_{y \in \mathbb{R}} [K(x, y) - (g(x) - g(y)) + u(y)]$$

and

$$(3.13) \quad \mathcal{L}u(x) \triangleq \sup_{\tau \in S} \mathbb{E}^x [e^{-\alpha \tau} \mathcal{M}u(X_{\tau-})]$$

for  $u \in \mathcal{H}$ . From the definition of the two operators,  $a_1(x) \leq a_2(x)$  for  $x \in \mathbb{R}$ ,  $a_1(\cdot), a_2(\cdot) \in \mathcal{H}$  implies  $\mathcal{M}a_1(x) \leq \mathcal{M}a_2(x)$  and  $\mathcal{L}a_1(x) \leq \mathcal{L}a_2(x)$  for all  $x \in \mathbb{R}$ .

On the other hand, consider the following recursive formula:

$$(3.14) \quad \begin{cases} w_0(x) = g(x), \\ w_n(x) = \sup_{\tau \in S, \xi \in \mathbb{R}_+} \mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau} (K(X_{\tau-}, X_\tau) + w_{n-1}(X_\tau)) \right] \end{cases}$$

for  $n = 1, 2, 3, \dots$ . It should be noted that, for each  $n$ , this is an optimal stopping problem over  $\tau$ . The second line of (3.14) is equivalent to

$$(3.15) \quad w_{n+1}(x) - g(x) = \sup_{\tau \in S, \xi \in \mathbb{R}_+} \mathbb{E}^x [e^{-\alpha \tau} (K(X_{\tau-}, X_\tau) - g(X_{\tau-}) + w_n(X_\tau))]$$

by applying the strong Markov property (with (3.6)) at time  $\tau$  to the integral term. Note that, on  $\{\omega : 0 \leq t \leq \tau(\omega)-\}$ , we have  $X(\omega) = X^0(\omega)$  almost surely. In fact, this derivation is explained in detail in subsection 3.2. By defining

$$\phi \triangleq w - g,$$

and adding and subtracting  $g(X_\tau)$  on the right-hand side of (3.15), it becomes

$$\phi_{n+1}(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x[e^{-\alpha\tau} \mathcal{M}\phi_n(X_{\tau-})].$$

Then it can be further simplified, by using the operator  $\mathcal{L}$  defined in (3.13):

$$(3.16) \quad \phi_{n+1}(x) = \mathcal{L}\phi_n(x).$$

Let us start this recursive scheme with  $w_0(x) = g(x)$  (i.e., no interventions are allowed, equivalently  $\phi_0(x) = 0$ ) and define recursively  $\phi_n(x) \triangleq w_n(x) - g(x) = \mathcal{L}(w_{n-1}(x) - g(x)) = \mathcal{L}\phi_{n-1}$ . Clearly,

$$\begin{aligned} \phi_1(x) &= \mathcal{L}\phi_0(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x[e^{-\alpha\tau} (\mathcal{M}(w_0(X_{\tau-}) - g(X_{\tau-})))] \\ &= \sup_{\tau \in \mathcal{S}, \xi \in \mathbb{R}_+} \mathbb{E}^x[e^{-\alpha\tau} \{K(X_{\tau-}, X_\tau) - g(X_{\tau-}) + g(X_\tau)\}]. \end{aligned}$$

On the other hand, by looking at the first (and the sole) intervention time,

$$\begin{aligned} v_1(x) - g(x) &= \sup_{\nu \in \mathcal{S}_1} \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + e^{-\alpha\tau} K(X_{\tau-}, X_\tau) \right] \\ &\quad - \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s^0) ds \right] \\ &= \sup_{\tau \in \mathcal{S}, \xi \in \mathbb{R}_+} \mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s) ds + e^{-\alpha\tau} \left( \mathbb{E}^{X_\tau} \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds \right] \right. \right. \\ &\quad \left. \left. + K(X_{\tau-}, X_\tau) \right) - \int_0^\tau e^{-\alpha s} f(X_s^0) ds - e^{-\alpha\tau} g(X_{\tau-}) \right] \\ &= \sup_{\tau \in \mathcal{S}, \xi \in \mathbb{R}_+} \mathbb{E}^x[e^{-\alpha\tau} \{K(X_{\tau-}, X_\tau) - g(X_{\tau-}) + g(X_\tau)\}]. \end{aligned}$$

The last equation is due to the fact that only one intervention is allowed. Hence we have  $w_1(x) = v_1(x)$ . By the definition of the recursive scheme,  $w_n$  is an increasing sequence (i.e.,  $w_1(x) \leq w_2(x) \leq \dots$  for all  $x \in \mathbb{R}$ ). In fact, we shall prove that  $w_n = v_n$  for all  $n$  in Lemma 3.2. Before that, we need the following lemma to relate this recursive scheme with the method described in section 2.

LEMMA 3.1. *The mapping  $x \rightarrow \frac{\mathcal{L}\phi(x)}{\varphi(x)} : \mathcal{I} \rightarrow \mathbb{R}$  is  $F$ -concave.*

*Proof.* We shall fix some  $x \in (l, r) \subseteq \mathcal{I}$ . Since  $\mathcal{M}\phi(\cdot)$  is bounded there, for a given  $\varepsilon > 0$ , there are admissible  $\varepsilon$ -optimal intervention pairs  $(\sigma_\varepsilon^l, \xi_\varepsilon^l)$  and  $(\sigma_\varepsilon^r, \xi_\varepsilon^r)$  such that

$$\mathbb{E}^l[e^{-\alpha\sigma_\varepsilon^l} \mathcal{M}\phi(X_{\sigma_\varepsilon^l})] > \mathcal{L}\phi(l) - \varepsilon \quad \text{and} \quad \mathbb{E}^r[e^{-\alpha\sigma_\varepsilon^r} \mathcal{M}\phi(X_{\sigma_\varepsilon^r})] > \mathcal{L}\phi(r) - \varepsilon.$$

Define another stopping time  $\sigma_\varepsilon^{lr} \in \mathcal{S}$ , with

$$\sigma_\varepsilon^{lr} \triangleq \begin{cases} \tau^l + \sigma_\varepsilon^l \circ \theta_{\tau^l} & \text{if } \tau^l < \tau^r, \\ \tau^r + \sigma_\varepsilon^r \circ \theta_{\tau^r} & \text{if } \tau^l > \tau^r. \end{cases}$$

Putting it all together, with the strong Markov property of  $X$ , which is  $X^0$  a.s. until the stopping time  $\tau$ ,

$$\begin{aligned}\mathcal{L}\phi(x) &\geq \mathbb{E}^x[e^{-\alpha\sigma_\varepsilon^{lr}} \mathcal{M}\phi(X_{\sigma_\varepsilon^{lr}})] \\ &> (\mathcal{L}\phi(l) - \varepsilon)\mathbb{E}^x[e^{-\alpha\tau^l} 1_{\{\tau^l < \tau^r\}}] + (\mathcal{L}\phi(r) - \varepsilon)\mathbb{E}^x[e^{-\alpha\tau^r} 1_{\{\tau^l > \tau^r\}}] \\ &\geq \frac{\mathcal{L}\phi(l)}{\varphi(l)}\varphi(x)\frac{F(r) - F(x)}{F(r) - F(l)} + \frac{\mathcal{L}\phi(r)}{\varphi(r)}\varphi(x)\frac{F(x) - F(l)}{F(r) - F(l)} - \varepsilon.\end{aligned}$$

Since  $\varepsilon$  is arbitrary, we have an  $F$ -concavity.  $\square$

This lemma guarantees that we can use Propositions 2.1–2.3 to identify the value function and an optimal stopping rule for each of the recursive optimal stopping problems (3.14).

**3.2. Characterization of the intervention times and the value function:  $F$ -concave reward case.** Based on the results in the previous subsection, we first consider a special case where the mapping  $x \rightarrow \frac{\bar{K}}{\varphi}(x) : \mathcal{I} \rightarrow \mathbb{R}$  is  $F$ -concave. Let us define, for notational convenience,

$$(3.17) \quad \bar{K}(x, y) \triangleq K(x, y) - (g(x) - g(y)).$$

Further, we prove the following properties of the recursive optimization scheme.

LEMMA 3.2. *If we define  $w_n$  by (3.14) (with  $w_0 = g$ ) and  $v_n$  by (3.10), then*

$$w_n(x) = v_n(x) \quad \text{for each } n \quad \text{and} \quad v(x) = \lim_{n \rightarrow \infty} w_n(x).$$

Moreover,  $w(x) \triangleq \lim_{n \rightarrow +\infty} w_n(x)$  is the smallest solution majorizing  $g$  of the functional equation  $w - g = \mathcal{L}(w - g)$ .

*Proof.* The proof is given in the appendix.  $\square$

Hence if we solve the optimal stopping problem

$$(3.18) \quad \phi_{n+1}(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x[e^{-\alpha\tau} \mathcal{M}\phi_n(X_{\tau-})]$$

recursively for each  $n$ , then we obtain  $\phi(x) \triangleq \lim_{n \rightarrow \infty} \phi_n(x) = \lim_{n \rightarrow \infty} v_n(x) - g(x) = v(x) - g(x)$ . By summarizing the above argument, we have the following proposition.

PROPOSITION 3.3. *The value function  $v(x)$  for (3.9) is given by the smallest solution majorizing  $g$  of the functional equation  $v - g = \mathcal{L}(v - g)$ , and  $\frac{v-g}{\varphi} (= \frac{\phi}{\varphi})$  is always  $F$ -concave.*

*Proof.* The first statement comes from Lemma 3.2. By the recursive method that we described above, we are solving a series of optimal stopping problems for each  $\phi_n$ . Hence Lemma 3.1 and Proposition 2.1 give the second statement.  $\square$

Note that the functional equation  $v - g = \mathcal{L}(v - g)$  is in essence the same as (2.8) in Alvarez [1], where the optimal boundary is found by ordinary optimization techniques in a case where the size of the control is exogenously given. Similar ideas are also in Alvarez and Virtanen [2] and Alvarez and Lempa [3] that extend Alvarez [1] by finding optimal size of control as well under some practically reasonable assumptions on the reward and cost function. These papers identify the function (along with optimal control) that satisfies this relationship, by using the idea of  $\alpha$ -excessive mappings

and proving optimality with the verification of a weaker version of quasi-variational inequalities under the assumptions on the reward function. Now we consider different paths to reach the solution and develop a new method.

The argument in the previous subsection is modified to incorporate the existence of the ruin state. Instead of (3.10) and (3.14), we define, respectively,

$$\begin{aligned} v_n(x) &\triangleq \sup_{\nu \in S_n} \mathbb{E}^x \left[ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P + \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right], \\ w_{n+1}(x) &\triangleq \sup_{\tau \in \mathcal{S}, \xi} \mathbb{E}^x \left[ \int_0^{\tau_0 \wedge \tau} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P 1_{\{\tau_0 < \tau\}} \right. \\ &\quad \left. + e^{-\alpha \tau} \{K(X_{\tau-}, X_{\tau}) + w_n(X_{\tau})\} 1_{\{\tau < \tau_0\}} \right], \end{aligned}$$

with

$$w_0(x) = \mathbb{E}^x \left[ \int_0^{\infty} e^{-\alpha s} f(X_s^0) 1_{\{s < \tau_0\}} ds + e^{-\alpha \tau_0} P \right] \triangleq g_0(x).$$

Then by defining the operator  $\mathcal{L} : \mathcal{H} \rightarrow \mathcal{H}$  instead of (3.13),

$$(3.19) \quad \mathcal{L}u(x) \triangleq \sup_{\tau \in \mathcal{S}} \mathbb{E}^x [e^{-\alpha \tau} \mathcal{M}u(X_{\tau-}) 1_{\{\tau < \tau_0\}} + e^{-\alpha \tau_0} (P - g(0)) 1_{\{\tau_0 < \tau\}}],$$

we have the same recursion formula as in (3.16). We can obtain the same results as in Lemmas 3.1 and 3.2. Proposition 3.3 also holds with one change that the value function is given by the smallest solution majorizing  $g_0$  of the functional equation  $v - g = \mathcal{L}(v - g)$ , where  $\mathcal{L} : \mathcal{H} \rightarrow \mathcal{H}$  is given by (3.19). Now we consider the characterization of the intervention times.

**PROPOSITION 3.4.** *If the mapping  $x \rightarrow \frac{K}{\varphi}(x) : \mathbb{R}_+ \rightarrow \mathbb{R}$  is  $F$ -concave and 0 is an absorbing state, then the optimal intervention times  $T_i^*$  are given, for some  $b^* \in \mathbb{R}_+$ , by*

$$T_i^* = \inf\{t > T_{i-1}^*; X_t \notin (0, b^*), \quad i = 1, 2, \dots\}.$$

*Proof.* Our proof is constructive, describing the procedure of recursive optimization steps. For any  $n \geq 1$ , in view of Lemma 3.1,  $\phi_n(x)/\varphi(x)$  is the smallest  $F$ -concave majorant of  $\mathcal{L}\phi_{n-1}(x)/\varphi(x)$ . We claim that this majorant (that passes  $(F(0), \frac{P-g(0)}{\varphi(0)})$  in the transformed space) always exists. Indeed, since we consider the case of  $\xi_i > 0$ , i.e.,  $x > y$  for  $K(x, y)$  and

$$\begin{aligned} \mathcal{M}\phi_0(x) &= \sup_{y \in \mathbb{R}_+} [K(x, y) - (g(x) - g(y)) + \phi_0(y)] \\ &= \sup_{y \in \mathbb{R}_+} [K(x, y) - (g(x) - g(y)) + (g_0(y) - g(y))], \end{aligned}$$

we should check whether the concave majorant exists, namely, that

$$(3.20) \quad \lim_{x \downarrow 0} (K(x, y) - g(x) + g_0(y)) < P - g(0)$$

holds when  $y \downarrow 0$ . Note that  $\lim_{y \downarrow 0} g_0(y) = P$  and  $g(x) \rightarrow g(0)$  as  $x \rightarrow 0$  due to the continuity of  $f$ . Hence (3.20) holds in the neighborhood of  $y = 0$  because of (3.4). In the subsequent iterations, we consider

$$\mathcal{M}\phi_1(x) = \sup_{y \in \mathbb{R}_+} [K(x, y) - (g(x) - g(y)) + \phi_1(y)].$$

We should check if the expression inside the supremum operator becomes less than  $P - g(0)$  as  $x \downarrow 0$  and  $y \downarrow 0$ . Since  $\lim_{y \downarrow 0} \phi_1(y) = \phi_1(0) = P - g(0)$  by the concavity (hence continuity) of  $\phi_1$  and since  $\lim_{x \downarrow 0} g(x) = \lim_{y \downarrow 0} g(y)$ , we have, in the neighborhood of  $y = 0$ , that

$$\lim_{x \downarrow 0} K(x, 0) + P - g(0) < P - g(0)$$

holds. Hence the concave majorant always exists also in the subsequent iterations.

Now the  $F$ -concavity of  $\phi_n$  is obviously maintained for all  $n$ . The limit function of the increasing sequence of functions  $\phi(x) = \lim_{n \rightarrow \infty} \phi_n(x)$  exists and is also  $F$ -concave. Accordingly,  $\bar{K}(x, y)/\varphi(x) + \phi(y)/\varphi(x)$  is  $F$ -concave for all  $y$ . Hence  $\phi(x)/\varphi(x)$  and  $(\bar{K}(x, y) + \phi(y))/\varphi(x)$  meet once and only once in the transformed space. Recall that the value function satisfies  $\phi = \mathcal{L}\phi$ . This implies that the continuous region is in the form of  $(0, b^*)$  for some  $b^* \in \mathbb{R}_+$ , which completes the proof.  $\square$

By using the above characterization of intervention times, we next want to characterize the value function and reduce the impulse control problem (3.8) to some optimal stopping problem. Moreover, we shall present a method that does not have to go through the iteration scheme. Let us first simplify  $J^\nu$ :

$$(3.21) \quad J^\nu(x) = \mathbb{E}^x \left[ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P + \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right].$$

This is just a reproduction of (3.5). Let us split the right-hand side of (3.21) into pieces and use the strong Markov property of the uncontrolled process  $X^0$  at the first intervention time  $T_1$  (together with the shift operator  $\theta(\cdot)$ ) with each of them. Note that, on  $\{\omega : 0 \leq t \leq T_1(\omega)-\}$ , we have  $X(\omega) = X^0(\omega)$  almost surely. The first term becomes

$$\begin{aligned} \mathbb{E}^x \left[ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds \right] &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} \left\{ \int_0^{T_1} e^{-\alpha s} f(X_s) ds \right. \right. \\ &\quad \left. \left. + e^{-\alpha T_1} \mathbb{E}^{X_{T_1}} \int_0^\infty e^{-\alpha s} f(X_s) 1_{\{s < \tau_0\}} ds \right\} \right] \\ &\quad + \mathbb{E}^x \left[ 1_{\{T_1 > \tau_0\}} \int_0^{\tau_0} f(X_s) ds \right] \end{aligned}$$

since  $\int_{T_1-}^{T_1} e^{-\alpha s} f(X_s) ds = 0$ . The second and third terms become

$$\begin{aligned} \mathbb{E}^x [e^{-\alpha \tau_0} P] &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \mathbb{E}^x [e^{-\alpha(\tau_0 - T_1)} P | \mathcal{F}_{T_1}] \right] + \mathbb{E}^x [1_{\{T_1 > \tau_0\}} e^{-\alpha \tau_0} P] \\ &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \mathbb{E}^x [e^{-\alpha(\tau_0 \circ \theta(T_1))} P | \mathcal{F}_{T_1}] \right] + \mathbb{E}^x [1_{\{T_1 > \tau_0\}} e^{-\alpha \tau_0} P] \\ &= \mathbb{E}^x [1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \mathbb{E}^{X_{T_1}} (e^{-\alpha \tau_0} P)] + \mathbb{E}^x [1_{\{T_1 > \tau_0\}} e^{-\alpha \tau_0} P] \end{aligned}$$

and

$$\begin{aligned}
& \mathbb{E}^x \left[ \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right] \\
&= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} \left\{ e^{-\alpha T_1} K(X_{T_1-}, X_{T_1}) + e^{-\alpha T_1} \sum_{i=2} e^{-\alpha(T_i - T_1)} K(X_{T_i-}, X_{T_i}) 1_{\{T_i < \tau_0\}} \right\} \right] \\
&= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} \left\{ e^{-\alpha T_1} K(X_{T_1-}, X_{T_1}) \right. \right. \\
&\quad \left. \left. + e^{-\alpha T_1} \mathbb{E}^x \left[ \sum_{T_i < \tau_0} e^{-\alpha(T_i \circ \theta(T_1))} K(X_{S_i-}, X_{S_i}) \mid \mathcal{F}_{T_1} \right] \right\} \right] \\
&= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \left\{ K(X_{T_1-}, X_{T_1}) + \mathbb{E}^{X_{T_1}} \sum_{i=1} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) 1_{\{T_i < \tau_0\}} \right\} \right],
\end{aligned}$$

where  $S_i \triangleq T_1 + T_i \circ \theta(T_1)$  and the index  $i$  runs from 1 for the sum in the second equality. By combining the three terms and rearranging, we have

$$\begin{aligned}
(3.22) \quad J^\nu(x) &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} \left\{ \int_0^{T_1} e^{-\alpha s} f(X_s) ds + e^{-\alpha T_1} K(X_{T_1-}, X_{T_1}) + e^{-\alpha T_1} J^\nu(X_{T_1}) \right\} \right] \\
&\quad + \mathbb{E}^x \left[ 1_{\{T_1 > \tau_0\}} \left\{ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P \right\} \right].
\end{aligned}$$

For any  $\mathbb{F}$  stopping time  $\tau$ , the strong Markov property of  $X^0$ , with our assumption (3.6), gives us

$$\mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s^0) ds \right] = g(x) - \mathbb{E}^x \left[ e^{-\alpha \tau} g(X_\tau^0) \right],$$

where  $g(\cdot)$  is defined as in (3.11). We apply this result to (3.22) by reading  $\tau = T_1$  and  $\tau = \tau_0$  to derive

$$\begin{aligned}
(3.23) \quad J^\nu(x) &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \{ K(X_{T_1-}, X_{T_1}) - g(X_{T_1}^0) + J^\nu(X_{T_1}) \} \right] \\
&\quad + \mathbb{E}^x \left[ 1_{\{T_1 > \tau_0\}} e^{-\alpha \tau_0} \{ P - g(X_{\tau_0}) \} \right] + g(x).
\end{aligned}$$

By noting that  $g(X_{T_1}^0) = g(X_{T_1-})$ , adding and subtracting  $g(X_{T_1})$ , and further defining

$$u(x) \triangleq J^\nu(x) - g(x),$$

(3.23) finally becomes

$$\begin{aligned}
(3.24) \quad u(x) &= \mathbb{E}^x \left[ 1_{\{T_1 < \tau_0\}} e^{-\alpha T_1} \{ K(X_{T_1-}, X_{T_1}) + u(X_{T_1}) - g(X_{T_1-}) + g(X_{T_1}) \} \right] \\
&\quad + \mathbb{E}^x \left[ 1_{\{T_1 > \tau_0\}} e^{-\alpha \tau_0} \{ P - g(X_{\tau_0}) \} \right],
\end{aligned}$$

and we consider the maximization of this  $u(\cdot)$  function and add back  $g(x)$  since  $\sup u(x) = \sup \{ J^\nu(x) - g(x) \} = \sup J^\nu(x) - g(x)$ . Note that this simplification leading to (3.24) does not depend on the  $F$ -concavity assumption.

Since we have confirmed that optimal intervention times are exit times of the process from an interval, let us use a simpler notation:  $X_{T_i-} = b$  and  $X_{T_i} = a$  for all  $i = 0, 1, 2, \dots$ . We can denote  $T_i- = \tau_b \triangleq \inf\{t > T_{i-1}; X_t \geq b\}$ . By observing (3.24),

$$\begin{aligned} u(b) &= u(X_{T_1-}) = K(X_{T_1-}, X_{T_1}) + g(X_{T_1}) - g(X_{T_1-}) + u(X_{T_1}) \\ (3.25) \quad &= K(b, a) + g(a) - g(b) + u(a) = \bar{K}(b, a) + u(a), \\ u(0) &= u(X_{\tau_0}) = P - g(X_{\tau_0}) = P - g(0), \end{aligned}$$

and we have

$$(3.26) \quad u(x) = \begin{cases} u_0(x), & x \in [0, b), \\ \bar{K}(x, a) + u_0(a), & x \in [b, \infty), \end{cases}$$

where

$$u_0(x) \triangleq \mathbb{E}^x[1_{\{\tau_b < \tau_0\}} e^{-\alpha \tau_b} u(b)] + \mathbb{E}^x[1_{\{\tau_b > \tau_0\}} e^{-\alpha \tau_0} u(0)].$$

The second equation of (3.26) is obtained from (3.24) by noticing that, on  $x \in [b, \infty)$ ,  $\mathbb{P}^x(T_1 < \tau_0) = 1$ . Indeed, in this case, we immediately jump to  $a$ , so that  $X_{T_1-} = x$  and  $X_{T_1} = a$ . Since  $a \in (0, b)$ ,  $u(a) = u_0(a)$ . Now let us note that we have the following representations in (3.24):

$$\mathbb{E}^x[e^{-\alpha \tau_r} 1_{\{\tau_r < \tau_l\}}] = \frac{\psi(l)\varphi(x) - \psi(x)\varphi(l)}{\psi(l)\varphi(r) - \psi(r)\varphi(l)}, \quad x \in [l, r],$$

where  $\tau_l \triangleq \inf\{t > 0; X_t = l\}$  and  $\tau_r \triangleq \inf\{t > 0; X_t = r\}$ ;  $\varphi(\cdot)$  and  $\psi(\cdot)$  are defined in the previous section. Finally, with  $F(\cdot)$  being defined as in (2.3), we have a characterization of  $u(x)$  in the continuation region:

$$(3.27) \quad \frac{u(x)}{\varphi(x)} = \frac{u(b)(F(x) - F(0))}{\varphi(b)(F(b) - F(0))} + \frac{u(0)(F(b) - F(x))}{\varphi(0)(F(b) - F(0))}, \quad x \in [0, b].$$

Define the transformation

$$(3.28) \quad W \triangleq \frac{u}{\varphi} \circ F^{-1},$$

and (3.27) becomes, for any  $a > 0$  and  $b > 0$ ,

$$(3.29) \quad W(F(x)) = W(F(b)) \frac{F(x) - F(0)}{F(b) - F(0)} + W(F(0)) \frac{F(b) - F(x)}{F(b) - F(0)}, \quad x \in [0, b],$$

which represents a *linear function* that passes a fixed point  $(F(0), W(F(0)))$ .

To discuss how to find the optimal pair  $(a^*, b^*)$ , we write  $u(x)$  as  $u_{a,b}(x)$  to emphasize the dependence on  $a, b$ , then on  $x \in [0, b]$ :

$$\begin{aligned} (3.30) \quad \sup_{a \in \mathbb{R}_+, b \in \mathbb{R}_+} u_{a,b}(x) &= \sup_{a \in \mathbb{R}_+} \sup_{b \in \mathbb{R}_+} \{ \mathbb{E}^x[1_{\{\tau_b < \tau_0\}} e^{-\alpha \tau_b} (\bar{K}(b, a) \\ &\quad + u_{a,b}(a))] + \mathbb{E}^x[1_{\{\tau_b > \tau_0\}} e^{-\alpha \tau_0} u_{a,b}(0)] \}. \end{aligned}$$

This can be considered as a two-stage optimization problem. First, let  $a$  be fixed. For each  $a$ , the inner maximization of (3.30) becomes

$$(3.31) \quad V_a(x) \triangleq \sup_{\tau_b \in \mathcal{S}} \{ \mathbb{E}^x [1_{\{\tau_b < \tau_0\}} e^{-\alpha \tau_b} (\bar{K}(b, a) + V_a(a))] + \mathbb{E}^x [1_{\{\tau_b > \tau_0\}} e^{-\alpha \tau_0} (P - g(0))] \},$$

and, among  $a$ 's, choose an optimal  $a$  in the sense that  $\tilde{v}(x) \triangleq \sup_a V_a(x)$  for any  $x$ . It should be pointed out that  $V_a(x)$  may take negative values if  $P - g(0)$  does. Now we discuss a solution method of the first stage optimization (3.31). For this purpose, we need a technical lemma.

LEMMA 3.5. *If we define*

$$G(x, \gamma) \triangleq \sup_{\tau \in \mathcal{S}} \mathbb{E}^x [e^{-\alpha \tau} (h(X_\tau^0) + \gamma)], \quad x \in \mathbb{R}, \gamma \in \mathbb{R},$$

for some Borel function  $h : \mathbb{R} \rightarrow \mathbb{R}$  and with condition (3.6), then, for  $\gamma_1 > \gamma_2 \geq 0$ ,

$$(3.32) \quad G(x, \gamma_1) - G(x, \gamma_2) \leq \gamma_1 - \gamma_2$$

for any  $x$ .

*Proof.* The left-hand side of (3.32) is well-defined due to (3.6). It is clear that  $G(x, \gamma)$  is convex in  $\gamma$  for any  $x$ . Then  $D_\gamma^+ G(x, \gamma_0) \triangleq \lim_{\gamma \downarrow \gamma_0} \frac{G(x, \gamma_0) - G(x, \gamma)}{\gamma_0 - \gamma}$  exists at every  $\gamma_0 \in \mathbb{R}$ , and

$$(3.33) \quad \frac{G(x, \gamma_1) - G(x, \gamma_2)}{\gamma_1 - \gamma_2} \leq D_\gamma^+ G(x, \gamma_1).$$

Consider the bound of  $G(x, \gamma)$  for  $x$  fixed:

$$G(x, \gamma) \leq \sup_{\tau \in \mathcal{S}} \mathbb{E}^x [e^{-\alpha \tau} |h(X_\tau^0)|] + |\gamma| \sup_{\tau \in \mathcal{S}} \mathbb{E}^x [e^{-\alpha \tau}].$$

The first term on the right-hand side is constant in  $\gamma$ ; the second term is linear in  $\gamma$ , and  $\mathbb{E}^x [e^{-\alpha \tau}] \leq 1$  for any  $\tau \in \mathcal{S}$ . Due to the convexity of  $G(x, \gamma)$  in  $\gamma$ , for the above inequality to hold,  $D_\gamma^+ G(x, \gamma) \leq 1$  for all  $\gamma \in \mathbb{R}$ . On account of (3.33), we have (3.32).  $\square$

Coming back to (3.31), we need some care because the value function  $V_a(x)$  contains its value at  $a$ , i.e.,  $V_a(a)$  in the definitive equation. Let us consider a family of optimal stopping problem parameterized by  $\gamma \in \mathbb{R}$ :

$$(3.34) \quad \begin{aligned} V_a^\gamma(x) &\triangleq \sup_{\tau \in \mathcal{S}} \{ \mathbb{E}^x [1_{\{\tau < \tau_0\}} e^{-\alpha \tau} (\bar{K}(X_\tau, a) + \gamma)] + \mathbb{E}^x [1_{\{\tau > \tau_0\}} e^{-\alpha \tau_0} (P - g(0))] \} \\ &= \sup_{\tau \in \mathcal{S}} \mathbb{E}^x [e^{-\alpha \tau} r^\gamma(X_\tau, a)], \end{aligned}$$

where

$$r^\gamma(x, a) = \begin{cases} P - g(0), & x = 0, \\ \bar{K}(x, a) + \gamma, & x > 0. \end{cases}$$

Obviously, this parameterized problem can be solved by using Propositions 2.1–2.3. Now we link this parameterized optimal stopping problem to (3.31).

LEMMA 3.6. *For  $a > 0$  given, if there exists a solution to (3.34), then there always exists unique  $\gamma$  such that  $\gamma = V_a^\gamma(a)$  holds, provided that (3.4) holds.*

*Proof.* Without loss of generality, we need only to consider the case where

$$(3.35) \quad \sup_{x \in \mathbb{R}_+} \bar{K}(x, a) > 0$$

for some  $a > 0$ . Indeed, suppose that there is no such  $a$ , and let us consider a sequence of optimal stopping scheme. In each iteration, the value function for the optimal stopping problem takes negative values, so that  $\phi_n(\cdot) < 0$  for all  $n$ . Then in the next iteration,  $\bar{K}(x, y)$  function will be shifted downwards, leading to  $\phi_{n+1}(\cdot) < 0$ . Hence the “no interventions” strategy is trivially optimal.

In (3.34), since  $\gamma$  is some constant parameter, we benefit from Proposition 2.1 and claim that  $V_a^\gamma(x)$  is characterized as the smallest  $F$ -concave majorant of  $r^\gamma(\cdot, a)$  that passes  $(F(0), \frac{P-g(0)}{\varphi(0)})$ . In terms of the notation of Proposition 2.3, if we define  $W_a^\gamma(\cdot)$  such that

$$V_a^\gamma(x) = \varphi(x)W_a^\gamma(F(x)),$$

then  $W_a^\gamma(\cdot)$  passes through the fixed point  $A = (F(0), W_a^\gamma(F(0)))$  and is the smallest concave majorant of  $H^\gamma(\cdot, a) \triangleq \frac{r^\gamma(F^{-1}(\cdot), a)}{\varphi(F^{-1}(\cdot))} = \frac{\bar{K}(F^{-1}(\cdot), a)}{\varphi(F^{-1}(\cdot))} + \frac{\gamma}{\varphi(F^{-1}(\cdot))}$ .

Now fix  $a$ . Our approach here is that, by starting with  $\gamma = 0$ , we move  $\gamma$  upwards, evaluate  $V_a^\gamma(a)$ , and try to find  $\gamma$  such that  $\gamma = V_a^\gamma(a)$ . Due to (3.35), we have  $W_a^0(F(a)) > 0$ . By the monotonicity of  $F$ , it is equivalent to saying that  $V_a^0(a) > 0 = \gamma$ . As  $\gamma$  increases,  $W_a^\gamma(F(a))$  increases monotonically: See the right-hand side of (3.34).

Lemma 3.5 implies that, for  $\gamma_1 > \gamma_2 \geq 0$ ,

$$(3.36) \quad V_a^{\gamma_1}(x) - V_a^{\gamma_2}(x) \leq \gamma_1 - \gamma_2$$

for any  $x \in \mathbb{R}_+$ . Note that  $W_a^\gamma(F(a)) \geq H^\gamma(F(a), a)$ . However, since  $V_a^\gamma$  has less than the linear growth in  $\gamma$  as demonstrated by (3.36), there is a certain  $\gamma'$  large enough such that  $W_a^\gamma(F(a)) = H^\gamma(F(a), a)$  for  $\gamma \geq \gamma'$ . This implies that

$$\begin{aligned} \varphi(a)W_a^{\gamma'}(F(a)) &= \varphi(a)H^{\gamma'}(F(a), a) \\ \Leftrightarrow V_a^{\gamma'}(a) &= \bar{K}(a, a) + \gamma' < \gamma', \end{aligned}$$

where the inequality is due to the assumption (3.4). For this  $\gamma'$ , we have  $V_a^{\gamma'}(a) < \gamma'$ .

The monotonicity and continuity of  $W^\gamma(F(a))$  (due to the convexity of  $V_a^\gamma(\cdot)$ ) with respect to  $\gamma$ , together with (3.36), implies that, for any  $a$ , there exists one and only one  $\gamma$  such that  $V_a^\gamma(a) = \gamma$ .  $\square$

**3.3. Methodology to find  $v(x)$  and  $(a^*, b^*)$ .** By using (3.27), namely, the characterization of  $u_{a,b}$ , we describe an optimization procedure based on Propositions 2.2 and 2.3.

1. Fix  $a > 0$ . Consider the function

$$(3.37) \quad R(\cdot, a) \triangleq \frac{\bar{K}(F^{-1}(\cdot), a)}{\varphi(F^{-1}(\cdot))}.$$

Define  $W_a(\cdot)$  such that  $V_a(x) = \varphi(x)W_a(F(x))$  and, by the linear characterization (3.29), it is a straight line with a slope, say,  $\beta(a)$ , and passes through  $(F(0), W_a(F(0))) = (F(0), \frac{P-g(0)}{\varphi(0)})$ . We can write the linear majorant, in general,

$$(3.38) \quad W_a(y) = \beta(a)y + \delta.$$

2. *First stage optimization:* For each slope  $\beta(a)$ , we can calculate the value of  $W_a(F(a))$ , but we have to find the  $W_a(\cdot)$  function such that, at some point  $F(b(a))$ , we have

$$(3.39) \quad W_a(F(b)) = R(F(b), a) + W_a(F(a)) \frac{\varphi(a)}{\varphi(b)},$$

where we write  $b(a) \equiv b$  for notational simplicity. This requirement is equivalent to finding  $\gamma$  in (3.34) in Lemma 3.6 such that

$$\frac{\gamma}{\varphi(a)} = W_a^\gamma(F(a)).$$

Let us denote the right-hand side of (3.39) by

$$(3.40) \quad \Phi(y, a) \triangleq R(y, a) + W_a(F(a)) \frac{\varphi(a)}{\varphi(F^{-1}(y))}, \quad y \in (F(c), F(d)).$$

By Proposition 3.4,  $(0, b(a))$  is the continuation region. If  $R$  is a differentiable function with respect to the first argument, we can find the optimal point  $b(a)$  analytically. In fact, it is to find a point  $b(a)$  such that the linear majorant and the shifted function  $\Phi(y, a)$  have a tangency point. This is equivalent to calculating the smallest linear majorant of  $\Phi(y, a)$  (due to Proposition 3.3 and the linear characterization (3.29)). Explicitly, we solve

$$(3.41) \quad \left( \frac{\bar{K}(b, a)}{\varphi(b)} \right)' - \frac{\varphi'(b)\varphi(a)}{\varphi(b)^2} \delta = \beta(a) \left( F'(b) + \frac{\varphi'(b)\varphi(a)}{\varphi(b)^2} F(a) \right)$$

for  $b(a)$ , where  $\beta(a)$  is

$$(3.42) \quad \beta(a) = \frac{\varphi(b)R(F(b), a) - \delta(\varphi(b) - \varphi(a))}{F(b)\varphi(b) - F(a)\varphi(a)}.$$

For the absorbing boundary case, these equations can be easily modified. Let us denote that  $D \triangleq W_a(F(0)) = (P - g(0))/\varphi(0)$ . Then (3.41) and (3.42) become, by substituting

$$(3.43) \quad \delta = D - \beta(a)F(0)$$

in (3.41),

$$(3.44) \quad \left( \frac{\bar{K}(b, a)}{\varphi(b)} \right)' - \frac{\varphi'(b)\varphi(a)}{\varphi(b)^2} D = \beta(a) \left( F'(b) + \frac{\varphi'(b)\varphi(a)}{\varphi(b)^2} (F(a) - F(0)) \right)$$

and

$$(3.45) \quad \beta(a) = \frac{\varphi(b)R(F(b), a) - D(\varphi(b) - \varphi(a))}{(F(b) - F(0))\varphi(b) - (F(a) - F(0))\varphi(a)},$$

respectively.

3. *Second stage optimization:* To summarize up to this point, we set  $a$  and find  $b(a)$  and in turn  $\beta(a)$ . Now, let  $a$  vary, and choose, among  $\beta(a)$ , the largest slope  $\beta^* \triangleq \max_{a \in \mathbb{R}_+} \beta(a)$ , if it exists, and also the corresponding  $a^*$  and

$b(a^*)$ . Due to the characterization of the value function with (3.30), these  $a^*$  and  $b^* \triangleq b(a^*)$  must be the solution to (3.8).

If  $\bar{K}(x, y)$  is a differentiable function with respect to both the first and second arguments, then we can find  $a^*$  analytically. If, for any  $a \in \mathbb{R}_+$ ,  $\Phi(y, a)$  is strictly concave in  $y$  at  $F(b)$ ,  $a^*$  must satisfy

$$(3.46) \quad \left( \frac{\partial \bar{K}(b, a)}{\partial a} + \delta \varphi'(a) \right) (\psi(b) - \psi(a)) \\ = - (\bar{K}(b, a) - \delta(\varphi(b) - \varphi(a))) (F'(a)\varphi(a) + F(a)\varphi'(a)).$$

Therefore, in this case, our nonlinear optimization procedure is just to solve (3.41) and (3.46) with (3.42), simultaneously. We postpone the derivation of (3.46) to the appendix.

*Remark 3.1.* With respect to the third point of the proposed method above, we should check if there exists a concave majorant as  $a \downarrow 0$ . Namely, we consider whether

$$\lim_{a \downarrow 0} (K(x, a) - (g(x) - g(a)) + u(a)) < P - g(0)$$

holds in the neighborhood of  $a = 0$ . Since  $\lim_{x \downarrow 0} g(x) = \lim_{a \downarrow 0} g(a)$  and  $\lim_{a \rightarrow 0} u(a) = u(0) = P - g(0)$  by the continuity of  $u$ , the last inequality holds due to (3.4).

### 3.4. Characterization of the intervention times and the value function:

**General case.** Let us move on to a general case where the mapping  $x \rightarrow \frac{\bar{K}}{\varphi}(x) : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is not necessarily  $F$ -concave. First, we extend Proposition 3.4 to characterize optimal intervention times.

**PROPOSITION 3.7.** *The value function  $v(x)$  for (3.8) is given by the smallest solution majorizing  $g$  of  $v - g = \mathcal{L}(v - g)$ , and optimal intervention times  $T_i^*$  are given by exit times from an interval if and only if, for all  $y \in \mathbb{R}_+$ ,*

$$(3.47) \quad x \rightarrow \bar{K}(x, y) \text{ is continuous and } q \triangleq \limsup_{x \rightarrow \infty} D^- \left( \frac{\bar{K}}{\varphi} \circ F^{-1} \right) (x) \text{ is finite,}$$

where  $D^- f(x_0) \triangleq \limsup_{x \uparrow x_0} \frac{f(x) - f(x_0)}{x - x_0}$ .

*Proof.* For any given  $a \in \mathbb{R}_+$ , if we can find the smallest linear majorant of  $\frac{\bar{K}(F^{-1}(\cdot), a) + \gamma}{\varphi(F^{-1}(\cdot))}$  for an arbitrary  $\gamma \in \mathbb{R}_+$ , we can find  $\gamma = \varphi(a)W_a(F(a))$  by Lemma 3.6. Due to the constancy of  $\gamma$ , it suffices to show that condition (3.47) is necessary and sufficient for the existence of concave majorant of  $\frac{\bar{K}}{\varphi} \circ F^{-1}$  on  $F(\mathcal{I})$ . The sufficiency is immediate. For the necessity, we assume that  $q = +\infty$ . We can take a sequence of points  $\{x^k\} \subset \mathbb{R}$  such that  $x^k \rightarrow \infty$  and  $D^-(\frac{\bar{K}}{\varphi} \circ F^{-1})(x^k) \rightarrow \infty$  as  $k \rightarrow \infty$ . If necessary, by taking a subsequence, we can make this sequence  $\{x^k\}$  monotone. Consider the smallest concave majorant of  $\frac{\bar{K}}{\varphi} \circ F^{-1}$  on  $[F(0), F(x^k)]$ . Call it  $v^k(x)$ . It is clear that  $v^k(x)$  is monotone increasing in  $k$  for all  $x \in [F(0), F(x^k)]$ . As  $k \rightarrow \infty$ ,  $x^k \rightarrow \infty$  and  $v(x) \geq v^k(x)$ . We thus have  $v(x) = \lim_{k \rightarrow \infty} v^k(x) = \infty$  for all  $x \in \mathbb{R}_+$ . There is no optimal intervention policy.  $\square$

Suppose that the  $F$ -concavity of the reward function is violated, so that the intervention point may be multiple. For the rest of this subsection, as is practically the case (see our examples in section 4), we study the case where  $\Phi(y, a)$ , with  $y = F(x)$ , is increasing to infinity and becomes eventually concave and then derive linear characterization as in section 3.2.

Let us consider a strategy where we have two intervention points  $b_1$  and  $b_2$  being arbitrarily chosen such that  $0 < b_1 < b_2$ . We want to characterize function  $J^\nu(x)$  as in (3.5) again. Recall that there are no controls in a way that the process is pulled up to avoid ruin. In other words,  $\mathbb{P}^x[\tau_0 < \infty] = 1$ . Assume, for the moment, that we always apply control at these boundaries  $b_1$  and  $b_2$  and then, once applied, the process moves to  $a_1 < b_1$  and  $a_2 < b_2$ , respectively.

If we start with a point  $x \in [0, b_1]$ , the problem is equivalent to the case we considered already, since the process cannot go beyond the level  $b_1$ . Hence by following (3.26), we have for  $x \in [0, b_1]$

$$J_1^\nu(x) \triangleq \mathbb{E}^x \left[ \int_0^{\tau_0} e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau_0} P + \sum_{T_i < \tau_0} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right]$$

and

$$u_1(x) = \mathbb{E}^x[1_{\{\tau_{b_1} < \tau_0\}} e^{-\alpha \tau_{b_1}} u_1(b_1)] + \mathbb{E}^x[1_{\{\tau_{b_1} > \tau_0\}} e^{-\alpha \tau_0} u_1(0)], \quad x \in [0, b_1],$$

by defining  $u_1(x) \triangleq J_1^\nu(x) - g(x)$ . If we start with a point  $x \in [b_1, b_2]$ , there are two strategies available:

- (A) Let  $X_t$  move along. (It hits either  $b_1$  or  $b_2$  first.)
- (B) Apply the control immediately ( $t = 0$ ) by moving the process from  $x$  to  $a_1$  (the postcontrol point that corresponds to  $b_1$ ), and let the process start at  $a_1$ . (Recall that we do not let  $X$  enter into  $(b_1, \infty)$  after moving to  $a_1$ .)

Consider strategy (A) first. Let us define

$$J_2^\nu(x) \triangleq \mathbb{E}^x \left[ \int_0^{\tau_{b_1}} e^{-\alpha s} f(X_s) ds + \sum_{T_i < \tau_{b_1}} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right] \quad x \in [b_1, b_2].$$

By using the strong Markov property at the first intervention, we can reduce  $J_2^\nu$  to a simpler form. For any  $(a_1, b_1)$  and  $(a_2, b_2)$ , we have

$$\begin{aligned} J_2^\nu(x) &= \mathbb{E}^x[1_{\{\tau_{b_1} < \tau_{b_2}\}} e^{-\alpha \tau_{b_1}} K(X_{\tau_{b_1}-}, X_{\tau_{b_1}}) - g(X_{\tau_{b_1}}) + J_1^\nu(X_{\tau_{b_1}}) + g(X_{\tau_{b_1}}) - g(X_{\tau_{b_1}-})] \\ &+ \mathbb{E}^x[1_{\{\tau_{b_1} > \tau_{b_2}\}} e^{-\alpha \tau_{b_2}} K(X_{\tau_{b_2}-}, X_{\tau_{b_2}}) - g(X_{\tau_{b_2}}) + J_2^\nu(X_{\tau_{b_2}}) + g(X_{\tau_{b_2}}) - g(X_{\tau_{b_2}-})] + g(x). \end{aligned}$$

We shall use  $u_1(x) = J_1^\nu(x) - g(x)$  in the first term. Now let us define  $u_2(x) \triangleq J_2^\nu(x) - g(x)$ . Then the last equation becomes

$$\begin{aligned} u_2(x) &= \mathbb{E}^x[1_{\{\tau_{b_1} < \tau_{b_2}\}} e^{-\alpha \tau_{b_1}} K(X_{\tau_{b_1}-}, X_{\tau_{b_1}}) + u_1(X_{\tau_{b_1}}) + g(X_{\tau_{b_1}}) - g(X_{\tau_{b_1}-})] \\ &+ \mathbb{E}^x[1_{\{\tau_{b_1} > \tau_{b_2}\}} e^{-\alpha \tau_{b_2}} K(X_{\tau_{b_2}-}, X_{\tau_{b_2}}) + u_2(X_{\tau_{b_2}}) + g(X_{\tau_{b_2}}) - g(X_{\tau_{b_2}-})] \\ &= \mathbb{E}^x[1_{\{\tau_{b_1} < \tau_{b_2}\}} e^{-\alpha \tau_{b_1}} (\bar{K}(b_1, a_1) + u_1(a_1))] \\ (3.48) \quad &+ \mathbb{E}^x[1_{\{\tau_{b_1} > \tau_{b_2}\}} e^{-\alpha \tau_{b_2}} (\bar{K}(b_2, a_2) + u_2(a_2))] \end{aligned}$$

on  $x \in [b_1, b_2]$ . By identifying  $\bar{K}(b_2, a_2) + u_2(a_2) = u_2(b_2)$  and  $u_2(b_1) = \bar{K}(b_1, a_1) + u_1(a_1) = u_1(b_1)$  (the latter shows that  $u_1(x)$  and  $u_2(x)$  are connected at  $x = b_1$ ),

$$(3.49) \quad u_2(x) = \frac{\varphi(x)}{\varphi(b_1)} \frac{F(b_2) - F(x)}{F(b_2) - F(b_1)} u_2(b_1) + \frac{\varphi(x)}{\varphi(b_2)} \frac{F(x) - F(b_1)}{F(b_2) - F(b_1)} u_2(b_2), \quad x \in [b_1, b_2].$$

To summarize this result, if we define  $W_i(\cdot) \triangleq \frac{u_i}{\varphi} \circ F^{-1}(\cdot)$  for  $i = 1, 2$  on  $F(\mathcal{I})$ , this is again a linear function for each  $i$ . Hence by defining

$$W_A(F(x)) \triangleq \begin{cases} W_1(F(x)) = W_1(F(0)) \frac{F(b_1) - F(x)}{F(b_1) - F(0)} + W_1(F(b_1)) \frac{F(x) - F(0)}{F(b_1) - F(0)}, & x \in [0, b_1], \\ W_2(F(x)) = W_2(F(b_1)) \frac{F(b_2) - F(x)}{F(b_2) - F(b_1)} + W_2(F(b_2)) \frac{F(x) - F(b_1)}{F(b_2) - F(b_1)}, & x \in [b_1, b_2], \end{cases}$$

we have a piecewise linear function on  $F(\mathcal{I})$ .

Next consider strategy (B), whose value function is

$$(3.50) \quad W_B(F(x)) \triangleq \begin{cases} W_1(F(x)), & 0 \leq x \leq b_1, \\ \overline{W}_1(F(x)) \triangleq \frac{\varphi(a_1)}{\varphi(x)} W_1(F(a_1)) + R(F(x), a_1), & b_1 < x. \end{cases}$$

LEMMA 3.8. (A) is better than (B) only if

$$\beta_1 \triangleq \frac{W(F(b_1)) - W(F(0))}{F(b_1) - F(0)} < \frac{W(F(b_2)) - W(F(b_1))}{F(b_2) - F(b_1)} \triangleq \beta_2.$$

*Proof.* Since the value function of strategy (B) is (3.50), choosing (A) over (B) is equivalent to

$$\overline{W}_1(F(x)) < W_2(F(x)) \quad \text{on } x > b_1.$$

If  $W_1(F(x))$  majorizes  $\overline{W}_1(F(x))$  on  $x \in [0, \infty)$ , then this problem reduces to the  $F$ -concavity case discussed in the previous subsection. Hence we consider the case where there exists some  $x \in [b_1, \infty)$  such that

$$W_1(F(x)) < \overline{W}_1(F(x)).$$

Now suppose that we have  $\beta_1 \geq \beta_2$ . Then it is clear that we cannot have  $W_2(F(x)) > \overline{W}_1(F(x))$  on  $x \in [b_1, \infty)$ .  $\square$

There are two cases to consider:

- (1) If  $W_2(F(x))$  majorizes  $\overline{W}_1(F(x))$  on  $x \in [b_1, \infty)$ , then we adopt the point  $b_2$  as an intervention point. In this case,  $\beta_2 > \beta_1$  holds. However, this implies that if we connect  $A \triangleq (F(0), W_1(F(0)))$  and  $C \triangleq (F(b_2), W_2(F(b_2)))$ , then this line segment  $AC$  is above the line segment connecting, piece by piece, points  $A$ ,  $B \triangleq (F(b_1), W_1(F(b_1)))$  and  $C$ . We can show that there exists a point  $b' \geq b_2$  such that its corresponding linear majorant  $W'(F(x))$  satisfies  $W'(F(x)) > W_1(F(x))$  on  $x \in [0, b_1]$  and  $W'(F(x)) > W_2(F(x))$  on  $[b_1, b_2]$ . The proof of the existence of a postintervention point  $a'$  corresponding to this point  $b'$  follows in a similar manner to Lemma 3.6.
- (2) If  $W_2(F(x))$  does not majorize  $\overline{W}_1(F(x))$ , we can find another point  $\bar{b}$ , instead of  $b_1$ , such that the linear (not piecewise linear) function  $W(F(x))$  corresponding to  $\bar{b}$  majorizes  $R(F(x), \bar{a}) + W(F(\bar{a})) \frac{\varphi(\bar{a})}{\varphi(x)}$  on  $x \in \mathbb{R}_+$  by Proposition 3.7.

In either case, the value function in the transformed space should be a linear function that attains the largest slope among all of the possible linear majorants. This argument holds true for any  $b_1$  and  $b_2$  with  $b_1 < b_2$ . We can continue this argument inductively to the case of  $n$  intervention points  $(b_1, \dots, b_n)$ . We here summarize our argument up to this point as a main proposition.

PROPOSITION 3.9. Suppose that (3.47) holds and the optimal continuation region is connected. The value function corresponding to (3.5) of the impulse problem described in (3.3)–(3.8) is written as

$$(3.51) \quad v(x) = \begin{cases} v_0(x) \triangleq \varphi(x)W^*(F(x)) + g(x), & 0 \leq x \leq b^*, \\ v_0(a^*) + K(x, a^*), & b^* \leq x, \end{cases}$$

where  $W^*(\cdot)$  is the line segment connecting  $(F(0), W^*(F(0)))$  and  $(F(b^*), W^*(F(b^*)))$  and satisfies the following:

1.  $W^*(F(\cdot))$  is the smallest linear majorant of  $W^*(F(a^*))\frac{\varphi(a^*)}{\varphi(\cdot)} + R(F(\cdot), a^*)$  and meets with  $W^*(F(a^*)) + R(F(\cdot), a^*)\frac{\varphi(a^*)}{\varphi(\cdot)}$  at point  $F(b^*)$  and passes  $(F(0), \frac{P-g(0)}{\varphi(0)})$ . If  $R$  is differentiable,  $(a^*, b^*)$  satisfy (3.41).
2. The slope of  $W^*(\cdot)$ , denoted as  $\beta^*$ , is the largest slope among  $\beta(a)$ 's of all of the possible linear majorants  $W_a(\cdot)$ .

Moreover, if the mapping  $x \rightarrow \frac{\bar{K}}{\varphi}(x) : \mathbb{R}_+ \rightarrow \mathbb{R}_+$  is  $F$ -concave, then the optimal continuation region  $(0, b^*)$  is uniquely determined.

Note that, at  $x = 0$ ,

$$v(0) = \varphi(0)W^*(F(0)) + g(0) = \varphi(0)\frac{P-g(0)}{\varphi(0)} + g(0) = P$$

as expected.

Remark 3.2. If the  $F$ -concavity of  $\bar{K}/\varphi$  is violated, there are at least two possible cases (and a combination of them) where we have multiple continuation regions with a linear value function in the continuation region of the transformed space.

1. For some  $a_i^*$ , with  $i = 1, 2, \dots$ , we have the common  $\beta^*$ . This is the case which we shall show in the next example. In this case, the continuation region is  $C = \{(0, b_1^*), (b_1^*, b_2^*), (b_2^*, b_3^*) \dots\}$ , where  $b_i^*$  corresponds to  $a_i^*$  for each  $i$ , and the intervention region is  $\Gamma = \{\{b_1^*\}, \{b_2^*\}, \{b_3^*\} \dots\}$ . Each time the process hits one of the points  $\{b_i^*\}$ , the control pulls the process back to the corresponding  $a_i^*$ .
2. Another case is that, for the unique optimal  $a^*$ , there exist nonunique  $b_1^*$  and  $b_2^*$ . In this case, the continuation region is  $C = \{(0, b_1^*), (b_1^*, b_2^*)\}$ , and the stopping region is  $\Gamma = \{\{b_1^*\}, [b_2^*, \infty)\}$ . If the process hits  $b_1^*$  or  $b_2^*$ , then the control pulls the process back to  $a^*$  in either situation. It makes sense to continue in the region  $(b_1^*, b_2^*)$  because there is a positive probability that one can extract  $\bar{K}(b_2^*, a^*) (> \bar{K}(b_1^*, a^*))$  within a finite time.

**3.5. No absorbing boundary case.** Next, we extend our argument to a problem without the absorbing boundary. Hence the process can move along in the state space in an infinite amount of time. The problem becomes

$$(3.52) \quad J^\nu(x) = \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + \sum_{i=1} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right].$$

We can characterize intervention times as exit times from a certain boundary and simplify the performance measure (3.52):

$$\begin{aligned} J^\nu(x) &= \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + \sum_{i=1} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right] \\ &= \mathbb{E}^x [e^{-\alpha T_1} \{K(X_{T_1-}, X_{T_1}) - g(X_{T_1-}) + J^\nu(X_{T_1})\}] + g(x). \end{aligned}$$

The second equation is easily obtained in the same way as in the previous section by noting that  $\mathbb{P}^x(T_1 < \infty) = 1$ . The last term does not depend on controls, so we define  $u(x) \triangleq J^\nu(x) - g(x)$ :

$$u(x) = \mathbb{E}^x[e^{-\alpha T_1}\{K(X_{T_1-}, X_{T_1}) - g(X_{T_1-}) + g(X_{T_1}) + u(X_{T_1})\}].$$

Again, we consider the  $F$ -concave case with the notation  $T_i- = \tau_b$  for all  $i$ , and we have

$$u(x) = \mathbb{E}^x[e^{-\alpha \tau_b}(K(b, a) - g(b) + g(a) + u(a))] = \mathbb{E}^x[e^{-\alpha \tau_b}(\bar{K}(b, a) + u(a))].$$

By defining  $W = (u/\varphi) \circ F^{-1}$ , we have

$$W(F(x)) = W(F(c))\frac{F(b) - F(x)}{F(b) - F(c)} + W(F(b))\frac{F(x) - F(c)}{F(b) - F(c)}, \quad x \in (c, b].$$

We should note that  $F(c) \triangleq F(c+) = \psi(c+)/\varphi(c+) = 0$  and

$$W(F(c)) = l_c \triangleq \limsup_{x \downarrow c} \frac{\bar{K}(x, a)^+}{\varphi(x)}$$

for any  $a \in (c, d]$ . For a more detailed mathematical meaning of this value  $l_c$ , we refer the reader to Dayanik and Karatzas [13]. We can effectively consider  $(F(c), l_c)$  as the absorbing boundary.

**4. Examples.** In this section, we work out some examples from financial engineering problems. As described in section 3.3, the main task to find solutions now reduces to analyzing the reward function in the transformed space and finding the smallest linear majorant. Let us recall that, for given  $a \in \mathbb{R}$ , the shifted reward function in the transformed space is (3.40), that is,

$$(4.1) \quad \Phi(y, a) = R(y, a) + W_a(F(a))\frac{\varphi(a)}{\varphi(F^{-1}(y))}, \quad y \in (F(c), F(d)),$$

in which  $R(\cdot, a)$  is given by (3.37) and  $W_a(\cdot)$  is given by (3.38). For the purpose of analyzing  $\Phi(\cdot, a)$ , we recall some useful observations: If  $h(\cdot)$  is twice-differentiable at  $x \in \mathcal{I}$  and  $y \triangleq F(x)$ , then  $H'(y) = m(x)$  and  $H''(y) = m'(x)/F'(x)$ , with

$$(4.2) \quad m(x) = \frac{1}{F'(x)} \left( \frac{h}{\varphi} \right)'(x), \quad \text{and} \quad H''(y)(\mathcal{A} - \alpha)h(x) \geq 0, \quad y = F(x),$$

with strict inequality if  $H''(y) \neq 0$ . These identities are of practical use in identifying the concavities of  $H(\cdot)$  when it is hard to calculate its derivatives explicitly. Before the transformation defined by (3.28), (4.1) is of the form  $\bar{K}(x, a) + u(a)$ . Hence, for a fixed  $a$ , we read  $h(x) = \bar{K}(x, a)$  for the first term of (4.1) and  $h(x) = \text{constant}$  for the second term of (4.1) to apply (4.2).

*Remark 4.1.* It is worth examining  $h(x) = k$ , where  $k \in \mathbb{R}_+$  is a constant. The first equation of (4.2) is  $m(x) = -\frac{k\varphi'(x)}{F'(x)\varphi(x)^2} > 0$  since  $\varphi'(x) < 0$  and  $F'(x) > 0$  for all  $x \in \mathcal{I}$ . As to the second inequality of (4.2),  $(\mathcal{A} - \alpha)k = -\alpha k < 0$ . These facts imply that the second term of (4.1) is always increasing and concave in the transformed space for an  $a$  that makes  $W_a(F(a)) > 0$ .

*Example 4.1.* Øksendal [24] considers the following problem:

$$(4.3) \quad J_o^\nu(x) = \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} X_s^2 ds + \sum_i^\infty e^{-\alpha T_i} (c + \lambda \xi_i) \right],$$

where  $X_t^0 = B_t$  is a standard Brownian motion and  $c > 0$  and  $\lambda \geq 0$  are constants. The Brownian motion represents the exchange rate of some currency, and each impulse represents an interventions taken by the central bank in order to keep the exchange rate in a given target zone. Here we are allowed only to give the system impulses  $\zeta$  with values in  $(0, +\infty)$ . By reducing a level from  $b$  to  $a$  (i.e.,  $b > a$ ) through interventions, one can save continuously incurred cost (which is high if the process is at a high level). The problem is to minimize the expected total discounted cost  $v_o(x) = \inf_\nu J_o^\nu(x)$ . We want to solve its sup version and change the sign afterwards (i.e.,  $v_o(x) = -v(x)$ ):

$$v(x) = \sup_\nu \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} (-X_s^2) ds - \sum_i^\infty e^{-\alpha T_i} (c + \lambda \xi_i) \right].$$

*Data:* The continuous cost rate  $f(x) = -x^2$ , and the intervention cost is  $K(x, y) = -c - \lambda(x - y)$  in our terminology. By solving the equation  $(\mathcal{A} - \alpha)v(x) = \frac{1}{2}v''(x) - \alpha v(x) = 0$ , we find  $\psi(x) = e^{x\sqrt{2\alpha}}$  and  $\varphi(x) = e^{-x\sqrt{2\alpha}}$ . Hence  $F(x) = e^{2x\sqrt{2\alpha}}$  and  $F^{-1}(x) = \frac{\log x}{2\sqrt{2\alpha}}$ .  $g(x)$  can be calculated by Fubini's theorem:

$$g(x) = \mathbb{E}^x \left[ \int_0^\infty -e^{-\alpha s} (x + B_s)^2 ds \right] = - \left( \frac{x^2}{\alpha} + \frac{1}{\alpha^2} \right).$$

Note that, when  $b > a$ ,  $g(a) - g(b) > 0$  is the source of cost savings. Hence  $\bar{K}(x, a) = -c - \lambda(x - a) + \frac{x^2 - a^2}{\alpha}$ .

*Analysis of the reward function:* Let us fix  $a > 0$  and consider  $h(x) \triangleq \bar{K}(x, a) = -c - \lambda(x - a) + \frac{x^2 - a^2}{\alpha}$  and  $H(y) \triangleq (h/\varphi)(F^{-1}(y))$ ,  $y > 0$ . By the first equation in (4.2), the sign of  $(\frac{h}{\varphi})'(x)$  will lead us to conclude that  $H(F(x))$  is increasing to infinity from a certain point, say,  $x = p$  on  $(p, \infty)$ , and so is  $H(F(x))$ . Also, by direct calculation,  $H'(+\infty) = 0$ , from which we can assert that the value function is finite by Proposition 3.7.

If we set  $p(x) \triangleq -x^2 + a^2 + \lambda\alpha(x - a) + \alpha c + 1/\alpha$ , then  $(\mathcal{A} - \alpha)h(x) = p(x)$  for every  $x > 0$ . This quadratic function  $p(x)$  possibly has one or two positive roots. Let  $k$  be the largest one. Since  $\lim_{x \rightarrow \infty} p(x) = -\infty$ , by the second inequality in (4.2),  $H(\cdot)$  is concave on  $(F(k), +\infty)$ . Hence  $H(y, a)$  is increasing (to infinity) and concave on  $y \in (F(k), \infty)$ . Since it is obvious that there exists  $a$  such that  $W(F(a)) > 0$ , due to Remark 4.1, the second term of (4.1) is increasing and concave on  $\mathbb{R}_+$ .

Since the cost function in the transformed space is increasing and concave from a certain point on, there is a linear majorant that touches the cost function once and only once. We can conclude that, for any  $a > 0$  and the parameter set, we have a connected continuation region in the form of  $(0, b^*)$ .

*Solution:* For a fixed  $a$ , let us define  $W_a(\cdot)$  such that  $V_a(x) = \varphi(x)W_a(F(x))$  and  $r(x, a) = -c$  if  $x < a$  and  $r(x, a) = h(x) = -c - \lambda(x - a) + \frac{x^2}{\alpha} - \frac{a^2}{\alpha}$  if  $x \geq a$ . Then we have, for any  $a > 0$ ,

$$(4.4) \quad l_{-\infty} = \limsup_{x \downarrow -\infty} \frac{r(x, a)^+}{\varphi(x)} = 0.$$

Recall that the left boundary  $-\infty$  is natural for a Brownian motion. Hence  $W_a(y)$  that passes the origin of the transformed space is the straight-line majorant of  $R(\cdot, a) + W_a(F(a))/\varphi(F^{-1}(\cdot))$ , where  $R(\cdot, a)$  is defined in (3.37):

$$R(y, a) = \begin{cases} -c\sqrt{y}, & 0 \leq y \leq F(a), \\ H(y, a) = \sqrt{y} \left( -c - \frac{\lambda}{2\sqrt{2\alpha}} \log y + \lambda a + \frac{(\log y)^2}{8\alpha^2} - \frac{a^2}{\alpha} \right), & y > F(a). \end{cases}$$

We can represent  $W_a$  as  $W(y) = \beta y$ . Since  $R(x, a)$  is differentiable with respect to  $x$  on  $x \geq a$ , we can use (3.41) to find  $b(a)$  and corresponding  $\beta(a)$ . Then by varying  $a$ , one can find the optimal  $(a^*, b^*, \beta^*)$ . Going back to the original space, on  $x \in (-\infty, b^*]$

$$\tilde{v}(x) \triangleq \sup u(x) = \varphi(x)W^*(F(x)) = \varphi(x)(\beta^*)F(x) = \beta^*e^{x\sqrt{2\alpha}}.$$

To get  $v(x) = \sup_{\nu} J^{\nu}(x)$ , we add back  $g(x)$ :

$$v(x) = \tilde{v}(x) + g(x) = \beta^*e^{x\sqrt{2\alpha}} - \left( \frac{x^2}{\alpha} + \frac{1}{\alpha^2} \right).$$

Finally, flip the sign, and obtain the optimal cost function

$$v_o(x) = \begin{cases} \hat{v}_o(x) \triangleq \left( \frac{x^2}{\alpha} + \frac{1}{\alpha^2} \right) - \beta^*e^{x\sqrt{2\alpha}}, & 0 \leq x \leq b^*, \\ \hat{v}_o(a^*) + c + \lambda(x - a^*), & b^* \leq x, \end{cases}$$

which coincides with the solution given by Øksendal [24]. Figure 1 displays the solution with parameters  $(c, \lambda, \alpha) = (150, 50, 0.2)$ .

*Example 4.2.* This example is a dividend payout problem where the underlying process follows an Ornstein–Uhlenbeck process. This problem was originally studied by Cadenillas, Sarkar, and Zapatero [6]. Suppose that  $X^0$  has the dynamics

$$dX_t^0 = \delta(m - X_t)dt + \sigma dW_t, \quad t \geq 0,$$

where  $\delta > 0$ ,  $\sigma > 0$ , and  $m \in \mathbb{R}$ . Only positive impulse is allowed in this problem. We consider the impulse control problem

$$v(x) \triangleq \sup_{\nu \in S} \mathbb{E}^x \left[ \sum_{T_i < \tau_0}^{\infty} e^{-\alpha T_i} (-K + k\xi_i^{\gamma}) \right],$$

with some positive constants  $K, k$  and the risk-aversion parameter  $\gamma \in (0, 1]$ .

*Data:*  $x = 0$  is an absorbing boundary. Since  $\xi \in \mathbb{R}_+$ , we have

$$\bar{K}(x, y) = k(x - y)^{\gamma} - K, \quad x > y > 0.$$

Since  $f(x) = 0$  for all  $x \in \mathbb{R}$ , we have  $g(x) = 0$ . The functions  $\psi(\cdot)$  and  $\varphi(\cdot)$  are positive, increasing, and decreasing solutions of the differential equation  $(\mathcal{A} - \alpha)v(x) = (1/2)\sigma^2 v''(x) + \delta(m - x)v'(x) - \alpha v(x) = 0$ . We denote, by  $\tilde{\psi}(\cdot)$  and  $\tilde{\varphi}(\cdot)$ , the functions of the fundamental solutions for the auxiliary process  $Z_t \triangleq (X_t - m)/\sigma, t \geq 0$ , which satisfies  $dZ_t = -\delta Z_t dt + dW_t$ . For every  $x \in \mathbb{R}$ ,

$$\tilde{\psi}(x) = e^{\delta x^2/2} \mathcal{D}_{-\alpha/\delta}(-x\sqrt{2\delta}), \quad \tilde{\varphi}(x) = e^{\delta x^2/2} \mathcal{D}_{-\alpha/\delta}(x\sqrt{2\delta}),$$

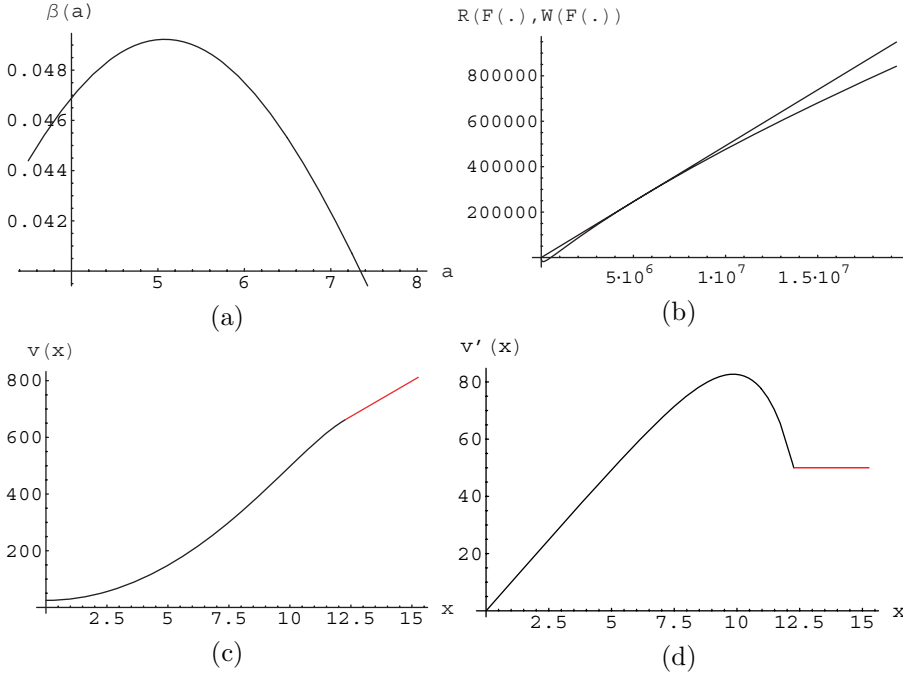

FIG. 1. (a) The plot of  $\beta(a)$  against  $a$ , the former being maximized at  $a^* = 5.077$  with  $\beta^* = 0.0492$ . (b) The functions  $R(F(\cdot), a^*)$  shifted by the amount  $W_{a^*}(F(a^*)) \frac{\varphi(a)}{\varphi(x)}$  (lower curve) and the majorant  $W_{a^*}(F(\cdot))$  (upper curve) corresponding to  $a^*$ , giving us  $b^* = 12.261$ . (c) The cost function  $v_o(x)$ . (d) The derivative of  $v_o(x)$ , showing that the smooth-fit principle holds at  $b^*$ .

$\psi(x) = \tilde{\psi}((x-m)/\sigma)$ , and  $\varphi(x) = \tilde{\varphi}((x-m)/\sigma)$ , where  $\mathcal{D}_\nu(\cdot)$  is the parabolic cylinder function (see [5, Appendices 1.24 and 2.9] and [8, Section 6.3]). By using the relation

$$(4.5) \quad \mathcal{D}_\nu(z) = 2^{-\nu/2} e^{-z^2/4} \mathcal{H}_\nu(z/\sqrt{2}), \quad z \in \mathbb{R},$$

in terms of the Hermite function  $\mathcal{H}_\nu$  of degree  $\nu$  and its integral representation,

$$(4.6) \quad \mathcal{H}_\nu(z) = \frac{1}{\Gamma(-\nu)} \int_0^\infty e^{-t^2 - 2tz} t^{-\nu-1} dt, \quad \operatorname{Re}(\nu) < 0$$

(see, for example, [21, pp. 284, 290]).

*Analysis of the reward function:* Let us consider the function

$$h(x) \triangleq k(x-a)^\gamma - K, \quad x > 0, \gamma \in (0, 1].$$

Since the function  $h(\cdot)$  is positive when  $x$  is large enough and it is increasing to infinity on the whole real line, so is the function  $H(y) = (h/\varphi) \circ F^{-1}(y)$ ,  $y \in (0, \infty)$ .

Since it is obvious that there exists  $a$  such that  $W(F(a)) > 0$ , due to Remark 4.1, the second term of (4.1) is increasing and concave on  $(F(0), \infty)$ . Let us concentrate on the first term and define the function

$$p(x) \triangleq \frac{1}{2} \sigma^2 k \gamma (\gamma - 1) x^{\gamma-2} + m \delta k \gamma x^{\gamma-1} - k(\delta \gamma + \alpha) x^\gamma + \alpha K,$$

which satisfies  $(\mathcal{A} - \alpha)h(x) = p(x)$ . By using (4.2),  $H''(y)$  and  $p(F^{-1}(y))$  have the same sign at every  $y$  where  $h$  is twice-differentiable. Hence we study the (positive)

roots of  $p(x) = 0$ . We have to divide two cases: (1)  $\gamma = 1$  and (2)  $\gamma < 1$ . In either case, it can be shown that  $H'(+\infty) < \infty$  by using (4.5) and (4.6) and the identity  $\mathcal{H}'_\nu(z) = 2\nu\mathcal{H}_{\nu-1}(z)$ ,  $z \in \mathbb{R}$ . Therefore, the finiteness of the value function is proved.

- (1)  $\gamma = 1$ :  $h(\cdot)$  reduces to a linear function, and  $p(x) = 0$  always has one positive root, say,  $p > 0$ . The  $H(\cdot)$  function is convex on  $[0, F(p))$  and concave on  $(F(p), +\infty)$ . Hence we have a connected continuation region  $(0, b^*)$ .
- (2)  $\gamma < 1$ : We observe that  $\lim_{x \downarrow 0} p(x) = -\infty$ ,  $\lim_{x \uparrow +\infty} p(x) = -\infty$ ,  $\lim_{x \downarrow 0} p'(x) = +\infty$ , and  $\lim_{x \uparrow +\infty} p'(x) = 0-$ . A direct analysis of  $p'(x)$  shows that there is only one stationary point in  $(0, \infty)$ , and the number of the roots of  $p(x) = 0$  is either 0, 1, or 2. Hence, in the first two cases,  $H(\cdot)$  is concave on  $[0, \infty)$  and the continuation region is connected. In the last case there are two roots, say,  $0 < p_1 < p_2$ . The  $H(\cdot)$  function is then concave on  $[0, F(p_1)) \cup (F(p_2), +\infty)$  and is convex on  $(F(p_1), F(p_2))$ . Since  $H(\cdot)$  increases and is concave on  $y \in (F(p_2), \infty)$ , we can conclude that the continuation region is connected in this case as well.

*Solution:* Let us move on to finding an optimal continuation region. Unlike the previous example, it is not easy (at least analytically) to find  $F^{-1}(y)$  explicitly. But it is not necessary. We can solve (3.44) for  $b(a)$  with  $D = 0$ :

$$\left( \frac{\bar{K}(b, a)}{\varphi(b)} \right)' = \frac{\bar{K}(b, a)}{\varphi(b)(F(b) - F(0)) - \varphi(a)(F(a) - F(0))} \left( F'(b) + \frac{\varphi'(b)\varphi(a)}{\varphi(b)^2}(F(a) - F(0)) \right).$$

As in the previous examples,  $W_a(\cdot)$  is a straight line passing  $(F(0), 0)$  in the form of  $W_a(y) = \beta(y - F(0))$ . The value function  $v(x)$  in  $x \in (0, b^*)$  is

$$\begin{aligned} \hat{v}(x) &= \varphi(x)W(F(x)) = \beta(F(x) - F(0))\varphi(x) \\ &= \beta^*(\psi(x) - F(0)\varphi(x)) = \beta^*e^{\frac{\delta}{2}\frac{(x-m)^2}{\sigma^2}} \left\{ \mathcal{D}_{-\alpha/\delta} \left( -\left( \frac{x-m}{\sigma} \right) \sqrt{2\delta} \right) \right. \\ &\quad \left. - F(0)\mathcal{D}_{-\alpha/\delta} \left( \left( \frac{x-m}{\sigma} \right) \sqrt{2\delta} \right) \right\}. \end{aligned}$$

Therefore, the solution to the problem is

$$v(x) = \begin{cases} \hat{v}(x), & 0 \leq x \leq b^*, \\ \hat{v}(a^*) + k(x - a^*)^\gamma - K, & b^* \leq x. \end{cases}$$

This solves the problem. See Figure 2(b) for the value function in the case of parameters  $\delta = 0.1$ ,  $m = 0.9$ ,  $\sigma = 0.35$ ,  $\alpha = 0.105$  for the diffusions. As for the reward/cost function parameters,  $k = 0.7$ ,  $K = 0.1$ , and  $\gamma = 0.75$ . The solution is  $(a^*, b^*, \beta) = (0.2192, 0.6220, 0.5749)$ .

*Example 4.3.* We show a simple example where we have multiple continuation regions, the first case of Remark 3.2. Let the uncontrolled process be a standard Brownian motion  $B_t$ , and let  $\alpha = 0$ ,  $f = 0$ , and

$$K(x, y) = -c(\sin x - \sin y) - \delta,$$

with  $c \in \mathbb{R}_+$  and  $\delta \in \mathbb{R}_+$  being some constant parameters. We want to solve

$$v(x) = \sup_{\nu \in \mathcal{S}} \mathbb{E}^x \left[ \sum_{T_i < \tau_0} (\xi_i - \delta) \right].$$

FIG. 2. (a) The value function for the Cadenillas–Sarkar–Zapatero [6] problem and (b) its derivative.

In this case  $F(x) = x$ , and let us define

$$R(x, a) = r(x, a) = \begin{cases} 0, & x = 0, \\ -c(\sin x - \sin a) - \delta, & x > 0. \end{cases}$$

By solving (3.41) with some parameter  $(c, \delta) = (10, 0.35)$ , we find that  $a_k^* = 2.75 + 4k\pi$  and  $b_k^* = 3.52 + 4k\pi$ , with  $k = 0, 1, 2, \dots$ . For all of these pairs,  $\beta^*$  has a common value of 9.30. Hence all of these pairs are optimal. This implies that if the initial state  $x \in (b_k^*, b_{k+1}^*)$ , then we let the process move until it reaches  $b_k^*$  or  $b_{k+1}^*$ . If it reaches  $b_k^*$  first, then an intervention is made to  $a_k^*$ . Now we are in the interval  $(b_{k-1}^*, b_k^*)$ . We continue until the process is absorbed at  $x = 0$ .

**5. Conclusions.** Before we conclude this article, we shall mention an immediate extension to two boundary impulse control problems:

(5.1)

$$J^\nu(x) = \mathbb{E}^x \left[ \int_0^\infty e^{-\alpha s} f(X_s) ds + \sum_{i=1} e^{-\alpha T_i} C_1(X_{T_i-}, X_{T_i}) + \sum_{j=1} e^{-\alpha S_j} C_2(X_{S_j-}, X_{S_j}) \right]$$

and

$$(5.2) \quad v(x) = \sup_{\nu} J^\nu(x) = J^{\nu^*}(x)$$

for all  $x \in \mathbb{R}$ , where

$$\nu = (T_1, T_2, \dots; \zeta_1, \zeta_2, \dots; S_1, S_2, \dots; \eta_1, \eta_2, \dots),$$

with  $\zeta_i > 0$  corresponding to interventions at the upper boundary at intervention time  $T_i$  and  $\eta_j < 0$  at the lower boundary at intervention time  $S_j$ .

Examples of this type include the storage model analyzed by Harrison, Sellke, and Taylor [15] and the foreign exchange rate model studied by Jeanblanc-Picqué [17]. The former problem, for example, is that a controller continuously monitors the inventory so that the inventory level will not fall below the zero level. He is allowed to make interventions by increasing and decreasing the inventory by paying costs associated with interventions. In this case, the process remains within some band(s). In other words, the optimal intervention times are characterized as exit times from an interval in the form of  $(p^*, b^*)$  for  $0 \leq p^* < b^*$ . See Korn [20] for a survey.

Under suitable assumptions, we can develop an argument similar to the previous sections. Among others, the intervention times can be characterized as exit times from an interval  $(p^*, b^*)$ . We can also simplify the performance measure:

$$J^\nu(x) = \mathbb{E}^x[1_{\{T_1 < S_1\}} e^{-\alpha T_1} \{C_1(X_{T_1-}, X_{T_1}) - g(X_{T_1-}) + J^\nu(X_{T_1})\}] \\ + \mathbb{E}^x[1_{\{T_1 > S_1\}} e^{-\alpha S_1} \{C_2(X_{S_1-}, X_{S_1}) - g(X_{S_1-}) + J^\nu(X_{S_1})\}] + g(x),$$

where  $g(x) = \mathbb{E}^x \int_0^\infty e^{-\alpha s} f(X_s^0) ds$  as usual. Again, the last term does not depend on controls, we define  $u(x)$  as  $u(x) = J^\nu(x) - g(x)$ ,

$$(5.3) \quad u(x) = \mathbb{E}^x[1_{\{\tau_b < \tau_p\}} e^{-\alpha \tau_b} u(b)] + \mathbb{E}^x[1_{\{\tau_b > \tau_p\}} e^{-\alpha \tau_p} u(p)], \quad x \in [p, b],$$

where  $T_1 = \tau_b$  and  $S_1 = \tau_p$ , and it follows that

$$(5.4) \quad \frac{u(x)}{\varphi(x)} = \frac{u(b)(F(x) - F(p))}{\varphi(b)(F(b) - F(p))} + \frac{u(p)(F(b) - F(x))}{\varphi(p)(F(b) - F(p))}, \quad x \in [p, b].$$

Hence if we define  $W \triangleq \frac{u}{\varphi} \circ F^{-1}$ , we have linear characterization again in the transformed space:

$$(5.5) \quad W(F(x)) = W(F(b)) \frac{F(x) - F(p)}{F(b) - F(p)} + W(F(p)) \frac{F(b) - F(x)}{F(b) - F(p)}, \quad x \in [p, b],$$

and the solution to the problem is described as

$$u(x) = \begin{cases} \bar{C}_2(x, q) + u_0(q), & x \leq p, \\ u_0(x) \triangleq \mathbb{E}^x[1_{\{\tau_b < \tau_p\}} e^{-\alpha \tau_b} u(b)] + \mathbb{E}^x[1_{\{\tau_b > \tau_p\}} e^{-\alpha \tau_p} u(p)], & p \leq x \leq b, \\ \bar{C}_1(x, a) + u_0(a), & b \leq x, \end{cases}$$

where  $\bar{C}_i(x, y) = C_i(x, y) - g(x) + g(y)$  for  $i = 1$  and  $2$ .

We have studied impulse control problems. The intervention times are characterized as exit times of the process from a finite union of disjoint intervals on the real line. A sufficient condition is given for the connectedness of the continuation region. The value function is shown to be linear in the continuation region of the transformed space, and a direct calculation method is described. This method can handle impulse control problems with nonsmooth reward and cost functions. The finiteness of the value function is shown to be equivalent to the existence of a concave majorant of the suitable transformed reward function. The latter is easier to check by using elementary geometric arguments.

The new characterization of the value function and optimal strategies can be extended to other optimization problems, such as optimal switching and combined problems of optimal stopping and impulse control. If an optimal strategy exists in the class of exit times, then the problem can be reduced to a sequence of optimal stopping problems, and an effective characterization of the value function is possible.

## Appendix A.

**A.1. Proof of Lemma 3.2.** To make the proof more intuitive, we will work with (3.14) rather than with (3.15) where the integration part is converted to  $g$  functions. For this purpose, it is convenient to define the following two operators  $\mathcal{M}_o : \mathcal{H} \rightarrow \mathcal{H}$  and  $\mathcal{L}_o : \mathcal{H} \rightarrow \mathcal{H}$ :

$$(A.1) \quad \mathcal{M}_o u(x) = \sup_{y \in \mathbb{R}} [K(x, y) + u(y)]$$

and

$$(A.2) \quad \mathcal{L}_o u(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau} \mathcal{M}_o u(X_{\tau-}) \right].$$

Hence we can proceed with the arguments developed by Davis [12]. In terms of the two operators just defined, (3.14) becomes

$$(A.3) \quad w_{n+1}(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau} \mathcal{M}_o w_n(X_{\tau-}) \right]$$

$$(A.4) \quad = \mathcal{L}_o w_n(x).$$

(1)  $w_n = v_n$  for all  $n$ : Note that  $F$ -concavity of the function  $\bar{K}/\varphi$  guarantees that the value  $u(y)$  in (3.12) is a finite number as is shown in Proposition 3.4. Hence  $f$  and  $\mathcal{M}w_n$  satisfy the condition (polynomial growth) of Theorem 7.2 in Øksendal and Sulem [25], which shows that  $w_n = v_n$ .

(2)  $v(x) = \lim_{n \rightarrow \infty} w_n(x)$ : Since  $w_n$  is monotone increasing, the limit  $w(x) = \lim_{n \rightarrow \infty} w_n(x)$  exists. Since  $S_n \subset S$ ,  $w_n(x) \leq v(x)$ . Hence  $w(x) \leq v(x)$ . To show the reverse inequality, we define  $S^*$  be a set of interventions such that

$$S^* = \{\nu \in \mathcal{S} : J^\nu(x) < \infty \text{ for all } x \in \mathbb{R}\}.$$

Let us assume that  $\underline{v(x)} < +\infty$  and consider strategy  $\nu^* \in S^*$  such that

$$(A.5) \quad J^{\nu^*}(x) \geq v(x) - \epsilon$$

for some  $\epsilon > 0$  and another strategy  $\nu_n$  that coincides with  $\nu^*$  up to and including time  $T_n$  and then takes no further interventions.

$$J^{\nu^*}(x) - J^{\nu_n}(x) = \mathbb{E}^x \left[ \int_{T_n}^\infty e^{-\alpha s} (f(X_s) - f(X_s^0)) ds + \sum_{i \geq n+1} e^{-\alpha T_i} K(X_{T_i-}, X_{T_i}) \right],$$

which implies that

$$|J^{\nu^*}(x) - J^{\nu_n}(x)| \leq \mathbb{E}^x \left[ \int_{T_n}^\infty e^{-\alpha s} (|f(X_s)| + |f(X_s^0)|) ds + \sum_{i \geq n+1} e^{-\alpha T_i} |K(X_{T_i-}, X_{T_i})| \right].$$

As  $n \rightarrow +\infty$ ,  $T_n \rightarrow +\infty$ , and the first term of the right-hand side can be arbitrarily small due to (3.6); so is the second term by the finiteness of  $v(x)$  with (3.7). Hence it is shown that  $|J^{\nu^*}(x) - J^{\nu_n}(x)| < \epsilon$  for  $n$  large enough, which implies with (A.5) that

$$\liminf_{n \rightarrow +\infty} J^{\nu_n}(x) \geq J^{\nu^*}(x) - \epsilon \geq v(x) - 2\epsilon$$

so that  $v(x) \leq \lim_{n \rightarrow +\infty} v_n(x)$  since  $\epsilon$  is arbitrary. Now we have established that  $v(x) = \lim_{n \rightarrow \infty} w_n(x)$  when  $v(x) < +\infty$ . Next, consider the case of  $v(x) = +\infty$ . Then by the recursive method described in section 3.1, we see that  $v_1(\overline{x}) = \overline{w_1(x)} = \infty$ . By the first statement of this lemma, we can conclude that  $v_n(x) = w_n(x) = \infty$  for all  $n \in \mathbb{N}$ , obtaining  $v(x) = \lim_{n \rightarrow \infty} w_n(x)$ . This completes the proof of the second statement.

(3)  $w = \mathcal{L}_o w$  : Since  $w_n \uparrow w$ , we have the following chain of equalities:

$$\begin{aligned}\mathcal{M}_o w(x) &= \sup_{y \in \mathbb{R}} [K(x, y) + w(y)] = \sup_{y \in \mathbb{R}} \sup_{n \in \mathbb{N}} [K(x, y) + w_n(y)] \\ &= \sup_{n \in \mathbb{N}} \sup_{y \in \mathbb{R}} [K(x, y) + w_n(y)] = \sup_{n \in \mathbb{N}} \mathcal{M}_o w_n(x).\end{aligned}$$

In view of this, if we take the limit on both sides of (A.3) as  $n \rightarrow \infty$ , by the monotone convergence theorem,

$$w(x) = \sup_{\tau \in \mathcal{S}} \mathbb{E}^x \left[ \int_0^\tau e^{-\alpha s} f(X_s) ds + e^{-\alpha \tau} \mathcal{M}_o w(X_{\tau-}) \right].$$

This shows that  $w = \mathcal{L}_o w$ . Suppose that  $w'(x)$  satisfies  $w' = \mathcal{L}_o w'$  and majorizes  $g(x) = v_0(x)$ . Then  $w' = \mathcal{L}_o w' \geq \mathcal{L}_o v_0 = w_1$ . If we assume that  $w' \geq v_n$ , then

$$w' = \mathcal{L}_o w' \geq \mathcal{L}_o v_n = v_{n+1} = w_{n+1}.$$

This shows that, by the induction argument, we have  $w' \geq w_n$  for all  $n$ , leading to  $w' \geq \lim_{n \rightarrow \infty} w_n = w$ . Thus it shows that  $w$  is the smallest solution majorizing  $g$  of the functional equation  $w - g = \mathcal{L}(w - g)$ . This completes the third statement of the lemma.

**A.2. Derivation of (3.46).** The first order condition of the optimality with respect to  $a$  is

$$(A.6) \quad d\beta(a)/da = d\beta/db \times db/da = 0.$$

For a fixed  $a$ , from (3.41) by viewing  $\beta$  as a function of state  $x = F^{-1}(y)$ , that is,  $\beta = \beta(F^{-1}(y))$ , it is clear that  $d\beta(F^{-1}(y))/dy = \frac{1}{F'(x)} d\beta/dx$ . Since  $F'(x) > 0$  for all  $x \in \mathcal{I}$ , we have  $d\beta(F^{-1}(y))/dy = 0$  if and only if  $d\beta/dx = 0$ . But  $d\beta(F^{-1}(y))/dy = 0$  at  $x = F^{-1}(y) = b$  implies the following: At  $x = b(a)$ , where the shifted function  $\Phi(y, a)$  becomes tangent to the linear function  $W_a(F(x)) = \beta(a)F(x) + \delta$ , the second derivative of the shifted function vanishes. But it is clearly impossible if  $\Phi(y, a)$  is strictly concave at  $F(b)$ . Hence in view of (A.6), we can claim that  $d\beta(a)/da = 0$  only if  $db/da = 0$ , provided that  $\Phi(y, a)$  is strictly concave at  $y = F(b)$ . Now we differentiate (3.42) with respect to  $a$  with noting  $db/da = 0$ , and we obtain (3.46). In particular, for the case of absorbing boundary, (3.46) is of the form:

$$\begin{aligned}& \left( \frac{\partial \bar{K}(b, a)}{\partial a} + D\varphi'(a) \right) ((F(b) - F(a))\varphi(b) - (F(a) - F(0))\varphi(a)) \\ &= -(\bar{K}(b, a) - D(\varphi(b) - \varphi(a))) (F'(a)\varphi(a) + (F(a) - F(0))\varphi'(a)),\end{aligned}$$

which is to be solved simultaneously with (3.44) and (3.45).

**Acknowledgments.** The author thanks Savas Dayanik for valuable comments. He is also grateful to Erhan Bayraktar and the participants at the INFORMS 2004 Annual Meeting in Denver, CO, at the Civitas Foundation Finance Seminar in Princeton, NJ, and at various university seminars. The author also thanks the two anonymous referees for their comments that improved the manuscript.

## LOCAL CONTROLLABILITY OF A ONE-DIMENSIONAL BEAM EQUATION\*

KARINE BEAUCHARD†

**Abstract.** We prove that the beam equation with clamped ends is locally controllable in a  $H^{5+\epsilon} \times H^{3+\epsilon}((0, 1), \mathbb{R})$ -neighborhood of a particular trajectory of the free system, with  $\epsilon > 0$  and with control functions in  $H_0^1((0, T), \mathbb{R})$ . Ball, Marsden, and Slemrod already proved that this equation is not controllable in  $H_0^2 \times L^2((0, 1), \mathbb{R})$  with control functions in  $L_{\text{loc}}^r(\mathbb{R}, \mathbb{R})$ ,  $r > 1$ . This article justifies that their negative result is due to a choice of functional spaces which does not allow controllability. Our proof uses moment theory and the Nash–Moser theorem.

**Key words.** control of partial differential equations, bilinear control problem, beam equation, Nash–Moser theorem, trigonometric moment problem

**AMS subject classifications.** 35B37, 93C10, 93C20, 35Q72, 42A70

**DOI.** 10.1137/050642034

### 1. Introduction.

**1.1. Main result.** We consider the beam equation with clamped ends

$$(\Sigma) \begin{cases} u_{tt} + u_{xxxx} + p(t)u_{xx} = 0, (t, x) \in \mathbb{R}_+ \times (0, 1), \\ u = u_x = 0 \text{ at } x = 0, 1. \end{cases}$$

It is a nonlinear control system where

- the state is the couple  $(u, u_t)$  and
- the control is the real-valued function  $t \mapsto p(t)$ .

We introduce the operator  $A$  defined by

$$(1.1) \quad D(A) := H^4 \cap H_0^2((0, 1), \mathbb{R}), \quad Av := \frac{d^4 v}{dx^4}.$$

Let  $(\lambda_n)_{n \in \mathbb{N}^*} \subset \mathbb{R}_+^*$  be the increasing sequence of eigenvalues of  $A$  and  $(\varphi_n)_{n \in \mathbb{N}^*}$  associated orthonormalized eigenvectors. Then, for every  $n \in \mathbb{N}^*$ , the functions

$$\varphi_n(x) \cos(\sqrt{\lambda_n} t) \text{ and } \varphi_n(x) \sin(\sqrt{\lambda_n} t)$$

are solutions of  $(\Sigma)$ , with  $p \equiv 0$ . For  $s > 0$ , we introduce the space

$$(1.2) \quad H_{(0)}^s((0, 1), \mathbb{R}) := D(A^{s/4}),$$

equipped with the norm

$$(1.3) \quad \|\varphi\|_{H_{(0)}^s((0, 1), \mathbb{C})} := \left( \sum_{k=1}^{\infty} |\lambda_k^{s/4} \langle \varphi, \varphi_k \rangle|^2 \right)^{1/2}.$$

\*Received by the editors October 6, 2005; accepted for publication (in revised form) October 2, 2007; published electronically March 21, 2008.

†CMLA, ENS Cachan, CNRS, Universud, 61 avenue du président Wilson, F-94230 Cachan, France (Karine.Beauchard@cmla.ens-cachan.fr).

In particular, we have

$$(1.4) \quad \begin{aligned} H_{(0)}^s((0, 1), \mathbb{R}) &= \{\varphi \in H^s((0, 1), \mathbb{R}); \varphi = \varphi' = 0 \text{ at } x = 0, 1\} \text{ for } s \in \{2, 3, 4\}, \\ H_{(0)}^5((0, 1), \mathbb{R}) &= \{\varphi \in H^5((0, 1), \mathbb{R}); \varphi = \varphi' = \varphi^{(4)} = 0 \text{ at } x = 0, 1\}, \\ H_{(0)}^s((0, 1), \mathbb{R}) &= \{\varphi \in H^s((0, 1), \mathbb{R}); \varphi = \varphi' = \varphi^{(4)} = \varphi^{(5)} = 0 \text{ at } x = 0, 1\} \\ &\quad \text{for } s = 6, 7, 8. \end{aligned}$$

The main result of this article is the following one.

**THEOREM 1.** *Let  $T := 8/\pi$ ,  $\epsilon > 0$ , and*

$$(1.5) \quad u^{ref}(t, x) := \varphi_2(x) \sin(\sqrt{\lambda_2}t) + \varphi_3(x) \sin(\sqrt{\lambda_3}t).$$

*There exists a neighborhood  $V_0$  of  $(u^{ref}(0), \dot{u}^{ref}(0))$  and a neighborhood  $V_T$  of  $(u^{ref}(T), \dot{u}^{ref}(T))$  in  $H_{(0)}^{5+\epsilon} \times H_{(0)}^{3+\epsilon}((0, 1), \mathbb{R})$  such that, for every  $(u_0, \dot{u}_0) \in V_0$ , for every  $(u_T, \dot{u}_T) \in V_T$ , there exists  $p \in H_0^1((0, T), \mathbb{R})$  such that the solution of  $(\Sigma)$  with  $(u(0), \dot{u}(0)) = (u_0, \dot{u}_0)$  and control  $p$  satisfies  $(u(T), \dot{u}(T)) = (u_T, \dot{u}_T)$ .*

**1.2. A previous noncontrollability result.** In [1], Ball, Marsden, and Slemrod discuss the controllability of infinite dimensional bilinear control systems of the form

$$(1.6) \quad \dot{w}(t) = \mathcal{A}w(t) + p(t)\mathcal{B}w(t).$$

Thanks to the Baire lemma, they prove the following noncontrollability result.

**THEOREM 2.** *Let  $X$  be a Banach space with  $\dim(X) = +\infty$ . Let  $\mathcal{A}$  generate a  $C^0$ -semigroup of bounded linear operators on  $X$  and  $\mathcal{B} : X \rightarrow X$  be a bounded linear operator. Let  $w_0 \in X$  be fixed, and let  $w(t; p, w_0)$  denote the unique solution of (1.6) for  $p \in L_{loc}^1([0, +\infty), \mathbb{R})$ . The set of states accessible from  $w_0$  defined by*

$$S(w_0) := \{w(t; p, w_0); t \geq 0, p \in L_{loc}^r([0, \infty), \mathbb{R}), r > 1\}$$

*is contained in a countable union of compact subsets of  $X$  and, in particular, has a dense complement.*

We can write  $(\Sigma)$  in the first order form (1.6), with

$$(1.7) \quad w := \begin{pmatrix} u \\ u_t \end{pmatrix}, \quad \mathcal{A} := \begin{pmatrix} 0 & I \\ -A & 0 \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} 0 & 0 \\ -\frac{d^2}{dx^2} & 0 \end{pmatrix}.$$

Let  $X := H_0^2((0, 1), \mathbb{R}) \times L^2((0, 1), \mathbb{R})$ , with inner product

$$\langle (u_1, u_2), (v_1, v_2) \rangle_X := \int_0^1 \left( A^{1/2} u_1 A^{1/2} v_1 + u_2 v_2 \right) dx.$$

As noticed in [1], Theorem 2 shows that, for every  $(u_0, \dot{u}_0) \in X$ , the set of  $(u, u_t)$  in  $X$  accessible from  $(u_0, \dot{u}_0)$  with controls in  $L_{loc}^r([0, \infty), \mathbb{R})$ ,  $r > 1$ , has a dense complement in  $X$ . In particular,  $(\Sigma)$  is not controllable in  $H_0^2((0, 1), \mathbb{R}) \times L^2((0, 1), \mathbb{R})$ , with control functions  $p$  in  $L_{loc}^2([0, +\infty), \mathbb{R})$ .

However, this theorem does not give any obstruction for having controllability in other spaces. For example, Theorem 2 does not apply with
