

## CARLEMAN ESTIMATES FOR A CLASS OF DEGENERATE PARABOLIC OPERATORS\*

P. CANNARSA<sup>†</sup>, P. MARTINEZ<sup>‡</sup>, AND J. VANCOSTENOBLE<sup>‡</sup>

**Abstract.** Given  $\alpha \in [0, 2)$  and  $f \in L^2((0, T) \times (0, 1))$ , we derive new Carleman estimates for the degenerate parabolic problem  $w_t + (x^\alpha w_x)_x = f$ , where  $(t, x) \in (0, T) \times (0, 1)$ , associated to the boundary conditions  $w(t, 1) = 0$  and  $w(t, 0) = 0$  if  $0 \leq \alpha < 1$  or  $(x^\alpha w_x)(t, 0) = 0$  if  $1 \leq \alpha < 2$ . The proof is based on the choice of suitable weighted functions and Hardy-type inequalities. As a consequence, for all  $0 \leq \alpha < 2$  and  $\omega \subset\subset (0, 1)$ , we deduce null controllability results for the degenerate one-dimensional heat equation  $u_t - (x^\alpha u_x)_x = h\chi_\omega$  with the same boundary conditions as above.

**Key words.** degenerate parabolic equation, null controllability, Carleman estimates, Hardy-type inequality

**DOI.** 10.1137/04062062X

**1. Introduction.** The study of controllability for nondegenerate parabolic equations has attracted the interest of several authors in the past few decades. After the pioneering works [14, 19, 20, 37, 38], there has been substantial progress in understanding the controllability properties of nondegenerate parabolic equations with variable coefficients. In [30], local Carleman estimates for elliptic equations were used to study the null controllability of the heat equation on a manifold. Finally, a powerful new approach, based on global estimates of Carleman type, was developed in [26].

The theory has also been extended to semilinear problems (see, for example, [2, 3, 12, 15, 21, 24, 25]) and to equations in unbounded domains (see, for example, [13, 33, 34]; see also [31, 41]). For the Stokes and Navier–Stokes equations we also refer the reader to [4, 10, 11, 18, 22, 23, 26, 27, 28].

On the contrary, few results are known for degenerate equations, even though many problems that are relevant for applications are described by parabolic equations degenerating at the boundary of the space domain. For instance, in [5, 32, 8, 9] the reader will find a motivating example of a Crocco-type equation coming from the study of the velocity field of a laminar flow on a flat plate.

The goal of this paper is to study the controllability of a simple model of degenerate parabolic equation, namely,

$$u_t - (x^\alpha u_x)_x = h\chi_\omega, \quad x \in (0, 1), t \in (0, T),$$

where the control  $h$  acts on a nonempty subinterval  $\omega$  of  $(0, 1)$ .

## 2. Results.

**2.1. Statement of the controllability problem.** Given  $0 \leq \alpha < 2$ , define

$$\forall x \in [0, 1], \quad a(x) := x^\alpha,$$

and let  $\omega$  be a nonempty subinterval of  $(0, 1)$ . For  $T > 0$ , set

$$Q_T = (0, T) \times (0, 1),$$

and consider the initial-boundary value problem

$$(2.1) \quad \begin{cases} u_t - (au_x)_x = h \chi_\omega, & (t, x) \in Q_T, \\ u(t, 1) = 0, & t \in (0, T), \\ \text{and } \begin{cases} u(t, 0) = 0 & \text{for } 0 \leq \alpha < 1, \\ (au_x)(t, 0) = 0 & \text{for } 1 \leq \alpha < 2, \end{cases} & t \in (0, T), \\ u(0, x) = u_0(x), & x \in (0, 1), \end{cases}$$

where  $u_0$  is given in  $L^2(0, 1)$  and  $h \in L^2(Q_T)$ .

**2.2. Well-posedness.** Let us recall that the above problem is well-posed in appropriate weighted spaces. For  $0 \leq \alpha < 1$ , define the Hilbert space  $H_a^1(0, 1)$  as

$$H_a^1(0, 1) := \{u \in L^2(0, 1) \mid u \text{ absolutely continuous in } [0, 1], \\ \sqrt{a}u_x \in L^2(0, 1) \text{ and } u(0) = u(1) = 0\},$$

and the unbounded operator  $A : D(A) \subset L^2(0, 1) \rightarrow L^2(0, 1)$  by

$$\begin{cases} \forall u \in D(A), & Au := (au_x)_x, \\ D(A) := \{u \in H_a^1(0, 1) \mid au_x \in H^1(0, 1)\}. \end{cases}$$

Notice that if  $u \in D(A)$  (or even  $u \in H_a^1(0, 1)$ ), then  $u$  satisfies the Dirichlet boundary conditions  $u(0) = u(1) = 0$ .

For  $1 \leq \alpha < 2$ , let us change the definition of  $H_a^1(0, 1)$  to

$$H_a^1(0, 1) := \{u \in L^2(0, 1) \mid u \text{ locally absolutely continuous in } (0, 1], \\ \sqrt{a}u_x \in L^2(0, 1) \text{ and } u(1) = 0\}.$$

Then the operator  $A : D(A) \subset L^2(0, 1) \rightarrow L^2(0, 1)$  will be defined by

$$\begin{cases} \forall u \in D(A), & Au := (au_x)_x, \\ D(A) := \{u \in H_a^1(0, 1) \mid au_x \in H^1(0, 1)\} \\ \quad = \{u \in L^2(0, 1) \mid u \text{ locally absolutely continuous in } (0, 1], \\ \quad \quad au \in H_0^1(0, 1), au_x \in H^1(0, 1), \text{ and } (au_x)(0) = 0\}. \end{cases}$$

Notice that if  $u \in D(A)$ , then  $u$  satisfies the Neumann boundary condition  $(au_x)(0) = 0$  at  $x = 0$  and the Dirichlet boundary condition  $u(1) = 0$  at  $x = 1$ .

In both cases, the following results hold (see, e.g., [7] and [9]).

**PROPOSITION 2.1.**  *$A : D(A) \subset L^2(0, 1) \rightarrow L^2(0, 1)$  is a closed self-adjoint negative operator with dense domain.*

Hence,  $A$  is the infinitesimal generator of a strongly continuous semigroup  $e^{tA}$  on  $L^2(0, 1)$ . Consequently, we have the following well-posedness result.

**THEOREM 2.1.** *Let  $h$  be given in  $L^2(Q_T)$ . For all  $u_0 \in L^2(0, 1)$ , problem (2.1) has a unique solution*

$$(2.2) \quad u \in C^0([0, T]; L^2(0, 1)) \cap L^2(0, T; H_a^1(0, 1)).$$

Moreover, if  $u_0 \in D(A)$ , then

$$(2.3) \quad u \in C^0([0, T]; H_a^1(0, 1)) \cap L^2(0, T; D(A)) \cap H^1(0, T; L^2(0, 1)).$$

*Remark 2.1.* Most of the results of this paper hold and will be stated for solutions in the above class (2.2). However, in the proofs, we will assume—often without further notice—that solutions belong to the stronger class (2.3). This can be done without loss of generality, since the general result can always be recovered by a standard density argument.

**2.3. Carleman estimates for degenerate problems.** In order to study the controllability properties of (2.1), we need to derive a Carleman estimate for the adjoint problem. Keeping the notation

$$a(x) := x^\alpha, \quad \text{with } 0 \leq \alpha < 2, \quad \text{and } Q_T = (0, T) \times (0, 1) \quad \text{for } T > 0,$$

let us consider the parabolic problem

$$(2.4) \quad \begin{cases} w_t + (aw_x)_x = f, & (t, x) \in Q_T, \\ w(t, 1) = 0, & t \in (0, T), \\ \text{and } \begin{cases} w(t, 0) = 0 & \text{for } 0 \leq \alpha < 1, \\ (aw_x)(t, 0) = 0 & \text{for } 1 \leq \alpha < 2, \end{cases} & t \in (0, T), \\ w(T, x) = w_T(x), & x \in (0, 1), \end{cases}$$

where  $w_T \in L^2(0, 1)$  and  $f \in L^2(Q_T)$ . Our main result is the following.

**THEOREM 2.2.** *Let  $0 \leq \alpha < 2$  and  $T > 0$  be given. Then there exists  $\sigma : (0, T) \times [0, 1] \rightarrow \mathbb{R}_+^*$  of the form  $\sigma(t, x) = \theta(t)p(x)$ , with*

$$p(x) > 0 \quad \forall x \in [0, 1] \quad \text{and} \quad \theta(t) \rightarrow \infty \text{ as } t \rightarrow 0^+, T^-,$$

*and two positive constants,  $C$  and  $R_0$ , such that, for all  $w_T \in L^2(0, 1)$  and  $f \in L^2(Q_T)$ , the solution  $w$  of (2.4) satisfies, for all  $R \geq R_0$ ,*

$$\begin{aligned} \iint_{Q_T} \left( R\theta x^\alpha w_x^2 + R^3\theta^3 x^{2-\alpha} w^2 \right) e^{-2R\sigma} dx dt \\ \leq C \iint_{Q_T} e^{-2R\sigma} f^2 dx dt + C \int_0^T \left\{ R\theta e^{-2R\sigma} w_x^2 \right\}_{|x=1}. \end{aligned}$$

*Remark 2.2.* The functions  $p$  and  $\theta$  will be explicitly constructed in the proof. As we shall see, the choice of  $\theta$  will be

$$\forall t \in (0, T), \quad \theta(t) = \left( \frac{1}{t(T-t)} \right)^4.$$

This weight function satisfies the following essential properties:

$$\theta(t) \rightarrow +\infty \text{ as } t \rightarrow 0^+ \text{ or } T^- \quad \text{and} \quad |\theta_t| \leq c\theta^{5/4}, \quad |\theta_{tt}| \leq c\theta^{3/2}$$

for some constant  $c > 0$  depending on  $T$ . Moreover, we will take

$$p(x) := \frac{2 - x^{2-\alpha}}{(2 - \alpha)^2} \quad \forall x \in [0, 1].$$

**2.4. Observability inequalities.** As it is well known, very useful tools for studying controllability are provided by observability inequalities for the adjoint problem

$$(2.5) \quad \begin{cases} v_t + (av_x)_x = 0, & (t, x) \in Q_T, \\ v(t, 1) = 0, & t \in (0, T), \\ \text{and } \begin{cases} v(t, 0) = 0 & \text{for } 0 \leq \alpha < 1, \\ (av_x)(t, 0) = 0 & \text{for } 1 \leq \alpha < 2, \end{cases} & t \in (0, T), \\ v(T, x) = v_T(x), & x \in (0, 1), \end{cases}$$

where  $v_T$  is given in  $L^2(0, 1)$ . From the Carleman estimate of Theorem 2.2, we obtain the following observability inequalities for (2.5).

**THEOREM 2.3.** *Let  $0 \leq \alpha < 2$  and  $T > 0$  be given, and let  $\omega$  be a nonempty subinterval of  $(0, 1)$ . Then there exists  $C > 0$  such that, for all  $v_T \in L^2(0, 1)$ , the solution  $v$  of (2.5) satisfies*

$$(2.6) \quad \int_0^1 x^\alpha v_x(0, x)^2 dx \leq C \int_0^T \int_\omega v(t, x)^2 dx dt.$$

**2.5. Application to controllability.** For any  $0 \leq \alpha < 2$ , the following observability inequality follows from Theorem 2.3 and Hardy's inequalities (see the proof in section 5):

$$(2.7) \quad \int_0^1 v(0, x)^2 dx \leq C \int_0^T \int_\omega v(t, x)^2 dx dt.$$

The above inequality is well known in the nondegenerate case ( $\alpha = 0$ ) since it follows, for instance, from classical Carleman estimates for nondegenerate parabolic equations.

For  $\alpha \in [0, 1/2) \cup [5/4, 2)$ , inequality (2.7) was proved in [9] by means of a different Carleman estimate that had been obtained using a different weight function  $p$  but gave no information for  $\alpha \in [1/2, 5/4)$ .

Therefore, inequality (2.7) above fills the gap between  $1/2$  and  $5/4$  which was left open in [9]. Thus, we obtain, by standard arguments (see, e.g., [14, 26]), a null controllability result for degenerate heat equations with initial data in  $L^2(0, 1)$ .

**THEOREM 2.4.** *Let  $0 \leq \alpha < 2$  and  $T > 0$  be given, and let  $\omega$  be a nonempty subinterval of  $(0, 1)$ . Then, for all  $u_0 \in L^2(0, 1)$ , there exists  $h \in L^2((0, T) \times \omega)$  such that the solution of the degenerate problem (2.1) satisfies  $u(T) \equiv 0$  in  $(0, 1)$ .*

**Remark 2.3.** Let us recall that the above result is optimal since, for  $\alpha \geq 2$ , problem (2.1) fails to be null controllable (see [8]). Indeed, a standard change of variable transforms problem (2.1) into the heat equation in the unbounded domain  $]0, +\infty[$ , whereas control supports are still bounded. Then a result by Escauriaza, Seregin, and Šverák [16, 17], which generalizes a result by Micu and Zuazua [33], ensures that null controllability fails for such an equation.

**Remark 2.4.** In [9], inequality (2.7) was applied to a Crocco-type equation to obtain a null controllability result for  $\alpha \in [0, 1/2) \cup [5/4, 2)$ . Thus, the results of the present paper also show the null controllability of this equation for all values of  $\alpha \in [0, 2)$ .

**2.6. Hardy-type inequalities.** A major ingredient for the proofs of Theorems 2.2 and 2.3 is the following well-known lemma (see, for example, [35]; for the reader's convenience, we recall the proof in section 6).

LEMMA 2.1 (Hardy-type inequalities).

- (i) *Let  $0 \leq \alpha^* < 1$ . Then, for all locally absolutely continuous functions  $z$  on  $(0, 1)$  satisfying*

$$z(x) \rightarrow 0 \quad \text{as } x \rightarrow 0^+ \quad \text{and} \quad \int_0^1 x^{\alpha^*} z_x^2 < \infty,$$

*the following inequality holds:*

$$(2.8) \quad \int_0^1 x^{\alpha^*-2} z^2 \leq \frac{4}{(1-\alpha^*)^2} \int_0^1 x^{\alpha^*} z_x^2.$$

- (ii) *Let  $1 < \alpha^* < 2$ . Then the above inequality (2.8) still holds for all locally absolutely continuous functions  $z$  on  $(0, 1)$  satisfying*

$$z(x) \rightarrow 0 \quad \text{as } x \rightarrow 1^- \quad \text{and} \quad \int_0^1 x^{\alpha^*} z_x^2 < +\infty.$$

*Remark 2.5.* Notice that (2.8) is false for  $\alpha^* = 1$ .

**2.7. Further remarks.** In the present paper, we study the case of a degenerate operator of the form  $-(x^\alpha u_x)_x$  with the boundary condition  $u(x=0) = 0$  when  $0 \leq \alpha < 1$  or  $(x^\alpha u_x)(x=0) = 0$  when  $1 \leq \alpha < 2$ . The choice of such an operator in divergence form probably simplifies parts of the computations arising in the proof of Carleman estimates. Of course, it would be interesting to study, in a next step, other operators like  $-x^\alpha u_{xx}$ . On the other hand, the choice of the boundary condition at  $x=0$  ensures a relatively simple framework for the statement of well-posedness. Here again, it would be interesting to study the cases of other boundary conditions. For example, an interesting problem would be the case of Wentzell boundary conditions; see, e.g., [6, 39]. The techniques developed here may be useful to treat such problems. However, both the form of the operator and the boundary conditions play an important role in the computations of the proof of Carleman estimates. For this reason, these other problems have yet to be studied.

On the other hand, let us mention that the ideas of the present paper allow us to prove similar null controllability results for degenerate semilinear problems using a classical fixed point method (see [1]).

Next, instead of a distributed control on  $\omega \subset (0, 1)$ , one could consider a boundary control acting at one extreme point of the domain  $(0, 1)$ . Theorem 2.2 readily implies a boundary null controllability result if the control acts at  $x=1$ . The case of a boundary control at  $x=0$  has not yet been studied.

Finally, another interesting question would be the study of degenerate operators in higher dimensions. Of course, this opens a lot of perspectives since the study will depend on the domain where the operator degenerates and the way it degenerates. This question will be the subject of a forthcoming paper.

### 3. Proof of Theorem 2.2 (Carleman estimates).

**3.1. Notation and reformulation of the problem.** We recall that  $a(x) = x^\alpha$  for all  $x \in [0, 1]$  with  $\alpha \in [0, 2)$  given. Let  $\sigma(t, x) = \theta(t)p(x)$ , where

$$p(x) > 0 \quad \forall x \in [0, 1] \quad \text{and} \quad \theta(t) \rightarrow \infty \text{ as } t \rightarrow 0^+, T^-.$$

For  $R > 0$ , define

$$(3.1) \quad z(t, x) = e^{-R\sigma(t, x)} w(t, x),$$

where  $w$  is a solution of (2.4). Notice that,

$$(3.2) \quad \forall n \in \mathbb{N}, \quad \theta^n z = 0 \quad \text{and} \quad z_x = 0 \quad \text{at time } t = 0 \text{ and } t = T.$$

Moreover  $z$  satisfies

$$(3.3) \quad \begin{cases} (e^{R\sigma} z)_t + (a(e^{R\sigma} z)_x)_x = f, & (t, x) \in Q_T, \\ z(t, 1) = 0, & t \in (0, T), \\ \text{and } \begin{cases} z(t, 0) = 0 & \text{for } 0 \leq \alpha < 1, \\ (az_x)(t, 0) = -R(a\sigma_x z)(t, 0) & \text{for } 1 \leq \alpha < 2, \end{cases} & t \in (0, T). \end{cases}$$

This equation may be recast as follows:

$$P_R z = P_R^+ z + P_R^- z = f e^{-R\sigma},$$

where

$$\begin{aligned} P_R^+ z &:= R\sigma_t z + R^2 a \sigma_x^2 z + (az_x)_x, \\ P_R^- z &:= z_t + R(a\sigma_x z)_x + Ra\sigma_x z_x \\ &= z_t + R(a\sigma_x)_x z + 2Ra\sigma_x z_x. \end{aligned}$$

Moreover, we have

$$(3.4) \quad \|f e^{-R\sigma}\|^2 \geq \|P_R^+ z\|^2 + \|P_R^- z\|^2 + 2\langle P_R^+ z, P_R^- z \rangle \geq 2\langle P_R^+ z, P_R^- z \rangle,$$

where  $\|\cdot\|$  and  $\langle \cdot, \cdot \rangle$  denote the usual norm and scalar product in  $L^2(Q_T)$ .

**3.2. Computation of the scalar product.** We now want to compute the scalar product in  $L^2(Q_T)$  of  $P_R^+ z$  and  $P_R^- z$ . This will be done in two steps.

LEMMA 3.1. *The following identity holds:*

$$\begin{aligned} \langle P_R^+ z, P_R^- z \rangle &= \int_0^T \left[ az_x z_t + R^2 a \sigma_t \sigma_x z^2 + R^3 a^2 \sigma_x^3 z^2 \right. \\ &\quad \left. + Ra(a\sigma_x)_x z z_x + Ra^2 \sigma_x z_x^2 \right]_0^1 \quad (b.t.) \\ &\quad + \left. \int \int_{Q_T} \left( -\frac{1}{2} R \sigma_{tt} - 2R^2 a \sigma_x \sigma_{xt} - R^3 a \sigma_x (a \sigma_x^2)_x \right) z^2 \right. \\ &\quad \left. + \int \int_{Q_T} -R \frac{a}{\sigma_x} (a \sigma_x^2)_x z_x^2 - Ra(a\sigma_x)_{xx} z z_x \right. \quad (d.t.) \end{aligned}$$

Then, using the fact that  $a(x) = x^\alpha$  and  $\sigma(t, x) = \theta(t)p(x)$ , we compute the distributed and boundary terms as follows.

LEMMA 3.2. *For all  $0 \leq \alpha < 2$ , we have*

$$\begin{aligned} (d.t.) = & -\frac{1}{2}R \iint_{Q_T} \theta_{tt} p z^2 - 2R^2 \iint_{Q_T} \theta \theta_t x^\alpha p_x^2 z^2 \\ & - R^3 \iint_{Q_T} \theta^3 x^{2\alpha-1} (2x p_{xx} + \alpha p_x) p_x^2 z^2 \\ & - R \iint_{Q_T} \theta x^{2\alpha-1} (2x p_{xx} + \alpha p_x) z_x^2 - R \iint_{Q_T} \theta x^\alpha (x^\alpha p_x)_{xx} z z_x. \end{aligned}$$

Moreover, for  $0 \leq \alpha < 1$ , the boundary terms (b.t.) are given by

$$(b.t.)_{\text{for } 0 \leq \alpha < 1} = \int_0^T \left\{ R \theta a^2 p_x z_x^2 \right\}_{|x=1} - \int_0^T \left\{ R \theta a^2 p_x z_x^2 \right\}_{|x=0}.$$

For  $1 \leq \alpha < 2$ , the boundary terms (b.t.) become

$$\begin{aligned} (b.t.)_{\text{for } 1 \leq \alpha < 2} = & \int_0^T \left\{ R \theta a^2 p_x z_x^2 \right\}_{|x=1} \\ & + \int_0^T \left\{ -\frac{R}{2} \theta_t a p_x z^2 - R^2 \theta_t \theta a p p_x z^2 - 2R^3 \theta^3 a^2 p_x^3 z^2 + R^2 \theta^2 a p_x (a p_x)_x z^2 \right\}_{|x=0}. \end{aligned}$$

*Proof of Lemma 3.1.* We have

$$\langle P_R^+ z, P_R^- z \rangle = Q_1 + Q_2 + Q_3 + Q_4,$$

where

$$\begin{aligned} Q_1 &:= \langle R \sigma_t z + R^2 a \sigma_x^2 z + (a z_x)_x, z_t \rangle, \\ Q_2 &:= R^2 \langle \sigma_t z, (a \sigma_x)_x z + 2a \sigma_x z_x \rangle, \\ Q_3 &:= R^3 \langle a \sigma_x^2 z, (a \sigma_x)_x z + 2a \sigma_x z_x \rangle, \\ Q_4 &:= R \langle (a z_x)_x, (a \sigma_x)_x z + 2a \sigma_x z_x \rangle. \end{aligned}$$

*First term:*  $Q_1$ .

$$\begin{aligned} Q_1 &= \iint_{Q_T} \left( R \sigma_t z + R^2 a \sigma_x^2 z + (a z_x)_x \right) z_t \\ &= \iint_{Q_T} (R \sigma_t + R^2 a \sigma_x^2) \left( \frac{z^2}{2} \right)_t + \iint_{Q_T} (a z_x)_x z_t \\ &= \left[ \int_0^1 \frac{1}{2} \left( R \sigma_t + R^2 a \sigma_x^2 \right) z^2 \right]_0^T - \iint_{Q_T} \frac{1}{2} \left( R \sigma_t + R^2 a \sigma_x^2 \right)_t z^2 \\ &\quad + \int_0^T \left[ a z_x z_t \right]_0^1 - \iint_{Q_T} a z_x z_{xt} \\ &= \left[ \int_0^1 \left( R \sigma_t + R^2 a \sigma_x^2 \right) \frac{1}{2} z^2 - \frac{1}{2} a z_x^2 \right]_0^T \\ &\quad - \iint_{Q_T} \frac{1}{2} \left( R \sigma_t + R^2 a \sigma_x^2 \right)_t z^2 + \int_0^T \left[ a z_x z_t \right]_0^1. \end{aligned}$$

By (3.2), the terms integrated in time are equal to zero. Hence,

$$(3.5) \quad Q_1 = \int_0^T \left[ az_x z_t \right]_0^1 + \iint_{Q_T} \left( -\frac{1}{2} R \sigma_{tt} - R^2 a \sigma_x \sigma_{xt} \right) z^2.$$

*Second term:  $Q_2$ .*

$$\begin{aligned} Q_2 &= R^2 \iint_{Q_T} \sigma_t z \left( (a\sigma_x)_x z + 2a\sigma_x z_x \right) = R^2 \iint_{Q_T} \sigma_t (a\sigma_x)_x z^2 + a\sigma_t \sigma_x (z^2)_x \\ &= R^2 \iint_{Q_T} \sigma_t (a\sigma_x)_x z^2 + R^2 \int_0^T \left[ a\sigma_t \sigma_x z^2 \right]_0^1 - R^2 \iint_{Q_T} (a\sigma_t \sigma_x)_x z^2. \end{aligned}$$

Therefore,

$$(3.6) \quad Q_2 = R^2 \int_0^T \left[ a\sigma_t \sigma_x z^2 \right]_0^1 - R^2 \iint_{Q_T} a\sigma_x \sigma_{xt} z^2.$$

*Third term:  $Q_3$ .*

$$\begin{aligned} Q_3 &= R^3 \iint_{Q_T} a\sigma_x^2 z \left( (a\sigma_x)_x z + 2a\sigma_x z_x \right) = R^3 \iint_{Q_T} a\sigma_x^2 z \left( (a\sigma_x z)_x + a\sigma_x z_x \right) \\ &= R^3 \int_0^T \left[ a^2 \sigma_x^3 z^2 \right]_0^1 - R^3 \iint_{Q_T} (a\sigma_x^2)_x a\sigma_x z + R^3 \iint_{Q_T} a^2 \sigma_x^3 z z_x. \end{aligned}$$

Thus,

$$(3.7) \quad Q_3 = R^3 \int_0^T \left[ a^2 \sigma_x^3 z^2 \right]_0^1 - R^3 \iint_{Q_T} a\sigma_x (a\sigma_x^2)_x z^2.$$

*Last term:  $Q_4$ .*

$$\begin{aligned} Q_4 &= R \iint_{Q_T} (az_x)_x \left( (a\sigma_x)_x z + 2a\sigma_x z_x \right) \\ &= R \int_0^T \left[ az_x (a\sigma_x)_x z \right]_0^1 - R \iint_{Q_T} az_x \left( (a\sigma_x)_x z \right)_x + R \iint_{Q_T} \sigma_x \left( (az_x)^2 \right)_x \\ &= R \int_0^T \left[ a(a\sigma_x)_x z z_x \right]_0^1 - R \iint_{Q_T} a(a\sigma_x)_x z_x^2 + a(a\sigma_x)_{xx} z z_x \\ &\quad + R \int_0^T \left[ \sigma_x a^2 z_x^2 \right]_0^1 - R \iint_{Q_T} \sigma_{xx} a^2 z_x^2. \end{aligned}$$

Consequently,

$$(3.8) \quad \begin{aligned} Q_4 &= R \int_0^T \left[ a(a\sigma_x)_x z z_x + a^2 \sigma_x z_x^2 \right]_0^1 \\ &\quad - R \iint_{Q_T} \frac{a}{\sigma_x} (a\sigma_x^2)_x z_x^2 - R \iint_{Q_T} a(a\sigma_x)_{xx} z z_x. \end{aligned}$$

Finally, Lemma 3.1 follows from (3.5)–(3.8).  $\square$

*Proof of Lemma 3.2.* With  $a(x) = x^\alpha$  and  $\sigma(t, x) = \theta(t)p(x)$ , the distributed terms (d.t.) can be computed as follows:

$$\begin{aligned}
(d.t.) &= -\frac{1}{2}R \iint_{Q_T} \theta_{tt} p z^2 - 2R^2 \iint_{Q_T} \theta \theta_t x^\alpha p_x^2 z^2 - R^3 \iint_{Q_T} \theta^3 x^\alpha p_x (x^\alpha p_x^2)_x z^2 \\
&\quad - R \iint_{Q_T} \theta \frac{x^\alpha}{p_x} (x^\alpha p_x^2)_x z_x^2 - R \iint_{Q_T} \theta x^\alpha (x^\alpha p_x)_{xx} z z_x \\
&= -\frac{1}{2}R \iint_{Q_T} \theta_{tt} p z^2 - 2R^2 \iint_{Q_T} \theta \theta_t x^\alpha p_x^2 z^2 \\
&\quad - R^3 \iint_{Q_T} \theta^3 x^{2\alpha-1} (2x p_{xx} + \alpha p_x) p_x^2 z^2 \\
&\quad - R \iint_{Q_T} \theta x^{2\alpha-1} (2x p_{xx} + \alpha p_x) z_x^2 - R \iint_{Q_T} \theta x^\alpha (x^\alpha p_x)_{xx} z z_x.
\end{aligned}$$

On the other hand, also taking into account the fact that  $z(t, 1) = 0$ , the boundary terms (b.t.) become

$$\begin{aligned}
(b.t.) &= \int_0^T \left\{ R\theta a^2 p_x z_x^2 \right\}_{|x=1} - \int_0^T \left\{ a z_x z_t + R^2 \theta_t \theta a p p_x z^2 + R^3 \theta^3 a^2 p_x^3 z^2 \right. \\
&\quad \left. + R\theta a (a p_x)_{xx} z z_x + R\theta a^2 p_x z_x^2 \right\}_{|x=0}.
\end{aligned}$$

Now, for  $0 \leq \alpha < 1$ , use the fact that  $z(t, 0) = 0$  to obtain

$$(b.t.)_{\text{for } 0 \leq \alpha < 1} = \int_0^T \left\{ R\theta a^2 p_x z_x^2 \right\}_{|x=1} - \int_0^T \left\{ R\theta a^2 p_x z_x^2 \right\}_{|x=0}.$$

Similarly, for  $1 \leq \alpha < 2$ , recall that  $(a z_x)(t, 0) = -R\theta(t)(a p_x z)(t, 0)$  to conclude that

$$\begin{aligned}
(b.t.)_{\text{for } 1 \leq \alpha < 2} &= \int_0^T \left\{ R\theta a^2 p_x z_x^2 \right\}_{|x=1} + \int_0^T \left\{ R\theta a p_x \left( \frac{z^2}{2} \right)_t \right. \\
&\quad \left. - R^2 \theta_t \theta a p p_x z^2 - R^3 \theta^3 a^2 p_x^3 z^2 + R^2 \theta^2 a p_x (a p_x)_{xx} z^2 - R^3 \theta^3 a^2 p_x^3 z^2 \right\}_{|x=0}.
\end{aligned}$$

Hence

$$\begin{aligned}
(b.t.)_{\text{for } 1 \leq \alpha < 2} &= \int_0^T \left\{ R\theta a^2 p_x z_x^2 \right\}_{|x=1} + \int_0^T \left\{ -\frac{R}{2} \theta_t a p_x z^2 \right. \\
&\quad \left. - R^2 \theta_t \theta a p p_x z^2 - 2R^3 \theta^3 a^2 p_x^3 z^2 + R^2 \theta^2 a p_x (a p_x)_{xx} z^2 \right\}_{|x=0}. \quad \square
\end{aligned}$$

**3.3. Bounds from below.** Let us first define

$$\forall t \in (0, T), \quad \theta(t) := \left( \frac{1}{t(T-t)} \right)^4.$$

Observe that  $\theta$  satisfies the following properties:

$$|\theta_t| \leq c\theta^{5/4} \leq c\theta^2 \quad \text{and} \quad |\theta_{tt}| \leq c\theta^{3/2} \leq c\theta^3.$$

Next, let us recall that  $\alpha \in [0, 2)$  and let us choose

$$\forall x \in [0, 1], \quad p(x) := \frac{2 - x^{2-\alpha}}{(2 - \alpha)^2}.$$

Then

$$p_x(x) = \frac{-x^{1-\alpha}}{2 - \alpha}, \quad p_{xx}(x) = \frac{-(1 - \alpha)}{2 - \alpha} x^{-\alpha}.$$

Hence

$$2xp_{xx} + \alpha p_x = -x^{1-\alpha}$$

and

$$(x^\alpha p_x)_x = \frac{-1}{2 - \alpha}; \quad \text{thus } (x^\alpha p_x)_{xx} = 0.$$

With this choice of  $\theta$  and  $p$ , the distributed and boundary terms can be first computed and then estimated as follows.

LEMMA 3.3. *For all  $\alpha \in [0, 2)$ , the distributed terms (d.t.) become*

$$\begin{aligned} (d.t.) = & -\frac{R}{(2 - \alpha)^2} \iint_{Q_T} \theta_{tt} z^2 + \frac{R}{2(2 - \alpha)^2} \iint_{Q_T} \theta_{tt} x^{2-\alpha} z^2 \\ & - \frac{2R^2}{(2 - \alpha)^2} \iint_{Q_T} \theta \theta_t x^{2-\alpha} z^2 + \frac{R^3}{(2 - \alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + R \iint_{Q_T} \theta x^\alpha z_x^2. \end{aligned}$$

For  $0 \leq \alpha < 1$ , the boundary terms (b.t.) become

$$(b.t.)_{\text{for } 0 \leq \alpha < 1} = -\frac{1}{2 - \alpha} \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1} + \frac{1}{2 - \alpha} \int_0^T \left\{ R\theta x^{1+\alpha} z_x^2 \right\}_{|x=0}.$$

For  $1 \leq \alpha < 2$ , the boundary terms (b.t.) become

$$\begin{aligned} (b.t.)_{\text{for } 1 \leq \alpha < 2} = & -\frac{1}{2 - \alpha} \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1} + \int_0^T \left\{ \frac{R\theta_t}{2(2 - \alpha)} x z^2 \right. \\ & \left. + \frac{2R^2 \theta_t \theta}{(2 - \alpha)^3} x z^2 - \frac{R^2 \theta_t \theta}{(2 - \alpha)^3} x^{3-\alpha} z^2 + \frac{2R^3 \theta^3}{(2 - \alpha)^3} x^{3-\alpha} z^2 + \frac{R^2 \theta^2}{(2 - \alpha)^2} x z^2 \right\}_{|x=0}. \end{aligned}$$

LEMMA 3.4. *For all  $\alpha \in [0, 2)$ , the distributed terms (d.t.) and the boundary terms (b.t.) satisfy, for  $R$  large enough (depending on  $\alpha$  and  $T$ ),*

$$(d.t.) \geq \frac{1}{4} \frac{R^3}{(2 - \alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + \frac{3}{4} R \iint_{Q_T} \theta x^\alpha z_x^2,$$

$$(b.t.) \geq -\frac{1}{2 - \alpha} \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1}.$$

*Proof of Lemma 3.3.* The conclusion follows from the above choice of  $p$  and the expressions of (d.t.) and (b.t.) given in Lemma 3.2.  $\square$

*Proof of Lemma 3.4.* Let us first analyze the distributed terms. Recall that, owing to Lemma 3.3,

$$\begin{aligned} (d.t.) = & -\frac{R}{(2-\alpha)^2} \iint_{Q_T} \theta_{tt} z^2 + \frac{R}{2(2-\alpha)^2} \iint_{Q_T} \theta_{tt} x^{2-\alpha} z^2 \\ & - \frac{2R^2}{(2-\alpha)^2} \iint_{Q_T} \theta \theta_t x^{2-\alpha} z^2 + \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + R \iint_{Q_T} \theta x^\alpha z_x^2. \end{aligned}$$

Since the two last terms are nonnegative, we only need to estimate the three other terms. We begin with the second term: since  $|\theta_{tt}| \leq c\theta^{3/2} \leq c\theta^3$ , we have

$$\begin{aligned} \left| \frac{R}{2(2-\alpha)^2} \iint_{Q_T} \theta_{tt} x^{2-\alpha} z^2 \right| & \leq \frac{cR}{2(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 \\ & \leq \frac{1}{4} \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 \end{aligned}$$

for  $R$  large enough. Next, using  $|\theta \theta_t| \leq c\theta^{9/4} \leq c\theta^3$ , we also obtain a bound of the third term for  $R$  large enough:

$$\begin{aligned} \left| \frac{2R^2}{(2-\alpha)^2} \iint_{Q_T} \theta \theta_t x^{2-\alpha} z^2 \right| & \leq \frac{2cR^2}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 \\ & \leq \frac{1}{4} \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2. \end{aligned}$$

Therefore,

$$(3.9) \quad (d.t.) \geq -\frac{R}{(2-\alpha)^2} \iint_{Q_T} \theta_{tt} z^2 + \frac{1}{2} \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + R \iint_{Q_T} \theta x^\alpha z_x^2.$$

It remains to bound the first term on the right-hand side above. First let us observe that the solution  $w$  of (2.4) belongs to  $L^2(0, T; H_a^1(0, 1))$  by Theorem 2.1. Since  $z = e^{-R\sigma} w$ , some direct computations imply that  $z$  also belongs to  $L^2(0, T; H_a^1(0, 1))$ . Next we write

$$\begin{aligned} (3.10) \quad \left| \frac{R}{(2-\alpha)^2} \iint_{Q_T} \theta_{tt} z^2 \right| & \leq \frac{cR}{(2-\alpha)^2} \iint_{Q_T} \theta^{3/2} z^2 \\ & = \frac{cR}{(2-\alpha)^2} \iint_{Q_T} \left( \theta x^{(\alpha-2)/3} z^2 \right)^{3/4} \left( \theta^3 x^{2-\alpha} z^2 \right)^{1/4} \\ & \leq \frac{3\epsilon cR}{4(2-\alpha)^2} \iint_{Q_T} \theta x^{(\alpha-2)/3} z^2 + \frac{cR}{4\epsilon^3(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2. \end{aligned}$$

As this point, we separate the case  $\alpha = 1$  from the other ones. This case is peculiar since Hardy's inequality (Lemma 2.1) does not hold for  $\alpha^* = 1$ .

In the case  $\alpha \neq 1$ , we observe that  $x^{(\alpha-2)/3} \leq x^{\alpha-2}$  (since  $\alpha < 2$ ), and we apply Lemma 2.1 with  $\alpha^* = \alpha \neq 1$  ( $z$  satisfies the assumptions of Lemma 2.1 for almost every  $t$  since it belongs to  $L^2(0, T; H_a^1(0, 1))$ ) to obtain

$$(3.11) \quad \iint_{Q_T} \theta x^{(\alpha-2)/3} z^2 \leq \iint_{Q_T} \theta x^{\alpha-2} z^2 \leq \frac{4}{(\alpha-1)^2} \iint_{Q_T} \theta x^\alpha z_x^2.$$

In the case  $\alpha = 1$ , we apply Lemma 2.1 with  $\alpha^* = 5/3$  and then use the fact that  $x^{5/3} \leq x$  to arrive at a similar conclusion:

$$(3.12) \quad \iint_{Q_T} \theta x^{(\alpha-2)/3} z^2 = \iint_{Q_T} \theta x^{-1/3} z^2 \leq \frac{4}{(\alpha^* - 1)^2} \iint_{Q_T} \theta x^{5/3} z_x^2 \\ \leq 9 \iint_{Q_T} \theta x z_x^2 = 9 \iint_{Q_T} \theta x^\alpha z_x^2.$$

In both cases, combining (3.10) with (3.11) or (3.12), we deduce

$$\left| \frac{R}{(2-\alpha)^2} \iint_{Q_T} \theta_{tt} z^2 \right| \leq \varepsilon c' R \iint_{Q_T} \theta x^\alpha z_x^2 + \frac{cR}{4\varepsilon^3(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2$$

for some constant  $c' > 0$ . Then, for  $\varepsilon$  small enough and  $R$  large enough, we have

$$(3.13) \quad \left| \frac{R}{(2-\alpha)^2} \iint_{Q_T} \theta_{tt} z^2 \right| \leq \frac{1}{4} R \iint_{Q_T} \theta x^\alpha z_x^2 + \frac{1}{4} \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2.$$

Summing up, we obtain by (3.9) and (3.13)

$$(d.t.) \geq \frac{1}{4} \frac{R^3}{(2-\alpha)^2} \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + \frac{3}{4} R \iint_{Q_T} \theta x^\alpha z_x^2 \geq 0.$$

We now turn to the boundary terms. In the case  $0 \leq \alpha < 1$ , there is nothing else to do since, by Lemma 3.3,

$$(b.t.)_{\text{for } 0 \leq \alpha < 1} = -\frac{1}{2-\alpha} \int_0^T \left\{ R \theta z_x^2 \right\}_{|x=1} + \frac{1}{2-\alpha} \int_0^T \left\{ R \theta x^{1+\alpha} z_x^2 \right\}_{|x=0} \\ \geq -\frac{1}{2-\alpha} \int_0^T \left\{ R \theta z_x^2 \right\}_{|x=1}.$$

In the case  $1 \leq \alpha < 2$ , we recall that, by Lemma 3.3,

$$(b.t.)_{\text{for } 1 \leq \alpha < 2} = -\frac{1}{2-\alpha} \int_0^T \left\{ R \theta z_x^2 \right\}_{|x=1} + \int_0^T \left\{ \left( \frac{R \theta_t}{2(2-\alpha)} \right. \right. \\ \left. \left. + \frac{2R^2 \theta_t \theta}{(2-\alpha)^3} - \frac{R^2 \theta_t \theta}{(2-\alpha)^3} x^{2-\alpha} + \frac{2R^3 \theta^3}{(2-\alpha)^3} x^{2-\alpha} + \frac{R^2 \theta^2}{(2-\alpha)^2} \right) x z^2 \right\}_{|x=0}.$$

Thus, applying Lemma 3.5 below (since  $z \in H_a^1(0, 1)$  for almost every  $t$ ), it follows that, for almost every  $t \in (0, T)$ ,

$$x z^2(t, x) \rightarrow 0 \quad \text{as } x \rightarrow 0.$$

Hence,

$$(b.t.)_{\text{for } 1 \leq \alpha < 2} = -\frac{1}{2-\alpha} \int_0^T \left\{ R \theta z_x^2 \right\}_{|x=1}. \quad \square$$

LEMMA 3.5. *Let  $\alpha \in [1, 2)$  be given. Then, for all  $v \in H_a^1(0, 1)$ ,*

$$(3.14) \quad x v^2(x) \rightarrow 0 \quad \text{as } x \rightarrow 0^+.$$

*Proof.* Let  $v$  be given in  $H_a^1(0,1)$ . By the definition of  $H_a^1(0,1)$  in the case  $1 \leq \alpha < 2$ , we know that  $v \in L^2(0,1)$  and  $\sqrt{a}v_x = x^{\alpha/2}v_x \in L^2(0,1)$ . Then  $xv^2 \in L^1(0,1)$ . Moreover,

$$(xv^2)_x = v^2 + 2xvv_x,$$

with  $v^2 \in L^1(0,1)$  and with  $xvv_x = (x^{1-\alpha/2}v)(x^{\alpha/2}v_x) \in L^1(0,1)$ . Hence,  $xv^2 \in W^{1,1}(0,1)$ . Thus,  $xv^2 \rightarrow L \geq 0$  as  $x \rightarrow 0^+$ . Finally,  $L = 0$  since  $L \neq 0$  would imply  $v \notin L^2(0,1)$ . This completes the proof.  $\square$

**3.4. Conclusion.** From Lemmas 3.1 and 3.4 we obtain, for all  $0 \leq \alpha < 2$ ,

$$\begin{aligned} \langle P_R^+ z, P_R^- z \rangle &= (d.t.) + (b.t.) \\ &\geq cR^3 \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + cR \iint_{Q_T} \theta x^\alpha z_x^2 - c' \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1} \end{aligned}$$

for some constants  $c, c' > 0$ . By (3.4), we have

$$\begin{aligned} \|f e^{-R\sigma}\|^2 &= \|P_R^+ z\|^2 + \|P_R^- z\|^2 + 2\langle P_R^+ z, P_R^- z \rangle \geq 2\langle P_R^+ z, P_R^- z \rangle \\ &\geq cR^3 \iint_{Q_T} \theta^3 x^{2-\alpha} z^2 + cR \iint_{Q_T} \theta x^\alpha z_x^2 - c' \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1}. \end{aligned}$$

We recall that  $\sigma(t, x) = \theta(t)p(x)$  and  $p_x(x) = -x^{1-\alpha}/(2-\alpha)$ . Hence,  $x^\alpha \sigma_x^2 = c\theta^2 x^\alpha x^{2-2\alpha} = c\theta^2 x^{2-\alpha}$ . Moreover,  $w = e^{R\sigma} z$ . Thus,  $w_x = R\sigma_x e^{R\sigma} z + e^{R\sigma} z_x$ . Therefore,

$$\begin{aligned} R^3 \theta^3 x^{2-\alpha} w^2 + R\theta x^\alpha w_x^2 &\leq R^3 \theta^3 x^{2-\alpha} e^{2R\sigma} z^2 + R\theta x^\alpha \left( 2R^2 \sigma_x^2 e^{2R\sigma} z^2 + 2e^{2R\sigma} z_x^2 \right) \\ &\leq c \left( R^3 \theta^3 x^{2-\alpha} e^{2R\sigma} z^2 + R\theta x^\alpha e^{2R\sigma} z_x^2 \right). \end{aligned}$$

So,

$$\iint_{Q_T} \left( R^3 \theta^3 x^{2-\alpha} w^2 + R\theta x^\alpha w_x^2 \right) e^{-2R\sigma} \leq c \iint_{Q_T} f^2 e^{-2R\sigma} + c \int_0^T \left\{ R\theta z_x^2 \right\}_{|x=1}.$$

Moreover  $z_x(x=1) = (e^{-R\sigma} w_x)(x=1)$  since  $z(x=1) = 0$ . It follows that

$$\begin{aligned} \iint_{Q_T} \left( R^3 \theta^3 x^{2-\alpha} w^2 + R\theta x^\alpha w_x^2 \right) e^{-2R\sigma} \\ \leq c \iint_{Q_T} f^2 e^{-2R\sigma} + c \int_0^T \left\{ R\theta e^{-2R\sigma} w_x^2 \right\}_{|x=1}. \quad \square \end{aligned}$$

**4. Proof of Theorem 2.3 (observability inequalities).** Theorem 2.2 yields a Carleman estimate for the solutions of (2.5).

LEMMA 4.1. *For all  $0 \leq \alpha < 2$  and all  $T > 0$ , there exist positive constants,  $R_0, C, c > 0$ , such that, for all  $v_T \in L^2(0,1)$ , the solution  $v$  of (2.5) satisfies, for all  $R \geq R_0$ ,*

$$\int_0^T \int_0^1 \left( R\theta x^\alpha v_x^2 + R^3 \theta^3 x^{2-\alpha} v^2 \right) e^{-2cR\theta} dx dt \leq C \int_0^T \int_\omega v^2 dx dt.$$

Let us put off the proof of the above lemma and proceed with the reasoning. Multiplying the equation in (2.5) by  $v_t$  and integrating by parts, we get

$$\begin{aligned} 0 &= \int_0^1 \left( v_t + (x^\alpha v_x)_x \right) v_t dx \\ &= \int_0^1 v_t^2 dx + \left[ x^\alpha v_x v_t \right]_0^1 - \int_0^1 x^\alpha v_x v_{tx} dx \geq -\frac{1}{2} \frac{d}{dt} \int_0^1 x^\alpha v_x^2 dx. \end{aligned}$$

Therefore  $t \mapsto \int_0^1 x^\alpha v_x^2 dx$  is increasing and

$$\int_0^1 x^\alpha v_x(0, x)^2 dx \leq \int_0^1 x^\alpha v_x(t, x)^2 dx \quad \forall t \in [0, T].$$

Integrating over  $[T/4, 3T/4]$ , we have

$$\begin{aligned} \int_0^1 x^\alpha v_x(0, x)^2 dx &\leq \frac{2}{T} \int_{T/4}^{3T/4} \int_0^1 x^\alpha v_x(t, x)^2 dx dt \\ &\leq C \int_{T/4}^{3T/4} \int_0^1 \theta x^\alpha v_x(t, x)^2 e^{-2cR\theta} dx dt. \end{aligned}$$

Hence, owing to Lemma 4.1,

$$(4.1) \quad \int_0^1 x^\alpha v_x(0, x)^2 dx \leq C \int_0^T \int_\omega v^2 dx dt. \quad \square$$

*Proof of Lemma 4.1.* Let  $\omega = (x_0, x_1)$  with  $0 \leq x_0 < x_1 \leq 1$  and consider a smooth cut-off function  $\psi : \mathbb{R} \rightarrow \mathbb{R}$ , such that

$$\begin{cases} 0 \leq \psi(x) \leq 1 & \forall x \in \mathbb{R}, \\ \psi(x) = 1 & \text{for } x \in (0, (2x_0 + x_1)/3), \\ \psi(x) = 0 & \text{for } x \in ((x_0 + 2x_1)/3, 1). \end{cases}$$

We define  $w := \psi v$  where  $v$  is the solution of (2.5). Then  $w$  satisfies

$$(4.2) \quad \begin{cases} w_t + (aw_x)_x = (a\psi_x v)_x + \psi_x a v_x =: f, & (t, x) \in Q_T, \\ w(t, 1) = 0, & t \in (0, T), \\ \text{and } \begin{cases} w(t, 0) = 0 & \text{for } 0 \leq \alpha < 1, \\ (aw_x)(t, 0) = 0 & \text{for } 1 \leq \alpha < 2, \end{cases} & t \in (0, T). \end{cases}$$

Therefore, applying Theorem 2.2 and using the fact that  $w \equiv 0$  in a neighborhood of  $x = 1$  (hence  $w_x(1, t) = 0$ ), we have, for all  $R \geq R_0$ ,

$$\iint_{Q_T} \left( R\theta x^\alpha w_x^2 + R^3 \theta^3 x^{2-\alpha} w^2 \right) e^{-2R\sigma} dx dt \leq C \iint_{Q_T} e^{-2R\sigma} f^2 dx dt.$$

Then using the definition of  $\psi$  and in particular the fact that  $\psi_x$  and  $\psi_{xx}$  are supported in  $\omega' := ((2x_0 + x_1)/3, (x_0 + 2x_1)/3)$ , we can write

$$f^2 = \left( (a\psi_x v)_x + \psi_x a v_x \right)^2 = \left( a_x \psi_x v + 2a\psi_x v_x + a\psi_{xx} v \right)^2 \chi_{\omega'} \leq C(v^2 + v_x^2) \chi_{\omega'},$$

since the function  $a_x$  is bounded on  $\omega'$ . Hence

$$(4.3) \quad \iint_{Q_T} \left( R\theta x^\alpha w_x^2 + R^3\theta^3 x^{2-\alpha} w^2 \right) e^{-2R\sigma} dx dt \leq C \int_0^T \int_{\omega'} e^{-2R\sigma} (v_x^2 + v^2) dx dt,$$

where  $\omega' := ((2x_0 + x_1)/3, (x_0 + 2x_1)/3)$ . At this point, let us apply the following standard estimate, to be proved later on.

LEMMA 4.2 (Caccioppoli's inequality). *For all  $R > 0$ ,*

$$\int_0^T \int_{\omega'} e^{-2R\sigma} v_x^2 dx dt \leq C(R, T) \int_0^T \int_{\omega} v^2 dx dt.$$

Let us continue with the proof of Lemma 4.1. The proof of Lemma 4.2 will be given later. By (4.3) and Lemma 4.2, we obtain a bound for  $v$  on  $(0, (2x_0 + x_1)/3)$  of the form

$$\begin{aligned} & \int_0^T \int_0^{(2x_0+x_1)/3} \left( R\theta x^\alpha v_x^2 + R^3\theta^3 x^{2-\alpha} v^2 \right) e^{-2R\sigma} dx dt \\ &= \int_0^T \int_0^{(2x_0+x_1)/3} \left( R\theta x^\alpha w_x^2 + R^3\theta^3 x^{2-\alpha} w^2 \right) e^{-2R\sigma} dx dt \\ &\leq \iint_{Q_T} \left( R\theta x^\alpha w_x^2 + R^3\theta^3 x^{2-\alpha} w^2 \right) e^{-2R\sigma} dx dt \leq C_R \int_0^T \int_{\omega} v^2 dx dt. \end{aligned}$$

Hence,

$$\int_0^T \int_0^{(2x_0+x_1)/3} \left( R\theta x^\alpha v_x^2 + R^3\theta^3 x^{2-\alpha} v^2 \right) e^{-2c_0 R\theta} dx dt \leq C_R \int_0^T \int_{\omega} v^2 dx dt,$$

where  $c_0 = \max \{p(x); x \in [0, 1]\} = 2/(2 - \alpha)^2$ .

Now, to complete the reasoning, one has to recover a similar inequality on the interval  $((x_0 + 2x_1)/3, 1)$ . But the equation is uniformly parabolic on such a domain. Therefore, the well-known Carleman estimate for the nondegenerate case (see [26]) yields, for  $R$  large enough,

$$\int_0^T \int_{(x_0+2x_1)/3}^1 \left( R\theta v_x^2 + R^3\theta^3 v^2 \right) e^{-2c_1 R\theta} dx dt \leq C_R \int_0^T \int_{\omega} v^2 dx dt$$

for some constant  $c_1 > 0$ . Indeed it is sufficient to apply the classical Carleman estimate to the function  $\tilde{v} = \rho v$  in the space interval  $((2x_0 + x_1)/3, 1)$ , where  $\rho : \mathbb{R} \rightarrow \mathbb{R}$  is some smooth cut-off function, such that

$$\begin{cases} 0 \leq \rho(x) \leq 1 & \forall x \in \mathbb{R}, \\ \rho(x) = 1 & \text{for } x \in ((x_0 + 2x_1)/3, 1), \\ \rho(x) = 0 & \text{for } x \in (0, (2x_0 + x_1)/3). \end{cases}$$

Hence we obtain

$$\int_0^T \int_{(x_0+2x_1)/3}^1 \left( R\theta x^\alpha v_x^2 + R^3\theta^3 x^{2-\alpha} v^2 \right) e^{-2c_1 R\theta} dx dt \leq C_R \int_0^T \int_{\omega} v^2 dx dt.$$

Combining the above estimates and using Lemma 4.2 to bound the integral on the middle interval, we obtain

$$\int_0^T \int_0^1 \left( R\theta x^\alpha v_x^2 + R^3 \theta^3 x^{2-\alpha} v^2 \right) e^{-2c_2 R\theta} dx dt \leq C_R \int_0^T \int_\omega v^2 dx dt,$$

where  $c_2 = \max(c_0, c_1)$ .  $\square$

*Proof of Lemma 4.2.* Consider a smooth function  $\xi : \mathbb{R} \rightarrow \mathbb{R}$  such that

$$\begin{cases} 0 \leq \xi(x) \leq 1 & \forall x \in \mathbb{R}, \\ \xi(x) = 1 & \text{for } x \in \omega', \\ \xi(x) = 0 & \text{for } x \notin \omega. \end{cases}$$

Then, for all  $R > 0$ ,

$$\begin{aligned} 0 &= \int_0^T \frac{d}{dt} \int_0^1 \xi^2 e^{-2R\sigma} v^2 = \iint_{Q_T} -2\xi^2 R\sigma_t e^{-2R\sigma} v^2 + 2\xi^2 e^{-2R\sigma} v v_t \\ &= -2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 - 2 \iint_{Q_T} \xi^2 e^{-2R\sigma} v (av_x)_x \\ &= -2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 + 2 \iint_{Q_T} (\xi^2 e^{-2R\sigma})_x a v_x \\ &= -2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 + 2 \iint_{Q_T} a (\xi^2 e^{-2R\sigma})_x v v_x + \xi^2 e^{-2R\sigma} a v_x^2. \end{aligned}$$

Hence,

$$\begin{aligned} 2 \iint_{Q_T} \xi^2 e^{-2R\sigma} a v_x^2 &= 2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 - 2 \iint_{Q_T} a (\xi^2 e^{-2R\sigma})_x v v_x \\ &= 2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 - 2 \iint_{Q_T} \left( \sqrt{a} \xi e^{-R\sigma} v_x \right) \left( \sqrt{a} \frac{(\xi^2 e^{-2R\sigma})_x}{\xi e^{-R\sigma}} v \right) \\ &\leq 2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 + \iint_{Q_T} \left( \sqrt{a} \xi e^{-R\sigma} v_x \right)^2 + \iint_{Q_T} \left( \sqrt{a} \frac{(\xi^2 e^{-2R\sigma})_x}{\xi e^{-R\sigma}} v \right)^2 \\ &\leq 2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 + \iint_{Q_T} \left( \sqrt{a} \frac{(\xi^2 e^{-2R\sigma})_x}{\xi e^{-R\sigma}} v \right)^2 + \iint_{Q_T} \xi^2 e^{-2R\sigma} a v_x^2. \end{aligned}$$

Therefore,

$$\begin{aligned} \iint_{Q_T} \xi^2 e^{-2R\sigma} a v_x^2 &\leq 2 \iint_{Q_T} \xi^2 R\sigma_t e^{-2R\sigma} v^2 + \iint_{Q_T} \left( \sqrt{a} \frac{(\xi^2 e^{-2R\sigma})_x}{\xi e^{-R\sigma}} v \right)^2 \\ &\leq C(R, T) \int_0^T \int_\omega v^2. \quad \square \end{aligned}$$

**5. Proof of Theorem 2.4 (controllability result).** By standard arguments, the null controllability result stated in Theorem 2.4 follows from (2.7). Hence it remains to prove (2.7). For  $\alpha \neq 1$ , we apply Hardy's inequality (Lemma 2.1) with  $\alpha^* = \alpha$  to deduce from (2.6) that

$$\int_0^1 x^{\alpha-2} v(0, x)^2 dx \leq C \int_0^1 x^\alpha v_x(0, x)^2 dx \leq C \int_0^T \int_\omega v^2 dx dt.$$

In the case of  $\alpha = 1$ , from (2.6) we deduce that, for all  $0 < \eta < 1$ ,

$$\int_0^1 x^{1+\eta} v_x(0, x)^2 dx \leq \int_0^1 x v_x(0, x)^2 dx \leq C \int_0^T \int_\omega v^2 dx dt.$$

Now, applying Hardy's inequality (Lemma 2.1) with  $\alpha^* = 1 + \eta$ , we obtain

$$\int_0^1 x^{\eta-1} v(0, x)^2 dx \leq C \int_0^1 x^{1+\eta} v_x(0, x)^2 dx \leq C \int_0^T \int_\omega v^2 dx dt.$$

In both cases, (2.7) follows.  $\square$

## 6. Proof of Lemma 2.1 (Hardy's inequalities).

*First case.*  $0 \leq \alpha^* < 1$ . Since  $z$  is absolutely continuous on  $(0, 1)$ , we have

$$\begin{aligned} |z(x) - z(\varepsilon)|^2 &= \left( \int_\varepsilon^x z_x(s) s^{(3-\gamma)/4} s^{(-3+\gamma)/4} ds \right)^2 \\ &\leq \left( \int_\varepsilon^x z_x(s)^2 s^{(3-\gamma)/2} ds \right) \left( \int_\varepsilon^x s^{(-3+\gamma)/2} ds \right), \end{aligned}$$

where we denote  $\gamma := 2 - \alpha^* \in (1, 2]$ . Letting  $\varepsilon \rightarrow 0^+$ , we get

$$|z(x)|^2 \leq \left( \int_0^x z_x(s)^2 s^{(3-\gamma)/2} ds \right) \left( \int_0^x s^{(-3+\gamma)/2} ds \right).$$

Therefore

$$\begin{aligned} \int_0^1 x^{\alpha^*-2} z(x)^2 dx &\leq \int_0^1 x^{-\gamma} \left( \int_0^x z_x(s)^2 s^{(3-\gamma)/2} ds \right) \left( \int_0^x s^{(-3+\gamma)/2} ds \right) dx \\ &= \int_0^1 x^{-\gamma} \left( \int_0^x z_x(s)^2 s^{(3-\gamma)/2} ds \right) \frac{x^{(\gamma-1)/2}}{(\gamma-1)/2} dx \\ &= \frac{2}{\gamma-1} \int_0^1 z_x(s)^2 s^{(3-\gamma)/2} \left( \int_s^1 x^{(-\gamma-1)/2} dx \right) ds \\ &\leq \frac{2}{\gamma-1} \int_0^1 z_x(s)^2 s^{(3-\gamma)/2} \frac{s^{(1-\gamma)/2}}{(\gamma-1)/2} ds = \frac{4}{(1-\alpha^*)^2} \int_0^1 s^{\alpha^*} z_x(s)^2 ds. \end{aligned}$$

*Second case.*  $1 < \alpha^* < 2$ . Denoting  $\gamma := 2 - \alpha^* \in (0, 1)$ , we have

$$\begin{aligned} \int_0^1 x^{\alpha^*-2} z(x)^2 dx &\leq \int_0^1 x^{-\gamma} \left( \int_x^1 z_x(s)^2 s^{(3-\gamma)/2} ds \right) \left( \int_x^1 s^{(-3+\gamma)/2} ds \right) dx \\ &\leq \int_0^1 x^{-\gamma} \left( \int_x^1 z_x(s)^2 s^{(3-\gamma)/2} ds \right) \frac{x^{-(1-\gamma)/2}}{(1-\gamma)/2} dx \\ &= \frac{2}{1-\gamma} \int_0^1 z_x(s)^2 s^{(3-\gamma)/2} \left( \int_0^s x^{(-\gamma-1)/2} dx \right) ds \\ &\leq \frac{4}{(1-\gamma)^2} \int_0^1 z_x(s)^2 s^{2-\gamma} ds = \frac{4}{(\alpha^*-1)^2} \int_0^1 s^{\alpha^*} z_x(s)^2 ds. \quad \square \end{aligned}$$

**Acknowledgments.** The authors wish to thank O. Imanuvilov for many fruitful discussions on the subject and for suggestions concerning the case  $\alpha = 1$  and the referees for their valuable comments that helped improve the presentation of this paper. They also wish to thank the Université Paul Sabatier Toulouse III, the Università di Roma “Tor Vergata,” and the Istituto Nazionale di Alta Matematica for their hospitality and financial support.

## OPTIMAL CONTROL OF A CONVECTIVE BOUNDARY CONDITION IN A THERMISTOR PROBLEM\*

VOLODYMYR HRYNKIV<sup>†</sup>, SUZANNE LENHART<sup>‡</sup>, AND VLADIMIR PROTOPODESCU<sup>§</sup>

**Abstract.** We consider the optimal control of a two-dimensional steady-state thermistor. The problem is described by a system of two nonlinear elliptic partial differential equations with appropriate boundary conditions which model the coupling of the thermistor to its surroundings. Based on physical considerations, an objective functional to be minimized is introduced and the convective boundary coefficient is taken as the control. Existence and uniqueness of the optimal control are proven. To characterize this optimal control, the optimality system consisting of the state and adjoint equations is derived.

**Key words.** optimal control, thermistor problem, elliptic systems

**AMS subject classifications.** 49J20, 49K20

**DOI.** 10.1137/06066401X

**1. Introduction.** Thermistor is a generic name for a device made from materials whose electrical conductivity is highly dependent on temperature. The advantages of thermistors as temperature measurement devices include their low cost, high resolution, and flexibility in size and shape. The applications of thermistors include [11, 13]

- (i) temperature sensing and control: thermistors provide inexpensive and reliable temperature sensing for a wide temperature range;
- (ii) thermal relay and switch: voltage regulation, surge protection;
- (iii) indirect measurement of other parameters: when a thermistor is heated its rate of change of temperature depends on its surroundings. This property can be used to monitor other quantities such as liquid level and fluid flow; and
- (iv) long-wavelength detector.

We consider the two-dimensional steady-state thermistor problem

$$\begin{aligned}
 \nabla \cdot (\sigma(u) \nabla \varphi) &= 0 & \text{in } \Omega, \\
 \Delta u + \sigma(u) |\nabla \varphi|^2 &= 0 & \text{in } \Omega, \\
 \frac{\partial u}{\partial n} + \beta u &= 0 & \text{on } \partial\Omega, \\
 \varphi &= \varphi_0 & \text{on } \partial\Omega,
 \end{aligned}
 \tag{1.1}$$

where  $\varphi(x)$  is the electric potential,  $u(x)$  is the temperature, and  $\sigma(u)$  is the temperature-dependent electrical conductivity. Here  $n$  denotes the outward unit normal and  $\partial/\partial n = n \cdot \nabla$  is the normal derivative on  $\partial\Omega$ . The first equation represents the conservation of charge and the second equation describes the steady diffusion of heat in the presence of Joule heating due to the electric current. Boundary conditions show how the thermistor is connected thermally and electrically to its surroundings. Throughout the paper, solutions to system (1.1) are understood in the weak sense. For a more detailed discussion about the physical justification of equations (1.1) the reader is referred to [7, 9, 15].

It is known that large temperature gradients may cause the thermistor to crack. Numerical experiments indicate (see [7, 21]) that low values of the heat transfer coefficient  $\beta$  will result in small temperature variations. On the other hand, low values of the heat transfer coefficient lead to high operating temperatures of a thermistor which are also undesirable. This motivated us to consider the heat transfer coefficient as a control in the optimal control problem of minimizing the heat transfer while keeping the operating temperature of the thermistor reasonably low. These requirements lead us to the following objective functional:

$$J(\beta) = \int_{\Omega} u \, dx + \int_{\partial\Omega} \beta^2 \, ds.$$

Denoting the set of admissible controls by

$$U_M = \{\beta \in L^\infty(\partial\Omega) : 0 < \lambda \leq \beta \leq M\},$$

the optimal control problem is as follows:

$$(1.2) \quad \text{Find } \beta^* \in U_M \text{ such that } J(\beta^*) = \min_{\beta \in U_M} J(\beta).$$

Henceforth we use the standard notation for Sobolev spaces: we denote  $\|\cdot\|_p = \|\cdot\|_{L^p(\Omega)}$  for each  $p \in [1, \infty]$ ; other norms will be clearly marked.

Theoretical analysis of both the steady-state and time-dependent thermistor equations with different types of boundary and initial conditions has received a significant amount of attention. See [1, 4, 6, 5, 7, 9, 15, 17, 18, 19] for existence of weak solutions, uniqueness, and related regularity results in different settings with various assumptions on the coefficients. For example, existence of a weak solution to a stationary problem with Dirichlet boundary conditions was proven by Cimatti and Prodi in [6], whereas the time-dependent case in two dimensions was first considered by Cimatti in [4]. This restriction on the space dimension was eliminated by Shi, Shillor, and Xu in [15]. Asymptotic results for the time-dependent thermistor problem can be found in [7]. So far, the only known optimal control paper on a thermistor problem is a time-dependent case by Lee and Shilkin in [12], where the source is taken to be the control. Thus our work is the first result on optimal control of the thermistor problem for the steady-state case.

In section 2 we derive a priori estimates under the assumption of small boundary data. In section 3 we prove existence of an optimal control. Also, in section 3 we explain why the space dimension is restricted to  $N = 2$ . The optimality system is derived and an optimal control is characterized in section 4. Uniqueness of the optimal control is proven in section 5. For more details on the estimates in this paper, see [10].

**2. A priori estimates.** Throughout we make the following assumptions:

1.  $\Omega \subset R^2$  is a bounded domain with smooth boundary;
2.  $\sigma(s) \in C^1(R)$ ,  $0 < C_1 \leq \sigma(s) \leq C_2$  for all  $s \in R$ ;
3.  $\sigma(s)$  is Lipschitz:  $|\sigma(s_1) - \sigma(s_2)| \leq K |s_1 - s_2|$  for all  $s_1, s_2 \in R$ ;
4.  $\varphi_0|_{\partial\Omega} \in W^{1,\infty}(\partial\Omega)$ ;
5.  $\|\varphi_0\|_{W^{1,\infty}(\Omega)} \leq C_H$  is sufficiently small, where  $C_H$  is derived from formula (30) in [9].

We will need the following result due to Meyers [3, 14, 16].

**THEOREM 2.1.** *Let  $\Omega \subset R^N$  be a bounded domain with a smooth boundary and suppose that  $A : H_0^1(\Omega) \rightarrow H^{-1}(\Omega)$  is the uniformly elliptic operator with bounded coefficients*

$$A = - \sum_{i,j=1}^n \frac{\partial}{\partial x_i} \left( a_{ij}(x) \frac{\partial}{\partial x_j} \right).$$

Consider the Dirichlet problem

$$(2.1) \quad Av = f, \quad v \in H_0^1(\Omega), f \in H^{-1}(\Omega).$$

Then there exists  $r > 2$  (which depends on  $\alpha$ , the  $L^\infty$  norm of the coefficients  $a_{ij}$ 's, the domain  $\Omega$ , and the dimension) such that if  $f \in W^{-1,r}(\Omega)$ , then  $v \in W_0^{1,r}(\Omega)$ , where  $v$  solves (2.1) and satisfies

$$\|v\|_{W_0^{1,r}(\Omega)} \leq C \|f\|_{W^{-1,r}(\Omega)}$$

and  $C$  depends on the same quantities as  $r$ .

To derive a weak formulation for (1.1) we follow Lemma 1 from [9] and the discussion preceding it. Note that we extend  $\varphi_0$  to the whole domain  $\Omega$  and use the same notation, i.e.,  $\varphi_0 \in W^{1,\infty}(\Omega)$ . We say that  $\{u, \varphi\}$  is a weak solution to (1.1) if

$$(2.2) \quad \begin{aligned} \int_{\Omega} \nabla u \cdot \nabla v \, dx + \int_{\partial\Omega} \beta uv \, ds &= \int_{\Omega} \sigma(u) |\nabla \varphi|^2 v \, dx \quad \forall v \in H^1(\Omega), \\ \int_{\Omega} \sigma(u) \nabla \varphi \cdot \nabla w \, dx &= 0, \quad \varphi_0 - \varphi \in H_0^1(\Omega) \quad \forall w \in H_0^1(\Omega). \end{aligned}$$

The quadratic term on the right-hand side of the first equation in (2.2) creates a difficulty because  $|\nabla \varphi|^2$  is only known to belong to  $L^1(\Omega)$ . Therefore, for an arbitrary  $v \in C^1(\bar{\Omega})$ , take  $w = (\varphi - \varphi_0)v \in H_0^1(\Omega)$  as a test function in the second equation of (2.2). Then

$$\int_{\Omega} \sigma(u) \{ |\nabla \varphi|^2 v - v \nabla \varphi \cdot \nabla \varphi_0 + (\varphi - \varphi_0) \nabla \varphi \cdot \nabla v \} \, dx = 0.$$

By the density argument, the weak formulation of (1.1) is as follows: Find  $u \in H^1(\Omega)$  and  $\varphi \in H^1(\Omega)$  such that

$$(2.3) \quad \begin{aligned} \int_{\Omega} \nabla u \cdot \nabla v \, dx + \int_{\partial\Omega} \beta uv \, ds &= \int_{\Omega} (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \cdot \nabla v \, dx + \int_{\Omega} (\sigma(u) \nabla \varphi \cdot \nabla \varphi_0) v \, dx \\ \int_{\Omega} \sigma(u) \nabla \varphi \cdot \nabla w \, dx &= 0, \quad \varphi_0 - \varphi \in H_0^1(\Omega) \quad \forall w \in H_0^1(\Omega), \forall v \in H^1(\Omega). \end{aligned}$$

Now the terms on the right-hand side of the first equation in (2.3) make sense. Indeed, by Theorem 2.1, there exists  $r > 2$  such that  $\varphi \in W^{1,r}(\Omega)$ . Therefore, since  $\nabla\varphi \in L^r(\Omega)$  and  $\nabla\varphi_0 \in L^2(\Omega)$ , it follows that there exists  $s'$  such that  $\nabla\varphi \cdot \nabla\varphi_0 \in L^{s'}(\Omega)$  and

$$(2.4) \quad \frac{1}{s'} = \frac{1}{2} + \frac{1}{r}.$$

Since  $\Omega \subset \mathbb{R}^2$  it follows that  $v \in H^1(\Omega) \subset L^s(\Omega)$  for  $s \in [1, \infty)$ . This implies that the integral

$$\int_{\Omega} (\sigma(u) \nabla\varphi \cdot \nabla\varphi_0) v \, dx$$

in (2.3) makes sense, since  $\sigma(u)$  is bounded and  $(\sigma(u) \nabla\varphi \cdot \nabla\varphi_0) \in L^{s'}(\Omega)$ , and  $s$  can be chosen such that

$$(2.5) \quad \frac{1}{s'} + \frac{1}{s} = 1.$$

If we denote  $\tilde{M} := \sup_{\partial\Omega} |\varphi_0|$ , then by the weak maximum principle (see formula (16) in [9])

$$(2.6) \quad \sup_{\Omega} |\varphi| \leq \tilde{M}.$$

Therefore the integral  $\int_{\Omega} (\varphi_0 - \varphi) \sigma(u) \nabla\varphi \cdot \nabla v \, dx$  in (2.3) also makes sense. Thus, any solution of (2.2) is a solution to (2.3), and vice versa.

Note that  $r > 2$  is chosen from the Meyers estimate; then  $s'$  and  $s$  are determined and satisfy  $s' < 2 < s$ .

Existence of a solution to (2.3) was proven by Howison, Rodrigues, and Shillor in [9] using Schauder's fixed point theorem. It was also shown in [9] that the solution is unique provided assumption 5 is satisfied. Given  $\beta \in U_M$ , we denote the solution of (2.3) by  $u(\beta), \varphi(\beta)$ , under assumption 5 giving uniqueness.

Here we proceed to the derivation of a priori estimates. Note that as a result of the maximum principle solutions to (1.1) satisfy  $u \geq 0$  on  $\bar{\Omega}$ .

**THEOREM 2.2.** *Let assumptions 1 through 4 hold and let  $\beta \in U_M$  be given. Then  $u$  and  $\varphi$  solving (2.3) satisfy*

$$(2.7) \quad \begin{aligned} \|\varphi\|_{W^{1,r}(\Omega)} &\leq \Phi \text{ for some } r > 2, \\ \|u\|_{H^1(\Omega)} &\leq \tilde{C}, \end{aligned}$$

where  $\Phi$  and  $\tilde{C}$  are some positive constants.

*Proof.* We show the estimate for  $\varphi$  first. Because of assumption 2 we treat  $\sigma(u)$  in (1.1) as a bounded coefficient. Consider the following Dirichlet problem with zero boundary data:

$$(2.8) \quad \begin{aligned} -\nabla \cdot (\sigma(u) \nabla \tilde{\varphi}) &= \nabla \cdot (\sigma(u) \nabla \varphi_0) \text{ in } \Omega, \\ \tilde{\varphi} &= 0 \text{ on } \partial\Omega. \end{aligned}$$

Since the right-hand side of (2.8) is in  $H^{-1}(\Omega)$ , by the standard theory for elliptic equations in divergence form [8], there exists  $\tilde{\varphi} = (\varphi - \varphi_0) \in H_0^1(\Omega)$  that solves (2.8).

By Theorem 2.1, there exists  $r > 2$  such that  $\tilde{\varphi} \in W_0^{1,r}(\Omega)$  and

$$\|\tilde{\varphi}\|_{W_0^{1,r}(\Omega)} \leq C \|\nabla \cdot (\sigma(u) \nabla \varphi_0)\|_{W^{-1,r}(\Omega)} \leq C \|\sigma(u) \nabla \varphi_0\|_r \leq CC_2 \|\nabla \varphi_0\|_r.$$

Since

$$\|\varphi\|_{W^{1,r}(\Omega)} \leq \|\varphi - \varphi_0\|_{W^{1,r}(\Omega)} + \|\varphi_0\|_{W^{1,r}(\Omega)}$$

and

$$\|\varphi - \varphi_0\|_{W^{1,r}(\Omega)} \equiv \|\tilde{\varphi}\|_{W^{1,r}(\Omega)} \leq C' \|\tilde{\varphi}\|_{W_0^{1,r}(\Omega)} \leq C' CC_2 \|\nabla \varphi_0\|_r,$$

we obtain

$$\|\varphi\|_{W^{1,r}(\Omega)} \leq C' CC_2 \|\nabla \varphi_0\|_r + \|\varphi_0\|_{W^{1,r}(\Omega)}.$$

We also have

$$\begin{aligned} \|\nabla \varphi_0\|_r &\leq C_3 \|\nabla \varphi_0\|_\infty, \\ \|\varphi_0\|_{W^{1,r}(\Omega)} &\leq C_4 \|\varphi_0\|_{W^{1,\infty}(\Omega)}, \end{aligned}$$

whence

$$(2.9) \quad \|\varphi\|_{W^{1,r}(\Omega)} \leq \Phi \text{ for some } r > 2,$$

where

$$(2.10) \quad \Phi \stackrel{\text{def}}{=} C' CC_2 C_3 \|\nabla \varphi_0\|_\infty + C_4 \|\varphi_0\|_{W^{1,\infty}(\Omega)}.$$

We show that  $\|u\|_{H^1(\Omega)} \leq \tilde{C}$ . From the weak formulation (2.3) we get

$$\int_\Omega |\nabla u|^2 dx + \int_{\partial\Omega} \beta u^2 ds = \int_\Omega (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \cdot \nabla u dx + \int_\Omega \sigma(u) u \nabla \varphi \cdot \nabla \varphi_0 dx.$$

Taking into account that  $\beta(x) \geq \lambda > 0$  we have

$$\begin{aligned} \int_\Omega |\nabla u|^2 dx + \lambda \int_{\partial\Omega} u^2 ds &\leq \int_\Omega (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \cdot \nabla u dx + \int_\Omega \sigma(u) u \nabla \varphi \cdot \nabla \varphi_0 dx \\ &\leq 2C_2 \tilde{M} \|\nabla \varphi\|_2 \cdot \|\nabla u\|_2 + C_2 \|\nabla \varphi_0\|_\infty \|u\|_2 \cdot \|\nabla \varphi\|_2 \\ &\leq 2C_2 \tilde{M} C_5 \Phi \|\nabla u\|_2 + C_2 \|\nabla \varphi_0\|_\infty C_5 \Phi \|u\|_2 \\ &\leq \tilde{C}_1 \|u\|_{H^1(\Omega)}, \end{aligned}$$

where we used (2.6),  $\|\nabla \varphi\|_2 \leq C_5 \|\nabla \varphi\|_r$ , and  $\tilde{C}_1 \equiv \max(2C_2 \tilde{M} C_5 \Phi, C_2 \|\nabla \varphi_0\|_\infty C_5 \Phi)$ . It can be shown (for example, see [2, 20]) that the quantity

$$\|v\|_*^2 \stackrel{\text{def}}{=} \int_\Omega |\nabla v|^2 dx + \lambda \int_{\partial\Omega} v^2 ds$$

defines a norm on  $H^1(\Omega)$  which is equivalent to the  $\|\cdot\|_{H^1(\Omega)}$  norm; then for some  $k > 0$

$$(2.11) \quad k \|u\|_{H^1(\Omega)}^2 \leq \|u\|_*^2 \leq \tilde{C}_1 \|u\|_{H^1(\Omega)},$$

whence  $\|u\|_{H^1(\Omega)} \leq \tilde{C}_1/k$ .  $\square$

**3. Existence of an optimal control.** Having obtained a priori estimates we proceed to the proof of existence of an optimal control. For the remainder of the paper we assume that assumptions 1 through 5 are satisfied.

**THEOREM 3.1.** *There exists a solution to the optimal control problem (1.2).*

*Proof.* Using the estimate from Theorem 2.2, we can choose a minimizing sequence  $\{\beta_n\}_{n=1}^\infty \subset U_M$  such that

$$\lim_{n \rightarrow \infty} J(\beta_n) = \inf_{\beta \in U_M} J(\beta).$$

Let  $u_n = u(\beta_n)$  and  $\varphi_n = \varphi(\beta_n)$  be the corresponding solutions to (2.3). By Theorem 2.2 we have  $\|u_n\|_{H^1(\Omega)} \leq C$ ,  $\|\varphi_n\|_{W^{1,r}(\Omega)} \leq C$  for all  $n$ , where  $C > 0$  denotes a constant independent of  $n$ . Therefore, there exist  $u^* \in H^1(\Omega)$  and  $\varphi^* \in W^{1,r}(\Omega)$  such that on a subsequence

$$u_n \xrightarrow{w} u^* \text{ in } H^1(\Omega) \quad \text{and} \quad \varphi_n \xrightarrow{w} \varphi^* \text{ in } W^{1,r}(\Omega).$$

Since  $r > 2$  and  $N = 2$ , we have  $W^{1,r}(\Omega) \subset \subset C(\bar{\Omega})$  and  $W^{1,r}(\Omega) \subset H^1(\Omega) \subset \subset L^s(\Omega)$ . Hence, there exists  $\beta^* \in U_M$  such that on a subsequence

$$(3.1) \quad \begin{aligned} \varphi_n &\xrightarrow{s} \varphi^* \quad \text{in } C(\bar{\Omega}), & \nabla \varphi_n &\xrightarrow{w} \nabla \varphi^* \quad \text{in } L^r(\Omega), \\ u_n &\xrightarrow{s} u^* \quad \text{in } L^s(\Omega), & \nabla u_n &\xrightarrow{w} \nabla u^* \quad \text{in } L^2(\Omega), \\ \beta_n &\xrightarrow{w} \beta^* \quad \text{in } L^2(\partial\Omega), & \beta_n &\xrightarrow{w^*} \beta^* \quad \text{in } L^\infty(\partial\Omega), \\ u_n &\xrightarrow{s} u^* \quad \text{in } L^2(\partial\Omega). \end{aligned}$$

Next, we want to show that  $u^* = u(\beta^*)$  and  $\varphi^* = \varphi(\beta^*)$  solve (2.3) with control  $\beta^*$ . We show that for  $v \in H^1(\Omega)$

$$(3.2) \quad \int_{\partial\Omega} \beta_n u_n v \, ds \rightarrow \int_{\partial\Omega} \beta^* u^* v \, ds \text{ as } n \rightarrow \infty.$$

Indeed, by the trace inequality  $u^* \in H^1(\Omega)$  implies  $u^* \in L^2(\partial\Omega)$ , and we obtain

$$\begin{aligned} \left| \int_{\partial\Omega} \beta_n u_n v \, ds - \int_{\partial\Omega} \beta^* u^* v \, ds \right| &\leq \int_{\partial\Omega} |\beta_n u_n v - \beta_n u^* v| \, ds + \left| \int_{\partial\Omega} \beta_n u^* v - \beta^* u^* v \, ds \right| \\ &\leq M \int_{\partial\Omega} |u_n - u^*| \cdot |v| \, ds + \left| \int_{\partial\Omega} (\beta_n - \beta^*) u^* v \, ds \right| \\ &\leq M \|u_n - u^*\|_{L^2(\partial\Omega)} \cdot \|v\|_{L^2(\partial\Omega)} \\ &\quad + \left| \int_{\partial\Omega} (\beta_n - \beta^*) u^* v \, ds \right| \rightarrow 0 \text{ as } n \rightarrow \infty. \end{aligned}$$

This proves (3.2). Next, we show

$$(3.3) \quad \int_{\Omega} \sigma(u_n) v \nabla \varphi_n \cdot \nabla \varphi_0 \, dx \rightarrow \int_{\Omega} \sigma(u^*) v \nabla \varphi^* \cdot \nabla \varphi_0 \, dx \text{ as } n \rightarrow \infty.$$

We have

$$\begin{aligned} &\left| \int_{\Omega} \sigma(u_n) v \nabla \varphi_n \cdot \nabla \varphi_0 \, dx - \int_{\Omega} \sigma(u^*) v \nabla \varphi^* \cdot \nabla \varphi_0 \, dx \right| \\ &\leq K \|\nabla \varphi_0\|_\infty \int_{\Omega} |u_n - u^*| \cdot |v| \cdot |\nabla \varphi_n| \, dx + \left| \int_{\Omega} \sigma(u^*) v (\nabla \varphi_n - \nabla \varphi^*) \cdot \nabla \varphi_0 \, dx \right| \\ &\leq K \|\nabla \varphi_0\|_\infty \|u_n - u^*\|_s \cdot \|v\|_2 \cdot \|\nabla \varphi_n\|_r + \left| \int_{\Omega} \sigma(u^*) v (\nabla \varphi_n - \nabla \varphi^*) \cdot \nabla \varphi_0 \, dx \right| \rightarrow 0 \end{aligned}$$

since  $u_n \xrightarrow{s} u^*$  in  $L^s(\Omega)$ ,  $\nabla \varphi \xrightarrow{w} \nabla \varphi^*$  in  $L^2(\Omega)$ , and  $\|\nabla \varphi_n\|_r \leq C$ . This completes the proof of (3.3). Now we show

$$(3.4) \quad \int_{\Omega} (\varphi_0 - \varphi_n) \sigma(u_n) \nabla \varphi_n \cdot \nabla v \, dx \rightarrow \int_{\Omega} (\varphi_0 - \varphi^*) \sigma(u^*) \nabla \varphi^* \cdot \nabla v \, dx \text{ as } n \rightarrow \infty.$$

Indeed, we can write

$$\begin{aligned} & \left| \int_{\Omega} (\varphi_0 - \varphi_n) \sigma(u_n) \nabla \varphi_n \cdot \nabla v \, dx - \int_{\Omega} (\varphi_0 - \varphi^*) \sigma(u^*) \nabla \varphi^* \cdot \nabla v \, dx \right| \\ & \leq \left| \int_{\Omega} [\sigma(u_n) (\varphi_0 - \varphi_n) \nabla \varphi_n \cdot \nabla v - \sigma(u^*) (\varphi_0 - \varphi_n) \nabla \varphi^* \cdot \nabla v] \, dx \right| \\ & \quad + \left| \int_{\Omega} [\sigma(u^*) (\varphi_0 - \varphi_n) \nabla \varphi^* \cdot \nabla v - \sigma(u^*) (\varphi_0 - \varphi^*) \nabla \varphi^* \cdot \nabla v] \, dx \right| \stackrel{\text{def}}{=} A + B. \end{aligned}$$

We deal with the term  $B$  first:

$$\begin{aligned} B &= \left| \int_{\Omega} \sigma(u^*) \nabla \varphi^* \cdot \nabla v [(\varphi_0 - \varphi_n) - (\varphi_0 - \varphi^*)] \, dx \right| \\ &= \left| \int_{\Omega} \sigma(u^*) \nabla \varphi^* \cdot \nabla v (\varphi^* - \varphi_n) \, dx \right| \\ &\leq C_2 \|\varphi^* - \varphi_n\|_{C(\bar{\Omega})} \cdot \|\nabla v\|_2 \cdot \|\nabla \varphi^*\|_2 \rightarrow 0 \text{ as } n \rightarrow \infty. \end{aligned}$$

Now we look at the term  $A$ :

$$\begin{aligned} A &\leq \left| \int_{\Omega} (\varphi_0 - \varphi_n) (\sigma(u_n) - \sigma(u^*)) \nabla \varphi_n \cdot \nabla v \, dx \right| \\ &\quad + \left| \int_{\Omega} (\varphi_0 - \varphi_n) \sigma(u^*) (\nabla \varphi_n - \nabla \varphi^*) \cdot \nabla v \, dx \right| \stackrel{\text{def}}{=} A_1 + A_2, \end{aligned}$$

where

$$A_1 \leq 2\tilde{M}K \|u_n - u^*\|_s \cdot \|\nabla \varphi_n\|_r \cdot \|\nabla v\|_2 \rightarrow 0 \text{ as } n \rightarrow \infty.$$

For  $A_2$  we get

$$\begin{aligned} A_2 &\leq \left| \int_{\Omega} (\varphi_0 - \varphi^*) \sigma(u^*) (\nabla \varphi_n - \nabla \varphi^*) \cdot \nabla v \, dx \right| \\ &\quad + \left| \int_{\Omega} (\varphi^* - \varphi_n) \sigma(u^*) (\nabla \varphi_n - \nabla \varphi^*) \cdot \nabla v \, dx \right| \stackrel{\text{def}}{=} A_{21} + A_{22}. \end{aligned}$$

It is easy to see that  $A_{21} \rightarrow 0$  as  $n \rightarrow \infty$ . Similarly,

$$A_{22} \leq C_2 \|\varphi^* - \varphi_n\|_{C(\bar{\Omega})} \cdot (\|\nabla \varphi_n\|_2 + \|\nabla \varphi^*\|_2) \cdot \|\nabla v\|_2 \rightarrow 0 \text{ as } n \rightarrow \infty.$$

We can also obtain

$$\int_{\Omega} \sigma(u_n) \nabla \varphi_n \cdot \nabla w \, dx \rightarrow \int_{\Omega} \sigma(u^*) \nabla \varphi^* \cdot \nabla w \, dx \text{ as } n \rightarrow \infty.$$

Therefore  $(u^*, \varphi^*)$  is the weak solution of (2.3) with  $\beta = \beta^*$ :  $u^* = u(\beta^*)$  and  $\varphi^* = \varphi(\beta^*)$ . Using weak lower semicontinuity of  $J(\beta)$  with respect to the  $L^2$  norm, it is easy to show that the infimum is achieved at  $\beta^*$ .  $\square$

**4. Derivation of the optimality system.** In order to characterize an optimal control, we need to derive an optimality system which consists of the original state system coupled with an adjoint system. To obtain the necessary conditions for the optimality system, we differentiate the objective functional with respect to the control. Since the objective functional depends on  $u$ , which is coupled to  $\varphi$  through the PDE, we will need to differentiate  $u$  and  $\varphi$  with respect to control  $\beta$ . Note that to obtain this result,  $\|\varphi_0\|_{W^{1,\infty}}$  may need to be smaller than in assumption 5.

**THEOREM 4.1** (sensitivities). *There exists  $\Lambda_1 > 0$  such that  $\|\varphi_0\|_{W^{1,\infty}} \leq \Lambda_1$ , and the mapping  $\beta \mapsto (u, \varphi)$  is differentiable in the following sense:*

$$(4.1) \quad \begin{aligned} \frac{u(\beta + \varepsilon \ell) - u(\beta)}{\varepsilon} &\xrightarrow{w} \psi_1 \text{ in } H^1(\Omega), \\ \frac{\varphi(\beta + \varepsilon \ell) - \varphi(\beta)}{\varepsilon} &\xrightarrow{w} \psi_2 \text{ in } H_0^1(\Omega) \text{ as } \varepsilon \rightarrow 0 \end{aligned}$$

for any  $\beta, \ell \in U_M$  such that  $(\beta + \varepsilon \ell) \in U_M$  for small  $\varepsilon$ . Moreover, the sensitivities,  $\psi_1 \in H^1(\Omega)$  and  $\psi_2 \in H_0^1(\Omega)$ , satisfy

$$(4.2) \quad \begin{aligned} \Delta \psi_1 + \sigma'(u) |\nabla \varphi|^2 \psi_1 + 2\sigma(u) \nabla \varphi \cdot \nabla \psi_2 &= 0 \text{ in } \Omega, \\ \nabla \cdot [\sigma'(u) \psi_1 \nabla \varphi + \sigma(u) \nabla \psi_2] &= 0 \text{ in } \Omega, \\ \frac{\partial \psi_1}{\partial n} + \beta \psi_1 + \ell u &= 0 \text{ on } \partial\Omega, \\ \psi_2 &= 0 \text{ on } \partial\Omega. \end{aligned}$$

*Proof.* Recall that we denoted  $u = u(\beta)$  and  $\varphi = \varphi(\beta)$ . Now we also denote  $u^\varepsilon = u(\beta^\varepsilon)$ ,  $\varphi^\varepsilon = \varphi(\beta^\varepsilon)$ , where  $\beta^\varepsilon := \beta + \varepsilon \ell$ . We present the proof in three steps.

*Step 1.* First, we derive an estimate for  $(\varphi^\varepsilon - \varphi)/\varepsilon$  in terms of  $(u^\varepsilon - u)/\varepsilon$ . The quotients  $(u^\varepsilon - u)/\varepsilon$  and  $(\varphi^\varepsilon - \varphi)/\varepsilon$  satisfy

$$(4.3) \quad \begin{aligned} &\int_{\Omega} \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \cdot \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) dx + \int_{\partial\Omega} \beta \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \left( \frac{u^\varepsilon - u}{\varepsilon} \right) ds \\ &= - \int_{\partial\Omega} \ell u^\varepsilon \left( \frac{u^\varepsilon - u}{\varepsilon} \right) ds \\ &\quad + \frac{1}{\varepsilon} \int_{\Omega} [(\varphi_0 - \varphi^\varepsilon) \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - (\varphi_0 - \varphi) \sigma(u) \nabla \varphi] \cdot \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) dx \\ &\quad + \frac{1}{\varepsilon} \int_{\Omega} [\sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi] \cdot \nabla \varphi_0 \left( \frac{u^\varepsilon - u}{\varepsilon} \right) dx, \\ &\quad \frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) - \sigma(u) \nabla \varphi \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right] dx = 0. \end{aligned}$$

Since  $(\varphi^\varepsilon - \varphi)/\varepsilon \in H_0^1(\Omega)$  it follows from Poincaré's inequality that it is sufficient to have a bound on  $\|\nabla(\varphi^\varepsilon - \varphi)/\varepsilon\|_2$ . The second equation in (4.3) implies

$$(4.4) \quad \int_{\Omega} \sigma(u^\varepsilon) \nabla \left( \frac{\varphi^\varepsilon}{\varepsilon} \right) \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) dx = \int_{\Omega} \sigma(u) \nabla \left( \frac{\varphi}{\varepsilon} \right) \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) dx.$$

Taking into account (4.4) we can write

$$(4.5) \quad \int_{\Omega} \sigma(u) \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right|^2 dx = \int_{\Omega} \left( \sigma(u) - \sigma(u^\varepsilon) \right) \nabla \left( \frac{\varphi}{\varepsilon} \right) \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) dx.$$

Using (4.4) and (4.5) we obtain

$$\begin{aligned}
C_1 \left\| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right\|_2^2 &\leq \int_{\Omega} \sigma(u) \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right|^2 dx \\
&= \int_{\Omega} \left( \sigma(u) - \sigma(u^\varepsilon) \right) \nabla \left( \frac{\varphi^\varepsilon}{\varepsilon} \right) \cdot \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) dx \\
&\leq K \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_s \cdot \|\nabla \varphi^\varepsilon\|_r \cdot \left\| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right\|_2,
\end{aligned}$$

whence

$$(4.6) \quad \left\| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right\|_2 \leq \frac{K}{C_1} \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)} \cdot \|\nabla \varphi^\varepsilon\|_r.$$

*Step 2.* Now we outline the derivation of an  $H^1$  norm estimate for  $(u^\varepsilon - u)/\varepsilon$ . From the first equation in (4.3) we obtain

$$\begin{aligned}
&\int_{\Omega} \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right|^2 dx + \lambda \int_{\partial\Omega} \left( \frac{u^\varepsilon - u}{\varepsilon} \right)^2 ds \leq \left| - \int_{\partial\Omega} \ell u^\varepsilon \left( \frac{u^\varepsilon - u}{\varepsilon} \right) ds \right. \\
&+ \frac{1}{\varepsilon} \int_{\Omega} \left[ (\varphi_0 - \varphi^\varepsilon) \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \right] \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) dx \\
&+ \left. \frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi \right] \nabla \varphi_0 \left( \frac{u^\varepsilon - u}{\varepsilon} \right) dx \right| \\
&\stackrel{\text{def}}{=} \left| - \int_{\partial\Omega} \ell u^\varepsilon \left( \frac{u^\varepsilon - u}{\varepsilon} \right) ds + \mathcal{C} + \mathcal{D} \right|.
\end{aligned}$$

We have

$$\begin{aligned}
|\mathcal{C}| &\leq \int_{\Omega} |\varphi_0 - \varphi| \cdot \left| \frac{\sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi}{\varepsilon} \right| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&+ \int_{\Omega} \left| \frac{\varphi - \varphi^\varepsilon}{\varepsilon} \right| \sigma(u^\varepsilon) |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&\leq 2\tilde{M} \int_{\Omega} \left| \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&+ 2\tilde{M} \int_{\Omega} \sigma(u) \cdot \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&+ C_2 \int_{\Omega} \left| \frac{\varphi - \varphi^\varepsilon}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&\leq 2\tilde{M}K \int_{\Omega} \left| \frac{u^\varepsilon - u}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&+ 2\tilde{M}C_2 \int_{\Omega} \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\
&+ C_2 \int_{\Omega} \left| \frac{\varphi - \varphi^\varepsilon}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx.
\end{aligned}$$

Similarly, for  $\mathcal{D}$  we obtain

$$\begin{aligned} |\mathcal{D}| &\leq K \|\nabla \varphi_0\|_\infty \int_\Omega \left| \frac{u^\varepsilon - u}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \frac{u^\varepsilon - u}{\varepsilon} \right| dx \\ &\quad + C_2 \|\nabla \varphi_0\|_\infty \int_\Omega \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right| \cdot \left| \frac{u^\varepsilon - u}{\varepsilon} \right| dx. \end{aligned}$$

Taking into account the expressions for  $|\mathcal{C}|$ ,  $|\mathcal{D}|$ , and the trace inequality  $\|u^\varepsilon\|_{L^2(\partial\Omega)} \leq M_2 \|u^\varepsilon\|_{H^1(\Omega)}$  we get

$$\begin{aligned} &\int_\Omega \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right|^2 dx + \lambda \int_{\partial\Omega} \left( \frac{u^\varepsilon - u}{\varepsilon} \right)^2 ds \\ &\leq M M_2^2 \|u^\varepsilon\|_{H^1(\Omega)} \cdot \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)} + 2\tilde{M}K \int_\Omega \left| \frac{u^\varepsilon - u}{\varepsilon} \right| \cdot |\nabla \varphi^\varepsilon| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\ &\quad + 2\tilde{M}C_2 \int_\Omega \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right| \cdot \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx + C_2 \int_\Omega \left| \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right| |\nabla \varphi^\varepsilon| \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right| dx \\ &\quad + K \|\nabla \varphi_0\|_\infty \int_\Omega \left| \frac{u^\varepsilon - u}{\varepsilon} \right| |\nabla \varphi^\varepsilon| \left| \frac{u^\varepsilon - u}{\varepsilon} \right| dx + C_2 \|\nabla \varphi_0\|_\infty \int_\Omega \left| \nabla \left( \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right) \right| \left| \frac{u^\varepsilon - u}{\varepsilon} \right| dx. \end{aligned}$$

For the rest of this paper, when dealing with constants, we only keep track of explicit dependence on  $\Phi$  and otherwise use generic constants. Using Hölder's inequality and corresponding a priori bounds we have

$$\begin{aligned} \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_*^2 &\equiv \int_\Omega \left| \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \right|^2 dx + \lambda \int_{\partial\Omega} \left( \frac{u^\varepsilon - u}{\varepsilon} \right)^2 ds \leq C_8 \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)} \\ &\quad + \left( C_9 \Phi + C_{10} \Phi^2 \right) \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)}^2. \end{aligned}$$

Due to the equivalence of norms expressed by (2.11) we get

$$k \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)}^2 \leq \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_*^2 \leq C_8 \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)} + \left( C_9 \Phi + C_{10} \Phi^2 \right) \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)}^2.$$

Recall that by definition,  $\Phi$  includes  $\|\nabla \varphi_0\|_\infty$  and  $\|\varphi_0\|_{W^{1,\infty}(\Omega)}$  (see (2.10)). Therefore, if  $\|\varphi_0\|_{W^{1,\infty}(\Omega)}$  is chosen sufficiently small such that

$$k_1 \stackrel{\text{def}}{=} k - \left( C_9 \Phi + C_{10} \Phi^2 \right) > 0,$$

then

$$(4.7) \quad \left\| \frac{u^\varepsilon - u}{\varepsilon} \right\|_{H^1(\Omega)} \leq \frac{C_8}{k_1},$$

where the constant in (4.7) does not depend on  $\varepsilon$ . Consequently,

$$(4.8) \quad \left\| \frac{\varphi^\varepsilon - \varphi}{\varepsilon} \right\|_{H^1(\Omega)} \leq C_{11}.$$

*Step 3.* Now we are ready to derive the sensitivity system (4.2). The above

estimates imply that for a subsequence of  $\varepsilon \rightarrow 0$ , there exist  $\psi_1$  and  $\psi_2$  such that

$$\begin{aligned} \frac{u^\varepsilon - u}{\varepsilon} &\xrightarrow{w} \psi_1 \quad \text{in } H^1(\Omega), & \frac{u^\varepsilon - u}{\varepsilon} &\xrightarrow{s} \psi_1 \quad \text{in } L^s(\Omega), \\ \frac{\varphi^\varepsilon - \varphi}{\varepsilon} &\xrightarrow{w} \psi_2 \quad \text{in } H^1(\Omega), & \frac{\varphi^\varepsilon - \varphi}{\varepsilon} &\xrightarrow{s} \psi_2 \quad \text{in } L^s(\Omega), \\ u^\varepsilon &\xrightarrow{s} u \quad \text{in } L^s(\Omega), & \varphi^\varepsilon &\xrightarrow{s} \varphi \quad \text{in } C(\bar{\Omega}), \\ \nabla \varphi^\varepsilon &\xrightarrow{w} \nabla \varphi \quad \text{in } L^r(\Omega), & \frac{u^\varepsilon - u}{\varepsilon} &\xrightarrow{s} \psi_1 \quad \text{in } L^2(\partial\Omega), \\ \beta^\varepsilon &\xrightarrow{w} \beta \quad \text{in } L^2(\partial\Omega), & \beta^\varepsilon &\xrightarrow{w^*} \beta \quad \text{in } L^\infty(\partial\Omega) \text{ as } \varepsilon \rightarrow 0. \end{aligned}$$

Using these convergences we show that the sensitivities satisfy the system (4.2). After subtracting the corresponding weak formulations and dividing by  $\varepsilon$ , we obtain

$$\begin{aligned} (4.9) \quad & \int_{\Omega} \nabla \left( \frac{u^\varepsilon - u}{\varepsilon} \right) \cdot \nabla v \, dx + \int_{\partial\Omega} \beta \left( \frac{u^\varepsilon - u}{\varepsilon} \right) v \, ds + \int_{\partial\Omega} \ell u^\varepsilon \, ds \\ &= \frac{1}{\varepsilon} \int_{\Omega} \left[ (\varphi_0 - \varphi^\varepsilon) \sigma(u^\varepsilon) \nabla \varphi^\varepsilon \cdot \nabla v - (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \cdot \nabla v \right] dx \\ &+ \frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi \right] \cdot \nabla \varphi_0 v \, dx \quad \forall v \in H^1(\Omega), \end{aligned}$$

$$(4.10) \quad \frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon \cdot \nabla w - \sigma(u) \nabla \varphi \cdot \nabla w \right] dx = 0 \quad \forall w \in H_0^1(\Omega).$$

The terms on the left-hand side of (4.9) can be shown to converge by weak convergence. We write the first term on the right-hand side of (4.9) in the form

$$\begin{aligned} & \frac{1}{\varepsilon} \int_{\Omega} \left[ (\varphi_0 - \varphi^\varepsilon) \sigma(u^\varepsilon) \nabla \varphi^\varepsilon \cdot \nabla v - (\varphi_0 - \varphi) \sigma(u) \nabla \varphi \cdot \nabla v \right] dx \\ &= \frac{1}{\varepsilon} \int_{\Omega} (\varphi_0 - \varphi^\varepsilon) \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi \right] \cdot \nabla v \, dx + \frac{1}{\varepsilon} \int_{\Omega} (\varphi - \varphi^\varepsilon) \sigma(u) \nabla \varphi \cdot \nabla v \, dx \\ &= \mathcal{G} + \mathcal{F}. \end{aligned}$$

We illustrate the type of estimates by considering terms coming from  $\mathcal{G}$ . We write

$$\begin{aligned} \mathcal{G} &= \frac{1}{\varepsilon} \int_{\Omega} (\varphi_0 - \varphi^\varepsilon) \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi \right] \cdot \nabla v \, dx \\ &= \frac{1}{\varepsilon} \int_{\Omega} (\varphi_0 - \varphi^\varepsilon) \left[ \sigma(u^\varepsilon) - \sigma(u) \right] \nabla \varphi^\varepsilon \cdot \nabla v \, dx \\ &+ \frac{1}{\varepsilon} \int_{\Omega} (\varphi_0 - \varphi^\varepsilon) \sigma(u) \left[ \nabla \varphi^\varepsilon - \nabla \varphi \right] \cdot \nabla v \, dx = \mathcal{G}_1 + \mathcal{G}_2. \end{aligned}$$

One can show

$$(4.11) \quad \mathcal{G}_2 \rightarrow \int_{\Omega} (\varphi_0 - \varphi) \sigma(u) \nabla \psi_2 \cdot \nabla v \, dx \text{ as } \varepsilon \rightarrow 0,$$

and we illustrate terms from  $\mathcal{G}_1$ . Namely, we show the convergence for  $\mathcal{G}_1$ :

$$\begin{aligned}
& \left| \int_{\Omega} (\varphi_0 - \varphi^\varepsilon) \left( \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} \right) \nabla \varphi^\varepsilon \cdot \nabla v \, dx - \int_{\Omega} (\varphi_0 - \varphi) \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla v \, dx \right| \\
& \leq \left| \int_{\Omega} (\varphi_0 - \varphi) \left\{ \left( \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} \right) \nabla \varphi^\varepsilon - \sigma'(u) \psi_1 \nabla \varphi \right\} \cdot \nabla v \, dx \right| \\
& + \left| \int_{\Omega} (\varphi - \varphi^\varepsilon) \left( \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} - \sigma'(u) \psi_1 + \sigma'(u) \psi_1 \right) \nabla \varphi^\varepsilon \cdot \nabla v \, dx \right| \\
& \leq \left| \int_{\Omega} \left\{ (\varphi_0 - \varphi) \left[ \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} - \sigma'(u) \psi_1 \right] \nabla \varphi^\varepsilon \cdot \nabla v \right. \right. \\
& + \left. \left. (\varphi_0 - \varphi) \sigma'(u) \psi_1 \nabla (\varphi^\varepsilon - \varphi) \cdot \nabla v \right\} dx \right| \\
& + \left| \int_{\Omega} (\varphi - \varphi^\varepsilon) \left( \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} - \sigma'(u) \psi_1 \right) \nabla \varphi^\varepsilon \cdot \nabla v + (\varphi - \varphi^\varepsilon) \sigma'(u) \psi_1 \nabla \varphi^\varepsilon \cdot \nabla v \, dx \right| \\
& \leq \|\varphi_0 - \varphi\|_\infty \cdot \left\| \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} - \sigma'(u) \psi_1 \right\|_s \cdot \|\nabla \varphi^\varepsilon\|_r \cdot \|\nabla v\|_2 \\
& + \left| \int_{\Omega} (\varphi_0 - \varphi) \sigma'(u) \psi_1 \nabla (\varphi^\varepsilon - \varphi) \cdot \nabla v \, dx \right| \\
& + \|\varphi - \varphi^\varepsilon\|_{C(\bar{\Omega})} \cdot \left\| \frac{\sigma(u^\varepsilon) - \sigma(u)}{\varepsilon} - \sigma'(u) \psi_1 \right\|_s \cdot \|\nabla \varphi^\varepsilon\|_r \cdot \|\nabla v\|_2 \\
& + \|\varphi - \varphi^\varepsilon\|_{C(\bar{\Omega})} \cdot \|\sigma'(u) \psi_1\|_s \cdot \|\nabla \varphi^\varepsilon\|_r \cdot \|\nabla v\|_2 \rightarrow 0 \text{ as } \varepsilon \rightarrow 0.
\end{aligned}$$

Notice that we need the assumption  $\Omega \subset R^2$  to justify convergence of the integral  $\int_{\Omega} (\varphi - \varphi^\varepsilon) \sigma'(u) \psi_1 \nabla \varphi^\varepsilon \cdot \nabla v \, dx$  to 0 using the imbedding  $W^{1,r}(\Omega) \subset\subset C(\bar{\Omega})$ .

One can show that the second term on the right-hand side of (4.9) is

$$\begin{aligned}
\frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon - \sigma(u) \nabla \varphi \right] \cdot \nabla \varphi_0 v \, dx & \rightarrow \int_{\Omega} \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla \varphi_0 v \, dx \\
& + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla \varphi_0 v \, dx \text{ as } \varepsilon \rightarrow 0.
\end{aligned}$$

Finally, the terms of (4.10) satisfy

$$\begin{aligned}
\frac{1}{\varepsilon} \int_{\Omega} \left[ \sigma(u^\varepsilon) \nabla \varphi^\varepsilon \cdot \nabla w - \sigma(u) \nabla \varphi \cdot \nabla w \right] dx & \rightarrow \int_{\Omega} \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla w \, dx \\
& + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla w \, dx \text{ as } \varepsilon \rightarrow 0.
\end{aligned}$$

Letting  $\varepsilon \rightarrow 0$  in (4.9) and (4.10) we obtain

$$\begin{aligned}
& \int_{\Omega} \nabla \psi_1 \cdot \nabla v \, dx + \int_{\partial\Omega} (\beta \psi_1 + \ell u) v \, ds = \int_{\Omega} (\varphi_0 - \varphi) \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla v \, dx \\
& + \int_{\Omega} (\varphi_0 - \varphi) \sigma(u) \nabla \psi_2 \cdot \nabla v \, dx - \int_{\Omega} \psi_2 \sigma(u) \nabla \varphi \cdot \nabla v \, dx \\
(4.12) \quad & + \int_{\Omega} \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla \varphi_0 v \, dx + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla \varphi_0 v \, dx \quad \forall v \in H^1(\Omega), \\
& \int_{\Omega} \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla w + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla w \, dx = 0 \quad \forall w \in H_0^1(\Omega).
\end{aligned}$$

We can show that the limit of any subsequence satisfies (4.12). By uniqueness of solutions to (4.12), we get convergence of quotients for all  $\varepsilon \rightarrow 0$ . Now the weak formulation for (4.2) is

$$(4.13) \quad \begin{aligned} & \int_{\Omega} \nabla \psi_1 \cdot \nabla v \, dx + \int_{\partial\Omega} (\beta \psi_1 + \ell u) v \, ds = \int_{\Omega} \sigma'(u) \psi_1 |\nabla \varphi|^2 v \, dx \\ & + 2 \int_{\Omega} \sigma(u) \nabla \varphi \cdot \nabla \psi_2 v \, dx \quad \forall v \in H^1(\Omega), \end{aligned}$$

$$(4.14) \quad \int_{\Omega} (\sigma'(u) \psi_1 \nabla \varphi + \sigma(u) \nabla \psi_2) \cdot \nabla w \, dx = 0 \quad \forall w \in H_0^1(\Omega).$$

The quadratic term on the right-hand side of (4.13) is dealt with as before (see [9]). We use (2.4) and (2.5) to conclude

$$(4.15) \quad \frac{1}{s'} = \frac{1}{s} + \frac{1}{r/2}.$$

Since  $\psi_1 \in H^1(\Omega)$  implies  $\psi_1 \in L^s(\Omega)$ , and taking into account that  $|\nabla \varphi|^2 \in L^{r/2}(\Omega)$ , it follows from (4.15) that  $\sigma'(u) |\nabla \varphi|^2 \psi_1 \in L^{s'}(\Omega)$ . Hence,  $\int_{\Omega} \sigma'(u) |\nabla \varphi|^2 \psi_1 v \, dx$  makes sense as  $v \in H^1(\Omega) \subset L^s(\Omega)$ . Eventually, (4.13) can be written as

$$(4.16) \quad \begin{aligned} & \int_{\Omega} \nabla \psi_1 \cdot \nabla v \, dx + \int_{\partial\Omega} (\beta \psi_1 + \ell u) v \, ds = \int_{\Omega} \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla \varphi_0 v \, dx \\ & + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla \varphi_0 v \, dx + \int_{\Omega} (\varphi_0 - \varphi) \sigma'(u) \psi_1 \nabla \varphi \cdot \nabla v \, dx \\ & + \int_{\Omega} (\varphi_0 - \varphi) \sigma(u) \nabla \psi_2 \cdot \nabla v \, dx + \int_{\Omega} \sigma(u) \nabla \psi_2 \cdot \nabla \varphi v \, dx \quad \forall v \in H^1(\Omega). \end{aligned}$$

We see that these two weak formulations coincide since  $\int_{\Omega} \sigma(u) v \nabla \psi_2 \cdot \nabla \varphi \, dx = - \int_{\Omega} \sigma(u) \psi_2 \nabla v \cdot \nabla \varphi \, dx$  and  $\nabla \cdot (\sigma(u) \nabla \varphi) = 0$  in  $\Omega$ .  $\square$

In order to characterize the optimal control, we need to introduce adjoint functions  $p$  and  $q$  and the adjoint of the operator  $\mathcal{L}$  in system (4.2). Imposing the boundary conditions  $\frac{\partial p}{\partial n} + \beta^* p = 0$  on  $\partial\Omega$ ,  $q = 0$  on  $\partial\Omega$  gives

$$\begin{aligned} & \int_{\Omega} \begin{pmatrix} p & q \end{pmatrix} \mathcal{L} \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} dx = \int_{\Omega} p \Delta \psi_1 \, dx + \int_{\Omega} p \sigma'(u) |\nabla \varphi|^2 \psi_1 \, dx \\ & + 2 \int_{\Omega} p \sigma(u) \nabla \varphi \cdot \nabla \psi_2 \, dx + \int_{\Omega} q \nabla \cdot [\sigma(u) \nabla \psi_2] \, dx + \int_{\Omega} q \nabla \cdot [\sigma'(u) \psi_1 \nabla \varphi] \, dx \\ & = \int_{\Omega} \psi_1 \Delta p \, dx + \int_{\Omega} \psi_1 \sigma'(u) |\nabla \varphi|^2 p \, dx - 2 \int_{\Omega} \psi_2 \nabla \cdot [p \sigma(u) \nabla \varphi] \, dx \\ & - \int_{\Omega} \psi_1 \sigma'(u) \nabla \varphi \cdot \nabla q \, dx + \int_{\Omega} \psi_2 \nabla \cdot [\sigma(u) \nabla q] \, dx = \int_{\Omega} \begin{pmatrix} \psi_1 & \psi_2 \end{pmatrix} \mathcal{L}^* \begin{pmatrix} p \\ q \end{pmatrix} dx, \end{aligned}$$

where

$$\mathcal{L}^* \begin{pmatrix} p \\ q \end{pmatrix} = \begin{pmatrix} \Delta p + \sigma'(u) |\nabla \varphi|^2 p - \sigma'(u) \nabla \varphi \cdot \nabla q \\ \nabla \cdot [-2p \sigma(u) \nabla \varphi + \sigma(u) \nabla q] \end{pmatrix}.$$

Thus, the adjoint system reads

$$\begin{aligned}
 \Delta p + \sigma'(u)|\nabla\varphi|^2 p - \sigma'(u)\nabla\varphi \cdot \nabla q &= 1 \text{ in } \Omega, \\
 \nabla \cdot [-2p\sigma(u)\nabla\varphi + \sigma(u)\nabla q] &= 0 \text{ in } \Omega, \\
 \frac{\partial p}{\partial n} + \beta^* p &= 0 \text{ on } \partial\Omega, \\
 q &= 0 \text{ on } \partial\Omega,
 \end{aligned}
 \tag{4.17}$$

where the nonhomogeneous term “1” comes from differentiating the integrand of  $J(\beta)$  with respect to the state  $u$ .

**THEOREM 4.2.** *Given an optimal control  $\beta^* \in U_M$  and corresponding states  $u, \varphi$ , there exists  $\Lambda_2 > 0$  such that  $\|\varphi_0\|_{W^{1,\infty}(\Omega)} < \Lambda_2$ , and there exists a solution  $(p, q) \in H^1(\Omega) \times H_0^1(\Omega)$  to the adjoint system (4.17). Furthermore,  $\beta^*$  can be explicitly characterized as*

$$\beta^*(x) = \min \left( \max \left( -\frac{up}{2}, \lambda \right), M \right).
 \tag{4.18}$$

*Proof.* The weak formulation of (4.17) is

$$\begin{aligned}
 & - \int_{\Omega} \nabla p \cdot \nabla v \, dx - \int_{\partial\Omega} \beta^* p v \, ds + \int_{\Omega} \sigma'(u)|\nabla\varphi|^2 p v \, dx \\
 & - \int_{\Omega} \sigma'(u)(\nabla\varphi \cdot \nabla q) v \, dx = \int_{\Omega} v \, dx \quad \forall v \in H^1(\Omega), \\
 & 2 \int_{\Omega} p \sigma(u) \nabla\varphi \cdot \nabla w \, dx - \int_{\Omega} \sigma(u) \nabla q \cdot \nabla w \, dx = 0 \quad \forall w \in H_0^1(\Omega).
 \end{aligned}
 \tag{4.19}$$

*Step 1.* First, we show that the solution to the adjoint system (4.17) exists. Define the map  $F : H^1(\Omega) \times H_0^1(\Omega) \mapsto H^1(\Omega) \times H_0^1(\Omega)$  with  $F(V, W) = (p, q)$  as follows:

$$\begin{aligned}
 \Delta p + \sigma'(u)|\nabla\varphi|^2 V - \sigma'(u)\nabla\varphi \cdot \nabla W &= 1 \text{ in } \Omega, \\
 \nabla \cdot [-2V\sigma(u)\nabla\varphi + \sigma(u)\nabla W] &= 0 \text{ in } \Omega, \\
 \frac{\partial p}{\partial n} + \beta^* p &= 0 \text{ on } \partial\Omega, \\
 q &= 0 \text{ on } \partial\Omega.
 \end{aligned}
 \tag{4.20}$$

Standard  $L^2$ -theory for elliptic problems and the Lax–Milgram lemma imply that this is a well-defined map. The weak formulation of (4.20) is

$$\begin{aligned}
 & - \int_{\Omega} \nabla p \cdot \nabla \Theta \, dx - \int_{\partial\Omega} \beta^* p \Theta \, ds + \int_{\Omega} \sigma'(u)|\nabla\varphi|^2 V \Theta \, dx \\
 & - \int_{\Omega} \sigma'(u)(\nabla\varphi \cdot \nabla W) \Theta \, dx = \int_{\Omega} \Theta \, dx \quad \forall \Theta \in H^1(\Omega), \\
 & 2 \int_{\Omega} V \sigma(u) \nabla\varphi \cdot \nabla \Psi \, dx = \int_{\Omega} \sigma(u) \nabla W \cdot \nabla \Psi \, dx \quad \forall \Psi \in H_0^1(\Omega).
 \end{aligned}$$

We use the Banach fixed point theorem. Let  $F(V_1, W_1) = (p_1, q_1)$  and  $F(V_2, W_2) = (p_2, q_2)$ . We show the contraction property

$$\|p_1 - p_2\|_{H^1} + \|q_1 - q_2\|_{H_0^1} \leq \delta \left( \|V_1 - V_2\|_{H^1} + \|W_1 - W_2\|_{H_0^1} \right)
 \tag{4.21}$$

for some  $0 < \delta < 1$ . Let us denote  $\bar{p} \stackrel{\text{def}}{=} p_1 - p_2$ ,  $\bar{q} \stackrel{\text{def}}{=} q_1 - q_2$ ,  $\bar{W} \stackrel{\text{def}}{=} W_1 - W_2$ , and  $\bar{V} \stackrel{\text{def}}{=} V_1 - V_2$ . Taking  $\Theta = \bar{p}$ , the  $p_1$  and  $p_2$  equations give

$$\int_{\Omega} |\nabla \bar{p}|^2 dx + \int_{\partial\Omega} \beta^* \bar{p}^2 ds = \int_{\Omega} \sigma'(u) |\nabla \varphi|^2 \bar{V} \bar{p} dx - \int_{\Omega} \sigma'(u) \nabla \varphi \cdot \nabla \bar{W} \bar{p} dx.$$

Thus, we obtain

$$\int_{\Omega} |\nabla \bar{p}|^2 dx + \lambda \int_{\partial\Omega} \bar{p}^2 ds \leq \left| \int_{\Omega} \sigma'(u) |\nabla \varphi|^2 \bar{V} \bar{p} dx \right| + \left| \int_{\Omega} \sigma'(u) \nabla \varphi \cdot \nabla \bar{W} \bar{p} dx \right|.$$

Estimating the various terms, one obtains

$$\begin{aligned} \|\bar{p}\|_{H^1(\Omega)} + \|\bar{q}\|_{H_0^1(\Omega)} &\leq (C_{14}\Phi^2 + C_{15}\Phi) \|\bar{V}\|_{H^1(\Omega)} + C_{16}\Phi \|\bar{W}\|_{H^1(\Omega)} \\ &\leq \max \{C_{14}\Phi^2 + C_{15}\Phi, C_{16}\Phi\} (\|\bar{W}\|_{H^1} + \|\bar{V}\|_{H^1}). \end{aligned}$$

Recalling that  $\Phi = c_1 \|\nabla \varphi_0\|_{\infty} + c_2 \|\varphi_0\|_{W^{1,\infty}(\Omega)}$ , where  $c_1, c_2 > 0$  denote generic constants (see (2.10)), and choosing  $\varphi_0$  such that  $\|\varphi_0\|_{W^{1,\infty}(\Omega)}$  is sufficiently small, we obtain

$$\delta = \max \{C_{14}\Phi^2 + C_{15}\Phi, C_{16}\Phi\} < 1.$$

This proves the contraction property (4.21), which gives the desired fixed point of the map and therefore the existence and uniqueness of solutions to the adjoint system.

*Step 2.* We derive the characterization of the optimal control. Recall that for variation  $\ell \in U_M$ , with  $\beta^* + \varepsilon \ell \in U_M$  for  $\varepsilon$  small, the weak formulation of the sensitivity system (4.2) is given by (4.13) and (4.14). Now we are ready to characterize the optimal control. Since the minimum of  $J$  is achieved at  $\beta^*$  and for small  $\varepsilon > 0$ ,  $\beta^* + \varepsilon \ell \in U_M$ , and denoting  $u^\varepsilon = u(\beta^* + \varepsilon \ell)$ ,  $\varphi^\varepsilon = \varphi(\beta^* + \varepsilon \ell)$ , we obtain

$$\begin{aligned} 0 &\leq \lim_{\varepsilon \rightarrow 0^+} \frac{J(\beta^* + \varepsilon \ell) - J(\beta^*)}{\varepsilon} \\ &= \int_{\Omega} \psi_1 dx + \int_{\partial\Omega} 2\beta^* \ell ds = \int_{\Omega} \begin{pmatrix} \psi_1 & \psi_2 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} dx + \int_{\partial\Omega} 2\beta^* \ell ds \\ &= \left\{ - \int_{\Omega} \nabla p \nabla \psi_1 dx - \int_{\partial\Omega} \beta^* p \psi_1 ds + \int_{\Omega} \psi_1 \sigma'(u) |\nabla \varphi|^2 p dx \right. \\ &\quad \left. + 2 \int_{\Omega} p \sigma(u) \nabla \varphi \nabla \psi_2 dx \right\} + \left[ - \int_{\Omega} \psi_1 \sigma'(u) \nabla \varphi \cdot \nabla q dx - \int_{\Omega} \sigma(u) \nabla q \cdot \nabla \psi_2 dx \right] \\ &\quad + \int_{\partial\Omega} 2\beta^* \ell ds = \int_{\partial\Omega} \ell (2\beta^* + up) ds, \end{aligned}$$

where we used the sensitivity system (4.13), (4.14) with test functions  $p$  and  $q$ . Using a standard argument on the choice of  $\ell$ , we obtain (4.18).  $\square$

Substituting (4.18) into the state system (1.1) and the adjoint equations (4.17)

we obtain the optimality system

$$\begin{aligned}
 (4.22) \quad & \Delta u^* + \sigma(u^*)|\nabla \varphi^*|^2 = 0 \text{ in } \Omega, \\
 & \nabla \cdot (\sigma(u^*)\nabla \varphi^*) = 0 \text{ in } \Omega, \\
 & \Delta p + \sigma'(u^*)|\nabla \varphi^*|^2 p - \sigma'(u^*)\nabla \varphi^* \cdot \nabla q = 1 \text{ in } \Omega, \\
 & \nabla \cdot [-2p\sigma(u^*)\nabla \varphi^* + \sigma(u^*)\nabla q] = 0 \text{ in } \Omega, \\
 & \frac{\partial p}{\partial n} + \min(\max(-u^*p/2, \lambda), M)p = 0 \text{ on } \partial\Omega, \\
 & q = 0 \text{ on } \partial\Omega, \\
 & \frac{\partial u^*}{\partial n} + \min(\max(-u^*p/2, \lambda), M)u^* = 0 \text{ on } \partial\Omega, \\
 & \varphi^* = \varphi_0 \text{ on } \partial\Omega.
 \end{aligned}$$

Note that existence of solution to the optimality system (4.22) follows from the existence of solution to the state system (1.1) and Theorem 4.2.

*Remarks 1.* If we take into account the second equation in (4.22), then the last equation in (4.22) can be rewritten as

$$-2\sigma(u^*)\nabla \varphi^* \cdot \nabla p + \nabla \cdot [\sigma(u^*)\nabla q] = 0.$$

2. We show that if  $\varphi_0 \equiv \text{constant}$ , then  $\beta^* = \lambda$ . Indeed, the maximum principle for weak solutions implies that  $\varphi^* \equiv \text{constant}$  and therefore  $\nabla \varphi^* = 0$ . This simplifies (4.22) significantly. Namely, we obtain

$$\begin{aligned}
 (4.23) \quad & \Delta u^* = 0 \text{ in } \Omega, \\
 & \Delta p = 1 \text{ in } \Omega, \\
 & \nabla \cdot [\sigma(u^*)\nabla q] = 0 \text{ in } \Omega, \\
 & \frac{\partial u^*}{\partial n} + \beta^* u^* = 0 \text{ on } \partial\Omega, \\
 & \frac{\partial p}{\partial n} + \beta^* p = 0 \text{ on } \partial\Omega, \\
 & q = 0 \text{ on } \partial\Omega.
 \end{aligned}$$

Applying the maximum principle to  $q$  gives  $q \equiv 0$  in  $\bar{\Omega}$ , and therefore only the  $u$  and  $p$  equations remain in (4.23). Now if we integrate the  $u$  equation in (4.23) over  $\Omega$  and integrate by parts, we obtain  $\int_{\partial\Omega} \beta^* u^* ds = 0$ . Since  $\beta^*(x) > 0$  and  $u^*(x) \geq 0$  for all  $x \in \partial\Omega$  it follows that  $u^* = 0$  a.e. on  $\partial\Omega$ . Hence, we can write

$$\begin{aligned}
 \Delta u^* &= 0 \text{ in } \Omega, \\
 u^* &= 0 \text{ a.e. on } \partial\Omega.
 \end{aligned}$$

This implies that  $u^* = 0$  a.e. in  $\Omega$ . Thus, (4.18) implies  $\beta^* = \lambda$  and

$$\begin{aligned}
 (4.24) \quad & \Delta p = 1 \text{ in } \Omega, \\
 & \frac{\partial p}{\partial n} + \lambda p = 0 \text{ on } \partial\Omega.
 \end{aligned}$$

The solution of (4.24) satisfies the equality  $\int_{\partial\Omega} \frac{\partial p}{\partial n} ds = \int_{\Omega} dx$ , which implies that  $-\lambda \int_{\partial\Omega} p ds = \text{meas}(\Omega)$ .

**5. Uniqueness of the optimal control.** In this section we prove that the solution to the optimality system (4.22) is unique under some additional assumptions, in particular, the boundedness of  $u$  and  $p$ . We assume that  $\sigma'$  is Lipschitz with constant  $K_1 > 0$ ,

$$(5.1) \quad |\sigma'(s_1) - \sigma'(s_2)| \leq K_1 |s_1 - s_2| \quad \forall s_1, s_2 \in R.$$

**THEOREM 5.1.** *In addition to all the standard assumptions from section 3, let (5.1) hold. There exists  $\Lambda_3 > 0$  such that  $\|\varphi_0\|_{W^{1,\infty}(\Omega)} \leq \Lambda_3$ , and if in addition  $\lambda$  is large enough, then the solution to the optimality system (4.22), with  $u$  and  $p$  components assumed to belong to  $L^\infty(\Omega)$ , is unique, and therefore the optimal control  $\beta^*$  is unique.*

*Proof.* Let  $(u_1, \varphi_1, p_1, q_1)$  and  $(u_2, \varphi_2, p_2, q_2)$  be two solutions to the optimality system. Using the weak formulation of the state and adjoint equations and taking into account that by the Meyers estimate  $p \in L^\infty(\Omega)$  implies  $\nabla q \in L^r(\Omega)$  we get

$$\begin{aligned} \int_{\Omega} \nabla u_i \cdot \nabla v \, dx + \int_{\partial\Omega} \beta_i u_i v \, ds &= \int_{\Omega} \sigma(u_i) |\nabla \varphi_i|^2 v \, dx \quad \forall v \in H^1(\Omega), \\ \int_{\Omega} \sigma(u_i) \nabla \varphi_i \cdot \nabla w \, dx &= 0, \quad \varphi_0 - \varphi_i \in H_0^1(\Omega) \quad \forall w \in H_0^1(\Omega), \\ \int_{\Omega} \nabla p_i \cdot \nabla \tilde{v} \, dx + \int_{\partial\Omega} \beta_i p_i \tilde{v} \, ds + \int_{\Omega} \tilde{v} \, dx &= \int_{\Omega} \sigma'(u_i) |\nabla \varphi_i|^2 p_i \tilde{v} \, dx \\ &\quad - \int_{\Omega} \sigma'(u_i) \nabla \varphi_i \cdot \nabla q_i \tilde{v} \, dx \quad \forall \tilde{v} \in H^1(\Omega), \\ 2 \int_{\Omega} p_i \sigma(u_i) \nabla \varphi_i \cdot \nabla \tilde{w} \, dx &= \int_{\Omega} \sigma(u_i) \nabla q_i \cdot \nabla \tilde{w} \, dx \quad \forall \tilde{w} \in H_0^1(\Omega), \quad i = 1, 2, \end{aligned}$$

where  $\beta_i = \min(\max(-u_i p_i / 2, \lambda), M)$ .

We set  $\bar{u} = u_1 - u_2$ ,  $\bar{\varphi} = \varphi_1 - \varphi_2$ ,  $\bar{p} = p_1 - p_2$ , and  $\bar{q} = q_1 - q_2$ . Now, taking  $w = \varphi_1 - \varphi_2$  in the equation satisfied by  $u_1$  and  $w = \varphi_1 - \varphi_2$  in the equation satisfied by  $u_2$  yields

$$(5.2) \quad \int_{\Omega} \sigma(u_1) \nabla \varphi_1 \cdot \nabla (\varphi_1 - \varphi_2) \, dx = \int_{\Omega} \sigma(u_2) \nabla \varphi_2 \cdot \nabla (\varphi_1 - \varphi_2) \, dx.$$

Adding  $-\int_{\Omega} \sigma(u_1) \nabla \varphi_2 \cdot \nabla (\varphi_1 - \varphi_2) \, dx$  to both sides of (5.2), one verifies

$$\int_{\Omega} \sigma(u_1) |\nabla \bar{\varphi}|^2 \, dx = \int_{\Omega} (\sigma(u_2) - \sigma(u_1)) \nabla \varphi_2 \cdot \nabla \bar{\varphi} \, dx.$$

Hence,

$$\begin{aligned} C_1 \|\nabla \bar{\varphi}\|_2^2 &= C_1 \int_{\Omega} |\nabla \bar{\varphi}|^2 \, dx \leq \int_{\Omega} \sigma(u_1) |\nabla \bar{\varphi}|^2 \, dx \\ &= \int_{\Omega} (\sigma(u_2) - \sigma(u_1)) \nabla \varphi_2 \cdot \nabla \bar{\varphi} \, dx \\ &\leq K \int_{\Omega} |\bar{u}| |\nabla \varphi_2| |\nabla \bar{\varphi}| \, dx \leq K \Phi \|\bar{u}\|_s \|\nabla \bar{\varphi}\|_2, \end{aligned}$$

which implies

$$(5.3) \quad \|\nabla \bar{\varphi}\|_2 \leq \frac{K\Phi}{C_1} \|\bar{u}\|_s.$$

From PDEs for  $u_1$  and  $u_2$ , we obtain

$$\int_{\Omega} |\nabla \bar{u}|^2 dx + \int_{\partial\Omega} \beta_1 \bar{u}^2 + (\beta_1 - \beta_2) u_2 \bar{u} ds = \int_{\Omega} \left( \sigma(u_1) |\nabla \varphi_1|^2 - \sigma(u_2) |\nabla \varphi_2|^2 \right) \bar{u} dx,$$

which yields

$$\begin{aligned} \int_{\Omega} |\nabla \bar{u}|^2 dx + \lambda \int_{\partial\Omega} \bar{u}^2 ds &\leq \frac{1}{2} \|u_1\|_{\infty} \|u_2\|_{\infty} \|\bar{u}\|_{L^2(\partial\Omega)} \|\bar{p}\|_{L^2(\partial\Omega)} \\ &\quad + \frac{1}{2} \|p_2\|_{\infty} \|u_2\|_{\infty} \|\bar{u}\|_{L^2(\partial\Omega)}^2 \\ &\quad + \int_{\Omega} |\sigma(u_1) |\nabla \varphi_1|^2 - \sigma(u_2) |\nabla \varphi_2|^2| \cdot |\bar{u}| dx, \end{aligned}$$

where we used  $|\beta_1 - \beta_2| \leq \frac{1}{2} |u_1 p_1 - u_2 p_2|$ . Denoting  $\alpha_1 := \|u_1\|_{\infty} \|u_2\|_{\infty}$  and  $\alpha_2 := \|p_2\|_{\infty} \|u_2\|_{\infty}$ , we can write

$$\begin{aligned} \int_{\Omega} |\nabla \bar{u}|^2 dx + \left( \lambda - \frac{\alpha_2}{2} - \frac{\alpha_1}{4} \right) \int_{\partial\Omega} \bar{u}^2 ds &\leq \frac{\alpha_1}{4} \|\bar{p}\|_{L^2(\partial\Omega)}^2 \\ &\quad + \int_{\Omega} |\sigma(u_1) |\nabla \varphi_1|^2 - \sigma(u_2) |\nabla \varphi_2|^2| \cdot |\bar{u}| dx. \end{aligned}$$

We deal with the last term

$$\begin{aligned} \int_{\Omega} |\sigma(u_1) |\nabla \varphi_1|^2 - \sigma(u_2) |\nabla \varphi_2|^2| \cdot |\bar{u}| dx &\leq \|\sigma(u_1) |\nabla \varphi_1|^2 - \sigma(u_2) |\nabla \varphi_2|^2\|_{s'} \|\bar{u}\|_s \\ &\leq \|\sigma(u_1) \nabla \bar{\varphi} \cdot \nabla (\varphi_1 + \varphi_2)\|_{s'} \|\bar{u}\|_s + \|(\sigma(u_1) - \sigma(u_2)) |\nabla \varphi_2|^2\|_{s'} \|\bar{u}\|_s \\ &\leq C_2 \|\nabla \bar{\varphi}\|_2 \cdot \|\nabla (\varphi_1 + \varphi_2)\|_r \cdot \|\bar{u}\|_s + K \|\bar{u}\|_s \|\nabla \varphi_2\|_2^2 \\ &\leq C_{16} \Phi \|\nabla (\varphi_1 + \varphi_2)\|_r \cdot \|\bar{u}\|_s^2 + K \|\nabla \varphi_2\|_2^2 \|\bar{u}\|_s^2 \\ &\leq C_{17} \Phi^2 \|\bar{u}\|_{H^1(\Omega)}^2, \end{aligned}$$

where we have taken into account that  $\|\nabla \varphi\|_r \leq \Phi$ ,  $\|\bar{u}\|_s \leq M_1 \|\bar{u}\|_{H^1(\Omega)}$ , and (5.3). Consequently, we obtain

$$(5.4) \quad \int_{\Omega} |\nabla \bar{u}|^2 dx + \left( \lambda - \frac{\alpha_2}{2} - \frac{\alpha_1}{4} \right) \int_{\partial\Omega} \bar{u}^2 ds \leq \frac{\alpha_1}{4} \|\bar{p}\|_{L^2(\partial\Omega)}^2 + C_{19} \Phi^2 \|\bar{u}\|_{H^1(\Omega)}^2.$$

The estimate for  $\bar{p}$  is derived in a similar manner [10], albeit after rather lengthy calculations, in which condition (5.1) is explicitly used. The result is

$$\begin{aligned} \int_{\Omega} |\nabla \bar{p}|^2 dx + \left( \lambda - \frac{\alpha_3}{2} - \frac{\alpha_4^2}{4} \right) \int_{\partial\Omega} \bar{p}^2 ds &\leq \frac{\alpha_4^2}{4} \|\bar{u}\|_{L^2(\partial\Omega)}^2 + C_{20} \Phi \|\bar{p}\|_{H^1(\Omega)}^2 \\ (5.5) \quad &\quad + C_{21} \Phi \|\bar{p}\|_{H^1} \|\nabla \bar{q}\|_2 + C_{22} \Phi \|\bar{u}\|_{H^1} \|\bar{p}\|_{H^1}, \end{aligned}$$

where  $\alpha_3 := \|u_1\|_{\infty} \|p_2\|_{\infty}$ ,  $\alpha_4 := \|p_2\|_{\infty}$ . Note that the estimate for  $\bar{\varphi}$  is given by

$$(5.6) \quad \|\nabla \bar{\varphi}\|_2 \leq C_{23} \Phi \|\bar{u}\|_{H^1(\Omega)},$$

where we have taken into account that  $\|\bar{u}\|_s \leq M_1 \|\bar{u}\|_{H^1(\Omega)}$ .

Using  $\bar{q} = \bar{w}$  as a test function in the equations for  $q$ , we have

$$\begin{aligned} 2 \int_{\Omega} p_1 \sigma(u_1) \nabla \varphi_1 \cdot \nabla \bar{q} dx &= \int_{\Omega} \sigma(u_1) \nabla q_1 \cdot \nabla \bar{q} dx, \\ 2 \int_{\Omega} p_2 \sigma(u_2) \nabla \varphi_2 \cdot \nabla \bar{q} dx &= \int_{\Omega} \sigma(u_2) \nabla q_2 \cdot \nabla \bar{q} dx. \end{aligned}$$

Upon subtracting and estimating the difference, we obtain

$$(5.7) \quad \|\nabla \bar{q}\|_2 \leq C_{24}\Phi\|\bar{u}\|_{H^1(\Omega)} + C_{25}\Phi\|\bar{p}\|_{H^1(\Omega)}.$$

Now adding (5.4) and (5.5) gives

$$(5.8) \quad \begin{aligned} & \int_{\Omega} |\nabla \bar{u}|^2 dx + \left( \lambda - \frac{\alpha_2}{2} - \frac{\alpha_1}{4} - \frac{\alpha_4^2}{4} \right) \int_{\partial\Omega} \bar{u}^2 ds + \int_{\Omega} |\nabla \bar{p}|^2 dx \\ & + \left( \lambda - \frac{\alpha_3}{2} - \frac{\alpha_4^2}{4} - \frac{\alpha_1}{4} \right) \int_{\partial\Omega} \bar{p}^2 ds \leq C_{19}\Phi^2\|\bar{u}\|_{H^1(\Omega)}^2 + C_{20}\Phi\|\bar{p}\|_{H^1(\Omega)}^2 \\ & + C_{21}\Phi\|\bar{p}\|_{H^1(\Omega)}\|\nabla \bar{q}\|_2 + C_{22}\Phi\|\bar{u}\|_{H^1(\Omega)}\|\bar{p}\|_{H^1(\Omega)}. \end{aligned}$$

Using the estimate for  $\nabla \bar{q}$  allows us to rewrite (5.8) in the following way:

$$\begin{aligned} & \int_{\Omega} |\nabla \bar{u}|^2 dx + \left( \lambda - \frac{\alpha_2}{2} - \frac{\alpha_1}{4} - \frac{\alpha_4^2}{4} \right) \int_{\partial\Omega} \bar{u}^2 ds + \int_{\Omega} |\nabla \bar{p}|^2 dx \\ & + \left( \lambda - \frac{\alpha_3}{2} - \frac{\alpha_4^2}{4} - \frac{\alpha_1}{4} \right) \int_{\partial\Omega} \bar{p}^2 ds \\ & \leq C_{19}\Phi^2\|\bar{u}\|_{H^1(\Omega)}^2 + (C_{20}\Phi + C_{27}\Phi^2)\|\bar{p}\|_{H^1(\Omega)}^2 \\ & + (C_{26}\Phi^2 + C_{22}\Phi)\|\bar{u}\|_{H^1(\Omega)}\|\bar{p}\|_{H^1(\Omega)} \\ & \leq (C_{27}\Phi^2 + C_{28}\Phi)(\|\bar{u}\|_{H^1(\Omega)}^2 + \|\bar{p}\|_{H^1(\Omega)}^2). \end{aligned}$$

Upon properly redefining the constants, we conclude that

$$\mathcal{A}\|\bar{u}\|_{H^1(\Omega)}^2 + \mathcal{B}\|\bar{p}\|_{H^1(\Omega)}^2 \leq 0.$$

Therefore, if  $\lambda$  is large and the boundary data  $\varphi_0$  is sufficiently small, then  $\mathcal{A}$  and  $\mathcal{B}$  are positive and  $\bar{u} = 0, \bar{p} = 0, \nabla \bar{q} = 0$ , and  $\nabla \bar{\varphi} = 0$ . Then it follows that  $\bar{q} = 0$  and  $\bar{\varphi} = 0$  (since  $\nabla \bar{q} = 0, \nabla \bar{\varphi} = 0$  and  $\bar{q} = 0, \bar{\varphi} = 0$  on the boundary), which gives the uniqueness of solutions of the optimality system. This implies the uniqueness of the optimal control.  $\square$

*Remark.* The boundedness of  $\sigma$  and the  $L^\infty$  boundedness of temperature are quite realistic assumptions since physical quantities are bounded. For homogeneous media, the Lipschitz condition is also reasonable; in fact, it can be assumed to hold true even for nonhomogeneous media without sharp interfaces.

## OPTIMAL OUTPUT REGULATION FOR DISCRETE-TIME SWITCHED AND MARKOVIAN JUMP LINEAR SYSTEMS\*

JI-WOONG LEE<sup>†</sup> AND PRAMOD P. KHARGONEKAR<sup>‡</sup>

**Abstract.** First, three different but related output regulation performance criteria for the linear time-varying system are defined in the discrete-time domain, namely, the peak impulse response, peak output variance, and average output variance per unit time. Then they are extended for switched linear systems and Markovian jump linear systems, and characterized by an increasing union of finite-dimensional linear matrix inequality conditions. Finally, the infinite-horizon suboptimal LQG control problem, which aims to maintain the average output variance below a given level subject to the uniform exponential stability of the closed-loop system, is solved for both switched linear systems and Markovian jump linear systems; the solution is given by a dynamic linear output feedback controller that not only perfectly observes the present mode but also recalls a finite number of past modes.

**Key words.** discrete linear inclusions, dynamic output feedback,  $\mathcal{H}^2$  control, linear matrix inequalities, LQG control, linear time-varying systems, semidefinite programming

**1. Introduction.** Switched systems and Markovian jump systems are abstractions of hybrid (or multimodal) systems; they idealize complex interactions between the continuous state trajectory and the discrete state (or mode) transitions by a finite number of state-space representations, together with a constraint on the admissible switching paths among these representations. If the switching path constraint is specified via a set of autonomous switching sequences, then the resulting abstract model is called a switched system; on the other hand, if the switching sequences are specified to be realizations of a homogeneous Markov chain, then the model is called a Markovian jump system. Many complex control systems today exhibit hybrid and multimodal dynamics due to the presence of digital computers [30, 7], communication networks [31, 9, 47], distributed agents [26], etc. Consequently, the study of switched and Markovian jump systems is becoming increasingly important [36, 45, 38, 12]. In this paper, we focus on the output regulation performance and establish exact convex conditions for the analysis and synthesis of discrete-time switched and Markovian jump linear systems via linear matrix inequalities. We make the restrictive, but standard, assumption that the mode of the system is perfectly observed at each time instant. There are many real-world applications where this assumption is satisfied: e.g., missile autopilot via gain scheduling [1] and networked control subject to randomly delayed but time-stamped measurements [47].

There is a strong link between the properties of switched linear systems and those of standard linear systems. Indeed, exact convex conditions for the uniform exponential stabilization and uniform disturbance attenuation (i.e., root-mean-square gain control) of discrete-time switched linear systems have been obtained [34, 33] using the operator theoretic  $\ell^2$ -induced norm analysis of time-varying systems [24, 19] and

the semidefinite programming-based  $\mathcal{H}^\infty$  synthesis of time-invariant systems [41, 20]; here, the uniformity is over all admissible switching sequences as well as over all time instants. In this paper, we continue to exploit this link to solve output regulation problems. First, inspired by the operator theoretic  $\ell^2$  seminorm analysis of time-varying systems [25], we define three different performance criteria and establish their relation in terms of observability and reachability gramians. Different performance criteria lead to different output regulation problems, including the infinite-horizon LQG control problem, where the average output variance, and hence the average output root-mean-square value, per unit time is minimized subject to the internal stability of the closed-loop system. These problems all coincide with the  $\mathcal{H}^2$  control problem when the number of modes is equal to one; thus our results build on the semidefinite programming-based  $\mathcal{H}^2$  synthesis of time-invariant systems [43, 39]. Similar results are also established for the output regulation of Markovian jump linear systems subject to the almost sure uniform exponential stability. These results form an “output regulation” counterpart to the “disturbance attenuation” results in [33]; except for stability analysis, key elements of [33] such as a uniformly stabilizing property of the Riccati inequality and an elegant matrix completion-based linear matrix embedding technique do not apply here.

Our approach to the infinite-horizon LQG control of switched systems has three important ingredients. The first is the increasing union of “path-dependent” Lyapunov inequality conditions first introduced in [34]; this enables a control-oriented convex characterization of the uniform exponential stability and stabilizability of switched linear systems. The second ingredient is the “change of variable” argument in [43] that provides a systematic means of turning dynamic output feedback requirements into linear matrix inequalities without any assumption on the system parameters. Finally, the third is the notion of “minimal” switching sequences that we adopt from [35]; if the admissible switching sequences are defined by a directed graph of a row-allowable matrix, then we show that, to determine the average output variance level of the switched linear system, it suffices to check the average output variance level of the periodic systems associated with the switching sequences that are minimal with respect to the given directed graph. Putting these ingredients together leads to a complete solution to the infinite-horizon LQG problem, and other output regulation problems, for switched linear systems. The solution to each sub-optimal infinite-horizon LQG problem is given by a finite-path-dependent dynamic output feedback controller; moreover, in many cases with a reasonable tolerance level, the optimal controller is still finite-path dependent. There are few results in the literature that this result can be compared to, mainly because there has not been a control-oriented convex characterization of the stability, let alone stabilizability, of discrete-time switched linear systems until very recently. Earlier relevant results include stability analysis [15, 2, 21, 16, 3], (conservative) stability synthesis [6, 14], and analysis of problem complexity and decidability [46, 4]; see [5] for the Kalman filtering result for a class of discrete-time switched systems.

In the case of Markovian jump linear systems, the infinite-horizon LQG control problem has already been studied with respect to mean square stability (also known as stochastic stability) in both continuous time [28, 17] and discrete time [27, 13]. Particularly in the discrete-time domain, existing results provide a nice state-space formula for the solution and extend the well-known separation principle to the Markovian jump system. However, a key limitation of these results is that the restriction to mode-dependent controllers, and hence to the Markovian filtering, is suboptimal

compared to the path-dependent controller resulting from the Kalman filtering—see the numerical comparison in [13]; another limitation is that there is no convex characterization of the mean square “stabilizability” of discrete-time Markovian jump linear systems [29, 10]. We show in this paper that if the requirement of mean square stability is replaced with the stronger requirement of almost sure “uniform” stability, the infinite-horizon LQG control result for switched linear systems carries over to Markovian jump linear systems without any of these limitations. As in the case of switched systems, all suboptimal controllers are finite-path dependent, and the optimal controller is often finite-path dependent, too, with a short path length for a reasonable tolerance level. Moreover, our result can be applied to any Markov chain and any controlled plant (e.g., nonergodic chains and plants without the standard orthogonality and rank conditions). To our knowledge, with the exception of [34, 33], the almost sure uniform stability of Markovian jump systems has not been explicitly dealt with in the literature. Almost sure uniform stability is a deterministic notion, and hence is useful when only the sparsity pattern of the underlying transition probability matrix, but not the individual transition probabilities, is exactly known [34]. Moreover, unlike the usual stochastic stability-based approaches to controlling Markovian jump systems, our LQG control framework conforms to the classical stochastic control settings where deterministic uniform stability is the commonly used stability notion.

This paper is organized as follows. In section 2, we consider three output regulation performance criteria for the discrete-time linear time-varying system, namely, the peak impulse response, peak output variance, and average output variance per unit time. In section 3, these performance criteria are extended for switched linear systems and characterized by linear matrix inequality conditions. Section 4 is devoted to establishing the synthesis condition for the LQG control problem where the average output variance is minimized; synthesis conditions for the other two output regulation problems are only briefly noted. These results are extended to Markovian jump linear systems in section 5. Finally, concluding remarks on the results and future research are made in section 6.

*Notation.* For  $x \in \mathbb{R}^n$ , denoted by  $\|x\|$  is the Euclidean vector norm  $\|x\| = \sqrt{x^T x}$  of  $x$ . If  $\mathbf{X}, \mathbf{Y} \in \mathbb{R}^{n \times n}$  are symmetric and  $\mathbf{X} - \mathbf{Y}$  is positive definite (resp., nonnegative definite), we write  $\mathbf{X} > \mathbf{Y}$  (resp.,  $\mathbf{X} \geq \mathbf{Y}$ ). The trace of  $\mathbf{X}$  is denoted by  $\text{tr } \mathbf{X}$ , and the spectral radius of  $\mathbf{X}$  by  $\rho \mathbf{X}$ . The identity matrix is denoted by  $\mathbf{I}$  with  $n$  understood. If  $\mathbf{X}$  and  $\mathbf{Y}$  are two matrices, then the direct sum  $\mathbf{X} \oplus \mathbf{Y}$  denotes the block diagonal matrix  $\begin{bmatrix} \mathbf{X} & \mathbf{0} \\ \mathbf{0} & \mathbf{Y} \end{bmatrix}$ , where  $\mathbf{0}$  denotes the zero matrix of appropriate dimension.

## 2. Analysis of linear time-varying systems. Let

$$(2.1a) \quad \mathcal{G} = \{(\mathbf{A}_0, \mathbf{B}_0, \mathbf{C}_0, \mathbf{D}_0), (\mathbf{A}_1, \mathbf{B}_1, \mathbf{C}_1, \mathbf{D}_1), \dots\}$$

be an indexed family of matrices  $\mathbf{A}_t \in \mathbb{R}^{n \times n}$ ,  $\mathbf{B}_t \in \mathbb{R}^{n \times m}$ ,  $\mathbf{C}_t \in \mathbb{R}^{l \times n}$ , and  $\mathbf{D}_t \in \mathbb{R}^{l \times m}$  over all  $t = 0, 1, \dots$ . Let a sequence  $\boldsymbol{\theta} = (\theta(0), \theta(1), \dots)$  in  $\{0, 1, \dots\}$  by

$$(2.1b) \quad \theta(t) = t$$

for all  $t = 0, 1, \dots$ . Then we have  $(\mathbf{A}_{\theta(t)}, \mathbf{B}_{\theta(t)}, \mathbf{C}_{\theta(t)}, \mathbf{D}_{\theta(t)}) = (\mathbf{A}_t, \mathbf{B}_t, \mathbf{C}_t, \mathbf{D}_t)$ , and the pair  $(\mathcal{G}, \boldsymbol{\theta})$  defines the discrete-time linear time-varying system

$$(2.2) \quad \begin{aligned} x(t+1) &= \mathbf{A}_t x(t) + \mathbf{B}_t w(t), \\ z(t) &= \mathbf{C}_t x(t) + \mathbf{D}_t w(t). \end{aligned}$$

Given the initial state  $x(0)$  and disturbance sequence  $\mathbf{w} = (w(0), w(1), \dots)$ , equation (2.2) determines the state sequence  $\mathbf{x} = (x(0), x(1), \dots)$  and output sequence  $\mathbf{z} = (z(0), z(1), \dots)$ .

DEFINITION 2.1. *The system  $(\mathcal{G}, \boldsymbol{\theta})$  is said to be uniformly (exponentially) stable if there exist  $c \geq 1$  and  $\lambda \in (0, 1)$  such that, whenever  $\mathbf{w} = 0$ ,*

$$\|x(t)\| \leq c \lambda^{t-t_0} \|x(t_0)\|$$

for all  $t_0 \geq 0$ ,  $t \geq t_0$ , and  $x(t_0) \in \mathbb{R}^n$ .

The set  $\mathcal{G}$  is said to be bounded if there are a  $b > 0$  and a norm  $|\cdot|$  such that  $|g| \leq b$  for all  $g \in \mathcal{G}$ . The following characterizes the stability of linear time-varying systems in terms of an infinite-dimensional system of Lyapunov inequalities.

LEMMA 2.2. *Let  $\mathcal{G}$  and  $\boldsymbol{\theta}$  be as in (2.1); let  $\mathcal{G}$  be bounded. The following are equivalent:*

- (a) *The system  $(\mathcal{G}, \boldsymbol{\theta})$  is uniformly exponentially stable.*
- (b) *There exist  $\alpha, \beta > 0$  and  $\mathbf{X}_t \in \mathbb{R}^{n \times n}$  such that*

$$\alpha \mathbf{I} \leq \mathbf{X}_t \leq \beta \mathbf{I}; \quad \mathbf{A}_t^T \mathbf{X}_{t+1} \mathbf{A}_t - \mathbf{X}_t \leq -\alpha \mathbf{I}$$

for all  $t \geq 0$ .

- (c) *There exist  $\epsilon, \delta > 0$  and  $\mathbf{Y}_t \in \mathbb{R}^{n \times n}$  such that*

$$\epsilon \mathbf{I} \leq \mathbf{Y}_t \leq \delta \mathbf{I}; \quad \mathbf{A}_t \mathbf{Y}_t \mathbf{A}_t^T - \mathbf{Y}_{t+1} \leq -\epsilon \mathbf{I}$$

for all  $t \geq 0$ .

Moreover, if either (b) or (c) holds, then one may take  $\mathbf{X}_t^{-1} = \mathbf{Y}_t$  for all  $t \geq 0$ .

*Proof.* The equivalence of (a) and (b) is a special case of [19, Theorem 11]. A Schur complement argument shows the equivalence of (b) and (c) via the relation  $\mathbf{X}_t^{-1} = \mathbf{Y}_t$ .  $\square$

Let  $\mathbf{X}_t^{(T)} \geq \mathbf{0}$  be the unique solution to the backward Lyapunov equation

$$\mathbf{A}_t^T \mathbf{X}_{t+1}^{(T)} \mathbf{A}_t - \mathbf{X}_t^{(T)} = -\mathbf{C}_t^T \mathbf{C}_t$$

for  $t = 0, 1, \dots, T$ , with the terminal condition  $\mathbf{X}_{T+1}^{(T)} = \mathbf{0}$ . Similarly, let  $\mathbf{Y}_t^{(t_0)} \geq \mathbf{0}$  be the unique solution to the forward Lyapunov equation

$$\mathbf{A}_t \mathbf{Y}_t^{(t_0)} \mathbf{A}_t^T - \mathbf{Y}_{t+1}^{(t_0)} = -\mathbf{B}_t \mathbf{B}_t^T$$

for  $t = t_0, t_0 + 1, \dots$ , with the initial condition  $\mathbf{Y}_{t_0}^{(t_0)} = \mathbf{0}$ . If  $\Phi(t, t_0)$  is the state transition matrix defined by

$$\Phi(t, t_0) = \begin{cases} \mathbf{I}, & t = t_0; \\ \mathbf{A}_{t-1} \cdots \mathbf{A}_{t_0}, & t > t_0, \end{cases}$$

for  $t \geq t_0 \geq 0$ , then we have

$$(2.3a) \quad \mathbf{X}_t^{(T)} = \sum_{s=t}^T \Phi(s, t)^T \mathbf{C}_s^T \mathbf{C}_s \Phi(s, t)$$

for  $0 \leq t \leq T$ , and

$$(2.3b) \quad \mathbf{Y}_{t+1}^{(t_0)} = \sum_{s=t_0}^t \Phi(t+1, s+1) \mathbf{B}_s \mathbf{B}_s^T \Phi(t+1, s+1)^T$$

for  $t \geq t_0 \geq 0$ .

The symmetric nonnegative definite matrix  $\mathbf{X}_t^{(T)}$ ,  $t \leq T$ , is the observability gramian; that is, under  $\mathbf{w} = 0$ , any state  $x(t) = x_0$  is uniquely determined by the output sequence  $(z(t), \dots, z(T))$  if and only if  $\mathbf{X}_t^{(T)} > \mathbf{0}$ . Similarly, the matrix  $\mathbf{Y}_t^{(t_0)}$ ,  $t_0 < t$ , is the reachability gramian; that is, under  $x(t_0) = 0$ , associated with any state  $x_f \in \mathbb{R}^n$  is a disturbance input sequence  $(w(t_0), \dots, w(t-1))$  such that  $x(t) = x_f$  if and only if  $\mathbf{Y}_t^{(t_0)} > \mathbf{0}$ . The following lemma summarizes some of the simple properties of these matrices.

LEMMA 2.3. *Let  $\mathcal{G}$  be as in (2.1a); let  $\mathbf{X}_t^{(T)}$  and  $\mathbf{Y}_{t+1}^{(t_0)}$  be as in (2.3) whenever  $t_0 \leq t \leq T$ . The following hold:*

(a) *We have*

$$\mathbf{X}_t^{(T)} \leq \mathbf{X}_t^{(T+1)}; \quad \mathbf{Y}_{t+1}^{(t_0+1)} \leq \mathbf{Y}_{t+1}^{(t_0)}$$

*whenever  $t_0 \leq t \leq T$ .*

(b) *We have*

$$(2.4) \quad \sum_{t=t_0}^T \text{tr} \mathbf{B}_t^T \mathbf{X}_{t+1}^{(T)} \mathbf{B}_t = \sum_{t=t_0}^T \text{tr} \mathbf{C}_t \mathbf{Y}_t^{(t_0)} \mathbf{C}_t^T$$

*whenever  $t_0 \leq t \leq T$ .*

(c) *If*

$$\mathbf{A}_t^T \mathbf{X}_{t+1} \mathbf{A}_t - \mathbf{X}_t \leq -\mathbf{C}_t^T \mathbf{C}_t; \quad \mathbf{A}_t \mathbf{Y}_t \mathbf{A}_t^T - \mathbf{Y}_{t+1} \leq -\mathbf{B}_t \mathbf{B}_t^T$$

*for  $t_0 \leq t \leq T$ , with  $\mathbf{X}_{T+1} \geq \mathbf{0}$  and  $\mathbf{Y}_{t_0} \geq \mathbf{0}$ , then*

$$\mathbf{X}_t \geq \mathbf{X}_t^{(T)}; \quad \mathbf{Y}_{t+1} \geq \mathbf{Y}_{t+1}^{(t_0)}$$

*whenever  $t_0 \leq t \leq T$ .*

*Proof.* The proof is immediate from the definitions.  $\square$

Remark 1. If  $\mathcal{G}$  is bounded and the system  $(\mathcal{G}, \theta)$  is uniformly stable, then by (2.4) we have that

$$\limsup_{T \rightarrow \infty} \frac{1}{T - t_0} \sum_{t=t_0}^T \text{tr} \mathbf{B}_t^T \mathbf{X}_{t+1}^{(T)} \mathbf{B}_t = \limsup_{T \rightarrow \infty} \frac{1}{T - t_0} \sum_{t=t_0}^T \text{tr} \mathbf{C}_t \mathbf{Y}_t^{(t_0)} \mathbf{C}_t^T$$

for all  $t_0 \geq 0$ . (Note that the partial sums above are divided by  $T - t_0$ , not by  $T - t_0 + 1$ , because  $\text{tr} \mathbf{B}_T^T \mathbf{X}_{T+1}^{(T)} \mathbf{B}_T = \text{tr} \mathbf{C}_{t_0} \mathbf{Y}_{t_0}^{(t_0)} \mathbf{C}_{t_0}^T = 0$ .) This is a time-varying version of the classical result that if  $\mathbf{A}_t = \mathbf{A}$ ,  $\mathbf{B}_t = \mathbf{B}$ , and  $\mathbf{C}_t = \mathbf{C}$  for all  $t$ , and if  $\rho \mathbf{A} < 1$ , then

$$\text{tr} \mathbf{B}^T \mathbf{X} \mathbf{B} = \text{tr} \mathbf{C} \mathbf{Y} \mathbf{C}^T,$$

where  $\mathbf{X}$ ,  $\mathbf{Y} \geq \mathbf{0}$  uniquely solve the Lyapunov equations

$$\mathbf{A}^T \mathbf{X} \mathbf{A} - \mathbf{X} = -\mathbf{C}^T \mathbf{C}; \quad \mathbf{A} \mathbf{Y} \mathbf{A}^T - \mathbf{Y} = -\mathbf{B} \mathbf{B}^T.$$

A similar relation holds if the time-varying system is represented as a doubly infinite block matrix [25].

In the remainder of this section, three criteria for the output regulation performance of linear time-varying systems will be formulated in terms of the quantities  $\text{tr} \mathbf{B}_t^T \mathbf{X}_{t+1}^{(T)} \mathbf{B}_t$  and  $\text{tr} \mathbf{C}_t \mathbf{Y}_t^{(t_0)} \mathbf{C}_t^T$ . We assume that the family  $\mathcal{G}$  is bounded and the system  $(\mathcal{G}, \theta)$  is uniformly stable. Note that if  $x(0) = 0$  and  $\mathbf{w} = (w(0), w(1), \dots)$ , we have

$$z(t) = \begin{cases} \mathbf{D}_0 w(0), & t = 0; \\ \sum_{s=0}^{t-1} \mathbf{C}_t \Phi(t, s+1) \mathbf{B}_s w(s) + \mathbf{D}_t w(t), & t > 0. \end{cases}$$

Define

$$(2.5) \quad w_k^{(t_0)}(t) = \begin{cases} e_k, & t = t_0; \\ 0, & t \neq t_0, \end{cases}$$

for  $t_0, t \geq 0$  and  $1 \leq k \leq m$ , where  $e_k$  is the  $k$ th standard basis vector in  $\mathbb{R}^m$  (i.e., the  $k$ th column of  $\mathbf{I} \in \mathbb{R}^{m \times m}$ ). Then, with  $x(0) = 0$  and  $\mathbf{w} = (w_k^{(t_0)}(0), w_k^{(t_0)}(1), \dots)$ , the system  $(\mathcal{G}, \theta)$  yields  $z = (z_k^{(t_0)}(0), z_k^{(t_0)}(1), \dots)$ , where

$$(2.6) \quad z_k^{(t_0)}(t) = \begin{cases} \mathbf{D}_{t_0} e_k, & t = t_0; \\ \mathbf{C}_t \Phi(t, t_0+1) \mathbf{B}_{t_0} e_k, & t > t_0. \end{cases}$$

The first performance criterion is based on this, and defined to be the square root of

$$(2.7) \quad \sup_{\{t_0, T: t_0 \leq T\}} \sum_{k=1}^m \sum_{t=t_0}^T \|z_k^{(t_0)}(t)\|^2 = \sup_{\{t_0, T: t_0 \leq T\}} \text{tr} (\mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(T)} \mathbf{B}_{t_0} + \mathbf{D}_{t_0}^T \mathbf{D}_{t_0}) \\ = \sup_{t_0 \geq 0} \text{tr} (\mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(\infty)} \mathbf{B}_{t_0} + \mathbf{D}_{t_0}^T \mathbf{D}_{t_0}),$$

where the second equality is due to part (a) of Lemma 2.3; the limit

$$\mathbf{X}_{t_0+1}^{(\infty)} = \lim_{T \rightarrow \infty} \mathbf{X}_{t_0+1}^{(T)}$$

is well-defined for all  $t_0 \geq 0$  (as long as  $\mathbf{G}$  is bounded and  $(\mathcal{G}, \theta)$  is uniformly stable). We shall call the square root of the quantity in (2.7) the *peak impulse response level* of the system  $(\mathcal{G}, \theta)$ . This is a time-varying extension of the deterministic interpretation of the  $\mathcal{H}^2$  norm of linear time-invariant systems, which is defined to be the square root of the sum of the output energies over impulsive inputs.

The second performance criterion extends the stochastic interpretation of the  $\mathcal{H}^2$ -norm as the square root of the output variance under zero-mean white Gaussian disturbance. Define  $(w^{(t_0)}(0), w^{(t_0)}(1), \dots)$  to be an independent identically distributed random sequence such that each  $w^{(t_0)}(t)$  is Gaussian distributed with

$$(2.8) \quad \mathbb{E} [w^{(t_0)}(t)] = 0; \quad \mathbb{E} [w^{(t_0)}(t) w^{(t_0)}(t)^T] = \begin{cases} \mathbf{0}, & t < t_0; \\ \mathbf{I}, & t \geq t_0, \end{cases}$$

for  $t_0, t \geq 0$ , where  $\mathbb{E}[\cdot]$  denotes the expectation over the probability distribution of  $(w^{(t_0)}(0), w^{(t_0)}(1), \dots)$ . Then, with  $x(0) = 0$  and  $\mathbf{w} = (w^{(t_0)}(0), w^{(t_0)}(1), \dots)$ , the

system  $(\mathcal{G}, \theta)$  yields  $\mathbf{z} = (z^{(t_0)}(0), z^{(t_0)}(1), \dots)$ , where

$$(2.9) \quad \mathbb{E} \|z^{(t_0)}(t)\|^2 = \begin{cases} \mathbb{E} \|\mathbf{D}_{t_0} w^{(t_0)}(t_0)\|^2, & t = t_0; \\ \sum_{s=t_0}^{t-1} \mathbb{E} \|\mathbf{C}_t \Phi(t, s+1) \mathbf{B}_s w^{(t_0)}(s)\|^2 + \mathbb{E} \|\mathbf{D}_t w^{(t_0)}(t)\|^2, & t > t_0. \end{cases}$$

From this, we have that

$$(2.10) \quad \sup_{\{t_0, t: t_0 \leq t\}} \mathbb{E} \|z^{(t_0)}(t)\|^2 = \sup_{\{t_0, t: t_0 \leq t\}} \text{tr} (\mathbf{C}_t \mathbf{Y}_t^{(t_0)} \mathbf{C}_t^T + \mathbf{D}_t \mathbf{D}_t^T) \\ = \sup_{t \geq 0} \text{tr} (\mathbf{C}_t \mathbf{Y}_t^{(0)} \mathbf{C}_t^T + \mathbf{D}_t \mathbf{D}_t^T),$$

where the second equality follows from part (a) of Lemma 2.3. The quantity in (2.10) shall be called the *peak output variance level* of the system  $(\mathcal{G}, \theta)$ .

The third performance criterion draws on the interpretation of the  $\mathcal{H}^2$  norm as the square root of the average output variance per unit time. This stochastic interpretation coincides with the deterministic interpretation of the  $\mathcal{H}^2$  norm as the square root of the sum of the average output energies over impulsive inputs. For time-varying systems, we have the following.

PROPOSITION 2.4. *Let  $\mathcal{G}$  and  $\theta$  be as in (2.1); let  $\mathcal{G}$  be bounded. If the system  $(\mathcal{G}, \theta)$  is uniformly exponentially stable, and if  $z_k^{(t_0)}(t)$  and  $z^{(0)}(t)$  are as in (2.6) and (2.9), respectively, then*

$$(2.11) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \sum_{k=1}^m \sum_{t=t_0}^T \|z_k^{(t_0)}(t)\|^2 \\ = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \text{tr} (\mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(\infty)} \mathbf{B}_{t_0} + \mathbf{D}_{t_0}^T \mathbf{D}_{t_0}) \\ = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \text{tr} (\mathbf{C}_t \mathbf{Y}_t^{(0)} \mathbf{C}_t^T + \mathbf{D}_t \mathbf{D}_t^T) \\ = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(0)}(t)\|^2.$$

*Proof.* Because of (2.7), (2.10), and part (b) of Lemma 2.3, it suffices to show that

$$(2.12) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \text{tr} \mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(\infty)} \mathbf{B}_{t_0} = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \text{tr} \mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(T)} \mathbf{B}_{t_0}.$$

Since  $\mathcal{G}$  is bounded and  $(\mathcal{G}, \theta)$  is uniformly stable, there exist  $\tilde{c} \geq 1$  and  $\tilde{\lambda} \in (0, 1)$  such that

$$\text{tr} \mathbf{B}_{t_0}^T \Phi(s, t_0+1)^T \mathbf{C}_s^T \mathbf{C}_s \Phi(s, t_0+1) \mathbf{B}_{t_0} \leq \tilde{c} \tilde{\lambda}^{s-t_0-1},$$

so

$$\begin{aligned}
& \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \text{tr} \mathbf{B}_{t_0}^T (\mathbf{X}_{t_0+1}^{(\infty)} - \mathbf{X}_{t_0+1}^{(T)}) \mathbf{B}_{t_0} \\
&= \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \sum_{s=T+1}^{\infty} \text{tr} \mathbf{B}_{t_0}^T \Phi(s, t_0+1)^T \mathbf{C}_s^T \mathbf{C}_s \Phi(s, t_0+1) \mathbf{B}_{t_0} \\
&\leq \lim_{T \rightarrow \infty} \frac{1}{T+1} \frac{\tilde{c}(1 - \tilde{\lambda}^{T+1})}{(1 - \tilde{\lambda})^2} = 0.
\end{aligned}$$

This leads to equality (2.12), and hence completes the proof.  $\square$

The quantity in (2.11) shall be called the *average output variance level* of the system  $(\mathcal{G}, \theta)$ . In general, the three performance measures given by (2.7), (2.10), and (2.11) are all different for time-varying systems—see Example 1 below. However, as is well known, they are all equal in the case of time-invariant systems.

*Example 1.* Let  $n = m = l = 1$ . If a linear periodic system is defined by

$$\mathbf{A}_t = 1/\sqrt{2}; \quad \mathbf{B}_t = 1; \quad \mathbf{C}_t = \begin{cases} 1 & \text{if } t \text{ is even;} \\ 0 & \text{if } t \text{ is odd;} \end{cases} \quad \mathbf{D}_t = 0$$

for  $t \geq 0$ , then

$$\mathbf{X}_t^{(\infty)} = \begin{cases} 4/3 & \text{if } t \text{ is even;} \\ 2/3 & \text{if } t \text{ is odd;} \end{cases} \quad \mathbf{Y}_t^{(0)} = \frac{2^t - 1}{2^{t-1}}$$

for  $t \geq 0$ . The quantities in (2.7) and (2.10) are computed as

$$\sup_{t_0 \geq 0} \text{tr} \mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(\infty)} \mathbf{B}_{t_0} = \max\{4/3, 2/3\} = 4/3,$$

$$\sup_{t \geq 0} \text{tr} \mathbf{C}_t \mathbf{Y}_t^{(0)} \mathbf{C}_t^T = \sup_{t \geq 0} (2^t - 1)/2^{t-1} = 2,$$

and that in (2.11) as

$$\begin{aligned}
\limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t_0=0}^T \text{tr} \mathbf{B}_{t_0}^T \mathbf{X}_{t_0+1}^{(\infty)} \mathbf{B}_{t_0} &= \lim_{T \rightarrow \infty} \frac{1}{T+1} \begin{cases} T + 4/3 & \text{if } T \text{ is even;} \\ T + 1 & \text{if } T \text{ is odd} \end{cases} \\
&= 1
\end{aligned}$$

or

$$\begin{aligned}
\limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \text{tr} \mathbf{C}_t \mathbf{Y}_t^{(0)} \mathbf{C}_t^T &= \lim_{T \rightarrow \infty} \frac{1}{T+1} \begin{cases} T - 2/3 + (2/3)(1/2)^T & \text{if } t \text{ is even;} \\ T - 5/3 + (4/3)(1/2)^T & \text{if } t \text{ is odd} \end{cases} \\
&= 1. \quad \square
\end{aligned}$$

**3. Analysis of switched linear systems.** In this section, we extend the three output regulation properties of time-varying systems to switched systems and derive convex characterizations of the systems that are stable and meet desired performance levels. Given a positive integer  $N$ , let

$$(3.1) \quad \mathcal{G} = \{(\mathbf{A}_1, \mathbf{B}_1, \mathbf{C}_1, \mathbf{D}_1), \dots, (\mathbf{A}_N, \mathbf{B}_N, \mathbf{C}_N, \mathbf{D}_N)\},$$

with  $\mathbf{A}_i \in \mathbb{R}^{n \times n}$ ,  $\mathbf{B}_i \in \mathbb{R}^{n \times m}$ ,  $\mathbf{C}_i \in \mathbb{R}^{l \times n}$ ,  $\mathbf{D}_i \in \mathbb{R}^{l \times m}$  for  $i = 1, \dots, N$ . Let  $\Omega$  be the set of all infinite sequences in  $\{1, \dots, N\}$ , so that  $\Omega = \{1, \dots, N\}^\infty$ . Each member  $\theta = (\theta(0), \theta(1), \dots)$  of  $\Omega$  is called a *switching sequence*, and  $\theta(t)$  the *mode* at time  $t$ . If  $\Theta$  is a nonempty subset of  $\Omega$ , then the pair  $(\mathcal{G}, \Theta)$  defines the *switched linear system*, which is the collection of linear time-varying systems

$$(3.2) \quad \begin{aligned} x(t+1) &= \mathbf{A}_{\theta(t)}x(t) + \mathbf{B}_{\theta(t)}w(t), \\ z(t) &= \mathbf{C}_{\theta(t)}x(t) + \mathbf{D}_{\theta(t)}w(t) \end{aligned}$$

over all switching sequences  $\theta \in \Theta$ . When the set  $\Theta$  is equal to the entire set  $\Omega$ , the pair  $(\mathcal{G}, \Omega)$  defines the *discrete linear inclusion*, which is the switched linear system without switching path constraint; on the other hand, if  $\Theta = \{\theta\}$  is a singleton, then the pair  $(\mathcal{G}, \Theta)$  is nothing but the linear time-varying system  $(\mathcal{G}, \theta)$  whose parameters vary within the finite set  $\mathcal{G}$  according to  $\theta$ .

Let us first define the stability and performance criteria for switched linear systems. If  $x(0) = 0$ ,  $\mathbf{w} = (w(0), w(1), \dots)$ , and  $\theta = (\theta(0), \theta(1), \dots)$ , then we have  $\mathbf{z} = (z(0), z(1), \dots)$  with

$$z(t) = \begin{cases} \mathbf{D}_{\theta(0)}w(0), & t = 0; \\ \sum_{s=0}^{t-1} \mathbf{C}_{\theta(t)}\Phi_{\theta}(t, s+1)\mathbf{B}_{\theta(s)}w(s) + \mathbf{D}_{\theta(t)}w(t), & t > 0, \end{cases}$$

where

$$\Phi_{\theta}(t, t_0) = \begin{cases} \mathbf{I}, & t = t_0; \\ \mathbf{A}_{\theta(t-1)} \cdots \mathbf{A}_{\theta(t_0)}, & t > t_0. \end{cases}$$

In particular, as in the previous section, if  $\mathbf{w} = (w_k^{(t_0)}(0), w_k^{(t_0)}(1), \dots)$  is an impulsive input sequence where  $w_k^{(t_0)}(t)$  are given by (2.5) for  $t_0, t \geq 0$  and  $1 \leq k \leq m$ , then write  $\mathbf{z} = (z_k^{(t_0)}(0), z_k^{(t_0)}(1), \dots)$ . On the other hand, if  $\mathbf{w} = (w^{(t_0)}(0), w^{(t_0)}(1), \dots)$  is an independent identically distributed random sequence such that  $w^{(t_0)}(t)$  are Gaussian distributed with (2.8) for  $t_0, t \geq 0$ , then write  $\mathbf{z} = (z^{(t_0)}(0), z^{(t_0)}(1), \dots)$ .

**DEFINITION 3.1.** *The system  $(\mathcal{G}, \Theta)$  is said to be uniformly (exponentially) stable if there exist  $c \geq 1$  and  $\lambda \in (0, 1)$  such that, whenever  $\mathbf{w} = 0$ ,*

$$\|x(t)\| \leq c \lambda^{t-t_0} \|x(t_0)\|$$

for all  $t_0 \geq 0, t \geq t_0, x(t_0) \in \mathbb{R}^n$ , and  $\theta \in \Theta$ .

**Remark 2.** By definition, uniformly stable switched linear systems are asymptotically stable (i.e.,  $\|x(t)\| \rightarrow 0$  as  $t \rightarrow \infty$  for each  $\theta \in \Theta$ ). The reverse implication also holds if  $\Theta = \Omega$ : every asymptotically stable discrete linear inclusion is in fact uniformly stable. See, e.g., [34].

DEFINITION 3.2. Let  $\gamma > 0$ . The system  $(\mathcal{G}, \Theta)$  is said to satisfy uniform impulse response level  $\gamma$  if there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that, whenever  $x(0) = 0$ ,

$$\sum_{k=1}^m \sum_{s=t_0}^t \|z_k^{(t_0)}(s)\|^2 \leq \tilde{\gamma}^2$$

for all  $t_0 \geq 0$ ,  $t \geq t_0$ , and  $\theta \in \Theta$ .

DEFINITION 3.3. Let  $\gamma > 0$ . The system  $(\mathcal{G}, \Theta)$  is said to satisfy uniform output regulation level  $\gamma$  if there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that, whenever  $x(0) = 0$ ,

$$(3.3) \quad \mathbb{E} \|z^{(t_0)}(t)\|^2 \leq \tilde{\gamma}^2$$

for all  $t_0 \geq 0$ ,  $t \geq t_0$ , and  $\theta \in \Theta$ , where  $\mathbb{E}$  denotes the expectation with respect to  $\mathbf{w} = (w^{(t_0)}(0), w^{(t_0)}(1), \dots)$ .

DEFINITION 3.4. Let  $\gamma > 0$ . The system  $(\mathcal{G}, \Theta)$  is said to satisfy uniform average output regulation level  $\gamma$  if there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that, whenever  $x(0) = 0$ ,

$$(3.4) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(0)}(t)\|^2 \leq \tilde{\gamma}^2$$

for all  $t \geq 0$  and  $\theta \in \Theta$ , where  $\mathbb{E}$  denotes the expectation with respect to  $\mathbf{w} = (w^{(0)}(0), w^{(0)}(1), \dots)$ .

We adopt and extend the notation used in [33] as follows. To help state the analysis results, introduce a dummy mode 0 and think of each  $\theta \in \Theta$  as a two-sided sequence  $(\dots, \theta(-1), \theta(0), \theta(1), \dots)$  by putting  $\theta(t) = 0$  for  $t < 0$ . Given a nonnegative integer  $L$ , each element of the set  $\{0, \dots, N\}^{L+1}$  shall be called a *switching path* of length  $L$ , or simply an *L-path*. For  $\theta \in \Theta$  and  $t \geq 0$ , let

$$\theta_L(t) = (\theta(t-L), \dots, \theta(t)).$$

Each  $\theta \in \Theta$  generates an *L-path switching sequence*  $\theta_L$  defined by

$$\theta_L = (\theta_L(0), \theta_L(1), \dots).$$

Denote the set of *L-paths* occurring in  $\Theta$  by  $\mathcal{L}_L(\Theta)$ , so that

$$\mathcal{L}_L(\Theta) = \{\theta_L(t) : \theta \in \Theta, t \geq 0\}.$$

If  $(i_0, \dots, i_L) \in \mathcal{L}_L(\Theta)$ , then write

$$(i_0, \dots, i_L)_- = (i_0, \dots, i_{L-1}), \quad (i_0, \dots, i_L)_+ = (i_1, \dots, i_L)$$

for  $L > 0$ , and write  $(i_0, \dots, i_L)_- = (i_0, \dots, i_L)_+ = 0$  for  $L = 0$ . If  $L > 0$ , define  $\mathcal{M}_L(\Theta)$  to be the smallest subset of  $\mathcal{L}_L(\Theta)$  such that the following hold:  $\theta_L(t) \in \mathcal{M}_L(\Theta)$  for all  $t \geq L$  and for all  $\theta \in \Theta$ ; and, for each  $j \in \mathcal{L}_0(\Theta)$ , there exists a switching path  $(i_0^j, \dots, i_{L-1}^j) \in \{0, \dots, N\}^L$  such that

$$(3.5) \quad (i_0^{\theta(0)}, \dots, i_{L-1}^{\theta(0)}, \theta(0)), \quad (i_1^{\theta(0)}, \dots, i_{L-1}^{\theta(0)}, \theta(0), \theta(1)), \quad \dots,$$

$$(i_{L-1}^{\theta(0)}, \theta(0), \dots, \theta(L-1)) \in \mathcal{M}_L(\Theta)$$

for all  $\theta \in \Theta$ . If  $L = 0$ , then let  $\mathcal{M}_0(\Theta) = \mathcal{L}_0(\Theta)$ . Define

$$\mathcal{W}_L(\Theta) = \{\theta_L : \theta \in \Theta, t \geq L\} = \mathcal{L}_L(\Theta) \cap \{1, \dots, N\}^{M+1}.$$

Then, in general,

$$\mathcal{W}_L(\Theta) \subset \mathcal{M}_L(\Theta) \subset \mathcal{L}_L(\Theta)$$

for all  $\Theta$  and  $L$ . (While the set  $\mathcal{L}_L(\Theta)$  contains all the  $L$ -paths that occur in  $\Theta$ , the set  $\mathcal{W}_L(\Theta)$  contains only the  $L$ -paths that occur in  $\Theta$  at or after time  $t = L$ . The  $L$ -paths occurring in  $\Theta$  before time  $L$  contain the dummy mode 0, and some of them are redundant in determining the output regulation performance; the set  $\mathcal{M}_L(\Theta)$  is what remains after removing these redundant  $L$ -paths from  $\mathcal{L}_L(\Theta)$ .) Define

$$\mathcal{W}_L^-(\Theta) = \{i_- : i \in \mathcal{W}_L(\Theta)\},$$

$$\mathcal{M}_L^-(\Theta) = \{i_- : i \in \mathcal{M}_L(\Theta)\},$$

$$\mathcal{L}_L^-(\Theta) = \{i_- : i \in \mathcal{L}_L(\Theta)\}.$$

*Example 2.* Let  $N = 3$ . Suppose that  $\Theta$  is the set of all  $\theta \in \Omega$  such that  $\theta(0) \in \{1, 2\}$ ,  $\theta(t+1) = 2$  whenever  $\theta(t) \in \{1, 3\}$ , and  $\theta(t+1) \in \{2, 3\}$  whenever  $\theta(t) = 2$ . Then, writing  $i_0 \cdots i_L$  for  $(i_0, \dots, i_L)$  to simplify notation, we have

$$\mathcal{L}_0(\Theta) = \mathcal{M}_0(\Theta) = \mathcal{W}_0(\Theta) = \{1, 2, 3\}$$

for  $L = 0$ ;

$$\mathcal{L}_1(\Theta) = \{01, 02, 12, 22, 23, 32\},$$

$$\mathcal{M}_1(\Theta) = \{01, 12, 22, 23, 32\},$$

$$\mathcal{W}_1(\Theta) = \{12, 22, 23, 32\}$$

for  $L = 1$ ; and

$$\mathcal{L}_2(\Theta) = \{001, 002, 012, 022, 023, 122, 123, 222, 223, 232, 322, 323\},$$

$$\mathcal{M}_2(\Theta) = \{001, 012, 122, 123, 222, 223, 232, 322, 323\},$$

$$\mathcal{W}_2(\Theta) = \{122, 123, 222, 223, 232, 322, 323\}$$

for  $L = 2$ .  $\square$

**THEOREM 3.5.** *Let  $\mathcal{G}$  be as in (3.1); let  $\Theta \subset \Omega$  be nonempty. The system  $(\mathcal{G}, \Theta)$  is uniformly exponentially stable and satisfies uniform impulse response level  $\gamma > 0$  if and only if there exist a nonnegative integer  $M$  and an indexed family  $\{\mathbf{X}_j : j \in \mathcal{W}_M^-(\Theta)\}$  of symmetric positive definite matrices  $\mathbf{X}_j \in \mathbb{R}^{n \times n}$  such that*

$$(3.6a) \quad \mathbf{A}_{i_0}^T \mathbf{X}_{(i_0, \dots, i_M)_+} \mathbf{A}_{i_0} - \mathbf{X}_{(i_0, \dots, i_M)_-} < -\mathbf{C}_{i_0}^T \mathbf{C}_{i_0},$$

$$(3.6b) \quad \text{tr}(\mathbf{B}_{i_0}^T \mathbf{X}_{(i_0, \dots, i_M)_+} \mathbf{B}_{i_0} + \mathbf{D}_{i_0}^T \mathbf{D}_{i_0}) < \gamma^2$$

for all  $M$ -paths  $(i_0, \dots, i_M) \in \mathcal{W}_M(\Theta)$ .

**THEOREM 3.6.** *Let  $\mathcal{G}$  be as in (3.1); let  $\Theta \subset \Omega$  be nonempty. The system  $(\mathcal{G}, \Theta)$  is uniformly exponentially stable and satisfies uniform output regulation level  $\gamma > 0$  if and only if there exist a nonnegative integer  $M$  and an indexed family  $\{\mathbf{Y}_j : j \in \mathcal{M}_M^-(\Theta)\}$  of symmetric positive definite matrices  $\mathbf{Y}_j \in \mathbb{R}^{n \times n}$  such that*

$$(3.7a) \quad \mathbf{A}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{A}_{i_M}^T - \mathbf{Y}_{(i_0, \dots, i_M)_+} < -\mathbf{B}_{i_M} \mathbf{B}_{i_M}^T,$$

$$(3.7b) \quad \text{tr}(\mathbf{C}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{C}_{i_M}^T + \mathbf{D}_{i_M} \mathbf{D}_{i_M}^T) < \gamma^2$$

for all  $M$ -paths  $(i_0, \dots, i_M) \in \mathcal{M}_M(\Theta)$ .

*Proof of Theorems 3.5 and 3.6.* We will first present a complete proof of Theorem 3.6; the proof of Theorem 3.5 will be sketched only briefly. To show the necessity part of Theorem 3.6, suppose that  $(\mathcal{G}, \Theta)$  is uniformly exponentially stable and that there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that (3.3) holds. For  $\varepsilon > 0$ , consider the augmented disturbance signal  $\tilde{w}(t) = [w(t)^T v(t)^T]^T$  with  $v(t) \in \mathbb{R}^n$ ,  $t \geq 0$ , and the perturbed system  $(\mathcal{G}^{(\varepsilon)}, \Theta)$ , where

$$(3.8a) \quad \mathcal{G}^{(\varepsilon)} = \{(\mathbf{A}_1, \mathbf{B}_1^{(\varepsilon)}, \mathbf{C}_1, \mathbf{D}_1^{(\varepsilon)}), \dots, (\mathbf{A}_N, \mathbf{B}_N^{(\varepsilon)}, \mathbf{C}_N, \mathbf{D}_N^{(\varepsilon)})\},$$

$$(3.8b) \quad \mathbf{B}_i^{(\varepsilon)} = [\mathbf{B}_i \sqrt{\varepsilon} \mathbf{I}] \in \mathbb{R}^{n \times (m+n)}, \quad \mathbf{D}_i^{(\varepsilon)} = [\mathbf{D}_i \mathbf{0}] \in \mathbb{R}^{l \times (m+n)}.$$

If  $\mathbf{Y}_{\theta, t}^{(\varepsilon, t_0)}$ ,  $t \geq t_0 \geq 0$ , are such that

$$\mathbf{A}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, t_0)} \mathbf{A}_{\theta(t)}^T - \mathbf{Y}_{\theta, t+1}^{(\varepsilon, t_0)} = -\mathbf{B}_{\theta(t)}^{(\varepsilon)} \mathbf{B}_{\theta(t)}^{(\varepsilon)T}$$

for  $\theta \in \Theta$  and  $t \geq t_0$ , with  $\mathbf{Y}_{\theta, t_0}^{(\varepsilon, t_0)} = 0$ , then

$$\mathbf{Y}_{\theta, t+1}^{(\varepsilon, t_0)} = \sum_{s=t_0}^t \Phi_{\theta}(t+1, s+1) (\mathbf{B}_{\theta(s)} \mathbf{B}_{\theta(s)}^T + \varepsilon \mathbf{I}) \Phi_{\theta}(t+1, s+1)^T.$$

Hence there exists a sufficiently small  $\varepsilon$ , and a corresponding  $\eta \in (0, \gamma)$  such that

$$\mathbf{A}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \mathbf{A}_{\theta(t)}^T - \mathbf{Y}_{\theta, t+1}^{(\varepsilon, 0)} = -\mathbf{B}_{\theta(t)}^{(\varepsilon)} \mathbf{B}_{\theta(t)}^{(\varepsilon)T},$$

$$\text{tr}(\mathbf{C}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)}^{(\varepsilon)} \mathbf{D}_{\theta(t)}^{(\varepsilon)T}) \leq \eta^2$$

for all  $\theta \in \Theta$  and  $t \geq 0$ . Choose a small  $\mathbf{Y} > \mathbf{0}$  such that  $\mathbf{A}_i \mathbf{Y} \mathbf{A}_i^T < \varepsilon \mathbf{I}$  and  $\text{tr}(\mathbf{C}_i \mathbf{Y} \mathbf{C}_i^T) < \gamma^2 - \eta^2$  for all  $i = 1, \dots, N$ , and put

$$\mathbf{Y}_{\theta, t}^{(t_0)} = \begin{cases} \mathbf{Y}, & t = t_0; \\ \mathbf{Y}_{\theta, t}^{(\varepsilon, t_0)}, & t > t_0. \end{cases}$$

Then we have that there are  $\tilde{\varepsilon} > 0$  and  $\tilde{\eta} \in (0, \gamma)$  such that

$$\mathbf{A}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(0)} \mathbf{A}_{\theta(t)}^T - \mathbf{Y}_{\theta, t+1}^{(0)} \leq -\mathbf{B}_{\theta(t)} \mathbf{B}_{\theta(t)}^T - \tilde{\varepsilon} \mathbf{I},$$

$$\text{tr}(\mathbf{C}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(0)} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T) \leq \tilde{\eta}^2$$

for all  $\theta \in \Theta$  and  $t \geq 0$ . Since  $(\mathcal{G}^{(\varepsilon)}, \Theta)$  is uniformly stable, there exist  $\tilde{c} \geq 1$  and  $\tilde{\lambda} \in (0, 1)$ , independent of  $\theta$ , such that

$$\Phi_\theta(t+1, t-M+1)(\mathbf{B}_{\theta(t-M)}\mathbf{B}_{\theta(t-M)}^\top + \varepsilon\mathbf{I})\Phi_\theta(t+1, t-M+1)^\top \leq \tilde{c}\tilde{\lambda}^M\mathbf{I}$$

for  $\theta \in \Theta$  and  $t \geq M \geq 0$ . Choose an  $M > 0$  such that

$$\tilde{c}\tilde{\lambda}^M < \varepsilon.$$

Then

$$\mathbf{A}_{\theta(t)}\mathbf{Y}_{\theta,t}^{(t-M)}\mathbf{A}_{\theta(t)}^\top - \mathbf{Y}_{\theta,t+1}^{(t-M+1)} \leq \tilde{c}\tilde{\lambda}^M - \mathbf{B}_{\theta(t)}\mathbf{B}_{\theta(t)}^\top - \varepsilon\mathbf{I} < -\mathbf{B}_{\theta(t)}\mathbf{B}_{\theta(t)}^\top$$

for  $t \geq M$ . Now, since

$$\mathbf{A}_{\theta(t)}\mathbf{Y}_{\theta,t}^{(0)}\mathbf{A}_{\theta(t)}^\top - \mathbf{Y}_{\theta,t+1}^{(0)} < -\mathbf{B}_{\theta(t)}\mathbf{B}_{\theta(t)}^\top,$$

putting

$$\mathbf{Y}_{(\theta(t-M), \dots, \theta(t-1))} = \begin{cases} \mathbf{Y}_{\theta,t}^{(0)}, & t < M; \\ \mathbf{Y}_{\theta,t}^{(t-M)}, & t \geq M, \end{cases}$$

leads to (3.7a) for all  $(i_0, \dots, i_M) \in \mathcal{L}_M(\Theta)$ , where  $\mathcal{M}_M(\Theta) \subset \mathcal{L}_M(\Theta)$ . Also, it is immediate from part (a) of Lemma 2.3 that (3.7b) holds for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\Theta)$ .

To show the sufficiency part of Theorem 3.6, suppose that (3.7) holds for some integer  $M \geq 0$  and for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\Theta)$ . Assume  $M > 0$  without loss of generality. By the definition of  $\mathcal{M}_M(\Theta)$ , one can choose  $(i_0^j, \dots, i_{M-1}^j) \in \{0, \dots, N\}^M$ ,  $j \in \{\theta(0) : \theta \in \Theta\}$ , such that (3.5), with  $L$  replaced by  $M$ , holds for all  $\theta \in \Theta$ . Put

$$\mathbf{Y}_t = \begin{cases} \mathbf{Y}_{(i_0^{\theta(0)}, \dots, i_{M-1}^{\theta(0)})}, & t = 0; \\ \mathbf{Y}_{(i_t^{\theta(0)}, \dots, i_{M-1}^{\theta(0)}, \theta(0), \dots, \theta(t-1))}, & 0 < t < M; \\ \mathbf{Y}_{(\theta(t-M), \dots, \theta(t-1))}, & t \geq M. \end{cases}$$

Then, since  $\mathcal{M}_M(\Theta)$  is finite, one can choose  $\epsilon, \delta > 0$  such that

$$\epsilon\mathbf{I} \leq \mathbf{Y}_t \leq \delta\mathbf{I}; \quad \mathbf{A}_{\theta(t)}\mathbf{Y}_t\mathbf{A}_{\theta(t)}^\top - \mathbf{Y}_{t+1} \leq -\epsilon\mathbf{I}$$

for all  $\theta \in \Theta$  and for all  $t \geq 0$ . Then the system  $(\mathcal{G}, \Theta)$  is uniformly stable due to Lemma 2.2. On the other hand, due to part (c) of Lemma 2.3, we have that

$$\text{tr}(\mathbf{C}_{\theta(t)}\mathbf{Y}_{\theta,t}^{(0)}\mathbf{C}_{\theta(t)}^\top) \leq \text{tr}(\mathbf{C}_{\theta(t)}\mathbf{Y}_t\mathbf{C}_{\theta(t)}^\top)$$

for all  $\theta \in \Theta$ . Hence there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that (3.3) holds. This concludes the proof of Theorem 3.6.

The proof of Theorem 3.5 is analogous to that of Theorem 3.6. In particular, to show sufficiency involves the solution

$$\mathbf{X}_{\theta,t}^{(\varepsilon,T)} = \sum_{s=t}^T \Phi_\theta(s, t)^\top (\mathbf{C}_{\theta(s)}^\top \mathbf{C}_{\theta(s)} + \varepsilon\mathbf{I}) \Phi_\theta(s, t)$$

to

$$\mathbf{A}_{\theta(t)}^T \mathbf{X}_{\theta, t+1}^{(\varepsilon, T)} \mathbf{A}_{\theta(t)} - \mathbf{X}_{\theta, t}^{(\varepsilon, T)} = -\mathbf{C}_{\theta(t)}^T \mathbf{C}_{\theta(t)} - \varepsilon \mathbf{I}$$

for  $\theta \in \Theta$  and  $t \leq T$ , with  $\mathbf{X}_{\theta, T+1}^{(\varepsilon, T)} = 0$ ; for some  $\varepsilon > 0$  and some nonnegative integer  $M$ , we may put

$$\mathbf{X}_{(\theta(t), \dots, \theta(t+M))_+} = \mathbf{X}_{\theta, t+1}^{(\varepsilon, t+M)}$$

for all  $\theta \in \Theta$  and  $t \geq 0$ .  $\square$

To characterize the output regulation performance in terms of the average output variance level, we will consider a special but still quite general case where  $\Theta$  is defined by the directed graph of a matrix  $\mathbf{Q}$  with possible starting nodes given by a row vector  $q$ . Let  $\mathbf{Q} = (q_{ij}) \in \mathbb{R}^{N \times N}$  be a componentwise nonnegative matrix where each row has at least one positive component; that is,  $q_{ij} \geq 0$  for all  $i$  and  $j$ , and  $\sum_{j=1}^N q_{ij} > 0$  for all  $i$ . Similarly, let  $q = (q_i) \in \mathbb{R}^{1 \times N}$  be a componentwise nonnegative row vector with at least one positive component; that is,  $\sum_{i=1}^N q_i > 0$ . Then the pair  $(\mathbf{Q}, q)$  shall be called *row-allowable*. Define

$$\Theta(\mathbf{Q}, q) = \{\theta \in \Omega: q_{\theta(0)} > 0 \text{ and } q_{\theta(t)\theta(t+1)} > 0 \text{ for } t \geq 0\},$$

where  $q_{\theta(0)} = q_i$  if  $\theta(0) = i$  and  $q_{\theta(t)\theta(t+1)} = q_{ij}$  if  $(\theta(t), \theta(t+1)) = (i, j)$ , and write

$$\mathcal{W}_L(\mathbf{Q}, q) = \mathcal{W}_L(\Theta(\mathbf{Q}, q)), \quad \mathcal{W}_L^-(\mathbf{Q}, q) = \mathcal{W}_L^-(\Theta(\mathbf{Q}, q));$$

$$\mathcal{M}_L(\mathbf{Q}, q) = \mathcal{M}_L(\Theta(\mathbf{Q}, q)), \quad \mathcal{M}_L^-(\mathbf{Q}, q) = \mathcal{M}_L^-(\Theta(\mathbf{Q}, q));$$

$$\mathcal{L}_L(\mathbf{Q}, q) = \mathcal{L}_L(\Theta(\mathbf{Q}, q)), \quad \mathcal{L}_L^-(\mathbf{Q}, q) = \mathcal{L}_L^-(\Theta(\mathbf{Q}, q))$$

for nonnegative integers  $L$ .

We need a few definitions adopted from [35]: given a nonnegative integer  $L$  and a row-allowable pair  $(\mathbf{Q}, q)$ , a set  $\mathcal{N} \subset \mathcal{W}_L(\mathbf{Q}, q)$  is said to be a  $(\mathbf{Q}, q)$ -admissible set of  $L$ -paths if, for each  $(i_0, \dots, i_L) \in \mathcal{N}$ , there exist an integer  $K > L$  and a switching path  $(i_{L+1}, \dots, i_K)$  such that  $(i_{K-L}, \dots, i_K) = (i_0, \dots, i_L)$  and  $(i_t, \dots, i_{t+L}) \in \mathcal{N}$  for  $0 \leq t \leq K - L$ . Define  $\mathcal{N}_L(\mathbf{Q}, q)$  to be the union of all  $(\mathbf{Q}, q)$ -admissible sets of  $L$ -paths, and write

$$\mathcal{N}_L^-(\mathbf{Q}, q) = \{i_- : i \in \mathcal{N}_L(\mathbf{Q}, q)\}.$$

If the only  $(\mathbf{Q}, q)$ -admissible set  $\widetilde{\mathcal{N}}$  of  $L$ -paths satisfying  $\widetilde{\mathcal{N}} \subset \mathcal{N}$  is  $\mathcal{N}$  itself, then  $\mathcal{N}$  is said to be a  $(\mathbf{Q}, q)$ -minimal set of  $L$ -paths. It is readily seen that  $\mathcal{N}$  is a  $(\mathbf{Q}, q)$ -admissible set of  $L$ -paths if and only if it is a finite union of  $(\mathbf{Q}, q)$ -minimal sets of  $L$ -paths. Thus the set  $\mathcal{N}_L(\mathbf{Q}, q)$  is obtained by taking the union of all  $(\mathbf{Q}, q)$ -minimal sets. Whenever  $\mathcal{N}$  is a  $(\mathbf{Q}, q)$ -admissible set of  $L$ -paths, there is a periodic switching sequence  $\theta \in \Omega$  such that  $\mathcal{N} = \mathcal{W}_L(\{\theta\})$  and such that the period of  $\theta$  is equal to the cardinality of  $\mathcal{N}$ ; in particular, if  $\mathcal{N}$  is  $(\mathbf{Q}, q)$ -minimal, then such a  $\theta$  is unique up to a time shift and shall be called a  $(\mathbf{Q}, q)$ -minimal switching sequence associated with  $\mathcal{N}$ .

*Example 3.* Let  $N = 3$ . If

$$\mathbf{Q} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 0 \end{bmatrix} \quad \text{and} \quad q = [1 \quad 1 \quad 0],$$

then the set  $\Theta(\mathbf{Q}, q)$  is nothing but the set  $\Theta$  considered in Example 2. We will consider the cases of  $L = 0, 1$ , and  $2$ . The  $(\mathbf{Q}, q)$ -minimal sets of zero-paths are  $\{1\}$ ,  $\{2\}$ , and  $\{3\}$ , and the minimal switching sequences associated with them are  $(1, 1, \dots)$ ,  $(2, 2, \dots)$ , and  $(3, 3, \dots)$ , respectively. Note that these switching sequences do not necessarily belong to  $\Theta(\mathbf{Q}, q)$ . The  $(\mathbf{Q}, q)$ -minimal sets of one-paths are  $\{22\}$  and  $\{23, 32\}$ , and associated with them are the minimal switching sequences  $(2, 2, \dots)$  and  $(2, 3, 2, 3, \dots)$ , respectively. Finally, in the case of  $L = 2$ , there are three  $(\mathbf{Q}, q)$ -minimal sets of two-paths, namely,  $\{222\}$ ,  $\{223, 232, 322\}$ , and  $\{232, 323\}$ ; the minimal switching sequences associated with them are  $(2, 2, \dots)$ ,  $(2, 2, 3, 2, 2, 3, \dots)$ , and  $(2, 3, 2, 3, \dots)$ , respectively. We have that

$$\begin{aligned}\mathcal{N}_0(\mathbf{Q}, q) &= \{1, 2, 3\}, \\ \mathcal{N}_1(\mathbf{Q}, q) &= \{22, 23, 32\}, \\ \mathcal{N}_2(\mathbf{Q}, q) &= \{222, 223, 232, 322, 323\}. \quad \square\end{aligned}$$

**THEOREM 3.7.** *Let  $\mathcal{G}$  be as in (3.1); let  $(\mathbf{Q}, q)$  be a row-allowable pair. The system  $(\mathcal{G}, \Theta(\mathbf{Q}, q))$  is uniformly exponentially stable and satisfies uniform average output regulation level  $\gamma > 0$  if and only if there exist a nonnegative integer  $M$  and an indexed family  $\{\mathbf{Y}_j : j \in \mathcal{M}_M^-(\mathbf{Q}, q)\}$  of symmetric positive definite matrices  $\mathbf{Y}_j \in \mathbb{R}^{n \times n}$  such that*

$$(3.9a) \quad \mathbf{A}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{A}_{i_M}^T - \mathbf{Y}_{(i_0, \dots, i_M)_+} < -\mathbf{B}_{i_M} \mathbf{B}_{i_M}^T$$

for all  $M$ -paths  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ , and

$$(3.9b) \quad \frac{1}{N_{\mathcal{N}}} \sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr}(\mathbf{C}_{k_M} \mathbf{Y}_{(k_0, \dots, k_M)_-} \mathbf{C}_{k_M}^T + \mathbf{D}_{k_M} \mathbf{D}_{k_M}^T) < \gamma^2$$

for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, where  $N_{\mathcal{N}}$  is the cardinality of  $\mathcal{N}$ .

*Proof.* To show necessity, suppose that  $(\mathcal{G}, \Theta(\mathbf{Q}, q))$  is uniformly stable and that there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that (3.4) holds. For  $\varepsilon > 0$ , consider the perturbed system  $(\mathcal{G}^{(\varepsilon)}, \Theta(\mathbf{Q}, q))$ , where  $\mathcal{G}^{(\varepsilon)}$  is as in (3.8). Write the output that  $(\mathcal{G}^{(\varepsilon)}, \Theta(\mathbf{Q}, q))$  generates under  $x(0) = 0$  and  $\mathbf{w} = (w^{(0)}(0), w^{(0)}(1), \dots)$  as  $\mathbf{z} = (z^{(\varepsilon, 0)}(0), z^{(\varepsilon, 0)}(1), \dots)$ , and let  $\mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \geq \mathbf{0}$  be the solution to

$$\mathbf{A}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \mathbf{A}_{\theta(t)}^T - \mathbf{Y}_{\theta, t+1}^{(\varepsilon, 0)} = -\mathbf{B}_{\theta(t)}^{(\varepsilon)} \mathbf{B}_{\theta(t)}^{(\varepsilon)T}$$

for  $\theta \in \Theta(\mathbf{Q}, q)$  and  $t \geq 0$ , with the initial condition  $\mathbf{Y}_{\theta, 0}^{(\varepsilon, 0)} = \mathbf{0}$ , so that

$$\limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(\varepsilon, 0)}(t)\|^2 = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \text{tr}(\mathbf{C}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)}^{(\varepsilon)} \mathbf{D}_{\theta(t)}^{(\varepsilon)T}).$$

Then it follows from the proof of the necessity part of Theorem 3.6 that, for a sufficiently small  $\varepsilon > 0$ , there are a nonnegative integer  $M$  and an indexed family of matrices  $\mathbf{Y}_j > \mathbf{0}$ ,  $j \in \mathcal{L}_M^-(\Theta)$ , such that

$$\mathbf{A}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{A}_{i_M}^T - \mathbf{Y}_{(i_0, \dots, i_M)_+} < -\mathbf{B}_{i_M} \mathbf{B}_{i_M}^T$$

for  $(i_0, \dots, i_M) \in \mathcal{L}_M(\mathbf{Q}, q)$ , and such that

$$(3.10) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \text{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{(\theta(t-M), \dots, \theta(t))_-} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T) < \gamma^2$$

for all  $\theta \in \Theta(\mathbf{Q}, q)$ . Since  $\mathcal{M}_M(\mathbf{Q}, q) \subset \mathcal{L}_M(\mathbf{Q}, q)$ , we have that (3.9a) holds for  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ . Choose any  $(\mathbf{Q}, q)$ -minimal set  $\mathcal{N}$  of  $M$ -paths and a  $(\mathbf{Q}, q)$ -minimal switching sequence  $\theta$  associated with  $\mathcal{N}$ . If  $\tau_0$  is any integer satisfying  $\tau_0 N_{\mathcal{N}} \geq M$ , where  $N_{\mathcal{N}}$  is the cardinality of  $\mathcal{N}$ , then

$$(3.11) \quad \sum_{t=\tau_0 N_{\mathcal{N}}}^{(\tau_0+1)N_{\mathcal{N}}-1} \text{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{(\theta(t-M), \dots, \theta(t))_-} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T) \\ = \sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr} (\mathbf{C}_{k_M} \mathbf{Y}_{(k_0, \dots, k_M)_-} \mathbf{C}_{k_M}^T + \mathbf{D}_{k_M} \mathbf{D}_{k_M}^T).$$

Since the left-hand side of the established inequality (3.10) is equal to

$$\lim_{\tau \rightarrow \infty} \frac{1}{(\tau - \tau_0)N_{\mathcal{N}}} \sum_{t=\tau_0 N_{\mathcal{N}}}^{\tau N_{\mathcal{N}}-1} \text{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{(\theta(t-M), \dots, \theta(t))_-} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T)$$

for the chosen  $\theta$ , equality (3.11) implies that (3.9b) holds.

Conversely, to show sufficiency, suppose that (3.9) holds for some integer  $M \geq 0$ , for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ , and for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths. Then, due to the proof of the sufficiency part of Theorem 3.6, we have that the system  $(\mathcal{G}, \Theta(\mathbf{Q}, q))$  is uniformly stable. Choose any  $\theta \in \Theta(\mathbf{Q}, q)$ . Then, since the set  $\mathcal{L}_M(\mathbf{Q}, q)$  is finite, there exists an  $M$ -path  $(i_0, \dots, i_M) \in \{1, \dots, N\}^{M+1}$  that occurs infinitely many times in  $\theta$ . Let  $(t_1, t_2, \dots)$  be a sequence of time instants with  $t_1 \geq M$  such that  $(\theta(t_j - M), \dots, \theta(t_j)) = (i_0, \dots, i_M)$  for  $j = 1, 2, \dots$ . Then the set of  $M$ -paths

$$(3.12) \quad (\theta(t_j - M), \dots, \theta(t_j)), \quad (\theta(t_j - M + 1), \dots, \theta(t_j + 1)), \quad \dots, \\ (\theta(t_{j+1} - M - 1), \dots, \theta(t_{j+1} - 1))$$

is  $(\mathbf{Q}, q)$ -admissible for each  $j$ . We will show that there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that

$$(3.13) \quad \frac{1}{t_{r+1} - t_1} \sum_{t=t_1}^{t_{r+1}-1} \text{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{(\theta(t-M), \dots, \theta(t))_-} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T) \leq \tilde{\gamma}^2$$

for all  $r = 1, 2, \dots$ , so that part (c) of Lemma 2.3 establishes immediately that  $(\mathcal{G}, \Theta(\mathbf{Q}, q))$  satisfies uniform average output variance level  $\gamma$ . Let  $\mathcal{N}_1, \dots, \mathcal{N}_k$  be all the distinct  $(\mathbf{Q}, q)$ -minimal sets of  $M$ -paths, and denote the cardinality of  $\mathcal{N}_i$  by  $N_i$ . Define

$$c_i = \sum_{(k_0, \dots, k_M) \in \mathcal{N}_i} \text{tr} (\mathbf{C}_{k_M} \mathbf{Y}_{(k_0, \dots, k_M)_-} \mathbf{C}_{k_M}^T + \mathbf{D}_{k_M} \mathbf{D}_{k_M}^T)$$

for  $i = 1, \dots, k$ . For each  $j$  there are nonnegative integers  $\tau_1(j), \dots, \tau_k(j)$  such that the set of  $M$ -paths in (3.12), counting multiplicity, is the union of exactly  $\tau_i(j)$   $\mathcal{N}_i$ 's

over all  $i$ , so that

$$t_{j+1} - t_j = \sum_{i=1}^k \tau_i(j) N_i;$$

otherwise, the condition  $(\theta(t_j - M), \dots, \theta(t_j)) = (\theta(t_{j+1} - M), \dots, \theta(t_{j+1}))$ , which implies that the set of  $M$ -paths in (3.12) is  $(\mathbf{Q}, q)$ -admissible, would not hold. Thus the left-hand side of the desired inequality (3.13) is precisely equal to

$$\frac{1}{\sum_{i=1}^k \sum_{j=1}^r \tau_i(j) N_i} \sum_{i=1}^k \sum_{j=1}^r \tau_i(j) c_i$$

for all  $r = 1, 2, \dots$ . Here, since (3.9b) holds for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that  $c_i/N_i \leq \tilde{\gamma}^2$  for all  $i$ . This shows that, indeed, inequality (3.13) holds for all  $r$ .  $\square$

*Remark 3.* The semidefinite program that minimizes  $\gamma^2$  over all path lengths  $M$  subject to the linear matrix inequalities (3.6), (3.7), or (3.9) gives the best performance level that the system satisfies. A potential difficulty is that the computational burden grows exponentially in  $M$  in the worst case. However, the required path length  $M$  that achieves the minimum value of  $\gamma$  up to a reasonable tolerance level is often small. See Examples 5 and 6; see also the remarks and examples in [34, 33].

*Example 4.* Let  $(\mathbf{Q}, q)$ , and hence  $\Theta(\mathbf{Q}, q)$ , be as in Example 3. The condition that (3.9b) holds for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, where  $M = 0$  for instance, reads that

$$\text{tr}(\mathbf{C}_i \mathbf{Y}_0 \mathbf{C}_i^T + \mathbf{D}_i \mathbf{D}_i^T) < \gamma^2$$

for all  $i = 1, 2, 3$  and for a single  $\mathbf{Y}_0 > \mathbf{0}$ . If  $M = 1$ , then the condition reads that

$$\text{tr}(\mathbf{C}_2 \mathbf{Y}_2 \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T) < \gamma^2,$$

$$\text{tr}(\mathbf{C}_3 \mathbf{Y}_2 \mathbf{C}_3^T + \mathbf{D}_3 \mathbf{D}_3^T + \mathbf{C}_2 \mathbf{Y}_3 \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T) < 2\gamma^2$$

for some  $\mathbf{Y}_2, \mathbf{Y}_3 > \mathbf{0}$ . Finally, if  $M = 2$ , then the condition becomes that

$$\text{tr}(\mathbf{C}_2 \mathbf{Y}_{(2,2)} \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T) < \gamma^2,$$

$$\text{tr}(\mathbf{C}_3 \mathbf{Y}_{(2,2)} \mathbf{C}_3^T + \mathbf{D}_3 \mathbf{D}_3^T + \mathbf{C}_2 \mathbf{Y}_{(2,3)} \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T + \mathbf{C}_2 \mathbf{Y}_{(3,2)} \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T) < 3\gamma^2,$$

$$\text{tr}(\mathbf{C}_2 \mathbf{Y}_{(2,3)} \mathbf{C}_2^T + \mathbf{D}_2 \mathbf{D}_2^T + \mathbf{C}_3 \mathbf{Y}_{(3,2)} \mathbf{C}_3^T + \mathbf{D}_3 \mathbf{D}_3^T) < 2\gamma^2$$

for some  $\mathbf{Y}_{(2,2)}, \mathbf{Y}_{(2,3)}, \mathbf{Y}_{(3,2)} > \mathbf{0}$ .  $\square$

**4. Control of switched linear systems.** In this section, we will give an exact synthesis condition for controlling the average output variance level. Then we will remark only briefly on the controller synthesis for minimizing the peak impulse response and peak output variance. Consider the set

$$(4.1) \quad \mathcal{T} = \{(\mathbf{A}_i, \mathbf{B}_{1,i}, \mathbf{B}_{2,i}, \mathbf{C}_{1,i}, \mathbf{C}_{2,i}, \mathbf{D}_{11,i}, \mathbf{D}_{12,i}, \mathbf{D}_{21,i}) : i = 1, \dots, N\}$$

with  $\mathbf{A}_i \in \mathbb{R}^{n \times n}$ ,  $\mathbf{B}_{1,i} \in \mathbb{R}^{n \times m_1}$ ,  $\mathbf{B}_{2,i} \in \mathbb{R}^{n \times m_2}$ ,  $\mathbf{C}_{1,i} \in \mathbb{R}^{l_1 \times n}$ ,  $\mathbf{C}_{2,i} \in \mathbb{R}^{l_2 \times n}$ ,  $\mathbf{D}_{11,i} \in \mathbb{R}^{l_1 \times m_1}$ ,  $\mathbf{D}_{12,i} \in \mathbb{R}^{l_1 \times m_2}$ ,  $\mathbf{D}_{21,i} \in \mathbb{R}^{l_2 \times m_1}$  for  $i = 1, \dots, N$ . If  $(\mathbf{Q}, q)$  is a

row-allowable pair, then the pair  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$  defines the *controlled switched linear system* represented by

$$(4.2) \quad \begin{aligned} x(t+1) &= \mathbf{A}_{\theta(t)}x(t) + \mathbf{B}_{1,\theta(t)}w(t) + \mathbf{B}_{2,\theta(t)}u(t), \\ z(t) &= \mathbf{C}_{1,\theta(t)}x(t) + \mathbf{D}_{11,\theta(t)}w(t) + \mathbf{D}_{12,\theta(t)}u(t), \\ y(t) &= \mathbf{C}_{2,\theta(t)}x(t) + \mathbf{D}_{21,\theta(t)}w(t). \end{aligned}$$

Given the initial state  $x(0)$ , disturbance sequence  $\mathbf{w} = (w(0), w(1), \dots)$ , control sequence  $\mathbf{u} = (u(0), u(1), \dots)$ , and switching sequence  $\boldsymbol{\theta} = (\theta(0), \theta(1), \dots) \in \Theta(\mathbf{Q}, q)$ , this system of equations defines the evolution of the state  $x(t)$ , controlled output  $z(t)$ , and measured output  $y(t)$  for  $t \geq 0$ .

We make the standard assumption that *the mode  $\theta(t)$  is perfectly observed at each time instant  $t$* . Also, as in [34, 33], we consider all controllers that have finite memory of past modes and make perfect observation of the present mode. Fix a nonnegative integer  $L$ . Let

$$\Theta_L(\mathbf{Q}, q) = \{\boldsymbol{\theta}_L : \boldsymbol{\theta} \in \Theta(\mathbf{Q}, q)\}$$

be the set of  $L$ -path switching sequences generated by  $(\mathbf{Q}, q)$ ; let

$$\mathcal{K} = \{(\mathbf{A}_{K,i}, \mathbf{B}_{K,i}, \mathbf{C}_{K,i}, \mathbf{D}_{K,i}) : i \in \mathcal{L}_L(\mathbf{Q}, q)\}$$

with  $\mathbf{A}_{K,i} \in \mathbb{R}^{n_K \times n_K}$ ,  $\mathbf{B}_{K,i} \in \mathbb{R}^{n_K \times l_2}$ ,  $\mathbf{C}_{K,i} \in \mathbb{R}^{m_2 \times n_K}$ ,  $\mathbf{D}_{K,i} \in \mathbb{R}^{m_2 \times l_2}$  for  $i \in \mathcal{L}_L(\mathbf{Q}, q)$ . Then the pair  $(\mathcal{K}, \Theta_L(\mathbf{Q}, q))$  defines the  $L$ -path-dependent (linear feedback) controller (of order  $n_K$ ), which determines the control sequence  $\mathbf{u}$  according to

$$(4.3) \quad \begin{aligned} x_K(t+1) &= \mathbf{A}_{K,\theta_L(t)}x_K(t) + \mathbf{B}_{K,\theta_L(t)}y(t), \\ u(t) &= \mathbf{C}_{K,\theta_L(t)}x_K(t) + \mathbf{D}_{K,\theta_L(t)}y(t) \end{aligned}$$

given the initial controller state  $x_K(0)$  and  $L$ -path switching sequence  $\boldsymbol{\theta}_L \in \Theta_L(\mathbf{Q}, q)$ . Controllers that are  $L$ -path dependent for some nonnegative integer  $L$  shall be said to be *finite-path dependent*; zero-path-dependent controllers are called *mode dependent*. The dependence of these controllers on the past measurements  $y(0), \dots, y(t)$  at each time instant  $t$  is encoded in the partition

$$\mathbf{K}_i = \begin{bmatrix} \mathbf{A}_{K,i} & \mathbf{B}_{K,i} \\ \mathbf{C}_{K,i} & \mathbf{D}_{K,i} \end{bmatrix} \in \mathbb{R}^{(n_K+m_2) \times (n_K+l_2)}$$

for  $i \in \mathcal{L}_L(\mathbf{Q}, q)$ .

For our purpose, the set  $\mathcal{K}$  can be replaced by the smaller set

$$\tilde{\mathcal{K}} = \{(\mathbf{A}_{K,i}, \mathbf{B}_{K,i}, \mathbf{C}_{K,i}, \mathbf{D}_{K,i}) : i \in \mathcal{M}_L(\mathbf{Q}, q)\},$$

and the pair  $(\tilde{\mathcal{K}}, \Theta_L(\mathbf{Q}, q))$  shall also be called an  $L$ -path-dependent controller. The reason is that one can always recover  $\mathcal{K}$  from  $\tilde{\mathcal{K}}$ ; this point will become clear later in this section.

Given a finite-path-dependent controller  $(\mathcal{K}, \Theta_L(\mathbf{Q}, q))$ , where  $L$  is the path length, let

$$\begin{aligned} \tilde{\mathbf{A}}_i &= \hat{\mathbf{A}}_{i_L} + \hat{\mathbf{B}}_{2,i_L} \mathbf{K}_i \hat{\mathbf{C}}_{2,i_L}, & \tilde{\mathbf{B}}_i &= \hat{\mathbf{B}}_{1,i_L} + \hat{\mathbf{B}}_{2,i_L} \mathbf{K}_i \hat{\mathbf{D}}_{21,i_L}, \\ \tilde{\mathbf{C}}_i &= \hat{\mathbf{C}}_{1,i_L} + \hat{\mathbf{D}}_{12,i_L} \mathbf{K}_i \hat{\mathbf{C}}_{2,i_L}, & \tilde{\mathbf{D}}_i &= \mathbf{D}_{11,i_L} + \hat{\mathbf{D}}_{12,i_L} \mathbf{K}_i \hat{\mathbf{D}}_{21,i_L} \end{aligned}$$

for  $\mathbf{i} = (i_0, \dots, i_L) \in \mathcal{L}_L(\mathbf{Q}, q)$ , with

$$\begin{aligned}\widehat{\mathbf{A}}_i &= \begin{bmatrix} \mathbf{A}_i & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} \in \mathbb{R}^{(n+n_K) \times (n+n_K)}, \\ \widehat{\mathbf{B}}_{1,i} &= \begin{bmatrix} \mathbf{B}_{1,i} \\ \mathbf{0} \end{bmatrix} \in \mathbb{R}^{(n+n_K) \times m_1}, \quad \widehat{\mathbf{B}}_{2,i} = \begin{bmatrix} \mathbf{0} & \mathbf{B}_{2,i} \\ \mathbf{I} & \mathbf{0} \end{bmatrix} \in \mathbb{R}^{(n+n_K) \times (n_K+m_2)}, \\ \widehat{\mathbf{C}}_{1,i} &= [\mathbf{C}_{1,i} \quad \mathbf{0}] \in \mathbb{R}^{l_1 \times (n+n_K)}, \quad \widehat{\mathbf{C}}_{2,i} = \begin{bmatrix} \mathbf{0} & \mathbf{I} \\ \mathbf{C}_{2,i} & \mathbf{0} \end{bmatrix} \in \mathbb{R}^{(n_K+l_2) \times (n+n_K)}, \\ \widehat{\mathbf{D}}_{12,i} &= [\mathbf{0} \quad \mathbf{D}_{12,i}] \in \mathbb{R}^{l_1 \times (n_K+m_2)}, \quad \widehat{\mathbf{D}}_{21,i} = \begin{bmatrix} \mathbf{0} \\ \mathbf{D}_{21,i} \end{bmatrix} \in \mathbb{R}^{(n_K+l_2) \times m_1}\end{aligned}$$

for  $i \in \{1, \dots, N\}$ . Let

$$\mathcal{T}_{\mathcal{K}} = \{(\tilde{\mathbf{A}}_{\mathbf{i}}, \tilde{\mathbf{B}}_{\mathbf{i}}, \tilde{\mathbf{C}}_{\mathbf{i}}, \tilde{\mathbf{D}}_{\mathbf{i}}) : \mathbf{i} \in \mathcal{L}_L(\mathbf{Q}, q)\}.$$

If we define the closed-loop state by

$$\tilde{x}(t) = [x(t)^T \ x_K(t)^T]^T \in \mathbb{R}^{n+n_K},$$

then the *closed-loop system*  $(\mathcal{T}_{\mathcal{K}}, \Theta_L(\mathbf{Q}, q))$  has the representation

$$\begin{aligned}(4.4) \quad \tilde{x}(t+1) &= \tilde{\mathbf{A}}_{\theta_L(t)} \tilde{x}(t) + \tilde{\mathbf{B}}_{\theta_L(t)} w(t), \\ z(t) &= \tilde{\mathbf{C}}_{\theta_L(t)} \tilde{x}(t) + \tilde{\mathbf{D}}_{\theta_L(t)} w(t)\end{aligned}$$

for each  $L$ -path switching sequence  $\theta_L \in \Theta_L(\mathbf{Q}, q)$ .

If  $N_L$  is the cardinality of  $\mathcal{L}_L(\mathbf{Q}, q)$ , then there exists a one-to-one correspondence  $f: \mathcal{L}_L(\mathbf{Q}, q) \rightarrow \{1, \dots, N_L\}$ . Label each element of  $\mathcal{L}_L(\mathbf{Q}, q)$  with its image under such an  $f$ . Then each  $L$ -path switching sequence  $\theta_L = (\theta_L(0), \theta_L(1), \dots) \in \Theta_L(\mathbf{Q}, q)$  is mapped to, and hence can be considered to be, a *closed-loop switching sequence* belonging to the set of infinite sequences in  $\{1, \dots, N_L\}$ . On the other hand, if we set  $\theta_L(t) = 0$  for  $t < 0$ , then there is a one-to-one correspondence  $g$  that maps the *closed-loop switching path*  $(\theta_L(t-M), \dots, \theta_L(t))$  to the switching path  $(\theta(t-L-M), \dots, \theta(t))$  of length  $L+M$  for each triple  $(t, L, M)$  of nonnegative integers. In summary, we have the following identities for all integers  $L > 0$  and  $M \geq 0$ :

$$(4.5) \quad \mathcal{M}_M(\Theta_L(\mathbf{Q}, q)) = \mathcal{L}_M(\Theta_L(\mathbf{Q}, q)) = \mathcal{L}_{M+L}(\mathbf{Q}, q).$$

Here, the first identity is due to the mapping  $f$ , and the second identity due to  $g$ . Hence, even if  $L > 0$ , the closed-loop system  $(\mathcal{T}_{\mathcal{K}}, \Theta_L(\mathbf{Q}, q))$  is a switched linear system, where the *closed-loop modes* are the  $L$ -paths in  $\mathcal{L}_L(\mathbf{Q}, q)$ , and the *closed-loop  $M$ -paths* are the  $(M+L)$ -paths in  $\mathcal{L}_{M+L}(\mathbf{Q}, q)$  for each nonnegative integer  $M$ .

**DEFINITION 4.1.** *Let  $\gamma > 0$ . The controller  $(\mathcal{K}, \Theta_L(\mathbf{Q}, q))$  is said to be a  $\gamma$ -admissible ( $L$ -path-dependent) synthesis (of order  $n_K$ ) for the system  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$  if the closed-loop system  $(\mathcal{T}_{\mathcal{K}}, \Theta_L(\mathbf{Q}, q))$  is uniformly exponentially stable and satisfies uniform average output regulation level  $\gamma$ .*

If  $(\mathcal{K}, \Theta_L(\mathbf{Q}, q))$  is an  $\gamma$ -admissible synthesis for  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$ , then it follows from Theorem 3.7 and identity (4.5) that there exist a nonnegative integer  $M \geq L$  and matrices  $\mathbf{Y}_j > \mathbf{0}$  such that

$$\tilde{\mathbf{A}}_{(i_{M-L}, \dots, i_M)} \mathbf{Y}_{(i_0, \dots, i_M)-} \tilde{\mathbf{A}}_{(i_{M-L}, \dots, i_M)}^T - \mathbf{Y}_{(i_0, \dots, i_M)+} < -\tilde{\mathbf{B}}_{(i_{M-L}, \dots, i_M)} \tilde{\mathbf{B}}_{(i_{M-L}, \dots, i_M)}^T$$

for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ , and

$$\begin{aligned} \frac{1}{N_{\mathcal{N}}} \sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr} \left( \tilde{\mathbf{C}}_{(k_{M-L}, \dots, k_M)} \mathbf{Y}_{(k_0, \dots, k_M)-} \tilde{\mathbf{C}}_{(k_{M-L}, \dots, k_M)}^T \right. \\ \left. + \tilde{\mathbf{D}}_{(k_{M-L}, \dots, k_M)} \tilde{\mathbf{D}}_{(k_{M-L}, \dots, k_M)}^T \right) < \gamma^2 \end{aligned}$$

for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, where  $N_{\mathcal{N}}$  is the cardinality of  $\mathcal{N}$ . A Schur complement argument gives that this condition is equivalent to the requirement that

$$(4.6a) \quad \begin{bmatrix} -\mathbf{Y}_{(i_0, \dots, i_M)-}^{-1} & \tilde{\mathbf{A}}_{(i_{M-L}, \dots, i_M)}^T & \mathbf{0} \\ \tilde{\mathbf{A}}_{(i_{M-L}, \dots, i_M)} & -\mathbf{Y}_{(i_0, \dots, i_M)+} & \tilde{\mathbf{B}}_{(i_{M-L}, \dots, i_M)} \\ \mathbf{0} & \tilde{\mathbf{B}}_{(i_{M-L}, \dots, i_M)}^T & -\mathbf{I} \end{bmatrix} < \mathbf{0},$$

$$(4.6b) \quad \begin{bmatrix} -\mathbf{Y}_{(j_0, \dots, j_M)-}^{-1} & \tilde{\mathbf{C}}_{(j_{M-L}, \dots, j_M)}^T & \mathbf{0} \\ \tilde{\mathbf{C}}_{(j_{M-L}, \dots, j_M)} & -\mathbf{Z}_{(j_0, \dots, j_M)} & \tilde{\mathbf{D}}_{(j_{M-L}, \dots, j_M)} \\ \mathbf{0} & \tilde{\mathbf{D}}_{(j_{M-L}, \dots, j_M)}^T & -\mathbf{I} \end{bmatrix} < \mathbf{0},$$

and  $\sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr} \mathbf{Z}_{(k_0, \dots, k_M)} < \gamma^2 N_{\mathcal{N}}$  for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ , for all  $(j_0, \dots, j_M) \in \mathcal{N}_M(\mathbf{Q}, q)$ , and for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths. Partition  $\mathbf{Y}_j^{-1}$  and  $\mathbf{Y}_j$ ,  $j \in \mathcal{M}_M(\mathbf{Q}, q)$ , as

$$\mathbf{Y}_j^{-1} = \begin{bmatrix} \mathbf{S}_j & \mathbf{U}_j \\ \mathbf{U}_j^T & * \end{bmatrix}, \quad \mathbf{Y}_j = \begin{bmatrix} \mathbf{R}_j & \mathbf{T}_j \\ \mathbf{T}_j^T & * \end{bmatrix},$$

where  $\mathbf{S}_j, \mathbf{R}_j \in \mathbb{R}^{n \times n}$  and  $\mathbf{U}_j, \mathbf{T}_j \in \mathbb{R}^{n \times n_K}$ . Adopting the change of variable technique in [43], define

$$(4.7) \quad \begin{bmatrix} \mathbf{W}_{11, \mathbf{i}} & \mathbf{W}_{12, \mathbf{i}} \\ \mathbf{W}_{21, \mathbf{i}} & \mathbf{W}_{22, \mathbf{i}} \end{bmatrix} = \begin{bmatrix} \mathbf{S}_{\mathbf{i}_+} \mathbf{A}_{i_M} \mathbf{R}_{\mathbf{i}_-} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{bmatrix} + \begin{bmatrix} \mathbf{U}_{\mathbf{i}_+} & \mathbf{S}_{\mathbf{i}_+} \mathbf{B}_{2, i_M} \\ \mathbf{0} & \mathbf{I} \end{bmatrix} \\ \times \begin{bmatrix} \mathbf{A}_{K, (i_{M-L}, \dots, i_M)} & \mathbf{B}_{K, (i_{M-L}, \dots, i_M)} \\ \mathbf{C}_{K, (i_{M-L}, \dots, i_M)} & \mathbf{D}_{K, (i_{M-L}, \dots, i_M)} \end{bmatrix} \begin{bmatrix} \mathbf{T}_{\mathbf{i}_-}^T & \mathbf{0} \\ \mathbf{C}_{2, i_M} \mathbf{R}_{\mathbf{i}_-} & \mathbf{I} \end{bmatrix}$$

for  $\mathbf{i} = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ . Let

$$\mathbf{M}_{X, \mathbf{i}_+} = \begin{bmatrix} \mathbf{I} & \mathbf{S}_{\mathbf{i}_+} \\ \mathbf{0} & \mathbf{U}_{\mathbf{i}_+}^T \end{bmatrix}, \quad \mathbf{M}_{Y, \mathbf{i}_-} = \begin{bmatrix} \mathbf{I} & \mathbf{R}_{\mathbf{i}_-} \\ \mathbf{0} & \mathbf{T}_{\mathbf{i}_-}^T \end{bmatrix}$$

for all  $\mathbf{i} \in \mathcal{M}_M(\mathbf{Q}, q)$ . If  $n_K = n$ , and if  $\mathbf{U}_{\mathbf{i}_+}$  and  $\mathbf{T}_{\mathbf{i}_-}$  are both invertible, then the change of variable given by (4.7) together with the congruence transformation with

$\mathbf{M}_{Y,i_-} \oplus \mathbf{M}_{X,i_+} \oplus \mathbf{I}$  and  $\mathbf{M}_{Y,i_-} \oplus \mathbf{I} \oplus \mathbf{I}$  on inequalities (4.6a) and (4.6b), respectively, leads to linear matrix inequalities, and we obtain the following result.

**THEOREM 4.2.** *Let  $\mathcal{T}$  be as in (4.1); let  $(\mathbf{Q}, q)$  be a row-allowable pair. Suppose that  $n_K \geq n$  and  $\gamma > 0$ . There exists a  $\gamma$ -admissible finite-path-dependent synthesis of order  $n_K$  for the system  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$  if and only if there exist a nonnegative integer  $M$  and indexed families  $\{(\mathbf{R}_j, \mathbf{S}_j) : j \in \mathcal{M}_M^-(\mathbf{Q}, q)\}$  and  $\{(\mathbf{Z}_i, \mathbf{W}_i) : i \in \mathcal{N}_M(\mathbf{Q}, q)\}$  of symmetric matrices  $\mathbf{R}_j \in \mathbb{R}^{n \times n}$ ,  $\mathbf{S}_j \in \mathbb{R}^{n \times n}$ ,  $\mathbf{Z}_i \in \mathbb{R}^{l_1 \times l_1}$  and rectangular matrices  $\mathbf{W}_i \in \mathbb{R}^{(n+m_2) \times (n+l_2)}$  such that*

$$(4.8a) \quad \mathbf{H}_i + \mathbf{F}_{i_M}^T \mathbf{W}_i \mathbf{G}_{i_M} + \mathbf{G}_{i_M}^T \mathbf{W}_i^T \mathbf{F}_{i_M} < \mathbf{0}$$

for all  $M$ -paths  $i = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ ,

$$(4.8b) \quad \hat{\mathbf{H}}_i + \hat{\mathbf{F}}_{i_M}^T \mathbf{W}_i \hat{\mathbf{G}}_{i_M} + \hat{\mathbf{G}}_{i_M}^T \mathbf{W}_i^T \hat{\mathbf{F}}_{i_M} < \mathbf{0}$$

for all  $M$ -paths  $i = (i_0, \dots, i_M) \in \mathcal{N}_M(\mathbf{Q}, q)$ , and

$$(4.8c) \quad \frac{1}{N_{\mathcal{N}}} \sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr } \mathbf{Z}_{(k_0, \dots, k_M)} < \gamma^2$$

for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, where  $N_{\mathcal{N}}$  is the cardinality of  $\mathcal{N}$ , and

$$\mathbf{H}_i = \begin{bmatrix} -\mathbf{S}_{i_-} & -\mathbf{I} & \mathbf{A}_{i_M}^T & \mathbf{A}_{i_M}^T \mathbf{S}_{i_+} & \mathbf{0} \\ -\mathbf{I} & -\mathbf{R}_{i_-} & \mathbf{R}_{i_-} \mathbf{A}_{i_M}^T & \mathbf{0} & \mathbf{0} \\ \mathbf{A}_{i_M} & \mathbf{A}_{i_M} \mathbf{R}_{i_-} & -\mathbf{R}_{i_+} & -\mathbf{I} & \mathbf{B}_{1,i_M} \\ \mathbf{S}_{i_+} \mathbf{A}_{i_M} & \mathbf{0} & -\mathbf{I} & -\mathbf{S}_{i_+} & \mathbf{S}_{i_+} \mathbf{B}_{1,i_M} \\ \mathbf{0} & \mathbf{0} & \mathbf{B}_{1,i_M}^T & \mathbf{B}_{1,i_M}^T \mathbf{S}_{i_+} & -\mathbf{I} \end{bmatrix},$$

$$\mathbf{F}_{i_M} = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{I} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{B}_{2,i_M}^T & \mathbf{0} & \mathbf{0} \end{bmatrix}, \quad \mathbf{G}_{i_M} = \begin{bmatrix} \mathbf{0} & \mathbf{I} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{C}_{2,i_M} & \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{D}_{21,i_M} \end{bmatrix},$$

$$\hat{\mathbf{H}}_i = \begin{bmatrix} -\mathbf{S}_{i_-} & -\mathbf{I} & \mathbf{C}_{1,i_M}^T & \mathbf{0} \\ -\mathbf{I} & -\mathbf{R}_{i_-} & \mathbf{R}_{i_-} \mathbf{C}_{1,i_M}^T & \mathbf{0} \\ \mathbf{C}_{1,i_M} & \mathbf{C}_{1,i_M} \mathbf{R}_{i_-} & -\mathbf{Z}_i & \mathbf{D}_{11,i_M} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_{11,i_M}^T & -\mathbf{I} \end{bmatrix},$$

$$\hat{\mathbf{F}}_{i_M} = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{D}_{12,i_M}^T & \mathbf{0} \end{bmatrix}, \quad \hat{\mathbf{G}}_{i_M} = \begin{bmatrix} \mathbf{0} & \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{C}_{2,i_M} & \mathbf{0} & \mathbf{0} & \mathbf{D}_{21,i_M} \end{bmatrix}$$

for all  $i = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ . Moreover, if this condition is satisfied, then given any nonsingular matrices  $\mathbf{T}_j, \mathbf{U}_j \in \mathbb{R}^{n \times n}$  such that

$$(4.9) \quad \mathbf{T}_j \mathbf{U}_j^T = \mathbf{I} - \mathbf{R}_j \mathbf{S}_j$$

for all  $j \in \mathcal{M}_M^-(\mathbf{Q}, q)$ , and

$$\mathbf{W}_i = \begin{bmatrix} \mathbf{W}_{11,i} & \mathbf{W}_{12,i} \\ \mathbf{W}_{21,i} & \mathbf{W}_{22,i} \end{bmatrix}$$

with  $\mathbf{W}_{11,\mathbf{i}} \in \mathbb{R}^{n \times n}$ ,  $\mathbf{W}_{12,\mathbf{i}} \in \mathbb{R}^{n \times l_2}$ ,  $\mathbf{W}_{21,\mathbf{i}} \in \mathbb{R}^{m_2 \times n}$ , and  $\mathbf{W}_{22,\mathbf{i}} \in \mathbb{R}^{m_2 \times l_2}$ , a  $\gamma$ -admissible  $M$ -path-dependent synthesis of order  $n$  is obtained by solving (4.7), with  $n_K = n$  and  $L = M$ , for matrices  $\mathbf{A}_{K,\mathbf{i}}$ ,  $\mathbf{B}_{K,\mathbf{i}}$ ,  $\mathbf{C}_{K,\mathbf{i}}$ ,  $\mathbf{D}_{K,\mathbf{i}}$ ,  $\mathbf{i} \in \mathcal{M}_M(\mathbf{Q}, q)$ .

*Proof.* The proof is essentially the same as the change of variables argument in [43, section IV-B] once we note that

$$\begin{aligned} \mathbf{M}_{X,\mathbf{i}_+}^T \mathbf{Y}_{\mathbf{i}_+} \mathbf{M}_{X,\mathbf{i}_+} &= \begin{bmatrix} \mathbf{R}_{\mathbf{i}_+} & \mathbf{I} \\ \mathbf{I} & \mathbf{S}_{\mathbf{i}_+} \end{bmatrix}, \quad \mathbf{M}_{Y,\mathbf{i}_-}^T \mathbf{Y}_{\mathbf{i}_-}^{-1} \mathbf{M}_{Y,\mathbf{i}_-} = \begin{bmatrix} \mathbf{S}_{\mathbf{i}_-} & \mathbf{I} \\ \mathbf{I} & \mathbf{R}_{\mathbf{i}_-} \end{bmatrix}, \\ \mathbf{M}_{X,\mathbf{i}_+}^T \tilde{\mathbf{A}}_{\mathbf{i}} \mathbf{M}_{Y,\mathbf{i}_-} &= \begin{bmatrix} \mathbf{A}_{i_M} + \mathbf{B}_{2,i_M} \mathbf{W}_{22,\mathbf{i}} \mathbf{C}_{2,i_M} & \mathbf{A}_{i_M} \mathbf{R}_{\mathbf{i}_-} + \mathbf{B}_{2,i_M} \mathbf{W}_{21,\mathbf{i}} \\ \mathbf{S}_{\mathbf{i}_+} \mathbf{A}_{i_M} + \mathbf{W}_{12,\mathbf{i}} \mathbf{C}_{2,i_M} & \mathbf{W}_{11,\mathbf{i}} \end{bmatrix}, \\ \mathbf{M}_{X,\mathbf{i}_+}^T \tilde{\mathbf{B}}_{\mathbf{i}} &= \begin{bmatrix} \mathbf{B}_{1,i_M} + \mathbf{B}_{2,i_M} \mathbf{W}_{22,\mathbf{i}} \mathbf{D}_{21,i_M} \\ \mathbf{S}_{\mathbf{i}_+} \mathbf{B}_{1,i_M} + \mathbf{W}_{12,\mathbf{i}} \mathbf{D}_{21,i_M} \end{bmatrix}, \\ \tilde{\mathbf{C}}_{\mathbf{i}} \mathbf{M}_{Y,\mathbf{i}_-} &= [\mathbf{C}_{1,i_M} + \mathbf{D}_{12,i_M} \mathbf{W}_{22,\mathbf{i}} \mathbf{C}_{2,i_M} \quad \mathbf{C}_{1,i_M} \mathbf{R}_{\mathbf{i}_-} + \mathbf{D}_{12,i_M} \mathbf{W}_{21,\mathbf{i}}], \\ \tilde{\mathbf{D}}_{\mathbf{i}} &= \mathbf{D}_{11,i_M} + \mathbf{D}_{12,i_M} \mathbf{W}_{22,\mathbf{i}} \mathbf{D}_{21,i_M}. \quad \square \end{aligned}$$

*Remark 4.* Since stability and average output regulation performance do not depend on the change in dynamics during any finite number of time instants, the set  $\mathcal{M}_M(\mathbf{Q}, q)$  in Theorem 4.2 can be replaced with  $\mathcal{N}_M(\mathbf{Q}, q)$ . However, using the bigger set  $\mathcal{M}_M(\mathbf{Q}, q)$  is convenient because it allows the control objective to be replaced or mixed with other performance measures such as the uniform output variance level (in Theorem 3.6) and the uniform disturbance attenuation level (considered in [33]), where every single time instant matters.

*Remark 5.* Theorem 3.6 suggests that the synthesis condition for the uniform output variance level control is similar to Theorem 4.2: let  $\gamma > 0$ ,  $n_K \geq n$ , and  $\Theta \subset \Omega$  be nonempty; there exists a finite-path-dependent controller for  $(\mathcal{T}, \Theta)$  such that the closed-loop system is uniformly exponentially stable and satisfies uniform output regulation level  $\gamma$  if and only if there exist a nonnegative integer  $M$  and indexed families  $\{(\mathbf{R}_j, \mathbf{S}_j) : j \in \mathcal{M}_M^-(\Theta)\}$  and  $\{(\mathbf{Z}_i, \mathbf{W}_i) : i \in \mathcal{N}_M(\Theta)\}$  of symmetric matrices  $\mathbf{R}_j$ ,  $\mathbf{S}_j$ ,  $\mathbf{Z}_i$  and rectangular matrices  $\mathbf{W}_i$  such that (4.8a) and  $\text{tr } \mathbf{Z}_i < \gamma^2$  hold for all  $M$ -paths  $\mathbf{i} = (i_0, \dots, i_M) \in \mathcal{M}_M(\Theta)$ , and (4.8b) holds for all  $M$ -paths  $\mathbf{i} = (i_0, \dots, i_M) \in \mathcal{N}_M(\Theta)$ . On the other hand, a condition analogous to this would lead to a synthesis condition for the uniform impulse response level control; however, Theorem 3.5 suggests that if  $M > 0$  in this case, the resulting controller would be required to anticipate future modes as well as observe the present mode.

Suppose that we have obtained a set of controller matrices  $\mathbf{K}_i$ ,  $i \in \mathcal{M}_L(\mathbf{Q}, q)$ , by applying Theorem 4.2. If  $L = 0$ , then it follows from  $\mathcal{M}_0(\mathbf{Q}, q) = \mathcal{L}_0(\mathbf{Q}, q)$  that we have all the matrices  $\mathbf{K}_i$ ,  $i \in \mathcal{L}_0(\mathbf{Q}, q)$ , that define an admissible mode-dependent controller synthesis. If  $L > 0$ , on the other hand, then choose switching paths  $(i_0^j, \dots, i_{L-1}^j) \in \{0, \dots, N\}^L$ ,  $j \in \mathcal{L}_0(\mathbf{Q}, q)$ , such that (3.5) holds for all  $\theta \in \Theta(\mathbf{Q}, q)$ , and put

$$\mathbf{K}_{\theta_L(t)} = \mathbf{K}_{(i_t^{\theta(0)}, \dots, i_{L-1}^{\theta(0)}, \theta(0), \dots, \theta(t))}$$

whenever  $\theta_L \in \Theta_L(\mathbf{Q}, q)$ ,  $t < L$ , and  $\theta_L(t) \notin \mathcal{M}_L(\mathbf{Q}, q)$ ; then we recover all matrices  $\mathbf{K}_i$ ,  $i \in \mathcal{L}_L(\mathbf{Q}, q)$ , that define an admissible  $L$ -path-dependent controller synthesis.

*Example 5.* Let  $\mathcal{T}$  be with  $N = 3$  and

$$\begin{aligned} \mathbf{A}_1 &= 0.5, \quad \mathbf{A}_2 = 1, \quad \mathbf{A}_3 = 0.5; \\ \mathbf{B}_{1,1} &= \mathbf{B}_{1,2} = \mathbf{B}_{1,3} = \begin{bmatrix} 1 & 0 \end{bmatrix}; \quad \mathbf{B}_{2,1} = 0, \quad \mathbf{B}_{2,2} = 1, \quad \mathbf{B}_{2,3} = 0; \\ \mathbf{C}_{1,1} &= \mathbf{C}_{1,2} = \mathbf{C}_{1,3} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}; \quad \mathbf{C}_{2,1} = \mathbf{C}_{2,2} = \mathbf{C}_{2,3} = 1; \\ \mathbf{D}_{11,1} &= \mathbf{D}_{11,2} = \mathbf{D}_{11,3} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}; \quad \mathbf{D}_{12,1} = \mathbf{D}_{12,2} = \mathbf{D}_{12,3} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}; \\ \mathbf{D}_{21,1} &= \begin{bmatrix} 1 & 0 \end{bmatrix}, \quad \mathbf{D}_{21,2} = \begin{bmatrix} 0 & 1 \end{bmatrix}, \quad \mathbf{D}_{21,3} = \begin{bmatrix} 0 & 1 \end{bmatrix}. \end{aligned}$$

Let

$$\mathbf{Q} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad q = \begin{bmatrix} 1 & 0 & 1 \end{bmatrix}.$$

For nonnegative integers  $M$ , denote by  $\gamma_M$  the infimum of  $\gamma > 0$  such that (4.8) holds for all  $M$ -paths  $\mathbf{i} = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$  and for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths. Then we find by numerical computation that  $1.4953 < \gamma_0 < 1.4954$  and  $1.2395 < \gamma_M < 1.2396$  for all  $M > 0$ . Thus the optimal achievable uniform average output regulation level for the switched system  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$  is  $\gamma^* = 1.2396$  (up to the fourth digit below the decimal point). In particular, if we choose  $M = 1$ , then

$$\mathcal{M}_1(\mathbf{Q}, q) = \{11, 12, 21, 33\},$$

$$\mathcal{N}_1(\mathbf{Q}, q) = \mathcal{N}_1^{(1)} \cup \mathcal{N}_1^{(2)} \cup \mathcal{N}_1^{(3)} = \{11, 12, 21, 33\},$$

where

$$\mathcal{N}_1^{(1)} = \{11\}, \quad \mathcal{N}_1^{(2)} = \{12, 21\}, \quad \mathcal{N}_1^{(3)} = \{33\}$$

are the distinct  $(\mathbf{Q}, q)$ -minimal sets of one-paths; solving (4.8) with  $M = 1$  and  $\gamma = \gamma^*$  yields

$$\begin{aligned} \mathbf{R}_1 &= 1.3335, \quad \mathbf{R}_2 = 1.3339, \quad \mathbf{R}_3 = 1.4086; \\ \mathbf{S}_1 &= 7.5795, \quad \mathbf{S}_2 = 0.89526, \quad \mathbf{S}_3 = 0.83913; \\ \mathbf{Z}_{(1,1)} &= \begin{bmatrix} 1.4012 & 0 \\ 0 & 0.067705 \end{bmatrix}, \quad \mathbf{Z}_{(1,2)} = \begin{bmatrix} 1.3335 & -0.70268 \\ -0.70268 & 0.40576 \end{bmatrix}, \\ \mathbf{Z}_{(2,1)} &= \begin{bmatrix} 1.3339 & 0 \\ 0 & 0.000020022 \end{bmatrix}, \quad \mathbf{Z}_{(3,3)} = \begin{bmatrix} 1.4513 & 0 \\ 0 & 0.042656 \end{bmatrix}; \end{aligned}$$

and

$$\mathbf{W}_{(1,1)} = \begin{bmatrix} -0.0086375 & -6.5753 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{W}_{(1,2)} = \begin{bmatrix} 0.10530 & -0.10426 \\ -0.70268 & -0.067303 \end{bmatrix},$$

$$\mathbf{W}_{(2,1)} = \begin{bmatrix} -1.9995 & -5.5798 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{W}_{(3,3)} = \begin{bmatrix} 0.30236 & -0.18147 \\ 0 & 0 \end{bmatrix}.$$

Plugging  $\mathbf{U}_i = (\mathbf{S}_i - \mathbf{R}_i^{-1})^{1/2}$ ,  $\mathbf{T}_i = -\mathbf{R}_i \mathbf{U}_i$ , and  $L = M$  into (4.7) leads to a  $\gamma^*$ -admissible one-path-dependent synthesis of order one; the resulting controller matrices are

$$\mathbf{K}_{(1,1)} = \begin{bmatrix} -0.40691 & -2.5160 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{K}_{(1,2)} = \begin{bmatrix} 0.30141 & -0.11534 \\ 0.17589 & -0.067303 \end{bmatrix},$$

$$\mathbf{K}_{(2,1)} = \begin{bmatrix} -0.29192 & -2.1351 \\ 0 & 0 \end{bmatrix}, \quad \mathbf{K}_{(3,3)} = \begin{bmatrix} 0.18146 & -0.50482 \\ 0 & 0 \end{bmatrix}.$$

If we choose  $i_0^1 = 1$  and  $i_0^3 = 3$ , then this controller is implemented as follows: at  $t = 0$ , use  $\mathbf{K}_{(1,1)}$  if  $\theta(0) = 1$ , and  $\mathbf{K}_{(3,3)}$  if  $\theta(0) = 3$ ; for  $t > 0$ , use  $\mathbf{K}_{(\theta(t-1), \theta(t))}$ .

If, for some reason, a two-path-dependent controller is desired, then the minimal sets of two-paths are

$$\mathcal{N}_2^{(1)} = \{111\}, \quad \mathcal{N}_2^{(2)} = \{112, 121, 211\}, \quad \mathcal{N}_2^{(3)} = \{121, 212\}, \quad \mathcal{N}_2^{(4)} = \{333\},$$

from which one can obtain controller matrices  $\mathbf{K}_{(1,1,1)}$ ,  $\mathbf{K}_{(1,1,2)}$ ,  $\mathbf{K}_{(1,2,1)}$ ,  $\mathbf{K}_{(2,1,1)}$ ,  $\mathbf{K}_{(2,1,2)}$ , and  $\mathbf{K}_{(3,3,3)}$  proceeding similarly to the case of  $M = 1$ . Choosing  $(i_1^1, i_0^1) = (1, 1)$  and  $(i_1^3, i_0^3) = (3, 3)$  yields the following controller implementation: at  $t = 0$ , use  $\mathbf{K}_{(1,1,1)}$  if  $\theta(0) = 1$ , and  $\mathbf{K}_{(3,3,3)}$  if  $\theta(0) = 3$ ; at  $t = 1$ , use  $\mathbf{K}_{(1,1,1)}$  if  $(\theta(0), \theta(1)) = (1, 1)$ ,  $\mathbf{K}_{(1,1,2)}$  if  $(\theta(0), \theta(1)) = (1, 2)$ , and  $\mathbf{K}_{(3,3,3)}$  if  $(\theta(0), \theta(1)) = (3, 3)$ ; for  $t \geq 2$ , use  $\mathbf{K}_{(\theta(t-2), \theta(t-1), \theta(t))}$ .  $\square$

For the sake of completeness, we conclude this section by presenting a result for the state feedback control under perfect observation of both the state and mode.

**THEOREM 4.3.** *Let  $\mathcal{T}$  be as in (4.1) with  $\mathbf{C}_{2,i} = \mathbf{I}$  and  $\mathbf{D}_{21,i} = \mathbf{0}$  for all  $i$ ; let  $(\mathbf{Q}, q)$  be a row-allowable pair. Suppose that  $\gamma > 0$ . There exists a  $\gamma$ -admissible finite-path-dependent synthesis of order  $n_K = 0$  for the system  $(\mathcal{T}, \Theta(\mathbf{Q}, q))$  if and only if there exist a nonnegative integer  $M$  and indexed families  $\{\mathbf{Y}_j : j \in \mathcal{M}_M^-(\mathbf{Q}, q)\}$  and  $\{(\mathbf{Z}_i, \mathbf{W}_i) : i \in \mathcal{N}_M(\mathbf{Q}, q)\}$  of symmetric matrices  $\mathbf{Y}_j \in \mathbb{R}^{n \times n}$ ,  $\mathbf{Z}_i \in \mathbb{R}^{l_1 \times l_1}$  and rectangular matrices  $\mathbf{W}_i \in \mathbb{R}^{m_2 \times n}$  such that*

$$\begin{bmatrix} -\mathbf{Y}_{i_-} & \mathbf{Y}_{i_-} \mathbf{A}_{i_M}^T + \mathbf{W}_i^T \mathbf{B}_{2,i_M}^T \\ \mathbf{A}_{i_M} \mathbf{Y}_{i_-} + \mathbf{B}_{2,i_M} \mathbf{W}_i & \mathbf{B}_{1,i_M} \mathbf{B}_{1,i_M}^T - \mathbf{Y}_{i_+} \end{bmatrix} < \mathbf{0}$$

for all  $M$ -paths  $i = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{Q}, q)$ ,

$$\begin{bmatrix} -\mathbf{Y}_{i_-} & \mathbf{Y}_{i_-} \mathbf{C}_{1,i_M}^T + \mathbf{W}_i^T \mathbf{D}_{12,i_M}^T \\ \mathbf{C}_{1,i_M} \mathbf{Y}_{i_-} + \mathbf{D}_{12,i_M} \mathbf{W}_i & \mathbf{D}_{11,i_M} \mathbf{D}_{11,i_M}^T - \mathbf{Z}_i \end{bmatrix} < \mathbf{0}$$

for all  $M$ -paths  $i = (i_0, \dots, i_M) \in \mathcal{N}_M(\mathbf{Q}, q)$ , and

$$\frac{1}{N_{\mathcal{N}}} \sum_{(k_0, \dots, k_M) \in \mathcal{N}} \text{tr} \mathbf{Z}_{(k_0, \dots, k_M)} < \gamma^2$$

for all  $(\mathbf{Q}, q)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths, where  $N_{\mathcal{N}}$  is the cardinality of  $\mathcal{N}$ . Moreover, if this condition holds, then a  $\gamma$ -admissible  $M$ -path-dependent synthesis of order zero has

$$\mathbf{D}_{K,i} = \mathbf{W}_i \mathbf{Y}_{i_-}^{-1}$$

for all  $i \in \mathcal{M}_M(\mathbf{Q}, q)$ .

*Proof.* Once the inequalities in (4.6) are congruence transformed with  $\mathbf{Y}_{i_-} \oplus \mathbf{I} \oplus \mathbf{I}$ , the result is immediate from the change of variable  $\mathbf{W}_i = \mathbf{D}_{K,i} \mathbf{Y}_{i_-}$  and the Schur complement formula.  $\square$

**5. Control of Markovian jump linear systems.** In this section, we focus on the case where the switching sequences are realizations of a finite-state homogeneous Markov chain. If  $p = (p_i) \in \mathbb{R}^{1 \times N}$  is a row vector whose entries are nonnegative and sum to one, and if  $\mathbf{P} = (p_{ij}) \in \mathbb{R}^{N \times N}$  is a (row) stochastic matrix where each row of  $\mathbf{P}$  has nonnegative entries that sum to one, then the row-allowable pair  $(\mathbf{P}, p)$  defines the Markov chain with transition probability matrix  $\mathbf{P}$  and initial distribution  $p$ . Let  $\mathcal{G}$  be as in (3.1). Then the triple  $(\mathcal{G}, \mathbf{P}, p)$  defines the discrete-time *Markovian jump linear system*, which is the collection of the linear time-varying systems (3.2) over all realizations  $\theta = (\theta(0), \theta(1), \dots)$  of the Markov chain  $(\mathbf{P}, p)$ . The state  $\theta(t)$  of the chain  $(\mathbf{P}, p)$  at time  $t$  defines the mode of the system  $(\mathcal{G}, \mathbf{P}, p)$  at time  $t$ ; the distribution of the mode at time  $t$  is given by  $p\mathbf{P}^t$ . As in the previous section, let  $\Omega$  be the space of all infinite sequences in  $\{1, \dots, N\}$ . Let  $P$  be the unique consistent probability measure [44] on  $\Omega$  such that

$$P\{\theta(t+1) = j \mid \theta(t) = i\} = p_{ij}, \quad P\{\theta(0) = i\} = p_i$$

for all  $i, j$ , and  $t$ .

If  $x(0) = 0$ , and if  $\mathbf{w} = (w^{(t_0)}(0), w^{(t_0)}(1), \dots)$  is an independent identically distributed random sequence independent of  $\theta$  such that  $w^{(t_0)}(t)$  are Gaussian distributed with (2.8) for  $t_0, t \geq 0$ , then write  $\mathbf{z} = (z^{(t_0)}(0), z^{(t_0)}(1), \dots)$ .

**DEFINITION 5.1.** *The system  $(\mathcal{G}, \mathbf{P}, p)$  is said to be almost surely uniformly (exponentially) stable if there exists a set  $\Theta \subset \Omega$  with  $P(\Theta) = 1$  such that the system  $(\mathcal{G}, \Theta)$  is uniformly exponentially stable.*

**Remark 6.** By definition, if a Markovian jump system is almost surely uniformly stable, and if the transition probability matrix  $\mathbf{P}$  is irreducible, then the system is  $\delta$ -moment stable (i.e., the expectation of  $\|x(t)\|^\delta$  converges to zero for all  $x(0)$  and for all  $p$ ) for all  $\delta > 0$ , and hence is mean square stable (i.e., 2-moment stable). Moreover, mean square stable Markovian jump linear systems are almost surely (but not necessarily uniformly) stable [29, 11]. Thus the notion of almost sure uniform stability is conservative; in particular, a mean square stable system can have an unstable mode  $i$  with  $p_{ii} > 0$ , but almost surely uniformly stable systems cannot—see [11, 34] for more details. On the other hand, unlike the usual definitions for the stability of Markovian jump systems, the almost sure uniform stability is defined here with respect to the probability measure  $P$ , and hence to the given pair  $(\mathbf{P}, p)$ , not to the family of  $(\mathbf{P}, p)$  over all  $p$ ; of course, this distinction becomes irrelevant if  $\mathbf{P}$  is irreducible.

**DEFINITION 5.2.** *Let  $\gamma > 0$ . The system  $(\mathcal{G}, \mathbf{P}, p)$  is said to satisfy almost sure impulse response level  $\gamma$  if there exists a set  $\Theta \subset \Omega$  with  $P(\Theta) = 1$  such that the system  $(\mathcal{G}, \Theta)$  satisfies uniform impulse response level  $\gamma$ .*

DEFINITION 5.3. Let  $\gamma > 0$ . The system  $(\mathcal{G}, \mathbf{P}, p)$  is said to satisfy almost sure output regulation level  $\gamma$  if there exists a set  $\Theta \subset \Omega$  with  $P(\Theta) = 1$  such that the system  $(\mathcal{G}, \Theta)$  satisfies uniform output regulation level  $\gamma$ .

DEFINITION 5.4. Let  $\gamma > 0$ . The system  $(\mathcal{G}, \mathbf{P}, p)$  is said to satisfy average output regulation level  $\gamma$  if there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that, whenever  $x(0) = 0$ ,

$$(5.1) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(0)}(t)\|^2 \leq \tilde{\gamma}^2,$$

where  $\mathbb{E}$  denotes the expectation with respect to  $\theta$  and  $\mathbf{w} = (w^{(0)}(0), w^{(0)}(1), \dots)$ .

THEOREM 5.5. Let  $\mathcal{G}$  be as in (3.1); let  $(\mathbf{P}, p)$  be a Markov chain. The system  $(\mathcal{G}, \mathbf{P}, p)$  is almost surely uniformly exponentially stable and satisfies almost sure impulse response level  $\gamma > 0$  if and only if the system  $(\mathcal{G}, \Theta(\mathbf{P}, p))$  is uniformly exponentially stable and satisfies uniform impulse response level  $\gamma$ .

THEOREM 5.6. Let  $\mathcal{G}$  be as in (3.1); let  $(\mathbf{P}, p)$  be a Markov chain. The system  $(\mathcal{G}, \mathbf{P}, p)$  is almost surely uniformly exponentially stable and satisfies almost sure output regulation level  $\gamma > 0$  if and only if the system  $(\mathcal{G}, \Theta(\mathbf{P}, p))$  is uniformly exponentially stable and satisfies uniform output regulation level  $\gamma$ .

*Proof of Theorems 5.5 and 5.6.* The results are immediate from Theorems 3.5 and 3.6: necessity follows from the fact that  $\Theta \subset \Omega$  and  $P(\Theta) = 1$  implies  $\mathcal{M}_L(\mathbf{P}, p) \subset \mathcal{M}_L(\Theta)$ , and sufficiency from  $P(\Theta(\mathbf{P}, p)) = 1$ .  $\square$

Label the  $L$ -paths in  $\mathcal{L}_L(\mathbf{P}, p)$  in dictionary order from 1 to  $N_L$ , where  $N_L$  is the cardinality of  $\mathcal{L}_L(\mathbf{P}, p)$ . Define the matrix  $\mathbf{Q}_L(\mathbf{P}, p) = (q_{ij}) \in \mathbb{R}^{N_L \times N_L}$  as follows: whenever  $(i_0, \dots, i_L)$  and  $(j_0, \dots, j_L)$  are  $L$ -paths labeled  $i$  and  $j$ , respectively, set  $q_{ij} = p_{i_L j_L}$  if  $(i_0, \dots, i_L)_+ = (j_0, \dots, j_L)_-$ ; otherwise, set  $q_{ij} = 0$ . Also, define the row vector  $q_L(\mathbf{P}, p) = (q_i) \in \mathbb{R}^{N_L}$  as follows: whenever  $(i_0, \dots, i_L)$  is an  $L$ -path labeled  $i$ , set  $q_i = p_{i_L}$  if  $(i_0, \dots, i_L)_- = (0, \dots, 0)$ ; otherwise, set  $q_i = 0$ . Then the pair  $(\mathbf{Q}_L(\mathbf{P}, p), q_L(\mathbf{P}, p))$  defines the  $L$ -path Markov chain generated by  $(\mathbf{P}, p)$ . If  $L = 0$ , then

$$(5.2a) \quad \mathbf{Q}_0(\mathbf{P}, p) = \mathbf{Q}_{11}, \quad q_0(\mathbf{P}, p) = q$$

for some submatrix  $\mathbf{Q}_{11}$  of  $\mathbf{P}$  and some subvector  $q$  of  $p$ ; if  $L > 0$ , then it is readily seen that  $\mathbf{Q}_L(\mathbf{P}, p)$  is an  $(L+1)$ -by- $(L+1)$  block matrix and  $q_L(\mathbf{P}, p)$  a 1-by- $(L+1)$  block row vector of the form

$$(5.2b) \quad \mathbf{Q}_L(\mathbf{P}, p) = \begin{bmatrix} \mathbf{0} & \mathbf{Q}_{12} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{Q}_{23} & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{Q}_{LL+1} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{Q}_{L+1L+1} \end{bmatrix}, \quad q_L(\mathbf{P}, p) = [q \quad \mathbf{0} \quad \cdots \quad \mathbf{0} \quad \mathbf{0}].$$

The matrices  $\mathbf{Q}_{ij}$  and the vector  $q$  in general depend on  $L$ . The matrices  $\mathbf{Q}_{ij}$  define the transition probabilities from the  $L$ -paths that contain  $i$  nonzero modes to those that contain  $j$  nonzero modes; in particular,  $\mathbf{Q}_{L+1L+1}$  is stochastic.

LEMMA 5.7. Let  $(\mathbf{P}, p)$  be a Markov chain. If we partition  $\mathbf{Q}_L(\mathbf{P}, p)$  and  $q_L(\mathbf{P}, p)$  as in (5.2), then for each  $L \geq 0$  we have

$$\lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T q_L(\mathbf{P}, p) \mathbf{Q}_L(\mathbf{P}, p)^t = \begin{cases} \pi_0(\mathbf{P}, p), & L = 0; \\ \begin{bmatrix} \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & \pi_L(\mathbf{P}, p) \end{bmatrix}, & L > 0, \end{cases}$$

where

$$(5.3) \quad \pi_L(\mathbf{P}, p) = \begin{cases} q \lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbf{Q}_{11}^t, & L = 0; \\ q \mathbf{Q}_{12} \cdots \mathbf{Q}_{LL+1} \lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbf{Q}_{L+1L+1}^t, & L > 0. \end{cases}$$

*Proof.* Since  $\mathbf{Q}_L(\mathbf{P}, p)$  is a stochastic matrix, the Cesaro limit

$$(5.4) \quad \lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbf{Q}_L(\mathbf{P}, p)^t$$

of the sequence  $(\mathbf{I}, \mathbf{Q}_L(\mathbf{P}, p), \mathbf{Q}_L(\mathbf{P}, p)^2, \dots)$  always exists—see, e.g., [8, Theorem 8.2.2]. The Cesaro limit of the sequence  $(\mathbf{Q}_L(\mathbf{P}, p)^{t_0}, \mathbf{Q}_L(\mathbf{P}, p)^{t_0+1}, \dots)$  is the same as (5.4) for all  $t_0 \geq 0$ . Consider the case of  $t_0 = L$  in particular: it follows from (5.2) that, for all  $t \geq 0$ ,

$$q_L(\mathbf{P}, p) \mathbf{Q}_L(\mathbf{P}, p)^{t+L} = \begin{cases} q \mathbf{Q}_{11}^t, & L = 0; \\ \begin{bmatrix} \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} & q \mathbf{Q}_{12} \cdots \mathbf{Q}_{LL+1} \mathbf{Q}_{L+1L+1}^t \end{bmatrix}, & L > 0. \end{cases}$$

Since  $\mathbf{Q}_{L+1L+1}$  is stochastic, the limit (5.3) exists, so the result follows.  $\square$

*Remark 7.* If  $\mathbf{P}$  is irreducible, then the stochastic matrix  $\mathbf{Q}_{L+1L+1}$  in (5.2) is irreducible and the limit  $\lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbf{Q}_{L+1L+1}^t$  has all rows equal to  $\pi_L(\mathbf{P}, p)$ , which defines the unique stationary distribution of  $\mathbf{Q}_{L+1L+1}$ . Moreover, if  $\mathbf{P}$  is aperiodic as well as irreducible (i.e., if  $\mathbf{P}$  defines an ergodic chain), then  $\pi_L(\mathbf{P}, p)$  defines the unique steady-state distribution and (5.4) can be replaced by the usual limit  $\lim_{t \rightarrow \infty} \mathbf{Q}_L(\mathbf{P}, p)^t$ . See, e.g., [8, 32].

**THEOREM 5.8.** *Let  $\mathcal{G}$  be as in (3.1); let  $(\mathbf{P}, p)$  be a Markov chain. The system  $(\mathcal{G}, \mathbf{P}, p)$  is almost surely uniformly exponentially stable and satisfies average output regulation level  $\gamma > 0$  if and only if there exist a nonnegative integer  $M$  and an indexed family  $\{\mathbf{Y}_j : j \in \mathcal{M}_M^-(\mathbf{P}, p)\}$  of symmetric positive definite matrices  $\mathbf{Y}_j \in \mathbb{R}^{n \times n}$  such that*

$$(5.5a) \quad \mathbf{A}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{A}_{i_M}^T - \mathbf{Y}_{(i_0, \dots, i_M)_+} < -\mathbf{B}_{i_M} \mathbf{B}_{i_M}^T$$

for all  $M$ -paths  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{P}, p)$ , and

$$(5.5b) \quad \sum_{(k_0, \dots, k_M) \in \mathcal{W}_M(\mathbf{P}, p)} \pi_{(k_0, \dots, k_M)} \text{tr}(\mathbf{C}_{k_M} \mathbf{Y}_{(k_0, \dots, k_M)_-} \mathbf{C}_{k_M}^T + \mathbf{D}_{k_M} \mathbf{D}_{k_M}^T) < \gamma^2,$$

where  $\pi_M(\mathbf{P}, p) = (\pi_{(k_0, \dots, k_M)})$ .

*Proof.* To show necessity, suppose that  $(\mathcal{G}, \mathbf{P}, p)$  is almost surely uniformly stable and that there exists a  $\tilde{\gamma} \in (0, \gamma)$  such that (5.1) holds. For  $\varepsilon > 0$ , consider the perturbed system  $(\mathcal{G}^{(\varepsilon)}, \mathbf{P}, p)$ , where  $\mathcal{G}^{(\varepsilon)}$  is as in (3.8). Choose a  $\Theta \subset \Omega$  such that  $P(\Theta) = 1$  and such that the system  $(\mathcal{G}, \Theta)$  is uniformly stable. Write the output that  $(\mathcal{G}^{(\varepsilon)}, \mathbf{P}, p)$  generates under  $x(0) = 0$  and  $\mathbf{w} = (w^{(0)}(0), w^{(0)}(1), \dots)$  as  $\mathbf{z} = (z^{(\varepsilon, 0)}(0), z^{(\varepsilon, 0)}(1), \dots)$ , and let  $\mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \geq \mathbf{0}$  be the solution to

$$\mathbf{A}_{\theta(t)} \mathbf{Y}_{\theta, t}^{(\varepsilon, 0)} \mathbf{A}_{\theta(t)}^T - \mathbf{Y}_{\theta, t+1}^{(\varepsilon, 0)} = -\mathbf{B}_{\theta(t)}^{(\varepsilon)} \mathbf{B}_{\theta(t)}^{(\varepsilon)T},$$

with the initial condition  $\mathbf{Y}_{\theta,0}^{(\varepsilon,0)} = 0$ , for  $\theta \in \Theta$  and  $t \geq 0$ , so that

$$\begin{aligned} \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(\varepsilon,0)}(t)\|^2 \\ = \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \operatorname{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{\theta,t}^{(\varepsilon,0)} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)}^{(\varepsilon)} \mathbf{D}_{\theta(t)}^{(\varepsilon)T}). \end{aligned}$$

Then it follows from the proof of the necessity part of Theorem 3.6 that, for a sufficiently small  $\varepsilon > 0$ , there are a nonnegative integer  $M$  and an indexed family of matrices  $\mathbf{Y}_{(i_0, \dots, i_M)_-} > \mathbf{0}$ ,  $(i_0, \dots, i_M) \in \mathcal{L}_M(\Theta)$ , such that

$$\mathbf{A}_{i_M} \mathbf{Y}_{(i_0, \dots, i_M)_-} \mathbf{A}_{i_M}^T - \mathbf{Y}_{(i_0, \dots, i_M)_+} < -\mathbf{B}_{i_M} \mathbf{B}_{i_M}^T$$

for  $(i_0, \dots, i_M) \in \mathcal{L}_M(\Theta)$ , and such that

$$(5.6) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \operatorname{tr} (\mathbf{C}_{\theta(t)} \mathbf{Y}_{(\theta(t-M), \dots, \theta(t))_-} \mathbf{C}_{\theta(t)}^T + \mathbf{D}_{\theta(t)} \mathbf{D}_{\theta(t)}^T) < \gamma^2.$$

Since  $\mathcal{M}_M(\mathbf{P}, p) \subset \mathcal{M}_M(\Theta) \subset \mathcal{L}_M(\Theta)$ , we have that (5.5a) holds for  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{P}, p)$ . Label the  $M$ -paths in  $\mathcal{L}_M(\mathbf{P}, p)$  in dictionary order from 1 to  $N_M$ , where  $N_M$  is the cardinality of  $\mathcal{L}_M(\mathbf{P}, p)$ . Form a column vector  $c \in \mathbb{R}^{N_M}$  such that its  $i$ th component is equal to  $\operatorname{tr} (\mathbf{C}_{k_M} \mathbf{Y}_{(k_0, \dots, k_M)_-} \mathbf{C}_{k_M}^T - \mathbf{D}_{k_M} \mathbf{D}_{k_M}^T)$  whenever  $(k_0, \dots, k_M)$  is the  $i$ th  $M$ -path in  $\mathcal{L}_M(\mathbf{P}, p)$ . Then we have that the left-hand side of inequality (5.6) is equal to

$$\lim_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T q_L(\mathbf{P}, p) \mathbf{Q}_L(\mathbf{P}, p)^t c.$$

Now, by Lemma 5.7, we have that

$$(5.7) \quad \limsup_{T \rightarrow \infty} \frac{1}{T+1} \sum_{t=0}^T \mathbb{E} \|z^{(\varepsilon,0)}(t)\|^2 = \sum_{(k_0, \dots, k_M) \in \mathcal{W}_M(\mathbf{P}, p)} \pi_{(k_0, \dots, k_M)} c_{(k_0, \dots, k_M)} < \gamma^2,$$

where  $c_{(k_0, \dots, k_M)}$  is the component of  $c$  associated with the  $M$ -path  $(k_0, \dots, k_M)$ . Hence (5.5b) holds.

To show sufficiency, suppose that (5.5) holds for some integer  $M \geq 0$  and for all  $(i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{P}, p)$ . Then, by the proof of the sufficiency part of Theorem 3.6, we have that the system  $(\mathcal{G}, \mathbf{P}, p)$  is almost surely uniformly stable because the system  $(\mathcal{G}, \Theta(\mathbf{P}, p))$  is uniformly stable with  $P(\Theta(\mathbf{P}, p)) = 1$ ; also, there exists a  $\tilde{\gamma} \in (0, \gamma)$  satisfying (5.1) because of (5.7).  $\square$

Let  $\mathcal{T}$  be as in (4.1), and let  $(\mathbf{P}, p)$  be a Markov chain. Then the triple  $(\mathcal{T}, \mathbf{P}, p)$  defines the *controlled Markovian jump linear system* represented by (4.2), where  $\theta$  is a realization of  $(\mathbf{P}, p)$ . As in the previous section, we make the standard assumption that *the state  $\theta(t)$  of the chain  $(\mathbf{P}, p)$  is perfectly observed at each time instant  $t$* ; we consider all finite-path-dependent controllers.

Fix a nonnegative integer  $L$ . Let

$$\mathcal{K} = \{(\mathbf{A}_{K,i}, \mathbf{B}_{K,i}, \mathbf{C}_{K,i}, \mathbf{D}_{K,i}) : i \in \mathcal{L}_L(\mathbf{P}, p)\}.$$

Then the pair  $(\mathcal{K}, \Theta_L(\mathbf{P}, p))$ , with

$$\Theta_L(\mathbf{P}, p) = \{\theta_L : \theta \in \Theta(\mathbf{P}, p)\},$$

defines an  $L$ -path-dependent controller, whose state-space representation is given by (4.3). Since the pair  $(\mathbf{Q}_L(\mathbf{P}, p), q_L(\mathbf{P}, p))$  defines the  $L$ -path Markov chain generated by  $(\mathbf{P}, p)$ , the closed-loop system is a Markovian jump linear system given by the triple  $(\mathcal{T}_\mathcal{K}, \mathbf{Q}_L(\mathbf{P}, p), q_L(\mathbf{P}, p))$ , with

$$\mathcal{T}_\mathcal{K} = \{(\tilde{\mathbf{A}}_i, \tilde{\mathbf{B}}_i, \tilde{\mathbf{C}}_i, \tilde{\mathbf{D}}_i) : i \in \mathcal{L}_L(\mathbf{P}, p)\},$$

and represented by (4.4) for each realization  $\theta_L$  of  $(\mathbf{Q}_L(\mathbf{P}, p), q_L(\mathbf{P}, p))$ .

**DEFINITION 5.9.** Let  $\gamma > 0$ . The controller  $(\mathcal{K}, \Theta_L(\mathbf{P}, p))$  is said to be a  $\gamma$ -admissible ( $L$ -path-dependent) synthesis (of order  $n_K$ ) for the system  $(\mathcal{T}, \mathbf{P}, p)$  if the closed-loop system  $(\mathcal{T}_\mathcal{K}, \mathbf{Q}_L(\mathbf{P}, p), q_L(\mathbf{P}, p))$  is almost surely uniformly exponentially stable and satisfies average output regulation level  $\gamma$ .

**THEOREM 5.10.** Let  $\mathcal{T}$  be as in (4.1); let  $(\mathbf{P}, p)$  be a Markov chain. Suppose that  $n_K \geq n$  and  $\gamma > 0$ . There exists a  $\gamma$ -admissible finite-path-dependent synthesis of order  $n_K$  for the system  $(\mathcal{T}, \mathbf{P}, p)$  if and only if there exist a nonnegative integer  $M$  and indexed families  $\{(\mathbf{R}_j, \mathbf{S}_j) : j \in \mathcal{M}_M^-(\mathbf{Q}, q)\}$  and  $\{(\mathbf{Z}_i, \mathbf{W}_i) : i \in \mathcal{W}_M(\mathbf{Q}, q)\}$  of symmetric matrices  $\mathbf{R}_j \in \mathbb{R}^{n \times n}$ ,  $\mathbf{S}_j \in \mathbb{R}^{n \times n}$ ,  $\mathbf{Z}_i \in \mathbb{R}^{l_1 \times l_1}$  and rectangular matrices  $\mathbf{W}_i \in \mathbb{R}^{(n+m_2) \times (n+l_2)}$  such that (4.8a) holds for all  $i = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{P}, p)$ , (4.8b) holds for all  $i = (i_0, \dots, i_M) \in \mathcal{W}_M(\mathbf{P}, p)$ , and

$$(5.8) \quad \sum_{(k_0, \dots, k_M) \in \mathcal{W}_M(\mathbf{P}, p)} \pi_{(k_0, \dots, k_M)} \text{tr } \mathbf{Z}_{(k_0, \dots, k_M)} < \gamma^2,$$

where  $\pi_M(\mathbf{P}, p) = (\pi_{(k_0, \dots, k_M)})$ . Moreover, if this condition is satisfied, then given any nonsingular matrices  $\mathbf{T}_j, \mathbf{U}_j \in \mathbb{R}^{n \times n}$  such that (4.9) holds for all  $j \in \mathcal{M}_M^-(\mathbf{P}, p)$ , a  $\gamma$ -admissible  $M$ -path-dependent synthesis of order  $n$  is obtained by solving (4.7), with  $n_K = n$  and  $L = M$ , for matrices  $\mathbf{A}_{K,i}, \mathbf{B}_{K,i}, \mathbf{C}_{K,i}, \mathbf{D}_{K,i}, i \in \mathcal{M}_M(\mathbf{P}, p)$ .

*Proof.* The result follows from Theorem 5.8 and the proof of Theorem 4.2.  $\square$

**Remark 8.** As in Theorem 4.2, it is possible to replace  $\mathcal{M}_M(\mathbf{P}, p)$  and  $\mathcal{W}_M(\mathbf{P}, p)$  with smaller sets. However, using these bigger sets is more convenient, as stated in Remark 4.

**Remark 9.** The condition (5.8) is weaker than the condition that (4.8c) holds for all  $(\mathbf{P}, p)$ -minimal sets  $\mathcal{N}$  of  $M$ -paths. In general, for all  $\gamma$  and  $M$ , there exists a  $\gamma$ -admissible  $M$ -path-dependent synthesis for the Markovian jump system  $(\mathcal{T}, \mathbf{P}, p)$  whenever there exists a  $\gamma$ -admissible  $M$ -path-dependent synthesis for the switched system  $(\mathcal{T}, \Theta(\mathbf{P}, p))$ .

**Example 6.** Let  $\mathcal{T}$  be as in Example 5. Let

$$\mathbf{P} = \begin{bmatrix} 1/2 & 1/2 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad p = [1/2 \quad 0 \quad 1/2].$$

Since the sparsity pattern of  $(\mathbf{P}, p)$  is the same as that of  $(\mathbf{Q}, q)$  in Example 5, we have  $\mathcal{M}_M(\mathbf{P}, p) = \mathcal{M}_M(\mathbf{Q}, q)$  for all path lengths  $M$ . Moreover, in this particular example,  $\mathcal{N}_M(\mathbf{P}, p) = \mathcal{W}_M(\mathbf{P}, p) = \mathcal{M}_M(\mathbf{P}, p)$  for all  $M$ . If  $M = 0$ , then  $\mathbf{Q}_{11} = \mathbf{P}$

TABLE 5.1  
In Example 6,  $\gamma_M$  is decreasing in  $M$  and saturates at  $M = 5$ .

$M$	0	1	2	3	4	5	6	7
$\gamma_M$	1.3280	1.1837	1.1815	1.1812	1.1809	1.1808	1.1808	1.1808

and  $q = p$ , so

$$\begin{aligned}\pi_0(\mathbf{P}, p) &= [\pi_1 \quad \pi_2 \quad \pi_3] \\ &= [1/2 \quad 0 \quad 1/2] \begin{bmatrix} 2/3 & 1/3 & 0 \\ 2/3 & 1/3 & 0 \\ 0 & 0 & 1 \end{bmatrix} = [1/3 \quad 1/6 \quad 1/2].\end{aligned}$$

If  $M = 1$ , then

$$\mathbf{Q}_{12} = \begin{bmatrix} 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad \mathbf{Q}_{22} = \begin{bmatrix} 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \quad q = [1/2 \quad 1/2],$$

so

$$\begin{aligned}\pi_1(\mathbf{P}, p) &= [\pi_{(1,1)} \quad \pi_{(1,2)} \quad \pi_{(2,1)} \quad \pi_{(3,3)}] \\ &= [1/2 \quad 1/2] \begin{bmatrix} 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1/3 & 1/3 & 1/3 & 0 \\ 1/3 & 1/3 & 1/3 & 0 \\ 1/3 & 1/3 & 1/3 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \\ &= [1/6 \quad 1/6 \quad 1/6 \quad 1/2].\end{aligned}$$

Similarly, we obtain

$$\begin{aligned}\pi_2(\mathbf{P}, p) &= [\pi_{(1,1,1)} \quad \pi_{(1,1,2)} \quad \pi_{(1,2,1)} \quad \pi_{(2,1,1)} \quad \pi_{(2,1,2)} \quad \pi_{(3,3,3)}] \\ &= [1/12 \quad 1/12 \quad 1/6 \quad 1/12 \quad 1/12 \quad 1/2],\end{aligned}$$

and so on.

For nonnegative integers  $M$ , denote by  $\gamma_M$  the infimum of  $\gamma > 0$  such that (4.8a), (4.8b), and (5.8) hold for all  $M$ -paths  $\mathbf{i} = (i_0, \dots, i_M) \in \mathcal{M}_M(\mathbf{P}, p)$ . Then semidefinite programming gives us Table 5.1; as expected,  $\gamma_M$  decreases as  $M$  gets larger, but it saturates at  $M = 5$ . Thus, we determine that the optimal achievable value of  $\gamma$  is approximately  $\gamma^* = 1.1808$ , and that there exists a  $\gamma^*$ -admissible five-path-dependent synthesis; the resulting 22 controller matrices are denoted  $\mathbf{K}_{(1,1,1,1,1,1)}$ ,  $\mathbf{K}_{(1,1,1,1,1,2)}$ ,  $\mathbf{K}_{(1,1,1,1,2,1)}$ ,  $\dots$ ,  $\mathbf{K}_{(2,1,2,1,2,1)}$ ,  $\mathbf{K}_{(3,3,3,3,3,3)}$ .  $\square$

**6. Conclusion.** A convex characterization of the output regulation performance of switched linear systems and Markovian jump linear systems was given by an increasing union of linear matrix inequality conditions. This characterization gives rise to semidefinite programming-based “offline” algorithms for finding an optimal solution from (almost surely) uniformly stabilizing dynamic output feedback controllers

that have finite memory of past modes. Due to the nature of problem, however, the computational burden can grow drastically in the number of the past modes that the controller recalls. Although this limitation often allows us the complete freedom in controlling the conservatism, or suboptimality, of the resulting controllers, some systems may be better dealt with in practice via, e.g., the dwell-time approaches [23, 48, 22].

The results presented are not only exact and convex, but also very general. One should be able to characterize a large class of performance objectives under which the convexity is preserved in the spirit of [43, 39]. This generality is gained in exchange for giving up the closed-form solutions that standard Riccati equation-based approaches such as those in [18, 42] would yield. However, one could adopt these standard approaches to enhance and complement our results. Possible topics in this direction include whether the noncausality of the solution to the impulse response level minimization problem is due to the nature of problem or not, and a separation principle for the problems formulated in this paper.

The output regulation problems can be easily extended to the simultaneous design of the supervisor-controller pair. As is well known in the context of LQG measurement scheduling [40], the problem of jointly optimizing both the switching sequence and the output feedback controller is separated into two problems: one is to determine the optimal switching rule via an algorithm analogous to that developed in [35], and the other is, given a switching rule, to obtain a path-dependent controller using the results of this paper. For discrete-time switched systems, existing results in this direction seem to be limited to the finite-horizon state feedback problem [37].

## SINGULARLY PERTURBED PIECEWISE DETERMINISTIC GAMES\*

ALAIN HAURIE<sup>†</sup> AND FRANCESCO MORESINO<sup>‡</sup>

**Abstract.** In this paper we consider a class of hybrid stochastic games with the piecewise open-loop information structure. These games are indexed over a parameter  $\varepsilon$  which represents the time scale ratio between the stochastic (jump process) and the deterministic (differential state equation) parts of the dynamical system. We study the limit behavior of Nash equilibrium solutions to the hybrid stochastic games when the time scale ratio tends to 0. We also establish that an approximate equilibrium can be obtained for the hybrid stochastic games using a Nash equilibrium solution of a reduced order sequential discrete state stochastic game and a family of local deterministic infinite horizon open-loop differential games defined in the stretched out time scale. A numerical illustration of this approximation scheme is also developed.

**Key words.**  $n$ -person games, noncooperative games, stochastic games, differential games, time scale analysis, singular perturbations

**1. Introduction.** This paper deals with a class of piecewise deterministic stochastic games where the stochastic jump process has a slower time scale than the deterministic continuous time control systems that are defined between successive random jumps. These types of games may occur, for example, in imperfect competition models where the deterministic subsystem describes the productive capital accumulation of the firms competing on a market and where the market conditions are subject to infrequent random switches that are influenced by the actions of the economic agents. Situations where oligopolistic markets can be subject to abrupt modal changes are observed, for example, in the energy sector or in the new technology or telecommunication domains. Another interesting domain where this type of paradigm could be used is the modeling of economic dimensions of climate change. The fast modes would correspond to the competitive economic growth processes of different world economies, whereas the slow modes would be associated with different climate conditions. Indeed the transition from a climate mode to a different one would be influenced by the global emissions of greenhouse gases from all nations.

The information structure that we consider for these games is called *piecewise open-loop*; it has been introduced in [7] and consists in playing open-loop controls between successive jump times; the open-loop controls are adapted to the history of jump times and system states observed at jump times. It has been recognized that these piecewise deterministic games, when played under the piecewise open-loop information structure, are akin to the general class of stochastic sequential games

with general (Borel) action and state spaces, considered in particular in [17] and [15], where existence and approximation of Nash equilibria have been studied. We also suppose that the players have separated deterministic dynamics and are linked only through the payoff rewards at that level. This means that between two successive modal changes each player  $j = 1, \dots, m$  selects a deterministic trajectory  $x_j(\cdot)$  that has a given initial state determined by the state at the time of the first jump and which will be in force until the second jump occurs. We assume that the  $m$  state variables  $x_j$ ,  $j = 1, \dots, m$ , together influence the jump rates of the discrete modal stochastic process.

The aim of this paper is to develop a theory of approximation for a Nash equilibrium solution to this class of differential games when the time scale ratio between the (continuous) deterministic and (jump) stochastic dynamics tends to 0. This is the realm of *singular perturbation* theory in control. In [6] one can find a rather complete theory of singularly perturbed piecewise deterministic control systems and an illustration of the role played by “turnpikes” (i.e., global attractors for optimal trajectories in infinite horizon control problems) in the definition of the “limit control problem.” The initial objective of this paper was to explore the possibility of extending the results obtained in [6] to the case of piecewise open-loop Nash equilibria. As is often the case when one passes from a single optimizer control formalism to the context of dynamic games with a Nash equilibrium solution, these results cannot be readily generalized, and we obtain substantially different and weaker limit theorems.

In the present paper we consider only the case of infinite horizon hybrid games with discounted payoffs. In brief the contribution of this paper can be stated as follows: (i) We define, in the slow time scale, a limit game problem in the form of a controlled Markov chain. A Nash equilibrium for this limit game, if it exists, will serve to build an approximate equilibrium solution of the original game. (ii) We prove that given a Nash equilibrium for the limit game, defined in terms of attractors for the players  $x_j(\cdot)$ -trajectories, one can construct a  $\zeta$ -equilibrium for any  $G^\varepsilon$  game, where  $\varepsilon$  is small enough by using strategies characterized by a uniform attractor property. (iii) Having solved the limit Nash game, we can use the associated potential function to characterize a set of local infinite horizon open-loop games, whose Nash equilibria satisfy the uniform attractor property. (iv) We thus derive a decomposition principle for this class of games and illustrate it on a numerical example.

The paper is organized as follows: in section 2 we recall the definition of a piecewise deterministic game played with piecewise open-loop strategies; in section 3 we study the limit game when the time scale ratio  $\varepsilon$  between fast and slow modes tends to 0; in section 4 we propose a method to construct a  $\zeta$ -equilibrium solutions for the hybrid game, using uniform attractor policies; in section 5 we study a class of local open-loop games for which the Nash equilibrium strategies satisfy the uniform attractor property; in section 6 we derive from these results a decomposition principle; and in section 7 we provide a numerical illustration of these limit properties and sketch an economic model of climate change policies having this two-time scale structure; in section 8 we summarize what has been achieved.

**2. A class of piecewise deterministic games.** In this section we define the class of dynamic games that are considered in this work. They are particular instances of piecewise deterministic games, as introduced in [7]. We use both a formalism of control systems and a formalism of calculus of variations, very much in the same way as in [4], where the so-called turnpike property for open-loop differential games with decoupled dynamics was established.

**2.1. The dynamics.** Consider  $m$  players, denoted  $j \in M = \{1, \dots, m\}$ , controlling a system that has  $p$  discrete modes denoted  $i \in I = \{0, \dots, p-1\}$ . Each player  $j \in M$  also controls her own dynamical subsystem with mode-dependent dynamics,

$$(2.1) \quad \varepsilon \dot{x}_j(t) = f_j^i(x_j(t), u_j(t)),$$

$$(2.2) \quad u_j(t) \in U_j^i \subset \mathbb{R}^{n_j},$$

$$(2.3) \quad x_j(t) \in X_j \subset \mathbb{R}^{n_j},$$

where the control sets  $U_j^i$  are compacts and the state sets  $X_j$  are bounded. The functions  $f_j^i(x_j, u_j)$  are supposed to satisfy the usual regularity assumptions made in control theory. Here  $\varepsilon$  is a parameter that will eventually be very small. We denote  $\underline{x} = (x_j : j \in M) \in \underline{X}$  and  $\underline{u} = (u_j : j \in M) \in \underline{U}$  to be the state and control vectors, respectively.

The “mode” dynamics is represented by a continuous time jump process  $\xi(\cdot)$ , with state set  $I$  and transition rates

$$q_{k\ell}(\underline{x}(t)) = \lim_{dt \rightarrow 0} \frac{1}{dt} \mathbb{P}[\xi(t+dt) = \ell \mid \xi(t) = k, \underline{x}(t)], \quad k, \ell \in I, \underline{x}(t) \in \underline{X},$$

that depend on the trajectory choice made by all players. Indeed we assume  $q_{k\ell}(\underline{x}) \geq 0$  if  $k \neq \ell$  and  $q_{kk}(\underline{x}) = -\sum_{\ell \neq k} q_{k\ell}(\underline{x})$ . As usual we introduce the notation

$$q^k(\underline{x}) \doteq \sum_{\ell \neq k} q_{k\ell}(\underline{x}).$$

*Remark 1.* The parameter  $\varepsilon$  represents the time scale ratio. Its inverse  $1/\varepsilon$  is therefore a speed of adjustment factor for the deterministic part of the hybrid system; when  $\varepsilon \rightarrow 0$  the deterministic part of the system is allowed to adjust much faster than the stochastic jumps occurrences.

It will be convenient to use a calculus of variations formalism, obtained in the following way: We assume that at time  $t$  the reward rate to Player  $j$ , when the mode is  $i$ , is given by a function  $L_j^i(\underline{x}(t), u_j(t))$  which is  $C^1$  in  $\underline{x}$  and continuous in  $u_j$ . Let  $F_j^i(z_j, x_j) = \{u_j \in U_j^i : z_j = f_j^i(x_j, u_j)\}$  be the set of controls for Player  $j$  that yield a velocity  $z_j$  at state  $x_j$ . We introduce a function  $\mathcal{L}_j^i(\underline{x}, z_j)$  that associates a value in  $\mathbb{R} \cup \{-\infty\}$  with every  $\underline{x} \in \Pi_{l=1}^n X_l \subset \mathbb{R}^n$ ,  $n = \sum_{j \in M} n_j$ , and  $z_j \in \mathbb{R}^{n_j}$  as follows:

$$(2.4) \quad \mathcal{L}_j^i(\underline{x}, z_j) = \begin{cases} -\infty & \text{if } x_j \notin X_j \text{ or } F_j^i(z_j, x_j) = \emptyset; \\ \sup\{L_j^i(\underline{x}, u_j) : u_j \in F_j^i(z_j, x_j)\} & \text{otherwise.} \end{cases}$$

We can now consider a dynamic game where each player  $j \in M = \{1, \dots, m\}$  controls an absolutely continuous trajectory  $x_j(\cdot)$  with state  $x_j(t) \in X_j$  at time  $t \in [0, \infty)$ , where  $X_j$  is a compact subset in  $\mathbb{R}^{n_j}$ .

The game is played as follows: at jump times  $\tau^0 = 0, \tau^1, \dots, \tau^\nu, \dots$  of the  $\xi(\cdot)$  process the players observe the state of the system, i.e., the pair  $s^\nu = (\xi^\nu, \underline{x}^\nu)$ , where  $\xi^\nu = \xi(\tau^\nu)$  and  $\underline{x}^\nu = \underline{x}(\tau^\nu)$ . Then Player  $j$  selects an absolutely continuous function  $y_j : [0, \infty) \rightarrow X_j$ , with initial condition  $y_j(0) = x_j^\nu$ . The trajectory for Player  $j$  will thus be defined, between jump times  $\tau^\nu$  and  $\tau^{\nu+1}$ , by  $x_j(t) = y_j(t - \tau^\nu)$ . We denote by  $\mathcal{X}_j$  the class of admissible functions  $y_j : [0, \infty) \rightarrow X_j$  that serve to define the action set of Player  $j$ . A piecewise open-loop strategy for Player  $j$  is then defined as a mapping  $\gamma_j : (\tau^\nu, s^\nu) \mapsto \mathcal{X}_j$ .

At time  $t$  the reward rate to Player  $j$  is given by  $\mathcal{L}_j^{\xi(t)}(\underline{x}(t), \varepsilon \dot{x}_j(t))$  and depends on the current mode  $\xi(t)$ , the state vector  $\underline{x}(t) = (x_j(t))_{j \in M}$ , and the time derivative  $\dot{x}_j(\cdot)$  of Player  $j$ 's own trajectory multiplied by the time scale ratio  $\varepsilon$ .

**2.2. The hybrid game  $G^\varepsilon$ .** We call *hybrid game*  $G^\varepsilon$  the game in normal form where the players select piecewise open-loop strategies as defined above and obtain payoffs defined as follows:

Let  $\rho_j$  be the discount rate of Player  $j$ . Associated with a strategy  $m$ -tuple  $\underline{\gamma} = \{\gamma_j : j \in M\}$  the payoffs to the players are given by

$$(2.5) \quad V_j^\varepsilon(\underline{\gamma}; i, \underline{x}^o) = \mathbb{E}_{\underline{\gamma}} \left[ \int_0^\infty e^{-\rho_j t} \mathcal{L}_j^{\xi(t)}(\underline{x}(t), \varepsilon \dot{x}_j(t)) dt \mid (\xi(t^0) = i, \underline{x}(t^0) = \underline{x}^o) \right]$$

$$j \in M, \quad (i, \underline{x}^o) \in I \times \underline{X},$$

where  $\mathbb{E}_{\underline{\gamma}}$  is the expectation given the probability measure induced by the strategy vector  $\underline{\gamma}$ .

**DEFINITION 2.1.** (i) A strategy  $m$ -tuple  $\underline{\gamma}^*$  is a  $\varsigma$ -equilibrium, with  $\varsigma \geq 0$  given, if

$$(2.6) \quad V_j^{\varepsilon*}(i, \underline{x}^o) = V_j^\varepsilon(\underline{\gamma}^*; i, \underline{x}^o) \geq V_j^\varepsilon([\underline{\gamma}_{M-j}^*, \gamma_j]; i, \underline{x}^o) - \varsigma \quad \forall \gamma_j \in \Gamma_j$$

$$j \in M, \quad (i, \underline{x}^o) \in I \times \underline{X},$$

where  $[\underline{\gamma}_{M-j}^*, \gamma_j]$  denotes the strategy vector obtained from  $\underline{\gamma}^*$  when only Player  $j$  unilaterally changes her strategy to  $\gamma_j$ .

(ii) A 0-equilibrium is also called a Nash equilibrium.

The reader will note that we distinguish between  $\varepsilon > 0$ , which is the time scale ratio, and  $\varsigma > 0$ , which is the approximation used in the equilibrium conditions.

Indeed, when  $\varepsilon$  becomes very small this game will become ill-conditioned. In the rest of the paper we propose an approach for defining a limit game which is easier to solve and which can be used to construct approximate equilibria of the original game when  $\varepsilon$  is small.

**3. The limit game  $G^0$ .** In this section we introduce the so-called *limit game*  $G^0$ , which is defined as a multiagent controlled Markov chain with states in  $I$  and controls in  $X_j^i$ ,  $i \in I$ ,  $j \in M$ .

**3.1. A discrete-state Markov game.** The limit game  $G^0$  is defined as a controlled Markov chain on the discrete set  $I$  where Player  $j$ 's strategy is defined by a vector  $\tilde{x}_j = (x_j^i : i \in I)$  with  $x_j^i \in X_j$ ,  $j \in M$ . The controlled transition rates of the Markov chain are given by  $q_{k,\ell}(\underline{x}^k)$ , where we use the notation  $\underline{x}^k = (x_j^k : j \in J)$ . The payoff for Player  $j$ , when the game starts in state  $i$  and when the players use the strategy  $m$ -tuple  $\tilde{\underline{x}} = (\tilde{x}_j : j \in M)$ , is defined as follows:

$$(3.1) \quad V_j(\tilde{\underline{x}}; i) = \mathbb{E}_{\tilde{\underline{x}}} \left[ \int_0^\infty e^{-\rho_j t} \mathcal{L}_j^{\xi(t)}(\underline{x}^{\xi(t)}, 0) dt \mid \xi(0) = i \right].$$

**3.2. Nash equilibrium in the limit game.** We assume the following.

**ASSUMPTION 1.** There exists an equilibrium  $\tilde{\underline{x}}^*$  for the limit game. The equilibrium value function for Player  $j$  is given by

$$(3.2) \quad V_j^*(i) = \max_{\tilde{x}_j} \mathbb{E}_{\tilde{\underline{x}}} \left[ \int_0^\infty e^{-\rho_j t} \mathcal{L}_j^{*\xi(t)}([\underline{x}_{M-j}^{*\xi(t)}, \underline{x}_j^{*\xi(t)}], 0) dt \mid (\xi(0) = i) \right],$$

$$i \in I, \quad j \in M,$$

for each player  $j$ .

The Hamilton–Jacobi–Bellman (HJB) system of equations associated with this equilibrium is

$$(3.3) \quad \rho_j V_j^*(i) = \max_{x_j^i \in X_j} \mathcal{L}_j^i([\underline{x}_{M-j}^{*i}, x_j^i], 0) + \sum_{k \in I} q_{ik}([\underline{x}_{M-j}^{*i}, x_j^i]) V_j^*(k), \quad i \in I, j \in M.$$

*Remark 2.* The existence of an equilibrium for a sequential game has been proved in particular in [15] and [17]. A more general theory that covers the class of stochastic games considered here has been proposed in [2]. These theories could be applied to prove that a Nash equilibrium exists for the limit game. However, the assumption is more restrictive since it assumes that the equilibrium can be obtained in pure strategies.

**3.3. Occupation measures.** It will be convenient to use occupation measures to prove the main convergence results in the paper. Introducing the indicator function

$$(3.4) \quad \delta(i, k) = \begin{cases} 1 & \text{if } i = k, \\ 0 & \text{otherwise,} \end{cases}$$

we define, for any strategy  $m$ -tuple  $\tilde{x}$  and state  $k$ , given the initial state  $i$ , with  $k, i \in I$ , the occupation measures

$$(3.5) \quad \Pi_j^k(\tilde{x}, i) = \mathbb{E}_{\tilde{x}} \left[ \int_0^\infty e^{-\rho_j t} \delta(k, \xi(t)) dt \mid \xi(0) = i \right].$$

For each  $j \in M$  these occupation measures satisfy the coupled equations

$$(3.6) \quad \rho_j \Pi_j^\ell(\tilde{x}; i) - \sum_{k \in I} q_{ki}(\underline{x}^k) \Pi_j^k(\tilde{x}; i) = \delta(\ell, i), \quad i \in I.$$

We can also rewrite the payoff, given in (3.1), as

$$(3.7) \quad V_j(\tilde{x}; i) = \sum_k \Pi_j^k(\tilde{x}; i) \mathcal{L}_j^k(\underline{x}^k, 0).$$

**4. Uniform attractor policies and  $\varsigma$ -equilibria.** One can make a change of time scale in the dynamical system (2.1)–(2.3) by introducing a *stretched out* time  $\tau = \frac{t}{\varepsilon}$ . We shall assume a uniform reachability condition in this extended time scale.

**ASSUMPTION 2.** *In the stretched out time scale (or when  $\varepsilon = 1$ ), for any  $\eta > 0$  and mode  $i \in I$ , any target state  $\underline{x}^f$  in  $\underline{X}$  can be reached within  $\eta$  by the dynamical system (2.1)–(2.3) from any initial state  $\underline{x}^o \in \underline{X}$  in a uniformly bounded time. We call  $\theta(\eta)$  the uniform bound on the  $\eta$ -reachability time. In summary we assume the following:*

$$\begin{aligned} &\forall \eta > 0, \exists \theta(\eta) > 0 \text{ s.t. } \forall i \in I, \forall \underline{x}^o \text{ and } \underline{x}^f \in \underline{X}, \text{ there exists a} \\ &\text{trajectory } \underline{x}(\cdot) \text{ s.t. } \underline{x}(0) = \underline{x}^o, \mathcal{L}_j^i(\underline{x}(t), \dot{x}_j(t)) < \infty, j \in M \text{ a.e. and} \\ &\forall t > \theta(\eta) \quad \|\underline{x}(t) - \underline{x}^f\| < \eta \text{ holds.} \end{aligned}$$

We shall further assume that this reachability is achieved through the use of “admissible decentralized system behavior.”

**DEFINITION 4.1.** *An admissible decentralized system behavior is a family of mappings  $s_j^i(x_j)$  taking values in  $\mathbb{R}^{n_j}$ ,  $i \in I$ ,  $j \in J$ , and such that the differential equations  $\dot{x}_j(t) = s_j^i(x_j(t))$  admit a uniquely defined solution in  $X_j$  for  $t \in [0, \infty)$ , given  $x(0) = x^o \in X_j$  and such that  $\mathcal{L}_j^i(\underline{x}(t), s_j^i(x_j(t))) > -\infty$  a.e. on  $[0, \infty)$ .*

ASSUMPTION 3. *The uniform reachability Assumption 2 is achieved by a set of admissible decentralized system behavior  $s_j^i(x_j; \underline{x}^o, \underline{x}^f) = \dot{x}_j$  such that*

$$\mathcal{L}_j^i(\underline{x}, s_j^i(x_j; \underline{x}^o, \underline{x}^f)) < \infty \quad \text{and} \quad s_j^i(x_j^f; \underline{x}^o, \underline{x}^f) = 0.$$

*Remark 3.* The notion of admissible decentralized system behavior is closely related to the concept of decentralized feedback control laws in the state equation formulation of the dynamical system.

We also make the following continuity assumption, which should be not too restrictive.

ASSUMPTION 4. *The control laws of admissible decentralized system behavior have the following continuity property:*

$$(4.1) \quad \lim_{\underline{x} \rightarrow \underline{x}^f} s_j^i(x_j; \underline{x}^o, \underline{x}) = s_j^i(x_j^f; \underline{x}^o, \underline{x}^f) = 0.$$

**4.1. A correspondence mapping.** Given a strategy  $\tilde{\underline{x}}$  for the limit game  $G^0$ , we associate a strategy  $\tilde{\underline{\gamma}}^\varepsilon = \sigma^\varepsilon(\tilde{\underline{x}})$  for the  $G^\varepsilon$  game defined as follows: For any discrete state  $i \in I$  and any initial state  $\underline{x}^o$  select the trajectory  $\underline{x}^i(\cdot) : [0, \infty) \rightarrow \underline{X}$ , where each component  $x_j(t)$  is a solution of  $s_j^i(x_j(t); \underline{x}^o, \tilde{\underline{x}}) = \varepsilon \dot{x}_j(t)$  with  $x_j^i(0) = x_j^o$ . This is always possible by Assumption 3, and the following holds:

$$(4.2) \quad \forall \eta > 0, \exists \theta(\eta) \text{ s.t. } \|x_j^i(t) - x_j^i\| < \eta \quad \forall j \in M \quad \forall t \geq \theta(\eta)\varepsilon.$$

Define the occupation measures associated with  $\tilde{\underline{\gamma}}^\varepsilon$  in the  $G^\varepsilon$  game

$$(4.3) \quad \Pi_j^{k\varepsilon}(\tilde{\underline{\gamma}}^\varepsilon; i, x^o) = \mathbb{E}_{\tilde{\underline{\gamma}}^\varepsilon} \left[ \int_0^\infty e^{-\rho_j t} \delta(k, \xi(t)) dt \mid (\xi(0) = i, x(0)) = x^o \right].$$

For any function  $g(\underline{x})$  which is continuous the asymptotic reachability condition (4.2) implies that there exists  $\theta'(\eta)$  such that

$$(4.4) \quad |g(\underline{x}^i(t)) - g(\underline{x}^i)| < \eta \quad \forall t \geq \theta'(\eta)\varepsilon.$$

For the sake of simplifying the notation we shall use simply  $\theta$  instead of  $\theta'(\eta)$  when there is no possibility of confusion. We can now prove the following.

PROPOSITION 4.2. *For any  $i \in I$  and any  $\underline{x}^o \in \underline{X}$  the following convergence holds for the occupation measures:*

$$(4.5) \quad \lim_{\varepsilon \rightarrow 0} |\Pi_j^k(\tilde{\underline{x}}; i) - \Pi_j^{k\varepsilon}(\sigma^\varepsilon(\tilde{\underline{x}}); i, x^o)| = 0.$$

*Proof.* The detailed proof, which is straightforward but lengthy, is given in Appendix A. We summarize here its general development. As  $\delta(i, k)$  is an indicator function it is uniformly bounded and one has for any strategy  $\gamma$  for a game  $G^\varepsilon$

$$(4.6) \quad \mathbb{E}_\gamma \left[ \int_0^\infty e^{-\rho t} \delta(i, \xi(t)) dt \right] = \lim_{T \rightarrow \infty} \mathbb{E}_\gamma \left[ \int_0^T e^{-\rho t} \delta(i, \xi(t)) dt \right],$$

and this convergence is uniform for all  $\gamma$  and  $\varepsilon$ . For any realization, the integral  $\int_0^T e^{-\rho t} \delta(i, \xi(t, \omega)) dt$  can be shown to be a continuous function of the sample path  $\xi(t, \omega)$  in an appropriate norm  $d(\cdot)$  (see Appendix A). Then to establish (4.5) it suffices to show that the weak convergence limit

$$(4.7) \quad P_\varepsilon[\sigma^\varepsilon(\tilde{\underline{x}})] \Rightarrow P[\tilde{\underline{x}}]$$

holds, where  $P_\varepsilon[\sigma^\varepsilon(\underline{x})]$  and  $P[\underline{x}]$  are the probability measures induced on the restriction of the sample space to functions defined over the interval  $[0, T]$  by  $\sigma^\varepsilon(\underline{x})$  and  $\underline{x}$  for the games  $G^\varepsilon$  and  $G^0$ , respectively.

Applying<sup>1</sup> Theorem 15.4 from [1] we can say that the weak convergence property (4.7) holds if, for any finite set of sample times  $t_1, \dots, t_p$ , the probability measures induced on the  $p$  random variables  $\xi(t_1), \dots, \xi(t_p)$  by the strategy  $\sigma^\varepsilon(\underline{x})$  converge weakly to the probability measure induced by the limit game strategy  $\underline{x}$ . We summarize this by the expression

$$(4.8) \quad P_\varepsilon \pi_{t_1, \dots, t_p}^{-1} \Rightarrow P \pi_{t_1, \dots, t_p}^{-1},$$

where  $\pi_{t_1, \dots, t_p}^{-1}$  is the inverse image of the projection of the  $\xi(\cdot)$  process on the  $p$  sample times. This property is shown to hold in the rest of the proof presented in the appendix.  $\square$

The next result will establish convergence for the payoff functionals.

**PROPOSITION 4.3.** *For any strategy  $\underline{x}$  of the limit game  $G^0$  the following holds true:*

$$(4.9) \quad \lim_{\varepsilon \rightarrow 0} |V_j^\varepsilon(\sigma^\varepsilon(\underline{x}); i, x^o) - V_j(\underline{x}; i)| = 0 \quad \forall i \in I.$$

*Proof.* Consider the sample paths of the process  $\{(\xi(\cdot, \omega), \underline{x}(\cdot, \omega)) : [t, \infty) \rightarrow I \times \mathbb{R}^n : \omega \in \Omega\}$  generated by a strategy  $\underline{\gamma}^\varepsilon = \sigma^\varepsilon(\underline{x})$ . Almost surely any sample path has a countable number of jump times denoted  $t_l(\omega)$ ,  $l = 0, \dots, \infty$ . The following holds true:

$$(4.10) \quad \mathbb{E}_{\underline{\gamma}^\varepsilon} \left[ \sum_{l=0}^{\infty} e^{-\rho_j t_l} \right] \leq M.$$

Therefore we can write

$$(4.11) \quad \begin{aligned} V_j^\varepsilon(\underline{\gamma}^\varepsilon; x^o, i) &= \mathbb{E}_{\underline{\gamma}^\varepsilon} \left[ \int_0^\infty e^{-\rho_j t} \mathcal{L}_j^{\xi(t)}(\underline{x}(t), \dot{x}_j(t)) dt \mid \underline{x}(0) = x^o; \xi(0) = i \right] \\ &= \mathbb{E}_{\underline{\gamma}^\varepsilon} \left[ \sum_{l=0}^{\infty} \int_{t_l}^{t_{l+1}} e^{-\rho_j t} \mathcal{L}_j^{\xi_l}(\underline{x}(t), \dot{x}_j(t)) dt \mid \underline{x}(0) = x^o; \xi(0) = i \right] \\ &= \mathbb{E}_{\underline{\gamma}^\varepsilon} \left[ \sum_{l=0}^{\infty} \int_{t_l}^{t_{l+1}} e^{-\rho_j t} \mathcal{L}_j^{\xi_l}(\underline{x}^{\xi_l}, 0) dt \right. \\ &\quad + \sum_{l=0}^{\infty} \int_{t_l}^{\min\{t_l + \varepsilon\theta, t_{l+1}\}} e^{-\rho_j t} \left( \mathcal{L}_j^{\xi_l}(\underline{x}(t), \dot{x}_j(t)) - \mathcal{L}_j^{\xi_l}(\underline{x}^{\xi_l}, 0) \right) dt \\ &\quad + \sum_{l=0}^{\infty} \int_{\min\{t_l + \varepsilon\theta, t_{l+1}\}}^{t_{l+1}} e^{-\rho_j t} \left( \mathcal{L}_j^{\xi_l}(\underline{x}(t), \dot{x}_j(t)) - \mathcal{L}_j^{\xi_l}(\underline{x}^{\xi_l}, 0) \right) dt \\ &\quad \left. \mid \underline{x}(0) = x^o; \xi(0) = i \right]. \end{aligned}$$

<sup>1</sup>For continuous time Markov chains the condition (15.11) in [1] holds as the probability of having more than one jump in an interval  $[t, t + \delta]$  tends to zero as  $\delta$  tends to zero. Furthermore the set of trajectories that have a jump at  $t = T$  has a zero measure. Therefore we can apply Theorem 15.4 from [1].

As  $\mathcal{L}_j^i$  is bounded in  $X \times U_j$ , the second term in (4.11) tends to zero as  $\varepsilon$  tends to zero. As  $\mathcal{L}_j^i$  is continuous, the last term in (4.11) can be made as small as desired as  $\varepsilon$  tends to zero. It remains to show that the first term in (4.11) tends to  $V_j(\tilde{x}; i)$  when  $\varepsilon$  tends to zero, to conclude that (4.9) holds. Since

$$(4.12) \quad \begin{aligned} & \mathbb{E}_{\tilde{\gamma}^\varepsilon} \left[ \sum_{l=0}^{\infty} \int_{t_l}^{t_{l+1}} e^{-\rho_j t} \mathcal{L}_j^{\xi_l}(\underline{x}^l, 0) dt \mid \underline{x}(0) = x^o; \xi(0) = i \right] \\ &= \sum_{k \in I} \Pi^k(\tilde{\gamma}^\varepsilon; i, x^o) \mathcal{L}_j^k(\underline{x}^k, 0), \end{aligned}$$

the result holds true by Proposition 4.2.  $\square$

**4.2. The auxiliary  $\varepsilon$ -control problems.** Given the strategy  $\sigma^\varepsilon(\tilde{x})$  in the game  $G^\varepsilon$  and an initial state  $x^o$ , we define for each player  $j \in M$  an auxiliary  $\varepsilon$ -control problem as follows:

$$(4.13) \quad W_j^\varepsilon(\gamma_j^\varepsilon; i, \underline{x}^o \mid \sigma^\varepsilon(\tilde{x})) = \mathbb{E}_{\gamma_j} \left[ \int_0^\infty e^{-\rho_j t} L_j^{\xi(t)}(\underline{x}(t), u_j(t)) dt \mid \xi(0) = i, \underline{x}(0) = x^o \right],$$

where the Markov jump process  $\xi(\cdot)$  is still characterized by jump rates  $q_{k\ell}(\underline{x}(t))$  and the state equations in mode  $k \in I$  are

$$(4.14) \quad \varepsilon \dot{x}_j(t) = f_j^k(x_j(t), u_j(t)),$$

$$(4.15) \quad \varepsilon \dot{x}_\ell(t) = s_\ell^k(x_\ell(t); \underline{x}^k, \tilde{x}) \quad \text{if } \ell \neq j.$$

In the equations above  $(k, \underline{x}^k) = (\xi(t^{k+}), \underline{x}(t^{k+}))$  is the state of the system right after the last jump time and  $s_\ell^k(x_\ell(t); \underline{x}^k, \tilde{x})$  is the admissible decentralized system behavior associated with strategy  $\sigma^\varepsilon(\tilde{x})$  for Player  $\ell$ . This control problem for Player  $j$  is thus obtained by fixing the dynamics of the other players to their admissible decentralized system behavior, and therefore the following holds:

$$(4.16) \quad W_j^\varepsilon(\gamma_j^\varepsilon; i, \underline{x}^o \mid \sigma^\varepsilon(\tilde{x})) = V_j^\varepsilon([\sigma_{M-j}^\varepsilon(\tilde{x}), \gamma_j^\varepsilon]; i, \underline{x}^o).$$

Using these auxiliary control problems we will be able to exploit existing results from the theory of singularly perturbed systems, in particular those established in [6].

**4.3. The auxiliary limit-control problem.** For a given  $\tilde{x}$  and for a given set of potential vectors  $\tilde{w}_j = (w_j^i)_{i \in I}$  for each player  $j$ , define the Hamiltonians

$$H_j^i(\tilde{w}_j; \tilde{x}) = \max_{x_j, u_j} \left\{ L_j^i([\tilde{x}_{-j}^i, x_j], u_j) + \sum_{k \in I} q_{ik}(\tilde{x}_{-j}^i, x_j) w_j^i \mid \text{s.t. } f_j^i(x_j, u_j) = 0 \right\}.$$

For each player  $j$  we consider then the solution of the algebraic equations

$$(4.17) \quad \rho_j w_j^{i*} = H_j^i(\tilde{w}_j^*; \tilde{x}), \quad i \in I.$$

Note that these problems, for all  $j \in M$ , correspond to the solution of the limit game introduced in section 3, with the HJB equations given in (3.3).

**4.4. Convergence of the auxiliary  $\varepsilon$ -control problem.** These control problems have been studied in [6], where the following convergence result is established.

**THEOREM 4.4.** *Let the assumptions of Theorems 3 and 4 in [6] be satisfied (see Appendix B for a reminder of these assumptions). Let  $\gamma_j^{\varepsilon*}$  be the optimal strategy in the  $\varepsilon$ -control problem and let  $v_j^*$  be the optimal control in the limit-control problem; then there exists a constant  $C$  such that*

$$(4.18) \quad |W_j^\varepsilon(\gamma_j^{\varepsilon*}; i, \underline{x}^o \mid \sigma^\varepsilon(\tilde{\underline{x}}^*)) - w_j^{i*}| \leq C\varepsilon^{\frac{\alpha}{1+\alpha}}.$$

*Remark 4.* Notice that we have  $w_j^{i*} = V_j(\tilde{\underline{x}}^*; i) = V_j^*(i)$ .

**4.5. Convergence of the  $\varepsilon$ -game.** We can now establish the following result.

**THEOREM 4.5.** *Let  $\tilde{\underline{x}}^*$  be an equilibrium in the limit game  $G^0$ . Then for all positive  $\varsigma$  there exists  $\varepsilon_0$  such that for all  $0 < \varepsilon \leq \varepsilon_0$ , the strategy  $m$ -tuple  $\sigma^\varepsilon(\tilde{\underline{x}}^*)$  defines a  $\varsigma$ -Nash equilibrium for the game  $G^\varepsilon$ .*

*Proof.* Let  $\tilde{\underline{x}}^*$  be an equilibrium in the limit game. Let  $\gamma_j^\varepsilon$  be a strategy for Player  $j$  in the game  $G^\varepsilon$ . Given  $\sigma_{M-j}^\varepsilon(\tilde{\underline{x}}^*)$ , let  $\gamma_j^{\varepsilon*}$  be the optimal strategy in the  $\varepsilon$ -control problem.

Given  $\varsigma$ , there exist  $\varepsilon_0$  such that for  $\varepsilon < \varepsilon_0$  we have

$$(4.19) \quad V_j^\varepsilon([\sigma_{M-j}^\varepsilon(\tilde{\underline{x}}^*), \gamma_j^\varepsilon]; i, \underline{x}^o) = W_j^\varepsilon(\gamma_j^\varepsilon; i, \underline{x}^o \mid \sigma^\varepsilon(\tilde{\underline{x}}^*))$$

$$(4.20) \quad \leq W_j^\varepsilon(\gamma_j^{\varepsilon*}; i, \underline{x}^o \mid \sigma^\varepsilon(\tilde{\underline{x}}^*))$$

$$(4.21) \quad \leq V_j(\tilde{\underline{x}}^*; i) + \varsigma/2$$

$$(4.22) \quad \leq V_j^\varepsilon(\sigma^\varepsilon(\tilde{\underline{x}}^*); i, \underline{x}^o) + \varsigma.$$

The first equality is valid by definition. The first inequality comes from the fact that  $\gamma_j^{\varepsilon*}$  is the optimal strategy in the  $\varepsilon$ -control problem. The second inequality comes from Theorem 4.4 and Remark 4. The last inequality comes from Proposition 4.3.  $\square$

We have thus proved that the correspondence mapping introduced in section 4.1 tends to define an approximate Nash equilibrium when the time scale ratio tends to 0.

**5. The local infinite horizon open-loop games.** We have established that a correspondence mapping based on a property of uniform reachability of steady states defines an approximate equilibrium for the  $G^\varepsilon$  game when  $\varepsilon$  is small. We can now go one step further and show that such a correspondence mapping can be obtained from the equilibrium solutions of a class of local infinite horizon open-loop differential games (IHOLDGs), with the overtaking optimality criterion.

Let  $V_j^*(i) : i \in I$  be the potential function associated with Player  $j$  in the equilibrium solution for the limit game. For any discrete state  $i$  and initial continuous state  $\underline{x}(0) = \underline{x}^o$  define in the stretched out time scale the open-loop differential game with rewards over the time interval  $[0, \theta]$  given by

$$(5.1) \quad J_j^\Theta[\underline{x}^o; \underline{x}(\cdot)] = \int_0^\Theta \left\{ \mathcal{L}_j^i(\underline{x}(\tau), \dot{\underline{x}}_j(\tau)) + \sum_{\ell \in I} q_{i\ell}(\underline{x}(\tau)) V_j^*(\ell) \right\} d\tau, \quad j \in M,$$

where each player  $j$  selects an absolutely continuous trajectory  $\{x_j(\tau) : \tau \geq 0\}$  with  $x_j(0) = x_j^o$ .

**DEFINITION 5.1.** *An overtaking equilibrium for the open-loop game defined by the payoff functionals (5.1) is an  $M$ -trajectory  $(\underline{x}^*(\tau), \tau \geq 0)$  such that, for each player  $j \in M$  and trajectory  $(x_j(\tau), \tau \geq 0)$  the following holds:*

$$(5.2) \quad \liminf_{\Theta \rightarrow \infty} (J_j^\Theta[\underline{x}^o; \underline{x}^*(\cdot)] - J_j^\Theta[\underline{x}^o; [\underline{x}^{*-j}(\cdot), x_j(\cdot)]]) \geq 0.$$

ASSUMPTION 5. *The jump rates  $q_{i\ell}(\underline{x})$  are affine in  $\underline{x}$ . The reward rates  $\mathcal{L}_j^i(\underline{x}, z_j)$  are concave in  $x_j$  and  $u_j$  for each  $j \in M$  and satisfy globally the following condition, also called “strict diagonal concavity” in [16] and [4]:*

$$(5.3) \quad \begin{aligned} & \forall \underline{x}^a, \underline{x}^b \in \underline{X}, \underline{x}^a \neq \underline{x}^b \\ & \forall \zeta_j^a \in \partial_{x_j} \mathcal{L}_j^i(\underline{x}^a, z_j), \zeta_j^b \in \partial_{x_j} \mathcal{L}_j^i(\underline{x}^b, z_j), \\ & \sum_{j \in M} (\zeta_j^a - \zeta_j^b)(x_j^a - x_j^b) > 0. \end{aligned}$$

Under this assumption we can establish the following.

- An overtaking equilibrium for this game exists and is unique. It is characterized by a “turnpike,” which is an attractor for all the equilibrium trajectories emanating from different initial states  $\underline{x}^o$ .
- This attractor corresponds to the equilibrium control associated with  $i \in I$  in the limit game.
- From the overtaking equilibrium solutions to these open-loop games defined for all  $i \in I$  and all initial state  $\underline{x}^o$  we can construct an approximate  $(\varsigma)$  equilibrium for the hybrid game problem.

The existence and uniqueness results with the turnpike property have been proved in [4]. The correspondence between the turnpikes and the equilibrium solutions in the limit game is easily obtained in the following lemma.

LEMMA 5.2. *The turnpike attractor for the IHOLDG defined in (5.1) coincides with the equilibrium solution to the limit game.*

The existence and uniqueness results with the turnpike property have been proved in Carlson and Haurie [4]. The correspondence between the turnpikes and the equilibrium solution in the limit game is easily obtained in the following lemma.

LEMMA 5.3. *The turnpike attractor for the open-loop game defined in (5.1) coincides with the equilibrium solution to the limit game.*

*Proof.* Introduce for each player  $j \in M$  the Hamiltonians  $\mathcal{H}^i : \mathbb{R}^n \times \mathbb{R}^{n_j} \rightarrow \mathbb{R} \cup \{-\infty\}$  defined as

$$(5.4) \quad \mathcal{H}^i(\underline{x}, p_j) = \sup_{z_j} \left\{ \mathcal{L}_j^i(\underline{x}, z_j) + \sum_{\ell \in I} q_{i\ell}(\underline{x}) V_j^*(\ell) + p_j z_j \right\}.$$

If  $\underline{x}^*(\cdot)$  is an overtaking equilibrium at  $\underline{x}^o$ , then there exists, for each player  $j \in M$ , an absolutely continuous function  $p_j^*(\cdot)$  such that

$$(5.5) \quad \dot{x}_j(t) \in \partial_{p_j} \mathcal{H}^i(\underline{x}^*(t), p_j^*(t)),$$

$$(5.6) \quad \dot{p}_j(t) \in -\partial_{x_j} \mathcal{H}^i(\underline{x}^*(t), p_j^*(t)).$$

The turnpike is a solution of

$$(5.7) \quad 0 \in \partial_{p_j} \mathcal{H}^i(\bar{\underline{x}}^i, \bar{p}_j^i),$$

$$(5.8) \quad 0 \in -\partial_{x_j} \mathcal{H}^i(\bar{\underline{x}}^i, \bar{p}_j^i),$$

$$(5.9) \quad j \in M.$$

Under the strict diagonal concavity assumption there exists a unique solution to (5.7)–(5.8), and any solution to (5.5)–(5.6) which remains bounded is such that

$$\lim_{t \rightarrow \infty} \underline{x}^*(t) = \bar{\underline{x}}^i, \quad \lim_{t \rightarrow \infty} p_j^*(t) = \bar{p}_j^i, \quad j \in M.$$

Now it is an easy matter to check that the conditions (5.7)–(5.8) correspond to the sufficient optimality conditions for the problem

$$(5.10) \quad \max_{x_j^i} \left[ \mathcal{L}_j^i(\underline{x}_{M-j}^{*i}, x_j^i, 0) + \sum_{\ell \in I} q_{i\ell}(\underline{x}_{M-j}^{*i}, x_j^i) V_j^*(\ell) \right], \quad j \in M,$$

which is also the right-hand side for mode  $i$  of the HJB equations in the limit game. Therefore the unique turnpike defines also an equilibrium in the limit game  $G^0$ .  $\square$

It is established, in the theory of turnpikes for infinite horizon control or open-loop equilibrium problems under the overtaking optimality criterion that the uniform  $\varsigma$ -reachability condition is satisfied by the trajectories converging toward their respective attractors; see the book [5] for a complete discussion of these topics. In order to link these trajectories with a  $\varsigma$ -equilibrium of the  $G^\varepsilon$  game we need this last assumption.

**ASSUMPTION 6.** *In mode  $i$ , the overtaking trajectories of Player  $j$ , emanating from different initial states  $x_j^o$ , can be synthesized, i.e., they are obtained as solutions to a system of state equations*

$$(5.11) \quad \dot{x}_j(t) = f_j^i(x_j(t), \mu_j^{*i}(x_j(t))); \quad x_j(0) = x^o,$$

where  $\mu_j^{*i}(\cdot)$  is an admissible and continuous decentralized feedback law.

We can summarize the developments in the following.

**PROPOSITION 5.4.** *Given the potential functions associated with the Nash equilibrium of the limit game  $G^0$ , one can construct a family of IHOLDGs, with payoffs defined in (5.1). If Assumptions 5 and 6 are satisfied, the Nash equilibria of these IHOLDGs, under the overtaking optimality criterion, define a piecewise open-loop strategy for the  $G^\varepsilon$  game which is a  $\varsigma$ -equilibrium if  $\varepsilon$  is small enough.*

*Proof.* It suffices to apply Theorem 4.5 with a strategy  $m$ -tuple  $\sigma^\varepsilon(\underline{x}^*)$  obtained from the admissible decentralized system behavior (5.11).  $\square$

**6. A decomposition principle.** The result obtained can be interpreted as a decomposition principle for this two-time scale game. At a higher level one solves the limit stochastic game  $G^0$  and one obtains for each player an equilibrium steady state  $\tilde{x}_j$  and an equilibrium potential function  $V_j^*(k) : k \in I$ . These potential functions are transmitted to all players. The  $G^\varepsilon$  game is then played as follows:

*At a jump time  $t^o$  of the process  $\xi(\cdot)$ , the players observe the state  $(\xi(t^{o+}), \underline{x}(t^{o+})) = (i, \underline{x}^i)$ . Making a time translation to get  $t^o = 0$ , the players solve an IHOLDG where for each player  $j \in M$  the payoff is defined for any  $\Theta > 0$  by*

$$J_j^\Theta[\underline{x}^o; \underline{x}(\cdot)] = \int_0^\Theta \left\{ \mathcal{L}_j^i(\underline{x}(\tau), \dot{x}_j(\tau)) + \sum_{\ell \in I} q_{i\ell}(\underline{x}(\tau)) V_j^*(\ell) \right\} d\tau.$$

*The players find the unique Nash overtaking equilibrium for this open-loop game and they follow this trajectory, as long as the jump process remains in state  $i$ .*

This way of playing the game is close to being a piecewise open-loop Nash equilibrium when the time scale ratio  $\varepsilon$  is small.

**7. Examples.** In this section we provide two illustrations of the application of the theory developed above. The first one is a complete numerical computation realized on a dynamic duopoly model. In this example one shows how one can easily solve

the different dynamic games used in this approximation theory. The second illustration is the reformulation as an hybrid stochastic system of a well-known integrated assessment model of climate change with noncooperative behavior of the economic agents (groups of nations). The stochastic jump process represents modifications in climate modes. The complete development and exploitation of this model would take too much space and will be the subject of another article. We nevertheless indicate how the theory of approximation developed herein would permit an important simplification in the type of game to solve.

**7.1. A simple numerical example.** As a complete illustrative example, let us first consider a simple but nontrivial model and compute the equilibrium turnpike values of the limit game and the equilibrium trajectories of the local IHOLDG that exhibit the turnpike property. We consider a duopoly ( $M = \{1, 2\}$ ) with two slow market modes ( $I = \{0, 1\}$ ).

The fast economic dynamics is defined by the state equations that describe the accumulation of production capacities ( $x_j$ ) through investment ( $u_j$ ) by the two firms

$$(7.1) \quad f_j^i(x_j, u_j) = u_j^i - x_j^i, \quad i \in I, j \in M.$$

The slow dynamics is described by the two transition rates between market modes

$$(7.2) \quad q_{01}(x) = x_1^0 + x_2^0,$$

$$(7.3) \quad q_{10}(x) = 1,$$

and  $\xi(0) = 0$ . Typically mode  $\xi = 0$  would represent a “strong” market and mode  $\xi = 1$  would represent a “depressed” market. The transition from strength to depression is influenced by the total supply on the market. The return from depression to strength is random and not controlled.

The reward functions are the firms’ profits expressed as  $L_j^i(x, u) = a_j^i x_j^i - (u_j^i)^2$ . A common discount rate is fixed at  $\rho_j = \rho = 0.05$ . Payoffs are total expected discounted rewards over an infinite time horizon.

This dynamic duopoly model is similar (it has normalized parameter values) to the model proposed in [9], where a theory of stochastic duopoly with modal jumps is developed and a numerical solution method is proposed. We shall solve now the limit game problem and the local IHOLDGs for this singularly perturbed dynamic game.

**7.1.1. Solving the limit game.** In that particular case, it is possible to find an explicit solution to (3.6). Using Maple we obtain the following expressions for the occupation measures:

$$(7.4) \quad \Pi_j^0(0; \tilde{x}) = \frac{(1 + \rho)}{\rho(1 + \rho + x_1^0 + x_2^0)},$$

$$(7.5) \quad \Pi_j^1(0; \tilde{x}) = \frac{x_1^0 + u_2^0}{\rho(1 + \rho + x_1^0 + x_2^0)}.$$

Now using the expression (3.7) for the payoffs associated with the strategy  $\underline{x}$  in the limit game  $G^0$ , we reduce the search for a Nash equilibrium to the solution of a variational inequality which can be solved with an algorithm given by Konnov [11]. The results are displayed in Table 7.1, which provides the equilibrium steady state values for different sets of parameters  $a_j^i$  used in the reward function. These steady state values, provided by the equilibrium solutions of the limit game, indicate the target production capacity to which the duopolists should aim depending on the prevailing market mode.

TABLE 7.1  
Equilibrium policy for different values of  $a_j^i$ .

$a_1^0$	$a_2^0$	$a_1^1$	$a_2^1$	$x_1^0$	$x_2^0$	$x_1^1$	$x_2^1$
2.00	2.00	2.00	2.00	1.0000	1.0000	1.0000	1.0000
2.00	2.00	0.50	0.50	0.8325	0.8325	0.2500	0.2500
2.00	2.00	1.00	0.25	0.8665	0.8261	0.5000	0.1250
4.00	2.00	1.00	0.25	1.4865	0.8580	0.5000	0.1250
4.00	2.00	0.25	1.00	1.4572	0.8914	0.1250	0.5000

**7.1.2. Solving the local IHOLDG.** We also computed an approximation of the equilibrium trajectories of the local IHOLDG. This is done by discretizing the time scale and taking a finite, but large, time horizon. Doing so, we reduce the problem to a variational inequality that can be solved with the same algorithm [11]. Figure 7.1 displays two trajectories with different initial states  $x$ , for the state  $i = 0$  and for the case where  $a_1^0 = 4.00$ ,  $a_2^0 = 2.00$ ,  $a_1^1 = 1.00$ , and  $a_2^1 = 0.25$ . Note that in this case, the potential values (equilibrium payoffs in the limit game) are  $V_1(0) = 26.5682$ ,  $V_2(0) = 6.2776$ ,  $V_1(1) = 25.5411$ ,  $V_2(1) = 5.9936$ , respectively.

FIG. 7.1. Optimal trajectories for  $i = 0$  when  $a_1^0 = 4$ ,  $a_2^0 = 2$ ,  $a_1^1 = 1$ ,  $a_2^1 = 0.25$ , and  $\rho = 5\%$ . Solid line:  $x_1(0) = 4$  and  $x_2(0) = 3$ . Dotted line:  $x_1(0) = 0$  and  $x_2(0) = 0$ .

As expected, we distinctly see that the trajectories are attracted by the turnpike values given in Table 7.1.

This provides a complete illustration of the results obtained in this paper. The limit game equilibrium tells the player what they should do in the “slow” time scale; the local IHOLDG tells them what they could do in the “fast” time scale in order to be consistent with the long-term equilibrium solution.

**7.2. A model of competitive economic growth with climate change thresholds.** A stochastic control approach to climate change modeling has been advocated in [8] and applied in [10]. These models extended the formalism proposed by Nordhaus [12] by introducing a stochastic jump process representing sudden switches in climate or global environment conditions. Nordhaus and Yang proposed in [14] a deterministic differential game model which represents the noncooperative behavior

of different groups of nations involved in the climate change process. We propose here to extend the model by introducing a description of climate dynamics in the form of discrete modal changes. More precisely let us assume that there exist different climate modes, denoted  $\xi$ , which correspond to different patterns of the general circulation which determines climate dynamics. For example, we distinguish the current pattern ( $\xi = 0$ ) from a second pattern ( $\xi = 1$ ) where the thermo-haline circulation has been stopped and a third pattern ( $\xi = 2$ ) where, in addition, the West-Antarctic ice sheet has collapsed (this type of threshold event was considered in the stochastic control model proposed in [10]).

**7.2.1. The model equations.** Let us denote the following.

**Parameters.**

- $j = 1, \dots, m$  the  $m$  groups of nations, also called players
- $\mu_j$  capital depreciation rate in country  $j$  (typically 10% per year)
- $\nu$  greenhouse gas (GHG) natural elimination rate
- $\rho_j$  long-term discount rate for country  $j$  (typically 0.08% per decade)

**State variables.**

- $K_j$  productive capital stock of country  $j$
- $M$  GHG concentration
- $\xi$  climate mode (discrete value  $\xi \in \{0, 1, 2\}$ )

**Control variables.**

- $I_j$  investment in productive capital stock of country  $j$
- $C_j$  consumption in country  $j$
- $u_j$  abatement effort in country  $j$
- $E_j$  GHG emission in country  $j$

**Production and emission functions.**

- $F_j^{\xi(t)}(K_j, u_j)$  economic output of country; this function is increasing and concave in  $K_j$ , decreasing and concave in  $u_j$ ; its shape depends on  $\xi$
- $G_j^{\xi(t)}(K_j, u_j)$  GHG emissions of country; increasing and convex in  $K_j$ , decreasing and convex in  $u_j$ ; its shape depends on  $\xi$

**State equations.**

- $\dot{K}_j(t) = I_j(t) - \mu_j K_j(t)$  capital accumulation process
- $\dot{M}(t) = \sum_{j=1, \dots, m} E_j(t) - \nu M(t)$  GHG concentration process

**Modal jump rates.**

- $q_{k\ell}(M) = \lim_{dt \rightarrow 0} \frac{P[\xi(t+dt)=\ell | \xi(t)=k]}{dt}$  transition rate from mode  $k$  to mode  $\ell$

**Constraints.**

- $F_j^{\xi(t)}(K_j, u_j) \geq I_j(t) + C_j(t)$  the economic output of country  $j$  can be consumed or saved as an investment
- $G_j^{\xi(t)}(K_j, u_j) \leq E_j(t)$  GHG emissions of country  $j$  are bounded below by the emission function

**Payoffs.**

- $J_j = \int_0^\infty e^{-\rho_j t} U_j(C_j(t)) dt$  the long-term welfare of country  $j$ ;  $U_j(\cdot)$  is a utility function

**Initial conditions.**

$$\begin{aligned}
K_j(0) &= K_j^o && \text{initial physical capital stock of each nation} \\
M(0) &= M^o && \text{initial GHG concentration} \\
\xi(0) &= 0 && \text{initial climate mode}
\end{aligned}$$

**7.2.2. The dynamic game.** This model summarizes the situation of economies where the production activity generates GHG emissions which accumulate and may trigger a climate modal change. An abatement effort can be made by each country at a cost represented by a loss of output in the production function. The climate mode has also a direct influence, also expressed in terms of loss of output, on the economic production function. In this model the  $m$  groups of nations play a noncooperative dynamic game where the objective of the player is to reach an equilibrium for the long-term expected welfare,

$$(7.6) \quad V_j(\gamma; 0, K^o, M^o) = E_\gamma \left[ \int_0^\infty e^{-\rho_j t} U_j(C_j(t)) dt \right],$$

where  $\gamma = (\gamma_1, \gamma_2, \dots, \gamma_m)$  is the vector of piecewise open-loop strategies, and the expectation is taken with respect to the measure induced by  $\gamma$  and the economic and climate dynamics described above. This model retains the cost-benefit analysis framework proposed in [13] and [14] and represents climate change as a stochastic modal switch process.

**7.2.3. The limit game.** Notice that this model combines decoupled dynamics (for the  $K_j$  capital stocks) and a fully coupled state equation (for the GHG concentration  $M$ ). However,  $M$  is a “passive” state variable which influences only the jump rates. It could be shown (see the paper [3] for a discussion of differential games with active and passive variables) that the turnpike property will also hold for differential games having this structure.

The model proposed here introduces the cost of climate change as a modification of the economic production function triggered by a random change of climate mode. The limit game will be a Markov game played over the discrete climate modes and where the controls are the long-term steady state values of the economies. The local IHOLDGs are infinite horizon differential games representing optimal economic growth with an adapted reward and zero discount rate.

**8. Conclusion.** We have considered here a class of hybrid games, under the piecewise open-loop information structure. We have given conditions under which, when the time scale ratio between the stochastic jump process and the deterministic part tend to 0, the Nash equilibrium solutions can be approximated by playing a family of auxiliary infinite horizon open-loop differential games (IHOLDGs). These local games are constructed using the potential functions obtained from the Markov Nash equilibrium of a simplified sequential game. This theory uses the asymptotic stability properties established for IHOLDGs under the strict diagonal concavity assumption. These conditions are the usual ones when one deals with Cournot solutions in dynamic imperfect competition models [16]. The results established in this paper are therefore useful for studying dynamic economic competition, when the market conditions change randomly but relatively seldom, compared with the adjustment speed of the economic decision variables. As indicated in the introduction we can envision such a situation in the framework of competitive economic growth with global environmental impact, like climate change triggered by greenhouse gas emissions, for example.

The evolution of the environmental state, and therefore the evaluation of the environmental damage, is random but evolving slowly. The economies of the world have the possibility to adjust at a much faster speed than the global environment modifications (see [8] for a discussion of control models with different time scales in the climate change modeling domain).

**Appendix A. Continuity and convergence of the occupation measure.**

Let  $D$  be the space of functions on  $[0, 1]$  that are right-continuous and have left-hand limits. Adapting results from [1] we prove that the integral  $\int_0^1 e^{-\rho t} \delta(i, \xi(t, \omega)) dt$  is a continuous function of  $\xi(t, \omega)$  in  $D$ . Let  $\Lambda$  denote the class of strictly increasing, continuous mappings from  $\lambda(\cdot) : [0, 1] \rightarrow [0, 1]$ . For  $\zeta(\cdot)$  and  $\xi(\cdot)$  in  $D$ , define  $d(\zeta(\cdot), \xi(\cdot))$  to be the infimum of the  $\varepsilon > 0$  for which there exists in  $\Lambda$  a  $\lambda(\cdot)$  such that

$$(A.1) \quad \sup_t |\lambda(t) - t| \leq \varepsilon$$

and

$$(A.2) \quad \sup_t |\zeta(t) - \xi(\lambda(t))| \leq \varepsilon.$$

We are now ready to prove that under the norm  $d$ , the function

$$\int_0^1 e^{-\rho t} \delta(i, \xi(t, \omega)) dt$$

is continuous. We know that  $\xi(\cdot, \omega)$  has at most countably many discontinuities. Say that  $\xi(\cdot, \omega)$  has  $N$  discontinuities. Recall that  $\xi(\cdot, \omega)$  takes value in  $I = \{1, 2, \dots, p\}$ . Therefore, given  $\xi(\cdot, \omega) \in D$  for any  $\xi(\cdot, \tilde{\omega}) \in D$  such that  $d(\xi(\cdot, \omega), \xi(\cdot, \tilde{\omega})) < \varepsilon < 1$ , both  $\xi(\cdot, \omega)$  and  $\xi(\cdot, \tilde{\omega})$  must have the same sequence of jumps since otherwise  $d(\xi(\cdot, \omega), \xi(\cdot, \tilde{\omega})) \geq 1$ . Let  $\{t_1, \dots, t_N\}$  (respectively,  $\{\tilde{t}_1, \dots, \tilde{t}_N\}$ ) be the jump times of  $\xi(\cdot, \omega)$  (respectively,  $\xi(\cdot, \tilde{\omega})$ ). By definition of the norm  $|\tilde{t}_n - t_n| < \varepsilon$  for all  $n \in \{1, \dots, N\}$ . We have therefore

$$(A.3) \quad \left| \int_0^1 e^{-\rho t} (\delta(i, \xi(t, \omega)) - \delta(i, \xi(t, \tilde{\omega}))) dt \right| \leq \int_0^1 |\delta(i, \xi(t, \omega)) - \delta(i, \xi(t, \tilde{\omega}))| dt \leq N(p-1)\varepsilon.$$

Since  $p$  and  $N$  are finite and  $\varepsilon$  can be taken as small as desired, the continuity is proved.

*Proof of Proposition 4.2.* For  $\xi(0) = i$ , let us consider in the limit game  $G^0$  and for a game  $G^\varepsilon$ , the probability to have no jump in the interval  $[0, t]$  induced by  $P[\underline{x}]$  and  $P_\varepsilon[\sigma^\varepsilon(\underline{\hat{x}})]$ , respectively. For the limit game  $G^0$  this probability is given by

$$(A.4) \quad \mathcal{P}^0[t, 0, i, i] = e^{-\int_0^t q_{ii}(\underline{x}^i) ds}.$$

For the game  $G^\varepsilon$ , under the strategy  $\sigma^\varepsilon(\underline{\hat{x}})$  this probability is given by

$$(A.5) \quad \mathcal{P}^\varepsilon[t, 0, i, i] = e^{-\int_0^t q_{ii}(\underline{x}(s)) ds},$$

which can be rewritten as

$$\mathcal{P}^\varepsilon[t, 0, i, i] = e^{-\int_0^t q_{ii}(\underline{x}^i) ds - \int_0^{\min(t, \varepsilon\theta)} (q_{ii}(\underline{x}(s)) - q_{ii}(\underline{x}^i)) ds - \int_{\min(t, \varepsilon\theta)}^t (q_{ii}(\underline{x}(s)) - q_{ii}(\underline{x}^i)) ds}.$$

As the jump rates are bounded over  $X$ , the second integral in the expression above converges to 0 when  $\varepsilon \rightarrow 0$ . When  $\varepsilon \rightarrow 0$ , the absolute value of the integral in the third term is bounded by  $\eta t$ , which can be made as small as desired by choosing  $\theta$  sufficiently large. Only the first term remains in the exponent, and this corresponds to (A.5). Therefore this establishes the convergence of  $\mathcal{P}^\varepsilon[t, 0, i, i]$  to  $\mathcal{P}^0[t, 0, i, i]$  when  $\varepsilon \rightarrow 0$ .

We can prove similarly that the probability  $\mathcal{P}^\varepsilon[t, 1, i, k]$  of having  $\xi(t) = k$  and having exactly one jump in the interval  $[0, t]$ , induced by  $\sigma^\varepsilon(\underline{x})$  for the game  $G^\varepsilon$ , converges to the probability  $\mathcal{P}^0[t, 1, i, k]$  of having  $\xi(t) = k$  with exactly one jump in the interval  $[0, t]$ , induced by  $\tilde{x}$  for the game  $G^0$ .  $\mathcal{P}^0[t, 1, i, k]$  is given by

$$(A.6) \quad \mathcal{P}^0[t, 1, i, k] = \int_0^t q_{ik}(\underline{x}^i) e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} ds,$$

whereas the probability  $\mathcal{P}^\varepsilon[t, 1, i, k]$  is given by

$$(A.7) \quad \mathcal{P}^\varepsilon[t, 1, i, k] = \int_0^t q_{ik}(\underline{x}(s)) e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} ds.$$

For a given  $t$ , if  $\varepsilon$  is small enough we have  $\varepsilon\theta < t/2$  and thus can write

$$\begin{aligned} & |\mathcal{P}^\varepsilon[t, 1, i, k] - \mathcal{P}^0[t, 1, i, k]| \\ & \leq \int_0^{\varepsilon\theta} \left| q_{ik}(\underline{x}(s)) e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} - q_{ik}(\underline{x}^i) e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} \right| ds \\ & + \int_{t-\varepsilon\theta}^t \left| q_{ik}(\underline{x}(s)) e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} - q_{ik}(\underline{x}^i) e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} \right| ds \\ & + \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| q_{ik}(\underline{x}(s)) e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} - q_{ik}(\underline{x}^i) e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} \right| ds. \end{aligned}$$

The first two terms tend to zero as  $\varepsilon$  tends to zero, whereas the last term can be rewritten as

$$\begin{aligned} & \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| (q_{ik}(\underline{x}(s)) - q_{ik}(\underline{x}^i)) e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} \right. \\ & \left. - q_{ik}(\underline{x}^i) \left( e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} - e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} \right) \right| ds \\ & \leq \int_{\varepsilon\theta}^{t-\varepsilon\theta} |q_{ik}(\underline{x}(s)) - q_{ik}(\underline{x}^i)| \left| e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} \right| ds \\ & + \int_{\varepsilon\theta}^{t-\varepsilon\theta} |q_{ik}(\underline{x}^i)| \left| e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} - e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} \right| ds. \end{aligned}$$

When  $\varepsilon$  tends to zero, the first term on the right-hand side of the inequality above can be made as small as desired, choosing  $\theta$  sufficiently big. The second term can be

rewritten as

$$\begin{aligned}
& \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| e^{-\int_0^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^t q_{kk}(\underline{x}^k) dv} - e^{-\int_0^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^t q_{kk}(\underline{x}(v)) dv} \right| ds \\
&= \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| e^{-\int_0^{\varepsilon\theta} q_{ii}(\underline{x}^i) dv} e^{-\int_{\varepsilon\theta}^s q_{ii}(\underline{x}^i) dv} e^{-\int_s^{s+\varepsilon\theta} q_{kk}(\underline{x}^k) dv} e^{-\int_{s+\varepsilon\theta}^t q_{kk}(\underline{x}^k) dv} \right. \\
&\quad \left. - e^{-\int_0^{\varepsilon\theta} q_{ii}(\underline{x}(v)) dv} e^{-\int_{\varepsilon\theta}^s q_{ii}(\underline{x}(v)) dv} e^{-\int_s^{s+\varepsilon\theta} q_{kk}(\underline{x}(v)) dv} e^{-\int_{s+\varepsilon\theta}^t q_{kk}(\underline{x}(v)) dv} \right| ds \\
&\leq \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| e^{-\int_0^{\varepsilon\theta} q_{ii}(\underline{x}^i) dv} e^{-\int_s^{s+\varepsilon\theta} q_{kk}(\underline{x}^k) dv} \right| \\
&\quad \left| e^{-\int_{\varepsilon\theta}^s q_{ii}(\underline{x}^i) dv} e^{-\int_{s+\varepsilon\theta}^t q_{kk}(\underline{x}^k) dv} - e^{-\int_{\varepsilon\theta}^s q_{ii}(\underline{x}(v)) dv} e^{-\int_{s+\varepsilon\theta}^t q_{kk}(\underline{x}(v)) dv} \right| ds \\
&\quad + \int_{\varepsilon\theta}^{t-\varepsilon\theta} \left| e^{-\int_{\varepsilon\theta}^s q_{ii}(\underline{x}(v)) dv} e^{-\int_{s+\varepsilon\theta}^t q_{kk}(\underline{x}(v)) dv} \right| \\
&\quad \left| e^{-\int_0^{\varepsilon\theta} q_{ii}(\underline{x}^i) dv} e^{-\int_s^{s+\varepsilon\theta} q_{kk}(\underline{x}^k) dv} - e^{-\int_0^{\varepsilon\theta} q_{ii}(\underline{x}(v)) dv} e^{-\int_s^{s+\varepsilon\theta} q_{kk}(\underline{x}(v)) dv} \right| ds.
\end{aligned}$$

By continuity of the exponential and  $q(\cdot)$  functions and (4.2), this expression can be made as small as desired, when  $\varepsilon$  tends to zero. We can now extend this approach via an induction argument. Suppose that for  $n-1$ ,  $\mathcal{P}^\varepsilon[t, n-1, i, k]$  tends to  $\mathcal{P}^0[t, n-1, i, k]$  when  $\varepsilon$  tends to zero. We have

$$(A.8) \quad \mathcal{P}^\varepsilon[t, n, i, k] = \sum_{l \neq k} \int_0^t \mathcal{P}^\varepsilon[s, n-1, i, l] \mathcal{P}^\varepsilon[t-s, 1, l, k] ds.$$

Using the result proved for  $n=1$ , we can easily conclude that the following also holds:

$$(A.9) \quad \lim_{\varepsilon \rightarrow 0} \mathcal{P}^\varepsilon[t, n, i, k] = \sum_{l \neq k} \int_0^t \mathcal{P}^0[s, n-1, i, l] \mathcal{P}^0[t-s, 1, l, k] ds = \mathcal{P}^0[t, n, i, k].$$

We can thus prove, by induction, that for each finite  $n$ ,  $\mathcal{P}^\varepsilon[t, n, i, k]$  tends to  $\mathcal{P}^0[t, n, i, k]$  when  $\varepsilon$  tends to zero. Knowing that the probability of having more than  $n$  jumps tends to zero as  $n$  tends to infinity, it follows that

$$(A.10) \quad P_\varepsilon \pi_{t_1, \dots, t_k}^{-1} \Rightarrow P \pi_{t_1, \dots, t_k}^{-1},$$

and this establishes the convergence result (4.5), as was indicated at the beginning of the proof.

**Appendix B. Results of [6].** In [6] the single player case is solved and the convergence result used in this paper as Theorem 4.4 is based on the following assumption.

**ASSUMPTION 7.** For any vector  $\underline{v} = \{v(i)\}_{i \in I}$  consider the family of deterministic optimal control problems

$$\begin{aligned}
H^i(\theta, x^o, \underline{v}) &= \inf \frac{1}{\theta} \int_0^\theta \left( L^i(x(t), u(t)) + \sum_{i \in I} q_{ik}(x(t)) v(k) \right), \\
\frac{dx(t)}{dt} &= f^i(x(t), u(t)), \\
u(t) &\in U^i, \\
x(0) &= x^o.
\end{aligned}$$

One assumes that there exist two constants  $A > 0$  and  $\alpha \in (0, 1]$ , and for each  $i \in I$  a function  $H^i(\underline{v})$ , such that for each  $i \in I$ ,  $x^o \in X$ , and  $\underline{v}$  in a bounded set  $\Omega$

$$(B.1) \quad |H^i(\theta, x^o, \underline{v}) - H^i(\underline{v})| \leq \frac{1}{\theta^\alpha}.$$

Under this assumption Theorem 4.4 is established.

**Acknowledgment.** The authors thank Prof. Biancamaria D'Onofrio from the University of Rome La Sapienza for her help in this research.

## SUFFICIENT OPTIMALITY CONDITIONS FOR DIRICHLET BOUNDARY CONTROL OF WAVE EQUATIONS\*

ANDRZEJ NOWAKOWSKI†

**Abstract.** We study optimal control problems for wave equations (focusing on the multidimensional wave equation) with control functions in the Dirichlet boundary conditions under pointwise control (and we admit state—by assuming weak hypotheses) constraints.

**Key words.** sufficient optimality condition, wave equations, Dirichlet boundary controls, dual dynamic programming

**AMS subject classifications.** Primary, 49K20, 49J20; Secondary, 93C20, 35L20

**DOI.** 10.1137/050644008

The paper we present is devoted to the study of optimal control problems for state-constrained wave equations with controls as well in state equation as in Dirichlet boundary conditions. We focus our attention to the following problem (P) governed by the multidimensional wave equation:

$$\begin{aligned} \text{minimize } J(x, u, v) = & \int_{[0,T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz \\ & + \int_{\Sigma} h(t, z, v(t, z)) dt dz + \int_{\Omega} l(x(T, z)) dz \end{aligned}$$

subject to

$$(0.1) \quad x_{tt}(t, z) - \Delta_z x(t, z) = f(t, z, x(t, z), u(t, z)) \quad \text{a.e. on } (0, T) \times \Omega,$$

$$(0.2) \quad x(0, z) = \varphi(0, z), \quad x_t(0, z) = \psi(0, z) \quad \text{on } \Omega,$$

$$(0.3) \quad x(t, z) = v(t, z) \quad \text{on } (0, T) \times \Gamma,$$

$$(0.4) \quad u(t, z) \in U \quad \text{a.e. on } (0, T) \times \Omega,$$

$$(0.5) \quad v(t, z) \in \mathbf{V} \quad \text{on } (0, T) \times \Gamma,$$

where  $\Omega$  is a given bounded domain of  $R^n$  with boundary  $\Gamma = \partial\Omega$  of  $C^2$ ,  $\Sigma = (0, T) \times \Gamma$ ;  $U \subset R^m$  and  $\mathbf{V} \subset R$  are given nonempty sets,  $\mathbf{V}$ -closed;  $L, f : [0, T] \times \bar{\Omega} \times R \times R^m \rightarrow R$ ,  $l : R \rightarrow R$ ,  $h : [0, T] \times \bar{\Omega} \times R \rightarrow R$ , and  $\varphi, \psi : R^{n+1} \rightarrow R$  are given functions;  $\varphi(0, \cdot) \in L^2(\Omega)$ ,  $\psi(0, \cdot) \in H^{-1}(\Omega)$ ;  $x : [0, T] \times \Omega \rightarrow R$ ,  $x \in W^{2,2}((0, T) \times \Omega) \cap C([0, T]; L^2(\Omega))$ ; and  $u : [0, T] \times \Omega \rightarrow R^m$ ,  $v : [0, T] \times \Gamma \rightarrow R$  are Lebesgue measurable functions in suitable sets. We assume that the functions  $L, f, h, l$  are lower semicontinuous in their domains of definitions. Assuming the lower semicontinuity of these functions only, we

†Faculty of Math, University of Lodz, Banacha 22, 90-238 Lodz, Poland (annowako@math.uni.lodz.pl).

admit that state  $x$  may satisfy some pointwise state constraints, e.g., that  $x(t, z) \in C$  for a.e.  $(t, z) \in [0, T] \times \Omega$  with  $C$  a closed set in  $R$ . We call a trio  $x(t, z)$ ,  $u(t, z)$ ,  $v(t, z)$  admissible if it satisfies (0.1)–(0.5) and  $L(t, z, x(t, z), u(t, z))$ ,  $h(t, z, v(t, z))$  are summable; then the corresponding trajectory  $x(t, z)$  is said to be admissible.

It is well known that optimal control problems with pointwise state constraints belong to one of the most challenging and difficult classes in control theory. Quite recently, growing interest in such problems for parabolic equations has been taken in [1], [2], [11], [13], [25], [26]; see also the references therein. Much less has been done for wave equations. Some control problems for the wave equation in the presence of state constraints are considered in [12], [31], [32], [23], [24] for distributed controls. There are only a few results [23], [24] on boundary control problems for the wave equation and/or for other partial differential equations (PDEs) of the hyperbolic type. Note that there are essential differences between parabolic and hyperbolic systems. Generally, hyperbolic equations exhibit less regularity. This is why in that paper we assume that system (0.1)–(0.5) admits at least one solution belonging to  $W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ . About the existence and regularity problems for that system, see, e.g., [20] and the extensive discussion of our problem in [23], [24].

The aim of the paper is to present sufficient optimality conditions for problem (P) in terms of dynamic programming conditions directly. In the literature, there are no works which study problem (P) directly by a dynamic programming method. The only results known to the author for the parabolic (as well as abstract) case (see, e.g., [7], [8], [9], [10], [11], [12], [13], [14], [15], [22], [27] and the references therein) treat problem (P) first as an abstract problem with an abstract evolution equation (0.1) and then derive from abstract Hamilton–Jacobi equations suitable sufficient optimality conditions for problem (P). We would like to stress that the problem with Dirichlet boundary control is rather difficult to treat by abstract formulation of the problem as then the abstract space of function on  $\Omega$  must depend on control also on  $\partial\Omega$ , i.e., we need to consider the abstract space depending on control. We refer the reader to [12], [20] and their bibliographies for more discussions on important differences between parabolic and hyperbolic systems.

We propose almost a direct method to study (P) by a dual dynamic programming approach following the method described in [28] for the one-dimensional case and in [16] for the multidimensional case. We move all notions of a dynamic programming to a dual space (the space of multipliers) and then develop a dual dynamic approach together with a dual Hamilton–Jacobi equation and as a consequence sufficient optimality conditions for (P). We also define an optimal dual feedback control and formulate sufficient conditions for optimality in terms of it. Such an approach allows us to significantly weaken the assumptions on the data. An approximate minimum in terms of the dual dynamic programming is also investigated.

**1. A dual dynamic programming.** In this section we describe an intuition of a dual dynamic approach to optimal control problems governed by wave equations. Let us recall what is meant by dynamic programming. We have an initial condition  $(t_0, x_0(t_0, z))$ ,  $z \in \Omega$ , and for it assume we have an optimal solution  $(\bar{x}, \bar{u}, \bar{v})$ . Then by necessary optimality conditions (see, e.g., [23]) there exists a function  $\bar{p}(t, z) = (y^0, y(t, z))$  on  $(0, T) \times \Omega$ —conjugate function—that is a solution to the corresponding adjoint system. That  $p = (y^0, y)$  plays the role of multiplier from the classical Lagrange problem with constraints (with multiplier  $y^0$  corresponding to the functional and  $y$  corresponding to the constraint). If we perturb  $(t_0, x_0)$ , then assuming that the optimal solution for each perturbed problem exists we also have

corresponding to it a conjugate function. Therefore making perturbations of our initial conditions, we obtain two sets of functions: optimal trajectories  $\bar{x}$  and corresponding to them conjugate functions  $\bar{p}$ . The graph of those sets of functions cover some sets in state space  $(t, z, x)$ , say a set  $X$  (in the classical calculus of variations it is called the field of extremals), and in conjugate space  $(t, z, p)$ , say a set  $P$  (in classical mechanics it is called the space of momentums). In the classical dynamic programming (see, e.g., [7]) approach, we explore the state space  $(t, z, x)$ , i.e., the set  $X$ , and in the dual dynamic programming (see [28] for the one-dimensional case and [16] for the multidimensional case) approach we explore the conjugate space (the dual space)  $(t, z, p)$ , i.e., the set  $P$ . It is worth noting that in elliptic control optimization problems there is no possibility of perturbing the problems; however, we can still apply dual dynamic programming (see [17]). It is natural that if we want to explore the dual space  $(t, z, p)$ , then we need a mapping between the set  $P$  and the set  $X$ ,  $P \ni (t, z, p) \rightarrow (t, z, \tilde{x}(t, z, p)) \in X$ , to make it possible at the end of some consideration in  $P$  to formulate some conditions about optimality for our original problem as well as on an optimal solution  $\bar{x}$ . (In the classical calculus of variations, when we form a field of extremals, we do have such a mapping  $(t, \beta) \rightarrow (t, x(t, \beta))$  which parametrizes by  $\beta$  the field of extremals.) Of course, such a mapping should have the following property (in calculus of variations  $(t, \beta) \rightarrow (t, x(t, \beta))$  has this property): for each admissible function  $x(t, z)$  lying in  $X$  there must exist a function  $p(t, z)$  lying in  $P$  such that  $x(t, z) = \tilde{x}(t, z, p(t, z))$ . Hence, we do all our investigations in a dual space  $(t, z, p)$  (in Young [33] it is done for fields of extremals of calculus of variations in the space  $(t, \beta)$ ); i.e., most of our notions concerning dynamic programming are defined in the dual space and thus also a dynamic programming equation, which becomes now a dual dynamic programming equation. We would like to stress that Weierstrass sufficient optimality conditions which use the field of extremals are only optimality conditions concerning the relative minimum, i.e.,  $\tilde{x}$  is an argument of minimum relative to all admissible trajectories whose graphs are lying in the set covered by the graphs of extremals of the field  $x(t, \beta)$ . We do exactly the same. Our function corresponding to the field is now  $\tilde{x}(t, z, p)$  and we are able also to investigate only the relative minimum, relative to the set  $X$ . In calculus of variations  $x(t, \beta)$  is defined by a field of extremals; in our case  $\tilde{x}(t, z, p)$  will be defined by derivative of function which satisfies a dual dynamic equation and which to some extent corresponds to a function defining the field of extremals in the classical setting; i.e., if we confine ourselves to the one-dimensional calculus of variations problem, then that function will define exactly a field of extremals.

Therefore let  $P \subset R^{n+3}$  be a set of the variables  $(t, z, p) = (t, z, y^0, y)$ ,  $(t, z) \in [0, T] \times \bar{\Omega}$ ,  $y^0 \leq 0$ ,  $y \in R$ , and let  $\bar{c} = (c^0, c) \in R^2$  be fixed. The constant  $\bar{c}$  is introduced for practical purpose only, in order to make easier calculations of some relations stated below for concrete problems (see section 4). We adopt the convention that  $\bar{c}p = (c^0 y^0, cy)$  for  $(t, z, p) \in P$ . Let  $\tilde{x} : P \rightarrow R$  be such a function of the variables  $(t, z, p)$  that for each admissible trajectory  $x(t, z)$  there exists a function  $p(t, z) = (y^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \bar{\Omega}) \cap C([0, T]; L^2(\Omega))$ ,  $(t, z, p(t, z)) \in P$ , such that

$$(1.1) \quad x(t, z) = \tilde{x}(t, z, p(t, z)) \quad \text{for } (t, z) \in [0, T] \times \bar{\Omega}.$$

Now, let us introduce an auxiliary function  $V(t, z, p) : P \rightarrow R$  being of  $C^2$  such that

the following two conditions are satisfied:

$$(1.2) \quad V(t, z, \bar{c}p) = c^0 y^0 V_{y^0}(t, z, \bar{c}p) + cy V_y(t, z, \bar{c}p) = \bar{c}p V_p(t, z, \bar{c}p) \\ \text{for } (t, z) \in (0, T) \times \Omega, (t, z, \bar{c}p) \in P,$$

$$(1.3) \quad \nabla_z V(t, z, \bar{c}p) \nu(z) = c^0 y^0 \nabla_z V_{y^0}(t, z, \bar{c}p) \nu(z) \\ \text{for } (t, z) \in [0, T] \times \partial\Omega, (t, z, \bar{c}p) \in P,$$

where  $\nu(\cdot)$  is the exterior unit normal vector to  $\partial\Omega$  and  $\nabla V(t, z, p)$  means “ $\nabla$ ” of the function  $z \rightarrow V(t, z, p)$ . The condition (1.2) is a generalization of the transversality condition known in classical mechanics as orthogonality of momentum to the front of the wave. The condition (1.3) has the same meaning but taken on the boundary. Similarly as in classical dynamic programming, define at  $(t, \tilde{p}(\cdot))$ , where  $\tilde{p}(\cdot) = (\tilde{y}^0, \tilde{y}(\cdot))$  is any function  $\tilde{p} \in W^{2,2}(\Omega)$ ,  $(t, z, \tilde{p}(z)) \in P$ ,  $(t, z) \in [0, T] \times \Omega$ , a dual value function  $S_D$  by the formula

$$(1.4) \quad S_D(t, \tilde{p}(\cdot)) := \inf \left\{ -c^0 \tilde{y}^0 \int_{[t, T] \times \Omega} L(\tau, z, x(\tau, z), u(\tau, z)) d\tau dz \right. \\ \left. - c^0 \tilde{y}^0 \int_{\Omega} l(x(T, z)) dz - c^0 \tilde{y}^0 \int_{[t, T] \times \partial\Omega} h(\tau, z, v(\tau, z)) d\tau dz \right\},$$

where the infimum is taken over all admissible trios  $x(\tau, \cdot)$ ,  $u(\tau, \cdot)$ ,  $v(\tau, \cdot)$ ,  $\tau \in [t, T]$ , such that

$$(1.5) \quad x(t, z) = \tilde{x}(t, z, \tilde{p}(z)) \quad \text{for } z \in \Omega,$$

$$(1.6) \quad \tilde{x}(t, z, \tilde{p}(z)) = v(t, z) \quad \text{for } z \in \partial\Omega,$$

i.e., whose trajectories start at  $(t, \tilde{x}(t, \cdot, \tilde{p}(\cdot)))$  and for which there exists such a function  $p(\tau, z) = (\tilde{y}^0, y(\tau, z))$ ,  $p \in W^{2,2}([t, T] \times \bar{\Omega}) \cap C([t, T]; L^2(\Omega))$ ,  $(\tau, z, \bar{c}p(\tau, z)) \in P$ , such that  $x(\tau, z) = \tilde{x}(\tau, z, \bar{c}p(\tau, z))$  for  $(\tau, z) \in (t, T) \times \bar{\Omega}$  and

$$(1.7) \quad y(t, z) = \tilde{y}(z) \quad \text{for } z \in \bar{\Omega}.$$

Then, integrating (1.2) over  $\Omega$ , for any function  $\tilde{p}(\cdot) = (\tilde{y}^0, \tilde{y}(\cdot))$ ,  $\tilde{p} \in W^{2,2}(\Omega)$ ,  $(t, z, \tilde{p}(z)) \in P$ ,  $(t, z, \bar{c}\tilde{p}(z)) \in P$ , such that  $x(\cdot, \cdot)$  satisfying  $x(t, z) = \tilde{x}(t, z, \tilde{p}(z))$  for  $z \in \bar{\Omega}$  is an admissible trajectory, we also have the equalities

$$(1.8) \quad \int_{\Omega} V(t, z, \bar{c}\tilde{p}(z)) dz + \int_{\partial\Omega} \nabla_z V(t, z, \bar{c}\tilde{p}(z)) \nu(z) dz \\ = -c \int_{\Omega} \tilde{y}(z) x(t, z, \tilde{p}(z)) dz - S_D(t, \tilde{p}(\cdot)),$$

with

$$(1.9) \quad \int_{\Omega} c^0 \tilde{y}^0 V_{y^0}(t, z, \bar{c}\tilde{p}(z)) dz + c^0 \tilde{y}^0 \int_{\partial\Omega} \nabla_z V_{y^0}(t, z, \bar{c}\tilde{p}(z)) \nu(z) dz = -S_D(t, \tilde{p}(\cdot))$$

and assuming

$$\tilde{x}(t, z, \tilde{p}(z)) = -V_y(t, z, \bar{c}\tilde{p}(z)) \quad \text{for } (t, z) \in (0, T) \times \bar{\Omega}, (t, z, \bar{c}\tilde{p}(z)) \in P.$$

Denote by the symbol  $\Delta_z h$  the sum of the second partial derivatives of the function  $h : P \longrightarrow R$  with respect to the variable  $z_i$ ,  $i = 1, \dots, n$ , i.e.,

$$(1.10) \quad \Delta_z h(t, z, p) := \sum_{i=1}^n \frac{\partial^2 h}{\partial z_i^2}(t, z, p).$$

It turns out that the function  $V(t, z, p)$  as defined by (1.8), (1.9) satisfies the second order partial differential system

$$(1.11) \quad \begin{aligned} V_{tt}(t, z, \bar{c}p) - \Delta_z V(t, z, \bar{c}p) + H(t, z, -V_y(t, z, \bar{c}p), \bar{c}p) &= 0, \\ (t, z) &\in (0, T) \times \Omega, \quad (t, z, \bar{c}p) \in P, \\ \nabla_z V(t, z, \bar{c}p)\nu(z) + H_\Sigma(t, z, \bar{c}p) &= 0, \quad (t, z) \in (0, T) \times \partial\Omega, \quad (t, z, \bar{c}p) \in P, \end{aligned}$$

where

$$(1.12) \quad \begin{aligned} H(t, z, x, \bar{c}p) &= c^0 y^0 L(t, z, x, u(t, z, p)) + cyf(t, z, x, u(t, z, p)), \\ H_\Sigma(t, z, \bar{c}p) &= c^0 y^0 h(t, z, v(t, z, p)) \end{aligned}$$

and  $u(t, z, p)$ ,  $v(t, z, p)$  are optimal dual feedback controls, respectively, on  $(0, T) \times \Omega$  and  $(0, T) \times \partial\Omega$ , and the dual second order partial differential system of multidimensional dynamic programming (DSPDEMDP)

$$(1.13) \quad \begin{aligned} \sup \{ &V_{tt}(t, z, \bar{c}p) - \Delta_z V(t, z, \bar{c}p) + c^0 y^0 L(t, z, -V_y(t, z, \bar{c}p), u) \\ &+ cyf(t, z, -V_y(t, z, \bar{c}p), u) : u \in U \} = 0, \quad (t, z) \in (0, T) \times \Omega, \quad (t, z, \bar{c}p) \in P, \\ \sup \{ &\nabla_z V(t, z, \bar{c}p)\nu(z) + c^0 y^0 h(t, z, v) : v \in \mathbf{V} \} = 0, \\ &(t, z) \in (0, T) \times \partial\Omega, \quad (t, z, \bar{c}p) \in P. \end{aligned}$$

Let us note that the function  $\tilde{x}(t, z, p)$  was introduced at the beginning of this section a little bit artificially; in fact it is defined by  $-V_y(t, z, p)$ , where  $V$  is a solution to (1.13); i.e., knowing the set  $P$  and  $V_y$  we are able to know the set  $\dot{X}$ , where we need to consider our original problem.

*Remark.* We would like to stress that the duality which is sketched in this section is not a duality in the sense of convex optimization. It is a new nonconvex duality, first described in [28] and next developed in [16], for which we do not have the relation  $\sup(\mathbf{D}) \leq \inf(\mathbf{P})$  ( $\mathbf{D}$  signifies a dual problem,  $\mathbf{P}$  a primal one). But instead we have other relations, namely, (1.2) and (1.8), (1.9), which are generalizations of transversality conditions from classical mechanics. If we find a solution to (1.13), then checking the relation (1.2) for concrete problems is not very difficult.

**2. A verification theorem.** The most important conclusion of a dynamic programming is a verification theorem. We present it in a dual form according to our dual dynamic programming approach described in the previous section.

**THEOREM 2.1.** *Let  $\bar{x}(t, z)$ ,  $\bar{u}(t, z)$ ,  $(t, z) \in (0, T) \times \bar{\Omega}$ ,  $\bar{v}(t, z)$ ,  $(t, z) \in (0, T) \times \partial\Omega$ , be an admissible trio. Assume that there exist  $\bar{c} = (c^0, c) \in R^2$  and a  $C^2$  solution  $V(t, z, p)$  of DSPDEMDP (1.13) on  $P$  such that (1.2), (1.3) hold. Further, let  $\bar{p}(t, z) = (\bar{y}^0, \bar{y}(t, z))$ ,  $\bar{p} \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $\bar{p} \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}p(t, z)) \in$*

$P$ , be such a function that  $\bar{x}(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \bar{\Omega}$ . Suppose that  $V(t, z, p)$  satisfies the boundary condition for  $(T, z, \bar{c}p) \in P$ ,

$$(2.1) \quad c^0 \bar{y}^0 \int_{\Omega} (d/dt) V_{y^0}(T, z, \bar{c}p) dz = c^0 \bar{y}^0 \int_{\Omega} l(-V_y(T, z, \bar{c}p)) dz.$$

Moreover, assume that

$$(2.2) \quad \begin{aligned} & V_{tt}(t, z, \bar{c}p(t, z)) - \Delta_z V(t, z, \bar{c}p(t, z)) + c^0 \bar{y}^0 L(t, z, -V_y(t, z, \bar{c}p(t, z)), \bar{u}(t, z)) \\ & + c \bar{y}(t, z) f(t, z, -V_y(t, z, \bar{c}p(t, z)), \bar{u}(t, z)) = 0 \quad \text{for } (t, z) \in (0, T) \times \Omega, \end{aligned}$$

$$(\nabla_z) V(t, z, \bar{c}p(t, z)) \nu(z) + c^0 y^0 h(t, z, \bar{v}(t, z)) = 0 \quad \text{for } (t, z) \in (0, T) \times \partial\Omega.$$

Then  $\bar{x}(t, z)$ ,  $\bar{u}(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $\bar{v}(t, z)$ ,  $(t, z) \in (0, T) \times \partial\Omega$ , is an optimal trio relative to all admissible trios  $x(t, z)$ ,  $u(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z)$ ,  $(t, z) \in (0, T) \times \partial\Omega$ , for which there exists such a function  $p(t, z) = (\bar{y}^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $p \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}p(t, z)) \in P$ , such that  $x(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \partial\Omega$  and

$$(2.3) \quad y(0, z) = \bar{y}(0, z) \quad \text{for } z \in \Omega.$$

*Proof.* Let  $x(t, z)$ ,  $u(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z)$ ,  $(t, z) \in (0, T) \times \partial\Omega$ , be an admissible trio for which there exists such a function  $p(t, z) = (\bar{y}^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $p \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}p(t, z)) \in P$ , such that  $x(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \partial\Omega$  and (2.3) is satisfied. From transversality condition (1.2), (1.3), we obtain that for  $(t, z) \in (0, T) \times \Omega$ ,

$$(2.4) \quad \begin{aligned} & V_{tt}(t, z, \bar{c}p(t, z)) - \Delta_z V(t, z, \bar{c}p(t, z)) \\ & = c^0 \bar{y}^0 \left[ (d^2/dt^2) V_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) V_{y^0}(t, z, \bar{c}p(t, z)) \right] \\ & + cy(t, z) \left[ (d^2/dt^2) V_y(t, z, \bar{c}p(t, z)) - (\Delta_z) V_y(t, z, \bar{c}p(t, z)) \right] \end{aligned}$$

(since  $V$  is of  $C^2$ ,  $V_y(t, z, \bar{c}p(t, z)) = -x(t, z)$ , and  $x \in W^{2,2}([0, T] \times \Omega)$ , therefore, by (1.2), the above derivatives make sense) and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$(2.5) \quad (\nabla_z) V(t, z, \bar{c}p(t, z)) \nu(z) = c^0 \bar{y}^0 (\nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \nu(z).$$

Since  $x(t, z) = -V_y(t, z, \bar{c}p(t, z))$ , for  $(t, z) \in (0, T) \times \bar{\Omega}$ , (0.1) shows that for  $(t, z) \in (0, T) \times \Omega$ ,

$$(2.6) \quad \begin{aligned} & (d^2/dt^2) V_y(t, z, \bar{c}p(t, z)) - (\Delta_z) V_y(t, z, \bar{c}p(t, z)) \\ & = -f(t, z, -V_y(t, z, \bar{c}p(t, z)), u(t, z)) \end{aligned}$$

and boundary control (0.3) shows that for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$-V_y(t, z, \bar{c}p(t, z)) = v(t, z).$$

We conclude from (2.4)–(2.6) that for  $(t, z) \in (0, T) \times \Omega$ ,

$$(2.7) \quad \begin{aligned} & c^0 \bar{y}^0 \left[ (d^2/dt^2) V_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) V_{y^0}(t, z, \bar{c}p(t, z)) \right. \\ & \quad \left. + L(t, z, -V_y(t, z, \bar{c}p(t, z)), u(t, z)) \right] \\ & = V_{tt}(t, z, p(t, z)) - \Delta_z V(t, z, p(t, z)) + c^0 \bar{y}^0 L(t, z, -V_y(t, z, \bar{c}p(t, z)), u(t, z)) \\ & \quad + cy(t, z) f(t, z, -V_y(t, z, \bar{c}p(t, z)), u(t, z)) \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$(2.8) \quad \begin{aligned} & c^0 \bar{y}^0 (\nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \nu(z) + c^0 \bar{y}^0 h(t, z, v(t, z)) \\ &= (\nabla_z) V(t, z, \bar{c}p(t, z)) \nu(z) + c^0 \bar{y}^0 h(t, z, v(t, z)). \end{aligned}$$

Hence, by (1.13) and (2.7), we infer that

$$(2.9) \quad \begin{aligned} & c^0 \bar{y}^0 \left[ (d^2/dt^2) V_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) V_{y^0}(t, z, \bar{c}p(t, z)) \right. \\ & \left. + L(t, z, -V_y(t, z, \bar{c}p(t, z)), u(t, z)) \right] \leq 0 \quad \text{for } (t, z) \in (0, T) \times \Omega \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$(2.10) \quad c^0 \bar{y}^0 (\nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \nu(z) + c^0 \bar{y}^0 h(t, z, v(t, z)) \leq 0,$$

and finally, after integrating (2.9) and applying (2.10), that

$$(2.11) \quad \begin{aligned} & c^0 \bar{y}^0 \int_{[0, T] \times \Omega} \left[ (d^2/dt^2) V_{y^0}(t, z, \bar{c}p(t, z)) - (\operatorname{div} \nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \right] dt dz \\ & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz. \end{aligned}$$

Similarly, in the set  $(0, T) \times \partial\Omega$  we have

$$(2.12) \quad \begin{aligned} & c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega} (\nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \nu(z) dt dz \\ & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega} h(t, z, v(t, z)) dt dz. \end{aligned}$$

Thus from (2.11), (2.12), (2.1), (2.3), and the Green formula it follows that

$$(2.13) \quad \begin{aligned} & c^0 \bar{y}^0 \int_{\Omega} \left[ l(-V_y(T, z, \bar{c}p(T, z))) - (d/dt) V_{y^0}(0, z, c^0 \bar{y}^0, c\bar{y}(0, z)) \right] dz \\ & - c^0 \bar{y}^0 \int_{[0, T]} \left( \int_{\partial\Omega} (\nabla_z) V_{y^0}(t, z, c^0 \bar{y}^0, cy(t, z)) \nu(z) dz \right) dt \\ & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, x(t, z), u(\tau, z)) dt dz. \end{aligned}$$

So by (2.13) and (2.12) we get

$$(2.14) \quad \begin{aligned} & -c^0 \bar{y}^0 \int_{\Omega} (d/dt) V_{y^0}(0, z, c^0 \bar{y}^0, c\bar{y}(0, z)) dz \\ & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz - c^0 \bar{y}^0 \int_{\Omega} l(x(T, z)) dz \\ & - c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega} h(t, z, v(t, z)) dt dz. \end{aligned}$$

In the same manner applying (2.2) and (2.7) we have for  $(t, z) \in (0, T) \times \Omega$

$$\begin{aligned} & c^0 \bar{y}^0 \left[ (d^2/dt^2) V_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) V_{y^0}(t, z, \bar{c}p(t, z)) \right. \\ & \left. + L(t, z, -V_y(t, z, \bar{c}p(t, z)), \bar{u}(t, z)) \right] = 0, \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$c^0 \bar{y}^0 (\nabla_z) V_{y^0}(t, z, \bar{c}p(t, z)) \nu(z) + c^0 \bar{y}^0 h(t, z, \bar{v}(t, z)) = 0.$$

Further, we have

$$\begin{aligned} & -c^0 \bar{y}^0 \int_{\Omega} (d/dt) V_{y^0}(0, z, c^0 \bar{y}^0, c\bar{y}(0, z)) dz \\ (2.15) \quad & = -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}(t, z), \bar{u}(t, z)) dt dz - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z)) dz \\ & - c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega} h(t, z, \bar{v}(t, z)) dt dz. \end{aligned}$$

Combining (2.14) with (2.15) gives

$$\begin{aligned} & -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}(t, z), \bar{u}(t, z)) dt dz - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z)) dz \\ & - c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega}^0 h(t, z, \bar{v}(t, z)) dt dz \\ (2.16) \quad & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz \\ & - c^0 \bar{y}^0 \int_{\Omega} l(x(T, z)) dz - c^0 \bar{y}^0 \int_{[0, T] \times \partial\Omega}^0 h(t, z, v(t, z)) dt dz, \end{aligned}$$

which completes the proof.  $\square$

*Remark 2.2.* The notion of relative minimum derives from Weierstrass. His strong relative minimum in the classical calculus of variations is just minimum relative to all admissible trajectories lying in a set covered by trajectories of his “field of extremals.” In our case such a set is defined by  $V_y$ , i.e., this set equals  $X = \{(t, z, x) : x = -V_y(t, z, \bar{c}p), (t, \bar{c}p) \in P\}$ . It is obvious that in general  $X$  is not covered by all admissible trajectories. It depends on the set  $P$ , chosen at the beginning, where the equation DSPDEMDP (1.13) is considered and the solution  $V$  of (1.13) (which generally is not unique). In practice (see the examples below), we choose for  $P = [0, T] \times \bar{\Omega} \times \{(y^0, y) \in R^2 : y^0 \leq 0, y > 0\}$  or even  $P = [0, T] \times \bar{\Omega} \times \{(y^0, y) \in R^2 : y^0 \leq 0\}$ , and we assume  $V_y$  to be of  $C^1$  so then  $X$  is not a thin set except for a degenerate case  $V_y \equiv 0$  (by transversality condition (1.2), then  $V = c^0 y^0 V_{y^0}$ —a case which does not occur in mechanics).

*Remark 2.3.* The requirement in the theorem that  $V(t, z, p)$  is a  $C^2$  solution of DSPDEMDP (1.13) on  $P$  such that (1.2), (1.3), and (2.1) hold looks very complicated and difficult to satisfy. However, if we rewrite it in a better form, it is not much different from known PDE systems. Thus let us assume that  $l \equiv 0$ , put  $w = V_y$ , and rewrite (1.2) to the form  $V_{y^0} = \frac{1}{c^0 y^0} V - \frac{cy}{c^0 y^0} w$  (for  $y^0 < 0$ ). Then we get that  $V$  must satisfy in  $P$  the following system of equations:

$$\begin{aligned} (2.17) \quad & V_{y^0} = \frac{1}{c^0 y^0} V - \frac{cy}{c^0 y^0} w, \\ & V_y = w, \end{aligned}$$

$$V_{tt} - \Delta_z V + H(t, z, -w, \bar{c}p) = 0$$

with initial (end) condition

$$V_{y^0}(T, z, \bar{c}p) = 0$$

and Neumann boundary condition

$$\nabla_z V(t, z, \bar{c}p)\nu(z) + H_\Sigma(t, z, \bar{c}p) = 0,$$

$$(2.18) \quad (t, z) \in (0, T) \times \partial\Omega, (t, z, \bar{c}p) \in P,$$

where  $H$  and  $H_\Sigma$  are defined in the former section. If it happens that both  $H$  and  $H_\Sigma$  are smooth enough functions and  $n \geq 4$  (dimension of  $\Omega$ ), then the existence of continuous and then smooth solutions for (2.17)–(2.18) can be obtained by a standard fixed point method (compare [24] and the smooth case for  $\Omega = R^n$  [30]; see also [21]).

**3. An optimal dual feedback control.** It often occurs that for engineering and practical applications a feedback control is more important than a value function. It turns out that the dual dynamic programming approach allows us also to investigate a kind of feedback control which we call a dual feedback control. Surprisingly it can have better properties than the classical one: now our state equation depends only on parameters and not additionally on state constraints in the feedback function, which made the state equation difficult to solve.

**DEFINITION 3.1.** A pair of functions  $u = \tilde{u}(t, z, p)$  from  $P$  of the points  $(t, z, p) = (t, z, y^0, y)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $y^0 \leq 0$ ,  $y \in R$ , into  $U$  and  $\tilde{v}(t, z, p)$  from a subset  $P$  of those points  $(t, z, p) = (t, z, y^0, y)$ ,  $(t, z) \in (0, T) \times \partial\Omega$ ,  $(t, z, p) \in P$ , into  $\mathbf{V}$  is called a dual feedback control if there is any solution  $\tilde{x}(t, z, p)$ ,  $P$ , of the PDE

$$(3.1) \quad \tilde{x}_{tt}(t, z, p) - \Delta_z \tilde{x}(t, z, p) = f(t, z, \tilde{x}(t, z, p), \tilde{u}(t, z, p))$$

satisfying boundary condition

$$\tilde{x}(t, z, p) = \tilde{v}(t, z, p) \quad \text{on } (0, T) \times \Gamma, (t, z, p) \in P$$

such that for each admissible trajectory  $x(t, z)$ ,  $(t, z) \in [0, T] \times \Omega$ , there exists such a function  $p(t, z) = (y^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $p \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, p(t, z)) \in P$ , such that (1.1) holds.

**DEFINITION 3.2.** A dual feedback control  $(\bar{u}(t, z, p), \bar{v}(t, z, p))$  is called an optimal dual feedback control if there exist a function  $\bar{x}(t, z, p)$ ,  $(t, z, p) \in P$ , corresponding to  $\bar{u}(t, z, p)$ ,  $\bar{v}(t, z, p)$  as in Definition 3.1, and a function  $\bar{p}(t, z) = (\bar{y}^0, \bar{y}(t, z))$ ,  $\bar{p} \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $\bar{p} \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{p}(t, z)) \in P$ ,  $(t, z, \bar{c}\bar{p}(t, z)) \in P$  with  $\bar{c} = (c^0, c)$ , such that dual value function  $S_D$  (see (1.4)) is defined at  $(t, \bar{p}(t, \cdot))$  by  $\bar{u}(\tau, z, p)$ ,  $\bar{v}(\tau, z, p)$  and corresponding to them  $\bar{x}(\tau, z, p)$ ,  $(\tau, z, p) \in P$ ,  $\tau \in [t, T]$ , i.e.,

$$(3.2) \quad \begin{aligned} S_D(t, \bar{p}(t, \cdot)) &= -c^0 \bar{y}^0 \int_{[t, T] \times \Omega} L(\tau, z, \bar{x}(\tau, z, \bar{p}(\tau, z)), \bar{u}(\tau, z, \bar{p}(\tau, z))) d\tau dz \\ &- c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z, \bar{p}(T, z))) dz - c^0 y^0 \int_{[t, T] \times \partial\Omega} h(\tau, z, \bar{v}(\tau, z, \bar{p}(\tau, z))) d\tau dz. \end{aligned}$$

Moreover there is  $V(t, z, p)$  satisfying (1.2) and (1.3) for which  $V_{y^0}$  satisfies the equality

$$\int_{\Omega} c^0 y^0 V_{y^0}(t, z, \bar{c}\bar{p}(t, z)) dz + c^0 \bar{y}^0 \int_{\partial\Omega} (\nabla_z) V_{y^0}(t, z, \bar{c}\bar{p}(t, z)) \nu(z) dz = -S_D(t, \bar{p}(t, \cdot))$$

and  $V_y$  satisfies

$$(3.3) \quad V_y(t, z, \bar{c}p) = -\bar{x}(t, z, p) \quad \text{for } (t, z) \in (0, T) \times \bar{\Omega}, \quad (t, z, p) \in P, \quad (t, z, \bar{c}p) \in P.$$

The next theorem is nothing more than the above verification theorem formulated in terms of a dual feedback control.

**THEOREM 3.3.** *Let  $(\bar{u}(t, z, p), \bar{v}(t, z, p))$  be a dual feedback control in  $P$ . Suppose that there exist  $\bar{c} = (c^0, c) \in R^2$  and a  $C^2$  solution  $V(t, z, p)$  of (1.13) on  $P$  such that (1.2) and (2.1) hold. Let  $\bar{p}(t, z) = (\bar{y}^0, \bar{y}(t, z))$ ,  $\bar{p} \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $\bar{p} \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{p}(t, z)) \in P$ ,  $(t, z, \bar{c}\bar{p}(t, z)) \in P$ , be such a function that  $\bar{x}(t, z) = \bar{x}(t, z, \bar{p}(t, z))$ ,  $\bar{u}(t, z) = \bar{u}(t, z, \bar{p}(t, z))$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $\bar{v}(t, z) = \bar{v}(t, z, \bar{p}(t, z))$ ,  $(t, z) \in (0, T) \times \partial\Omega$ , is an admissible trio, where  $\bar{x}(t, z, p)$ ,  $(t, z, p) \in P$ , corresponds to  $\bar{u}(t, z, p)$  and  $\bar{v}(t, z, p)$  as in Definition 3.1. Assume further that  $V_y$  and  $V_{y^0}$  satisfy*

$$(3.4) \quad V_y(t, z, \bar{c}p) = -\bar{x}(t, z, p) \quad \text{for } (t, z) \in [0, T] \times \Omega, \quad (t, z, p) \in P, \quad (t, z, \bar{c}p) \in P,$$

$$(3.5) \quad \begin{aligned} & c^0 \bar{y}^0 \int_{\Omega} V_{y^0}(t, z, \bar{c}\bar{p}(t, z)) dz \\ & + c^0 \bar{y}^0 \int_{[0, T]} \left( \int_{\partial\Omega} (\nabla_z) V_{y^0}(t, z, c^0 \bar{y}^0, c \bar{y}(t, z)) \nu(z) dz \right) dt \\ & = -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}(t, z, \bar{p}(t, z)), \bar{u}(t, z, \bar{p}(t, z))) dt dz \\ & - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z, \bar{p}(T, z))) dz - c^0 \bar{y}^0 \int_{[t, T] \times \partial\Omega} h(\tau, s, \bar{v}(\tau, z, \bar{p}(\tau, z))) d\tau ds. \end{aligned}$$

Then  $(\bar{u}(t, z, p), \bar{v}(t, z, p))$  is an optimal dual feedback control.

*Proof.* Take any function

$$p(t, z) = (\bar{y}^0, y(t, z)), \quad p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega)),$$

$$p \in L^2([0, T] \times \partial\Omega), \quad (t, z, p(t, z)) \in P, \quad (t, z, \bar{c}p(t, z)) \in P,$$

such that  $x(t, z) = \bar{x}(t, z, p(t, z))$ ,  $u(t, z) = \bar{u}(t, z, p(t, z))$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z) = \bar{v}(t, z, p(t, z))$ ,  $(t, z) \in [0, T] \times \partial\Omega$ , is an admissible trio and (2.3) holds. By (3.4), it follows that  $x(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in (0, T) \times \Omega$ . As in the proof of Theorem 2.1, (3.5) gives

$$(3.6) \quad \begin{aligned} & -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}(t, z, p(t, z)), \bar{u}(t, z, p(t, z))) dt dz \\ & - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z, p(T, z))) dz - c^0 \bar{y}^0 \int_{[t, T] \times \partial\Omega} h(\tau, s, \bar{v}(\tau, z, p(\tau, z))) d\tau ds \\ & \leq -c^0 \bar{y}^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}(t, z, p(t, z)), \bar{u}(t, z, p(t, z))) dt dz \\ & - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z, p(T, z))) dz - c^0 \bar{y}^0 \int_{[t, T] \times \partial\Omega} h(\tau, s, \bar{v}(\tau, z, p(\tau, z))) d\tau ds. \end{aligned}$$

We conclude from (3.6) that

$$(3.7) \quad \begin{aligned} S_D(t, \bar{p}(t, \cdot)) &= -c^0 \bar{y}^0 \int_{[t, T] \times \Omega} L(\tau, z, \bar{x}(\tau, z, \bar{p}(\tau, z)), \bar{u}(\tau, z, \bar{p}(\tau, z))) d\tau dz \\ &\quad - c^0 \bar{y}^0 \int_{\Omega} l(\bar{x}(T, z, \bar{p}(T, z))) dz - c^0 y^0 \int_{[t, T] \times \partial\Omega} h(\tau, s, \bar{v}(\tau, z, \bar{p}(\tau, z))) d\tau ds, \end{aligned}$$

and it is sufficient to show that  $(\bar{u}(t, z, p), \bar{v}(t, z, p))$  is an optimal dual feedback control, by Theorem 2.1 and Definition 3.2.  $\square$

#### 4. Examples.

*Example 1.* Let us denote the following:

$$\begin{aligned} L(t, z, x, u) &:= t^2 x^{-7/6} u^{1/2}, \\ f(t, z, x, u) &:= t^6 x^{1/2} u^{3/2} / n, \\ h(t, z, v) &:= t^4 \left( \sum_{i=1}^{n/2} z_i^2 \right) \left( v - \left( \sum_{i=1}^n z_i \right)^{-2/3} \right)^6, \\ l(x) &= 0, \quad \varphi(0, z) = \left( \sum_{i=1}^n z_i \right)^{-2/3}, \quad \psi(0, z) = 0, \end{aligned}$$

where  $(t, z, x, u) \in [0, T] \times \Omega \times R \times R^+$ ,  $n$ -even,  $\Omega := \{z \in R^n : \sum_{i=1}^n z_i^2 < 1\}$ ,  $Y := \{(y^0, y) \in R^2 : y^0 \leq 0, y > 0\}$ ,  $\bar{c} := (c^0, c) \in R^2$ ,  $\bar{c}p \in Y$ , so  $c^0 > 0$ ,  $c > 0$ ,  $U = R^+$ ,  $\mathbf{V} = [-10, 10]$ .

The Hamiltonian  $H : [0, T] \times \Omega \times R^+ \times Y \rightarrow R$

$$(4.1) \quad H(t, z, x, \bar{c}p) := \max_{u \in R^+} \mathcal{H}(t, z, x, \bar{c}p, u),$$

where  $\mathcal{H} : [0, T] \times \Omega \times R^+ \times Y \times R^+ \rightarrow R$

$$(4.2) \quad \mathcal{H}(t, z, x, \bar{c}p, u) := c^0 y^0 t^2 x^{-7/6} u^{1/2} + c y t^6 x^{1/2} u^{3/2} / n.$$

From (4.1)–(4.2) and taking  $c^0 = 2/9$ ,  $c = 4/9$  we calculate easily that

$$(4.3) \quad H(t, z, x, \bar{c}p) = -2\sqrt{6n}(-y^0)^{3/2} / 27y^{1/2}x^2.$$

Hence the PDE for the same  $c^0 = 2/9$ ,  $c = 4/9$  has the form

$$(4.4) \quad V_{tt}(t, z, \bar{c}p) - \Delta_z V(t, z, \bar{c}p) - 2\sqrt{6n}(-y^0)^{3/2} / \left( 27y^{1/2} (-V_y(t, z, \bar{c}p))^2 \right) = 0.$$

For  $c^0 = 2/9$ ,  $c = 4/9$ , let

$$(4.5) \quad V(t, z, \bar{c}p) := -4/3 y^{3/4} - \sqrt{n} \left( -\frac{2}{3} y^0 \right)^{3/2} \sum_{i=1}^n z_i^2 / 6n.$$

Then the function  $V(t, z, \bar{c}p)$  satisfies on  $P = [0, T] \times \Omega \times Y$  the first equation of DPDEMDP (1.13) and (1.2). Let us take for  $\nu(z)$  the exterior unit normal vector to  $\partial\Omega$  the vector  $(-z_2, z_1, -z_4, z_3, \dots, -z_n, z_{n-1})$ . Then (1.3) is also satisfied as both sides

are simply equal to zero for  $(t, z) \in [0, T] \times \partial\Omega$ ,  $(t, z, \bar{c}p) \in P$ . Moreover for similar reasons the second equation in (1.13) is also satisfied ( $\sup\{c^0 y^0 h(t, z, v) : v \in \mathbf{V}\} = 0$ ). If we take  $y^0 = -(32n/3)^{1/3}$ , then the equation

$$(4.6) \quad x_{tt}(t, z, y) - \Delta_z x(t, z, y) = \sqrt{n} (-y^0)^{3/2} / \left( (6y)^{3/2} (x(t, z, y))^2 \right)$$

has the solution

$$\bar{x}(t, z, y) = y^{-1/2} \left( \sum_{i=1}^n z_i \right)^{2/3}$$

on  $[0, T] \times \Omega$ . We denote that  $y^0$  by  $\bar{y}^0$ . Moreover, (2.2) is fulfilled by  $\bar{p}(t, z) = (\bar{y}^0, \bar{y}(t, z))$ , where  $\bar{y}^0$  comes from (4.6),

$$\bar{y}(t, z) = \left( \sum_{i=1}^n z_i \right)^{8/3},$$

and  $V(t, z, \bar{c}p)$  is given by (4.5). It is also seen that

$$\bar{x}(t, z) = \bar{x}(t, z, \bar{y}(t, z)) = \left( \sum_{i=1}^n z_i \right)^{-2/3}$$

satisfies  $\bar{x}(t, z) = -V_y(t, z, \bar{c}p(t, z))$  for  $(t, z) \in [0, T] \times \Omega$  and

$$\bar{x}(t, z) = \bar{v}(t, z) = \left( \sum_{i=1}^n z_i \right)^{-2/3} \quad \text{for } (t, z) \in [0, T] \times \partial\Omega,$$

and

$$\bar{u}(t, z) = -\bar{y}^0 / \left( 6t^4 \left( \sum_{i=1}^n z_i \right)^{14/9} \right).$$

Moreover, assumptions of Theorem 3.3 hold. Therefore, by Theorem 3.3 we obtain that  $\bar{x}(t, z)$ ,  $\bar{u}(t, z, p)$ ,  $\bar{v}(t, z)$  is an optimal trio.

The next example is linear but with control on the boundary so it cannot be treated by any classical dynamic programming approach. Moreover it is an applied example.

*Example 2.* We shall consider the simple case of a structural acoustic system. Let  $\Omega = \{(z_1, z_2) : -1 \leq z_1 \leq 1, -1 \leq z_2 \leq 1\}$  be the domain occupied by an acoustic medium (air). The boundary  $S$  of the domain consists of two parts,  $S_1$  and  $S_2$ . The part  $S_1$  corresponds to a thin wall (a shell), and  $S_2$  corresponds to a hard wall. An external acoustic eld, through structural acoustic coupling, leads to high interior sound pressure levels in  $\Omega$ . Piezoelectric elements (patches) are used to active control in order to reduce the sound pressure levels in  $\Omega$ . Coupled problems for structural acoustic systems were studied in a series of works; see [3], [4], [5], [6], [18], [19] and the references therein. The acoustic dynamics is described by the equation

$$(4.7) \quad x_{tt}(t, z) - c_0^2 \Delta_z x(t, z) = 0 \quad \text{in } Q = (0, 1) \times \Omega.$$

Here  $c_0^2$  is a positive constant and the pressure function  $q$  in the acoustic medium is defined by  $q(t, z) = \rho_0 x_t(t, z)$ , where  $\rho_0$  is the density of the acoustic medium in

the ground state, and  $\rho_0$  is a positive constant. Let us denote

$$\begin{aligned} L(t, z, x, u) &:= 0, \\ f(t, z, x, u) &:= 0, \\ h(t, z, v) &:= \left( v - \cos\left(t - \frac{\pi}{2}\right) \sin\left(\frac{1}{2c_0}z_1\right) \sin\left(\frac{1}{2c_0}z_2\right) \right)^2, \\ l(x(\cdot)) &= \rho_0 \int_{\Omega} x(1, z) dz, \quad \varphi(0, z) = 0, \end{aligned}$$

where  $(t, z, x, u) \in [0, 1] \times \Omega \times R \times R$ ,  $n = 2$ ,  $Y := \{(y^0, y) \in R^2 : y^0 \leq 0, y \in R\}$ ,  $\bar{c} := (c^0, c) \in R^2$ ,  $\bar{c}p \in Y$ , so  $c^0 > 0$ ,  $c \in R$ ,  $U = R$ ,  $V = R$ . We have chosen the simplest case of  $h$  so as not to concentrate on technicalities which are not related to the described dual method itself.

The Hamiltonian  $H : [0, 1] \times \Omega \times R \times Y \rightarrow R$ ,

$$H(t, z, x, \bar{c}p) = 0.$$

Therefore the first equation of DSPDEMDP (1.13) has the form

$$(4.8) \quad V_{tt}(t, z, \bar{c}p) - c_0^2 \Delta_z V(t, z, \bar{c}p) = 0 \quad \text{in } Q = (0, 1) \times \Omega \times R.$$

The solutions to (4.7), depending on  $\{a_j\}$ , have the form

$$(4.9) \quad \begin{aligned} x(t, z) &= \sum_{j \geq 2} a_j \cos\left(jt - \frac{\pi}{2}\right) \sin\left(\frac{1}{2c_0}jz_1\right) \sin\left(\frac{1}{2c_0}jz_2\right) \\ &\quad + \frac{1}{2} \cos\left(t - \frac{\pi}{2}\right) \sin\left(\frac{1}{2c_0}z_1\right) \sin\left(\frac{1}{2c_0}z_2\right). \end{aligned}$$

We take into account only those solutions (4.9) which belong to  $W^{2,2}((0, 1) \times \Omega) \cap C([0, 1]; L^2(\Omega))$ . By controls on the boundary we take only the functions

$$v = x|_{(0,1) \times \partial\Omega}.$$

Our aim is to minimize the pressure level in  $\Omega$  and the cost of activations of controls on the boundary, i.e., we minimize the functional

$$J(x, v) = \rho_0 \int_{\Omega} x(1, z) dz + \int_{(0,1) \times \partial\Omega} h(t, z, v(t, z)) dt dz.$$

For solution to (4.8) we take

$$(4.10) \quad \begin{aligned} V(t, z, \bar{c}p) &= c^0 y^0 \sin\left(t - \frac{\pi}{2}\right) \sin\left(\frac{1}{2c_0}z_1\right) \sin\left(\frac{1}{2c_0}z_2\right) + c^0 y^0 c y t \\ &\quad + (cy)^2 + tcy - cy \cos\left(t - \frac{\pi}{2}\right) \sin\left(\frac{1}{2c_0}z_1\right) \sin\left(\frac{1}{2c_0}z_2\right). \end{aligned}$$

If we take  $c^0 = 1$ ,  $c = 1/2$ ,  $\bar{y}^0 = -1$ , then we can easily check that  $V$  from (4.10) satisfies transversality conditions (1.2), (1.3) and boundary condition (2.1). Let us observe that

$$-V_y(t, z, \bar{c}p(t, z)) = x(t, z)$$

for

$$y(t, z) = -2 \sum_{j \geq 2} a_j \cos \left( jt - \frac{\pi}{2} \right) \sin \left( \frac{1}{2c_0} j z_1 \right) \sin \left( \frac{1}{2c_0} j z_2 \right), \bar{y}^0 = -1.$$

Let us take for  $\nu(z)$ , the exterior unit normal vector to  $\partial\Omega$ , the vector

$$\nu(z) = \begin{cases} (1, 0) & \text{for } z = (-1, z_2), \quad -1 \leq z_2 \leq 1, \\ (1, 0) & \text{for } z = (1, z_2), \quad -1 \leq z_2 \leq 1, \\ (0, 1) & \text{for } z = (z_1, -1), \quad -1 \leq z_1 \leq 1, \\ (0, 1) & \text{for } z = (z_1, 1), \quad -1 \leq z_1 \leq 1. \end{cases}$$

Then, taking into account (4.10), we see that  $(\nabla_z) V(t, z, \bar{c}p(t, z))\nu(z) = 0$  for  $(t, z) \in (0, 1) \times \partial\Omega$ . Therefore

$$(\nabla_z) V(t, z, \bar{c}p(t, z))\nu(z) + c^0 y^0 h(t, z, \bar{v}(t, z)) = 0 \quad \text{for } (t, z) \in (0, 1) \times \partial\Omega$$

is realized for

$$\bar{v}(t, z) = \cos \left( t - \frac{\pi}{2} \right) \sin \left( \frac{1}{2c_0} z_1 \right) \sin \left( \frac{1}{2c_0} z_2 \right).$$

Hence

$$\bar{x}(t, z) = \cos \left( t - \frac{\pi}{2} \right) \sin \left( \frac{1}{2c_0} z_1 \right) \sin \left( \frac{1}{2c_0} z_2 \right).$$

**5. An  $\varepsilon$ -optimization.** If we want to solve the concrete problem (0.1)–(0.4) for particular data, then usually we are not able to solve it exactly, especially if the problem we consider is nonlinear. Therefore each possibility to approximate our optimal problem (0.1)–(0.4) may turn out very useful. Below we find a certain type of such an approximation.

**DEFINITION 5.1.** Let  $\varepsilon > 0$  and  $c^0 > 0$  be fixed. A function  $S_{\varepsilon D}(t, p(t, \cdot))$  is called an  $\varepsilon$ -dual value function if

$$(5.1) \quad S_D(t, p(t, \cdot)) \leq S_{\varepsilon D}(t, p(t, \cdot)) \leq S_D(t, p(t, \cdot)) - 2\varepsilon c^0 \bar{y}_\varepsilon^0 \text{Vol}(\Omega)$$

for any fixed  $\bar{y}_\varepsilon^0 < 0$ .

**DEFINITION 5.2.** Let  $\varepsilon > 0$  and  $\bar{c} = (c^0, c) \in R^2$ ,  $c^0 > 0$ , be fixed and let  $\tilde{V}(t, z, p)$  be a given  $C^2$  function such that (1.2) and (2.1) hold. Let  $\bar{x}_\varepsilon(t, z)$ ,  $\bar{u}_\varepsilon(t, z)$ ,  $t \in (0, T) \times \Omega$ ,  $\bar{v}_\varepsilon(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , be an admissible trio and let  $\bar{p}_\varepsilon(t, z) = (\bar{y}_\varepsilon^0, \bar{y}_\varepsilon(t, z))$ ,  $\bar{p}_\varepsilon \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $\bar{p}_\varepsilon \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) \in P$ , be such a function that  $\bar{x}_\varepsilon(t, z) = -\tilde{V}_y(t, z, \bar{c}\bar{p}_\varepsilon(t, z))$  for  $(t, z) \in (0, T) \times \Omega$ . The trio  $\bar{x}_\varepsilon(t, z)$ ,  $\bar{u}_\varepsilon(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $\bar{v}_\varepsilon(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , is called an  $\varepsilon$ -optimal trio if

$$(5.2) \quad \begin{aligned} & -c^0 \bar{y}_\varepsilon^0 \int_{[0, T] \times \Omega} L(t, z, \bar{x}_\varepsilon(t, z), \bar{u}_\varepsilon(t, z)) dt dz - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(\bar{x}_\varepsilon(T, z)) dz \\ & - c^0 \bar{y}_\varepsilon^0 \int_{[0, T] \times \partial\Omega} h(t, s, \bar{v}_\varepsilon(t, z)) dt ds \\ & \leq -c^0 \bar{y}_\varepsilon^0 \int_{[0, T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(x(T, z)) dz \\ & - c^0 \bar{y}_\varepsilon^0 \int_{[0, T] \times \partial\Omega} h(t, s, v(t, z)) dt ds - \varepsilon c^0 \bar{y}_\varepsilon^0 \text{Vol}(\Omega) \end{aligned}$$

for all admissible trios  $x(t, z)$ ,  $u(t, z)$ ,  $t \in (0, T) \times \Omega$ ,  $v(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , for which there exists such a function  $p(t, z) = (\bar{y}_\varepsilon^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $p \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}p(t, z)) \in P$ , such that

$$x(t, z) = -\tilde{V}_y(t, z, \bar{c}p(t, z)) \quad \text{for } (t, z) \in (0, T) \times \Omega$$

and

$$(5.3) \quad y(0, z) = \bar{y}_\varepsilon(0, z) \quad \text{for } z \in \Omega.$$

**THEOREM 5.3.** *Let  $\bar{x}_\varepsilon(t, z)$ ,  $\bar{u}_\varepsilon(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $\bar{v}_\varepsilon(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , be an admissible trio. Assume that there exist  $\varepsilon > 0$ ,  $\bar{c} = (c^0, c) \in R^2$ ,  $c^0 > 0$ , and a  $C^2$  function  $\tilde{V}(t, z, p)$  such that for  $(t, z, \bar{c}p) \in P$ ,*

$$(5.4) \quad \sup \left\{ \tilde{V}_{tt}(t, z, \bar{c}p) - \Delta_z \tilde{V}(t, z, \bar{c}p) + c^0 y^0 L(t, z, -\tilde{V}_y(t, z, \bar{c}p), u) + cyf(t, z, -\tilde{V}_y(t, z, \bar{c}p), u) : u \in U \right\} \leq -\varepsilon c^0 \bar{y}_\varepsilon^0,$$

$$\sup \left\{ \nabla_z \tilde{V}(t, z, \bar{c}p) \nu(z) + c^0 y^0 h(t, z, v) : v \in \mathbf{V} \right\} \leq -\varepsilon c^0 \bar{y}_\varepsilon^0, \\ (t, z) \in (0, T) \times \partial\Omega, \quad (t, z, \bar{c}p) \in P,$$

$$(5.5) \quad \tilde{V}(t, z, \bar{c}p) = \bar{c}p \tilde{V}_p(t, z, \bar{c}p), \quad (t, z) \in (0, T) \times \Omega, \quad (t, z, \bar{c}p) \in P,$$

$$\nabla_z V(t, z, \bar{c}p) \nu(z) = c^0 y^0 \nabla_z V_{y^0}(t, z, \bar{c}p) \nu(z)$$

$$\text{for } (t, z) \in (0, T) \times \partial\Omega, \quad (t, z, \bar{c}p) \in P.$$

Further, let  $\bar{p}_\varepsilon(t, z) = (\bar{y}_\varepsilon^0, \bar{y}_\varepsilon(t, z))$ ,  $\bar{p}_\varepsilon \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $\bar{p}_\varepsilon \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) \in P$ , be such a function that  $\bar{x}_\varepsilon(t, z) = -\tilde{V}_y(t, z, \bar{c}\bar{p}_\varepsilon(t))$  for  $(t, z) \in (0, T) \times \Omega$ . Suppose that  $\tilde{V}(t, z, p)$  satisfies the boundary condition for  $(T, z, \bar{c}p) \in P$ :

$$(5.6) \quad c^0 \bar{y}_\varepsilon^0 \int_\Omega (d/dt) \tilde{V}_{y^0}(T, z, \bar{c}p) dz = c^0 \bar{y}_\varepsilon^0 \int_\Omega l \left( -\tilde{V}_y(T, z, \bar{c}p) \right) dz.$$

Moreover, suppose that for almost all  $(t, z) \in (0, T) \times \Omega$ ,

$$(5.7) \quad \tilde{V}_{tt}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) - \Delta_z \tilde{V}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) + c^0 \bar{y}_\varepsilon^0 L(t, z, -\tilde{V}_y(t, z, \bar{c}\bar{p}_\varepsilon(t, z)), \bar{u}_\varepsilon(t, z)) + \bar{c}\bar{y}_\varepsilon(t, z) f(t, z, -\tilde{V}_y(t, z, \bar{c}\bar{p}_\varepsilon(t, z)), \bar{u}_\varepsilon(t, z)) \geq 0,$$

$(\nabla_z) \tilde{V}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) \nu(z) + c^0 \bar{y}_\varepsilon^0 h(t, z, \bar{v}_\varepsilon(t, z)) \geq 0$  for almost all  $(t, z) \in (0, T) \times \partial\Omega$ . Then  $\bar{x}_\varepsilon(t, z)$ ,  $\bar{u}_\varepsilon(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $\bar{v}_\varepsilon(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , is an  $\varepsilon$ -optimal trio relative to all admissible trios  $x(t, z)$ ,  $u(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , for which there exists such a function  $p(t, z) = (\bar{y}_\varepsilon^0, y(t, z))$ ,  $p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega))$ ,  $p \in L^2([0, T] \times \partial\Omega)$ ,  $(t, z, \bar{c}p(t, z)) \in P$ , such that

$$x(t, z) = -\tilde{V}_y(t, z, \bar{c}p(t, z)) \quad \text{for } (t, z) \in (0, T) \times \Omega$$

and (5.3) is satisfied.

*Proof.* Take any admissible trio  $x(t, z)$ ,  $u(t, z)$ ,  $(t, z) \in (0, T) \times \Omega$ ,  $v(t, z)$ ,  $t \in (0, T) \times \partial\Omega$ , for which there exists such a function

$$p(t, z) = (\bar{y}_\varepsilon^0, y(t, z)), p \in W^{2,2}([0, T] \times \Omega) \cap C([0, T]; L^2(\Omega)),$$

$$p \in L^2([0, T] \times \partial\Omega), (t, z, \bar{c}p(t, z)) \in P,$$

such that

$$x(t, z) = -\tilde{V}_y(t, z, \bar{c}p(t, z)) \quad \text{for } (t, z) \in (0, T) \times \Omega$$

and (5.3) holds. Then, from (5.5), we have, for  $(t, z) \in (0, T) \times \Omega$ ,

$$\begin{aligned} & \tilde{V}_{tt}(t, z, \bar{c}p(t, z)) - \Delta_z \tilde{V}(t, z, \bar{c}p(t, z)) \\ (5.8) \quad &= c^0 \bar{y}_\varepsilon^0 \left[ (d^2/dt^2) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) \right] \\ &+ cy(t, z) \left[ (d^2/dt^2) \tilde{V}_y(t, z, \bar{c}p(t, z)) - (\Delta_z) \tilde{V}_y(t, z, \bar{c}p(t, z)) \right], \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$(5.9) \quad (\nabla_z) \tilde{V}(t, z, \bar{c}p(t, z))\nu(z) = c^0 \bar{y}_\varepsilon^0 (\nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z))\nu(z).$$

Since

$$\begin{aligned} & (d^2/dt^2) \tilde{V}_y(t, z, \bar{c}p(t, z)) - (\Delta_z) \tilde{V}_y(t, z, \bar{c}p(t, z)) \\ &= -f(t, z, -\tilde{V}_y(t, z, \bar{c}p(t, z)), u(t, z)) \end{aligned}$$

for  $(t, z) \in (0, T) \times \Omega$ , it follows, by (5.9), that for  $(t, z) \in (0, T) \times \Omega$ ,

$$\begin{aligned} & c^0 \bar{y}_\varepsilon^0 \left[ (d^2/dt^2) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) \right. \\ & \quad \left. + L(t, z, -\tilde{V}_y(t, z, \bar{c}p(t, z)), u(t, z)) \right] \\ (5.10) \quad &= \tilde{V}_{tt}(t, z, \bar{c}p(t, z)) - \Delta_z \tilde{V}(t, z, \bar{c}p(t, z)) \\ &+ c^0 \bar{y}_\varepsilon^0 L(t, z, -\tilde{V}_y(t, z, \bar{c}p(t, z)), u(t, z)) \\ &+ cy(t, z) f(t, z, -\tilde{V}_y(t, z, \bar{c}p(t, z)), u(t, z)) \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$ ,

$$\begin{aligned} & c^0 \bar{y}_\varepsilon^0 (\nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z))\nu(z) + c^0 \bar{y}_\varepsilon^0 h(t, z, v(t, z)) \\ (5.11) \quad &= (\nabla_z) \tilde{V}(t, z, \bar{c}p(t, z))\nu(z) + c^0 \bar{y}_\varepsilon^0 h(t, z, v(t, z)). \end{aligned}$$

Thus, by (5.4) and (5.10), we get for  $(t, z) \in (0, T) \times \Omega$

$$\begin{aligned} & c^0 \bar{y}_\varepsilon^0 \left[ (d^2/dt^2) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) - (\Delta_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) \right. \\ (5.12) \quad & \quad \left. + L(t, z, -\tilde{V}_y(t, z, \bar{c}p(t, z)), u(t, z)) \right] \leq -\varepsilon c^0 \bar{y}_\varepsilon^0 \end{aligned}$$

and for  $(t, z) \in (0, T) \times \partial\Omega$

$$(5.13) \quad c^0 \bar{y}_\varepsilon^0 (\nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z))\nu(z) + c^0 \bar{y}_\varepsilon^0 h(t, z, v(t, z)) \leq -\varepsilon c^0 \bar{y}_\varepsilon^0,$$

and finally, after integrating (5.12), that

$$\begin{aligned} & c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} \left[ (d^2/dt^2) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) - (\operatorname{div} \nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) \right] dt dz \\ & \leq -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz - \varepsilon c^0 \bar{y}_\varepsilon^0 \operatorname{Vol}(\Omega). \end{aligned}$$

Similarly, in the set  $(0, T) \times \partial\Omega$  we have

$$\begin{aligned} & c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} (\nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}p(t, z)) \nu(z) dt dz \\ & \leq -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} h(t, z, v(t, z)) dt dz - \varepsilon c^0 \bar{y}_\varepsilon^0 \operatorname{Vol}(\Omega). \end{aligned}$$

Next we obtain

$$\begin{aligned} & -c^0 \bar{y}_\varepsilon^0 \int_{\Omega} (d/dt) \tilde{V}_{y^0}(0, z, c^0 \bar{y}_\varepsilon^0, c\bar{y}(0, z)) dz \\ (5.14) \quad & \leq -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(x(T, z)) dz \\ & - c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} h(t, z, v(t, z)) dt dz - 2\varepsilon c^0 \bar{y}_\varepsilon^0 \operatorname{Vol}(\Omega). \end{aligned}$$

Similarly, we obtain

$$(5.15) \quad c^0 \bar{y}_\varepsilon^0 [(d^2/dt^2) \tilde{V}_{y^0}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) - (\Delta_z) \tilde{V}_{y^0}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) + L(t, z, -\tilde{V}_y(t, z, \bar{c}\bar{p}_\varepsilon(t, z)), \bar{u}_\varepsilon(t, z))] \geq 0 \text{ for } (t, z) \in (0, T) \times \Omega,$$

$$(5.16) \quad c^0 \bar{y}_\varepsilon^0 (\nabla_z) \tilde{V}_{y^0}(t, z, \bar{c}\bar{p}_\varepsilon(t, z)) \nu(z) + c^0 \bar{y}_\varepsilon^0 h(t, z, \bar{v}_\varepsilon(t, z)) \geq 0 \text{ for } (t, z) \in (0, T) \times \partial\Omega.$$

Now from (5.15), (5.16), (5.6), and the Green formula we have

$$\begin{aligned} & -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} L(t, z, \bar{x}_\varepsilon(t, z), \bar{u}_\varepsilon(t, z)) dt dz \\ (5.17) \quad & - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(\bar{x}_\varepsilon(T, z)) dz - c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} h(t, z, \bar{v}_\varepsilon(t, z)) dt dz \\ & \leq -c^0 \bar{y}_\varepsilon^0 \int_{\Omega} (d/dt) \tilde{V}_{y^0}(0, z, c^0 \bar{y}_\varepsilon^0, c\bar{y}(0, z)) dz. \end{aligned}$$

Therefore, combining (5.14) with (5.17) yields

$$\begin{aligned} & -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} L(t, z, \bar{x}_\varepsilon(t, z), \bar{u}_\varepsilon(t, z)) dt dz - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(\bar{x}_\varepsilon(T, z)) dz \\ & - c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} h(t, z, \bar{v}_\varepsilon(t, z)) dt dz \\ (5.18) \quad & \leq -c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \Omega} L(t, z, x(t, z), u(t, z)) dt dz - c^0 \bar{y}_\varepsilon^0 \int_{\Omega} l(x(T, z)) dz \\ & - c^0 \bar{y}_\varepsilon^0 \int_{[0,T] \times \partial\Omega} h(t, z, v(t, z)) dt dz - 2\varepsilon c^0 \bar{y}_\varepsilon^0 \operatorname{Vol}(\Omega), \end{aligned}$$

which proves the assertion of the theorem.  $\square$

## LIMIT TIME OPTIMAL SYNTHESIS FOR A CONTROL-AFFINE SYSTEM ON $S^{2*}$

P. MASON<sup>†</sup>, R. SALMONI<sup>‡</sup>, U. BOSCAIN<sup>§</sup>, AND Y. CHITOUR<sup>‡</sup>

**Abstract.** For  $\alpha \in ]0, \pi/2[$ , let  $(\Sigma)_\alpha$  be the control system  $\dot{x} = (F + uG)x$ , where  $x$  belongs to the two-dimensional unit sphere  $S^2$ ,  $u \in [-1, 1]$ , and  $F, G$  are  $3 \times 3$  skew-symmetric matrices generating rotations with perpendicular axes and of respective norms  $\cos(\alpha)$  and  $\sin(\alpha)$ . In this paper, we study the time optimal synthesis (TOS) from the north pole  $(0, 0, 1)^T$  associated to  $(\Sigma)_\alpha$ , as the parameter  $\alpha$  tends to zero; this problem is motivated by specific issues in the control of quantum systems. We first prove that the TOS is characterized by a “two-snakes” configuration on the whole  $S^2$ , except for a neighborhood  $U_\alpha$  of the south pole  $(0, 0, -1)^T$  of diameter at most  $\mathcal{O}(\alpha)$ . We next show that, inside  $U_\alpha$ , the TOS depends on the relationship between  $r(\alpha) := \pi/2\alpha - [\pi/2\alpha]$  and  $\alpha$ . More precisely, we characterize three main relationships by considering sequences  $(\alpha_k)_{k \geq 0}$  satisfying (a)  $r(\alpha_k) = \bar{r}$ , (b)  $r(\alpha_k) = C\alpha_k$ , and (c)  $r(\alpha_k) = 0$ , where  $\bar{r} \in (0, 1)$  and  $C > 0$ . In each case, we describe the TOS and provide, after a suitable rescaling, the limiting behavior, as  $\alpha$  tends to zero, of the corresponding TOS inside  $U_\alpha$ .

**Key words.** control-affine systems, optimal synthesis, control of quantum systems, minimum time, asymptotics

**1. Introduction.** Let  $\alpha \in ]0, \pi/2[$ . On the unit sphere  $S^2 \subset \mathbb{R}^3$ , consider the control system  $(\Sigma)_\alpha$  defined by

$$(1) \quad (\Sigma)_\alpha \quad \dot{x} = (F + uG)x, \quad x = (x_1, x_2, x_3)^T, \quad \|x\|^2 = 1, \quad |u| \leq 1,$$

where  $F$  and  $G$  are two  $3 \times 3$  skew-symmetric matrices representing two orthogonal rotations with axes of length, respectively,  $\cos(\alpha)$  and  $\sin(\alpha)$ ,  $\alpha \in ]0, \pi/2[$  (for the precise meaning of length, see section 2.3). With no loss of generality, we assume that

$$(2) \quad F := \begin{pmatrix} 0 & -\cos(\alpha) & 0 \\ \cos(\alpha) & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad G := \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -\sin(\alpha) \\ 0 & \sin(\alpha) & 0 \end{pmatrix}.$$

In this paper, we aim at describing the time optimal synthesis (TOS) from the north pole  $N := (0, 0, 1)^T$  for  $(\Sigma)_\alpha$ ; i.e., for every  $\bar{x} \in S^2$  we want to find the time optimal trajectory steering  $N$  to  $\bar{x}$  in minimum time (see Figure 1).

In particular *we are interested in the qualitative shape of the time optimal synthesis in a neighborhood of the south pole  $S = (0, 0, -1)^T$ , in the limit  $\alpha \rightarrow 0$* . The interest for that problem stems from quantum control issues. Indeed consider the population transfer problem for a two-level quantum system driven by a single external field. This model describes the evolution of the  $z$ -component of the spin of a

FIG. 1. Geometric interpretation of the system  $(\Sigma)_\alpha$ . The vector fields  $X_+ := F + G$  and  $X_- := F - G$  are two rotations of norm one making an angle  $\alpha$  with the axis  $x_3$ .

(spin-1/2) particle driven by a magnetic field that is constant along the  $z$ -axis and controlled along the  $x$ -axis. Equivalently it describes the first two levels of a molecule driven by an external field without the rotating wave approximation [4, 9]. The dynamics of such a system is governed by the time-dependent Schrödinger equation (in a system of units such that  $\hbar = 1$ ):

$$(3) \quad i \frac{d\psi(t)}{dt} = (H_0 + \Omega(t)H_1)\psi(t).$$

Here  $\psi(\cdot) = (\psi_1(\cdot), \psi_2(\cdot))^T : [0, T] \rightarrow \mathbb{C}^2$  denotes the wave function and verifies  $\sum_{j=1}^2 |\psi_j(t)|^2 = 1$ ; i.e.,  $\psi(t)$  belongs to the sphere  $S^3 \subset \mathbb{C}^2$ . The free Hamiltonian  $H_0$  and the controlled Hamiltonian  $H_1$  are given by

$$(4) \quad H_0 = \begin{pmatrix} -E & 0 \\ 0 & E \end{pmatrix}, \quad H_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

where  $-E$  and  $E$  ( $E > 0$ ) are the two energy levels and the control  $\Omega(\cdot)$  is a real function describing the amplitude of the external field. Here  $|\psi_1(t)|^2$  (respectively,  $|\psi_2(t)|^2$ ) represents the probability of measuring at time  $t$  the energy  $E$  (respectively,  $-E$ ). The control task consists of inducing a transition from the first eigenstate of  $H_0$  (i.e.,  $|\psi_1|^2 = 1$ ) to any other *physical state*. We recall that two states  $\psi$  and  $\psi'$  are physically equivalent if they differ by a factor of phase. More precisely by physical state we mean a point of the two-dimensional sphere (called *Bloch sphere* in this context)  $S^2 = S^3 / \sim$ , where the equivalence relation  $\sim$  is defined as follows:  $\psi \sim \psi'$  (where  $\psi, \psi' \in S^3$ ) if and only if  $\psi = \exp(i\Phi)\psi'$  for some  $\Phi \in [0, 2\pi[$ . The projection  $\Pi : S^3 \rightarrow S^2$  is called a *Hopf projection*. A particularly interesting transition is of course from the first to the second eigenstates of  $H_0$  (i.e., from  $|\psi_1|^2 = 1$  to  $|\psi_2|^2 = 1$ ).

In many applications, the external field should have bounded amplitude  $M$  (i.e.,  $|\Omega(\cdot)| \leq M$ ), and, in order to minimize the unavoidable effects of relaxation and decoherence [3, 13], the transfer should occur as quickly as possible. Therefore we end up addressing a minimum time control problem with one bounded control. Sometimes decoherence is also reduced by taking  $M$  small with respect to  $E$ : This guarantees that the energy injected by the control action into the system is close to the minimal one necessary to induce the transition.

As was shown in [9], the projection of the minimum time control problem for the system (3) on the Bloch sphere gives rise, after time renormalization, to the minimum time control problem for system (1) where (i) the first and second eigenstates of  $H_0$  project respectively onto the north pole  $N$  and the south pole  $S$ , (ii)  $\tan(\alpha) = M/E$  and  $u(t) = \Omega(t)/M$ , and (iii)  $H_0$  project on  $F$  and  $H_1$  on  $G$ . The case  $M \ll E$  corresponds now to the limit  $\alpha \rightarrow 0$ .

Nowadays two-level quantum systems are central in the implementation of the so-called quantum gates (the basic blocks of a quantum computer); see, for instance, [12, 18].

The present paper is actually a continuation of [5, 9] in the sense that it answers questions raised in these papers.

In [5], the purpose was to provide a lower and an upper bound for  $N(\alpha)$ , the maximum number of switchings for time optimal trajectories for the left invariant control system

$$(5) \quad (S)_\alpha \quad \dot{g} = g(F + uG), \quad g \in SO(3), \quad |u| \leq 1,$$

where  $F$  and  $G$  are defined in (2). Recall that, for such control systems, it is known (cf., for instance, [5, 9]) that every time optimal trajectory is a finite concatenation of bang arcs (i.e.,  $u \equiv \pm 1$ ) or singular arcs ( $u = 0$ ). A bang arc is an integral trajectory corresponding to the rotations

$$(6) \quad X_+ := F + G, \quad X_- := F - G$$

and is denoted by  $e^{tX_\varepsilon}x$ ,  $t \in [0, T]$ , where  $\varepsilon = \pm$ ,  $x$  is the starting point of the bang arc and  $T$  is its time duration. Moreover, a switching time—or simply a switching—along a time optimal trajectory is a time  $t_0$  so that the control  $u$  is not constant in any open neighborhood of  $t_0$ .

To estimate  $N(\alpha)$ , a suitable Hopf map  $\Pi : SO(3) \rightarrow S^2$  was introduced to project  $(S)_\alpha$  onto  $(\Sigma)_\alpha$ . In particular, every time optimal trajectory of  $(\Sigma)_\alpha$  is the projection by  $\Pi$  of a time optimal trajectory of  $(S)_\alpha$ . It results that, if a time optimal trajectory on  $S^2$  has a certain number of switchings, then this number is lower than or equal to the maximum number of switchings for the optimal problem on  $SO(3)$ . The construction of time optimal trajectories of  $(\Sigma)_\alpha$  was performed according to the general theory of time optimal synthesis on two-dimensional (2-D) manifolds developed in [6, 7, 10, 11, 14, 15, 19, 20] and recently gathered in the book [8].

The question of studying  $N(\alpha)$  was first addressed in [1], where, using the index theory developed by Agrachev, the authors proved that  $N(\alpha) \leq [\pi/\alpha]$ , where  $[\cdot]$  stands for the integer part. That result was not only an indirect indication that  $N(\alpha)$  would tend to infinity as  $\alpha$  tends to zero, but it also provided a hint on the asymptotic of  $N(\alpha)$  as  $\alpha$  tends to zero. Notice that for  $\alpha = 0$  the systems (1) and (5) are not controllable. With the techniques developed in [5], enough properties for the TOS associated to  $(\Sigma)_\alpha$ ,  $\alpha < \pi/4$ , were identified in order to improve the upper bound of [1] and to actually show that, for  $\alpha$  small,

$$N(\alpha) \leq k_M + 5, \quad \text{where} \quad k_M := \left\lceil \frac{\pi}{2\alpha} \right\rceil.$$

In [5], it is proved that, for  $\alpha < \pi/4$ , the extremals associated to  $(\Sigma)_\alpha$  (i.e., the trajectories candidate for time optimality obtained after using the Pontryagin maximum principle (PMP)), starting from the north pole  $N$  are bang-bang trajectories, i.e.,

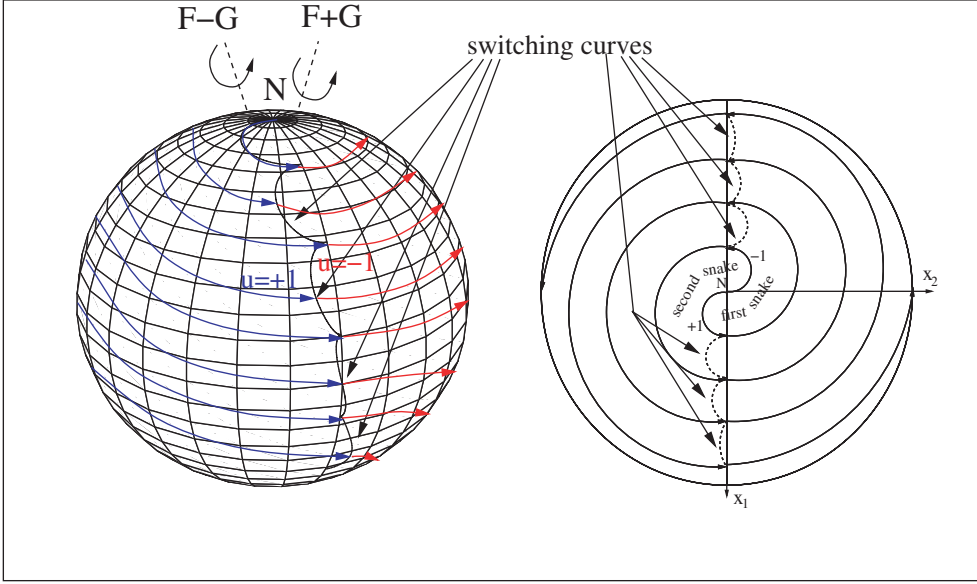

FIG. 2. The two-snakes configuration defined by the extremal flow. Notice that this set of trajectories covers the whole sphere, but in principle not all extremals are optimal, and a point can be reached by more than one trajectory at the same or at different times.

finite concatenations of bang arcs of the type

$$e^{s_f X_{-\varepsilon'}} e^{v(s_i) X_{\varepsilon'}} \dots e^{v(s_i) X_{-\varepsilon}} e^{s_i X_{\varepsilon}} N,$$

where the initial time duration  $s_i$  verifies  $s_i \in (0, \pi]$ , all of the time durations of the interior bang arcs are equal to  $v(s_i)$ , where the function  $v$  is defined in (14) below, and the final time duration  $s_f$  verifies  $s_f \leq v(s_i)$ . Of particular importance for the construction of the TOS are the *switching curves*, i.e., the curves made by points where the control switches from  $+1$  to  $-1$  or vice versa and defined inductively by

$$(7) \quad C_1^\varepsilon(s) = e^{X_\varepsilon v(s)} e^{X_{-\varepsilon} s} N, \quad C_k^\varepsilon(s) = e^{X_\varepsilon v(s)} C_{k-1}^{-\varepsilon}(s) \quad (\text{where } \varepsilon = \pm 1 \text{ and } k = 2, \dots, k_M).$$

Since the PMP gives just a necessary condition for optimality, it is crucial to determine the time after which an extremal is no more optimal. In [5], we showed that the number of bangs must be lower than or equal to  $k_M + 1$  and the extremals cover the sphere  $S^2$  according to the “two-snakes” configuration as depicted in Figure 2. The two “snakes” correspond to extremal trajectories starting with control  $+1$  and  $-1$ , respectively. For more details, see [5].

However, in [5], we were not able to construct the complete TOS associated to  $(\Sigma)_\alpha$ . In particular, we could not show the optimality of all of the extremals up to  $k_M - 1$  bangs arcs, and we could not complete analytically the construction of the synthesis in a neighborhood of the south pole  $S$ . There, the minimum time front develops singularities due to the compactness of  $S^2$ . We provided only numerical simulations describing the evolution of the extremal front in a neighborhood of the south pole. As  $\alpha \rightarrow 0$ , these numerical simulations suggested the emergence of an interesting phenomenon (see Figure 3): Define the remainder

$$(8) \quad r(\alpha) := \pi/2\alpha - [\pi/2\alpha].$$

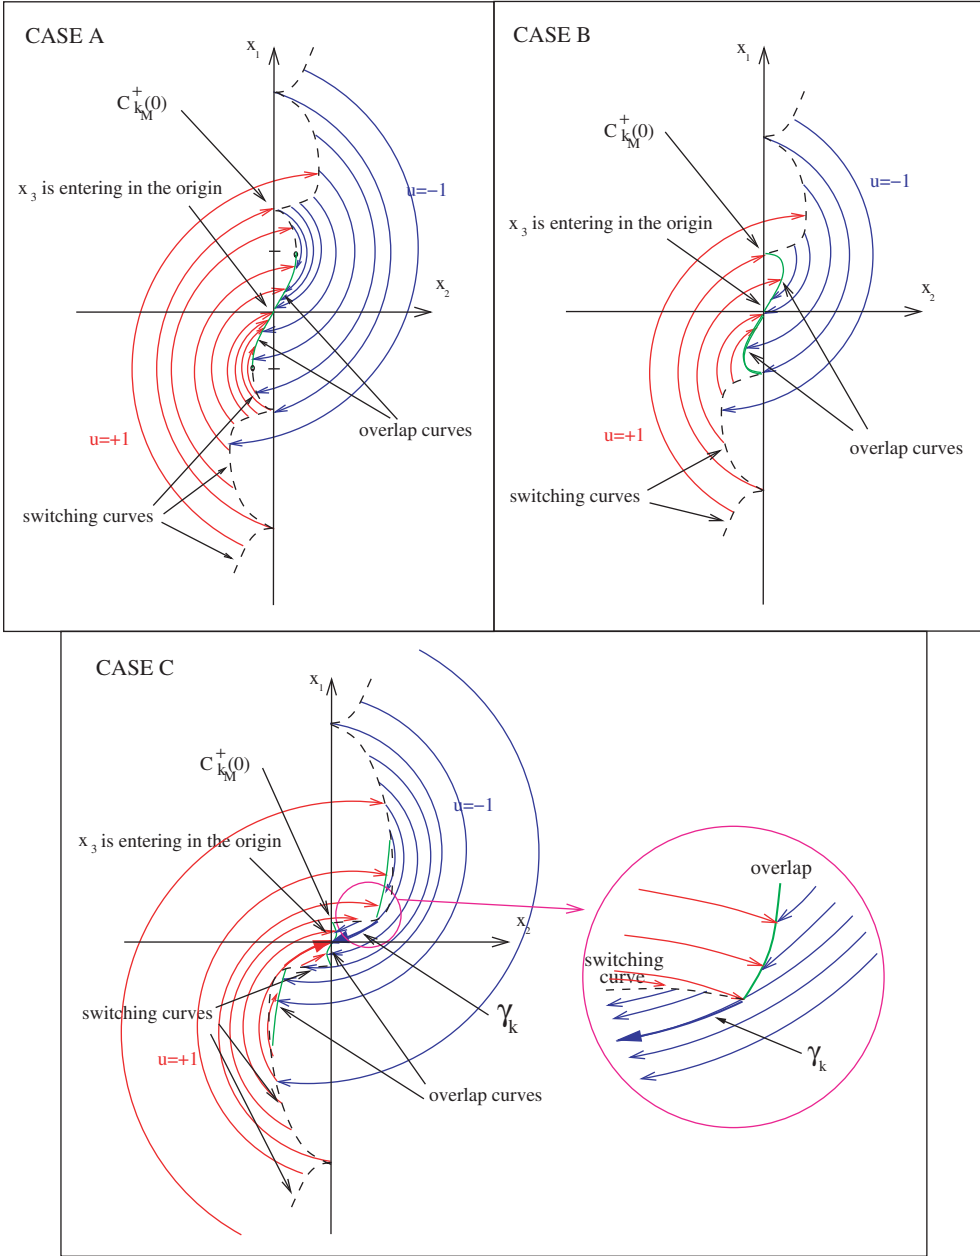

FIG. 3. Conjectured shapes of the synthesis in a neighborhood of the south pole. Switching curves are  $C^1$  curves made by points in which the control switches from  $+1$  to  $-1$  or vice versa. Overlap curves are  $C^1$  curves made by points reached optimally by more than one trajectory. The curve  $\gamma_k$  is a bang arc that is also an overlap curve since trajectories having a different history travel on it at the same time. The singularity appearing at the starting point of  $\gamma_k$  (called  $(C, K)_1$  according to the taxonomy of [8]) is a singularity of the synthesis predicted by the general theory [8], and it is due to a nonlocal phenomenon (see section 7 for more details).

Then there are three possible patterns of TOS in the neighborhood of the south pole  $S$ , each of them depending on a relation between  $r(\alpha)$  and  $\alpha$ . See section 2.2 below, where these relations are formulated as well as conjectures.

In [9], the TOS for  $(\Sigma_\alpha)$  was studied in the context of quantum control as described previously. In that paper, the TOS for  $\alpha \geq \pi/4$  was completed, and, in the case  $\alpha < \pi/4$ , further information was obtained, for what concerns time optimal trajectories steering the north to the south pole (in fact the most interesting trajectories for the quantum mechanical problem). Such optimal trajectories belong to a set  $\Xi$  containing at most eight trajectories, half of them starting with control  $+1$  and the other half starting with control  $-1$ , and switching exactly at the same times. It was also proved that the cardinality of  $\Xi$  depends on the remainder  $r(\alpha)$  defined in (8). For instance, for  $\alpha$  and  $r(\alpha)$  small enough, then  $\Xi$  contains exactly eight trajectories (four of them are optimal) while if  $r(\alpha)$  is close to 1, then  $\Xi$  contains only four trajectories (two of them are optimal).

The purpose of the present paper consists in studying the TOS associated to  $(\Sigma)_\alpha$  as  $\alpha$  tends to zero, focusing in particular on its behavior inside a neighborhood of the south pole. Roughly speaking, we want to determine, as  $\alpha$  tends to zero, what could be a possible limit for the TOS associated to  $(\Sigma)_\alpha$  (as suggested, for instance, by the patterns depicted in Figure 3) and then to prove the convergence (in some suitable sense) of the TOS associated to  $(\Sigma)_\alpha$  to that limit. To proceed, we embark on the study of a geometric object  $\mathcal{F}(\alpha, T)$  called the *extremal front at time  $T$*  along  $(\Sigma)_\alpha$  and defined as the set of points reached at time  $T$  by extremal trajectories starting from  $N$  (see section 3.1 for a precise definition). The extremal front  $\mathcal{F}(\alpha, T)$  contains the *minimum time front*  $OF(\alpha, T)$ , i.e., the set of points reached at time  $T$  by time optimal trajectories. When  $\mathcal{F}(\alpha, T) = OF(\alpha, T)$ , we say that  $\mathcal{F}(\alpha, T)$  is *optimal*.

We first prove, in the case in which  $k_M$  is odd (the other case being analogous), that the extremal front  $\mathcal{F}(\alpha, k_M\pi)$  is made up of the union of two curves  $\mathcal{E}^\varepsilon(\alpha, \cdot) : (0, \pi] \rightarrow S^2$ ,  $\varepsilon = \pm$ , with  $\mathcal{E}^\varepsilon(\alpha, \cdot) = \Pi_{x_3} \mathcal{E}^{-\varepsilon}(\alpha, \cdot)$ , where  $\Pi_{x_3}$  is the orthogonal symmetry with respect to the  $x_3$ -axis. Moreover, for  $\alpha$  small enough,  $\mathcal{E}^\varepsilon(\alpha, \cdot)$  admits a convergent power series of the type  $\sum_{l \geq 0} f_l^\varepsilon(s, r(\alpha))\alpha^l$ , where the  $f_l^\varepsilon(s, r)$  are real-analytic functions of  $(s, r) \in \mathbb{R}^2$ ,  $2\pi$ -periodic in  $s$  with

$$(9) \quad \begin{aligned} f_0^+(s, r) &= \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}, & f_1^+(s, r) &= \begin{pmatrix} -2r\mathbf{c}_s \\ 2r\mathbf{s}_s \\ 0 \end{pmatrix}, \\ f_2^+(s, r) &= \begin{pmatrix} \frac{\pi}{2}(4r + \mathbf{c}_s)\mathbf{s}_s^2 \\ \frac{\pi}{4}(3 + 8r\mathbf{c}_s + \mathbf{c}_{2s})\mathbf{s}_s \\ 2r^2 \end{pmatrix}, & f_l^-(s, r) &= \Pi_{x_3} f_l^+(s, r). \end{aligned}$$

As a trivial consequence, we deduce that, for  $r \in [0, 1]$ ,  $s \in \mathbb{R}$ , and  $\alpha$  small enough, we have

$$(10) \quad \mathcal{E}^\varepsilon(\alpha, s) = f_0^\varepsilon(s, r(\alpha)) + f_1^\varepsilon(s, r(\alpha))\alpha + f_2^\varepsilon(s, r(\alpha))\alpha^2 + \mathcal{O}(\alpha^3)$$

and

$$(11) \quad \frac{\partial}{\partial s} \mathcal{E}^\varepsilon(\alpha, s) = \frac{\partial}{\partial s} f_1^\varepsilon(s, r(\alpha))\alpha + \frac{\partial}{\partial s} f_2^\varepsilon(s, r(\alpha))\alpha^2 + \mathcal{O}(\alpha^3),$$

where  $|\mathcal{O}(\alpha^3)| \leq \bar{C}|\alpha|^3$ , with  $\bar{C} > 0$  constant independent of  $(r, s, \alpha)$ .

Then we show that  $\mathcal{F}(\alpha, T)$  is actually optimal for  $T \leq (k_M - 1)\pi$  and  $\alpha$  small enough (see Remark 7 below). Moreover, we show that  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  is a circle of radius  $2(1 + r(\alpha))\alpha$  up to order  $\alpha^2$  (see Remark 6 below). As a consequence of the optimality of  $\mathcal{F}(\alpha, (k_M - 1)\pi)$ , we get that all of the extremals of the two-snakes configuration depicted in Figure 2 are optimal up to time  $(k_M - 1)\pi$ . In other words, if  $U_\alpha$  is the connected component of  $S^2 \setminus \mathcal{F}(\alpha, (k_M - 1)\pi)$  containing the south pole,

we obtain the optimal synthesis on  $S^2 \setminus U_\alpha$ . Notice that  $U_\alpha$  is a neighborhood of the south pole of size proportional to  $\alpha$ .

In that way we answer the question stated in [5] about optimality of extremals of the two-snake configuration in the case  $\alpha$  small, and it is, of course, of interest for applications to the two-level quantum system.

The expressions (10)–(11) are central tools to understand the possible asymptotic behaviors of the TOS associated to  $(\Sigma)_\alpha$ , as  $\alpha$  tends to zero.

For this purpose we observe that the expressions of  $f_1^+$  and  $f_2^+$  in (9) depend explicitly on the remainder  $r(\alpha)$ . This fact suggests the need to impose particular relationships between  $\alpha$  and  $r(\alpha)$  in order to define any asymptotic behavior. In other words we must let  $\alpha$  go to zero only along certain subsequences  $(\alpha_k)_{k \geq 0}$  where a specific relationship holds between  $\alpha_k$  and  $r(\alpha_k)$ . The analysis of (9) will help us to determine such relationships and to prove that the conjectures made in [5] about the qualitative shape of the synthesis near the south pole were true (see section 2.2 and Figure 3). In particular we will see that there are exactly three qualitatively different asymptotic behaviors of the synthesis as  $\alpha$  goes to zero, described by the following cases.

First, we analyze the case in which  $\alpha$  is arbitrarily small, with  $r(\alpha) \in (0, 1)$  uniformly far from 0 and 1. To further simplify the discussion, it is reasonable to consider the following:

(C1) For  $\bar{r} \in (0, 1)$ , let  $\alpha$  tend to zero along the subsequence  $\alpha_k := \frac{\pi}{2(k + \bar{r})}$ , so that

$$r(\alpha_k) = \bar{r}.$$

In this case  $\mathcal{E}^\varepsilon(\alpha, \cdot)$  is approximated, up to order  $\alpha^2$ , by the expression  $S + f_1^\varepsilon(\cdot, \bar{r})$ . As a consequence  $\mathcal{F}(\alpha, k_M \pi)$  is approximately a circle of radius  $2\bar{r}\alpha$  centered at the south pole. We are then able to give a qualitative description of the optimal synthesis, as stated below in Theorem 1. We then deduce that, if  $\alpha$  is small enough and  $r(\alpha)$  is far enough from 0 and 1, the synthesis in a neighborhood of the south pole is topologically equivalent to the limit synthesis obtained, as  $k$  tends to infinity, along the sequence  $\alpha_k$  above. That synthesis turns out to be exactly the one described in Figure 3 (case B), as predicted in [5].

It remains then to study the cases in which  $r(\alpha)$  can be arbitrarily close to 0 or 1. For this purpose we first consider the case in which  $r(\alpha)/\alpha$  remains bounded above and below by positive constants as  $\alpha$  tends to zero. From (9) it is clear that this is equivalent to saying that  $f_1^\varepsilon(\cdot, r)\alpha$  is comparable to  $f_2^\varepsilon(\cdot, r)\alpha^2$ . For simplicity we consider the following:

(C2) For  $C > 0$ , let  $\alpha$  tend to zero along a subsequence  $(\alpha_k)_{k \geq 0}$  such that

$$r(\alpha_k) = C\alpha_k.$$

In this case  $\mathcal{E}^\varepsilon(\alpha, \cdot)$  is well approximated by  $S + (f_1^\varepsilon(\cdot, C) + f_2^\varepsilon(\cdot, 0))\alpha^2$ . If  $C > \pi/4$ , the synthesis is equivalent to that of the previous case. On the other hand, if  $C < \pi/4$ , the synthesis is more complicated (see section 5), and it turns out to be exactly the one described in Figure 3 (case C), as predicted in [5].

If  $\alpha$  and  $r(\alpha)$  tend to zero, with  $r(\alpha)/\alpha$  tending to infinity (respectively, to zero), it is possible to see that the synthesis is qualitatively equivalent to the one of case (C1) (respectively, (C2)).

The third interesting case is the following:

(C3) Let  $\alpha$  tend to zero along the subsequence  $\alpha_k := \frac{\pi}{2k}$ , so that  $r(\alpha_k) = 0$ .

In this case the extremal front at time  $k_M\pi$  contains the south pole, and the corresponding optimal front reduces to that point. The optimal synthesis is then described starting from the extremal front  $\mathcal{F}(\alpha, (k_M - 1)\pi) = OF(\alpha, (k_M - 1)\pi)$ , and it corresponds to the one described in Figure 3 (case A), as predicted in [5].

With similar arguments, one can see that, in the case in which  $\alpha$  is small and  $r(\alpha)$  is close to 1, the optimal synthesis is qualitatively equivalent either to that of case (C1) or to that of case (C3), and this concludes the description of the possible asymptotic behaviors as  $\alpha$  tends to 0.

*Remark 1.* It is interesting to notice that numerical simulations show that, for  $\alpha$  decreasing to zero continuously, the qualitative shape of the optimal synthesis described in Figure 3 alternates cyclically in the order BCABCA...

Let us describe the results obtained in case (C1) in more details. Since  $\mathcal{F}(\alpha, k_M\pi)$  is approximated, up to  $\mathcal{O}(\alpha^2)$ , by a circle of center  $S$  and radius  $2\bar{r}\alpha$ , we are able to show that it is optimal, so that all of the extremals of the two-snakes configuration depicted in Figure 2 are optimal up to time  $k_M\pi$ . In other words, if  $V_\alpha$  is the connected component of  $S^2 \setminus \mathcal{F}(\alpha, k_M\pi)$  containing the south pole, we obtain the optimal synthesis on  $S^2 \setminus V_\alpha$ .

As  $\alpha$  tends to zero,  $V_\alpha$  collapses on  $S$ . Hence one must rescale the problem by a factor  $1/\alpha$  in order to describe the TOS inside  $V_\alpha$ . Also notice that since we are in a neighborhood of the south pole we can project the problem on the plane  $(x_1, x_2)$ . We are now in a position to define a possible limit behavior for the TOS inside  $V_\alpha$ . Let  $M_\alpha$  be the linear mapping from  $\mathbb{R}^3$  onto  $\mathbb{R}^2$  defined as the composition of the projection  $(x_1, x_2, x_3) \mapsto (x_1, x_2)$  followed by the dilation by  $1/\alpha$ . Denote by  $(\tilde{\Sigma})_\alpha$  (respectively,  $OF(\alpha, k_M\pi)$ ) the image by  $M_\alpha$  of  $(\Sigma)_\alpha$  (respectively,  $OF(\alpha, k_M\pi)$ ). Then  $(\tilde{\Sigma})_\alpha$  is a perturbation by  $\mathcal{O}(\alpha^2)$  of the forced linear pendulum

$$(12) \quad (Pen) : \begin{cases} \dot{z}_1 = -z_2, \\ \dot{z}_2 = z_1 + u, \end{cases} \quad (z_1, z_2) \in \mathbb{R}^2, \quad |u| \leq 1,$$

while  $\widetilde{OF}(\alpha, k_M\pi)$  is a perturbation by  $\mathcal{O}(\alpha^2)$  of  $C(0, 2\bar{r})$ , the planar circle of center  $(0, 0)$  and radius  $2\bar{r}$ . As a consequence, the candidate limit TOS inside  $V_\alpha$  is the one associated to the problem of reaching in minimum time every point of the ball  $B(0, 2\bar{r})$  starting from  $C(0, 2\bar{r})$ , along the dynamics of the standard linearized pendulum. To prove such a result, we first study the above-mentioned optimal control problem and show that the corresponding TOS is characterized by an overlap curve  $\gamma_{pen}^o$ , which is the set of points  $z \in \mathbb{R}^2$ , with  $z_1 z_2 \geq 0$ , and belonging to the locus (see Figure 4)

$$z_1^4 + z_2^4 + 2z_1^2 z_2^2 - 4\bar{r}^2 z_1^2 + (4 - 4\bar{r}^2) z_2^2 = 0.$$

The optimal synthesis inside  $C(0, 2\bar{r})$  is then described by the following feedback, defined on  $B(0, 2\bar{r}) \setminus \gamma_{pen}^o$ : “Above”  $\gamma_{pen}^o$ , the control  $u$  is constantly equal to  $-1$ , and “below”  $\gamma_{pen}^o$ , it is constantly equal to  $1$  (see Figure 5). Finally, the asymptotic result we prove in section 4.2 is the following.

**THEOREM 1.** *For  $\bar{r} \in (0, 1)$ , let  $(\alpha_k)_{k \geq 1}$  be the sequence defined by  $\alpha_k := \frac{\pi}{2(k+\bar{r})}$  for  $k \geq 1$ . Consider  $\gamma_{pen}^o$ , the overlap curve of the TOS for the optimal control problem consisting of starting from  $C(0, 2\bar{r})$ , the planar circle of center  $(0, 0)$  and radius  $2\bar{r}$ , and reaching in minimum time every point of  $B(0, 2\bar{r})$  along the control system (12). Then, for  $k$  large enough, the TOS associated to  $(\tilde{\Sigma})_{\alpha_k}$  inside  $\widetilde{OF}(\alpha_k, k_M\pi)$  is characterized by an overlap curve  $\gamma_{\alpha_k}^o$  so that the optimal feedback takes the value  $-1$  above  $\gamma_{\alpha_k}^o$  and the value  $1$  below  $\gamma_{\alpha_k}^o$ . Moreover,  $\gamma_{\alpha_k}^o$  converges to  $\gamma_{pen}^o$  in the  $C^0$  topology, uniformly with respect to  $\bar{r}$  in any compact interval of  $(0, 1)$ .*

FIG. 4. The overlap curve for the pendulum problem.

FIG. 5. Optimal synthesis for the linear pendulum.

The results in cases (C2) and (C3) are described in more details in sections 5 and 6.

*Remark 2.* Notice that the sequence  $(\alpha_k)_{k \geq 1}$  defined above has been chosen in order to simplify the previous statement. Indeed the same result could be restated in a more general way by taking an arbitrary sequence  $(\tilde{\alpha}_k)_{k \geq 1}$  converging to zero and such that  $r(\tilde{\alpha}_k)$  converges to  $\bar{r}$  or by letting the remainder vary on a compact subinterval of  $(0, 1)$ .

The paper is organized as follows. In the second section, we collect basic facts, notations, results, and conjectures of [5]. The third section gathers the detailed description of the extremal front and the proof of (9). Sections 4, 5, and 6 treat, respectively, cases (C1), (C2), and (C3). In section 7, we make some final remarks, and we stress the importance of our result in connection with singularity theory for time optimal syntheses on 2-D manifolds. In the appendix, we finally prove a technical result needed throughout the paper.

## 2. Notations and previous results.

### 2.1. Basic facts.

DEFINITION 1. An admissible control  $u(\cdot)$  for the system (1)–(2) is a measurable function  $u(\cdot) : [a, b] \rightarrow [-1, 1]$ , while an admissible trajectory is an absolutely continuous function  $x(\cdot) : [a, b] \rightarrow S^2$  satisfying (1) a.e. for some admissible control  $u(\cdot)$ . If  $x(\cdot)$  is an admissible trajectory and  $u(\cdot)$  the corresponding control, we say that  $(x(\cdot), u(\cdot))$  is an admissible pair.

For every  $\bar{x} \in S^2$ , the minimization problem consists of determining an admissible pair steering the north pole to  $\bar{x}$  in minimum time. More precisely we write the following.

Problem (P). Consider the control system (1)–(2). For every  $\bar{x} \in S^2$ , find an admissible pair  $(x(\cdot), u(\cdot))$  defined on  $[0, T]$  such that  $x(0) = N$ ,  $x(T) = \bar{x}$ , and  $x(\cdot)$  is time optimal.

An optimal synthesis from the north pole (in the following optimal synthesis, for short) is the collection of all of the solutions to the problem (P). More precisely we write the following.

DEFINITION 2 (optimal synthesis). An optimal synthesis for the problem (P) is the collection of all time optimal trajectories  $\Gamma = \{x_{\bar{x}}(\cdot) : [0, b_{\bar{x}}] \mapsto S^2, \bar{x} \in S^2 : x_{\bar{x}}(0) = N, x_{\bar{x}}(b_{\bar{x}}) = \bar{x}\}$ .

For more elaborated definitions of optimal synthesis, see [8, 16], and references therein. The standard tool to look for optimal trajectories is a first order necessary condition for optimality known as the PMP (cf. [2, 17]) as stated below for our minimum time problem on  $S^2$ .

Define the following real-valued map on  $T^*S^2 \times [-1, 1]$ , called the Hamiltonian:

$$\mathcal{H}(\lambda, x, u) := \langle \lambda, (F + uG)x \rangle.$$

Set

$$(13) \quad H(\lambda, x) := \max_{v \in [-1, 1]} \mathcal{H}(\lambda, x, v).$$

The PMP asserts that, if  $\gamma : [a, b] \rightarrow S^2$  is a time optimal trajectory corresponding to a control  $u : [a, b] \rightarrow [-1, 1]$ , there exists a nontrivial field of covectors along  $\gamma$  that is a never vanishing absolutely continuous function  $\lambda : t \in [a, b] \mapsto \lambda(t) \in T_{\gamma(t)}^*S^2$  and a constant  $\lambda_0 \leq 0$  such that, for a.e.  $t \in \text{Dom}(\gamma)$ , we have the following:

- (i)  $\dot{\lambda}(t) = -\frac{\partial \mathcal{H}}{\partial x}(\lambda(t), \gamma(t), u(t)) = -\lambda(t)(F + u(t)G)$ ,
- (ii)  $\mathcal{H}(\lambda(t), \gamma(t), u(t)) + \lambda_0 = 0$ ,
- (iii)  $\mathcal{H}(\lambda(t), \gamma(t), u(t)) = H(\gamma(t), \lambda(t))$ .

In the more general case in which the target and the initial datum (also called *source*) are two smooth manifolds  $\mathcal{N}_0$  and  $\mathcal{N}_1$ , the previous statement must be modified by adding the so-called *transversality conditions*:

- (iv)  $\langle \lambda(a), v \rangle = 0$  for all  $v \in T_{\gamma(a)}\mathcal{N}_0$ ,  $\langle \lambda(b), w \rangle = 0$  for all  $w \in T_{\gamma(b)}\mathcal{N}_1$ .

Remark 3. A trajectory  $\gamma$  (respectively, a couple  $(\gamma, \lambda)$ ) satisfying the conditions given by the PMP is said to be an *extremal* (respectively, an *extremal pair*). An extremal corresponding to  $\lambda_0 = 0$  is said to be an *abnormal extremal*; otherwise we call it a *normal extremal*.

DEFINITION 3 (bang, singular for the problem (1)–(2)). A control  $u(\cdot) : [a, b] \rightarrow [-1, 1]$  is said to be a bang control if  $u(t) = +1$  a.e. in  $[a, b]$  or  $u(t) = -1$  a.e. in  $[a, b]$ . A control  $u(\cdot) : [a, b] \rightarrow [-1, 1]$  is said to be a singular control if  $u(t) = 0$  a.e. in  $[a, b]$ . A finite concatenation of bang controls is called a bang-bang control. A

FIG. 6. Time optimal trajectories for  $\alpha < \pi/4$ .

switching time of  $u(\cdot)$  is a time  $\bar{t} \in [a, b]$  such that, for every  $\varepsilon > 0$ ,  $u$  is not bang or singular on  $(\bar{t} - \varepsilon, \bar{t} + \varepsilon) \cap [a, b]$ . A trajectory of the control system (1)–(2) is said to be a bang trajectory (or arc), singular trajectory (or arc), or bang-bang trajectory if it corresponds, respectively, to a bang control, singular control, or bang-bang control. If  $\bar{t}$  is a switching time, the corresponding point on the trajectory  $x(\bar{t})$  is called a switching point.

**2.2. Description of previous results.** In [5, 9] it was proved that, for every couple of points, there exists a time optimal trajectory joining them. Moreover it was proved that every time optimal trajectory is a finite concatenation of bang and singular trajectories. More precisely we have the following.

**PROPOSITION 1.** *For the minimum time problem associated to (1)–(2), for each pair of points  $p$  and  $q$  belonging to  $S^2$ , there exists a time optimal trajectory joining  $p$  to  $q$ . Moreover every time optimal trajectory for (1)–(2) is a finite concatenation of bang and singular trajectories.*

Notice that the previous proposition does not apply if  $\alpha = 0$  or  $\alpha = \pi/2$ , since in these cases the controllability property is lost.

In [9] it has been proved that  $\alpha = \pi/4$  is a bifurcation for the qualitative shape of the time optimal synthesis; for instance, the time optimal synthesis contains a singular arc if and only if  $\alpha > \pi/4$ . Since in this paper we are interested in the limit  $\alpha \rightarrow 0$ , in the following we always assume  $\alpha < \pi/4$ . In this case, using the PMP, the following properties characterizing the optimal trajectories were established in [5] (see Figure 6):

- (i)  $x(\cdot)$  is bang bang;
- (ii) the duration  $s_i$  of the first bang arc satisfies  $s_i \in (0, \pi]$ ;
- (iii) the time duration between two consecutive switchings is the same for all interior bang arcs (i.e., excluding the first and the last bangs), and it is equal to  $v(s_i)$ , where  $v(\cdot)$  is the following function:

$$(14) \quad v(s) = \pi + 2 \arctan \left( \frac{\sin(s)}{\cos(s) + \cot^2(\alpha)} \right).$$

One can immediately check that this function satisfies  $v(0) = v(\pi) = \pi$  and  $v(s) > \pi$  for every  $s \in (0, \pi)$ ;

- (iv) the time duration of the last arc is  $s_f \in (0, v(s_i)]$ .

Moreover, thanks to the analysis given in [5], one easily gets (always in the case  $\alpha < \pi/4$ ):

- (v) the number of switchings  $N_x$  of  $x(\cdot)$  satisfies the following inequality:

$$(15) \quad N_x \leq \left\lceil \frac{\pi}{2\alpha} \right\rceil + 1.$$

Conditions (i)–(v) define a set of candidate optimal trajectories. Notice that conditions (i)–(v) are just necessary conditions for optimality, and one is faced with the

FIG. 7. *Locally optimal switching curves and non locally optimal switching curves with the corresponding synthesis.*

problem of selecting, among them, those that are really optimal. In particular, given a trajectory satisfying conditions (i)–(v), one would like to find the time after which it is no more optimal.

Some questions remained unsolved, in particular questions relative to local optimality of the switching curves defined in (7). Roughly speaking we say that a switching curve is locally optimal if it never “reflects” the trajectories (see Figure 7(A)).<sup>1</sup> When a family of trajectories is reflected by a switching curve, then local optimality is lost, and some *cut loci* appear in the optimal synthesis.

**DEFINITION 4.** *A cut locus is a set of points reached at the same time by two (or more) time optimal trajectories. A subset of a cut locus that is a connected  $\mathcal{C}^1$  manifold is called an overlap curve.*

An example showing how a “reflection” on a switching curve generates a cut locus is portrayed in Figures 7(B) and 7(C). More precisely the following questions were formulated in [5]:

- Question 1.* Are the switching curves  $C_k^\varepsilon(s)$ ,  $s \in (0, \pi]$ , locally optimal? More precisely, one would like to understand how the candidate optimal trajectories described above lose optimality.
- Question 2.* What is the shape of the optimal synthesis in a neighborhood of the south pole?

Numerical simulations suggested some conjectures regarding the above questions. More precisely, in [5] the following conjectures were made:

- C1. The curves  $C_k^\varepsilon(s)$ , ( $k = 1, \dots, k_M$ ) are locally optimal if and only if  $k \leq \left\lceil \frac{\pi - \alpha}{2\alpha} \right\rceil - 1$ .

Analyzing the evolution of the minimum time wave front in a neighborhood of the south pole, it is reasonable to conjecture that:

- C2. The shape of the optimal synthesis in a neighborhood of the south pole depends on the remainder  $r(\alpha)$  defined in (8). Notice that  $r(\alpha)$  belongs to the interval  $[0, 1)$ . More precisely, it was conjectured in [5] that for  $\alpha \in (0, \pi/4)$  there exist two positive numbers  $\alpha_1$  and  $\alpha_2$  such that  $0 < \alpha_1 < \alpha < \alpha_2 < 2\alpha$  and the following:

Case A:  $r(\alpha) \in (\frac{\alpha_2}{2\alpha}, 1)$ . The switching curve  $C_{k_M}^\varepsilon$  glues to an overlap curve that passes through the origin (Figure 3, case A).

<sup>1</sup>More precisely consider a smooth switching curve  $C$  between two smooth vector fields  $Y_1$  and  $Y_2$  on a smooth two-dimensional manifold. Let  $C(s)$  be a smooth parametrization of  $C$ . We say that  $C$  is *locally optimal* if, for every  $s \in \text{Dom}(C)$ , we have  $\dot{C}(s) \neq \alpha_1 Y_1(C(s)) + \alpha_2 Y_2(C(s))$  for every  $\alpha_1, \alpha_2$  such that (s.t.)  $\alpha_1 \alpha_2 \geq 0$ . The points of a switching curve on which this relation is not satisfied are usually called “conjugate points.” See Figure 7.

Case B:  $r(\alpha) \in [\frac{\alpha_1}{2\alpha}, \frac{\alpha_2}{2\alpha}]$ . The switching curve  $C_{k_M}^\varepsilon$  is not reached by optimal trajectories in the interval  $]0, \pi]$ . At the point  $C_{k_M}^\varepsilon(0)$ , an overlap curve starts and passes through the origin (Figure 3, case B).

Case C:  $r(\alpha) \in (0, \frac{\alpha_1}{2\alpha})$ . The situation is more complicated, and it is depicted in the bottom of Figure 3, case C.

For  $r = 0$ , the situation is the same as in Case A but for the switching curve starting at  $C_{k_M-1}^\varepsilon(0)$ .

As explained in the introduction, the presence of several cyclically alternating patterns of optimal synthesis, each of them depending on an arithmetic property of  $\alpha$ , was already confirmed in [9] by counting the number of optimal trajectories reaching the south pole.

*Remark 4.* The first conjecture is implicitly disproved by the results of this paper. More precisely an immediate consequence of our results is that the switching curve  $C_{k_M-2}^\varepsilon$  is always locally optimal, while  $C_{k_M-1}^\varepsilon$  is not, in general. However, for every fixed  $\bar{r} < \frac{1}{2}$  there exists  $\alpha$  small enough with  $\bar{r} \leq r(\alpha) < \frac{1}{2}$  such that  $C_{k_M-1}^\varepsilon$  is locally optimal too, which contradicts the conjecture. On the other hand, conjecture C2 is correct and, in light of our main results, is completely proved and clarified.

**2.3. Notations.** All throughout the paper we use the notation  $\varepsilon = \pm 1$ . The set  $so(3)$  of  $3 \times 3$  skew-symmetric matrices is a three-dimensional vector space on which the bilinear map

$$\langle A, B \rangle = -\text{Tr}(AB), \quad A, B \in so(3),$$

is an inner product. For  $A \in so(3)$ ,  $\|A\| := \sqrt{\langle A, A \rangle}$  is the norm (or length) of  $A$ . With the above notations,  $F$  and  $G$  are perpendicular and normalized so that  $\|F\| = \cos(\alpha)$  and  $\|G\| = \sin(\alpha)$ .

Let  $Id$  be the  $3 \times 3$  identity matrix. We recall that  $N = (0, 0, 1)^T$  and denote the south pole as  $S = (0, 0, -1)^T$ . Set  $\mathbf{c}_t := \cos(t)$  and  $\mathbf{s}_t := \sin(t)$  for  $t \in [0, 2\pi)$ . Recall that  $X_+ := F + G$  and  $X_- := F - G$ , and we have

$$X_+ = \begin{pmatrix} 0 & -\mathbf{c}_\alpha & 0 \\ \mathbf{c}_\alpha & 0 & -\mathbf{s}_\alpha \\ 0 & \mathbf{s}_\alpha & 0 \end{pmatrix}, \quad X_- = \begin{pmatrix} 0 & -\mathbf{c}_\alpha & 0 \\ \mathbf{c}_\alpha & 0 & \mathbf{s}_\alpha \\ 0 & -\mathbf{s}_\alpha & 0 \end{pmatrix}.$$

Let  $\Pi_{x_3}$  be the orthogonal symmetry with respect to the  $x_3$ -axis; i.e.,  $\Pi_{x_3}$  is represented in the canonical basis by  $\text{Diag}(-1, -1, 1)$ . Then we have the following trivial but useful property:

$$(16) \quad \Pi_{x_3} X_\varepsilon = X_{-\varepsilon} \Pi_{x_3}.$$

We next recall standard formulas for a rotation  $e^{tY}$  of  $SO(3)$  in terms of its axis  $Y$  (whose length is equal to one) and its angle  $t$ . We have

$$(17) \quad e^{tY} = Id + \mathbf{s}_t Y + (1 - \mathbf{c}_t) Y^2.$$

Moreover, for  $t \in [0, 2\pi)$ , we have

$$e^{\Theta(t)Z_-(t)} := e^{tX_+} e^{tX_-}, \quad e^{\Theta(t)Z_+(t)} := e^{tX_-} e^{tX_+},$$

where the matrices  $Z_+(t)$  and  $Z_-(t)$  are defined by

$$(18) \quad Z_+(t) = \begin{pmatrix} 0 & -C(t) & -B(t) \\ C(t) & 0 & 0 \\ B(t) & 0 & 0 \end{pmatrix}, \quad Z_-(t) = \begin{pmatrix} 0 & -C(t) & B(t) \\ C(t) & 0 & 0 \\ -B(t) & 0 & 0 \end{pmatrix},$$

respectively, with  $B(t) := \frac{\mathbf{s}_\alpha \mathbf{s}_{t/2}}{\sqrt{\mathbf{s}_{t/2}^2 \mathbf{s}_\alpha^2 + \mathbf{c}_{t/2}^2}}$ ,  $C(t) := -\frac{\mathbf{c}_{t/2}}{\sqrt{\mathbf{s}_{t/2}^2 \mathbf{s}_\alpha^2 + \mathbf{c}_{t/2}^2}}$ , and the angle  $\Theta(t)$  by

$$(19) \quad \Theta(t) = 2 \arccos(\mathbf{s}_{t/2}^2 \mathbf{c}_{2\alpha} - \mathbf{c}_{t/2}^2).$$

### 3. The extremal front.

**3.1. Definition and description.** As said in the introduction,  $\mathcal{F}(\alpha, T)$  the extremal front along  $(\Sigma)_\alpha$  at time  $T$  is the set of points reached at time  $T$  by extremal trajectories starting from  $N$ , i.e.,

$$(20) \quad \mathcal{F}(\alpha, T) := \{\bar{x} \in S^2 : \exists \text{ an extremal pair } (x(\cdot), \lambda(\cdot)) \text{ s.t. } x(0) = N, \ x(T) = \bar{x}\}.$$

Such extremals are parametrized by the length of the first bang arc, the length of the last bang arc, and the number of arcs:

$$(21) \quad \Xi^+(s, t) = \overbrace{e^{X_\varepsilon t} e^{X_{-\varepsilon} v(s)} \dots e^{X_{-v(s)}} e^{X_{+s}}}^{n \text{ terms}} N,$$

$$(22) \quad \Xi^-(s, t) = \overbrace{e^{X_{\varepsilon'} t} e^{X_{-\varepsilon'} v(s)} \dots e^{X_{+v(s)}} e^{X_{-s}}}^{n' \text{ terms}} N,$$

where  $s \in (0, \pi]$ ,  $t \in (0, v(s)]$ , the number of bang arcs ( $n$  and  $n'$ , respectively) is an integer and

- $\varepsilon = +1$  (respectively,  $\varepsilon = -1$ ) if  $n$  is odd (respectively, even), and
- $\varepsilon' = +1$  (respectively,  $\varepsilon' = -1$ ) if  $n'$  is even (respectively, odd).

Roughly speaking, we would like to compute the limit, as  $\alpha \rightarrow 0$ , of  $\mathcal{F}(\alpha, T)$ , when  $T$  is such that the extremal front reaches a neighborhood of the south pole.

The idea is that, once one knows the extremal front  $\mathcal{F}(\alpha, T)$  and if it is optimal, then one can continue to build the synthesis for times bigger than  $T$  using  $\mathcal{F}(\alpha, T)$  as a *source* for the minimization problem.

The identification of the front  $\mathcal{F}(\alpha, T)$  is not easy since it requires the computation of the product of several exponentials of matrices. Moreover, if  $\mathcal{F}(\alpha, T)$  crosses some switching curve, then the number of exponentials in general depends on the point.

This problem is overcome by considering  $\mathcal{F}(\alpha, T)$  only at times equal to multiples of  $\pi$ . Indeed, first notice that, for  $T = \pi \left\lfloor \frac{\pi}{2\alpha} \right\rfloor$ , the extremal front reaches the points  $C_{k_M}^\pm(0)$ , i.e., the points where the last switching curves  $C_{k_M}^\pm$  start. Thanks to Proposition 2 below, at these times, every extremal trajectory has the same number of switchings. The extremal front at times that are not a multiple of  $\pi$  can be obtained a posteriori, continuing the extremal front, as explained above.

From the structure of the extremal trajectories it follows that the time at which the point  $C_k^\pm(s)$  is reached is  $T_k(s) = s + kv(s)$ .

LEMMA 1. *Let  $k$  be an integer satisfying  $1 \leq k \leq \mathcal{N}_{mon} := \left\lfloor \frac{(\cot(\alpha)^2 - 1)^2}{2\cot(\alpha)^2 - 1} \right\rfloor$ , and then  $T_k(s)$  is a strictly increasing function of  $s$ .*

*Proof.* It holds that

$$(23) \quad \frac{d}{ds} T_k(s) = \frac{1 + 2\mathbf{c}_s \cot(\alpha)^2 + \cot(\alpha)^4 + k \left( 2 + 2\mathbf{c}_s \cot(\alpha)^2 \right)}{1 + 2\mathbf{c}_s \cot(\alpha)^2 + \cot(\alpha)^4}.$$

It is clear that the denominator of the above fraction is never vanishing on  $[0, \pi]$  if  $\alpha < \pi/4$ . On the other hand, the numerator, as a function of  $s$ , reaches its minimum

at  $s = \pi$ , where it is equal to  $(\cot(\alpha)^2 - 1)^2 - k(2\cot(\alpha)^2 - 1)$ , and then the conclusion follows easily.  $\square$

As a consequence, we obtain the following important corollary.

**COROLLARY 1.** *Let  $k$  be an integer satisfying  $1 \leq k \leq \mathcal{N}_{\text{mon}}$ . If an extremal trajectory is switching at time  $T = k\pi$ , then the length  $s$  of the first bang arc satisfies  $s = \pi$ .*

Since for  $\alpha$  small  $k_M \leq \mathcal{N}_{\text{mon}}$ , then, for  $T = k\pi$ , where  $k$  is a positive integer such that  $k \leq [\pi/(2\alpha)]$ , we have that all of the extremal trajectories switch exactly  $k$  times (except the trajectories with length of the first switching equal to  $\pi$  that switch  $k - 1$  times). Therefore, the extremal front  $\mathcal{F}(\alpha, k\pi)$  is described by the next proposition.

**PROPOSITION 2.** *Let  $k$  be a positive integer such that  $1 \leq k \leq [\pi/(2\alpha)]$ . Then, if  $\alpha$  is small enough, we have*

$$(24) \quad \mathcal{F}(\alpha, k\pi) = \{\mathcal{E}^+(\alpha, k, s), \quad s \in (0, \pi]\} \cup \{\mathcal{E}^-(\alpha, k, s), \quad s \in (0, \pi]\}, \quad \text{where :}$$

$$(25) \quad \mathcal{E}^+(\alpha, k, s) := \begin{cases} e^{(k\pi - (k-1)v(s) - s)X_-} e^{\frac{k-1}{2}\Theta(v(s))Z_-} e^{(v(s))} e^{sX_+} N & \text{for } k \text{ odd,} \\ e^{(k(\pi - v(s)) - s)X_+} e^{\frac{k}{2}\Theta(v(s))Z_-} e^{(v(s))} e^{sX_+} N & \text{for } k \text{ even.} \end{cases}$$

The expression for  $\mathcal{E}^-$  is the same as the expression for  $\mathcal{E}^+$  after exchanging the subscripts  $+$  and  $-$ . As a consequence,  $\mathcal{E}^{-\varepsilon} = \Pi_{x_3} \mathcal{E}^\varepsilon$ , where  $\Pi_{x_3}$  is the orthogonal symmetry with respect to the  $x_3$ -axis.

*Remark 5.* Notice that  $\mathcal{E}^\varepsilon(\alpha, k, 0) = \mathcal{E}^{-\varepsilon}(\alpha, k, \pi)$ ,  $\varepsilon = \pm$ , so that  $\mathcal{F}$  is described by a continuous closed curve.

**3.2. Description of the extremal front  $\mathcal{F}(\alpha, k_M\pi)$  and consequences.** As sketched in the introduction, we must describe the optimal synthesis on  $S^2$  deprived of a neighborhood of the south pole. For that purpose, we will provide the precise asymptotics of  $\mathcal{F}(\alpha, k_M\pi)$ , as  $\alpha$  tends to zero, and derive, from its topological nature, the minimum time front at time  $k_M\pi$ .

From now on, for simplicity, we drop the dependence of  $\mathcal{E}^\varepsilon$  on  $k_M$ ; i.e., we set  $\mathcal{E}^\varepsilon(\alpha, s) := \mathcal{E}^\varepsilon(\alpha, k_M, s)$ , and we assume that  $k_M$  is odd.

In the following, it will be useful to think of  $\alpha$  and  $r$  as two independent variables. For this purpose, define

$$\begin{aligned} \psi(\alpha, r, s) &:= \left( \frac{\pi}{2\alpha} - r \right) (\pi - v(s)) + v(s) - s, \\ \theta(\alpha, r, s) &:= \left( \frac{\pi}{4\alpha} - \frac{1+r}{2} \right) \Theta(v(s)), \\ \chi^\varepsilon(\alpha, r, s) &:= e^{\psi(\alpha, r, s)X_-} e^{\theta(\alpha, r, s)Z_-} e^{(v(s))} e^{sX_\varepsilon} N. \end{aligned}$$

It is clear from (25) that

$$\mathcal{E}^\varepsilon(\alpha, s) = \chi^\varepsilon(\alpha, r(\alpha), s).$$

The following result is the key point in order to describe the extremal front at time  $k_M\pi$ .

**LEMMA 2.** *There exists  $\alpha_0 > 0$  such that the function  $\chi^\varepsilon$ ,  $\varepsilon = \pm$ , defined above, is real-analytic for  $(r, s, \alpha) \in \mathbb{R}^2 \times I$ , where  $I = (-\alpha_0, \alpha_0)$ . Moreover, it admits a convergent power series*

$$(26) \quad \chi^\varepsilon(\alpha, r, s) = \sum_{l \geq 0} f_l^\varepsilon(s, r) \alpha^l,$$

where the  $f_l^\varepsilon(s, r)$  are real-analytic functions of  $(s, r) \in \mathbb{R}^2$ ,  $2\pi$ -periodic in  $s$  (therefore they are bounded over  $\mathbb{R} \times [0, 1]$ ).

As a consequence, the extremal front  $\mathcal{F}(\alpha, k_M\pi)$ , which is a continuous closed curve, is piecewise analytic with discontinuities at  $s = 0, \pi$  for derivatives of order greater than or equal to one.

*Proof of Lemma 2.* We will prove the proposition only for  $\chi^+$ . Since  $\chi^+$  is  $2\pi$ -periodic in  $s$  and  $r$  enters in an affine way in  $\psi$  and  $\theta$ , the real issue of analyticity revolves around the variable  $\alpha$ . First of all, it is clear that  $v(s)$  is actually a real-analytic function for  $(s, \alpha) \in \mathbb{R} \times I$ , where  $I = (-\alpha_0, \alpha_0)$ , with  $\alpha_0 > 0$  small enough. Therefore, one has only to prove the real-analyticity of  $\tilde{\psi}(\alpha, s) := \frac{v(s) - \pi}{\alpha}$  and  $\frac{\beta(s, \alpha)}{\alpha}$ , where  $\beta(s, \alpha) := \Theta(v(s))$ , for  $(s, \alpha) \in \mathbb{R} \times I$ , where  $I = (-\alpha_0, \alpha_0)$ , for some  $\alpha_0 > 0$ .

Note that

$$\tilde{\psi}(\alpha, s) = \frac{2}{\alpha} \arctan(\mathbf{s}_\alpha^2 \mu(s)), \quad \mu(s) := \frac{\mathbf{s}_s}{\mathbf{c}_\alpha^2 + \mathbf{s}_\alpha^2 \mathbf{c}_s}.$$

The function  $\mu$  is real-analytic for  $(s, \alpha) \in \mathbb{R} \times I$ , with  $I$  an open neighborhood of zero, and thus uniformly bounded over  $\mathbb{R} \times I$ . In addition,  $\arctan(\cdot)$  is real-analytic in a neighborhood of zero. Hence the conclusion for  $\tilde{\psi}(\alpha, s)$ .

As for  $\frac{\beta(s, \alpha)}{\alpha}$ , first rewrite (19) as

$$\cos(\beta(s)) = 1 - G(s, \alpha),$$

with

$$(27) \quad G(s, \alpha) := 2\mathbf{s}_\alpha^2 \left[ 1 + \frac{\mathbf{c}_\alpha^2 \mathbf{s}_\alpha^2 \mu^2(s)}{1 + \mathbf{s}_\alpha^4 \mu^2(s)} + 2\mathbf{s}_\alpha^2 \left( 1 + \frac{\mathbf{c}_\alpha^2 \mathbf{s}_\alpha^2 \mu^2(s)}{1 + \mathbf{s}_\alpha^4 \mu^2(s)} \right)^2 \right].$$

We first need to determine a convergent power series for  $\beta$  from the expression

$$(28) \quad \beta = \arccos(1 - G).$$

Note that  $|G(s, \alpha)| \leq 5\alpha^2$  for  $\alpha$  small enough. We first expand  $\arccos(1 - G)$  in a power series in  $G$ . Starting from the power series

$$(1 - t)^{-1/2} = 1 + \sum_{m \geq 1} s_m t^m,$$

with radius of convergence equal to 1 we get

$$\frac{d}{dG}(\arccos(1 - G)) = -\frac{1}{\sqrt{2G}} \frac{1}{\sqrt{1 - G/2}},$$

and, after simple integration,

$$(29) \quad \arccos(1 - G) = -\sqrt{2G} \left( 1 + \sum_{m \geq 1} \frac{s_m}{2^{m+1}(m + 1/2)} G^m \right).$$

Finally, from (27),  $G$  can be written as  $2\mathbf{s}_\alpha^2(1 + \mathbf{s}_\alpha^2 H(s, \alpha))$ , with  $H(s, \alpha)$  uniformly bounded by 3. Then

$$(30) \quad \sqrt{2G(s, \alpha)} = 2\mathbf{s}_\alpha(1 + \mathbf{s}_\alpha^2 H(s, \alpha))^{1/2}.$$

Gathering (28)–(30), we get the real-analyticity of  $\frac{\beta(s, \alpha)}{\alpha}$  for  $(s, \alpha) \in \mathbb{R} \times I$ , where  $I = (-\alpha_0, \alpha_0)$ , for some  $\alpha_0 > 0$  small enough.  $\square$

We next compute  $f_0^\varepsilon, f_1^\varepsilon$ , and  $f_2^\varepsilon$  and obtain the following proposition.

**PROPOSITION 3.** *For  $\alpha$  small enough, the function  $\chi^\varepsilon$ ,  $\varepsilon = \pm$ , defined above and its derivative with respect to  $s$  have the following expansion:*

$$(31) \quad \chi^\varepsilon(\alpha, r, s) = f_0^\varepsilon(s, r) + f_1^\varepsilon(s, r)\alpha + f_2^\varepsilon(s, r)\alpha^2 + \mathcal{O}(\alpha^3),$$

$$(32) \quad \frac{\partial}{\partial s} \chi^\varepsilon(\alpha, r, s) = \frac{\partial}{\partial s} f_0^\varepsilon(s, r) + \frac{\partial}{\partial s} f_1^\varepsilon(s, r)\alpha + \frac{\partial}{\partial s} f_2^\varepsilon(s, r)\alpha^2 + \mathcal{O}(\alpha^3),$$

where  $f_l^\varepsilon$ ,  $l = 0, 1, 2$ , are defined as in (9) and  $|\mathcal{O}(\alpha^3)| \leq C|\alpha^3|$ , with the constant  $C$  independent of  $s \in \mathbb{R}$  and  $r \in [0, 1)$ .

*Proof of Proposition 3.* We will prove the proposition only for  $\chi^+$ . To proceed, we list the expansions of the form (31) for several quantities, obtained after elementary computations:

$$(33) \quad \psi(\alpha, r, s) = \pi - s - \pi \mathbf{s}_s \alpha + 2(1 - r) \mathbf{s}_s \alpha^2 + \mathcal{O}(\alpha^3),$$

$$(34) \quad \theta(\alpha, r, s) = \pi - 2\alpha(1 + r) + \frac{\pi \mathbf{s}_s^2}{2} \alpha^2 + \mathcal{O}(\alpha^3),$$

$$(35) \quad Z_-(v(s)) = \begin{pmatrix} 0 & -\alpha \mathbf{s}_s & 1 - \frac{\mathbf{s}_s^2}{2} \alpha^2 \\ \alpha \mathbf{s}_s & 0 & 0 \\ -1 + \frac{\mathbf{s}_s^2}{2} \alpha^2 & 0 & 0 \end{pmatrix} + \mathcal{O}(\alpha^3).$$

Using (33) and (34), we get that

$$(36) \quad \sin(\psi(\alpha, r, s)) = \mathbf{s}_s + \pi \mathbf{s}_s \mathbf{c}_s \alpha - \left( 2(1 - r) \mathbf{s}_s \mathbf{c}_s + \frac{\pi}{2} \mathbf{s}_s^3 \right) \alpha^2 + \mathcal{O}(\alpha^3),$$

$$(37) \quad \cos(\psi(\alpha, r, s)) = \mathbf{c}_s - \pi \mathbf{s}_s^2 \alpha + \left( 2(1 - r) \mathbf{s}_s^2 - \frac{\pi^2}{2} \mathbf{s}_s^2 \mathbf{c}_s \right) \alpha^2 + \mathcal{O}(\alpha^3),$$

$$(38) \quad \sin(\theta(\alpha, r, s)) = 2\alpha(1 + r) - \frac{\pi \mathbf{s}_s^2}{2} \alpha^2 + \mathcal{O}(\alpha^3),$$

$$(39) \quad \cos(\theta(\alpha, r, s)) = -1 + 2\alpha^2(1 + r)^2 + \mathcal{O}(\alpha^3).$$

Using (17), (36), and (37), we obtain

$$(40) \quad e^{\psi(\alpha, r, s) X_-} = \begin{pmatrix} -\mathbf{c}_s + \pi \mathbf{s}_s^2 \alpha & -\mathbf{s}_s - \pi \mathbf{c}_s \mathbf{s}_s \alpha & -(1 + \mathbf{c}_s) \alpha \\ \mathbf{s}_s + \pi \mathbf{s}_s \mathbf{c}_s \alpha & \mathbf{c}_s + \pi \mathbf{s}_s^2 \alpha & \mathbf{s}_s \alpha \\ -(1 + \mathbf{c}_s) \alpha & -\mathbf{s}_s \alpha & 1 \end{pmatrix} + \mathcal{R}(s) \alpha^2 + \mathcal{O}(\alpha^3),$$

where

$$\mathcal{R}(s) = \begin{pmatrix} \mathbf{c}_s + \frac{\pi^2}{2} \mathbf{c}_s \mathbf{s}_s^2 + 1 - 2(1 + r) \mathbf{s}_s^2 & \frac{\mathbf{s}_s}{2} + 2\mathbf{c}_s \mathbf{s}_s(1 + r) + \frac{\pi^2}{2} \mathbf{s}_s^3 & \pi \mathbf{s}_s^2 \\ -\frac{\mathbf{s}_s}{2} - 2\mathbf{c}_s \mathbf{s}_s(1 + r) - \frac{\pi^2}{2} \mathbf{s}_s^3 & -2(1 + r) \mathbf{s}_s^2 + \frac{\pi^2}{2} \mathbf{c}_s \mathbf{s}_s^2 & \pi \mathbf{s}_s \mathbf{c}_s \\ \pi \mathbf{s}_s^2 & -\pi \mathbf{s}_s \mathbf{c}_s & -1 - \mathbf{c}_s \end{pmatrix},$$

and, using (17), we have

$$(41) \quad e^{s X_+} N = \begin{pmatrix} \mathbf{s}_\alpha \mathbf{c}_\alpha (1 - \mathbf{c}_s) \\ -\mathbf{s}_\alpha \mathbf{s}_s \\ 1 - \mathbf{s}_\alpha^2 (1 - \mathbf{c}_s) \end{pmatrix} = \begin{pmatrix} \alpha(1 - \mathbf{c}_s) \\ -\alpha \mathbf{s}_s \\ 1 - \alpha^2(1 - \mathbf{c}_s) \end{pmatrix} + \mathcal{O}(\alpha^3).$$

An easy computation yields

$$(42) \quad Z_-^2(v(s)) = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -\alpha^2 \mathbf{s}_s^2 & \alpha \mathbf{s}_s \\ 0 & \alpha \mathbf{s}_s & -1 + \alpha^2 \mathbf{s}_s^2 \end{pmatrix} + \mathcal{O}(\alpha^3).$$

Using (17), (38), (39), (41), and the previous equation, we get

$$(43) \quad e^{\theta(\alpha, r, s)Z_-(v(s))} e^{sX_+} N = \begin{pmatrix} \alpha(1 + 2r + \mathbf{c}_s) - \alpha^2 \frac{\pi}{2} \mathbf{s}_s^2 \\ \alpha \mathbf{s}_s \\ -1 + \alpha^2 (1 + 2r + 2r^2 + \mathbf{c}_s + 2r \mathbf{c}_s) \end{pmatrix} + \mathcal{O}(\alpha^3).$$

Applying  $e^{\psi(s)X_-}$  to the previous equation and using (40), we finally get (31) for  $\varepsilon = +$ . The expression of the derivative (32) is then an immediate consequence of the analyticity of the function  $\chi^+$ .

The results for  $\chi^-$  and  $\frac{\partial}{\partial s}\chi^-$  are obtained similarly together with (16).  $\square$

Since the quantities of the form  $\mathcal{O}(\alpha^3)$  in Proposition 3 satisfy  $|\mathcal{O}(\alpha^3)| \leq C|\alpha^3|$  for some  $C$  independent of  $r$ , the expressions (10)–(11) are straightforward consequences. Hence the shape of the extremal front at time  $T = k_M\pi$  is known for  $\alpha$  small. In particular its image with respect to the map  $M_\alpha$  defined in section 1 is approximated, in the  $\mathcal{C}^1$  sense, by a circle of radius  $2r(\alpha)$  centered at the origin.

We finally note that, for  $k_M$  even, Lemma 2 is still valid, while, with computations similar to those made in the proof of Proposition 3, it is easy to see that the formulas for  $f_k^\varepsilon$ ,  $k = 0, 1, 2$ , simply differ, with respect to (9), for the sign of the first two components.

*Remark 6.* Repeating the previous computations, we also obtain series expansions for  $\mathcal{E}^\varepsilon(s, k_M - 1, \alpha)$  and  $\frac{\partial}{\partial s}\mathcal{E}^\varepsilon(s, k_M - 1, \alpha)$ . Indeed, we just have to replace  $r$  by  $1 + r$ . In that case the shape of the extremal front  $\mathcal{F}(\alpha, (k_M - 1)\pi)$ , after applying the map  $M_\alpha$ , is approximated, in the  $\mathcal{C}^1$  sense, by a circle of radius  $2(1 + r(\alpha))$  centered at the origin.

**4. Case  $r(\alpha) = \bar{r} \in (0, 1)$ .** In this section, we study the case in which  $\alpha$  tends to zero, with  $r(\alpha) = \bar{r}$ , for a constant  $\bar{r} \in (0, 1)$ . More precisely we consider the decreasing sequence  $\alpha_k = \frac{\pi}{2(k + \bar{r})}$  for  $k \geq 1$ . We first describe the minimum time front at  $T = k_M\pi$ , then we identify and study the candidate for the limit synthesis, and finally we prove Theorem 1.

**4.1. Description of the minimum time front at  $T = k_M\pi$ .** The purpose of the subsection is to prove the following proposition.

**PROPOSITION 4.** *Fix  $\delta > 0$  small. For  $\alpha$  small enough, with  $r(\alpha) > \delta$ , the extremal front  $\mathcal{F}(\alpha, k_M\pi)$  is homeomorphic to a circle. As a consequence, the switching curves defined inductively in (7) are optimal up to  $k = k_M$ , and  $OF(\alpha, k_M\pi)$ , the minimum time front at time  $k_M\pi$ , coincides with  $\mathcal{F}(\alpha, k_M\pi)$ .*

*Proof of Proposition 4.* From Proposition 3 we get that the extremal front  $\mathcal{F}(\alpha, k_M\pi)$  is the union of two arcs  $\mathcal{E}^+(\alpha, s)$ ,  $s \in [0, \pi]$  and  $\mathcal{E}^-(\alpha, s)$ ,  $s \in [0, \pi]$  so that, for  $\varepsilon = \pm$  and  $s \in [0, \pi]$ ,

$$(44) \quad \mathcal{E}^\varepsilon(\alpha, s) = \begin{pmatrix} -2r(\alpha)\varepsilon\alpha\mathbf{c}_s \\ 2r(\alpha)\varepsilon\alpha\mathbf{s}_s \\ -1 \end{pmatrix} + \mathcal{O}(\alpha^2),$$

and

$$(45) \quad \frac{\partial}{\partial s} \mathcal{E}^\varepsilon(\alpha, s) = 2r(\alpha) \varepsilon \alpha \begin{pmatrix} \mathbf{s}_s \\ \mathbf{c}_s \\ 0 \end{pmatrix} + \mathcal{O}(\alpha^2).$$

Moreover, at  $s = 0$  and  $s = \pi$ , the derivatives of  $\mathcal{E}^\varepsilon(\alpha, s)$  are only one-sided, i.e., as  $s > 0$  tends to zero and  $s < \pi$  tends to  $\pi$ . By a trivial continuity argument, one can parametrize  $\mathcal{F}(\alpha, k_M \pi)$  as a closed continuous curve  $\gamma$  defined on  $[0, 2\pi]$  so that  $\gamma(s) = \mathcal{E}^+(\alpha, s)$  for  $s \in (0, \pi]$  and  $\gamma(s) = \mathcal{E}^-(\alpha, s - \pi)$  for  $s \in (\pi, 2\pi]$ . Moreover, with the previous computations, it is immediate that  $\gamma$  is in fact piecewise  $C^1$  with possible discontinuity jumps for  $\frac{d}{ds}\gamma$  at  $s = 0$  and  $s = \pi$ .

Since the curve  $\gamma$  is in a neighborhood of the south pole of size proportional to  $\alpha$  (thanks to (44)), it is enough to prove that the orthogonal projection  $\gamma_1$  of  $\gamma$  on the  $(x_1, x_2)$ -plane is homeomorphic to the circle  $e^{is}$ ,  $s \in [0, 2\pi]$ . Using (44), we see that  $\|\gamma_1(s)\| = 2r(\alpha)\alpha + \mathcal{O}(\alpha^2)$  on  $[0, 2\pi]$ , which implies that the continuous function  $\|\gamma_1(s)\|$  is always strictly positive for  $\alpha$  small enough. We can therefore parametrize  $\gamma_1$  using polar coordinates  $(\rho, \beta)$ , i.e., for  $s \in [0, 2\pi]$ ,

$$\gamma_1(s) = \rho(s)e^{i\beta(s)},$$

where  $\rho(\cdot) := \|\gamma_1(\cdot)\|$  and the function  $\beta(\cdot)$  are defined on  $[0, 2\pi]$ , continuous, and piecewise  $C^1$ , with possible jumps of discontinuity for their derivatives at  $s = 0$  and  $s = \pi$ .

In addition  $\rho(0) = \rho(2\pi)$ ,  $\beta(0) \equiv \beta(2\pi) \equiv \pi \pmod{2\pi}$ , and, from (44),  $\beta(s) = \pi - s + \mathcal{O}(\alpha)$ . To prove Proposition 4, it suffices now to prove that  $\beta$  is a monotone bijection from  $[0, 2\pi]$  to  $[-\pi, \pi]$ . The latter simply results from (45). Indeed, from that equation, we get that  $\frac{d}{ds}\beta(s) = -1 + \mathcal{O}(\alpha)$ , where  $\beta$  is differentiable and the one-sided derivatives at  $s = 0$  and  $s = \pi$  verify the same equation. We deduce that  $\beta$  is strictly decreasing for  $\alpha$  small enough.

We next show that  $OF(\alpha, k_M \pi)$ , the minimum time front at time  $k_M \pi$ , coincides with  $\mathcal{F}(\alpha, k_M \pi)$ . By the results of [9], we first notice that any time minimal trajectory starting at the north pole reaches the south pole in time  $T > k_M \pi$ . Therefore  $OF(\alpha, k_M \pi)$  is not empty and is included in  $\mathcal{F}(\alpha, k_M \pi)$  according to the PMP. According to Theorem 27 of [8],  $OF(\alpha, k_M \pi)$  is a one-dimensional piecewise  $C^1$  compact embedded submanifold of  $S^2$ . By an easy topological argument, we deduce from the above that  $OF(\alpha, k_M \pi)$  coincides with  $\mathcal{F}(\alpha, k_M \pi)$ .  $\square$

*Remark 7.* Thanks to Remark 6, and with arguments similar to those of the previous proof, one can prove that  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  is optimal for  $\alpha$  small enough, with no assumptions on the remainder  $r$ .

**4.2. Optimal synthesis for the linear pendulum control problem.** Recall that  $M_\alpha : \mathbb{R}^3 \rightarrow \mathbb{R}^2$  is the composition of the projection  $(x_1, x_2, x_3) \mapsto (x_1, x_2)$  followed by the dilation by  $1/\alpha$ . With the results of the previous subsection, it is clear that the original control problem on  $S^2$  can be reduced, near the south pole, to a planar control problem on the neighborhood of the south pole delimited by  $\widetilde{OF}(\alpha, k_M \pi) := M_\alpha(OF(\alpha, k_M \pi))$  along  $(\widetilde{\Sigma})_\alpha$ , the control system obtained as the image of  $(\Sigma)_\alpha$  by  $M_\alpha$ , i.e.,

$$(46) \quad (\widetilde{\Sigma})_\alpha : \begin{cases} \dot{z}_1 = -\cos(\alpha)z_2, \\ \dot{z}_2 = \cos(\alpha)z_1 + u \frac{\sin(\alpha)}{\alpha} \sqrt{1 - (\alpha z_1)^2 - (\alpha z_2)^2}, \end{cases} \quad (z_1, z_2) \in \mathbb{R}^2, \quad |u| \leq 1.$$

It is therefore natural to conjecture (simply set  $\alpha = 0$  in  $\widetilde{OF}(\alpha, k_M\pi)$  and  $(\widetilde{\Sigma})_\alpha$ ) that the limit synthesis should be that of connecting the circle of radius  $2r(\alpha)$ ,  $C(0, 2r(\alpha))$ , to every point of the disk  $B(0, 2r(\alpha))$  along the control system  $(Pen)$  given by (12), which we rewrite as

$$(47) \quad (Pen) \quad \dot{z} = A_0 z + u b_0, \quad \text{with} \quad A_0 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad b_0 = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

where  $z \in \mathbb{R}^2$  and  $u \in [-1, 1]$ . The control system  $(Pen)$  corresponds to a linear pendulum with a forcing term.

Theorem 1 simply states that the conjecture is correct, and, as a first step for an argument, we describe, in more detail in this subsection, the conjectured limit synthesis. Hence we focus on the following problem.

(P). *Given fixed  $\rho \in ]0, 2]$ , for any given  $\bar{y} \in B(0, \rho)$  find a time optimal trajectory connecting the circle of radius  $\rho$  centered at the origin to  $\bar{y}$  along the control system  $(Pen)$ .*

*Remark 8.* The problem of computing the TOS for the linear pendulum, taking the origin as a source, is studied in any textbook of optimal control. Here as the source we take the circle of radius  $\rho$  centered at the origin, which is a level set of the Hamiltonian  $H = \frac{1}{2}(z_1^2 + z_2^2)$  associated to the uncontrolled system.

It is easy to see that the solutions of problem (P) must be bang-bang trajectories. Indeed since  $(Pen)$  is a bidimensional linear control system it is well known that this property is guaranteed by the Kalman controllability condition  $\det(b_0, A_0 b_0) \neq 0$ , which is satisfied by  $(Pen)$ . To determine the TOS, we first look for the switching curves. We know that every extremal trajectory for the problem (P) must satisfy the transversality condition of the PMP stated in section 2.1. Here the source manifold is the circle  $C(0, \rho)$ , and the transversality condition essentially translates into the property that the vector  $\lambda(0)$  (that, without loss of generality, we will assume unitary) is proportional to  $z(0) \in C(0, \rho)$  (identifying the cotangent space with the plane  $\mathbb{R}^2$ ). To determine completely  $\lambda(0)$ , it is enough to observe that a necessary condition for  $z(\cdot)$  to be optimal is that  $\dot{z}(0)$  points inside the disk  $B(0, \rho)$ ; i.e., if we denote by  $u_{opt}$  the corresponding control, then

$$\langle z(0), \dot{z}(0) \rangle \leq 0 \iff \langle z(0), A_0 z(0) + u_{opt} b_0 \rangle \leq 0 \iff \langle z(0), u_{opt} b_0 \rangle \leq 0.$$

Therefore,  $u_{opt} = -\text{sgn}\langle z(0), b_0 \rangle$ . On the other hand, from the maximality condition of the PMP, we have  $u_{opt} = \text{sgn}\langle \lambda(0), b_0 \rangle$ , and, therefore, one can define  $\lambda(0) := -z(0)/\rho$ . Finally  $u_{opt} = -\text{sgn}(z_2(0))$  (except at the points  $\pm(\rho, 0)$ ), while the switching time  $t_{sw}$  must satisfy the condition  $\langle \lambda(t_{sw}), b_0 \rangle = \lambda_2(t_{sw}) = 0$ .

Consider now the adjoint system

$$(48) \quad \begin{cases} \dot{\lambda}_1 = -\lambda_2, \\ \dot{\lambda}_2 = \lambda_1. \end{cases}$$

If we identify  $\mathbb{R}^2$  with the complex plane, so that  $z = z_1 + iz_2$  and  $\lambda = \lambda_1 + i\lambda_2$ , then (47) and (48) become

$$\dot{z} = i(z + u) \quad \text{and} \quad \dot{\lambda} = i\lambda.$$

Moreover we can set  $z(0) = -\rho e^{-i\theta}$  and  $\lambda(0) = e^{-i\theta}$  for some  $\theta \in [0, 2\pi[$ , and the corresponding solutions are

$$\begin{cases} z(t) = (z(0) + u_{opt})e^{it} - u_{opt} = -\rho e^{i(t-\theta)} + u_{opt}(e^{it} - 1), \\ \lambda(t) = \lambda(0)e^{it} = e^{i(t-\theta)}. \end{cases}$$

The switching curves are determined by the relation  $t_{sw} \equiv \theta \pmod{\pi}$ , and this allows one to conclude that the switching curves are the following two semicircles of radius 1:

$$\begin{cases} z(\theta) = 1 - \rho - e^{i\theta} & \theta \in [0, \pi[, \\ z(\theta) = \rho - 1 - e^{i\theta} & \theta \in [\pi, 2\pi[. \end{cases}$$

These switching curves cannot be optimal for  $\rho < 2$  since they are not locally optimal, as can be easily checked using the definition given in section 2.2. We conclude that the optimal trajectories are bang arcs and the corresponding control depends on the sign of the component  $z_2(0)$  of the starting point.

To conclude the description of the synthesis, it is enough to determine the cut locus, i.e., the set of points that are reached by two or more optimal trajectories at the same time. Assume that  $z \in \mathbb{C}$  belongs to the cut locus. Then there exist  $s \in [0, \pi)$ ,  $s' \in [\pi, 2\pi)$  and  $t$  such that

$$(49) \quad \begin{cases} z = -\rho e^{i(t-s)} + 1 - e^{it}, \\ z = -\rho e^{i(t-s')} - 1 + e^{it}. \end{cases}$$

Therefore  $|z - 1 + e^{it}| = |z + 1 - e^{it}| = \rho$ . In particular, denoting by  $\bar{z}$  the complex conjugate to  $z$ , we have

$$(50) \quad \begin{aligned} (z - 1 + e^{it})(\bar{z} - 1 + e^{-it}) - (z + 1 - e^{it})(\bar{z} + 1 - e^{-it}) \\ = -4z_1 + 4z_1 \cos t + 4z_2 \sin t = 0, \end{aligned}$$

$$(51) \quad \begin{aligned} (z - 1 + e^{it})(\bar{z} - 1 + e^{-it}) + (z + 1 - e^{it})(\bar{z} + 1 - e^{-it}) \\ = 2z_1^2 + 2z_2^2 + 4 - 4 \cos t = 2\rho^2. \end{aligned}$$

From (50) we have that  $\cos t = \frac{z_1^2 - z_2^2}{z_1^2 + z_2^2}$ , and, substituting in (51), we find that  $z$  must satisfy the equation

$$(52) \quad z_1^4 + z_2^4 + 2z_1^2 z_2^2 - \rho^2 z_1^2 + (4 - \rho^2) z_2^2 = 0.$$

The previous computations show that the cut locus is a subset of the set of points belonging to the locus defined by (52). Actually it is easy to see that this is the proper subset obtained with the additional condition  $z_1 z_2 \geq 0$  that corresponds to  $t \leq \pi$ . The precise shape of the optimal synthesis, which is now clear, is portrayed in Figure 5 for a particular value of  $\rho < 2$ . Notice that, from the previous computations, we have  $\rho e^{is'} = \rho e^{is} + 2 - 2e^{it}$ , and, since  $\rho e^{is'} + \rho e^{is} = 2\rho e^{is'} - 2 + 2e^{it}$  and  $\rho e^{is'} - \rho e^{is} = 2 - 2e^{it}$  are orthogonal in the complex plane, we find easily the following equation:

$$(2 - \rho \cos s')(\cos t - 1) - \rho \sin s' \sin t = 0.$$

Consequently, for  $t \in [0, 2\pi[$  and  $s' \in [\pi, 2\pi[$ , one has along the overlap curve

$$(53) \quad t = t(s') = -2 \arctan \frac{\rho \sin s'}{2 - \rho \cos s'}.$$

This expression will be useful in the following. Also, notice that by combining (49) and (53) one easily finds a parametrization of the overlap curve in terms of  $s'$  and that in an analogous way it is possible to parametrize it by means of  $s$ . From now on

FIG. 8. Propositions 5 and 6.

we will denote by  $\gamma_{pen}^o(\cdot)$  the parametrization of the overlap curve with respect to the parameter  $s$ .

*Remark 9.* If  $\rho = 2$ , the previous reasoning does not apply, and indeed the synthesis is different. In this case the overlap curve coincides with the switching curves and with the trajectories reaching the origin corresponding to  $u = \pm 1$ . A simple way to prove this fact is to study the optimal synthesis starting from the origin with vector fields with opposite signs and to observe that the extremal front at time  $\pi$  is a circle of radius 2.

**4.3. Proof of Theorem 1.** The proof of Theorem 1 is divided in two parts. Roughly speaking, defining  $P_\varepsilon^\alpha := M_\alpha(C_{k_M}^\varepsilon(0))$  for  $\varepsilon = \pm$ , we will look separately at the shape of the synthesis far from  $P_\varepsilon^\alpha$  and inside neighborhoods of  $P_\varepsilon^\alpha$ ,  $\varepsilon = \pm$ . Let us call  $V_\alpha$  the image with respect to  $M_\alpha$  of the neighborhood of the south pole enclosed by  $OF(\alpha, k_M\pi)$  and  $B_\varepsilon^{\alpha_k}(\xi)$  the ball of center  $P_\varepsilon^\alpha$  and radius  $\xi$ .

Then the previous cases correspond to the following two propositions whose meaning is clarified by Figure 8.

**PROPOSITION 5.** Let  $\bar{r} \in (0, 1)$  and  $\alpha_k := \frac{\pi}{2(k+\bar{r})}$ . Then for any  $\xi > 0$  there exist a positive integer  $\bar{k}$  and a compact interval  $I \subset (0, \pi)$  such that it is possible to find a curve  $\gamma_k^o$ , defined on  $I$  for  $k \geq \bar{k}$ , verifying the following:  $\gamma_k^o$  divides  $V_{\alpha_k} \setminus (B_+^{\alpha_k}(\xi) \cup B_-^{\alpha_k}(\xi))$  in two connected components, such that above  $\gamma_k^o$  the optimal feedback associated to the synthesis for  $\alpha = \alpha_k$  takes the value  $-1$ , and below  $\gamma_k^o$  it is equal to  $1$ , and in particular  $\gamma_k^o$  is an overlap curve for  $\alpha = \alpha_k$ . Moreover,  $\gamma_k^o$  converges to  $\gamma_{pen}^o$  in the  $C^0$  topology of  $I$ .

**PROPOSITION 6.** Consider the notations defined above. Then there exist  $\xi > 0$ ,  $\tau_\varepsilon$ ,  $\varepsilon = \pm$ , with  $0 < \tau_- < \tau_+ < \pi$  and a positive integer  $\bar{k}$  such that, for every  $k \geq \bar{k}$ , it is possible to find two curves  $\gamma_{\varepsilon,k}^o$  and  $\gamma_{+\varepsilon,k}^o$ , defined respectively on  $[0, \tau_-]$  and  $[\tau_+, \pi]$ , verifying the following:  $\gamma_{\varepsilon,k}^o$  divides  $V_{\alpha_k} \cap B_\varepsilon^{\alpha_k}(\xi)$  in two connected components, such that above  $\gamma_{\varepsilon,k}^o$  the optimal feedback associated to the synthesis for  $\alpha = \alpha_k$  takes the value  $-1$ , and below  $\gamma_{\varepsilon,k}^o$  it is equal to  $1$ , and in particular the  $\gamma_{\varepsilon,k}^o$  are overlap curves for  $\alpha = \alpha_k$ . Moreover,  $\gamma_{\varepsilon,k}^o$  and  $\gamma_{+\varepsilon,k}^o$  converge to  $\gamma_{pen}^o$  in the  $C^0$  topology, respectively, of  $[0, \tau_-]$  and  $[\tau_+, \pi]$ .

The choice of studying the synthesis separately in neighborhoods of  $P_\varepsilon^\alpha$  and far from  $P_\varepsilon^\alpha$  is justified by the fact that the proofs of the previous propositions rely on different implicit function arguments.

It is clear that, by combining Proposition 5, for an appropriate choice of  $\xi$ , with Proposition 6, one almost completes the proof of Theorem 1. We will not prove explicitly that the convergence of  $\gamma_k^o$  to  $\gamma_{pen}^o$  with respect to the parameter  $\bar{r}$  is uniform in any closed interval of  $(0, 1)$ . As explained in Remark 10, this can be done with the same methods used in the proofs of Propositions 5 and 6.

We will therefore provide only the complete proofs of the propositions. For this purpose, the first step consists in checking whether the switching curves  $C_{k_M}^\varepsilon$ ,  $\varepsilon = \pm 1$ , are optimal or not. In that regard and similarly to the case of the linear pendulum, we have the following result.

**LEMMA 3.** *Let  $\bar{r} \in ]0, 1[$ . Then, if  $\alpha$  is small enough and  $r(\alpha) = \bar{r}$ , the switching curve  $C_{k_M}^\varepsilon$  is nowhere locally optimal; i.e., all of the extremal trajectories switching on  $C_{k_M}^\varepsilon$  lose optimality before reaching it.*

*Proof of Lemma 3.* For simplicity we define  $S(s) := C_{k_M}^+(s)$ , and we assume  $k_M$  odd. As in the proof of Proposition 3, we get the following asymptotic expansions, after applying the map  $M_\alpha$ :

$$(54) \quad S(s) = \begin{pmatrix} 2r - 1 + \mathbf{c}_s \\ \mathbf{s}_s \end{pmatrix} + \mathcal{O}(\alpha), \quad S(0) = \begin{pmatrix} 2r + \mathcal{O}(\alpha) \\ 0 \end{pmatrix},$$

$$(55) \quad S'(s) = \begin{pmatrix} -\mathbf{s}_s \\ \mathbf{c}_s \end{pmatrix} + \mathcal{O}(\alpha), \quad S'(0) = \begin{pmatrix} 0 \\ 1 + \mathcal{O}(\alpha) \end{pmatrix},$$

$$(56) \quad S''(s) = \begin{pmatrix} -\mathbf{c}_s \\ -\mathbf{s}_s \end{pmatrix} + \mathcal{O}(\alpha).$$

Integrating the above equation, we have

$$(57) \quad S'(s) = S'(0) + \int_0^s S''(\tau) d\tau = \begin{pmatrix} -\mathbf{s}_s + \mathcal{O}(s\alpha) \\ \mathbf{c}_s + \mathcal{O}(\alpha) \end{pmatrix},$$

$$(58) \quad S(s) = S(0) + \int_0^s S'(\tau) d\tau = \begin{pmatrix} 2r - 1 + \mathbf{c}_s + \mathcal{O}(\alpha) \\ \mathbf{s}_s + \mathcal{O}(s\alpha) \end{pmatrix},$$

and therefore

$$\begin{aligned} \frac{1}{\mathbf{c}_\alpha} X_\pm(S(s)) &= \begin{pmatrix} -S_2(s) \\ S_1(s) \pm \frac{\tan \alpha}{\alpha} \sqrt{1 - \alpha^2 S_1(s)^2 - \alpha^2 S_2(s)^2} \end{pmatrix} \\ &= \begin{pmatrix} -\mathbf{s}_s + \mathcal{O}(s\alpha) \\ 2r - 1 + \mathbf{c}_s + \mathcal{O}(\alpha) \pm (1 + \mathcal{O}(\alpha^2)) \end{pmatrix}. \end{aligned}$$

Here  $S_i$ ,  $i = 1, 2$ , denotes the  $i$ th component of  $S$ . Dividing the above equation by  $1 + \mathcal{O}(\alpha)$ , we can assume that the first component is identically equal to  $-\mathbf{s}_s$ . The same can be done with the expression (57), so that it is possible to compare the three vectors obtained in this way simply by looking at the second components, which are equal to, respectively,  $2r - 1 + \mathbf{c}_s \pm 1 + \mathcal{O}(\alpha)$  and  $\mathbf{c}_s + \mathcal{O}(\alpha)$ . In particular, the fact that  $S(\cdot)$  is nowhere locally optimal if  $\alpha$  is small enough follows from the inequalities  $2r - 2 + \mathbf{c}_s + \mathcal{O}(\alpha) < \mathbf{c}_s + \mathcal{O}(\alpha) < 2r + \mathbf{c}_s + \mathcal{O}(\alpha)$ .  $\square$

A straightforward consequence of the previous result is the presence of a nontrivial cut locus in the neighborhood of the south pole enclosed by  $F(\alpha, k_M\pi)$ . It remains to clearly define that cut locus, which is the purpose of Propositions 5 and 6.

**4.3.1. Proof of Proposition 5.** As usual, we provide only an argument in the case  $k_M$  odd, and we fix the remainder equal to  $\bar{r} \in (0, 1)$ .

Recall that, according to section 4.1,  $OF(\alpha, k_M\pi)$  is approximately (up to order  $\alpha^2$ ) a circle of radius  $2\bar{r}\alpha$ . To describe the synthesis inside the neighborhood of the south pole enclosed by  $OF(\alpha, k_M\pi)$ , it is more convenient to use the two-dimensional control system  $(\tilde{\Sigma})_\alpha$ , which is rewritten as follows by using (46):

$$\dot{z} = \mathbf{c}_\alpha A_0 z + u \frac{\mathbf{s}_\alpha}{\alpha} \sqrt{1 - \alpha^2 \|z\|^2} b_0.$$

We set  $\tilde{X}_\varepsilon^\alpha(z) := \mathbf{c}_\alpha A_0 z + \varepsilon \frac{\mathbf{s}_\alpha}{\alpha} \sqrt{1 - \alpha^2 \|z\|^2} b_0$  and  $\tilde{X}_\varepsilon^{pen}(z) := A_0 z + \varepsilon b_0$  for  $\varepsilon = \pm$ , and we define  $\widetilde{OF}(\alpha, k_M\pi)$  as the image by  $M_\alpha$  of  $OF(\alpha, k_M\pi)$ . Then we know that, up to order  $\alpha$ ,  $\widetilde{OF}(\alpha, k_M\pi)$  is a circle of radius  $2\bar{r}$ . In particular, as in the proof of Proposition 4, one can construct a piecewise smooth parametrization  $\sigma_\alpha : [0, 2\pi] \rightarrow \tilde{F}(\alpha, k_M\pi)$  so that  $\sigma_\alpha(0) = P_-^\alpha$ ,  $\sigma_\alpha(\pi) = P_+^\alpha$  with a loss of regularity occurring only at  $s = 0, \pi$  (with two-sided differentials at any order). In particular  $\sigma_\alpha(\cdot)$  approximates in the  $\mathcal{C}^0$  sense the function  $\sigma : [0, 2\pi] \rightarrow \mathbb{C} \sim \mathbb{R}^2$ , defined as  $\sigma(s) = 2\bar{r} e^{i(\pi-s)}$ , which is a parametrization of the circle of radius  $2\bar{r}$ .

Taking into account Lemma 3, the cut locus in  $V_\alpha$  is contained inside the set of points  $Q \in \mathbb{R}^2$ , besides  $P_\varepsilon^\alpha$ , such that there exists  $(s, s', t) \in (0, \pi) \times (\pi, 2\pi) \times (0, 2\pi)$  for which  $Q = e^{t\tilde{X}_+^\alpha} \sigma_\alpha(s') = e^{t\tilde{X}_-^\alpha} \sigma_\alpha(s)$ .

In view of applying an inverse function result for characterizing this set, we consider the map  $\Phi$  defined on  $[0, \pi] \times [\pi, 2\pi] \times [0, \pi]$  by

$$\Phi(s, s', t) := (s, e^{t\tilde{X}_+^{pen}} \sigma(s') - e^{t\tilde{X}_-^{pen}} \sigma(s)),$$

which takes values in  $\mathbb{R}^3$ . Similarly, for  $k \geq 1$  and  $\alpha_k$  as in the proposition, we consider the map  $\Phi_k$  defined on  $[0, \pi] \times [\pi, 2\pi] \times [0, \pi]$  by

$$\Phi_k(s, s', t) := (s, e^{t\tilde{X}_+^{\alpha_k}} \sigma_{\alpha_k}(s') - e^{t\tilde{X}_-^{\alpha_k}} \sigma_{\alpha_k}(s)).$$

Note that, since the vector fields  $\tilde{X}_\varepsilon^{\alpha_k}$  converge uniformly to  $\tilde{X}_\varepsilon^{pen}$  on  $V_\alpha$ , it is easy to see that  $\Phi_k$  converges to  $\Phi$  in the  $\mathcal{C}^1$  norm.

For  $(Pen)$ , a point of the overlap curve, besides  $P_\varepsilon^\alpha$ , is then identified with a triple  $(s, s', t) \in (0, \pi) \times (\pi, 2\pi) \times (0, \pi)$  such that  $\Phi(s, s', t) = (s, 0, 0)$ . In other words, the overlap curve can be parametrized by means of the map  $w : [0, \pi] \rightarrow \mathbb{R}^3$  defined implicitly by  $\Phi(w(s)) = (s, 0, 0)$ , while  $\gamma_{pen}^o$  can be obtained as the composition of the two maps  $e^{t\tilde{X}_-^{pen}} \sigma(s)$  and  $w(s)$ .

Similarly, we would like to define the overlap curve corresponding to  $(\Sigma)_{\alpha_k}$ , for  $k$  large enough, by means of the function  $w_k$  defined by  $\Phi_k(w_k(s)) = (s, 0, 0)$ . To proceed, we will apply Theorem 3. The first task consists of computing  $\det D\Phi$  along the overlap curve.

**LEMMA 4.** *Along the set of triples  $(s, s', t) \in (0, \pi) \times (\pi, 2\pi) \times (0, \pi)$  for which  $e^{t\tilde{X}_+^{pen}} \sigma(s') = e^{t\tilde{X}_-^{pen}} \sigma(s)$ , we have*

$$\det D\Phi(s, s', t) = \frac{4\bar{r}(1 - \bar{r}^2) \sin s'}{(1 - \bar{r} \cos s')^2 + (\bar{r} \sin s')^2}.$$

*Proof of Lemma 4.* One has

$$\det D\Phi(s, s', t) = \det \left( (e^{t\tilde{X}_+^{pen}})_* \frac{d\sigma}{ds'}, \tilde{X}_+^{pen} e^{t\tilde{X}_+^{pen}} \sigma(s') - \tilde{X}_-^{pen} e^{t\tilde{X}_-^{pen}} \sigma(s) \right).$$

By taking into account that  $\Phi(s, s', t) = 0$ , the previous determinant is equal to twice the first component of  $(e^{t\tilde{X}_+^{pen}})_* \frac{d\sigma}{ds'}$ , i.e.,  $\det \mathcal{D}\Phi(s, s', t) = 4\bar{r} \sin(s' - t)$ . Using (53), one concludes.  $\square$

Observe that  $\det D\Phi \neq 0$  if  $s' \neq 0, \pi$ . In particular, if we consider a closed interval  $I \subset (0, \pi)$ , then the set  $\text{Im}(w)|_I$  plays the role of the compact set  $\mathcal{K}$  in Theorem 3. All of the assumptions of the theorem are then verified, and therefore we have proved the existence of a map  $w_k$  defined on  $I$ , satisfying  $\Phi_k(w_k(s)) = (s, 0, 0)$  and converging uniformly to  $w$ . If we define  $\gamma_k^\circ$  as the composition of the two maps  $e^{t\tilde{X}_-^{\alpha_k}} \sigma(s)$  and  $w(s)$ , then, since  $I$  was chosen arbitrarily, the proof of the theorem is complete.  $\square$

**4.3.2. Proof of Proposition 6.** With the previous notations, let  $\varphi_k$  be the smooth map defined on  $[0, \pi] \times [\pi, 2\pi] \times [0, 2\pi]$  by

$$\varphi_k(s, s', t) = e^{t\tilde{X}_+^{\alpha_k}} \sigma_k(s') - e^{tX_-^{\alpha_k}} \sigma_k(s).$$

For the rest of this paragraph, we drop the index  $k$  to get lighter notations.

From the Taylor expansion of  $\varphi$  around the points  $(0, 2\pi, 0)$  and  $(\pi, \pi, 0)$ , we derive the asymptotic behaviors of the cut locus close to the points  $P_\varepsilon^\alpha$ ,  $\varepsilon = \pm$ , since that cut locus belongs to the level set  $\varphi = 0$ . We will perform computations only at  $(0, 2\pi, 0)$  since they are entirely similar at  $(\pi, \pi, 0)$ .

Let us call  $\varphi^{(1)}$  and  $\varphi^{(2)}$  the two components of  $\varphi$ . We use  $\varphi_s^{(i)}$  to denote the partial derivative of the component  $\varphi^{(i)}$  with respect to  $s$  evaluated in  $(0, 2\pi, 0)$ , and we define in an analogous way all of the (multiple) partial derivatives evaluated in  $(0, 2\pi, 0)$ . Set  $\tilde{s} := s' - 2\pi$ . Then, after computations, we have  $\varphi_s^{(1)} = \varphi_{\tilde{s}}^{(1)} = \varphi_t^{(1)} = 0$  and

$$\begin{aligned} \varphi_{ss}^{(1)} &= -2\bar{r} + \mathcal{O}(\alpha), & \varphi_{\tilde{s}\tilde{s}}^{(1)} &= 2\bar{r} + \mathcal{O}(\alpha), & \varphi_{tt}^{(1)} &= 2 + \mathcal{O}(\alpha), \\ \varphi_{s\tilde{s}}^{(1)} &= 0, & \varphi_{st}^{(1)} &= -2\bar{r} + \mathcal{O}(\alpha), & \varphi_{\tilde{s}t}^{(1)} &= 2\bar{r} + \mathcal{O}(\alpha), \\ \varphi_s^{(2)} &= 2\bar{r} + \mathcal{O}(\alpha), & \varphi_{\tilde{s}}^{(2)} &= -2\bar{r} + \mathcal{O}(\alpha), & \varphi_t^{(2)} &= 2\bar{r} + \mathcal{O}(\alpha). \end{aligned}$$

We thus get

$$\begin{aligned} \varphi^{(1)}(s, \tilde{s}, t) &= \varphi_{ss}^{(1)} s^2 + \varphi_{\tilde{s}\tilde{s}}^{(1)} \tilde{s}^2 + \varphi_{tt}^{(1)} t^2 + 2\varphi_{st}^{(1)} st + 2\varphi_{\tilde{s}t}^{(1)} \tilde{s}t + \mathcal{O}(|(s, \tilde{s}, t)|^3) \\ (59) \quad &= -2\bar{r}s^2 + 2r\tilde{s}^2 + 2t^2 - 4\bar{r}st + 4r\tilde{s}t + \mathcal{O}(\alpha|(s, \tilde{s}, t)|^2) + \mathcal{O}(|(s, \tilde{s}, t)|^3), \end{aligned}$$

and

$$\begin{aligned} \varphi^{(2)}(s, \tilde{s}, t) &= \varphi_s^{(2)} s + \varphi_{\tilde{s}}^{(2)} \tilde{s} + \varphi_t^{(2)} t + \mathcal{O}(|(s, \tilde{s}, t)|^2) \\ (60) \quad &= 2\bar{r}s - 2r\tilde{s} - 2t + \mathcal{O}(\alpha|(s, \tilde{s}, t)|) + \mathcal{O}(|(s, \tilde{s}, t)|^2), \end{aligned}$$

where, here,  $\mathcal{O}(\cdot)$  is uniform with respect to  $\alpha$ .

Fix  $\xi_0 > 0$  small. We are looking at the cut locus in a neighborhood of  $P_\varepsilon^\alpha$ , and thus we can assume  $|(s, \tilde{s}, t)| < \xi_0$  for some  $\xi_0 > 0$ . The purpose of subsequent computations consists of expressing  $\tilde{s} < 0$  and  $t > 0$  as functions of  $s$ , for  $0 \leq s \leq \xi_0$ , by using the equations  $\varphi^{(1)} = 0$  and  $\varphi^{(2)} = 0$ .

From  $\varphi^{(2)} = 0$ , by applying the implicit function theorem, for  $\xi_0$  small enough and  $|(s, \tilde{s})| < \xi_0$ , we get  $t = h(s, \tilde{s})$ , with  $h \in \mathcal{C}^1$ . Moreover, since  $h(s, \tilde{s}) = \mathcal{O}(|(s, \tilde{s})|)$  we have

$$(61) \quad h(s, \tilde{s}) = \bar{r}s - r\tilde{s} + \mathcal{O}(\alpha|(s, \tilde{s})|) + \mathcal{O}(|(s, \tilde{s})|^2).$$

Consider now the map

$$\phi(s, \tilde{s}) = \frac{\varphi^{(1)}(s, \tilde{s}, h(s, \tilde{s}))}{s - \tilde{s}},$$

which is well defined and  $\mathcal{C}^1$  for  $s > 0, \tilde{s} < 0$ . Again, it is possible to apply the implicit function theorem to the equation  $\phi = 0$ , so that we get  $\tilde{s}$  as a  $\mathcal{C}^1$  function of  $s$ , and this gives the existence of the overlap curve. Moreover, by combining (60) and (61), we get the following:

$$(62) \quad \phi(s, \tilde{s}) = s(1 + \bar{r}) + \tilde{s}(1 - \bar{r}) + \mathcal{O}(\alpha|(s, \tilde{s})|) + \mathcal{O}(|(s, \tilde{s})|^2) = 0,$$

and then  $|\tilde{s}| = \mathcal{O}(|s|)$ . Therefore, from this estimate and the above ones, we immediately obtain that

$$(63) \quad \tilde{s} = -\left(\frac{1 + \bar{r}}{1 - \bar{r}} + \mathcal{O}(\alpha)\right)s + \mathcal{O}(s^2), \quad t = \left(\frac{2\bar{r}}{1 - \bar{r}} + \mathcal{O}(\alpha)\right)s + \mathcal{O}(s^2),$$

from which we get that the overlap curve converges uniformly to  $\gamma_{pen}^o$ .

The proof of Proposition 6 is now complete.  $\square$

*Remark 10.* In order to prove that the overlap curve  $\gamma_k^o$  converges to  $\gamma_{pen}^o$  uniformly with respect to  $\bar{r}$  in any closed interval  $I \subset (0, 1)$ , it is enough to follow the lines of the proofs of Propositions 5 and 6 by considering  $\bar{r}$  as an additional variable. For instance, for Proposition 5, one needs to define the maps  $\tilde{\Phi} : \mathbb{R}^4 \rightarrow \mathbb{R}^4$ ,  $\tilde{\Phi}(\bar{r}, s, s', t) := (\bar{r}, s, e^{t\tilde{X}_+^{pen}}\sigma(s') - e^{t\tilde{X}_-^{pen}}\sigma(s))$  (recall that  $\sigma(\cdot)$  depends on  $\bar{r}$ ) and  $\tilde{\Phi}_k : \mathbb{R}^4 \rightarrow \mathbb{R}^4$ ,  $\tilde{\Phi}_k(\bar{r}, s, s', t) := (\bar{r}, s, e^{t\tilde{X}_+^{\alpha_k}}\sigma_k(s') - e^{t\tilde{X}_-^{\alpha_k}}\sigma_k(s))$  (where  $\alpha_k = \pi/(2(\bar{r} + k))$ ) and  $\sigma_k(\cdot)$  depends on  $\bar{r}$ ).

The uniformity with respect to  $\bar{r}$  is then proved by applying Theorem 3 to  $\tilde{\Phi}, \tilde{\Phi}_k$  with  $\mathcal{K} = \{\tilde{\Phi}^{-1}(\bar{r}, s, 0, 0) : (\bar{r}, s) \in I \times J\}$ , where  $I \times J$  is a compact subset of  $(0, 1) \times (0, \pi)$ .

## 5. Case $r = C\alpha$ .

**5.1. Description of the minimum time front at time  $k_M\pi$ .** Fix  $C > 0$ , and consider the sequence  $(\alpha_k)$  such that  $r(\alpha_k) = C\alpha_k$ ,  $k \geq 0$ . As before, we drop the index  $k$  when possible. For  $\alpha_k$  small enough, one deduces, from the analysis of [9], that the south pole is not reached at time  $k_m\pi = [\frac{\pi}{2\alpha}] \pi$ , so that the optimal front at time  $k_M\pi$  is not empty. The next result provides a description of the extremal front at time  $k_M\pi$ .

LEMMA 5. Define the planar curve  $\mathcal{L} : [0, 2\pi] \rightarrow \mathbb{R}^2$  by

$$(64) \quad \mathcal{L}(s) = \begin{pmatrix} \mathbf{c}_s(-2C + \pi \mathbf{s}_s^2/2) \\ \mathbf{s}_s(\pi + 2C - \pi \mathbf{s}_s^2/2) \end{pmatrix}.$$

Then, for  $s \in [0, \pi]$ , we have

$$(65) \quad \mathcal{E}^+(\alpha, s) = (\alpha^2 \mathcal{L}(s), -1)^T + \mathcal{O}(\alpha^3),$$

and

$$(66) \quad \frac{\partial}{\partial s} \mathcal{E}^+(\alpha, s) = \left( \alpha^2 \frac{d}{ds} \mathcal{L}(s), 0 \right)^T + \mathcal{O}(\alpha^3).$$

At  $s = 0$  and  $s = \pi$ , the derivatives are only one-sided, i.e., as  $s > 0$  tends to zero and  $s < \pi$  tends to  $\pi$ .

Similarly, we have, for  $s \in [0, \pi]$ ,

$$(67) \quad \mathcal{E}^-(\alpha, k_M \pi, s) = (\alpha^2 \mathcal{L}(s + \pi), -1)^T + \mathcal{O}(\alpha^3),$$

and

$$(68) \quad \frac{\partial}{\partial s} \mathcal{E}^-(\alpha, k_M \pi, s) = \left( \alpha^2 \frac{d}{ds} \mathcal{L}(s + \pi), 0 \right)^T + \mathcal{O}(\alpha^3),$$

with one-sided derivatives at  $s = 0$  and  $s = \pi$ .

*Proof of Lemma 5.* The proof is immediate from Proposition 3 applied in the case  $r(\alpha) = C\alpha$ .  $\square$

For  $C < \pi/4$ , consider  $\theta_d \in (0, \pi/2)$ , with  $\sin(\theta_d) = 2\sqrt{C/\pi}$ . The curve  $\mathcal{L}(s)$  has two double points  $D^+ = \mathcal{L}(s_1^+) = \mathcal{L}(s_2^+)$ , with  $s_1^+ = \theta_d$  and  $s_2^+ = \pi - \theta_d$ , and  $D^- = \mathcal{L}(s_1^-) = \mathcal{L}(s_2^-)$ , with  $s_1^- = \pi + \theta_d$  and  $s_2^- = 2\pi - \theta_d$ . It also has four cuspidal points  $Cp_i^\varepsilon$ ,  $i = 1, 2$  and  $\varepsilon = \pm$ , corresponding to the values  $s = s_{cusp,i}^\varepsilon$ , where  $\sin^2 s = \frac{2+4C/\pi}{3}$ .

Finally, let  $\sigma$  be the closed Jordan curve defined as the restriction of  $\mathcal{L}(s)$  to  $[0, s_1^+] \cup [s_2^+, s_1^-] \cup [s_2^-, 2\pi]$ . If  $C > \pi/4$ , we simply define  $\sigma$  to be  $\mathcal{L}$ .

In light of the previous result, we get that  $\mathcal{F}(\alpha, k_M \pi)$ , the extremal front at time  $k_M \pi$ , is contained inside a neighborhood  $W_\alpha$  of the south pole of order  $\mathcal{O}(\alpha^2)$  neighborhood of the south pole. Therefore, in order to understand the shape of the optimal synthesis inside  $W_\alpha$ , we must rescale the whole problem by  $N_\alpha$ , the linear mapping from  $\mathbb{R}^3$  onto  $\mathbb{R}^2$  defined as the composition of the orthogonal projection  $(x_1, x_2, x_3) \mapsto (x_1, x_2)$  followed by the dilation by  $1/\alpha^2$ .

For  $x \in W_\alpha$ , we first consider  $(\Lambda)_\alpha$ , the image of  $(\Sigma)$  by  $N_\alpha$ ; i.e.,  $(\Lambda)_\alpha$  is the planar control system given by

$$(69) \quad (\Lambda)_\alpha : \begin{cases} \dot{z}_1 = -\mathbf{c}_\alpha z_2, \\ \dot{z}_2 = \mathbf{c}_\alpha z_1 + u \frac{\mathbf{s}_\alpha}{\alpha^2} \sqrt{1 - \alpha^4 \|z\|^2}. \end{cases}$$

Let  $\mathcal{L}_\alpha$  be the image of  $\mathcal{F}(\alpha, k_M \pi)$  by  $N_\alpha$ . From Lemma 5,  $\mathcal{L}_\alpha$  converges to  $\mathcal{L}$  in the  $C^1$  topology. It is clear that, for  $C > \pi/4$ ,  $\mathcal{L}_\alpha : [0, 2\pi] \rightarrow \mathbb{R}^2$  is homeomorphic to  $e^{is}$ ,  $s \in [0, 2\pi]$ . In the case where  $C < \pi/4$ , the next lemma shows that, for  $\alpha$  small enough,  $\mathcal{L}_\alpha$  has the same shape as  $\mathcal{L}$ .

**LEMMA 6.** *If  $C < \pi/4$ , then  $\mathcal{L}_\alpha$  is described by the Figure 9, where  $Cp_i^\varepsilon(\alpha) = \mathcal{L}_\alpha(s_{cusp,i}^\varepsilon(\alpha))$ ,  $i = 1, 2$  and  $\varepsilon = \pm$ , are cuspidal points and  $D^\varepsilon(\alpha)$  are double points, with*

$$(70) \quad D^+(\alpha) = \mathcal{L}_\alpha(s_1^+(\alpha)) = \mathcal{L}_\alpha(s_2^+(\alpha)), \quad D^-(\alpha) = \mathcal{L}_\alpha(s_1^-(\alpha)) = \mathcal{L}_\alpha(s_2^-(\alpha)),$$

where  $s_{cusp,i}^\varepsilon(\alpha)$  and  $s_i^\varepsilon(\alpha)$  tend to, respectively,  $s_{cusp,i}^\varepsilon$  and  $s_i^\varepsilon$  as  $\alpha$  tends to zero for  $i = 1, 2$  and  $\varepsilon = \pm$ . For  $\alpha$  small enough, set  $\sigma_\alpha$ , the closed curve defined as the restriction of  $\mathcal{L}_\alpha(s)$ , to  $[0, s_1^+(\alpha)] \cup [s_2^+(\alpha), s_1^-(\alpha)] \cup [s_2^-(\alpha), 2\pi]$ . Then it is a Jordan curve.

*Proof of Lemma 6.* For  $i = 1, 2$  and  $\varepsilon = \pm$ , the existence of the cuspidal points  $Cp_i^\varepsilon(\alpha)$  is obtained by applying the implicit function theorem to the equation  $DL(s, \alpha) = 0$ , where the function  $DL(s, \alpha)$  is defined by

$$DL(s, \alpha) := \frac{d}{ds} \mathcal{L}_\alpha(s),$$

FIG. 9. Graph of the function  $\mathcal{L}_\alpha$  for  $C < \pi/4$ .

in the neighborhood of each  $(s_{cusp,i}^\varepsilon, 0)$ . We have

$$\partial_s DL(s_{cusp,i}^\varepsilon, 0) = \frac{d^2}{ds^2} \mathcal{L}(s_{cusp,i}^\varepsilon) \neq 0,$$

and we conclude. The uniqueness of these four points, on  $[0, 2\pi]$ , is trivial since  $DL(s, \alpha) = \frac{d}{ds} \mathcal{L}(s) + \mathcal{O}(\alpha)$ .

Similarly, for  $\varepsilon = \pm$ , the existence of the double points  $D^\varepsilon(\alpha)$  follows after applying the implicit function theorem to the equation  $DP(s, s', \alpha) = 0$ , where the function  $DP(s, s', \alpha)$  is defined by

$$DP(s, s', \alpha) = \mathcal{L}_\alpha(s) - \mathcal{L}_\alpha(s'),$$

in the neighborhood of each  $(s_1^\varepsilon, s_2^\varepsilon, 0)$ . For the uniqueness, we proceed as before.  $\square$

In the case  $C > \pi/4$ , we also define  $\sigma_\alpha$  to be equal to  $\mathcal{L}_\alpha$ . As a consequence, we are able to characterize  $OF(\alpha, k_M\pi)$ , the minimum time front at time  $k_M\pi$  when  $C \neq \pi/4$ .

**PROPOSITION 7.** *For  $\alpha$  small enough and  $C \neq \pi/4$ , the minimum time front at time  $k_M\pi$ ,  $OF(\alpha_k, k_M\pi)$  is equal to  $\tilde{\sigma}_\alpha$ , the inverse image on  $S^2$ , by  $N_\alpha$ , of  $\sigma_\alpha$ .*

*Remark 11.* As a consequence, we deduce that, for  $C > \pi/4$  and  $\alpha$  small enough, the optimal synthesis between  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  and  $\mathcal{F}(\alpha, k_M\pi)$  is simply given by the extremal flow, whereas, for  $C < \pi/4$ , there is a loss of optimality along certain extremal curves starting at  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  before reaching  $\mathcal{F}(\alpha, k_M\pi)$ . The values of  $s$  corresponding to such curves can be deduced from the previous characterizations of  $\mathcal{F}(\alpha, k_M\pi)$  and  $OF(\alpha_k, k_M\pi)$ .

*Proof of Proposition 7.* Recall that  $OF(\alpha_k, k_M\pi)$  is a piecewise  $\mathcal{C}^1$  submanifold of  $\mathcal{F}(\alpha, k_M\pi)$ . As in the proof of Proposition 4, the result to establish is a consequence

of the fact that  $\sigma_\alpha = \mathcal{L}_\alpha : [0, 2\pi] \rightarrow \mathbb{R}^2$  is homeomorphic to  $e^{is}$ ,  $s \in [0, 2\pi]$ , and it can be achieved by means of simple topological arguments.

In the case  $C < \pi/4$ ,  $\sigma_\alpha$  is a piecewise  $\mathcal{C}^1$  Jordan curve homeomorphic to  $e^{is}$ ,  $s \in [0, 2\pi]$ . A simple topological argument yields the conclusion.  $\square$

**5.2. Limit of the synthesis.** It remains to describe the limiting dynamics close to the south pole. In order to take the limit, as  $\alpha$  tends to zero, in  $(\Lambda)_\alpha$ , one must reparametrize by the time  $\alpha t$ . The limit is then given by the control system

$$(\Lambda) : \quad \begin{cases} \dot{z}_1 = 0, \\ \dot{z}_2 = u. \end{cases}$$

We now describe the optimal synthesis for the limit problem, i.e., for the problem of reaching in minimum time every point inside  $\sigma$  along  $(\Lambda)$  and starting from  $\sigma$ . Because of the symmetries of  $\sigma$  and because the tangent vector to  $\sigma$  is vertical only at  $s = 0$  and  $s = \pi$ , there exists a unique overlap curve  $(Seg)_C$ , defined as the segment of the  $z_1$ -axis between the points  $(-2C, 0)$  and  $(2C, 0)$ . Above it, the input  $u$  takes the constant value  $-1$ , and, below that overlap curve, the constant value  $1$ . Integral curves are clearly vertical lines.

We next intend to prove that the optimal synthesis consisting of reaching in minimum time every point inside  $\sigma_\alpha$  along  $(\Lambda)_\alpha$  and starting from  $\sigma_\alpha$  converges to the previous synthesis in the following sense.

**THEOREM 2.** *Assume that  $C \neq \pi/4$ . As  $\alpha$  tends to zero, the time optimal synthesis associated to  $(\Lambda)_\alpha$  inside  $\sigma_\alpha$  is characterized by an overlap curve  $(Seg)_C^\alpha$ , converging to  $(Seg)_C$  in the  $C^0$  topology, and, above  $(Seg)_C^\alpha$ , the control  $u$  takes the constant value  $-1$ , and, below  $(Seg)_C^\alpha$ , it is equal to  $1$ . Moreover, there exist only two time optimal trajectories reaching the origin, and, in the case  $C < \pi/4$ , these trajectories start from  $D_\alpha^\varepsilon$ ,  $\varepsilon = \pm$ , the double points of  $\mathcal{L}_\alpha$ .*

*Proof of Theorem 2.* Fix  $C \neq \pi/4$ . We first notice that, for  $\alpha$  small enough, there are not switching curves inside  $\sigma_\alpha$ . Therefore, the cut locus may occur only as images by  $N_\alpha$  of points  $M \in S^2$  such that  $M = e^{\frac{t}{\alpha}X} \tilde{\sigma}(s) = e^{\frac{t}{\alpha}X} \tilde{\sigma}(s')$  for  $t \in [0, \frac{2\pi}{\alpha}]$ ,  $s \in [0, \pi]$ , and  $s' \in [\pi, 2\pi]$ . Proceeding exactly as in the proof of Theorem 1, we apply inverse function arguments first in neighborhoods of  $\sigma_\alpha(0)$  and  $\sigma_\alpha(\pi)$  and second in a region enclosed by  $\sigma_\alpha$  excluding such neighborhoods. It is then easy to determine the values of the input  $u$  in each connected component of the region enclosed by  $\sigma_\alpha$  minus  $(Seg)_C^\alpha$ .

By a continuity argument, it is clear that there exist only two time optimal trajectories reaching the origin: one above  $(Seg)_C^\alpha$  and one below. Finally, suppose that  $C < \pi/4$ . In that case, it was proved in [9] that the only extremals starting at a point  $\mathcal{L}_\alpha(s)$  and reaching the origin from above the overlap curve  $(Seg)_C^\alpha$  correspond to values of  $s$  verifying one of the following three possibilities as  $\alpha$  tends to zero: (a)  $s$  tends to zero, (b)  $s$  tends to  $\pi/2$ , or (c)  $\mathcal{L}_\alpha(s)$  is a double point also associated to  $s' = v(s) - s$ . In view of what precedes, only possibility (c) is allowed for optimality. Theorem 2 is proved.  $\square$

*Remark 12.* As a consequence of the previous argument and from the results of [9], we get that, for  $\alpha$  small enough and  $C < \pi/4$ ,

$$s_2^+(\alpha) = v(s_1^+(\alpha)) - s_1^+(\alpha), \quad s_2^-(\alpha) = 2\pi + v(s_1^-(\alpha) - \pi) - s_1^-(\alpha),$$

where  $s_i^\varepsilon(\alpha)$ ,  $i = 1, 2$   $\varepsilon = \pm$ , were defined in (70).

**6. Case  $r(\alpha) = 0$ .** We assume here that  $r(\alpha) = 0$ , i.e.,  $\alpha_k = \frac{\pi}{2k}$  for  $k \geq 1$ . From Proposition 3, we know that the extremal front at time  $([\frac{\pi}{2\alpha}] - 1)\pi = \frac{\pi}{2\alpha} - \pi$  encloses the south pole, is optimal, and is approximately (in the  $\mathcal{C}^1$  sense) a circle of radius  $2r(\alpha)\alpha$  around the south pole. Moreover, at time  $[\frac{\pi}{2\alpha}]\pi$ , we know that the extremal front must contain the south pole and is equal, up to  $\mathcal{O}(\alpha^3)$ , to  $(\alpha^2\mathcal{L}, -1)^T$  given in (65) and (67) with  $C = 0$ . In that case, the minimum time front reduces to the south pole.

In this case it is interesting to consider the synthesis starting from the extremal front at time  $(k_M - 1)\pi$ , and it is natural to compare it with the synthesis of the linear pendulum studied in section 4.2 and corresponding to  $\rho = 2$ . See Figure 10. Let us first describe briefly that synthesis. Let  $D_2$  and  $C_2$  be the disc and the circle centered at the origin and of radius 2, respectively. The overlap curve inside  $D_2$  coincides with the switching curves and with the trajectories, corresponding to  $u = \pm 1$ , connecting points  $(\pm 2, 0)$  to the origin. In particular, it means that an optimal trajectory of the synthesis starting at any point  $P \in C_2$  reaches the origin, and thus there exists an infinite number of optimal trajectories from  $C_2$  to the origin.

For  $\alpha > 0$  and  $r(\alpha) = 0$ , the situation is rather different. Let us first define  $\tilde{F}(\alpha, (k_M - 1)\pi)$  to be the image of  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  by  $M_\alpha$ . Then, for  $\alpha$  small enough, it was shown in [9] that the only optimal trajectories starting from  $\tilde{F}(\alpha, (k_M - 1)\pi)$  and reaching the origin are those starting at  $P_+^\alpha$  and  $P_-^\alpha$ . Let us refer to them as  $\gamma^+$  and  $\gamma^-$ . Therefore, in the case  $r(\alpha) = 0$ , the synthesis for  $\alpha > 0$  is rather different than the synthesis of the limit candidate when  $\alpha$  tends to zero. It is a clear indication that the case  $r(\alpha) = 0$  is more delicate than the cases  $r(\alpha)$  positive constant or  $r(\alpha) = C\alpha$ . However, we are still able to give a partial description of the limit synthesis as the next proposition shows.

**PROPOSITION 8.** *Assume that  $r(\alpha) = 0$  and  $\alpha$  is small enough. Then the switching curve  $C_{k_M}^+$  (respectively,  $C_{k_M}^-$ ) is optimal for some interval  $[0, s(\alpha)]$ ,  $s(\alpha) < \pi$ , and it is above (respectively, below)  $\gamma^+$  (respectively,  $\gamma^-$ ) as long as it is optimal. Moreover, we have*

$$(71) \quad \lim_{\alpha \rightarrow 0, r(\alpha)=0} s(\alpha) = \bar{s} := \arccos \sqrt{1/3}.$$

FIG. 10. Comparison between the optimal synthesis for the linear pendulum and the optimal synthesis on the bottom of the sphere in the case  $r(\alpha) = 0$ .

*Proof of Proposition 8.* We provide only an argument for  $C_{k_M}^+$ , the other case being analogous. To prove the first statement of the proposition, we reason by contradiction. If the switching curve is not optimal on any interval  $[0, \tau]$ ,  $\tau > 0$ , we get the existence of an optimal trajectory starting at  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  above  $P_\alpha^+$  and reaching the origin, which is equal to the concatenation of an integral curve of  $X_-$  and a piece of  $\gamma^+$ . Therefore, an optimal integral curve of  $X_-$ , starting above  $\gamma^+$ , must either switch or lose optimality before reaching  $\gamma^+$ . If the second possibility occurs, we must have an overlap; i.e., at that point an optimal integral curve of  $X_+$  arrives. Close to  $P_\alpha^+$ , the latter would imply that the optimal integral curve of  $X_+$  starts at  $\mathcal{F}(\alpha, (k_M - 1)\pi)$  above  $P_\alpha^+$ . This is impossible, because, from every point of  $\mathcal{E}^+(\alpha, (k_M - 1)\pi)$ , the value of the optimal control is  $-1$ . Let  $s(\alpha) \leq \pi$  be the first value of  $s$  for which  $C_{k_M}^+$  ceases to be optimal. Define

$$H(s) := \det \left( X_+(C_{k_M}^+(s)), \frac{dC_{k_M}^+(s)}{ds}, C_{k_M}^+(s) \right)$$

for  $s \in [0, \pi]$ . Then  $s(\alpha)$  is the smallest solution in  $(0, \pi]$  of  $H(s) = 0$ . It is easy to see that  $H$  must take the value zero before  $\pi$ . We deduce that  $s(\alpha) < \pi$ . By taking the asymptotic expansion of the previous expression as  $\alpha$  tends to zero, we get

$$H(s) = \frac{\pi}{4} \mathbf{s}_s \alpha^3 (1 + 3 \cos(2s) + \mathcal{O}(\alpha)).$$

Then  $s(\alpha)$  must converge to  $\bar{s}$  as  $\alpha$  tends to zero, the smallest solution in  $[0, \pi]$  of  $1 + 3 \cos(2s) = 0$ .  $\square$

**7. Conclusion and final remarks.** In this paper, we built the time optimal synthesis for a two-level quantum system driven by an external field, in the case  $M \ll E$ , where  $M$  is the bound on the fields and  $-E$  and  $E$  are the two energy levels. In particular, we answered several questions stated in [5, 9], regarding the locus where extremals lose optimality and the shape of the synthesis at the south pole. To that purpose we characterized a concept of “asymptotic” optimal synthesis in the “noncontrollability” limit  $M/E \rightarrow 0$ , and we described it in detail: There are three main patterns which cyclically alternate as  $M/E \rightarrow 0$ .

Another point of interest of our results lies in the fact that, to the best of our knowledge, we provided here the first nontrivial example of time optimal synthesis with one bounded control on a 2-D compact manifold. Indeed, similarly to what happens in Riemannian geometry, singularities near the south pole appear, as a consequence of the nontrivial topology of  $S^2$ .

As a byproduct of our studies, we obtain the first not “ad hoc” example of the singularity  $(C, K)_1$  predicted by the general theory [8]. Recall that a singularity of an optimal synthesis is the intersection between two special curves (i.e., overlaps, switching curves, singular curves, etc.).

The  $(C, K)_1$  singularity has a “nonlocal” character in the sense that the two optimal trajectories merging at  $(C, K)_1$  are projections of extremals which are “far” in the cotangent bundle (see Figure 3).

**Appendix.** The following version of the inverse function theorem is used in the argument of Proposition 5.

**THEOREM 3.** *Let  $\Phi : \mathbb{R}^n \rightarrow \mathbb{R}^n$  be a  $\mathcal{C}^1$  map and  $\mathcal{K} \subset \mathbb{R}^n$  a compact set such that  $\Phi|_{\mathcal{K}} : \mathcal{K} \rightarrow \Phi(\mathcal{K})$  is bijective and the differential  $D\Phi(x)$  is invertible for  $x \in \mathcal{K}$ . Then there exists an open neighborhood  $U \supset \mathcal{K}$  such that  $\Phi|_U$  is a  $\mathcal{C}^1$  diffeomorphism.*

Let now  $(\Phi_k)_{k \geq 1}$  be a sequence of  $\mathcal{C}^1$  maps converging in the  $\mathcal{C}_{loc}^1$  sense to  $\Phi$ . Then, for every open set  $\tilde{U}$  with closure included in  $U$ , there exists  $\bar{k}$  such that, for every  $k \geq \bar{k}$ ,  $\Phi_{k|_{\tilde{U}}}$  is a  $\mathcal{C}^1$  diffeomorphism and, for every compact subset  $\tilde{\mathcal{K}}$  of  $\tilde{U}$ ,  $\Phi(\tilde{\mathcal{K}}) \subset \Phi_k(\tilde{U})$  and  $\lim_{k \rightarrow \infty} \Phi_k^{-1}(v) = \Phi^{-1}(v)$  uniformly with respect to  $v \in \Phi(\tilde{\mathcal{K}})$ .

*Proof.* Let us define, for  $k \geq 0$ , the following open neighborhoods of  $\mathcal{K}$ :

$$A := \{x \in \mathbb{R}^n : \det D\Phi(x) \neq 0\}, \quad A_k := \cup_{x \in \mathcal{K}} B\left(x, \frac{1}{k}\right) \cap A.$$

In view of the inverse function theorem, in order to conclude the proof of the first part, it is enough to show that for  $k$  large enough the restriction  $\Phi|_{A_k}$  is one-to-one.

We argue by contradiction. Let  $x_k \neq y_k \in A_k$  such that  $\Phi(x_k) = \Phi(y_k)$  for all  $k$ . Then, up to extractions of subsequences, we can assume that the two sequences converge to  $\bar{x}$  and  $\bar{y}$ , respectively. Since  $\bar{x}, \bar{y} \in \cap_k A_k = \mathcal{K}$  and  $\Phi(\bar{x}) = \Phi(\bar{y})$ , we deduce that  $\bar{x} = \bar{y}$ . However, since  $\det D\Phi(\bar{x}) \neq 0$ , we have that  $\Phi$  is bijective in a neighborhood of  $\bar{x}$ , which contradicts the assumption  $\Phi(x_k) = \Phi(y_k)$  for  $k$  large enough.

The proof of the second part is similar. First, fix a subset  $\tilde{U}$  of  $U$ . By the uniform convergence of  $D\phi_k$  to  $D\phi$  on every compact subset of  $U$ , we get  $\det D\Phi_k(x) \neq 0$  for every  $x \in \tilde{U}$  and  $k$  large enough. We also obtain that  $\Phi_k$  is one-to-one with the same argument as above. For the remaining results to establish, they simply follow from the uniform convergence of  $\Phi_k$  to  $\Phi$  on every compact subset of  $U$ .  $\square$

## DUBOVITSKII–MILYUTIN APPROACH IN SET-VALUED OPTIMIZATION\*

G. ISAC<sup>†</sup> AND A. A. KHAN<sup>‡</sup>

**Abstract.** By exploring the ideas around the Dubovitskii–Milyutin approach, necessary optimality conditions are given for various optimality notions in set-valued optimization. These optimality conditions are given by using the contingent derivative and the generalized contingent epiderivative of the objective set-valued map and the set-valued maps defining the constraints. The notions of subgradients and scalarized subgradients for set-valued maps are proposed and used to state some regularity conditions.

**Key words.** set-valued optimization, contingent cone, contingent derivative, generalized contingent epiderivative, Aubin’s property, Lagrange multipliers, optimality conditions, subgradients for set-valued maps

**1. Introduction.** Let  $\Xi$  be a real normed space and let  $\Sigma_i$ ,  $i = 0, 1, \dots, n+1$ , be nonempty convex cones. Let the cones  $\Sigma_i$ ,  $i = 0, 1, \dots, n$ , be open. The Dubovitskii–Milyutin lemma (DM-lemma) asserts an equivalence between the following two statements (see [9]):

- ( $\alpha$ )  $\bigcap_{i=0}^{n+1} \Sigma_i = \emptyset$ .
- ( $\beta$ ) There exist functionals  $l_i \in \Sigma_i^*$  (dual of  $\Sigma_i$ ),  $i = 0, 1, \dots, n+1$ , which are not all simultaneously equal to zero, such that  $l_0 + l_1 + \dots + l_{n+1} = 0$ .

In optimization theory the relevance of the DM-lemma comes from the fact that the optimality of a point can be conveniently expressed as the disjunction of certain sets. Now, if these sets are locally approximated by using suitable tangent cones so that the disjunction is maintained, then, under suitable convexity assumptions, the functionals appearing in ( $\beta$ ) in fact would give rise to the Lagrange multipliers. In applications of the DM-lemma, the cone  $\Sigma_{n+1}$  is often an approximation of the equality constraints, and the cones  $\Sigma_i$ ,  $i = 0, \dots, n$ , contain some information about the behavior of the derivatives of the objective map and the inequality constraints. The approach based on the DM-lemma is very flexible for many applications and has been proved to be of great use in dealing with scalar and vector optimization problems (see [9], [13], [31]).

In this paper, we present an extension of the Dubovitskii–Milyutin approach to the problems which can be written in the following form:

$$(*) \quad \text{minimize}_C F(x) \quad \text{subject to } x \in Q.$$

Current address: Department of Mathematics and Computer Science, Northern Michigan University, 1001 New Science Facility, Marquette, MI 49855 (akhan@nmu.edu). The work of this author was partially supported by the German Research Foundation (DFG) and was partly carried out during the author’s stay at the Institute of Applied Mathematics, University of Erlangen–Nürnberg, Martensstr. 3, 91058 Erlangen, Germany.

Here  $X$  and  $Y$  are real normed spaces (unless stated otherwise all the spaces here will be real),  $Q \subset X$ ,  $C \subset Y$  is a proper pointed convex cone, the map  $F : X \rightrightarrows Y$  is set-valued, and the minimum is taken in the sense that we seek  $(\bar{x}, \bar{y}) \in X \times Y$  such that  $\bar{y} \in F(\bar{x})$  and  $(\bigcup_{x \in Q} F(x)) \cap (\{\bar{y}\} - C) = \{\bar{y}\}$ . We recall that given a pointed convex cone  $C \subset Y$ , the set of minimal points of  $A \subset Y$ , henceforth denoted by  $\text{Min}(A, C)$ , is defined as  $\text{Min}(A, C) = \{x \in A \mid A \cap (\{x\} - C) = \{x\}\}$ . Being equipped with this terminology, a minimizer to  $(*)$  is a point  $(\bar{x}, \bar{y}) \in X \times Y$  such that  $\bar{y} \in F(\bar{x}) \cap \text{Min}(F(Q), C)$ , where  $F(Q) := \bigcup_{x \in Q} F(x)$ .

The following example explains the above notion of minimality.

*Example 1.1.* Consider a set-valued map  $F : [0, 1] \rightrightarrows \mathbb{R}^2$  defined by

$$F(x) := \{(y_1, y_2) \in \mathbb{R}^2 \mid y_1^2 + y_2^2 \leq x^2\}.$$

Let  $C := \{(x, x) \in \mathbb{R}^2 \mid x \in \mathbb{R}_+\}$  be the ordering cone and let  $Q := [0, 1]$ . Then  $F(Q) = \{(x, y) \in \mathbb{R}^2 \mid x^2 + y^2 \leq 1\}$  and the minima of  $(*)$  form the set  $\{1\} \times \{(\cos \phi, \sin \phi) \mid \phi \in [\frac{3}{4}\pi, \frac{7}{4}\pi]\}$ . On the other hand, if the ordering cone is

$$C := \{(x, y) \in \mathbb{R}^2 \mid x, y \in \mathbb{R}_+\},$$

then the minima of  $(*)$  form the set  $\{1\} \times \{(\cos \phi, \sin \phi) \mid \phi \in [\pi, \frac{3}{2}\pi]\}$ .

Notice that if the map  $F$  is single-valued, then  $(*)$  collapses to the known vector optimization problem (see [18]). Additionally, if  $Y = \mathbb{R}$  and  $C = \mathbb{R}_+ = \{t \in \mathbb{R} \mid t \geq 0\}$ , then we recover the framework of classical optimization problems (see [9]).

Problems of the type shown above belong to the realm of set-valued optimization, a subject which has attracted a great deal of attention in recent years (cf. [3], [4], [5], [6], [7], [8]). In general, set-valued optimization represents the optimization problems with set-valued objective and/or set-valued constraints. In recent years set-valued optimization has emerged as an important generalization of scalar and vector optimization. Moreover, there are many research areas which directly lead to the type of problem shown above. We illustrate this by depicting the appearance of set-valued optimization problems in connection with the duality principles in vector optimization and the gap functions for vector variational inequalities [12], [17].

*Example 1.2* (duality principles). Consider the following vector optimization problem:

$$(**) \quad \text{minimize}_Q \varphi(x) \quad \text{subject to} \quad x \in \Delta_1 = \{x \in \Delta \mid -\psi(x) \in Q_1\},$$

where  $\Delta \subset \mathbb{R}^n$ ,  $Q \subset \mathbb{R}^p$ , and  $Q_1 \subset \mathbb{R}^m$  are pointed closed convex cones and  $\varphi : \mathbb{R}^n \rightarrow \mathbb{R}^p$  and  $\psi : \mathbb{R}^n \rightarrow \mathbb{R}^m$  are single-valued mappings. Let  $\mathcal{L}$  be the family of  $p \times m$  matrices  $\Lambda$  such that  $\Lambda Q_1 \subset Q$  and let  $L : \Delta \times \mathcal{L} \rightarrow \mathbb{R}^p$  be the vector-valued Lagrangian given by  $L(x, \Lambda) = \varphi(x) + \Lambda \psi(x)$ . We define a set-valued map  $\Phi : \mathcal{L} \rightrightarrows \mathbb{R}^p$  as follows:

$$\Phi(\Lambda) = \text{Min}(\{L(x, \Lambda) \mid x \in \Delta\}, Q).$$

Then the dual problem associated with  $(**)$  is the following set-valued optimization problem:

$$\text{maximize}_Q \Phi(\Lambda) \quad \text{subject to} \quad \Lambda \in \mathcal{L}.$$

Details on the above model are available in [33]. An infinite-dimensional analogue of this model has been studied by Corley (see the references in [8]).

*Example 1.3* (gap functions). Let  $X$  and  $Y$  be normed spaces and let  $\mathcal{L}(X, Y)$  be the set of all linear continuous operators from  $X$  to  $Y$ . Let  $Q \subset X$  be a nonempty closed convex set, let  $Q_0 \subset X$  be a pointed closed convex cone, and let  $\Gamma : X \rightarrow Y$  be a given map.

Consider the following vector variational inequality (VVI): Find  $\bar{x} \in Q$  such that

$$\langle \Gamma(\bar{x}), x - \bar{x} \rangle \notin -Q_0 \setminus \{0\} \quad \text{for every } x \in Q.$$

We define a set-valued mapping  $\Phi : X \rightrightarrows Y$  by

$$\Phi(x) = \text{Max}(\{\langle \Gamma(\bar{x}), x - Q \rangle, x \in Q\}, Q_0).$$

Then the above VVI is equivalent to the following set-valued optimization problem (cf. [24]):

$$\text{minimize}_{Q_0} \Phi(x) \quad \text{subject to } x \in Q.$$

Another genuine source for such problems is the situation in mathematical programming when the objective and the constraint functions cannot be assigned to some exact values but are allowed to vary in a specified range, hence leading to set-valued data (for example, in stochastic and fuzzy programming). In fuzzy programming this fact is usually characterized by a membership function. However, in the general setting of set-valued optimization the use of the membership function can be avoided as the whole sets are taken into account (cf. [8], [32]). Several other interesting appearances of set-valued optimization are in sensitivity analysis for vector optimization problems (cf. [34]).

In recent years a great deal of attention has been given to set-valued optimization. The starting point for this interesting research domain was the influential paper by Corley [8], where the contingent derivative and the circatangent derivative were used to give general optimality conditions. His results were substantially improved by Luc and Malivert [26] (see also [25]). In the aforementioned works, the derivative notions revolved around the graphs of the involved set-valued maps. Another useful approach based on employing the epigraphs of the involved set-valued maps was initiated by Jahn and Rauh [21], which was further pursued in [3], [11], [14], [19], [20], [23], among others. An interesting approach for set-valued optimization which is based on the notion of coderivatives is given in [10].

As already mentioned above, the main goal of this paper is to present some necessary optimality conditions in set-valued optimization by using the ideas surrounding the Dubovitskii–Milyutin approach. The optimality conditions given here can be divided into two categories. In the first category, we express the optimality of a point as an empty intersection of certain sets in the domain space. Although this result is completely analogous to the results in classical nonlinear programming, it is in contrast with the results obtained so far in set-valued optimization, where the optimality conditions of this nature have always been given in the image space. The second type of optimality conditions which we give here is comparable to the classical KKT optimality conditions. A special emphasis is given to the case when the ordering cone may have an empty interior. As concerns the solvability of set-valued optimization problems, it is known that the notion of a solution in set-valued optimization is not unequivocal and there are many solution concepts. In this paper we present necessary optimality conditions for minimality, proper minimality, weak minimality, and strong minimality. However, keeping in mind the narrow gap among the techniques used

for deriving these optimality conditions for various minimality notions, we present a detailed treatment only for proper minimality. For other optimality notions, we either state the results without a proof or we just mark the differences whenever it becomes necessary.

The contents of this paper are divided into five sections. In section 2, we briefly recall some notation and concepts to be used and formulate the problem. Basic notions which we recall include various definitions of tangent cones and derivatives and epiderivatives for set-valued maps. We devote section 3 to the necessary optimality conditions for proper and weak minimality. In this section we also introduce several subgradients for set-valued maps. However, the use of these subgradients is limited mainly to expressing some regularity conditions. Section 4 is devoted to the necessary optimality conditions for the strong minimality. The final section contains some remarks concerning the approach.

**2. Preliminaries and problem formulation.** First we recall the notions of some tangent cones (cf. [2], [30]). We set  $\mathbb{P} := \{t \in \mathbb{R} \mid t > 0\}$ . In the following  $\text{cl}(S)$  and  $\text{int}(S)$  will represent the closure and the interior of a set  $S$ , respectively.

**DEFINITION 2.1.** *Let  $Z$  be a normed space, let  $S \subset Z$ , and let  $\bar{z} \in S$ .*

- (a) *The contingent cone  $T(S, \bar{z})$  of  $S$  at  $\bar{z}$  is the set of all  $z \in Z$  such that there are sequences  $(\lambda_n) \subset \mathbb{P}$  and  $(z_n) \subset Z$  with  $\lambda_n \downarrow 0$ ,  $z_n \rightarrow z$ , and  $\bar{z} + \lambda_n z_n \in S$  for all  $n \in \mathbb{N}$ .*
- (b) *The interiorly contingent cone  $IT(S, \bar{z})$  of  $S$  at  $\bar{z}$  is the set of all  $z \in Z$  such that for any sequences  $(\lambda_n) \subset \mathbb{P}$  and  $(z_n) \subset Z$  with  $\lambda_n \downarrow 0$  and  $z_n \rightarrow z$  there exists an integer  $m \in \mathbb{N}$  such that  $\bar{z} + \lambda_n z_n \in S$  for all  $n \geq m$ .*
- (c) *The Clarke's tangent cone  $C(S, \bar{z})$  of  $S$  at  $\bar{z}$  is the set of all  $z \in Z$  such that for every sequence  $(z_n) \subset S$  with  $z_n \rightarrow \bar{z}$  and for every  $(\lambda_n) \subset \mathbb{P}$  with  $\lambda_n \downarrow 0$  there exists a sequence  $(\tilde{z}_n)$  with  $\tilde{z}_n \rightarrow z$  such that  $z_n + \lambda_n \tilde{z}_n \in S$  for all  $n \in \mathbb{N}$ .*

**Remark 2.1.** It is known that  $T(S, \bar{z})$  is a closed cone possessing the isotony property; that is, for subsets  $S_1$  and  $S_2$  such that  $S_1 \subset S_2$ , we have  $T(S_1, \bar{z}) \subset T(S_2, \bar{z})$  for every  $\bar{z} \in S_1$ . The Clarke's tangent cone is closed and convex, but it is not isotone. Moreover, the inclusion  $C(S, \bar{z}) \subseteq T(S, \bar{z})$  holds. On the other hand the interiorly contingent cone  $IT(S, \bar{z})$  is an isotone open cone. As concerns the relationship between  $T(S, \bar{z})$  and  $IT(S, \bar{z})$ , we have  $IT(S, \bar{z}) = Z \setminus T(Z \setminus S, \bar{z})$ . As a useful implication of this relationship, the cones  $T(S, \bar{z})$  and  $IT(S, \bar{z})$  form an admissible pair; that is, for every pair of sets  $S_1, S_2 \subset Z$  with  $S_1 \cap S_2 = \emptyset$ , we have  $T(S_1, \bar{z}) \cap IT(S_2, \bar{z}) = \emptyset$  for every  $\bar{z} \in Z$ . Also for arbitrary sets  $S_1, S_2 \subset Z$  we have  $IT(S_1 \cap S_2, \bar{z}) = IT(S_1, \bar{z}) \cap IT(S_2, \bar{z})$  for every  $\bar{z} \in S_1 \cap S_2$ . In general, this property is not shared by the contingent cones. For some  $S \subset Z$ , the identities  $T(S, \bar{z}) = T(\text{cl}(S), \bar{z})$  and  $IT(S, \bar{z}) = IT(\text{int}(S), \bar{z})$  hold. Moreover, for a convex solid set  $S$ , we have  $\text{cl}(IT(S, \bar{z})) = T(S, \bar{z})$  and  $\text{int}(T(S, \bar{z})) = IT(S, \bar{z})$ . For details see [2], [29], [30].

Now we collect some definitions for set-valued maps. Let  $X$  and  $Y$  be normed spaces. Let  $F : X \rightrightarrows Y$  be a set-valued map; that is, for each  $x \in X$ , we have  $F(x) \subset 2^Y$  (power set of  $Y$ ). The (effective) domain and the graph of  $F$  are defined by  $\text{dom}(F) := \{x \in X \mid F(x) \neq \emptyset\}$  and  $\text{gph}(F) := \{(x, y) \in X \times Y \mid y \in F(x)\}$ , respectively. We shall say that  $F$  is *strict* if  $\text{dom}(F) = X$ . We define the *weak-inverse image*  $F[S]^-$  of  $F$  with respect to  $S \subseteq Y$  by  $F[S]^- := \{x \in X \mid F(x) \cap S \neq \emptyset\}$ . If  $Y$  is partially ordered by a convex cone  $C \subset Y$ , the profile map  $F_+ : X \rightrightarrows Y$  is given by  $F_+(x) := F(x) + C$  for every  $x \in \text{dom}(F)$ . In this setting, the epigraph of  $F$

can be defined as the graph of  $F_+$ , that is,  $\text{epi}(F) = \text{gph}(F_+)$ . The map  $F$  is called *convex* if  $\text{gph}(F)$  is convex and *C-convex* if  $\text{epi}(F)$  is convex. We shall say that the map  $F$  is *locally C-convex* at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  if  $T(\text{epi}(F), (\bar{x}, \bar{y}))$  is convex. Let  $B_Y$  be the unit ball of the space  $Y$ . The map  $F$  is said to have the *Aubin property around*  $(u, v) \in \text{gph}(F)$  if there are a constant  $L \geq 0$  and neighborhoods  $U$  of  $u$  and  $V$  of  $v$  so that

$$F(x_1) \cap V \subseteq F(x_2) + L\|x_1 - x_2\|B_Y \quad \text{for all } x_1, x_2 \in U \cap \text{dom}(F).$$

This concept is due to Aubin. For several useful features of this notion, see [2], [28], [32].

The contingent derivative, given by Aubin [1], is at the heart of our approach. We recall that given normed spaces  $X, Y$  and a set-valued map  $F : X \rightrightarrows Y$ , the contingent derivative of  $F$  at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is the set-valued map  $\mathcal{D}F(\bar{x}, \bar{y}) : X \rightrightarrows Y$  defined by

$$(1) \quad \text{gph}(\mathcal{D}F(\bar{x}, \bar{y})) = T(\text{gph}(F), (\bar{x}, \bar{y})).$$

A related notion where the center of attraction, instead of  $\text{gph}(F)$ , is  $\text{epi}(F)$  is of the generalized contingent epiderivative proposed in [7] and [4]. We recall that the generalized contingent epiderivative of  $F$  at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is the set-valued map  $D_g F(\bar{x}, \bar{y}) : X \rightrightarrows Y$  given by

$$(2) \quad D_g F(\bar{x}, \bar{y})(x) = \text{Min}(\mathcal{D}F_+(x), C), \quad x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y})).$$

We say that epiderivative  $D_g F(\bar{x}, \bar{y})$  *dominates* at  $x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))$  if the inclusion  $\mathcal{D}F_+(\bar{x}, \bar{y})(x) \subseteq D_g F(\bar{x}, \bar{y})(x) + C$  holds. It is known that if  $D_g F(\bar{x}, \bar{y})$  dominates at all  $x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))$ , then

$$(3) \quad \text{epi}(D_g F(\bar{x}, \bar{y})) = T(\text{epi}(F), (\bar{x}, \bar{y})).$$

Conditions ensuring the existence and the domination of the above epiderivative are given in [4] and [20]. For example, it is known that if  $C$  is regular (see [16]) and  $\mathcal{D}F_+(\bar{x}, \bar{y})(x)$  is  $C$ -lower-bounded, then  $D_g F(\bar{x}, \bar{y})(x) \neq \emptyset$  and the epiderivative dominates at  $x$  (see [20]). An important difference between the contingent derivative and the generalized contingent epiderivative is that in the latter case we concentrate only on a boundary part of the underlying contingent cone.

*Remark 2.2.* Replacing  $T(\text{gph}(F), (\bar{x}, \bar{y}))$  by  $C(\text{gph}(F), (\bar{x}, \bar{y}))$  in (1), we get circatangent derivative  $\mathcal{C}F(\bar{x}, \bar{y})$  of  $F$  at  $(\bar{x}, \bar{y})$  (cf. [2]). We define generalized circatangent epiderivative  $\mathcal{C}_g F(\bar{x}, \bar{y})$  of  $F$  at  $(\bar{x}, \bar{y})$  by taking  $\mathcal{C}F_+(\bar{x}, \bar{y})(x)$  for  $\mathcal{D}F_+(\bar{x}, \bar{y})$  in (2).

Besides the minimality notion defined above, we also need some other related concepts (cf. [18, 25]). Let  $Y$  be a normed space partially ordered by a proper pointed convex cone  $C \subset Y$ . Given  $C$ , let  $\mathcal{K}$  be the set of all proper pointed closed convex solid cones  $K \subset Y$  such that  $C \setminus \{0_Y\} \subset \text{int}(K)$ . Let  $D \subset Y$  and let  $y \in D$  be arbitrary.

- An element  $y$  is said to be a strongly minimal point of  $D$  if  $D \subseteq \{y\} + C$ .
- Assume that the ordering cone  $C$  is solid, that is, it has a nonempty interior  $\text{int}(C)$ . An element  $y$  is said to be a weakly minimal point of  $D$  if  $D \cap (\{y\} - \text{int}(C)) = \emptyset$ .
- An element  $y$  is said to be a properly minimal point of  $D$  if for some  $K \in \mathcal{K}$  we have  $D \cap (\{y\} - K) = \{y\}$ , that is, the element  $y$  is a minimal point of  $D$  with respect to  $K$ .

The set of all strongly minimal points, weakly minimal points, and properly minimal points of  $D$  with respect to  $C$  will be denoted by  $\text{SMin}(D, C)$ ,  $\text{WMin}(D, C)$ , and  $\text{PMin}(D, C)$ . Moreover, the following chain of inclusions is known to hold:

$$\text{SMin}(D, C) \subseteq \text{PMin}(D, C) \subseteq \text{Min}(D, C) \subseteq \text{WMin}(D, C).$$

We remark that there are a few more notions of minimal points in set optimization which we do not explore in this work (cf. [6], [22], [27]).

Let  $W, X, Y, Z$  be normed spaces and let the spaces  $Y$  and  $Z$  be partially ordered by nontrivial pointed closed convex cones  $C \subset Y$  and  $D \subset Z$ . Let  $Q_0 \subset X$  be nonempty and let  $h \in W$  be a given element. Let  $F : X \rightrightarrows Y$ ,  $G : X \rightrightarrows Z$ , and  $H : X \rightrightarrows W$  be given set-valued maps.

We are concerned with the following set-valued optimization problems:

$$\begin{aligned} (P_0) \quad & \text{Min } F(x) \quad \text{subject to} \quad x \in Q_0. \\ (P_1) \quad & \text{Min } F(x) \quad \text{subject to} \quad x \in Q_1 := \{x \in Q_0 \mid G(x) \cap -D \neq \emptyset\}. \\ (P_2) \quad & \text{Min } F(x) \quad \text{subject to} \quad x \in Q_2 := \{x \in Q_0 \mid G(x) \cap -D \neq \emptyset, h \in H(x)\}. \end{aligned}$$

In the following, we define the optimality for  $(P_2)$ . We set  $F(Q_2) := \bigcup_{x \in Q_2} F(x)$ .

**DEFINITION 2.2.** A pair  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is called a (a) minimizer of  $(P_2)$  if  $\bar{y} \in \text{Min}(F(Q_2), C)$ ; (b) strong minimizer of  $(P_2)$  if  $\bar{y} \in \text{SMin}(F(Q_2), C)$ ; (c) weak minimizer of  $(P_2)$  if  $\bar{y} \in \text{WMin}(F(Q_2), C)$ ; (d) proper minimizer of  $(P_2)$  if  $\bar{y} \in \text{PMin}(F(Q_2), C)$ .

In view of the definition of the minimal points,  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is a minimizer if and only if  $F(Q_2) \cap (\bar{y} - C) = \{\bar{y}\}$ . Similar relations are valid for other kinds of minimizers defined above. Observe that  $(P_2)$  reduces to  $(P_0)$  if  $G(x) = 0_Z$  and  $H(x) = h$  uniformly on  $Q_0$ . In this case the set of constraints  $Q_0$  is not explicitly specified. If additionally we have  $Q_0 = Z$ , then  $(P_2)$  is an unconstrained set-valued optimization problem. The optimality notions given in the above definition are global ones; that is, the whole set  $F(Q_2)$  has been taken into account. Their local versions are defined as follows: The point  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is said to be a local strong minimizer if there exists a neighborhood  $U$  of  $\bar{x}$  such that  $\bar{y} \in \text{SMin}(F(Q_2 \cap U), C)$ . Local minimizers, local weak minimizers, and local proper minimizers are defined analogously by using Definition 2.2.

Notice that in the context of Example 1.1, the proper minima of  $(P_0)$  contain the set  $\{1\} \times \{(\cos \phi, \sin \phi) \mid \phi \in [\frac{3}{4}\pi, \frac{3}{2}\pi]\}$ . There is no strong minimizer.

### 3. Necessary optimality conditions for proper and weak minimality.

**3.1. Necessary optimality conditions for  $(P_1)$ .** We begin with the following necessary optimality condition for  $(P_1)$ .

**THEOREM 3.1.** Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_1)$ . Assume that the map  $F_+ (:= F + C)$  possesses the Aubin property around  $(\bar{x}, \bar{y})$ . Then

$$(4) \quad \mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- \bigcap IT(Q_0, \bar{x}) \bigcap T(G[-D]^-, \bar{x}) = \emptyset.$$

*Proof.* Since  $(\bar{x}, \bar{y})$  is a local proper minimizer, there are a neighborhood  $U_1$  of  $\bar{x}$  and a pointed closed convex solid cone  $K \in \mathcal{K}$  such that  $\bar{y} \in \text{Min}(F(Q_1 \cap U_1), K)$ . We claim that

$$(5) \quad \mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- \bigcap IT(Q_0, \bar{x}) \bigcap T(G[-D]^-, \bar{x}) = \emptyset.$$

Notice that since  $\text{int}(K)$  contains  $C \setminus \{0_Y\}$ , (5) trivially implies (4).

We show that if (5) fails, then a feasible  $u$  can be obtained in a vicinity of  $\bar{x}$  with  $F(u) \cap (\bar{y} - \text{int}(K)) \neq \emptyset$ , hence violating the local proper minimality of  $(\bar{x}, \bar{y})$ . Assume that there exists

$$x \in \mathcal{DF}_+(\bar{x}, \bar{y})[-\text{int}(K)]^- \bigcap IT(Q_0, \bar{x}) \bigcap T(G[-D]^-, \bar{x}).$$

Then in view of the containment  $x \in T(G[-D]^-, \bar{x})$ , there are sequences  $(\lambda_n) \subset \mathbb{P}$  and  $(\tilde{x}_n) \subset X$  such that  $\lambda_n \downarrow 0$ ,  $\tilde{x}_n \rightarrow x$ , and  $G(\bar{x} + \lambda_n \tilde{x}_n) \cap (-D) \neq \emptyset$  for every  $n \in \mathbb{N}$ .

Since we also have  $x \in \mathcal{DF}_+(\bar{x}, \bar{y})[-\text{int}(K)]^-$ , there exists  $y \in -\text{int}(K)$  such that  $(x, y) \in T(\text{epi}(F), (\bar{x}, \bar{y}))$ . Therefore, there are sequences  $(\beta_n) \subset \mathbb{P}$  and  $((\tilde{x}_n, \tilde{y}_n)) \subset X \times Y$  such that  $\beta_n \downarrow 0$ ,  $(\tilde{x}_n, \tilde{y}_n) \rightarrow (x, y)$ , and  $\bar{y} + \beta_n \tilde{y}_n \in F(\bar{x} + \beta_n \tilde{x}_n) + C$  for every  $n \in \mathbb{N}$ .

Because  $(\lambda_n)$  and  $(\beta_n)$  are sequences of strictly positive reals, both converging to zero, there exist increasing sequences of positive integers  $(k_n)$  and  $(m_n)$  such that  $\beta_{m_n}/\lambda_{k_n} \rightarrow 1$  (see [24, Lemma 2.1]). We pick subsequences  $(\beta_{m_n}) \subset (\beta_n)$ ,  $(x_{m_n}) \subset (\tilde{x}_n)$ ,  $(y_{m_n}) \subset (\tilde{y}_n)$  and set  $x_n = (\beta_{m_n} \setminus \lambda_{k_n})x_{m_n}$ ,  $y_n = (\beta_{m_n} \setminus \lambda_{k_n})y_{m_n}$ , and  $\alpha_n = \lambda_{k_n}$ . Clearly  $x_n \rightarrow x$ ,  $y_n \rightarrow y$ ,  $\alpha_n \downarrow 0$  and we have  $\bar{y} + \alpha_n y_n \in F(\bar{x} + \alpha_n x_n) + C$  for every  $n \in \mathbb{N}$ . We also pick a subsequence  $(x_{k_n}) \subset (\tilde{x}_n)$  and set  $\hat{x}_n = x_{k_n}$ . Notice that  $\hat{x}_n \rightarrow x$  and we have  $G(\bar{x} + \alpha_n \hat{x}_n) \cap (-D) \neq \emptyset$  for every  $n \in \mathbb{N}$ . Because  $u_n := (\bar{x} + \alpha_n x_n) \rightarrow \bar{x}$  and  $\tilde{u}_n := (\bar{x} + \alpha_n \hat{x}_n) \rightarrow \bar{x}$ , there exists  $n_1 \in \mathbb{N}$  such that  $u_n, \tilde{u}_n \in U$  for  $n \geq n_1$ . Here  $U := U_1 \cap U_2$  and  $U_2$  is a neighborhood of  $\bar{x}$  which exists, along with a neighborhood  $V$  of  $\bar{y}$ , as a consequence of the Aubin property. Moreover, since  $(\bar{y} + \alpha_n y_n) \rightarrow \bar{y}$ , there exists  $n_2 \in \mathbb{N}$  so that  $\bar{y} + \alpha_n y_n \in V$  for all  $n \geq n_2$ . In view of the Aubin property of  $F_+$  at  $(\bar{x}, \bar{y})$ , we get

$$\begin{aligned} \bar{y} + \alpha_n y_n &\in [F(\bar{x} + \alpha_n x_n) + C] \cap V \quad (\text{for } n \geq n_2) \\ &\subseteq F(\bar{x} + \alpha_n \hat{x}_n) + C + L \alpha_n \|x_n - \hat{x}_n\| B_Y \quad (\text{for } n \geq \max\{n_1, n_2\}), \end{aligned}$$

and hence we can choose a sequence  $b_n \in B_Y$  such that for  $n \geq \max\{n_1, n_2\}$  we have  $\bar{y} + \alpha_n \tilde{y}_n \in F(\bar{x} + \alpha_n \hat{x}_n) + C$ , where  $\tilde{y}_n = (y_n - L b_n \|x_n - \hat{x}_n\|) \rightarrow y$ . Because  $y \in -\text{int}(K)$ ,  $\alpha_n > 0$ , and  $\tilde{y}_n \rightarrow y$  there exists  $n_3 \in \mathbb{N}$  such that  $\alpha_n \tilde{y}_n \in -\text{int}(K)$ . Choose  $w_n \in F(\tilde{u}_n)$  such that  $\bar{y} + \alpha_n \tilde{y}_n \in w_n + C$  for every  $n \in \mathbb{N}$ . We have  $w_n \in \bar{y} + \lambda_n \tilde{y}_n - C \subseteq \bar{y} - \text{int}(K) - C \subset \bar{y} - \text{int}(K)$  and consequently  $w_n \in F(\tilde{u}_n) \cap (\bar{y} - \text{int}(K))$  for  $n \geq \max\{n_1, n_2, n_3\}$ .

Finally we notice that because  $\alpha_n \downarrow 0$  and  $\hat{x}_n \rightarrow x$ , the containment  $x \in IT(Q_0, \bar{x})$  implies that there is an integer  $n_4 \in \mathbb{N}$  such that  $\tilde{u}_n := \bar{x} + \alpha_n \hat{x}_n \in Q_0$  for every  $n \geq n_4$ . Therefore, we have shown that for every  $n \geq \max\{n_1, n_2, n_3, n_4\}$  there are  $\tilde{u}_n \in Q_1 \cap U_1$  such that  $F(\tilde{u}_n) \cap (\bar{y} - \text{int}(K)) \neq \emptyset$ . This, however, contradicts the optimality of  $(\bar{x}, \bar{y})$ . The proof is complete.  $\square$

*Remark 3.1.* If either  $G[-D]^-$  is derivable at  $\bar{x}$  or  $\text{epi}(F)$  is derivable at  $(\bar{x}, \bar{y})$ , then the mechanism of choosing subsequences is unnecessary. Here, by the derivability of  $S \subset Z$  (normed space) at  $\bar{z} \in \text{cl}(S)$ , we mean  $T(S, \bar{z}) = A(S, \bar{z})$ , where  $A(S, \bar{z})$  is the adjacent cone given by  $A(S, \bar{z}) := \{y \in Z \mid \forall (\lambda_n) \subset \mathbb{P}, \lambda_n \downarrow 0 \exists (y_n) \rightarrow y : \bar{z} + \lambda_n y_n \in S \forall n \in \mathbb{N}\}$  (cf. [2]).

In view of the proof of Theorem 3.1 the following useful corollaries are immediate.

**COROLLARY 3.1.** *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_1)$ . Let either  $\text{dom}(F) = \text{dom}(G) = Q_0$  or  $\bar{x} \in \text{int}(Q_0)$  and let  $F_+$  possess the Aubin property around  $(\bar{x}, \bar{y})$ . Then*

$$\mathcal{DF}_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- \bigcap T(G[-D]^-, \bar{x}) = \emptyset.$$

COROLLARY 3.2. *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_0)$ . Then*

$$IT(Q_0, \bar{x}) \bigcap \text{cl}(\mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^-) = \emptyset.$$

Moreover, if either  $\text{dom}(F) = Q_0$  or  $\bar{x} \in \text{int}(Q_0)$ , then

$$\mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- = \emptyset.$$

*Remark 3.2.* Notice that all the above results remain valid if instead of  $\mathcal{D}F_+(\bar{x}, \bar{y})$  we take either  $\mathcal{C}F_+(\bar{x}, \bar{y})$  or  $D_g F(\bar{x}, \bar{y})$ . Moreover, we remark that all the above results in fact will characterize the weak minimality if we replace  $C \setminus \{0_Y\}$  by  $\text{int}(C)$ , provided that  $\text{int}(C) \neq \emptyset$ . Also notice that for weak minimality, Corollary 3.2 states that  $\mathcal{D}F_+(\bar{x}, \bar{y})(x) \subset Y \setminus \text{int}(C)$  for every  $x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))$ . In fact, in most of the available results, this necessary optimality condition is proved by direct arguments, which, primarily because of the definition of the derivative, demands that  $\text{dom}(F) = Q_0$ . See [4], [21] for details.

Our above results are suitable when the cone  $C$  is not solid and when the set-valued maps are not necessarily confined to  $Q_0$ . We illustrate this by slightly modifying Example 1.1.

*Example 3.1.* Consider again the set-valued map  $F : [0, 2] \rightrightarrows \mathbb{R}^2$  defined by

$$F(x) := \{(y_1, y_2) \in \mathbb{R}^2 \mid y_1^2 + y_2^2 \leq x^2\}.$$

Let  $C := \{(x, x) \in \mathbb{R}^2 \mid x \in \mathbb{R}_+\}$  be the ordering cone and let  $Q_0 := [0, 1]$  be the set of implicit constraints. It is easy to verify that the point  $(1, (0, -1)) \in \text{gph}(F)$  is a (global) proper minimizer to  $(P_0)$ . For  $x \in \text{dom}(D_g F(1, (0, -1))) = \mathbb{R}$ , we have

$$D_g F(1, (0, -1))(x) = \{(y_1, y_2) \in \mathbb{R}^2 \mid y_1 \in \mathbb{R}, y_2 = -x\}$$

and hence  $D_g F(1, (0, -1))(x) \cap (-C \setminus \{0_{\mathbb{R}^2}\}) \neq \emptyset$  for every  $x \in \mathbb{P}$ . However, since  $IT(Q_0, \bar{x}) = -\mathbb{P}$  and  $D_g F(1, (0, -1))[-C \setminus \{0_{\mathbb{R}^2}\}]^- = \mathbb{P}$ , the necessary optimality condition announced in Corollary 3.2 holds good as

$$D_g F(1, (0, -1))[-C \setminus \{0_{\mathbb{R}^2}\}]^- \bigcap IT(Q_0, \bar{x}) = \emptyset.$$

Another approach to prove (4), in fact more akin to the classical Dubovitskii–Milyutin approach, is to express the optimality as a disjunction of certain sets and then use some Farkas lemma-type results. In the present setting, the following two results generalize the Dubovitskii–Milyutin approach and give an alternative proof of Theorem 3.1.

LEMMA 3.1. *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_1)$ . Then*

$$(6) \quad IT(Q_0, \bar{x}) \bigcap IT(F[\bar{y} - C \setminus \{0_Y\}]^-, \bar{x}) \bigcap T(G[-D]^-, \bar{x}) = \emptyset.$$

*Proof.* We claim that  $U \bigcap Q_0 \bigcap F[\bar{y} - \text{int}(K)]^- \bigcap G[-D]^- = \emptyset$ , where  $U$  is a neighborhood of  $\bar{x}$  and  $K \in \mathcal{K}$ , both corresponding to the local proper minimality. In fact, if there exists  $x \in U \bigcap Q_0 \bigcap F[\bar{y} - \text{int}(K)]^- \bigcap G[-D]^-$ , then from  $x \in U \bigcap Q_0 \bigcap G[-D]^-$  we notice that  $x$  is feasible and from  $x \in F[\bar{y} - \text{int}(K)]^-$  we obtain  $F(x) \cap (\bar{y} - \text{int}(K)) \neq \emptyset$ , which is a contradiction of the optimality of  $(\bar{x}, \bar{y})$ . The assertion now follows from the properties of the interiorly contingent cones and the contingent cones stated in Remark 2.1. The proof is complete.  $\square$

Besides giving an alternative proof for (4), the following result has its own significance.

**PROPOSITION 3.1.** *Let  $X$  and  $Y$  be normed spaces, and let  $F : X \rightrightarrows Y$  be a set-valued map possessing the Aubin property around  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ . Then for every  $K \in \mathcal{K}$  we have*

$$\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- \subseteq IT(F[\bar{y} - \text{int}(K)]^-, \bar{x}).$$

*Proof.* The proof is based on the arguments given in the proof of Theorem 3.1.  $\square$

Let  $\text{dom}(F) = \text{dom}(G) = Q_0$ , let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ , and let  $\bar{z} \in G(\bar{x}) \cap (-D)$ . Then a necessary optimality condition for  $(\bar{x}, \bar{y})$  to be a *weak minimizer* to  $(P_1)$  is that (cf. [8])

$$\mathcal{D}(F, G)(\bar{x}, \bar{y}, \bar{z})(S) \cap (-\text{int}(C) \times (-\text{int}(D) - \bar{z})) = \emptyset,$$

where  $\mathcal{D}(F, G)(\bar{x}, \bar{y}, \bar{z})$  is the contingent derivative of the map  $(F, G) := F \times G$  at  $(\bar{x}, \bar{y}, \bar{z})$  and  $S$  is the domain of this derivative. It is clear that under suitable convexity assumptions these disjoint sets, given in the image space, can be separated and a multiplier rule can be obtained (see [14]). However, the optimality condition (4) is of different nature. First, the disjunction in (4) is taking place in the objective space. Second, in (4) we have not taken into account any derivative of  $G$ . To get a multiplier rule from Theorem 3.1, we need to apply the DM-lemma to (4). For this, among other things, we need to gather some information about the dual of  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^-$  and a suitable regularity condition relating the cone  $T(G[-D]^-, \bar{x})$  with some derivative of  $G$  at a feasible point. All this is done in the next section.

**3.2. Inverse images and subgradients of set-valued maps.** Let  $X$  be a normed space, let  $X^*$  be the topological dual of  $X$ , and let  $M \subset X$ . The polar  $M^\circ$  of  $M$  is a subset of  $X^*$  defined by  $M^\circ = \{l \in X^* : l(x) \leq 0 \text{ for every } x \in M\}$ . It is known that if  $M_1 \subseteq M_2$ , then  $M_2^\circ \subseteq M_1^\circ$ . The positive dual  $M^*$  is defined by  $M^* = -M^\circ$ .

Given a set  $\mathcal{A} \subset \mathbb{R}$  and  $b \in \mathbb{R}$ , by the inequality  $\mathcal{A} \geq b$  we understand that  $a \geq b$  for every  $a \in \mathcal{A}$ . Now let  $X$  and  $Y$  be normed spaces, let  $C \subset Y$  be a proper pointed convex cone and let  $F : X \rightrightarrows Y$  be set-valued with  $F_+ = F + C$  as its profile map. Given  $A \subset Y^*$ , we introduce a scalarized subgradient  $\partial_A F(\bar{x}, \bar{y})$  of  $F$  at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  as follows:

$$\partial_A F(\bar{x}, \bar{y}) = \{L \in X^* \mid \exists y^* \in A : L(x) \leq (y^* \circ \mathcal{D}F_+(\bar{x}, \bar{y}))(x) \forall x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))\}.$$

Further, given  $B \subset Y$ , we define a  $B$ -subgradient  $\partial_B F(\bar{x}, \bar{y})$  of  $F$  at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  by

$$\partial_B F(\bar{x}, \bar{y}) = \{L \in \mathcal{L}(X, Y) \mid (\mathcal{D}F_+(\bar{x}, \bar{y})(x) - L(x)) \cap B = \emptyset \forall x \in \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))\},$$

where  $\mathcal{L}(X, Y)$  represents the set of all linear and continuous functions defined from  $X$  to  $Y$ . We shall use the terms generalized subgradient, proper subgradient, and weak subgradient if  $B = -C \setminus \{0_Y\}$ ,  $-\text{int}(K)$ , where  $K \subset \mathcal{K}$ , and  $-\text{int}(C)$ , and we denote these variants by  $\partial_g F(\bar{x}, \bar{y})$ ,  $\partial_p F(\bar{x}, \bar{y})$ , and  $\partial_w F(\bar{x}, \bar{y})$ , respectively. If in the above definition of  $B$ -subgradient we replaced  $\mathcal{D}F_+(\bar{x}, \bar{y})$  by  $D_g F(\bar{x}, \bar{y})$ , then we shall replace the term subgradient by subdifferential. In the following the generalized, the proper, and the weak subdifferential of  $F$  at  $(\bar{x}, \bar{y})$  will be denoted by  $\Gamma_g F(\bar{x}, \bar{y})$ ,  $\Gamma_p F(\bar{x}, \bar{y})$ , and  $\Gamma_w F(\bar{x}, \bar{y})$ , respectively. Sticking to our terminology, the notion of weak subdifferential was recently studied by Wong [35]. Other notions are new.

The above notions are motivated by a similar notion due to Baier and Jahn [3]. Recall that, given a set-valued map  $F : X \rightrightarrows Y$  and  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ , the contingent epiderivative  $D_e F(\bar{x}, \bar{y}) : X \rightarrow Y$  is a *single-valued map* satisfying (3). By employing this epiderivative, a notion of subgradients for set-valued maps, given in [3], is as follows:

$$\partial F(\bar{x}, \bar{y}) := \{L \in \mathcal{L}(X, Y) \mid L(x) \leq D_e F(\bar{x}, \bar{y})(x) \ \forall x \in X\}.$$

Though our primary goal is to state some regularity conditions in terms of the scalarized subgradient, we take a pause to give its relationship with the generalized subgradient.

**PROPOSITION 3.2.** *Let  $X$  and  $Y$  be normed spaces, and let  $F : X \rightrightarrows Y$  be a set-valued map locally  $C$ -convex at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ . Then  $\partial_p F(\bar{x}, \bar{y}) \neq \emptyset$  implies that  $\partial_{C^* \setminus \{0_{Y^*}\}} F(\bar{x}, \bar{y}) \neq \emptyset$ .*

*Proof.* Let  $\partial_p F(\bar{x}, \bar{y}) \neq \emptyset$  and let  $L \in \partial_p F(\bar{x}, \bar{y})$  be arbitrary. By the definition of the proper subgradient, there is a cone  $K \in \mathcal{K}$  such that  $(\mathcal{D}F_+(\bar{x}, \bar{y}) - L)(x) \cap (-\text{int}(K)) = \emptyset$  for every  $x \in S := \text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))$ . We claim that the set  $(\mathcal{D}F_+(\bar{x}, \bar{y}) - L)(S)$  is convex. Indeed, for  $i \in \{1, 2\}$ , let  $y_i \in (\mathcal{D}F_+(\bar{x}, \bar{y}) - L)(S)$ . There is  $x_i \in S$  such that  $y_i \in \mathcal{D}F_+(\bar{x}, \bar{y})(x_i) - L(x_i)$  and hence  $y_i + L(x_i) \in \mathcal{D}F_+(\bar{x}, \bar{y})(x_i)$ . This implies that for some  $\lambda \in (0, 1]$  we have  $\lambda y_1 + (1 - \lambda)y_2 \in (\mathcal{D}F(\bar{x}, \bar{y}) - L)(\lambda x_1 + (1 - \lambda)x_2)$ . Since the set  $S$  is convex, we conclude that  $\lambda y_1 + (1 - \lambda)y_2 \in (\mathcal{D}F_+(\bar{x}, \bar{y}) - L)(S)$ . Now, by employing a separation theorem we assure the existence of  $y^* \in K^* \setminus \{0_{Y^*}\} \subseteq C^* \setminus \{0_{Y^*}\}$  such that

$$(y^* \circ \mathcal{D}F_+(\bar{x}, \bar{y}))(x) \geq (y^* \circ L)(x) \quad \text{for all } x \in S.$$

Since  $L \in \mathcal{L}(X, Y)$  and  $y^* \in Y^*$ , we have  $y^* \circ L \in X^*$  and hence  $y^* \circ L \in \partial_{C^* \setminus \{0_{Y^*}\}} F(\bar{x}, \bar{y})$ . The proof is complete.  $\square$

The following is the main result of the section.

**THEOREM 3.2.** *Let  $X$  and  $Y$  be normed spaces, and let  $F : X \rightrightarrows Y$  be a set-valued map locally  $C$ -convex at  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ . Let  $\mathbb{K}$  be a solid closed convex cone such that  $C \subseteq \mathbb{K}$ . Let  $\text{dom}(\mathcal{D}F_+(\bar{x}, \bar{y}))$  be convex. If  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(\mathbb{K})]^- \neq \emptyset$ , then*

$$(7) \quad (\mathcal{D}F_+(\bar{x}, \bar{y})[-\mathbb{K}]^-)^\circ \subset (\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(\mathbb{K})]^-)^\circ \subset \partial_{C^*} F(\bar{x}, \bar{y}).$$

*Furthermore, if  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(\mathbb{K})]^- = \emptyset$ , then  $0_{X^*} \in \partial_{C^* \setminus \{0_{Y^*}\}} F(\bar{x}, \bar{y})$ .*

We shall deduce the above assertion from the following result.

**PROPOSITION 3.3.** *Let  $X$  and  $Y$  be normed spaces, let  $\Omega \subseteq X$  be convex, and let  $A \subset Y$  be a solid closed convex cone. Let  $\Psi : \Omega \rightrightarrows Y$  be an  $A$ -convex set-valued map. If  $\Psi[-\text{int}(A)]^- \neq \emptyset$ , then for every  $\psi \in (\Psi[-A])^\circ$  there exists  $t \in A^*$  such that*

$$t \circ \Psi(x) \geq \psi(x) \quad \text{for every } x \in \Omega.$$

*If  $\Psi[-\text{int}(A)]^- = \emptyset$ , then there exists  $t \in A^* \setminus \{0_{Y^*}\}$  such that*

$$t \circ \Psi(x) \geq 0 \quad \text{for every } x \in \Omega.$$

*Proof.* We begin with the case when the set  $\Psi[-\text{int}(A)]^-$  is nonempty. Then the polar  $\Phi^\circ$  of  $\Phi := \Psi[-A]^-$  is also nonempty. We choose  $\psi \in \Phi^\circ$  arbitrarily and define a set

$$E := \{(y, \psi(x)) \in Y \times \mathbb{R} \mid y \in \Psi(x) + A, x \in \Omega\}.$$

In view of the assumptions that  $\Omega$  is convex,  $\Psi$  is  $A$ -convex, and  $\psi \in X^*$ , we deduce that  $E$  is a convex set. Indeed, let  $(y_1, z_1), (y_2, z_2) \in E$  be arbitrary. Then by the definition of  $E$ , for  $i = 1, 2$ , there exists  $x_i \in \Omega \subset X$  with  $z_i = \psi(x_i)$  and  $y_i \in \Psi(x_i) + A$ . For  $\lambda \in (0, 1]$ , we have  $\lambda z_1 + (1 - \lambda)z_2 = \psi(\lambda x_1 + (1 - \lambda)x_2)$ . Further, in view of the  $A$ -convexity of  $\Psi$ , we have  $\lambda y_1 + (1 - \lambda)y_2 \in \lambda\Psi(x_1) + (1 - \lambda)\Psi(x_2) + A \subseteq \Psi(\lambda x_1 + (1 - \lambda)x_2) + A$ . This, in view of the convexity of the set  $\Omega$ , implies that  $\lambda(y_1, z_1) + (1 - \lambda)(y_2, z_2) \in E$ .

Next, we claim that  $E \cap (-\text{int}(A) \times \mathbb{P}) = \emptyset$ . In fact, if this is not the case, then there exists  $(x, y) \in X \times Y$  such that  $y \in (\Psi(x) + A) \cap (-\text{int}(A))$  and  $\psi(x) > 0$ . Let  $w \in \Psi(x)$  be such that  $y \in w + A$ . Then  $w \in y - A \subset -\text{int}(A) - A = -\text{int}(A)$ . This, however, contradicts that  $\psi \in \Phi^\circ$ . Therefore  $E \cap (-\text{int}(A) \times \mathbb{P}) = \emptyset$ , and hence by a separation theorem, we get the existence of  $(f, g) \in Y^* \times \mathbb{R} \setminus \{0_{Y^*}, 0\}$  and a real number  $\alpha$  such that we have

$$(8) \quad f(u) + g \cdot v \geq \alpha \quad \text{for every } (u, v) \in E,$$

$$(9) \quad f(c) + g \cdot v < \alpha \quad \text{for every } (c, d) \in -\text{int}(A) \times \mathbb{P}.$$

Since  $A$  is a cone, we can set  $\alpha = 0$  in (8) and (9). By taking  $d \in \mathbb{P}$  arbitrarily close to 0 and  $c \in -\text{int}(A)$  arbitrarily close to  $0_Y$ , we obtain  $f \in A^*$  and  $g \leq 0$ , respectively. We claim that  $g < 0$ . Indeed, if  $g = 0$ , we get  $f(c) < 0$  for every  $c \in -\text{int}(A)$  and  $f(u) \geq 0$  for every  $u \in \Psi(\Omega) + A$ . This, however, is impossible because we have  $(\Psi(\Omega) + A) \cap (-\text{int}(A)) \neq \emptyset$ . Therefore  $g < 0$ . Moreover, from (8), for every  $x \in \Omega$  we have  $f \circ (\Psi + A)(x) \geq -(g \cdot \psi)(x)$ . By setting  $t = (-f/g) \in A^*$  and noticing that  $0_Y \in A$ , we finish the proof of the first part.

For the second part, we notice that if  $\Psi[-\text{int}(A)]^- = \emptyset$ , we have  $\Psi(\Omega) \cap -\text{int}(A) = \emptyset$ , and hence by arguments similar to those given above we can prove the existence of  $t \in A^* \setminus \{0_Y\}$  such that  $t \circ \Psi(x) \geq 0$  for every  $x \in \Omega$ .  $\square$

The following particular case is worth mentioning. Henceforth we set  $(T(\cdot, \cdot))^\circ = N(\cdot, \cdot)$ .

**COROLLARY 3.3.** *If in Proposition 3.3 we assume that  $A = T(B, -\bar{w})$ , where  $B \subset Y$  is a proper solid convex cone with  $\bar{w} \in -B$  and  $\Psi$  is  $B$ -convex, then  $t \in B^*$  and  $t(\bar{w}) = 0$ .*

*Proof.* To apply Proposition 3.3 it suffices to show that the map  $\Psi$  is  $T(B, -\bar{w})$ -convex. For this, we notice that due to  $\bar{w} \in -B$ , we have  $B \subseteq T(B, -\bar{w})$ . Now  $T(B, -\bar{w})$ -convexity of  $\Psi$  follows from its  $B$ -convexity. By invoking Proposition 3.3, for every  $\psi \in (\Psi[-A])^\circ$ , there exists a functional  $t \in -N(B, -\bar{w})$  which satisfies the assertion. Since  $B$  is convex, we have  $T(B, -\bar{w}) \supseteq B + \bar{w}$  and consequently

$$(10) \quad t(b + \bar{w}) \geq 0 \quad \text{for all } b \in B.$$

By setting  $b = 0_Y$  in the above inequality, we obtain  $t(\bar{w}) \geq 0$ . Because  $B$  is a cone and  $\bar{w} \in -B$ , we can substitute  $b = -2\bar{w} \in B$  in (10) to obtain  $t(\bar{w}) \leq 0$ . Therefore, combining the preceding two inequalities, we have  $t(\bar{w}) = 0$  and this, in view of (10), yields  $t \in B^*$ .  $\square$

Now we are ready to give the following proof.

*Proof of Theorem 3.2.* The first inclusion is a consequence of

$$\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(\mathbb{K})]^- \subset \mathcal{D}F_+(\bar{x}, \bar{y})[-\mathbb{K}]^-,$$

and the second inclusion is essentially a restatement of Proposition 3.3 when we notice that the map  $\mathcal{D}F_+(\bar{x}, \bar{y})$  is  $\mathbb{K}$ -convex and set  $\Psi \equiv \mathcal{D}F_+(\bar{x}, \bar{y})$ .  $\square$

We conclude this section by using the scalarized subgradient to express a necessary optimality condition for the local proper minimality in set-valued optimization.

**PROPOSITION 3.4.** *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_0)$ . Let the map  $F : X \rightrightarrows Y$  be locally  $C$ -convex at  $(\bar{x}, \bar{y})$  with  $\text{dom}(F) = Q_0$ . Then  $0_{X^*} \in \partial_{C^* \setminus \{0_{Y^*}\}} F(\bar{x}, \bar{y})$ .*

*Proof.* Since  $(\bar{x}, \bar{y})$  is a local proper minimizer, by arguments similar to those in Theorem 3.1 we can show that  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- = \emptyset$  for some  $K \in \mathcal{K}$ . (In fact this link has led to the proof of Corollary 3.1.) Now by applying Theorem 3.2 we obtain that  $0_{X^*} \in \partial_{C^* \setminus \{0_{Y^*}\}} F(\bar{x}, \bar{y})$ .  $\square$

**3.3. Lagrange multiplier rule.** We begin this section by proposing the following notion of regularity for set-valued maps.

**DEFINITION 3.1.** *Let  $E_1$  and  $E_2$  be normed spaces and let  $\mathcal{C} \subset E_2$  be a convex cone. Let  $\mathcal{F} : E_1 \rightrightarrows E_2$  be a set-valued map and let  $(x_0, y_0) \in \text{gph}(\mathcal{F})$ . The map  $\mathcal{F}$  is called  $\mathcal{C}$ -regular at  $(x_0, y_0)$  if  $(\mathcal{F} + \mathcal{C})$  has the Aubin property around  $(x_0, y_0)$  and  $\mathcal{F}$  is locally  $\mathcal{C}$ -convex at  $(x_0, y_0)$ .*

**Remark 3.3.** In the above definition, if  $E_2$  is finite-dimensional,  $x_0 \in \text{int}(\text{dom}(\mathcal{F}))$ , and  $\text{epi}(\mathcal{F})$  is closed convex, then  $\mathcal{F}$  is  $\mathcal{C}$ -regular at  $(x_0, y_0)$ . This is a consequence of a known fact that if a set-valued map has a closed convex graph and the image space is finite-dimensional, then the map is locally Lipschitz at the interior of its domain. For details see [15, p. 588].

In our next result we give the promised Lagrange multiplier rule. Recall that  $G_+ := G + D$ .

**THEOREM 3.3.** *Assume that  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is a local proper minimizer to  $(P_1)$ . Assume that  $F$  is locally  $C$ -regular at  $(\bar{x}, \bar{y})$  and there exists an open convex cone  $M \subset IT(Q_0, \bar{x})$ . Assume that for  $K \in \mathcal{K}$  either  $IT(F[\bar{y} - \text{int}(K)]^-, \bar{x})$  is convex or  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^-$  is open. Assume that  $\mathcal{D}F_+(\bar{x}, \bar{y})$  and  $\mathcal{D}G_+(\bar{x}, \bar{z})$ , where  $\bar{z} \in G(\bar{x}) \cap (-D)$ , are strict and the following regularity condition (RC) holds: If  $\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_{Z^*}\}]^- = \emptyset$ , then  $0_{X^*} \in \partial_{-N(D, -\bar{z}) \setminus \{0_{Z^*}\}} G(\bar{x}, \bar{z})$ ; otherwise  $T(G[-D]^-, \bar{x})$  is convex and we have*

$$(11) \quad N(G[-D]^-, \bar{x}) \subseteq \partial_{-N(D, -\bar{z})} G(\bar{x}, \bar{z}).$$

*Then there exist  $(s, t, u) \in X^* \times Y^* \times Z^*$ , not all zero, such that  $s \in M^*$ ,  $t \in C^*$ , and  $u \in D^*$ . Moreover the complementary slackness condition  $u(\bar{z}) = 0$  and the following inequality hold:*

$$(12) \quad t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) + u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) \geq s(x) \quad \text{for every } x \in X.$$

*If either  $\bar{x} \in \text{int}(Q_0)$  or  $\text{dom}(F) = \text{dom}(G) = Q_0$ , then  $s \in Z^*$  can be set to zero. In this particular case, we have  $t \neq 0_{Y^*}$  if the following regularity condition holds:*

$$(13) \quad \mathcal{D}G_+(\bar{x}, \bar{z})(X) + \text{cone}(D + \bar{z}) = Z.$$

*Proof.* We begin by showing that the assertions would hold trivially if we have either  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- = \emptyset$ , where  $K \in \mathcal{K}$ , or  $\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_{Z^*}\}]^- = \emptyset$ . Indeed, if  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- = \emptyset$ , then in view of Theorem 3.2 there exists  $t \in C^* \setminus \{0_{Y^*}\}$  such that for every  $x \in X$  we have  $t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) \subseteq \mathbb{R}_+$ . By choosing  $s = 0_{X^*}$  and  $u = 0_{Z^*}$  we get the desired result.

On the other hand, if  $\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_{Z^*}\}]^- = \emptyset$ , then in view of the condition  $0_{X^*} \in \partial_{-N(D, -\bar{z}) \setminus \{0_{Z^*}\}} G(\bar{x}, \bar{z})$  we ensure the existence of  $u \in -N(D, -\bar{z}) \setminus \{0_{Z^*}\}$  such that for every  $x \in X$  we have  $u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) \subseteq \mathbb{R}_+$ . We choose  $s = 0_{X^*}$  and

$t = 0_{Y^*}$  to obtain (12). The proof for  $u \in D^*$  and the complementary slackness condition follows from Corollary 3.3.

Therefore, without any loss of generality, we can assume that

$$\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- \neq \emptyset$$

and

$$\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^- \neq \emptyset.$$

We first consider the case when  $IT(F[\bar{y} - \text{int}(K)]^-, \bar{x})$  is convex. Now, by using Lemma 3.1 and the containment  $M \subset IT(Q_0, \bar{x})$ , we have

$$IT(F[\bar{y} - \text{int}(K)]^-, \bar{x}) \cap M \cap T(G[-D]^-, \bar{x}) = \emptyset.$$

The above disjunction, in view of the DM-lemma and Proposition 3.1, ensures the existence of functionals  $l_1 \in M^\circ$ ,  $l_2 \in (\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^-)^\circ$ , and  $l_3 \in N(G[-D]^-, \bar{x})$  such that

$$(14) \quad l_1 + l_2 + l_3 = 0.$$

Notice that if  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^-$  is open, then since it is a convex cone, we can directly obtain the above conclusion. Now, because  $\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^- \neq \emptyset$ , we have  $N(G[-D]^-, \bar{x}) \subseteq \partial_{-N(D, -\bar{z})}G(\bar{x}, \bar{z})$ , and consequently  $l_3 \in \partial_{-N(D, -\bar{z})}G(\bar{x}, \bar{z})$ . This observation and Theorem 3.2 ensure the existence of functionals  $t \in C^*$  and  $u \in -N(D, -\bar{z})$  such that

$$\begin{aligned} t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) &\geq l_2(x) && \text{for every } x \in X, \\ u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) &\geq l_3(x) && \text{for every } x \in X. \end{aligned}$$

Combining the above two inequalities with (14) yields

$$t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) + u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) \geq -l_1(x) \quad \text{for every } x \in X.$$

By setting  $s = -l_1 \in M^*$  we finish the proof of (11). The remaining proof for  $u \in D^*$  and for the complementary slackness condition  $u(\bar{z}) = 0$  is the same as that of Corollary 3.3.

Finally, if either  $\bar{x} \in \text{int}(Q_0)$  or  $\text{dom}(F) = \text{dom}(G) = Q_0$ , then we can apply the above arguments to the disjunction given in Corollary 3.1. Notice that this disjunction does not take into account the space  $Z$ . It remains to show that under the regularity condition (13) we have  $t \neq 0_{Y^*}$ . For this assume that  $t = 0_{Y^*}$  and choose  $\tilde{z} \in Z$  arbitrarily. Since

$$\tilde{z} = z + \beta(d + \bar{z}), \quad \text{where } z \in \mathcal{D}G_+(\bar{x}, \bar{z})(X), \quad d \in D, \quad \beta > 0,$$

we deduce that for an arbitrary  $\tilde{z} \in Z$  we have  $u(\tilde{z}) = u(z) + \beta(u(d) + u(\bar{z})) \geq 0$ . This, however, implies that  $u = 0_{Z^*}$ , and we have a contradiction of  $(t, u) \neq (0_{Y^*}, 0_{Z^*})$ . The proof is complete.  $\square$

As is evident from the above proof, the assumption  $(\mathcal{RC})$  is vital to ensure the existence of the multipliers. In the following we justify this assumption by identifying the cases under which it holds. We begin with a result justifying the inclusion  $0_{X^*} \in \partial_{-N(D, -\bar{z}) \setminus \{0_{Z^*}\}}G(\bar{x}, \bar{z})$ .

PROPOSITION 3.5. *Besides the notation of Theorem 3.3, assume that  $T(D, -\bar{z})$  is locally compact and  $Z$  is reflexive Banach. Assume that  $G : X \rightrightarrows Z$  is locally  $D$ -convex at  $(\bar{x}, \bar{z})$ . Then  $0_{X^*} \in \partial_{-N(D, -\bar{z}) \setminus \{0_Z\}} G(\bar{x}, \bar{z})$ , provided that*

$$\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^- = \emptyset.$$

*Proof.* Since  $\mathcal{D}G_+(\bar{x}, \bar{z})[T(-D, \bar{z}) \setminus \{0_Z\}]^- = \emptyset$ , we have  $\mathcal{D}G_+(\bar{x}, \bar{z})(S) \cap T(-D, \bar{z}) = \{0_Z\}$ , where  $S = \text{dom}(\mathcal{D}G_+(\bar{x}, \bar{z}))$ . Now, by employing a cone separation theorem (see [6]), we ensure the existence of  $l \in Z^* \setminus \{0_{Z^*}\}$  such that

$$\begin{aligned} l \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) &\geq 0 \quad \text{for every } x \in S, \\ l(T(D, -\bar{z})) &\geq 0. \end{aligned}$$

The condition  $0_{X^*} \in \partial_{-N(D, -\bar{z}) \setminus \{0_{Z^*}\}} G(\bar{x}, \bar{z})$  now follows from the above inequalities.  $\square$

As concerns (11), in fact it is motivated by the conclusions in Proposition 3.3 and Corollary 3.3, and by the condition

$$(15) \quad \mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z})]^- \subseteq T(G[-D]^- , \bar{x}) \quad (Q_0 = \text{dom}(G)),$$

which is very comparable to the well-known Guignard constraint qualification (cf. [36]). Since

$$\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^- \subseteq \mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z})]^- ,$$

an obvious implication of (15) is the inclusion

$$N(G[-D]^- , \bar{x}) \subseteq (\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^-)^\circ,$$

provided that  $\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^- \neq \emptyset$ . Hence, if (15) is valid, then in view of  $N(G[-D]^- , \bar{x}) \subseteq (\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^-)^\circ$ , for (11) it suffices to show that

$$(\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^-)^\circ \subseteq \partial_{-N(D, -\bar{z})} G(\bar{x}, \bar{z}).$$

For this, we notice that if we choose  $p \in (\mathcal{D}G_+(\bar{x}, \bar{z})[-T(D, -\bar{z}) \setminus \{0_Z\}]^-)^\circ$  arbitrarily, we have

$$(16) \quad Q \cap (-T(D, -\bar{z}) \setminus \{0_Z\} \times -\mathbb{P}) = \emptyset,$$

where  $Q = \{(y, p(x)) \in Z \times \mathbb{R} \mid y \in \mathcal{D}G_+(\bar{x}, \bar{z})(x), x \in X\}$ . Now, if  $\text{int}(T(D, -\bar{z})) = IT(D, -\bar{z})$  is nonempty, we repeat the above arguments by replacing  $-T(D, -\bar{z}) \setminus \{0_Z\}$  with  $-IT(D, -\bar{z})$  and, as in Proposition 3.3, we will get that  $p \in \partial_{-N(D, -\bar{z})} G(\bar{x}, \bar{z})$ . However, notice that the above nonintersecting cones may also be separated by cone separation theorems or in cases when  $Q$  has a nonempty interior. On the other hand, it can be shown that the condition  $(\mathcal{RC})$  becomes superfluous if the cone  $D$  is solid and some convexity hypothesis holds. To show this we first prove the following result.

PROPOSITION 3.6. *Let  $X$  and  $Y$  be real normed spaces, let  $G : X \rightrightarrows Y$  be set-valued, and let  $(\bar{x}, \bar{z}) \in \text{gph}(G)$ . Let  $D \subset Y$  be a solid convex cone. Then*

$$\text{cl}(\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^-) \subseteq T(G[-D]^- , \bar{x}).$$

*Proof.* It suffices to show that  $\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^- \subseteq T(G[-D]^- , \bar{x})$ . Choose  $x \in \mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]$  arbitrarily. Then there exists  $z \in Z$  such that  $z \in$

$\mathcal{D}G_+(\bar{x}, \bar{z})(x) \cap IT(-D, \bar{z})$ . Since  $(x, z) \in \text{gph}(\mathcal{D}G(\bar{x}, \bar{z}))$ , there are sequences  $(\lambda_n) \subset \mathbb{P}$ ,  $((x_n, z_n)) \subset X \times Y$  such that  $\lambda_n \downarrow 0$ ,  $x_n \rightarrow x$ ,  $z_n \rightarrow z$ , and  $\bar{z} + \lambda_n z_n \in G(\bar{x} + \lambda_n x_n) + D$  for every  $n \in \mathbb{N}$ . By the definition of  $IT(-D, \bar{z})$ , there exists  $n_1 \in \mathbb{N}$  such that  $\bar{z} + \lambda_n z_n \in -D$  for every  $n \geq n_1$ . Now, let  $w_n \in G(\bar{x} + \lambda_n x_n)$  be such that  $\bar{z} + \lambda_n z_n \in w_n + D$ . Then  $w_n \in -D$  for every  $n \geq n_1$ , implying  $\bar{x} + \lambda_n x_n \in G[-D]^-$  for every  $n \geq n_1$ . Therefore  $x \in T(G[-D]^-, \bar{x})$ .  $\square$

In view of the above result we have the following analogue of Theorem 3.1 where derivatives of both  $F$  and  $G$  are taken into account.

**THEOREM 3.4.** *Assume that  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is a local proper minimizer to  $(P_1)$  and assume that  $D$  is a solid closed convex cone. Assume that the map  $F_+ (:= F + C)$  possesses the Aubin property around  $(\bar{x}, \bar{y})$ . Then*

$$(17) \quad \mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- \bigcap IT(Q_0, \bar{x}) \bigcap \text{cl}(\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^-) = \emptyset.$$

Now we are in a position to give the following important particular case of Theorem 3.3.

**COROLLARY 3.4.** *The conclusions of Theorem 3.3 remain valid if instead of  $(\mathcal{RC})$  we assume that the map  $G$  is locally  $D$ -convex at  $(\bar{x}, \bar{z})$  and  $\text{int}(D) \neq \emptyset$ .*

*Proof.* We can consider two cases, namely, when the set  $\mathcal{D}G_+(\bar{x}, \bar{y})[-\text{int}(T(D, -\bar{z}))]^-$  is empty and when it is not empty. In the first case by modifying Proposition 3.5 we get the first part of  $(\mathcal{RC})$ . For the second case we can use (16) and Proposition 3.3. The proof is complete.  $\square$

In fact while dealing with the cases when  $D$  is solid, we can also cope with the situation in which  $IT(Q_0, \bar{x})$  is not defined. For this the following result is instrumental.

**PROPOSITION 3.7.** *Besides the hypothesis of Proposition 3.6, assume that the map  $G$  possess the Aubin property around  $(\bar{x}, \bar{z})$ . Then*

$$\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^- \subseteq IT(G[-D]^-, \bar{x}).$$

*Proof.* The proof is based on the arguments given in the proof of Proposition 3.6 and the use of the Aubin property depicted in Theorem 3.1.  $\square$

The following is an analogue of Corollary 3.4.

**COROLLARY 3.5.** *The conclusions of Corollary 3.4 remain valid if the hypothesis that there exists some open convex cone  $M \subset IT(Q_0, \bar{x})$  is replaced by the requirement that there exist a closed convex cone  $M \subset T(Q_0, \bar{x})$  and that  $G$  possess the Aubin property around  $(\bar{x}, \bar{z})$ .*

**3.4. Necessary optimality condition for  $(P_2)$ .** We begin this subsection by the following necessary optimality condition for  $(P_2)$ .

**THEOREM 3.5.** *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_2)$ . Let  $D$  be solid and let  $F_+$  have the Aubin property around  $(\bar{x}, \bar{y})$ . Then*

$$(18) \quad IT(Q_0, \bar{x}) \bigcap \mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- \bigcap IT(G[-D]^-, \bar{x}) \bigcap T(H[h]^-, \bar{x}) = \emptyset.$$

*Proof.* Since  $(\bar{x}, \bar{y})$  is a local proper minimizer of  $(P_2)$ , there are a neighborhood  $U_1$  of  $\bar{x}$  and a pointed convex solid cone  $K \in \mathcal{K}$  such that  $\bar{y} \in \text{Min}(F(Q_1 \cap U), K)$ . The disjunction (18) can be obtained from

$$IT(Q_0, \bar{x}) \bigcap \mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^- \bigcap IT(G[-D]^-, \bar{x}) \bigcap T(H[h]^-, \bar{x}) = \emptyset,$$

which can be proved by using arguments similar to those given in the proof of Theorem 3.1.  $\square$

A variant of Theorem 3.5, involving the derivatives of both  $F$  and  $G$ , is as follows.

**THEOREM 3.6.** *Let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  be a local proper minimizer to  $(P_2)$ . Let  $D$  be solid, let  $F_+$  have the Aubin property around  $(\bar{x}, \bar{y})$ , and let  $G_+$  have the Aubin property around  $(\bar{x}, \bar{z})$  where  $\bar{z} \in G(\bar{x}) \cap -D$ . Then*

$$IT(Q_0, \bar{x}) \cap \mathcal{D}F_+(\bar{x}, \bar{y})[-C \setminus \{0_Y\}]^- \cap \mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^- \cap T(H[h]^- , \bar{x}) = \emptyset.$$

*Proof.* The proof follows by combining Theorem 3.5 and Proposition 3.7.  $\square$

In our next result we give a Lagrange multiplier rule for  $(P_2)$ .

**THEOREM 3.7.** *Assume that  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is a local proper minimizer to  $(P_2)$  and  $\bar{z} \in G(\bar{x}) \cap (-D)$ . Assume that  $F$  is locally  $C$ -regular at  $(\bar{x}, \bar{y})$  and  $G_+$  is locally  $D$ -regular at  $(\bar{x}, \bar{z})$ . Assume that there are an open convex cone  $M_1 \subset IT(Q_0, \bar{x})$  and a closed convex cone  $M_2 \subset T(H[h]^- , \bar{x})$  and that for  $K \in \mathcal{K}$  either  $IT(F[\bar{y} - \text{int}(K)]^- , \bar{x})$  is convex or  $\mathcal{D}F_+(\bar{x}, \bar{y})[-\text{int}(K)]^-$  is open. Assume that either  $IT(G[-D]^- , \bar{x})$  is convex or  $\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^-$  is open. Assume that  $\mathcal{D}F_+(\bar{x}, \bar{y})$  and  $\mathcal{D}G_+(\bar{x}, \bar{z})$  are strict. Then there exists  $(s, t, u, v) \in X^* \times Y^* \times Z^* \times W^*$ , not all simultaneously zero, such that  $s \in M_1^*$ ,  $t \in C^*$ ,  $u \in D^*$ , and  $v \in M_2^*$ . Moreover the complementary slackness condition  $u(\bar{z}) = 0$  and the following inequality hold:*

$$t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) + u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) \geq s(x) + v(x) \quad \text{for every } x \in X.$$

*Proof.* The proof is similar to the proof of Theorem 3.3.  $\square$

It is clear that in the above we have not imposed any differentiability assumption on the map  $H$ . For this, it would be of interest to obtain a variant of the well-known theorem of Lyusternik [18], fitting the present setting, so that the cone  $M_2^o$  contains information about some derivative of  $H$ . In fact, this is completely true if  $H$  is single-valued and sufficiently smooth [31]. To state this particular case, we recall the following known result.

**LEMMA 3.2** (see [31]). *Let  $X$  and  $Y$  be Banach spaces and let  $H : X \rightarrow Y$  be a single-valued map strongly differentiable at  $\bar{x} \in X$ . Let the derivative  $DH(\bar{x}) : X \rightarrow Y$  be a projection. Then*

$$\{h \in X : DH(\bar{x})(h) = 0\} = T(H[H(\bar{x})]^- , \bar{x}).$$

We have the following particular case of Theorem 3.7.

**COROLLARY 3.6.** *Let the hypothesis of Theorem 3.7 be altered in a sense that the map  $H$  satisfies the conditions of Lemma 3.2. Then there exist  $(s, t, u, v) \in X^* \times Y^* \times Z^* \times W^*$ , not all zero, such that  $s \in M_1^*$ ,  $t \in C^*$ , and  $u \in D^*$ . Moreover the complementary slackness condition  $u(\bar{z}) = 0$  and the following inequality hold:*

$$t \circ \mathcal{D}F_+(\bar{x}, \bar{y})(x) + u \circ \mathcal{D}G_+(\bar{x}, \bar{z})(x) + v \circ DH(\bar{x})(x) \geq s(x) \quad \text{for every } x \in X.$$

*Proof.* As in the proof of Theorem 3.3, we can show that there exists  $l_4 \in A^o$ , where  $A := \{x \in X \mid DH(\bar{x})(x) = 0\}$  is a subspace of  $X$ . Clearly, there exists  $v \in W^*$  such that  $v \circ DH(\bar{x}) = l_4$ . This observation then finishes the proof.  $\square$

**4. Optimality conditions for strong minimality.** Recall that a point  $(\bar{x}, \bar{y}) \in \text{gph}(F)$  is called a local strong minimizer of  $(P_2)$  if there exists a neighborhood  $U$  of  $\bar{x}$  such that  $F(Q_2 \cap U) \subseteq \bar{y} + C$ . In the following result, we give necessary optimality

conditions for the local strong minimality. Let the cone  $C$  be closed and convex and let the cone  $D$  be solid.

**THEOREM 4.1.** *Let  $X$  and  $Y$  be normed spaces, let  $F : X \rightrightarrows Y$  be set-valued, and let  $(\bar{x}, \bar{y}) \in \text{gph}(F)$ . Let the map  $F_+$  possess the Aubin property around  $(\bar{x}, \bar{y})$ .*

(a) *If  $(\bar{x}, \bar{y})$  is a strong minimizer to  $(P_1)$ , then the following holds:*

$$\mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^- \bigcap IT(Q_0, \bar{x}) \bigcap T(G[-D]^-, \bar{x}) = \emptyset.$$

(b) *If  $(\bar{x}, \bar{y})$  is a strong minimizer to  $(P_1)$ , then for  $\bar{z} \in G(\bar{x}) \cap -D$  the following holds:*

$$\mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^- \bigcap IT(Q_0, \bar{x}) \bigcap \text{cl}(\mathcal{D}G_+(\bar{x}, \bar{z})[IT(-D, \bar{z})]^-) = \emptyset.$$

(c) *If  $(\bar{x}, \bar{y})$  is a strong minimizer to  $(P_2)$ , then the following holds:*

$$\mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^- \bigcap IT(Q_0, \bar{x}) \bigcap IT(G[-D]^-, \bar{x}) \bigcap T(H[h]^-, \bar{x}) = \emptyset.$$

(d) *Let the map  $G_+$  possess the Aubin property around  $(\bar{x}, \bar{z})$  where  $\bar{z} \in G(\bar{x}) \cap -D$ . If  $(\bar{x}, \bar{y})$  is a strong minimizer to  $(P_2)$ , then the following holds:*

$$\mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^- \bigcap IT(Q_0, \bar{x}) \bigcap \mathcal{D}G_+[IT(-D), \bar{z}]^- \bigcap T(H[h]^-, \bar{x}) = \emptyset.$$

*Proof.* (a) Assume that there exists

$$x \in \mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^- \bigcap IT(Q_0, \bar{x}) \bigcap T(G[-D]^-, \bar{x}).$$

In view of the inclusion  $x \in \mathcal{D}F_+(\bar{x}, \bar{y})[Y \setminus C]^-$ , there exists  $y \in Y \setminus C$  such that  $(x, y) \in \text{gph}(\mathcal{D}F_+(\bar{x}, \bar{y}))$ . This implies that there are sequences  $(\lambda_n) \subset \mathbb{P}$  and  $((x_n, y_n)) \subset X \times Y$  such that  $\lambda_n \rightarrow 0$ ,  $(x_n, y_n) \rightarrow (x, y)$ , and  $\bar{y} + \lambda_n y_n \in F(\bar{x} + \lambda_n x_n) + C$  for all  $n \in \mathbb{N}$ . Also, since  $x \in IT(Q_0, \bar{x})$ , there exists  $n_1 \in \mathbb{N}$  such that  $\bar{x} + \lambda_n x_n \in Q_0$  for  $n \geq n_1$ .

Since  $y \notin C$ ,  $y_n \rightarrow y$ , and the cone  $C$  is closed, there exists  $n_2 \in \mathbb{N}$  such that  $y_n \notin C$  for all  $n \geq n_2$ . Because  $\lambda_n > 0$ , we have  $\lambda_n y_n \notin C$ . For  $u_n := \bar{x} + \lambda_n x_n$ , let  $w_n \in F(u_n)$  be such that for  $n \in \mathbb{N}$ ,  $\bar{y} + \lambda_n y_n = w_n + c_n$ , where  $c_n \in C$ . Hence  $w_n + c_n \notin \bar{y} + C$  for  $n \geq n_2$ . Since  $C + C = C$ , we have  $w_n \notin \bar{y} + C$  for  $n \geq n_2$ . As in the proof of Theorem 3.1, we can show that there exists  $n_3 \in \mathbb{N}$  such that  $G(u_n) \cap (-D) \neq \emptyset$  for all  $n \geq n_3$ .

Therefore, we have shown that for sufficiently large  $n \in \mathbb{N}$  there are  $w_n \in F(Q_1)$  such that  $w_n \notin \bar{y} + C$ . This, however, is a contradiction of the assumption that  $(\bar{x}, \bar{y})$  is a strong minimizer. Hence part (a) is true. Parts (b)–(d) can now be shown by unifying the above arguments with those given in the preceding section.  $\square$

**5. Concluding remarks.** New optimality conditions in set-valued optimization are given by employing the ideas around the so-called Dubovitskii–Milyutin approach. For inequality constraints our results appear to be satisfactory; however, the treatment of the equality constraints needs further research. In fact, a generalization of the theorem of Lyusternik is needed which fits the present setting.

It should also be stressed that although our approach is motivated by the Dubovitskii–Milyutin approach, there are significant differences in using the separation schemes for set optimization and for classical optimization. The main challenge is in identifying that the Aubin property enables the disjunction (4). Under suitable

differentiability assumptions such a restriction can be avoided in classical optimization (cf. [13], [31]). Moreover, in classical optimization, the existence of multipliers can also be proved without imposing convexity assumptions [18, section 17.4].

Our main objective in this work is to present a detailed treatment of new necessary optimality conditions. One important question which remained unanswered is whether these conditions are sufficient as well. We strongly believe the conditions stated in Theorem 3.3 become sufficient when stronger convexity conditions are imposed on the set-valued maps involved (see [8], [3]). However, since there are many new concepts of convexity for set-valued maps, a challenging aspect is to choose the most optimal notion for the sufficient optimality conditions. We plan to address this issue in a future work. Another interesting aspect of this study is to apply these results to some concrete problems, for example, those arising in control theory and inverse problems.

**Acknowledgments.** The second author is grateful to Prof. Dr. Johannes Jahn for the stimulating discussion and helpful remarks on this work. The authors are grateful to the referees for their careful reading of the paper and for the suggested improvements.

## REAL TIME SOLUTION OF THE NONLINEAR FILTERING PROBLEM WITHOUT MEMORY II\*

SHING-TUNG YAU<sup>†</sup> AND STEPHEN S.-T. YAU<sup>‡</sup>

*Dedicated to Professor Tyrone Duncan on the occasion of his 65th birthday*

**Abstract.** It is well known that the nonlinear filtering problem has important applications in both military and commercial industries. The central problem of nonlinear filtering is to solve the Duncan–Mortensen–Zakai (DMZ) equation in real time and in a memoryless manner. The purpose of this paper is to show that, under very mild conditions (which essentially say that the growth of the observation  $|h|$  is greater than the growth of the drift  $|f|$ ), the DMZ equation admits a unique nonnegative weak solution  $u$  which can be approximated by a solution  $u_R$  of the DMZ equation on the ball  $B_R$  with  $u_R|_{\partial B_R} = 0$ . The error of this approximation is bounded by a function of  $R$  which tends to zero as  $R$  goes to infinity. The solution  $u_R$  can in turn be approximated efficiently by an algorithm depending only on solving the observation-independent Kolmogorov equation on  $B_R$ . In theory, our algorithm can solve basically all engineering problems in real time. Specifically, we show that the solution obtained from our algorithms converges to the solution of the DMZ equation in the  $L^1$  sense. Equally important, we have a precise error estimate of this convergence, which is important in numerical computation.

**1. Introduction.** In 1961, Kalman and Bucy [Ka-Bu] first established the finite-dimensional filter for the linear filtering model with Gaussian initial distribution, which is highly influential in modern industry. Since then filtering theory has proved useful in science and engineering, for example, the navigational and guidance systems, radar tracking, sonar ranging, and satellite and airplane orbit determination. Despite its usefulness, however, the Kalman–Bucy filter is not perfect. Its main weakness is that it is restricted to the linear dynamical system with Gaussian initial distribution. Therefore there has been tremendous interest in solving the nonlinear filtering problem which involves the estimation of a stochastic process  $x = \{x_t\}$  (called the signal or state process) that cannot be observed directly. Information containing  $x$  is obtained from observations of a related process  $y = \{y_t\}$  (the observation process). The goal of nonlinear filtering is to determine the conditional density  $\rho(t, x)$  of  $x_t$  given the observation history of  $\{y_s : 0 \leq s \leq t\}$ . In the late 1960s, Duncan [Du], Mortensen [Mo], and Zakai [Za] independently derived the Duncan–Mortensen–Zakai (DMZ) equation for the nonlinear filtering theory, which the conditional probability density  $\rho(t, x)$  has to satisfy. The central problem of nonlinear filtering theory is to solve the DMZ equation in real time and in a memoryless way.

In 2000, we [Ya-Ya] proposed a novel algorithm to do just that. Under the as-

sumptions that the drift terms  $f_i(x)$ ,  $1 \leq i \leq n$ , and their first and second derivatives, and the observation terms  $h_i(x)$ ,  $1 \leq i \leq m$ , and their first derivatives, have linear growth, we showed that the solution obtained from our algorithms converges to the true solution of the DMZ equation. Although the above approach is quite successful, so far it cannot handle the famous cubic sensor in engineering in which  $f(x) = 0$  and  $h(x) = x^3$ . It is well known that there is no finite-dimensional filter for the cubic sensor [Su].

The purpose of this paper is to show that under very mild conditions (A.2), (A.17), and (C.3) (which essentially say that the growth of  $|h|$  is greater than the growth of  $|f|$ ), the DMZ equation admits a unique nonnegative solution  $u \in W_0^{1,1}((0, T) \times \mathbb{R}^n)$  which can be approximated by solutions  $u_R$  of the DMZ equation on the ball  $B_R$  with  $u_R|_{\partial B_R} = 0$ . The rate of convergence can be efficiently estimated in the  $L^1$  norm. The solution  $u_R$  can in turn be approximated efficiently by an algorithm depending only on solving the time-independent Kolmogorov equation on  $B_R$ . Our algorithm can solve practically all engineering problems, including the cubic sensor problem in real time and in a memoryless fashion. Specifically we show that the solution obtained from our algorithms converges to the solution of the DMZ equation in the  $L^1$  sense. Equally important, we have a precise error estimate of this convergence, which is important in numerical computation.

The filtering problem considered here is based on the signal observation model

$$(1.1) \quad \begin{cases} dx(t) = f(x(t)) dt + dv(t), & x(0) = x_0, \\ dy(t) = h(x(t)) dt + dw(t), & y(0) = 0, \end{cases}$$

in which  $x, v, y$ , and  $w$  are, respectively,  $\mathbb{R}^n$ -,  $\mathbb{R}^n$ -,  $\mathbb{R}^m$ -, and  $\mathbb{R}^m$ -valued processes and  $v$  and  $w$  have components that are independent, standard Brownian processes. We further assume that  $f$  and  $h$  are  $C^\infty$  smooth vector-valued. We shall refer to  $x(t)$  as the state of the system at time  $t$  and  $y(t)$  as the observation at time  $t$ .

Let  $\rho(t, x)$  denote the conditional probability density of the state given the observation  $\{y(s): 0 \leq s \leq t\}$ . It is well known that  $\rho(t, x)$  is given by normalizing a function,  $\sigma(t, x)$ , which satisfies the following DMZ equation:

$$(1.2) \quad d\sigma(t, x) = L_0\sigma(t, x) dt + \sum_{i=1}^n L_i\sigma(t, x) dy_i(t), \quad \sigma(0, x) = \sigma_0,$$

where

$$(1.3) \quad L_0 = \frac{1}{2} \sum_{i=1}^n \frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^n f_i \frac{\partial}{\partial x_i} - \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} - \frac{1}{2} \sum_{i=1}^m h_i^2,$$

and for  $i = 1, \dots, m$ ,  $L_i$  is the zero degree differential operator of multiplication by  $h_i$ . (Here we have used the notation  $p_i$  to represent the  $i$ th component of the vector  $p$ .)  $\sigma_0$  is the probability density of the initial point  $x_0$ .

Equation (1.2) is a stochastic partial differential equation. In real applications, we are interested in constructing robust state estimators from observed sample paths with some property of robustness. Davis [Da] studied this problem and proposed some robust algorithms. In our case, his basic idea reduces to defining a new unnormalized density

$$(1.4) \quad u(t, x) = \exp \left( - \sum_{i=1}^m h_i(x) y_i(t) \right) \sigma(t, x).$$

It is easy to show that  $u(t, x)$  satisfies the time-varying partial differential equation

$$(1.5) \quad \begin{cases} \frac{\partial u}{\partial t}(t, x) = L_0 u(t, x) + \sum_{i=1}^m y_i(t) [L_0, L_i] u(t, x) \\ \quad + \frac{1}{2} \sum_{i,j=1}^m y_i(t) y_j(t) [[L_0, L_i], L_j] u(t, x), \\ u(0, x) = \sigma_0, \end{cases}$$

where  $[\cdot, \cdot]$  denotes the Lie bracket. It is shown in [Ya-Ya, p. 236] that the robust DMZ equation (1.5) is of the form

$$(1.6) \quad \begin{cases} \frac{\partial u}{\partial t}(t, x) = \frac{1}{2} \Delta u(t, x) + (-f(x) + \nabla K(t, x)) \cdot \nabla u(t, x) \\ \quad + \left( -\operatorname{div} f(x) - \frac{1}{2} |h(x)|^2 + \frac{1}{2} \Delta K(t, x) \right. \\ \quad \left. - f(x) \cdot \nabla K(t, x) + \frac{1}{2} |\nabla K(t, x)|^2 \right) u(t, x), \\ u(0, x) = \sigma_0(x), \end{cases}$$

where  $K = \sum_{j=1}^m y_j(t) h_j(x)$ ,  $f = (f_1, \dots, f_n)$ , and  $h = (h_1, \dots, h_m)$ .

To simplify our presentation, we introduce the following condition.

*Condition (C<sub>1</sub>).*

$$-\frac{1}{2} |h|^2 - \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 + |f - \nabla K| \leq c_1 \quad \forall (t, x) \in [0, T] \times \mathbb{R}^n,$$

where  $c_1$  is a constant possibly depending on  $T$ .

Our main theorems are as follows.

**THEOREM A.** *Consider the filtering model (1.1). For any  $T > 0$ , let  $u$  be a solution of the robust DMZ equation (1.6) in  $[0, T] \times \mathbb{R}^n$ . Assume Condition (C<sub>1</sub>) is satisfied.*

*Then*

$$(1.7) \quad \sup_{0 \leq t \leq T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(t, x) \leq e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x).$$

*In particular,*

$$(1.8) \quad \sup_{0 \leq t \leq T} \int_{|x| \geq R} u(t, x) \leq e^{-\sqrt{1+R^2}} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x).$$

Theorem A above says that one can choose a ball large enough to capture almost all the density. In fact by (1.8) we have a precise estimate of density lying outside this ball.

**THEOREM B.** *Consider the filtering model (1.1). For any  $T > 0$ , let  $u$  be a solution of the robust DMZ equation (1.6) in  $[0, T] \times \mathbb{R}^n$ . Assume the following:*

(1) *Condition (C<sub>1</sub>) is satisfied.*

(2)  $-\frac{1}{2} |h|^2 - \frac{1}{2} \Delta K - f(x) \cdot \nabla K(t, x) + \frac{1}{2} |\nabla K|^2 + 12 + 2n + 4|f - \nabla K| \leq c_2$  for all  $(t, x) \in [0, T] \times \mathbb{R}^n$ , where  $c_2$  is a constant possibly depending on  $T$ .

(3)  $e^{-\sqrt{1+|x|^2}} [12 + 2n + 4|f - \nabla K|] \leq c_3$  for all  $(t, x) \in [0, T] \times \mathbb{R}^n$ .

Let  $R \geq 1$  and  $u_R$  be the solution of the following DMZ equation on the ball  $B_R$ :

$$(1.9) \quad \begin{cases} \frac{\partial u_R}{\partial t} = \frac{1}{2} \Delta u_R + (-f + \nabla K) \cdot \nabla u_R \\ \quad + \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) u_R, \\ u_R(t, x) = 0 \quad \text{for } (t, x) \in [0, T] \times \partial B_R, \\ u_R(0, x) = \sigma_0(x). \end{cases}$$

Let  $v = u - u_R$ . Then  $v \geq 0$  for all  $(t, x) \in [0, T] \times B_R$  and

$$(1.10) \quad \int_{B_R} \phi v(T, x) \leq \frac{e^{c_2 T} - 1}{c_2} c_3 e^{-R} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x),$$

where  $\phi(x) = e^{\frac{|x|^4}{R^3} - \frac{2|x|^2}{R}} - e^{-R}$ . In particular

$$(1.11) \quad \int_{B_{\frac{R}{2}}} v(T, x) \leq \frac{2(e^{c_2 T} - 1)}{c_2} c_3 e^{-\frac{9}{16}R} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x).$$

Theorem B above says that we can approximate  $u$  by  $u_R$ . The approximation is good if  $R$  is large enough. In fact we have a precise error estimate of this approximation by (1.11).

**THEOREM C.** Let  $\Omega$  be a bounded domain in  $\mathbb{R}^n$ . Let  $F: [0, T] \times \Omega \rightarrow \mathbb{R}^n$  be a family of vector fields  $C^\infty$  in  $x$  and Hölder continuous in  $t$  with exponent  $\alpha$  and let  $J: [0, T] \times \Omega \rightarrow \mathbb{R}$  be a  $C^\infty$  function in  $x$  and Hölder continuous in  $t$  with exponent  $\alpha$  such that the following properties are satisfied:

$$(1.12) \quad |\operatorname{div} F(t, x)| + 2|J(t, x)| + |F(t, x)| \leq c \quad \text{for } (t, x) \in [0, T] \times \Omega,$$

$$(1.13) \quad |F(t, x) - F(\bar{t}, x)| + |\operatorname{div} F(t, x) - \operatorname{div} F(\bar{t}, x)| + |J(t, x) - J(\bar{t}, x)| \leq c_1 |t - \bar{t}|^\alpha \\ \text{for } (t, x), (\bar{t}, x) \in [0, T] \times \Omega.$$

Let  $u(t, x)$  be the solution on  $[0, T] \times \Omega$  of the equation

$$(1.14) \quad \begin{cases} \frac{\partial u}{\partial t}(t, x) = \frac{1}{2} \Delta u(t, x) + F(t, x) \cdot \nabla u(t, x) + J(t, x) u(t, x), \\ u(0, x) = \sigma_0(x), \\ u(t, x)|_{\partial\Omega} = 0. \end{cases}$$

For any  $0 \leq \tau \leq T$ , let  $\mathcal{P}_k = \{0 = \tau_0 < \tau_1 < \tau_2 < \cdots < \tau_k = \tau\}$  be a partition of  $[0, \tau]$ , where  $\tau_i = \frac{i\tau}{k}$ . Let  $u_i(t, x)$  be the solution on  $[\tau_{i-1}, \tau_i] \times \Omega$  of the equation

$$(1.15) \quad \begin{cases} \frac{\partial u_i}{\partial t}(t, x) = \frac{1}{2} \Delta u_i(t, x) + F(\tau_{i-1}, x) \cdot \nabla u_i(t, x) + J(\tau_{i-1}, x) u_i(t, x), \\ u_i(\tau_{i-1}, x) = u_{i-1}(\tau_{i-1}, x), \\ u_i(t, x)|_{\partial\Omega} = 0. \end{cases}$$

Here we use the convention  $u_0(t, x) = \sigma(x)$ . Then the solution  $u(t, x)$  of (1.14) can be computed by means of the solution  $u_i(t, x)$  of (1.15). More specifically,  $u(\tau, x) = \lim_{k \rightarrow \infty} u_k(\tau, x)$  in the  $L^1$  sense on  $\Omega$  and the following estimate holds:

$$(1.16) \quad \int_{\Omega} |u - u_k|(\tau_k, x) \leq \frac{2c_2}{\alpha + 1} \frac{T^{\alpha+1} e^{cT}}{k^\alpha},$$

where

$$(1.17) \quad c_2 = c_1 e^{cT} + c_1 \sqrt{\operatorname{Vol}(\Omega)} e^{c^2 T} \sqrt{2c^2 T \int_{\Omega} u^2(0, x) + \int_{\Omega} |\nabla u(0, x)|^2}.$$

The right-hand side of (1.16) goes to zero as  $k \rightarrow \infty$ .

In case (1.14) and (1.15) are DMZ equations, i.e.,  $F(t, x) = -f(x) + \nabla K$  and  $J(t, x) = -\operatorname{div} f - \frac{1}{2}|h|^2 + \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2$ , by Proposition 2.1 below (which is similar to Proposition 3.1 of [Ya-Ya]),  $u_i(\tau_i, x)$  can be computed by  $\tilde{u}_i(\tau_i, x)$ , where  $\tilde{u}_i(t, x)$  for  $\tau_{i-1} \leq t \leq \tau_i$  satisfies the Kolmogorov equation

(1.18)

$$\begin{cases} \frac{\partial \tilde{u}_i}{\partial t}(t, x) = \frac{1}{2}\Delta \tilde{u}_i(t, x) - \sum_{j=1}^n f_j(x) \frac{\partial \tilde{u}_i}{\partial x_j}(t, x) - \left( \operatorname{div} f(x) + \frac{1}{2} \sum_{j=1}^m h_j^2(x) \right) \tilde{u}_i(t, x), \\ \tilde{u}_i(\tau_{i-1}, x) = \exp \left( \sum_{j=1}^m (y_j(\tau_{i-1}) - y_j(\tau_{i-2})) h_j(x) \right) \tilde{u}_{i-1}(\tau_{i-1}, x). \end{cases}$$

In fact

$$(1.19) \quad u_i(\tau_i, x) = \exp \left( - \sum_{j=1}^m y_j(\tau_{i-1}) h_j(x) \right) \tilde{u}_i(\tau_i, x).$$

Therefore theoretically to solve the DMZ equation in a real time manner, we only need to compute the following Kolmogorov equation off-line:

$$\begin{cases} \frac{\partial \tilde{u}}{\partial t}(t, x) = \frac{1}{2}\Delta \tilde{u}(t, x) - \sum_{j=1}^n f_j(x) \frac{\partial \tilde{u}}{\partial x_j}(t, x) - \left( \operatorname{div} f(x) + \frac{1}{2} \sum_{j=1}^m h_j^2(x) \right) \tilde{u}(t, x), \\ \tilde{u}(0, x) = \phi_i(x), \end{cases}$$

where  $\{\phi_i(x)\}$  is an orthonormal base in  $L^2(\mathbb{R}^n)$ . The only real time computation here is to express arbitrary initial condition  $\phi(x)$  as the linear combination of  $\phi_i(x)$ . But this can be done by means of parallel computation.

The idea of solving the Kolmogorov equation “off-line” for the elements of an orthogonal basis has a substantial history; see, for example, [L-M-R] and the references therein. In the Lototsky–Mikulevicius–Rozovskii [L-M-R] approach, the authors used the Cameron–Martin expansion for the solution of the DMZ equation. Unfortunately, to determine the coefficients of the expansion, they need to consider a system of Kolmogorov-type equations which is a recursive system. The advantage of our method is that we need to deal with only one Kolmogorov equation.

**THEOREM D.** *Let  $u_R$  be the solution of (1.9), the DMZ equation on  $B_R$ . Assume the following:*

- (1)  $f(x)$  and  $h(x)$  have at most polynomial growth.
- (2) For any  $0 \leq t \leq T$ , there exist positive integer  $m$  and positive constants  $c'$  and  $c''$  independent of  $R$  such that the following two inequalities hold on  $\mathbb{R}^n$ :
  - (a)  $\frac{m^2}{2}|x|^{2m-2} - \frac{m}{2}(m+n-2)|x|^{m-2} - m|x|^{m-2}x \cdot (f - \nabla K) - \frac{\Delta K}{2} - \frac{1}{2}|h|^2 - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \geq -c'$ .
  - (b)  $|\frac{m^2|x|^{2m-2}}{2} - \frac{m(m+n-2)}{2}|x|^{m-2} - m|x|^{m-2}(f - \nabla K) \cdot x| \leq \frac{m(m+1)}{2}|x|^{2m-2} + c''$ .
- (3)  $-\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - \sum_{j=1}^n f_j \frac{\partial K}{\partial x_j} + \frac{1}{2}|\nabla K|^2 \leq c_1$  for all  $(t, x) \in [0, T] \times \mathbb{R}^n$ , where  $c_1$  is a constant possibly depending on  $T$ .

Then for any  $R_0 < R$ ,

$$\begin{aligned} & \int_{B_{R_0}} (e^{-|x|^m} - e^{-R_0^m}) u_R(T, x) \\ & \geq e^{-c'T} \int_{B_{R_0}} (e^{-|x|^m} - e^{-R_0^m}) \sigma_0(x) \\ & \quad + \frac{e^{-R_0^m}}{c'} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) (1 - e^{c'T}) \int_{B_R} \sigma_0(x). \end{aligned}$$

In particular, the solution  $u$  of the robust DMZ equation on  $\mathbb{R}^n$  has the estimate

$$\int_{\mathbb{R}^n} e^{-|x|^m} u(T, x) \geq e^{-c'T} \int_{\mathbb{R}^n} e^{-|x|^m} \sigma_0(x).$$

In practical nonlinear filtering computation, it is important to know how much density remains within the given ball. Theorem D provides such a lower estimate. In particular, the solution  $u$  of the DMZ equation in  $\mathbb{R}^n$  obtained by taking  $\lim_{R \rightarrow \infty} u_R$ , where  $u_R$  is the solution of the DMZ equation in the ball  $B_R$ , is a nontrivial solution.

In the appendix, we give a priori estimation of derivatives of the solution of the DMZ equation up to second order. As a consequence we prove the existence of a weak solution of the DMZ equation. The uniqueness of the weak solution is shown in Appendix C.

Existence and uniqueness of solutions to the robust DMZ equation (1.6) have been treated by many well-known authors, including Pardoux [Pa1], [Pa2], Chaleyat-Maurel, Michel, and Pardoux [C-M-P], Rozovskii [Ro], Bensoussan [Be], Fleming and Mitter [Fl-Mi], Sussmann [Su], Michel [Mi], and Baras, Blankenship, and Hopkins [B-B-H]. They all obtained important estimates on the DMZ equation under special conditions. For example, Fleming and Mitter [Fl-Mi] treated the case where  $f$  and  $\nabla f$  are bounded, while Michel [Mi] analyzed regularity properties of solutions to DMZ equations with bounded  $f$  and  $h$ . Pardoux's earlier paper [Pa1] treated the case  $f, h$  bounded using arguments based on coercivity. It also contains many other interesting ideas. Pardoux [Pa2] has also treated nonlinear filtering problems with unbounded coefficients ( $f, h$  have linear growth). Starting with methods somewhat like those used by [Pa3], Baras, Blankenship, and Hopkins also obtained important results on existence, uniqueness, and asymptotic behavior of solutions to a class of DMZ equations with unbounded coefficients. However, they focused on only one spatial dimension and their result cannot cover the linear case. The Sobolev space setup of Appendices B and C in this paper is quite standard in partial differential equations and has been used by many people; see, for example, [Pa1].

The splitting up method has been used extensively by many authors. This technique is like the Trotter product formula from semigroup theory. Hopkins and Wong [Ho-Wo] used the Trotter product formula to study nonlinear filtering. The approximation method proposed for the DMZ equation, that of operator splitting, has a history going back to Bensoussan, Glowinski, and Rascanu [B-G-R1], [B-G-R2]. More recent articles on operator splitting methods in nonlinear filtering are [Gy-Kr], [Na], [It], [It-Ro]. Rates of convergence and “true” numerical schemes are developed in [Fl-Le], [It], and [It-Ro]. As pointed out by Bensoussan, Glowinski, and Rascanu [B-G-R1, section 4.3, p. 1431] the method bears the serious limitation that  $h$  must be bounded. The numerics of the Kushner–Stratonovitch equations were studied by many people. Two highly competitive classes of methods are “particle methods” (see, for example, [D-J-P] and [Cr-Ly]), in which particles move according to the signal dynamics and are weighted, killed, or duplicated according to their likelihood, and “discrete state” approximations (see, for example, [Ku] and [Pa-Ph]). These methods work nicely under the assumption that  $h$  is bounded (cf. [D-J-P, p. 348]).

**2. Some basic results.** In this section, we recall some results from our previous paper. The following proposition plays a fundamental role in our real time solution to the robust DMZ equation (1.6) in a memoryless manner.

PROPOSITION 2.1.  $\tilde{u}(t, x)$  satisfies the Kolmogorov equation

$$(2.1) \quad \frac{\partial \tilde{u}}{\partial t}(t, x) = \frac{1}{2} \Delta \tilde{u}(t, x) - f(x) \cdot \nabla \tilde{u}(t, x) - \left( \operatorname{div} f(x) + \frac{1}{2} \sum_{i=1}^m h_i^2(x) \right) \tilde{u}(t, x)$$

for  $\tau_{\ell-1} \leq t \leq \tau_\ell$  if and only if

$$(2.2) \quad u(t, x) = e^{-\sum_{i=1}^m y_i(\tau_{\ell-1}) h_i(x)} \tilde{u}(t, x)$$

satisfies the robust DMZ equation with observation being frozen at  $y(\tau_{\ell-1})$ :

$$(2.3) \quad \begin{aligned} \frac{\partial u}{\partial t}(t, x) = & \frac{1}{2} \Delta u(t, x) + (-f(x) + \nabla K(\tau_{\ell-1}, x)) \cdot \nabla u(t, x) \\ & + \left( -\operatorname{div} f(x) - \frac{1}{2} |h(x)|^2 + \frac{1}{2} \Delta K(\tau_{\ell-1}, x) \right. \\ & \left. - f(x) \cdot \nabla K(\tau_{\ell-1}, x) + \frac{1}{2} |\nabla K(\tau_{\ell-1}, x)|^2 \right) u(t, x). \end{aligned}$$

*Proof.* Proposition 2.1 is the left-hand version of Proposition 3.1 in [Ya-Ya]. The proof is a straightforward computation.  $\square$

We remark that (2.3) is obtained from the robust DMZ equation by freezing the observation term  $y(t)$  to  $y(\tau_{\ell-1})$ . We shall show that the solution of (2.3) approximates the solution of the robust DMZ equation very well in the  $L^1$  sense.

Suppose that  $u(t, x)$  is the solution of the robust DMZ equation and we want to compute  $u(\tau, x)$ . Let  $\mathcal{P}_k = \{0 = \tau_0 < \tau_1 < \tau_2 < \dots < \tau_k = \tau\}$  be a partition of  $[0, \tau]$ , where  $\tau_i = \frac{i\tau}{k}$ . Let  $u_i(t, x)$  be a solution of the following partial differential equation for  $\tau_{i-1} \leq t \leq \tau_i$ :

$$(2.4) \quad \begin{cases} \frac{\partial u_i}{\partial t}(t, x) = \frac{1}{2} \Delta u_i(t, x) + (-f(x) + \nabla K(\tau_{i-1}, x)) \cdot \nabla u_i(t, x) \\ \quad + \left( -\operatorname{div} f(x) - \frac{1}{2} |h(x)|^2 + \frac{1}{2} \Delta K(\tau_{i-1}, x) \right. \\ \quad \left. - f(x) \cdot \nabla K(\tau_{i-1}, x) + \frac{1}{2} |\nabla K(\tau_{i-1}, x)|^2 \right) u_i(t, x), \\ u_i(\tau_{i-1}, x) = u_{i-1}(\tau_{i-1}, x). \end{cases}$$

In section 4 below we shall show that  $u(\tau, x) = \lim_{k \rightarrow \infty} u_k(\tau_k, x)$  in the  $L^1$  sense. By Proposition 2.1,  $u_1(\tau_1, x)$  can be computed by  $\tilde{u}_1(\tau_1, x)$ , where  $\tilde{u}_1(t, x)$  for  $0 \leq t \leq \tau_1$  satisfies (2.1) with initial condition

$$(2.5) \quad \tilde{u}_1(0, x) = \sigma_0(x).$$

In fact

$$(2.6) \quad u_1(\tau_1, x) = \tilde{u}_1(\tau_1, x).$$

In general Proposition 2.1 tells us that for  $i \geq 2$ ,  $u_i(\tau_i, x)$  can be computed by  $\tilde{u}_i(\tau_i, x)$ , where  $\tilde{u}_i(t, x)$  for  $\tau_{i-1} \leq t \leq \tau_i$  satisfies (2.1) with initial condition

$$(2.7) \quad \tilde{u}_i(\tau_{i-1}, x) = \exp \left[ \sum_{j=1}^m (y_j(\tau_{i-1}) - y_j(\tau_{i-2})) h_j(x) \right] \tilde{u}_{i-1}(\tau_{i-1}, x),$$

where the last initial condition comes from

$$\begin{aligned}
\tilde{u}_i(\tau_{i-1}, x) &= u_i(\tau_{i-1}, x) \exp \left( \sum_{j=1}^m y_j(\tau_{i-1}) h_j(x) \right) \\
&= u_{i-1}(\tau_{i-1}, x) \exp \left( \sum_{j=1}^m y_j(\tau_{i-1}) h_j(x) \right) \\
&= \exp \left( - \sum_{j=1}^m y_j(\tau_{i-2}) h_j(x) \right) \tilde{u}_{i-1}(\tau_{i-1}, x) \exp \left( \sum_{j=1}^m y_j(\tau_{i-1}) h_j(x) \right) \\
&= \exp \left[ \sum_{j=1}^m (y_j(\tau_{i-1}) - y_j(\tau_{i-2})) h_j(x) \right] \tilde{u}_{i-1}(\tau_{i-1}, x).
\end{aligned}$$

In fact,

$$(2.8) \quad u_i(\tau_i, x) = \exp \left( - \sum_{j=1}^m y_j(\tau_{i-1}) h_j(x) \right) \tilde{u}_i(\tau_i, x).$$

**3. Reduction of the problem to the bounded domain case.** In this section, we shall prove that in order to solve the robust DMZ equation (1.6) in  $\mathbb{R}^n$ , it suffices to solve the same equation in a bounded ball  $B_R$  with radius  $R$ . The important points here are that we know how large the  $R$  needs to be and that a precise error estimate is given. These are the essential ingredients for a successful implementation of nonlinear filters.

*Proof of Theorem A.* Let  $\phi$  be a  $C^\infty$  function on  $\mathbb{R}^n$  and  $B_R = \{x \in \mathbb{R}^n : |x| \leq R\}$ .

Let  $u_R$  be the solution of (1.9), the DMZ equation on the ball  $B_R$ :

$$\begin{aligned}
\frac{d}{dt} \int_{B_R} e^\phi u_R &= \frac{1}{2} \int_{B_R} e^\phi \Delta u_R + \int_{B_R} e^\phi (-f + \nabla K) \cdot \nabla u_R \\
&\quad + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) e^\phi u_R \\
&= -\frac{1}{2} \int_{B_R} e^\phi \nabla \phi \cdot \nabla u_R + \frac{1}{2} \int_{\partial B_R} e^\phi \frac{\partial u_R}{\partial \nu} - \int_{B_R} \operatorname{div} [e^\phi (-f + \nabla K)] u_R \\
&\quad + \int_{\partial B_R} e^\phi u_R (-f + \nabla K) \cdot \nu \\
&\quad + \int_{B_R} e^\phi u_R \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \\
&= \frac{1}{2} \int_{B_R} \operatorname{div} [e^\phi \nabla \phi] u_R - \frac{1}{2} \int_{\partial B_R} u_R e^\phi \nabla \phi \cdot \nu + \frac{1}{2} \int_{\partial B_R} e^\phi \frac{\partial u_R}{\partial \nu} \\
&\quad - \int_{B_R} e^\phi \nabla \phi \cdot (-f + \nabla K) u_R - \int_{B_R} e^\phi (-\operatorname{div} f + \Delta K) u_R
\end{aligned}$$

$$\begin{aligned}
& + \int_{\partial B_R} u_R e^\phi (-f + \nabla K) \cdot \nu \\
& + \int_{B_R} e^\phi u_R \left( -\operatorname{div} f - \frac{1}{2}|h|^2 + \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) \\
& = \frac{1}{2} \int_{B_R} e^\phi u_R (\Delta \phi + |\nabla \phi|^2) + \int_{B_R} e^\phi u_R \nabla \phi \cdot (f - \nabla K) \\
& + \int_{B_R} e^\phi u_R \left( -\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) \\
& - \frac{1}{2} \int_{\partial B_R} e^\phi u_R \nabla \phi \cdot \nu + \frac{1}{2} \int_{\partial B_R} e^\phi \frac{\partial u_R}{\partial \nu} + \int_{\partial B_R} e^\phi u_R (-f + \nabla K) \cdot \nu,
\end{aligned}$$

where  $\nu$  is the unit outward normal of  $\partial B_R$ . Choose  $\phi = \sqrt{1+|x|^2}$ . Then  $\phi_i = \frac{x_i}{\sqrt{1+|x|^2}}$ ,  $\phi_{ii} = \frac{1}{\sqrt{1+|x|^2}} - \frac{x_i^2}{(1+|x|^2)^{3/2}}$ . Recall that  $u|_{\partial B_R} = 0$  and  $\frac{\partial u_R}{\partial \nu}|_{\partial B_R} \leq 0$ . It follows that

$$\begin{aligned}
\frac{d}{dt} \int_{B_R} e^\phi u_R & \leq \int_{B_R} e^\phi u_R \left[ -\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right. \\
& \quad \left. + \frac{1}{2}\Delta \phi + \frac{1}{2}|\nabla \phi|^2 + \nabla \phi \cdot (f - \nabla K) \right] \\
& = \int_{B_R} e^\phi u_R \left[ -\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 + \frac{n}{2\sqrt{1+|x|^2}} \right. \\
& \quad \left. - \frac{|x|^2}{2(1+|x|^2)^{3/2}} + \frac{1}{2} \frac{|x|^2}{1+|x|^2} + \frac{x}{\sqrt{1+|x|^2}} (f - \nabla K) \right] \\
& \leq \int_{B_R} e^\phi u_R \left[ -\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 + \frac{n+1}{2} + |f - \nabla K| \right] \\
& \leq \left( c_1 + \frac{n+1}{2} \right) \int_{B_R} e^\phi u_R.
\end{aligned}$$

Hence

$$\int_{B_R} e^\phi u_R(t, x) \leq e^{(c_1 + \frac{n+1}{2})t} \int_{B_R} e^\phi u_R(0, x) \quad \forall t \in [0, T].$$

Let  $R$  go to infinity. We have

$$\int_{\mathbb{R}^n} e^\phi u(t, x) \leq e^{(c_1 + \frac{n+1}{2})t} \int_{\mathbb{R}^n} e^\phi u(0, x) \quad \forall t \in [0, T],$$

which implies

$$\sup_{0 \leq t \leq T} \int_{\mathbb{R}^n} e^\phi u(t, x) \leq e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^\phi u(0, x).$$

In particular

$$\begin{aligned}
e^{\sqrt{1+R^2}} \sup_{0 \leq t \leq T} \int_{|x| \geq R} u(t, x) & \leq \sup_{0 \leq t \leq T} \int_{|x| \geq R} e^\phi u(t, x) \leq \sup_{0 \leq t \leq T} \int_{\mathbb{R}^n} e^\phi u(t, x) \\
& \leq e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^\phi u(0, x).
\end{aligned}$$

This implies

$$\sup_{0 \leq t \leq T} \int_{|x| \geq R} u(t, x) \leq e^{-\sqrt{1+R^2} e^{(c_1 + \frac{n+1}{2})T}} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x). \quad \square$$

Theorem A says that we can choose  $R$  large enough so that  $\sup_{0 \leq t \leq T} \int_{|x| \geq R} u(t, x)$  is arbitrarily small. For numerical calculation, we can restrict the DMZ equation to the ball  $B_R$ . In fact we can prove Theorem B, which states that  $u_R$  is a good approximation of  $u$  when  $R$  is large.

*Proof of Theorem B.* By the maximum principle (cf. Theorem 1, p. 34 in Friedman's book [Fr]), we have  $v \geq 0$  for  $(t, x) \in [0, T] \times B_R$  since  $v|_{\partial B_R} \geq 0$  for  $0 \leq t \leq T$ :

$$\begin{aligned} \frac{d}{dt} \int_{B_R} \psi v &= \int_{B_R} \psi \frac{dv}{dt} \\ &= \frac{1}{2} \int_{B_R} \psi \Delta v + \int_{B_R} \psi (-f + \nabla K) \cdot \nabla v \\ &\quad + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \psi v \\ &= -\frac{1}{2} \int_{B_R} \nabla \psi \cdot \nabla v + \frac{1}{2} \int_{\partial B_R} \psi \frac{\partial v}{\partial \nu} - \int_{B_R} \operatorname{div} [\psi (-f + \nabla K)] v \\ &\quad + \int_{\partial B_R} \psi v (-f + \nabla K) \cdot \nu \\ &\quad + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \psi v \\ &= \frac{1}{2} \int_{B_R} (\Delta \psi) v - \frac{1}{2} \int_{\partial B_R} v \frac{\partial \psi}{\partial \nu} + \frac{1}{2} \int_{\partial B_R} \psi \frac{\partial v}{\partial \nu} - \int_{B_R} \nabla \psi \cdot (-f + \nabla K) v \\ &\quad - \int_{B_R} \psi (-\operatorname{div} f + \Delta K) v + \int_{\partial B_R} \psi v (-f + \nabla K) \cdot \nu \\ &\quad + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \psi v. \end{aligned}$$

Let  $\phi$  be a radial symmetric function such that  $\phi|_{\partial B_R} = R$ ,  $\nabla \phi|_{\partial B_R} = 0$ , and  $\phi$  is increasing with  $|x|$ . Let

$$\psi = e^{-\phi(x)} - e^{-R}.$$

Then  $\psi|_{\partial B_R} = 0$  and  $\nabla \psi|_{\partial B_R} = 0$ . Hence

$$\begin{aligned} \frac{d}{dt} \int_{B_R} \psi v &= \frac{1}{2} \int_{B_R} (\Delta \psi) v - \int_{B_R} \nabla \psi \cdot (-f + \nabla K) v \\ &\quad + \int_{B_R} \left( -\frac{1}{2} |h|^2 - \frac{1}{2} \Delta K - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \psi v \\ &= \frac{1}{2} \int_{B_R} v e^{-\phi} (-\Delta \phi + |\nabla \phi|^2) - \int_{B_R} e^{-\phi} v [\nabla \phi \cdot (f - \nabla K)] \end{aligned}$$

$$\begin{aligned}
 & + \int_{B_R} \left( -\frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) \psi v \\
 & = \int_{B_R} \psi v \left[ -\frac{1}{2}\Delta\phi + \frac{1}{2}|\nabla\phi|^2 - \nabla\phi \cdot (f - \nabla K) \right. \\
 & \quad \left. - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right] \\
 & \quad + e^{-R} \int_{B_R} \left[ \frac{1}{2}(-\Delta\phi + |\nabla\phi|^2) - \nabla\phi \cdot (f - \nabla K) \right] v \\
 & \leq \sup_{B_R} \left[ -\frac{1}{2}\Delta\phi + \frac{1}{2}|\nabla\phi|^2 - \nabla\phi \cdot (f - \nabla K) \right. \\
 & \quad \left. - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right] \cdot \int_{B_R} \psi v \\
 & \quad + e^{-R} \sup_{B_R} \left\{ e^{-\sqrt{1+|x|^2}} \left[ \frac{1}{2}(-\Delta\phi + |\nabla\phi|^2) - \nabla\phi \cdot (f - \nabla K) \right] \right\} \\
 & \quad \times \int_{B_R} e^{\sqrt{1+|x|^2}} v.
 \end{aligned}$$

Observe that  $0 \leq v \leq u$  for  $(t, x) \in [0, T] \times B + R$ . Let

$$\chi(x) = 1 - (1 - x)^2 \quad \text{and} \quad \phi(x) = R\chi\left(\frac{|x|^2}{R^2}\right).$$

Then

$$\begin{aligned}
 & \chi'(x) = 2(1 - x), \quad \chi''(x) = -2, \quad \chi(1) = 1, \quad \chi'(1) = 0, \\
 & \nabla\phi(x) = \frac{2x}{R}\chi'\left(\frac{|x|^2}{R^2}\right), \quad \Delta\phi = \frac{4|x|^2}{R^3}\chi''\left(\frac{|x|^2}{R^2}\right) + \frac{2n}{R}\chi'\left(\frac{|x|^2}{R^2}\right), \\
 & \sup_{B_R} \left[ -\frac{1}{2}\Delta\phi + \frac{1}{2}|\nabla\phi|^2 - \nabla\phi \cdot (f - \nabla K) - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right] \\
 & = \sup_{B_R} \left\{ -\frac{2|x|^2}{R^3}\chi''\left(\frac{|x|^2}{R^2}\right) - \frac{n}{R}\chi'\left(\frac{|x|^2}{R^2}\right) + 2\frac{|x|^2}{R^2} \left[ \chi'\left(\frac{|x|^2}{R^2}\right) \right]^2 \right. \\
 & \quad \left. - \frac{2}{R}\chi'\left(\frac{|x|^2}{R^2}\right) [x \cdot f - x \cdot \nabla K] - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right\} \\
 & \leq \sup_{B_R} \left[ \frac{4|x|^2}{R^3} + \frac{2n}{R} + \frac{8|x|^2}{R} + \frac{4}{R}|x||f - \nabla K| - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right] \\
 & \leq 12 + 2n + 4|x||f - \nabla K| - \frac{1}{2}|h|^2 - \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \\
 & \leq c_2.
 \end{aligned}$$

Similarly

$$\begin{aligned} & \sup_{B_R} \left\{ e^{-\sqrt{1+|x|^2}} \left[ \frac{1}{2}(-\Delta\phi + |\nabla\phi|^2) - \nabla\phi \cdot (f - \nabla K) \right] \right\} \\ & \leq \sup_{B_R} \left\{ e^{-\sqrt{1+|x|^2}} [12 + 2n + 4|x||f - \nabla K|] \right\} \leq c_3. \end{aligned}$$

In view of Theorem A, we have

$$\begin{aligned} \frac{d}{dt} \int_{B_R} \psi v & \leq c_2 \int_{B_R} \psi v + e^{-R} c_3 \int_{B_R} e^{\sqrt{1+|x|^2}} u \\ & \leq c_2 \int_{B_R} \psi v + e^{-R} c_3 e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x), \\ \frac{d}{dt} \left[ e^{-c_2 t} \int_{B_R} \psi v \right] & = e^{-c_2 t} \frac{d}{dt} \int_{B_R} \psi v - c_2 e^{-c_2 t} \int_{B_R} \psi v \\ & \leq c_3 e^{-R} e^{-c_2 t} e^{c_1 + \frac{n+1}{2}T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x). \end{aligned}$$

Recall that  $v(0, x) = 0$  on  $B_R$ . Therefore we have

$$e^{-c_2 T} \int_{B_R} \psi v(T, x) \leq \frac{e^{-c_2 T} - 1}{-c_2} c_3 e^{-R} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x),$$

which implies

$$\int_{B_R} \psi v(T, x) \leq \frac{e^{c_2 T} - 1}{c_2} c_3 e^{-R} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x).$$

Notice that  $\psi(x) = e^{\frac{|x|^4}{R^3} - \frac{2|x|^2}{R}} - e^{-R}$ :

$$\begin{aligned} \int_{B_R} \psi v(T, x) & \geq \int_{B_{\frac{R}{2}}} [e^{\frac{|x|^4}{R^3} - \frac{2|x|^2}{R}} - e^{-R}] v(T, x) \\ & \geq (e^{-\frac{7}{16}R} - e^{-R}) \int_{B_{\frac{R}{2}}} v(T, x) \\ & = e^{-\frac{7}{16}R} (1 - e^{-\frac{9}{16}R}) \int_{B_{\frac{R}{2}}} v(T, x) \\ & \geq \frac{1}{2} e^{-\frac{7}{16}R} \int_{B_{\frac{R}{2}}} v(T, x). \end{aligned}$$

Therefore

$$\int_{B_{\frac{R}{2}}} v(T, x) \leq \frac{2(e^{c_2 T} - 1)}{c_2} c_3 e^{-\frac{9}{16}R} e^{(c_1 + \frac{n+1}{2})T} \int_{\mathbb{R}^n} e^{\sqrt{1+|x|^2}} u(0, x). \quad \square$$

Theorem B above says that if we replace  $u$  by  $u_R$ , then the error is small when  $R$  goes to infinity. In fact (1.11) gives the precise error estimate.

**4.  $L^1$ -convergence.** In this section, we shall show that our algorithm described in section 2 will yield an  $L^1$ -convergence for bounded domains, i.e.,  $u(\tau, x) = \lim_{k \rightarrow \infty} u_k(\tau_k, x)$  in the  $L^1$  sense for bounded domain. We first begin with the following technical lemma.

LEMMA 4.1. *Let  $\Omega$  be a bounded domain in  $\mathbb{R}^n$  and let  $v: [0, T] \times \overline{\Omega} \rightarrow \mathbb{R}$  be a  $C^1$  function. Assume that  $v(t, x) = 0$  for  $(t, x) \in [0, T] \times \partial\Omega$ . Let  $\Omega_t^+ = \{x \in \Omega: v(t, x) \geq 0\}$ . Then*

$$\frac{d}{dt} \int_{\Omega_t^+} v(t, x) = \int_{\Omega_t^+} \frac{dv}{dt}(t, x) \quad \text{for almost all } t \in [0, t].$$

*Proof.*

$$\begin{aligned} \frac{d}{dt} \int_{\Omega_t^+} v(t, x) &= \lim_{\Delta t \rightarrow 0} \frac{\int_{\Omega_{t+\Delta t}^+} v(t + \Delta t, x) - \int_{\Omega_t^+} v(t, x)}{\Delta t} \\ &= \lim_{\Delta t \rightarrow 0} \int_{\Omega_{t+\Delta t}^+} \frac{v(t + \Delta t, x) - v(t, x)}{\Delta t} + \lim_{\Delta t \rightarrow 0} \frac{\int_{\Omega_{t+\Delta t}^+} v(t, x) - \int_{\Omega_t^+} v(t, x)}{\Delta t} \\ &= \int_{\Omega_t^+} \frac{dv}{dt}(t, x) + \lim_{\Delta t \rightarrow 0} \frac{\int_{\Omega_{t+\Delta t}^+ - \Omega_t^+} v(t, x) - \int_{\Omega_t^+ - \Omega_{t+\Delta t}^+} v(t, x)}{\Delta t} \\ &= \int_{\Omega_t^+} \frac{dv}{dt}(t, x) + \lim_{\Delta t \rightarrow 0} \frac{v(t, \xi_1) \text{Vol}(\Omega_{t+\Delta t}^+ - \Omega_t^+)}{\Delta t} \\ &\quad - \lim_{\Delta t \rightarrow 0} \frac{v(t, \xi_2) \text{Vol}(\Omega_t^+ - \Omega_{t+\Delta t}^+)}{\Delta t}, \end{aligned} \tag{4.1}$$

where  $\xi_1 \in \Omega_{t+\Delta t}^+ - \Omega_t^+$  and  $\xi_2 \in \Omega_t^+ - \Omega_{t+\Delta t}^+$ . Clearly we have  $\lim_{\Delta t \rightarrow 0} v(t, \xi_1) = 0 = \lim_{\Delta t \rightarrow 0} v(t, \xi_2)$ . Therefore it remains to prove that

$$\lim_{\Delta t \rightarrow 0} \frac{\text{Vol}(\Omega_{t+\Delta t}^+ - \Omega_t^+)}{\Delta t} \quad \text{and} \quad \lim_{\Delta t \rightarrow 0} \frac{\text{Vol}(\Omega_t^+ - \Omega_{t+\Delta t}^+)}{\Delta t}$$

are bounded for almost all  $t$ .

Let  $w: A \rightarrow \mathbb{R}$  be a Lipschitz function, where  $A \subset \mathbb{R}^n$  is measurable. The coarea formula for Euclidean space, an important tool of geometric measure theory (cf. [Fe], [Ma]), reads as follows:

$$\int_A h(x) |\nabla w(x)| dx = \int_{\mathbb{R}} \int_{w^{-1}(y)} h(x) \mathcal{H}_{|\cdot|}^{n-1}(x) dy, \tag{4.2}$$

where  $\mathcal{H}_{|\cdot|}^{n-1}$  denotes the Hausdorff measure with respect to the Euclidean distance and  $h: A \rightarrow [-\infty, \infty]$  is a measurable function.

Let  $A = \overline{\Omega_t^+ - \Omega_{t+\Delta t}^+} = \{x \in \Omega_t^+: v(t + \Delta t, x) \leq 0\}$ . Let  $L$  be the Lipschitz constant such that

$$|v(t, x) - v(t + \Delta t, x)| \leq L\Delta t \quad \forall x \in \overline{\Omega}. \tag{4.3}$$

Since  $v(t, x) \geq 0$  for  $x \in A$ , we have

$$v(t + \Delta t, x) \geq v(t, x) - L\Delta t \geq -L\Delta t \quad \text{for } x \in A. \tag{4.4}$$

Let  $h(x) = \frac{1}{|\nabla v(t+\Delta t, x)|}$  and  $w(x) = v(t+\Delta t, x)$  in the coarea formula (4.2). We have

$$(4.5) \quad \begin{aligned} \text{Vol}(\Omega_t^+ - \Omega_{t+\Delta t}^+) &= \text{Vol}(A) \\ &= \int_{-L\Delta t}^0 \int_{\{x \in A: v(t+\Delta t, x)=y\}} \frac{1}{|\nabla v(t+\Delta t, x)|} \mathcal{H}_{|\cdot|}^{n-1}(x) dy. \end{aligned}$$

Consider the map  $\Phi: [0, T] \times \overline{\Omega} \rightarrow [0, T] \times \mathbb{R}$  given by  $\Phi(t, x) = (t, v(t, x))$ . By Sard's theorem, the set of critical values of  $\Phi$  has Lebesgue measure zero. Therefore for almost all  $t$ , almost all  $\Delta t$ , and almost all  $y$ ,  $\nabla v(t+\Delta t, x) \neq 0$  for all  $x \in \{x: v(t+\Delta t, x) = y\}$ . It follows that  $\lim_{\Delta t \rightarrow 0} \frac{\text{Vol}(\Omega_t^+ - \Omega_{t+\Delta t}^+)}{\Delta t}$  is bounded for almost all  $t$ . Similarly one can prove that  $\lim_{\Delta t \rightarrow 0} \frac{\text{Vol}(\Omega_{t+\Delta t}^+ - \Omega_t^+)}{\Delta t}$  is bounded for almost all  $t$ .  $\square$

*Remark 4.2.* Lemma 4.1 is not true for all  $t \in [0, T]$ . As we shall see from the following example, this is because  $\lim_{\Delta t \rightarrow 0} \frac{\text{Vol}(\Omega_t^+ - \Omega_{t+\Delta t}^+)}{\Delta t}$  is not necessarily bounded for all  $t$ .

*Example 4.3.* Let  $0 < a < b < c < d < \infty$  and  $\overline{\Omega} = [a, d]$ . Let  $v(t, x) = (x-a)(x-b-\sqrt{t})(x-c-\sqrt{t})(x-d)$  be defined on  $[0, T] \times \overline{\Omega}$ . Then  $\Omega_t^+ = [b+\sqrt{t}, c+\sqrt{t}]$  and  $\Omega_{t+\Delta t} = [b+\sqrt{t+\Delta t}, c+\sqrt{t+\Delta t}]$ , and

$$\lim_{\Delta t \rightarrow 0} \frac{\text{length}(\Omega_t^+ - \Omega_{t+\Delta t}^+)}{\Delta t} = \lim_{\Delta t \rightarrow 0} \frac{\sqrt{t+\Delta t} - \sqrt{t}}{\Delta t} = \frac{1}{2\sqrt{t}},$$

which is finite except at  $t = 0$ .

*Proof of Theorem C.* Observe that (4.14) and (4.15) imply

$$(4.6) \quad \begin{aligned} \frac{\partial u}{\partial t}(t, x) - \frac{\partial u_i}{\partial t}(t, x) &= \frac{1}{2} \Delta(u - u_i)(t, x) + F(\tau_{i-1}, x) \cdot \nabla(u - u_i)(t, x) \\ &\quad + (F(t, x) - F(\tau_{i-1}, x)) \cdot \nabla u(t, x) + J(\tau_{i-1}, x)(u - u_i)(t, x) \\ &\quad + (J(t, x) - J(\tau_{i-1}, x))u(t, x). \end{aligned}$$

Let  $\Omega_t^+ = \{x \in \Omega: u(t, x) - u_i(t, x) \geq 0\}$ .

$$\begin{aligned} \frac{d}{dt} \int_{\Omega_t^+} (u - u_i)(t, x) &= \frac{1}{2} \int_{\Omega_t^+} \Delta(u - u_i)(t, x) + \int_{\Omega_t^+} F(\tau_{i-1}, x) \cdot \nabla(u - u_i)(t, x) \\ &\quad + \int_{\Omega_t^+} (F(t, x) - F(\tau_{i-1}, x)) \cdot \nabla u(t, x) \\ &\quad + \int_{\Omega_t^+} J(\tau_{i-1}, x)(u - u_i)(t, x) \\ &\quad + \int_{\Omega_t^+} (J(t, x) - J(\tau_{i-1}, x))u(t, x) \\ &= \frac{1}{2} \int_{\partial \Omega_t^+} \frac{\partial(u - u_i)}{\partial \nu}(t, x) - \int_{\Omega_t^+} \text{div} F(\tau_{i-1}, x)(u - u_i)(t, x) \\ &\quad + \int_{\Omega_t^+} (F(t, x) - F(\tau_{i-1}, x)) \cdot \nabla u(t, x) \end{aligned}$$

$$\begin{aligned}
 & + \int_{\Omega_t^+} J(\tau_{i-1}, x)(u - u_i)(t, x) \\
 & + \int_{\Omega_t^+} (J(t, x) - J(\tau_{i-1}, x))u(t, x) \\
 & \leq c \int_{\Omega_t^+} (u - u_i)(t, x) + c_1(t - \tau_{i-1})^\alpha \int_{\Omega_t^+} u(t, x) \\
 (4.7) \quad & + c_1(t - \tau_{i-1})^\alpha \int_{\Omega_t^+} |\nabla u(t, x)|.
 \end{aligned}$$

Notice that

$$\begin{aligned}
 \frac{d}{dt} \int_{\Omega} u(t, x) & = \frac{1}{2} \int_{\Omega} \Delta u + \int_{\Omega} F(t, x) \cdot \nabla u(t, x) + \int_{\Omega} J(t, x)u(t, x) \\
 & = \frac{1}{2} \int_{\partial\Omega} \frac{\partial u}{\partial \nu} - \int_{\Omega} \operatorname{div} F(t, x)u(t, x) + \int_{\Omega} J(t, x)u(t, x) \\
 (4.8) \quad & \leq c \int_{\Omega} u(t, x).
 \end{aligned}$$

This implies, for  $0 \leq t \leq T$ ,

$$(4.9) \quad \int_{\Omega} u(t, x) \leq e^{cT} \int_{\Omega} u(0, x).$$

In order to estimate  $\int_{\Omega} |\nabla u(t, x)|^2$ , we need to estimate the  $L^2$  norm of  $u(t, x)$ .

$$\begin{aligned}
 \frac{d}{dt} \int_{\Omega} u^2(t, x) & = 2 \int_{\Omega} u(t, x) \frac{\partial u}{\partial t}(t, x) \\
 (4.10) \quad & = \int_{\Omega} u(t, x) \Delta u(t, x) + 2 \int_{\Omega} u(t, x) F(t, x) \cdot \nabla u(t, x) + 2 \int_{\Omega} J(t, x)u^2(t, x).
 \end{aligned}$$

Observe that

$$\begin{aligned}
 \int_{\Omega} u(t, x) F(t, x) \cdot \nabla u(t, x) & = - \int_{\Omega} u(t, x) \operatorname{div}[u(t, x) F(t, x)] + \int_{\partial\Omega} u^2(t, x) F(t, x) \cdot \nu \\
 & = - \int_{\Omega} u(t, x) \nabla u(t, x) \cdot F(t, x) - \int_{\Omega} u^2(t, x) \operatorname{div} F(t, x).
 \end{aligned}$$

This implies

$$(4.11) \quad \int_{\Omega} u(t, x) F(t, x) \nabla u(t, x) = -\frac{1}{2} \int_{\Omega} u^2(t, x) \operatorname{div} F(t, x).$$

Putting (4.11) into (4.10), we get

$$\begin{aligned}
 \frac{d}{dt} \int_{\Omega} u^2(t, x) & = - \int_{\Omega} |\nabla u(t, x)|^2 + \int_{\partial\Omega} u(t, x) \frac{\partial u}{\partial \nu}(t, x) - \int_{\Omega} u^2(t, x) \operatorname{div} F(t, x) \\
 & \quad + 2 \int_{\Omega} J(t, x)u^2(t, x) \\
 (4.12) \quad & \leq c \int_{\Omega} u^2(t, x).
 \end{aligned}$$

This implies

$$(4.13) \quad \int_{\Omega} u^2(t, x) \leq e^{ct} \int_{\Omega} u^2(0, x) \leq e^{cT} \int_{\Omega} u^2(0, x).$$

Now we are ready to estimate  $\int_{\Omega} |\nabla u(t, x)|^2$ .

$$\begin{aligned}
 \frac{d}{dt} \int_{\Omega} |\nabla u|^2(t, x) &= \int_{\Omega} 2 \nabla \frac{\partial u}{\partial t}(t, x) \cdot \nabla u(t, x) \\
 &= -2 \int_{\Omega} \frac{\partial u}{\partial t}(t, x) \Delta u(t, x) + 2 \int_{\partial \Omega} \frac{\partial u}{\partial t}(t, x) \frac{\partial u}{\partial \nu}(t, x) \\
 &= - \int_{\Omega} (\Delta u(t, x))^2 - 2 \int_{\Omega} F(t, x) \cdot \nabla u(t, x) \Delta u(t, x) \\
 &\quad - 2 \int_{\Omega} J(t, x) u(t, x) \Delta u(t, x) \\
 &\leq - \int_{\Omega} (\Delta u(t, x))^2 + 2 \int_{\Omega} |F(t, x)|^2 |\nabla u(t, x)|^2 + \frac{1}{2} \int_{\Omega} (\Delta u(t, x))^2 \\
 &\quad + 2 \int_{\Omega} J^2(t, x) u^2(t, x) + \frac{1}{2} \int_{\Omega} (\Delta u(t, x))^2 \\
 &\leq 2c^2 \int_{\Omega} |\nabla u(t, x)|^2 + 2c^2 \int_{\Omega} u^2(t, x) \\
 (4.14) \quad &\leq 2c^2 \int_{\Omega} |\nabla u(t, x)|^2 + 2c^2 e^{ct} \int_{\Omega} u^2(0, x).
 \end{aligned}$$

This implies

$$\begin{aligned}
 \frac{d}{dt} \left[ e^{-2c^2 t} \int_{\Omega} |\nabla u(t, x)|^2 \right] &= e^{-2c^2 t} \left[ \frac{d}{dt} \int_{\Omega} |\nabla u(t, x)|^2 - 2c^2 \int_{\Omega} |\nabla u(t, x)|^2 \right] \\
 (4.15) \quad &\leq 2c^2 e^{-(2c^2 - c)t} \int_{\Omega} u^2(0, x) \leq 2c^2 \int_{\Omega} u^2(0, x).
 \end{aligned}$$

Hence

$$e^{-2c^2 t} \int_{\Omega} |\nabla u(t, x)|^2 - \int_{\Omega} |\nabla u(0, x)|^2 \leq 2c^2 t \int_{\Omega} u^2(0, x)$$

and

$$\begin{aligned}
 \int_{\Omega} |\nabla u(t, x)|^2 &\leq 2c^2 t e^{2c^2 t} \int_{\Omega} u^2(0, x) + e^{2c^2 t} \int_{\Omega} |\nabla u(0, x)|^2 \\
 (4.16) \quad &\leq 2c^2 T e^{2c^2 T} \int_{\Omega} u^2(0, x) + e^{2c^2 T} \int_{\Omega} |\nabla u(0, x)|^2.
 \end{aligned}$$

It follows that

$$\begin{aligned}
 \int_{\Omega} |\nabla u(t, x)| &\leq \sqrt{\text{Vol } (\Omega)} \left[ \int_{\Omega} |\nabla u(t, x)|^2 \right]^{\frac{1}{2}} \\
 (4.17) \quad &\leq \sqrt{\text{Vol } (\Omega)} e^{c^2 T} \sqrt{2c^2 T \int_{\Omega} u^2(0, x) + \int_{\Omega} |\nabla u(0, x)|^2}.
 \end{aligned}$$

Putting (4.9), (4.17) into (4.7), we get

$$\begin{aligned}
 \frac{d}{dt} \int_{\Omega_t^+} (u - u_i)(t, x) &\leq c \int_{\Omega_t^+} (u - u_i)(t, x) + c_1(t - \tau_{i-1})^\alpha \int_{\Omega} u(t, x) \\
 &\quad + c_1(t - \tau_{i-1})^\alpha \int_{\Omega} |\nabla u(t, x)| \\
 &\leq c \int_{\Omega_t^+} (u - u_i)(t, x) + c_1(t - \tau_{i-1})^\alpha e^{cT} \int_{\Omega} u(0, x) \\
 &\quad + c_1(t - \tau_{i-1})^\alpha \sqrt{\text{Vol}(\Omega)} e^{c^2 T} \\
 &\quad \sqrt{2c^2 T \int_{\Omega} u^2(0, x) + \int_{\Omega} |\nabla u(0, x)|^2} \\
 (4.18) \quad &= c \int_{\Omega_t^+} (u - u_i)(t, x) + c_2(t - \tau_{i-1})^\alpha,
 \end{aligned}$$

where

$$(4.19) \quad c_2 = c_1 e^{cT} \int_{\Omega} u(0, x) + c_1 \sqrt{\text{Vol}(\Omega)} e^{c^2 T} \sqrt{2c^2 T \int_{\Omega} u^2(0, x) + \int_{\Omega} |\nabla u(0, x)|^2},$$

$$\begin{aligned}
 &\frac{d}{dt} \left[ e^{-c(t-\tau_{i-1})} \int_{\Omega_t^+} (u - u_i)(t, x) \right] \\
 &= e^{-c(t-\tau_{i-1})} \left[ \frac{d}{dt} \int_{\Omega_t^+} (u - u_i)(t, x) - c \int_{\Omega_t^+} (u - u_i)(t, x) \right] \\
 &\leq c_2(t - \tau_{i-1})^\alpha e^{-c(t-\tau_{i-1})}.
 \end{aligned}$$

This implies

$$\begin{aligned}
 &e^{-c(t-\tau_{i-1})} \int_{\Omega_t^+} (u - u_i)(t, x) - \int_{\Omega_{\tau_{i-1}}^+} (u - u_i)(\tau_{i-1}, x) \\
 (4.20) \quad &\leq c_2 \int_{\tau_{i-1}}^t (s - \tau_{i-1})^\alpha e^{-c(s-\tau_{i-1})} \leq c_2 \frac{(t - \tau_{i-1})^{\alpha+1}}{\alpha + 1}.
 \end{aligned}$$

Hence

$$\begin{aligned}
 \int_{\Omega_t^+} (u - u_i)(t, x) &\leq e^{c(t-\tau_{i-1})} \int_{\Omega_{\tau_{i-1}}^+} (u - u_{i-1})(\tau_{i-1}, x) \\
 (4.21) \quad &+ c_2 \frac{(t - \tau_{i-1})^{\alpha+1}}{\alpha + 1} e^{c(t-\tau_{i-1})}.
 \end{aligned}$$

Similarly one can prove that

$$\begin{aligned}
 \int_{\Omega_t^-} (u - u_i)(t, x) &\leq e^{c(t-\tau_{i-1})} \int_{\Omega_{\tau_{i-1}}^-} (u_{i-1} - u)(\tau_{i-1}, x) \\
 (4.22) \quad &+ c_2 \frac{(t - \tau_{i-1})^{\alpha+1}}{\alpha + 1} e^{c(t-\tau_{i-1})}.
 \end{aligned}$$

Consequently, we have

$$\begin{aligned}
 \int_{\Omega} |u - u_i|(t, x) &= \int_{\Omega_t^+} (u - u_i)(t, x) + \int_{\Omega_t^-} (u_i - u)(t, x) \\
 (4.23) \quad &\leq e^{c(t-\tau_{i-1})} \left[ \int_{\Omega} |u - u_{i-1}|(\tau_{i-1}, x) + 2c_2 \frac{t - \tau_{i-1}}{\alpha + 1} \right]^{\alpha+1}.
 \end{aligned}$$

By applying (4.23) inductively, we have the following estimate:

$$\begin{aligned}
 &\int_{\Omega} |u - u_k|(\tau_k, x) \\
 &\leq e^{c(\tau_k - \tau_{k-1})} \left[ \int_{\Omega} |u - u_{k-1}|(\tau_{k-1}, x) + 2c_2 \frac{(\tau_k - \tau_{k-1})^{\alpha+1}}{\alpha + 1} \right] \\
 &\leq e^{c(\tau_k - \tau_{k-1})} e^{c(\tau_{k-1} - \tau_{k-2})} \left[ \int_{\Omega} |u - u_{k-2}|(\tau_{k-2}, x) + 2c_2 \frac{(\tau_{k-1} - \tau_{k-2})^{\alpha+1}}{\alpha + 1} \right] \\
 &\quad + e^{c(\tau_k - \tau_{k-1})} 2c_2 \frac{(\tau_k - \tau_{k-1})^{\alpha+1}}{\alpha + 1} \\
 &= e^{c(\tau_k - \tau_{k-2})} \int_{\Omega} |u - u_{k-2}|(\tau_{k-2}, x) + \frac{2c_2}{\alpha + 1} [(\tau_{k-1} - \tau_{k-2})^{\alpha+1} e^{c(\tau_k - \tau_{k-2})} \\
 &\quad + (\tau_k - \tau_{k-1})^{\alpha+1} e^{c(\tau_k - \tau_{k-1})}] \\
 &\leq e^{c(\tau_k - \tau_{k-i})} \int_{\Omega} |u - u_{k-i}|(\tau_{k-i}, x) \\
 &\quad + \frac{2c_2}{\alpha + 1} [(\tau_k - \tau_{k-1})^{\alpha+1} e^{c(\tau_k - \tau_{k-1})} + (\tau_{k-1} - \tau_{k-2})^{\alpha+1} e^{c(\tau_k - \tau_{k-2})} \\
 &\quad + \cdots + (\tau_{k-i+1} - \tau_{k-i})^{\alpha+1} e^{c(\tau_k - \tau_{k-i})}] \\
 &\leq e^{cT} \int_{\Omega} |u - u_0|(0, x) + \frac{2c_2}{\alpha + 1} [(\tau_k - \tau_{k-1})^{\alpha+1} e^{c(\tau_k - \tau_{k-1})} \\
 &\quad + (\tau_{k-1} - \tau_{k-2})^{\alpha+1} e^{c(\tau_k - \tau_{k-2})} + \cdots + (\tau_1 - \tau_0)^{\alpha+1} e^{c(\tau_k - \tau_0)}] \\
 &= \frac{2c_2}{\alpha + 1} \frac{T^{\alpha+1}}{k^{\alpha+1}} [e^{c\frac{T}{k}} + e^{c\frac{2T}{k}} + \cdots + e^{c\frac{kT}{k}}] \\
 (4.24) \quad &\leq \frac{2c_2}{\alpha + 1} \frac{T^{\alpha+1} e^{cT}}{k^{\alpha}},
 \end{aligned}$$

which goes to zero as  $k \rightarrow \infty$ .  $\square$

**5. Lower estimate of density function.** In practical nonlinear filtering computation, it is important to know how much density remains within a given ball. In this section, we shall provide such a lower estimate. In particular, the solution  $u$  of the DMZ equation in  $\mathbb{R}^n$  obtained by taking  $\lim_{R \rightarrow \infty} u_R$ , where  $u_R$  is the solution of the DMZ equation in the ball  $B_R$ , is a nontrivial solution.

*Proof of Theorem D.* Let  $\phi = e^{-\rho(x)} - e^{-\rho(R_0)}$ , where  $\rho$  is an increasing function of  $|x|$ . Observe that  $\phi \geq 0$  for  $x \in B_{R_0}$ ,  $\phi = 0$  on  $\partial B_{R_0}$ , and  $\frac{\partial \phi}{\partial \nu}|_{\partial B_{R_0}} \leq 0$ , where  $\nu$  is

the outward normal of  $\partial B_{R_0}$ .

$$\begin{aligned}
\frac{d}{dt} \int_{B_{R_0}} \phi u_R &= \frac{1}{2} \int_{B_{R_0}} \phi \Delta u_R + \int_{B_{R_0}} \phi (-f + \nabla K) \cdot \nabla u_R \\
&\quad + \int_{B_{R_0}} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{\Delta K}{2} - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \phi u_R \\
&= \frac{1}{2} \int_{B_{R_0}} u_R \Delta \phi - \frac{1}{2} \int_{\partial B_{R_0}} \frac{\partial \phi}{\partial \nu} u_R + \frac{1}{2} \int_{\partial B_{R_0}} \phi \frac{\partial u_R}{\partial \nu} \\
&\quad - \int_{B_{R_0}} u_R \operatorname{div} [\phi (-f + \nabla K)] + \int_{\partial B_{R_0}} \phi u_R (-f + \nabla K) \cdot \nu \\
&\quad + \int_{B_{R_0}} \left( -\operatorname{div} f - \frac{1}{2} |h|^2 + \frac{\Delta K}{2} - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \phi u_R \\
&\geq \frac{1}{2} \int_{B_{R_0}} u_R \Delta \phi + \int_{B_{R_0}} u_R \nabla \phi \cdot (f - \nabla K) \\
&\quad + \int_{B_{R_0}} \left( -\frac{\Delta K}{2} - \frac{1}{2} |h|^2 - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \phi u_R.
\end{aligned}$$

Notice that  $\nabla \phi = -e^{-\rho(x)} \nabla \rho$  and  $\Delta \phi = e^{-\rho(x)} (|\nabla \rho|^2 - \Delta \rho)$ . Hence

$$\begin{aligned}
\frac{d}{dt} \int_{B_{R_0}} \phi u_R &\geq \int_{B_{R_0}} u_R e^{-\rho(x)} \left[ -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) \right] \\
&\quad + \int_{B_{R_0}} \left( -\frac{\Delta K}{2} - \frac{1}{2} |h|^2 - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right) \phi u_R.
\end{aligned}$$

Let  $r = |x|$ . We have

$$\nabla \rho = \frac{\rho'(\gamma)}{r} x \quad \text{and} \quad \Delta \rho = \rho''(r) + \rho'(r) \frac{n-1}{r}.$$

Hence

$$\begin{aligned}
\frac{d}{dt} \int_{B_{R_0}} \phi u_R &\geq \int_{B_{R_0}} u_R e^{-\rho(R_0)} \left[ -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) \right] \\
&\quad + \int_{B_{R_0}} \left[ -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) \right. \\
&\quad \quad \left. - \frac{\Delta K}{2} - \frac{1}{2} |h|^2 - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right] \phi u_R \\
&= e^{-\rho(R_0)} \int_{B_{R_0}} \left[ \frac{\rho'^2}{2} - \frac{\rho''}{2} - \frac{n-1}{2r} \rho' - \rho' (f - \nabla K) \cdot \frac{x}{r} \right] u_R \\
&\quad + \int_{B_{R_0}} \left[ -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) \right. \\
&\quad \quad \left. - \frac{\Delta K}{2} - \frac{1}{2} |h|^2 - f \cdot \nabla K + \frac{1}{2} |\nabla K|^2 \right] \phi u_R.
\end{aligned} \tag{5.1}$$

We want to choose  $\rho$  such that

$$e^{-\rho(R_0)} \left| \int_{B_{R_0}} \left[ \frac{\rho^{12}}{2} - \frac{\rho''}{2} - \frac{n-1}{2r} \rho' - \rho'(f - \nabla K) \cdot \frac{x}{r} \right] u_R \right| \leq \epsilon(R_0),$$

where  $\epsilon(R_0)$  is small and will be determined later. Then (5.1) implies

$$(5.2) \quad \begin{aligned} \frac{d}{dt} \int_{B_{R_0}} \phi u_R \geq & -\epsilon(R_0) + \int_{B_{R_0}} \left[ -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) \right. \\ & \left. - \frac{\Delta K}{2} - \frac{1}{2}|h|^2 - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right] \phi u_R. \end{aligned}$$

We now take  $\rho = |x|^m$ . Then

$$\begin{aligned} \Delta \rho &= \rho''(r) + \rho'(r) \frac{n-1}{r} = m(m+n-2)r^{m-2}, \\ |\nabla \rho|^2 &= (\rho'(r))^2 = m^2 r^{2m-2}. \end{aligned}$$

Since  $f$  and  $h$  are of polynomial growth, we can choose a positive integer  $m$  large enough such that

$$\begin{aligned} & -\frac{\Delta \rho}{2} + \frac{|\nabla \rho|^2}{2} - \nabla \rho \cdot (f - \nabla K) - \frac{\Delta K}{2} - \frac{1}{2}|h|^2 - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \\ &= -\frac{1}{2}m(m+n-2)r^{m-2} + \frac{1}{2}m^2 r^{2m-2} \\ &\quad - \frac{\rho'(r)}{r} x \cdot (f - \nabla K) - \frac{\Delta K}{2} - \frac{1}{2}|h|^2 - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \\ &\leq -c' \quad \text{on } \mathbb{R}^n, \end{aligned}$$

where  $c'$  is a positive constant independent of  $R$  and  $R_0$ . Hence

$$(5.3) \quad \begin{aligned} \frac{d}{dt} \int_{B_{R_0}} \phi u_R &\geq -\epsilon(R_0) - c' \int_{B_{R_0}} \phi u_R \\ &\Rightarrow \frac{d}{dt} \left[ e^{c't} \int_{B_{R_0}} \phi u_R \right] \geq -\epsilon(R_0) e^{c't} \\ &\Rightarrow e^{c'T} \int_{B_{R_0}} \phi u_R(T, x) - \int_{B_{R_0}} \phi u_R(0, x) \geq \frac{\epsilon(R_0)}{c'} (1 - e^{c'T}). \end{aligned}$$

We are now ready to estimate  $\epsilon(R_0)$ . Observe that  $\frac{\partial u_R}{\partial \nu} \leq 0$  on  $\partial B_R$ , where  $\nu$  is the outward normal of  $\partial B_R$ .

$$\begin{aligned} \frac{d}{dt} \int_{B_R} u_R &= \frac{1}{2} \int_{B_R} \Delta u_R + \int_{B_R} (-f + \nabla K) \cdot \nabla u_R \\ &\quad + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2}|h|^2 + \frac{1}{2}\Delta K - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) u_R \\ &= \frac{1}{2} \int_{\partial B_R} \frac{\partial u_R}{\partial \nu} - \int_{B_R} u_R \operatorname{div}(-f + \nabla K) + \int_{\partial B_R} u_R (-f + \nabla K) \cdot \nu \end{aligned}$$

$$\begin{aligned}
 & + \int_{B_R} \left( -\operatorname{div} f - \frac{1}{2}|h|^2 + \frac{\Delta K}{2} - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) u_R \\
 & \leq \int_{B_R} \left( -\frac{1}{2}|h|^2 - \frac{\Delta K}{2} - f \cdot \nabla K + \frac{1}{2}|\nabla K|^2 \right) u_R \leq c_1 \int_{B_R} u_R.
 \end{aligned}$$

Hence

$$(5.4) \quad \int_{B_R} u_R(t, x) \leq e^{c_1 t} \int_{B_R} u_R(0, x), \quad 0 \leq t \leq T.$$

In order to estimate  $\epsilon(R_0)$ , we need to determine the upper bound of

$$e^{-\rho(R_0)} \left| \int_{B_{R_0}} \left[ \frac{\rho'^2}{2} - \frac{\rho''}{2} - \frac{n-1}{2r} \rho' - \rho'(f - \nabla K) \cdot \frac{x}{r} \right] u_R \right|.$$

Recall that  $\rho = r^m$ . Then for  $m$  large enough,

$$\begin{aligned}
 & \left| \frac{\rho'^2}{2} - \frac{\rho''}{2} - \frac{n-1}{2r} \rho' - \rho'(f - \nabla K) \cdot \frac{x}{r} \right| \\
 & = \left| \frac{m^2 r^{2m-2}}{2} - \frac{m(m+n-2)}{2} r^{m-2} - m r^{m-2} (f - \nabla K) \cdot x \right| \\
 & \leq \frac{m(m+1)}{2} r^{2m-2} + c'',
 \end{aligned}$$

where  $c''$  is independent of  $R$  and  $R_0$ . Therefore

$$\begin{aligned}
 & e^{-\rho(R_0)} \left| \int_{B_{R_0}} \left[ \frac{\rho'^2}{2} - \frac{\rho''}{2} - \frac{n-1}{2r} \rho' - \rho'(f - \nabla K) \cdot \frac{x}{r} \right] u_R(t, x) \right| \\
 & \leq e^{-R_0^m} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) \int_{B_{R_0}} u_R(t, x) \\
 & \leq e^{c'T - R_0^m} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) \int_{B_R} u_R(0, x),
 \end{aligned}$$

by (5.4)

and we can set

$$\epsilon(R_0) = e^{c'T - R_0^m} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) \int_{B_R} u_R(0, x).$$

In view of (5.3), we have

$$\begin{aligned}
 & e^{c'T} \int_{B_{R_0}} \phi u_R(T, x) - \int_{B_{R_0}} \phi u_R(0, x) \\
 & \geq \frac{e^{c'T - R_0^m}}{c'} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) (1 - e^{c'T}) \int_{B_R} u_R(0, x),
 \end{aligned}$$

which implies

$$\begin{aligned}
 & \int_{B_{R_0}} \phi u_R(T, x) \geq e^{-c'T} \int_{B_{R_0}} \phi u_R(0, x) \\
 & + \frac{e^{-R_0^m}}{c'} \left( \frac{m(m+1)}{2} R_0^{2m-2} + c'' \right) (1 - e^{c'T}) \int_{B_R} u_R(0, x).
 \end{aligned} \tag{5.5}$$

Observe that the second term on the right-hand side of (5.5) tends to zero as  $R_0 \rightarrow \infty$ . Therefore we have

$$\int_{\mathbb{R}^n} e^{-|x|^m} u(T, x) \geq e^{-c'T} \int_{\mathbb{R}^n} e^{-|x|^m} u(0, x). \quad \square$$

**Appendix A. A priori estimation of derivatives up to second order.** In this section, we shall give a priori estimation of zero, first, and second derivatives of the solution of the robust DMZ equation on  $[0, T] \times B_R$ .

**THEOREM A.1.** *Consider the robust DMZ equation (1.9) on  $[0, T] \times B_R$ , where  $B_R = \{x \in \mathbb{R}^n : |x| \leq R\}$  is a ball of radius  $R$ . Let  $C_1 = \max_{0 \leq t \leq T} [\sum_{i=1}^m |y_i(t)|^2]^{\frac{1}{2}}$  be the smallest constant such that*

$$(A.1) \quad |\nabla K(t, x)| \leq C_1 |\nabla h(x)| \quad \text{for } (t, x) \in [0, T] \times B_R,$$

where  $|\nabla h|^2 = \sum_{i=1}^m |\nabla h_i(x)|^2$ .

Suppose that there exists a constant  $C > 0$  such that for any  $r \geq 0$

$$(A.2) \quad \min_{|x|=r} \frac{|h|^2 + \operatorname{div} f + C}{\sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C + |f|}} - C_1 \max_{|x|=r} |\nabla h| \geq 0.$$

Let  $g(x)$  be a positive radial symmetric function on  $\mathbb{R}^n$  (i.e.,  $g = g(r)$ , where  $r = |x| = (\sum_{i=1}^n x_i^2)^{\frac{1}{2}}$ ) such that

$$(A.3) \quad |g'(r)| \leq \min_{|x|=r} \frac{|h|^2 + \operatorname{div} f + C}{\sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C + |f|}} - C_1 \max_{|x|=r} |\nabla h|.$$

Then, for  $0 \leq t \leq T$ ,

$$(A.4) \quad \int_{B_R} e^{2g} u_R^2(t, x) \leq e^{ct} \int_{B_R} e^{2g} \sigma^2(x).$$

*Proof.* Let  $\rho$  be any smooth function on  $\mathbb{R} \times \mathbb{R}^n$ . Then

$$\begin{aligned} \frac{d}{dt} \left( \frac{1}{2} \int_{B_R} \rho^2 u_R^2 \right) &= \int_{B_R} \rho \rho_t u_R^2 + \int_{B_R} \rho^2 u_R \frac{\partial u_R}{\partial t} \\ &= \int_{B_R} \rho \rho_t u_R^2 + \int_{B_R} \frac{1}{2} \rho^2 u_R \Delta u_R - \int_{B_R} \rho^2 u_R (f - \nabla K) \cdot \nabla u_R \\ &\quad - \int_{B_R} \rho^2 u_R^2 \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] \\ &= \int_{B_R} \rho \rho_t u_R^2 - \int_{B_R} \rho u_R \nabla \rho \cdot \nabla u_R - \frac{1}{2} \int_{B_R} \rho^2 |\nabla u_R|^2 \\ &\quad + \int_{B_R} \rho u_R^2 \nabla \rho \cdot (f - \nabla K) + \frac{1}{2} \int_{B_R} \rho^2 (\operatorname{div} f - \nabla K) u_R^2 \\ &\quad - \int_{B_R} \rho^2 u_R^2 \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] \\ &\leq \int_{B_R} \rho \rho_t u_R^2 + \frac{1}{2} \int_{B_R} |\nabla \rho|^2 u_R^2 - \int_{B_R} \rho^2 u_R^2 \left[ \frac{1}{2} |h|^2 + \frac{1}{2} \operatorname{div} f \right. \\ (A.5) \quad &\quad \left. + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 - \sum_{i=1}^n \nabla(\log \rho) \cdot (f - \nabla K) \right]. \end{aligned}$$

If we set  $\rho = e^g$ , then we get

$$\begin{aligned}
 & \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} \rho^2 u_R^2 \right] \\
 & \leq \int_{B_R} \left[ g_t + \frac{|\nabla g|^2}{2} - \frac{1}{2} |h|^2 - \frac{1}{2} \operatorname{div} f - f \cdot \nabla K \right. \\
 & \quad \left. + \frac{1}{2} |\nabla K|^2 + \nabla g \cdot (f - \nabla K) \right] \rho^2 u_R^2 \\
 & = \int_{B_R} \left[ g_t + \frac{|\nabla g|^2}{2} + \frac{1}{2} |f - \nabla K|^2 - \frac{1}{2} |f|^2 \right. \\
 & \quad \left. - \frac{1}{2} |h|^2 - \frac{1}{2} \operatorname{div} f + \nabla g \cdot (f - \nabla K) \right] g^2 u_R^2 \\
 (A.6) \quad & = \int_{B_R} \left[ g_t + \frac{1}{2} |\nabla g + f - \nabla K|^2 - \frac{1}{2} |f|^2 - \frac{1}{2} |h|^2 - \frac{1}{2} \operatorname{div} f \right] \rho^2 u_R^2.
 \end{aligned}$$

We shall choose  $g$  to be independent of  $t$  and a constant  $C > 0$  so that

$$(A.7) \quad |\nabla g + f - \nabla K| \leq \sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C}.$$

Notice that (A.6) and (A.7) imply

$$(A.8) \quad \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} \rho^2 u_R^2 \right] \leq C \int_{B_R} \frac{1}{2} \rho^2 u_R^2.$$

Inequality (A.7) can be achieved if we have

$$\begin{aligned}
 (A.9) \quad |\nabla g| & \leq \sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C} - |f| - |\nabla K| \\
 & = \frac{|h|^2 + \operatorname{div} f + C}{\sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C} + |f|} - |\nabla K|.
 \end{aligned}$$

Notice that, for  $0 \leq t \leq T$ ,

$$\begin{aligned}
 |\nabla K(t, x)| & = \left| \sum_{i=1}^m y_i(t) \nabla h_i \right| \leq \sum_{i=1}^m |y_i(t)| |\nabla h_i(x)| \\
 & \leq \left( \sum_{i=1}^m |y_i(t)|^2 \right)^{\frac{1}{2}} \left( \sum_{i=1}^m |\nabla h_i(x)|^2 \right)^{\frac{1}{2}}.
 \end{aligned}$$

Let  $C_1 = \max_{0 \leq t \leq T} \left( \sum_{i=1}^m |y_i(t)|^2 \right)^{\frac{1}{2}}$ . Then we have

$$(A.10) \quad |\nabla K(t, x)| \leq C_1 |\nabla h(x)|.$$

Now we shall choose  $g$  to be radial symmetric so that

$$(A.11) \quad |g'(r)| = |\nabla g| \leq \min_{|x|=r} \frac{|h|^2 + \operatorname{div} f + C}{\sqrt{|f|^2 + |h|^2 + \operatorname{div} f + C} + |f|} - C_1 \max_{|x|=r} |\nabla h|.$$

Inequality (A.9) implies

$$(A.12) \quad \int_{B_R} e^{2g} u_R^2(t, x) \leq e^{ct} \int_{B_R} e^{2g} \sigma(x). \quad \square$$

*Remark A.2.* Notice that from (A.11), if  $h$  grows fast, then we can allow  $g$  to grow fast.

We next give a priori estimation of the first and second derivatives of the solution of the robust DMZ equation on  $[0, T] \times B_R$ . We first observe that for estimation of second derivatives it is sufficient to estimate the Laplacian of the solution.

**LEMMA A.3.** *Let  $\rho$  be a smooth function with compact support in  $B_R$ . Let  $u_R$  be the solution of (1.9). Then*

$$(A.13) \quad \int_{B_R} \sum_{i,j=1}^n \rho^2 (u_R)_{ji}^2 \leq 4 \int_{B_R} \rho^2 (\Delta u_R)^2 + 6 \sup |\nabla \rho|^2 \int_{B_R} |\nabla u_R|^2.$$

*Proof.*

$$\begin{aligned} \int_{B_R} \rho^2 (\Delta u_R)^2 &= - \int_{B_R} 2\rho (\nabla \rho \cdot \nabla u_R) \Delta u_R - \int_{B_R} \rho^2 \nabla (\Delta u_R) \cdot \nabla u_R \\ &= - \int_{B_R} 2\rho \Delta u_R (\nabla u_R \cdot \nabla \rho) - \int_{B_R} \rho^2 \sum_{i,j=1}^n (u_R)_{jji} (u_R)_i \\ &= - \int_{B_R} 2\rho \Delta u_R (\nabla u_R \cdot \nabla \rho) \\ (A.14) \quad &+ \sum_{i,j=1}^n \int_{B_R} 2\rho \rho_j (u_R)_{ji} u_i + \sum_{i,j=1}^n \int_{B_R} \rho^2 (u_R)_{ji}^2. \end{aligned}$$

By the Schwartz inequality, we have

$$\begin{aligned} \int_{B_R} 2\rho \Delta u_R (\nabla u_R \cdot \nabla \rho) &\leq \int_{B_R} 2\rho \Delta u_R |\nabla u_R| |\nabla \rho| \\ (A.15) \quad &\leq \int_{B_R} \rho^2 (\Delta u_R)^2 + \int_{B_R} |\nabla u_R|^2 |\nabla \rho|^2 \end{aligned}$$

$$(A.16) \quad \sum_{i,j=1}^n \int_{B_R} 2\rho \rho_j (u_R)_{ji} (u_R)_i \leq \sum_{i,j=1}^n \int_{B_R} \left[ \frac{1}{2} \rho^2 (u_R)_{ji}^2 + 2\rho_j^2 (u_R)_i^2 \right].$$

Inequalities (A.14), (A.15), and (A.16) imply

$$\begin{aligned} \int_{B_R} \rho^2 (\Delta u_R)^2 &\geq - \int_{B_R} \rho^2 (\Delta u_R)^2 - \int_{B_R} |\nabla u_R|^2 |\nabla \rho|^2 \\ &\quad - \frac{1}{2} \int_{B_R} \sum_{i,j=1}^n \rho^2 (u_R)_{ji}^2 - 2 \sum_{i,j=1}^n \int_{B_R} \rho_j^2 u_i^2 + \sum_{i,j=1}^n \int_{B_R} \rho^2 (u_{ji})^2 \\ &= - \int_{B_R} \rho^2 (\Delta u_R)^2 - \int_{B_R} |\nabla u_R|^2 |\nabla \rho|^2 - 2 \int_{B_R} |\nabla \rho|^2 |\nabla u_R|^2 \\ &\quad + \frac{1}{2} \int_{B_R} \sum_{i,j=1}^n \rho^2 (u_R)_{ji}^2, \end{aligned}$$

which is equivalent to

$$\frac{1}{2} \int_{B_R} \sum_{i,j=1}^n \rho^2(u_R)_{ji}^2 \leq 2 \int_{B_R} \rho^2(\Delta u_R)^2 + 3 \int_{B_R} |\nabla \rho|^2 |\nabla u_R|^2.$$

Hence

$$\int_{B_R} \sum_{i,j=1}^n \rho^2(u_R)_{ji}^2 \leq 4 \int_{B_R} \rho^2(\Delta u_R)^2 + 6 \sup |\nabla \rho|^2 \int_{B_R} |\nabla u_R|^2. \quad \square$$

Now we are ready to give a priori estimation of the first and second derivatives of the solution of the robust DMZ equation on  $[0, T] \times B_R$ .

**THEOREM A.4.** *Consider the robust DMZ equation (1.9) on  $[0, T] \times B_R$ , where  $B_R = \{x \in \mathbb{R}^n : |x| < R\}$  is a ball of radius  $R$ . Assume that*

$$(A.17) \quad \sqrt{\frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 + \frac{C}{2}} - |f| - |\nabla K| \geq 0,$$

where  $C$  is the constant in Theorem A.1. Choose a nonnegative function  $\tilde{g}$  so that

$$(A.18) \quad |\nabla \tilde{g}| \leq \sqrt{\frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 + \frac{C}{2}} - |f| - |\nabla K|$$

and

$$(A.19) \quad e^{2\tilde{g}} \left| \nabla \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \right|^2 \leq e^{2g},$$

where  $g$  is chosen as in Theorem A.1. Then

$$(A.20) \quad \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2(T, x) + \frac{1}{2} \int_0^T \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2(t, x) \\ \leq \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2(0, x) + T \int_{B_R} e^{2g} \sigma^2(x).$$

*Proof.* Recall that  $\frac{\partial u_R}{\partial t} \Big|_{\partial B_R} = 0$ . We have

$$\begin{aligned} & \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] \\ &= \int_{B_R} e^{2\tilde{g}} \nabla u_R \cdot \nabla \frac{\partial u_R}{\partial t} \\ &= \int_{B_R} e^{2\tilde{g}} (-2 \nabla u_R \cdot \nabla g - \Delta u_R) \frac{\partial u_R}{\partial t} \\ &= \int_{B_R} e^{2\tilde{g}} (-2 \nabla u_R \cdot \nabla \tilde{g} - \Delta u_R) \left[ \frac{1}{2} \Delta u_R - (f - \nabla K) \cdot \nabla u_R \right. \\ & \quad \left. - \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) u_R \right] \end{aligned}$$

$$\begin{aligned}
&= \int_{B_R} e^{2\tilde{g}} \left\{ -\frac{1}{2}(\Delta u_R)^2 + \left[ -\nabla u_R \cdot \nabla \tilde{g} + (f - \nabla K) \cdot \nabla u_R \right] \Delta u_R \right. \\
&\quad + 2(\nabla u_R \cdot \nabla \tilde{g})(f - \nabla K) \cdot \nabla u_R \\
&\quad + u_R \Delta u_R \left( -\frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \\
&\quad \left. + 2u_R \nabla u_R \cdot \nabla \tilde{g} \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \right\}.
\end{aligned}$$

This implies

$$\begin{aligned}
&\frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] + \frac{1}{4} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2 \\
&= \int_{B_R} e^{2\tilde{g}} \left\{ -\frac{1}{4} \left[ (\Delta u_R)^2 - 4 \left( -\nabla u_R \cdot \nabla \tilde{g} + (f - \nabla K) \cdot \nabla u_R \right) \Delta u_R \right] \right. \\
&\quad + 2(\nabla u_R \cdot \nabla \tilde{g})(f - \nabla K) \cdot \nabla u_R \\
&\quad + u_R \Delta u_R \left( -\frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \\
&\quad \left. + 2u_R \nabla u_R \cdot \nabla \tilde{g} \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \right\} \\
&= \int_{B_R} e^{2\tilde{g}} \left\{ -\frac{1}{4} \left[ \Delta u_R + 2\nabla u_R \cdot \nabla \tilde{g} - 2(f - \nabla K) \cdot \nabla u_R \right]^2 + \frac{1}{4} [2\nabla u_R \cdot \nabla \tilde{g} \right. \\
&\quad - 2(f - \nabla K) \cdot \nabla u_R]^2 + 2(\nabla u_R \cdot \nabla \tilde{g})(f - \nabla K) \cdot \nabla u_R \\
&\quad + u_R \Delta u_R \left( -\frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \\
&\quad \left. + 2u_R (\nabla u_R \cdot \nabla \tilde{g}) \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \right\}.
\end{aligned} \tag{A.21}$$

Notice that

$$\begin{aligned}
&\frac{1}{4} \left[ 2\nabla u_R \cdot \nabla \tilde{g} - 2(f - \nabla K) \cdot \nabla u_R \right]^2 + 2(\nabla u_R \cdot \nabla \tilde{g}) \left[ (f - \nabla K) \cdot \nabla u_R \right] \\
&= \left[ \nabla u_R \cdot \nabla \tilde{g} - (f - \nabla K) \cdot \nabla u_R \right]^2 + 2(\nabla u_R \cdot \nabla \tilde{g}) \left[ (f - \nabla K) \cdot \nabla u_R \right] \\
&= \left[ \nabla u_R \cdot (\nabla \tilde{g} + f - \nabla K) \right]^2
\end{aligned} \tag{A.22}$$

and

$$\begin{aligned}
&\int_{B_R} e^{2\tilde{g}} u_R \Delta u_R \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \\
&= - \int_{B_R} e^{2\tilde{g}} \left[ 2u_R \nabla u_R \cdot \nabla \tilde{g} \left( \frac{1}{2}|h|^2 + \operatorname{div} f - \frac{1}{2}\Delta K + f \cdot \nabla K - \frac{1}{2}|\nabla K|^2 \right) \right]
\end{aligned}$$

$$\begin{aligned}
 & - \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) \\
 (A.23) \quad & - \int_{B_R} e^{2\tilde{g}} u_R \nabla u_R \cdot \nabla \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right).
 \end{aligned}$$

Putting (A.22), (A.23) in (A.21), we get

$$\begin{aligned}
 & \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] + \frac{1}{4} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2 \\
 & \leq \int_{B_R} e^{2\tilde{g}} |u_R|^2 |\nabla \tilde{g} + f - \nabla K|^2 \\
 & \quad - \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) \\
 (A.24) \quad & - \int_{B_R} e^{2\tilde{g}} u_R \nabla u_R \cdot \nabla \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right).
 \end{aligned}$$

As before, we look for  $\tilde{g}$  so that

$$|\nabla \tilde{g} + f - \nabla K| \leq \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 + \frac{C}{2} \right)^{\frac{1}{2}}.$$

Hence it suffices to set  $\tilde{g}$  so that

$$|\nabla \tilde{g}| \leq \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 + \frac{C}{2} \right)^{\frac{1}{2}} - |f| - |\nabla K|.$$

For such  $\tilde{g}$ , we have

$$\begin{aligned}
 & \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] + \frac{1}{4} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2 \\
 & \leq C \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] + \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \\
 (A.25) \quad & + \frac{1}{2} \int_{B_R} e^{2\tilde{g}} u_R^2 \left| \nabla \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) \right|^2.
 \end{aligned}$$

We can choose  $\tilde{g}$  so that

$$(A.26) \quad e^{2\tilde{g}} \left| \nabla \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) \right|^2 \leq e^{2g}.$$

Inequalities (A.25) and (A.26) imply

$$\begin{aligned}
 & \frac{d}{dt} \left[ \frac{1}{2} \int_{B_R} e^{2\tilde{g}} |\nabla u_R|^2 \right] + \frac{1}{4} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2 \\
 & \leq (c+1) \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2 + \frac{1}{2} e^{ct} \int_{B_R} e^{2g} \sigma^2(x).
 \end{aligned}$$

Hence

$$\begin{aligned}
& \frac{d}{dt} \left[ e^{-(c+1)t} \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2 \right] \\
&= e^{-(c+1)t} \left[ \frac{d}{dt} \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2 - (c+1) \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2 \right] \\
&\leq \frac{1}{2} e^{-t} \int_{B_R} e^{2g} \sigma^2(x) - \frac{1}{4} e^{-(c+1)t} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2,
\end{aligned}$$

which implies

$$\begin{aligned}
& e^{-(c+1)T} \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2(T, x) - \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2(0, x) \\
&\leq \frac{1}{2} T \int_{B_R} e^{2g} \sigma^2(x) - \frac{1}{4} \int_0^T e^{-(c+1)t} \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2(t, x).
\end{aligned}$$

It follows that

$$\begin{aligned}
& e^{-(c+1)T} \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2(T, x) + \frac{1}{4} e^{-(c+1)T} \int_0^T \int_{B_R} e^{2\tilde{g}} (\Delta u_R)^2(t, x) \\
&\leq \int_{B_R} \frac{1}{2} e^{2\tilde{g}} |\nabla u_R|^2(0, x) + \frac{1}{2} T \int_{B_R} e^{2g} \sigma^2(x),
\end{aligned}$$

and (A.20) follows immediately.  $\square$

**Appendix B. Existence of a weak solution for the DMZ equation.** Let  $Q = (0, T) \times \mathbb{R}^n$  and let  $L^2(Q)$  be the space of functions that are square integrable over  $Q$ . The scalar product of two elements  $v_1, v_2$  of  $L^2(Q)$  is defined by the equation

$$(v_1, v_2) = \iint_Q v_1 v_2 \, dx \, dt.$$

The class of  $C^\infty$  functions in  $\overline{Q}$  with compact supports in  $Q$  will be denoted by  $C_0^\infty(Q)$ .

**DEFINITION B.1.** A locally  $L^2$ -integrable function is called a generalized derivative of a locally  $L^2$ -integrable function  $v(t, x)$  in  $Q$  with respect to  $x$  if for each  $\Phi(t, x) \in C_0^\infty(Q)$  the equation

$$(B.1) \quad \iint_Q \left( v \frac{\partial \Phi}{\partial x_k} + w \Phi \right) dx \, dt = 0$$

holds. In this case, we write  $w = \frac{\partial v}{\partial x_k}$ . The generalized derivative with respect to  $t$  and generalized derivatives of higher order are defined similarly (see [So]).

**Remark B.2.** If the sequence of functions  $v_m(t, x)$  weakly tends to  $v(t, x)$  in the space  $L^2(Q)$  as  $m \rightarrow \infty$  and the norms of  $\frac{\partial v_m}{\partial x_k}$  in  $L^2(Q)$  are uniformly bounded with respect to  $m$ , then  $v(t, x)$  has a generalized derivative  $\frac{\partial v}{\partial x_k} \in L^2(Q)$  and  $\frac{\partial v_m}{\partial x_k}$  weakly tends to  $\frac{\partial v}{\partial x_k}$  [So].

DEFINITION B.3. We denote by  $W^1(\mathbb{R}^n)$  the space of functions  $\phi(x)$  such that  $\phi(x) \in L^2(\mathbb{R}^n)$  and  $\frac{\partial \phi}{\partial x_i} \in L^2(\mathbb{R}^n)$  for  $i = 1, \dots, n$ , with the scalar product

$$(B.2) \quad (\phi_1, \phi_2)_1 := \int_{\mathbb{R}^n} \phi_1(x) \phi_2(x) dx + \int_{\mathbb{R}^n} \sum_{i=1}^n \frac{\partial \phi_1}{\partial x_i} \frac{\partial \phi_2}{\partial x_i} dx.$$

We shall denote by  $W^{1,1}(Q)$  the space of functions  $v(t, x)$  for which  $v(t, x) \in L^2(Q)$ ,  $\frac{\partial v(t, x)}{\partial x_i} \in L^2(Q)$  ( $i = 1, \dots, n$ ), and  $\frac{\partial v(t, x)}{\partial t} \in L^2(Q)$ , with the scalar product

$$(B.3) \quad (v_1, v_2)_{1,1} := \iint_Q v_1(t, x) v_2(t, x) dt dx + \iint_Q \left( \sum_{i=1}^n \frac{\partial v_1}{\partial x_i} \frac{\partial v_2}{\partial x_i} + \frac{\partial v_1}{\partial t} \frac{\partial v_2}{\partial t} \right) dx dt.$$

It is known [So] that  $W^1(\mathbb{R}^n)$  and  $W^{1,1}(\mathbb{R}^n)$  are complete. The norms in  $L^2(Q)$ ,  $W^1(\mathbb{R}^n)$ , and  $W^{1,1}(Q)$  will be written  $\|v\|_0$ ,  $\|v\|_1$ , and  $\|v\|_{1,1}$ , respectively.

Remark B.4. It follows from the embedding theorems of Sobolev that a function of  $W^{1,1}(Q)$  can be modified on a set of measure zero in such a way that it is  $L^2$ -integrable on the section of the cylinder  $Q$  by any  $n$ -dimensional plane or  $n$ -dimensional  $C^1$  surface. In particular, such a function is  $L^2$ -integrable on the section of  $Q$  by any plane  $t = \text{constant}$ . Moreover, the values of  $v(t, x) \in W^{1,1}(Q)$  on sufficiently close  $n$ -dimensional planes will differ in mean by as little as we please [So]. In particular, if  $v(t, x) \in W^{1,1}(Q)$  and  $v(x, 0) = \phi(x)$ , then  $\int_Q [v(t, x) - \phi(x)]^2 dx \rightarrow 0$  as  $t \rightarrow 0$ .

DEFINITION B.5. The subspace of  $W^1(\mathbb{R}^n)$  consisting of functions that have compact supports in  $\mathbb{R}^n$  is written  $W_0^1(\mathbb{R}^n)$ , and the subspace of  $W^{1,1}(Q)$  consisting of functions  $v(t, x)$  which have compact supports in  $\mathbb{R}^n$  for any  $t$  is written  $W_0^{1,1}(Q)$ .

DEFINITION B.6. The function  $u(t, x)$  in  $W_0^{1,1}(Q)$  is called a weak solution of the initial value problem

$$(B.4) \quad \begin{cases} \sum_{i,j=1}^n \frac{\partial}{\partial x_i} \left( A_{ij}(t, x) \frac{\partial u}{\partial x_j} \right) + \sum_{i=1}^n B_i(t, x) \frac{\partial u}{\partial x_i} + C(t, x) u = \frac{\partial u}{\partial t}, \\ u(0, x) = \phi(x) \end{cases}$$

if for any function  $\Phi(t, x) \in W_0^{1,1}(Q)$  the following relation is valid:

$$(B.5) \quad \iint_Q \left[ \sum_{i,j=1}^n A_{ij} \frac{\partial u}{\partial x_j} \frac{\partial \Phi}{\partial x_i} - \left( \sum_{i=1}^n B_i \frac{\partial u}{\partial x_i} + C u - \frac{\partial u}{\partial t} \right) \Phi \right] dx dt = 0$$

and  $u(0, x) = \phi(x)$ .

We now recall some facts concerning convergence in Hilbert spaces.

Remark B.7. A sequence  $\{u_m\}$ , in a Hilbert space  $H$  with scalar product  $(\cdot, \cdot)$ , is said to be *weakly convergent* (to  $u$ ) if the sequence  $\{(u_m, f)\}$  is convergent (to  $(u, f)$ ) for any  $f \in H$ . A weakly convergent sequence is bounded. From any bounded sequence  $\{u_m\}$  in  $H$  one can extract a weakly convergent subsequence. If  $\{u_m\}$  is weakly convergent to  $u$ , then there exists a subsequence  $\{u_{m'}\}$  whose arithmetic means converge to  $u$  in the  $H$  norm (see [Fr, p. 273]).

THEOREM B.8. Under the hypothesis of Theorem A.4 the robust DMZ equation (1.6) on  $[0, T] \times \mathbb{R}^n$  with initial condition  $\sigma_0(x) \in W_0^1(\mathbb{R}^n)$  has a weak solution.

Proof. Let  $\{R_k\}$  be a sequence of positive number such that  $\lim_{k \rightarrow \infty} R_k = \infty$ . Let  $u_k(x)$  be the solution of the robust DMZ equation (1.9) on  $[0, T] \times B_{R_k}$ , where

$B_{R_k} = \{x \in \mathbb{R}^n : |x| \leq R_k\}$  is a ball of radius  $R_k$ . Let

$$u_k(t, x) \begin{cases} u_{R_k}(t, x) & \text{if } x \in B_{R_k}, \\ 0 & \text{if } x \notin B_{R_k}, \end{cases} \quad \sigma_k(x) \begin{cases} \sigma_0(x) & \text{if } x \in B_{R_k}, \\ 0 & \text{if } x \notin B_{R_k}. \end{cases}$$

In view of Theorems A.1 and A.4, the sequence  $\{u_k\}$  is a bounded set in  $W_0^{1,1}(Q)$ . By Remark B.7, there exists a subsequence  $\{u_{k'}\}$  which is weakly convergent to  $u$ . Moreover,  $u(t, x)$  has generalized derivative  $\frac{\partial u}{\partial x_i}, \frac{\partial^2 u}{\partial x_i^2} \in L^2(Q)$ , and  $\frac{\partial u_{k'}}{\partial x_i}, \frac{\partial^2 u_{k'}}{\partial x_i^2}$  weakly tend to  $\frac{\partial u}{\partial x_i}, \frac{\partial^2 u}{\partial x_i^2}$ , respectively. Now we claim that the weak derivative  $\frac{\partial u}{\partial t}$  exists and is equal to the right-hand side of (B.3). To see this, let  $\Phi(t, x) \in W_0^{1,1}(Q)$ . Then

$$\begin{aligned} & \iint \left[ \frac{1}{2} \Delta u - (f(x) - \nabla K) \cdot \nabla u - \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K \right. \right. \\ & \quad \left. \left. + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) u \right] \Phi(t, x) dx dt \\ &= \lim_{k' \rightarrow \infty} \iint \left[ \frac{1}{2} \Delta u_{k'} - (f(x) - \nabla K) \cdot \nabla u_{k'} \right. \\ & \quad \left. - \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K \right. \right. \\ & \quad \left. \left. + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) u_{k'} \right] \Phi(t, x) dx dt \\ &= \lim_{k' \rightarrow \infty} \iint \frac{\partial u_{k'}}{\partial t} \Phi(t, x) dx dt \\ &= - \lim_{k' \rightarrow \infty} \iint u_{k'} \frac{\partial \Phi}{\partial t}(t, x) dx dt \\ &= - \iint u \frac{\partial \Phi}{\partial t}(t, x) dx dt. \end{aligned}$$

Clearly  $u(0, x) = \lim_{k' \rightarrow \infty} u_{k'}(0, x) = \lim_{k' \rightarrow \infty} \sigma_{k'}(x) = \sigma_0(x)$ .  $\square$

**Appendix C. Uniqueness of a weak solution for the DMZ equation.** We are now ready to establish the uniqueness of a weak solution for the DMZ equation. We shall follow the notation in previous sections.

**THEOREM C.1.** *Let  $Q = (0, T) \times \mathbb{R}^n$ . Assume that for some  $c > 0$ ,*

$$(C.1) \quad \sup_{0 \leq t \leq T} \int_{\mathbb{R}^n} e^{cr} u^2(t, x) dx < \infty,$$

$$(C.2) \quad \int_0^T \int_{\mathbb{R}^n} e^{cr} |\nabla u(t, x)|^2 dx dt < \infty,$$

where  $r = \sqrt{x_1^2 + \cdots + x_n^2}$ . Suppose that there exists a finite number  $\alpha$  such that

$$(C.3) \quad \left| \frac{c}{2} \nabla r + f - \nabla K \right|^2 - 2 \left( \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right) \leq \alpha.$$

Then the weak solution  $u(t, x)$  of the robust DMZ equation on  $Q$  is unique.

*Proof.* We only need to prove that  $u(t, x) = 0$  on  $Q$  if  $u(0, x) = 0$ . By iteration, we may assume that  $\alpha T < 1$ . Let  $\Phi \in C_0^\infty(\mathbb{R}^n)$ . According to the definition of weak solution (B.5), we have

$$(C.4) \quad \begin{aligned} \iint_Q \frac{\partial u}{\partial t} \Phi \, dt \, dx &= -\frac{1}{2} \int_0^T \int_{\mathbb{R}^n} \nabla u \cdot \nabla \Phi \, dx \, dt - \int_0^T \int_{\mathbb{R}^n} (f - \nabla K) \cdot \nabla u \Phi \, dx \, dt \\ &\quad - \int_0^T \int_{\mathbb{R}^n} \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] u \Phi \, dx \, dt. \end{aligned}$$

Replacing  $\Phi$  by  $\Phi e^{cr}$ , we have

$$(C.5) \quad \begin{aligned} \int_{\mathbb{R}^n} u(T, x) \Phi e^{cr} &= -\frac{1}{2} \int_0^T \int_{\mathbb{R}^n} \nabla u \cdot (e^{cr} \nabla \Phi) - \frac{c}{2} \int_0^T \int_{\mathbb{R}^n} \Phi e^{cr} \nabla r \cdot \nabla u \\ &\quad + \int_0^T \int_{\mathbb{R}^n} e^{cr} \Phi (-f + \nabla K) \cdot \nabla u \\ &\quad - \int_0^T \int_{\mathbb{R}^n} \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] \Phi u e^{cr} \\ &\quad + \int_0^T \int_{\mathbb{R}^n} u \frac{\partial \Phi}{\partial t} e^{cr}. \end{aligned}$$

Approximating  $u$  by  $\Phi$  in the  $W^{1,1}(Q)$  norm, we get

$$\begin{aligned} \int_{\mathbb{R}^n} u^2(T, x) e^{cr} &= -\frac{1}{2} \int_0^T \int_{\mathbb{R}^n} e^{cr} |\nabla u|^2 - \frac{c}{2} \int_0^T \int_{\mathbb{R}^n} u e^{cr} \nabla r \cdot \nabla u \\ &\quad + \int_0^T \int_{\mathbb{R}^n} e^{cr} u (-f + \nabla K) \cdot \nabla u \\ &\quad - \int_0^T \int_{\mathbb{R}^n} \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] u^2 e^{cr} \\ &\quad + \int_0^T \int_{\mathbb{R}^n} u \frac{\partial u}{\partial t} e^{cr} \\ &= -\frac{1}{2} \int_0^T \int_{\mathbb{R}^n} e^{cr} \left\{ |\nabla u|^2 + [cu \nabla r - 2u(-f + \nabla K)] \cdot \nabla u \right\} \\ &\quad - \int_0^T \int_{\mathbb{R}^n} \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] u^2 e^{cr} \\ &\quad + \int_0^T \int_{\mathbb{R}^n} \frac{1}{2} e^{cr} u \Delta u - \int_0^T \int_{\mathbb{R}^n} e^{cr} u (f - \nabla K) \cdot \nabla u \\ &\quad - \int_0^T \int_{\mathbb{R}^n} e^{cr} u^2 \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] \\ &= -\int_0^T \int_{\mathbb{R}^n} e^{cr} \left\{ |\nabla u|^2 + [cu \nabla r - 2u(-f + \nabla K)] \cdot \nabla u \right\} \end{aligned}$$

$$\begin{aligned}
& -2 \int_0^T \int_{\mathbb{R}^n} \left[ \frac{1}{2} |h|^2 + \operatorname{div} f - \frac{1}{2} \Delta K + f \cdot \nabla K - \frac{1}{2} |\nabla K|^2 \right] u^2 e^{cr} \\
& = - \int_0^T \int_{\mathbb{R}^n} e^{cr} \left| \nabla u - \frac{cu}{2} \nabla r - uf + u \nabla K \right|^2 \\
& \quad + \int_0^T \int_{\mathbb{R}^n} e^{cr} u^2 \left\{ \left| \frac{c}{2} \nabla r + f - \nabla K \right|^2 \right. \\
& \quad \quad \left. - \left( |h|^2 + 2 \operatorname{div} f - \Delta K + 2f \cdot \nabla K - |\nabla K|^2 \right) \right\} \\
(C.6) \quad & \leq \alpha \int_0^T \int_{\mathbb{R}^n} e^{cr} u^2(t, x).
\end{aligned}$$

By the mean value theorem, there exists  $T_1 \in (0, T)$  such that

$$\int_0^T \int_{\mathbb{R}^n} e^{cr} u^2(t, x) = T \int_{\mathbb{R}^n} e^{cr} u^2(T_1, x).$$

In view of (C.5), we have

$$(C.7) \quad \int_{\mathbb{R}^n} u^2(T, x) e^{cr} \leq \alpha T \int_{\mathbb{R}^n} u^2(T_1, x) e^{cr}.$$

By applying (C.5) successfully, there exists  $T_m \in (0, T)$  such that

$$(C.8) \quad \int_{\mathbb{R}^n} u^2(T, x) e^{cr} \leq (\alpha T)^m \int_{\mathbb{R}^n} u^2(T_m, x) e^{cr}.$$

As  $\alpha T < 1$ , we conclude that  $u = 0$ .  $\square$

**Acknowledgments.** We gratefully acknowledge the long term support from the Army Research Office, which allowed us to answer the challenge proposed by the Naval Research Office ten years ago: Given adequate computational resources, how can one solve the nonlinear filtering problem?

The authors also gratefully acknowledge the referees for many useful suggestions to improve the presentation of this paper. They would particularly like to thank the second referee for providing many useful references.

# ROBUST SEMIGLOBAL STABILIZATION OF THE SECOND ORDER SYSTEM BY RELAY FEEDBACK WITH AN UNCERTAIN VARIABLE TIME DELAY\*

EUGENII SHUSTIN<sup>†</sup>, LEONID FRIDMAN<sup>‡</sup>, EMILIA FRIDMAN<sup>§</sup>, AND  
FERNANDO CASTAÑOS<sup>¶</sup>

**Abstract.** We present sufficient conditions for robust relay-delayed *semiglobal* stabilization of second order systems, which relate the upper bound to an uncertain time delay and the parameters of the plant. We also suggest an algorithm of delayed relay control gain adaptation for semiglobal stabilization, which is based on *delayed information about the sign of the controlled variable only*. The proposed algorithm suppresses *bounded uncertainties in the time delay*; that is, being designed for the upper bound of uncertainty in the time delay, the control law ensures semiglobal stabilization independently of any variable time delay obeying the given upper bound.

**Key words.** variable structure systems, time delay, robust control

## 1. Introduction.

**1.1. Statement of the problem.** We study the control problem for the second order system

$$(1) \quad \alpha \ddot{x}(t) = -\beta \dot{x}(t) + F(x(t), t) + u,$$

with positive constants  $\alpha$  and  $\beta$  and some function  $F(x, t)$ , satisfying

$$(2) \quad F \in C^1(R^2), \quad \sup \left| \frac{\partial F}{\partial x} \right| < \infty.$$

The uncontrolled system

$$\alpha \ddot{x} = -\beta \dot{x} + F(x, t)$$

may be unstable, as, for example, in the case  $F(x, t) = kx$ ,  $k > 0$ , and we propose to stabilize it by a negative feedback of relay type:

$$(3) \quad u = -K(t) \cdot \text{sign } x(t - \tau),$$

with a controllable bounded magnitude  $K(t) > 0$  and a positive variable uncertain delay  $\tau$ , assumed to be a measurable function of  $t$  obeying the condition

$$(4) \quad 0 < \tau_0(t) \leq \tau(t) \leq h = \text{const}, \quad t \geq 0,$$

where  $\tau_0(t)$  is a positive nonincreasing function.

Our aim is to design a piecewise constant controller  $K(t)$ , which provides a robust semiglobal stabilization of the oscillation magnitude of the solutions to system (1), (3).

**1.2. Motivation.** For the motivation, we point out that time delay in control systems is usually present and must be taken into account. In practice, many systems with time delay naturally admit relay controllers, in particular,

- *systems which can work in switching modes*, for example, power converters (see, for example, [19]);
- *systems with measuring devices that work in the switching mode and have time delay*, for example, controllers of exhausted gas in the fuel injector automotive control systems [15], which act with delay and, moreover, generate relay signals only;
- *sliding mode systems with delayed actuators*, for example, the stabilizers of the fingers for an underwater manipulator [2];
- *mathematical biology systems* as, for example, those considered in [12, 13].

It has been shown in [5, 6] that, in the simplest one-dimensional relay control systems with a constant delay, only oscillatory solutions can occur. Moreover, any such solution becomes periodic after a finite time interval, but only slowly oscillating solutions are stable. The latter property is used to design an algorithm controlling the motion amplitudes.

P.I. (proportional-integral) control algorithms for the amplitude control in one-dimensional relay systems with delay in the input have been suggested in [1]. A Padé approximation of delay that reduces the relay delay output tracking problem to the sliding mode control for a nonminimum phase system was suggested in [16]. Delayed relay control algorithms, suggested in [7, 8], allow one to reach local and nonlocal stabilization of oscillations amplitudes for MIMO systems, respectively, with the use of the delayed value of the magnitude of a current trajectory.

In [11], periodic properties of second order systems via relay-delayed controllers based on the suboptimal control algorithm were investigated, whereas the article [3] studies oscillations in first order systems, containing external forcing in the relay-delayed control element.

**1.3. The main result. Restrictions to the nonlinear element.** Throughout the paper we impose the following bound of the nonlinear term  $F(x, t)$  of (1):

$$(5) \quad 0 \leq \frac{F(x, t) - F(0, t)}{x} \leq k_0, \quad x \neq 0, \quad t \geq 0,$$

with some positive constant  $k_0$ . Furthermore, we separate between the two situations:

$$(6) \quad F(0, t) \equiv 0,$$

and

$$(7) \quad |F(0, t)| \leq \delta, \quad t \geq 0, \quad \delta = \text{const} \in (0, 1),$$

in which the suggested controller and the respective solutions to (1) and (3) behave differently.

**The initial value problem and the definition of the discontinuous element.** For system (1), (3), we state the initial value problem

$$(8) \quad x(t) = \varphi(t), \quad t \in [-h, 0], \quad \varphi \in C_0[-h, 0], \quad \dot{x}(0) = \dot{\varphi}(0),$$

by defining the initial data range to be the space  $C_0[-h, 0]$  of continuous functions  $\varphi : [-h, 0] \rightarrow \mathbb{R}$ , differentiable at the origin. We equip  $C_0[-h, 0]$  with the norm

$$(9) \quad \|\varphi\| = \max_{[-h, 0]} |\varphi(t)| + |\dot{\varphi}(0)|.$$

The fact that the functions  $\varphi \in C_0[-h, 0]$  may vanish along intervals raises an important issue of an appropriate choice of the values of the sign function at vanishing arguments. From the control theory point of view, sign should be a binary sensor or actuator; i.e., it takes the only values  $\pm 1$ . So we will define

$$(10) \quad \text{sign } x(t) = \begin{cases} 1 & \text{if } x(t) > 0, \\ -1 & \text{if } x(t) < 0, \\ \zeta(t) & \text{if } x(t) = 0, \end{cases}$$

where  $\zeta(t)$  is any measurable function with  $|\zeta(t)| = 1$ , and consider the solutions to system (1), (3) in the sense of Carathéodory (see, for example, [9]).<sup>1</sup>

Then we have the following.

LEMMA 1.1. *The equation*

$$\alpha \ddot{x}(t) = -\beta \dot{x}(t) + F(x(t), t) - \text{sign } x(t - \tau),$$

*satisfying (2), (4), and (7), with initial condition (8) supplied with (10), has a unique continuous solution  $x_\varphi(t)$ ,  $t \in [-h, \infty)$ . Moreover,  $x_\varphi$  is differentiable in the interval  $(0, \infty)$ , and its derivative is absolutely continuous and differentiable almost everywhere.*

We omit the proof, which basically coincides with the proof of Lemma 1.1 in [17], and notice only that the lower bound to  $\tau$  in (4) is needed for an accurate justification of the existence and uniqueness of the solution  $x_\varphi$ .

*Remark 1.* (i) The solutions  $x(t)$  to system (1), (3) considered in what follows will satisfy the condition  $|F(x(t), t)| < K(t)$  (cf. the combination of bounds (5), (7), and (20) and of Lemmas A.1, A.2, and A.3 below), and thus, in the same way as in Lemma 1.1, the zero locus of such a solution  $x(t)$  in the interval  $t \geq 0$  will have zero measure whatever the zero locus of the initial function  $\varphi(t) \in C_0[-h, 0]$  is, and hence the results do not depend on the choice of the function  $\zeta(t)$  in (10) for  $t \geq 0$ . In particular, shifting the initial interval to  $[0, h]$ , one obtains the zero locus of zero measure for the (new) initial function, getting rid of any dependence of the function  $\zeta(t)$ . In addition,  $\dot{x}(t)$  turns out to be differentiable almost everywhere.

(ii) The Filippov differential inclusion theory [4] commonly used for nondelayed differential equations with discontinuity and intended to turn solutions into sliding

<sup>1</sup>The sliding modes cannot occur in the considered class of the systems. That is why it is not necessary to use more complicated definitions of the solutions for relay systems with delay (see, for example, [10, 14]).

modes, i.e., motions along the discontinuity locus (see detailed accounts in [10] and [14]), is not quite relevant in our situation. Indeed, the motion along the discontinuity locus should correspond to the zero solution  $x(t) \equiv 0$ , which cannot be stable. The reason is that, in the norm (9), the zero function  $\varphi(t) \equiv 0$  can be approximated by functions with at most one zero, which in turn generate either unbounded solutions or solutions with the sup-norm separated from zero (see, for example, [17]). On the other hand, an attempt to keep the zero level of an eventually vanishing solution leads to the relation

$$(\text{sign } x(t - \tau)) \big|_{x(t-\tau)=0} = F(x(t), t),$$

which is not natural for a controller based on only delayed information.

**The statement.** We provide here a general statement, solving the stated problem, and leave the precise formulation for section 3.

**Main result.** *Given system (1), (3) with  $F(x, t)$  satisfying (5), under certain restrictions to  $\alpha$ ,  $\beta$ ,  $h$ ,  $\delta$ , and  $k_0$ , there exist positive constants  $c, T_0, m$ , and  $\rho < 1$  such that*

(i) *in the case (6), for*

$$(11) \quad K(t) = \rho^n, \quad nT_0 \leq t < (n+1)T_0, \quad n = 0, 1, 2, \dots,$$

*all of the solutions with  $\max\{|x(0)|, |\dot{x}(0)|\} < c$  exponentially decay to zero;*

(ii) *in the case (7), for*

$$(12) \quad K(t) = \begin{cases} \rho^n, & nT_0 \leq t < (n+1)T_0, \quad n = 0, 1, 2, \dots, m-1, \\ \rho^m, & t \geq mT_0, \end{cases}$$

*all of the solutions with  $\max\{|x(0)|, |\dot{x}(0)|\} < c$  come to a neighborhood of zero, whose size is proportional to  $\delta$ .*

In section 3.1, we provide explicit formulas for all of the parameters  $\alpha$ ,  $\beta$ ,  $h$ ,  $\delta$ , and  $k_0$ , and in section 5, we make a numerical simulation.

The meaning of main result is that, whenever the parameters of the system (1) and the controller delay  $\tau$  satisfy some explicitly written restriction, a control presented by a step function  $K(t)$  with a priori fixed switch moments and amplitudes brings solutions to a prescribed neighborhood of zero. In other words, we propose an algorithm for a robust *semiglobal* stabilization of the oscillation magnitude, based on a retarded relay switching of the control gain, which requires only the knowledge of the sign for the controlled variable in the past and allows us to reject uncertainty in the time delay.

**1.4. The ideas behind the main result.** The idea of a piecewise constant control function  $u(t)$  can be traced back to [6], where such a controller, acting with a constant delay, has been used for an exponential stabilization of oscillations in the first order system

$$\dot{x}(t) = F(x(t), t) - \text{sign } x(t - h),$$

with  $F$  satisfying (5) and (6). The key observation was that, if  $k_0 h < \log 2$ , the solutions starting in a small neighborhood of zero cannot reach some critical value  $|x| = M_0$  during the time interval  $h$  and then must return to the zero level, that is, remain bounded and oscillating. Furthermore, for such solutions,  $\sup |x(t)| < M_1 <$

$M_0$ , and hence, switching the magnitude of sign from 1 to  $\rho = M_1/M_0 < 1$  at the moment  $t^*$ , with  $x(t^*) = 0$ , and making change  $x = \rho x^{(1)}$ , we come to an equation

$$\dot{x}^{(1)}(t) = F^{(1)}(x^{(1)}(t), t) - \text{sign } x^{(1)}(t - h),$$

with  $F^{(1)}$  again satisfying (5) and (6), which in turn means  $|x(t)| < \rho M_0$  as  $t \geq t^*$ . Performing inductively the same procedure, one obtains exponentially decreasing solutions. However, that controller was depending on the term  $F(x, t)$  and on the current solution, which made it hard to realize in practice. This difficulty has been resolved in [18], where a similar piecewise constant controller acting with a variable uncertain bounded delay and having a priori fixed switches provided an exponential decay of solutions with sufficiently small initial values.

In a similar way we obtain the main result for the second order system (1), (3). The background property, established in [17], states that, under certain restrictions on the positive parameters  $\alpha, \beta, k, K, h, c$ , the solutions to the equation

$$\alpha \ddot{x} = -\beta \dot{x} + kx - K \cdot \text{sign } x(t - h),$$

which obey the initial conditions  $x(0) = 0$ ,  $|\dot{x}(0)| < c$ , remain bounded by a constant  $M$ , proportional to  $K$ , and, moreover, the derivatives  $\dot{x}(t^*)$  for all  $t^* > 0$ ,  $x(t^*) = 0$ , belong to a *smaller* range  $(-c_1, c_1)$ , where  $c_1 < c$ . Here we extend this fact to the case of arbitrary functions  $F(x, t)$  with bounded values and derivative and a variable uncertain delay  $\tau(t)$ . So, again after a suitable period of time, we switch the controller magnitude from  $K$  to  $\rho K$ , with some  $\rho \in (c_1/c_0, 1)$ , and make change  $x = \rho x^{(1)}$ , coming to an equation for  $x^{(1)}$ , analogous to (1), (3) and satisfying the hypotheses, which provide  $|x^{(1)}| < M$  and  $|\dot{x}^{(1)}| < c$ , and, in particular,  $|x(t)| < \rho M$  for large  $t > 0$ .

To find suitable bounds to the given data, we model the “worst” behavior of a solution to (1), (3), which means that the absolute value  $|x|$  maximally grows against the negative feedback  $u$  intended to bring the solution to the zero level. That is, if a solution starts at zero with some, say, positive derivative, we assume that  $F(x, t) = \delta + kx$  and  $\tau = h$ , so that the feedback  $u$  remains positive on the largest possible interval of length  $h$ . Then we assume that the value of the control undergoes a switch only after a period of time  $h$  has elapsed, and we know that reversing the sign of the control will eventually force the solution to reach a maximum. When the maximum value is attained, we take  $F(x, t) = -\delta$  and wait until the solution reaches the next zero. We call the pieces of that worst solution *majorating functions*. They are treated in the next section in order to precisely state the sufficient conditions for the existence of the controller proposed in the main result, and these conditions finally reduce to the claim that the absolute value of the derivative of the worst solution at its zero is *strictly greater* than that value at the next zero.

## 2. Majorating functions.

**2.1. Definition of the majorating functions.** First, we point out that restriction (5) on the nonlinearity  $F(x, t)$  comes from the comparison of system (1), (3) with the equation  $\alpha \ddot{x} = -\beta \dot{x} + k_0 x - \text{sign } x(t - \tau)$ , and this makes it natural to introduce the roots  $\lambda_1 > 0 > \lambda_2$  of the characteristic equation  $\alpha \lambda^2 + \beta \lambda - k_0 = 0$ , which will play an important role in the further consideration.

In order to deal with uncertainty, we introduce a majorating function for the actual response  $x(t)$ . This function is intended to model “the worst type of behavior” of the stable solutions to (1), (3). As previously stated, such solutions are periodic

FIG. 1. Actual response  $x(t)$  and the majorating functions.

and slow. In Figure 1 we show (as a dotted line) the upper lobe of one of the periods. Assuming that the distance between the neighboring zeros of  $x(t)$  is greater than  $h$ , we can divide the interval between such zeros into three parts:

1. an interval between the current zero and the (first) control switch,
2. an interval between the control switch and the global extremum,
3. the remaining part from the extremum to the next zero.

For the first interval consider the equation

$$\alpha \ddot{y}(t) = -\beta \dot{y}(t) + k_0 y(t) + 1 + \delta.$$

We assume that the control switch is delayed by  $h$  from the current zero, and, since we are considering the upper lobe, the initial derivative is positive. Hence we impose

$$0 \leq t \leq h, \quad y(0) = 0, \quad \dot{y}(0) = a,$$

where  $a$  is a nonnegative parameter.

The family of functions  $y_{\delta,a}(t)$  (see Figure 1)

$$y_{\delta,a}(t) = \frac{ak_0 - \lambda_2(1 + \delta)}{k_0(\lambda_1 - \lambda_2)} e^{\lambda_1 t} + \frac{\lambda_1(1 + \delta) - ak_0}{k_0(\lambda_1 - \lambda_2)} e^{\lambda_2 t} - \frac{1 + \delta}{k_0}$$

are the solutions of the previous equation.

For the second interval we introduce the solution

$$(13) \quad \begin{aligned} z_{\delta,a}(t) = & -\frac{2e^{-\lambda_1 h} - 1 - \delta - \alpha a \lambda_1}{\alpha \lambda_1(\lambda_1 - \lambda_2)} e^{\lambda_1 t} + \frac{2e^{-\lambda_2 h} - 1 - \delta - \alpha a \lambda_2}{\alpha \lambda_2(\lambda_1 - \lambda_2)} e^{\lambda_2 t} \\ & + \frac{1 - \delta}{k_0} \end{aligned}$$

of the equation

$$\alpha \ddot{z}(t) = -\beta \dot{z}(t) + k_0 z(t) - 1 + \delta, \quad z(h) = y_{\delta,a}(h), \quad \dot{z}(h) = \dot{y}_{\delta,a}(h).$$

Suppose that  $2e^{-\lambda_1 h} - 1 > 0$ ,

$$(14) \quad \delta < 2e^{-\lambda_1 h} - 1,$$

and

$$(15) \quad a < \frac{2e^{-\lambda_1 h} - 1 - \delta}{\alpha \lambda_1}.$$

This means, in particular, that the coefficients of  $e^{\lambda_1 t}$  and  $e^{\lambda_2 t}$  in (13) are negative. Hence  $z_{\delta,a}(t)$  is a concave function, which in view of  $\dot{z}_{\delta,a}(h) = \dot{y}_{\delta,a}(h) > 0$  has a unique maximum in  $(h, \infty)$ . The maximum occurs at the time moment

$$(16) \quad t_{\delta,a} = \frac{1}{\lambda_1 - \lambda_2} \log \frac{2e^{-\lambda_2 h} - 1 - \delta - \alpha a \lambda_2}{2e^{-\lambda_1 h} - 1 - \delta - \alpha a \lambda_1},$$

so for  $z_{\delta,a}(t)$  we add the restriction

$$h \leq t \leq t_{\delta,a}.$$

To keep the notation simple, we will set

$$(17) \quad \sigma_\delta \triangleq z_{\delta,a}(t_{\delta,a}).$$

For the last interval we introduce the equation

$$\alpha \ddot{w}(t) = -\beta \dot{w}(t) - 1 - \delta.$$

In what follows, we will be more concerned about the value of the global extremum  $\sigma_\delta$ , rather than the time of its occurrence  $t_{\delta,a}$ , so we add

$$w(0) = \sigma_\delta, \quad \dot{w}(0) = 0,$$

which defines a majorating function which is shifted in time (see Figure 1). The solution is given by

$$(18) \quad w_{\delta,\sigma_\delta}(t) = \frac{\alpha(1+\delta)}{\beta^2} (1 - e^{-t\beta/\alpha}) - \frac{1+\delta}{\beta} t + \sigma_\delta,$$

which has a unique positive root  $t'$  (see Figure 2).

Now we can build the majorating function. For any perturbation with a bound  $\delta$  satisfying (14) and an initial derivative  $a$  satisfying (15), the function

$$(19) \quad \phi_{\delta,a}(t) \triangleq \begin{cases} y_{\delta,a}(t), & 0 \leq t \leq h, \\ z_{\delta,a}(t), & h \leq t \leq t_{\delta,a}, \\ w_{\delta,\sigma_\delta}(t - t_{\delta,a}), & t_{\delta,a} \leq t \leq t' + t_{\delta,a}, \end{cases}$$

bounds from above the solutions to (1), (3) and their derivatives. We shall call  $\phi_{\delta,a}(t)$  *the worst solution* to (1), (3).

FIG. 2. Behavior of the last majorating function  $w(t - t_{\delta,a})$ .

**2.2. Properties of the majorating functions.** The next property will play a key role in the argumentation that follows.

**DEFINITION 2.1.** A function  $\phi_a(t) \in C_1$  is said to be differentially contractive (DC) if, whenever it starts at a zero with a derivative belonging to some interval, its derivative at the next zero belongs to a smaller interval.

Notice that  $\phi_{\delta,a}$  is continuous (see Figure 1). Its initial derivative  $a$  is taken from the interval (15), and we want its terminal derivative

$$\xi_\delta(\sigma_\delta) \triangleq |\dot{w}_{\delta,\sigma_\delta}(t')|$$

to belong to a smaller interval.

To fulfill the DC property, we first use (18) to estimate  $t'$

$$\frac{\alpha(1+\delta)}{\beta^2} (1 - e^{-t'/\beta/\alpha}) = \frac{1+\delta}{\beta} t' - \sigma_\delta.$$

Due to  $\dot{z}_{\delta,a}(t_{\delta,a}) = 0$  and  $\ddot{z}_{\delta,a}(t_{\delta,a}) < 0$ , we have

$$(20) \quad \sigma_\delta = \frac{1 - \delta + \beta \dot{z}_{\delta,a}(t_{\delta,a}) + \alpha \ddot{z}_{\delta,a}(t_{\delta,a})}{k_0} < \frac{1 - \delta}{k_0}.$$

Hence  $t' \leq \theta$ , where  $\theta$  is the positive root of the equation

$$(21) \quad \frac{\alpha(1+\delta)}{\beta^2} (1 - e^{-\theta\beta/\alpha}) = \frac{1+\delta}{\beta} \theta - \frac{1-\delta}{k_0}.$$

Notice that, given  $\alpha, \beta, \delta, k_0$ , (21) always has a unique positive root  $\theta$ , since the left-hand side is a positive concave function of  $\theta$  and the right-hand side is an increasing linear function of  $\theta$ , negative at the origin. Next, we have that

$$(22) \quad \xi_\delta(\sigma_\delta) = \frac{1+\delta}{\beta} (1 - e^{-t'/\beta/\alpha}) \leq \frac{1+\delta}{\beta} (1 - e^{-\theta\beta/\alpha}).$$

In view of the last inequality and (15) it is easy to see that  $\phi_{\delta,a}$  fulfills the DC property if

$$(23) \quad \frac{1+\delta}{\beta} (1 - e^{-\theta\beta/\alpha}) < \frac{2e^{-\lambda_1 h} - 1 - \delta}{\alpha\lambda_1}.$$

To understand inequality (23), consider the equality

$$(24) \quad \frac{1+\delta}{\beta} (1 - e^{-\theta(k)\beta/\alpha}) = \frac{2e^{-\lambda_1(k)h} - 1 - \delta}{\alpha\lambda_1(k)}$$

as an equation to the unknown  $k$  with fixed  $\alpha, \beta, \delta$ . Here the left-hand side is a bounded positive function of  $k$ , whereas the right-hand side drops from infinity to negative values as  $k$  grows from zero to infinity. Hence (24) has positive roots,<sup>2</sup> and the minimal one among them we denote by  $k_{\min}$ . So, finally, we reduce (23) to

$$(25) \quad k_0 < k_{\min},$$

which guarantees the DC property.

*Remark 2.* According to (20) the extremum  $\sigma_\delta$  is bounded from above. We shall call that bound  $\sigma_{\max}$ , i.e.,

$$\sigma_\delta < \sigma_{\max} \triangleq \frac{1-\delta}{k_0}.$$

Suppose that the extremum attains the maximum value in the current period; in view of (20), the extremum at the following period satisfies

$$\sigma_\delta^{(1)} \triangleq z_{\delta, \xi_\delta(\sigma_{\max})}(t_{\xi_\delta(\sigma_{\max})}) < \sigma_{\max}.$$

### 3. Main results in detail.

**DEFINITION 3.1.** Denote by  $\Phi_{\delta,a}$  the set of functions  $\varphi \in C_0[-h, 0]$  such that either

$$\varphi^{-1}(0) \neq \emptyset, \quad |\varphi(0)| \leq y_{\delta,a}(-t^*), \quad |\dot{\varphi}(0)| \leq \dot{y}_{\delta,a}(-t^*),$$

where  $t^* = \max \varphi^{-1}(0) > -h$ , or

$$\varphi|_{(-h, 0]} \neq 0, \quad |\varphi(0)| \leq z_{\delta,a}(t^*), \quad |\dot{\varphi}(0)| \leq \dot{z}_{\delta,a}(t^*)$$

for some  $t^* \in [h, t_{\delta,a}]$ .

**3.1. Perturbations that vanish at the origin.** Assume that  $\delta = 0$ . In order to simplify the notation, in this case we always skip the subindex  $\delta$  (i.e., 0) in the notation for  $t, \xi, \sigma, \Phi, x, y, z$ .

Introduce the following parameter. Given

$$0 < a < b < \frac{2e^{-\lambda_1 h} - 1}{\alpha\lambda_1},$$

set

$$(26) \quad \rho(a, b) \triangleq \frac{\alpha a(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h}) + (e^{\lambda_1 h} - e^{\lambda_2 h})}{\alpha b(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h}) + (e^{\lambda_1 h} - e^{\lambda_2 h})}.$$

<sup>2</sup>It is an easy exercise to show that a positive root is unique, but we shall not need this fact.

Clearly,  $\rho(a, b) < 1$ . Then introduce

$$(27) \quad \rho \triangleq \rho(\xi(\sigma^{(1)}), \xi(\sigma_{\max})).$$

Notice that  $\rho$  is defined properly, since  $\xi$  is a strictly increasing function.

**THEOREM 1.** *Assume that  $F(x, t)$  and  $\tau(t)$  satisfy (2), (4), (5), (6), and (25) with  $\delta = 0$ . Let a constant  $c$  satisfy*

$$(28) \quad 0 < c < \frac{2e^{-\lambda_1 h} - 1}{\alpha \lambda_1}.$$

Put

$$K(t) = \begin{cases} 1 & \text{if } 0 \leq t < t_c, \\ \rho^n & \text{if } t_c + nt_{\xi(\sigma_{\max})} \leq t < t_c + (n+1)t_{\xi(\sigma_{\max})}, \\ & n = 0, 1, 2, \dots, \end{cases}$$

where  $\rho$  is defined by (27), and  $t_c$  and  $t_{\xi(\sigma_{\max})}$  are the roots of  $z_c(t)$  and  $z_{\xi(\sigma_{\max})}(t)$ , respectively (see Figure 1).

Then any solution  $x_\varphi(t)$  to (1), (3), (8) with  $\varphi \in \Phi_c$  obeys the restriction

$$(29) \quad |x_\varphi(t)| \leq \frac{1}{k_0} \exp \left( - \left( \log \frac{1}{\rho} \right) \frac{t - t_c - t_{\xi(\sigma_{\max})}}{t_{\xi(\sigma_{\max})}} \right), \quad t \geq t_c + t_{\xi(\sigma_{\max})}.$$

**3.2. Perturbations that do not vanish at the origin.** In realistic models,  $F(0, t)$  does not vanish identically, so we'll consider the case  $\delta \neq 0$ , but we'll maintain restriction (14). In this case, one can drive the system in a finite time to a neighborhood of zero, proportional to  $\delta$ . More precisely, we design a set of controllers, which depend on one continuous and one discrete parameter. The parameters can be chosen in their range according to the initial magnitude, the required rate of convergence, and the size of the target neighborhood of zero. We remark only that one cannot optimize the two latter values simultaneously.

Given  $\delta$  satisfying (14), the range of a positive parameter  $\varepsilon$  is defined by the inequality

$$(30) \quad \frac{1 + \delta}{\beta} (1 - e^{-\theta\beta/\alpha}) + \frac{\delta}{\alpha \lambda_1} < \frac{2e^{-\lambda_1 h} - 1 - \varepsilon}{\alpha \lambda_1}.$$

Observe that (30) defines a nonempty interval, since it turns into (23) for  $\varepsilon = 0$ . Next we choose any natural  $m \geq 1$  and put  $q = q(\varepsilon, m)$  to be the positive root of the equation

$$(31) \quad \frac{1}{q} \left( \frac{1 - e^{-\theta\beta/\alpha}}{\beta} + \frac{(1 - q)(e^{\lambda_1 h} - e^{\lambda_2 h})}{\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})} \right) + \frac{\delta}{q^m} \left( \frac{1 - e^{-\theta\beta/\alpha}}{\beta} + \frac{1}{\alpha \lambda_1} \right) = \frac{2e^{-\lambda_1 h} - 1 - \varepsilon}{\alpha \lambda_1}.$$

Such a root does exist; furthermore, it is unique and belongs to the interval  $(0, 1)$ . Indeed, the left-hand side of (31) monotonically decreases from infinity to the left-hand

side of (30), whereas the right-hand sides of (30) and (31) coincide. Furthermore,

$$(32) \quad \frac{1}{q} \left( \frac{1 - e^{-\theta\beta/\alpha}}{\beta} + \frac{(1-q)(e^{\lambda_1 h} - e^{\lambda_2 h})}{\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})} \right) + \frac{\delta}{q^{m'}} \left( \frac{1 - e^{-\theta\beta/\alpha}}{\beta} + \frac{1}{\alpha\lambda_1} \right) \leq \frac{2e^{-\lambda_1 h} - 1 - \varepsilon}{\alpha\lambda_1}$$

for all  $m' \leq m$ . At last, put

$$(33) \quad T(\varepsilon) = \frac{1}{\lambda_1} \log \frac{(1-\delta)(\lambda_1 - \lambda_2)}{-\lambda_2 \varepsilon}.$$

**THEOREM 2.** *Under the hypotheses (2), (4), (5), (7), and (25) with  $\delta > 0$  satisfying (14), let  $\varepsilon$  obey (30). Put*

$$(34) \quad K(t) = \begin{cases} q^s & \text{if } sT(\varepsilon) \leq t < (s+1)T(\varepsilon), \quad s = 0, 1, \dots, m-1, \\ q^m & \text{if } t \geq mT(\varepsilon). \end{cases}$$

Then any solution  $x_\varphi(t)$  to (1), (3), (8), with  $\varphi \in \Phi_{\delta,c}$ , where

$$(35) \quad c = \frac{2e^{-\lambda_1 h} - 1 - \delta - \varepsilon}{\alpha\lambda_1},$$

obeys the restriction

$$(36) \quad |x_\varphi(t)| \leq \frac{q^m - \delta}{k_0} \quad \text{as } t \geq mT(\varepsilon).$$

### Comments to Theorem 2.

(i) We point out that the parameters of  $u(t)$  depend only on  $h$ ,  $k_0$ , and the chosen constants  $c$ ,  $\varepsilon$ ,  $m$  and do not depend on the function  $\tau_0(t)$  from (4); i.e., our feedback  $-K(t) \cdot \text{sign } x(t - \tau(t))$  is *robust* with respect to an uncertain variable delay  $\tau(t)$ , as well as a deviation of  $F(x, t)$  in the framework of restrictions (2), (7), (5), (25), (21).

(ii) If  $m \rightarrow \infty$  and  $\varepsilon \rightarrow 0$  in Theorem 2, then

$$q^m \rightarrow \delta \frac{\alpha\lambda_1(1 - e^{-\theta\beta/\alpha}) + \beta}{(2e^{-\lambda_1 h} - 1)\beta - \alpha\lambda_1(1 - e^{-\theta\beta/\alpha})},$$

and hence, the right-hand side of (36) tends to

$$(37) \quad K_0 \delta \triangleq \frac{2(\alpha\lambda_1(1 - e^{-\theta\beta/\alpha}) + \beta(1 - e^{-\lambda_1 h}))}{k_0((2e^{-\lambda_1 h} - 1)\beta - \alpha\lambda_1(1 - e^{-\theta\beta/\alpha}))} \delta.$$

(iii) The hypotheses (14), (25), and (30) in Theorem 2 contain restrictions to the parameters of system (1), (3) in an implicit form. However, one can in principle extract some explicit conditions from them. First of all, given  $\alpha$  and  $\beta$ , the parameter  $k_0$  must satisfy (25) for  $\delta = 0$ . Suppose now that such  $\alpha$ ,  $\beta$ , and  $k_0$  are fixed, and describe  $\delta$  which meet the hypotheses (14), (25), and (30).

Condition (14) is an explicit upper bound to  $\delta$ .

In turn,  $k_{\min} = k_{\min}(\delta)$  in (25) is a strictly decreasing function of  $\delta$  (indeed, when  $\delta$  grows, the allowed range for  $k_0$  must shrink), and this function is given by (21) and (24). That is, (25) also can be written as an upper bound  $\delta < (k_{\min})^{-1}(k_0)$ .

At last, condition (30) after removing  $\varepsilon$  (which can be arbitrarily small positive) reduces to inequality (23), where  $\theta$  comes from (21). It is not difficult to show that the latter equation defines  $\theta$  as a strictly decreasing function of  $\delta$ . Inequality (23) holds for  $\delta = 0$ , since this is equivalent to the above assumption  $k_0 < k_{\min}|_{\delta=0}$ . Thus, the left-hand side of (23) is a positive function of  $\delta$ , whereas the right-hand side drops from positive to negative as  $\delta$  goes from zero to  $\infty$ . Equating both sides of (23), we then obtain the minimal positive root  $\delta_{\min}$  and finally reduce condition (30) to an upper bound  $\delta < \delta_{\min}$ .

**4. Control algorithm.** We shortly describe how to apply Theorems 1 and 2. One begins with a few common initial steps:

1. Given system (1), (3), obeying (2), (4), and (7) with known  $h > 0$  and  $\delta \geq 0$ , we start by solving simultaneously the equations

$$(38a) \quad \frac{\alpha(1+\delta)}{\beta^2} (1 - e^{-\theta_m \beta / \alpha}) = \frac{1+\delta}{\beta} \theta_m - \frac{1-\delta}{k_m},$$

$$(38b) \quad \frac{1+\delta}{\beta} (1 - e^{-\theta_m \beta / \alpha}) = \frac{2e^{-\lambda_1(k_m)h} - 1 - \delta}{\alpha \lambda_1(k_m)}$$

with respect to positive unknowns  $k_m$  and  $\theta_m$ .

2. Take the solution  $(k_m, \theta_m)$ , and verify that the given function  $F(x, t)$  satisfies (5) with certain positive  $k_0 < k_m$ ; then find the positive root  $\theta$  of (21).
3. Compute the roots  $\lambda_1 > 0 > \lambda_2$  of the characteristic equation, and check the validity of (14).

**4.1. Perturbations that vanish at the origin.** Perform steps 1–3 as described above and then do the following.

4. Pick a constant  $c$ , satisfying (28), and compute the values of  $\xi(\sigma_{\max})$ ,  $t_c$ ,  $t_{\xi(\sigma_{\max})}$ , and  $\rho$  using the formulas of Theorem 1. Verify that the initial function  $\varphi$  belongs to  $\Phi_c$  as described in Definition 3.1.

*Remark 3.* It is possible to set a limit  $n^*$  to the maximum number of allowed switches of the controller or to the time interval  $t \leq t^*$ , when switches are allowed. Pick  $n \leq n^*$  or  $n \leq (t^* - t_c)/t_{\xi(\sigma_{\max})}$ , respectively. The solution becomes bounded by  $|x(t)| \leq \rho^n/k_0$  after  $t \geq t^*$ .

**4.2. Perturbations that do not vanish at the origin.** Again perform steps 1–3 as above, and then proceed in the following way.

4. Pick a positive  $\varepsilon$  satisfying (30), and compute  $T(\varepsilon)$  by (33).
5. For the last step there are three possibilities:
  - (a) Choose an upper bound  $m^*$  to the number of allowed switches of the controller, and pick  $m \leq m^*$ .
  - (b) Set the size  $t^*$  of the time interval when switches are allowed, and pick  $m \leq t^*/T(\varepsilon)$ .

In both cases solve (31) with respect to  $q$ . The solution will be bounded according to (36).

- (c) In this case we bring the solution to the  $\delta(K_0 + \kappa)$ -neighborhood of zero, where  $K_0$  is taken from (37), and  $\kappa$  is a (relatively) small prescribed positive parameter. Using (31) we compute

$$q = \frac{B_1 + B_2}{C + B_2 - (1 - \varepsilon)/(k_0(K_0 + \kappa) + 1)},$$

where

$$B_1 = \frac{1 - e^{-\theta\beta/\alpha}}{\beta}, \quad B_2 = \frac{(e^{\lambda_1 h} - e^{\lambda_2 h})}{\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})}, \quad C = \frac{2e^{-\lambda_1 h} - 1 - \varepsilon}{\alpha\lambda_1},$$

and, finally, put

$$m = \left\lceil \frac{\log(\delta(k_0(K_0 + \kappa) + 1)/(1 - \varepsilon))}{\log q} \right\rceil + 1.$$

**5. Numerical example: Stabilization of an inverted pendulum.** Consider the stabilization problem of an inverted pendulum via a controller with uncertain delay. The oscillations of an inverted pendulum with unit mass with such a controller are described by

$$(39) \quad \ddot{x} + k\dot{x} - p\sin x + \delta = u(t - \tau(t)),$$

where  $k > 0$  is a friction coefficient,  $p = g/l > 0$ ,  $\delta$  is uncertainty, and  $\tau$  is an uncertain time delay  $0 < \tau_0(t) \leq \tau(t) \leq h$ . Consider the case when  $k = 1$  and  $p = g/l = 1.4$ . In this case (39) takes the form

$$\ddot{x}(t) = -\dot{x}(t) + 1.4\sin(x) + \delta - K(t)\text{sign}(x(t - \tau(t))),$$

with  $\tau = 0.05 + 0.04\sin(t)$ . It is clear that

$$\alpha = \beta = 1 \quad \text{and} \quad F(x, t) = 1.4\sin(x) + \delta$$

and that the bound

$$0 < \tau_0(t) \leq \tau(t) \leq h = 0.1$$

holds.

**5.1. Application of Theorem 1 ( $\delta = 0$ ).** The solution to (38) is  $k_m = 2.69518$ ,  $\theta_m = 1.00498$ . A possible  $k_0 < k_m$  that satisfies (5) is  $k_0 = 1.5$ . For that  $k_0$  we use (21) to obtain  $\theta = 1.42652$ . The roots of the characteristic equation are

$$\lambda_1 = 0.82288 \quad \text{and} \quad \lambda_2 = -1.82288.$$

The validity of (14) is easily verified:  $\delta = 0 < 2e^{-\lambda_1 h} - 1 = 0.84301$ .

Now we pick a constant  $c$  satisfying (28)

$$c = 1 < \frac{2e^{-\lambda_1 h} - 1}{\alpha\lambda_1} = 1.0233.$$

Next, we have

$$\xi(\sigma_{\max}) = \frac{1 - e^{-\theta\beta/\alpha}}{\beta} = 0.7599, \quad t_c = 5.26, \quad t_{\xi(\sigma_{\max})} = 2.294, \quad \rho = 0.837.$$

Figure 3 shows the response of the system when the initial conditions are set to  $\dot{x}(-h) = 1$  and  $x(-h) = 0.05$ .

FIG. 3. *System's response*,  $\delta = 0$ .FIG. 4. *System's response*,  $\delta = 0.05$ .

**5.2. Application of Theorem 2 ( $\delta = 0.05$ ).** The following parameters were obtained as in the previous section:

$$\begin{aligned} k_m &= 2.2854, & k_0 &= 1.5, & \lambda_1 &= 0.8229, \\ \theta_m &= 1.0438, & \theta &= 1.3418, & \lambda_2 &= -1.8229, \\ \delta &< 2e^{-\lambda_1 h} - 1 &= 0.7930. \end{aligned}$$

Now we pick an  $\varepsilon = 0.15$  satisfying (30) and evaluate  $T(\varepsilon) = 2.696$ . For the last step we choose  $m = m^* = 40$  and obtain  $q = 0.9975$ .

The results are shown in Figure 4. The initial data were  $\dot{x}(-h) = 1$  and  $x(-h) = -0.05$ .

**6. Conclusions.** The dynamics of the second order systems with a delayed relay control is analyzed. Sufficient conditions for robust delayed relay *semiglobal* stabilization of second order systems are found. Such conditions relate to the upper bound of an uncertainty in time delay and the parameters of the plant. An algorithm for a delayed relay control with gain adaptation is suggested. The algorithm *is based on delayed information about the sign of the controlled variable only*. The proposed algorithm suppresses *bounded uncertainties in the time delay*: Once being designed for the upper bound of time delay in the given system, this control law ensures semiglobal stabilization for any constant or variable time delay within the given constraint.

## Appendix A. Proofs.

**A.1. Preliminary estimates.** In what follows we always suppose that  $\tau(t)$  and  $F(x, t)$  satisfy restrictions (4) and (7), respectively.

LEMMA A.1. (i) *Let*

$$0 < a < b < \frac{2e^{-\lambda_1 h} - 1}{\alpha \lambda_1}.$$

*Then*

$$(A.1) \quad y_a(t) \leq \rho(a, b)y_b(t), \quad \dot{y}_{0,a}(t) \leq \rho(a, b)\dot{y}_{0,b}(t), \quad 0 \leq t \leq h,$$

$$(A.2) \quad z_a(t) \leq \rho(a, b)z_b(t), \quad \dot{z}_{0,a}(t) \leq \rho(a, b)\dot{z}_{0,b}(t), \quad h \leq t \leq t_a,$$

*with  $\rho(a, b)$  defined by (26).*

(ii) *Let  $0 < q < 1$  and  $a \geq 0$ . Put*

$$(A.3) \quad \delta_1 = \frac{\delta}{q}, \quad a_1 = \frac{a}{q} + \frac{(1-q)(e^{\lambda_1 h} - e^{\lambda_2 h})}{q\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})}.$$

*Then*

$$(A.4) \quad q^{-1}y_{\delta,a}(t) \leq y_{\delta_1,a_1}(t), \quad q^{-1}\dot{y}_{\delta,a}(t) \leq \dot{y}_{\delta_1,a_1}(t), \quad 0 \leq t \leq h,$$

$$(A.5) \quad q^{-1}z_{\delta,a}(t) \leq z_{\delta_1,a_1}(t), \quad q^{-1}\dot{z}_{\delta,a}(t) \leq \dot{z}_{\delta_1,a_1}(t), \quad h \leq t \leq t_{\delta,a}.$$

*Proof.* (i) The first inequality in (A.1) follows from the second one, and, respectively, the first inequality in (A.2) follows from the second inequality and from (A.1).

The second inequality in (A.1) can be rewritten as

$$\rho(a, b) \geq \max_{[0, h]} \frac{\dot{y}_a(t)}{\dot{y}_b(t)}.$$

We have

$$\frac{\dot{y}_a(t)}{\dot{y}_b(t)} = \frac{a\alpha\Sigma(t) + 1}{b\alpha\Sigma(t) + 1}, \quad \Sigma(t) = \frac{\lambda_1 e^{\lambda_1 t} - \lambda_2 e^{\lambda_2 t}}{e^{\lambda_1 t} - e^{\lambda_2 t}}.$$

Since

$$\frac{d}{ds} \left( \frac{a\alpha s + 1}{b\alpha s + 1} \right) = \frac{\alpha(a-b)}{(b\alpha s + 1)^2} < 0, \quad \dot{\Sigma}(t) = -\frac{(\lambda_1 - \lambda_2)^2 e^{-t/\alpha}}{(e^{\lambda_1 t} - e^{\lambda_2 t})^2} < 0,$$

we obtain in view of (26)

$$\max_{[0,h]} \frac{\dot{y}_a(t)}{\dot{y}_b(t)} = \frac{\dot{y}_b(h)}{\dot{y}_b(h)} = \rho(a, b).$$

We start proving the second inequality in (A.2) with the observation that  $t_a < t_b$ . Then, in particular,  $\dot{z}_{0,b}(t) > 0$  as  $h \leq t \leq t_a$ . Again we have to show that

$$\rho(a, b) \geq \max_{h, t_a} \frac{\dot{z}_a(t)}{\dot{z}_b(t)} = \max_{[h, t_a]} \frac{A_1(a)e^{\lambda_1 t} + A_2(a)e^{\lambda_2 t}}{A_1(b)e^{\lambda_1 t} + A_2(b)e^{\lambda_2 t}},$$

where

$$A_1(\sigma) = -(2e^{-\lambda_1 h} - 1 - \alpha\sigma\lambda_1), \quad A_2(\sigma) = 2e^{-\lambda_2 h} - 1 - \alpha\sigma\lambda_2.$$

Since

$$\frac{d}{dt} \left( \frac{A_1(a)e^{\lambda_1 t} + A_2(a)e^{\lambda_2 t}}{A_1(b)e^{\lambda_1 t} + A_2(b)e^{\lambda_2 t}} \right) = \frac{(A_1(a)A_2(b) - A_2(a)A_1(b))(\lambda_1 - \lambda_2)e^{-t/\alpha}}{(A_1(b)e^{\lambda_1 t} + A_2(b)e^{\lambda_2 t})^2}$$

and

$$A_1(a)A_2(b) - A_2(a)A_1(b) = \alpha(b-a)(\lambda_2(2e^{-\lambda_1 h} - 1) - \lambda_1(2e^{-\lambda_2 h} - 1)) < 0,$$

we derive in view of (26) that

$$\max_{h, t_a} \frac{\dot{z}_a(t)}{\dot{z}_b(t)} = \frac{\dot{z}_a(h)}{\dot{z}_b(h)} = \rho(a, b).$$

(ii) It is enough to establish the second inequality both in (A.4) and in (A.5). The second inequality in (A.4) can be rewritten as

$$q \geq \max_{[0,h]} \frac{\dot{y}_{\delta,a}(t)}{\dot{y}_{\delta_1,a_1}(t)} = \max_{[0,h]} \frac{a\alpha\Sigma(t) + 1 + \delta}{a_1\alpha\Sigma(t) + 1 + \delta_1}.$$

Since

$$\frac{d}{ds} \left( \frac{a\alpha s + 1 + \delta}{a_1\alpha s + 1 + \delta_1} \right) = -\frac{1-q}{q} \cdot \frac{a + (1+\delta)(\alpha\Sigma(h))^{-1}}{(a_1\alpha s + 1 + \delta_1)^2} < 0$$

and  $\dot{\Sigma}(t) < 0$ , we obtain

$$\max_{[0,h]} \frac{\dot{y}_{\delta,a}(t)}{\dot{y}_{\delta_1,a_1}(t)} = \frac{\dot{y}_{\delta,a}(h)}{\dot{y}_{\delta_1,a_1}(h)} = q.$$

The second inequality in (A.5) follows, first, from the fact that the function  $q^{-1}z_{\delta,a}(t)$  solves the problem

$$\alpha\ddot{z} = -\beta\dot{z} + k_0z - q^{-1} + \delta_1, \quad z(h) = q^{-1}y_{\delta,a}(h), \quad \dot{z}(h) = q^{-1}\dot{y}_{\delta,a}(h),$$

whereas the function  $z_{\delta_1,a_1}(t)$  solves the problem

$$\alpha\ddot{z} = -\beta\dot{z} + k_0z - 1 + \delta_1, \quad z(h) = y_{\delta_1,a_1}(h), \quad \dot{z}(h) = \dot{y}_{\delta_1,a_1}(h),$$

where  $y_{\delta_1, a_1}(h) \geq q^{-1}y_{\delta, a}(h)$ ,  $\dot{y}_{\delta_1, a_1}(h) = q^{-1}\dot{y}_{\delta, a}(h)$ , and, second, from the inequality  $t_{\delta, a} \leq t_{\delta_1, a_1}$ . In turn, the latter relation is an immediate consequence of (16).

LEMMA A.2. (i) Assume that  $t^* > 0$ ,  $t_0 \in [t^* - h, t^*]$ , and that  $a \geq 0$  satisfies (15). Let a solution  $x_\varphi(t)$  to the equation

$$(A.6) \quad \alpha \ddot{x}(t) = -\beta \dot{x}(t) + F(x(t), t) - \text{sign } x(t - \tau(t))$$

be such that

$$(A.7) \quad 0 \leq x_\varphi(t^*) \leq y_{\delta, a}(t^* - t_0), \quad \dot{x}_\varphi(t^*) \leq \dot{y}_{\delta, a}(t^* - t_0).$$

Then

$$x_\varphi(t) \leq y_{\delta, a}(t - t_0), \quad \dot{x}_\varphi(t) \leq \dot{y}_{\delta, a}(t - t_0), \quad t \in [t^*, t_0 + h].$$

(ii) Assume that  $t_0 \geq 0$  and that  $a \geq 0$  satisfies (15). Let a solution  $x_\varphi(t)$  obey the conditions

$$x_\varphi(t) > 0, \quad t \in (t_0, t_0 + h], \quad x_\varphi(t_0 + h) \leq z_{\delta, a}(\sigma), \quad \dot{x}_\varphi(t_0 + h) \leq \dot{z}_{\delta, a}(\sigma)$$

for some  $\sigma \in [h, t_{\delta, a}]$ . Then

$$x_\varphi(t) \leq z_{\delta, a}(t - \sigma + t_0 + h), \quad \dot{x}_\varphi(t) \leq \dot{z}_{\delta, a}(t - \sigma + t_0 + h)$$

for all  $t \geq t_0 + h$  such that  $x_\varphi(t) \geq 0$ .

*Proof.* (i) Since  $y_{\delta, a}(t)$  is a strictly increasing function, it is sufficient to consider the case when  $\dot{x}_\varphi(t) \geq 0$ ,  $t \in [t^*, t_0 + h]$ . Then, in the interval  $[t^*, t_0 + h]$ , we have

$$\alpha \ddot{x}_\varphi(t) = -\beta \dot{x}_\varphi(t) + F(x_\varphi(t), t) \pm 1 \leq -\beta \dot{x}_\varphi(t) + k_0 x_\varphi(t) + 1 + \delta,$$

which after a double integration turns into

$$(A.8) \quad \dot{x}_\varphi(t) \leq \dot{x}_\varphi(t^*) e^{-\beta(t-t^*)/\alpha} + \frac{1}{\alpha} \int_{t^*}^t (k_0 x_\varphi(\xi) + 1 + \delta) e^{\beta(\xi-t)/\alpha} d\xi,$$

$$(A.9) \quad \begin{aligned} x_\varphi(t) - x_\varphi(t^*) &\leq \frac{1+\delta}{\beta}(t-t^*) + \frac{\alpha}{\beta} \left( \dot{x}_\varphi(t^*) - \frac{1+\delta}{\beta} \right) (1 - e^{-(t-t^*)/\alpha}) \\ &\quad + \frac{k_0}{\beta} \int_{t^*}^t x_\varphi(\xi) (1 - e^{\beta(\xi-t)/\alpha}) d\xi. \end{aligned}$$

Due to the monotonicity of the right-hand sides with respect to  $x_\varphi$  and  $\dot{x}_\varphi$ , inequality (A.7), and the fact that the substitution of  $y_{\delta, a}(t)$  for  $x_\varphi(t)$  turns (A.8) and (A.9) into equalities, we obtain subsequently that  $x_\varphi(t) \leq y_{\delta, a}(t - t_0)$  and  $\dot{x}_\varphi(t) \leq \dot{y}_{\delta, a}(t - t_0)$ ,  $t \in [t^*, t_0 + h]$ .

(ii) Let  $x_\varphi(t) > 0$  in an interval  $[t_0 + h, t_1]$  for some  $t_1 > t_0 + h$ . Since  $x_\varphi(t)$  is positive in  $(t_0, t_0 + h]$ , and  $\tau(t) \leq h$ , we obtain

$$\alpha \ddot{x}_\varphi(t) \leq -\beta \dot{x}_\varphi(t) + k_0 x_\varphi(t) - 1 + \delta, \quad t \in [t_0 + h, t_1],$$

and hence

$$\begin{aligned}
 \dot{x}_\varphi(t) &\leq \dot{x}_\varphi(t_0 + h)e^{-\beta(t-t_0-h)/\alpha} \\
 &+ \frac{1}{\alpha} \int_{t_0+h}^t (k_0 x_\varphi(\xi) - 1 + \delta) e^{\beta(\xi-t)/\alpha} d\xi, \\
 x_\varphi(t) - x_\varphi(t_0 + h) &\leq -\frac{1-\delta}{\beta}(t - t_0 - h) \\
 &+ \frac{\alpha}{\beta} \left( \dot{x}_\varphi(t_0 + h) + \frac{1-\delta}{\beta} \right) (1 - e^{-\beta(t-t_0-h)/\alpha}) \\
 &+ \frac{k_0}{\beta} \int_{t_0+h}^t x_\varphi(\sigma) (1 - e^{\beta(\sigma-t)/\alpha}) d\sigma.
 \end{aligned}
 \tag{A.10}$$

These relations are monotone with respect to  $x_\varphi$  and  $\dot{x}_\varphi$  and thereby imply  $x_\varphi(t) \leq z_a(t - \sigma + t_0 + h)$ ,  $\dot{x}_\varphi(t) \leq \dot{z}_a(t - \sigma + t_0 + h)$ ,  $t \in [t_0 + h, t_1]$ , since the replacement of  $x_\varphi(t)$  by  $z_a(t - \sigma + t_0 + h)$  turns (A.10) and (A.11) into equalities.

LEMMA A.3. *For any nonnegative  $a$  satisfying (15), and any  $\varphi \in C_0[-h, 0]$  such that*

$$\varphi(0) = 0, \quad \dot{\varphi}(0) = a, \tag{A.12}$$

*the solution  $x_\varphi(t)$  to (A.6) satisfies the following conditions:*

- $x_\varphi(t)$  has an unbounded zero locus;
- the first positive zero of  $x_\varphi(t)$  does not exceed  $t_{\delta,a}$ ;
- if  $x_\varphi(t') = 0$  at  $t' > 0$ , then  $x_\varphi$  vanishes at some  $t'' \in (t', t' + t_{\delta,\xi_\delta((1-\delta)/k_0)})$ ;
- $x_\varphi(t)$  obeys the condition

$$|x_\varphi(t)| \leq z_{\delta,\xi_\delta((1-\delta)/k_0)}(t_{\delta,\xi_\delta((1-\delta)/k_0)}) \quad \text{if } t \geq t_{\delta,a}, \tag{A.13}$$

$$|\dot{x}_\varphi(t)| \leq \xi_\delta((1-\delta)/k_0) \quad \text{for all } t \in x_\varphi^{-1}(0) \cap (0, \infty). \tag{A.14}$$

*Proof. Step 1.* We first show that  $x_\varphi(t)$  has a positive root. Assume on the contrary that  $x_\varphi(t) > 0$  for all  $t > 0$ . By Lemma A.2(i),  $x_\varphi(t) \leq y_a(t)$ ,  $\dot{x}_\varphi(t) \leq \dot{y}_a(t)$  as  $t \in [0, h]$ , and hence by Lemma A.2(i),  $x_\varphi(t) \leq z_a(t)$  as  $t \geq h$ . However,  $z_a(t)$  becomes negative for large  $t$ , and so does  $x_\varphi$ . Furthermore, we obtain that  $x(t)$  vanishes at some point  $t_1 \leq t_a$ , where  $t_a$  denotes the positive zero of  $z_a(t)$ . The same argument provides the upper bound  $|x_\varphi(t)| \leq z_a(t_a)$  in the interval  $(0, t_1)$ .

*Step 2.* We intend now to estimate  $|\dot{x}_\varphi(t_1)|$ . Change sign of  $x_\varphi$  so that  $x_\varphi(t) < 0$  as  $t \in (0, t_1)$ . Let  $t' = \max\{t \in (0, t_1) \mid \dot{x}_\varphi(t) = 0\}$ . Since  $|x_\varphi(t')| \leq z_a(t_a) < \frac{1}{k_0}$ , in the interval  $[t', t_1]$ , we have

$$\alpha \ddot{x}_\varphi(t) = -\beta \dot{x}_\varphi(t) + F(x_\varphi(t), t) \pm 1 < -\dot{x}_\varphi(t) + 1, \tag{A.15}$$

which yields

$$\dot{x}_\varphi(t) < 1 - e^{(t'-t)/\alpha} < 1, \quad t \in [t', t_1].$$

Furthermore,  $x_\varphi(t)$  is strongly increasing in  $[t', t_1]$ , and then we can choose it as a variable and rewrite (A.15) in the form

$$\alpha \frac{d\dot{x}_\varphi}{dx_\varphi} \dot{x}_{1,\varphi} + \dot{x}_\varphi < 1 \quad \stackrel{0 \leq \dot{x}_\varphi < 1}{\implies} \int_0^{\dot{x}_\varphi(t_1)} \frac{\alpha \dot{x}_\varphi}{1 - \dot{x}_\varphi} d\dot{x}_{1,\varphi} < -x_\varphi(t').$$

The latter formula turns into the relation for  $\xi(1/k_0)$ , when replacing “ $<$ ” by “ $=$ ” and  $-x_\varphi(t')$  by  $\frac{1}{k_0}$ . Hence  $\dot{x}_\varphi(t_1) < \xi(1/k_0)$ .

*Step 3.* Observe now that (23) is equivalent to

$$\xi\left(\frac{1}{k_0}\right) < \frac{2e^{-\lambda_1 h} - 1}{\alpha\lambda_1}.$$

That is,  $x_\varphi(t - t_1)$  satisfies the hypotheses of Lemma A.3, and one can proceed inductively, proving the statements of the lemma for the whole interval  $[0, \infty)$ .

**A.2. Proof of Theorem 1.** In the interval  $[0, t_c + t_{\xi(1/k_0)}]$ , we have  $x_{u,\varphi}(t) = x_\varphi(t)$ . Hence the conditions imposed on the set  $\Phi_c \subset C_0[-h, 0]$  and Lemmas A.2 and A.3 yield that  $|x_{u,\varphi}(t)| \leq \frac{1}{k_0}$  as  $t \in [0, t_c]$  and  $(x_{u,\varphi})^{-1}(0) \cap (0, t_c] \neq \emptyset$ . Furthermore, for any  $t^* \in (x_{u,\varphi})^{-1}(0) \cap (0, t_c]$ , we have  $|\dot{x}_{u,\varphi}(t^*)| \leq \xi(1/k_0)$ . Next we apply Lemmas A.2 and A.3 to  $x_{u,\varphi}$  restricted to the interval  $[t_c, t_c + t_{\xi(1/k_0)}]$  and obtain that  $|x_{u,\varphi}(t)| \leq z_{\xi(1/k_0)}(t_{\xi(1/k_0)})$  if  $t \in [t_c, t_c + t_{\xi(1/k_0)}]$ , the set  $(x_{u,\varphi})^{-1}(0) \cap (t_c, t_c + t_{\xi(1/k_0)})$  is nonempty, and, for any  $t^* \in (x_{u,\varphi})^{-1}(0) \cap (t_c, t_c + t_{\xi(1/k_0)})$ , it holds that  $|\dot{x}_{u,\varphi}(t^*)| \leq \xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))$ .

In the interval  $[t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)}]$ , we have

$$\alpha \ddot{x}_{u,\varphi}(t) = -\beta \dot{x}_{u,\varphi} + F(x_{u,\varphi}(t), t) - \rho \cdot \text{sign } x_{u,\varphi}(t - \tau(t)).$$

The variable change  $x_{u,\varphi}(t) = \rho \cdot x_{u,\varphi}^{(1)}(t)$ ,  $t \in [t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)}]$ , leads to the equation

$$\alpha \frac{d^2}{dt^2} x_{u,\varphi}^{(1)}(t) = -\beta \frac{d}{dt} x_{u,\varphi}^{(1)}(t) + \frac{1}{\rho} F(\rho x_{u,\varphi}^{(1)}(t), t) - \text{sign } x_{u,\varphi}^{(1)}(t - \tau(t)).$$

Observe that the function  $F^{(1)}(x, t) := \frac{1}{\rho} F(\rho x, t)$  satisfies restrictions (2) and (5).

Put

$$(A.16) \quad s = \max\left((x_{u,\varphi})^{-1}(0) \cap [0, t_c + t_{\xi(1/k_0)}]\right).$$

Assume, first, that  $s > t_c + t_{\xi(1/k_0)} - h$ . Then by Lemma A.2(i)

$$|x_{u,\varphi}(t_c + t_{\xi(1/k_0)})| \leq y_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))}(t_c + t_{\xi(1/k_0)} - s),$$

$$|\dot{x}_{u,\varphi}(t_c + t_{\xi(1/k_0)})| \leq \dot{y}_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))}(t_c + t_{\xi(1/k_0)} - s).$$

Consequently, by Lemma A.1(i) and by the definition of  $\rho$ ,

$$|x_{u,\varphi}^{(1)}(t_c + t_{\xi(1/k_0)})| \leq y_{\xi(1/k_0)}(t_c + t_{\xi(1/k_0)} - s),$$

$$\left| \frac{d}{dt} x_{u,\varphi}^{(1)}(t_c + t_{\xi(1/k_0)}) \right| \leq \dot{y}_{\xi(1/k_0)}(t_c + t_{\xi(1/k_0)} - s);$$

that is,  $x_{u,\varphi}^{(1)}(t - t_c - t_{\xi(1/k_0)})$  satisfies the conditions of Lemmas A.2(i) and A.3 with  $a = \xi(1/k_0)$ .

Now assume that  $s$  from (A.16) satisfies  $s \leq t_c + t_{\xi(1/k_0)} - h$ . Then by Lemma A.2(ii)

$$|x_{u,\varphi}(t_c + t_{\xi(1/k_0)})| \leq z_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))}(\sigma),$$

$$|\dot{x}_{u,\varphi}(t_c + t_{\xi(1/k_0)})| \leq \dot{z}_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))}(\sigma)$$

for some  $\sigma \in [h, t_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))}]$ . Consequently, by Lemma A.1(i) and by the definition of  $\rho$ ,

$$|x_{u,\varphi}^{(1)}(t_c + t_{\xi(1/k_0)})| \leq z_{\xi(1/k_0)}(\sigma), \quad \left| \frac{d}{dt} x_{u,\varphi}^{(1)}(t_c + t_{\xi(1/k_0)}) \right| \leq \dot{z}_{\xi(1/k_0)}(\sigma),$$

and here  $h \leq \sigma \leq t_{\xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))} < t_{\xi(1/k_0)}$ . Hence  $x_{u,\varphi}^{(1)}(t - t_c - t_{\xi(1/k_0)})$  satisfies the conditions of Lemmas A.2(ii) and A.3 with  $a = \xi(1/k_0)$ .

Under both of the assumptions, Lemmas A.2 and A.3 yield that

$$|x_{u,\varphi}^{(1)}(t)| \leq z_{\xi(1/k_0)}(t_{\xi(1/k_0)}), \quad t \in [t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)}],$$

the set  $(x_{u,\varphi}^{(1)})^{-1}(0) \cap (t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)})$  is nonempty, and

$$\left| \frac{d}{dt} x_{u,\varphi}^{(1)}(t^*) \right| \leq \xi(z_{\xi(1/k_0)}(t_{\xi(1/k_0)}))$$

as  $t^* \in (x_{u,\varphi}^{(1)})^{-1}(0) \cap (t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)})$ . These properties of  $x_{u,\varphi}^{(1)}|_{[t_c + t_{\xi(1/k_0)}, t_c + 2t_{\xi(1/k_0)}]}$  coincide with the aforementioned properties of  $x_{u,\varphi}|_{[t_c, t_c + t_{\xi(1/k_0)}]}$ . Thus, one can proceed inductively, defining

$$x_{u,\varphi}(t) = \rho^n x_{u,\varphi}^{(n)}(t), \quad t \in [t_c + nt_{\xi(1/k_0)}, t_c + (n+1)t_{\xi(1/k_0)}], \quad n = 2, 3, \dots,$$

and deriving

$$|x_{u,\varphi}^{(n)}(t)| \leq z_{\xi(1/k_0)}(t_{\xi(1/k_0)}), \quad t \in [t_c + nt_{\xi(1/k_0)}, t_c + (n+1)t_{\xi(1/k_0)}].$$

The upper bound (29) follows immediately.

**A.3. Proof of Theorem 2.** In the interval  $[0, T(\varepsilon)]$ , we have  $x_{u,\varphi}(t) = x_{1,\varphi}(t)$ . The conditions imposed on the set  $\Phi_c \subset C_0[-h, 0]$  and Lemmas A.2 and A.3 yield that  $|x_{\varphi}(t)| \leq \frac{1-\delta-\varepsilon}{k_0}$  as  $t \geq 0$  and that  $(x_{u,\varphi})^{-1}(0) \cap (0, t_{\delta,c}] \neq \emptyset$ .

Indeed, using (13) for the equation  $z_{\delta,c}(t_{\delta,c}) = 0$ , we obtain

$$\frac{2e^{-\lambda_1 h} - 1 - \delta - \alpha c \lambda_1}{\alpha \lambda_1 (\lambda_1 - \lambda_2)} e^{\lambda_1 t_{\delta,c}} < \frac{1 - \delta}{k_0},$$

$$t_{\delta,c} < \frac{1}{\lambda_1} \log \frac{(1 - \delta) \alpha \lambda_1 (\lambda_1 - \lambda_2)}{k_0 (2e^{-\lambda_1 h} - 1 - \delta - \alpha c \lambda_1)} = \frac{1}{\lambda_1} \log \frac{(1 - \delta) (\lambda_1 - \lambda_2)}{-\lambda_2 \varepsilon} = T(\varepsilon)$$

(cf. (33) and (35)). Furthermore, we have  $|\dot{x}_{\varphi}(t^*)| < \xi_{\delta}((1 - \delta)/k_0)$  for any  $t^* \in (x_{\varphi})^{-1}(0) \cap (0, T(\varepsilon)]$ . That means  $x_{\varphi}(T(\varepsilon))$  and  $\dot{x}_{\varphi}(T(\varepsilon))$  satisfy the hypotheses of Lemma A.2(i) or (ii) with  $a = \xi_{\delta}(\sigma_{\delta})$ ,  $\sigma_{\delta}$  being defined by (17). Furthermore, using (20) and (22), we obtain

$$\begin{aligned} a = \xi_{\delta}(\sigma_{\delta}) &= \frac{1 + \delta}{\beta} (1 - e^{-t' \beta / \alpha}) = \frac{\beta}{\alpha} \left( \frac{1 + \delta}{\beta} t' - \sigma_{\delta} \right) \\ &> \frac{\beta}{\alpha} \left( \frac{1 + \delta}{\beta} t' - \frac{1 - \delta}{k_0} \right) \implies t' < \theta \\ (A.17) \quad &\implies a < \frac{1 + \delta}{\beta} (1 - e^{-\theta \beta / \alpha}). \end{aligned}$$

In the interval  $[T(\varepsilon), 2T(\varepsilon))$ , we have  $K(t) = q$ , and the variable change  $x_{u,\varphi}(t) = qx^{(1)}(t)$  leads to the equation

$$\alpha \frac{d^2}{dt^2} x^{(1)}(t) = -\beta \frac{d}{dt} x^{(1)}(t) + F_1(x^{(1)}(t), t) - \text{sign } x^{(1)}(t - \tau(t)), \quad t \in [T(\varepsilon), 2T(\varepsilon)),$$

where  $F_1(x, t) := q^{-1}F(qx, t)$  obeys restriction (5) and restriction (7) with  $\delta$  replaced by  $\delta_1 = \delta/q$ . In view of (A.17) and by Lemma A.1(ii),  $x^{(1)}(t)$  satisfies the conditions of Lemma A.2 with  $F$ ,  $\delta$ ,  $a$  replaced, respectively, by  $F_1$ ,  $\delta_1$ ,  $a_1$  defined in (A.3). Moreover,

$$\begin{aligned} a_1 &= \frac{a}{q} + \frac{(1-q)(e^{\lambda_1 h} - e^{\lambda_2 h})}{q\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})} < \frac{1+\delta}{q\beta}(1 - e^{-\theta\beta/\alpha}) + \frac{(1-q)(e^{\lambda_1 h} - e^{\lambda_2 h})}{q\alpha(\lambda_1 e^{\lambda_1 h} - \lambda_2 e^{\lambda_2 h})} \\ (A.18) \quad &\leq \frac{2e^{-\lambda_1 h} - 1 - \delta/q - \varepsilon}{\alpha\lambda_1} = \frac{2e^{-\lambda_1 h} - 1 - \delta_1 - \varepsilon}{\alpha\lambda_1}, \end{aligned}$$

the first inequality following from (A.17) and the second one from (32). We obtain also that

$$|x_{u,\varphi}(t)| = q|x^{(1)}(t)| \leq q \frac{1 - \delta_1}{k_0} = \frac{q - \delta}{k_0}.$$

Relation (A.18) allows one to continue the procedure inductively by defining  $K(t)$  by (34) and the functions  $x^{(s)}(t)$ ,  $t \geq sT(\varepsilon)$ , by the formula  $x_{u,\varphi}(t) = q^s x^{(s)}(t)$  for  $s = 1, \dots, m$ . Inequality (36) follows immediately.

# CONTROLLED STOCHASTIC DIFFERENTIAL EQUATIONS UNDER CONSTRAINTS IN INFINITE DIMENSIONAL SPACES\*

RAINER BUCKDAHN<sup>†</sup>, MARC QUINCAMPOIX<sup>†</sup>, AND GIANMARIO TESSITORE<sup>‡</sup>

**Abstract.** In this paper we study the compatibility (or viability) of a given state constraint  $K$  with respect to a controlled stochastic evolution equation in a real Hilbert space  $H$ . We allow the noise to be a cylindrical Wiener process and admit an unbounded linear operator in the state equation. Our assumptions cover, for instance, controlled heat equations with space-time white noise. Our main result is to prove that if  $K$  is  $\varepsilon$ -viable, then the square of the distance from  $K$ :  $d_K^2(x) := \inf_{y \in K} |x - y|^2$  is a viscosity supersolution of a suitable class of fully nonlinear Hamilton–Jacobi–Bellman equations in  $H$ . This extends already obtained results into the finite dimensional case. We use the definition of viscosity supersolutions for “unbounded” elliptic equations in infinite variables that have been recently introduced by Świąch and Kelome. We discuss several cases where the above necessary condition is also sufficient.

**Key words.** viability, stochastic control

**AMS subject classifications.** 93E20, 35R60, 60H15, 49L25

**DOI.** 10.1137/060674284

**1. Introduction.** We investigate the (approximate) compatibility of the controlled stochastic differential equations

$$(1.1) \quad dX_t = (AX_t + F(X_t, u_t)) dt + G(X_t, u_t) dW_t, \quad t \geq 0,$$

with the state constraint

$$X_t \in K \text{ for every } t \geq 0.$$

The constraint set  $K$  is a closed subset of a separable Hilbert space  $H$ . A complete right continuous filtration  $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$  is given on a complete probability space  $(\Omega, \mathcal{F}, P)$ . The process  $W$  is a cylindrical Brownian motion on a separable Hilbert space  $\Xi$ . The control  $u_t$  is an  $\mathbb{F}$ -progressively measurable process from  $u : [0, \infty[ \times \Omega$  into a bounded closed subset  $U$  of a given Banach space. We denote by  $\mathcal{U}$  the set of all controls. The assumptions on the functions  $F : H \times U \rightarrow H$ ,  $G : H \times U \rightarrow L(\Xi, H)$ , and on the linear operator  $A : D(A) \subset H \rightarrow H$  will be discussed later in this section.

A solution  $X_t$  of (1.1) is said to be compatible (or viable) with the constraint  $K$  if and only if for all  $t \geq 0$  we have  $X_t \in K$   $P$  almost surely. Noticing that a viable trajectory  $X_t$  satisfies

$$\mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(X_t) dt \right] = 0$$

(where  $d_K(x) = \inf_{y \in K} |x - y|$  is the distance to  $K$  and  $C > 0$  a constant), we say that the constraint  $K$  is  $\varepsilon$ -viable (or approximatively compatible) for the control system (1.1) if and only if there exists a constant  $C$  large enough such that, for  $x \in K$ ,

$$(1.2) \quad \inf_{u \in \mathcal{U}} \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(X_t^{x,u}) dt \right] = 0,$$

where  $X^{x,u}$  denotes the solution of (1.1) associated with the initial condition  $X_0^{x,u} = x$  and with the control  $u \in \mathcal{U}$ . Remark that, obviously, when the infimum in (1.2) is achieved, we obtain a viable trajectory  $X_t$ .

Our main aim consists of characterizing of  $K$  for the control system (1.1).

Since pioneering work of Nagumo [26] for deterministic differential equations, this problem has been solved for deterministic control systems in various cases (see [1] and its bibliography). For finite dimensional stochastic control a characterization of viability has been obtained in [2, 3, 4, 17] through stochastic tangent cones to the set  $K$ . Also in finite dimension, another characterization has been obtained in [7] through the distance function to the set  $K$ . We refer the reader to [8, 9, 10, 28] for various extensions and applications of this method.

The characterization of [7] is crucially based on the Hamilton–Jacobi–Bellman equation

$$(1.3) \quad \Psi(x, V(x), DV(x), D^2V(x)) = 0, \quad x \in \mathbb{R}^n,$$

satisfied by the value function

$$(1.4) \quad x \in \mathbb{R}^n \mapsto V(x) := \inf_{u \in \mathcal{U}} \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(X_t^{x,u}) dt \right].$$

Indeed, the result of [7] says that  $K$  is viable if and only if the map  $x \mapsto d_K^2(x)$  is a viscosity supersolution to (1.3). The proofs relies on Ito's calculus and on comparison theorem for sub- and supersolutions to (1.3).

In the infinite dimensional case, we are facing several difficulties we wish to point out:

- the meaning of solutions to (1.1) (mild solutions see [12, 13]),
- the relation between  $K$  and the domain of the operator  $A$ ,
- the comparison result for a Hamilton–Jacobi equation is not valid in general (see [24, 30] for a particular case),
- the fact that the Brownian motion is cylindrical forbids a direct application of Ito's calculus,
- the lack of compactness and the consequent difficulty in proving existence of optimal controls for (1.4) (see [18, 19] for some results in the direction of existence of relaxed controls).

For the viability in Hilbert spaces, we mention the approach of [27] in the uncontrolled case and when both  $K$  and the coefficients of the state equation are regular and the Brownian motion is finite dimensional. This approach is based on a tangent characterization of the viability and on a Wong–Zakai approximation of the noise. We notice that, for such an approach, the above mentioned smoothness assumptions seem to be crucial; this precludes, for instance, applicability of the method if the coefficients of the equation are evaluation (Nemitskii) operators even if the noise is finite dimensional.

In contrast our method is concerned with the fully controlled case with a cylindrical Brownian motion. Namely, we propose a new criterion for  $\varepsilon$ -viability of controlled

systems extending results of [2, 3, 4, 7, 17] in both directions: the case where the state variable lies in a Hilbert space, and the case where the Brownian motion is infinite dimensional (cylindrical).

Let us explain how this paper is organized.

In section 1, we set the problem recalling the notion of mild solution and giving hypothesis on the control system.

In section 2, we provide a necessary condition for  $\varepsilon$  viability for a closed convex set  $K$ . This condition says that the function  $x \mapsto d_K^2(x)$  is a viscosity supersolution of a suitable Hamilton–Jacobi–Bellman equation. This relies on two different classes of modification of the original state equation (beside usual approximations obtained replacing unbounded operator  $A$  by its Yosida approximations):

(a) the first modified equation is the stochastic differential equation, which is the equation satisfied by  $\mathbb{E}[X_t^{x,u} | \mathcal{F}_\infty^m]$ , where  $\mathcal{F}_t^m = \sigma\{W_s^m, s \leq t\} \vee \mathcal{N}_P$  is the filtration generated by the projection  $W^m$  of the cylindrical Brownian motion on the  $m$  dimensional space spanned by the  $m$  first elements of an orthonormal base of  $\Xi$ .

(b) the second equation is obtained by replacing  $W$  by  $W^m$  in the original (1.1).

The idea of introducing the previous modified equations is due to the following easy observation: If  $X_t^{x,u}$  is viable in a convex set  $K$ , so is  $\mathbb{E}[X_t^{x,u} | \mathcal{F}_\infty^m]$ . It is worth pointing out that modified equations (a) and (b) are not needed when  $W$  is trace class: in this case we are able to consider (possibly) nonconvex closed sets.

Then we explain how our general necessary condition can be simplified for more smooth sets as linear spaces, balls.

Section 3 is devoted to cases when the necessary condition of section 2 is also sufficient. This can be obtained for instance when  $K$  is a closed ball. We also prove that when  $K$  is a locally compact linear subset then necessarily  $K$  is contained in the domain of the operator  $A$  (we give an alternative proof of the result in Nakayama [27]). In this last case we again prove that the necessary condition of section 2 is also sufficient. Finally, we consider the special case in which the noise is trace class and the diffusion has the restrictive regularity properties required in [24]. In that case we are able to prove that the necessary condition is also sufficient for all sets  $K$  (not necessarily convex) such that the distance  $d_K^2$  is lower semicontinuous with respect to weak topology (this is, for instance, the case when  $K$  is locally compact). The result is obtained by a comparison principle for viscosity solutions with an argument similar to the finite dimensional case; see [30, 24].

Section 4 is concerned with the application of our results to a semilinear heat equation. The characterization of the  $\varepsilon$ -viability is deduced for simple sets like balls and locally compact smooth sets.

**2. Statement of the problem.** We will be dealing with the following state equation:

$$(2.1) \quad \begin{cases} dX_t^{x,u} &= (AX_t^{x,u} + F(X_t^{x,u}, u_t)) dt + G(X_t^{x,u}, u_t) dW_t, \quad t \geq 0, \\ X_0^{x,u} &= x. \end{cases}$$

We work under the following general assumptions and notations:

- $(H, \langle \cdot, \cdot \rangle)$ ,  $(\Xi, \langle \cdot, \cdot \rangle_\Xi)$  are separable real Hilbert spaces. By  $L(\Xi, H)$  we denote the space of bounded linear operators  $\Xi \rightarrow H$ . Moreover, by  $L_2(\Xi, H)$  we denote the subspace of  $L(\Xi, H)$  given by all Hilbert–Schmidt operators. We endow  $L_2(\Xi, H)$  with its natural Hilbertian norm.
- If  $\phi$  is a Fréchet differentiable map  $H \rightarrow \mathbb{R}$  by  $D\phi$ , then we always denote its Fréchet derivative.

- $(\Omega, \mathcal{F}, P)$  is a complete probability space and  $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$  is a filtration defined on  $(\Omega, \mathcal{F}, P)$  that we assume to be complete and right-continuous.
- $W$  is  $\Xi$  valued cylindrical Wiener process with respect to the filtration  $\mathbb{F}$ .
- $A$  is an unbounded linear operator  $A : H \supset D(A) \rightarrow H$  and we assume that  $A$  is an  $m$ -dissipative operator (that is,  $\langle Ax, x \rangle \leq 0$ , for all  $x \in D(A)$ , and  $(I - A)$  is invertible). Consequently,  $A$  is the generator of a  $C_0$  semigroup of contractions  $(T_t)_{t \geq 0}$ .
- $E$  is a real separable and reflexive Banach space and  $U \subset E$  is a bounded closed subset. The space  $U$  is endowed with the Borel  $\sigma$ -field  $\mathcal{B}(U)$  and  $\mathcal{U} = L^0_{\mathbb{F}}(\mathbb{R}_+; U)$  is the set of all  $\mathbb{F}$ -progressively measurable processes  $u : [0, \infty[ \times \Omega \rightarrow U$ .
- $F : H \times U \rightarrow H$ ,  $G : H \times U \rightarrow L(\Xi, H)$  satisfy, for suitable  $C \in \mathbb{R}_+$  and  $\gamma \in (0, 1/2)$  and for all  $t > 0, u \in U, x, y \in H$ ,

$$(2.2) \quad |F(x, u) - F(y, u)| \leq C|x - y|, \quad |F(x, u)| \leq C, \quad |G(x, u)|_{L(\Xi, H)} \leq C,$$

$$(2.3) \quad |T_t G(x, u) - T_t G(y, u)|_{L_2(\Xi, H)} \leq C(1 \wedge t)^{-\gamma}|x - y|,$$

$$(2.4) \quad |T_t G(x, u)|_{L_2(\Xi, H)} \leq C(1 \wedge t)^{-\gamma}.$$

- For all  $x \in H$  and  $t > 0$ ,  $F(x, \cdot) : U \rightarrow H$  and  $T_t G(x, \cdot) : U \rightarrow L_2(\Xi, H)$  are continuous.
- There exists an orthonormal basis  $\{e_i, i \in \mathbb{N}\}$  in  $\Xi$  such that, for all  $i \in \mathbb{N}$  and all  $u \in U, x, y \in H$ ,

$$(2.5) \quad |G(x, u)e_i - G(y, u)e_i| \leq C_i|x - y|,$$

where  $C_i \in \mathbb{R}$  are suitable constants. The basis  $\{e_i, i \in \mathbb{N}\}$  will be fixed throughout this paper.

REMARK 2.1. *We could relax the assumption on dissipativity of  $A$  just requiring that  $A - \lambda I$  is  $m$ -dissipative for a suitable constant  $\lambda$ . This would only slightly complicate the computations.*

We recall that an  $\mathcal{F}$ -progressively measurable process  $X^{x,u}$  such that  $\mathbb{E}[\sup_{s \in [0, T]} |X_s^{x,u}|^2] < +\infty$  is a mild solution of (2.1) if  $P$ -a.s. for all  $t > 0$ :

$$(2.6) \quad X_t^{x,u} = T_t x + \int_0^t T_{t-s} F(X_s^{x,u}, u_s) ds + \int_0^t T_{t-s} G(X_s^{x,u}, u_s) dW_s.$$

The following existence and uniqueness result is standard under the present assumptions (see [12, 16]). The convergence result follows by a straightforward application of a parameter depending contraction argument exactly as in the proof of Proposition 3.2 in [16].

LEMMA 2.2. *For all  $x \in H$  and  $u \in \mathcal{U}$  there exists a unique mild solution  $X^{x,u}$  of (2.1). Moreover, for every  $p \geq 1$  we can find a constant  $C_p \in \mathbb{R}$  such that, for all  $x \in H, u \in \mathcal{U}, T > 0$ ,*

$$\mathbb{E} \sup_{s \in [0, T]} |X_s^{x,u}|^p \leq \exp(C_p T)(1 + |x|^p).$$

Finally, if  $\{u^n : n \geq 1\} \subset \mathcal{U}$  and  $u \in \mathcal{U}$  are such that  $u^n \rightarrow u$  in measure  $ds dP$ , then

$$\mathbb{E} \sup_{s \in [0, T]} |X_s^{x,u^n} - X_s^{x,u}|^p \rightarrow 0.$$

Our objective is to find conditions on  $A, F, G$  under which  $K$  is  $\varepsilon$ -viable for the above stochastic differential equation (SDE).

Let us now recall the definition of  $(\varepsilon)$ -viability. We use the notation in  $d_K(x) := \inf_{y \in K} |x - y|$ ,  $x \in H$ .

DEFINITION 2.3. *A closed subset  $K \subset H$  is  $\varepsilon$ -viable if there exists a constant  $C$  large enough such that, for  $x \in K$ ,*

$$(2.7) \quad \inf_{u \in \mathcal{U}} \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(X_t^{x,u}) dt \right] = 0.$$

Obviously, if  $K$  is viable for (1.1), then it is also  $\varepsilon$ -viable. The converse is true if the infimum is achieved in (2.7) for every  $x \in K$ . In the infinite dimensional case there are not good conditions on the dynamics ensuring the existence of an optimal control in (2.7); we have only the existence of  $\varepsilon$ -optimal controls. In contrast, in the finite dimensional case ( $H = \mathbb{R}^n$  and  $A \equiv 0$ ), the existence of such an optimal control could be obtained assuming conditions on the right-hand side of the control system (see [15]) and it is then possible to study the viability instead of  $\varepsilon$ -viability [7].

We recall now the following characterization result in finite dimensional space.

THEOREM 2.4 (see [7]). *Suppose that the spaces  $H$  and  $\Xi$  are finite dimensional and  $A \equiv 0$ .*

*Then the closed nonempty set  $K \subset H$  is  $\varepsilon$ -viable w.r.t. (2.1) if and only if there exists  $C > 0$  (large enough) such that  $d_K^2$  is a viscosity supersolution of the following HJB-equation:*

$$(2.8) \quad \Psi(x, V(x), DV(x), D^2V(x)) = 0, \quad x \in H,$$

where

$$(2.9) \quad \Psi(x, v, p, X) = - \inf_{u \in U} \left( \frac{1}{2} \text{Tr} \langle XG(x, u)G(x, u)^* \rangle + \langle F(x, u), p \rangle \right) + Cv - d_K^2(x).$$

In Hilbert spaces, our method will use two different classes of modifications of the state equation which we introduce now.

For the orthonormal basis  $\{(e_i) : i \in \mathbb{N}\}$  in  $\Xi$  fixed above we put  $\beta_t^i := \langle W_t, e_i \rangle$ . By construction  $\{(\beta_i) : i \in \mathbb{N}\}$  is a sequence of mutually independent 1-dimensional Brownian motions and  $W_s^m := \sum_{i=1}^m \beta_t^i e_i$  is an  $m$ -dimensional Brownian motion.

We set  $\mathcal{F}_t^m = \sigma\{W_s^m, 0 \leq s \leq t\} \vee \mathcal{N}_P$ ,  $\mathcal{F}_t^{m,M} = \sigma\{\beta_s^i, 0 \leq s \leq t, m+1 \leq i \leq M\} \vee \mathcal{N}_P$ ,  $t \in [0, +\infty)$  (here  $\mathcal{N}_P$  is the set of all  $P$ -null sets). Moreover,  $\mathcal{F}_\infty^m = \sigma(\bigcup_{t>0} \mathcal{F}_t^m)$ ,  $\mathcal{F}_\infty^{m,M} = \sigma(\bigcup_{t>0} \mathcal{F}_t^{m,M})$ . Finally, by  $\mathbb{F}^m = (\mathcal{F}_t^m)_{t \geq 0}$ ,  $\mathbb{F}^{m,M} = (\mathcal{F}_t^{m,M})_{t \geq 0}$  we denote the corresponding filtrations.

We now define  $Y_t^{x,u,m} := \mathbb{E}(X_t^{x,u} | \mathcal{F}_\infty^m)$ . It is easy to verify that  $Y_t^{x,u,m}$  satisfies

$$(2.10) \quad Y_t^{x,u,m} = T_t x + \int_0^t T_{t-s} \mathbb{E}(F(X_s^{x,u}, u_s) | \mathcal{F}_\infty^m) ds + \int_0^t T_{t-s} \mathbb{E}(G(X_s^{x,u}, u_s) | \mathcal{F}_\infty^m) dW_s^m$$

or, writing formally, we get

$$(2.11) \quad \begin{cases} dY_t^{x,u,m} = AY_t^{x,u,m} dt + \mathbb{E}(F(X_t^{x,u}, u_t) | \mathcal{F}_\infty^m) dt + \mathbb{E}(G(X_t^{x,u}, u_t) | \mathcal{F}_\infty^m) dW_t^m, & t \geq 0, \\ Y_0^{x,u,m} = x. \end{cases}$$

REMARK 2.5. *The idea related to the introduction of the processes  $Y^{x,u,m}$  is the following. Since  $K$  is convex if  $P\{X^{x,u} \in K\} = 1$ , then  $P\{Y^{x,u,m} \in K\} = 1$  for all  $m \in \mathbb{N}$ .*

We shall also consider the equation obtained from (2.1) by replacing  $W$  by its projections  $W^m$ , namely

$$(2.12) \quad \begin{cases} dX_t^{x,u,m} &= AX_t^{x,u,m} dt + F(X_t^{x,u,m}, u_t) dt + G(X_t^{x,u,m}, u_t) dW_t^m, \quad t \geq 0, \\ X_0^{x,u,m} &= x. \end{cases}$$

As in the case of the original (2.1) we have the following lemma.

LEMMA 2.6. *For all  $x \in H$ ,  $m \in \mathbb{N}$ , and  $u \in \mathcal{U}$  there exists a unique mild solution  $X^{x,u,m}$  of (2.12). Moreover, for all  $p \geq 1$  we can find a constant  $C_p \in \mathbb{R}$  such that, for all  $x \in H$ ,  $m \in \mathbb{N}$ ,  $u \in \mathcal{U}$ , and  $T > 0$ ,*

$$\mathbb{E} \sup_{s \in [0, T]} |X_s^{x,u,m}|^p \leq \exp(C_p T) (1 + |x|^p).$$

Finally, if  $\{u^n : n \geq 1\} \subset \mathcal{U}$  and  $u \in \mathcal{U}$  are such that  $u^n \rightarrow u$  in measure  $ds dP$ , then  $ds dP$  then

$$\mathbb{E} \sup_{s \in [0, T]} |X_s^{x,u^n,m} - X_s^{x,u,m}|^p \rightarrow 0.$$

REMARK 2.7. *Observe that if  $u \in \mathcal{U}$  is progressively measurable with respect to  $\mathcal{F}^m$ , then  $X^{x,u,m}$  is progressively measurable with respect to  $\mathcal{F}^m$  as well.*

**3. Necessary conditions.** We will prove our result under two different sets of assumptions. In the second we require much less on the coefficients but a bit more on the semigroup generated by  $A$ .

ASSUMPTION 3.1. For all  $x \in H$  the mapping  $u \rightarrow (F(x, u), G(x, u)) : U \rightarrow H \times L(\Xi, H)$  is the restriction of an affine map  $U \rightarrow H \times L(\Xi, H)$ .

ASSUMPTION 3.2. For all  $x \in H$ , the set  $\{(F(x, u), G(x, u)) : u \in U\}$  is a convex subset of  $H \times L(\Xi, H)$  and, moreover, the semigroup  $\{T_t : t \geq 0\}$  is analytic.

REMARK 3.3. *Clearly, if Assumption 3.1 holds,  $U$  is convex and the semigroup  $\{T_t : t \geq 0\}$  is analytic, then Assumption 3.2 holds.*

Our necessary condition will be formulated in terms of viscosity supersolutions of a suitable Hamilton–Jacobi–Bellman (HJB) type equation. The following definition is taken from [30].

DEFINITION 3.4. Let  $\Sigma(H) := \{L \in L(H) : L \text{ selfadjoint}\}$  and  $\Psi : H \times \mathbb{R} \times H \times \Sigma(H) \rightarrow \mathbb{R}$  be a continuous mapping. Just to fix ideas we also assume that  $\Psi(x, y, p, X) \leq \Psi(x, y, p, Y)$  for all  $x, p \in H$ ,  $y \in \mathbb{R}$ ,  $X, Y \in \Sigma(H)$  with  $X \geq Y$ . A continuous function  $V : H \rightarrow \mathbb{R}$  is called a viscosity supersolution of the partial differential equation (PDE)

$$(3.1) \quad \Psi(x, V(x), DV(x), D^2V(x)) - \langle Ax, DV(x) \rangle = 0, \quad x \in H,$$

if for all  $x \in H$  and  $\varphi \in C^2(H)$  such that

1.  $\varphi(x) = V(x)$ ,  $\varphi(y) \leq V(y)$ ,  $y \in \overline{B_r(x)}$ , for some  $r > 0$ ;
2.  $\varphi(y) = \varphi_0(y) + g(y)$ ,  $y \in H$ , where  $\varphi_0, g \in C^2(H)$  are supposed to be bounded on bounded subsets of  $H$  together with their first order derivatives and to

verify

- (i)  $A^*D\varphi_0 : H \rightarrow H$  is continuous and bounded on bounded sets,
- (ii)  $g(y) = \hat{g}(|y|)$ ,  $y \in H$ , where  $\hat{g} : \mathbb{R} \rightarrow \mathbb{R}$  is a decreasing function,

it holds that

$$\Psi(x, V(x), D\varphi(x), D^2\varphi(x)) - \langle A^*D\varphi_0(x), x \rangle \geq 0.$$

We are now able to formulate the main result of this section.

**THEOREM 3.5.** *Suppose that either Assumption 3.1 or Assumption 3.2 holds and that the closed convex nonempty set  $K \subset H$  is  $\varepsilon$ -viable w.r.t. (2.1). Then there exists  $C > 0$  (large enough) such that for every  $m \geq 1$ ,  $d_K^2$  is a viscosity supersolution of the HJB equation*

$$(3.2) \quad \Psi_m(x, V(x), DV(x), D^2V(x)) - \langle Ax, DV(x) \rangle = 0, \quad x \in H,$$

where for  $X \in \Sigma(H)$ ,  $p \in H$ ,  $v \in \mathbb{R}$ ,  $x \in H$

(3.3)

$$\Psi_m(x, v, p, X) = - \inf_{u \in U} \left( \frac{1}{2} \sum_{i=1}^m \langle XG(x, u)e_i, G(x, u)e_i \rangle + \langle F(x, u), p \rangle \right) + Cv - d_K^2(x).$$

The proof will be based on the following lemma comparing the solution of (2.11) and the solution of (2.12). In order to make this comparison it is crucial to associate for  $m \geq 1$  and  $\delta > 0$  an appropriately chosen  $\delta$ -optimal,  $\mathbb{F}$ -progressively measurable control process  $u$  with an  $\mathbb{F}^m$ -progressively measurable control process  $v$  such that the estimate (3.5) holds.

**LEMMA 3.6.** *Suppose that either Assumption 3.1 or Assumption 3.2 holds and that  $K$  is  $\varepsilon$ -viable. Then there exist two large enough constants  $C, c > 0$  such that for all  $x \in H$ ,  $y \in K$ ,  $m \geq 1$ , and  $\delta > 0$  we can find an  $\mathbb{F}$ -progressively measurable control process  $u \in L_{\mathbb{F}}^0([0, +\infty]; U)$  and an  $\mathbb{F}^m$ -progressively measurable control process  $v \in L_{\mathbb{F}^m}^0([0, 1]; U)$  verifying*

$$(3.4) \quad \mathbb{E} \int_0^{+\infty} e^{-Cs} d_K^2(X_s^{y,u}) ds \leq \delta$$

and

$$(3.5) \quad \mathbb{E} |X_\tau^{x,v,m} - Y_\tau^{y,u,m}|^2 - |x - y|^2 \leq ct|x - y|^2 + ct(t^{1-2\gamma} \vee t^{1/2})(1 + |x|^2 + |y|^2)$$

for all  $t \in ]0, 1]$  and all  $\mathbb{F}^m$ -stopping times  $\tau \leq t$ . We stress that constants  $c$  and  $C$  depend only on the data of the problem and on  $m$  but not on  $x$  and  $y$ .

*Proof.* We start by proving the claim in the case in which Assumption 3.2 holds since it is by far the most difficult. We will comment on the case with Assumption 3.1 at the end of this proof.

Consider for  $M \in \mathbb{N}$ ,  $M > m$  the class  $\mathcal{U}^{m,M}$  given by all processes  $u \in \mathcal{U}$  which are stepwise constant in  $[0, 1]$ , and that verify

$$u|_{[0,1]} = \sum_{i=0}^{N-1} \eta_i I_{(t_i, t_{i+1}]}, \quad 0 = t_0 < \dots < t_N = 1, \quad \eta_i \in \mathcal{L}_{t_i}^{m,M}, \quad 1 \leq i \leq N-1, \quad \eta_0 \in U,$$

where  $\mathcal{L}_t^{m,M}$  denotes the family of  $\mathcal{F}_t$ -measurable simple random variables  $\eta$  of the

form  $\eta = \sum_{i,j=1}^L \alpha_{i,j} I_{A_i \cap B_j}$ , with  $\alpha_{i,j} \in U$ ,  $A_i \in \mathcal{F}_t^m$ ,  $B_j \in \mathcal{F}_t^{m,M}$ ,  $1 \leq i, j \leq L$ , s.t.  $\sum_{i,j=1}^L I_{A_i \cap B_j} = 1$ .

Since, as it can be easily proved,  $\bigcup_{M>m} \mathcal{U}^{m,M}$  is dense in  $\mathcal{U}$  endowed with the norm  $|u|_{\mathcal{U}} = \mathbb{E}[\int_0^{+\infty} e^{-Ct} |u_t| dt]$  and  $K$  is supposed to be  $\varepsilon$ -viable with respect to (2.1), there exist  $M > m$  and  $u \in \mathcal{U}^{m,M}$  such that (3.4) holds.

Fixing  $m \in \mathbb{N}$  and  $u \in \mathcal{U}^{m,M}$  that verifies (3.4) we seek a  $\mathbb{F}^m$ -progressively measurable control process  $v \in L_{\mathbb{F}^m}^0([0, T]; U)$  s.t. (3.5) holds. This will be done in several steps.

*Step 1.* For all  $u \in U$  and  $x \in H$ , let  $G^m(x, u) := (G(x, u)e_1, \dots, G(x, u)e_m) \in H^m$  and  $(G^m, F)(x, u) := (G^m(x, u), F(x, u)) \in H^{m+1}$ . We consider  $\eta \in \mathcal{L}_t^{m,M}$  of the above form. Then

$$\mathbb{E}[(G^m, F)(x, \eta) | \mathcal{F}_t^m] = \sum_{i=1}^L I_{A_i} \left( \sum_{j=1}^L (G^m, F)(x, \alpha_{i,j}) P(B_j) \right).$$

Since  $\sum_{j=1}^L \mathbb{P}(B_j) = 1$  the convexity of  $\{(G^m, F)(x, u) : u \in U\}$  (assumed in Assumption 3.2) gives  $\sum_{j=1}^L (G^m, F)(x, \alpha_{i,j}) P(B_j) \in \{(G^m, F)(x, u) : u \in U\}$ .

From the Jankov-von Neumann measurable selection theorem (see Proposition 7.49 in [6]), there exists a universally measurable mapping  $\ell_i : (H, \mathcal{B}^u(H)) \rightarrow (U, \mathcal{B}(U))$  s.t.

$$\sum_{j=1}^L (G^m, F)(x, \alpha_{i,j}) P(B_j) = (G, F)(x, \ell_i(x)) \quad \text{for all } x \in H.$$

Then, given  $\zeta \in L^2(\Omega, \mathcal{F}_t^m, P; H)$  we put  $\Phi_t^\eta(\zeta) := \sum_{i=1}^L \ell_i(\zeta) I_{A_i}$ .

We notice that  $\Phi_t^\eta(\zeta) \in L^0(\Omega, \mathcal{F}_t^m, P; U)$ . Indeed, since  $\ell_i$  is  $\mathcal{B}^u(H) - \mathcal{B}(U)$ -measurable, it coincides  $P\zeta$ -a.s. with some  $\mathcal{B}(H) - \mathcal{B}(U)$ -measurable mapping  $\theta_i : H \rightarrow U$ . Consequently,  $\ell_i(\zeta) = \theta_i(\zeta)$ ,  $P$ -a.s. But since  $\mathcal{F}_t^m$  contains all  $P$ -null sets, the  $\mathcal{F}_t^m - \mathcal{B}(U)$ -measurability of  $\theta_i(\zeta)$  implies that of  $\ell_i(\zeta)$ .

Moreover, by construction  $\mathbb{E}[(G^m, F)(\zeta, \eta) | \mathcal{F}_\infty^m] = (G^m, F)(\zeta, \Phi_t^\eta(\zeta))$ ,  $P$ -a.s.

*Step 2.* We construct now  $v$  proceeding by iteration. We recall that we have fixed  $u \in \mathcal{U}^{m,M}$ ,  $u = \sum_{i=0}^{N-1} \eta_i I_{(t_i, t_{i+1}]}$ ,  $0 = t_0 < \dots < t_N = 1$ ,  $\eta_i \in \mathcal{L}_{t_i}^{m,M}$ ,  $1 \leq i \leq N-1$ , and  $\eta_0 \in U$  deterministic.

We define, for  $s \in [0, t_1]$ ,  $v_s := u_s = \eta_0$ . Thus  $v$  is deterministic in  $[0, t_1]$  and  $X_s^{x,v,m}$  is  $\mathcal{F}_s^m$ -measurable for all  $s \in [0, t_1]$ .

Then, for  $s \in (t_1, t_2]$ , let  $v_s := \Phi_{t_1}^{\eta_1}(X_{t_1}^{x,v,m})$ . Note that  $(v_s, s \in [0, t_2]) \in L_{\mathbb{F}^m}^0([0, t_2]; U)$  and  $X^{x,v,m} \in L_{\mathbb{F}^m}^2([0, t_2]; H)$ .

We proceed by iteration letting, for  $0 \leq i \leq N-1$  and  $s$  in  $(t_i, t_{i+1}]$ ,  $v_s := \Phi_{t_i}^{\eta_i}(X_{t_i}^{x,v,m})$ . Note that  $v \in L_{\mathbb{F}^m}^0([0, 1]; U)$ ,  $X^{x,v,m} \in L_{\mathbb{F}^m}^2([0, 1]; H)$  and

$$\mathbb{E}[(G^m, F)(X_{t_i}^{x,v,m}, u_s) | \mathcal{F}_\infty^m] = (G^m, F)(X_{t_i}^{x,v,m}, v_s), \quad s \in (t_i, t_{i+1}], \quad 1 \leq i \leq N-1.$$

*Step 3.* We have now to deduce an estimation similar to (3.6) but for  $t$  different from  $t_i$ . This will be done by exploiting the analyticity of the semigroup  $(T_t)_{t \geq 0}$ . To shorten the notation, let  $\hat{X}_t := X_t^{x,v,m}$ ,  $t \in [0, 1]$ .

For  $\alpha \in (0, 1/2)$  we put  $|x|_\alpha^2 = |x|^2 + |(I - A)^\alpha x|^2$ ,  $x \in H$ . Standard estimates yield

$$\mathbb{E}|\hat{X}_s|_\alpha^2 \leq C_\alpha^2 \left( 1 + \left( 1 + \frac{1}{s^{2\alpha}} \right) |y|^2 \right), \quad s \in (0, 1].$$

Moreover, for  $s \in [t_i, t_{i+1}]$ ,

$$\widehat{X}_s = T_{s-t_i} \widehat{X}_{t_i} + \int_{t_i}^s T_{r-t_i} F(\widehat{X}_r, v_r) dr + \int_{t_i}^s T_{r-t_i} G^m(\widehat{X}_r, v_r) dW_r^m,$$

thus

$$\mathbb{E} \left| \widehat{X}_s - T_{s-t_i} \widehat{X}_{t_i} \right|^2 \leq C_m (s - t_i) (1 + |y|^2), \quad s \in (t_i, t_{i+1}].$$

On the other hand,  $|T_t x - x| \leq C_\alpha t^\alpha |x|_\alpha$  and, consequently, for  $c$  depending on  $\alpha$

$$\mathbb{E} \left[ \left| T_{s-t_i} \widehat{X}_{t_i} - \widehat{X}_{t_i} \right|^2 \right] \leq c (s - t_i)^{2\alpha} \mathbb{E} \left[ |\widehat{X}_{t_i}|_\alpha^2 \right] \leq c \left( 1 + \left( 1 + \frac{1}{t_i^{2\alpha}} \right) |x|^2 \right) (s - t_i)^{2\alpha}.$$

This implies for  $\alpha = 1/4$

$$\mathbb{E} \left[ \left| \widehat{X}_s - \widehat{X}_{t_i} \right|^2 \right] \leq c \left( 1 + \left( 1 + \frac{1}{\sqrt{t_i}} \right) |x|^2 \right) (s - t_i)^{1/2}.$$

Hence, for  $s \in (t_i, t_{i+1}]$ ,  $1 \leq i \leq N - 1$ ,

$$\begin{aligned} & \mathbb{E} \left| \mathbb{E} \left[ (G^m, F) \left( \widehat{X}_s, u_s \right) | \mathcal{F}_\infty^m \right] - (G^m, F) \left( \widehat{X}_s, v_s \right) \right|_{H^{m+1}}^2 \\ & \leq 3 \mathbb{E} \left| \mathbb{E} \left[ (G^m, F) \left( \widehat{X}_s, u_{t_{i+1}} \right) - (G^m, F) \left( \widehat{X}_{t_i}, u_{t_{i+1}} \right) | \mathcal{F}_\infty^m \right] \right|_{H^{m+1}}^2 \\ & \quad + 3 \mathbb{E} \left| \mathbb{E} \left[ (G^m, F) \left( \widehat{X}_{t_i}, u_{t_{i+1}} \right) | \mathcal{F}_\infty^m \right] - (G^m, F) \left( \widehat{X}_{t_i}, v_{t_{i+1}} \right) \right|_{H^{m+1}}^2 (= 0) \\ & \quad + 3 \mathbb{E} \left| (G^m, F) \left( \widehat{X}_{t_i}, v_{t_{i+1}} \right) - (G^m, F) \left( \widehat{X}_s, v_{t_{i+1}} \right) \right|_{H^{m+1}}^2 \\ & \leq c \mathbb{E} |\widehat{X}_s - \widehat{X}_{t_i}|^2 \leq c \left( 1 + \left( 1 + \frac{1}{\sqrt{t_i}} \right) |x|^2 \right) (s - t_i)^{1/2}. \end{aligned}$$

We stress the fact that if  $s \in [0, t_1]$ , then  $\mathbb{E}[(G^m, F)(\widehat{X}_s, u_s) | \mathcal{F}_\infty^m] = (G^m, F)(\widehat{X}_s, v_s)$ .

Consequently, for all  $1 \leq i \leq N - 1$ ,  $s \in (t_i, t_{i+1}]$

$$(3.7) \quad \begin{aligned} & \mathbb{E} \int_{t_i}^s \left| \mathbb{E} \left[ (G^m, F) \left( \widehat{X}_r, u_r \right) | \mathcal{F}_\infty^m \right] - (G^m, F) \left( \widehat{X}_r, v_r \right) \right|_{H^{m+1}}^2 dr \\ & \leq c \left( 1 + \left( 1 + \frac{1}{\sqrt{t_i}} \right) |x|^2 \right) (s - t_i)^{3/2}, \end{aligned}$$

while the left-hand side is zero for  $i = 0$ .

*Step 4.* We can now conclude the proof. Recall that to shorten notation we have denoted  $\widehat{X}_t = X_t^{x, v, m}$ . For the same reason we let  $\widehat{Y}_t := Y_t^{y, u, m}$ . Notice that

$$(3.8) \quad \begin{aligned} \widehat{X}_t - \widehat{Y}_t &= T_t(x - y) + \int_0^t T_{t-s} \left( F(\widehat{X}_s, v_s) - \mathbb{E}[F(X_s^{y, u}, u_s) | \mathcal{F}_\infty^m] \right) ds \\ & \quad + \int_0^t T_{t-s} \left( G(\widehat{X}_s, v_s) - \mathbb{E}[G(X_s^{y, u}, u_s) | \mathcal{F}_\infty^m] \right) dW_s^m. \end{aligned}$$

Applying Itô's rule to  $|n(nI - A)^{-1}(\widehat{X}_t - \widehat{Y}_t)|^2$ , and taking into account the dissipativity

of  $A$ , we get that, for every  $\mathbb{F}$ -stopping time  $\tau \leq t(\leq T)$ ,

$$\begin{aligned} & \mathbb{E}|n(nI - A)^{-1}(\widehat{X}_\tau - \widehat{Y}_\tau)|^2 - |n(nI - A)^{-1}(x - y)|^2 \\ & \leq 2\mathbb{E} \int_0^t \left| \left\langle n(nI - A)^{-1} \left( F(\widehat{X}_s, v_s) - \mathbb{E}[F(X_s^{y,u}, u_s) | \mathcal{F}_\infty^m] \right), \right. \right. \\ & \quad \left. \left. n(nI - A)^{-1} (\widehat{X}_s - \widehat{Y}_s) \right\rangle \right| ds \\ & \quad + \sum_{i=1}^m \mathbb{E} \int_0^t \left| n(nI - A)^{-1} \left( G(\widehat{X}_s, v_s) e_i - \mathbb{E}[G(X_s^{y,u}, u_s) e_i | \mathcal{F}_\infty^m] \right) \right|^2 ds, \end{aligned}$$

and letting  $n \rightarrow \infty$ ,

$$\begin{aligned} & \mathbb{E}|\widehat{X}_\tau - \widehat{Y}_\tau|^2 - |x - y|^2 \\ & \leq \mathbb{E} \int_0^t \left| F(\widehat{X}_s, v_s) - \mathbb{E}[F(X_s^{y,u}, u_s) | \mathcal{F}_\infty^m] \right|^2 ds + \mathbb{E} \int_0^t |\widehat{X}_s - \widehat{Y}_s|^2 ds \\ & \quad + \sum_{j=1}^m \mathbb{E} \int_0^t \left| G(\widehat{X}_s, v_s) e_j - \mathbb{E}[G(X_s^{y,u}, u_s) e_j | \mathcal{F}_\infty^m] \right|^2 ds \\ & \leq \mathbb{E} \int_0^t |\widehat{X}_s - \widehat{Y}_s|^2 ds + \mathbb{E} \int_0^t \left| (G^m, F)(\widehat{X}_s, v_s) - \mathbb{E}[(G^m, F)(X_s^{y,u}, u_s) | \mathcal{F}_\infty^m] \right|^2 ds \\ & \leq c_m \mathbb{E} \int_0^t |\widehat{X}_s - \widehat{Y}_s|^2 ds + c_m \sum_{i=1}^{N-1} \left( 1 + \left( 1 + \frac{1}{\sqrt{t_i}} \right) |x|^2 \right) (t_{i+1} \wedge t - t_i \wedge t)^{3/2} \\ & \quad + 2\mathbb{E} \int_0^t \left| (G^m, F)(\widehat{X}_s, u_s) - (G^m, F)(X_s^{y,u}, u_s) \right|^2 ds \end{aligned}$$

for a suitable constant  $c_m$  (from now to the end of the proof its value can change from line to line). Let us come back to (3.8). Since  $F$  and  $G$  are bounded, an application of the standard factorization argument (see [12]) yields

$$\mathbb{E} \sup_{s \in [0, t]} |\widehat{X}_s - X_s^{y,u}|^2 + \mathbb{E} \sup_{s \in [0, t]} |\widehat{X}_s - \widehat{Y}_s|^2 \leq c_m(|x - y|^2 + t^{1-2\gamma}(1 + |x|^2 + |y|^2)),$$

and plugging this into the above equation we obtain

$$\begin{aligned} \mathbb{E}|\widehat{X}_\tau - \widehat{Y}_\tau|^2 - |x - y|^2 & \leq c_m t |x - y|^2 + c_m t^{2-2\gamma}(1 + |x|^2 + |y|^2) \\ & \quad + c_m \sum_{i=1}^{N-1} \left( 1 + \left( 1 + t_i^{-1/2} \right) |x|^2 \right) (t_{i+1} \wedge t - t_i \wedge t)^{3/2}. \end{aligned}$$

Without loss of generality, we can suppose that  $t_{i+1} - t_i \leq t_i^2$ ,  $i = 1, \dots, N-1$  (notice that  $t_i \geq t_1 > 0$  and that we need to add to the partition only points larger than  $t_1$ ; this will only modify the value of  $N$  and the control  $v$  in  $[t_1, 1]$  but not  $t_1$  nor  $v|_{[0, t_1]}$  or  $u$ ). Then

$$\begin{aligned} & \sum_{i=1}^{N-1} \left( 1 + \left( 1 + t_i^{-1/2} \right) |x|^2 \right) (t_{i+1} \wedge t - t_i \wedge t)^{3/2} \\ & \leq \sup_{i=1, \dots, N-1} \left[ (1 + 2t_i^{-1/2} |x|^2) (t_{i+1} \wedge t - t_i \wedge t)^{1/2} \right] \sum_{i=1}^{N-1} (t_{i+1} \wedge t - t_i \wedge t) \\ & \leq 2(1 + |x|^2) \sqrt{t} \sum_{i=1}^{N-1} (t_{i+1} \wedge t - t_i \wedge t) \leq 2(1 + |x|^2) t^{3/2}, \end{aligned}$$

and this completes the proof in the case in which Assumption 3.2 holds.

Finally, let us briefly discuss the case in which Assumption 3.2 is replaced by Assumption 3.1. It turns out that if we set  $v_t = \mathbb{E}[u_t | \mathcal{F}_\infty^m]$ , then instead of (3.7) we get the stronger relation

$$\mathbb{E}[(G^m, F)(\hat{X}_r, u_r) | \mathcal{F}_\infty^m] = (G^m, F)(\hat{X}_r, v_r), \quad \mathbb{P} - \text{a.s. for all } r \in [0, 1].$$

This allows us to conclude as in step 4 previously (indeed, even in an easier way).  $\square$

We are now able to complete the proof that if  $K$  is  $\epsilon$ -viable, then  $d_K^2$  is a viscosity supersolution of (3.2).

*Proof of Theorem 3.5.* We fix arbitrarily  $x \in H$ ,  $m \in \mathbb{N}$ , and a test function  $\varphi \in C^2(H)$  verifying

1.  $\varphi(x) = d_K^2(x)$ ,  $\varphi(z) \leq d_K^2(z)$ ,  $z \in \overline{B_r(x)}$ , for some  $r > 0$ ;
2.  $\varphi(z) = \varphi_0(z) + g(z)$ ,  $z \in H$ , where  $\varphi_0, g \in C^2(H)$  are supposed to be bounded on bounded subsets of  $H$  together with their first order derivatives and to verify
  - (i)  $A^* D\varphi_0 : H \rightarrow H$  is continuous,
  - (ii)  $g(z) = \hat{g}(|z|)$ ,  $z \in H$ , where  $\hat{g} : \mathbb{R} \rightarrow \mathbb{R}$  is a decreasing function.

Let  $y := \pi_K(x) (\in K)$  and  $C > 0$  large enough. Moreover, for any  $\varepsilon > 0$  let  $u^\varepsilon$  and  $v^\varepsilon$  be given by Lemma 3.6 with  $\delta = \varepsilon^4$ .

From the convexity of  $K$  and, hence, that of  $d_K^2$  it follows that

$$\mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2 \left( Y_t^{y, u^\varepsilon, m} \right) dt \right] \leq \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2 \left( X_t^{y, v^\varepsilon, m} \right) dt \right] \leq \varepsilon^4.$$

To shorten notation let  $\hat{Y}_t^\varepsilon := Y_t^{y, u^\varepsilon, m} (= \mathbb{E}[X_t^{y, u^\varepsilon} | \mathcal{F}_\infty^m])$ ,  $\hat{X}_t^\varepsilon := X_t^{y, v^\varepsilon, m}$ , and  $t \geq 0$ .

We observe that  $\hat{X}^\varepsilon, \hat{Y}^\varepsilon$  are  $\mathbb{F}^m$ -progressively measurable and define

$$\tau_\varepsilon := \inf\{t > 0 : |\hat{X}_t^\varepsilon - x| > \delta_1\} \wedge \inf\{t > 0 : |\hat{Y}_t^\varepsilon - y| > 1\}$$

for some  $\delta_1 \in (0, r)$  which will be specified later. Let us also remark that, for all  $t \geq 0$ ,

$$\begin{aligned} d_K \left( \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right) &\leq \left| \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon - \pi_K(\hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon) \right| \leq \left| \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right| + d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right), \\ d_K(\hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon) &\leq \left| \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon - y \right| \leq 1, \end{aligned}$$

from where we get

$$\begin{aligned} d_K^2 \left( \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right) &\leq \left| \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right|^2 + d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right) \left( d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right) + 2 \left| \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right| \right) \\ &\leq \left| \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right|^2 + 2d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right) (2 + r + |y| + |x|) \\ &\leq \left| \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right|^2 + C_{x, y, r} d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right). \end{aligned}$$

Hence, for all  $t \in [0, T]$ ,

$$\begin{aligned} \varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x) &\leq d_K^2 \left( \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon \right) - d_K^2(x) \\ &\leq \left( \left| \hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon - \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right|^2 - |x - y|^2 \right) + C_{x, y, r} d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right), \end{aligned}$$

and from Lemma 3.6,

(3.9)

$$\begin{aligned} E \left[ \varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x) \right] &\leq \mathbb{E} \left[ \left| \hat{Y}_{\tau \wedge t}^\varepsilon - \hat{X}_{\tau \wedge t}^\varepsilon \right|^2 \right] - |x - y|^2 + C_{x,y,r} \mathbb{E} \left[ d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right) \right] \\ &\leq Ct|x - y|^2 + C_{x,y,r} \mathbb{E} \left[ d_K \left( \hat{Y}_{t \wedge \tau_\varepsilon}^\varepsilon \right) \right] + c_m(t^{2-2\gamma} \vee t^{3/2}). \end{aligned}$$

We claim now that for a suitable  $C_{x,y,\delta_1}$  that depends only on  $x, y, \delta_1$ , and on the data of the problem it holds that

$$P\{\tau_\varepsilon < \varepsilon\} \leq C_{x,y,\delta_1} \varepsilon^4 \quad \text{for all } \varepsilon > 0.$$

To prove the claim we recall that

$$\hat{Y}_t^\varepsilon = T_t y + \int_0^t T_{t-s} \mathbb{E}(F(X_s^{y,u^\varepsilon}, u_s^\varepsilon) | \mathcal{F}_\infty^m) ds + \int_0^t T_{t-s} \mathbb{E}(G(X_s^{y,u^\varepsilon}, u_s^\varepsilon) | \mathcal{F}_\infty^m) dW_s^m$$

and

$$\hat{X}_t^\varepsilon = T_t x + \int_0^t T_{t-s} F(\hat{X}_s^\varepsilon, v_s^\varepsilon) ds + \int_0^t T_{t-s} G(\hat{X}_s^\varepsilon, v_s^\varepsilon) dW_s^m.$$

By standard estimates based on factorization technique (see [12]) we find that for all  $p \geq 1$  there exists a constant  $c_{p,\gamma}$  depending on  $p, \gamma$  and on the data of the problem, but not on  $t$ , such that

$$\mathbb{E} \sup_{s \in [0,t]} \left[ |\hat{Y}_s^\varepsilon - T_s y|^{2p} + |\hat{X}_s^\varepsilon - T_s x|^{2p} \right] \leq c_{p,\gamma} t^{p(1-2\gamma)}.$$

Since the semigroup is strongly continuous, there exists  $s_0 > 0$  depending on  $x, y$ , and  $\delta_1$  such that  $|x - T_s x| \leq \delta_1/2$   $|y - T_s y| \leq 1/2$  for all  $s \in [0, s_0]$ . Thus for all  $\varepsilon \leq s_0$ ,

$$\begin{aligned} \mathbb{P}\{\tau_\varepsilon < \varepsilon\} &\leq \mathbb{P} \left\{ \sup_{s \leq \varepsilon} |\hat{X}_s^\varepsilon - x| \geq \delta_1 \right\} + \mathbb{P} \left\{ \sup_{s \leq \varepsilon} |\hat{Y}_s^\varepsilon - y| \geq 1 \right\} \\ &\leq \mathbb{P} \left\{ \sup_{s \leq \varepsilon} |\hat{X}_s^\varepsilon - T_s x| \geq \delta_1/2 \right\} + \mathbb{P} \left\{ \sup_{s \leq \varepsilon} |\hat{Y}_s^\varepsilon - T_s y| \geq 1/2 \right\} \\ &\leq c_{p,\gamma} 2^{2p} (\delta_1^{-2p} + 1) \varepsilon^{p(1-2\gamma)}, \end{aligned}$$

and the claim is proved choosing  $p$  large enough.

Coming back now to estimate (3.9) and taking into account that  $d_K(\hat{Y}_t^\varepsilon) \leq 1$  for  $0 \leq t \leq \tau_\varepsilon$ , we have

(3.10)

$$\begin{aligned} &\int_0^\varepsilon \mathbb{E} \left[ \varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x) \right] dt \\ &\leq C\varepsilon^2 |x - y|^2 + C_{x,y,r} \mathbb{E} \left[ \int_0^\varepsilon d_K(\hat{Y}_t^\varepsilon) dt \right] + C_{x,y,r} \varepsilon P\{\tau_\varepsilon < \varepsilon\} + c_m(\varepsilon^{3-2\gamma} \vee \varepsilon^{5/2}) \\ &\leq C\varepsilon^2 |x - y|^2 + C_{x,y,r} e^{C\varepsilon} \mathbb{E} \left[ \int_0^\varepsilon e^{-Ct} d_K(\hat{Y}_t^\varepsilon) dt \right] + c_{m,x,y,\delta_1}(\varepsilon^{3-2\gamma} \vee \varepsilon^{5/2}) \\ &\leq C\varepsilon^2 |x - y|^2 + C_{x,y,r} e^{C\varepsilon} \varepsilon^{1/2} \left( \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(\hat{Y}_t^\varepsilon) dt \right] \right)^{1/2} \\ &\quad + c_{m,x,y,\delta_1}(\varepsilon^{3-2\gamma} \vee \varepsilon^{5/2}) \\ &\leq C\varepsilon^2 d_K^2(x) + c_{m,x,y,r,\delta_1}(\varepsilon^{3-2\gamma} \vee \varepsilon^{5/2}), \end{aligned}$$

where  $c_{m,x,y,r,\delta_1}$  is a suitable constant depending on the indicated parameters.

We need now to get a lower estimate for  $\int_0^\varepsilon \mathbb{E}[\varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(y)]dt$ .

To this end we consider the usual Yosida approximation  $J_n = n(nI - A)^{-1}$ ,  $n \geq 1$  (recall that  $J_n \in L(H)$ ,  $J_n : H \rightarrow D(A)$ ,  $J_n x \rightarrow x$  for all  $x \in H$ ), and the approximating equation

$$\hat{X}_t^{\varepsilon,n} = T_t(J_n x) + \int_0^t T_{t-s}(J_n F(\hat{X}_s^{\varepsilon,n}, v_s^\varepsilon))ds + \int_0^t T_{t-s}(J_n G(\hat{X}_s^{\varepsilon,n}, v_s^\varepsilon))dW_s^m, \quad t \in [0, T].$$

Exactly as for (2.12) it can be easily shown that the above equation admits a unique mild solution  $\hat{X}^{\varepsilon,n} \in L_{\mathbb{R}^m}^p(\Omega, C([0, T]; D(A)))$ ,  $p \geq 1$ . Moreover,

- (i)  $\mathbb{E}[\sup_{t \in [0, T]} |\hat{X}_t^{\varepsilon,n} - \hat{X}_t^\varepsilon|_H^p] \rightarrow 0$ , as  $n \rightarrow +\infty$ ;
- (ii)  $\hat{X}^{\varepsilon,n}$  is a strong solution of the SDE

$$\begin{cases} d\hat{X}_t^{\varepsilon,n} = A\hat{X}_t^{\varepsilon,n}dt + J_n F(\hat{X}_t^{\varepsilon,n}, v_t^\varepsilon)dt + J_n G(\hat{X}_t^{\varepsilon,n}, v_t^\varepsilon)dW_t^m, & t \geq 0, \\ \hat{X}_0^{\varepsilon,n} = J_n x. \end{cases}$$

Thus we can apply Itô's formula to  $\varphi(\hat{X}_t^\varepsilon)$  and obtain

$$\begin{aligned} & \mathbb{E}[\varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(J_n x)] \\ &= \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle D\varphi(\hat{X}_s^{\varepsilon,n}), A\hat{X}_s^{\varepsilon,n} \rangle ds\right] + \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle D\varphi(\hat{X}_s^{\varepsilon,n}), J_n F(\hat{X}_s^{\varepsilon,n}, v_s^\varepsilon) \rangle ds\right] \\ &+ \frac{1}{2} \sum_{i=1}^m \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle D^2\varphi(\hat{X}_s^{\varepsilon,n})J_n G(\hat{X}_s^{\varepsilon,n}, v_s^\varepsilon)e_i, J_n G(\hat{X}_s^{\varepsilon,n}, v_s^\varepsilon)e_i \rangle ds\right]. \end{aligned}$$

Since

$$\begin{aligned} \langle D\varphi(\hat{X}_s^{\varepsilon,n}), A\hat{X}_s^{\varepsilon,n} \rangle &= \langle A^* D\varphi_0(\hat{X}_s^{\varepsilon,n}), \hat{X}_s^{\varepsilon,n} \rangle + \hat{g}'(|\hat{X}_s^{\varepsilon,n}|)|\hat{X}_s^{\varepsilon,n}| \oplus \langle A\hat{X}_s^{\varepsilon,n}, \hat{X}_s^{\varepsilon,n} \rangle \\ &\geq \langle A^* D\varphi_0(\hat{X}_s^{\varepsilon,n}), \hat{X}_s^{\varepsilon,n} \rangle, \end{aligned}$$

and  $A^* D\varphi_0 : H \rightarrow H$  is continuous, the dominated convergence theorem allows us to take the limit  $n \rightarrow +\infty$  in the preceding relation:

$$\begin{aligned} \mathbb{E}[\varphi(\hat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x)] &\geq \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle A^* D\varphi_0(\hat{X}_s^\varepsilon), \hat{X}_s^\varepsilon \rangle ds\right] \\ &+ \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle D\varphi(\hat{X}_s^\varepsilon), F(\hat{X}_s^\varepsilon, v_s^\varepsilon) \rangle ds\right] \\ &+ \frac{1}{2} \sum_{i=1}^m \mathbb{E}\left[\int_0^{t \wedge \tau_\varepsilon} \langle D^2\varphi(\hat{X}_s^\varepsilon)G(\hat{X}_s^\varepsilon, v_s^\varepsilon)e_i, G(\hat{X}_s^\varepsilon, v_s^\varepsilon)e_i \rangle ds\right]. \end{aligned}$$

Now let for  $z \in H, \psi \in C^2(H)$ ,

$$\begin{aligned} & L^m \psi(z) \\ &:= \inf_{u \in U} \left\{ \frac{1}{2} \sum_{i=1}^m \langle D^2\psi(z)G(z, u)e_i, G(z, u)e_i \rangle + \langle D\psi(z), F(z, u) \rangle + \langle A^* D\varphi_0(z), z \rangle \right\}. \end{aligned}$$

As the infimum over functions which are uniformly bounded on bounded sets and continuous, uniformly in  $u \in U$ , the function  $L^m \varphi$  is continuous and bounded on

bounded subsets of  $H$ . Given an arbitrarily small  $\rho > 0$  we choose  $\delta_1 > 0$  in the definition of the stopping time  $\tau_\varepsilon$  s.t.  $|L^m\varphi(z) - L^m\varphi(x)| \leq \rho$  for all  $z \in \overline{B_{\delta_1}(x)}$ . Obviously,

$$\begin{aligned} & \int_0^\varepsilon \mathbb{E} \left[ \varphi(\widehat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x) \right] dt \\ & \geq \mathbb{E} \left[ \int_0^\varepsilon \int_0^{t \wedge \tau_\varepsilon} L^m \varphi(\widehat{X}_s^\varepsilon) ds dt \right] \geq \mathbb{E} \left[ \int_0^\varepsilon \int_0^{t \wedge \tau_\varepsilon} (L^m \varphi(x) - \rho) ds dt \right] \\ & \geq 1/2 \cdot \mathbb{P}\{\tau_\varepsilon \geq \varepsilon\} \varepsilon^2 (L^m \varphi(x) - \rho) - c\varepsilon^2 \mathbb{P}\{\tau_\varepsilon < \varepsilon\}. \end{aligned}$$

Consequently, from the above estimates and (3.10) we have

$$\begin{aligned} & 1/2 \cdot \mathbb{P}\{\tau_\varepsilon \geq \varepsilon\} \varepsilon^2 (L^m \varphi(x) - \rho) - c\varepsilon^2 \mathbb{P}\{\tau_\varepsilon < \varepsilon\} \\ & \leq \int_0^\varepsilon \mathbb{E} \left[ \varphi(\widehat{X}_{t \wedge \tau_\varepsilon}^\varepsilon) - \varphi(x) \right] dt \leq C\varepsilon^2 d_K^2(x) + c_{m,x,y,r,\delta_1} (\varepsilon^{3-2\gamma} \vee \varepsilon^{5/2}). \end{aligned}$$

Since  $\mathbb{P}\{\tau_\varepsilon \geq \varepsilon\} \rightarrow 1$ , by dividing both sides of the inequality by  $1/2 \cdot \varepsilon^2$  and taking the limit as  $\varepsilon \downarrow 0$ , we obtain

$$L^m \varphi(x) - \rho \leq 2C d_K^2(x).$$

Finally, letting  $\rho \downarrow 0$ , we get the wished result.  $\square$

It is worth pointing out that with the above argument (in simplified form) we obtain a more precise result when the noise is trace class: in particular the convexity of  $K$  is not needed. This is done in the following remark.

**REMARK 3.7.** *Suppose that assumptions (2.3), (2.4), and (2.5) are replaced by the stronger*

$$(3.12) \quad |G(x, u) - G(y, u)|_{L_2(\Xi, H)} \leq C|x - y|, \quad |G(x, u)|_{L_2(\Xi, H)} \leq C,$$

and let  $K$  be a general nonempty closed subset of  $H$ .

The above argument yields that if  $K$  is  $\varepsilon$ -viable w.r.t. (2.1), then there exists  $C > 0$  (large enough) such that  $d_K^2$  is a viscosity supersolution of the HJB equation

$$(3.13) \quad \Psi(x, V(x), DV(x), D^2V(x)) - \langle Ax, DV(x) \rangle = 0, \quad x \in H,$$

where  $\Psi(x, v, p, X) = -\inf_{u \in U} \left( \frac{1}{2} \sum_{i=1}^\infty \langle XG(x, u)e_i, G(x, u)e_i \rangle + \langle F(x, u), p \rangle \right) + Cv - d_K^2(x)$  (recall that in this case  $\sum_{i=1}^\infty |G(x, u)e_i|^2 < \infty$ ). We stress the fact that in this case the convexity of  $K$  is not needed and we can drop Assumption 3.1 (or 3.2).

The proof is the simplified version of the above argument obtained replacing  $X^{x,u,m}$  and  $Y^{x,u,m}$  by  $X^{x,u}$  itself (avoiding projections on  $\mathcal{F}^m$  measurable processes and approximations). The reason why this simplification works is that, to obtain the analogue of (3.11), we can directly apply Itô's rule to  $\phi(J_n X^{x,u})$ . Moreover, in the present case in Lemma 3.6, we can just take  $v = u$  and easily prove that

$$\mathbb{E} |X_\tau^{x,u} - X_\tau^{y,u}|^2 - |x - y|^2 \leq ct|x - y|^2.$$

#### 4. Necessary and sufficient conditions.

**4.1. Viability of balls.** Let us consider here the case in which  $K = B(0, R) = \{x \in H : |x| \leq R\}$ . We will derive from the general necessary condition in Theorem 3.5 specific conditions and show that they are also sufficient.

We denote by  $\{J_n : n \in \mathbb{N}\}$  a family of linear bounded operators  $H \rightarrow D(A^*)$  such that  $|J_n|_{L(H)} \leq 1$  and  $J_n x \rightarrow x$ , as  $n \rightarrow \infty$  for all  $x \in H$ . For instance, we can define  $J_n = n(nI - A^*)^{-1}$ , or, if there exists an orthonormal basis  $\{f_n : n \in \mathbb{N}\}$  of eigenvectors of  $A$  (that, consequently, has to be diagonal), then we can define  $J_n$  as the orthogonal projection on the linear subspace generated by  $f_1, \dots, f_n$ .

**PROPOSITION 4.1.** *Assume that  $B(0, R)$  is  $\varepsilon$ -viable for (2.1). Then for all  $x \in D(A^*)$  with  $|x| = R$  and for all  $n \in \mathbb{N}$  there exists a sequence of controls  $\{u_\ell : \ell \in \mathbb{N}\} \subset U$  such that for all  $m \in \mathbb{N}$*

$$(4.1) \quad \begin{aligned} & \lim_{\ell \rightarrow +\infty} \langle G(x, u_\ell) e_i, x \rangle = 0, \quad i \in \mathbb{N}, \\ & \limsup_{\ell \rightarrow +\infty} \left\{ \frac{1}{2} \sum_{i=1}^m |J_n G(x, u_\ell) e_i|^2 + \langle F(x, u_\ell), x \rangle + \langle A^* x, x \rangle \right\} \leq 0. \end{aligned}$$

*Proof.* With our choice of  $K$  we have  $d_K^2(x) = [(|x| - R)^+]^2$ . Let us fix arbitrarily  $x \in D(A^*)$  with  $|x| > R$  and  $\rho < |x| - R$ . Expanding (in Taylor sense)  $d_K^2(x)$  around  $x$  we get that if  $|y - x| \leq \rho$ , then

$$\begin{aligned} d_K^2(y) & \geq d_K^2(x) + 2 \left( 1 - \frac{R}{|x|} \right) \langle y - x, x \rangle \\ & \quad + \frac{R}{(|x| + \rho)^3} \langle y - x, x \rangle^2 + \left( 1 - \frac{R}{|x| - \rho} - \frac{2\rho R|x|}{(|x| + \rho)^3} \right) |x - y|^2. \end{aligned}$$

Choosing  $\rho$  small enough we can assume that  $(1 - \frac{R}{|x| - \rho} - \frac{2\rho R|x|}{(|x| + \rho)^3}) \geq 0$ . Consequently, if we define

$$\begin{aligned} \varphi(y) & := d_K^2(x) + 2 \left( 1 - \frac{R}{|x|} \right) \langle y - x, x \rangle + \frac{R \langle y - x, x \rangle^2}{(|x| + \rho)^3} \\ & \quad + \left( 1 - \frac{R}{|x| - \rho} - \frac{2\rho R|x|}{(|x| + \rho)^3} \right) |J_n^*(x - y)|^2, \end{aligned}$$

then we get  $\varphi(y) \leq d_K^2(y)$  for all  $y \in B(x, \rho)$  (recall that  $|J_n| \leq 1$ ). Moreover, since  $x \in D(A^*)$ , we have that  $A^* D\varphi$  is well defined and continuous (notice that we are considering  $\varphi$  as a function of  $y$ ). Indeed, we have

$$D\varphi(y) := 2 \left( 1 - \frac{R}{|x|} \right) x + \frac{2R \langle y - x, x \rangle}{(|x| + \rho)^3} x + 2 \left( 1 - \frac{R}{|x| - \rho} - \frac{2\rho R|x|}{(|x| + \rho)^3} \right) J_n J_n^*(x - y).$$

We now apply Theorem 3.5 with the test function  $\varphi$  and then let  $\rho \searrow 0$ . This yields

$$\begin{aligned} & \inf_{u \in U} \left\{ \sum_{i=1}^m \left[ \frac{|x| - R}{|x|} |J_n G(x, u) e_i|^2 + \frac{R}{|x|^3} \langle G(x, u) e_i, x \rangle^2 \right] \right. \\ & \quad \left. + 2 \frac{|x| - R}{|x|} \langle F(x, u), x \rangle \right\} + 2 \frac{|x| - R}{|x|} \langle x, A^* x \rangle \leq C_m [(|x| - R)^+]^2. \end{aligned}$$

Now we fix  $x \in D(A^*)$ , with  $|x| = R$ , and apply the previous inequality to  $x_\ell = \ell(\ell - 1)^{-1}x$ . This yields

$$2\frac{1}{\ell}\langle x_\ell, A^*x_\ell \rangle + \inf_{u \in U} \left\{ \sum_{i=1}^m \left[ \frac{1}{\ell} |J_n G(x_\ell, u)e_i|^2 + \frac{(\ell - 1)^3}{R^2 \ell^3} \langle G(x_\ell, u)e_i, x_\ell \rangle^2 \right] + \frac{2}{\ell} \langle F(x_\ell, u), x_\ell \rangle \right\} \leq C_m \frac{R^2}{(\ell - 1)^2}.$$

Thus for all  $\ell \in \mathbb{N}$  large enough, we can find  $u_\ell^m$  such that

$$2\ell \langle x_\ell, A^*x_\ell \rangle + 2\ell \langle F(x_\ell, u_\ell^m), x_\ell \rangle + \sum_{i=1}^m \left[ \ell |J_n G(x_\ell, u_\ell^m)e_i|^2 + \frac{(\ell - 1)^2}{R^2} \langle G(x_\ell, u_\ell^m)e_i, x_\ell \rangle^2 \right] \leq 2C_m R^2.$$

Letting  $\ell \rightarrow \infty$  we then get

$$\lim_{\ell \rightarrow \infty} \sum_{i=1}^m \langle G(x_\ell, u_\ell^m)e_i, x_\ell \rangle^2 = 0, \\ \limsup_{\ell \rightarrow \infty} \left\{ 2\langle x_\ell, A^*x_\ell \rangle + 2\langle F(x_\ell, u_\ell^m), x_\ell \rangle + \sum_{i=1}^m |J_n G(x_\ell, u_\ell^m)e_i|^2 \right\} \leq 0.$$

Since both  $\sum_{i=1}^m \langle G(\cdot, u)e_i, \cdot \rangle^2$  and  $2\langle F(\cdot, u), \cdot \rangle + \sum_{i=1}^m |J_n G(\cdot, u)e_i|^2$  are continuous on  $D(A^*)$ , uniformly in  $u \in U$ , we immediately get that

$$\lim_{\ell \rightarrow \infty} \sum_{i=1}^m \langle G(x, u_\ell^m)e_i, x \rangle^2 = 0, \\ \limsup_{\ell \rightarrow \infty} \left\{ 2\langle x, A^*x \rangle + 2\langle F(x, u_\ell^m), x \rangle + \sum_{i=1}^m |J_n G(x, u_\ell^m)e_i|^2 \right\} \leq 0.$$

Choosing, in a suitable way, the sequence  $\{u_\ell^m : \ell \in \mathbb{N}\}$ , we can assume that

$$\langle G(x, u_\ell^m)e_i, x \rangle^2 \leq 1/\ell, \quad i = 1, \dots, m, \\ 2\langle x, A^*x \rangle + 2\langle F(x, u_\ell^m), x \rangle + \sum_{i=1}^m |J_n G(x, u_\ell^m)e_i|^2 \leq 1/\ell.$$

Then the claim is proved by letting  $u_\ell = u_\ell^\ell$ .  $\square$

**COROLLARY 4.2.** *Assume that  $B(0, R)$  is  $\varepsilon$ -viable for (2.1) and that either  $U$  is compact or the mappings  $u \rightarrow F(x, u)$ ,  $u \rightarrow G(x, u)e_i$ ,  $i \in \mathbb{N}$ , are affine and  $U$  is convex; then for all  $x \in D(A^*)$  with  $|x| = R$  there exists a control  $u \in U$  such that*

$$(4.2) \quad G^*(x, u)x = 0, \quad \frac{1}{2}|G(x, u)e_i|_{L_2(\Xi, H)}^2 + \langle F(x, u), x \rangle + \langle A^*x, x \rangle \leq 0.$$

*Proof.* We prove the claim only in the case in which the mappings  $u \rightarrow F(x, u)$ ,  $u \rightarrow G(x, u)e_i$ ,  $i \in \mathbb{N}$ , are affine since the proof in the other case is identical. Let  $x \in D(A^*)$  be such that  $|x| \geq R$ . We notice that  $U$  is a convex, closed (thus weakly closed), and bounded subset of a reflexive Banach space. Thus we can assume, for the

sequence  $\{u_\ell : \ell \in \mathbb{N}\}$  got by Proposition 4.1, that  $u_\ell \rightharpoonup u_\infty$  (weakly) for some  $u_\infty \in U$ . Since the mappings  $u \rightarrow F(x, u)$  and  $u \rightarrow G(x, u)e_i$  are continuous with respect to the weak topology, we have  $F(x, u_\ell) \rightharpoonup F(x, u_\infty)$  and  $G(x, u_\ell)e_i \rightharpoonup G(x, u_\infty)e_i$ , and passing to the limit as  $\ell \rightarrow \infty$ , relation (4.1) yields

$$\langle G(x, u_\infty)e_i, x \rangle = 0, \quad i \in \mathbb{N}; \quad \frac{1}{2} \sum_{i=1}^m |J_n G(x, u_\infty)e_i|^2 + \langle F(x, u_\infty), x \rangle + \langle A^*x, x \rangle \leq 0.$$

Thus, fixed  $m \in \mathbb{N}$  for all  $n \in \mathbb{N}$ , there exists  $u^n \in U$  such that

$$\langle G(x, u^n)e_i, x \rangle = 0, \quad i \in \mathbb{N}, \quad \frac{1}{2} \sum_{i=1}^m |J_n G(x, u^n)e_i|^2 + \langle F(x, u^n), x \rangle + \langle A^*x, x \rangle \leq 0.$$

Again we can extract a subsequence such that  $u^n \rightharpoonup u^\infty$ . Then  $J_n G(x, u^n)e_i \rightharpoonup G(x, u^\infty)e_i$ ,  $\langle G(x, u^n)e_i, x \rangle \rightarrow \langle G(x, u^\infty)e_i, x \rangle$  for all  $i \in \mathbb{N}$ , and  $\langle F(x, u^n), x \rangle \rightarrow \langle F(x, u^\infty), x \rangle$ . Thus, letting  $n \rightarrow \infty$  we obtain

$$\langle G(x, u^\infty)e_i, x \rangle = 0, \quad i \in \mathbb{N}, \quad \frac{1}{2} \sum_{i=1}^m |G(x, u^\infty)e_i|^2 + \langle F(x, u^\infty), x \rangle + \langle A^*x, x \rangle \leq 0.$$

The claim follows repeating the same argument for  $m \rightarrow \infty$ .  $\square$

REMARK 4.3. Notice that (4.2) immediately implies (4.1).

We now start to show that condition (4.1) implies  $\varepsilon$ -viability of the ball. We will complete the proof under the following additional assumption on  $A$ .

ASSUMPTION 4.4.  $A$  is diagonal and  $\{f_i : i \in \mathbb{N}\}$  is an orthonormal basis of eigenvectors corresponding to the eigenvalues  $\{-\lambda_i : i \in \mathbb{N}\}$  with  $0 \leq \lambda_1 \leq \lambda_2, \dots$ , and  $\lambda_n \nearrow +\infty$ .

By  $J_n$  we denote the orthogonal projection on the space  $H_n$  generated by  $f_1, \dots, f_n$ . Finally, to shorten notation, we assume that  $R = 1$ .

For all  $x \in H$  and  $u \in \mathcal{U}$  we consider

$$(4.3) \quad \begin{cases} dZ_t^{n,m,x,u} = (AZ_t^{n,m,x,u} + J_n F(Z_t^{n,m,x,u}, u_t)) dt + J_n G(Z_t^{n,m,x,u}, u_t) dW_t^m, & t \geq 0, \\ Z_0^{n,m,x,u} = J_n x. \end{cases}$$

We notice that any solution of (4.3) lives in the finite dimensional space  $H_n$  and that its coefficients are Lipschitz (in  $H_n$ ). Thus, by totally standard arguments the above equation has a unique (classical) continuous solution.

LEMMA 4.5. Assume that  $U$  is compact and that  $G^*$  is strongly continuous (that is for all  $h \in H$  the mappings  $(x, u) \rightarrow G^*(x, u)h : H \times U \rightarrow \Xi$  are continuous). Then for all  $a > 0$  and for all  $\varepsilon > 0$  we can find  $n, m \in \mathbb{N}$  verifying

$$\mathbb{E} \int_0^a |X_t^{x,u} - Z_t^{n,m,x,u}|^2 dt \leq \varepsilon \quad \text{for all } u \in \mathcal{U}.$$

*Proof.* For all  $n \in \mathbb{N}$  we consider

$$(4.4) \quad \begin{cases} dZ_t^{n,x,u} = (AZ_t^{n,x,u} + J_n F(Z_t^{n,x,u}, u_t)) dt + J_n G(Z_t^{n,x,u}, u_t) dW_t, & t \geq 0, \\ Z_0^{n,x,u} = J_n x. \end{cases}$$

Exactly as (2.1), the above equation has a unique  $\mathbb{F}$ -progressively measurable mild solution  $Z^{n,x,u}$  satisfying  $\mathbb{E}[\sup_{s \in [0,T]} |Z_s^{n,x,u}|^p] < +\infty$ .

Clearly, it is enough to prove that for an arbitrary  $a > 0$ ,  $x \in H$ , and the arbitrary sequence  $\{u^n : n \in \mathbb{N}\} \subset \mathcal{U}$ , we have

$$(4.5) \quad \lim_{n \rightarrow +\infty} \mathbb{E} \int_0^a |Z_s^{n,x,u^n} - X_s^{x,u^n}|^2 ds = 0$$

and that, for any  $n \in \mathbb{N}$  and any sequence  $\{u^m : m \in \mathbb{N}\} \subset \mathcal{U}$ , we have

$$(4.6) \quad \lim_{m \rightarrow +\infty} \mathbb{E} \int_0^a |Z_s^{n,m,x,u^m} - Z_s^{n,x,u^m}|^2 ds = 0.$$

To prove (4.5) we start by noticing that  $Ax = \sum_{i=1}^{+\infty} (-\lambda_i) \langle x, f_i \rangle f_i$  and  $T_t x = \sum_{i=1}^{+\infty} e^{-\lambda_i t} \langle x, f_i \rangle f_i$ . Thus,  $T_t(x - J_n x) = \sum_{i=n+1}^{+\infty} e^{-\lambda_i t} \langle x, f_i \rangle f_i$  and, consequently,

$$(4.7) \quad |T_t(I - J_n)x| \leq e^{-\lambda_{n+1}t} |x|.$$

Let  $\bar{Z}_t = Z_t^{n,x,u^n} - X_t^{x,u^n}$ . By trivial computations recalling that  $T_t$  and  $J_n$  commute

$$\begin{aligned} \bar{Z}_t &= T_t(J_n - I)x + \int_0^t T_{t-s}(J_n - I)F(X_s^{x,u^n}, u_s^n) ds \\ &\quad + \int_0^t T_{t-s}J_n \left[ F(Z_s^{n,x,u^n}, u_s^n) - F(X_s^{x,u^n}, u_s^n) \right] ds \\ &\quad + \int_0^t T_{t-s}J_n \left[ G(Z_s^{n,x,u^n}, u_s^n) - G(X_s^{x,u^n}, u_s^n) \right] dW_s \\ &\quad + \int_0^t T_{(t-s)/2}(J_n - I)T_{(t-s)/2}G(X_s^{x,u^n}, u_s^n) dW_s. \end{aligned}$$

Thus, exploiting Lipschitzianity and boundedness of  $F$  and  $G$  we get for all  $0 < t \leq a$ , all  $b > 0$ , and a suitable constant  $c$  that may depend on  $a$  but is independent on  $u$ ,  $n$ , and  $b$

$$\begin{aligned} e^{-bt} \mathbb{E} |\bar{Z}_t|^2 &\leq ce^{-2\lambda_{n+1}t} |x|^2 + c \int_0^t (1 + (t-s)^{-2\gamma}) e^{-b(t-s)} e^{-bs} \mathbb{E} |\bar{Z}_s|^2 ds \\ &\quad + c \int_0^t e^{-2\lambda_{n+1}(t-s)} ds + c \int_0^t e^{-\lambda_{n+1}(t-s)} ((t-s)/2)^{-2\gamma} ds. \end{aligned}$$

Therefore,

$$\begin{aligned} \sup_{t \leq a} e^{-bt} \mathbb{E} |\bar{Z}_t|^2 &\leq ce^{-2\lambda_{n+1}t} |x|^2 + c \left[ \int_0^a (1 + \zeta^{-2\gamma}) e^{-b\zeta} d\zeta \right] \left[ \sup_{t \leq a} e^{-bt} \mathbb{E} |\bar{Z}_t|^2 \right] \\ &\quad + c \int_0^a e^{-2\lambda_{n+1}\zeta} d\zeta + c \int_0^a e^{-\lambda_{n+1}\zeta} (\zeta/2)^{-2\gamma} d\zeta. \end{aligned}$$

Choosing  $b$  large enough, we can assume that  $c \int_0^a (1 + \zeta^{-2\gamma}) e^{-b\zeta} d\zeta \leq 1/2$  and deduce that  $\sup_{t \leq a} e^{-bt} \mathbb{E} |\bar{Z}_t|^2 \rightarrow 0$  as  $n \rightarrow \infty$ . We can, consequently, conclude that (4.5) holds.

We now come to (4.6). Let us put  $\bar{Z}_t = Z_t^{n,m,x,u^m} - Z_t^{n,x,u^m}$ . By trivial computations recalling that  $T_t$  and  $J_n$ , commute

$$\begin{aligned} \bar{Z}_t &= \int_0^t T_{t-s} J_n \left[ F(Z_s^{n,m,x,u^m}, u_s^m) - F(Z_s^{n,x,u^m}, u_s^m) \right] ds \\ &\quad + \int_0^t T_{t-s} J_n \left[ G(Z_s^{n,m,x,u^m}, u_s^m) - G(Z_s^{n,x,u^m}, u_s^m) \right] dW_s \\ &\quad - \int_0^t T_{t-s} J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m) dW_s, \end{aligned}$$

where  $\Pi_m$  is the orthogonal projection on the linear space generated by  $e_1, \dots, e_m$  (recall that  $\{e_i : i \in \mathbb{N}\}$  is the orthonormal basis in  $\Xi$  we have fixed in (2.5)). Since  $J_n$  is Hilbert–Schmidt we get

$$\mathbb{E} \sup_{s \leq t} |\bar{Z}_s|^2 \leq c_n \mathbb{E} \int_0^t |\bar{Z}_s|^2 ds + c \int_0^t \mathbb{E} |J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 ds,$$

where  $c_n$  is a suitable constant depending on  $n$  but independent on  $u$ ,  $m$ , and  $x$ . Thus, by Gronwall’s lemma, to get (4.6) it is enough to prove that for all fixed  $n$

$$(4.8) \quad \mathbb{E} \int_0^t |J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 ds \rightarrow 0 \text{ as } m \rightarrow +\infty.$$

We start showing that, fixed  $r > 0$ ,  $\mathbb{E} \int_0^t I_{\{|Z_s^{n,x,u^m}| \leq r\}} |J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 ds \rightarrow 0$ . Since  $|J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m)|_{L_2(\Xi, H)} \leq |J_n|_{L_2(\Xi, H)} |G(Z_s^{n,x,u^m}, u_s^m)|_{L(\Xi, H)}$ , by the dominated convergence theorem, relation (4.8) follows if we can prove that for arbitrary sequences  $\{z_m \in H_n : m \in \mathbb{N}; |z_m| \leq c\}$  and  $\{v_m \in U : m \in \mathbb{N}\}$  it holds that  $|J_n G(z_m, v_m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 \rightarrow 0$ . Since  $H_n$  is finite dimensional and  $U$  is compact, w.l.o.g. we can assume that  $z_m \rightarrow z_\infty$ ,  $v_m \rightarrow v_\infty$  for a suitable  $z_\infty \in H_n$ ,  $u_\infty \in U$ . Moreover,

$$\begin{aligned} |J_n G(z_m, v_m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 &\leq 2 |J_n [G(z_m, v_m) - G(z_\infty, v_\infty)] (I - \Pi_m)|_{L_2(\Xi, H)}^2 \\ &\quad + 2 |J_n G(z_\infty, v_\infty) (I - \Pi_m)|_{L_2(\Xi, H)}^2 \doteq 2I_m^1 + 2I_m^2. \end{aligned}$$

We notice that

$$I_m^1 = \sum_{i=1}^n \sum_{j=m+1}^\infty \langle f_i, [G(z_m, v_m) - G(z_\infty, v_\infty)] e_j \rangle^2 \leq \sum_{i=1}^n |[G(z_m, v_m) - G(z_\infty, v_\infty)]^* f_i|^2.$$

Thus,  $I_m^1 \rightarrow 0$  by the strong continuity of  $G^*$ . In a similar way

$$I_m^2 = \sum_{i=1}^n \sum_{j=m+1}^\infty \langle G^*(z_\infty, v_\infty) f_i, e_j \rangle^2 \rightarrow 0$$

since  $\sum_{j=1}^\infty \langle G^*(z_\infty, v_\infty) f_i, e_j \rangle^2 = |G^*(z_\infty, v_\infty) f_i|^2 < \infty$ . It remains to be proven that

$$\mathbb{E} \int_0^t I_{\{|Z_s^{n,x,u^m}| > r\}} |J_n G(Z_s^{n,x,u^m}, u_s^m) (I - \Pi_m)|_{L_2(\Xi, H)}^2 ds \rightarrow 0$$

as  $r \nearrow +\infty$  (uniformly with respect to  $m$ ). Since  $J_n$  is Hilbert–Schmidt and  $G$  is bounded, it is enough to show that  $P \otimes \lambda\{|Z_s^{n,x,u^m}| > r : s \in [0, a]\} \rightarrow 0$  as  $r \rightarrow \infty$

(here  $\lambda$  denotes the Lebesgue measure on  $\mathbb{R}$ ). This last statement is obvious since, as in Lemma 2.2, we have  $\mathbb{E} \sup_{s \in [0, a]} |Z_s^{n, x, u^m}|^2 \leq c_a(1 + |x|)$ , where  $c_a$  is a constant independent on  $m$  (and even  $n$ ).  $\square$

We now extend (4.1) holding on the boundary of the ball to its exterior.

LEMMA 4.6. *Assume (4.1) (with  $R = 1$ ) and fix  $m, n \in \mathbb{N}$ . Then there exists a constant  $c$  such that, for all  $\varepsilon > 0$  and  $x \in H_n$  with  $|x| \in [1, 2]$ , there exists an  $\bar{u}(x) \in U$  verifying*

$$(4.9) \quad \begin{aligned} \sum_{i=1}^m \langle G(y, \bar{u}(x))e_i, y \rangle^2 &\leq \varepsilon + c[(1 - |y|)^+]^2, \\ \frac{1}{2} \sum_{i=1}^m |J_n G(y, \bar{u}(x))e_i|^2 &+ \langle F(y, \bar{u}(x)), y \rangle + \langle Ay, y \rangle \leq \varepsilon + c(1 - |y|)^+ \end{aligned}$$

for all  $y \in H_n$  with  $|y - x| \leq \delta_\varepsilon$ , where  $\delta_\varepsilon$  is a suitable constant independent of  $x$  and  $y$ . Moreover, the mapping  $x \rightarrow \bar{u}(x)$  can be chosen to be measurable.

*Proof.* In the following we denote by  $c$  a constant that depends on the data of the problem and on  $n$  and  $m$  but not on  $x$ ,  $y$ , and  $\varepsilon$ ; the value of  $c$  can change from line to line. Let us notice that, clearly,  $H_n \subset D(A) = D(A^*)$ .

If  $x \in H_n$  and  $|x| \in [1, 2]$ , then for all  $u \in U$ ,  $i \in \mathbb{N}$ ,

$$\begin{aligned} |\langle G(x, u)e_i, x \rangle| &\leq |\langle G(x/|x|, u)e_i, x/|x| \rangle| + |\langle G(x, u)e_i, x \rangle - \langle G(x/|x|, u)e_i, x/|x| \rangle| \\ &\leq \langle G(x/|x|, u)e_i, x/|x| \rangle + c|x - x/|x||, \end{aligned}$$

and by (4.1) we immediately have that there exists some  $\bar{u}(x)$  such that

$$\sum_{i=1}^m |\langle G(x, \bar{u}(x))e_i, x \rangle|^2 \leq \varepsilon + c(|x| - 1)^2.$$

Similarly, recalling that  $A$  is a bounded linear operator on  $H_n$ , we get that there exists an  $\tilde{u}(x)$  such that

$$\frac{1}{2} \sum_{i=1}^m |J_n G(x, \tilde{u}(x))e_i|^2 + \langle F(x, \tilde{u}(x)), x \rangle + \langle Ax, x \rangle \leq \varepsilon + c(|x| - 1)^+.$$

From (4.1) we see that we can choose  $\bar{u}(x)$  and  $\tilde{u}(x)$  such that they coincide. Moreover we notice that, for all  $v \in U$ , the mappings

$$y \rightarrow \sum_{i=1}^m |\langle G(y, v)e_i, y \rangle|^2, \quad y \rightarrow \frac{1}{2} \sum_{i=1}^m |J_n G(y, v)e_i|^2 + \langle F(y, v), y \rangle + \langle Ay, y \rangle$$

are Lipschitz on the bounded subsets of  $H_n$  with Lipschitz constant independent on  $v$ . This yields (4.9) for all  $y \in H_n$  with  $|y - x| \leq \delta_\varepsilon$ , where  $\delta_\varepsilon$  can be chosen independently of  $x$  and  $y$ . Finally, the fact that  $\bar{u} : H_n \rightarrow U$  can be gotten as in a measurable function of  $x$  is a direct consequence of well known measurable selection results (see, e.g., [5, Theorem 8.2.10, p. 316]).  $\square$

LEMMA 4.7. *Assume (4.1) (with  $R = 1$ ). For all  $T > 0$ ,  $m, n \in \mathbb{N}$ ,  $\varepsilon > 0$ , and all  $x \in H_n$  with  $|x| \leq 1$  there exists  $u \in \mathcal{U}$  such that*

$$E \int_0^T \left[ (|Z_s^{n, m, x, u}| - 1)^+ \right]^2 ds \leq \varepsilon$$

(recall that the process  $Z^{n,m,x,u}$  has been introduced in (4.3)).

*Proof.* For the sake of simplicity we restrict ourselves to the case  $T = 1$ . The proof for the case  $T > 1$  is clearly identical. Let us extend the definition of  $\bar{u}$  given in Lemma 4.6 by putting  $\bar{u}(x) = u_0$  for all  $x \in H_n$  with  $|x| > 2$  or  $|x| < 1$ . Moreover, we denote by  $Z^{n,m,\tau,\eta,u}$  the solution of (4.3) starting at  $\tau$  from the random variable  $J_n\eta$ . More precisely, for all stopping time  $\tau$ , all  $\eta \in L^2(\Omega, \mathcal{F}_\tau, H)$ , and all  $u \in \mathcal{U}$ ,  $Z^{n,m,\tau,\eta,u}$  is the solution of

$$\begin{cases} dZ_t^{n,m,\tau,\eta,u} = (AZ_t^{n,m,\tau,\eta,u} + J_n F(Z_t^{n,m,\tau,\eta,u}, u_t)) dt \\ \quad + J_n G(Z_t^{n,m,\tau,\eta,u}, u_t) dW_t^m, \quad t \geq \tau, \\ Z_\tau^{n,m,\tau,\eta,u} = J_n \eta. \end{cases}$$

Given  $x \in H_n$ , we let

$$\tilde{\tau}_1 = \left( \inf\{s > 0 : |Z_s^{n,m,0,x,\bar{u}(x)} - x| \geq \delta_\varepsilon\} \vee \inf\{s > 0 : |Z_s^{n,m,0,x,\bar{u}(x)}| \geq 1\} \right) \wedge 1,$$

and we define  $Z_s^\sharp = Z_s^{n,m,0,x,\bar{u}(x)}$ ,  $u_s^\sharp = \bar{u}(x)$  for  $s \in [0, \tilde{\tau}_1[$ . We then proceed iteratively by letting

$$\begin{aligned} \tilde{\tau}_{\ell+1} = & \left( \inf \left\{ s > \tau_\ell : |Z_s^{n,m,\tilde{\tau}_\ell, Z_{\tilde{\tau}_\ell}^\sharp, \bar{u}(Z_{\tilde{\tau}_\ell}^\sharp)} - Z_{\tilde{\tau}_\ell}^\sharp| \geq \delta_\varepsilon \right\} \right. \\ & \left. \vee \inf \left\{ s > \tau_\ell : |Z_s^{n,m,\tilde{\tau}_\ell, Z_{\tilde{\tau}_\ell}^\sharp, \bar{u}(Z_{\tilde{\tau}_\ell}^\sharp)}| \geq 1 \right\} \right) \wedge 1 \end{aligned}$$

and defining  $Z_s^\sharp = Z_s^{n,m,\tilde{\tau}_\ell, Z_{\tilde{\tau}_\ell}^\sharp, \bar{u}(Z_{\tilde{\tau}_\ell}^\sharp)}$ ,  $u_s^\sharp = \bar{u}(Z_{\tilde{\tau}_\ell}^\sharp)$ , for  $s \in [\tilde{\tau}_\ell, \tilde{\tau}_{\ell+1}[$ . By construction  $Z^\sharp$  is the solution of

$$\begin{cases} dZ_t^\sharp = \left( AZ_t^\sharp + J_n F(Z_t^\sharp, u_t^\sharp) \right) dt + J_n G(Z_t^\sharp, u_t^\sharp) dW_t^m, \quad t \in [0, \lim_{\ell \rightarrow \infty} \tilde{\tau}_\ell], \\ Z_0^\sharp = J_n x, \end{cases}$$

or, with the notation introduced by (4.3),  $Z^\sharp = Z^{n,m,x,u^\sharp}$ . Since (4.3) is a SDE on the finite dimensional space  $H_n$  with finite dimensional Brownian noise and uniformly Lipschitz coefficients, standard arguments from the stochastic control theory show that

$$P(\cup_{\ell=1}^\infty \{\tilde{\tau}_\ell = 1\}) = 1 \quad \text{and in particular} \quad \tilde{\tau}_\infty \doteq \lim_{\ell \rightarrow \infty} \tilde{\tau}_\ell = 1, \quad P - \text{a.s..}$$

Indeed, putting

$$\begin{aligned} \eta_1 &= \inf\{s > 0 : |Z_s^{n,m,0,x,u_0^\sharp} - x| \geq \delta_\varepsilon\}, \\ \eta_{\ell+1} &= \inf\{s > \tau_\ell : |Z_s^{n,m,\tilde{\tau}_\ell, Z_{\tilde{\tau}_\ell}^\sharp, u_{\tilde{\tau}_\ell}^\sharp} - Z_{\tilde{\tau}_\ell}^\sharp| \geq \delta_\varepsilon\} \end{aligned}$$

(notice that  $\eta_\ell \leq \tilde{\tau}_\ell$  on  $\{\tilde{\tau}_\ell < 1\}$ ), we have for all  $\ell \in \mathbb{N}$  and all  $h > 0$

$$\begin{aligned} P\{\eta_{\ell+1} - \tilde{\tau}_\ell \leq h | \mathcal{F}_{\tilde{\tau}_\ell}\} &= P\left\{ \sup_{\tilde{\tau}_\ell \leq s \leq \tilde{\tau}_\ell + h} |Z_s^{n,m,\tilde{\tau}_\ell, Z_{\tilde{\tau}_\ell}^\sharp, u_{\tilde{\tau}_\ell}^\sharp} - Z_{\tilde{\tau}_\ell}^\sharp| \geq \delta_\varepsilon \middle| \mathcal{F}_{\tilde{\tau}_\ell} \right\} \\ &\leq c \frac{h^{p/2}}{\delta_\varepsilon^p} (1 + |Z_{\tilde{\tau}_\ell}^\sharp|^p). \end{aligned}$$

Consequently, for  $p > 2$ ,

$$P(\cup_{\ell \geq 0} \{\eta_{\ell+1} - \tilde{\tau}_\ell \leq h/\ell\}) \leq c \frac{h^{p/2}}{\delta_\varepsilon^p} \sum_{\ell=1}^{\infty} \ell^{-p/2} \left( 1 + \mathbb{E} \sup_{s \in [0, \tilde{\tau}_\infty]} \mathbb{E} |Z_{\tilde{\tau}_\ell}^\#|^p \right) \leq c_p \frac{h^{p/2}}{\delta_\varepsilon^p} (1 + |x|^p)$$

from where

$$P(\cup_{\ell=1}^{\infty} \{\tilde{\tau}_\ell = 1\}) \geq \mathbb{P}(\cap_{\ell=1}^{\infty} \{\eta_{\ell+1} - \tilde{\tau}_\ell > h/\ell\}) \geq 1 - c_p \frac{h^{p/2}}{\delta_\varepsilon^p} \rightarrow 1 \text{ as } h \searrow 0.$$

Finally, we let  $\rho = \inf\{t > 0 : |Z_t^\#| \geq 2\} \wedge 1$  and  $\tau_\ell = \tilde{\tau}_\ell \wedge \rho$ . In this way  $P(\cup_{\ell=1}^{\infty} \{\tau_\ell = \rho\}) = 1$ ; moreover,  $|Z_{\tau_\ell}^\#| \in [1, 2]$  and

$$I_{\{|Z_t^\#| \geq 1\}} |Z_t^\# - Z_{\tau_\ell}^\#| \leq \delta_\varepsilon \text{ for all } \ell \in \mathbb{N} \text{ and all } t \in [\tau_\ell, \tau_{\ell+1}[.$$

Finally, by construction, we have  $P$ -a.s. for all  $t \leq \rho$ ,  
(4.10)

$$\begin{aligned} I_{\{|Z_t^\#| \geq 1\}} \left[ \sum_{i=1}^m \langle J_n G(Z_t^\#, u_t^\#) e_i, Z_t^\# \rangle^2 \right] &\leq \varepsilon + c[ (|Z_t^\#| - 1)^+ ]^2, \\ I_{\{|Z_t^\#| \geq 1\}} \left[ \frac{1}{2} \sum_{i=1}^m |J_n G(Z_t^\#, u_t^\#) e_i|^2 + \langle F(Z_t^\#, u_t^\#), Z_t^\# \rangle + \langle A Z_t^\#, Z_t^\# \rangle \right] &\leq \varepsilon + c(|Z_t^\#| - 1)^+. \end{aligned}$$

Now let  $\psi_\varepsilon(r) = 2 \int_0^r \int_0^s [\varepsilon^{-1}(\sigma - 1 + \varepsilon)]^+ \wedge 1 \, d\sigma \, ds$  for  $r \in \mathbb{R}_+$ . We notice that  $\psi_\varepsilon(r) \searrow [(r - 1)^+]^2$ , uniformly on bounded subsets of  $\mathbb{R}_+$ ,  $\psi'_\varepsilon(r) \searrow 2(r - 1)^+$ , uniformly on bounded subsets of  $\mathbb{R}_+$  and  $\psi''_\varepsilon(r) \searrow 2$  if  $r \geq 1$  and  $\psi''_\varepsilon(r) \searrow 0$  if  $r < 1$ . Moreover,  $\psi_\varepsilon(r) \leq c|r|^2$ ,  $\psi'_\varepsilon(r) \leq c|r|$ ,  $\psi''_\varepsilon(r) \leq c$  for a suitable  $c > 0$  and all  $r \in \mathbb{R}_+$ ,  $\varepsilon \in ]0, 1]$ . Finally,  $\psi_\varepsilon(r)$  is of class  $C^2$  and  $\psi_\varepsilon(r) = 0$  for all  $r < 1 - \varepsilon$ .

If we compute by Itô's rule  $d_t \psi_\varepsilon(|Z_t^\#|)$ , integrate between 0 and  $t \wedge \rho$ , and compute the mean value we get, for  $|x| \leq 1$ ,

$$\begin{aligned} \mathbb{E} \psi_\varepsilon(|Z_{t \wedge \rho}^\#|) &= \mathbb{E} \int_0^{t \wedge \rho} \frac{\psi'_\varepsilon(|Z_s^\#|)}{|Z_s^\#|} \\ &\quad \times \left[ \langle Z_s^\#, A Z_s^\# \rangle + \langle Z_s^\#, J_n F(Z_s^\#, u_s^\#) \rangle + \frac{1}{2} \sum_{i=1}^m |J_n G(Z_s^\#, u_s^\#) e_i|^2 \right] ds + \psi_\varepsilon(|x|) \\ &\quad + \frac{1}{2} \mathbb{E} \int_0^{t \wedge \rho} \left[ \frac{\psi''_\varepsilon(|Z_s^\#|)}{|Z_s^\#|^2} - \frac{\psi'_\varepsilon(|Z_s^\#|)}{|Z_s^\#|^3} \right] \left[ \sum_{i=1}^m \langle Z_s^\#, J_n G(Z_s^\#, u_s^\#) e_i \rangle^2 \right] ds. \end{aligned}$$

Note that  $|\psi''_\varepsilon(r)/r^2| + |\psi'_\varepsilon(r)/r^3| \leq c$ ,  $r > 0$ . In the above formula and in the following,  $c$  is a constant independent on  $\varepsilon$  small enough. If we let  $\varepsilon \searrow 0$  in the above equation, then we obtain

$$\begin{aligned} &\mathbb{E}[(|Z_{t \wedge \rho}^\#| - 1)^+]^2 \\ &\leq c \mathbb{E} \int_0^{t \wedge \rho} I_{\{|Z_t^\#| > 1\}} \left[ \sum_{i=1}^m \langle Z_s^\#, J_n G(Z_s^\#, u_s^\#) e_i \rangle^2 \right] ds + c \mathbb{E} \int_0^{t \wedge \rho} (|Z_s^\#| - 1)^+ \\ &\quad \times \left[ \langle Z_s^\#, A Z_s^\# \rangle + \langle Z_s^\#, J_n F(Z_s^\#, u_s^\#) \rangle + \frac{1}{2} \sum_{i=1}^m |J_n G(Z_s^\#, u_s^\#) e_i|^2 \right] ds \end{aligned}$$

and by (4.10)

$$\mathbb{E}[(|Z_{t \wedge \rho}^\#| - 1)^+]^2 \leq c\varepsilon + c\mathbb{E} \int_0^{t \wedge \rho} [(|Z_s^\#| - 1)^+]^2 ds \leq c\varepsilon + c\mathbb{E} \int_0^t [(|Z_{s \wedge \rho}^\#| - 1)^+]^2 ds.$$

Thus, by Gronwall's lemma

$$(4.11) \quad \mathbb{E}[(|Z_{t \wedge \rho}^\#| - 1)^+]^2 \leq c\varepsilon, \quad t \in [0, 1[.$$

Moreover, by dominated convergence, letting  $t \nearrow 1$  the above inequality also yields  $\mathbb{E}[(|Z_\rho^\#| - 1)^+]^2 \leq c\varepsilon$ . On the other side,

$$\mathbb{E} \int_\rho^1 [(|Z_s^\#| - 1)^+]^2 ds \leq (P(\rho < 1))^{1/2} \left( \mathbb{E} \sup_{s \in [0, 1]} |Z_s^\#|^4 \right)^{1/2}.$$

Since, as in Lemma 2.6,  $\mathbb{E} \sup_{s \in [0, 1]} |Z_s^{n, m, x, u}|^4 \leq c(1 + |x|^4)$ , we deduce that

$$\begin{aligned} \mathbb{E} \int_\rho^1 [(|Z_s^\#| - 1)^+]^2 ds &\leq c\sqrt{P(\rho < 1)} \leq c\sqrt{P(|Z_\rho^\#| - 1)^2 = 1)} \\ &\leq c\sqrt{\mathbb{E}[(|Z_\rho^\#| - 1)^+]^2} \leq c\sqrt{\varepsilon}, \end{aligned}$$

and the claim immediately follows from the above relation and (4.11).  $\square$

We can now easily conclude our argument

**COROLLARY 4.8.** *Assume (4.1) (with  $R = 1$ ). Then the ball  $B(0, 1)$  is  $\varepsilon$ -viable.*

*Proof.* By Lemmas 4.5 and 4.7 we have that for arbitrary great  $a > 0$  and all  $x \in H$ ,  $|x| \leq 1$ ,  $\varepsilon > 0$ , the existence of an admissible control  $u$  verifying

$$\mathbb{E} \int_0^a [(|X_s^{x, u}| - 1)^+]^2 \leq \varepsilon.$$

Then it is enough to notice that under our assumptions we have by straightforward computations  $\mathbb{E}|X_t^{x, u}|^2 \leq e^{ct}c(1 + |x|^2)$  with  $c$  independent of  $x$ ,  $u$ , and  $t$ .  $\square$

**4.2. Viability of linear spaces.** We consider here the case in which  $K$  is a finite dimensional linear subspace of  $H$ . As in the previous section we derive from (4.1) specific conditions and show that they are sufficient. To start with we adapt the argument in [27] to show that any  $\varepsilon$ -invariant subset of a finite dimensional linear subspace of  $H$  is a subset of  $D(A)$ .

**LEMMA 4.9.** *Let  $K \subset H$  be an  $\varepsilon$ -viable (not necessarily linear) subset of  $H$ , and let  $\widehat{K}$  be the linear space generated by  $K$ . Then for all  $x \in K$  there exist sequences  $t_n \searrow 0$ ,  $\{u^n : n \in \mathbb{N}\} \subset \mathcal{U}$ ,  $\{k_n : n \in \mathbb{N}\} \subset \widehat{K}$  such that  $|\mathbb{E}X_{t_n}^{x, u^n} - k_n|/t_n \rightarrow 0$ .*

*Proof.* Let  $x \in H$  be arbitrarily chosen and  $\Pi_{\widehat{K}}$  denote its orthogonal projection on  $\widehat{K}$ . Then by the  $\varepsilon$ -viability of  $K$ , since  $d_K(x) \geq |\Pi_{\widehat{K}}x|$ , we know that there exists a sequence  $\{u^n : n \in \mathbb{N}\} \subset \mathcal{U}$  such that

$$\mathbb{E} \int_{n^{-2}}^{2n^{-2}} |X_s^{x, u^n} - \Pi_{\widehat{K}}X_s^{x, u^n}|^2 ds \leq 2^{-2n}, \quad n \geq 1;$$

thus there exists some  $t_n$  with  $n^{-2} \leq t_n \leq 2n^{-2}$  such that

$$\mathbb{E} |X_{t_n}^{x, u^n} - \Pi_{\widehat{K}}X_{t_n}^{x, u^n}|^2 \leq 2^{-2n}n^2.$$

Now let  $k_n = \mathbb{E}\Pi_{\widehat{K}}X_{t_n}^{x,u^n}$ . We notice that  $k_n \in \widehat{K}$ . Finally, by Cauchy inequality,

$$\left| \mathbb{E}X_{t_n}^{x,u^n} - k_n \right| \leq \left( \mathbb{E} \left| X_{t_n}^{x,u^n} - \Pi_{\widehat{K}}X_{t_n}^{x,u^n} \right|^2 \right)^{1/2} \leq 2^{-n}n,$$

and the claim follows.  $\square$

The following result, needed below, is a straightforward consequence of [14, Theorem 1.24]. We report the statement for the reader's convenience.

LEMMA 4.10. *Assume that  $y \in H$  is such that there exists a sequence  $t_n \searrow 0$  for which  $\{|T_{t_n}y - y|/t_n : n \in \mathbb{N}\}$  is bounded. Then  $y \in D(A)$ .*

PROPOSITION 4.11. *If  $K \subset H$  is  $\varepsilon$ -viable and it is included in a finite dimensional linear subspace of  $H$ , then  $K \subset D(A)$ .*

*Proof.* Fix  $x \in K$  and again let  $\widehat{K}$  be the linear space generated by  $K$ . By Lemma 4.9 there exist sequences  $t_n \searrow 0$  and  $\{u^n : n \in \mathbb{N}\} \subset \mathcal{U}$ ,  $\{k_n : n \in \mathbb{N}\} \subset \widehat{K}$  such that

$$\frac{1}{t_n} \left| T_{t_n}x + \int_0^{t_n} \mathbb{E}F(X_s^{x,u^n}, u_s^n) ds - k_n \right| \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

Notice that, since  $\sup_n |\mathbb{E} \int_0^{t_n} F(X_s^{x,u^n}, u_s^n) ds|/t_n < \infty$ , the above convergence immediately yields

$$(4.12) \quad \sup_n \frac{1}{t_n} |T_{t_n}x - k_n| < \infty.$$

If  $k_n = x$  for infinitely many indices  $n$ , then, along this subsequence,  $\sup_n (t_n)^{-1} |T_{t_n}x - x| < \infty$ , and by Lemma 4.10 we obtain that  $x \in D(A)$ . Hence, w.l.o.g., we can assume that  $k_n \neq x$  for all  $n \in \mathbb{N}$ . Since  $\widehat{K}$  is locally compact, we have, at least along a subsequence (that we still denote by  $\{h_n\}$ ), that there exists some  $v \in \widehat{K}$  with  $(k_n - x)/|k_n - x| \rightarrow v$  and  $|v| = 1$ .

Extracting again a suitable subsequence, if necessary, we can distinguish between two different cases: the one in which  $\sup_n |k_n - x|/t_n < \infty$  and the one in which  $|k_n - x|/t_n \nearrow \infty$ . In the second case

$$\left| \frac{T_{t_n}x - x}{|k_n - x|} - v \right| \leq \frac{t_n}{|k_n - x|} \frac{|T_{t_n}x - k_n|}{t_n} + \left| \frac{k_n - x}{|k_n - x|} - v \right| \rightarrow 0.$$

Now let  $N_n = [t/t_n]$  (where  $[a]$  means the integer part of  $a \in \mathbb{R}_+$ ). By direct computation we get

$$(4.13) \quad \frac{t_n}{|k_n - x|} (T_{N_n t_n}x - x) = t_n \sum_{\ell=1}^{N_n} T_{(\ell-1)t_n} v + t_n \sum_{\ell=1}^{N_n} T_{(\ell-1)t_n} \left[ \frac{T_{t_n}x - x}{|k_n - x|} - v \right].$$

The left-hand side converges to 0 since  $t_n/|k_n - x| \searrow 0$ . Moreover,  $t_n \sum_{\ell=1}^{N_n} T_{(\ell-1)t_n} v \rightarrow \int_0^t T_s v ds$ . Finally since we know that  $[(T_{t_n}x - x)/|k_n - x| - v] \rightarrow 0$ , we have  $t_n \sum_{\ell=1}^{N_n} T_{(\ell-1)t_n} \left[ \frac{T_{t_n}x - x}{|k_n - x|} - v \right] \rightarrow 0$ . Consequently,  $\int_0^t T_s v ds = 0$ . But since  $t$  has been arbitrarily chosen this implies that  $v = 0$ , which is impossible. Therefore we can assume that  $\sup_n |k_n - x|/t_n < \infty$ . Together with (4.12) this implies that  $\sup_n |T_{t_n}x - x|/t_n < +\infty$ , and the claim follows by Lemma 4.10.  $\square$

For the rest of this section we will restrict ourselves to the case in which  $K$  is a finite dimensional linear subspace of  $H$  with  $K \subset D(A)$ .

As in section 4.1 we will derive from Theorem 3.5 specific necessary conditions for the  $\varepsilon$ -viability and show that they are also sufficient.

For this end we make the technical assumption that  $D(A) \subset D(A^*)$  and we denote again by  $\{J_n : n \in \mathbb{N}\}$  a family of linear bounded operators  $H \rightarrow D(A^*)$  such that  $|J_n|_{L(H)} \leq 1$  and  $J_n x \rightarrow x$  as  $n \rightarrow \infty$  for all  $x \in H$ .

**PROPOSITION 4.12.** *Assume that the finite dimensional linear subspace  $K \subset H$  is  $\varepsilon$ -viable for (2.1). We denote by  $\Pi$  the orthogonal projection on  $K^\perp$ . Then, for any  $n \in \mathbb{N}$ , arbitrarily fixed  $x \in K$ , and  $y \in D(A^*) \cap K^\perp$  there exists a sequence of controls  $\{u_\ell : \ell \in \mathbb{N}\} \subset U$  such that*

$$(4.14) \quad \lim_{\ell \rightarrow +\infty} \langle F(x, u_\ell), y \rangle + \langle A^* y, x \rangle \leq 0, \quad \lim_{\ell \rightarrow +\infty} |J_n \Pi G(x, u_\ell) e_i|^2 = 0, \quad i \in \mathbb{N}.$$

*Proof.* Clearly  $d_K^2(z) = |\Pi z|^2$ . Moreover, due to Proposition 4.11 and to our assumption that  $D(A) \subset D(A^*)$ ,  $\Pi = I - \Pi_K$  mappings  $D(A^*)$  into  $K^\perp \cap D(A^*)$ . We fix  $z \in D(A^*)$  and notice that for all  $v \in H$

$$d_K^2(v) = |\Pi(v - z) + \Pi z|^2 \geq d_K^2(z) + |J_n \Pi(v - z)|^2 + 2\langle \Pi z, v - z \rangle := \varphi(v).$$

Since  $D\varphi(v) = 2\Pi z + 2\Pi J_n^* J_n \Pi(v - z) \in D(A^*)$  we can apply Theorem 3.5 to the test function  $\varphi$  obtaining

$$\inf_{u \in U} \left\{ \frac{1}{2} \sum_{i=1}^m |J_n \Pi G(z, u) e_i|^2 + \langle F(z, u), \Pi z \rangle + \langle A^* \Pi z, z \rangle \right\} \leq c |\Pi z|^2.$$

If we now apply the above to  $z = x_\ell \doteq x + \ell^{-1}y$ , by proceeding as in the proof of Proposition 4.1 we can find, for  $\ell \in \mathbb{N}$  large enough, some  $u_\ell^m$  such that

$$\begin{aligned} \lim_{\ell \rightarrow \infty} \sum_{i=1}^m |J_n \Pi G(x_\ell, u_\ell^m) e_i|^2 &= 0, \\ \limsup_{\ell \rightarrow \infty} \{ \langle x_\ell, A^* y \rangle + \langle F(x_\ell, u_\ell^m), y \rangle \} &\leq 0. \end{aligned}$$

Thus, since  $x_\ell \rightarrow x$ , by choosing a suitable subsequence of  $\{u_\ell^m : \ell \in \mathbb{N}\}$  we can assume that

$$\begin{aligned} |J_n \Pi G(x, u_\ell^m) e_i|^2 &\leq \frac{1}{\ell}, \quad i = 1, \dots, m, \\ \langle x, A^* y \rangle + \langle F(x, u_\ell^m), y \rangle &\leq \frac{1}{\ell}. \end{aligned}$$

The claim is proved by putting  $u_\ell = u_\ell^m$ .  $\square$

Exactly as in Corollary 4.2 we also have the following corollary.

**COROLLARY 4.13.** *Assume that  $K$  is  $\varepsilon$ -viable and that either*

1.  *$U$  is compact,*
2.  *$U$  is convex and the mappings  $u \rightarrow F(x, u)$ ,  $u \rightarrow G(x, u) e_i$ , and  $i \in \mathbb{N}$  are affine.*

*Then for all  $x \in K$  and  $y \in D(A^*) \cap K^\perp$  there exists a control  $u \in U$  such that*

$$(4.15) \quad \langle F(x, u), y \rangle + \langle A^* y, x \rangle \leq 0, \quad G(x, u) v \in K, \quad v \in \Xi.$$

As in the previous section we prove that conditions (4.14) are also necessary. Again we assume that  $A$  is diagonal and that  $\{f_i : i \in \mathbb{N}\}$  is an orthonormal basis of eigenvectors corresponding to the eigenvalues  $\{-\lambda_i : i \in \mathbb{N}\}$  with  $0 \leq \lambda_1 \leq \lambda_2, \dots$  and  $\lambda_n \nearrow +\infty$ . Moreover, by  $J_n$  we denote now the orthogonal projection on the space  $H_n$  generated by  $f_1, \dots, f_n$  and  $K$ .

**PROPOSITION 4.14.** *Assume that  $U$  is compact and that  $G^*$  is strongly continuous. Moreover, suppose that (4.14) holds. Then the finite dimensional linear subset  $K \subset H$  is  $\varepsilon$ -viable.*

*Proof.* First of all we notice that  $\Pi J_n = J_n \Pi$  (recall that  $\Pi$  is the projection on  $K^\perp$ ). Indeed  $H_n$  is the space generated by  $K$  and  $\Pi f_1, \dots, \Pi f_n$ . Therefore both  $\Pi J_n$  and  $J_n \Pi$  are equal to the projection on  $\Pi f_1, \dots, \Pi f_n$ .

Moreover, since  $(I - J_n)H$  is included in the space generated by  $\{f_i : i \geq n+1\}$  relation (4.7) still holds.

By (4.14) for all  $x \in H_n$  with  $|\Pi x| \leq 1$  there exists some  $\bar{u}(x) \in U$  verifying

$$\sum_{i=1}^m |J_n \Pi G(\Pi_K x, \bar{u}(x)) e_i|^2 \leq \varepsilon/2, \quad \langle F(\Pi_K x, \bar{u}(x)), \Pi x \rangle + \langle A \Pi_K x, \Pi x \rangle \leq \varepsilon/2$$

(recall that  $\Pi_K$  is the projection on  $K$ ).

Since  $A$  is bounded on  $H_n$  and  $F, G$  are Lipschitz uniformly with respect to  $u \in U$ , we have for all fixed  $m \in \mathbb{N}$

$$(4.16) \quad \sum_{i=1}^m |J_n \Pi G(x, \bar{u}(x)) e_i|^2 \leq \varepsilon/2 + c |\Pi x|^2, \quad \langle F(x, \bar{u}(x)), \Pi x \rangle + \langle Ax, \Pi x \rangle \leq \varepsilon/2 + c |\Pi x|^2.$$

Moreover, the above functions are continuous on bounded subsets of  $H_n$ , uniformly in  $u \in U$ . Thus there exists a constant  $c$  such that for all  $\varepsilon > 0$  and  $x \in H_n$  with  $|\Pi x| \leq 1$  there exists an  $\bar{u}(x) \in U$  verifying

$$(4.17) \quad \sum_{i=1}^m |J_n \Pi G(x, \bar{u}(x)) e_i|^2 \leq \varepsilon + c |\Pi y|^2, \quad \langle F(y, \bar{u}(x)), \Pi y \rangle + \langle Ay, \Pi y \rangle \leq \varepsilon + c |\Pi y|^2$$

for all  $y \in H_n$  with  $|y - x| \leq \delta_\varepsilon$ . Here  $\delta_\varepsilon > 0$  is a suitable constant independent of  $x$  and  $y$ . Moreover, the mapping  $x \rightarrow \bar{u}(x)$  can be chosen to be measurable.

Now let  $a > 0$  and  $x \in K$  be arbitrarily fixed. Using (4.17) and following the argument developed for Lemma 4.7 we can find  $u^\sharp \in \mathcal{U}$  such that denoting by  $Z^\sharp$  the solution to

$$\begin{cases} dZ_t^\sharp = (AZ_t^\sharp + J_n F(Z_t^\sharp, u_t^\sharp)) dt + J_n G(Z_t^\sharp, u_t^\sharp) dW_t^m, & t \geq 0, \\ Z_0^\sharp = J_n x, \end{cases}$$

and by  $\rho$  the stopping time  $\rho = \inf\{t \geq 0 : |\Pi Z_t^\sharp| > 1\} \wedge 1$ , we have,  $P$ -a.s. for all  $t \leq \rho$ ,

$$(4.18) \quad \sum_{i=1}^m |J_n \Pi G(Z_t^\sharp, u_t^\sharp) e_i|^2 \leq \varepsilon + c |\Pi Z_t^\sharp|^2, \\ \langle F(Z_t^\sharp, u_t^\sharp), \Pi Z_t^\sharp \rangle + \langle AZ_t^\sharp, \Pi Z_t^\sharp \rangle \leq \varepsilon + c |\Pi Z_t^\sharp|^2.$$

Again similar to Lemma 4.7, let  $\psi_\varepsilon(r) = 2 \int_0^r \int_0^s [\varepsilon^{-1} \sigma] \wedge 1 d\sigma ds$  for  $r > 0$ ,  $\psi_\varepsilon(r) = 0$  for  $r \leq 0$ . We notice that  $\psi_\varepsilon(r) \nearrow (r^+)^2$  and  $\psi'_\varepsilon(r) \nearrow 2r^+$ , uniformly on bounded

subsets of  $\mathbb{R}_+$  and  $\psi''_\varepsilon(r) \nearrow 2I_{]0,\infty[}(r)$ . Moreover,  $\psi_\varepsilon(r) \leq r^2$ ,  $\psi'_\varepsilon(r) \leq 2|r|$ , and  $\psi''_\varepsilon(r) \leq 2$  for all  $r \in \mathbb{R}, \varepsilon \in ]0, 1]$ . Finally,  $\psi_\varepsilon$  is of class  $C^2$ .

We now compute  $d_t \phi_\varepsilon(|\Pi Z_t^\#|)$ , by Itô's rule, integrate over the interval  $[0, t \wedge \rho]$ , and compute the mean value. Then letting  $\varepsilon \searrow 0$ , we obtain

$$\mathbb{E}(|\Pi Z_{t \wedge \rho}^\#|^2) = \mathbb{E} \int_0^{t \wedge \rho} \left[ \langle 2\Pi Z_s^\#, AZ_s^\# \rangle + 2\langle \Pi Z_s^\#, J_n F(Z_s^\#, u_s^\#) \rangle + \sum_{i=1}^m |\Pi J_n G(Z_s^\#, u_s^\#) e_i|^2 \right] ds$$

and by (4.18)

$$\mathbb{E}|\Pi Z_{t \wedge \rho}^\#|^2 \leq c\varepsilon + c\mathbb{E} \int_0^{t \wedge \rho} |\Pi Z_{t \wedge \rho}^\#|^2 ds \leq c\varepsilon + c\mathbb{E} \int_0^t |\Pi Z_{t \wedge \rho}^\#|^2 ds.$$

Thus, by Gronwall's lemma we get  $\mathbb{E}|\Pi Z_{t \wedge \rho}^\#|^2 \leq c\varepsilon$  and taking the limit as  $t \nearrow \infty$ ,  $\mathbb{E}|\Pi Z_\rho^\#|^2 \leq c\varepsilon$ . Finally, since again as in Lemma 4.7,

$$\mathbb{E} \int_\rho^a |\Pi Z_s^\#|^2 ds \leq c\sqrt{P(\rho < a)} \leq c\sqrt{P(|\Pi Z_\rho^\#| = 1)} \leq c\sqrt{\mathbb{E}|Z_\rho^\#|^2} \leq c\sqrt{\varepsilon},$$

we have  $\mathbb{E} \int_0^a |\Pi Z_s^\#|^2 ds \leq c\sqrt{\varepsilon}$ . Since  $a > 0$   $n$  and  $m$  are arbitrary, the claim follows by Lemma 4.5.  $\square$

### 4.3. Sufficiency of the necessary condition by comparison principle.

In this section we assume that (3.12) holds and, following [24], that there exists a self-adjoint bounded positive operator  $B \in L(H)$  with  $BH \subset D(A^*)$  and a constant  $C_0 > 0$  such that

$$(4.19) \quad -A^*B + C_0B \geq I$$

(for instance, if  $A$  is selfadjoint it is enough to take  $B = (-A^* + I)^{-1}$ ). Condition (4.19) was first introduced in [11] where many examples are given. Moreover a general sufficient condition for (4.19) to hold was given in [29].

We define  $H_{-1}$  as the completion of  $H$  under the norm  $\|x\|_{-1}^2 \doteq \langle Bx, x \rangle = |B^{1/2}x|$ .

**DEFINITION 4.15.** *We say that a continuous function  $u : [0, T] \times H \rightarrow \mathbb{R}$  is B-lower semicontinuous if  $u(t, x) \leq \liminf_{n \rightarrow \infty} u(t_n, x_n)$  whenever  $t_n \rightarrow t$  and  $x_n \rightarrow x$ ,  $Bx_n \rightarrow Bx$ . Clearly,  $u : [0, T] \times H \rightarrow \mathbb{R}$  is B-upper semicontinuous whenever  $-u$  is B-lower semicontinuous.*

In this section we obtain sufficiency of the condition for general  $K$  (in some cases for nonconvex  $K$ ), but the price to pay is that we have to assume, beside the trace class condition included in (3.12), that the two following restrictive requirements hold:

$$(4.20) \quad |G(x, u) - G(y, u)|_{L_2(\Xi, H)} \leq C\|x - y\|_{-1}, \quad \text{for all } x, y, \text{ in } H, \text{ for all } u \in U,$$

$$(4.21) \quad d_K^2 \text{ is B-lower semicontinuous.}$$

**PROPOSITION 4.16.** *Condition (4.21) is satisfied, for instance, in the following cases.*

1.  $K$  is locally compact.
2.  $K$  is convex.
3.  $K$  is a linear subspace of  $H$  with  $K^\perp \subset B^{1/2}H$ .

*Proof.* To prove the first assertion, we assume that  $K$  is locally compact and, by contradiction, that there exist  $x \in K$  and  $\alpha > 0$  such that

$$\liminf_{y \rightarrow x} d_K(y) \leq d_K(x) - 4\alpha < d_K(x).$$

Consider a sequence  $y_n \rightarrow x$  with  $\liminf_{y \rightarrow x} d_K(y) = \lim_n d_K(y_n)$  and observe that there exist  $\Pi_K(y_n) \in K$  and  $\Pi_K(x) \in K$  such that

$$d_K(y_n) = |y_n - \Pi_K(y_n)|, \quad d_K(x) = |x - \Pi_K(x)|.$$

So for any  $n$  large enough

$$(4.22) \quad |y_n - \Pi_K(y_n)| \leq d_K(x) - 3\alpha < d_K(x).$$

The sequence  $\Pi_K(y_n)$  is bounded in the locally compact set  $K$ ; hence one can extract a subsequence (again similarly denoted) which converges to some  $z \in K$ . Hence for any  $n$  large enough

$$(4.23) \quad |z - \Pi_K(y_n)| \leq \alpha.$$

From (4.22) and (4.23), we obtain for  $n$  large enough

$$|y_n - z| \leq d_K(x) - 2\alpha < d_K(x).$$

Namely,  $y_n$  belongs to the closed ball  $B(z, d_K(x) - 2\alpha)$  which is convex and (strongly) closed, hence weakly closed by Mazur's theorem. Consequently,  $x$  belongs to this ball because it is the weak limit of  $y_n$ . Hence

$$|x - z| \leq d_K(x) - 2\alpha < d_K(x) \quad \text{and} \quad z \in K$$

which is a contradiction with the very definition of  $d_K(x)$ . As far as the second assertion is concerned, we remark that if  $K$  is convex, then  $d_K^2$  is convex as well. Thus the epigraph of  $d_K^2$  is convex and closed (since  $d_K^2$  is continuous), thus weakly closed.

Finally if  $K$  is linear with  $K^\perp \subset B^{1/2}H$ , then we get

$$d_K(x) = |\Pi_{K^\perp} x| = \sup_{y \in H, |y|=1} \langle \Pi_{K^\perp} x, y \rangle = \sup_{y \in H, |y|=1} \langle B^{1/2} x, B^{-1/2} \Pi_{K^\perp} y \rangle.$$

Since  $B^{-1/2} \Pi_{K^\perp}$  is bounded it is immediate to verify that  $d_K$  is continuous with respect to the norm  $\|\cdot\|_{-1}$ .  $\square$

We introduce here a weak (in probabilistic sense) notion of  $\varepsilon$ -viability.

**DEFINITION 4.17.** *A closed subset  $K \subset H$  is weakly  $\varepsilon$ -viable if for all  $x \in K$  it holds that*

$$(4.24) \quad \inf_{\mathfrak{U}} \mathbb{E} \left[ \int_0^{+\infty} e^{-Ct} d_K^2(X_t^{x, \mathfrak{U}}) dt \right] = 0,$$

where the infimum is computed over all settings  $\mathfrak{U} = (\Omega, \mathcal{E}, \mathbb{P}, \mathbb{F}, u)$ , where  $(\Omega, \mathcal{E}, \mathbb{P})$  is a probability space;  $\mathbb{F} = \{\mathcal{F}_t\}_{t \geq 0}$  is a filtration in  $\mathcal{E}$  satisfying the usual conditions:  $\{W_t\}_{t \geq 0}$  is a cylindrical,  $\Xi$ -valued  $\mathbb{F}$ -Wiener process, and  $u$  is an  $\mathbb{F}$ -progressively measurable process with values in  $U$ . Moreover, by  $X^{x, \mathfrak{U}}$  we denote the solution of (4.26) with respect to the setting  $\mathfrak{U}$ .

REMARK 4.18. Since, as it is stated in Remark 3.7, under assumptions (3.12), the filtrations  $\mathbb{F}$  and  $\mathbb{F}^m$  do not play any role in the proof of Theorem 3.5. Then the argument of the proof of Theorem 3.5 still yields, taking into account the simplifications stated in Remark 3.7, that if  $K$  is weakly  $\varepsilon$ -viable, then  $d_K^2$  is a viscosity supersolution of the HJB equation (3.13) for a suitable constant  $C > 0$  (large enough).

PROPOSITION 4.19. Assume that (3.12), (4.19), (4.20), and (4.21) hold; then  $K$  is weakly  $\varepsilon$ -viable if and only if there exists  $C > 0$  (large enough) such that  $d_K^2$  is a viscosity supersolution of the HJB equation (3.13).

*Proof.* We start by noticing that it is easy to verify, just by comparing the two definitions, that if a function  $u : H \rightarrow \mathbb{R}$  is a viscosity supersolution of the HJB equation (3.13) in the sense of Definition 3.4 and it is B-lower semicontinuous, then it is a (stationary) viscosity supersolution of the parabolic HJB equation

$$(4.25) \quad \begin{aligned} & -\frac{\partial}{\partial t}V(t, x) + \Psi(x, V(x), D_x V(t, x), D_x^2 V(t, x)) - \langle Ax, D_x V(t, x) \rangle = 0, \\ & \quad \quad \quad t \in [0, T] \ x \in H, \\ & \text{with } \Psi(x, v, p, X) = - \inf_{u \in U} \left( \frac{1}{2} \sum_{i=1}^{\infty} \langle XG(x, u)e_i, G(x, u)e_i \rangle + \langle F(x, u), p \rangle \right) \\ & \quad \quad \quad + Cv - d_K^2(x) \end{aligned}$$

in the sense of in [24, Definition 2.2].

We fix an arbitrary  $T > 0$  and define

$$V(t, x) = \inf_{\mathfrak{U}} \mathbb{E} \int_t^T e^{-Cs} d_K^2(X_s^{t,x,\mathfrak{U}}) ds, \quad x \in H,$$

where  $\mathfrak{U} = (\Omega, \mathcal{E}, \mathbb{P}, \mathbb{F}, u)$  is as in Definition 4.17 and  $X^{t,x,\mathfrak{U}}$  is the solution of

$$(4.26) \quad \begin{cases} d_s X_s = (AX_s + F(X_s, u_s)) ds + G(X_s, u_s) dW_s, & s \in [t, T], \\ X_t = x, \end{cases}$$

corresponding to  $\mathfrak{U}$ .

By [24, Theorem 4.1]  $V$  is the unique  $B$ -continuous viscosity solution of

$$\begin{cases} -\frac{\partial}{\partial t}V(t, x) + \Psi(x, V(x), D_x V(t, x), D_x^2 V(t, x)) - \langle Ax, D_x V(t, x) \rangle = 0, \\ V(T, x) = 0, \end{cases} \quad t \in [0, T] \ x \in H,$$

with quadratic growth. Since  $d_K^2$  is a viscosity supersolution of (4.25) by the comparison result in [24, Theorem 3.3] (see also [24, Remark 3.3], notice that in [24, section 3] it is also shown that the assumptions of [24, Theorem 3.3] are satisfied in the present case); we get  $V(t, x) \leq d_K^2(x)$ ,  $t \in [0, T]$ . In particular  $V(0, x) = 0$  for  $x \in K$ . Due to the arbitrariness of  $T$  we deduce that for all  $\varepsilon > 0$  and all  $T > 0$  there exists some  $\mathfrak{U} = (\Omega, \mathcal{E}, \mathbb{P}, \mathbb{F}, u)$  such that

$$\mathbb{E} \int_0^T e^{-Cs} d_K^2(X_s^{x,\mathfrak{U}}) ds \leq \varepsilon.$$

The claim follows since, by Lemma 2.2, for an arbitrary  $C > C_2$  (see Lemma 2.2),

$$\mathbb{E} \int_T^\infty e^{-Cs} d_K^2(X_s^{x,\mathfrak{U}}) ds \leq e^{-(C-C_2)T} / (C - C_2). \quad \square$$

**5. Application.** Finally, we briefly show how our results can be applied to a general semilinear controlled heat equation with multiplicative white noise. Namely we consider, for  $t \in [0, T]$ ,  $\xi \in [0, 1]$ ,

$$(5.1) \quad \begin{cases} d_t X^u(t, \xi) = \frac{\partial^2}{\partial \xi^2} X^u(t, \xi) dt + f(X^u(t, \xi), u(t, \xi)) dt + \sigma(X^u(t, \xi), u(t, \xi)) \frac{\partial}{\partial t} \mathcal{W}(t, \xi), \\ X^u(t, 0) = X^u(t, 1) = 0, \\ X^u(t_0, \xi) = x_0(\xi), \end{cases}$$

where  $\mathcal{W}$  is a space-time white noise on  $[0, T] \times [0, 1]$ . The functions  $f$  and  $\sigma$  are continuous functions defined on  $\mathbb{R}^2$  with values in  $\mathbb{R}$ . Moreover we assume that  $f$  and  $g$  are Lipschitz in  $x$  and uniformly in  $u$ , if  $u$  varies on a bounded subset of  $\mathbb{R}$ .

Finally, we assume that  $x_0 \in L^2([0, 1])$  and that  $U$  is a subset of  $\{u \in L^2([0, 1]) : |u(\xi)| \leq \delta \text{ for almost all } \xi \in [0, 1]\}$  for a suitable  $\delta > 0$ .

To rewrite the above problem in the abstract way we set  $H = \Xi = L^2([0, 1])$ .

We set  $\{W_t : t \geq 0\}$  to be a cylindrical Wiener process in  $L^2([0, 1])$  (that is formally  $(\partial \mathcal{W} / \partial t)(t, \xi) = \sum_{i=1}^{\infty} \beta_i(t) e_i(\xi)$ , where  $\{\beta_i : i \in \mathbb{N}\}$  is a sequence of independent, real valued Brownian motions and  $\{e_i : i \in \mathbb{N}\}$  is an orthonormal basis in  $H$ ).

Moreover, we define the operator  $A$  with domain  $\mathcal{D}(A)$  by

$$\mathcal{D}(A) = H^2([0, 1]) \cap H_0^1([0, 1]), \quad (Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi) \quad \text{for all } y \in \mathcal{D}(A),$$

where  $H^2([0, 1])$  and  $H_0^1([0, 1])$  are the usual Sobolev spaces and

$$F(x, u)(\xi) = f(\xi, x(\xi), u(\xi)), \quad [G(x, u)z](\xi) = \sigma(\xi, x(\xi), u(\xi))z(\xi)$$

for all  $x, z \in L^2([0, 1])$ ,  $u \in L^2([0, 1])$  and a.a.  $\xi \in [0, 1]$ .

With this setting and under the above hypotheses, the general assumptions in section 2 are satisfied; see [13, section 11.2.1] (to ensure that (2.5) holds it is enough to choose a basis in  $L^2([0, 1])$  given by bounded functions). Moreover, it is well known that the operator  $A$  is selfadjoint.

**5.1. Viability of balls.** Let  $K$  be the unit ball in  $H$  and  $U = \{u \in L^2([0, 1]) : |u(\xi)| \leq 1 \text{ for a.e. } \xi \in [0, 1]\}$ . Moreover, we assume that  $f$  is affine,  $f(x, u) = f_0(x)u + f_1(x)$  with  $f_0$  and  $f_1$  continuous and bounded. The coefficient  $\sigma$  is also supposed to be linear,  $\sigma(x, u) = \sigma_0(x)u$ , where  $\sigma_0$  is a continuous and bounded function  $\mathbb{R} \rightarrow \mathbb{R}$ . Finally we suppose that  $\sigma_0(x) \neq 0$  if  $x \neq 0$ .

In this case the first condition in (4.2) takes the form

$$(5.2) \quad \sigma_0(x(\xi))u(\xi)x(\xi) = 0 \text{ for a.e. } \xi \in [0, 1] \text{ and for all } x \in \mathcal{D}(A) \text{ with } |x|_H = 1.$$

Thus  $u(\xi)x(\xi) = 0$ , for a.e.  $\xi \in [0, 1]$  and for all  $x \in \mathcal{D}(A)$  with  $|x|_H = 1$ .

Consequently, the second condition in (4.2) becomes

$$(5.3) \quad \int_0^1 f_1(x(\xi))x(\xi)d\xi - \int_0^1 (x'(\xi))^2 d\xi \leq 0$$

for all  $x \in \mathcal{D}(A)$  with  $|x|_H = 1$ . Resuming, (5.2) and (5.3) give the desired necessary and sufficient condition for the  $\varepsilon$ -viability of  $K$ .

**5.2. Viability of linear spaces.** Now let  $K$  be a finite dimensional linear subspace of  $D(A)$  and

$$U = \{u \in H^1([0, 1]) : |u|_{H^1([0, 1])} \leq r\}$$

for some  $r > 0$  (we notice that  $U$  is a compact subset of  $\{u \in L^2([0, 1]) : |u(\xi)| \leq \delta \text{ for all } \xi \in [0, 1]\}$  for  $\delta$  large enough).

Moreover, we assume that the functions  $f$  and  $g$  are convex in  $u$  (but not necessarily linear), where  $\sigma : \mathbb{R}^2 \rightarrow \mathbb{R}$  is assumed to be of class  $C^1(\mathbb{R}^2)$  satisfying  $|\partial\sigma(a, b)/\partial b| > 0$  for all  $a \in \mathbb{R}$  and  $b \in [-\delta, \delta]$ .

In this case the second relation in (4.15) becomes  $\sigma(x(\xi), u(\xi)) = 0$  for all  $\xi \in [0, 1]$ . Indeed, since  $\sigma$ ,  $x$ , and  $u$  are continuous, if we had  $\sigma(x(\xi), u(\xi)) \neq 0$  for some  $\xi \in [0, 1]$ , then the set  $\{\sigma(x, u)v : v \in L^2([0, 1])\}$  would automatically be an infinite dimensional subset of  $L^2([0, 1])$ . Thus, taking into account that  $|\partial\sigma/\partial u(x, u)| > 0$ , the above implies that for all  $a \in \mathbb{R}$  there exists a unique  $b = h(a) \in [-\delta, \delta]$  such that  $\sigma(a, h(a)) = 0$ . Moreover,  $h \in C^1(\mathbb{R}, [-\delta, \delta])$ .

We now observe that the first formula in (4.15) gives

$$(5.4) \quad f(x, h(x)) + x'' \in K \quad \text{for all } x \in K.$$

Resuming  $K$  is  $\varepsilon$ -viable if and only if the following two statements hold:

1. for all  $a \in \mathbb{R}$  there exists a (unique)  $b = h(a) \in [-\delta, \delta]$  such that  $\sigma(a, h(a)) = 0$ ,
2. for all  $x \in K$ ,  $h(x) \in U$  and  $f(x, h(x)) + x'' \in K$ .

**5.3. Nonconvex  $K$ .** We consider here a state equation with more regular diffusion and finite dimensional noise

$$(5.5) \quad \begin{cases} d_t X^u(t, \xi) = \frac{\partial^2}{\partial \xi^2} X^u(t, \xi) dt + f(X^u(t, \xi), u(t, \xi), v(t)) dt \\ \quad + \sum_{i=1}^N \sigma^i \left( \langle X^u(t, \xi), h^i(\xi) \rangle_{L^2([0, 1])}, v(t) \right) d\beta_t^i, \\ X^u(t, 0) = X^u(t, 1) = 0, \\ X^u(t_0, \xi) = x_0(\xi), \end{cases}$$

where  $\beta^1, \dots, \beta^N$  are independent real-valued Brownian. The functions  $f : \mathbb{R}^{2+M} \rightarrow \mathbb{R}$  and  $\sigma : \mathbb{R}^{1+M} \rightarrow \mathbb{R}$  are again continuous and we assume that  $f$  and  $g$  are Lipschitz in  $x$ , uniformly in  $u$  and  $v$ .

The control is now given by  $(u, v)$  with  $u \in L^2([0, 1])$  and  $v \in \mathbb{R}^M$ . We set  $U = \{(u, v) : |u|_{L^2([0, 1])} \leq 1, |v| \leq 1\}$ .

Finally, we assume that  $h_i \in H_0^1([0, 1])$ , and let  $K$  be a (possibly nonconvex) locally compact closed subset of  $L^2([0, 1])$ .

As above we let  $H = L^2([0, 1])$  and  $\mathcal{D}(A) = H^2([0, 1]) \cap H_0^1([0, 1])$ ,  $(Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi)$ .

We notice that  $A$  is selfadjoint and we can choose  $B = (I - A)^{-1}$ . Thus  $B^{-1/2} = (I - A)^{1/2}$  with  $D(B^{-1/2}) = H_0^1$ . Moreover, since  $h_i \in D(B^{-1/2})$  the map  $x \rightarrow \langle x, h^i \rangle_{L^2([0, 1])}$  can be rewritten as  $x \rightarrow \langle B^{1/2}x, B^{-1/2}h^i \rangle_{L^2([0, 1])}$ . Thus if  $F$  is defined as in the previous sections and  $G(x, u, v) = (\sigma^1(\langle x, u \rangle_{L^2([0, 1])}, v), \dots, \sigma^N(\langle x, u \rangle_{L^2([0, 1])}, v))$ ,  $x, u \in L^2([0, 1])$ ,  $v \in \mathbb{R}^M$  it is easy to verify that the assumptions of Proposition 4.19 are verified. Thus applying Proposition 4.19 we obtain that the set  $K$  is  $\varepsilon$ -viable if and only if there exists  $C > 0$  (large enough) such that  $d_K^2$  is a viscosity supersolution of the HJB equation (3.13).

# STOCHASTIC OPTIMAL CONTROL PROBLEMS AND PARABOLIC EQUATIONS IN BANACH SPACES\*

FEDERICA MASIERO†

**Abstract.** We consider stochastic optimal control problems in Banach spaces. These problems are related to nonlinear controlled equations with dissipative nonlinearity and are treated via the backward stochastic differential equation approach, which also allows us to solve, in a mild sense, Hamilton–Jacobi–Bellman equations in Banach spaces. We apply the results to controlled stochastic heat and wave equations with a cost functional that is well defined on continuous functions, and to delay equations in spaces of  $p$ -integrable functions.

**Key words.** stochastic optimal control, infinite dimensional stochastic processes, Banach spaces, backward stochastic differential equations, Hamilton–Jacobi–Bellman equations

**DOI.** 10.1137/050632725

**1. Introduction.** In this paper we develop an abstract theory for stochastic optimal control problems with cost functionals that are defined on a Banach space. This allows us to treat, for example, stochastic optimal control problems for heat equations with temperature control in a finite number of points: in an abstract setting this cost functional is well defined on the Banach space of continuous functions, but it is not well defined on the Hilbert space of square integrable functions. In many other situations arising from concrete models, the cost is naturally defined on a Banach space, but not on a Hilbert space; hence, the novelty of this paper is that we can consider such optimal control problems in a general framework and extend the results found in the existing literature. The control problems are treated via backward stochastic differential equations (BSDEs); a similar approach for stochastic optimal control problems in infinite dimensional Hilbert spaces is studied in [16].

First, we consider a stochastic differential equation, with additive noise, in a Banach space  $E$ :

$$(1.1) \quad \begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t = x. \end{cases}$$

$W$  is a cylindrical Wiener process in a separable Hilbert space  $\Xi$ ,  $A$  generates a strongly continuous semigroup of linear operators,  $F : [0, T] \times E \rightarrow E$  is continuous, and there exists  $\eta \in \mathbb{R}$  such that  $A + F(\tau, \cdot) - \eta$  is dissipative on  $E$ , for every  $\tau \in [0, T]$ ;  $G$  is a linear operator from  $\Xi$  to  $H$ ,  $x \in E$  and  $0 \leq t \leq T$ . The Banach space is continuously and densely embedded in another real and separable Hilbert space  $H$ . We make suitable assumptions such that the stochastic convolution

$$W_A(\tau) = \int_0^\tau e^{(\tau-s)A} G dW_s$$

†Dipartimento di Matematica e Applicazioni, Università di Milano-Bicocca, via Cozzi, 53, 20125 Milano, Italy (federica.masiero@unimib.it).

is well defined as a Gaussian process in  $H$ . Moreover, we assume that the stochastic convolution  $W_A(\tau)$  admits an  $E$ -continuous version. It is well known that under these assumptions, (1.1) admits a unique mild solution, i.e., it satisfies  $\mathbb{P}$ -almost surely ( $\mathbb{P}$ -a.s.)

$$X_\tau = e^{(\tau-t)A}x + \int_t^\tau e^{(\tau-s)A}F(s, X_s)ds + \int_t^\tau e^{(\tau-s)A}GdW_s, \quad \tau \in [t, T];$$

see, e.g., [11], [12], and [13]. We want to remark that  $F$  is well defined only on the Banach space  $E$ , while on the Hilbert space  $H$ ,  $F$  is not even defined: this is a natural situation arising in many evolution equations, and the problem of solving (1.1) has been extensively studied, but not in relation to stochastic optimal control problems. To this end, we have to prove new results on the dependence of the solution  $X$  of (1.1) on the initial datum, in a suitable sense. We prove that if  $F$  is differentiable, then  $X$  is differentiable with respect to the initial datum. This result will be used while proving the so-called fundamental relation via BSDEs.

The controlled stochastic evolution equations that we study have the following form:

$$(1.2) \quad \begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau)d\tau + GdW_\tau + GR(\tau, X_\tau, u_\tau)d\tau, & \tau \in [t, T], \\ X_t = x, \end{cases}$$

where  $R$  is defined on  $[0, T] \times E \times U$ , and  $U$  denotes the set of control actions. In (1.2), we notice the occurrence of the operator  $G$  in the control term: this is a restriction imposed by our techniques, but it arises in the abstract formulation of controlled delay and wave equations. In the particular case  $R(\tau, x, u) = u$ , the term  $u_\tau d\tau + dW_\tau$  admits a natural interpretation as a control affected by noise.

Following the approach of [15], we consider the control problem in the weak formulation, that is, we have to minimize a cost functional over all admissible control systems (a.c.s.'s)  $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W, u, X)$ . Namely, to every a.c.s.  $(W, u, X^u)$  we associate a cost  $J$  given by

$$(1.3) \quad J(t, x, (W, u, X)) = \mathbb{E} \int_t^T g(s, X_s, u_s)ds + \mathbb{E}\phi(X_T),$$

where  $g : [0, T] \times E \times U \rightarrow \mathbb{R}$  and  $\phi : E \rightarrow \mathbb{R}$ . The value function of this control problem is defined by

$$(1.4) \quad V(t, x) = \inf_{(W, u, X^u) \text{ a.c.s.}} J(t, x, (W, u, X)).$$

In order to solve the optimal control problem, we introduce the BSDE

$$(1.5) \quad Y_\tau + \int_\tau^T Z_\sigma dW_\sigma = \phi(X_T) + \int_\tau^T \psi(\sigma, X_\sigma, Z_\sigma)d\sigma, \quad \tau \in [t, T];$$

see, e.g., [22]. The solution of this equation is a pair of predictable processes  $(Y, Z)$ , taking values in  $\mathbb{R} \times \Xi^*$ .  $\phi$  is the final cost, and  $\psi : [0, T] \times E \times \Xi^* \rightarrow \mathbb{R}$  is the Hamiltonian function defined in a classical way:

$$(1.6) \quad \psi(\tau, x, z) = \inf_{u \in U} \{g(\tau, x, u) + zR(\tau, x, u)\}.$$

We recall that the process  $X$  takes values in the Banach space  $E$ . It is trivial to deduce existence and uniqueness of the solution of (1.5). The fundamental relation via the BSDE is

$$(1.7) \quad Y_t = J(t, x, u) + \mathbb{E} \int_t^T [\psi(\sigma, X_\sigma, Z_\sigma) - Z_\sigma R(\sigma, X_\sigma, u_\sigma) - g(\sigma, X_\sigma, u_\sigma)] d\sigma.$$

Thus a control  $u$  such that

$$u_\tau \in \Gamma(\tau, x, z) := \{u \in U : g(\tau, x, u) + zR(\tau, x, u) = \psi(\tau, x, z)\}$$

is optimal. In order to characterize the optimal control via a feedback law, we need to identify the process  $Z$  with some function of the process  $X$ . Namely, we define the function  $v(t, x)$  as  $Y(t, t, x)$ , where  $Y(t, t, x)$  is the solution  $Y$  of the BSDE, considered at time  $t$  and depending on the Markov process  $X$ , which is a solution to an equation with the same structure as (1.1), and with initial condition  $x$  given at the initial time  $t$ . We prove that the value function  $V(t, x)$ , defined in (1.4), is equal to  $v(t, x)$ . Our goal is to prove that, when  $v(t, x)$  is differentiable with respect to  $x$ ,  $Z_t = \nabla v(t, X_t)G$ . For such an identification,  $Y(t, t, x)$  has to be differentiable with respect to  $x$ , and this can be proved by requiring the final cost  $\phi$  and the Hamiltonian  $\psi$  to be differentiable with respect to  $x$ , and by using the fact that the process  $X$  is differentiable with respect to the initial datum  $x$ . Differentiability assumptions on the Hamiltonian and on the final cost are a genuine restriction; but the identification of  $Z_t$  with  $\nabla v(t, X_t)G$  allows us to characterize the optimal control via a feedback law. When  $X$  evolves in a Hilbert space  $H$ , in the more general case of multiplicative noise in (1.1) (that is,  $G$  not necessarily constant),  $Z_t$  is identified with  $\nabla v(t, X_t)G(X_t)$  by means of the Malliavin calculus; see [16]. In this paper we deal with equations evolving in a Banach space, so we cannot make direct use of Malliavin calculus. By an idea taken from [2], we can prove that  $Z_t = \nabla v(t, X_t)G$  by avoiding the use of Malliavin calculus.

Moreover, by using the BSDE approach we are able to solve the associated Hamilton–Jacobi–Bellman equation

$$(1.8) \quad \begin{cases} \frac{\partial v}{\partial t}(t, x) = -\mathcal{A}_t v(t, x) - \psi(t, x, \nabla v(t, x)G), & t \in [0, T], x \in E, \\ v(T, x) = \phi(x). \end{cases}$$

We can prove the existence and uniqueness of a mild solution to (1.8), i.e., a function  $v(t, x)$ , which is continuous and Gâteaux differentiable with respect to  $x$  and satisfies

$$v(t, x) = P_{t,T}[\varphi](x) + \int_t^T P_{t,s}[\psi(s, \cdot, \nabla v(s, \cdot)G)](x) ds, \quad t \in [0, T], x \in E.$$

For every  $t \leq \tau \leq T$ , we denote by  $P_{t,\tau}$  the transition semigroup corresponding to the Markov process  $X(\tau, t, x)$ ,  $t \leq \tau \leq T$ , which is solution of (1.1), i.e., for a continuous and bounded function  $\varphi : E \rightarrow \mathbb{R}$ ,  $P_{t,\tau}[\varphi](x) = \mathbb{E}\varphi(X(\tau, t, x))$ . It turns out that the mild solution  $v(t, x)$  of the Hamilton–Jacobi–Bellman equation (1.8) is equal to  $Y(t, t, x)$ .

For the solution of Hamilton–Jacobi–Bellman equations via a BSDE, we cite [26], where the finite dimensional case is treated, and [16], where existence and uniqueness of a mild solution are proved for a Hamilton–Jacobi–Bellman equation on an infinite

dimensional Hilbert space. For Hamilton–Jacobi–Bellman equations on an infinite dimensional Hilbert space, the notion of a viscosity solution has been studied by many authors; we refer the reader to the general reference [9] and to the fundamental papers [6], [19], and [20]. The class of equations that can be treated is much more general than in our case; however, none of the known results guarantee differentiability of the solution. We are not aware of other results in the literature about the solution of stochastic partial differential equations of parabolic type in Banach spaces, apart from the papers [7] and [8], where viscosity solutions are presented for first order partial differential equations. Here we require more regularity on  $\phi$  and  $\psi$ , and we solve the equation in a stronger sense.

We apply the results to some specific models: we treat controlled heat equations in one space dimension with Dirichlet and Neumann boundary conditions, with the cost functional defined on the Banach space of continuous functions. The stochastic heat equation is nonlinear, and the nonlinear term is dissipative in the space of continuous functions, and it cannot be naturally extended to the whole Hilbert space of square integrable functions. Stochastic reaction diffusion equations have been extensively studied; we cite [29] as a general reference. In the papers [3] and [4], where more general reaction diffusion equations are studied in space dimension greater than 1, even when the equation is solved in the space of continuous functions, the related costs are defined in the Hilbert space of square integrable functions. We also cite [18] and [23], where nonlinear reaction diffusion equations with a nonlinear term satisfying polynomial growth conditions are studied. We remark that it is more natural to treat nonlinear terms with polynomial growth conditions in the space of continuous functions rather than in the space of square integrable functions. Indeed, in the first case the nonlinear term is defined on the whole space, while on the contrary it is easy to verify that this is not the case in the space of square integrable functions. We also study stochastic delay equations, with the cost defined on the space of  $p$ -integrable functions, and finally, stochastic wave equations in one space dimension with the cost functional defined on the Banach space of continuous functions; to this end we study the abstract wave equation in a Besov space, which is continuously and densely embedded in the space of continuous functions.

The paper is organized as follows. In section 2 we introduce some notations and recall some results that are needed throughout the paper. Section 3 is devoted to the study of the regularity of the solution of (1.1) with respect to the initial datum and to the identification of  $Z$ . In section 4 we study the regularity of the solution of a forward-backward system with respect to the initial datum in the forward equation. In section 5 we formulate the stochastic optimal control problem and solve it when the final cost and the running cost have polynomial growth with respect to  $x$ . In section 6 we solve, in a mild sense, the Hamilton–Jacobi–Bellman equation, and in section 7 we apply the results to some concrete models.

**2. Preliminaries and notations.** We list some notations that are used in the paper. If  $E$  and  $K$  are Banach spaces,  $L(E, K)$  denotes the space of bounded linear operators from  $E$  to  $K$ , endowed with the usual operator norm. By  $E^*$  we denote the dual space of  $E$ , and the duality product between  $E^*$  and  $E$  is denoted by  $\langle \cdot, \cdot \rangle_{E^*, E}$ . We will always deal with real separable Banach spaces.

The letters  $\Xi$  and  $H$  will always denote real and separable Hilbert spaces with scalar product  $\langle \cdot, \cdot \rangle$ .  $L_2(\Xi, H)$  is the space of Hilbert–Schmidt operators from  $\Xi$  to  $H$ , endowed with the Hilbert–Schmidt norm.

We specify in what sense we consider differentiability between Banach spaces.

Following [16, section 2.2], if  $E$  and  $K$  are two Banach spaces, we say that a function  $f : E \rightarrow K$  belongs to the class  $\mathcal{G}^1(E, K)$  if  $f$  is continuous and Gâteaux differentiable on  $E$  and if the gradient  $\nabla f : E \rightarrow L(E, K)$  is strongly continuous; that is, for every direction  $h \in E$  the map  $\nabla f(\cdot)h : E \rightarrow K$  is continuous. We say that  $f : [0, T] \times E \rightarrow K$  is in  $\mathcal{G}^{0,1}([0, T] \times E, K)$  if  $f$  is continuous and Gâteaux differentiable with respect to every  $e \in E$  on  $[0, T] \times E$  and the gradient  $\nabla f : [0, T] \times E \rightarrow L(E, K)$  is strongly continuous. If  $F$  is another Banach space, we say that  $f : E \times F \rightarrow K$  belongs to  $\mathcal{G}^{1,1}(E \times F, K)$  if it is continuous, if it is Gâteaux differentiable on  $E \times F$ , and if  $\nabla f : E \times F \rightarrow L(E \times F, K)$  is strongly continuous. If  $K = \mathbb{R}$  we write, respectively,  $\mathcal{G}^1(E)$ ,  $\mathcal{G}^{0,1}([0, T] \times E)$ , and  $\mathcal{G}^{1,1}(E \times F)$  instead of  $\mathcal{G}^1(E, \mathbb{R})$ ,  $\mathcal{G}^{0,1}([0, T] \times E\mathbb{R})$ , and  $\mathcal{G}^{1,1}(E \times F, \mathbb{R})$ .

From now on, by  $(\Omega, \mathcal{F}, \mathbb{P})$  we mean a complete probability space endowed with a filtration  $\{\mathcal{F}_t, t \geq 0\}$  satisfying the usual conditions. By a cylindrical Wiener process defined on  $(\Omega, \mathcal{F}, \mathbb{P})$ , and with values in a Hilbert space  $\Xi$ , we mean a family  $\{W_t, t \geq 0\}$  of linear mappings  $\Xi \rightarrow L^2(\Omega)$  such that for every  $\xi, \eta \in \Xi$ ,  $\{W_t\xi, t \geq 0\}$  is a real Wiener process and  $\mathbb{E}(W_t\xi \cdot W_t\eta) = \langle \xi, \eta \rangle_\Xi$ . In the following,  $\{W_t, t \geq 0\}$  is a cylindrical Wiener process adapted to the filtration  $\{\mathcal{F}_t, t \geq 0\}$ . We remember that the natural filtration of a Wiener process, augmented with the family of  $\mathbb{P}$ -null sets, satisfies the usual conditions.

Also, a cylindrical Wiener process can be seen as a  $Q$ -Wiener process with values in another Hilbert space  $\Xi_1$ . Let us recall an explicit construction that will be used in the following. Let  $\Xi_1$  be an arbitrary Hilbert space such that  $\Xi$  is continuously embedded in  $\Xi_1$  and the embedding  $i : \Xi \hookrightarrow \Xi_1$  is of Hilbert–Schmidt type with its image dense in  $\Xi_1$ . Let  $Q = ii^*$ .  $Q_1$  is a positive, symmetric trace class operator. Consider  $(\eta_k)_{k \geq 1}$ , a complete orthonormal system in  $\Xi_1$ , and a sequence of positive real numbers  $(\lambda_k)_{k \geq 1}$  such that

$$Q\eta_k = \lambda_k\eta_k.$$

Fix  $\xi_k = \frac{i^*\eta_k}{\sqrt{\lambda_k}}$  as a complete orthonormal system in  $\Xi$ . We can consider a  $Q$ -Wiener process  $W_t^1$ ,  $t \geq 0$ , taking values in  $\Xi_1$ , which admits the following representation:

$$W_t^1 = \sum_{k=1}^{\infty} \sqrt{\lambda_k} \beta_k(t) \eta_k,$$

where  $\beta_k(t)$ ,  $k \geq 1$ , are real, independent standard Wiener processes. Moreover,

$$\beta_k(t) = \frac{\langle W_t^1, \eta_k \rangle_{\Xi_1}}{\sqrt{\lambda_k}}.$$

For every  $\eta \in \Xi_1$  we set

$$\langle W_t^1, \eta \rangle_{\Xi_1} = W_t^{i^*\eta},$$

and for every  $\xi \in \Xi$ ,

$$W_t^\xi = \sum_{k=1}^{\infty} \beta_k(t) \langle \xi, \xi_k \rangle_\Xi$$

and  $\beta_k(t) = W_t^{\xi_k}$ ,  $k \geq 1$ .

Next we define a class of processes with values in a Banach space  $E$ . For every  $0 \leq t < T$ ,  $\mathcal{H}^p([0, T], E)$  is the space of predictable processes  $(Y_\tau)_{\tau \in [t, T]}$  admitting a continuous version and such that

$$\mathbb{E} \sup_{\tau \in [t, T]} \|Y_\tau\|_E^p < \infty.$$

We recall some results on BSDEs. Consider a BSDE of the form

$$(2.1) \quad Y_\tau + \int_\tau^T Z_\sigma dW_\sigma = \eta + \int_\tau^T \psi_\sigma d\sigma, \quad \tau \in [0, T],$$

in  $(\Omega, \mathcal{F}, \mathbb{P})$ .  $\{W_t, t \geq 0\}$  is a cylindrical Wiener process, and the filtration  $\{\mathcal{F}_t, t \geq 0\}$  is the natural filtration of the Wiener process augmented in the usual way.  $Y$  is a process taking values in  $\mathbb{R}$ , and  $Z$  is a process with values in  $\Xi^*$ , the dual of the separable Hilbert space  $\Xi$ .  $\eta$  is an  $\mathcal{F}_T$ -measurable random variable in  $L^2(\Omega, \mathbb{R})$ , and  $\psi_\sigma$  is an adapted square integrable process satisfying

$$(2.2) \quad \mathbb{E} \int_t^T |\psi_\sigma|^2 d\sigma < \infty.$$

Under the previous assumptions, (2.1) admits a unique solution that is a pair of predictable processes  $(Y_\tau, Z_\tau)$ , taking values in  $\mathbb{R} \times \Xi^*$ , such that  $Y$  has continuous paths and

$$\mathbb{E} \sup_{\tau \in [0, T]} |Y_\tau|^2 + \mathbb{E} \int_t^T \|Z_\sigma\|_{\Xi^*}^2 d\sigma < \infty;$$

see, e.g., [25]. In the following we denote by  $\mathbb{K}_{cont}([0, T])$  the space of such processes.

**3. Stochastic evolution equations in Banach spaces.** In this section we collect some results on the existence and uniqueness of mild solutions for stochastic evolution equations in Banach spaces, and then we investigate the regular dependence of the solution on the initial datum.

In the probability space  $(\Omega, \mathcal{F}, \mathbb{P})$ , we consider the following stochastic differential equation with values in a Banach space  $E$ :

$$(3.1) \quad \begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t = x, \end{cases}$$

where  $x \in E$  and  $[t, T] \subset [0, T]$ . Throughout the paper, we assume that the Banach space  $E$  is separable and it is continuously and densely embedded in a Hilbert space  $H$ ;  $A$  is a linear operator in  $E$  with domain  $D(A)$ . We will need the following assumptions.

*Hypothesis 3.1.* We assume that either

1.  $A$  generates a  $C_0$ -semigroup in  $E$ , or
2.  $A$  is a sectorial operator in  $E$ .

We cite [21, p. 33] for a definition of sectorial operator. In both cases we denote by  $e^{tA}$ ,  $t \geq 0$ , the semigroup of bounded linear operators on  $E$  generated by  $A$  and we know that for  $t > 0$  the map  $t \mapsto e^{tA}$  is continuous and there exist  $M > 0$  and  $\omega \in \mathbb{R}$  such that  $\|e^{tA}\|_{L(E, E)} \leq Me^{\omega t}$  for all  $t \geq 0$ ; moreover, we assume that  $\|e^{tA}\|_{L(E, E)} \leq e^{\omega t}$  for all  $t \geq 0$  and some  $\omega \in \mathbb{R}$ . Finally, we assume that  $e^{tA}$ ,  $t \geq 0$ , admits an extension to a  $C_0$ -semigroup of bounded linear operators in  $H$ , still denoted by the same symbol,  $e^{tA}$ .

$W$  is a cylindrical Wiener process in another separable Hilbert space  $\Xi$ . We have to make assumptions on  $F$ ,  $G$ , and the stochastic convolution

$$W_A(\tau) = \int_0^\tau e^{(\tau-s)A} G dW_s.$$

Indeed, the Gaussian process  $W_A(\tau)$  is well defined in  $H$  when its covariance operator

$$Q_\tau = \int_0^\tau e^{sA} G G^* e^{sA^*} ds, \quad \tau \geq 0,$$

is a trace class operator on  $H$ .

*Hypothesis 3.2.*

1.  $F : [0, T] \times E \longrightarrow E$  is continuous and is bounded on bounded sets, and there exists  $\eta \in \mathbb{R}$  such that  $A + F(\tau, \cdot) - \eta$  is dissipative on  $E$  for every  $\tau \in [0, T]$ .
2.  $G$  is a linear operator from  $\Xi$  to  $H$  such that the operator  $Q_\tau$ , which turns out to be positive and symmetric, is of trace class for every  $\tau \in [0, T]$ .
3. The stochastic convolution  $W_A(\tau)$  admits an  $E$ -continuous version.

Throughout the paper, for every  $x \in E$ , we denote by  $\partial(\|x\|_E)$ , the subdifferential of the norm at  $x$ , the set of functionals  $x^* \in E^*$  such that  $\langle x^*, x \rangle_{E^*, E} = \|x\|_E$  and  $\|x^*\|_{E^*} = 1$ .

*Remark 3.3.* By [10, Proposition II.7.4], if a map  $f : D(f) \longrightarrow E$  is continuous and dissipative, then it is strongly dissipative, and, again by [10, p. 46], this is equivalent to asking that for every  $x, y \in E$  and  $x^* \in \partial\|x - y\|_E$ , we have  $\langle x^*, f(x) - f(y) \rangle_{E^*, E} \leq 0$ . Thus the map  $A + F(\tau, \cdot) - \eta I : D(A) \longrightarrow E$  is strongly dissipative.

*Remark 3.4.* It is well known that  $W_A$  can be regarded as a Gaussian random variable in  $L^2([0, T], H)$ ; see, e.g., [12, Theorem 5.2.]. We want to remark that it is a Gaussian random variable in  $C([0, T], E)$ , too. Indeed, let us denote  $B = C([0, T], E)$  and  $K = L^2([0, T], H)$ . We have to show that for every  $\Lambda \in B^*$ ,  $\Lambda W_A$  is a real Gaussian random variable. Since  $B$  is continuously and densely embedded in  $K$ , for every  $\Lambda \in B^*$  there exists a net  $\Lambda_\alpha \in K^*$  weakly\* convergent to  $\Lambda$ , i.e., such that  $\Lambda_\alpha x$  converges to  $\Lambda x$ , for every  $x \in B$ . By the Banach Steinhaus theorem the family  $\Lambda_\alpha$  is uniformly bounded in the norm of  $B^*$ . Let us denote  $M = \max(\|\Lambda\|, \sup_\alpha \|\Lambda_\alpha\|)$ . Since  $B$  is separable, in the dual space  $B^*$  the balls of radius  $M$  are weakly\* metrizable (see, e.g., [5, Theorem 5.1]), so there exists a subsequence  $(\Lambda_n)_n$  of  $(\Lambda_\alpha)_\alpha$  such that  $\Lambda_n x$  converges to  $\Lambda x$ . Since  $\Lambda_n W_A$  is a real Gaussian random variable, and  $\Lambda W_A$  is its pointwise limit, we conclude that  $\Lambda W_A$  is a real Gaussian random variable. Thus,  $W_A$  is a Gaussian random variable in  $C([0, T], E)$  and, in particular, it has finite moments of every order.

*Remark 3.5.* In Hypothesis 3.2, point 1, we make dissipative assumptions on  $F$ . The theory applies also to the more restrictive case of  $F$  Lipschitz continuous. In general this is a less interesting case also because, as it will be made clear in section 7.1, when we apply our theory to the heat equation, such nonlinearities are often well defined not only in the Banach space  $E$ , but also in the whole Hilbert space  $H$ , so from the point of view of the evolution equation, a Banach space approach is not so interesting. Nevertheless, when considering the associated control problem, also in the case of linear evolution equations or evolution equations with Lipschitz continuous nonlinearity, it can become necessarily a Banach space approach, e.g., when the cost is well defined on a Banach space but not on a Hilbert space.

We can state the following theorem; see, e.g., [11], [12, Theorem 7.13], and [13, Theorem 5.5.13]. In all these references only the autonomous case is treated, but the

extension to the nonautonomous case is immediate: in [13] Proposition 5.5.6 is applied in the proof of Theorem 5.5.13, and this proposition is about existence and uniqueness of a solution for a deterministic equation in the nonautonomous case. Moreover, the above mentioned theorems deal with a dissipative nonlinearity  $f$ : if  $f$  is Lipschitz continuous, on  $A$  it suffices to ask that it be the generator of a strongly continuous semigroup, but if, as in this paper,  $f$  is only dissipative, in order to guarantee existence and uniqueness of a mild solution of (3.1), we need to take  $A - \omega I$  dissipative; see, e.g., the proof of Theorem 7.13 in [12].

**THEOREM 3.6.** *Assume that Hypotheses 3.1 and 3.2 hold true. Then for every  $x \in E$  (3.1) admits a unique mild solution, that is, an adapted and continuous  $E$ -valued process satisfying  $\mathbb{P}$ -a.s.*

$$X_\tau = e^{(\tau-t)A}x + \int_t^\tau e^{(\tau-s)A}F(s, X_s)ds + \int_t^\tau e^{(\tau-s)A}GdW_s, \quad \tau \in [t, T].$$

If Hypothesis 3.1, point 1, holds true, then the mild solution has paths in  $C([t, T], E)$ ,  $\mathbb{P}$ -a.s. If Hypothesis 3.1, point 2, holds true, then the mild solution has paths in  $C([t, T], E) \cap L^\infty([t, T], E)$ ,  $\mathbb{P}$ -a.s.

We denote the solution by  $X(\tau, t, x)$ ,  $x \in E$ ,  $t \in [0, T]$ , and  $\tau \in [t, T]$ . For  $\tau \in [0, t]$  we define  $X(\tau, t, x) = x$ . By the Markov property it is well known that, for every  $0 \leq t \leq s \leq \sigma \leq T$ ,

$$X(\sigma, s, X(s, t, x)) = X(\sigma, t, x).$$

Now we want to investigate the dependence of the solution on the initial datum.

**PROPOSITION 3.7.** *Let Hypotheses 3.1 and 3.2 hold true. Then the solution  $X(\tau, t, x)$  of (3.1) is Lipschitz in  $x$  uniformly in  $\tau \in [0, T]$ ; more precisely,  $\mathbb{P}$ -a.s.*

$$\begin{aligned} & \|X(\tau, t, x_1) - X(\tau, t, x_2)\|_E \\ & \leq \max\left(1, e^{\eta(T-t)}\right) \|x_1 - x_2\|_E, \quad 0 \leq t \leq \tau \leq T, \quad x_1, x_2 \in E. \end{aligned}$$

*Proof.* Let  $X_1(\tau) = X(\tau, t, x_1)$  and  $X_2(\tau) = X(\tau, t, x_2)$ ,  $x_1, x_2 \in E$ . For  $i = 1, 2$  we set  $X_i^n(\tau) = nR(n, A)X_i(\tau)$ , where  $R(n, A) = (nI - A)^{-1}$  is the resolvent operator of  $A$ . Since  $X_i^n(\tau) \in \mathcal{D}(A)$  for every  $\tau \in [t, T]$ , and

$$\begin{aligned} X_i^n(\tau) &= e^{\tau A}nR(n, A)x_i + \int_t^\tau e^{(\tau-s)A}nR(n, A)F(s, X_i(s))ds \\ &\quad + \int_t^\tau e^{(\tau-s)A}nR(n, A)GdW_s, \end{aligned}$$

we get

$$\begin{aligned} \frac{d}{d\tau}(X_1^n(\tau) - X_2^n(\tau)) &= A(X_1^n(\tau) - X_2^n(\tau)) \\ &\quad + nR(n, A)[F(\tau, X_1(\tau)) - F(\tau, X_2(\tau))]. \end{aligned}$$

Thus, by Proposition II.8.5 in [27],  $\|X_1^n(\tau) - X_2^n(\tau)\|_E$  also admits the lower and upper derivatives with respect to  $\tau$ , and there exists  $x_n^*(\tau) \in \partial(\|X_1^n(\tau) - X_2^n(\tau)\|_E)$  such that the lower derivative of  $\|X_1^n(\tau) - X_2^n(\tau)\|_E$  satisfies

$$\frac{d^-}{d\tau} \|X_1^n(\tau) - X_2^n(\tau)\|_E = \left\langle x_n^*(\tau), \frac{d}{d\tau}(X_1^n(\tau) - X_2^n(\tau)) \right\rangle_{E^*, E}.$$

Thus we have

$$\begin{aligned}
\frac{d^-}{d\tau} \|X_1^n(\tau) - X_2^n(\tau)\|_E &= \langle x_n^*(\tau), A(X_1^n(\tau) - X_2^n(\tau)) \\
&\quad + nR(n, A)[F(\tau, X_1(\tau)) - F(\tau, X_2(\tau))] \rangle_{E^*, E} \\
&= \langle x_n^*(\tau), A(X_1^n(\tau) - X_2^n(\tau)) + F(\tau, X_1^n(\tau)) \\
&\quad - F(\tau, X_2^n(\tau)) \rangle_{E^*, E} \\
&\quad + \langle x_n^*(\tau), nR(n, A)F(\tau, X_1(\tau)) - F(\tau, X_1^n(\tau)) \rangle_{E^*, E} \\
&\quad - \langle x_n^*(\tau), nR(n, A)F(\tau, X_2(\tau)) - F(\tau, X_2^n(\tau)) \rangle_{E^*, E} \\
&\leq \eta \|X_1^n(\tau) - X_2^n(\tau)\|_E + \|\delta_1^n(\tau) - \delta_2^n(\tau)\|_E,
\end{aligned}$$

where for  $i = 1, 2$  we have set  $\delta_i^n(\tau) = nR(n, A)F(\tau, X_i(\tau)) - F(\tau, X_i^n(\tau))$ . We claim that  $\delta_i^n(\tau)$  tends to 0 uniformly in  $\tau \in [t, T]$ . Indeed,

$$\delta_i^n(\tau) = nR(n, A)[F(\tau, X_i(\tau)) - F(\tau, X_i^n(\tau))] + (nR(n, A) - I)F(\tau, X_i^n(\tau)),$$

and the convergence to 0 follows by a classical argument (see, e.g., the proof of Theorem 7.10 in [12]) since  $X_i^n(\tau)$  tends to  $X_i(\tau)$  uniformly in  $\tau \in [t, T]$  and the maps  $\tau \mapsto F(\tau, X_i(\tau))$  and  $\tau \mapsto F(\tau, X_i^n(\tau))$  are continuous with respect to  $\tau$ . By the Gronwall lemma,

$$\begin{aligned}
\|X_1^n(\tau) - X_2^n(\tau)\|_E &\leq \|nR(n, A)(x_1 - x_2)\|_E \max\left(1, e^{\eta(\tau-t)}\right) \\
&\quad + \int_t^\tau e^{(\tau-s)\eta} \|\delta_1^n(s) - \delta_2^n(s)\|_E ds \\
&\leq \|nR(n, A)(x_1 - x_2)\|_E \max\left(1, e^{\eta(T-t)}\right) \\
&\quad + \max\left(1, e^{\eta(T-t)}\right) \int_t^\tau \|\delta_1^n(s) - \delta_2^n(s)\|_E ds.
\end{aligned}$$

Letting  $n \rightarrow \infty$  we get

$$\|X_1(\tau) - X_2(\tau)\|_E \leq \max\left(1, e^{\eta(T-t)}\right) \|x_1 - x_2\|_E. \quad \square$$

*Remark 3.8.* If  $A$ ,  $F$ , and  $G$  satisfy Hypotheses 3.1 and 3.2, then by Proposition 3.7 we get

$$(3.2) \quad \sup_{\tau \in [t, T]} \left\| \frac{X(\tau, t, x + rh) - X(\tau, t, x)}{r} \right\|_E^p \leq \max\left(1, e^{p\eta(T-t)}\right) \|h\|_E^p.$$

The next step is to show that if  $F$  is differentiable with respect to  $x$ , then  $X(\tau, t, x)$  is pathwise differentiable with respect to the initial datum. We make the following assumptions on  $F$  in (3.1).

*Hypothesis 3.9.*  $F \in \mathcal{G}^{0,1}([0, T] \times E, E)$  and its derivative  $\nabla F$  is bounded on bounded sets.

Under this assumption, we can state a result on pathwise differentiability of  $X(\tau, t, x)$  with respect to  $x$ , that is, as a map from  $E$  to  $E$ .

PROPOSITION 3.10. *Assume that Hypotheses 3.1 and 3.2 hold true and that  $F$  satisfies Hypothesis 3.9. Then,  $\mathbb{P}$ -a.s. and for all  $0 \leq t \leq \tau \leq T$ , the map  $x \mapsto X(\tau, t, x)$  belongs to  $\mathcal{G}^1(E, E)$ , and  $\nabla X(\tau, t, x)$  is a mild solution to the equation with values in  $L(E, E)$ :*

$$(3.3) \quad \begin{cases} \frac{dY_\tau}{d\tau} = AY_\tau + \nabla F(\tau, X(\tau, t, x)) Y_\tau, & \tau \in [t, T], \\ Y_t = I. \end{cases}$$

Namely, for every  $h \in E$ ,  $\nabla X(\tau, t, x)h$  satisfies  $\mathbb{P}$ -a.s. the integral equation

$$Y_\tau h = e^{(\tau-t)A}h + \int_t^\tau e^{(\tau-s)A} \nabla F(s, X_s) Y_s h ds.$$

*Proof.* For every  $h \in E$  and for every  $r > 0$ , we consider the difference quotient

$$\begin{aligned} \Delta^r X(\tau, t, x)h &= \frac{X(\tau, t, x + rh) - X(\tau, t, x)}{r} \\ &= e^{(\tau-t)A}h + \int_t^\tau e^{(\tau-s)A} \frac{F(s, X(s, t, x + rh)) - F(s, X(s, t, x))}{r} ds \end{aligned}$$

and we want to show that, as  $r$  tends to 0, its limit exists and it is equal to the mild solution of (3.3) evaluated in  $h$ , that is, to  $Y_\tau h$  satisfying

$$Y_\tau h = e^{(\tau-t)A}h + \int_t^\tau e^{(\tau-s)A} \nabla F(s, X(s, t, x)) Y_s h ds.$$

We evaluate

$$\begin{aligned} &\|\Delta^r X(\tau, t, x)h - Y_\tau h\|_E \\ &= \left\| \int_t^\tau e^{(\tau-s)A} \left[ \frac{F(s, X(s, t, x + rh)) - F(s, X(s, t, x))}{r} - \nabla F(s, X(s, t, x)) Y_s h \right] ds \right\|_E \\ &= \left\| \int_t^\tau e^{(\tau-s)A} \left[ \int_0^1 \nabla F(s, X(s, t, x) + w(X(s, t, x + rh) - X(s, t, x))) \right. \right. \\ &\quad \left. \left. \Delta^r X(s, t, x)h dw - \nabla F(s, X(s, t, x)) Y_s h \right] ds \right\|_E \\ &\leq \int_t^\tau \max\left(1, e^{\omega(\tau-s)}\right) \int_0^1 \|\nabla F(s, X(s, t, x) + w(X(s, t, x + rh) - X(s, t, x))) \\ &\quad - \nabla F(s, X(s, t, x))\| \|\Delta^r X(s, t, x)h\|_E dw ds \\ &\quad + \int_t^\tau \left\| e^{\omega(\tau-s)} \nabla F(s, X(s, t, x)) [\Delta^r X(s, t, x)h - Y_s h] \right\|_E ds \\ &\leq \epsilon(r) + \max\left(1, e^{\omega(T-t)}\right) \int_t^\tau \|\nabla F(s, X(s, t, x))\|_{L(E, E)} \|\Delta^r X(s, t, x)h - Y_s h\|_E ds, \end{aligned}$$

where

$$(3.4) \quad \epsilon(r) = \max \left( 1, e^{\omega(T-t)} \right) \int_t^T \int_0^1 \left\| [\nabla F(s, X(s, t, x) + w(X(s, t, x + rh) - X(s, t, x))) - \nabla F(s, X(s, t, x))] \Delta^r X(s, t, x) h \right\|_E dw ds.$$

By the Gronwall lemma in integral form we deduce that

$$(3.5) \quad \left\| \Delta^r X(\tau, t, x) h - Y_\tau h \right\|_E \leq \epsilon(r) \exp \left\{ \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \left\| \nabla F(s, X(s, t, x)) \right\|_{L(E, E)} ds \right\}.$$

By dominated convergence, in definition (3.4) we can pass to the limit as  $r$  goes to 0: indeed, by Hypothesis 3.9  $\nabla F$  is locally bounded, and by estimate (3.2)  $\left\| \Delta^r X(s, t, x) h \right\|_E \leq c \|h\|_E$ , where  $c$  is a constant independent on  $s$  and  $x$ , so the integrand is bounded in  $s$  and  $w$ . It remains to show that  $x \mapsto \nabla X(\tau, t, x)$  is strongly continuous. We note that for every  $x \in E$  the mapping  $h \mapsto \nabla X(\tau, t, x) h$  is continuous from  $E$  to  $E$ : For every  $h, h' \in E$ ,

$$\begin{aligned} \left\| \nabla X(\tau, t, x) h' - \nabla X(\tau, t, x) h \right\|_E &\leq \left\| \nabla X(\tau, t, x) h' - \Delta^r X(\tau, t, x) h' \right\|_E \\ &+ \left\| \Delta^r X(\tau, t, x) h' - \Delta^r X(\tau, t, x) h \right\|_E + \left\| \Delta^r X(\tau, t, x) h - \nabla X(\tau, t, x) h \right\|_E. \end{aligned}$$

For every  $r > 0$  the second term tends to 0 as  $h'$  tends to  $h$ , and as  $r$  tends to 0 the first and third terms in the right-hand side tend to 0. Thus, by Lemma 2.3 in [16], we need only show that the mapping  $\nabla X(\tau, t, \cdot)h : E \rightarrow E$  is continuous. In fact, for every  $x, x', h \in E$ ,

$$\begin{aligned} &\left\| \nabla X(\tau, t, x') h - \nabla X(\tau, t, x) h \right\|_E \\ &= \left\| \int_t^\tau e^{(\tau-s)A} [\nabla F(s, X(s, t, x')) \nabla X(s, t, x') h - \nabla F(s, X(s, t, x)) \nabla X(s, t, x) h] ds \right\|_E \\ &\leq \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \left\| \nabla F(s, X(s, t, x')) \nabla X(s, t, x') h - \nabla F(s, X(s, t, x)) \nabla X(s, t, x) h \right\|_E ds \\ &\leq \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \left\| \nabla F(s, X(s, t, x')) (\nabla X(s, t, x') h - \nabla X(s, t, x) h) \right\|_E ds \\ &\quad + \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \left\| (\nabla F(s, X(s, t, x')) - \nabla F(s, X(s, t, x))) \nabla X(s, t, x) h \right\|_E ds \\ &\leq \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \left\| \nabla F(s, X(s, t, x')) \right\|_E \left\| \nabla X(s, t, x') h - \nabla X(s, t, x) h \right\|_E ds + \epsilon(x, x'), \end{aligned}$$

where in the last passage  $\epsilon(x, x')$  tends to 0 as  $x$  tends to  $x'$  in  $E$ : we can apply dominated convergence again since  $\nabla F$  is locally bounded, and by estimate (3.2),

$$\sup_{\tau \in [t, T]} \|\nabla X(\tau, t, x) h\|_E^p \leq \max \left( 1, e^{p\eta(T-t)} \right) \|h\|_E^p.$$

By the Gronwall lemma in integral form we get

$$(3.6) \quad \|\nabla X(\tau, t, x') h - \nabla X(\tau, t, x) h\|_E \leq \epsilon(x, x') \exp \left\{ \max \left( 1, e^{\omega(T-t)} \right) \int_t^\tau \|\nabla F(s, X(s, t, x'))\|_{L(E, E)} ds \right\},$$

and this concludes the proof.  $\square$

We remember that here and in the following,  $(X(\tau, t, x))_\tau$  can be regarded as a process defined in the whole time interval  $[0, T]$  by setting  $X(\tau, t, x) = x$  for  $\tau \in [0, t]$ . Next we make assumptions of polynomial growth on  $F$  in order for the process  $X(\tau, t, x)$  to belong to  $\mathcal{H}^p([0, T], E)$ . Moreover, we will prove that  $X(\tau, t, x)$  is differentiable with respect to  $x$  as a map taking values in  $\mathcal{H}^p([0, T], E)$ .

*Hypothesis 3.11.*  $F \in \mathcal{G}^{0,1}([0, T] \times E, E)$ , its derivative  $\nabla F$  is bounded on bounded sets, and there exist an integer  $k \geq 0$  and a constant  $c > 0$  such that

$$\|F(\tau, x)\|_E \leq c \left( 1 + \|x\|_E^k \right)$$

for every  $\tau \in [0, T]$  and  $x \in E$ .

**LEMMA 3.12.** *Assume that  $A$ ,  $F$ , and  $G$  satisfy Hypotheses 3.1 and 3.2 and that  $F$  satisfies Hypothesis 3.11. Then the process  $(X_\tau)_{\tau \in [0, T]}$  belongs to  $\mathcal{H}^p([0, T], E)$  for every  $1 \leq p < \infty$ .*

*Proof.* Let  $Y_\tau = X_\tau - W_A(\tau)$  so that  $Y_\tau$  satisfies the equation

$$\begin{cases} dY_\tau = AY_\tau d\tau + F(\tau, Y_\tau + W_A(\tau)), \\ Y_t = x. \end{cases}$$

We set  $Y_\tau^n = nR(n, A)Y_\tau$ , where  $R(n, A) = (nI - A)^{-1}$  is the resolvent operator of  $A$ . Since  $Y_\tau^n \in \mathcal{D}(A)$  for every  $\tau \in [t, T]$ , and

$$Y_\tau^n = e^{\tau A} nR(n, A) x + \int_t^\tau e^{(\tau-s)A} nR(n, A) F(s, Y_s + W_A(s)) ds,$$

we get

$$\frac{d}{d\tau} Y_\tau^n = AY_\tau^n + nR(n, A) F(\tau, Y_\tau + W_A(\tau)).$$

Thus, by Proposition II.8.5 in [27],  $\|Y_\tau^n\|_E$  also admits the lower and upper derivatives with respect to  $\tau$  and there exists  $y_{n,\tau}^* \in \partial(\|Y_\tau^n\|_E)$  such that the lower derivative of  $\|Y_\tau^n\|_E$  satisfies

$$\begin{aligned} \frac{d^-}{d\tau} \|Y_\tau^n\|_E &= \left\langle y_{n,\tau}^*, \frac{d}{d\tau} Y_\tau^n \right\rangle_{E^*, E} \\ &= \langle y_\tau^*, AY_\tau^n + F(\tau, Y_\tau^n + W_A(\tau)) - F(\tau, W_A(\tau)) \rangle_{E^*, E} \\ &\quad + \langle y_\tau^*, nR(n, A) F(\tau, Y_\tau + W_A(\tau)) \\ &\quad - F(\tau, Y_\tau^n + W_A(\tau)) + F(\tau, W_A(\tau)) \rangle_{E^*, E} \end{aligned}$$

$$\begin{aligned} &\leq \eta \|Y_\tau\|_E + \|nR(n, A) F(\tau, Y_\tau + W_A(\tau)) \\ &\quad - F(\tau, Y_\tau^n + W_A(\tau))\|_E + c \left(1 + \|W_A(\tau)\|_E^k\right). \end{aligned}$$

By the Gronwall lemma,

$$\|Y_\tau^n\|_E \leq \|x\|_E e^{\eta(\tau-t)} + c \int_t^\tau \left( \|\delta_s^n\|_E + c \left(1 + \|W_A(s)\|_E^k\right) e^{\eta(s-t)} \right) ds,$$

where  $\delta_s^n = nR(n, A)F(s, Y_s + W_A(s)) - F(s, Y_s^n + W_A(s))$ . By the same procedure as in the proof of Proposition 3.7, as  $n \rightarrow \infty$ ,  $\delta_s^n$  tends to 0 uniformly in time. Thus, letting  $n \rightarrow \infty$ , we get

$$\|Y_\tau\|_E \leq \|x\|_E e^{\eta(\tau-t)} + \int_t^\tau c \left(1 + \|W_A(s)\|_E^k\right) e^{\eta(s-t)} ds,$$

and consequently,

$$\begin{aligned} \mathbb{E} \sup_{\tau \in [t, T]} \|Y_\tau\|_E^p &\leq 2^{p-1} \left( \max \left(1, e^{p\eta(T-t)}\right) \|x\|_E^p \right. \\ &\quad \left. + c \mathbb{E} \left( \int_t^T \left(1 + \|W_A(s)\|_E^k\right) e^{\eta(s-t)} ds \right)^p \right) \\ &\leq 2^{p-1} \left( \max \left(1, e^{p\eta(T-t)}\right) \|x\|_E^p + C_{T,k,p} \right). \end{aligned}$$

In the last estimate we refer to Remark 3.4, where we have deduced that as a process with values in  $C([0, T], E)$  the stochastic convolution is a Gaussian process and so it has finite moments of every order. So the process  $(Y_\tau)_{\tau \in [0, T]}$ , and consequently the process  $(X(\tau, t, x))_{\tau \in [0, T]}$ , belongs to  $\mathcal{H}^p([0, T], E)$  for every  $1 \leq p < \infty$ .  $\square$

Now we are ready to prove a result about differentiability of the process  $(X(\tau, t, x))_{\tau \in [0, T]}$ .

**PROPOSITION 3.13.** *Assume that Hypotheses 3.1 and 3.2 hold true and that  $F$  satisfies Hypothesis 3.11. Then for every  $t \in [0, T]$ , the map  $x \mapsto (X(\tau, t, x))_{\tau \in [0, T]} \in \mathcal{G}^1(E, \mathcal{H}^p([0, T], E))$ .*

*Proof.* With the notation of Proposition 3.10 we have to prove that, for every  $h \in E$ , the difference quotient  $\Delta^r X(\tau, t, x)h$  converges to  $\nabla X(\tau, t, x)h$  in  $\mathcal{H}^p([0, T], E)$ : we evaluate

$$\mathbb{E} \sup_{\tau \in [0, T]} \|\Delta^r X(\tau, t, x)h - \nabla X(\tau, t, x)h\|_E^p$$

as  $r$  goes to 0. By estimate (3.2) and by Proposition 3.10 we deduce the following estimate:

$$\sup_{\tau \in [0, T]} (\|\Delta^r X(\tau, t, x)h\|_E^p + \|\nabla X(\tau, t, x)h\|_E^p) \leq 2 \max \left(1, e^{p\eta(T-t)}\right) \|h\|_E^p.$$

Thus by dominated convergence,

$$\begin{aligned} &\lim_{r \rightarrow 0} \mathbb{E} \sup_{\tau \in [0, T]} \|\Delta^r X(\tau, t, x)h - \nabla X(\tau, t, x)h\|_E^p \\ &= \mathbb{E} \lim_{r \rightarrow 0} \sup_{\tau \in [0, T]} \|\Delta^r X(\tau, t, x)h - \nabla X(\tau, t, x)h\|_E^p. \end{aligned}$$

By estimate (3.5), and since  $\nabla F$  is locally bounded, we get

$$\begin{aligned} & \lim_{r \rightarrow 0} \mathbb{E} \sup_{\tau \in [0, T]} \|\Delta^r X(\tau, t, x)h - \nabla X(\tau, t, x)h\|_E^p \\ & \leq \mathbb{E} \lim_{r \rightarrow 0} \left[ \epsilon(r)^p \exp \left( p \max \left( 1, e^{\omega(T-t)} \right) \int_t^T \|\nabla F(s, X(s, t, x))\|_{L(E, E)} ds \right) \right] = 0. \end{aligned}$$

It remains to show that the mapping  $x \mapsto \nabla X(\tau, t, x)h$ , from  $E$  to  $\mathcal{H}^p([0, T], E)$ , is continuous. For every  $x, x', h \in E$ , we evaluate

$$\mathbb{E} \sup_{\tau \in [0, T]} \|\nabla X(\tau, t, x')h - \nabla X(\tau, t, x)h\|_E^p.$$

By (3.2) and by dominated convergence, we get

$$\begin{aligned} & \lim_{\|x-x'\|_E \rightarrow 0} \mathbb{E} \sup_{\tau \in [0, T]} \|\nabla X(\tau, t, x')h - \nabla X(\tau, t, x)h\|_E^p \\ & = \mathbb{E} \lim_{\|x-x'\|_E \rightarrow 0} \sup_{\tau \in [0, T]} \|\nabla X(\tau, t, x')h - \nabla X(\tau, t, x)h\|_E^p \\ & \leq \mathbb{E} \lim_{\|x-x'\|_E \rightarrow 0} \epsilon^p(x, x') \\ & \quad \times \exp \left\{ p \max \left( 1, e^{\omega(T-t)} \right) \int_t^T \|\nabla F(s, X(s, t, x'))\|_{L(E, E)} ds \right\} = 0, \end{aligned}$$

where in the last passages we have used estimate (3.6).  $\square$

**3.1. Representation of the derivative.** In this subsection we consider a function  $v : [0, T] \times E \rightarrow \mathbb{R}$  continuous and such that, for every  $t \in [0, T]$ ,  $v(t, \cdot) \in \mathcal{G}^1(E)$  and the map  $(t, x) \mapsto \nabla v(t, x)$  is Borel measurable. Let  $t \in [0, T]$  and  $x \in E$  be fixed. We are going to prove the following identification for the process  $\nabla v(\tau, X_\tau)$ , where  $X$  is the solution of the forward equation (3.1). For brevity we will write  $X_\tau = X(\tau, t, x)$ . Namely, let  $Z$  be a square integrable process and let  $\psi$  satisfy

$$\mathbb{E} \int_0^T |\psi_\sigma|^2 d\sigma < \infty.$$

Assume that  $Z$  and  $\psi$  depend on  $t$  and  $x$ . If  $v(\tau, X_\tau)$  admits the representation

$$(3.7) \quad v(\tau, X_\tau) = v(T, X_T) + \int_\tau^T \psi_\sigma d\sigma - \int_\tau^T Z_\sigma dW_\sigma, \quad \tau \in [t, T],$$

then  $\nabla v(\tau, X_\tau)G = Z_\tau$  for every  $0 \leq t \leq \tau \leq T$ .

*Remark 3.14.* If  $v$  is sufficiently regular and  $E$  is a Hilbert space, this is an obvious consequence of the Ito rule; see [12, Theorem 4.17].

*Remark 3.15.* The identification of  $Z_s$  with  $\nabla v(s, X_s)G$  is in fact a result of the joint quadratic variation between the process  $v(s, X_s)$ , which turns out to be a semimartingale if  $Z$  is a square integrable process and  $\psi \in L^2(\Omega \times [0, T])$ , and the process  $W^\xi(s) = \int_t^s \xi_\sigma^* dW_\sigma$ , where  $(\xi_\tau)_\tau$  is a bounded predictable process with values in  $\Xi$ . Indeed, by (3.7), the joint quadratic variation is equal to  $\int_t^s Z_\sigma \xi_\sigma d\sigma$ . By the identification  $\nabla v(s, X_s)G = Z_s$ , we can conclude that this joint quadratic variation

between  $v(s, X_s)$  and  $W^\xi(s)$  is equal to  $\int_t^s \nabla v(\sigma, X_\sigma) G \xi_\sigma d\sigma$ . An analogous result about joint quadratic variations is proved in [16], where the process  $X$  evolves in a Hilbert space and  $G$  is not necessarily constant. As far as we know, in the literature there are no results in which  $X$  evolves in a Banach space.

As in the previous section,  $F$  in the forward equation satisfies Hypothesis 3.11, and so  $X$  belongs to  $\mathcal{H}^p$ . On  $A$  and  $G$  we have to require some additional properties: We cannot guarantee that  $G(\Xi) \subset E$ , but we can make the following assumptions, which are verified in most of the applications.

*Hypothesis 3.16.* There exists a Banach subspace  $\Xi_0$  dense in  $\Xi$  such that  $G(\Xi_0) \subset E$  and  $G : \Xi_0 \rightarrow E$  is continuous.

**THEOREM 3.17.** *Assume that Hypotheses 3.1, 3.2, 3.11, and 3.16 hold true. Let  $v : [0, T] \times E \rightarrow \mathbb{R}$  be continuous such that, for every  $t \in [0, T]$ ,  $v(t, \cdot) \in \mathcal{G}^1(E)$ , the map  $(t, x) \mapsto \nabla v(t, x)$  is measurable, and for every  $0 \leq t \leq s \leq T$ ,  $|\nabla v(s, x)h| \leq c(1 + \|x\|_E^j) \|h\|_E$  for some integer  $j \geq 0$  and for every  $x, h \in E$ . Assume that  $v$  verifies equality (3.7), with  $Z$  a square integrable process and  $\psi \in L^2(\Omega \times [0, T])$ , and  $Z$  and  $\psi$  depend on  $t$  and  $x$ . Then, for almost every  $s \in [0, T]$ ,  $Z_s \varsigma = \nabla v(s, X_s) G \varsigma$ ,  $\mathbb{P}$ -almost everywhere and for every  $\varsigma \in \Xi_0$ .*

*Proof.* Let  $\tau = t$  in (3.7). By the definition of  $v$  we can write

$$(3.8) \quad v(t, x) + \int_t^T Z_\sigma dW_\sigma = v(T, X_T) + \int_t^T \psi_\sigma d\sigma.$$

For  $t \leq s \leq T$  we consider the process

$$\begin{aligned} v(s, X(s, t, x)) &= - \int_s^T Z_\sigma dW_\sigma + v(T, X(T, s, X(s, t, x))) + \int_s^T \psi_\sigma d\sigma \\ &= \int_t^s Z_\sigma dW_\sigma - \int_t^s \psi_\sigma d\sigma + v(t, x). \end{aligned}$$

Let  $\mathcal{F}_\tau$  be the natural filtration generated by the Wiener process and augmented in the usual way. We now define a family  $\mathcal{S}$  of predictable processes with real values. For every  $n \in \mathbb{N}$ , we subdivide the interval  $[0, T]$  into subintervals

$$\left[ \frac{kT}{2^n}, \frac{(k+1)T}{2^n} \right), \quad k = 0, \dots, 2^n - 1.$$

A predictable process  $\eta$  belongs to  $\mathcal{S}$  if on

$$\left[ \frac{kT}{2^n}, \frac{(k+1)T}{2^n} \right), \quad k = 0, \dots, 2^n - 1,$$

it has the form

$$(3.9) \quad \eta_t = \eta^k(W_{t_1}, \dots, W_{t_{l_k}}), \quad t \in \left[ \frac{kT}{2^n}, \frac{(k+1)T}{2^n} \right), \quad 0 \leq t_1 \leq \dots \leq t_{l_k} \leq \frac{kT}{2^n},$$

where  $\eta^k$  is a bounded function in  $C^\infty(\mathbb{R}^{l_k}, \mathbb{R})$ , with bounded derivatives of all orders. In the following we will briefly write  $\eta_t = \eta_t(W.)$ , where by  $W.$  we mean the trajectory of  $W$  up to time  $t$ . For  $\varsigma \in \Xi_0$ , we set  $\xi_t = \eta_t \varsigma$ .

Let  $s > t$  and  $\delta > 0$ , small enough such that  $s - \delta > t$ . From now on we identify  $\Xi$  with its dual  $\Xi^*$ , and we write  $\xi$  for  $\xi^*$ . We multiply both sides of (3.8) by  $\int_{s-\delta}^s \xi_\sigma dW_\sigma$

and we take expectation:

$$\begin{aligned}\mathbb{E}\left[v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] &= \mathbb{E}\left[\int_t^{s-\delta} \psi_\sigma d\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] + \mathbb{E}\left[\int_{s-\delta}^s \psi_\sigma d\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] \\ &\quad + \mathbb{E}\left[\int_t^s Z_\sigma dW_\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right].\end{aligned}$$

It is immediate that

$$\mathbb{E}\left[\int_t^{s-\delta} \psi_\sigma d\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] = 0, \quad \mathbb{E}\left[\int_t^s Z_\sigma dW_\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] = \mathbb{E}\left[\int_{s-\delta}^s Z_\sigma \xi_\sigma d\sigma\right].$$

We estimate

$$\begin{aligned}\mathbb{E}\left[\int_{s-\delta}^s \psi_\sigma d\sigma \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] &\leq \left(\mathbb{E}\left|\int_{s-\delta}^s \psi_\sigma d\sigma\right|^2\right)^{1/2} \left(\mathbb{E}\left|\int_{s-\delta}^s \xi_\sigma dW_\sigma\right|^2\right)^{1/2} \\ &\leq \sqrt{\delta} \left(\mathbb{E} \int_{s-\delta}^s |\psi_\sigma|^2 d\sigma\right)^{1/2} \left(\mathbb{E} \int_{s-\delta}^s \|\xi_\sigma\|_\Xi^2 d\sigma\right)^{1/2} \\ &\leq C\delta \left(\mathbb{E} \int_{s-\delta}^s |\psi_\sigma|^2 d\sigma\right)^{1/2}.\end{aligned}$$

If we divide both sides by  $\delta$  and let  $\delta \rightarrow 0$ , then we get, for almost every  $s$ ,

$$\mathbb{E}[Z_s \xi_s] = \lim_{\delta \rightarrow 0} \frac{1}{\delta} \mathbb{E}\left[v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma\right].$$

The final step for the identification of  $Z$  is to prove that

$$\lim_{\delta \rightarrow 0} \frac{1}{\delta} \mathbb{E}\left[v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] = \mathbb{E}[\nabla v(s, X_s) G \xi_s].$$

We proceed as in [2]. For  $0 \leq t \leq \sigma \leq T$ , we define  $W_\sigma^\varepsilon$  by

$$(3.10) \quad W_\sigma^\varepsilon = W_\sigma - \varepsilon \int_t^\sigma \xi_r(W^\varepsilon) dr,$$

where  $\xi_r(W^\varepsilon)$  depends on the trajectories of  $W^\varepsilon$  up to time  $r$ , and the dependence is given by the definition (3.9) of  $\eta$ . The process  $(W_\sigma^\varepsilon)_\sigma$  is defined as the solution of (3.10), which is not considered as a stochastic differential equation, as specified in [2, p. 476]. Equation (3.10) can be solved step by step in each interval

$$\left[\frac{kT}{2^n}, \frac{(k+1)T}{2^n}\right), \quad k = 0, \dots, 2^n - 1.$$

As we recalled in section 2, cylindrical Wiener processes can be seen as  $Q$ -Wiener processes with values in another Hilbert space  $\Xi_1$ . We solve (3.10) in  $\Xi_1$ . If  $\sigma < t$ ,  $W_\sigma^\varepsilon = W_\sigma$ . Let

$$\bar{k} = \max\left(k : t \geq \frac{kT}{2^n}\right).$$

If

$$\sigma \in \left[ t, \frac{(\bar{k} + 1)T}{2^n} \right),$$

then

$$W_\sigma^\varepsilon = W_\sigma - \varepsilon \int_t^\sigma \xi_{\bar{k}}^\varepsilon(W_{t_1}^\varepsilon, \dots, W_{t_{\bar{k}}}^\varepsilon) dr = W_\sigma - \varepsilon (\sigma - t) \xi_{\bar{k}}^\varepsilon(W_{t_1}, \dots, W_{t_{\bar{k}}}).$$

For

$$\sigma \in \left[ \frac{(\bar{k} + 1)T}{2^n}, \frac{(\bar{k} + 2)T}{2^n} \right),$$

we have

$$\begin{aligned} W_\sigma^\varepsilon &= W_\sigma - \varepsilon \int_t^{\frac{(\bar{k}+1)T}{2^n}} \xi_{\bar{k}}^\varepsilon(W_{t_1}^\varepsilon, \dots, W_{t_{\bar{k}}}^\varepsilon) dr - \varepsilon \int_{\frac{(\bar{k}+1)T}{2^n}}^\sigma \xi_{\bar{k}+1}^\varepsilon(W_{t_1}^\varepsilon, \dots, W_{t_{\bar{k}+1}}}^\varepsilon) dr \\ &= W_\sigma - \varepsilon \left( \frac{(\bar{k} + 1)T}{2^n} - t \right) \xi_{\bar{k}}^\varepsilon(W_{t_1}^\varepsilon, \dots, W_{t_{\bar{k}}}^\varepsilon) \\ &\quad - \varepsilon \left( \sigma - \frac{(\bar{k} + 1)T}{2^n} \right) \xi_{\bar{k}+1}^\varepsilon(W_{t_1}^\varepsilon, \dots, W_{t_{\bar{k}+1}}}^\varepsilon), \end{aligned}$$

and by this procedure,  $(W_\sigma^\varepsilon)_\sigma$  is well defined for every  $0 \leq \sigma \leq T$ . Moreover,  $W_\sigma^\varepsilon$  is a function of the trajectories of  $W$  up to time  $\sigma$ , that is,  $W_\sigma^\varepsilon = W_\sigma^\varepsilon(W)$ . So we can write

$$W_\sigma^\varepsilon = W_\sigma - \varepsilon \int_t^\sigma \xi_r(W_r^\varepsilon(W)) dr, \quad 0 \leq t \leq \sigma \leq T.$$

Now we define a probability measure  $Q_\varepsilon$  such that

$$\frac{dQ_\varepsilon}{d\mathbb{P}} = \exp \left( \varepsilon \int_t^T \xi_\sigma(W_\sigma^\varepsilon(W)) dW_\sigma - \frac{\varepsilon^2}{2} \int_t^T |\xi_\sigma(W_\sigma^\varepsilon(W))|^2 d\sigma \right).$$

By the Girsanov theorem (see, e.g., [12, Theorem 10.14]), under  $Q_\varepsilon$ ,  $W_\sigma^\varepsilon = W_\sigma - \varepsilon \int_t^\sigma \xi_r(W_r^\varepsilon(W)) dr$  is a  $Q$ -Wiener process in  $\Xi_1$  and a cylindrical Wiener process in  $\Xi$ . By this construction of  $(W_\sigma^\varepsilon)_\sigma$ , it is also clear that for every  $0 \leq \sigma \leq T$ ,  $W_\sigma^\varepsilon$  is pathwise differentiable with respect to  $\varepsilon$  and  $\frac{d}{d\varepsilon}|_{\varepsilon=0} W_\sigma^\varepsilon = -\int_t^\sigma \xi_r(W_r) dr$ ; see also [2, p. 476].

By (3.7),  $v(s, X_s)$  is square integrable; indeed,

$$\begin{aligned} \mathbb{E} v^2(s, X_s) &\leq c \left[ 1 + \mathbb{E} \left( \int_t^s \xi_\sigma dW_\sigma \right)^2 + \mathbb{E} \left( \int_t^s \psi_\sigma d\sigma \right)^2 \right] \\ &\leq c \left[ 1 + \mathbb{E} \int_t^s \|\xi_\sigma\|_\Xi^2 d\sigma + T^{1/2} \mathbb{E} \int_t^s \psi_\sigma^2 d\sigma \right] < \infty. \end{aligned}$$

So, by the Cauchy–Schwarz inequality, the expectation of  $v(s, X_s) \int_t^s \xi_\sigma dW_\sigma$  is well defined. We are going to prove that

$$\begin{aligned} & \mathbb{E} \left[ v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma \right] \\ &= \frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E} \left[ v(s, X_s) \exp \left( \varepsilon \int_{s-\delta}^s \xi_\sigma (W^\varepsilon) dW_\sigma - \frac{\varepsilon^2}{2} \int_{s-\delta}^s \|\xi_\sigma (W^\varepsilon)\|_\Xi^2 d\sigma \right) \right]. \end{aligned}$$

We evaluate

$$\begin{aligned} & \frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E} \left[ v(s, X_s) \exp \left( \varepsilon \int_{s-\delta}^s \xi_\sigma dW_\sigma - \frac{\varepsilon^2}{2} \int_{s-\delta}^s \|\xi_\sigma\|_\Xi^2 d\sigma \right) \right] \\ &= \lim_{\varepsilon \rightarrow 0} \mathbb{E} \left[ v(s, X_s) \frac{\exp \left( \varepsilon \int_{s-\delta}^s \xi_\sigma dW_\sigma - \frac{\varepsilon^2}{2} \int_{s-\delta}^s \|\xi_\sigma\|_\Xi^2 d\sigma \right) - 1}{\varepsilon} \right] \\ &= \mathbb{E} \left[ v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma \right], \end{aligned}$$

where in the last passage the limit goes into the expectation by dominated convergence since  $\xi$  is bounded. So

$$\mathbb{E} \left[ v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma \right] = \frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E}_{Q_\varepsilon} [v(s, X_s)].$$

Moreover, in  $(\Omega, \mathcal{F}, Q_\varepsilon)$ ,  $X$  is a mild solution to equation

$$\begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + G\varepsilon \xi_\tau (W^\varepsilon) d\tau + GdW_\tau^\varepsilon, & \tau \in [s-\delta, T], \\ X_{s-\delta} = X(s-\delta, t, x). \end{cases}$$

Since  $\xi$  takes values in  $\Xi_0$ , and by Hypothesis 3.16  $G$  maps  $\Xi_0$  in  $E$ , such a mild solution is well defined as a process with values in  $E$ . In  $(\Omega, \mathcal{F}, \mathbb{P})$  we consider the process  $X_\tau^\varepsilon$ , which is a mild solution to the equation

$$\begin{cases} dX_\tau^\varepsilon = AX_\tau^\varepsilon d\tau + F(\tau, X_\tau^\varepsilon) d\tau + G\varepsilon \xi_\tau (W) d\tau + GdW_\tau, & \tau \in [s-\delta, T], \\ X_{s-\delta}^\varepsilon = X(s-\delta, t, x). \end{cases}$$

Then the process  $X$  under  $Q_\varepsilon$  and the process  $X^\varepsilon$  under  $\mathbb{P}$  have the same law, so we get

$$\frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E}_{Q_\varepsilon} [v(s, X_s)] = \frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E} [v(s, X_s^\varepsilon)].$$

Finally, we claim that

$$\frac{d}{d\varepsilon|_{\varepsilon=0}} \mathbb{E} [v(s, X_s^\varepsilon)] = \mathbb{E} \left[ \nabla v(s, X_s) \dot{X}_s \right],$$

where we have set  $\dot{X}_s := \frac{d}{d\varepsilon|_{\varepsilon=0}} X_s^\varepsilon$ ,  $\mathbb{P}$ -a.s. One can easily check that  $\dot{X}_s$  is the unique mild solution to the equation

$$(3.11) \quad \begin{cases} d\dot{X}_\tau = A\dot{X}_\tau d\tau + \nabla F(\tau, X_\tau) \dot{X}_\tau d\tau + G\xi_\tau d\tau, & \tau \in [s-\delta, T], \\ \dot{X}_{s-\delta} = 0. \end{cases}$$

Such a mild solution exists, and it is unique by Hypothesis 3.9 and since (3.11) is a linear equation in  $\dot{X}$ . Let us denote

$$\Delta^\varepsilon X_\tau = \frac{X_\tau^\varepsilon - X_\tau}{\varepsilon}.$$

We want to show that, as  $\varepsilon$  tends to 0, its limit exists and it is equal to the mild solution of (3.11). We set  $X_\tau^n = nR(n, A)X_\tau$ ,  $X_\tau^{n,\varepsilon} = nR(n, A)X_\tau^\varepsilon$ , and  $\Delta^{n,\varepsilon} X_\tau = \frac{X_\tau^{n,\varepsilon} - X_\tau^n}{\varepsilon}$ , where  $R(n, A) = (nI - A)^{-1}$  is the resolvent operator of  $A$ . We note that  $X_\tau^{n,\varepsilon} - X_\tau^n$  is differentiable with respect to  $\tau$ , and so, by Proposition II.8.5 in [27]  $\|X_\tau^{n,\varepsilon} - X_\tau^n\|_E$  also admits the lower and upper derivatives with respect to  $\tau$  and there exists  $x_{n,\tau}^* \in \partial(\|X_\tau^{n,\varepsilon} - X_\tau^n\|_E)$  such that the lower derivative of  $\|X_\tau^{n,\varepsilon} - X_\tau^n\|_E$  satisfies

$$\begin{aligned} \frac{d^-}{d\tau} \|X_\tau^{n,\varepsilon} - X_\tau^n\|_E &= \left\langle x_{n,\tau}^*, \frac{d}{d\tau} (X_\tau^{n,\varepsilon} - X_\tau^n) \right\rangle_{E^*, E} \\ &\leq \eta \|X_\tau^{n,\varepsilon} - X_\tau^n\|_E + |\varepsilon| \|G\xi_\tau\|_E. \end{aligned}$$

Since  $\xi \in \Xi_0$ , by Hypothesis 3.16,  $G\xi \in E$ . By the Gronwall lemma, we get that  $\mathbb{P}$ -a.s.

$$\|X_\tau^{n,\varepsilon} - X_\tau^n\|_E \leq |\varepsilon| \|G\|_{L[\Xi_0, E]} C(T, \xi),$$

where  $C(T, \xi)$  is a constant depending only on the time  $T$  and on the norm of  $\xi(\omega)$ ,  $\omega \in \Omega$ , in  $\Xi_0$ , which is bounded uniformly with respect to  $\omega \in \Omega$ . Thus

$$\|\Delta^{n,\varepsilon} X_\tau\|_E \leq \|G\|_{L[\Xi_0, E]} C(T, \xi),$$

and, letting  $n \rightarrow \infty$ , we get

$$\|\Delta^\varepsilon X_\tau\|_E \leq \|G\|_{L[\Xi_0, E]} C(T, \xi).$$

This estimate is used in order to prove that  $\lim_{\varepsilon \rightarrow 0} \Delta^\varepsilon X_\tau = \dot{X}_\tau$ . We evaluate

$$\begin{aligned} &\left\| \Delta^\varepsilon X_\tau - \dot{X}_\tau \right\|_E \\ &\leq \left\| \int_{s-\delta}^\tau e^{(\tau-r)A} \left[ \frac{F(r, X_r^\varepsilon) - F(r, X_r)}{\varepsilon} - \nabla F(r, X_r) \dot{X}_r \right] dr \right\|_E \\ &= \left\| \int_{s-\delta}^\tau e^{(\tau-r)A} \left[ \int_0^1 \nabla F(r, X_r + w(X_r^\varepsilon - X_r)) \Delta^\varepsilon X_r dw - \nabla F(r, X_r) \dot{X}_r \right] dr \right\|_E \\ &\leq \int_{s-\delta}^\tau e^{\omega(\tau-r)} \left\| \nabla F(r, X_r) \left( \Delta^\varepsilon X_r - \dot{X}_r \right) \right\|_E dr \\ &\quad + \int_{s-\delta}^\tau e^{\omega(\tau-r)} \left\| \int_0^1 [\nabla F(r, X_r + w(X_r^\varepsilon - X_r)) - \nabla F(r, X_r)] \Delta^\varepsilon X_r dw \right\|_E dr. \end{aligned}$$

By the Gronwall lemma and dominated convergence, we get that  $\lim_{\varepsilon \rightarrow 0} \|\Delta^\varepsilon X_\tau - \dot{X}_\tau\|_E = 0$ . Moreover,  $\dot{X}$  is bounded uniformly with respect to time and to  $\omega \in \Omega$ . By an application of the chain rule and of the dominated convergence theorem, which we

can apply since by hypothesis the derivative of  $v$  has polynomial growth with respect to  $x$  and the process  $X$  has finite moments of every order, we can conclude that

$$\frac{d}{d\varepsilon}\bigg|_{\varepsilon=0} \mathbb{E}[v(s, X_s^\varepsilon)] = \mathbb{E}\left[\nabla v(s, X_s) \dot{X}_s\right].$$

We claim that

$$(3.12) \quad \dot{X}_\tau = \int_{s-\delta}^\tau \nabla X(\tau, \sigma, X(\sigma, t, x)) G\xi_\sigma d\sigma.$$

Let relation (3.12) be true. In this case, by the following calculations we conclude that proof:

$$\begin{aligned} \mathbb{E}[Z_s \xi_s] &= \lim_{\delta \rightarrow 0} \frac{1}{\delta} \mathbb{E}\left[\nabla v(s, X_s) \int_{s-\delta}^s \xi_\sigma dW_\sigma\right] \\ &= \lim_{\delta \rightarrow 0} \frac{1}{\delta} \mathbb{E}\left[\nabla v(s, X_s) \dot{X}_s\right] \\ &= \lim_{\delta \rightarrow 0} \frac{1}{\delta} \mathbb{E}\left[\nabla v(s, X_s) \int_{s-\delta}^s \nabla X(s, \sigma, X(\sigma, t, x)) G\xi_\sigma d\sigma\right] \\ &= \mathbb{E}[\nabla v(s, X_s) \nabla X(s, s, X(s, t, x)) G\xi_s] \\ &= \mathbb{E}[\nabla v(s, X_s) G\xi_s]. \end{aligned}$$

So for every  $\eta \in \mathcal{S}$ ,  $\mathbb{E}[Z_s \zeta \eta_s] = \mathbb{E}[\nabla v(s, X_s) G\zeta \eta_s]$  for almost every  $s \in [0, T]$ . By the arbitrariness of  $\eta$  it follows that for almost every  $s \in [0, T]$ ,  $Z_s \zeta = \nabla v(s, X_s) G\zeta$ ,  $\mathbb{P}$ -a.s.

Now it remains to prove (3.12). By Proposition 3.10, for  $0 \leq t \leq s \leq \tau \leq T$ ,

$$\nabla X(\tau, \sigma, y) = e^{(\tau-\sigma)A} + \int_\sigma^\tau e^{(\tau-r)A} \nabla F(r, X(r, \sigma, y)) \nabla X(r, \sigma, y) dr.$$

We multiply both sides by  $G\xi_\sigma$  and integrate. Taking  $y = X(\sigma, t, x)$  we get

$$\begin{aligned} &\int_{s-\delta}^\tau \nabla X(\tau, \sigma, X(\sigma, t, x)) G\xi_\sigma d\sigma \\ &= \int_{s-\delta}^\tau e^{(\tau-\sigma)A} G\xi_\sigma d\sigma + \int_{s-\delta}^\tau e^{(\tau-r)A} \\ &\quad \left\{ \int_\sigma^\tau \nabla F(r, X(r, \sigma, X(\sigma, t, x))) \nabla X(r, \sigma, X(\sigma, t, x)) dr \right\} G\xi_\sigma d\sigma \\ &= \int_{s-\delta}^\tau e^{(\tau-\sigma)A} G\xi_\sigma d\sigma + \int_{s-\delta}^\tau e^{(\tau-r)A} \nabla F(r, X_r) \\ &\quad \left\{ \int_{s-t}^\tau \nabla X(r, \sigma, X(\sigma, t, x)) G\xi_\sigma d\sigma \right\} dr. \end{aligned}$$

This gives the identification

$$\dot{X}_\tau = \int_{s-\delta}^\tau \nabla X(\tau, \sigma, X(\sigma, t, x)) G\xi_\sigma d\sigma$$

by the uniqueness of a mild solution of (3.11).  $\square$

*Remark 3.18.* By the previous theorem, for every  $\varsigma \in \Xi_0$  we have  $Z_s \varsigma = \nabla v(s, X_s)G \varsigma$   $\mathbb{P}$ -a.s. and for almost every  $s \in [0, T]$ . Since  $\Xi_0$  is dense in  $\Xi$ , for every  $\xi \in \Xi$  there exists a sequence  $(\varsigma_n)_n \in \Xi_0$  such that  $\varsigma_n \rightarrow \xi$  in  $\Xi$ . For almost every  $s \in [0, T]$  and almost surely with respect to the law of  $X_s$ , the operator  $\nabla v(s, x)G : \Xi_0 \rightarrow E$  extends to an operator defined in the whole  $\Xi$ . For the sake of brevity, we denote such an extension by  $\nabla v(s, x)G$ . We can conclude that  $Z_s = \nabla v(s, X_s)G$ ,  $\mathbb{P}$ -a.s. and for almost every  $s \in [0, T]$ .

**4. Preliminaries on the forward-backward system.** In this section we study a backward equation like (2.1), with  $\psi$  depending on the Markov process  $X$ , which is solution of (3.1) with initial condition  $x$  given at the initial time  $t$ . Namely, in a complete probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  let  $\{W_\tau, \tau \geq 0\}$  be a cylindrical Wiener process with values in  $\Xi$ , and let  $(\mathcal{F}_\tau)_{\tau \geq 0}$  be its natural filtration, augmented in the usual way. We consider the forward-backward system

$$(4.1) \quad \begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + GdW_\tau, & \tau \in [t, T], \\ dY_\tau = -\psi(\tau, X_\tau, Z_\tau) d\tau + Z_\tau dW_\tau, & \tau \in [t, T], \\ X_t = x, \\ Y_T = \phi(X_T), \end{cases}$$

where  $\psi : [0, T] \times E \times \Xi^* \rightarrow \mathbb{R}$  and  $\phi : E \rightarrow \mathbb{R}$  satisfy some suitable assumptions. We want to investigate the existence and uniqueness of a solution of this forward-backward system and its regular dependence on  $x$ . The solution will be denoted by  $(X_\tau, Y_\tau, Z_\tau)$  or, to stress the dependence on the initial condition  $x$  in the forward equation given at the initial time  $t$ , by  $(X(\tau, t, x), Y(\tau, t, x), Z(\tau, t, x))$ . For  $0 \leq \tau \leq t$ , we put  $X(\tau, t, x) = x$ , and the pair  $(Y_\tau, Z_\tau)$  is the solution of the corresponding backward equation.

In section 2, we have already recalled an existence and uniqueness result for a mild solution of the forward equation,

$$\begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t = x, \end{cases}$$

with  $A$ ,  $F$ , and  $G$  satisfying Hypotheses 3.1 and 3.2. Moreover, we have studied the differentiable dependence of this solution on the initial condition  $x$ . We are going to study the dependence of the pair  $(Y_\tau, Z_\tau)$  on  $x \in E$ , where  $(Y_\tau, Z_\tau)$  is a pair of processes which solves the BSDE of the form

$$(4.2) \quad Y_\tau + \int_\tau^T Z_\sigma dW_\sigma = \phi(X_T) + \int_\tau^T \psi(\sigma, X_\sigma, Z_\sigma) d\sigma, \quad \tau \in [t, T].$$

In particular, we recall that  $Y(t, t, x)$  is a deterministic function; let us define  $v(t, x) := Y(t, t, x)$ , where  $v(t, x)$  is a continuous function; we want to prove that  $v(t, \cdot) \in \mathcal{G}^1(E)$  for every  $t \in [0, T]$ . We make suitable assumptions on  $\psi$  such that

$$\mathbb{E} \int_t^T |\psi(\sigma, 0, 0)|^2 d\sigma < \infty.$$

Thus, for the pair of processes  $(Y, Z)$ , which are solution of (4.2), the following a priori estimate holds (see [16, Proposition 4.3]):

$$(4.3) \quad \mathbb{E} \sup_{\tau \in [t, T]} |Y_\tau|^2 + \mathbb{E} \int_t^T \|Z_\sigma\|_{\Xi^*}^2 d\sigma \leq c \mathbb{E} \int_t^T |\psi(\sigma, 0, 0)|^2 d\sigma + c \mathbb{E} |\phi(X_T)|^2.$$

In the following we assume that  $A$ ,  $F$ , and  $G$  satisfy Hypotheses 3.1, 3.2, and 3.11. Moreover, we require that  $\psi$  and  $\phi$  satisfy the following assumptions that guarantee the solvability of the backward equation and the differentiable dependence of the solution  $(Y_\tau, Z_\tau)$  with respect to  $x$ .

*Hypothesis 4.1.* The maps  $\psi : [0, T] \times E \times \Xi^* \longrightarrow \mathbb{R}$  and  $\phi : E \longrightarrow \mathbb{R}$  are Borel measurable and satisfy the following assumptions:

1. There exists  $L > 0$  such that

$$|\psi(\sigma, x, z_1) - \psi(\sigma, x, z_2)| \leq L \|z_1 - z_2\|_{\Xi^*}$$

for every  $\sigma \in [0, T]$ ,  $x \in E$ , and  $z_1, z_2 \in \Xi^*$ ;

2. for every  $\sigma \in [0, T]$ , we have  $\psi(\sigma, \cdot, \cdot) \in \mathcal{G}^{1,1}(E \times \Xi^*)$ ;
3. there exist  $L > 0$  and  $m \geq 0$  such that

$$|\nabla_x \psi(\sigma, x, z) h| \leq L \|h\|_E (1 + \|x\|_E)^m (1 + \|z\|_{\Xi^*})$$

for every  $\sigma \in [0, T]$ ,  $x, h \in E$ , and  $z \in \Xi^*$ ;

4.  $\phi \in \mathcal{G}^1(E)$  and there exists  $L > 0$  such that for every  $x_1, x_2 \in E$ ,

$$|\phi(x_1) - \phi(x_2)| \leq L \|x_1 - x_2\|_E.$$

Under these assumptions we can state a result on the existence and uniqueness of a solution of the BSDE (4.2) and on its regular dependence on  $x$ .

**PROPOSITION 4.2.** *Assume that Hypotheses 3.1, 3.2, and 3.11 hold true and that  $\psi$  and  $\phi$  satisfy Hypothesis 4.1. Then (4.2) admits a unique solution  $(Y_\tau, Z_\tau) \in \mathbb{K}_{\text{cont}}([0, T])$  such that the map  $(t, x) \mapsto (Y(\tau, t, x), Z(\tau, t, x))$  is continuous from  $[0, T] \times E$  with values in  $\mathbb{K}_{\text{cont}}([0, T])$ , and for every  $t \in [0, T]$ , the map  $x \mapsto (Y(\cdot, t, x), Z(\cdot, t, x))$  belongs to  $\mathcal{G}^1(E, \mathbb{K}_{\text{cont}}([0, T]))$ . Moreover, the following estimate holds true: For every  $p \geq 2$ ,*

$$\left[ \mathbb{E} \sup_{\tau \in [0, T]} |\nabla_x Y(\tau, t, x) h|^p \right]^{1/p} \leq C \|h\|_E \left( 1 + \|x\|_E^{(m+1)^2} \right).$$

*Proof.* We give only a sketch of the proof. By Lemma 3.12 and by  $|\psi(\sigma, x, z)| \leq L(1 + \|x\|_E)^m$ , we get that, defining

$$\psi_\sigma = \psi(\sigma, X_\sigma, Z_\sigma),$$

condition (2.2) is satisfied, so existence and uniqueness of the solution of the backward equation follows, e.g., by [16]. The proof of differentiability of the map  $x \mapsto (Y(\cdot, t, x), Z(\cdot, t, x))$  substantially follows the proof of Proposition 5.2 in [16]. In that paper the process  $(X(\tau, t, x))_{\tau \in [0, T]}$  takes its values in a separable Hilbert space  $H$ , while in our context the process  $(X(\tau, t, x))_{\tau \in [0, T]}$  takes its values in the Banach space  $E$ ; nevertheless, the same arguments apply. Indeed, in Lemma 3.12 we have proved that  $(X(\tau, t, x))_{\tau \in [0, T]}$  belongs to  $\mathcal{H}^p([0, T], E)$  for every  $1 \leq p < \infty$ , and in Proposition 3.13 we have proved that the map  $x \mapsto (X(\tau, t, x))_{\tau \in [0, T]} \in \mathcal{G}^1(E, \mathcal{H}^p([0, T], E))$ . By these two facts and following the proof of Proposition 5.2 in [16], we get that for every  $t \in [0, T]$  the map  $x \mapsto (Y(\cdot, t, x), Z(\cdot, t, x))$  belongs to  $\mathcal{G}^1(E, \mathbb{K}_{\text{cont}}([0, T]))$ .  $\square$

*Remark 4.3.* By standard arguments,  $Y(t, t, x)$  is a deterministic function, and we have set  $v(t, x) = Y(t, t, x)$ . We notice that  $v$  depends on  $t, x, A, F, G, \phi$ , and  $\psi$  but not on the probability space and not on the Wiener process.

COROLLARY 4.4. Assume that Hypotheses 3.1, 3.2, and 3.11 hold true and that  $\psi$  and  $\phi$  satisfy Hypothesis 4.1. Then the function  $v(t, x) := Y(t, t, x)$  is continuous and for every  $t \in [0, T]$ ,  $v(t, \cdot)$  belongs to  $\mathcal{G}^1(E, \mathbb{R})$ , and there exists  $C > 0$  such that  $|\nabla_x v(t, x)h| \leq C\|h\|_E(1 + \|x\|_E^{(m+1)^2})$  for all  $t \in [0, T]$ ,  $x, h \in E$ .

*Proof.* It is a direct consequence of the previous proposition and of the properties of the evaluation map.  $\square$

COROLLARY 4.5. Assume that Hypotheses 3.1, 3.2, 3.11, 3.16, and 4.1 hold true and set  $v(t, x) := Y(t, t, x)$ ; then  $Z_s = \nabla v(s, X_s)G$ ,  $\mathbb{P}$ -a.s. and for almost every  $s \in [0, T]$ .

*Proof.* We apply Theorem 3.17 to the case when  $v(t, x) = Y(t, t, x)$ , where  $(Y, Z)$  is solution to (4.2). By Proposition 4.2 and Corollary 4.4,  $v(t, \cdot)$  belongs to  $\mathcal{G}^1(E)$ . Let  $\tau = t$  in (4.2). By the definition of  $v$  we can write

$$v(t, x) + \int_t^T Z_\sigma dW_\sigma = \phi(X_T) + \int_t^T \psi(\sigma, X_\sigma, Z_\sigma) d\sigma.$$

For  $t \leq s \leq T$  we consider the process

$$\begin{aligned} v(s, X(s, t, x)) &= - \int_s^T Z_\sigma dW_\sigma + \phi(X(T, s, X(s, t, x))) \\ &\quad + \int_s^T \psi(\sigma, X(\sigma, s, X(s, t, x)), Z_\sigma) d\sigma \\ &= \int_t^s Z_\sigma dW_\sigma - \int_t^s \psi(\sigma, X(\sigma, s, X(s, t, x)), Z_\sigma) d\sigma + v(t, x). \end{aligned}$$

Thus  $v(s, X(s, t, x))$  admits a representation analogous to the one in (3.7). Then by Theorem 3.17 and Remark 3.18 the corollary is proved.  $\square$

**5. The optimal control problem.** We formulate the optimal control problem in the weak sense following the approach of [15]; see, e.g., Chapter III. The main advantage is that we will be able to solve the closed loop equation in a weak sense, and hence find an optimal control, even if the feedback law is nonsmooth.

As in the previous section, in  $(\Omega, \mathcal{F}, \mathbb{P})$  we consider a cylindrical Wiener process  $\{W_\tau, \tau \geq 0\}$  in  $\Xi$  and  $(\mathcal{F}_\tau)_{\tau \geq 0}$  is its natural filtration, augmented in the usual way. We consider controlled stochastic evolution equations of the form

$$(5.1) \quad \begin{cases} dX_\tau^u = AX_\tau^u d\tau + F(\tau, X_\tau^u) d\tau + GdW_\tau + GR(\tau, X_\tau^u, u_\tau) d\tau, & \tau \in [t, T], \\ X_t^u = x. \end{cases}$$

The control  $u$  is an  $(\mathcal{F}_\tau)$ -predictable process taking values in a normed space  $U$ ; we call such control processes admissible controls and we denote by  $\mathcal{A}_d$  the set of such admissible controls.  $R$  is a map from  $[0, T] \times E \times U$  to  $\Xi$ . The solution of this equation will be denoted by  $X^u(\tau, t, x)$ , or simply by  $X_\tau^u$ .  $X$  denotes the state,  $u$  the control, and  $T > 0$ ,  $t \in [0, T]$  are fixed. We assume that  $R$  satisfies the following.

*Hypothesis 5.1.*  $R : [0, T] \times E \times U \longrightarrow \Xi$  is measurable and  $\|R(\tau, x, u)\|_\Xi \leq K_R$  for a suitable positive constant  $K_R > 0$  and every  $\tau \in [0, T]$ ,  $x \in E$ ,  $u \in U$ .

If  $A$ ,  $F$ , and  $G$  satisfy Hypotheses 3.1 and 3.2, and if  $R$  satisfies Hypothesis 5.1, then (5.1) admits a solution in the weak sense: Since by Hypothesis 5.1  $R$  is measurable and bounded, we can apply the Girsanov theorem. By the Girsanov theorem

the law of this solution depends only on  $x$ ,  $A$ ,  $F$ , and  $G$ , and so the weak solution is unique in law. Notice the occurrence of the operator  $G$  in the control term of (5.1). In the particular case  $R(\tau, x, u) = u$  the term  $u_\tau d\tau + dW_\tau$  admits a natural interpretation as a control affected by noise. In this case Hypothesis 5.1 holds if  $U$  is a bounded subset of  $\Xi$ .

We call  $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W)$  an admissible setup if  $(\Omega, \mathcal{F}, \mathbb{P})$  is a complete probability space with a filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$  satisfying the usual conditions, and  $\{W_\tau, \tau \geq 0\}$  is a cylindrical Wiener process taking values in a Hilbert space  $\Xi$ , with respect to the filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$ . We call  $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W, u, X^u)$  an admissible control system (a.c.s.), briefly denoted by  $(W, u, X^u)$ , if

- $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W)$  is an admissible setup;
- the control  $u$  is an  $(\mathcal{F}_\tau)$ -predictable process with values in  $U$ ;
- $X_\tau^u$  is an adapted process in  $E$  that solves (5.1) in the mild sense.

To every a.c.s. we associate the cost  $J$ :

$$(5.2) \quad J(t, x, (W, u, X^u)) = \mathbb{E} \int_t^T g(s, X_s^u, u_s) ds + \mathbb{E} \phi(X_T^u),$$

where  $g : [0, T] \times E \times U \rightarrow \mathbb{R}$  and  $\phi : E \rightarrow \mathbb{R}$  are continuous functions satisfying some growth conditions with respect to  $x \in E$  that will be specified in the following. We define the value function of the control problem as

$$V(t, x) = \inf_{(W, u, X^u) \text{ a.c.s.}} J(t, x, (W, u, X^u)).$$

The control problem in the weak sense is to find an a.c.s.  $(\overline{W}, \overline{u}, \overline{X}^u)$  such that

$$J(t, x, (\overline{W}, \overline{u}, \overline{X}^u)) \leq J(t, x, (W, u, X^u))$$

for every a.c.s.  $(W, u, X^u)$ . Then  $(\overline{W}, \overline{u}, \overline{X}^u)$  is called optimal. In this case the value function is given by  $V(t, x) = J(t, x, (\overline{W}, \overline{u}, \overline{X}^u))$ .

For all  $\tau \in [0, T]$ ,  $x \in E$ ,  $z \in \Xi^*$ , we define in a classical way the Hamiltonian function  $\psi : [0, T] \times E \times \Xi^* \rightarrow \mathbb{R}$ :

$$(5.3) \quad \psi(\tau, x, z) = \inf \{g(\tau, x, u) + zR(\tau, x, u) : u \in U\}.$$

We define the, possibly empty, set

$$(5.4) \quad \Gamma(\tau, x, z) = \{u \in U : g(\tau, x, u) + zR(\tau, x, u) = \psi(\tau, x, z)\}.$$

We remark that by the Filippov theorem (see, e.g., [1, Theorem 8.2.10, p. 316] if  $\Gamma$  is nonempty there exists a Borel measurable map  $\Gamma_0 : [0, T] \times E \times \Xi^* \rightarrow U$  such that, for  $\tau \in [0, T]$ ,  $x \in E$ , and  $z \in \Xi^*$ , we have  $\Gamma_0(\tau, x, z) \in \Gamma(\tau, x, z)$ .

In order to solve the control problem, we will not solve the associated Hamilton–Jacobi–Bellman equation, but we will use the BSDEs, which turns out to be the adequate approach in this situation, since the forward equation evolves in the Banach space  $E$  and the cost functional is well defined in the Banach space  $E$ .

In this paper we treat control problems related to current and final costs which can have polynomial growth with respect to  $x$ . We assume that  $A$ ,  $F$ , and  $G$  in the controlled equation (5.1) satisfy Hypothesis 3.1, 3.2, and 3.11.

On the cost functional defined in (5.2) we make the following assumptions.

*Hypothesis 5.2.* The function  $g : [0, T] \times E \times U \rightarrow \mathbb{R}$  is measurable, and for almost all (a.a.)  $\tau \in [0, T]$ , the map  $g(\tau, \cdot, \cdot) : E \times U \rightarrow \mathbb{R}$  is continuous. Moreover, for some  $j \geq 0$ ,  $|g(\tau, x, u)| \leq c_2(1 + \|x\|_E^j)$ . The function  $\phi : E \rightarrow \mathbb{R}$  is in  $\mathcal{G}^1(E)$  and  $|\phi(x)| \leq c_3(1 + \|x\|_E^j)$ .

We remark that by this hypothesis on  $g$ , the Hamiltonian defined in (5.3) is finite. Moreover, also by Hypothesis 5.1 on  $R$ , there exists  $L > 0$  such that

$$|\psi(\sigma, x, z_1) - \psi(\sigma, x, z_2)| \leq L \|z_1 - z_2\|_{\Xi^*}$$

for every  $\sigma \in [0, T]$ ,  $x \in E$ , and  $z_1, z_2 \in \Xi^*$ . We need that the Hamiltonian  $\psi$  satisfies some regularity assumptions that guarantee differentiable dependence of the solution  $(Y_\tau, Z_\tau)$  with respect to  $x$ , the initial datum of the forward equation (3.1). Namely, the Hamiltonian  $\psi$  defined in (5.3) has to satisfy Hypothesis 4.1, points 2 and 3.

*Remark 5.3.* We clarify why we need the assumptions stated previously on the running and final costs and on the Hamiltonian. By Hypothesis 5.2, namely, by the polynomial growth of  $g$ , together with Lemma 3.12, the cost is well defined. Differentiability assumptions on the Hamiltonian and on the final cost are quite restrictive but are essential in the BSDE approach: The value function is defined, as in Corollary 4.4, by means of the solution of a suitable BSDE. Essential tools are Theorem 3.17 and Corollary 4.5 applied to the value function. Moreover (see also section 6), by the BSDE approach, without requiring any regularizing property of the transition semigroup, we are able to find a unique, Gâteaux differentiable mild solution of the corresponding Hamilton–Jacobi–Bellman equation. We can achieve Gâteaux differentiability of this mild solution by taking  $\psi$  and  $\phi$  Gâteaux differentiable.

*Example 5.4.* Hypothesis 4.1 for the Hamiltonian function can be verified in some concrete cases. We present a situation where we can directly verify that the Hamiltonian  $\psi$  satisfies Hypothesis 4.1, points 2 and 3. We take  $R(t, x, u) = u$ : The space  $U$  coincides with  $\Xi$  and the set of admissible controls is given by  $A_d = \{u \in \Xi : \|u\|_\Xi \leq \delta\}$  for some fixed  $\delta > 0$ . Moreover, we consider a current cost given by  $g(t, x, u) = g_0(\|u\|_\Xi^\alpha) + g_1(t, x)$ , where  $\alpha > 1$ ,  $g_0 \in C^1(\mathbb{R}^+, \mathbb{R}^+)$  convex, and  $g_0'(0) > 0$ , and for every  $t \in [0, T]$ ,  $g_1(t, \cdot) \in \mathcal{G}^1(E)$ , and there exist  $L > 0$  and  $m \geq 0$  such that

$$|\nabla_x g(t, x) h| \leq L \|h\|_E (1 + \|x\|_E)^m$$

for every  $h \in E$ . It turns out also that  $\psi(t, x, z)$  is differentiable with respect to  $z$  and so  $\psi$  satisfies Hypothesis 4.1, points 2 and 3.

Now let us consider a complete probability space  $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$  and a cylindrical Wiener process  $\{\tilde{W}_\tau, \tau \geq 0\}$  with values in  $\Xi$ . In  $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$  we consider the following forward-backward system, where  $(X, Y, Z) \in E \times \mathbb{R} \times \Xi^*$ :

$$\begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + G d\tilde{W}_\tau, & \tau \in [t, T], \\ dY_\tau = -\psi(\tau, X_\tau, Z_\tau) d\tau + Z_\tau d\tilde{W}_\tau, & \tau \in [t, T], \\ X_t = x, \\ Y_T = \phi(X_T). \end{cases}$$

By Remark 4.3, if we define

$$(5.5) \quad v : [0, T] \times E \rightarrow \mathbb{R}, \quad v(t, x) = Y(t, t, x),$$

$v$  does not depend either on the space  $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$  or on the Wiener process  $\{\tilde{W}_\tau, \tau \geq 0\}$ .

In the following proposition we prove the so-called fundamental relation in terms of BSDEs.

**PROPOSITION 5.5.** *Assume Hypotheses 3.1, 3.2, 3.11, 5.1, and 5.2 and that the Hamiltonian  $\psi$  defined in (5.3) satisfies Hypothesis 4.1, points 2 and 3. Let  $v$  be defined in (5.5). Then for every  $t \in [0, T]$  and  $x \in E$ , and for every a.c.s.  $(W, u, X^u)$ , we have  $J(t, x, (W, u, X^u)) \geq v(t, x)$ .*

*Proof.* Let  $X_\tau^u$  be the solution to (5.1) corresponding to the control  $u$ . We define the process

$$W_\tau^u = W_\tau + \int_{t \wedge \tau}^\tau R(\sigma, X_\sigma^u, u_\sigma) d\sigma, \quad \tau \in [0, T],$$

and we note that  $X^u$  solves the equation

$$\begin{cases} dX_\tau^u = AX_\tau^u d\tau + F(\tau, X_\tau^u) d\tau + GdW_\tau^u, & \tau \in [t, T], \\ X_t^u = x. \end{cases}$$

Since  $R$  is bounded, we can apply the Girsanov theorem and deduce that there exists a probability measure  $\mathbb{P}^u$  on  $(\Omega, \mathcal{F})$  such that  $W^u$  is a Wiener process with respect to  $\mathbb{P}^u$ . In  $(\Omega, \mathcal{F}, \mathbb{P}^u)$  let us consider the backward equation for the unknown process  $(Y_\tau^u, Z_\tau^u)$ ,  $\tau \in [t, T]$ :

$$(5.6) \quad Y_\tau^u + \int_\tau^T Z_\sigma^u dW_\sigma^u = \phi(X_T^u) + \int_\tau^T \psi(\sigma, X_\sigma^u, Z_\sigma^u) d\sigma, \quad \tau \in [t, T].$$

Let  $\tau = t$  in (5.6). It turns out that  $Y^u(t, t, x)$ , which is deterministic, depends on only  $t, x, F, G, \phi$ , and  $\psi$  and not on the a.c.s.  $(W, u, X^u)$ ; indeed, in (5.6) the dependence on the control system has disappeared. Thus  $Y^u(t, t, x) = v(t, x)$ , where  $v$  is defined as in (5.5). Now we notice that  $W^u$  is not a  $\mathbb{P}$ -Wiener process, so  $\int_\tau^T Z_\sigma^u dW_\sigma^u$  is not a  $\mathbb{P}$ -martingale; nevertheless, we can state that  $\int_\tau^T Z_\sigma^u dW_\sigma$  is a  $\mathbb{P}$ -martingale. Indeed, we can prove that

$$\mathbb{E} \left( \int_t^T \|Z_\sigma^u\|_{\Xi^*}^2 d\sigma \right)^{1/2} < \infty.$$

We remember that

$$\frac{d\mathbb{P}^u}{d\mathbb{P}} = \exp \left( - \int_t^T R(\sigma, X_\sigma^u, u_\sigma) dW_\sigma - \frac{1}{2} \int_t^T \|R(\sigma, X_\sigma^u, u_\sigma)\|_{\Xi}^2 d\sigma \right).$$

We denote  $\frac{d\mathbb{P}^u}{d\mathbb{P}}$  by  $\rho$ . We estimate

$$\begin{aligned} \mathbb{E} \left( \int_t^T \|Z_\sigma^u\|_{\Xi}^2 d\sigma \right)^{1/2} &= \mathbb{E}^u \left[ \left( \int_t^T \|Z_\sigma^u\|_{\Xi}^2 d\sigma \right)^{1/2} \rho^{-1} \right] \\ &\leq \mathbb{E}^u \left[ \left( \int_t^T \|Z_\sigma^u\|_{\Xi}^2 d\sigma \right)^{1/2} \right] \mathbb{E}^u [\rho^{-2}]^{1/2}. \end{aligned}$$

It remains to prove that  $\mathbb{E}^u [\rho^{-2}]$  is bounded, knowing that

$$\mathbb{E}^u [\rho^{-1}] = \mathbb{E}^u \left[ \exp \left( \int_t^T R(\sigma, X_\sigma^u, u_\sigma) dW_\sigma^u - \frac{1}{2} \int_t^T \|R(\sigma, X_\sigma^u, u_\sigma)\|_\Xi^2 d\sigma \right) \right] = 1.$$

We get

$$\begin{aligned} \mathbb{E}^u [\rho^{-2}] &= \mathbb{E}^u \left[ \exp 2 \left( \int_t^T R(\sigma, X_\sigma^u, u_\sigma) dW_\sigma^u - \frac{1}{2} \int_t^T \|R(\sigma, X_\sigma^u, u_\sigma)\|_\Xi^2 d\sigma \right) \right] \\ &= \mathbb{E}^u \left[ \exp \left( \int_t^T 2R(\sigma, X_\sigma^u, u_\sigma) dW_\sigma^u - \frac{1}{2} \int_t^T 4 \|R(\sigma, X_\sigma^u, u_\sigma)\|_\Xi^2 d\sigma \right) \right. \\ &\quad \left. \times \exp \left( \int_t^T \|R(\sigma, X_\sigma^u, u_\sigma)\|_\Xi^2 d\sigma \right) \right] \\ &\leq \exp \left( T (K_R \mathcal{K}_u)^2 \right). \end{aligned}$$

Then, by applying the Burkholder–Davis–Gundy inequality,  $\int_t^T Z_\sigma dW_\sigma$  is a  $\mathbb{P}$ -martingale, so the stochastic integral in (5.6) has zero expectation with respect to the original probability  $\mathbb{P}$ . If in (5.6) we set  $\tau = t$  and take expectation with respect to the original probability  $\mathbb{P}$ , we obtain

$$(5.7) \quad v(t, x) = \mathbb{E} \phi(X_T^u) + \mathbb{E} \int_t^T [\psi(\sigma, X_\sigma^u, Z_\sigma^u) - Z_\sigma^u R(\sigma, X_\sigma^u, u_\sigma)] d\sigma.$$

Adding and subtracting  $\mathbb{E} \int_t^T g(\sigma, X_\sigma^u, u_\sigma) d\sigma$ , we arrive at

$$(5.8) \quad \begin{aligned} v(t, x) &= J(t, x, (W, u, X^u)) \\ &\quad + \mathbb{E} \int_t^T [\psi(\sigma, X_\sigma^u, Z_\sigma^u) - Z_\sigma^u R(\sigma, X_\sigma^u, u_\sigma) - g(\sigma, X_\sigma^u, u_\sigma)] d\sigma. \end{aligned}$$

By the definition of  $\psi$ , the term in the square brackets is nonpositive, and consequently,

$$J(t, x, (W, u, X^u)) \geq v(t, x). \quad \square$$

Relation (5.8) is a version of the fundamental relation in terms of BSDEs. We immediately deduce the following consequences.

**COROLLARY 5.6.** *Let  $t \in [0, T]$  and  $x \in E$  be fixed. If, for an a.c.s.  $(W, u, X^u)$ , we have  $J(t, x, (W, u, X^u)) = v(t, x)$ , then  $(W, u, X^u)$  is optimal for the control problem starting from  $x$  at time  $t$ . If  $\Gamma$  is nonempty, let us denote by  $\Gamma_0 : [0, T] \times E \times \Xi^* \longrightarrow U$  a Borel measurable map such that, for  $\tau \in [0, T]$ ,  $x \in E$ ,  $z \in \Xi^*$ , we have  $\Gamma_0(\tau, x, z) \in \Gamma(\tau, x, z)$ . If  $u$  is an admissible control satisfying*

$$(5.9) \quad u_\tau = \Gamma_0(\tau, X_\tau^u, Z_\tau^u), \quad \mathbb{P}\text{-a.s. for almost every } \tau \in [t, T],$$

*then  $J(t, x, (W, u, X^u)) = v(t, x)$ , and  $(W, u, X^u)$  is optimal.*

If also Hypothesis 3.16 holds true, by Corollary 4.5 relation (5.8) can be rewritten as

$$(5.10) \quad \begin{aligned} v(t, x) = & J(t, x, (W, u, X^u)) \\ & + \mathbb{E} \int_t^T [\psi(\sigma, X_\sigma^u, \nabla v(\sigma, X_\sigma^u) G) \\ & - \nabla v(\sigma, X_\sigma^u) GR(\sigma, X_\sigma^u, u_\sigma) - g(\sigma, X_\sigma^u, u_\sigma)] d\sigma. \end{aligned}$$

In order to prove the existence of an optimal control, we say that if there exists a measurable selection  $\Gamma_0$  of  $\Gamma$ , then we can study the closed loop equation

$$(5.11) \quad \begin{cases} dX_\tau^u = AX_\tau^u d\tau + F(\tau, X_\tau^u) d\tau + GR(\tau, X_\tau^u, \Gamma_0(\tau, X_\tau^u, \nabla v(\tau, X_\tau^u) G)) d\tau \\ \quad + GdW_\tau, \quad \tau \in [t, T], \\ X_t^u = x. \end{cases}$$

We can prove the main result of this subsection.

**THEOREM 5.7.** *Let  $v$  be defined as in Proposition 5.5. Assume that Hypotheses 3.1, 3.2, 3.11, 3.16, 5.1, and 5.2 hold true and that the Hamiltonian  $\psi$  defined in (5.3) satisfies Hypothesis 4.1, points 2 and 3. For all a.c.s.  $(W, u, X^u)$  we have*

$$J(t, x, (W, u, X^u)) \geq v(t, x),$$

and the equality holds if and only if

$$(5.12) \quad u_\tau \in \Gamma(\tau, X_\tau^u, \nabla v(\tau, X_\tau^u) G), \quad \mathbb{P}\text{-a.s. for a.a. } \tau \in [t, T].$$

Moreover, let us denote by  $\Gamma_0$  a measurable selection of  $\Gamma$ ; then an a.c.s. satisfying the feedback law

$$(5.13) \quad u_\tau = \Gamma_0(\tau, X_\tau^u, \nabla v(\tau, X_\tau^u) G), \quad \mathbb{P}\text{-a.s. for a.a. } \tau \in [t, T],$$

is optimal. The closed loop equation,

$$(5.14) \quad \begin{cases} dX_\tau^* = [AX_\tau^* + F(\tau, X_\tau^*) + GR(\tau, X_\tau^*, \Gamma_0(\tau, X_\tau^*, \nabla v(\tau, X_\tau^*) G))] d\tau + GdW_\tau, \\ X_t^* = x, \quad \tau \in [t, T], \end{cases}$$

admits a weak solution, which is unique in law, and the corresponding a.c.s. is optimal.

*Proof.* The proof follows from the fundamental relation (5.10) and by Corollary 5.6. The closed loop equation can be solved in the weak sense via a Girsanov change of measure. Namely, we fix an arbitrary cylindrical Wiener process  $\{W_\tau, \tau \geq 0\}$  on a probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  and with values in  $\Xi$ . Let  $\bar{X}_\tau^*$  be the mild solution to

$$(5.15) \quad \begin{cases} d\bar{X}_\tau^* = [A\bar{X}_\tau^* + F(\tau, \bar{X}_\tau^*)] d\tau + G(\tau, \bar{X}_\tau^*) dW_\tau, \\ \bar{X}_t^* = x. \end{cases}$$

Let  $\widehat{\mathbb{P}}$  be the probability on  $\Omega$  under which

$$\widehat{W}_\tau := - \int_t^\tau R(s, X_s^*, \Gamma_0(s, X_s^*, \nabla v(s, X_s^*) G)) ds + W_\tau$$

is a Wiener process. Then  $\overline{X}^*$  is the mild solution to (5.14) relative to the probability  $\widehat{\mathbb{P}}$  and to the Wiener process  $\widehat{W}$ . The law of  $\overline{X}^*$  is unique since it depends on  $A$ ,  $F$ , and  $G$ . The closed loop equation (5.14) always admits a solution in the weak sense. So if  $\Gamma$  is nonempty, then by the Filippov theorem a measurable selection  $\Gamma_0$  of  $\Gamma$  exists, and it is possible to perform the synthesis of the optimal control.  $\square$

**6. Mild solutions of the Hamilton–Jacobi–Bellman equation.** In this section we find mild solutions of the Hamilton–Jacobi–Bellman equation associated with this control problem. Hamilton–Jacobi–Bellman equations associated with the control problem we have already treated are formally given by

$$(6.1) \quad \begin{cases} \frac{\partial v}{\partial t}(t, x) = -\mathcal{A}_t v(t, x) - \psi(t, x, \nabla v(t, x) G), & t \in [0, T], x \in E, \\ v(T, x) = \phi(x). \end{cases}$$

The linear operator  $\mathcal{A}_t$  is formally defined by

$$\mathcal{A}_t f(x) = \frac{1}{2} \text{Trace}_H (GG^* \nabla^2 f(x)) + \langle Ax, \nabla f(x) \rangle_{E, E^*} + \langle F(t, x), \nabla f(x) \rangle_{E, E^*}.$$

We do not look for classical solutions of (6.1); rather, we want to find mild solutions, which we are going to define. In Hilbert spaces, the problem of solving (6.1) has already been treated by an analytical approach in many papers; we cite [17], where  $G$  is such that the Ornstein–Uhlenbeck semigroup is regularizing, namely, in the finite dimensional case; this is equivalent to asking that the second order differential operator  $\mathcal{A}_t$  be hypoelliptic in the sense of Hormander. We also cite [24], where the case of  $G$  not necessarily constant is treated and where, moreover, less restrictive regularizing properties on the associated Ornstein–Uhlenbeck semigroup are required. In [16], (6.1) is studied in the more general case of  $G$  not necessarily constant, and without any nondegeneracy assumptions, via the BSDE approach. As far as we know, apart from the papers [7] and [8], where viscosity solutions are presented for first order partial differential equations, there are no results in the literature concerning mild solutions for (6.1) considered in a Banach space.

In this paper we consider the case when  $F$  in the forward equation has polynomial growth with respect to  $x$ , and thus we also can allow the running cost and the final cost to have polynomial growth with respect to  $x$ .

Let  $X(\tau, t, x)$  be the solution to (3.1) when  $A$ ,  $F$ , and  $G$  satisfy Hypotheses 3.1, 3.2, and 3.11. We remember that this solution is an  $E$ -valued Markov process. We can define the transition semigroup on continuous and bounded functions  $\varphi : E \rightarrow \mathbb{R}$  as

$$P_{t, \tau} [\varphi] (x) = \mathbb{E} \varphi (X (\tau, t, x)).$$

Moreover, the semigroup is also well defined on continuous functions  $\varphi : E \rightarrow \mathbb{R}$  with polynomial growth with respect to  $x$ . Indeed, let  $\varphi : E \rightarrow \mathbb{R}$  such that  $|\varphi(x)| \leq c(1 + \|x\|_E^k)$ . Then

$$\begin{aligned} |P_{t, \tau} [\varphi] (x)| &\leq \mathbb{E} |\varphi (X (\tau, t, x))| \leq \sup_{x \in E} \frac{|\varphi(x)|}{1 + \|x\|_E^k} \mathbb{E} (1 + \|X (\tau, t, x)\|_E^k) \\ &\leq c \sup_{y \in E} \frac{|\varphi(y)|}{1 + \|y\|_E^k}, \end{aligned}$$

where the last passage follows from the fact that, for every  $p \geq 1$ ,  $X \in \mathcal{H}^p([0, T], E)$ .

We look for mild solutions of (6.1), that is, functions  $v(t, x)$  satisfying

$$(6.2) \quad v(t, x) = P_{t,T}[\phi](x) + \int_t^T P_{t,\tau}[\psi(\tau, \cdot, \nabla v(\tau, \cdot)G)](x) d\tau, \quad t \in [0, T], \quad x \in E.$$

We notice that this formula is meaningful if  $v$  has only the first derivative  $\nabla v(t, x)$ , and provided  $\phi$  and  $\psi$  satisfy some growth and measurability conditions. Namely, we give the following definition of a mild solution of the Hamilton–Jacobi–Bellman equation (6.1).

**DEFINITION 6.1.** *A function  $v : [0, T] \times E \rightarrow \mathbb{R}$  is a mild solution of the Hamilton–Jacobi–Bellman equation (6.1) if the following are satisfied:*

1.  *$v$  is continuous, for every  $t \in [0, T]$  we have  $v(t, \cdot) \in \mathcal{G}^1(E)$ , and the map  $(t, x) \mapsto \nabla v(t, x)$  is measurable from  $[0, T] \times E$  with values in  $E^*$ ;*
2. *there exists  $C > 0$  such that  $|v(t, x)| \leq C(1 + \|x\|_E^j)$  and  $|\nabla_x v(t, x)h| \leq C\|h\|_E(1 + \|x\|_E^k)$  for every  $t \in [0, T]$ ,  $x, h \in E$ , and some positive integers  $j$  and  $k$ ;*
3. *equality (6.2) holds.*

In order to solve (6.1) we consider the forward-backward system

$$(6.3) \quad \begin{cases} dX_\tau = AX_\tau d\tau + F(\tau, X_\tau) d\tau + GdW_\tau, & \tau \in [t, T], \\ dY_\tau = -\psi(\tau, X_\tau, Z_\tau) d\tau + Z_\tau dW_\tau, & \tau \in [t, T], \\ X_t = x, \\ Y_T = \phi(X_T). \end{cases}$$

We are ready to prove that there exists a unique solution of (6.3).

**THEOREM 6.2.** *Assume that Hypotheses 3.1, 3.2, 3.11, and 3.16 hold true, and let  $\phi$  and  $\psi$  satisfy Hypothesis 4.1. Then there exists a unique mild solution of the Hamilton–Jacobi–Bellman equation (6.1), given by the formula*

$$v(t, x) = Y(t, t, x),$$

where  $(X, Y, Z)$  is the solution of the forward-backward system (6.3).

*Proof.* The main ideas of the proof are essentially taken from [16, Theorem 6.2] and adapted to this different context.

First, we prove existence. We want to prove that the function  $v(t, x) := Y(t, t, x)$  is in fact a mild solution to (6.1). We have already proved in Proposition 4.2 that for every  $t \in [0, T]$ ,  $v(t, \cdot) \in \mathcal{G}^1(E)$  and that there exists  $C > 0$  such that  $|\nabla_x v(t, x)h| \leq C\|h\|_E(1 + \|x\|_E^j)$  and  $|\nabla_x v(t, x)h| \leq C\|h\|_E(1 + \|x\|_E^k)$  for every  $t \in [0, T]$ ,  $x, h \in E$ , and some positive integers  $j$  and  $k$ . It remains to prove that  $v$  satisfies equality (6.2). To this end we evaluate

$$\begin{aligned} P_{t,\tau}[\psi(\tau, \cdot, \nabla v(\tau, \cdot)G)](x) &= \mathbb{E}[\psi(\tau, X(\tau, t, x), \nabla_x Y(\tau, X(\tau, t, x))G)] \\ &= \mathbb{E}[\psi(\tau, X(\tau, t, x), \nabla_x Y(\tau, t, x)G)] \\ &= \mathbb{E}[\psi(\tau, X(\tau, t, x), Z(\tau, t, x))], \end{aligned}$$

where the last equality is a consequence of Corollary 4.5. In particular, we obtain

$$(6.4) \quad \int_t^T P_{t,\tau}[\psi(\tau, \cdot, \nabla v(\tau, \cdot)G)](x) d\tau = \mathbb{E} \int_t^T \psi(\tau, X(\tau, t, x), Z(\tau, t, x)) d\tau.$$

Next, the pair  $(Y, Z)$  is a solution to the backward equation in the forward-backward system (6.1),

$$Y(t, t, x) + \int_t^T Z(\tau, t, x) dW_\tau = \phi(X(T, t, x)) + \int_t^T \psi(\tau, X(\tau, t, x), Z(\tau, t, x)) d\tau.$$

Taking expectation and applying formula (6.4), we get the integral formula (6.2).

It remains to prove uniqueness. Let  $v$  be a mild solution. Since  $v$  is a mild solution to (6.1), then for every  $s \in [t, T]$ ,

$$v(s, x) = \mathbb{E}\phi(X(T, s, x)) + \mathbb{E} \int_s^T \psi(\tau, X(\tau, s, x), \nabla_x v(\tau, X(\tau, s, x))) G d\tau,$$

and since  $X(\tau, s, x)$  is independent of  $\mathcal{F}_s$ , the expectation coincides with the conditional expectation given  $\mathcal{F}_s$ ; next we can replace  $x$  with  $X(s, t, x)$ , since  $X(s, t, x)$  is  $\mathcal{F}_s$ -measurable. So we obtain

$$\begin{aligned} v(s, X(s, t, x)) &= \mathbb{E}^{\mathcal{F}_s} \phi(X(T, t, x)) \\ &\quad + \mathbb{E}^{\mathcal{F}_s} \int_s^T \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau \\ &= \mathbb{E}^{\mathcal{F}_s} \eta - \mathbb{E}^{\mathcal{F}_s} \int_t^s \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau, \end{aligned}$$

where we have defined  $\eta = \phi(X(T, t, x)) + \int_t^T \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau$ . By the representation theorem of martingales (see, e.g., [12, Theorem 8.2]), there exists a process  $\tilde{Z} \in L^2_{\mathcal{P}}(\Omega \times [0, T], L_2(\Xi, \mathbb{R}))$  such that  $\mathbb{E}^{\mathcal{F}_s} \eta = \int_t^s \tilde{Z}_\tau dW_\tau + v(t, x)$ . Thus

$$(6.5) \quad v(s, X(s, t, x)) = v(t, x) + \int_t^s \tilde{Z}_\tau dW_\tau - \int_t^s \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau.$$

By Corollary 4.5, equality (6.5) can be rewritten as

$$\begin{aligned} v(s, X(s, t, x)) &= v(t, x) + \int_t^s \nabla_x v(\tau, X(\tau, t, x)) G dW_\tau \\ &\quad - \int_t^s \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau \\ &= \phi(X(T, t, x)) - \int_s^T \nabla_x v(\tau, X(\tau, t, x)) G dW_\tau \\ &\quad + \int_s^T \psi(\tau, X(\tau, t, x), \nabla_x v(\tau, X(\tau, t, x))) G d\tau. \end{aligned}$$

By comparing with the backward equation in (6.3), we see that the pairs of processes

$$(Y(s, t, x), Z(s, t, x))_{t \leq s \leq T}$$

and

$$(v(s, X(s, t, x)), \nabla_x v(s, X(s, t, x)) G)_{t \leq s \leq T}$$

solve the same equation. By uniqueness of the solution of this backward equation we have, in particular, that  $Y(s, t, x) = v(s, X(s, t, x))$ ,  $t \leq s \leq T$ , and for  $s = t$  we get the desired equality  $Y(t, t, x) = v(t, x)$ .  $\square$

**7. Application to some specific models.** In this section we introduce some stochastic controlled equations which have the structure of (5.1) and can be treated with our techniques. For the sake of simplicity, we consider bounded costs and a coefficient  $F$  in the forward equation with polynomial growth with respect to  $x$ .

**7.1. The controlled semilinear heat equation: Dirichlet boundary conditions, Neumann boundary conditions.** In this subsection we show how our results can be applied to perform the synthesis of the optimal control when the state equation is a general semilinear heat equation with additive noise in one space dimension. As we will see, we consider the space of continuous functions, where the heat semigroup with Dirichlet boundary conditions turns out to be analytic but not strongly continuous. Heat equations, and in general, reaction diffusion equations, arise naturally in applications; for example, reaction diffusion equations with Neumann boundary conditions arise naturally in chemical reactions, and we think that, in view of applications, it is interesting to treat optimal control problems related to them in the Banach space of continuous functions: this allows us, for instance, to control some variable of the state, say, the temperature, in a finite number of points; see below for a mathematical formulation of this problem.

We are given a complete probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  with a filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$  satisfying the usual conditions. We consider, for  $\tau \in [t, T]$  and  $\xi \in [0, 1]$ , the equation

$$(7.1) \quad \begin{cases} d_\tau X^u(\tau, \xi) = \left[ \frac{\partial^2}{\partial \xi^2} X^u(\tau, \xi) + f(\tau, \xi, X^u(\tau, \xi)) + \sigma(\xi) r(\xi) u(\tau, \xi) \right] d\tau \\ \quad + \sigma(\xi) \dot{W}(\tau, \xi) d\tau, \\ X^u(\tau, 0) = X^u(\tau, 1) = 0, \\ X^u(t, \xi) = x_0(\xi), \end{cases}$$

where  $\dot{W}(\tau, \xi)$  is a space-time white noise on  $[0, T] \times [0, 1]$ .

We introduce the cost functional

$$(7.2) \quad J(t, x, u) = \mathbb{E} \int_t^T \int_0^1 l(s, \xi, X^u(s, \xi), u) \mu(d\xi) ds + \mathbb{E} \int_0^1 k(\xi, X^u(T, \xi)) \mu(d\xi)$$

that we minimize over all admissible setups. Here  $\mu$  is a finite regular measure on  $[0, 1]$ . An admissible control  $u(\tau, \xi)$  is a predictable process such that  $u(\tau, \cdot) \in L^2([0, 1])$ , and  $|u(\tau, \xi)| \leq \delta$ . We denote by  $\mathcal{U}$  the set of such admissible controls. The cost introduced in (7.2) is well defined on the space of continuous function on the interval  $[0, 1]$ , but for an arbitrary  $\mu$  it is not well defined on the Hilbert space of square integrable functions. So this example makes it clear that with this theory we can treat a larger class of stochastic optimal control problems than the class of problems covered by the Hilbert space theory. Stochastic optimal control problems for reaction diffusion equations have been extensively studied in the literature; see, e.g., [18] and [23]. We cite in particular the papers [3] and [4]. In these works, equations with a more general structure than (7.1) are treated, but the costs are defined on the Hilbert space of square integrable functions: In particular, in [3] also the reaction diffusion equation is studied in this Hilbert space, while in [4] the equation is considered in the space of continuous functions, and the cost is defined in the space of square integrable functions.

To satisfy our Hypotheses 3.1, 3.2, 3.11, 5.1, and 5.2 we have to assume the following.

*Hypothesis 7.1.* The functions  $f$ ,  $\sigma$ ,  $r$ ,  $l$ ,  $k$  are all Borel measurable and real valued. Moreover,

1.  $f : [0, T] \times [0, 1] \times \mathbb{R} \longrightarrow \mathbb{R}$  is continuous; for every  $\tau \in [0, T]$  and every  $\xi \in [0, 1]$ , we have  $f(\tau, \xi, \cdot) \in C^1(\mathbb{R})$ ; and there exists  $c_1$  continuous on  $[0, 1]$  such that

$$|f(\tau, \xi, x)| \leq c_1(\xi) (1 + |x|^K), \quad |\nabla_x f(\tau, \xi, x) h| \leq c_1(\xi) |h| (1 + |x|^K)$$

for every  $\tau \in [0, T]$ ,  $\xi \in [0, 1]$ ,  $x, h \in \mathbb{R}$ . For every  $\tau \in [0, T]$ , for every  $\xi \in [0, 1]$ , for every  $x, y \in \mathbb{R}$ , and for every  $\alpha > 0$ ,

$$|x - y| \leq |x - y - \alpha(f(\tau, \xi, x) - f(\tau, \xi, y))|;$$

2.  $\sigma \in C([0, 1], \mathbb{R})$ ;
3.  $r \in L^\infty([0, 1], \mathbb{R})$ ;
4.  $l : [0, T] \times [0, 1] \times \mathbb{R} \times \mathcal{U} \rightarrow \mathbb{R}$  is continuous and bounded.
5.  $k : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}$  is continuous and bounded, and  $k(\xi, \cdot) \in C_b^1(\mathbb{R})$ ; moreover, there exists  $c_2$  continuous on  $[0, 1]$  such that  $|\nabla_x k(\xi, x)| \leq c_2(\xi)$ ;
6.  $x_0 \in C([0, 1])$ .

A classical example of a map  $f$  satisfying Hypothesis 7.1, point 1, is  $f(\tau, \xi, x) = f(x) = -x^3$ .

In the following we denote  $C_0([0, 1]) = \{f \in C([0, 1]) : f(0) = f(1) = 0\}$ . To rewrite the problem in an abstract way we set  $H = \Xi = L^2([0, 1])$  and  $E = C([0, 1])$ : The generator  $A$  in  $H$  is given by

$$\mathcal{D}(A) = H^2([0, 1]) \cap H_0^1([0, 1]), \quad (Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi) \quad \text{for every } y \in \mathcal{D}(A),$$

and its restriction to  $E$  is given by

$$\mathcal{D}(A) = C^2([0, 1]) \cap C_0([0, 1]), \quad (Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi) \quad \text{for every } y \in \mathcal{D}(A).$$

We set

$$(7.3) \quad \begin{aligned} F(\tau, x)(\xi) &= f(\tau, \xi, x(\xi)), & (Gz)(\xi) &= \sigma(\xi) z(\xi), \\ (Ru)(\xi) &= r(\xi) u(\xi), \\ g(\tau, x, u)(\xi) &= \int_0^1 l(s, \xi, x(\xi), u) \mu(d\xi), & \phi(x)(\xi) &= \int_0^1 k(\xi, x(\xi)) \mu(d\xi) \end{aligned}$$

for a.a.  $\tau \in [0, T]$  and  $\xi \in [0, 1]$ , for all  $x, z \in C([0, 1])$ , and for all admissible controls  $u$ . It turns out that, with Hypothesis 7.1, the assumptions in Hypotheses 3.1, 3.2, 3.11, 5.1, and 5.2 are satisfied.

Also Hypothesis 3.16 is satisfied by taking  $\Xi_0 = C([0, 1])$ .

With notations (7.3), the heat equation (7.1) can be written in an abstract way in the Banach space  $E$  as

$$(7.4) \quad \begin{cases} dX_\tau^u = [AX_\tau^u + F(\tau, X_\tau^u)] d\tau + GRu_\tau d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t^u = x_0, \end{cases}$$

where  $\{W_\tau, \tau \geq 0\}$  is a cylindrical Wiener process in  $H$  with respect to the filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$ , and it is such that the stochastic convolution admits a version in  $C([0, T], E)$ ; see, e.g., [12, Chapter 5].  $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W, u, X^u)$  is an a.c.s.

*Remark 7.2.* We remark that, in order to guarantee more generality, in this paper the nonlinear term  $F$  is assumed to be dissipative and not Lipschitz continuous. In the case of the heat equation, if in (7.1)  $f(\tau, \xi, x) = -x^3$ , the nonlinear term in (7.4) is dissipative but not Lipschitz continuous. Moreover, in this case a Lipschitz continuous nonlinearity turns out to be well defined in  $L^2[(0, 1)]$ , while a nonlinear term with polynomial growth is not well defined in  $L^2([0, 1])$  but is well defined in  $C([0, 1])$ .

We consider the Hamilton–Jacobi–Bellman equation relative to (7.4),

$$(7.5) \quad \begin{cases} \frac{\partial v}{\partial t}(t, x) = -\mathcal{A}_t v(t, x) - \psi(t, x, \nabla v(t, x) G), & t \in [0, T], \ x \in H, \\ u(T, x) = \phi(x), \end{cases}$$

where  $\psi$  is the Hamiltonian function defined in (5.3). In order to solve the optimal control problem and to find mild solutions of the Hamilton–Jacobi–Bellman equation, we need  $\psi$  to satisfy Hypothesis 4.1, points 1, 2, and 3. We state direct hypotheses on  $l$  and  $k$  in the definition (7.2) of the concrete cost  $J$  when the measure  $\mu$  is a combination of Dirac measures, that is,

$$\mu = \sum_{i=1}^N \delta_{\xi_i}.$$

$\delta_x$  denotes the Dirac measure at  $x$ , and  $\xi_1, \dots, \xi_N$  belongs to the interval  $[0, 1]$ . In this case the Hamiltonian is given by

$$(7.6) \quad \psi(t, x, z) = \inf_{u \in \mathcal{U}} \left\{ \sum_{i=1}^N l(t, \xi_i, x(\xi_i), u) + \int_0^1 z(\xi) r(\xi) u(\xi) d\xi \right\}.$$

We make the following assumption.

*Hypothesis 7.3.* Let  $\bar{\psi} : [0, T] \times \mathbb{R}^N \times \Xi^* \rightarrow \mathbb{R}$  be given by

$$\bar{\psi}(t, y_1, \dots, y_N, z) = \inf_{u \in \mathcal{U}} \left\{ \sum_{i=1}^N l(t, \xi_i, y_i, u) + \int_0^1 z(\xi) r(\xi) u(\xi) d\xi \right\}.$$

Assume that for every  $t \in [0, T]$ ,  $\bar{\psi}(t, \cdot, \dots, \cdot) : \mathbb{R}^N \times \Xi^* \rightarrow \mathbb{R}$  is differentiable with bounded derivatives.

If Hypothesis 7.3 holds true, then the Hamiltonian defined in (7.6) satisfies Hypothesis 4.1, points 1, 2, and 3. A case when Hypothesis 7.3 can be checked directly on the cost functional is when

$$\sum_{i=1}^N l(t, \xi_i, y_i, u) = \sum_{i=1}^N l(t, \xi_i, y_i) + \int_0^1 \frac{u^2(\xi)}{2} d\xi,$$

where  $l : [0, T] \times [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}$  is continuous and for every  $t \in [0, T]$  and  $\xi_i \in [0, 1]$ ,  $l(t, \xi_i, \cdot)$  is differentiable with bounded derivatives. It turns out that

$$\psi(t, x, z) = \sum_{i=1}^N l(t, \xi_i, x(\xi_i)) + \inf_{u \in \mathcal{U}} \int_0^1 \frac{u^2(\xi)}{2} d\xi + \int_0^1 z(\xi) r(\xi) u(\xi) d\xi.$$

Thus, with our assumptions,  $\psi(t, \cdot, \cdot) \in \mathcal{G}^{1,1}(E \times \Xi^*)$ . Indeed, differentiability with respect to  $x$  is straightforward, and differentiability with respect to  $z$  can be proved

directly by noting that

$$\inf_{u \in \mathcal{U}} \int_0^1 \frac{u^2(\xi)}{2} d\xi + \int_0^1 z(\xi) r(\xi) u(\xi) d\xi = \int_0^1 \gamma(z(\xi) r(\xi)) d\xi,$$

where  $\gamma(y) = \inf_{u \in \mathbb{R}, |u| \leq \delta} (\frac{u^2}{2} + yu)$ . By direct computations,

$$\gamma(y) = \begin{cases} -\frac{y^2}{2} & \text{if } |y| \leq \delta, \\ \frac{\delta^2}{2} - \delta|y| & \text{if } |y| > \delta. \end{cases}$$

**THEOREM 7.4.** *Assume that Hypothesis 7.1 holds true and that the Hamiltonian function satisfies Hypothesis 4.1, points 1, 2, and 3. Then (7.5) has a unique mild solution  $v$ , and for all a.c.s.'s  $(W, u, X^u)$ ,  $J(t, x, (W, u, X^u)) \geq v(t, x)$ . Moreover,  $J(t, x, (W, u, X^u)) = v(t, x)$  if and only if (5.12) holds. If (5.13) holds, there exists an optimal a.c.s.*

Similar arguments apply to stochastic optimal control problems and Hamilton–Jacobi–Bellman equations associated with heat equations with Neumann boundary conditions, that is, equations of the following form:

$$(7.7) \quad \begin{cases} d_\tau X^u(\tau, \xi) = \left[ \frac{\partial^2}{\partial \xi^2} X^u(\tau, \xi) + f(\tau, \xi, X^u(\tau, \xi)) + \sigma(\xi) r(\xi) u(\tau, \xi) \right] d\tau \\ \quad + \sigma(\xi) \dot{W}(\tau, \xi) d\tau, \\ \frac{\partial}{\partial \xi} X^u(\tau, 0) = \frac{\partial}{\partial \xi} X^u(\tau, 1) = 0, \\ X^u(t, \xi) = x(\xi). \end{cases}$$

We consider a cost functional of the form of (7.2), and we assume that Hypothesis 7.1 is satisfied. To rewrite the problem in an abstract way, we set  $H = L^2([0, 1])$  and  $E = C([0, 1])$ ,

$$\mathcal{D}(A) = \{y \in H^2([0, 1]) : y'(0) = y'(1) = 0\},$$

$$(Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi) \quad \text{for every } y \in \mathcal{D}(A),$$

and the restriction of  $A$  to  $E$  is given by

$$\mathcal{D}(A) = \{y \in C^2([0, 1]) : y'(0) = y'(1) = 0\},$$

$$(Ay)(\xi) = \frac{\partial^2}{\partial \xi^2} y(\xi) \quad \text{for every } y \in \mathcal{D}(A),$$

and in this case  $A$  is the generator of a strongly continuous semigroup. Then analogous results to the ones stated in Theorem 7.4 can be obtained.

**7.2. A controlled delay equation.** In  $(\Omega, \mathcal{F}, \mathbb{P})$  we consider the following stochastic delay equation with values in  $\mathbb{R}^n$ :

$$(7.8) \quad \begin{cases} dz^u(\tau) = \left[ \int_{-r}^0 a(d\theta) z^u(\tau + \theta) \right] d\tau + u(\tau) d\tau + dW(\tau), & \tau \in [t, T], \\ z^u(t) = h_0, \\ z^u(t + \theta) = h_1(\theta), & \theta \in [-r, 0], \end{cases}$$

where  $a(d\theta)$  is a matrix valued finite measure on  $[-r, 0]$  and  $W$  is a standard Wiener process in  $\mathbb{R}^n$ . The value  $r > 0$  denotes the maximum delay,  $h_1 \in L^p([-r, 0], \mathbb{R}^n)$ , and  $u_\tau$  is an admissible control, that is, an  $(\mathcal{F}_\tau)$ -predictable process taking values in a bounded subset of  $\mathbb{R}^n$ .

We want to rewrite (7.8) in an abstract way. Consider the nonstochastic case and take  $u$  identically zero; let  $z$  be the solution of the problem

$$\begin{cases} dz(\tau) = \left[ \int_{-r}^0 a(d\theta) z(\tau + \theta) \right] d\tau, & \tau \geq t, \\ z(t) = h_0, \\ z(t + \theta) = h_1(\theta), & \theta \in [-r, 0]. \end{cases}$$

Define the Banach space  $E = \mathbb{R}^n \oplus L^p([-r, 0], \mathbb{R}^n)$ . It turns out that

$$e^{\tau A} : E \longrightarrow E, \quad e^{\tau A} \begin{pmatrix} h_0 \\ h_1 \end{pmatrix} = \begin{pmatrix} z(\tau) \\ z_\tau \end{pmatrix}, \quad \tau \geq t \text{ with } z_\tau(\theta) = z(\theta + \tau)$$

defines a  $C_0$ -semigroup; see, e.g., [14] and [30]. The infinitesimal generator  $A$  of  $e^{\tau A}$ ,  $\tau \geq 0$ , is given by

$$\begin{aligned} \mathcal{D}(A) &= \left\{ \begin{pmatrix} h_0 \\ h_1 \end{pmatrix} \in E, h_1 \in W^{1,p}([-r, 0], \mathbb{R}^n), h_1(0) = h_0 \right\}, \\ Ah &= A \begin{pmatrix} h_0 \\ h_1 \end{pmatrix} = \begin{pmatrix} \int_{-r}^0 a(d\theta) h_1(\theta) \\ dh_1/d\theta \end{pmatrix}. \end{aligned}$$

If  $p > 2$ , the Banach space  $E = \mathbb{R}^n \oplus L^p([-r, 0], \mathbb{R}^n)$  is embedded in the Hilbert space  $H = \mathbb{R}^n \oplus L^2([-r, 0], \mathbb{R}^n)$ , where  $e^{\tau A}$  defines a  $C_0$ -semigroup. In  $H$  the infinitesimal generator  $A$  is given by

$$\begin{aligned} \mathcal{D}(A) &= \left\{ \begin{pmatrix} h_0 \\ h_1 \end{pmatrix} \in H, h_1 \in H^1([-r, 0], \mathbb{R}^n), h_1(0) = h_0 \right\}, \\ Ah &= \begin{pmatrix} \int_{-r}^0 a(d\theta) h_1(\theta) \\ dh_1/d\theta \end{pmatrix}. \end{aligned}$$

By setting

$$G : \mathbb{R}^n \longrightarrow E, \quad G = \begin{pmatrix} I \\ 0 \end{pmatrix}, \quad X_\tau^u = \begin{pmatrix} z^u(\tau) \\ z_\tau^u \end{pmatrix}, \quad \text{and} \quad X_t^u = \begin{pmatrix} h_0 \\ h_1 \end{pmatrix},$$

problem (7.8) can be rewritten in an abstract way as a controlled stochastic evolution equation in  $E$ :

$$(7.9) \quad \begin{cases} dX_\tau^u = AX_\tau^u d\tau + Gu_\tau d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t^u = x. \end{cases}$$

The techniques developed in this paper allow us to treat delay equations that evolve in spaces of  $p$ -integrable functions, but not in spaces of continuous functions because in such spaces the operator  $A$  is not, in general, the generator of a strongly continuous semigroup. Thus the treatment of stochastic optimal control problems in such spaces needs substantial technical modification of our result and will be the object of future work. Also when treating delay equations in spaces of  $p$ -integrable functions, which in (7.9) are formulated as evolution equations in  $E = \mathbb{R}^n \oplus L^p([-r, 0], \mathbb{R}^n)$ , we cannot directly apply the results of the previous sections since  $A$ , in general, is not dissipative in  $E$ . It is possible to find  $\gamma \in \mathbb{R}$  such that  $A - \gamma I$  is dissipative if we consider, instead of  $L^p([-r, 0], \mathbb{R}^n)$ , a weighted space, namely,  $L^p([-r, 0], \mathbb{R}^n; \mu)$ ; see [30] for more details. Nevertheless, since in (7.9)  $F = 0$ , in order to apply the results of the previous sections it suffices to prove that  $A$  generates a strongly continuous semigroup  $e^{\tau A}$  in  $E$  which extends to a strongly continuous semigroup in  $H$ . We briefly show that under these assumptions on  $A$ , and if  $G$  satisfies Hypothesis 3.2, the results in section 3 are true for the solution of a linear equation in  $E$ :

$$\begin{cases} dX_\tau = AX_\tau d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t = x. \end{cases}$$

The mild solution of this equation is given by

$$X_\tau = X(\tau, t, x) = e^{(\tau-t)A}x + \int_t^\tau e^{(\tau-s)A}GdW_s,$$

so it is immediate to see that the solution is Lipschitz continuous with respect to the initial datum and is also pathwise differentiable—results that are proved in Proposition 3.7, and in Proposition 3.10 for the more general case of  $F \neq 0$ . Moreover, since we assume that the stochastic convolution admits an  $E$ -continuous version, the process  $(X_\tau)_{\tau \in [0, T]}$  belongs to  $\mathcal{H}^p([0, T], E)$  for every  $1 \leq p < \infty$ , and also the map  $x \mapsto (X(\tau, t, x))_{\tau \in [0, T]}$  belongs to  $\mathcal{G}^1(E, \mathcal{H}^p([0, T], E))$ . These results are the counterpart of Lemma 3.12 and Proposition 3.13.

In the case of the delay semigroup, by simple direct calculations it turns out there exist  $j \geq 0$  and  $C > 0$  such that  $\|e^{\tau A}\|_E \leq C\tau^j$ . In the following lemma we prove that the stochastic convolution admits a continuous version with values in  $E = \mathbb{R}^n \oplus L^p([-r, 0], \mathbb{R}^n)$ .

LEMMA 7.5. *The stochastic convolution  $W_A(\tau) = \int_0^\tau e^{(\tau-s)A}GdW_s$  admits an  $E$ -continuous version.*

*Proof.* By the factorization method (see, e.g., [12, p. 128]), for some  $0 < \alpha < 1/2$ , we can write

$$\begin{aligned} W_A(\tau) &= \int_0^\tau e^{(\tau-s)A}BdW_s = \frac{\sin \pi \alpha}{\pi} \int_0^\tau \left[ \int_s^\tau (\tau - \sigma)^{\alpha-1} (\sigma - s)^{-\alpha} d\sigma \right] e^{(\tau-s)A}GdW_s \\ &= \frac{\sin \pi \alpha}{\pi} \int_0^\tau e^{(\tau-\sigma)A} (\tau - \sigma)^{\alpha-1} Y_\sigma d\sigma, \end{aligned}$$

where we have set  $Y_\sigma = \int_0^\sigma (\sigma - s)^{-\alpha} e^{(\sigma-s)A}GdW_s$ . If we show that for some  $q > 2$ ,  $Y$  is in  $L^q([0, T], E)$ ,  $\mathbb{P}$ -almost everywhere, then the stochastic convolution admits a continuous version in  $E$ . We are going to show the stronger condition

$$\mathbb{E} \int_0^T \|Y_\sigma\|_E^q d\sigma < \infty.$$

The process  $Y$  admits the representation

$$Y_\sigma = \begin{pmatrix} Y_\sigma^1 \\ Y_\sigma^2 \end{pmatrix} = \begin{pmatrix} \int_0^\sigma (\sigma-s)^{-\alpha} \Pi_1 e^{(\sigma-s)A} B dW_s \\ \int_0^\sigma (\sigma-s)^{-\alpha} \Pi_2 e^{(\sigma-s)A} B dW_s \end{pmatrix}$$

and  $Y_\sigma^2(\theta) = Y_{\sigma+\theta}^1 \chi_{(-\sigma,0)}(\theta)$ , where by  $\chi_A$  we mean the indicator function of the set  $A$ . We have recalled that there exist  $j \geq 0$  and  $C > 0$  such that  $\|e^{tA}\|_E \leq C\tau^j$ , so for every  $a \in \mathbb{R}^n$ ,  $\|e^{tA}Ga\|_E \leq C\tau^j|a|_{\mathbb{R}^n}$ . Let  $\Pi_1 : E \rightarrow \mathbb{R}^n$  be the projection on the first component of  $E$ , and  $\Pi_2 : E \rightarrow L^p([-r,0], \mathbb{R}^n)$  be the projection on the second component of  $E$ , that is, for every  $\begin{pmatrix} k_1 \\ k_2 \end{pmatrix} \in E$ ,  $\Pi_1\begin{pmatrix} k_1 \\ k_2 \end{pmatrix} = k_1$ , and  $\Pi_2\begin{pmatrix} k_1 \\ k_2 \end{pmatrix} = k_2$ . We take  $q = p$ , and so  $q > 2$ , and we estimate

$$\begin{aligned} \mathbb{E} \int_0^T |Y_\sigma^1|_{\mathbb{R}^n}^p d\sigma &= \int_0^T \mathbb{E} \left| \int_0^\sigma (\sigma-s)^{-\alpha} \Pi_1 e^{(\sigma-s)A} dW_s \right|_{\mathbb{R}^n}^p d\sigma \\ &\leq c_p \int_0^T \mathbb{E} \left( \int_0^\sigma (\sigma-s)^{-2\alpha} \left| \Pi_1 e^{(\sigma-s)A} G \right|_{\mathbb{R}^n}^2 ds \right)^{p/2} d\sigma \\ &\leq c \int_0^T \left( \int_0^\sigma (\sigma-s)^{-2\alpha} (\sigma-s)^{2j} ds \right)^{p/2} d\sigma < +\infty, \end{aligned}$$

where  $c$  is a positive constant. So we also get that for every  $\theta \in [-r,0]$ ,

$$\begin{aligned} \mathbb{E} \int_0^T |Y_\sigma^2(\theta)|_{\mathbb{R}^n}^p d\sigma &= \int_0^T \mathbb{E} \left| \int_0^\sigma (\sigma-s)^{-\alpha} \Pi_2 e^{(\sigma-s)A} G dW_s(\theta) \right|_{\mathbb{R}^n}^p d\sigma \\ &= \int_0^T \mathbb{E} \left| \int_0^\sigma (\sigma-s)^{-\alpha} \chi_{(-\sigma+s,0)}(\theta) \Pi_1 e^{(\sigma+\theta-s)A} G dW_s \right|_{\mathbb{R}^n}^p d\sigma \\ &= \int_{-\theta}^T \mathbb{E} \left| \int_0^{\sigma+\theta} (\sigma-s)^{-\alpha} \Pi_1 e^{(\sigma+\theta-s)A} B dW_s \right|_{\mathbb{R}^n}^p d\sigma \\ &\leq c \int_{-\theta}^T \mathbb{E} \left( \int_0^{\sigma+\theta} (\sigma-s)^{-2\alpha} \left| \Pi_1 e^{(\sigma+\theta-s)A} G \right|_{\mathbb{R}^n}^2 ds \right)^{p/2} d\sigma \\ &\leq cT^{pj} \int_{-\theta}^T \left( \int_0^{\sigma+\theta} (\sigma-s)^{-2\alpha} ds \right)^{p/2} d\sigma \\ &\leq cg(\theta). \end{aligned}$$

$c$  is a positive constant depending on  $p$ ,  $C$ , and  $T$ , and  $g : [-r,0] \rightarrow \mathbb{R}^n$  is bounded. We get

$$\mathbb{E} \int_0^T \|Y_\sigma^2\|_{L^p([-r,0], \mathbb{R}^n)}^p d\sigma \leq c \left( \int_{-r}^0 g^p(\theta) d\theta \right)^{1/p} < +\infty,$$

and the proof is concluded.  $\square$

For the delay equation, Hypothesis 3.16 is trivial, since  $\Xi = \mathbb{R}^n$  and  $G$  is the inclusion of  $\mathbb{R}^n$  in the product space  $E = \mathbb{R}^n \times L^p([-r, 0], \mathbb{R}^n)$ .

In relation to the controlled equation (7.8) we want to study the following stochastic control problem, which we are going to state in its weak formulation. We define the cost functional

$$(7.10) \quad J(t, h_0, h_1, u) = \mathbb{E} \int_{-r}^0 z^u(T + \theta) y(\theta) d\theta,$$

where  $y \in L^q([-r, 0], \mathbb{R}^n)$ , with  $q$  the conjugate exponent of  $p$ . The main advantage in treating delay equations in the space of  $p$ -integrable functions, with  $p > 2$ , is that we can treat costs as in (7.10), with  $y$  not necessarily square integrable; indeed, in order to have the cost be well defined, we have only to ask that  $y \in L^q([-r, 0], \mathbb{R}^n)$ , and  $q < 2$  since it is the conjugate exponent of  $p$ .

We have to minimize the cost  $J$  over all admissible controls. An admissible control  $u_\tau$  is a predictable process

$$(\Omega, \mathcal{F}, (\mathcal{F}_\tau)_{\tau \geq 0}, \mathbb{P}) \rightarrow \mathcal{U},$$

where  $\mathcal{U}$  is a bounded subset in  $\mathbb{R}^n$ .

In the abstract setting, the cost functional can be rewritten as

$$J(t, h, u) = \mathbb{E} \phi(X_T^u),$$

where, for  $j \in E$ ,

$$j = \begin{pmatrix} j_1 \\ j_2 \end{pmatrix}, \quad \phi(j) = \int_{-r}^0 j_2(\theta) y(\theta) d\theta, \quad \text{and } \Pi_2 : E \longrightarrow L^p([-r, 0], \mathbb{R}^n)$$

is the projection on the second component of  $E$ .

We can also prove existence and uniqueness of a mild solution of the Hamilton–Jacobi–Bellman equation, associated with a delay equation,

$$(7.11) \quad \begin{cases} \frac{\partial v}{\partial t}(t, x) = -\mathcal{A}_t v(t, x) - \psi(t, x, \nabla v(t, x) G), & t \in [0, T], \quad x \in H, \\ u(T, x) = \phi(x). \end{cases}$$

We summarize the results in the following theorem.

**THEOREM 7.6.** *Equation (7.11) has a unique mild solution  $v$ , and if the cost  $J$  is defined as in (7.10), then for all a.c.s.'s  $(W, u, X^u)$  we have  $J(t, x, (W, u, X^u)) \geq v(t, x)$ , and the equality holds if and only if (5.12) holds. If (5.13) holds, there exists an optimal a.c.s.*

**7.3. A controlled wave equation.** In this section we show how our results can be applied to perform the synthesis of the optimal control when the state equation is a controlled wave equation. Our goal is to solve an optimal control problem for a stochastic wave equation where the cost functional is well defined on continuous functions, so the cost is not necessary well defined on the space of square integrable functions: for such costs, existing results in the literature concerning stochastic optimal control problems in Hilbert spaces do not apply. The Banach space  $E$ , where the wave equation evolves, will be the product of two Besov spaces. The choice of this space will be made clear in the following.

This section is organized as follows. We introduce the wave operator  $A$  with its domain in a Banach space  $E$ , which turns out to be the product of two Besov spaces, and we observe that  $A$  is dissipative in  $E$ . For the stochastic case, we prove that the stochastic convolution admits a continuous version in  $E$ . Finally, we introduce the stochastic controlled wave equation and, by applying the results of the previous sections, we solve a stochastic optimal control problem and the related Hamilton–Jacobi–Bellman equation.

Let us consider a wave equation in one space dimension:

$$(7.12) \quad \begin{cases} \frac{\partial^2}{\partial \tau^2} y(\tau, \xi) = \frac{\partial^2}{\partial \xi^2} y(\tau, \xi), \\ y(\tau, 0) = y(\tau, 1) = 0, \\ y(0, \xi) = x_0(\xi), \\ \frac{\partial y}{\partial \tau}(0, \xi) = x_1(\xi), \end{cases}$$

where  $\tau \in [0, T]$  and  $\xi \in [0, 1]$ . We want to write (7.12) in abstract form. We follow a standard procedure; see, e.g., [12]. We define  $\Lambda$  by

$$\mathcal{D}(\Lambda) = H^2([0, 1]) \cap H_0^1([0, 1]), \quad (\Lambda y)(\xi) = -\frac{\partial^2}{\partial \xi^2} y(\xi)$$

for every  $y \in \mathcal{D}(\Lambda)$ . We introduce the Hilbert space

$$H_1 = H_0^1([0, 1]) \oplus L^2([0, 1]).$$

On  $H_1$  we define the operator  $A$  by

$$\mathcal{D}(A) = H^2([0, 1]) \cap H_0^1([0, 1]) \oplus H_0^1([0, 1]), \quad A \begin{pmatrix} y \\ z \end{pmatrix} = \begin{pmatrix} 0 & I \\ -\Lambda & 0 \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix}$$

for every  $\begin{pmatrix} y \\ z \end{pmatrix} \in \mathcal{D}(A)$ . Next we introduce the Hilbert space

$$H_2 = L^2([0, 1]) \oplus H^{-1}([0, 1]).$$

On  $H_2$  we define the operator  $A$  by

$$\mathcal{D}(A) = H_0^1([0, 1]) \oplus L^2([0, 1]), \quad A \begin{pmatrix} y \\ z \end{pmatrix} = \begin{pmatrix} 0 & I \\ -\Lambda & 0 \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix}$$

for every  $\begin{pmatrix} y \\ z \end{pmatrix} \in \mathcal{D}(A)$ . In both  $H_1$  and  $H_2$ ,  $A$ , with the suitable domain, is the generator of the contractive group

$$e^{tA} \begin{pmatrix} y \\ z \end{pmatrix} = \begin{pmatrix} \cos \sqrt{\Lambda} t & \frac{1}{\sqrt{\Lambda}} \sin \sqrt{\Lambda} t \\ -\sqrt{\Lambda} \sin \sqrt{\Lambda} t & \cos \sqrt{\Lambda} t \end{pmatrix} \begin{pmatrix} y \\ z \end{pmatrix}, \quad t \in \mathbb{R}.$$

Equation (7.12) can be rewritten in an abstract way as

$$(7.13) \quad \begin{cases} dX_\tau = AX_\tau d\tau, & \tau \in [0, T], \\ X_0 = x. \end{cases}$$

Next, we consider a stochastic wave equation in  $(\Omega, \mathcal{F}, (\mathcal{F}_\tau)_{\tau \geq 0}, \mathbb{P})$ . We consider, for  $0 \leq t \leq \tau \leq T$  and  $\xi \in [0, 1]$ , the following state equation:

$$(7.14) \quad \begin{cases} \frac{\partial^2}{\partial \tau^2} y(\tau, \xi) = \frac{\partial^2}{\partial \xi^2} y(\tau, \xi) + \dot{W}(\tau, \xi), \\ y(\tau, 0) = y(\tau, 1) = 0, \\ y(0, \xi) = x_0(\xi), \\ \frac{\partial y}{\partial \tau}(0, \xi) = x_1(\xi). \end{cases}$$

$\dot{W}(\tau, \xi)$  is a space-time white noise on  $[0, T] \times [0, 1]$ . This equation can be rewritten in an abstract way in the Hilbert space  $H_2$  in the following form:

$$(7.15) \quad \begin{cases} dX_\tau = AX_\tau d\tau + GdW_\tau, & \tau \in [0, T], \\ X_0 = x, \end{cases}$$

where  $\{W_\tau, \tau \geq 0\}$  is a cylindrical Wiener process in  $L^2([0, 1])$  with respect to the filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$ . The operator  $G : L^2([0, 1]) \longrightarrow H_2$  is defined by  $Gu = \begin{pmatrix} 0 \\ u \end{pmatrix} = \begin{pmatrix} 0 \\ I \end{pmatrix} u$ , where  $I$  is the embedding of  $L^2([0, 1])$  in  $H^{-1}([0, 1])$ . The solution of (7.15) belongs to  $H_2 = L^2([0, 1]) \oplus H^{-1}([0, 1])$ , since in this space the operators

$$\int_0^t e^{sA} G G^* e^{sA^*} ds$$

are of trace class; see [12, Example 5.8]. So the process

$$W_A(t) = \int_0^t e^{(t-s)A} G dW(s)$$

is well defined in  $H_2$ .

We introduce the Banach space  $E = B_{2,p,\{0\}}^s([0, 1]) \oplus B_{2,p}^{s-1}([0, 1])$ , with  $s \in (0, 1)$  and  $p > 2$ , where  $B_{2,p,\{0\}}^s([0, 1])$  is the Besov space with Dirichlet boundary conditions and  $B_{2,p}^{s-1}([0, 1])$  is a Besov space with negative exponent. The space  $E$  can be obtained by interpolating  $H_1$  and  $H_2$ :

$$\begin{aligned} (H_2, H_1)_{s,p} &= (L^2([0, 1]), H_0^1([0, 1]))_{s,p} \oplus (H^{-1}([0, 1]), L^2([0, 1]))_{s,p} \\ &= B_{2,p,\{0\}}^s([0, 1]) \oplus B_{2,p}^{s-1}([0, 1]). \end{aligned}$$

For more details on real interpolation and Besov spaces, see, e.g., [21, Chapter I] and [28]. The operator  $A$  with domain  $\mathcal{D}(A) = B_{2,p,\{0\}}^{s+1}([0, 1]) \oplus B_{2,p,\{0\}}^s([0, 1])$  is the generator of a group in  $E$ , and, moreover, since  $A$  is dissipative in both  $H_1$  and  $H_2$ , it turns out that  $A$  is dissipative in  $E$ . Equation (7.14) can be written as an evolution equation in the Banach space  $E$ :

$$(7.16) \quad \begin{cases} dX_\tau = AX_\tau d\tau + GdW_\tau, & \tau \in [t, T], \\ X_0 = x, \end{cases}$$

where  $G : L^2([0, 1]) \longrightarrow E$  is defined by  $Gu = \begin{pmatrix} 0 \\ u \end{pmatrix} = \begin{pmatrix} 0 \\ I \end{pmatrix} u$ , and  $I$  is the embedding of  $L^2([0, 1])$  in  $B_{2,p}^{s-1}([0, 1])$ .

*Remark 7.7.* The idea of the wave equation in a Besov space is inspired by the fact that if  $s - 1/2 > 0$ , then  $B_{2,p,\{0\}}^s([0, 1])$  is contained in  $C([0, 1])$ ; see [28,

Theorem 4.6.1]. Moreover, since  $E$  can be obtained by interpolating  $H_1$  and  $H_2$ , dissipativity of the operator is straightforward. In this paper, we take  $s = 1/2 + \beta$ , for some  $0 < \beta < 1/2$ , to be chosen in the proof of the following lemma.

In order to apply our results we note that the Banach space  $E$  is continuously and densely embedded in the Hilbert space  $H_2$ , where the stochastic convolution  $W_A(t)$  takes values. We need to prove that  $W_A(t)$  admits a version in  $C([0, T], E)$ .

LEMMA 7.8. *The stochastic convolution  $W_A(t) = \int_0^t e^{(t-s)A} G dW(s)$  admits a version in  $C([0, T], E)$  for every  $p \geq 6$  and some  $s \in (\frac{1}{2}, 1)$ , i.e.,  $s = \frac{1}{2} + \beta$ , with  $\beta > 0$ .*

*Proof.* Let

$$W_A(t) = \begin{pmatrix} W_A^1(t) \\ W_A^2(t) \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{\Lambda}} \int_0^t \sin(\sqrt{\Lambda}(t-s)) dW_s \\ \int_0^t \cos(\sqrt{\Lambda}(t-s)) dW_s \end{pmatrix}.$$

We start by proving that  $W_A^1(t)$  admits a version in  $C([0, T], B_{2,p,\{0\}}^s([0, 1]))$ . Indeed, we prove a stronger result:  $W_A^1(t)$  admits a version in  $C([0, T], B_{p,p,\{0\}}^s([0, 1]))$ . Since  $p > 2$ ,  $B_{p,p,\{0\}}^s([0, 1]) \subset B_{2,p,\{0\}}^s([0, 1])$ . We recall that  $B_{p,p,\{0\}}^s([0, 1])$  is a Sobolev space with fractional exponent and it is usually denoted by  $W_{p,\{0\}}^s([0, 1])$ . With the norm

$$\|f\|_{W_{p,\{0\}}^s}^p = \int_0^1 |f(\xi)|^p d\xi + \int_0^1 \int_0^1 \frac{|f(\xi) - f(\eta)|^p}{|\xi - \eta|^{1+sp}} d\xi d\eta,$$

$W_{p,\{0\}}^s([0, 1])$  is a Banach space. Let  $\beta_k, k \geq 1$ , be standard independent real Wiener processes. Let us first prove that

$$W_A^1(t)(\xi) = \frac{1}{\sqrt{\Lambda}} \int_0^t \sin(\sqrt{\Lambda}(t-s)) dW_s(\xi) = \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi\xi d\beta_k(s)$$

takes values in  $W_{p,\{0\}}^s([0, 1])$ . By its definition,  $W_A^1(t)$  vanishes at the boundary. We prove that, for every  $t \in [0, T]$ ,  $\|W_A^1(t)\|_{W_{p,\{0\}}^s}^p$  is finite a.s.

$$\begin{aligned} & \|W_A^1(t)\|_{W_{p,\{0\}}^s}^p \\ &= \int_0^1 \left| \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi\xi d\beta_k(s) \right|^p d\xi + \int_0^1 \int_0^1 \\ & \quad \times \frac{\left| \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi\xi d\beta_k(s) - \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi\eta d\beta_k(s) \right|^p}{|\xi - \eta|^{1+sp}} d\xi d\eta \\ &= I + II. \end{aligned}$$

In order to prove that  $\|W_A^1(t)\|_{W_{p,\{0\}}^s}^p$  is finite a.s., we prove that  $\mathbb{E}\|W_A^1(t)\|_{W_{p,\{0\}}^s}^p < \infty$ .

We evaluate

$$\begin{aligned}
\mathbb{E}(I) &= \mathbb{E} \int_0^1 \left| \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi \xi d\beta_k(s) \right|^p d\xi \\
&= \int_0^1 \mathbb{E} \left| \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi \xi d\beta_k(s) \right|^p d\xi \\
&\leq c \int_0^1 \left( \mathbb{E} \left| \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} \sin k\pi \xi d\beta_k(s) \right|^2 \right)^{p/2} d\xi \\
&= c \int_0^1 \left( \int_0^t \sum_{k \geq 1} \frac{\sin^2 k\pi(t-s)}{k^2 \pi^2} \sin^2 k\pi \xi ds \right)^{p/2} d\xi \\
&\leq c \left( \sum_{k \geq 1} \frac{1}{k^2 \pi^2} \right)^{p/2} \left( \int_0^t \sin^2 k\pi(t-s) ds \right)^{p/2} \\
&\leq c \left( \sum_{k \geq 1} \frac{1}{k^2 \pi^2} \right)^{p/2} t^{p/2},
\end{aligned}$$

and so it is finite for every  $p$ . Then we evaluate  $\mathbb{E}(II)$ . In the following calculations we consider only integer even  $p \geq 6$ ; this suffices to prove the result for every  $p \geq 6$ :

$$\begin{aligned}
\mathbb{E}(II) &= \mathbb{E} \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1+sp}} \\
&\quad \times \left( \int_0^t \sum_{k \geq 1} \frac{\sin k\pi(t-s)}{k\pi} (\sin k\pi \xi - \sin k\pi \eta) d\beta_k(s) \right)^p d\xi d\eta \\
&= \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1+sp}} \mathbb{E} \sum_{k \geq 1} \left( \int_0^t \frac{\sin k\pi(t-s)}{k\pi} (\sin k\pi \xi - \sin k\pi \eta) d\beta_k(s) \right)^p d\xi d\eta \\
&\quad + \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1+sp}} \mathbb{E} \sum_{n=2}^{p-2} c_n \\
&\quad \times \left\{ \sum_{\substack{k, j \geq 1 \\ k \neq j}} \left( \int_0^t \frac{\sin k\pi(t-s)}{k\pi} |\sin k\pi \xi - \sin k\pi \eta| d\beta_k(s) \right)^n \right. \\
&\quad \times \left. \left( \int_0^t \frac{\sin j\pi(t-s)}{j\pi} |\sin j\pi \xi - \sin j\pi \eta| d\beta_j(s) \right)^{p-n} \right\} d\xi d\eta.
\end{aligned}$$

In the last passage the terms with  $n = 1$  or  $n = p - 1$  do not appear since they have null expectation, and  $c_n$  denotes a constant depending only on  $n$ . By applying the Burkholder–Davis–Gundy inequality, we get

$$\begin{aligned}
\mathbb{E}(II) &\leq c_p \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1+sp}} \sum_{k \geq 1} \\
&\quad \left( \int_0^t \frac{\sin^2 k\pi(t-s)}{k^2\pi^2} (\sin k\pi\xi ds - \sin k\pi\eta)^2 ds \right)^{p/2} d\xi d\eta \\
&\quad + c_p \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1+sp}} \sum_{n=2}^{p-2} c_n \\
&\quad \left\{ \sum_{\substack{k,j \geq 1 \\ k \neq j}} \left( \int_0^t \frac{\sin^2 k\pi(t-s)}{k^2\pi^2} (\sin k\pi\xi - \sin k\pi\eta)^2 ds \right)^{n/2} \right. \\
&\quad \left. \left( \int_0^t \frac{\sin^2 j\pi(t-s)}{j^2\pi^2} (\sin j\pi\xi - \sin j\pi\eta)^2 ds \right)^{(p-n)/2} \right\} d\xi d\eta \\
&\leq c_p t^{p/2} \sum_{k \geq 1} \frac{1}{k^p \pi^p} \int_0^1 \int_0^1 \frac{|\sin k\pi\xi - \sin k\pi\eta|^p}{|\xi - \eta|^{1+sp}} d\xi d\eta \\
&\quad + 2c_p t^{p/2} \sum_{n=2}^{p/2} c_n \sum_{\substack{k,j \geq 1 \\ k \neq j}} \frac{1}{k^n \pi^n} \frac{1}{j^{p-n} \pi^{p-n}} \int_0^1 \int_0^1 \\
&\quad \frac{|\sin k\pi\xi - \sin k\pi\eta|^n |\sin j\pi\xi - \sin j\pi\eta|^{p-n}}{|\xi - \eta|^{1+sp}} d\xi d\eta \\
&\leq c_p t^{p/2} \left\{ 2^{p(1-s-\epsilon)} \sum_{k \geq 1} \frac{1}{k^p \pi^p} \int_0^1 \int_0^1 \frac{|\sin k\pi\xi - \sin k\pi\eta|^{p(s+\epsilon)}}{|\xi - \eta|^{1+sp}} d\xi d\eta \right. \\
&\quad + \frac{2^{1+p(1-s-3\beta)}}{\pi^p} * \sum_{n=2}^{p/2} 2^{5n\beta} c_n \sum_{\substack{k,j \geq 1 \\ k \neq j}} \frac{1}{k^n} \frac{1}{j^{p-n}} \int_0^1 \int_0^1 \\
&\quad \left. \frac{|\sin k\pi\xi - \sin k\pi\eta|^{n(s-2\beta)} |\sin j\pi\xi - \sin j\pi\eta|^{(p-n)(s+3\beta)}}{|\xi - \eta|^{1+sp}} d\xi d\eta \right\}
\end{aligned}$$

$$\begin{aligned}
&\leq c_p T^{p/2} \left\{ 2^{p(1-s-\epsilon)} \sum_{k \geq 1} \frac{k^{p(s+\epsilon)} \pi^{p(s+\epsilon)}}{k^p \pi^p} \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1-p\epsilon}} d\xi d\eta \right. \\
&\quad + \frac{2^{1+p(1-s-3\beta)}}{\pi^p} \sum_{n=2}^{p/2} c_n \sum_{\substack{k, j \geq 1 \\ k \neq j}} \frac{k^{n(s-2\beta)} \pi^{n(s-2\beta)}}{k^n} \\
&\quad \left. \frac{k^{(p-n)(s+3\beta)} \pi^{(p-n)(s+3\beta)}}{j^{p-n}} \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1-3\beta p+5\beta n}} d\xi d\eta \right\} \\
&= c_p T^{p/2} \left\{ \frac{2^{p(1-s-\epsilon)}}{\pi^{p(1-s-\epsilon)}} \sum_{k \geq 1} \frac{1}{k^{p(1-s-\epsilon)}} \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1-p\epsilon}} d\xi d\eta \right. \\
&\quad + 2^{1+p(1-s-3\beta)} \sum_{n=2}^{p/2} \frac{c_n}{\pi^{p-5n\beta-ps-3p\beta}} \sum_{\substack{k, j \geq 1 \\ k \neq j}} \frac{1}{k^{n(1-s+2\beta)}} \\
&\quad \left. \frac{1}{j^{(p-n)(1-s-3\beta)}} \int_0^1 \int_0^1 \frac{1}{|\xi - \eta|^{1-3\beta p+5\beta n}} d\xi d\eta \right\}.
\end{aligned}$$

Take  $\epsilon > 0$  such that  $\epsilon < 1 - s$  and  $p > \frac{1}{1-s-\epsilon}$ . Next, remember that we have taken  $s = 1/2 + \beta$ ,  $\beta > 0$ . So for every  $n = 2, \dots, p/2$ ,  $n(1-s+2\beta) > 1$ . Now choose  $\beta$  such that for every  $n = 2, \dots, p/2$ ,  $(p-n)(1-s-3\beta) > 1$ . It is enough to find  $\beta$  such that  $p/2(1-s-3\beta) > 1$ . This leads to taking  $0 < \beta < 1/8 - 1/2p$ , that is,  $1/2 < s < 5/8 - 1/2p$ . With these choices, and with  $C_p$  a constant depending only on  $p$  and  $s$ , we get

$$\mathbb{E}(II) \leq C_p T^{p/2} \left( \sum_{k \geq 1} \frac{1}{k^{p(1-s-\epsilon)}} + \sum_{n=2}^{p/2} c_n \sum_{\substack{k, j \geq 1 \\ k \neq j}} \frac{1}{k^{n(1-s+2\beta)}} \frac{1}{j^{(p-n)(1-s-3\beta)}} \right) < \infty.$$

Thus we conclude that, a.s.,  $W_A^1(t) \in W_{p, \{0\}}^s([0, 1]) \subset B_{2,p, \{0\}}^s([0, 1])$ . Moreover, we claim that, a.s.,  $W_A^2(t) \in B_{2,p}^{s-1}([0, 1])$ . Indeed,

$$W_A^2(t) = \int_0^t \cos(\sqrt{\Lambda}(t-s)) dW_s = \sqrt{\Lambda} \left( \frac{1}{\sqrt{\Lambda}} \int_0^t \cos(\sqrt{\Lambda}(t-s)) dW_s \right).$$

By analogous calculations we have performed in order to prove that  $W_A^1(t) \in B_{2,p, \{0\}}^s([0, 1])$ , we can prove that

$$\left( \frac{1}{\sqrt{\Lambda}} \int_0^t \cos(\sqrt{\Lambda}(t-s)) dW(s) \right) \in B_{2,p}^s([0, 1]);$$

the difference with respect to  $W_A^1(t)$  is that there is  $\cos(\sqrt{\Lambda}(t-s))$  instead of  $\sin(\sqrt{\Lambda}(t-s))$ , so this process does not vanish on the boundary; on the contrary, the calculations are analogous to the ones proving that  $W_A^1(t) \in B_{2,p,\{0\}}^s([0,1])$ . Thus  $W_A^2(t) \in B_{2,p}^{s-1}([0,1])$ .

Next we want to show the existence of a version of the stochastic convolution in  $C([0,T], E)$ . We note that by the factorization method (see, e.g., [12]), for  $0 < \alpha < \frac{1}{2}$  we can write

$$\begin{aligned} W_A(t) &= \int_0^t e^{(t-s)A} G dW_s = \frac{\sin \pi \alpha}{\pi} \int_0^t \left[ \int_s^t (t-\sigma)^{\alpha-1} (\sigma-s)^{-\alpha} d\sigma \right] e^{(t-s)A} G dW_s \\ &= \frac{\sin \pi \alpha}{\pi} \int_0^t e^{(t-\sigma)A} (t-\sigma)^{\alpha-1} Y_\sigma d\sigma, \end{aligned}$$

where we have set  $Y_\sigma = \int_0^\sigma (\sigma-s)^{-\alpha} e^{(\sigma-s)A} G dW_s$ . If we show that for some  $q > 2$ ,  $Y$  is in  $L^q([0,T], E)$ ,  $\mathbb{P}$ -almost everywhere, then the stochastic convolution admits a continuous version in  $E$ . We take  $q = p$ , so that  $q \geq 6$ , and we prove the stronger condition

$$\mathbb{E} \int_0^T \|Y_\sigma\|_E^p d\sigma < \infty.$$

We write the two components of  $Y_\sigma$ ,

$$Y_\sigma = \begin{pmatrix} Y_\sigma^1 \\ Y_\sigma^2 \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{\Lambda}} \int_0^\sigma (\sigma-s)^{-\alpha} \sin(\sqrt{\Lambda}(\sigma-s)) dW_s \\ \int_0^\sigma (\sigma-s)^{-\alpha} \cos(\sqrt{\Lambda}(\sigma-s)) dW_s \end{pmatrix}.$$

We evaluate, at first,

$$\begin{aligned} &\mathbb{E} \int_0^T \|Y_\sigma^1\|_{B_{2,p,\{0\}}^s}^p d\sigma \\ &\leq c \mathbb{E} \int_0^T \|Y_\sigma^1\|_{W_{p,\{0\}}^s}^p d\sigma \\ &= c \mathbb{E} \int_0^T \int_0^1 \left| \int_0^\sigma (\sigma-s)^{-\alpha} \sum_{k \geq 1} \frac{\sin k\pi(\sigma-s)}{k\pi} \sin k\pi\xi d\beta_k(s) \right|^p d\xi d\sigma \\ &\quad + c \mathbb{E} \int_0^T \int_0^1 \int_0^1 \frac{\left| \int_0^\sigma (\sigma-s)^{-\alpha} \sum_{k \geq 1} \frac{\sin k\pi(\sigma-s)}{k\pi} (\sin k\pi\xi - \sin k\pi\eta) d\beta_k(s) \right|^p}{|\xi - \eta|^{1+sp}} d\xi d\eta d\sigma. \end{aligned}$$

By an analogous procedure we have used to evaluate the norm of  $W_A^1(t)$ , we can get that

$$\mathbb{E} \int_0^T \|Y_\sigma^1\|_{B_{2,p,\{0\}}^s}^p d\sigma < \infty.$$

In order to evaluate  $\mathbb{E} \int_0^T \|Y_\sigma^2\|_{B_{2,p}^{s-1}}^p d\sigma$  we note that  $\sqrt{\Lambda} : B_{2,p}^s \longrightarrow B_{2,p}^{s-1}$  continuously. Thus

$$\begin{aligned} \mathbb{E} \int_0^T \|Y_\sigma^2\|_{B_{2,p}^{s-1}}^p d\sigma &= \mathbb{E} \int_0^T \left\| \int_0^\sigma (\sigma-s)^{-\alpha} \cos\left(\sqrt{\Lambda}(\sigma-s)\right) dW_s \right\|_{B_{2,p}^{s-1}}^p d\sigma \\ &= \mathbb{E} \int_0^T \left\| \sqrt{\Lambda} \int_0^\sigma \frac{1}{\sqrt{\Lambda}} (\sigma-s)^{-\alpha} \cos\left(\sqrt{\Lambda}(\sigma-s)\right) dW_s \right\|_{B_{2,p}^{s-1}}^p d\sigma \\ &\leq c \mathbb{E} \int_0^T \left\| \int_0^\sigma \frac{1}{\sqrt{\Lambda}} (\sigma-s)^{-\alpha} \cos\left(\sqrt{\Lambda}(\sigma-s)\right) dW_s \right\|_{B_{2,p}^{s-1}}^p d\sigma < \infty. \end{aligned}$$

We have achieved the desired estimate

$$\mathbb{E} \int_0^T \|Y_\sigma\|_E^p d\sigma < \infty,$$

from which we get that the stochastic convolution  $W_A(t)$  admits a version in  $C([0, T], E)$ .  $\square$

We remark that Hypothesis 3.16 is satisfied; indeed,  $G(\Xi) \subset E$ .

Now, let us consider, for  $0 \leq t \leq \tau \leq T$  and  $\xi \in [0, 1]$ , the following controlled stochastic wave equation:

$$(7.17) \quad \begin{cases} \frac{\partial^2}{\partial \tau^2} y(\tau, \xi) = \frac{\partial^2}{\partial \xi^2} y(\tau, \xi) + u(\tau, \xi) + \dot{W}(\tau, \xi), \\ y(\tau, 0) = y(\tau, 1) = 0, \\ y(t, \xi) = x_0(\xi), \\ \frac{\partial y}{\partial \tau}(t, \xi) = x_1(\xi). \end{cases}$$

$\dot{W}(\tau, \xi)$  is a space-time white noise on  $[0, T] \times [0, 1]$  and  $u(\tau, \cdot)$  is an admissible control, that is, a predictable process

$$\left( \Omega, \mathcal{F}, (\mathcal{F}_\tau)_{\tau \geq 0}, \mathbb{P} \right) \rightarrow L^2(0, 1),$$

taking values in the subset  $\mathcal{U} \subset L^2[0, 1]$ ,  $\mathcal{U} = \{v \in L^2[0, 1] \mid v : [0, 1] \longrightarrow [-\delta, \delta]\}$ . Equation (7.17) can be rewritten in an abstract way in the following form:

$$(7.18) \quad \begin{cases} dX_\tau^u = AX_\tau^u d\tau + Gu_\tau d\tau + GdW_\tau, & \tau \in [t, T], \\ X_t^u = x, \end{cases}$$

where  $\{W_\tau, \tau \geq 0\}$  is a cylindrical Wiener process in  $L^2([0, 1])$  with respect to the filtration  $(\mathcal{F}_\tau)_{\tau \geq 0}$ .

Moreover, we introduce the cost functional

$$\gamma(t, x_0, x_1, u) = \mathbb{E} \int_t^T \left[ \sum_{i=1}^n l(s, \xi_i, y(s, \xi_i)) + \int_0^1 \frac{u^2(s, \xi)}{2} d\xi \right] ds + \mathbb{E} \sum_{i=1}^n k(\xi_i, y(T, \xi_i)).$$

The optimal control problem is to minimize  $\gamma$  over all admissible controls. To satisfy Hypothesis 5.2 we have to assume the following.

*Hypothesis 7.9.* We make the following assumptions:

1. For every  $i = 1, \dots, n$ ,  $l(\cdot, \xi_i, \cdot) : [0, T] \times \mathbb{R} \rightarrow \mathbb{R}$  is continuous and bounded, and the map  $l(\tau, \xi_i, \cdot) : \mathbb{R} \rightarrow \mathbb{R}$  is differentiable and there exists  $c_1$  such that

$$|\nabla_x l(\tau, \xi_i, x) h| \leq c_1 L |h|$$

for every  $\tau \in [0, T]$  and  $x, h \in \mathbb{R}$ .

2. For every  $i = 1, \dots, n$ ,  $k(\xi_i, \cdot) : [0, 1] \times \mathbb{R} \rightarrow \mathbb{R}$  is continuous and  $k(\xi_i, \cdot) \in C_b^1(\mathbb{R})$ ; moreover,  $|\nabla_x k(\xi_i, x)| \leq c_2$ .
3.  $x_0 \in H^1([0, 1])$  and  $x_1 \in L^2([0, 1])$ .

Let  $\Pi_1 : E \rightarrow B_{2,p,\{0\}}^s([0, 1])$  be the projection on the first component of  $E$ . We set

$$g(s, x) + \frac{1}{2} \|u\|_{L^2(0,1)}^2 = \sum_{i=1}^n l(s, \xi_i, \Pi_1 x(\xi_i)) + \int_0^1 \frac{u^2(s, \xi)}{2} d\xi,$$

$$\phi(x) = \sum_{i=1}^n k(\xi_i, \Pi_1 x(\xi_i)) d\xi.$$

In abstract formulation, the cost functional can be written as

$$J(t, x, u) = \mathbb{E} \int_t^T \left[ g(s, X_s^u) + \frac{1}{2} \|u_s\|_{L^2(0,1)}^2 \right] ds + \mathbb{E} \phi(X_T^u).$$

With Hypothesis 7.9,  $\phi$  and  $g$  satisfy Hypothesis 5.2.

The Hamiltonian is given by

$$\psi(t, x, z) = g(t, x) + \inf_u \left\{ \frac{1}{2} \|u_s\|_{L^2(0,1)}^2 + \int_0^1 z(\xi) u(s, \xi) d\xi \right\}.$$

$\psi$  and  $\phi$  satisfy Hypothesis 4.1. In fact, to verify Gâteaux differentiability of  $g$  and  $\phi$  with respect to  $x \in E$ , we note that both  $g$  and  $\phi$  depend only on  $\Pi_1 x$ . So it suffices to show Gâteaux differentiability with respect to  $\Pi_1 x \in B_{2,p,\{0\}}^s([0, 1])$ . Indeed,  $g(s, \cdot, u)$  and  $\phi(\cdot)$  are defined for  $\Pi_1 x \in C([0, 1])$ , and they are Gâteaux differentiable in  $C([0, 1])$ . Thus they are also Gâteaux differentiable with respect to  $\Pi_1 x \in B_{2,p,\{0\}}^s([0, 1])$ . Differentiability with respect to  $z$  can be proved, as we have done while treating the controlled heat equation; see section 7.1.

The process  $u$  turns out to be an admissible control and  $(\Omega, \mathcal{F}, \mathcal{F}_\tau, \mathbb{P}, W, u, X^u)$  turns out to be an a.c.s. We want to study the optimal control problem related to (7.15).

We write the Hamilton–Jacobi–Bellman equation relative to (7.4):

$$(7.19) \quad \begin{cases} \frac{\partial v}{\partial t}(t, x) = -\mathcal{A}_t v(t, x) - \psi(t, x, \nabla v(t, x) G), & t \in [0, T], \ x \in H, \\ u(T, x) = \phi(x). \end{cases}$$

**THEOREM 7.10.** *Assume that Hypothesis 7.9 is satisfied. Then (7.19) has a unique mild solution  $v$ , and, moreover, for all a.c.s.'s  $(W, u, X^u)$  we have  $J(t, x, (W, u, X^u)) \geq v(t, x)$ , and the equality holds if and only if (5.12) holds. If (5.13) holds, there exists an optimal a.c.s.*

**Acknowledgments.** I would like to thank Marco Fuhrman and Gianmario Tesitore for their constant interest in this work, Alessandra Lunardi for suggestions about interpolation theory and Besov spaces, and Susanna Piazzera for bibliographical references on delay equations.

## CONTROL LYAPUNOV FUNCTIONS AND ZUBOV'S METHOD\*

FABIO CAMILLI<sup>†</sup>, LARS GRÜNE<sup>‡</sup>, AND FABIAN WIRTH<sup>§</sup>

**Abstract.** For finite-dimensional nonlinear control systems we study the relation between asymptotic null-controllability and control Lyapunov functions. It is shown that control Lyapunov functions (CLFs) may be constructed on the domain of asymptotic null-controllability as viscosity solutions of a first order PDE that generalizes Zubov's equation. The solution is also given as the value function of an optimal control problem from which several regularity results may be obtained.

**Key words.** asymptotic null-controllability, control Lyapunov functions, Hamilton–Jacobi–Bellman equation, viscosity solutions, Zubov's method

**AMS subject classifications.** 93D10, 35B37, 49L25

**DOI.** 10.1137/06065129X

**1. Introduction.** We consider finite-dimensional control systems of the form

$$(1.1) \quad \dot{x}(t) = f(x(t), u(t)),$$

where  $x \in \mathbb{R}^n$  denotes the state,  $u \in \mathbb{R}^m$  denotes the input, and  $f$  is sufficiently regular with  $f(0, 0) = 0$ . We call a point  $x_0 \in \mathbb{R}^n$  *asymptotically controllable* to 0 if there exists a measurable, essentially bounded function  $u_0 : \mathbb{R}_+ \rightarrow \mathbb{R}^m$  such that the corresponding solution  $\varphi(t, x_0, u_0)$  of (1.1) satisfies  $\varphi(t, x_0, u_0) \rightarrow 0$  for  $t \rightarrow \infty$ . The *domain of asymptotic null-controllability* is the collection of all points that are asymptotically controllable to 0. The main results of this paper are twofold: On the one hand, we provide a converse theorem for maximal *control Lyapunov functions* (CLFs) on the domain of asymptotic null-controllability. On the other hand, we consider a generalized Zubov equation and prove that the maximal CLF is the unique viscosity solution of this equation. Thus beyond the proof of existence of CLFs, a way to their numerical generation is provided.

The construction of CLFs in this paper relies on optimal control methods as they are frequently used in Lyapunov theory. One of the contributions of the paper is to present easily checkable conditions on the running cost that result in an appropriate CLF and give rise to a tractable Hamilton–Jacobi equation.

Converse theorems have a fundamental role in Lyapunov theory, as they state that certain stability properties imply the existence of a Lyapunov function. The direct implication that the existence of a Lyapunov function implies a stability property is usually much easier to prove. Early converse results were obtained by Persidskii (see the discussion in [20, Chapter VI]), Massera [26], and Kurčevič' [21]. In recent times these results have been extended in several directions to cover perturbed systems and differential inclusions [23, 12, 37, 7].

While for linear systems a constructive procedure to find Lyapunov functions has already been given by Lyapunov, the first general constructive procedure to find Lyapunov functions was obtained by Zubov [39]. Namely, a Lyapunov function on the domain of attraction of an asymptotically stable fixed point  $x^* \in \mathbb{R}^n$  of the system

$$\dot{x}(t) = f(x(t)), \quad t \in \mathbb{R}, x \in \mathbb{R}^n,$$

may be found by solving the first order PDE, called Zubov's equation,

$$Dv(x)f(x) = -h(x)(1 - v(x))\sqrt{1 + \|f\|^2}, \quad x \in \mathbb{R}^n,$$

under the condition that  $v(0) = 0$ . Here  $h$  is an auxiliary function; see [39, 20] for details. This method has been recently extended by the authors to the case of perturbed systems; see [9], where also a discussion of the impact of Zubov's result may be found. Further constructive approaches valid for  $C^2$  systems and based on approximations by radial basis functions (respectively, on linear programming methods) have recently been described in [18, 19].

While for (perturbed) ordinary differential equations the property of interest is stability, for systems with control inputs a basic question concerns the existence of control functions steering the system to a desired target. In contrast to the case of asymptotically stable fixed points of ordinary differential equations, for which smooth Lyapunov functions always exist, it is not reasonable to require too many regularity properties of Lyapunov functions for controllability questions for systems of the form (1.1). For this reason it is now standard to formulate the concept of a CLF in non-differential terms. Recall that a function  $V : \mathbb{R}^n \rightarrow \mathbb{R}$  is called positive definite if  $V(x) \geq 0$  for all  $x \in \mathbb{R}^n$  and  $V(x) = 0$  iff  $x = 0$ . The function  $V$  is proper if preimages of compact sets are compact. A positive definite, proper function  $V$  is called a CLF for (1.1) if there is a positive definite function  $W$  such that for every compact set  $X \subset \mathbb{R}^n$  there is a compact set  $U_X$  of control values so that  $V$  is a continuous viscosity supersolution of

$$(1.2) \quad \max_{u \in U_X} -DV(x)f(x, u) \geq W(x), \quad x \in X.$$

For the definition of viscosity solutions we refer to [3]. In many articles CLFs are defined in terms of proximal subgradients of  $V$ , but the two notions are in fact equivalent [10].

The interest in the theory of control Lyapunov has received widespread attention in recent years, in particular in connection with the design of stabilizing feedbacks. While design techniques using Lyapunov functions have been popular in applied control theory for a long time, the systematic study of converse theorems for CLFs only started with Artstein [1], who proved for the case of systems affine in the control term  $u$  that the existence of a smooth CLF is equivalent to stabilizability by continuous state feedback. For general systems of the form (1.1) the existence of a global continuous CLF is equivalent to global asymptotic null-controllability [31]. Interestingly, the existence of a differentiable CLF is equivalent to the existence of (discontinuous) stabilizing feedbacks that are robust with respect to perturbations in the measurement of the state [22].

Now, in general, asymptotic null-controllability does not imply the existence of continuous stabilizing feedback as there may be topological obstructions to this which even carry over to the case of upper semicontinuous set-valued feedbacks [8, 13, 29]. For this reason discontinuous feedbacks and associated solution concepts have been

one of the focal points of the research on CLFs in recent times starting with [11]. In this context it has been shown by Clarke et al. [10] and Rifford [27, 28] using tools from nonsmooth analysis that semiconcavity of the CLF is an essential tool in order to establish the existence of feedback with nice properties.

Usually, the knowledge of a CLF requests a certain structure of the control system, while a general procedure for its determination is not available. Constructive approaches have therefore received widespread attention in the literature, most notably with techniques known as backstepping and forwarding [17, 30], which, however, rely heavily on the differentiability of the CLF that is obtained. In this article we aim to derive a constructive approach by going back to the original ideas for the construction of CLFs. Here constructive is to be understood in the way that we determine a class of PDEs which have unique solutions in the viscosity sense that are maximal CLFs on the domain of asymptotic null-controllability.

It is a classical approach to the problem to regard CLFs as solutions of steady state Hamilton–Jacobi (HJ) equations. In the uncontrolled case this may be regarded as one of the central elements of the work of Zubov [20]. In [16] the connection between smooth CLFs and HJ equations has been studied in detail. In particular, it is shown in that paper that smooth CLFs may always be interpreted as value functions of an appropriate optimal control problem. This “inverse optimality” property can be exploited in several ways [17]. In a different approach, in [15] a CLF was obtained by a truncating series expansion of analytical solutions of HJ equations in an approach very similar to early studies around Zubov’s equation.

In the present paper we use ideas from [9], where, for the case of a perturbed system, the classical Zubov method was reinterpreted using a suitable notion of weak solution. For controlled or perturbed systems Zubov’s equation becomes a nonlinear first order PDE of HJ type, and it is well known that this class of equations does not admit, in general, classical solutions. Therefore a suitable concept of weak solution has to be introduced, and the one of viscosity solution seems to be appropriate; see [9, 25]. In the construction of the corresponding result for CLFs, several additional technical obstacles have to be overcome, which stem from the possibility of solutions with finite escape time and the unboundedness of the control set, both of which pose no problem in the perturbed case. To this end reparametrization techniques are used—an idea which was introduced in [5] and has been applied by various authors.

A problem similar to the CLF construction in this paper has been studied in [24], in which optimal control and viscosity methods are used in relation to the problem of steering the state of a system to a prescribed target. This leads to an optimal control problem with a positive but vanishing Lagrangian; see [25, 24] for further references. In [24] a “small-time controllability” property is used, which requires in particular that the target can be reached exactly in finite time starting from small neighborhoods of it. In the general context of CLFs, this reachability property is undesirable, so that we have to apply different arguments.

We use this generalization of Zubov’s method to construct a CLF for a finite-dimensional nonlinear control system that is asymptotically null-controllable in a neighborhood of the origin. Our aim is to determine a CLF as (i) an optimal value function of a suitable control problem and (ii) a unique viscosity solution to a suitable HJ equation which is a generalization of the Zubov’s equation.

Concerning the first point, i.e., the connection between CLF and optimal control problems, our procedure can be viewed as an extension of [31], where the equivalence between asymptotic null-controllability and the existence of a CLF has been proved

using an optimal control approach. The significant advantage of the characterization of a CLF as a *unique* viscosity solution of the generalized Zubov equation is that this characterization can be used as the basis for the numerical approximation of the CLF.

From the point of view of the PDE approach, the equation presents some difficulties when attacked using the standard theory of viscosity solution because of the unbounded control set; see [4, 5, 14, 36, 35] for some related papers. In the proof of the necessary comparison result we use the local asymptotic controllability to obtain a local comparison result in a neighborhood of the origin. We then extend the comparison result to all  $\mathbb{R}^n$ , taking advantage, as in the classical Zubov method, of the freedom in the choice of cost function of the associated control problem. For this reason we can make rather general assumptions on the dependence of the dynamics with respect to the control variable compensating them with an appropriate choice of the cost. An example for an explicit construction of the cost function satisfying all requirements is provided.

The comparison result extends results in [36, 35] at the price of studying a much more specific situation. The main difference is that in the setting studied in this paper a uniqueness result is obtained.

We proceed as follows: In the ensuing section 2 the class of systems under consideration is defined, and we prove some preliminary results. In section 3 the optimal control problem that characterizes the domain of asymptotic null-controllability is introduced, and it is shown that under suitable conditions the corresponding value function is continuous, positive definite, and proper on the domain of asymptotic null-controllability. In section 4 we show that the value function of the optimal control problem is the unique viscosity solution of the generalized Zubov equation. In section 5 we discuss an approximation of the problem with an unbounded control set with a sequence of problems with a bounded control set. In the last section we discuss the necessity of our assumptions at the hand of a few examples. It is also shown that for the classical linear quadratic control problem the general equations of this paper reduce to the standard algebraic Riccati equation.

**2. The domain of null-controllability.** We consider nonlinear control systems of the type

$$(2.1) \quad \dot{x}(t) = f(x(t), u(t)),$$

where  $f : \mathbb{R}^n \times U \rightarrow \mathbb{R}^n$  is continuous,  $U \subset \mathbb{R}^m$  is a closed set, and the space of admissible control functions is given by

$$u \in \mathcal{U} := L^\infty([0, \infty), U).$$

Solutions corresponding to an initial value  $x$  and a control  $u \in \mathcal{U}$  at time  $t$  are denoted by  $\varphi(t, x, u)$ , which are defined on a maximal positive interval of definition  $[0, T_{\max}(x, u))$ , where we do not exclude the case that  $T_{\max}(x, u) < \infty$ , i.e., that solutions explode. In the following the open ball of radius  $r$  around a point  $z \in \mathbb{R}^p$  is denoted by  $B(z, r)$ .

Uniqueness of solutions is a consequence of our further standard assumption on  $f$ . These are formulated using comparison functions, a fashionable approach these days.<sup>1</sup>

---

<sup>1</sup>As usual we call a function  $\alpha$  of class  $\mathcal{K}_\infty$  if it is a homeomorphism of  $[0, \infty)$ , and a continuous function  $\beta$  in two real nonnegative arguments is called of class  $\mathcal{KL}$  if it is of class  $\mathcal{K}_\infty$  in the first and decreasing to zero in the second argument.

(H0) There exists  $\gamma \in \mathcal{K}_\infty$  such that for any  $R > 0$  there is  $C_R > 0$ , with

$$\|f(x, u) - f(y, u)\| \leq C_R(1 + \gamma(\|u\|))\|x - y\|,$$

for all  $x, y$  with  $\|x\|, \|y\| \leq R$ .

(H1)  $f(0, 0) = 0$ .

(H2) There exist an open ball  $B(0, r)$ , a constant  $\bar{u} > 0$ , and  $\beta \in \mathcal{KL}$  such that for any  $x \in B(0, r)$  there exists  $u_x \in \mathcal{U}$  with  $\|u_x\|_\infty \leq \bar{u}$ ,  $T_{\max}(x, u_x) = \infty$ , and

$$\|\varphi(t, x, u_x)\| \leq \beta(\|x\|, t) \quad \forall t \geq 0.$$

*Remark 2.1.* The Lipschitz assumption (H0) is weaker than the following assumption: For any  $R > 0$  there exists  $C_R > 0$ , with

$$(2.2) \quad \|f(x, u) - f(y, u)\| \leq C_R(1 + \|u\|)\|x - y\|,$$

for all  $x, y$  with  $\|x\|, \|y\| \leq R$ .

Assumption (2.2) is used in many papers on viscosity solutions, in particular in [35, 36], whose results we will use later. In order to be able to use these results under the weaker assumption (H0), we define the map  $R : \mathbb{R}^m \rightarrow \mathbb{R}^m$  by  $R(u) = \gamma^{-1}(\|u\|)u/\|u\|$  and consider the vector field

$$\hat{f}(x, u) = f(x, R(u)),$$

with  $u \in \tilde{U} := R^{-1}(u)$ . This input-transformed system satisfies

$$\|\hat{f}(x, u) - \hat{f}(y, u)\| \leq C_R(1 + \gamma(\|R(u)\|))\|x - y\| = C_R(1 + \|u\|)\|x - y\|,$$

i.e., (2.2). Hence by applying the results from [35, 36] to  $\hat{f}$ , these immediately carry over to  $f$  under the weaker assumption (H0).

Property (H2) is a local asymptotic controllability property, which ensures that at least from a neighborhood of 0 the system may be steered to 0.

For certain systems it makes sense to strengthen this local asymptotic controllability property (H2) by requiring that  $u_x$  not only is bounded but also converges to 0 as  $t \rightarrow \infty$ . In this case we can strengthen (H2) to the so-called *small control property*:

(H2') There exist an open ball  $B(0, r)$  and  $\beta \in \mathcal{KL}$  such that for any  $x \in B(0, r)$  there exists  $u_x \in \mathcal{U}$  with  $T_{\max}(x, u_x) = \infty$  and

$$\|\varphi(t, x, u_x)\| + \|u_x(t)\| \leq \beta(\|x\|, t), \quad \text{a.e. } t \geq 0.$$

Note that (H2') implies (H2) with  $\bar{u} = \beta(r, 0)$ .

It is known [32] that for any  $\beta \in \mathcal{KL}$  there exist two functions  $\alpha_1, \alpha_2 \in \mathcal{K}_\infty$  such that  $\beta(r, t) \leq \alpha_2(\alpha_1(r)e^{-t})$ . These functions can be computed from  $\beta$ ; e.g., in the case of exponential convergence, i.e.,  $\beta(r, t) = ce^{-\sigma t}r$  for  $c, \sigma > 0$ , one obtains  $\alpha_1(r) = r^{1/\sigma}$  and  $\alpha_2(r) = cr^\sigma$ . Note that (H2) or (H2') immediately implies  $\beta(r, 0) \geq r$  and thus

$$\alpha_2 \circ \alpha_1(r) = \alpha_2(\alpha_1(r)e^{-0}) \geq \beta(r, 0) = r.$$

We note for later use that, by applying  $\alpha_1^{-1} \circ \alpha_2^{-1} = (\alpha_2 \circ \alpha_1)^{-1}$  on both sides of this inequality, we obtain

$$(2.3) \quad r \geq \alpha_1^{-1} \circ \alpha_2^{-1}(r).$$

For ease of presentation we will work with these two functions from now on. Furthermore, we will from now on tacitly assume that  $T_{\max}(x, u) = \infty$  if we write  $\varphi(t, x, u) \rightarrow 0$  as  $t \rightarrow \infty$ .

We define the *domain of null-controllability* by

$$\mathcal{D}_0 := \{x \in \mathbb{R}^n \mid \text{there exists } u \in \mathcal{U} \text{ with } \|\varphi(t, x, u)\| \rightarrow 0 \text{ for } t \rightarrow \infty\}$$

and the *first hitting time* with respect to  $B(0, r)$  by

$$t(x, u) := \inf\{t \geq 0 \mid \varphi(t, x, u) \in B(0, r)\},$$

with the convention  $\inf \emptyset = \infty$ . The following lemma shows how  $\mathcal{D}_0$  and  $t(x, u)$  are related.

LEMMA 2.2. *The set  $\mathcal{D}_0$  is given by*

$$\mathcal{D}_0 = \left\{x \in \mathbb{R}^n \mid \inf_{u \in \mathcal{U}} t(x, u) < \infty\right\}.$$

*Proof.* If we find  $u \in \mathcal{U}$  with  $t(x, u) < \infty$ , then for some  $t(x, u) < t_1$  we have  $\varphi(t_1, x, u) \in B(0, r)$ , and we can concatenate  $u|_{[0, t_1]}$  with the control  $u_{\varphi(t_1, x, u)}$  from (H2), which implies  $\varphi(t, x, u) \rightarrow 0$ . Hence we obtain

$$\mathcal{D}_0 \subseteq \left\{x \in \mathbb{R}^n \mid \inf_{u \in \mathcal{U}} t(x, u) < \infty\right\}.$$

Conversely, if  $x \in \mathcal{D}_0$ , then we have  $\varphi(t, x, u) \rightarrow 0$  for some suitable  $u \in \mathcal{U}$ , which implies  $\varphi(t_1, x, u) \in B(0, r)$  for some  $t_1 > 0$ , and consequently  $t(x, u) \leq t_1 < \infty$ , which implies the converse direction.  $\square$

For the formulation of the next result recall that a set  $M$  is called *viable* (or controlled or weakly invariant) if for every  $x \in M$  there is a  $u \in \mathcal{U}$  such that  $\varphi(t, x, u) \in M$  for all  $t \geq 0$  (see [2]). In the following the convex hull of a set  $M$  is denoted by  $\text{co } M$ .

PROPOSITION 2.3. *Assume (H0), (H1), and (H2) or (H2'). Then the following properties hold:*

- (i)  $\text{cl } B(0, r) \subset \mathcal{D}_0$ ;
- (ii) *the set  $\mathcal{D}_0$  is open, connected, and viable.*

*Proof.* (i) It is clear that  $B(0, r) \subset \mathcal{D}_0$ . In order to show  $\text{cl } B(0, r) \subset \mathcal{D}_0$ , pick  $x \in \partial B(0, r)$  and a sequence  $\{x_n\} \subset B(0, r)$  with  $\lim_{n \rightarrow \infty} x_n = x$ . By assumption for each  $x_n$  there exists a control  $u_n \in \mathcal{U} \cap L^\infty(\mathbb{R}, B(0, \bar{u}))$  such that  $\|\varphi(t, x_n, u_n)\| \leq \alpha_2(\alpha_1(r)e^{-t})$ . This shows that on each compact interval the solutions are bounded uniformly in  $n$ . Since, furthermore, the  $u_n$  are uniformly bounded by continuity, we get  $\lim_{n \rightarrow \infty} \|\varphi(t, x_n, u_n) - \varphi(t, x, u_n)\| = 0$  for each  $t \geq 0$ . Thus, by picking  $t^* > 0$  such that  $\alpha_2(\alpha_1(r)e^{-t^*}) \leq r/2$  for  $n^*$  sufficiently large, we obtain  $\|\varphi(t^*, x, u_{n^*})\| \leq 3r/4$ ; hence,  $\varphi(t^*, x, u_{n^*}) \in B(0, r)$ , and consequently  $t(x, u_{n^*}) < \infty$ . Now Lemma 2.2 yields the assertion.

(ii) Let  $x_0 \in \mathcal{D}_0$  and  $u \in \mathcal{U}$ , with  $\varphi(t, x_0, u) \rightarrow 0$  for  $t \rightarrow \infty$ . Then there exists  $T > 0$  such that  $\varphi(T, x_0, u) \in B(0, r)$ . By continuous dependence on the initial value we obtain

$$\varphi(T, x, u) \in B(0, r)$$

for all  $x$  in a neighborhood of  $x_0$ . Thus  $t(\cdot, u)$  is finite on that neighborhood, which shows that it is contained in  $\mathcal{D}_0$ . As  $x_0$  was arbitrary, this shows the assertion.

Since for any  $x \in \mathcal{D}_0$  there exists a trajectory from  $x$  to  $B(0, r)$ , we obtain that  $\mathcal{D}_0$  is connected.

In order to see viability, consider a point  $x \in \mathcal{D}_0$  and the trajectory  $\varphi(t, x, u) \rightarrow 0$ . Clearly, each point  $x(t) = \varphi(t, x, u)$ ,  $t \geq 0$ , can be controlled to the origin by the control  $u(t + \cdot)$ ; thus  $x(t) \in \mathcal{D}_0$ , and hence  $\varphi(t, x, u) \in \mathcal{D}_0$  for all  $t \geq 0$ ; i.e.,  $\mathcal{D}_0$  is viable.  $\square$

*Remark 2.4.* Note that the domain of null-controllability  $\mathcal{D}_0$  is in general not diffeomorphic to  $\mathbb{R}^n$ . This is in contrast to the theory of domains of attraction of (perturbed) ordinary differential equations, i.e., the set  $\{x_0 \in \mathbb{R}^n : \varphi(t, x_0, u) \rightarrow 0 \text{ as } t \rightarrow +\infty \text{ for any } u \in \mathcal{U}\}$ . In the case of asymptotically stable fixed points the domain of attraction is diffeomorphic to  $\mathbb{R}^n$  even for perturbed systems; see, e.g., [9, 38].

**3. Characterization of  $\mathcal{D}_0$  using optimal control.** In this section we describe how to characterize the domain of asymptotic null-controllability via an optimal control problem and show continuity of the corresponding value function. In order to set up the problem we need a running cost  $g : \mathbb{R}^n \times U \rightarrow \mathbb{R}$ . The assumptions on  $g$  are as follows:

(H3) The function  $g : \mathbb{R}^n \times U \rightarrow \mathbb{R}$  is continuous and satisfies (H0) with the same  $\gamma \in \mathcal{K}_\infty$  as  $f$ . Furthermore, for all  $c > 0$  we have

$$\inf \{g(x, u) \mid \|x\| \geq c, u \in U\} =: g_c > 0.$$

Note that the assumption “with the same  $\gamma \in \mathcal{K}_\infty$  as  $f$ ” can always be met by enlarging the  $\gamma$  from (H0) for  $f$ , if necessary.

We need to ensure convergence of the integral cost that is introduced shortly for the “right” stabilizing solutions. Recall that we use the simplification  $\beta(r, t) \leq \alpha_2(\alpha_1(r)e^{-t})$  for  $\beta$  from (H2) and choose some arbitrary  $\eta > 0$ . We assume that there exists a constant  $C > 0$  such that

$$(H4) \quad g(x, u) \leq C(\alpha_2^{-1}(\|x\|))^\eta \quad \forall (x, u) \in B(0, r) \times B(0, \bar{u}),$$

$$(H5) \quad g(x, u) \geq \|f(x, u)\| + \gamma(\|u\|) \text{ whenever } \|x\| \geq 2r \text{ or } \|u\| \geq 2\bar{u}.$$

*Remark 3.1.* If the small control asymptotic controllability property (H2') holds, then we can weaken assumption (H4) to

$$(H4') \quad g(x, u) \leq C(\alpha_2^{-1}(\|x\| + \|u\|))^\eta \quad \forall (x, u) \in B(0, r) \times B(0, \bar{u}).$$

In what follows we will always assume that either (H2) and (H4) or (H2') and (H4') hold.

We now define the functional

$$(3.1) \quad J(x, u) := \begin{cases} \int_0^\infty g(\varphi(t, x, u), u(t)) dt & \text{if } T_{\max}(x, u) = \infty, \\ \infty & \text{otherwise,} \end{cases}$$

the (extended real-valued) optimal value function

$$(3.2) \quad V(x) := \inf_{u \in \mathcal{U}} J(x, u), \quad x \in \mathbb{R}^n,$$

and the function

$$(3.3) \quad v(x) := 1 - e^{-V(x)}, \quad x \in \mathbb{R}^n.$$

Note that both  $V$  and  $v$  satisfy appropriate dynamic programming principles (see, for example, [35, 36]); i.e., for each  $T > 0$  we have

$$(3.4) \quad V(x) = \inf_{u \in \mathcal{U}} \left\{ \int_0^T g(\varphi(t, x, u), u(t)) dt + V(\varphi(T, x, u)) \right\},$$

and

$$(3.5) \quad v(x) = \inf_{u \in \mathcal{U}} \{1 + G(x, T, u)(v(\varphi(T, x, u)) - 1)\},$$

where

$$G(x, T, u) := \exp \left( - \int_0^T g(\varphi(t, x, u), u(t)) dt \right).$$

We now investigate the properties of  $V$  and  $v$ . For this purpose we need the following observation on the solutions of (2.1). Using the function  $\gamma$  from (H0), we define for  $u \in \mathcal{U}$

$$\|u\|_{\gamma, T} := \int_0^T \gamma(\|u(t)\|) dt.$$

LEMMA 3.2. *Let  $T > 0$ . If  $x \in \mathbb{R}^n$  and  $u \in \mathcal{U}$  are such that  $\|\varphi(t, x, u)\| \geq 2r$ ,  $t \in [0, T]$ , or  $\|u(t)\| \geq 2\bar{u}$  a.e.  $t \in [0, T]$ , then*

$$\int_0^T g(\varphi(t, x, u), u(t)) dt \geq \|\varphi(T, x, u) - x\| + \|u\|_{\gamma, T}.$$

*Proof.* Using (H5), we have that

$$\int_0^T g(\varphi(t, x, u), u(t)) dt \geq \int_0^T \|f(\varphi(t, x, u), u(t))\| dt + \int_0^T \gamma(\|u(t)\|) dt,$$

and the claim follows.  $\square$

PROPOSITION 3.3. *Assume (H0)–(H4) or the respective variants from Remark 3.1. Then*

- (i) *the inequalities  $V(x) < \infty$  and  $v(x) < 1$  hold iff  $x \in \mathcal{D}_0$ , and*
- (ii) *if in addition (H5) holds, then  $V(x) = 0 \Leftrightarrow x = 0$  and  $v(x) = 0 \Leftrightarrow x = 0$ .*

*Proof.* From the definition of  $v$  it immediately follows that the claims for  $V$  and  $v$  are equivalent. We show the statements for  $V$ .

(i) Pick a point  $x \in \mathcal{D}_0$ . Then there exist  $u \in \mathcal{U}$  and  $t_1 > 0$  such that  $\|\varphi(t_1, x, u)\| \leq \alpha_1^{-1} \circ \alpha_2^{-1}(r)$ . (Note that  $\alpha_1^{-1} \circ \alpha_2^{-1}(r) \leq r$  by (2.3).) By assumption (H1) we can assume (by changing  $u$  on  $[t_1, \infty)$  if necessary) that  $\|\varphi(t_1 + t, x, u)\| \leq \alpha_2(\alpha_1(\|\varphi(t_1, x, u)\|)e^{-t}) \leq r$  for all  $t \geq 0$ . Since  $u \in \mathcal{U} = L^\infty([0, \infty), U)$  is essentially bounded, we can find  $\bar{u} > 0$  such that  $\|u(t)\| \leq \bar{u}$  for almost all  $t \geq 0$ . Furthermore, by continuity of  $\varphi(t, x, u)$  in  $t$  we find  $R > 0$  such that  $\|\varphi(t, x, u)\| \leq R$  for all  $t \in [0, t_1]$ . Hence using (H4), we can estimate

$$(3.6) \quad \begin{aligned} V(x) &\leq \int_0^{t_1} g(\varphi(t, x, u), u(t)) dt + \int_{t_1}^\infty g(\varphi(t, x, u), u(t)) dt \\ &\leq t_1 \sup_{x \in B(0, R), u \in B(0, \bar{u})} g(x, u) + \int_{t_1}^\infty C(\alpha_2^{-1}(\|\varphi(t, x, u)\|))^\eta dt \\ &\leq t_1 \sup_{x \in B(0, R), u \in B(0, \bar{u})} g(x, u) + \frac{C}{\eta} \alpha_1(\|\varphi(t_1, x, u)\|)^\eta < \infty. \end{aligned}$$

If (H2') and (H4') hold, then the proof is completely analogous.

Conversely, let  $x \notin \mathcal{D}_0$ . Then we obtain  $t(x, u) = \infty$  for all  $u \in \mathcal{U}$ , which implies

$$J(x, u) = \int_0^\infty g(\varphi(t, x, u), u(t)) dt \geq \int_0^\infty g_r dt = \infty$$

for each  $u \in \mathcal{U}$  and thus also  $V(x) = \inf_{u \in \mathcal{U}} J(x, u) = \infty$ .

(ii) It is clear that  $V(0) = 0$ , so let  $x \neq 0$ . Assume to the contrary that there is a sequence  $\{u_k\} \subset \mathcal{U}$  such that  $J(x, u_k) \rightarrow 0$ . Let  $c := \|x\|/2$ , and denote

$$t_k := \inf\{t \geq 0 \mid \|\varphi(t, x, u_k)\| \leq c\}.$$

By (H3) we have for all  $k$  that  $J(x, u_k) \geq \int_0^{t_k} g(\varphi(s, x, u_k), u_k(s)) ds \geq t_k g_c$ , which implies that  $t_k \rightarrow 0$ . Now  $\|f\|$  is bounded on  $B(0, 2r) \times B(0, 2\bar{u})$  by the constant  $C := C_{2r}(1 + \gamma(2\bar{u}))2r$ . Denote

$$E(k) := \{t \in [0, t_k] \mid (\varphi(t, x, u_k), u(t)) \in B(0, 2r) \times B(0, 2\bar{u})\},$$

which is well defined up to a set of measure zero. Then

$$\int_{E(k)} \|f(\varphi(t, x, u_k), u_k(t))\| dt \leq t_k C.$$

On the other hand, we have for all  $k$  that

$$\int_0^{t_k} \|f(\varphi(t, x, u_k), u_k(t))\| dt \geq \|x - \varphi(t_k, x, u_k)\| \geq c.$$

Using (H5), this implies that

$$\begin{aligned} J(x, u_k) &\geq \int_{[0, t_k] \setminus E(k)} g(\varphi(s, x, u_k), u_k(s)) ds \\ &\geq \int_{[0, t_k] \setminus E(k)} \|f(\varphi(s, x, u_k), u_k(s))\| ds \geq c - t_k C. \end{aligned}$$

As  $t_k \rightarrow 0$  this contradicts  $J(x, u_k) \rightarrow 0$ .  $\square$

Next we turn to the investigation of the regularity properties of the functions  $V$  and  $v$ . We start by proving continuity properties for the trajectories of (2.1).

LEMMA 3.4. Assume (H0), and let  $T > 0$  and  $R > 0$  be arbitrary constants. Then for all  $x, y \in \mathbb{R}^n$  and all  $u \in \mathcal{U}$  satisfying

$$\|\varphi(t, x, u)\| \leq R, \quad \|\varphi(t, y, u)\| \leq R \quad \forall t \in [0, T],$$

we have

$$(3.7) \quad \|\varphi(t, x, u) - \varphi(t, y, u)\| \leq e^{C_R(\|u\|_{\gamma, t} + t)} \|x - y\|$$

for all  $t \in [0, T]$ .

*Proof.* The assumption (H0) yields for almost all  $t \in [0, T]$

$$\begin{aligned} (3.8) \quad &\|f(\varphi(t, x, u), u(t)) - f(\varphi(t, y, u), u(t))\| \\ &\leq C_R(1 + \gamma(\|u(t)\|)) \|\varphi(t, x, u) - \varphi(t, y, u)\|. \end{aligned}$$

Using (3.8), Gronwall's lemma, we then obtain

$$\|\varphi(t, x, u) - \varphi(t, y, u)\| \leq e^{C_R(\int_0^t (1+\gamma(\|u\|))dt)} \|x - y\|,$$

and the assertion follows.  $\square$

Using this lemma, we can prove the following continuity statement.

**PROPOSITION 3.5.** *Assume (H0)–(H5) or their respective variants from Remark 3.1. Then  $V$  and  $v$  are continuous on  $\mathcal{D}_0$ .*

*Proof.* We show the continuity of  $V$ , and then the statement for  $v$  follows immediately from its definition. The proof is performed in several steps. Throughout the proof the constants  $C_R, C$ , etc., are those defined in (H0) and (H4) (respectively, (H4')).

First note that from (3.6) we have

$$(3.9) \quad V(x) \leq \frac{C}{\eta} \alpha_1(\|x\|)^\eta \quad \text{for } x \in B(0, \alpha_1^{-1} \circ \alpha_2^{-1}(r)).$$

(i) (Local boundedness of  $V$  on  $\mathcal{D}_0$ ) Pick an arbitrary  $x_0 \in \mathcal{D}_0$ , and fix  $\varepsilon > 0$ . Then there exists a  $u_0 \in \mathcal{U}$  such that  $J(x_0, u_0) \leq V(x_0) + \varepsilon$ . Since  $J(x_0, u_0)$  is finite, it follows from (H3) that there exists a time  $T_0 > 0$  such that  $\|\varphi(T_0, x_0, u_0)\| \leq \alpha_1^{-1} \circ \alpha_2^{-1}(r)/2$ . By continuity of  $\varphi$  in  $x$  we can pick a ball  $B(x_0, \delta)$  such that

$$(3.10) \quad \|\varphi(T_0, x, u_0)\| \leq \alpha_1^{-1} \circ \alpha_2^{-1}(r) \quad \forall x \in \text{cl } B(x_0, \delta).$$

We define the set

$$K = \{\varphi(t, x, u_0) \mid x \in \text{cl } B(x_0, \delta), t \in [0, T_0]\},$$

which is compact since  $\varphi$  is continuous in  $t$  and  $x$  (recall that  $u_0$  is essentially bounded). Using (3.10), we obtain from Bellman's optimality principle for all  $x \in B(x_0, \delta)$  the inequality

$$\begin{aligned} V(x) &\leq \int_0^{T_0} g(\varphi(t, x, u), u(t))dt + V(\varphi(T_0, x, u)) \\ &\leq \max_{x \in K, u \in B(0, \|u_0\|_\infty)} g(x, u)T_0 + \frac{C}{\eta} \alpha_1(r)^\eta, \end{aligned}$$

where we have used (3.9). This shows that  $\sup_{x \in B(x_0, \delta)} V(x) =: B_V$  is finite.

(ii) (Bounds on  $\varepsilon$ -optimal controls and trajectories) For any  $x \in B(x_0, \delta)$  and any  $\varepsilon \in (0, 1]$  we pick an  $\varepsilon$ -optimal control function  $u_{x, \varepsilon} \in \mathcal{U}$ , i.e.,

$$J(x, u_{x, \varepsilon}) \leq V(x) + \varepsilon.$$

We claim that for any  $\varepsilon, T > 0$  the set

$$K_\varepsilon := \{\varphi(t, x, u_{x, \varepsilon}) \mid t \geq 0, x \in B(x_0, \delta)\}$$

and the sets

$$\{\|u_{x, \varepsilon}\|_{\gamma, T} \mid x \in B(x_0, \delta)\}$$

are bounded. If the first set were unbounded, then there would be an  $x \in B(x_0, \delta)$  and  $t_1 > 0$  such that  $\|\varphi(t_1, x, u_{x,\varepsilon})\| \geq V(x) + 2\varepsilon + 2r$ . If  $t_2 > t_1$  is the first time at which  $\|\varphi(t_2, x, u_{x,\varepsilon})\| = 2r$  again, then we obtain using Lemma 3.2 that

$$\begin{aligned} J(x, u_{x,\varepsilon}) &\geq \int_{t_1}^{t_2} g(\varphi(t, x, u_{x,\varepsilon}), u_{x,\varepsilon}(t)) dt \\ &\geq \|\varphi(t_1, x, u_{x,\varepsilon}) - \varphi(t_2, x, u_{x,\varepsilon})\| \geq V(x) + 2\varepsilon, \end{aligned}$$

a contradiction.

On the other hand, if  $\{\|u_{x,\varepsilon}\|_{\gamma,T} \mid x \in B(x_0, \delta)\}$  is unbounded for a given  $T > 0$ , then there have to be  $x, u_{x,\varepsilon}$  such that  $\|u_{x,\varepsilon}\|_{\gamma,T} \geq V(x) + 2\varepsilon + T\gamma(2\bar{u})$ . This implies that if we integrate over the (measurable) set

$$E := \{t \in [0, T] \mid \|u_{x,\varepsilon}(t)\| \geq 2\bar{u}\},$$

then we obtain

$$\int_E \gamma(\|u_{x,\varepsilon}(t)\|) dt \geq V(x) + 2\varepsilon,$$

as the contribution of the integral over  $[0, T] \setminus E$  to  $\|u_{x,\varepsilon}\|_{\gamma,T}$  can be at most  $T\gamma(2\bar{u})$ . By using an estimate over the set  $E$  and again Lemma 3.2, we obtain again a contradiction to  $J(x, u_{x,\varepsilon}) \leq V(x) + \varepsilon$ .

(iii) (Continuity of trajectories) We denote by  $R_\varepsilon$  an upper bound on the set  $K_\varepsilon$ . By Lemma 3.4 we can conclude that for  $x, y \in B(x_0, \delta)$  and all  $t \geq 0$  such that

$$\|x - y\| \leq R_\varepsilon \exp(-C_{2R_\varepsilon}(\|u_{x,\varepsilon}\|_{\gamma,t} + t))$$

we have

$$(3.11) \quad \|\varphi(t, x, u_{x,\varepsilon}) - \varphi(t, y, u_{x,\varepsilon})\| \leq \exp(C_{2R_\varepsilon}(\|u_{x,\varepsilon}\|_{\gamma,t} + t)) \|x - y\|.$$

(iv) (Continuity of  $V$ ) We show the continuity of  $V$  on  $B(x_0, \delta)$ . Since  $x_0 \in \mathcal{D}_0$  was arbitrary, this proves the proposition. So pick  $\varepsilon > 0$ , and assume without loss of generality that  $\varepsilon < \alpha_2^{-1}(r)C$ .

From the lower bound  $g_c$  on  $g$  in (H3) and the boundedness of  $J(x, u_{x,\varepsilon})$  on  $B(x_0, \delta)$ , it follows that for any  $\rho > 0$  there is a time  $T_\rho$  such that for  $x \in B(x_0, \delta)$  we have  $\varphi(t, x, u_{x,\varepsilon}) \in B(0, \rho)$  for some  $t \leq T_\rho$ . Using (3.9), we may thus assume that the controls  $u_{x,\varepsilon}$  are chosen in such a way that there exists  $T_\varepsilon > 0$  (depending on  $B_V$ ) such that for all  $t \geq T_\varepsilon, x \in B(0, \delta)$  we have

$$\varphi(t, x, u_{x,\varepsilon}) \in B(0, \alpha_1^{-1}(\varepsilon/C)/2) \subset B(0, \alpha_1^{-1} \circ \alpha_2^{-1}(r)/2).$$

Denote

$$m := \exp\left(-C_{2R_\varepsilon}\left(\max_{z \in B(x_0, \delta)} \|u_{z,\varepsilon}\|_{\gamma,T_\varepsilon} + T_\varepsilon\right)\right),$$

and note that the right-hand side is finite by (ii). Choose two points  $x, y \in B(x_0, \delta)$  such that

$$\|x - y\| \leq R_\varepsilon m.$$

Without loss of generality, assume  $V(y) \geq V(x)$ . Abbreviating  $u := u_{x,\varepsilon}$ ,  $T := T_\varepsilon$ , we obtain

$$\begin{aligned} |V(y) - V(x)| &= V(y) - V(x) \\ &\leq V(y) - \int_0^\infty g(\varphi(t, x, u), u(t)) dt + \varepsilon \\ &\leq \int_0^T |g(\varphi(t, y, u), u(t)) - g(\varphi(t, x, u), u(t))| dt + V(\varphi(T, y, u)) + \varepsilon; \end{aligned}$$

using the Lipschitz condition in (H3) and (3.11) we continue

$$\leq \int_0^T C_{2R_\varepsilon} (1 + \gamma(\|u(t)\|)) \quad m \|x - y\| dt + V(\varphi(T, y, u)) + \varepsilon,$$

and we obtain

$$\leq C_{2R_\varepsilon} (T + \|u\|_{\gamma,T}) m \|x - y\| + 2\varepsilon,$$

provided  $\|y - x\| \leq \alpha_1^{-1}(\eta\varepsilon^{1/\eta}/C)/(2m)$ , because in this case we obtain from (3.11) that  $\varphi(T, y, u) \in B(0, \alpha_1^{-1}(\eta\varepsilon^{1/\eta}/C))$ , and thus from (3.9)

$$V(\varphi(T, y, u)) \leq \frac{C}{\eta} \alpha_1(\|\varphi(T, y, u)\|)^\eta \leq \varepsilon.$$

Thus for any  $\varepsilon \in (0, 1]$  and any  $x \in B(x_0, \delta)$  we can find  $\delta_\varepsilon > 0$  such that  $|V(y) - V(x)| \leq 3\varepsilon$  for all  $x, y \in B(x_0, \delta)$ , with  $\|x - y\| \leq \delta_\varepsilon$ . This implies continuity of  $V$  in  $B(x_0, \delta)$  and, since  $x_0 \in \mathcal{D}_0$  was arbitrary, continuity on the whole set  $\mathcal{D}_0$ .  $\square$

The next proposition makes a statement of the behavior of  $V(x)$  near the boundary of  $\mathcal{D}_0$  or at  $\infty$ .

**PROPOSITION 3.6.** *Assume (H0)–(H5) or their respective variants from Remark 3.1. Then for any sequence  $x_k$  which satisfies  $\text{dist}(x_k, \partial\mathcal{D}_0) \rightarrow 0$  or  $\|x_k\| \rightarrow \infty$  we have  $V(x_k) \rightarrow \infty$  and  $v(x_k) \rightarrow 1$ . In particular,  $v$  is continuous on  $\mathbb{R}^n$ .*

*Proof.* If  $\|x_k\| \rightarrow \infty$ , then we have for every  $k$  either that  $x_k \notin \mathcal{D}_0$ , in which case  $V(x_k) = \infty$ , or  $x_k \in \mathcal{D}_0$ . In the latter case we have by Lemma 3.2 that  $V(x_k) \geq \|x_k\| - 2r$  for all  $k$  large enough. This shows the assertion for  $V$ , and the conclusion for  $v$  is immediate from the definition.

To prove the assertion for  $\text{dist}(x_k, \partial\mathcal{D}_0) \rightarrow 0$ , we may now assume that there exist a sequence  $x_k \rightarrow x_0 \in \partial\mathcal{D}_0$  and some  $C > 0$  such that  $V(x_k) \leq C$  holds for all  $k \in \mathbb{N}$ . Pick  $\varepsilon > 0$ , and for each  $k$  choose a control function  $u_k \in \mathcal{U}$  such that we have

$$J(x_k, u_k) \leq V(x_k) + \varepsilon \leq C + \varepsilon.$$

Following step (ii) of the proof of Proposition 3.5, we obtain that  $\{\varphi(t, x_k, u_k) \mid t \geq 0, k \in \mathbb{N}\}$  is bounded and that  $\|u_k\|_{\gamma,t}$  is uniformly bounded in  $k$  for all  $t \geq 0$ . Then we may apply (3.11) as in step (iv) of the proof of Proposition 3.5 to conclude that for every  $t \geq 0$  and every  $\delta > 0$  there is a  $k_0$  such that  $\|\varphi(t, x_k, u_k) - \varphi(t, x_0, u_k)\| < \delta$  for all  $k \geq k_0$ .

Because of the lower bound on  $g$  in (H3) we may assume that there exists  $T > 0$  (independent of  $k$ ) such that

$$\varphi(t, x_k, u_k) \in B(0, r/2) \quad \forall t \geq T, k \in \mathbb{N}.$$

This implies  $\varphi(T, x_0, u_k) \in B(0, r/2)$  for all sufficiently large  $k \in \mathbb{N}$ , which in turn implies  $x_0 \in \mathcal{D}_0$ . This contradicts  $x_0 \in \partial\mathcal{D}_0$  because  $\mathcal{D}_0$  is open.  $\square$

**4. Characterizations of  $V$  and  $v$  by Zubov's method.** The aim of this section is to characterize the functions  $V$  and  $v$  introduced in (3.2) and (3.3) as the (unique) viscosity solutions of the equations

$$(4.1) \quad \sup_{u \in U} \{-DV(x)f(x, u) - g(x, u)\} = 0$$

and

$$(4.2) \quad \sup_{u \in U} \{-Dv(x)f(x, u) - (1 - v(x))g(x, u)\} = 0,$$

respectively (for the definition of viscosity solution we refer to [6, 3]).

Recalling that  $V$  is locally bounded in  $\mathcal{D}_0$  and  $v$  is bounded in  $\mathbb{R}^n$ , our first result follows from a standard application of the dynamic programming principles (3.4) and (3.5); see [3].

**PROPOSITION 4.1.** *Assume (H0)–(H5) or their respective variants from Remark 3.1. Then the functions  $V$  and  $v$  defined in (3.2) and (3.3) are viscosity solutions of (4.1) in  $\mathcal{D}_0$  and of (4.2) in  $\mathbb{R}^n$ , respectively.*

**Remark 4.2.** Note that it follows from these characterizations that  $v$  is a CLF on  $\mathcal{D}_0$  in the usual sense [34]. In fact, a small calculation shows that  $v$  is a viscosity supersolution on  $\mathcal{D}_0$  of

$$\inf_{u \in U} Dv(x)f(x, u) \leq -W(x)g_{\|x\|},$$

where  $0 < W(x) < 1 - v(x)$  for  $x \in \mathcal{D}_0 \setminus \{0\}$  and  $g_{\|x\|}$  denotes the constant from (H3) for  $c = \|x\|$ .

The main result in this section will be a uniqueness statement for (4.1) and (4.2), showing that the above functions are the unique viscosity solutions of these equations.

In order to obtain such a result we make use of the so-called optimality principles developed by Soravia [35, 36]. For the application of the results from these references, we need our system to be defined by a bounded vector field  $f$ . To this end we introduce a standard tool for unbounded control systems which consists in rescaling the coefficients of the equations (see [5, 35])

$$(4.3) \quad \begin{aligned} \tilde{f}(x, u) &= \frac{f(x, u)}{1 + \|f(x, u)\|}, \\ \tilde{g}(x, u) &= \frac{g(x, u)}{1 + \|f(x, u)\|}. \end{aligned}$$

The following summarizes the main properties of the rescaled functions.

**PROPOSITION 4.3.** *Assume (H0)–(H3) and (H5) or their respective variants from Remark 3.1. Then  $\tilde{f}$  and  $\tilde{g}$  satisfy (H0)–(H3) for suitably adjusted  $\mathcal{K}_\infty$  and  $\mathcal{KL}$  functions, and the optimal value functions  $V$  and  $v$  of the original and the rescaled problems coincide.*

*Proof.* First note that (H0), (H1), and the first part of (H3) follow by straightforward computations. In order to prove the second part of (H3) we fix an arbitrary  $c > 0$  and show that

$$\tilde{g}_c := \inf \{\tilde{g}(x, u) \mid \|x\| \geq c, u \in U\}$$

is positive. To this end we pick arbitrary  $x \in \mathbb{R}^n$ ,  $u \in U$ , with  $\|x\| \geq c$ , and distinguish three cases.

*Case 1.*  $\|f(x, u)\| \leq 1$ : In this case from (H3) we get  $\tilde{g}(x, u) \geq g_c/2$ .

*Case 2.*  $\|f(x, u)\| > 1$  and  $(x, u) \in B(0, 2r) \times B(0, 2\bar{u})$ : In this case from (H3) we get  $\tilde{g}(x, u) \geq g_c/(1 + \bar{f})$ , with  $\bar{f} := \max\{\|f(x, u)\| \mid (x, u) \in B(0, 2r) \times B(0, 2\bar{u})\} < \infty$ .

*Case 3.*  $\|f(x, u)\| > 1$  and  $(x, u) \notin B(0, 2r) \times B(0, 2\bar{u})$ : In this case (H5) implies  $\tilde{g}(x, u) \geq \|f(x, u)\|/(1 + \|f(x, u)\|) \geq 1/2$ .

By combining the three cases, we obtain

$$\tilde{g}_c \geq \min\{g_c/2, g_c/(1 + \bar{f}), 1/2\} > 0,$$

which shows the second part of (H3).

In order to show that the optimal value functions coincide, observe that the introduction of the vector field  $\tilde{f}$  and the running cost  $\tilde{g}$  amounts to nothing more than a rescaling of time that does not change trajectories or values associated to a particular control. To see this, let  $x \in \mathbb{R}^n$ ,  $u \in U$  be given. Now introduce a new time variable  $\tau$  through the differential equation

$$\frac{dt(\tau)}{d\tau} = \frac{1}{1 + \|f(\phi(t(\tau), x, u), u(t(\tau)))\|} \quad \text{a.e.},$$

and a control  $\tilde{u}(\tau) := u(t(\tau))$  a.e. Then the function  $\psi(\tau) := \phi(t(\tau), x, u)$  satisfies the differential equation

$$\frac{d\psi(\tau)}{d\tau} = \frac{f(\phi(t(\tau), x, u), u(t(\tau)))}{1 + \|f(\phi(t(\tau), x, u), u(t(\tau)))\|} = \tilde{f}(\psi(\tau), \tilde{u}(\tau)).$$

So if we consider the system

$$(4.4) \quad \dot{x}(t) = \tilde{f}(x(t), u(t)),$$

then using standard transformation of integral formulas, it is also easy to see that if  $T(x, u) = \infty$ , then  $\tilde{J}(x, \tilde{u}) = J(x, u)$ , where  $\tilde{J}$  defines the value along a rescaled trajectory using the running cost  $\tilde{g}$  in (3.1). If the solution explodes, i.e.,  $T(x, u) < \infty$ , then we have so far simply defined the value to be infinity. However, since (H3) holds for  $\tilde{g}$ , the associated integral of the transformed system also diverges because it will never enter  $B(0, r)$ . Thus, the optimal value functions coincide.  $\square$

Note that we do not need (H4) and (H5) for the rescaled problem in order to establish the previous result: (H4) is needed in order to ensure finiteness of  $V$  on  $\mathcal{D}_0$ , while (H5) is needed in order to establish the continuity of  $V$ . Both properties readily carry over to the rescaled problem via the integral transformations.

In order to prove our uniqueness statement we need one final assumption.

(H6) The rescaled function  $\tilde{g}$  satisfies  $\tilde{g}(x, u) \rightarrow \infty$  as  $\|u\| \rightarrow \infty$  for each  $x \in \mathbb{R}^n$ .

To Zubov's equations (4.1) and (4.2) we associate the Hamiltonians

$$H_V : \mathbb{R}^n \times (\mathbb{R}^n)^* \rightarrow \mathbb{R}, \quad H_V(x, p) = \sup_{u \in U} \{-f(x, u)p - g(x, u)\},$$

and

$$H_v : \mathbb{R}^n \times \mathbb{R} \times (\mathbb{R}^n)^* \rightarrow \mathbb{R}, \quad H_v(x, r, p) = \sup_{u \in U} \{-f(x, u)p - (1 - r)g(x, u)\}.$$

From (H5) we obtain that the supremum in these Hamiltonians is attained in a compact subset of  $U$  for  $r < 1$  in the case of  $H_v$ . This implies that the Hamiltonians  $H_V$  and  $H_v$  are locally Lipschitz continuous with respect to their arguments, again for  $r < 1$  in the case of  $H_v$ .

The following Theorem 4.4 and its Corollary 4.5 are the main results of this paper.

**THEOREM 4.4.** *Assume that  $f$  and  $g$  satisfy the assumptions (H0)–(H6) (or their respective variants from Remark 3.1). Then*

- (i) *the function  $v$  from (3.3) is the unique bounded viscosity solution of (4.2) with  $v(0) = 0$ ;*
- (ii) *there exists a unique pair  $(\mathcal{O}, V)$  such that  $\mathcal{O}$  is an open set containing the origin and  $V$  is a locally bounded, nonnegative continuous viscosity solution of (4.1) in  $\mathcal{O}$ , with  $V(0) = 0$  and  $V(x) \rightarrow +\infty$  for  $x \rightarrow \partial\mathcal{O}$  (here  $V$  is the function from (3.2));*
- (iii) *the functions  $v$  and  $V$  characterize the domain of asymptotic controllability via*

$$\mathcal{D}_0 = \{x \in \mathbb{R}^n \mid v(x) < 1\} = \{x \in \mathbb{R}^n \mid V(x) < \infty\};$$

- (iv) *the functions  $v$  and  $V$  satisfy  $v(x_k) \rightarrow 1$  and  $V(x_k) \rightarrow \infty$  for all sequences with  $x_k \rightarrow \partial\mathcal{D}_0$  or  $\|x_k\| \rightarrow \infty$ .*

Before turning to the proof we state the following corollary, whose proof in particular shows how a cost function  $g$  meeting the assumptions of Theorem 4.4 can be constructed.

**COROLLARY 4.5.** *Assume that  $f$  satisfies the conditions (H0)–(H2). Then there exists a continuous function  $v : \mathbb{R}^n \rightarrow [0, 1]$  which is a CLF (in the usual sense; cf. Remark 4.2) on the domain of asymptotic controllability  $\mathcal{D}_0$  and constant equal to 1 on  $\mathbb{R}^n \setminus \mathcal{D}_0$ . Furthermore, this  $v$  is the unique bounded viscosity solution of (4.2), with  $v(0) = 0$  for some suitable  $g : \mathbb{R}^n \times U \rightarrow \mathbb{R}$ .*

*Proof.* In order to prove the theorem it is sufficient to construct a function  $g$  satisfying (H4)–(H6). Then the Lyapunov function property follows immediately from Theorem 4.4 and Remark 4.2.

To this end, consider the Lipschitz function  $\rho : \mathbb{R}_0^+ \rightarrow \mathbb{R}_0^+$  given by

$$\rho(s) := \begin{cases} 0, & s \in [0, 1], \\ s - 1, & s \in [1, 2], \\ 1, & s \in [2, \infty), \end{cases}$$

and set

$$\bar{g}(x, u) := \alpha_2^{-1}(\|x\|) + \rho(s(x, u)) [1 + \|f(x, u)\|] [1 + \|u\|],$$

with

$$s(x, u) = \frac{1}{2} \sqrt{\frac{\|x\|^2}{r^2} + \frac{\|u\|^2}{\bar{u}^2}}.$$

For this function (H3), (H4), and (H6) follow immediately from the construction. We obtain the desired  $g$  by modifying  $\bar{g}$  as follows: Let  $\gamma \in \mathcal{K}_\infty$  such that (H0) and (H3) are satisfied, and set

$$g(x, u) := \bar{g}(x, u) + \rho(s(x, u))\gamma(\|u\|).$$

Then (H5) is satisfied, while straightforward computations show that (H3), (H4), and (H6) carry over from  $\tilde{g}$  to  $g$ .  $\square$

In the proof of Theorem 4.4 we encounter two difficulties: the unbounded dependence of the functions on the control variable and the vanishing of the cost  $g$  at the origin.

To solve the first problem we use the rescaled functions from above. Associated to these functions we introduce two rescaled equations which share with (4.1) and (4.2) the same set of sub- and supersolutions.

LEMMA 4.6. *Assume (H0) and (H3), and consider the equations*

$$(4.5) \quad \sup_{u \in U} \{-D\tilde{V}(x)\tilde{f}(x, u) - \tilde{g}(x, u)\} = 0$$

and

$$(4.6) \quad \sup_{u \in U} \{-D\tilde{v}(x)\tilde{f}(x, u) - (1 - \tilde{v}(x))\tilde{g}(x, u)\} = 0.$$

Then

- (i) *any viscosity subsolution of (4.1) is a viscosity subsolution for (4.5) and vice versa;*
- (ii) *any viscosity supersolution of (4.1) is a viscosity supersolution for (4.5), and, if in addition (H6) holds, then any viscosity supersolution of (4.5) is also a viscosity supersolution for (4.1).*

*The same assertions hold for (4.6) and (4.2).*

The proof of Lemma 4.6 is postponed to the appendix. The following corollary is a simple consequence of the previous lemma.

COROLLARY 4.7. *Assume (H0), (H3), and (H6). Then*

- (i) *any viscosity solution of (4.1) is a viscosity solution of (4.5) in  $\mathcal{D}_0$  and vice versa;*
- (ii) *any viscosity solution of (4.2) is a viscosity solution of (4.6) and vice versa.*

Even if the coefficients of the rescaled equations have a better dependence on the variable  $u$ , there is still the problem of the vanishing of  $\tilde{g}$  at the origin. In order to prove a uniqueness result for (4.5) and (4.6), we use a control theoretic argument and some optimality principles introduced in [35, 36], as stated in the following lemma.

LEMMA 4.8. *Assume (H0), (H3), and (H5), and let  $\tilde{\varphi}(t, x, u)$  be the solution of (4.4). Define*

$$\tilde{G}(x, t, u) := \exp \left( - \int_0^t \tilde{g}(\tilde{\varphi}(\tau, x, u), u(\tau)) d\tau \right).$$

*Then the following properties hold:*

- (i) *Any upper semicontinuous viscosity subsolution  $w^-$  of (4.6) satisfies*

$$(4.7) \quad w^-(x) \leq \inf_{u \in \mathcal{U}} \inf_{t \in [0, T]} \left\{ 1 + \tilde{G}(x, t, u)(w^-(\tilde{\varphi}(t, x, u)) - 1) \right\}$$

*for each  $T > 0$ .*

- (ii) *Consider a continuous viscosity supersolution  $w^+$  of (4.6), and let  $\Omega \subset \mathbb{R}^n$  be an open and bounded set with  $\sup_{x \in \Omega} w^+(x) < 1$ . Consider the first exit time from  $\Omega$  given by*

$$T_{ex}(x, u, \Omega) = \min\{t \geq 0 \mid \varphi(t, x_0, u) \notin \Omega\}.$$

Then  $w^+$  satisfies

$$(4.8) \quad w^+(x) \geq \inf_{u \in \mathcal{U}} \sup_{t \in [0, T_{ex}(x, u, \Omega)]} \left\{ 1 + \tilde{G}(x, t, u)(w^+(\tilde{\varphi}(t, x, u)) - 1) \right\}.$$

*Proof.* Let  $\Omega \subset \mathbb{R}^n$  be an open and bounded set, and let  $\tilde{U}$  be a compact subset of  $U$  with the corresponding space of measurable control functions denoted by  $\tilde{\mathcal{U}}$ . If  $w^-$  is an upper semicontinuous viscosity subsolution of (4.6) in  $\mathbb{R}^n$ , then the restriction of  $w^-$  to  $\Omega$  is also a subsolution of (4.6) on  $\Omega$  with  $\tilde{U}$  instead of  $U$ . For the restricted control value set  $\tilde{U}$ , (4.6) is continuous, and furthermore  $\tilde{f}, \tilde{g}$  are uniformly Lipschitz on  $\Omega$ . Hence we can apply [36, Theorem 3.2(i)], which for each  $u \in \tilde{\mathcal{U}}$  yields

$$w^-(x) \leq \inf_{t \in [0, T_{ex}(x, u, \Omega)]} \left\{ 1 + \tilde{G}(x, t, u)(w^-(\tilde{\varphi}(t, x, u)) - 1) \right\},$$

where  $T_{ex}(x, u, \Omega)$  is the first exit time of  $\tilde{\varphi}(t, x_0, u)$  from the set  $\Omega$  defined in (ii).

Since  $\tilde{f}$  is globally bounded, for any  $x \in \mathbb{R}^n$  and any  $T > 0$  we may find an open and bounded set  $\Omega_{x,T} \subset \mathbb{R}^n$  such that  $T_{ex}(x, u, \Omega_{x,T}) \geq T$  for each  $u \in \mathcal{U}$ . Since each  $u \in \mathcal{U}$  is essentially locally bounded, it lies in  $\tilde{U}$  for an appropriate choice of  $\tilde{U}$ , which shows (i).

The proof of (ii) follows from [36, Theorem 3.2(ii)], observing that (4.6) is continuous on  $\Omega$  since  $w^-(x) < 1$ ; hence, here we do not need to restrict the control value set  $U$ .  $\square$

*Remark 4.9.* Note that the asymmetry of the statements (i) and (ii) is due to the fact that we imposed different conditions in order to obtain continuity of (4.6), which is needed for the application of [36, Theorem 3.2]. In (i) we restrict the set of control values  $U$ , obtaining a result for arbitrary  $\Omega$  (thus for arbitrary  $T$ ) and for upper semicontinuous functions. In (ii) this restriction is not possible because the supersolution property will not persist passing from  $U$  to  $\tilde{U}$ . Thus here we ensure the continuity of (4.6) by considering suitable subsets  $\Omega$  of the state space.

Using these inequalities, we can now prove the following uniqueness results.

LEMMA 4.10. Assume (H0)–(H6), and consider the functions  $V$  and  $v$  defined by (3.2) and (3.3). Then

- (i)  $v$  is the unique bounded continuous viscosity solution of (4.6), with  $v(0) = 0$ ;
- (ii)  $(\mathcal{D}_0, V)$  is the unique pair of an open set containing the origin and a locally bounded, nonnegative continuous viscosity solution of (4.5) in the open set such that  $V(0) = 0$  and  $V(x) \rightarrow +\infty$  for  $x \rightarrow \partial\tilde{\mathcal{O}}$ .

*Proof.* We prove only (i), since the proof of assertion (ii) is similar. Note that by Proposition 4.3 the functions  $v$  and  $V$  can be taken to be defined through (4.4) and the running cost  $\tilde{g}$ . In the following we work with this representation. Again by  $\tilde{\varphi}(t, x, u)$  we denote the solutions of (4.4).

*Claim 1.* If  $w^-$  is a bounded continuous subsolution of (4.6) on  $\mathbb{R}^n$  with  $w^-(0) \leq 0$ , then  $w^- \leq v$ .

By the upper semicontinuity of  $w^-$  and  $w^-(0) \leq 0$  we obtain that for every  $\varepsilon > 0$  there exists a  $\delta > 0$  with  $w^-(x) \leq \varepsilon$  for all  $x \in \mathbb{R}^n$ , with  $\|x\| \leq \delta$ . Now we distinguish two cases:

(i)  $x_0 \in \mathcal{D}_0$ : We choose  $u^* \in \mathcal{U}$  such that  $v(x_0) + \varepsilon > \tilde{J}(x_0, u^*) = 1 - \tilde{G}(x_0, \infty, u^*)$ . Then (H3) (cf. Proposition 4.3) implies that there exists a sequence  $t_k \rightarrow \infty$  such that

$\tilde{\varphi}(t_k, x_0, u^*) \rightarrow 0$  as  $k \rightarrow \infty$ . Thus it follows from the lower optimality principle (4.7) and the definition of  $v$  that

$$\begin{aligned} w^-(x_0) &\leq \limsup_{k \rightarrow \infty} 1 + \tilde{G}(x_0, t_k, u^*)(w^-(\tilde{\varphi}(t_k, x_0, u^*)) - 1) \\ &\leq 1 + \tilde{G}(x_0, \infty, u^*)(\varepsilon - 1) \leq v(x_0) + 2\varepsilon, \end{aligned}$$

which shows the claim as  $\varepsilon > 0$  was arbitrary.

(ii)  $x_0 \notin \mathcal{D}_0$ : In this case by Proposition 3.3 it is sufficient to show that  $w^-(x_0) \leq 1$ . Let  $M$  be a bound on  $|w^-|$ . In this case we have  $\tilde{\varphi}(\tau, x_0, u) \notin B(0, r)$  for all  $\tilde{u} \in \mathcal{U}$  and all  $\tau \geq 0$ , which implies

$$\int_0^\tau \tilde{g}(\tilde{\varphi}(s, x_0, u), \tilde{u}(s)) ds \geq \tilde{g}_r \tau$$

for the constant  $\tilde{g}_r > 0$  from (H3); see Proposition 4.3. Therefore  $\tilde{G}(x_0, \tau, \tilde{u}) \leq \exp(-\tilde{g}_r \tau)$  for all  $\tau \geq 0, \tilde{u} \in \mathcal{U}$ . Hence

$$1 + \tilde{G}(x_0, \tau, \tilde{u})(w^-(\tilde{\varphi}(\tau, x_0, \tilde{u})) - 1) \leq 1 + \exp(-\tilde{g}_r \tau)(M + 1)$$

for all  $\tilde{u} \in \mathcal{U}$ , and the result follows by (4.7) as the right-hand side tends to 1 for  $\tau \rightarrow \infty$ .

Therefore Claim 1 is proved. To conclude the proof we now consider the following.

*Claim 2.* Let  $w^+$  be a bounded continuous supersolution of (4.2) on  $\mathbb{R}^n$  with  $w^+(0) \geq 0$ . Then  $w^+ \geq v$ .

Again we distinguish two cases.

(i)  $x_0 \notin \mathcal{D}_0$ : In this case we know  $v(x_0) = 1$ , and it is sufficient to show  $w^+(x_0) \geq 1$ . In order to prove this inequality by contradiction, we assume  $w^+(x_0) = 1 - \delta$  for some suitable  $\delta > 0$ . Since  $\|\tilde{f}\|$  is bounded by 1 for any ball  $B(R, x_0)$ , we have  $T_{ex}(x_0, u, B(R, x_0)) \geq R$  for all  $u \in \mathcal{U}$ . Furthermore,  $x_0 \notin \mathcal{D}_0$  implies  $\tilde{\varphi}(t, x_0, u) \notin B(r, 0)$  for all  $t \geq 0, u \in \mathcal{U}$ ; hence, by (H3) (cf. Proposition 4.3) we have the inequality  $\tilde{g}(\tilde{\varphi}(t, x_0, u), u(t)) \geq \tilde{g}_r > 0$  for all  $t \geq 0, u \in \mathcal{U}$ . This implies the existence of  $R > 0$  such that  $\tilde{G}(x_0, t, u) \leq \delta/(2(M + 1))$  for all  $t \geq R$  and all  $u \in \mathcal{U}$ , where  $M > 0$  is a bound on  $|w^+|$ . Now pick the set  $\Omega = \{x \in \mathbb{R}^n \mid w^+(x) < 1 - \delta/2\} \cap B(R, x_0)$ . For this set Lemma 4.8(ii) is applicable, and thus by (4.8), for any  $\varepsilon > 0$  we can find  $u_\varepsilon$  with

$$\begin{aligned} w^+(x_0) &\geq \sup_{\tau \in [0, T_{ex}(x_0, u_\varepsilon, \Omega)]} \{1 + \tilde{G}(x_0, \tau, u_\varepsilon)(w^+(\tilde{\varphi}(\tau, x_0, u_\varepsilon)) - 1)\} - \varepsilon \\ &\geq \sup_{\tau \in [0, T_{ex}(x_0, u_\varepsilon, \Omega)]} \{[1 - \exp(-\tau g_r)] - \exp(-\tau g_r)M\} - \varepsilon. \end{aligned}$$

If  $T_{ex}(x_0, u_\varepsilon, \Omega) = \infty$ , then this expression equals  $1 - \varepsilon$ , and hence we obtain a contradiction to  $w^+(x_0) = 1 - \delta < 1$  for  $\varepsilon$  sufficiently small. If  $T_{ex}(x_0, u_\varepsilon, \Omega)$  is finite, then either we have  $\tilde{\varphi}(T_{ex}(x_0, u_\varepsilon, \Omega)) \notin B(R, x_0)$ , in which case we get  $T_{ex}(x_0, u_\varepsilon, \Omega) \geq R$  and thus  $\tilde{G}(x_0, T_{ex}(x_0, u_\varepsilon, \Omega), u_\varepsilon) \leq \delta/(2(M + 1))$ , or we have  $\tilde{\varphi}(T_{ex}(x_0, u_\varepsilon, \Omega)) \in B(R, x_0)$ , which by construction of  $\Omega$  implies  $w^+(\tilde{\varphi}(T_{ex}(x_0, u_\varepsilon, \Omega), x_0, u_\varepsilon)) \geq 1 - \delta/2$ . Since  $\tilde{G}(x_0, t, u) \leq 1$  holds for all  $t \geq 0, u \in \mathcal{U}$ , in both cases we get

$$\begin{aligned} w^+(x_0) &\geq \sup_{\tau \in [0, T_{ex}(x_0, u_\varepsilon, \Omega)]} \{1 + \tilde{G}(x_0, \tau, u_\varepsilon)(w^+(\tilde{\varphi}(\tau, x_0, u_\varepsilon)) - 1)\} - \varepsilon \\ &\geq 1 + \tilde{G}(x_0, T_{ex}(x_0, u_\varepsilon, \Omega), u_\varepsilon)(w^+(\tilde{\varphi}(T_{ex}(x_0, u_\varepsilon, \Omega), x_0, u_\varepsilon)) - 1) - \varepsilon \\ &\geq 1 - \delta/2 - \varepsilon. \end{aligned}$$

This again contradicts our assumption that  $w^+(x_0) = 1 - \delta$  for  $\varepsilon$  sufficiently small.

(ii)  $x_0 \in \mathcal{D}_0$ : In this case we know that  $v(x_0) < 1$ , and hence for  $w^+(x_0) \geq 1$  there is nothing to show. Thus we can assume  $w^+(x_0) = 1 - \delta$  for some suitable  $\delta > 0$  and again consider the set  $\Omega = \{x \in \mathbb{R}^n \mid w^+(x) < 1 - \delta/2\} \cap B(R, x_0)$  from part (i), above. Now fix  $\varepsilon > 0$ , with  $\varepsilon < \delta/2$  implying

$$(4.9) \quad w^+(x_0) + \varepsilon < 1 - \delta/2.$$

Then (4.8) yields the existence of a control function  $u_\varepsilon \in \mathcal{U}$  with

$$(4.10) \quad w^+(x_0) + \varepsilon \geq \sup_{t \in [0, T_{ex}(x_0, u_\varepsilon, \Omega)]} \{1 + \tilde{G}(x_0, t, u_\varepsilon)(w^+(\tilde{\varphi}(t, x_0, u_\varepsilon)) - 1)\}.$$

If  $T_{ex}(x_0, u_\varepsilon, \Omega) < \infty$ , then as in part (i) above, we obtain from (4.9) and (4.10)

$$\begin{aligned} 1 - \delta/2 &> w^+(x_0) + \varepsilon \\ &\geq 1 + \tilde{G}(x_0, T_{ex}(x_0, \tilde{u}, \Omega), \tilde{u})(w^+(\tilde{\varphi}(T_{ex}(x_0, \tilde{u}, \Omega), x_0, \tilde{u})) - 1) \\ &\geq 1 - \delta/2, \end{aligned}$$

which is a contradiction. Thus we obtain  $T_{ex}(x_0, u_\varepsilon, \Omega) = \infty$ .

Now for each  $\eta > 0$  we find  $t$  such that  $\|\tilde{\varphi}(t, x_0, u_\varepsilon)\| \leq \eta$ , because otherwise—as in the first inequality of case (i), above—the right-hand side in (4.10) would be equal to 1, contradicting (4.9). The continuity of  $w^+$  and the assumption  $w^+(0) \geq 0$  imply that there exists a  $\eta_1 > 0$  such that

$$(4.11) \quad w^+(x) \geq -\varepsilon \quad \forall \|x\| \leq \eta_1.$$

On the other hand, since  $v(0) = 0$  and  $v$  is continuous, we find  $\eta_2 > 0$  such that

$$(4.12) \quad v(x) \leq \varepsilon \quad \forall \|x\| \leq \eta_2.$$

Combining these results, we can conclude that for all sufficiently large times  $t > 0$  we have

$$\tilde{w}^+(\tilde{\varphi}(t, x_0, u_\varepsilon)) \geq v(\tilde{\varphi}(t, x_0, u_\varepsilon)) - 2\varepsilon.$$

Thus using (4.10), (3.5), and the inequality  $\tilde{G}(x_0, t_n, u_n) \leq 1$  for sufficiently large  $t > 0$ , we can conclude

$$\begin{aligned} w^+(x_0) &\geq 1 + \tilde{G}(x_0, t, u_\varepsilon)(w^+(\tilde{\varphi}(t, x_0, u_\varepsilon)) - 1) - \varepsilon \\ &\geq 1 + \tilde{G}(x_0, t, u_\varepsilon)(v(\tilde{\varphi}(t, x_0, u_\varepsilon)) - 1) - 3\varepsilon \\ &\geq v(x_0) - 3\varepsilon, \end{aligned}$$

which shows Claim 2, as  $\varepsilon > 0$  is arbitrary.

Finally, since every viscosity solution  $\tilde{w}$  is both a subsolution and a supersolution, the combination of Claims 1 and 2 proves the lemma.  $\square$

*Proof of Theorem 4.4.* All properties follow from the fact that by Lemma 4.10 the functions  $V$  and  $v$  defined by (3.2) and (3.3) are the unique continuous viscosity solutions for (4.6) and (4.5), respectively.

(i) and (ii): By Corollary 4.7 all viscosity solutions to (4.6) and (4.5) are also viscosity solutions of (4.2) and (4.1), respectively, and vice versa. Hence,  $v$  and  $V$  are also the unique viscosity solutions of (4.2) and (4.1), respectively.

(iii): It follows from Proposition 3.3.

(iv): It follows from Proposition 3.6.  $\square$

**5. Approximation with bounded control values.** In this section we consider the bounded approximations  $U_k = U \cap \text{cl } B(0, k)$  of the (possibly) unbounded set  $U$  of control values and the corresponding set  $\mathcal{U}_k := L^\infty([0, \infty), U_k)$  of control functions. Throughout this section we assume that (H0)–(H2) hold, which implies that we can find  $g$ , meeting (H3)–(H6).

PROPOSITION 5.1. *Consider the functions*

$$V_k(x) = \inf_{u \in \mathcal{U}_k} J(x, u) \quad \text{and} \quad v_k(x) = 1 - e^{V_k(x)}.$$

*Then the relations*

$$V(x) = \inf_{k \in \mathbb{N}} V_k(x) \quad \text{and} \quad v(x) = \inf_{k \in \mathbb{N}} v_k(x)$$

*hold.*

*Proof.* Since  $\mathcal{U}_k \subseteq \mathcal{U}$  we obviously have the inequality  $V_k(x) \geq V(x)$ . Now let  $x \in \mathcal{D}_0$  and  $u \in \mathcal{U}$  be such that

$$J(x, u) \leq V(x) + \varepsilon$$

for some  $\varepsilon > 0$ . Since  $u \in \mathcal{U}$ , there exists  $k_0 \in \mathbb{N}$  such that  $\|u\|_\infty \leq k_0$ , and hence  $u \in \mathcal{U}_{k_0}$ . This implies

$$\inf_{k \in \mathbb{N}} V_k(x) \leq V_{k_0}(x) \leq V(x) + \varepsilon.$$

Since  $\varepsilon$  was arbitrary, this shows the claim on  $\mathcal{D}_0$  for both  $V$  and  $v$ . For  $x \notin \mathcal{D}_0$  we have  $V_k(x) = V(x) = \infty$  and  $v_k(x) = v(x) = 1$ , which shows the claim also in this case.  $\square$

*Remark 5.2.* If the assumptions of Proposition 3.6 hold, then, since  $v_k$  is decreasing in  $k$ , Dini's theorem yields that  $v_k$  converges to  $v$  locally uniformly on  $\mathbb{R}^n$ .

For the following proposition recall the definition of set limits, which for a sequence of sets  $X_k$  are given by

$$\limsup_{k \rightarrow \infty} X_k := \bigcap_{k \in \mathbb{N}} \bigcup_{m \geq k} X_m \quad \text{and} \quad \liminf_{k \rightarrow \infty} X_k := \bigcup_{k \in \mathbb{N}} \bigcap_{m \geq k} X_m$$

and, if these two sets coincide,

$$\lim_{k \rightarrow \infty} X_k := \limsup_{k \rightarrow \infty} X_k = \liminf_{k \rightarrow \infty} X_k.$$

PROPOSITION 5.3. *Consider the sets*

$$\mathcal{D}_k := \{x \in \mathbb{R}^n \mid \text{there exists } u \in \mathcal{U}_k \text{ with } \|\varphi(t, x, u)\| \rightarrow 0 \text{ for } t \rightarrow \infty\}.$$

*Then the set limit  $\lim_{k \rightarrow \infty} \mathcal{D}_k$  exists and satisfies*

$$\mathcal{D}_0 = \lim_{k \rightarrow \infty} \mathcal{D}_k.$$

*Proof.* Since we have that  $V \leq \dots \leq V_{k+1} \leq V_k$ , we obtain the inclusion

$$\mathcal{D}_k \subseteq \mathcal{D}_{k+1} \subseteq \dots \subseteq \mathcal{D}_0.$$

It follows that  $\bigcup_{m \geq k} \mathcal{D}_m \subseteq \mathcal{D}_0$  for each  $k$  and hence

$$\limsup_{k \rightarrow \infty} \mathcal{D}_k = \bigcap_{k \in \mathbb{N}} \bigcup_{m \geq k} \mathcal{D}_m \subseteq \mathcal{D}_0.$$

On the other hand, if  $x \in \mathcal{D}_0$ , then for any  $\varepsilon > 0$  there exists  $k_0 \in \mathbb{N}$  with  $V_k(x) \leq V(x) + \varepsilon$  for all  $k \geq k_0$ . This implies that  $x \in \mathcal{D}_k$  for all  $k \geq k_0$  and consequently  $x \in \bigcap_{m \geq k_0} \mathcal{D}_m$ . This implies

$$x \in \bigcup_{k \in \mathbb{N}} \bigcap_{m \geq k} \mathcal{D}_m = \liminf_{k \rightarrow \infty} \mathcal{D}_k,$$

and since  $x \in \mathcal{D}_0$  was arbitrary we obtain

$$\mathcal{D}_0 \subseteq \liminf_{k \rightarrow \infty} \mathcal{D}_k,$$

which shows the claim.  $\square$

*Remark 5.4.* This proposition implies that for any compact set  $K \subset \mathbb{R}^n$  the convergence

$$d_H(K \cap \mathcal{D}_k, K \cap \mathcal{D}_0) \rightarrow 0$$

in the Hausdorff metric holds (see, e.g., [2, Proposition 1.1.5]). In particular, if  $\mathcal{D}_0$  is bounded, then we obtain uniform convergence of  $\mathcal{D}_k$  to  $\mathcal{D}_0$  in the Hausdorff metric.

In particular, this implies that for any compact set  $K \subset \mathcal{D}_0$  we obtain  $K \subset \mathcal{D}_k$  for all sufficiently large  $k$ . Thus, in order to steer the system to 0 from a compact subset  $K \subset \mathcal{D}_0$ , it is sufficient to consider bounded control functions.

**6. Examples.** In this section we discuss the necessity of some of our assumptions. Also it is explained how the classical case of linear quadratic control fits within the present framework.

*Example 6.1.* Consider the one-dimensional dynamics

$$(6.1) \quad \dot{x}(t) = (x(t) - 1)(u(t) + 1) + 1 = x(t)(u(t) + 1) - u(t), \quad t \geq 0,$$

where  $U = \mathbb{R}$ . The origin is an equilibrium point so that (H1) is satisfied, while  $x = 1$  is repulsive, in the sense that any trajectory starting from  $x_0 \geq 1$  cannot reach the origin. With this it is easy to see that (H2) is satisfied and  $\mathcal{D}_0 = (-\infty, 1)$ . Furthermore, (H0) is satisfied with  $\gamma(u) = |u|$ .

Now consider the cost function  $g_1(x, u) = |x|$ , which satisfies (H3) and (H4) but neither (H5) nor (H6). For  $x_0 \in (0, 1)$  and an arbitrary constant  $\alpha > 0$ , choose

$$u(t) = \frac{-\alpha - 1}{\phi(t) - 1} \chi_{[0, x_0/\alpha]}(t),$$

where  $\chi_{[0, x_0/\alpha]}$  denotes the indicator function of the interval  $[0, x_0/\alpha]$ . The corresponding solution of (6.1) is given by

$$\phi(t) = (x_0 - \alpha t) \chi_{[0, x_0/\alpha]}(t).$$

Observe that for  $x_0$  close to 1 we need a very large control to start to move towards the origin. This is because the control  $u$  is multiplied by  $x - 1$ .

By calculating the corresponding cost, we obtain

$$V_1(x_0) \leq \int_0^\infty g_1(\phi(t), u(t)) dt = x_0^2/2\alpha,$$

and therefore, sending  $\alpha \rightarrow +\infty$ , it follows that  $V_1(x_0) = 0$  for any  $x_0 \in (0, 1)$ . Of course,  $V_1(x) = \infty$  for  $x \geq 1$ . Summarizing this shows that  $v_1$  is discontinuous on  $\mathbb{R}$  and not a CLF on  $\mathcal{D}_0$ .

On the other hand, by setting  $g_2(x, u) = \max\{|x| + |u|, (|x| + |u|)^2\}$ , a cost function satisfying (H6) is obtained. To analyze the associated value functions, fix  $x_0 \in (0, 1)$  and choose a control  $u$  such that  $\phi(t) := \phi(t, x, u) \rightarrow 0$ . We will assume that  $\phi$  is strictly decreasing, as otherwise it is clearly not optimal. Now let  $T > 0$  be a time such that  $\phi(T) > 0$ , and then we have

$$\begin{aligned} J_2(x, u) &\geq \int_0^T g_2(\phi(t), u(t)) dt \geq \int_0^T \phi(t) + u(t) dt = \int_0^T \phi(t) + \frac{\phi(t) - \dot{\phi}(t)}{1 - \phi(t)} dt \\ &\geq \int_0^T \frac{-\dot{\phi}(t)}{1 - \phi(t)} dt = \log(1 - \phi(T)) - \log(1 - x_0). \end{aligned}$$

As  $\phi(T)$  approaches 0 (in finite or infinite time) this calculation shows that  $V_2(x_0) \geq -\log(1 - x_0)$  for  $x_0 \in (0, 1)$  so that in particular  $v_2$  is continuous on  $\mathbb{R}$  and a CLF on  $\mathcal{D}_0$  (where we leave the assertion for  $(-\infty, 0)$  to the reader).

Finally note that a combination of the previous examples leads to an intermediate situation. To this end, let  $h : \mathbb{R} \rightarrow [0, 1]$  be a continuous function such that  $h(x) = 1$  if  $x \in (-\infty, 1/2]$ ,  $h(x) = 0$  for  $x \in [3/4, \infty)$ , and let  $g_3(x, u) = |x| + h(x)|u|$ . Then it follows for  $x \in [0, 1/2]$  that  $V_3(x) = V_2(x) \geq -\log(1 - x)$  by the considerations on  $g_2$ , whereas for  $x \in (3/4, 1)$  we have  $V_3(x) = V(3/4)$  using that  $V_1$  is constant on that interval. In this example (H5) and (H6) are not satisfied,  $v_3$  is not continuous, and  $V_3$  is a CLF only on a subset of  $\mathcal{D}_0$ .

*Example 6.2.* Finally we show that the classical linear quadratic control problem fits into our setup. This problem is obtained if we set

$$f(x, u) = Ax + Bu \quad \text{and} \quad g(x, u) = x^T Qx + u^T Ru,$$

where  $A, B, Q, R$  are matrices of appropriate dimensions, with  $Q$  and  $R$  being symmetric and positive definite.

By direct computations one sees that these functions satisfy (H0) for any  $\gamma \in \mathcal{K}_\infty$ , (H1), (H3), and (H5). The linear system also satisfies (H2'), because it is known that local asymptotic controllability implies the existence of a feedback matrix  $F$  such that  $A + BF$  is exponentially stable; i.e., this matrix has all of its eigenvalues in the open left half-plane, which yields (H2') with  $\beta(r, t) = Ke^{-\lambda t}r$  for suitable constants  $K, \lambda > 0$ . Hence we obtain  $\beta(r, t) = \alpha_2(\alpha_1(r)e^{-t})$ , with  $\alpha_2(r) = r^\lambda$ , which implies (H4') for our  $g$  with  $\delta = 2/\lambda$  and  $C = \|Q + R\|$ . Finally, (H6) is satisfied because  $g$  grows quadratically in  $u$  while  $f$  grows only linearly in  $u$ . Thus, the classical linear quadratic problem is a special case of our setup, and the resulting equation (4.1) is given by

$$(6.2) \quad \sup_{u \in U} \{-DV(x)(Ax + Bu) - x^T Qx - u^T Ru\} = 0.$$

For the quadratic ansatz  $V(x) = x^T Px$ , with symmetric matrix  $P$ , we obtain

$$DV(x)(Ax + Bu) = x^T P(Ax + Bu) + (Ax + Bu)^T Px.$$

Assuming  $U = \mathbb{R}^m$ , we can explicitly solve the maximization problem over  $u$  by setting the first derivative of the resulting expression to 0 and obtain

$$u(x) = -R^{-1}B^T Px.$$

Plugging this into (6.2) and multiplying by  $-1$  yields

$$x^T PBR^{-1}B^T Px - x^T PAx - x^T A^T Px - x^T Qx = 0,$$

which is equivalent to

$$PBR^{-1}B^T P - PA - A^T P - Q = 0;$$

i.e., (4.1) reduces to the well-known algebraic Riccati equation from linear optimal control; see [33, section 8.4].

**Appendix.** In this appendix we give the proof of Lemma 4.6.

*Proof.* We prove the lemma for (4.1) and (4.5), and the assertions for (4.2) and (4.6) follow by the same arguments.

(i) If  $V^-$  is a viscosity subsolution of (4.1), then for any supergradient  $p$  of  $V^-$  in  $x$  we have that

$$\sup_{u \in U} \{-f(x, u)p - g(x, u)\} \leq 0.$$

This implies

$$-f(x, u)p - g(x, u) \leq 0 \quad \forall u \in U,$$

and, since  $1 + \|f(x, u)\|$  is positive, this implies

$$-\tilde{f}(x, u)p - \tilde{g}(x, u) = (1 + \|f(x, u)\|)^{-1}(-f(x, u)p - g(x, u)) \leq 0 \quad \forall u \in U,$$

which in turn implies

$$\sup_{u \in U} \{-\tilde{f}(x, u)p - \tilde{g}(x, u)\} \leq 0,$$

and hence  $V^-$  is a viscosity supersolution of (4.5).

The converse direction follows by the same argument, since again we multiply by a positive factor, now  $1 + \|f(x, u)\|$ .

(ii) Let  $V^+$  be a viscosity supersolution of (4.1). Then for any subgradient  $p$  of  $V^+$  in  $x$  we have

$$\sup_{u \in U} \{-f(x, u)p - g(x, u)\} \geq 0.$$

Now we distinguish two cases:

(a) We can find  $u^* \in U$  such that

$$-f(x, u^*)p - g(x, u^*) \geq 0.$$

Since  $1 + \|f(x, u^*)\|$  is positive, we obtain

$$-\tilde{f}(x, u^*)p - \tilde{g}(x, u^*) = (1 + \|f(x, u^*)\|)^{-1}(-f(x, u^*)p - g(x, u^*)) \geq 0.$$

This implies

$$\sup_{u \in U} \{-\tilde{f}(x, u)p - \tilde{g}(x, u)\} \geq 0,$$

and hence  $V^+$  is a viscosity supersolution of (4.5).

(b) For all  $u \in U$  the inequality

$$-f(x, u)p - g(x, u) \leq 0$$

holds. In this case, since  $1 + \|f(x, u)\| \geq 1$ , for all  $u \in U$  we obtain

$$\begin{aligned} -\tilde{f}(x, u)p - \tilde{g}(x, u) &= \underbrace{(1 + \|f(x, u)\|)^{-1}}_{\leq 1} \underbrace{(-f(x, u)p - g(x, u))}_{\leq 0} \\ &\geq -f(x, u)p - g(x, u). \end{aligned}$$

This implies

$$\sup_{u \in U} \{-\tilde{f}(x, u)p - \tilde{g}(x, u)\} \geq \sup_{u \in U} \{-f(x, u)p - g(x, u)\} \geq 0.$$

Thus also in this case  $V^+$  is a viscosity supersolution of (4.5).

Conversely, let  $V^+$  be a viscosity supersolution of (4.5). Then for any subgradient  $p$  of  $V^+$  in  $x$  we have

$$\sup_{u \in U} \{-\tilde{f}(x, u)p - \tilde{g}(x, u)\} \geq 0.$$

Since  $\tilde{f}$  is bounded and  $\tilde{g}$  grows unbounded in  $u$  due to (H6), the supremum over  $u$  is contained in a compact set. Hence by continuity we can find a control value  $u^* \in U$  for which the maximum is attained, i.e.,

$$-\tilde{f}(x, u^*)p - \tilde{g}(x, u^*) \geq 0.$$

Since  $1 + \|f(x, u^*)\|$  is positive, we obtain

$$-f(x, u^*)p - g(x, u^*) = (1 + \|f(x, u^*)\|)(-\tilde{f}(x, u^*)p - \tilde{g}(x, u^*)) \geq 0.$$

This implies

$$\sup_{u \in U} \{-f(x, u)p - g(x, u)\} \geq 0,$$

and hence  $V^+$  is a viscosity supersolution of (4.1).  $\square$

## A NEW PERSPECTIVE IN THE STABILITY ASSESSMENT OF NEUTRAL SYSTEMS WITH MULTIPLE AND CROSS-TALKING DELAYS\*

NEJAT OLGAC<sup>†</sup>, TOMÁŠ VYHLÍDAL<sup>‡</sup>, AND RIFAT SIPAHI<sup>§</sup>

**Abstract.** The stability of neutral systems with two cross-talking delays is investigated using the method of cluster treatment of characteristic roots (CTCR). There are two main outcomes of this study: (a) we create the “strong stabilizability” (also called the “delay stabilizability”) of the system directly from the CTCR procedure. This is achieved by a small-delay stability treatment while performing the steps of the CTCR. For the “delay-stabilizable systems,” we also arrive at the exact bounds of the stability regions in the domain of the delays. (b) We deploy a point-wise algorithm which computes the rightmost roots of the characteristic quasi polynomial for cross-verification of these stability regions. Several examples are presented. The correspondence between the two methods for all of them is shown to be very strong.

**Key words.** time delay, neutral systems, multiple delay, cross-talking delays, cluster treatment of characteristic roots

**DOI.** 10.1137/070679302

**1. Problem statement and an explicit function for stability.** The method of cluster treatment of characteristic roots (CTCR) provides an efficient procedure for determining the complete stability picture of linear time invariant time delay systems (TDS) in the domain of delays. In [20], [21], the method is applied to retarded systems with multiple delays and to neutral systems [16], [17], [19] with single delay only. In this paper, three new aspects are considered within the neutral dynamics: (i) multiple rationally independent delays, (ii) cross-talk among the delays which affect both retarded as well as the neutral parts of the dynamics, and (iii) numerical cross-validation of the results of CTCR. The general dynamic structure is taken as follows:

$$(1) \quad \begin{aligned} \frac{d}{dt}[\mathbf{x}(t) - \mathbf{A}\mathbf{x}(t - \tau_1) - \mathbf{B}\mathbf{x}(t - \tau_2) - \mathbf{C}\mathbf{x}(t - \tau_1 - \tau_2)] \\ = \mathbf{D}\mathbf{x}(t - \tau_1) + \mathbf{F}\mathbf{x}(t - \tau_2) + \mathbf{G}\mathbf{x}(t - \tau_1 - \tau_2) + \mathbf{H}\mathbf{x}(t), \end{aligned}$$

where  $\mathbf{x}(t) \in \mathbb{R}^n$  is the dependent variable,  $\boldsymbol{\tau} = (\tau_1, \tau_2) \in \mathbb{R}^{2+}$  are the delays, and  $\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}, \mathbf{F}, \mathbf{G}, \mathbf{H}$  are the constant coefficient matrices of compatible dimensions. Notice that the terms with  $\mathbf{C}$  and  $\mathbf{G}$  represent the cross-talk between the delays within the neutral and retarded segments of the equation, respectively. The objective is to

---

analyze the stability robustness of the dynamics with respect to the uncertain time delays in the semi-infinite first quadrant of  $(\tau_1, \tau_2) \in \mathbb{R}^{2+}$ .

The characteristic equation of the system (1) is of quasi-polynomial form with infinitely many roots:

$$(2) \quad CE(s, \tau_1, \tau_2) = \det(s(\mathbf{I} - \mathbf{A}e^{-\tau_1 s} - \mathbf{B}e^{-\tau_2 s} - \mathbf{C}e^{-(\tau_1 + \tau_2)s}) - \mathbf{D}e^{-\tau_1 s} - \mathbf{F}e^{-\tau_2 s} - \mathbf{G}e^{-(\tau_1 + \tau_2)s} - \mathbf{H}) = 0.$$

Assuming the system matrices are constant, the stability of this system reduces to finding  $(\tau_1, \tau_2)$  regions where all the roots of (2) remain in  $\mathbb{C}^-$ , i.e., in the open left half of the complex plane. This root set is also commonly referred to as the spectrum of  $CE(s, \tau_1, \tau_2)$ , which we denote with the notation  $\sigma[CE(s, \tau_1, \tau_2)]$ . We will represent the right-half open plane by  $\mathbb{C}^+$  and the imaginary axis by  $\mathbb{C}^0$  in the rest of the text. The entire complex plane becomes the union of all three:  $\mathbb{C} = \mathbb{C}^- \cup \mathbb{C}^0 \cup \mathbb{C}^+$ .

It is also important to note that the nondelayed neutral system may be stable or unstable. The treatment we present here is transparent to this feature. For nonzero delays, however, there may be some intriguing features regarding the root continuity of (2) with respect to the delays [9], [10]. These features are the main discriminators between the neutral and retarded classes of TDS which we will revisit in the text. At this point, however, we wish to present a critical feature: The necessary (but not sufficient) condition for the stability of (1) is the stability of the difference equation

$$(3) \quad \mathbf{x}(t) - \mathbf{A}\mathbf{x}(t - \tau_1) - \mathbf{B}\mathbf{x}(t - \tau_2) - \mathbf{C}\mathbf{x}(t - \tau_1 - \tau_2) = 0.$$

It implies that the spectrum of (3), i.e., the roots of

$$(4) \quad L(s, \tau_1, \tau_2) = \det(\mathbf{I} - \mathbf{A}e^{-\tau_1 s} - \mathbf{B}e^{-\tau_2 s} - \mathbf{C}e^{-(\tau_1 + \tau_2)s}) = 0,$$

must lie in  $\mathbb{C}^-$ . However, it is shown in the cited literature that the stability of (3) at a given  $(\tau_1, \tau_2)$  may be destroyed even for infinitesimal variations of the delays; some root discontinuities and infinitely many unstable roots may appear [1], [9], [11]. To handle such occurrences, a concept called “strong stability” was introduced. The difference equation (3) is strongly stable if it is asymptotically stable for the complete domain of  $(\tau_1, \tau_2) \in \mathbb{R}^{2+}$  [1], [9], [11]; see also [14]. Furthermore, an upper bound of the spectrum which is insensitive to small-delay variations has also been suggested in [15]. If this difference equation (3) is strongly stable, we call the system (1) a “delay-stabilizable” system.

We now look at the main objective of the CTCR procedure, which is the exhaustive determination of the stability robustness picture of (1) against uncertain delays  $(\tau_1, \tau_2)$ , and encounter a surprisingly simple, intermediate result: The strong stability necessary condition, as stated above, becomes evident as a natural by-product of CTCR. This point creates one of the contributory points of the paper.

In the text, we present a cross-validation study for the results of CTCR, utilizing a recent numerical root-finding procedure [24] for computing the roots of a quasi polynomial, such as  $CE(s, \boldsymbol{\tau})$  in (2), at a given point in the delay space  $(\tau_1, \tau_2)$ . The procedure itself is briefly described, and examples are provided to display the concurrence with CTCR.

The paper is organized as follows. In section 2, a review of the CTCR algorithm is provided. The main results are given in section 3, where an original *delay-stabilizability* test is proposed, which is directly obtained from the CTCR approach. A numerical cross-validation work is presented in section 4 over the findings of the CTCR. In section 5, we provide two application examples and in section 6 the conclusions.

**2. Review of CTCR.** The CTCR algorithm was described comprehensively in [16], [17], [20], [21]. We provide a short review here, describing only the main ideas. It is known that for a linear dynamics to switch the stability posture, the characteristic roots should cross the imaginary axis, say, at  $\omega i$ . Thus, for a successful stability analysis, one needs to detect exhaustively all the potential imaginary root crossings for all combinations of delays  $(\tau_1, \tau_2)$ . Let us denote the complete set of such crossing frequencies with  $\Omega$  and the corresponding root set with  $S_\Omega$ :

$$(5) \quad \begin{aligned} \Omega &= \{ \omega | CE(s, \tau) = 0, s = \omega i, \tau \in \mathbb{R}^{2+}, \omega \in \mathbb{R} \}, \\ S_\Omega &= \{ \omega i | \omega \in \Omega \}. \end{aligned}$$

We use  $\langle \tau, \omega \rangle$  notation to indicate this causality relation between  $\tau$  and  $\omega$ . It is trivial to show that an imaginary root  $s = \omega i$  with  $\langle \tau, \omega \rangle$  correspondence will be repeated infinitely many times at the mesh points with equidistant grid size of  $2\pi/\omega$ , as

$$(6) \quad (\tau_{1j}, \tau_{2k}) = \left( \tau_1 + \frac{2\pi}{\omega} j, \tau_2 + \frac{2\pi}{\omega} k \right), \quad j = 0, 1, 2, \dots, \quad k = 0, 1, 2, \dots$$

It has also been shown in earlier studies that the root continuity exists for the retarded class of TDS [1], [10], [11]. That is, small perturbations on  $\tau$  yield small perturbations on  $\omega$ , which can be formalized as

$$(7) \quad \langle \tau + \varepsilon, \omega + \varepsilon_c \rangle, \quad 0 < |\varepsilon| \ll 1, \quad 0 < |\varepsilon_c| \ll 1.$$

Clearly,  $\varepsilon = (\varepsilon_1, \varepsilon_2)$  and  $\varepsilon_c$  are interdependent through the characteristic equation (2). If one single point  $\langle \tau, \omega \rangle$  is known, one can determine infinitely many other points earmarked by the same  $\omega$ , as defined in (6). Obviously, the same remark holds for small perturbations on  $\omega$  as per (7). Therefore, we claim that these infinitely many trajectories generated by the delays,  $\tau$ , for varying  $\omega \in \Omega$  will comply with the rule (6) point by point. According to the D-subdivision method [6], these trajectories continuously partition the  $\tau$  domain into encapsulated regions in which the number of unstable roots,  $NU$ , remains fixed. Consequently, if there is any stability switching, it has to occur at the boundaries of these regions.

The above argument brings us to a complex problem of determining exhaustively the boundaries of these infinitely many regions. Interestingly, however, there is a discipline in this complex picture with two intriguing properties. It is proven in [16], [20], [21] as Proposition I that there is only a *manageably small number* of curves in  $\tau$  space called the “kernel curves”:

$$(8) \quad \wp_0(\tau_1, \tau_2) = \left\{ \tau | \langle \tau, \omega \rangle, \tau \in \mathbb{R}^{2+}, \omega \in \Omega, 0 \leq \tau_k \leq \frac{2\pi}{\omega}, k = 1, 2 \right\},$$

where  $\langle \tau, \omega \rangle$  correspondence creates the complete set of  $\Omega$ . Notice that for all  $\omega \in \Omega$  values  $\wp_0(\tau_1, \tau_2)$  represents the smallest  $\tau_1$  and  $\tau_2$  combination. And all the other curves are created from this set,  $\wp_0(\tau_1, \tau_2)$ , utilizing the point-wise property (6) for  $j, k > 0$ . Obviously, all of these curves will be representing the imaginary root crossings of  $\omega \in \Omega$ . These curves are called the “offspring curves” and are denoted by  $\wp_{jk}(\tau_1, \tau_2)$ , where  $j$  and  $k$  identify the  $j$ th and  $k$ th generation offspring in  $\tau_1$  and  $\tau_2$ , respectively, as per (6). Consequently, the complete set of kernel and offspring curves becomes  $\wp(\tau_1, \tau_2)$ :

$$(9) \quad \wp(\tau_1, \tau_2) = \wp_0(\tau_1, \tau_2) \cup \bigcup_{j=1}^{\infty} \bigcup_{k=1}^{\infty} \wp_{jk}(\tau_1, \tau_2).$$

Any kernel point on the trajectories of  $\wp_0(\tau_1, \tau_2)$  defined by  $j = k = 0$  imposes its  $\omega$  signature identically onto its offspring ( $j > 0$  and  $k > 0$ ). Thus,  $\Omega$  remains invariant from kernel curves to offspring curves. The kernel curves and the offspring constitute the complete (and exhaustive) distribution of  $(\tau_1, \tau_2)$  points where the characteristic equation  $CE(s, \tau_1, \tau_2)$  has root sets containing at least one pair of imaginary roots. And more interestingly, there exists no point in  $(\tau_1, \tau_2) \in \mathbb{R}^{2+}$ , outside the set  $\wp(\tau_1, \tau_2)$ , which renders imaginary characteristic roots.

Another perspective for exhaustive determination of stability switching boundaries in the delay domain is studied by [8] for a retarded class of systems with two delays but without a cross-talking feature (i.e.,  $\mathbf{A} = \mathbf{B} = \mathbf{C} = \mathbf{G} = \mathbf{0}$ ). They cleverly use a geometric triangulation property to capture the potential root crossing frequencies completely. In a separate study [5] and [22] offer a numerical procedure for determining the stability picture based on direct computation of the system roots (the code is publicly available now under the name “Trace-DDE”). We wish to emphasize that all of these findings comply with two fundamental propositions which are the cornerstone of the CTCR paradigm [20], [21].

A crucial property is the directional *root tendency* along the  $\tau_j$ ,  $j = 1, 2$ , axis at the crossing of  $s = \omega i$ , which is defined by

$$(10) \quad RT_{s=\omega i}^{\tau_j} = \operatorname{sgn} [\Re(\partial s / \partial \tau_j) |_{s=\omega i}].$$

$RT$  has a very interesting feature:  $s \in \mathbf{S}_\Omega$  along the  $\tau_1$  (or  $\tau_2$ ) axes across the corresponding points on a kernel curve, and its offspring, the root tendency,  $RT_s^{\tau_j}$ , remains unchanged so long as  $\tau_2$  (or  $\tau_1$ ) is kept fixed. This, which we call the “root tendency invariance” property, is proven in earlier publications; see Proposition II in [17], [20], [21]. This feature, in essence, declares the stabilizing (or destabilizing) transitions along the regional boundaries defined by  $\wp(\tau_1, \tau_2)$ .

Using the two properties above, one can establish the stability robustness picture of the system against delay uncertainties performing the following steps of the CTCR algorithm:

- (1) Determine exhaustively the kernel and offspring curves,  $\wp(\tau_1, \tau_2)$ .
- (2) Start from the nondelayed system,  $\boldsymbol{\tau} = \mathbf{0}$ , and evaluate  $NU(0)$ , which is a trivial task.
- (3) Following line segments in  $\boldsymbol{\tau} \in \mathbb{R}^{2+}$ , which are parallel to the individual coordinates  $\tau_1$  and  $\tau_2$ , connect the origin ( $\boldsymbol{\tau} = \mathbf{0}$ ) to a point of interest  $\boldsymbol{\tau}_0$ .
- (4) As this path crosses the kernel and offspring curves, increase  $NU$  by  $+2$  (or  $-2$ ) for the  $RT = +1$  ( $-1$ ), according to the D-subdivision method of [6].
- (5) Exhaustively identify the regions in  $(\tau_1, \tau_2)$  space with  $NU = 0$  as “stable” and the others ( $NU > 0$ ) as “unstable.”

Step (1) is the most critical one in this procedure, and we present a discussion on it next for clarity. To determine  $\wp(\tau_1, \tau_2)$  exhaustively we utilize Rekasius substitution for the exponential terms [18]

$$(11) \quad e^{-\tau_j s} \Rightarrow \frac{1 - T_j s}{1 + T_j s}, \quad T_j \in \mathbb{R}, \quad j = 1, 2.$$

This representation becomes exact for  $s = \omega i$ , with a constraint between  $T_i$  and  $\tau_i$ :

$$(12) \quad \tau_j = \frac{2}{\omega} [\tan^{-1}(\omega T_j) + k\pi], \quad k = 0, 1, 2, \dots$$

TABLE 1  
Routh's array for  $\overline{CE}(s, T_1, T_2)$ .

$s^{3n}$	$p_{3n}(T_1, T_2)$	$p_{3n-2}(T_1, T_2)$	$\vdots$	$\vdots$	$p_0$
$s^{3n-1}$	$p_{3n-1}(T_1, T_2)$	$p_{3n-3}(T_1, T_2)$	$\vdots$	$\vdots$	
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$	
$s^2$	$R_{21}(T_1, T_2)$	$R_{22}(T_1, T_2) = p_0$			
$s^1$	$R_1(T_1, T_2)$				
$s^0$	$R_0(T_1, T_2) = p_0$				

This relation transforms the original characteristic equation  $CE(s, \tau_1, \tau_2) = 0$  given by (2) into a new form  $CE_T(s, T_1, T_2) = 0$  which is of fractional polynomial type. Multiplying this equation by  $(1 + T_1 s)^n(1 + T_2 s)^n$ , one obtains

$$\begin{aligned}
 \overline{CE}(s, T_1, T_2) &= \det[s((1 + T_1 s)(1 + T_2 s)\mathbf{I} - (1 + T_2 s)(1 - T_1 s)\mathbf{A} \\
 &\quad - (1 + T_1 s)(1 - T_2 s)\mathbf{B} - (1 - T_1 s)(1 - T_2 s)\mathbf{C} - (1 + T_2 s)(1 - T_1 s)\mathbf{D} \\
 &\quad - (1 + T_1 s)(1 - T_2 s)\mathbf{F} - (1 - T_1 s)(1 - T_2 s)\mathbf{G} - (1 + T_1 s)(1 + T_2 s)\mathbf{H}] \\
 &= \det(\mathbf{Q}(s, T_1, T_2)) = \sum_{j=0}^{3n} p_j(T_1, T_2) s^j = 0,
 \end{aligned}
 \tag{13}$$

where  $\mathbf{Q}(s, T_1, T_2)$  is a self-evident matrix. An interesting relation between the infinite-dimensional equation (2) and the  $3n$  degree equation (13) is that *they share the same imaginary root sets completely*. That is,

$$\begin{aligned}
 \mathbf{S}_{\Omega} &= \mathbf{S}_{\Omega} [s \mid CE(s, \tau_1, \tau_2) = 0, (\tau_1, \tau_2) \in \mathbb{R}^{2+}] \cap \mathbb{C}^0 \\
 &\equiv \mathbf{S}_{\Omega} [s \mid \overline{CE}(s, T_1, T_2) = 0, (T_1, T_2) \in \mathbb{R}^2] \cap \mathbb{C}^0,
 \end{aligned}
 \tag{14}$$

where  $\mathbf{S}_{\Omega}$  represents the complete topology of root sets of  $\overline{CE}$  for the entire space of  $(T_1, T_2) \in \mathbb{R}^2$ . The most beneficial point in transforming  $CE(s, \tau_1, \tau_2)$  into  $\overline{CE}(s, T_1, T_2)$  is obvious: the parametric equation (13) is much easier to study compared with (2). Thus, the projections of the kernel curves in  $(T_1, T_2)$  space, which are called “core curves,” are obtained.

We now present how to determine the core curve of  $\overline{CE}(s, T_1, T_2)$ , i.e., those  $(T_1, T_2)$  that give rise to  $s = \omega i \in \mathbf{S}_{\Omega} \cap \mathbb{C}^0$ . The easiest procedure to find all the imaginary roots of such characteristic polynomials is the classical Routh–Hurwitz method [12]. From the rules of Routh's array of Table 1, the imaginary roots of (13) are found at

$$R_1(T_1, T_2) = 0, \quad \text{with the condition}$$

$$R_{21}(T_1, T_2)p_0 > 0.$$

At every point  $(T_1, T_2)$  satisfying (15) and (16) there exists a crossing frequency  $\omega = \sqrt{p_0/R_{21}(T_1, T_2)}$ .

The next step in CTCR is to numerically map these core curves into kernel curves via (12) and further to offspring in  $(\tau_1, \tau_2)$  space via (6). This completes the deter-

mination of the entire set of kernel and offspring curves,  $\wp(\tau_1, \tau_2)$ , i.e., the first step in the CTCR procedure. The remaining steps are performed relatively easily.

**3. Delay stabilizability and strong stability concepts.** The “strong stability” concept is an interesting feature of the neutral TDS which was carefully studied in the literature [1], [9], [11]; see also [14], [15]. Following the conceptual discussions in the earlier investigation, we state the following:

(i) “Strong stability” of (3) implies that the system (1) may be asymptotically stable in a two-dimensional region around a point  $\tau_0 \in \mathbb{R}^{2+}$ , defined by  $0 < |\tau - \tau_0| < \varepsilon \ll 1$ .

(ii) There is a necessary condition for (1) to be “delay-stabilizable,” which requires the difference equation (3) to be strongly stable. A system that is not strongly stable cannot be delay-stabilizable. In other words, the spectrum of the respective characteristic equation (4) must be in the left-half open space (excluding the imaginary axis) for  $|\tau - \tau_0| < \varepsilon, \varepsilon \text{ finite}$ , where  $\tau_0 \in \mathbb{R}^{2+}$  is a point in the delay domain, or  $\sigma[L(s, \tau)] \in \mathbb{C}^-$ . Notice that if a system is not “strongly stabilizable,” there exists no point  $\tau_0 \in \mathbb{R}^{2+}$ , for which

$$(17) \quad \sigma[CE(s, \tau)]|_{\forall \tau: |\tau - \tau_0| < \varepsilon, \varepsilon \text{ finite}} \in \mathbb{C}^-.$$

(iii) The “strong-stabilizability” condition is (a) independent of the delays,  $\tau$  [1], [9], [11], and (b) independent of the retarded terms of (1), i.e.,  $\mathbf{D}$ ,  $\mathbf{F}$ ,  $\mathbf{G}$ , and  $\mathbf{H}$ .

(iv) As a direct consequence of (iii(a)), the strong stability condition can be simply tested at  $|\tau| = \varepsilon \ll 1$ , i.e., for small delays. If the system (1) is “strongly stable” for small delays, the necessary condition for strong stability holds.

What motivates this work is that (a) the “strong stability” condition is obtained as a simple by-product of the CTCR procedure, and (b) further deployment of CTCR creates an exhaustive and exact “stability robustness” picture for the system (1) in the entire  $\tau \in \mathbb{R}^{2+}$  domain. We present the details of these claims.

From these discussions, it results that further investigating the stability picture of a neutral system, of which the associated difference equation (3) is not strongly stable, is unnecessary. Even though for some rationally dependent (i.e., commensurate) delays all the roots may lie in the left half of the complex plane (see [14]), when the delays become rationally independent, due to, for example, arbitrarily small changes in the delays, infinitely many destabilizing roots cross the imaginary axis.

### 3.1. Main lemma: Delay stabilizability resulting from CTCR.

**MAIN LEMMA.** *The “delay-stabilizability” (or strong stability) necessary conditions as stated in observations (i)–(iv) above result as a by-product of direct deployment of CTCR.*

*Proof.* The steps of the CTCR procedure are given in section 2. As we perform the second step, a very peculiar feature appears. If for small delays

$$(18) \quad \sigma[CE(s, \tau)|_{\tau=0}] \cap \mathbb{C}^+ \neq \sigma[CE(s, \tau)|_{\tau=0^+}] \cap \mathbb{C}^+$$

it implies that  $\tau : 0 \rightarrow 0^+$  transition introduces some new right-half plane roots. These new roots may be (a) finite, in which case they are the imaginary roots of the nondelayed system, and therefore they are easily identified, or (b) at infinity and with unbounded magnitudes. It is proven that these roots at infinity are infinitely many, and they may show discontinuity complying with the Riemann sphere concept [13]; see also [10]. Earlier investigations state that the mentioned discontinuity as  $\tau : 0 \rightarrow 0^+$  invites infinitely many unbounded unstable roots iff the difference equation (3) is

not strongly stable. Further findings declare that such systems cannot be stabilized anywhere in  $\tau \in \mathbb{R}^+$ , except possibly at those points where  $\tau_1, \tau_2$  are rationally dependent [1], [14], [15]. For single delay cases, [16], [17] study the Riemann sphere concept further. Therefore, we propose imposing the condition that the  $\tau : \mathbf{0} \rightarrow \mathbf{0}^+$  transition does not create any infinite root transition to  $\mathbb{C}^+$  on the Riemann sphere. This feature is referred to as the “no root migration” requirement in the rest of the text.

We now look at this “small-delay” phenomenon under Rekasius transformation and explain how it shapes up if there is an imaginary root  $\omega i$  for  $\tau = \mathbf{0}$ . Even if the migration of roots takes place over the Riemann sphere, since the sphere has only one point at infinity it can be taken as purely imaginary; see [13].

(i) For small delays, (12) becomes

$$(19) \quad \tan \left( \frac{\tau_j \omega}{2} \right) = T_j \omega, \quad j = 1, 2,$$

which implies that

$$(20) \quad \tau_j : 0 \rightarrow \varepsilon_j \implies T_j : 0 \rightarrow \varepsilon_j / 2.$$

Notice that the  $CE(s, \tau)$ ,  $\tau = \mathbf{0}$ , and  $\overline{CE}(s, \mathbf{T})$ ,  $\mathbf{T} = \mathbf{0}$ , are identical, and so are their spectra. In the two-dimensional  $\tau$  domain such a transition can be represented using a parameter

$$(21) \quad m = \frac{\tau_2}{\tau_1} = \frac{T_2}{T_1}, \quad m \in [0, \infty).$$

(ii) The “no root migration” requirement must be independent of  $m$ . Using (21) in (13) it becomes

$$(22) \quad \begin{aligned} \overline{CE}(s, T_1, m T_1) &= \det \mathbf{Q}(s, T_1, m T_1) = \det s [(1 + (1 + m)T_1 s + mT_1^2 s^2)\mathbf{I} \\ &\quad - (1 - (1 - m)T_1 s - mT_1^2 s^2)\mathbf{A} - (1 + (1 - m)T_1 s - mT_1^2 s^2)\mathbf{B} \\ &\quad - (1 - (1 + m)T_1 s + mT_1^2 s^2)\mathbf{C}] - (1 - (1 - m)T_1 s - mT_1^2 s^2)\mathbf{D} \\ &\quad - (1 + (1 - m)T_1 s - mT_1^2 s^2)\mathbf{F} - (1 - (1 + m)T_1 s + mT_1^2 s^2)\mathbf{G} \\ &\quad - (1 + (1 + m)T_1 s + mT_1^2 s^2)\mathbf{H}] = \sum_{j=0}^{3n} p_j(m, T_1) s^j = 0. \end{aligned}$$

Each element of the characteristic matrix  $\mathbf{Q}(s, T_1, m T_1)$  is a third degree polynomial in  $s$  in the generic form

$$(23) \quad \begin{aligned} q_{i,j}(T_1, m, s) &= (e_{i,j} + a_{i,j} + b_{i,j} - c_{i,j})mT_1^2 s^3 \\ &\quad + [(d_{i,j} + f_{i,j} - g_{i,j} - h_{i,j})mT_1^2((1 + m)(e_{i,j} + c_{i,j}) + (1 - m)(a_{i,j} - b_{i,j}))T_1]s^2 \\ &\quad + [(1 - m)(d_{i,j} - f_{i,j}) + (1 + m)(g_{i,j} - h_{i,j}))T_1 + e_{i,j} - a_{i,j} - b_{i,j} - c_{i,j}]s \\ &\quad - d_{i,j} - f_{i,j} - g_{i,j} - h_{i,j} = \alpha_3^{i,j}(m, T_1)s^3 + \alpha_2^{i,j}(m, T_1)s^2 + \alpha_1^{i,j}(m, T_1)s + \alpha_0^{i,j}, \end{aligned}$$

where  $e_{i,j}$  are the elements of the identity matrix  $\mathbf{I}$  ( $e_{i,j} = 1$  for  $i = j$  and  $e_{i,j} = 0$  for  $i \neq j$ ) and lowercase notations represent the elements of the respective uppercase matrices.  $\alpha_k^{i,j}(m, T_1)$  are self-evident expressions. Notice there is no influence of

matrices **A**, **B**, **C** (i.e., the neutral part of the dynamics) in  $\alpha_0^{i,j}$  and no influence of matrices **D**, **F**, **G**, **H** (i.e., the retarded part of the dynamics) in  $\alpha_3^{i,j}(m, T_1)$ . On the other hand, in  $\alpha_1^{i,j}(m, T_1)$  and  $\alpha_2^{i,j}(m, T_1)$  traces of all matrices, **A**,  $\dots$ , **H**, can be found. However, for the limiting case of  $T_1 \rightarrow 0$ , we may drop higher order  $T_1$  terms in favor of lower order ones; i.e., in  $\alpha_2^{i,j}(m, T_1)$  one can eliminate  $T_1^2$  terms but keep the  $T_1$  terms only. This term-wise limit operation on (23) yields

$$\begin{aligned}
 \tilde{q}_{i,j}(T_1, s) &= (e_{i,j} + a_{i,j} + b_{i,j} - c_{i,j})mT_1^2s^3 \\
 &+ [(1+m)(e_{i,j} + c_{i,j}) + (1-m)(a_{i,j} - b_{i,j})]T_1s^2 \\
 &+ (e_{i,j} - a_{i,j} - b_{i,j} - c_{i,j})s - d_{i,j} - f_{i,j} - g_{i,j} - h_{i,j} \\
 &= \tilde{\alpha}_3^{i,j}mT_1^2s^3 + \tilde{\alpha}_2^{i,j}T_1s^2 + \tilde{\alpha}_1^{i,j}s^2 + \alpha_0^{i,j},
 \end{aligned}
 \tag{24}$$

where  $\tilde{\bullet}$  notation is used for limiting formation of  $\bullet$ . Dropping the terms with higher powers of  $T_1$  at each step as we expand the determinant in (22), repeated applications of this step-wise limit operation yield

$$\begin{aligned}
 \widetilde{CE}(s, T_1, mT_1) &= \tilde{p}_{3n}(m)T_1^{2n}s^{3n} + \tilde{p}_{3n-1}(m)T_1^{2n-1}s^{3n-1} \\
 &+ \dots + \tilde{p}_{n+1}(m)T_1s^{n+1} + \tilde{p}_ns^n + \tilde{p}_{n-1}s^{n-1} + \dots + \tilde{p}_1s + \tilde{p}_0 = 0.
 \end{aligned}
 \tag{25}$$

It is trivial to show that  $\tilde{p}_j, j = 0, \dots, 3n$ , coefficients depend on

**A**, **B**, **C** only for  $j = n+1, \dots, 3n$ ,

**A**, **B**, **C**, **D**, **F**, **G**, **H** for  $j = 1, \dots, n$ ,

**D**, **F**, **G**, **H** for  $j = 0$ .

Furthermore,  $\tilde{p}_j, j = 0, \dots, n$ , are constants independent of  $m$ , while  $\tilde{p}_j, j = n+1, \dots, 3n$ , are polynomial functions of  $m$ . One can, therefore, partition the characteristic equation (25) as

$$\widetilde{CE}(s, T_1, mT_1) = \widetilde{CE}_1(s, T_1, mT_1) + \widetilde{CE}_2(s) - \tilde{p}_n(m)s^n = 0,
 \tag{26}$$

where

$$\widetilde{CE}_1(s, T_1, mT_1) = s^n \sum_{j=0}^{2n} \tilde{p}_{j+n}(m)T_1^j s^j
 \tag{27}$$

and

$$\widetilde{CE}_2(s) = \sum_{j=0}^n \tilde{p}_j s^j.
 \tag{28}$$

Please notice two critical features:

(a) Within the  $\widetilde{CE}_1$  expression, the terms given under summation have an important implication:

$$\sum_{j=0}^{2n} \tilde{p}_{j+n}(m)T_1^j s^j = \tilde{L}(s, T_1, mT_1),
 \tag{29}$$

where  $\tilde{L}(s, T_1, mT_1)$  is nothing other than the respective step-wise limiting conversion of the function  $L(s, \tau_1, m\tau_1)$  of (4), following the identical procedures which converted

from  $CE(s, \tau_1, m\tau_1)$  to  $\widetilde{CE}(s, T_1, mT_1)$ . This observation can be stated as follows: the limiting form of the difference equation (3) for small delays is a factor in  $\widetilde{CE}_1$ .

(b)  $\widetilde{CE}_2(s)$  is the characteristic function of the delay free system,  $\tau_1 = \tau_2 = 0$ .

(iii) When we inquire about the imaginary root crossing of (25) using Routh's array, it shapes up as given in Table 2. Note again that the step-wise limit operation is performed in the same manner as described above throughout the formation of the array. The following observations are made on this table:

- $\widetilde{CE}_1$  and  $\widetilde{CE}_2$  (shaded) blocks are clearly separated, except one term of overlap,  $\tilde{p}_n(m)s^n$ .
- $\xi_j$ ,  $j = n+1, \dots, 3n-2$ , are simple constants, and they are functions only of  $m$ .
- Block ① is determined by the coefficients of  $\widetilde{CE}_1(s, T_1)$ , and it is formed only by the elements of the matrices of the difference equation (3).
- Because of the special formation in the array and repeated step-wise limits, the shaded block shifts to the left identically as the array shapes. And ultimately it forms the basis of the nondelayed system's Routh array (see rows marked by  $s^n$  and  $s^{n-1}$ ).
- Following on the previous observation, block ② consists of the elements of  $\widetilde{CE}_2(s, T_1)$  only, the characteristic function of the nondelayed system.

TABLE 2  
Routh's array of (25) with step-wise limit for small  $T_1$  (displayed for  $n$  even).

	$\widetilde{CE}_1$	$\widetilde{CE}_2$
$s^{3n}$	$\tilde{p}_{3n}T_1^{2n}$	$\tilde{p}_{n+4}T_1^4$
$s^{3n-1}$	$\tilde{p}_{3n-1}T_1^{2n-1}$	$\tilde{p}_{n+3}T_1^3$
$s^{3n-2}$	$\xi_{3n-2,1}T_1^{2n-2}$	$\tilde{p}_{n+2}T_1^2$
$s^{3n-3}$	$\xi_{3n-3,1}T_1^{2n-3}$	$\tilde{p}_{n+1}T_1$
$\vdots$		
$s^{n+1}$	$\xi_{n+1,1}T_1$	$\tilde{p}_n$
$s^n$	$\tilde{p}_n$	$\tilde{p}_{n-2}$
$s^{n-1}$	$\tilde{p}_{n-1}$	$\tilde{p}_{n-3}$
$s^{n-2}$	$\tilde{p}_{n-2}$	$\tilde{p}_{n-4}$
$\vdots$		
$s^1$	$\tilde{p}_1$	
$s^0$	$\tilde{p}_0$	

Based on the Routh–Hurwitz criterion, the determining condition for “no root migration” is that the first column should exhibit no additional sign change as  $T_1 : 0 \rightarrow 0^+$  transition occurs. That is,  $T_1 : 0 \rightarrow 0^+$  transition for all  $m \in \mathbb{R}^+$  implies that the number of sign changes in the first column of the array remains unchanged. Block ② is independent of  $m$ , and it declares the number of unstable roots for the nondelayed system. Block ① should not add a sign change; i.e., all the  $2n+1$  elements in this block must be in sign agreement, for all  $m \in \mathbb{R}^+$ , with  $\tilde{p}_n$  (which is independent of  $m$ ). In other words, the number of sign changes in the first column should be coming from block ②, i.e., due to the unstable roots of the delay free system. And the small

delays must not change the number of unstable roots.

Since  $T_1 > 0$ , it plays no role in the signs of these elements. By enforcing the sign agreement for all  $m \in \mathbb{R}^+$ , we declare the independence of the number of sign changes in block ① from  $m$ . Together with (20) and (21), this enforcement becomes independent of the actual values of the small delays,  $\tau_1, \tau_2$ .

It is clear that block ① is created strictly from  $L(s, \tau_1, \tau_2)$  given in (4). Then the function  $L(s, \tau_1, \tau_2)$  must be stable for small delays, in order for the system (1) not to have imaginary root migration for  $\tau : \mathbf{0} \rightarrow \mathbf{0}^+$  transition. This is the “delay-stabilizability” necessary condition, or “strong stability condition.”  $\square$

*Remark 1.* “No sign change in the first column” for  $m \in [0, \infty)$  can be verified easily. The terms corresponding to  $s^j$ ,  $j = n + 1, \dots, 3n$ , in Table 2 are polynomials in  $m$ , while the term corresponding to  $s^n$  is a constant. For no sign change in block ① for  $m \in [0, \infty)$ , the two following conditions have to be satisfied simultaneously: (a) none of the polynomials in block ① has any positive real roots; (b) all the terms in block ① have to agree in sign for arbitrarily chosen positive  $m$ .

**3.2. Application to scalar case.** We next apply the above procedure to a scalar version of system (1), that is, for  $n = 1$ . The limiting form of (25) is found as

$$(30) \quad \begin{aligned} \widetilde{CE}(s, T_1, mT_1) = & (1 + a + b - c)mT_1^2s^3 \\ & + (1 + a - b + c + m(1 - a + b + c))T_1s^2 \\ & + (1 - a - b - c)s - d - f - g - h. \end{aligned}$$

Let us recall that in the coefficients of the powers of  $s$  within  $\widetilde{CE}(s, T_1, mT_1)$ , the terms with lower order of magnitude in  $T_1$ , i.e., with higher powers of  $T_1$ , are omitted in favor of the lowest powered term via earlier explained step-wise limit operations. Routh’s array for (30) is given in Table 3, again with successive deployment of step-wise limit operations.

TABLE 3  
Routh’s array of (30) with step-wise limit for small  $T_1$ .

$s^3$	$(1 + a + b - c) m T_1^2$	$(1 - a - b - c)$
$s^2$	$(1 + a - b + c + m\{1 - a + b + c\}) T_1$	$(-d - f - g - h)$
$s^1$	$(1 - a - b - c)$	①
$s^0$	$(-d - f - g - h)$	
		②

Notice that block ① has no influence on the retarded segments of the equation but only the neutral part. This block is fully determined by the characteristic function of the difference equation corresponding to (4) after Rekasius substitution, i.e.,

$$(31) \quad \begin{aligned} \widetilde{L}(s, T_1, mT_1) = & (1 + T_1s)(1 + mT_1s) - (1 + mT_1s)(1 - T_1s)a \\ & - (1 + T_1s)(1 - mT_1s)b - (1 - T_1s)(1 - mT_1s)c = (1 + a + b - c)mT_1^2s^2 \\ & + (1 + a - b + c + m\{1 - a + b + c\})T_1s + 1 - a - b - c = 0, \end{aligned}$$

while block ② consists of the coefficients of the characteristic equation for the non-delayed system. The strong stability of the difference equation requires that elements

in block ① have the same sign for all  $m \in [0, \infty)$  (i.e., they should all be positive or negative). A closer observation shows that the case with all negative elements results in a contradiction. Therefore, the following inequalities with positive elements are considered:

$$(32) \quad \begin{aligned} 1 + a + b - c &> 0, \\ 1 + a - b + c + m(1 - a + b + c) &> 0, \\ 1 - a - b - c &> 0. \end{aligned}$$

And these conditions can be reduced to

$$(33) \quad 1 + a > |b - c|, \quad 1 - a > |b + c|,$$

determining a tetrahedron as the *strong stability* domain in the coordinates of the parameters  $a$ ,  $b$ , and  $c$ ; see Figure 1 (left). These are identical to the findings of [9] based on a fundamentally different approach. If the scalar difference equation (3) (i.e., with  $n = 1$ ) were to be considered with three independent delays (simply by substituting a third delay,  $\tau_3$ , in place of  $\tau_1 + \tau_2$ ) as studied in [9], the *strong stability* condition becomes

$$(34) \quad |a| + |b| + |c| < 1,$$

which is depicted in Figure 1 (right). As expected, the shaded region in Figure 1 (right) is within that of Figure 1 (left); since the former allows the selection of three delays totally arbitrarily, it results in a more confined strong stability region.

FIG. 1. *Strong stability domain of the scalar difference equation (3): left, with two cross-talking delays; right, with three independent delays.*

Inspired by the remark of an anonymous reviewer we wish to share with the reader the following example dynamics. Take the difference equation

$$(35) \quad x(t) - \exp(1) x(t - \tau) = 0,$$

which represents  $a = -\exp(1)$ ,  $b = c = 0$  in (31). Since inequalities (33) are not satisfied, as well as inequality (34), the difference equation is not strongly stable. The roots of (35) are trivially found as

$$s_1 = \frac{1}{\tau}, \quad s_{2k, 2k+1} = \frac{1}{\tau} \pm i \frac{2k\pi}{\tau}, \quad k = 1, 2, \dots$$

Apparently the transition  $\tau : \mathbf{0}^- \rightarrow \mathbf{0}^+$  brings infinitely many infinite roots *migrating* from the left-half complex plane to the right-half plane. This migration takes place over the single point on the Riemann sphere at infinity, although there does not exist a dynamics for the  $\tau = \mathbf{0}$  value exactly.

**3.3. Application to  $\mathbb{R}^2$  case.** Consider a neutral system (1) for  $n = 2$  this time. After Rekasius substitution we obtain a sixth degree characteristic function  $\widetilde{CE}(s, T_1, T_2)$  as in (13). Substituting  $T_2 = mT_1$  and, again, performing the step-wise limit operation, we arrive at a sixth degree polynomial  $\widetilde{CE}(s, T_1, mT_1)$  which is in the form of (25). Routh’s array corresponding to this polynomial is given in Table 4. We then check the delay-stabilizability condition, i.e., the requirement for no sign changes in the first column for all  $m \in [0, \infty)$ . If this condition is satisfied, the neutral system (1) is strongly stable (or delay-stabilizable). Then the system may have some finite two-dimensional region in delay space  $\tau$ , where it is asymptotically stable. It is critical to state two subtleties here: (a) If the system were not strongly stable, CTCR could declare it from the small-delay analysis shown in Table 4. That means infinitely many unstable characteristic roots of (2) would appear as  $\tau : \mathbf{0} \rightarrow \mathbf{0}^+$  transition occurs. (b) This instability may be reversed at some lower-dimensional regions in  $\tau$  space where  $\tau_1$  and  $\tau_2$  are rationally dependent (i.e., commensurate). Clearly, at these locations there is no finite two-dimensional region of potential stability but isolated one-dimensional lines; i.e.,  $\tau_1/\tau_2 = k, k$  being a rational number. It is obvious that, when the delays are rationally dependent, the system reduces to a single-delay dynamics. Corresponding delay-stabilizability conditions are valid only along the specific one-dimensional space (i.e., lines) designated by  $k$ .

Since the concept of stability robustness in  $\tau \in \mathbb{R}^{2+}$  truly aims at the detection of two-dimensional regions of asymptotic stability, we do not pursue those cases which are not strongly stable. For the strongly stable (i.e., delay-stabilizable) case, however, we continue with the steps of CTCR as given in section 2 and exhaustively determine the stability robustness picture of the system in the two-dimensional space of  $\tau \in \mathbb{R}^{2+}$ . We provide example studies for this in section 5.

TABLE 4  
Routh’s array of (25) for  $n = 2$  with step-wise limit for small  $T_1$ .

	$\widetilde{CE}_1$	$\widetilde{CE}_2$
$s^6$	$\tilde{p}_6 m^2 T_1^4$	$\tilde{p}_4(m) T_1^2$
$s^5$	$\tilde{p}_5(m) T_1^3$	$\tilde{p}_3(m) T_1$
$s^4$	$(\tilde{p}_5(m) \tilde{p}_4(m) - \tilde{p}_6(m) \tilde{p}_3(m)) T_1^2$	$\tilde{p}_2$
$s^3$	$(\tilde{p}_5(m) \tilde{p}_4(m) \tilde{p}_3(m) - \tilde{p}_6(m) \tilde{p}_3^2(m) - \tilde{p}_5(m) \tilde{p}_2(m)) T_1$	$\tilde{p}_1$
$s^2$	$\tilde{p}_2$	$\tilde{p}_0$
$s^1$	$\tilde{p}_1$	
$s^0$	$\tilde{p}_0$	

Please notice that the system (1) does not have to be stable for  $\tau = \mathbf{0}$  for the deployment of CTCR. If, however, this delay-free system is stable, coefficients in block

②, i.e.,  $\tilde{p}_2, \tilde{p}_1, \tilde{p}_0$ , will agree in sign. The CTCR procedure pursues regardless, in order to declare the stable regions exhaustively. An important nuance is that the “delay-stabilizable system” may end up having no stable regions in  $\tau \in \mathbb{R}^{2+}$ . This is clearly the reflection of the “necessary condition” attribute.

**4. Numerical cross-validation of the results of CTCR.** In order to verify the results of CTCR, we use a numerical method. It determines the regions in the delay domain, where  $NU$  remains fixed, by using a point-wise analysis. This method deploys a quasi-polynomial mapping based rootfinder (QPmR) technique [24], and it is based on the direct computation of the rightmost characteristic roots at points of a sufficiently dense grid, which is spread over the domain of interest  $[0, \tau_{1,\max}] \times [0, \tau_{2,\max}]$ . Let us remark that besides the QPmR algorithm, there exist other approaches for approximating the dominant roots of TDS, using the system solution operator [3], [7] or the infinitesimal generator procedure [4]. The QPmR algorithm was chosen here, because it computes all the roots within the same accuracy, and it is utilized in determining the number of unstable roots.

The procedure of the QPmR algorithm is as follows. Substituting  $s = \beta + \omega i$ , the characteristic equation (2) is first split into real and imaginary parts:

$$(36) \quad R(\beta, \omega) = \Re(CE(\beta + \omega i, \tau_1, \tau_2)) = 0,$$

$$(37) \quad I(\beta, \omega) = \Im(CE(\beta + \omega i, \tau_1, \tau_2)) = 0.$$

Intersection points of the curves described by (36) and (37) in space  $(\beta, \omega)$  reveal the characteristic roots of (2). The numerical problem reduces to determine these intersection points exhaustively. Mapping of these curves over a region  $\mathcal{D} = [\beta_{\min}, \beta_{\max}] \times [0, \omega_{\max}]$  is done numerically by applying a contour plotting algorithm; see, e.g., [23] and the references therein (available, e.g., in MATLAB function *contour*).

Since the QPmR performs the rootfinding task over a prescribed search region, it is crucial to determine its boundaries to guarantee that any unstable roots would be captured. For determining the boundaries  $\beta_{\min}, \beta_{\max}$ , we use the following adaptation rule. Consider one of the delays being fixed, e.g.,  $\tau_2$ , and  $s_r$  is the position of the rightmost root for delays  $(\tau_1, \tau_2)$ . When increasing the other delay  $\tau_1$  by  $\Delta\tau_1$ , the boundaries are arranged according to the following rule, which considers the root sensitivities to the delay:

$$(38) \quad \begin{aligned} \beta_{\max} &= \Re \left( s_r + \left[ \frac{\partial s}{\partial \tau_1} \Big|_{s=s_r} \right] \Delta\tau_1 \right) + \Delta\beta, \\ \beta_{\min} &= \min \left[ 0, \Re \left( s_r + \left[ \frac{\partial s}{\partial \tau_1} \Big|_{s=s_r} \right] \Delta\tau_1 \right) - \Delta\beta \right], \end{aligned}$$

where  $\Delta\beta$  determines the width of the region, preferably  $\Delta\beta > |\Re[\frac{\partial s}{\partial \tau_1} \Big|_{s=s_r}] \cdot \Delta\tau_1|$ ,  $\Delta\beta > 0$ . Naturally, the same adaptation rule is applied when  $\tau_1$  is fixed and  $\tau_2$  increases by  $\Delta\tau_2$ . If one starts the computation at the origin,  $\tau = \mathbf{0}$ , the characteristic function  $CE(s, \tau)$  in (2) results in the first  $s_r$ , which iteratively primes (38) for the increased values of delays.

The upper bound  $\omega_{\max}$  of the search region  $\mathcal{D}$  is selected following the root distribution property of [2]

$$(39) \quad \omega_{\max} \gg \min \left( \Omega, \frac{\pi}{n(\tau_1 + \tau_2)} \right),$$

where  $\Omega \gg s_I$  and  $s_I$  is the root of (2) with the largest imaginary part for  $\tau = 0$ .

In this work, we use the QPmR method simply to validate the findings of CTCR. Therefore, the selection of the search region  $\mathcal{D}$ , especially at the expected stability switching locations, is relatively easy to determine. For this, we utilize the information gained from the CTCR algorithm and select sufficiently large  $\omega_{\max} > \omega_c$ , where  $\omega_c$  is the root crossing frequency for a point on either the kernel or an offspring for  $\tau \neq 0$ .

In summary, the QPmR procedure determines the exact position of the rightmost roots for all points of the mesh grid in the delay domain  $[0, \tau_{1,\max}] \times [0, \tau_{2,\max}]$ . This allows us to construct the regions with an equal number of unstable roots ( $NU$ ). Example cases are provided for clarity next.

## 5. Example case studies.

**5.1. Example 1.** Consider a scalar neutral system (1) with  $a = 0.5$ ,  $b = -0.35$ ,  $c = 0.31$ ,  $d = -1.5$ ,  $f = 2$ ,  $g = -2$ ,  $h = -3$ . The first step is to check the strong stability, which is given for the scalar case by inequalities (33). Both inequalities are satisfied; thus the neutral system is strongly stable (i.e., the system is delay-stabilizable). Applying the CTCR algorithm step by step, we obtain the stability picture given in Figure 2. The color of the curves (when viewed in color) distinguishes the root tendency with respect to the delay  $\tau_1$ ; red  $RT^{\tau_1} = 1$ , blue  $RT^{\tau_1} = -1$ . The number of unstable roots in each region,  $NU$ , is also shown sparingly. Obviously, the stable regions are marked by  $NU = 0$ . As can be seen, such a region in Figure 2 consists of two branches; one stable zone covers a narrow region close to axis  $\tau_2$ , while the boundaries of the other one, which is wider, tend to infinity parallel to the line  $\tau_1 = \tau_2$ .

In Figure 3, we present the results obtained by the QPmR algorithm. To create this figure, the algorithm was used at sufficiently dense grid points in the  $(\tau_1, \tau_2)$  plane, here  $150 \times 150$  points. One can see the regions with equal  $NU$  (number of

FIG. 2. Stability picture obtained using CTCR for Example 1; kernel (thick), offspring (thin), stable region (shaded).

unstable roots), as they are shaded at different levels. The results obtained by CTCR and QPmR are in complete agreement.

In Figure 4 the spectra of the neutral system and its associated difference equation are computed using QPmR. They are shown for two selected points in the delay domain,  $P_1(\pi, 3)$  and  $P_2(\pi, 4)$ ; see also Figure 2. The number of unstable roots agrees with those found by CTCR (as declared in Figure 2), i.e., for  $P_1$ ,  $NU = 0$  and for  $P_2$ ,  $NU = 6$ .

**5.2. Example 2.** Consider a neutral equation (1), with  $n = 2$ , with the matrices

$$\mathbf{A} = \begin{bmatrix} -0.7 & 0 \\ 0 & -0.1 \end{bmatrix}, \quad \mathbf{B} = \begin{bmatrix} 0 & -0.4 \\ -0.1 & -0.2 \end{bmatrix}, \quad \mathbf{C} = \begin{bmatrix} 0 & -0.9 \\ 0 & -0.3 \end{bmatrix},$$

$$\mathbf{D} = \begin{bmatrix} -0.5 & 0 \\ 0 & -0.3 \end{bmatrix}, \quad \mathbf{F} = \begin{bmatrix} 0 & -0.1 \\ 0.4 & 0 \end{bmatrix},$$

$$\mathbf{G} = \begin{bmatrix} -0.7 & -0.1 \\ 0 & -0.4 \end{bmatrix}, \quad \mathbf{H} = \begin{bmatrix} -0.5 & 0.2 \\ 0.1 & -0.3 \end{bmatrix}.$$

The corresponding characteristic equation is

$$(40) \quad \begin{aligned} CE(s, \tau_1, \tau_2) = & s^2 + 0.8s + 0.13 + (0.8s^2 + 1.06s + 0.3)e^{-\tau_1 s} \\ & + (0.07s^2 + 0.26s + 0.15)e^{-2\tau_1 s} + (0.2s^2 + 0.16s - 0.07)e^{-\tau_2 s} \\ & + (-0.04s^2 + 0.15s + 0.04)e^{-2\tau_2 s} + (0.44s^2 + 1.44s + 0.42)e^{-(\tau_1 + \tau_2)s} \\ & + (0.21s^2 + 0.5s + 0.41)e^{-(2\tau_1 + \tau_2)s} + (0.21s + 0.28)e^{-2(\tau_1 + \tau_2)s} \\ & + (-0.09s^2 + 0.49s + 0.04)e^{-(\tau_1 + 2\tau_2)s} = 0. \end{aligned}$$

FIG. 3. Number of unstable roots ( $NU$ ) for Example 1 determined using the QPmR algorithm.

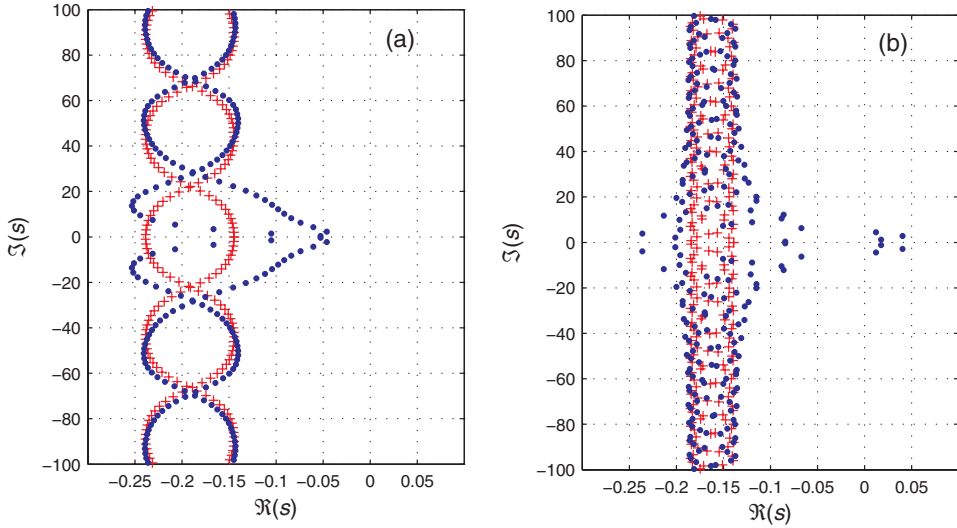

FIG. 4. Spectra of the neutral system for Example 1 (dots) and the associated difference equation (crosses) for (a)  $P_1(\pi, 3)$  and (b)  $P_2(\pi, 4)$ .

The delay stabilizability is checked first as described in subsection 3.1. The difference equation is stable, as small-delay analysis reveals no sign change on the first column of the array described in Table 2. So the difference equation is strongly stable, and the system is delay-stabilizable. CTCR continues to determine the robust stability regions with respect to the uncertain delays. The results of both CTCR and QPmR are shown in Figures 5 and 6, respectively. As can be seen, only one stability region (with  $NU = 0$ ) appears over the selected delay regions. Its shape is determined by the kernel and the offspring curves. QPmR declares the dominant characteristic roots of which the real parts are displayed in Figure 6. The stability boundary is marked by a thick black curve. Both methods again concur.

**6. Conclusions.** A general class of neutral systems with two time delays is studied for the stability robustness against delay uncertainties. The delays appear both in the neutral and retarded parts, and in the cross-talking format, which is a challenging feature. First, the method of cluster treatment of characteristic roots (CTCR) is employed to determine the stability domain in the delays. As the main contribution of the paper, we demonstrate that the CTCR procedure reveals a very critical feature, called the “delay stabilizability,” as a by-product. It is based on small-delay analysis of the dynamics. Even though the criterion is designed for a general system with  $n$ -dimensional matrices, special attention is paid to the scalar and two-dimensional cases for ease of conveyance. Furthermore, an alternative numerical algorithm is deployed for cross-validating the findings of CTCR. This algorithm is based on precisely computing the rightmost characteristic roots of the system for given delay values. Example cases are presented to display the concurrence of the two methods.

FIG. 5.  $NU$  distribution obtained by CTCR for Example 2; kernel (thick), stable region (shaded).

FIG. 6. Real part of the rightmost root  $s_r$  of the spectrum for Example 2 as  $(\tau_1, \tau_2)$  vary. The thick line is the stability boundary in the delay space.

## DESIGN OF POSITIVE LINEAR OBSERVERS FOR POSITIVE LINEAR SYSTEMS VIA COORDINATE TRANSFORMATIONS AND POSITIVE REALIZATIONS\*

JUHOON BACK<sup>†</sup> AND ALESSANDRO ASTOLFI<sup>‡</sup>

**Abstract.** Two new approaches to designing positive linear observers for positive linear systems are proposed. The first one employs a coordinates transformation and the second relies on the theory of positive realization. These approaches allow one to enlarge the class of positive systems that admit positive linear observers. New results on compartmental systems are also presented.

**Key words.** positive systems, positive observers, positive realization

**AMS subject classifications.** 15A48, 93B07, 93B51

**DOI.** 10.1137/060663891

**1. Introduction.** A positive linear system is a linear system whose trajectories originating from the nonnegative orthant evolve therein for all positive times. Since there are many physical systems whose state variables represent some quantities that should be nonnegative, such as density and population, a lot of researchers have studied this class of systems; see, for example, [13, 16, 19, 20, 23, 25, 27, 28, 29] and the references therein.

In this paper we are concerned with the observer design problem for positive linear systems. It should be mentioned that for general linear systems the observer design problem has been completely solved; i.e., there exists a (Luenberger) observer if and only if the system is detectable [22]. However, in this case, the state estimate may not belong to the nonnegative orthant for some time interval even if the actual state of the system remains therein. This means that the classical Luenberger observer, if used for estimating the state of a positive system, may generate a meaningless estimate for the actual state, which is always nonnegative. Thus, it is natural to develop observers for positive systems which always produce meaningful information on the system states.

Motivated by this, some results have been published. For example, results on positive linear observers for compartmental systems [32] (see section 2 for the definition) and positive systems [9] have been developed. Although these papers provide checkable conditions for the existence of a positive observer, a system theoretic existence criterion, such as detectability for general linear systems, is not available yet.

The approaches of the aforementioned works share a fundamental restriction: they use the Luenberger (identity) observer to find conditions under which a positive (or compartmental) linear observer exists. This means that the observer is designed in the original coordinates system and is of the same dimension as the system *to be observed*. However, as can be seen from the examples in the paper, this framework severely

restricts the class of systems that admit (Luenberger-type) positive linear observers.

The main objective of this paper is to introduce new approaches for positive linear observers and to provide conditions on their existence. The first idea is to employ a coordinate transformation. It is motivated by the fact that even though a linear system is not a positive system in one coordinate system, it can be positive in another coordinate system. The second idea is to formulate the problem as a positive realization problem [2, 5, 12, 24]. It is based on the fact that a positive linear observer can be regarded as a transfer function which has a positive realization. This method allows us to circumvent the inverse eigenvalue problem [10, 21], which should be solved if we fix the dimension of the observer equal to that of the system. In other words, in the positive realization approach, the dimension of the observer is also a design parameter.

The contribution of this paper (and the organization) is summarized as follows.

1. Luenberger-type observers (section 3): some existing results are examined and corrected to establish basic results, especially on compartmental systems (section 3.2).
2. Positive observers using a coordinates transformation (section 4): two necessary conditions (section 4.2) and one sufficient condition (section 4.3) on the spectrum are provided.
3. Positive observers via positive realization (section 5): a sufficient condition which is less restrictive than other approaches is obtained and applied to compartmental systems (section 5.2).

Several illustrative examples are presented to show the effectiveness of the approaches.

**2. Preliminaries and notation.** Let  $\mathbb{R}$  ( $\mathbb{C}$ , resp.) be the set of real numbers (complex numbers, resp.) and  $\mathbb{R}^n$  the set of  $n$ -tuples with each component belonging to  $\mathbb{R}$ . Define  $\mathbb{R}_+ := [0, \infty)$ ,  $\mathbb{R}_- := (-\infty, 0)$ .  $\mathbb{R}_+^n$  is the set of  $n$ -tuples of  $\mathbb{R}_+$  and  $\text{int } \mathbb{R}_+^n$  is the interior of  $\mathbb{R}_+^n$ . Let  $\mathbb{R}^{n \times m}$  ( $\mathbb{R}_+^{n \times m}$ ) be the set of  $n \times m$  matrices whose elements are in  $\mathbb{R}$  ( $\mathbb{R}_+$ , resp.). Given  $A \in \mathbb{R}^{n \times m}$ ,  $A^t$  is the transpose of  $A$ , and  $\sigma(A)$  the set of all eigenvalues of  $A$ . A matrix  $A$  is said to be singular if  $0 \in \sigma(A)$ .

For  $\lambda \in \mathbb{C}$ ,  $\text{Re } \lambda$  is the real part of  $\lambda$ .  $\mathbb{C}_- := \{\lambda \in \mathbb{C} \mid \text{Re } \lambda < 0\}$ .

Given  $A, B \in \mathbb{R}^{n \times m}$ ,  $A > B$  ( $A \geq B$ , resp.) if and only if  $A_{ij} > B_{ij}$  ( $A_{ij} \geq B_{ij}$ , resp.)  $\forall 1 \leq i \leq n, 1 \leq j \leq m$ .  $A < B$  and  $A \leq B$  are defined similarly.

A matrix  $A \in \mathbb{R}^{n \times n}$  is called a Metzler matrix if  $A_{ij} \geq 0 \forall i \neq j$  (i.e.,  $\exists \alpha \in \mathbb{R}_+$  such that  $A + \alpha I \in \mathbb{R}_+^{n \times n}$ ). A matrix  $A$  is said to be inverse-positive if it is invertible and  $A^{-1} \geq 0$ .

Given  $A_1, \dots, A_n$  where  $A_i \in \mathbb{R}^{n_i \times m_i}$ ,  $\text{diag}\{A_1, \dots, A_n\}$  is a block diagonal matrix whose  $(i, i)$ th block is  $A_i$ , while the nondiagonal blocks are all zero matrices. The matrix  $1_{n \times m} \in \mathbb{R}^{n \times m}$  ( $0_{n \times m}$ , resp.) stands for the matrix whose elements are all 1 (0, resp.).

A compartmental matrix  $A \in \mathbb{R}^{n \times n}$  is a Metzler matrix with the property  $\sum_{i=1}^n a_{ij} \leq 0 \forall j \in \{1, \dots, n\}$ .

A matrix  $A \in \mathbb{R}^{n \times n}$  is said to be reducible if there exists a permutation matrix  $P \in \mathbb{R}^{n \times n}$  such that

$$PAP^t = \begin{bmatrix} \overline{A}_{11} & 0 \\ \overline{A}_{21} & \overline{A}_{22} \end{bmatrix},$$

where  $\overline{A}_{11}$ ,  $\overline{A}_{22}$  are square matrices.  $A$  is said to be irreducible if  $A$  is not reducible.

The following properties are well known.

**THEOREM 2.1** (see [6, 17, 23]). *Let  $A \in \mathbb{R}^{n \times n}$  be a Metzler matrix.*

1. *There exist a real number  $\lambda_{\max}(A)$  and a vector  $v_{\max} \in \mathbb{R}_+^n$  such that (1)  $Av_{\max}$*

$= \lambda_{\max}(A)v_{\max}$  and (2) if  $\lambda \neq \lambda_{\max}(A)$  is any other eigenvalue of  $A$ , then  $\operatorname{Re} \lambda < \lambda_{\max}(A)$ .

2. If  $A$  is irreducible, then the eigenvalue with maximal real part  $\lambda_{\max}(A)$  has (algebraic) multiplicity one and there exists a positive eigenvector  $v_{\max}$  associated to  $\lambda_{\max}(A)$ .
3. If  $A$  is a compartmental matrix, then  $\sigma(A) \subseteq \{\lambda \in \mathbb{C} \mid \operatorname{Re} \lambda < 0 \text{ or } \lambda = 0\}$ .

Recall that  $\lambda_{\max}(A)$  is often called the Perron–Frobenius eigenvalue.

Now we recall the definition of positive linear systems (with positive inputs and positive outputs) and one of their characterizations.

DEFINITION 2.2 (see [23, 32]). Consider a continuous-time linear dynamic system

$$(2.1) \quad \begin{aligned} \dot{x} &= Ax + Bu, & x(t_0) &= x_0, \\ y &= Cx + Du, \end{aligned}$$

where  $x \in \mathbb{R}^n$  is the system state,  $u \in \mathbb{R}^p$  the system input, and  $y \in \mathbb{R}^q$  the system output. This system is called a positive linear system if  $\forall x_0 \in \mathbb{R}_+^n$  and  $\forall u(t) \in \mathbb{R}_+^p$ ,  $\forall t \geq 0$ , we have  $x(t) \in \mathbb{R}_+^n$  and  $y(t) \in \mathbb{R}_+^q$   $\forall t \geq 0$ .

PROPOSITION 2.3 (see [23, 32]). A linear dynamic system of the form (2.1) is a positive linear system if and only if  $B \geq 0$ ,  $C \geq 0$ ,  $D \geq 0$ , and  $A$  is a Metzler matrix.

We close this section with a result on the shift of  $\lambda_{\max}(A)$  which follows trivially from Theorem 2.9 of [7]. (See also [26] for a proof of Brauer’s theorem.)

THEOREM 2.4 (adapted from Theorem 2.9 of [7]). Let  $A \in \mathbb{R}^{n \times n}$  be an irreducible Metzler matrix and let  $v_{\max}$  be the eigenvector associated to  $\lambda_1 := \lambda_{\max}(A)$ . Also, let  $v \in \mathbb{R}^n$ . Then

$$\sigma(A - v_{\max}v^t) = (\sigma(A) \setminus \{\lambda_1\}) \cup \{\lambda_1 - v^t v_{\max}\}.$$

**3. Luenberger-type positive linear observers.** In this section, Luenberger-type positive linear observers are discussed. At first, the problem is defined and a characterization is provided. We also discuss the problem for a special class of positive systems whose maximal real eigenvalue is less than or equal to zero and present a necessary and sufficient condition on the existence of observers.

**3.1. Problem formulation and basic results.** Consider unforced multioutput linear systems,

$$(3.1) \quad \begin{aligned} \dot{x} &= Ax, & x(t_0) &= x_0, \\ y &= Cx, \end{aligned}$$

where  $A \in \mathbb{R}^{n \times n}$ ,  $C \in \mathbb{R}^{q \times n}$ . Throughout the paper, we assume that  $C$  has rank  $q$  and that system (3.1) is a positive linear system (i.e.,  $A$  is Metzler and  $C \geq 0$ ).

As far as the state observation problem is concerned, it is natural to consider the Luenberger-type observer (linear identity observer)

$$(3.2) \quad \dot{\hat{x}} = A\hat{x} + K(y - C\hat{x}),$$

because the observer problem for linear systems has been completely solved in this form [22].

As mentioned in section 1, we would like to design an observer which estimates the states of the system and is itself a positive system whose input is the system’s output  $y$  and whose output is the state estimate  $\hat{x}$ . In other words, we require (3.2) to satisfy

1.  $K \in \mathbb{R}_+^{q \times n}$ ;
2.  $A - KC$  is a Metzler and Hurwitz matrix.

For the single output case ( $q = 1$ ), a necessary and sufficient condition has been stated in [9] whose proof requires the property shown below.

LEMMA 3.1 (adapted from Problem 6.9.1 in [23]). *Let  $A$  be a Metzler matrix. Let  $Z_1, Z_2 \in \mathbb{R}_+^{n \times n}$  be such that  $Z_1 \leq Z_2$ . If  $A - Z_1$  and  $A - Z_2$  are Metzler, then  $\lambda_{\max}(A - Z_1) \geq \lambda_{\max}(A - Z_2)$ .*

With this lemma, it is possible to establish the following result. A slight modification of the proof provided in [9] proves the assertion.

THEOREM 3.2 (see [9]). *Given a Metzler matrix  $A \in \mathbb{R}^{n \times n}$  and a nonzero matrix  $C \in \mathbb{R}_+^{1 \times n}$ , let  $K^* = [k_1^* \ \dots \ k_n^*]^t \in \mathbb{R}_+^n$  be a nonnegative matrix defined as follows. If there exists an index  $i$  such that  $c_i \neq 0$ , while  $c_j = 0$  for  $j \neq i$ , then*

$$k_i^* > \frac{a_{ii}}{c_i},$$

$$k_j^* = \frac{a_{ji}}{c_i} \text{ for } j \neq i.$$

*Otherwise,*

$$k_j^* = \min_{i \neq j, c_i \neq 0} \left\{ \frac{a_{ji}}{c_i} \right\} \quad \forall j.$$

*Then there exists a nonnegative matrix  $K \in \mathbb{R}_+^n$  such that  $A - KC$  is a Hurwitz and Metzler matrix if and only if  $\lambda_{\max}(A - K^*C) < 0$ .*

As mentioned in [9], one can easily check the condition for the existence of positive observers of the form (3.2). Moreover, if  $C$  contains more than two nonzero elements, then Theorem 3.2 gives a gain matrix  $K^*$  such that  $\lambda_{\max}(A - K^*C) \leq \lambda_{\max}(A - KC) \forall K \in \mathbb{R}_+^{n \times 1}$  making  $A - KC$  Metzler; i.e.,  $K^*$  pushes the maximum real eigenvalue toward  $-\infty$  as far as possible.

**3.2. Result on a class of positive systems.** Consider a positive linear system (3.1) with

$$(3.3) \quad 0 \in \sigma(A) \subset \{\lambda \in \mathbb{C} \mid \operatorname{Re}(\lambda) < 0\} \cup \{\lambda = 0\}.$$

Note that the matrix  $A$  is Metzler and its spectrum satisfies the condition (3.3), but it is not in general a compartmental matrix. This class of systems has been dealt with in [19] and contains compartmental systems (see [1, 16] and the references therein). In particular, the paper [19] considers the stabilization problem of single input positive linear systems. As far as the observer design problem is concerned, [32] characterizes systems that admit positive linear observers.

We provide a complement to the main result of [32, Theorems 3.13 and 4.12], especially for the reducible case. Since the class of systems in this subsection covers compartmental systems, the result of this section is a new (and corrected) version of Theorem 3.13 of [32], and its dual is an extension of [19] to the multi-input case.

To remove any notational ambiguity, we use  $[A]_{ij}$  for the  $(i, j)$ th entry of  $A$  (this notation is confined to this subsection). We note that for a compartmental matrix  $A$ , if  $A - B$  is Metzler for some matrix  $B \in \mathbb{R}_+^{n \times n}$ , then  $A - B$  is compartmental. This property is used several times in this subsection.

Following the same procedure of [19] with a transformation  $T = \operatorname{diag}\{t_1, \dots, t_n\}$ ,  $t_i > 0$ , and a suitable permutation matrix  $P$ ,  $A$  is assumed to have the form (3.4)

shown below:

$$(3.4) \quad A := \begin{bmatrix} A_{11} & 0 & \cdots & 0 \\ A_{21} & A_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ A_{\nu 1} & A_{\nu 2} & \cdots & A_{\nu \nu} \end{bmatrix}$$

for  $\nu = 1$  ( $A$  is irreducible) or  $\nu \in \{2, \dots, n\}$  ( $A$  is reducible), where the block matrices  $A_{ij}$  are such that

1.  $A_{ii}$ ,  $1 \leq i \leq \nu$ , is a square irreducible *compartmental* matrix;
2.  $A_{ij} \geq 0$  if  $i \neq j$ .

Let  $d_i$  be the dimension of the matrix  $A_{ii}$ , and let  $1 \leq s_1 < \dots < s_m$  be such that  $A_{s_i s_i}$  is a singular block in  $A$ . Note that if  $i \notin \{s_1, \dots, s_m\}$ ,  $A_{ii}$  is Hurwitz. Since the matrices  $A_{ii}$  are irreducible, 0 is a simple eigenvalue of each  $A_{s_i s_i}$  and hence  $m$  coincides with the algebraic multiplicity of 0 as an eigenvalue of  $A$ .

The matrices  $C$  and  $K$  (obtained, in turn, by means of the transformation  $T$  and the permutation  $P$ ) can be block-partitioned as follows:

$$(3.5) \quad C := \begin{bmatrix} C_{11} & \cdots & C_{1\nu} \\ \vdots & \ddots & \vdots \\ C_{q1} & \cdots & C_{q\nu} \end{bmatrix},$$

where  $C_{ij} \in \mathbb{R}_+^{1 \times d_j}$ ,  $1 \leq i \leq q$ ,  $1 \leq j \leq \nu$  ( $C_{ij}$  is a row vector with dimension compatible with  $A_{jj}$ ), and

$$(3.6) \quad K := \begin{bmatrix} K_{11} & \cdots & K_{1q} \\ \vdots & \ddots & \vdots \\ K_{\nu 1} & \cdots & K_{\nu q} \end{bmatrix},$$

where  $K_{ij} \in \mathbb{R}_+^{d_i \times 1}$ ,  $1 \leq i \leq \nu$ ,  $1 \leq j \leq q$ .

From this decomposition, we obtain the following result.

**LEMMA 3.3.** *Suppose system (3.1) satisfies (3.3). If the system admits a positive linear observer of the form (3.2), then the algebraic multiplicity  $m$  of the zero eigenvalue of  $A$  is at most  $q$ .*

*Proof.* The existence of a positive linear observer implies that there exists  $K \in \mathbb{R}_+^{n \times q}$ , which renders the matrix  $A - KC$  Metzler (hence, compartmental) and Hurwitz. Since  $A$  is lower block triangular, it is necessary that all blocks  $A_{ij} - \sum_{l=1}^q K_{il} C_{lj}$  for  $j > i$  be zero, namely,

$$(3.7) \quad K_{il} C_{lj} = 0, \quad j > i, \quad l = 1, \dots, q.$$

Then necessarily the diagonal block  $A_{s_i s_i} - \sum_{\mu=1}^q K_{s_i \mu} C_{\mu s_i}$  is compartmental and Hurwitz  $\forall i = 1, \dots, m$ . Thus, there exist  $\eta_1, \dots, \eta_m \in \{1, \dots, q\}$  such that

$$(3.8) \quad K_{s_l \eta_l} C_{\eta_l s_l} \neq 0, \quad l = 1, \dots, m.$$

This relation with  $l = 1$  yields  $K_{s_1 \eta_1} \neq 0$ . This fact and (3.7) imply  $C_{\eta_1 s_2} = 0, \dots, C_{\eta_1 s_m} = 0$ . Thus, it follows from (3.8) that  $\eta_1 \neq \eta_2, \eta_1 \neq \eta_3, \dots, \eta_1 \neq \eta_m$ . Repeating this argument for  $l = 2, \dots, m$ , we have

$$(3.9) \quad \eta_i \neq \eta_j, \quad i \neq j, \quad 1 \leq i, j \leq m,$$

which proves the assertion.  $\square$

Now, we state the main result of this subsection.

**THEOREM 3.4.** *There exists  $K \in \mathbb{R}_+^{n \times q}$  such that system (3.2) is a positive linear observer if and only if there exist  $m$  numbers  $\eta_1, \dots, \eta_m$  with  $\eta_i \leq q$ ,  $i = 1, \dots, m$ , and  $\eta_i \neq \eta_j$  if  $i \neq j$ , and  $m$  numbers  $\xi_1, \dots, \xi_m$  with  $\xi_i \in \{1, \dots, d_{s_i}\}$ ,  $1 \leq i \leq m$ , such that for each  $i \in \{1, \dots, m\}$  the following conditions hold:*

1.  $C_{\eta_i s_i} \neq 0$  and  $\forall \mu \in \{1, \dots, d_{s_i}\}$  with  $\mu \neq \xi_i$  and  $[C_{\eta_i s_i}]_\mu \neq 0$ ; it holds that  $[A_{s_i s_i}]_{\xi_i \mu} \neq 0$ .
2.  $C_{\eta_i s_i+1} = 0, \dots, C_{\eta_i \nu} = 0$ .
3. For every  $\mu \in \{1, \dots, d_{s_i}\}$  and every  $l \in \{1, \dots, s_i - 1\}$ , condition  $[C_{\eta_i l}]_\mu \neq 0$  implies  $[A_{s_i l}]_{\xi_i \mu} \neq 0$ .

*Proof.* Necessity: By Lemma 3.3, it follows that  $m \leq q$ . Moreover, since  $A$  is lower block triangular and  $A - KC$  is Hurwitz and Metzler, one has, as in the proof of Lemma 3.3,

$$(3.10) \quad A_{ij} - \sum_{\eta=1}^q K_{i\eta} C_{\eta j} \geq 0, \quad j < i,$$

$$(3.11) \quad A_{ii} - \sum_{\eta=1}^q K_{i\eta} C_{\eta i} : \text{Hurwitz and compartmental}, \quad 1 \leq i \leq \nu,$$

$$(3.12) \quad \sum_{\eta=1}^q K_{i\eta} C_{\eta j} = 0, \quad j > i.$$

Consider (3.11). Since  $A_{s_i s_i}$  is singular, the matrix  $\sum_{\eta=1}^q K_{s_i \eta} C_{\eta s_i}$  must be nonzero. This means that there exists  $\eta_i \in \{1, \dots, q\}$  such that  $K_{s_i \eta_i} C_{\eta_i s_i} \neq 0$  and  $A_{s_i s_i} - K_{s_i \eta_i} C_{\eta_i s_i}$  is compartmental. Moreover, since  $A_{s_i s_i}$  is an irreducible compartmental matrix and  $A_{s_i s_i} - K_{s_i \eta_i} C_{\eta_i s_i}$  is also a compartmental matrix, it follows from Proposition 3.12 in [32] that  $A_{s_i s_i} - K_{s_i \eta_i} C_{\eta_i s_i}$  is a Hurwitz and compartmental matrix. Since  $K_{s_i \eta_i}$  is a nonzero vector, there exist  $\xi_i \in \{1, \dots, d_{s_i}\}$  such that  $[K_{s_i \eta_i}]_{\xi_i} \neq 0$ , i.e.,  $[K_{s_i \eta_i}]_{\xi_i} > 0$ .

We show that the indices  $\eta_i$  and  $\xi_i$  satisfy Condition 1. Let  $\mu \in \{1, \dots, d_{s_i}\}$  and  $\mu \neq \xi_i$ . Suppose  $[C_{\eta_i s_i}]_\mu \neq 0$  (equivalently,  $[C_{\eta_i s_i}]_\mu > 0$ ). Recalling that  $A_{s_i s_i} - K_{s_i \eta_i} C_{\eta_i s_i}$  is compartmental,  $\mu \neq \xi_i$  implies that

$$0 \leq [A_{s_i s_i} - K_{s_i \eta_i} C_{\eta_i s_i}]_{\xi_i \mu} = [A_{s_i s_i}]_{\xi_i \mu} - [K_{s_i \eta_i}]_{\xi_i} [C_{\eta_i s_i}]_\mu.$$

From the fact that  $[C_{\eta_i s_i}]_\mu > 0$  and  $[K_{s_i \eta_i}]_{\xi_i} > 0$ , it follows that  $[A_{s_i s_i}]_{\xi_i \mu} > 0$ . Therefore, the existence of  $\eta_i$  and  $\xi_i$  satisfying Condition 1 has been proved. Note that the fact  $\eta_i \neq \eta_j$  if  $i \neq j$  has not been proved yet.

We will prove Conditions 2 and 3 for this choice of  $\eta_i$ 's and of  $\xi_i$ 's.

By (3.12) and  $K_{s_i \eta_i} \neq 0$ , we obtain  $C_{\eta_i s_i+1} = 0, \dots, C_{\eta_i \nu} = 0$ , which proves that Condition 2 holds true.

Now, we prove the fact  $\eta_i \neq \eta_j$  if  $i \neq j$ . Note that when  $m = 1$ , there is only one index and hence there is nothing to prove. For the case  $m \geq 2$ , suppose there exist  $i, j \in \{1, \dots, m\}$  such that  $i < j$  and  $\eta_i = \eta_j$ . Then, by Condition 2, we have  $C_{\eta_i s_i+1} = 0, \dots, C_{\eta_i s_j} = 0, \dots, C_{\eta_i \nu} = 0$ . Moreover, the fact  $\eta_i = \eta_j$  results in  $C_{\eta_j s_j} = 0$ . However, this is a contradiction to Condition 1 ( $C_{\eta_i s_i} \neq 0 \forall i$ ).

Moving to Condition 3, let  $\mu \in \{1, \dots, d_{s_i}\}$  and  $l \in \{1, \dots, s_i - 1\}$  and suppose  $[C_{\eta_i l}]_\mu \neq 0$ . Since  $l < s_i$ , relation (3.10) holds, and therefore  $0 \leq A_{s_i l} - \sum_{\eta=1}^q K_{s_i \eta} C_{\eta l}$ .

Hence,  $K_{s_i\eta_i}C_{\eta_i l} \leq \sum_{\eta=1}^q K_{s_i\eta}C_{\eta l} \leq A_{s_i l}$ . Recalling that  $[K_{s_i\eta_i}]_{\xi_i} > 0$ , which has been shown in the first part of this proof, one has  $0 < [K_{s_i\eta_i}]_{\xi_i}[C_{\eta_i l}]_{\mu} = [K_{s_i\eta_i}C_{\eta_i l}]_{\xi_i\mu} \leq [A_{s_i l}]_{\xi_i\mu}$ , which proves that Condition 3 holds true. Therefore the proof of necessity is complete.

Sufficiency: We take  $K_{vw} = 0$  if there is no  $i \in \{1, \dots, m\}$  such that  $v = s_i$  and  $w = \eta_i$ . That is to say, only the vectors  $K_{s_i\eta_i}$ ,  $i = 1, \dots, m$ , will be chosen to be nonzero. Indeed, let  $K_{s_i\eta_i}$ ,  $i = 1, \dots, m$ , be defined as follows.

1. In case  $C_{\eta_i 1} = 0, \dots, C_{\eta_i s_i-1} = 0$ , and  $[C_{\eta_i s_i}]_{\xi} = 0, \xi \neq \xi_i$ ,

$$[K_{s_i\eta_i}]_{\xi} = 0, \quad \xi \neq \xi_i,$$

$$[K_{s_i\eta_i}]_{\xi_i} = \alpha_i, \quad \alpha_i : \text{arbitrary positive number.}$$

2. Otherwise

$$[K_{s_i\eta_i}]_{\xi} = 0, \quad \xi \neq \xi_i,$$

$$[K_{s_i\eta_i}]_{\xi_i} = \min_{\substack{1 \leq \mu \leq n, \mu \neq \mu_i^* \\ [C]_{\eta_i\mu} \neq 0}} \frac{[A_{s_i}]_{\xi_i\mu}}{[C]_{\eta_i\mu}}, \quad \mu_i^* := \xi_i + \sum_{j=1}^{s_i-1} d_j,$$

where  $A_{[s_i]} := [A_{s_i 1} \ \dots \ A_{s_i s_i} \ 0 \ \dots \ 0] \in \mathbb{R}_+^{d_{s_i} \times n}$ .

It is easy to see that the matrix  $K$  constructed above is nonzero and renders  $A - KC$  a Hurwitz and Metzler matrix. Thus the assertion follows.  $\square$

Since our class of systems includes compartmental systems, it is expected that Theorem 3.4 can be refined further. To do this, we assume that (3.1) is a compartmental system ( $A$  is a compartmental matrix and  $C \in \mathbb{R}_+^{q \times n}$ ) with  $0 \in \sigma(A)$  and the algebraic multiplicity of the zero eigenvalue is  $m$ . Without loss of generality it can be assumed that  $A$  has the form (Theorem 3.6 in [32])

$$(3.13) \quad A = \begin{bmatrix} A_{11} & 0 & 0 & 0 & \dots & 0 \\ \vdots & \ddots & 0 & & & \\ A_{\nu-m,1} & & A_{\nu-m,\nu-m} & 0 & & \\ A_{\nu-m+1,1} & & A_{\nu-m+1,\nu-m} & A_{\nu-m+1,\nu-m+1} & & \\ \vdots & & \vdots & 0 & \ddots & 0 \\ A_{\nu 1} & \dots & A_{\nu,\nu-m} & 0 & 0 & A_{\nu\nu} \end{bmatrix},$$

where  $A_{ii} \in \mathbb{R}^{d_i \times d_i}$  is compartmental and irreducible  $\forall i = 1, \dots, \nu$ , and  $0 \in \sigma(A_{ii})$  with multiplicity 1  $\forall i = \nu - m + 1, \dots, \nu$ . Note that  $A_{11}, \dots, A_{\nu-m,\nu-m}$  are Hurwitz and  $A_{ij} \geq 0, i \neq j$ . We also decompose  $C$  as in (3.5). Thus,  $C_{ij} \in \mathbb{R}_+^{1 \times d_j}$ .

The special structure of  $A$  allows us to refine Theorem 3.4 as follows. Note that this result is a correct version of Theorem 3.13 in [32].<sup>1</sup>

<sup>1</sup>Theorem 3.13 in [32]: Consider a linear compartmental system (3.1) with  $A, C$  decomposed as in (3.13) and (3.5). Let  $C_i = [C_{1i}^t \ \dots \ C_{qi}^t]^t$ . Suppose the zero eigenvalue of  $A$  is of multiplicity  $m$ .

1. If  $m = 0$ , then  $(A, C)$  is positively detectable if and only if  $(A, C)$  is positively modifiable.
2. For  $m \geq 1$ ,  $(A, C)$  is positively detectable if and only if  $(A_{ii}, C_i)$  is positively modifiable  $\forall i = \nu - m + 1, \dots, \nu$ .

$(A, C)$  is said to be positively detectable if  $\exists K \geq 0$  such that  $A - KC$  is Hurwitz and compartmental, and  $(A, C)$  is said to be positively modifiable if  $\exists K \geq 0$  such that  $KC \neq 0$  and  $A - KC$  is compartmental.

**COROLLARY 3.5.** *Consider the positive system (3.1) with  $A$  being a compartmental matrix decomposed as in (3.13) and suppose the multiplicity of the zero eigenvalue of  $A$  is  $m \geq 1$ . This system admits a positive linear observer of the form (3.2) with  $K \in \mathbb{R}_+^{n \times q}$  if and only if there exist  $m$  numbers  $\eta_{\nu-m+1}, \dots, \eta_\nu$  with  $\eta_i \leq q$ ,  $\nu - m + 1 \leq i \leq \nu$ , and  $\eta_i \neq \eta_j$  if  $i \neq j$ , and  $m$  numbers  $\xi_{\nu-m+1}, \dots, \xi_\nu$  with  $\xi_i \in \{1, \dots, d_i\}$ ,  $\nu - m + 1 \leq i \leq \nu$ , such that for each  $i \in \{\nu - m + 1, \dots, \nu\}$  the following conditions hold:*

1.  $C_{\eta_i i} \neq 0$ , and  $\forall \mu \in \{1, \dots, d_i\}$  with  $\mu \neq \xi_i$  and  $[C_{\eta_i i}]_\mu \neq 0$ , it holds that  $[A_{ii}]_{\xi_i \mu} \neq 0$ .
2.  $C_{\eta_i k} = 0 \ \forall k \in \{\nu - m + 1, \dots, \nu\} - \{i\}$ .
3. For every  $\mu \in \{1, \dots, d_i\}$  and every  $l \in \{1, \dots, \nu - m\}$ , condition  $[C_{\eta_i l}]_\mu \neq 0$  implies  $[A_{il}]_{\xi_i \mu} \neq 0$ .

Condition 1 of Corollary 3.5 is the detectability condition with a positive gain matrix (in [32], it is called positive detectability). The second condition says that each output associated to the singular block should be decoupled in some sense. The last condition guarantees that  $A - KC$  is a Metzler matrix.

*Example 3.6.* Consider a positive linear system with  $(A, C)$  defined by

$$A = \begin{bmatrix} M & 0 \\ 0 & M \end{bmatrix},$$

$$M := \begin{bmatrix} -1 & 1 \\ 1 & -1 \end{bmatrix},$$

$$C = [1 \quad 1 \quad 1 \quad 1].$$

Since  $0 \in \sigma(A)$ ,  $m = 2$ , and the pair  $(M, [1 \quad 1])$  is positively modifiable in the sense of [32], Theorem 3.13 of [32] asserts that there exists  $K \in \mathbb{R}_+^{4 \times 1}$  such that  $A - KC$  is a Hurwitz and compartmental matrix. However, any nonzero value of  $k_i$  ( $i$ th component of  $K$ ) yields a negative off-diagonal entry in  $A - KC$ . Thus, this system does not admit a positive linear observer of the form (3.2). (Furthermore, it is not possible to find a  $K \in \mathbb{R}^{4 \times 1}$  rendering  $A - KC$  a Hurwitz matrix, because  $(A, C)$  is not a detectable pair.) Note that this can be verified easily by Corollary 3.5 or Lemma 3.3 since  $m > q = 1$ .

Theorem 3.13 of [32] is not complete even if a detectability condition is added to the conditions. Consider the pair  $(A, C)$  defined by

$$A = \begin{bmatrix} -1 & 0 \\ 0 & M \end{bmatrix}, \quad C = [1 \quad 1 \quad 1].$$

It is easy to see that  $(A, C)$  is a detectable pair, but there is no  $K \in \mathbb{R}_+^3$  that renders  $A - KC$  Hurwitz and compartmental, although this pair satisfies the condition of [32]. According to Corollary 3.5, the problem can be solved if  $(A, C)$  satisfies additional conditions, for example,  $[A]_{2,1} > 0$  or  $[A]_{3,1} > 0$ , or  $C = [0 \quad 1 \quad 1]$ .

*Remark 3.7.* 1. The condition  $m \leq q$  is inspired by the result [19, Proposition 10], which deals with the stabilization problem for single input positive systems (i.e., find a gain vector  $k$  such that  $-k \in R_+^n$  and  $A + gk$  is Hurwitz and Metzler where  $A$  satisfies the condition (3.3)). One can modify Lemma 3.3 and Theorem 3.4 to obtain multi-input extensions of the results in [19].

2. When system (3.1) has an input vector field (i.e.,  $\dot{x} = Ax + Bu$ ,  $y = Cx$ ), the observer becomes  $\dot{\hat{x}} = A\hat{x} + K(y - C\hat{x}) + Bu$ .

#### 4. Positive linear observers using coordinate transformations.

**4.1. Problem formulation and basic results.** In this section, we propose a new design method for positive linear observers. It is based on the fact that even though a linear system is not positive with respect to (w.r.t.) a coordinate system, it can be positive w.r.t. a different coordinate system. With this fact in mind, we propose a new positive observer which employs a coordinate transformation.

**DEFINITION 4.1.** *Consider system (3.1). If there exist  $K \in \mathbb{R}^{n \times q}$  such that  $A - KC$  is Hurwitz and a nonsingular matrix  $T \in \mathbb{R}^{n \times n}$  such that the dynamic system described by*

$$(4.1) \quad \begin{aligned} \dot{\hat{z}} &= T(A - KC)T^{-1}\hat{z} + TKy, \\ \hat{x} &= T^{-1}\hat{z} \end{aligned}$$

*is a positive system w.r.t. input  $y$  and output  $\hat{x}$ , we call this a positive observer for system (3.1).*

Clearly, the system defined above is a positive observer since it guarantees that  $\lim_{t \rightarrow \infty} (\hat{x}(t) - x(t)) = 0$  and  $\hat{x}(t) \in \mathbb{R}_+^n \forall t \geq 0$ . Note that the observers developed in the previous section are special cases of the observer in (4.1) ( $T = I$ ). Before proceeding, we present an example to show the effectiveness of our approach.

*Example 4.2.* Consider the positive system

$$(4.2) \quad \dot{x} = \begin{bmatrix} -1 & 1 \\ 2 & 0 \end{bmatrix} x =: Ax, \quad y = [1 \quad 0] x =: Cx.$$

Theorem 3.2 tells us that it is not possible to design a positive observer with the structure (3.2). (It results in  $k_1^* > -1$  and  $k_2^* = 2$ , which make  $\lambda_{\max}(A - K^*C) \geq 0$ .)

Now, take  $K = [2 \quad 4]^t$ . Then the Luenberger observer becomes

$$\dot{\hat{x}} = \begin{bmatrix} -3 & 1 \\ -2 & 0 \end{bmatrix} \hat{x} + \begin{bmatrix} 2 \\ 4 \end{bmatrix} y,$$

which is not a positive system. However, if we transform this system using  $\hat{z} = T\hat{x}$ , where  $T := \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{5}} \\ \frac{1}{\sqrt{2}} & \frac{2}{\sqrt{5}} \end{bmatrix}^{-1}$  with  $T^{-1} \in \mathbb{R}_+^{2 \times 2}$ , one has

$$\begin{aligned} \dot{\hat{z}} &= T(A - KC)T^{-1}\hat{z} + TKy \\ &= \begin{bmatrix} -2 & 0 \\ 0 & -1 \end{bmatrix} \hat{z} + \begin{bmatrix} 0 \\ 2\sqrt{5} \end{bmatrix} y, \\ \hat{x} &= T^{-1}\hat{z}, \end{aligned}$$

which is a positive system.

Now, we present a preliminary result whose proof is standard.

**THEOREM 4.3.** *Consider a positive linear system (3.1). Suppose  $(A, C)$  is detectable. There exists a positive linear observer (4.1) if and only if there exist  $F, G$ , and  $T$  such that*

1.  $F \in \mathbb{R}^{n \times n}$  is Hurwitz and Metzler, and  $G \in \mathbb{R}_+^{n \times q}$ ;
2.  $T$  is a solution of the Sylvester equation

$$(4.3) \quad TA - FT = GC.$$

3.  $T$  is invertible and  $T^{-1} \in \mathbb{R}_+^{n \times n}$ .

It is well known from linear systems theory that if  $A$  and  $F$  have no common eigenvalues, then a solution  $T$  to (4.3) always exists and is unique. Moreover, if  $A$  and  $F$  have no common eigenvalues, observability of  $(A, C)$  and controllability of  $(F, G)$  are necessary conditions for the existence of a nonsingular solution  $T$  of (4.3) [8]. (It is also sufficient in the single output case.) If  $(A, C)$  is detectable, but not observable, then  $\sigma(A) \cap \sigma(F) \neq \emptyset$ , and hence we will not consider this case, but rather the restrictive one when  $\sigma(A) \cap \sigma(F) = \emptyset$ .

*Remark 4.4.* 1. An inverse-positive matrix  $T$  solves (4.3) if and only if an invertible nonnegative matrix  $S = T^{-1}$  solves the equation

$$(4.4) \quad AS - SF = SGCS.$$

Note that (4.3) is a linear equation w.r.t.  $T$  while (4.4) is a quadratic one w.r.t.  $S$ . Equation (4.4) is called a nonsymmetric algebraic Riccati equation in the literature.

2. To check the existence of positive linear observers, that is to say, to check whether the equation  $TA - FT = GC$  admits a solution such that  $T^{-1} \in \mathbb{R}_+^{n \times n}$ , one should use information on the structure of  $F$  and  $G$ , and in particular on the eigenvalues of  $F$ . However, to the best of the authors' knowledge, the problem of the realization (or of the existence) of a Metzler matrix which has prescribed eigenvalues is not solved. This problem, the so-called inverse eigenvalue problem, has been recognized as a very hard problem (note that a Metzler matrix  $M$  is a nonnegative matrix up to a shift process, i.e.,  $M + \alpha I \in \mathbb{R}_+^{n \times n}$  for some  $\alpha \in \mathbb{R}$ ), and there are very few results on general cases (see [6, 10, 21, 30] and the references therein).

3. For controlled systems ( $\dot{x} = Ax + Bu$ ,  $y = Cx$ ), the matrix  $T$  should satisfy  $TB \geq 0$  in addition to the conditions of Theorem 4.3.

**4.2. Necessary conditions: Single output case.** Two necessary conditions on the system matrix, in particular on the number of real eigenvalues, are provided.

The first necessary condition utilizes the explicit solution  $T$  of (4.3). It also exploits the structure of the matrix  $F$ . As mentioned in Remark 4.4, we do not have sufficient information on the structure the matrix  $F$  may be endowed with in the general case. To make the problem tractable, additional structural conditions on the observers are imposed. We also assume that  $F$  is chosen so that  $\sigma(F) \cap \sigma(A) = \emptyset$  to ensure that the Sylvester equation  $TA - FT = GC$  has a unique solution  $T$  [8].

**THEOREM 4.5.** *Suppose the positive system (3.1) admits a positive linear observer of the form (4.1). Let  $F = T(A - KC)T^{-1}$  and  $G = TK$ . If  $F$  is chosen to satisfy (1)  $\sigma(F) \cap \sigma(A) = \emptyset$ , and (2)  $F = \text{diag}\{\lambda_1, \dots, \lambda_n\}$ ,  $\lambda_i \in \mathbb{R}_-$ , then  $A$  has at least  $n - 1$  distinct negative real eigenvalues.*

*Proof.* Let  $\Delta_A(s)$  be the characteristic polynomial of  $A$ , i.e.,

$$(4.5) \quad \Delta_A(s) = \det(sI - A) = s^n + \alpha_1 s^{n-1} + \alpha_2 s^{n-2} + \dots + \alpha_n.$$

Without loss of generality we assume that  $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_n$ . In fact, if this is not the case, we transform  $F$  with a suitable permutation matrix  $P$  such that the diagonal elements of  $\bar{F} = PFP^t$  are ordered as required, since an inverse-positive matrix  $T$  is a solution to  $TA - FT = GC$  if and only if  $\bar{T} = PT$  is an inverse-positive matrix satisfying  $\bar{T}A - \bar{F}\bar{T} = \bar{G}C$ ,  $\bar{G} = PG$ .

Now, following the same derivations as in [8], we have

$$\begin{aligned}
 TI - IT &= 0, \\
 TA - FT &= GC, \\
 TA^2 - F^2T &= GCA + FGC, \\
 &\vdots \\
 TA^n - F^nT &= GCA^{n-1} + FGCA^{n-2} + \cdots + F^{n-2}GCA + F^{n-1}GC,
 \end{aligned}$$

and

$$\begin{aligned}
 T\Delta_A(A) - \Delta_A(F)T &= \begin{bmatrix} G & FG & \cdots & F^{n-1}G \end{bmatrix} \begin{bmatrix} \alpha_{n-1} & \alpha_{n-2} & \cdots & \alpha_1 & 1 \\ \alpha_{n-2} & \alpha_{n-3} & \cdots & 1 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ \alpha_1 & 1 & \cdots & 0 & 0 \\ 1 & 0 & \cdots & 0 & 0 \end{bmatrix} \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{n-2} \\ CA^{n-1} \end{bmatrix} \\
 &=: U_F \Lambda_\alpha V_A.
 \end{aligned}$$

Note that the matrices  $U_F$  and  $V_A$  are the controllability matrix of the pair  $(F, G)$  and the observability matrix of the pair  $(C, A)$ , respectively.

Since  $\Delta_A(A) = 0$ , and the condition  $\sigma(F) \cap \sigma(A) = \emptyset$  ensures that  $\Delta_A(F) = \text{diag}\{\Delta_A(\lambda_1), \dots, \Delta_A(\lambda_n)\}$  is nonsingular, we have

$$(4.6) \quad T = -(\Delta_A(F))^{-1} U_F \Lambda_\alpha V_A.$$

In addition, the existence of a positive linear observer (4.1) implies that there exists  $S \in \mathbb{R}_+^{n \times n}$  such that

$$TS = I.$$

In other words,

$$(4.7) \quad U_F \Lambda_\alpha V_A S = -\Delta_A(F).$$

Now, expand  $U_F$  as follows.

$$U_F = \begin{bmatrix} g_1 & \lambda_1 g_1 & \cdots & \lambda_1^{n-1} g_1 \\ \vdots & \vdots & & \vdots \\ g_n & \lambda_n g_n & \cdots & \lambda_n^{n-1} g_n \end{bmatrix} = \begin{bmatrix} g_1 & & & \\ & \ddots & & \\ & & g_n & \end{bmatrix} \begin{bmatrix} 1 & \lambda_1 & \cdots & \lambda_1^{n-1} \\ \vdots & \vdots & & \vdots \\ 1 & \lambda_n & \cdots & \lambda_n^{n-1} \end{bmatrix}.$$

Notice that since  $\Delta_A(F)$  is nonsingular,  $U_F$  is nonsingular as well, and hence

- $g_i \neq 0$  for every  $i$  (equivalently,  $g_i > 0$  since  $G \geq 0$ );
- the Vandermonde matrix [8] on the right-hand side is nonsingular (equivalently, all  $\lambda_i$ 's are distinct).

Set  $\Theta := U_F \Lambda_\alpha$ , so that (4.7) becomes

$$\Theta V_A S = - \begin{bmatrix} \Delta_A(\lambda_1) & & \\ & \ddots & \\ & & \Delta_A(\lambda_n) \end{bmatrix},$$

and notice that

$$(4.8) \quad \det \Theta = \left( \prod_{i=1}^n g_i \right) \left( \prod_{1 \leq i < j \leq n} (\lambda_i - \lambda_j) \right).$$

If we let  $S_i$  denote the  $i$ th column of  $S$ , we get

$$\Theta V_A S_i = \begin{bmatrix} 0_{(i-1) \times 1} \\ -\Delta_A(\lambda_i) \\ 0_{(n-i) \times 1} \end{bmatrix}.$$

Consequently, by recalling the definition of  $V_A$ , we get for every  $i = 1, \dots, n$

$$\begin{aligned} CS_i &= [1 \quad 0 \quad \cdots \quad 0] V_A S_i = [1 \quad 0 \quad \cdots \quad 0] \Theta^{-1} \begin{bmatrix} 0_{(i-1) \times 1} \\ -\Delta_A(\lambda_i) \\ 0_{(n-i) \times 1} \end{bmatrix} \\ &= (-1)^i \frac{\Delta_A(\lambda_i)}{\det \Theta} \cdot \det \Theta_{[i]}, \end{aligned}$$

where  $\Theta_{[i]}$  is the  $(n-1) \times (n-1)$  submatrix of  $\Theta$  obtained by deleting in  $\Theta$  the first column and the  $i$ th row.

Using (4.8), we compute

$$\begin{aligned} \frac{\det \Theta_{[i]}}{\det \Theta} &= \frac{\prod_{1 \leq u < v \leq n, u \neq i, v \neq i} (\lambda_u - \lambda_v)}{g_i \prod_{1 \leq u < v \leq n} (\lambda_u - \lambda_v)} \\ &= \begin{cases} \frac{1}{g_i \left[ \prod_{1 \leq u < i} (\lambda_u - \lambda_i) \right] \left[ \prod_{i < v \leq n} (\lambda_i - \lambda_v) \right]}, & 2 \leq i \leq n-1, \\ \frac{1}{g_1 (\lambda_1 - \lambda_2) \cdots (\lambda_1 - \lambda_n)}, & i = 1, \\ \frac{1}{g_n (\lambda_1 - \lambda_n) \cdots (\lambda_{n-1} - \lambda_n)}, & i = n. \end{cases} \end{aligned}$$

Since  $\lambda_i < \lambda_{i+1}$ ,  $i = 1, \dots, n-1$ , and  $g_i > 0$ , it follows that

$$CS_i = (-1)^{i+n-1} \Delta_A(\lambda_i) \left| \frac{\det \Theta_{[i]}}{\det \Theta} \right|,$$

which in turn implies that

$$(-1)^{i+n-1} \Delta_A(\lambda_i) > 0, \quad i = 1, \dots, n.$$

Moreover, by the relation

$$(-1)^{i+n-1} \Delta_A(\lambda_i) \cdot (-1)^{i+1+n-1} \Delta_A(\lambda_{i+1}) > 0, \quad i = 1, \dots, n-1,$$

we have

$$\Delta_A(\lambda_i) \Delta_A(\lambda_{i+1}) < 0, \quad i = 1, \dots, n-1.$$

Since  $\Delta_A(\cdot)$  is a continuous function, there exists  $\lambda_{*i}$  such that

$$\Delta_A(\lambda_{*i}) = 0, \quad \lambda_i < \lambda_{*i} < \lambda_{i+1}, \quad i = 1, \dots, n-1.$$

That is to say, there are at least  $n-1$  negative real eigenvalues of  $A$ , which completes the proof.  $\square$

The second result of this subsection is on the number of positive real eigenvalues of the system matrix in the general case, i.e., in the case that no assumption, apart from stability, on the eigenvalues of  $F$  is imposed. To prove the result, we need the following fact.

**LEMMA 4.6.** *Let  $A \in \mathbb{R}^{n \times n}$  be Metzler and  $C \in \mathbb{R}_+^{q \times n}$ . If there exists  $K \in \mathbb{R}_+^{n \times q}$  such that  $A - KC$  is Metzler and  $\lambda_{\max}(A - KC) < \lambda_{\max}(A)$ , then the algebraic multiplicity of  $\lambda_{\max}(A)$  is at most  $q$ .*

*Proof.* Let  $m$  be the multiplicity of  $\lambda_{\max}(A)$  as an eigenvalue of  $A$ . The Metzler matrix  $\bar{A} := A - \lambda_{\max}(A)I_n$  satisfies (3.3) and has 0 as an eigenvalue of multiplicity  $m$ . Also, since  $\lambda_{\max}(\bar{A} - KC) < 0$ , the matrix  $K$  corresponds to the gain matrix of a positive linear observer of the form (3.2) for the system. So, by Lemma 3.3,  $m \leq q$ .  $\square$

This lemma says that for the single output case, we cannot make  $\lambda_{\max}(A - KC)$  less than  $\lambda_{\max}(A)$  if the multiplicity of  $\lambda_{\max}(A)$  is greater than 1.

**THEOREM 4.7.** *Let  $A \in \mathbb{R}^{n \times n}$  be a Metzler matrix and  $C := [c_1, \dots, c_n] \in \mathbb{R}_+^{1 \times n}$ . If there exists a positive linear observer of the form (4.1), then the number of nonnegative real eigenvalues of  $A$  counting the multiplicity is at most 1.*

*Proof.* First recall that the existence of a positive linear observer of the form (4.1) implies that there exists  $G \in \mathbb{R}_+^n$ ,  $S \in \mathbb{R}_+^{n \times n}$  with  $\det S \neq 0$  such that  $F = S^{-1}AS - GCS$  is Metzler and Hurwitz.

Let  $\bar{A} = S^{-1}AS$ ,  $\bar{C} = CS$ . If  $\bar{C}$  is a zero vector, the proof is trivial. Thus,  $\bar{C}$  is assumed to be a nonzero vector.

Let  $G \in \mathbb{R}_+^n$  be such that  $\bar{A} - G\bar{C}$  is Metzler and Hurwitz. Then it is evident that  $\bar{A} - \delta G\bar{C}$ ,  $\delta \in [0, 1]$ , is Metzler. Moreover, since the zeros of a polynomial depend continuously on its coefficients, there exists  $\delta^* \in [0, 1)$  such that  $\bar{A} - \delta G\bar{C}$  is Metzler and Hurwitz  $\forall \delta \in [\delta^*, 1]$ . Let  $\Delta(s, \delta) = \det(sI - \bar{A} + \delta G\bar{C})$ . We will investigate the loci of the roots of  $\Delta(s, \delta)$  changing  $\delta$  from 0 to 1. To do this, the structure of  $\Delta(s, \delta)$  is considered. Note that

$$\begin{aligned} (4.9) \quad \det(sI - \bar{A} + \delta G\bar{C}) &= \det((sI - \bar{A})(I + \delta(sI - \bar{A})^{-1}G\bar{C})) \\ &= \det(sI - \bar{A})(1 + \delta\bar{C}(sI - \bar{A})^{-1}G) \\ &= \det(sI - \bar{A}) + \delta\bar{C}\text{adj}(sI - \bar{A})G \\ &=: D(s) + \delta N(s), \end{aligned}$$

where we used the relation

$$\det(I + xy^t) = 1 + x^t y = 1 + y^t x, \quad x, y \in \mathbb{R}^n.$$

From the structure of (4.9), we can use the classical root locus method to investigate the location of the zeros of  $\Delta(s, \delta)$  parameterized by  $\delta$ . Letting  $G_o(s) := N(s)/D(s)$  ( $n$ : degree of  $D(s)$ ;  $m$ : degree of  $N(s)$ ), we recall basic rules of root locus as follows. For details on the root locus, see, for example, [11, 15, 31].

- RL1. The branches of the root locus are continuous curves that start at each of the  $n$  poles of  $G_o(s)$  for  $\delta = 0$ . As  $\delta \rightarrow \infty$ , the locus branches approach the  $m$  zeros of  $G_o(s)$ . Locus branches for excess poles extend infinitely far from the origin.
- RL2. The root locus includes all points along the real axis to the left of an odd number of poles and zeros of  $G_o(s)$ .
- RL3. If there is a breakaway point (multiple root of  $G_o(s)$ ) on the real axis, the root loci leave the real axis at a gain  $\delta_*$  that is the maximum  $\delta$  in that region of the real axis.

Suppose  $A$  has more than one nonnegative real eigenvalue. Let  $\lambda_M$  ( $\lambda_m$ , resp.) be the largest (the second largest, resp.) nonnegative real eigenvalue of  $A$ . If  $N(\lambda_M) = 0$  or  $N(\lambda_m) = 0$ , then  $\Delta(\lambda_M, \delta) = 0$  or  $\Delta(\lambda_m, \delta) = 0 \forall \delta \in [0, \infty)$ , which means that  $\bar{A} - G\bar{C}$  is not Hurwitz and contradicts the assumption. Thus, we assume  $N(\lambda_M) \neq 0$  and  $N(\lambda_m) \neq 0$ .

We complete the proof by considering three cases.

*Case 1.* The multiplicity of  $\lambda_M$  is greater than 1.

*Case 2.*  $\lambda_M$  is simple and  $(\lambda_M, \infty)$  contains an odd number of zeros of  $N(s)$ .

*Case 3.*  $\lambda_M$  is simple and  $(\lambda_M, \infty)$  contains an even number of zeros of  $N(s)$ .

Case 1 contradicts Lemma 4.6. In Case 2, by RL2,  $\forall \delta \in [0, \infty)$ , there exists  $s^* \in [\lambda_m, \infty)$  (which may depend on  $\delta$ ) such that  $\Delta(s^*, \delta) = 0$ , which means that  $\bar{A} - \delta G\bar{C}$  is not Hurwitz  $\forall \delta \in [0, \infty)$  and contradicts the assumption on the existence of  $G$ .

Consider Case 3. Since  $\lambda_M$  is simple, one has  $\lambda_m < \lambda_M$ . Suppose there exists  $\mu^* \in (\lambda_m, \lambda_M)$  such that  $N(\mu^*) = 0$ . Let  $\mu_M^*$  be the largest one among the  $\mu^*$ 's. Then, again by RL2, there exists  $s^* \in [\mu_M^*, \lambda_M]$  ( $s^*$  may depend on  $\delta$ ) such that  $\Delta(s^*, \delta) = 0 \forall \delta \in [0, \infty)$ , which is, similar to Case 2, a contradiction. Thus, there should be no  $s^* \in (\lambda_m, \lambda_M)$  such that  $N(s^*) = 0$ . This fact implies that the line segment  $(\lambda_m, \lambda_M)$  is a part of the root locus (by RL2) and that there exists  $\delta_* \in (0, \infty)$  such that the equation  $\Delta(s, \delta_*) = 0$  w.r.t.  $s$  has a solution  $s^*$  with multiplicity greater than 1 in the region  $(\lambda_m, \lambda_M)$  where the root locus leaves the real axis (by RL3). If  $\delta_* \geq 1$ , then  $\bar{A} - G\bar{C} = (\bar{A} - \delta_* G\bar{C})|_{\delta=1}$  is not Hurwitz, which contradicts the assumption that  $\bar{A} - G\bar{C}$  is Hurwitz. When  $0 < \delta_* < 1$ ,  $\bar{A} - \delta_* G\bar{C}$  has a nonnegative real eigenvalue  $s^*$  with multiplicity greater than 1. However, since  $\bar{A} - G\bar{C} = \bar{A} - \delta_* G\bar{C} - (1 - \delta_*)G\bar{C}$  ( $\bar{A} - \delta_* G\bar{C}$  is Metzler but not Hurwitz) and  $\bar{A} - G\bar{C}$  is Hurwitz and Metzler, this contradicts Lemma 4.6. Thus, the proof is complete.  $\square$

This result imposes a rather strong condition for the positive linear observer problem solution. According to this theorem, it is not possible to design positive linear observers for single output linear positive systems with more than one nonnegative real eigenvalue.

*Remark 4.8.* The necessary condition given in Theorem 4.5 provides more information on the spectrum of  $A$  (stable eigenvalues as well as unstable eigenvalues) than that of Theorem 4.7, since we fix the structure and the spectrum of the matrix  $F$ . On the contrary, Theorem 4.7 does not rely on a specific structure for  $F$ ; hence it does not allow us to conclude anything on the stable eigenvalues of  $A$ .

**4.3. Sufficient condition: Single output case.** With the necessary conditions developed in mind, we provide a sufficient condition for the existence of positive linear observers. The irreducibility of a matrix plays an important role in this section.

We assume that  $A$  has  $n$  real distinct eigenvalues  $\lambda_1, \dots, \lambda_n$  satisfying  $\lambda_1 > \dots > \lambda_n$ . This spectral assumption enables the transformation of  $A$  into the Jordan form

given by

$$(4.10) \quad A = VJV^{-1},$$

$$(4.11) \quad J := \text{diag}\{\lambda_1, \dots, \lambda_n\},$$

$$(4.12) \quad V := [v_1 \quad \dots \quad v_n],$$

where  $v_i$  satisfies  $Av_i = \lambda_i v_i$ .

**THEOREM 4.9.** *For a single output positive system (3.1), suppose  $A$  is irreducible and  $(A, C)$  is observable. There exists a positive linear observer using coordinates transformation (4.1) if  $A$  has  $n$  distinct real eigenvalues,  $n-1$  of which are negative.*

*Proof.* If  $A$  is Hurwitz, the problem is trivial. Thus, it is assumed that one eigenvalue is nonnegative. Let  $\lambda_i$  (eigenvalues of  $A$ ) and  $v_i$  (eigenvectors of  $A$ ) be such that  $\lambda_1 \geq 0 > \lambda_2 > \dots > \lambda_n$ . Since  $A$  is irreducible, by Theorem 2.1, the eigenvector  $v_1$  corresponding to  $\lambda_1$  satisfies  $v_1 \in \text{int } \mathbb{R}_+^n$ . By the observability assumption, we have  $\forall i = 1, \dots, n$ ,  $Cv_i \neq 0$ . After a suitable scaling, it is assumed that

$$(4.13) \quad Cv_i = 1, \quad i = 1, \dots, n.$$

Let  $\beta, \gamma$  be real numbers in the open interval  $(0, 1)$ . We define

$$(4.14) \quad \bar{S}(\beta, \gamma) = \begin{bmatrix} 1 - \beta & (1 - \gamma)1_{1 \times (n-1)} \\ -\beta 1_{(n-1) \times 1} & \gamma I_{n-1} \end{bmatrix}.$$

Using the properties of determinant, it is easy to see that

$$\det \bar{S} = \det \begin{bmatrix} 1 - n\beta & 1_{1 \times (n-1)} \\ -\beta 1_{(n-1) \times 1} & \gamma I_{n-1} \end{bmatrix} = \det \begin{bmatrix} 1 - n\beta + (n-1)\beta/\gamma & 1_{1 \times (n-1)} \\ 0_{(n-1) \times 1} & \gamma I_{n-1} \end{bmatrix}.$$

Hence,

$$\det \bar{S} = \gamma^{n-2}[\gamma - n\beta\gamma + (n-1)\beta] = \gamma^{n-2}[(1-\beta)\gamma + (n-1)\beta(1-\gamma)].$$

Note that  $\det \bar{S} > 0 \quad \forall \beta, \gamma \in (0, 1)$ , which is obvious from the last relation. During this proof we will use the inverse of  $\bar{S}$ , which can be computed as follows:

$$(4.15) \quad \bar{S}^{-1} = \frac{\gamma^{n-3}}{\det \bar{S}} \begin{bmatrix} \gamma^2 & -\gamma(1-\gamma)1_{1 \times (n-1)} \\ \beta\gamma 1_{(n-1) \times 1} & -\beta(1-\gamma)1_{(n-1) \times (n-1)} + \pi_{\beta, \gamma} I_{n-1} \end{bmatrix},$$

where  $\pi_{\beta, \gamma} := (1-\beta)\gamma + (n-1)\beta(1-\gamma)$ . Notice that  $\pi_{\beta, \gamma} > 0 \quad \forall \beta, \gamma \in (0, 1)$ .

Now, we consider a matrix  $S$  defined by

$$(4.16) \quad S(\beta, \gamma) = V\bar{S}(\beta, \gamma).$$

Let  $\bar{\beta}^* \in (0, 1)$ ,  $\bar{\gamma}^* \in (0, 1)$  such that

$$(4.17) \quad S(\beta, \gamma) \geq 0 \quad \forall \beta \in (0, \bar{\beta}^*), \gamma \in (0, \bar{\gamma}^*).$$

It can be shown that such  $\bar{\beta}^*$  and  $\bar{\gamma}^*$  always exist. In fact, let  $S_i$  be the  $i$ th column of  $S$ . Then

$$(4.18) \quad \begin{aligned} S_1 &= (1-\beta)v_1 + \beta(-v_2 - \dots - v_n), \\ S_i &= (1-\gamma)v_1 + \gamma v_i, \quad i = 2, \dots, n. \end{aligned}$$

Recall that each element of  $v_1$  is positive and note that  $S_i$ 's move continuously from  $v_1$  to  $-(v_2 + \dots + v_n)$  or  $v_i$  as  $\beta$  and  $\gamma$  increase. Thus, by continuity, the existence of  $\bar{\beta}^*$  and  $\bar{\gamma}^*$  is proved.

Using  $S(\beta, \gamma)$ , define a state transformation  $T(\beta, \gamma) = S^{-1}(\beta, \gamma)$  parameterized by  $\beta$  and  $\gamma$ . By construction,  $T^{-1}$  exists and is nonnegative  $\forall \beta \in (0, \bar{\beta}^*), \gamma \in (0, \bar{\gamma}^*)$ . With  $T$ , consider  $F$  given by

$$(4.19) \quad F = TAT^{-1} - GCT^{-1}.$$

Noting that the first column of  $\bar{S}^{-1}$  is elementwise positive, we choose a positive gain matrix  $G$  as

$$(4.20) \quad G = \mu \bar{S}^{-1} e_1,$$

where  $e_1 := [1 \ 0_{1 \times (n-1)}]^t$  and  $\mu$  is a positive number to be chosen later. The transformation constructed so far and the gain  $G$  yield

$$\begin{aligned} F &= S^{-1}VJV^{-1}S - GCS \\ &= \bar{S}^{-1}V^{-1}VJV^{-1}V\bar{S} - \bar{S}^{-1}\mu e_1 CV\bar{S} \\ &= \bar{S}^{-1}[J - \mu e_1 1_{1 \times n}]\bar{S}. \end{aligned}$$

We now need to find  $\mu, \beta, \gamma$  rendering  $F$  Hurwitz and Metzler. Let  $\tilde{F} = \frac{\det \bar{S}}{\gamma^{n-3}} F$  ( $\tilde{F}$  is Metzler if and only if  $F$  is Metzler) and  $\bar{T} := \frac{\det \bar{S}}{\gamma^{n-3}} \bar{S}^{-1}$ . Then

$$\begin{aligned} \tilde{F} &= \bar{T}[J - \mu e_1 1_{1 \times n}]\bar{S} \\ &= \bar{T} \begin{bmatrix} \bar{\pi}_{\beta, \gamma} & [\lambda_1(1 - \gamma) - \mu] 1_{1 \times (n-1)} \\ -\beta [\lambda_2 \ \cdots \ \lambda_n]^t & \gamma \text{diag}\{\lambda_2, \dots, \lambda_n\} \end{bmatrix}, \end{aligned}$$

where  $\bar{\pi}_{\beta, \gamma} := (\lambda_1 - \mu)(1 - \beta) + (n - 1)\mu\beta$ . Thus,

$$\begin{bmatrix} \tilde{F}_{11} \\ \tilde{F}_{21} \\ \vdots \\ \tilde{F}_{n1} \end{bmatrix} = \begin{bmatrix} \gamma^2 \bar{\pi}_{\beta, \gamma} + \beta \gamma (1 - \gamma) \sum_{i=2}^n \lambda_i \\ \beta \gamma \bar{\pi}_{\beta, \gamma} - \beta \pi_{\beta, \gamma} \lambda_2 + \beta^2 (1 - \gamma) \sum_{i=2}^n \lambda_i \\ \vdots \\ \beta \gamma \bar{\pi}_{\beta, \gamma} - \beta \pi_{\beta, \gamma} \lambda_n + \beta^2 (1 - \gamma) \sum_{i=2}^n \lambda_i \end{bmatrix},$$

and for  $k = 2, \dots, n$ ,

$$\begin{bmatrix} \tilde{F}_{1k} \\ \tilde{F}_{2k} \\ \vdots \\ \tilde{F}_{nk} \end{bmatrix} = \begin{bmatrix} \gamma^2 [(\lambda_1 - \lambda_k)(1 - \gamma) - \mu] \\ \beta \gamma [(\lambda_1 - \lambda_k)(1 - \gamma) - \mu] + \delta_{2,k} \gamma \pi_{\beta, \gamma} \lambda_k \\ \vdots \\ \beta \gamma [(\lambda_1 - \lambda_k)(1 - \gamma) - \mu] + \delta_{n,k} \gamma \pi_{\beta, \gamma} \lambda_k \end{bmatrix},$$

where  $\delta_{i,j} = 1$  if  $i = j$  and  $\delta_{i,j} = 0$  otherwise.

From this computation, we derive some properties of  $\tilde{F}$ , which can be easily seen.

P1.  $\forall k = 3, \dots, n, \tilde{F}_{21} \leq \tilde{F}_{k1}$ .

P2.  $\forall k = 2, \dots, n, \tilde{F}_{1k} \geq 0$  if and only if  $\tilde{F}_{jk} \geq 0, j = 2, \dots, n, j \neq k$ .

P3.  $\forall k = 3, \dots, n, \tilde{F}_{12} \leq \tilde{F}_{1k}$ .

Note that the properties P1–P3 ensure that  $\tilde{F}$  is Metzler if and only if  $\tilde{F}_{12} \geq 0$ ,  $\tilde{F}_{21} \geq 0$ . Moreover, since  $F$  is similar to  $J - \mu e_1 1_{1 \times n}$  whose spectrum is  $\{\lambda_1 - \mu, \lambda_2, \dots, \lambda_n\}$ , it follows that  $F$  is Hurwitz and Metzler if there exist  $\mu, \beta \in (0, \bar{\beta}^*)$ , and  $\gamma \in (0, \bar{\gamma}^*)$  such that the following inequalities hold:

$$(4.21) \quad \lambda_1 - \mu < 0,$$

$$(4.22) \quad \gamma \bar{\pi}_{\beta, \gamma} - \pi_{\beta, \gamma} \lambda_2 + \beta(1 - \gamma) \sum_{i=2}^n \lambda_i \geq 0,$$

$$(4.23) \quad (\lambda_1 - \lambda_2)(1 - \gamma) - \mu \geq 0.$$

We choose  $\mu$  in  $(\lambda_1, \lambda_1 - \lambda_2)$  and define

$$\gamma^* = \min \left\{ \bar{\gamma}^*, \frac{\lambda_1 - \lambda_2 - \mu}{\lambda_1 - \lambda_2} \right\}.$$

Then, for each  $\gamma$  in  $(0, \gamma^*)$ , inequalities (4.21) and (4.23) hold. With  $\mu$  and  $\gamma$  chosen above, it remains to choose  $\beta$  for (4.22). To do this, we expand the left-hand side of (4.22) as follows:

$$\begin{aligned} & \gamma \bar{\pi}_{\beta, \gamma} - \pi_{\beta, \gamma} \lambda_2 + \beta(1 - \gamma) \sum_{i=2}^n \lambda_i \\ &= -\beta \gamma (\lambda_1 - \lambda_2 - n\mu) + \beta(1 - \gamma) \sum_{i=2}^n (-\lambda_2 + \lambda_i) \\ & \quad + (\lambda_1 - \lambda_2 - \mu) \gamma. \end{aligned}$$

Thus, inequality (4.22) is equivalent to

$$(4.24) \quad (\lambda_1 - \lambda_2 - \mu) \gamma \geq \Upsilon(\gamma, \mu, \lambda_1, \dots, \lambda_n) \beta,$$

where  $\Upsilon(\gamma, \mu, \lambda_1, \dots, \lambda_n) = \gamma(\lambda_1 - \lambda_2 - n\mu) + (1 - \gamma) \sum_{i=2}^n (\lambda_2 - \lambda_i)$ . This inequality (hence (4.22)) holds for any  $\beta \in (0, \beta^*)$  ( $\beta^*$  may depend on  $\gamma$  and  $\mu$ ), where

$$\beta^* = \begin{cases} \bar{\beta}^* & \text{if } \Upsilon \leq 0, \\ \min \left\{ \bar{\beta}^*, \frac{(\lambda_1 - \lambda_2 - \mu) \gamma}{\Upsilon(\gamma, \mu, \lambda_1, \dots, \lambda_n)} \right\} & \text{if } \Upsilon > 0. \end{cases}$$

Thus, the proof is complete.  $\square$

One novel feature of the matrix  $\bar{S}(\beta, \gamma)$  is that its inverse is fully known, and it is easy to add additional degrees of freedom to this matrix since the parameters are nothing but the convex interpolation coefficients. Moreover, the first column of  $\bar{S}^{-1}(\beta, \gamma)$  is positive, which makes the choice of  $G$  easy.

When the multiplicity of the unstable eigenvalue is greater than 1, it is natural to use the generalized eigenvectors to generalize the idea used here. But this case does not seem to be easy since the scaling involved to make  $Cv_i = 1$  does not hold anymore. This case may require additional degrees of freedom in the scaling matrix, while two parameters are sufficient in the case of distinct eigenvalues.

Similar problems arise when one deals with complex eigenvalues. A basic idea would be to use the real Jordan block representation of a given matrix [18]. When one transforms  $A$  into the real Jordan block, there are two real eigenvectors corresponding

to a pair of conjugate eigenvalues, and they are related in some sense (one of them should be the real part of a complex eigenvector and the other the complex part of it); thus the scaling approach does not apply directly. Moreover, the real Jordan form is not Metzler if a matrix has a complex eigenvalue, which makes the problem more difficult. To illustrate this point, we provide an example where  $A$  has complex eigenvalues. This example shows how to parameterize the matrix  $\bar{S}$  when we use the real Jordan form to solve the problem.

*Example 4.10.* The main idea used in this subsection is applied to the system

$$(4.25) \quad \dot{x} = Ax = \frac{1}{3} \begin{bmatrix} 1 - \sqrt{3} & 1 + \sqrt{3} & 1 \\ 1 & 1 - \sqrt{3} & 1 + \sqrt{3} \\ 1 + \sqrt{3} & 1 & 1 - \sqrt{3} \end{bmatrix} x, \quad y = Cx = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix} x,$$

where  $\sigma(A) = \{1, -\frac{1}{2}\sqrt{3} \pm j\frac{1}{2}\}$ . Note that there is no  $K \in \mathbb{R}_+^3$  such that  $A - KC$  is Hurwitz and Metzler by Theorem 3.2.

We consider a real Jordan form  $A_J$  of  $A$ :

$$AV = VA_J, \quad V := \begin{bmatrix} 1 & -1 & \sqrt{3} \\ 1 & 2 & 0 \\ 1 & -1 & -\sqrt{3} \end{bmatrix}, \quad A_J := \begin{bmatrix} 1 & 0 & 0 \\ 0 & -\sqrt{3}/2 & -1/2 \\ 0 & 1/2 & -\sqrt{3}/2 \end{bmatrix}.$$

With three parameters for  $\bar{S}$ ,  $S$  is defined by

$$S = V\bar{S}, \quad \bar{S} := \begin{bmatrix} 1 - \beta & 1 - \gamma_1 & 1 - \gamma_2 \\ -\beta & \gamma_1 & 0 \\ -\beta & 0 & \gamma_2 \end{bmatrix}.$$

Choosing  $\beta = 0.1$ ,  $\gamma_1 = 0.12$ , and  $\gamma_2 = 0.16$  yields

$$S = \begin{bmatrix} 0.8268 & 0.7600 & 1.1171 \\ 0.7000 & 1.1200 & 0.8400 \\ 1.1732 & 0.7600 & 0.5629 \end{bmatrix}, \quad S^{-1}AS = \begin{bmatrix} -0.1362 & 0.6149 & 0.9981 \\ 1.0249 & -0.3536 & 0.1650 \\ 0.1437 & 0.7593 & -0.2422 \end{bmatrix},$$

$$CS = \begin{bmatrix} 0.8268 & 0.7600 & 1.1171 \end{bmatrix}.$$

Thus, if we select  $G = [0.8090 \quad 0.1477 \quad 0.1737]^t$  (from Theorem 3.2), it follows that

$$F = \begin{bmatrix} -0.8051 & 0 & 0.0942 \\ 0.9027 & -0.4659 & 0 \\ 0 & 0.6272 & -0.4363 \end{bmatrix},$$

which is Hurwitz ( $\sigma(F) = \{-0.1626, -0.7724 \pm j0.2863\}$ ) and Metzler, and the positive observer is given by

$$\begin{aligned} \dot{\hat{z}} &= \begin{bmatrix} -0.8051 & 0 & 0.0942 \\ 0.9027 & -0.4659 & 0 \\ 0 & 0.6272 & -0.4363 \end{bmatrix} \hat{z} + \begin{bmatrix} 0.8090 \\ 0.1477 \\ 0.1737 \end{bmatrix} y, \\ \hat{x} &= \begin{bmatrix} 0.8268 & 0.7600 & 1.1171 \\ 0.7000 & 1.1200 & 0.8400 \\ 1.1732 & 0.7600 & 0.5629 \end{bmatrix} \hat{z}. \end{aligned}$$

Note that once  $S$  is chosen,  $G$  can be obtained using Theorem 3.2 with the pair  $(S^{-1}AS, CS)$ . The estimate  $\hat{x}$  of  $x$  resides in the set  $\{S\mu | \mu \in \mathbb{R}_+^3\}$ , which is a proper subset of  $\mathbb{R}_+^3$ .

**5. Positive linear observers via positive realization.** In this section we first formulate the observer design problem as a positive realization problem, and then we propose a novel observer design method.

**5.1. Positive realization approach.** As mentioned in the previous section, the inverse eigenvalue problem is a hard obstacle when we fix the dimension of  $F$ . In this section, we reformulate the problem allowing the dimension of  $F$  to be an additional degree of freedom. To do this, the positive linear observer is defined as follows.

DEFINITION 5.1. *Given a positive linear system (3.1), a linear system*

$$(5.1) \quad \begin{aligned} \dot{\hat{z}} &= F\hat{z} + Gy, \quad \hat{z} \in \mathbb{R}^N, \\ \hat{x} &= H\hat{z}, \quad \hat{x} \in \mathbb{R}^n, \end{aligned}$$

*is called a positive linear observer for (3.1) if  $F$  is Hurwitz and Metzler,  $G \in \mathbb{R}_+^{N \times q}$ ,  $H \in \mathbb{R}_+^{n \times N}$ , and  $\lim_{t \rightarrow \infty} \|H\hat{z}(t) - x(t)\| = 0 \forall \hat{z}(0) \in \mathbb{R}_+^N$  and  $\forall x(0) \in \mathbb{R}_+^n$ .*

Two natural questions arise: (1) Under what conditions is the existence of a positive linear observer guaranteed? (2) How can one construct  $(F, G, H)$ ?

If one recalls the observer design for linear systems, the first thing to do would be to choose the spectrum of  $F$  (if  $N = n$  and  $(A, C)$  is an observable pair, one can assign the spectrum of  $F$  arbitrarily) and compute the appropriate gain matrix  $G$ . This process does not seem to work well in our problem because the requirement that  $F$  be a Metzler matrix restricts the spectrum of  $F$ . As discussed in the previous section, this restriction is a very hard obstacle in our problem.

To circumvent this problem, we do not fix the dimension at the first stage. In other words, the dimension of the observer  $N$  is an additional degree of freedom. To be more precise, note first that  $(F, G, H)$  is a positive realization of some transfer function  $G_o(s)$ . (By a positive realization of a transfer function  $G_o(s)$ , we mean a realization  $(F, G, H)$  such that  $F$  is a Metzler matrix,  $G \geq 0$ , and  $H \geq 0$ . For an outstanding tutorial on this problem, the readers are referred to [5]. See also the references cited in that paper, for example, [2, 3, 12, 24].) Suppose we have designed  $(F_m, G_m, H_m)$  such that (1)  $F_m \in \mathbb{R}^{N \times N}$  is Hurwitz (not necessarily Metzler),  $G_m \in \mathbb{R}^{N \times q}$ , and  $H_m \in \mathbb{R}^{n \times N}$ , (2)  $(F_m, G_m)$  is a controllable pair and  $(F_m, H_m)$  is an observable pair, and (3)  $\dot{\hat{z}} = F_m\hat{z} + G_my$ ,  $\hat{x} = H_m\hat{z}$  is a linear observer (not necessarily a positive system) for (3.1). If  $G_o(s) = H_m(sI - F_m)^{-1}G_m$  admits a positive realization  $(F, G, H)$ , then system (5.1) can be a positive linear observer for system (3.1).

We now recall some results on the positive realization problem.

THEOREM 5.2 (see [12, Theorem 3.1]). *Let  $G_o(s)$  be a rational transfer function.  $G_o(s)$  has a positive realization if and only if*

1. *the impulse response function  $g_o(t)$  is positive, i.e.,  $g_o(t) > 0$  for every  $t > 0$  and  $g_o(0) \geq 0$ ;*
2. *there is a unique (possibly multiple) pole of  $G_o(s)$  with maximal real part.*

Note that this result is for scalar transfer functions. For a general matrix transfer function  $G_o(s)$ , it has been shown in [14, Theorem 2.4] (although it is for discrete time transfer functions, the same argument applies to continuous time ones) that  $G_o(s)$  has a positive realization if and only if each entry of  $G_o(s)$  has a positive realization. Thus, we require each component of  $G_o(s)$ , which is an  $n \times q$  matrix of transfer functions, to have a positive realization.

Based on this observation, the inverse eigenvalue problem does not appear anymore if  $(F_m, G_m, H_m)$  is appropriately chosen such that each component of  $H_m(sI - F_m)^{-1}G_m$  satisfies the conditions of this theorem. It is essential to recall that the positive realization problem is equivalent to finding a finite-dimensional invariant cone  $\mathcal{M}$  generated by the columns of some matrix  $M$  ( $\mathcal{M}$  will be denoted by Cone  $M$ ) and that enlarging the dimension to obtain a positive realization is mandatory in many cases [4], which corresponds to making  $N$  a design freedom in our problem. Recall that once  $M$  is found,  $(F, G, H)$  can be obtained solving the following equations [24, Theorem 5]:

$$(5.2) \quad F_m M = F M, \quad G_m = G M, \quad H = H_m M.$$

One possible way to choose  $(F_m, G_m, H_m)$  is  $(A - KC, K, I)$ , i.e., a matrix  $K \in \mathbb{R}^{n \times q}$  such that  $A - KC$  is Hurwitz (detectability of  $(A, C)$  guarantees this). Note that  $(A - KC, I)$  is observable, while  $(A - KC, K)$  may not be controllable (but it is at least stabilizable).

Now, we state the main result of this section.

**THEOREM 5.3.** *Consider a positive linear system (3.1) with  $(A, C)$  detectable. If there exists  $K \in \mathbb{R}^{n \times q}$  such that  $A - KC$  is a Hurwitz matrix and the transfer function  $G_o(s) = (sI - A + KC)^{-1}K$  admits a positive realization, then there exists a positive realization  $(F, G, H)$ , with  $F$  being Hurwitz, such that the dynamic system (5.1) is a positive linear observer for system (3.1).*

*Proof.* Let  $A_K = A - KC$  and let  $T$  be the transformation matrix decomposing  $(A_K, K, I)$  into controllable and uncontrollable parts [8],

$$TA_K = \begin{bmatrix} \bar{A}_{K,c} & \bar{A}_{12} \\ 0 & \bar{A}_{K,\bar{c}} \end{bmatrix} T, \quad TK = \begin{bmatrix} \bar{K}_c \\ 0 \end{bmatrix}, \quad T^{-1} = \begin{bmatrix} \bar{C}_c & \bar{C}_{\bar{c}} \end{bmatrix},$$

such that  $(\bar{A}_{K,c}, \bar{K}_c)$  is controllable. Then  $G_o(s) = \bar{C}_c(sI - \bar{A}_{K,c})^{-1}\bar{K}_c$ .

Let  $(\bar{F}, \bar{G}, \bar{H})$  be a positive realization of  $G_o(s)$ . Note that this realization may not be Hurwitz (i.e., there may be a positive real eigenvalue which is uncontrollable or unobservable). Following the same procedure of [2, Theorem 3.2], one can exclude these modes to obtain a reduced order positive realization  $(F, G, H)$  such that  $\lambda_{\max}(F)$  is a pole of  $G_o(s)$ , i.e.,  $F$  is Hurwitz.

Now, suppose  $(F, G, H)$ , with  $F$  being Hurwitz, is a positive realization of  $G_o(s)$  with a cone  $\mathcal{M}$  generated by  $M$ , i.e.,

$$(5.3) \quad \bar{A}_{K,c}M = MF, \quad \bar{K}_c = MG, \quad H = \bar{C}_cM.$$

Since  $A_K T^{-1} = A_K \begin{bmatrix} \bar{C}_c & \bar{C}_{\bar{c}} \end{bmatrix} = \begin{bmatrix} \bar{C}_c & \bar{C}_{\bar{c}} \end{bmatrix} \begin{bmatrix} \bar{A}_{K,c} & \bar{A}_{12} \\ 0 & \bar{A}_{K,\bar{c}} \end{bmatrix} = T^{-1} \begin{bmatrix} \bar{A}_{K,c} & \bar{A}_{12} \\ 0 & \bar{A}_{K,\bar{c}} \end{bmatrix}$ , it follows that  $A_K \bar{C}_c = \bar{C}_c \bar{A}_{K,c}$ . Similarly, one has  $\bar{C}_c \bar{K}_c = K$ . Hence,

$$\begin{aligned} AH - HGCH &= A_K H + KCH - HGCH \\ &= A_K \bar{C}_c M + \bar{C}_c \bar{K}_c CH - HGCH \\ &= \bar{C}_c \bar{A}_{K,c} M + \bar{C}_c M GCH - HGCH \\ &= HF. \end{aligned}$$

Let  $e = \hat{x} - x$ . Then

$$\begin{aligned}\dot{e} &= HF\hat{z} + HGCx - Ax \\ &= (AH - HGCH)\hat{z} + HGCx - Ax \\ &= A\hat{x} - HGC\hat{x} + HGCx - Ax \\ &= (A - \bar{C}_c\bar{K}_cC)e \\ &= (A - KC)e.\end{aligned}$$

Thus, the assertion follows.  $\square$

**THEOREM 5.4.** *Consider the positive linear observer (5.1) for system (3.1). Suppose that there exists  $K$  which satisfies the assumptions of Theorem 5.3, and that  $(F, G, H)$  is a positive realization of  $G_o(s) = (sI - A + KC)^{-1}K$ . Let  $n_c$  be the dimension of the controllable part of  $(A - KC, K)$ . Then*

1.  $K \geq 0$ ;
2.  $\text{rank } H = n_c$ ;
3.  $AH - HF = HGCH$ .

*Proof.* The fact  $K \geq 0$  follows from  $g_o(0) = K$ , and the proof of Theorem 5.3 ensures the last statement.

For the second statement, let  $F \in \mathbb{R}^{N \times N}$  and consider the decomposition derived in the proof of Theorem 5.3. We first show that  $\text{rank } M = n_c$ . Since  $M \in \mathbb{R}^{n_c \times N}$ , it follows that  $\text{rank } M \leq n_c$ . Suppose  $\text{rank } M < n_c$ . Then there exists a nonzero row vector  $w$  such that  $wM = 0$ , which results in  $w\bar{K}_c = wMG = 0$ . Moreover, one has  $w\bar{A}_{K,c}\bar{K}_c = 0$  since  $w\bar{A}_{K,c}\bar{K}_c = wMFG = 0$ . Repeating this process results in

$$w \begin{bmatrix} \bar{K}_c & \bar{A}_{K,c}\bar{K}_c & \cdots & \bar{A}_{K,c}^{n_c-1}\bar{K}_c \end{bmatrix} = 0,$$

which contradicts the controllability of  $(\bar{A}_{K,c}, \bar{K}_c)$ . Thus,  $\text{rank } M = n_c$ . From the fact that  $\bar{C}_c$  has full column rank and  $M$  has full row rank, it follows that  $\text{rank } H = n_c$ .  $\square$

From the proof of Theorem 5.3, the following result is straightforward.

**COROLLARY 5.5.** *Consider the positive linear system (3.1). If there exist  $F, G$ , and  $H$  such that (1)  $F$  is Metzler and Hurwitz,  $H \geq 0$ ,  $G \geq 0$ , (2)  $AH - HF = HGCH$ , and (3)  $A - HGC$  is Hurwitz, then the system (5.1) is a positive linear observer for system (3.1).*

**Remark 5.6.** 1. Note that the estimate  $\hat{x}(t)$  will reside in the cone generated by the columns of  $H$ . Thus, the initial condition  $\hat{x}(0)$  of the observer is confined to Cone  $H$ , which may not coincide with  $\mathbb{R}_+^n$ . This reduction of the set of initial conditions  $\hat{x}(0)$  can be thought of as the price for enlarging the class of systems that admit positive linear observers.

2. For controlled systems ( $\dot{x} = Ax + Bu$ ,  $y = Cx$ ), one can reformulate the problem by considering the transfer function matrix  $G_o(s) = (sI - A + KC)^{-1} \begin{bmatrix} K & B \end{bmatrix}$ .

Recall that Cone  $H$  is said to be solid if it contains an open ball in  $\mathbb{R}^n$ , i.e.,  $\text{rank } H = n$ . Theorem 5.4 ensures that if  $K$  is chosen such that  $(A - KC, K)$  is controllable, then for each interior point  $\bar{x}$  of Cone  $H$  there exists a neighborhood  $\mathcal{N}$  centered at  $\bar{x}$  such that  $x(0) \in \mathcal{N}$  implies the existence of  $\hat{x}(0) \in \mathcal{N}$  such that  $x(t) = \hat{x}(t) \forall t \geq 0$ . Note that if Cone  $H$  is not solid, this is not possible. Therefore, one might want Cone  $H$  to be solid. To this end, we provide the following result.

**THEOREM 5.7.** *For the positive linear system (3.1), suppose  $(A, C)$  is an observable pair. Suppose there is  $\bar{K} \in \text{int } \mathbb{R}_+^{n \times q}$  such that the transfer function matrix  $G_o^{\bar{K}}(s) := (sI - A + \bar{K}C)^{-1}\bar{K}$  satisfies the following conditions:*

1.  *$A - \bar{K}C$  has a simple and unique eigenvalue denoted by  $\lambda_{\max}$  whose real part is greater than any other eigenvalues, and  $G_o^{\bar{K}}(s)$  has a unique dominant pole denoted by  $p_{\max}$ . Moreover,  $p_{\max} = \lambda_{\max} < 0$ .*
2. *Let  $G_{o,ij}^{\bar{K}}(s)$  be the  $(i, j)$ th component of  $G_o^{\bar{K}}(s)$ . Then every zero of  $G_{o,ij}^{\bar{K}}(s)$  has real part less than  $p_{\max}$  and each  $G_{o,ij}^{\bar{K}}(s)$  has a simple and unique dominant pole  $p_{\max,ij}$  which is equal to  $p_{\max}$ .*
3.  *$G_o^{\bar{K}}(s)$  admits a positive realization  $(\bar{F}, \bar{G}, \bar{H})$ , which is a positive linear observer.*

*Then there exists a positive linear observer  $(F, G, H)$  of the form (5.1) with Cone  $H$  being solid.*

*Proof.* At first, note that  $\lambda_{\max}$  is real by assumption 1. It is assumed that  $n \geq 2$  since the case  $n = 1$  is trivial.

Consider the space  $\mathbb{R}^{n \times q}$ , equipped with the topology induced by some matrix norm, and let  $\delta > 0$  be such that the neighborhood of radius  $\delta$  of the matrix  $\bar{K}$ ,  $\mathcal{N}_\delta(\bar{K})$ , is included in  $\mathbb{R}_+^{n \times q}$ . Then observability of  $(A, C)$  guarantees that for almost every  $K \in \mathcal{N}_\delta(\bar{K})$ , the pair  $(A, K)$  (and equivalently  $(A - KC, K)$ ) is controllable.

Define  $\epsilon_1 = \min\{|\lambda_i - \lambda_j| \mid \lambda_i, \lambda_j \in \sigma(A - \bar{K}C), \lambda_i \neq \lambda_j\}$ . Recalling that the eigenvalues of  $(A - KC)$  change continuously w.r.t.  $K$ , we can find  $\delta_1 > 0$  such that  $\forall K \in \mathcal{N}_{\delta_1}(\bar{K})$ ,

$$\begin{aligned} & \text{dist}(\sigma(A - KC), \sigma(A - \bar{K}C)) \\ &:= \min\{|\lambda_i - \lambda_j| \mid \lambda_i \in \sigma(A - KC), \lambda_j \in \sigma(A - \bar{K}C)\} < \frac{1}{3}\epsilon_1. \end{aligned}$$

By assumption 2,  $G_{o,ij}^{\bar{K}}(s)$  has the form

$$G_{o,ij}^{\bar{K}}(s) = \frac{\pi_{ij}(\bar{K})(s - z_1) \cdots (s - z_{\bar{n}(i,j)})}{(s - p_1) \cdots (s - p_{\bar{d}(i,j)})}, \quad z_l \neq p_m \quad \forall l, m, \bar{d}(i, j) > \bar{n}(i, j),$$

where  $z_l \in \mathbb{C}$  and  $p_l \in \mathbb{C}$  represent zeros and poles of  $G_{o,ij}^{\bar{K}}(s)$ , respectively,  $\text{Re } z_l < 0$ ,  $\text{Re } p_l < 0$ , and  $\pi_{ij}(\cdot)$  is a continuous function defined on  $\mathcal{N}_{\delta_1}(\bar{K})$  with  $\pi_{ij}(\bar{K}) \neq 0$ . Note that  $z_l$ 's and  $p_l$ 's (and  $\mu_l$ 's and  $\eta_l$ 's used in (5.4)) vary with  $i, j$ . However, for simplicity of notation, we drop the explicit dependence on  $i, j$  whenever not needed.

We fix  $p_1 = p_{\max} \forall G_{o,ij}^{\bar{K}}(s)$  (by assumption 2) and define

$$\epsilon_2 = \min_{1 \leq i \leq n, 1 \leq j \leq q} \{|z_l - p_1| \mid 1 \leq l \leq \bar{n}(i, j)\}.$$

Define a transfer function  $G_o^K(s) = (sI - A + KC)^{-1}K$  parameterized by  $K \in \mathcal{N}_{\delta_1}(\bar{K})$ , and let  $G_{o,ij}^K(s)$  be the  $(i, j)$ th component of  $G_o^K(s)$ , which can be described by

$$(5.4) \quad G_{o,ij}^K(s) = \frac{\pi_{ij}(K)(s - z_1 + \mu_1(K)) \cdots (s - z_{\bar{n}(i,j)} + \mu_{\bar{n}(i,j)}(K))}{(s - p_1 + \eta_1(K)) \cdots (s - p_{\bar{d}(i,j)} + \eta_{\bar{d}(i,j)}(K))} \tilde{G}_{o,ij}(s),$$

where

$$(5.5) \quad \tilde{G}_{o,ij}(s) = \frac{(s - p_{\bar{d}(i,j)+1} + \mu_{\bar{d}(i,j)+1}(K)) \cdots (s - p_{d(i,j)} + \mu_{d(i,j)}(K))}{(s - p_{\bar{d}(i,j)+1} + \eta_{\bar{d}(i,j)+1}(K)) \cdots (s - p_{d(i,j)} + \eta_{d(i,j)}(K))}$$

and  $\eta_l$ 's and  $\mu_l$ 's are (complex valued) continuous functions defined on  $\mathcal{N}_{\delta_1}(\overline{K})$  and vanishing at  $\overline{K}$ . Note that for any real  $K$ ,  $\eta_i$  and  $\mu_i$  render  $G_{o,ij}^K(s)$  a rational function whose coefficients are real numbers.

Since  $p_1$  is real,  $\eta_1(K)$  is real by the way  $\delta_1$  is chosen. The transfer function  $\tilde{G}_{o,ij}(s)$  describes the pole zero cancellation (thus becoming unity) when  $K$  happens to be  $\overline{K}$ .

It is important to note that there is no restriction on  $\mu_i$ 's in (5.4)–(5.5) at this moment; i.e., it might happen that  $p_1 - \eta_1(K) = z_i - \mu_i(K)$ . Thus, we take  $\delta_2 > 0$  such that the poles and zeros of  $G_{o,ij}^K(s)$  do not change significantly. Indeed, by continuity and assumption 2, there exists  $0 < \delta_2 < \delta_1$  such that  $\forall K \in \mathcal{N}_{\delta_2}(\overline{K})$ , it holds that

$$\max \left\{ \max_{l \in I_{\mu,ij}} \{|\mu_l(K)|\}, \max_{l \in I_{\eta,ij}} \{|\eta_l(K)|\} \right\} < \frac{1}{3} \min\{\epsilon_1, \epsilon_2\} \quad \forall 1 \leq i \leq n, 1 \leq j \leq q,$$

$$p_1 - \eta_1^{ij}(K) < 0 \quad \forall 1 \leq i \leq n, 1 \leq j \leq q,$$

where  $I_{\mu,ij} = \{1, \dots, \bar{n}(i, j), \bar{d}(i, j) + 1, \dots, d(i, j)\}$  and  $I_{\eta,ij} = \{1, \dots, d(i, j)\}$ . (Note that  $I_{\mu,ij}$  and  $I_{\eta,ij}$  represent the set of indices appearing in (5.4) and (5.5).) By the way  $\delta_2$  is chosen, it is guaranteed that  $\forall K \in \mathcal{N}_{\delta_2}(\overline{K})$ , the pole  $p_1 - \eta_1(K)$  is the dominant pole of  $G_{o,ij}^K(s)$  and is a negative real number.

Rewrite  $G_{o,ij}^K(s)$  as

$$G_{o,ij}^K(s) = \frac{s - p_1}{s - p_1 + \eta_1(K)} G_{o,ij}^{\overline{K}}(s) \hat{G}_{o,ij}(s) \tilde{G}_{o,ij}(s),$$

where

$$\hat{G}_{o,ij}(s) := \frac{\pi_{ij}(K)}{\pi_{ij}(\overline{K})} \prod_{l=2}^{\bar{d}(i,j)} \frac{s - p_l}{s - p_l + \eta_l(K)} \cdot \prod_{l=1}^{\bar{n}(i,j)} \frac{s - z_l + \mu_l(K)}{s - z_l}.$$

It follows from the structure of  $\hat{G}_{o,ij}(s)$  and  $\tilde{G}_{o,ij}(s)$  that

$$G_{o,ij}^{\overline{K}}(s) \hat{G}_{o,ij}(s) \tilde{G}_{o,ij}(s) = G_{o,ij}^{\overline{K}}(s) + G_{o,ij}^{*K}(s),$$

where  $G_{o,ij}^{*K}(s)$  is a transfer function parameterized by  $K$  in a continuous way. Note that every pole of  $G_{o,ij}^{*K}(s)$  (i.e.,  $p_l - \eta_l(K)$ ,  $l = 2, \dots, d(i, j)$ , and  $z_l$ ,  $l = 1, \dots, \bar{n}(i, j)$ ) resides in  $\mathbb{C}^-$  and the dominant pole of  $G_{o,ij}^{*K}(s)$  is  $p_1$ .

Consider the impulse response functions of  $G_{o,ij}^{\overline{K}}(s)$  and  $G_{o,ij}^{*K}(s)$  denoted by  $g_{o,ij}^{\overline{K}}(t)$  and  $g_{o,ij}^{*K}(t)$ , respectively. Since  $p_1$  is the dominant pole of these two transfer functions, we can rewrite the impulse response functions as

$$\begin{aligned} g_{o,ij}^{\overline{K}}(t) &= e^{p_1 t} \bar{f}_{ij}(t), \quad \bar{f}_{ij}(t) > 0 \quad \forall t, \\ g_{o,ij}^{*K}(t) &= e^{p_1 t} f_{ij}^{*K}(t), \end{aligned}$$

where  $\bar{f}_{ij}(t)$  and  $f_{ij}^{*K}(t)$  can be expressed by the sum of a real constant (the coefficient associated to the dominant pole  $p_1$ ) and exponential functions (multiplied by some power of  $t$ , in general) which decay to zero as  $t \rightarrow \infty$ . Note that the coefficients of the exponential functions associated to  $f_{ij}^{*K}(t)$  are continuous functions of  $K$  and become zero when  $K = \overline{K}$ , i.e.,  $f_{ij}^{*\overline{K}}(t) = 0 \quad \forall t \geq 0$ . It is seen that there exists

$\epsilon_3 > 0$  such that  $\bar{f}_{ij}(t) > \epsilon_3 \ \forall t \geq 0$ . In fact, note that  $\bar{f}_{ij}(t)$  can be decomposed as  $\bar{f}_{ij}(t) = \hat{f}_{ij} + \tilde{f}_{ij}(t)$ , where  $0 < \hat{f}_{ij} \in \mathbb{R}$  and  $\lim_{t \rightarrow \infty} \tilde{f}_{ij}(t) = 0$  (exponential terms). Then there exists  $T > 0$  such that  $|\tilde{f}_{ij}(t)| < \hat{f}_{ij}/2 \ \forall t > T$ . Thus, the claim follows by taking  $\epsilon_3 = \frac{1}{2} \min\{\min_{t \in [0, T]} \bar{f}_{ij}(t), \hat{f}_{ij}\}$ .

By continuity, there exists  $\delta_3 > 0$  ( $\delta_3 < \delta_2$ ) such that  $\forall K \in \mathcal{N}_{\delta_3}(\bar{K})$ ,  $|f_{ij}^{*K}(t)| < \epsilon_3/2$ . This ensures that there exist  $\underline{f}_{ij}, \bar{f}_{ij}$  such that  $0 < \underline{f}_{ij} < \bar{f}_{ij}(t) + f_{ij}^{*K}(t) := f_{ij}(t) < \bar{f}_{ij}$ . Therefore, it follows that  $\forall K \in \mathcal{N}_{\delta_3}(\bar{K})$ ,

$$0 < \underline{f}_{ij} e^{p_1 t} \leq \mathcal{L}^{-1} \left[ G_{o,ij}^{\bar{K}}(s) \hat{G}_{o,ij}(s) \tilde{G}_{o,ij}(s) \right] (t) = e^{p_1 t} f_{ij}(t) \leq \bar{f}_{ij} e^{p_1 t} \quad \forall t \geq 0.$$

To complete the proof we find  $K^* \in \mathcal{N}_{\delta_3}(\bar{K})$  such that  $\eta_1^{ij}(K^*) < 0 \ \forall i, j$ . (Note that  $\eta_1$  of  $G_{o,ij}^K(s)$  is different from that of  $G_{o,\bar{i}\bar{j}}^K(s)$ , in general.) To do this, we write  $A - \bar{K}C$  in the real Jordan form, i.e.,  $A - \bar{K}C = J A_{\bar{K},J} J^{-1}$ . With no loss of generality,  $J_1$  (the first column of  $J$ ) is assumed to be the eigenvector  $v_{\max}$  corresponding to the eigenvalue  $p_{\max}$ .

Choose the  $i^*$ th row of  $C$  such that  $C_{i^*} v_{\max} \neq 0$  (by observability,  $i^*$  exists). Let

$$K^* = -\eta^* v_{\max} e_{i^*}^t, \quad \eta^* := \frac{\xi \delta_3}{C_{i^*} v_{\max}},$$

where  $e_{i^*} \in \mathbb{R}^q$  is the vector whose  $i^*$ th component is one, while the others are zero, and  $\xi > 0$  is chosen sufficiently small such that  $K^* + \bar{K} \in \mathcal{N}_{\delta_3/2}(\bar{K})$ . Thus,  $K^*$  has just one nonzero column (the  $i^*$ th column). From the relation

$$A - \bar{K}C - K^*C = J [A_{\bar{K},J} + \xi \delta_3 e_1 [1 \quad * \quad \cdots \quad *]] J^{-1},$$

it follows that the maximal real eigenvalue of  $A - \bar{K}C - K^*C$  is shifted to  $p_{\max} + \xi \delta_3$ . Thus, by continuity, there exists  $\delta_4 > 0$  such that  $\forall K \in \mathcal{N}_{\delta_4}(\bar{K} + K^*)$ ,  $\eta_1^{ij}(K) < 0 \ \forall 1 \leq i \leq n, 1 \leq j \leq q$  and  $\mathcal{N}_{\delta_4}(\bar{K} + K^*) \subset \mathcal{N}_{\delta_3}(\bar{K})$ .

Pick a  $K \in \mathcal{N}_{\delta_4}(\bar{K} + K^*)$  such that  $(A - KC, K)$  is a controllable pair. From the relation

$$\begin{aligned} g_{o,ij}^K(t) &= \mathcal{L}^{-1} \left[ \frac{s - p_1}{s - p_1 + \eta_1(K)} \right] (t) * \mathcal{L}^{-1} \left[ G_{o,ij}^{\bar{K}}(s) \hat{G}_{o,ij}(s) \tilde{G}_{o,ij}(s) \right] (t) \\ &= e^{p_1 t} f_{ij}(t) - \eta_1(K) \int_0^t e^{(p_1 - \eta_1(K))(t-\tau)} e^{p_1 \tau} f_{ij}(\tau) d\tau > 0 \quad \forall t \geq 0, \end{aligned}$$

where “ $*$ ” represents the convolution integral, and the fact that  $G_{o,ij}^K(s)$  has a simple dominant pole  $p_{\max} - \eta_1(K) < 0$ , we conclude that  $G_{o,ij}^K(s)$  has a positive realization.

Thus, it follows that there exists  $K$  such that  $G_o^K(s)$  has a positive realization  $(F^*, G^*, H^*)$ , and  $(A - KC, K)$  is controllable. By Theorem 5.3, there exists a positive realization  $(F, G, H)$  with  $F$  being Hurwitz such that the realization  $(F, G, H)$  is a positive linear observer. Moreover, by Theorem 5.4 (rank  $H = n$ ), Cone  $H$  is solid. Therefore, the assertion follows.  $\square$

Note that Theorem 5.7 provides only a sufficient condition on the existence of a positive linear observer. It is unclear at this moment whether the converse is true.

Now we present an extension of Theorem 4.9.

**THEOREM 5.8.** *For a single output positive system (3.1), suppose  $A$  is irreducible and  $(A, C)$  is detectable. Let  $\lambda_1 = \lambda_{\max}(A)$ . There exists a positive linear observer*

via positive realization (5.1) if all eigenvalues of  $A$  except  $\lambda_1$  lie in the open left half complex plane.

*Proof.* Since  $A$  is irreducible and  $(A, C)$  is detectable, there exists  $v_{\max} \in \text{int } \mathbb{R}_+^n$  such that  $Av_{\max} = \lambda_{\max}(A)v_{\max}$  and  $Cv_{\max} = 1$ . Let  $K = (\lambda_1 + \epsilon)v_{\max}$ , where  $\epsilon > 0$  is chosen such that  $\lambda^* < -\epsilon < 0$ , where  $\lambda^* = \max\{\text{Re } \lambda \mid \lambda \in \sigma(A), \lambda \neq \lambda_1\}$ . From Theorem 2.4, we have  $\sigma(A - KC) = (\sigma(A) \setminus \{\lambda_1\}) \cup \{-\epsilon\}$  since  $Cv_{\max} = 1$ . That is to say, all the eigenvalues of  $A$  and  $A - KC$  coincide except that  $\lambda_1$  is replaced by  $-\epsilon$ . Thus,  $A - KC$  is Hurwitz and the eigenvalue with maximal real part is  $-\epsilon$ .

Define  $G_o(s) = (sI - A + KC)^{-1}K$ . Then the gain matrix  $K$  chosen above yields

$$\begin{aligned} g_o(t) &= e^{(A-KC)t}K \\ &= e^{(A-(\lambda_1+\epsilon)v_{\max}C)t}(\lambda_1 + \epsilon)v_{\max} \\ &= (\lambda_1 + \epsilon) \left[ \sum_{i=0}^{\infty} \frac{1}{i!} [A - (\lambda_1 + \epsilon)v_{\max}C]^i t^i \right] v_{\max} \\ &= (\lambda_1 + \epsilon) \left[ \sum_{i=0}^{\infty} \frac{1}{i!} (-\epsilon t)^i \right] v_{\max} \\ &= (\lambda_1 + \epsilon)e^{-\epsilon t}v_{\max} > 0, \end{aligned}$$

which implies that  $G_o(s)$  has a positive realization. Therefore, the assertion follows by Theorem 5.3.  $\square$

*Remark 5.9.* 1. The proof of Theorem 5.8 ensures that if  $(A, C)$  is observable, there exists  $\bar{K}$  satisfying all assumptions of Theorem 5.7. Thus, a gain matrix  $K$  sufficiently close to  $\bar{K}$  renders  $\text{rank } H = n$ . Note that if  $(A, C)$  is detectable, this does not hold in general. For example, if  $A = \text{diag}\{1, -1, -1\}$ ,  $C = [1 \ 0 \ 0]$ , then there is no  $K \in \mathbb{R}^3$  such that  $(A, K)$  (equivalently  $(A - KC, K)$ ) is controllable.

2. Theorem 5.8 extends Theorem 4.9. If  $K$  is chosen to be a scalar product of  $v_{\max}$ , then any positive  $\epsilon$  results in a positive observer. In the proof of Theorem 5.8,  $\epsilon$  is selected so that all conditions of Theorem 5.8 are satisfied for the observable case.

3. The observer structure in section 4 is a special case of (5.1). Note that the coordinates transformation is involved during the positive realization procedure.

**5.2. Application to compartmental systems.** In this subsection, we apply the observer design method developed in section 5.1 to compartmental systems. Before proceeding, without loss of generality, assume  $A, C$  are decomposed as in (3.13) and (3.5). Define

$$\begin{aligned} A_- &:= \begin{bmatrix} A_{11} & 0 & 0 \\ \vdots & \ddots & 0 \\ A_{\nu-m,1} & \cdots & A_{\nu-m,\nu-m} \end{bmatrix} \in \mathbb{R}^{(d_1+\cdots+d_{\nu-m}) \times (d_1+\cdots+d_{\nu-m})}, \\ A_+ &:= \text{diag}\{A_{\nu-m+1,\nu-m+1}, \dots, A_{\nu\nu}\}. \end{aligned}$$

Similarly,

$$C_- := \begin{bmatrix} C_{11} & \cdots & C_{1,\nu-m} \\ \vdots & & \vdots \\ C_{q1} & \cdots & C_{q,\nu-m} \end{bmatrix}, \quad C_+ := \begin{bmatrix} C_{1,\nu-m+1} & \cdots & C_{1\nu} \\ \vdots & & \vdots \\ C_{q,\nu-m+1} & \cdots & C_{q\nu} \end{bmatrix}.$$

Then  $A$  and  $C$  can be written as

$$(5.6) \quad A = \begin{bmatrix} A_- & 0 \\ A_* & A_+ \end{bmatrix}, \quad C = [C_- \quad C_+],$$

where  $A_*$  is clearly defined by this. We decompose the state vector  $x$  into  $x_-$  and  $x_+$  according to  $A_-$  and  $A_+$ .

Our observer has the form

$$(5.7) \quad \dot{\hat{z}} = \begin{bmatrix} A_- & 0 \\ 0 & F \end{bmatrix} \hat{z} + \begin{bmatrix} 0 \\ G \end{bmatrix} y, \quad \hat{x} = \begin{bmatrix} I_{d_1+\dots+d_{\nu-m}} & 0 \\ 0 & H \end{bmatrix} \hat{z},$$

where  $F \in \mathbb{R}^{N \times N}$ ,  $G \in \mathbb{R}^{N \times q}$ ,  $H \in \mathbb{R}^{(d_{\nu-m+1}+\dots+d_{\nu}) \times N}$ , and the matrices  $F$ ,  $G$ ,  $H$  and the dimension  $N$  are design parameters. Note that this observer is of the form (5.1).

**THEOREM 5.10.** *Consider the positive system (3.1) where  $A$  is a compartmental matrix and the matrices  $A$  and  $C$  are decomposed as in (5.6). Assume  $q = m$ . If  $C_+ = \text{diag}\{C_{1,\nu-m+1}, \dots, C_{m\nu}\}$  up to renumbering the outputs, then there exists a positive linear observer of the form (5.1) if and only if  $(A, C)$  is detectable.*

*Proof.* Necessity follows trivially.

For sufficiency, it is noted that the pairs  $(A_{\nu-m+1,\nu-m+1}, C_{1,\nu-m+1}), \dots, (A_{\nu\nu}, C_{m\nu})$  are detectable. Let  $v_i$  be the eigenvector associated to the zero eigenvalue of  $A_{ii}$  ( $i = \nu - m + 1, \dots, \nu$ ) such that  $C_{i-\nu+m,i}v_i = 1$ , and choose  $\epsilon_i$  ( $i = \nu - m + 1, \dots, \nu$ ) such that  $\lambda_i^* < -\epsilon_i < 0$ , where  $\lambda_i^* = \max\{\text{Re } \lambda \mid \lambda \in \sigma(A_{ii}), \lambda \neq 0\}$ .

Setting

$$K := \begin{bmatrix} K_- \\ K_+ \end{bmatrix}$$

with  $K_- := 0_{(d_1+\dots+d_{\nu-m}) \times q}$ ,  $K_+ := \text{diag}\{\epsilon_{\nu-m+1}v_{\nu-m+1}, \dots, \epsilon_{\nu}v_{\nu}\}$ , it follows that

$$G_{o+}(s) = (sI - A_+ + K_+C_+)^{-1}K_+ = \text{diag} \left\{ \frac{\epsilon_{\nu-m+1}}{s + \epsilon_{\nu-m+1}}v_{\nu-m+1}, \dots, \frac{\epsilon_{\nu}}{s + \epsilon_{\nu}}v_{\nu} \right\},$$

which has a positive realization

$$F = \text{diag}\{-\epsilon_{\nu-m+1}, \dots, -\epsilon_{\nu}\}, \quad G = \text{diag}\{\epsilon_{\nu-m+1}, \dots, \epsilon_{\nu}\},$$

$$H = \text{diag}\{v_{\nu-m+1}, \dots, v_{\nu}\}.$$

Noting that  $\lim_{t \rightarrow \infty} x_-(t) = 0$ , one can easily prove the convergence of the observer error to zero by modifying the proof of Theorem 5.3.  $\square$

The following result is a direct consequence of Theorem 5.10.

**COROLLARY 5.11.** *Consider the positive system (3.1) where  $A$  is a compartmental matrix and the matrices  $A$  and  $C$  are decomposed as in (5.6). If the multiplicity of the zero eigenvalue of  $A$  is less than or equal to 1, then there exists a positive linear observer of the form (5.1) if and only if  $(A, C)$  is detectable.*

Note that the decoupling condition (block diagonal structure of  $C_+$ ) also plays an important role in Corollary 3.5. Note also that if  $(A, C)$  is observable, each block diagonal component of  $G_{o+}(s)$  satisfies the conditions of Theorem 5.7 ( $A$ ,  $\overline{K}$ , and  $C$  replaced by  $A_{ii}$ ,  $v_i$ , and  $C_{i-\nu+m}$ , respectively, for  $i = \nu - m + 1, \dots, \nu$ ), which implies that one can design a state observer with rank  $H = n$  by changing  $K$  slightly.

*Example 5.12.* Consider a detectable positive linear system described by

$$\dot{x} = Ax = \begin{bmatrix} -2 & 2 & 0 \\ 0 & -2 & 2 \\ 2 & 0 & -2 \end{bmatrix} x, \quad y = Cx = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} x.$$

Simple computation yields that  $\sigma(A) = \{0, -3 \pm j\sqrt{3}\}$  and 0 is the only observable mode. Note that there is no  $K \in \mathbb{R}_+^3$  such that  $A - KC$  is Hurwitz and Metzler (this can be checked by Theorem 3.2).

Now, we apply Theorem 5.10. First note that  $A_+ = A$  and  $C_+ = C$  (we have no  $A_-$  and  $C_-$ ). If we choose  $K_+ = \epsilon \begin{bmatrix} \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{bmatrix}^t$ ,  $\epsilon > 0$ , then

$$G_o(s) = G_{o+}(s) = (sI - A_+ + K_+C_+)^{-1}K_+ = \frac{\epsilon}{3(s + \epsilon)} 1_{3 \times 1}.$$

Thus, the positive linear system

$$\begin{aligned} \dot{\hat{z}} &= -\epsilon \hat{z} + \epsilon y, \\ \hat{x} &= \frac{1}{3} 1_{3 \times 1} \hat{z} \end{aligned}$$

is a positive linear observer for the system. Note that  $\epsilon$  can be chosen arbitrarily positive.

To obtain a positive observer whose output matrix generates a solid cone, we select  $K_+ = \begin{bmatrix} \frac{1}{5} & \frac{2}{5} & \frac{2}{5} \end{bmatrix}^t$  (thus,  $(A_+, K_+)$  is controllable), which results in

$$\begin{aligned} G_{o+}(s) &= (sI - A_+ + K_+C_+)^{-1}K_+ \\ &= \begin{bmatrix} s^2 + 8s + 20 \\ 2s^2 + 12s + 20 \\ 2s^2 + 10s + 20 \end{bmatrix} \frac{1}{5(s^2 + 6s + 12)(s + 1)}. \end{aligned}$$

We follow the procedure described in [5] to obtain a positive realization  $(F, G, H)$ . Let  $G_{o+,i}(s)$  be the  $i$ th component of  $G_{o+}(s)$  and let  $(A_{c,i}, B_{c,i}, C_{c,i})$  be the controllable realization of  $G_{o+,i}(s)$ , i.e.,

$$\begin{aligned} A_{c,1} = A_{c,2} = A_{c,3} = A_c &= \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -12 & -18 & -7 \end{bmatrix}, \\ B_{c,1} = B_{c,2} = B_{c,3} = B_c &= \begin{bmatrix} 0 & 0 & 1 \end{bmatrix}^t, \\ C_{c,1} = \frac{1}{5} \begin{bmatrix} 20 & 8 & 1 \end{bmatrix}, C_{c,2} = \frac{2}{5} \begin{bmatrix} 10 & 6 & 1 \end{bmatrix}, C_{c,3} = \frac{2}{5} \begin{bmatrix} 10 & 5 & 1 \end{bmatrix}. \end{aligned}$$

Let  $\mathcal{P} = \text{Cone } P$ , where

$$P = \begin{bmatrix} B_c & \bar{A}_c B_c & \bar{A}_c^2 B_c & \bar{A}_c^3 B_c \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 & 2 \\ 0 & 1 & -1 & -5 \\ 1 & -4 & -2 & 14 \end{bmatrix}, \quad \bar{A}_c := A_c + 3I.$$

Note that the shift term  $3I$  in  $\overline{A}_c$  corresponds to the real part of the leftmost pole (the pole with the least real part) of  $G_{o+}(s)$ . It is easy to see that Cone  $P$  is a proper invariant cone with respect to  $A_c$ . Solving

$$\overline{A}_c P = P \overline{F}, \quad B_c = P G, \quad H = \begin{bmatrix} C_{c,1} \\ C_{c,2} \\ C_{c,3} \end{bmatrix} P, \quad \overline{F} \geq 0, G \geq 0, H \geq 0,$$

one gets

$$F = \overline{F} - 3I = \begin{bmatrix} -3 & 0 & 0 & 12 \\ 1 & -3 & 0 & 0 \\ 0 & 1 & -3 & 1 \\ 0 & 0 & 1 & -3 \end{bmatrix}, \quad G = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad H = \frac{1}{5} \begin{bmatrix} 1 & 4 & 10 & 14 \\ 2 & 4 & 4 & 8 \\ 2 & 2 & 6 & 18 \end{bmatrix}.$$

Note that  $\sigma(F) = \{-1, -3 \pm j\sqrt{3}, -5\} \supset \sigma(A - KC)$  and  $\text{rank } H = 3$ . Therefore, the dynamics  $\dot{\hat{z}} = F\hat{z} + Gy, \hat{x} = H\hat{z}$  is the positive linear observer with  $H$  being solid.

*Example 5.13.* Consider the system

$$\dot{x} = Ax = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 1 \\ 0 & 1 & -1 \end{bmatrix} x, \quad y = Cx = \begin{bmatrix} 1 & 1 & 1 \end{bmatrix} x.$$

Recall that (Example 3.6) it is not possible to design a Luenberger-type positive observer. Corollary 5.11 guarantees that this system admits a positive linear observer of the form (5.7).

**6. Conclusion.** The problem of designing positive linear observers for positive linear systems has been addressed considering the use of coordinates transformations and of observers of higher dimension than the system to be observed. In ascending order of complexity, existence conditions for Luenberger-type positive linear observers, for linear observers using coordinates transformations, and for positive realization-based linear observers are derived. As expected, the class of systems which can be *observed* by a positive linear observer is enlarged in these new frameworks. Although the positive realization approach is the most complex design method, it is a well organized and constructive method, since there are several well-established tools to obtain positive realizations. Future research topics include extension of the work to systems which may have unstable complex eigenvalues, stabilization for positive linear systems, which has some duality to the observation problem, and positive observers for nonlinear positive systems.

# NONZERO SUM STOCHASTIC DIFFERENTIAL GAMES WITH DISCOUNTED PAYOFF CRITERION: AN APPROXIMATING MARKOV CHAIN APPROACH\*

K. SURESH KUMAR†

**Abstract.** We develop a new constructive method for proving the existence of Nash equilibrium for a class of nonzero sum stochastic differential games. Under certain usual assumptions, we prove the existence of Nash equilibrium for discounted payoff criteria. A novel feature of our method is that it allows us to compute Nash equilibrium for a large class of stochastic differential games.

**1. Introduction.** We develop a new method for finding Nash equilibria for a class of stochastic differential games where state process  $X(\cdot)$  of the game is given by the solution of the controlled SDE

$$(1.1) \quad \left. \begin{aligned} dX(t) &= [b_1(X(t), v_1(t)) + b_2(X(t), v_2(t))] dt + \sigma(X(t)) dW(t), \\ X(0) &= x \in \mathbb{R}^d, \end{aligned} \right\}$$

where  $v_i$  is the strategy of player  $i, i = 1, 2$ . The payoff criterion of the game for the player  $i = 1, 2$  is given by

$$(1.2) \quad R_{\alpha}^i[v_1, v_2](x) = E \left[ \int_0^{\infty} e^{-\alpha t} [r_{1i}(X(t), v_1(t)) + r_{2i}(X(t), v_2(t))] dt \middle| X(0) = x \right],$$

$i = 1, 2$ . In a two-player game, a Nash equilibrium is a pair of strategies such that unilateral deviation from this pair of strategies by any player is disadvantageous to him. If the first player announces his strategy in advance, then the second player would maximize his payoff. Any strategy of the second player that maximizes his payoff is called his optimal response corresponding to the announced strategy of the first player. Note that there may be several optimal responses of the second player corresponding to each announced strategy of the first player. Similarly, optimal response of the first player is defined. This gives a map which takes each pair of strategies of the players to a corresponding pair of a set of optimal responses. It can be seen that any fixed point of this multivalued map is a Nash equilibrium. Note that this multivalued map may have several fixed points. Thus we may have multiple Nash equilibria. The traditional method of establishing the existence of a Nash equilibrium is to prove the existence of a fixed point of this multivalued map by using a fixed point theorem [8]. The main step in this method lies in establishing the upper semicontinuity of this multivalued map under a suitable metrizable topology on the appropriate set of

†Department of Mathematics, Indian Institute of Technology, Bombay, Powai, Mumbai 400 076, India (suresh@math.iitb.ac.in).

strategies. Though this methodology is very useful in establishing Nash equilibria, it does not lead to a constructive procedure for computing Nash equilibria.

In this paper we develop a new method based on a discretization procedure which enables us to construct a Nash equilibrium. By suitably discretizing the original stochastic differential game, we construct a parametric family of stochastic games in such a way that the state of the stochastic game is given by a controlled discrete time process  $\{X_n^h | n \geq 0\}$ , defined in section 3, satisfying a certain “local consistency” condition, and the payoff criterion is given by

$$R_\alpha^{ih}[v_1^h, v_2^h](x) = \Delta t^h E \left[ \sum_{n=0}^{\infty} \left( e^{-\alpha \Delta t^h} \right)^n [r_{1i}(X_n^h, v_{1n}^h) + r_{2i}(X_n^h, v_{2n}^h)] \middle| X_0^h = x \right],$$

where  $\Delta t^h$  is the constant step size for time discretization; its explicit form is given in section 3. The local consistency condition enables us to show that, as the parameter  $h$  tends to 0, a Nash equilibrium of the stochastic game converges in an appropriate sense to a Nash equilibrium of the stochastic differential game.

Our convergence analysis is crucially based on the specific structure of the drift vector in (1.1) and the payoff functions in (1.2). Note that the dependence of the variables  $v_1, v_2$  on the drift vector of the process  $X(\cdot)$  as in (1.1) appears in separate functions in an additive manner. The same holds for the payoff functions in (1.2). These separability conditions are typical in stochastic dynamic games in discrete time with general (uncountable) state space as well. In stochastic games in discrete time with uncountable state space, these types of conditions are referred to as AR-AT, which stands for additive reward-additive transition structure; see, for example, [11], [22]. To our knowledge, the problem of establishing the existence of a Nash equilibrium in stationary strategies without the AR-AT structure for discrete time stochastic game in a general state space is still open. The same holds for stochastic differential games as well. In the discrete time case, some progress has been made in this direction. In [25] the authors have established the existence of a Nash equilibrium in stationary strategies without AR-AT structure but under the assumption that the transition is state-independent. Without using the AR-AT structure, in [21] the existence of a subgame perfect equilibrium is established, whereas in [23] the existence of a correlated equilibrium in stationary strategies is established.

The basic idea of approximating SDE (1.1) by using the chain  $\{X_n^h | n \geq 1\}$  was pioneered by Kushner; see [14], [15], [19]. These works deal with numerical procedures for stochastic optimal control problems. The idea has been extended to zero sum stochastic differential games as well; see [16], [17], [26]. A numerical approximation of nonzero sum stochastic differential games is treated in [18]. Our present paper is different from [18] in two aspects. First of all, we consider a different class of stochastic differential games. Second, our main focus lies in using the approximation argument to get a constructive procedure for computing a Nash equilibrium. This point is not addressed in [18].

In the literature of nonzero sum stochastic differential games, not much is known about the computational aspects of Nash equilibrium. Nash equilibria can be explicitly computed only in some specific games; see, for example, [12], [24]. To the best of our knowledge, [20] is the latest in the literature which tries to construct Nash equilibrium for a class of stochastic differential games on the finite horizon. In [20], it is assumed that

$$b_k(x, v_k) = \tilde{b}_k(x)v_k, \quad r_1(x, v_1, v_2) = \tilde{r}_1(x)v_1, \quad r_2(x, v_1, v_2) = \tilde{r}_2(x)v_2,$$

where  $\tilde{b}_k, \tilde{r}_k$  are of  $C^1$  class. Also assume that  $\sigma\sigma'$  and  $(\sigma\sigma')^{-1}$  are Lipschitz continuous. These affine structural conditions are quite crucial in the analysis in [20]. In our paper, we compute Nash equilibrium for a class of stochastic differential games where the conditions in [20] may be treated as a special case. Note that it is our Example 5.6 with  $r_{12} \equiv r_{21} \equiv 0$ .

The rest of this paper is organized as follows: In section 2, we give a detailed description of the stochastic differential game problem. In section 3, we give a description of the approximating chain  $\{X_n^h\}$  and prove two important results (Theorems 3.1 and 3.2), which establish that Markov chains  $\{X_n^h\}$  under Markov strategies are indeed approximations of controlled diffusion given by (1.1) for a suitable pair of admissible strategies of the players. In section 4, we describe a stochastic game with the state equation given by  $\{X_n^h\}$  and payoff criterion (4.1), which is “close” to the payoff criterion (1.2). By using the convergence results proved in section 3, we prove that a Nash equilibrium of the stochastic game converges to a Nash equilibrium of the stochastic differential game along a subsequence. This proves the existence of a Nash equilibrium for the stochastic differential game. In section 5, by using the optimality equation (5.2), which characterizes a Nash equilibrium of the approximate stochastic game described in section 4, we derive an iterative procedure for constructing a Nash equilibrium for the approximate stochastic game. Then by using an additional assumption (A4) we show that iterates indeed converge. The Nash equilibrium we construct by using our procedure is given by the particular selector map  $\bar{u}_x^k(\cdot)$  given in (A4). Hence if multiple selector maps exist, then multiple Nash equilibria can be computed. We also give examples when the selector map is unique. Section 5 deals with numerical results for constructing a Nash equilibrium by using the above iterative procedure. We conclude our paper in section 6 with a few remarks.

**2. Description of the problem.** Let  $U_i$  be a compact subset of  $\mathbb{R}^{n_i}, i = 1, 2$ , and  $V_i = \mathcal{P}(U_i), i = 1, 2$ , the space of probability measures with the topology of weak convergence.

Let  $\bar{b}_k : \mathbb{R}^d \times U_k \rightarrow \mathbb{R}^d$  and  $\sigma : \mathbb{R}^d \rightarrow \mathbb{R}^{d \times d}, k = 1, 2$ . Define  $b_k : \mathbb{R}^d \times V_k \rightarrow \mathbb{R}^d, k = 1, 2$ , as follows:

$$b_k(x, v_k) = \int_{U_k} \bar{b}_k(x, u) v_k(du), \quad x \in \mathbb{R}^d, v_k \in V_k.$$

We assume that the following applies.

(A1) (i) The functions  $\sigma, \bar{b}_k, k = 1, 2$ , are bounded, continuous, and Lipschitz continuous in the first uniformly with respect to the second variable; i.e., there exists a constant  $C > 0$  such that

$$\|\bar{b}_k(x, u) - \bar{b}_k(y, u)\| + \|\sigma(x, u) - \sigma(y, u)\| \leq C \|x - y\|$$

for all  $x, y \in \mathbb{R}^d$  and  $u \in U_k, k = 1, 2$ .

(ii) The function  $a := \sigma\sigma'$  is uniformly elliptic; i.e., there exists  $\delta > 0$  such that

$$za(x)z' \geq \delta \|z\|^2 \text{ for all } z, x \in \mathbb{R}^d.$$

Consider the controlled diffusion process  $X(\cdot)$  on  $\mathbb{R}^d$  given by SDE

$$(2.1) \quad \left. \begin{aligned} dX(t) &= [b_1(X(t), v_1(t)) + b_2(X(t), v_2(t))] dt + \sigma(X(t)) dW(t), \\ X(0) &= x \in \mathbb{R}^d, \end{aligned} \right\}$$

where  $W(\cdot)$  is a standard  $d$ -dimensional Wiener process defined on a complete probability space  $(\Omega, \mathcal{F}, P)$ .

A  $V_i$ -valued process  $v_i(\cdot)$  is said to be an admissible strategy for player  $i$  if  $v_i(t) = f_i(t, X(\cdot))$ , for some  $f_i : [0, \infty) \times C([0, \infty); \mathbb{R}^d) \rightarrow V_i$ , is a measurable map and, for each  $t$ ,  $f_i(t, X(\cdot))$  is measurable with respect to  $\sigma(X(s) | s \leq t)$ . The set of all admissible strategies of player  $i$  is denoted by  $A_i$ . By following [6], we have the following interpretation of the admissible strategies of the players. Note that an admissible strategy player  $i$  is a nonanticipative functional of the process  $X(\cdot)$  taking values in the set  $V_i$ . The idea behind this is that whatever extraneous randomization the players might want to incorporate into their controls is already subsumed in the fact that they are choosing  $V_i$ -valued processes rather than  $U_i$ -valued ones. One consequence of this is that the conditional law of  $X(\cdot)$  given  $X(0) = x$  is a.s. the law of a process  $X(x, \cdot)$  controlled by strategies  $f_i(\cdot, X(x, \cdot))$ , with  $X(x, 0) = x$ . Thus we may prescribe the strategies  $(v_1(\cdot), v_2(\cdot))$  for arbitrary initial data by prescribing the  $f_i$ 's. Therefore player 1 chooses the function  $f_1$ , whereas player 2 chooses  $f_2$ . Also note that these choices are made independently of each other. Hence the strict noncooperative nature of the game is maintained at all times.

Suppose that  $(v_1, v_2) \in A_1 \times A_2$  is such that there exist measurable maps  $\bar{v}_i : [0, \infty) \times \mathbb{R}^d \rightarrow V_i, i = 1, 2$ , satisfying  $v_i(t) = \bar{v}_i(t, X(t))$ , where  $X(\cdot)$  solves (2.1) corresponding to the above admissible strategies. Then  $v_i$  is said to be a Markov strategy for player  $i$ . By an abuse of notation we refer to the map  $\bar{v}_i$  itself as a Markov strategy. A Markov strategy  $\bar{v}_i$  is said to be stationary if the map  $\bar{v}_i$  doesn't have any explicit dependence on  $t$ . The set of all stationary Markov strategies for player  $i$  is denoted by  $M_i$ .

Let  $R(U_k \times [0, \infty))$ ,  $k = 1, 2$ , denote the set of all  $V_k$ -valued processes which is nonanticipative w.r.t. an  $\mathbb{R}^d$ -valued Wiener process. The space of strategies  $R(U_k \times [0, \infty))$  is endowed with the weak topology given in [19, pp. 265–267]; i.e.,  $v_k^n$  converges to  $v_k$  in  $R(U_k \times [0, \infty))$  if

$$\int_0^\infty \int_{U_k} \phi(t, u) v_k^n(t)(du) dt \rightarrow \int_0^\infty \int_{U_k} \phi(t, u) v_k(t)(du) dt$$

for all  $\phi \in C_0^\infty((0, \infty) \times U_k)$ . The set  $A_k \subseteq R(U_k \times [0, \infty))$  is endowed with the above weak topology induced on it.

Let  $\bar{r}_{ki} : \mathbb{R}^d \times U_k \rightarrow \mathbb{R}$ ,  $k, i = 1, 2$ , be the payoff functions satisfying the following assumption.

(A2) For each  $k, i$ ,  $\bar{r}_{ki}$  is bounded and continuous, and there exists a constant  $C > 0$  such that

$$|\bar{r}_{ki}(x, u_i) - \bar{r}_{ki}(y, u_i)| \leq C \|x - y\| \text{ for all } x, y \in \mathbb{R}^d, u_i \in U_i.$$

We consider only two-person nonzero sum stochastic differential games for notational simplicity; a general  $N$ -person game follows by mimicking the arguments of two-person games. The description of the two-person nonzero sum game is as follows.

If the state of the system, which is evolving according to the controlled diffusion process given by (2.1), is at  $x \in \mathbb{R}^d$  and the player  $i$  chooses his action  $u_i \in U_i$ , then the player  $i$  receives a payoff  $\bar{r}_{1i}(x, u_1) + \bar{r}_{2i}(x, u_2)$ . We use the relaxed setup, and the randomized payoff is given by

$$r_{ki}(x, v) = \int_{U_k} \bar{r}_{ki}(x, u) v(du) \text{ for } x \in \mathbb{R}^d, v \in V_k;$$

i.e., in the relaxed setup, when the state of the system is at  $x$  and the player  $i$  chooses his mixed action  $v_i \in V_i$ , player  $i$  receives a payoff  $r_{1i}(x, v_1) + r_{2i}(x, v_2)$ .

At time  $t$ , both players have the common knowledge of the state process  $\{X(s) | s \leq t\}$ . With this information players choose their action at  $t$  independent of each other. Each player wants to choose a strategy so that his “cumulative” payoff is maximized. The planning horizon is infinite, and for payoff evaluation criterion we use the discounted payoff given below.

**Discounted payoff criterion.** Let  $\alpha > 0$  be the discount factor. For  $(v_1, v_2) \in A_1 \times A_2$ , the  $\alpha$ -discounted payoff to player  $i$ , for the initial condition  $x \in \mathbb{R}^d$  is given by

$$R_\alpha^i[v_1, v_2](x) = E \left[ \int_0^\infty e^{-\alpha t} [r_{1i}(X(t), v_1(t)) + r_{2i}(X(t), v_2(t))] dt \mid X(0) = x \right],$$

$i = 1, 2$ .

A pair of strategies  $(v_1^*, v_2^*) \in A_1 \times A_2$  is said to be a Nash equilibrium for the initial condition  $x \in \mathbb{R}^d$  if

$$R_\alpha^1[v_1^*, v_2^*](x) \geq R_\alpha^1[v_1, v_2^*](x) \text{ for all } v_1 \in A_1$$

and

$$R_\alpha^2[v_1^*, v_2^*](x) \geq R_\alpha^2[v_1^*, v_2](x) \text{ for all } v_2 \in A_2.$$

**3. Approximating Markov chain.** In this section we derive an approximating Markov chain for the controlled diffusion process (2.1). See [16], [26] for similar approximations. We make the following assumption.

(A3) (i)

$$a_{ii}(x) - \sum_{j:j \neq i} |a_{ij}(x)| \geq 0 \text{ for all } i = 1, 2, \dots, d, x \in \mathbb{R}^d.$$

(ii) There exists  $\delta_0 > 0$  such that

$$\sum_{i=1}^d a_{ii}(x) - \frac{1}{2} \sum_{i \neq j} |a_{ij}(x)| \geq \delta_0 \text{ for all } x \in \mathbb{R}^d.$$

For  $h > 0$ , define the grid

$$\mathbb{R}_h^d = \left\{ x \in \mathbb{R}^d \mid x = \sum_{i=1}^d n_i h e_i, n_i \in \mathbb{Z}, \text{ for all } i \right\},$$

where  $\{e_1, e_2, \dots, e_d\}$  is the usual basis of  $\mathbb{R}^d$ .

For  $x \in \mathbb{R}_h^d$ ,  $v_1 \in V_1$ , and  $v_2 \in V_2$ , set

$$Q^h(x, v_1, v_2) = h \sum_{i=1}^d (|b_{1i}(x, v_1)| + |b_{2i}(x, v_2)|) + \sum_{i=1}^d a_{ii}(x) - \frac{1}{2} \sum_{i \neq j} |a_{ij}(x)|$$

and

$$\bar{Q}^h = \sup_{x \in \mathbb{R}_h^d, (v_1, v_2) \in V_1 \times V_2} Q^h(x, v_1, v_2).$$

Now define transition law  $p^h$  as follows, for  $x \in \mathbb{R}_h^d$ ,  $v_k \in V_k$ :

$$(3.1) \quad \left. \begin{aligned} p^h(x, x, v_1, v_2) &= \frac{1}{\bar{Q}^h} [\bar{Q}^h - Q^h(x, v_1, v_2)], \\ p^h(x, x \pm h e_i, v_1, v_2) &= \frac{1}{\bar{Q}^h} \left[ h (b_{1i}^+(x, v_1) + b_{2i}^+(x, v_2)) \right. \\ &\quad \left. + \frac{1}{2} a_{ii}(x) - \frac{1}{2} \sum_{j:j \neq i} |a_{ij}(x)| \right], \\ p^h(x, x \pm h e_i \pm h e_j, v_1, v_2) &= \frac{1}{4 \bar{Q}^h} a_{ij}^+(x), \\ p^h(x, x \pm h e_i \mp h e_j, v_1, v_2) &= \frac{1}{4 \bar{Q}^h} a_{ij}^-(x), \\ p^h(x, y, v_1, v_2) &= 0 \text{ otherwise,} \end{aligned} \right\}$$

where  $f^+ := \max\{f, 0\}$ ,  $f^- := -\min\{f, 0\}$ .

For a pair of strategies  $(v_1^h, v_2^h)$ , i.e.,  $v_i^h = \{v_{in}^h | n \geq 1\}$ ,  $v_{in}^h : \mathbb{R}_h^d \rightarrow V_i$ , the corresponding controlled chain  $\{X_n^h\}$  is defined such that

$$P\{X_{n+1}^h = y | X_m^h, v_{1m}^h, v_{2m}^h, m \leq n\} = p^h(X_n^h, y, v_{1n}^h(X_n^h), v_{2n}^h(X_n^h)).$$

By a straightforward calculation we can show that, for  $x \in \mathbb{R}_h^d$ ,  $v_1 \in V_1$ ,  $v_2 \in V_2$ ,

$$(3.2) \quad \left. \begin{aligned} E \left[ \Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n-1, X_n^h = x, v_{1n}^h = v_1, v_{2n}^h = v_2 \right] \\ = [b_1(x, v_1) + b_2(x, v_2)] \Delta t^h, \\ E \left( \left[ \Delta X_n^h - E \left[ \Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n-1, X_n^h = x, v_{1n}^h = v_1, v_{2n}^h = v_2 \right] \right] \right. \\ \left. \left[ \Delta X_n^h - E \left[ \Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n-1, X_n^h = x, v_{1n}^h = v_1, v_{2n}^h = v_2 \right] \right]' \right. \\ \left. \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n-1, X_n^h = x, v_{1n}^h = v_1, v_{2n}^h = v_2 \right) \\ = a(x) \Delta t^h, \end{aligned} \right\}$$

where

$$\Delta X_n^h = X_{n+1}^h - X_n^h, \quad \Delta t^h = \frac{h^2}{\bar{Q}^h}.$$

Equation (3.2) is called the local consistency conditions; see [19, p. 71] for more details.

Let  $A_i^h$  and  $M_i^h$  denote, respectively, the set of all admissible and the set of all stationary Markov strategies for player  $i$ ,  $i = 1, 2$ . See [7, p. 48] for a description of admissible strategies and stationary Markov strategies. Let  $\{X_n^h | n \geq 0\}$  be the controlled chain corresponding to  $(v_1^h, v_2^h) \in A_1^h \times A_2^h$  and initial condition  $x_0^h \in \mathbb{R}_h^d$ .

Now we define the corresponding interpolated continuous time process as follows:

$$X^h(t) = x_0^h + \sum_{n: t_{n+1}^h \leq t} \Delta X_n^h,$$

where  $t_n^h = n \Delta t^h$ ,  $n = 0, 1, \dots$

For  $v_i = \{v_{in} | n \geq 0\} \in A_i^h$ , the interpolated continuous time strategy for player  $i$  is given by

$$v_i(t) = v_{in} \text{ if } t \in [t_n^h, t_{n+1}^h).$$

We use  $A_i^h$  also to denote the set of all interpolated continuous time admissible strategies. Similarly the set of all interpolated continuous time stationary Markov strategies denoted by  $M_i^h$ ,  $i = 1, 2$ , is defined.

We make use of the following representation for the chain  $\{X_n^h | n \geq 0\}$  corresponding to  $(v_1^h, v_2^h) \in A_1^h \times A_2^h$ :

$$\begin{aligned} X_{n+1}^h &= X_n^h + E\left[\Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n\right] \\ &\quad + \Delta X_n^h - E\left[\Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n\right]. \end{aligned}$$

By using the local consistency conditions (3.2), we have

$$X_{n+1}^h = X_n^h + (b_1(X_n^h, v_{1n}^h) + b_2(X_n^h, v_{2n}^h))\Delta t^h + \beta_n^h,$$

where

$$\beta_n^h = \Delta X_n^h - E\left[\Delta X_n^h \mid X_m^h, v_{1m}^h, v_{2m}^h, m \leq n\right].$$

Therefore

$$X^h(t) = x_0^h + \sum_{n:t_{n+1}^h \leq t} (b_1(X_n^h, v_{1n}^h) + b_2(X_n^h, v_{2n}^h)) \Delta t^h + \sum_{n:t_{n+1}^h \leq t} \beta_n^h.$$

Since  $b_i$  is bounded, we can show that

$$\sum_{n:t_{n+1}^h \leq t} (b_1(X_n^h, v_{1n}^h) + b_2(X_n^h, v_{2n}^h)) \Delta t^h = F^h(t) + o(\Delta t^h),$$

where

$$F^h(t) = \int_0^t (b_1(X^h(s), v_1(s)) + b_2(X^h(s), v_2(s))) ds.$$

Define

$$W^h(t) = \sum_{n:t_{n+1}^h \leq t} \Delta W_n^h, \text{ where } \Delta W_n^h = (\sigma(X_n^h))^{-1} \beta_n^h,$$

We can see that  $W^h(\cdot)$  is a martingale with respect to  $\mathcal{F}_n^h = \sigma(X_m^h, v_{1m}^h, v_{2m}^h, m \leq n)$  and

$$\begin{aligned} E[\Delta W_n^h | X_m^h, v_{1m}^h, v_{2m}^h, m \leq n] &= 0, \\ E[(\Delta W_n^h)' \Delta W_n^h] | X_m^h, v_{1m}^h, v_{2m}^h, m \leq n &= \Delta t^h I_{d \times d}, \\ E[(\Delta W_n^h)' \Delta W_m^h] &= 0 \text{ for all } n \neq m, \end{aligned}$$

where  $I_{d \times d}$  is the  $d \times d$  identity matrix. Consider

$$\begin{aligned} \sum_{n: t_{n+1}^h \leq t} \beta_n^h &= \sum_{n: t_{n+1}^h \leq t} \sigma(X_n^h) \Delta W_n^h \\ &= \int_0^t \sigma(X^h(s)) dW^h(s) := B^h(t). \end{aligned}$$

Thus  $X^h(\cdot)$  takes the form

$$(3.3) \quad X^h(t) = x_0^h + B^h(t) + F^h(t).$$

Now we are ready to prove the following theorem.

**THEOREM 3.1.** *Assume (A1) and (A3). Let  $x_0^h \in \mathbb{R}_h^d$  converge to  $x \in \mathbb{R}^d$ ,  $(v_1^h, v_2^h) \in M_h^1 \times M_h^2$ , and  $X^h(\cdot)$  be the process (3.3) corresponding to  $(v_1^h, v_2^h)$  with initial condition  $x_0^h$ . Then the process  $\Phi^h(\cdot) := (X^h(\cdot), B^h(\cdot), F^h(\cdot), W^h(\cdot), v_1^h, v_2^h)$  is tight. Moreover, there exists a process  $\Phi(\cdot) = (X(\cdot), B(\cdot), F(\cdot), W(\cdot), v_1, v_2)$  in  $D^{4d}[0, \infty) \times R(U_1 \times [0, \infty)) \times R(U_2 \times [0, \infty))$  such that the process  $\Phi(\cdot)$  has continuous paths a.s. and  $\Phi^h(\cdot)$  converges weakly along a subsequence to  $\Phi(\cdot)$ .*

*Proof.* Let  $\delta > 0$ . It is easy to see that

$$(3.4) \quad E \left[ \sup_{s \leq t \leq s+\delta} |F^h(t) - F^h(s)| \right] \leq K \delta,$$

where  $K$  is a common bound for  $b_k, r_{ki}, a, i, k = 1, 2$ . Now

$$\begin{aligned} (3.5) \quad E \left[ \sup_{s \leq t \leq s+\delta} |B^h(t) - B^h(s)|^2 \right] &\leq 4E |B^h(s+\delta) - B^h(s)|^2 \\ &= 4E \int_s^{s+\delta} \text{trace}\{a(X^h(s))\} ds \leq 4K\delta, \end{aligned}$$

where  $\bar{v}_i^h(s) = v_i^h(X^h(s))$ ,  $i = 1, 2$ , and

$$\begin{aligned} (3.6) \quad E \left[ \sup_{s \leq t \leq s+\delta} |W^h(t) - W^h(s)|^2 \right] &\leq 4E |W^h(s+\delta) - W^h(s)|^2 \\ &= \sum_{n: s \leq t_n^h < t_{n+1}^h \leq s+\delta} \Delta t^h \leq \delta. \end{aligned}$$

Also, since  $v_i^h, i = 1, 2$ , is taking values in a compact set, the tightness of  $v_i^h$  follows. In view of (3.4), (3.5), and (3.6), from [3, Theorems 15.5 and 8.3] or [14, pp. 31–33], the tightness of  $\Phi^h(\cdot)$  in  $D^{4d}([0, \infty) \times R(U_1 \times [0, \infty)) \times R(U_2 \times [0, \infty))$  follows. The proof of the existence of the process  $\Phi(\cdot)$  follows from standard arguments.  $\square$

**THEOREM 3.2.** *Assume the hypothesis of Theorem 3.1, that the process  $W(\cdot)$  in Theorem 3.1 is a standard Wiener process. Also  $(v_1, v_2) \in A_1 \times A_2$  and*

$$\begin{aligned} B(t) &= \int_0^t \sigma(X(s), v_1(s), v_2(s)) dW(s), \\ F(t) &= \int_0^t (b_1(X(s), v_1(s)) + b_2(X(s), v_2(s))) ds. \end{aligned}$$

*Proof.* By using Skorohod's theorem, there exists a  $P$ -null set  $\mathcal{N}$  such that  $X^h(s, \omega) \rightarrow X(s, \omega)$  and  $W^h(s, \omega) \rightarrow W(s, \omega)$  for all  $s \geq 0$  and  $\omega \in \Omega/\mathcal{N}$ . Then, by following the arguments in the proof of [5, Lemmas 1.2 and 1.3, pp. 24–26], we can show that along the same sequence

$$(3.7) \quad \lim_{h \rightarrow 0} \int_0^t \int_{U_i} f(s, u_i, \omega) \bar{v}_i^h(s, \omega) (du_i) ds = \int_0^t \int_{U_i} f(s, u_i, \omega) v_i(s, \omega) (du_i) ds$$

for all  $f \in C([0, T] \times U_i)$ ,  $T > 0$ ,  $0 \leq t \leq T$ ,  $\omega \in \Omega/\mathcal{N}$ .

Set

$$\bar{F}(t) = \int_0^t [b_1(X(s), v_1(s)) + b_2(X(s), v_2(s))] ds.$$

Now for  $\omega \in \Omega/\mathcal{N}$

$$(3.8) \quad \left. \begin{aligned} & |F^h(t, \omega) - \bar{F}(t, \omega)| \\ & \leq \left| \int_0^t (b_1(X^h(s, \omega), \bar{v}_1^h(s, \omega)) + b_2(X^h(s, \omega), \bar{v}_2^h(s, \omega))) ds \right. \\ & \quad \left. - \int_0^t (b_1(X(s, \omega), \bar{v}_1^h(s, \omega)) + b_2(X(s, \omega), \bar{v}_2^h(s, \omega))) ds \right| \\ & \quad + \left| \int_0^t (b_1(X(s, \omega), \bar{v}_1^h(s, \omega)) + b_2(X(s, \omega), \bar{v}_2^h(s, \omega))) ds \right. \\ & \quad \left. - \int_0^t (b_1(X(s, \omega), v_1(s, \omega)) + b_2(X(s, \omega), v_2(s, \omega))) ds \right|. \end{aligned} \right\}$$

It follows from the Lipschitz continuity of  $b_i$ ,  $i = 1, 2$ , that the first term on the right-hand side of (3.8) converges to zero. The second term on the right-hand side of (3.8) converges to zero by using (3.7). We have, by using Skorohod's theorem and Theorem 3.1, that along the same sequence and same  $\mathcal{N}$  (without the loss of generality)

$$F^h(t, \omega) \rightarrow F(t, \omega), \quad \omega \in \Omega/\mathcal{N}, \quad t > 0.$$

Now by the uniqueness of the limit we have  $\bar{F}(t) = F(t)$ ,  $t > 0$  a.s.

Next we show that  $W(\cdot)$  is a standard Wiener process with respect to  $\mathcal{F}_t = \sigma(X(s), v_1(s), v_2(s) | s \leq t)$ . We have

$$\begin{aligned} E[W^h(t)' W^h(t)] &= E \left( \sum_{n: t_{n+1}^h \leq t} \Delta W_n^h \right)' \left( \sum_{n: t_{n+1}^h \leq t} \Delta W_n^h \right) \\ &= E \left[ \sum_{n, m: t_{n+1}^h, t_{m+1}^h \leq t} \Delta W_{n+1}^h' \Delta W_{m+1}^h \right] \\ &= \left[ \sum_{n: t_{n+1}^h \leq t} \Delta t^h \right] I_{d \times d} = t I_{d \times d} + o(\Delta t^h). \end{aligned}$$

By using similar arguments, we can show that  $E|W^h(t)|^4$  is uniformly bounded in  $h$ . Hence we can see that  $W^h(t)'W^h(t)$  is uniformly integrable. Now, by using the fact that  $W^h(\cdot)$  converges weakly to  $W(\cdot)$ , we have

$$E[W(t)'W(t)] = t I_{d \times d}.$$

Now, by using the arguments in [14, pp. 99–100], we can show that  $W(\cdot)$  is a martingale with respect to  $\mathcal{F}_t$ . Hence, it follows that  $W(\cdot)$  is a standard Wiener process. Consider for  $i = 1, 2$

$$\begin{aligned} & E \left| \int_0^t \sigma(X^h(s)) dW^h(s) - \int_0^t \sigma(X(s)) dW(s) \right|^2 \\ & \leq 8 \left\{ E \left| \int_0^t [\sigma(X^h(s)) - \sigma_\delta(X^h(s))] dW^h(s) \right|^2 \right. \\ & \quad + E \left| \int_0^t \sigma_\delta(X^h(s)) dW^h(s) - \int_0^t \sigma_\delta(X^h(s)) dW(s) \right|^2 \\ & \quad + E \left| \int_0^t [\sigma_\delta(X^h(s)) - \sigma_\delta(X(s))] dW(s) \right|^2 \\ & \quad \left. + E \left| \int_0^t [\sigma_\delta(X(s)) - \sigma(X(s))] dW(s) \right|^2 \right\} \\ & = 8 \left\{ E \sum_{k=0}^{\frac{t}{\delta}} \int_{k\delta}^{(k+1)\delta} \text{trace} [(\sigma(X^h(s)) - \sigma(X^h(k\delta))) \right. \\ & \quad \left. (\sigma(X^h(s)) - \sigma(X^h(k\delta)))'] ds \right. \\ & \quad + E \left| \int_0^t \sigma_\delta(X^h(s)) dW^h(s) - \int_0^t \sigma_\delta(X^h(s)) dW(s) \right|^2 \\ & \quad + E \int_0^t \text{trace} [(\sigma_\delta(X^h(s)) - \sigma_\delta(X(s))) \\ & \quad \left. (\sigma_\delta(X^h(s)) - \sigma_\delta(X(s)))'] ds, \right. \\ & \quad \left. + E \int_0^t \text{trace} [(\sigma_\delta(X(s)) - \sigma(X(s))) \right. \\ & \quad \left. (\sigma_\delta(X(s)) - \sigma(X(s)))'] ds \right\}, \end{aligned}$$

where  $\delta > 0$  is chosen such that  $\frac{t}{\delta}$  is an integer and

$$\int_0^t \sigma_\delta(X^h(s)) dW^h(s) := \sum_{k=0}^{\frac{t}{\delta}} \sigma(X^h(k\delta)) [W^h((k+1)\delta) - W^h(k\delta)].$$

By letting  $h \rightarrow 0$  and then  $\delta \rightarrow 0$  we can see that the right-hand side above converges to zero. Hence along a suitable subsequence (denoted by the same sequence without the loss of generality)

$$\int_0^t \sigma(X^h(s)) dW^h(s) \text{ converges a.s. to } \int_0^t \sigma(X(s)) dW(s) \text{ for all } t.$$

Hence by using the uniqueness of the limit we have

$$B(t) = \int_0^t \sigma(X(s)) dW(s).$$

Note that for any  $f_i \in C_b(\mathbb{R}^d \times V_i)$ ,  $i = 1, 2$ ,  $\int_0^t [f_1(X(s), v_1(s)) + f_2(X(s), v_2(s))] ds$  is nonanticipative with respect to  $\mathcal{F}_t$ . In view of this and by using Theorem 2.2(a) of [5, p. 18], we can assume without any loss of generality that  $(v_1, v_2) \in A_1 \times A_2$ . This completes the proof.  $\square$

**4. Discounted payoff criterion.** In this section we prove the existence of a Nash equilibrium for the stochastic differential game problem with the  $\alpha$ -discounted payoff criterion described in section 2. The main idea is to approximate the nonzero sum stochastic differential game problem by an appropriate nonzero sum stochastic game.

Consider the nonzero sum stochastic game with state space  $\mathbb{R}_h^d$  and  $p^h$  given by (3.1) describing the law of motion. The  $\alpha$ -discounted payoff to player  $i$  for the admissible pair of strategies  $(v_1^h, v_2^h) \in A_1^h \times A_2^h$  for the initial state  $x \in \mathbb{R}_h^d$  is given by (4.1)

$$R_\alpha^{ih}[v_1^h, v_2^h](x) = \Delta t^h E \left[ \sum_{n=0}^{\infty} \left( e^{-\alpha \Delta t^h} \right)^n [r_{1i}(X_n^h, v_{1n}^h) + r_{2i}(X_n^h, v_{2n}^h)] \middle| X_0^h = x \right].$$

The existence of a Nash equilibrium in the class of stationary Markov strategies follows from [9, Theorem 1]. Let  $(v_1^{*h}, v_2^{*h}) \in M_1^h \times M_2^h$  denote a pair of Nash equilibrium for the above approximated stochastic game.

**THEOREM 4.1.** *Assume (A1)–(A3). There exists an  $\alpha$ -discounted Nash equilibrium.*

*Proof.* Fix  $x \in \mathbb{R}^d$ . Let  $x_h \in \mathbb{R}_h^d$  be such that  $x_h \rightarrow x$ . Also let  $\Phi^{*h}(\cdot) = (X^{*h}(\cdot), B^{*h}(\cdot), F^{*h}(\cdot), v_1^{*h}, v_2^{*h})$  be the process given by (3.3), with  $(v_1^{*h}, v_2^{*h}) \in M_1^h \times M_2^h$  given above and for the initial condition  $x_h$ . Then by Theorem 3.2 there exist  $\Phi^*(\cdot) = (X^*(\cdot), B^*(\cdot), F^*(\cdot), v_1^*, v_2^*)$  and a Wiener process  $W(\cdot)$  such that  $X^*(\cdot)$  is the solution of (2.1) for some pair of admissible strategies  $(v_1^*, v_2^*) \in A_1 \times A_2$  and initial condition  $x$ . Also,  $\Phi^{*h}(\cdot)$  converges to  $\Phi^*(\cdot)$  weakly in  $D^{3d+n_1+n_2}[0, \infty)$ . Note that

$$\begin{aligned} & R_\alpha^{1h}[v_1^h, v_2^h](x) \\ &= E \left[ \int_0^\infty e^{-\alpha t} [r_{1i}(X^h(s), v_1^h(s)) + r_{2i}(X^h(s), v_2^h(s))] ds \middle| X^h(0) = x \right] + o(\Delta t^h). \end{aligned}$$

In view of the above, by closely mimicking the arguments of Theorem 3.2, we can show that

$$(4.2) \quad \lim_{h \rightarrow 0} R_\alpha^{1h}[v_1^{*h}, v_2^{*h}](x_h) = R_\alpha^1[v_1^*, v_2^*](x).$$

By using Theorem 2.2(b) of [5, p. 18], for each  $(\bar{v}_1, \bar{v}_2) \in A_1 \times A_2$  and the corresponding solution  $\bar{X}(\cdot)$  of (2.1) with initial condition  $x$ , there exists a process  $X(\cdot)$ , on a possibly augmented probability space, satisfying (2.1) with initial condition  $x$  corresponding to  $(v_1, v_2) \in A_1 \times A_2$  for the prescribed Wiener process  $W(\cdot)$  constructed in the previous theorem. Also  $(\bar{v}_1, \bar{v}_2)$ ,  $(v_1, v_2)$  have the same functional form, and

$$R_\alpha^i[\bar{v}_1, \bar{v}_2](x) = R_\alpha^i[v_1, v_2](x), \quad x \in \mathbb{R}^d, \quad i = 1, 2.$$

Hence we can assume without the loss of generality that  $(v_1, v_2) \in A_1 \times A_2$  is in a common probability space and, in particular,  $(v_1, v_2^*)$  is in a common probability space for all  $v_1 \in A_1$ .

For  $\varepsilon > 0$ , by using Theorem 1.2 of [19, p. 278], there exists a  $\delta > 0$  and  $v_1^\varepsilon \in A_1$  such that  $v_1^\varepsilon$  is constant on intervals  $[n\delta, n\delta + \delta)$ ,  $n = 0, 1, 2, \dots$ , and satisfies

$$(4.3) \quad |R_\alpha^1[v_1^\varepsilon, v_2^*](x) - R_\alpha^1[v_1, v_2^*](x)| < \varepsilon.$$

Now for  $h$  sufficiently small, i.e., for all  $h$  such that  $\Delta t^h < \delta$ , we have  $v_1^\varepsilon \in A_1^h$ . Let  $X^{*\varepsilon h}(\cdot)$  denote the process (3.3) corresponding to  $(v_1^\varepsilon, v_2^{*h})$  for the initial condition  $x_h$  and  $X^{*\varepsilon}(\cdot)$  denote the process (2.1) for the initial condition  $x$  and the pair of admissible strategies  $(v_1^\varepsilon, v_2^*)$ .

Then  $X^{*\varepsilon h}(\cdot)$  converges weakly to  $X^{*\varepsilon}(\cdot)$ . Now, by mimicking the arguments in the proof of Theorem 3.2, we have

$$(4.4) \quad \lim_{h \rightarrow 0} R_\alpha^{1h}[v_1^\varepsilon, v_2^{*h}](x_h) = R_\alpha^1[v_1^\varepsilon, v_2^*](x).$$

Since  $(v_1^{*h}, v_2^{*h})$  is a Nash equilibrium for the stochastic game described above, we have

$$R_\alpha^{1h}[v_1^{*h}, v_2^{*h}](x_h) \geq R_\alpha^{1h}[v_1^{\varepsilon h}, v_2^{*h}](x_h).$$

Let  $h \rightarrow 0$ , and by using (4.2) and (4.4) we have

$$R_\alpha^1[v_1^*, v_2^*](x) \geq R_\alpha^1[v_1^\varepsilon, v_2^*](x).$$

Now, by using (4.3), we get

$$R_\alpha^1[v_1^*, v_2^*](x) \geq R_\alpha^1[v_1, v_2^*](x) - \varepsilon.$$

Since  $\varepsilon > 0$  is arbitrary, we have

$$R_\alpha^1[v_1^*, v_2^*](x) \geq R_\alpha^1[v_1, v_2^*](x).$$

In a similar fashion, we can show that

$$R_\alpha^2[v_1^*, v_2^*](x) \geq R_\alpha^2[v_1^*, v_2](x) \text{ for } v_2 \in A_2.$$

Hence  $(v_1^*, v_2^*)$  is a Nash equilibrium.  $\square$

*Remark 4.2.* We can in fact obtain a Nash equilibrium in the class of stationary Markov strategies. This could be seen as follows: Recall that  $(v_1^{*h}, v_2^{*h}) \subseteq M_1 \times M_2$  and converges to  $(v_1^*, v_2^*)$  according to the convergence criterion in (3.7). Note that  $M_i$ ,  $i = 1, 2$ , is compact in the metric topology defined in [5, p. 30]. Hence there exists  $\tilde{v}_i \in M_i$  such that  $v_i^{*h} \rightarrow \tilde{v}_i$  in  $M_i$ ,  $i = 1, 2$ , along a suitable subsequence. Now, by using [15, Theorem 3.1, p. 151],  $X^h(\cdot)$  converges weakly to  $\tilde{X}(\cdot)$ , where  $\tilde{X}(\cdot)$  is a solution to (2.1) corresponding to  $(\tilde{v}_1, \tilde{v}_2)$ . Since  $X^h(\cdot)$  converges weakly to  $X^*(\cdot)$ , the existence of a Nash equilibrium which is Markov thus follows.

**5. Construction of Nash equilibrium.** In this section, we describe a numerical procedure to construct a Nash equilibrium for the nonzero sum stochastic differential game described in section 2. By using the separable form of the drift coefficient in (2.1), we can write the transition probabilities given in (3.1) in the form

$$(5.1) \quad p^h(x, y, v_1, v_2) = p_1^h(x, y, v_1) + p_2^h(x, y, v_2) \text{ for all } x, y \in \mathbb{R}_h^d, v_i \in V_i,$$

where  $p_1^h, p_2^h$  are continuous functions whose explicit form can be written down in terms of the drift and diffusion coefficients of the SDE (2.1). We omit the details, since we don't require the explicit form for our purpose. Consider the approximate nonzero sum stochastic game described in section 4. We avoid the term  $\Delta t^h$  from the payoff criterion (4.1) of the stochastic game, since it won't affect the analysis once  $h$  is fixed. Now, throughout this section, we fix  $h$ . We use the following lemma, and the proof follows from [4, Theorem 6].

LEMMA 5.1. *A pair of stationary Markov strategies  $(v_1^*, v_2^*) \in M_1^h \times M_2^h$  is a Nash equilibrium iff  $(v_1^*, v_2^*)$  satisfies the optimality equation*

$$(5.2) \quad \left. \begin{aligned} R_\alpha^{1h}[v_1^*, v_2^*](x) &= \sup_{v_1 \in V_1} \left[ r_{11}(x, v_1) + r_{21}(x, v_2^*(x)) \right. \\ &\quad \left. + \beta \sum_{y \in \mathbb{R}_h^d} p^h(x, y, v_1, v_2^*(x)) R_\alpha^{1h}[v_1^*, v_2^*](y) \right], \\ R_\alpha^{2h}[v_1^*, v_2^*](x) &= \sup_{v_2 \in V_2} \left[ r_{12}(x, v_1^*(x)) + r_{22}(x, v_2) \right. \\ &\quad \left. + \beta \sum_{y \in \mathbb{R}_h^d} p^h(x, y, v_1^*(x), v_2) R_\alpha^{2h}[v_1^*, v_2^*](y) \right], \end{aligned} \right\}$$

where  $\beta = e^{-\alpha \Delta t^h}$ .

By using (5.1), the optimality equation becomes

$$(5.3) \quad \left. \begin{aligned} R_\alpha^{1h}[v_1^*, v_2^*](x) &= \sup_{v_1 \in V_1} \left[ r_{11}(x, v_1) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1) R_\alpha^{1h}[v_1^*, v_2^*](y) \right] \\ &\quad + r_{21}(x, v_2^*(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, v_2^*(x)) R_\alpha^{1h}[v_1^*, v_2^*](y), \\ R_\alpha^{2h}[v_1^*, v_2^*](x) &= \sup_{v_2 \in V_2} \left[ r_{22}(x, v_2) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, v_2) R_\alpha^{2h}[v_1^*, v_2^*](y) \right] \\ &\quad + r_{12}(x, v_1^*(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1^*(x)) R_\alpha^{2h}[v_1^*, v_2^*](y). \end{aligned} \right\}$$

Let  $l^\infty(\mathbb{R}_h^d; \mathbb{R}) = \{\phi : \mathbb{R}_h^d \rightarrow \mathbb{R} \mid \phi \text{ is bounded}\}$  with sup norm. Now define  $\pi_k^* : l^\infty(\mathbb{R}_h^d; \mathbb{R}) \rightarrow M_k^h, k = 1, 2$  as follows: For  $\phi \in l^\infty(\mathbb{R}_h^d; \mathbb{R})$ ,  $\pi_k^*(\phi) \in M_k^h$  is such that, for all  $x \in \mathbb{R}_h^d$ ,

$$\begin{aligned} & r_{kk}(x, \pi_k^*(\phi)(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, \pi_k^*(\phi)(x)) \phi(y) \\ &= \sup_{v_k \in V_k} \left[ r_{kk}(x, v_k) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, v_k) \phi(y) \right]. \end{aligned}$$

Now, by using standard stochastic optimal control arguments (see, for example, [2, pp. 225–232]), we can show that if  $(\Phi_1, \Phi_2)$  satisfies the equation

$$(5.4) \quad \left. \begin{aligned} \Phi_1(x) &= r_{11}(x, \pi_1^*(\Phi_1)(x)) + r_{21}(x, \pi_2^*(\Phi_2)(x)) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\Phi_1)(x)) \Phi_1(y) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\Phi_2)(x)) \Phi_1(y), \\ \Phi_2(x) &= r_{12}(x, \pi_1^*(\Phi_1)(x)) + r_{22}(x, \pi_2^*(\Phi_2)(x)) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\Phi_1)(x)) \Phi_2(y) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\Phi_2)(x)) \Phi_2(y), \end{aligned} \right\}$$

then  $\Phi_k(x) = R_\alpha^{kh}[\pi_1^*(\Phi_1), \pi_2^*(\Phi_2)]$ . This fact with the help of Lemma 5.1 will imply that, for any solution  $(\Phi_1, \Phi_2)$  of (5.4),  $(\pi_1^*(\Phi_1), \pi_2^*(\Phi_2))$  is a Nash equilibrium. Thus constructing a Nash equilibrium reduces to the construction of the solution to (5.4). To do this we first state the following lemma whose proof follows by closely mimicking the arguments in [9, Theorem 1].

LEMMA 5.2. For each  $x \in \mathbb{R}_h^d$ ,  $k = 1, 2$ , the map  $T_x^k : \mathbb{R}^N \rightarrow 2^{V_k}$  defined by

$$T_x^k(\Phi[x]) = \operatorname{argmax}_{v_k \in V_k} \left[ r_{kk}(x, v_k) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, v_k) \Phi(y) \right],$$

where  $\Phi[x] = (\Phi(y) \mid y = x, x \bar{+} h e_i, x \bar{+} h e_i \bar{+} h e_j)$ ,  $N = \#\{y \mid y = x, x \bar{+} h e_i, x \bar{+} h e_i \bar{+} h e_j\}$ , is upper semicontinuous.

Now we give an iterative procedure to construct a Nash equilibrium. Define  $(\Phi_1^n, \Phi_2^n)$  as follows:  $\Phi_1^0 = 1$ ,  $\Phi_2^0 = 1$ , and for  $n \geq 0$

$$(5.5) \quad \left. \begin{aligned} \Phi_1^{n+1}(x) &= r_{11}(x, \pi_1^*(\Phi_1^n)(x)) + r_{21}(x, \pi_2^*(\Phi_2^n)(x)) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\Phi_1^n)(x)) \Phi_1^n(y) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\Phi_2^n)(x)) \Phi_1^n(y), \\ \Phi_2^{n+1}(x) &= r_{12}(x, \pi_1^*(\Phi_1^n)(x)) + r_{22}(x, \pi_2^*(\Phi_2^n)(x)) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\Phi_1^n)(x)) \Phi_2^n(y) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\Phi_2^n)(x)) \Phi_2^n(y). \end{aligned} \right\}$$

THEOREM 5.3. If the iterates  $(\Phi_1^n, \Phi_2^n)$  in (5.5) converge, say, to  $(\Phi_1, \Phi_2)$ , then  $\Phi_k(x) = R_\alpha^{kh}[v_1^*, v_2^*](x)$  for some Nash equilibrium  $(v_1^*, v_2^*)$ .

Proof. From the hypothesis, it follows that  $\Phi_k^n[x] \rightarrow \Phi_k[x]$ . Now since  $V_k$  is compact, along a subsequence, we have, for some  $v_k^* \in M_k^h$ ,

$$(5.6) \quad \Phi_k^n[x] \rightarrow \Phi_k[x], \quad \pi_k^*(\Phi_k^n)(x) \rightarrow v_k^*(x) \text{ for all } x \in \mathbb{R}_h^d.$$

Now, by using Lemma 5.2, we have  $v_k^*(x) \in T_x^k(\Phi_k[x])$  for all  $x \in \mathbb{R}_h^d$ ; i.e.,

$$(5.7) \quad \left. \begin{aligned} & \max_{v_k \in V_k} \left[ r_{kk}(x, v_k) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, v_k) \Phi_k(y) \right] \\ & = \left[ r_{kk}(x, v_k^*(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, v_k^*(x)) \Phi_k(y) \right]. \end{aligned} \right\}$$

Also by using the continuity of  $r_{kl}$ ,  $p_k^h$ ,  $k, l = 1, 2$ , and (5.5) we can see that

$$(5.8) \quad \left. \begin{aligned} \Phi_1(x) &= r_{11}(x, v_1^*(x)) + r_{21}(x, v_2^*(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1^*(x)) \Phi_1(y) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, v_2^*(x)) \Phi_1(y), \\ \Phi_2(x) &= r_{12}(x, v_1^*(x)) + r_{22}(x, v_2^*(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1^*(x)) \Phi_2(y) \\ &\quad + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, v_2^*(x)) \Phi_2(y). \end{aligned} \right\}$$

Now from (5.7) and (5.8) it follows that  $(\Phi_1, \Phi_2), (v_1^*, v_2^*)$  satisfies the optimality equation. Hence  $(v_1^*, v_2^*)$  is a Nash equilibrium.  $\square$

Now we give a sufficient condition for the convergence of the iterates.

(A4) (i) The functions  $\bar{p}_k^h, \bar{r}_{12}, \bar{r}_{21}$  are Lipschitz continuous in the second argument, where  $\bar{p}_k^h(x, u_k) = p_k^h(x, \delta_{u_k})$  for  $u_k \in U_k$  and  $\delta_{u_k}$  denotes the dirac delta at  $u_k$ .

(ii) For each  $x \in \mathbb{R}_h^d$ ,  $k = 1, 2$ , there exists a map  $\bar{u}_x^k : l_M^\infty(\mathbb{R}_h^d) \rightarrow U_k$  such that

$$\bar{u}_x^k(\phi) \in \operatorname{argmax}_{u_k \in U_k} \left[ r_{kk}(x, u_k) + \beta \sum_{y \in \mathbb{R}_h^d} p_k^h(x, y, u_k) \phi(y) \right],$$

which is Lipschitz continuous and the Lipschitz constant is independent of  $x$ . Here  $l_M^\infty(\mathbb{R}_h^d) = \{\phi : \mathbb{R}_h^d \rightarrow \mathbb{R} \mid 0 \leq \phi(y) \leq M\}$  and  $M$  is an upper bound for  $\{R_\alpha^i[v_1, v_2](x) \mid v_i \in A_i, x \in \mathbb{R}_h^d, i = 1, 2\}$ .

*Remark 5.4.* If  $(v_1^*, v_2^*)$  with functional form given by  $(f_1, f_2)$  is a Nash equilibrium of the stochastic differential game given by the state equation

$$dY(t) = [cb(c^{-1}Y(t), v_1(t)) + cb_2(c^{-1}Y(t), v_2(t))]dt + c\sigma(c^{-1}Y(t))dW(t)$$

and payoff criteria

$$R_\alpha^i[v_1, v_2](y) = E \left[ \int_0^\infty ce^{-\alpha t} [r_{1i}(c^{-1}Y(t), v_1(t)) + r_{2i}(c^{-1}Y(t), v_2(t))] dt \mid Y(0) = y \right],$$

$i = 1, 2$ , where  $c > 0$  is a constant, then  $(\tilde{v}_1^*, \tilde{v}_2^*), \tilde{v}_i^*(t) = f_i(t, cX(\cdot))$  is a Nash equilibrium of the original stochastic differential game. Hence by a suitable choice of the constant  $c$ , the Lipschitz coefficient of  $\bar{r}_{12}, \bar{r}_{21}$  in (A4)(i) can be chosen to be any fixed positive constant.

*Example 5.5.* Take  $U_1 = [a, b]$ ,  $U_2 = [c, d]$ . Define  $\bar{b}(x, u_k) = \tilde{b}_k(x)u_k^2$ ,  $\bar{r}_{ki}(x, u_k) = \tilde{r}_{ki}(x)u_k^2$ ,  $k, i = 1, 2$ . The functions  $\tilde{b}_k$ ,  $\tilde{r}_{ki}$  are Lipschitz continuous functions. The function  $\sigma$  is also assumed to be bounded Lipschitz continuous, and  $\tilde{r}_{ki}$  is assumed to be nonnegative. Now, for  $h$  sufficiently small, we can verify that (A4) is satisfied. Moreover, the selector map  $\bar{u}_x^k$  is unique for each  $x$ .

*Example 5.6.* Take  $U_1 = U_2 = [0, 1]$ . Define  $\bar{b}_k(x, u_k) = \tilde{b}_k(x)u_k$ ,  $\bar{r}_{ki}(x, u_k) = \tilde{r}_{ki}(x)u_k$ ,  $k, i = 1, 2$ . The functions  $\tilde{b}_k$ ,  $\tilde{r}_{ki}$  are bounded Lipschitz continuous functions. Then clearly (A4) is satisfied for  $h$  sufficiently small with a unique selector map. This is the setup discussed in [20].

*Example 5.7.* Take  $U_i$ ,  $i = 1, 2$ , to be compact and convex subsets of  $\mathbb{R}^{n_i}$ . Define

$$\bar{b}_k(x, u_k) = b_k(x) f_k(u_k), \quad \bar{r}_{ki}(x, u_k) = \tilde{r}_{ki}(x) g_{ki}(u_k), \quad k, i = 1, 2.$$

For each  $k, i$ , assume that  $b_k, \tilde{r}_{ki}$  are bounded and Lipschitz continuous. Also assume that  $g_{kk}, f_k$  are differentiable,  $f'_k$  is Lipschitz continuous, and  $g'_{kk}$  satisfies

$$K |g'_{kk}(u_1) - g'_{kk}(u_2)| \geq \|u_1 - u_2\|, \quad u_1, u_2 \in U_k, \quad \text{for some } K > 0.$$

Now for  $\phi \in l_M^\infty(\mathbb{R}_h^d)$

$$\begin{aligned} & \max_{0 \leq u_1 \leq 1} \left[ \tilde{r}_{11}(x) g_{11}(u_1) + \beta \sum_{y \in \mathbb{R}_h^d} \bar{p}_1^h(x, y, u_1) \phi(y) \right] \\ &= A(x) + \max_{0 \leq u_1 \leq 1} \left[ \tilde{r}_{11}(x) g_{11}(u_1) + \frac{h\beta}{Q^h} \left\{ \sum_{i=1}^d b_{1i}^+(x) (\phi(x + he_i) - \phi(x)) \right. \right. \\ & \quad \left. \left. + \sum_{i=1}^d b_{1i}^-(x) (\phi(x - he_i) - \phi(x)) \right\} f_1(u_1) \right], \end{aligned}$$

where

$$\begin{aligned} A(x) &= \frac{\beta}{2} \phi(x) + \frac{\beta}{4Q^h} \sum_{i=1}^d a_{ii}(x) [\phi(x + he_i) - 2\phi(x) + \phi(x - he_i)] \\ &+ \frac{\beta}{4Q^h} \sum_{i=1}^d \left( \sum_{j:j \neq i}^d |a_{ij}(x)| \right) [\phi(x + he_i) - 2\phi(x) + \phi(x - he_i)] \\ &+ \frac{\beta}{4Q^h} \sum_{i,j=1}^d a_{ij}^+(x) \phi(x \pm he_i \pm he_j) + \frac{\beta}{4Q^h} \sum_{i,j=1}^d a_{ij}^-(x) \phi(x \pm he_i \mp he_j). \end{aligned}$$

Consider

$$\max_{0 \leq u_1 \leq 1} \left[ \tilde{r}_{11}(x) g_{11}(u_1) + h g(x, \phi, h) f_1(u_1) \right],$$

where

$$g(x, \phi, h) = \frac{\beta}{Q^h} \left\{ \sum_{i=1}^d b_{1i}^+(x) (\phi(x + he_i) - \phi(x)) + \sum_{i=1}^d b_{1i}^-(x) (\phi(x - he_i) - \phi(x)) \right\}.$$

Now by using the assumptions we can see that, for each fixed  $x$ , there exists  $u_1^*$ ,  $u_1^{*h}(\phi)$  (for  $h$  sufficiently small) such that

$$\begin{aligned}\tilde{r}_{11}(x) g'_{11}(u_1^*) &= 0, \\ \tilde{r}_{11}(x) g'_{11}(u_1^{*h}(\phi)) + h g(x, \phi, h) f'_1(u_1^{*h}(\phi)) &= 0 \text{ for all } h, \phi.\end{aligned}$$

Now

$$\begin{aligned}|u_1^{*h}(\phi_1) - u_1^{*h}(\phi_2)| &\leq K |g'_{11}(u_1^{*h}(\phi_1)) - g'_{11}(u_1^{*h}(\phi_2))| \\ &= K_1 |\tilde{r}_{11}(x) g'_{11}(u_1^{*h}(\phi_1)) - \tilde{r}_{11}(x) g'_{11}(u_1^{*h}(\phi_2))| \\ &= h K_1 |g(x, \phi_1, h) f'_1(u_1^{*h}(\phi_1)) - g(x, \phi_2, h) f'_1(u_1^{*h}(\phi_2))|,\end{aligned}$$

where  $K_1 = \frac{K}{|\tilde{r}_{11}(x)|}$ . Therefore, we have

$$\begin{aligned}|u_1^{*h}(\phi_1) - u_1^{*h}(\phi_2)| &\leq h K_1 \left[ |g(x, \phi_1, h) - g(x, \phi_2, h)| |f'_1(u_1^{*h}(\phi_1))| \right. \\ &\quad \left. + |g(x, \phi_2, h)| |f'_1(u_1^{*h}(\phi_1)) - f'_1(u_1^{*h}(\phi_2))| \right] \\ &\leq h K_2 \left[ |g(x, \phi_1, h) - g(x, \phi_2, h)| \right. \\ &\quad \left. + |f'_1(u_1^{*h}(\phi_1)) - f'_1(u_1^{*h}(\phi_2))| \right] \\ &\leq h K_2 |g(x, \phi_1, h) - g(x, \phi_2, h)| \\ &\quad + h K_3 |u_1^{*h}(\phi_1) - u_1^{*h}(\phi_2)|,\end{aligned}$$

where  $K_2, K_3$  are positive constants. Hence, we have

$$|u_1^{*h}(\phi_1) - u_1^{*h}(\phi_2)| \leq \left( \frac{h K_2}{1 - h K_3} \right) |g(x, \phi_1, h) - g(x, \phi_2, h)|.$$

Also a routine calculation shows that  $g$  is Lipschitz continuous and the Lipschitz constant is independent of  $x \in \mathbb{R}_h^d$ . Thus the assumption (A4) is satisfied for  $h$  sufficiently small.

By using (A4) we can see that, for each  $\phi \in l_M^\infty(\mathbb{R}_h^d)$ ,  $\pi_k^*(\phi)(x) = \delta_{\bar{u}_x^k(\phi)}$ . For each fixed  $x$ , define  $T(\phi_1, \phi_2) = (\psi_1(x), \psi_2(x))$ , where

$$\begin{aligned}\psi_1(x) &= \sup_{v_1 \in V_1} \left[ r_{11}(x, v_1) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1) \phi_1(y) \right] \\ &\quad + r_{21}(x, \pi_2^*(\phi_2)(x)) + \beta \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\phi_2)(x)) \phi_1(y),\end{aligned}$$

and  $\psi_2$  is defined analogously. For  $\phi_i, \tilde{\phi}_i \in l^\infty(\mathbb{R}_h^d; \mathbb{R})$ ,  $i = 1, 2$ , set

$$\begin{aligned}\|(\phi_1, \phi_2)(x) - (\tilde{\phi}_1, \tilde{\phi}_2)(x)\| &= |\phi_1(x) - \tilde{\phi}_1(x)| + |\phi_2(x) - \tilde{\phi}_2(x)|, \quad x \in \mathbb{R}_h^d, \\ \|(\phi_1, \phi_2) - (\tilde{\phi}_1, \tilde{\phi}_2)\|_{l^\infty} &= \|\phi_1 - \tilde{\phi}_1\|_{l^\infty} + \|\phi_2 - \tilde{\phi}_2\|_{l^\infty}.\end{aligned}$$

Then

$$\begin{aligned}
& \|T(\phi_1, \phi_2)(x) - T(\tilde{\phi}_1, \tilde{\phi}_2)(x)\| \\
& \leq \left| \sup_{v_1 \in V_1} \left[ r_{11}(x, v_1) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1) \phi_1(y) \right] \right. \\
& \quad \left. - \sup_{v_1 \in V_1} \left[ r_{11}(x, v_1) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_1) \tilde{\phi}_1(y) \right] \right| \\
& \quad + \left| r_{21}(x, \pi_2^*(\phi_2)(x)) - r_{21}(x, \pi_2^*(\tilde{\phi}_2)(x)) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\phi_2)(x)) \phi_1(y) - \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\tilde{\phi}_2)(x)) \tilde{\phi}_1(y) \right| \\
& \quad + \left| \sup_{v_2 \in V_2} \left[ r_{22}(x, v_2) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_2) \phi_2(y) \right] \right. \\
& \quad \left. - \sup_{v_2 \in V_2} \left[ r_{22}(x, v_2) + \beta \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, v_2) \tilde{\phi}_2(y) \right] \right| \\
& \quad + \left| r_{12}(x, \pi_1^*(\phi_1)(x)) - r_{12}(x, \pi_1^*(\tilde{\phi}_1)(x)) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\phi_1)(x)) \phi_2(y) - \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\tilde{\phi}_1)(x)) \tilde{\phi}_2(y) \right| \\
& \leq \beta \left| \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\phi_1)(x)) \phi_1(y) - \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\phi_1)(x)) \tilde{\phi}_1(y) \right| \\
& \quad + \left| r_{21}(x, \pi_2^*(\phi_2)(x)) - r_{21}(x, \pi_2^*(\tilde{\phi}_2)(x)) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\phi_2)(x)) \phi_1(y) - \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\tilde{\phi}_2)(x)) \tilde{\phi}_1(y) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\phi_2)(x)) \phi_2(y) - \sum_{y \in \mathbb{R}_h^d} p_2^h(x, y, \pi_2^*(\phi_2)(x)) \tilde{\phi}_2(y) \right| \\
& \quad + \left| r_{12}(x, \pi_1^*(\phi_1)(x)) - r_{12}(x, \pi_1^*(\tilde{\phi}_1)(x)) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\phi_1)(x)) \phi_2(y) - \sum_{y \in \mathbb{R}_h^d} p_1^h(x, y, \pi_1^*(\tilde{\phi}_1)(x)) \tilde{\phi}_2(y) \right| \\
& \leq \beta \|(\phi_1, \phi_2) - (\tilde{\phi}_1, \tilde{\phi}_2)\|_{l^\infty} + K_1 \|\phi_1 - \tilde{\phi}_1\|_{l^\infty} + K_1 \|\phi_2 - \tilde{\phi}_2\|_{l^\infty} \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} [p_2^h(x, y, \pi_2^*(\phi_2)(x)) - p_2^h(x, y, \pi_2^*(\tilde{\phi}_2)(x))] \tilde{\phi}_2(y) \right| \\
& \quad + \beta \left| \sum_{y \in \mathbb{R}_h^d} [p_1^h(x, y, \pi_1^*(\phi_1)(x)) - p_1^h(x, y, \pi_1^*(\tilde{\phi}_1)(x))] \tilde{\phi}_1(y) \right|
\end{aligned}$$

for some constant  $K_1 > 0$ . Therefore

$$\begin{aligned} & \|T(\phi_1, \phi_2)(x) - T(\tilde{\phi}_1, \tilde{\phi}_2)(x)\| \\ & \leq \beta \|(\phi_1, \phi_2) - (\tilde{\phi}_1, \tilde{\phi}_2)\|_{l^\infty} + K_2 \|\phi_1 - \tilde{\phi}_1\|_{l^\infty} + K_2 \|\phi_2 - \tilde{\phi}_2\|_{l^\infty}, \end{aligned}$$

where  $K_2 > 0$  is a constant. Hence we have

$$(5.9) \quad \|T(\phi_1, \phi_2) - T(\tilde{\phi}_1, \tilde{\phi}_2)\|_{l^\infty} \leq K_3 \|(\phi_1, \phi_2) - (\tilde{\phi}_1, \tilde{\phi}_2)\|_{l^\infty}.$$

By using Remark 4.2 we can choose  $K_3 < 1$ . Hence from (5.9) it follows that the iterates in (5.5) converge.

**Numerical results.** Consider the stochastic differential game with the following specifications:

$$\begin{aligned} \bar{b}_1(x, u_1) &= b_1(x)u_1^2, \quad \bar{b}_2(x, u_1) = b_2(x)u_2^2, \\ \bar{r}_1(x, u_1, u_2) &= \tilde{r}_{11}(x) \left( \frac{u_1^2}{2} - u_1 \right) + \tilde{r}_{21}(x)u_2, \\ \bar{r}_2(x, u_1, u_2) &= \tilde{r}_{12}(x)u_1 + \tilde{r}_{22}(x) \left( \frac{u_2^2}{2} - u_2 \right), \\ \sigma(x) &= \sigma, \quad x \in \mathbb{R}, u_1, u_2 \in [0, 1]. \end{aligned}$$

A simple calculation shows that

$$\overline{Q}^h = \frac{2h}{\sqrt{e}} + \sigma^2, \quad \Delta t^h = \frac{h^2 \sqrt{e}}{2h + \sigma^2 \sqrt{e}}.$$

With the condition  $\tilde{r}_{kk} \leq 0$ ,  $k = 1, 2$ , we can see that

$$\bar{u}_x^k(\phi) = \begin{cases} \frac{\tilde{r}_{kk}(x)}{\tilde{r}_{kk}(x) + \frac{2h\beta}{\overline{Q}^h} b_k(x)(\phi(x+h) - \phi(x))} & \text{if } \phi(x+h) < \phi(x), \\ 1 & \text{if } \phi(x+h) \geq \phi(x). \end{cases}$$

Now one can see that the assumption (A4) is satisfied. We have run the program for calculating Nash equilibrium and the iterates for the values of  $x$  in  $[-10, 10]$ . Since the input functions  $\tilde{r}_{kj}$  vanish at infinity, we are able to put an artificial boundary for the state, and values of the iterates are set to zero beyond this boundary. By using arguments similar to [1] one can see the following.

Let  $\tau_M = \inf\{t > 0 \mid \|X^h(t)\| \geq M\}$  and  $\epsilon(M)$  denote the error bound  $\|\phi^* - \phi^{M*}\|_{l^\infty}$ , with

$$\phi^* = (R_\alpha^{1h}[v_1^*, v_2^*], R_\alpha^{2h}[v_1^*, v_2^*]), \quad \phi^{M*} = (R_\alpha^{1Mh}[v_1^*, v_2^*], R_\alpha^{2Mh}[v_1^*, v_2^*]),$$

where  $(v_1^*, v_2^*)$  is a Nash equilibrium for the stochastic game ( $h$ -step) and

$$R_\alpha^{iMh}[v_1^*, v_2^*] = E \int_0^\infty e^{-\alpha t} [r_{1i}(X^h(t)), v_1^*(X^h(t)) + r_{2i}(X^h(t)), v_2^*(X^h(t))] I\{\tau_M \geq t\} dt.$$

Then

$$\begin{aligned} (5.10) \quad \epsilon(M) &= E \int_{\tau_M}^\infty e^{-\alpha t} [r_{1i}(X^h(t)), v_1^*(X^h(t)) + r_{2i}(X^h(t)), v_2^*(X^h(t))] dt \\ &= E \int_0^\infty e^{-\alpha t} [r_{1i}(X^h(t)), v_1^*(X^h(t)) + r_{2i}(X^h(t)), v_2^*(X^h(t))] I\{t \geq \tau_M\} dt \\ &\leq K \int_0^\infty e^{-\alpha t} P\{\tau_M \leq t\} dt, \end{aligned}$$

where  $K$  is a bound for the coefficients  $r_1, r_2$ . Consider the process (3.3) corresponding to  $(v_1^*, v_2^*)$  given by

$$X^h(t) = x_0^h + \int_0^t [b_1(X^h(s)), v_1^*(s) + b_2(X^h(s)), v_2^*(s)] ds + \int_0^t \sigma(X^h(s)) dW^h(s). \quad (5.11)$$

$$\begin{aligned} E \sup_{0 \leq t \leq T} \|X^h(t)\|^2 &\leq 5(x_0^h)^2 + 5E \sup_{0 \leq t \leq T} \left\| \int_0^t \sigma(X^h(s)) dW^h(s) \right\|^2 \\ &\quad + 5E \sup_{0 \leq t \leq T} \left\| \int_0^t [b_1(X^h(s)), v_1^*(s) + b_2(X^h(s)), v_2^*(s)] ds \right\|^2 \\ &\leq 5(x_0^h)^2 + 5K_2 \int_0^T E \|\sigma(X^h(t))\|^2 dt + 5K_1 T^2 \\ &\leq 5(x_0^h)^2 + 5K_1 T^2 + 5K_1 K_2 T, \end{aligned}$$

where  $K_1$  is the square of the common bound for  $b_1, b_2$  and  $\sigma$  and  $K_2$  is the constant in the Burkholder–Davis–Gundy inequality. Now

$$\begin{aligned} P\{\tau_M \leq t\} &\leq P\left(\sup_{0 \leq s \leq t} \|X^h(s)\| \geq M\right) \\ &\leq \frac{E \sup_{0 \leq s \leq t} \|X^h(s)\|^2}{M} \\ &\leq \frac{5(x_0^h)^2 + 5K_1 t^2 + 5K_1 K_2 t}{M}. \end{aligned} \quad (5.12)$$

Now from (5.10)–(5.12) we have

$$\begin{aligned} \epsilon(M) &\leq K \int_0^\infty e^{-\alpha t} P\{\tau_M \leq t\} dt \\ &\leq \frac{5K}{\alpha^3 M} [\alpha^2 (x_0^h)^2 + \alpha K_1 K_2 + 2K_1]. \end{aligned}$$

Now for a given accuracy requirement, say, within the limit  $\delta$ , choose  $M$  such that

$$\frac{5K}{\alpha^3 M} [\alpha^2 (x_0^h)^2 + \alpha K_1 K_2 + 2K_1] < \delta;$$

i.e., the boundary  $\partial[-M, M]^d$  depends on the choice of  $h$  and the accuracy requirement. For our example, the choice of boundary was  $x = -20, 20$ . For the calculation, we choose

$$\begin{aligned} b_1(x) &= (10^4 + |x|)e^{-|x|}, & b_2(x) &= |x|e^{-|x|}, \sigma = 1, \\ \tilde{r}_{11}(x) &= -\frac{2}{1 + |x|^3}, & \tilde{r}_{21}(x) &= \frac{1}{1 + 20|x|}, \\ \tilde{r}_{12}(x) &= \frac{2}{2 + x^2}, & \tilde{r}_{22}(x) &= -\frac{1}{1 + 10|x(x+1)|}, \alpha = \frac{1}{2}. \end{aligned}$$

We have run the program for  $h = 0.002, 0.001, 0.0005$ , and  $0.00025$  and performed 1000 iterations. Convergence has been achieved in all cases.

FIG. 1

FIG. 2

In Figure 1, the state of the game is the  $x$  component, and the Nash equilibrium component of player 1 is the  $y$  component. Similarly, in Figure 2, the Nash equilibrium component of player 2 against the state of the game is given. The figures display that as  $h$  decreases the Nash equilibrium is approaching the pure strategies  $(1, 1)$ , i.e.,  $v_i^*(x) = 1$ ,  $x \in \mathbb{R}$ ,  $i = 1, 2$ .

**6. Conclusions.** We have developed a new method for obtaining a Nash equilibrium for stochastic differential games based on a discretization procedure. Our method relies mostly on probabilistic arguments, whereas the standard method in the literature involves a direct application of Fan's fixed point theorem. Moreover our method is constructive which can be used to compute Nash equilibria for a large class of stochastic differential games.

## CONSTRAINED OPTIMAL CONTROL THEORY FOR DIFFERENTIAL LINEAR REPETITIVE PROCESSES\*

M. DYM KOV<sup>†</sup>, E. ROGERS<sup>‡</sup>, S. DYM KOU<sup>§</sup>, AND K. GALKOWSKI<sup>¶</sup>

**Abstract.** Differential repetitive processes are a distinct class of continuous-discrete two-dimensional linear systems of both systems theoretic and applications interest. These processes complete a series of sweeps termed passes through a set of dynamics defined over a finite duration known as the pass length, and once the end is reached the process is reset to its starting position before the next pass begins. Moreover the output or pass profile produced on each pass explicitly contributes to the dynamics of the next one. Applications areas include iterative learning control and iterative solution algorithms, for classes of dynamic nonlinear optimal control problems based on the maximum principle, and the modeling of numerous industrial processes such as metal rolling, long-wall cutting, etc. In this paper we develop substantial new results on optimal control of these processes in the presence of constraints where the cost function and constraints are motivated by practical application of iterative learning control to robotic manipulators and other electromechanical systems. The analysis is based on generalizing the well-known maximum and  $\epsilon$ -maximum principles to them.

**1. Introduction.** Repetitive processes are a distinct class of two-dimensional (2D) systems of both systems theoretic and applications interest. The unique characteristic of such a process is a series of sweeps, termed passes, through a set of dynamics defined over a fixed finite duration known as the pass length. On each pass an output, termed the pass profile, is produced which acts as a forcing function on, and hence contributes to, the dynamics of the next pass profile. This, in turn, leads to the unique control problem in that the output sequence of pass profiles generated can contain oscillations which increase in amplitude in the pass-to-pass direction.

To introduce a formal definition, let  $\alpha < +\infty$  denote the pass length (assumed constant). Then in a repetitive process the pass profile  $y_k(t)$ ,  $0 \leq t \leq \alpha$ , generated on pass  $k$  acts as a forcing function on, and hence contributes to, the dynamics of the next pass profile  $y_{k+1}(t)$ ,  $0 \leq t \leq \alpha$ ,  $k \geq 0$ .

Physical examples of repetitive processes include long-wall coal cutting and metal-rolling operations (see, for example, the references cited in [17]). Also in recent years applications have arisen where adopting a repetitive process setting for analysis has distinct advantages over alternatives. Examples of these so-called algorithmic applications include classes of iterative learning control (ILC) schemes (see, for example, [13]) and iterative algorithms for solving nonlinear dynamic optimal control problems based on the maximum principle [15]. In the case of iterative learning control for the linear

dynamics case, the stability theory for differential (and discrete) linear repetitive processes is one method which can be used to undertake a stability/convergence analysis of a powerful class of such algorithms and thereby produce vital design information concerning the trade-offs required between convergence and transient performance (see, for example, [14]).

Attempts to control these processes using standard (or 1D) systems theory and associated algorithms fail (except in a few very restrictive special cases) precisely because such an approach ignores their inherent 2D systems structure, i.e., information propagation occurs from pass to pass and along a given pass. Also the initial conditions are reset before the start of each new pass, and the structure of these can be somewhat complex. For example, if they are an explicit function of points on the previous pass profile, then this alone can destroy stability. In seeking a rigorous foundation on which to develop a control theory for these processes, it is natural to attempt to exploit structural links which exist between these processes and other classes of 2D linear systems.

The case of 2D discrete linear systems recursive in the positive quadrant  $(i, j) : i \geq 0, j \geq 0$  (where  $i$  and  $j$  denote the directions of information propagation) has been the subject of much research effort over the years using, in the main, the well-known Roesser [16] and Fornasini–Marchesini [8] state-space models. One approach which has been the subject of productive research is optimal control—see, for example, [4, 18]. More recently, productive research has been reported on  $\mathcal{H}_\infty$  and  $\mathcal{H}_2$  approaches to analysis and controller design—see, for example, [19, 7]. In this paper we consider so-called differential linear repetitive processes where information propagation along the pass is governed by a matrix differential equation. The systems theory for 2D discrete linear systems is therefore not applicable. (Also, as noted above, for discrete processes the resetting and structure of the boundary conditions may cause problems which have no Roesser or Fornasini–Marchesini state-space model counterparts.)

In this paper we develop substantial new results on the optimal control of differential linear repetitive processes with constraints which we motivate from the iterative learning control application. The results themselves are obtained by extending the maximum principle and the  $\epsilon$ -maximum principle [11] to them. A sensitivity analysis of the resulting optimal control is also undertaken, and some relevant differentiation properties are established. Finally, a numerical example is given.

**2. Preliminaries.** ILC is a technique for controlling systems which are required to continually repeat the same operation with the requirement that a reference trajectory defined over a finite interval is followed to a high precision. In particular, the system completes a pass (also known as a trial in some literature) and is then reset, the next pass is completed, and so on. The basic idea of ILC is to use information from previous executions of the task in order to improve performance from pass to pass in the sense that the tracking error is sequentially reduced. It is clear therefore that ILC can easily be formulated as a repetitive process, and the stability theory for them can be used to explain why an incorrectly designed ILC scheme can result in nonconvergent behavior which manifests itself as oscillations that increase in amplitude from pass to pass [14].

Since the original work in the mid-1980s [3], the general area of ILC has been the subject of considerable research in terms of the underlying theory (with experimental verification in some cases). Commonly used ILC algorithms construct the input to the plant or process from the input used on the last pass plus an additive increment, which is typically a function of the past values of the measured output error, i.e.,

the difference between the achieved output on the current pass and the desired plant output. Suppose that  $u_k(t)$  denotes the input to the plant on pass  $k$  which is of duration  $\alpha$ , i.e.,  $0 \leq t \leq \alpha < \infty$ . Suppose also that  $e_k(t) = r(t) - y_k(t)$  denotes the current pass error. Then the objective of constructing a sequence of input functions such that the performance achieved is gradually improving with each successive pass can be refined to a convergence condition on the input and error, i.e.,

$$\lim_{k \rightarrow \infty} \|e_k\| = 0, \quad \lim_{k \rightarrow \infty} \|u_k - u_\infty\| = 0,$$

where  $\|\cdot\|$  is a signal norm in a suitably chosen function space with a norm-based topology and  $u_\infty$  is termed the learned control.

A large number of design algorithms have been developed for this general area, some of which have also been experimentally tested. Of these, a good number are based on minimization of a cost function. Given the tracking nature of this general problem in the pass-to-pass direction, it is clearly necessary to penalize control action to prevent a “large” error resulting in the demand for an unacceptably high control input on the next pass in an attempt to minimize the error. One class of such algorithms is termed norm-optimal (with an extension to so-called predictive norm-optimal which is not relevant here). Here (see [1] for full details) on completion of pass  $k$ , the control input for pass  $k+1$  is computed as the solution of the minimum norm optimization problem

$$u_{k+1} = \arg \min_{u_{k+1}} \{J_{k+1}(u_{k+1}) : e_{k+1} = r - y_{k+1}, y_{k+1} = Gu_{k+1}\},$$

where the performance index, or optimality criterion, used is defined to be

$$J_{k+1}(u_{k+1}) = \|e_{k+1}\|_{\mathcal{Y}}^2 + \|u_{k+1} - u_k\|_{\mathcal{U}}^2,$$

where  $\mathcal{Y}$  is a real Hilbert space of output or pass profile signals ( $y_k$ ) and  $\mathcal{U}$  is a real (and possibly distinct) Hilbert space of input signals ( $u_k$ ). Here the initial control  $u_0 \in \mathcal{U}$  can be arbitrary in theory but, in practice, will be a good first guess at the solution of the problem. This problem can be interpreted as the determination of the control input on pass  $k+1$  with the properties that: (i) the tracking error is reduced in an optimal way; and (ii) this new control input does not deviate too much from the control input used on pass  $k$ . The relative weighting of these two objectives can be absorbed into the definitions of the norms in  $\mathcal{Y}$  and  $\mathcal{U}$ . Other approaches to learning control in the presence of input constraints can be found in, for example, [9, 20] (but note that repetitive processes appear in formulations which have no iterative learning control interpretation). Suppose now that the plant dynamics are described by the following matrix differential equation:

$$(1) \quad \frac{dx_k(t)}{dt} = Ax_k(t) + Dx_{k-1}(t) + bu_k(t), \quad 0 \leq t \leq \alpha, \quad k \geq 0,$$

where, on pass  $k$ ,  $x_k(t)$  is the  $n \times 1$  state (equal to the pass profile or output) vector,  $u_k(t)$  is the scalar control input,  $A, D$  are constant  $n \times n$  matrices, and  $b$  is a given  $n \times 1$  vector. (This model is chosen for simplicity of presentation and is easily extended to the case when the pass profile vector is a linear combination of the current pass state, input, and previous pass profile vectors.)

Then it is straightforward to show that the above formulation includes the choice of a linear quadratic cost function as a special case, but the solution has to be modified

slightly to guarantee that the resulting Riccati equation-based solution is causal in the sense that it does not, as the dynamics evolve, require use of information which is not yet available—see [1] for the details here. Algorithms resulting from this approach have been experimentally tested on a chain conveyor system with, on the whole, very encouraging results [2]. However, in some cases it was observed that the computed control input (a scalar variable in this application) was still above the safe operating range of the actuator device and the experiment had to be stopped to prevent damage. Also there was a tendency for the output at the end of each pass to “dip down” in value.

Another feature of repetitive processes which does not appear in the above optimal control problem is that in each practical application only a finite number of passes will actually be completed. Suppose therefore that  $N < \infty$  denotes the number of passes actually completed, introduce the set  $K = \{1, 2, \dots, N\}$ , and let  $T$  denote the finite interval (the pass length)  $[0, \alpha]$ . Then, with the above observations in mind, consider (1) with boundary conditions

$$(2) \quad x_k(0) = d_k, \quad k \in K, \quad x_0(t) = f(t), \quad t \in T,$$

where  $d_k$  is an  $n \times 1$  vector with constant entries and  $f(t)$  is a known function  $t \in T$ . Then the optimal control problem considered is

$$(3) \quad \max_{u_k} J(u), \quad J(u) = \sum_{k \in K} p_k^T x_k(\alpha),$$

where  $p_k$ ,  $k = 1, \dots, N$ , is a given  $n \times 1$  vector subject to an end of pass (or terminal) constraint of the form

$$(4) \quad H_k x_k(\alpha) = o_k, \quad k \in K,$$

where  $o_k$  is an  $m \times 1$  vector and  $H_k$  is an  $m \times n$  matrix, and the control inputs satisfy the following admissibility condition.

**DEFINITION 1.** *For each pass number  $k \in K$  the piecewise continuous function  $u_k : T \rightarrow R$  is termed an admissible control for this pass if it satisfies*

$$(5) \quad |u_k(t)| \leq 1, \quad t \in T,$$

*and the corresponding state vector  $x_k(t)$ ,  $t \in T$ , of (1) satisfies the boundary conditions*

$$x_k(0) = d_k, \quad H_k x_k(\alpha) = o_k.$$

Also, without loss of generality, we assume that the matrix  $A$  has simple eigenvalues  $\lambda_i$ ,  $1 \leq i \leq n$ , and that it is stable in the sense that  $\text{Re } \lambda_i < 0$ ,  $1 \leq i \leq n$ . (Stability of the matrix  $A$  is a necessary condition for so-called stability along the pass (essentially bounded input bounded output stability) independent of the pass length [17].)

**3. Optimality conditions for the supporting control functions.** Consider first (1)–(2) in the absence of the terminal conditions (4). Then it has been shown elsewhere [5] that the solution of these equations can be written as

$$(6) \quad \begin{aligned} x_k(t) = & \sum_{j=1}^k K_j(t) d_{k+1-j} + \int_0^t K_k(t-\tau) D f(\tau) d\tau \\ & + \sum_{j=1}^k \int_0^t K_j(t-\tau) b u_{k+1-j}(\tau) d\tau, \quad k = 1, \dots, N, \end{aligned}$$

where the  $K_i(t)$  are the solutions of the following  $n \times n$  matrix differential equations:

$$(7) \quad \dot{K}_1(t) = AK_1(t), \quad \dot{K}_i(t) = AK_i(t) + DK_{i-1}(t), \quad i = 2, \dots, N,$$

with initial conditions

$$(8) \quad K_1(0) = I_n, \quad K_i(0) = 0, \quad i = 2, \dots, N.$$

Also it is easy to show that these solutions have the following properties:

$$(9) \quad \begin{aligned} K_j(t - \sigma) &= \int_{\sigma}^t K_{j-k}(t - \tau) DK_k(\tau - \sigma) d\tau, \quad 0 \leq \sigma < t \leq \alpha, \quad k = 1, \dots, j-1, \\ K_j(t - \sigma) &= \sum_{s=1}^j K_s(t - \tau) K_{j+1-s}(\tau - \sigma), \quad j = 2, \dots, N-1, \end{aligned}$$

which will be used below.

Now by using (6) we can rewrite the optimal problem considered here in the following integral form:

$$(10) \quad \max_{u_1, \dots, u_N} J(u), \quad J(u) = \sum_{j=1}^N \int_0^{\alpha} c_j(\tau) u_j(\tau) d\tau + \gamma,$$

subject to the terminal conditions (4) and the control constraint (5). Also we can write

$$(11) \quad \begin{aligned} &\int_0^{\alpha} g_{11}(\tau) u_1(\tau) d\tau = h_1, \\ &\int_0^{\alpha} \left[ g_{21}(\tau) u_1(\tau) + g_{22}(\tau) u_2(\tau) \right] d\tau = h_2 \\ &\dots\dots\dots \\ &\int_0^{\alpha} \left[ g_{N1}(\tau) u_1(\tau) + \dots + g_{NN}(\tau) u_N(\tau) \right] d\tau = h_N, \end{aligned}$$

and

$$|u_k(\tau)| \leq 1, \quad \tau \in T, \quad k = 1, \dots, N,$$

where the scalar  $\gamma$  and the scalar functions  $c_j(\tau)$  are defined as follows:

$$\begin{aligned} \gamma &= \sum_{k=1}^N \sum_{j=1}^k p_k^T K_j(\alpha) d_{k+1-j} + \sum_{k=1}^N \int_0^{\alpha} p_k^T K_k(\alpha - \tau) Df(\tau) d\tau, \\ c_j(\tau) &= \sum_{k=j}^N p_k^T K_{k+1-j}(\alpha - \tau) b, \quad j = 1, \dots, N, \quad g_{kj}(\tau) = H_k K_{k+1-j}(\alpha - \tau) b, \quad j \leq k, \\ h_k &= o_k - \sum_{j=1}^k H_k K_j(\alpha) d_{k+1-j} - \int_0^{\alpha} H_k K_k(\alpha - \tau) Df(\tau) d\tau, \quad k = 1, \dots, N. \end{aligned}$$

Also we require the following.

values are less than those on the control constraint boundary and satisfy (11); i.e., the support control function is nonsingular if there exist numbers  $\lambda_0 > 0$ ,  $\mu_0 > 0$ ,  $u_j^k(\lambda)$ ,  $j = 1, \dots, m$ ,  $k = 1, \dots, N$ , such that the following equalities:

$$(17) \quad \sum_{j=1}^k \sum_{i=1}^m u_j^i(\lambda) \int_{\tau_{ij}-\lambda}^{\tau_{ij}+\lambda} g_{kj}(t) dt = \sum_{j=1}^k \sum_{i=1}^m \int_{\tau_{ij}-\lambda}^{\tau_{ij}+\lambda} g_{kj}(t) u_j(t) dt, \\ |u_j^k| \leq 1 - \mu_0, \quad j = 1, \dots, m, \quad k = 1, \dots, N,$$

hold for all  $\lambda$ ,  $0 < \lambda < \lambda_0$ , and  $k$ ,  $1 \leq k \leq N$ . This fact will be used below in the proof of the optimality conditions.

Associate with each supporting time instance  $\tau_{kj}$  a small subinterval  $T_{kj}$  from  $T$  such that the matrix  $G_{gen}^k := \{ \int_{T_{kj}} g_{kk}(\tau) d\tau, j = 1, \dots, m \}$  is nonsingular. Also without loss of generality we can assume that  $\tau_{kj}$  is one or the other of the end points of  $T_{kj}$  and the supporting control functions  $u_k(t) = u_j^k$  for  $t \in T_{kj}$ ,  $j = 1, \dots, N$ , are constant over the segments  $T_{kj}$ . Then we have the following result.

**THEOREM 1.** *A supporting control function  $\{\tau_{sup}^k, u_k^0(t), k = 1, \dots, N\}$  is an optimal solution of the problem (1)–(4) if*

$$(18) \quad u_k^0(t) = -\text{sgn}(\Delta_k(t)), \quad k = 1, \dots, N, \quad t \in T.$$

*Moreover, if this supporting control function is nondegenerate, then the above condition is necessary and sufficient.*

*Proof.* Let  $u_k(t) \neq u_k^0(t)$ ,  $k = 1, \dots, N$ , be an admissible control and  $x_k(t)$  the corresponding trajectory of the system (1)–(2). Then standard transformations yield that the increment  $\Delta J(u) := J(u^0) - J(u)$  of the cost function can be expressed in the form

$$\Delta J(u) = \int_0^{t^*} \sum_{j=1}^N c_j(t) [u_j^0(t) - u_j(t)] dt = - \sum_{j=1}^N \int_0^{t^*} \Delta_j(t) [u_j^0(t) - u_j(t)] dt.$$

Hence by using (18) we have that  $\Delta J(u) \geq 0$  for any admissible control  $u$ ; i.e.,  $\{\tau_{sup}^k, u_k^0\}$  is an optimal supporting control function.

Let  $\{\tau_{sup}^k, u_k^0(t), k = 1, \dots, N\}$  be an optimal nondegenerate control, but there exists  $k_*, 1 \leq k_* \leq N$ , and there exists  $t_* \in T$  such that the theorem is not valid. Suppose also that  $t_* \in [\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda]$ , where  $\lambda > 0$  is a small number; i.e., the instance  $t_*$  lies in an neighborhood of some supporting time instance  $\tau_{k_*j}$ . Then since the supporting control is nondegenerate there exists a control variation  $\Delta u_{k_*}^0(t)$ , defined on the intervals  $[\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda]$ , such that  $J(u^0) > 0$ , which contradicts the optimality of  $u_k^0(t)$ .

Given this last fact, we now suppose that  $t_* \notin [\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda]$  for all  $j = 1, \dots, m$ , for some small  $\lambda > 0$ . Also, without loss of generality, we assume that  $\Delta_{k_*}^0(t_*) > 0$  and  $u_{k_*}(t_*) > 0$ . Then, by continuity of  $\Delta_{k_*}(t)$  and piecewise-continuity of  $u_{k_*}(t)$ , there exists a neighborhood  $T_{k_*}(t_*)$  of  $t_*$ , such that  $\Delta_{k_*}(t) > 0$ ,  $u_{k_*}(t) > -1$  for  $t \in T_{k_*}(t_*)$ . Now we have to construct the admissible control variation such that the corresponding increment of the cost function satisfies  $\Delta J(u) > 0$ , which is impossible for the optimal controls  $u_k^0(t)$ .

Consider now the case of a small real number  $\lambda_0 > 0$  (we see below that the existence of such a number  $\lambda_0$  is guaranteed by the fact that the supporting control is nondegenerate), and for all  $\lambda$ ,  $0 < \lambda < \lambda_0$ , define the control variation  $\Delta u(t) =$

$(\Delta u_1(t), \dots, \Delta u_N(t))$ ,  $t \in T$ , as

$$\Delta u_k(t) = 0, \quad k < k_*, \quad t \in T,$$

$$\Delta u_{k_*}(t) = \begin{cases} \theta(-1 - u_{k_*}(t)), & \theta > 0, \quad t \in T_{k_*}(t), \\ 0, & t \in T \setminus \left( \bigcup_{j=1}^m [\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda] \cup T_{k_*}(t) \right). \end{cases}$$

We now have that the control variations on the intervals  $[\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda]$ ,  $j = 1, \dots, m$ , can be chosen as constant functions  $\Delta u_{k_*}(t) \equiv \Delta \vartheta_j^k(\lambda)$ . Those for the remaining passes  $k > k_*$  are defined as

$$\Delta u_k(t) \equiv 0, \quad k = k_* + 1, \dots, N, \quad t \in T \setminus \bigcup_{j=1}^m [\tau_{kj} - \lambda, \tau_{kj} + \lambda],$$

$$\Delta u_k(t) \equiv \Delta \vartheta_j^k(\lambda), \quad t \in [\tau_{kj} - \lambda, \tau_{kj} + \lambda], \quad j = 1, \dots, m, \quad k > k_*,$$

where the  $\Delta \vartheta_j^k(\lambda)$  are unknown constants determined below.

By using (11), it follows that the conditions

$$(19) \quad \int_0^\alpha \sum_{s=1}^k g_{ks}(\tau) \Delta u_s(\tau) d\tau = 0, \quad k = 1, \dots, N,$$

hold for any admissible variation  $\Delta u(t)$ , and these can be rewritten in the form

$$\begin{aligned} \phi_{k_*}(\lambda) &= \sum_{j=1}^m \int_{\tau_{k_*j}-\lambda}^{\tau_{k_*j}+\lambda} g_{k_*k_*}(\tau) \vartheta_j^{k_*}(\lambda) d\tau \\ &= -\theta \int_{T_{k_*}(t_*)} g_{k_*k_*}(\tau) (-1 - u_{k_*}(\tau)) d\tau, \\ \phi_{k_*+1}(\lambda) &:= \sum_{j=1}^m \int_{\tau_{k_*+1j}-\lambda}^{\tau_{k_*+1j}+\lambda} g_{k_*+1k_*+1}(\tau) \vartheta_j^{k_*+1}(\lambda) d\tau \\ &= -\sum_{j=1}^m \int_{\tau_{k_*j}-\lambda}^{\tau_{k_*j}+\lambda} g_{k_*+1k_*}(\tau) \vartheta_j^{k_*}(\lambda) d\tau - \theta \int_{T_{k_*}(t_*)} g_{k_*+1k_*}(\tau) (-1 - u_{k_*}(\tau)) d\tau, \\ &\dots\dots\dots \\ \phi_N(\lambda) &= \sum_{j=1}^m \int_{\tau_{Nj}-\lambda}^{\tau_{Nj}+\lambda} g_{NN}(\tau) \vartheta_j^N(\lambda) d\tau - \sum_{j=1}^m \int_{\tau_{k_*j}-\lambda}^{\tau_{k_*j}+\lambda} g_{Nk_*}(\tau) \vartheta_j^{k_*}(\lambda) d\tau \\ &\quad - \theta \int_{T_{k_*}(t_*)} g_{Nk_*}(\tau) (-1 - u_{k_*}(\tau)) d\tau \\ (20) \quad &- \dots - \sum_{j=1}^m \int_{\tau_{N-1j}-\lambda}^{\tau_{N-1j}+\lambda} g_{NN-1}(\tau) \vartheta_j^{N-1}(\lambda) d\tau. \end{aligned}$$

Expanding the function  $\phi_{k_*}(\lambda)$  of (20) as a Taylor series and setting  $\Delta \vartheta_\lambda^{k_*} = (\Delta \vartheta_1^{k_*}(\lambda), \dots, \Delta \vartheta_m^{k_*}(\lambda))$  now yields

$$\begin{aligned} 2\lambda G_{sup}^{k_*} \Delta \vartheta_\lambda^{k_*} + \frac{\lambda^3}{3} \left\{ \frac{d^2 g_{k_*k_*}(\tau_{k_*j})}{d\tau}, \quad j = 1, \dots, m \right\} \Delta \vartheta_\lambda^{k_*} + o_{k_*}(\lambda^3) \\ = -\theta \int_{T_{k_*}(t_*)} g_{k_*k_*}(\tau) (-1 - u_{k_*}(\tau)) d\tau, \end{aligned}$$

where  $o_{k_*}(\lambda^3)$  denotes terms of degree 3 and above, which are neglected here. Hence the required vector  $\Delta\vartheta_\lambda^{k_*}$  can be represented as

$$\Delta\vartheta_\lambda^{k_*} = \frac{1}{\lambda}\theta\hat{u}_{k_*} + \theta o_{k_*}(\lambda), \quad \text{where} \quad \hat{u}_{k_*} = -\frac{1}{2}G_{sup}^{k_*-1} \int_{T_{k_*}(t_*)} g_{k_*k_*}(\tau)(-1 - u_{k_*}(\tau))d\tau, \quad (21)$$

and  $o_{k_*}(\lambda)$  denotes a residual first order term. Using (17) and (21), it follows that for a small value of  $\lambda \in (0, \lambda_0)$  there exists the real number  $\theta = \theta(\lambda)$  such that  $\theta(\lambda) = \mu_{k_*}\lambda \leq 1$ , where  $\mu_{k_*} > 0$  does not depend on  $\lambda$ , and the following inequalities:

$$|u_j^{k_*}(\lambda) + \Delta\vartheta_j^{k_*}(\lambda)| \leq 1, \quad j = 1, \dots, m,$$

hold. Here we have exploited the fact that the admissible controls are constants  $u_j^k(\lambda)$  over the intervals  $T_j^k$ , containing the supporting points  $\tau_{kj}$ . Hence, the function

$$\bar{u}_{k_*}(t) = \begin{cases} u_j^{k_*}(\lambda) + \Delta\vartheta_j^{k_*}(\lambda), & t \in [\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda], \\ u_{k_*}(t) + \theta(\lambda)(-1 - u_{k_*}(t)), & t \in T_{k_*}(t_*), \end{cases}$$

is an admissible control function for  $\theta(\lambda) = \mu_{k_*}\lambda \leq 1$  and a sufficiently small  $\mu_{k_*}$ .

In order to find  $\Delta\vartheta_\lambda^{k_*+1}$  and  $\theta(\lambda)$ , expand  $\phi_{k_*+1}(\lambda)$  as a Taylor series to yield

$$\begin{aligned} \sum_{j=1}^m \int_{\tau_{k_*j}-\lambda}^{\tau_{k_*j}+\lambda} g_{k_*+1k_*}(\tau) \Delta\vartheta_j^{k_*}(\lambda) d\tau &= 2\lambda \sum_{j=1}^m g_{k_*+1k_*}(\xi_j) \Delta\vartheta_j^{k_*}(\lambda) \\ &= 2\lambda \tilde{G}_\xi^{k_*+1} \Delta\vartheta_\lambda^{k_*+1} \\ &= 2\lambda \tilde{G}_\xi^{k_*+1} \left( \frac{1}{\lambda} \mu_{k_*} \lambda \hat{u}_{k_*} + \mu_{k_*} \lambda o_{k_*}(\lambda) \right) \\ &= 2\tilde{G}_\xi^{k_*+1} \mu_{k_*} \lambda \hat{u}_{k_*} + \mu_{k_*} \lambda o_{k_*}(\lambda^3). \end{aligned} \quad (22)$$

Here the matrix  $\tilde{G}_\xi^{k_*+1}$  is constructed from the rows  $\{g_{k_*+1k_*}(\xi_j), j = 1, \dots, m\}$ , where  $\xi_j$  are points from the intervals  $[\tau_{k_*j} - \lambda, \tau_{k_*j} + \lambda]$ . Next, set  $\Delta\vartheta_\lambda^{k_*+1} = (\Delta\vartheta_1^{k_*+1}(\lambda), \dots, \Delta\vartheta_m^{k_*+1}(\lambda))$  to obtain

$$\begin{aligned} 2\lambda G_{sup}^{k_*+1} \Delta\vartheta_\lambda^{k_*+1} + \frac{\lambda^3}{3} \left\{ \frac{d^2 g_{k_*+1k_*+1}(\tau_{k_*j})}{d\tau}, j = 1, \dots, m \right\} \Delta\vartheta_\lambda^{k_*+1} + o_{k_*+1}(\lambda^3) \\ = -\mu_{k_*} \lambda \left\{ \tilde{G}_\xi^{k_*+1} \hat{u}_{k_*} + \int_{T_{k_*}(t_*)} g_{k_*+1k_*+1}(\tau)(-1 - u_{k_*}(\tau))d\tau \right\} \\ + \mu_{k_*} \lambda o_{k_*}(\lambda^3), \end{aligned} \quad (23)$$

and hence the required vector  $\Delta\vartheta_\lambda^{k_*+1}$  can be expressed as

$$\begin{aligned} \Delta\vartheta_\lambda^{k_*+1} &= \frac{1}{\lambda} \mu_{k_*} \lambda \hat{u}_{k_*+1} + \mu_{k_*} \lambda o_{k_*+1}(\lambda), \\ \hat{u}_{k_*+1} &= -\frac{1}{2} (G_{sup}^{k_*+1})^{-1} \left\{ \tilde{G}_\xi^{k_*+1} \hat{u}_{k_*} - \int_{T_{k_*}(t_*)} g_{k_*+1k_*+1}(\tau)(-1 - u_{k_*}(\tau))d\tau \right\}. \end{aligned} \quad (24)$$

Now choose  $\Delta\vartheta_\lambda^{k_*+1}$  such that the following inequalities hold:

$$|u_j^{k_*+1}(\lambda) + \Delta\vartheta_j^{k_*+1}(\lambda)| \leq 1, \quad j = 1, \dots, m,$$

and hence the values of  $\mu_{k_*}$  and  $\lambda_0$  can be decreased as required. Continuing this expansion procedure for the remaining equations in (20), we obtain the desired admissible control function in the form

$$\bar{u}(t) = u^0(t) + \Delta u(t) = \left\{ u_1^0(t) + \Delta u_1(t), \dots, u_N^0(t) + \Delta u_N(t) \right\}, \quad t \in T,$$

and note here that  $\Delta u_k(t) = 0$  for all  $k < k_*$ .

At this stage we can calculate the increment of the cost function generated by the designed control function  $\bar{u}(t)$  as

$$\begin{aligned} \Delta J(u) &= J(\bar{u}) - J(u^0) = \sum_{k=1}^N \int_0^\alpha \Delta_k(t) \Delta u_k(t) dt = \sum_{k=k_*}^N \int_0^\alpha \Delta_k(t) \Delta u_k(t) dt \\ &= -\theta \int_{T_{k_*}(t_*)} \Delta_{k_*}(t) (-1 - u_{k_*}(t)) dt \\ &\quad - \sum_{j=1}^m \int_{\tau_{k_*j}-\lambda}^{\tau_{k_*j}+\lambda} \Delta_{k_*}(t) [u_j^{k_*}(\lambda) + \Delta \vartheta_j^{k_*}(\lambda) - u_j^{k_*}(t)] dt \\ (25) \quad &\quad - \sum_{s=k_*+1}^N \sum_{j=1}^m \int_{\tau_{sj}-\lambda}^{\tau_{sj}+\lambda} \Delta_s(t) [u_j^s(\lambda) + \Delta \vartheta_j^s(\lambda) - u_j^s(t)] dt. \end{aligned}$$

Since  $\Delta_k(\tau_{kj}) = 0$ ,  $k = k_*, \dots, N$ ,  $j = 1, \dots, m$ , then, again using the Taylor series expansion in  $\lambda$ , we have the following estimate for the integral components:

$$\begin{aligned} \int_{\tau_{sj}-\lambda}^{\tau_{sj}+\lambda} \Delta_s(t) [u_j^s(\lambda) + \Delta \vartheta_j^s(\lambda) - u_j^s(t)] dt &= \int_{\tau_{sj}}^{\tau_{sj}} \Delta_s(t) [u_j^s(\lambda) + \Delta \vartheta_j^s(\lambda) - u_j^s(t)] dt \\ &\quad + 2\lambda \Delta_s(\tau_{sj}) [u_j^s(\lambda) + \Delta \vartheta_j^s(\lambda) - u_j^s(\tau_{sj})] \\ &\quad + \lambda^2 \frac{d\Delta_s(\tau_{sj})}{dt} [u_j^s(\lambda) + \Delta \vartheta_j^s(\lambda) - u_j^s(\tau_{sj})] \\ (26) \quad &\quad + o_1(\lambda^2) \cong o(\lambda^2). \end{aligned}$$

Hence (25) and (26) yield

$$(27) \quad \Delta J(u) = -\mu_{k_*} \lambda \int_{T_{k_*}(t_*)} \Delta_{k_*}(t) (-1 - u_{k_*}(t)) dt + o(\lambda) > 0$$

for a sufficiently small  $\lambda > 0$ , which contradicts the optimality of control functions  $u_k^0(t)$ ,  $k = 1, \dots, N$ .  $\square$

*Remark 3.* The analysis which now follows shows that the above result can be reformulated in the traditional maximum principle form. In particular, it will be shown that the cocontrol functions  $\Delta_k(t)$ ,  $t \in T$ , here are connected directly to the adjoint (dual) variables  $\psi_k(t)$ ,  $t \in T$ , as  $\Delta_k(t) = -\psi_k^T(t)b$ . Note also that the term  $\psi_k^T(t)b$  is part of the Hamiltonian function which arises in the maximum principle statement of the result here. Moreover, the vectors  $\{\nu^{(k)}, k = 1, \dots, N\}$  (termed Lagrange multipliers in some literature) will be used as the boundary conditions for the corresponding differential equations describing the adjoint (dual) variables  $\psi_k(t)$  (in contrast to the classic maximum principle, where such boundary conditions are not specified).

Let  $\psi_N(t)$  be the solution of

$$(28) \quad \frac{d\psi_N(t)}{dt} = -A^T \psi_N(t), \quad \psi_N(\alpha) = p_N - H_N^T \nu^N, \quad t \in T,$$

or

$$(29) \quad \psi_N(t) = K_1^T(\alpha - t)\psi(\alpha), \quad t \in T.$$

Hence

$$(30) \quad \begin{aligned} \psi_N^T(t)b &= (p_N^T - (\nu^N)^T H_N) K_1(\alpha - t)b = p_N^T K_1(\alpha - t)b \\ &- (\nu^N)^T H_N K_1(\alpha - t)b = c_N(t) - (\nu^N)^T g_{NN}(t) = -\Delta_N(t). \end{aligned}$$

In order to verify the validity of the corresponding conditions for subsequent passes we use (9) for the differential equations (7). Let  $\psi_{N-1}(t)$ ,  $t \in T$ , be a solution of the differential equation

$$(31) \quad \frac{d\psi_{N-1}(t)}{dt} = -A^T \psi_{N-1}(t) - D^T \psi_N(t), \quad \psi_{N-1}(\alpha) = p_{N-1} - H_{N-1}^T \nu^{N-1}, \quad t \in T.$$

Then

$$(32) \quad \begin{aligned} \psi_{N-1}^T(t)b &= (p_{N-1}^T - (\nu^{N-1})^T H_{N-1}) K_1(\alpha - t)b \\ &- (p_N^T - (\nu^N)^T H_N) \int_0^t K_1^T(t - \tau) D^T K_1^T(\alpha - \tau) b d\tau \\ &= p_{N-1}^T K_1(\alpha - t)b - (\nu^{N-1})^T H_{N-1} K_1(\alpha - t)b \\ &- (p_N^T - (\nu^N)^T H_N) K_2(\alpha - t)b \\ &= c_{N-1}(t) - (\nu^{N-1})^T g_{N-1N-1}(t) - (\nu^N)^T g_{NN-1}(t) = -\Delta_{N-1}(t). \end{aligned}$$

By analogy with the case for (31)–(32), we have

$$(33) \quad \psi_k^T(t)b = -\Delta_k(t), \quad k = 2, \dots, N,$$

where  $\psi_k(t)$ ,  $t \in T$ , are the solutions of the following differential equations:

$$(34) \quad \frac{d\psi_k(t)}{dt} = -A^T \psi_k(t) - D^T \psi_{k+1}(t), \quad \psi_k(\alpha) = p_k - H_k^T \nu^k, \quad t \in T.$$

For each  $k = 1, \dots, N$  introduce the associated Hamilton function as

$$(35) \quad H_k(x_{k-1}, x_k, \psi_k, u_k) = \psi_k^T(Ax_k + Dx_{k-1} + bu_k), \quad t \in T.$$

Then the use of (33) yields that the optimality conditions (18) can be reformulated in maximum principle form as the following corollary to Theorem 1.

**COROLLARY 1.** *The admissible supporting control  $\{\tau_{sup}^k, u_k^0(t), k = 1, \dots, N\}$  is optimal if along the corresponding trajectories  $x_k^0(t)$ ,  $\psi_k(t)$  of (1)–(2) and (34) the Hamiltonian function has maximum value, i.e.,*

$$(36) \quad H_k(x_{k-1}^0(t), x_k^0(t), \psi_k, u_k^0(t)) = \max_{|v| \leq 1} H_k(x_{k-1}^0(t), x_k^0(t), \psi_k, v), \quad t \in T,$$

for  $k = 1, \dots, N$ . If the admissible supporting control is nondegenerate, then this condition is necessary and sufficient.

*Remark 4.* In order to further emphasize the relationship between the support elements and the control function, note that the optimality conditions given by Theorem 1 can be equivalently stated in the form

$$(37) \quad \begin{aligned} \Delta_k(t) &> 0 \text{ at } u_k^0(t) = -1, \quad \Delta_k(t) < 0 \text{ at } u_k^0(t) = 1, \\ \Delta_k(t) &= 0 \text{ at } -1 < u_k^0(t) < 1, \quad k = 1, 2, \dots, N, \quad t \in T. \end{aligned}$$

Hence the supporting elements and control function of optimal solution are interconnected such that the supporting instances are the switching moments for optimal bang-bang control functions.

In the next section, the maximum principle for arbitrary admissible control functions of (1)–(4) is established using the suboptimality conditions.

**3.1.  $\epsilon$ -optimality conditions.** Often in the numerical implementation of optimal control algorithms it is beneficial to exploit approximate solutions with corresponding error estimation. Hence it is necessary to introduce the “suboptimality” concept as it is often sufficient to stop the numerical computations when a satisfactory accuracy level has been achieved.

Assume that  $\{u_k^0(t), k \in K\}$  is the optimal control for (1)–(4), and let  $J(u^0)$  denote the corresponding optimal cost function value.

**DEFINITION 5.** We say that the admissible control function  $\{u_k^\epsilon(t), k \in K\}$  is  $\epsilon$ -optimal if the corresponding solution  $\{x_k^\epsilon(t), t \in T, k \in K\}$  of (1)–(4) satisfies  $J(u^0) - J(u^\epsilon) \leq \epsilon$ .

Now we proceed to calculate an estimate of a supporting control function

$$\{u_k, \tau_{sup}^k, k \in K, t \in T\},$$

i.e., a measure of the nonoptimality of the control. Note also that this estimate can be partitioned into two principal parts: one of which evaluates the degree of nonoptimality of the chosen admissible control functions  $u_k(t)$ , and the second the error produced by nonoptimality of the support  $\tau_{sup}^k$ . This partition is a major advantage in the design of numerically applicable solution algorithms.

Introduce an estimate of optimality  $\beta = \beta(\tau_{sup}, u)$  as the value of the maximum increment for the cost function here calculated in the absence of the principal constraints (4); i.e., this estimate is given by the solution of the following relaxed optimization problem:

$$(38) \quad \max_{\Delta u_k} \Delta J(u), \quad |u_k(t) + \Delta_k u(t)| \leq 1, \quad t \in T, \quad k = 1, \dots, N.$$

It is easy to see that

$$(39) \quad \beta = \beta(\tau_{sup}, u) = \sum_{k=1}^N \int_{T_k^+} \Delta_k(t)(u_k(t) + 1)dt + \sum_{k=1}^N \int_{T_k^-} \Delta_k(t)(u_k(t) - 1)dt,$$

where

$$T_k^+ = \{t \in T : \Delta_k(t) > 0\}, \quad T_k^- = \{t \in T : \Delta_k(t) < 0\},$$

and we have the following result.

THEOREM 2 ( $\epsilon$ -maximum principle). *Given any  $\epsilon \geq 0$ , the admissible control  $\{u_k(t), t \in T, k \in K\}$  is  $\epsilon$ -optimal for (1)–(4) if and only if there exists a support  $\{\tau_{sup}^k, k \in K\}$  such that along the solutions  $x_k(t), \psi_k(t), t \in T, k \in K$ , of (1)–(4) and (34) the Hamiltonian attains its  $\epsilon$ -maximum value, i.e.,*

$$H_k(x_{k-1}(t), x_k(t), \psi_k, u_k(t)) = \max_{|v| \leq 1} H_k(x_{k-1}(t), x_k(t), \psi_k, v) - \epsilon_k(t), \quad t \in T, \quad (40)$$

where the functions  $\epsilon_k(t)$ ,  $k \in K$ , satisfy the following inequality:

$$\sum_{k \in K} \int_T \epsilon_k(t) dt \leq \epsilon. \quad (41)$$

*Proof.* Assume that (40) and (41) hold for an admissible control  $\{u_k(t), t \in T, k \in K\}$ . Then by (33) the suboptimal estimate is

$$\begin{aligned} \beta &= \beta(\tau_{sup}, u) = \sum_{k=1}^N \int_{T_k^+} \psi_k^T(t) b(-u_k(t) - 1) dt + \sum_{k=1}^N \int_{T_k^-} \psi_k^T(t) b(1 - u_k(t)) dt \\ &= \sum_{k=1}^N \int_{T_k^+} \psi_k^T(t) (Ax_k(t) + Dx_{k-1}(t) - b) dt \\ &\quad - \sum_{k=1}^N \int_{T_k^+} \psi_k^T(t) (Ax_k(t) + Dx_{k-1}(t) + bu_k(t)) dt \\ &= \sum_{k=1}^N \int_{T_k^-} \psi_k^T(t) (Ax_k(t) + Dx_{k-1}(t) + b) dt \\ &\quad - \sum_{k=1}^N \int_{T_k^-} \psi_k^T(t) (Ax_k(t) + Dx_{k-1}(t) - bu_k(t)) dt \\ &\quad + \sum_{k=1}^N \int_T \left[ \max_{|v| \leq 1} H_k(x_{k-1}(t), x_k(t), \psi_k(t), v) - H_k(x_{k-1}(t), x_k(t), \psi_k(t), u_k(t)) \right] dt \\ &= \sum_{k=1}^N \int_T \epsilon_k(t) dt \leq \epsilon. \end{aligned}$$

Since the suboptimal estimate (38) has been calculated in the absence of constraints (4), then it is obvious that

$$J(u^0) - J(u) \leq \beta(\tau_{sup}, u) \leq \epsilon.$$

This proves the  $\epsilon$ -optimality property of the admissible control  $\{u_k(t), t \in T, k \in K\}$ .

For the converse argument, let  $\{u_k(t), t \in T, k \in K\}$  be an  $\epsilon$ -optimal admissible control, and let  $\{\tau_{sup}^k, k \in K\}$  be an arbitrary support. Then the suboptimal estimate of the control corresponding to the chosen support is given by

$$(42) \quad \beta(\tau_{sup}, u) = \sum_{k=1}^N \int_T \Delta_k(t) u_k(t) dt + \sum_{k=1}^N \int_{T_k^+} \Delta_k(t) dt - \sum_{k=1}^N \int_{T_k^-} \Delta_k(t) dt.$$

Also introduce the following dual optimization problem:

$$(43) \quad \min_{y,v,w} I(y,v,w), \quad I(y,v,w) = \sum_{k \in K} \left[ h_k^T y_k + \int_T v_k(t) dt + \int_T w_k(t) dt \right],$$

subject to

$$(44) \quad \sum_{s=k}^N y_s^T g_{sk}(t) - v_k(t) + w_k(t) = c_k(t), \quad v_k(t) \geq 0, \quad w_k(t) \geq 0, \quad t \in T, \quad k \in K.$$

At this stage we have to check that this dual optimization problem has a nonempty set of admissible variables  $z_k = \{y_k, v_k, w_k, k \in K\}$ . Suppose therefore that we denote the chosen support by  $\tau_{sup}^k, k \in K$ , and then use (18) to construct the vectors  $z_k = \{y_k, v_k, w_k, k \in K\}$  as

$$\begin{aligned} y_k &= \nu_k, \quad \nu_k(t) = \Delta_k(t); \quad w_k(t) = 0 \text{ if } \Delta_k(t) \geq 0, \\ v_k(t) &= 0, \quad w_k(t) = \Delta_k(t) \text{ if } \Delta_k(t) < 0. \end{aligned}$$

Then, by (18), these satisfy the constraint (44) of the dual problem. Also since this dual problem has a nonempty set of feasible variables

$$\{y_k, v_k, w_k, k \in K\},$$

it is routine to show that it has an optimal solution if there exists an optimal control for (1)–(4).

Let  $\{y_k^0, v_k^0(t), w_k^0(t), t \in T, k \in K\}$  denote an optimal solution of (43)–(44). Then (43) and (18) yield

$$\begin{aligned} \beta(\tau_{sup}, u) &= \sum_{k=1}^N \sum_{s=k}^N \int_T \nu_s^T(t) g_{sk}(t) u_k(t) dt - \sum_{k=1}^N \int_T c_k^T(t) u_k(t) dt \\ &\quad + \sum_{k=1}^N \int_T v_k(t) dt - \sum_{k=1}^N \int_T w_k(t) dt \\ &= \left[ \sum_{k=1}^N (\nu^k)^T \sum_{s=1}^k \int_T g_{ks}(t) u_s(t) dt + \sum_{k=1}^N \int_T v_k(t) dt - \sum_{k=1}^N \int_T w_k(t) dt \right] \\ &\quad - \left[ \sum_{k=1}^N \sum_{s=k}^N \int_T (y_s^0)^T g_{sk}(t) u_k^0(t) dt + \sum_{k=1}^N \int_T v_k^0(t) dt - \sum_{k=1}^N \int_T w_k^0(t) dt \right] \\ &\quad + \sum_{k=1}^N \int_T c_k(t) u_k^0(t) dt - \sum_{k=1}^N \int_T c_k(t) u_k(t) dt \\ &= \left[ \sum_{k=1}^N (\nu^k)^T h_k + \sum_{k=1}^N \int_T (v_k(t) - w_k(t)) dt \right] \\ &\quad - \left[ \sum_{k=1}^N (y_k^0)^T h_k + \sum_{k=1}^N \int_T (v_k^0(t) - w_k^0(t)) dt \right] \\ &\quad + \sum_{k=1}^N \int_T c_k(t) u_k^0(t) dt - \sum_{k=1}^N \int_T c_k(t) u_k(t) dt. \end{aligned}$$

Hence the suboptimal estimate can be written in the form

$$(45) \quad \beta(\tau_{sup}, u) = \beta_{sup} + \beta_u,$$

where

$$(46) \quad \beta_{sup} = \sum_{k=1}^N h_k^T(\nu_k - y^{0k}) + \sum_{k=1}^N \int_T \left[ (v_k(t) - v_k^0(t)) - (w_k(t) - w_k^0(t)) \right] dt$$

denotes the nonoptimality measure of the chosen support  $\{\tau_{sup}^k, k \in K\}$  and

$$(47) \quad \beta_u = \sum_{k=1}^N \int_T c_k(t)(u_k(t) - u_k^0(t)) dt$$

denotes the nonoptimality measure of the given control function  $\{u_k(t), t \in T, k \in K\}$ .

Now choose the support  $\tau_{sup}^0 = \{\tilde{\tau}_{sup}^k, k \in K\}$  such that the corresponding collection  $z_k^0 = \{y_k^0, v_k^0, w_k^0, k \in K\}$  of dual variables is an optimal solution of (43)–(44). Then the support  $\tau_{sup}^0 = \{\tilde{\tau}_{sup}^k(\epsilon), k \in K\}$  is the one required for the given  $\epsilon$ -optimal control functions  $\{u_k(t), k \in K\}$ , since  $\beta_{sup} = 0$ , and then  $\beta = \beta(u, \tau_{sup}^0) = \beta_u \leq \epsilon$ . Next set

$$\begin{aligned} \epsilon_k(t) &= \Delta_k(t)(u_k(t) + 1), \quad t \in T_k^+, \\ \epsilon_k(t) &= \Delta_k(t)(u_k(t) - 1), \quad t \in T_k^-, \\ \epsilon_k(t) &= 0 \quad \text{if } \Delta_k(t) = 0, \quad t \in T, \end{aligned}$$

and note from the definition of  $\Delta_k(t)$  that

$$\begin{aligned} \epsilon_k(t) &= -\psi_k^T(t)b(u_k(t) + 1) = \psi_k^T(t)(Ax_k(t) + Dx_{k-1}(t) + b(-1)) \\ &\quad - \psi_k^T(t)(Ax_k(t) + Dx_{k-1}(t) + bu_k(t)) \quad \text{if } \psi_k(t)b < 0, \\ \epsilon_k(t) &= \psi_k^T(t)(Ax_k(t) + Dx_{k-1}(t) + b(+1)) \\ &\quad - \psi_k^T(t)(Ax_k(t) + Dx_{k-1}(t) + bu_k(t)) \quad \text{if } \psi_k(t)b > 0, \\ \epsilon_k(t) &= 0 \quad \text{if } \psi_k(t)b = 0, \quad t \in T, \quad k \in K. \end{aligned}$$

Use of the Hamiltonian (35) now enables these last expressions to be written in the form

$$\epsilon_k(t) = \max_{|v| \leq 1} H_k(x_{k-1}(t), x_k(t), \psi_k, v) - H_k(x_{k-1}(t), x_k(t), \psi_k, u_k(t)), \quad t \in T, \quad k \in K.$$

Finally, noting that  $\{u_k(t)\}$  is a suboptimal control yields

$$\begin{aligned} \sum_{k=1}^N \int_T \epsilon_k(t) dt &= \sum_{k=1}^N \int_{T_k^+} \Delta_k(t)(u_k(t) + 1) dt \\ &\quad + \sum_{k=1}^N \int_{T_k^-} \Delta_k(t)(u_k(t) - 1) dt = \beta(u, \tau_{sup}^0) = \beta_u \leq \epsilon, \end{aligned}$$

and the proof is complete.  $\square$

The maximum principle now follows from this last result on setting  $\epsilon = 0$  as stated formally in the following corollary.

**COROLLARY 2.** *The admissible control  $\{u_k^0(t), k \in K, t \in T\}$  is optimal if and only if there exists a support  $\{\tau_{sup}^{0k}, k \in K\}$  such that the supporting control  $\{u_k^0(t), \tau_{sup}^{0k}, t \in T, k \in K\}$  satisfies the maximum conditions*

$$\max_{|v| \leq 1} H_k(x_{k-1}^0(t), x_k^0(t), \psi_k, v) = H_k(x_{k-1}^0(t), x_k^0(t), \psi_k, u_k^0(t))$$

for all  $k \in K, t \in T$ , where  $\psi_k(t)$  are the corresponding solutions of (34).

**4. Differentiable properties of the optimal solutions.** An important aspect of the optimization theory is sensitivity analysis of optimal controls since, in practice, the system considered can be subject to disturbances or parameters in the available model can easily arise. Mathematically, perturbations can, for example, be described by some parameters in the initial data, boundary conditions, and control and state constraints. Hence it is clearly important to know how a problem solution depends on these parameters, and in this section we aim to characterize the changes in the solutions developed due to “small” perturbations in the parameters. This could, in turn, enable us to design fast and reliable real-time algorithms to correct the solutions for these effects. As shown next, the major advantage of the constructive approach developed in this paper is that the sensitivity analysis and some differential properties of the optimal controls under disturbances can be analyzed.

Suppose that disturbances influence the initial data for (1)–(4). In particular, consider the system (1)–(4) on the interval  $T_s = [s, \alpha]$  with the initial data  $x_k(s) = z_k, z_k \in G_k, k \in K$ , where  $G_k \subset \mathbb{R}^n$  is some neighborhood of the point  $x_k = d_k$  and  $s$  belongs to the neighborhood  $G_0$  of  $t = 0$ . We also assume that the following regularity condition holds: For the given disturbance domain  $G_k, k \in K \cup \{0\}$ , the structure of the optimal control functions for the nondisturbed data is preserved; i.e., the number of switching instances together with their order is constant.

Using Theorem 1, the optimal controls  $\{u_k^0(t, s, z), k \in K\}$  are determined by the supporting time instances  $\tau_{kj} = \tau_{kj}(s, z), k \in K, j = 1, \dots, m$ , which are dependent on the disturbances  $(s, z_k), s \in G_0, z_k \in G_k, k \in K$ . Here we study the differential properties of the functions  $\tau_{kj} = \tau_{kj}(s, z), k \in K, j = 1, \dots, m$ , and for ease of notation we set  $\tau \equiv \tau(s, z) = \{\tau_{kj}(s, z), k \in K, j = 1, \dots, m\}, z = \{z_k, k \in K\}$  in what follows.

**THEOREM 3.** *If (1)–(4) is regular, then for any  $k \in K$  and  $j = 1, \dots, m$  the functions  $\tau_{kj} = \tau_{kj}(s, z)$  are differentiable in the domain  $G_0 \times G_k \subset \mathbb{R} \times \mathbb{R}^n$ .*

*Proof.* Using (10)–(11) and Theorem 1 it follows immediately that the switching instances  $\tau_{kj} = \tau_{kj}(s, z), k \in K, j = 1, \dots, m$ , of the optimal bang-bang control  $\{u_k^0(t, s, z), k \in K\}$  for (1)–(4) in this case are the solutions of the following optimization problem:

$$(48) \quad \max_{\tau_{kj}} \sum_{k \in K} R_k(s, z) \sum_{j=1}^{m+1} (-1)^j \int_{\tau_{kj-1}}^{\tau_{kj}} c_k(t) dt,$$

subject to

$$(49) \quad \sum_{l \in K} R_l(s, z) \sum_{j=1}^{m+1} (-1)^j \int_{\tau_{lj-1}}^{\tau_{lj}} g_{kl}(t) dt = h_k(s, z), \quad k \in K.$$

Here the constant  $R_k(s, z) = \pm 1$  denotes the value ( $u = +1$  or  $u = -1$ ) of the optimal control on pass  $k$  over the first control interval  $t \in [s, \tau_{k1}]$ , and

$$(50) \quad h_k(s, z) = o_k - \sum_{j=1}^k H_k K_j(\alpha) z_{k+1-j} - \int_s^\alpha H_k K_k(\alpha - t) Df(t) dt.$$

Also it is clear that the switching instances  $\tau_{kj} = \tau_{kj}(s, z)$  satisfy

$$\tau_{k0} < \tau_{k1} < \tau_{k2} < \cdots < \tau_{km} < \tau_{km+1}, \quad \tau_{k0} = s, \quad \tau_{km+1} = \alpha.$$

Since  $\{u_k^0, \tau_{sup}^0, k \in K\}$  is the optimal supporting control for (1)–(4) in the absence of disturbances, the optimization problem (48)–(49) has the optimal solution  $\tau_{kj}^0, k \in K, j = 1, \dots, m$  at  $s = 0, z_k = \alpha_k, k \in K, j = 1, \dots, m$ . Hence there exist Lagrange multipliers  $\lambda_k^0 \in \mathbb{R}^m, k \in K$ , which are not simultaneously equal to zero, such that the collection  $\{\lambda_k^0, \tau_{kj}^0\}$  is a stationary point for the following Lagrange function associated with the optimization problem (48)–(49):

$$(51) \quad \begin{aligned} L(\lambda, \tau_{sup}) = & \sum_{k \in K} R_k(s, z) \sum_{j=1}^{m+1} (-1)^j \int_{\tau_{kj-1}}^{\tau_{kj}} c_k(t) dt \\ & + \sum_{k \in K} \lambda_k \left[ \sum_{l \in K} R_l(s, z) \sum_{j=1}^{m+1} (-1)^j \int_{\tau_{lj-1}}^{\tau_{lj}} g_{kl}(t) dt - h_k(s, z) \right]. \end{aligned}$$

The well-known stationarity conditions for a Lagrange function now yield

$$(52) \quad 2R_k(s, z) \left[ c_k(\tau_{kj}) + \sum_{l=k}^N \lambda_l g_{lk}(\tau_{kj}) \right] = 0, \quad j = 1, \dots, m, \quad k \in K,$$

$$(53) \quad \sum_{l=1}^k R_l(s, z) \sum_{j=1}^{m+1} (-1)^j \int_{\tau_{lj-1}}^{\tau_{lj}} g_{kl}(t) dt - h_k(s, z) = 0, \quad k \in K,$$

with respect to the unknown  $\lambda_k$  and  $\tau_k(s, z)$ ,  $k \in K, j = 1, \dots, m$ . Also the Jacobian matrix  $D$  of the mapping (52) with respect to variables  $(\lambda, \tau_{sup})$  calculated at  $s = 0$  and  $z_k = \alpha_k$  can be written in the form

$$(54) \quad D = \prod_{k \in K} 2R_k(0, \alpha) \begin{pmatrix} \hat{G}_{sup} & F \\ 0 & \hat{G}_{sup} \end{pmatrix},$$

where (see also (15) for the notation here) the matrix  $\hat{G}_{sup}$  is given by

$$(55) \quad \hat{G}_{sup} = \begin{pmatrix} g_{kj}(t), & t \in \tau_{sup}^j \\ j \leq k \leq N, & j = 1, \dots, N \end{pmatrix},$$

and the matrix  $F$  is formed from the derivatives of the functions  $c_k(t), g_{kl}(t)$  evaluated at the corresponding points. By the definition of the supporting time instances we have  $\det D \neq 0$ , and by the implicit function theorem there exists a neighborhood of the point  $(0, \alpha_k, k \in K)$  where (52) has a unique solution  $\lambda = \lambda(s, z)$ ,  $\tau_{kj} = \tau_{kj}(s, z)$ , and these functions are also differentiable. This completes the proof.  $\square$

The differential properties of the optimal controls developed above can be used for sensitivity analysis and the solution of the synthesis problem considered here. In

particular, the supporting control approach [10] can be used to produce the differential equations for the switching time functions  $\tau(s, z)$  necessary to design the optimal controllers. In a similar manner to [6] it can be shown that these satisfy the following differential equations:

$$(56) \quad G \frac{\partial \tau}{\partial s} + Q = \frac{\partial h}{\partial s}, \quad P \frac{\partial \tau}{\partial z} = \frac{\partial h}{\partial z},$$

where  $h(s, z) = (h_1(s, z), \dots, h_m(t, s))$  is an  $mN \times 1$ -vector given by (50) and the matrices  $G, Q, P$  are defined (see [6]) by those defining the process dynamics and information associated with the disturbance-free optimal solution. For example (see also (13)),  $G = \Lambda \tilde{G}_{sup}$ , where the compatibly dimensioned block matrix  $\Lambda$  is constructed by the disturbance-free optimal control values  $u_k^0(t); k = 1, \dots, N$  calculated in the supporting moments  $\tau_{kj}$  from  $\tau_{sup}^0$ . Also, by Theorem 1, these values are equivalent to the values of  $\frac{d\Delta_i(\tau_{kj})}{dt}$  evaluated for the corresponding indexes  $i; j; k$ , where the functions  $\Delta_i(t); i = 1, \dots, N$  are designed using the switching times of the basic optimal control function. Note also that analogous differential equations can be established for the optimal values of the cost function (treated as the function  $J(s, z) \equiv J(u(\tau(s, z)))$ ).

*Remark 5.* The equations (56) are (sometimes) termed Pfaff differential equations and model an essentially distinct class of continuous  $nD$  systems. The main characteristic feature of this model is that it is overdetermined (the number of equations exceeds the unknown functions). It can also be shown that if the nondegenerate assumption on the supporting control functions holds, then so do the so-called Frobenius conditions which guarantee the existence and uniqueness of solutions of the Pfaff differential equations.

**5. An example.** In order to demonstrate the advantages of the supporting control function approach, we give an example where, as a preliminary, it is instructive to consider the case of  $N = 1$  and, in particular,

$$(57) \quad \max_{|u| \leq 1} J(u), \quad J(u) := x^{(2)}(1),$$

for

$$(58) \quad \begin{aligned} \frac{dx^{(1)}(t)}{dt} &= x^{(2)}, & x^{(1)}(t), x^{(2)}(t) &\in \mathbb{R}, & t &\in [s, 1], \\ \frac{dx^{(2)}(t)}{dt} &= u(t), & x^{(1)}(s) &= z_1, & x^{(2)}(s) &= z_2, \end{aligned}$$

subject to the following constraints on the control signal and a terminal state constraint, respectively:

$$(59) \quad |u(t)| \leq 1, \quad x^{(1)}(1) = 1/8.$$

Note that here the superscript  $(\cdot)$  is used to denote a particular element in the state vector.

In this case it is easy to verify that for  $s = 0$  and  $x^{(1)}(0) = 0$ ,  $x^{(2)}(0) = 0$  the optimal control signal is given by

$$u^0(t) = -1 \quad \text{for} \quad 0 \leq t \leq 1 - \sqrt{5/8} \quad \text{and} \quad u^0(t) = +1 \quad \text{for} \quad 1 - \sqrt{5/8} < t \leq 1.$$

Synthesis of the optimal control can be realized using the switching instance function  $\tau = \tau(z_1, z_2, s)$ , which has to satisfy the following differential equations:

$$(60) \quad \frac{\partial \tau}{\partial z_1} = \frac{1}{2(1-\tau)},$$

$$\frac{\partial \tau}{\partial z_2} = \frac{1-s}{2(1-\tau)},$$

$$(61) \quad \frac{\partial \tau}{\partial s} = \frac{1-s-z_2}{2(1-\tau)},$$

with the initial condition

$$\tau(0, 0, 0) = 1 - \sqrt{5/8},$$

which is a particular case of (56).

The solution of this Pfaff differential system is given by

$$\tau(z_1, z_2, s) = 1 - \sqrt{5/8 + (s-1)z_2 - z_1 - s + s^2/2}.$$

Also, without loss of generality, assume  $s = 0$ , and then the optimal switching function is

$$\tau(z_1, z_2, 0) = 1 - \sqrt{5/8 - z_1 - z_2}.$$

Figures 1 and 2 illustrate the form of this solution. In particular, Figure 1 shows the state-space variables together with additional variable  $t$ . The optimal trajectories (57)–(59) corresponding to the bang-bang control law lie on the parabolic cylinders  $(Z_1) : x^{(1)} = -\frac{1}{2}(x^{(2)})^2 + C_1 + C_2$  and  $(Z_2) : x^{(1)} = +\frac{1}{2}(x^{(2)})^2 + \tilde{C}_1 + \tilde{C}_2$ , where the constants  $C_i, \tilde{C}_i$ ,  $i = 1, 2$ , are determined by the initial data  $x^{(1)}(0) = z_1$ ,  $x^{(2)}(0) = z_2$ . These cylinders correspond to the solutions of differential equations (58) with  $u \equiv -1$  or  $u \equiv +1$ , respectively. It can also be shown that the admissible initial domain for which the problem can be solved is determined by the inequalities:  $-\frac{3}{8} \leq z_1 + z_2 \leq \frac{5}{8}$ . The switching manifold  $Z_h$  is described in parametric form by

$$\begin{aligned} x^{(1)} &= -\frac{(1 - \sqrt{5/8 - z_2 - z_1})^2}{2} + z_2(1 - \sqrt{5/8 - z_2 - z_1}) + z_1, \\ x^{(2)} &= -1 + \sqrt{5/8 - z_2 - z_1} + z_2, \\ T &= 1 - \sqrt{5/8 - z_2 - z_1} - \frac{3}{8} \leq z_1 + z_2 \leq \frac{5}{8}. \end{aligned}$$

Finally, each optimal trajectory consists of two parts—first it evolves along the vertical parabolic cylinder  $Z_1$  until  $\tau = 1 - \sqrt{5/8 - z_2 - z_1}$ , when it meets the switching manifold  $Z_h$ , and then immediately is switched to continue along the second vertical cylinder  $Z_2$  to meet the target plane  $x^{(1)} = 1/8$ . Figure 1 also shows the optimal trajectory in the space  $R^3$  for zero initial data, and Figure 2 shows the projection of this trajectory onto the  $x^{(1)}, x^{(2)}$  plane.

Consider now the following example where  $N = 2$  (again the superscript  $(\cdot)$  is used to denote a particular element in the state or control vector on any pass):

$$(62) \quad \max_{u_1, u_2} J(u), \quad J(u) := x_1^{(2)}(1) + x_2^{(2)}(1),$$

FIG. 1. *Optimal control synthesis.*

FIG. 2. *Projection on the  $x_1$ - $x_2$  plane.*

for the process

$$(63) \quad \begin{aligned} \frac{dx_1^{(1)}(t)}{dt} &= x_1^{(2)}(t), & \frac{dx_2^{(1)}(t)}{dt} &= x_2^{(2)}(t), \quad t \in [s, 1], \\ \frac{dx_1^{(2)}(t)}{dt} &= u_1(t), & \frac{dx_2^{(2)}(t)}{dt} &= x_1^{(1)}(t) + u_2(t), \end{aligned}$$

with boundary conditions of the form

$$(64) \quad x_1^{(1)}(s) = z_1^{(1)}, \quad x_1^{(2)}(s) = z_1^{(2)}, \quad x_2^{(1)}(s) = z_2^{(1)}, \quad x_2^{(2)}(s) = z_2^{(2)},$$

subject to

$$(65) \quad x_1^{(1)}(1) = 1/8, \quad x_2^{(1)}(1) = 1/384, \quad |u_1(t)| \leq 1, \quad |u_2(t)| \leq 1.$$

Equivalently, we can write the problem here as

$$(66) \quad \begin{bmatrix} \dot{x}_{k+1}^{(1)}(t) \\ \dot{x}_{k+1}^{(2)}(t) \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} x_{k+1}^{(1)}(t) \\ x_{k+1}^{(2)}(t) \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} x_k^{(1)}(t) \\ x_k^{(2)}(t) \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} u_{k+1}(t), \quad k = 0, 1.$$

Without loss of generality we set  $x_0(t) = 0$ ,  $t \in [s, 1]$ .

To apply the results developed here to this example we first rewrite (63)–(65) in the following integral form:

$$\max_{u_1, u_2} \left\{ z_2^{(1)} + z_2^{(2)} + (1-s)z_1^{(1)} + \frac{(1-s)^2}{2}z_2^{(2)} + \int_s^1 \frac{(1-t)^2 + 2}{2}u_1(t)dt + \int_s^1 u_2(t)dt \right\}, \quad (67)$$

subject to

$$\begin{aligned} \int_s^1 (1-t)u_1(t)dt &= \frac{1}{8} - z_1^{(1)} + (1-s)z_1^{(2)}, \\ \int_s^1 \left[ \frac{(1-t)^3}{6}u_1(t) + (1-t)u_2(t) \right] dt &= \frac{1}{384} - z_2^{(1)} - (1-s)z_2^{(2)} - \frac{(1-s)^2}{2}z_1^{(1)} \\ &\quad - \frac{(1-s)^3}{6}z_1^{(2)}. \end{aligned} \quad (68)$$

Hence

$$\begin{aligned} g_{11}(t) &= 1-t, \quad g_{21}(t) = \frac{(1-t)^3}{6}, \quad g_{22}(t) = 1-t, \\ c_1(t) &= \frac{(1-t)^2 + 2}{2}, \quad c_2(t) = 1, \end{aligned} \quad (69)$$

and the multipliers required to design the cocontrol function  $\Delta_i(t)$ ,  $i = 1, 2$ , can, by noting (12), be written as

$$(70) \quad \nu^{(2)}g_{22}(\tau_{2sup}) - c_2(\tau_{2sup}) = 0, \quad \nu^{(1)}g_{11}(\tau_{1sup}) + \nu^{(2)}g_{21}(\tau_{1sup}) - c_1(\tau_{1sup}) = 0.$$

We now have that

$$\begin{aligned} \Delta_1(t) &= (1-t) \left[ \frac{1}{1-\tau_{1sup}} + \frac{1-\tau_{1sup}}{2} - \frac{(1-\tau_{1sup})^2}{6(1-\tau_{2sup})} \right] + \frac{(1-t)^3}{6(1-\tau_{2sup})} - \frac{(1-t)^2}{2} - 1, \\ \Delta_2(t) &= \frac{1-t}{1-\tau_{2sup}} - 1, \end{aligned} \quad (71)$$

and the problem is to find the basic optimal trajectory when all variables in (64) are zero, i.e.,

$$(72) \quad s = 0, \quad x_1^{(1)}(0) = 0, \quad x_1^{(2)}(0) = 0, \quad x_2^{(1)}(0) = 0, \quad x_2^{(2)}(0) = 0.$$

Take the supporting instances as

$$(73) \quad \tau_{1sup} = 1 - \sqrt{\frac{5}{8}}, \quad \tau_{2sup} = 1 - \sqrt{\frac{131}{256}}.$$

Then it follows immediately from Theorem 1 that the optimal control functions for (62)–(65) with initial data (72) are given by

$$\begin{aligned} u_1^0(t) &= \begin{cases} -1, & 0 \leq t < 1 - \sqrt{\frac{5}{8}}, \\ +1, & 1 - \sqrt{\frac{5}{8}} \leq t \leq 1, \end{cases} \\ u_2^0(t) &= \begin{cases} -1, & 0 \leq t < 1 - \sqrt{\frac{131}{256}}, \\ +1, & 1 - \sqrt{\frac{131}{256}} \leq t \leq 1, \end{cases} \end{aligned} \quad (74)$$

and (56) gives the switching functions  $\tau_1 \equiv \tau_1(z_1^{(1)}, z_1^{(2)}, s)$ ,  $\tau_2 \equiv \tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s)$  as

$$\begin{aligned}
 & -2 \frac{\partial \tau_2}{\partial s} (1 - \tau_2) - \frac{2(1 - \tau_1)^3}{6} \frac{\partial \tau_1}{\partial s} = \frac{(1 - s)^2}{2} z_1^{(2)} + (1 - s) z_1^{(1)} \\
 & \quad + z_2^{(2)} - \frac{(1 - s)^3}{6} - (1 - s) \\
 & \quad - 2 \frac{\partial \tau_2}{\partial z_1^{(1)}} (1 - \tau_2) - \frac{(1 - \tau_1)^3}{3} \frac{\partial \tau_1}{\partial z_1^{(1)}} \\
 & = -\frac{(1 - s)^2}{2} - 2 \frac{\partial \tau_2}{\partial z_1^{(2)}} (1 - \tau_2) - \frac{(1 - \tau_1)^3}{3} \frac{\partial \tau_1}{\partial z_1^{(2)}} \\
 & = -\frac{(1 - s)^3}{6} - 2 \frac{\partial \tau_2}{\partial z_2^{(1)}} (1 - \tau_2) = -1, \\
 (75) \quad & -2 \frac{\partial \tau_2}{\partial z_2^{(2)}} (1 - \tau_2) = -(1 - s),
 \end{aligned}$$

with initial conditions

$$(76) \quad \tau_1(0, 0, 0) = 1 - \sqrt{\frac{5}{8}}, \quad \tau_2(0, 0, 0, 0, 0) = 1 - \sqrt{\frac{131}{16^2}}.$$

The solutions of this differential system are

$$\begin{aligned}
 & \tau_1(z_1^{(1)}, z_1^{(2)}, s) = 1 - \sqrt{SR_1(z_1^{(1)}, z_1^{(2)}, s)}, \\
 (77) \quad & \tau^{(2)}(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s) = 1 - \sqrt{SR_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s)},
 \end{aligned}$$

where

$$\begin{aligned}
 & SR_1(z_1^{(1)}, z_1^{(2)}, s) = \frac{5}{8} + (s - 1)z_1^{(2)} - z_1^{(1)} - s + s^2/2, \\
 & SR_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s) = \frac{131}{256} + \frac{2s^4 - 8s^3 + 59s^2 - 102s}{96} + \frac{-20s^2 + 40s - 19}{48} z_1^{(1)} \\
 & \quad - \frac{1}{12} z_1^{(1)2} + \frac{4s^3 - 12s^2 + 11s - 3}{48} z_1^{(2)} + \frac{-s^2 + 2s - 1}{12} z_1^{(2)2} \\
 (78) \quad & \quad + \frac{s z_1^{(1)} z_1^{(2)}}{6} - \frac{z_1^{(1)} z_1^{(2)}}{6} - z_1^{(2)} + (s - 1) z_2^{(2)}.
 \end{aligned}$$

It easy to see that the solution of the differential equations describing the process dynamics with both  $u_1$  and  $u_2$  constant is

$$\begin{aligned}
 & x_1^{(1)}(t) = u_1 \frac{t^2}{2} + tC_1 + C_2, \\
 & x_1^{(2)}(t) = u_1 t + C_1, \\
 & x_2^{(1)}(t) = u_1 \frac{t^4}{24} + C_1 \frac{t^3}{6} + C_2 \frac{t^2}{2} + u_2 \frac{t^2}{2} + tC_3 + C_4, \\
 (79) \quad & x_2^{(2)}(t) = u_1 \frac{t^3}{6} + C_1 \frac{t^2}{2} + tC_2 + tu_2 + C_3
 \end{aligned}$$

and in this case that the optimal control for pass  $k = 1$  coincides with that given earlier in this example.

Now consider disturbances  $\Omega$  such that the optimal control is preserved for the case of zero initial conditions, i.e.,  $u_1 = -1$  for  $t \leq \tau_1(z_1^{(1)}, z_1^{(2)}, s)$ ,  $u_2^0 = -1$  for  $t \leq \tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s)$ , and the inequality  $\tau_1(z_1^{(1)}, z_1^{(2)}, s) < \tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s)$  holds. Using (77) we have that the domain  $\Omega$  is described by

$$0 \leq \tau_1(z_1^{(1)}, z_1^{(2)}, s) < \tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s) \leq 1,$$

$$SR_1(z_1^{(1)}, z_1^{(2)}, s) \geq 0, \quad SR_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s) \geq 0.$$

To construct the solution for pass  $k = 2$ , it is necessary to construct the switching surface  $F$ , which is defined by the vectors

$$x_2^{(1)}(t) \big|_{t=\tau_2} = x_2^{(1)}(\tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s), \tau)$$

$$x_2^{(2)}(t) \big|_{t=\tau_2} = x_2^{(2)}(\tau_2(z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s)),$$

when the parameters  $z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s$  are members of the set  $\Omega$ . The parametric description of the switching surface in this case is given by

$$x_2^{(1)}(t) = -\frac{t^4}{24} + C_1 \frac{t^3}{6} + C_2 \frac{t^2}{2} - \frac{t^2}{2} + tC_3 + C_4,$$

$$(80) \quad x_2^{(2)}(t) = -\frac{t^3}{6} + C_1 \frac{t^2}{2} + tC_2 - t + C_3,$$

where the coefficients  $C_i$  are found from the parameters  $z_1^{(1)}, z_2^{(1)}, z_1^{(2)}, z_2^{(2)}, s$ .

**6. Conclusions.** In this paper the supporting control functions approach has been applied to study an optimal control problem for differential linear repetitive processes. The main contribution is the development of constructive necessary and sufficient optimality conditions in forms which can be effectively used for the design of numerical algorithms. The iterative method developed in this work is based on the principle of decrease of the suboptimality estimate; i.e., the iteration  $\{\tau_{sup}^k, u_k(t), k = 1, \dots, N\} \rightarrow \{\hat{\tau}_{sup}^k, \hat{u}_k(t), k = 1, \dots, N\}$  is performed in such a way as to achieve  $\beta(\hat{\tau}_{sup}, \hat{u}) < \beta(\tau_{sup}, u)$ . Also this procedure can be separated into two stages: (i) transformation of the admissible control functions  $\{u_k(t), k = 1, \dots, N\} \rightarrow \{\hat{u}_k(t), k = 1, \dots, N\}$ , which decreases the nonoptimality measure of the admissible controls  $\beta(\hat{u}) < \beta(u)$ , and (ii) variation of the support  $\{\tau_{sup}^k, k = 1, \dots, N\} \rightarrow \{\hat{\tau}_{sup}^k, k = 1, \dots, N\}$  to again decrease the nonoptimality measure of the support, i.e.,  $\beta(\hat{\tau}_{sup}) < \beta(\tau_{sup})$ . These transformations involve, in effect, the duality theory for the problems defined in this work by (1)–(4) and (43)–(44) and exploit the  $\epsilon$ -optimality conditions also developed in this work. These results are the first in this general area, and work is currently proceeding in a number of followup areas. One such area is sensitivity analysis of optimal control in the presence of disturbances, where in the case of the ordinary linear control systems some work on this topic can be found in, for example, [12].

## CONNECTIONS BETWEEN SINGULAR CONTROL AND OPTIMAL SWITCHING\*

XIN GUO<sup>†</sup> AND PASCAL TOMECEK<sup>‡</sup>

**Abstract.** This paper builds a new theoretical connection between singular control of finite variation and optimal switching problems. This correspondence provides a novel method for solving high-dimensional singular control problems and enables us to extend the theory of reversible investment: Sufficient conditions are derived for the existence of optimal controls and for the regularity of value functions. Consequently, our regularity result links singular controls and Dynkin games through sequential optimal stopping problems.

**Key words.** singular stochastic control, optimal switching, Dynkin games, reversible investment

**DOI.** 10.1137/060669024

**1. Introduction with a motivating control problem.** Let  $(\Omega, \mathcal{F}, P)$  be a complete probability space and  $\mathbb{F} = \{\mathcal{F}_t; 0 \leq t < \infty\}$  a completed filtration that is right continuous. Consider the following (motivating) singular control problem from [33]:

(1)

$$V(x, y) = \sup_{(\xi^+, \xi^-) \in \mathcal{A}} E \left[ \int_0^\infty e^{-rt} h(X_t, Y_t) dt - K^+ \int_0^\infty e^{-rt} d\xi_t^+ - K^- \int_0^\infty e^{-rt} d\xi_t^- \right],$$

where  $Y_t = y + \xi_t^+ - \xi_t^-$ ,  $(\xi_t^+, \xi_t^-)_{t \geq 0}$  is a pair of  $\mathbb{F}$ -adapted, nondecreasing càglàd processes,  $X_t$  is a diffusion process with  $X_0 = x$ ,  $h(X_t, Y_t)$  is a concave function of  $Y_t$  satisfying appropriate integrability conditions, and  $K^+, K^-, r > 0$  are some constants. Here the supremum is taken over the set  $\mathcal{A}$  of all singular controls with a finite variation.

This multidimensional control problem and its variants have been studied extensively in both the mathematics and the economics literature. For example, taking  $h$  as a concave function with a special additive form  $h(X_t + Y_t)$  and  $K^- + K^+ \geq 0$ , this is the well-known monotone fuel follower problem, for which explicit solutions can be found in [4, 5, 6, 25, 24]. In mathematical economics, (1) is a typical (ir)reversible investment problem in which a company, by adjusting its production capacity through expansion and contraction according to market fluctuations, wishes to maximize its overall expected net profit over an infinite horizon. Under the special additive form (again) of  $h(X_t + Y_t)$ , with  $X_t + Y_t = y + \mu t + \sigma W_t + \xi_t^+$  and  $\xi_t^- = K^- = 0$ , this problem has been investigated by numerous authors (see, for instance, [14, 31, 1, 2, 34, 36, 13, 3, 21]). With another special form of  $h(1 - Y_t + X_t Y_t)$ , where  $h$  is a power function,  $K^- = K^+ = 0$ , and  $Y_t \in [0, 1]$ , the problem was analyzed

via a dimension reduction technique in [35]. For a standard reference on irreversible investment, see [15].

Most recently, [33] treated this problem with a more general and genuinely high-dimensional form, where  $X_t$  is a geometric Brownian motion and  $h$  is a function of both  $X_t$  and  $Y_t$ , subject to some technical conditions. They used the traditional approach of the dynamic programming principle: First construct (by ad hoc methods) a solution to the Bellman equation and then validate the optimality of the solution by a sufficient verification theorem for smooth functions.

In this paper, we establish a generic theoretical connection between singular control and optimal switching problems: We define a consistency property for collections of switching controls and prove that there is an exact correspondence between the set of finite variation càglàd processes and the set of consistent collections of switching controls. We then apply this correspondence, in conjunction with direct integration arguments, to obtain an integral representation for the value function of a very general reversible investment problem in terms of the values of corresponding optimal switching problems. Finally, we exploit this representation to study the regularity of the value function and to obtain sufficient conditions on the existence of optimal controls. As a corollary, we are able to represent the value of a Dynkin game as the difference between the values of two related switching problems, thereby linking the general reversible investment problem, the Dynkin game, and the optimal switching problem.

It is worth pointing out that this approach of connecting singular control problems and related optimal stopping problems dates back to the seminal paper of [4] and has since been developed and applied to monotone singular control problems in [25, 26, 27, 28, 29, 17, 18, 19, 2].<sup>1</sup> Indeed, our integral representation theorem for the reversible investment problem is in part inspired by the elegant integration arguments of [2] for irreversible investment. Another closely related body of work is [11, 8, 9, 10]. However, the connections between the singular control problem, the entry-exit problem, and Dynkin's game in their works are established within the framework of forward backward stochastic differential equations and require a finite time horizon with the restrictive assumption that the control has only an additive affect on the diffusion. As such, their results cannot be used to solve the more general reversible investment problems such as (1).

Compared to all previous works and approaches, the correspondence between singular controls and switching controls in our paper *does not depend on the specific form of the control problem*. Thus, our methodology applies to cases for which  $X_t$  can be any diffusion process other than the geometric Brown motion and to cases for which the running payoff function  $h$  is a *general and nonsmooth function* of both the diffusion  $X_t$  and the control process  $Y_t$ . In fact, our method is applicable when the *underlying randomness is not necessarily captured by a diffusion*. This enables us to solve very general reversible investment problems. In particular, when  $h$  is smooth enough, the regularity assumptions for the value function in [33] are recovered.

The organization of the paper is as follows. In section 2, we define consistent collections of switching controls and describe how to obtain such a collection from a singular control and vice versa. We prove that these transformations define a bijection between the set of singular controls and the set of consistent collections of switching controls and prove a change of variable formula. In section 3, we apply this corre-

---

<sup>1</sup>Recently, in [22] it was observed that both the Dynkin game and the two regime optimal switching problem lead to backward stochastic differential equations with two reflecting barriers.

spondence to the problem of reversible investment and show how the value function of the singular control problem can be represented in terms of the value functions of optimal switching problems. Using this representation, we prove the differentiability of the value function and show that, due to the relationship between optimal switching problems and Dynkin games, the derivative can be represented in terms of either one. Last, we give a two-dimensional example with an explicit solution.

## 2. Correspondence between singular controls and switching controls.

In this section, we establish by explicit construction a bijection between admissible singular controls and consistent collections of switching controls with two regimes. Our result is analogous to the well-known correspondence between a nondecreasing,  $\mathbb{F}$ -adapted, càglàd singular control  $(\xi_t)_{t \geq 0}$  and a collection of stopping times  $(\tau^\xi(z))_{z \in \mathbb{R}}$ , given by

$$\tau^\xi(z) = \inf\{t \geq 0 : \xi_t > z\}, \quad \text{and} \quad \xi_t = \sup\{z \in \mathbb{R} : \tau^\xi(z) < t\}.$$

**2.1. Definitions.** Let  $(\Omega, \mathcal{F}, P)$  be a complete probability space and  $\mathbb{F} = \{\mathcal{F}_t; 0 \leq t < \infty\}$  a filtration satisfying the usual hypotheses. Let  $\mathcal{I} \subset \mathbb{R}$  be an open (possibly unbounded) interval and  $\bar{\mathcal{I}}$  be its closure.

Let us first recall the notion of *admissible singular controls*.

**DEFINITION 2.1.** *Given  $y \in \bar{\mathcal{I}}$ , an admissible singular control is a pair  $(\xi_t^+, \xi_t^-)_{t \geq 0}$  of  $\mathbb{F}$ -adapted, nondecreasing càglàd processes such that  $\xi^+(0) = \xi^-(0) = 0$ ,  $Y_t := y + \xi_t^+ - \xi_t^- \in \bar{\mathcal{I}}$ , for all  $t \in [0, \infty)$ , and  $d\xi^+$ ,  $d\xi^-$  are supported on disjoint subsets.*

We denote here  $\mathcal{A}_y$  to be the set of admissible strategies corresponding to an initial capacity level of  $y$ .

Since  $d\xi^+$  and  $d\xi^-$  are supported on disjoint subsets,  $\xi^+$  and  $\xi^-$  are the positive and negative variations of  $Y$ , respectively. By the uniqueness of the variation decomposition, there is a one-to-one correspondence between strategies  $(\xi^+, \xi^-) \in \mathcal{A}_y$  and  $\mathbb{F}$ -adapted càglàd finite variation processes  $Y$ , with  $Y_0 = y$  and  $Y_t \in \bar{\mathcal{I}}$  for all  $t$ .

*Throughout the paper,  $(Y_t)_{t \geq 0}$  is a finite variation control process with  $Y_0 = y$ .*

Next, we introduce *admissible switching controls* (with two regimes).

**DEFINITION 2.2.** *A switching control  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  consists of an increasing sequence of stopping times  $(\tau_n)_{n \geq 0}$  and a sequence of new regime values  $(\kappa_n)_{n \geq 0}$  that are assumed immediately after each stopping time.*

When there are only two distinct regimes, an optimal switching problem is often referred to as the starting and stopping problem ([12, 23], etc.) or the entry and exit problem ([9, 16], etc.). Following convention, we label the two regimes 0 and 1.

**DEFINITION 2.3.** *A switching control  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$  is admissible if the following hold almost surely:  $\tau_0 = 0$ ,  $\tau_{n+1} > \tau_n$  for  $n \geq 1$ ,  $\tau_n \rightarrow \infty$ , and for all  $n \geq 0$ ,  $\kappa_n \in \{0, 1\}$  is  $\mathcal{F}_{\tau_n}$  measurable, with  $\kappa_n = \kappa_0$  for even  $n$  and  $\kappa_n = 1 - \kappa_0$  for odd  $n$ .*

Alternatively, an admissible switching control has a more mathematically convenient representation given by its regime indicator function.

**PROPOSITION 2.4.** *There is a one-to-one correspondence between admissible switching controls and the regime indicator function  $I_t(\omega)$ , which is an  $\mathbb{F}$ -adapted càglàd process of finite variation, so that  $I_t(\omega) : \Omega \times [0, \infty) \rightarrow \{0, 1\}$ , with*

$$(2) \quad I_t := \sum_{n=0}^{\infty} \kappa_n 1_{\{\tau_n < t \leq \tau_{n+1}\}}, \quad I_0 = \kappa_0.$$

LEMMA 2.5. *Given an admissible switching control  $\alpha = (\tau_n, \kappa_n)_{n \geq 0}$ , define the increasing càglàd processes  $I^+$  and  $I^-$  by*

$$I_t^+ := \sum_{n>0, \kappa_n=1}^{\infty} 1_{\{\tau_n < t\}}, \quad I_0^+ = 0 \quad \text{and} \quad I_t^- := \sum_{n>0, \kappa_n=0}^{\infty} 1_{\{\tau_n < t\}}, \quad I_0^- = 0.$$

*Then for all  $t \geq 0$ ,  $I_t^\pm < \infty$  almost surely,  $I_t = \kappa_0 + I_t^+ - I_t^-$ , and  $I_t^+$  ( $I_t^-$ ) is the positive (negative) variation of the corresponding regime indicator function.*

Finally, we define a class of *consistent collections of switching controls*. We shall see later that it is exactly this class of consistent collections of switching controls that corresponds to singular controls of finite variation.

DEFINITION 2.6. *Let  $y \in \bar{\mathcal{I}}$  be given, and for each  $z \in \mathcal{I}$ , let  $\alpha(z) = (\tau_n(z), \kappa_n(z))_{n \geq 0}$  be a switching control. The collection  $(\alpha(z))_{z \in \mathcal{I}}$  is consistent if*

$$(3) \quad \alpha(z) \text{ is admissible for Lebesgue-almost every } z \in \mathcal{I},$$

$$(4) \quad I_0(z) := \kappa_0(z) = 1_{\{z \leq y\}} \text{ for Lebesgue-almost every } z \in \mathcal{I},$$

*and, for all  $t < \infty$ ,*

$$(5) \quad \int_{\mathcal{I}} (I_t^+(z) + I_t^-(z)) dz < \infty, \text{ almost surely, and}$$

$$(6) \quad I_t(z) \text{ is decreasing in } z \text{ for } \mathbb{P} \otimes dz\text{-almost every } (\omega, z).$$

Here  $I_t(z)$ ,  $I_t^+(z)$ , and  $I_t^-(z)$  are defined as in (2) and Lemma 2.5.

For  $I_t(z)$  to be decreasing in  $z$  for  $\mathbb{P} \otimes dz$ -almost every  $(\omega, z)$ , it means there exists a set  $E \subset \Omega \times \bar{\mathcal{I}}$  such that  $\mathbb{P} \otimes dz(E) = 0$ , and if  $(\omega, z_0), (\omega, z_1) \in (\Omega \times \bar{\mathcal{I}}) \setminus E$ , with  $z_0 \leq z_1$ , then  $I_t(\omega, z_0) \geq I_t(\omega, z_1)$ .

**2.2. Bijection.** First, we describe how a consistent collection of switching controls can be obtained from an admissible singular control. To this end, we quote two technical lemmas, the first one adapted from [20, Theorem 5.5.1].

LEMMA 2.7 (Evans and Gariepy). *Let  $f : [0, \infty) \rightarrow \mathbb{R}$  be a function of finite (i.e., locally bounded) variation, and define  $E : [0, \infty) \times \mathbb{R} \rightarrow \mathbb{R}$  by  $E(s, z) = 1_{\{f(s) > z\}}$ . Then*

1. *the function  $E(\cdot, z)$  is of finite variation for almost all  $z \in \mathbb{R}$ , and*
2.  *$\|df\|([0, t)) = \int_{-\infty}^{\infty} \|dE(\cdot, z)\|([0, t)) dz$  for all  $t \in (0, \infty)$ .*

LEMMA 2.8. *Let  $f : [0, \infty) \rightarrow \{0, 1\}$  be of finite variation, and define  $g(t) = \lim_{s \uparrow t} f(s)$ . Then almost surely the paths of  $g$  are càglàd, and, for all  $T < \infty$ ,*

$$\|dg\|([0, T)) \leq \|df\|([0, T)) < \infty.$$

PROPOSITION 2.9 (from singular to switching controls). *Given  $(\xi^+, \xi^-) \in \mathcal{A}_y$ , define a switching control  $\alpha(z) = (\tau_n(z), \kappa_n(z))_{n \geq 0}$  for each  $z \in \mathcal{I}$  through the regime indicator function  $I_t(z) := \lim_{s \uparrow t} 1_{\{Y_s > z\}}$ . Then the resulting collection  $(\alpha(z))_{z \in \mathcal{I}}$  of switching controls is consistent.*

*Proof.* First we show that  $I$  is a regime indicator function as per Proposition 2.4. Let  $Y_t = y + \xi_t^+ - \xi_t^-$ . Since  $Y$  is  $\mathbb{F}$ -adapted, so is  $I(z)$ . Furthermore, since  $Y$  is of finite variation, Lemma 2.7 implies that the function  $s \mapsto 1_{\{Y_s(\omega) > z\}}$  is of finite variation for  $\mathbb{P} \otimes dz$ -almost every  $(\omega, z)$ . Hence  $I_t(\omega, z)$  is càglàd and of finite variation  $(\omega, z)$ -a.e.

by Lemma 2.8. Thus, for almost all  $z$ , there is an admissible switching control  $\alpha(z)$  corresponding to  $I(z)$ .

Moreover, Lemma 2.7, in conjunction with Lemmas 2.8 and 2.5, implies that

$$\begin{aligned} \|dY\|([0, t)) &= \xi_t^+ + \xi_t^- = \int_{-\infty}^{\infty} \|d1_{\{Y > z\}}\|([0, t)) dz \geq \int_{\mathcal{I}} \|dI(z)\|([0, t)) dz \\ &= \int_{\mathcal{I}} I_t^+(z) + I_t^-(z) dz. \end{aligned}$$

Hence  $\int_{\mathcal{I}} I_t^+(z) + I_t^-(z) dz < \infty$ . In addition,  $I_t(z)$  is decreasing in  $z$  and  $I_0(z) = 1_{\{y \geq z\}}$  for all  $z$  (except for  $z = y$ ), so the collection  $(\alpha(z))_{z \in \mathcal{I}}$  is consistent.  $\square$

Next, we construct an admissible singular control  $(\xi^+, \xi^-)$  from a consistent collection of switching controls via their regime indicator functions. Consequently, we give two useful representations of a finite variation process  $Y$ .

**PROPOSITION 2.10** (from switching controls to singular controls). *Given  $y \in \bar{\mathcal{I}}$  and a consistent collection of switching controls  $(\alpha(z))_{z \in \mathcal{I}}$ , define two processes  $\xi^+$  and  $\xi^-$  by setting  $\xi_0^+ = 0$ ,  $\xi_0^- = 0$ , and for  $t > 0$ :  $\xi_t^+ := \int_{\mathcal{I}} I_t^+(z) dz$ ,  $\xi_t^- := \int_{\mathcal{I}} I_t^-(z) dz$ . Then*

1. *the pair  $(\xi^+, \xi^-) \in \mathcal{A}_y$  is an admissible singular control,*
2. *up to indistinguishability,*

$$Y_t = y + \int_y^{\infty} I_t(z) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y (I_t(z) - 1) 1_{\{z \in \mathcal{I}\}} dz, \quad \text{and}$$

3. *for all  $t$ , we almost surely have*

$$Y_t = \text{ess sup}\{z \in \mathcal{I} : I_t(z) = 1\} = \text{ess inf}\{z \in \mathcal{I} : I_t(z) = 0\},$$

where  $\text{ess sup } \emptyset := \inf \mathcal{I}$  and  $\text{ess inf } \emptyset := \sup \mathcal{I}$ .

*Proof.*

1. The proof is obvious from the property of  $(\alpha(z))_{z \in \mathcal{I}}$ , Definition 2.6, and Lemma 2.5.
2. By applying Lemma 2.5, we have a.e. for every  $t \geq 0$ ,

$$\begin{aligned} Y_t &= y + \xi_t^+ - \xi_t^- = y + \int_{\mathcal{I}} (I_t^+(z) - I_t^-(z)) dz \\ &= y + \int_y^{\infty} I_t(z) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y (I_t(z) - 1) 1_{\{z \in \mathcal{I}\}} dz. \end{aligned}$$

3. By fixing  $t \geq 0$  and observing that  $I_t(z) \in \{0, 1\}$  is decreasing in  $z$ ,  $(\omega, z)$ -a.e., we see

$$\begin{aligned} Y_t &= y + \int_y^{\infty} I_t(z) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y (I_t(z) - 1) 1_{\{z \in \mathcal{I}\}} dz \\ &= y + [\text{ess sup}\{z \in \mathcal{I} : I_t(z) = 1\} - y]^+ - [\text{ess sup}\{z \in \mathcal{I} : I_t(z) = 1\} - y]^- \\ &= \text{ess sup}\{z \in \mathcal{I} : I_t(z) = 1\}. \quad \square \end{aligned}$$

PROPOSITION 2.11 (one-to-one mapping). *The mapping from consistent collections of switching controls to singular controls defined by Proposition 2.10 is one-to-one.*

Finally, we shall show that the two mappings defined in Propositions 2.9 and 2.10 are inverses of each other, thus inducing a bijection.

THEOREM 2.12 (bijection). *The mappings in Propositions 2.9 and 2.10 define a bijection between admissible singular controls  $(\xi^+, \xi^-) \in \mathcal{A}_y$  and consistent collections of switching controls (up to equivalence).*

*Proof.* To show that the constructions in Propositions 2.9 and 2.10 are inverses of each other, let us start with a singular control  $(\xi^+, \xi^-) \in \mathcal{A}_y$ . First, applying Proposition 2.9 to  $(\xi^+, \xi^-) \in \mathcal{A}_y$  generates a collection  $(\alpha(z))_{z \in \mathcal{I}}$  of switching controls. Then, applying Proposition 2.10 to  $(\alpha(z))_{z \in \mathcal{I}}$  yields another pair of singular controls  $(\tilde{\xi}^+, \tilde{\xi}^-)$ . We shall show that  $(\xi^+, \xi^-) = (\tilde{\xi}^+, \tilde{\xi}^-)$ .

By Proposition 2.9 we have  $I_t(z) = \lim_{s \uparrow t} 1_{\{Y_s > z\}}$ . Therefore, by Proposition 2.10, the dominated convergence theorem, and with  $Y \in \mathcal{I}$  almost surely, we have

$$\begin{aligned} \tilde{Y}_t &= y + \int_y^\infty I_t(z) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y (I_t(z) - 1) 1_{\{z \in \mathcal{I}\}} dz \\ &= y + \int_y^\infty \lim_{s \uparrow t} 1_{\{Y_s > z\}} 1_{\{z \in \mathcal{I}\}} dz - \int_{-\infty}^y \lim_{s \uparrow t} 1_{\{Y_s \leq z\}} 1_{\{z \in \mathcal{I}\}} dz \\ &= y + \lim_{s \uparrow t} \int_y^\infty 1_{\{Y_s > z\}} 1_{\{z \in \mathcal{I}\}} dz - \lim_{s \uparrow t} \int_{-\infty}^y 1_{\{Y_s \leq z\}} 1_{\{z \in \mathcal{I}\}} dz \\ &= y + [Y_t - y]^+ - [Y_t - y]^- = Y_t. \end{aligned}$$

Thus,  $\tilde{Y}_t$  and  $Y_t$  have the same variation decompositions, and hence  $(\xi^+, \xi^-) = (\tilde{\xi}^+, \tilde{\xi}^-)$  almost surely.

Since the mapping in Proposition 2.10 is one-to-one by Proposition 2.11, this proves that the mappings in Propositions 2.10 and 2.9 are inverses of each other, and hence a bijection exists.  $\square$

Given this correspondence, we shall use the following terminology in what follows. Given a singular control  $(\xi^+, \xi^-) \in \mathcal{A}_y$ , the corresponding collection of switching controls  $(\alpha(z))_{z \in \mathcal{I}}$  refers to the one defined in Proposition 2.9; given a consistent collection of switching controls, the corresponding singular control refers to that in Proposition 2.10.

**2.3. Change of variable formula.** With the bijection established in Theorem 2.12, we are ready to establish a change of variable formula for integration with respect to the variation of a singular control.

LEMMA 2.13. *Let  $(\xi^+, \xi^-) \in \mathcal{A}_y$  be an admissible singular control and  $(\alpha(z))_{z \in \mathcal{I}}$  be the corresponding collection of switching controls. For every càdlàg process  $g : \Omega \times [0, \infty] \rightarrow [0, \infty)$ , with  $g(\infty) \equiv 0$ ,*

$$\begin{aligned} \int_{[0, \infty)} g(t) d\xi_t^+ &= \int_{\mathcal{I}} \sum_{\substack{n > 0 \\ \kappa_n = 1}} g(\tau_n(z)) dz, \quad \text{a.s.}, \\ \text{and } \int_{[0, \infty)} g(t) d\xi_t^- &= \int_{\mathcal{I}} \sum_{\substack{n > 0 \\ \kappa_n = 0}} g(\tau_n(z)) dz, \quad \text{a.s.} \end{aligned}$$

*Proof.* We shall show only the result for  $\xi^+$  as the proof for  $\xi^-$  is almost identical. Suppose  $g$  is a càdlàg process with the representation

$$g(t) = \sum_{i=0}^N g_i 1_{[\sigma_i, \sigma_{i+1})}(t),$$

where  $N$  is finite and constant,  $0 = \sigma_0 \leq \sigma_1 \leq \dots \leq \sigma_{N+1} < \infty$ ,  $g_i \in \mathcal{F}_{\sigma_i}$ , and  $|g_i| < \infty$  almost surely. Then, by Proposition 2.10, the monotone convergence theorem, and Fubini's theorem,

$$\begin{aligned} \int_{[0, \infty)} g(t) d\xi_t^+ &= \int_{[0, \infty)} \sum_{i=0}^N g_i 1_{[\sigma_i, \sigma_{i+1})}(t) d\xi_t^+ = \sum_{i=0}^N g_i \int_{[0, \infty)} 1_{[\sigma_i, \sigma_{i+1})}(t) d\xi_t^+ \\ &= \sum_{i=0}^N g_i (\xi_{\sigma_{i+1}}^+ - \xi_{\sigma_i}^+) \\ &= \sum_{i=0}^N g_i \left( \int_{\mathcal{I}} \sum_{\substack{n>0 \\ \kappa_n=1}} 1_{\{\tau_n(z) < \sigma_{i+1}\}} dz - \int_{\mathcal{I}} \sum_{\substack{n>0 \\ \kappa_n=1}} 1_{\{\tau_n(z) < \sigma_i\}} dz \right) \\ &= \sum_{i=0}^N g_i \left( \int_{\mathcal{I}} \sum_{\substack{n>0 \\ \kappa_n=1}} 1_{\{\sigma_i \leq \tau_n(z) < \sigma_{i+1}\}} dz \right) \\ &= \int_{\mathcal{I}} \sum_{\substack{n>0 \\ \kappa_n=1}} \sum_{i=0}^N g_i 1_{\{\sigma_i \leq \tau_n(z) < \sigma_{i+1}\}} dz \\ &= \int_{\mathcal{I}} \sum_{\substack{n>0 \\ \kappa_n=1}} g(\tau_n(z)) dz. \end{aligned}$$

Since piecewise constant left continuous functions can uniformly approximate càglàd functions, this formula holds for all càglàd processes.  $\square$

In particular, when  $Y$  is nondecreasing (i.e.,  $\xi^- \equiv 0$ ),  $\bar{\mathcal{I}} = [0, \infty)$ , and  $y \geq 0$ , we have  $\tau_n(z) \equiv 0$  for all  $n > 1$  and for  $n = 1$  when  $z \leq y$ . In this case, our change of variable formula reduces to the one for monotone controls in [2], after adjusting for notational differences:

$$\int_{[0, \infty)} g(t) d\xi_t^+ = \int_y^\infty g(\tau_1(z)) dz.$$

**3. Application: Reversible investment.** Having established the correspondence between singular controls and consistent collections of switching controls, we shall illustrate how this theory can be applied to solving singular control problems.

As an example, we return to the aforementioned infinite-horizon, *reversible* investment problem (1): A company adjusts its reversible production capacity (or investment) level by proper controls of expansion and contraction in the presence of a stochastic economic environment. The net profit of such an investment depends on the running production function of the actual capacity, the economic uncertainty

such as price or demand for the product, the benefits of contraction (e.g., via spinning off part of the business), and the cost of expanding and reducing the capital. The company's objective is to maximize the expected profit over an infinite time horizon by controlling expansion and contraction.

**3.1. The singular control problem for reversible investment.** More specifically, the instantaneous operating profit of the company is a function of the production capacity and random variables representing the uncertain economic environment:

$$(7) \quad \Pi(\omega, t, z) : \Omega \times [0, \infty) \times \bar{\mathcal{I}} \rightarrow \mathbb{R}.$$

The unit cost of increasing the capacity at time  $t$  is  $\gamma_+(\omega, t) : \Omega \times [0, \infty) \rightarrow \mathbb{R}$ , and the unit cost of decreasing capacity is  $\gamma_-(\omega, t) : \Omega \times [0, \infty) \rightarrow \mathbb{R}$ , where both  $\gamma_+$  and  $\gamma_-$  are adapted to  $\mathbb{F}$ .<sup>2</sup>

The control of the production capacity  $Y_t$  is represented by a pair  $(\xi_t^+, \xi_t^-)_{t \geq 0}$  of  $\mathbb{F}$ -adapted, nondecreasing càglàd processes such that

$$(8) \quad \xi^+(0) = \xi^-(0) = 0,$$

$$(9) \quad Y_t = y + \xi_t^+ - \xi_t^- \in \bar{\mathcal{I}} \quad \forall t \in [0, \infty).$$

Here  $\xi_t^+$  and  $\xi_t^-$  represent the cumulative expansion and reduction of capital until time  $t$ , respectively. We say the policy  $(\xi^+, \xi^-)$  is integrable if the integrability condition is satisfied for the initial capacity level  $y$ . That is,

$$(10) \quad \mathbb{E} \left[ \int_0^\infty |\Pi(t, Y_t)| dt + \int_{[0, \infty)} |\gamma_+(t)| d\xi_t^+ + \int_{[0, \infty)} |\gamma_-(t)| d\xi_t^- \right] < \infty.$$

We denote  $\mathcal{A}'_y \subset \mathcal{A}_y$  as the set of integrable strategies.

Faced with these profit and cost functions, the company must choose an investment strategy of capacity expansion and reduction which produces the following expected payoff over an infinite horizon:

$$(11) \quad J(y, \xi^+, \xi^-) := \mathbb{E} \left[ \int_0^\infty \Pi(t, Y_t) dt - \int_{[0, \infty)} \gamma_+(t) d\xi_t^+ - \int_{[0, \infty)} \gamma_-(t) d\xi_t^- \right].$$

The objective is to maximize over all integrable policies  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ . Accordingly, the value function is defined as

$$(12) \quad V(y) := \sup_{(\xi^+, \xi^-) \in \mathcal{A}'_y} J(y, \xi^+, \xi^-).$$

Note that, for any  $y \in \bar{\mathcal{I}}$ ,  $\mathcal{A}'_y$  is not empty, as the expected profit of not investing at all (i.e.,  $\xi^+ \equiv 0 \equiv \xi^-$ ) is finite and is given by

$$(13) \quad R(y) := J(y, 0, 0) = \mathbb{E} \left[ \int_0^\infty \Pi(t, y) dt \right].$$

Throughout the remaining section, we impose several conditions.

<sup>2</sup>When there is no risk of ambiguity, we suppress the dependence of the profit and cost functions on  $\omega$ , writing  $\Pi(t, z)$ ,  $\gamma_+(t)$ , and  $\gamma_-(t)$ .

**Standing assumptions.**

- A1.  $\Pi$  is concave in  $y$  and continuous at the boundary of  $\mathcal{I}$ , so that for  $y_1 < y_2 \in \bar{\mathcal{I}}$ ,

$$(14) \quad \Pi(t, y_2) - \Pi(t, y_1) := \int_{y_1}^{y_2} \pi(t, z) dz,$$

where  $\pi$  is decreasing in  $z$  a.s. and adapted to  $\mathbb{F}$ . Furthermore,

$$(15) \quad \mathbb{E} \left[ \int_0^\infty |\Pi(t, z)| dt \right] < \infty \quad \forall z \in \bar{\mathcal{I}},$$

$$(16) \quad \mathbb{E} \left[ \int_0^\infty |\pi(t, z)| dt \right] < \infty \quad \forall z \in \mathcal{I}.$$

This assumption implies that the value function is well-defined, and, although it may take values of  $+\infty$ , it is never  $-\infty$  since  $V(y) \geq R(y) > -\infty$  by (15).

- A2.  $\gamma_+$  and  $\gamma_-$  are adapted to  $\mathbb{F}$ ,  $\gamma^\pm(\infty) := 0$  and

$$(17) \quad \gamma_+(t) + \gamma_-(t) > 0, \quad \text{for all } t, \text{ a.s.}$$

This restriction eliminates the opportunity of making profit by simply switching regimes and immediately switching back.

- A3.
  - If  $\mathcal{I}$  is not bounded above, then  $\gamma_+(t) \geq 0$  for all  $t$  almost surely;
  - if  $\mathcal{I}$  is not bounded below,  $\gamma_-(t) \geq 0$  for all  $t$  almost surely.

This is to ensure that, when the domain is unbounded, an arbitrarily large profit is not obtainable by arbitrarily large changes in the capacity level.

A very special case for the above problem (12) is  $\Pi(\omega, t, z) = e^{-\rho t} (X_t^x(\omega))^\lambda z^\beta$ , where the randomness in the economy is captured by the price process  $X$  of the commodity, and  $X$  is modeled by a geometric Brownian motion  $dX_t^x = bX_t^x dt + \sqrt{2}\sigma X_t^x dW_s$ , with  $X_0 = x > 0$ . The cost functions are  $\gamma_+(\omega, t) = e^{-\rho t} K_1$ ,  $\gamma_-(\omega, t) = e^{-\rho t} K_0$  for some constant  $\rho > 0$ ,  $K_0, K_1$ . We shall provide a detailed analysis and an explicit solution to this case in section 3.4.

**3.2. The corresponding optimal switching problems.** The key to using the connection between singular controls and switching controls to solve problem (12) in section 3.1 is to write the payoff of this problem in terms of the payoffs of its corresponding optimal switching problems. This is accomplished by exploiting the absolute continuity of the running payoff and the change of variable formula for the cost processes.

**3.2.1. Switching controls from singular controls.** First, given the running profit and cost functions from the singular control problem (12), we define a collection of optimal switching problems, indexed by  $z \in \mathcal{I}$ .

DEFINITION 3.1. *The switching cost process  $\gamma : \Omega \times [0, \infty) \times \{0, 1\} \rightarrow \mathbb{R}$  is given by*

$$\gamma(t, \kappa) := \gamma_+(t) 1_{\{\kappa=1\}} + \gamma_-(t) 1_{\{\kappa=0\}}.$$

Here  $\gamma(t, \kappa)$  represents the cost of switching to regime  $\kappa$  at time  $t$ .

The following lemma shows that, for the integrable singular control  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , the switching controls in the corresponding collection satisfy a certain integrability

condition. It is a simple application of Fubini's theorem, from Lemma 2.13 and condition (10).

LEMMA 3.2. *If  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , then, for the corresponding consistent collection of switching controls  $(\alpha(z))_{z \in \mathcal{I}}$ , we have  $\alpha(z) \in \mathcal{B}$  for Lebesgue almost every  $z \in \mathcal{I}$ , where  $\mathcal{B}$  is the set of admissible switching controls  $(\tau_n, \kappa_n)_{n \geq 0}$  satisfying*

$$(18) \quad \mathbb{E} \left[ \sum_{n=1}^{\infty} |\gamma(\tau_n, \kappa_n)| \right] < \infty.$$

Note that the converse of the lemma is not true: A consistent collection of switching controls, each of which is integrable, does not necessarily correspond to an integrable singular control.

Next, we establish the following.

PROPOSITION 3.3. *Assume  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ . Let  $(\alpha(z))_{z \in \mathcal{I}}$  be the corresponding consistent collection of switching controls with regime indicator functions  $I(z)$ ; then*

$$J(y, \xi^+, \xi^-) - R(y) = \int_y^{\infty} m_+(z, \alpha(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha(z)) 1_{\{z \in \mathcal{I}\}} dz,$$

where

$$(19) \quad m_+(z, \alpha) := \mathbb{E} \left[ \int_0^{\infty} \pi(t, z) I_t dt - \sum_{n=1}^{\infty} \gamma(\tau_n, \kappa_n) \right] \in (-\infty, \infty)$$

$$(20) \quad \text{and } m_-(z, \alpha) := \mathbb{E} \left[ \int_0^{\infty} -\pi(t, z) (1 - I_t) dt - \sum_{n=1}^{\infty} \gamma(\tau_n, \kappa_n) \right] \in (-\infty, \infty).$$

Here  $m_+(z, \alpha)$  and  $m_-(z, \alpha)$  are two expected payoffs for the switching controls for each  $z \in \mathcal{I}$  and  $\alpha \in \mathcal{B}$ , with  $\kappa_0 = k \in \{0, 1\}$ .

*Proof of Proposition 3.3.* Since  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , we have the integrability conditions (10) and (18). By applying Lemma 2.13 to the positive and negative parts of  $\gamma_+$  and  $\gamma_-$ , we see that

$$\int_{[0, \infty)} \gamma_+(t) d\xi_t^+ + \int_{[0, \infty)} \gamma_-(t) d\xi_t^- = \int_{-\infty}^{\infty} \sum_{n=1}^{\infty} \gamma(\tau_n(z), \kappa_n(z)) dz.$$

Moreover, Proposition 2.9 implies that  $I_t(z) = \lim_{s \uparrow t} 1_{\{Y_s > z\}}$ ,  $(\omega, z)$ -a.e. and that  $I(z)$  is of finite variation,  $(\omega, z)$ -a.e. Thus,  $I_t(z) = 1_{\{Y_t > z\}}$ ,  $(\omega, z, t)$ -a.e.

Therefore, by Fubini's theorem and (14), we almost surely have

$$\begin{aligned} \int_0^{\infty} (\Pi(t, Y_t) - \Pi(t, y)) dt &= \int_0^{\infty} \int_y^{\infty} \pi(t, z) 1_{\{Y_t > z\}} dz dt \\ &\quad - \int_0^{\infty} \int_{-\infty}^y \pi(t, z) 1_{\{Y_t \leq z\}} dz dt \\ &= \int_y^{\infty} \int_0^{\infty} \pi(t, z) I_t(z) dt dz \\ &\quad + \int_{-\infty}^y \int_0^{\infty} -\pi(t, z) (1 - I_t(z)) dt dz. \end{aligned}$$

Resorting again to the integrability conditions (10) and (18) and Fubini's theorem yields

$$\begin{aligned}
& J(y, \xi^+, \xi^-) - R(y) \\
&= \mathbb{E} \left[ \int_0^\infty \Pi(t, Y_t) dt - \int_{[0, \infty)} \gamma_+(t) d\xi_t^+ - \int_{[0, \infty)} \gamma_-(t) d\xi_t^- \right] - \mathbb{E} \left[ \int_0^\infty \Pi(t, y) dt \right] \\
&= \mathbb{E} \left[ \int_y^\infty \int_0^\infty \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) dz \right] \\
&\quad + \mathbb{E} \left[ \int_{-\infty}^y \int_0^\infty -\pi(t, z)(1 - I_t(z)) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) dz \right] \\
&= \int_y^\infty \mathbb{E} \left[ \int_0^\infty \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) \right] dz \\
&\quad + \int_{-\infty}^y \mathbb{E} \left[ \int_0^\infty -\pi(t, z)(1 - I_t(z)) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) \right] dz \\
&= \int_y^\infty m_+(z; \alpha(z)) dz + \int_{-\infty}^y m_-(z; \alpha(z)) dz.
\end{aligned}$$

The finiteness of the payoff for  $z \in \mathcal{I}$  follows from the assumed integrability of  $\pi$  in (16) and  $|I_t| \leq 1$ .  $\square$

**3.2.2. Representation theorem.** Now, for each  $z \in \mathcal{I}$ , the optimal switching control problem is to maximize the expected payoff over possible switching controls  $\alpha \in \mathcal{B}$  such that  $\kappa_0 = k \in \{0, 1\}$ . This leads to the value functions given by

$$(21) \quad m_+^*(z, k) := \sup_{\substack{\alpha \in \mathcal{B} \\ \kappa_0 = k}} m_+(z, \alpha),$$

$$(22) \quad m_-^*(z, k) := \sup_{\substack{\alpha \in \mathcal{B} \\ \kappa_0 = k}} m_-(z, \alpha),$$

where  $m_+(z, \alpha)$  and  $m_-(z, \alpha)$  are given by (19) and (20).

In fact, these two value functions (21) and (22) are essentially the same as shown in the following lemma.

**LEMMA 3.4.** *The value functions  $m_+^*(z, k)$  and  $m_-^*(z, k)$  in (21) and (22) satisfy, for  $k \in \{0, 1\}$ ,*

$$m_+^*(z, k) - m_-^*(z, k) = \mathbb{E} \left[ \int_0^\infty \pi(t, z) dt \right].$$

*In addition, for fixed  $k \in \{0, 1\}$ , each switching control  $\alpha \in \mathcal{B}$  that is optimal for (21) will also be optimal for (22) and vice versa.*

The proof follows easily by observing that, for any control  $\alpha \in \mathcal{B}$  and any fixed  $z \in \mathcal{I}$ ,

$$m_+(z, \alpha) - m_-(z, \alpha) = \mathbb{E} \left[ \int_0^\infty \pi(t, z) I_t + \pi(t, z)(1 - I_t) dt \right] = \mathbb{E} \left[ \int_0^\infty \pi(t, z) dt \right]. \quad \square$$

Next, we obtain the following lower bounds on the value functions of the switching problems, by considering the no-switching strategies ( $\tau_n = \infty$  for all  $n$ ).

PROPOSITION 3.5. *Given  $m_+^*(z, k)$  and  $m_-^*(z, k)$  in (21) and (22),*

$$\begin{aligned} m_+^*(z, 0) &\geq 0, & m_+^*(z, 1) &\geq \mathbb{E} \left[ \int_0^\infty \pi(t, z) dt \right], \\ m_-^*(z, 0) &\geq -\mathbb{E} \left[ \int_0^\infty \pi(t, z) dt \right], & m_-^*(z, 1) &\geq 0. \end{aligned}$$

Moreover, we have the following upper bound on the value function of the singular control problem.

PROPOSITION 3.6. *Given  $V(y)$  and  $R(y)$  from (12) and (13) and  $m_+^*(z, k)$  and  $m_-^*(z, k)$  in (21) and (22),*

$$(23) \quad V(y) - R(y) \leq \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz.$$

*Proof of Proposition 3.6.* Given any integrable strategy  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ , let  $(\alpha(z))_{z \in \mathcal{I}}$  be the corresponding consistent collection of switching controls. From Proposition 3.3,

$$\begin{aligned} J(y, \xi^+, \xi^-) - R(y) &= \int_y^\infty m_+(z, \alpha(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha(z)) 1_{\{z \in \mathcal{I}\}} dz \\ &\leq \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz, \end{aligned}$$

since for  $z > y$ ,  $m_+(z, \alpha(z)) \leq m_+^*(z, 0)$  and for  $z \leq y$ ,  $m_-(z, \alpha(z)) \leq m_-^*(z, 1)$ .

(23) follows easily by taking the supremum over all  $(\xi^+, \xi^-) \in \mathcal{A}'_y$ .  $\square$

However, the other direction of the inequality requires additional conditions to guarantee the existence of a consistent collection of optimal (or near-optimal) switching controls and that this consistent collection corresponds to an integrable singular control.

THEOREM 3.7 (representation). *Fix  $y \in \bar{\mathcal{I}}$ , and let  $V(y)$  and  $R(y)$  be given from (12),  $m_+^*(z, k)$  and  $m_-^*(z, k)$  be given by (21) and (22), and  $(\hat{\xi}^{j+}, \hat{\xi}^{j-}) \in \mathcal{A}_y$  be the corresponding singular control as per Proposition 2.10. Assume there is a sequence of consistent collections of switching controls  $(\alpha_j(z))_{z \in \mathbb{R}}$  so that, as  $j \rightarrow \infty$ ,*

$$\begin{aligned} &\int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz \\ &\rightarrow \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz. \end{aligned}$$

*Assume also that  $(\hat{\xi}^{j+}, \hat{\xi}^{j-}) \in \mathcal{A}'_y$  for all  $j$ . Then*

$$V(y) - R(y) = \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz.$$

*Proof of Theorem 3.7.* Define

$$Q(y) := \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz.$$

First, we treat the case where  $Q(y) = \infty$ . Let  $\epsilon > 0$  be given. From the assumption, find  $j$  so large that  $\frac{1}{\epsilon} < \int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz$ . By Proposition 3.3 we have

$$\begin{aligned} V(y) - R(y) &\geq J(y, \hat{\xi}^{j+}, \hat{\xi}^{j-}) - R(y) \\ &= \int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz > \frac{1}{\epsilon}. \end{aligned}$$

Since  $\epsilon$  is arbitrary and  $R(y)$  is finite,  $V(y) = \infty = Q(y)$ .

Next, suppose  $Q(y) < \infty$ , and let  $\epsilon > 0$  be given. Again from the assumption, find  $j$  so large that  $\int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz > Q(y) - \epsilon$ . By Propositions 3.3 and 3.6,

$$\begin{aligned} V(y) - R(y) &\geq J(y, \hat{\xi}^+, \hat{\xi}^-) - R(y) \\ &= \int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz \\ &> Q(y) - \epsilon \geq V(y) - R(y) - \epsilon. \end{aligned}$$

Since  $\epsilon$  is arbitrary,  $V(y) - R(y) = Q(y)$  as desired.  $\square$

Moreover, with stronger assumptions, one can further establish the existence of an optimal control strategy, from Propositions 3.3 and 3.6.

*Assumption 3.8.*

1. [Existence of consistent controls]. Fix  $y \in \bar{\mathcal{I}}$ , and let  $m_+^*(z, k)$  and  $m_-^*(z, k)$  be given by (21) and (22). For almost all  $z \in \mathcal{I}$ , there exists an optimal admissible switching control  $\alpha(z) \in \mathcal{B}$  such that

$$\begin{aligned} m_+^*(z, 0) &= m_+(z, \alpha(z)) \quad \text{for } z > y \\ \text{and } m_+^*(z, 1) &= m_+(z, \alpha(z)) \quad \text{for } z \leq y. \end{aligned}$$

Furthermore, the collection  $(\alpha(z))_{z \in \mathbb{R}}$  is consistent.

2. [Integrability of singular control]. Let  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}_y$  be the corresponding singular control as per Proposition 2.10, and then  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$ .

**THEOREM 3.9** (representation and existence). *Under Assumption 3.8, the representation Theorem 3.7 holds. Moreover, the strategy  $(\hat{\xi}^+, \hat{\xi}^-)$  is optimal.*

**3.2.3. Remarks on integrability of singular controls.** Although establishing simpler conditions for the consistency of the switching controls requires more structure for the control problem, the equally technical integrability assumption on the singular controls can be reduced to easily verifiable ones when  $\mathcal{I}$  is bounded. These extra assumptions are in line with some of those in [33].

**THEOREM 3.10** (sufficient condition for integrability). *Let  $\mathcal{I}$  be bounded, assume 3.8.1, and let  $(\hat{\xi}^+, \hat{\xi}^-)$  be the corresponding singular control as per Proposition 2.10. Furthermore, suppose*

1.  $\sup_{0 \leq t \leq T} \sup_{z \in \mathcal{I}} |\Pi(\omega, t, z)| < \infty$ , almost surely, for all  $T > 0$ ,
2.  $\limsup_{T \rightarrow \infty} \mathbb{E}[|\gamma_+(T)| + |\gamma_-(T)|] < \infty$ , and
3. for every strategy  $(\xi^+, \xi^-) \in \mathcal{A}_y$ , either  $(\xi^+, \xi^-) \in \mathcal{A}'_y$  or there exists an  $\mathbb{F}$ -adapted process  $Z$  such that  $U. \leq Z$ . almost surely,  $\mathbb{E}[|Z_T|] < \infty$  for all  $T \geq 0$ , and  $\limsup_{T \rightarrow \infty} \mathbb{E}[Z_T] = -\infty$ , where

$$(24) \quad U_T(y, \xi^+, \xi^-) := \int_0^T \Pi(t, Y_t) dt - \int_{[0, T)} \gamma_+(t) d\xi_t^+ - \int_{[0, T)} \gamma_-(t) d\xi_t^-.$$

Then  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$ . Hence Assumption 3.8 holds, yielding Theorem 3.9.

The proof is somewhat technical and thus is given in the appendix.

Note that, when  $\mathcal{I}$  is unbounded, integrable consistent controls may not exist under these extra conditions. Nevertheless, we see the following.

**COROLLARY 3.11.** *If  $\mathcal{I}$  is unbounded, the assumptions of Theorem 3.10 yield Theorem 3.7.*

*Proof.* Let  $\mathcal{I}$  be unbounded and  $(\alpha(z))_{z \in \mathcal{I}}$  be the optimal consistent collection from Assumption 3.8.1. For each  $j \geq 1$ , define  $\alpha_j(z) = \alpha(z)$  for  $z \in \mathcal{I} \cap (-j, j)$ . For  $z \notin \mathcal{I} \cap (-j, j)$ , define  $\alpha_j(z)$  to be the no action switching control (corresponding to the regime indicator function  $I_t^j(z) = 1_{\{z \leq y\}}$ ).

The resulting collection  $(\alpha_j(z))_{z \in \mathcal{I}}$  is clearly consistent, so we let  $(\hat{\xi}^{j+}, \hat{\xi}^{j-})$  be the corresponding singular controls. Furthermore, by considering the control problem restricted to  $\bar{\mathcal{I}} \cap [-j, j]$ , Theorem 3.10 implies that  $(\hat{\xi}^{j+}, \hat{\xi}^{j-}) \in \mathcal{A}'_y$ . Last, by the monotone convergence theorem (since  $m_+^*(z, 0)$  and  $m_-^*(z, 1)$  are nonnegative), we have, as  $j \rightarrow \infty$ ,

$$\begin{aligned} & \int_y^\infty m_+(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-(z, \alpha_j(z)) 1_{\{z \in \mathcal{I}\}} dz \\ &= \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I} \cap (-j, j)\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I} \cap (-j, j)\}} dz \\ &\rightarrow \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz. \quad \square \end{aligned}$$

**3.3. Regularity of the value function.** In this section, we provide conditions under which the value function of the switching controls is not only continuous but also continuously differentiable. As a result, we prove directly the smooth fit condition assumed a priori in [33].

**PROPOSITION 3.12.** *Suppose that, for some  $y \in \mathcal{I}$ ,*

$$(25) \quad \lim_{z \rightarrow y} \mathbb{E} \left[ \int_0^\infty |\pi(t, z) - \pi(t, y)| dt \right] = 0.$$

*Then for  $k \in \{0, 1\}$ ,  $m_+^*(\cdot, k)$  and  $m_-^*(\cdot, k)$  (from (21) and (22)) are continuous at  $y$ .*

*Proof of Proposition 3.12.* Let  $y \in \mathcal{I}$  and  $k \in \{0, 1\}$  be given, and consider any admissible strategy  $\alpha \in \mathcal{B}$ . By (18), (19), and (25),

$$\lim_{z \rightarrow y} |m_+(z, \alpha) - m_+(y, \alpha)| \leq \lim_{z \rightarrow y} \mathbb{E} \left[ \int_0^\infty |\pi(t, z) - \pi(t, y)| dt \right] = 0.$$

Note that convergence to zero is uniform across all strategies  $\alpha \in \mathcal{B}$ .

Let  $\epsilon > 0$  be given. There exists  $\delta > 0$  so that, for any strategy  $\alpha \in \mathcal{B}$ ,  $|m_+(z, \alpha) - m_+(y, \alpha)| < \frac{\epsilon}{2}$  for all  $z \in \mathcal{I}$  such that  $|z - y| < \delta$ .

Now there exists a strategy  $\hat{\alpha} \in \mathcal{B}$  with  $\kappa_0 = k$  such that

$$m_+^*(y, k) \leq m_+(y, \hat{\alpha}) + \frac{\epsilon}{2}.$$

So for all  $z \in \mathcal{I}$  such that  $|z - y| < \delta$ ,

$$m_+^*(y, k) \leq m_+(y, \hat{\alpha}) + \frac{\epsilon}{2} \leq m_+(z, \hat{\alpha}) + \epsilon \leq m_+^*(z, k) + \epsilon.$$

Furthermore, for any such  $z$ , there exists a switching control  $\alpha_z \in \mathcal{B}$  with  $\kappa_0 = 0$  such that

$$m_+^*(z, k) \leq m_+(z, \alpha_z) + \frac{\epsilon}{2} \leq m_+(y, \alpha_z) + \epsilon \leq m_+^*(y, k) + \epsilon.$$

Hence for all  $z \in \mathcal{I}$  such that  $|z - y| < \delta$ ,

$$m_+^*(y, k) - \epsilon \leq m_+^*(z, k) \leq m_+^*(y, k) + \epsilon.$$

Thus,  $\lim_{z \rightarrow y} m_+^*(z, k) = m_+^*(y, k)$ . Moreover,  $\lim_{z \rightarrow y} m_-^*(z, k) = m_-^*(y, k)$  follows from Lemma 3.4.  $\square$

**THEOREM 3.13** (regularity). *Assume the conditions in Proposition 3.12 on an open interval  $\mathcal{J} \subset \mathcal{I}$ . Suppose that, on  $\mathcal{J}$ , the value function has the representation*

$$V(y) - R(y) = \int_y^\infty m_+^*(z, 0) 1_{\{z \in \mathcal{I}\}} dz + \int_{-\infty}^y m_-^*(z, 1) 1_{\{z \in \mathcal{I}\}} dz.$$

Then  $V$  is  $C^1$  on  $\mathcal{J}$ , and, for any  $y \in \mathcal{J}$ ,

$$V'(y) = \mathbb{E} \left[ \int_0^\infty \pi(t, y) dt \right] + m_-^*(y, 1) - m_+^*(y, 0) = m_+^*(y, 1) - m_+^*(y, 0).$$

*Proof of Theorem 3.13.* By Proposition 3.12, it remains to show that  $R'(y) = \mathbb{E} \left[ \int_0^\infty \pi(t, y) dt \right]$ . Fixing  $z_0 \in \mathcal{I}$ , this follows easily from (14) and (15), and

$$\begin{aligned} R(y) - R(z_0) &= \mathbb{E} \left[ \int_0^\infty (\Pi(t, y) - \Pi(t, z_0)) dt \right] \\ &= \mathbb{E} \left[ \int_0^\infty \int_{z_0}^y \pi(t, z) dz dt \right] = \int_{z_0}^y \mathbb{E} \left[ \int_0^\infty \pi(t, z) dz dt \right]. \quad \square \end{aligned}$$

Note that previous results of [30, 8, 9, 10] on the differentiability of the value function for the (ir)reversible investment problem are special cases of ours. Another major difference is that the derivative in their work is in terms of the value of a Dynkin game, whereas the derivative here is the difference between the value functions of an optimal switching problem.

In the remainder of this section, we shall show that, under very mild assumptions, the value of a Dynkin game exists and is equal to the difference of the value functions for the optimal switching problem defined by (19) and (20); thereby we demonstrate that optimal switching problems provide a “missing link” between Dynkin games and singular control problems.

For simplicity, we consider an infinite-horizon Dynkin game with no terminal payoff. With a slight modification, our arguments can be adapted for the finite-horizon case.

**3.3.1. Dynkin games.** A Dynkin game is a game of timing between two players, whom we call MAX and MIN, following [10]. We fix some level  $z \in \mathcal{I}$ . While the game is in progress, MIN pays MAX at rate  $\pi(t, z)$ , and the game ends when one player chooses to stop. Thus, MAX and MIN each choose strategies on when to exit the game (the stopping times  $\sigma_-$  and  $\sigma_+$ , respectively). The player to exit first pays an amount to her opponent equal to  $\gamma_-(\sigma_-)$  if MAX exits first and  $\gamma_+(\sigma_+)$  if MIN exits first. If both players exit at the same time, we treat it as though MIN exited first. Furthermore, each player may choose never to exit, i.e.,  $\sigma = \infty$ . MAX chooses her strategy  $\sigma_-$  to maximize her payoff, and MIN chooses  $\sigma_+$  in order to minimize MAX's payoff.

This game is formally described below. To ensure that the payoff of the game is well-defined, we assume in this section that, for every stopping time  $\sigma$ ,  $\mathbb{E}[|\gamma_-(\sigma)|] < \infty$  and  $\mathbb{E}[|\gamma_+(\sigma)|] < \infty$ .

**DEFINITION 3.14.** *Given  $z \in \mathcal{I}$  and  $\mathbb{F}$ -stopping times  $\sigma_-$  and  $\sigma_+$ , the payoff of the Dynkin game is*

$$D(\sigma_-, \sigma_+; z) = \int_0^{\sigma_- \wedge \sigma_+} \pi(t, z) dt + \gamma_+(\sigma_+) 1_{\{\sigma_+ \leq \sigma_-\}} - \gamma_-(\sigma_-) 1_{\{\sigma_- < \sigma_+\}}.$$

*The game has a value if*

$$\sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E}[D(\sigma_-, \sigma_+; z)] = \inf_{\sigma_+} \sup_{\sigma_-} \mathbb{E}[D(\sigma_-, \sigma_+; z)].$$

It is easy to see that  $\sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E}[D(\sigma_-, \sigma_+; z)] \leq \inf_{\sigma_+} \sup_{\sigma_-} \mathbb{E}[D(\sigma_-, \sigma_+; z)]$ . Moreover, we have the following theorem.

**THEOREM 3.15.** *Given any  $z \in \mathcal{I}$  such that conditions (16) and (17) hold, the value of the Dynkin game exists and is equal to*

$$m_+^*(z, 1) - m_+^*(z, 0) = \sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E}[D(\sigma_-, \sigma_+; z)] = \inf_{\sigma_+} \sup_{\sigma_-} \mathbb{E}[D(\sigma_-, \sigma_+; z)].$$

*Proof of Theorem 3.15.* It suffices to show  $m_+^*(z, 1) - m_+^*(z, 0) \leq \sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E}[D(\sigma_-, \sigma_+; z)]$ , since it follows similarly for  $m_+^*(z, 1) - m_+^*(z, 0) \geq \inf_{\sigma_+} \sup_{\sigma_-} \mathbb{E}[D(\sigma_-, \sigma_+; z)]$ .

Note that  $m_+^*(z, 1) - m_+^*(z, 0) \leq \sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E}[D(\sigma_-, \sigma_+; z)]$  if and only if, for all  $\epsilon > 0$ , there exists  $\hat{\sigma}_-$  such that, for all  $\sigma_+$ ,  $\mathbb{E}[D(\hat{\sigma}_-, \sigma_+; z)] + \epsilon \geq m_+^*(z, 1) - m_+^*(z, 0)$ .

Let  $\epsilon > 0$  be given, let  $\alpha^1 \in \mathcal{B}$  be a switching control with  $\kappa_0 = 1$  such that

$$m_+(z, \alpha^1) + \epsilon \geq m_+^*(z, 1),$$

and define  $\hat{\sigma}_- = \tau_1 = \inf\{t : I_t^1 = 0\}$ .

Let  $\sigma_+$  be an arbitrary stopping time, and define  $\alpha^0$  by taking  $I_t^0 = 0$  for  $t \leq \hat{\sigma}_- \wedge \sigma_+$  and  $I_t^0 = I_t^1$  for  $t > \hat{\sigma}_- \wedge \sigma_+$ . Thus  $I^0$  is a regime indicator function, and hence  $\alpha^0$  is an admissible switching control. In fact, since  $\alpha^1 \in \mathcal{B}$ , we also have  $\alpha^0 \in \mathcal{B}$ .

Thus, for any  $\sigma_+$ ,

$$\begin{aligned}
m_+^*(z, 1) - m_+^*(z, 0) &\leq m_+^*(z, 1) - m_+(z, \alpha^0) \leq m_+(z, \alpha^1) - m_+(z, \alpha^0) + \epsilon \\
&= \mathbb{E} \left[ \int_0^\infty \pi(t, z)(I_t^1 - I_t^0) dt + \gamma_+(\sigma_+) 1_{\{\sigma_+ < \hat{\sigma}_-\}} - \gamma_-(\hat{\sigma}_-) 1_{\{\hat{\sigma}_- \leq \sigma_+\}} \right] + \epsilon \\
&= \mathbb{E} \left[ \int_0^{\hat{\sigma}_- \wedge \sigma_+} \pi(t, z) dt + \gamma_+(\sigma_+) 1_{\{\sigma_+ < \hat{\sigma}_-\}} - \gamma_-(\hat{\sigma}_-) 1_{\{\hat{\sigma}_- \leq \sigma_+\}} \right] + \epsilon \\
&= \mathbb{E} \left[ \int_0^{\hat{\sigma}_- \wedge \sigma_+} \pi(t, z) dt + \gamma_+(\sigma_+) 1_{\{\sigma_+ < \hat{\sigma}_-\}} \right. \\
&\quad \left. - \gamma_-(\hat{\sigma}_-) 1_{\{\hat{\sigma}_- < \sigma_+\}} - \gamma_-(\sigma_+) 1_{\{\hat{\sigma}_- = \sigma_+\}} \right] + \epsilon \\
&\leq \mathbb{E} \left[ \int_0^{\hat{\sigma}_- \wedge \sigma_+} \pi(t, z) dt + \gamma_+(\sigma_+) 1_{\{\sigma_+ \leq \hat{\sigma}_-\}} - \gamma_-(\hat{\sigma}_-) 1_{\{\hat{\sigma}_- < \sigma_+\}} \right] + \epsilon \\
&= \mathbb{E} [D(\hat{\sigma}_-, \sigma_+; z)] + \epsilon,
\end{aligned}$$

where the last inequality follows from (17). Thus,

$$m_+^*(z, 1) - m_+^*(z, 0) \leq \sup_{\sigma_-} \inf_{\sigma_+} \mathbb{E} [D(\sigma_-, \sigma_+; z)]. \quad \square$$

Furthermore, we see the following.

**COROLLARY 3.16.** *If (16) and (17) hold and  $\pi(t, z)$  is decreasing in  $z$ , then  $m_+^*(z, 1) - m_+^*(z, 0)$  is decreasing in  $z$ .*

That is, when the marginal payoff is decreasing in the capacity level  $z$ , the added benefit of being invested in the project at level  $z$  is also decreasing in  $z$ . The economic interpretation is that there are decreasing returns to scale.

**3.4. Examples with explicit solutions.** We now illustrate how our methodology can be used to solve a reversible investment problem with a Cobb–Douglas production function. This is a special case of the problem solved in [33]. Note that, although our method can handle the general problem in [33] among others, we nevertheless have selected this simple case to illustrate our techniques: Unlike [33], we solve *without* assuming a priori the continuous differentiability of the value function or any assumptions on the structure of the switching regions.

*Singular control problem.*

$$(26) \quad V(x, y) := \sup_{(\xi^+, \xi^-) \in \mathcal{A}_y} \mathbb{E} \left[ \int_0^\infty \Pi(t, Y_t) dt - \int_{[0, \infty)} \gamma_+(t) d\xi_t^+ - \int_{[0, \infty)} \gamma_-(t) d\xi_t^- \right],$$

subject to

$$\begin{aligned}\xi^+(0) &= \xi^-(0) := 0, \\ Y_t &:= y + \xi_t^+ - \xi_t^- \in \bar{\mathcal{I}} \quad \forall t \in [0, \infty), \\ \Pi(\omega, t, y) &:= e^{-\rho t} (X_t^x(\omega))^\lambda y^\beta, \\ dX_t^x &:= bX_t^x dt + \sqrt{2}\sigma X_t^x dW_t, \quad X_0 := x > 0, \\ \text{and } \gamma_+(t) &:= e^{-\rho t} K_1, \gamma_-(t) := e^{-\rho t} K_0.\end{aligned}$$

For simplicity, we assume  $\bar{\mathcal{I}} = [A, B] \subset [0, \infty)$  is a bounded interval,  $\rho > 0$ ,  $\lambda \in (0, n)$ ,  $\beta \in (0, 1]$ , and  $K_0 < 0$ ,  $K_1 > 0$ , with  $K_0 + K_1 > 0$ . Here  $n = \frac{-(b-\sigma^2) + \sqrt{(b-\sigma^2)^2 + 4\sigma^2\rho}}{2\sigma^2}$ . This formulation is from [33].

This problem is solved in several steps.

*Step 1: Corresponding optimal switching problem.* First, one can check that standing assumptions A1, A2, and A3 and the assumptions in Theorem 3.10 hold for this problem, with

$$\pi(\omega, t, y) = \beta e^{-\rho t} (X_t^x(\omega))^\lambda y^{-(1-\beta)}.$$

Also,  $R(x, y)$  is differentiable in  $y$ , so that

$$R(x, y) = \mathbb{E} \left[ \int_0^\infty \Pi(t, y) dt \right] = \frac{-x^\lambda y^\beta}{\sigma^2 \lambda^2 + (b - \sigma^2) \lambda - \rho},$$

and

$$r(x, y) = R_y(x, y) = \mathbb{E} \left[ \int_0^\infty \pi(t, y) dt \right] = \frac{-\beta x^\lambda y^{-(1-\beta)}}{\sigma^2 \lambda^2 + (b - \sigma^2) \lambda - \rho}.$$

By Lemma 3.4, it suffices to solve for the optimal switching problem defined by

(27)

$$v_k(x, z) := m_+^*(x, z, k) = \sup_{\substack{\alpha \in \mathcal{B} \\ \kappa_0 = k}} \mathbb{E} \left[ \int_0^\infty e^{-\rho t} \beta z^{-(1-\beta)} (X_t^x)^\lambda I_t dt - \sum_{n=1}^\infty e^{-\rho \tau_n} K_{\kappa_n} \right].$$

*Step 2: Consistent collection of optimal switching controls.* Applying the regularity results of [32] for switching controls to problem (27), we see that, for any given  $z \in (A, B)$  and  $k \in \{0, 1\}$ , the value function  $v_k(\cdot, z)$  is continuously differentiable. Moreover, for each  $z \in (A, B)$ , an optimal switching control exists and can be described in terms of the switching regions: For each  $z \in (A, B)$ , there exist  $0 < F(z) < G(z) < \infty$  such that it is optimal to switch from regime 0 to regime 1 (to invest in the project at level  $z$ ) when  $X_t^x \in [G(z), \infty)$  and to switch from regime 1 to regime 0 (disinvest at level  $z$ ) when  $X_t^x \in [0, F(z)]$ .

Therefore, given any initial value  $y \in [A, B]$  for the singular control problem, a collection of optimal switching controls can be defined as follows.

For  $(x, z) \in \mathcal{X} \times (A, B)$ , define the switching control  $\hat{\alpha}(x, z) = (\hat{\tau}_n, \hat{\kappa}_n)_{n \geq 0}$ , starting from  $\hat{\tau}_0 = 0$  and  $\kappa_0 = 1_{\{z \leq y\}}$  by setting  $\hat{\kappa}_n := 1 - \kappa_{n-1}$  for all  $n \geq 1$  and

- if  $\kappa_{n-1} = 0$ ,  $\hat{\tau}_n := \inf\{t > \tau_{n-1} : X_t^x \geq G(z)\}$ , or

- if  $\kappa_{n-1} = 1$ ,  $\hat{\tau}_n := \inf\{t > \tau_{n-1} : X_t^x \leq F(z)\}$ .

Moreover, by the regularity of the value functions, we solve for  $F(z)$  and  $G(z)$  explicitly in our case, obtaining  $F(z) = \kappa z^{\frac{1-\beta}{\lambda}}$  and  $G(z) = \nu z^{\frac{1-\beta}{\lambda}}$ , where  $\kappa$  and  $\nu$  are unique solutions to

$$\frac{\beta}{\lambda - m} [\nu^{\lambda-m} - \kappa^{\lambda-m}] = -\frac{\rho}{m} [K_1 \nu^{-m} + K_0 \kappa^{-m}],$$

$$\frac{\beta}{n - \lambda} [\nu^{\lambda-n} - \kappa^{\lambda-n}] = \frac{\rho}{n} [K_1 \nu^{-n} + K_0 \kappa^{-n}].$$

Here  $m < 0 < n$ , and  $n, m = \frac{-(b-\sigma^2) \pm \sqrt{(b-\sigma^2)^2 + 4\sigma^2 r}}{2\sigma^2}$ .

Finally, by checking the appropriate integrability conditions, and by noting that  $F$  and  $G$  are increasing in  $z$ , it is not hard to verify that the above collection of optimal switching controls is consistent. (See Figure 1.)

*Step 3: Optimal singular control and value functions.* By Proposition 2.10, this consistent collection of optimal switching control corresponds to an admissible singular control  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}_y$ . Moreover, since  $\mathcal{I}$  is bounded, it is integrable following Theorem 3.10.

Put together, the investment region is given by  $\{(x, z) : x \geq G(z)\}$  and the disinvestment region by  $\{(x, z) : x \leq F(z)\}$ .  $Y_t$  is constant when  $(X_t, Y_t)$  is in the wait region, given by  $\{(x, z) : F(z) < x < G(z)\}$ . If  $(x, y)$  is in the investment (or disinvestment) region, then a jump is exerted at time zero to make  $Y_{0+} = G^{-1}(x)$  (or  $Y_{0+} = F^{-1}(x)$ ).

(1) For fixed  $z_0$  switching control

(2) For general  $z$ , consistent switching controls

FIG. 1. Illustration of optimal consistent switching control from optimal singular control.

Finally, by Lemma 3.4 and Theorem 3.9 the value function has the following representation:

$$\begin{aligned} V(x, y) &= R(x, y) + \int_y^B v_0(x, z) dz + \int_A^y (v_1(x, z) - r(x, z)) dz \\ &= R(x, A) + \int_y^B v_0(x, z) dz + \int_A^y v_1(x, z) dz, \end{aligned}$$

where  $v_0$  and  $v_1$  are given by [32, Theorem 4.2.3]

$$\begin{aligned} v_0(x, z) &= \begin{cases} A(z)x^n, & x < G(z), \\ B(z)x^m + r(x, z) - K_1, & x \geq G(z), \end{cases} \\ v_1(x, z) &= \begin{cases} A(z)x^n - K_0, & x \leq F(z), \\ B(z)x^m + r(x, z), & x > F(z), \end{cases} \end{aligned}$$

where  $A(z) = \frac{\nu^{-n}}{n-m} \left( \frac{\beta\nu^\lambda}{\sigma^2(n-\lambda)} + mK_1 \right) z^{\frac{-n(1-\beta)}{\lambda}}$ ,  $B(z) = -\frac{\kappa^{-m}}{n-m} \left( \frac{\beta\kappa^\lambda}{\sigma^2(\lambda-m)} + nK_0 \right) z^{\frac{-m(1-\beta)}{\lambda}}$ .

The above results are consistent with equations (117)–(120) and Remark 4 in [33].

**4. Conclusions.** This paper builds a generic connection between singular controls of finite variation and sequential optimal stopping problems. This correspondence is independent of any particular formulation of control problems and provides a novel method for solving explicitly high-dimensional singular control problems where randomness may not be necessarily captured by a diffusion and where payoff functions can be nonsmooth. It also enables us to derive sufficient conditions for the existence of optimal controls, for the smooth fit principle, and for the regularity of value functions. Consequently, this regularity result links singular controls and Dynkin games through sequential optimal stopping problems.

**Appendix A. Proof of Theorem 3.10.** The proof is built on the following proposition.

PROPOSITION A.1. *Under Assumption 3.8.1, for almost all  $z \in \mathcal{I}$  and any  $T > 0$ ,*

$$\mathbb{E}[u_T(z, \alpha(z))] \geq \begin{cases} -\mathbb{E}[\gamma_+(T)I_{T+}(z)] & \text{when } z > y, \\ -\mathbb{E}[\gamma_-(T)(1 - I_{T+}(z))] & \text{when } z \leq y, \end{cases}$$

where  $\alpha(z) \in \mathcal{B}$  is given by Assumption 3.8.1 and

$$u_T(z, \alpha(z)) = \begin{cases} \int_0^T \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) 1_{\{\tau_n(z) < T\}}, & z > y, \\ \int_0^T -\pi(t, z) (1 - I_t(z)) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) 1_{\{\tau_n(z) < T\}}, & z \leq y. \end{cases}$$

*Proof.* By Assumption 3.8.1,  $\alpha(z)$  is an optimal admissible switching control for almost all  $z \in \mathcal{I}$ . Fix such a  $z \in \mathcal{I}$ . Consider the admissible switching control  $\tilde{\alpha}_T(z)$  defined by the regime indicator function

$$\tilde{I}_t(z) = I_0(z) 1_{\{t \leq T\}} + I_t(z) 1_{\{t > T\}}.$$

Assume for now  $z > y$ . In the new switching control we have defined, we may have to switch at time  $T$  from regime  $\kappa_0 = 0$  to regime  $I_{T+}(z)$ , if  $I_{T+}(z) = 1$ . Hence,

the cost of the possible switch at  $T$  is given by  $-\gamma_+(T)I_{T+}(z)$ . After time  $T$ , the switching costs are the same for both strategies.

Since the switching control  $\alpha(z) \in \mathcal{B}$  is optimal,  $m_+(z, \alpha(z)) - m_+(z, \tilde{\alpha}_T(z)) \geq 0$ . This means that

$$\begin{aligned} 0 &\leq m_+(z, \alpha(z)) - m_+(z, \tilde{\alpha}_T(z)) = \mathbb{E} \left[ \int_0^\infty \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) \right] \\ &\quad - \mathbb{E} \left[ \int_0^\infty \pi(t, z) \tilde{I}_t(z) dt - \sum_{n=1}^\infty \gamma(\tilde{\tau}_n(z), \tilde{\kappa}_n(z)) \right] \\ &= \mathbb{E} \left[ \int_0^\infty \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) \right] \\ &\quad - \mathbb{E} \left[ \int_T^\infty \pi(t, z) I_t(z) dt - \gamma_+(T) I_{T+}(z) - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) 1_{\{T < \tau_n(z)\}} \right] \\ &= \mathbb{E} [\gamma_+(T) I_{T+}(z)] + \mathbb{E} \left[ \int_0^T \pi(t, z) I_t(z) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) 1_{\{\tau_n(z) < T\}} \right]. \end{aligned}$$

Thus, by Assumption 3.8,  $\mathbb{E}[u_T(z)] \geq -\mathbb{E}[\gamma_+(T) I_{T+}(z)]$  for almost all  $z > y$ .

Similarly, for almost all  $z \leq y$ ,

$$\begin{aligned} 0 &\leq \mathbb{E} [\gamma_-(T)(1 - I_{T+}(z))] \\ &\quad + \mathbb{E} \left[ \int_0^T -\pi(t, z)(1 - I_t(z)) dt - \sum_{n=1}^\infty \gamma(\tau_n(z), \kappa_n(z)) 1_{\{\tau_n(z) < T\}} \right]. \end{aligned}$$

Hence the claim.  $\square$

*Proof of Theorem 3.10.* Suppose  $\mathcal{I}$  is bounded, and let  $(\alpha(z))_{z \in \mathcal{I}}$  be the collection of optimal, consistent switching controls given by Assumption 3.8.1 and  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}_y$  be the corresponding singular control. The idea of the proof is to show that, for any  $\mathbb{F}$ -adapted process  $Z$  with  $U_T \leq Z_T$  and  $\mathbb{E}[|Z_T|] < \infty$  almost surely for each  $T > 0$ , we have  $\limsup_{T \rightarrow \infty} \mathbb{E}[Z_T] > -\infty$ . It then follows from the assumptions of the theorem that  $(\hat{\xi}^+, \hat{\xi}^-) \in \mathcal{A}'_y$ .

By the assumptions of the theorem, for any fixed  $T < \infty$ ,  $|U_T(y, \hat{\xi}^+, \hat{\xi}^-)| < \infty$  almost surely. Furthermore, by applying the same arguments as in the proof of Proposition 3.3 we get

$$U_T(y, \hat{\xi}^+, \hat{\xi}^-) - \int_0^T \Pi(t, y) dt = \int_{\mathcal{I}} u_T(z) dz,$$

where  $u_T$  is defined in Proposition A.1.

Let  $Z$  be any  $\mathbb{F}$ -adapted process with  $U_T \leq Z_T$  and  $\mathbb{E}[|Z_T|] < \infty$  almost surely for each  $T > 0$ . Thus,

$$Z_T \geq U_T(y, \hat{\xi}^+, \hat{\xi}^-) = \int_{\mathcal{I}} u_T(z, \alpha(z)) dz.$$

Since  $\mathcal{I}$  is bounded and  $|u_T|$  has finite expectation,  $\int_{\mathcal{I}} \mathbb{E}[|u_T(z, \alpha(z))|] dz < \infty$ . Hence by Fubini's theorem and Proposition A.1,

$$\begin{aligned}
 \mathbb{E}[Z_T] &\geq \mathbb{E} \left[ \int_{\mathcal{I}} u_T(z, \alpha(z)) dz + \int_0^T \Pi(t, y) dt \right] \\
 &\geq \int_{\mathcal{I}} \mathbb{E}[u_T(z, \alpha(z))] dz - \mathbb{E} \left[ \int_0^\infty |\Pi(t, y)| dt \right] \\
 &\geq - \int_y^\infty \mathbb{E}[\gamma_+(T) I_{T+}(z)] 1_{\{z \in \mathcal{I}\}} dz - \int_{-\infty}^y \mathbb{E}[\gamma_-(T)(1 - I_{T+}(z))] 1_{\{z \in \mathcal{I}\}} dz \\
 &\quad - \mathbb{E} \left[ \int_0^\infty |\Pi(t, y)| dt \right] \\
 &= \mathbb{E}[-\gamma_+(T)[Y_{T+} - y]^+ - \gamma_-(T)[Y_{T+} - y]^-] - \mathbb{E} \left[ \int_0^\infty |\Pi(t, y)| dt \right] \\
 &\geq -C\mathbb{E}[|\gamma_+(T)| + |\gamma_-(T)|] - \mathbb{E} \left[ \int_0^\infty |\Pi(t, y)| dt \right],
 \end{aligned}$$

where  $C = \sup \mathcal{I} - \inf \mathcal{I} < \infty$ .

Thus, by (15) and the assumptions of the theorem,  $\limsup_{T \rightarrow \infty} \mathbb{E}[Z_T] > -\infty$ .  $\square$

# STOCHASTIC DIFFERENTIAL GAMES AND VISCOSITY SOLUTIONS OF HAMILTON–JACOBI–BELLMAN–ISAACS EQUATIONS\*

RAINER BUCKDAHN<sup>†</sup> AND JUAN LI<sup>‡</sup>

**Abstract.** In this paper we study zero-sum two-player stochastic differential games with the help of the theory of backward stochastic differential equations (BSDEs). More precisely, we generalize the results of the pioneering work of Fleming and Souganidis [*Indiana Univ. Math. J.*, 38 (1989), pp. 293–314] by considering cost functionals defined by controlled BSDEs and by allowing the admissible control processes to depend on events occurring before the beginning of the game. This extension of the class of admissible control processes has the consequence that the cost functionals become random variables. However, by making use of a Girsanov transformation argument, which is new in this context, we prove that the upper and the lower value functions of the game remain deterministic. Apart from the fact that this extension of the class of admissible control processes is quite natural and reflects the behavior of the players who always use the maximum of available information, its combination with BSDE methods, in particular that of the notion of stochastic “backward semigroups” introduced by Peng [*BSDE and stochastic optimizations*, in *Topics in Stochastic Analysis*, Science Press, Beijing, 1997], allows us then to prove a dynamic programming principle for both the upper and the lower value functions of the game in a straightforward way. The upper and the lower value functions are then shown to be the unique viscosity solutions of the upper and the lower Hamilton–Jacobi–Bellman–Isaacs equations, respectively. For this Peng’s BSDE method is extended from the framework of stochastic control theory into that of stochastic differential games.

**1. Introduction.** With their pioneering paper of 1989 Fleming and Souganidis [14] were the first to study in a rigorous manner two-player zero-sum stochastic differential games and to prove that the lower and the upper value functions of such games satisfy the dynamic programming principle and that they are the unique viscosity solutions of the associated Bellman–Isaacs equations and coincide under the Isaacs condition. Their work has translated former results on differential games by Isaacs [23], Friedman [15], and, in particular, Evans and Souganidis [13] from the purely deterministic into the stochastic framework and has given an important impulse for the research in the theory of stochastic differential games. The paper of Fleming and Souganidis [14] has been the starting point for a lot of works using their approach and translating it into new contexts. So, for instance, Buckdahn, Cardaliaguet, and Rainer [6] adapted the methods of [14] in order to prove the existence of Nash equilibrium points for stochastic nonzero-sum differential games and to characterize them.

Another direction for generalization was chosen by Bayraktar and Poor [4]: They studied stochastic differential games whose modulating process is a fractional Brownian motion, while Browne [5] considered stochastic dynamic investment games in continuous time, provided conditions under which a general payoff function has an achievable value, and gave, under these conditions, an explicit representation for the value and resulting equilibrium strategies. Concerning optimal stopping games the interested reader is referred to the work of Ekström and Peskir [11], of Karatzas and Sudderth [21], as well as of Karatzas and Zamfirescu [22]. Finally, the reader more interested in the subject of stochastic differential games is also referred to the references given in [14].

The present work also investigates two-player zero-sum stochastic differential games, but with two main differences to the setting chosen by Fleming and Souganidis [14] and the other papers mentioned above: On the one hand, we allow our admissible control processes to depend on the full past of the trajectories of the driving Brownian motion; this means, in particular, that they can also depend on information occurring before the beginning of the game (which has the consequence that the cost functionals become random variables); on the other hand, we consider a more general running cost functional, which implies that the cost functionals will be given by a backward stochastic differential equation (BSDE). Both of these extensions of the framework in [14] are crucial because they allow one to harmonize the setting for stochastic differential games with that for the stochastic control theory and to simplify considerably the approach in [14] by using BSDE methods.

BSDEs in their general nonlinear form were introduced by Pardoux and Peng [24] in 1990. They have been studied since then by a lot of authors and have found various applications, namely, in stochastic control, finance, and the second order PDE theory. BSDE methods, originally developed by Peng [26], [27] for the stochastic control theory, have been introduced in the theory of stochastic differential games by Hamadene and Lepeltier [16] and Hamadene, Lepeltier, and Peng [17] to study games with a dynamics whose diffusion coefficient is strictly elliptic and does not depend on the controls. In our present work there is not any such restriction on the diffusion coefficient and the application of BSDE methods; in particular, the notion of stochastic backward semigroups (Peng [26]) allows us to prove the dynamic programming principle for the upper and lower value functions of the game in a very straightforward way (i.e., in particular without making use of  $r$ -strategies (see Definition 1.7 in [14]) and  $\pi$ -admissible strategies (see Definition 2.2 in [14]) playing an essential role in [14]) and to derive from it with the help of Peng's method (see [26], [27]) the associated Bellman–Isaacs equations.

The dynamics of the stochastic differential game we investigate is given by the controlled stochastic differential equation

$$(1.1) \quad \begin{cases} dX_s^{t,x;u,v} &= b(s, X_s^{t,x;u,v}, u_s, v_s)ds + \sigma(s, X_s^{t,x;u,v}, u_s, v_s)dB_s, \\ X_t^{t,x;u,v} &= x (\in \mathbb{R}^n), \end{cases} \quad s \in [t, T],$$

where  $T > 0$  is an arbitrarily fixed finite time horizon,  $B = (B_s)_{s \in [0, T]}$  is a  $d$ -dimensional standard Brownian motion, and  $u = (u_s)_{s \in [t, T]}$ ,  $v = (v_s)_{s \in [t, T]}$  are progressively measurable with respect to the Brownian filtration and take their values in some compact metric spaces  $U$  and  $V$ , respectively (we will say that  $u \in \mathcal{U}_{t, T}$ ,  $v \in \mathcal{V}_{t, T}$ ). Precise assumptions on the coefficients  $b : [0, T] \times \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^n$  and  $\sigma : [0, T] \times \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^{n \times d}$  are given in the next section.

The cost functional (interpreted as a payoff for player I and as a cost for player

II) is introduced by a BSDE:

$$(1.2) \quad \begin{cases} -dY_s^{t,x;u,v} &= f(s, X_s^{t,x;u,v}, Y_s^{t,x;u,v}, Z_s^{t,x;u,v}, u_s, v_s)ds - Z_s^{t,x;u,v}dB_s, \\ Y_T^{t,x;u,v} &= \Phi(X_T^{t,x;u,v}), \end{cases} \quad s \in [t, T],$$

where the driver  $f : [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U \times V \rightarrow \mathbb{R}$  describes the running cost and  $\Phi : \mathbb{R}^n \rightarrow \mathbb{R}$  the terminal cost. Under the assumptions on  $f$  and  $\Phi$  that will be introduced in the next section, the above BSDE has a unique solution  $(Y_s^{t,x;u,v}, Z_s^{t,x;u,v})_{s \in [t, T]}$ , and the cost functional is given by

$$(1.3) \quad J(t, x; u, v) = Y_t^{t,x;u,v}.$$

As usual in the differential game theory, the players cannot restrict to play only control processes, and one player has to fix a strategy while the other player chooses the best answer to this strategy in the form of a control process. A strategy admissible for player I (resp., player II) is a nonanticipating mapping  $\alpha : \mathcal{V}_{t,T} \rightarrow \mathcal{U}_{t,T}$  (resp.,  $\beta : \mathcal{U}_{t,T} \rightarrow \mathcal{V}_{t,T}$ ) which associates every admissible control of the other player with one of his own admissible controls (we write:  $\alpha \in \mathcal{A}_{t,T}, \beta \in \mathcal{B}_{t,T}$ ; the precise definitions can be found in section 3). We define the lower value function of our stochastic differential game as follows:

$$(1.4) \quad W(t, x) := \operatorname{essinf}_{\beta \in \mathcal{B}_{t,T}} \operatorname{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u)),$$

and the upper value function is given by

$$(1.5) \quad U(t, x) := \operatorname{esssup}_{\alpha \in \mathcal{A}_{t,T}} \operatorname{essinf}_{v \in \mathcal{V}_{t,T}} J(t, x; \alpha(v), v).$$

The objective of our paper is to investigate these lower and upper value functions. The main results of the paper state that  $W$  and  $U$  are deterministic (Proposition 3.3) continuous viscosity solutions of the Bellman–Isaacs equations (Theorem 4.2)

$$(1.6) \quad \begin{cases} \frac{\partial}{\partial t} W(t, x) + H^-(t, x, W, DW, D^2W) = 0, & (t, x) \in [0, T] \times \mathbb{R}^n, \\ W(T, x) = \Phi(x), & x \in \mathbb{R}^n, \end{cases}$$

and

$$(1.7) \quad \begin{cases} \frac{\partial}{\partial t} U(t, x) + H^+(t, x, U, DU, D^2U) = 0, & (t, x) \in [0, T] \times \mathbb{R}^n, \\ U(T, x) = \Phi(x), & x \in \mathbb{R}^n, \end{cases}$$

respectively, associated with the Hamiltonians

$$H^-(t, x, y, p, X) = \sup_{u \in U} \inf_{v \in V} H(t, x, y, p, X, u, v),$$

$$H^+(t, x, y, p, X) = \inf_{v \in V} \sup_{u \in U} H(t, x, y, p, X, u, v),$$

$(t, x, y, p, X) \in [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times S^n$  (recall that  $S^n$  denotes the set of all  $n \times n$  symmetric matrices), where

$$(1.8) \quad \begin{aligned} H(t, x, y, p, X, u, v) &= 1/2 \cdot \operatorname{tr}(\sigma \sigma^T(t, x, u, v)X) \\ &+ p \cdot b(t, x, u, v) + f(t, x, y, p \cdot \sigma(t, x, u, v), u, v). \end{aligned}$$

Moreover, we prove the uniqueness (Theorem 5.3) in a class of continuous functions with a growth condition which was introduced by Barles, Buckdahn, and Pardoux [3] and is weaker than the polynomial growth assumption. Fleming and Souganidis [14] obtained the above equations for stochastic differential games with the running cost  $f(t, x, y, z, u, v) = f(t, x, u, v)$ . Let us also mention that Cheridito et al. [7] discussed Bellman–Isaacs equations with  $f(t, x, y, z, u, v) = \alpha(t, x, u, v) + \beta(t, x, u, v)y$  as an example of nonlinear PDEs to which they gave a stochastic control interpretation in terms of so-called 2-BSDEs and auxiliary stochastic target problems.

Notice the fact that  $W$  and  $U$ , introduced as a combination of essential infimum and essential supremum over a class of random variables, are deterministic is far from being trivial. The method developed by Peng [26], [27] (see also Theorem A.2 of the present paper) for value functions involving only control processes but not strategies does not apply here since the strategies from  $\mathcal{A}_{t,T}$  and  $\mathcal{B}_{t,T}$  do not have, in general, any continuity property. To overcome this difficulty we show in Proposition 3.3 and Lemma 3.4 that  $W$  and  $U$  are invariant under Girsanov transformation and use the fact that a functional of the Brownian motion which is invariant under Girsanov transformation into all directions of the Cameron–Martin space must be deterministic. We emphasize that the proof of Lemma 3.4 does not use BSDE methods which makes this method also applicable to other situations, such as standard stochastic control problems.

Our paper is organized as follows. Section 2 and Appendix A recall some elements of the theory of backward SDEs and forward-backward SDEs which will be needed in what follows. Section 3 introduces the setting of the stochastic differential game and, in particular, the notion of the lower and the upper value functions (see (1.4) and (1.5)). Both functions  $W$  and  $U$ , a priori random fields, turn out to be deterministic functions (Proposition 3.3) which are Lipschitz in  $x$  (Lemma 3.5) and  $\frac{1}{2}$ -Hölder continuous in  $t$  (Theorem 3.10). Moreover, they satisfy the dynamic programming principle (DPP) (Theorem 3.6). The DPP allows us to derive in section 4 with the help of Peng’s method that  $W$  and  $U$  are viscosity solutions of the associated Bellman–Isaacs equations (Theorem 4.2). The uniqueness is studied in section 5. The main result of this section is a comparison result which compares viscosity sub- and supersolutions of Bellman–Isaacs equations (Theorem 5.3). This theorem not only allows us to characterize  $W$  and  $U$  as unique viscosity solutions of associated Bellman–Isaacs equations but also to show that, under the Isaacs condition,  $W$  and  $U$  coincide (one says that the game has a value; see Remark 5.2), while, in general, without the Isaacs condition we have only  $W \leq U$  (see Remark 5.1). Finally, under the more restrictive assumptions of Fleming and Souganidis, we identify  $W$  and  $U$  with the value functions defined by them in [14]; see Remark 5.3.

**2. Preliminaries.** Let us first introduce the setting in which we want to study stochastic differential games. The probability space on which we work is the classical Wiener space  $(\Omega, \mathcal{F}, P)$ , and the driving Brownian motion  $B$  will be the coordinate process on  $\Omega$ . Let us be more precise:  $\Omega$  is the set of continuous functions from  $[0, T]$  to  $\mathbb{R}^d$  starting from 0 ( $\Omega = C_0([0, T]; \mathbb{R}^d)$ ),  $\mathcal{F}$  is the Borel  $\sigma$ -algebra over  $\Omega$ , completed with respect to the Wiener measure  $P$  on this space, and  $B$  denotes the coordinate process:  $B_s(\omega) = \omega_s$ ,  $s \in [0, T]$ ,  $\omega \in \Omega$ . By  $\mathbb{F} = \{\mathcal{F}_s, 0 \leq s \leq T\}$  we denote the natural filtration generated by  $\{B_s\}_{0 \leq s \leq T}$  and augmented by all  $P$ -null sets, i.e.,

$$\mathcal{F}_s = \sigma\{B_r, r \leq s\} \vee \mathcal{N}_P, \quad s \in [0, T],$$

where  $\mathcal{N}_P$  is the set of all  $P$ -null subsets and  $T > 0$  a fixed real time horizon. For any  $n \geq 1$ ,  $|z|$  denotes the Euclidean norm of  $z \in \mathbb{R}^n$ . We also shall introduce the

following spaces of processes which will be used frequently in what follows:

$$\mathcal{S}^2(0, T; \mathbb{R}) := \{(\psi_t)_{0 \leq t \leq T} \text{ real-valued adapted càdlàg process} :$$

$$E[\sup_{0 \leq t \leq T} |\psi_t|^2] < +\infty\};$$

$$\mathcal{H}^2(0, T; \mathbb{R}^n) := \{(\psi_t)_{0 \leq t \leq T} \text{ } \mathbb{R}^n\text{-valued progressively measurable process} :$$

$$\|\psi\|_2^2 = E[\int_0^T |\psi_t|^2 dt] < +\infty\}.$$

Let us now consider a function  $g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}$  with the property that  $(g(t, y, z))_{t \in [0, T]}$  is progressively measurable for each  $(y, z)$  in  $\mathbb{R} \times \mathbb{R}^d$ , and we also make the following assumptions on  $g$  throughout the paper:

(A1) There exists a constant  $C \geq 0$  such that,  $P$ -a.s., for all  $t \in [0, T]$ ,  $y_1, y_2 \in \mathbb{R}$ ,  $z_1, z_2 \in \mathbb{R}^d$ ,

$$|g(t, y_1, z_1) - g(t, y_2, z_2)| \leq C(|y_1 - y_2| + |z_1 - z_2|).$$

(A2)  $g(\cdot, 0, 0) \in \mathcal{H}^2(0, T; \mathbb{R})$ .

The following result on BSDEs is by now well known; for its proof the reader is referred to Pardoux and Peng [24].

LEMMA 2.1. *Under the assumptions (A1) and (A2), for any random variable  $\xi \in L^2(\Omega, \mathcal{F}_T, P)$ , the BSDE*

$$(2.1) \quad y_t = \xi + \int_t^T g(s, y_s, z_s) ds - \int_t^T z_s dB_s, \quad 0 \leq t \leq T,$$

has a unique adapted solution

$$(y_t^{T, g, \xi}, z_t^{T, g, \xi})_{t \in [0, T]} \in \mathcal{S}^2(0, T; \mathbb{R}) \times \mathcal{H}^2(0, T; \mathbb{R}^d).$$

In what follows, we always assume that the driving coefficient  $g$  of a BSDE satisfies (A1) and (A2).

Let us remark that Lemma 2.1 remains true when assumption (A1) is replaced by weaker assumptions, for instance those studied in Bahlali [1], Bahlali et al. [2], or Pardoux and Peng [25]. However, here, for the sake of simplicity of the calculus we prefer to work with the Lipschitz assumption.

We also shall recall the following basic results on BSDEs. We begin with the well-known comparison theorem (see Theorem 2.2 in El Karoui, Peng, and Quenez [12]).

LEMMA 2.2 (comparison theorem). *Given two coefficients  $g_1$  and  $g_2$  satisfying (A1) and (A2) and two terminal values  $\xi_1, \xi_2 \in L^2(\Omega, \mathcal{F}_T, P)$ , we denote by  $(y^1, z^1)$  and  $(y^2, z^2)$  the solution of BSDE with the data  $(\xi_1, g_1)$  and  $(\xi_2, g_2)$ , respectively. Then we have:*

(i) (Monotonicity). *If  $\xi_1 \geq \xi_2$  and  $g_1 \geq g_2$ , a.s., then  $y_t^1 \geq y_t^2$ , a.s., for all  $t \in [0, T]$ .*

(ii) (Strict monotonicity). *If, in addition to (i), we also assume that  $P(\xi_1 > \xi_2) > 0$ , then  $P\{y_t^1 > y_t^2\} > 0$ ,  $0 \leq t \leq T$ , and, in particular,  $y_0^1 > y_0^2$ .*

Using the notation introduced in Lemma 2.2 we now suppose that, for some  $g : \Omega \times [0, T] \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}$  satisfying (A1) and (A2) and for some  $i \in \{1, 2\}$ , the drivers  $g_i$ ,  $i = 1, 2$ , are of the form

$$g_i(s, y_s^i, z_s^i) = g(s, y_s^i, z_s^i) + \varphi_i(s), \quad \text{dsdP-a.e., } i = 1, 2,$$

where  $\varphi_i \in \mathcal{H}^2(0, T; \mathbb{R})$ ,  $i = 1, 2$ . Then, for terminal values  $\xi_1, \xi_2$  belonging to  $L^2(\Omega, \mathcal{F}_T, P)$  we have the following.

LEMMA 2.3. *The difference of the solutions  $(y^1, z^1)$  and  $(y^2, z^2)$  of BSDE with the data  $(\xi_1, g_1)$  and  $(\xi_2, g_2)$ , respectively, satisfies the following estimate:*

$$\begin{aligned} & |y_t^1 - y_t^2|^2 + \frac{1}{2} E \left[ \int_t^T e^{\beta(s-t)} [|y_s^1 - y_s^2|^2 + |z_s^1 - z_s^2|^2] ds | \mathcal{F}_t \right] \\ & \leq E[e^{\beta(T-t)} |\xi_1 - \xi_2|^2 | \mathcal{F}_t] + E \left[ \int_t^T e^{\beta(s-t)} |\varphi_1(s) - \varphi_2(s)|^2 ds | \mathcal{F}_t \right], \\ & \quad P\text{-a.s., for all } 0 \leq t \leq T, \end{aligned}$$

where  $\beta = 16(1 + C^2)$ .

*Proof.* For the proof the reader is referred to Proposition 2.1 in El Karoui, Peng, and Quenez [12] or Theorem 2.3 in Peng [26].  $\square$

**3. Stochastic differential games and associated dynamic programming principles.** Now we can study our stochastic differential games. The set of admissible control processes  $\mathcal{U}$  (resp.,  $\mathcal{V}$ ) for the first (resp., second) player is the set of all  $U$  (resp.,  $V$ )-valued  $\mathcal{F}_t$ -progressively measurable processes. The control state spaces  $U$  and  $V$  are supposed to be compact metric spaces.

For given admissible controls  $u(\cdot) \in \mathcal{U}$  and  $v(\cdot) \in \mathcal{V}$ , the according orbit which regards  $t$  as the initial time and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$  as the initial state is defined by the solution of the following SDE:

$$(3.1) \quad \begin{cases} dX_s^{t, \zeta; u, v} &= b(s, X_s^{t, \zeta; u, v}, u_s, v_s) ds + \sigma(s, X_s^{t, \zeta; u, v}, u_s, v_s) dB_s, \quad s \in [t, T], \\ X_t^{t, \zeta; u, v} &= \zeta, \end{cases}$$

where the mappings

$$b : [0, T] \times \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^n \quad \text{and} \quad \sigma : [0, T] \times \mathbb{R}^n \times U \times V \rightarrow \mathbb{R}^{n \times d}$$

satisfy the following conditions:

(H3.1)

- (i) For every fixed  $x \in \mathbb{R}^n$ ,  $b(\cdot, x, \cdot, \cdot)$  and  $\sigma(\cdot, x, \cdot, \cdot)$  are continuous in  $(t, u, v)$ ;
- (ii) there exists a  $C > 0$  such that, for all  $t \in [0, T]$ ,  $x, x' \in \mathbb{R}^n$ ,  $u \in U$ ,  $v \in V$ ,  $|b(t, x, u, v) - b(t, x', u, v)| + |\sigma(t, x, u, v) - \sigma(t, x', u, v)| \leq C|x - x'|$ .

From (H3.1) we can get the global linear growth conditions of  $b$  and  $\sigma$ , i.e., the existence of some  $C > 0$  such that, for all  $0 \leq t \leq T$ ,  $u \in U$ ,  $v \in V$ ,  $x \in \mathbb{R}^n$ ,

$$(3.2) \quad |b(t, x, u, v)| + |\sigma(t, x, u, v)| \leq C(1 + |x|).$$

It follows from (A.2) in the Appendix that, under the above assumptions, for any  $u(\cdot) \in \mathcal{U}$  and  $v(\cdot) \in \mathcal{V}$ , SDE (3.1) has a unique strong solution. Moreover, for any  $p \geq 2$ , there exists  $C_p \in \mathbb{R}$  such that, for any  $t \in [0, T]$ ,  $u(\cdot) \in \mathcal{U}$ ,  $v(\cdot) \in \mathcal{V}$ , and  $\zeta, \zeta' \in L^p(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we also have the following estimates,  $P$ -a.s.:

$$(3.3) \quad \begin{aligned} E \left[ \sup_{s \in [t, T]} |X_s^{t, \zeta; u, v} - X_s^{t, \zeta'; u, v}|^p | \mathcal{F}_t \right] &\leq C_p |\zeta - \zeta'|^p, \\ E \left[ \sup_{s \in [t, T]} |X_s^{t, \zeta; u, v}|^p | \mathcal{F}_t \right] &\leq C_p (1 + |\zeta|^p). \end{aligned}$$

The constant  $C_p$  depends only on the Lipschitz and the linear growth constants of  $b$  and  $\sigma$  with respect to  $x$ .

Let now be given two functions

$$\Phi : \mathbb{R}^n \rightarrow \mathbb{R}, \quad f : [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U \times V \rightarrow \mathbb{R}$$

that satisfy the following conditions:

(H3.2)

- (i) For every fixed  $(x, y, z) \in \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d$ ,  $f(\cdot, x, y, z, \cdot, \cdot)$  is continuous in  $(t, u, v)$ , and there exists a constant  $C > 0$  such that, for all  $t \in [0, T]$ ,  $x, x' \in \mathbb{R}^n$ ,  $y, y' \in \mathbb{R}$ ,  $z, z' \in \mathbb{R}^d$ ,  $u \in U$ , and  $v \in V$ ,

$$|f(t, x, y, z, u, v) - f(t, x', y', z', u, v)| \leq C(|x - x'| + |y - y'| + |z - z'|);$$

- (ii) there is a constant  $C > 0$  such that, for all  $x, x' \in \mathbb{R}^n$ ,

$$|\Phi(x) - \Phi(x')| \leq C|x - x'|.$$

From (H3.2) we see that  $f$  and  $\Phi$  also satisfy the global linear growth condition in  $x$ , i.e., there exists some  $C > 0$  such that, for all  $0 \leq t \leq T$ ,  $u \in U$ ,  $v \in V$ , and  $x \in \mathbb{R}^n$ ,

$$(3.4) \quad |f(t, x, 0, 0, u, v)| + |\Phi(x)| \leq C(1 + |x|).$$

For any  $u(\cdot) \in \mathcal{U}$ ,  $v(\cdot) \in \mathcal{V}$ , and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , the mappings  $\xi := \Phi(X_T^{t, \zeta; u, v})$  and  $g(s, y, z) := f(s, X_s^{t, \zeta; u, v}, y, z, u_s, v_s)$  satisfy the conditions of Lemma 2.1 on the interval  $[t, T]$ . Therefore, there exists a unique solution to the following BSDE:

$$(3.5) \quad \begin{cases} -dY_s^{t, \zeta; u, v} &= f(s, X_s^{t, \zeta; u, v}, Y_s^{t, \zeta; u, v}, Z_s^{t, \zeta; u, v}, u_s, v_s)ds - Z_s^{t, \zeta; u, v}dB_s, \\ Y_T^{t, \zeta; u, v} &= \Phi(X_T^{t, \zeta; u, v}), \end{cases}$$

where  $X^{t, \zeta; u, v}$  is introduced by (3.1).

Moreover, in analogy to Proposition A.1, we can see that there exists some constant  $C > 0$  such that, for all  $0 \leq t \leq T$ ,  $\zeta, \zeta' \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ ,  $u(\cdot) \in \mathcal{U}$ , and  $v(\cdot) \in \mathcal{V}$ ,  $P$ -a.s.,

$$(3.6) \quad \begin{aligned} \text{(i)} \quad & |Y_t^{t, \zeta; u, v} - Y_t^{t, \zeta'; u, v}| \leq C|\zeta - \zeta'|; \\ \text{(ii)} \quad & |Y_t^{t, \zeta; u, v}| \leq C(1 + |\zeta|). \end{aligned}$$

We now introduce the following subspaces of admissible controls.

**DEFINITION 3.1.** *An admissible control process  $u = \{u_r, r \in [t, s]\}$  (resp.,  $v = \{v_r, r \in [t, s]\}$ ) for player I (resp., II) on  $[t, s]$  ( $t < s \leq T$ ) is an  $\mathcal{F}_r$ -progressively measurable process taking values in  $U$  (resp.,  $V$ ). The set of all admissible controls for player I (resp., II) on  $[t, s]$  is denoted by  $\mathcal{U}_{t,s}$  (resp.,  $\mathcal{V}_{t,s}$ ). We identify two processes  $u$  and  $\bar{u}$  in  $\mathcal{U}_{t,s}$  and write  $u \equiv \bar{u}$  on  $[t, s]$ , if  $P\{u = \bar{u} \text{ a.e. in } [t, s]\} = 1$ . Similarly we interpret  $v \equiv \bar{v}$  on  $[t, s]$  in  $\mathcal{V}_{t,s}$ .*

Finally, we have still to define the admissible strategies for the game.

**DEFINITION 3.2.** *A nonanticipative strategy for player I on  $[t, s]$  ( $t < s \leq T$ ) is a mapping  $\alpha : \mathcal{V}_{t,s} \rightarrow \mathcal{U}_{t,s}$  such that, for any  $\mathbb{F}$ -stopping time  $S : \Omega \rightarrow [t, s]$  and any  $v_1, v_2 \in \mathcal{V}_{t,s}$ , with  $v_1 \equiv v_2$  on  $\llbracket t, S \rrbracket$ , it holds that  $\alpha(v_1) \equiv \alpha(v_2)$  on  $\llbracket t, S \rrbracket$ . Nonanticipative strategies for player II on  $[t, s]$ ,  $\beta : \mathcal{U}_{t,s} \rightarrow \mathcal{V}_{t,s}$ , are defined similarly. The set of all nonanticipative strategies  $\alpha : \mathcal{V}_{t,s} \rightarrow \mathcal{U}_{t,s}$  for player I on  $[t, s]$  is denoted by  $\mathcal{A}_{t,s}$ . The set of all nonanticipative strategies  $\beta : \mathcal{U}_{t,s} \rightarrow \mathcal{V}_{t,s}$  for player II on  $[t, s]$  is denoted by  $\mathcal{B}_{t,s}$ . (Recall that  $\llbracket t, S \rrbracket = \{(r, \omega) \in [0, T] \times \Omega, t \leq r \leq S(\omega)\}$ .)*

Given the control processes  $u(\cdot) \in \mathcal{U}_{t,T}$  and  $v(\cdot) \in \mathcal{V}_{t,T}$  we introduce the following associated cost functional:

$$(3.7) \quad J(t, x; u, v) := Y_t^{t,x;u,v}, \quad (t, x) \in [0, T] \times \mathbb{R}^n,$$

where the process  $Y^{t,x;u,v}$  is defined by BSDE (3.5).

Similarly to the proof of Theorem A.2 we can get that, for any  $t \in [0, T]$  and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ ,

$$(3.8) \quad J(t, \zeta; u, v) = Y_t^{t,\zeta;u,v}, \quad P\text{-a.s.}$$

Being particularly interested in the case of a deterministic  $\zeta$ , i.e.,  $\zeta = x \in \mathbb{R}^n$ , we define the lower value function of our stochastic differential game

$$(3.9) \quad W(t, x) := \operatorname{ess\,inf}_{\beta \in \mathcal{B}_{t,T}} \operatorname{ess\,sup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u))$$

and its upper value function

$$(3.10) \quad U(t, x) := \operatorname{ess\,sup}_{\alpha \in \mathcal{A}_{t,T}} \operatorname{ess\,inf}_{v \in \mathcal{V}_{t,T}} J(t, x; \alpha(v), v).$$

The names “lower value function” and “upper value function” for  $W$  and  $U$ , respectively, are justified later by Remark 5.1.

*Remark 3.1.* (1) Here the essential infimum and the essential supremum should be understood as one with respect to indexed families of random variables (see, e.g., Dunford and Schwartz [10], Dellacherie [9], or the appendix in Karatzas and Shreve [20] for detailed discussions). For the convenience of the reader we recall the notion of  $\operatorname{ess\,inf}$  of processes. Given a family of real-valued random variables  $\eta_\alpha$ ,  $\alpha \in I$ , a random variable  $\eta$  is said to be  $\operatorname{ess\,inf}_{\alpha \in I} \eta_\alpha$ , if

- (i)  $\eta \leq \eta_\alpha$ ,  $P$ -a.s., for any  $\alpha \in I$ ;
- (ii) if there is another random variable  $\xi$  such that  $\xi \leq \eta_\alpha$ ,  $P$ -a.s., for any  $\alpha \in I$ , then  $\xi \leq \eta$ ,  $P$ -a.s.

The random variable  $\operatorname{ess\,sup}_{\alpha \in I} \eta_\alpha$  can be introduced now by the relation

$$\operatorname{ess\,sup}_{\alpha \in I} \eta_\alpha = -\operatorname{ess\,inf}_{\alpha \in I} (-\eta_\alpha).$$

Finally, recall that  $\operatorname{ess\,inf}_{\alpha \in I} \eta_\alpha = \inf_{n \geq 1} \eta_{\alpha_n}$  for some countable family  $(\alpha_n) \subset I$ ;  $\operatorname{ess\,sup}_{\alpha \in I} \eta_\alpha$  has the same property.

(2) Obviously, under the assumptions (H3.1)–(H3.2), the lower value function  $W(t, x)$  as well as the upper value function  $U(t, x)$  are well-defined, and a priori they both are bounded  $\mathcal{F}_t$ -measurable random variables. But it turns out that  $W(t, x)$  and  $U(t, x)$  are even deterministic. Indeed, concentrating on the study of the properties of  $W(t, x)$  (the function  $U(t, x)$  can be analyzed in the same manner), we can state the following,

**PROPOSITION 3.3.** *For any  $(t, x) \in [0, T] \times \mathbb{R}^n$ , we have  $W(t, x) = E[W(t, x)]$ ,  $P$ -a.s. By identifying  $W(t, x)$  with its deterministic version  $E[W(t, x)]$  we can consider  $W : [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R}$  as a deterministic function.*

*Remark 3.2.* Recall that the fact that the lower and the upper value functions defined by Fleming and Souganidis [14] are deterministic is an immediate consequence of their definition. Indeed, for a game over the time interval  $[t, T]$  only control processes which are independent of the past  $\mathcal{F}_t$  are considered as admissible, and since the admissible strategies are supposed to associate admissible control processes of

one player with those of the other player, all of the associated cost functionals are independent of  $\mathcal{F}_t$  and hence deterministic.

*Proof.* Let  $H$  denote the Cameron–Martin space of all absolutely continuous elements  $h \in \Omega$  whose derivative  $\dot{h}$  belongs to  $L^2([0, T], \mathbb{R}^d)$ .

For any  $h \in H$ , we define the mapping  $\tau_h \omega := \omega + h$ ,  $\omega \in \Omega$ . Obviously,  $\tau_h : \Omega \rightarrow \Omega$  is a bijection, and its law is given by  $P \circ [\tau_h]^{-1} = \exp\{\int_0^T \dot{h}_s dB_s - \frac{1}{2} \int_0^T |\dot{h}_s|^2 ds\} P$ . Let  $(t, x) \in [0, T] \times \mathbb{R}^n$  be arbitrarily fixed, and put  $H_t = \{h \in H | h(\cdot) = h(\cdot \wedge t)\}$ . We split now the proof in the following steps:

First step: For any  $u \in \mathcal{U}_{t,T}$ ,  $v \in \mathcal{V}_{t,T}$ , and  $h \in H_t$ ,  $J(t, x; u, v)(\tau_h) = J(t, x; u(\tau_h), v(\tau_h))$ ,  $P$ -a.s.

Indeed, we apply the Girsanov transformation to SDE (3.1) (with  $\zeta = x$ ) and compare the obtained equation with the SDE obtained from (3.1) by substituting the transformed control processes  $u(\tau_h)$  and  $v(\tau_h)$  for  $u$  and  $v$ . Then from the uniqueness of the solution of (3.1) we get  $X_s^{t,x;u,v}(\tau_h) = X_s^{t,x;u(\tau_h),v(\tau_h)}$  for any  $s \in [t, T]$ ,  $P$ -a.s. Furthermore, by a similar Girsanov transformation argument we get from the uniqueness of the solution of BSDE (3.5)

$$Y_s^{t,x;u,v}(\tau_h) = Y_s^{t,x;u(\tau_h),v(\tau_h)} \text{ for any } s \in [t, T], \text{ } P\text{-a.s.,}$$

$$Z_s^{t,x;u,v}(\tau_h) = Z_s^{t,x;u(\tau_h),v(\tau_h)}, \text{ dsd } P\text{-a.e. on } [t, T] \times \Omega.$$

That means

$$J(t, x; u, v)(\tau_h) = J(t, x; u(\tau_h), v(\tau_h)), \text{ } P\text{-a.s.}$$

Second step: For  $\beta \in \mathcal{B}_{t,T}$ ,  $h \in H_t$ , let  $\beta^h(u) := \beta(u(\tau_{-h}))(\tau_h)$ ,  $u \in \mathcal{U}_{t,T}$ . Then  $\beta^h \in \mathcal{B}_{t,T}$ .

Obviously,  $\beta^h$  maps  $\mathcal{U}_{t,T}$  into  $\mathcal{V}_{t,T}$ . Moreover, this mapping is nonanticipating. Indeed, let  $S : \Omega \rightarrow [t, T]$  be an  $\mathbb{F}$ -stopping time and  $u_1, u_2 \in \mathcal{U}_{t,T}$ , with  $u_1 \equiv u_2$  on  $\llbracket t, S \rrbracket$ . Then, obviously,  $u_1(\tau_{-h}) \equiv u_2(\tau_{-h})$  on  $\llbracket t, S(\tau_{-h}) \rrbracket$  (notice that  $S(\tau_{-h})$  is still a stopping time), and because  $\beta \in \mathcal{B}_{t,T}$  we have  $\beta(u_1(\tau_{-h})) \equiv \beta(u_2(\tau_{-h}))$  on  $\llbracket t, S(\tau_{-h}) \rrbracket$ . Therefore,

$$\beta^h(u_1) = \beta(u_1(\tau_{-h}))(\tau_h) \equiv \beta(u_2(\tau_{-h}))(\tau_h) = \beta^h(u_2) \text{ on } \llbracket t, S \rrbracket.$$

Third step: For all  $h \in H_t$  and  $\beta \in \mathcal{B}_{t,T}$  we have

$$\{\text{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u))\}(\tau_h) = \text{esssup}_{u \in \mathcal{U}_{t,T}} \{J(t, x; u, \beta(u))(\tau_h)\}, \text{ } P\text{-a.s.}$$

Indeed, with the notation  $I(t, x, \beta) := \text{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u))$ ,  $\beta \in \mathcal{B}_{t,T}$ , we have  $I(t, x, \beta) \geq J(t, x; u, \beta(u))$ , and thus  $I(t, x, \beta)(\tau_h) \geq J(t, x; u, \beta(u))(\tau_h)$ ,  $P$ -a.s., for all  $u \in \mathcal{U}_{t,T}$ . On the other hand, for any random variable  $\zeta$  satisfying  $\zeta \geq J(t, x; u, \beta(u))(\tau_h)$ , and hence also  $\zeta(\tau_{-h}) \geq J(t, x; u, \beta(u))$ ,  $P$ -a.s., for all  $u \in \mathcal{U}_{t,T}$ , we have  $\zeta(\tau_{-h}) \geq I(t, x, \beta)$ ,  $P$ -a.s., i.e.,  $\zeta \geq I(t, x, \beta)(\tau_h)$ ,  $P$ -a.s. Consequently,

$$I(t, x, \beta)(\tau_h) = \text{esssup}_{u \in \mathcal{U}_{t,T}} \{J(t, x; u, \beta(u))(\tau_h)\}, \text{ } P\text{-a.s.}$$

Fourth step:  $W(t, x)$  is invariant with respect to the Girsanov transformation  $\tau_h$ , i.e.,

$$W(t, x)(\tau_h) = W(t, x), \text{ } P\text{-a.s., for any } h \in H.$$

Indeed, similarly to the third step we can show that for all  $h \in H_t$

$$\{\text{essinf}_{\beta \in \mathcal{B}_{t,T}} I(t, x; \beta)\}(\tau_h) = \text{essinf}_{\beta \in \mathcal{B}_{t,T}} \{I(t, x; \beta)(\tau_h)\}, \text{ } P\text{-a.s.}$$

Then, from the first step to the third step we have, for any  $h \in H_t$ ,

$$\begin{aligned} W(t, x)(\tau_h) &= \text{essinf}_{\beta \in \mathcal{B}_{t,T}} \text{esssup}_{u \in \mathcal{U}_{t,T}} \{J(t, x; u, \beta(u))(\tau_h)\} \\ &= \text{essinf}_{\beta \in \mathcal{B}_{t,T}} \text{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u(\tau_h), \beta^h(u(\tau_h))) \\ &= \text{essinf}_{\beta \in \mathcal{B}_{t,T}} \text{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta^h(u)) \\ &= \text{essinf}_{\beta \in \mathcal{B}_{t,T}} \text{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u)) \\ &= W(t, x), \text{ } P\text{-a.s.}, \end{aligned}$$

where we have used  $\{u(\tau_h)|u(\cdot) \in \mathcal{U}_{t,T}\} = \mathcal{U}_{t,T}$  and  $\{\beta^h|\beta \in \mathcal{B}_{t,T}\} = \mathcal{B}_{t,T}$  in order to obtain both latter equalities. Therefore, for any  $h \in H_t$ ,  $W(t, x)(\tau_h) = W(t, x)$ ,  $P$ -a.s., and since  $W(t, x)$  is  $\mathcal{F}_t$ -measurable, we have this relation even for all  $h \in H$ . Indeed, recall that our underlying fundamental space is  $\Omega = C_0([0, T]; \mathbb{R}^d)$  and that, due to the definition of the filtration, the  $\mathcal{F}_t$ -measurable random variable  $W(t, x)(\omega)$ ,  $\omega \in \Omega$ , depends only on the restriction of  $\omega$  to the time interval  $[0, t]$ .

The result of the fourth step combined with the following auxiliary Lemma 3.4 completes the proof.  $\square$

LEMMA 3.4. *Let  $\zeta$  be a random variable defined over our classical Wiener space  $(\Omega, \mathcal{F}_T, P)$ , such that  $\zeta(\tau_h) = \zeta$ ,  $P$ -a.s., for any  $h \in H$ . Then  $\zeta = E\zeta$ ,  $P$ -a.s.*

*Proof.* Let  $h \in H$  and  $A \in \mathcal{B}(\mathbb{R})$ . Then

$$\begin{aligned} &E \left[ \mathbf{1}_{\{\zeta \in A\}} \exp \left\{ \int_0^T \dot{h}_s dB_s - \frac{1}{2} \int_0^T |\dot{h}_s|^2 ds \right\} \right] \\ &= E \left[ \mathbf{1}_{\{\zeta(\tau_{-h}) \in A\}} \exp \left\{ \int_0^T \dot{h}_s dB_s - \frac{1}{2} \int_0^T |\dot{h}_s|^2 ds \right\} \right] \\ &= E[\mathbf{1}_{\{\zeta \in A\}}], \end{aligned}$$

from which we deduce that

$$E \left[ \mathbf{1}_{\{\zeta \in A\}} \exp \left\{ \int_0^T \dot{h}_s dB_s \right\} \right] = E[\mathbf{1}_{\{\zeta \in A\}}] E \left[ \exp \left\{ \int_0^T \dot{h}_s dB_s \right\} \right],$$

i.e., for any  $\varphi \in L^2([0, T]; \mathbb{R}^d)$ ,

$$(3.11) \quad E \left[ \mathbf{1}_{\{\zeta \in A\}} \exp \left\{ \int_0^T \varphi_s dB_s \right\} \right] = E[\mathbf{1}_{\{\zeta \in A\}}] E \left[ \exp \left\{ \int_0^T \varphi_s dB_s \right\} \right].$$

Consequently, taking into consideration the arbitrariness of  $A \in \mathcal{B}(\mathbb{R})$  and of  $\varphi \in L^2([0, T]; \mathbb{R}^d)$ , the independence of  $\zeta$  of  $B$  and hence of  $\mathcal{F}_T$  follows, but this is possible only for deterministic  $\zeta$ .  $\square$

The first property of the lower value function  $W(t, x)$  which we present is an immediate consequence of (3.6) and (3.9).

LEMMA 3.5. *There exists a constant  $C > 0$  such that, for all  $0 \leq t \leq T$ ,  $x, x' \in \mathbb{R}^n$ ,*

$$(3.12) \quad \begin{aligned} \text{(i)} \quad &|W(t, x) - W(t, x')| \leq C|x - x'|; \\ \text{(ii)} \quad &|W(t, x)| \leq C(1 + |x|). \end{aligned}$$

We now discuss (the generalized) DPP for our stochastic differential game (3.1), (3.5), and (3.9). For this end we have to define the family of (backward) semigroups associated with BSDE (3.5). This notion of stochastic backward semigroups was first introduced by Peng [26] which was applied to study the DPP for stochastic control problems. Our approach adapts Peng's ideas to the framework of stochastic differential games.

Given the initial data  $(t, x)$ , a positive number  $\delta \leq T - t$ , admissible control processes  $u(\cdot) \in \mathcal{U}_{t, t+\delta}$  and  $v(\cdot) \in \mathcal{V}_{t, t+\delta}$ , and a real-valued random variable  $\eta \in L^2(\Omega, \mathcal{F}_{t+\delta}, P; \mathbb{R})$ , we put

$$(3.13) \quad G_{s, t+\delta}^{t, x; u, v}[\eta] := \tilde{Y}_s^{t, x; u, v}, \quad s \in [t, t + \delta],$$

where the couple  $(\tilde{Y}_s^{t, x; u, v}, \tilde{Z}_s^{t, x; u, v})_{t \leq s \leq t+\delta}$  is the solution of the following BSDE with the time horizon  $t + \delta$ :

$$\begin{cases} -d\tilde{Y}_s^{t, x; u, v} = f(s, X_s^{t, x; u, v}, \tilde{Y}_s^{t, x; u, v}, \tilde{Z}_s^{t, x; u, v}, u_s, v_s)ds \\ \quad - \tilde{Z}_s^{t, x; u, v} dB_s, & s \in [t, t + \delta], \\ \tilde{Y}_{t+\delta}^{t, x; u, v} = \eta, \end{cases}$$

and  $X^{t, x; u, v}$  is the solution of SDE (3.1). Then, obviously, for the solution  $(Y^{t, x; u, v}, Z^{t, x; u, v})$  of BSDE (3.5) we have

$$(3.14) \quad G_{t, T}^{t, x; u, v}[\Phi(X_T^{t, x; u, v})] = G_{t, t+\delta}^{t, x; u, v}[Y_{t+\delta}^{t, x; u, v}].$$

Moreover,

$$\begin{aligned} J(t, x; u, v) &= Y_t^{t, x; u, v} = G_{t, T}^{t, x; u, v}[\Phi(X_T^{t, x; u, v})] = G_{t, t+\delta}^{t, x; u, v}[Y_{t+\delta}^{t, x; u, v}] \\ &= G_{t, t+\delta}^{t, x; u, v}[J(t + \delta, X_{t+\delta}^{t, x; u, v}; u, v)]. \end{aligned}$$

*Remark 3.3.* When  $f$  is independent of  $(y, z)$  it holds that

$$G_{s, t+\delta}^{t, x; u, v}[\eta] = E \left[ \eta + \int_s^{t+\delta} f(r, X_r^{t, x; u, v}, u_r, v_r) dr \middle| \mathcal{F}_s \right], \quad s \in [t, t + \delta].$$

**THEOREM 3.6.** *Under the assumptions (H3.1) and (H3.2), the lower value function  $W(t, x)$  obeys the following DPP: For any  $0 \leq t < t + \delta \leq T$ ,  $x \in \mathbb{R}^n$ ,*

$$(3.15) \quad W(t, x) = \operatorname{essinf}_{\beta \in \mathcal{B}_{t, t+\delta}} \operatorname{esssup}_{u \in \mathcal{U}_{t, t+\delta}} G_{t, t+\delta}^{t, x; u, \beta(u)}[W(t + \delta, X_{t+\delta}^{t, x; u, \beta(u)})].$$

*Proof.* To simplify notations we put

$$W_\delta(t, x) = \operatorname{essinf}_{\beta \in \mathcal{B}_{t, t+\delta}} \operatorname{esssup}_{u \in \mathcal{U}_{t, t+\delta}} G_{t, t+\delta}^{t, x; u, \beta(u)}[W(t + \delta, X_{t+\delta}^{t, x; u, \beta(u)})].$$

The proof that  $W_\delta(t, x)$  coincides with  $W(t, x)$  will be split into the following lemmas, which all are supposed to satisfy (H3.1) and (H3.2).  $\square$

**LEMMA 3.7.**  *$W_\delta(t, x)$  is deterministic.*

*Proof.* The proof of this lemma uses the same ideas as that of Proposition 3.3, so it can be omitted here.  $\square$

**LEMMA 3.8.**  *$W_\delta(t, x) \leq W(t, x)$ .*

*Proof.* Let  $\beta \in \mathcal{B}_{t,T}$  be arbitrarily fixed. Then, given a  $u_2(\cdot) \in \mathcal{U}_{t+\delta,T}$ , we define as follows the restriction  $\beta_1$  of  $\beta$  to  $\mathcal{U}_{t,t+\delta}$ :

$$\beta_1(u_1) := \beta(u_1 \oplus u_2)|_{[t,t+\delta]}, \quad u_1(\cdot) \in \mathcal{U}_{t,t+\delta},$$

where  $u_1 \oplus u_2 := u_1 \mathbf{1}_{[t,t+\delta]} + u_2 \mathbf{1}_{(t+\delta,T]}$  extends  $u_1(\cdot)$  to an element of  $\mathcal{U}_{t,T}$ . It is easy to check that  $\beta_1 \in \mathcal{B}_{t,t+\delta}$ . Moreover, from the nonanticipativity property of  $\beta$  we deduce that  $\beta_1$  is independent of the special choice of  $u_2(\cdot) \in \mathcal{U}_{t+\delta,T}$ . Consequently, from the definition of  $W_\delta(t, x)$ ,

$$(3.16) \quad W_\delta(t, x) \leq \text{esssup}_{u_1 \in \mathcal{U}_{t,t+\delta}} G_{t,t+\delta}^{t,x;u_1,\beta_1(u_1)}[W(t+\delta, X_{t+\delta}^{t,x;u_1,\beta_1(u_1)})], \quad P\text{-a.s.}$$

We use the notation  $I_\delta(t, x, u, v) := G_{t,t+\delta}^{t,x;u,v}[W(t+\delta, X_{t+\delta}^{t,x;u,v})]$  and notice that there exists a sequence  $\{u_i^1, i \geq 1\} \subset \mathcal{U}_{t,t+\delta}$  such that

$$I_\delta(t, x, \beta_1) := \text{esssup}_{u_1 \in \mathcal{U}_{t,t+\delta}} I_\delta(t, x, u_1, \beta_1(u_1)) = \sup_{i \geq 1} I_\delta(t, x, u_i^1, \beta_1(u_i^1)), \quad P\text{-a.s.}$$

For any  $\varepsilon > 0$ , we put  $\tilde{\Gamma}_i := \{I_\delta(t, x, \beta_1) \leq I_\delta(t, x, u_i^1, \beta_1(u_i^1)) + \varepsilon\} \in \mathcal{F}_t$ ,  $i \geq 1$ . Then  $\Gamma_1 := \tilde{\Gamma}_1$ ,  $\Gamma_i := \tilde{\Gamma}_i \setminus (\cup_{l=1}^{i-1} \tilde{\Gamma}_l) \in \mathcal{F}_t$ ,  $i \geq 2$ , form an  $(\Omega, \mathcal{F}_t)$ -partition, and  $u_1^\varepsilon := \sum_{i \geq 1} \mathbf{1}_{\Gamma_i} u_i^1$  belongs obviously to  $\mathcal{U}_{t,t+\delta}$ . Moreover, from the nonanticipativity of  $\beta_1$  we have  $\beta_1(u_1^\varepsilon) = \sum_{i \geq 1} \mathbf{1}_{\Gamma_i} \beta_1(u_i^1)$ , and from the uniqueness of the solution of the forward-backward SDE (FBSDE), we deduce that  $I_\delta(t, x, u_1^\varepsilon, \beta_1(u_1^\varepsilon)) = \sum_{i \geq 1} \mathbf{1}_{\Gamma_i} I_\delta(t, x, u_i^1, \beta_1(u_i^1))$ ,  $P$ -a.s. Hence,

$$(3.17) \quad \begin{aligned} W_\delta(t, x) &\leq I_\delta(t, x, \beta_1) \leq \sum_{i \geq 1} \mathbf{1}_{\Gamma_i} I_\delta(t, x, u_i^1, \beta_1(u_i^1)) + \varepsilon = I_\delta(t, x, u_1^\varepsilon, \beta_1(u_1^\varepsilon)) + \varepsilon \\ &= G_{t,t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}[W(t+\delta, X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)})] + \varepsilon, \quad P\text{-a.s.} \end{aligned}$$

On the other hand, using the fact that  $\beta_1(\cdot) := \beta(\cdot \oplus u_2) \in \mathcal{B}_{t,t+\delta}$  does not depend on  $u_2(\cdot) \in \mathcal{U}_{t+\delta,T}$ , we can define  $\beta_2(u_2) := \beta(u_1^\varepsilon \oplus u_2)|_{[t+\delta,T]}$ , for all  $u_2(\cdot) \in \mathcal{U}_{t+\delta,T}$ . The such defined  $\beta_2 : \mathcal{U}_{t+\delta,T} \rightarrow \mathcal{V}_{t+\delta,T}$  belongs to  $\mathcal{B}_{t+\delta,T}$  since  $\beta \in \mathcal{B}_{t,T}$ . Therefore, from the definition of  $W(t+\delta, y)$  we have, for any  $y \in \mathbb{R}^n$ ,

$$W(t+\delta, y) \leq \text{esssup}_{u_2 \in \mathcal{U}_{t+\delta,T}} J(t+\delta, y; u_2, \beta_2(u_2)), \quad P\text{-a.s.}$$

Finally, because there exists a constant  $C \in \mathbb{R}$  such that

$$(3.18) \quad \begin{aligned} &\text{(i)} \quad |W(t+\delta, y) - W(t+\delta, y')| \leq C|y - y'| \text{ for any } y, y' \in \mathbb{R}^n; \\ &\text{(ii)} \quad |J(t+\delta, y, u_2, \beta_2(u_2)) - J(t+\delta, y', u_2, \beta_2(u_2))| \leq C|y - y'|, \quad P\text{-a.s.,} \\ &\quad \text{for any } u_2 \in \mathcal{U}_{t+\delta,T}, \end{aligned}$$

(see Lemma 3.5(i) and (3.6)(i)) we can show by approximating  $X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}$  that

$$W(t+\delta, X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}) \leq \text{esssup}_{u_2 \in \mathcal{U}_{t+\delta,T}} J(t+\delta, X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}; u_2, \beta_2(u_2)), \quad P\text{-a.s.}$$

To estimate the right side of the latter inequality we note that there exists some sequence  $\{u_j^2, j \geq 1\} \subset \mathcal{U}_{t+\delta,T}$  such that

$$\begin{aligned} &\text{esssup}_{u_2 \in \mathcal{U}_{t+\delta,T}} J(t+\delta, X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}; u_2, \beta_2(u_2)) \\ &= \sup_{j \geq 1} J(t+\delta, X_{t+\delta}^{t,x;u_1^\varepsilon,\beta_1(u_1^\varepsilon)}; u_j^2, \beta_2(u_j^2)), \quad P\text{-a.s.} \end{aligned}$$

Then, putting  $\tilde{\Delta}_j := \{\text{esssup}_{u_2 \in \mathcal{U}_{t+\delta, T}} J(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_2, \beta_2(u_2)) \leq J(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_j^2, \beta_2(u_j^2)) + \varepsilon\} \in \mathcal{F}_{t+\delta}$ ,  $j \geq 1$ ; we have with  $\Delta_1 := \tilde{\Delta}_1$ ,  $\Delta_j := \tilde{\Delta}_j \setminus (\cup_{l=1}^{j-1} \tilde{\Delta}_l) \in \mathcal{F}_{t+\delta}$ ,  $j \geq 2$ , an  $(\Omega, \mathcal{F}_{t+\delta})$ -partition and  $u_2^\varepsilon := \sum_{j \geq 1} \mathbf{1}_{\Delta_j} u_j^2 \in \mathcal{U}_{t+\delta, T}$ . From the nonanticipativity of  $\beta_2$  we have  $\beta_2(u_2^\varepsilon) = \sum_{j \geq 1} \mathbf{1}_{\Delta_j} \beta_2(u_j^2)$ , and from the definition of  $\beta_1$ ,  $\beta_2$  we know that  $\beta(u_1^\varepsilon \oplus u_2^\varepsilon) = \beta_1(u_1^\varepsilon) \oplus \beta_2(u_2^\varepsilon)$ . Thus, again from the uniqueness of the solution of our FBSDE, we get

$$\begin{aligned} J(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_2^\varepsilon, \beta_2(u_2^\varepsilon)) &= Y_{t+\delta}^{t+\delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_2^\varepsilon, \beta_2(u_2^\varepsilon)} \quad (\text{see (3.8)}) \\ &= \sum_{j \geq 1} \mathbf{1}_{\Delta_j} Y_{t+\delta}^{t+\delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_j^2, \beta_2(u_j^2)} \\ &= \sum_{j \geq 1} \mathbf{1}_{\Delta_j} J(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_j^2, \beta_2(u_j^2)), \quad P\text{-a.s.} \end{aligned}$$

Consequently,

$$\begin{aligned} (3.19) \quad W(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}) &\leq \text{esssup}_{u_2 \in \mathcal{U}_{t+\delta, T}} J(t + \delta, X_{t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)}; u_2, \beta_2(u_2)) \\ &\leq \sum_{j \geq 1} \mathbf{1}_{\Delta_j} Y_{t+\delta}^{t, x; u_1^\varepsilon \oplus u_j^2, \beta(u_1^\varepsilon \oplus u_j^2)} + \varepsilon \\ &= Y_{t+\delta}^{t, x; u_1^\varepsilon \oplus u_2^\varepsilon, \beta(u_1^\varepsilon \oplus u_2^\varepsilon)} + \varepsilon \\ &= Y_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)} + \varepsilon, \quad P\text{-a.s.}, \end{aligned}$$

where  $u^\varepsilon := u_1^\varepsilon \oplus u_2^\varepsilon \in \mathcal{U}_{t, T}$ . From (3.17) and (3.19) and Lemmas 2.2 (comparison theorem for BSDEs) and 2.3, we have

$$\begin{aligned} (3.20) \quad W_\delta(t, x) &\leq G_{t, t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)} [Y_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)} + \varepsilon] + \varepsilon \\ &\leq G_{t, t+\delta}^{t, x; u_1^\varepsilon, \beta_1(u_1^\varepsilon)} [Y_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}] + (C + 1)\varepsilon \\ &= G_{t, t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)} [Y_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}] + (C + 1)\varepsilon \\ &= Y_t^{t, x; u^\varepsilon, \beta(u^\varepsilon)} + (C + 1)\varepsilon \\ &\leq \text{esssup}_{u \in \mathcal{U}_{t, T}} Y_t^{t, x; u, \beta(u)} + (C + 1)\varepsilon, \quad P\text{-a.s.} \end{aligned}$$

Since  $\beta \in \mathcal{B}_{t, T}$  has been arbitrarily chosen we have (3.20) for all  $\beta \in \mathcal{B}_{t, T}$ . Therefore,

$$(3.21) \quad W_\delta(t, x) \leq \text{essinf}_{\beta \in \mathcal{B}_{t, T}} \text{esssup}_{u \in \mathcal{U}_{t, T}} Y_t^{t, x; u, \beta(u)} + (C + 1)\varepsilon = W(t, x) + (C + 1)\varepsilon.$$

Finally, letting  $\varepsilon \downarrow 0$ , we get  $W_\delta(t, x) \leq W(t, x)$ .  $\square$

LEMMA 3.9.  $W(t, x) \leq W_\delta(t, x)$ .

*Proof.* We continue to use the notations introduced above, and from the definition of  $W_\delta(t, x)$  we have

$$\begin{aligned} W_\delta(t, x) &= \text{essinf}_{\beta_1 \in \mathcal{B}_{t, t+\delta}} \text{esssup}_{u_1 \in \mathcal{U}_{t, t+\delta}} G_{t, t+\delta}^{t, x; u_1, \beta_1(u_1)} [W(t + \delta, X_{t+\delta}^{t, x; u_1, \beta_1(u_1)})] \\ &= \text{essinf}_{\beta_1 \in \mathcal{B}_{t, t+\delta}} I_\delta(t, x, \beta_1), \end{aligned}$$

and, for some sequence  $\{\beta_i^1, i \geq 1\} \subset \mathcal{B}_{t, t+\delta}$ ,

$$W_\delta(t, x) = \inf_{i \geq 1} I_\delta(t, x, \beta_i^1), \quad P\text{-a.s.}$$

For any  $\varepsilon > 0$ , we let  $\tilde{\Lambda}_i := \{I_\delta(t, x, \beta_i^1) - \varepsilon \leq W_\delta(t, x)\} \in \mathcal{F}_t$ ,  $i \geq 1$ ,  $\Lambda_1 := \tilde{\Lambda}_1$  and  $\Lambda_i := \tilde{\Lambda}_i \setminus (\cup_{l=1}^{i-1} \tilde{\Lambda}_l) \in \mathcal{F}_t$ ,  $i \geq 2$ . Then  $\{\Lambda_i, i \geq 1\}$  is an  $(\Omega, \mathcal{F}_t)$ -partition,  $\beta_1^\varepsilon := \sum_{i \geq 1} \mathbf{1}_{\Lambda_i} \beta_i^1$  belongs to  $\mathcal{B}_{t, t+\delta}$ , and from the uniqueness of the solution of our FBSDE we conclude that  $I_\delta(t, x, u_1, \beta_1^\varepsilon(u_1)) = \sum_{i \geq 1} \mathbf{1}_{\Lambda_i} I_\delta(t, x, u_1, \beta_i^1(u_1))$ ,  $P$ -a.s., for all  $u_1(\cdot) \in \mathcal{U}_{t, t+\delta}$ . Hence,

(3.22)

$$\begin{aligned} W_\delta(t, x) &\geq \sum_{i \geq 1} \mathbf{1}_{\Lambda_i} I_\delta(t, x, \beta_i^1) - \varepsilon \\ &\geq \sum_{i \geq 1} \mathbf{1}_{\Lambda_i} I_\delta(t, x, u_1, \beta_i^1(u_1)) - \varepsilon \\ &= I_\delta(t, x, u_1, \beta_1^\varepsilon(u_1)) - \varepsilon \\ &= G_{t, t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}[W(t + \delta, X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)})] - \varepsilon, \quad P\text{-a.s., for all } u_1 \in \mathcal{U}_{t, t+\delta}. \end{aligned}$$

On the other hand, from the definition of  $W(t + \delta, y)$ , with the same technique as before, we deduce that, for any  $y \in \mathbb{R}^n$ , there exists  $\beta_y^\varepsilon \in \mathcal{B}_{t+\delta, T}$  such that

$$(3.23) \quad W(t + \delta, y) \geq \text{esssup}_{u_2 \in \mathcal{U}_{t+\delta, T}} J(t + \delta, y; u_2, \beta_y^\varepsilon(u_2)) - \varepsilon, \quad P\text{-a.s.}$$

Let  $\{O_i\}_{i \geq 1} \subset \mathcal{B}(\mathbb{R}^n)$  be a decomposition of  $\mathbb{R}^n$  such that  $\sum_{i \geq 1} O_i = \mathbb{R}^n$  and  $\text{diam}(O_i) \leq \varepsilon$ ,  $i \geq 1$ . Let  $y_i$  be an arbitrarily fixed element of  $O_i$ ,  $i \geq 1$ . Defining  $[X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}] := \sum_{i \geq 1} y_i \mathbf{1}_{\{X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)} \in O_i\}}$ , we have

$$(3.24) \quad |X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)} - [X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}]| \leq \varepsilon, \quad \text{everywhere on } \Omega, \text{ for all } u_1 \in \mathcal{U}_{t, t+\delta}.$$

Moreover, for each  $y_i$ , there exists some  $\beta_{y_i}^\varepsilon \in \mathcal{B}_{t+\delta, T}$  such that (3.23) holds, and, clearly,  $\beta_{u_1}^\varepsilon := \sum_{i \geq 1} \mathbf{1}_{\{X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)} \in O_i\}} \beta_{y_i}^\varepsilon \in \mathcal{B}_{t+\delta, T}$ .

Now we can define the new strategy  $\beta^\varepsilon(u) := \beta_1^\varepsilon(u_1) \oplus \beta_{u_1}^\varepsilon(u_2)$ ,  $u \in \mathcal{U}_{t, T}$ , where  $u_1 = u|_{[t, t+\delta]}$ ,  $u_2 = u|_{(t+\delta, T]}$  (restriction of  $u$  to  $[t, t+\delta] \times \Omega$  and  $(t+\delta, T] \times \Omega$ , resp.). Obviously,  $\beta^\varepsilon$  maps  $\mathcal{U}_{t, T}$  into  $\mathcal{V}_{t, T}$ . Moreover,  $\beta^\varepsilon$  is nonanticipating: Indeed, let  $S : \Omega \rightarrow [t, T]$  be an  $\mathbb{F}$ -stopping time and  $u, u' \in \mathcal{U}_{t, T}$  be such that  $u \equiv u'$  on  $\llbracket t, S \rrbracket$ . Decomposing  $u, u'$  into  $u_1, u'_1 \in \mathcal{U}_{t, t+\delta}$ ,  $u_2, u'_2 \in \mathcal{U}_{t+\delta, T}$  such that  $u = u_1 \oplus u_2$  and  $u' = u'_1 \oplus u'_2$ . We have  $u_1 \equiv u'_1$  on  $\llbracket t, S \wedge (t+\delta) \rrbracket$  from which we get  $\beta_1^\varepsilon(u_1) \equiv \beta_1^\varepsilon(u'_1)$  on  $\llbracket t, S \wedge (t+\delta) \rrbracket$  (recall that  $\beta_1^\varepsilon$  is nonanticipating). On the other hand,  $u_2 \equiv u'_2$  on  $\llbracket t+\delta, S \vee (t+\delta) \rrbracket \subset (t+\delta, T] \times \{S > t+\delta\}$ , and on  $\{S > t+\delta\}$  we have  $X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)} = X_{t+\delta}^{t, x; u'_1, \beta_1^\varepsilon(u'_1)}$ . Consequently, from our definition,  $\beta_{u_1}^\varepsilon = \beta_{u'_1}^\varepsilon$  on  $\{S > t+\delta\}$  and  $\beta_{u_1}^\varepsilon(u_2) \equiv \beta_{u'_1}^\varepsilon(u'_2)$  on  $\llbracket t+\delta, S \vee (t+\delta) \rrbracket$ . This yields  $\beta^\varepsilon(u) = \beta_1^\varepsilon(u_1) \oplus \beta_{u_1}^\varepsilon(u_2) \equiv \beta_1^\varepsilon(u'_1) \oplus \beta_{u'_1}^\varepsilon(u'_2) = \beta^\varepsilon(u')$  on  $\llbracket t, S \rrbracket$ , from which it follows that  $\beta^\varepsilon \in \mathcal{B}_{t, T}$ .

Let now  $u \in \mathcal{U}_{t, T}$  be arbitrarily chosen and decomposed into  $u_1 = u|_{[t, t+\delta]} \in \mathcal{U}_{t, t+\delta}$  and  $u_2 = u|_{(t+\delta, T]} \in \mathcal{U}_{t+\delta, T}$ . Then, from (3.22), (3.18)(i), (3.24), and Lemmas 2.2 (comparison theorem) and 2.3, we obtain

(3.25)

$$\begin{aligned} W_\delta(t, x) &\geq G_{t, t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}[W(t + \delta, X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)})] - \varepsilon \\ &\geq G_{t, t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}[W(t + \delta, [X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}]) - C\varepsilon] - \varepsilon \\ &\geq G_{t, t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}[W(t + \delta, [X_{t+\delta}^{t, x; u_1, \beta_1^\varepsilon(u_1)}])] - C\varepsilon \end{aligned}$$

$$= G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \left[ \sum_{i \geq 1} \mathbf{1}_{\{X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \in O_i\}} W(t+\delta, y_i) \right] - C\varepsilon, \quad P\text{-a.s.}$$

Furthermore, from (3.23), (3.18)(ii), (3.24), and Lemmas 2.2 and 2.3, we have

(3.26)

$$\begin{aligned} W_\delta(t, x) &\geq G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \left[ \sum_{i \geq 1} \mathbf{1}_{\{X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \in O_i\}} J(t+\delta, y_i; u_2, \beta_{y_i}^\varepsilon(u_2)) - \varepsilon \right] - C\varepsilon \\ &\geq G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \left[ \sum_{i \geq 1} \mathbf{1}_{\{X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} \in O_i\}} J(t+\delta, y_i; u_2, \beta_{y_i}^\varepsilon(u_2)) \right] - C\varepsilon \\ &= G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} [J(t+\delta, [X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)}]; u_2, \beta_{u_1}^\varepsilon(u_2))] - C\varepsilon \\ &\geq G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} [J(t+\delta, X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)}; u_2, \beta_{u_1}^\varepsilon(u_2)) - C\varepsilon] - C\varepsilon \\ &\geq G_{t,t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)} [J(t+\delta, X_{t+\delta}^{t,x;u_1,\beta_1^\varepsilon(u_1)}; u_2, \beta_{u_1}^\varepsilon(u_2))] - C\varepsilon \\ &= G_{t,t+\delta}^{t,x;u,\beta^\varepsilon(u)} [Y_{t+\delta}^{t,x,u,\beta^\varepsilon(u)}] - C\varepsilon \\ &= Y_t^{t,x;u,\beta^\varepsilon(u)} - C\varepsilon, \quad P\text{-a.s., for any } u \in \mathcal{U}_{t,T}. \end{aligned}$$

Consequently,

$$\begin{aligned} W_\delta(t, x) &\geq \operatorname{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta^\varepsilon(u)) - C\varepsilon \\ (3.27) \quad &\geq \operatorname{essinf}_{\beta \in \mathcal{B}_{t,T}} \operatorname{esssup}_{u \in \mathcal{U}_{t,T}} J(t, x; u, \beta(u)) - C\varepsilon \\ &= W(t, x) - C\varepsilon, \quad P\text{-a.s.} \end{aligned}$$

Finally, letting  $\varepsilon \downarrow 0$  we get  $W_\delta(t, x) \geq W(t, x)$ . The proof is complete.  $\square$

*Remark 3.4.* (i) From the inequalities (3.17) and (3.22) we see that for all  $(t, x) \in [0, T] \times \mathbb{R}^n$ ,  $\delta > 0$ , with  $0 < \delta \leq T - t$  and  $\varepsilon > 0$ , the following hold: (a) For every  $\beta \in \mathcal{B}_{t,t+\delta}$ , there exists some  $u^\varepsilon(\cdot) \in \mathcal{U}_{t,t+\delta}$  such that

$$(3.28) \quad W(t, x) (= W_\delta(t, x)) \leq G_{t,t+\delta}^{t,x;u^\varepsilon,\beta(u^\varepsilon)} [W(t+\delta, X_{t+\delta}^{t,x;u^\varepsilon,\beta(u^\varepsilon)})] + \varepsilon, \quad P\text{-a.s.}$$

(b) There exists some  $\beta^\varepsilon \in \mathcal{B}_{t,t+\delta}$  such that, for all  $u \in \mathcal{U}_{t,t+\delta}$ ,

$$(3.29) \quad W(t, x) (= W_\delta(t, x)) \geq G_{t,t+\delta}^{t,x;u,\beta^\varepsilon(u)} [W(t+\delta, X_{t+\delta}^{t,x;u,\beta^\varepsilon(u)})] - \varepsilon, \quad P\text{-a.s.}$$

(ii) Recall that the lower value function  $W$  is deterministic. Thus, by choosing  $\delta = T - t$  and taking the expectation on both sides of (3.28) and (3.29) we can show that

$$W(t, x) = \inf_{\beta \in \mathcal{B}_{t,T}} \sup_{u \in \mathcal{U}_{t,T}} E[J(t, x; u, \beta(u))].$$

In analogy we also have

$$U(t, x) = \sup_{\alpha \in \mathcal{A}_{t,T}} \inf_{v \in \mathcal{V}_{t,T}} E[J(t, x; \alpha(v), v)].$$

The above formulas look similar to the definitions of the lower and the upper value functions defined by Fleming and Souganidis [14] for the case of  $f$  being independent

of  $(y, z)$ . However, they consider only control processes which are independent of the past  $\mathcal{F}_t$ . In Remark 5.3 we will come back to this comparison and identify their value functions with ours for such a coefficient  $f$ .

In Lemma 3.5 we have already seen that the lower value function  $W(t, x)$  is Lipschitz continuous in  $x$ , uniformly in  $t$ . With the help of Theorem 3.6 we can now also study the continuity property of  $W(t, x)$  in  $t$ .

**THEOREM 3.10.** *Let us suppose that the assumptions (H3.1) and (H3.2) hold. Then the lower value function  $W(t, x)$  is  $\frac{1}{2}$ -Hölder continuous in  $t$ : There exists a constant  $C$  such that, for every  $x \in \mathbb{R}^n$ ,  $t, t' \in [0, T]$ ,*

$$|W(t, x) - W(t', x)| \leq C(1 + |x|)|t - t'|^{\frac{1}{2}}.$$

*Proof.* Let  $(t, x) \in [0, T] \times \mathbb{R}^n$  and  $\delta > 0$  be arbitrarily given such that  $0 < \delta \leq T - t$ . Our objective is to prove the following inequality by using (3.28) and (3.29):

$$(3.30) \quad -C(1 + |x|)\delta^{\frac{1}{2}} \leq W(t, x) - W(t + \delta, x) \leq C(1 + |x|)\delta^{\frac{1}{2}}.$$

From it we obtain immediately that  $W$  is  $\frac{1}{2}$ -Hölder continuous in  $t$ . We will check only the second inequality in (3.30); the first one can be shown in a similar way. To this end we note that due to (3.28), for an arbitrarily small  $\varepsilon > 0$ ,

$$(3.31) \quad W(t, x) - W(t + \delta, x) \leq I_\delta^1 + I_\delta^2 + \varepsilon,$$

where

$$\begin{aligned} I_\delta^1 &:= G_{t, t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}[W(t + \delta, X_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)})] - G_{t, t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}[W(t + \delta, x)], \\ I_\delta^2 &:= G_{t, t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}[W(t + \delta, x)] - W(t + \delta, x) \end{aligned}$$

for arbitrarily chosen  $\beta \in \mathcal{B}_{t, t+\delta}$  and  $u^\varepsilon \in \mathcal{U}_{t, t+\delta}$  such that (3.28) holds. From Lemma 2.3 and the estimate (3.12) we obtain that, for some constant  $C$  independent of the controls  $u^\varepsilon$  and  $\beta(u^\varepsilon)$ ,

$$\begin{aligned} |I_\delta^1| &\leq [CE(|W(t + \delta, X_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}) - W(t + \delta, x)|^2 | \mathcal{F}_t)]^{\frac{1}{2}} \\ &\leq [CE(|X_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)} - x|^2 | \mathcal{F}_t)]^{\frac{1}{2}}, \end{aligned}$$

and since  $E[|X_{t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)} - x|^2 | \mathcal{F}_t] \leq C(1 + |x|^2)\delta$  we deduce that  $|I_\delta^1| \leq C(1 + |x|)\delta^{\frac{1}{2}}$ . From the definition of  $G_{t, t+\delta}^{t, x; u^\varepsilon, \beta(u^\varepsilon)}[\cdot]$  (see (3.13)) we know that the second term  $I_\delta^2$  can be written as

$$\begin{aligned} I_\delta^2 &= E \left[ W(t + \delta, x) + \int_t^{t+\delta} f(s, X_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Y}_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Z}_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, u_s^\varepsilon, \beta_s(u_s^\varepsilon)) ds \right. \\ &\quad \left. - \int_t^{t+\delta} \tilde{Z}_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)} dB_s | \mathcal{F}_t \right] - W(t + \delta, x) \\ &= E \left[ \int_t^{t+\delta} f(s, X_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Y}_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Z}_s^{t, x; u^\varepsilon, \beta(u^\varepsilon)}, u_s^\varepsilon, \beta_s(u_s^\varepsilon)) ds | \mathcal{F}_t \right]. \end{aligned}$$

With the help of the Schwartz inequality and the estimates (3.3) and (A.4)(i), we

then have

$$\begin{aligned}
 |I_\delta^2| &\leq \delta^{\frac{1}{2}} E \left[ \int_t^{t+\delta} |f(s, X_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Y}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}, \tilde{Z}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}, u_s^\varepsilon, \beta_s(u^\varepsilon))|^2 ds | \mathcal{F}_t \right]^{\frac{1}{2}} \\
 &\leq \delta^{\frac{1}{2}} E \left[ \int_t^{t+\delta} (|f(s, X_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}, 0, 0, u_s^\varepsilon, \beta_s(u^\varepsilon))| + C|\tilde{Y}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}| \right. \\
 &\quad \left. + C|\tilde{Z}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}|)^2 ds | \mathcal{F}_t \right]^{\frac{1}{2}} \\
 &\leq C\delta^{\frac{1}{2}} E \left[ \int_t^{t+\delta} (|1 + |X_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}| + |\tilde{Y}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}| + |\tilde{Z}_s^{t,x;u^\varepsilon, \beta(u^\varepsilon)}|)^2 ds | \mathcal{F}_t \right]^{\frac{1}{2}} \\
 &\leq C(1 + |x|)\delta^{\frac{1}{2}}.
 \end{aligned}$$

Hence, from (3.31),

$$W(t, x) - W(t + \delta, x) \leq C(1 + |x|)\delta^{\frac{1}{2}} + \varepsilon,$$

and letting  $\varepsilon \downarrow 0$  we get the second inequality of (3.30). The proof is complete.  $\square$

**4. Viscosity solution of Isaacs' equation: Existence theorem.** In this section we consider the following Isaacs' equations:

$$(4.1) \quad \begin{cases} \frac{\partial}{\partial t} W(t, x) + H^-(t, x, W, DW, D^2W) = 0, & (t, x) \in [0, T] \times \mathbb{R}^n, \\ W(T, x) = \Phi(x), & x \in \mathbb{R}^n, \end{cases}$$

and

$$(4.2) \quad \begin{cases} \frac{\partial}{\partial t} U(t, x) + H^+(t, x, U, DU, D^2U) = 0, & (t, x) \in [0, T] \times \mathbb{R}^n, \\ U(T, x) = \Phi(x), & x \in \mathbb{R}^n, \end{cases}$$

associated with the Hamiltonians

$$H^-(t, x, y, p, X) = \sup_{u \in U} \inf_{v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) X) + p \cdot b(t, x, u, v) + f(t, x, y, p \cdot \sigma, u, v) \right\}$$

and

$$H^+(t, x, y, p, X) = \inf_{v \in V} \sup_{u \in U} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) X) + p \cdot b(t, x, u, v) + f(t, x, y, p \cdot \sigma, u, v) \right\},$$

respectively, where  $t \in [0, T]$ ,  $x \in \mathbb{R}^n$ ,  $y \in \mathbb{R}$ ,  $p \in \mathbb{R}^n$ , and  $X \in \mathbf{S}^n$  (recall that  $\mathbf{S}^n$  denotes the set of  $n \times n$  symmetric matrices). Here the functions  $b, \sigma, f$ , and  $\Phi$  are supposed to satisfy (H3.1) and (H3.2), respectively.

In this section we want to prove that the lower value function  $W(t, x)$  introduced by (3.9) is the viscosity solution of (4.1), while the upper value function  $U(t, x)$  defined by (3.10) is the viscosity solution of (4.2). For this we extend Peng's BSDE approach [26] developed in the framework of stochastic control theory into that of stochastic differential games. The difficulties related with this extension come from the fact that now, contrarily to the framework of stochastic control theory studied by Peng, we have to do with stochastic differential games in which strategies are played versus controls. In order to overcome these difficulties in the proof that  $W$  is a viscosity supersolution, we have, in particular, to enrich Peng's BSDE method by Lemma

4.6 and to adapt heavily the proof of Lemma 4.5. On the other hand, the proof that  $W$  is a viscosity subsolution is not covered by Peng's BSDE method and requires a quite new approach. The uniqueness of the viscosity solution will be shown in the next section for the class of continuous functions satisfying some growth assumption which is weaker than the polynomial growth condition. We first recall the definition of a viscosity solution of (4.1) and similarly for (4.2). The reader more interested in viscosity solutions is referred to Crandall, Ishii, and Lions [8].

DEFINITION 4.1. A real-valued continuous function  $W \in C([0, T] \times \mathbb{R}^n)$  is called  
(i) a viscosity subsolution of (4.1) if  $W(T, x) \leq \Phi(x)$  for all  $x \in \mathbb{R}^n$  and if for all functions  $\varphi \in C_{l,b}^3([0, T] \times \mathbb{R}^n)$  and  $(t, x) \in [0, T) \times \mathbb{R}^n$  such that  $W - \varphi$  attains its local maximum at  $(t, x)$ :

$$\frac{\partial \varphi}{\partial t}(t, x) + H^-(t, x, \varphi, D\varphi, D^2\varphi) \geq 0;$$

(ii) a viscosity supersolution of (4.1) if  $W(T, x) \geq \Phi(x)$  for all  $x \in \mathbb{R}^n$  and if for all functions  $\varphi \in C_{l,b}^3([0, T] \times \mathbb{R}^n)$  and  $(t, x) \in [0, T) \times \mathbb{R}^n$  such that  $W - \varphi$  attains its local minimum at  $(t, x)$ :

$$\frac{\partial \varphi}{\partial t}(t, x) + H^-(t, x, \varphi, D\varphi, D^2\varphi) \leq 0;$$

(iii) a viscosity solution of (4.1) if it is both a viscosity sub- and a supersolution of (4.1).

Remark 4.1.  $C_{l,b}^3([0, T] \times \mathbb{R}^n)$  denotes the set of the real-valued functions that are continuously differentiable up to the third order and whose derivatives of order from 1 to 3 are bounded.

We first prove that the lower value function  $W(t, x)$  is a viscosity solution of (4.1).

THEOREM 4.2. Under the assumptions (H3.1) and (H3.2) the lower value function  $W(t, x)$  is a viscosity solution of (4.1).

For the proof of this theorem we need four auxiliary lemmas. To abbreviate notations we put, for some arbitrarily chosen but fixed  $\varphi \in C_{l,b}^3([0, T] \times \mathbb{R}^n)$ ,

$$(4.3) \quad F(s, x, y, z, u, v) = \frac{\partial}{\partial s} \varphi(s, x) + \frac{1}{2} \text{tr}(\sigma \sigma^T(s, x, u, v) D^2 \varphi) + D\varphi \cdot b(s, x, u, v) \\ + f(s, x, y + \varphi(s, x), z + D\varphi(s, x) \cdot \sigma(s, x, u, v), u, v),$$

$(s, x, y, z, u, v) \in [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U \times V$ , and we consider the following BSDE defined on the interval  $[t, t + \delta]$  ( $0 < \delta \leq T - t$ ):

$$(4.4) \quad \begin{cases} -dY_s^{1,u,v} = F(s, X_s^{t,x;u,v}, Y_s^{1,u,v}, Z_s^{1,u,v}, u_s, v_s) ds - Z_s^{1,u,v} dB_s, \\ Y_{t+\delta}^{1,u,v} = 0, \end{cases}$$

where the process  $X^{t,x,u,v}$  has been introduced by (3.1) and  $u(\cdot) \in \mathcal{U}_{t,t+\delta}$ ,  $v(\cdot) \in \mathcal{V}_{t,t+\delta}$ .

Remark 4.2. It is not hard to check that  $F(s, X_s^{t,x;u,v}, y, z, u_s, v_s)$  satisfies (A1) and (A2). Thus, due to Lemma 2.1, (4.4) has a unique solution.

We can characterize the solution process  $Y^{1,u,v}$  as follows.

LEMMA 4.3. For every  $s \in [t, t + \delta]$ , we have the following relationship:

$$(4.5) \quad Y_s^{1,u,v} = G_{s,t+\delta}^{t,x;u,v}[\varphi(t + \delta, X_{t+\delta}^{t,x;u,v})] - \varphi(s, X_s^{t,x;u,v}), \quad P\text{-a.s.}$$

*Proof.* We recall that  $G_{s,t+\delta}^{t,x;u,v}[\varphi(t+\delta, X_{t+\delta}^{t,x;u,v})]$  is defined with the help of the solution of the BSDE

$$\begin{cases} -dY_s^{u,v} = f(s, X_s^{t,x;u,v}, Y_s^{u,v}, Z_s^{u,v}, u_s, v_s)ds - Z_s^{u,v}dB_s, & s \in [t, t+\delta], \\ Y_{t+\delta}^{u,v} = \varphi(t+\delta, X_{t+\delta}^{t,x;u,v}), \end{cases}$$

by the following formula:

$$(4.6) \quad G_{s,t+\delta}^{t,x;u,v}[\varphi(t+\delta, X_{t+\delta}^{t,x;u,v})] = Y_s^{u,v}, \quad s \in [t, t+\delta]$$

(see (3.13)). Therefore we only need to prove that  $Y_s^{u,v} - \varphi(s, X_s^{t,x;u,v}) \equiv Y_s^{1,u,v}$ . This result can be obtained easily by applying Itô's formula to  $\varphi(s, X_s^{t,x;u,v})$ . Indeed, we get that the stochastic differentials of  $Y_s^{u,v} - \varphi(s, X_s^{t,x;u,v})$  and  $Y_s^{1,u,v}$  coincide, while at the terminal time  $t+\delta$ ,  $Y_{t+\delta}^{u,v} - \varphi(t+\delta, X_{t+\delta}^{t,x;u,v}) = 0 = Y_{t+\delta}^{1,u,v}$ . So the proof is complete.  $\square$

Now we consider the following simple BSDE in which the driving process  $X^{t,x;u,v}$  is replaced by its deterministic initial value  $x$ :

$$(4.7) \quad \begin{cases} -dY_s^{2,u,v} = F(s, x, Y_s^{2,u,v}, Z_s^{2,u,v}, u_s, v_s)ds - Z_s^{2,u,v}dB_s, \\ Y_{t+\delta}^{2,u,v} = 0, \quad s \in [t, t+\delta], \end{cases}$$

where  $u(\cdot) \in \mathcal{U}_{t,t+\delta}$ ,  $v(\cdot) \in \mathcal{V}_{t,t+\delta}$ . The following lemma will allow us to neglect the difference  $|Y_t^{1,u,v} - Y_t^{2,u,v}|$  for sufficiently small  $\delta > 0$ .

LEMMA 4.4. *For every  $u \in \mathcal{U}_{t,t+\delta}$ ,  $v \in \mathcal{V}_{t,t+\delta}$ , we have*

$$(4.8) \quad |Y_t^{1,u,v} - Y_t^{2,u,v}| \leq C\delta^{\frac{3}{2}}, \quad P\text{-a.s.},$$

where  $C$  is independent of the control processes  $u$  and  $v$ .

*Proof.* From (3.3) we have for all  $p \geq 2$  the existence of some  $C_p \in \mathbb{R}_+$  such that

$$E \left[ \sup_{t \leq s \leq T} |X_s^{t,x;u,v}|^p | \mathcal{F}_t \right] \leq C_p(1 + |x|^p), \quad P\text{-a.s.}, \quad \text{uniformly in } u \in \mathcal{U}_{t,t+\delta}, v \in \mathcal{V}_{t,t+\delta}.$$

This combined with the estimate

$$\begin{aligned} E \left[ \sup_{t \leq s \leq t+\delta} |X_s^{t,x;u,v} - x|^p | \mathcal{F}_t \right] &\leq 2^{p-1} E \left[ \sup_{t \leq s \leq t+\delta} \left| \int_t^s b(r, X_r^{t,x;u,v}, u_r, v_r) dr \right|^p | \mathcal{F}_t \right] \\ &\quad + 2^{p-1} E \left[ \sup_{t \leq s \leq t+\delta} \left| \int_t^s \sigma(r, X_r^{t,x;u,v}, u_r, v_r) dB_r \right|^p | \mathcal{F}_t \right] \end{aligned}$$

yields

$$(4.9) \quad E \left[ \sup_{t \leq s \leq t+\delta} |X_s^{t,x;u,v} - x|^p | \mathcal{F}_t \right] \leq C_p \delta^{\frac{p}{2}}, \quad P\text{-a.s.}, \quad \text{uniformly in } u \in \mathcal{U}_{t,t+\delta}, v \in \mathcal{V}_{t,t+\delta}.$$

We now apply Lemma 2.3 combined with (4.9) to (4.4) and (4.7). For this we set in Lemma 2.3:

$$\xi_1 = \xi_2 = 0, \quad g(s, y, z) = F(s, X_s^{t,x;u,v}, y, z, u_s, v_s),$$

$$\varphi_1(s) = 0, \quad \varphi_2(s) = F(s, x, Y_s^{2,u,v}, Z_s^{2,u,v}, u_s, v_s) - F(s, X_s^{t,x;u,v}, Y_s^{2,u,v}, Z_s^{2,u,v}, u_s, v_s).$$

Obviously, the function  $g$  is Lipschitz with respect to  $(y, z)$ , and  $|\varphi_2(s)| \leq C(1 + |x|^2)(|X_s^{t,x;u,v} - x| + |X_s^{t,x;u,v} - x|^3)$  for  $s \in [t, t + \delta]$ ,  $(t, x) \in [0, T] \times \mathbb{R}^n$ ,  $u \in \mathcal{U}_{t,t+\delta}$ ,  $v \in \mathcal{V}_{t,t+\delta}$ . Thus, with the notation  $\rho_0(r) = (1 + |x|^2)(r + r^3)$ ,  $r \geq 0$ , we have

$$\begin{aligned} & E \left[ \int_t^{t+\delta} (|Y_s^{1,u,v} - Y_s^{2,u,v}|^2 + |Z_s^{1,u,v} - Z_s^{2,u,v}|^2) ds | \mathcal{F}_t \right] \\ & \leq CE \left[ \int_t^{t+\delta} \rho_0^2(|X_s^{t,x,u,v} - x|) ds | \mathcal{F}_t \right] \\ & \leq C\delta E \left[ \sup_{t \leq s \leq t+\delta} \rho_0^2(|X_s^{t,x,u,v} - x|) | \mathcal{F}_t \right] \\ & \leq C\delta^2. \end{aligned}$$

Therefore,

$$\begin{aligned} & |Y_t^{1,u,v} - Y_t^{2,u,v}| = |E[(Y_t^{1,u,v} - Y_t^{2,u,v}) | \mathcal{F}_t]| \\ & = \left| E \left[ \int_t^{t+\delta} (F(s, X_s^{t,x,u,v}, Y_s^{1,u,v}, Z_s^{1,u,v}, u_s, v_s) - F(s, x, Y_s^{2,u,v}, Z_s^{2,u,v}, u_s, v_s)) ds | \mathcal{F}_t \right] \right| \\ & \leq CE \left[ \int_t^{t+\delta} [\rho_0(|X_s^{t,x,u,v} - x|) + |Y_s^{1,u,v} - Y_s^{2,u,v}| + |Z_s^{1,u,v} - Z_s^{2,u,v}|] ds | \mathcal{F}_t \right] \\ & \leq CE \left[ \int_t^{t+\delta} \rho_0(|X_s^{t,x,u,v} - x|) ds | \mathcal{F}_t \right] + C\delta^{\frac{1}{2}} \left\{ E \left[ \int_t^{t+\delta} |Y_s^{1,u,v} - Y_s^{2,u,v}|^2 ds | \mathcal{F}_t \right]^{\frac{1}{2}} \right. \\ & \quad \left. + E \left[ \int_t^{t+\delta} |Z_s^{1,u,v} - Z_s^{2,u,v}|^2 ds | \mathcal{F}_t \right]^{\frac{1}{2}} \right\} \\ & \leq C\delta^{\frac{3}{2}}. \end{aligned}$$

Thus, the proof is complete.  $\square$

LEMMA 4.5. *Let  $Y_0(\cdot)$  be the solution of the following ordinary differential equation:*

$$(4.10) \quad \begin{cases} -\dot{Y}_0(s) &= F_0(s, x, Y_0(s), 0), \quad s \in [t, t + \delta], \\ Y_0(t + \delta) &= 0, \end{cases}$$

where the function  $F_0$  is defined by

$$(4.11) \quad F_0(s, x, y, z) = \sup_{u \in U} \inf_{v \in V} F(s, x, y, z, u, v).$$

Then,  $P$ -a.s.,

$$(4.12) \quad \text{esssup}_{u \in \mathcal{U}_{t,t+\delta}} \text{essinf}_{v \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v} = Y_0(t).$$

*Proof.* Obviously,  $F_0(s, x, y, z)$  is Lipschitz in  $(y, z)$ , uniformly with respect to  $(s, x)$ . This guarantees existence and uniqueness for (4.10). We first introduce the function

$$(4.13) \quad F_1(s, x, y, z, u) = \inf_{v \in V} F(s, x, y, z, u, v), \quad (s, x, y, z, u) \in [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U$$

and consider the BSDE

$$(4.14) \quad \begin{cases} -dY^{3,u}(s) &= F_1(s, x, Y^{3,u}(s), Z^{3,u}(s), u_s)ds - Z^{3,u}(s)dB_s, \\ Y^{3,u}(t+\delta) &= 0, \quad s \in [t, t+\delta], \end{cases}$$

for  $u \in \mathcal{U}_{t,t+\delta}$ . We notice that since  $F_1(s, x, y, z, u_s)$  is Lipschitz in  $(y, z)$ , for every  $u \in \mathcal{U}_{t,t+\delta}$ , there exists a unique solution  $(Y^{3,u}, Z^{3,u})$  to the BSDE (4.14). Moreover,

$$Y^{3,u}(t) = \operatorname{essinf}_{v(\cdot) \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v}, \quad P\text{-a.s.}, \quad \text{for any } u \in \mathcal{U}_{t,t+\delta}.$$

Indeed, from the definition of  $F_1$  and Lemma 2.2 (comparison theorem) we have

$$Y^{3,u}(t) \leq \operatorname{essinf}_{v(\cdot) \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v}, \quad P\text{-a.s.}, \quad \text{for all } u \in \mathcal{U}_{t,t+\delta}.$$

On the other hand, there exists a measurable function  $v^3 : [t, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \times U \rightarrow V$  such that

$$F_1(s, x, y, z, u) = F(s, x, y, z, u, v^3(s, x, y, z, u)) \quad \text{for any } s, x, y, z, u.$$

We then put

$$\tilde{v}_s^3 := v^3(s, x, Y_s^{3,u}, Z_s^{3,u}, u_s), \quad s \in [t, t+\delta],$$

and we observe that  $\tilde{v}^3 \in \mathcal{V}_{t,t+\delta}$ , and

$$F_1(s, x, Y_s^{3,u}, Z_s^{3,u}, u_s) = F(s, x, Y_s^{3,u}, Z_s^{3,u}, u_s, \tilde{v}_s^3), \quad s \in [t, t+\delta].$$

Consequently, from the uniqueness of the solution of the BSDE it follows that  $(Y^{3,u}, Z^{3,u}) = (Y^{2,u,\tilde{v}^3}, Z^{2,u,\tilde{v}^3})$  and, in particular,  $Y_t^{3,u} = Y_t^{2,u,\tilde{v}^3}$ ,  $P$ -a.s., for any  $u \in \mathcal{U}_{t,t+\delta}$ . This proves that

$$Y^{3,u}(t) = \operatorname{essinf}_{v \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v}, \quad P\text{-a.s.}, \quad \text{for all } u \in \mathcal{U}_{t,t+\delta}.$$

Finally, since  $F_0(s, x, y, z) = \sup_{u \in U} F_1(s, x, y, z, u)$ , an argument similar to that developed above yields

$$Y_0(t) = \operatorname{esssup}_{u \in \mathcal{U}_{t,t+\delta}} Y^{3,u}(t) (= \operatorname{esssup}_{u \in \mathcal{U}_{t,t+\delta}} \operatorname{essinf}_{v \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v}), \quad P\text{-a.s.}$$

It uses the fact that (4.10) can be considered as a BSDE with the solution  $(Y_s, Z_s) = (Y_0(s), 0)$ . The proof is complete.  $\square$

LEMMA 4.6. *For every  $u \in \mathcal{U}_{t,t+\delta}$ ,  $v \in \mathcal{V}_{t,t+\delta}$ , we have*

$$(4.15) \quad E \left[ \int_t^{t+\delta} |Y_s^{2,u,v}| ds | \mathcal{F}_t \right] + E \left[ \int_t^{t+\delta} |Z_s^{2,u,v}| ds | \mathcal{F}_t \right] \leq C\delta^{\frac{3}{2}}, \quad P\text{-a.s.},$$

where the constant  $C$  is independent of the controls  $u, v$ .

*Proof.* Since  $F(s, x, \cdot, \cdot, u, v)$  has a linear growth in  $(y, z)$ , uniformly in  $(u, v)$ , we get from Lemma 2.3 that, for some constant  $C$  independent of  $\delta$  and the control processes  $u, v$ ,

$$|Y_s^{2,u,v}|^2 \leq C\delta, \quad E \left[ \int_s^{t+\delta} |Z_r^{2,u,v}|^2 dr | \mathcal{F}_s \right] \leq C\delta, \quad s \in [t, t+\delta].$$

On the other hand, from (4.7),

$$\begin{aligned} |Y_s^{2,u,v}| &\leq E \left[ \int_s^{t+\delta} |F(r, x, Y_r^{2,u,v}, Z_r^{2,u,v}, u_r, v_r)| dr | \mathcal{F}_s \right] \\ &\leq CE \left[ \int_s^{t+\delta} (1 + |x|^2 + |Y_r^{2,u,v}| + |Z_r^{2,u,v}|) dr | \mathcal{F}_s \right] \\ &\leq C\delta + C\sqrt{\delta} \left( E \left[ \int_s^{t+\delta} |Z_r^{2,u,v}|^2 dr | \mathcal{F}_s \right] \right)^{\frac{1}{2}} \leq C\delta, \quad P\text{-a.s.}, s \in [t, t + \delta], \end{aligned}$$

and, since

$$\int_t^{t+\delta} Z_s^{2,u,v} dB_s = \int_t^{t+\delta} F(s, x, Y_s^{2,u,v}, Z_s^{2,u,v}, u_s, v_s) ds - Y_t^{2,u,v},$$

we can get  $E[\int_t^{t+\delta} |Z_s^{2,u,v}|^2 ds | \mathcal{F}_t] \leq C\delta^2$ . Finally,

$$\begin{aligned} E \left[ \int_t^{t+\delta} |Y_s^{2,u,v}|^2 ds | \mathcal{F}_t \right] + E \left[ \int_t^{t+\delta} |Z_s^{2,u,v}|^2 ds | \mathcal{F}_t \right] \\ \leq C\delta^2 + \delta^{\frac{1}{2}} \left\{ E \left[ \int_t^{t+\delta} |Z_s^{2,u,v}|^2 ds | \mathcal{F}_t \right] \right\}^{\frac{1}{2}} \leq C\delta^{\frac{3}{2}}. \end{aligned}$$

The proof is complete.  $\square$

Now we are able to give the proof of Theorem 4.2.

*Proof.* (1) Obviously,  $W(T, x) = \Phi(x)$ ,  $x \in \mathbb{R}^n$ . Let us show in a first step that  $W$  is a viscosity supersolution. For this we suppose that  $\varphi \in C_{l,b}^3([0, T] \times \mathbb{R}^n)$  and  $(t, x) \in [0, T] \times \mathbb{R}^n$  are such that  $W - \varphi$  attains its minimum at  $(t, x)$ . Notice that we can replace the condition of a local minimum by that of a global one in the definition of the viscosity supersolution since  $W$  is continuous and of at most linear growth. Without loss of generality we may also suppose that  $\varphi(t, x) = W(t, x)$ . Then, due to the DPP (see Theorem 3.6),

$$\begin{aligned} \varphi(t, x) = W(t, x) &= \text{essinf}_{\beta \in \mathcal{B}_{t,t+\delta}} \text{esssup}_{u \in \mathcal{U}_{t,t+\delta}} G_{t,t+\delta}^{t,x;u,\beta(u)} [W(t + \delta, X_{t+\delta}^{t,x;u,\beta(u)})], \\ &0 \leq \delta \leq T - t, \end{aligned}$$

and from  $W \geq \varphi$  and the monotonicity property of  $G_{t,t+\delta}^{t,x;u,\beta(u)}[\cdot]$  (see Lemma 2.2) we obtain

$$\text{essinf}_{\beta \in \mathcal{B}_{t,t+\delta}} \text{esssup}_{u \in \mathcal{U}_{t,t+\delta}} \{G_{t,t+\delta}^{t,x;u,\beta(u)}[\varphi(t + \delta, X_{t+\delta}^{t,x;u,\beta(u)})] - \varphi(t, x)\} \leq 0, \quad P\text{-a.s.}$$

Thus, from Lemma 4.3,

$$\text{essinf}_{\beta \in \mathcal{B}_{t,t+\delta}} \text{esssup}_{u \in \mathcal{U}_{t,t+\delta}} Y_t^{1,u,\beta(u)} \leq 0, \quad P\text{-a.s.},$$

and further, from Lemma 4.4 we have

$$\text{essinf}_{\beta \in \mathcal{B}_{t,t+\delta}} \text{esssup}_{u \in \mathcal{U}_{t,t+\delta}} Y_t^{2,u,\beta(u)} \leq C\delta^{\frac{3}{2}}, \quad P\text{-a.s.}$$

Consequently, since  $\operatorname{ess\,inf}_{v \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v} \leq Y_t^{2,u,\beta(u)}$ ,  $\beta \in \mathcal{B}_{t,t+\delta}$ , we get

$$\operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} \operatorname{ess\,inf}_{v \in \mathcal{V}_{t,t+\delta}} Y_t^{2,u,v} \leq \operatorname{ess\,inf}_{\beta \in \mathcal{B}_{t,t+\delta}} \operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} Y_t^{2,u,\beta(u)} \leq C\delta^{\frac{3}{2}}, \text{ } P\text{-a.s.},$$

and Lemma 4.5 implies

$$Y_0(t) \leq C\delta^{\frac{3}{2}}, \text{ } P\text{-a.s.},$$

where  $Y_0$  is the unique solution of (4.10). It then follows easily that

$$\sup_{u \in U} \inf_{v \in V} F(t, x, 0, 0, u, v) = F_0(t, x, 0, 0) \leq 0,$$

and from the definition of  $F$  we see that  $W$  is a viscosity supersolution of (4.1).

(2) The second step is devoted to the proof that  $W$  is a viscosity subsolution. For this we suppose that  $\varphi \in C_{l,b}^3([0, T] \times \mathbb{R}^n)$  and  $(t, x) \in [0, T] \times \mathbb{R}^n$  are such that  $W - \varphi$  attains its maximum at  $(t, x)$ . Without loss of generality we suppose again that  $\varphi(t, x) = W(t, x)$ . We must prove that

$$\sup_{u \in U} \inf_{v \in V} F(t, x, 0, 0, u, v) = F_0(t, x, 0, 0) \geq 0.$$

Let us suppose that this is not true. Then there exists some  $\theta > 0$  such that

$$(4.16) \quad F_0(t, x, 0, 0) = \sup_{u \in U} \inf_{v \in V} F(t, x, 0, 0, u, v) \leq -\theta < 0,$$

and we can find a measurable function  $\psi : U \rightarrow V$  such that

$$F(t, x, 0, 0, u, \psi(u)) \leq -\frac{3}{4}\theta \text{ for all } u \in U.$$

Moreover, since  $F(\cdot, x, 0, 0, \cdot, \cdot)$  is uniformly continuous on  $[0, T] \times U \times V$ , there exists some  $T - t \geq R > 0$  such that

$$(4.17) \quad F(s, x, 0, 0, u, \psi(u)) \leq -\frac{1}{2}\theta \text{ for all } u \in U \text{ and } |s - t| \leq R.$$

On the other hand, due to the DPP (see Theorem 3.6), for every  $\delta \in (0, R]$ ,

$$\varphi(t, x) = W(t, x) = \operatorname{ess\,inf}_{\beta \in \mathcal{B}_{t,t+\delta}} \operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} G_{t,t+\delta}^{t,x;u,\beta(u)}[W(t + \delta, X_{t+\delta}^{t,x;u,\beta(u)})],$$

and from  $W \leq \varphi$  and the monotonicity property of  $G_{t,t+\delta}^{t,x;u,\beta(u)}[\cdot]$  (see Lemma 2.2) we obtain

$$\operatorname{ess\,inf}_{\beta \in \mathcal{B}_{t,t+\delta}} \operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} \{G_{t,t+\delta}^{t,x;u,\beta(u)}[\varphi(t + \delta, X_{t+\delta}^{t,x;u,\beta(u)})] - \varphi(t, x)\} \geq 0, \text{ } P\text{-a.s.}$$

Thus, from Lemma 4.3,

$$\operatorname{ess\,inf}_{\beta \in \mathcal{B}_{t,t+\delta}} \operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} Y_t^{1,u,\beta(u)} \geq 0, \text{ } P\text{-a.s.},$$

and, in particular,

$$\operatorname{ess\,sup}_{u \in \mathcal{U}_{t,t+\delta}} Y_t^{1,u,\psi(u)} \geq 0, \text{ } P\text{-a.s.}$$

Here, by putting  $\psi_s(u)(\omega) = \psi(u_s(\omega))$ ,  $(s, \omega) \in [t, T] \times \Omega$ , we identify  $\psi$  as an element of  $\mathcal{B}_{t, t+\delta}$ . Given an arbitrarily  $\varepsilon > 0$  we can choose  $u^\varepsilon \in \mathcal{U}_{t, t+\delta}$  such that  $Y_t^{1, u^\varepsilon, \psi(u^\varepsilon)} \geq -\varepsilon\delta$ . From Lemma 4.4 we further have

$$(4.18) \quad Y_t^{2, u^\varepsilon, \psi(u^\varepsilon)} \geq -C\delta^{\frac{3}{2}} - \varepsilon\delta, \quad P\text{-a.s.}$$

Taking into account that

$$Y_t^{2, u^\varepsilon, \psi(u^\varepsilon)} = E \left[ \int_t^{t+\delta} F(s, x, Y_s^{2, u^\varepsilon, \psi(u^\varepsilon)}, Z_s^{2, u^\varepsilon, \psi(u^\varepsilon)}, u_s^\varepsilon, \psi_s(u^\varepsilon)) ds | \mathcal{F}_t \right]$$

we get from the Lipschitz property of  $F$  in  $(y, z)$ , (4.17), and Lemma 4.6 that

$$(4.19) \quad \begin{aligned} Y_t^{2, u^\varepsilon, \psi(u^\varepsilon)} &\leq E \left[ \int_t^{t+\delta} (C|Y_s^{2, u^\varepsilon, \psi(u^\varepsilon)}| + C|Z_s^{2, u^\varepsilon, \psi(u^\varepsilon)}| + F(s, x, 0, 0, u_s^\varepsilon, \psi_s(u^\varepsilon))) ds | \mathcal{F}_t \right] \\ &\leq C\delta^{\frac{3}{2}} - \frac{1}{2}\theta\delta, \quad P\text{-a.s.} \end{aligned}$$

From (4.18) and (4.19),  $-C\delta^{\frac{1}{2}} - \varepsilon \leq C\delta^{\frac{1}{2}} - \frac{1}{2}\theta$ ,  $P$ -a.s. Letting  $\delta \downarrow 0$ , and then  $\varepsilon \downarrow 0$ , we deduce that  $\theta \leq 0$ , which induces a contradiction. Therefore,

$$F_0(t, x, 0, 0) = \sup_{u \in U} \inf_{v \in V} F(t, x, 0, 0, u, v) \geq 0,$$

and from the definition of  $F$ , we know that  $W$  is a viscosity subsolution of (4.1). Finally, the results from the first and the second steps prove that  $W$  is a viscosity solution of (4.1).  $\square$

*Remark 4.3.* Similarly, we can prove that  $U$  is a viscosity solution of (4.2).

**5. Viscosity solution of Isaacs' equation: Uniqueness theorem.** The objective of this section is to study the uniqueness of the viscosity solution of Isaacs' equation (4.1):

$$(5.1) \quad \begin{cases} \frac{\partial}{\partial t} \omega(t, x) + H^-(t, x, \omega, D\omega, D^2\omega) = 0, & (t, x) \in [0, T] \times \mathbb{R}^n, \\ \omega(T, x) = \Phi(x), & x \in \mathbb{R}^n. \end{cases}$$

Recall that

$$H^-(t, x, y, p, X) = \sup_{u \in U} \inf_{v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) X) + p \cdot b(t, x, u, v) + f(t, x, y, p \cdot \sigma, u, v) \right\},$$

$t \in [0, T]$ ,  $x \in \mathbb{R}^n$ ,  $y \in \mathbb{R}$ ,  $p \in \mathbb{R}^n$ , and  $X \in \mathbf{S}^n$ . The functions  $b, \sigma, f$ , and  $\Phi$  are still supposed to satisfy (H3.1) and (H3.2), respectively.

We will prove the uniqueness for (5.1) in the following space of continuous functions:

$$\Theta = \{ \varphi \in C([0, T] \times \mathbb{R}^n) : \exists \tilde{A} > 0 \text{ such that } \lim_{|x| \rightarrow \infty} \varphi(t, x) \exp\{-\tilde{A}[\log(|x|^2 + 1)^{\frac{1}{2}}]^2\} = 0, \text{ uniformly in } t \in [0, T] \}.$$

This space of continuous functions is endowed with a growth condition which is slightly weaker than the assumption of polynomial growth but more restrictive than that of exponential growth. This growth condition was introduced by Barles, Buckdahn, and

Pardoux [3] to prove the uniqueness of the viscosity solution of an integro-partial differential equation associated with a decoupled FBSDE with jumps. It was shown in [3] that this kind of growth condition is optimal for the uniqueness and can, in general, not be weakened. We adapt the ideas developed in [3] to Isaacs' equation (5.1) to prove the uniqueness of the viscosity solution in  $\Theta$ . Since the proof of the uniqueness in  $\Theta$  for (4.2) is the same, we will restrict ourselves to only that of (5.1). Before stating the main result of this section, let us begin with two auxiliary lemmas. Denoting by  $K$  a Lipschitz constant of  $f(t, x, \cdot, \cdot, \cdot, \cdot)$ , that is, uniformly in  $(t, x)$ , we have the following.

LEMMA 5.1. *Let  $u_1 \in \Theta$  be a viscosity subsolution and  $u_2 \in \Theta$  be a viscosity supersolution of (5.1). Then the function  $\omega := u_1 - u_2$  is a viscosity subsolution of the equation*

$$(5.2) \quad \begin{cases} \frac{\partial}{\partial t} \omega(t, x) + \sup_{u \in U, v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) D^2 \omega) + D\omega \cdot b(t, x, u, v) + K|\omega| \right. \\ \quad \left. + K|D\omega \cdot \sigma(t, x, u, v)| \right\} = 0, & (t, x) \in [0, T) \times \mathbb{R}^n, \\ \omega(T, x) = 0, & x \in \mathbb{R}^n. \end{cases}$$

The proof of this lemma follows directly that of Lemma 3.7 in [3], and it is even simpler because, contrary to Lemma 3.7 in [3], we do not have any integral part here in (5.1). In analogy to [3] we also have the following.

LEMMA 5.2. *For any  $\tilde{A} > 0$ , there exists  $C_1 > 0$  such that the function*

$$\chi(t, x) = \exp[(C_1(T - t) + \tilde{A})\psi(x)],$$

with

$$\psi(x) = [\log((|x|^2 + 1)^{\frac{1}{2}}) + 1]^2, \quad x \in \mathbb{R}^n,$$

satisfies

$$(5.3) \quad \begin{aligned} & \frac{\partial}{\partial t} \chi(t, x) + \sup_{u \in U, v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) D^2 \chi) + D\chi \cdot b(t, x, u, v) + K\chi(t, x) \right. \\ & \quad \left. + K|D\chi(t, x) \cdot \sigma(t, x, u, v)| \right\} < 0 \quad \text{in } [t_1, T] \times \mathbb{R}^n, \quad \text{where } t_1 = T - \frac{\tilde{A}}{C_1}. \end{aligned}$$

*Proof.* By direct calculus we first deduce the following estimates for the first and second derivatives of  $\psi$ :

$$|D\psi(x)| \leq \frac{2[\psi(x)]^{\frac{1}{2}}}{(|x|^2 + 1)^{\frac{1}{2}}} \leq 4, \quad |D^2\psi(x)| \leq \frac{C(1 + [\psi(x)]^{\frac{1}{2}})}{|x|^2 + 1}, \quad x \in \mathbb{R}^n.$$

These estimates imply that, if  $t \in [t_1, T]$ ,

$$\begin{aligned} |D\chi(t, x)| & \leq (C_1(T - t) + \tilde{A})\chi(t, x)|D\psi(x)| \\ & \leq C\chi(t, x) \frac{[\psi(x)]^{\frac{1}{2}}}{(|x|^2 + 1)^{\frac{1}{2}}}, \end{aligned}$$

and, similarly,

$$|D^2\chi(t, x)| \leq C\chi(t, x) \frac{\psi(x)}{|x|^2 + 1}.$$

We should notice that the above estimates do not depend on  $C_1$  because of the definition of  $t_1$ . By virtue with the above estimates we have

$$\begin{aligned} & \frac{\partial}{\partial t} \chi(t, x) + \sup_{u \in U, v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t, x, u, v) D^2 \chi) + D\chi \cdot b(t, x, u, v) + K\chi(t, x) \right. \\ & \quad \left. + K|D\chi(t, x) \cdot \sigma(t, x, u, v)| \right\} \\ & \leq -\chi(t, x) \{C_1 \psi(x) - C\psi(x) - C[\psi(x)]^{\frac{1}{2}} - K\} \\ & < -\chi(t, x) \{C_1 - [2C + K]\} \psi(x) < 0, \text{ if } C_1 > 2C + K \text{ large enough.} \quad \square \end{aligned}$$

Now we can prove the uniqueness theorem.

**THEOREM 5.3.** *We assume that (H3.1) and (H3.2) hold. Let  $u_1$  (resp.,  $u_2$ )  $\in \Theta$  be a viscosity subsolution (resp., supersolution) of (5.1). Then we have*

$$(5.4) \quad u_1(t, x) \leq u_2(t, x) \quad \text{for all } (t, x) \in [0, T] \times \mathbb{R}^n.$$

*Proof.* Let us put  $\omega := u_1 - u_2$ . Then we have, for some  $\tilde{A} > 0$ ,

$$\lim_{|x| \rightarrow \infty} \omega(t, x) e^{-\tilde{A}[\log((|x|^2 + 1))^{\frac{1}{2}}]^2} = 0,$$

uniformly with respect to  $t \in [0, T]$ . This implies, in particular, that, for any  $\alpha > 0$ ,  $\omega(t, x) - \alpha\chi(t, x)$  is bounded from above in  $[t_1, T] \times \mathbb{R}^n$  and that

$$M := \max_{[t_1, T] \times \mathbb{R}^n} (\omega - \alpha\chi)(t, x) e^{-K(T-t)}$$

is achieved at some point  $(t_0, x_0) \in [t_1, T] \times \mathbb{R}^n$  (depending on  $\alpha$ ). We now have to distinguish between two cases.

For the first case we suppose that:  $\omega(t_0, x_0) \leq 0$ , for any  $\alpha > 0$ .

Then, obviously  $M \leq 0$  and  $u_1(t, x) - u_2(t, x) \leq \alpha\chi(t, x)$  in  $[t_1, T] \times \mathbb{R}^n$ . Consequently, letting  $\alpha$  tend to zero we obtain

$$u_1(t, x) \leq u_2(t, x) \quad \text{for all } (t, x) \in [t_1, T] \times \mathbb{R}^n.$$

For the second case we assume that there exists some  $\alpha > 0$  such that  $\omega(t_0, x_0) > 0$ .

We notice that  $\omega(t, x) - \alpha\chi(t, x) \leq (\omega(t_0, x_0) - \alpha\chi(t_0, x_0))e^{-K(t-t_0)}$  in  $[t_1, T] \times \mathbb{R}^n$ . Then, putting

$$\varphi(t, x) = \alpha\chi(t, x) + (\omega - \alpha\chi)(t_0, x_0)e^{-K(t-t_0)}$$

we get  $\omega - \varphi \leq 0 = (\omega - \varphi)(t_0, x_0)$  in  $[t_1, T] \times \mathbb{R}^n$ . Consequently, since  $\omega$  is a viscosity subsolution of (5.2), from Lemma 5.1 we have

$$\begin{aligned} & \frac{\partial}{\partial t} \varphi(t_0, x_0) + \sup_{u \in U, v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t_0, x_0, u, v) D^2 \varphi(t_0, x_0)) + D\varphi(t_0, x_0) \cdot b(t_0, x_0, u, v) \right. \\ & \quad \left. + K|\varphi(t_0, x_0)| + K|D\varphi(t_0, x_0) \cdot \sigma(t_0, x_0, u, v)| \right\} \geq 0. \end{aligned}$$

Moreover, due to our assumption that  $\omega(t_0, x_0) > 0$  and since  $\omega(t_0, x_0) = \varphi(t_0, x_0)$ , we can replace  $K|\varphi(t_0, x_0)|$  by  $K\varphi(t_0, x_0)$  in the above formula. Then, from the definition of  $\varphi$  and Lemma 5.2,

$$0 \leq \alpha \left\{ \frac{\partial \chi}{\partial t}(t_0, x_0) + \sup_{u \in U, v \in V} \left\{ \frac{1}{2} \text{tr}(\sigma \sigma^T(t_0, x_0, u, v) D^2 \chi(t_0, x_0)) + D\chi(t_0, x_0) \cdot b(t_0, x_0, u, v) \right. \right. \\ \left. \left. + K\chi(t_0, x_0) + K|D\chi(t_0, x_0) \cdot \sigma(t_0, x_0, u, v)| \right\} \right\} < 0,$$

which is a contradiction. Finally, by applying successively the same argument on the interval  $[t_2, t_1]$ , with  $t_2 = (t_1 - \frac{\tilde{A}}{C_1})^+$ , and then, if  $t_2 > 0$ , on  $[t_3, t_2]$ , with  $t_3 = (t_2 - \frac{\tilde{A}}{C_1})^+$ , etc., we get

$$u_1(t, x) \leq u_2(t, x), \quad (t, x) \in [0, T] \times \mathbb{R}^n.$$

Thus, the proof is complete.  $\square$

*Remark 5.1.* Obviously, since the lower value function  $W(t, x)$  is of at most linear growth, it belongs to  $\Theta$ , and so  $W(t, x)$  is the unique viscosity solution in  $\Theta$  of (5.1). Similarly we get that the upper value function  $U(t, x)$  is the unique viscosity solution in  $\Theta$  of (4.2). On the other hand, since  $H^- \leq H^+$ , any viscosity solution of (4.2) is a supersolution of (5.1). Then, again from Theorem 5.3, it follows that  $W \leq U$ . This justifies calling  $W$  the lower value function and  $U$  the upper value function.

*Remark 5.2.* If the Isaacs' condition holds, that is, if for all  $(t, x, y, p, X) \in [0, T] \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^n \times \mathbf{S}^n$

$$H^-(t, x, y, p, X) = H^+(t, x, y, p, X),$$

then (5.1) and (4.2) coincide, and from the uniqueness in  $\Theta$  of viscosity solution it follows that the lower value function  $W(t, x)$  equals the upper value function  $U(t, x)$  which means that the associated stochastic differential game has a value.

*Remark 5.3.* Let us assume that the coefficient of BSDE (3.5)  $f(t, x, y, z, u, v) \equiv f(t, x, u, v)$  is independent of  $(y, z)$  and denote by  $\tilde{W}(t, x)$  (resp.,  $\tilde{U}(t, x)$ ) the lower value function (resp., the upper value function) defined by Fleming and Souganidis [14]; see Remark 3.4. It is shown in [14] that  $\tilde{W}(t, x)$  is a viscosity solution in  $\Theta$  of (5.1) and  $\tilde{U}(t, x)$  a viscosity solution in  $\Theta$  of (4.2). Then, due to Theorem 5.3,  $W(t, x) = \tilde{W}(t, x)$  and  $U(t, x) = \tilde{U}(t, x)$ ,  $(t, x) \in [0, T] \times \mathbb{R}^n$ . Moreover, if the Isaacs' condition holds, then  $W(t, x) = \tilde{W}(t, x) = \tilde{U}(t, x) = U(t, x)$ .

### Appendix A. Forward-backward SDEs (FBSDEs).

In this section we give an overview over basic results which are necessary for us on BSDEs associated with forward SDEs. We consider measurable functions  $b : [0, T] \times \Omega \times \mathbb{R}^n \rightarrow \mathbb{R}^n$  and  $\sigma : [0, T] \times \Omega \times \mathbb{R}^n \rightarrow \mathbb{R}^{n \times d}$ , which are supposed to satisfy the following conditions:

(H6.1)

- (i)  $b(\cdot, 0)$  and  $\sigma(\cdot, 0)$  are  $\mathcal{F}_t$ -adapted processes, and there exists some constant  $C > 0$  such that  $|b(t, x)| + |\sigma(t, x)| \leq C(1 + |x|)$ , a.s., for all  $0 \leq t \leq T$ ,  $x \in \mathbb{R}^n$ ;
- (ii)  $b$  and  $\sigma$  are Lipschitz in  $x$ ; i.e., there is some constant  $C > 0$  such that

$$|b(t, x) - b(t, x')| + |\sigma(t, x) - \sigma(t, x')| \leq C|x - x'|, \text{ a.s.,} \\ \text{for all } 0 \leq t \leq T, \ x, \ x' \in \mathbb{R}^n.$$

We now consider the following SDE parameterized by the initial condition  $(t, \zeta) \in [0, T] \times L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ :

$$(A.1) \quad \begin{cases} dX_s^{t, \zeta} &= b(s, X_s^{t, \zeta})ds + \sigma(s, X_s^{t, \zeta})dB_s, \quad s \in [t, T], \\ X_t^{t, \zeta} &= \zeta. \end{cases}$$

Under the assumption (H6.1), SDE (A.1) has a unique strong solution, and, for any  $p \geq 2$ , there exists  $C_p \in \mathbb{R}$  such that, for any  $t \in [0, T]$  and  $\zeta, \zeta' \in L^p(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ ,

$$(A.2) \quad \begin{aligned} E \left[ \sup_{t \leq s \leq T} |X_s^{t, \zeta} - X_s^{t, \zeta'}|^p | \mathcal{F}_t \right] &\leq C_p |\zeta - \zeta'|^p, \quad a.s., \\ E \left[ \sup_{t \leq s \leq T} |X_s^{t, \zeta}|^p | \mathcal{F}_t \right] &\leq C_p (1 + |\zeta|^p), \quad a.s. \end{aligned}$$

These well-known standard estimates can be consulted, for instance, in Ikeda and Watanabe [18, pp. 166–168] and also in Karatzas and Shreve [19, pp. 289–290].

We emphasize that the constant  $C_p$  in (A.2) depends only on the Lipschitz and the growth constants of  $b$  and  $\sigma$ . Let now be given two real-valued functions  $f(t, x, y, z)$  and  $\Phi(x)$  which shall satisfy the following conditions:

(H6.2)

- (i)  $\Phi : \Omega \times \mathbb{R}^n \rightarrow \mathbb{R}$  is an  $\mathcal{F}_T \otimes \mathcal{B}(\mathbb{R}^n)$ -measurable random variable and  $f : [0, T] \times \Omega \times \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d \rightarrow \mathbb{R}$  is a measurable process such that  $f(\cdot, x, y, z)$  is  $\mathcal{F}_t$ -adapted, for all  $(x, y, z) \in \mathbb{R}^n \times \mathbb{R} \times \mathbb{R}^d$ ;
- (ii) There exists a constant  $C > 0$  such that  $|f(t, x, y, z) - f(t, x', y', z')| + |\Phi(x) - \Phi(x')| \leq C(|x - x'| + |y - y'| + |z - z'|)$ , *a.s.*, for all  $0 \leq t \leq T$ ,  $x, x' \in \mathbb{R}^n$ ,  $y, y' \in \mathbb{R}$  and  $z, z' \in \mathbb{R}^d$ ;
- (iii)  $f$  and  $\Phi$  satisfy a linear growth condition; i.e., there exists some  $C > 0$  such that,  $dt \times dP$ -a.e., for all  $x \in \mathbb{R}^n$ ,  $|f(t, x, 0, 0)| + |\Phi(x)| \leq C(1 + |x|)$ .

With the help of the above assumptions we can verify that the coefficient  $f(s, X_s^{t, \zeta}, y, z)$  satisfies the hypotheses (A.1) and (A.2) and  $\xi = \Phi(X_T^{t, \zeta}) \in L^2(\Omega, \mathcal{F}_T, P; \mathbb{R})$ . Therefore, the following BSDE possesses a unique solution:

$$(A.3) \quad \begin{cases} -dY_s^{t, \zeta} &= f(s, X_s^{t, \zeta}, Y_s^{t, \zeta}, Z_s^{t, \zeta})ds - Z_s^{t, \zeta}dB_s, \quad s \in [t, T], \\ Y_T^{t, \zeta} &= \Phi(X_T^{t, \zeta}). \end{cases}$$

**PROPOSITION A.1.** *We suppose that the hypotheses (H6.1) and (H6.2) hold. Then, for any  $0 \leq t \leq T$  and the associated initial conditions  $\zeta, \zeta' \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we have the following estimates:*

- (i)  $E \left[ \sup_{t \leq s \leq T} |Y_s^{t, \zeta}|^2 + \int_t^T |Z_s^{t, \zeta}|^2 ds | \mathcal{F}_t \right] \leq C(1 + |\zeta|^2), \quad a.s.;$
- (ii)  $E \left[ \sup_{t \leq s \leq T} |Y_s^{t, \zeta} - Y_s^{t, \zeta'}|^2 + \int_t^T |Z_s^{t, \zeta} - Z_s^{t, \zeta'}|^2 ds | \mathcal{F}_t \right] \leq C|\zeta - \zeta'|^2, \quad a.s.$

*In particular,*

$$(A.4) \quad \text{(iii) } |Y_t^{t, \zeta}| \leq C(1 + |\zeta|), \quad a.s.; \quad \text{(iv) } |Y_t^{t, \zeta} - Y_t^{t, \zeta'}| \leq C|\zeta - \zeta'|, \quad a.s.,$$

where the constant  $C > 0$  depends only on the Lipschitz and the growth constants of  $b$ ,  $\sigma$ ,  $f$ , and  $\Phi$ .

For the proof the reader is referred to Proposition 4.1 of Peng [26]; a similar result can be found in El Karoui, Peng, and Quenez [12, Proposition 4.1].

Let us now introduce the random field:

$$(A.5) \quad u(t, x) = Y_s^{t,x}|_{s=t}, \quad (t, x) \in [0, T] \times \mathbb{R}^n,$$

where  $Y^{t,x}$  is the solution of BSDE (A.3) with  $x \in \mathbb{R}^n$  at the place of  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ .

As a consequence of Proposition A.1 we have that, for all  $t \in [0, T]$ ,  $P$ -a.s.,

$$(A.6) \quad \begin{aligned} (i) \quad & |u(t, x) - u(t, y)| \leq C|x - y| \text{ for all } x, y \in \mathbb{R}^n; \\ (ii) \quad & |u(t, x)| \leq C(1 + |x|) \text{ for all } x \in \mathbb{R}^n. \end{aligned}$$

*Remark A.1.* In the general situation  $u$  is an adapted random function; that is, for any  $x \in \mathbb{R}^n$ ,  $u(\cdot, x)$  is an  $\mathcal{F}_t$ -adapted real-valued process. Indeed, recall that  $b$ ,  $\sigma$ , and  $f$  all are  $\mathbb{F}$ -adapted random functions while  $\Phi$  is  $\mathcal{F}_T$ -measurable. On the other hand, it is well known that, under the additional assumption that the functions

$$(H6.3) \quad b, \sigma, f, \text{ and } \Phi \text{ are deterministic,}$$

$u$  is also a deterministic function of  $(t, x)$ .

The random field  $u$  and  $Y^{t,\zeta}$ ,  $(t, \zeta) \in [0, T] \times L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , are related by the following theorem.

**THEOREM A.2.** *Under the assumptions (H6.1) and (H6.2), for any  $t \in [0, T]$  and  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ , we have*

$$(A.7) \quad u(t, \zeta) = Y_t^{t,\zeta}, \quad P\text{-a.s.}$$

The proof of Theorem A.2 can be found in Peng [26]; we give it for the reader's convenience. It makes use of the following definition.

**DEFINITION A.3.** *For any  $t \in [0, T]$ , a sequence  $\{A_i\}_{i=1}^N \subset \mathcal{F}_t$  (with  $1 \leq N \leq \infty$ ) is called a partition of  $(\Omega, \mathcal{F}_t)$  if  $\cup_{i=1}^N A_i = \Omega$  and  $A_i \cap A_j = \emptyset$ , whenever  $i \neq j$ .*

*Proof of Theorem A.2.* We first consider the case where  $\zeta$  is a simple random variable of the form

$$(A.8) \quad \zeta = \sum_{i=1}^N x_i \mathbf{1}_{A_i},$$

where  $\{A_i\}_{i=1}^N$  is a finite partition of  $(\Omega, \mathcal{F}_t)$  and  $x_i \in \mathbb{R}^n$ , for  $1 \leq i \leq N$ .

For each  $i$ , we put  $(X_s^i, Y_s^i, Z_s^i) \equiv (X_s^{t,x_i}, Y_s^{t,x_i}, Z_s^{t,x_i})$ . Then  $X^i$  is the solution of the SDE

$$X_s^i = x_i + \int_t^s b(r, X_r^i) dr + \int_t^s \sigma(r, X_r^i) dB_r, \quad s \in [t, T],$$

and  $(Y^i, Z^i)$  is the solution of the associated BSDE

$$Y_s^i = \Phi(X_T^i) + \int_s^T f(r, X_r^i, Y_r^i, Z_r^i) dr - \int_s^T Z_r^i dB_r, \quad s \in [t, T].$$

The above two equations are multiplied by  $\mathbf{1}_{A_i}$  and summed up with respect to  $i$ . Thus, taking into account that  $\sum_i \varphi(x_i) \mathbf{1}_{A_i} = \varphi(\sum_i x_i \mathbf{1}_{A_i})$ , we get

$$\sum_{i=1}^N \mathbf{1}_{A_i} X_s^i = \sum_{i=1}^N x_i \mathbf{1}_{A_i} + \int_t^s b\left(r, \sum_{i=1}^N \mathbf{1}_{A_i} X_r^i\right) dr + \int_t^s \sigma\left(r, \sum_{i=1}^N \mathbf{1}_{A_i} X_r^i\right) dB_r$$

and

$$\begin{aligned} \sum_{i=1}^N \mathbf{1}_{A_i} Y_s^i &= \Phi \left( \sum_{i=1}^N \mathbf{1}_{A_i} X_T^i \right) + \int_s^T f \left( r, \sum_{i=1}^N \mathbf{1}_{A_i} X_r^i, \sum_{i=1}^N \mathbf{1}_{A_i} Y_r^i, \sum_{i=1}^N \mathbf{1}_{A_i} Z_r^i \right) dr \\ &\quad - \int_s^T \sum_{i=1}^N \mathbf{1}_{A_i} Z_r^i dB_r. \end{aligned}$$

Then the strong uniqueness property of the solution of the SDE and the BSDE yields

$$X_s^{t,\zeta} = \sum_{i=1}^N X_s^i \mathbf{1}_{A_i}, \quad (Y_s^{t,\zeta}, Z_s^{t,\zeta}) = \left( \sum_{i=1}^N \mathbf{1}_{A_i} Y_s^i, \sum_{i=1}^N \mathbf{1}_{A_i} Z_s^i \right), \quad s \in [t, T].$$

Finally, from  $u(t, x_i) = Y_t^i$ ,  $1 \leq i \leq N$ , we deduce that

$$Y_t^{t,\zeta} = \sum_{i=1}^N Y_t^i \mathbf{1}_{A_i} = \sum_{i=1}^N u(t, x_i) \mathbf{1}_{A_i} = u \left( t, \sum_{i=1}^N x_i \mathbf{1}_{A_i} \right) = u(t, \zeta).$$

Therefore, for simple random variables, we have the desired result.

Given a general  $\zeta \in L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$  we can choose a sequence of simple random variables  $\{\zeta_i\}$  which converges to  $\zeta$  in  $L^2(\Omega, \mathcal{F}_t, P; \mathbb{R}^n)$ . Consequently, from the estimates (A.4) and (A.6) and the first step of the proof, we have

$$\begin{aligned} E|Y_t^{t,\zeta_i} - Y_t^{t,\zeta}|^2 &\leq CE|\zeta_i - \zeta|^2 \rightarrow 0, \quad i \rightarrow \infty, \\ E|u(t, \zeta_i) - u(t, \zeta)|^2 &\leq CE|\zeta_i - \zeta|^2 \rightarrow 0, \quad i \rightarrow \infty, \end{aligned}$$

and

$$Y_t^{t,\zeta_i} = u(t, \zeta_i), \quad i \geq 1.$$

Then the proof is complete.  $\square$

*Remark A.2.* Under (H6.1), (H6.2), and (H6.3) we know  $u(t, x)$  is  $\frac{1}{2}$ -Hölder continuous in  $t$ : There exists a constant  $C$  such that, for every  $x \in \mathbb{R}^n$ ,  $t, t' \in [0, T]$ ,

$$|u(t, x) - u(t', x)| \leq C(1 + |x|)|t - t'|^{\frac{1}{2}}.$$

This inequality can be proved with the help of Theorem A.2. Since, on the other hand, a similar result but in a more general setting is proved (see Theorem 3.10), we do not give the proof here.

Although it is not used in our paper, let us also mention that, in the case of random coefficients  $b, \sigma, f$ , and  $\Phi$  the following holds true.

*Remark A.3.* Let us suppose in addition to the assumptions (H6.1) and (H6.2) that  $\sigma(\omega, t, \cdot)$  and  $b(\omega, t, \cdot)$  are continuously differentiable with a Lipschitz derivative such that, for some constant  $C$ ,

$$\begin{aligned} |D_x \sigma(\omega, t, x)| + |D_x b(\omega, t, x)| &\leq C, \quad \text{dtd}P\text{-a.e., for all } x \in \mathbb{R}^n; \\ D_x \sigma(\omega, t, \cdot), D_x b(\omega, t, \cdot) &\text{ are Lipschitz, uniformly in } (\omega, t). \end{aligned}$$

Then the random field  $u(\omega, t, x) : \Omega \times [0, T] \times \mathbb{R}^n \rightarrow \mathbb{R}$  possesses a continuous version.

The proof of the above property uses a standard argument for BSDEs based on the fact that  $u(s, x)$  can be written as  $Y_s^{t, \overline{X}_s^{t,x}}$  for  $0 < s - t$  small enough, where  $\overline{X}_s^{t,x}$  denotes the local inversion of the stochastic flow generated by (A.1):  $\overline{X}_s^{t,x} = (X_s^{t,\cdot})^{-1}(x)$ .

## FINITE HORIZON ROBUST STATE ESTIMATION FOR UNCERTAIN FINITE-ALPHABET HIDDEN MARKOV MODELS WITH CONDITIONAL RELATIVE ENTROPY CONSTRAINTS\*

LI XIE<sup>†</sup>, VALERY A. UGRINOVSKII<sup>‡</sup>, AND IAN R. PETERSEN<sup>‡</sup>

**Abstract.** We consider a robust state estimation problem for time-varying uncertain discrete-time, homogeneous, first-order, finite-state finite-alphabet hidden Markov models (HMMs). A class of time-varying uncertain HMMs is considered in which the uncertainty is sequentially described by a conditional relative entropy constraint on perturbed conditional probability measures given a realized observation sequence. For this class of uncertain HMMs, the robust state estimation problem is formulated as a constrained optimization problem. Using a Lagrange multiplier technique and a variational formula for conditional relative entropy, the above problem is converted into an unconstrained optimization problem and a problem related to partial information risk-sensitive filtering. A measure transformation technique and an information state method are employed to solve this equivalent problem related to risk-sensitive filtering. A characterization of the solution to the robust state estimation problem is also presented.

**Key words.** finite-alphabet hidden Markov models, robust state estimation, conditional relative entropy constraints, finite horizon

**1. Introduction.** First state estimation algorithms for hidden Markov models (HMMs) are traditionally associated with problems of speech processing [15], and over the years many variations of the HMM state estimation problem were considered in the literature; we refer the reader to the comprehensive survey [9]. In loose terms, the problem is to estimate the state of a Markov process based on the observed data, and the optimization under various criteria is commonly regarded as one way to obtain such an estimate. The most common optimality criteria are the minimum symbol error probability criterion and minimum sequence error probability criterion. The first criterion results in the maximum a posteriori (MAP) symbol decision rule. Estimation of the state sequence using the second criterion results in a sequence estimate which is obtained by using the celebrated Viterbi algorithm.

In the control literature, the paradigm of optimal HMM state estimation has received much attention. For example, in [4, 8, 16] the HMM state estimation problem was formulated as an optimization problem in which a state estimate was sought to attain the minimum of a conditional mean square error cost or an exponential risk-sensitive cost, given a realized observation sequence. To solve such a risk-sensitive optimization problem, a probability measure transformation technique [8], an information state method, and dynamic programming were used [4, 16]. It was also observed using simulations [4] that, when the risk-sensitive parameter is within a

certain range, risk-sensitive filters exhibited useful robustness properties in an uncertain noise environment. Other types of the HMM estimation problem considered in the literature concern the estimation of states of discrete and continuous range partially observed Markov processes subject to Gaussian or Poisson measurement noises; e.g., see [5, 6, 12]. Another related line of research concerns applications to filtering and control of hybrid stochastic systems whose dynamics are modulated by Markov chains [26]. These problems, however, are substantially different from the one considered in this paper, both in the structure of the process being estimated and controlled and the information about the statistics of the process and noise disturbances.

Recently, the notion of relative entropy has been introduced into the areas of robust control and estimation for stochastic uncertain systems to describe uncertainties arising in stochastic control systems [1, 14, 19]. Petersen, James, and Dupuis [14] and Ugrinovskii and Petersen [19] introduced a new description of stochastic uncertain systems which uses the relative entropy between noise distributions to measure the uncertainty in uncertain systems; see also more recent papers [24, 25]. As demonstrated in these papers, the quantity of relative entropy allows one to quantify the amount of uncertainty in the underlying stochastic system and also allows for this quantitative information to be translated into a tractable robust control or robust filter design. The robust state estimation problem for a class of uncertain HMMs considered in this paper is defined under similar uncertain information constraints. We introduce a direct description for the uncertainty in HMMs which uses an a posteriori probability distance between HMMs. Then we show that the corresponding robust state estimation problem for the class of uncertain hidden Markov models under consideration can be solved using a framework similar to the one developed in [14, 19] since an HMM is essentially a probabilistic model. Techniques developed in [4, 8] are instrumental in this approach to robust state estimation.

For an HMM under consideration, we suppose that the true parameter set which defines the true HMM probability distribution is unknown, but a margin on the divergence from some design (reference) probability distribution is available. This is a key difference of our problem formulation from the one considered in [4, 8, 16]. Based on the relationship between HMM parameter sets and Kolmogorov measures of HMMs, this also means that the true Kolmogorov measure of the HMM under consideration is unknown (see [17] for further details concerning the Kolmogorov measure of a process and [23]). Instead, the estimation algorithm is constructed using a different reference parameter set satisfying some conditions. In our approach to the state estimation problem, since the observation sequence is available up to time step  $k$ , the difference between the true and reference parameter sets can be characterized using a posteriori probability distributions, and it is natural to compare the true and reference HMMs using related conditional probability measures. From this viewpoint, given an observation sequence, the true conditional probability measure related to the true Kolmogorov measure can be viewed as a perturbation of the reference conditional probability measure.

The relative entropy between conditional probability measures, or for short, the conditional relative entropy, can be viewed as an a posteriori measure of discrepancy between HMMs after a realized observation sequence is observed. In our robust state estimation problem, we will use the conditional relative entropy between the perturbed and reference conditional probability measures to define a constraint on the mismatch between the two HMMs, given measurements up to time step  $k$ . As a result, the uncertainty about the true conditional probability measure is sequentially described in terms of a conditional relative entropy constraint. More specifically, we define

a feasible uncertainty set for our robust state estimation problem as follows. Let  $y_{1,k} \triangleq \{y_1, y_2, \dots, y_k\}$  denote a realization of the observation process up to time step  $k$  which has positive probability to occur under the reference probability measure. For a given  $y_{1,k}$ , the feasible set of probability measures consists of all conditional probability measures given  $y_{1,k}$  whose conditional relative entropy with respect to the reference conditional probability measure satisfies a certain bound. The feasible set is therefore determined by the reference probability measure and certain design parameters. It is also a function of realizations of the observation process and a time step. We seek worst-case optimal estimates, and the robust state estimation problem under consideration is defined as a minimax optimization problem. In this problem the infimum with respect to the state estimate is taken over the state space. Also, the supremum with respect to conditional probability measures is taken over the feasible set.

The state estimator presented in this paper is based on processing realized observation sequences generated by the HMM with its true parameter set. The estimation error computed under the true conditional probability measure is guaranteed not to exceed a certain error cost value for the estimator. The upper bound on the estimation error is uniform, and it does not depend on the true probability distribution of the HMM, provided that the true probability distribution satisfies the specified conditional relative entropy constraint at each time step. This property indicates robustness of the estimator. In general, the robust state estimator which is presented is a finite horizon state estimator. The only exception to this is in the special case in which the only uncertainty is in the initial distribution. For this case, the robust state estimator can be generalized to the infinite horizon case if the state transition matrix satisfies an extra condition.

The organization of this paper is as follows. In section 2, we first introduce the notion of observability of states. Then the class of uncertain HMMs under consideration is defined and the conditional relative entropy uncertainty description is presented based on a calculation of the relative entropy between HMMs. The robust state estimation problem for this class of uncertain HMMs is introduced in section 3. Furthermore, we define an unconstrained optimization problem related to the underlying robust state estimation problem. This involves the use of a Lagrange multiplier. Using a variational formula for the conditional relative entropy, we show that the above unconstrained optimization problem with a positive Lagrange multiplier is equivalent to a problem related to partial information, risk-sensitive filtering. Furthermore, using a Lagrange multiplier technique, we convert the underlying robust state estimation problem into an unconstrained optimization problem which depends on a parameter which is optimized over  $[0, \infty)$ . It is interesting to note that in this associated risk-sensitive optimization problem, the Lagrange multiplier plays a role similar to that of a risk-sensitivity parameter. However, the resulting risk-sensitive optimization problem is different from the problem considered in [4], since in our case the running cost of the problem is also dependent on the Lagrange multiplier. Also, our solution method involves optimization over the Lagrange multiplier at each step of the algorithm. In contrast in [4], the risk-sensitivity parameter is kept constant once selected. In section 4, an information state method is used to compute the cost values of the above unconstrained optimization problem with a positive Lagrange multiplier. In section 5, a mathematical characterization of the solution to the robust state estimation problem under consideration is presented. In section 6, an illustrative example is given.

Throughout the paper, we use the standard conventions  $0 \log 0 = 0$ ,  $0 \cdot \infty = 0$ ,

$\frac{0}{0} = 1$ , and  $\infty \pm x = \infty$ , where  $|x| < \infty$ . We use upper case letters to denote random variables and lower case letters to denote values, i.e., realizations, of random variables.

**2. Finite-alphabet HMMs.** Consider an HMM with the parameter set  $\zeta = (A, C, p)$ . Here  $A = (a_{ji})$  is the one-step state transition matrix,  $C = (c_{qi})$  is the one-step state-observation transition matrix, and  $p = (p_i)$  is the initial distribution of the state process. Without loss of generality, we assume that the state space is  $\mathbb{E}_X = \{e_1, \dots, e_N\}$ , where  $e_i = (0, \dots, 1, \dots, 0)' \in \mathbb{R}^N$  with a 1 in the  $i$ th position and  $N$  is the size of  $\mathbb{E}_X$ . Also, we assume that the observation space is  $\mathbb{E}_Y = \{f_1, \dots, f_M\}$ , where  $f_j = (0, \dots, 1, \dots, 0)' \in \mathbb{R}^M$  with a 1 in the  $j$ th position and  $M$  is the size of  $\mathbb{E}_Y$ ; see [8].

Let  $(\Omega, \mathcal{B})$  be the canonical measurable space related to the HMM under consideration. That is,  $\Omega$  consists of all infinite sequences  $(x_0, \dots, x_k, \dots; y_1, \dots, y_k, \dots)$ , where  $x_0, \dots, x_k \in \mathbb{E}_X$  and  $y_1, \dots, y_k \in \mathbb{E}_Y$ , and  $\mathcal{B}$  is the smallest  $\sigma$ -algebra generated by cylinder sets with finite-dimensional measurable bases. Let a probability measure  $\mathbf{P}$  on  $(\Omega, \mathcal{B})$  be defined by extending finite-dimensional probability distribution functions of the HMM with the parameter set  $\zeta = (A, C, p)$  onto  $(\Omega, \mathcal{B})$  using Kolmogorov's extension theorem; see [17, 18]. The probability measure  $\mathbf{P}$  is called the Kolmogorov measure of the HMM with the parameter set  $\zeta$ . Obviously under  $\mathbf{P}$ , the pair of coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  is an HMM and  $\zeta$  is the parameter set of this HMM. The probability space  $(\Omega, \mathcal{B}, \mathbf{P})$  and the coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  are called the Kolmogorov model of the HMM with the parameter set  $\zeta$  and will be used to denote the HMM under consideration. The marginal distributions of the coordinate processes of this HMM can be expressed by

$$\mathbf{P}(X_0 = x_0, \dots, X_k = x_k; Y_1 = y_1, \dots, Y_k = y_k) = a_{x_k x_{k-1}} c_{y_k x_{k-1}} \dots a_{x_1 x_0} c_{y_1 x_0} p_{x_0},$$

where  $a_{x_k x_{k-1}} = \mathbf{P}(X_k = x_k | X_{k-1} = x_{k-1})$ ,  $c_{y_k x_{k-1}} = \mathbf{P}(Y_k = y_k | X_{k-1} = x_{k-1})$ , and  $p_{x_0} = \mathbf{P}(X_0 = x_0)$ .

Let  $\mathcal{G}_k = \sigma(X_0, \dots, X_k, Y_1, \dots, Y_k)$ . The sub- $\sigma$ -algebra  $\mathcal{Y}_k = \sigma\{Y_1, \dots, Y_k\}$  is generated by a finite partition of  $\Omega$ :

$$\mathcal{Y}_k = \sigma\{\{\omega : Y_1(\omega) = y_1, \dots, Y_k(\omega) = y_k | y_1 \in \mathbb{E}_Y, \dots, y_k \in \mathbb{E}_Y\}\}.$$

In accordance with this partitioning, each observation path  $y_{1,k}$  corresponds to an event  $\{\omega : Y_1(\omega) = y_1, \dots, Y_k(\omega) = y_k\}$ . In what follows we will be concerned with observation sequences and corresponding events of  $\mathcal{Y}_k$  which occur with positive probability under  $\mathbf{P}$ . Such sequences will be referred to as *feasible* sequences.

Let  $\mathbf{P}_k$  and  $\mathbf{P}_{\mathcal{Y}_k}$  denote the restrictions of  $\mathbf{P}$  to  $\mathcal{G}_k$  and  $\mathcal{Y}_k$ , respectively.

**2.1. The observability of states.** We now introduce the notion of observability of states for HMMs under consideration.

**DEFINITION 2.1.** *Under the probability measure  $\mathbf{P}$ , consider an HMM with  $\mathbb{E}_X$  and  $\mathbb{E}_Y$  as its state and observation spaces. We say a state  $x_k \in \mathbb{E}_X$  at time step  $k$  is observable in the sense of probability if for any feasible observation path  $y_{1,k}$ , we have  $\mathbf{P}(X_k = x_k; Y_1 = y_1, \dots, Y_k = y_k) > 0$ . We also say that the HMM is observable at time step  $k$  under the probability measure  $\mathbf{P}$  if each of its states is observable at time step  $k$  under  $\mathbf{P}$ .*

Next, we make an assumption about the observability of the HMMs.

**Assumption 2.1.** Under the probability measure  $\mathbf{P}$ , the HMM with the parameter set  $\zeta$  is observable at any time step  $k > 0$ .

Assumption 2.1 is a technical assumption which will be used later in the paper to guarantee that the supremum of a certain unconstrained optimization problem with zero Lagrange multiplier can be attained and a function related to an unconstrained optimization problem is strictly convex almost surely. We next state a necessary and sufficient condition in terms of  $\xi = (A, C, p)$  under which any state is observable at any time step  $k > 0$ .

LEMMA 2.1. *An HMM is observable at any time step  $k > 0$  if and only if the following conditions are satisfied:*

1. *For any  $z \in \mathbb{E}_X$  and for any  $y \in \mathbb{E}_Y$  satisfying  $D_y = \{x : c_{yx}p_x > 0\} \neq \emptyset$ , there exists an  $x \in D_y$  such that  $a_{zx} > 0$ . Here  $x$  is dependent on  $y, z$ .*
2. *Let  $\bar{D} = \{y : c_{yx} = 0 \forall x \in \mathbb{E}_X\}$ . For any  $y \in \mathbb{E}_Y - \bar{D}$  and  $z \in \mathbb{E}_X$ , there exists an  $x \in \mathbb{E}_X$  such that  $a_{zx}c_{yx} > 0$ . Here  $x$  is dependent on  $y, z$ .*

The proof of this lemma as well as proofs of other auxiliary lemmas used in what follows are given in the appendices. Since the sets  $\{\omega : Y_1(\omega) = y_1, \dots, Y_k(\omega) = y_k | y_1 \in \mathbb{E}_Y, \dots, y_k \in \mathbb{E}_Y\}$  form a finite partition of the sample space  $\Omega$  (that is,  $\Omega = \cup_{y_1 \in \mathbb{E}_Y, \dots, y_k \in \mathbb{E}_Y} \{\omega : Y_1(\omega) = y_1, \dots, Y_k(\omega) = y_k\}$ ), then there exists at least one feasible observation path  $(y_1, \dots, y_k)$ . It is obvious that the observability of a state  $x_k$  at time step  $k > 0$  implies that  $\mathbf{P}(X_k = x_k) > 0$ . This can be seen from

$$P(X_k = x_k) = \sum_{y_1 \in \mathbb{E}_Y} \cdots \sum_{y_k \in \mathbb{E}_Y} P(X_k = x_k; Y_1 = y_1, \dots, Y_k = y_k).$$

This fact will be used in the proof of Theorem 3.1. From now on we suppose Assumption 2.1 holds.

**2.2. Conditional relative entropy constraints.** Consider another HMM with  $\bar{\zeta} = (\bar{A}, \bar{C}, \bar{p})$  as its parameter set. We say that  $\bar{\zeta}$  is absolutely continuous with respect to  $\zeta$  and denote this fact by  $\bar{\zeta} \ll \zeta$ , provided that all of the following implications hold:  $\bar{a}_{ji} = 0$  if  $a_{ji} = 0$ ,  $\bar{c}_{qi} = 0$  if  $c_{qi} = 0$ , and  $\bar{p}_i = 0$  if  $p_i = 0$ . Let  $\bar{\mathbf{P}}$  be the Kolmogorov measure of the HMM with the parameter set  $\bar{\zeta}$ . Also, let  $\bar{\mathbf{P}}_k$  and  $\bar{\mathbf{P}}_{y_k}$  be the restrictions of  $\bar{\mathbf{P}}$  to  $\mathcal{G}_k$  and  $\mathcal{Y}_k$ , respectively.

In the robust state estimation problem considered in this paper the parameter sets  $\zeta$  and  $\bar{\zeta}$  will be regarded as the reference or nominal parameter set and the true (or perturbed) parameter set, respectively. This section introduces a bound on the discrepancy between these parameter sets and corresponding HMMs, given a realized feasible  $k$  step long observation sequence  $y_{1,k}$ . Note that since the conditional probability measures  $\mathbf{P}(\cdot | y_{1,k})$  and  $\bar{\mathbf{P}}(\cdot | y_{1,k})$  are probability measures on  $\mathcal{G}_k$ , the relative entropy between these probability measures, or conditional relative entropy,  $\mathcal{R}(\bar{\mathbf{P}}_k(\cdot | y_{1,k}) \| \mathbf{P}_k(\cdot | y_{1,k}))$  can be considered. The conditional relative entropy between two arbitrary conditional probability measures  $\mathbf{P}(\cdot | y_{1,k})$  and  $\bar{\mathbf{P}}(\cdot | y_{1,k})$  is defined by

$$(2.1) \quad \mathcal{R}(\bar{\mathbf{P}}_k(\cdot | y_{1,k}) \| \mathbf{P}_k(\cdot | y_{1,k})) \triangleq \begin{cases} \mathbf{E}^{\bar{\mathbf{P}}_k(\cdot | y_{1,k})} [\log \frac{d\bar{\mathbf{P}}_k(\cdot | y_{1,k})}{d\mathbf{P}_k(\cdot | y_{1,k})}] & \text{if } \bar{\mathbf{P}}_k(\cdot | y_{1,k}) \ll \mathbf{P}_k(\cdot | y_{1,k}); \\ +\infty & \text{otherwise,} \end{cases}$$

where  $\frac{d\bar{\mathbf{P}}_k(\cdot | y_{1,k})}{d\mathbf{P}_k(\cdot | y_{1,k})}$  is the Radon–Nikodym derivative of  $\bar{\mathbf{P}}_k(\cdot | y_{1,k})$  with respect to  $\mathbf{P}_k(\cdot | y_{1,k})$ .

The conditional relative entropy describes the discrepancy between the two HMMs with the parameter sets  $\bar{\zeta}$  and  $\zeta$  after a path of measurement process is realized.

Hence the conditional relative entropy  $\mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k}))$  can be used as an a posteriori probability distance to describe the amount of uncertainty contained in the true (perturbed) HMM with the parameter set  $\bar{\zeta}$  relative to the nominal HMM with the parameter set  $\zeta$ . Using this a posteriori probability distance, given  $y_{1,k}$ , we define a set of conditional probability measures for the robust state estimation problem to be considered in the next section as follows:

$$(2.2) \quad \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k}) \triangleq \{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) : \bar{\mathbf{P}}_k(y_{1,k}) > 0, \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k})) < \infty\}.$$

In (2.2),  $\bar{\mathbf{P}}_k$  is an arbitrary probability measure defined on  $(\Omega, \mathcal{G}_k)$  and satisfying the condition  $\bar{\mathbf{P}}_k(y_{1,k}) > 0$ . Note that since  $\mathcal{G}_k$  is generated by a finite partition of  $\Omega$ , the condition  $\mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k})) < \infty$  in (2.2) is equivalent to  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \ll \mathbf{P}_k(\cdot|y_{1,k})$ .

In general, the set (2.2) is larger than the set of Kolmogorov measures corresponding to HMM parameter sets  $\bar{\zeta}$  such that  $\bar{\zeta} \ll \zeta$ . If there exists a probability measure  $\bar{\mathbf{P}}$  on  $(\Omega, \mathcal{B})$  whose restriction on  $\mathcal{G}_k$  is  $\bar{\mathbf{P}}_k$ , then under  $\bar{\mathbf{P}}$ , the pair of the coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  may not be an HMM.

It was shown in Lemma 2.2 of [21] that for the two HMMs under consideration, if  $\bar{\zeta} \ll \zeta$ , then the relative entropy between the corresponding regular conditional probability measures  $\bar{\mathbf{P}}_k(\cdot|\mathcal{Y}_k)(\omega)$  and  $\mathbf{P}_k(\cdot|\mathcal{Y}_k)(\omega)$  (or “regular conditional relative entropy”) satisfies the following inequality:

$$(2.3) \quad \mathbf{E}^{\bar{\mathbf{P}}_k}[\mathcal{R}(\bar{\mathbf{P}}_k(\cdot|\mathcal{Y}_k)\|\mathbf{P}_k(\cdot|\mathcal{Y}_k))] \leq \bar{d}_0 + \sum_{l=1}^k \sum_{r=1}^N \bar{d}_r \mathbf{E}^{\bar{\mathbf{P}}_k}[\langle X_{l-1}, e_r \rangle].$$

In (2.3),  $\mathbf{E}^{\bar{\mathbf{P}}_k}[\cdot]$  denotes the expectation with respect to  $\bar{\mathbf{P}}_k$ ,  $\bar{d}_r = \sum_{s=1}^N \bar{a}_{sr} \log \frac{\bar{a}_{sr}}{\bar{a}_{sr}} + \sum_{q=1}^M \bar{c}_{qr} \log \frac{\bar{c}_{qr}}{\bar{c}_{qr}}$ , and  $\bar{d}_0 = \sum_{r=1}^N \bar{p}_r \log \frac{\bar{p}_r}{p_r}$ . The notation  $\langle X_{l-1}, e_r \rangle$  denotes the inner product satisfying  $\langle X_{l-1}, e_r \rangle = 0$  if  $X_{l-1} \neq e_r$ , otherwise 1, where  $e_r \in \mathbb{E}_X$ . For a feasible observation path  $y_{1,k}$ ,  $\mathcal{R}(\bar{\mathbf{P}}_k(\cdot|\mathcal{Y}_k)\|\mathbf{P}_k(\cdot|\mathcal{Y}_k))(\omega) = \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k}))$ . Inequality (2.3) provides a useful insight into how a conditional relative entropy constraint is to be defined to describe sequentially the mismatch between a perturbed conditional probability measure and the reference conditional probability measure given  $y_{1,k}$ . We now give a formal definition.

**DEFINITION 2.2.** Let  $d > 0$ ,  $d_r \geq 0$ ,  $r = 1, \dots, N$ , be given constants. These constants will be the design parameters in our robust state estimator design. Given a feasible sequence  $y_{1,k}$ , the conditional relative entropy of the conditional probability measure  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$  with respect to  $\mathbf{P}_k(\cdot|y_{1,k})$  defines an admissible (perturbed) conditional probability measure if

$$(2.4) \quad \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k})) \leq d + \sum_{l=1}^k \sum_{r=1}^N d_r \mathbf{E}^{\bar{\mathbf{P}}_k}[\langle X_{l-1}, e_r \rangle | y_{1,k}].$$

That is, given  $y_{1,k}$ , if  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  satisfies inequality (2.4), then  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  is called an admissible conditional probability measure for this  $y_{1,k}$ .

A set of admissible conditional probability measures  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  for the robust state estimation problem, which will be defined in the next section, consists of all conditional probability measures  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  satisfying the above definition:

$$(2.5) \quad \Xi_k(y_{1,k}) \triangleq \{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) : \bar{\mathbf{P}}_k(y_{1,k}) > 0, \bar{\mathbf{P}}_k(\cdot|y_{1,k}) \text{ satisfies (2.4)}\}.$$

Obviously, it follows from (2.2) and (2.5) that  $\Xi_k(y_{1,k}) \subset \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$ .

Inequality (2.4) is called the conditional relative entropy constraint for a feasible observation path  $y_{1,k}$ . The conditional relative entropy constraint (2.4) is introduced based on the insights gained from our study on probability distance problems for the HMMs (see [22, 23]), though inequality (2.3) does not imply that (2.4) holds for all feasible observation sequences. From Definition 2.2, a conditional probability measure may be admissible for a feasible observation path, but it may be inadmissible for another feasible observation path. In other words, the set consisting of all admissible conditional probability measures is a function of feasible observation sequences.

Observing inequality (2.4), the right-hand side describes a bound on the conditional relative entropy at time step  $k$ . This bound represents a weighted sum of the occupation probability estimates of the states  $e_r$  given the measurements up to time step  $k$  with respect to  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$ . The more often the state  $e_r$  occurs, the more discrepancy is allowed by the state  $e_r$ . The parameters  $d_r$  weight the contribution of each state into the bound. Condition (2.4) defines a constraint on the perturbed conditional probability measure in terms of the conditional relative entropy. Note that (2.4) defines a time-varying constraint. The reason for considering time-varying constraints is that the conditional relative entropy between HMMs may increase as the time step increases; see Theorem 3.2 in [22].

*Remark 2.1.* As a special case of the conditional relative entropy constraint defined by (2.4), the conditional relative entropy constraint (2.4) with zero  $d_r$  for  $r = 1, \dots, N$  describes the uncertainty in the initial distribution of the perturbed HMM only. Indeed, in this special case the conditional relative entropy between an admissible perturbed measure  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  and the reference measure  $\mathbf{P}_k(\cdot|y_{1,k})$  is bounded uniformly in  $k$ . Since the conditional relative entropy generally increases with time, this can be only when the uncertainty does not affect the state-to-state and state-to-measurement transition probability matrices  $A$  and  $C$ .

**3. A robust state estimation problem.** In this section, we will present our main results. Consider an HMM on the canonical measurable space  $(\Omega, \mathcal{B})$ . We do not know the exact parameter set of this HMM. Instead, we choose the reference parameter set  $\zeta = (A, C, p)$  as its parameter set. Then under the reference Kolmogorov measure  $\mathbf{P}$ , the pair of the coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  is an HMM with  $\zeta = (A, C, p)$  as its parameter set.

Let  $\Psi_k(x, \xi) = (x - \xi)'Q_k(x - \xi)$ , where  $x$  and  $\xi$  take values in the state space  $\mathbb{E}_X$ , and  $Q_k$  is a positive definite matrix. The sequence  $Q_k$  is assumed to be bounded in  $k$ . Let  $\Xi_k(y_{1,k})$  be defined by (2.5). Given a feasible observation sequence  $y_{1,k}$ , we address the following robust state estimation problem: Find an estimate  $\hat{X}_k$  of the HMM state process  $X_k$  which can be computed in a recursive fashion, where  $\hat{X}_k$  takes values in  $\mathbb{E}_X$  and is a function of  $y_{1,k}$  (and hence  $\hat{X}_k$  is a  $\mathcal{Y}_k$ -measurable estimate of  $X_k$ ). This estimate is required to be such that given  $y_{1,k}$ , the estimate  $\hat{X}_k$  solves the following minimax problem subject to the constraint (2.4):

$$(3.1) \quad \hat{X}_k = \arg \inf_{\xi \in \mathbb{E}_X} \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}].$$

The optimization problem (3.1) is a constrained optimization problem in which the maximizer  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  is constrained to take values from the set  $\Xi_k(y_{1,k})$ . As in [14], a Lagrange multiplier technique will be used to convert the constrained optimization problem (3.1) into an unconstrained optimization problem. This conversion will be considered in section 3.2. In the next subsection, we introduce such an unconstrained

optimization problem and present some properties of a cost functional related to this problem.

**3.1. An unconstrained optimization problem.** Given a  $\tau \in \mathbb{R}$  and a  $\xi \in \mathbb{E}_X$ , for a feasible observation sequence  $y_{1,k}$ , we define an augmented cost functional:

$$(3.2) \quad \begin{aligned} F(\bar{\mathbf{P}}_k(\cdot|y_{1,k}), \xi, \tau) &= \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] - \tau \left( \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \|\mathbf{P}_k(\cdot|y_{1,k})) \right. \\ &\quad \left. - d - \sum_{l=1}^k \sum_{r=1}^N d_r \mathbf{E}^{\bar{\mathbf{P}}_k}[\langle X_{l-1}, e_r \rangle | y_{1,k}] \right). \end{aligned}$$

The following optimization problem is instrumental in the derivation of a solution to the robust state estimation problem (3.1):

$$(3.3) \quad V_k(\tau, \xi, y_{1,k}) = \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} F(\bar{\mathbf{P}}_k(\cdot|y_{1,k}), \xi, \tau).$$

Unlike (3.1), here the supremum is taken over the entire set  $\mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$  of feasible perturbation conditional probability measures.

For  $\tau > 0$ , we write

$$(3.4) \quad V_k(\tau, \xi, y_{1,k}) = \tau(W_k(\tau, \xi, y_{1,k}) + d),$$

where

$$(3.5) \quad \begin{aligned} W_k(\tau, \xi, y_{1,k}) &= \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} \left( \mathbf{E}^{\bar{\mathbf{P}}_k} \left[ \tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] \right. \\ &\quad \left. - \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \|\mathbf{P}_k(\cdot|y_{1,k})) \right) \end{aligned}$$

and

$$(3.6) \quad q(x) \triangleq \sum_{r=1}^N d_r \langle x, e_r \rangle, \quad x \in \mathbb{E}_X.$$

In order to establish our results, a conditional version of the variational formula for probability measures will be used which is presented in Lemma 3.1. This lemma is a direct extension of Proposition 1.4.2 presented in [7, p. 33] for the standard relative entropy.

**LEMMA 3.1.** *Let  $g(\omega)$  be a bounded measurable function. With the above definitions, we have the following variational formula:*

$$(3.7) \quad \begin{aligned} -\log \mathbf{E}^{\mathbf{P}_k}[e^{-g}|y_{1,k}] &= \inf_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} \left\{ \mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \|\mathbf{P}_k(\cdot|y_{1,k})) \right. \\ &\quad \left. + \mathbf{E}^{\bar{\mathbf{P}}_k}[g|y_{1,k}] \right\}. \end{aligned}$$

The variational formula for conditional relative entropy (3.7) will be used to calculate  $V_k(\tau, \xi, y_{1,k})$  defined by (3.3). The next theorem presents this result.

**THEOREM 3.1.** *The cost functional  $V_k(\tau, \xi, y_{1,k})$  defined by (3.3) can be calculated in two cases as follows:*

(i) When  $\tau = 0$ ,

$$(3.8) \quad V_k(0, \xi, y_{1,k}) = \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi).$$

(ii) For any given  $\tau \in (0, \infty)$ ,

$$(3.9) \quad V_k(\tau, \xi, y_{1,k}) = \tau \left( \log \mathbf{E}^{\mathbf{P}_k} \left[ \exp \left( \tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1}) \right) | y_{1,k} \right] + d \right).$$

*Proof.* We first consider the case  $\tau = 0$ . Since the state space  $\mathbb{E}_X$  of the process  $\{X_k\}_{k \geq 0}$  is finite,  $\Psi_k(x, \xi)$  is a bounded function, where  $\xi \in \mathbb{E}_X$ . Let  $x_k^* \in \mathbb{E}_X$  satisfy

$$\Psi_k(x_k^*, \xi) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi).$$

Clearly, such an  $x_k^*$  exists and is a function of  $\xi$ . Then for all  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$ ,

$$(3.10) \quad \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] \leq \Psi_k(x_k^*, \xi).$$

Hence we conclude that  $V_k(0, \xi, y_{1,k}) \leq \Psi_k(x_k^*, \xi)$ . We now show that there exists a probability measure on  $(\Omega, \mathcal{G}_k)$  which attains the equality in (3.10). Let

$$(3.11) \quad D_\xi = \{\omega : X_k(\omega) = x_k^*\}.$$

Note that under Assumption 2.1, we have  $\mathbf{P}_k(D_\xi) > 0$ , and hence we can define the required probability measure  $\check{\mathbf{P}}_k$  on  $\mathcal{G}_k$  by letting  $\check{\mathbf{P}}_k(D) = \mathbf{P}_k(D|D_\xi)$  for any  $D \in \mathcal{G}_k$  and noting that  $\check{\mathbf{P}}_k(D|y_{1,k}) = \mathbf{P}_k(D|D_\xi, y_{1,k})$ ; see also Remark 3.1. Hence  $\check{\mathbf{P}}_k(D_\xi) = 1$  and  $\check{\mathbf{P}}_k(D_\xi|y_{1,k}) = 1$ . It follows from this definition that  $\check{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$ . Furthermore, it can be shown using a direct calculation that

$$\mathbf{E}^{\check{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] = \Psi_k(x_k^*, \xi) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi)$$

from which claim (i) follows.<sup>1</sup>

To prove claim (ii), we note that for each given  $\tau \in (0, \infty)$ ,  $\xi$ , and  $k$ ,  $\tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1})$  is a bounded measurable random variable. Then by applying (3.7) in Lemma 3.1 to (3.5), we have

$$(3.12) \quad W_k(\tau, \xi, y_{1,k}) = \log \mathbf{E}^{\mathbf{P}_k} \left[ \exp \left( \tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1}) \right) | y_{1,k} \right].$$

Furthermore, (3.12) and (3.4) yield (3.9). This completes the proof of the theorem.  $\square$

*Remark 3.1.* Without Assumption 2.1, when  $\tau = 0$  the value of  $\max_{x \in \mathbb{E}_X} \Psi_k(x, \xi)$  may not be attained in the unconstrained optimization problem. To illustrate this fact, suppose there exists a unique  $x^*$  such that  $\Psi_k(x^*, \xi) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi)$ . For any  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$ , it follows from  $\mathcal{R}(\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \| \mathbf{P}_k(\cdot|y_{1,k})) < \infty$  and

<sup>1</sup>The above result can also be derived from a more general setting considered in Theorem 5.2 of [21].

Definition 2.1 that we must have  $\bar{\mathbf{P}}(\cdot|y_{1,k}) \ll \mathbf{P}(\cdot|y_{1,k})$ . Now suppose Assumption 2.1 does not hold, and therefore the set  $D_\xi$  defined by (3.11) can have zero probability under  $\mathbf{P}(\cdot|y_{1,k})$ . If  $\mathbf{P}(D_\xi|y_{1,k}) = 0$ , then  $\bar{\mathbf{P}}(D_\xi|y_{1,k}) = 0$ . As a result, for any  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$ , we have

$$\begin{aligned} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] &= \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)I_{D_\xi}|y_{1,k}] + \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)I_{D_\xi^c}|y_{1,k}] \\ &= \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)I_{D_\xi^c}|y_{1,k}] < \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi), \end{aligned}$$

where  $D_\xi^c$  is the complement of  $D_\xi$ . Thus Assumption 2.1 on the reference parameter set, which guarantees  $\mathbf{P}(D_\xi|y_{1,k}) > 0$ , also guarantees that the unconstrained optimization problem with  $\tau = 0$  attains the maximum.

**3.2. A solution to the constrained optimization problem.** Next, we will use the following standard result on constrained optimization to convert the constrained optimization problem (3.1) into the unconstrained optimization problem (3.3) dependent on a parameter  $\tau$ . The result and its proof can be found in [11, p. 217]. In [14] this result is presented as follows.

**LEMMA 3.2.** *Let  $\mathbb{X}$  be a linear vector space, and let  $\tilde{\Omega}$  be a convex subset of  $\mathbb{X}$ . Also, let  $f$  be a real-valued concave functional on  $\tilde{\Omega}$ , and let  $g$  be a real-valued convex functional on  $\tilde{\Omega}$ . Assume a point exists  $x_1 \in \tilde{\Omega}$  such that  $g(x_1) < 0$  (this is a constraint qualification condition), and let*

$$(3.13) \quad \mu_0 = \sup f(x) \quad \text{subject to } x \in \tilde{\Omega}, \quad g(x) \leq 0.$$

1. *If  $\mu_0$  is finite, then there exists a  $\tau \geq 0$  such that*

$$(3.14) \quad \mu_0 = \sup_{x \in \tilde{\Omega}} \{f(x) - \tau g(x)\}.$$

2. *If the supremum in (3.13) is achieved by an  $x_0 \in \tilde{\Omega}$ ,  $g(x_0) \leq 0$ , it is achieved by  $x_0$  in (3.14) and  $\tau g(x_0) = 0$ .*

Theorem 2.1 of [14] makes it possible to convert the constrained optimization problem (3.1) into the unconstrained optimization problem (3.3) dependent on a parameter  $\tau$  which is then optimized over  $[0, \infty)$ . We now use a similar argument to the one used in the proof of Theorem 2.1 of [14] to present the main result of this paper.

**THEOREM 3.2.** *Consider the robust state estimation problem defined by (3.1). For each  $k$ , we have*

$$(3.15) \quad \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] = \inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}).$$

Furthermore, the robust state estimate  $\hat{X}_k$  is given by

$$(3.16) \quad \hat{X}_k = \arg \inf_{\xi} \inf_{\xi \in \mathbb{E}_X} \inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}).$$

*Proof.* Let

$$L_k(\xi, y_{1,k}) \triangleq \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}].$$

Since  $\Xi_k(y_{1,k}) \subset \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})$  and  $\tau \geq 0$ , it follows from (3.3) and (3.2) that

$$\begin{aligned} V_k(\tau, \xi, y_{1,k}) &= \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} F(\bar{\mathbf{P}}_k(\cdot|y_{1,k}), \xi, \tau) \\ (3.17) \quad &\geq \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})} F(\bar{\mathbf{P}}_k(\cdot|y_{1,k}), \xi, \tau) \geq L_k(\xi, y_{1,k}). \end{aligned}$$

Note that (3.17) holds for any  $\tau \in [0, \infty)$ . Hence

$$(3.18) \quad L_k(\xi, y_{1,k}) \leq \inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) \leq V_k(0, \xi, y_{1,k}) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi).$$

Thus  $L_k(\xi, y_{1,k})$  is finite. Then for any  $\xi \in \mathbb{E}_X$ , applying part 1 of Lemma 3.2 to  $L_k(\xi, y_{1,k})$  with respect to the conditional probability measures  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  since all required conditions are satisfied, it follows that a  $\tau_k^*(\xi, y_{1,k}) \in [0, \infty)$  exists such that

$$\begin{aligned} L_k(\xi, y_{1,k}) &= \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k|y_{1,k})} F(\bar{\mathbf{P}}_k(\cdot|y_{1,k}), \xi, \tau_k^*(\xi, y_{1,k})) \\ (3.19) \quad &= V_k(\tau_k^*(\xi, y_{1,k}), \xi, y_{1,k}). \end{aligned}$$

Furthermore, for each  $\tau_k^*(\xi, y_{1,k}) \in [0, \infty)$ ,

$$\inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) \leq V_k(\tau_k^*(\xi, y_{1,k}), \xi, y_{1,k}).$$

Hence, the last line in (3.19) implies that

$$(3.20) \quad \inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) \leq L_k(\xi, y_{1,k}).$$

Combining the first inequality of (3.18) and (3.20) yields (3.15). The robust state estimate  $\hat{X}_k$  is given by (3.16). Obviously,  $\hat{X}_k$  is a function of  $y_{1,k}$ . Note that the robust state estimate may not be unique and  $\inf_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k})$  attains its infimum on the finite set  $\mathbb{E}_X$ . This completes the proof of the theorem.  $\square$

*Remark 3.2.* In what follows, we will observe that in general, the robust state estimator presented in this paper applies only to finite horizon problems except for the special case of  $d_r = 0$ , for  $r = 1, \dots, N$ , and under some additional special conditions. In section 5, we will discuss how to specify the maximum allowable time interval  $K$ , based on a necessary and sufficient condition for the existence of a certain stationary point in the optimization of the cost.

**4. Calculation of the unconstrained cost functional.** Theorem 3.2 shows that the solution to the constrained optimization problem (3.1) can be obtained from the solution to the unconstrained optimization problem on the right-hand side of (3.15). This requires that the quantity  $V_k(\tau, \xi, y_{1,k})$  be readily computable for all  $\tau \in [0, \infty)$ . Part (i) of Theorem 3.1 shows how this quantity can be computed for the case  $\tau = 0$ . In this section we consider the second case and calculate  $V_k(\tau, \xi, y_{1,k})$  for the case  $\tau > 0$  using (3.9). This is done by using the information state approach to risk-sensitive control and filtering.

**4.1. A change of probability measure.** Define a new probability measure  $\tilde{\mathbf{P}}$ , under which the pair of coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  has the parameter set  $(A, (1/M)_{M \times N}, p)$  and the  $\sigma$ -algebra  $\sigma\{Y_k\}$  is independent of  $\sigma\{X_0, \dots, X_k, Y_1, \dots, Y_{k-1}\}$  by letting

$$\tilde{\mathbf{P}}(X_0 = x_0, \dots, X_k = x_k; Y_1 = y_1, \dots, Y_k = y_k) = \frac{1}{M^k} a_{x_k x_{k-1}} \dots a_{x_1 x_0} p_{x_0}.$$

This probability measure is related to the reference probability measure  $\mathbf{P}$  via the Radon–Nikodym derivative  $\frac{d\tilde{\mathbf{P}}_k}{d\mathbf{P}_k} = \bar{\Lambda}_k$ , where

$$\bar{\Lambda}_k = \prod_{l=0}^k \bar{\lambda}_l, \quad \bar{\lambda}_l = \prod_{r=1}^N \prod_{q=1}^M (M c_{qr})^{\langle X_{l-1}, e_r \rangle \langle Y_l, f_q \rangle}, \quad \text{and} \quad \bar{\lambda}_0 = 1;$$

see [8]. For a feasible observation path  $y_{1,k}$ , using the conditional Bayes theorem [8], the cost functional  $V_k(\tau, \xi, y_{1,k})$  given by (3.9) can be reformulated under the new probability measure  $\tilde{\mathbf{P}}_k$  as

$$V_k(\tau, \xi, y_{1,k}) = \tau \left( \log \left( \frac{\mathbf{E}^{\tilde{\mathbf{P}}_k} [\bar{\Lambda}_k \exp(\tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1})) | y_{1,k}]}{\mathbf{E}^{\tilde{\mathbf{P}}_k} [\bar{\Lambda}_k | y_{1,k}]} \right) + d \right).$$

**4.2. Information states.** We now apply the information state method for the HMMs of [8] and [4] to evaluate the expression on the right-hand side of the above equation.

**DEFINITION 4.1.** Define  $\alpha_k(y_{1,k}) \triangleq (\alpha_k(e_1, y_{1,k}), \dots, \alpha_k(e_n, y_{1,k}))'$  and  $\beta_k(y_{1,k}) \triangleq (\beta(e_1, y_{1,k}), \dots, \beta(e_n, y_{1,k}))'$  to be unnormalized information states such that

$$(4.1) \quad \alpha_k(e_i, y_{1,k}) = \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_k \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \langle X_k, e_i \rangle | y_{1,k} \right],$$

$$(4.2) \quad \beta_k(e_i, y_{1,k}) = \mathbf{E}^{\tilde{\mathbf{P}}_k} [\bar{\Lambda}_k \langle X_k, e_i \rangle | y_{1,k}].$$

*Remark 4.1.* The above definition defines the information states  $\alpha_k$  and  $\beta_k$  as  $\mathcal{Y}_k$  measurable random variables. Indeed the identities (4.1) and (4.2) are equivalent to

$$(4.3) \quad \alpha_k(e_i) = \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_k \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \langle X_k, e_i \rangle | \mathcal{Y}_k \right],$$

$$(4.4) \quad \beta_k(e_i) = \mathbf{E}^{\tilde{\mathbf{P}}_k} [\bar{\Lambda}_k \langle X_k, e_i \rangle | \mathcal{Y}_k].$$

Using the statistical independence of  $\{Y_{k+1}\}_{k \geq 0}$  under  $\tilde{\mathbf{P}}$ , the information states can be calculated recursively.

**LEMMA 4.1.** The information states  $\alpha_k(y_{1,k})$  and  $\beta_k(y_{1,k})$  obey the following recursions:

$$(4.5) \quad \alpha_k(y_{1,k}) = A D_k(y_{1,k}) \alpha_{k-1}(y_{1,k}),$$

$$(4.6) \quad \beta_k(y_{1,k}) = A \bar{D}_k(y_{1,k}) \beta_{k-1}(y_{1,k}),$$

where  $\alpha_0(y_{1,k}) = \beta_0(y_{1,k}) = p$ , and

$$D_k(y_{1,k}) = \text{diag} \left( \prod_{j=1}^M (Mc_{j1})^{y_k^j} \exp(d_1), \dots, \prod_{j=1}^M (Mc_{jN})^{y_k^j} \exp(d_N) \right),$$

$$\overline{D}_k(y_{1,k}) = \text{diag} \left( \prod_{j=1}^M (Mc_{j1})^{y_k^j}, \dots, \prod_{j=1}^M (Mc_{jN})^{y_k^j} \right),$$

where  $y_k^j$  denotes the  $j$ th component of  $y_k$ .

The next lemma shows that the information states are positive for a feasible observation sequence.

LEMMA 4.2. *The information states  $\alpha_k$  and  $\beta_k$  satisfy the conditions*

$$(4.7) \quad \alpha_k(e_i, y_{1,k}) > 0, \quad \beta_k(e_i, y_{1,k}) > 0$$

for any  $e_i \in \mathbb{E}_X$ .

Let

$$J_k(\xi, \tau, y_{1,k}) = \frac{\mathbf{E}^{\tilde{\mathbf{P}}_k}[\overline{\Lambda}_k \exp(\tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1})) | y_{1,k}]}{\mathbf{E}^{\tilde{\mathbf{P}}_k}[\overline{\Lambda}_k | y_{1,k}]}.$$

Then we can express  $J_k(\xi, \tau, y_{1,k})$  in terms of the information states  $\alpha_k$  and  $\beta_k$ .

THEOREM 4.1. *The cost functional  $V_k(\tau, \xi, y_{1,k})$ ,  $\tau > 0$ , given by (3.9) can be written as*

$$V_k(\tau, \xi, y_{1,k}) = \tau(\log J_k(\xi, \tau, y_{1,k}) + d),$$

where

$$(4.8) \quad J_k(\xi, \tau, y_{1,k}) = \frac{H_k \alpha_k(y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} = \frac{H_k A D_k(y_{1,k}) \alpha_{k-1}(y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})},$$

$$H_k = \left[ \exp\left(\frac{1}{\tau}(e_1 - \xi)' Q_k(e_1 - \xi)\right), \dots, \exp\left(\frac{1}{\tau}(e_N - \xi)' Q_k(e_N - \xi)\right) \right].$$

Remark 4.2. A special case in which the underlying HMM is not subject to uncertainty can be recovered by letting  $d \rightarrow 0$ . In this case,

$$\lim_{\tau \rightarrow \infty} \tau \log J_k(\xi, \tau, y_{1,k}) = R_k \beta_k(y_{1,k}) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}),$$

where  $R_k = [(e_1 - \xi)' Q_k(e_1 - \xi), \dots, (e_N - \xi)' Q_k(e_N - \xi)]$ . That is, the limit of the robust state estimate is the HMM risk-neutral recursive filter; see [8].

**5. Characterization of the robust state estimator.** The aim in this section is to derive a mathematical characterization of the solution of the robust state estimation problem. From Theorems 3.1 and 4.1, the cost functional  $V_k(\tau, \xi, y_{1,k})$  can be written as

$$(5.1) \quad V_k(\tau, \xi, y_{1,k}) = \begin{cases} \bar{b}_k(\xi), & \tau = 0; \\ \tau(\log J_k(\xi, \tau, y_{1,k}) + d), & \tau \in (0, \infty), \end{cases}$$

where  $\bar{b}_k(\xi) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi)$  and  $J_k(\xi, \tau, y_{1,k})$  is given by (4.8).

DEFINITION 5.1. We say  $\tau_k^* \in (0, \infty)$  is a stationary point of  $V_k(\tau, \xi, y_{1,k})$  if

$$\left. \frac{d(\tau(\log J_k(\xi, \tau, y_{1,k}) + d))}{d\tau} \right|_{\tau=\tau_k^*} = 0.$$

A stationary point, if it exists, is a function of  $\xi$  and  $y_{1,k}$  and can be found from the above equation in which

$$\begin{aligned} \frac{d(\tau(\log J_k(\xi, \tau, y_{1,k}) + d))}{d\tau} &= \log \left( \left( \alpha_k(\xi, y_{1,k}) + \sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau} \right) \right. \right. \\ &\quad \times \alpha_k(e_i, y_{1,k}) \Big) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}) \Big) + d \\ &\quad - \frac{1}{\tau} \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})}, \end{aligned} \quad (5.2)$$

where for  $\xi = e_j$ ,  $\mathcal{S} = \{1, \dots, j-1, j+1, \dots, N\}$  and  $b_i = \Psi_k(e_i, \xi)$ ,  $i \in \mathcal{S}$ , is a function of  $\xi$  and  $k$ . Clearly,  $\mathcal{S}$  is also a function of  $\xi$ . An explicit expression for a stationary point in terms of the information states  $\alpha_k$  and  $\beta_k$  and  $b_i$ ,  $d$  does not seem to be readily obtainable from the above equation. The stationary point over  $(0, \infty)$  can, however, be found numerically if it exists.

**5.1. The existence of a stationary point.** We first establish the continuity of  $V_k(\tau, \xi, y_{1,k})$  and its first derivative and the strict convexity of  $V_k(\tau, \xi, y_{1,k})$  with respect to  $\tau$ .

LEMMA 5.1. As functions of  $\tau$ ,  $V_k(\tau, \xi, y_{1,k})$  and  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  are continuous with respect to  $\tau$  over  $[0, \infty)$  for each  $\xi$ . Also  $V_k(\tau, \xi, y_{1,k})$  is a strictly convex function of  $\tau$  on  $(0, \infty)$  for each  $\xi$ .

We now present a necessary and sufficient condition for the existence of a stationary point. This condition is expressed in terms of the value of the first derivative of  $V_k(\tau, \xi, y_{1,k})$  with respect to  $\tau$  at  $\tau = 0$ .

THEOREM 5.1. For a given  $\xi$ , a stationary point exists on  $(0, \infty)$  if and only if

$$d < -\log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})}, \quad (5.3)$$

where  $\mathcal{W}$  denotes the set of all  $i \in \mathcal{S}$  satisfying  $(e_i - \xi)' Q_k(e_i - \xi) = \bar{b}_k(\xi)$  for this given  $\xi \in \mathbb{E}_X$ .

*Proof.* We first prove the necessity part of the theorem. By Lemma 5.1, since  $\frac{d^2 V_k(\tau, \xi, y_{1,k})}{d\tau^2} > 0$  for  $\tau > 0$ , and  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  is continuous with respect to  $\tau$  over  $[0, \infty)$ , we have that  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  is strictly monotonically increasing with  $\tau$  increasing. Also, in this part of the theorem, the stationary point is assumed to exist on  $(0, \infty)$ . This then implies that

$$\left. \frac{dV_k(\tau, \xi, y_{1,k})}{d\tau} \right|_{\tau=0^+} = d + \log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} < 0. \quad (5.4)$$

The necessity part of the theorem now follows directly from (5.4).

Conversely, from (5.2), we have

$$(5.5) \quad \lim_{\tau \rightarrow \infty} \frac{d\tau(\log J_k(\xi, \tau, y_{1,k}) + d)}{d\tau} = \log \frac{\sum_{i=1}^N \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} + d > 0$$

since  $\alpha_k(e_i, y_{1,k}) \geq \beta_k(e_i, y_{1,k})$  and  $d > 0$ . Hence, the sufficiency part of this theorem follows from (5.3), the equality in (5.4), and the continuity of  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  with respect to  $\tau$ .  $\square$

We now consider the special case of the conditional relative entropy constraint (2.4) in which  $d_r = 0$  for  $r = 1, \dots, N$ .

**COROLLARY 5.1.** *For a given  $\xi$ , if  $d_r = 0$  for  $r = 1, \dots, N$ , then a stationary point of  $V_k(\tau, \xi, y_{1,k})$  exists if and only if*

$$(5.6) \quad d < -\log \sum_{i \in \mathcal{W}} \mathbf{P}(X_k = e_i | y_{1,k}).$$

## 5.2. The maximum robust state estimator horizon. Let

$$(5.7) \quad d_c = -\log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})}.$$

Note that  $d_c$  is a function of  $k, \xi$  and is a  $\mathcal{Y}_k$  measurable random variable. The next theorem shows the behavior of  $d_c$  as  $k \rightarrow \infty$  in the case where at least one of the design parameters  $d_r$  in the definition of feasible uncertain probabilities is positive and all entries of the state transition matrix  $A$  are greater than zero.

**THEOREM 5.2.** *Assume all entries of the state transition matrix  $A$  are greater than zero. Then the following conclusions hold:*

(i) *If not all of  $d_r, r = 1, \dots, N$ , equal zero, then for any  $\xi$ ,  $d_c$  tends to  $-\infty$  almost surely with respect to the reference probability measure  $\mathbf{P}$  as  $k$  approaches  $\infty$ .*

(ii) *If  $d_r > 0$  for  $r = 1, \dots, N$ , then for any  $\xi$ , there exists a time step  $K$  such that for  $k \geq K$ , inequality (5.3) does not hold.*

*Proof.* We first prove the first part of this theorem. It follows from (4.1), (4.2), and the conditional Bayes theorem that

$$d_c = -\log \sum_{i \in \mathcal{W}} \frac{\alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} = -\log \mathbf{E}^{\mathbf{P}^k} \left[ \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \sum_{i \in \mathcal{W}} \langle X_k, e_i \rangle | y_{1,k} \right].$$

Furthermore, since  $\exp(\sum_{l=1}^k q(X_{l-1}))$  is  $\mathcal{G}_{k-1}$ -measurable and given that  $\mathcal{G}_{k-1}$ ,  $Y_k$ , and  $X_k$  are conditionally independent, using part (iv) of Theorem 7.3.1 in [2], we have

$$\begin{aligned}
 d_c &= -\log \mathbf{E}^{\mathbf{P}^k} \left[ \mathbf{E}^{\mathbf{P}^k} \left[ \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \sum_{i \in \mathcal{W}} \langle X_k, e_i \rangle | \mathcal{G}_{k-1}, Y_k \right] | y_{1,k} \right] \\
 &= -\log \mathbf{E}^{\mathbf{P}^k} \left[ \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \mathbf{E}^{\mathbf{P}^k} \left[ \sum_{i \in \mathcal{W}} \langle X_k, e_i \rangle | \mathcal{G}_{k-1} \right] | y_{1,k} \right] \\
 &= -\log \mathbf{E}^{\mathbf{P}^k} \left[ \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \sum_{i \in \mathcal{W}} A_i X_{k-1} | y_{1,k} \right] \\
 &\leq -\mathbf{E}^{\mathbf{P}^k} \left[ \log \left( \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \sum_{i \in \mathcal{W}} A_i X_{k-1} \right) | y_{1,k} \right]
 \end{aligned}$$

(by the convexity of  $-\log$  and Jensen's inequality; cf. Theorem 9.1.4 in [2])

$$(5.8) \quad = -\mathbf{E}^{\mathbf{P}^k} \left[ \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] - \mathbf{E}^{\mathbf{P}^k} \left[ \log \sum_{i \in \mathcal{W}} A_i X_{k-1} | y_{1,k} \right],$$

where  $A_i$  is the  $i$ th row of the state transition matrix  $A$ . It follows from the assumption in this theorem that the state transition matrix  $A$  is irreducible and all states are positive recurrent. Then from the ergodic theorem in [13] and (3.6), we have that

$$\frac{1}{k} \sum_{l=1}^k q(X_{l-1}) = \sum_{r=1}^N d_r \left( \frac{1}{k} \sum_{l=1}^k \langle X_{l-1}, e_r \rangle \right) \rightarrow \sum_{r=1}^N d_r \pi_r \text{ as } k \rightarrow \infty, \text{ } \mathbf{P}\text{-a.s.},$$

where  $\pi = [\pi_1, \dots, \pi_N]'$  is the stationary distribution of  $A$  and  $\pi_r > 0$  for  $r = 1, \dots, N$ . Furthermore, from Corollary 11.4 in [2] or Theorem 9.4.8 in [3], the following equality holds (almost surely under  $\mathbf{P}$ ):

$$\lim_{k \rightarrow \infty} \frac{1}{k} \mathbf{E}^{\mathbf{P}^k} \left[ \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] = \mathbf{E}^{\mathbf{P}} \left[ \lim_{k \rightarrow \infty} \frac{1}{k} \sum_{l=1}^k q(X_{l-1}) | y_{1,\infty} \right] = \sum_{r=1}^N d_r \pi_r$$

since  $\frac{1}{k} \sum_{l=1}^k q(X_{l-1}) \leq \sum_{r=1}^N d_r$  and  $\sum_{r=1}^N d_r$  is a nonrandom constant. Hence, for feasible observation sequences,

$$(5.9) \quad \lim_{k \rightarrow \infty} \mathbf{E}^{\mathbf{P}^k} \left[ \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] \rightarrow \infty \text{ as } k \rightarrow \infty$$

holds almost surely. Let  $\underline{a}$  be the minimum entry of  $A$ . Since we assume  $a_{ji} > 0$  for all  $i, j = 1, \dots, N$ , we have  $1 > \underline{a} > 0$ . Then the second term of (5.8) satisfies

$$(5.10) \quad -\mathbf{E}^{\mathbf{P}^k} \left[ \log \sum_{i \in \mathcal{W}} A_i X_{k-1} | y_{1,k} \right] \leq -\log \underline{a}.$$

This implies the second term of (5.8) is bounded. Hence, as time step  $k$  increases, it follows from (5.8)–(5.10) that  $d_c$  tends to  $-\infty$ . This completes the proof of the first part of the theorem.

We now prove the second part of this theorem. Since

$$(5.11) \quad \sum_{l=1}^k q(X_{l-1}) = \sum_{l=1}^k \sum_{r=1}^N d_r \langle X_{l-1}, e_r \rangle \geq \sum_{l=1}^k \underline{d}_r \sum_{r=1}^N \langle X_{l-1}, e_r \rangle = k\underline{d},$$

where  $\underline{d} = \min\{d_r, r = 1, \dots, N\} > 0$ , we have, for each  $\xi$ ,

$$d_c \leq -\mathbf{E}^{\mathbf{P}^k} \left[ \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] - \mathbf{E}^{\mathbf{P}^k} \left[ \log \sum_{i \in \mathcal{W}} A_i X_{k-1} | y_{1,k} \right] \leq -k\underline{d} + \log \underline{a}^{-1},$$

where  $\log \underline{a}^{-1} > 0$  is finite. Hence it follows that there exists a finite time step at which  $d_c$  will be less than  $d$ . From this, the second part of the theorem follows.  $\square$

By Theorem 5.2, if  $d_r > 0$  for  $r = 1, \dots, N$  and  $a_{ji} > 0$  for  $i, j = 1, \dots, N$ , then there exists a  $K$  such that if  $k \geq K$ , then inequality (5.3) fails for any  $\xi$ . For a given  $\xi$  and a feasible observation path  $y_{1,k}$ , for simplicity, let us assume that inequality (5.3) holds for all  $k$  such that  $0 < k < K$  and fails for all  $k \geq K$ . Then we have  $d_c > d$  and the cost functional  $V_k(\tau, \xi, y_{1,k})$  has a stationary point  $\tau_k^* \in (0, \infty)$ . This implies that

$$(5.12) \quad V_k(\tau_k^*, \xi, y_{1,k}) = \min_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) = \min_{\tau \in (0, \infty)} V_k(\tau, \xi, y_{1,k}) < V_k(0, \xi, y_{1,k}),$$

where  $V_k(0, \xi, y_{1,k}) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi) = \bar{b}_k(\xi)$  is a constant. On the contrary, for  $k \geq K$ , we have  $d \geq d_c$ . Then  $V_k(\tau, \xi, y_{1,k}) \geq V_k(0, \xi, y_{1,k})$  and

$$\min_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) = \min \left\{ V_k(0, \xi, y_{1,k}), \min_{\tau \in (0, \infty)} V_k(\tau, \xi, y_{1,k}) \right\} = V_k(0, \xi, y_{1,k}).$$

This implies that for this case,  $\tau_k^* = 0$ .

Since  $V_k(0, \xi, y_{1,k})$  is independent of the measurements, then the state estimate obtained from taking  $\min_{\xi \in \mathbb{E}_X} V_k(0, \xi, y_{1,k})$  is also independent of the measurements. In order to obtain an estimate which depends on the measurements, it is necessary to exclude the case  $\tau_k^* = 0$ . This is done by defining the robust state estimator under consideration as a finite horizon estimator.

**DEFINITION 5.2.** *For a feasible observation path  $y_{1,k}$ , we say the robust state estimator under consideration is a finite horizon state estimator if there exists a finite time step such that at this time step, inequality (5.3) does not hold for some  $\xi$ . The maximum of time steps at which inequality (5.3) holds for any  $\xi$ ,  $K$  is referred to as the maximum horizon of the robust state estimator under consideration and is characterized by inequality (5.3).*

Note that in Definition 5.2, we do not make any additional assumptions on the design parameters  $d_r$  and the state transition matrix  $A$ . That is, as long as inequality (5.3) does not hold for some finite time step  $k$ , we define the robust state estimator as a finite horizon estimator.

When the parameters  $d_r$ ,  $r = 1, \dots, N$ , all equal zero, it is possible that we can find a number  $\bar{d}$  such that if  $d < \bar{d}$ , then the robust state estimator can be applied on an infinite horizon. Note that here an infinite horizon implies that the time step can take any finite value.

LEMMA 5.2. *Consider the uncertainty in the initial distribution. Let  $d_r = 0$ ,  $r = 1, \dots, N$ . For  $j = 1, \dots, N$ , let  $\bar{a}_j$  denote the maximum of the  $j$ th row of the state transition matrix  $A$ . Let  $\bar{a}$  be  $\max_{i=1, \dots, N} \{\sum_{j=1}^N \bar{a}_j - \bar{a}_i\}$  and  $\bar{d} = -\log \bar{a}$ . If  $\bar{a} < 1$  and  $d < \bar{d}$ , then inequality (5.6) holds for any time step  $k$ .*

Note that the condition  $\bar{a} < 1$  of Lemma 5.2 implies that  $a_{i,j} > 0$  for all  $i, j = 1, \dots, N$ . From (3.15) in Theorem 3.2, for a feasible observation path  $y_{1,k}$  and  $0 < k \leq K$ , let  $x_k$  denote the robust state estimate at time step  $k$ . Then for any  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})$ , we have

$$\begin{aligned}
 \min_{\xi \in \mathbb{E}_X} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi)|y_{1,k}] &\leq \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, x_k)|y_{1,k}] \\
 &\leq \sup_{\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})} \mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, x_k)|y_{1,k}] \\
 (5.13) \qquad &= \min_{\tau \in [0, \infty)} V_k(\tau, x_k, y_{1,k}) = \min_{\xi \in \mathbb{E}_X} \min_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}).
 \end{aligned}$$

This means that for a feasible observation path  $y_{1,k}$ , at each time step  $k$ , the estimation error with the optimal state estimate or robust state estimate under  $\bar{\mathbf{P}}_k(\cdot|y_{1,k})$  does not exceed the cost value of the robust state estimator.

**5.3. Monotonicity results and the dynamic behavior of the optimal parameter and minimum cost value.** Let  $K$  be the maximum horizon of the robust state estimator defined in Definition 5.2. For a fixed  $k$ ,  $k \leq K$ , the following lemma gives monotonicity results for the optimal parameter  $\tau_k^*$  and the minimum cost value as  $d$  is varied. It also gives a monotonicity result for the maximum horizon as one of the design parameters is varied. As before let  $\bar{b}_k(\xi) = \max_{x \in \mathbb{E}_X} \Psi_k(x, \xi)$  and  $b_i(\xi) = \Psi_k(e_i, \xi)$  for  $i \in \mathcal{S}$ , where  $\mathcal{S} = \{1, \dots, j-1, j+1, \dots, N\}$  whenever  $\xi = e_j$ . Note that  $b_i(\xi)$  is a function of  $k$ . Sometimes for simplicity we will omit the variable  $\xi$ .

LEMMA 5.3. *For a given  $\xi$  and a feasible observation path  $y_{1,k}$ , at time step  $k \leq K$ ,  $\tau_k^*$  is strictly decreasing as  $d$  increases. Also, the minimum cost value is strictly monotone increasing with  $\tau_k^*$  decreasing and with  $d$  increasing, respectively. In addition, the maximum horizon  $K$  is decreasing as any of the design parameters increases.*

Next, we will consider the dynamic behavior of the optimal parameter  $\tau_k^*$  and the minimum cost value as  $k$  increases based on an upper bound of the optimal parameter  $\tau_k^*$ . For simplicity, let  $Q_k = Q > 0$ , where  $Q$  is a finite positive definite matrix. Then for each  $\xi$ ,  $\bar{b}_k(\xi)$  and  $b_i(\xi)$  are constant. We use  $\bar{b}(\xi)$  to denote  $\bar{b}_k(\xi)$ .

LEMMA 5.4. *Assume all of the design parameters  $d_r$  are greater than zero. Then for a given feasible observation sequence  $y_{1,k}$ , the optimal parameter  $\tau_k^*$  approaches zero as  $k$  increases for each  $\xi$ .*

*Proof.* We first give an upper bound on the optimal parameter  $\tau_k^*$ . Let

$$d_{y_{1,k}} \triangleq \log \frac{\sum_{i=1}^N \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})}.$$

By its definition and (5.2),  $\tau_k^* \in (0, \infty)$  satisfies the following equation:

$$(5.14) \quad d = -\log \left( \left( \alpha_k(\xi, y_{1,k}) + \sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) \right) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}) \right) \\ + \frac{1}{\tau_k^*} \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})}.$$

Then since  $\exp(\frac{b_i}{\tau_k^*}) > 1$  and  $\log$  is a strictly monotone increasing function, it follows from (5.14) that

$$\begin{aligned} & \frac{1}{\tau_k^*} \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})} \\ &= d + \log \left( \left( \alpha_k(\xi, y_{1,k}) + \sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) \right) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}) \right) \\ &> d + \log \left( \left( \alpha_k(\xi, y_{1,k}) + \sum_{i \in \mathcal{S}} \alpha_k(e_i, y_{1,k}) \right) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}) \right) \\ &= d + d_{y_{1,k}}. \end{aligned}$$

Note that  $d_{y_{1,k}} \geq 0$  since  $\alpha_k(e_i, y_{1,k}) \geq \beta_k(e_i, y_{1,k})$ . Hence,

$$(5.15) \quad \begin{aligned} \tau_k^* &< \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})} \frac{1}{d + d_{y_{1,k}}} \\ &< \frac{\bar{b}(\xi) \sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k})}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})} \frac{1}{d + d_{y_{1,k}}} < \frac{\bar{b}(\xi)}{d + d_{y_{1,k}}}. \end{aligned}$$

Furthermore, it follows from (5.11) that

$$(5.16) \quad d_{y_{1,k}} = \log \mathbf{E}^{\mathbf{P}_k} \left[ \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) | y_{1,k} \right] \geq \mathbf{E}^{\mathbf{P}_k} \left[ \sum_{l=1}^k q(X_{l-1}) | y_{1,k} \right] \geq k \underline{d},$$

where  $\underline{d} = \min\{d_r, r = 1, \dots, N\} > 0$ . Hence, it follows from (5.15) and (5.16) that

$$\tau_k^* < \frac{\bar{b}(\xi)}{d + k \underline{d}}.$$

This implies that  $\tau_k^*$  approaches zero as  $k$  increases. This completes the proof of the lemma.  $\square$

**THEOREM 5.3.** *Assume all of the design parameters  $d_r$  are greater than zero. Then for a given feasible observation sequence  $y_{1,k}$ , the minimum cost value approaches  $\min_{\xi \in \mathbb{E}_X} \bar{b}(\xi)$  as  $k$  increases. In particular, for each  $\xi$ ,  $\min_{\tau \in (0, \infty)} V_k(\tau, \xi, y_{1,k})$  approaches  $\bar{b}(\xi)$  as  $k$  increases.*

*Proof.* By (5.14), the stationary point  $\tau_k^*$  must satisfy

$$(5.17) \quad \tau_k^* \left( \log \left( \alpha_k(\xi, y_{1,k}) + \sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) / \sum_{i=1}^N \beta_k(e_i, y_{1,k}) \right) + d \right) = \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})}.$$

The left-hand side of (5.17) is the minimum of the cost functional; see (4.8). Then

$$(5.18) \quad \min_{\tau \in (0, \infty)} \tau (\log J_k(\xi, \tau, y_{1,k}) + d) = \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})}.$$

Dividing the numerator and denominator of the right-hand side of (5.18) by  $\sum_{i=1}^N \alpha_k(e_i, y_{1,k}) = \alpha_k(y_{1,k}) > 0$  and  $\exp(\frac{\bar{b}}{\tau_k^*})$ , simultaneously, we have

$$(5.19) \quad \begin{aligned} & \min_{\tau \in (0, \infty)} \tau (\log J_k(\xi, \tau, y_{1,k}) + d) \\ &= \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i}{\tau_k^*} \right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k})} \\ &= \frac{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} b_i}{\sum_{i \in \mathcal{S}} \exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} + \exp \left( \frac{-\bar{b}}{\tau_k^*} \right) \frac{\alpha_k(\xi, y_{1,k})}{\alpha_k(y_{1,k})}} \\ &= \frac{\sum_{i \in \mathcal{S} - \mathcal{W}} \exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} b_i + \bar{b} \sum_{i \in \mathcal{W}} \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})}}{\sum_{i \in \mathcal{S} - \mathcal{W}} \exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} + \sum_{i \in \mathcal{W}} \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} + \exp \left( \frac{-\bar{b}}{\tau_k^*} \right) \frac{\alpha_k(\xi, y_{1,k})}{\alpha_k(y_{1,k})}}, \end{aligned}$$

where  $\mathcal{W} \subseteq \mathcal{S}$  denotes the set of all  $i \in \mathcal{S}$  satisfying  $b_i(\xi) = \bar{b}(\xi)$ . It follows from  $\frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} < 1$  that

$$\exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})} < \exp \left( \frac{b_i - \bar{b}}{\tau_k^*} \right) \text{ for } i \in \mathcal{S} - \mathcal{W}$$

and

$$\exp\left(\frac{-\bar{b}}{\tau_k^*}\right) \frac{\alpha_k(\xi, y_{1,k})}{\alpha_k(y_{1,k})} < \exp\left(\frac{-\bar{b}}{\tau_k^*}\right).$$

Hence from Lemma 5.4, the following statements hold:

1.  $\exp\left(\frac{b_i - \bar{b}}{\tau_k^*}\right) \frac{\alpha_k(e_i, y_{1,k})}{\alpha_k(y_{1,k})}$  approaches zero as  $k$  increases for  $i \in \mathcal{S} - \mathcal{W}$ .
2.  $\exp\left(\frac{-\bar{b}}{\tau_k^*}\right) \frac{\alpha_k(\xi, y_{1,k})}{\alpha_k(y_{1,k})}$  approaches zero as  $k$  increases.

Here  $-\bar{b} < 0$ ,  $b_i - \bar{b} < 0$  for  $i \in \mathcal{S} - \mathcal{W}$ . Since for each  $\xi$ ,  $\min_{\tau \in (0, \infty)} \tau(\log J_k(\xi, \tau, y_{1,k}) + d)$  is a continuous function of  $\tau_k^*$  and  $\xi$  belongs to a finite value space, the theorem follows from (5.19) and statements 1 and 2 as above.  $\square$

**5.4. Connection with a maximum information state estimator.** In the next theorem, we will establish a connection between the robust state estimator presented in this paper and a maximum a posteriori (MAP) probability or a conditional expectation estimator. We also point out that the MAP probability estimator (cf. section 2.B in [16]) is a special case of the robust state estimator presented in this paper as  $d \rightarrow 0$  and  $d_r = 0$  for  $r = 1, \dots, N$ .

**THEOREM 5.4.** *Let  $K$  be the maximum horizon of the robust state estimator for a feasible observation sequence  $y_{1,k}$ . At time step  $k$  with  $0 < k \leq K$ , if for any  $\xi \in \mathbb{E}_X$ , for all  $i \in \mathcal{S}$ ,  $b_i(\xi)$  is a constant, then the robust state estimate under consideration equals the maximum information state estimate. Specifically, the robust state estimate equals the MAP probability or conditional expectation estimate under the reference probability measure  $\mathbf{P}$ .*

*Proof.* For simplicity, we prove this theorem only for the case  $N = 3$ ; i.e.,  $\mathbb{E}_X = \{e_1, e_2, e_3\}$ . Then it follows from  $0 < k \leq K$  and (4.8) that

$$(5.20) \quad \min_{\tau \in [0, \infty)} V_k(\tau, \xi, y_{1,k}) = \begin{cases} \tau_k^*(e_1, y_{1,k}) \left( \log \left( \bar{\alpha}_k(e_1, y_{1,k}) + \exp\left(\frac{b_2(e_1)}{\tau_k^*(e_1, y_{1,k})}\right) \bar{\alpha}_k(e_2, y_{1,k}) \right. \right. \\ \quad \left. \left. + \exp\left(\frac{b_3(e_1)}{\tau_k^*(e_1, y_{1,k})}\right) \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right), & \xi = e_1; \\ \tau_k^*(e_2, y_{1,k}) \left( \log \left( \exp\left(\frac{b_1(e_2)}{\tau_k^*(e_2, y_{1,k})}\right) \bar{\alpha}_k(e_1, y_{1,k}) + \bar{\alpha}_k(e_2, y_{1,k}) \right. \right. \\ \quad \left. \left. + \exp\left(\frac{b_3(e_2)}{\tau_k^*(e_2, y_{1,k})}\right) \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right), & \xi = e_2; \\ \tau_k^*(e_3, y_{1,k}) \left( \log \left( \exp\left(\frac{b_1(e_3)}{\tau_k^*(e_3, y_{1,k})}\right) \bar{\alpha}_k(e_1, y_{1,k}) + \exp\left(\frac{b_2(e_3)}{\tau_k^*(e_3, y_{1,k})}\right) \bar{\alpha}_k(e_2, y_{1,k}) \right. \right. \\ \quad \left. \left. + \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right), & \xi = e_3, \end{cases}$$

where  $\bar{\alpha}_k(e_i, y_{1,k}) = \frac{\alpha_k(e_i, y_{1,k})}{\sum_{j=1}^N \beta_k(e_j, y_{1,k})}$  and  $b_i(e_j) = (e_i - e_j)' Q_k(e_i - e_j)$  for  $i \neq j$ ,  $1 \leq i, j \leq N$ . Also note that  $b_i(e_j) = b_j(e_i)$ . Suppose  $\bar{\alpha}_k(e_3, y_{1,k}) = \max_{i=1,2,3} \bar{\alpha}_k(e_i, y_{1,k})$ . By the assumption in this theorem,  $b_2(e_3) = b_2(e_1) = b_1(e_3)$ ; i.e., for any  $\xi \in \mathbb{E}_X$ , for all  $i \in \mathcal{S}$ ,  $b_i$  is a constant. Then we claim that

$$(5.21) \quad V_k(\tau_k^*, e_3, y_{1,k}) = \min_{i=1,2,3} V_k(\tau_k^*, e_i, y_{1,k}).$$

That is,  $e_3$  is the robust state estimate at time step  $k$ . We next prove this claim. It follows from (5.20) that

$$\begin{aligned}
 V_k(\tau_k^*, e_3, y_{1,k}) &= \tau_k^*(e_3, y_{1,k}) \left( \log \left( \exp \left( \frac{b_1(e_3)}{\tau_k^*(e_3, y_{1,k})} \right) \bar{\alpha}_k(e_1, y_{1,k}) + \exp \left( \frac{b_2(e_3)}{\tau_k^*(e_3, y_{1,k})} \right) \right. \right. \\
 &\quad \left. \left. \times \bar{\alpha}_k(e_2, y_{1,k}) + \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right) \\
 &\leq \tau_k^*(e_1, y_{1,k}) \left( \log \left( \exp \left( \frac{b_1(e_3)}{\tau_k^*(e_1, y_{1,k})} \right) \bar{\alpha}_k(e_1, y_{1,k}) + \exp \left( \frac{b_2(e_3)}{\tau_k^*(e_1, y_{1,k})} \right) \right. \right. \\
 &\quad \left. \left. \bar{\alpha}_k(e_2, y_{1,k}) + \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right) \\
 &\quad (\text{by } V_k(\tau_k^*, e_3, y_{1,k}) \text{ is the minimum at } \tau_k^*(e_3, y_{1,k})) \\
 &\leq \tau_k^*(e_1, y_{1,k}) \left( \log \left( \bar{\alpha}_k(e_1, y_{1,k}) + \exp \left( \frac{b_2(e_1)}{\tau_k^*(e_1, y_{1,k})} \right) \bar{\alpha}_k(e_2, y_{1,k}) \right. \right. \\
 &\quad \left. \left. + \exp \left( \frac{b_3(e_1)}{\tau_k^*(e_1, y_{1,k})} \right) \bar{\alpha}_k(e_3, y_{1,k}) \right) + d \right) \\
 &= V_k(\tau_k^*, e_1, y_{1,k}).
 \end{aligned}$$

Here the last inequality follows from the facts that  $\bar{\alpha}_k(e_1, y_{1,k}) \leq \bar{\alpha}_k(e_3, y_{1,k})$ ,  $b_2(e_3) = b_2(e_1)$ , and

$$\begin{aligned}
 &\bar{\alpha}_k(e_3, y_{1,k}) + \exp \left( \frac{b_1(e_3)}{\tau_k^*(e_1, y_{1,k})} \right) \bar{\alpha}_k(e_1, y_{1,k}) \\
 &\leq \bar{\alpha}_k(e_1, y_{1,k}) + \exp \left( \frac{b_3(e_1)}{\tau_k^*(e_1, y_{1,k})} \right) \bar{\alpha}_k(e_3, y_{1,k}).
 \end{aligned}$$

Similarly, we have  $V_k(\tau_k^*, e_3, y_{1,k}) \leq V_k(\tau_k^*, e_2, y_{1,k})$ . Hence, (5.21) holds. Note that here we have assumed that  $\bar{\alpha}_k(e_3, y_{1,k})$  is the maximum among  $\{\bar{\alpha}_k(e_1, y_{1,k}), \bar{\alpha}_k(e_2, y_{1,k}), \bar{\alpha}_k(e_3, y_{1,k})\}$ . Also since

$$\bar{\alpha}_k(e_i, y_{1,k}) = \frac{\alpha_k(e_i, y_{1,k})}{\sum_{j=1}^N \beta_k(e_j, y_{1,k})}$$

and  $\sum_{i=1}^N \beta_k(e_j, y_{1,k})$  is independent of  $e_i$ , maximizing  $\bar{\alpha}_k(y_{1,k})$  is equivalent to maximizing the information state  $\alpha_k(e_i, y_{1,k})$ . Hence, the robust state estimate equals the maximum information state estimate. Furthermore, under the reference probability measure  $\mathbf{P}$ ,

(5.22)

$$\bar{\alpha}_k(e_i, y_{1,k}) = \begin{cases} \mathbf{P}(X_k = e_i | y_{1,k}), & d_r = 0, r = 1, \dots, N; \\ \mathbf{E}^{\mathbf{P}}[\exp(\sum_{l=1}^k q(X_{l-1})) \langle X_k, e_i \rangle | y_{1,k}], & \text{otherwise.} \end{cases}$$

Hence, the robust state estimate equals the MAP probability or conditional expectation estimate. The above proof can be extended in a straightforward manner to the

general case when the dimension  $N$  of  $\mathbb{E}_X$  is finite and arbitrary. This completes the proof of the theorem.  $\square$

*Remark 5.1.* If  $Q_k = \alpha I$  for  $0 < k \leq K$ , where  $\alpha > 0$  is constant, then the robust state estimator is equivalent to the maximum information state estimator (i.e., the MAP probability or conditional expectation estimator) given the measurements under the reference probability measure  $\mathbf{P}$ . Note that for  $d_r = 0$  for  $r = 1, \dots, N$ , by (5.22), the robust state estimates are independent of the parameter  $d$  and the optimal cost value is a function of  $d$ .

*Remark 5.2.* We consider an HMM with an unknown parameter set and choose the triple  $(A, C, p)$  as the reference parameter set satisfying Assumption 2.1. Let  $\mathbf{P}$  be the reference probability measure. Then under  $\mathbf{P}$ , the pair of the coordinate processes  $\{X_k, Y_{k+1}\}_{k \geq 0}$  on  $(\Omega, \mathcal{B})$  is an HMM with  $(A, C, p)$  as its parameter set. By Theorem 5.4, in the case of  $d_r = 0$  for  $r = 1, \dots, N$ , it is interesting to note that the MAP probability estimator under  $\mathbf{P}$  can be equivalent to a robust state estimator with uncertainty in the initial distribution if we can find the design parameter  $d$  such that inequality (5.6) holds. Hence, we can say the MAP estimator has a natural level of robustness. A similar argument can be used in the more general case, i.e., the case in which there exists a  $d_r > 0$ .

*Remark 5.3.* Under the same assumption as in Theorem 5.4 (that is, for any  $\xi \in \mathbb{E}_X$ ,  $b_i(\xi)$  is a constant for all  $i \in \mathcal{S}$ ), then as  $d \rightarrow 0$ , it is clear that inequality (5.6) holds for  $k > 0$ , any  $\xi$ , and feasible observation sequence  $y_{1,k}$ . This follows since  $\mathcal{W} \subseteq \mathcal{S} \subset \{1, \dots, N\}$ ,  $\mathbf{P}(X_k = \xi | y_{1,k}) > 0$ , and  $\sum_{i \in \mathcal{W}} \mathbf{P}(X_k = e_i | y_{1,k}) < 1$ . Hence the MAP probability estimator (cf. section 2.B in [16]) is a special case of the robust state estimator presented in this paper in the limit, when  $d_r = 0$  for  $r = 1, \dots, N$  and the true parameter set equals the reference one.

**6. Illustrative example.** In this section, we present an example to illustrate the main results of this paper. Consider an HMM whose true parameter set  $\bar{\zeta} = (\bar{A}, \bar{C}, \bar{p})$  is given by

$$\bar{A} = \begin{bmatrix} 0.695 & 0.3 & 0 \\ 0.105 & 0.18 & 0.71 \\ 0.2 & 0.52 & 0.29 \end{bmatrix}, \bar{C} = \begin{bmatrix} 0.49 & 0.21 & 0.49 \\ 0 & 0.51 & 0 \\ 0.51 & 0.28 & 0.51 \end{bmatrix}, \text{ and } \bar{p} = \begin{bmatrix} 0.35 \\ 0 \\ 0.65 \end{bmatrix}.$$

Although we will use this true parameter set in computer experiments to generate realized sequences of the observation process  $\{Y_{k+1}\}_{k \geq 0}$ , we suppose that the true parameter set is not known exactly and select the following reference parameter set  $\zeta = (A, C, p)$  for the design of a state estimator for this HMM:

$$A = \begin{bmatrix} 0.7 & 0.3 & 0 \\ 0.1 & 0.2 & 0.7 \\ 0.2 & 0.5 & 0.3 \end{bmatrix}, C = \begin{bmatrix} 0.5 & 0.2 & 0.5 \\ 0 & 0.5 & 0 \\ 0.5 & 0.3 & 0.5 \end{bmatrix}, \text{ and } p = \begin{bmatrix} 0.4 \\ 0 \\ 0.6 \end{bmatrix}.$$

In this example at any finite time step  $k$ , the marginal probability measures  $\bar{\mathbf{P}}_k$  and  $\mathbf{P}_k$  corresponding to the true and reference parameter sets  $\bar{\zeta}$  and  $\zeta$  are equivalent,  $\bar{\mathbf{P}}_k \sim \mathbf{P}_k$ , since the true parameter set  $\bar{\zeta}$  is equivalent to the reference parameter set  $\zeta$  in the sense of the absolute continuity of parameter sets. Hence, for any feasible  $y_{1,k}$ , we have  $\bar{\mathbf{P}}_k(\cdot | y_{1,k}) \in \mathcal{P}(\Omega, \mathcal{G}_k, \mathbf{P}_k | y_{1,k})$ . Also under  $\mathbf{P}$ , Assumption 2.1 holds. Meanwhile, the event  $\{\omega : Y_1(\omega) = f_2\}$ , where  $f_2 = (0 \ 1 \ 0)'$ , has zero probability under both  $\mathbf{P}$  and  $\bar{\mathbf{P}}$ , and hence this event does not occur almost surely.

In every experiment only a path of the measurement process  $\{Y_{k+1}\}_{k \geq 0}$  is observed up to time step  $k$ . That is, in each experiment we obtain sequentially the

realized sequence of the observation process,  $Y_1(\omega) = y_1, \dots, Y_k(\omega) = y_k$ . This observation path defines an event which consists of all sample  $\omega \in \Omega$  compatible with the realized observation path  $y_{1,k}$ . However, the corresponding realized sequence of the state process,  $X_1(\omega) = x_1, \dots, X_k(\omega) = x_k$ , cannot be observed directly. We will use the robust state estimator presented in this paper to construct robust state estimates of this realized sequence of the state process  $\{X_{k+1}\}_{k \geq 0}$  based on the realized sequence of the observation process.

In our numerical experiments, we generated a sequence  $y_{1,k}$  using the true parameter set  $\bar{\zeta}$ . For this realized observation path, we verified numerically that the true probability measure  $\bar{\mathbf{P}}_k$  satisfied the conditional relative entropy constraint (2.4) in which the design parameters were selected as follows:

$$(6.1) \quad d = 0.006, \quad d_1 = 0.001, \quad d_2 = 0.0015, \quad d_3 = 0.0005.$$

Hence, we ensured that the true probability distribution satisfied the constrained condition  $\bar{\mathbf{P}}_k(\cdot|y_{1,k}) \in \Xi_k(y_{1,k})$ ; this fact is illustrated in Figure 6.1 in which data2 and data1 represent the conditional relative entropy and the bound on the right-hand side of (2.4), respectively.

FIG. 6.1. The conditional relative entropy and the bound on the right-hand side of (2.4) vs. time step.

Next, we considered the robust state estimation problem (3.1) in which the weighting matrices in the cost functional (3.1) were chosen to be

$$Q_k = \text{diag}(0.07, 0.08, 0.07).$$

Computer simulation showed that for this given observation sequence, the maximum horizon  $K$  equaled 331. Figure 6.2 shows the cost value  $V_k(\tau, \xi, y_{1,k})$  corresponding to  $k = 17$  and  $\xi = e_1$ . The optimal parameter  $\tau_k^*$  for each  $k = 1, \dots, K$  is shown in Figure 6.3. In Figure 6.4, data1 represents the cost values  $V_k(\tau_k^*, \xi_k^*, y_{1,k})$ , where  $\xi_k^*$  and  $\tau_k^*$  are the robust state estimate and the value of  $\tau$  at which  $V_k(\tau, \xi_k^*, y_{1,k})$  attains its minimum at time step  $k$ . Also, the conditional expectation values  $\mathbf{E}^{\bar{\mathbf{P}}_k}[\Psi_k(X_k, \xi_k^*)|y_{1,k}]$

FIG. 6.2. The cost value vs. parameter  $\tau_k$  at time step  $k = 17$ .

FIG. 6.3. The optimal  $\tau_k^*$  at each time step.

are given by data2, and data3 shows the cost values  $V_k(0, \xi, y_{1,k})$  corresponding to the unconstrained estimation problem. Figure 6.4 shows that with the robust state estimates  $\xi_k^*$  at each time step  $k$ , the cost values  $\mathbf{E}^{\mathbf{P}^k}[\Psi_k(X_k, \xi_k^*)|y_{1,k}]$  are less than the guaranteed cost values of the robust state estimator.

We also considered another HMM with the true parameter set  $\hat{\zeta} = (\hat{A}, \hat{C}, \hat{p})$ , where

$$\hat{A} = \begin{bmatrix} 0.695 & 0.6 & 0 \\ 0.105 & 0.18 & 0.5 \\ 0.2 & 0.22 & 0.5 \end{bmatrix},$$

FIG. 6.4. Cost values vs time step.

FIG. 6.5. Conditional relative entropy and bound vs. time step.

$\hat{C} = \bar{C}$ , and  $\hat{p} = \bar{p}$ ; let  $\hat{\mathbf{P}}$  denote the Kolmogorov measure of this HMM. For this HMM we also generated a realized observation sequence  $y_{1,k}$  using  $\hat{\zeta}$  and checked whether  $\hat{\mathbf{P}}_k(\cdot|y_{1,k})$  satisfied the constraint (2.4) with the same design parameters given in (6.1). As Figure 6.5 shows, the conditional relative entropy  $\mathcal{R}(\hat{\mathbf{P}}_k(\cdot|y_{1,k})\|\mathbf{P}_k(\cdot|y_{1,k}))$  does not satisfy the constraint (2.4) with the design parameters (6.1) for any  $k$ , and therefore  $\hat{\mathbf{P}}_k(\cdot|y_{1,k})(y_{1,k}) \notin \Xi_k(y_{1,k})$ . Hence even though we were using the same algorithm for computing robust state estimates, the cost values  $\mathbf{E}^{\hat{\mathbf{P}}_k}[\Psi_k(X_k, \xi_k^*)|y_{1,k}]$  were not guaranteed to be less than the predicted bounds on the cost values of the robust state estimator. In fact, the cost values  $\mathbf{E}^{\hat{\mathbf{P}}_k}[\Psi_k(X_k, \xi_k^*)|y_{1,k}]$  exceeded the predicted bounds; this can be seen in Figure 6.6.

FIG. 6.6. Cost values vs. time step.

**7. Conclusion.** In this paper, a robust state estimator for uncertain HMMs has been introduced in which the uncertainty is characterized in terms of a conditional relative entropy constraint. A finite horizon robust state estimator has been derived that guarantees a certain bound on the state estimation error, provided that the true conditional probability measure satisfies the conditional relative entropy constraint. Also it is pointed out that under certain conditions, our robust state estimator is equivalent to the MAP probability or a conditional expectation estimator given the measurements under the reference probability measure.

We have presented a necessary and sufficient condition for the existence of a stationary point, under which the conditional relative entropy constraint is active. This condition allows one to determine the maximum time horizon for the estimator. A characterization of the solution to the robust state estimation problem is also presented. In many HMM applications, however, a robust state estimator is most desirable which is capable of producing estimates over an infinite interval of time, as in [20]. For this further work, Lemma 1 in [10] deserves attention.

**Appendix A. Proof of Lemma 2.1.** We now establish the sufficiency part by induction. We first consider the case  $k = 1$ . Consider a state  $x_1 \in \mathbb{E}_X$  and let  $y_1$  be an arbitrary feasible 1-step observed sequence. Since  $\mathbf{P}(Y_1 = y_1) = \sum_{x_0 \in \mathbb{E}_X} c_{y_1 x_0} p_{x_0} > 0$ , then clearly there must exist  $x_0 \in \mathbb{E}_X$  such that  $c_{y_1 x_0} p_{x_0} > 0$ , and hence the set  $D_{y_1}$  is not empty. Therefore it follows from condition 1 of the lemma that  $a_{x_1 x_0} > 0$  and thus

$$\mathbf{P}(X_1 = x_1, Y_1 = y_1) = \sum_{x_0 \in \mathbb{E}_X} a_{x_1 x_0} c_{y_1 x_0} p_{x_0} > 0.$$

That is, at  $k = 1$ , the state  $x_1$  is observable.

Furthermore, we consider an arbitrary  $k$ -step long feasible observed sequence  $\{y_1, \dots, y_k\}$ ; that is,  $\mathbf{P}(Y_1 = y_1, \dots, Y_{k-1} = y_{k-1}, Y_k = y_k) > 0$ . Clearly,  $y_k \notin \bar{D}$

since for any  $y \in \bar{D}$ ,

$$\mathbf{P}(Y_k = y) = \sum_{x_0, \dots, x_{k-1} \in \mathbb{E}_X} c_{yx_{k-1}} a_{x_{k-1}x_{k-2}} \cdots a_{x_1x_0} p_{x_0} = 0.$$

Also  $\mathbf{P}(Y_1 = y_1, \dots, Y_{k-1} = y_{k-1}) > 0$ . We next assume the conclusion in the lemma holds at time step  $k-1$ . Hence  $\mathbf{P}(X_{k-1} = x_{k-1}, Y_1 = y_1, \dots, Y_{k-1} = y_{k-1}) > 0$  for any  $x_{k-1}$ . It follows from

$$\begin{aligned} & \mathbf{P}(X_k = x_k, Y_1 = y_1, \dots, Y_k = y_k) \\ &= \sum_{x_{k-1} \in \mathbb{E}_X} a_{x_k x_{k-1}} c_{y_k x_{k-1}} \mathbf{P}(X_{k-1} = x_{k-1}, Y_1 = y_1, \dots, Y_{k-1} = y_{k-1}) > 0 \end{aligned}$$

that any state is observable at time step  $k$ .

We now prove the necessity part. We first consider part 1. For any  $y_1$  satisfying  $D_{y_1} \neq \emptyset$ , it follows that

$$\mathbf{P}(Y_1 = y_1) = \sum_{x_0 \in \mathbb{E}_X} c_{y_1 x_0} p_{x_0} > 0;$$

that is, the 1-step sequence  $y_1$  is feasible. Since in this part of the proof we assume that any state is observable, it follows that for any  $x_1$ ,

$$\mathbf{P}(X_1 = x_1, Y_1 = y_1) = \sum_{x_0 \in \mathbb{E}_X} a_{x_1 x_0} c_{y_1 x_0} p_{x_0} > 0.$$

Hence for any  $x_1 \in \mathbb{E}_X$ , there must exist an  $x_0 \in D_{y_1}$  such that  $a_{x_1 x_0} c_{y_1 x_0} p_{x_0} > 0$ . Since the condition  $x_0 \in D_{y_1}$  implies that  $c_{y_1 x_0} p_{x_0} > 0$ , then  $a_{x_1 x_0} > 0$ , and condition 1 of the lemma holds. It is clear from this proof that  $x_0$  depends on  $y_1$  and  $x_1$ .

We now establish condition 2. Since the sets  $\{Y_1 = y_1 | y_1 \in \mathbb{E}_Y\}$  form a finite partition of the sample space, there exists a  $y_1$  such that  $\mathbf{P}(Y_1 = y_1) > 0$ . Then, since any state of the HMM is assumed to be observable, we have that for any  $x_1$ ,

$$\mathbf{P}(X_1 = x_1, Y_1 = y_1) = \sum_{x_0 \in \mathbb{E}_X} a_{x_1 x_0} c_{y_1 x_0} p_{x_0} > 0.$$

Moreover, it follows from the definition of the set  $\bar{D}$  given in condition 2 of this lemma that for any  $y_2 \in \mathbb{E}_Y - \bar{D}$ , there exists an  $x_1$  such that  $c_{y_2 x_1} > 0$ , and hence

$$\mathbf{P}(Y_1 = y_1, Y_2 = y_2) = \sum_{x_1 \in \mathbb{E}_X} c_{y_2 x_1} \mathbf{P}(X_1 = x_1, Y_1 = y_1) > 0.$$

Note that  $\bar{D} \neq \mathbb{E}_Y$  since  $\sum_{y_2 \in \mathbb{E}_Y} c_{y_2 x_1} = 1$ . That is,  $\mathbb{E}_Y - \bar{D} \neq \emptyset$ . Finally, it follows from the fact that any state is observable that

$$\mathbf{P}(X_2 = x_2, Y_1 = y_1, Y_2 = y_2) = \sum_{x_1 \in \mathbb{E}_X} c_{y_2 x_1} a_{x_2 x_1} \mathbf{P}(X_1 = x_1, Y_1 = y_1) > 0.$$

This implies that for any  $y_2 \in \mathbb{E}_Y - \bar{D}$  and any  $x_2 \in \mathbb{E}_X$ , there exists an  $x_1 \in \mathbb{E}_X$  such that  $a_{x_2 x_1} c_{y_2 x_1} > 0$ . That is, condition 2 holds. Here  $x_1$  is a function of  $y_2$  and  $x_2$ . This completes the proof of the necessity of conditions 1 and 2 in this lemma.

**Appendix B. Proof of Lemma 4.1.** Since under  $\tilde{\mathbf{P}}_k$ ,  $\sigma\{Y_k\}$  is independent of  $\sigma\{X_0, \dots, X_k, Y_1, \dots, Y_{k-1}\}$ , we have

$$\begin{aligned}
& \alpha_k(e_i, y_{1,k}) \\
&= \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\lambda}_k \exp(q(X_{k-1})) \bar{\Lambda}_{k-1} \exp \left( \sum_{l=1}^{k-1} q(X_{l-1}) \right) \langle X_k, e_i \rangle | \mathcal{G}_{k-1}, Y_k \right] | y_{1,k} \right] \\
&= \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\lambda}_k \exp(q(X_{k-1})) \bar{\Lambda}_{k-1} \exp \left( \sum_{l=1}^{k-1} q(X_{l-1}) \right) \mathbf{E}^{\tilde{\mathbf{P}}_k} [\langle X_k, e_i \rangle | \mathcal{G}_{k-1}, Y_k] | y_{1,k} \right] \\
&= \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\lambda}_k \exp(q(X_{k-1})) \bar{\Lambda}_{k-1} \exp \left( \sum_{l=1}^{k-1} q(X_{l-1}) \right) \langle AX_{k-1}, e_i \rangle | y_{1,k} \right] \\
&= \sum_{n=1}^N \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\lambda}_k \exp(q(X_{k-1})) \bar{\Lambda}_{k-1} \exp \left( \sum_{l=1}^{k-1} q(X_{l-1}) \right) \langle AX_{k-1}, e_i \rangle \right. \\
&\quad \left. \times \langle X_{k-1}, e_n \rangle | y_{1,k} \right] \\
&= \sum_{n=1}^N \prod_{j=1}^M (M c_{jn})^{y_k^j} \exp(d_n) \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_{k-1} \exp \left( \sum_{l=1}^{k-1} q(X_{l-1}) \right) \langle AX_{k-1}, e_i \rangle \right. \\
&\quad \left. \times \langle X_{k-1}, e_n \rangle | y_{1,k-1} \right]
\end{aligned}$$

(B.1)

$$= \sum_{n=1}^N \prod_{j=1}^M (M c_{jn})^{y_k^j} \exp(d_n) a_{in} \alpha_{k-1}(e_n).$$

Using the matrix notation on the right-hand side of (B.1) yields (4.5). Furthermore, (4.6) follows from (4.5) as a special case in which  $q(X_{l-1}) = 0, l = 1, \dots, k$ . Note that (4.6) defines a risk-neutral recursive filter for HMMs [8].

**Appendix C. Proof of Theorem 4.1.** Using arguments similar to those used in the proof of Lemma 4.1, we have

$$\begin{aligned}
& \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_k \exp \left( \tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1}) \right) | y_{1,k} \right] \\
&= \sum_{i=1}^N \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_k \exp \left( \tau^{-1} \Psi_k(X_k, \xi) + \sum_{l=1}^k q(X_{l-1}) \right) \langle X_k, e_i \rangle | y_{1,k} \right] \\
&= \sum_{i=1}^N \exp \left( \frac{1}{\tau} (e_i - \xi)' Q_k (e_i - \xi) \right) \mathbf{E}^{\tilde{\mathbf{P}}_k} \left[ \bar{\Lambda}_k \exp \left( \sum_{l=1}^k q(X_{l-1}) \right) \langle X_k, e_i \rangle | y_{1,k} \right] \\
&= H_k \alpha_k(y_{1,k})
\end{aligned}$$

and

$$\mathbf{E}^{\tilde{\mathbf{P}}_k}[\bar{\Lambda}_k|y_{1,k}] = \sum_{i=1}^N \beta_k(e_i, y_{1,k}).$$

Then (4.8) follows.

**Appendix D. Proof of Lemma 4.2.** It is obvious that we need only establish  $\beta_k(e_i, y_{1,k}) > 0$  for any  $e_i$  since  $\alpha_k(e_i, y_{1,k}) > \beta_k(e_i, y_{1,k})$ . By the conditional Bayes theorem,

$$(D.1) \quad \mathbf{E}^{\mathbf{P}_k}[\langle X_k, e_i \rangle | y_{1,k}] = \frac{\beta(e_i, y_{1,k})}{\sum_{i=1}^N \beta(e_i, y_{1,k})}.$$

Under Assumption 2.1, any state is observable at any  $k$ . Hence,

$$\mathbf{E}^{\mathbf{P}_k}[\langle X_k, e_i \rangle | y_{1,k}] = \mathbf{P}_k(X_k = e_i | y_{1,k}) > 0;$$

from this and (D.1), then  $\beta(e_i, y_{1,k}) > 0$  follows.

**Appendix E. Proof of Lemma 5.1.** To establish that  $V_k(\tau, \xi, y_{1,k})$  is continuous with respect to  $\tau$  over  $[0, \infty)$ , we need only prove that  $V_k(\tau, \xi, y_{1,k})$  is right continuous at  $\tau = 0$ . This can be seen from  $\lim_{\tau \rightarrow 0^+} V_k(\tau, \xi, y_{1,k}) = V_k(0, \xi, y_{1,k}) = \bar{b}_k$ . Furthermore, after a tedious computation, we have

$$\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau} \Big|_{\tau=0^+} = \lim_{\tau \rightarrow 0^+} \frac{d\tau(\log J_k(\xi, \tau, y_{1,k}) + d)}{d\tau}.$$

This means that at  $\tau = 0$ ,  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  is right continuous. Thus,  $\frac{dV_k(\tau, \xi, y_{1,k})}{d\tau}$  is continuous with respect to  $\tau$  over  $[0, \infty)$ . We now calculate the second derivative of  $\tau(\log J_k(\xi, \tau, y_{1,k}) + d)$  with respect to  $\tau$ . Let  $a_i = \exp(\frac{1}{\tau}(e_i - \xi))' Q_k(e_i - \xi) \alpha_k(e_i, y_{1,k})$ ,  $i \in \mathcal{S}$ , and  $a_j = \alpha_k(\xi, y_{1,k})$ . By (5.2), we have

$$\begin{aligned} & \frac{d^2 \tau(\log J_k(\xi, \tau, y_{1,k}) + d)}{d\tau^2} \\ &= \frac{1}{\tau^3} \left( \frac{\sum_{i \in \mathcal{S}} a_i b_i^2 \sum_{i \in \mathcal{S}} a_i - (\sum_{i \in \mathcal{S}} a_i b_i)^2}{(\sum_{i=1}^N a_i)^2} + \frac{a_j \sum_{i \in \mathcal{S}} a_i b_i^2}{(\sum_{i=1}^N a_i)^2} \right) \\ &= \frac{1}{\tau^3} \left( \frac{\sum_{i \in \mathcal{S}} (b_i \sqrt{a_i})^2 \sum_{i \in \mathcal{S}} (\sqrt{a_i})^2 - (\sum_{i \in \mathcal{S}} b_i \sqrt{a_i} \sqrt{a_i})^2}{(\sum_{i=1}^N a_i)^2} + \frac{a_j \sum_{i \in \mathcal{S}} a_i b_i^2}{(\sum_{i=1}^N a_i)^2} \right) > 0. \end{aligned}$$

The last inequality follows from the Cauchy inequality  $(\sum_{i=1}^n a_i b_i)^2 \leq \sum_{i=1}^n a_i^2 \sum_{i=1}^n b_i^2$  and the fact that  $a_j \sum_{i \in \mathcal{S}} a_i b_i^2 > 0$  since  $b_l > 0$ , for all  $l \in \mathcal{S}$ , and  $a_i > 0$  for any  $i$ ; see Lemma 4.2. Thus,  $\tau(\log J_k(\xi, \tau, y_{1,k}) + d)$  is a strictly convex function of  $\tau$  on  $(0, \infty)$ .

**Appendix F. Proof of Corollary 5.1.** When  $d_r = 0, r = 1, \dots, N$ , we have  $\alpha_k(y_{1,k}) = \beta_k(y_{1,k})$ . Then from inequality (5.3), the definition of  $\alpha_k(y_{1,k})$  and  $\beta_k(y_{1,k})$ , and the conditional Bayes theorem, we have

$$\begin{aligned} \log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} &= \log \frac{\sum_{i \in \mathcal{W}} \mathbf{E}^{\tilde{\mathbf{P}}_k}[\bar{\Lambda}_k \langle X_k, e_i \rangle | y_{1,k}]}{\mathbf{E}^{\tilde{\mathbf{P}}_k}[\bar{\Lambda}_k | y_{1,k}]} \\ &= \log \sum_{i \in \mathcal{W}} \mathbf{E}^{\mathbf{P}}[\langle X_k, e_i \rangle | y_{1,k}] = \log \sum_{i \in \mathcal{W}} \mathbf{P}(X_k = e_i | y_{1,k}) \end{aligned}$$

from which (5.6) follows.

**Appendix G. Proof of Lemma 5.2.** From (B.1),

$$\begin{aligned}
 -\log \sum_{i \in \mathcal{W}} \mathbf{P}(X_k = e_i | y_{1,k}) &= -\log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \alpha_k(e_i, y_{1,k})} \\
 &= -\log \frac{\sum_{i \in \mathcal{W}} \sum_{n=1}^N \prod_{j=1}^M (Mc_{jn})^{y_k^j} a_{in} \alpha_{k-1}(e_n, y_{1,k})}{\sum_{n=1}^N \prod_{j=1}^M (Mc_{jn})^{y_k^j} \alpha_{k-1}(e_n, y_{1,k})} \\
 (G.1) \quad &\geq -\log \left( \sum_{i \in \mathcal{W}} \max_{j=1, \dots, N} a_{ij} \right).
 \end{aligned}$$

In order to derive the last inequality, we use the assumption  $\bar{a} < 1$  in this lemma, which implies that all entries of the state transition matrix  $A$  are greater than zero. Furthermore, under the assumption in this lemma and from (G.1), we have

$$d < -\log \bar{a} \leq -\log \left( \sum_{i \in \mathcal{W}} \max_{j=1, \dots, N} a_{ij} \right) \leq -\log \sum_{i \in \mathcal{W}} \mathbf{P}(X_k = e_i | y_{1,k}).$$

That is, inequality (5.6) holds such that a stationary point always exists for any  $\xi$  and  $k$ . Note that any such  $\bar{d}$  is independent of the measurements. Also the condition  $\bar{a} < 1$ , and  $d < \bar{d}$  is a sufficient condition under which inequality (5.6) holds.

**Appendix H. Proof of Lemma 5.3.** We first prove the first statement of this lemma. From the proof of the second part of Lemma 5.1, the first derivative of the right-hand side of the above equation with respect to  $\tau_k^*$  is strictly less than zero. Hence,  $\tau_k^*$  is strictly decreasing with  $d$  increasing if the inequality (5.3) holds.

We now prove the second statement of this lemma. Using the same argument as used in Lemma 5.1, we can calculate the first derivative of the right-hand side of (5.18) with respect to  $\tau_k^*$  as follows:

$$\begin{aligned}
 &-\frac{1}{(\tau_k^*)^2} \left( \frac{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) b_i^2 \right) \left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k}) \right)}{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k}) \right)^2} \right. \\
 &\quad \left. - \frac{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) b_i \right)^2}{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k}) \right)^2} \right) \\
 &= \frac{-1}{(\tau_k^*)^2} \frac{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) b_i^2 \right) \left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) \right)}{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k}) \right)^2} \\
 &\quad - \frac{1}{(\tau_k^*)^2} \frac{-\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) b_i \right)^2 + \alpha_k(\xi, y_{1,k}) \left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) b_i^2 \right)}{\left( \sum_{i \in \mathcal{S}} \exp\left(\frac{b_i}{\tau_k^*}\right) \alpha_k(e_i, y_{1,k}) + \alpha_k(\xi, y_{1,k}) \right)^2} \\
 &< 0.
 \end{aligned}$$

Hence, the minimum cost value is strictly monotone increasing with  $\tau_k^*$  decreasing. From the first statement of this lemma, we can now conclude the minimum cost value is strictly monotone increasing with  $d$  increasing.

Finally, we assume that  $d_j, 1 \leq j \leq N$ , increases. Let  $\bar{d}_j = d_j + \delta, \delta > 0$ . Then from (5.7), for any  $k$ , we have

$$\begin{aligned} \bar{d}_c &= -\log \frac{\sum_{i \in \mathcal{W}} \alpha_k(e_i, y_{1,k})}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} \\ &= -\log \frac{\sum_{i \in \mathcal{W}} \mathbf{E}^{\bar{\mathbf{P}}_k} [\bar{\Lambda}_k \exp(\sum_{l=1}^k q(X_{l-1})) \exp(\sum_{l=1}^k \delta \langle X_j, e_r \rangle) \langle X_k, e_i \rangle | y_{1,k}]}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} \\ &\leq -\log \frac{\sum_{i \in \mathcal{W}} \mathbf{E}^{\bar{\mathbf{P}}_k} [\bar{\Lambda}_k \exp(\sum_{l=1}^k q(X_{l-1})) \langle X_k, e_i \rangle | y_{1,k}]}{\sum_{i=1}^N \beta_k(e_i, y_{1,k})} = d_c. \end{aligned}$$

Hence from the definition of the maximum horizon, we have  $\bar{K} \leq K$ . It follows directly from (5.3) that  $K$  is decreasing as  $d$  increases. This completes the proof of the lemma.

## ADAPTIVE FINITE ELEMENTS FOR ELLIPTIC OPTIMIZATION PROBLEMS WITH CONTROL CONSTRAINTS\*

B. VEXLER<sup>†</sup> AND W. WOLLNER<sup>‡</sup>

**Abstract.** In this paper we develop a posteriori error estimates for finite element discretization of elliptic optimization problems with pointwise inequality constraints on the control variable. We derive error estimators for assessing the discretization error with respect to the cost functional as well as with respect to a given quantity of interest. These error estimators provide quantitative information about the discretization error and guide an adaptive mesh refinement algorithm allowing for substantial saving in degrees of freedom. The behavior of the method is demonstrated on numerical examples.

**Key words.** mesh adaptivity, optimal control, a posteriori error estimates, finite element method, quantity of interest, pointwise inequality constraints

**DOI.** 10.1137/070683416

**1. Introduction.** In this paper we develop a posteriori error estimates for finite element approximations of optimization problems governed by elliptic partial differential equations. We discuss this question in a general manner, including the consideration of optimal control and parameter identification problems with control constraints given through a closed convex admissible set. The derived error estimates have the goal of guiding an adaptive mesh refinement algorithm for finding economical meshes for the optimization problem under consideration.

The use of adaptive techniques based on a posteriori error estimation is well accepted in the context of finite element discretization of partial differential equations; see, e.g., [6, 13, 35]. To our knowledge there are only a few results published on adaptive finite elements for optimization problems; see [2, 17, 20, 23, 25, 27, 4, 7, 8, 30].

In articles [17, 20, 23, 25, 27] the authors provide a posteriori error estimates for elliptic optimal control problems with distributed or Neumann control subject to box constraints. These estimates assess the error in the control, state, and the adjoint variable with respect to the natural norms of the corresponding spaces. In [2] another approach for the estimation of the error with respect to the norm of the control space is presented. In [17] convergence of an adaptive algorithm for a control constrained optimal control problem is shown.

However, in many applications, the error in global norms does not provide a useful error bound for the error in the quantity of physical interest. The a posteriori estimators derived in this paper grant access to the error with respect to given functionals.

In [4, 6] the authors present a general concept for a posteriori estimation of the discretization error with respect to the cost functional in the context of optimal control problems. In articles [7, 8] the authors have extended this approach to the estimation of the discretization error with respect to an arbitrary functional depending on both the control and the state variable, so-called *quantity of interest*. This allowed, among other things, the treatment of parameter identification and model calibration problems. However, in all these publications, the control variable was searched for in a Hilbert space  $Q$  without additional (inequality) constraints. Therefore the main contribution of this work is the extension of these techniques to the case of optimization problems with additional control constraints given through a closed convex admissible set  $Q_{\text{ad}} \subset Q$ . In the majority of practical cases this admissible set is described by inequality control constraints of box type  $q_- \leq q(x) \leq q_+$ . Therefore we will concentrate on this case, although our techniques may also be extended to the consideration of more general admissible sets  $Q_{\text{ad}}$ .

In this paper we consider optimization problems governed by (nonlinear) partial differential equations. The aim is to minimize a given cost functional  $J(q, u)$  which depends on the state variable  $u \in V$  and the control variable  $q \in Q$ , with Hilbert spaces  $V$  and  $Q$ . These variables have to satisfy the state equation

$$(1.1) \quad A(q, u) = f,$$

where  $A$  denotes a (nonlinear) differential operator and  $f$  represents the given data. The optimization problem is then formulated as follows:

$$(1.2) \quad \begin{cases} \text{Minimize } J(q, u), & u \in V, q \in Q_{\text{ad}}, \\ A(q, u) = f. \end{cases}$$

Constraints on the control are incorporated via the definition of the closed and convex set  $Q_{\text{ad}}$  representing the set of admissible controls.

For numerical treatment this infinite dimensional optimization problem is discretized in virtue of finite element methods; see the discussion in section 3. Let the solution to the discretized problem be denoted by  $(q_h, u_h)$ . Our aim is to derive a posteriori error estimates for the error between the solutions to the continuous and the discrete problem. A crucial point for our error analysis is the choice of a quantity, which describes the goal of the computation. If this quantity coincides with the cost functional, we have to estimate the error

$$J(q, u) - J(q_h, u_h).$$

In a more general case, we suppose  $I: Q \times V \rightarrow \mathbb{R}$  to be a given functional describing the quantity of interest. Then the error to be estimated is

$$I(q, u) - I(q_h, u_h).$$

The consideration of quantities of interest is important, for instance, in the context of parameter identification and model calibration problem; see [8] for an application of this concept to an optimization problem from computational fluid dynamics.

To the authors' knowledge this is the first article providing a posteriori error estimates with respect to a given functional for optimization problems with partial differential equations and subject to control constraints.

The paper is organized as follows. In the next section we describe the optimization problem under consideration, discuss necessary optimality conditions, and sketch the

solution algorithm on the continuous level. In section 3 we describe the discretization of the optimization problem in virtue of finite element methods. Section 4 is devoted to a posteriori error estimation. In sections 4.1 and 4.2 we derive two different error estimates for the error with respect to the cost functional  $J$ . The first error estimator is based on the optimality system involving a variational inequality, whereas the second one exploits Lagrange multipliers for the treatment of inequality constraints. Due to the fact that the optimal control  $q$  is not expected to be sufficiently smooth (due to inequality constraints), the approximation of (interpolation) weights involved in the error estimator cannot be treated in a usual way. To overcome this difficulty we exploit the projection formula (2.9) from the optimality conditions and propose an approximation on the (interpolation) weights using a postprocessing step (4.7), which is motivated by the considerations in [31]. In section 4.3 we provide an error estimator with respect to a given quantity of interest. To this end we utilize an additional (dual) linear-quadratic optimal control problem describing the sensitivity with respect to the quantity of interest. In the last section we present numerical examples to illustrate the behavior of our method.

**2. Optimization problem.** In this section we give a precise formulation of the optimization problem under consideration and describe necessary optimality conditions and the solution algorithm.

In order to deal with different types of optimization problems simultaneously, we seek the control variable  $q$  in the Hilbert space  $Q = L^2(\omega)$  with scalar product  $(\cdot, \cdot)$  and norm  $\|\cdot\|$ . Typically,  $\omega$  is a subset of the computational domain  $\Omega$  or a subset of its boundary  $\partial\Omega$ . The case of finite dimensional controls is realized by choosing  $\omega = \{1, 2, \dots, n\}$  resulting in  $Q \cong \mathbb{R}^n$ .

Throughout this paper we suppose that the state equation (1.1) for  $u \in V$  is given in a weak form:

$$(2.1) \quad a(q, u)(\varphi) = f(\varphi) \quad \forall \varphi \in V,$$

where  $a: Q \times V \times V \rightarrow \mathbb{R}$  is a four times directional differentiable form which is linear in the third argument and  $f$  is in the dual space  $V'$ . A possible choice for this space is  $V = H^1(\Omega)$ , or  $V = H_0^1(\Omega)$ , or a direct product of such spaces. In the presence of inhomogeneous Dirichlet boundary conditions, one seeks the state variable  $u$  in  $\hat{u} + V$ , where  $\hat{u}$  represents the boundary data. However, for clarity of notation, we assume throughout that  $\hat{u} = 0$ .

*Remark 2.1.* Throughout this paper we use two pairs of parentheses after a form to indicate that the form is linear in all variables enclosed by the second pair of parentheses, as seen in (2.1) for  $a(\cdot, \cdot)(\cdot)$ .

The cost function is given by

$$(2.2) \quad J(q, u) = J_1(u) + \frac{\alpha}{2} \|q\|^2,$$

where  $J_1$  is a four times directionally differentiable operator on  $V$  and  $\alpha > 0$ . Let the admissible set  $Q_{\text{ad}}$  be given through box constraints on  $q$ , i.e.,

$$(2.3) \quad Q_{\text{ad}} = \{q \in Q \mid q_- \leq q(x) \leq q_+ \text{ a.e. on } \omega\},$$

with bounds  $q_-, q_+ \in \mathbb{R} \cup \{\pm\infty\}$  and  $q_- < q_+$ .

Now we are able to formulate the optimization problem as

$$(2.4) \quad \text{Minimize } J(q, u), \quad u \in V, q \in Q_{\text{ad}}, \quad \text{subject to (2.1).}$$

*Remark 2.2.* The choice of constant bounds  $q_-, q_+ \in \mathbb{R} \cup \{\pm\infty\}$  is not a limitation, since one can transform an optimal control problem with bounds  $q_-, q_+ \in Q$  into an equivalent one with constant bounds for the control.

To shorten notation we introduce the space  $\mathcal{X}$  and the admissible set  $\mathcal{X}_{\text{ad}}$  by

$$(2.5) \quad \mathcal{X} = Q \times V \times V,$$

$$(2.6) \quad \mathcal{X}_{\text{ad}} = Q_{\text{ad}} \times V \times V.$$

In addition we shall write  $\xi = (q, u, z)$  for a vector in  $\mathcal{X}$  or  $\mathcal{X}_{\text{ad}}$ , where  $z$  will denote an adjoint state.

Throughout the paper we assume that the problem (2.4) admits a solution. Conditions ensuring the existence of solutions to optimal control problems may, for instance, be found in [16, 26, 34]. We shall especially assume that the primal and dual equations associated with (2.4) are solvable for every given  $q \in Q$ .

To establish an optimality system, we introduce the Lagrangian  $\mathcal{L}: \mathcal{X} \rightarrow \mathbb{R}$  as follows:

$$\mathcal{L}(\xi) = J_1(u) + \frac{\alpha}{2} \|q\|^2 + f(z) - a(q, u)(z),$$

where  $z$  denotes the dual variable. Due to the convexity of the admissible set  $Q_{\text{ad}}$ , the first-order necessary optimality condition for  $(q, u) \in Q_{\text{ad}} \times V$  reads as follows:

There exists  $z \in V$  such that the triple  $\xi = (q, u, z) \in \mathcal{X}_{\text{ad}}$  satisfies

$$(2.7a) \quad \mathcal{L}'_u(\xi)(\delta u) = 0 \quad \forall \delta u \in V,$$

$$(2.7b) \quad \mathcal{L}'_q(\xi)(\delta q - q) \geq 0 \quad \forall \delta q \in Q_{\text{ad}},$$

$$(2.7c) \quad \mathcal{L}'_z(\xi)(\delta z) = 0 \quad \forall \delta z \in V.$$

This system can be stated explicitly in the following form:

$$(2.8a) \quad J'_1(u)(\delta u) - a'_u(q, u)(\delta u, z) = 0 \quad \forall \delta u \in V,$$

$$(2.8b) \quad \alpha(q, \delta q - q) - a'_q(q, u)(\delta q - q, z) \geq 0 \quad \forall \delta q \in Q_{\text{ad}},$$

$$(2.8c) \quad f(\delta z) - a(q, u)(\delta z) = 0 \quad \forall \delta z \in V.$$

We introduce a projection operator  $\mathcal{P}_{Q_{\text{ad}}}: Q \rightarrow Q_{\text{ad}}$  by

$$\mathcal{P}_{Q_{\text{ad}}}(p) = \max(q_-, \min(p, q_+))$$

pointwise a.e. This allows us to rewrite variational inequality (2.8b) (see, e.g., [34]) as

$$(2.9) \quad q = \mathcal{P}_{Q_{\text{ad}}} \left( \frac{1}{\alpha} a'_q(q, u)(\cdot, z) \right),$$

where  $a'_q(u, q)(\cdot, z)$  is understood as a Riesz representative of a linear functional on  $Q$ .

For a solution  $(q, u)$  of (2.4) we introduce active sets  $\omega_-$  and  $\omega_+$  as follows:

$$(2.10) \quad \omega_- = \{x \in \omega \mid q(x) = q_-\},$$

$$(2.11) \quad \omega_+ = \{x \in \omega \mid q(x) = q_+\}.$$

Let  $\xi \in \mathcal{X}$  be a solution to (2.7); then we introduce an additional Lagrange multiplier  $\mu \in Q$  by the following identification:

$$(2.12) \quad (\mu, \delta q) = -\alpha(q, \delta q) + a'_q(q, u)(\delta q, z) = -\mathcal{L}'_q(\xi)(\delta q) \quad \forall \delta q \in Q.$$

The variational inequality (2.8b) or the projection formula (2.9) are known to be equivalent to the following conditions:

$$(2.13a) \quad \mu(x) \leq 0 \quad \text{a.e. on } \omega_-,$$

$$(2.13b) \quad \mu(x) \geq 0 \quad \text{a.e. on } \omega_+,$$

$$(2.13c) \quad \mu(x) = 0 \quad \text{a.e. on } \omega \setminus (\omega_- \cup \omega_+).$$

Using this representation of the optimality condition (2.8b) we apply nonlinear primal dual active set strategy (see, e.g., [9, 24]) to solve (2.4). In the following we sketch the corresponding algorithm on the continuous level.

**Nonlinear primal-dual active set strategy**

1. Choose initial guess  $q^0, \mu^0$  and  $c > 0$  and set  $n = 1$ .
2. While not converged
3. Determine the active sets  $\omega_+^n$  and  $\omega_-^n$ :

$$\omega_-^n = \{x \in \omega \mid q^{n-1}(x) + \mu^{n-1}(x)/c - q_- \leq 0\},$$

$$\omega_+^n = \{x \in \omega \mid q^{n-1}(x) + \mu^{n-1}(x)/c - q_+ \geq 0\}.$$

4. Solve the equality-constrained optimization problem

$$\text{Minimize} \quad J_1(u^n) + \frac{\alpha}{2} \|q^n\|^2, \quad u^n \in V, q^n \in Q,$$

subject to (2.1) and

$$q^n(x) = q_- \text{ on } \omega_-^n, \quad q^n(x) = q_+ \text{ on } \omega_+^n.$$

5. Set

$$\mu^n = -\alpha q^n + a'_q(q^n, u^n)(\cdot, z^n)$$

with adjoint variable  $z^n$ .

6. Set  $n = n + 1$  and go to 2.

*Remark 2.3.* The convergence in step 2 can be determined conveniently from agreement of the active sets in two consecutive iterations.

*Remark 2.4.* The algorithm above is known to be globally convergent for a class of optimal control problems if  $\alpha$  is sufficiently large; see, e.g., [9, 24]. Moreover, local superlinear convergence can be shown; see, e.g., [21].

In our practical realization, the equality-constrained optimization problem in step 4 is solved by Newton's method on the control space without assembling the Hessian. The finite element discretization of the optimization problem, described in the next section, allows us to directly translate these algorithms onto the discrete level.

As we will encounter some trouble with the variational inequality in the necessary optimality condition (2.8) due to missing Galerkin orthogonality, we consider in addition the full Lagrangian  $\tilde{\mathcal{L}}: \mathcal{X} \times Q \times Q \rightarrow \mathbb{R}$  which is given by

$$\tilde{\mathcal{L}}(\chi) = \mathcal{L}(\xi) + (\mu^-, q_- - q) + (\mu^+, q - q_+),$$

with  $\chi = (\xi, \mu^-, \mu^+) = (q, u, z, \mu^-, \mu^+) \in \mathcal{X} \times Q \times Q$ , where  $\mu^-$  and  $\mu^+$  denote the variables corresponding to Lagrange multipliers for the inequality constraints. To shorten notation we introduce the abbreviation

$$(2.14) \quad \mathcal{Y} = \mathcal{X} \times Q \times Q.$$

Using the subspaces

$$\begin{aligned} Q_- &= \{r \in Q \mid r = 0 \text{ a.e. on } \omega \setminus \omega_-\}, \\ Q_+ &= \{r \in Q \mid r = 0 \text{ a.e. on } \omega \setminus \omega_+\}, \end{aligned}$$

we introduce

$$(2.15) \quad \mathcal{Y}_{\text{ad}} = \mathcal{X}_{\text{ad}} \times Q_- \times Q_+,$$

$$(2.16) \quad \tilde{\mathcal{Y}}_{\text{ad}} = \mathcal{X} \times Q_- \times Q_+$$

and see that the following equality holds for all  $\chi \in \mathcal{Y}_{\text{ad}}$ :

$$(2.17) \quad \mathcal{L}(\xi) = \tilde{\mathcal{L}}(\chi).$$

We can rewrite the first-order necessary optimality condition for  $(q, u) \in Q_{\text{ad}} \times V$  equivalently as follows (cf. [34]):

There exist  $z \in V$ ,  $\mu^- \in Q_-$ ,  $\mu^+ \in Q_+$  such that the following conditions hold for  $\chi = (q, u, z, \mu^-, \mu^+) \in \mathcal{Y}_{\text{ad}}$ :

$$(2.18a) \quad \tilde{\mathcal{L}}'_u(\chi)(\delta u) = 0 \quad \forall \delta u \in V,$$

$$(2.18b) \quad \tilde{\mathcal{L}}'_q(\chi)(\delta q) = 0 \quad \forall \delta q \in Q,$$

$$(2.18c) \quad \tilde{\mathcal{L}}'_z(\chi)(\delta z) = 0 \quad \forall \delta z \in V,$$

$$(2.18d) \quad \tilde{\mathcal{L}}'_{\mu^-}(\chi)(\delta \mu^-) = 0 \quad \forall \delta \mu^- \in Q_-,$$

$$(2.18e) \quad \tilde{\mathcal{L}}'_{\mu^+}(\chi)(\delta \mu^+) = 0 \quad \forall \delta \mu^+ \in Q_+,$$

$$(2.18f) \quad \mu^+, \mu^- \geq 0 \quad \text{a.e. on } \omega.$$

It is easy to verify that the Lagrange multipliers  $\mu^+$  and  $\mu^-$  are given as the positive and negative part of the Lagrange multiplier  $\mu$  from (2.12); cf. [34].

Note that (2.18d), (2.18e) are equivalent to the complementarity conditions

$$(2.19) \quad \mu^-(q_- - q) = \mu^+(q - q_+) = 0 \quad \text{a.e. on } \omega.$$

For later use we recall a second-order sufficient optimality condition.

**LEMMA 2.1** (sufficient optimality condition). *Let  $\xi = (q, u, z) \in \mathcal{X}_{\text{ad}}$  satisfy the first-order necessary condition (2.7a)–(2.7c) of optimization problem (2.4). Moreover, let  $z \mapsto a'_u(q, u)(\cdot, z) : V \rightarrow V'$  be surjective. If there exists  $\rho > 0$  such that*

$$(2.20) \quad (\delta q, \delta u) \begin{bmatrix} \mathcal{L}''_{qq}(\xi)(\cdot, \cdot) & \mathcal{L}''_{qu}(\xi)(\cdot, \cdot) \\ \mathcal{L}''_{uq}(\xi)(\cdot, \cdot) & \mathcal{L}''_{uu}(\xi)(\cdot, \cdot) \end{bmatrix} \begin{pmatrix} \delta q \\ \delta u \end{pmatrix} \geq \rho (\|\delta u\|_V^2 + \|\delta q\|_Q^2)$$

*holds for all  $(\delta q, \delta u)$  satisfying the linear (tangent) partial differential equation*

$$(2.21) \quad a'_u(q, u)(\delta u, \varphi) + a'_q(q, u)(\delta q, \varphi) = 0 \quad \forall \varphi \in V,$$

*then  $(q, u)$  is a (strict) local solution to the optimization problem (2.4).*

We refer the reader to [29] for the proof.

*Remark 2.5.* Throughout the paper we exploit only first-order information. This means that the error estimators proposed in section 4 are applicable to all solutions of the optimality system (2.8) or (2.18), respectively.

For the convenience of the reader we list the assumptions made in the preceding section.

*Assumption 1.* The optimization problem (2.4) possesses a solution  $(q, u)$ . In addition there exists  $z \in V$  such that the first-order necessary conditions (2.8) are fulfilled by the triple  $(q, u, z)$ .

*Remark 2.6.* It is sufficient for the existence of  $z$  in the preceding assumption if the mapping  $z \mapsto a'_u(q, u)(\cdot, z)$  is surjective onto  $V'$ . This is one of the requirements in Lemma 2.1 and is fulfilled by all examples given in this article.

*Assumption 2.* The functional  $a(\cdot, \cdot)(\cdot) : Q \times V \times V \rightarrow \mathbb{R}$  defined in (2.1) is assumed to be four times directional differentiable.

*Assumption 3.* The functional  $J(\cdot, \cdot) : Q \times V \rightarrow \mathbb{R}$  defined in (2.2) is assumed to be four times directional differentiable.

*Assumption 4.* The functional  $I(\cdot, \cdot) : Q \times V \rightarrow \mathbb{R}$  mentioned in the introduction (see also (4.20)) is assumed to be three times directional differentiable.

**3. Finite element discretization.** In this section we discuss finite element discretization of the optimization problem (2.4).

To keep the following sections simple we restrain ourselves to the case of problems where  $H^1$ -conforming finite elements are satisfactory. However, the ideas can be adapted to other problems.

Let  $\mathcal{T}_h$  be a triangulation (mesh) of the computational domain  $\Omega$  consisting of closed cells  $K$  which are either triangles or quadrilaterals. The straight parts which make up the boundary  $\partial K$  of a cell  $K$  are called *faces*. The mesh parameter  $h$  is defined as a cellwise constant function by setting  $h|_K = h_K$ , and  $h_K$  is the diameter of  $K$ . The mesh  $\mathcal{T}_h$  is assumed to be shape regular. In order to ease the mesh refinement we allow the cells to have nodes, which lie on midpoints of faces of neighboring cells. But at most one of such *hanging nodes* is permitted per face.

On the mesh  $\mathcal{T}_h$  we define a finite element space  $V_h \subset V$  consisting of linear or bilinear shape functions; see, e.g., [14] or [10]. The case of hanging nodes requires some additional remarks. There are no degrees of freedom corresponding to these irregular nodes, and therefore the value of the finite element function is determined by pointwise interpolation. This implies continuity and therefore global conformity.

For the discretization of the optimization problem (2.4) we introduce an additional finite dimensional subspace  $Q_h \subset Q$  of the control space. Depending on the concrete situation there are different possible ways to choose the space  $Q_h$ . It is reasonable to set  $Q_h = Q$  if  $Q$  is finite dimensional. In the case where the control variable is a distributed function on the computational domain  $\Omega$ , i.e.,  $Q = L^2(\Omega)$ , one may choose  $Q_h$  as an analogue to  $V_h$  or consider  $Q_h$  as a space of cellwise constant functions on the mesh  $\mathcal{T}_h$ . A priori error analysis for the last two choices in the context of distributed (or boundary) elliptic optimal control problems can be found, e.g., in [1, 11, 15, 18, 28] for cellwise constant control or in [12, 32, 33] for continuous cellwise linear control. An approach without discretization of the control variable is presented in [22].

We denote a basis of  $Q_h$  by

$$(3.1) \quad \mathcal{B} = \{\psi_i\}, \text{ with } \psi_i \geq 0, \quad \sum_i \psi_i = 1, \quad \max_{x \in \omega} \psi_i(x) = 1.$$

*Remark 3.1.* It might be desirable to use different meshes for the control and the state variable in the case of distributed control. The error estimator presented below can provide information for separate refinement of the control and state meshes. One can split the error estimator into two parts, one containing the functionals on the space  $V$  which give information for the refinement of the state mesh and one part consisting of the functionals defined on the control space  $Q$  which give information for the refinement of the control mesh. The refinement then follows an equilibration strategy for both estimators; cf. [30].

The discrete admissible set  $Q_{\text{ad},h}$  is defined as

$$Q_{\text{ad},h} = Q_h \cap Q_{\text{ad}},$$

and the discretized optimization problem is formulated as follows:

$$(3.2) \quad \text{Minimize } J(q_h, u_h), \quad u_h \in V_h, \quad q_h \in Q_{\text{ad},h},$$

subject to

$$(3.3) \quad a(q_h, u_h)(v_h) = f(v_h) \quad \forall v_h \in V_h.$$

We introduce the discretized versions of (2.5) and (2.6) by

$$(3.4) \quad \mathcal{X}_h = Q_h \times V_h \times V_h,$$

$$(3.5) \quad \mathcal{X}_{\text{ad},h} = Q_{\text{ad},h} \times V_h \times V_h$$

and denote a vector from these sets by  $\xi_h = (q_h, u_h, z_h)$ . The optimality system for the discretized optimization problem is formulated as follows:

$$(3.6a) \quad J'_1(u_h)(\delta u_h) - a'_u(q_h, u_h)(\delta u_h, z_h) = 0 \quad \forall \delta u_h \in V_h,$$

$$(3.6b) \quad \alpha(q_h, \delta q_h - q_h) - a'_q(q_h, u_h)(\delta q_h - q_h, z_h) \geq 0 \quad \forall \delta q_h \in Q_{\text{ad},h},$$

$$(3.6c) \quad f(\delta z_h) - a(q_h, u_h)(\delta z_h) = 0 \quad \forall \delta z_h \in V_h.$$

The nonlinear primal dual active set strategy, described in the previous section, can be translated directly into the discrete level to solve (3.6a)–(3.6c).

In order to formulate the analog system to (2.18a)–(2.18f) we introduce discrete active sets  $\omega_{-,h}$  and  $\omega_{+,h}$  for a solution  $(q_h, u_h)$  to (3.2), (3.3) by

$$(3.7) \quad \omega_{-,h} = \{x \in \omega \mid q_h(x) = q_-\},$$

$$(3.8) \quad \omega_{+,h} = \{x \in \omega \mid q_h(x) = q_+\}$$

and define a Lagrange multiplier  $\mu_h \in Q_h$  via

$$(3.9) \quad (\mu_h, \delta q_h) = -\mathcal{L}'_q(q_h, u_h, z_h)(\delta q_h) \quad \forall \delta q_h \in Q_h.$$

Moreover, we introduce  $\mu_h^- \in Q_h$  and  $\mu_h^+ \in Q_h$  by

$$(3.10) \quad \mu_h^+ - \mu_h^- = \mu_h, \quad (\mu_h^-, \psi_i) \geq 0, \quad (\mu_h^+, \psi_i) \geq 0 \quad \forall \psi_i \in \mathcal{B}$$

by which  $\mu_h^\pm$  are uniquely determined if in addition the following complementarity conditions hold:

$$(3.11) \quad (\mu_h^-, q_h - q_-) = (\mu_h^+, q_+ - q_h) = 0.$$

*Remark 3.2.* This definition corresponds to the Lagrange multipliers obtained for the inequality constraints if the discrete optimization problem (3.2), (3.3) is considered a finite dimensional optimization problem for  $q_h = \sum_i q_i \psi_i \in Q_h$  with the following restrictions:

$$q_- \leq q_i \leq q_+ \quad \forall i.$$

Note that due to the choice of the basis  $\mathcal{B}$  in (3.1) this is equivalent to  $q_- \leq q_h(x) \leq q_+$  for all  $x \in \omega$ . Utilizing this fact, the discrete active sets  $\omega_{-,h}$ ,  $\omega_{+,h}$  are completely determined by the values of the coordinate vector of  $q_h$ . In particular they consist only of whole cells, edges, and nodes.

To obtain the complementarity conditions with respect to the  $Q = L^2(\omega)$ -inner product (3.11) one requires

$$(\mu_h^+, \psi_i) = 0 \text{ if } q_i < q_+ \text{ and } (\mu_h^-, \psi_i) = 0 \text{ if } q_i > q_-.$$

We now define the discretized versions of (2.14), (2.16), and (2.15) by

$$(3.12) \quad \mathcal{Y}_h = \mathcal{X}_h \times Q_h \times Q_h,$$

$$(3.13) \quad \mathcal{Y}_{\text{ad},h} = \mathcal{X}_{\text{ad},h} \times Q_{-,h} \times Q_{+,h},$$

$$(3.14) \quad \tilde{\mathcal{Y}}_{\text{ad},h} = \mathcal{X}_h \times Q_{-,h} \times Q_{+,h},$$

where

$$Q_{-,h} = \{r \in Q_h \mid r(x) = 0 \text{ a.e. on } \omega \setminus \omega_h^-\},$$

$$Q_{+,h} = \{r \in Q_h \mid r(x) = 0 \text{ a.e. on } \omega \setminus \omega_h^+\}.$$

A vector from these spaces will be abbreviated by  $\chi_h = (q_h, u_h, z_h, \mu_h^-, \mu_h^+)$ .

Using the definitions above we have the first-order necessary optimality condition for  $(q_h, u_h) \in Q_{\text{ad},h} \times V_h$ :

There exist  $z_h \in V_h$ ,  $\mu_h^- \in Q_{-,h}$ ,  $\mu_h^+ \in Q_{+,h}$  such that for  $\chi_h = (q_h, u_h, z_h, \mu_h^-, \mu_h^+) \in \mathcal{Y}_{\text{ad}}$  the following conditions hold:

$$(3.15a) \quad \tilde{\mathcal{L}}'_u(\chi_h)(\delta u) = 0 \quad \forall \delta u \in V_h,$$

$$(3.15b) \quad \tilde{\mathcal{L}}'_q(\chi_h)(\delta q) = 0 \quad \forall \delta q \in Q_h,$$

$$(3.15c) \quad \tilde{\mathcal{L}}'_z(\chi_h)(\delta z) = 0 \quad \forall \delta z \in V_h,$$

$$(3.15d) \quad \tilde{\mathcal{L}}'_{\mu^-}(\chi_h)(\delta \mu^-) = 0 \quad \forall \delta \mu^- \in Q_{-,h},$$

$$(3.15e) \quad \tilde{\mathcal{L}}'_{\mu^+}(\chi_h)(\delta \mu^+) = 0 \quad \forall \delta \mu^+ \in Q_{+,h},$$

$$(3.15f) \quad \mu_h^+ - \mu_h^- = \mu_h, \quad (\mu_h^-, \psi_i) \geq 0, \quad (\mu_h^+, \psi_i) \geq 0 \quad \forall \psi_i \in \mathcal{B}.$$

Here again (3.15d), (3.15e) are equivalent to the complementarity condition

$$(3.16) \quad (\mu_h^-, q_- - q_h) = (\mu_h^+, q_h - q_+) = 0.$$

Finally we state the following assumption concerning our discretization which is the analogue to Assumption 1.

*Assumption 5.* The optimization problem (3.2), (3.3) possesses a solution  $(q_h, u_h)$ . In addition there exists  $z_h \in V_h$  such the first-order necessary conditions (3.6) are fulfilled by the triple  $(q_h, u_h, z_h)$ .

**4. A posteriori error estimation.** The aim of this section is to derive a posteriori error estimates for the error with respect to the cost functional and to an arbitrary quantity of interest. These error estimates extend the results from [4, 6, 7, 8] to the case of optimization problems with control constraints. The provided estimators will be used within the following adaptive algorithm for error control and mesh refinement: We start on a coarse mesh, solve the discretized optimization problem, and evaluate the error estimator. Thereafter we refine the current mesh using local information obtained from the error estimator, allowing for efficient reduction of the discretization error with respect to the quantity of interest. This procedure is iterated until the value of the error estimator is below a given tolerance; see, e.g., [7] for a detailed description of this algorithm.

The section is structured as follows: First we will derive two a posteriori error estimators for the error with respect to the cost functional. The first one is based on the first-order necessary condition (2.8), which involves a variational inequality, and the second estimator uses the information obtained from the Lagrange multipliers for the inequality constraints. Both estimators can be evaluated in terms of the solution to the discretized optimization problem (3.2), (3.3). Then we will proceed with the error estimator with respect to an arbitrary quantity of interest, which requires the solution to an auxiliary linear-quadratic optimization problem. Even though the idea behind the estimators remains unchanged, the latter estimators require a more technical discussion.

Throughout this section we shall denote a solution to the optimization problem (2.4) by  $(q, u)$  and the corresponding solution to the optimality system (2.7) by  $\xi = (q, u, z) \in \mathcal{X}_{\text{ad}}$  and its discrete counterpart (3.6) by  $\xi_h = (q_h, u_h, z_h) \in \mathcal{X}_{\text{ad},h}$ . The corresponding solution to (2.18) and its discrete counterpart (3.15) will be abbreviated as  $\chi = (q, u, z, \mu^-, \mu^+) \in \mathcal{Y}_{\text{ad}}$  and  $\chi_h = (q_h, u_h, z_h, \mu_h^-, \mu_h^+) \in \mathcal{Y}_{\text{ad},h}$ .

**4.1. Error in the cost functional.** For the derivation of the error estimator with respect to the cost functional, we introduce the residual functionals  $\rho_u(\xi_h)(\cdot)$ ,  $\rho_z(\xi_h)(\cdot) \in V'$ , and  $\rho_q(\xi_h)(\cdot) \in Q'$  by

$$(4.1) \quad \rho_u(\xi_h)(\cdot) = f(\cdot) - a(q_h, u_h)(\cdot),$$

$$(4.2) \quad \rho_z(\xi_h)(\cdot) = J'_1(u_h)(\cdot) - a'_u(q_h, u_h)(\cdot, z_h),$$

$$(4.3) \quad \rho_q(\xi_h)(\cdot) = \alpha(q_h, \cdot) - a'_q(u_h, q_h)(\cdot, z_h).$$

The following theorem is an extension of the result from [6].

**THEOREM 4.1.** *Let  $\xi \in \mathcal{X}_{\text{ad}}$  be a solution to the first-order necessary system (2.7) and  $\xi_h \in \mathcal{X}_{\text{ad},h}$  be its Galerkin approximation (3.6). Then the following estimate holds:*

$$(4.4) \quad J(q, u) - J(q_h, u_h) \leq \frac{1}{2} \rho_u(\xi_h)(z - \tilde{z}_h) + \frac{1}{2} \rho_z(\xi_h)(u - \tilde{u}_h) + \frac{1}{2} \rho_q(\xi_h)(q - q_h) + R_1,$$

where  $\tilde{u}_h, \tilde{z}_h \in V_h$  are arbitrarily chosen and  $R_1$  is a remainder term given by

$$(4.5) \quad R_1 = \frac{1}{2} \int_0^1 \mathcal{L}'''(\xi_h + s(\xi - \xi_h))(\xi - \xi_h, \xi - \xi_h, \xi - \xi_h) s(s-1) ds.$$

*Proof.* From optimality system (2.7a)–(2.7c) we obtain that

$$J(q, u) = \mathcal{L}(\xi).$$

A similar equality holds on the discrete level. Therefore we have

$$J(q, u) - J(q_h, u_h) = \mathcal{L}(\xi) - \mathcal{L}(\xi_h) = \int_0^1 \mathcal{L}'(\xi_h + s(\xi - \xi_h))(\xi - \xi_h) ds.$$

We approximate this integral by the trapezoidal rule and obtain

$$(4.6) \quad J(q, u) - J(q_h, u_h) = \frac{1}{2} \mathcal{L}'(\xi)(\xi - \xi_h) + \frac{1}{2} \mathcal{L}'(\xi_h)(\xi - \xi_h) + R_1,$$

with the reminder term  $R_1$  as in (4.5). For the first term we have

$$\mathcal{L}'(\xi)(\xi - \xi_h) = \mathcal{L}'_u(\xi)(u - u_h) + \mathcal{L}'_z(\xi)(z - z_h) + \mathcal{L}'_q(\xi)(q - q_h).$$

Using optimality system (2.7a)–(2.7c) and the fact that  $q_h \in Q_{\text{ad},h} \subset Q_{\text{ad}}$ , we deduce that

$$\mathcal{L}'(\xi)(\xi - \xi_h) = -\mathcal{L}'_q(\xi)(q_h - q) \leq 0.$$

Rewriting the second term in (4.6) we obtain

$$\mathcal{L}'(\xi_h)(\xi - \xi_h) = \rho_u(\xi_h)(z - z_h) + \rho_z(\xi_h)(u - u_h) + \rho_q(\xi_h)(q - q_h).$$

Due to the Galerkin orthogonality for the state and adjoint equations, we have for arbitrary  $\tilde{u}_h, \tilde{z}_h \in V_h$

$$\rho_u(\xi_h)(z - z_h) = \rho_u(\xi_h)(z - \tilde{z}_h) \quad \text{and} \quad \rho_z(\xi_h)(u - u_h) = \rho_z(\xi_h)(u - \tilde{u}_h).$$

This completes the proof.  $\square$

*Remark 4.1.* We note that, in contrast to the terms involving the residuals of state and the adjoint equations, the error  $q - q_h$  in the term  $\rho_q(\xi_h)(q - q_h)$  in (4.4) cannot be replaced by  $q - \tilde{q}_h$  with an arbitrary  $\tilde{q}_h \in Q_{\text{ad},h}$ . This fact is caused by the control constraints. However, we may replace  $\rho_q(\xi_h)(q - q_h)$  by  $\rho_q(\xi_h)(q - q_h + \tilde{q}_h)$  with arbitrary  $\tilde{q}_h$  fulfilling  $\text{supp}(\tilde{q}_h) \subset \omega \setminus (\omega_{-,h} \cup \omega_{+,h})$  due to the structure of  $\rho_q(\xi_h)(\cdot)$ .

In order to use the estimate from the theorem above for computable error estimation we proceed as follows: First we choose  $\tilde{u}_h = i_h u$ ,  $\tilde{z}_h = i_h z$ , with an interpolation operator  $i_h: V \rightarrow V_h$ ; then we have to approximate the corresponding interpolation errors  $u - i_h u$  and  $z - i_h z$ . There are several heuristic techniques to do this; see, for instance, [6, 7]. Assume we have an operator  $\pi: V_h \rightarrow \tilde{V}_h$ , with  $\tilde{V}_h \neq V_h$ , such that  $u - \pi u_h$  has a better local asymptotical behavior as  $u - i_h u$ . Then we approximate

$$\rho_u(\xi_h)(z - i_h z) \approx \rho_u(\xi_h)(\pi z_h - z_h) \quad \text{and} \quad \rho_z(\xi_h)(u - i_h u) \approx \rho_z(\xi_h)(\pi u_h - u_h).$$

Such an operator can be constructed, for example, by the interpolation of the computed bilinear finite element solution in the space of biquadratic finite elements on patches of cells. For this operator the improved approximation property relies on local smoothness of  $u$  and superconvergence properties of the approximation  $u_h$ . The use of such “local higher-order approximation” is observed to work very successfully in the context of a posteriori error estimation; see, e.g., [6, 7].

The approximation of the term  $\rho_q(\xi_h)(q - q_h)$  requires more care. In contrast to the state  $u$  and the adjoint state  $z$ , the control variable  $q$  can generally not be approximated by “local higher-order approximation” for the following reasons:

- In the case of finite dimensional control space  $Q$ , there is no “patch-like” structure allowing for “local higher-order approximation.”

• If  $q$  is a distributed control, it typically does not possess sufficient smoothness (due to the inequality constraints) for the improved approximation property. We therefore suggest another approximation of  $\rho_q(\xi_h)(q - q_h)$  based on the projection formula (2.9). To this end we introduce  $\tilde{q} \in Q_{\text{ad}}$  by

$$(4.7) \quad \tilde{q} = \mathcal{P}_{Q_{\text{ad}}} \left( \frac{1}{\alpha} a'_q(q_h, \pi u_h)(\cdot, \pi z_h) \right).$$

In some cases one can show better approximation behavior of  $q - \tilde{q}$  in comparison with  $q - q_h$ ; see [31] and [22] for similar considerations in the context of a priori error analysis.

This construction results in the following computable a posteriori error estimator:

$$\eta_1 = \frac{1}{2} (\rho_u(\xi_h)(\pi z_h - z_h) + \rho_z(\xi_h)(\pi u_h - u_h) + \rho_q(\xi_h)(\tilde{q} - q_h)).$$

*Remark 4.2.* In order to use this error estimator as an indicator for mesh refinement, we have to localize it to cellwise or nodewise contributions. A direct localization of the terms like  $\rho_u(\xi_h)(\pi z_h - z_h)$  leads, in general, to the local contributions of wrong order (overestimation) due to oscillatory behavior of the residual terms. To overcome this, one may integrate the residual terms by part (see, e.g., [6]) or use a filtering operator; see [36] for details.

We should note that (4.4) does not provide an estimate for the absolute value of  $J(q, u) - J(q_h, u_h)$ , which is due to the inequality sign in (4.4). In the next section we will overcome this difficulty utilizing the alternative optimality system (2.18a)–(2.18f).

**4.2. Error in the cost functional reviewed.** In order to derive an error estimator for the absolute value of  $J(q, u) - J(q_h, u_h)$  we introduce the additional residual functionals  $\tilde{\rho}_q(\chi_h)(\cdot)$ ,  $\tilde{\rho}_{\mu^-}(\chi_h)(\cdot)$ ,  $\tilde{\rho}_{\mu^+}(\chi_h)(\cdot) \in Q'$  by

$$(4.8) \quad \tilde{\rho}_q(\chi_h)(\cdot) = \alpha(q_h, \cdot) - a'_q(q_h, u_h)(\cdot, z_h) + (\mu_h^+ - \mu_h^-, \cdot),$$

$$(4.9) \quad \tilde{\rho}_{\mu^-}(\chi_h)(\cdot) = (\cdot, q_- - q_h),$$

$$(4.10) \quad \tilde{\rho}_{\mu^+}(\chi_h)(\cdot) = (\cdot, q_h - q_+).$$

In what follows, the last two residual functional will also be evaluated in the point  $\chi$  where they read as follows:

$$\tilde{\rho}_{\mu^-}(\chi)(\cdot) = (\cdot, q_- - q), \quad \tilde{\rho}_{\mu^+}(\chi)(\cdot) = (\cdot, q - q_+).$$

Analogous to Theorem 4.1 we obtain the following theorem.

**THEOREM 4.2.** *Let  $\chi \in \mathcal{Y}_{\text{ad}}$  be a solution to the first-order necessary condition (2.18a)–(2.18f) and  $\chi_h \in \mathcal{Y}_{\text{ad},h}$  be its Galerkin approximation (3.15a)–(3.16). Then the following estimate holds:*

$$(4.11) \quad \begin{aligned} J(q, u) - J(q_h, u_h) = & \frac{1}{2} \rho_u(\chi_h)(z - \tilde{z}_h) + \frac{1}{2} \rho_z(\chi_h)(u - \tilde{u}_h) + \frac{1}{2} \tilde{\rho}_q(\chi_h)(q - \tilde{q}_h) \\ & + \frac{1}{2} \tilde{\rho}_{\mu^-}(\chi_h)(\mu^- - \tilde{\mu}_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\chi_h)(\mu^+ - \tilde{\mu}_h^+) \\ & + \frac{1}{2} \tilde{\rho}_{\mu^-}(\chi)(\tilde{\mu}^- - \mu_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\chi)(\tilde{\mu}^+ - \mu_h^+) + R_2, \end{aligned}$$

where  $\tilde{u}_h, \tilde{z}_h \in V_h$ ,  $\tilde{q}_h \in Q_h$ ,  $\tilde{\mu}_h^- \in Q_{-,h}$ ,  $\tilde{\mu}_h^+ \in Q_{+,h}$ ,  $\tilde{\mu}^- \in Q_-$ ,  $\tilde{\mu}^+ \in Q_+$  are arbitrarily chosen and  $R_2$  is a remainder term given by

$$(4.12) \quad R_2 = \frac{1}{2} \int_0^1 \tilde{\mathcal{L}}'''(\chi_h + s(\chi - \chi_h))(\chi - \chi_h, \chi - \chi_h, \chi - \chi_h) s(s-1) ds.$$

*Proof.* From (2.17) and optimality system (2.8a)–(2.8c) we obtain

$$J(q, u) = \mathcal{L}(\xi) = \tilde{\mathcal{L}}(\chi).$$

The analog result holds on the discrete level. We therefore have

$$J(q, u) - J(q_h, u_h) = \tilde{\mathcal{L}}(\chi) - \tilde{\mathcal{L}}(\chi_h) = \int_0^1 \tilde{\mathcal{L}}'(\chi_h + s(\chi - \chi_h))(\chi - \chi_h) ds.$$

As in the proof of Theorem 4.1 we approximate this integral by the trapezoidal rule and obtain

$$(4.13) \quad J(q, u) - J(q_h, u_h) = \frac{1}{2} \tilde{\mathcal{L}}'(\chi)(\chi - \chi_h) + \frac{1}{2} \tilde{\mathcal{L}}'(\chi_h)(\chi - \chi_h) + R_2,$$

with the remainder term  $R_2$  as in (4.12). For the first term we have

$$\begin{aligned} \tilde{\mathcal{L}}'(\chi)(\chi - \chi_h) &= \tilde{\mathcal{L}}'_u(\chi)(u - u_h) + \tilde{\mathcal{L}}'_z(\chi)(z - z_h) + \tilde{\mathcal{L}}'_q(\chi)(q - q_h) \\ &\quad + \tilde{\mathcal{L}}'_{\mu^-}(\chi)(\mu^- - \mu_h^-) + \tilde{\mathcal{L}}'_{\mu^+}(\chi)(\mu^+ - \mu_h^+). \end{aligned}$$

Using optimality system (2.18a)–(2.18f) we deduce that

$$\tilde{\mathcal{L}}'(\chi)(\chi - \chi_h) = \tilde{\mathcal{L}}'_{\mu^-}(\chi)(\mu^- - \mu_h^-) + \tilde{\mathcal{L}}'_{\mu^+}(\chi)(\mu^+ - \mu_h^+).$$

From (2.18d) and (2.18e) together with linearity of  $\tilde{\mathcal{L}}'_{\mu^-}(\chi)(\cdot)$  and  $\tilde{\mathcal{L}}'_{\mu^+}(\chi)(\cdot)$  we obtain that for arbitrary  $\tilde{\mu}^- \in Q_-$  and  $\tilde{\mu}^+ \in Q_+$

$$\tilde{\mathcal{L}}'_{\mu^-}(\chi)(\mu^- - \mu_h^-) = \tilde{\mathcal{L}}'_{\mu^-}(\chi)(\tilde{\mu}^- - \mu_h^-), \quad \tilde{\mathcal{L}}'_{\mu^+}(\chi)(\mu^+ - \mu_h^+) = \tilde{\mathcal{L}}'_{\mu^+}(\chi)(\tilde{\mu}^+ - \mu_h^+)$$

holds, and thus we obtain

$$\tilde{\mathcal{L}}'(\chi)(\chi - \chi_h) = \tilde{\rho}_{\mu^-}(\chi)(\tilde{\mu}^- - \mu_h^-) + \tilde{\rho}_{\mu^+}(\chi)(\tilde{\mu}^+ - \mu_h^+).$$

Rewriting the second term in (4.13) we obtain

$$\begin{aligned} \tilde{\mathcal{L}}'(\chi_h)(\chi - \chi_h) &= \rho_u(\chi_h)(u - u_h) + \rho_z(\chi_h)(z - z_h) + \tilde{\rho}_q(\chi_h)(q - q_h) \\ &\quad + \tilde{\rho}_{\mu^-}(\chi_h)(\mu^- - \mu_h^-) + \tilde{\rho}_{\mu^+}(\chi_h)(\mu^+ - \mu_h^+), \end{aligned}$$

where we can use linearity of the residual functionals in the second argument and (3.15a)–(3.15c) to obtain the following equalities:

$$(4.14) \quad \rho_u(\chi_h)(u - u_h) = \rho_u(\chi_h)(u - \tilde{u}_h),$$

$$(4.15) \quad \rho_z(\chi_h)(z - z_h) = \rho_z(\chi_h)(z - \tilde{z}_h),$$

$$(4.16) \quad \tilde{\rho}_q(\chi_h)(q - q_h) = \tilde{\rho}_q(\chi_h)(q - \tilde{q}_h)$$

for arbitrary  $\tilde{u}_h, \tilde{z}_h \in V_h$ ,  $\tilde{q}_h \in Q_h$ . Additionally we gain from (3.15d) and (3.15e) that for arbitrary  $\tilde{\mu}_h^- \in Q_{-,h}$  and  $\tilde{\mu}_h^+ \in Q_{+,h}$

$$(4.17) \quad \tilde{\rho}_{\mu^-}(\chi_h)(\mu^- - \mu_h^-) = \tilde{\rho}_{\mu^-}(\chi_h)(\mu^- - \tilde{\mu}_h^-),$$

$$(4.18) \quad \tilde{\rho}_{\mu^+}(\chi_h)(\mu^+ - \mu_h^+) = \tilde{\rho}_{\mu^+}(\chi_h)(\mu^+ - \tilde{\mu}_h^+)$$

holds. This completes the proof.  $\square$

To gain a computable error estimator we proceed as in the previous section. In order to deal with the new residual functionals we utilize (2.12) and construct an approximation for  $\mu$  by

$$(4.19) \quad \tilde{\mu} = -\alpha\tilde{q} + a'_q(\tilde{q}, \pi u_h)(\cdot, \pi z_h),$$

where  $\tilde{q}$  is given by (4.7). This leads to a computable a posteriori error estimator:

$$\begin{aligned} \eta_2 = & \frac{1}{2}(\rho_u(\chi_h)(\pi z_h - z_h) + \rho_z(\chi_h)(\pi u_h - u_h) + \tilde{\rho}_q(\chi_h)(\tilde{q} - q_h), \\ & \tilde{\rho}_{\mu^-}(\chi_h)(\tilde{\mu}^- - \mu_h^-) + \tilde{\rho}_{\mu^+}(\chi_h)(\tilde{\mu}^+ - \mu_h^+), \\ & \tilde{\rho}_{\mu^-}(\tilde{\chi})(\tilde{\mu}^- - \mu_h^-) + \tilde{\rho}_{\mu^+}(\tilde{\chi})(\tilde{\mu}^+ - \mu_h^+)). \end{aligned}$$

*Remark 4.3.* We note that the a posteriori error estimates derived in Theorems 4.1 and 4.2 coincide if the control constraints are inactive, e.g., if  $Q_{\text{ad}} = Q$ . Moreover, if the active sets are approximated from outside, i.e.,  $\omega_- \subset \omega_{-,h}$  and  $\omega_+ \subset \omega_{+,h}$ , these error estimators coincide as well.

**4.3. Error in the quantity of interest.** The aim of this section is the derivation of an error estimator for the error

$$(4.20) \quad I(q, u) - I(q_h, u_h)$$

with a given functional  $I : Q \times V \rightarrow \mathbb{R}$  describing the quantity of interest which we require to be three times directional differentiable. To this end we consider an additional Lagrangian  $\mathcal{M} : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$  defined by

$$(4.21) \quad \mathcal{M}(\chi)(\psi) = I(q, u) + \tilde{\mathcal{L}}'(\chi)(\psi),$$

where we abbreviate  $\chi = (q, u, z, \mu^-, \mu^+)$  and  $\psi = (p, v, y, \nu^-, \nu^+)$ . Here  $(p, v, y, \nu^-, \nu^+)$  will be variables dual to  $(q, u, z, \mu^-, \mu^+)$ . Note that for the solution  $\chi$  to the optimality system (2.18a)–(2.18f) of the optimization problem (2.4) the identity

$$(4.22) \quad \mathcal{M}(\chi)(\psi) = I(q, u)$$

holds for all  $\psi \in \tilde{\mathcal{Y}}_{\text{ad}}$ . To proceed as in the proof of Theorem 4.2 it remains to find  $\psi \in \tilde{\mathcal{Y}}_{\text{ad}}$  such that  $(\chi, \psi)$  is a stationary point of  $\mathcal{M}$  on  $\tilde{\mathcal{Y}}_{\text{ad}} \times \tilde{\mathcal{Y}}_{\text{ad}}$ .

Therefore we consider the auxiliary (linear-quadratic) optimization problem

$$(4.23) \quad \text{Minimize } K(\chi, p, v), \quad p \in P_{\text{ad}}, v \in V,$$

$$(4.24) \quad \text{subject to } \tilde{\mathcal{L}}''_{uz}(\chi)(v, \varphi) + \tilde{\mathcal{L}}''_{qz}(\chi)(p, \varphi) = 0 \quad \forall \varphi \in V$$

for given  $\chi \in \mathcal{Y}$ . The admissible set  $P_{\text{ad}}$  is given as

$$(4.25) \quad P_{\text{ad}} = \{p \in Q \mid p_-(x) \leq p(x) \leq p_+(x) \text{ a.e. on } \omega\},$$

with the bounds

$$\begin{aligned} p_-(x) &= \begin{cases} 0, & \mu(x) \neq 0 \text{ or } q(x) = q_-(x), \\ -\infty & \text{else,} \end{cases} \\ p_+(x) &= \begin{cases} 0, & \mu(x) \neq 0 \text{ or } q(x) = q_+(x), \\ +\infty & \text{else,} \end{cases} \end{aligned}$$

and the cost functional  $K : \mathcal{Y} \times Q \times V \rightarrow \mathbb{R}$  is defined via

$$(4.26) \quad K(\chi, p, v) = I'_u(q, u)(v) + I'_q(q, u)(p) + \tilde{\mathcal{L}}''_{uq}(\chi)(v, p) + \frac{1}{2}\tilde{\mathcal{L}}''_{uu}(\chi)(v, v) + \frac{1}{2}\tilde{\mathcal{L}}''_{qq}(\chi)(p, p).$$

We introduce the following abbreviation for later use:

$$(4.27) \quad \bar{\mathcal{Y}}_{\text{ad}} = P_{\text{ad}} \times V \times V \times Q_- \times Q_+.$$

*Remark 4.4.* Consideration of the auxiliary optimization problem (4.23), (4.24) is motivated by the unconstrained case  $Q_{\text{ad}} = Q$ . There the stationary point of  $\mathcal{M}$  is given as the solution to (4.23), (4.24) with  $P_{\text{ad}} = Q$ . A similar linear-quadratic optimization problem is considered in [19] in the context of sensitivity analysis.

*Remark 4.5.* If we assume that the second-order sufficient condition from Lemma 2.1 holds, the linear-quadratic optimization problem (4.23) possesses a solution. This is the case, as the quadratic part  $\tilde{\mathcal{L}}''_{uq}(\chi)(v, p) + \frac{1}{2}\tilde{\mathcal{L}}''_{uu}(\chi)(v, v) + \frac{1}{2}\tilde{\mathcal{L}}''_{qq}(\chi)(p, p)$  of  $K(p, v)$  is positive definite (see (2.20)) for all solutions to the linear equation (2.21), which is exactly the same as (4.24).

We introduce an auxiliary Lagrangian  $\mathcal{N} : \mathcal{Y} \times \mathcal{X} \rightarrow \mathbb{R}$  for (4.23), (4.24) by

$$(4.28) \quad \mathcal{N}(\chi, p, v, y) = K(\chi, p, v) + \tilde{\mathcal{L}}''_{uz}(\chi)(v, y) + \tilde{\mathcal{L}}''_{qz}(\chi)(p, y).$$

For a solution  $(p, v)$  to (4.23), (4.24) the following first-order necessary condition holds:

There exists  $y \in V$  such that

$$(4.29a) \quad \mathcal{N}'_y(\chi, p, v, y)(\delta y) = 0 \quad \forall \delta y \in V,$$

$$(4.29b) \quad \mathcal{N}'_v(\chi, p, v, y)(\delta v) = 0 \quad \forall \delta v \in V,$$

$$(4.29c) \quad \mathcal{N}'_p(\chi, p, v, y)(\delta p - p) \geq 0 \quad \forall \delta p \in P_{\text{ad}}$$

or, if written more explicitly,

$$(4.30a) \quad \tilde{\mathcal{L}}''_{uz}(\chi)(v, \delta y) + \tilde{\mathcal{L}}''_{qz}(\chi)(p, \delta y) = 0 \quad \forall \delta y \in V,$$

$$(4.30b) \quad I'_u(q, u)(\delta v) + \tilde{\mathcal{L}}''_{uq}(\chi)(\delta v, p) + \tilde{\mathcal{L}}''_{uu}(\chi)(\delta v, v) + \tilde{\mathcal{L}}''_{uz}(\chi)(\delta v, y) = 0 \quad \forall \delta v \in V,$$

$$(4.30c) \quad I'_q(q, u)(\delta p) + \tilde{\mathcal{L}}''_{uq}(\chi)(v, \delta p) + \tilde{\mathcal{L}}''_{qq}(\chi)(\delta p, p) + \tilde{\mathcal{L}}''_{qz}(\chi)(\delta p, y) \geq 0 \quad \forall \delta p \in P_{\text{ad}} - p.$$

Again we can introduce the full Lagrangian  $\tilde{\mathcal{N}} : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$  by

$$(4.31) \quad \tilde{\mathcal{N}}(\chi, \psi) = \mathcal{N}(\chi, p, v, y) + (\nu^-, p_- - p) + (\nu^+, p - p_+).$$

As in (2.18a)–(2.18f) we can rewrite the necessary optimality condition for  $\psi \in \bar{\mathcal{Y}}_{\text{ad}}$  as

$$(4.32a) \quad \tilde{\mathcal{N}}'_v(\chi, \psi)(\delta v) = 0 \quad \forall \delta v \in V,$$

$$(4.32b) \quad \tilde{\mathcal{N}}'_p(\chi, \psi)(\delta p) = 0 \quad \forall \delta p \in Q,$$

$$(4.32c) \quad \tilde{\mathcal{N}}'_y(\chi, \psi)(\delta y) = 0 \quad \forall \delta y \in V,$$

$$(4.32d) \quad \tilde{\mathcal{N}}'_{\nu^-}(\chi, \psi)(\delta \nu^-) = 0 \quad \forall \delta \nu^- \in Q_-,$$

$$(4.32e) \quad \tilde{\mathcal{N}}'_{\nu^+}(\chi, \psi)(\delta \nu^+) = 0 \quad \forall \delta \nu^+ \in Q_+,$$

$$(4.32f) \quad \nu^+ - \nu^- = \nu, \quad \nu^-(p_- - p) = \nu^+(p - p_+) = 0 \quad \text{a.e. on } \omega,$$

$$(4.32g) \quad \text{supp } \nu^+ \subseteq \omega \setminus \{x \in \omega \mid q = q_- \text{ and } \mu \neq 0\}, \quad \nu^+ \geq 0, \quad \text{a.e. where } \mu = 0,$$

$$(4.32h) \quad \text{supp } \nu^- \subseteq \omega \setminus \{x \in \omega \mid q = q_+ \text{ and } \mu \neq 0\}, \quad \nu^- \geq 0, \quad \text{a.e. where } \mu = 0,$$

where  $\nu^-$  and  $\nu^+$  are given by the following relations depending on  $\nu = -\mathcal{N}'_p(\chi, p, v, y)(\cdot)$ :

$$\nu^+(x) = \begin{cases} \nu, & q(x) = q_+ \text{ and } \mu(x) \neq 0, \\ 0, & q(x) = q_- \text{ and } \mu(x) \neq 0, \\ \max(0, \nu) & \text{else,} \end{cases}$$

$$\nu^-(x) = \begin{cases} \nu, & q(x) = q_- \text{ and } \mu(x) \neq 0, \\ 0, & q(x) = q_+ \text{ and } \mu(x) \neq 0, \\ \max(0, -\nu) & \text{else.} \end{cases}$$

Note that due to the choice of  $p_-$  and  $p_+$  the Lagrange multipliers are contained in the desired spaces, e.g.,  $\nu^- \in Q_-$  and  $\nu^+ \in Q_+$ .

*Remark 4.6.* It should be noted that we use the convention  $\pm\infty \cdot 0 = 0$  in (4.31), (4.32f) to ease notation. The same convention will be used throughout this section.

*Remark 4.7.* The condition (4.32g) arises naturally, as  $\nu^+$  is the Lagrange multiplier which corresponds to the equality and inequality constraints for  $p$  that are induced by the active upper control bound  $q_+$ . Similarly (4.32h) arises from the active lower control bound  $q_-$ .

We introduce

$$(4.33) \quad \bar{\mathcal{Y}}_{\text{ad},h} = P_{\text{ad},h} \times V_h \times V_h \times Q_{-,h} \times Q_{+,h}$$

to shorten notation. This is discretized using the discretized admissible set

$$(4.34) \quad P_{\text{ad},h} = \{p \in Q_h \mid p_{h,-}(x) \leq p(x) \leq p_{h,+}(x) \text{ a.e. on } \omega\},$$

with the bounds

$$p_{h,-}(x) = \begin{cases} 0, & \mu_h(x) \neq 0 \text{ or } q_h(x) = q_-(x), \\ -\infty & \text{else,} \end{cases}$$

$$p_{h,+}(x) = \begin{cases} 0, & \mu_h(x) \neq 0 \text{ or } q_h(x) = q_+(x), \\ +\infty & \text{else.} \end{cases}$$

Then the following first-order condition holds with the discretized full Lagrangian:

$$\tilde{\mathcal{N}}_h(\chi, \psi) = \mathcal{N}(\chi, p, v, y) + (\nu^-, p_{h,-} - p) + (\nu^+, p - p_{h,+}),$$

where  $\tilde{\mathcal{N}}_h : \mathcal{Y} \times \mathcal{Y} \rightarrow \mathbb{R}$ . There exist  $y_h \in V_h$ ,  $\nu_h^+, \nu_h^- \in Q_h$  such that for  $\psi_h = (p_h, v_h, y_h, \nu_h^-, \nu_h^+) \in \bar{\mathcal{Y}}_{ad,h}$  the following hold:

$$(4.35a) \quad \tilde{\mathcal{N}}'_{h,v}(\chi_h, \psi_h)(\delta v) = 0 \quad \forall \delta v \in V_h,$$

$$(4.35b) \quad \tilde{\mathcal{N}}'_{h,p}(\chi_h, \psi_h)(\delta p) = 0 \quad \forall \delta p \in Q_h,$$

$$(4.35c) \quad \tilde{\mathcal{N}}'_{h,y}(\chi_h, \psi_h)(\delta y) = 0 \quad \forall \delta y \in V_h,$$

$$(4.35d) \quad \tilde{\mathcal{N}}'_{h,\nu^-}(\chi_h, \psi_h)(\delta \nu^-) = 0 \quad \forall \delta \nu^- \in Q_{-,h},$$

$$(4.35e) \quad \tilde{\mathcal{N}}'_{h,\nu^+}(\chi_h, \psi_h)(\delta \nu^+) = 0 \quad \forall \delta \nu^+ \in Q_{+,h},$$

$$(4.35f) \quad \nu_h^+ - \nu_h^- = \nu_h \quad (\nu_h^-, p_{h,-} - p_h) = (\nu_h^+, p_h - p_{h,+}) = 0,$$

$$(4.35g) \quad (\nu_h^+, \psi_i) = 0 \quad \forall i : (\mu_h, \psi_i) \neq 0 \text{ and } q_i = q_-,$$

$$(4.35h) \quad (\nu_h^+, \psi_i) \geq 0 \quad \forall i : (\mu_h, \psi_i) = 0,$$

$$(4.35i) \quad (\nu_h^-, \psi_i) = 0 \quad \forall i : (\mu_h, \psi_i) \neq 0 \text{ and } q_i = q_+,$$

$$(4.35j) \quad (\nu_h^-, \psi_i) \geq 0 \quad \forall i : (\mu_h, \psi_i) = 0.$$

For the error estimator with respect to the quantity of interest we introduce the residual functionals  $\tilde{\rho}_v(\chi_h, \psi_h)(\cdot)$ ,  $\tilde{\rho}_y(\chi_h, \psi_h)(\cdot) \in V'$  and  $\tilde{\rho}_p(\chi_h, \psi_h)(\cdot)$ ,  $\tilde{\rho}_{\nu^-}(\chi_h, \psi_h)(\cdot)$ ,  $\tilde{\rho}_{\nu^+}(\chi_h, \psi_h)(\cdot) \in Q'$  by

$$(4.36) \quad \tilde{\rho}_v(\chi_h, \psi_h)(\cdot) = \tilde{\mathcal{L}}''_{zu}(\chi_h)(\cdot, v_h) + \tilde{\mathcal{L}}''_{zq}(\chi_h)(\cdot, p_h),$$

$$(4.37) \quad \begin{aligned} \tilde{\rho}_y(\chi_h, \psi_h)(\cdot) &= I'_u(q_h, u_h)(\cdot) + \tilde{\mathcal{L}}''_{uu}(\chi_h)(\cdot, v_h) + \tilde{\mathcal{L}}''_{uz}(\chi_h)(\cdot, y_h) \\ &\quad + \tilde{\mathcal{L}}''_{uq}(\chi_h)(\cdot, p_h), \end{aligned}$$

$$(4.38) \quad \begin{aligned} \tilde{\rho}_p(\chi_h, \psi_h)(\cdot) &= I'_q(q_h, u_h)(\cdot) + \tilde{\mathcal{L}}''_{qu}(\chi_h)(\cdot, v_h) + \tilde{\mathcal{L}}''_{qz}(\chi_h)(\cdot, y_h) \\ &\quad + \tilde{\mathcal{L}}''_{qq}(\chi_h)(\cdot, p_h) + (\cdot, \nu_h), \end{aligned}$$

$$(4.39) \quad \tilde{\rho}_{\nu^-}(\chi_h, \psi_h)(\cdot) = -(\cdot, p_h),$$

$$(4.40) \quad \tilde{\rho}_{\nu^+}(\chi_h, \psi_h)(\cdot) = (\cdot, p_h),$$

in addition to the already defined residual functionals (4.1)–(4.10). Again the last two residual functionals also have to be evaluated in the point  $(\chi, \psi)$  where they read as follows:

$$\tilde{\rho}_{\nu^-}(\chi, \psi)(\cdot) = -(\cdot, p), \quad \tilde{\rho}_{\nu^+}(\chi, \psi)(\cdot) = (\cdot, p).$$

**THEOREM 4.3.** *Let  $\chi \in \mathcal{Y}_{ad}$  be a solution to the necessary optimality condition (2.18) and  $\chi_h \in \mathcal{Y}_{ad,h}$  be its Galerkin approximation (3.15). In addition let  $\psi \in \bar{\mathcal{Y}}_{ad}$  be a solution to the necessary optimality condition (4.32) of the auxiliary optimization problem (4.23), (4.24) and  $\psi_h \in \bar{\mathcal{Y}}_{ad,h}$  be its discrete approximation (4.35). Then the*

following estimate holds:

(4.41)

$$\begin{aligned}
 I(q, u) - I(q_h, u_h) = & \frac{1}{2} \rho_u(\chi_h)(y - \tilde{y}_h) + \frac{1}{2} \rho_z(\chi_h)(v - \tilde{v}_h) + \frac{1}{2} \tilde{\rho}_q(\chi_h)(p - \tilde{p}_h) \\
 & + \frac{1}{2} \tilde{\rho}_{\mu^-}(\chi_h)(\nu^- - \tilde{\nu}_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\chi_h)(\nu^+ - \tilde{\nu}_h^+) \\
 & + \frac{1}{2} \tilde{\rho}_v(\chi_h, \psi_h)(z - \tilde{z}_h) + \frac{1}{2} \tilde{\rho}_y(\chi_h, \psi_h)(u - \tilde{u}_h) + \frac{1}{2} \tilde{\rho}_p(\chi_h, \psi_h)(q - \tilde{q}_h) \\
 & + \frac{1}{2} \tilde{\rho}_{\nu^-}(\chi_h, \psi_h)(\mu^- - \tilde{\mu}_h^-) + \frac{1}{2} \tilde{\rho}_{\nu^+}(\chi_h, \psi_h)(\mu^+ - \tilde{\mu}_h^+) \\
 & + \frac{1}{2} \tilde{\rho}_{\mu^-}(\chi)(\tilde{\nu}^- - \nu_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\chi)(\tilde{\nu}^+ - \nu_h^+) \\
 & + \frac{1}{2} \tilde{\rho}_{\nu^-}(\chi, \psi)(\tilde{\mu}^- - \mu_h^-) + \frac{1}{2} \tilde{\rho}_{\nu^+}(\chi, \psi)(\tilde{\mu}^+ - \mu_h^+) + R_3,
 \end{aligned}$$

where  $\tilde{u}_h, \tilde{v}_h, \tilde{z}_h, \tilde{y}_h \in V_h, \tilde{q}_h, \tilde{p}_h \in Q_h, \tilde{\mu}_h^-, \tilde{\nu}_h^- \in Q_{-,h}, \tilde{\mu}_h^+, \tilde{\nu}_h^+ \in Q_{+,h}$  as well as  $\tilde{\mu}^-, \tilde{\nu}^- \in Q_-, \tilde{\mu}^+, \tilde{\nu}^+ \in Q_+$  are arbitrarily chosen and  $R_3$  is a remainder term given by

$$(4.42) \quad R_3 = \frac{1}{2} \int_0^1 \mathcal{M}'''((\chi_h, \psi_h) + se)(e, e, e)s(s-1) ds,$$

with  $e = (\chi - \chi_h, \psi - \psi_h)$ .

*Proof.* From (4.22) and the analog discrete result we obtain

$$I(q, u) - I(q_h, u_h) = \mathcal{M}(\chi, \psi) - \mathcal{M}(\chi_h, \psi_h) = \int_0^1 \mathcal{M}'((\chi_h, \psi_h) + se)(e) ds.$$

Approximation by the trapezoidal rule gives

$$(4.43) \quad I(q, u) - I(q_h, u_h) = \frac{1}{2} \mathcal{M}'(\chi, \psi)(e) + \frac{1}{2} \mathcal{M}'(\chi_h, \psi_h)(e) + R_3,$$

with the remainder term  $R_3$  as in (4.42). For the first term we have

$$\begin{aligned}
 \mathcal{M}'(\chi, \psi)(e) = & \mathcal{M}'_u(\chi, \psi)(u - u_h) + \mathcal{M}'_v(\chi, \psi)(v - v_h) \\
 & + \mathcal{M}'_z(\chi, \psi)(z - z_h) + \mathcal{M}'_y(\chi, \psi)(y - y_h) \\
 & + \mathcal{M}'_q(\chi, \psi)(q - q_h) + \mathcal{M}'_p(\chi, \psi)(p - p_h) \\
 & + \mathcal{M}'_{\mu^-}(\chi, \psi)(\mu^- - \mu_h^-) + \mathcal{M}'_{\nu^-}(\chi, \psi)(\nu^- - \nu_h^-) \\
 & + \mathcal{M}'_{\mu^+}(\chi, \psi)(\mu^+ - \mu_h^+) + \mathcal{M}'_{\nu^+}(\chi, \psi)(\nu^+ - \nu_h^+).
 \end{aligned}$$

Using the identities

$$\begin{aligned}
 \mathcal{M}'_u(\chi, \psi)(\cdot) &= \tilde{\mathcal{N}}'_v(\chi, p, v, y)(\cdot), & \mathcal{M}'_v(\chi, \psi)(\cdot) &= \tilde{\mathcal{L}}'_u(\chi)(\cdot), \\
 \mathcal{M}'_z(\chi, \psi)(\cdot) &= \tilde{\mathcal{N}}'_y(\chi, p, v, y)(\cdot), & \mathcal{M}'_y(\chi, \psi)(\cdot) &= \tilde{\mathcal{L}}'_z(\chi)(\cdot), \\
 \mathcal{M}'_q(\chi, \psi)(\cdot) &= \tilde{\mathcal{N}}'_p(\chi, p, v, y)(\cdot), & \mathcal{M}'_p(\chi, \psi)(\cdot) &= \tilde{\mathcal{L}}'_q(\chi)(\cdot),
 \end{aligned}$$

we see that the first six terms on the right-hand side vanish due to (2.18a)–(2.18c) and (4.32a)–(4.32c). Furthermore we see from (2.18d), (2.18e) and (4.32d), (4.32e)

that with arbitrary  $\tilde{\mu}^-, \tilde{\nu}^- \in Q_-$  and  $\tilde{\mu}^+, \tilde{\nu}^+ \in Q_+$  the following identities hold:

$$(4.44) \quad \mathcal{M}'_{\mu^-}(\chi, \psi)(\mu^- - \mu_h^-) = \mathcal{M}'_{\mu^-}(\chi, \psi)(\tilde{\mu}^- - \mu_h^-) = \tilde{\rho}_{\nu^-}(\chi, \psi)(\tilde{\mu}^- - \mu_h^-),$$

$$(4.45) \quad \mathcal{M}'_{\nu^-}(\chi, \psi)(\nu^- - \nu_h^-) = \mathcal{M}'_{\nu^-}(\chi, \psi)(\tilde{\nu}^- - \nu_h^-) = \tilde{\rho}_{\mu^-}(\chi)(\tilde{\nu}^- - \nu_h^-),$$

$$(4.46) \quad \mathcal{M}'_{\mu^+}(\chi, \psi)(\mu^+ - \mu_h^+) = \mathcal{M}'_{\mu^+}(\chi, \psi)(\tilde{\mu}^+ - \mu_h^+) = \tilde{\rho}_{\nu^+}(\chi, \psi)(\tilde{\mu}^+ - \mu_h^+),$$

$$(4.47) \quad \mathcal{M}'_{\nu^+}(\chi, \psi)(\nu^+ - \nu_h^+) = \mathcal{M}'_{\nu^+}(\chi, \psi)(\tilde{\nu}^+ - \nu_h^+) = \tilde{\rho}_{\mu^+}(\chi)(\tilde{\nu}^+ - \nu_h^+).$$

Thus we obtain

$$\begin{aligned} \mathcal{M}'(\chi, \psi)(e) &= \tilde{\rho}_{\mu^-}(\chi)(\tilde{\nu}^- - \nu_h^-) + \tilde{\rho}_{\mu^+}(\chi)(\tilde{\nu}^+ - \nu_h^+) \\ &\quad + \tilde{\rho}_{\nu^-}(\chi, \psi)(\tilde{\mu}^- - \mu_h^-) + \tilde{\rho}_{\nu^+}(\chi, \psi)(\tilde{\mu}^+ - \mu_h^+). \end{aligned}$$

For the second term we obtain from (3.15a)–(3.15e) and (4.32a)–(4.32e) that

$$\mathcal{M}'(\chi_h, \psi_h)(e) = \mathcal{M}'(\chi_h, \psi_h)(\chi - \tilde{\chi}_h, \psi - \tilde{\psi}_h)$$

for each  $\tilde{\chi}_h, \tilde{\psi}_h \in \tilde{\mathcal{Y}}_{\text{ad},h}$ , which completes the proof.  $\square$

*Remark 4.8.* Note that in the case  $I = J$  the solution  $(p, v, y)$  to (4.29) is given by  $(0, 0, z)$ , which can be seen after some calculations. Using this, one obtains that for  $I = J$  the estimates in Theorems 4.2 and 4.3 coincide.

We define the projection onto the admissible set by

$$\mathcal{P}_{P_{\text{ad},h}}(p) = \max(p_{h,-}, \min(p, p_{h,+})).$$

To obtain a computable error estimator we introduce  $\tilde{p} \in P_{\text{ad}}$  as an approximation to  $p$  by

$$(4.48) \quad \tilde{p} = \mathcal{P}_{P_{\text{ad},h}} \left( \frac{1}{\alpha} (a'_q(\cdot, \pi y_h) + a''_{qu}(\cdot, \pi v_h, \pi z_h) + a''_{qq}(\cdot, p_h, \pi z_h) - I'_q(\tilde{q}, \pi u_h)(\cdot)) \right),$$

where  $()$  is an abbreviation for  $(\tilde{q}, \pi u_h)$ , and  $\tilde{\nu}$  is introduced as an approximation to  $\nu$  by

$$(4.49) \quad \tilde{\nu} = -\alpha \tilde{p} + a'_q(\cdot, \pi y_h) + a''_{qu}(\cdot, \pi v_h, \pi z_h) + a''_{qq}(\cdot, p_h, \pi z_h) - I'_q(\tilde{q}, \pi u_h)(\cdot),$$

which is an analogue to the construction of the approximations  $\tilde{q}$  and  $\tilde{\mu}$  in (4.7) and (4.19).

Using these approximations we obtain the following computable error estimator:

$$\begin{aligned} \eta_{\text{QI}} &= \frac{1}{2} \rho_u(\chi_h)(\pi y - y_h) + \frac{1}{2} \rho_z(\chi_h)(\pi v - v_h) + \frac{1}{2} \tilde{\rho}_q(\chi_h)(\tilde{p} - p_h) \\ &\quad + \frac{1}{2} \tilde{\rho}_{\mu^-}(\chi_h)(\tilde{\nu}^- - \nu_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\chi_h)(\tilde{\nu}^+ - \nu_h^+) \\ &\quad + \frac{1}{2} \tilde{\rho}_v(\chi_h, \psi_h)(\pi z - z_h) + \frac{1}{2} \tilde{\rho}_y(\chi_h, \psi_h)(\pi u - u_h) + \frac{1}{2} \tilde{\rho}_p(\chi_h, \psi_h)(\tilde{q} - q_h) \\ &\quad + \frac{1}{2} \tilde{\rho}_{\nu^-}(\chi_h, \psi_h)(\tilde{\mu}^- - \mu_h^-) + \frac{1}{2} \tilde{\rho}_{\nu^+}(\chi_h, \psi_h)(\tilde{\mu}^+ - \mu_h^+) \\ &\quad + \frac{1}{2} \tilde{\rho}_{\mu^-}(\tilde{\chi})(\tilde{\nu}^- - \nu_h^-) + \frac{1}{2} \tilde{\rho}_{\mu^+}(\tilde{\chi})(\tilde{\nu}^+ - \nu_h^+) \\ &\quad + \frac{1}{2} \tilde{\rho}_{\nu^-}(\tilde{\chi}, \tilde{\psi})(\tilde{\mu}^- - \mu_h^-) + \frac{1}{2} \tilde{\rho}_{\nu^+}(\tilde{\chi}, \tilde{\psi})(\tilde{\mu}^+ - \mu_h^+), \end{aligned}$$

where  $\tilde{\chi} = (\tilde{q}, \pi u, \pi z, \tilde{\mu}^-, \tilde{\mu}^+)$  and  $\tilde{\psi} = (\tilde{p}, \pi v, \pi y, \tilde{\nu}^-, \tilde{\nu}^+)$ .

*Remark 4.9.* We would like to point out that in case of strict complementarity, e.g., if the set

$$\{x \in \omega \mid q(x) = q_-(x) \text{ or } q(x) = q_+(x)\} \setminus \{x \in \omega \mid \mu(x) \neq 0\}$$

has zero measure, the auxiliary problem (4.23), (4.24) does not involve inequality constraints for the controls. In that case the set  $P_{\text{ad}}$  is not only convex but in fact a real subspace of  $Q$ .

*Remark 4.10.* The constrained linear-quadratic optimization problem (4.23), (4.24) can be solved using primal-dual active set strategy. In the case of strict complementarity the algorithm will converge in one step due to the fact that  $P_{\text{ad}}$  is a linear subspace of  $Q$  in this case.

*Remark 4.11.* Due to the definition of  $P_{\text{ad}}$  (4.25), the solution  $p \in Q$  of auxiliary optimization problem (4.23)–(4.24) is usually discontinuous. Therefore, a cellwise constant discretization of the control space  $Q$  seems to be more suitable than a discretization with continuous trial functions if the error with respect to a quantity of interest is estimated.

**5. Numerical examples.** In this section we discuss two numerical examples illustrating the behavior of our method. For both examples we use bilinear ( $H^1$ -conforming) finite elements for the discretization of the state variable and cellwise constant discretization of the control space. The optimization problems are solved by primal-dual active set strategy as sketched in section 2, where the equality-constrained problems in the inner loop are solved using Newton's method for the reduced cost functional.

All examples have been computed using the optimization library RoDoBo [5] and the finite element toolkit Gascoigne [3].

**5.1. Example 1.** We consider the following nonlinear optimization problem:

$$(5.1) \quad \text{Minimize} \quad \frac{1}{2} \|u - u^d\|_{L^2(\Omega)}^2 + \frac{\alpha}{2} \|q\|_{L^2(\Omega)}^2, \quad u \in V, \quad q \in Q_{\text{ad}},$$

subject to

$$(5.2) \quad \begin{aligned} -\Delta u + 30u^3 + u &= f + q && \text{in } \Omega, \\ u &= 0 && \text{on } \partial\Omega, \end{aligned}$$

where  $\Omega = \omega = (0, 1)^2 \setminus [0.4, 0.6]^2$ ,  $V = H_0^1(\Omega)$ ,  $Q = L^2(\Omega)$ , and the admissible set  $Q_{\text{ad}}$  is given by

$$Q_{\text{ad}} = \{q \in Q \mid -7 \leq q(x) \leq 20 \text{ a.e. on } \Omega\}.$$

The desired state  $u^d$  and the right-hand side  $f$  are defined as

$$u^d(x) = x_1 \cdot x_2, \quad f(x) = ((x_1 - 0.5)^2 + (x_2 - 0.5)^2)^{-1},$$

and the regularization parameter is chosen as  $\alpha = 10^{-4}$ . We note that the state equation (5.2) is a monotone semilinear equation, which possesses a unique solution  $u \in V$  for each  $q \in Q$ . The proof of the existence of a global solution as well as derivation of necessary and sufficient optimality conditions for the corresponding optimization problem (5.1)–(5.2) can be found, e.g., in [34].

In section 4 we derived two different error estimators for the error with respect to the cost functional and one error estimator with respect to a quantity of interest. In this example, we choose the quantity of interest as

$$(5.3) \quad I(q, u) = \frac{1}{2} \int_{(0.7, 0.8)^2} |\nabla u(x)|^2 dx + \int_{(0.2, 0.3)^2} q(x) dx.$$

In order to check the quality of the error estimators, we define the following effectivity indices:

$$(5.4) \quad I_{\text{eff}}(\eta_1) = \frac{J(u) - J(u_h)}{\eta_1}, \quad I_{\text{eff}}(\eta_2) = \frac{J(u) - J(u_h)}{\eta_2}, \quad I_{\text{eff}}(\eta_{\text{QI}}) = \frac{I(q, u) - I(q_h, u_h)}{\eta_{\text{QI}}}.$$

In Table 5.1 these effectivity indices are listed for different types of mesh refinement: random refinement and refinement based on the error estimator  $\eta_{\text{QI}}$  for the quantity of interest.

TABLE 5.1

(a) Random refinement

(b) Refinement according to  $\eta_{\text{QI}}$

We observe that the error estimators provide quantitative information about the discretization error. We note that the results for  $\eta_1$  and  $\eta_2$  are very close to each other in this example; cf. Remark 4.3.

In addition, our results show that the local mesh refinement based on error estimators derived above leads to substantial saving in degrees of freedom for achieving a given level of the discretization error. In Figure 5.1 the dependence of discretization error on the number of degrees of freedom is shown for different refinement criteria: global (uniform) refinement, refinement based on the error estimator  $\eta_1$  for the cost functional, and refinement based on the error estimator  $\eta_{\text{QI}}$  for the quantity of interest. In Figure 5.1(a) the error with respect to the cost functional (5.1) and in Figure 5.1(b) the error with respect to the quantity of interest (5.3) are considered, respectively.

We observe the best behavior of error with respect to the cost functional if the mesh is refined based on  $\eta_1$  and the best behavior of error with respect to the quantity of interest for the refinement based on  $\eta_{\text{QI}}$ .

A series of meshes generated according to the information obtained from the error estimators are shown in Figure 5.2 together with the optimal control  $q$  and the corresponding state  $u$ .

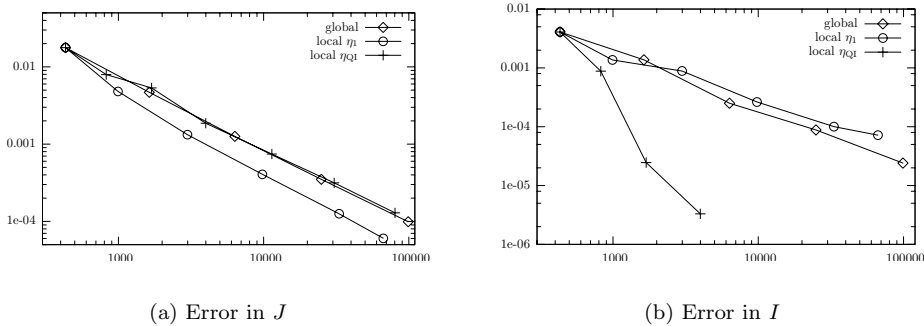

FIG. 5.1. Discretization error for different refinement criteria.

**5.2. Example 2.** Our second example is motivated by a parameter identification problem. The minimization problem is given by

(5.5)      Minimize       $\frac{1}{2}\|u - u^d\|_{L^2(\Omega)}^2 + \frac{\alpha}{2}\|q\|_{L^2(\Omega)}^2, \quad u \in V, \ q \in Q_{\text{ad}},$

subject to

(5.6)      
$$\begin{aligned} -\Delta u + qu &= f && \text{in } \Omega, \\ u &= 0 && \text{on } \partial\Omega, \end{aligned}$$

where  $\Omega = \omega = (0, 0.5) \times (0, 1) \cup (0, 1) \times (0.5, 1)$ ,  $V = H_0^1(\Omega)$ ,  $Q = L^2(\Omega)$ , and the admissible set  $Q_{\text{ad}}$  is given by

$$Q_{\text{ad}} = \{q \in Q \mid q_-(x) \leq q(x) \leq q_+(x) \text{ a.e. on } \Omega\}, \text{ with } q_-(x) = 0, \quad q_+(x) = 0.3.$$

The desired state  $u^d$  and the right-hand side  $f$  are defined as

$$u^d(x) = \frac{1}{8\pi^2} \sin(2\pi x_1) \sin(2\pi x_2), \quad f(x) = 1,$$

and the regularization parameter is chosen  $\alpha = 10^{-4}$ . Note that for any given  $q \in Q_{\text{ad}}$  the state equation (5.6) possesses a unique solution  $u \in V$  due to  $q \geq 0$ .

We are interested in the error in the unknown parameter, and thus we choose

$$I(q, u) = \int_{\Omega_O} q(x) \, dx,$$

where  $\Omega_O = (0, 0.25) \times (0.75, 1)$ .

In Table 5.2 the effectivity indices, defined as in (5.4), are listed for different types of mesh refinement: global (uniform) refinement, random refinement, refinement based on the error estimator  $\eta_1$  for the cost functional, and refinement based on the error estimator  $\eta_{QI}$  for the quantity of interest. As in the first example we observe that the error estimators provide quantitative information on the discretization errors.

## NECESSARY CONDITIONS FOR CONSTRAINED PROBLEMS UNDER MANGASARIAN–FROMOWITZ CONDITIONS\*

MARIA DO ROSÁRIO DE PINHO<sup>†</sup> AND JAVIER F. ROSENBLUETH<sup>‡</sup>

**Abstract.** The focus of this paper is on first order necessary conditions for optimal control problems with mixed state-control equality and inequality constraints. We consider the case when the cost and dynamics are nonsmooth, and the constraints satisfy Mangasarian–Fromowitz-type assumptions that weaken the commonly used hypothesis that the Jacobian of the active constraints, with respect to the free variable, is of full rank. The results are formulated as unmaximized Hamiltonian inclusion-type conditions involving not the customary product of partial subdifferentials but the joint subdifferential with respect to the state and control variables.

**Key words.** optimal control, nonsmooth analysis, mixed constraints

**AMS subject classification.** 49K15

**DOI.** 10.1137/060663623

**1. Introduction.** Consider the following optimal control problem with mixed constraints:

$$(P) \quad \left\{ \begin{array}{ll} \text{Minimize } l(x(0), x(1)) \text{ subject to} \\ \dot{x}(t) = f(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ 0 = b(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ 0 \geq g(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ v(t) \in V(t) & \text{a.e. in } T, \\ (x(0), x(1)) \in C, \end{array} \right.$$

where  $T = [0, 1]$ , and we are given functions

$$l: \mathbf{R}^n \times \mathbf{R}^n \rightarrow \mathbf{R}, \quad (f, b, g): T \times \mathbf{R}^n \times \mathbf{R}^{k_u} \times \mathbf{R}^{k_v} \rightarrow \mathbf{R}^n \times \mathbf{R}^{m_b} \times \mathbf{R}^{m_g},$$

$V(t) \subset \mathbf{R}^{k_v}$  for all  $t \in T$ , and  $C \subset \mathbf{R}^n \times \mathbf{R}^n$ . Let  $m := m_b + m_g$ , let  $k := k_u + k_v$ , and assume that  $k \geq m$ . Usually one has  $m_b \geq 1$  and  $m_g \geq 1$ , but we allow for  $m_b = 0$  (no equality constraints) or  $m_g = 0$  (no inequality constraints).

For (P), a *process* is a triple  $(x, u, v)$  comprising a function  $x \in W^{1,1}(T; \mathbf{R}^n)$  and measurable functions  $u: T \rightarrow \mathbf{R}^{k_u}$  and  $v: T \rightarrow \mathbf{R}^{k_v}$  satisfying the constraints. Here  $W^{1,1}(T; \mathbf{R}^n)$  denotes the space of absolutely continuous functions mapping  $T$  to  $\mathbf{R}^n$ . A process  $(\bar{x}, \bar{u}, \bar{v})$  is a *strong minimizer* for (P) if there exists  $\epsilon > 0$  such that it minimizes the cost over all processes  $(x, u, v)$  satisfying  $|x(t) - \bar{x}(t)| \leq \epsilon$  for all  $t \in T$ , and it is a *weak minimizer* if, for some  $\epsilon > 0$ , it minimizes the cost over all processes  $(x, u, v)$  satisfying  $|x(t) - \bar{x}(t)| \leq \epsilon$  for all  $t \in T$  and

$$|u(t) - \bar{u}(t)| \leq \epsilon, \quad |v(t) - \bar{v}(t)| \leq \epsilon \quad \text{a.e. in } T.$$

<sup>‡</sup>IIMAS-UNAM, Universidad Nacional Autónoma de México, Apartado Postal 20-726, México DF 01000, México (jfrl@servidor.unam.mx).

The set  $\mathcal{I}_a(t)$  denotes the set of indexes of the *active constraints*, that is,

$$\mathcal{I}_a(t) = \{i \in \{1, \dots, m_g\} \mid g_i(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = 0\},$$

and  $q_a(t)$  denotes the cardinality of  $\mathcal{I}_a(t)$ . Also

$$\nabla_u g^{\mathcal{I}_a(t)}(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) \in \mathbf{R}^{q_a(t) \times k_u}$$

(if  $q_a(t) = 0$ , the latter holds vacuously) is the matrix we obtain after removing from  $\nabla_u g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t))$  all the rows of index  $i \notin \mathcal{I}_a(t)$ .

In what follows the set of necessary conditions for optimal control problems with nonsmooth data in the spirit of [3] is referred to as *nonsmooth maximum principle*.

This paper focuses on necessary conditions of optimality for problem (P) with cost and dynamics possibly nonsmooth and with smooth mixed constraints. The distinct aspects of (P) are the equality and inequality mixed constraints and the fact that the control variable comprises two components,  $u$  (unconstrained) and  $v$  (pointwise constrained). This splitting decomposition of the control variable is common in the literature (see [2, 13] for an explanation, as well as [1, 12, 14], where the statement of the problem is proposed as a canonical one and there is a deep investigation on the subject). We keep such division because optimal control problems with mixed constraints are relevant to optimal control problems involving differential and algebraic equations (for a discussion on this topic we refer the reader to [9, 10]).

Although it is well known that the maximum principle is not in general valid for (P), weak and strong forms of the maximum principle have been shown to hold when some regularity assumptions are imposed on the mixed constraints (see, for example, [2, 13, 16, 17, 20, 24] to name but a few). Derivation of optimality conditions for problems with nonregular mixed constraints remains a largely unexplored area (see [13] and the references therein).

For problems with smooth data including continuity with respect to  $t$ , regularity assumptions commonly involve the full rank condition

$$(1.1) \quad \det M(t)M(t)^T \neq 0 \quad \text{for all } t \in T$$

for a certain matrix  $M$ , the more general being

$$(1.2) \quad F(t) := \begin{pmatrix} \nabla_u b(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) \\ \nabla_u g^{\mathcal{I}_a(t)}(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) \end{pmatrix}.$$

Exceptions are to be found in [2, 13], where strong versions of the maximum principle for smooth problems with data *measurable* with respect to  $t$  are validated under assumptions that may be viewed in analogy to Mangasarian–Fromowitz constraint qualifications (to be defined below), also known as *positive linear independence* conditions.

Strong forms of the nonsmooth maximum principle for (P), which apply to strong minimizers, are derived in [10, 11]. In the aforementioned papers, regularity assumptions on the mixed constraints involve convexity. Weak nonsmooth maximum principles for (P), which in turn apply to weak minimizers, have also been derived in [7, 21], where convexity assumptions are replaced by differentiability with respect to  $(x, u, v)$  of the functions defining the mixed constraints. Because the data of (P) in [7, 21] are assumed to be merely measurable with respect to  $t$ , the full rank condition (1.1) is replaced by a uniform full rank condition of the form

$$(1.3) \quad \det M(t)M(t)^T \geq K \quad \text{a.e. in } T$$

for some  $K > 0$ , applied to the matrix

$$\Upsilon(t) := \begin{pmatrix} \nabla_u b(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) & 0 \\ \nabla_u g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) & \text{diag} \{ \sqrt{-g_i(t, \bar{x}(t), \bar{u}(t), \bar{v}(t))} \} \end{pmatrix}.$$

A weak version of the nonsmooth maximum principle, derived in [7] under the uniform full rank condition imposed on  $\Upsilon$  (that is,  $M = \Upsilon$  in (1.3)), is extended in [5] to cover problems for which (1.3) is imposed on  $F$ . Remarkably, the uniform full rank condition (1.3) on  $\Upsilon$  implies (1.3) on  $F$ , but the converse may not hold (see [7]). Notice that condition (1.1) on  $\Upsilon$  is in fact equivalent to (1.1) on  $F$ .

Here we establish the validity of a weak nonsmooth maximum principle for (P) under regularity assumptions on the mixed constraints that may be viewed in analogy to Mangasarian–Fromowitz constraint qualifications in mathematical programming. The conditions we consider are an adaptation of [15, condition (23)]. Regularity assumptions of similar nature are imposed in [4, 13], where strong versions of the maximum principle are derived for smooth problems. Also, they are used in [22] to derive first and second order optimality conditions for problems involving more general constraints. However, in contrast to [4, 13, 22], we treat problems with possibly nonsmooth dynamics and cost. Moreover, as we illustrate through an example, the Mangasarian–Fromowitz-type conditions we impose on (P) are in general less restrictive constraint qualifications than the uniform full rank condition (1.3) imposed on  $F$  (though both sets of conditions coincide when  $m_g = 0$ ).

The novelty of this paper concerns both the nature of the regularity assumptions and the analytic techniques used to derive necessary conditions for (P) with possibly nonsmooth data. Although we impose some degree of smoothness on the mixed constraints, the proof of our main result (Theorem 3.1) relies heavily on techniques developed for nonsmooth analysis. The key idea behind the proof is based on a technique introduced in [3] for problems with pure state constraints (see also [25]). A crucial step in the proof is the definition of a sequence of optimization problems leading to a sequence of optimal control problems with mixed constraints to which optimality necessary conditions under the uniform full rank condition (1.3), previously obtained in [5], apply.

Similarly to [5, 7], the necessary conditions for (P) validated in this paper involve  $\partial_{x,u,v}H$ , the joint subdifferential of the function

$$H(t, x, p, q, r, u, v) = p \cdot f(t, x, u, v) + q \cdot b(t, x, u, v) + r \cdot g(t, x, u, v)$$

in the state and control variables. The necessary conditions we deal with in this paper were first derived in [8] for “standard” optimal control problems (that is, when the mixed constraints defined by  $g$  and  $b$  are absent), and they were later extended to cover more general problems as, for example, problems with pure state constraints (see [6] and the references therein). In [8] such conditions are designated as Euler–Lagrange inclusion conditions. This designation was soon abandoned to avoid confusion with the same name used in nonsmooth optimal control for conditions involving generalized normals to the graph of the admissible velocity mapping. Since, for standard nonsmooth optimal control problems, our conditions involve the *unmaximized Hamiltonian* (also known as pseudo-Hamiltonian or Pontryagin’s Hamiltonian), they were coined *unmaximized Hamiltonian inclusion (UHI)-type conditions*.

UHI-type conditions are distinct from the conventional weak nonsmooth maximum principle which involves  $\partial_x H \times \partial_u H \times \partial_v H$ , the product of the partial subdifferentials of  $H$  in the state and control variables. As shown in [5, 6], the main features of

UHI-type conditions are retained in the presence of mixed or pure state constraints. Namely, these conditions are optimality sufficient conditions in the linear-convex normal case, whereas the nonsmooth maximum principle is not. Moreover, for standard optimal control problems and for problems with pure state constraints, UHI-type conditions can eliminate processes that satisfy strong nonsmooth maximum principles and yet are not locally optimal (see [6, 8]), a feature which is retained for UHI-type conditions for (P).

**2. Preliminaries.** The notation  $r \geq 0$  for  $r \in \mathbf{R}^p$  ( $p \in \mathbf{N}$ ) means that each component of  $r$  is nonnegative. Throughout,  $|\cdot|$  denotes the Euclidean norm, and  $B$  represents the closed unit ball centered at the origin regardless of the dimension of the underlined space. For much of the analysis we shall denote by  $(\bar{x}, \bar{u}, \bar{v})$  a local minimizer of (P) and by  $\bar{\phi}(t)$  the evaluation of a function  $\phi$  at  $(t, \bar{x}(t), \bar{u}(t), \bar{v}(t))$ . The set  $\Omega_\epsilon(t)$  is defined as

$$\Omega_\epsilon(t) := (\bar{x}(t) + \epsilon B) \times (\bar{u}(t) + \epsilon B) \times ((\bar{v}(t) + \epsilon B) \cap V(t)).$$

The linear space  $W^{1,1}(T; \mathbf{R}^p)$  denotes the space of absolutely continuous functions,  $L^1(T; \mathbf{R}^p)$  the space of integrable functions, and  $L^\infty(T; \mathbf{R}^p)$  the space of essentially bounded functions mapping  $T$  to  $\mathbf{R}^p$ , respectively. For  $\delta \in L^\infty(T; \mathbf{R}^{m_a})$ ,  $\delta^{\mathcal{I}_a(t)}(t) \in \mathbf{R}^{q_a(t)}$  denotes the vector we get after removing from  $\delta(t)$  all the components  $\delta_i(t)$  such that  $i \notin \mathcal{I}_a(t)$ .

Since we consider (P) with possibly nonsmooth data, we make use of standard constructs from nonsmooth analysis. The full calculus for some basic constructions in nonsmooth analysis can be found, for example, in [3, 18, 19, 23, 25]. The following definition will be essential in our setup.

**DEFINITION 2.1.** Let  $A \subset \mathbf{R}^k$  be a closed set and  $x \in A$ . We say that  $p \in \mathbf{R}^k$  is a limiting normal to  $A$  at  $x$  if there exist  $p_i \rightarrow p$  and  $x_i \rightarrow x$  in  $A$  and a sequence of positive numbers  $\{M_i\}$  such that, for each  $i \in \mathbf{N}$ ,

$$p_i \cdot (y - x_i) \leq M_i |y - x_i|^2 \quad \text{for all } y \in A.$$

The limiting normal cone to  $A$  at  $x$ , written  $N_A(x)$ , is the set of all limiting normals to  $A$  at  $x$ .

Given a lower semicontinuous function  $f: \mathbf{R}^k \rightarrow \mathbf{R} \cup \{+\infty\}$  and a point  $x \in \mathbf{R}^k$  such that  $f(x) < \infty$ , the limiting subdifferential of  $f$  at  $x$  (also referred to as Mordukhovich subdifferential) is the set

$$\partial f(x) := \{\zeta \mid (-1, \zeta) \in N_{\text{epi}\{f\}}(f(x), x)\},$$

where  $\text{epi}\{f\} := \{(\eta, x) \mid \eta \geq f(x)\}$  denotes the epigraph set (when  $f$  is Lipschitz continuous near  $x$ , the convex hull of the limiting subdifferential,  $\text{co } \partial f(x)$ , coincides with the Clarke subdifferential (see [3])).

For completeness we state two results that will be of importance in what follows. The first one corresponds to a uniform implicit function theorem [9, Corollary 4.2].

**PROPOSITION 2.2.** Consider a set  $A \subset \mathbf{R}^k$ , a number  $\alpha > 0$ , a family of functions  $\{\psi_a: \mathbf{R}^m \times \mathbf{R}^n \rightarrow \mathbf{R}^n\}_{a \in A}$ , and a point  $(u_0, v_0) \in \mathbf{R}^m \times \mathbf{R}^n$  such that  $\psi_a(u_0, v_0) = 0$  for all  $a \in A$ . Assume that

- (i)  $\psi_a$  is continuously differentiable on  $(u_0, v_0) + \alpha B$  for all  $a \in A$ ,
- (ii) there exists a monotone increasing function  $\theta: (0, \infty) \rightarrow (0, \infty)$  with  $\theta(s) \downarrow 0$  as  $s \downarrow 0$  such that, for all  $a \in A$  and  $(u, v) \neq (u', v') \in (u_0, v_0) + \alpha B$ ,

$$|\nabla \psi_a(u, v) - \nabla \psi_a(u', v')| \leq \theta(|(u, v) - (u', v')|),$$

(iii)  $\nabla_v \psi_a(u_0, v_0)$  is nonsingular for each  $a \in A$  and there exists  $c > 0$  such that, for all  $a \in A$ ,  $|\nabla_v \psi_a(u_0, v_0)|^{-1} \leq c$ .

Then there exist  $\delta \geq 0$  and a family of continuously differentiable functions  $\{\phi_a: u_0 + \delta B \rightarrow v_0 + \alpha B\}_{a \in A}$  which are Lipschitz continuous with common Lipschitz constant  $k$  such that, for all  $a \in A$ ,

- (a)  $v_0 = \phi_a(u_0)$ ,
- (b)  $\psi_a(u, \phi_a(u)) = 0$  for all  $u \in u_0 + \delta B$ ,
- (c)  $\nabla_u \phi(u_0) = -[\nabla_v \psi_a(u_0, v_0)]^{-1} \nabla_u \psi_a(u_0, v_0)$ .

The numbers  $\delta$  and  $k$  depend on  $\theta$ ,  $c$ , and  $\alpha$  only. Furthermore, if  $A$  is a Borel set and  $a \mapsto \psi_a(u, v)$  is a Borel measurable function for each  $(u, v) \in (u_0, v_0) + \alpha B$ , then  $a \mapsto \phi_a(u)$  is a Borel measurable function for each  $u \in u_0 + \delta B$ .

The second result we state (see [5, Theorem 3.1]) corresponds to UHI-type conditions for (P) under full rank assumptions. We invoke the following hypotheses on (P), which make reference to a parameter  $\epsilon > 0$  and a process  $(\bar{x}, \bar{u}, \bar{v})$ . The notation  $(b, g)(\cdot)$  means  $(b(\cdot), g(\cdot))$ .

(H1) The function  $t \mapsto f(t, x, u, v)$  is Lebesgue measurable for each  $(x, u, v)$  and there exists an integrable function  $k_f$  such that, for almost every  $t \in T$ ,

$$|f(t, x, u, v) - f(t, x', u', v')| \leq k_f(t) |(x, u, v) - (x', u', v')|$$

for all  $(x, u, v), (x', u', v') \in \Omega_\epsilon(t)$ .

(H2) Graph  $V$  is a Borel measurable set and  $V_\epsilon(t) := (\bar{v}(t) + \epsilon B) \cap V(t)$  is closed for almost every  $t \in T$ .

(H3)  $C$  is closed and  $l$  is locally Lipschitz in a neighborhood of  $(\bar{x}(0), \bar{x}(1))$ .

(H4)  $(b, g)(\cdot, x, u, v)$  is measurable for each  $(x, u, v)$  and  $t \mapsto g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t))$  is  $L^\infty(T, \mathbf{R}^{m_g})$ .

(H5)  $(b, g)(t, \cdot, \cdot, \cdot)$  is continuously differentiable on  $(\bar{x}(t), \bar{u}(t), \bar{v}(t)) + \epsilon B$  a.e. in  $T$  and there exists an integrable function  $L_{b,g}$  such that, for almost every  $t \in T$ ,

$$|(b, g)(t, x, u, v) - (b, g)(t, x', u', v')| \leq L_{b,g}(t) |(x, u, v) - (x', u', v')|$$

for all  $(x, u, v), (x', u', v') \in \Omega_\epsilon(t)$ .

(H6) There exist  $K_{b,g} > 0$  and an increasing function  $\tilde{\theta}: (0, \infty) \rightarrow (0, \infty)$  with  $\tilde{\theta}(s) \downarrow 0$  as  $s \downarrow 0$  such that, for almost every  $t \in T$ ,

$$|\nabla_x(\bar{b}, \bar{g})(t)| + |\nabla_u(\bar{b}, \bar{g})(t)| + |\nabla_v(\bar{b}, \bar{g})(t)| \leq K_{b,g},$$

$$|\nabla_{x,u,v}(b, g)(t, x, u, v) - \nabla_{x,u,v}(b, g)(t, x', u', v')| \leq \tilde{\theta}(|(x, u, v) - (x', u', v')|)$$

for all  $(x, u, v) \neq (x', u', v')$  belonging to  $\Omega_\epsilon(t)$ .

(H\*) There exists  $K > 0$  such that  $\det F(t)F(t)^T \geq K$  a.e. in  $T$ , where  $F$  is defined in (1.2).

**THEOREM 2.3.** *Let  $(\bar{x}, \bar{u}, \bar{v})$  be a weak minimizer for (P). Set*

$$H(t, x, p, q, r, u, v) := p \cdot f(t, x, u, v) + q \cdot b(t, x, u, v) + r \cdot g(t, x, u, v).$$

*If, for some  $\epsilon > 0$ , (H1)–(H6) and (H\*) are satisfied, then there exist  $p \in W^{1,1}(T; \mathbf{R}^n)$ ,  $q \in L^1(T; \mathbf{R}^{m_b})$ ,  $r \in L^1(T; \mathbf{R}^{m_g})$ ,  $\zeta \in L^1(T; \mathbf{R}^{k_v})$ , and  $\lambda \geq 0$  such that*

- (i)  $\|p\|_\infty + \lambda \neq 0$ ,
- (ii)  $(-\dot{p}(t), 0, \zeta(t)) \in \text{co } \partial_{x,u,v} H(t, \bar{x}(t), p(t), q(t), r(t), \bar{u}(t), \bar{v}(t))$  a.e. in  $T$ ,
- (iii)  $\zeta(t) \in \text{co } N_{V(t)}(\bar{v}(t))$  a.e. in  $T$ ,
- (iv)  $r(t) \cdot g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = 0$  and  $r(t) \leq 0$  a.e. in  $T$ ,
- (v)  $(p(0), -p(1)) \in N_C(\bar{x}(0), \bar{x}(1)) + \lambda \partial l(\bar{x}(0), \bar{x}(1))$ .

*Furthermore, for some integrable function  $K_m$ ,  $|(q(t), r(t))| \leq K_m(t)|p(t)|$  a.e. in  $T$ .*

**3. Main results.** In this section we validate the UHI-type conditions given in Theorem 2.3 to cover problems with data satisfying merely Mangasarian–Fromowitz-type assumptions. In this respect, Theorem 2.3 and Proposition 2.2 play a crucial role.

We shall invoke the following additional hypothesis which, like (H1)–(H6), makes reference to some process  $(\bar{x}, \bar{u}, \bar{v})$  and a parameter  $\epsilon > 0$ .

(H7) There exist constants  $K_1, K_2 > 0$  and functions  $h \in L^\infty(T; \mathbf{R}^{k_u})$  and  $a \in L^\infty(T; \mathbf{R}^{m_g})$  with  $|h(t)| = 1$  a.e. in  $T$  such that, for almost every  $t \in T$ ,

- (i)  $a_i(t) > K_2$  for  $i \in \mathcal{I}_a(t)$ ,
- (ii)  $\nabla_u \bar{g}^{\mathcal{I}_a(t)}(t) \cdot h(t) = a^{\mathcal{I}_a(t)}(t)$ ,
- (iii)  $\nabla_u \bar{b}(t) \cdot h(t) = 0$ ,
- (iv)  $\det \nabla_u \bar{b}(t) \nabla_u \bar{b}(t)^T \geq K_1$ .

The difference between (H7) and assumptions previously considered in [13] resides in the fact that (H7) needs to be checked only along the optimal solution. On the other hand, (H7) coincides with (R3) in [22] (in this respect we refer the reader to Theorem 4.1 in [22]).

Hypothesis (H7) is a uniform Mangasarian–Fromowitz-type condition, the term “uniform” being used to emphasize the fact that assumptions (H7)(i) and (H7)(iv) are bounded away from the origin, uniformly in  $t$ .

Let us first state UHI-type conditions for (P) without *equality* constraints; that is, let us concentrate on the problem

$$(Q) \quad \begin{cases} \text{Minimize } l(x(0), x(1)) \text{ subject to} \\ \dot{x}(t) = f(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ 0 \geq g(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ (u(t), v(t)) \in \mathbf{R}^{k_u} \times V(t) & \text{a.e. in } T, \\ (x(0), x(1)) \in C. \end{cases}$$

Note that, for this case, hypotheses (H7)(iii) and (H7)(iv) are ignored.

**THEOREM 3.1.** *Let  $(\bar{x}, \bar{u}, \bar{v})$  be a weak minimizer for (Q) with  $m_g \geq 1$ . Set*

$$H(t, x, p, r, u, v) := p \cdot f(t, x, u, v) + r \cdot g(t, x, u, v).$$

*If, for some  $\epsilon > 0$ , (H1)–(H7) are satisfied, then there exist  $p \in W^{1,1}(T; \mathbf{R}^n)$ ,  $r \in L^1(T; \mathbf{R}^{m_g})$ ,  $\zeta \in L^1(T; \mathbf{R}^{k_v})$ , and  $\lambda \geq 0$  such that*

- (i)  $\|p\|_\infty + \lambda \neq 0$ ,
- (ii)  $(-\dot{p}(t), 0, \zeta(t)) \in \text{co } \partial_{x,u,v} H(t, \bar{x}(t), p(t), r(t), \bar{u}(t), \bar{v}(t))$  a.e. in  $T$ ,
- (iii)  $\zeta(t) \in \text{co } N_{V(t)}(\bar{v}(t))$  a.e. in  $T$ ,
- (iv)  $r(t) \cdot g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = 0$  and  $r(t) \leq 0$  a.e. in  $T$ ,
- (v)  $(p(0), -p(1)) \in N_C(\bar{x}(0), \bar{x}(1)) + \lambda \partial l(\bar{x}(0), \bar{x}(1))$ .

*Furthermore, for some integrable function  $R$ ,  $|r(t)| \leq R(t)|p(t)|$  a.e. in  $T$ .*

We now turn to problem (P) with mixed constraints in the form of equalities and inequalities.

**THEOREM 3.2.** *Theorem 2.3 remains valid if we replace (H\*) with (H7).*

Let us point out that, for problems *without* inequality constraints, Theorem 3.2 coincides with [7, Theorem 3.1]. The novelty of the above theorem is that, in the presence of inequality constraints, it subsumes previous UHI-type conditions for (P) validated under full rank conditions (Theorem 2.3). We shall prove this new result by associating (P) with an auxiliary problem in the form of (Q) to which Theorem 3.1 applies.

As mentioned in the introduction, it has been shown that UHI-type conditions in the normal form, for standard optimal control problems, are also sufficient for linear convex problems (see [8]). This feature is retained when UHI-type conditions are extended to cover problems with mixed constraints under the uniform full rank condition  $(H^*)$  as proved in [5, Proposition 2.1]. However, that proposition does not depend on  $(H^*)$  but only on the conclusions (ii)–(v) of [5, Theorem 3.1] which coincide with conclusions (ii)–(v) of Theorem 2.3 above. Consequently, UHI-type conditions for (P) in the normal form, validated under assumption (H7) as in Theorem 3.2, are also sufficient for linear convex problems.

We end this section with two examples. Let us first compare the two hypotheses  $(H^*)$  and (H7). It is a simple matter to see that  $(H^*)$  implies (H7), but the opposite implication may not hold, as the following example shows.

*Example 3.3.* Consider the problem of minimizing  $x(1)$  subject to

$$\dot{x}(t) = u_1^2(t) + u_3^2(t), \quad u_1(t) + u_2^2(t) + u_3^2(t) \leq 0, \quad u_1(t) - u_2^3(t) \leq 0, \quad x(0) = 0.$$

Here the control variable is  $(u_1, u_2, u_3)$ . This is a problem without equality constraints. A minimizer is  $(0, 0, 0, 0)$  and  $\mathcal{I}_a(t) = \{1, 2\}$  for all  $t \in T$ . It is easy to check that Theorem 3.1 holds with  $p(t) = -1$  and  $\lambda = 1$ . For this problem, the matrix

$$F(t) = \begin{pmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}$$

does satisfy (H7) but not  $(H^*)$ : set  $h(t) = (1, 0, 0)^T$ ,  $a(t) = (1, 1)^T$ , and  $K_2 = 1/2$ .

In situations when  $m_g \neq 0$  and  $m_b \neq 0$ , it is crucial for  $h \in L^\infty(T; \mathbf{R}^{k_u})$  to satisfy simultaneously (H7)(ii) and (H7)(iii). The following simple example, for which there is no such  $h$ , illustrates this fact.

*Example 3.4.* Consider the problem of minimizing  $x(1)$  subject to

$$\dot{x}(t) = u_1(t), \quad u_2(t) - x^2(t) = 0, \quad u_2(t) - u_1^3(t) \leq 0, \quad x(0) = 0.$$

It is easy to see that  $(\bar{x}, \bar{u}_1, \bar{u}_2) \equiv (0, 0, 0)$  is a minimizer. Along this minimizer the inequality constraint is active for all  $t \in T$ . For this problem we have

$$H(t, x, p, q, r, u_1, u_2) = pu_1 + q(u_2 - x^2) + r(u_2 - u_1^3).$$

Theorem 3.2 does not hold for this problem. Indeed, by applying the conclusions of this theorem, we get

$$(-\dot{p}(t), 0, 0) = (0, p(t), q(t) + r(t))$$

and  $p(1) = -\lambda$ . It follows that  $p \equiv 0$ . Consequently  $\lambda = 0$ , contradicting the nontriviality condition (i) of Theorem 3.2. The pathological aspect of this problem is that (H7) is not satisfied. Indeed, since

$$\nabla_{u_1, u_2} b(t, 0, 0, 0) = \nabla_{u_1, u_2} g(t, 0, 0, 0) = (0, 1) \quad \text{for all } t \in T,$$

it is impossible to define a vector  $h \in \mathbf{R}^2$  for which

$$\nabla_{u_1, u_2} b(t, 0, 0, 0) \cdot h = 0 \quad \text{and} \quad \nabla_{u_1, u_2} g(t, 0, 0, 0) \cdot h \neq 0.$$

**4. Proof of Theorem 3.1.** The proof technique we shall use consists in defining a sequence of optimization problems  $(R_k)$ , and, by applying Ekeland's variational principle to such a sequence, we obtain a sequence of optimal control problems with mixed constraints, satisfying full rank conditions, to which Theorem 2.3 applies. Taking limits, we get necessary conditions for (Q) satisfying (ii)–(v) of Theorem 3.1. Finally, by appealing to (H7), we prove that the nontriviality condition (i) of Theorem 3.1 is also verified. We proceed in six steps.

*Step 1.* Introduction of new sets and functions.

We shall find it convenient to introduce auxiliary functions  $\bar{\alpha}, \bar{z}, \bar{w}: T \rightarrow \mathbf{R}^{m_g}$  such that  $\bar{\alpha}(t) = \bar{z}(t) = \bar{w}(t) = 0$  a.e. in  $T$ . Also, set

$$U_\epsilon(t) := \bar{u}(t) + \epsilon B, \quad V_\epsilon(t) := V(t) \cap (\bar{v}(t) + \epsilon B), \quad \mathcal{A}_\epsilon(t) := \bar{\alpha}(t) + \epsilon B,$$

and consider the functions

$$F_z(w, \alpha) := w - \alpha, \quad F_w(\alpha) := \alpha^2, \quad G(t, x, z, u, v, \alpha) := g(t, x, u, v) + z + \alpha$$

which take values in  $\mathbf{R}^{m_g}$ . Componentwise, these functions are defined as

$$F_{z_i}(w, \alpha) = w_i - \alpha_i, \quad F_{w_i}(\alpha) = \alpha_i^2(t), \quad G_i(t, x, z, u, v, \alpha) = g_i(t, x, u, v) + z_i + \alpha_i$$

for all  $i \in \{1, \dots, m_g\}$ . Under the hypotheses,  $F_z$ ,  $F_w$ , and  $G$  are measurable with respect to  $t$  and Lipschitz continuous with respect to the remaining variables near

$$(\bar{x}(t), \bar{z}(t), \bar{w}(t), \bar{u}(t), \bar{v}(t), \bar{\alpha}(t)).$$

Also, as it can be easily proved, there exist integrable functions  $C_f, C_{F_z}, C_{F_w}$ , and  $C_G$  such that  $|f(t, x, u, v)| \leq C_f(t)$ ,  $|F_z(w, \alpha)| \leq C_{F_z}(t)$ ,  $|F_w(\alpha)| \leq C_{F_w}(t)$ , and

$$|G(t, x, z, u, v, \alpha)| \leq C_G(t)$$

for all  $(x, z, w, u, v, \alpha) \in (\bar{x}(t), \bar{z}(t), \bar{w}(t), \bar{u}(t), \bar{v}(t), \bar{\alpha}(t)) + \epsilon B$  a.e. in  $T$ .

*Step 2.* Definition of a sequence of optimization problems and verification that Ekeland's variational principle applies to such a sequence.

Define  $W$  as the set of all measurable functions  $(u, v, \alpha)$  and all vectors  $(a, b) \in \mathbf{R}^n \times \mathbf{R}^n$  such that, for almost every  $t \in T$ ,  $(u(t), v(t), \alpha(t)) \in U_\epsilon(t) \times V_\epsilon(t) \times \mathcal{A}_\epsilon(t)$  and  $(a, b) \in C$ , and for which there exist absolutely continuous functions  $x, y, z$ , and  $w$  such that

$$\begin{cases} \dot{x}(t) = f(t, x(t), u(t), v(t)), \quad \dot{y}(t) = 0, \quad \dot{z}(t) = F_z(w(t), \alpha(t)), \quad \dot{w}(t) = F_w(\alpha(t)) & \text{a.e.}, \\ 0 \geq G(t, x(t), z(t), u(t), v(t), \alpha(t)) & \text{a.e.}, \\ (x(t), y(t), z(t), w(t)) \in (\bar{x}(t), \bar{x}(1), \bar{z}(t), \bar{w}(t)) + \epsilon B & \text{a.e.}, \\ (x(0), y(0), z(0), w(0)) = (a, b, 0, 0). \end{cases}$$

Here  $z$  and  $y$  are two additional state variables and  $\alpha$  an additional control.

Let  $\{\epsilon_k\}_{k \in \mathbf{N}}$  be a sequence of positive scalars such that  $\epsilon_k \rightarrow 0$  and  $k \rightarrow \infty$ , and define

$$\Psi_k(x, y, x', y', z, w) := \max\{l(x, y) - l(\bar{x}(0), \bar{x}(1)) + \epsilon_k^2, \epsilon_k^2|w|, |w - z|, |x' - y'|\}.$$

To simplify the notation set  $E = (a, b) \in \mathbf{R}^{2n}$ . Let  $|E - E'| = |a - a'| + |b - b'|$  and

$$\nu((u, v, \alpha), (u', v', \alpha')) := \int_0^1 |u(t) - u'(t)| dt + \int_0^1 |v(t) - v'(t)| dt + \int_0^1 |\alpha(t) - \alpha'(t)| dt.$$

Define  $\delta_W: W \times W \rightarrow \mathbf{R}$  by

$$\delta_W((u, v, \alpha, E), (u', v', \alpha', E')) = \nu((u, v, \alpha), (u', v', \alpha')) + |E - E'|.$$

Consider the sequence of optimization problems

$$(R_k) \quad \text{Minimize } J_k(u, v, \alpha, E) \text{ subject to } (u, v, \alpha, E) \in W,$$

where

$$J_k(u, v, \alpha, E) = \Psi_k(x(0), y(0), x(1), y(1), z(1), w(1)).$$

Set  $\bar{E} = (\bar{x}(0), \bar{x}(1))$ . Since  $(\bar{u}, \bar{v}, \bar{\alpha}, \bar{E}) \in W$ ,  $W$  is nonempty. Moreover, as one readily verifies,  $\delta_W$  defines a metric in  $W$ , the set  $W$  is a complete metric space with respect to this metric, and the function  $(u, v, \alpha, E) \mapsto J_k(u, v, \alpha, E)$  is continuous on  $(W, \delta_W)$ . Now, for all  $k \in \mathbf{N}$ , we have

$$J_k(\bar{u}, \bar{v}, \bar{\alpha}, \bar{E}) = \Psi_k(\bar{x}(0), \bar{x}(1), \bar{x}(1), \bar{x}(1), \bar{z}(1), \bar{w}(1)) = \epsilon_k^2.$$

Since, for all  $k \in \mathbf{N}$ ,  $J_k(u, v, \alpha, E) \geq 0$ ,  $(\bar{u}, \bar{v}, \bar{\alpha}, \bar{E})$  is an “ $\epsilon_k^2$ -minimizer” for  $(R_k)$ . By Ekeland’s variational principle (see [25]), there exists a sequence  $(u_k, v_k, \alpha_k, E_k) \in W$  such that, for each  $k \in \mathbf{N}$ ,

$$(4.1) \quad \delta_W((u_k, v_k, \alpha_k, E_k), (\bar{u}, \bar{v}, \bar{\alpha}, \bar{E})) \leq \epsilon_k$$

and  $(u_k, v_k, \alpha_k, E_k)$  minimizes the perturbed cost function

$$J_k(u, v, \alpha, E) + \epsilon_k \delta_W((u_k, v_k, \alpha_k, E_k), (u, v, \alpha, E))$$

for all  $(u, v, \alpha, E) \in W$ .

*Step 3.* Derivation of a sequence of standard optimal control problems by rewriting the conclusions of Ekeland’s theorem in control theoretic terms.

Let  $(x_k, y_k, z_k, w_k)$  be the trajectory corresponding to  $(u_k, v_k, \alpha_k, E_k)$ . For each  $k \in \mathbf{N}$ , the process

$$(x_k, y_k, z_k, w_k, \omega_1, \omega_2, \omega_3, u_k, v_k, \alpha_k) \quad \text{with} \quad (\omega_1, \omega_2, \omega_3) \equiv (0, 0, 0)$$

solves the control problem  $(C_k)$  of minimizing

$$\begin{aligned} \Phi_k(\gamma(0), \gamma(1)) &:= \Psi_k(x(0), y(0), x(1), y(1), z(1), w(1)) \\ &\quad + \epsilon_k |x(0) - x_k(0)| + \epsilon_k |y(0) - y_k(0)| + \sum_{i=1}^3 \epsilon_k \omega_i(1), \end{aligned}$$

where  $\gamma(t) = (x(t), y(t), z(t), w(t), \omega_1(t), \omega_2(t), \omega_3(t))$ , subject to

$$\left\{ \begin{array}{l} \dot{x}(t) = f(t, x(t), u(t), v(t)), \quad \dot{y}(t) = 0, \quad \dot{z}(t) = F_z(w(t), \alpha(t)), \quad \dot{w}(t) = F_w(\alpha(t)), \\ \dot{\omega}_1(t) = |u(t) - u_k(t)|, \quad \dot{\omega}_2(t) = |v(t) - v_k(t)|, \quad \dot{\omega}_3(t) = |\alpha(t) - \alpha_k(t)|, \\ 0 \geq G(t, x(t), z(t), u(t), v(t), \alpha(t)), \\ (x(t), y(t), z(t), w(t)) \in (\bar{x}(t), \bar{x}(1), \bar{z}(t), \bar{w}(t)) + \epsilon B, \\ (u(t), v(t), \alpha(t)) \in U_\epsilon(t) \times V_\epsilon(t) \times \mathcal{A}_\epsilon(t), \\ (x(0), y(0), z(0), w(0)) \in C \times \{(0, 0)\}, \quad (\omega_1(0), \omega_2(0), \omega_3(0)) = (0, 0, 0), \end{array} \right.$$

all the relations but the last two being understood in an a.e. sense. Since  $\epsilon_k \downarrow 0$ , we can arrange by subsequence extraction, if necessary, that  $\sum \epsilon_k < \infty$ . By (4.1) we deduce that  $(u_k, v_k, \alpha_k) \rightarrow (\bar{u}, \bar{v}, \bar{\alpha})$  strongly in  $L^1$  and  $E_k \rightarrow (\bar{x}(0), \bar{x}(1))$ . Subsequence extraction yields  $(u_k(t), v_k(t), \alpha_k(t)) \rightarrow (\bar{u}(t), \bar{v}(t), \bar{\alpha}(t))$  a.e. We deduce from the above that  $(x_k, y_k, z_k, w_k) \rightarrow (\bar{x}, \bar{x}(1), \bar{z}, \bar{w})$  *uniformly*. By discarding initial terms of the sequence, if necessary, we have

$$(x_k(t), y_k(t), z_k(t), w_k(t)) \in (\bar{x}(t), \bar{x}(1), \bar{z}(t), \bar{w}(t)) + (\epsilon/2)B \quad \text{for all } k.$$

Then  $S_k := (x_k, y_k, z_k, w_k, 0, 0, 0, u_k, v_k, \alpha_k)$  is a weak minimizer of  $(\tilde{C}_k)$ , a variant of  $(C_k)$  obtained by dropping the state constraint

$$(x(t), y(t), z(t), w(t)) \in (\bar{x}(t), \bar{x}(1), \bar{z}(t), \bar{w}(t)) + \epsilon B.$$

*Step 4.* Derivation of necessary conditions for  $(\tilde{C}_k)$ .

Let  $\mathcal{R} := \{(\rho_1, \rho_2, \rho_3, \rho_4) \in \mathbf{R}^4 \mid \rho_i \geq 0, \rho_1 + \dots + \rho_4 = 1\}$ , and define  $\tilde{H}$  as

$$\begin{aligned} \tilde{H}(t, x, z, w, p, q_z, q_w, r, u, v, \alpha) \\ := p \cdot f(t, x, u, v) + q_z \cdot F_z(w, \alpha) + q_w \cdot F_w(\alpha) + r \cdot G(t, x, z, u, v, \alpha). \end{aligned}$$

LEMMA 4.1. *There exist scalars  $\lambda_k$ ,  $\rho_{1_k}$ ,  $\rho_{2_k}$ ,  $\rho_{3_k}$ , and  $\rho_{4_k}$ , vectors  $e_{2_k}$ ,  $e_{3_k} \in \mathbf{R}^{m_g}$ , and  $e_{4_k} \in \mathbf{R}^n$ , integrable functions  $\zeta_k: T \rightarrow \mathbf{R}^{k_v}$  and  $r_k: T \rightarrow \mathbf{R}^{m_g}$ , and absolutely continuous functions  $p_k$ ,  $q_{z_k}$ , and  $q_{w_k}$ , such that*

- (a)  $\lambda_k \rho_{1_k} + \|p_k\|_\infty + \|q_{z_k}\|_\infty + \|q_{w_k}\|_\infty + 3\lambda_k \epsilon_k = 1$ ,
- (b)  $\lambda_k \geq 0$ ,  $|e_{i_k}| = 1$  for  $i = 2, 3, 4$  and  $\rho_k = (\rho_{1_k}, \rho_{2_k}, \rho_{3_k}, \rho_{4_k}) \in \mathcal{R}$ ,
- (c)  $p_k(1) = -\lambda_k \rho_{4_k} e_{4_k}$ ,  $q_{w_k}(1) = -q_{z_k}(1) + \lambda_k \rho_{2_k} \epsilon_k^2 e_{2_k}$ ,  $q_{z_k}(1) = -\lambda_k \rho_{3_k} e_{3_k}$ ,
- (d)  $(p_k(0), -p_k(1)) \in N_C(x_k(0), y_k(0)) + \lambda_k \rho_{1_k} \partial l(x_k(0), y_k(0)) + \lambda_k \epsilon_k (B \times B)$ ,
- (e)  $\zeta_k(t) \in \text{co } N_{V(t)}(v_k(t))$  a.e.,
- (f)  $(-\dot{p}_k(t), -\dot{q}_{z_k}(t), -\dot{q}_{w_k}(t), 0, \zeta_k(t), 0) \in \text{co } \partial \tilde{H}(t, x_k(t), z_k(t), w_k(t), p_k(t), q_{z_k}(t), q_{w_k}(t), r_k(t), u_k(t), v_k(t), \alpha_k(t)) + \lambda_k \epsilon_k (\{(0, 0, 0)\} \times B \times B \times B)$  a.e.,

where  $\partial \tilde{H}$  refers to the subdifferential of  $\tilde{H}$  in the  $(x, z, w, u, v, \alpha)$  variables,

- (g)  $r_k(t) \cdot G(t, x_k(t), z_k(t), u_k(t), v_k(t), \alpha_k(t)) = 0$  and  $r_k(t) \leq 0$  a.e.

*Proof.* Without loss of generality assume that  $|w_k(1)| < 1$  for all  $k \in \mathbf{N}$ . Define

$$\begin{aligned} h(t, x, y, z, w, \omega_1, \omega_2, \omega_3, p, s, q_z, q_w, r, \Pi, u, v, \alpha) \\ := p \cdot f(t, x, u, v) + s \cdot 0 + q_z \cdot F_z(w, \alpha) + q_w \cdot F_w(\alpha) + r \cdot G(t, x, z, u, v, \alpha) \\ + \pi_1 |u - u_k(t)| + \pi_2 |v - v_k(t)| + \pi_3 |\alpha - \alpha_k(t)|, \end{aligned}$$

where  $\Pi = (\pi_1, \pi_2, \pi_3)$ . To simplify the notation, set  $P_k := (p_k, s_k, q_{z_k}, q_{w_k})$ . It is a simple matter to see that

$$\frac{\partial}{\partial \alpha} G(t, x_k(t), z_k(t), u_k(t), v_k(t), \alpha_k(t)) = I \quad \text{a.e. in } T,$$

where  $I$  is the identity matrix. Thus problem  $(\tilde{C}_k)$  satisfies the conditions under which Theorem 2.3 applies. Observing that  $u_k$  and  $\alpha_k$  take values in the interior of the appropriated control sets, an application of Theorem 2.3 yields absolutely continuous functions  $P_k(t)$ ,  $\Pi_k(t)$ , a scalar  $\lambda_k \geq 0$ , and integrable functions  $r_k$ ,  $\zeta_k$  such that

$$(A) \quad \lambda_k + \|p_k\|_\infty + \|s_k\|_\infty + \|q_{z_k}\|_\infty + \|q_{w_k}\|_\infty + \sum_{i=1}^3 \|\pi_{i_k}\|_\infty > 0,$$

- (B)  $(-\dot{P}_k(t), -\dot{\Pi}_k(t), 0, \zeta_k(t), 0) \in \text{co } \partial h_k(t)$  a.e.,  
 (C)  $\zeta_k(t) \in \text{co } N_{V(t)}(v_k(t))$  a.e.,  
 (D)  $(P_k(0), \Pi_k(0), -P_k(1), -\Pi_k(1))$   
 $\in (N_C(x_k(0), y_k(0)) \times \mathbf{R}^{m_g} \times \mathbf{R}^{m_g}) \times \mathbf{R}^3 \times \{(0, 0, 0, 0)\} \times \{(0, 0, 0)\}$   
 $+ \lambda_k \partial \Phi_k(\gamma_k(0), \gamma_k(1)),$   
 (E)  $r_k(t) \cdot G(t, x_k(t), z_k(t), u_k(t), v_k(t), \alpha_k(t)) = 0$  and  $r_k(t) \leq 0$  a.e.,  
 where  $\partial h_k(t)$  denotes the subdifferential of  $h$  with respect to

$$(x, y, z, w, \omega_1, \omega_2, \omega_3, u, v, \alpha)$$

evaluated at  $S_k$ . Since  $h$  does not depend on  $y, \omega_1, \omega_2$ , and  $\omega_3$ , we deduce from (B) that

$$(4.2) \quad -\dot{P}_k(t) = (-\dot{p}_k(t), 0, -\dot{q}_{z_k}(t), -\dot{q}_{w_k}(t)) \quad \text{and} \quad -\dot{\Pi}_k(t) = (0, 0, 0).$$

We now turn to  $\Psi_k$ . Observe that, by (H3),  $\Psi_k(x, y, x', y', z, w)$  is Lipschitz around

$$(\bar{x}(0), \bar{x}(1), \bar{x}(1), \bar{x}(1), \bar{z}(1), \bar{w}(1)).$$

We claim that, for  $k$  sufficiently large,

$$(4.3) \quad \Psi_k(x_k(0), y_k, x_k(1), y_k, z_k(1), w_k(1)) > 0.$$

By definition this relation is nonnegative. Suppose it equals zero. Then

$$(4.4) \quad y_k(1) = x_k(1), \quad l(x_k(0), y_k(0)) < l(\bar{x}(0), \bar{x}(1)),$$

$$(4.5) \quad (x_k(0), x_k(1)) \in C, \quad z_k(1) = 0, \quad w_k(1) = 0.$$

Since  $\dot{w}_k(t) \geq 0$  a.e. and  $w_k(0) = w_k(1) = 0$  we have  $w_k(t) = 0$  and  $\alpha_k(t) = 0$  a.e. Thus  $\dot{z}_k(t) = 0$  a.e., which, together with  $z_k(0) = 0$ , implies that  $z_k(t) = 0$  a.e. It follows from the above that

$$(4.6) \quad G_i(t, x_k(t), z_k(t), u_k(t), v_k(t), \alpha_k(t)) = g_i(t, x_k(t), u_k(t), v_k(t)) \leq 0 \quad \text{a.e.}$$

for all  $i \in \{1, \dots, m_g\}$ . Thus, if  $\Psi_k(x_k(0), y_k, x_k(1), y_k, z_k(1), w_k(1)) = 0$ , we deduce from (4.4)–(4.6) that  $(x_k, u_k, v_k)$  is an admissible process for (Q), contradicting the optimality of  $(\bar{x}, \bar{u}, \bar{v})$ . This proves the claim.

Let us now prove that the limiting subdifferential calculus (Max Rule; see [25, Theorem 5.2.2]) and (4.3) yield the following estimation of the subdifferential of  $\Psi_k$  with respect to  $(x, y, x', y', z, w)$ :

$$(4.7) \quad \partial \Psi_k(x_k(0), y_k(0), x_k(1), y_k(1), z_k(1), w_k(1)) \subset \{\rho_1(\theta_1, \theta_2, 0, 0, 0, 0) \\ + \rho_2(0, 0, 0, 0, \epsilon_k^2 e_2) + \rho_3(0, 0, 0, 0, e_3, -e_3) + \rho_4(0, 0, e_4, -e_4, 0, 0) \mid \\ (\theta_1, \theta_2) \in \partial l(x_k(0), y_k(0)), |e_2| = |e_3| = |e_4| = 1, \rho \in \mathcal{R}, \rho_i = 0 \text{ if } \bar{\psi}_{i_k} < \bar{\Psi}_k\},$$

where  $e_2, e_3$ , and  $e_4$  are vectors such that  $e_2, e_3 \in \mathbf{R}^{m_g}, e_4 \in \mathbf{R}^n$ ,

$$\Psi_k = \max\{\psi_{1_k}, \psi_{2_k}, \psi_{3_k}, \psi_{4_k}\},$$

$$\psi_{1_k} = l(x, y) - l(\bar{x}(0), \bar{x}(1)) + \epsilon_k^2, \quad \psi_{2_k} = \epsilon_k^2 |w|, \quad \psi_{3_k} = |w - z|, \quad \psi_{4_k} = |x' - y'|,$$

and  $\bar{\Psi}_k$  and  $\bar{\psi}_{i_k}$  denote, respectively, the functions  $\Psi_k$  and  $\psi_{i_k}$  evaluated at

$$(x_k(0), y_k(0), x_k(1), y_k(1), z_k(1), w_k(1)).$$

Suppose that  $x_k(1) \neq y_k(1)$ . Then inclusion (4.7) holds with  $e_4 \in \mathbf{R}^n$  and  $|e_4| = 1$ . Analogously, if  $w_k(1) \neq z_k(1)$ , then (4.7) holds with  $e_3 \in \mathbf{R}^{m_g}$ ,  $|e_3| = 1$ . Finally, if  $w_k(1) \neq 0$ , then (4.7) also holds with  $e_2 \in \mathbf{R}^{m_g}$ ,  $|e_2| = 1$ . On the other hand, if  $\bar{\psi}_{i_k} = 0$  for some  $i \in \{2, 3, 4\}$ , from (4.3) we have  $\rho_{i_k} = 0$ . Thus (4.7) holds.

From (D), (4.2), and (4.7) we deduce the existence of vectors

$$\rho_k = (\rho_{1_k}, \rho_{2_k}, \rho_{3_k}, \rho_{4_k}), \quad e_{2_k}, e_{3_k} \in \mathbf{R}^{m_g}, \quad e_{4_k} \in \mathbf{R}^n$$

such that  $\rho_k \in \mathcal{R}$ ,  $\rho_{i_k} = 0$  if  $\bar{\psi}_{i_k} < \bar{\Psi}_k$ ,

$$(4.8) \quad |e_{2_k}| = |e_{3_k}| = |e_{4_k}| = 1,$$

$$(4.9) \quad \Pi_k(t) \equiv \lambda_k \epsilon_k (1, 1, 1).$$

Also,  $s_k$  is constant, and

$$(4.10) \quad q_{z_k}(1) = -\lambda_k \rho_{3_k} e_{3_k},$$

$$(4.11) \quad q_{w_k}(1) = -q_{z_k}(1) + \lambda_k \rho_{2_k} \epsilon_k^2 e_{2_k},$$

$$(4.12) \quad p_k(1) = -s_k = -\lambda_k \rho_{4_k} e_{4_k},$$

$$(4.13) \quad |p_k(1)| = \lambda_k \rho_{4_k},$$

$$(4.14) \quad (p_k(0), s_k) \in N_C(x_k(0), y_k(0)) + \lambda_k \rho_{1_k} \partial l(x_k(0), y_k(0)) + \lambda_k \epsilon_k (B \times B).$$

Equations (4.8), (4.12), and (4.13) yield  $|s_k| = |p_k(1)|$ . Since  $\rho_k \in \mathcal{R}$  we have  $|s_k| = \lambda_k(1 - \rho_{1_k} - \rho_{2_k} - \rho_{3_k})$ , which, together with (4.10), implies that  $\lambda_k = |s_k| + |q_{z_k}(1)| + \lambda_k \rho_{1_k} + \lambda_k \rho_{2_k}$ . It follows from (A) and the above that

$$(4.15) \quad \lambda_k \rho_{1_k} + \lambda_k \rho_{2_k} + \|p_k\|_\infty + 2|p_k(1)| + \|q_{z_k}\|_\infty + |q_{z_k}(1)| + \|q_{w_k}\|_\infty + 3\lambda_k \epsilon_k > 0.$$

We claim that this last inequality implies that

$$(4.16) \quad \lambda_k \rho_{1_k} + \|p_k\|_\infty + 2|p_k(1)| + \|q_{z_k}\|_\infty + |q_{z_k}(1)| + \|q_{w_k}\|_\infty + 3\lambda_k \epsilon_k > 0.$$

Seeking a contradiction suppose that (4.15) holds and

$$(4.17) \quad \lambda_k \rho_{1_k} + \|p_k\|_\infty + 2|p_k(1)| + \|q_{z_k}\|_\infty + |q_{z_k}(1)| + \|q_{w_k}\|_\infty + 3\lambda_k \epsilon_k = 0.$$

Then  $\lambda_k \rho_{2_k} \neq 0$ , i.e.,  $\lambda_k \neq 0$  and  $\rho_{2_k} \neq 0$ . It follows from (4.17) that  $\rho_{1_k} = \rho_{3_k} = \rho_{4_k} = 0$  and, consequently,  $\rho_{2_k} = 1$ . By (4.17) we also have  $q_{z_k}(1) = 0$  and  $q_{w_k}(t) \equiv 0$ . However, since  $\lambda_k \rho_{2_k} \neq 0$ , it follows from (4.11) that  $q_{w_k}(1) \neq 0$ , a contradiction. Thus (4.16) holds, a condition which ensures that

$$\lambda_k \rho_{1_k} + \|p_k\|_\infty + \|q_{z_k}\|_\infty + \|q_{w_k}\|_\infty + 3\lambda_k \epsilon_k > 0.$$

Equations (4.10)–(4.13) yield (c). On the other hand, the requirement that  $\lambda_k \geq 0$ ,  $\rho_k \in \mathcal{R}$ , and (4.8) correspond to (b). Inclusion (4.14), together with (4.12), implies (d), and (C) and (E) are, respectively, (e) and (g). To prove (f), note that

$$\begin{aligned} h(t, x, y, z, w, \omega_1, \omega_2, \omega_3, p, s, q_z, q_w, r_k, \Pi, u, v, \alpha) \\ = \tilde{H}(t, x, z, w, p, q_z, q_w, r_k, u, v, \alpha) + \pi_1 |u - u_k| + \pi_2 |v - v_k| + \pi_3 |\alpha - \alpha_k|. \end{aligned}$$

Estimating the subdifferential  $\text{co } \partial h_k$  with the help of the sum rule and (4.9), we have

$$\begin{aligned} \text{co } \partial h_k \subset \{(\varrho_1, 0, \varrho_2, \varrho_3, 0, 0, 0, \varrho_4, \varrho_5, \varrho_6) \mid (\varrho_1, \varrho_2, \varrho_3, \varrho_4, \varrho_5, \varrho_6) \\ \in \text{co } \partial_{x, z, w, u, v, \alpha} \tilde{H}(t, x_k, z_k, w_k, p_k, q_{z_k}, q_{w_k}, r_k, u_k, v_k, \alpha_k)\} \\ + \lambda_k \epsilon_k (\{(0, 0, 0, 0, 0, 0)\} \times B \times B \times B), \end{aligned}$$

and so (f) holds in virtue of the above, (B), and (4.2). Finally, by a simple scaling argument, we can normalize to one the sum of the multipliers norms without affecting the other conclusions of the lemma, implying that (a) also holds. This completes the proof of the lemma.  $\square$

*Step 5.* Derivation of necessary conditions for (P) by considering  $\epsilon_k \rightarrow 0$  and taking limits.

The sequences  $\{e_{2_k}\}$ ,  $\{e_{3_k}\}$ ,  $\{e_{4_k}\}$ , and  $\{\rho_k\}$  are uniformly bounded by Lemma 4.1(b). From Lemma 4.1(a), the sequences  $\{\lambda_k\}$ ,  $\{\|p_k\|_\infty\}$ ,  $\{\|q_{z_k}\|_\infty\}$ , and  $\{\|q_{w_k}\|_\infty\}$  are also uniformly bounded. We can therefore arrange, by subsequence extraction, if necessary, that

$$e_{2_k} \rightarrow e_2, \quad e_{3_k} \rightarrow e_3, \quad e_{4_k} \rightarrow e_4, \quad \lambda_k \rightarrow \hat{\lambda}, \quad \text{and} \quad \rho_k \rightarrow \rho = (\rho_1, \rho_2, \rho_3, \rho_4),$$

where  $|e_2| = |e_3| = |e_4| = 1$ ,  $\hat{\lambda} \geq 0$ , and  $\rho \in \mathcal{R}$ .

Now, by appealing to measurable selection theorems and taking into account the differentiability properties of  $g$ ,  $F_z$ , and  $F_w$ , we deduce, in view of Lemma 4.1(f), the existence of an integrable function  $K_r$  such that  $|r_k(t)| \leq K_r(t)$  a.e. in  $T$ . We also deduce that the sequences  $\{\dot{p}_k\}$ ,  $\{\dot{q}_{z_k}\}$ , and  $\{\dot{q}_{w_k}\}$  are uniformly integrably bounded and there exists an integrable function  $K_\zeta$  such that  $|\zeta_k(t)| \leq K_\zeta(t)$  a.e. in  $T$ .

We shall find it convenient to introduce the following scaled version  $\tilde{r}_k$  of  $r_k$ , given by  $\tilde{r}_k(t) = (1 + K_r(t))^{-1} r_k(t)$ . Note that the sequence  $\{\|\tilde{r}_k\|_\infty\}$  is uniformly bounded and  $\{t \mapsto \int_0^t \zeta_k ds\}$  is equicontinuous and uniformly bounded. Following extraction of subsequences we have that, for some absolutely continuous functions  $p$ ,  $q_z$ ,  $q_w$ , an integrable function  $\zeta$ , and  $\tilde{r} \in L^\infty$ ,

$$p_k \rightarrow p, \quad q_{z_k} \rightarrow q_z, \quad q_{w_k} \rightarrow q_w, \quad \int_0^t \zeta_k ds \rightarrow \int_0^t \zeta ds \quad \text{uniformly,}$$

$\dot{p}_k \rightarrow \dot{p}$ ,  $\dot{q}_{z_k} \rightarrow \dot{q}_z$ ,  $\dot{q}_{w_k} \rightarrow \dot{q}_w$ ,  $\zeta_k \rightarrow \zeta$  weakly in  $L^1$ , and  $\tilde{r}_k \rightarrow \tilde{r}$  weakly\* in  $L^\infty$ . Taking into account Lemma 4.1(g) we deduce that, for any measurable set  $B \subset T$ ,

$$0 = \int_B \tilde{r}_k(t) \cdot G_k(t) dt = \int_B \tilde{r}_k(t) \cdot \{G_k(t) - \bar{G}(t)\} dt + \int_B \tilde{r}_k(t) \cdot \bar{G}(t) dt$$

and  $\int_B \tilde{r}_k(t) dt \leq 0$ , where

$$G_k(t) = G(t, x_k(t), z_k(t), u_k(t), v_k(t), \alpha_k(t)), \quad \bar{G}(t) = G(t, \bar{x}(t), \bar{z}(t), \bar{u}(t), \bar{v}(t), \bar{\alpha}(t)).$$

By taking limits, we conclude that  $\tilde{r}(t) \leq 0$  and  $\tilde{r}(t) \cdot \bar{G}(t) = 0$  a.e. in  $T$ . Also, a straightforward modification of the proof of [3, Theorem 3.1.7] and an appeal to the upper semicontinuity properties of limiting normal cones and subdifferentials allow us to pass to the limit in the relationships (a)–(f) of Lemma 4.1. There results

$$(A') \quad \lambda + \|p\|_\infty + \|q_z\|_\infty + \|q_w\|_\infty > 0,$$

$$(B') \quad (-\dot{p}(t), -\dot{q}_z(t), -\dot{q}_w(t), 0, \zeta(t), 0)$$

$$\in \text{co } \partial \bar{H}(t, \bar{x}(t), \bar{z}(t), \bar{w}(t), p(t), q_z(t), q_w(t), r(t), \bar{u}(t), \bar{v}(t), \bar{\alpha}(t)) \quad \text{a.e.,}$$

$$(C') \quad \zeta(t) \in \text{co } N_{V(t)}(\bar{v}(t)) \quad \text{a.e.,}$$

$$(D') \quad (p(0), -p(1)) \in N_C(\bar{x}(0), \bar{x}(1)) + \lambda \partial l(\bar{x}(0), \bar{x}(1)),$$

$$(E') \quad |q_w(1)| = |q_z(1)|, \quad r(t) \leq 0, \quad \text{and} \quad r(t) \cdot G(t, \bar{x}(t), \bar{z}(t), \bar{u}(t), \bar{v}(t), \bar{\alpha}(t)) = 0 \quad \text{a.e.,}$$

where  $r(t) = (1 + K_r(t))\tilde{r}(t)$ .

*Step 6.* Rewriting relations (A')–(E') in the required form.

Recall that

$$\begin{aligned} \tilde{H}(t, x, z, w, p, q_z, q_w, r, u, v, \alpha) \\ = p \cdot f(t, x, u, v) + q_z \cdot (w - \alpha) + q_w \cdot \alpha^2 + r \cdot (g(t, x, u, v) + z + \alpha). \end{aligned}$$

We are now in a position to get an estimation for  $\text{co } \partial \tilde{H}$ . We have

$$\begin{aligned} \text{co } \partial \tilde{H}(t, x, z, w, p, q_z, q_w, r, u, v, \alpha) \subset \{(\theta_1 + r \nabla_x g, r, q_z, \theta_2 + r \nabla_u g, \\ \theta_3 + r \nabla_v g, -q_z + 2q_w \alpha + r) \mid (\theta_1, \theta_2, \theta_3) \in \text{co } \partial_{x,u,v} p \cdot f\}. \end{aligned}$$

Since  $\bar{\alpha}(t) = 0$  and  $\bar{w}(t) = 0$  a.e. in  $T$ , by appealing to an appropriate selection theorem, we deduce the existence of measurable functions  $\theta_1$ ,  $\theta_2$ ,  $\theta_3$ , and  $\zeta$  satisfying

$$(4.18) \quad (\theta_1(t), \theta_2(t), \theta_3(t)) \in \text{co } \partial_{x,u,v} p(t) \cdot f(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) \quad \text{a.e. in } T, \\ \zeta(t) \in N_{V(t)}(\bar{v}(t)) \quad \text{a.e. in } T.$$

We conclude from the above that

$$(4.19) \quad (-\dot{p}(t), -\dot{q}_z(t), -\dot{q}_w(t), 0, \zeta(t), 0) = (\theta_1(t) + r(t) \nabla_x \bar{g}(t), r(t), q_z(t), \\ \theta_2(t) + r(t) \nabla_u \bar{g}(t), \theta_3(t) + r(t) \nabla_v \bar{g}(t), r(t) - q_z(t)).$$

From (4.19) and (E') we deduce that, a.e. in  $T$ ,

$$(4.20) \quad q_z(t) = r(t), \quad \dot{q}_z(t) = -r(t), \quad \dot{q}_w(t) = -q_z(t)$$

and  $|q_w(1)| = |q_z(1)|$ . Set

$$H(t, x, p, r, u, v) := p \cdot f(t, x, u, v) + r \cdot g(t, x, u, v).$$

From the above and (4.19) we have

$$(4.21) \quad (-\dot{p}(t), 0, \zeta(t)) = (\theta_1(t) + r(t) \nabla_x \bar{g}(t), \theta_2(t) + r(t) \nabla_u \bar{g}(t), \theta_3(t) + r(t) \nabla_v \bar{g}(t))$$

for some  $(\theta_1(t), \theta_2(t), \theta_3(t)) \in \text{co } \partial_{x,u,v} p \cdot f(t, \bar{x}(t), \bar{u}(t), \bar{v}(t))$  a.e. in  $T$ . It follows that

$$(4.22) \quad (-\dot{p}(t), 0, \zeta(t)) \in \text{co } \partial_{x,u,v} H(t, \bar{x}(t), p(t), r(t), \bar{u}(t), \bar{v}(t)) \quad \text{a.e. in } T.$$

Taking into account (E'), we also have

$$(4.23) \quad r(t) \cdot g(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = 0 \quad \text{and} \quad r(t) \leq 0 \quad \text{a.e. in } T.$$

We deduce that (4.22), (C'), (4.23), and (D') are, respectively, (ii), (iii), (iv), and (v) of the theorem.

It remains to prove (i). We claim that

$$(4.24) \quad \lambda + |p(t)| > 0 \quad \text{for all } t \in T.$$

First observe that if  $q_z \equiv 0$  and  $q_w \equiv 0$ , then (4.24) holds. Seeking a contradiction assume that  $\lambda = 0$  and  $p(\tau) = 0$  for some  $\tau \in T$ . There are two cases to consider.

*Case 1.* Suppose that  $r(t) = 0$  a.e. Then by (4.20) we have  $q_z \equiv 0$ ,  $q_w \equiv 0$ . We deduce from (4.21) and (H1) the existence of  $K_1$  integrable with  $K_1(t) \geq 0$  a.e. such that  $|\dot{p}(t)| \leq K_1(t)|p(t)|$  a.e. Gronwall's inequality (see [25]) and the fact that  $p(\tau) = 0$

for some  $\tau \in T$  imply that  $p \equiv 0$ . But this, together with the fact that  $\lambda = 0$  and  $q_z \equiv 0$ ,  $q_w \equiv 0$ , and  $p \equiv 0$ , contradicts (A').

*Case 2.* Suppose now that  $r(t) \neq 0$  on a subset of  $T$  of Lebesgue measure different from zero. We deduce from (4.21) that  $0 = \theta_2(t) + r(t) \cdot \nabla_u \bar{g}(t)$  a.e. in  $T$ , where  $\theta_2(t)$  is defined in (4.18). Taking the inner product of the left-hand side of the previous equation and the vector  $h$  (defined in (H7)) we obtain, from (H7) and (iv) of the theorem, that  $\theta_2(t) \cdot h(t) = -r(t) \cdot a(t)$  a.e. in  $T$ . By hypotheses, there exists  $K_2$  integrable with  $K_2(t) \geq 0$  a.e. such that

$$(4.25) \quad |r(t)| \leq K_2(t)|p(t)| \quad \text{a.e. in } T.$$

We deduce from (4.21), (4.25), and (H1) the existence of  $K_3$  integrable with  $K_3(t) \geq 0$  a.e. such that  $|\dot{p}(t)| \leq K_3(t)|p(t)|$  a.e. in  $T$ . Again Gronwall's inequality and the fact that  $p(\tau) = 0$  for some  $\tau \in T$  imply that  $p \equiv 0$ . But then, by (4.25), we have  $r(t) = 0$  a.e., a contradiction.

We proved that  $\lambda + |p(t)| > 0$  for all  $t \in T$ , a condition which ensures that  $\lambda + \|p\|_\infty > 0$ . The proof is complete.  $\square$

**5. Proof of Theorem 3.2.** Consider the function  $\mu: T \times (\mathbf{R}^n \times \mathbf{R}^{k_u} \times \mathbf{R}^{k_v}) \times \mathbf{R}^{m_b} \rightarrow \mathbf{R}^{m_b}$  given by

$$\mu(t, (\xi, u, v), \eta) := b(t, \bar{x}(t) + \xi, \bar{u}(t) + u + \nabla_u \bar{b}(t)^T \eta, \bar{v}(t) + v).$$

We have  $\mu(t, (0, 0, 0), 0) = 0$  a.e. in  $T$ . Choose  $S_0 \subset T$  to be the largest subset such that this relation and each of the hypotheses do not hold for every  $t \in S_0$ . By assumption,  $S_0$  is of Lebesgue measure zero. Thus, there exists a Borel set  $S_1$ , which is the intersection of a countable collection of open sets, such that  $S_0 \subset S_1$  and  $S_1 \setminus S_0$  has measure zero. Thus  $S_1$  is a Borel set of measure zero. We define  $S := T \setminus S_1$ , a Borel set of full measure. We have

$$\frac{\partial \mu}{\partial \eta}(t, (0, 0, 0), 0) = \Gamma(t) := \nabla_u \bar{b}(t) \nabla_u \bar{b}(t)^T \quad \text{for all } t \in S.$$

By (H6) and (H7)(iv) there exists a constant  $M > 0$  such that  $|\Gamma(t)|^{-1} \leq M$  for all  $t \in S$ . Thus Proposition 2.2 applies to the function  $\mu$ , and it asserts the existence of  $\epsilon_1 \in (0, \epsilon)$ ,  $\delta_1 \in (0, \epsilon)$ , and an implicit map  $d: T \times \epsilon_1 B \times \epsilon_1 B \times \epsilon_1 B \rightarrow \delta_1 B$  such that  $d(\cdot, \xi, u, v)$  is a measurable function for fixed  $(\xi, u, v)$ , the functions  $\{d(t, \cdot, \cdot, \cdot) \mid t \in S\}$  are Lipschitz continuous with common Lipschitz constant  $K_d > 0$ , and  $d(t, \cdot, \cdot, \cdot)$  is continuously differentiable for fixed  $t \in S$ . Choose  $\sigma_1, \delta > 0$  such that

$$(5.1) \quad \sigma_1 \in (0, \min\{\epsilon_1, \epsilon/2\}), \quad \delta \in (0, \min\{\delta_1, \epsilon/2\}), \quad \sigma_1 + K_{b,g}\delta \in (0, \epsilon/2),$$

where  $\epsilon_1$  and  $\delta_1$  (which do not depend on  $t$ ) are as above and  $K_{b,g}$  is given by (H6).

In what follows, and without loss of generality, we consider the implicit function  $d$  defined on  $T \times \sigma_1 B \times \sigma_1 B \times \sigma_1 B$  and taking values in  $\delta B$ . The function  $d(t, \cdot, \cdot, \cdot)$  is continuously differentiable and Lipschitz continuous on  $\sigma_1 B \times \sigma_1 B \times \sigma_1 B$  with Lipschitz constant  $K_d$ , and it satisfies  $d(t, 0, 0, 0) = 0$  a.e. in  $T$ :

$$\mu(t, (\xi, u, v), d(t, \xi, u, v)) = 0 \quad \text{a.e. in } T, \quad \text{for all } (\xi, u, v) \in \sigma_1 B \times \sigma_1 B \times \sigma_1 B,$$

$$(d_\xi, d_u, d_v)(t, 0, 0, 0) = -\Gamma(t)^{-1}(\nabla_x \bar{b}(t), \nabla_u \bar{b}(t), \nabla_v \bar{b}(t)) \quad \text{a.e. in } T.$$

Define the functions

$$\begin{aligned} D(t, x, u, v) &:= d(t, x - \bar{x}(t), u - \bar{u}(t), v - \bar{v}(t)), \\ F(t, x, u, v) &:= f(t, x, u + \nabla_u \bar{b}(t)^T D(t, x, u, v), v), \\ G(t, x, u, v) &:= g(t, x, u + \nabla_u \bar{b}(t)^T D(t, x, u, v), v) \end{aligned}$$

and the sets  $\mathcal{U}(t) := \bar{u}(t) + \sigma_1 B$ ,  $\mathcal{V}(t) := V(t) \cap (\bar{v}(t) + \sigma_1 B)$ . Consider the problem

$$(P_{\text{aux}}) \quad \begin{cases} \text{Minimize } l(x(0), x(1)) \text{ subject to} \\ \dot{x}(t) = F(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ 0 \geq G(t, x(t), u(t), v(t)) & \text{a.e. in } T, \\ (u(t), v(t)) \in \mathcal{U}(t) \times \mathcal{V}(t) & \text{a.e. in } T, \\ (x(0), x(1)) \in C. \end{cases}$$

The process  $(\bar{x}, \bar{u}, \bar{v})$  is admissible for  $(P_{\text{aux}})$ . Assume that  $(\tilde{x}, \tilde{u}, \tilde{v})$  is a solution with lesser cost. Set

$$\begin{aligned} \hat{u}(t) &:= \tilde{u}(t) + \nabla_u \bar{b}(t)^T D(t, \tilde{x}(t), \tilde{u}(t), \tilde{v}(t)), \\ \xi(t) &:= \tilde{x}(t) - \bar{x}(t), \quad u_1(t) := \tilde{u}(t) - \bar{u}(t), \quad v_1(t) := \tilde{v}(t) - \bar{v}(t). \end{aligned}$$

From (5.1) and the definition of  $d$  it follows that

$$|\hat{u}(t) - \bar{u}(t)| \leq |\tilde{u}(t) - \bar{u}(t)| + K_{b,g} \delta \leq \sigma_1 + K_{b,g} \delta < \epsilon, \quad |\tilde{v}(t) - \bar{v}(t)| \leq \sigma_1 < \epsilon.$$

By definition of  $d$ , for almost all  $t \in T$  we have

$$\mu(t, (\xi(t), u_1(t), v_1(t)), d(t, \xi(t), u_1(t), v_1(t))) = b(t, \tilde{x}(t), \hat{u}(t), \tilde{v}(t)) = 0.$$

We conclude that  $(\tilde{x}, \hat{u}, \tilde{v})$  is a solution to  $(P)$  with lesser cost, contradicting the optimality of  $(\bar{x}, \bar{u}, \bar{v})$ . It follows that  $(\bar{x}, \bar{u}, \bar{v})$  is a minimizer for  $(P_{\text{aux}})$ .

Let us now check that  $(P_{\text{aux}})$  satisfies the conditions under which Theorem 3.1 holds. We need only verify that

$$(5.2) \quad \nabla_u \bar{G}^{\mathcal{I}_a(t)}(t) \cdot h(t) = a^{\mathcal{I}_a(t)}(t) \quad \text{a.e. in } T,$$

where  $h$  and  $a$  are the functions whose existence is postulated in (H7) and satisfy (H7)(i) and (H7)(ii). Observe that

$$\nabla_u G(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = \nabla_u \bar{g}(t) - \nabla_u \bar{g}(t) \nabla_u \bar{b}(t)^T \Gamma(t)^{-1} \nabla_u \bar{b}(t).$$

Taking into account (H7), the inner product of the left-hand side of the previous equation and vector  $h(t)$  leads to

$$\nabla_u \bar{G}^{\mathcal{I}_a(t)}(t) \cdot h(t) = \nabla_u \bar{g}^{\mathcal{I}_a(t)}(t) \cdot h(t) = a^{\mathcal{I}_a(t)}(t) \quad \text{a.e. in } T$$

proving (5.2). We now apply Theorem 3.1 to  $(P_{\text{aux}})$ . It asserts the existence of  $\lambda \geq 0$ ,  $p \in W^{1,1}(T; \mathbf{R}^n)$ ,  $r \in L^1(T; \mathbf{R}^{m_g})$ , and  $\zeta \in L^1(T; \mathbf{R}^{k_v})$  such that

- (i)  $\|p\|_\infty + \lambda \neq 0$ ,
- (ii)  $(-\dot{p}(t), 0, \zeta(t)) \in \text{co } \partial_{x,u,v} \tilde{H}(t, \bar{x}(t), p(t), r(t), \bar{u}(t), \bar{v}(t))$  a.e. in  $T$ ,
- (iii)  $\zeta(t) \in \text{co } N_{V(t)}(\bar{v}(t))$  a.e. in  $T$ ,
- (iv)  $r(t) \cdot G(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)) = 0$  and  $r(t) \leq 0$  a.e. in  $T$ ,
- (v)  $(p(0), -p(1)) \in N_C(\bar{x}(0), \bar{x}(1)) + \lambda \partial l(\bar{x}(0), \bar{x}(1))$ ,

where  $\tilde{H}(t, x, p, r, u, v) = p \cdot F(t, x, u, v) + r \cdot G(t, x, u, v)$ . From the nonsmooth chain rule (see [25]), the differentiability properties of  $d$ , and an appropriate selection theorem, there exist measurable functions  $\theta_1$ ,  $\theta_2$ ,  $\theta_3$ , and  $\zeta$  satisfying, a.e. in  $T$ ,

$$\begin{aligned} (\theta_1(t), \theta_2(t), \theta_3(t)) &\in \text{co } \partial_{x,u,v} p(t) \cdot f(t, \bar{x}(t), \bar{u}(t), \bar{v}(t)), \quad \zeta(t) \in \text{co } N_{V(t)}(\bar{v}(t)), \\ (-\dot{p}(t), 0, \zeta(t)) &= (\theta_1(t) + q(t) \nabla_x \bar{b}(t) + r(t) \nabla_x \bar{g}(t), \\ \theta_2(t) + q(t) \nabla_u \bar{b}(t) + r(t) \nabla_u \bar{g}(t) \theta_3(t) + q(t) \nabla_v \bar{b}(t) + r(t) \nabla_v \bar{g}(t)), \end{aligned}$$

where

$$(5.3) \quad q(t) = -(\theta_2(t) + r(t)\nabla_u \bar{g}(t))\nabla_u \bar{b}(t)^T \Gamma(t)^{-1}.$$

Under the hypotheses,  $\theta_1$ ,  $\theta_2$ ,  $\theta_3$ ,  $r$ , and  $\zeta$  are all integrable functions, and so is  $q$ . This proves that  $\lambda$ ,  $p$ ,  $q$ ,  $r$ , and  $\zeta$  satisfy (i)–(iv) of the theorem. Since there exists  $R$  integrable such that  $|r(t)| \leq R(t)|p(t)|$  a.e. in  $T$ , we deduce from (5.3) the existence of  $K_m$  integrable such that the last conclusion of the theorem holds. This completes the proof.  $\square$

## CONTROL OF A TIP-FORCE DESTABILIZED SHEAR BEAM BY OBSERVER-BASED BOUNDARY FEEDBACK\*

MIROSLAV KRSTIC<sup>†</sup>, BAO-ZHU GUO<sup>‡</sup>, ANDRAS BALOGH<sup>§</sup>, AND  
ANDREY SMYSHLYAEV<sup>¶</sup>

**Abstract.** We consider a model of the undamped shear beam with a destabilizing boundary condition. The motivation for this model comes from atomic force microscopy, where the tip of the cantilever beam is destabilized by van der Waals forces acting between the tip and the material surface. Previous research efforts relied on collocated actuation and sensing at the tip, exploiting the passivity property between the corresponding input and output in the beam model. In this paper we design a stabilizing output-feedback controller in a noncollocated setting, with measurements at the free end (tip) of the beam and actuation at the beam base. Our control design is a novel combination of the classical “damping boundary feedback” idea with a recently developed backstepping approach. A change of variables is constructed which converts the beam model into a wave equation (for a very short string) with boundary damping. This approach is physically intuitive and allows both an elegant stability analysis and an easy selection of design parameters for achieving desired performance. Our observer design is a dual of the similar ideas, combining the damping feedback with backstepping, adapted to the observer error system. Both stability and well-posedness of the closed-loop system are proved. The simulation results are presented.

**1. Introduction.** Flexible beams constitute an important benchmark problem in many application areas ranging from aerospace to civil structures. In some of the exciting modern fields such as atomic force microscopy, the cantilever beam is more than just a prototype problem and constitutes an important application topic in its own right.

In this paper we consider a model of the undamped shear beam [3] with a destabilizing boundary condition. It consists of a wave equation coupled with a second-order-in-space ODE or can be alternatively represented as a fourth-order-in-space/second-order-in-time PDE. This makes it more complex than the Euler–Bernoulli model [3], similar in structure to the Rayleigh beam model [3], and slightly simpler than the Timoshenko model [3]. The destabilizing boundary condition is motivated by the physics of the atomic force microscopy (AFM), where the tip of the cantilever beam is destabilized by van der Waals forces acting between the tip and the material surface [19].

Extensive literature exists on control of beam models [1, 2, 8, 4, 7, 9, 11, 17, 20, 21]. However, previous research efforts all relied on collocated actuation and sensing at the tip, exploiting in an elegant way the passivity property between the corresponding input and output in the beam model. The main drawback of this approach is that the tip of the beam is not a very convenient place to put an actuator. Therefore such feedbacks are usually implemented via passive dampers or through rather elaborate ways, such as electromagnets or small airjets at the tip of the beam.

Our objective is different—to design controllers implementable through noncollocated architecture, with actuation only at the base and sensing only at the tip of the beam. This architecture makes active control more readily implementable to several applications; for example, in AFM this allows a natural use of piezo actuation at the base of the beam. Our control design is a novel combination of the classical “damping boundary feedback” idea with a recently developed backstepping approach, which has been used to design boundary controllers [12, 14] and observers [13] for parabolic equations and for the Timoshenko beam model with a small amount of Kelvin–Voigt damping [6]. A change of variables is constructed which converts the beam model into a wave equation (for a very short string) with boundary damping. This approach is physically intuitive and allows both an elegant stability analysis and an easy selection of design parameters for achieving desired performance. Our observer design is a dual of the similar ideas, combining the damping feedback with backstepping, adapted to the observer error system.

In addition to rigorous stability and well-posedness analysis of the closed-loop system, we also present the results of simulations that illustrate the performance of the controller.

**2. Model.** The shear beam model can be represented in a number of equivalent ways [3]. One often used form is a single second-order-in-time fourth-order-in-space PDE

$$(2.1) \quad aw_{tt}(x, t) - \delta w_{xxtt}(x, t) + w_{xxxx}(x, t) = 0, \quad 0 < x < 1, t > 0,$$

with  $a, \delta > 0$  and two “free end” boundary conditions  $\delta w_{tt}(0, t) = w_{xx}(0, t)$  and  $\delta w_{xtt}(0, t) = w_{xxx}(0, t) - q_\delta w(0, t)$ .

We, however, will use another common form of this model, consisting of a wave equation coupled with a second-order ODE:

$$(2.2) \quad \left\{ \begin{array}{l} \delta w_{tt}(x, t) = w_{xx}(x, t) - \alpha_x(x, t), \quad 0 < x < 1, t > 0, \\ w_x(0, t) = \alpha(0, t) - qw(0, t), \quad t \geq 0, \\ w(1, t) = u_1(t), \quad t \geq 0, \\ 0 = \alpha_{xx}(x, t) - b^2 \alpha(x, t) + b^2 w_x(x, t), \quad 0 < x < 1, t > 0, \\ \alpha_x(0, t) = 0, \quad t \geq 0, \\ \alpha(1, t) = u_2(t), \quad t \geq 0, \\ y(t) = (w(0, t), \alpha(0, t)), \quad t \geq 0, \end{array} \right.$$

which is obtained from (2.1) by introducing a new state  $\alpha_x = w_{xx} - \delta w_{tt}$  and denoting  $b = \sqrt{a/\delta}$ . The state  $w$  represents the transversal displacement of the beam, and  $\alpha$  is the angle due to bending. The objective is to use the control input  $u(t) = (u_1(t), u_2(t))$  at the base of the beam to stabilize the tip of the beam with the measurement  $y(t)$  available only at the free end.

It is important to note the term  $-qw(0, t)$  in the boundary condition (2.2). This type of boundary condition corresponds to situations where the tip of the beam is subject to an external force which depends on the displacement. Such a force arises in AFM as a van der Waals force acting between the atoms on the material surface and the beam tip. The term  $-qw(0, t)$  is the linearized model of that force; the original nonlinear model has cubic nonlinearity [19]. Typically  $q > 0$  has a destabilizing effect (in that case, one can think of this parameter as “antistiffness”), whereas  $q < 0$  has a stabilizing effect. We stress that this force occurs on the opposite end of the beam from where the actuator is located. If the actuator were at the tip, canceling the effect of this force would be trivial. In the configuration that we pursue here, stabilization, and even vibration suppression when  $q = 0$ , is a nontrivial problem.

We will first present control and observer designs separately to make the ideas clear and then prove the certainty equivalence principle and well-posedness of the closed-loop system in sections 5–7.

**3. Controller.** In order to proceed with the control design we first need to write the model (2.2) in yet another form. To this end, we solve the ODE part of (2.2) as a two point boundary value problem for  $\alpha$  with boundary condition  $\alpha_x(0, t) = 0$ :

$$(3.1) \quad \alpha(x, t) = \cosh(bx)\alpha(0, t) - b \int_0^x \sinh(b(x-s))w_x(s, t) ds.$$

Setting  $x = 1$  in (3.1) and using the boundary condition  $\alpha(1, t) = u_2(t)$ , we can express  $\alpha(0, t)$  in terms of  $w$  and  $u_2$ :

$$(3.2) \quad \alpha(0, t) = \frac{1}{\cosh(b)}u_2(t) + \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-s))w_x(s, t) ds.$$

Next, we differentiate (3.1) in  $x$  and substitute the result into the first equation of (2.2). This way, instead of a wave equation coupled with a second-order ODE, we obtain a single hyperbolic partial integrodifferential equation for  $w$ :

$$(3.3) \quad \left\{ \begin{array}{l} \delta w_{tt}(x, t) = w_{xx}(x, t) - b^2 \cosh(bx)w(0, t) + b^3 \int_0^x \sinh(b(x-y))w(y, t) dy \\ \quad + b^2 w(x, t) - \frac{b \sinh(bx)}{\cosh(b)} \left[ u_2(t) + b \int_0^1 \sinh(b(1-s))w_x(s, t) ds \right], \\ w_x(0, t) = \frac{1}{\cosh(b)} \left[ u_2(t) + b \int_0^1 \sinh(b(1-s))w_x(s, t) ds \right] - qw(0, t), \\ w(1, t) = u_1(t). \end{array} \right.$$

Since the backstepping control design [12] needs the PDE to be in a “strict-feedback” form (in other words, its right-hand side must be “causal” in  $x$ ), we are going to use the control  $u_2(t)$  to cancel the definite integral both in the domain and in the boundary condition:

$$(3.4) \quad u_2(t) = -b \int_0^1 \sinh(b(1-s))w_x(s, t) ds.$$

We get the following PDE:

$$(3.5) \quad \begin{cases} \delta w_{tt}(x, t) = w_{xx}(x, t) + b^2 w(x, t) - b^2 \cosh(bx)w(0, t) \\ \quad + b^3 \int_0^x \sinh(b(x-y))w(y, t)dy, \\ w_x(0, t) = -qw(0, t), \\ w(1, t) = u_1(t). \end{cases}$$

The basic idea of the backstepping design is to use the transformation

$$(3.6) \quad \bar{w}(x, t) = w(x, t) - \int_0^x k(x, y)w(y, t) dy,$$

with specially designed control kernel  $k(x, y)$  along with the boundary feedback law

$$(3.7) \quad \begin{cases} u_1(t) = w(1, t), \\ w_x(1, t) = k(1, 1)w(1, t) - c_1 w_t(1, t) \\ \quad + c_1 \int_0^1 k(1, y)w_t(y, t) dy + \int_0^1 k_x(1, y)w(y, t) dy \end{cases}$$

to map (3.5) into the exponentially stable target system

$$(3.8) \quad \begin{cases} \delta \bar{w}_{tt}(x, t) = \bar{w}_{xx}(x, t), \\ \bar{w}_x(0, t) = c_0 \bar{w}(0, t), \\ \bar{w}_x(1, t) = -c_1 \bar{w}_t(1, t), \end{cases}$$

where  $c_0 > 0$  and  $c_1 > 0$  are design parameters. The system (3.8) is exponentially stable at the origin iff  $c_0$  and  $c_1$  are positive. Note the crucial difference between the second equations of (3.5) and (3.8)—the destabilizing negative sign in the former and the stabilizing positive sign in the latter. The gain kernel  $k(x, y)$  is given by the following PDE:

$$(3.9) \quad \begin{cases} k_{xx}(x, y) = k_{yy}(x, y) + b^2 k(x, y) - b^3 \sinh(b(x-y)) \\ \quad + b^3 \int_y^x k(x, \xi) \sinh(b(\xi-y))d\xi, \\ k(x, x) = -\frac{b^2}{2}x - c_0 - q, \\ k_y(x, 0) = -b^2 \left[ \cosh(bx) - \int_0^x k(x, y) \cosh(by)dy \right] - qk(x, 0), \end{cases}$$

which is obtained by substituting (3.6) into (3.8) and matching the terms. Incidentally, this equation for  $k(x, y)$  is in the same class as the one obtained in the control design for parabolic PDEs [12]. As shown in [12], the PDE (3.9) has a unique solution  $k \in C^2(\Omega)$ .

It can be solved either numerically or by using the following symbolic recursion:

$$(3.10) \quad \left\{ \begin{array}{l} k(x, y) = \lim_{n \rightarrow \infty} k_n(x, y), \\ k_0 = -\frac{b}{2}[-\sinh(b(x-y)) + by \cosh(b(x-y))] - c_0 - q, \\ k_{n+1} = k_0 + b^2 \int_{\frac{x-y}{2}}^{\frac{x+y}{2}} \int_0^{\frac{x-y}{2}} k_n(\sigma+s, \sigma-s) ds d\sigma + q \int_0^{x-y} k_n(\sigma, 0) d\sigma \\ \quad + b^2 \int_0^{\frac{x-y}{2}} \int_0^\sigma [2k_n(\sigma+s, \sigma-s) - k_n(\sigma, s) \cosh(bs)] ds d\sigma \\ \quad + b^3 \int_{\frac{x-y}{2}}^{\frac{x+y}{2}} \int_0^{\frac{x-y}{2}} \int_{\sigma-s}^{\sigma+s} k_n(\sigma+s, \xi) \sinh(b(\xi-\sigma+s)) d\xi ds d\sigma \\ \quad + 2b^3 \int_0^{\frac{x-y}{2}} \int_0^\sigma \int_{\sigma-s}^{\sigma+s} k_n(\sigma+s, \xi) \sinh(b(\xi-\sigma+s)) d\xi ds d\sigma. \end{array} \right.$$

The first step of this recursion provides approximate control gain kernels, which are explicit:

$$(3.11) \quad \left\{ \begin{array}{l} k_0(1, y) = -\frac{b}{2}[-\sinh(b(1-y)) + by \cosh(b(1-y))] - c_0 - q, \\ k_{0x}(1, y) = -\frac{b}{2}[-\cosh(b(1-y)) + by \sinh(b(1-y))], \\ k_0(1, 1) = k(1, 1) = -\frac{b^2}{2} - c_0 - q. \end{array} \right.$$

Since  $k \in C^2(\Omega)$ , the transformation (3.6) is bounded invertible, and therefore the system (3.5) with the controller (3.7) dynamically behaves as (3.8). The important question is why we chose our system's "target" behavior as in (3.8). This PDE with a homogeneous Dirichlet boundary condition at  $x = 0$  (i.e., for  $c_0 = \infty$ ) has been studied in many papers on control of wave equations by "boundary damper" feedback. For a large positive  $c_0$ , our "target" system has a similar behavior to those well-studied problems. Obviously, the most desirable behavior would be with  $c_0 = 0$ ; however, such behavior is achievable only if one could put an actuator at the tip. In that case, the end  $x = 0$  would be clamped, and the end  $x = 1$  would be actuated with a "boundary damper." Since we are pursuing the opposite problem, where the tip end  $x = 0$  is free and the actuator is at the opposite end  $x = 1$ , it is only through the very sophisticated construction that we presented above that a behavior similar to the boundary damper feedback is achievable. The plant boundary condition at  $x = 0$  is of Robin type, and no state transformation can change it into Dirichlet. However, we can change it into a Robin condition of favorable sign ( $c_0 > 0$ ) and make it behave similar to a Dirichlet condition (with large  $c_0$ ). To achieve all of this, we construct the change of variable (3.6) which starts at  $x = 0$  and goes towards  $x = 1$ , collecting all of the terms in the shear beam model and converting them into a wave equation model. But it is ultimately the boundary feedback (3.7) that absorbs the effects of the transformation and results in a damping boundary condition at the end  $x = 1$ . Clearly such feedback has to be rather complicated because it achieves a similar effect as the boundary damper but from the opposite end. In addition to the first two terms on the right-hand side of (3.7), which arise in boundary dampers and essentially amount to PD control, our feedback law incorporates the two integral operators acting on

the displacement and velocity fields (as we will show in the next section, the direct measurement of  $w(x, t)$  and  $w_t(x, t)$  along the whole beam is not necessary).

The control law (3.7) has to be implemented by solving for  $w(1, t)$ . In the frequency domain it is equivalent to employing a low pass filter acting on  $w_x(1, s)$  and the integral operator:

$$(3.12) \quad u_1(s) = \frac{1}{c_1 s + \frac{b^2}{2} + c_0 + q} \left[ -w_x(1, s) + \int_0^1 (c_1 s k(1, y) + k_x(1, y)) w(y, s) dy \right].$$

In AFM  $u_1$  is implemented via a piezo actuator which actuates the beam base displacement. Implementation of  $u_2$  would involve two piezo actuators to produce a commanded  $u_2$ .

**4. Observer.** Before we start with the observer design, we write the model (3.3) in a slightly different form using (3.2):

$$(4.1) \quad \begin{cases} \delta w_{tt}(x, t) = w_{xx}(x, t) + b^2 w(x, t) + b^3 \int_0^x \sinh(b(x-y)) w(y, t) dy \\ \quad - b^2 \cosh(bx) w(0, t) - b \sinh(bx) \alpha(0, t), \\ w_x(0, t) = \alpha(0, t) - q w(0, t), \\ w(1, t) = u_1(t). \end{cases}$$

Note that in this form  $u_2$  is not selected as in (3.4) and the observer is designed for arbitrary inputs  $u_1$  and  $u_2$ .

We assume that the only available measurements are of the tip displacement  $w(0, t)$  and of the tip angle due to bending  $\alpha(0, t)$ . In AFM the displacement and the slope of the tip are routinely measured using a laser and a photodiode.

The observer is designed along the lines of the design presented in [13] for parabolic systems and follows a standard finite-dimensional approach “copy of the plant plus output injection terms”:

$$(4.2) \quad \begin{cases} \delta \hat{w}_{tt}(x, t) = \hat{w}_{xx}(x, t) + b^2 \hat{w}(x, t) + b^3 \int_0^x \sinh(b(x-y)) \hat{w}(y, t) dy \\ \quad - b^2 \cosh(bx) w(0, t) - b \sinh(bx) \alpha(0, t) \\ \quad + p_y(x, 0)[w(0, t) - \hat{w}(0, t)] - c_2 p(x, 0)[w_t(0, t) - \hat{w}_t(0, t)], \\ \hat{w}_x(0, t) = \alpha(0, t) - q w(0, t) + p(0, 0)[w(0, t) - \hat{w}(0, t)] \\ \quad - c_2 [w_t(0, t) - \hat{w}_t(0, t)], \\ \hat{w}(1, t) = u_1(t). \end{cases}$$

The constant  $c_2 > 0$  is the design parameter that sets the convergence rate of the observer. Note that the output error terms are injected both in the domain and in the boundary condition. The observer gains  $p(x, 0)$ ,  $p_y(x, 0)$ , and  $p(0, 0)$  in (4.2) are determined by solving the following PDE in  $\Omega = \{(x, y) | 0 \leq y \leq x \leq 1\}$ :

$$(4.3) \quad \begin{cases} p_{yy}(x, y) = p_{xx}(x, y) + b^2 p(x, y) - b^3 \sinh(b(x-y)) \\ \quad + b^3 \int_y^x p(\xi, y) \sinh(b(x-\xi)) d\xi, \\ p(x, x) = \frac{b^2}{2}(x-1), \\ p(1, y) = 0. \end{cases}$$

It has been shown in [13] that this equation has a unique solution  $p \in C^2(\Omega)$ . One can see the similarity between this PDE and the one for the control kernel. This is due to the duality between observer and control designs, a concept well known in finite-dimensional control. One can think of the gains  $p(x, 0)$ ,  $p_y(x, 0)$ , and  $p(0, 0)$  as dual counterparts to the control gains  $k(1, y)$ ,  $k_x(1, y)$ , and  $k(1, 1)$ .

(4.3) can be solved numerically or symbolically using the following recursive procedure [13]:

$$(4.4) \quad \left\{ \begin{array}{l} p(x, y) = \lim_{n \rightarrow \infty} p_n(x, y), \\ p_0 = -\frac{b}{2}[-\sinh(b(x-y)) + b(1-x)\cosh(b(x-y))], \\ p_{n+1} = p_0 + b^2 \int_{\frac{x-y}{2}}^{\frac{2-x-y}{2}} \int_0^{\frac{x-y}{2}} p_n(\sigma+s, \sigma-s) ds d\sigma \\ \quad + 2b^2 \int_0^{\frac{x-y}{2}} \int_0^\sigma p_n(\sigma+s, \sigma-s) ds d\sigma \\ \quad + b^3 \int_{\frac{x-y}{2}}^{\frac{2-x-y}{2}} \int_0^{\frac{x-y}{2}} \int_{\sigma-s}^{\sigma+s} p_n(\sigma+s, \xi) \sinh(b(\xi-\sigma+s)) d\xi ds d\sigma \\ \quad + 2b^3 \int_0^{\frac{x-y}{2}} \int_0^\sigma \int_{\sigma-s}^{\sigma+s} p_n(\sigma+s, \xi) \sinh(b(\xi-\sigma+s)) d\xi ds d\sigma. \end{array} \right.$$

The observer gain in the boundary condition (4.2) is known exactly:

$$(4.5) \quad p(0, 0) = -\frac{b^2}{2}.$$

Let us denote the observer error by  $\varepsilon(x, t) = w(x, t) - \hat{w}(x, t)$ . Using (4.2) and (4.1) we obtain the observer error dynamics

$$(4.6) \quad \left\{ \begin{array}{l} \delta \varepsilon_{tt}(x, t) = \varepsilon_{xx}(x, t) + b^2 \varepsilon(x, t) + b^3 \int_0^x \sinh(b(x-y)) \varepsilon(y, t) dy \\ \quad - p_y(x, 0) \varepsilon(0, t) + c_2 p(x, 0) \varepsilon_t(0, t), \\ \varepsilon_x(0, t) = -p(0, 0) \varepsilon(0, t) + c_2 \varepsilon_t(0, t), \\ \varepsilon(1, t) = 0. \end{array} \right.$$

The convergence of the observer is established by the following lemma.

LEMMA 4.1. *Suppose the classical solution of (4.6) exists. Then the invertible transformation*

$$(4.7) \quad \left\{ \begin{array}{l} \varepsilon(x, t) = \tilde{\varepsilon}(x, t) - \int_0^x p(x, y) \tilde{\varepsilon}(y, t) dy = [(I - \mathbb{P}_1) \tilde{\varepsilon}](x, t), \\ \tilde{\varepsilon}(x, t) = [(I - \mathbb{P}_1)^{-1} \varepsilon](x, t) = \varepsilon(x, t) - \int_0^x p^\ominus(x, y) \varepsilon(y, t) dy \end{array} \right.$$

converts the error system (4.6) into the exponentially stable system

$$(4.8) \quad \left\{ \begin{array}{l} \delta \tilde{\varepsilon}_{tt}(x, t) = \tilde{\varepsilon}_{xx}(x, t), \\ \tilde{\varepsilon}_x(0, t) = c_2 \tilde{\varepsilon}_t(0, t), \\ \tilde{\varepsilon}(1, t) = 0. \end{array} \right.$$

*Proof.* We differentiate the transformation (4.7) with respect to  $t$  and  $x$ :

$$\begin{aligned}
 \delta \varepsilon_{tt}(x, t) &= \delta \tilde{\varepsilon}_{tt}(x, t) - \int_0^x p(x, y) \delta \tilde{\varepsilon}_{tt}(y, t) dy - \varepsilon_{xx}(x, t) + \varepsilon_{xx}(x, t) \\
 &= \delta \tilde{\varepsilon}_{tt}(x, t) - \int_0^x p_{yy}(x, y) \tilde{\varepsilon}(y, t) dy - p(x, x) \tilde{\varepsilon}_x(x, t) + p(x, 0) \tilde{\varepsilon}_x(0, t) \\
 &\quad + p_y(x, x) \tilde{\varepsilon}(x, t) - p_y(x, 0) \tilde{\varepsilon}(0, t) - \tilde{\varepsilon}_{xx}(x, t) + [2p_x(x, x) + p_y(x, x)] \tilde{\varepsilon}(x, t) \\
 &\quad + p(x, x) \tilde{\varepsilon}_x(x, t) + \int_0^x p_{xx}(x, y) \tilde{\varepsilon}(y, t) dy + \varepsilon_{xx}(x, t) \\
 &= \varepsilon_{xx}(x, t) + b^2 \varepsilon(x, t) + c_2 p(x, 0) \varepsilon_t(0, t) - p_y(x, 0) \varepsilon(0, t) \\
 &\quad + \int_0^x (p_{xx}(x, y) - p_{yy}(x, y) + b^2 p(x, y)) \tilde{\varepsilon}(y, t) dy.
 \end{aligned}$$

Using the observer gain PDE (4.3) in the above equation we get the governing equation of (4.8).

Next we differentiate the transformation (4.7) with respect to  $x$  and set  $x = 0$ :

$$\varepsilon_x(0, t) = \tilde{\varepsilon}_x(0) - p(0, 0) \tilde{\varepsilon}(0, t).$$

Comparing this with the boundary condition of (4.6), which can be written as

$$\varepsilon_x(0, t) = -p(0, 0) \tilde{\varepsilon}(0, t) + c_2 \tilde{\varepsilon}_t(0, t),$$

we get the boundary condition of (4.8) at  $x = 0$ . Finally, the boundary condition at  $x = 1$  is obviously satisfied because  $p(1, y) = 0$ .  $\square$

**5. Output feedback.** Consider the observer (4.2) and the control (3.4), (3.7) with the observer state instead of the unmeasured plant state:

$$(5.1) \quad \left\{ \begin{array}{l} u_1(t) = \hat{w}(1, t), \\ \hat{w}_x(1, t) = k(1, 1) \hat{w}(1, t) - c_1 \hat{w}_t(1, t) \\ \quad + c_1 \int_0^1 k(1, y) \hat{w}_t(y, t) dy + \int_0^1 k_x(1, y) \hat{w}(y, t) dy, \\ u_2(t) = -b \int_0^1 \sinh(b(1 - y)) \hat{w}_x(y, t) dy. \end{array} \right.$$

We employ an invertible state transformation

$$(5.2) \quad \left\{ \begin{array}{l} \tilde{w}(x, t) = \hat{w}(x, t) - \int_0^x k(x, y) \hat{w}(y, t) dy = [(I - \mathbb{P}_2) \hat{w}](x, y), \\ \hat{w}(x, t) = [(I - \mathbb{P}_2)^{-1} \tilde{w}](x, y) = \tilde{w}(x, t) - \int_0^x k^\ominus(x, y) \tilde{w}(x, y) dy, \end{array} \right.$$

where  $k(x, y)$  is given by (3.10) and both  $k(x, y)$  and  $k^\ominus(x, y)$  are of  $C^2$  in  $\Omega$  [12].

LEMMA 5.1. *Suppose the classical solution of (4.2) with the control (5.1) exists. Then the transformation (5.2) converts (4.2) and (5.1) into*

$$(5.3) \quad \left\{ \begin{array}{l} \delta \tilde{w}_{tt}(x, t) = \tilde{w}_{xx}(x, t) - b \sinh(bx) \alpha(0, t) + k(x, 0) \alpha(0, t) + p_y(x, 0) \varepsilon(0, t) \\ \quad + k(x, 0) p(0, 0) \varepsilon(0, t) + k_y(x, 0) \varepsilon(0, t) - c_2 k(x, 0) \varepsilon_t(0, t) \\ \quad + b \int_0^x k(x, y) \sinh(by) dy \alpha(0, t) - \int_0^x k(x, y) p_y(y, 0) dy \varepsilon(0, t) \\ \quad - c_2 p(x, 0) \varepsilon_t(0, t) + c_2 \int_0^x k(x, y) p(y, 0) dy \varepsilon_t(0, t), \\ \tilde{w}_x(0, t) = c_0 \tilde{w}(0, t) + \alpha(0, t) + p(0, 0) \varepsilon(0, t) - c_2 \varepsilon_t(0, t), \\ \tilde{w}_x(1, t) = -c_1 \tilde{w}_t(1, t). \end{array} \right.$$

*Proof.* First we compute the second spatial derivative of the transformation (5.2):

$$(5.4) \quad \begin{aligned} \tilde{w}_{xx}(x, t) &= \widehat{w}_{xx}(x, t) - [2k_x(x, x) + k_y(x, x)] \widehat{w}(x, t) - k(x, x) \widehat{w}_x(x, t) \\ &\quad - \int_0^x k_{xx}(x, y) \widehat{w}(y, t) dy. \end{aligned}$$

The next step is to compute  $\tilde{w}_{tt}$ :

$$(5.5) \quad \begin{aligned} \delta \tilde{w}_{tt}(x, t) &= \delta \widehat{w}_{tt}(x, t) - \int_0^x k(x, y) \delta \widehat{w}_{tt}(y, t) dy \\ &= \widehat{w}_{xx}(x, t) + b^2 \widehat{w}(x, t) + b^3 \int_0^x \sinh(b(x-y)) \widehat{w}(y, t) dy \\ &\quad - b^2 \cosh(bx) w(0, t) - b \sinh(bx) \alpha(0, t) + p_y(x, 0) \varepsilon(0, t) \\ &\quad - c_2 p(x, 0) \varepsilon_t(0, t) - \int_0^x k(x, y) \widehat{w}_{yy}(y, t) dy - b^2 \int_0^x k(x, y) \widehat{w}(y, t) dy \\ &\quad - b^3 \int_0^x \int_y^x k(x, \xi) \sinh(b(\xi-y)) \widehat{w}(y, t) dy \\ &\quad + b^2 \int_0^x k(x, y) \cosh(by) dy w(0, t) + b \int_0^x k(x, y) \sinh(by) dy \alpha(0, t) \\ &\quad - \int_0^x k(x, y) p_y(y, 0) dy \varepsilon(0, t) + c_2 \int_0^x k(x, y) p(y, 0) dy \varepsilon_t(0, t). \end{aligned}$$

We notice that

$$(5.6) \quad \begin{aligned} \int_0^x k(x, y) \widehat{w}_{yy}(y, t) dy &= \int_0^x k_{yy}(x, y) \widehat{w}(y, t) dy \\ &\quad + k(x, x) \widehat{w}_x(x, t) - k(x, 0) \widehat{w}_x(0, t) \\ &\quad - k_y(x, x) \widehat{w}(x, t) + k_y(x, 0) \widehat{w}(0, t) \\ &= \int_0^x k_{yy}(x, y) \widehat{w}(y, t) dy + k(x, x) \widehat{w}_x(x, t) - k(x, 0) \alpha(0, t) \\ &\quad + qk(x, 0) w(0, t) + k(x, 0) p(0, 0) \varepsilon(0, t) + c_2 k(x, 0) \varepsilon_t(0, t) \\ &\quad - k_y(x, x) \widehat{w}(x, t) - k_y(x, 0) \varepsilon(0, t) + k_y(x, 0) w(0, t). \end{aligned}$$

Subtracting (5.4) from (5.5) and using (5.6), we get (5.3).

The boundary condition at  $x = 1$  is verified in the following way:

$$\begin{aligned} 0 &= \tilde{w}_x(1, t) + c_1 \tilde{w}_t(1, t) \\ &= \hat{w}_x(1, t) - k(1, 1) \hat{w}(1, t) - \int_0^1 k_x(1, y) \hat{w}(y, t) \\ &\quad + c_1 \hat{w}_t(1, t) - c_1 \int_0^1 k(1, y) \hat{w}_t(y, t) dy, \end{aligned}$$

which gives exactly the controller (5.1). Finally, for the boundary condition at  $x = 0$  we have

$$\begin{aligned} \tilde{w}_x(0, t) &= \hat{w}_x(0, t) - k(0, 0) \hat{w}(0, t) = \hat{w}_x(0, t) - k(0, 0) \tilde{w}(0, t) \\ &= \alpha(0, t) - qw(0, t) + p(0, 0) \varepsilon(0, t) - c_2 \varepsilon_t(0, t) - k(0, 0) \tilde{w}(0, t) \\ &= c_0 \tilde{w}(0, t) + \alpha(0, t) + p(0, 0) \varepsilon(0, t) - c_2 \varepsilon_t(0, t). \end{aligned}$$

The proof is complete.  $\square$

**6. Well-posedness and stability of the transformed system.** Lemmas 4.1 and 5.1 establish the following transformed system  $(\tilde{\varepsilon}, \tilde{w})$  which is a cascade of two wave equations (with additional integral terms):

$$(6.1) \quad \left\{ \begin{array}{l} \delta \tilde{\varepsilon}_{tt}(x, t) = \tilde{\varepsilon}_{xx}(x, t), \\ \tilde{\varepsilon}_x(0, t) = c_2 \tilde{\varepsilon}_t(0, t), \\ \tilde{\varepsilon}(1, t) = 0, \\ \delta \tilde{w}_{tt}(x, t) = \tilde{w}_{xx}(x, t) - b \sinh(bx) \alpha(0, t) + k(x, 0) \alpha(0, t) - c_2 k(x, 0) \tilde{\varepsilon}_t(0, t) \\ \quad + p_y(x, 0) \tilde{\varepsilon}(0, t) + k(x, 0) p(0, 0) \tilde{\varepsilon}(0, t) + k_y(x, 0) \tilde{\varepsilon}(0, t) \\ \quad + b \int_0^x k(x, y) \sinh(by) dy \alpha(0, t) - \int_0^x k(x, y) p_y(y, 0) dy \tilde{\varepsilon}(0, t) \\ \quad - c_2 p(x, 0) \tilde{\varepsilon}_t(0, t) + c_2 \int_0^x k(x, y) p(y, 0) dy \tilde{\varepsilon}_t(0, t), \\ \tilde{w}_x(0, t) = c_0 \tilde{w}(0, t) + \alpha(0, t) + p(0, 0) \tilde{\varepsilon}_t(0, t) - c_2 \tilde{\varepsilon}_t(0, t), \\ \tilde{w}_x(1, t) = -c_1 \tilde{w}_t(1, t). \end{array} \right.$$

Here  $\alpha(0, t)$  is expressed in terms of  $\tilde{\varepsilon}$  using (3.2) and (4.7):

$$(6.2) \quad \begin{aligned} \alpha(0, t) &= \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-x)) [\tilde{\varepsilon}_x(x, t) - p(x, x) \tilde{\varepsilon}(x, t)] dx \\ &\quad - \frac{b}{\cosh(b)} \int_0^1 \int_x^1 \sinh(b(1-y)) p_x(y, x) dy \tilde{\varepsilon}(x, t) dx. \end{aligned}$$

From (6.2) and the fact that  $\tilde{\varepsilon}(1, t) = 0$ , we know that there exists a constant  $C_1 > 0$  such that

$$(6.3) \quad |\alpha(0, t)|^2 \leq C_1 \int_0^1 \tilde{\varepsilon}_x^2(x, t) dx.$$

We consider the system (6.1) in the space  $H = H_R^1(0, 1) \times L^2(0, 1) \times H^1(0, 1) \times L^2(0, 1)$ ,

$H_R^1(0, 1) = \{f \mid f \in H^1(0, 1) \mid f(1) = 0\}$ , with the inner product

$$\begin{aligned} & \langle (f_1, g_1, \phi_1, \psi_1), (f_2, g_2, \phi_2, \psi_2) \rangle \\ &= K \int_0^1 \left[ f_1'(x) \overline{f_2'(x)} + \frac{1}{\delta} g_1(x) \overline{g_2(x)} + \delta_0(x-1)(f_1'(x) \overline{g_2(x)} + g_1(x) \overline{f_2'(x)}) \right] dx \\ &+ \int_0^1 \left[ \phi_1'(x) \overline{\phi_2'(x)} + \frac{1}{\delta} \psi_1(x) \overline{\psi_2(x)} + \delta_0(x+1)(\phi_1'(x) \overline{\psi_2(x)} + \psi_1(x) \overline{\phi_2'(x)}) \right] dx \\ &+ c_1 \phi_1(0) \overline{\phi_2(0)} \quad \forall (f, g, \phi, \psi) \in H, \end{aligned}$$

where  $\delta_0 > 0$  is sufficiently small so that above inner product is well-defined and  $K > 0$  is large enough so that  $A$  is dissipative in  $H$  as in the proof of Lemma 5.1 below. Define the system operator  $A : D(A) \subset H \rightarrow H$  as follows:

$$(6.4) \quad \left\{ \begin{aligned} D(A) &= \left\{ (f, g, \phi, \psi) \in (H^2(0, 1) \cap H_R^1(0, 1)) \times H_R^1(0, 1) \times H^2(0, 1) \right. \\ &\quad \times H^1(0, 1) \mid f'(0) = \frac{c_2}{\delta} g(0), \phi'(1) = -\frac{c_1}{\delta} \psi(1) \\ &\quad \left. \phi'(0) = c_0 \phi(0) + \frac{1}{\delta} [p(0, 0) - c_2] g(0) + \alpha(0) \right\}, \\ A(f, g, \phi, \psi) &= \left( \frac{g}{\delta}, f'', \frac{\psi}{\delta}, \phi'' - b \sinh(bx) \alpha(0) + [p_y(x, 0) + k_y(x, 0)] f(0) \right. \\ &\quad + k(x, 0) [\alpha(0) + p(0, 0) f(0)] - \int_0^x k(x, y) p_y(y, 0) dy f(0) \\ &\quad + b \int_0^x k(x, y) \sinh(by) dy \alpha(0) - \frac{c_2}{\delta} k(x, 0) g(0) \\ &\quad \left. + \frac{c_2}{\delta} \left[ -p(x, 0) + \int_0^x k(x, y) p(y, 0) dy \right] g(0) \right), \\ \alpha(0) &= \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-x)) [f'(x) - p(x, x) f(x)] dx \\ &\quad - \frac{b}{\cosh(b)} \int_0^1 \int_x^1 \sinh(b(1-y)) p_x(y, x) dy f(x) dx \\ &\quad \forall (f, g, \phi, \psi) \in D(A). \end{aligned} \right.$$

Then the system (6.1) can be written as

$$(6.5) \quad \frac{d}{dt} (\tilde{\varepsilon}(\cdot, t), \delta \tilde{\varepsilon}_t(\cdot, t), \tilde{w}(\cdot, t), \delta \tilde{w}_t(\cdot, t)) = A(\tilde{\varepsilon}(\cdot, t), \delta \tilde{\varepsilon}_t(\cdot, t), \tilde{w}(\cdot, t), \delta \tilde{w}_t(\cdot, t)).$$

**THEOREM 6.1.** *Let  $A$  be defined by (6.4). Then  $A$  generates an exponential stable  $C_0$ -semigroup on  $H$ . For any initial value  $(\tilde{\varepsilon}(\cdot, 0), \delta \tilde{\varepsilon}_t(\cdot, 0), \tilde{w}(\cdot, 0), \delta \tilde{w}_t(\cdot, 0)) \in H$ , there exists a unique (mild) solution to (6.1) such that  $(\tilde{\varepsilon}(\cdot, t), \delta \tilde{\varepsilon}_t(\cdot, t), \tilde{w}(\cdot, t), \delta \tilde{w}_t(\cdot, t)) \in C([0, \infty); H)$ , and there exists a positive constant  $\omega$  such that*

$$(6.6) \quad \begin{aligned} & \|(\tilde{\varepsilon}(\cdot, t), \delta \tilde{\varepsilon}_t(\cdot, t), \tilde{w}(\cdot, t), \delta \tilde{w}_t(\cdot, t))\|_H \\ & \leq e^{-\omega t} \|(\tilde{\varepsilon}(\cdot, 0), \delta \tilde{\varepsilon}_t(\cdot, 0), \tilde{w}(\cdot, 0), \delta \tilde{w}_t(\cdot, 0))\|_H. \end{aligned}$$

Moreover, if  $(\tilde{\varepsilon}(\cdot, 0), \delta \tilde{\varepsilon}_t(\cdot, 0), \tilde{w}(\cdot, 0), \delta \tilde{w}_t(\cdot, 0)) \in D(A)$ , then

$$(6.7) \quad (\tilde{\varepsilon}(\cdot, t), \delta \tilde{\varepsilon}_t(\cdot, t), \tilde{w}(\cdot, t), \delta \tilde{w}_t(\cdot, t)) \in C^1([0, \infty); H)$$

is the classical solution of (6.1).

*Proof.* Define the Lyapunov functions

$$(6.8) \quad E_{\tilde{\varepsilon}}(t) = \frac{1}{2} \int_0^1 [\tilde{\varepsilon}_x^2(x, t) + \delta \tilde{\varepsilon}_t^2(x, t)] dx + \delta_0 \int_0^1 (x-1) \tilde{\varepsilon}_x(x, t) \delta \tilde{\varepsilon}_t(x, t) dx$$

and

$$(6.9) \quad E_{\tilde{w}}(t) = \frac{1}{2} \int_0^1 [\tilde{w}_x^2(x, t) + \delta \tilde{w}_t^2(x, t)] dx + \frac{\tilde{\delta}_0}{2} \tilde{w}^2(0, t) + \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) \delta \tilde{w}_t(x, t) dx.$$

Both of them are positive definite for small  $\delta_0, \tilde{\delta}_0 > 0$ . The time derivatives of  $E_{\tilde{\varepsilon}}$  and  $E_{\tilde{w}}$  along the trajectory of (6.1) are, respectively,

$$(6.10) \quad \dot{E}_{\tilde{\varepsilon}}(t) = - \left[ c_2 - \frac{\delta_0}{2} (1 + c_2^2) \right] \tilde{\varepsilon}_t^2(0, t) - \frac{\delta_0}{2} \int_0^1 [\tilde{\varepsilon}_x^2(x, t) + \delta \tilde{\varepsilon}_t^2(x, t)] dx,$$

$$(6.11) \quad \begin{aligned} \dot{E}_{\tilde{w}}(t) = & -c_1 \tilde{w}_t^2(1, t) - c_0 \tilde{w}^2(0, t) - \alpha(0, t) \tilde{w}_t(0, t) - p(0, 0) \tilde{w}_t(0, t) \tilde{\varepsilon}_t(0, t) \\ & + c_2 \tilde{w}_t(0, t) \tilde{\varepsilon}_t(0, t) + \int_0^1 [k(x, 0) - b \sinh(bx)] \tilde{w}_t(x, t) dx \alpha(0, t) \\ & + \int_0^1 \tilde{w}_t(x, t) p_y(x, 0) dx \tilde{\varepsilon}(0, t) + b \int_0^1 \tilde{w}_t(x, t) dx \int_0^x k(x, y) \sinh(by) dy \alpha(0, t) \\ & + \int_0^1 \tilde{w}_t(x, t) k(x, 0) dx p(0, 0) \tilde{\varepsilon}(0, t) + \int_0^1 \tilde{w}_t(x, t) k_y(x, 0) dx \tilde{\varepsilon}(0, t) \\ & - \int_0^1 \tilde{w}_t(x, t) dx \int_0^x k(x, y) p_y(y, 0) dy \tilde{\varepsilon}(0, t) - c_2 \int_0^1 \tilde{w}_t(x, t) k(x, 0) dx \tilde{\varepsilon}_t(0, t) \\ & - c_2 \int_0^1 \tilde{w}_t(x, t) p(x, 0) dx \tilde{\varepsilon}_t(0, t) + c_2 \int_0^1 \tilde{w}_t(x, t) dx \int_0^x k(x, y) p(y, 0) dy \tilde{\varepsilon}_t(0, t) \\ & - \frac{\delta_0}{2} \int_0^1 [\tilde{w}_x^2(x, t) + \delta \tilde{w}_t^2(x, t)] dx - \frac{\delta \delta_0}{2} \tilde{w}_t^2(0, t) + \delta_0 (\delta + c_1^2) \tilde{w}_t^2(1, t) \\ & - \frac{\delta_0}{2} [c_0 \tilde{w}(0, t) + \alpha(0, t) + p(0, 0) \tilde{\varepsilon}_t(0, t) - c_2 \tilde{\varepsilon}_t(0, t)]^2 \\ & + \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) (k(x, 0) - b \sinh(bx)) dx \alpha(0, t) \\ & + \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) (p_y(x, 0) + k_y(x, 0) + p(0, 0) k(x, 0)) dx \tilde{\varepsilon}(0, t) \\ & + b \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) dx \int_0^x k(x, y) \sinh(by) dy \alpha(0, t) \\ & - \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) dx \int_0^x k(x, y) p_y(y, 0) dy \tilde{\varepsilon}(0, t) \\ & - c_2 \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) (p(x, 0) + k(x, 0)) dx \tilde{\varepsilon}_t(0, t) \\ & + c_2 \delta_0 \int_0^1 (1+x) \tilde{w}_x(x, t) dx \int_0^x k(x, y) p(y, 0) dy \tilde{\varepsilon}_t(0, t) + \tilde{\delta}_0 \tilde{w}(0, t) \tilde{w}_t(0, t). \end{aligned}$$

Using (6.3) and the fact that  $k, p \in C^2(\Omega)$ , we obtain

$$\begin{aligned} \dot{E}_{\tilde{w}}(t) \leq & \left[ \frac{\delta_0}{2} - \delta_1 \right] \int_0^1 [\tilde{w}_x^2(x, t) + \delta \tilde{w}_t^2(x, t)] dx - \left[ c_0 + \frac{\delta c_0^2}{2} - \delta_2 \right] \tilde{w}^2(0, t) \\ & - [c_1 - \delta_0(\delta + c_1^2)] \tilde{w}_t^2(1, t) - \left[ \frac{\delta \delta_0}{2} - \delta_3 \right] \tilde{w}_t^2(0, t) \\ & + C_2 \alpha^2(0, t) + C_2 \tilde{\varepsilon}^2(0, t) + C_2 \tilde{\varepsilon}_t^2(0, t), \end{aligned}$$

where  $C_2$  and  $\delta_i, i = 1, 2, 3$ , are some positive constants satisfying

$$(6.12) \quad \delta_1 < \frac{\delta_0}{2}, \quad \delta_2 < c_0 + \frac{\delta c_0^2}{2}, \quad \delta_3 < \frac{\delta \delta_0}{2}.$$

Now for large  $K > 0$ , we take the overall Laypunov function as

$$(6.13) \quad E(t) = E_{\tilde{w}}(t) + K E_{\tilde{\varepsilon}}(t).$$

Since from (6.3),  $\alpha^2(0, t) + \tilde{\varepsilon}^2(0, t) \leq (1 + C_1) \|\tilde{\varepsilon}_x(\cdot, t)\|_{L^2(0,1)}^2$ , we obtain its derivative along the solution of (6.1) that

$$\begin{aligned} \dot{E}(t) \leq & -K \left[ c_2 - \frac{\delta_0}{2} (1 + c_2^2) \right] \tilde{\varepsilon}_t^2(0, t) - K \frac{\delta_0}{2} \int_0^1 [\tilde{\varepsilon}_x^2(x, t) + \delta \tilde{\varepsilon}_t^2(x, t)] dx \\ (6.14) \quad & - \left[ \frac{\delta_0}{2} - \delta_1 \right] \int_0^1 [\tilde{w}_x^2(x, t) + \delta \tilde{w}_t^2(x, t)] dx - \left[ c_0 + \frac{\delta c_0^2}{2} - \delta_2 \right] \tilde{w}^2(0, t) \\ & + C_2 \alpha^2(0, t) + C_2 \tilde{\varepsilon}^2(0, t) + C_2 \tilde{\varepsilon}_t^2(0, t), \end{aligned}$$

where we assumed that

$$(6.15) \quad \delta_0(\delta + c_1^2) < c_1.$$

Hence

$$\begin{aligned} \dot{E}(t) \leq & - \left[ K \left( c_2 - \frac{\delta_0}{2} (1 + c_2^2) \right) - C_2 \right] \tilde{\varepsilon}_t^2(0, t) \\ (6.16) \quad & - \left[ K \frac{\delta_0}{2} - C_2(1 + C_1) \right] \int_0^1 [\tilde{\varepsilon}_x^2(x, t) + \delta \tilde{\varepsilon}_t^2(x, t)] dx \\ & - \left[ \frac{\delta_0}{2} - \delta_1 \right] \int_0^1 [\tilde{w}_x^2(x, t) + \delta \tilde{w}_t^2(x, t)] dx - \left[ c_0 + \frac{\delta c_0^2}{2} - \delta_2 \right] \tilde{w}^2(0, t). \end{aligned}$$

Choosing  $K > 0$  sufficiently large, it follows from (6.16) that there exists an  $\omega > 0$  such that

$$(6.17) \quad \dot{E}(t) \leq -\omega E(t).$$

The above procedure also gives the following estimate:

$$\operatorname{Re} \langle A(f, g, \phi, \psi), (f, g, \phi, \psi) \rangle_H \leq -\omega \|(f, g, \phi, \psi)\|_H^2 \quad \forall (f, g, \phi, \psi) \in D(A).$$

So  $A$  is dissipative in  $H$  ([10]), and if  $A$  generates a  $C_0$ -semigroup, this semigroup must be exponentially stable. By the Lumer–Phillips theorem (Theorem 4.3, p. 14 in [10]), the proof will be accomplished if we can show that  $A^{-1}$  exists and is bounded on  $H$ . Actually, a simple computation shows that

$$A^{-1}(f, g, \phi, \psi) = (f^*, g^*, \phi^*, \psi^*) \quad \forall (f, g, \phi, \psi) \in H,$$

where  $g^* = \delta f$ ,  $\psi^* = \delta\phi$  and

$$\begin{aligned}
 f^*(x) &= c_2 f(0)(x-1) + \int_0^x (x-\tau)g(\tau)d\tau - \int_0^1 (1-\tau)g(\tau)d\tau, \\
 \phi^*(x) &= \int_1^x (x-\tau)\psi(\tau)d\tau + \int_1^x (x-\tau)F(\tau)d\tau - c_1\phi(1)x \\
 &\quad - \int_0^1 \tau\psi(\tau)d\tau - \int_0^1 \tau F(\tau)d\tau + \phi^*(0), \\
 \phi^*(0) &= -\frac{1}{c_0} \int_0^1 \psi(\tau)d\tau - \frac{1}{c_0} \int_0^1 F(\tau)d\tau - \frac{c_1}{c_0}\phi(1) - \frac{\alpha^*(0)}{c_0} - \frac{p(0,0) - c_2}{c_0}f(0), \\
 F(x) &= b \sinh(bx)\alpha^*(0) - k(x,0)\alpha^*(0) - [p_y(x,0) + k(x,0)p(0,0) + k_y(x,0)]f^*(0) \\
 &\quad - b \int_0^x k(x,y) \sinh(by)dy\alpha^*(0) + \int_0^x k(x,y)p_y(y,0)dyf^*(0) \\
 &\quad + \left[ c_2k(x,0) + c_2p(x,0) - c_2 \int_0^x k(x,y)p(y,0)dy \right] f(0), \\
 \alpha^*(0) &= \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-x))f^{*'}(x)dx \\
 &\quad - \frac{b}{\cosh(b)} \int_0^1 \left[ \sinh(b(1-x))p(x,x) + \int_x^1 \sinh(b(1-y))p_x(y,x)dy \right] f^*(x)dx.
 \end{aligned}$$

The proof is complete.  $\square$

**7. Well-posedness and stability of the closed-loop system.** The closed-loop system consists of the plant (3.3), the observer (4.2), and the feedback controller (5.1):

$$(7.1) \quad \left\{ \begin{aligned}
 \delta w_{tt}(x,t) &= w_{xx}(x,t) + b^2 w(x,t) + b^3 \int_0^x \sinh(b(x-y))w(y,t)dy \\
 &\quad - b^2 \cosh(bx)w(0,t) - b \sinh(bx)\alpha(0,t), \\
 w_x(0,t) &= \alpha(0,t) - qw(0,t), \\
 w(1,t) &= \hat{w}(1,t), \\
 \delta \hat{w}_{tt}(x,t) &= \hat{w}_{xx}(x,t) + b^2 \hat{w}(x,t) + b^3 \int_0^x \sinh(b(x-y))\hat{w}(y,t)dy \\
 &\quad - b^2 \cosh(bx)w(0,t) - b \sinh(bx)\alpha(0,t) \\
 &\quad + p_y(x,0)[w(0,t) - \hat{w}(0,t)] - c_2 p(x,0)[w_t(0,t) - \hat{w}_t(0,t)], \\
 \hat{w}_x(0,t) &= \alpha(0,t) - qw(0,t) + p(0,0)[w(0,t) - \hat{w}(0,t)] \\
 &\quad - c_2[w_t(0,t) - \hat{w}_t(0,t)], \\
 \hat{w}_x(1,t) &= -c_1 \hat{w}_t(1,t) + k(1,1)\hat{w}(1,t) \\
 &\quad + c_1 \int_0^1 k(1,y)\hat{w}_t(y,t)dy + \int_0^1 k_x(1,y)\hat{w}(y,t)dy, \\
 \alpha(0,t) &= \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-s))[w_x(x,t) - \hat{w}_x(x,t)]dx,
 \end{aligned} \right.$$

and

$$(7.2) \quad \alpha(x, t) = \cosh(bx)\alpha(0, t) - b \int_0^x \sinh(b(x-s))w_x(s, t)ds.$$

We consider the system (7.1) in the state space  $\mathcal{H} = \{(f, g, \phi, \psi) \in (H^1(0, 1) \times L^2(0, 1))^2 \mid f(1) = \phi(1)\}$ . Define the system operator

$$(7.3) \quad \left\{ \begin{array}{l} D(\mathcal{A}) = \left\{ (f, g, \phi, \psi) \in \mathcal{H} \mid \mathcal{A}(f, g, \phi, \psi) \in \mathcal{H}, f'(0) = \alpha(0) - qf(0), \right. \\ \quad \phi'(0) = \alpha(0) - qf(0) + p(0, 0)[f(0) - \phi(0)] - \frac{c_2}{\delta}[g(0) - \psi(0)], \\ \quad \phi'(1) = k(1, 1)\phi(1) - \frac{c_1}{\delta}\psi(1) + \frac{c_1}{\delta} \int_0^1 k(1, x)\psi(x)dx + \int_0^1 k_x(1, x)\phi(x)dx \Big\}, \\ \quad [\mathcal{A}(f, g, \phi, \psi)](x) = \left( \frac{g(x)}{\delta}, f''(x) + b^2f + b^3 \int_0^x \sinh(b(x-y))f(y)dy \right. \\ \quad \left. - b^2 \cosh(bx)f(0) - b \sinh(bx)\alpha(0), \frac{\psi(x)}{\delta}, \phi''(x) + b^2\phi(x) \right. \\ \quad \left. + b^3 \int_0^x \sinh(b(x-y))\phi(y)dy - b^2 \cosh(bx)f(0) - b \sinh(bx)\alpha(0) \right. \\ \quad \left. + p_y(x, 0)[f(0) - \phi(0)] - \frac{c_2}{\delta}p(x, 0)[g(0) - \psi(0)] \right), \\ \quad \alpha(0) = \frac{b}{\cosh(b)} \int_0^1 \sinh(b(1-s))[f'(x) - \phi'(x)]dx \quad \forall (f, g, \phi, \psi) \in D(\mathcal{A}). \end{array} \right.$$

Then the system (7.3) can be written as an evolution equation in  $\mathcal{H}$ :

$$(7.4) \quad \frac{d}{dt}(w(\cdot, t), \delta w_t(\cdot, t), \widehat{w}(\cdot, t), \delta \widehat{w}_t(\cdot, t)) = \mathcal{A}(w(\cdot, t), \delta w_t(\cdot, t), \delta \widehat{w}_t(\cdot, t), \widehat{w}_t(\cdot, t)).$$

**THEOREM 7.1.** *Let  $\mathcal{A}$  be defined by (7.3). Then  $\mathcal{A}$  generates a  $C_0$ -semigroup  $e^{\mathcal{A}t}$  on  $\mathcal{H}$ , which is exponentially stable:*

$$\|e^{\mathcal{A}t}\|_{\mathcal{H}} \leq Me^{-\omega t} \quad \forall t \geq 0$$

for some positive constants  $M$  and  $\omega$  independent of  $t$ . In particular,

$$(7.5) \quad E_o(t) \leq Ce^{-\omega t}E_o(0)$$

for some  $C > 0$ , where

$$(7.6) \quad E_o(t) = \int_0^1 [w_x^2(x, t) + \delta w_t^2(x, t) + \widehat{w}_x^2(x, t) + \delta \widehat{w}_t^2(x, t) + \alpha^2(x, t)] dx.$$

*Proof.* For any initial value  $(w(\cdot, 0), \delta w_t(\cdot, 0), \widehat{w}(\cdot, 0), \delta \widehat{w}_t(\cdot, 0)) \in D(\mathcal{A})$ , let

$$(7.7) \quad \left\{ \begin{array}{l} \widetilde{\varepsilon}(x, 0) = [(I - \mathbb{P}_1)^{-1}(w(\cdot, 0) - \widehat{w}(\cdot, 0))](x, 0), \\ \delta \widetilde{\varepsilon}_t(x, 0) = [(I - \mathbb{P}_1)^{-1}(\delta w_t(\cdot, 0) - \delta \widehat{w}_t(\cdot, 0))](x, 0), \\ \widetilde{w}(x, 0) = \widehat{w}(x, 0) - \int_0^x k(x, y)\widehat{w}(y, 0)dy, \\ \delta \widetilde{w}_t(x, 0) = \delta \widehat{w}_t(x, 0) - \int_0^x k(x, y)\delta \widehat{w}_t(y, 0)dy. \end{array} \right.$$

A direct computation shows that  $(\tilde{\varepsilon}(\cdot, 0), \delta\tilde{\varepsilon}_t(\cdot, 0), \tilde{w}(\cdot, 0), \delta\tilde{w}_t(\cdot, 0)) \in D(A)$ . So there exists a unique classical solution to (6.1) with this initial value. Let

$$(7.8) \quad \begin{cases} w(x, t) = \hat{w}(x, t) + \tilde{\varepsilon}(x, t) - \int_0^x p(x, y)\tilde{\varepsilon}(y, t)dy, \\ \hat{w}(x, t) = [(I - \mathbb{P}_2)^{-1}\tilde{w}](x, t). \end{cases}$$

Similarly to (5.5), one can show that  $(w, \hat{w})$  defined in this way satisfies (7.1) with initial value  $(w(\cdot, 0), \delta w_t(\cdot, 0), \hat{w}(\cdot, 0), \delta\hat{w}_t(\cdot, 0))$ . This solution is unique by the invertible transformation and the uniqueness of the classical solution to (6.1), where  $\mathbb{T}$  is a one to one

$$(7.9) \quad \begin{pmatrix} \tilde{\varepsilon} \\ \delta\tilde{\varepsilon}_t \\ \tilde{w} \\ \delta\tilde{w}_t \end{pmatrix} = \begin{pmatrix} I - \mathbb{P}_1 & 0 & -I + \mathbb{P}_1 & 0 \\ 0 & I - \mathbb{P}_1 & 0 & -I + \mathbb{P}_1 \\ 0 & 0 & I - \mathbb{P}_2 & 0 \\ 0 & 0 & 0 & I - \mathbb{P}_2 \end{pmatrix} \begin{pmatrix} w \\ \delta w_t \\ \hat{w} \\ \delta\hat{w}_t \end{pmatrix},$$

$$\begin{pmatrix} w \\ \delta w_t \\ \hat{w} \\ \delta\hat{w}_t \end{pmatrix} = \begin{pmatrix} I - \mathbb{P}_1 & 0 & (I - \mathbb{P}_2)^{-1} & 0 \\ 0 & I - \mathbb{P}_1 & 0 & (I - \mathbb{P}_1)^{-1} \\ 0 & 0 & (I - \mathbb{P}_2)^{-1} & 0 \\ 0 & 0 & 0 & (I - \mathbb{P}_2)^{-1} \end{pmatrix} \begin{pmatrix} \tilde{\varepsilon} \\ \delta\tilde{\varepsilon}_t \\ \tilde{w} \\ \delta\tilde{w}_t \end{pmatrix}$$

and onto operator from  $\mathcal{H}$  to  $H$ . Moreover, this solution is exponentially stable by (6.6) and (7.9):

$$(7.10) \quad \begin{aligned} & \| (w(\cdot, t), \delta w_t(\cdot, t), \hat{w}(\cdot, t), \delta\hat{w}_t(\cdot, t)) \|_{\mathcal{H}} \\ & \leq M e^{-\omega t} \| (w(\cdot, 0), \delta w_t(\cdot, 0), \hat{w}(\cdot, 0), \delta\hat{w}_t(\cdot, 0)) \|_{\mathcal{H}} \end{aligned}$$

for some positive constant  $M$  independent of  $t$ . From transformation (7.9), we know that  $\mathcal{A} = \mathbb{T}^{-1}A\mathbb{T}$ , and hence  $\mathcal{A} = \mathbb{T}A\mathbb{T}^{-1}$ , where  $A$  is the operator defined by (6.4). Hence  $\mathcal{A}^{-1}$  exists and is bounded on  $\mathcal{H}$ , which implies that  $\rho(\mathcal{A})$ , the resolvent set of  $\mathcal{A}$ , is not empty. Since obviously  $D(\mathcal{A})$  is dense in  $\mathcal{H}$ , it follows from Theorem 1.3 on page 102 of [10] that  $\mathcal{A}$  generates a  $C_0$ -semigroup  $e^{\mathcal{A}t}$  on  $\mathcal{H}$ . (7.10) shows that  $e^{\mathcal{A}t}$  is exponentially stable, with  $\|e^{\mathcal{A}t}\| \leq M e^{-\omega t}$  for all  $t \geq 0$ . Finally, it follows from (7.2) that  $\|\alpha(\cdot, t)\|_{L^2(0,1)} \leq \tilde{C}[\|w_x(\cdot, t)\|_{L^2(0,1)} + \|\hat{w}_x(\cdot, t)\|_{L^2(0,1)}]$  for some constant  $\tilde{C} > 0$  independent of  $t$ . This together with (7.10) gives (7.5). The proof is complete.  $\square$

**8. Simulation results.** In this section we demonstrate through numerical simulations the effectiveness of the control and the observer.

We use the backward Euler method in the time domain and the Chebyshev spectral method in space. For this purpose the second-order-in-time equations are first converted into first-order-in-time (evolution-type) systems of equations. The control kernel  $k$  is first approximated on a uniform grid using the iterative scheme (3.10), and then linear interpolation was used to obtain values on the nonuniform Chebyshev grid. The boundary conditions were implemented using second-order explicit discretization. In the numerical simulations we used grid size  $N = 40$  in space and time step  $dt = 10^{-4}$ . The convergence of the numerical method was checked by varying  $N$  between  $N = 30$  and  $N = 70$  and varying  $dt$  between  $dt = 10^{-2}$  and  $dt = 10^{-5}$ . The maximum variation of the solution did not exceed  $10^{-3}$  over the whole time and space domain. The numerical code was programed in MATLAB (see, e.g., [18]).

The main system parameters are set to  $\delta = 1$ ,  $b = 0.6$ , and  $q = 0.9$ . The design parameters are set to  $c_0 = 10$ ,  $c_1 = 1$ , and  $c_2 = 1$ . The initial conditions are

FIG. 8.1. Initial conditions of the beam. Solid line,  $w(0, x)$ ; dashed line,  $w_t(0, x)$ .

FIG. 8.2. Beam response  $w(x, t)$ . Uncontrolled case, clamped at  $x = 1$ . Note the instability that results from  $q = 0.9$ .

FIG. 8.3. Beam response  $w(x, t)$  with control  $w_x(1, t)$  applied at  $x = 1$ . Note that the instability at  $x = 0$  is stabilized.

$w(x, 0) = -0.1(1 - x) \sin(1.52\pi(1 - x))$  for  $x \in [0, 1]$  and

$$w_t(x, 0) = \begin{cases} -3(x - x_0)^2 & \text{if } x \in [0, x_0], \\ 0 & \text{if } x \in [x_0, 1], \end{cases}$$

with  $x_0 = 0.1753$ . These initial conditions correspond to hitting the tip part of an already bent beam (Figure 8.1).

**8.1. No observer, full state feedback.** First we consider the full state feedback case. This is equivalent to assuming that the observer starts from the same initial conditions as the plant itself, and hence it is identical with it for all time. Figures 8.2 and 8.3 show the results of our simulation for the shear beam with a zero

FIG. 8.4. Snapshots of the beam movements with increasing darkness denoting increasing time in the sequences.

FIG. 8.5. Time trace of controls  $w(1, t) = u_1(t)$  and  $\alpha(1, t) = u_2(t)$ .

Dirichlet boundary condition at  $x = 1$  in the uncontrolled case and with control (5.1) in the controlled case. The uncontrolled case shows that the relatively large value  $q = 0.9$  destabilizes the trivial zero solution. The controlled case shows asymptotic stability with small control effort. Snapshots of beam movements (uncontrolled and controlled) are depicted in Figure 8.4, where vibrations are shown in sequences of time intervals. In each sequence the time evolution is represented by increasing darkness. The control effort is shown explicitly as function of time in Figure 8.5. Notice that the maximum control effort is about one magnitude smaller than the maximum of the uncontrolled solution. Gain kernels  $k(1, y)$  and  $k_x(1, y)$  of the first control law (4.3) are shown in Figure 8.6 for  $y \in [0, 1]$ . These kernel functions have small spatial variations and can be easily approximated by low order polynomials.

**8.2. Observer design.** We now introduce the observer (4.2) in the simulations. We assume no knowledge of the initial state of the beam, which means that the observer is started with zero initial conditions  $\hat{w}(x, 0) = \hat{w}_t(x, 0)$  for  $x \in [0, 1]$ . Figure 8.7 shows that in the uncontrolled case, although the observer starts far from the state, the observer error quickly converges to zero over a time period of  $t \in [0, 4]$ . As expected in the controlled case (see Figure 8.8) the convergence takes place over a longer time period  $t \in [0, 6]$ . The reason for this short delay in the convergence is that the observer has to compensate for the additional error introduced by the control feedback of the observer into the plant. Nevertheless, the closed-loop state quickly converges to zero (Figure 8.9). Finally, the observer gains  $p(x, 0)$  and  $p_y(x, 0)$  can be seen in Figure 8.10.

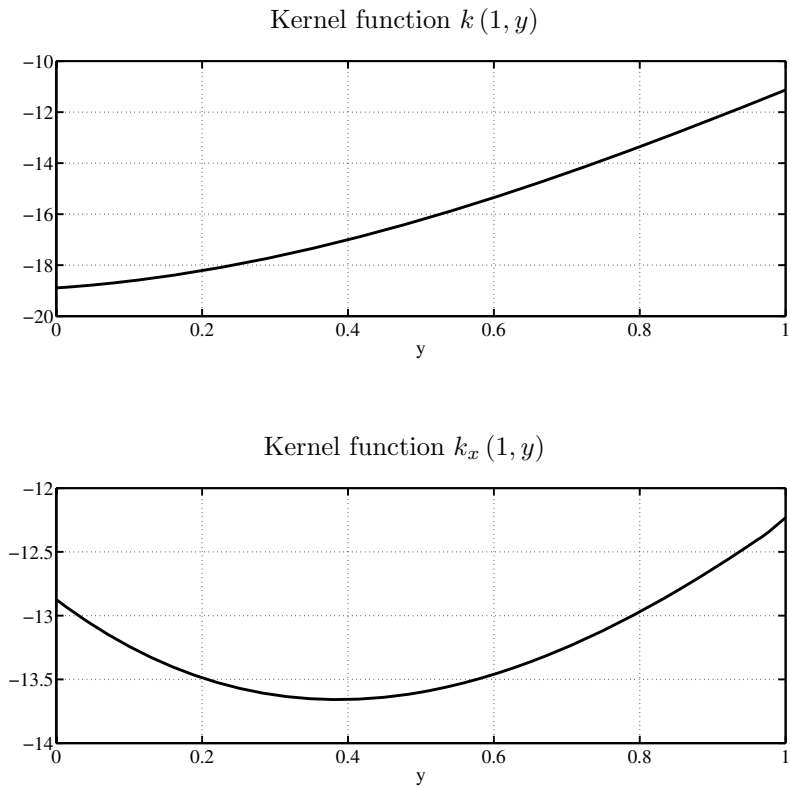

FIG. 8.6. Kernel functions  $k(1, y)$  and  $k_x(1, y)$  of control law (5.1) for  $y \in [0, 1]$ .

FIG. 8.7. Observer error  $\hat{w} - w$  in the uncontrolled case.

 FIG. 8.8. Observer error  $\hat{w} - w$  in the controlled case.

FIG. 8.9. Plant controlled using the observer.

 FIG. 8.10. Kernel functions  $p(x, 0)$  and  $p_y(x, 0)$  of the observer (4.2) for  $x \in [0, 1]$ .

**9. Conclusion.** In this paper we presented the output-feedback controller for an undamped shear beam. Future efforts will be concentrated on developing the controllers for higher-dimensional flexible structures such as plates and shells. Another interesting avenue of research is the control of beams (plates, shells) in the presence of parametric uncertainties, such as unknown structural damage. Successful backstepping boundary adaptive controllers for parabolic PDEs were recently developed in [5, 15, 16], and similar ideas could be applied to the hyperbolic equations.

## REACHING A CONSENSUS IN A DYNAMICALLY CHANGING ENVIRONMENT: A GRAPHICAL APPROACH\*

MING CAO<sup>†</sup>, A. STEPHEN MORSE<sup>‡</sup>, AND BRIAN D. O. ANDERSON<sup>‡</sup>

**Abstract.** This paper presents new graph-theoretic results appropriate for the analysis of a variety of consensus problems cast in dynamically changing environments. The concepts of rooted, strongly rooted, and neighbor-shared are defined, and conditions are derived for compositions of sequences of directed graphs to be of these types. The graph of a stochastic matrix is defined, and it is shown that under certain conditions the graph of a Sarymsakov matrix and a rooted graph are one and the same. As an illustration of the use of the concepts developed in this paper, graph-theoretic conditions are obtained which address the convergence question for the leaderless version of the widely studied Vicsek consensus problem.

**Key words.** cooperative control, graph theory, switched systems, multiagent systems

**1. Introduction.** Current interest in cooperative control of groups of mobile autonomous agents has led to the rapid increase in the application of graph-theoretic ideas to problems of analyzing and synthesizing a variety of desired group behaviors such as maintaining a formation, swarming, rendezvousing, or reaching a consensus. While this in-depth assault on group coordination using a combination of graph theory and system theory is in its early stages, it is likely to significantly expand in the years to come. One line of research which illustrates the combined use of these concepts is the recent theoretical work by a number of individuals [17, 19, 22, 1, 3, 26] which successfully explains the heading synchronization phenomenon observed in simulation by Vicsek et al. [29], Reynolds [23], and others more than a decade ago. Vicsek and coauthors consider a simple discrete-time model consisting of  $n$  autonomous agents or particles all moving in the plane with the same speed but with different headings. Each agent's heading is updated using a local rule based on the average of its own heading plus the current headings of its "neighbors." Agent  $i$ 's *neighbors* at time  $t$  are those agents which are either in or on a circle of prespecified radius centered at agent  $i$ 's current position. In their paper, Vicsek et al. provide a variety of interesting simulation results which demonstrate that the nearest neighbor rule they are studying can cause all agents to eventually move in the same direction despite the absence of centralized coordination and despite the fact that each agent's set of nearest neighbors can change with time. A theoretical explanation for this observed behavior

has recently been given in [17]. The explanation exploits ideas from graph theory [13] and from the theory of nonhomogeneous Markov chains [25, 30, 15]. Experience has shown that it is more the graph theory than the Markov chains which is key to this line of research. An illustration of this is the recent extension of the findings of [17] which explain the behavior of Reynolds' full nonlinear "boid" system [26].

Mathematically Vicsek's problem is what in statistics and computer science is called a "consensus problem" [10] or an "agreement problem" [21], although in computer science the issues tend to be concerned more with fault tolerance [12] rather than convergence. Roughly speaking, one has a group of agents which are all trying to agree on a specific value of some quantity. Each agent initially has only limited information available. The agents then try to reach a consensus by communicating what they know to their neighbors either just once or repeatedly, depending on the specific problem of interest. For the Vicsek problem, each agent knows only its own heading and the headings of its current neighbors. One feature of the Vicsek problem which sharply distinguishes it from other consensus problems is that each agent's neighbors can change with time, because all agents are in motion. The theoretical consequence of this is profound: it renders essentially useless, without elaboration, a large body of literature appropriate to the convergence analysis of "nearest neighbor" algorithms with fixed neighbor relationships. Said differently, for the linear heading update rules considered in this paper, understanding the difference between fixed neighbor relationships and changing neighbor relationships is much the same as understanding the difference between the stability of time-invariant linear systems and time-varying linear systems. Various mathematically similar versions of Vicsek's problem have been addressed in the literature [17, 19, 22, 1, 3]; some it turns out well before Vicsek's own paper was published [10, 9, 27, 28, 2].

The central aim of this paper is to establish a number of basic properties of "compositions" of sequences of directed graphs which, as shown in [7], are useful in explaining how a consensus is achieved in various settings. To motivate the graph-theoretic questions addressed and to demonstrate the utility of the answers obtained, we reconsider the version of the Vicsek consensus problem studied by Moreau [19] and Ren and Beard [22]. We derive a condition for agents to reach a consensus exponentially fast which is slightly different than but equivalent to the condition established in [19]. What this paper contributes, then, is a different approach to the understanding of the consensus phenomenon, one in which graphs and their compositions are at center stage. Of course if the consensus problem studied in [19, 22] were the only problem to which this approach were applicable, its development would have hardly been worth the effort. In a sequel to this paper [7] and elsewhere [4, 8, 6, 5] it is demonstrated that in fact the graph-theoretic approach we are advocating is applicable to a broad range of consensus problems which have so far either been only partially resolved or not studied at all.

To the best of our knowledge, all of the statements in this paper about graph compositions are original. However, because the literature on nonhomogeneous Markov chains is vast, some of these statements can undoubtedly be shown to be equivalent to statements about stochastic matrix product in the existing literature [25, 15]. The main convergence result on leaderless flocking, namely Theorem 3, is equivalent to one of the main results of [19]. Corollary 1 is in essence the main result of [17].

In section 2 we reconsider the leaderless coordination problem studied in [17] but without the assumption that the agents all have the same sensing radii. Agents are labelled 1 to  $n$  and are represented by correspondingly labelled vertices in a directed

graph  $\mathbb{N}$  whose arcs represent current neighbor relationships. We define the concept of a “strongly rooted graph” and show by an elementary argument that convergence to a common heading is achieved if the neighbor graphs encountered along a system trajectory are all strongly rooted. We also derive a worst case convergence rate for these types of trajectories. We next define the concept of a “rooted graph” and the operation of “graph composition.” The directed graphs appropriate to the Vicsek model have self-arcs at all vertices. We prove that any composition of  $(n-1)^2$  such rooted graphs is strongly rooted. Armed with this fact, we establish conditions under which consensus is achieved which are different than but equivalent to those obtained in [19, 22]. We then turn to a more in-depth study of rooted graphs. We prove that a so-called neighbor-shared graph is a special type of rooted graph and in so doing make a connection between the consensus problem under consideration and the elegant theory of “scrambling matrices” found in the literature on nonhomogeneous Markov chains [25, 15]. By exploiting this connection in [7], we are able to derive worst case convergence rate results for several versions of the Vicsek problem. The nonhomogeneous Markov chain literature also contains interesting convergence results for a class of stochastic matrices studied by Sarymsakov [24]. The class of Sarymsakov matrices is bigger than the class of all stochastic scrambling matrices. We make contact with this literature by proving that the graph of any Sarymsakov matrix is rooted and also that any stochastic matrix with a rooted graph whose vertices all have self-arcs is a Sarymsakov matrix.

**2. Leaderless coordination.** The system to be studied consists of  $n$  autonomous agents, labelled 1 through  $n$ , all moving in the plane with the same speed but with different headings. Each agent’s heading is updated using a simple local rule based on the average of its own heading plus the headings of its “neighbors.” Agent  $i$ ’s *neighbors* at time  $t$  are those agents, including itself, which are in a closed disk of prespecified radius  $r_i$  centered at agent  $i$ ’s current position. In what follows  $\mathcal{N}_i(t)$  denotes the set of labels of those agents which are neighbors of agent  $i$  at time  $t$ . Agent  $i$ ’s heading, written  $\theta_i$ , evolves in discrete time in accordance with a model of the form

$$(1) \quad \theta_i(t+1) = \frac{1}{n_i(t)} \left( \sum_{j \in \mathcal{N}_i(t)} \theta_j(t) \right),$$

where  $t$  is a discrete-time index taking values in the nonnegative integers  $\{0, 1, 2, \dots\}$ , and  $n_i(t)$  is the number of neighbors of agent  $i$  at time  $t$ .

**2.1. Neighbor graph.** The explicit form of the update equations determined by (1) depends on the relationships between neighbors which exist at time  $t$ . These relationships can be conveniently described by a directed graph  $\mathbb{N}(t)$  with vertex set  $\mathcal{V} = \{1, 2, \dots, n\}$  and “arc set”  $\mathcal{A}(\mathbb{N}(t)) \subset \mathcal{V} \times \mathcal{V}$  which is defined so that  $(i, j)$  is an *arc* or directed edge from  $i$  to  $j$  just in case agent  $i$  is a neighbor of agent  $j$ . Thus  $\mathbb{N}(t)$  is a directed graph on  $n$  vertices with at most one arc connecting each ordered pair of distinct vertices and with exactly one self-arc at each vertex. We write  $\mathcal{G}_{sa}$  for the set of all such graphs and  $\mathcal{G}$  for the set of all directed graphs with vertex set  $\mathcal{V}$ . It is natural to call a vertex  $i$  a *neighbor* of vertex  $j$  in  $\mathbb{G} \in \mathcal{G}$  if  $(i, j)$  is an arc in  $\mathbb{G}$ . In addition we sometimes refer to a vertex  $k$  as an *observer* of vertex  $j$  in  $\mathbb{G}$  if  $(j, k)$  is an arc in  $\mathbb{G}$ . Thus every vertex of  $\mathbb{G}$  can *observe* its neighbors, which with the interpretation of vertices as agents is precisely the kind of relationship  $\mathbb{G}$  is supposed to represent.

**2.2. State equation.** The set of agent heading update rules defined by (1) can be written in state form. Towards this end, for each graph  $\mathbb{N} \in \mathcal{G}_{sa}$ , define the *flocking matrix*

$$(2) \quad F = D^{-1}A',$$

where  $A'$  is the transpose of the “adjacency matrix” of  $\mathbb{N}$  and  $D$  the diagonal matrix whose  $j$ th diagonal element is the “in-degree” of vertex  $j$  within the graph.<sup>1</sup> The function  $\mathbb{N} \mapsto F$  is bijective. Then

$$(3) \quad \theta(t+1) = F(t)\theta(t), \quad t \in \{0, 1, 2, \dots\},$$

where  $\theta$  is the heading vector  $\theta = [\theta_1 \ \theta_2 \ \dots \ \theta_n]'$  and  $F(t)$  is the flocking matrix of the *neighbor graph*  $\mathbb{N}(t)$  which represents the neighbor relationships of (1) at time  $t$ . A complete description of this system would have to include a model which explains how  $\mathbb{N}(t)$  changes over time as a function of the positions of the  $n$  agents in the plane. While such a model is easy to derive and is essential for simulation purposes, it would be difficult to take into account in a convergence analysis. To avoid this difficulty, we shall adopt a more conservative approach which ignores how  $\mathbb{N}(t)$  depends on the agent positions in the plane and assumes instead that  $t \mapsto \mathbb{N}(t)$  might be any signal in some suitably defined set of interest.

Our ultimate goal is to show for a large class of signals  $t \mapsto \mathbb{N}(t)$  and for any initial set of agent headings that the headings of all  $n$  agents will converge to the same steady state value  $\theta_{ss}$ . Convergence of the  $\theta_i$  to  $\theta_{ss}$  is equivalent to the state vector  $\theta$  converging to a vector of the form  $\theta_{ss}\mathbf{1}$ , where  $\mathbf{1} \triangleq [1 \ 1 \ \dots \ 1]_{n \times 1}'$ . Naturally there are situations where convergence to a common heading cannot occur. The most obvious of these is when one agent—say the  $i$ th—starts so far away from the rest that it never acquires any neighbors. Mathematically this would mean not only that  $\mathbb{N}(t)$  is never strongly connected<sup>2</sup> at any time  $t$  but also that vertex  $i$  remains an isolated vertex of  $\mathbb{N}(t)$  for all  $t$  in the sense that within each  $\mathbb{N}(t)$ , vertex  $i$  has no incoming arcs other than its own self-arc. This situation is likely to be encountered if the  $r_i$  are very small. At the other extreme, which is likely if the  $r_i$  are very large, all agents might remain neighbors of all others for all time. In this case,  $\mathbb{N}(t)$  would remain fixed along such a trajectory as the complete graph. Convergence of  $\theta$  to  $\theta_{ss}\mathbf{1}$  can easily be established in this special case because with  $\mathbb{N}(t)$  so fixed, (3) is a linear, time-invariant, discrete-time system. The situation of perhaps the greatest interest is between these two extremes when  $\mathbb{N}(t)$  is not necessarily complete or even strongly connected for any  $t \geq 0$  but when no strictly proper subset of  $\mathbb{N}(t)$ ’s vertices is isolated from the rest for all time. Establishing convergence in this case is challenging because  $F(t)$  changes with time and (3) is not time-invariant. It is this case which we intend to study.

**2.3. Strongly rooted graphs.** In what follows we will call a vertex  $i$  of a directed graph  $\mathbb{G}$  a *root* of  $\mathbb{G}$  if for each other vertex  $j$  of  $\mathbb{G}$ , there is a path from  $i$  to

<sup>1</sup>By the *adjacency matrix* of a directed graph  $\mathbb{G} \in \mathcal{G}$  we mean an  $n \times n$  matrix whose  $ij$ th entry is 1 if  $(i, j)$  is an arc in  $\mathcal{A}(\mathbb{G})$  and 0 if it is not. The *in-degree* of vertex  $j$  in  $\mathbb{G}$  is the number of arcs in  $\mathcal{A}(\mathbb{G})$  of the form  $(i, j)$ ; thus  $j$ ’s in-degree is the number of *incoming* arcs to vertex  $j$ .

<sup>2</sup>A directed graph  $\mathbb{G} \in \mathcal{G}$  with arc set  $\mathcal{A}$  is *strongly connected* if it has a “path” between each distinct pair of its vertices  $i$  and  $j$ ; by a *path* (of *length*  $m$ ) between vertices  $i$  and  $j$  we mean a sequence of arcs in  $\mathcal{A}$  of the form  $(i, k_1), (k_1, k_2), \dots, (k_{m-1}, k_m)$ , where  $k_m = j$  and, if  $m > 1$ ,  $i, k_1, \dots, k_{m-1}$  are distinct vertices.  $\mathbb{G}$  is *complete* if it has a path of length one (i.e., an arc) between each distinct pair of its vertices.

$j$ . Thus  $i$  is a root of  $\mathbb{G}$  if it is the root of a directed spanning tree of  $\mathbb{G}$ . We will say that  $\mathbb{G}$  is *rooted at  $i$*  if  $i$  is in fact a root. Thus  $\mathbb{G}$  is rooted at  $i$  just in case each other vertex of  $\mathbb{G}$  is *reachable* from vertex  $i$  along a path within the graph.  $\mathbb{G}$  is *strongly rooted at  $i$*  if each other vertex of  $\mathbb{G}$  is reachable from vertex  $i$  along a path of length 1. Thus  $\mathbb{G}$  is strongly rooted at  $i$  if  $i$  is a neighbor of every other vertex in the graph. A *rooted graph*  $\mathbb{G}$  is a directed graph which possesses at least one root. Finally, a *strongly rooted graph* is a graph which has at least one vertex at which it is strongly rooted. It is now possible to state the following elementary convergence result which illustrates, under a restrictive assumption, the more general types of results to be derived later in the paper.

**THEOREM 1.** *Let  $\theta(0)$  be fixed. For any trajectory of the system (3) along which each graph in the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is strongly rooted, there is a constant steady state heading  $\theta_{ss}$  for which*

$$(4) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

**2.3.1. Stochastic matrices.** In order to explain why Theorem 1 is true, we will make use of certain structural properties of the flocking matrices determined by the neighbor graphs in  $\mathcal{G}_{sa}$ . As defined, each flocking matrix  $F$  is square and nonnegative, where by a *nonnegative* matrix we mean a matrix whose entries are all nonnegative. Each  $F$  also has the property that its row sums all equal 1 (i.e.,  $F\mathbf{1} = \mathbf{1}$ ). Matrices with these two properties are called (row) *stochastic* [16]. It is easy to verify that the class of all  $n \times n$  stochastic matrices is closed under multiplication. It is worth noting that because the vertices of the graphs in  $\mathcal{G}_{sa}$  all have self-arcs, the  $F$  also have the property that their diagonal elements are positive. While the proof of Theorem 1 does not exploit this property, the more general results derived later in the paper depend crucially on it.

In what follows we write  $M \geq N$  whenever  $M - N$  is a nonnegative matrix. We also write  $M > N$  whenever  $M - N$  is a positive matrix where by a *positive matrix* we mean a matrix with all positive entries.

**2.3.2. Products of stochastic matrices.** Stochastic matrices have been extensively studied in the literature for a long time largely because of their connection with Markov chains [25, 30, 14]. One problem studied which is of particular relevance here is to describe the asymptotic behavior of products of  $n \times n$  stochastic matrices of the form

$$S_j S_{j-1} \cdots S_1$$

as  $j$  tends to infinity. This is equivalent to looking at the asymptotic behavior of all solutions to the recursion equation

$$(5) \quad x(j+1) = S_j x(j)$$

since any solution  $x(j)$  can be written as

$$x(j) = (S_j S_{j-1} \cdots S_1) x(1), \quad j \geq 1.$$

One especially useful idea, which goes back at least to [11] and has been extensively used [27], is to consider the behavior of the scalar-valued nonnegative function  $V(x) =$

$\lceil x \rceil - \lfloor x \rfloor$  along solutions to (5), where  $x = [x_1 \ x_2 \ \dots \ x_n]'$  is a nonnegative  $n$  vector and  $\lceil x \rceil$  and  $\lfloor x \rfloor$  are its largest and smallest elements, respectively. The key observation is that for any  $n \times n$  stochastic matrix  $S$ , the  $i$ th entry of  $Sx$  satisfies

$$\sum_{j=1}^n s_{ij}x_j \geq \sum_{j=1}^n s_{ij}\lfloor x \rfloor = \lfloor x \rfloor$$

and

$$\sum_{j=1}^n s_{ij}x_j \leq \sum_{j=1}^n s_{ij}\lceil x \rceil = \lceil x \rceil.$$

Since these inequalities hold for all rows of  $Sx$ , it must be true that  $\lfloor Sx \rfloor \geq \lfloor x \rfloor$ , that  $\lceil Sx \rceil \leq \lceil x \rceil$ , and, as a consequence, that  $V(Sx) \leq V(x)$ . These inequalities and (5) imply that the sequences

$$\lfloor x(1) \rfloor, \lfloor x(2) \rfloor, \dots, \quad \lceil x(1) \rceil, \lceil x(2) \rceil, \dots, \quad V(x(1)), V(x(2)), \dots$$

are each monotone. Thus because each of these sequences is also bounded, the limits

$$\lim_{j \rightarrow \infty} \lfloor x(j) \rfloor, \quad \lim_{j \rightarrow \infty} \lceil x(j) \rceil, \quad \lim_{j \rightarrow \infty} V(x(j))$$

each exist. Note that whenever the limit of  $V(x(j))$  is zero, all components of  $x(j)$  together with  $\lfloor x(j) \rfloor$  and  $\lceil x(j) \rceil$  must tend to the same constant value.

There are various different ways in which one might approach the problem of developing conditions under which  $x(j)$  converges to some scalar multiple of  $\mathbf{1}$  or equivalently  $S_j S_{j-1} \cdots S_1$  converges to a constant matrix of the form  $\mathbf{1}c$  for some constant row vector  $c$ . For example, since for any  $n \times n$  stochastic matrix  $S$ ,  $S\mathbf{1} = \mathbf{1}$ , it must be true that  $\text{span}\{\mathbf{1}\}$  is an  $S$ -invariant subspace for any such  $S$ . From this and standard existence conditions for solutions to linear algebraic equation, it follows that for any  $(n-1) \times n$  matrix  $P$  with kernel spanned by  $\mathbf{1}$ , the equation  $PS = \tilde{S}P$  has unique solutions  $\tilde{S}$ , and, moreover, that

$$(6) \quad \text{spectrum } S = \{1\} \cup \text{spectrum } \tilde{S}.$$

As a consequence of the equation  $PS_j = \tilde{S}_j P$ ,  $j \geq 1$ , it can easily be seen that

$$\tilde{S}_j \tilde{S}_{j-1} \cdots \tilde{S}_1 P = PS_j S_{j-1} \cdots S_1.$$

Since  $P$  has full row rank and  $P\mathbf{1} = 0$ , the convergence of a product  $S_j S_{j-1} \cdots S_1$  to a matrix of the form  $\mathbf{1}c$  is equivalent to convergence of the corresponding product  $\tilde{S}_j \tilde{S}_{j-1} \cdots \tilde{S}_1$  to the zero matrix. There are two problems with this approach. First, since  $P$  is not unique, neither are the  $\tilde{S}_i$ . Second, it is not so clear how to go about picking  $P$  to make tractable the problem of proving that the resulting product  $\tilde{S}_j \tilde{S}_{j-1} \cdots \tilde{S}_1$  tends to zero. Tractability of the latter problem generally boils down to choosing a norm for which the  $\tilde{S}_i$  are all contractive. For example, one might seek to choose a suitably weighted 2-norm. This is in essence the same thing as choosing a common quadratic Lyapunov function. Although each  $\tilde{S}_i$  can easily be shown to be discrete-time stable with all eigenvalues of magnitude less than 1, it is known that there are classes of  $S_i$  which give rise to  $\tilde{S}_i$  for which no such common Lyapunov

matrix exists [18] regardless of the choice of  $P$ . Of course there are many other possible norms to choose from other than 2-norms. In the end, success with this approach requires one to simultaneously choose *both* a suitable  $P$  and an appropriate norm with respect to which the  $\tilde{S}_i$  are all contractive. In what follows we adopt a slightly different but closely related approach which ensures that we can work with what is perhaps the most natural norm for this type of convergence problem, the infinity norm.

To proceed, we need a few more ideas concerned with nonnegative matrices. For any nonnegative matrix  $R$  of any size, we write  $\|R\|$  for the largest of the row sums of  $R$ . Note that  $\|R\|$  is the induced infinity norm of  $R$  and consequently is submultiplicative. Note in addition that  $\|x\| = \lceil x \rceil$  for any nonnegative  $n$  vector  $x$ . Moreover,  $\|M_1\| \leq \|M_2\|$  if  $M_1 \leq M_2$ . Observe that for any  $n \times n$  stochastic matrix  $S$ ,  $\|S\| = 1$  because the row sums of a stochastic matrix all equal 1. We extend the domain of definitions of  $\lfloor \cdot \rfloor$  and  $\lceil \cdot \rceil$  to the class of all nonnegative  $n \times m$  matrix  $M$  by letting  $\lfloor M \rfloor$  and  $\lceil M \rceil$  now denote the  $1 \times m$  row vectors whose  $j$ th entries are the smallest and largest elements, respectively, of the  $j$ th column of  $M$ . Note that  $\lfloor M \rfloor$  is the largest  $1 \times m$  nonnegative row vector  $c$  for which  $M - \mathbf{1}c$  is nonnegative and that  $\lceil M \rceil$  is the smallest nonnegative row vector  $c$  for which  $\mathbf{1}c - M$  is nonnegative. Note in addition that for any  $n \times n$  stochastic matrix  $S$ , one can write

$$(7) \quad S = \mathbf{1} \lfloor S \rfloor + \lceil S \rceil \quad \text{and} \quad S = \mathbf{1} \lceil S \rceil - \lfloor S \rfloor,$$

where  $\lfloor S \rfloor$  and  $\lceil S \rceil$  are nonnegative matrices defined by the equations

$$(8) \quad \lfloor S \rfloor = S - \mathbf{1} \lfloor S \rfloor \quad \text{and} \quad \lceil S \rceil = \mathbf{1} \lceil S \rceil - S,$$

respectively. Moreover, the row sums of  $\lfloor S \rfloor$  are all equal to  $1 - \lfloor S \rfloor \mathbf{1}$  and the row sums of  $\lceil S \rceil$  are all equal to  $\lceil S \rceil \mathbf{1} - 1$ , and so

$$(9) \quad \|\lfloor S \rfloor\| = 1 - \lfloor S \rfloor \mathbf{1} \quad \text{and} \quad \|\lceil S \rceil\| = \lceil S \rceil \mathbf{1} - 1.$$

In what follows we will also be interested in the matrix

$$(10) \quad \llbracket S \rrbracket = \lfloor S \rfloor + \lceil S \rceil.$$

This matrix satisfies

$$(11) \quad \llbracket S \rrbracket = \mathbf{1}(\lceil S \rceil - \lfloor S \rfloor)$$

because of (7).

For any infinite sequence of  $n \times n$  stochastic matrices  $S_1, S_2, \dots$ , we henceforth use the symbol  $\lfloor \dots S_j \dots S_1 \rfloor$  to denote the limit

$$(12) \quad \lfloor \dots S_j \dots S_2 S_1 \rfloor = \lim_{j \rightarrow \infty} \lfloor S_j \dots S_2 S_1 \rfloor.$$

From the preceding discussion it is clear that for  $i \in \{1, 2, \dots, n\}$ , the limit  $\lfloor \dots S_j \dots S_1 \rfloor e_i$  exists, where  $e_i$  is the  $i$ th unit  $n$ -vector. Thus the limit  $\lfloor \dots S_j \dots S_1 \rfloor$  always exists, and this is true even if the product  $S_j \dots S_2 S_1$  itself does not have a limit. Two situations can occur. Either the product  $S_j \dots S_2 S_1$  converges to a rank one matrix or it does not. In fact, even if  $S_j \dots S_2 S_1$  does converge, it is quite possible that the limit is not a rank one matrix. An example of this would be a sequence in which  $S_1$  is any stochastic matrix of rank greater than 1 and for all  $i > 1$ ,  $S_i = I_{n \times n}$ . In what follows we will develop sufficient conditions for  $S_j \dots S_2 S_1$  to converge to a rank one

matrix as  $j \rightarrow \infty$ . Note that if this occurs, then the limit must be of the form  $\mathbf{1}c$ , where  $c\mathbf{1} = 1$  because stochastic matrices are closed under multiplication.

In what follows we will say that a matrix product  $S_j S_{j-1} \cdots S_1$  converges to  $\mathbf{1}[\cdots S_j \cdots S_1]$  exponentially fast at a rate no slower than  $\lambda$  if there are nonnegative constants  $b$  and  $\lambda$  with  $\lambda < 1$ , such that

$$(13) \quad \|(S_j \cdots S_1) - \mathbf{1}[\cdots S_j \cdots S_2 S_1]\| \leq b\lambda^j, \quad j \geq 1.$$

The following proposition implies that such a stochastic matrix product will so converge if  $\|S_j \cdots S_1\|$  converges to 0.

**PROPOSITION 1.** *Let  $\bar{b}$  and  $\lambda$  be nonnegative numbers with  $\lambda < 1$ . Suppose that  $S_1, S_2, \dots$  is an infinite sequence of  $n \times n$  stochastic matrices for which*

$$(14) \quad \|[S_j \cdots S_1]\| \leq \bar{b}\lambda^j, \quad j \geq 0.$$

*Then the matrix product  $S_j \cdots S_2 S_1$  converges to  $\mathbf{1}[\cdots S_j \cdots S_1]$  exponentially fast at a rate no slower than  $\lambda$ .*

The proof of Proposition 1 makes use of the first of the two inequalities which follow.

**LEMMA 1.** *For any two  $n \times n$  stochastic matrices  $S_1$  and  $S_2$ ,*

$$(15) \quad \lfloor S_2 S_1 \rfloor - \lfloor S_1 \rfloor \leq \lceil S_2 \rceil \lfloor S_1 \rfloor,$$

$$(16) \quad \lceil S_2 S_1 \rceil \leq \lceil S_2 \rceil \lceil S_1 \rceil.$$

*Proof of Lemma 1.* Since  $S_2 S_1 = S_2(\mathbf{1}\lfloor S_1 \rfloor + \lceil S_1 \rceil) = \mathbf{1}\lfloor S_1 \rfloor + S_2 \lceil S_1 \rceil$  and  $S_2 = \mathbf{1}\lceil S_2 \rceil - \lfloor S_2 \rfloor$ , it must be true that  $S_2 S_1 = \mathbf{1}(\lfloor S_1 \rfloor + \lceil S_2 \rceil \lfloor S_1 \rfloor) - \lfloor S_2 \rfloor \lceil S_1 \rceil$ . Thus  $\mathbf{1}(\lfloor S_1 \rfloor + \lceil S_2 \rceil \lfloor S_1 \rfloor) - \lfloor S_2 \rfloor \lceil S_1 \rceil$  is nonnegative. But  $\lceil S_2 S_1 \rceil$  is the smallest nonnegative row vector  $c$  for which  $\mathbf{1}c - S_2 S_1$  is nonnegative. Therefore

$$(17) \quad \lceil S_2 S_1 \rceil \leq \lfloor S_1 \rfloor + \lceil S_2 \rceil \lfloor S_1 \rfloor.$$

Moreover,  $\lfloor S_2 S_1 \rfloor \leq \lceil S_2 S_1 \rceil$  because of the definitions of  $\lfloor \cdot \rfloor$  and  $\lceil \cdot \rceil$ . This and (17) imply that  $\lfloor S_2 S_1 \rfloor \leq \lfloor S_1 \rfloor + \lceil S_2 \rceil \lfloor S_1 \rfloor$  and thus that (15) is true.

Since  $S_2 S_1 = S_2(\mathbf{1}\lfloor S_1 \rfloor + \lceil S_1 \rceil) = \mathbf{1}\lfloor S_1 \rfloor + S_2 \lceil S_1 \rceil$  and  $S_2 = \lfloor S_2 \rfloor + \lceil S_2 \rceil$ , it must be true that  $S_2 S_1 = \mathbf{1}(\lfloor S_1 \rfloor + \lfloor S_2 \rfloor \lceil S_1 \rceil) + \lceil S_2 \rceil \lceil S_1 \rceil$ . Thus  $S_2 S_1 - \mathbf{1}(\lfloor S_1 \rfloor + \lfloor S_2 \rfloor \lceil S_1 \rceil)$  is nonnegative. But  $\lfloor S_2 S_1 \rfloor$  is the largest nonnegative row vector  $c$  for which  $S_2 S_1 - \mathbf{1}c$  is nonnegative, and so

$$(18) \quad S_2 S_1 \leq \mathbf{1}\lfloor S_2 S_1 \rfloor + \lceil S_2 \rceil \lceil S_1 \rceil.$$

Now it is also true that  $S_2 S_1 = \mathbf{1}\lfloor S_2 S_1 \rfloor + \lceil S_2 S_1 \rceil$ . From this and (18) it follows that (16) is true.  $\square$

*Proof of Proposition 1.* Set  $X_j = S_j \cdots S_1, j \geq 1$ , and note that each  $X_j$  is a stochastic matrix. In view of (15),

$$\lfloor X_{j+1} \rfloor - \lfloor X_j \rfloor \leq \lceil S_{j+1} \rceil \lfloor X_j \rfloor, \quad j \geq 1.$$

By hypothesis,  $\|[X_j]\| \leq \bar{b}\lambda^j, j \geq 1$ . Moreover,  $\|\lceil S_{j+1} \rceil\| \leq n$  because all entries in  $S_{j+1}$  are bounded above by 1. Therefore

$$(19) \quad \|\lfloor X_{j+1} \rfloor - \lfloor X_j \rfloor\| \leq n\bar{b}\lambda^j, \quad j \geq 1.$$

Clearly

$$\lfloor X_{j+i} \rfloor - \lfloor X_j \rfloor = \sum_{k=1}^i (\lfloor X_{i+j+1-k} \rfloor - \lfloor X_{i+j-k} \rfloor), \quad i, j \geq 1.$$

Thus, by the triangle inequality

$$||\lfloor X_{j+i} \rfloor - \lfloor X_j \rfloor|| \leq \sum_{k=1}^i ||\lfloor X_{i+j+1-k} \rfloor - \lfloor X_{i+j-k} \rfloor||, \quad i, j \geq 1.$$

This and (19) imply that

$$||\lfloor X_{j+i} \rfloor - \lfloor X_j \rfloor|| \leq n\bar{b} \sum_{k=1}^i \lambda^{(i+j-k)}, \quad i, j \geq 1.$$

Now

$$\sum_{k=1}^i \lambda^{(i+j-k)} = \lambda^j \sum_{k=1}^i \lambda^{(i-k)} = \lambda^j \sum_{q=1}^i \lambda^{q-1} \leq \lambda^j \sum_{q=1}^{\infty} \lambda^{q-1}.$$

But  $\lambda < 1$ , and so

$$\sum_{q=1}^{\infty} \lambda^{q-1} = \frac{1}{1-\lambda}.$$

Therefore

$$(20) \quad ||\lfloor X_{i+j} \rfloor - \lfloor X_j \rfloor|| \leq n\bar{b} \frac{\lambda^j}{1-\lambda}, \quad i, j \geq 1.$$

Set  $c = \lfloor \cdots S_j \cdots S_1 \rfloor$  and note that

$$||\lfloor X_j \rfloor - c|| = ||\lfloor X_j \rfloor - \lfloor X_{i+j} \rfloor + \lfloor X_{i+j} \rfloor - c|| \leq ||\lfloor X_j \rfloor - \lfloor X_{i+j} \rfloor|| + ||\lfloor X_{i+j} \rfloor - c||, \quad i, j \geq 1.$$

In view of (20)

$$||\lfloor X_j \rfloor - c|| \leq n\bar{b} \frac{\lambda^j}{1-\lambda} + ||\lfloor X_{i+j} \rfloor - c||, \quad i, j \geq 1.$$

Since

$$\lim_{i \rightarrow \infty} ||\lfloor X_{i+j} \rfloor - c|| = 0$$

it must be true that

$$||\lfloor X_j \rfloor - c|| \leq n\bar{b} \frac{\lambda^j}{1-\lambda}, \quad j \geq 1.$$

But  $||\mathbf{1}(\lfloor X_j \rfloor - c)|| = ||\lfloor X_j \rfloor - c||$  and  $X_j = S_j \cdots S_1$ . Therefore

$$(21) \quad ||\mathbf{1}(\lfloor S_j \cdots S_1 \rfloor - c)|| \leq n\bar{b} \frac{\lambda^j}{1-\lambda}, \quad j \geq 1.$$

In view of (7)

$$S_j \cdots S_1 = \mathbf{1} \lfloor S_j \cdots S_1 \rfloor + \lVert S_j \cdots S_1 \rVert, \quad j \geq 1.$$

Therefore

$$\begin{aligned} \|(S_j \cdots S_1) - \mathbf{1}c\| &= \|\mathbf{1} \lfloor S_j \cdots S_1 \rfloor + \lVert S_j \cdots S_1 \rVert - \mathbf{1}c\| \\ &\leq \|\mathbf{1} \lfloor S_j \cdots S_1 \rfloor - \mathbf{1}c\| + \|\lVert S_j \cdots S_1 \rVert\|, \quad j \geq 1. \end{aligned}$$

From this, (14), and (21) it follows that

$$\|S_j \cdots S_1 - \mathbf{1}c\| \leq \bar{b} \left(1 + \frac{n}{1-\lambda}\right) \lambda^j, \quad j \geq 1,$$

and thus that (13) holds with  $b = \bar{b}(1 + \frac{n}{1-\lambda})$ .  $\square$

**2.3.3. Convergence.** We are now in a position to make some statements about the asymptotic behavior of a product of  $n \times n$  stochastic matrices of the form  $S_j S_{j-1} \cdots S_1$  as  $j$  tends to infinity. Note first that (16) generalizes to sequences of stochastic matrices of any length. Thus

$$(22) \quad \lfloor S_j S_{j-1} \cdots S_2 S_1 \rfloor \leq \lfloor S_j \rfloor \lfloor S_{j-1} \rfloor \cdots \lfloor S_1 \rfloor.$$

It is therefore clear that condition (14) of Proposition 1 will hold with  $\bar{b} = 1$  if

$$(23) \quad \|\lVert S_j \rVert\| \cdots \lVert S_1 \rVert\| \leq \lambda^j$$

for some nonnegative number  $\lambda < 1$ . Because  $\|\cdot\|$  is submultiplicative, this means that a product of stochastic matrices  $S_j \cdots S_1$  will converge to a limit of the form  $\mathbf{1}c$  for some constant row vector  $c$  if each of the matrices  $S_i$  in the sequence  $S_1, S_2, \dots$  satisfies the norm bound  $\|\lVert S_i \rVert\| \leq \lambda$ . We now develop a condition, tailored to our application, for this to be so.

As a first step it is useful to characterize those stochastic matrices  $S$  for which  $\|\lVert S \rVert\| < 1$ . Note that this condition is equivalent to the requirement that the row sums of  $\lfloor S \rfloor$  are less than 1. This, in turn, is equivalent to the requirement that  $\mathbf{1} \lfloor S \rfloor \neq 0$  since  $\lVert S \rVert = S - \mathbf{1} \lfloor S \rfloor$ . Now  $\mathbf{1} \lfloor S \rfloor \neq 0$  if and only if  $S$  has at least one nonzero column since the indices of the nonzero columns of  $S$  are the same as the indices of the nonzero columns of  $\lfloor S \rfloor$ . Thus  $\|\lVert S \rVert\| < 1$  if and only if  $S$  has at least one nonzero column. For our purposes it proves to be especially useful to restate this condition in equivalent graph theoretic terms. For this we need the following definition.

*The graph of a stochastic matrix.* For any  $n \times n$  stochastic matrix  $S$ , let  $\gamma(S)$  denote the graph  $\mathbb{G} \in \mathcal{G}$  whose adjacency matrix is the transpose of the matrix obtained by replacing all of  $S$ 's nonzero entries with 1's. The graph-theoretic condition is as follows.

LEMMA 2. *A stochastic matrix  $S$  has a strongly rooted graph  $\gamma(S)$  if and only if*

$$(24) \quad \|\lVert S \rVert\| < 1.$$

*Proof.* Let  $A$  be the adjacency matrix of  $\gamma(S)$ . Since the positions of the nonzero entries of  $S$  and  $A$  are the same, the  $i$ th column of  $S$  will be positive if and only if  $A$ 's  $i$ th row is positive. Thus (23) will hold just in case  $A$  has a positive row. But strongly

rooted graphs in  $\mathcal{G}$  are precisely those graphs whose adjacency matrices have at least one positive row. Therefore (23) will hold if and only if  $\gamma(S)$  is strongly rooted.  $\square$

Lemma 2 can be used to prove the following.

**PROPOSITION 2.** *Let  $\mathcal{S}_{sr}$  be any closed set of stochastic matrices which are all the same size and whose graphs  $\gamma(S)$ ,  $S \in \mathcal{S}_{sr}$ , are all strongly rooted. Then as  $j \rightarrow \infty$ , any product  $S_j \cdots S_1$  of matrices from  $\mathcal{S}_{sr}$  converges exponentially fast to  $\mathbf{1}[\cdots S_j \cdots S_1]$  at a rate no slower than*

$$\lambda = \max_{S \in \mathcal{S}_{sr}} \|\|S\|\|,$$

where  $\lambda$  is a nonnegative constant satisfying  $\lambda < 1$ .

*Proof of Proposition 2.* In view of Lemma 2,  $\|\|S\|\| < 1$ ,  $S \in \mathcal{S}_{sr}$ . Because  $\mathcal{S}_{sr}$  is closed and bounded and  $\|\|\cdot\|\|$  is continuous,  $\lambda < 1$ . Clearly  $\|\|S_i\|\| \leq \lambda$ ,  $i \geq 1$ , and so (23) must hold for any sequence of matrices  $S_1, S_2, \dots$  from  $\mathcal{S}_{sr}$ . Therefore for any such sequence  $\|\|S_j \cdots S_1\|\| \leq \lambda^j$ ,  $j \geq 0$ . Thus by Proposition 1, the product  $\Pi(j) = S_j S_{j-1} \cdots S_1$  converges to  $\mathbf{1}[\cdots S_j \cdots S_1]$  exponentially fast at a rate no slower than  $\lambda$ .  $\square$

*Proof of Theorem 1.* Let  $\mathcal{F}_{sr}$  denote the set of flocking matrices with strongly rooted graphs. Since  $\mathcal{S}_{sa}$  is a finite set, so is the set of strongly rooted graphs in  $\mathcal{G}_{sa}$ . Therefore  $\mathcal{F}_{sr}$  is closed. By assumption,  $F(t) \in \mathcal{F}_{sr}$ ,  $t \geq 0$ . In view of Proposition 2, the product  $F(t) \cdots F(0)$  converges exponentially fast to  $\mathbf{1}[\cdots F(t) \cdots F(0)]$  at a rate no slower than

$$\lambda = \max_{F \in \mathcal{F}_{sr}} \|\|F\|\|.$$

But it is clear from (3) that  $\theta(t) = F(t-1) \cdots F(1)F(0)\theta(0)$ ,  $t \geq 1$ . Therefore (4) holds with  $\theta_{ss} = \mathbf{1}[\cdots F(t) \cdots F(0)]\theta(0)$  and the convergence is exponential.  $\square$

**2.3.4. Convergence rate.** Using (9) it is possible to calculate a worst case value for the convergence rate  $\lambda$  used in the proof of Theorem 1. Fix  $F \in \mathcal{F}_{sr}$ . Because  $\gamma(F)$  is strongly rooted, at least one vertex—say the  $k$ th—must be a root with arcs to each other vertex. In the context of (1), this means that agent  $k$  must be a neighbor of every agent. Thus  $\theta_k$  must be in each sum in (1). Since each  $n_i$  in (1) is bounded above by  $n$ , this means that the smallest element in column  $k$  of  $F$  is bounded below by  $\frac{1}{n}$ . Since (9) asserts that  $\|\|F\|\| = 1 - \lfloor F \rfloor \mathbf{1}$ , it must be true that  $\|\|F\|\| \leq 1 - \frac{1}{n}$ . This holds for all  $F \in \mathcal{F}_{sr}$ . Moreover, in the worst case when  $\mathbb{F}$  is strongly rooted at just one vertex and all vertices are neighbors of at least one common vertex,  $\|\|F\|\| = 1 - \frac{1}{n}$ . It follows that the worst case convergence rate is

$$(25) \quad \max_{F \in \mathcal{F}_{sr}} \|\|F\|\| = 1 - \frac{1}{n}.$$

An example of a graph of a flocking matrix for which (25) holds is shown in Figure 1.

**2.4. Rooted graphs.** The proof of Theorem 1 depends crucially on the fact that the graphs encountered along a trajectory of (3) are all strongly rooted. It is natural to ask if this requirement can be relaxed and still have all agents' headings converge to a common value. The aim of this section is to show that this can indeed be accomplished. To do this we need to have a meaningful way of “combining” sequences of graphs so that only the combined graph need be strongly rooted but not necessarily the individual graphs making up the combination. One possible notion of combination

FIG. 1. *Example.*

of a sequence  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_k$  with the same vertex set  $\mathcal{V}$  would be the graph with vertex set  $\mathcal{V}$  whose arc set is the union of the arc sets of the graphs in the sequence. It turns out that because we are interested in *sequences* of graphs rather than mere *sets* of graphs, a simple union is not quite the appropriate notion for our purposes because a union does not take into account the order in which the graphs are encountered along a trajectory. What is appropriate is a slightly more general notion which we now define.

**2.4.1. Composition of graphs.** By the *composition* of a directed graph  $\mathbb{G}_p \in \mathcal{G}$  with a directed graph  $\mathbb{G}_q \in \mathcal{G}$ , written  $\mathbb{G}_q \circ \mathbb{G}_p$ , we mean the directed graph with the vertex set  $\{1, 2, \dots, n\}$  and arc set defined in such a way so that  $(i, j)$  is an arc of the composition just in case there is a vertex  $k$  such that  $(i, k)$  is an arc of  $\mathbb{G}_p$  and  $(k, j)$  is an arc of  $\mathbb{G}_q$ . Thus  $(i, j)$  is an arc in  $\mathbb{G}_q \circ \mathbb{G}_p$  if and only if  $i$  has an observer in  $\mathbb{G}_p$  which is also a neighbor of  $j$  in  $\mathbb{G}_q$ . Note that  $\mathcal{G}$  is closed under composition and that composition is an associative binary operation; because of this, the definition extends unambiguously to any finite sequence of directed graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_k$ .

If we focus exclusively on graphs with self-arcs at all vertices, namely the graphs in  $\mathcal{G}_{sa}$ , more can be said. In this case the definition of composition implies that the arcs of  $\mathbb{G}_p$  and  $\mathbb{G}_q$  are arcs of  $\mathbb{G}_q \circ \mathbb{G}_p$ . The definition also implies in this case that if  $\mathbb{G}_p$  has a directed path from  $i$  to  $k$  and  $\mathbb{G}_q$  has a directed path from  $k$  to  $j$ , then  $\mathbb{G}_q \circ \mathbb{G}_p$  has a directed path from  $i$  to  $j$ . Both of these implications are consequences of the requirement that the vertices of the graphs in  $\mathcal{G}_{sa}$  all have self-arcs. Note in addition that  $\mathcal{G}_{sa}$  is closed under composition. It is worth emphasizing that the union of the arc sets of a sequence of graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_k$  in  $\mathcal{G}_{sa}$  must be contained in the arc set of their composition. However, the converse is not true in general, and it is for this reason that composition rather than union proves to be the more useful concept for our purposes.

Suppose that  $A_p = [a_{ij}(p)]$  and  $A_q = [a_{ij}(q)]$  are the adjacency matrices of  $\mathbb{G}_p \in \mathcal{G}$  and  $\mathbb{G}_q \in \mathcal{G}$ , respectively. Then the adjacency matrix of the composition  $\mathbb{G}_q \circ \mathbb{G}_p$  must be the matrix obtained by replacing all nonzero elements in  $A_p A_q$  with ones. This is because the  $ij$ th entry of  $A_p A_q$ , namely

$$\sum_{k=1}^n a_{ik}(p) a_{kj}(q),$$

will be nonzero just in case there is at least one value of  $k$  for which both  $a_{ik}(p)$  and  $a_{kj}(q)$  are nonzero. This of course is exactly the condition for the  $ij$ th element of the adjacency matrix of the composition  $\mathbb{G}_q \circ \mathbb{G}_p$  to be nonzero. Note that if  $S_1$  and  $S_2$  are  $n \times n$  stochastic matrices for which  $\gamma(S_1) = \mathbb{G}_p$  and  $\gamma(S_2) = \mathbb{G}_q$ , then the matrix which results by replacing by ones all nonzero entries in the stochastic

matrix  $S_2 S_1$  must be the transpose of the adjacency matrix of  $\mathbb{G}_q \circ \mathbb{G}_p$ . In view of the definition of  $\gamma(\cdot)$ , it therefore must be true that  $\gamma(S_2 S_1) = \gamma(S_2) \circ \gamma(S_1)$ . This obviously generalizes to finite products of stochastic matrices.

LEMMA 3. *For any sequence of stochastic matrices  $S_1, S_2, \dots, S_j$  which are all the same size,*

$$\gamma(S_j \cdots S_1) = \gamma(S_j) \circ \cdots \circ \gamma(S_1).$$

**2.4.2. Compositions of rooted graphs.** We now give several different conditions under which the composition of a sequence of graphs is strongly rooted.

PROPOSITION 3. *Suppose  $n > 1$  and let  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  be a finite sequence of rooted graphs in  $\mathcal{G}_{sa}$ .*

1. *If  $m \geq (n-1)^2$ , then  $\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \cdots \circ \mathbb{G}_{p_1}$  is strongly rooted.*
2. *If  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  are all rooted at  $v$  and  $m \geq n-1$ , then  $\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \cdots \circ \mathbb{G}_{p_1}$  is strongly rooted at  $v$ .*

The requirement of assertion 2 above that all the graphs in the sequence be rooted at a single vertex  $v$  is obviously more restrictive than the requirement of assertion 1 that all the graphs be rooted but not necessarily at the same vertex. The price for the less restrictive assumption is that the bound on the number of graphs needed in the more general case is much higher than the bound given in the case in which all the graphs are rooted at  $v$ . It is probably true that the bound  $(n-1)^2$  for the more general case is too conservative, but this remains to be shown. The more special case when all graphs share a common root is relevant to the leader-follower version of the problem which will be discussed later in the paper. Proposition 3 will be proved shortly.

Note that a strongly connected graph is the same as a graph which is rooted at every vertex and that a complete graph is the same as a graph which is strongly rooted at every vertex. In view of these observations and Proposition 3 we can state the following proposition.

PROPOSITION 4. *Suppose  $n > 1$  and let  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  be a finite sequence of strongly connected graphs in  $\mathcal{G}_{sa}$ . If  $m \geq n-1$ , then  $\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \cdots \circ \mathbb{G}_{p_1}$  is complete.*

To prove Proposition 3 we will need some more ideas. We say that a vertex  $v \in \mathcal{V}$  is an *observer* of a subset  $\mathcal{S} \subset \mathcal{V}$  in a graph  $\mathbb{G} \in \mathcal{G}$  if  $v$  is an observer of at least one vertex in  $\mathcal{S}$ . By the *observer function* of a graph  $\mathbb{G} \in \mathcal{G}$ , written  $\alpha(\mathbb{G}, \cdot)$ , we mean the function  $\alpha(\mathbb{G}, \cdot) : 2^{\mathcal{V}} \rightarrow 2^{\mathcal{V}}$  which assigns to each subset  $\mathcal{S} \subset \mathcal{V}$  the subset of vertices in  $\mathcal{V}$  which are observers of  $\mathcal{S}$  in  $\mathbb{G}$ . Thus  $j \in \alpha(\mathbb{G}, i)$  just in case  $(i, j) \in \mathcal{A}(\mathbb{G})$ . Note that if  $\mathbb{G}_p \in \mathcal{G}$  and  $\mathbb{G}_q$  in  $\mathcal{G}_{sa}$ , then

$$(26) \quad \alpha(\mathbb{G}_p, \mathcal{S}) \subset \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S}), \quad \mathcal{S} \in 2^{\mathcal{V}},$$

because  $\mathbb{G}_q \in \mathcal{G}_{sa}$  implies that the arcs in  $\mathbb{G}_p$  are all arcs in  $\mathbb{G}_q \circ \mathbb{G}_p$ . Observer functions have the following important and easily proved property.

LEMMA 4. *For all  $\mathbb{G}_p, \mathbb{G}_q \in \mathcal{G}$  and any nonempty subset  $\mathcal{S} \subset \mathcal{V}$ ,*

$$(27) \quad \alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, \mathcal{S})) = \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S}).$$

*Proof.* Suppose first that  $i \in \alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, \mathcal{S}))$ . Then  $(j, i)$  is an arc in  $\mathbb{G}_q$  for some  $j \in \alpha(\mathbb{G}_p, \mathcal{S})$ . Hence  $(k, j)$  is an arc in  $\mathbb{G}_p$  for some  $k \in \mathcal{S}$ . In view of the definition of composition,  $(k, i)$  is an arc in  $\mathbb{G}_q \circ \mathbb{G}_p$ , and so  $i \in \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S})$ . Since this holds for all  $i \in \mathcal{V}$ ,  $\alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, \mathcal{S})) \subset \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S})$ .

For the reverse inclusion, fix  $i \in \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S})$  in which case  $(k, i)$  is an arc in  $\mathbb{G}_q \circ \mathbb{G}_p$  for some  $k \in \mathcal{S}$ . By definition of composition, there exists an  $j \in \mathcal{V}$  such that  $(k, j)$  is an arc in  $\mathbb{G}_p$  and  $(j, i)$  is an arc in  $\mathbb{G}_q$ . Thus  $j \in \alpha(\mathbb{G}_p, \mathcal{S})$ . Therefore  $i \in \alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, \mathcal{S}))$ . Since this holds for all  $i \in \mathcal{V}$ ,  $\alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, \mathcal{S})) \supset \alpha(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S})$ . Therefore (27) is true.  $\square$

To proceed, let us note that each subset  $\mathcal{S} \subset \mathcal{V}$  induces a unique subgraph of  $\mathbb{G}$  with vertex set  $\mathcal{S}$  and arc set  $\mathcal{A}$  consisting of those arcs  $(i, j)$  of  $\mathbb{G}$  for which both  $i$  and  $j$  are vertices of  $\mathcal{S}$ . This, together with the natural partial ordering of  $\mathcal{V}$  by inclusion, provides a corresponding partial ordering of  $\mathcal{G}$ . Thus if  $\mathcal{S}_1$  and  $\mathcal{S}_2$  are subsets of  $\mathcal{V}$  and  $\mathcal{S}_1 \subset \mathcal{S}_2$ , then  $\mathbb{G}_1 \subset \mathbb{G}_2$ , where, for  $i \in \{1, 2\}$ ,  $\mathbb{G}_i$  is the subgraph of  $\mathbb{G}$  induced by  $\mathcal{S}_i$ . For any  $v \in \mathcal{V}$ , there is a unique largest subgraph rooted at  $v$ , namely the graph induced by the vertex set  $\mathcal{V}(v) = \{v\} \cup \alpha(\mathbb{G}, v) \cup \dots \cup \alpha^{n-1}(\mathbb{G}, v)$ , where  $\alpha^i(\mathbb{G}, \cdot)$  denotes the composition of  $\alpha(\mathbb{G}, \cdot)$  with itself  $i$  times. We call this graph the *rooted graph generated by  $v$* . It is clear that  $\mathcal{V}(v)$  is the smallest  $\alpha(\mathbb{G}, \cdot)$ -invariant subset of  $\mathcal{V}$  which contains  $v$ .

The proof of Proposition 3 depends on the following lemma.

LEMMA 5. *Let  $\mathbb{G}_p$  and  $\mathbb{G}_q$  be graphs in  $\mathcal{G}_{sa}$ . If  $\mathbb{G}_q$  is rooted at  $v$  and  $\alpha(\mathbb{G}_p, v)$  is a strictly proper subset of  $\mathcal{V}$ , then  $\alpha(\mathbb{G}_p, v)$  is also a strictly proper subset of  $\alpha(\mathbb{G}_q \circ \mathbb{G}_p, v)$ .*

*Proof of Lemma 5.* In general  $\alpha(\mathbb{G}_p, v) \subset \alpha(\mathbb{G}_q \circ \mathbb{G}_p, v)$  because of (26). Thus if  $\alpha(\mathbb{G}_p, v)$  is not a strictly proper subset of  $\alpha(\mathbb{G}_q \circ \mathbb{G}_p, v)$ , then  $\alpha(\mathbb{G}_p, v) = \alpha(\mathbb{G}_q \circ \mathbb{G}_p, v)$ , and so  $\alpha(\mathbb{G}_q \circ \mathbb{G}_p, v) \subset \alpha(\mathbb{G}_p, v)$ . In view of (27),  $\alpha(\mathbb{G}_q \circ \mathbb{G}_p, v) = \alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, v))$ . Therefore  $\alpha(\mathbb{G}_q, \alpha(\mathbb{G}_p, v)) \subset \alpha(\mathbb{G}_p, v)$ . Moreover,  $v \in \alpha(\mathbb{G}_p, v)$  because  $v$  has a self-arc in  $\mathbb{G}_p$ . Thus  $\alpha(\mathbb{G}_p, v)$  is a strictly proper subset of  $\mathcal{V}$  which contains  $v$  and is  $\alpha(\mathbb{G}_q, \cdot)$ -invariant. But this is impossible because  $\mathbb{G}_q$  is rooted at  $v$ .  $\square$

*Proof of Proposition 3.* Assertion 2 will be proved first. Suppose that  $m \geq n - 1$  and that  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  are all rooted at  $v$ . In view of (26),  $\mathcal{A}(\mathbb{G}_{p_k} \circ \mathbb{G}_{p_{k-1}} \circ \dots \circ \mathbb{G}_{p_1}) \subset \mathcal{A}(\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \dots \circ \mathbb{G}_{p_1})$  for any positive integer  $k \leq m$ . Thus  $\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \dots \circ \mathbb{G}_{p_1}$  will be strongly rooted at  $v$  if there exists an integer  $k \leq n - 1$  such that

$$(28) \quad \alpha(\mathbb{G}_{p_k} \circ \mathbb{G}_{p_{k-1}} \circ \dots \circ \mathbb{G}_{p_1}, v) = \mathcal{V}.$$

It will now be shown that such an integer exists.

If  $\alpha(\mathbb{G}_{p_1}, v) = \mathcal{V}$ , set  $k = 1$ , in which case (28) clearly holds. If  $\alpha(\mathbb{G}_{p_1}, v) \neq \mathcal{V}$ , then let  $i > 1$  be the greatest positive integer not exceeding  $n - 1$  for which  $\alpha(\mathbb{G}_{p_{i-1}} \circ \dots \circ \mathbb{G}_{p_1}, v)$  is a strictly proper subset of  $\mathcal{V}$ . If  $i < n - 1$ , set  $k = i$ , in which case (28) is clearly true. Therefore suppose  $i = n - 1$ ; we will prove that this cannot be so. Assuming that it is,  $\alpha(\mathbb{G}_{p_{j-1}} \circ \dots \circ \mathbb{G}_{p_1}, v)$  must be a strictly proper subset of  $\mathcal{V}$  for  $j \in \{2, 3, \dots, n - 1\}$ ; by Lemma 5,  $\alpha(\mathbb{G}_{p_{j-1}} \circ \dots \circ \mathbb{G}_{p_1}, v)$  is also a strictly proper subset of  $\alpha(\mathbb{G}_{p_j} \circ \dots \circ \mathbb{G}_{p_1}, v)$  for  $j \in \{2, 3, \dots, n - 1\}$ . In view of this and (26), each containment in the ascending chain

$$\alpha(\mathbb{G}_{p_1}, v) \subset \alpha(\mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, v) \subset \dots \subset \alpha(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_1}, v)$$

is strict. Since  $\alpha(\mathbb{G}_{p_1}, v)$  has at least two vertices in it, and there are  $n$  vertices in  $\mathcal{V}$ , (28) must hold with  $k = n - 1$ . Thus assertion 2 is true.

To prove assertion 1, suppose that  $m \geq (n - 1)^2$ . Since there are  $n$  vertices in  $\mathcal{V}$ , the sequence  $p_1, p_2, \dots, p_m$  must contain a subsequence  $q_1, q_2, \dots, q_{n-1}$  for which the graphs  $\mathbb{G}_{q_1}, \mathbb{G}_{q_2}, \dots, \mathbb{G}_{q_{n-1}}$  all have a common root. By assertion 2,  $\mathbb{G}_{q_{n-1}} \circ \dots \circ \mathbb{G}_{q_1}$  must be strongly rooted. But  $\mathcal{A}(\mathbb{G}_{q_{n-1}} \circ \dots \circ \mathbb{G}_{q_1}) \subset \mathcal{A}(\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \dots \circ \mathbb{G}_{p_1})$

because  $\mathbb{G}_{q_1}, \mathbb{G}_{q_2}, \dots, \mathbb{G}_{q_{n-1}}$  is a subsequence of  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  and all graphs in the sequence  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_m}$  have self-arcs. Therefore  $\mathbb{G}_{p_m} \circ \mathbb{G}_{p_{m-1}} \circ \dots \circ \mathbb{G}_{p_1}$  must be strongly rooted.  $\square$

Proposition 3 implies that every sufficiently long composition of graphs from a given subset  $\widehat{\mathcal{G}} \subset \mathcal{G}_{sa}$  will be strongly rooted if each graph in  $\widehat{\mathcal{G}}$  is rooted. The converse is also true. To understand why, suppose to the contrary that it is not. In this case there would have to be a graph  $\mathbb{G} \in \widehat{\mathcal{G}}$ , which is not rooted but for which  $\mathbb{G}^m$  is strongly rooted for  $m$  sufficiently large, where  $\mathbb{G}^m$  is the  $m$ -fold composition of  $\mathbb{G}$  with itself. Thus  $\alpha(\mathbb{G}^m, v) = \mathcal{V}$ , where  $v$  is a root of  $\mathbb{G}^m$ . But via repeated application of (27),  $\alpha(\mathbb{G}^m, v) = \alpha^m(\mathbb{G}, v)$ , where  $\alpha^m(\mathbb{G}, \cdot)$  is the  $m$ -fold composition of  $\alpha(\mathbb{G}, \cdot)$  with itself. Thus  $\alpha^m(\mathbb{G}, v) = \mathcal{V}$ . But this can occur only if  $\mathbb{G}$  is rooted at  $v$  because  $\alpha^m(\mathbb{G}, v)$  is the set of vertices reachable from  $v$  along paths of length  $m$ . Since this is a contradiction,  $\mathbb{G}$  must be rooted. We summarize.

**PROPOSITION 5.** *Every possible sufficiently long composition of graphs from a given subset  $\widehat{\mathcal{G}} \subset \mathcal{G}_{sa}$  is strongly rooted if and only if every graph in  $\widehat{\mathcal{G}}$  is rooted.*

**2.4.3. Sarymsakov graphs.** We now briefly discuss a class of graphs in  $\mathcal{G}$ , namely “Sarymsakov graphs,” whose corresponding stochastic matrices form products which are known to converge to rank one matrices [25] even though the graphs in question need not have self-arcs at all vertices. Sarymsakov graphs are defined as follows.

First, let us agree to say that a vertex  $v \in \mathcal{V}$  is a *neighbor of a subset*  $\mathcal{S} \subset \mathcal{V}$  in a graph  $\mathbb{G} \in \mathcal{G}$  if  $v$  is a neighbor of at least one vertex in  $\mathcal{S}$ . By a *Sarymsakov graph* we mean a graph  $\mathbb{G} \in \mathcal{G}$  with the property that for each pair of nonempty subsets  $\mathcal{S}_1$  and  $\mathcal{S}_2$  in  $\mathcal{V}$  which have no neighbors in common,  $\mathcal{S}_1 \cup \mathcal{S}_2$  contains a smaller number of vertices than does the set of neighbors of  $\mathcal{S}_1 \cup \mathcal{S}_2$ . Such seemingly obscure graphs are so named because they are the graphs of an important class of nonnegative matrices studied by Sarymsakov in [24]. In what follows we will prove that Sarymsakov graphs are in fact rooted graphs. We will also prove that the class of rooted graphs we are primarily interested in, namely those in  $\mathcal{G}_{sa}$ , are Sarymsakov graphs.

It is possible to characterize Sarymsakov graphs a little more concisely using the following concept. By the *neighbor function* of a graph  $\mathbb{G} \in \mathcal{G}$ , written  $\beta(\mathbb{G}, \cdot)$ , we mean the function  $\beta(\mathbb{G}, \cdot) : 2^{\mathcal{V}} \rightarrow 2^{\mathcal{V}}$  which assigns to each subset  $\mathcal{S} \subset \mathcal{V}$  the subset of vertices in  $\mathcal{V}$  which are neighbors of  $\mathcal{S}$  in  $\mathbb{G}$ . Thus in terms of  $\beta$ , a Sarymsakov graph is a graph  $\mathbb{G} \in \mathcal{G}$  with the property that for each pair of nonempty subsets  $\mathcal{S}_1$  and  $\mathcal{S}_2$  in  $\mathcal{V}$  which have no neighbors in common,  $\mathcal{S}_1 \cup \mathcal{S}_2$  contains fewer vertices than does the set  $\beta(\mathbb{G}, \mathcal{S}_1 \cup \mathcal{S}_2)$ . Note that if  $\mathbb{G} \in \mathcal{G}_{sa}$ , the requirement that  $\mathcal{S}_1 \cup \mathcal{S}_2$  contain fewer vertices than  $\beta(\mathbb{G}, \mathcal{S}_1 \cup \mathcal{S}_2)$  simplifies to the equivalent requirement that  $\mathcal{S}_1 \cup \mathcal{S}_2$  be a strictly proper subset of  $\beta(\mathbb{G}, \mathcal{S}_1 \cup \mathcal{S}_2)$ . This is because every vertex in  $\mathbb{G}$  is a neighbor of itself if  $\mathbb{G} \in \mathcal{G}_{sa}$ .

**PROPOSITION 6.**

1. *Each Sarymsakov graph in  $\mathcal{G}$  is rooted.*
2. *Each rooted graph in  $\mathcal{G}_{sa}$  is a Sarymsakov graph.*

It follows that if we restrict attention exclusively to graphs in  $\mathcal{G}_{sa}$ , then rooted graphs and Sarymsakov graphs are one and the same.

In what follows  $\beta^m(\mathbb{G}, \cdot)$  denotes the  $m$ -fold composition of  $\beta(\mathbb{G}, \cdot)$  with itself. The proof of Proposition 6 depends on the following ideas.

**LEMMA 6.** *Let  $\mathbb{G} \in \mathcal{G}$  be a Sarymsakov graph. Let  $\mathcal{S}$  be a nonempty subset of  $\mathcal{V}$  such that  $\beta(\mathbb{G}, \mathcal{S}) \subset \mathcal{S}$ . Let  $v$  be any vertex in  $\mathcal{V}$ . Then there exists a nonnegative integer  $m \leq n$  such that  $\beta^m(\mathbb{G}, v) \cap \mathcal{S}$  is nonempty.*

*Proof.* If  $v \in \mathcal{S}$ , set  $m = 0$ . Suppose next that  $v \notin \mathcal{S}$ . Set  $\mathcal{T} = \{v\} \cup \beta(\mathbb{G}, v) \cup \cdots \cup \beta^{n-1}(\mathbb{G}, v)$  and note that  $\beta^n(\mathbb{G}, v) \subset \mathcal{T}$  because  $\mathbb{G}$  has  $n$  vertices. Since  $\beta(\mathbb{G}, \mathcal{T}) = \beta(\mathbb{G}, v) \cup \beta^2(\mathbb{G}, v) \cup \cdots \cup \beta^n(\mathbb{G}, v)$ , it must be true that  $\beta(\mathbb{G}, \mathcal{T}) \subset \mathcal{T}$ . Therefore

$$(29) \quad \beta(\mathbb{G}, \mathcal{T} \cup \mathcal{S}) \subset \mathcal{T} \cup \mathcal{S}.$$

Suppose  $\beta(\mathbb{G}, \mathcal{T}) \cap \beta(\mathbb{G}, \mathcal{S})$  is empty. Then because  $\mathbb{G}$  is a Sarymsakov graph,  $\mathcal{T} \cup \mathcal{S}$  contains fewer vertices than  $\beta(\mathbb{G}, \mathcal{T} \cup \mathcal{S})$ . This contradicts (29), and so  $\beta(\mathbb{G}, \mathcal{T}) \cap \beta(\mathbb{G}, \mathcal{S})$  is not empty. In view of the fact that  $\beta(\mathbb{G}, \mathcal{T}) = \beta(\mathbb{G}, v) \cup \beta^2(\mathbb{G}, v) \cup \cdots \cup \beta^n(\mathbb{G}, v)$ , it must therefore be true for some positive integer  $m \leq n$  that  $\beta^m(\mathbb{G}, v) \cap \beta(\mathbb{G}, \mathcal{S})$  is nonempty. But by assumption  $\beta(\mathbb{G}, \mathcal{S}) \subset \mathcal{S}$ , and so  $\beta^m(\mathbb{G}, v) \cap \mathcal{S}$  is nonempty.  $\square$

LEMMA 7. *Let  $\mathbb{G} \in \mathcal{G}$  be rooted at  $r$ . Each nonempty subset  $\mathcal{S} \subset \mathcal{V}$  not containing  $r$  is a strictly proper subset of  $\mathcal{S} \cup \beta(\mathbb{G}, \mathcal{S})$ .*

*Proof of Lemma 7.* Let  $\mathcal{S} \subset \mathcal{V}$  be nonempty and not containing  $r$ . Pick  $v \in \mathcal{S}$ . Since  $\mathbb{G}$  is rooted at  $r$ , there must be a path in  $\mathbb{G}$  from  $r$  to  $v$ . Since  $r \notin \mathcal{S}$  there must be a vertex  $x \in \mathcal{S}$  which has a neighbor which is not in  $\mathcal{S}$ . Thus there is a vertex  $y \in \beta(\mathbb{G}, \mathcal{S})$  which is not in  $\mathcal{S}$ . This implies that  $\mathcal{S}$  is a strictly proper subset of  $\mathcal{S} \cup \beta(\mathbb{G}, \mathcal{S})$ .  $\square$

By a *maximal rooted subgraph* of  $\mathbb{G}$  we mean a subgraph  $\mathbb{G}^*$  of  $\mathbb{G}$  which is rooted and which is not contained in any rooted subgraph of  $\mathbb{G}$  other than itself. Graphs in  $\mathcal{G}$  may have one or more maximal rooted subgraphs. Clearly  $\mathbb{G}^* = \mathbb{G}$  just in case  $\mathbb{G}$  is rooted. Note that if  $\widehat{\mathcal{R}}$  is the set of all roots of a maximal rooted subgraph  $\widehat{\mathbb{G}}$ , then  $\beta(\mathbb{G}, \widehat{\mathcal{R}}) \subset \widehat{\mathcal{R}}$ . For if this were not so, then it would be possible to find a vertex  $x \in \beta(\mathbb{G}, \widehat{\mathcal{R}})$  which is not in  $\widehat{\mathcal{R}}$ . This would imply the existence of a path from  $x$  to some root  $\widehat{v} \in \widehat{\mathcal{R}}$ ; consequently the graph induced by the set of vertices along this path together with  $\widehat{\mathcal{R}}$  would be rooted at  $x \notin \widehat{\mathcal{R}}$  and would contain  $\widehat{\mathbb{G}}$  as a strictly proper subgraph. But this contradicts the hypothesis that  $\widehat{\mathbb{G}}$  is maximal. Therefore  $\beta(\mathbb{G}, \widehat{\mathcal{R}}) \subset \widehat{\mathcal{R}}$ . Now suppose that  $\widehat{\mathbb{G}}$  is any rooted subgraph in  $\mathcal{G}$ . Suppose that  $\widehat{\mathbb{G}}$ 's set of roots  $\widehat{\mathcal{R}}$  satisfies  $\beta(\mathbb{G}, \widehat{\mathcal{R}}) \subset \widehat{\mathcal{R}}$ . We claim that  $\widehat{\mathbb{G}}$  must then be maximal. For if this were not so, there would have to be a rooted graph  $\mathbb{G}^*$  containing  $\widehat{\mathbb{G}}$  as a strictly proper subset. This, in turn, would imply the existence of a path from a root  $x^*$  of  $\mathbb{G}^*$  to a root  $v$  of  $\widehat{\mathbb{G}}$ ; consequently  $x^* \in \beta^i(\mathbb{G}, \widehat{\mathcal{R}})$  for some  $i \geq 1$ . But this is impossible because  $\widehat{\mathcal{R}}$  is  $\beta(\mathbb{G}, \cdot)$  invariant. Thus  $\widehat{\mathbb{G}}$  is maximal. We summarize.

LEMMA 8. *A rooted subgraph of a graph  $\mathbb{G}$  generated by any vertex  $v \in \mathcal{V}$  is maximal if and only if its set of roots is  $\beta(\mathbb{G}, \cdot)$ -invariant.*

*Proof of Proposition 6.* Write  $\beta(\cdot)$  for  $\beta(\mathbb{G}, \cdot)$ . To prove assertion 1, pick  $\mathbb{G} \in \mathcal{G}$ . Let  $\mathbb{G}^*$  be any maximal rooted subgraph of  $\mathbb{G}$  and write  $\mathcal{R}$  for its root set; in view of Lemma 8,  $\beta(\mathcal{R}) \subset \mathcal{R}$ . Pick any  $v \in \mathcal{V}$ . Then by Lemma 6, for some positive integer  $m \leq n$ ,  $\beta^m(v) \cap \mathcal{R}$  is nonempty. Pick  $z \in \beta^m(v) \cap \mathcal{R}$ . Then there is a path from  $z$  to  $v$  and  $z$  is a root of  $\mathbb{G}^*$ . But  $\mathbb{G}^*$  is maximal, and so  $v$  must be a vertex of  $\mathbb{G}^*$ . Therefore every vertex of  $\mathbb{G}$  is a vertex of  $\mathbb{G}^*$ , which implies that  $\mathbb{G}$  is rooted.

To prove assertion 2, let  $\mathbb{G} \in \mathcal{G}_{sa}$  be rooted at  $r$ . Pick any two nonempty subsets  $\mathcal{S}_1, \mathcal{S}_2$  of  $\mathcal{V}$  which have no neighbors in common. If  $r \notin \mathcal{S}_1 \cup \mathcal{S}_2$ , then  $\mathcal{S}_1 \cup \mathcal{S}_2$  must be a strictly proper subset of  $\mathcal{S}_1 \cup \mathcal{S}_2 \cup \beta(\mathcal{S}_1 \cup \mathcal{S}_2)$  because of Lemma 7.

Suppose next that  $r \in \mathcal{S}_1 \cup \mathcal{S}_2$ . Since  $\mathbb{G} \in \mathcal{G}_{sa}$ ,  $\mathcal{S}_i \subset \beta(\mathcal{S}_i)$ ,  $i \in \{1, 2\}$ . Thus  $\mathcal{S}_1$  and  $\mathcal{S}_2$  must be disjoint because  $\beta(\mathcal{S}_1)$  and  $\beta(\mathcal{S}_2)$  are. Therefore  $r$  must be in either  $\mathcal{S}_1$  or  $\mathcal{S}_2$  but not both. Suppose that  $r \notin \mathcal{S}_1$ . Then  $\mathcal{S}_1$  must be a strictly proper subset of  $\beta(\mathcal{S}_1)$  because of Lemma 7. Since  $\beta(\mathcal{S}_1)$  and  $\beta(\mathcal{S}_2)$  are disjoint,  $\mathcal{S}_1 \cup \mathcal{S}_2$  must be a strictly proper subset of  $\beta(\mathcal{S}_1 \cup \mathcal{S}_2)$ . By the same reasoning,  $\mathcal{S}_1 \cup \mathcal{S}_2$  must be a strictly proper subset of  $\beta(\mathcal{S}_1 \cup \mathcal{S}_2)$  if  $r \notin \mathcal{S}_2$ . Thus in conclusion  $\mathcal{S}_1 \cup \mathcal{S}_2$  must be a strictly

proper subset of  $\beta(\mathcal{S}_1 \cup \mathcal{S}_2)$  whether or not  $r$  is in  $\mathcal{S}_1 \cup \mathcal{S}_2$ . Since this conclusion holds for all such  $\mathcal{S}_1$  and  $\mathcal{S}_2$  and  $\mathbb{G} \in \mathcal{G}_{sa}$ ,  $\mathbb{G}$  must be a Sarymsakov graph.  $\square$

**2.5. Neighbor-shared graphs.** There is a different assumption which one can make about a sequence of graphs from  $\mathcal{G}$  which also ensures that the sequence's composition is strongly rooted. For this we need the concept of a “neighbor-shared graph.” Let us call  $\mathbb{G} \in \mathcal{G}$  *neighbor-shared* if each set of two distinct vertices shares a common neighbor. Suppose that  $\mathbb{G}$  is neighbor-shared. Then both vertices in any given pair of vertices are clearly reachable from a single vertex along directed paths. Suppose that for some integer  $k \in \{2, 3, \dots, n-1\}$ , each subset of  $k$  vertices  $\{v_1, v_2, \dots, v_k\}$  has the property that every vertex in  $\{v_1, v_2, \dots, v_k\}$  is reachable from a single vertex. Let  $\{v_1, v_2, \dots, v_k\}$  be any such set and  $v$  be a vertex from which all  $k$  vertices in the set can be reached. Let  $w$  be any vertex not in  $\{v_1, v_2, \dots, v_k\}$ . Since  $v$  and  $w$  can be reached from a common vertex  $y$ , every vertex in  $\{v_1, v_2, \dots, v_k, w\}$  can be reached from  $y$ . This proves that each subset of  $k+1$  vertices has the property that every vertex in the subset is reachable from a single vertex. By induction we can therefore conclude that every vertex in  $\mathbb{G}$  is reachable from a single vertex. We have proved the following proposition.

PROPOSITION 7. *Each neighbor-shared graph in  $\mathcal{G}$  is rooted.*

It is worth noting that although neighbor-shared graphs are rooted, the converse is not necessarily true. The reader may wish to construct a three-vertex example which illustrates this. Although rooted graphs in  $\mathcal{G}_{sa}$  need not be neighbor-shared, it turns out that the composition of any  $n-1$  rooted graphs in  $\mathcal{G}_{sa}$  is.

PROPOSITION 8. *The composition of any set of  $m \geq n-1$  rooted graphs in  $\mathcal{G}_{sa}$  is neighbor-shared.*

This result is equivalent to Theorem 5.1 of [31], which was independently derived.

To prove Proposition 8 we need some more ideas. By the *reverse graph* of  $\mathbb{G} \in \mathcal{G}$ , written  $\mathbb{G}'$ , we mean the graph in  $\mathcal{G}$  which results when the directions of all arcs in  $\mathbb{G}$  are reversed. It is clear that  $\mathcal{G}_{sa}$  is closed under the reverse operation and that if  $A$  is the adjacency matrix of  $\mathbb{G}$ , then  $A'$  is the adjacency matrix of  $\mathbb{G}'$ . It is also clear that  $(\mathbb{G}_p \circ \mathbb{G}_q)' = \mathbb{G}'_q \circ \mathbb{G}'_p$ ,  $p, q \in \mathcal{P}$ , and that

$$(30) \quad \alpha(\mathbb{G}', \mathcal{S}) = \beta(\mathbb{G}, \mathcal{S}), \quad \mathcal{S} \in 2^{\mathcal{V}}.$$

LEMMA 9. *For all  $\mathbb{G}_p, \mathbb{G}_q \in \mathcal{G}$  and any nonempty subset  $\mathcal{S} \subset \mathcal{V}$ ,*

$$(31) \quad \beta(\mathbb{G}_q, \beta(\mathbb{G}_p, \mathcal{S})) = \beta(\mathbb{G}_p \circ \mathbb{G}_q, \mathcal{S}).$$

*Proof of Lemma 9.* In view of (27),  $\alpha(\mathbb{G}'_p, \alpha(\mathbb{G}'_q, \mathcal{S})) = \alpha(\mathbb{G}'_p \circ \mathbb{G}'_q, \mathcal{S})$ . But  $\mathbb{G}'_p \circ \mathbb{G}'_q = (\mathbb{G}_q \circ \mathbb{G}_p)'$ , and so  $\alpha(\mathbb{G}'_p, \alpha(\mathbb{G}'_q, \mathcal{S})) = \alpha((\mathbb{G}_q \circ \mathbb{G}_p)', \mathcal{S})$ . Therefore  $\beta(\mathbb{G}_p, \beta(\mathbb{G}_q, \mathcal{S})) = \beta(\mathbb{G}_q \circ \mathbb{G}_p, \mathcal{S})$  because of (30).  $\square$

LEMMA 10. *Let  $\mathbb{G}_p$  and  $\mathbb{G}_q$  be rooted graphs in  $\mathcal{G}_{sa}$ . If  $u$  and  $v$  are distinct vertices in  $\mathcal{V}$  for which*

$$(32) \quad \beta(\mathbb{G}_q, \{u, v\}) = \beta(\mathbb{G}_q \circ \mathbb{G}_p, \{u, v\}),$$

*then  $u$  and  $v$  have a common neighbor in  $\mathbb{G}_q \circ \mathbb{G}_p$ .*

*Proof.*  $\beta(\mathbb{G}_q, u)$  and  $\beta(\mathbb{G}_q, v)$  are nonempty because  $u$  and  $v$  are neighbors of themselves. Suppose  $u$  and  $v$  do not have a common neighbor in  $\mathbb{G}_q \circ \mathbb{G}_p$ . Then  $\beta(\mathbb{G}_q \circ \mathbb{G}_p, u)$  and  $\beta(\mathbb{G}_q \circ \mathbb{G}_p, v)$  are disjoint. But  $\beta(\mathbb{G}_q \circ \mathbb{G}_p, u) = \beta(\mathbb{G}_p, \beta(\mathbb{G}_q, u))$  and  $\beta(\mathbb{G}_q \circ \mathbb{G}_p, v) = \beta(\mathbb{G}_p, \beta(\mathbb{G}_q, v))$  because of (31). Therefore  $\beta(\mathbb{G}_p, \beta(\mathbb{G}_q, u))$  and

$\beta(\mathbb{G}_p, \beta(\mathbb{G}_q, v))$  are disjoint. But  $\mathbb{G}_p$  is rooted and thus a Sarymsakov graph because of Proposition 6. Thus  $\beta(\mathbb{G}_q, \{u, v\})$  is a strictly proper subset of  $\beta(\mathbb{G}_q, \{u, v\}) \cup \beta(\mathbb{G}_p, \beta(\mathbb{G}_q, \{u, v\}))$ . But  $\beta(\mathbb{G}_q, \{u, v\}) \subset \beta(\mathbb{G}_p, \beta(\mathbb{G}_q, \{u, v\}))$  because all vertices in  $\mathbb{G}_q$  are neighbors of themselves and  $\beta(\mathbb{G}_p, \beta(\mathbb{G}_q, \{u, v\})) = \beta(\mathbb{G}_q \circ \mathbb{G}_p, \{u, v\})$  because of (31). Therefore  $\beta(\mathbb{G}_q, \{u, v\})$  is a strictly proper subset of  $\beta(\mathbb{G}_q \circ \mathbb{G}_p, \{u, v\})$ . This contradicts (32), and so  $u$  and  $v$  have a common neighbor in  $\mathbb{G}_q \circ \mathbb{G}_p$ .  $\square$

*Proof of Proposition 8.* Let  $u$  and  $v$  be distinct vertices in  $\mathcal{V}$ . Let  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_{n-1}}$  be a sequence of rooted graphs in  $\mathcal{G}_{sa}$ . Since  $\mathcal{A}(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_{n-i}}) \subset \mathcal{A}(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_{n-(i+1)}})$  for  $i \in \{1, 2, \dots, n-2\}$ , it must be true that the  $\mathbb{G}_p$  yield the ascending chain

$$\beta(\mathbb{G}_{n-1}, \{u, v\}) \subset \beta(\mathbb{G}_{p_{n-1}} \circ \mathbb{G}_{p_{n-2}}, \{u, v\}) \subset \dots \subset \beta(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{u, v\}).$$

Because there are  $n$  vertices in  $\mathcal{V}$ , this chain must converge for some  $i < n-1$ , which means that

$$\beta(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_{n-i}}, \{u, v\}) = \beta(\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_{n-i}} \circ \mathbb{G}_{p_{n-(i+1)}}, \{u, v\}).$$

This and Lemma 10 imply that  $u$  and  $v$  have a common neighbor in  $\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_{n-i}}$  and thus in  $\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}$ . Since this is true for all distinct  $u$  and  $v$ ,  $\mathbb{G}_{p_{n-1}} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}$  is a neighbor-shared graph.  $\square$

If we restrict attention to those rooted graphs in  $\mathcal{G}_{sa}$  which are strongly connected, we can obtain a neighbor-shared graph by composing a smaller number of rooted graphs than the one claimed in Proposition 8.

**PROPOSITION 9.** *Let  $q$  be the integer quotient of  $n$  divided by 2. The composition of any set of  $m \geq q$  strongly connected graphs in  $\mathcal{G}_{sa}$  is neighbor-shared.*

*Proof of Proposition 9.* Let  $k < n$  be a positive integer and let  $v$  be any vertex in  $\mathcal{V}$ . Let  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}$  be a sequence of strongly connected graphs in  $\mathcal{G}_{sa}$ . Since each vertex of a strongly connected graph must be a root,  $v$  must be a root of each  $\mathbb{G}_{p_i}$ . Note that the  $\mathbb{G}_{p_i}$  yield the ascending chain

$$\{v\} \subset \beta(\mathbb{G}_{p_k}, \{v\}) \subset \beta(\mathbb{G}_{p_k} \circ \mathbb{G}_{p_{k-1}}, \{v\}) \subset \dots \subset \beta(\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{v\})$$

because  $\mathcal{A}(\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_{k-(i-1)}}) \subset \mathcal{A}(\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_{k-i}})$  for  $i \in \{1, 2, \dots, k-1\}$ . Moreover, since  $k < n$  and  $v$  is a root of each  $\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_{k-(i-1)}}$ ,  $i \in \{1, 2, \dots, k\}$ , it must be true for each such  $i$  that  $\beta(\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_{k-(i-1)}}, v)$  contains at least  $i+1$  vertices. In particular  $\beta(\mathbb{G}_{p_k} \circ \dots \circ \mathbb{G}_{p_1}, v)$  contains at least  $k+1$  vertices.

Set  $k = q$  and let  $v_1$  and  $v_2$  be any pair of distinct vertices in  $\mathcal{V}$ . Then there must be at least  $q+1$  vertices in  $\beta(\mathbb{G}_{p_q} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{v_1\})$  and  $q+1$  vertices in  $\beta(\mathbb{G}_{p_q} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{v_2\})$ . But  $2(q+1) > n$  because of the definition of  $q$ , and so  $\beta(\mathbb{G}_{p_q} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{v_1\})$  and  $\beta(\mathbb{G}_{p_q} \circ \dots \circ \mathbb{G}_{p_2} \circ \mathbb{G}_{p_1}, \{v_2\})$  must have at least one vertex in common. Since this is true for each pair of distinct vertices  $v_1, v_2 \in \mathcal{V}$ ,  $\mathbb{G}_{p_q} \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  must be neighbor-shared.  $\square$

Lemma 7 and Proposition 3 imply that any composition of  $(n-1)^2$  neighbor-shared graphs in  $\mathcal{G}_{sa}$  is strongly rooted. The following proposition asserts that the composition need only consist of  $(n-1)$  neighbor-shared graphs and, moreover, that the graphs need only be in  $\mathcal{G}$  and not necessarily in  $\mathcal{G}_{sa}$ .

**PROPOSITION 10.** *The composition of any set of  $m \geq n-1$  neighbor-shared graphs in  $\mathcal{G}$  is strongly rooted.*

Note that Propositions 8 and 10 imply the first assertion of Proposition 3.

To prove Proposition 10 we need a few more ideas. For any integer  $1 < k \leq n$ , we say that a graph  $\mathbb{G} \in \mathcal{G}$  is  $k$  neighbor-shared if each set of  $k$  distinct vertices shares

a common neighbor. Thus a neighbor-shared graph and a 2 neighbor-shared graph are one and the same. Clearly an  $n$  neighbor-shared graph is strongly rooted at the common neighbor of all  $n$  vertices.

LEMMA 11. *If  $\mathbb{G}_p \in \mathcal{G}$  is a neighbor-shared graph and  $\mathbb{G}_q \in \mathcal{G}$  is a  $k$  neighbor-shared graph with  $k < n$ , then  $\mathbb{G}_q \circ \mathbb{G}_p$  is a  $(k + 1)$  neighbor-shared graph.*

*Proof.* Let  $v_1, v_2, \dots, v_{k+1}$  be any distinct vertices in  $\mathcal{V}$ . Since  $\mathbb{G}_q$  is a  $k$  neighbor-shared graph, the vertices  $v_1, v_2, \dots, v_k$  share a common neighbor  $u_1$  in  $\mathbb{G}_q$  and the vertices  $v_2, v_3, \dots, v_{k+1}$  share a common neighbor  $u_2$  in  $\mathbb{G}_q$  as well. Moreover, since  $\mathbb{G}_p$  is a neighbor-shared graph,  $u_1$  and  $u_2$  share a common neighbor  $w$  in  $\mathbb{G}_p$ . It follows from the definition of composition that  $v_1, v_2, \dots, v_k$  have  $w$  as a neighbor in  $\mathbb{G}_q \circ \mathbb{G}_p$  as do  $v_2, v_3, \dots, v_{k+1}$ . Therefore  $v_1, v_2, \dots, v_{k+1}$  have  $w$  as a neighbor in  $\mathbb{G}_q \circ \mathbb{G}_p$ . Since this must be true for any set of  $k + 1$  vertices in  $\mathbb{G}_q \circ \mathbb{G}_p$ ,  $\mathbb{G}_q \circ \mathbb{G}_p$  must be a  $(k + 1)$  neighbor-shared graph as claimed.  $\square$

*Proof of Proposition 10.* The preceding lemma implies that the composition of any 2 neighbor-shared graphs is 3 neighbor-shared. From this and induction it follows that for  $m < n$ , the composition of  $m$  neighbor-shared graphs is  $(m + 1)$  neighbor-shared. Thus the composition of  $(n - 1)$  neighbor-shared graphs is  $n$  neighbor-shared and consequently strongly rooted.  $\square$

**2.6. Convergence.** We are now in a position to significantly relax the conditions under which the conclusion of Theorem 1 holds. Towards this end, recall that each flocking matrix  $F$  is row stochastic. Moreover, because each vertex of each  $F$ 's graph  $\gamma(F)$  has a self-arc, the  $F$  have the additional property that their diagonal elements are all nonzero. Let  $\mathcal{S}$  denote the set of all  $n \times n$  row stochastic matrices whose diagonal elements are all positive.  $\mathcal{S}$  is closed under multiplication because the class of all  $n \times n$  stochastic matrices is closed under multiplication and because the class of  $n \times n$  nonnegative matrices with positive diagonals is also.

THEOREM 2. *Let  $\theta(0)$  be fixed. For any trajectory of the system (3) along which each graph in the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is rooted, there is a constant steady state heading  $\theta_{ss}$  for which*

$$(33) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

The theorem says that a unique heading is achieved asymptotically along any trajectory on which all neighbor graphs are rooted. It is possible to deduce an explicit convergence rate for the situation addressed by this theorem [8, 7]. The theorem's proof relies on the following generalization of Proposition 2. The proposition exploits the fact that any composition of sufficiently many rooted graphs in  $\mathcal{G}_{sa}$  is strongly rooted (cf. Proposition 3).

PROPOSITION 11. *Let  $\mathcal{S}_r$  be any closed set of  $n \times n$  stochastic matrices with rooted graphs in  $\mathcal{G}_{sa}$ . There exists an integer  $m$  such that the graph of the product of every set of  $m$  matrices from  $\mathcal{S}_r$  is strongly rooted. Let  $m$  be any such integer and write  $\mathcal{S}_r^m$  for the set of all such matrix products. Then as  $j \rightarrow \infty$ , any product  $S_j \cdots S_1$  of matrices from  $\mathcal{S}_r$  converges exponentially fast to  $\mathbf{1}[\cdots S_j \cdots S_1]$  at a rate no slower than*

$$\lambda = \left( \max_{S \in \mathcal{S}_r^m} |||S||| \right)^{\frac{1}{m}},$$

where  $\lambda < 1$ .

*Proof of Proposition 11.* By assumption, each graph  $\gamma(S)$ ,  $S \in \mathcal{S}_r$ , is in  $\mathcal{G}_{sa}$  and is rooted. In view of Proposition 3,  $\gamma(S_q) \circ \cdots \circ \gamma(S_1)$  is strongly rooted for every list of  $q$  matrices  $\{S_1, S_2, \dots, S_q\}$  from  $\mathcal{S}_r$ , provided  $q \geq (n-1)^2$ . But  $\gamma(S_q) \circ \cdots \circ \gamma(S_1) = \gamma(S_q \cdots S_1)$  because of Lemma 3. Therefore  $\gamma(S_q \cdots S_1)$  is strongly rooted for all products  $S_q \cdots S_1$ , where each  $S_i \in \mathcal{S}_r$ . Thus  $m$  could be taken as  $q$ , which establishes the existence of such an integer.

Now any product  $S_j \cdots S_1$  of matrices in  $\mathcal{S}_r$  can be written as  $S_j \cdots S_1 = \bar{S}(j) \bar{S}_k \cdots \bar{S}_1$ , where  $\bar{S}_i = S_{im} \cdots S_{(i-1)m+1}$ ,  $1 \leq i \leq k$ , is a product in  $\mathcal{S}_r^m$ ,  $\bar{S}(j) = S_j \cdots S_{(km+1)}$ , and  $k$  is the integer quotient of  $j$  divided by  $m$ . In view of Proposition 2,  $\bar{S}_k \cdots \bar{S}_1$  must converge to  $\mathbf{1}[\cdots \bar{S}_k \cdots \bar{S}_1]$  exponentially fast as  $k \rightarrow \infty$  at a rate no slower than  $\bar{\lambda}$ , where

$$\bar{\lambda} = \max_{\bar{S} \in \mathcal{S}_r^m} \|\bar{S}\|.$$

But  $\bar{S}(j)$  is a product of at most  $m$  stochastic matrices, and so it is a bounded function of  $j$ . It follows that the product  $S_j S_{j-1} \cdots S_1$  must converge to  $\mathbf{1}[\cdots S_j \cdots S_1]$  exponentially fast at a rate no slower than  $\lambda = \bar{\lambda}^{\frac{1}{m}}$ .  $\square$

The proof of Proposition 11 can also be applied to any closed subset  $\mathcal{S}_{ns} \subset \mathcal{S}$  of stochastic matrices with neighbor-shared graphs. In this case, one would define  $m = n-1$  because of Proposition 10. Similarly, the proof also applies to any closed subset of stochastic matrices whose graphs share a common root; in this case one would define  $m = n-1$  because of the first assertion of Proposition 3.

*Proof of Theorem 2.* Let  $\mathcal{F}_r$  denote the set of flocking matrices with rooted graphs. Since  $\mathcal{G}_{sa}$  is a finite set, so is the set of rooted graphs in  $\mathcal{G}_{sa}$ . Therefore  $\mathcal{F}_r$  is closed. By assumption,  $F(t) \in \mathcal{F}_r$ ,  $t \geq 0$ . In view of Proposition 11, the product  $F(t) \cdots F(0)$  converges exponentially fast to  $\mathbf{1}[\cdots F(t) \cdots F(0)]$  at a rate no slower than

$$\lambda = \left( \max_{S \in \mathcal{F}_r^m} \|S\| \right)^{\frac{1}{m}},$$

where  $m = (n-1)^2$  and  $\mathcal{F}_r^m$  is the finite set of all  $m$ -term flocking matrix products of the form  $F_m \cdots F_1$  with each  $F_i \in \mathcal{F}_r$ . But it is clear from (3) that  $\theta(t) = F(t-1) \cdots F(1)F(0)\theta(0)$ ,  $t \geq 1$ . Therefore (33) holds with  $\theta_{ss} = \mathbf{1}[\cdots F(t) \cdots F(0)]\theta(0)$  and the convergence is exponential.  $\square$

The proof of Theorem 2 also applies to the case when all of the  $N(t)$ ,  $t \geq 0$ , are neighbor-shared. In this case, one would define  $m = n-1$  because of Proposition 10. By similar reasoning, the proof also applies to the case when all of the  $N(t)$ ,  $t \geq 0$ , shared a common root; one would also define  $m = n-1$  for this case because of the first assertion of Proposition 3.

**2.7. Jointly rooted sets of graphs.** It is possible to relax further still the conditions under which the conclusion of Theorem 1 holds. Towards this end, let us agree to say that a finite sequence of directed graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}$  in  $\mathcal{G}$  is *jointly rooted* if the composition  $\mathbb{G}_{p_k} \circ \mathbb{G}_{p_{k-1}} \circ \cdots \circ \mathbb{G}_{p_1}$  is rooted.

Note that since the arc sets of any graphs  $\mathbb{G}_p, \mathbb{G}_q \in \mathcal{G}_{sa}$  are contained in the arc set of any composed graph  $\mathbb{G}_q \circ \mathbb{G}_p$ ,  $\mathbb{G} \in \mathcal{G}_{sa}$ , it must be true that if  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}$  is a jointly rooted sequence in  $\mathcal{G}_{sa}$ , then so is  $\mathbb{G}_q, \mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}, \mathbb{G}_p$ . In other words, a jointly rooted sequence of graphs in  $\mathcal{G}_{sa}$  remain jointly rooted if additional graphs from  $\mathcal{G}_{sa}$  are added to either end of the sequence.

There is an analogous concept for neighbor-shared graphs. We say that a finite sequence of directed graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}$  from  $\mathcal{G}$  is *jointly neighbor-shared* if the

composition  $\mathbb{G}_{p_k} \circ \mathbb{G}_{p_{k-1}} \circ \cdots \circ \mathbb{G}_{p_1}$  is a neighbor-shared graph. Jointly neighbor-shared sequences of graphs from  $\mathcal{G}_{sa}$  remain jointly neighbor-shared if additional graphs from  $\mathcal{G}_{sa}$  are added to either end of the sequence. The reason for this is the same as for the case of jointly rooted sequences. Although the discussion which follows is just for the case of jointly rooted graphs, the material covered extends in the obvious way to the case of jointly neighbor-shared graphs.

In what follows we will say that an infinite sequence of graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots$  in  $\mathcal{G}$  is *repeatedly jointly rooted* if there is a positive integer  $q$  for which each finite sequence  $\mathbb{G}_{p_{q(k-1)+1}}, \dots, \mathbb{G}_{p_{qk}}, k \geq 1$ , is jointly rooted. If such an integer exists, we sometimes say that  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots$  is repeatedly jointly rooted *by subsequences of length  $q$* . We are now in a position to generalize Proposition 11.

**PROPOSITION 12.** *Let  $\bar{S}$  be any closed set of stochastic matrices with graphs in  $\mathcal{G}_{sa}$ . Suppose that  $S_1, S_2, \dots$  is an infinite sequence of matrices from  $\bar{S}$  whose corresponding sequence of graphs  $\gamma(S_1), \gamma(S_2), \dots$  is repeatedly jointly rooted by subsequences of length  $q$ . Suppose that the set of all products of  $q$  matrices from  $\bar{S}$  with rooted graphs, written  $\bar{S}(q)$ , is closed. There exists an integer  $m$  such that the product of every set of  $m$  matrices from  $\bar{S}(q)$  is strongly rooted. Let  $m$  be any such integer and write  $(\bar{S}(q))^m$  for the set of all such matrix products. Then as  $j \rightarrow \infty$ , the product  $S_j \cdots S_1$  converges exponentially fast to  $\mathbf{1}[\cdots S_j \cdots S_1]$  at a rate no slower than*

$$\lambda = \left( \max_{S \in (\bar{S}(q))^m} |||S||| \right)^{\frac{1}{mq}},$$

where  $\lambda < 1$ .

It is worth pointing out that the assumption that  $\bar{S}(q)$  is closed is not necessarily implied by the assumption that  $\bar{S}$  is closed. For example, if  $\bar{S}$  is the set of all  $2 \times 2$  stochastic matrices whose diagonal elements are no smaller than some positive number  $\alpha < 1$ , then  $\bar{S}(2)$  cannot be closed even though  $\bar{S}$  is; this is because there are matrices in  $\bar{S}(2)$  which are arbitrarily close (in the induced infinity norm) to the  $2 \times 2$  identity which, in turn, is not in  $\bar{S}(2)$ . There are at least three different situations where  $\bar{S}(q)$  turns out to be closed. The first is when  $\bar{S}$  is a finite set, as is the case when  $\bar{S}$  is all  $n \times n$  flocking matrices; in this case it is obvious that for any  $q \geq 1$ ,  $\bar{S}(q)$  is closed because it is also a finite set.

The second situation arises when the simple average rule (1) is replaced by a convex combination rule as was done in [3]. In this case, the set  $\bar{S}$  turns out to be all  $n \times n$  stochastic matrices whose diagonal entries are nonzero and whose nonzero entries (on the diagonal or not) are all underbounded by a positive number  $\alpha < 1$ . In this case it is easy to see that for each graph  $\mathbb{G} \in \mathcal{G}_{sa}$ , the subset  $\bar{S}(\mathbb{G})$  of  $S \in \bar{S}$  for which  $\gamma(S) = \mathbb{G}$  is closed. Thus for any pair of graphs  $\mathbb{G}_1, \mathbb{G}_2 \in \mathcal{G}_{sa}$ , the subset of products  $S_2 S_1$  such that  $S_1 \in \bar{S}(\mathbb{G}_1)$  and  $S_2 \in \bar{S}(\mathbb{G}_2)$  is also closed. Since  $\bar{S}(2)$  is the union of a finite number of sets of products of this type, namely those for which the pairs  $(\mathbb{G}_1, \mathbb{G}_2)$  have rooted compositions  $\mathbb{G}_2 \circ \mathbb{G}_1$ , it must be that  $\bar{S}(2)$  is closed. Continuing this reasoning, one can conclude that for any integer  $q > 0$ ,  $\bar{S}(q)$  is closed as well.

The third situation in which  $\bar{S}(q)$  turns out to be compact is considerably more complicated and arises in connection with an asynchronous version of the flocking problem we have been studying. In this case, the graphs of the matrices in  $\bar{S}$  do not have self-arcs at all vertices. We refer the reader to [6] for details.

*Proof of Proposition 12.* Since  $\gamma(S_1), \gamma(S_2), \dots$  is repeatedly jointly rooted by subsequences of length  $q$ , for each  $k \geq 1$ , the subsequence  $\gamma(S_{q(k-1)+1}), \dots, \gamma(S_{qk})$

is jointly rooted. For  $k \geq 1$  define  $\bar{S}_k = S_{qk} \cdots S_{q(k-1)+1}$ . By Lemma 3,  $\gamma(S_{qk} \cdots S_{q(k-1)+1}) = \gamma(S_{qk}) \circ \cdots \circ \gamma(S_{q(k-1)+1})$ ,  $k \geq 1$ . Therefore  $\gamma(\bar{S}_k)$  is rooted for  $k \geq 1$ . Thus each such  $\bar{S}_k$  is in the closed set  $\bar{\mathcal{S}}(q)$ .

By Proposition 11, there exists an integer  $m$  such that the graph of the product of every set of  $m$  matrices from  $\bar{\mathcal{S}}(q)$  is strongly rooted. Moreover, since each  $\bar{S}_k \in \bar{\mathcal{S}}(q)$ , Proposition 11 also implies that  $k \rightarrow \infty$ , and the product  $\bar{S}_k \cdots \bar{S}_1$  converges exponentially fast to  $\mathbf{1}[\cdots \bar{S}_k \cdots \bar{S}_1]$  at a rate no slower than

$$\bar{\lambda} = \left( \max_{S \in (\bar{\mathcal{S}}(q))^m} |||S||| \right)^{\frac{1}{m}},$$

where  $\bar{\lambda} < 1$ .

Now the product  $S_j \cdots S_1$  can be written as

$$S_j \cdots S_1 = \hat{S}(j) \bar{S}_k \cdots \bar{S}_1,$$

where  $k$  is the integer quotient of  $j$  divided by  $mq$  and  $\hat{S}(j)$  is the identity if  $mq$  is a factor of  $j$  or  $\hat{S}(j) = S_j \cdots S_{(kmq+1)}$  if it is not. But  $\hat{S}(j)$  is a product of at most  $mq$  stochastic matrices, and so it is a bounded function of  $j$ . It follows that the product  $S_j S_{j-1} \cdots S_1$  must converge to  $\mathbf{1}[\cdots S_j \cdots S_1]$  exponentially fast at a rate no slower than  $\lambda = \bar{\lambda}^{\frac{1}{mq}}$ .  $\square$

We are now in a position to apply Proposition 12 to leaderless coordination.

**THEOREM 3.** *Let  $\theta(0)$  be fixed. For any trajectory of the system (3) along which each graph in the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted, there is a constant steady state heading  $\theta_{ss}$  for which*

$$(34) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

*Proof of Theorem 3.* By hypothesis, the sequence of graphs  $\gamma(F(0)), \gamma(F(1)), \dots$  is repeatedly jointly rooted. Thus there is an integer  $q$  for which the sequence is repeatedly jointly rooted by subsequences of length  $q$ . Since the set of  $n \times n$  flocking matrices  $\mathcal{F}$  is finite, so is the set of all products of  $q$  flocking matrices with rooted graphs, namely  $\mathcal{F}(q)$ . Therefore  $\mathcal{F}(q)$  is closed. Moreover, if  $m = (n-1)^2$ , every product of  $m$  matrices from  $\mathcal{F}(q)$  is strongly rooted. It follows from Proposition 12 that the product  $F(t) \cdots F(1)F(0)$  converges to  $\mathbf{1}[\cdots F(t) \cdots F(1)F(0)]$  exponentially fast as  $t \rightarrow \infty$  at a rate no slower than

$$\lambda = \left( \max_{S \in (\mathcal{F}(q))^m} |||S||| \right)^{\frac{1}{mq}},$$

where  $m = (n-1)^2$ ,  $\lambda < 1$ , and  $(\mathcal{F}(q))^m$  is the closed set of all products of  $m$  matrices from  $\mathcal{F}(q)$ . But it is clear from (3) that

$$\theta(t) = F(t-1) \cdots F(1)F(0)\theta(0), \quad t \geq 1.$$

Therefore (34) holds with  $\theta_{ss} = [\cdots F_{\sigma(t)} \cdots F_{\sigma(0)}]\theta(0)$  and the convergence is exponential.  $\square$

It is possible to compare Theorem 3 with similar results derived in [19, 22]. To do this it is necessary to introduce a few concepts. By the *union*  $\mathbb{G}_1 \cup \mathbb{G}_2$  of two directed

graphs  $\mathbb{G}_1$  and  $\mathbb{G}_2$  with the same vertex set  $\mathcal{V}$  we mean the graph whose vertex set is  $\mathcal{V}$  and whose arc set is the union of the arc sets of  $\mathbb{G}_1$  and  $\mathbb{G}_2$ . The definition extends in the obvious way to finite sets of directed graphs with the same vertex set. Let us agree to say that a finite set of graphs  $\{\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_k}\}$  with the same vertex set is *collectively rooted* if the *union* of the graphs in the set is a rooted graph. In parallel with the notion of repeatedly jointly rooted, we say that an infinite sequence of graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots$  in  $\mathcal{G}_{sa}$  is *repeatedly collectively rooted* if there is a positive integer  $q$  for which each finite set  $\mathbb{G}_{p_{q(k-1)+1}}, \dots, \mathbb{G}_{p_{qk}}$ ,  $k \geq 1$  is collectively rooted. One of the main contributions of [19] is to prove that the conclusions of Theorem 3 hold if the theorem's hypothesis is replaced by the hypothesis that the sequence of graphs  $\mathbb{G}_{\sigma(0)}, \mathbb{G}_{\sigma(1)}, \dots$  is repeatedly collectively rooted. The two hypotheses prove to be equivalent. The reason this is so can be explained as follows.

Note first that because all graphs in  $\mathcal{G}_{sa}$  have self-arcs, each arc  $(i, j)$  in the union  $\mathbb{G}_2 \cup \mathbb{G}_1$  of two graphs  $\mathbb{G}_1, \mathbb{G}_2$  in  $\mathcal{G}_{sa}$  is an arc in the composition  $\mathbb{G}_2 \circ \mathbb{G}_1$ . While the converse is not true, the definition of composition does imply that for each arc  $(i, j)$  in the composition  $\mathbb{G}_2 \circ \mathbb{G}_1$  there is a *path* in the union  $\mathbb{G}_2 \cup \mathbb{G}_1$  of length at most two between  $i$  and  $j$ . More generally, simple induction proves that if  $(i, j)$  is an arc in the composition of  $q$  graphs from  $\mathcal{G}_{sa}$ , then the union of the same  $q$  graphs must contain a path of length at most  $q$  from  $i$  to  $j$ . These observations clearly imply that a sequence of  $q$  graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_q}$  in  $\mathcal{G}_{sa}$  is jointly rooted if and only if the set of graphs  $\{\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots, \mathbb{G}_{p_q}\}$  is collectively rooted. It follows that a sequence of graphs in  $\mathcal{G}_{sa}$  is repeatedly jointly rooted if and only if the set of graphs in the sequence is collectively jointly rooted.

Although Theorem 3 and the main result of [19] are equivalent, the difference between results based on unions and results based on compositions begins to emerge, when one looks deeper into the convergence question, especially when issues of convergence rate are taken into consideration. For example, if  $\pi_u(m, n)$  were the number of  $m$  term sequences of graphs in  $\mathcal{G}_{sa}$  whose unions are strongly rooted, and  $\pi_c(m, n)$  were the number of  $m$ -term sequences of graphs in  $\mathcal{G}_{sa}$  whose compositions are strongly rooted, then it is easy to see that the ratio  $\rho(m, n) = \pi_c(m, n)/\pi_u(m, n)$  would always be greater than 1. In fact,  $\rho(2, 3) = 1.04$  and  $\rho(2, 4) = 1.96$ . Moreover, probabilistic experiments suggest that this ratio can be as large as 18,181 for  $m = 2$  and  $n = 50$ . One would expect  $\rho(m, n)$  to increase not only with increasing  $n$  but also with increasing  $m$ . One would also expect similar comparisons for neighbor-shared graphs rather than strongly rooted graphs. Interestingly, preliminary experimental results suggest that this is not the case, but more work needs to be done to understand why this is so. Like strongly rooted graphs, neighbor-shared graphs also play a key role in determining convergence rates [7].

**3. Symmetric neighbor relations.** It is natural to call a graph in  $\mathcal{G}$  *symmetric* if for each pair of vertices  $i$  and  $j$  for which  $j$  is a neighbor of  $i$ ,  $i$  is also a neighbor of  $j$ . Note that  $\mathbb{G}$  is symmetric if and only if its adjacency matrix is symmetric. It is worth noting that for symmetric graphs, the properties of rooted and rooted at  $v$  are both equivalent to the property that the graph is strongly connected. Within the class of symmetric graphs, neighbor-shared graphs and strongly rooted graphs are also strongly connected graphs, but in neither case is the converse true. It is possible to represent a symmetric directed graph  $\mathbb{G}$  with an undirected graph  $\mathbb{G}^s$  in which each self-arc is replaced with an undirected edge and each pair of directed arcs  $(i, j)$  and  $(j, i)$  for distinct vertices is replaced with an undirected edge between  $i$  and  $j$ . Notions of strongly rooted and neighbor-shared extend in the obvious way

to undirected graphs. An undirected graph is said to be *connected* if there is an undirected path between each pair of vertices. Thus a strongly connected, directed graph which is symmetric is in essence the same as a connected, undirected graph. Undirected graphs are applicable when the sensing radii  $r_i$  of all agents are the same. It was the symmetric version of the flocking problem which Vicsek addressed in [29] and which was analyzed in [17] using undirected graphs.

Let  $\mathcal{G}^s$  and  $\mathcal{G}_{sa}^s$  denote the subsets of symmetric graphs in  $\mathcal{G}$  and  $\mathcal{G}_{sa}$ , respectively. Simple examples show that neither  $\mathcal{G}^s$  nor  $\mathcal{G}_{sa}^s$  is closed under composition. In particular, composition of two symmetric directed graphs in  $\mathcal{G}$  or  $\mathcal{G}_{sa}$  is not typically symmetric. On the other hand, the union is. It is clear that both  $\mathcal{G}^s$  and  $\mathcal{G}_{sa}^s$  are closed under the union operation. It is worth emphasizing that union and composition are really quite different operations. For example, as we have already seen with Proposition 4, the composition of any  $n - 1$  strongly connected graphs, symmetric or not, is always complete. On the other hand, the union of  $n - 1$  strongly connected graphs is not necessarily complete. In terms of undirected graphs, it is simply not true that the union of  $n - 1$  undirected graphs with vertex set  $\mathcal{V}$  is complete, even if each graph in the union has self-loops at each vertex. As noted before, the root cause of the difference between union and composition stems from the fact that the union and composition of two graphs in  $\mathcal{G}$  have different arc sets—and in the case of graphs from  $\mathcal{G}_{sa}$ , the arc set of the union is always contained in the arc set of the composition but not conversely.

In [17] use is made of the notion of a “jointly connected set of graphs.” Specifically, a set of undirected graphs with vertex set  $\mathcal{V}$  is *jointly connected* if the union of the graphs in the collection is a connected graph. The notion of jointly connected also applies to directed graphs in which case the collection is jointly connected if the union is strongly connected. In what follows we will say that an infinite sequence of graphs  $\mathbb{G}_{p_1}, \mathbb{G}_{p_2}, \dots$  in  $\mathcal{G}_{sa}$  is *repeatedly jointly connected* if there is a positive integer  $m$  for which each finite sequence  $\mathbb{G}_{p_{m(k-1)+1}}, \dots, \mathbb{G}_{p_{mk}}, k \geq 1$ , is jointly connected. The main result of [17] is, in essence, a corollary to Theorem 3.

**COROLLARY 1.** *Let  $\theta(0)$  be fixed. For any trajectory of the system (3) along which each graph in the sequence of symmetric neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly connected, there is a constant steady state heading  $\theta_{ss}$  for which*

$$(35) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

**4. Concluding remarks.** The main goal of this paper has been to establish a number of basic properties of compositions of directed graphs which are useful in explaining how a consensus is achieved under various conditions in a dynamically changing environment. The paper brings together in one place a number of results scattered throughout the literature and at the same time presents new results concerned with compositions of graphs as well as graphical interpretations of several specially structured stochastic matrices appropriate to nonhomogeneous Markov chains.

In a sequel to this paper [7], we consider a modified version of the Vicsek consensus problem in which integer-valued delays occur in sensing the values of headings which are available to agents. In keeping with our thesis that such problems can be conveniently formulated and solved using graphs and graph operations, we analyze the sensing delay problem from mainly a graph-theoretic point of view using the tools developed in this paper. In [7] we also consider another modified version of the Vicsek

problem in which each agent independently updates its heading at times determined by its own clock. We do not assume that the groups' clocks are synchronized together or that the times any one agent updates its heading are evenly spaced. Using graph-theoretic concepts from this paper we show in [7] that for both versions of the problem considered, the conditions under which a consensus is achieved are essentially the same as in the synchronized, delay-free case addressed here.

A number of questions are suggested by this work. For example, it would be interesting to have a complete characterization of those rooted graphs which are of Sarymaskov type. It would also be of interest to have convergence results for more general versions of the asynchronous consensus problem in which heading transitions occur continuously. Extensions of these results to more realistic settings such as the one considered in [26] would also be useful.

## REACHING A CONSENSUS IN A DYNAMICALLY CHANGING ENVIRONMENT: CONVERGENCE RATES, MEASUREMENT DELAYS, AND ASYNCHRONOUS EVENTS\*

MING CAO<sup>†</sup>, A. STEPHEN MORSE<sup>‡</sup>, AND BRIAN D. O. ANDERSON<sup>‡</sup>

**Abstract.** This paper uses recently established properties of compositions of directed graphs together with results from the theory of nonhomogeneous Markov chains to derive worst case convergence rates for the headings of a group of mobile autonomous agents which arise in connection with the widely studied Vicsek consensus problem. The paper also uses graph-theoretic constructions to solve modified versions of the Vicsek problem in which there are measurement delays, asynchronous events, or a group leader. In all three cases the conditions under which consensus is achieved prove to be almost the same as the conditions under which consensus is achieved in the synchronous, delay-free, leaderless case.

**Key words.** cooperative control, graph theory, switched systems, convergence rates, delays, asynchronism

**1. Introduction.** In a recent paper [6] the present authors defined the notion of “graph composition” and established a number of basic properties of compositions of directed graphs which are useful in explaining how a consensus might be reached by a group of mobile autonomous agents in a dynamically changing environment. The aim of this paper is to use the graph-theoretic findings of [6] to address several issues related to the well-known Vicsek consensus problem [20] which have either not been considered before or have been only partially resolved.

The paper begins with a brief review in section 2 of the basic leaderless consensus problem treated in [6, 14, 16]. Section 3 exploits the connection between “neighbor-shared” graphs and the elegant theory of “scrambling matrices” found in the literature on nonhomogeneous Markov chains [17, 9] to help in the derivation of worst case agent heading convergence rates for the leaderless version of the Vicsek problem. Section 4 addresses a modified version of the consensus problem in which integer-valued delays occur in the values of the headings which agents measure. In keeping with the overall theme of this paper, the effect of measurement delays is analyzed from a mainly graph-theoretic point of view. This enables us to significantly relax previously derived conditions [18, 19, 3] under which consensus can be achieved in the face of measurement delays. A comparison is made between the results of [3] and

the main result of this paper on measurement delays, namely Theorem 2. To model dynamics when delays are present requires a somewhat different type of stochastic “flocking matrix” than the one which is appropriate in the delay-free case. The graphs of the type of matrices to which we are referring are directed, just as in the delay-free case, but do not have self-arcs at every vertex. As a result, the set of such graphs, denoted by  $\mathcal{D}$ , is not closed under composition. The smallest set of directed graphs which contains  $\mathcal{D}$  and which is closed under composition is called the set of “extended delay graphs.” This class is explicitly characterized. Section 4 then develops the requisite properties of extended delay graphs needed to prove Theorem 2.

Section 5 considers a modified version of the flocking problem in which each agent independently updates its heading at times determined by its own clock. It is not assumed that the groups’ clocks are synchronized together or that the times any one agent updates its heading are evenly spaced. In this case, the deriving of conditions under which all agents eventually move with the same heading requires the analysis of the asymptotic behavior of an overall *asynchronous* process which models the  $n$ -agent system. The analysis is carried out by first embedding this process in a suitably defined *synchronous* discrete-time, hybrid dynamical system  $\mathbb{S}$ . This is accomplished using the concept of *analytic synchronization* outlined previously in [12, 13]. This enables us to bring to bear results derived earlier in [6] to characterize a rich class of system trajectories under which consensus is achieved.

In section 6 we briefly consider a modified version of the consensus problem for the same group of  $n$  agents as before but now with one of the group’s members (say agent 1) acting as the group’s *leader*. The remaining agents, called *followers* and labelled 2 through  $n$ , do not know who the leader is or even if there is a leader. Accordingly they continue to function as if there was no leader using the same update rules as are used in the leaderless case. The leader, on the other hand, acting on its own, ignores these update rules and moves with a constant heading. Using the main result on leaderless consensus summarized in section 2, we then develop conditions under which all follower agents eventually move in the same direction as the leader. These conditions correct prior findings on leader following in [11] which are in error.

**2. Background.** As in [6], the system of interest consists of  $n$  autonomous agents, labelled 1 through  $n$ , all moving in the plane with the same speed but with different headings. Each agent’s heading is updated using a simple local rule based on the average of its own heading plus the headings of its “neighbors.” Agent  $i$ ’s *neighbors* at time  $t$  are those agents, including itself, which are in a closed disk of prespecified radius  $r_i$  centered at agent  $i$ ’s current position. In what follows  $\mathcal{N}_i(t)$  denotes the set of labels of those agents which are neighbors of agent  $i$  at time  $t$ . Agent  $i$ ’s heading, written  $\theta_i$ , evolves in discrete time in accordance with a model of the form

$$(1) \quad \theta_i(t+1) = \frac{1}{n_i(t)} \left( \sum_{j \in \mathcal{N}_i(t)} \theta_j(t) \right),$$

where  $t$  is a discrete-time index taking values in the nonnegative integers  $\{0, 1, 2, \dots\}$ , and  $n_i(t)$  is the number of neighbors of agent  $i$  at time  $t$ .

**2.1. Neighbor graph.** The explicit form of the update equations determined by (1) depends on the relationships between neighbors which exist at time  $t$ . These relationships can be conveniently described by a directed graph  $\mathbb{N}(t)$  with vertex set

$\mathcal{V} = \{1, 2, \dots, n\}$  and arc set  $\mathcal{A}(\mathbb{N}(t)) \subset \mathcal{V} \times \mathcal{V}$  which is defined so that  $(i, j)$  is an arc or directed edge from  $i$  to  $j$  just in case agent  $i$  is a neighbor of agent  $j$  at time  $t$ . Thus  $\mathbb{N}(t)$  is a directed graph on  $n$  vertices with at most one arc connecting each ordered pair of distinct vertices and with exactly one self-arc at each vertex. We write  $\mathcal{G}_{sa}$  for the set of all such graphs and  $\mathcal{G}$  for the set of all directed graphs with vertex set  $\mathcal{V}$ . It is natural to call a vertex  $i$  a *neighbor* of vertex  $j$  in a graph  $\mathbb{G} \in \mathcal{G}$  if  $(i, j)$  is an arc in  $\mathbb{G}$ .

**2.2. Heading update rule.** The set of agent heading update rules defined by (1) can be written in state form. Towards this end, for each graph  $\mathbb{N} \in \mathcal{G}_{sa}$  define the *flocking matrix*

$$(2) \quad F = D^{-1}A',$$

where  $A'$  is the transpose of the adjacency matrix of  $\mathbb{N}$  and  $D$  the diagonal matrix whose  $j$ th diagonal element is the in-degree of vertex  $j$  within  $\mathbb{N}$ . Then

$$(3) \quad \theta(t+1) = F(t)\theta(t), \quad t \in \{0, 1, 2, \dots\},$$

where  $\theta$  is the heading vector  $\theta = [\theta_1 \ \theta_2 \ \dots \ \theta_n]'$  and  $F(t)$  is the flocking matrix of the *neighbor graph*  $\mathbb{N}(t)$ .

**2.3. Leaderless consensus.** To proceed, we need to recall a few definitions from [6]. We call a vertex  $i$  of a directed graph  $\mathbb{G}$  a *root* of  $\mathbb{G}$  if for each other vertex  $j$  of  $\mathbb{G}$ , there is a path from  $i$  to  $j$ . Thus  $i$  is a root of  $\mathbb{G}$  if it is the root of a directed spanning tree of  $\mathbb{G}$ . We say that  $\mathbb{G}$  is *rooted at  $i$*  if  $i$  is in fact a root. Thus  $\mathbb{G}$  is rooted at  $i$  just in case each other vertex of  $\mathbb{G}$  is *reachable* from vertex  $i$  along a path within the graph.  $\mathbb{G}$  is *strongly rooted at  $i$*  if each other vertex of  $\mathbb{G}$  is reachable from vertex  $i$  along a path of length 1. Thus  $\mathbb{G}$  is strongly rooted at  $i$  if  $i$  is a neighbor of every other vertex in the graph. A *rooted graph*  $\mathbb{G}$  is a graph which possesses at least one root. Finally, a *strongly rooted graph* is a graph which has at least one vertex at which it is strongly rooted.

By the *composition* of two directed graphs  $\mathbb{G}_p, \mathbb{G}_q$  with the same vertex set  $\mathcal{V}$  we mean the graph  $\mathbb{G}_q \circ \mathbb{G}_p$  with the same vertex set  $\mathcal{V}$  and arc set defined such that  $(i, j)$  is an arc of  $\mathbb{G}_q \circ \mathbb{G}_p$  if for some vertex  $k$ ,  $(i, k)$  is an arc of  $\mathbb{G}_p$  and  $(k, j)$  is an arc of  $\mathbb{G}_q$ . A finite sequence of directed graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_q$  with the same vertex set is *jointly rooted* if the composition  $\mathbb{G}_q \circ \mathbb{G}_{q-1} \circ \dots \circ \mathbb{G}_1$  is rooted. An infinite sequence of graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots$  with the same vertex set is *repeatedly jointly rooted by subsequences of length  $q$*  if there is a positive integer  $q$  for which each finite sequence  $\mathbb{G}_{qk+1}, \dots, \mathbb{G}_{q(k+1)}$ ,  $k \geq 0$ , is jointly rooted. The main result on leaderless consensus [14, 16] is equivalent to the following result from [6].

**THEOREM 1.** *Let  $\theta(0)$  be fixed. For any trajectory of the system determined by (1) along which the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted by sequences of length  $q$ , there is a constant  $\theta_{ss}$ , depending only on  $\theta(0)$ , for which*

$$(4) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

**3. Convergence rates.** The aim of this section is to derive a bound on the rate at which  $\theta$  converges.<sup>1</sup> There are two distinct ways to go about this, and below we

<sup>1</sup>This section summarizes and extends some of the key findings of [7].

describe both. To do this we will make use of certain structural properties of the  $F$ . As defined, each  $F$  is square and nonnegative, where by a *nonnegative* matrix we mean a matrix whose entries are all nonnegative. Each  $F$  also has the property that its row sums all equal 1 (i.e.,  $F\mathbf{1} = \mathbf{1}$ ). Matrices with these two properties are called (row) *stochastic* [10]. It is easy to verify that the class of all  $n \times n$  stochastic matrices is closed under multiplication. It is worth noting that because the vertices of the graphs in  $\mathcal{G}_{sa}$  all have self-arcs, the  $F$  also have the property that their diagonal elements are positive.

In what follows we write  $M \geq N$  whenever  $M - N$  is a nonnegative matrix. We also write  $M > N$  whenever  $M - N$  is a positive matrix, where by a *positive matrix* we mean a matrix with all positive entries. For any nonnegative matrix  $R$  of any size, we write  $\|R\|$  for the largest of the row sums of  $R$ . Note that  $\|R\|$  is the induced infinity norm of  $R$  and consequently is submultiplicative. Moreover,  $\|M_1\| \leq \|M_2\|$  if  $M_1 \leq M_2$ . Observe that for any  $n \times n$  stochastic matrix  $S$ ,  $\|S\| = 1$  because the row sums of a stochastic matrix all equal 1. As in [6] we write  $\lfloor M \rfloor$  and  $\lceil M \rceil$  for the  $1 \times m$  row vectors whose  $j$ th entries are the smallest and largest elements, respectively, of the  $j$ th column of  $M$ . Note that  $\lfloor M \rfloor$  is the largest  $1 \times m$  nonnegative row vector  $c$  for which  $M - \mathbf{1}c$  is nonnegative and that  $\lceil M \rceil$  is the smallest nonnegative row vector  $c$  for which  $\mathbf{1}c - M$  is nonnegative. Note in addition that for any  $n \times n$  stochastic matrix  $S$ , one can write

$$(5) \quad S = \mathbf{1}\lfloor S \rfloor + \lceil S \rceil \quad \text{and} \quad S = \mathbf{1}\lceil S \rceil - \lfloor S \rfloor,$$

where  $\lfloor S \rfloor$  and  $\lceil S \rceil$  are the nonnegative matrices defined by the equations

$$(6) \quad \lfloor S \rfloor = S - \mathbf{1}\lfloor S \rfloor \quad \text{and} \quad \lceil S \rceil = \mathbf{1}\lceil S \rceil - S,$$

respectively. Moreover, the row sums of  $\lfloor S \rfloor$  are all equal to  $1 - \lfloor S \rfloor \mathbf{1}$  and the row sums of  $\lceil S \rceil$  are all equal to  $\lceil S \rceil \mathbf{1} - 1$ , and so

$$(7) \quad \|\lfloor S \rfloor\| = 1 - \lfloor S \rfloor \mathbf{1} \quad \text{and} \quad \|\lceil S \rceil\| = \lceil S \rceil \mathbf{1} - 1.$$

In what follows we will also be interested in the matrix

$$(8) \quad \llbracket S \rrbracket = \lfloor S \rfloor + \lceil S \rceil.$$

This matrix satisfies

$$(9) \quad \llbracket S \rrbracket = \mathbf{1}(\lceil S \rceil - \lfloor S \rfloor)$$

because of (5).

To prove that all  $\theta_i$  converge to a common heading, it is necessary to prove that  $\theta$  converges to a vector of the form  $\theta_{ss}\mathbf{1}$ , where  $\mathbf{1}$  is the  $n \times 1$  vector of 1's. It is clear from (3) that  $\theta$  will converge to such a vector just in case, as  $t \rightarrow \infty$ , the matrix product  $F(t) \cdots F(0)$  converges to a rank one matrix of the form  $\mathbf{1}c$  for some  $n \times 1$  row vector  $c$ . Thus to study how such matrix products converge it is sufficient to study how products of stochastic matrices of the form  $S_j \cdots S_1$  converge as  $j \rightarrow \infty$ . As in [6], we say that a matrix product  $S_j S_{j-1} \cdots S_1$  *converges exponentially fast at a rate no slower than  $\lambda$*  to a matrix of the form  $\mathbf{1}c$  if there are nonnegative constants  $b$  and  $\lambda$  with  $\lambda < 1$ , such that

$$(10) \quad \|(S_j \cdots S_1) - \mathbf{1}c\| \leq b\lambda^j, \quad j \geq 1.$$

The following fact is proved in [6].

PROPOSITION 1. *If an infinite sequence of stochastic matrices  $S_1, S_2, \dots$  satisfies*

$$(11) \quad |||S_j \cdots S_1||| \leq \bar{b}\lambda^j, \quad j \geq 0,$$

*for some nonnegative constants  $\bar{b}$  and  $\lambda < 1$ , then the product  $S_j S_{j-1} \cdots S_1$  converges exponentially fast at a rate no slower than  $\lambda$  to a matrix of the form 1c.*

We will exploit this inequality in deriving specific convergence rates.

Any  $n \times n$  stochastic matrix  $S$  determines a directed graph  $\gamma(S)$  with the vertex set  $\{1, 2, \dots, n\}$  and arc set defined in such a way so that  $(i, j)$  is an arc of  $\gamma(S)$  from  $i$  to  $j$  just in case the  $j$ th entry of  $S$  is nonzero. Note that the graph of any stochastic matrix with positive diagonal elements must be in  $\mathcal{S}_{sa}$ . Since flocking matrices have this property, their graphs must be in  $\mathcal{G}_{sa}$ . It is known [6] that for the set of  $n \times n$  stochastic matrices  $S_1, S_2, \dots, S_p$

$$(12) \quad \gamma(S_p \cdots S_2 S_1) = \gamma(S_p) \circ \cdots \circ \gamma(S_2) \circ \gamma(S_1).$$

We will make use of the fact that for any two  $n \times n$  stochastic matrices  $S_1$  and  $S_2$ ,

$$(13) \quad \phi(S_2 S_1) \geq \phi(S_2)\phi(S_1),$$

where for any nonnegative matrix  $M$ ,  $\phi(M)$  denotes the smallest nonzero element of  $M$ . To prove that this is so, note first that any stochastic matrix  $S$  can be written as  $S = \phi(S)\bar{S}$ , where  $\bar{S}$  is a nonzero matrix whose nonzero entries are all bounded below by 1; moreover, if  $S = \hat{\phi}(S)\hat{S}$ , where  $\hat{\phi}(S)$  is a number and  $\hat{S}$  is also a nonzero matrix whose nonzero entries are all bounded below by 1, then  $\phi(S) \geq \hat{\phi}(S)$ . Accordingly, write  $S_i = \phi(S_i)\bar{S}_i$ ,  $i \in \{1, 2\}$ , where each  $\bar{S}_i$  is a nonzero matrix whose nonzero entries are all bounded below by 1. Since  $S_2 S_1 = \phi(S_2)\phi(S_1)\bar{S}_2\bar{S}_1$  and  $S_2 S_1$  is nonzero,  $\bar{S}_2\bar{S}_1$  must be nonzero as well. Moreover, the nonzero entries of  $\bar{S}_2\bar{S}_1$  must be bounded below by 1 because the product of any two  $n \times n$  matrices with all nonzero entries bounded below by 1 must be a matrix with the same property. Therefore  $\phi(S_2 S_1) \geq \phi(S_2)\phi(S_1)$  as claimed. An important consequence of (13) is that for any set of stochastic matrices  $S_1, S_2, \dots, S_m$  for which each  $\phi(S_i)$  is bounded below by a positive number  $b$ ,

$$(14) \quad \phi(S_m \cdots S_1) \geq b^m.$$

Our goal is now to use these facts to derive an explicit convergence rate for the situation considered by Theorem 1. We will do this in two different ways. The first way is based on properties of stochastic matrices with strongly rooted graphs.

**3.1. Strongly rooted graphs.** Let  $\mathcal{F}(q)$  denote the set of all products of  $q$  flocking matrices whose corresponding sequences of  $q$  graphs are each jointly rooted. In view of (12), each matrix in  $\mathcal{F}(q)$  must have a rooted graph in  $\mathcal{G}_{sa}$ . In other words, each matrix in  $\mathcal{F}(q)$  has a rooted graph and is a product of  $q$  flocking matrices. Since the set of all flocking matrices is finite, so is  $\mathcal{F}(q)$ . It is shown in [6] that the composition of any set of at least  $(n-1)^2$  rooted graphs in  $\mathcal{G}_{sa}$  is strongly rooted. This and (12) imply that the product of any  $(n-1)^2$  matrices in  $\mathcal{F}(q)$  must have a strongly rooted graph in  $\mathcal{G}_{sa}$ . Thus if we set  $m = (n-1)^2$  and write  $(\mathcal{F}(q))^m$  for the set of all products of  $m$  matrices from  $\mathcal{F}(q)$ , then each matrix in  $(\mathcal{F}(q))^m$  must have a

strongly rooted graph. Moreover,  $(\mathcal{F}(q))^m$  must be a finite set because  $\mathcal{F}(q)$  is. It is shown in [6] that convergence of the  $\theta_i$  in Theorem 1 occurs at a rate no slower than

$$\lambda = \left( \max_{S \in (\mathcal{F}(q))^m} |||S||| \right)^{\frac{1}{mq}}.$$

Our goal is to derive an explicit bound for  $\lambda$ .

As a first step towards this end, let  $S$  be any stochastic matrix with a strongly rooted graph. We claim that

$$(15) \quad |||S||| \leq 1 - \phi(S).$$

To understand why this is so, note first that because  $\gamma(S)$  is strongly rooted, at least one vertex—say the  $k$ th—must be a root with arcs to every other vertex. This means that the  $k$ th column of  $S$  must be positive. Since  $\phi(S)$  is a lower bound on all nonzero elements in  $S$ , the smallest element in the  $k$ th column of  $S$  is bounded below by  $\phi(S)$ . Therefore  $[S]\mathbf{1} \geq \phi(S)\mathbf{1}$ . But from (7)  $|||S||| = 1 - [S]\mathbf{1}$ . This implies that (15) is true.

As a second step, let us note that the definition of a flocking matrix implies that all nonzero entries are bounded below by  $\frac{1}{n}$ . In other words,  $F \in \mathcal{F}$  implies that  $\phi(F) \geq \frac{1}{n}$ . But the flocking matrix  $F = \frac{1}{n}\mathbf{1}\mathbf{1}'$  is in  $\mathcal{F}$ , and for this matrix  $\phi(F) = \frac{1}{n}$ . Therefore

$$(16) \quad \min_{F \in \mathcal{F}} \phi(F) = \frac{1}{n}.$$

Now suppose that  $S \in \mathcal{F}(q)$ . Thus  $S$  is the product of  $q$  matrices from  $\mathcal{F}$ . From this, (14), and (16) it follows that  $\phi(S) \geq \frac{1}{n^q}$ . Therefore

$$(17) \quad \min_{S \in \mathcal{F}(q)} \phi(S) \geq \frac{1}{n^q}.$$

Next suppose that  $S \in (\mathcal{F}(q))^m$ . Thus  $S$  is the product of  $m$  matrices from  $\mathcal{F}(q)$ . From this, (14), and (17) it follows that  $\phi(S) \geq \frac{1}{n^{qm}}$ . This and (15) thus imply that  $|||S||| \leq 1 - \frac{1}{n^{qm}}$  and thus that

$$\max_{S \in (\mathcal{F}(q))^{(n-1)^2}} |||S||| \leq 1 - \frac{1}{n^{qm}}.$$

Therefore, since  $m = (n-1)^2$ ,

$$(18) \quad \lambda \leq \left( 1 - \frac{1}{n^{q(n-1)^2}} \right)^{\frac{1}{q(n-1)^2}}.$$

The derivation of this particular upper bound on the rate at which the  $\theta_i$  converge to  $\theta_{ss}$  ultimately depends on two facts established in [6]. First, as we said before, the composition of at most  $(n-1)^2$  rooted graphs is strongly rooted. Second, for any infinite sequence of stochastic matrices  $S_1, S_2, \dots$ , with strongly rooted graphs which come from a compact set  $\mathcal{S}_{sr}$ , the product  $S_j \cdots S_1$  converges exponentially fast, as  $j \rightarrow \infty$ , to a rank one matrix  $\mathbf{1}c$  at a rate no slower than

$$\max_{S \in \mathcal{S}_{sr}} |||S|||.$$

It turns out that by exploiting two different but corresponding facts about stochastic matrices with “neighbor-shared” graphs we can obtain a significantly smaller bound than the one given by (18).

**3.2. Neighbor-shared graphs.** By a neighbor-shared graph we mean any graph with two or more vertices with the property that each pair of vertices in the graph shares a common neighbor. Every neighbor-shared graph is rooted, but the converse is false [6]. The convergence rate bounds we are about to derive depend on two facts. First, the composition of at most  $(n - 1)$  rooted graphs is neighbor shared [6]. Second, for any infinite sequence of stochastic matrices  $S_1, S_2, \dots$ , with neighbor-shared graphs which come from a compact set  $\mathcal{S}_{ns}$ , the product  $S_j \cdots S_1$  converges exponentially fast, as  $j \rightarrow \infty$ , to a rank one matrix  $\mathbf{1}c$  at a rate no slower than

$$\max_{S \in \mathcal{S}_{ns}} \mu(S),$$

where  $\mu(S)$  is a positive number, called a *scrambling constant*, which is defined by the formula

$$(19) \quad \mu(S) = \max_{i,j} \left( 1 - \sum_{k=1}^n \min\{s_{ik}, s_{jk}\} \right).$$

In what follows we will make use of some well-known ideas and constructions from the theory of nonhomogeneous Markov chains [17] to explain why this second statement is true.

**Scrambling constants.** Let  $S$  be any  $n \times n$  stochastic matrix. Observe that for any nonnegative  $n$ -vector  $x$ , the  $i$ th minus the  $j$ th entries of  $Sx$  can be written as

$$\sum_{k=1}^n (s_{ik} - s_{jk})x_k = \sum_{k \in \mathcal{K}} (s_{ik} - s_{jk})x_k + \sum_{k \in \bar{\mathcal{K}}} (s_{ik} - s_{jk})x_k,$$

where

$$\mathcal{K} = \{k : s_{ik} - s_{jk} \geq 0, k \in \{1, 2, \dots, n\}\}$$

and

$$\bar{\mathcal{K}} = \{k : s_{ik} - s_{jk} < 0, k \in \{1, 2, \dots, n\}\}.$$

Therefore

$$\sum_{k=1}^n (s_{ik} - s_{jk})x_k \leq \left( \sum_{k \in \mathcal{K}} (s_{ik} - s_{jk}) \right) \lceil x \rceil + \left( \sum_{k \in \bar{\mathcal{K}}} (s_{ik} - s_{jk}) \right) \lfloor x \rfloor.$$

But

$$\sum_{k \in \mathcal{K} \cup \bar{\mathcal{K}}} (s_{ik} - s_{jk}) = 0,$$

and so

$$\sum_{k \in \bar{\mathcal{K}}} (s_{ik} - s_{jk}) = - \sum_{k \in \mathcal{K}} (s_{ik} - s_{jk}).$$

Thus

$$\sum_{k=1}^n (s_{ik} - s_{jk})x_k \leq \left( \sum_{k \in \mathcal{K}} (s_{ik} - s_{jk}) \right) (\lceil x \rceil - \lfloor x \rfloor).$$

Now

$$\sum_{k \in \mathcal{K}} (s_{ik} - s_{jk}) = 1 - \sum_{k \in \bar{\mathcal{K}}} s_{ik} - \sum_{k \in \mathcal{K}} s_{jk}$$

because the row sums of  $S$  are all one. Moreover,

$$s_{ik} = \min\{s_{ik}, s_{jk}\}, \quad k \in \bar{\mathcal{K}},$$

$$s_{jk} = \min\{s_{ik}, s_{jk}\}, \quad k \in \mathcal{K},$$

and so

$$\sum_{k \in \mathcal{K}} (s_{ik} - s_{jk}) = 1 - \sum_{k=1}^n \min\{s_{ik}, s_{jk}\}.$$

It follows that

$$\sum_{k=1}^n (s_{ik} - s_{jk}) x_k \leq \left(1 - \sum_{k=1}^n \min\{s_{ik}, s_{jk}\}\right) (\lceil x \rceil - \lfloor x \rfloor).$$

Hence with  $\mu$  as defined by (19),

$$\sum_{k=1}^n (s_{ik} - s_{jk}) x_k \leq \mu(S)(\lceil x \rceil - \lfloor x \rfloor).$$

Since this holds for all  $i, j$ , it must hold for the  $i$  and  $j$  for which

$$\sum_{k=1}^n s_{ik} x_k = \lceil Sx \rceil \quad \text{and} \quad \sum_{k=1}^n s_{jk} x_k = \lfloor Sx \rfloor.$$

Therefore

$$(20) \quad \lceil Sx \rceil - \lfloor Sx \rfloor \leq \mu(S)(\lceil x \rceil - \lfloor x \rfloor).$$

Now let  $S_1$  and  $S_2$  be any two  $n \times n$  stochastic matrices and let  $e_i$  be the  $i$ th unit  $n$ -vector. Then from (20),

$$(21) \quad \lceil S_2 S_1 e_i \rceil - \lfloor S_2 S_1 e_i \rfloor \leq \mu(S_2)(\lceil S_1 e_i \rceil - \lfloor S_1 e_i \rfloor).$$

Meanwhile, from (9),

$$\llbracket S_2 S_1 \rrbracket e_i = \mathbf{1}(\lceil S_2 S_1 \rceil - \lfloor S_2 S_1 \rfloor) e_i$$

and

$$\llbracket S_1 \rrbracket e_i = \mathbf{1}(\lceil S_1 \rceil - \lfloor S_1 \rfloor) e_i.$$

But for any nonnegative matrix  $M$ ,  $\lceil M \rceil e_i = \lceil M e_i \rceil$  and  $\lfloor M \rfloor e_i = \lfloor M e_i \rfloor$ , and so

$$\llbracket S_2 S_1 \rrbracket e_i = \mathbf{1}(\lceil S_2 S_1 e_i \rceil - \lfloor S_2 S_1 e_i \rfloor)$$

and

$$\llbracket S_1 \rrbracket e_i = \mathbf{1}(\lceil S_1 e_i \rceil - \lfloor S_1 e_i \rfloor).$$

From these expressions and (21) it follows that

$$\llbracket S_2 S_1 \rrbracket e_i \leq \mu(S_2) \llbracket S_1 \rrbracket e_i.$$

Since this is true for all  $i$ , we arrive at the following fact.

LEMMA 1. *For any two stochastic matrices in  $\mathcal{S}$ ,*

$$(22) \quad \llbracket S_2 S_1 \rrbracket \leq \mu(S_2) \llbracket S_1 \rrbracket.$$

Note that since the row sums of  $S$  all equal 1,  $\mu(S)$  is nonnegative. It is easy to see that  $\mu(S) = 0$  just in case all the rows of  $S$  are equal. Let us note that for fixed  $i$  and  $j$ , the  $k$ th term in the sum appearing in (19) will be positive just in case both  $s_{ik}$  and  $s_{jk}$  are positive. It follows that the sum will be positive if and only if for at least one  $k$ ,  $s_{ik}$  and  $s_{jk}$  are both positive. Thus  $\mu(S) < 1$  if and only if for each distinct  $i$  and  $j$ , there is at least one  $k$  for which  $s_{ik}$  and  $s_{jk}$  are both positive. Matrices with this property have been widely studied and are called *scrambling matrices* [17]. Thus a stochastic matrix  $S$  is a scrambling matrix if and only if  $\mu(S) < 1$ . It is easy to see that the definition of a scrambling matrix also implies that  $S$  is scrambling if and only if its graph  $\gamma(S)$  is neighbor-shared.

As before, let  $\mathcal{S}_{ns}$  be a closed subset consisting of stochastic matrices whose graphs are all neighbor-shared. Then the scrambling constant  $\mu(S)$  defined in (19) satisfies  $\mu(S) < 1$ ,  $S \in \mathcal{S}_{ns}$  because each such  $S$  is a scrambling matrix. Let

$$\bar{\mu} = \max_{S \in \mathcal{S}_{ns}} \mu(S).$$

Then  $\bar{\mu} < 1$  because  $\mathcal{S}_{ns}$  is closed and bounded and because  $\mu(\cdot)$  is continuous. In view of Lemma 1,

$$\|\llbracket S_2 S_1 \rrbracket\| \leq \bar{\mu} \|\llbracket S_1 \rrbracket\|, \quad S_1, S_2 \in \mathcal{S}_{ns}.$$

Hence by induction, for any sequence of matrices  $S_1, S_2, \dots$  in  $\mathcal{S}_{ns}$

$$\|\llbracket S_j \cdots S_1 \rrbracket\| \leq \bar{\mu}^{j-1} \|\llbracket S_1 \rrbracket\|, \quad S_i \in \mathcal{S}_{ns}.$$

But from (8),  $\llbracket S \rrbracket \leq \llbracket S \rrbracket$ ,  $S \in \mathcal{S}$ , and so  $\|\llbracket S \rrbracket\| \leq \|\llbracket S \rrbracket\|$ ,  $S \in \mathcal{S}$ . Therefore for any sequence of stochastic matrices  $S_1, S_2, \dots$  with neighbor-shared graphs

$$(23) \quad \|\llbracket S_j \cdots S_1 \rrbracket\| \leq \bar{\mu}^{j-1} \|\llbracket S_1 \rrbracket\|.$$

Therefore from Proposition 1, any such product  $S_j \cdots S_1$  converges exponentially at a rate no slower than  $\bar{\mu}$  as  $j \rightarrow \infty$ . This establishes the validity of the statement about convergence of products of stochastic matrices made at the beginning of section 3.2.

Suppose now that  $F$  is a flocking matrix for which  $\gamma(F)$  is neighbor-shared. In view of the definition of a flocking matrix, any nonzero entry in  $F$  must be bounded below by  $\frac{1}{n}$ . Fix distinct  $i$  and  $j$  and suppose that  $k$  is a neighbor that  $i$  and  $j$  share. Then  $f_{ik}$  and  $f_{jk}$  are both nonzero, and so  $\min\{f_{ik}, f_{jk}\} \geq \frac{1}{n}$ . This implies that the sum in (19) must be bounded below by  $\frac{1}{n}$  and consequently that  $\mu(F) \leq 1 - \frac{1}{n}$ .

Now let  $F$  be that flocking matrix whose graph  $\gamma(F)$  is such that vertex 1 has no neighbors other than itself, vertex 2 has every vertex as a neighbor, and vertices 3 through  $n$  have only themselves and agent 1 as neighbors. Since vertex 1 has no neighbors other than itself,  $f_{1k} = 0$  for all  $k > 1$ . Thus for all  $i, j$ , it must be true that  $\sum_{k=1}^n \min\{f_{ik}, f_{jk}\} = \min\{f_{i1}, f_{j1}\}$ . Now vertex 2 has  $n$  neighbors, and so  $f_{2,1} = \frac{1}{n}$ .

Thus  $\min\{f_{i1}, f_{j1}\}$  attains its lower bound of  $\frac{1}{n}$  when either  $i = 2$  or  $j = 2$ . It thus follows that with this  $F$ ,  $\mu(F)$  attains its upper bound of  $1 - \frac{1}{n}$ . We summarize.

LEMMA 2. *Let  $\mathcal{F}_{ns}$  be the set of  $n \times n$  flocking matrices with neighbor-shared graphs. Then*

$$(24) \quad \max_{F \in \mathcal{F}_{ns}} \mu(F) = 1 - \frac{1}{n}.$$

Thus  $1 - \frac{1}{n}$  is a tight bound on the convergence rate for an infinite product of flocking matrices with neighbor-shared graphs. In [6] it is shown that

$$\max_{F \in \mathcal{F}_{sr}} \mu(F) = 1 - \frac{1}{n},$$

where  $\mathcal{F}_{sr}$  is the set of flocking matrices with strongly rooted graphs. Thus  $1 - \frac{1}{n}$  is also a tight bound on the convergence rate for an infinite product of flocking matrices with strongly rooted graphs. Of course a strongly rooted graph is a more special type of graph than a neighbor-shared graph because strongly rooted graphs are neighbor shared but not conversely.

We now use the preceding to derive a better convergence rate bound than the one in (18) for the type of trajectory addressed by Theorem 1. As a first step towards this end, we exploit the fact that for any  $n \times n$  stochastic scrambling matrix  $S$ , the scrambling constant of  $\mu(S)$  satisfies the inequality

$$(25) \quad \mu(S) \leq 1 - \phi(S).$$

To understand why this is so, assume that  $S$  is any given scrambling matrix. Note that for any distinct  $i$  and  $j$ , there must be a  $k$  for which  $\min\{s_{ik}, s_{jk}\}$  is nonzero and bounded below by  $\phi(S)$ . Thus

$$\sum_{k=1}^n \min\{s_{ik}, s_{jk}\} \geq \phi(S),$$

and so

$$1 - \sum_{k=1}^n \min\{s_{ik}, s_{jk}\} \leq 1 - \phi(S).$$

But this holds for all distinct  $i$  and  $j$ . In view of the definition of  $\mu(S)$  in (19), (25) must therefore be true.

As before, let  $\mathcal{F}(q)$  denote the set of products of  $q$  flocking matrices  $F_1, F_2, \dots, F_q$  from  $\mathcal{F}$  for which  $\{\gamma(F_1), \gamma(F_2), \dots, \gamma(F_q)\}$  is a jointly rooted set. Then as noted before, each matrix in  $\mathcal{F}(q)$  is rooted. Set  $p = (n-1)$  and let  $(\mathcal{F}(q))^p$  now denote the set of all products of  $p$  matrices from  $\mathcal{F}(q)$ . Then each matrix in  $(\mathcal{F}(q))^p$  is neighbor-shared. Let  $S$  be any such matrix. Then  $S$  is a product of  $qp$  flocking matrices. But each such flocking matrix  $F$  satisfies (16). Because of this and (14), it must be true that  $\phi(S) \geq \frac{1}{n^{qp}}$ . Therefore  $\mu(S) \leq 1 - \frac{1}{n^{qp}}$  because of (25). Since this is true for all  $S \in (\mathcal{F}(q))^p$ ,  $1 - \frac{1}{n^{qp}}$  must be a convergence rate upper bound for all infinite products of matrices from  $(\mathcal{F}(q))^p$ . Therefore, since  $p = n-1$ ,

$$(26) \quad \left(1 - \frac{1}{n^{q(n-1)}}\right)^{\frac{1}{q(n-1)}}$$

must be an upper bound on the convergence rate for all infinite products of flocking matrices  $F_1, F_2, \dots$  which have the property that the sequence of graphs  $\gamma(F_1), \gamma(F_2), \dots$  is repeatedly jointly rooted by subsequences of length  $q$ . Since this is precisely the type of sequence of flocking matrices which arise under the assumptions of Theorem 1, (26) is a convergence rate bound for the type of trajectory addressed by the theorem. Note that this convergence rate upper bound is much smaller (i.e., faster) than the one given by (18). We refer the reader to [7] for additional convergence rate calculations along these lines.

**4. Measurement delays.** In this section we consider a modified version of the flocking problem in which integer-valued delays occur in sensing the values of headings which are available to agents. More precisely we suppose that at each time  $t \in \{0, 1, 2, \dots\}$ , the value of neighboring agent  $j$ 's headings which agent  $i$  may sense is  $\theta_j(t - d_{ij}(t))$ , where  $d_{ij}(t)$  is a delay whose value at  $t$  is some integer between 0 and  $m_j - 1$ ; here  $m_j$  is a prespecified positive integer. While well-established principles of feedback control would suggest that delays should be dealt with using dynamic compensation, in this paper we will consider the situation in which the delayed value of agent  $j$ 's heading sensed by agent  $i$  at time  $t$  is the value which will be used in the heading update law for agent  $i$ . Thus

$$(27) \quad \theta_i(t+1) = \frac{1}{n_i(t)} \left( \sum_{j \in \mathcal{N}_i(t)} \theta_j(t - d_{ij}(t)) \right),$$

where  $d_{ij}(t) \in \{0, 1, \dots, (m_j - 1)\}$  if  $j \neq i$  and  $d_{ij}(t) = 0$  if  $i = j$ . Our main result is the following theorem, which states in essence that the conclusions of Theorem 1 continue to hold for the update model described by (27).

**THEOREM 2.** *Let  $\theta(0)$  be fixed. For any trajectory of the system determined by (27) along which the sequence of neighbor graphs  $\mathbb{N}(0), \mathbb{N}(1), \dots$  is repeatedly jointly rooted, there is a constant  $\theta_{ss}$ , depending only on  $\theta(0)$ , for which*

$$(28) \quad \lim_{t \rightarrow \infty} \theta(t) = \theta_{ss} \mathbf{1},$$

where the limit is approached exponentially fast.

As noted in the introduction, the consensus problem with measurement delays we have been discussing has been considered previously in [3]. It is possible to compare the hypotheses of Theorem 2 with the corresponding hypotheses for exponential convergence stated in [3], namely assumptions 2 and 3 of that paper. To do this, let us agree, as before, to say that the *union* of a set of graphs  $\mathbb{G}_{r_1}, \mathbb{G}_{r_2}, \dots, \mathbb{G}_{r_k}$  with vertex set  $\mathcal{V}$  is the graph with the vertex set  $\mathcal{V}$  and arc set consisting of the union of the arcs of all of the graphs  $\mathbb{G}_{r_1}, \mathbb{G}_{r_2}, \dots, \mathbb{G}_{r_k}$ . Taken together, assumptions 2 and 3 of [3] are essentially equivalent to assuming that there are finite positive integers  $q$  and  $s$  such that the *union*

$$\mathbb{G}(k) \triangleq \mathbb{N}((k+1)q-1) \cup \mathbb{N}((k+1)q-2) \cup \dots \cup \mathbb{N}(kq)$$

is strongly connected and independent of  $k$  for  $k \geq s$ . By way of comparison, the hypothesis of Theorem 2 is equivalent to assuming that there is a finite positive integer  $q$  such that the *composition*

$$\bar{\mathbb{G}}(k) \triangleq \mathbb{N}((k+1)q-1) \circ \mathbb{N}((k+1)q-2) \circ \dots \circ \mathbb{N}(kq)$$

is rooted for  $k \geq 0$ . The latter assumption is weaker than the former for several reasons. First, the arc set of  $\mathbb{G}(k)$  is always a subset of the arc set of  $\bar{\mathbb{G}}(k)$ , and in some cases the containment may be strict. Second,  $\bar{\mathbb{G}}(k)$  is not assumed to be independent of  $k$ , even for  $k$  sufficiently large, whereas  $\mathbb{G}(k)$  is; in other words,  $\bar{\mathbb{G}}(k)$  is not assumed to converge, whereas  $\mathbb{G}(k)$  is. Third, each  $\mathbb{G}(k)$  is assumed to be strongly connected, whereas each  $\bar{\mathbb{G}}(k)$  need only be rooted; note that a strongly connected graph is a special type of rooted graph in which every vertex is a root. Perhaps what is most important about Theorem 2 and the development which justifies it is that the underlying structural properties of the graphs involved required for consensus are explicitly determined.

**4.1. State space system.** Using standard lifting techniques for dealing with delays in discrete-time systems, it is possible to represent the agent system defined by (27) as a state space model similar to the model discussed earlier for the delay-free case. Our first objective is to characterize the class of graphs  $\mathcal{D}$  of the stochastic matrices which result from this lifting process. Towards this end, let  $\bar{\mathcal{G}}$  denote the set of all directed graphs with vertex set  $\bar{\mathcal{V}} = \mathcal{V}_1 \cup \mathcal{V}_2 \cup \dots \cup \mathcal{V}_n$ , where  $\mathcal{V}_i = \{v_{i1} \dots, v_{im_i}\}$ . Here vertex  $v_{ij}$  labels the  $j$ th possible delay value of agent  $i$ , namely  $j - 1$ . We sometimes write  $i$  for  $v_{i1}$ ,  $i \in \{1, 2, \dots, n\}$ , write  $\mathcal{V}$  for the subset of vertices  $\{v_{11}, v_{21}, \dots, v_{n1}\}$ , and think of  $v_{i1}$  as an alternative label of agent  $i$ .

To take account of the fact that each agent can use its own current heading in its update formula (27), we will utilize those graphs in  $\bar{\mathcal{G}}$  which have self-arcs at each vertex in  $\mathcal{V}$ . We will also require the arc set of each such graph to have, for  $i \in \{1, 2, \dots, n\}$ , an arc from each vertex  $v_{ij} \in \mathcal{V}_i$  except the last to its successor  $v_{i(j+1)} \in \mathcal{V}_i$ . Finally we stipulate that for each  $i \in \{1, 2, \dots, n\}$ , each vertex  $v_{ij}$  with  $j > 1$  has in-degree of exactly 1. In what follows we call any such graph a *delay graph* and write  $\mathcal{D}$  for the subset of all such graphs. Note that unlike the class of graphs  $\mathcal{G}_{sa}$  considered before, there are graphs in  $\mathcal{D}$  possessing vertices without self-arcs. Nonetheless each vertex of each graph in  $\mathcal{D}$  has positive in-degree. An example of a delay graph for a three-agent system is shown in Figure 1.

FIG. 1. Delay graph.

The specific delay graph representing the sensed headings the agents use at time  $t$  to update their own headings according to (27) is the graph  $\mathbb{D}(t) \in \mathcal{D}$  whose arc set contains an arc from  $v_{ik} \in \mathcal{V}_i$  to  $v_{j1} \in \mathcal{V}$  if agent  $j$  uses  $\theta_i(t + 1 - k)$  to update. There is a simple relationship between  $\mathbb{D}(t)$  and the neighbor graph  $\mathbb{N}(t)$  defined earlier. In particular,

$$(29) \quad \mathbb{N}(t) = Q(\mathbb{D}(t)),$$

where  $Q(\mathbb{D}(t))$  is the “quotient graph” of  $\mathbb{D}(t)$ . By the *quotient graph* of any  $\mathbb{G} \in \bar{\mathcal{G}}$ , written  $Q(\mathbb{G})$ , we mean the directed graph in  $\bar{\mathcal{G}}$  with vertex set  $\mathcal{V}$  whose arc set consists of those arcs  $(i, j)$  for which  $\mathbb{G}$  has an arc from some vertex in  $\mathcal{V}_i$  to some vertex in  $\mathcal{V}_j$ . The quotient graph of  $\mathbb{D}(t)$  thus models which headings are being used by each agent in updates at time  $t$  without describing the specific delayed headings actually being used. The quotient graph of the delay graph in Figure 1 is shown in Figure 2.

FIG. 2. Quotient graph.

The set of agent heading update rules defined by (27) can be written in state form. Towards this end, define  $\theta(t)$  to be the  $(m_1 + m_2 + \cdots + m_i)$  vector whose first  $m_1$  elements are  $\theta_1(t)$  to  $\theta_1(t+1-m_1)$ , whose next  $m_2$  elements are  $\theta_2(t)$  to  $\theta_2(t+1-m_2)$ , and so on. Order the vertices of  $\bar{\mathcal{V}}$  as  $v_{11}, \dots, v_{1m_1}, v_{21}, \dots, v_{2m_2}, \dots, v_{n1}, \dots, v_{nm_n}$ , and with respect to this ordering define for each graph  $\mathbb{D} \in \mathcal{D}$  the flocking matrix

$$(30) \quad F = D^{-1}A',$$

where  $A'$  is the transpose of the adjacency matrix of  $\mathbb{D}$  and  $D$  the diagonal matrix whose  $ij$ th diagonal element is the in-degree of vertex  $v_{ij}$  within the graph. Then  $\gamma(F) = \mathbb{D}$  and

$$(31) \quad \theta(t+1) = F(t)\theta(t), \quad t \in \{0, 1, 2, \dots\}.$$

Let  $\bar{\mathcal{F}}$  denote the set of all such  $F$ . As before our goal is to characterize the sequences of neighbor graphs  $N(0), N(1), \dots$  for which all entries of  $\theta(t)$  converge to a common steady state value.

There are a number of similarities and a number of differences between the situation under consideration here and the delay-free situation considered in [6]. For example, the notion of graph composition defined earlier can be defined in the obvious way for graphs in  $\bar{\mathcal{G}}$ . On the other hand, unlike the situation in the delay-free case, the set of graphs used to model the system under consideration, namely the set of delay graphs  $\mathcal{D}$ , is not closed under composition except in the special case when all of the delays are at most 1, i.e., when all of the  $m_i \leq 2$ . In order to characterize the smallest subset of  $\bar{\mathcal{G}}$  containing  $\mathcal{D}$  which is closed under composition, we will need several new concepts.

**4.2. Hierarchical graphs.** As before, let  $\mathcal{G}$  be the set of all directed graphs with vertex set  $\mathcal{V} = \{1, 2, \dots, n\}$ . Let us agree to say that a rooted graph  $\mathbb{G} \in \mathcal{G}$  is a *hierarchical graph* with *hierarchy*  $\{v_1, v_2, \dots, v_n\}$  if it is possible to relabel the vertices in  $\mathcal{V}$  as  $v_1, v_2, \dots, v_n$  in such a way so that  $v_1$  is a root of  $\mathbb{G}$  with a self-arc and for  $i > 1$ ,  $v_i$  has a neighbor  $v_j$  “lower” in the hierarchy where by *lower* we mean  $j < i$ . It is clear that any graph in  $\mathcal{G}$  with a root possessing a self-arc is hierarchical. Note that a graph may have more than one hierarchy and two graphs with the same hierarchy need not be equal. Note also that even though rooted graphs with the same hierarchy

share a common root, examples show that the composition of hierarchical graphs in  $\mathcal{G}$  need not be hierarchical or even rooted. On the other hand, the composition of two rooted graphs in  $\mathcal{G}$  with the same hierarchy is always a graph with the same hierarchy. To understand why this is so, consider two graphs  $\mathbb{G}_1$  and  $\mathbb{G}_2$  in  $\mathcal{G}$  with the same hierarchy  $\{v_1, v_2, \dots, v_n\}$ . Note first that  $v_1$  has a self-arc in  $\mathbb{G}_2 \circ \mathbb{G}_1$  because  $v_1$  has self-arcs in  $\mathbb{G}_1$  and  $\mathbb{G}_2$ . Next pick any vertex  $v_i$  in  $\mathcal{V}$  other than  $v_1$ . By definition, there must exist vertex  $v_j$  lower in the hierarchy than  $v_i$  such that  $(v_j, v_i)$  is an arc of  $\mathbb{G}_2$ . If  $v_j = v_1$ , then  $(v_1, v_i)$  is an arc in  $\mathbb{G}_2 \circ \mathbb{G}_1$  because  $v_1$  has a self-arc in  $\mathbb{G}_1$ . On the other hand, if  $v_j \neq v_1$ , then there must exist a vertex  $v_k$  lower in the hierarchy than  $v_j$  such that  $(v_k, v_j)$  is an arc of  $\mathbb{G}_1$ . It follows from the definition of composition that in this case  $(v_k, v_i)$  is an arc in  $\mathbb{G}_2 \circ \mathbb{G}_1$ . Thus  $v_i$  has a neighbor in  $\mathbb{G}_2 \circ \mathbb{G}_1$  which is lower in the hierarchy than  $v_i$ . Since this is true for all  $v_i$ ,  $\mathbb{G}_2 \circ \mathbb{G}_1$  must have the same hierarchy as  $\mathbb{G}_1$  and  $\mathbb{G}_2$ . This proves the claim that composition of two rooted graphs with the same hierarchy is a graph with the same hierarchy.

Our objective is to show that the composition of a sufficiently large number of graphs in  $\mathcal{G}$  with the same hierarchy is strongly rooted. Note that the fact that the composition of  $(n-1)^2$  graphs in  $\mathcal{G}_{sa}$  is rooted [6] cannot be used to reach this conclusion because the  $v_i$  in the graphs under consideration here do not all necessarily have self-arcs.

As before, let  $\mathbb{G}_1$  and  $\mathbb{G}_2$  be two graphs in  $\mathcal{G}$  with the same hierarchy  $\{v_1, v_2, \dots, v_n\}$ . Let  $v_i$  be any vertex in the hierarchy and suppose that  $v_j$  is a neighbor vertex of  $v_i$  in  $\mathbb{G}_2$ . If  $v_j = v_1$ , then  $v_i$  retains  $v_1$  as a neighbor in the composition  $\mathbb{G}_2 \circ \mathbb{G}_1$  because  $v_1$  has a self-arc in  $\mathbb{G}_1$ . On the other hand, if  $v_j \neq v_1$ , then  $v_j$  has a neighboring vertex  $v_k$  in  $\mathbb{G}_1$  which is lower in the hierarchy than  $v_j$ . Since  $v_k$  is a neighbor of  $v_i$  in the composition  $\mathbb{G}_2 \circ \mathbb{G}_1$ , we see that in this case  $v_i$  has acquired a neighbor in  $\mathbb{G}_2 \circ \mathbb{G}_1$  lower in the hierarchy than a neighbor it had in  $\mathbb{G}_2$ . In summary, any vertex  $v_i \in \mathcal{V}$  either has  $v_1$  as neighbor in  $\mathbb{G}_2 \circ \mathbb{G}_1$  or has a neighbor in  $\mathbb{G}_2 \circ \mathbb{G}_1$  which is at least one vertex lower in the hierarchy than any neighbor it had in  $\mathbb{G}_2$ .

Now consider three graphs  $\mathbb{G}_1, \mathbb{G}_2, \mathbb{G}_3$  in  $\mathcal{G}$  with the same hierarchy. By the same reasoning as above, any vertex  $v_i \in \mathcal{V}$  either has  $v_1$  as neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2 \circ \mathbb{G}_1$  or has a neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2 \circ \mathbb{G}_1$  which is at least one vertex lower in the hierarchy than any neighbor it had in  $\mathbb{G}_3 \circ \mathbb{G}_2$ . Similarly  $v_i$  either has  $v_1$  as neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2$  or has a neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2$  which is at least one vertex lower in the hierarchy than any neighbor it had in  $\mathbb{G}_3$ . Combining these two observations we see that any vertex  $v_i \in \mathcal{V}$  either has  $v_1$  as neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2 \circ \mathbb{G}_1$  or has a neighbor in  $\mathbb{G}_3 \circ \mathbb{G}_2 \circ \mathbb{G}_1$  which is at least two vertices lower in the hierarchy than any neighbor it had in  $\mathbb{G}_3$ . This clearly generalizes, and so after the composition of  $m$  such graphs  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_m$ ,  $v_i$  either has  $v_1$  as neighbor in  $\mathbb{G}_m \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  or has a neighbor in  $\mathbb{G}_m \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  which is at least  $m-1$  vertices lower in the hierarchy than any neighbor it had in  $\mathbb{G}_m$ . It follows that if  $m \geq n$ , then  $v_i$  must be a neighbor of  $v_1$ . Since this is true for all vertices, we have proved the following.

**PROPOSITION 2.** *Let  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_m$  denote a set of rooted graphs in  $\mathcal{G}$  which all have the same hierarchy. If  $m \geq n-1$ , then  $\mathbb{G}_m \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  is strongly rooted.*

**4.3. The Closure of  $\mathcal{D}$ .** We now return to the study of the graphs in  $\mathcal{D}$ . As before  $\mathcal{D}$  is the subset of  $\bar{\mathcal{G}}$  consisting of those graphs which (i) have self-arcs at each vertex in  $\mathcal{V} = \{v_{11}, v_{21}, \dots, v_{n1}\}$ , (ii) for each  $i \in \{1, 2, \dots, n\}$  have an arc from each vertex  $v_{ij} \in \mathcal{V}_i$  except the last to its successor  $v_{i(j+1)} \in \mathcal{V}_i$ , and (iii) for each  $i \in \{1, 2, \dots, n\}$ , each vertex  $v_{ij}$  with  $j > 1$  has in-degree of exactly 1. It can easily be shown by example that  $\mathcal{D}$  is not closed under composition. We deal with this

problem as follows. First, let us agree to say that a vertex  $v$  in a graph  $\mathbb{G} \in \bar{\mathcal{G}}$  is a *neighbor* of a subset of  $\mathbb{G}$ 's vertices  $\mathcal{U}$  if  $v$  is a neighbor of at least one vertex in  $\mathcal{U}$ . Next we say that a graph  $\mathbb{G} \in \bar{\mathcal{G}}$  is an *extended delay graph* if for each  $i \in \{1, 2, \dots, n\}$ , (i) every neighbor of  $\mathcal{V}_i$  which is not in  $\mathcal{V}_i$  is a neighbor of  $v_{i1}$  and (ii) the subgraph of  $\mathbb{G}$  induced by  $\mathcal{V}_i$  has  $\{v_{i1}, \dots, v_{im_i}\}$  as a hierarchy. We write  $\bar{\mathcal{D}}$  for the set of all extended delay graphs in  $\bar{\mathcal{G}}$ . It is easy to see that every delay graph is an extended delay graph. The converse, however, is not true. The set of extended delay graphs has the following property.

PROPOSITION 3.  $\bar{\mathcal{D}}$  is closed under composition.

In light of this proposition it is natural to call  $\bar{\mathcal{D}}$  the *closure* of  $\mathcal{D}$ . To prove the proposition, we will need the following fact.

LEMMA 3. Let  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_q$  be any sequence of  $q > 1$  directed graphs with vertex set  $\mathcal{V}$ . For  $i \in \{1, 2, \dots, q\}$ , let  $\bar{\mathbb{G}}_i$  be the subgraph of  $\mathbb{G}_i$  induced by  $\mathcal{U} \subset \mathcal{V}$ . Then  $\bar{\mathbb{G}}_q \circ \dots \circ \bar{\mathbb{G}}_2 \circ \bar{\mathbb{G}}_1$  is contained in the subgraph of  $\mathbb{G}_q \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  induced by  $\mathcal{U}$ .

*Proof of Lemma 3.* It will be enough to prove the lemma for  $q = 2$ , since the proof for  $q > 2$  would then directly follow by induction. Suppose  $q = 2$ . Let  $(i, j)$  be in  $\mathcal{A}(\bar{\mathbb{G}}_2 \circ \bar{\mathbb{G}}_1)$ . Then  $i, j \in \mathcal{U}$  and there exists an integer  $k \in \mathcal{U}$  such that  $(i, k) \in \mathcal{A}(\bar{\mathbb{G}}_1)$  and  $(k, j) \in \mathcal{A}(\bar{\mathbb{G}}_2)$ . Therefore  $(i, k) \in \mathcal{A}(\mathbb{G}_1)$  and  $(k, j) \in \mathcal{A}(\mathbb{G}_2)$ . Thus  $(i, j) \in \mathcal{A}(\mathbb{G}_2 \circ \mathbb{G}_1)$ . But  $i, j \in \mathcal{S}$ , and so  $(i, j)$  must be an arc in the subgraph of  $\mathbb{G}_2 \circ \mathbb{G}_1$  induced by  $\mathcal{U}$ . Since this clearly is true for all arcs in  $\mathcal{A}(\bar{\mathbb{G}}_2 \circ \bar{\mathbb{G}}_1)$ , the proof is complete.  $\square$

*Proof of Proposition 3.* Let  $\mathbb{G}_1$  and  $\mathbb{G}_2$  be two extended delay graphs in  $\bar{\mathcal{D}}$ . It will first be shown that for each  $i \in \{1, 2, \dots, n\}$ , every neighbor of  $\mathcal{V}_i$  which is not in  $\mathcal{V}_i$  is a neighbor of  $v_{i1}$  in  $\mathbb{G}_2 \circ \mathbb{G}_1$ . Fix  $i \in \{1, 2, \dots, n\}$  and let  $v$  be a neighbor of  $\mathcal{V}_i$  in  $\mathbb{G}_2 \circ \mathbb{G}_1$  which is not in  $\mathcal{V}_i$ . Then  $(v, k) \in \mathcal{A}(\mathbb{G}_2 \circ \mathbb{G}_1)$  for some  $k \in \mathcal{V}_i$ . Thus there is a  $s \in \bar{\mathcal{V}}$  such that  $(v, s) \in \mathcal{A}(\mathbb{G}_1)$  and  $(s, k) \in \mathcal{A}(\mathbb{G}_2)$ . If  $s \notin \mathcal{V}_i$ , then  $(s, v_{i1}) \in \mathcal{A}(\mathbb{G}_2)$  because  $\mathbb{G}_2$  is an extended delay graph. Thus in this case  $(v, v_{i1}) \in \mathcal{A}(\mathbb{G}_2 \circ \mathbb{G}_1)$  because of the definition of composition. If, on the other hand,  $s \in \mathcal{V}_i$ , then  $(v, v_{i1}) \in \mathcal{A}(\mathbb{G}_1)$  because  $\mathbb{G}_1$  is an extended delay graph. Thus in this case  $(v, v_{i1}) \in \mathcal{A}(\mathbb{G}_2 \circ \mathbb{G}_1)$  because  $v_{i1}$  has a self-arc in  $\mathbb{G}_2$ . This proves that every neighbor of  $\mathcal{V}_i$  which is not in  $\mathcal{V}_i$  is a neighbor of  $v_{i1}$  in  $\mathbb{G}_2 \circ \mathbb{G}_1$ . Since this must be true for each  $i \in \{1, 2, \dots, n\}$ ,  $\mathbb{G}_2 \circ \mathbb{G}_1$  has the first property defining extended delay graphs in  $\bar{\mathcal{D}}$ .

To establish the second property, we exploit the fact that the composition of two graphs with the same hierarchy is a graph with the same hierarchy. Thus for any integer  $i \in \{1, 2, \dots, n\}$ , the composition of the subgraphs of  $\mathbb{G}_1$  and  $\mathbb{G}_2$ , respectively, induced by  $\mathcal{V}_i$  must have the hierarchy  $\{v_{i1}, v_{i2}, \dots, v_{im_i}\}$ . But by Lemma 3, for any integer  $i \in \{1, 2, \dots, n\}$ , the composition of the subgraphs of  $\mathbb{G}_1$  and  $\mathbb{G}_2$ , respectively, induced by  $\mathcal{V}_i$  is contained in the subgraph of the composition of  $\mathbb{G}_1$  and  $\mathbb{G}_2$  induced by  $\mathcal{V}_i$ . This implies that for  $i \in \{1, 2, \dots, n\}$ , the subgraph of the composition of  $\mathbb{G}_1$  and  $\mathbb{G}_2$  induced by  $\mathcal{V}_i$  has  $\{v_{i1}, v_{i2}, \dots, v_{im_i}\}$  as a hierarchy.  $\square$

Our main result regarding extended delay graphs is as follows.

PROPOSITION 4. Let  $m$  be the largest integer in the set  $\{m_1, m_2, \dots, m_n\}$ . The composition of any set of at least  $m(n-1)^2 + m - 1$  extended delay graphs will be strongly rooted if the quotient graph of each of the graphs in the composition is rooted.

To prove this proposition we will need several more concepts. Let us agree to say that a extended delay graph  $\mathbb{G} \in \bar{\mathcal{D}}$  has *strongly rooted hierarchies* if for each  $i \in \mathcal{V}$ , the subgraph of  $\mathbb{G}$  induced by  $\mathcal{V}_i$  is strongly rooted. Proposition 2 states that a hierarchical graph on  $m_i$  vertices will be strongly rooted if it is the composition of at least  $m_i - 1$  rooted graphs with the same hierarchy. This and Lemma 3 imply that

the subgraph of the composition of at least  $m_i - 1$  extended delay graphs induced by  $\mathcal{V}_i$  will be strongly rooted. We are led to the following lemma.

LEMMA 4. *Any composition of at least  $m - 1$  extended delay graphs in  $\bar{\mathcal{D}}$  has strongly rooted hierarchies.*

To proceed we will need one more type of graph which is uniquely determined by a given graph in  $\bar{\mathcal{G}}$ . By the *agent subgraph* of  $\mathbb{G} \in \bar{\mathcal{G}}$  we mean the subgraph of  $\mathbb{G}$  induced by  $\mathcal{V}$ . Note that while the quotient graph of  $\mathbb{G}$  describes relations between distinct agent hierarchies, the agent subgraph of  $\mathbb{G}$  captures only the relationships between the roots of the hierarchies. Note in addition that both the agent subgraph of  $\mathbb{G}$  and the quotient graph of  $\mathbb{G}$  are graphs in  $\mathcal{G}_{sa}$  because all  $n$  vertices of  $\mathbb{G}$  in  $\mathcal{V}$  have self-arcs. The agent subgraph of the graph in Figure 1 is shown in Figure 3.

FIG. 3. Agent subgraph.

LEMMA 5. *Let  $\mathbb{G}_p$  and  $\mathbb{G}_q$  be extended delay graphs in  $\bar{\mathcal{D}}$ . If  $\mathbb{G}_p$  has a strongly rooted agent subgraph and  $\mathbb{G}_q$  has strongly rooted hierarchies, then the composition  $\mathbb{G}_q \circ \mathbb{G}_p$  is strongly rooted.*

*Proof of Lemma 5.* Let  $v_{i1}$  be a root of the agent subgraph of  $\mathbb{G}_p$  and let  $v_{jk}$  be any vertex in  $\bar{\mathcal{V}}$ . Then  $(v_{i1}, v_{j1}) \in \mathcal{A}(\mathbb{G}_p)$  because the agent subgraph of  $\mathbb{G}_p$  is strongly rooted. Moreover,  $(v_{j1}, v_{jk}) \in \mathcal{A}(\mathbb{G}_q)$  because  $\mathbb{G}_q$  has strongly rooted hierarchies. Therefore, in view of the definition of graph composition,  $(v_{i1}, v_{jk}) \in \mathcal{A}(\mathbb{G}_q \circ \mathbb{G}_p)$ . Since this must be true for every vertex  $v_{jk} \in \bar{\mathcal{V}}$ ,  $\mathbb{G}_q \circ \mathbb{G}_p$  is strongly rooted.  $\square$

LEMMA 6. *The agent subgraph of any composition of at least  $(n - 1)^2$  extended delay graphs in  $\bar{\mathcal{D}}$  will be strongly rooted if the agent subgraph of each of the graphs in the composition is rooted.*

*Proof of Lemma 6.* Let  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_q$  be any sequence of  $q \geq (n - 1)^2$  extended delay graphs in  $\bar{\mathcal{D}}$  whose agent subgraphs,  $\bar{\mathbb{G}}_i$ ,  $i \in \{1, 2, \dots, q\}$ , are all rooted. Since the  $\bar{\mathbb{G}}_i$  are in  $\mathcal{G}_{sa}$ , Proposition 3 of [6] applies, and it can therefore be concluded that  $\bar{\mathbb{G}}_q \circ \dots \circ \bar{\mathbb{G}}_2 \circ \bar{\mathbb{G}}_1$  is strongly rooted. But  $\bar{\mathbb{G}}_q \circ \dots \circ \bar{\mathbb{G}}_2 \circ \bar{\mathbb{G}}_1$  is contained in the agent subgraph of  $\mathbb{G}_q \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  because of Lemma 3. Therefore the agent subgraph of  $\mathbb{G}_q \circ \dots \circ \mathbb{G}_2 \circ \mathbb{G}_1$  is strongly rooted.  $\square$

LEMMA 7. *Let  $\mathbb{G}_p$  and  $\mathbb{G}_q$  be extended delay graphs in  $\bar{\mathcal{D}}$ . If  $\mathbb{G}_p$  has strongly rooted hierarchies and  $\mathbb{G}_q$  has a rooted quotient graph, then the agent subgraph of the composition  $\mathbb{G}_q \circ \mathbb{G}_p$  is rooted.*

*Proof of Lemma 7.* Let  $(i, j)$  be any arc in the quotient graph of  $\mathbb{G}_q$  with  $i \neq j$ . This means that  $(v_{ik}, v_{js}) \in \mathcal{A}(\mathbb{G}_q)$  for some  $v_{ik} \in \mathcal{V}_i$  and  $v_{js} \in \mathcal{V}_j$ . Clearly  $(v_{i1}, v_{ik}) \in \mathcal{A}(\mathbb{G}_p)$  because  $\mathbb{G}_p$  has strongly rooted hierarchies. Moreover, since  $i \neq j$ ,  $v_{ik}$  is a neighbor of  $\mathcal{V}_j$  which is not in  $\mathcal{V}_j$ . From this and the definition of an extended delay graph, it follows that  $v_{ik}$  is a neighbor of  $v_{j1}$ . Therefore  $(v_{ik}, v_{j1}) \in \mathcal{A}(\mathbb{G}_q)$ . Thus  $(v_{i1}, v_{j1}) \in \mathcal{A}(\mathbb{G}_q \circ \mathbb{G}_p)$ . We have therefore proved that for any path of length one between any two distinct vertices  $i, j$  in the quotient graph of  $\mathbb{G}_q$ , there is a corresponding path between vertices  $v_{i1}$  and  $v_{j1}$  in the agent subgraph of  $\mathbb{G}_q \circ \mathbb{G}_p$ . This implies that for any path of any length between any two distinct vertices  $i, j$  in the quotient graph of  $\mathbb{G}_q$ , there is a corresponding path between vertices  $v_{i1}$  and  $v_{j1}$  in the agent subgraph of  $\mathbb{G}_q \circ \mathbb{G}_p$ . Since by assumption the quotient graph of  $\mathbb{G}_q$  is rooted, the agent subgraph of  $\mathbb{G}_q \circ \mathbb{G}_p$  must be rooted as well.  $\square$

*Proof of Proposition 4.* Let  $\mathbb{G}_1, \mathbb{G}_2, \dots, \mathbb{G}_s$  be a sequence of at least  $m(n-1)^2 + m - 1$  extended delay graphs with rooted quotient graphs. The graph  $\mathbb{G}_s \circ \dots \circ \mathbb{G}_{(m(n-1)^2+1)}$  is composed of at least  $m - 1$  extended delay graphs. Therefore  $\mathbb{G}_s \circ \dots \circ \mathbb{G}_{(m(n-1)^2+1)}$  must have strongly rooted hierarchies because of Lemma 4. In view of Lemma 5, to complete the proof it is enough to show that  $\mathbb{G}_{m(n-1)^2} \circ \dots \circ \mathbb{G}_1$  has a strongly rooted agent subgraph. But  $\mathbb{G}_{m(n-1)^2} \circ \dots \circ \mathbb{G}_1$  is the composition of  $(n-1)^2$  graphs, each itself a composition of  $m$  extended delay graphs with rooted quotient graphs. In view of Lemma 6, to complete the proof it is enough to show that the agent subgraph of any composition of  $m$  extended delay graphs is rooted if each quotient graph of each extended delay graph in the composition is rooted. Let  $\mathbb{H}_1, \mathbb{H}_2, \dots, \mathbb{H}_m$  be such a family of extended delay graphs. By assumption,  $\mathbb{H}_m$  has a rooted quotient graph. In view of Lemma 7, the agent subgraph of  $\mathbb{H}_m \circ \mathbb{H}_{m-1} \circ \dots \circ \mathbb{H}_1$  will be rooted if  $\mathbb{H}_{m-1} \circ \dots \circ \mathbb{H}_1$  has strongly rooted hierarchies. But  $\mathbb{H}_{m-1} \circ \dots \circ \mathbb{H}_1$  has this property because of Lemma 4.  $\square$

Finally we will need the following fact.

**PROPOSITION 5.** *Let  $\mathbb{G}_1, \dots, \mathbb{G}_r$  be a sequence of extended delay graphs in  $\bar{\mathcal{D}}$ . If the composition  $Q(\mathbb{G}_r) \circ \dots \circ Q(\mathbb{G}_1)$  is rooted, then so is the quotient graph  $Q(\mathbb{G}_r \circ \dots \circ \mathbb{G}_1)$ .*

This proposition is a direct consequence of the following lemma.

**LEMMA 8.** *Let  $\mathbb{G}_p, \mathbb{G}_q$  be two extended delay graphs in  $\bar{\mathcal{D}}$ . For each arc  $(i, j)$  in the composition  $Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p)$ , there is a path from  $i$  to  $j$  in the quotient graph  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$ .*

*Proof of Lemma 8.* Fix  $(i, j) \in \mathcal{A}(Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p))$ . If  $i = j$ , then  $(i, j) \in \mathcal{A}(Q(\mathbb{G}_q \circ \mathbb{G}_p))$  because  $Q(\mathbb{G}_q \circ \mathbb{G}_p) \in \mathcal{G}_{sa}$ . Thus in this case there is a path of length 1 from  $i$  to  $j$  in  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$ .

Suppose  $i \neq j$ . Since  $(i, j) \in \mathcal{A}(Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p))$ , there exists an integer  $k \in \mathcal{V}$  such that  $(i, k) \in \mathcal{A}(Q(\mathbb{G}_p))$  and  $(k, j) \in \mathcal{A}(Q(\mathbb{G}_q))$ . Thus there are integers  $v_{is}, v_{kt}, v_{ku}, v_{jw} \in \mathcal{V}$  such that  $(v_{is}, v_{kt}) \in \mathcal{A}(\mathbb{G}_p)$  and  $(v_{ku}, v_{jw}) \in \mathcal{A}(\mathbb{G}_q)$ . Since  $\mathbb{G}_p \in \bar{\mathcal{D}}$ ,  $\mathbb{G}_p$  has a hierarchy rooted at  $v_{k1}$ . This means that there must be a vertex  $v_{kx}$  no higher in this hierarchy than  $v_{ku}$  such that  $(v_{kx}, v_{ku}) \in \mathcal{A}(\mathbb{G}_p)$ . Therefore  $(v_{kx}, v_{jw}) \in \mathcal{A}(\mathbb{G}_q \circ \mathbb{G}_p)$ . If  $k = i$ , then  $(v_{ix}, v_{jw}) \in \mathcal{A}(\mathbb{G}_q \circ \mathbb{G}_p)$ , and so  $(i, j) \in \mathcal{A}(Q(\mathbb{G}_q \circ \mathbb{G}_p))$ . Thus in this case there is a path of length 1 from  $i$  to  $j$  in  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$ .

Suppose  $k \neq i$ . Since  $(v_{is}, v_{kt}) \in \mathcal{A}(\mathbb{G}_p)$  and  $\mathbb{G}_p \in \bar{\mathcal{D}}$ ,  $(v_{is}, v_{k1}) \in \mathcal{A}(\mathbb{G}_p)$ . But  $\mathbb{G}_q$  must have a self-arc at  $v_{k1}$  because  $\mathbb{G}_q \in \bar{\mathcal{D}}$ . Therefore  $(v_{is}, v_{k1}) \in \mathcal{A}(\mathbb{G}_q \circ \mathbb{G}_p)$ . Moreover, there must be a path in  $\mathbb{G}_q \circ \mathbb{G}_p$  from  $v_{k1}$  to  $v_{kx}$  because  $v_{kx}$  is in the hierarchy rooted at  $v_{k1}$ . But both  $(v_{is}, v_{k1})$  and  $(v_{kx}, v_{jw})$  are arcs in  $\mathbb{G}_q \circ \mathbb{G}_p$ , and so there must be a path in  $\mathbb{G}_q \circ \mathbb{G}_p$  from  $v_{is}$  to  $v_{jw}$ . This implies that there must be a path in  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$  from  $i$  to  $j$ .  $\square$

*Proof of Proposition 5.* To prove the proposition it is enough to show that if  $Q(\mathbb{G}_r) \circ \dots \circ Q(\mathbb{G}_1)$  contains a path from some  $i \in \mathcal{V}$  to some  $j \in \mathcal{V}$ , then  $Q(\mathbb{G}_r \circ \dots \circ \mathbb{G}_1)$  also contains a path from  $i$  to  $j$ . As a first step towards this end, we claim that if  $\mathbb{G}_p, \mathbb{G}_q$  are graphs in  $\bar{\mathcal{D}}$  for which  $Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p)$  contains a path from  $u$  to  $v$ , for some  $u, v \in \mathcal{V}$ , then  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$  also contains a path from  $u$  to  $v$ . To prove that this is so, fix  $u, v \in \mathcal{V}$  and  $\mathbb{G}_p, \mathbb{G}_q \in \bar{\mathcal{D}}$  and suppose that  $Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p)$  contains a path from  $u$  to  $v$ . Then there must be a positive integer  $s$  and vertices  $k_1, k_2, \dots, k_s$  ending at  $k_s = v$  for which  $(u, k_1), (k_1, k_2), \dots, (k_{s-1}, k_s)$  are arcs in  $Q(\mathbb{G}_q) \circ Q(\mathbb{G}_p)$ . In view of Lemma 8, there must be paths in  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$  from  $i$  to  $k_1$ ,  $k_1$  to  $k_2$ ,  $\dots$ , and  $k_{s-1}$  to  $k_s$ . It follows that there must be a path in  $Q(\mathbb{G}_q \circ \mathbb{G}_p)$  from  $i$  to  $j$ . Thus the claim is established.

It will now be shown by induction for each  $s \in \{2, \dots, m\}$  that if  $Q(\mathbb{G}_s) \circ \dots \circ Q(\mathbb{G}_1)$  contains a path from  $i$  to some  $j_s \in \mathcal{V}$ , then  $Q(\mathbb{G}_r \circ \dots \circ \mathbb{G}_1)$  also contains a path from  $i$  to  $j_s$ . In view of the claim just proved above, the assertion is true if  $s = 2$ . Suppose the assertion is true for all  $s \in \{2, 3, \dots, t\}$ , where  $t$  is some integer in  $\{2, \dots, r-1\}$ . Suppose that  $Q(\mathbb{G}_{t+1}) \circ \dots \circ Q(\mathbb{G}_1)$  contains a path from  $i$  to  $j_{t+1}$ . Then there must be an integer  $k$  such that  $Q(\mathbb{G}_t) \circ \dots \circ Q(\mathbb{G}_1)$  contains a path from  $i$  to  $k$  and  $Q(\mathbb{G}_{t+1})$  contains a path from  $k$  to  $j_{t+1}$ . In view of the inductive hypothesis,  $Q(\mathbb{G}_t \circ \dots \circ \mathbb{G}_1)$  contains a path from  $i$  to  $k$ . Therefore  $Q(\mathbb{G}_{t+1}) \circ Q(\mathbb{G}_t \circ \dots \circ \mathbb{G}_1)$  has a path from  $i$  to  $j_{t+1}$ . Hence the claim established at the beginning of this proof applies, and it can be concluded that  $Q(\mathbb{G}_{t+1} \circ \mathbb{G}_t \circ \dots \circ \mathbb{G}_1)$  has a path from  $i$  to  $j_{t+1}$ . Therefore by induction the aforementioned assertion is true.  $\square$

**4.4. Proof of convergence.** Our aim is to make use of the properties of extended delay graphs just derived to prove Theorem 2. We will also need the following result from [6].
